$$e_{\underline{\alpha}}q_{\underline{\beta}}(u^{\underline{\gamma}}) = ad[iq_{\underline{\alpha}}(u^{\underline{\gamma}})]q_{\underline{\beta}}(u^{\underline{\gamma}}) = i[q_{\underline{\alpha}}(u^{\underline{\gamma}})q_{\underline{\beta}}(u^{\underline{\gamma}})] = W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}}. \tag{16}$$

The operators (16) define a linear space of anholonomic derivations satisfying the conditions (15), denoted Ader $M_k(\mathrm{IC}, u^{\underline{\alpha}})$, elongated by N connection and distinguished into irreducible h and v components, respectively, into $e_{\underline{i}}$ and $e_{\underline{b}}$, like $e_{\underline{\alpha}}=(e_{\underline{i}}=\partial_{\underline{i}}-N^{\underline{a}}_{\underline{i}}e_{\underline{a}}, e_{\underline{b}}=\partial_{\underline{b}})$. The space Ader $M_k(\mathrm{IC}, u^{\underline{\alpha}})$ is not a left module over the algebra $M_k(\mathrm{IC}, u^{\underline{\alpha}})$ which means that there is a substantial difference with respect to the usual commutative differential geometry where a vector field multiplied on the left by a function produces a new vector field.

The duals to operators (16), $e^{\underline{\mu}}$, found from $e^{\underline{\mu}}(e_{\underline{\alpha}})=\delta^{\underline{\mu}}_{\underline{\alpha}}I$, define a canonical basis of 1-forms $e^{\underline{\mu}}$ connected to the N-connection structure. By using these forms, we can span a left module over $M_k(\mathrm{IC}, u^{\underline{\alpha}})$ following $q_{\underline{\alpha}}e^{\underline{\mu}}(e_{\underline{\beta}})=q_{\underline{\alpha}}\delta^{\underline{\mu}}_{\underline{\beta}}I=q_{\underline{\alpha}}\delta^{\underline{\mu}}_{\underline{\beta}}$. For an arbitrary vector field

$$Y = Y^{\alpha}e_{\alpha} \to Y^{\underline{\alpha}}e_{\underline{\alpha}} = Y^{\underline{i}}e_{\underline{i}} + Y^{\underline{a}}e_{\underline{a}},$$

it is possible to define an exterior differential (in our case being N elongated), starting with the action on a function φ (equivalent, a 0-form),

$$\delta\varphi(Y) = Y\varphi = Y^{\underline{i}}\delta_{\underline{i}}\varphi + Y^{\underline{a}}\delta_{\underline{a}}\varphi$$

when

$$(\delta I)(e_{\underline{\alpha}}) = e_{\underline{\alpha}}I = ad(ie_{\underline{\alpha}})I = i[e_{\underline{\alpha}}, I] = 0, \quad \text{i.e.,}\ \delta I = 0,$$

and

$$\delta q_{\underline{\mu}}(e_{\underline{\alpha}}) = e_{\underline{\alpha}}(e_{\underline{\mu}}) = i[e_{\underline{\mu}}, e_{\underline{\alpha}}] = W^{\underline{\gamma}}_{\underline{\alpha}\underline{\mu}}e_{\underline{\gamma}}. \tag{17}$$

Considering the nondegenerated case, we can invert (17) as to obtain a similar expression with respect to $e^{\underline{\mu}}$,

$$\delta(e_{\underline{\alpha}}) = W^{\underline{\gamma}}_{\underline{\alpha}\underline{\mu}}e_{\underline{\gamma}}e^{\underline{\mu}}, \tag{18}$$

from which a very important property follows by using the Jacobi identity, $\delta^2=0$, resulting in a possibility to define a usual Grassman algebra of p-forms with the wedge product $\wedge$ stated as

$$e^{\underline{\mu}} \wedge e^{\underline{\nu}} = \tfrac{1}{2}(e^{\underline{\mu}} \otimes e^{\underline{\nu}} - e^{\underline{\nu}} \otimes e^{\underline{\mu}}).$$

We can write (18) as

$$\delta(e^{\underline{\alpha}}) = -\tfrac{1}{2}W^{\underline{\alpha}}_{\underline{\beta}\underline{\mu}}e^{\underline{\beta}}e^{\underline{\mu}}$$

and introduce the canonical 1-form $e=q_{\underline{\alpha}}e^{\underline{\alpha}}$ being coordinate independent and adapted to the N-connection structure and satisfying the condition $\delta e + e\wedge e = 0$.

In a standard manner, we can introduce the volume element induced by the canonical Cartan–Killing metric and the corresponding star operator $\star$ (Hodge duality). We define the volume element σ by using the complete antisymmetric tensor $\epsilon_{\underline{\alpha}_1\underline{\alpha}_2\cdots\underline{\alpha}_{k^2-1}}$ as

$$\sigma = \frac{1}{[(n'+m')^2-1]!}\epsilon_{\underline{\alpha}_1\underline{\alpha}_2\cdots\underline{\alpha}_{n'+m'}} e^{\underline{\alpha}_1}\wedge e^{\underline{\alpha}_2}\wedge\cdots\wedge e^{\underline{\alpha}_{n'+m'}}$$

to which any (k^2-1)-form is proportional $(k^2-1=n'+m')$. The integral of such a form is defined as the trace of the matrix coefficient in the form σ and the scalar product introduced for any couple of p-forms ϖ and ψ,

$$(\varpi,\psi) = \int (\varpi\wedge\star\psi).$$

Let us analyze how a noncommutative differential form calculus (induced by an anholonomic structure) can be developed and related to the Hamiltonian classical and quantum mechanics and Poisson bracket formalism.

For a p-form $\varpi^{[p]}$, the antiderivation i_Y with respect to a vector field $Y\in \mathrm{Ader}\, M_k(\mathrm{IC},u^{\underline{\alpha}})$ can be defined as in the usual formalism,

$$i_Y\varpi^{[p]}(X_1,X_2,\ldots,X_{p-1}) = \varpi^{[p]}(Y,X_1,X_2,\ldots,X_{p-1}),$$

where $X_1,X_2,\ldots,X_{p-1}\in \mathrm{Ader}\, M_k(\mathrm{IC},u^{\underline{\alpha}})$. By a straightforward calculus we can check that for a 2-form $\Xi=\delta e$ one holds

$$\delta\Xi = \delta^2 e = 0 \quad \text{and } L_Y\Xi = 0,$$

where the Lie derivative of forms is defined as $L_Y\varpi^{[p]}=(i_Y\ \delta+\delta\ i_Y)\varpi^{[p]}$.

The Hamiltonian vector field $H_{[\varphi]}$ of an element of algebra $\varphi\in M_k(\mathrm{IC},u^{\underline{\alpha}})$ is introduced following the equality $\Xi(H_{[\varphi]},Y)=Y\varphi$ which holds for any vector field. Then, we can define the Poisson bracket of two functions (in a quantum variant, observables) φ and χ, $\{\varphi,\chi\}=\Xi(H_{[\varphi]},H_{[\chi]})$ when

$$\{e_{\underline{\alpha}},e_{\underline{\beta}}\} = \Xi(e_{\underline{\alpha}},e_{\underline{\beta}}) = i[e_{\underline{\alpha}},e_{\underline{\beta}}].$$

This way, a simple version of noncommutative classical and quantum mechanics (up to a factor like the Planck constant, $\hbar$) is proposed, being derived by anholonomic relations for a certain class of exact off-diagonal solutions in commutative gravity.

We note that by using the Lie algebra SU (k,IC) we can elaborate an alternative noncommutative calculus related to the special unitary group SU_k in k dimensions when the anholonomic coefficients

$$W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}} = p^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}} + w^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}} \tag{19}$$

induce a linear connection in the associated noncommutative space (noncommutative geometries with $p^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ being the structure constants of SU_k were investigated in Refs. 44–49 and 8).

Let us state the main formulas for such realization of anholonomic noncommutativity: In this case, the matrix basis $q_{\underline{\alpha}}$ consists from anti-Hermitian (and not Hermitian) matrices and the relations (11) are stated in a different form

$$q_{\underline{\alpha}}q_{\underline{\beta}} = -\frac{1}{k}\rho_{\underline{\alpha}\underline{\beta}}I + Z^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}} + \frac{1}{2}p^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}}, \tag{20}$$

where $\rho_{\underline{\alpha}\underline{\gamma}}Z^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$ is trace free and symmetric in all pairs of indices and $\rho_{\underline{\alpha}\underline{\beta}}=p^{\underline{\tau}}_{\underline{\alpha}\underline{\gamma}}p^{\underline{\gamma}}_{\underline{\tau}\underline{\beta}}$. We consider dependencies of matrix coefficients on coordinates $u^{\underline{\alpha}}=(0,\ldots,u^{\alpha})$, i.e., we work in the space $M_k(\mathrm{IC},u^{\underline{\alpha}})$, and introduce the anholonomic derivations $e_{\underline{\alpha}}$,

$$e_{\underline{\alpha}}\varphi = [q_{\underline{\alpha}}, \varphi],$$

for arbitrary matrix function $\varphi \in M_k(\mathrm{IC}, u^{\underline{\alpha}})$ defining a basis for the Lie algebra of derivations $\mathrm{Der}[M_k(\mathrm{IC}, u^{\underline{\alpha}})]$ of $M_k(\mathrm{IC}, u^{\underline{\alpha}})$. In this case, we generalize (20) to

$$q_{\underline{\alpha}}(u^{\underline{\tau}})q_{\underline{\beta}}(u^{\underline{\tau}}) = -\frac{1}{k}\rho_{\underline{\alpha}\underline{\beta}}(u^{\underline{\tau}})I + Z^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}q_{\underline{\gamma}}(u^{\underline{\tau}}) + \frac{1}{2}W^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}(u^{\underline{\tau}})q_{\underline{\gamma}}(u^{\underline{\tau}}),$$

with an effective (of N-anholonomy origin) metric $\rho_{\underline{\alpha}\underline{\beta}}(u^{\underline{\lambda}}) = W^{\underline{\tau}}_{\underline{\alpha}\underline{\gamma}}(u^{\underline{\lambda}})W^{\underline{\gamma}}_{\underline{\tau}\underline{\beta}}(u^{\underline{\lambda}})$ being an anholonomic deformation of the Killing metric of SU_k.

In order to define the algebra of forms $\Omega^*[M_k(\mathrm{IC}, u^{\underline{\alpha}})]$ over $M_k(\mathrm{IC}, u^{\underline{\alpha}})$ we set $\Omega^0 = M_k$ and write

$$\delta\varphi(e_{\underline{\alpha}}) = e_{\underline{\alpha}}(\varphi)$$

for every matrix function $\varphi \in M_k(\mathrm{IC}, u^{\underline{\alpha}})$. As a particular case, we have

$$\delta q^{\underline{\alpha}}(e_{\underline{\beta}}) = -W^{\underline{\alpha}}_{\underline{\beta}\underline{\gamma}}q^{\underline{\gamma}},$$

where indices are raised and lowered with the anholonomically deformed metric $\rho_{\underline{\alpha}\underline{\beta}}(u^{\underline{\lambda}})$. This way, we can define the set of 1-forms $\Omega^1[M_k(\mathrm{IC}, u^{\underline{\alpha}})]$ to be the set of all elements of the form $\varphi\delta\beta$ with φ and β belonging to $M_k(\mathrm{IC}, u^{\underline{\alpha}})$. The set of all differential forms define a differential algebra $\Omega^*[M_k(\mathrm{IC}, u^{\underline{\alpha}})]$ with the couple $(\Omega^*[M_k(\mathrm{IC}, u^{\underline{\alpha}})], \delta)$ said to be a differential calculus in $M_k(\mathrm{IC}, u^{\underline{\alpha}})$ induced by the anholonomy of certain exact solutions (with off-diagonal metrics and associated N connections) in a gravity theory.

We can also find a set of generators $e^{\underline{\alpha}}$ of $\Omega^1[M_k(\mathrm{IC}, u^{\underline{\alpha}})]$, as a left/right module completely characterized by the duality equations $e^{\underline{\mu}}(e_{\underline{\alpha}}) = \delta^{\underline{\mu}}_{\underline{\alpha}}I$ and related to $\delta q^{\underline{\alpha}}$,

$$\delta q^{\underline{\alpha}} = W^{\underline{\alpha}}_{\underline{\beta}\underline{\gamma}}q^{\underline{\beta}}q^{\underline{\gamma}} \quad \text{and } e^{\underline{\mu}} = q_{\underline{\gamma}}q^{\underline{\mu}}\delta q^{\underline{\gamma}}.$$

Similarly to the formalism presented in details in Ref. 8, we can elaborate a differential calculus with derivations by introducing a linear torsionless connection

$$\mathcal{D}e^{\underline{\mu}} = -\omega^{\underline{\mu}}_{\ \underline{\gamma}} \otimes e^{\underline{\gamma}}$$

with the coefficients $\omega^{\underline{\mu}}_{\ \underline{\gamma}} = -\frac{1}{2}W^{\underline{\mu}}_{\ \underline{\gamma}\underline{\beta}}e^{\underline{\gamma}}$, resulting in the curvature 2-form,

$$\mathcal{R}^{\underline{\mu}}_{\ \underline{\gamma}} = \tfrac{1}{8}W^{\underline{\mu}}_{\ \underline{\gamma}\underline{\beta}}W^{\underline{\beta}}_{\ \underline{\alpha}\underline{\tau}}e^{\underline{\alpha}}e^{\underline{\tau}}.$$

So, even the anholonomy coefficients (6) of a solution, for instance, in string gravity, has nontrivial torsion coefficients, (9), the associated linear connection induced by the anholonomy coefficients in the associated noncommutative space of symmetries of the solution can be defined to be torsionless but to have a specific metrics and curvature being very different from the space–time curvature tensor. This is a surprising fact that commutative curved space–times provided with off-diagonal metrics and associated anholonomic frames and N connections may be characterized by a noncommutative shadow space with a Lie algebralike structure induced by the frame anholonomy. We argue that such metrics possess anholonomic noncommutative symmetries.

Finally, in this section, we conclude that for the holonomic solutions of the Einstein equations, with vanishing $w^{\underline{\gamma}}_{\underline{\alpha}\underline{\beta}}$, any associated noncommutative geometry or SL (k, IC), or SU_k type, decouples from the off-diagonal (anholonomic) gravitational background and transforms into a trivial one defined by the corresponding structure constants of the chosen Lie algebra. The anholonomic noncommutativity and the related differential geometry are induced by the anholonomy coefficients. All such structures reflect a specific type of symmetries of generic off-diagonal metrics and associated frame/N-connection structures. Considering exact solutions of the gravitational field equations, we can assert that we constructed a class of vacuum or nonvacuum metrics

possessing a specific noncommutative symmetry instead, for instance, of any usual Killing symmetry. In general, we can introduce a new classification of space–times following anholonomic noncommutative aglebraic properties of metrics and vielbein structures.

IV. BLACK ELLIPSOIDS WITH NONCOMMUTATIVE SYMMETRY

In this section, we shall analyze two classes of black ellipsoid solutions of the Einstein and (anti) de Sitter gravity (with arbitrary cosmological term) possessing hidden noncommutative symmetries. Such off-diagonal metrics will be constructed as to generate also exact solutions in complex gravity, with respect to complex N-elongated vielbeins (for simplicity, we shall consider the metric coefficients to be real with respect to such complex frames) which must be considered if any noncommutativity of coordinates with complex parameters and/or Wick-type rotations to Euclidean signatures are introduced. Such metrics are stable for certain configurations with complex off-diagonal terms (a rigorous proof may be performed by generalizing to complex spaces the results from Refs. 18 and 19).

A. Anholonomic complex deformations of the Schwarzschild solution

We consider a 4D off-diagonal metric ansatz [a complex generalization of (4), or equivalently, of (1) with complex frames (vielbeins) (2) and (3), see also the ansatz (C2) in Appendix C],

$$\delta s^2 = -\left(1-\frac{2m}{r}+\frac{\varepsilon}{r^2}\right)^{-1} dr^2 - r^2\gamma(r)d\theta^2 - \eta_3(r,\varphi)r^2\sin^2\theta\, d\varphi^2 + \eta_4(r,\varphi)\left(1-\frac{2m}{r}+\frac{\varepsilon}{r^2}\right)\delta t^2. \tag{21}$$

for usual local spherical and timelike coordinates $u=\{u^\alpha=(u^2=r,u^3=\theta,u^4=\varphi,u^5=t)\}$. In order to have compatibility with notations from Appendixes B and C, in this section, we consider that 4D greek indices run from 2 to 5 where the "polarization" functions $\eta_{3,4}$ are decomposed on a small parameter $\varepsilon, 0<|\varepsilon|\ll 1$,

$$\eta_4(r,\varphi) = \eta_{4[0]}(r,\varphi) + \varepsilon\lambda_4(r,\varphi) + \varepsilon^2\gamma_4(r,\varphi) + \cdots,$$

$$\eta_5(r,\varphi) = 1 + \varepsilon\lambda_5(r,\varphi) + \varepsilon^2\gamma_5(r,\varphi) + \cdots, \tag{22}$$

$\gamma(r)$ is a necessary smooth class function satisfying $\gamma(r)=1$ if $\varepsilon\to 0$ (it will be defined below) and

$$\delta t = dt + n_2(r,\varphi)dr \tag{23}$$

for $n_2=n_2^{[re]}+in_2^{[im]}\sim\varepsilon\cdots+\varepsilon^2$ terms being, in general, a complex valued function. In the particular case, when n_2 is real, i.e., when $n_2=n_2^{[re]}$ and $n_2^{[im]}=0$, the labels [re] and [im] being used, respectively, for the real and imaginary parts, the metric (21) was investigated in connection to the definition of static and nonstatic black ellipsoid configurations in Refs. 13–19, 30, and 31. The functions $\eta_{4,5}(r,\varphi)$ and $n_2(r,\varphi)$ will be found as the metric will define a solution of the vacuum Einstein equations (A6) [see Appendixes A–C for the explicit form of field equations (B3)–(B6) written for the 4D ansatz (C2)]. By introducing certain complex components of metric generated by small deformations of the spherical static symmetry on a small positive parameter ε (in the limits $\varepsilon\to 0$ and $\eta_{4,5}\to 1$ we have just the Schwarzschild solution for a point particle of mass m) we show here that it is possible to extend the results of Refs. 18 and 19 with respect to complex anholonomic structures (2) with a nontrivial component $N_2^5=n_2(r,\varphi)$ given by N elongation (23).

A more interesting class of exact solutions with an effective electric charge q induced from the complex/noncommutative/anholonomic gravity may be constructed if we state that the parameter of anholonomic deformations is of type $\varepsilon=(iq)^2$ for a real q and imaginary i. In this case the metric (21) will have real coefficients in the first order of ε, being very similar to those from the well-known Reissner–Nordström metric with, in our case effective, electric charge q. For convenience, in our further calculations we shall use both small parameters ε and/or q.

The set of η, λ and γ functions from (22) define arbitrary anholonomic (in our case with certain complexity) deformations of the Schwarzschild metric. As a particular case, we can consider the condition of vanishing of the metric coefficient before δt^2,

$$\eta_5(r,\varphi)\left(1-\frac{2m}{r}+\frac{\varepsilon}{r^2}\right)=1-\frac{2m}{r}+\varepsilon\frac{\Phi_5}{r^2}+\varepsilon^2\Theta_5=0,$$

$$\Phi_5=\lambda_4(r^2-2mr)+1, \tag{24}$$

$$\Theta_5=\gamma_4\left(1-\frac{2m}{r}\right)+\lambda_4,$$

defining a rotation ellipsoid configuration when

$$\lambda_5=\left(1-\frac{2m}{r}\right)^{-1}\left(\cos\varphi-\frac{1}{r^2}\right) \quad \text{and} \quad \gamma_5=-\lambda_5\left(1-\frac{2m}{r}\right)^{-1}.$$

Really, in the first order on ε, one follows a zero value for the coefficient before δt^2 if

$$r_+=\frac{2m}{1-q^2\cos\varphi}=2m[1+q^2\cos\varphi], \tag{25}$$

which is the equation for a three-dimensional (3D) ellipsoidlike hypersurface with a small eccentricity q^2. In general, we can consider arbitrary pairs of functions $\lambda_5(r,\theta,\varphi)$ and $\gamma_5(r,\theta,\varphi)$ [for φ-anisotropies, $\lambda_5(r,\varphi)$ and $\gamma_5(r,\varphi)$] which may be singular for some values of r, or on some hypersurfaces $r=r(\theta,\varphi)$ [$r=r(\varphi)$]. Such a configuration may define a static black ellipsoid object (a Schwarzschild-type static solution with the horizon slightly deformed to an ellipsoidal hypersurface[18,19]).

In general, not being restricted only to ellipsoidal configurations, the simplest way to analyze the condition of vanishing of the metric coefficient before δt^2 is to choose γ_5 and λ_5 as to have $\Theta=0$. In this case we find from (24),

$$r_\pm=m\pm m\sqrt{1-\varepsilon\frac{\Phi}{m^2}}\simeq m\left[1\pm\left(1+q^2\frac{\Phi_5}{2m^2}\right)\right], \tag{26}$$

where $\Phi_5(r,\varphi)$ is taken for $r=2m$.

Let us introduce a new radial coordinate

$$\xi=\int \mathrm{d}r\sqrt{\left|1-\frac{2m}{r}-\frac{q^2}{r^2}\right|} \tag{27}$$

and define

$$h_4=-\eta_4(\xi,\varphi)r^2(\xi)\sin^2\theta, \quad h_5=1-\frac{2m}{r}-q^2\frac{\Phi_5}{r^2}. \tag{28}$$

For $r=r(\xi)$ found as the inverse function after integration in (27), we can write the metric (21) as

$$\mathrm{d}s^2=-\mathrm{d}\xi^2-r^2(\xi)\gamma(\xi)\mathrm{d}\theta^2+h_4(\xi,\theta,\varphi)\delta\varphi^2+h_5(\xi,\theta,\varphi)\delta t^2,$$

$$\delta t=\mathrm{d}t+n_2(\xi,\varphi)\mathrm{d}\xi, \tag{29}$$

where the coefficient n_2 is taken to solve the Eq. (B6) and to satisfy the condition $\Omega^a_{jk}=0$ which states that we fix the canonical N-adapted connection (7) to coincide with the Levi–Civita connection (10), i.e., to consider a complexlike Einstein but not Einstein–Cartan theory, which to-

gether with the condition $r^2(\xi)\gamma(\xi)=\xi^2$ will be transformed into the usual Schwarzschild metric for $\varepsilon\to 0$.

Let us define the conditions when the coefficients of metric (21) define solutions of the vacuum Einstein equations (such solutions exists in the real case following Theorems 1–3 from Appendix B, in our case we only state a generalization for certain complex valued metric coefficients). For $g_2=-1$, $g_3=-r^2(\xi)\gamma(\xi)$ and arbitrary $h_4(\xi,\theta,\varphi)$ and $h_5(\xi,\theta)$, we get solutions of Eqs. (B3)–(B5). If h_5 depends on anisotropic variable φ, Eq. (B4) may be solved if

$$\sqrt{|\eta_4|}=\eta_0(\sqrt{|\eta_5|})^* \tag{30}$$

for $\eta_0=$const. Considering decompositions of type (22) we set $\eta_0=\eta/|\varepsilon|$, where the constant η is taken as to have $\sqrt{|\eta_3|}=1$ in the limits

$$\frac{(\sqrt{|\eta_4|})^*\to 0}{|\varepsilon|\to 0}\to\frac{1}{\eta}=\text{const}. \tag{31}$$

These conditions are satisfied if the functions $\eta_{4[0]}$, $\lambda_{4,5}$, and $\gamma_{4,5}$ are related via relations

$$\sqrt{|\eta_{4[0]}|}=\frac{\eta}{2}\lambda_5^*,\quad \lambda_5=\eta\sqrt{|\eta_{4[0]}|}\gamma_5^*$$

for arbitrary $\gamma_4(r,\varphi)$. In this paper we select only such solutions which satisfy the conditions (30) and (31) being a complex variant of the conditions (B16), see Appendix B. Similar classes of solutions were selected also in Refs. 18 and 19, for static black ellipsoid metrics for the (noncomplex) Einstein gravity with real ε parameter.

The next step is to construct the solution of (B6) which in general real form is (B18). To consider linear infinitesimal extensions on ε of the Schwarzschild metric, we may write the solution of (B6) as

$$n_2=\varepsilon\hat{n}_2(\xi,\varphi),$$

where

$$\hat{n}_2(\xi,\varphi)=n_{2[1]}(\xi)+n_{2[2]}(\xi)\int \mathrm{d}\varphi\, n_4(\xi,\varphi)/(\sqrt{|\eta_5(\xi,\varphi)|})^3,\quad \eta_5^*\neq 0=n_{2[1]}(\xi)+n_{2[2]}$$
$$\times(\xi)\int \mathrm{d}\varphi\,\eta_4(\xi,\varphi),\quad \eta_5^*=0=n_{2[1]}(\xi)+n_{2[2]}(\xi)\int \mathrm{d}\varphi/(\sqrt{|\eta_5(\xi,\varphi)|})^3,\quad \eta_4^*=0, \tag{32}$$

with the functions $n_{2[1,2]}(\xi)$ may be complex valued and must be stated by boundary conditions.

The data

$$g_1=-1,\quad g_2=-1,\quad g_3=-r^2(\xi)\gamma(\xi),$$

$$h_4=-\eta_4(\xi,\varphi)r^2(\xi)\sin^2\theta,\quad h_5=1-\frac{2m}{r}+\varepsilon\frac{\phi_5}{r^2}, \tag{33}$$

$$w_{2,3}=0,\quad n_2=\varepsilon\hat{n}_2(\xi,\varphi),\quad n_3=0,$$

for the metric (21) written in variables (ξ,θ,φ,t) define a class of solutions of the complex vacuum Einstein equations with nontrivial polarization function η_4 and extended on parameter ε up to the second order (the polarization functions being taken as to make zero the second order coefficients). Such solutions are generated by small complex deformations (in particular cases of rotation ellipsoid symmetry) of the Schwarzschild metric. It is possible to consider some particular

parametrizations of N coefficients resulting in Hermitian metrics and frames, or another type of complex configurations. Such constructions do not affect the stability properties of solutions elaborated in this paper.

We can relate our complex exact solutions (33) with some small deformations of the Schwarzschild metric to a Reissner–Nordström-type metric with the "electric" charge induced effectively from the anholonomic complex gravity, as well we can satisfy the asymptotically flat condition, if we choose such functions $n_{k[1,2]}(x^i)$ as $n_k \to 0$ for $\varepsilon \to 0$ and $\eta_4 \to 1$. These functions must also be selected as to vanish far away from the horizon, for instance, like $\sim 1/r^{1+\tau}$, $\tau > 0$, for long distances $r \to \infty$. We get a static metric with effective "electric" charge induced by a small, quadratic on ε, off-diagonal metric extension. Roughly, we can say that we have constructed a Reissner–Nordström-type world "living" in a slightly complexified frame which induced both an effective electric charge and certain polarizations of the metric coefficients via the functions $h_{4[0]}$, $\eta_{4,5}$, and n_5. Another very important property is that the deformed metric was stated to define a vacuum solution which differs substantially from the usual Reissner–Nördstrom metric being an exact static solution of the Einstein–Maxwell equations. For $\varepsilon \to 0$ and $h_{4[0]} \to 1$ and for $\gamma = 1$, the metric (21) transforms into the usual Schwarzschild metric. A solution with ellipsoid symmetry can be selected by a corresponding condition of vanishing of the coefficient before δt which defines an ellipsoidal hypersurfacelike for the Kerr metric, but in our case the metric is nonrotating.

B. Analytic extensions of ellipsoid complex metrics

In order to understand that the construction in this section of exact solution of vacuum complex gravity really defines black-hole-like objects we must analyze it's analytic extensions, horizon, and geodesic behavior and stability.

The metric (21) has a singular behavior for $r = r_{\pm}$, see (26) like the usual Reissner–Nördstrom one. Our aim is to prove that we have constructed a solution of the vacuum complex Einstein equations with a static "anisotropic" horizon being a small deformation on parameter ε of the Schwarzschild's solution horizon. We may analyze the anisotropic horizon's properties for some fixed "direction" given in a smooth vicinity of any values $\varphi = \varphi_0$ and $r_+ = r_+(\varphi_0)$. The final conclusions will be some general ones for arbitrary φ when the explicit values of coefficients will have a parametric dependence on angular coordinate φ. Of course, in order to avoid singularities induced by integration of Eq. (B6) we must choose such solutions (32) as the associated anholonomic frames with necessary smooth class, without singularities.

The metrics (21) and (29) are regular in the regions I ($\infty > r > r_+^{\Phi}$), II ($r_+^{\Phi} > r > r_-^{\Phi}$), and III ($r_-^{\Phi} > r > 0$). As in the Schwarzschild, Reissner–Nordström, and Kerr cases these singularities can be removed by introducing suitable coordinates and extending the manifold to obtain a maximal analytic extension.[50,51] We have similar regions as in the Reissner–Nördstrom space–time, but with just only one possibility $\varepsilon < 1$ instead of three relations for static electro-vacuum cases ($q^2 < m^2, q^2 = m^2, q^2 > m^2$; where q and m are correspondingly the electric charge and mass of the point particle in the Reissner–Nordström metric). This property holds for both types of anholonomic deformations, real or complex ones. So, we may consider the usual Penrose's diagrams as for a particular case of the Reissner–Nördstrom space–time but keeping in mind that such diagrams and horizons have an additional parametrization on an angular coordinate and that the frames have some complex coefficients.

We can construct the maximally extended manifold step by steps like in the Schwarzschild case (see details, for instance, in Ref. 52) by supposing that the complex valued coefficients of metrics and frame are of necessary smooth class as real and complex valued functions (for simplicity, we consider the simplest variant when the space–time is provided with a complex valued metric but admits covering by real coordinates which after certain coordinate transform may be also complex). We introduce a new coordinate

$$r^{\|} = \int \mathrm{d}r\left(1 - \frac{2m}{r} - \frac{q^2}{r^2}\right)^{-1}$$

for $r > r_+^1$ and find explicitly the coordinate

$$r^{\|} = r + \frac{(r_+^1)^2}{r_+^1 - r_-^1}\ln(r - r_+^1) - \frac{(r_-^1)^2}{r_+^1 - r_-^1}\ln(r - r_-^1), \tag{34}$$

where $r_\pm^1 = r_\pm^\Phi$ with $\Phi = 1$. If r is expressed as a function on ξ, than $r^{\|}$ can be also expressed as a function on ξ depending additionally on some parameters.

Defining the advanced and retarded coordinates, $v = t + r^{\|}$ and $w = t - r^{\|}$, with corresponding elongated differentials

$$\delta v = \delta t + \mathrm{d}r^{\|} \quad \text{and} \quad \delta w = \delta t - \mathrm{d}r^{\|}, \tag{35}$$

which are N-adapted frames like (2) but complex one, the metric (29) takes the form

$$\delta s^2 = -r^2(\xi)\gamma(\xi)\mathrm{d}\theta^2 - \eta_3(\xi,\varphi_0)r^2(\xi)\sin^2\theta\,\delta\varphi^2 + \left(1 - \frac{2m}{r(\xi)} - q^2\frac{\Phi_4(r,\varphi_0)}{r^2(\xi)}\right)\delta v\,\delta w,$$

where (in general, in nonexplicit form) $r(\xi)$ is a function of type $r(\xi) = r(r^{\|}) = r(v,w)$. Introducing new coordinates (v'', w'') by

$$v'' = \arctan\left[\exp\left(\frac{r_+^1 - r_-^1}{4(r_+^1)^2}v\right)\right], \quad w'' = \arctan\left[-\exp\left(\frac{-r_+^1 + r_-^1}{4(r_+^1)^2}w\right)\right] \tag{36}$$

and multiplying the last term on the conformal factor we obtain

$$\delta s^2 = -r^2\gamma(r)\mathrm{d}\theta^2 - \eta_4(r,\varphi_0)r^2\sin^2\theta\delta\varphi^2 + 64\frac{(r_+^1)^4}{(r_+^1 - r_-^1)^2}\left[1 - \frac{2m}{r(\xi)} - q^2\frac{\Phi_5(r,\varphi_0)}{r^2(\xi)}\right]\delta v''\,\delta w'', \tag{37}$$

where r is defined implicitly by

$$\tan v''\tan w'' = -\exp\left[\frac{r_+^1 - r_-^1}{2(r_+^1)^2}r\right]\sqrt{\frac{r - r_+^1}{(r - r_-^1)\chi}}, \quad \chi = \left(\frac{r_+^1}{r_-^1}\right)^2, \tag{38}$$

where the functions tan and exp should be considered as the complex functions. As particular cases, we may choose $\eta_5(r,\varphi)$ as the condition of vanishing of the metric coefficient before $\delta v''\,\delta w''$ will describe a horizon parametrized by a resolution ellipsoid hypersurface.

The metric (37) is very similar to that analyzed in Refs. 18 and 19 but the coordinate transforms defined by (35)–(38) involve complex coordinate transforms, so $\delta v''\,\delta w''$ is a product defined by complexified N-adapted frames.

The maximal extension of the Schwarzschild metric deformed by a small parameter ε, i.e., the extension of the metric (21), is defined by taking (37) as the metric on the maximal manifold (which for corresponding coordinate transforms can be considered as a real one but with complex valued coefficients of the metric and moving frames) on which this metric is of smooth class C^2. The Penrose diagram of this static but locally anisotropic space–time, for any fixed angular value φ_0 is similar to the Reissner–Nördstrom solution, for the case $q^2 \to \varepsilon$ and $q^2 < m^2$ (see, for instance, Ref. 52). There are an infinite number of asymptotically flat regions of type I, connected by intermediate regions II and III, where there is still an irremovable singularity at $r = 0$ for every region III. We may travel from a region I to another one by passing through the wormholes made by anisotropic deformations (ellipsoid off diagonality of metrics, or anholonomy) like in the Reissner–Nordström universe because $\sqrt{\varepsilon} \sim q$ may model an effective electric charge. One cannot turn back in such travel because the complex frames "do not allow us."

It should be noted that the metric (37) is analytic everywhere except at $r=r_{-}^{1}$ (we must use the term analytic as real functions for the metric coefficients in the lower approximations on ε and analytic as complex functions for the higher approximations of the metric coefficients and for all terms contained in the vielbein coefficients). We may eliminate this coordinate degeneration by introducing other new complex coordinates

$$v'''=\arctan\left[\exp\left(\frac{r_{+}^{1}-r_{-}^{1}}{2n_0(r_{+}^{1})^2}v\right)\right],\quad w'''=\arctan\left[-\exp\left(\frac{-r_{+}^{1}+r_{-}^{1}}{2n_0(r_{+}^{1})^2}w\right)\right],$$

where the integer $n_0\geqslant(r_{+}^{1})^2/(r_{-}^{1})^2$ and complex functions. In these coordinates, the metric is (in general, complex) analytic everywhere except at $r=r_{+}^{1}$ where it is degenerate. This way the space–time manifold can be covered by an analytic atlas by using coordinate carts defined by (v'',w'',θ,φ) and $(v''',w''',\theta,\varphi)$. We also note that the analytic extensions of the deformed metrics were performed with respect to anholonomic complex frames which distinguish such constructions from those dealing only with holonomic and/or real coordinates, like for the usual Reissner–Nördstrom and Kerr metrics.

A more rigorous analysis of the metric (21) should involve a computation of its curvature and investigation of singularity properties. We omit here this cumbersome calculus by emphasizing that anholonomic deformations of the Schwarzschild solution defined by a small real or complex parameter ε cannot remove the bulk singularity of such space–times; there are deformations of the horizon, frames, and specific polarizations of constants.

The metric (21) and its analytic extensions do not possess Killing symmetries being deformed by anholonomic transforms. Nevertheless, we can associate to such solutions certain noncommutative symmetries following the procedure described in Sec. III. Taking the data (33) and formulas (6), we compute the corresponding nontrivial anholonomy coefficients

$$w_{42}^{[N]5}=-w_{24}^{[N]5}=\partial n_2(\xi,\varphi)/\partial\varphi=n_2^{*}(\xi,\varphi) \tag{39}$$

with n_2 defined by (32). Our vacuum solution is for 4D, so for $n+m=4$, the condition $k^2-1=n+m$ cannot be satisfied in integer numbers. We may trivially extend the dimensions like $n'=6$ and $m'=m=2$ and for $k=3$ to consider the Lie group SL (3, IC) noncommutativity with corresponding values of $Q_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$ and structure constants $f_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$, see (11). An extension $w_{\alpha\beta}^{[N]\gamma}\to W_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$ may be performed by stating the N-deformed "structure" constants (14), $W_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}=f_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}+w_{\underline{\alpha}\underline{\beta}}^{[N]\underline{\gamma}}$, with only two nontrivial values of $w_{\underline{\alpha}\underline{\beta}}^{[N]\underline{\gamma}}$ given by (39).

The associated anholonomic noncommutative symmetries of the black ellipsoid solutions can be alternatively defined as in the trivial anholonomy limit they will result in a certain noncommutativity for the Lie group SU_3. In this case, we must consider a N deformation of the group structure constants $p_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$, like in (19), $W_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}=p_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}+w_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$. This variant of deformations can be related directly with the "de Sitter nonlinear gauge gravity model of (non)commutative gravity"[6] and the $SU_k[SO(k)]$ models of noncommutative gravity[7] by considering complex vielbeins.

C. Black ellipsoids and the cosmological constant

We can generalize the vacuum equations to the gravity with cosmological constant λ,

$$R_{\mu'\nu'}=\lambda g_{\mu'\nu'}, \tag{40}$$

where $R_{\mu'\nu'}$ is the Ricci tensor (A3), in general with anholonomic variables and the indices take values $i',k'=1,2$ and $a',b'=3,4$.

For an ansatz of type (C5),

$$\delta s^2=g_1(\mathrm{d}x^1)^2+g_2(\mathrm{d}x^2)^2+h_3(x^{i'},y^3)(\delta y^3)^2+h_4(x^{i'},y^3)(\delta y^4)^2,$$

$$\delta y^3 = \mathrm{d}y^3 + w_{i'}(x^{k'}, y^3)\mathrm{d}x^{i'}, \quad \delta y^4 = \mathrm{d}y^4 + n_{i'}(x^{k'}, y^3)\mathrm{d}x^{i'}, \tag{41}$$

the Einstein equations (40) are written [see Refs. 30, 31, and 13–19 for details on computation; this is a particular case of source of type (C14), see Appendix B]

$$R_1^1 = R_2^2 = -\frac{1}{2g_1g_2}\left[\ddot{g_2} - \frac{\dot{g_1}\dot{g_2}}{2g_1} - \frac{(\dot{g_2})^2}{2g_2} + g_1'' - \frac{g_1'g_2'}{2g_2} - \frac{(g_1')^2}{2g_1}\right] = \lambda, \tag{42}$$

$$R_3^3 = R_4^4 = -\frac{\beta}{2h_3h_4} = \lambda, \tag{43}$$

$$R_{3i'} = -w_{i'}\frac{\beta}{2h_4} - \frac{\alpha_{i'}}{2h_4} = 0, \tag{44}$$

$$R_{4i'} = -\frac{h_4}{3h_3}[n_{i'}^{***} + \gamma n_{i'}^{*}] = 0. \tag{45}$$

The coefficients of Eqs. (42)–(45) are given by

$$\alpha_i = \partial_i h_4^* - h_4^* \partial_i \ln\sqrt{|h_3h_4|}, \quad \beta = h_4^{***} - h_4^*[\ln\sqrt{|h_3h_4|}]^*, \quad \gamma = \frac{3h_4^*}{2h_4} - \frac{h_3^*}{h_3}. \tag{46}$$

The various partial derivatives are denoted as $a^{\cdot} = \partial a/\partial x^1$, $a' = \partial a/\partial x^2$, $a^* = \partial a/\partial y^3$. This system of equations can be solved by choosing one of the ansatz functions [e.g., $g_1(x^i)$ or $g_2(x^i)$] and one of the ansatz functions [e.g., $h_3(x^i, y^3)$ or $h_4(x^i, y^3)$] to take some arbitrary, but physically interesting form (see Theorem 3 in Appendix B). Then, the other ansatz functions can be analytically determined up to an integration in terms of this choice. In this way we can generate a loss of different solutions, but we impose the condition that the initial, arbitrary choice of the ansatz functions is "physically interesting" which means that one wants to make this original choice so that the generated final solution yields a well-behaved metric.

In Ref. 19 (see also the preceding section), we proved that for

$$g_1 = -1, \quad g_2 = r^2(\xi)q(\xi),$$

$$h_3 = -\eta_3(\xi,\varphi)r^2(\xi)\sin^2\theta, \tag{47}$$

$$h_4 = n_4(\xi,\varphi)h_{4[0]}(\xi) = 1 - \frac{2\mu}{r} + \varepsilon\frac{\Phi_4(\xi,\varphi)}{2\mu^2},$$

with coordinates $x^1 = \xi = \int \mathrm{d}r\sqrt{1 - 2m/r + \varepsilon/r^2}$, $x^2 = \theta$, $y^3 = \varphi$, $y^4 = t$ [the (r, θ, φ) being usual radial coordinates], the ansatz (41) is a vacuum solution with $\lambda = 0$ of the equations (40) which defines a black ellipsoid with mass μ, eccentricity ε, and gravitational polarizations $q(\xi)$, $\eta_3(\xi,\varphi)$, and $\Phi_4(\xi,\varphi)$. Such black holes are certain deformations of the Schawarzschild metrics to static configurations with ellipsoidal horizons which is possible if generic off-diagonal metrics and anholonomic frames are considered. A complex generalization of this solution is given by the values (33). In this section we show that the data (47) and/or (33) can be extended as to generate exact black ellipsoid solutions, defined correspondingly with respect to real or complex N frames, with nontrivial cosmological constant $\lambda = 1/4$ which can be imbedded in string theory.

At the first step, we find a class of solutions with $g_1 = -1$ and $g_2 = g_2(\xi)$ solving Eq. (42), which under such parametrizations transforms to

$$\ddot{g_2} - \frac{(\dot{g_2})^2}{2g_2} = 2g_2\lambda.$$

With respect to the variable $Z=(g_2)^2$ this equation is written as

$$\ddot{Z} + 2\lambda Z = 0$$

which can be integrated in explicit form, $Z=Z_{[0]}\sin(\sqrt{2\lambda}\xi+\xi_{[0]})$, for some constants $Z_{[0]}$ and $\xi_{[0]}$ which means that

$$g_2 = -Z^2_{[0]}\sin^2(\sqrt{2\lambda}\xi+\xi_{[0]}) \tag{48}$$

parametrize in real string gravity a class of solution of (42) for the signature $(-,-,-,+)$. For $\lambda\to 0$ we can approximate $g_2=r^2(\xi)$, $q(\xi)=-\xi^2$, and $Z^2_{[0]}=1$ which has compatibility with the data (47). The solution (48) with cosmological constant (of string or nonstring origin) induces oscillations in the "horizontal" part of the metric written with respect to *N*-adapted frames.

The next step is to solve Eq. (43),

$$h_4^{**} - h_4^{*}[\ln\sqrt{|h_3h_4|}]^{*} = -2\lambda h_3h_4.$$

For $\lambda=0$ a class of solution is given by any $\hat{h}_3$ and $\hat{h}_4$ related as

$$\hat{h}_3 = \eta_0[(\sqrt{|\hat{h}_4|})^{*}]^2$$

for a constant η_0 chosen to be negative in order to generate the signature $(-,-,-,+)$. For nontrivial λ, we may search the solution as

$$h_3 = \hat{h}_3(\xi,\varphi)f_3(\xi,\varphi) \quad \text{and } h_4 = \hat{h}_4(\xi,\varphi), \tag{49}$$

which solves (43) if $f_3=1$ for $\lambda=0$ and

$$f_3 = \frac{1}{4\lambda}\left[\int \frac{\hat{h}_3\hat{h}_4}{\hat{h}_4^{*}}d\varphi\right]^{-1} \quad \text{for } \lambda\neq 0.$$

Now it is easy to write down the solutions of equations (44) (being a linear equation for $w_{i'}$) and (45) (after two integrations of $n_{i'}$ on φ),

$$w_{i'} = \varepsilon\hat{w}_{i'} = -\alpha_{i'}/\beta, \tag{50}$$

where $\alpha_{i'}$ and β are computed by setting (49) into corresponding values from (46) (we choose the initial conditions as $w_{i'}\to 0$ for $\varepsilon\to 0$) and

$$n_1 = \varepsilon\hat{n}_1(\xi,\varphi),$$

where the coefficients

$$\hat{n}_1(\xi,\varphi) = n_{1[1]}(\xi) + n_{1[2]}(\xi)\int d\varphi\ \eta_3(\xi,\varphi)/(\sqrt{|\eta_4(\xi,\varphi)|})^3, \quad \eta_4^{*}\neq 0 = n_{1[1]}(\xi) + n_{1[2]}$$
$$\times(\xi)\int d\varphi\ \eta_3(\xi,\varphi), \quad \eta_4^{*}=0 = n_{1[1]}(\xi) + n_{1[2]}(\xi)\int d\varphi/(\sqrt{|\eta_4(\xi,\varphi)|})^3, \quad \eta_3^{*}=0, \tag{51}$$

being stated to be real or complex valued for a corresponding model of real or complex gravity, with the functions $n_{k[1,2]}(\xi)$ to be stated by boundary conditions.

We conclude that the set of data $g_1=-1$, with nontrivial $g_2(\xi)$, h_3, h_4, $w_{i'}$, and n_1 stated, respectively, by (48)–(51) we can define a black ellipsoid solution with explicit dependence on

cosmological constant λ, i.e., a metric (41). The stability of such static black ellipsoids in (anti) de Sitter space can be proven exactly as it was done in Ref. 19 for the real case vanishing cosmological constant.

The analytic extension of black ellipsoid solutions with cosmological constant can be performed similarly as in the preceding section when for the real/complex solutions we are dealing with real/complex values of $\hat{n}_1(\xi,\varphi)$ defining some components of N-adapted frames. We note that the solution from string theory contains a frame induced torsion with the components (9) (in general, with complex coefficients) computed for nontrivial $N^3_{i'}=-\alpha_{i'}/\beta$ [see (50)] and $N^4_1=\varepsilon\hat{n}_1(\xi,\varphi)$ [see (51)]. This is an explicit example illustrating that the anholonomic frame method is also powerful for generating exact solutions in models of gravity with nontrivial torsion, induced by anholonomic frame transforms. For such solutions we may elaborate corresponding analytic extension and Penrose diagram formalisms if the constructions are considered with respect to N-elongated vielbeins.

Finally, we analyze the structure of noncommutative symmetries associated to the (anti) de Sitter black ellipsoid solutions. The metric (41) with real and/or complex coefficients defining the corresponding solutions and its analytic extensions also do not possess Killing symmetries being deformed by anholonomic transforms. For this solution, we can associate certain noncommutative symmetries following the same procedure as for the Einstein real/complex gravity but with additional nontrivial coefficients of anholonomy and even with nonvanishing coefficients of the nonlinear connection curvature, $\Omega^3_{12}=\delta_1N^3_2-\delta_2N^3_1$. Taking the data (50) and (51) and formulas (6), we compute the corresponding nontrivial anholonomy coefficients

$$w^{[N]4}_{31}=-w^{[N]4}_{13}=\partial n_1(\xi,\varphi)/\partial\varphi=n^*_2(\xi,\varphi),$$
$$w^{[N]4}_{12}=-w^{[N]4}_{21}=\delta_1(\alpha_2/\beta)-\delta_2(\alpha_1/\beta) \tag{52}$$

for $\delta_1=\partial/\partial\xi-w_1\partial/\partial\varphi$ and $\delta_2=\partial/\partial\theta-w_2\partial/\partial\varphi$, with n_1 defined by (32) and $\alpha_{1,2}$ and β computed by using the formula (46) for the solutions (49). Our exact solution, with nontrivial cosmological constant, is for 4D, like in the preceding section. So, for $n+m=4$, the condition $k^2-1=n+m$ cannot be satisfied by any integer numbers. We may similarly trivially extend the dimensions like $n'=6$ and $m'=m=2$ and for $k=3$ to consider the Lie group SL (3, IC) noncommutativity with corresponding values of $Q^{\gamma}_{\underline{\alpha}\underline{\beta}}$ and structure constants $f^{\gamma}_{\underline{\alpha}\underline{\beta}}$, see (11). An extension $w^{[N]\gamma}_{\alpha\beta}\to W^{\gamma}_{\underline{\alpha}\underline{\beta}}$ may be performed by stating the N-deformed "structure" constants (14), $W^{\gamma}_{\underline{\alpha}\underline{\beta}}=f^{\gamma}_{\underline{\alpha}\underline{\beta}}+w^{[N]\gamma}_{\underline{\alpha}\underline{\beta}}$, with nontrivial values of $w^{[N]\gamma}_{\underline{\alpha}\underline{\beta}}$ given by (52). In a similar form, we can consider anholonomic deformations of the SU_k structure constants, see (19).

V. NONCOMMUTATIVE COMPLEX WORMHOLES

The black ellipsoid solutions defined by real and certain complex metrics elaborated in the preceding section were for the 4D Einstein gravity, in general, with nontrivial cosmological constant. In this section we construct and analyze an exact 5D solution which can be also complexified by using complex anholonomic transforms as well they can be provided with associated noncommutative structure. For such configurations we can apply directly the formulas stated in Appendix B. The metric ansatz (1) is taken in the form

$$\delta s^2=g_1(\mathrm{d}x^1)^2+g_2(\mathrm{d}x^2)^2+g_3(\mathrm{d}x^3)^2+h_4(\delta y^4)^2+h_5(\delta y^5)^2,$$
$$\delta y^4=\mathrm{d}y^4+w_{k'}(x^{i'},v)\mathrm{d}x^{k'},\quad \delta y^5=\mathrm{d}y^5+n_{k'}(x^{i'},v)\mathrm{d}x^{k'},\quad i',k'=1,2,3, \tag{53}$$

where

$$g_1=1,\quad g_2=g_2(r),\quad g_3=-a(r),$$

$$h_4 = \hat{h}_4 = \hat{\eta}_4(r,\theta,\varphi)h_{4[0]}(r), \quad h_5 = \hat{h}_5 = \hat{\eta}_5(r,\theta,\varphi)h_{5[0]}(r,\theta) \tag{54}$$

for the parametrization of coordinate of type

$$x^1 = t, \quad x^2 = r, \quad x^3 = \theta, \quad y^4 = v = \varphi, \quad y^5 = p = \chi, \tag{55}$$

where t is the time coordinate, (r,θ,φ) are spherical coordinates, χ is the fifth coordinate; φ is the anholonomic coordinate; for this ansatz there is not considered the dependence of metric coefficients on the second anholonomic coordinate χ. Following similar approximations as in Sec. IV C for deriving the equations (40), we can write the gravity equations with cosmological constant as a system of 5D Einstein equations with constant diagonal source (the related details on computing the Ricci tensors with anholonomic variables and possible sources are given in Appendix B):

$$\frac{1}{2}R_1^1 = R_2^2 = R_3^3 = -\frac{1}{2g_2g_3}\left[\ddot{g_3} - \frac{\dot{g_2}\dot{g_3}}{2g_2} - \frac{(\dot{g_3})^2}{2g_3} + g_2'' - \frac{g_2'g_3'}{2g_3} - \frac{(g_2')^2}{2g_2}\right] = \lambda, \tag{56}$$

$$R_4^4 = R_5^5 = -\frac{\beta}{2h_4h_5} = \lambda, \tag{57}$$

$$R_{4i'} = -w_{i'}\frac{\beta}{2h_5} - \frac{\alpha_{i'}}{2h_5} = 0, \tag{58}$$

$$R_{5i'} = -\frac{h_5}{2h_4}[n_{i'}^{**} + \gamma n_{i'}^{*}] = 0, \tag{59}$$

where $i' = 1,2,3$. The coefficients of the equations are given by

$$\alpha_{i'} = \partial_i h_5^* - h_5^*\partial_{i'}\ln\sqrt{|h_4h_5|}, \quad \beta = h_5^{**} - h_5^*[\ln\sqrt{|h_4h_5|}]^*, \quad \gamma = \frac{3h_5^*}{2h_5} - \frac{h_4^*}{h_4}. \tag{60}$$

The various partial derivatives are denoted as $a^{\cdot} = \partial a/\partial x^2$, $a' = \partial a/\partial x^3$, $a^* = \partial a/\partial v$.

The system of equations (56)–(59) can be solved by choosing one of the ansatz functions [e.g., $h_4(x^{i'},v)$ or $h_5(x^{i'},v)$] to take some arbitrary, but physically interesting form. Then the other ansatz functions can be analytically determined up to an integration in terms of this choice. In this way one can generate many solutions, but the requirement that the initial, arbitrary choice of the ansatz functions be "physically interesting" means that one wants to make this original choice so that the final solution generated in this way yield a well-behaved solution. To satisfy this requirement we start from well-known solutions of Einstein's equations and then use the above procedure to deform this solution in a number of ways as to include it in a string theory, for instance, as a gravity model with cosmological constant.

The data

$$g_1 = 1, \quad \hat{g}_2 = -1, \quad g_3 = -a(r),$$

$$h_{4[0]}(r) = -r_0^2 e^{2\psi(r)}, \quad \eta_4 = 1/\kappa_r^2(r,\theta,\varphi), \quad h_{5[0]} = -a(r)\sin^2\theta, \quad \eta_5 = 1,$$

$$w_1 = \hat{w}_1 = w(r), \quad w_2 = \hat{w}_2 = 0, \quad w_3 = \hat{w}_3 = n\cos\theta/\kappa_n^2(r,\theta,\varphi),$$

$$n_1 = \hat{n}_1 = 0, \quad n_{2,3} = \hat{n}_{2,3} = n_{2,3[1]}(r,\theta) \int \ln|\kappa_r^2(r,\theta,\varphi)|\mathrm{d}\varphi \tag{61}$$

for some constants r_0 and n and arbitrary functions $a(r)$, $\psi(r)$ and arbitrary vacuum gravitational polarizations $\kappa_r(r,\theta,\varphi)$ and $\kappa_n(r,\theta,\varphi)$ define an exact vacuum 5D solution of Kaluza–Klein gravity[14] describing a locally anisotropic wormhole with elliptic gravitational vacuum polarization of charges,

$$\frac{q_0^2}{4a(0)\kappa_r^2} + \frac{Q_0^2}{4a(0)\kappa_n^2} = 1,$$

where $q_0 = 2\sqrt{a(0)}\sin\alpha_0$ and $Q_0 = 2\sqrt{a(0)}\cos\alpha_0$ are, respectively, the electric and magnetic charges and $2\sqrt{a(0)}\kappa_r$ and $2\sqrt{a(0)}\kappa_n$ are ellipse's axes.

The first aim in this section is to prove that following the ansatz (53) we can construct locally anisotropic wormhole metrics in (anti) de Sitter gravity, in general complexified by a certain class of anholonomic frame transforms as solutions of the system of Eqs. (56)–(59) with redefined coordinates as in (55). For simplicity, we select such solutions when only the coefficients n_i can be real or complex valued functions. Having the vacuum data (61), we may try to generalize the solution for a nontrivial cosmological constant by supposing that the new solutions may be represented as

$$h_4 = \hat{h}_4(x^{i'},v)q_4(x^{i'},v) \quad \text{and } h_5 = \hat{h}_5(x^{i'},v), \tag{62}$$

with $\hat{h}_{4,5}$ taken as in (54) which solves (57) if $q_4 = 1$ for $\lambda = 0$ and

$$q_4 = \frac{1}{4\lambda}\left[\int \frac{\hat{h}_5(r,\theta,\varphi)\hat{h}_4(r,\theta,\varphi)}{\hat{h}_5^*(r,\theta,\varphi)}\mathrm{d}\varphi\right]^{-1} \quad \text{for } \lambda \neq 0.$$

This q_4 can be considered as an additional polarization to η_4 induced by the cosmological constant λ. We state $g_2 = -1$ but

$$g_3 = -\sin^2(\sqrt{2\lambda}\theta + \xi_{[0]}),$$

defining a solution of (56) with signature $(+,-,-,-,-)$ being different from the solution (18). A nontrivial q_4 results in modification of coefficients (60),

$$\alpha_{i'} = \hat{\alpha}_{i'} + \alpha_{i'}^{[q]}, \quad \beta = \hat{\beta} + \beta^{[q]}, \quad \gamma = \hat{\gamma} + \gamma^{[q]},$$

$$\hat{\alpha}_{i'} = \partial_i \hat{h}_5^* - \hat{h}_5^* \partial_{i'} \ln\sqrt{|\hat{h}_4\hat{h}_5|}, \quad \hat{\beta} = \hat{h}_5^{**} - \hat{h}_5^*[\ln\sqrt{|\hat{h}_4\hat{h}_5|}]^*, \quad \hat{\gamma} = \frac{3\hat{h}_5^*}{2\hat{h}_5} - \frac{\hat{h}_4^*}{\hat{h}_4},$$

$$\alpha_{i'}^{[q]} = -h_5^* \partial_{i'} \ln\sqrt{|q_4|}, \quad \beta^{[q]} = -h_5^*[\ln\sqrt{|q_4|}]^*, \quad \gamma^{[q]} = -\frac{q_4^*}{q_4},$$

which follow formulas (58) and (59) result in additional terms to the *N*-connection coefficients, i.e.,

$$w_{i'} = \hat{w}_{i'} + w_{i'}^{[q]} \quad \text{and } n_{i'} = \hat{n}_{i'} + n_{i'}^{[q]}, \tag{63}$$

with $w_{i'}^{[q]}$ and $n_{i'}^{[q]}$ computed by using, respectively, $\alpha_{i'}^{[q]}$, $\beta^{[q]}$, and $\gamma^{[q]}$.

The simplest way to generate complex solutions is to consider that $\hat{n}_{i'}$ from the data (61) and (63) can be complex valued functions, for instance, with complex valued coefficients $n_{2,3[1]} \times (r,\theta)$ resulting from integration. In this case the metric (53) has real coefficients describing

wormhole solutions with polarized constants but such metric coefficients are defined with respect to anholonomic frames being N elongated by some real and complex functions.

Having nontrivial values of (63), we can associate certain noncommutative symmetries following the same procedure as for real/complex black ellipsoids. The wormhole cases are described by a more general set of nontrivial coefficients of anholonomy $w_{\underline{\alpha}\underline{\beta}}^{[N]\underline{\gamma}}$, computed by using formulas (6) and (15) (for simplicity, we omit such cumbersome expressions), and a nontrivial nonlinear connection curvature, in our case $\Omega_{i'k'}^{a}=\delta_{i'}N_{k'}^{a}-\delta_{k'}N_{i'}^{a}$ with $N_{k'}^{4}=w_{k'}$ and $N_{k'}^{5}=n_{k'}$. Such coefficients depend on variables (r,θ,φ), in general, being complex valued functions. We must extend trivially the dimensions. We must extend the dimensions like $n=5\to n'=6$ and $m'=m=2$ and for $k=3$ if we want to associate a Lie group SL (3, IC) like noncommutativity with the corresponding values of $Q_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$ and structure constants $f_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$, see (11). An extension $w_{\alpha\beta}^{[N]\gamma}\to W_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}$ may be similarly performed by introducing N-deformed "structure" constants (14), $W_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}=f_{\underline{\alpha}\underline{\beta}}^{\underline{\gamma}}+w_{\underline{\alpha}\underline{\beta}}^{[N]\underline{\gamma}}$, with nontrivial values of $w_{\underline{\alpha}\underline{\beta}}^{[N]\underline{\gamma}}$ defined by (63).

VI. NONCOMMUTATIVE SYMMETRIES AND GAUGE GRAVITY

We start with discussing the results of Refs. 6 and 7 concerning noncommutative gauge models of gravity.

The basic idea of Ref. 6 was to use a geometrical result[21,22] that the Einstein gravity can be equivalently represented as a gauge theory with a specific connection in the bundle of affine frames. Such gauge theories are with nonsemisimple structure gauge groups, i.e., with degenerated metrics in the total spaces. Using an auxiliary symmetric form for the typical fiber, any such model can be transformed into a variational one. There is an alternative way to construct geometrically a usual Yang–Mills theory by applying a corresponding set of absolute derivations and dualities defined by the Hodge operator. For both such approaches, there is a projection formalism reducing the geometric field equations on the base space to be exactly the Einstein equations from the general relativity theory.

For more general purposes, it was suggested to consider also extensions to a nonlinear realization with the (anti) de Sitter gauge structural group.[23] The constructions with nonlinear group realizations are very important because they prescribe a consistent approach of distinguishing the frame indices and coordinate indices subjected to different rules of transformation. This approach to gauge gravity (of course, after a corresponding generalizations of the Seiberg–Witten map) may include, in general, quadratic on curvature and torsion terms (as it is stated in Ref. 6) being correlated to the results on gravity on noncommutative D-branes.[53] At the first step, it was very important to suggest an idea how to include the general relativity into a gauge model being more explicitly developed in noncommutative form[1,2,45] (see recent developments in Refs. 54–60).

A. Nonlinear gauge models for the (anti) de Sitter group

There were elaborated some alternative approaches to the noncommutative gauge gravity models in Ref. 7 [by deforming the Einstein gravity based on gauging the commutative inhomogeneous Lorentz group ISO (3,1) using the Seiberg–Witten map] and 60 [by considering some simplest noncommutative deformations of the gauge theory U (2,2) and of the Lorentz algebra SO (1,3)]. Such theories reduce to the general relativity if certain constraints and brocking symmetries are imposed. Perhaps, only some experimental data would emphasize a priority of a theory of noncommutative gravity with a proper prescription how the vielbeins and connection from "commutative" gravity must be combined into components of a linear/nonlinear realizations of a noncommutative gauge potentials defined by corresponding Seiberg–Witten maps. At the present state of elaboration of noncommutative geometry and physics, we have to analyze the physical consequences of different classes of models of noncommutative gravity.

We introduce vielbein decompositions of (in general) complex metrics (4),

$$\hat{g}_{\alpha\beta}(u)=e_{\alpha}{}^{\alpha'}(u)e_{\beta}{}^{\beta'}(u)\,\eta_{\alpha'\beta'},$$

$$e_{\alpha}^{\ \alpha'}e^{\beta}_{\ \alpha'}=\delta_{\alpha}^{\beta} \quad \text{and } e_{\alpha}^{\ \alpha'}e^{\alpha}_{\ \beta'}=\delta_{\beta'}^{\alpha'},$$

where $\eta_{\alpha'\beta'}$ is a constant diagonal matrix [for real space–times we can consider it as the flat Minkowski metric, for instance, $\eta_{\alpha'\beta'}=\mathrm{diag}(-1,+1,\ldots,+1)$] and δ_{α}^{β} and $\delta_{\beta'}^{\alpha'}$ are Kronecker's delta symbols. The vielbiens with an associated N-connection structure $N_i^a(x^j,y^a)$, being real or complex valued functions, have a special paramtrization

$$e_{\alpha}^{\ \alpha'}(u)=\begin{bmatrix} e_i^{\ i'}(x^j) & N_i^c(x^j,y^a)e_c^{\ b'}(x^j,y^a) \\ 0 & e_e^{\ e'}(x^j,y^a) \end{bmatrix} \tag{64}$$

and

$$e^{\alpha}_{\ \alpha'}(u)=\begin{bmatrix} e^i_{\ i'}(x^j) & -N_i^c(x^j,y^a)e^i_{\ i'}(x^j) \\ 0 & e^c_{\ c'}(x^j,y^a) \end{bmatrix} \tag{65}$$

with $e_i^{\ i'}(x^j)$ and $e_c^{\ b'}(x^j,y^a)$ generating the coefficients of metric (1) with the coefficients defined with respect to anholonmic frames,

$$g_{ij}(x^j)=e_i^{\ i'}(x^j)e_j^{\ j'}(x^j)n_{i'j'} \quad \text{and } h_{ab}(x^j,y^c)=e_a^{\ a'}(x^j,y^c)e_b^{\ b'}(x^j,y^c)\eta_{a'b'}. \tag{66}$$

By using vielbeins and metrics of type (64) and (65) and, respectively, (66), we can model in a unified manner various types of (pseudo) Riemannian, Einstein–Cartan, Riemann–Finsler and vector/covector bundle nonlinear connection commutative and noncommutative geometries in effective gauge and string theories (it depends on the parameterization of $e_i^{\ i'}$, $e_c^{\ b'}$, and N_i^c on coordinates and anholonomy relations, see details in Refs. 24–28).

We consider the de Sitter space Σ^4 as a hypersurface defined by the equations $\eta_{AB}u^Au^B=-l^2$ in the four-dimensional flat space enabled with diagonal metric η_{AB}, $\eta_{AA}=\pm 1$ (in this section $A,B,C,\ldots=1,2,\ldots,5$), where $\{u^A\}$ are global Cartesian coordinates in $\mathbb{R}^5$; $l>0$ is the curvature of de Sitter space (for simplicity, we consider here only the de Sitter case; the anti-de Sitter configuration is to be stated by a hypersurface $\eta_{AB}u^Au^B=l^2$). The de Sitter group $S_{(\eta)}=\mathrm{SO}_{(\eta)}(5)$ is the isometry group of Σ^5-space with six generators of Lie algebra $\mathrm{so}_{(\eta)}(5)$ satisfying the commutation relations

$$[M_{AB},M_{CD}]=\eta_{AC}M_{BD}-\eta_{BC}M_{AD}-\eta_{AD}M_{BC}+\eta_{BD}M_{AC}. \tag{67}$$

We can decompose the capital indices $A,B,\ldots$ as $A=(\alpha',5)$, $B=(\beta',5),\ldots,$, and the metric η_{AB} as $\eta_{AB}=(\eta_{\alpha'\beta',\eta_{55}})$. The operators (67) M_{AB} can be decomposed as $M_{\alpha'\beta'}=\mathcal{F}_{\alpha'\beta'}$ and $P_{\alpha'}=l^{-1}M_{5\alpha'}$ written as

$$[\mathcal{F}_{\alpha'\beta'},\mathcal{F}_{\gamma'\delta'}]=\eta_{\alpha'\gamma'}\mathcal{F}_{\beta'\delta'}-\eta_{\beta'\gamma'}\mathcal{F}_{\alpha'\delta'}-\eta_{\beta'\delta'}\mathcal{F}_{\alpha'\gamma'}-\eta_{\alpha'\delta'}\mathcal{F}_{\beta'\gamma'},$$

$$[P_{\alpha'},P_{\beta'}]=-l^{-2}\mathcal{F}_{\alpha'\beta'}, \tag{68}$$

$$[P_{\alpha'},\mathcal{F}_{\beta'\gamma'}]=\eta_{\alpha'\beta'}P_{\underline{\gamma}}-\eta_{\alpha'\gamma'}P_{\beta'},$$

where the Lie algebra $\mathrm{so}_{(\eta)}(5)$ is split into a direct sum, $\mathrm{SO}_{(\eta)}(5)=\mathrm{SO}_{(\eta)}(4)\oplus V_4$ with V_4 being the vector space stretched on vectors $P_{\underline{\alpha}}$. We remark that $\Sigma^4=S_{(\eta)}/L_{(\eta)}$, where $L_{(\eta)}=\mathrm{SO}_{(\eta)}(4)$. For $\eta_{AB}=\mathrm{diag}(-1,+1,+1,+1)$ and $S_{10}=\mathrm{SO}(1,4)$, $L_6=\mathrm{SO}(1,3)$ is the group of Lorentz rotations.

The generators $I^{\underline{a}}$ and structure constants $f_{\underline{t}}^{\underline{sp}}$ of the de Sitter–Lie group can be parameterized in a form distinguishing the de Sitter generators and commutations (68). The action of the group $S_{(\eta)}$ may be realized by using 4×4 matrices with a parameterization distinguishing the subgroup $L_{(\eta)}$,

$$B = bB_L, \tag{69}$$

where

$$B_L = \begin{pmatrix} L & 0 \\ 0 & 1 \end{pmatrix},$$

$L \in L_{(\eta)}$ is the de Sitter bust matrix transforming the vector $(0,0,\ldots,\rho) \in \mathbb{R}^5$ into the arbitrary point $(V^1,V^2,\ldots,V^5) \in \Sigma^5_\rho \subset \mathcal{R}^5$ with curvature ρ ($V_A V^A = -\rho^2, V^A = \tau^A \rho$), and the matrix b is expressed

$$b = \begin{pmatrix} \delta^{\alpha'}{}_{\beta'} + \dfrac{\tau^{\alpha'}\tau_{\beta'}}{(1+\tau^5)} & \tau^{\alpha'} \\ \tau_{\beta'} & \tau^5 \end{pmatrix}.$$

The de Sitter gauge field is associated with a $\mathrm{so}_{(\eta)}(5)$-valued connection 1-form,

$$\widetilde{\Omega} = \begin{pmatrix} \omega^{\alpha'}{}_{\beta'} & \widetilde{\theta}^{\alpha'} \\ \widetilde{\theta}_{\beta'} & 0 \end{pmatrix}, \tag{70}$$

where $\omega^{\alpha'}{}_{\beta'} \in \mathrm{SO}(4)_{(\eta)}$, $\widetilde{\theta}^{\alpha'} \in \mathcal{R}^4$, $\widetilde{\theta}_{\beta'} \in \eta_{\beta'\alpha'}\widetilde{\theta}^{\alpha'}$.

The actions of $S_{(\eta)}$ mix the components of the matrix $\omega^{\alpha'}{}_{\beta'}$ and $\widetilde{\theta}^{\alpha'}$ fields in (70). Because the introduced parameterization is invariant on action on $\mathrm{SO}_{(\eta)}(4)$ group, we cannot identify $\omega^{\alpha'}{}_{\beta'}$ and $\widetilde{\theta}^{\alpha'}$, respectively, with the connection $\Gamma^{[c]}$ and the 1-form e^α defined by a N-connection structure like in (2) with the coefficients chosen as in (64) and (65). To avoid this difficulty we can consider nonlinear gauge realizations of the de Sitter group $S_{(\eta)}$ by introducing the nonlinear gauge field

$$\Gamma = b^{-1}\widetilde{\Omega}b + b^{-1}\,\mathrm{d}b = \begin{pmatrix} \Gamma^{\alpha'}{}_{\beta'} & \theta^{\alpha'} \\ \theta_{\beta'} & 0 \end{pmatrix}, \tag{71}$$

where

$$\Gamma^{\alpha'}{}_{\beta'} = \omega^{\alpha'}{}_{\beta'} - (\tau^{\alpha'} D\tau_{\beta'} - \tau_{\beta'} D\tau^{\alpha'})/(1+\tau^5),$$

$$\theta^{\alpha'} = \tau^5\widetilde{\theta}^{\alpha'} + D\tau^{\alpha'} - \tau^{\alpha'}(\mathrm{d}r^5 + \widetilde{\theta}_{\gamma'}\tau^{\gamma'})/(1+\tau^5),$$

$$D\tau^{\alpha'} = \mathrm{d}\tau^{\alpha'} + \omega^{\alpha'}{}_{\beta'}\tau^{\beta'}.$$

The action of the group $\mathrm{S}(\eta)$ is nonlinear, yielding the transformation rules

$$\Gamma' = L'\Gamma(L')^{-1} + L'd(L')^{-1}, \quad \theta' = L\theta,$$

where the nonlinear matrix-valued function

$$L' = L'(\tau^\alpha, b, B_T)$$

is defined from $B_b = b'B_{L'}$ [see the parametrization (69)]. The de Sitter "nonlinear" algebra is defined by generators (68) and nonlinear gauge transforms of type (71).

B. de Sitter nonlinear gauge gravity and general relativity

We generalize the constructions from Refs. 23 and 6 to the case when the de Sitter nonlinear gauge gravitational connection (71) is defined by the viebeins (64) and (65) and the linear connection (7) $\Gamma^{[c]\alpha}{}_{\beta\mu}=\{\Gamma^{\alpha}{}_{\beta\mu}\}$,

$$\Gamma=\begin{pmatrix}\Gamma^{\alpha'}{}_{\beta'} & l_0^{-1}e^{\alpha'}\\ l_0^{-1}e_{\beta'} & 0\end{pmatrix}, \tag{72}$$

where

$$\Gamma^{\alpha'}{}_{\beta'}=\Gamma^{\alpha'}{}_{\beta'\mu}\delta u^{\mu}, \tag{73}$$

for

$$\Gamma^{\alpha'}{}_{\beta'\mu}=e_{\alpha}{}^{\alpha'}e^{\beta}{}_{\beta'}\Gamma^{\alpha}{}_{\beta\mu}+e_{\alpha}{}^{\alpha'}\delta_{\mu}e^{\alpha}{}_{\beta'},$$

$$e^{\alpha'}=e_{\mu}{}^{\alpha'}\delta u^{\mu}, \tag{74}$$

and l_0 being a dimensional constant.

The matrix components of the curvature of the connection (72),

$$\mathcal{R}^{(\Gamma)}=\mathrm{d}\Gamma+\Gamma\wedge\Gamma,$$

can be written

$$\mathcal{R}^{(\Gamma)}=\begin{pmatrix}\mathcal{R}^{\alpha'}{}_{\beta'}+l_0^{-1}\pi^{\alpha'}_{\beta'} & l_0^{-1}T^{\alpha'}\\ l_0^{-1}T^{\beta'} & 0\end{pmatrix}, \tag{75}$$

where

$$\pi^{\alpha'}_{\beta'}=e^{\alpha'}\wedge e_{\beta'},\quad \mathcal{R}^{\alpha'}{}_{\beta'}=\tfrac{1}{2}\mathcal{R}^{\alpha'}{}_{\beta'\mu\nu}\,\delta u^{\mu}\wedge\delta u^{\nu},$$

and

$$\mathcal{R}^{\alpha'}{}_{\beta'\mu\nu}=e^{\beta}{}_{\beta'}e_{\alpha}{}^{\alpha'}R^{\alpha}{}_{\beta\mu\nu}$$

with the coefficients $R^{\alpha}{}_{\beta\mu\nu}$ defined with $h-v$-invariant components, see (A2) in Appendix A.

The de Sitter gauge group is semisimple, we are able to construct a variational gauge gravitational theory with the Lagrangian

$$L=L_{(g)}+L_{(m)}, \tag{76}$$

where the gauge gravitational Lagrangian is defined

$$L_{(g)}=\frac{1}{4\pi}\mathrm{Tr}(\mathcal{R}^{(\Gamma)}\wedge *_G\mathcal{R}^{(\Gamma)})=\mathcal{L}_{(G)}|g|^{1/2}\delta^4u,$$

for

$$\mathcal{L}_{(g)}=\frac{1}{2l^2}T^{\alpha'}{}_{\mu\nu}T_{\alpha'}{}^{\mu\nu}+\frac{1}{8\lambda}\mathcal{R}^{\alpha'}{}_{\beta'\mu\nu}\mathcal{R}^{\beta'}{}_{\alpha'}{}^{\mu\nu}-\frac{1}{l^2}(\overleftarrow{R}(\mathrm{T})-2\lambda_1),$$

with δ^4u being the volume element, $|g|$ is the determinant computed the metric coefficients (1) stated with respect to N-elongated frames, the curvature scalar $\overleftarrow{R}(\Gamma)$ is computed as in (A4), $T^{\alpha'}{}_{\mu\nu}=e^{\alpha'}{}_{\alpha}T^{\alpha}{}_{\mu\nu}$ (the gravitational constant l^2 satisfies the relations $l^2=2l_0^2\lambda$, $\lambda_1=-3/l_0$), Tr denotes

the trace on α', β' indices. The matter field Lagrangian from (76) is defined

$$L_{(m)} = -\tfrac{1}{2}\mathrm{Tr}(\Gamma \wedge *_g \mathcal{I}) = \mathcal{L}_{(m)}|g|^{1/2}\,\delta^n u,$$

with the Hodge operator derived by $|g|$ and $|h|$, where

$$\mathcal{L}_{(m)} = \tfrac{1}{2}\Gamma^{\alpha'}{}_{\beta'\mu}S^{\beta'}{}_{\alpha'}{}^{\mu} - t^{\mu}{}_{\alpha'}l^{\alpha'}{}_{\mu}.$$

The matter field source $\mathcal{J}$ is obtained as a variational derivation of $\mathcal{L}_{(m)}$ on Γ and is parameterized in the form

$$\mathcal{J} = \begin{pmatrix} S^{\alpha'}{}_{\beta} & -l_0\tau^{\alpha'} \\ -l_0\tau_{\beta'} & 0 \end{pmatrix}$$

with $\tau^{\alpha'} = \tau^{\alpha'}{}_{\mu}\delta u^{\mu}$ and $S^{\alpha'}{}_{\beta'} = S^{\alpha'}{}_{\beta'\mu}\delta u^{\mu}$ being, respectively, the canonical tensors of energy momentum and spin density.

Varying the action

$$S = \int \delta^4 u(\mathcal{L}_{(g)} + \mathcal{L}_{(m)})$$

on the Γ-variables (72), we obtain the gauge-gravitational field equations,

$$d(*\mathcal{R}^{(\Gamma)}) + \Gamma \wedge (*\mathcal{R}^{(\Gamma)}) - (*\mathcal{R}^{(\Gamma)}) \wedge \Gamma = -\lambda(*\mathcal{J}), \tag{77}$$

where the Hodge operator $*$ is used. This equations can be alternatively derived in geometric form by applying the absolute derivation and dual operators.

Distinguishing the variations on Γ and e-variables, we rewrite (77),

$$\hat{\mathcal{D}}(*\mathcal{R}^{(\Gamma)}) + \frac{2\lambda}{l^2}(\hat{\mathcal{D}}(*\pi) + e \wedge (*T^T) - (*T) \wedge e^T) = -\lambda(*S),$$

$$\hat{\mathcal{D}}(*T) - (*\mathcal{R}^{(\Gamma)}) \wedge e - \frac{2\lambda}{l^2}(*\pi) \wedge e = \frac{l^2}{2}\left(*t + \frac{1}{\lambda} * \mathfrak{s}\right),$$

e^T being the transposition of e, where

$$T^t = \left\{T_{\alpha'} = \eta_{\alpha'\beta'}T^{\beta'}, T^{\beta'} = \tfrac{1}{2}T^{\beta'}{}_{\mu\nu}\delta u^{\mu} \wedge \delta u^{\nu}\right\},$$

$$e^T = \{e_{\alpha'} = \eta_{\alpha'\beta'}e^{\beta'}, e^{\beta'} = e^{\beta'}{}_{\mu}\delta u^{\mu}\}, \quad \hat{\mathcal{D}} = \delta + \hat{\Gamma}$$

($\hat{\Gamma}$ acts as $\Gamma^{\alpha'}{}_{\beta'\mu}$ on indices $\gamma', \delta', \ldots$ and as $\Gamma^{\alpha}{}_{\beta\mu}$ on indices $\gamma, \delta, \ldots$). The value $\mathfrak{s}$ defines the energy-momentum tensor of the gauge gravitational field $\hat{\Gamma}$,

$$\mathfrak{s}_{\mu\nu}(\hat{\Gamma}) = \tfrac{1}{2}\mathrm{Tr}\left(\mathcal{R}_{\mu\alpha}\mathcal{R}^{\alpha}{}_{\nu} - \tfrac{1}{4}\mathcal{R}_{\alpha\beta}\mathcal{R}^{\alpha\beta}G_{\mu\nu}\right).$$

Equations (77) make up the complete system of variational field equations for nonlinear de Sitter gauge gravity. We note that we can obtain a nonvariational Poincaré gauge gravitational theory if we consider the contraction of the gauge potential (72) to a potential $\Gamma^{[P]}$ with values in the Poincaré–Lie algebra

$$\Gamma = \begin{pmatrix} \Gamma^{\alpha'}{}_{\beta'} & l_0^{-1} e^{\alpha'} \\ l_0^{-1} e_{\beta'} & 0 \end{pmatrix} \to \Gamma^{[P]} = \begin{pmatrix} \Gamma^{\alpha'}{}_{\beta'} & l_0^{-1} e^{\alpha'} \\ 0 & 0 \end{pmatrix}. \tag{78}$$

A similar gauge potential was considered in the formalism of linear and affine frame bundles on curved space–times by Popov and Dikhin.[21,22] They considered the gauge potential (78) to be just the Cartan connection form in the affine gaugelike gravity and proved that the Yang–Mills equations of their theory are equivalent, after projection on the base, to the Einstein equations.

Let us give an example how an exact vacuum solution of the Einstein equations, with associated noncommutative symmetry, can be included as to define an exact solution in gauge gravity. Using the data (33) defining a 4D black ellipsoid solution, we write the nontrivial vielbein coefficients (64) as

$$e_2{}^{2'} = 1, \quad e_3{}^{3'} = \sqrt{|g_3|}, \quad e_4{}^{4'} = \sqrt{|h_4|}, \quad e_5{}^{5'} = \sqrt{|h_5|}, \quad N_2^5 = n_2 \tag{79}$$

for the diagonal Minkowski metric $\eta_{\alpha'\beta'} = (-1,-1,-1,1)$ with the tetrad and coordinate indices running, respectively, the values $\alpha', \beta', \ldots = 2,3,4,5$ and $\alpha, \beta, \ldots = 2,3,4,5$. The connection coefficients $\Gamma^{\alpha'}{}_{\beta'\mu}$, see formula (74), are computed by using the values $e_\alpha{}^{\alpha'}$ and (7) and used for definition of the potential $\Gamma^{[P]}$ (78) which defines a gauge gravity model with the Yang–Mills equations (77) being completely equivalent to the Einstein equations even the frames are anholonomic (see details in Refs. 21, 22, and 24–28). *N* coefficients, for instance, a complex $N_2^5 = n_2$ we can construct both complex Einstein and gauge gravity vacuum configurations which are stable and define anholonomically deformed black hole solutions with associated noncommutative symmetries.

Finally, we emphasize that in a similar manner, by extending the dimensions of spaces and gauge groups and introducing the cosmological constant, we can include the solutions for the (anti) de Sitter black ellipsoids and wormholes, with real or complex anholonomic structures (constructed, respectively, in Secs. IV C and V), into a gauge gravity theory [Einstein and Poincaré types, or as a degenerated configuration in the nonlinear (anti) de Sitter gravity].

VII. NONCOMMUTATIVE GAUGE DEFORMATIONS OF GRAVITY

The noncommutative gravity theories are confronted with the problem of definition of noncommutative variants of pseudo-Eucliedean and pseudo-Riemannian metrics. This is connected with another problem when the generation of noncommutative metric structures via the Moyal product and the Seiberg–Witten map[45] results in complex and noncommutative metrics for, in general, nonstable and/or unphysical gravitational vacua. In order to avoid the mentioned difficulties, we elaborated a model of noncommutative gauge gravity starting from a variant of gauge gravity being equivalent to the Einstein gravity and emphasizing in such approach the vielbein (frame) and connection structures, but not the metric configuration (see Refs. 6 and 61). The metric for such theories is induced by an anholonomic (in general) frame transform.

For explicit constructions, we follow the method of restricted enveloping algebras[62] and construct gauge gravitational theories by stating corresponding structures with semisimple or nonsemisimple Lie algebras and their extensions. We use power series of generators for the affine and nonlinearly realized de Sitter gauge groups and compute the coefficient functions of all the higher powers of the generators of the gauge group which are functions of the coefficients of the first power. Such constructions are based on the Seiberg–Witten map and on the formalism of $*$-product formulation of the algebra[45,63–69] when for functional objects, being functions of commuting variables, there are associated some algebraic noncommutative properties encoded in the $*$-product. Here we note that an approach to the gauge theory on noncommutative spaces was introduced geometrically[70] by defining the covariant coordinates without speaking about derivatives. This formalism was also developed for quantum planes.[71,72]

In this section, we shall prove the existence for noncommutative spaces of gauge models of gravity which agrees with usual gauge gravity theories being equivalent, or extending, the general

relativity theory in the limit of commuting spaces. We shall show how it is possible to adapt mutually the Seiberg–Witten map and anholonomic frame transforms in order to generate solutions of the gauge gravity preserving noncommutative symmetries even in the classical limit of commutative Einstein gravity.

A. Enveloping algebras for gauge gravity connections

We define the gauge fields on a noncommutative space as elements of an algebra $\mathcal{A}_u$ that form a representation of the generator I algebra for the de Sitter gauge group and the noncommutative space is modeled as the associative algebra of IC. This algebra is freely generated by the coordinates modulo ideal $\mathcal{R}$ generated by the relations (one accepts formal power series) $\mathcal{A}_u = \mathrm{IC}[[\hat{u}^1, \ldots, \hat{u}^N]]/\mathcal{R}$. A variational gauge gravitational theory can be formulated by using a minimal extension of the affine structural group $\mathcal{A}f_{3+1}(\mathbb{R})$ to the de Sitter gauge group $S_{10} = \mathrm{SO}(4+1)$ acting on $\mathbb{R}^{4+1}$ space. (See Refs. 73–78.)

Let now us consider a noncommutative space (see Appendix D for a brief outline of necessary concepts). The gauge fields are elements of the algebra $\hat{\psi} \in \mathcal{A}_I^{(\mathrm{dS})}$ that form the nonlinear representation of the de Sitter algebra $\mathrm{so}_{(\eta)}$ (5) (the whole algebra is denoted $\mathcal{A}_z^{(\mathrm{dS})}$). The elements transform

$$\delta\hat{\psi} = i\hat{\gamma}\hat{\psi}, \quad \hat{\psi} \in \mathcal{A}_u, \quad \hat{\gamma} \in \mathcal{A}_z^{(dS)'},$$

under a nonlinear de Sitter transformation. The action of the generators (68) on $\hat{\psi}$ is defined as the resulting element will form a nonlinear representation of $\mathcal{A}_I^{(\mathrm{dS})}$ and, in consequence, $\delta\hat{\psi} \in \mathcal{A}_u$ despite $\hat{\gamma} \in \mathcal{A}_z^{(\mathrm{dS})}$. We emphasize that for any representation the object $\hat{\gamma}$ takes values in enveloping de Sitter algebra but not in a Lie algebra as would be for commuting spaces.

We introduce a connection $\hat{\Gamma}^\nu \in \mathcal{A}_z^{(\mathrm{dS})}$ in order to define covariant coordinates,

$$\hat{U}^\nu = \hat{u}^\nu + \hat{\Gamma}^\nu.$$

The values $\hat{U}^\nu\hat{\psi}$ transform covariantly, i.e., $\delta\hat{U}^\nu\hat{\psi} = i\hat{\gamma}\hat{U}^\nu\hat{\psi}$, if and only if the connection $\hat{\Gamma}^\nu$ satisfies the transformation law of the enveloping nonlinear realized de Sitter algebra,

$$\delta\hat{\Gamma}^\nu\hat{\psi} = -i[\hat{u}^\nu, \hat{\gamma}] + i[\hat{\gamma}, \hat{\Gamma}^\nu],$$

where $\delta\hat{\Gamma}^\nu \in \mathcal{A}_z^{(\mathrm{dS})}$.

The enveloping algebra-valued connection has infinitely many component fields. Nevertheless, all component fields can be induced from a Lie algebra-valued connection by a Seiberg–Witten map[45,62] and, for $\mathrm{SO}(n)$ and $\mathrm{Sp}(n)$, see Ref. 79. Here, we show that similar constructions can be performed for nonlinear realizations of de Sitter algebra when the transformation of the connection is considered

$$\delta\hat{\Gamma}^\nu = -i[u^\nu, * \hat{\gamma}] + i[\hat{\gamma}, * \hat{\Gamma}^\nu].$$

We treat in more detail the canonical case with the star product (D4). The first term in the variation $\delta\hat{\Gamma}^\nu$ gives

$$-i[u^\nu, * \hat{\gamma}] = \theta^{\nu\mu}\frac{\partial}{\partial u^\mu}\gamma.$$

Assuming that the variation of $\hat{\Gamma}^\nu = \theta^{\nu\mu}Q_\mu$ starts with a linear term in θ, we have

$$\delta\hat{\Gamma}^\nu = \theta^{\nu\mu}\delta Q_\mu, \quad \delta Q_\mu = \frac{\partial}{\partial u^\mu}\gamma + i[\hat{\gamma}, * Q_\mu].$$

We expand the star product (D4) in θ but not in g_a and find up to first order in θ that

$$\gamma = \gamma^1_{\underline{a}} I^{\underline{a}} + \gamma^1_{\underline{ab}} I^{\underline{a}} I^{\underline{b}} + \cdots, \quad Q_\mu = q^1_{\mu,\underline{a}} I^{\underline{a}} + q^2_{\mu,\underline{ab}} I^{\underline{a}} I^{\underline{b}} + \cdots, \tag{80}$$

where $\gamma^1_{\underline{a}}$ and $q^1_{\mu,\underline{a}}$ are of order zero in θ and $\gamma^1_{\underline{ab}}$ and $q^2_{\mu,\underline{ab}}$ are of second order in θ. The expansion in $I^{\underline{b}}$ leads to an expansion in g_a of the $*$-product because the higher order $I^{\underline{b}}$ derivatives vanish. For the de Sitter case, we take the generators $I^{\underline{b}}$ (68), see commutators (D3), with the corresponding de Sitter structure constants $f^{\underline{bc}}_{\underline{d}} \simeq f^{\underline{\alpha\beta}}_{\underline{\beta}}$ (in our further identifications with space–time objects like frames and connections we shall use greek indices). The result of calculation of variations of (80), by using g_a to the order given in (D2), is

$$\delta q^1_{\mu,\underline{a}} = \frac{\partial \gamma^1_{\underline{a}}}{\partial u^\mu} - f^{\underline{bc}}_{\underline{a}} \gamma^1_{\underline{b}} q^1_{\mu,\underline{c}}, \quad \delta Q_\tau = \theta^{\mu\nu} \partial_\mu \gamma^1_{\underline{a}} \partial_\nu q^1_{\tau,\underline{b}} I^{\underline{a}} I^{\underline{b}} + \cdots,$$

$$\delta q^2_{\mu,\underline{ab}} = \partial_\mu \gamma^2_{\underline{ab}} - \theta^{\nu\tau} \partial_\nu \gamma^1_{\underline{a}} \partial_\tau q^1_{\mu,\underline{b}} - 2 f^{\underline{bc}}_{\underline{a}} \{ \gamma^1_{\underline{b}} q^2_{\mu,\underline{cd}} + \gamma^2_{\underline{bd}} q^1_{\mu,\underline{c}} \}.$$

Let us introduce the objects ε, taking the values in de Sitter Lie algebra and W_μ, taking values in the enveloping de Sitter algebra, i.e.,

$$\varepsilon = \gamma^1_{\underline{a}} I^{\underline{a}} \quad \text{and } W_\mu = q^2_{\mu,\underline{ab}} I^{\underline{a}} I^{\underline{b}},$$

with the variation δW_μ satisfying the equation

$$\delta W_\mu = \partial_\mu (\gamma^2_{\underline{ab}} I^{\underline{a}} I^{\underline{b}}) - \tfrac{1}{2} \theta^{\tau\lambda} \{ \partial_\tau \varepsilon, \partial_\lambda q_\mu \} + i[\varepsilon, W_\mu] + i[(\gamma^2_{\underline{ab}} I^{\underline{a}} I^{\underline{b}}), q_\nu].$$

This equation can be solved[70,45] in the form

$$\gamma^2_{\underline{ab}} = \tfrac{1}{2} \theta^{\nu\mu} (\partial_\nu \gamma^1_{\underline{a}}) q^1_{\mu,\underline{b}}, \quad q^2_{\mu,\underline{ab}} = -\tfrac{1}{2} \theta^{\nu\tau} q^1_{\nu,\underline{a}} (\partial_\tau q^1_{\mu,\underline{b}} + R^1_{\tau\mu,\underline{b}}).$$

The values

$$R^1_{\tau\mu,\underline{b}} = \partial_\tau q^1_{\mu,\underline{b}} - \partial_\mu q^1_{\tau,\underline{b}} + f^{\underline{ec}}_{\underline{d}} q^1_{\tau,\underline{e}} q^1_{\mu,\underline{e}}$$

could be identified with the coefficients $\mathcal{R}^{\underline{\alpha}}{}_{\underline{\beta}\mu\nu}$ of de Sitter nonlinear gauge gravity curvature [see formula (75)] if in the commutative limit

$$q^1_{\mu,\underline{b}} \simeq \begin{pmatrix} \Gamma^{\underline{\alpha}}{}_{\underline{\beta}} & l_0^{-1} \chi^{\underline{\alpha}} \\ l_0^{-1} \chi_{\underline{\beta}} & 0 \end{pmatrix}$$

[see (72)].

We note that the below presented procedure can be generalized to all the higher powers of θ. As an example, we compute the first order corrections to the gravitational curvature.

B. Noncommutative covariant gauge gravity dynamics

The constructions from the preceding section can be summarized by a conclusion that the de Sitter algebra valued object $\varepsilon = \gamma^1_{\underline{a}}(u)\, I^{\underline{a}}$ determines all the terms in the enveloping algebra

$$\gamma = \gamma^1_{\underline{a}} I^{\underline{a}} + \frac{1}{4} \theta^{\nu\mu} \partial_\nu \gamma^1_{\underline{a}} q^1_{\mu,\underline{b}} (I^{\underline{a}} I^{\underline{b}} + I^{\underline{b}} I^{\underline{a}}) + \cdots.$$

and the gauge transformations are defined by $\gamma^1_{\underline{a}}(u)$ and $q^1_{\mu,\underline{b}}(u)$, when

$$\delta_{\gamma^1} \psi = i \gamma(\gamma^1, q^1_\mu) * \psi.$$

Applying the formula (D4) we calculate

$$[\gamma, * \zeta] = i\gamma^1_{\underline{a}}\zeta^1_{\underline{b}}f^{\underline{ab}}_{\underline{c}}I^{\underline{c}} + \frac{i}{2}\theta^{\nu\mu}\{\partial_v(\gamma^1_{\underline{a}}\zeta^1_{\underline{b}}f^{\underline{ab}}_{\underline{c}})q_{\mu,\underline{c}} + (\gamma^1_{\underline{a}}\partial_v\zeta^1_{\underline{b}} - \zeta^1_{\underline{a}}\partial_v\gamma^1_{\underline{b}})q_{\mu,\underline{b}}f^{\underline{ab}}_{\underline{c}} + 2\partial_v\gamma^1_{\underline{a}}\partial_\mu\zeta^1_{\underline{b}}\}I^{\underline{d}}I^{\underline{c}},$$

where we used the properties that, for the de Sitter enveloping algebras, one holds the general formula for compositions of two transformations,

$$\delta_\gamma\delta_\varsigma - \delta_\varsigma\delta_\gamma = \delta_{i(\varsigma*\gamma-\gamma*\varsigma)}.$$

This is also true for the restricted transformations defined by γ^1,

$$\delta_{\gamma^1}\delta_{\varsigma^1} - \delta_{\varsigma^1}\delta_{\gamma^1} = \delta_{i(\varsigma^1*\gamma^1-\gamma^1*\varsigma^1)}.$$

Such commutators could be used for definition of tensors

$$\hat{S}^{\mu\nu} = [\hat{U}^\mu, \hat{U}^\nu] - i\hat{\theta}^{\mu\nu}, \tag{81}$$

where $\hat{\theta}^{\mu\nu}$ is, respectively, stated for the canonical, Lie and quantum plane structures. Under the general enveloping algebra one holds the transform

$$\delta\hat{S}^{\mu\nu} = i[\hat{\gamma}, \hat{S}^{\mu\nu}].$$

For instance, the canonical case is characterized by

$$S^{\mu\nu} = i\theta^{\mu\tau}\partial_\tau\Gamma^\nu - i\theta^{\nu\tau}\partial_\tau\Gamma^\mu + \Gamma^\mu * \Gamma^\nu - \Gamma^\nu * \Gamma^\mu = \theta^{\mu\tau}\theta^{\nu\lambda}\{\partial_\tau Q_\lambda - \partial_\lambda Q_\tau + Q_\tau * Q_\lambda - Q_\lambda * Q_\tau\}.$$

We introduce the gravitational gauge strength (curvature)

$$R_{\tau\lambda} = \partial_\tau Q_\lambda - \partial_\lambda Q_\tau + Q_\tau * Q_\lambda - Q_\lambda * Q_\tau, \tag{82}$$

which could be treated as a noncommutative extension of de Sitter nonlinear gauge gravitational curvature (75), and calculate

$$R_{\tau\lambda,\underline{a}} = R^1_{\tau\lambda,\underline{a}} + \theta^{\mu\nu}\Big\{R^1_{\tau\mu,\underline{a}}R^1_{\lambda\nu,\underline{b}} - \tfrac{1}{2}q^1_{\mu,\underline{a}}[(D_\nu R^1_{\tau\lambda,\underline{b}}) + \partial_\nu R^1_{\tau\lambda,\underline{b}}]\Big\}I^{\underline{b}},$$

where the gauge gravitation covariant derivative is introduced,

$$(D_\nu R^1_{\tau\lambda,\underline{b}}) = \partial_\nu R^1_{\tau\lambda,\underline{b}} + q_{\nu,\underline{c}}R^1_{\tau\lambda,\underline{d}}f^{\underline{cd}}_{\underline{b}}.$$

Following the gauge transformation laws for γ and q^1 we find

$$\delta_{\gamma^1}R^1_{\tau\lambda} = i[\gamma, {}^*R^1_{\tau\lambda}]$$

with the restricted form of γ. Such formulas were proved in Ref. 45 for usual gauge (nongravitational) fields. Here we reconsidered them for the gravitational gauge fields.

One can formulate gauge covariant gravitational dynamics of noncommutative spaces following the nonlinear realization of de Sitter algebra and the $*$-formalism and introducing derivatives in such a way that one does not obtain new relations for the coordinates. In this case, a Leibniz rule can be defined that

$$\hat{\partial}_\mu\hat{u}^\nu = \delta^\nu_\mu + d^{\nu\tau}_{\mu\sigma}\hat{u}^\sigma\hat{\partial}_\tau,$$

where the coefficients $d^{\nu\tau}_{\mu\sigma} = \delta^\nu_\sigma\delta^\tau_\mu$ are chosen to not have new relations when $\hat{\partial}_\mu$ acts again to the right-hand side. One holds the $*$-derivative formulas

$$\partial_\tau * f = \frac{\partial}{\partial u^\tau}f + f * \partial_\tau, \quad [\partial_l, {}^*(f * g)] = ([\partial_l, {}^*f]) * g + f * ([\partial_l, {}^*g])$$

and the Stokes theorem

$$\int [\partial_l, f] = \int d^N u [\partial_l, {}^* f] = \int d^N u \frac{\partial}{\partial u^l} f = 0,$$

where, for the canonical structure, the integral is defined,

$$\int \hat{f} = \int d^N u f(u^1, \ldots, u^N).$$

An action can be introduced by using such integrals. For instance, for a tensor of type (81), when

$$\delta \hat{L} = i[\hat{\gamma}, \hat{L}],$$

we can define a gauge invariant action

$$W = \int d^N u \, \mathrm{Tr}\, \hat{L}, \quad \delta W = 0,$$

where the trace must be taken for the group generators.

For the nonlinear de Sitter gauge gravity a proper action is

$$L = \tfrac{1}{4} R_{\tau\lambda} R^{\tau\lambda},$$

where $R_{\tau\lambda}$ is defined by (82) [in the commutative limit we shall obtain the connection (72)]. In this case the dynamic of noncommutative space is entirely formulated in the framework of quantum field theory of gauge fields. In general, we are dealing with anisotropic gauge gravitational interactions. The method works for matter fields as well to restrictions to the general relativity theory.

C. Noncommutative symmetries and star product deformations

The aim of this section is to prove that there are possible extensions of exact solutions from the Einstein and gauge gravity possessing hidden noncommutative symmetries without introducing new fields. For simplicity, we present the formulas including decompositions up to the second order on noncommutative parameter $\theta^{\alpha\beta}$ for vielbeins, connections, and curvatures which can be arranged to result in different models of noncommutative gravity. We give the data for the SU $(1, n+m-1)$ and SO $(1, n+m-1)$ gauge models containing, in general, complex N-elongated frames, modeling some exact solutions, for instance, those derived in Secs. IV and V. All data can be considered for extensions with nonlinear realizations into a bundle of affine or de Sitter frames (in this case, one generates noncommutative gauge theories of the type considered in Ref. 6 or to impose certain constraints and breaking of symmetries (in order to construct other models[7,60]).

In the preceding sections we considered noncommutative geometric structures introduced by frame anholonomic relations (5), or (15). The standard approaches to noncommutative geometry also contain certain noncommutative relations for coordinates,

$$[u^\alpha, u^\beta] = u^\alpha u^\beta - u^\beta u^\alpha = i\theta^{\alpha\beta}(u^\gamma), \tag{83}$$

where, in the simplest models, the commutator $[u^\alpha, u^\beta]$ is approximated to be constant, but there were elaborated approaches for general manifolds with the noncommutative parameter $\theta^{\alpha\beta}$ treated as functions on u^γ in Ref. 68. We define the star (Moyal) product to include possible N-elongated partial derivatives (3) and a quantum constant $\hbar$,

$$f * \varphi = f\varphi + \frac{\hbar}{2} B^{\underline{\alpha}\underline{\beta}}(\delta_{\underline{\alpha}} f \delta_{\underline{\beta}}\varphi + \delta_{\underline{\beta}} f \delta_{\underline{\alpha}}\varphi) + \hbar^2 B^{\underline{\alpha}\underline{\beta}} B^{\underline{\gamma}\underline{\mu}}[\delta_{(\underline{\alpha}}\delta_{\underline{\gamma})} f][\delta_{(\underline{\beta}}\delta_{\underline{\mu})}\varphi]$$

$$+ \frac{2}{3}\hbar^2 B^{\underline{\alpha}\underline{\beta}} \delta_{\underline{\beta}} B^{\underline{\gamma}\underline{\mu}}\{[\delta_{(\underline{\alpha}}\delta_{\underline{\gamma})} f]\delta_{\underline{\mu}}\varphi + [\delta_{(\underline{\alpha}}\delta_{\underline{\gamma})}\varphi]\delta_{\underline{\mu}} f\} + O(\hbar^3), \tag{84}$$

where, for instance, $\delta_{(\mu}\delta_{\nu)} = (1/2)(\delta_\mu\delta_\nu + \delta_\nu\delta_\mu)$,

$$B^{\underline{\alpha}\underline{\beta}} = \frac{\theta^{\alpha\beta}}{2}(\delta_\alpha u^{\underline{\alpha}} \delta_\beta u^{\underline{\beta}} + \delta_\beta u^{\underline{\alpha}} \delta_\alpha u^{\underline{\beta}}) + O(\hbar^3) \tag{85}$$

is defined for new coordinates $u^{\underline{\alpha}} = u^{\underline{\alpha}}(u^\alpha)$ inducing a suitable Poisson bi-vector field $B^{\underline{\alpha}\underline{\beta}}(\hbar)$ being related to a quantum diagram formalism [we shall not consider details concerning geometric quantization in this paper by investigating only classical deformations related to any anholonomic frame and coordinate (83) noncommutativity origin]. The formulas (84) and (85) transform into the usual ones with partial derivatives ∂_α and $\partial_{\underline{\alpha}}$ from Refs. 68 and 7 considered for vanishing anholonomy coefficients. We can define a star product being invariant under diffeomorphism transforms, $* \to *^{[-]}$, adapted to the *N*-connection structure (in a vector bundle provided with *N*-connection configuration, we use the label $[-]$ in order to emphasize the dependence on coordinates $u^{\underline{\alpha}}$ with "overlined" indices), by introducing the transforms

$$f^{[-]}(\hbar) = \Theta f(\hbar),$$

$$f^{[-]} *^{[-]} \varphi^{[-]} = \Theta(\Theta^{-1} f^{[-]} * \Theta^{-1})\varphi^{[-]}$$

for $\Theta = 1 + \Sigma_{[k=1]}\hbar^k \Theta_{[k]}$, for simplicity, computed up to the squared order on $\hbar$,

$$\Theta = 1 - 2\hbar^2 \theta^{\mu\nu}\theta^{\rho\sigma}\{[\delta_{(\mu}\delta_{\nu)} u^{\underline{\alpha}}][\delta_{(\rho}\delta_{\sigma)} u^{\underline{\beta}}]\delta_{(\underline{\alpha}}\delta_{\underline{\beta})} + [\delta_{(\mu}\delta_{\rho)} u^{\underline{\alpha}}](\delta_\nu u^{\underline{\beta}})(\delta_\sigma u^{\underline{\gamma}})[\delta_{(\underline{\alpha}}\delta_{\underline{\beta}}\delta_{\underline{\gamma})}]\} + O(\hbar^4),$$

where $\delta_{(\underline{\alpha}}\delta_{\underline{\beta}}\delta_{\underline{\gamma})} = (1/3!)(\delta_{\underline{\alpha}}\delta_{\underline{\beta}}\delta_{\underline{\gamma}} + \text{all } \textit{symmetric permutations})$. In our further constructions we shall omit the constant $\hbar$ considering that $\theta \sim \hbar$ is a small value by writing the necessary terms in the approximation $O(\theta^3)$ or $O(\theta^4)$.

We consider a noncommutative gauge theory on a space with *N*-connection structure stated by the gauge fields $\hat{A}_\mu = (\hat{A}_i, \hat{A}_a)$ when "hats" on symbols will be used for the objects defined on spaces with coordinate noncommutativity. In general, the gauge model can be with different types of structure groups like SL(k,IC), SU$_k$, U$_k$, SO($k-1,1$) and their nonlinear realizations. For instance, for the U($n+m$) gauge fields there are satisfied conditions $\hat{A}^+_\mu = -\hat{A}_\mu$, where "+" is the Hermitian conjugation. It is useful to present the basic geometric constructions for a unitary structural group containing the SO (4, 1) as a particular case if we want to consider noncommutative extensions of 4D exact solutions.

The noncommutative gauge transforms of potentials are defined by using the star product

$$\hat{A}^{[\varphi]}_\mu = \hat{\varphi} * \hat{A}_\mu \hat{\varphi}^{-1}_{[*]} - \hat{\varphi} * \delta_\mu \hat{\varphi}^{-1}_{[*]},$$

where the *N*-elongated partial derivatives (3) are used $\hat{\varphi} * \hat{\varphi}^{-1}_{[*]} = 1 = \hat{\varphi}^{-1}_{[*]} * \hat{\varphi}$. The matrix coefficients of fields will be distinguished by "underlined" indices, for instance, $\hat{A}_\mu = \{\hat{A}^{\underline{\alpha}\underline{\beta}}_\mu\}$, and for commutative values, $A_\mu = \{A^{\underline{\alpha}\underline{\beta}}_\mu\}$. Such fields are subjected to the conditions

$$(\hat{A}^{\underline{\alpha}\underline{\beta}}_\mu)^+(u,\theta) = -\hat{A}^{\underline{\beta}\underline{\alpha}}_\mu(u,\theta) \quad \text{and} \quad \hat{A}^{\underline{\alpha}\underline{\beta}}_\mu(u,-\theta) = -\hat{A}^{\underline{\beta}\underline{\alpha}}_\mu(u,\theta).$$

There is a basic assumption[45] that the noncommutative fields are related to the commutative fields by the Seiberg–Witten map in a manner that there are not new degrees of freedom being satisfied by the equation

$$\hat{A}^{\underline{\alpha\beta}}_{\mu}(A) + \Delta_{\hat{\lambda}}\hat{A}^{\underline{\alpha\beta}}_{\mu}(A) = \hat{A}^{\underline{\alpha\beta}}_{\mu}(A + \Delta_{\hat{\lambda}}A), \tag{86}$$

where $\hat{A}^{\underline{\alpha\beta}}_{\mu}(A)$ denotes a functional dependence on commutative field $A^{\underline{\alpha\beta}}_{\mu}$, $\hat{\varphi}=\exp\hat{\lambda}$, and the infinitesimal deformations $\hat{A}^{\underline{\alpha\beta}}_{\mu}(A)$ and of $A^{\underline{\alpha\beta}}_{\mu}$ are given, respectively, by

$$\Delta_{\hat{\lambda}}\hat{A}^{\underline{\alpha\beta}}_{\mu} = \delta_{\mu}\hat{\lambda}^{\underline{\alpha\beta}} + \hat{A}^{\underline{\alpha\gamma}}_{\mu} * \hat{\lambda}^{\underline{\gamma\beta}} - \hat{\lambda}^{\underline{\alpha\gamma}} * \hat{A}^{\underline{\gamma\beta}}_{\mu}$$

and

$$\Delta_{\lambda}A^{\underline{\alpha\beta}}_{\mu} = \delta_{\mu}\lambda^{\underline{\alpha\beta}} + A^{\underline{\alpha\gamma}}_{\mu} * \lambda^{\underline{\gamma\beta}} - \lambda^{\underline{\alpha\gamma}} * A^{\underline{\gamma\beta}}_{\mu},$$

where instead of partial derivatives ∂_{μ} we use the N-elongated ones, δ_{μ} and sum on index $\underline{\gamma}$.

Solutions of the Seiberg–Witten equations for models of gauge gravity are considered, for instance, in Refs. 6 and 7 (there are discussed procedures of deriving expressions on θ to all orders). Here we present only the first order on θ for the coefficients $\hat{\lambda}^{\underline{\alpha\beta}}$ and the first and second orders for $\hat{A}^{\underline{\alpha\beta}}_{\mu}$ including anholonomy relations and not depending on model considerations,

$$\hat{\lambda}^{\underline{\alpha\beta}} = \lambda^{\underline{\alpha\beta}} + \frac{i}{4}\theta^{\nu\tau}\{(\delta_{\nu}\lambda^{\underline{\alpha\gamma}})A^{\underline{\gamma\beta}}_{\mu} + A^{\underline{\alpha\gamma}}_{\mu}(\delta_{\nu}\lambda^{\underline{\gamma\beta}})\} + O(\theta^2)$$

and

$$\begin{aligned}
\hat{A}^{\underline{\alpha\beta}}_{\mu} = {} & A^{\underline{\alpha\beta}}_{\mu} - \frac{i}{4}\theta^{\nu\tau}\{A^{\underline{\alpha\gamma}}_{\mu}(\delta_{\tau}A^{\underline{\gamma\beta}}_{\nu} + R^{\underline{\gamma\beta}}{}_{\tau\nu}) + (\delta_{\tau}A^{\underline{\alpha\gamma}}_{\mu} + R^{\underline{\alpha\gamma}}{}_{\tau\mu})A^{\underline{\gamma\beta}}_{\nu}\} + \tfrac{1}{32}\theta^{\nu\tau}\theta^{\rho\sigma}\{[2A^{\underline{\alpha\gamma}}_{\rho}(R^{\underline{\gamma\varepsilon}}{}_{\sigma\nu}R^{\underline{\varepsilon\beta}}{}_{\mu\tau} \\
& + R^{\underline{\gamma\varepsilon}}{}_{\mu\tau}R^{\underline{\varepsilon\beta}}{}_{\sigma\nu}) + 2(R^{\underline{\alpha\varepsilon}}{}_{\sigma\nu}R^{\underline{\varepsilon\gamma}}{}_{\mu\tau} + R^{\underline{\alpha\varepsilon}}{}_{\mu\tau}R^{\underline{\varepsilon\gamma}}{}_{\sigma\nu})A^{\underline{\gamma\beta}}_{\rho}] - [A^{\underline{\alpha\gamma}}_{\nu}(D_{\tau}R^{\underline{\gamma\beta}}{}_{\sigma\mu} + \delta_{\tau}R^{\underline{\gamma\beta}}{}_{\sigma\mu}) \\
& + (D_{\tau}R^{\underline{\alpha\gamma}}{}_{\sigma\mu} + \delta_{\tau}R^{\underline{\alpha\gamma}}{}_{\sigma\mu})A^{\underline{\gamma\beta}}_{\nu}] - \delta_{\sigma}[A^{\underline{\alpha\gamma}}_{\nu}(\delta_{\tau}A^{\underline{\gamma\beta}}_{\mu} + R^{\underline{\gamma\beta}}{}_{\tau\mu}) + (\delta_{\tau}A^{\underline{\alpha\gamma}}_{\mu} + R^{\underline{\alpha\gamma}}{}_{\tau\mu})A^{\underline{\gamma\beta}}_{\nu}] \\
& + [(\delta_{\nu}A^{\underline{\alpha\gamma}}_{\rho})(2\delta_{(\tau}\delta_{\sigma)}A^{\underline{\gamma\beta}}_{\mu} + \delta_{\tau}R^{\underline{\gamma\beta}}{}_{\sigma\mu}) + (2\delta_{(\tau}\delta_{\sigma)}A^{\underline{\alpha\gamma}}_{\mu} + \delta_{\tau}R^{\underline{\alpha\gamma}}{}_{\sigma\mu})(\delta_{\nu}A^{\underline{\gamma\beta}}_{\rho})] - [A^{\underline{\alpha\varepsilon}}_{\nu}(\delta_{\tau}A^{\underline{\varepsilon\gamma}}_{\rho} + R^{\underline{\varepsilon\gamma}}{}_{\tau\rho}) \\
& + (\delta_{\tau}A^{\underline{\alpha\varepsilon}}_{\rho} + R^{\underline{\alpha\varepsilon}}{}_{\tau\rho})A^{\underline{\varepsilon\gamma}}_{\nu}](\delta_{\sigma}A^{\underline{\gamma\beta}}_{\mu} + R^{\underline{\gamma\beta}}{}_{\sigma\mu}) - (\delta_{\sigma}A^{\underline{\alpha\gamma}}_{\mu} + R^{\underline{\alpha\gamma}}{}_{\sigma\mu})[A^{\underline{\gamma\varepsilon}}_{\nu}(\delta_{\tau}A^{\underline{\varepsilon\beta}}_{\rho} + R^{\underline{\varepsilon\beta}}{}_{\tau\rho}) \\
& + (\delta_{\tau}A^{\underline{\gamma\varepsilon}}_{\rho} + R^{\underline{\gamma\varepsilon}}{}_{\tau\rho})A^{\underline{\varepsilon\beta}}_{\nu}] + O(\theta^3),
\end{aligned} \tag{87}$$

where the curvature is defined $R^{\underline{\alpha\beta}}{}_{\tau\nu} = e^{\underline{\alpha}}_{\alpha}e^{\beta\beta}R_{\beta}{}^{\alpha}{}_{\tau\nu}$ with $R_{\beta}{}^{\alpha}{}_{\tau\nu}$ computed as in Appendix A, see formula (A1), when $\Gamma \to A$, and for the gauge model of gravity, see (75) and (82). By using the star product, we can write symbolically the solution (87) in general form,

$$\Delta\hat{A}^{\underline{\alpha\beta}}_{\mu}(\theta) = -\frac{i}{4}\theta^{\nu\tau}[\hat{A}^{\underline{\alpha\gamma}}_{\mu} * (\delta_{\tau}\hat{A}^{\underline{\gamma\beta}}_{\nu} + \hat{R}^{\underline{\gamma\beta}}{}_{\tau\nu}) + (\delta_{\tau}\hat{A}^{\underline{\alpha\gamma}}_{\mu} + \hat{R}^{\underline{\alpha\gamma}}{}_{\tau\mu}) * \hat{A}^{\underline{\gamma\beta}}_{\nu}],$$

where $\hat{R}^{\underline{\gamma\beta}}{}_{\tau\nu}$ is defined by the same formulas as $R^{\underline{\alpha\beta}}{}_{\tau\nu}$ but with the star products, like $AA \to A*A$.

There is a problem how to determine the dependence of the noncommutative vielbeins $\hat{e}^{\underline{\alpha}}_{\alpha}$ on commutative ones $e^{\underline{\alpha}}_{\alpha}$. If we consider the frame fields to be included into a (anti) de Sitter gauge gravity model with the connection (72), the vielbein components should be treated as certain coefficients of the gauge potential with specific nonlinear transforms for which the results of Ref. 6 are found. The main difference (considered in this work) is that the frames are in general with anholonomy induced by a N-connection field. In order to derive in such model the Einstein gravity we must analyze the reduction (78) to a Poincaré gauge gravity. An explicit calculus of the curvature of such gauge potential (see details in Refs. 21, 22, and 24–28), show that the coefficients of the curvature of the connection (78), obtained as a reduction from the SO (4, 1) gauge group is given by the coefficients (75) with vanishing torsion and constraints of type $\hat{A}^{\underline{\gamma 5}}_{\nu} = \epsilon\hat{e}^{\underline{\gamma}}_{\nu}$ and $\hat{A}^{\underline{55}}_{\nu} = \epsilon\hat{\phi}_{\nu}$ with $\hat{R}^{\underline{55}}{}_{\tau\nu} \sim \epsilon$ vanishing in the limit $\epsilon \to 0$ like in Ref. 7 (we obtain the same formulas for the vielbein and curvature components derived for the inhomogeneous Lorentz group but gener-

alized to N-elongated derivatives and with distinguishing into $h-v$ components). The result for $\hat{e}^{\underline{\mu}}_{\mu}$ in the limit $\epsilon \to 0$ generalized to the case of canonical connections (7) defining the covariant derivatives D_{τ} and corresponding curvatures (A1) is

$$\hat{e}^{\underline{\mu}}_{\mu} = e^{\underline{\mu}}_{\mu} - \frac{i}{4}\theta^{\nu\tau}[A^{\underline{\mu}\underline{\gamma}}_{\nu}\delta_{\tau}e^{\underline{\gamma}}_{\mu} + (\delta_{\tau}A^{\underline{\mu}\underline{\gamma}}_{\mu} + R^{\underline{\mu}\underline{\gamma}}{}_{\tau\mu})e^{\underline{\gamma}}_{\nu}] + \tfrac{1}{32}\theta^{\nu\tau}\theta^{\beta\sigma}\{2(R^{\underline{\mu}\underline{\varepsilon}}{}_{\sigma\nu}R^{\underline{\varepsilon}\underline{\gamma}}{}_{\mu\tau} + R^{\underline{\mu}\underline{\varepsilon}}{}_{\mu\tau}R^{\underline{\varepsilon}\underline{\gamma}}{}_{\sigma\nu})e^{\underline{\gamma}}_{\beta}$$
$$- A^{\underline{\mu}\underline{\gamma}}_{\beta}(D_{\tau}R^{\underline{\gamma}\underline{\beta}}{}_{\sigma\mu} + \delta_{\tau}R^{\underline{\gamma}\underline{\beta}}{}_{\sigma\mu})e^{\underline{\beta}}_{\beta} - [A^{\underline{\mu}\underline{\gamma}}_{\nu}(D_{\tau}R^{\underline{\gamma}\underline{\beta}}{}_{\sigma\mu} + \delta_{\tau}R^{\underline{\gamma}\underline{\beta}}{}_{\sigma\mu}) + (D_{\tau}R^{\underline{\mu}\underline{\gamma}}{}_{\sigma\mu} + \delta_{\tau}R^{\underline{\mu}\underline{\gamma}}{}_{\sigma\mu})A^{\underline{\gamma}\underline{\beta}}_{\nu}]e^{\underline{\beta}}_{\beta}$$
$$- e^{\underline{\beta}}_{\beta}\delta_{\sigma}[A^{\underline{\mu}\underline{\gamma}}_{\nu}(\delta_{\tau}A^{\underline{\gamma}\underline{\beta}}_{\mu} + R^{\underline{\gamma}\underline{\beta}}{}_{\tau\mu}) + (\delta_{\tau}A^{\underline{\mu}\underline{\gamma}}_{\mu} + R^{\underline{\mu}\underline{\gamma}}{}_{\tau\mu})A^{\underline{\gamma}\underline{\beta}}_{\nu}] + 2(\delta_{\nu}A^{\underline{\mu}\underline{\gamma}}_{\beta})\delta_{(\tau}\delta_{\sigma)}e^{\underline{\gamma}}_{\mu} - A^{\underline{\mu}\underline{\gamma}}_{\beta}\delta_{\sigma}[A^{\underline{\gamma}\underline{\beta}}_{\nu}\delta_{\tau}e^{\underline{\beta}}_{\mu}$$
$$+ (\delta_{\tau}A^{\underline{\gamma}\underline{\beta}}_{\mu} + R^{\underline{\gamma}\underline{\beta}}{}_{\tau\mu})e^{\underline{\beta}}_{\nu}] - (\delta_{\nu}e^{\underline{\gamma}}_{\beta})\delta_{\tau}(\delta_{\sigma}A^{\underline{\mu}\underline{\gamma}}_{\mu} + R^{\underline{\mu}\underline{\gamma}}{}_{\sigma\mu}) - [A^{\underline{\mu}\underline{\gamma}}_{\nu}(\delta_{\tau}A^{\underline{\gamma}\underline{\beta}}_{\beta} + R^{\underline{\gamma}\underline{\beta}}{}_{\tau\beta}) + (\delta_{\tau}A^{\underline{\mu}\underline{\gamma}}_{\beta}$$
$$+ R^{\underline{\mu}\underline{\gamma}}{}_{\tau\beta})A^{\underline{\gamma}\underline{\beta}}_{\nu}]\delta_{\sigma}e^{\underline{\beta}}_{\mu} - (\delta_{\sigma}A^{\underline{\mu}\underline{\gamma}}_{\mu} + R^{\underline{\mu}\underline{\gamma}}{}_{\sigma\mu})[A^{\underline{\gamma}\underline{\beta}}_{\mu}(\delta_{\nu}e^{\underline{\beta}}_{\beta}) + e^{\underline{\beta}}_{\nu}(\delta_{\sigma}A^{\underline{\gamma}\underline{\beta}}_{\mu} + R^{\underline{\gamma}\underline{\beta}}{}_{\sigma\mu})]\} + O(\theta^3). \quad (88)$$

Having the decompositions (88), we can define the inverse vielbein $\hat{e}^{\mu}_{*\underline{\mu}}$ from the equation

$$\hat{e}^{\mu}_{*\underline{\mu}} * \hat{e}^{\underline{\nu}}_{\mu} = \delta^{\underline{\nu}}_{\underline{\mu}}$$

and consequently compute θ-deformations of connections, curvatures, torsions, and any type of actions and field equations (for simplicity, we omit such cumbersome formulas being certain analogies to those computed in Ref. 7 but with additional N deformations).

The main result of this section consists in formulation of a procedure allowing to map exact solutions of a commutative gravity model into a corresponding noncommutative model without introducing new fields. For instance, we can take the data (33) and (79) and construct the θ deformation of the exact solution defining a static black ellipsoid (a similar prescription works in transforming both real and complex wormholes from Sec. V). The analysis presented in Secs. IV B and IV C illustrates a possibility to preserve the black ellipsoid stability for a certain class of extensions of solutions to noncommutative/complex gravity with complexified N frames. In another turn, if we consider arbitrary noncommutative relations for coordinates (θ noncommutativity) (83) the resulting θ deformation of stable solution will be, in general, unstable because arbitrary decompositions of type (88) will induce arbitrary complex terms in the metric, connection, and curvature coefficients, i.e., will result in complex terms in the "inverse Schrödinger problem" and related instability (see Refs. 18 and 19). Perhaps, a certain class of stable θ-deformed solutions can be defined if we constrain the θ-noncommutativity (83) to be dual to the so-called anholonomic frame noncommutativity (5), or (15), by connecting the nontrivial values of $\theta^{\alpha\beta}$ to certain complex N^a_i resulting in stable noncommutative configurations, or (in the simplest case) to say that the noncommutative extensions are modeled only by N fields $N^a_i \sim \hbar\theta$. The resulting noncommutative extensions could be defined as to preserve stability at least in the first order of $(\hbar\theta)$ terms.

VIII. DISCUSSION AND CONCLUSIONS

With this paper we begin the investigation of space–times with anholonomic noncommutative symmetry. The exact solutions we find are parametrized by generic off-diagonal metric ansatz and anholonomic frame (vielbein) structures with associated nonlinear connections (defining nontrivial anholonomy relations and inducing natural matrix noncommutative differential geometries). Their noncommutative symmetries are derived from exact solutions of the field equations in the Einstein gravity theory and their extra dimension and gauge like generalizations.

We analyzed the geometric and physical properties of new classes of exact solutions with hidden noncommutativity describing specific nonperturbative vacuum and nonvacuum gravitational configurations. Such space–times with generic off-diagonal metrics are very different, for instance, from those possessing Killing symmetries. We also addressed a particular class of solutions with noncommutative symmetries defining static black ellipsoid space–times which are not

prohibited by the uniqueness black hole theorems (proved for metrics with Killing symmetries and satisfying asymptotic flat conditions) because the generic anholonomic noncommutative configurations are very different from the Killing ones.

Let us comment on the difference between our approach and the former elaborated ones: In the so-called Connes–Lot models,[1,2] the gravitational models with Euclidean signature were elaborated from a spectral analysis of Dirac operators connected to the noncommutative geometry. This type of noncommutative geometry was constructed by replacing the algebra of smooth function on a manifold with a more general associative but noncommutative algebra. The fundamental matter field interactions and Riemannian gravity were effectively derived from a corresponding spectral calculus. In an alternative approach, the noncommutative geometry, as a low energy noncommutativity of coordinates, can be obtained in string theory because of presence of the so-called *B* fields. A number of models of gravity were proposed in order to satisfy certain noncommutativity relations for coordinates and frames (of Lie group, or quantum group type, or by computing some effective actions from string/brane theory and noncommutative gauge generalizations of gauge, Kaluza–Klein, and Einstein gravity), see Refs. 3–5 and 8. All mentioned noncommutative theories suppose that that the noncommutative geometry transforms into a commutative one in some limits to the Einstein theory and its extra dimension generalizations. In our approach we argue that the existence of hidden noncommutative structures suggests a natural way for constructing noncommutative models of gravitational interactions.

Our strategy explained in Sec. III is quite different from the previous attempts to construct the noncommutative gravity theory. We give a proof and analyze some explicit examples illustrating that there are some specific hidden noncommutative geometric structures even in the classical Einstein and gauge gravity models. This fact can be of fundamental importance in constructing more general models of noncommutative gravity with complex and nonsymmetric metrics.

Of course, there are two different notions of noncommutativity: The first one is related to the space–time deformations via Seiberg–Witten transforms with noncommutative coordinates and the second one is associated to noncommutative algebra modeled by anholonomic vielbeins. In general, the result of such deformations and frame maps cannot be distinguished exactly on a resulting complex space–time because there is a "mixture" of coordinate, gauge and frame transforms in the case of noncommutative geometry. Nevertheless, there are certain types of gravitational configurations possessing Lie type (noncommutative) symmetries which "survive" in the limit of commutative coordinates and real valued metrics. We say that such type of solutions of the gravitational field equations possess hidden noncommutative symmetries and describe a generic off-diagonal class of metrics and anholonomic frame transforms. It is a very difficult task to get exact solutions of the deformed gravity. In this work, we succeeded to do this by generating such gravitational configurations which are adapted both to the Seiberg–Witten-type deformations and to the vielbein transforms. In Sec. VII C we proved that there are possible extensions (on deformation parameters) of exact solutions from the Einstein and gauge gravity possessing hidden noncommutative symmetries without introducing new fields.

In this work, from a number of results following from application of Seiberg–Witten maps and related anholonomic vielbein transforms, we selected only those which allow us to define classes of solutions as noncommutative generalizations of some commutative ones of special physical interest. Such metrics with hidden noncommutative symmetry are described by a general off-diagonal ansatz for the metric and vielbein coefficients. The solutions can be extended to complex metrics by allowing that some subsets of vielbein coefficients (with associated nonlinear connection structure) may be complex valued. With respect to adapted frames, such metrics have real coefficients describing vacuum black ellipsoid or wormhole configurations (there were elaborated procedures of their analytical extensions and proofs of stability). The new types of metrics may be considered as certain exact solutions in complex gravity which must be considered if some noncommutative relations for coordinates are introduced. Such configurations may play an important role in the further understanding of vacua of noncommutative gauge and gravity theories and investigation of their quantum variants.

The anholonomic noncommutative symmetry of exact solutions of four-dimensional vacuum

Einstein equations positively does not violate the local (real) Lorentz symmetry. This symmetry may be preserved in a specific form even by anholonomic complex vielbein transforms mapping the 4D real Einstein's metrics into certain complex ones for noncommutative gravity. Such frames may be defined as the generated new solutions will be a formal analogy with their real (diagonal) pedigrees, to be stable with well-defined geodesic and horizon properties, like it was concluded for black ellipsoid solutions in general relativity.[18,19] By complex frame transforms with noncommutative symmetries we demonstrated that we may deform the horizon of the Schwarzshild solution to a static ellipsoid configuration as well to induce an effective electric charge of complex noncommutative origin.

We compare the generated off-diagonal ellipsoidal (in general, complex) metrics possessing anholonomic noncommutative symmetries with those describing the distorted diagonal black hole solutions (see the vacuum case in Refs. 80 and 81 and an extension to the case of nonvanishing electric fields in Ref. 82). In the complex ellipsoidal cases the space–time distortion is caused by some anisotropic off-diagonal terms being nontrivial in some regions but in the case of "pure diagonal" distortions one treats such effects following the fact that the vacuum Einstein equations are not satisfied in some regions because of presence of matter. Alternatively, the complex ellipsoid solutions may be described as in a real world with real metric coefficients but defined with respect to complex frames.

Here we emphasize that the off-diagonal gravity may model some gravity–matter-like interactions (for instance, in the Kaluza–Klein theory by emphasizing some very particular metric's configurations and topological compactifications) but, in general, the off-diagonal vacuum gravitational dynamics cannot be associated to any effective matter dynamics in a holonomic gravitational background. So, we may consider that the anholonomic ellipsoidal deformations of the Schwarzschild metric defined by real and/or complex anholonomic frame transforms generate some kind of anisotropic off-diagonal distortions modeled by certain vacuum gravitational fields with the distortion parameters (equivalently, vacuum gravitational polarizations) depending both on radial, angular and extra dimension coordinates. For complex valued nonlinear connection coefficients, we obtain a very specific complex space–time distortion instead of matter type distortion. We note that both classes of off-diagonal anisotropic and "pure" diagonal distortions (like in Refs. 80 and 81) result in solutions which in general are not asymptotically flat. However, it is possible to find asymptotically flat extensions, as it was shown in this paper and in Refs. 18 and 19, even for ellipsoidal configurations by introducing the corresponding off-diagonal terms. The asymptotic conditions for the diagonal distortions are discussed in Ref. 82 where it was suggested that to satisfy such conditions one must include some additional matter fields in the exterior portion of space–time. For ellipsoidal real/complex metrics, we should consider that the off-diagonal metric terms have a corresponding behavior as to result far away from the horizon in the Minkowski metric.

The deformation parameter ε effectively seems to put an "electric charge" on the black hole which is of gravitational off-diagonal/anholonomic origin. For complex metrics such "electric charges" may be induced by complex values of off-diagonal metric/anholonomic frame coefficients. It can describe effectively both positive and negative gravitational polarizations (even some repulsive gravitational effects). The polarization may have very specific nonlinearities induced by complex gravity terms. This is not surprising because the coefficients of an anisotropic black hole are similar to those of the Reissner–Nördstrom solution only with respect to corresponding anholonomic complex/real frames which are subjected to some constraints (anholonomy conditions).

Applying the method of anholonomic frame transforms elaborated and developed in Refs. 13–19 and 24–31, we can construct off-diagonal ellipsoidal extensions of the already diagonally disturbed Schwarzschild metric [see the metric (3.7) from Ref. 82]. Such anholonomic deformations would contain in the diagonal limit configurations with $\varepsilon \to 0$ but $\eta_3 \neq 1$ [see (47) and/or (33) and (51)] for such configurations where the function η_3 must be related in the corresponding limits with the values $\overline{\gamma}_D$, $\overline{\psi}_D$, and A from Ref. 82. We remark that there are different classes of ellipsoidal deformations of the Schwarzschild metric which result in real or complex vacuum

configuration. The conditions $\varepsilon \to 0$ and $q,\ \eta_3=1$ and $\lambda \to 0$ select just the limit of the usual radial Schwarzschild asymptotics without any (also possible) additional diagonal distortions. For nontrivial values of $q,\ \eta_3$, and η_4 we may obtain diagonal distortions.

In the case of ellipsoidal metrics with the Schwarzschild asymptotics, the ellipsoidal character could result in some observational effects in the vicinity of the horizon. For instance, scattering of particles on a static ellipsoid can be computed. We can also model anisotropic matter accretion effects on an ellipsoidal black hole put in the center of a galactic being of ellipsoidal, toroidal or another configuration. Even in 4D the nonspheric topology of horizons seem to be prohibited in the general relativity theory[52,83–86,20] following some general differential geometry and censorship theorems, such objects can be induced from extra dimensions and can exist in theories with cosmological constant,[87–89] nontrivial torsion or induced by anholonomic frames.[13–19,30,31] We can consider black torus/ellipsoid solutions as a background for potential tests for existence of extra dimensions and of general relativity. A point of further investigations could be the anisotropic ellipsoidal collapse when both the matter and space–time are of ellipsoidal generic off-diagonal symmetry (former theoretical and computational investigations were performed only for rotoids with anisotropic matter and particular classes of perturbations of the Schwarzshild solutions[90]). It is interesting to elaborate collapse scenaria with respect to compexified anholonomic frames. For very small eccentricities, we may not have any observable effects like perihelion shift or light bending if we restrict our investigations only to the Schwarzschild–Newton asymptotics but some kind of dissipation can be considered for complex metrics.

We also present some comments on mechanics and thermodynamics of ellipsoidal black holes. For the static black ellipsoids/tori with flat asymptotics, we can compute the area of the ellipsoidal horizon, associate an entropy and develop corresponding black ellipsoid thermodynamics. But this is a rough approximation because, in general, we are dealing with off-diagonal metrics depending anisotropically on two/three coordinates. Such solutions are with anholonomically deformed Killing horizons, or with anholonomic noncommutative symmetries, and should be described by a thermodynamics (in general, both nonequilibrium and irreversible) of black ellipsoids/tori self-consistently embedded into an off-diagonal anisotropic gravitational vacuum with potential dissipation described by some complex metric and frame coefficients. This forms a ground for numerous new conceptual issues to be developed and related to anisotropic black holes and the anisotropic kinetics and thermodynamics[29] as well to a framework of isolated anisotropic horizons,[91–93] defined in a locally anistoropic/noncommutative/complex background with wormhole real and/or complex configurations which is a matter of our further investigations.

Finally, we note that we elaborated a general formalism of generating noncommutative solutions starting from exact vacuum solutions with anholonomic noncommutativity, but we do not know how to extend our solutions via star (Moyal) product as to preserve their stability because of induced general complex terms in the metrics. For some particular duality relations between the coordinate and frame noncommutativity it seems possible to get stability at least in the first approximation of noncommutative deformation parameter but an arbitrary noncommutative coordinate relation results in less defined physical configurations. A better understanding of the physical relevance of the anholonomic noncommutative configurations completed also to general coordinate noncommutativity is an interesting open question which we leave for the future.

APPENDIX A: EINSTEIN EQUATIONS AND *N* CONNECTIONS

For convenience, we present in this Appendix a selection of necessary results from Refs. 13–19, 30, and 31.

The curvature tensor of a connection $\Gamma^{[c]}$ with $h-v$ components (7) induced by anholonomic frames (2) and (3) with associated N-connection structure is defined $R(\delta_\tau, \delta_\gamma)\delta_\beta = R_\beta{}^\alpha{}_{\gamma\tau}\delta_\alpha$, where

$$R_{\beta}{}^{\alpha}{}_{\gamma\tau} = \delta_{\tau}\Gamma^{\alpha}{}_{\beta\gamma} - \delta_{\gamma}\Gamma^{\alpha}{}_{\beta\tau} + \Gamma^{\varphi}{}_{\beta\gamma}\Gamma^{\alpha}{}_{\varphi\tau} - \Gamma^{\varphi}{}_{\beta\tau}\Gamma^{\alpha}{}_{\varphi\gamma} + \Gamma^{\alpha}{}_{\beta\varphi}w^{\varphi}{}_{\gamma\tau}, \tag{A1}$$

splits into irreducible $h-v$ components $R_{\beta}{}^{\alpha}{}_{\gamma\tau}=\{R^{i}_{h.jk}, R^{a}_{b.jk}, P^{i}_{j.ka}, P^{c}_{b.ka}, S^{i}_{j.bc}, S^{a}_{b.cd}\}$, with

$$R^{i}_{h.jk} = \delta_k L^{i}_{.hj} - \delta_j L^{i}_{.hk} + L^{m}_{.hj}L^{i}_{mk} - L^{m}_{.hk}L^{i}_{mj} - C^{i}_{.ha}\Omega^{a}_{.jk},$$

$$R^{a}_{b.jk} = \delta_k L^{a}_{.bj} - \delta_j L^{a}_{.bk} + L^{c}_{.bj}L^{a}_{.ck} - L^{c}_{.bk}L^{a}_{.cj} - C^{a}_{.bc}\Omega^{c}_{.jk},$$

$$P^{i}_{j.ka} = \partial_a L^{i}_{.jk} + C^{i}_{.jb}T^{b}_{.ka} - (\delta_k C^{i}_{.ja} + L^{i}_{.lk}C^{l}_{.ja} - L^{l}_{.jk}C^{i}_{.la} - L^{c}_{.ak}C^{i}_{.jc}),$$

$$P^{c}_{b.ka} = \partial_a L^{c}_{.bk} + C^{c}_{.bd}T^{d}_{.ka} - (\delta_k C^{c}_{.ba} + L^{c}_{.dk}C^{d}_{.ba} - L^{d}_{.bk}C^{c}_{.da} - L^{d}_{.ak}C^{c}_{.bd}),$$

$$S^{i}_{j.bc} = \partial_c C^{i}_{.jb} - \partial_b C^{i}_{.jc} + C^{h}_{.jb}C^{i}_{.hc} - C^{h}_{.jc}C^{i}_{hb},$$

$$S^{a}_{b.cd} = \partial_d C^{a}_{.bc} - \partial_c C^{a}_{.bd} + C^{e}_{.bc}C^{a}_{.ed} - C^{e}_{.bd}C^{a}_{.ec}, \tag{A2}$$

where we omitted the label $[c]$ in formulas. The Ricci tensor $R_{\beta\gamma}=R_{\beta}{}^{\alpha}{}_{\gamma\alpha}$ has the irreducible $h-v$ components

$$R_{ij} = R^{k}_{i.jk}, \quad R_{ia} = -{}^{2}P_{ia} = -P^{k}_{i.ka},$$

$$R_{ai} = {}^{1}P_{ai} = P^{b}_{a.ib}, \quad R_{ab} = S^{c}_{a.bc}. \tag{A3}$$

This tensor is nonsymmetric, ${}^{1}P_{ai} \neq {}^{2}P_{ia}$ (this could be with respect to anholonomic frames of reference). The scalar curvature of the metric d connection, $\overleftarrow{R}=g^{\beta\gamma}R_{\beta\gamma}$, is computed

$$\overleftarrow{R} = G^{\alpha\beta}R_{\alpha\beta} = \hat{R} + S, \tag{A4}$$

where $\hat{R}=g^{ij}R_{ij}$ and $S=h^{ab}S_{ab}$.

By substituting (A3) and (A4) into the 5D Einstein equations,

$$R_{\alpha\beta} - \tfrac{1}{2}g_{\alpha\beta}R = \kappa\Upsilon_{\alpha\beta},$$

where κ and $\Upsilon_{\alpha\beta}$ are, respectively, the coupling constant and the energy-momentum tensor, we obtain the $h-v$ decomposition of the Einstein equations,

$$R_{ij} - \tfrac{1}{2}(\hat{R} + S)g_{ij} = \kappa\Upsilon_{ij},$$

$$S_{ab} - \tfrac{1}{2}(\hat{R} + S)h_{ab} = \kappa\Upsilon_{ab}, \tag{A5}$$

$${}^{1}P_{ai} = \kappa\Upsilon_{ai}, \quad {}^{2}P_{ia} = \kappa\Upsilon_{ia}.$$

The vacuum 5D gravitational field equations, in invariant $h-v$ components, are written

$$R_{ij} = 0, \quad S_{ab} = 0, \quad {}^{1}P_{ai} = 0, \quad {}^{2}P_{ia} = 0. \tag{A6}$$

The main trick of the anholonomic frames method of integrating the Einstein equations in general relativity and various (super) string and higher/lower dimension gravitational theories consist in a procedure of definition of such coefficients N^{a}_{j} such that the block matrices g_{ij} and h_{ab} are diagonalized. This substantially simplifies computations but we must apply N-elongated partial derivatives.

APPENDIX B: MAIN THEOREMS FOR 5D

We restrict our considerations to a five-dimensional (in brief, 5D) space–time provided with a generic off-diagonal (pseudo) Riemannian metric and labeled by local coordinates $u^{\alpha}=(x^i,y^4=v,y^5)$, for $i=1,2,3$. We state the condition when exact solutions of the Einstein equations depending on holonomic variables x^i and on one anholonomic (equivalently, anisotropic) variable $y^4=v$ can be constructed in explicit form. Every coordinate from a set u^{α} may be timelike, 3D spacelike, or extra dimensional. For simplicity, the partial derivatives will be denoted as $a^{\times}=\partial a/\partial x^1$, $a^{\cdot}=\partial a/\partial x^2$, $a'=\partial a/\partial x^3$, $a^{*}=\partial a/\partial v$.

The 5D quadratic line element is chosen

$$ds^2=g_{\alpha\beta}(x^i,v)du^{\alpha}\,du^{\beta} \tag{B1}$$

when the metric components $g_{\alpha\beta}$ are parametrized with respect to the coordinate dual basis by an off-diagonal matrix (ansatz),

$$\begin{bmatrix} g_1+w_1{}^2h_4+n_1{}^2h_5 & w_1w_2h_4+n_1n_2h_5 & w_1w_3h_4+n_1n_3h_5 & w_1h_4 & n_1h_5 \\ w_1w_2h_4+n_1n_2h_5 & g_2+w_2{}^2h_4+n_2{}^2h_5 & w_2w_3h_4+n_2n_3h_5 & w_2h_4 & n_2h_5 \\ w_1w_3h_4+n_1n_3h_5 & w_2w_3h_4+n_2n_3h_5 & g_3+w_3{}^2h_4+n_3{}^2h_5 & w_3h_4 & n_3h_5 \\ w_1h_4 & w_2h_4 & w_3h_4 & h_4 & 0 \\ n_1h_5 & n_2h_5 & n_3h_5 & 0 & h_5 \end{bmatrix}, \tag{B2}$$

with the coefficients being some necessary smooth class functions of type

$$g_1=\pm 1,\quad g_{2,3}=g_{2,3}(x^2,x^3),\quad h_{4,5}=h_{4,5}(x^i,v),$$

$$w_i=w_i(x^i,v),\quad n_i=n_i(x^i,v),$$

where the N coefficients from (3) and (2) are parametrized $N_i^4=w_i$ and $N_i^5=n_i$.

By straightforward calculation, we can prove[30,31] the following.

Theorem 1: *The nontrivial components of the 5D vacuum Einstein equations, $R_{\alpha}^{\beta}=0$ [see (A6) in the Appendix A] for the metric (1) defined by the ansatz (B2), computed with respect to anholonomic frames (2) and (3) can be written in the form*

$$R_2^2=R_3^3=-\frac{1}{2g_2g_3}\left[\ddot{g_3}-\frac{\dot{g_2}\dot{g_3}}{2g_2}-\frac{(\dot{g_3})^2}{2g_3}+g_2''-\frac{g_2'g_3'}{2g_3}-\frac{(g_2')^2}{2g_2}\right]=0, \tag{B3}$$

$$S_4^4=S_5^5=-\frac{\beta}{2h_4h_5}=0, \tag{B4}$$

$$R_{4i}=-w_i\frac{\beta}{2h_5}-\frac{\alpha_i}{2h_5}=0, \tag{B5}$$

$$R_{5i}=-\frac{h_5}{2h_4}[n_i^{**}+\gamma n_i^{*}]=0, \tag{B6}$$

where

$$\alpha_i=\partial_i h_5^{*}-h_5^{*}\partial_i\ln\sqrt{|h_4h_5|},\quad \beta=h_5^{**}-h_5^{*}[\ln\sqrt{|h_4h_5|}]^{*},\quad \gamma=3h_5^{*}/2h_5-h_4^{*}/h_4. \tag{B7}$$

Following this theorem, (1) we can define a function $g_2(x^2,x^3)$ for a given $g_3(x^2,x^3)$, or inversely, to define a function $g_2(x^2,x^3)$ for a given $g_3(x^2,x^3)$, from Eq. (B3); (2) we can define a function $h_4(x^1,x^2,x^3,v)$ for a given $h_5(x^1,x^2,x^3,v)$, or inversely, to define a function $h_5(x^1,x^2,x^3,v)$ for a given $h_4(x^1,x^2,x^3,v)$, from Eq. (B4); (3) and (4) having the values of h_4 and

h_5, we can compute the coefficients (B7) which allow to solve the algebraic equations (B5) and to integrate two times on v the equation (B6) which allows to find, respectively, the coefficients $w_i(x^k,v)$ and $n_i(x^k,v)$.

We can generalize the construction by introducing a conformal factor $\Omega(x^i,v)$ and additional deformations of the metric via coefficients $\zeta_{\hat{i}}(x^i,v)$ (here, the indices with a "hat" take values like $\hat{i}=1,2,3,5$), i.e., for metrics of type

$$ds^2=\Omega^2(x^i,v)\hat{g}_{\alpha\beta}(x^i,v)du^\alpha\, du^\beta, \tag{B8}$$

where the coefficients $\hat{g}_{\alpha\beta}$ are parametrized by the ansatz

$$\begin{bmatrix} g_1+(w_1{}^2+\zeta_1{}^2)h_4+n_1{}^2h_5 & (w_1w_2+\zeta_1\zeta_2)h_4+n_1n_2h_5 & (w_1w_3+\zeta_1\zeta_3)h_4+n_1n_3h_5 & (w_1+\zeta_1)h_4 & n_1h_5 \\ (w_1w_2+\zeta_1\zeta_2)h_4+n_1n_2h_5 & g_2+(w_2{}^2+\zeta_2{}^2)h_4+n_2{}^2h_5 & (w_2w_3+\zeta_2\zeta_3)h_4+n_2n_3h_5 & (w_2+\zeta_2)h_4 & n_2h_5 \\ (w_1w_3+\zeta_1\zeta_3)h_4+n_1n_3h_5 & (w_2w_3+\zeta_2\zeta_3)h_4+n_2n_3h_5 & g_3+(w_3{}^2+\zeta_3{}^2)h_4+n_3{}^2h_5 & (w_3+\zeta_3)h_4 & n_3h_5 \\ (w_1+\zeta_1)h_4 & (w_2+\zeta_2)h_4 & (w_3+\zeta_3)h_4 & h_4 & 0 \\ n_1h_5 & n_2h_5 & n_3h_5 & 0 & h_5+\zeta_5h_4 \end{bmatrix}. \tag{B9}$$

Such 5D metrics have a second order anisotropy[32,37,38] when the N coefficients are parametrized in the first order anisotropy like $N_i^4=w_i$ and $N_i^5=n_i$ (with three anholonomic, x^i, and two anholonomic, y^4 and y^5, coordinates) and in the second order anisotropy [on the second "shell," with four anholonomic (x^i,y^5), and one anholonomic, y^4, coordinates] with $N_{\hat{i}}^5=\zeta_{\hat{i}}$, in this work we state, for simplicity, $\zeta_5=0$. For trivial values $\Omega=1$ and $\zeta_{\hat{i}}=0$, the squared line interval (B8) transforms into (B1).

The Theorem 1 can be extended as to include the generalization to the second ansatz (B8).

Theorem 2: *The nontrivial components of the 5D vacuum Einstein equations, $R_\alpha^\beta=0$ [see (A6) in Appendix A] for the metric (B8) consist from the system (B3)–(B6) with the additional conditions that*

$$\hat{\delta}_i h_4=0 \quad \textit{and}\ \hat{\delta}_i\Omega=0 \tag{B10}$$

for $\hat{\delta}_i=\partial_i-(w_i+\zeta_i)\partial_4+n_i\partial_5$ when the values $\zeta_{\hat{i}}=(\zeta_i,\zeta_5=0)$ are to be found as to be a solution of (B10); for instance, if

$$\Omega^{q_1/q_2}=h_4 \quad (q_1 \textit{ and } q_2 \textit{ are integers}), \tag{B11}$$

ζ_i satisfy the equations

$$\partial_i\Omega-(w_i+\zeta_i)\Omega^*=0. \tag{B12}$$

The proof of Theorem 2 consists from a straightforward calculation of the components of the Ricci tensor (A3) as it is outlined in the Appendix A. The simplest way is to use the calculus for Theorem 1 and then to compute deformations of the canonical connection (7). Such deformations induce corresponding deformations of the Ricci tensor (A3). The condition that we have the same values of the Ricci tensor for the (B2) and (B9) results in Eqs. (B10) and (B12) which are compatible, for instance, if $\Omega^{q_1/q_2}=h_4$. There are also other possibilities to satisfy the condition (B10), for instance, if $\Omega=\Omega_1\Omega_2$, we can consider that $h_4=\Omega_1^{q_1/q_2}\Omega_2^{q_3/q_4}$ for some integers q_1, q_2, q_3, and q_4.

A very surprising result is that we are able to construct exact solutions of the 5D vacuum Einstein equations for both types of the ansatz (B2) and (B9).

Theorem 3: *The system of second order nonlinear partial differential equations (B3)–(B6) and (B12) can be solved in general form if there are given some values of functions $g_2(x^2,x^3)$ [or $g_3(x^2,x^3)$], $h_4(x^i,v)$ [or $h_5(x^i,v)$], and $\Omega(x^i,v)$.*

(i) *The general solution of Eq. (B3) can be written in the form*

$$\varpi = g_{[0]} \exp[a_2 \tilde{x}^2(x^2,x^3) + a_3 \tilde{x}^3(x^2,x^3)], \tag{B13}$$

where $g_{[0]}$, a_2, and a_3 are some constants and the functions $\tilde{x}^{2,3}(x^2,x^3)$ define any coordinate transforms $x^{2,3} \to \tilde{x}^{2,3}$ for which the 2D line element becomes conformally flat, i.e.,

$$g_2(x^2,x^3)(\mathrm{d}x^2)^2 + g_3(x^2,x^3)(\mathrm{d}x^3)^2 \to \varpi[(\mathrm{d}\tilde{x}^2)^2 + \epsilon(\mathrm{d}\tilde{x}^3)^2]. \tag{B14}$$

(ii) *The equation (B4) relates two functions $h_4(x^i,v)$ and $h_5(x^i,v)$ following two possibilities:*

(a) *to compute*

$$\sqrt{|h_5|} = h_{5[1]}(x^i) + h_{5[2]}(x^i) \int \sqrt{|h_4(x^i,v)|}\mathrm{d}v, \quad h_4^*(x^i,v) \neq 0 = h_{5[1]}(x^i) + h_{5[2]}(x^i)v,$$

$$h_4^*(x^i,v) = 0, \tag{B15}$$

for some functions $h_{5[1,2]}(x^i)$ stated by boundary conditions;

(b) *or, inversely, to compute h_4 for a given $h_5(x^i,v)$, $h_5^* \neq 0$,*

$$\sqrt{|h_4|} = h_{[0]}(x^i)(\sqrt{|h_5(x^i,v)|})^*, \tag{B16}$$

with $h_{[0]}(x^i)$ given by boundary conditions.

(iii) *The exact solutions of (B5) for $\beta \neq 0$ is*

$$w_k = \partial_k \ln[\sqrt{|h_4 h_5|}/|h_5^*|]/\partial_v \ln[\sqrt{|h_4 h_5|}/|h_5^*|], \tag{B17}$$

with $\partial_v = \partial/\partial v$ and $h_5^* \neq 0$. If $h_5^* = 0$, or even $h_5^* \neq 0$ but $\beta = 0$, the coefficients w_k could be arbitrary functions on (x^i,v). For vacuum Einstein equations this is a degenerated case which imposes the the compatibility conditions $\beta = \alpha_i = 0$, which are satisfied, for instance, if the h_4 and h_5 are related as in the formula (B6) but with $h_{[0]}(x^i) = const$..

(iv) *The exact solution of (B6) is*

$$n_k = n_{k[1]}(x^i) + n_{k[2]}(x^i) \int [h_4/(\sqrt{|h_5|})^3]\mathrm{d}v, \quad h_5^* \neq 0,$$

$$= n_{k[1]}(x^i) + n_{k[2]}(x^i) \int h_4 \, \mathrm{d}v, \quad h_5^* = 0, \tag{B18}$$

$$= n_{k[1]}(x^i) + n_{k[2]}(x^i) \int [1/(\sqrt{|h_5|})^3]\mathrm{d}v, \quad h_4^* = 0,$$

for some functions $n_{k[1,2]}(x^i)$ stated by boundary conditions.

(v) *The exact solution of (B12) is given by some arbitrary functions $\zeta_i = \zeta_i(x^i,v)$ if both $\partial_i \Omega = 0$ and $\Omega^* = 0$, we choose $\zeta_i = 0$ for $\Omega = const$, and*

$$\zeta_i = -w_i + (\Omega^*)^{-1}\partial_i \Omega, \quad \Omega^* \neq 0,$$

$$= (\Omega^*)^{-1}\partial_i \Omega, \quad \Omega^* \neq 0, \quad \textit{for vacuum solutions}. \tag{B19}$$

We note that a transform (B14) is always possible for 2D metrics and the explicit form of solutions depends on the chosen system of 2D coordinates and on the signature $\epsilon = \pm 1$. In the simplest case the equation (B3) is solved by arbitrary two functions $g_2(x^3)$ and $g_3(x^2)$. The equation (B4) is satisfied by arbitrary pairs of coefficients $h_4(x^i,v)$ and $h_{5[0]}(x^i)$.

The proof of Theorem 3, following from a direct integration of (B3)–(B6) and (B12) is given in the Appendix B of Ref. 30.

There are some important consequences of the Theorems 1–3.

Corollary 1: The nontrivial diagonal components of the Einstein tensor, $G^{\alpha}_{\beta}=R^{\alpha}_{\beta}-\frac{1}{2}R\delta^{\alpha}_{\beta}$, for the metric (1), given with respect to N frames, are

$$G^1_1=-(R^2_2+S^4_4),\quad G^2_2=G^3_3=-S^4_4,\quad G^4_4=G^5_5=-R^2_2 \tag{B20}$$

imposing the condition that the dynamics is defined by two values R^2_2 and S^4_4. The rest of the nondiagonal components of the Ricci (Einstein tensor) are compensated by fixing corresponding values of N coefficients.

The formulas (B20) are obtained following the relations for the Ricci tensor (B3)–(B6).

Corollary 2: We can extend the system of 5D vacuum Einstein equations (B3)–(B6) by introducing matter fields for which the coefficients of the energy-momentum tensor $\Upsilon_{\alpha\beta}$ given with respect to N frames satisfy the conditions

$$\Upsilon^1_1=\Upsilon^2_2+\Upsilon^4_4,\quad \Upsilon^2_2=\Upsilon^3_3,\quad \Upsilon^4_4=\Upsilon^5_5. \tag{B21}$$

We note that, in general, the tensor $\Upsilon_{\alpha\beta}$ for the nonvacuum Einstein equations,

$$R_{\alpha\beta}-\tfrac{1}{2}g_{\alpha\beta}R=\kappa\Upsilon_{\alpha\beta},$$

is not symmetric because with respect to anholonomic frames there are imposed constraints which makes nonsymmetric the Ricci and Einstein tensors [the symmetry conditions may be defined explicitly only with respect to holonomic, coordinate frames; for details see Appendix A and the formulas (A5)].

For simplicity, in our investigations we can consider only diagonal matter sources, given with respect to *N* frames, satisfying the conditions

$$\kappa\Upsilon^2_2=\kappa\Upsilon^3_3=\Upsilon_2,\quad \kappa\Upsilon^4_4=\kappa\Upsilon^5_5=\Upsilon_4,\quad \text{and } \Upsilon_1=\Upsilon_2+\Upsilon_4, \tag{B22}$$

where κ is the gravitational coupling constant. In this case the equations (B3) and (B4) are, respectively, generalized to

$$R^2_2=R^3_3=-\frac{1}{2g_2g_3}\left[\ddot{g_3}-\frac{\dot{g_2}\dot{g_3}}{2g_2}-\frac{(\dot{g_3})^2}{2g_3}+g_2''-\frac{g_2'g_3'}{2g_3}-\frac{(g_2')^2}{2g_2}\right]=-\Upsilon_4 \tag{B23}$$

and

$$S^4_4=S^5_5=-\frac{\beta}{2h_4h_5}=-\Upsilon_2. \tag{B24}$$

Corollary 3: An arbitrary solution of the system of equations (B3)–(B6) and (B12) is defined for a canonical connection (7) containing, in general, nontrivial torsion coefficients. This can be effectively applied in order to construct exact solutions, for instance, in string gravity containing nontrivial torsion. We can select solutions corresponding to the Levi–Civita connection (10) for a generic off-diagonal (pseudo) Riemannian metric if we impose the condition that the coefficients $N^4_i=w_i(x^k,v)$, $N^5_i=n_i(x^k,v)$, and $N^5_{\hat{i}}=\zeta_{\hat{i}}$ are fixed to result in a zero N curvature, $\Omega^a_{jk}=0$, on all "shells" of anisotropy. Such selections are possible by fixing corresponding boundary conditions and selecting corresponding classes of functions like $n_{k[1,2]}(x^i)$, obtained after a general integration, in formulas (B17)–(B19).

The above presented results are for generic 5D off-diagonal metrics, anholonomic transforms and nonlinear field equations. Reductions to a lower dimensional theory are not trivial in such cases. We emphasize here some specific points of this procedure (see details in Ref. 30).

APPENDIX C: REDUCTION FROM 5D TO 4D

The simplest way to construct a 5D$\to$4D reduction for the ansatz (B2) and (B9) is to eliminate from formulas the variable x^1 and to consider a 4D space [parametrized by local coordinates

(x^2,x^3,v,y^5)] being trivially embedded into 5D space [parametrized by local coordinates (x^1,x^2,x^3,v,y^5) with $g_{11}=\pm 1$, $g_{1\hat{\alpha}}=0$, $\hat{\alpha}=2,3,4,5$] with further possible 4D conformal and anholonomic transforms depending only on variables (x^2,x^3,v). We suppose that the 4D metric $g_{\hat{\alpha}\hat{\beta}}$ could be of arbitrary signature. In order to emphasize that some coordinates are stated just for such 4D space we underline the greek indices, $\hat{\alpha},\hat{\beta},\ldots$ and the italic indices from the middle of alphabet, $\hat{i},\hat{j},\ldots=2,3$, where $u^{\hat{\alpha}}=(x^{\hat{i}},y^a)=(x^2,x^3,y^4,y^5)$.

In result, the analogs, Theorems 1–3 and Corollaries 1–3 can be reformulated for 4D gravity with mixed holonomic–anholonomic variables. We outline here the most important properties of such reduction.

(i) The line element (B1) with ansatz (B2) and the line element (B1) with (B9) are, respectively, transformed on 4D space to the values.

The first type 4D quadratic line element is taken

$$ds^2 = g_{\hat{\alpha}\hat{\beta}}(x^{\hat{i}},v)du^{\hat{\alpha}}\,du^{\hat{\beta}} \tag{C1}$$

with the metric coefficients $g_{\hat{\alpha}\hat{\beta}}$ parametrized

$$\begin{bmatrix} g_2+w_2{}^2h_4+n_2{}^2h_5 & w_2w_3h_4+n_2n_3h_5 & w_2h_4 & n_2h_5 \\ w_2w_3h_4+n_2n_3h_5 & g_3+w_3{}^2h_4+n_3{}^2h_5 & w_3h_4 & n_3h_5 \\ w_2h_4 & w_3h_4 & h_4 & 0 \\ n_2h_5 & n_3h_5 & 0 & h_5 \end{bmatrix}, \tag{C2}$$

where the coefficients are some necessary smooth class functions of type

$$g_{2,3}=g_{2,3}(x^2,x^3),\quad h_{4,5}=h_{4,5}(x^{\hat{k}},v),$$

$$w_{\hat{i}}=w_{\hat{i}}(x^{\hat{k}},v),\quad n_{\hat{i}}=n_{\hat{i}}(x^{\hat{k}},v),\quad \hat{i},\hat{k}=2,3.$$

The anholonomically and conformally transformed 4D line element is

$$ds^2=\Omega^2(x^{\hat{i}},v)\hat{g}_{\hat{\alpha}\hat{\beta}}(x^{\hat{i}},v)du^{\hat{\alpha}}\,du^{\hat{\beta}}, \tag{C3}$$

where the coefficients $\hat{g}_{\hat{\alpha}\hat{\beta}}$ are parametrized by the ansatz

$$\begin{bmatrix} g_2+(w_2{}^2+\zeta_2{}^2)h_4+n_2{}^2h_5 & (w_2w_3+\zeta_2\zeta_3)h_4+n_2n_3h_5 & (w_2+\zeta_2)h_4 & n_2h_5 \\ (w_2w_3+\zeta_2\zeta_3)h_4+n_2n_3h_5 & g_3+(w_3{}^2+\zeta_3{}^2)h_4+n_3{}^2h_5 & (w_3+\zeta_3)h_4 & n_3h_5 \\ (w_2+\zeta_2)h_4 & (w_3+\zeta_3)h_4 & h_4 & 0 \\ n_2h_5 & n_3h_5 & 0 & h_5+\zeta_5h_4 \end{bmatrix}, \tag{C4}$$

where $\zeta_{\hat{i}}=\zeta_{\hat{i}}(x^{\hat{k}},v)$ and we shall restrict our considerations for $\zeta_5=0$.

(ii) We have a quadratic line element (1) which can be written

$$\delta s^2=g_2(dx^2)^2+g_3(dx^3)^2+h_4(\delta v)^2+h_5(\delta y^5)^2, \tag{C5}$$

with respect to the anholonomic coframe $(dx^{\hat{i}},\delta v,\delta y^5)$, where

$$\delta v=dv+w_{\hat{i}}\,dx^{\hat{i}}\quad\text{and}\quad \delta y^5=dy^5+n_{\hat{i}}\,dx^{\hat{i}} \tag{C6}$$

is the dual of $(\delta_{\hat{i}},\partial_4,\partial_5)$, where

$$\delta_{\hat{i}} = \partial_{\hat{i}} + w_{\hat{i}}\partial_4 + n_{\hat{i}}\partial_5. \tag{C7}$$

(iii) In the conditions of the 4D variant of the Theorem 1 we have the same equations (B3)–(B6) where we must set $h_4 = h_4(x^{\hat{k}}, v)$ and $h_5 = h_5(x^{\hat{k}}, v)$. As a consequence we have that $\alpha_i(x^k, v) \to \alpha_{\hat{i}}(x^{\hat{k}}, v)$, $\beta = \beta(x^{\hat{k}}, v)$, and $\gamma = \gamma(x^{\hat{k}}, v)$ which result that $w_{\hat{i}} = w_{\hat{i}}(x^{\hat{k}}, v)$ and $n_{\hat{i}} = n_{\hat{i}}(x^{\hat{k}}, v)$.

(iv) The 4D line element with conformal factor (B8) subjected to an anholonomic map with $\zeta_5 = 0$ transforms into

$$\delta s^2 = \Omega^2(x^{\hat{i}}, v)[g_2(\mathrm{d}x^2)^2 + g_3(\mathrm{d}x^3)^2 + h_4(\hat{\delta}v)^2 + h_5(\delta y^5)^2], \tag{C8}$$

given with respect to the anholonomic coframe $(\mathrm{d}x^{\hat{i}}, \hat{\delta}v, \delta y^5)$, where

$$\delta v = \mathrm{d}v + (w_{\hat{i}} + \zeta_{\hat{i}})\,\mathrm{d}x^{\hat{i}} \quad \text{and} \quad \delta y^5 = \mathrm{d}y^5 + n_{\hat{i}}\,\mathrm{d}x^{\hat{i}} \tag{C9}$$

is dual to the frame $(\hat{\delta}_{\hat{i}}, \partial_4, \hat{\partial}_5)$ with

$$\hat{\delta}_{\hat{i}} = \partial_{\hat{i}} - (w_{\hat{i}} + \zeta_{\hat{i}})\partial_4 + n_{\hat{i}}\partial_5, \quad \hat{\partial}_5 = \partial_5. \tag{C10}$$

(v) The formulas (B10) and (B12) from Theorem 2 must be modified into a 4D form

$$\hat{\delta}_{\hat{i}} h_4 = 0 \quad \text{and} \quad \hat{\delta}_{\hat{i}}\Omega = 0 \tag{C11}$$

and the values $\zeta_{\hat{i}} = (\zeta_{\hat{i}}, \zeta_5 = 0)$ are found as to be a unique solution of (B10); for instance, if

$$\Omega^{q_1/q_2} = h_4 \quad (q_1 \text{ and } q_2 \text{ are integers}),$$

$\zeta_{\hat{i}}$ satisfy the equations

$$\partial_{\hat{i}}\Omega - (w_{\hat{i}} + \zeta_{\hat{i}})\Omega^* = 0. \tag{C12}$$

(vi) One holds the same formulas (B15)–(B18) from the Theorem 3 on the general form of exact solutions with that difference that their 4D analogs are to be obtained by reductions of holonomic indices, $\hat{i} \to i$, and holonomic coordinates, $x^i \to x^{\hat{i}}$, i.e., in the 4D solutions there is not contained the variable x^1.

(vii) The formulas (B20) for the nontrivial coefficients of the Einstein tensor in 4D stated by the Corollary 1 are written

$$G_2^2 = G_3^3 = -S_4^4, \quad G_4^4 = G_5^5 = -R_2^2. \tag{C13}$$

(viii) For symmetries of the Einstein tensor (C13), we can introduce a matter field source with a diagonal energy momentum tensor, like it is stated in the Corollary 2 by the conditions (B21), which in 4D are transformed into

$$\Upsilon_2^2 = \Upsilon_3^3, \quad \Upsilon_4^4 = \Upsilon_5^5. \tag{C14}$$

APPENDIX D: STAR-PRODUCTS, ENVELOPING ALGEBRAS AND NONCOMMUTATIVE GEOMETRY

For a noncommutative space the coordinates $\hat{u}^i$ $(i = 1, \ldots, N)$ satisfy some noncommutative relations

$$[\hat{u}^i,\hat{u}^j]=\begin{cases} i\theta^{ij}, & \theta^{ij}\in \mathrm{IC}, \quad \text{canonical structure},\\ if_k^{ij}\hat{u}^k, & f_k^{ij}\in \mathrm{IC}, \quad \text{Lie structure},\\ iC_{kl}^{ij}\hat{u}^k\hat{u}^l, & C_{kl}^{ij}\in \mathrm{IC}, \quad \text{quantum plane}, \end{cases} \tag{D1}$$

where IC denotes the complex number field.

The noncommutative space is modeled as the associative algebra of IC; this algebra is freely generated by the coordinates modulo ideal $\mathcal{R}$ generated by the relations (one accepts formal power series) $\mathcal{A}_u=\mathrm{IC}[[\hat{u}^1,\ldots,\hat{u}^N]]/\mathcal{R}$. One restricts attention[94] to algebras having the (so-called, Poincaré–Birkhoff–Witt) property that any element of $\mathcal{A}_u$ is defined by its coefficient function and vice versa,

$$\hat{f}=\sum_{L=0}^{\infty} f_{i_1,\ldots,i_L}{:}\hat{u}^{i_1}\cdots\hat{u}^{i_L}{:} \quad \text{when } \hat{f}\sim\{f_i\},$$

where: $\hat{u}^{i_1}\cdots\hat{u}^{i_L}$: denotes that the basis elements satisfy some prescribed order (for instance, the normal order $i_1\leqslant i_2\leqslant\cdots\leqslant i_L$, or, another example, are totally symmetric). The algebraic properties are all encoded in the so-called diamond ($\diamondsuit$) product which is defined by

$$\hat{f}\hat{g}=\hat{h}\sim\{f_i\}\diamondsuit\{g_i\}=\{h_i\}.$$

In the mentioned approach to every function $f(u)=f(u^1,\ldots,u^N)$ of commuting variables $u^1,\ldots,u^N$ one associates an element of algebra $\hat{f}$ when the commuting variables are substituted by anticommuting ones,

$$f(u)=\sum f_{i_1,\ldots,i_L}u^1\cdots u^N\to\hat{f}=\sum_{L=0}^{\infty} f_{i_1,\ldots,i_L}{:}\hat{u}^{i_1}\cdots\hat{u}^{i_L}{:}$$

when the $\diamondsuit$ product leads to a bilinear $*$-product of functions (see details in Ref. 70)

$$\{f_i\}\diamondsuit\{g_i\}=\{h_i\}\sim(f*g)(u)=h(u).$$

The $*$-product is defined, respectively, for the cases (D1);

$$f*g=\begin{cases} \exp\left[\dfrac{i}{2}\dfrac{\partial}{\partial u^i}\theta^{ij}\dfrac{\partial}{\partial u'^j}\right]f(u)g(u')|_{u'\to u},\\ \exp\left[\dfrac{i}{2}u^k g_k\left(i\dfrac{\partial}{\partial u'},i\dfrac{\partial}{\partial u''}\right)\right]f(u')g(u'')|_{u''\to u}^{u'\to u},\\ q^{1/2[-u'(\partial/\partial u')v(\partial/\partial v)+u(\partial/\partial u)v'(\partial/\partial v')]}f(u,v)g(u',v')|_{v'\to v}^{u'\to u}, \end{cases}$$

where there are considered values of type

$$e^{ik_n\hat{u}^n},\quad e^{ip_n\hat{u}^n}=e^{i\{k_n+p_n+1/2g_n(k,p)\}\hat{u}^n},$$

$$g_n(k,p)=-k_ip_jf_n^{ij}+\tfrac{1}{6}k_ip_j(p_k-k_k)f_m^{ij}f_n^{mk}+\cdots, \tag{D2}$$

$$e^Ae^B=e^{A+B+1/2[A,B]+1/12([A,[A,B]]+[B,[B,A]])}+\cdots,$$

and for the coordinates on quantum (Manin) planes one holds the relation $uv=qvu$.

A non-Abelian gauge theory on a noncommutative space is given by two algebraic structures, the algebra $\mathcal{A}_u$ and a non-Abelian–Lie algebra $\mathcal{A}_I$ of the gauge group with generators $I^1,\ldots,I^S$ and the relations

$$[I^{\underline{s}},I^{\underline{p}}]=if^{\underline{sp}}_{\underline{t}}I^{\underline{t}}. \tag{D3}$$

In this case both algebras are treated on the same footing and one denotes the generating elements of the big algebra by $\hat{u}^{i}$,

$$\hat{z}^{\underline{i}}=\{\hat{u}^{1},\ldots,\hat{u}^{N},I^{1},\ldots,I^{S}\},\quad \mathcal{A}_{z}=\mathrm{IC}[[\hat{u}^{1},\ldots,\hat{u}^{N+S}]]/\mathcal{R}$$

and the $*$-product formalism is to be applied for the whole algebra $\mathcal{A}_{z}$ when there are considered functions of the commuting variables u^{i} $(i,j,k,\ldots=1,\ldots,N)$ and $I^{\underline{s}}$ $(s,p,\ldots=1,\ldots,S)$.

For instance, in the case of a canonical structure for the space variables u^{i} we have

$$(F*G)(u)=\exp\left[\frac{i}{2}\left(\theta^{ij}\frac{\partial}{\partial u'^{i}}\frac{\partial}{\partial u''^{j}}+t^{s}g_{s}\left(i\frac{\partial}{\partial t'},i\frac{\partial}{\partial t''}\right)\right)\times F(u',t')G(u'',t'')\Big|^{u'\to u,u''\to u.}_{t'\to t,t''\to t}\right]. \tag{D4}$$

This formalism was developed in Ref. 90 for general Lie algebras.

Two-spinor curvature structures for a class of conformally flat space–times

J. G. Cardoso
Department of Mathematics, Centre for Technological Sciences-UDESC, Joinville 89223-100 SC, Brazil

(Received 22 November 2004; accepted 24 January 2005; published online 22 March 2005)

A well-known class of conformally flat space–times which admit decomposable Christoffel connexions is considered. It is shown that the corresponding spin-affine configurations can be constructed within the framework of Infeld–van-der-Waerden's γ-formalism only if a specific constancy property is imposed on one of the densities borne by the expression for a typical metric function. Explicit expressions for the gravitational spinors of those space–times are then derived. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1876871]

I. INTRODUCTION

The present paper can be looked upon as an application of Infeld–van-der-Waerden's γ-formalism[1–5] that may be of a cosmological interest. Our procedures take up a work carried out originally by Penrose and Rindler,[6,7] which involves the utilization of a decomposable Christoffel connexion along with a particular spin-affine pattern for describing some properties of a class of conformally flat space–times. We establish that the consistency of the overall situation will be ensured only if the independent entry of any γ-metric spinor is taken to bear a specialized world-gauge form. In fact, this prescription automatically entails ascribing a specific symmetry property to the relevant spin-affine connexions, and likewise suggests a simple mechanism that allows one to keep track of all strongly required world behaviors[3] in a natural way. We deduce the conformal-flatness property by showing explicitly that the corresponding wave functions for gravitons vanish identically. It appears, in addition, that one of Infeld's expressions for Ricci scalars[2] becomes completely recoverable when the case of a real γ-metric function is effectively allowed for.

The world-spinor-index notation of Ref. 6 will be adopted throughout the work. Vertical bars surrounding an index block will mean that the indices singled out are not to partake of a symmetry operation. Space–time coordinates and a typical covariant world-metric tensor are denoted as x^a and g_{ab}, with

$$\partial_a \doteq \frac{\partial}{\partial x^a}.$$

One of the γ-metric spinors is set as

$$(\gamma_{AB}) = \begin{pmatrix} 0 & \gamma \\ -\gamma & 0 \end{pmatrix}, \quad \gamma = |\gamma| \exp(i\Phi),$$

where $(|\gamma|, \Phi)$ stands for a pair of differentiable real-valued world invariants. The Hermitian connecting objects for the γ-formalism are presumably taken as the elements of

$$\{\sigma_{aBB'}, \sigma^{a}_{BB'}, \sigma_{a}^{BB'}, \sigma^{aBB'}\},$$

while an appropriate unprimed-index spin connexion for it is written as $\gamma_{aB}{}^{C}$. For the eigenvalue occurring in the equation (see Ref. 5)

$$\partial_a \gamma_{AB} = \alpha_a \gamma_{AB},$$

we have the identification $\alpha_a = iK_a - \theta_a$, with

$$\theta_a = \partial_a \log|\gamma|^{-1}, \quad K_a \doteqdot \partial_a \Phi.$$

Some further conventions will be explained in due course.

We have outlined the paper as follows. All the specific metric and affine prescriptions are obtained in Sec. II. It will be expedient to build up in Sec. III some partial-derivative computational devices. The pertinent curvature structures are exhibited in Sec. IV. We shall make a few remarks on our work in Sec. V.

II. METRIC AND AFFINE PRESCRIPTIONS

Within the framework of the γ-formalism, the key metric prescription is written as[5]

$$|\gamma|^4 = \mu(-\mathfrak{g})^{1/2}, \tag{1}$$

where μ amounts to a real spin-scalar density of world weight -1 and absolute weight $+4$, which is defined by

$$\partial_a \log \mu = \sigma_b^{BB'} \partial_a \sigma_{BB'}^b. \tag{2}$$

These structures yield at once the expression

$$(-4)\theta_a = \partial_a \log[\mu(-\mathfrak{g})^{1/2}]. \tag{3}$$

Equation (3) can be specialized to the case wherein μ is identified with a density c that particularly bears ∂-constancy in a given world frame, namely

$$\sigma_b^{BB'} \partial_a \sigma_{BB'}^b = 0, \tag{4}$$

and, consequently, θ_a takes the noncovariant form

$$(-4)\theta_a = \partial_a \log[c(-\mathfrak{g})^{1/2}] = \Gamma_a. \tag{5}$$

Indeed, the required world covariance of γ_{aBC} and its complex conjugate[1] is simply recovered from the coordinate-transformation law (our Jacobian functional determinant Δ_W is the inverse of that used in Ref. 8)

$$c' = (\Delta_W)^{-1} c, \tag{6}$$

which also guarantees the world invariance of $|\gamma|$. The constancy of μ in the former world frame can be thought of as playing a "catalytic" role in the construction of a covariant vector θ_a from a metric expression of the form (3). Obviously, the affine relationship borne by Eq. (5) applies only to one of the frames of each character being eventually dealt with, while the law (6) ensures that the world behavior of the standard correlation[5]

$$\Gamma_{AA'BB'CC'} + \sigma_{sCC'} \partial_{AA'} \sigma_{BB'}^s = \gamma_{AA'BC} \gamma_{B'C'} + \gamma_{AA'B'C'} \gamma_{BC}, \tag{7}$$

will remain appropriately specified when Eq. (5) is actually called for.

To effectively derive the explicit affine expressions associated to the specialization (4), we initially make use of the eigenvalue equation

$$\partial_a(\gamma_{BC}\gamma_{B'C'}) = (-2\theta_a)\gamma_{BC}\gamma_{B'C'}, \tag{8}$$

together with its upper-spinor-index version, and implement configurations of the type

$$\sigma_b^{BB'}\partial_a\sigma_{BB'}^b = \sigma_b^{BB'}\partial_a(\sigma^{bCC'}\gamma_{CB}\gamma_{C'B'}). \tag{9}$$

Such a procedure leads us to the equations

$$\partial_a\sigma^{bBB'} = \left(-\tfrac{1}{2}\right)\Gamma_a\sigma^{bBB'}, \quad \partial_a\sigma_{bBB'} = \tfrac{1}{2}\Gamma_a\sigma_{bBB'}, \tag{10}$$

which immediately imply that

$$\partial_a g^{bc} = \left(-\tfrac{1}{2}\right)\Gamma_a g^{bc}, \quad \partial_a g_{bc} = \tfrac{1}{2}\Gamma_a g_{bc}. \tag{11}$$

We are then led to the constancy properties

$$\partial_a\sigma_b^{BB'} = 0, \quad \partial_a\sigma_{BB'}^b = 0, \tag{12}$$

along with the affine relationships[5]

$$\Gamma_{A(BC)A'(B'C')} = 0, \quad \tfrac{1}{2}\Gamma_{A(BC)A'D'}{}^{D'} = \theta_{A'(B}\,\gamma_{C)A} = \gamma_{AA'(BC)}, \tag{13}$$

which clearly satisfy

$$\gamma_{A'(ABC)} = 0. \tag{14}$$

It follows that we can write down the expansion[6]

$$\gamma_{AA'BC} = \theta_{BA'}\gamma_{CA} - i\Phi_{AA'}\gamma_{BC}, \tag{15}$$

from which we get the world expression

$$\Gamma_{abc} = \tfrac{1}{2}\sigma_c^{BB'}\sigma_{B'(a}^{A}\,\sigma_{b)B}^{A'}\Gamma_{AA'}, \tag{16}$$

with the quantity Φ_a being taken (the expansion given in Ref. 6 differs from ours by an overall "minus" sign) as a covariant world vector that bears a well-specified physical meaning (for further details, see Refs. 3 and 5). Hence, working out the index configuration of Eq. (16) produces the structures

$$\Gamma_{AA'BB'CC'} = \tfrac{1}{2}[\sigma_{CC'}^{h}(\partial_{BB'}\sigma_{hAA'} + \partial_{AA'}\sigma_{hBB'}) - \sigma_{BB'}^{h}\partial_{CC'}\sigma_{hAA'}] \tag{17}$$

and

$$\Gamma_{abc} = \tfrac{1}{2}\Gamma_{(a}\,g_{\,b)c} - \tfrac{1}{4}g_{ab}\Gamma_c. \tag{18}$$

We should observe that the first of Eqs. (13) amounts to the same thing as saying that the trace-free part of $\Gamma_{a(bc)}$ equals zero.

It will be established later in Sec. IV that world affinities of the type prescribed by Eq. (18) give rise to identically vanishing Weyl tensors, and thus specify parallel displacements in conformally flat space–times. In any such case, we can write down the derivatives

$$\nabla_{AA'}w_{BB'} = \partial_{AA'}w_{BB'} + \theta_{BA'}w_{AB'} + \theta_{AB'}w_{BA'} \tag{19}$$

and

$$\nabla_{AA'}u^{BB'} = \partial_{AA'}u^{BB'} - 2\theta_{AA'}u^{BB'} + \theta_A^B u_A^{B'} + \theta_A^{B'}u_{A'}^B, \tag{20}$$

which can therefore be reset as

$$\nabla_a w_b = \partial_a w_b + \tfrac{1}{4}g_{ab}(\Gamma^c w_c) - \tfrac{1}{2}\Gamma_{(a}\,w_{\,b)} \tag{21}$$

and

$$\nabla_a u^b = \partial_a u^b + \tfrac{1}{4}[(\Gamma_c u^c)\delta_a{}^b + \Gamma_a u^b - g_{ac}\Gamma^b u^c], \tag{22}$$

with $\Gamma^a \doteq g^{ab}\Gamma_b$.

III. ∂-DEVICES

Equations (12) make it legitimate to account for the spinor commutator

$$[\partial_{AA'}, \partial_{BB'}] = \sigma^a_{AA'}\sigma^b_{BB'}[\partial_a, \partial_b] = 0. \tag{23}$$

Transvecting (23) with γ^{AB} and $\gamma^{A'B'}$ provides us with the commutativity property

$$\partial^A_{(A'}\,\partial_{B')A} = 0 \Rightarrow \partial^A_{A'}\partial_{B'A} = \partial^A_{[A'}\,\partial_{B']A}, \tag{24}$$

along with its complex conjugate. Then, using either of the relations

$$\partial^A_{(A'}\,\partial_{B')A} = \partial^A_{(A'}\,(\gamma_{|BA|}\partial^B_{B')}), \quad \partial^A_{(A'}\,\partial_{B')A} = \gamma^{AB}\partial_{B(A'}\,\partial_{B')A}, \tag{25}$$

yields the derivative-order lowering device

$$\partial_{A(A'}\,\partial^A_{B')} = (-1)\alpha_{A(A'}\,\partial^A_{B')}, \tag{26}$$

together with the formal bivector splittings (henceforth, the symbol "c.c." will stand for an overall complex-conjugate piece),

$$[\partial_{AA'}, \partial_{BB'}] = (-1)(\gamma_{AB}\partial^C_{(A'}\,\partial_{B')C} + \text{c.c.}), \tag{27}$$

and

$$[\partial_{AA'}, \partial_{BB'}] = \gamma_{AB}(\partial_{C(A'}\,\partial^C_{B')} + \alpha_{C(A'}\,\partial^C_{B')}) + \text{c.c.} \tag{28}$$

It should be pointed out that the only ∂-prescriptions for manipulating adequately skew two-covariant-index structures are supplied by the rules

$$\partial_{A'[A}\,\partial_{B]B'} = \tfrac{1}{2}\gamma_{BA}\partial^C_{A'}\partial_{B'C} = \tfrac{1}{2}\partial_{A'C}(\gamma_{AB}\partial^C_{B'}), \tag{29}$$

and their complex conjugates. We thus have the useful relations

$$\partial_{AA'}\partial_{BB'} = \partial_{(A(A'}\,\partial_{B')B)} + \tfrac{1}{4}\gamma_{AB}\gamma_{A'B'}g^{ch}\partial_c\partial_h, \tag{30}$$

$$2(\partial_{AA'} + \alpha_{AA'})\partial^A_{B'} = 2(\partial_{A[A'} + \alpha_{A[A'})\partial^A_{B']} = \gamma_{A'B'}(\alpha^h\partial_h - \partial^{C'}_A\partial^A_{C'}), \tag{31}$$

and

$$\gamma^{AB}\partial^{C'}_D(\gamma_{AB}\partial^D_{C'}) = (-2)\partial^{CC'}\partial_{CC'} = \gamma^{A'B'}\partial^C_{D'}(\gamma_{A'B'}\partial^{D'}_C). \tag{32}$$

Therefore, we can utilize the configurations

$$\partial_{CA'}\partial^C_{B'} + \alpha_{CA'}\partial^C_{B'} = (-1)\partial^C_{A'}\partial_{CB'} \tag{33}$$

and

$$2(\partial_{AA'} + \alpha_{AA'})\partial^A_{B'} = \gamma_{A'B'}\partial^{CC'}\partial_{CC'}. \tag{34}$$

A remarkable feature of the upper-spinor-index version of Eq. (23) is the fact that a relation formally similar to (26) can also be derived, but now *no* zero operator actually arises. This result

reflects the noncommutativity of the partial-derivative operators that carry upper-world indices, namely

$$\partial^a \doteq g^{ab}\partial_b, \quad [\partial^a,\partial^b] = 2(\partial^{[a}\, g^{\,b]c})\partial_c = 4\theta^{[a}\,\partial^{\,b]}. \tag{35}$$

As regards the last equality of (35), it is worth observing that

$$g^{c[a}\, g^{\,b]h}\partial_c\partial_h = g^{a[c}\, g^{\,h]b}\partial_c\partial_h = 0. \tag{36}$$

We also remark that Eqs. (12) guarantee the applicability of the relations

$$\partial^{\mathcal{C}}\partial_c = \partial^{CC'}\partial_{CC'}, \quad \partial_c\partial^{\mathcal{C}} = \partial_{CC'}\partial^{CC'}. \tag{37}$$

A short calculation then gives the spinor relationships

$$\partial^{C'(A}\,\partial^{\,B)}_{C'} = \theta^{C'(A}\,\partial^{\,B)}_{C'} - iK^{C'(A}\,\partial^{\,B)}_{C'} \tag{38}$$

and

$$\partial^{(A'}_{C}\,\partial^{\,B')C} = 2\,\theta^{(A'}_{C}\,\partial^{\,B')C}, \tag{39}$$

as well as their complex conjugates. We thus have the structures

$$\gamma_{AC}\gamma_{BD}\partial^{C'(C}\,\partial^{\,D)}_{C'} = (-1)\,\alpha^{C'}_{(A}\,\partial_{\,B)C'}, \tag{40}$$

and

$$\gamma_{A'C'}\gamma_{B'D'}\partial^{(C'}_{C}\,\partial^{\,D')C} = (-2)(\mathrm{Re}\;\alpha^h)\sigma_{hC(A'}\,\partial^{C}_{\,B')}, \tag{41}$$

which, when worked out explicitly, turn out to agree with Eqs. (25) and (26). We notice that the contravariant counterparts of the devices (29) must be written as

$$\partial^{A'[A}\,\partial^{\,B]B'} = \tfrac{1}{2}\gamma^{AB}\partial^{A'}_{C}\,\partial^{B'C} = \tfrac{1}{2}\partial^{A'C}(\gamma^{BA}\partial^{B'}_{C}), \tag{42}$$

and, consequently, we can likewise put into practice the upper-primed-index version of the correlation (33), namely

$$\partial^{A'}_{C}\partial^{B'C} + \alpha^{A'}_{C}\,\partial^{B'C} = (-1)\partial^{CA'}\partial^{B'}_{C}. \tag{43}$$

Accordingly, the contravariant bivector configuration may be set as

$$[\partial^{AA'},\partial^{BB'}] = \gamma^{AB}\partial^{(A'}_{M}\,\partial^{\,B')M} + \gamma^{A'B'}\partial^{(A}_{M'}\partial^{\,B)M'}. \tag{44}$$

For some differentiable object χ_a, we particularly have the device

$$\partial_{AA'}\chi^{A}_{B'} + \alpha_{AA'}\chi^{A}_{B'} = (-1)\partial^{A}_{A'}\chi_{AB'}. \tag{45}$$

In case $\chi_a = \partial_a f$, with f being some adequate numerical function, Eq. (24) will immediately supply the skew-symmetry relation

$$\partial^{A}_{A'}\chi_{AB'} = \partial^{A}_{[A'}\,\chi_{\,B']A}. \tag{46}$$

Thus, on the basis of Eqs. (11) and (29), we can implement the statements

$$(-2)\partial^{A}_{[A'}\,\chi_{\,B']A} = \gamma_{A'B'}\partial^h\chi_h = \gamma_{A'B'}\Omega_h\chi^h \tag{47}$$

and

$$\partial_{A(A'}\,\chi^{A}_{\ B')} = (-1)\alpha_{A(A'}\,\chi^{A}_{\ B')}, \tag{48}$$

with $\Omega_h \doteq \partial_h - 2\theta_h$. Moreover, since θ_a and K_a are both expressed as ∂-derivatives, we can spell out the eigenvalue equations

$$\partial_{A(A'}\,\theta^{A}_{\ B')} = (-i)K_{A(A'}\,\theta^{A}_{\ B')}, \tag{49}$$

and

$$\partial_{A(A'}\,K^{A}_{\ B')} = \theta_{A(A'}\,K^{A}_{\ B')}, \tag{50}$$

along with their complex conjugates. Equations (47) and (48) will play a significant role in the development of Sec. IV.

IV. CURVATURE STRUCTURES

There are two essentially equivalent procedures for expressing in terms of explicit spin-affine pieces the curvature spinors of the connexion given as Eq. (15). One consists in working out the bivector configurations that arise out of the implementation of generalized covariant spinor commutators,[3,5] while the other just involves the spinor translation of the classical world expression for the Riemann tensor $R_{abc}^{\ \ d}$ of the Christoffel connexion (18). We will adopt the latter procedure here insofar the legitimacy of the work of the preceding section may automatically afford a verification of the curvature formulas for the class of space–times at issue. An identically vanishing Weyl spinor will thus emerge, but the point regarding the admissibility of its symmetries[6,9,10] will be illustrated. The configurations arising at this stage coincide with the cosmological ones afforded by Ref. 11.

To start with, let us consider the contribution

$$\begin{aligned} 2\partial_{[AA'}\,\Gamma_{\ BB']CC'}^{\ \ \ \ \ \ DD'} &= 2\gamma_{C'}^{\ \ D'}\partial_{[AA'}\,\gamma_{\ BB']C}^{\ \ \ D} + \text{c.c.} \\ &= \gamma^{D'}_{\ \ C'}(\gamma_{AB}\partial^{M}_{(A'}\,\gamma_{\ B')MC}^{\ \ \ \ D} + \gamma_{A'B'}\partial^{M'}_{(A}\,\gamma_{\ B)M'C}^{\ \ \ \ D}) + \text{c.c.}, \end{aligned} \tag{51}$$

where the square brackets accordingly mean skew-symmetrization over the index pairs. It is useful to implement the splittings

$$\partial^{M}_{(A'}\,\gamma_{\ B')MC}^{\ \ \ \ D} = \partial^{M}_{(A'}\,[\gamma^{DS}(\gamma_{\ B')M(CS)} + \gamma_{\ B')M[CS]})] \tag{52}$$

and

$$\partial^{M'}_{(A}\,\gamma_{\ B)M'C}^{\ \ \ \ D} = \partial^{M'}_{(A}[\gamma^{DS}(\gamma_{\ B)M'(CS)} + \gamma_{\ B)M'[CS]})], \tag{53}$$

together with their complex conjugates. The overall *CS*-skew contribution of (51) is proportional to

$$\begin{aligned} (\gamma_{AB}\partial^{M}_{(A'}\,\gamma_{\ B')ML}^{\ \ \ \ L} + \gamma_{A'B'}\partial^{M'}_{(A}\,\gamma_{\ B)M'L}^{\ \ \ \ L}) + \text{c.c.} &= (-1)[\gamma_{AB}(\partial^{M}_{(A'}\,\theta_{\ B')M} + 2i\partial^{M}_{(A'}\,\Phi_{\ B')M}) \\ &\quad + \gamma_{A'B'}(\partial^{M'}_{(A}\,\theta_{\ B)M'} + 2i\partial^{M'}_{(A}\,\Phi_{\ B)M'})] + \text{c.c.} \end{aligned} \tag{54}$$

Each of the $\partial\theta$ pieces of Eq. (54) vanishes because of the property (24), whereas each $\partial\Phi$ piece involved explicitly is cancelled by the complex-conjugate contribution. Calling upon the expansion (15), we perform the following calculation [one should notice that $\partial_a\gamma^{AB} = (-\alpha_a)\gamma^{AB}$] for the symmetric parts of Eqs. (52) and (53):

$$\gamma_{AB}\partial^{M}_{(A'}(\gamma^{DS}\gamma_{B')M(CS)}) + \gamma_{A'B'}\partial^{M'}_{(A}(\gamma^{DS}\gamma_{B)M'(CS)}) = \gamma^{DS}[\gamma_{AB}(\partial^{M}_{(A'}\gamma_{B')M(CS)} - \alpha^{M}_{(A'}\gamma_{B')M(CS)}) + \gamma_{A'B'}(\partial^{M'}_{(A}\gamma_{B)M'(CS)} - \alpha^{M'}_{(A}\gamma_{B)M'(CS)})] = \gamma^{DS}(\gamma_{A'B'}\gamma_{(C|(A}\partial^{M'}_{B)|}\theta_{S)M'} - \gamma_{AB}\partial_{(C(A'}\theta_{B')S)}). \tag{55}$$

In order to make up the expression for the left-hand side of (51), we invoke the complex-conjugate version of Eqs. (47) and (48), to obtain

$$\gamma_{(C|(A}\partial^{M'}_{B)|}\theta_{S)M'} = \left(-\tfrac{1}{2}\right)\gamma_{C(A}\gamma_{B)S}\Omega_h\theta^h. \tag{56}$$

Thus, the overall $\partial\Gamma$-contribution reads

$$2\partial_{[AA'}\Gamma_{BB']CC'}{}^{DD'} = \gamma_{C'}{}^{D'}\gamma^{DS}\left(\tfrac{1}{2}\gamma_{A'B'}\gamma_{C(A}\gamma_{B)S}\Omega_h\theta^h + \gamma_{AB}\partial_{(C(A'}\theta_{B')S)}\right) + \text{c.c.} \tag{57}$$

The relevant quadratic Γ term is written out as the bivector configuration

$$2\Gamma_{MM'[AA'}{}^{DD'}\Gamma_{BB']CC'}{}^{MM'} = [\gamma_{AB}(\gamma^{D'}{}_{(A'}\gamma_{B')SC}{}^{M}\gamma_{MC'}{}^{SD} + \gamma^{D'}{}_{(A'}\gamma_{B')SC'}{}^{M'}\gamma_{CM'}{}^{SD}) + \gamma_{A'B'}(\gamma_{MC'(A}{}^{D}\gamma^{D'}_{B)C}{}^{M} + \gamma_{CM'(A}{}^{D}\gamma^{D'}_{B)C'}{}^{M'})] + \text{c.c.} \tag{58}$$

Manipulating the indices of Eqs. (15) and (58) gives

$$2\Gamma_{MM'[AA'}{}^{DD'}\Gamma_{BB']CC'}{}^{MM'} = [\gamma_{AB}(\gamma^{D'}{}_{(A'}\theta_{B')C}\theta^{D}_{C'} - \gamma^{D'}{}_{(A'}\theta^{M}_{B')}\theta_{MC'}\gamma^{D}{}_{C}) + \gamma_{A'B'}(\theta^{D'}_{(A}\theta_{B)C'}\gamma_{C}{}^{D} - \gamma^{D}{}_{(A}\theta_{B)C'}\theta^{D'}_{C})] + \text{c.c.} \tag{59}$$

Hence, lowering the indices DD' of (57) and (59), after rearranging conjugate pieces and implementing the computational results

$$\gamma_{C'D'}\gamma_{D(A}\theta^{M'}_{B)}\theta_{CM'} + \gamma_{D(A}\theta_{B)C'}\theta_{CD'} + \gamma_{CD}\theta_{D'(A}\theta_{B)C'} + \theta_{CD'}\theta_{C'(A}\gamma_{B)D} = \gamma_{CD}\theta_{(C'(A}\theta_{B)D')} + \gamma_{C'D'}\theta_{M'(A}\gamma_{B)(C}\theta^{M'}_{D)} \tag{60}$$

and

$$\theta_{M'(A}\gamma_{B)(C}\theta^{M'}_{D)} = \left(-\tfrac{1}{2}\right)\gamma_{C(A}\gamma_{B)D}\theta_h\theta^h, \tag{61}$$

we arrive at the irreducible expression

$$R_{AA'BB'CC'DD'} = \gamma_{A'B'}\left[\gamma_{CD}(\partial_{(C'(A}\theta_{B)D')} + \theta_{(C'(A}\theta_{B)D')}) + \tfrac{1}{2}\gamma_{C'D'}\gamma_{C(A}\gamma_{B)D}(\Omega_h\theta^h - \theta_h\theta^h)\right] + \text{c.c.} \tag{62}$$

We emphasize that the Riemann spinor (62) bears world invariance. In essence, this comes from the fact that the operator Ω_h can be expressed covariantly as $(\nabla_h + 2\theta_h)$ upon acting on θ^h.

To carry through our main procedure, we simply apply to the left-hand side of Eq. (62) the formal definitions

$$\mathrm{X}_{ABCD} \doteqdot \tfrac{1}{4}M^{A'B'}M^{C'D'}R_{AA'BB'CC'DD'} \tag{63}$$

and

$$\Xi_{CA'DB'} \doteqdot \tfrac{1}{4}M^{AB}M^{C'D'}R_{AA'BB'CC'DD'}, \tag{64}$$

which amount to the gravitational spinors of $\gamma_{aB}{}^{C}$. We thus readily obtain the structures

$$\mathrm{X}_{ABCD} = \tfrac{1}{2}(\partial_h \theta^h - 3\theta_h \theta^h)\gamma_{C(A}\,\gamma_{B)D} = \tfrac{1}{2}(\nabla_h \theta^h + \theta_h \theta^h)\gamma_{C(A}\,\gamma_{B)D} \tag{65}$$

and

$$\Xi_{CA'DB'} = \partial_{(C(A'}\,\theta_{B')D)} + \theta_{(C(A'}\,\theta_{B')D)}, \tag{66}$$

which exhibit all the characteristic symmetries. (The most natural procedure for fixing the symmetries of the $X\Xi$ spinors is provided in Ref. 5.) Evidently, the X-spinor (65) bears a purely cosmological character, that is to say,

$$\mathrm{X}_{(ABCD)} \doteq \Psi_{ABCD} \equiv 0, \tag{67}$$

while the Ricci tensor of the connexion (18) appears to be associated to the configuration

$$R_{AA'BB'} = \left(-\tfrac{3}{2}\right)(\nabla_h \theta^h + \theta_h \theta^h)\gamma_{AB}\gamma_{A'B'} - 2(\partial_{(A(A'}\,\theta_{B')B)} + \theta_{(A(A'}\,\theta_{B')B)}), \tag{68}$$

which promptly yields the cosmological expressions

$$\lambda = \tfrac{3}{2}(3\theta_h \theta^h - \partial_h \theta^h) = \left(-\tfrac{3}{2}\right)(\nabla_h \theta^h + \theta_h \theta^h), \tag{69}$$

where λ is the so-called cosmological constant.[6,12]

The structures exhibited previously give rise to an expression for a Ricci scalar that coincides in the case of a real eigenvector α_a with a formula given much earlier by Infeld.[2] An easy way of deducing this result involves first implementing the relation

$$\partial_a \theta^a = \partial^A_{A'}\partial^{A'}_A \log|\gamma| - \alpha_a \theta^a, \tag{70}$$

and then performing the calculation

$$R = 6(3\theta_a \theta^a - \partial_a \theta^a) = 6[2\theta_a \theta^a + (iK_a \theta^a - \partial^A_{A'}\partial^{A'}_A \log|\gamma|)] = 3\left[4\theta_a \theta^a + 2iK_a \theta^a - \partial^A_{A'}\left(\frac{1}{|\gamma|^2}\partial^{A'}_A |\gamma|^2\right)\right]$$

$$= 3\left(2iK_a \theta^a - \frac{1}{|\gamma|^2}\partial^A_{A'}\partial^{A'}_A |\gamma|^2\right). \tag{71}$$

V. CONCLUSIONS AND OUTLOOK

The work we have presented above sheds some light on the spinor description of conformally flat space–times that bear affine structures having the form specified by Eq. (18). It thereby clarifies once and for all the situation concerning the geometric significance of the choice (14). We believe that it would be worthwhile to derive a set of pertinent world-transformation laws. It can be shown that, under the circumstances stipulated in Sec. II, any properties like those exhibited as Eqs. (12) must behave invariantly under the action of manifold mapping groups. We will probably elaborate upon these matters elsewhere.

A note on positive energy theorem for spaces with asymptotic SUSY compactification

Xianzhe Dai
Mathematics, University of California Santa Barbara, Santa Barbara, California 93106

(Received 22 November 2004; accepted 5 January 2005; published online 23 March 2005)

We extend the higher dimensional positive mass theorem in [Dai, X., Commun. Math. Phys. **244**, 335–345 (2004)] to the Lorentzian setting. This includes the original higher dimensional positive energy theorem whose spinor proof is given in [Witten, E., Commun. Math. Phys. **80**, 381–402 (1981)] and [Parker, T., and Taubes, C., Commun. Math. Phys. **84**, 223–238 (1982)] for dimension 4 and in [Zhang, X., J. Math. Phys. **40**, 3540–3552 (1999)] for dimension 5. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1862095]

I. INTRODUCTION AND STATEMENT OF THE RESULT

In this note, we formulate and prove the Lorentzian version of the positive mass theorem in Ref. 4. There we prove a positive mass theorem for spaces of any dimension which asymptotically approach the product of a flat Euclidean space with a compact manifold which admits a nonzero parallel spinor (such as a Calabi–Yau manifold or any special honolomy manifold except the quaternionic Kähler manifold). This is motivated by string theory, especially the recent work in Ref. 7. The application of the positive mass theorem of Ref. 4 to the study of stability of Ricci flat manifolds is discussed in Ref. 5.

In general relativity, a space–time is modelled by a Lorentzian 4-manifold (N,g) together with an energy-momentum tensor T satisfying Einstein equation

$$R_{\alpha\beta} - \tfrac{1}{2} g_{\alpha\beta} R = 8\pi T_{\alpha\beta}. \tag{1.1}$$

The positive energy theorem[11,14] says that an isolated gravitational system with non-negative local matter density must have non-negative total energy, measured at spatial infinity. More precisely, one considers a complete oriented spacelike hypersurface M of N satisfying the following two conditions.

(a) *M is asymptotically flat*, that is, there is a compact set K in M such that $M-K$ is the disjoint union of a finite number of subsets $M_1,\ldots,M_k$ and each end M_l is diffeomorphic to $\mathbb{R}^3 - B_R(0)$. Moreover, under this diffeomorphism, the metric of M_l is of the form

$$g_{ij} = \delta_{ij} + O(r^{-\tau}), \quad \partial_k g_{ij} = O(r^{-\tau-1}), \quad \partial_k \partial_l g_{ij} = O(r^{-\tau-2}). \tag{1.2}$$

Furthermore, the second fundamental form h_{ij} of M in N satisfies

$$h_{ij} = O(r^{-\tau-1}), \quad \partial_k h_{ij} = O(r^{-\tau-2}). \tag{1.3}$$

Here $\tau > 0$ is the asymptotic order and r is the Euclidean distance to a base point.

(b) *M has non-negative local mass density*: for each point $p \in M$ and for each timelike vector e_0 at p, $T(e_0,e_0) \geqslant 0$ and $T(e_0,\cdot)$ is a nonspacelike covector. This implies the dominant energy condition

$$T^{00} \geqslant |T^{\alpha\beta}|, \quad T^{00} \geqslant (-T_{0i}T^{0i})^{1/2}. \tag{1.4}$$

The total energy (the ADM mass) and the total (linear) momentum of M can then be defined as follows[1,10] [for simplicity we suppress the dependence here on l (the end M_l)]:

$$E = \lim_{R\to\infty} \frac{1}{4\omega_n} \int_{S_R} (\partial_i g_{ij} - \partial_j g_{ii}) * \mathrm{d}x_j,$$
$$P_k = \lim_{R\to\infty} \frac{1}{4\omega_n} \int_{S_R} 2(h_{jk} - \partial_{jk} h_{ii}) * \mathrm{d}x_j. \tag{1.5}$$

Here $x_1, \ldots, x_n$ are the Euclidean coordinates on the end; $*$ denotes the Hodge star operator; ω_n denotes the volume of the $n-1$ sphere and S_R the Euclidean sphere with radius R centered at the base point. When the asymptotic order $\tau > (n-2)/2$, these quantities are finite and independent of the asymptotic coordinates. [Here $n=3$.]

Theorem 1.1: (Refs. 12–14): *With the assumptions as above and assuming that M is spin, one has*

$$E - |P| \geqslant 0$$

on each end M_l. Moreover, if $E=0$ for some end M_l, then M has only one end and N is flat along M.

Now, according to string theory,[2] our universe is really 10-dimensional, modelled on $\mathbb{R}^{3,1} \times X$ where X is a Calabi–Yau threefold. This is the so-called Calabi–Yau compactification[6] which motivates the spaces we now consider.

Thus we consider a Lorentzian manifold N [with signature $(-, +, \cdots, +)$] of $\dim N = n+1$, with a energy-momentum tensor satisfying the Einstein equation. Then let M be a complete oriented spacelike hypersurface in N. Further, assume that the Riemannian manifold (M^n, g) with g induced from the Lorentzian metric decomposes $M = M_0 \cup M_1 \cup \cdots \cup M_s$, where M_0 is compact as before but now each of the ends $M_l \simeq (\mathbb{R}^k - B_R(0)) \times X_l$ for some radius $R > 0$ and X_l a compact simply connected spin manifold which admits a nonzero parallel spinor. Moreover the metric on each M_l satisfies

$$g = \mathring{g} + u, \quad \mathring{g} = g_{\mathbb{R}^k} + g_X, \quad u = O(r^{-\tau}), \quad \mathring{\nabla} u = O(r^{-\tau-1}), \quad \mathring{\nabla}\mathring{\nabla} u = O(r^{-\tau-2}), \tag{1.6}$$

and the second fundamental form h of M in N satisfies

$$h = O(r^{-\tau-1}), \quad \mathring{\nabla} h = O(r^{-\tau-2}). \tag{1.7}$$

Here $\mathring{\nabla}$ is the Levi–Civita connection of $\mathring{g}$ (extended to act on all tensor fields), r the Euclidean distance in the Euclidean factor, and $\tau > 0$ is the asymptotical order.

The total energy and total momentum for each end M_l can then be defined by (again we suppress the dependence on l here)

$$E = \lim_{R\to\infty} \frac{1}{4\omega_k vol(X)} \int_{S_R\times X} (\partial_i g_{ij} - \partial_j g_{aa}) * \mathrm{d}x_j \, \mathrm{d}vol(X),$$
$$P_k = \lim_{R\to\infty} \frac{1}{4\omega_k vol(X)} \int_{S_R\times X} 2(h_{jk} - \partial_{jk} h_{ii}) * \mathrm{d}x_j \, \mathrm{d}vol(X). \tag{1.8}$$

Here the $*$ operator is the one on the Euclidean factor, the index i, j run over the Euclidean factor and g_{aa} is the trace of the metric g on the manifold M.

Then we have the following.

Theorem 1.2: *Assuming that M is spin and $\tau > (k-2)/2$, $k \geqslant 2$, one has*

$$E - |P| \geqslant 0$$

on each end M_l. Moreover, if $E=0$ for some end M_l, then M has only one end and N is flat along M.

In particular, this result includes the original positive energy theorem whose spinor proof is given in Refs. 14 and 10 for dimension 4 and in Ref. 15 for dimension 5. The dimension specific nature in these work is due to the use of special isomorphisms of low dimensional spin groups. Here we construct the desired metrics directly using the Clifford algebra .

Remark: If M is globally a product $\mathbb{R}^k \times X$ topologically, then the compact factor X need not be simply connected. The simply connected condition is imposed to guarantee that the spin structure on the ends coincides with the one obtained by restricting the spin structure from the inside.

II. THE HYPERSURFACE DIRAC OPERATOR

We will adapt Witten's spinor method[14] to our situation. For that, we follow the presentation and notations of Ref. 10. The crucial ingredient here is the hypersurface Dirac operator on M, acting on the (restriction of the) spinor bundle of N. Let S be the spinor bundle of N and still denote by the same notation its restriction (or rather, pullback) to M. Denote by ∇ the connection on S induced by the Lorentzian metric on N. The Lorentzian metric on N also induces a Riemannian metric on M, whose Levi–Civita connection gives rise to another connection, $\overline{\nabla}$ on S. The two, of course, differ by a term involving the second fundamental form.

There are two choices of metrics on S, which is another subtlety here. Since part of the treatment in Ref. 10 is special to dimension 4, we will give a construction directly using the Clifford algebra Ref. 8.

Let $\mathrm{SO}(n,1)$ denote the identity component of the groups of orientation preserving isometries of the Minkowski space $\mathbb{R}^{n,1}$. A choice of a unit timelike covector e^0 gives rise to injective homomorphisms α, $\hat{\alpha}$, and a commutative diagram

$$\begin{array}{rccc} \alpha\colon & \mathrm{SO}(n) & \rightarrow & \mathrm{SO}(n,1) \\ & \uparrow & & \uparrow \\ \hat{\alpha}\colon & \mathrm{Spin}(n) & \rightarrow & \mathrm{Spin}(n,1). \end{array} \tag{2.1}$$

We now fix a choice of unit timelike normal covector e^0 of M in N. Let $F(N)$ denote the $\mathrm{SO}(n,1)$ frame bundle of N and $F(M)$ the $\mathrm{SO}(n)$ frame bundle of M. Then $i^*F(N)=F(M)\times_\alpha \mathrm{SO}(n,1)$, where $i\colon M\hookrightarrow N$ is the inclusion. If N is spin, then we have a principal $\mathrm{Spin}(n,1)$ bundle $P_{\mathrm{Spin}(n,1)}$ on N, whose restriction on M is then $i^*P_{\mathrm{Spin}(n,1)}=P_{\mathrm{Spin}(n)}\times_{\hat{\alpha}}\mathrm{Spin}(n,1)$, where $P_{\mathrm{Spin}(n)}$ is the principal $\mathrm{Spin}(n)$ bundle of M. Thus, even if N is not spin, $i^*P_{\mathrm{Spin}(n,1)}$ is still well-defined as long as M is spin.

Similarly, when N is spin, the spinor bundle S on N is the associated bundle $P_{\mathrm{Spin}(n,1)}\times_{\rho_{n,1}}\Delta$, where $\Delta=\mathbb{C}^{2^{[(n+1)/2]}}$ is the complex vector space of spinors and

$$\rho_{n,1}\colon \mathrm{Spin}(n,1)\rightarrow \mathrm{GL}(\Delta) \tag{2.2}$$

is the spin representation. Its restriction to M is given by $i^*P_{\mathrm{Spin}(n,1)}\times_{\rho_{n,1}}\Delta=P_{\mathrm{Spin}(n)}\times_{\rho_n}\Delta$ with

$$\rho_n\colon \mathrm{Spin}(n)\overset{\hat{\alpha}}{\hookrightarrow}\mathrm{Spin}(n,1)\xrightarrow{\rho_{n,1}}\mathrm{GL}(\Delta). \tag{2.3}$$

Again, the restriction is still well defined as long as M is spin.

Let e^0, e^i be an orthonormal basis of the Minkowski space $\mathbb{R}^{n,1}$ such that $|e^0|^2=-1$ (in this section the indices i and j range from 1 to n).

Lemma 2.1: There is a positive definite Hermitian inner product $\langle,\rangle$ on Δ which is Spin(n)-invariant. Moreover, $(s,s')=\langle e^0\cdot s,s'\rangle$ defines a Hermitian inner product which is also Spin(n)-invariant but not positive definite. In fact

$$(v\cdot s,s')=(s,v\cdot s')$$

for all $v\in\mathbb{R}^{n,1}$.

Proof: Detailed study via Γ matrices (Ref. 3, pp. 10 and 11) shows that there is a positive definite Hermitian inner product $\langle,\rangle$ on Δ with respect to which e^i is skew-Hermitian while e^0 is Hermitian. It follows then that $\langle,\rangle$ is Spin(n)-invariant. We now show that $(s,s')=\langle e^0\cdot s,s'\rangle$ defines a Spin(n)-invariant Hermitian inner product. Since e^0 is Hermitian with respect to $\langle,\rangle$, $(,)$ is clearly Hermitian. To show that $(,)$ is Spin(n)-invariant, we take a unit vector v in the Minkowski space, $v=a_0e^0+a_ie^i$, a_0, $a_i\in\mathbb{R}$, and $-a_0^2+\Sigma_{i=1}^n a_i^2=1$. Then

$$\begin{aligned}(vs,vs')&=\langle e^0vs,vs'\rangle=a_0^2\langle e^0e^0s,e^0s'\rangle+a_ia_0\langle e^0e^is,e^0s'\rangle+a_0a_i\langle e^0e^0s,e^is'\rangle+a_ia_j\langle e^0e^is,e^js'\rangle\\&=a_0^2\langle s,e^0s'\rangle-a_ia_j\langle e^je^0e^is,s'\rangle=a_0^2\langle e^0s,s'\rangle+a_ia_j\langle e^0e^je^is,s'\rangle\\&=a_0^2\langle e^0s,s'\rangle-a_i^2\langle e^0s,s'\rangle=-(s,s').\end{aligned}$$

Consequently, $(,)$ is Spin(n)-invariant. The above computation also implies that $v\cdot$ acts as Hermitian operator on Δ with respect to $(,)$. ■

Thus the spinor bundle S restricted to M inherits an Hermitian metric $(,)$ and a positive definite metric $\langle,\rangle$. They are related by the equation

$$(s,s')=\langle e^0\cdot s,s'\rangle. \tag{2.4}$$

Now the hypersurface Dirac operator is defined by the composition

$$\mathcal{D}:\Gamma(M,S)\xrightarrow{\nabla}\Gamma(M,T^*M\otimes S)\xrightarrow{c}\Gamma(M,S), \tag{2.5}$$

where c denotes the Clifford multiplication. In terms of a local orthonormal basis $e_1,e_2,\ldots,e_n$ of TM,

$$\mathcal{D}\psi=e^i\cdot\nabla_{e_i}\psi,$$

where e^i denotes the dual basis.

The two most important properties of hypersurface Dirac operator are the self-adjointness with respect to the metric $\langle,\rangle$ and the Bochner–Lichnerowicz–Weitzenbock formula.[14,10]

Lemma 2.2: Define a $(n-1)$*-form on* M *by* $\omega=\langle\phi,e^i\cdot\psi\rangle\mathrm{int}(e_i)\mathrm{d}vol$*, where* $\mathrm{d}vol$ *is the volume form of the Riemannian metric* g *and* $\mathrm{int}(e_i)$ *is the interior multiplication by* e_i*. We have*

$$[\langle\phi,\mathcal{D}\psi\rangle-\langle\mathcal{D}\phi,\psi\rangle]\mathrm{d}vol=\mathrm{d}\omega.$$

Thus $\mathcal{D}$ *is formally self-adjoint with respect to the* L^2 *metric defined by* $\langle,\rangle$ *and* $\mathrm{d}vol$*.*

Proof: Since ω is independent of the choice of the orthonormal basis, we do our computation locally using a preferred basis. For any given point $p\in M$, choose a local orthonormal frame e_i of TM near p such that $\overline{\nabla e_i}=0$ at p. Extend e_0, e_i to a neighborhood of p in N by parallel translating along e_0 direction. Then, at p, $\nabla_{e_i}e^j=-h_{ij}e^0$ and $\nabla_{e_i}e^0=-h_{ij}e^j$. Therefore (again at p),

$$\begin{aligned}\mathrm{d}\omega&=\nabla_{e_i}\langle\phi,e^i\cdot\psi\rangle\mathrm{d}vol\\&=[((\nabla_{e_i}e^0)\cdot\phi,e^i\cdot\psi)+(e^0\cdot\nabla_{e_i}\phi,e^i\cdot\psi)+(e^0\cdot\phi,(\nabla_{e_i}e^i)\cdot\psi)+(e^0\cdot\phi,e^i\cdot\nabla_{e_i}\psi)]\mathrm{d}vol\\&=[-h_{ij}(e^j\cdot\phi,e^i\cdot\psi)+(e^i\cdot e^0\cdot\nabla_{e_i}\phi,\psi)-h_{ii}(e^0\cdot\phi,e^0\cdot\psi)+\langle\phi,\mathcal{D}\psi\rangle]\mathrm{d}vol\\&=[-h_{ij}(e^i\cdot e^j\cdot\phi,\psi)-\langle\mathcal{D}\phi,\psi\rangle-h_{ii}(e^0\cdot\phi,e^0\cdot\psi)+\langle\phi,\mathcal{D}\psi\rangle]\mathrm{d}vol\\&=[-\langle\mathcal{D}\phi,\psi\rangle+\langle\phi,\mathcal{D}\psi\rangle]\mathrm{d}vol.\end{aligned}$$

■

The second property we need is the Bochner–Lichnerowicz–Weitzenbock formula. For a proof, see Ref. 10.

Lemma 2.3: One has

$$\mathcal{D}^2 = \nabla^* \nabla + \mathcal{R},$$
$$\mathcal{R} = \tfrac{1}{4}(R + 2R_{00} + 2R_{0i}e^0 \cdot e^i \cdot) \in \mathrm{End}(S). \tag{2.6}$$

Here the adjoint ∇^* is with respect to the metric $\langle,\rangle$.

III. PROOF OF THE THEOREM

By the Einstein equation,

$$\mathcal{R} = 4\pi(T_{00} + T_{0i}e^0 \cdot e^i \cdot).$$

It follows then from the dominant energy condition (1.4) that

$$\mathcal{R} \geqslant 0. \tag{3.1}$$

Now, for $\phi \in \Gamma(M,S)$ and a compact domain $\Omega \subset M$ with smooth boundary, the Bochner–Lichnerowicz–Weitzenbock formula yields

$$\int_\Omega [|\nabla \phi|^2 + \langle \phi, \mathcal{R}\phi\rangle - |\mathcal{D}\phi|^2]\mathrm{d}vol(g) = \int_{\partial\Omega} \sum \langle (\nabla_{e_a} + e_a \cdot \mathcal{D})\phi, \phi\rangle \mathrm{int}(e_a)\mathrm{d}vol(g) \tag{3.2}$$

$$= \int_{\partial\Omega} \sum \langle (\nabla_\nu + \nu \cdot \mathcal{D})\phi, \phi\rangle \mathrm{d}vol(g|_{\partial\Omega}), \tag{3.3}$$

where e_a is an orthonormal basis of g and ν is the unit outer normal of $\partial\Omega$.

Now without loss of generality, assume that M has only one end. That is, let the manifold $M = M_0 \cup M_\infty$ with M_0 compact and $M_\infty \simeq (\mathbb{R}^k - B_R(0)) \times X$, and (X, g_X) a compact Riemannian manifold with nonzero parallel spinors. Moreover, the metric g on M satisfies (1.6). Let e_a^0 be the orthonormal basis of $\mathring{g}$ which consists of $\partial/\partial x_i$ followed by an orthonormal basis f_α of g_X. Orthonormalizing e_a^0 with respect to g gives rise an orthonormal basis e_a of g. Moreover,

$$e_a = e_a^0 - \tfrac{1}{2}u_{ab}e_b^0 + O(r^{-2\tau}). \tag{3.4}$$

This gives rise to a gauge transformation

$$A: \mathrm{SO}(\mathring{g}) \ni e_a^0 \to e_a \in \mathrm{SO}(g)$$

which identifies the corresponding spin groups and spinor bundles.

We now pick a unit norm parallel spinor ψ_0 of $(\mathbb{R}^k, g_{\mathbb{R}^k})$ and a unit norm parallel spinor ψ_1 of (X, g_X). Then $\phi_0 = A(\psi_0 \otimes \psi_1)$ defines a spinor of M_∞. We extend ϕ_0 smoothly inside. Then $\nabla^0\phi_0 = 0$ outside the compact set.

Lemma 3.1: If a spinor ϕ is asymptotic to ϕ_0: $\phi = \phi_0 + O(r^{-\tau})$, then we have

$$\lim_{R\to\infty} \Re \int_{S_R \times X} \sum \langle (\nabla_{e_a} + e_a \cdot D)\phi, \phi\rangle \mathrm{int}(e_a)\mathrm{d}vol(g) = \omega_k vol(X)\langle \phi_0, E\phi_0 + P_k\, \mathrm{d}x^0 \cdot \mathrm{d}x^k \cdot \phi_0\rangle,$$

where $\Re$ means taking the real part.

Proof. Recall that $\overline{\nabla}$ denote the connection on S induced from the Levi–Civita connection on M. We have

$$\nabla_{e_a}\psi = \overline{\nabla}_{e_a}\psi - \tfrac{1}{2}h_{ab}e^0 \cdot e^b \cdot \psi. \tag{3.5}$$

By the Clifford relation,

$$\langle(\nabla_{e_a}+e_a\cdot D)\phi,\phi\rangle=-\tfrac{1}{2}\langle[e^a\cdot,e^b\cdot]\nabla_{e_b}\phi,\phi\rangle.$$

Hence

$$\begin{aligned}\int_{S_R\times X}\sum\langle(\nabla_{e_a}+e_a\cdot D)\phi,\phi\rangle\mathrm{int}(e_a)\mathrm{d}vol(g)\\ =-\frac{1}{2}\int_{S_R\times X}\langle[e^a\cdot,e^b\cdot]\overline{\nabla}_{e_b}\phi,\phi\rangle\mathrm{int}(e_a)\mathrm{d}vol(g)\\ +\frac{1}{4}\int_{S_R\times X}\sum\langle[e^a\cdot,e^b\cdot]h_{bc}e^0\cdot e^c\cdot\phi,\phi\rangle\mathrm{int}(e_a)\mathrm{d}vol(g).\end{aligned}$$

Using (3.4) and the asymptotic conditions (1.7), the second term on the right-hand side can be easily seen to give us

$$\lim_{R\to\infty}\frac{1}{4}\int_{S_R\times X}\langle 2(h_{ac}-\delta_{ac}h_{bb})e^0\cdot e^c\cdot\phi,\phi\rangle\mathrm{int}(e_a)\mathrm{d}vol(g)=\omega_k vol(X)\langle\phi_0,P_k\,\mathrm{d}x^0\cdot\mathrm{d}x^k\cdot\phi_0\rangle.$$

The first term is computed in Ref. 4 to limit

$$\omega_k vol(X)\langle\phi_0,E\phi_0\rangle.$$

■

The following lemma is standard, see Refs. 10 and 14.

Lemma 3.2: If

$$\langle\phi_0,E\phi_0+P_k\,\mathrm{d}x^0\cdot\mathrm{d}x^k\cdot\phi_0\rangle\geqslant 0$$

for all constant spinors ϕ_0*, then*

$$E-|P|\geqslant 0.$$

As usual, the trick to get the positivity now is to find a harmonic spinor ϕ asymptotic to ϕ_0.

Lemma 3.3: There exists a harmonic spinor ϕ *on* (M,g) *which is asmptotic to the parallel spinor* ϕ_0 *at infinity,*

$$\mathcal{D}\phi=0,\quad \phi=\phi_0+O(r^{-\tau}).$$

Proof: The proof is essentially the same as in Ref. 4 [Cf. Refs. 6 and 9]. We use the Fredholm property of $\mathcal{D}$ on a weighted Sobolev space and $\mathcal{R}\geqslant 0$ to show that it is an isomorphism. The harmonic spinor ϕ can then be obtained by setting $\phi=\phi_0+\xi$ and solving $\xi\in O(r^{-\tau})$ from the equation $\mathcal{D}\xi=-\mathcal{D}\phi_0$. ■

Thus, with the choice of harmonic spinor as above, the left-hand side of (3.4) will be nonnegative since $\mathcal{R}\geqslant 0$. Taking the limit as $R\to 0$ and using Lemma 3.1 and Lemma 3.2 then give us the desired result.[4,9,10,14]

Fractional boundary for the Gott-Hiscock string

J. P. Krisch
Department of Physics, University of Michigan, Ann Arbor, Michigan 48109

(Received 2 October 2004; accepted 11 January 2005; published online 4 April 2005)

A fractional boundary condition is used to join the Gott-Hiscock string to a Levi-Civita vacuum. The use of a fractional derivative generates Israel boundary layers whose density depends on the order of the fractional derivative. Variable boundary layers for the same two bounding space–times can be studied. The string angular deficit depends on the order of the fractional deficit. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1863692]

I. INTRODUCTION

The Gott-Hiscock[1,2] solution describes a constant density string matched to a vacuum Levi-Civita space–time with angular deficit. Two of the most common boundary matching conditions for non-null boundaries are due to Lichnerowicz and Darmois. These conditions have been discussed by Bonnor and Vickers.[3] Both conditions involve matching a metric and some metric derivatives across the boundary. The Darmois condition matches the metric and its second fundamental forms on the boundary while the Lichnerowicz condition matches the metric and its first derivatives on the boundary. The resulting space–time exterior to the string has an angular deficit related to the mass per unit length of the string interior. For general space—times, if a derivative, or extrinsic curvature, match is not possible, the most common procedure is to use the Israel[4] formalism, defining a surface boundary layer stress energy through the jump in the extrinsic curvature between space–times on either side of the boundary. Other space–times, whose extrinsic curvature was not continiuous across the boundary, could have been used for the exterior match, creating an Israel layer on the string boundary.

The Israel technique provides information about the stress energy content of the bounding surface layer. While the Israel surface layer can be used to describe the jump in the extrinsic curvature across a space–time boundary, it will not distinguish surface layers of different densities or structures that might bound the same two spacetimes. Within the Israel formalism, the only way of varying the boundary layer properties is to vary the bounding space–times.

One way of modifying the boundary conditions to include different kinds of boundary surfaces for the same bounding space–times is to generalize the Lichnerowicz boundary conditions to a fractional derivative matching and then to use the Israel formalism to describe the resulting surface layer. This creates boundary layers whose stress energy content depends on the order of the fractional derivative and allows the study of variable boundary structures between the same two space–times. In the next section, we apply this fractional matching method to the Gott-Hiscock string. The hallmark of string behavior, the angular deficit, also depends on the order of the fractional derivative. The change in the angular deficit introduced by the fractional match is discussed.

II. FRACTIONAL BOUNDARY CONDITION

A. The metrics

Consider a string oriented along the z axis with constant stress energy content

$$T_t^t = T_z^z = -\varepsilon. \tag{1}$$

From the field equations, the interior metric[2] is

$$ds^2 = -dt^2 + d\rho^2 + dz^2 + \rho^{*2}\sin^2\left(\frac{\rho}{\rho^*}\right)d\varphi^2, \tag{2}$$

where $\rho^* = (8\pi\epsilon)^{-1/2}$ and the string is assumed to be flat at $\rho = 0$.

The exterior vacuum space–time is

$$ds^2 = -dT^2 + dr^2 + dZ^2 + a^2r^2d\varphi^2. \tag{3}$$

B. The nonfractional boundary match

The metric match at $\rho = \rho_o$, $r = r_o$ provides the condition

$$ar_o = \rho^* \sin\left(\frac{\rho_o}{\rho^*}\right).$$

The extrinsic curvature is defined as[5]

$$K_{ij} = n_{(\alpha;\beta)}e_i^\alpha e_j^\beta,$$

where the e_i^α are the tangents to the boundary hypersurface with normal vector n_α. Calculating the extrinsic curvatures one finds in the interior

$$K_{\varphi\varphi} = \rho^* \sin\left(\frac{\rho_o}{\rho^*}\right)\cos\left(\frac{\rho_o}{\rho^*}\right). \tag{4}$$

In the exterior the extrinsic curvatures are

$$K_{tt} = 0,$$

$$K_{\varphi\varphi} = a^2r_o, \tag{5}$$

$$K_{zz} = 0.$$

The difference in the extrinsic curvatures across the boundary is

$$\langle K_{\phi\phi}\rangle = K_{\phi\phi}(\text{vacuum}) - K_{\phi\phi}(\text{interior}) = \left(a^2r_o - \rho^* \sin\left(\frac{\rho_o}{\rho^*}\right)\cos\left(\frac{\rho_o}{\rho^*}\right)\right),$$

$$\langle K\rangle = K_\varphi^\varphi(\text{vacuum}) - K_\varphi^\varphi(\text{interior}) = \frac{1}{r_o} - \frac{1}{\rho^*}\frac{\cos(\rho_o/\rho^*)}{\sin(\rho_o/\rho^*)} = \frac{1}{r_o} - \frac{1}{a}\frac{\cos(\rho_o/\rho^*)}{r_o}.$$

In the Israel formalism,[4] the stress energy of the boundary layer is

$$8\pi S_{ab} = -\{\langle K_{ab}\rangle - h_{ab}\langle K_c^c\rangle\},$$

$$8\pi S_{tt} = \langle K\rangle h_{oo} = \frac{\cos(\rho_o/\rho^*) - a}{ar_o},$$

$$8\pi S_{zz} = \frac{a - \cos(\rho_o/\rho^*)}{ar_o},$$

$$8\pi S_{\varphi\varphi} = 0. \tag{6}$$

If the extrinsic curvatures match, there is no stress energy in the boundary. The match of the extrinsic curvature provides the same condition as a match of the $g_{\phi\phi}$ derivatives across the string boundary,

$$a = \cos\left(\frac{\rho_o}{\rho^*}\right).$$

C. The fractional match

In the fractional boundary match, the metric matching conditions are the same as in the smooth boundary match:

$$ar_o = \rho^* \sin\left(\frac{\rho_o}{\rho^*}\right). \tag{7}$$

Instead of a match of the extrinsic curvatures, a fractional derivative match is used with the regular partial derivative, ∂_i replaced by an (α) order Caputo fractional derivative as described in the Appendix.

1. Fractional derivatives for the interior metric

In the interior, since the Caputo derivative of a constant is zero, the only function to consider is $f=\rho^{*2}\sin^2(\rho/\rho^*)$. Using α as the fractional index we have that the αth fractional derivative is

$$D^{(\alpha)}_{\rho,L}\left(\rho^{*2}\sin^2\left(\frac{\rho}{\rho^*}\right)\right) = \rho^* S_{\rho_o}(\alpha,\rho^*,\rho_o).$$

The form of the function $S_{\rho_o}(\alpha,\rho^*,\rho_o)$ depends on the range of the fractional derivative order. For $\alpha<1$ we have

$$S_{\rho_o}(\alpha,\rho^*,\rho_o) = \frac{(\rho^*/2)^{1-\alpha}}{\Gamma(1-\alpha)}\left[\sin\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*} z^{-\alpha}\cos(z)dz - \cos\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*} z^{-\alpha}\sin(z)dz\right]. \tag{8}$$

For $\alpha>1$ the function is

$$S_{\rho_o}(\alpha,\rho^*,\rho_o) = \frac{(\rho^*/2)^{1-\alpha}}{\Gamma(2-\alpha)}\left[\sin\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*} z^{1-\alpha}\sin(z)dz + \cos\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*} z^{1-\alpha}\cos(z)dz\right]. \tag{9}$$

The two can be related by an integration by parts and the use of a gamma function recursion relation. For $\alpha=1$, the usual first derivative is recovered.

2. Fractional derivatives for the exterior metric

In the exterior it is the right-handed derivative which should be applied. The exterior fractional derivative of the metric function is

$$D^{(\alpha)}_{r,R}(a^2r^2) = \frac{\Gamma(3)}{\Gamma(3-\alpha)}a^2r^{2-\alpha}. \tag{10}$$

TABLE I. Values of the function $h(\alpha,\rho_o/\rho^*)=\cos(\rho_o/\rho^*)-a$ as α and ρ_o/ρ^* vary. ρ_o is the radius of the string in the internal metric. $\rho^*=(8\pi\epsilon)^{(-1/2)}$ where ϵ is the constant internal energy density of the string. Complex values are indicated by C. When $\alpha=1$, $h(\alpha,\rho_o/\rho^*)=0$, providing the usual derivative matching condition.

	α					
ρ_o/ρ^*	0.1	0.3	0.7	0.9	1.1	1.2
0.1π	−0.013	−0.011	−0.006	−0.002	0.002	0.005
0.2π	−0.051	−0.043	−0.023	−0.008	0.010	0.021
0.3π	−0.113	−0.097	−0.052	−0.02	0.023	0.05
0.4π	−0.199	−0.172	−0.095	−0.038	0.047	0.107
0.45π	−0.25	−0.218	−0.125	−0.051	0.069	C
0.5π	−0.31	−0.272	−0.163	−0.071	C	C

3. The boundary match

The equation for the boundary match is

$$\frac{\Gamma(3)}{\Gamma(3-\alpha)}a^2 r_o^{2-\alpha}=\rho^* S_{\rho_o}(\alpha,\rho^*,\rho_o).$$

For $\alpha=1$ the usual derivative is obtained, leading to the original derivative matching result

$$a=\cos\left(\frac{\rho_o}{\rho^*}\right). \tag{11}$$

For $\alpha\neq 1$ there is a boundary layer which can be described by the Israel[4] formalism.

III. BOUNDARY STRESS ENERGY

The boundary stress energy, Eq. (6), involves the function

$$h\left(\alpha,\frac{\rho_o}{\rho^*}\right)=\cos\left(\frac{\rho_o}{\rho^*}\right)-a.$$

The two fractional matching equations, Eqs. (7) and (10), can be combined to give an equation for the parameter "*a*,"

$$\alpha<1{:}a^\alpha=\frac{\Psi(\alpha,\rho_o/\rho^*)}{\Gamma(1-\alpha)}\left[\sin\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*}z^{-\alpha}\cos(z)dz-\cos\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*}z^{-\alpha}\sin(z)dz\right], \tag{12}$$

$$\alpha>1{:}a^\alpha=\frac{\Psi(\alpha,\rho_o/\rho^*)}{\Gamma(2-\alpha)}\left[\sin\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*}z^{1-\alpha}\sin(z)dz+\cos\left(\frac{2\rho_o}{\rho^*}\right)\int_0^{2\rho_o/\rho^*}z^{1-\alpha}\cos(z)dz\right], \tag{13}$$

where $\Psi(\alpha,\rho_o/\rho^*)=[\Gamma(3-\alpha)\sin^{\alpha-2}(\rho_o/\rho^*)]/2^{2-\alpha}$. For a smooth match, $h(\alpha,\rho_o/\rho^*)$ should be zero. Using Eq. (12), Eq. (13), and MAPLE, $h(\alpha,\rho_o/\rho^*)$ was evaluated for a range of ρ_o/ρ^* and fractional indices. The results are in Table I.

Examining Table I, one sees in all cases that, as $\alpha=1$ is approached, the stress energy of the layer approaches zero. For $\alpha<1$ the boundary layer has negative density and positive *z*-stress. As ρ_o/ρ^* moves above $\pi/2$, the values become complex. For $\alpha>1$, the boundary layer density is positive and the stress is a *z*-tension. For $\alpha>1$ complex values occur for values of $\rho_o/\rho^*<\pi/2$.

TABLE II. Values of the angular deficit factor "a" as a function of α and ρ_o/ρ^*. ρ_o is the radius of the string in the internal metric. $\rho^*=(8\pi\epsilon)^{(-1/2)}$ where ϵ is the constant internal energy density of the string. Complex values are indicated by C.

	α					
ρ_o/ρ^*	0.1	0.3	0.7	1	1.1	1.2
0.1π	0.964	0.962	0.957	0.951	0.949	0.946
0.2π	0.86	0.852	0.832	0.809	0.799	0.788
0.3π	0.701	0.684	0.639	0.588	0.565	0.538
0.4π	0.507	0.48	0.404	0.309	0.263	0.202
0.5π	0.308	0.272	0.163	0	C	C

The string angular deficit, the cut in the range of the ϕ coordinate due to the presence of the parameter "a" in the exterior metric, is a hallmark of cosmic string behavior. The angular deficit depends on the energy density of the string.[2] When a fractional boundary condition is used, the internal stress energy of the string does not change but the energy density of the boundary layer affects the angular deficit since it must be included in the total energy density of the string. The angular deficit can be defined by

$$\delta\varphi = 2\pi[1 - a]. \tag{14}$$

The values of "a" for various α and ρ_o/ρ^* were calculated and are found in Table II. In Table II, the $\alpha=1$ column values are calculated from the standard nonfractional match. The linear density of the string is not affected by the boundary layer but the angular deficit is, increasing in value as α increases. For $\alpha<1$, the angular deficit is less than the zero-boundary-layer, $\alpha=1$, value because the negative boundary layer density is decreasing the overall mass density of the string. For $\alpha>1$ the deficit is larger than the zero-boundary-layer value because the positive boundary layer mass increases the string density.

One possible way to interpret the variation of the parameter "a" and the surface energy density is through a packing fraction. The packing fraction is normally defined as the ratio of the area covered by a tiling to the total area being tiled. Adapting this to the surface layer we can consider the ratio of the $\alpha\neq 1$ surface area to the $\alpha=1$ surface area which is just the ratio of the "a" values in each row of Table II to the "a" value for $\alpha=1$:

$$pf(\alpha) = \frac{2\pi a(\alpha\neq 1)Lr_o}{2\pi a(\alpha=1)Lr_o} = \frac{a(\alpha\neq 1)}{a(\alpha=1)}.$$

For $\alpha<1$, the layer with its negative density matter seems overpacked. For $\alpha>1$ this ratio can be used to make some qualitative comments about the energy distribution. From Table II, generally one notes that the packing fraction decreases as α increases for a given ρ_o/ρ^* and that the packing fraction decreases as the ρ_o/ρ^* increases. The latter effect can be simply explained by examining cylinders of constant radius and varying internal energy density. As the internal energy density decreases and the ratio ρ_o/ρ^* goes up, the packing fraction decreases as there is less energy to distribute over the surface. The first effect is more difficult to motivate. One possible explanation comes from assuming a specific tiling mechanism for the boundary layer and then using the packing fraction variation to motivate differences within the tiling. For example, if the surface layer is tiled with an Apollonian packing,[6,7] circles with increasing smaller circles packed in the interstitial regions, the packing fraction is given roughly by

$$pf = 1 - (r(\min)/r(\max))^{2-d}$$

where $r(\max)$ is the radius of the largest circle in the packing, $r(\min)$ is the smallest circle in the tiling, and $d\sim 1.3$ is the fractal dimension[8] of the tiling in flat space. Using this, the variation in

the packing fraction as a function of α can be explained as a variation in the range of granule sizes making up the surface layer.

IV. DISCUSSION

In this note, we have suggested using a Caputo space fractional derivative to generate variable density Israel surface layers on the Gott-Hiscock string bounded by a Levi-Civita vacuum. The method generates, for $\alpha>1$, a family of positive energy, increasingly dense boundary layers between the constant density string interior and the vacuum exterior. For $\alpha<1$, the energy density is negative. The Caputo derivatives can be more restrictive than the Riemann-Liouville forms since the derivatives of the matching metric functions must exist to use the Caputo definition. The Riemann-Liouville form would give an additional nonzero matching condition for the constant metric functions which would identify r_o and ρ_o.

When joining many hypersurfaces, it is common practice to match extrinsic curvatures. Since the extrinsic curvature is a Lie derivative, it can be calculated from simple partial derivatives and can be fractionally generalized. Because the string boundary, as defined in the bounding space–time, had a well-defined unit normal and derivatives, a simple fractional extrinsic curvature matching would have given the same result as the fractional derivative matching. However, null surfaces, for example, do not have a well-defined extrinsic curvature and junction conditions outside of an extrinsic curvature matching have been developed.[9–11] Mars and Senovilla[12] have discussed junction conditions using a rigged metric connection for general hypersurfaces. Hayward[13] has discussed an action for nonsmooth boundaries. Using fractional derivatives as a method for generating variable density boundary layers apart from the second fundamental form might instead be a way of giving physical meaning to possible fractional extrinsic curvature definitions.

A smooth boundary with well-defined derivatives is not a necessary condition for the use of a fractional derivative matching. The Riemann-Liouville derivatives can be applied to functions which themselves do not have a well defined derivatives. For example, using the Riemann-Liouville form, Rocco and West[14] showed that the continuous but nondifferentiable Wierstrass function had a well-defined fractional derivative. Kolwankar and Gangal[15] also discussed the fractional derivatives of the Weierstrass function. Fractional derivatives have seen increasing use in the development of fractional kinetics,[16] particularly in discussions of anomalous transport processes.[17] While the method presented in this note generates a family of surface layers of varying densities between the same two bounding static space–times, the use of fractional derivatives in boundary matching could reflect an underlying boundary matter structure that was built by an anomalous transport process. A single tiling was used as an example of the relation between possible matter distributions and the order of the fractional derivative. The results from other tilings or sums over tilings is an interesting question for investigation.

APPENDIX: FRACTIONAL OPERATIONS

The idea of a fractional derivative arose in 1695 when L'Hopital[18] asked Leibniz about the meaning of $d^n y/dx^n$ for $n=\frac{1}{2}$. The ideas of fractional calculus have attracted the attention of many of the same people that are associated with the development of physics: Lagrange, Laplace, Fourier, Liouville, Riemann, and Weyl, among others.[19] Since the first conference on fractional calculus in 1974, the applications to physics have grown enormously, describing phenomena such as the modeling of viscoelastic phenomena[20] and fractional matter transport.[17] There have been many definitions of fractional operations because of the diverse array of applications. Some of the fractional differentiation definitions are (a) the left-handed Riemann-Liouville form,[18]

$$D_a^\nu f(x) = \frac{d^m}{dx^m}\left\{ \frac{1}{\Gamma(m-\nu)} \int_a^x f(y)(x-y)^{m-\nu-1} dy \right\},$$

and (b) the right-handed Riemann-Liouville form,[18]

$$ {}_bD^{\nu}f(x) = \frac{d^m}{dx^m}\left\{ \frac{(-1)^m}{\Gamma(m-\nu)} \int_x^b f(y)(y-x)^{m-\nu-1} dy \right\}, $$

where, in both cases, m is the smallest integer bigger than ν. One very interesting thing about this form of the fractional derivative is that the derivative of a constant is not zero. For example, the left-handed derivative of "1" is

$$ D_a^{\nu}[1] = \frac{d^2}{dx^2}\left\{ \frac{1}{\Gamma(2-\nu)} \int_0^x (x-y)^{1-\nu} dy \right\} = \frac{x^{-\nu}\Gamma(1)}{\Gamma(1-\nu)}, $$

where the definition of the beta function,

$$ B(z,w) = \int_0^1 x^{z-1}(1-x)^{w-1} dx = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}, $$

and the recursion relation for the gamma function have been used. There are other fractional forms, with modified definitions. The Caputo[19] fractional derivatives are similar to the Riemann-Liouville derivatives except that the derivative appears inside of the integral; $f^{(m)}(y)$ is the mth derivative of $f(x)$. The left-hand Caputo[19] derivative is

$$ {}_CD^{\nu}{}_a[f(x)] = \frac{1}{\Gamma(m-\nu)} \int_a^x (x-y)^{m-\nu-1} f^{(m)}(y) dy. $$

The right-hand derivative is similar. Butzer and Westphal[21] credit Liouville with the definition. In this paper we shall use the Caputo form.

The notation that we will use is

$$ \partial_i -> D_{iL}^{(\nu)}, $$

$$ \partial_i -> D_{iR}^{(\nu)}, $$

where ν the fractional order, has been placed in parentheses to distinguish it from a tensor index, i is the index of the coordinate derivative, and L, R denote the left- or right-hand derivatives.

On quadratic Poisson brackets

Ali Ulas Özgür Kisisel[a)]
Department of Mathematics, Middle East Technical University, 06531, Ankara, Turkey

(Received 21 June 2004; accepted 10 December 2004; published online 17 March 2005)

In this paper, we present a method for constructing large families of quadratic Poisson brackets on a manifold using more elementary brackets on a different manifold. The method is then applied to several examples of completely integrable systems. One can recover several known brackets for systems such as the Toda lattice or the open discrete KP hierarchy. New brackets for a doubly periodic discrete KP hierarchy are also constructed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1866221]

I. INTRODUCTION

Poisson brackets are classical limits of commutators in deformation quantization, and play a key role in the theory of completely integrable systems. The so-called quadratic or second Poisson brackets carry a homogeneity property distinguishing them. It is possible to prove that many systems are completely integrable by exhibiting two compatible Poisson brackets one of which is quadratic; this was an idea which originated in Ref. 17 and evolved much further.

The aim of this paper is to present a systematic method for constructing quadratic Poisson brackets, and to apply it to several examples. The method is some sort of a hybrid of the Miura transform which involves factorizing the Lax operator noncommutatively and then using a reduction (see Refs. 1, 6, 7, and 16), and the method described in the paper[19] of Suris which involves starting from Poisson brackets satisfying r-matrix like conditions on $g\oplus g\oplus\cdots\oplus g$ to produce new r-matrix brackets on g. Our construction is different in the sense that we do not require any r-matrix like conditions, but rather start from a set of so-called simple brackets (to be defined) on a subspace of $g\oplus g\oplus\cdots\oplus g$, again to produce new, nonsimple brackets on g. In this context, the classical r-matrix brackets would be self-inducing (see Ref. 20).

The second section explains this construction. In the third section we work it out in detail for the smallest nontrivial example. In the fourth section, first we explain how the second bracket of the (A-series) Toda hierarchy can be obtained by this method. Afterwards, we demonstrate how the (known) quadratic Poisson bracket for the Kadomtsev-Petviashvili (KP) hierarchy, discrete in both space directions can be obtained. Finally, we show that a quadratic Poisson bracket for a doubly periodic discrete KP hierarchy can be tailor-made, and in a sense uniquely, using the general construction, if the two periods M and N are relatively prime. To our knowledge, these last brackets are new. Commutation of conserved quantities holds for these brackets, but is not proved in this paper. For this, we refer the reader to Ref. 12 or Ref. 13.

II. SIMPLE BRACKETS AND DESCENT PROPERTIES

Let M be a smooth manifold. Recall that a Poisson structure on M is a skew symmetric bilinear map from $C^\infty(M)\times C^\infty(M)$ to $C^\infty(M)$ which satisfies the Leibniz rule and the Jacobi identity. M equipped with a Poisson structure is called a Poisson manifold. A smooth map $f:M\to N$ between two Poisson manifolds is called a Poisson map if the naturally induced ring homomorphism $f^*:C^\infty(N)\to C^\infty(M)$ defined as $f^*(g)=g\circ f$ commutes with the brackets, i.e., $\{f^*(u),f^*(v)\}_M=f^*\{u,v\}_N$ for all u,v. Suppose that $A(M)$ is a graded subring of $C^\infty(M)$ closed

a)Electronic mail: akisisel@metu.edu.tr

under the bracket operation. [A typical example is where M is an algebraic variety, $A(M)$ denotes the ring of regular functions on M, and $\{,\}$ is defined by polynomial expressions, taking pairs of homogenous polynomials to homogenous polynomials. We also remark that more generally one can consider sheaves of rings rather than global functions on M.] We call a Poisson structure on M quadratic if $\deg(\{u,v\})=\deg(u)+\deg(v)$ for all homogenous $u,v\in A(M)$. (This name refers to the case when u,v have degree 1 and thus the degree of $\{u,v\}$ is 2.) In this paper quadratic Poisson brackets will be the main objects of our concern. For more general information about Poisson manifolds, please see Refs. 3 and 22.

Definition 1: Suppose that M, $A(M)$ and $\{,\}$ are as above. Say $\{x_1,\ldots,x_n\}$ is a set of generators for the ring $A(M)$. Assume that there exist constants $\mu_{i,j}$ such that $\mu_{i,j}=-\mu_{j,i}$ and

$$\{x_i,x_j\}=\mu_{i,j}x_ix_j$$

for all i,j. Then we will say that $\{,\}$ is simple (or diagonal, or diagonalized) with respect to this set of generators.

It is straightforward to check that for any choice of constants $\mu_{i,j}$ subject to the condition $\mu_{i,j}=-\mu_{j,i}$, the resulting bracket satisfies the Jacobi identity.

We remark that in a paper by Dufour and Haraki[5] it is shown that simple brackets are in some sense generic among all quadratic brackets. This is done as follows. It is well known that specifying a Poisson bracket is equivalent to specifying a bivector field π satisfying $[\pi,\pi]=0$ where $[,]$ denotes the Schouten bracket.[3] They associate π a vector field $D(\pi)$, called its curl. One proves that $[D(\pi),\pi]=0$. Then if $D(\pi)$ is diagonalizable and its eigenvalues avoid a certain finite set of identities, this relation forces π to be diagonalizable. This certainly is a generic condition among possible Jordan forms of $D(\pi)$, however there are new components in the parameter space of all quadratic brackets, which consist in π Schouten commuting with the nongeneric $D(\pi)$. Quadratic brackets of many familiar integrable systems, such as the Toda lattice, are not diagonalizable by a linear change of coordinates, even though they have a diagonalizable curl; hence they fall into this second class.

We also remark that the sum of any two simple brackets is a simple bracket. Thus any two members of the family of simple brackets form a compatible pair (equivalently, their Schouten bracket is 0).

We will describe a method through which some nonsimple brackets may be constructed using simple brackets. In the later sections we will show that the quadratic brackets of several well-known integrable systems arise in this way. We also use this method to construct a highly nonlocal quadratic bracket for an integrable system for which such a bracket was formerly unknown. Our setting is as follows: Let a be an associative algebra, g an affine or vector subspace of a, and $\mathbf{h}$ an affine or vector subspace of $a\oplus a\oplus\cdots\oplus a$ (M times) for some positive integer M.

Assume that the image of the map f on $\mathbf{h}$ defined by $f(L^{(1)},\ldots,L^{(M)})=L^{(1)},\ldots,L^{(M)}$ is equal to g. Then the induced map $f^*:C^\infty(g)\to C^\infty(\mathbf{h})$ is injective. Since f is a polynomial map f^* also induces a map from $A(g)$ to $A(\mathbf{h})$ where these denote the rings of polynomial functions on g and $\mathbf{h}$, respectively.

Next, choose a set of generators for $A(\mathbf{h})$ and consider the set of all simple Poisson brackets with respect to this set of generators. By the remarks above, this set of brackets is itself a vector space, and we will denote it by $\mathcal{S}(\mathbf{h})$.

Theorem 1: *Say $\{,\}_h$ is a Poisson bracket on $\mathbf{h}$. Suppose that for every $u,v\in A(g)$ there exists $w\in A(g)$ such that $\{f^*(u),f^*(v)\}_h=f^*(w)$. Then w is the unique element of $A(g)$ having this property, and the bracket defined by $\{u,v\}_g=w$ is a Poisson bracket on g.*

Proof: The uniqueness of w follows from the injectivity of f^*, and makes $\{,\}_g$ well defined. The bilinearity and the Jacobi identity for $\{,\}_g$ follow from the bilinearity and the Jacobi identity for $\{,\}_{\mathbf{h}}$ and the fact that f^* is a ring homomorphism. ■

We will say that a bracket on $\mathbf{h}$ satisfying the hypothesis of the previous theorem "descends" to a bracket on g.

Corollary 1: The set $\mathcal{D}(\mathbf{h})$ of simple quadratic brackets on $\mathbf{h}$ which descend to a bracket on g is a vector subspace of $\mathcal{S}(\mathbf{h})$.

Proof: It only remains to check that a linear combination of two elements of $\mathcal{D}(\mathbf{h})$ is in $\mathcal{D}(\mathbf{h})$. But this easily follows since f^* is an injective homomorphism. ■

There are at least two nice features of $\mathcal{D}(\mathbf{h})$ which in our opinion make it worthwhile to study. First, it is relatively easy to determine $\mathcal{D}(\mathbf{h})$ or some of its subspaces explicitly for concrete examples. Second, the induced brackets by this family on g give us a rich source of not necessarily simple brackets on g, among which one can find the quadratic brackets of many familiar integrable systems, along with new quadratic brackets for certain nonlocal systems.

III. EXAMPLE: M(2)

We will work out the general construction of the last section in detail for the example of $g=M(2)$ (over $\mathbb{R}$ or $\mathbb{C}$), the associative algebra of 2×2 matrices, $M=2$, and $\mathbf{h}=L(2)\oplus U(2)$ where $L(2)$ is the vector space of lower triangular 2×2 matrices, and $U(2)$ the vector space of upper triangular 2×2 matrices. Let $f:\mathbf{h}=L(2)\oplus U(2)\to g$ be given by $f(A,B)=AB$. Let a,b,c,d be coordinate functionals dual to the entries on g; x,y,z dual to those on $L(2)$ and u,v,w dual to those on $U(2)$ in the orders such that f^* is given by

$$\begin{bmatrix} x & 0 \\ y & z \end{bmatrix}\begin{bmatrix} u & v \\ 0 & w \end{bmatrix} \leftarrow \begin{bmatrix} a & b \\ c & d \end{bmatrix},$$

i.e., $f^*(a)=xu$, $f^*(b)=xv$, $f^*(c)=yu$, and $f^*(d)=yv+zw$. Consider an arbitrary simple bracket $\{,\}_{\mathbf{h}}$ on $\mathbf{h}$. Denote $\{x,y\}_{\mathbf{h}}=\mu_{x,y}xy$, $\{x,u\}_{\mathbf{h}}=\mu_{x,u}xu$ and so on. Recall that $\mu_{i,j}=-\mu_{j,i}\,\forall\, i,j$. An elementary computation gives

$$\{f^*(a),f^*(b)\}_{\mathbf{h}}=(\mu_{x,v}+\mu_{u,v}+\mu_{u,x})f^*(ab),$$

$$\{f^*(a),f^*(c)\}_{\mathbf{h}}=(\mu_{x,y}+\mu_{x,u}+\mu_{u,y})f^*(ac),$$

$$\{f^*(b),f^*(c)\}_{\mathbf{h}}=(\mu_{x,y}+\mu_{x,u}+\mu_{v,y}+\mu_{v,u})f^*(bc),$$

$$\begin{aligned}\{f^*(a),f^*(d)\}_{\mathbf{h}}&=(\mu_{x,y}+\mu_{x,v}+\mu_{u,y}+\mu_{u,v})xuyv+(\mu_{x,z}+\mu_{x,w}+\mu_{u,z}+\mu_{u,w})xuzw\\&=(\mu_{x,y}+\mu_{x,v}+\mu_{u,y}+\mu_{u,v}-\mu_{x,z}-\mu_{x,w}-\mu_{u,z}-\mu_{u,w})f^*(bc)+(\mu_{x,z}+\mu_{x,w}+\mu_{u,z}\\&\quad+\mu_{u,w})f^*(ad),\end{aligned}$$

$$\{f^*(b),f^*(d)\}_{\mathbf{h}}=(\mu_{x,y}+\mu_{x,v}+\mu_{v,y})xv^2y+(\mu_{x,z}+\mu_{x,w}+\mu_{v,z}+\mu_{v,w})xvzw,$$

$$\{f^*(c),f^*(d)\}_{\mathbf{h}}=(\mu_{y,v}+\mu_{u,y}+\mu_{u,v})y^2uv+(\mu_{y,z}+\mu_{y,w}+\mu_{u,z}+\mu_{u,w})yuzw.$$

This implies that a necessary and sufficient condition for $\{,\}_{\mathbf{h}}$ to descend on g is

$$\mu_{x,y}+\mu_{x,v}+\mu_{v,y}=\mu_{x,z}+\mu_{x,w}+\mu_{v,z}+\mu_{v,w} \tag{1}$$

and

$$\mu_{y,v}+\mu_{u,y}+\mu_{u,v}=\mu_{y,z}+\mu_{y,w}+\mu_{u,z}+\mu_{u,w}. \tag{2}$$

Therefore $\mathcal{D}(\mathbf{h})$ is a 13-dimensional subspace of the 15-dimensional vector space $\mathcal{S}(\mathbf{h})$. On the other hand, the linear transformation sending each element of $\mathcal{D}(\mathbf{h})$ to the associated bracket $\{,\}_g$ over g has a large kernel. To determine exactly what it is, set $\mu_{a,b}=\mu_{x,v}+\mu_{u,v}+\mu_{u,x}$, $\mu_{a,c}=\mu_{x,y}+\mu_{x,u}+\mu_{u,y}$, $\mu_{b,c}=\mu_{x,y}+\mu_{x,u}+\mu_{v,y}+\mu_{v,u}$, $l=\mu_{x,z}+\mu_{x,w}+\mu_{u,z}+\mu_{u,w}$, $k=\mu_{x,y}+\mu_{x,v}+\mu_{u,y}+\mu_{u,v}$, $\mu_{b,d}=\mu_{x,y}+\mu_{x,v}+\mu_{v,y}$, $\mu_{c,d}=\mu_{y,v}+\mu_{u,y}+\mu_{u,v}$. After a row reduction, and taking equations (1) and (2) into account, we have

$$\mu_{a,b} = k - \mu_{a,c}, \quad \mu_{b,c} = \mu_{a,c} - \mu_{c,d}, \quad \mu_{b,d} = k - \mu_{c,d}$$

and, the set $\{k, l, \mu_{a,c}, \mu_{c,d}\}$ is linearly independent considered as linear functions on $\mathcal{D}(\mathbf{h})$. Thus we obtain a complete description of all quadratic brackets on g which descend from simple brackets of $\mathbf{h}$,

$$\{a,b\}_g = (k - \mu_{a,c})ab, \quad \{a,c\}_g = \mu_{a,c}ac, \quad \{b,c\}_g = (\mu_{a,c} - \mu_{c,d})bc,$$

$$\{a,d\}_g = lad + (k - l)bc, \quad \{b,d\}_g = (k - \mu_{c,d})bd, \quad \{c,d\}_g = \mu_{c,d}cd.$$

This is a four-dimensional linear space of compatible brackets. Notice that such a bracket is simple on g if and only if $k=l$, hence those lie in a codimension 1 locus (thus the six-dimensional vector space of simple brackets on g meets the four-dimensional vector space of descended brackets in a three-dimensional subspace).

For $\mu_{a,c}=\mu_{c,d}=1, k=2, l=0$ one gets

$$\{a,b\}_g = ab, \quad \{a,c\}_g = ac, \quad \{b,c\}_g = 0,$$

$$\{a,d\}_g = 2bc, \quad \{b,d\}_g = bd, \quad \{c,d\}_g = cd$$

which is the r-matrix Poisson bracket on M(2) associated to $r=\pi_+ - \pi_-$ (Ref. 20, Example 5). For another example, set $\mu_{a,c}=\mu_{c,d}=k=0, l=-1$. The only nonzero bracket then is $\{a,d\}_g = bc - ad$. The submanifold given by $b=c$ is a Poisson submanifold for this bracket, and the resulting bracket on this submanifold is the example given in Ref. 18. It was shown here that this bracket does not come from a classical r-matrix.

Considering applications to integrable systems, one interesting question is the following: For which values of the constants do a set of given functions Poisson commute? As an example, let us take the trace and determinant functionals, $f_1 = a + d$ and $f_2 = ad - bc$. (This is a natural choice since for a system where the 2×2 matrix is one of the two matrices of the Lax pair, and the flows are the isospectral flows of L, f_1 and f_2 clearly have to be conserved quantities.) A calculation gives

$$\{f_1, f_2\}_g = -l(abc) + l(bcd).$$

Thus we deduce that $\{f_1, f_2\}_g = 0 \Leftrightarrow l = 0$.

The general question of which quadratic Poisson brackets can be obtained from any such descent process is unanswered at the moment. But for the current example, we note the following result.

Theorem 2: *Suppose that we have a quadratic Poisson bracket on g of the form*

$$\{a,b\}_g = \mu_{a,b}ab, \quad \{a,c\}_g = \mu_{a,c}ac, \quad \{b,c\}_g = \mu_{b,c}bc,$$

$$\{a,d\}_g = lad + rbc, \quad \{b,d\}_g = \mu_{b,d}bd, \quad \{c,d\}_g = \mu_{c,d}cd.$$

Then, either the bracket is simple, or, up to a linear change of coordinates $\{,\}_g$ *descends from a quadratic Poisson bracket on* $\mathbf{h}$ *as above.*

Proof: From the identity $\{a,\{c,d\}_g\}_g + \{d,\{a,c\}_g\}_g + \{c,\{d,a\}_g\}_g = 0$ we obtain

$$r(\mu_{c,d} - \mu_{a,c} + \mu_{b,c})bc^2 = 0.$$

Assume that the bracket is not simple. Therefore $r \neq 0$, so $\mu_{b,c} = \mu_{a,c} - \mu_{c,d}$. Next, using the identity $\{a,\{b,d\}_g\}_g + \{d,\{a,b\}_g\}_g + \{b,\{d,a\}_g\}_g = 0$ we obtain

$$r(\mu_{b,d} - \mu_{a,b} - \mu_{b,c})b^2c = 0.$$

Thus $\mu_{b,d} - \mu_{a,b} = \mu_{a,c} - \mu_{c,d}$. Now set $a' = ta$. Then $\{a',b\} = t\{a,b\} = t\mu_{a,b}ab = \mu_{a,b}a'b$, similarly $\{a',c\} = \mu_{a,c}a'c$ but $\{a',d\} = t\{a,d\} = tlad + trbc = la'd + trbc$. So the effect of this transformation on the bracket is to replace r with tr. Taking

$$t = \frac{\mu_{a,b} + \mu_{a,c} - l}{r}$$

and setting $k = l + tr$ we obtain that $\mu_{a,b} = k - \mu_{a,c}$, thus $\mu_{b,d} = k - \mu_{c,d}$, therefore the proof is complete. ■

IV. THE TODA AND DISCRETE KP HIERARCHIES

In what follows, let $\hat{\mathrm{M}}(\infty)$ denote the associative algebra of infinite matrices L having the property that $\exists n$ such that $L_{ij} = 0$ if $|i-j| > n$. (The last condition makes it possible to form ordinary matrix products of these matrices.)

The open Toda lattice equations (for the A series of Lie algebras) are given by

$$\dot{a}_i = 2(b_{i+1}^2 - b_i^2),$$

$$\dot{b}_i = b_i(a_i - a_{i-1}),$$

where $i \in \mathbb{Z}$ (Ref. 4) (please note the difference in notation from this paper). We obtain the finite Toda lattice of length N if $a_i = 0$ for $i \leqslant 0$ and for $i > N$, and $b_i = 0$ for $i \leqslant 1$ and for $i > N$. Similarly, we obtain the periodic Toda lattice of period N if $a_{i+N} = a_i$ and $b_{i+N} = b_i$ for all i (see Ref. 10).

Let g be the vector subspace of $\hat{\mathrm{M}}(\infty)$ consisting in symmetric tridiagonal matrices (i.e., $L_{ij} = 0$ if $|i-j| > 1$, and $L_{ij} = L_{ji}$). Also let $\mathbf{h}$ be the subspace of $\hat{\mathrm{M}}(\infty) \oplus \hat{\mathrm{M}}(\infty)$ consisting in pairs (K, K^t) such that $K_{ij} = 0$ unless $i = j$ or $i = j-1$. Define $f: \mathbf{h} \to g$ by $f(K, K^t) = KK^t$. Suppose that a_i, b_i are coordinate functionals on g and x_i, y_i coordinates on $\mathbf{h}$ in the way that f^* is given by

$$\begin{bmatrix} \cdots & \cdots & & & & & \\ & y_1 & x_1 & & & & \\ & & y_2 & x_2 & & & \\ & & & \cdots & \cdots & & \\ & & & & y_N & x_N & \\ & & & & & \cdots & \end{bmatrix} \begin{bmatrix} \cdots & & & & & & \\ x_0 & y_1 & & & & & \\ & x_1 & y_2 & & & & \\ & & \cdots & \cdots & & & \\ & & & x_{N-1} & y_N & & \\ & & & & \cdots & \cdots & \end{bmatrix} \leftarrow \begin{bmatrix} \cdots & \cdots & & & & & \\ b_1 & a_1 & b_2 & & & & \\ & b_2 & a_2 & b_3 & & & \\ & & \cdots & \cdots & \cdots & & \\ & & & b_N & a_N & b_{N+1} & \\ & & & & \cdots & \cdots & \end{bmatrix}. \tag{3}$$

In other words,

$$f^*(a_i) = x_i^2 + y_i^2, \quad f^*(b_i) = x_{i-1} y_i.$$

The following quadratic Poisson bracket on g is well known:

$$\{a_i, a_{i+1}\} = 2b_{i+1}^2, \quad \{a_i, b_i\} = -a_i b_i,$$

$$\{a_i, b_{i+1}\} = a_i b_{i+1} \quad \{b_i, b_{i+1}\} = \tfrac{1}{2} b_i b_{i+1}. \tag{4}$$

An important property of this bracket is the following: Denote the rightmost matrix in 3 by L. Then the coefficients of the characteristic polynomial of L commute with respect to this bracket.

Remark: For the infinite Toda lattice, one may define the kth coefficient of the characteristic polynomial of L as the coefficient of $\lambda^{\infty - k}$ in $\det(L - \lambda I)$. That is, let it be the formal sum, of monomials in a_i's and b_i's containing all but k of the λ's, over all permutations of $\mathbb{Z}$. Poisson brackets of such formal sums make sense here (as a formal sum again) because the bracket 4 is local.

Proposition 1: The bracket 4 is induced by the following simple bracket on **h**:

$$\{x_i, y_i\} = -\tfrac{1}{2} x_i y_i, \quad \{x_i, y_{i+1}\} = \tfrac{1}{2} x_i y_{i+1}.$$

Proof: This is a straightforward computation. ■

For our next class of examples, let a be the affine subalgebra of $\hat{\mathrm{M}}(\infty)$ consisting in lower unipotent matrices (i.e., $L \in a$ if $L_{ii}=1\ \forall i$, $L_{ij}=0$ if $j>i$, and $\exists n$ such that $L_{ij}=0$ if $i-j>n$). For a given positive integer M, let g_M be the affine subspace of a consisting in L such that $L_{ij}=0$ if $i-j>M$. Set $\mathbf{h}=g_1\oplus g_1\oplus\cdots\oplus g_1$ (M times) and let $f:\mathbf{h}\to g_M$ be the usual map, $f(L^{(1)},\ldots,L^{(M)})=L^{(1)},\ldots,L^{(M)}$. It is easy to see that f is surjective.

Let $u_j^{(i)}, i=1,\ldots,M, j\in\mathbb{Z}$ be coordinate functionals on $\mathbf{h}$ and v_{ij}, $i,j\in\mathbb{Z}, i>j, i-j\leqslant M$ be coordinate functionals on g_m so that f^* is given by

$$\begin{bmatrix} \cdots & & & & \\ \cdots & 1 & & & \\ & u_2^{(1)} & 1 & & \\ & & u_3^{(1)} & 1 & \\ & & & \cdots & \cdots \end{bmatrix} \cdots \begin{bmatrix} \cdots & & & & \\ \cdots & 1 & & & \\ & u_2^{(M)} & 1 & & \\ & & u_3^{(M)} & 1 & \\ & & & \cdots & \cdots \end{bmatrix} \leftarrow \begin{bmatrix} \cdots & & & & \\ \cdots & 1 & & & \\ \cdots & v_{21} & 1 & & \\ \cdots & v_{31} & v_{32} & 1 & \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{bmatrix}. \tag{5}$$

Denote these matrices by $I+U^{(1)},\ldots,I+U^{(M)}$ and V, respectively. Then this equation can be written as $f^*(V)=(I+U^{(1)})\cdots(I+U^{(M)})$.

One can verify by induction that

$$f^*(v_{ij})=\sum_{k_1<k_2<\cdots<k_{i-j}\leqslant M} u_i^{(k_1)}u_{i-1}^{(k_2)}\cdots u_{j+1}^{(k_{i-j})}.$$

Theorem 3: *Consider the following simple Poisson bracket on* $\mathbf{h}$:

$$\{u_i^{(k)},u_j^{(l)}\}_{\mathbf{h}}=(\delta_{i,j+1}-\delta_{i,j})u_i^{(k)}u_j^{(l)} \quad \text{if } k<l,$$

$$\{u_i^{(k)},u_j^{(l)}\}_{\mathbf{h}}=(\delta_{i,j}-\delta_{i,j-1})u_i^{(k)}u_j^{(l)} \quad \text{if } k>l.$$

$$\{u_i^{(k)},u_j^{(k)}\}_{\mathbf{h}}=0.$$

The bracket descends on g_m *to a bracket given by*

$$\{v_{ij},v_{nm}\}_{g_m}=0 \quad \text{if } n>i \text{ and } m<j, \text{or if } n<j,$$

$$\{v_{ij},v_{jm}\}_{g_m}=v_{im},$$

$$\{v_{kj},v_{ij}\}_{g_m}=v_{kj}v_{ij} \quad \text{if } k>i,$$

$$\{v_{ij},v_{ik}\}_{g_m}=v_{ij}v_{ik} \quad \text{if } j>k,$$

$$\{v_{ij},v_{kl}\}_{g_m}=v_{ij}v_{kl}+v_{kj}v_{il} \quad \text{if } i>k>j>l.$$

The resulting bracket is an r-matrix Poisson bracket, therefore a proof of this theorem can in principle be obtained using the method described in Ref. 19. We give an independent proof in the Appendix.

The bracket of theorem 3 is an element of $\mathcal{D}(\mathbf{h})$, and the bracket it induces on g_m is a quadratic Poisson bracket for the open and finite discrete KP hierarchies (see Refs 2 and 11). To be precise, the name "KP hierarchy" is usually attached to the completely integrable system associated to the pseudodifferential operator $L=\partial+v_{-1}\partial^{-1}+v_2\partial^{-2}+\cdots$ (see Refs. 8, 14, and 15). Above, the Lax operator is $V=S^0+V^{(1)}S^{-1}+V^{(2)}S^{-2}+\cdots+V^{(M)}S^{-M}$ where S is the finite difference analog of ∂, i.e.,

a subdiagonal matrix consisting of 1's, and $V^{(i)}$ the diagonal matrix such that $V^{(i)}_{jj}=V_{jj-i}$. It is a nontrivial theorem that the conserved quantities of these systems commute under this bracket.

For the discrete KP hierarchy periodic in one spatial direction (namely, $\exists N$ such that $v_{ij}=v_{i+Nj+N}\forall i,j$), the bracket produces a Hamiltonian interpretation in the same manner (Refs. 14 and 21): Assume the same periodicity on the $u^{(k)}_i$, i.e., set $u^{(k)}_{i+N}=u^{(k)}_i\forall i,k$ and modify the bracket above such that

$$\{u^{(k)}_i,u^{(l)}_j\}_{\mathbf{h}}=\left(\sum_{n=-\infty}^{\infty}(\delta_{i,j+1+nN}-\delta_{i,j+nN})\right)u^{(k)}_iu^{(l)}_j \quad \text{if } k<l,$$

$$\{u^{(k)}_i,u^{(l)}_j\}_{\mathbf{h}}=\left(\sum_{n=-\infty}^{\infty}(\delta_{i,j+nN}-\delta_{i,j-1+nN})\right)u^{(k)}_iu^{(l)}_j \quad \text{if } k>l,$$

$$\{u^{(k)}_i,u^{(k)}_j\}_{\mathbf{h}}=0.$$

Theorem 3 is valid for this simple bracket without much change.

Considering the presence of two space variables in the KP equation, it is natural to ask for a further symmetry in the system corresponding to periodicity in a second spatial direction. Such a system was considered in Ref. 9 for instance. For the purposes of this paper, let us only assume that we want to find a Poisson bracket such that the dependence of $\{u^{(k)}_i,u^{(l)}_j\}_{\mathbf{h}}$ on k and l is only via the value of $k-l$ in $\mathbb{Z}/M\mathbb{Z}$, and in particular does not depend on whether $k<l$ or $k>l$. The bracket $\{,\}_{\mathbf{h}}$ of Theorem 3 does not satisfy this condition.

Assume that M and N are relatively prime. Make a change of indexing by setting $w^{(k)}_i=u^{(k)}_{i-k}$. Below, we will construct another element of $\mathcal{D}(\mathbf{h})$ such that when added to the bracket of 3, we obtain a doubly periodic bracket on $w^{(k)}_i$'s.

We start from some general results. Recall the following notation: Say $A=(a_{ij})$ and $B=(b_{ij})$ where a_{ij},b_{ij} are C^∞ functions on a Poisson manifold. Define $\{A^{\otimes},B\}$ to be the matrix obtained in the same way as taking a Kronecker product, but where each product of a pair of functions is replaced by their Poisson brackets. It is easy to see that the matrix Leibniz rule holds, i.e., $\{AB^{\otimes},C\}=(A\otimes I)\{B^{\otimes},C\}+\{A^{\otimes},C\}(B\otimes I)$. Here I is the identity matrix.

Let us return to the setting of the Poisson manifolds $\mathbf{h}$ and g_m above. Suppose that S is a set of positive integers, and let t be a non-negative integer. Let E^t_S denote the matrix which is the tth elementary symmetric function in the matrices $U^{(i)}$ with $i\in S$. (Since $U^{(i)}$ do not commute, the order of products appearing in this symmetric function is important. In each case, we order the $U^{(i)}$ with respect to increasing order in i.) Notice that $f^*(V)=I+\Sigma_{t=1}^n E^t_{1,\ldots,m}$.

Lemma 1: Let c be a positive integer. For any fixed integer t such that $0\leqslant t\leqslant c$,

$$\sum_{i=1}^{m}E^t_{1,\ldots,i-1}U^{(i)}E^{c-t}_{i+1,\ldots,m}=E^{c+1}_{1,\ldots,m}.$$

Proof: Consider an arbitrary monomial of the form $U^{(j_1)}\cdots U^{(j_{c+1})}$ such that $j_1<\cdots<j_{c+1}$. We claim that this occurs once in both sides of the sum above. This is clear for the right-hand side, and for the left-hand side it is obtained for $i=j_{t+1}$. ■

Let $F\in\hat{\mathrm{M}}(\infty)\otimes\hat{\mathrm{M}}(\infty)$ be a diagonal matrix, i.e., $F_{ij,kl}=0$ unless $i=j$ and $k=l$. The formula $\{U^{(k)\otimes},U^{(l)}\}_{\mathbf{h}}=F(U^{(k)}\otimes U^{(l)})$, explicitly written, means

$$\{u^{(k)}_i,u^{(l)}_j\}=F_{i+1i+1,j+1j+1}u^{(k)}_iu^{(l)}_j.$$

Therefore this defines a simple quadratic Poisson bracket on $\mathbf{h}$ if and only if the antisymmetry condition is satisfied, which happens if and only if $F_{ii,jj}=-F_{jj,ii}$ for all i,j. Notice that this class of brackets does not include any brackets that depend on k or l, and in particular the bracket of Theorem 3.

Define $F^{a,b}$ to be the diagonal matrix such that $F^{a,b}_{ij,kl}=F_{i-aj-a,k-bl-b}$, i.e., F shifted a blocks downwards along the diagonal, and b entries within each block. Notice that $(U^{(i)}\otimes I)F=F^{1,0}(U^{(i)}\otimes I)$ and $(I\otimes U^{(i)})F=F^{0,1}(I\otimes U^{(i)})$.

Theorem 4: *Let $F\in\hat{\mathrm{M}}(\infty)\otimes\hat{\mathrm{M}}(\infty)$ be a diagonal matrix satisfying the antisymmetry condition above. Define a Poisson bracket on* $\mathbf{h}$ *via the formula $\{U^{(k)\otimes},U^{(l)}\}_{\mathbf{h}}=F(U^{(k)}\otimes U^{(l)})$ for all i,j. Then $\{,\}_{\mathbf{h}}\in\mathcal{D}(\mathbf{h})$.*

Proof: Compute $\{f^*(V)^{\otimes},f^*(V)\}_{\mathbf{h}}$,

$$\begin{aligned}\{f^*(V)^{\otimes},f^*(V)\}_{\mathbf{h}}&=\left\{\prod_{i=1}^{m}(I+U^{(i)})\otimes\prod_{i=1}^{m}(I+U^{(i)})\right\}_{\mathbf{h}}\\&=\sum_{i,j}\left(\prod_{k=1}^{i-1}(I+U^{(k)})\otimes\prod_{n=1}^{j-1}(I+U^{(n)})\right)F(U^{(i)}\otimes U^{(j)})\\&\quad\times\left(\prod_{k=i+1}^{m}(I+U^{(k)})\otimes\prod_{n=j+1}^{m}(I+U^{(n)})\right)\\&=\sum_{i,j,t,s,c_1,c_2}(E^{t}_{1,\ldots,i-1}\otimes E^{s}_{1,\ldots,j-1})F(U^{(i)}\otimes U^{(j)})(E^{c_1-t}_{i+1,\ldots,m}\otimes E^{c_2-s}_{j+1,\ldots,m})\\&=\sum_{i,j,t,s,c_1,c_2}F^{t,s}(E^{t}_{1,\ldots,i-1}\otimes E^{s}_{1,\ldots,j-1})(U^{(i)}\otimes U^{(j)})(E^{c_1-t}_{i+1,\ldots,m}\otimes E^{c_2-s}_{j+1,\ldots,m})\\&=\sum_{c_1,c_2}\left(\sum_{t=0}^{c_1}\sum_{s=0}^{c_2}F^{t,s}\right)E^{c_1+1}_{1,\ldots,m}\otimes E^{c_2+1}_{1,\ldots,m}.\end{aligned}$$

In the last step we used Lemma 1 for each fixed (t,s). This finishes the proof since each $E^{c}_{1,\ldots,m}$ is a diagonal of $f^*(V)$. ∎

Notice that in the proof we obtained, as a bonus, a formula for the descent bracket on g_m. We remark that this new bracket is simple on g_m as well.

Adding the bracket obtained from all possible F's of the type discussed above to the bracket of Theorem 3, we obtain the following set of simple brackets on $\mathbf{h}$:

$$\{u^{(k)}_i,u^{(l)}_j\}_{\mathbf{h}}=(F_{i+1i+1,j+1j+1}+\delta_{i,j+1}-\delta_{i,j})u^{(k)}_iu^{(l)}_j\quad\text{if } k<l,\text{and}$$

$$\{u^{(k)}_i,u^{(l)}_j\}_{\mathbf{h}}=(F_{i+1i+1,j+1j+1}+\delta_{i,j}-\delta_{i,j-1})u^{(k)}_iu^{(l)}_j\quad\text{if } k>l.$$

$$\{u^{(k)}_i,u^{(k)}_j\}_{\mathbf{h}}=F_{i+1i+1,j+1j+1}u^{(k)}_iu^{(l)}_j.$$

We assume that $F=F^{m,m}$ for all m. This implies that the bracket depends on $j-i$, but not on i and j separately. Notice that the bracket already depends on k and l via $l-k$ only. In order to do the same for the bracket periodic in one direction, it is enough to ensure F also produces periodic terms with the same period. For this we assume $F_{ii,jj}=F_{ii,j+Nj+N}\,\forall\, i,j$. The combined bracket is

$$\{u^{(k)}_i,u^{(l)}_j\}_{\mathbf{h}}=\left(F_{i+1i+1,j+1j+1}+\sum_{n=-\infty}^{\infty}(\delta_{i,j+1+nN}-\delta_{i,j+nN})\right)u^{(k)}_iu^{(l)}_j\quad\text{if } k<l,$$

and

$$\{u_i^{(k)},u_j^{(l)}\}_{\mathbf{h}}=\left(F_{i+1i+1,j+1j+1}+\sum_{n=-\infty}^{\infty}(\delta_{i,j+nN}-\delta_{i,j-1+nN})\right)u_i^{(k)}u_j^{(l)}\quad\text{if } k>l,$$

$$\{u_i^{(k)},u_j^{(k)}\}_{\mathbf{h}}=F_{i+1i+1,j+1j+1}u_i^{(k)}u_j^{(l)}.$$

Expressing this bracket in terms of the variables $w_i^{(k)}=u_{i-k}^{(k)}$, we obtain

$$\{w_i^{(k)},w_j^{(l)}\}_{\mathbf{h}}=\left(F_{i-k+1i-k+1,j-l+1j-l+1}+\sum_{n=-\infty}^{\infty}(\delta_{i-k,j-l+1+nN}-\delta_{i-k,j-l+nN})\right)w_i^{(k)}w_j^{(l)}$$

if $k<l$, and

$$\{w_i^{(k)},w_j^{(l)}\}_{\mathbf{h}}=\left(F_{i-k+1i-k+1,j-l+1j-l+1}+\sum_{n=-\infty}^{\infty}(\delta_{i-k,j-l+nN}-\delta_{i-k,j-l-1+nN})\right)w_i^{(k)}w_j^{(l)}$$

if $k>l$.

$$\{w_i^{(k)},w_j^{(k)}\}_{\mathbf{h}}=F_{i-k+1i-k+1,j-l+1j-l+1}w_i^{(k)}w_j^{(l)}.$$

This bracket is still simple, and let us denote the coefficient of $w_i^{(k)}w_j^{(l)}$ in $\{w_i^{(k)},w_j^{(k)}\}_{\mathbf{h}}$ above by κ_{j-i}^{l-k}, noting again that it depends only on $j-i$ and $l-k$, and not separately on the four variables. The indexing makes the formulas look very complicated, but observing the following properties of the function κ_b^a, where $b\in\mathbb{Z}, a\in\{1-k,\ldots,M-k\}$ results in considerable simplification:

$$\kappa_0^0=0,$$

$$\kappa_{b+N}^a=\kappa_b^a\quad\text{for all } a,b,(\text{so assume } b\in\mathbb{Z}/N\mathbb{Z} \text{ for the rest}),$$

$$\kappa_b^a-\kappa_{b-1}^{a-1}=\delta_{a,1}\delta_{b,0}-\delta_{a,1}\delta_{b,1}-\delta_{a,0}\delta_{b,1}+\delta_{a,0}\delta_{b,0}\quad\text{for all } b\in\mathbb{Z}/N\mathbb{Z},$$

and $a\in\{2-k,\ldots,M-k\}$

Finally, we want to select F above, equivalently κ, such that the bracket above becomes doubly periodic. This happens if and only if we can extend κ to all $a\in\mathbb{Z}$ such that $\kappa_b^{a+M}=\kappa_b^a$, and the conditions above are satisfied for all a,b. We prove the following.

Theorem 5: *If M and N are relatively prime positive integers, there exists a unique function κ on $\mathbb{Z}/N\mathbb{Z}\times\mathbb{Z}/M\mathbb{Z}$ such that $\kappa_0^0=0$ and*

$$\kappa_b^a-\kappa_{b-1}^{a-1}=\delta_{a,1}\delta_{b,0}-\delta_{a,1}\delta_{b,1}-\delta_{a,0}\delta_{b,1}+\delta_{a,0}\delta_{b,0}\quad \textit{for all } b\in\mathbb{Z}/N\mathbb{Z} \textit{ and } a\in\mathbb{Z}/M\mathbb{Z}.$$

Proof: Since M and N are relatively prime, $(1,1)$ is a generator for the group $\mathbb{Z}/N\mathbb{Z}\times\mathbb{Z}/M\mathbb{Z}$. Hence the difference equation and the initial value $\kappa_0^0=0$ determines κ uniquely if it exists. To prove existence, consider the sequence $(1,1),(2,2),\ldots$. The two elements $(1,0)$ and $(-1,0)$ of $\mathbb{Z}/N\mathbb{Z}\times\mathbb{Z}/M\mathbb{Z}$ appear in some order in this sequence. If $(1,0)$ appears first, then set

$$\kappa_1^1=\kappa_2^2=\cdots=\kappa^{0,-1}=-1,$$

$$\kappa_{-1}^{-1}=\kappa_{-2}^{-2}=\cdots=\kappa^{0,1}=1,$$

and $\kappa_b^a=0$ otherwise.

If the alternative happens, i.e., if $(-1,0)$ appears before $(1,0)$ then set

$$\kappa_1^1 = \kappa_2^2 = \cdots = \kappa^{-1,0} = -1,$$

$$\kappa_{-1}^{-1} = \kappa_{-2}^{-2} = \cdots = \kappa^{1,0} = 1,$$

and $\kappa_b^a = 0$ otherwise.

It is easy to check that in both cases the difference equation is satisfied. ■

Thus there exists a choice for F making the combined bracket doubly periodic, and we showed that if F is subject the requirements above, it is unique.

Remarks: The proof of the last theorem shows that there are two combinatorially distinct cases depending on M and N. One can check that the alternative which is realized depends on the parity of the number of steps in the Euclidean algorithm for N and M.

The system in Ref. 9 can be equipped with a quadratic Poisson bracket along these lines. However there, the variables on which periodicity is imposed are coordinate functionals in $(I + U_{2i+1})(I + U_{2i+2})$, i.e., the matrices are lumped in pairs. It is also true that the conserved quantities Poisson commute under the bracket obtained. For this computation, and more on the Hamiltonian properties of these systems see Ref. 12 or Ref. 13.

V. CONCLUSION

In this paper we presented a method for producing quadratic Poisson brackets from a family of brackets which are easy to construct (simple brackets), and applied this method to several examples. It is possible to produce large families of Poisson brackets using this method, and then one can seek for a particular element of the family satisfying further requirements, such as commutation of conserved quantities, or periodicity, etc. The method can produce nonlocal brackets which are sometimes indispensable (as in the doubly periodic KP hierarchy above).

We believe the following questions are worthy of further investigation: Given an algebra g, it is unclear at the moment what the locus of brackets obtainable by such a method in the moduli space of all quadratic brackets is. Also, understanding the interplay of conserved quantities with the descent process requires further work (e.g., can one characterize those brackets among descent brackets admitting a large set of commuting quantities?). In a different direction, it might be worthwhile to ask if these brackets can be used in the ways r-matrix brackets are used in geometry, such as in producing link invariants.

APPENDIX: PROOF OF THEOREM 3

We will prove Theorem 3. Recall the formula

$$f^*(v_{ij}) = \sum_{k_1<k_2<\ldots<k_{i-j}\leqslant M} u_i^{(k_1)} u_{i-1}^{(k_2)} \ldots u_{j+1}^{(k_{i-j})}.$$

Lemma 2: Suppose $i>j>m$ Then

$$\{v_{ij}, v_{jm}\}_{g_m} = v_{im}.$$

Also, if $k<j$ then $\{v_{ij}, v_{kl}\}_{g_m} = 0$

Proof: Using the formula above, we can express the bracket in terms of $u_j^{(i)}$'s,

$$\{v_{ij},v_{jm}\}_{g_m}=\left\{\sum_{k_1<k_2<\ldots<k_{i-j}\leqslant M}u_i^{(k_1)}u_{i-1}^{(k_2)}\ldots u_{j+1}^{(k_{i-j})},\sum_{l_1<l_2<\ldots<l_{j-m}\leqslant M}u_j^{(l_1)}u_{j-1}^{(l_2)}\ldots u_{m+1}^{(l_{j-m})}\right\}_{\mathbf{h}}.$$

When the bracket above is expanded using the Leibniz rule, all brackets except those of type $\{u_{j+1}^{(k_{i-j})},u_j^{(l_1)}\}_{\mathbf{h}}$ with $k_{i-j}<l_1$ are zero. Thus we obtain

$$\{v_{ij},v_{jm}\}_{g_m}=\sum_{k_1<\cdots<k_{i-j}<l_1<\cdots<l_{j-m}\leqslant M}u_i^{(k_1)}\cdots u_{j+1}^{(k_{i-j})}u_j^{(l_1)}\cdots u_{m+1}^{(l_{j-m})}=v_{im}.$$

The second part of the assertion is clear, since in that case there are no pairs of terms that give a nonzero bracket. ■

Lemma 3: (i) $\{v_{ii-1},v_{jm}\}_{g_m}=0$ *if* $j>i$ *and* $m<i-1$, (ii) $\{v_{ii-1},v_{im}\}_{g_m}=v_{ii-1}v_{im}$ *if* $m<i-1$, (iii) $\{v_{ii-1},v_{ji-1}\}_{g_m}=-v_{ii-1}v_{ji-1}$ *if* $j>i$.

Proof:

$$\{v_{ii-1},v_{jm}\}_{g_m}=\left\{\sum_{k\leqslant M}u_i^{(k)},\sum_{l_1<\cdots<l_{j-m}\leqslant M}u_j^{(l_1)}\cdots u_{m+1}^{(l_{j-m})}\right\}_{\mathbf{h}}.$$

Consider brackets of pairs of monomials. $u_i^{(k)}$ may have nonzero brackets only with the three terms $u_{i+1}^{(l_a)},u_i^{(l_b)}$ and $u_{i-1}^{(l_c)}$ of a monomial $\mathbf{m}$ in v_{jm}. For part (i), note that by the hypothesis $j>i>m+1$, each monomial $\mathbf{m}$ of v_{jm} contains all three terms. For convenience, $\mathbf{m}$ will be indexed as $\mathbf{m}_{l_a,l_b,l_c}$. If $k\leqslant l_a$, $l_c\leqslant k$ or $k=l_b$, one checks that $\{u_i^{(k)},\mathbf{m}_{l_a,l_b,l_c}\}_{\mathbf{h}}=0$. If $l_a<k<l_b$, then $\{u_i^{(k)},\mathbf{m}_{l_a,l_b,l_c}\}_{\mathbf{h}}=-\{u_i^{(l_b)},\mathbf{m}_{l_a,k,l_c}\}_{\mathbf{h}}$. Therefore the sum vanishes because of pairwise cancellation, and (i) is proven.

To prove (ii), note that $u_i^{(l_b)}$ and $u_{i-1}^{(l_c)}$, but not $u_{i+1}^{(l_a)}$ occur in each monomial $\mathbf{m}$ of v_{im} (hence, denoted by $\mathbf{m}_{l_b,l_c}$). If $k<l_b$, $\{u_i^{(k)},\mathbf{m}_{l_b,l_c}\}_{\mathbf{h}}=0$, if $l_b<k<l_c$, $\{u_i^{(k)},\mathbf{m}_{l_b,l_c}\}_{\mathbf{h}}=2u_i^{(k)}\mathbf{m}_{l_b,l_c}$. Therefore for $k<l_b$, $\{u_i^{(k)},\mathbf{m}_{l_b,l_c}\}_{\mathbf{h}}+\{u_i^{(l_b)},\mathbf{m}_{k,l_c}\}_{\mathbf{h}}=2u_i^{(k)}\mathbf{m}_{l_b,l_c}$. For $k=l_b$ and $k\geqslant l_c$ one gets $\{u_i^{(k)},\mathbf{m}_{l_b,l_c}\}_{\mathbf{h}}=u_i^{(k)}\mathbf{m}_{l_b,l_c}$. Therefore, the sum of all the terms gives $v_{ii-1}v_{im}$. (iii) is similar to (ii). ■

Lemma 4: $\{v_{ij},v_{nm}\}_{g_m}=0$ *if* $n>i$ *and* $m<j$.

Proof: Do induction on $i-j$. For $i-j=1$, the statement reduces to (i) of Lemma 3. Notice that by Lemma 2 $v_{ij}=\{v_{ij+1},v_{j+1j}\}_{g_m}$. Then

$$\{v_{ij},v_{nm}\}_{g_m}=\{\{v_{ij+1},v_{j+1j}\}_{g_m},v_{nm}\}_{g_m}=-\{\{v_{nm},v_{ij+1}\}_{g_m},v_{j+1j}\}_{g_m}-\{\{v_{j+1j},v_{nm}\}_{g_m},v_{ij+1}\}_{g_m}=0$$

by the Jacobi identity and the induction hypothesis. ■

Lemma 5: (i) $\{v_{kj},v_{ij}\}_{g_m}=v_{kj}v_{ij}$ *if* $k>i$. (ii) $\{v_{ij},v_{ik}\}_{g_m}=v_{ij}v_{ik}$ *if* $j>k$.

Proof: The two parts are similar, so we will only prove (i). Again, do induction on $i-j$. Notice $v_{ij}=\{v_{ij+1},v_{j+1j}\}_{g_m}$,

$$\begin{aligned}\{v_{kj},v_{ij}\}_{g_m}&=\{v_{kj},\{v_{ij+1},v_{j+1j}\}\}_{g_m}\\&=-\{v_{j+1j},\{v_{kj},v_{ij+1}\}_{g_m}\}_{g_m}-\{v_{ij+1},\{v_{j+1j},v_{kj}\}_{g_m}\}_{g_m}\\&=-\{v_{j+1j},0\}_{g_m}+\{v_{ij+1},v_{j+1j}v_{kj}\}_{g_m}\\&=\{v_{ij+1},v_{j+1j}\}_{g_m}v_{kj}+\{v_{ij+1},v_{kj}\}_{g_m}v_{j+1j}\\&=v_{ij}v_{kj}.\end{aligned}$$

■

Lemma 6: Suppose $i>k>j>l$. *Then* $\{v_{ij},v_{kl}\}_{g_m}=v_{ij}v_{kl}+v_{kj}v_{il}$.

Proof: We know that $v_{kl}=\{v_{kj},v_{jl}\}_{g_m}$. Then,

$$
\begin{aligned}
\{v_{ij},v_{kl}\}_{g_m} &= \{v_{ij},\{v_{kj},v_{jl}\}_{g_m}\}_{g_m} \\
&= -\{v_{jl},\{v_{ij},v_{kj}\}_{g_m}\}_{g_m} - \{v_{kj},\{v_{jl},v_{ij}\}_{g_m}\}_{g_m} \\
&= -\{v_{jl},v_{ij}v_{kj}\}_{g_m} + \{v_{kj},v_{il}\}_{g_m} \\
&= -\{v_{jl},v_{ij}v_{kj}\}_{g_m} \\
&= -\{v_{jl},v_{ij}\}_{g_m}v_{kj} - \{v_{jl},v_{kj}\}_{g_m}v_{ij} \\
&= v_{il}v_{kj} + v_{kl}v_{ij}.
\end{aligned}
$$

■

Thus the proof is complete.

On deformations of standard *R*-matrices for integrable infinite-dimensional systems

Błażej M. Szablikowski[a] and Maciej Błaszak[b]
Institute of Physics, A. Mickiewicz University, Poznań, Poland

(Received 2 December 2004; accepted 19 January 2005; published online 17 March 2005)

Simple deformations, with a parameter ϵ, of classical R-matrices which follow from decomposition of appropriate Lie algebras, are considered. As a result nonstandard Lax representations for some well-known integrable systems are presented and integrable evolution equations are constructed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1868373]

I. INTRODUCTION

In the theory of nonlinear evolutionary systems one of the most important problems is construction of integrable systems. By integrable systems we understand those which have infinite hierarchy of commuting symmetries. It is well known that a very powerful tool, called the classical R-matrix formalism, can be used for systematic construction of field and lattice integrable dispersive systems (soliton systems) as well as dispersionless integrable field systems (see Refs. 1–10 and the references therein).

The crucial point of the formalism is the observation that integrable systems can be obtained from Lax equations. Let $\mathfrak{g}$ be a Lie algebra, equipped with the Lie bracket $[\cdot,\cdot]$. A linear map $R:\mathfrak{g}\to\mathfrak{g}$, such that the bracket $[a,b]_R:=[Ra,b]+[a,Rb]$ is a second Lie product on $\mathfrak{g}$, is called the classical R-matrix. Assume that R satisfies a Yang–Baxter equation YB(α): $[Ra,Rb]-R[a,b]_R+\alpha[a,b]=0$, which is a sufficient condition for R to be an R-matrix. Then, powers of L generate mutually commuting vector fields

$$L_{t_n}=[R(L^n),L]. \tag{1}$$

For fixed n the remaining systems are considered as its symmetries. In this sense (1) represents a hierarchy of integrable dynamical systems.

In this paper the deformation method for systems (1), preserving the integrability, is presented. It has been done on the level of their Lax representations through simple deformations, with parameter ϵ, of classical R-matrices. It is shown that such a procedure leads to the construction of nonstandard Lax representations for some well-known integrable systems as well as to the construction of new integrable evolution equations.

II. DEFORMATIONS OF STANDARD *R*-MATRICES

To construct the simplest R-structure let us assume that the Lie algebra $\mathfrak{g}$ can be split into a direct sum of Lie subalgebras $\mathfrak{g}_+$ and $\mathfrak{g}_-$, i.e., $\mathfrak{g}=\mathfrak{g}_+\oplus\mathfrak{g}_-$, where $[\mathfrak{g}_\pm,\mathfrak{g}_\pm]\subset\mathfrak{g}_\pm$. Denoting the projections onto these subalgebras by $P_\pm$, we define the R-matrix as

$$R=\tfrac{1}{2}(P_+-P_-). \tag{2}$$

Straightforward calculation shows that (2) solves YB$\left(\frac{1}{4}\right)$. The classical R-matrices constructed in this way we understand as standard ones.

[a]Electronic mail: bszablik@amu.edu.pl
[b]Electronic mail: blaszakm@amu.edu.pl

Let us consider the following deformation of (2):

$$R'(a) = R(a) + \epsilon r(a), \tag{3}$$

where ϵ is an arbitrary constant playing the role of a deformation parameter and r is a linear deformation operator. First, assume that r satisfies the following two relations:

$$[ra,b_+] \in \mathfrak{g}_+, \quad [ra,b_-] \in \mathfrak{g}_-, \quad a \in \mathfrak{g}, \quad b_+ \in \mathfrak{g}_+, \quad b_- \in \mathfrak{g}_-. \tag{4}$$

So, the question arises when the deformed R preserves the property of being R-matrix. Once again, straightforward calculation shows that (3) solves $\mathrm{YB}(\frac{1}{4})$ when the following condition is fulfilled:

$$r[a,b]_R + \epsilon r[a,b]_r - \epsilon[ra,rb] = 0, \tag{5}$$

where $[a,b]_r = [ra,b] + [a,rb]$.

III. DISPERSIONLESS SYSTEMS

Let A be the algebra of formal Laurent series (Lax polynomials) in p (Ref. 6),

$$A = \left\{ L = \sum_{i \in Z} u_i(x) p^i \right\}, \tag{6}$$

where the coefficients $u_i(x)$ are smooth functions of x. Poisson brackets on A can be introduced in infinitely many ways as

$$[f,g] \equiv \{f,g\}_s := p^s \left(\frac{\partial f}{\partial p}\frac{\partial g}{\partial x} - \frac{\partial f}{\partial x}\frac{\partial g}{\partial p} \right), \quad s \in \mathbb{Z}. \tag{7}$$

Then, fixing s, A is the Poisson algebra with an appropriate bracket (7). We construct the standard R-matrix, through a decomposition of A into a direct sum of Lie subalgebras. For a fixed s let $A_{\geqslant -s+k} = \{\Sigma_{i \geqslant -s+k} u_i(x) p^i\}$ and $A_{<-s+k} = \{\Sigma_{i<-s+k} u_i(x) p^i\}$. Then, $A_{\geqslant -s+k}$, $A_{<-s+k}$ are Lie subalgebras in the following cases:

(1) $s=0$, $k=0$,
(2) $s \in \mathbb{Z}$, $k=1,2$,
(3) $s=2$, $k=3$.

So, fixing s we fix the Lie algebra structure with k numbering the standard R-matrices given in the following form:

$$R = \tfrac{1}{2}(P_{\geqslant -s+k} - P_{<-s+k}) = P_{\geqslant -s+k} - \tfrac{1}{2} = \tfrac{1}{2} - P_{<-s+k}, \tag{8}$$

where P are appropriate projections. The Lax hierarchy (1) can be represented by two equivalent representations,

$$L_{t_q} = \{(L^q)_{\geqslant -s+k}, L\}_s = -\{(L^q)_{<-s+k}, L\}_s. \tag{9}$$

Notice that different schemes are interrelated. Under the transformation

$$x' = x, \quad p' = p^{-1}, \quad t' = t \tag{10}$$

the Lax hierarchy (9) defined by k, s, and L transforms into the Lax hierarchy (9) defined by $k' = 3-k$, $s' = 2-s$, and $L' = L$, i.e.,

$$L \text{ for } k, \quad s \quad \Leftrightarrow \quad L' = L \quad \text{for } k' = 3-k, \quad s' = 2-s. \tag{11}$$

In such a situation it is enough to consider the cases of $k=0$ and $k=1$.

We are interested in extracting closed systems for a finite number of fields. To obtain a consistent Lax equation, the Lax operator L must form a proper submanifold of the full Poisson algebra A, i.e., the left- and right-hand sides of expression (9) must coincide. They are given in the form[7]

$$s=0, \quad k=0, \quad L=p^N+u_{N-2}p^{N-2}+u_{N-3}p^{N-3}+\cdots+u_1p+u_0, \tag{12}$$

$$s\in\mathbb{Z}, \quad k=1, \quad L=p^N+u_{N-1}p^{N-1}+\cdots+u_{1-m}p^{1-m}+u_{-m}p^{-m}, \tag{13}$$

where u_i are dynamical fields. Notice, that powers of L, in general fractional, can be calculated by expanding them around poles, for (12) around ∞ and for (13) around ∞ and 0. So, for $k=0$ we construct one Lax hierarchy and for $k=1$ we construct, in general, two mutually commuting Lax hierarchies.

We are looking for a simple deformation of (8) in the form

$$r=p^{\alpha}P_{\beta}, \quad P_{\beta}(L)=[L]_{\beta}=u_{\beta} \tag{14}$$

which will satisfy (4) and (5) for arbitrary ϵ. By some straightforward calculations, we find them in the form

$$r=p^{-s+k}P_{k-1} \quad \text{for} \begin{cases} (1) & s=0, \quad k=0, \\ (2) & s=0, \quad k=1, \\ (3) & s=1, \quad k=1 \end{cases} \tag{15}$$

and

$$r=p^{-s+k-1}P_{k-2} \quad \text{for} \begin{cases} (4) & s=1, \quad k=2, \\ (5) & s=2, \quad k=2, \\ (6) & s=2, \quad k=3. \end{cases} \tag{16}$$

We see that deformations of (8) given by the form (3) and (14), exist only for distinguished values of s and k. Nevertheless, for particular fixed values of ϵ and fixed s (i.e., fixed Lie algebra) there exist other deformations of the form (14), but they are trivial in the sense that they relate standard R-matrices (8) with different k. Moreover, deformations (16) are constructed from (15) by using transformation (10) and (11). Hence, the only relevant deformations are (15) and so further we will consider only them. The deformed R-matrices for the cases in (15) take the form

$$R'=P_{\geqslant -s+k}-\tfrac{1}{2}+\epsilon p^{-s+k}P_{k-1}=\tfrac{1}{2}-P_{<-s+k}+\epsilon p^{-s+k}P_{k-1}. \tag{17}$$

The case: $s=0$, $k=0$.

The Lax hierarchy for a deformed R-matrix is

$$L_{t_q}=\{(L^q)_{\geqslant 0}+\epsilon[L^q]_{-1},L\}_0=-\{(L^q)_{<0}-\epsilon[L^q]_{-1},L\}_0. \tag{18}$$

Consistent Lax equations are obtained for Lax operators of the form

$$L=p^N+u_{N-1}p^{N-1}+u_{N-2}p^{N-2}+\cdots+u_1p+u_0, \tag{19}$$

where u_i are dynamical fields. From (18) it follows that

$$\begin{aligned} (u_{N-1})_{t_q}&=-\epsilon N([L^q]_{-1})_x, \\ (u_{N-2})_{t_q}&=N([L^q]_{-1})_x-\epsilon(N-1)u_{N-1}([L^q]_{-1})_x, \\ &\cdots \quad . \end{aligned} \tag{20}$$

So, for $\epsilon=0$ the field u_{N-1} becomes time independent and without losing the generality we can

assume that it is zero. Then, Lax operator becomes a standard Lax operator (12) for the case with nondeformed R-matrix. From (20) the following relation between u_{N-1} and u_{N-2} results:

$$u_{N-2} = -\frac{1}{\epsilon}u_{N-1} + \frac{N-1}{2N}(u_{N-1})^2 \tag{21}$$

so we can eliminate one of them. Eliminating u_{N-2} we will consider constrained Lax operator in the form

$$L = p^N + u_{N-1}p^{N-1} + \left(-\frac{1}{\epsilon}u_{N-1} + \frac{N-1}{2N}(u_{N-1})^2\right)p^{N-2} + u_{N-3}p^{N-3} + \cdots + u_1 p + u_0. \tag{22}$$

Reparametrizing (22), $u_{N-1} \mapsto -\epsilon u_{N-2}$ and then taking the limit $\epsilon \to 0$ it becomes the standard Lax operator (12).

Lemma 3.1: For arbitrary ϵ the Lax hierarchy (18) and (22) *is equivalent to the Lax hierarchy* (9) and (12) *with* $s=k=0$.

The sketch of the proof is as follows. We are looking for transformations that will relate fields from (22) and fields from (12). We postulate the following form of these relations:

$$u_{N-1} \mapsto -\epsilon u_{N-2},$$

$$u_i \mapsto u_i + f_i(u_{N-2}, u_{N-3}, \ldots, u_{i+1}) \quad \text{for } N-3 \geqslant i \geqslant 0. \tag{23}$$

Then, we construct functions f_i in such a way, that hierarchy (18) will lead to the same evolution system as (9) for $s=k=0$. We compare the first nontrivial systems from these hierarchies. Functions f_i are recursively constructed comparing evolution expressions for u_{i+1t}. Such a procedure guarantees that the expressions for the fields will be the same only for components $u_{N-2_t}, \ldots, u_{1_t}$. So, the equality between both evolution expressions for u_0 must be argued. The systems for Lax operators (12) and (22) both can be understood as the reduction of infinite-field systems for Lax operators of the form $L' = a_1 p + a_0 + a_{-1}p^{-1} + \ldots$, given by constraint $L = L'^N$. The equivalence between the hierarchies considered, constructed from L', can be shown by explicit infinite recurrence form (23). Now, reducing them to finite-field systems one finds the appropriate transformation between finite-field systems, including the evolution for u_0. So, the Lax hierarchy (18) and (22) is a new representation of well-known integrable dispersionless hierarchies. The form of transformation (23), relating both systems, guarantees that it is an invertible transformation.

Example 3.2: Dispersionless KdV: $N=2$.

For $L = p^2 + up + v$ *and* $L_{t_i} = \{(L^{i/2})_{\geqslant 0} + \epsilon[L^{i/2}]_{-1}, L\}_0$ *we find*

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_1} = \begin{pmatrix} \frac{1}{2}\epsilon u u_x - \epsilon v_x \\ \frac{1}{4}(\epsilon u - 2)(u u_x - 2v_x) \end{pmatrix},$$

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_3} = \begin{pmatrix} -\frac{3}{16}\epsilon(u^2 - 4v)(u u_x - 2v_x) \\ -\frac{3}{32}\epsilon(\epsilon u - 2)(u^2 - 4v)(u u_x - 2v_x) \end{pmatrix}, \tag{24}$$

$$\cdots.$$

In the limit $\epsilon \to 0$ *and* $u=0$ *it becomes the standard dispersionless KdV hierarchy. Notice, that fields* u and v *are not independent. According to* (21) $v = -(1/\epsilon)u + \frac{1}{4}u^2$ *and the hierarchy* (24) *is equivalent to the one*

$$u_{t_1} = u_x, \quad u_{t_3} = -\frac{3}{2\epsilon}u u_x, \quad \cdots, \tag{25}$$

i.e., reparametrized dispersionless KdV. The transformation to the standard form of dispersionless

KdV is given by $u\mapsto -\epsilon u$. *The hierarchy* (25) *is generated from* $L=p^2+up+\frac{1}{4}u^2-(1/\epsilon)u$.

Example 3.3: Dispersionless Boussinesq: $N=3$.

Here we present only the result for the constrained Lax operator (22) $L=p^3+up^2+\left[\frac{1}{3}u^2-(1/\epsilon)u\right]p+w$. *Then, the first nontrivial system from the hierarchy is*

$$L_{t_2}=\{(L^{\frac{2}{3}})_{\geqslant 0}+\epsilon[L^{\frac{2}{3}}]_{-1},L\}_0 \Leftrightarrow \begin{pmatrix} u \\ w \end{pmatrix}_{t_2} = \begin{pmatrix} \frac{2}{9}(\epsilon u-6)uu_x-2\epsilon w_x \\ \frac{2}{81\epsilon^2}(\epsilon u-3)(\epsilon u(\epsilon u-9)+9)uu_x-\frac{2}{9}(\epsilon u-6)uw_x \end{pmatrix}.$$

Eliminating the field w *we obtain the reparametrized dispersionless Boussinesq,* $u_{tt}=(2/3\epsilon)\times(u^2)_{xx}$. *The transformation* (23) *to the standard form of the dispersionless Boussinesq system is given by* $u\mapsto -\epsilon u$, $w\mapsto w-\frac{1}{3}\epsilon u^2-\frac{1}{27}\epsilon^3u^3$.

The case: $s=0$, $k=1$.

The Lax hierarchy for the deformed R-matrix (17) is

$$L_{t_q}=\{(L^q)_{\geqslant 1}+\epsilon[L^q]_0p,L\}_0=-\{(L^q)_{<1}-\epsilon[L^q]_0p,L\}_0. \tag{26}$$

Appropriate Lax operators are of the form

$$L=u_Np^N+u_{N-1}p^{N-1}+\cdots+u_{1-m}p^{1-m}+u_{-m}p^{-m}. \tag{27}$$

From (26) one finds that $(u_N)_t=\epsilon(u_N)_x[L^q]_0-\epsilon Nu_N([L^q]_0)_x$. Hence, in the limit of $\epsilon=0$ the field u_N becomes a time-independent field c_N. Fixing $c_N=1$ the Lax operator becomes a standard Lax operator (13) for $s=0$, $k=1$. Moreover, there is no constraint contrary to the previous case. Hence, the Lax hierarchy (27) and (26) leads to new integrable dispersionless systems, at least to the best of our knowledge. Notice that the zero power of L always leads to the space translation symmetry, $L_{t_0}=\epsilon L_x$.

Example 3.4: Extended dispersionless Benney, $N=m=1$.

Let $L=up+v+wp^{-1}$, *then for* $L_{t_i}=\{(L^i)_{\geqslant 1}+\epsilon[L^i]_0p,L\}_0$ *we find*

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_0} = \epsilon\begin{pmatrix} u_x \\ v_x \\ w_x \end{pmatrix},$$

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} \epsilon u_xv-\epsilon uv_x \\ uv_x+\epsilon vv_x \\ u_xw+uw_x+\epsilon v_xw+\epsilon vw_x \end{pmatrix},$$

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_2} = \begin{pmatrix} \epsilon u_xv^2-2\epsilon uvv_x-2\epsilon u^2w_x \\ 2uu_xw+2uvv_x+2u^2w_x+\epsilon v^2v_x+2\epsilon uv_xw \\ 2u_xvw+2uv_xw+2uvw_x+2\epsilon u_xw^2+2\epsilon vv_xw+\epsilon v^2w_x+4\epsilon uww_x \end{pmatrix},$$

$$\cdots.$$

In the limit $\epsilon\to 0$ *and* $u=1$ *we obtain the standard dispersionless Benney system.*

Example 3.5: Two field system, $N=0$, $m=1$.

Consider $L=v+wp^{-1}$. *Then* $[L^i]_0=v^i$ *and* $(L^i)_{\geqslant 1}=0$ *for* $i=0,1,2,\ldots$. *Hence we obtain the system*

$$L_{t_i}=\{\epsilon[L^i]_0p,L\}_0 \Leftrightarrow \begin{pmatrix} v \\ w \end{pmatrix}_{t_i} = \begin{pmatrix} \epsilon v^iv_x \\ \epsilon(v^iw)_x \end{pmatrix} \tag{28}$$

which does not have any standard counterpart.

The case: $s=1$, $k=1$.

The Lax hierarchy is

$$L_{t_q} = \{(L^q)_{\geqslant 0} + \epsilon[L^q]_0, L\}_1 = -\{(L^q)_{<0} - \epsilon[L^q]_0, L\}_1 \tag{29}$$

and appropriate Lax operators take the form

$$L = u_N p^N + u_{N-1} p^{N-1} + \cdots + u_{1-m} p^{1-m} + u_{-m} p^{-m}. \tag{30}$$

From (29) it follows that

$$(u_N)_t = -\epsilon N u_N([L^q]_0)_x, \quad \cdots, \quad (u_{-m})_t = (1+\epsilon) m u_{-m}([L^q]_0)_x. \tag{31}$$

So, we find that the highest and lowest fields are related by

$$u_N^{(1+\epsilon)m} = u_{-m}^{-\epsilon N}.$$

For $\epsilon=0$ the field u_N becomes a time-independent field c_N (let $c_N=1$), then the Lax operator (30) becomes a standard Lax operator (13) for $s=k=1$. For $\epsilon=-1$ the field u_{-m} becomes time independent and the Lax operator becomes a standard Lax operator for $s=1$, $k=2$. This last case follows from the fact that for $s=1$, $k=1$, and $\epsilon=-1$ the deformed R-matrix (17) becomes the standard R-matrix (8) for $s=1$, $k=2$. Eliminating u_N field the Lax operator takes the form

$$L = u_{-m}^{-[\epsilon N/(1+\epsilon)m]} p^N + u_{N-1} p^{N-1} + \cdots + u_{1-m} p^{1-m} + u_{-m} p^{-m}. \tag{32}$$

In the limit $\epsilon \to 0$ it becomes the standard Lax operator (13) for $s=k=1$.

Lemma 3.6: For arbitrary ϵ*, the Lax hierarchy* (29) and (30) *is equivalent to the Lax hierarchy* (9) and (13) *with* $s=k=1$.

To show this let us make the following transformation:

$$u_i \mapsto u_i u_N^{i/N}, \quad p \mapsto u_N^{-1/N} p \quad \text{for } N-1 \geqslant i > -m. \tag{33}$$

The Poisson bracket (7) for $s=1$ is invariant under (33). Moreover, the Lax operators (30) transform into (13) one. Then, after the transformation of coordinates (33)

$$L_t \mapsto L_t + \frac{1}{N} u_N^{-1} (u_N)_t p L_p \overset{\text{by (31)}}{=} L_t - \epsilon([L^q]_0)_x p L_p = L_t + \{\epsilon[L^q]_0, L\}_1.$$

Hence, the hierarchy (29) turns into (9) one with $s=k=1$.

Example 3.7: Extended dispersionless Toda, $N=m=1$.

For Lax operator $L=up+v+wp^{-1}$ *from* $L_{t_1}=\{(L)_{\geqslant 0}+\epsilon[L]_0, L\}_0$ *we find*

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} -\epsilon u v_x \\ u_x w + u w_x \\ (1+\epsilon) v_x w \end{pmatrix}.$$

In the limit $\epsilon=0$ *and* $u=1$ *we obtain the standard dispersionless Toda system. In the limit* $\epsilon=-1$ and $w=1$ *we obtain the reparametrized dispersionless Toda system. The transformation* (33) *to the standard case is given by* $v \mapsto v$, $w \mapsto u^{-1} w$. *Eliminating field* u, *for* $L = w^{-[\epsilon/(1+\epsilon)]} p + v + w p^{-1}$, *we get*

$$\begin{pmatrix} v \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} \dfrac{1}{1+\epsilon} w^{-[\epsilon/1+\epsilon]} w_x \\ (1+\epsilon) v_x w \end{pmatrix}.$$

For $\epsilon=0$ *or by the transformation* $v \mapsto v$, $w \mapsto w^{1+\epsilon}$ *it becomes the standard dispersionless Toda system.*

Notice that for some dispersionless systems it is possible to construct their integrable dispersive counterparts, field and lattice soliton systems. Actually, one can do it on the level of their Lax representation through Weyl-Moyal-type deformation quantization procedure[10] of the dispersionless case. The idea relies on the deformation of the usual multiplication in A (6) to the new associative but noncommutative product,

$$f\star g = f\exp(\hbar p^s\partial_p \otimes \partial_x)g = \sum_{i\geqslant 0}\frac{\hbar^i}{i!}(p^s\partial_p)^i f\cdot\partial_x^i g, \quad f,g\in A \tag{34}$$

called $\star$-product. It depends on the formal deformation parameter $\hbar$. The Lie algebra structure is defined by the commutator $\{f,g\}_\star^s=(1/\hbar)(f\star g-g\star f)$. Then, the $\star$-product (34) in the limit $\hbar\to 0$ reduces to the standard multiplication and the commutator reduces to the Poisson bracket (7) for fixed s. To construct integrable dispersive systems one must split the algebra A with the $\star$-product into a direct sum of its Lie subalgebras and then construct the standard R-matrices. It can be done only for $s=0,1,2$. But, the case $s=2$ is equivalent to the case $s=0$. The algebra A with $\star$-product (34) for $s=0$ is isomorphic to the Lie algebra of pseudodifferentials operators (35), while for $s=1$ is isomorphic to the Lie algebra of shift operators (47) ($\mathcal{E}=\exp\hbar\partial_x$). The first case leads to the construction of field soliton systems, and the second one leads to the construction of lattice soliton systems. Obviously, integrable dispersionless systems can be constructed from integrable dispersive systems in the so-called quasiclassical (dispersionless) limit, $\partial_t\mapsto\hbar\partial_t$, $\partial_x\mapsto\hbar\partial_x$, and $\hbar\to 0$.

IV. FIELD SOLITON SYSTEMS

Let $\mathfrak{g}$ be the algebra of pseudodifferential operators[2]

$$\mathfrak{g}=\left\{L=\sum_{i\in\mathbf{Z}}u_i(x)\partial_x^i\right\}, \tag{35}$$

where the multiplication of two such operators uses the generalized Leibniz rule $\partial^m u=\sum_{s\geqslant 0}\binom{m}{s}u_{sx}\partial_x^{m-s}$. The Lie algebra structure of $\mathfrak{g}$ is given by the commutator $[L_1,L_2]=L_1L_2-L_2L_1$. We consider decomposition of $\mathfrak{g}$ in the form $\mathfrak{g}_{\geqslant k}=\{\sum_{i\geqslant k}u_i(x)\partial_x^i\}$ and $\mathfrak{g}_{<k}=\{L=\sum_{i<k}u_i(x)\partial_x^i\}$, which are Lie subalgebras for $k=0,1,2$. In this case the standard R-matrices are given by

$$R=\tfrac{1}{2}(P_{\geqslant k}-P_{<k})=P_{\geqslant k}-\tfrac{1}{2}=\tfrac{1}{2}-P_{<k}.$$

So, the Lax hierarchy has the form

$$L_{t_q}=[(L^q)_{\geqslant k},L]=-[(L^q)_{<k},L]. \tag{36}$$

Consistent Lax equations are obtained for Lax operators of the form[3]

$$k=0,\quad L=\partial_x^N+u_{N-2}\partial_x^{N-2}+\cdots+u_1\partial_x+u_0, \tag{37}$$

$$k=1,\quad L=\partial_x^N+u_{N-1}\partial_x^{N-1}+\cdots+u_0+\partial_x^{-1}u_{-1}, \tag{38}$$

$$k=2,\quad L=u_N\partial_x^N+u_{N-1}\partial_x^{N-1}+\cdots+u_0+\partial_x^{-1}u_{-1}+\partial_x^{-2}u_{-2}, \tag{39}$$

where u_i are dynamical fields. Comparing Lax operators (37)–(39) with those for the dispersionless case (12) and (13) for $s=0$ we see that not all dispersionless systems have dispersive counterparts.

The simple deformations satisfying (4) and (5) are the following ones:

$$r = P_{k-1}(\cdot)\partial_x^k \quad \text{for } k = 0,1.$$

Note, that the first case has been considered, in a little bit of a different manner, earlier in Ref. 4. Hence, the deformed R-matrices have the form

$$R' = P_{\geqslant k} - \tfrac{1}{2} + \epsilon P_{k-1}(\cdot)\partial_x^k = \tfrac{1}{2} - P_{<k} + \epsilon P_{k-1}(\cdot)\partial_x^k.$$

The case: $k=0$.

The Lax hierarchy is

$$L_{t_q} = [(L^q)_{\geqslant 0} + \epsilon[L^q]_{-1}, L] = -[(L^q)_{<0} - \epsilon[L^q]_{-1}, L] \tag{40}$$

and the appropriate Lax operators are given in the form

$$L = \partial_x^N + u_{N-1}\partial_x^{N-1} + u_{N-2}\partial_x^{N-2} + \cdots + u_1\partial_x + u_0. \tag{41}$$

From (40) one finds

$$(u_{N-1})_{t_q} = -\epsilon N([L^q]_{-1})_x,$$

$$(u_{N-2})_{t_q} = N([L^q]_{-1})_x - \epsilon(N-1)u_{N-1}([L^n]_{-1})_x - \epsilon\frac{N(N-1)}{2}([L^q]_{-1})_{2x}, \tag{42}$$

$$\cdots.$$

Hence, for $\epsilon=0$ the field u_{N-1} becomes the time-independent c_{N-1} one (let $c_{N-1}=0$), then Lax operator becomes a standard Lax operator (37). Expression (42) implies the relation between fields u_{N-1}, u_{N-2},

$$u_{N-2} = -\frac{1}{\epsilon}u_{N-1} + \frac{N-1}{2N}(u_{N-1})^2 + \frac{N-1}{2}(u_{N-1})_x.$$

We eliminate the field u_{N-2} and as a result the Lax operators take the form

$$L = \partial_x^N + u_{N-1}\partial_x^{N-1} + \left(-\frac{1}{\epsilon}u_{N-1} + \frac{N-1}{2N}(u_{N-1})^2 + \frac{N-1}{2}(u_{N-1})_x\right)\partial_x^{N-2} + \cdots + u_0. \tag{43}$$

In the dispersionless limit (43) reduces to (22). Reparametrizing (43), $u_{N-1} \mapsto -\epsilon u_{N-2}$ and then taking limit $\epsilon \to 0$ we obtain the standard Lax operator (37).

Lemma 4.1: For arbitrary ϵ *the Lax hierarchy* (40) and (43) *is equivalent to the Lax hierarchy* (36) and (37).

We are looking for relations between fields from Lax operators (43) and (37), respectively. They are given in the following form:

$$u_{N-1} \mapsto -\epsilon u_{N-2},$$

$$u_i \mapsto u_i + f_i[u_{N-2}, u_{N-3}, \ldots, u_{i+1}] \quad \text{for } N-3 \geqslant i \geqslant 0. \tag{44}$$

The square brackets in (44) mean that functions f_i, in opposite to the case (23), depend not only on u_i, but also on the derivatives $(u_i)_x, (u_i)_{xx}, \ldots$. Functions f_i are constructed in such a way that hierarchy (40) will lead to the same evolution system as hierarchy (36) for $k=0$. Argumentation that this equality indeed holds is of the same nature as in Sec. III, the paragraph $s=k=0$.

Example 4.2: KdV, $N=2$.

For the constrained Lax operator (43) *of the form* $L=\partial_x^2+u\partial_x+\frac{1}{4}u^2-(1/\epsilon)u+\frac{1}{2}u_x$ *we find reparametrized KdV,*

$$L_{t_3} = [(L^{3/2})_{\geqslant 0} + \epsilon[L^{3/2}]_{-1}, L] \Leftrightarrow u_{t_3} = \frac{1}{4}u_{3x} - \frac{3}{2\epsilon}uu_x.$$

The transformation to the standard form of KdV is given by $u \mapsto -\epsilon u$.

Example 4.3: Deformed Boussinesq, $N=3$.

Let $L = \partial_x^3 + u\partial_x^2 + \left[\frac{1}{3}u^2 - (1/\epsilon)u + u_x\right]\partial_x + w$ *then*

$$L_{t_2} = [(L^{2/3})_{\geqslant 0} + \epsilon[L^{2/3}]_{-1}, L] \Leftrightarrow$$

$$u_{t_2} = -\frac{4}{3}uu_x - u_{2x} + \frac{2}{9}\epsilon u^2 u_x + \frac{2}{3}\epsilon u_x^2 + \frac{2}{3}\epsilon uu_{2x} + \frac{2}{3}\epsilon u_{3x} - 2\epsilon w_x,$$

$$\begin{aligned} w_{t_2} = &-\frac{2}{3\epsilon}uu_x + \frac{8}{9\epsilon}u^2u_x + \frac{2}{3\epsilon}u_x^2 + \frac{4}{3\epsilon}uu_{2x} + \frac{2}{3\epsilon}u_{3x} - \frac{8}{27}u^3u_x - \frac{14}{9}uu_x^2 + \frac{4}{3}uw_x - \frac{10}{9}u^2u_{2x} - \frac{8}{3}u_xu_{2x} \\ &+ w_{2x} - \frac{14}{9}uu_{3x} - \frac{2}{3}u_{4x} + \frac{2}{81}\epsilon u^4u_x + \frac{8}{27}\epsilon u^2u_x^2 + \frac{10}{27}\epsilon u_x^3 - \frac{2}{9}\epsilon u^2w_x - \frac{2}{3}\epsilon u_xw_x + \frac{4}{27}\epsilon u^3u_{2x} \\ &+ \frac{4}{3}\epsilon uu_xu_{2x} + \frac{2}{3}\epsilon u_{2x}^2 - \frac{2}{3}\epsilon uw_{2x} + \frac{10}{27}\epsilon u^2u_{3x} + \frac{10}{9}\epsilon u_xu_{3x} - \frac{2}{3}\epsilon w_{3x} + \frac{4}{9}\epsilon uu_{4x} + \frac{2}{9}\epsilon u_{5x}. \end{aligned}$$

Eliminating the field w we obtain reparametrized Boussinesq, $u_{tt} = \left[(2/3\epsilon)u^2 - \frac{1}{3}u_{xx}\right]_{xx}$. *The transformation* (44) *to the standard form of the Boussinesq system is given by* $u \mapsto -\epsilon u$, $w \mapsto w - \frac{1}{3}\epsilon u^2 - \frac{1}{27}\epsilon^3 u^3 + \frac{1}{3}\epsilon^2 uu_x - \frac{1}{3}\epsilon u_{2x}$.

The case: $k=1$.

The Lax hierarchy becomes

$$L_{t_q} = [(L^q)_{\geqslant 1} + \epsilon[L^q]_0\partial_x, L] = -[(L^q)_{<1} - \epsilon[L^q]_0\partial_x, L] \tag{45}$$

and the appropriate Lax operators have the form

$$L = u_N\partial_x^N + u_{N-1}\partial_x^{N-1} + \cdots + u_0 + \partial_x^{-1}u_{-1}. \tag{46}$$

From (45) one finds that $(u_N)_t = \epsilon(u_N)_x[L^q]_0 - \epsilon N u_N([L^q]_0)_x$. Hence in the limit $\epsilon = 0$ the field u_N becomes a time-independent c_N one (let $c_N = 1$), then Lax operator becomes a standard Lax operator (46). There is no constraint contrary to the previous case. The Lax operators (45) with (46) lead to the construction of new integrable soliton systems, at least to the best of our knowledge. Again the zero power of L always leads to the space translation symmetry, $L_{t_0} = \epsilon L_x$.

Example 4.4: Extended Kaup–Broer, $N=1$.

Let $L = u\partial_x + v + \partial_x^{-1}w$, *then for* $L_{t_i} = [(L^i)_{\geqslant 1} + \epsilon[L^i]_0\partial_x, L]$ *we find*

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_0} = \epsilon\begin{pmatrix} u_x \\ v_x \\ w_x \end{pmatrix},$$

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} \epsilon u_x v - \epsilon u v_x \\ uv_x + \epsilon v v_x \\ u_x w + uw_x + \epsilon v_x w + \epsilon v w_x \end{pmatrix},$$

$$u_{t_2} = \epsilon u_x v^2 - 2\epsilon uvv_x - 2\epsilon u^2 w_x - \epsilon u^2 v_{2x},$$

$$v_{t_2} = 2uu_x w + 2uvv_x + 2u^2 w_x + uu_x v_x + u^2 v_{2x} + \epsilon v^2 v_x + 2\epsilon uv_x w + \epsilon uv_x^2,$$

$$w_{t_2} = 2u_x vw + 2uv_x w + 2uvw_x - u_x^2 w - 3uu_x w_x - uu_{2x} w - u^2 w_{2x} + 2\epsilon u_x w^2 + 2\epsilon vv_x w + \epsilon u_x v_x w + \epsilon v^2 w_x + 4\epsilon uww_x + \epsilon uv_x w_x + \epsilon uv_{2x} w,$$

$$\cdots .$$

It is dispersive counterpart of the hierarchy from Example 3.4. In the limit $\epsilon \to 0$ *and* $u=1$ *we obtain the standard Kaup–Broer system.*

Example 4.5: Two field system, $N=0$.

For $L=v+w\partial_x^{-1}$ *we have* $[L^i]_0=v^i$ *and* $(L^i)_{\geqslant 1}=0$, *where* $i=0,1,2,\ldots$. *Then, we obtain for* $L_{t_i}=[\epsilon[L^i]_0\partial_x, L]$ *again the dispersionless hierarchy* (28).

V. LATTICE SOLITON SYSTEMS

Let $\mathfrak{g}$ be the algebra of shift operators[9]

$$\mathfrak{g} = \left\{ L = \sum_{i\in\mathbf{Z}} u_i(x)\mathcal{E}^i \right\}, \tag{47}$$

where $\mathcal{E}$ is the shift operator such that $\mathcal{E}^m u(x) = u(x+m)\mathcal{E}^m$. The Lie algebra structure of $\mathfrak{g}$ is given by the commutator $[L_1, L_2] = L_1L_2 - L_2L_1$. We consider simple decomposition of $\mathfrak{g}$ in the form $\mathfrak{g}_{\geqslant k} = \{\Sigma_{i\geqslant k} u_i\mathcal{E}^i\}$ and $\mathfrak{g}_{<k} = \{\Sigma_{i<k} u_i\mathcal{E}^i\}$, which are Lie subalgebras for $k=0,1$. In these cases the standard R-matrix is given by

$$R = \tfrac{1}{2}(P_{\geqslant k} - P_{<k}) = P_{\geqslant k} - \tfrac{1}{2} = \tfrac{1}{2} - P_{<k}.$$

The Lax hierarchy is

$$L_{t_q} = [(L^q)_{\geqslant k}, L] = -[(L^q)_{<k}, L], \quad k = 0,1. \tag{48}$$

Notice that these two cases are related by simple transformation $\mathcal{E} \mapsto \mathcal{E}^{-1}$ and $u_i(x-m) \mapsto u_{-i}(x+m)$. Then, $k=0$ goes to $k=1$ and vice versa. So, it is enough to consider only the first case. For $k=0$, the appropriate Lax operators are of the form[9]

$$L = \mathcal{E}^N + u_{N-1}(x)\mathcal{E}^{N-1} + \cdots + u_{1-m}(x)\mathcal{E}^{1-m} + u_{-m}(x)\mathcal{E}^{-m}. \tag{49}$$

The powers of L are in general fractional and can be constructed in two ways, for $L^{1/N} = a_1\mathcal{E} + a_0 + a_{-1}\mathcal{E}^{-1} + \cdots$ by requiring $(L^{1/N})^N = L$ and for $L^{1/m} = \cdots + a_1\mathcal{E} + a_0 + a_{-1}\mathcal{E}^{-1}$ by requiring $(L^{1/m})^m = L$. Then, in (48) we use $L^{i/N}$ and $L^{i/m}$ for $i=0,1,2,\ldots$. The Lax hierarchies (48) for $k=0,1$ are dispersive counterparts of the dispersionless hierarchies (9) for $s=1$, $k=1$ and $s=1$, $k=2$, respectively.

The simple deformations satisfying (4) and (5) are of the form

$$k = 0,1, \quad r = P_0.$$

But for the same reason as above it is enough to consider the case $k=0$.

The case: $k=0$.

The deformed R-matrix is given by

$$R = P_{\geqslant 0} - \tfrac{1}{2} + \epsilon P_0 = \tfrac{1}{2} - P_{<0} + \epsilon P_0.$$

Hence

$$L_{t_q} = [(L^q)_{\geqslant 0} + \epsilon[L^q]_0, L] = -[(L^q)_{<0} + \epsilon[L^q]_0, L]. \tag{50}$$

The appropriate Lax operators are of the form

$$L = u_N(x)\mathcal{E}^N + u_{N-1}(x)\mathcal{E}^{N-1} + \cdots + u_{1-m}(x)\mathcal{E}^{1-m} + u_{-m}(x)\mathcal{E}^{-m}. \tag{51}$$

From (50) it follows that

$$u_N(x)_t = \epsilon u_N(x)(1-E^N)[L^q]_0, \quad \cdots, \; u_{-m}(x)_t = (1+\epsilon)u_{-m}(x)(1-E^{-m})[L^q]_0. \tag{52}$$

As a result we find that the highest and lowest field are interrelated in the following way:

$$\left(\frac{u_N(x)}{u_N(x-m)}\right)^{1+\epsilon} = \left(\frac{u_{-m}(x)}{u_{-m}(x+N)}\right)^{\epsilon}. \tag{53}$$

For $\epsilon=0$ the field u_N becomes a time-independent c_N one (let $c_N=1$), then the Lax operator (51) becomes a standard Lax operator (49) for $k=0$. For $\epsilon=-1$ the field u_{-m} becomes time independent and the Lax operator becomes a standard Lax operator for $k=1$. It is so, because for $k=0$ and $\epsilon=-1$ the deformed R-matrix becomes the standard R-matrix for $k=1$.

Lemma 5.1: For arbitrary ϵ, the Lax hierarchy (50) and (51) *is equivalent to the Lax hierarchy* (48) and (49) *for* $k=0$.

Consider the following transformations:

$$\mathcal{E}'^N = u_N(x)\mathcal{E}^N \Leftrightarrow \mathcal{E}' = a(x)\mathcal{E},$$

$$u_i'(x) = \begin{cases} \dfrac{u_i(x)}{a(x)a(x+1)\cdot\cdots\cdot a(x+i-1)} & \text{for } N-1 \geqslant i > 0, \\ u_0(x) & \text{for } i=0, \\ u_i(x)a(x-1)a(x-2)\cdot\cdots\cdot a(x-i) & \text{for } 0 > i > -m, \end{cases} \tag{54}$$

and $t'=t$, where $a(x)$ is given by the following relation:

$$u_N(x) = a(x)a(x+1)\cdot\cdots\cdot a(x+N-1). \tag{55}$$

It transforms the Lax operators (51) into the Lax operators (49) with $u_i'(x)$ components. From (54) it follows that

$$(\mathcal{E}'^i)_t = \Pi_i(\ln a(x))_t \mathcal{E}'^i, \tag{56}$$

where

$$\Pi_i = \begin{cases} 1+E+\cdots+E^{i-1} & \text{for } i \geqslant 1, \\ 0 & \text{for } i=0, \\ -E^{-1}-E^{-2}-\cdots-E^{i} & \text{for } i \leqslant -1. \end{cases}$$

One finds also from (55), that

$$(\ln a(x))_t = (\Pi_N)^{-1}(\ln u_N(x))_t \overset{\text{by (52)}}{=} \epsilon(\Pi_N)^{-1}(1-E^N)[L^q]_0.$$

Then, using relation $(1-E^N)\Pi_i=(1-E^i)\Pi_N$ which is valid for arbitrary N, $i>0$, we have

$$L_t = L_{t'} + \sum_{i=-m}^{N} u_i'(x)(\mathcal{E}'^i)_t \overset{\text{by (56)}}{=} L_{t'} + \epsilon\sum_{i=-m}^{N} u_i'(x)(1-E^N)\Pi_i(\Pi_N)^{-1}[L^q]_0\mathcal{E}'^i = L_{t'} + \epsilon\sum_{i=-m}^{N} u_i'(x)(1-E^i)$$
$$\times[L^q]_0\mathcal{E}'^i = L_{t'} + [\epsilon[L^q]_0, L],$$

where $u_N'(x)=1$. Hence, the hierarchy (50) becomes (48) with $k=0$.

Example 5.2: Extended Toda, $k=0$.

For the Lax operator $L=u(x)\mathcal{E}+v(x)+w(x)\mathcal{E}^{-1}$ and $L_{t_1}=[(L)_{\geqslant 0}+\epsilon[L]_0, L]$ we find

$$\begin{pmatrix} u(x) \\ v(x) \\ w(x) \end{pmatrix}_{t_1} = \begin{pmatrix} -\epsilon u(x)[v(x+1)-v(x)] \\ u(x)w(x+1)-u(x-1)w(x) \\ (1+\epsilon)[v(x)-v(x-1)]w(x) \end{pmatrix}. \tag{57}$$

Again, in the limit $\epsilon \to 0$ *and* $u(x)=1$ *or by the transformation* (54), $v(x)\mapsto v(x)$, $w(x)\mapsto w(x)/u(x-1)$ *we obtain the standard Toda system. In the limit* $\epsilon=-1$ *and* $w(x)=1$ *we obtain the reparametrized Toda system. The fields* $u(x)$ *and* $v(x)$ *in* (57) *according to* (53) *are related by* $u(x-1)^{1+\epsilon}=w(x)^{-\epsilon}$.

(Received 3 July 2004; accepted 13 October 2004; published online 18 March 2005)

We establish the exact solution of the nonlinear Schrödinger equation with a delta-function impurity, representing a pointlike defect which reflects and transmits. We solve the problem both at the classical and the second quantized levels. In the quantum case the Zamolodchikov–Faddeev algebra, familiar from the case without impurities, is substituted by the recently discovered reflection-transmission (RT) algebra, which captures both particle–particle and particle–impurity interactions. The off-shell quantum solution is expressed in terms of the generators of the RT algebra and the exact scattering matrix of the theory is derived. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1842353]

I. INTRODUCTION

Impurity problems arise in different areas of quantum field theory and are essential for understanding a number of phenomena in condensed matter physics. At the experimental side, the recent interest in pointlike impurities (defects) is triggered by the great progress in building nanoscale devices.

The interaction of quantum fields with impurities represents in general a hard and yet unsolved problem, but there are relevant achievements[1–11] in the case of integable systems in $1+1$ space–time dimensions. The study[12–19] of the special case of purely reflecting impurities (boundaries) indicates factorized scattering theory[20–24] as the most efficient method for dealing with this kind of problem. The method provides on-shell information about the system and allows to derive the exact scattering matrix. The goal of the present paper is to extend this framework, exploring the possibility to recover off-shell information and to reconstruct the quantum fields, generating the above scattering matrix. We test this possibility on one of the most extensively studied integrable systems—the nonlinear Schrödinger (NLS) model.[25–32] More precisely, we are concerned below with the NLS model coupled to a delta-function impurity. The basic tool of our investigation is a specific exchange algebra,[6,7] called reflection-transmission (RT) algebra. The RT algebra is a generalization of the Zamolodchikov–Faddeev (ZF)[21,23] algebra used in the case without defects. The RT algebra is originally designed for the construction of the total scattering operator from the fundamental scattering data, namely the two-body bulk scattering matrix and the reflec-

tion and transmission amplitudes of a single particle interacting with the defect. In what follows we demonstrate that in the NLS model the same algebra allows to reconstruct the corresponding off-shell quantum field as well. Being the first exactly solvable example with nontrivial bulk scattering matrix, the NLS model sheds some light on the interplay between pointlike impurities, integrability, and symmetries. In this respect our solution clarifies a debated question about the Galilean invariance of the bulk scattering matrix.

After introducing the model in Sec. II, we establish the solution, both at the classical (Sec. II B) and second-quantized (Sec. III) levels. We do this in detail, clarifying the basic properties of the solution. In Sec. IV we derive from the off-shell quantum field the total scattering matrix of the model, showing that it coincides with the one obtained directly from factorized scattering. In Sec. V we indicate some generalizations. Our conclusions and ideas about further developments are also collected there. Appendixes A and B are devoted to the proofs of some technical results.

We present below the analysis of the so-called δ-type impurity. A wider class of defects, interacting with the NLS model and preserving its integrability, can be treated in a similar way.[33] We have chosen to focus here on the particular δ-type defect in order to keep the length of the proofs reasonable, referring to Ref. 33 for a more physically oriented treatment of the general case (without detailed proofs).

II. INTRODUCING AN IMPURITY IN THE NLS MODEL

We start by recalling some well-known results about the NLS model without impurity. The reason for this is twofold: first, because this is a good guide to tackle the problem with impurity and second, because the central piece of the solution of the NLS model, the Rosales expansion,[34,35] can be adapted to the impurity case.

A. The model to solve

The field theoretic version of NLS is described by a classical complex field $\Phi(t,x)$ whose equation of motion reads

$$(i\partial_t + \partial_x^2)\Phi(t,x) = 2g|\Phi(t,x)|^2\Phi(t,x). \tag{2.1}$$

The corresponding action takes the form

$$\mathcal{A}_{\mathrm{NLS}} = \int_{\mathbb{R}} \mathrm{d}t \int_{\mathbb{R}} \mathrm{d}x (i\bar{\Phi}(t,x)\partial_t\Phi(t,x) - |\partial_x\Phi(t,x)|^2 - g|\Phi(t,x)|^4), \tag{2.2}$$

and, being in particular invariant under time translation, ensures the conservation of the energy

$$\mathcal{E}_{\mathrm{NLS}} = \int_{\mathbb{R}} \mathrm{d}x (|\partial_x\Phi(t,x)|^2 + g|\Phi(t,x\ |^4). \tag{2.3}$$

The latter is non-negative for $g \geqslant 0$.

It is well-known that this is a nonrelativistic integrable model[36] (see also Ref. 30 for a review) and an explicit solution for the field was given by Rosales in Ref. 34,

$$\Phi(t,x) = \sum_{n=0}^{\infty} (-g)^n \Phi^{(n)}(t,x), \tag{2.4}$$

where

$$\Phi^{(n)}(t,x)=\int_{\mathbb{R}^{2n+1}}\prod_{\substack{i=1\\ j=0}}^{n}\frac{\mathrm{d}p_i}{2\pi}\frac{\mathrm{d}q_j}{2\pi}\overline{\lambda}(p_1)\cdots\overline{\lambda}(p_n)\lambda(q_n)\cdots\lambda(q_0)\frac{e^{i\Sigma_{j=0}^{n}(q_jx-q_j^2t)-i\Sigma_{i=1}^{n}(p_ix-p_i^2t)}}{\prod_{i=1}^{n}(p_i-q_{i-1})(p_i-q_i)} \tag{2.5}$$

and the overbar denotes complex conjugation.

The level $n=0$ is the linear part of the field corresponding to the free Schrödinger equation. It was argued in Ref. 32 that this solution is well-defined for a large class of functions λ [containing the Schwarz space $\mathcal{S}(\mathbb{R})$] and an upper bound for g was given for the series (2.4) to converge uniformly in x. It also represents a physical field since it vanishes as $x\to\pm\infty$. In the same paper, the authors considered NLS on the half-line $\mathbb{R}^+$, which can be seen as the model on the whole line in the presence of a purely reflecting impurity sitting at the origin. Therefore, the latter represents a particular case of the model with transmitting and reflecting impurity at $x=0$ we wish to contemplate in this paper. They gave the following action:

$$\mathcal{A}_R=\int_{\mathbb{R}}\mathrm{d}t\int_{\mathbb{R}^+}\mathrm{d}x(i\overline{\Phi}(t,x)\partial_t\Phi(t,x)-|\partial_x\Phi(t,x)|^2-g|\Phi(t,x)|^4)-\eta\int_{\mathbb{R}}\mathrm{d}t|\Phi(t,0)|^2,$$

where $\eta\in\mathbb{R}$ is the parameter controlling the boundary condition

$$\lim_{x\to0^+}(\partial_x-\eta)\Phi(t,x)=0. \tag{2.6}$$

In our case, since the impurity is allowed to reflect and transmit, we must take the $\mathbb{R}^-$ part into account and we are led to work with the following action:

$$\mathcal{A}_{\mathrm{RT}}=\mathcal{A}_+ +\mathcal{A}_- +\mathcal{A}_0, \tag{2.7}$$

where

$$\mathcal{A}_\pm=\int_{\mathbb{R}}\mathrm{d}t\int_{\mathbb{R}^\pm}\mathrm{d}x(i\overline{\Phi}(t,x)\partial_t\Phi(t,x)-|\partial_x\Phi(t,x)|^2-g|\Phi(t,x)|^4), \tag{2.8}$$

$$\mathcal{A}_0=-2\eta\int_{\mathbb{R}}\mathrm{d}t|\Phi(t,0)|^2. \tag{2.9}$$

The form of $\mathcal{A}_{\mathrm{RT}}$ shows the particular status of the origin $x=0$ where the impurity sits. Again, the invariance of the action under time translations ensures the conservation of the energy,

$$\mathcal{E}_{\mathrm{RT}}=\int_{\mathbb{R}^-\oplus\mathbb{R}^+}\mathrm{d}x(|\partial_x\Phi(t,x)|^2+g|\Phi(t,x)|^4)+2\eta|\Phi(t,0)|^2. \tag{2.10}$$

It is positive for $g\geqslant0$, $\eta\geqslant0$, which is what we assume in the rest of this paper. We will see that η characterizes the transmission and reflection properties of the impurity. Using the variational principle, one deduces the equation of motion and the boundary conditions for the field: $\Phi(t,x)$ must be the solution of NLS on $\mathbb{R}^-$ and $\mathbb{R}^+$, continuous at $x=0$ and satisfy a "jump condition" at the origin. It must also vanish at infinity as a physical field.

Definition 2.1: The nonlinear Schrödinger model with a transmitting and reflecting impurity at the origin is described by the following boundary problem for the field $\Phi(t,x)$:

$$(i\partial_t+\partial_x^2)\Phi(t,x)-2g|\Phi(t,x)|^2\Phi(t,x)=0,\quad x\neq0, \tag{2.11}$$

$$\lim_{x\to0^+}\{\Phi(t,x)-\Phi(t,-x)\}=0, \tag{2.12}$$

$$\lim_{x\to 0^+}\{(\partial_x\Phi)(t,x)-(\partial_x\Phi)(t,-x)\}-2\eta\Phi(t,0)=0, \tag{2.13}$$

$$\lim_{x\to\pm\infty}\Phi(t,x)=0. \tag{2.14}$$

B. Explicit solution

As announced, the Rosales solution[34] can be adapted suitably to solve the problem of definition 2.1. Since (2.4) is a solution of NLS on $\mathbb{R}$, it is easy to devise a solution for (2.11). Starting from two copies of (2.4) and (2.5), one based on a function λ_+ and the other on a function λ_-, denoted $\Phi_+(t,x)$ and $\Phi_-(t,x)$, respectively, we define

$$\Phi(t,x)=\begin{cases}\Phi_+(t,x), & x>0,\\ \Phi_-(t,x), & x<0,\\ \frac{1}{2}(\Phi_+(t,0)+\Phi_-(t,0)), & x=0.\end{cases} \tag{2.15}$$

It is clearly solution of (2.11) for $x\neq 0$ and from the vanishing of $\Phi_\pm(t,x)$ as $x\to\pm\infty$, (2.14) is also satisfied. However, there is no reason why, in general, $\Phi(t,x)$ so defined should satisfy the boundary conditions (2.12) and (2.13). In order to satisfy these conditions, we parametrize λ_+, λ_- as follows:

$$\begin{pmatrix}\lambda_+(p)\\ \lambda_-(p)\end{pmatrix}=\begin{pmatrix}1 & T(p)\\ T(-p) & 1\end{pmatrix}\begin{pmatrix}\mu_+(p)\\ \mu_-(p)\end{pmatrix}+\begin{pmatrix}R(p) & 0\\ 0 & R(-p)\end{pmatrix}\begin{pmatrix}\mu_+(-p)\\ \mu_-(-p)\end{pmatrix}, \tag{2.16}$$

where

$$T(p)=\frac{p}{p+i\eta},\quad R(p)=\frac{-i\eta}{p+i\eta},\quad p\in\mathbb{R}, \tag{2.17}$$

and $\mu_\pm(p)$ are arbitrary Schwarz test functions. Then, the functions $\lambda_\pm(p)$ satisfy

$$\lambda_\pm(p)=T(\pm p)\lambda_\mp(p)+R(\pm p)\lambda_\pm(-p),\quad \forall\, p\in\mathbb{R} \tag{2.18}$$

which follows from the identities

$$R(p)R(-p)+T(p)T(-p)=1\quad\text{and}\quad T(p)R(-p)+R(p)T(-p)=0,\quad \forall\, p\in\mathbb{R}. \tag{2.19}$$

These relations plus a particular choice for the form of $\mu_\pm$ will be essential in the proof of the theorem 2.2 below.

Anticipating the quantum case, if we interpret λ_+ (respectively, λ_-) as a wave packet, (2.18) shows that each wave packet in $\mathbb{R}^+$ (respectively, $\mathbb{R}^-$) is equivalent to the superimposition of a transmitting part coming from $\mathbb{R}^-$ (respectively, $\mathbb{R}^+$) and a reflected part in $\mathbb{R}_+$ (respectively, $\mathbb{R}_-$). This physical interpretation will show up in the next section when we construct a Fock representation of the creation and annihilation operators.

We are now in position to state the main result of this section whose lengthy proof we defer until Appendix A.

Theorem 2.2: Let μ_+, μ_- *be given by*

$$\mu_\pm(k)=\pm\frac{\mu_0(\pm k)+(k\mp i\eta)\mu_1(k)}{k\mp i\eta+1}, \tag{2.20}$$

where μ_0, μ_1 *are arbitrary Schwartz functions,* μ_1 *being even and let* $\Phi_+(t,x)$, $\Phi_-(t,x)$ *be given by the Rosales expansion (2.4) and (2.5) with* λ *replaced by* λ_+ *and* λ_-, *respectively. Then,* $\Phi(t,x)$ *as defined in (2.15) satisfies the boundary conditions (2.12) and (2.13), i.e.,*

$$\lim_{x\to 0^+}\{\Phi(t,x)-\Phi(t,-x)\}=0,$$

$$\lim_{x\to 0^+}\{(\partial_x\Phi)(t,x)-(\partial_x\Phi)(t,-x)\}-2\eta\Phi(t,0)=0.$$

With this result, we can say that $\Phi(t,x)$ rewritten as

$$\Phi(t,x)=\theta(x)\Phi_+(t,x)+\theta(-x)\Phi_-(t,x), \tag{2.21}$$

where $\theta(x)$ is the Heaviside function defined here to be $\frac{1}{2}$ at $x=0$, is the classical solution of the nonlinear Schrödinger model with impurity as given in definition 2.1.

We want to emphasize that these boundary conditions decouple for the nonlinear part of the field (as shown in Appendix A) and this is due to the reflection-transmission property (2.18) satisfied by λ_+ and λ_-. This already gives a good hint that the construction of a local field from the quantum counterparts of λ_+, λ_- is achievable, as we now explain.

III. QUANTIZATION OF THE SYSTEM

In this section, we move on to the construction and resolution of the quantized version of NLS with impurity. As we mentioned earlier, the crucial ingredient is the RT algebra which encodes the properties of the impurity.

A. Reflection-transmission algebra

Here we rely on the constructions developed in Ref. 7 and recast them in the particular context of the scalar nonlinear Schrödinger model (no internal degrees of freedom, special form of the exchange matrix and of the generators, see also Ref. 11).

We consider the associative algebra with identity element **1** and two sets of generators, $\{a_\alpha(p),a_\alpha^\dagger(p);p\in\mathbb{R},\alpha=\pm\}$ and $\{r(p),t(p);p\in\mathbb{R}\}$, called the bulk and defect (reflection and transmission) generators. The label $\alpha=\pm$ refers to the half-line $\mathbb{R}^\pm$ with respect to the impurity (in practice it will indicate where the particle is created or annihilated). Introducing the measurable function $S:\mathbb{R}\times\mathbb{R}\to\mathbb{C}$ defined by

$$S(p)=\frac{p-ig}{p+ig} \tag{3.1}$$

the $\mathcal{S}$-matrix is defined in our context by

$$\mathcal{S}=\sum_{\alpha_1,\alpha_2=\pm}\mathcal{S}_{\alpha_1\alpha_2}(p_1,p_2)E_{\alpha_1\alpha_1}\otimes E_{\alpha_2\alpha_2}, \tag{3.2}$$

where $\mathcal{S}_{\alpha_1\alpha_2}(p_1,p_2)=S(\alpha_1p_1-\alpha_2p_2)$ and $(E_{\alpha\beta})_{\sigma\gamma}=\delta_{\alpha\sigma}\delta_{\beta\gamma}$. It is easy to check that $\mathcal{S}$ satisfies the unitarity condition and the quantum Yang–Baxter equation

$$\mathcal{S}_{12}(p_1,p_2)\mathcal{S}_{21}(p_2,p_1)=\mathbb{1}\otimes\mathbb{1}, \tag{3.3}$$

$$\mathcal{S}_{12}(p_1,p_2)\mathcal{S}_{13}(p_1,p_3)\mathcal{S}_{23}(p_2,p_3)=\mathcal{S}_{23}(p_2,p_3)\mathcal{S}_{13}(p_1,p_3)\mathcal{S}_{12}(p_1,p_2). \tag{3.4}$$

Our defect generators $r(p)$, $t(p)$ are related to $r_\alpha^\beta(p)$, $t_\alpha^\beta(p)$ defined in Ref. 7 by

$$r_\alpha^\beta(p)=\delta_\alpha^\beta r(\alpha p)\quad\text{and } t_\alpha^\beta(p)=\epsilon_\alpha^\beta t(\alpha p)\text{ with }\epsilon=\begin{pmatrix}0&1\\1&0\end{pmatrix}. \tag{3.5}$$

All this setup gives rise to a particular RT algebra whose defining relations then read as follows.

(i) Bulk exchange relations,

$$a_{\alpha_1}(p_1)a_{\alpha_2}(p_2) - S(\alpha_2 p_2 - \alpha_1 p_1)a_{\alpha_2}(p_2)a_{\alpha_1}(p_1) = 0, \tag{3.6}$$

$$a^\dagger_{\alpha_1}(p_1)a^\dagger_{\alpha_2}(p_2) - S(\alpha_2 p_2 - \alpha_1 p_1)a^\dagger_{\alpha_2}(p_2)a^\dagger_{\alpha_1}(p_1) = 0, \tag{3.7}$$

$$\begin{aligned} a_{\alpha_1}(p_1)a^\dagger_{\alpha_2}(p_2) - S(\alpha_1 p_1 - \alpha_2 p_2)a^\dagger_{\alpha_2}(p_2)a_{\alpha_1}(p_1) &= 2\pi\delta(p_1 - p_2)[\delta^{\alpha_2}_{\alpha_1}\mathbf{1} + \epsilon^{\alpha_2}_{\alpha_1}t(\alpha_1 p_1)] \\ &+ 2\pi\delta(p_1 + p_2)\delta^{\alpha_2}_{\alpha_1}r(\alpha_1 p_1). \end{aligned} \tag{3.8}$$

(ii) Defect exchange relations,

$$[r(p_1), r(p_2)] = 0, \tag{3.9}$$

$$[t(p_1), t(p_2)] = 0, \tag{3.10}$$

$$[t(p_1), r(p_2)] = 0. \tag{3.11}$$

(iii) Mixed exchange relations,

$$a_{\alpha_1}(p_1)r(p_2) = S(p_2 - p_1)S(p_2 + p_1)r(p_2)a_{\alpha_1}(p_1), \tag{3.12}$$

$$r(p_1)a^\dagger_{\alpha_2}(p_2) = S(p_1 - p_2)S(p_1 + p_2)a^\dagger_{\alpha_2}(p_2)r(p_1), \tag{3.13}$$

$$a_{\alpha_1}(p_1)t(p_2) = S(p_2 - p_1)S(p_2 + p_1)t(p_2)a_{\alpha_1}(p_1), \tag{3.14}$$

$$t(p_1)a^\dagger_{\alpha_2}(p_2) = S(p_1 - p_2)S(p_1 + p_2)a^\dagger_{\alpha_2}(p_2)t(p_1). \tag{3.15}$$

(iv) Finally, the defect generators are required to satisfy unitarity conditions,

$$t(p)t(-p) + r(p)r(-p) = \mathbf{1}, \tag{3.16}$$

$$t(p)r(-p) + r(p)t(-p) = 0, \tag{3.17}$$

which amount to implement the physical energy conservation when reflection and transmission occur.

Since we aim at second quantize a physical system, we now turn to the Fock representation of this algebraic setup as it is presented in Ref. 7. What we need is to represent the generators $\{a_\alpha(p), a^\dagger_\alpha(p), r(p), t(p), p \in \mathbb{R}\}$ as operator-valued distributions acting on a common invariant subspace of a Hilbert space, $\mathcal{F}$, to be defined. We should also identify a normalizable vacuum state Ω annihilated by a_α and cyclic with respect to $a^\dagger_\alpha$. Applying the general construction of Ref. 7, we know that each such Fock representation is characterized by two numerical matrices $\mathcal{T}(p)$ and $\mathcal{R}(p)$. Here we take

$$\mathcal{T}(p) = \begin{pmatrix} 0 & T(p) \\ T(-p) & 0 \end{pmatrix}, \quad \mathcal{R}(p) = \begin{pmatrix} R(p) & 0 \\ 0 & R(-p) \end{pmatrix} \tag{3.18}$$

with T, R given in (2.17). Now consider

$$\mathcal{L} = \bigoplus_{\alpha=\pm} L^2(\mathbb{R}) \tag{3.19}$$

endowed with the usual scalar product

$$\langle \varphi, \psi \rangle = \int_{\mathbb{R}} \mathrm{d}p \sum_{\alpha=\pm} \overline{\varphi}_\alpha(p) \psi_\alpha(p), \tag{3.20}$$

which makes it a Hilbert space for the associated norm denoted $\|\cdot\|$. Then, the n-particle subspace $\mathcal{H}^{(n)}$ is the subspace of the n-fold tensor product $\mathcal{L}^{\otimes n}$ defined as follows. If $\varphi^{(n)} \in \mathcal{L}^{\otimes n}$, we identify it with the column whose entries are $\varphi^{(n)}_{\alpha_1,\ldots,\alpha_n}$. Then explicitly, $\mathcal{H}^{(0)}=\mathcal{C}$ and for $n \geqslant 1$, $\varphi^{(n)} \in \mathcal{H}^{(n)}$ if and only if

$$\varphi^{(n)} \in \mathcal{L}^{\otimes n},$$

$$\varphi^{(n)}_{\alpha_1 \cdots \alpha_n}(p_1, \ldots, p_n) = T(\alpha_n p_n) \varphi^{(n)}_{\alpha_1 \cdots \alpha_{n-1}, -\alpha_n}(p_1, \ldots, p_{n-1}, p_n) + R(\alpha_n p_n) \varphi^{(n)}_{\alpha_1 \cdots \alpha_{n-1} \alpha_n}(p_1, \ldots, p_{n-1}, -p_n), \tag{3.21}$$

$$\begin{aligned} n > 1,\ \varphi^{(n)}_{\alpha_1 \cdots \alpha_i \alpha_{i+1} \cdots \alpha_n}(p_1, \ldots, p_i, p_{i+1}, \ldots, p_n) &= S(\alpha_i p_i - \alpha_{i+1} p_{i+1}) \\ &\times \varphi^{(n)}_{\alpha_1 \cdots \alpha_{i+1} \alpha_i \cdots \alpha_n}(p_1, \ldots, p_{i+1}, p_i, \ldots, p_n), \quad 1 < i < n-1. \end{aligned} \tag{3.22}$$

The Fock space is $\mathcal{F}=\oplus_{n=0}^{\infty} \mathcal{H}^{(n)}$ and the common invariant subspace is the finite particle space $\mathcal{D}$ spanned by the linear combination of sequences $\varphi=(\varphi^{(0)}, \varphi^{(1)}, \ldots, \varphi^{(n)}, \ldots)$ with $\varphi^{(n)} \in \mathcal{H}^{(n)}$ and $\varphi^{(n)}=0$ for n large enough. $\mathcal{D}$ is dense in $\mathcal{F}$. We extend the scalar product, again denoted by $\langle \cdot, \cdot \rangle$, to $\mathcal{F}$,

$$\begin{aligned} \forall \varphi, \psi \in \mathcal{F}, \quad \langle \varphi, \psi \rangle &= \sum_{n=0}^{\infty} \langle \varphi^{(n)}, \psi^{(n)} \rangle \\ &= \sum_{n=0}^{\infty} \int_{\mathbb{R}^n} \mathrm{d}p_1 \cdots \mathrm{d}p_n \sum_{\alpha_1, \ldots, \alpha_n = \pm} \overline{\varphi}_{\alpha_1 \cdots \alpha_n}(p_1, \ldots, p_n) \psi_{\alpha_1 \cdots \alpha_n}(p_1, \ldots, p_n). \end{aligned}$$

The unit norm vacuum state is $\Omega=(1,0,\ldots,0,\ldots)$ and belongs to $\mathcal{D}$.

Now, we can define the action of the smeared bulk operators $\{a(\mathfrak{f}), a^\dagger(\mathfrak{f}); \mathfrak{f} \in \oplus_{\alpha=\pm} C_0^\infty(\mathbb{R})\}$ on $\mathcal{D}$ as follows:

$$a(\mathfrak{f})\Omega = 0, \tag{3.23}$$

and for any $\varphi^{(n)} \in \mathcal{H}^{(n)}$,

$$[a(\mathfrak{f})\varphi]^{(n-1)}_{\alpha_1 \cdots \alpha_{n-1}}(p_1, \ldots, p_{n-1}) = \sqrt{n} \int_{-\infty}^{\infty} \frac{\mathrm{d}p}{2\pi} \sum_{\alpha=\pm} \overline{\mathfrak{f}}_\alpha(p) \varphi^{(n)}_{\alpha \alpha_1 \cdots \alpha_{n-1}}(p, p_1, \ldots, p_{n-1}), \tag{3.24}$$

$$[a^\dagger(\mathfrak{f})\varphi]^{(n+1)}_{\alpha_1 \cdots \alpha_{n+1}}(p_1, \ldots, p_{n+1}) = \sqrt{n+1} [P^{(n+1)} \mathfrak{f} \otimes \varphi^{(n)}]_{\alpha_1 \cdots \alpha_{n+1}}(p_1, \ldots, p_{n+1}), \tag{3.25}$$

where $P^{(n)}$ is the orthogonal projector in $\mathcal{L}^{\otimes n}$ defined in Ref. 7. For completeness, the explicit form of (3.25) is given in Appendix B. These operators are bounded on each $\mathcal{H}^{(n)}$,

$$\forall \varphi \in \mathcal{H}^{(n)}, \quad \|a(\mathfrak{f})\varphi\| \leqslant \sqrt{n} \|\mathfrak{f}\| \, \|\varphi\|, \quad \|a^\dagger(\mathfrak{f})\varphi\| \leqslant \sqrt{n+1} \|\mathfrak{f}\| \, \|\varphi\|. \tag{3.26}$$

In particular, they are continuous in the smearing function $\mathfrak{f}$. Finally, they satisfy

$$\forall \varphi, \psi \in \mathcal{D}, \quad \langle \varphi, a(\mathfrak{f})\psi \rangle = \langle a^\dagger(\mathfrak{f})\varphi, \psi \rangle. \tag{3.27}$$

The defect generators are represented as multiplicative operators on $\mathcal{D}$, preserving the bulk particle number,

$$[r(p)\varphi]^{(n)}_{\alpha_1\cdots\alpha_n}(p_1,\ldots,p_n) = S(p-\alpha_1 p_1)\cdots S(p-\alpha_n p_n)R(p)S(\alpha_n p_n+p)\cdots S(\alpha_1 p_1+p) \times \varphi^{(n)}_{\alpha_1\cdots\alpha_n}(p_1,\ldots,p_n), \tag{3.28}$$

$$[t(p)\varphi]^{(n)}_{\alpha_1\cdots\alpha_n}(p_1,\ldots,p_n) = S(p-\alpha_1 p_1)\cdots S(p-\alpha_n p_n)T(p)S(\alpha_n p_n+p)\cdots S(\alpha_1 p_1+p) \times \varphi^{(n)}_{\alpha_1\cdots\alpha_n}(p_1,\ldots,p_n). \tag{3.29}$$

It follows then that r and t have nonvanishing vacuum expectation values

$$\langle\Omega, r(p)\Omega\rangle = R(p), \quad \langle\Omega, t(p)\Omega\rangle = T(p). \tag{3.30}$$

Introducing finally the operator-valued distributions $a_\alpha(p)$, $a^\dagger_\alpha(p)$ as

$$a(\mathfrak{f}) = \int_{\mathbb{R}} \frac{dp}{2\pi} \sum_{\alpha=\pm} \overline{\mathfrak{f}}_\alpha(p) a_\alpha(p), \quad a^\dagger(\mathfrak{f}) = \int_{\mathbb{R}} \frac{dp}{2\pi} \sum_{\alpha=\pm} a^\dagger_\alpha(p)\mathfrak{f}_\alpha(p) \tag{3.31}$$

one can check that the defining relations of the RT algebra are satisfied on $\mathcal{D}$. The operators $a, a^\dagger$ will be referred to as annihilation and creation operators, respectively. Implementing the automorphism ϱ defined in Ref. 7 for which we know that it is realized by the identity operator for any Fock representation, we get the quantum analog of the reflection-transmission property (2.18)

$$a_\alpha(p) = \epsilon^\beta_\alpha t(\alpha p) a_\beta(p) + \delta^\beta_\alpha r(\alpha p) a_\beta(-p), \tag{3.32}$$

$$a^\dagger_\alpha(p) = \epsilon^\alpha_\beta a^\dagger_\beta(p) t(\beta p) + \delta^\alpha_\beta a^\dagger_\beta(-p) r(-\beta p). \tag{3.33}$$

B. The question of operator domains

From the above it appears that the natural domain to start with is $\mathcal{D}$. Actually, it is much too big for practical calculations and we would like to work on a dense subspace of $\mathcal{D}$ which would play the role of the standard formal "state space," a basis of which is usually denoted by $|k_1,\ldots,k_n\rangle$, $k_1>\cdots>k_n$. As a first step, we define

$$\mathcal{D}_0^0 = \mathbb{C},$$

$$\mathcal{D}_0^n = \{a^\dagger_{\alpha_1}(\mathfrak{f}_1)\cdots a^\dagger_{\alpha_n}(\mathfrak{f}_n)\Omega; \mathfrak{f}_i \in C_0^\infty(\mathbb{R}), \quad \alpha_i = \pm, i=1,\ldots,n\}, \quad n \geqslant 1. \tag{3.34}$$

One can check that $\mathcal{D}_0^n$ is dense in $\mathcal{H}^{(n)}$, i.e., Ω is cyclic with respect to $a^\dagger_\alpha$. The corresponding domain $\mathcal{D}_0$, dense in $\mathcal{D}$, is the linear space of sequences $\varphi=(\varphi^{(0)},\varphi^{(1)},\ldots,\varphi^{(n)},\ldots)$ with $\varphi^{(n)} \in \mathcal{D}_0^n$ and $\varphi^{(n)}=0$ for n large enough. $\mathcal{D}_0$ is stable under the action of $a_\alpha(\mathfrak{f})$ and $a^\dagger_\alpha(\mathfrak{f})$. Finally, since T, R, and S are bounded, C^∞-functions, $\mathcal{D}_0^n \subset C_0^\infty(\mathbb{R}^n)$. Now in order to formulate the desired properties of the quantum field in the next paragraph, we introduce a partial ordering relation on $C_0^\infty(\mathbb{R})$ by

$$f \succ g \Leftrightarrow \forall\, x \in \mathrm{supp}(f), \quad \forall\, y \in \mathrm{supp}(g), \quad |x| > |y|, \tag{3.35}$$

which extends naturally to $C_0^\infty(\mathbb{R}^\alpha)$, $\alpha=\pm$. Let us introduce

$$\tilde{a}^\dagger_\alpha(t,x) = \int_{\mathbb{R}} \frac{dp}{2\pi} a^\dagger_\alpha(p) e^{-ipx+ip^2 t}, \quad (t,x) \in \mathbb{R}^2,$$

$$\tilde{a}^{\dagger}_{\alpha}(t,f) = \int_{\mathbb{R}} \mathrm{d}x\, \tilde{a}^{\dagger}_{\alpha}(t,x) f(x), \quad f \in C_0^{\infty}(\mathbb{R}). \tag{3.36}$$

Now, fix $t \in \mathbb{R}$ and $\alpha_1, \ldots, \alpha_n$ and define (vect standing for "linear span of") $\tilde{\mathcal{D}}_0^0 = \mathbb{C}$ and for $n \geqslant 1$,

$$\tilde{\mathcal{D}}^n_{0,\alpha_1\cdots\alpha_n} = \mathrm{vect}\{\tilde{a}^{\dagger}_{\alpha_1}(t,f_{1,\alpha_1})\cdots\tilde{a}^{\dagger}_{\alpha_n}(t,f_{n,\alpha_n})\Omega;\ f_{1,\alpha_1} \succ \cdots \succ f_{n,\alpha_n}, f_{i,\alpha_i} \in C_0^{\infty}(\mathbb{R}^{\alpha_i}),$$
$$0 \notin \mathrm{supp}(f_{i,\alpha_i}),\ i = 1, \ldots, n\} \tag{3.37}$$

then the following theorem holds.

Theorem 3.1: $\forall t \in \mathbb{R}$, $\forall \alpha_1, \ldots, \alpha_n = \pm$, $\tilde{\mathcal{D}}^n_{0,\alpha_1\cdots\alpha_n}$ *is dense in* $\mathcal{H}^{(n)}$.

Proof: We only need to consider $n \geqslant 1$. The proof relies on two known results of standard analysis. First, the Fourier transform of a C^{∞}-function with compact support is real analytic (i.e., a Gevrey class 1 function). Second, a real analytic function vanishing on a given open subset U of an open connected set O, vanishes on the whole of O (see, e.g., Ref. 37).

Here, it suffices to show that $\tilde{\mathcal{D}}^n_{0,\alpha_1\cdots\alpha_n}$ is dense in $\mathcal{D}_0^n$ for any $t \in \mathbb{R}$ so let us consider the matrix element

$$\tilde{A}_{t,\varphi,\alpha_1\cdots\alpha_n}(x_1, \ldots, x_n) = \langle \varphi^{(n)}, \tilde{a}^{\dagger}_{\alpha_1}(t,x_1)\cdots\tilde{a}^{\dagger}_{\alpha_n}(t,x_n)\Omega\rangle, \tag{3.38}$$

where $\varphi^{(n)} \in \mathcal{D}_0^n$ is arbitrary. To prove the statement, we now have to show that

$$\tilde{A}_{t,\varphi,\alpha_1\cdots\alpha_n}(x_1, \ldots, x_n) = 0, \quad \forall\, |x_1| > \cdots > |x_n| > 0, \quad x_i \in \mathbb{R}^{\alpha_i}, \quad i = 1, \ldots, n \tag{3.39}$$

implies $\varphi^{(n)} = 0$. From (3.36), we get

$$\tilde{A}_{t,\varphi,\alpha_1\cdots\alpha_n}(x_1, \ldots, x_n) = \int_{\mathbb{R}^n} \prod_{j=1}^{n} \frac{\mathrm{d}p_j}{2\pi} e^{-ip_jx_j + itp_j^2} \langle \varphi^{(n)}, a^{\dagger}_{\alpha_1}(p_1)\cdots a^{\dagger}_{\alpha_n}(p_n)\Omega\rangle, \tag{3.40}$$

which shows that $\tilde{A}_{t,\varphi,\alpha_1\cdots\alpha_n}$ is the Fourier transform of a C^{∞}-function with compact support and is therefore real analytic. Condition (3.39) amounts to saying that $\tilde{A}_{t,\varphi,\alpha_1\cdots\alpha_n}$ vanishes on the set

$$U_{\alpha_1\cdots\alpha_n} = \{x \in \mathbb{R}^n\, s.t.\, |x_1| > \cdots > |x_n| > 0,\ x_i \in \mathbb{R}^{\alpha_i},\ i = 1, \ldots, n\}. \tag{3.41}$$

$U_{\alpha_1\cdots\alpha_n}$ being an open subset of (the open and connected space) $\mathbb{R}^n$, we conclude that $\tilde{A}_{t,\varphi,\alpha_1\cdots\alpha_n}$ vanishes on $\mathbb{R}^n$. This gives in turn that

$$\langle \varphi^{(n)}, a^{\dagger}_{\alpha_1}(p_1)\cdots a^{\dagger}_{\alpha_n}(p_n)\Omega\rangle = 0, \quad \forall\, p_j \in \mathbb{R}, \quad j = 1, \ldots, n, \tag{3.42}$$

or, equivalently, from the cyclicity of Ω with respect to $a^{\dagger}$

$$\varphi^{(n)}_{\alpha_1\cdots\alpha_n}(p_1, \ldots, p_n) = 0, \quad \forall\, p_j \in \mathbb{R}, \quad j = 1, \ldots, n. \tag{3.43}$$

Now using the properties (3.21) and (3.22) satisfied by $\varphi^{(n)}$, we get

$$\varphi^{(n)}_{\alpha_1\cdots\alpha_n}(p_1, \ldots, p_n) = 0, \quad \forall\, p_j \in \mathbb{R}, \quad \forall\, \alpha_j = \pm, \quad j = 1, \ldots, n \tag{3.44}$$

that is $\varphi^{(n)} = 0$. ■

This theorem will prove to be fundamental in the sequel to derive the required properties of the quantum field operator. Indeed, it will be enough to perform all calculations only on states in

$$\tilde{\mathcal{D}}_0^{n,\alpha} = \tilde{\mathcal{D}}^n_{0,\underbrace{\alpha\cdots\alpha}_{n}} \quad \text{with } \alpha = \pm \tag{3.45}$$

and conclude for the whole domain $\mathcal{D}$ by a continuity argument.

Lemma 3.2: Let $f_{1,\alpha_1} \succ \cdots \succ f_{n,\alpha_n}$ *and* $h_{1,\beta_1} \succ \cdots \succ h_{n,\beta_n}$, *then*

$$\langle \tilde{a}^\dagger_{\alpha_1}(t,f_{1,\alpha_1}) \cdots \tilde{a}^\dagger_{\alpha_n}(t,f_{n,\alpha_n})\Omega, \tilde{a}^\dagger_{\beta_1}(t,h_{1,\beta_1}) \cdots \tilde{a}^\dagger_{\beta_n}(t,h_{n,\beta_n})\Omega\rangle = \prod_{j=1}^{n} \delta_{\alpha_j\beta_j}\langle f_{j,\alpha_j}, h_{j,\beta_j}\rangle. \tag{3.46}$$

In particular, for $\varphi \in \tilde{D}^n_{0,\alpha_1\cdots\alpha_n}$ *represented as*

$$\varphi = \sum_{\beta\in B} \tilde{a}^\dagger_{\alpha_1}(t,f^\beta_{1,\alpha_1}) \cdots \tilde{a}^\dagger_{\alpha_n}(t,f^\beta_{n,\alpha_n}), \quad f^\beta_{1,\alpha_1} \succ \cdots \succ f^\beta_{n,\alpha_n}, \quad \forall\, \beta \in B, \tag{3.47}$$

where B *is a finite set, one has* $\|\varphi\| = \|\Sigma_{\beta\in B} f^\beta_{1,\alpha_1} \otimes \cdots \otimes f^\beta_{n,\alpha_n}\|$.

Proof: To get (3.46), one uses an induction on n and combines (3.36), (3.27), (3.8), and (3.23) together with the support conditions on the smearing functions. Using a contour integral argument, these support conditions imply that all the contributions arising from the RT algebra vanish except for the usual δ- term producing the right-hand side. Equation (3.47) is a mere consequence of (3.46). ■

Remark: It is important to realize that the n particle space $\mathcal{H}^{(n)}$ is the central piece in this construction and that, on this space, any operation we have considered (scalar product, creation operator, Fourier transform) is continuous in the smearing functions. Since $C_0^\infty(\mathbb{R})$ is dense in $\mathcal{S}(\mathbb{R})$, the Schwarz space, we can extend the above (especially the definition of $\mathcal{D}_0^n$) to smearing functions in $\mathcal{S}(\mathbb{R})$.

C. Quantum field

We start by defining $\Phi(t,f)$ as

$$\Phi(t,f) = \int_{\mathbb{R}} dx \sum_{\alpha=\pm} \overline{f_\alpha}(x)\Phi_\alpha(t,x), \quad f \in \mathcal{C} \text{ where } \mathcal{C} = \bigoplus_{\alpha=\pm} C_0^\infty(\mathbb{R}^\alpha). \tag{3.48}$$

f is viewed as a column vector $f = \binom{f_+}{f_-}$ with $f_\alpha \in C_0^\infty(\mathbb{R}^\alpha)$ and $0 \notin \mathrm{supp}(f_\alpha)$. Following the standard argument of Ref. 29, we replace $\lambda_\alpha(p), \overline{\lambda_\alpha}(p)$ in the Rosales expansion of the classical field (2.4) and (2.5) by the operators $a_\alpha(p), a^\dagger_\alpha(p)$ in order to define

$$\Phi_\alpha(t,x) = \sum_{n=0}^{\infty} (-g)^n \Phi^{(n)}_\alpha(t,x), \quad g > 0 \tag{3.49}$$

and

$$\Phi^{(n)}_\alpha(t,x) = \int_{\mathbb{R}^{2n+1}} \prod_{\substack{i=1\\ j=0}}^{n} \frac{dp_i}{2\pi}\frac{dq_j}{2\pi} a^\dagger_\alpha(p_1)\cdots a^\dagger_\alpha(p_n)a_\alpha(q_n)\cdots a_\alpha(q_0) \frac{e^{i\Sigma_{j=0}^n (q_j x - q_j^2 t) - i\Sigma_{i=1}^n (p_i x - p_i^2 t)}}{\prod_{i=1}^{n} (p_i - q_{i-1} - i\alpha\varepsilon)(p_i - q_i - i\alpha\varepsilon)}, \tag{3.50}$$

where we used an $i\varepsilon$ prescription depending on $\alpha = \pm$.

We now have several requirements to meet for our quantum theory to be well defined. We must give a precise meaning to $\Phi_\alpha(t,x)$, show that the canonical commutation relations as well as the boundary conditions (2.12) and (2.13) hold in a sense we shall make precise and that $\Phi_\alpha(t,x)$ is indeed the quantum solution we look for.

We start by associating $\Phi_\alpha(t,x)$ with the quadratic form defined on $\mathcal{D}\times\mathcal{D}$ by

$$(\varphi,\psi)\mapsto\langle\varphi,\Phi_\alpha(t,x)\psi\rangle, \tag{3.51}$$

$\mathcal{D}$ containing only finite particle vectors, it is enough to investigate $\langle\varphi,\Phi_\alpha^{(n)}(t,x)\psi\rangle$ for arbitrary n.

Proposition 3.3: $\forall\ n\geqslant 0$, $\forall\ \varphi,\psi\in\mathcal{D}$, $(t,x)\mapsto\langle\varphi,\Phi_\alpha^{(n)}(t,x)\psi\rangle$ *is a* C^∞ *function.*

Proof: The proof is the same as in Ref. 32. ■

We define the conjugate $\Phi_\alpha^\dagger(t,x)$ again as a quadratic form on $\mathcal{D}\times\mathcal{D}$ by

$$\langle\varphi,\Phi_\alpha^\dagger(t,x)\psi\rangle=\langle\Phi_\alpha(t,x)\varphi,\psi\rangle. \tag{3.52}$$

It has the same smoothness properties and from (3.27), we get

$$\Phi_\alpha^{\dagger(n)}(t,x)=\int_{\mathbb{R}^{2n+1}}\prod_{\substack{i=1\\ j=0}}^{n}\frac{\mathrm{d}p_i}{2\pi}\frac{\mathrm{d}q_j}{2\pi}a_\alpha^\dagger(q_0)\cdots a_\alpha^\dagger(q_n)a_\alpha(p_n)\cdots a_\alpha(p_1)$$
$$\times\frac{e^{-i\Sigma_{j=0}^n(q_jx-q_j^2t)+i\Sigma_{i=1}^n(p_ix-p_i^2t)}}{\prod_{i=1}^n(p_i-q_{i-1}+i\alpha\varepsilon)(p_i-q_i+i\alpha\varepsilon)}. \tag{3.53}$$

Defining the smeared version

$$\Phi^\dagger(t,f)=\int_{\mathbb{R}}\mathrm{d}x\sum_{\alpha=\pm}\Phi_\alpha^\dagger(t,x)f_\alpha(x),\quad f\in\mathcal{C} \tag{3.54}$$

we conclude that $\Phi(t,f)$ and $\Phi^\dagger(t,f)$ are understood as quadratic forms on the domain $\mathcal{D}$ and are related by

$$\langle\varphi,\Phi_\alpha^\dagger(t,f)\psi\rangle=\langle\Phi_\alpha(t,f)\varphi,\psi\rangle. \tag{3.55}$$

To get true quantum fields, we need to show that these quadratic forms give rise to operators on $\mathcal{D}$. This requires the following two lemmas.

Lemma 3.4: $\forall\ \varphi,\psi\in\mathcal{D}$,

(i) *For* $h_{1,\alpha}\succ\cdots\succ h_{n,\alpha}$,

$$\langle\varphi,\Phi_\alpha(t,f_\alpha)\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega\rangle=\sum_{j=1}^n\langle f_\alpha,h_{j,\alpha}\rangle$$
$$\times\langle\varphi,\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\widehat{\tilde{a}_\alpha^\dagger(t,h_{j,\alpha})}\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega\rangle, \tag{3.56}$$

where the hatted symbol is omitted.

(ii) *For* $h_\alpha\succ f_\alpha$,

$$\langle\varphi,\Phi_\alpha^\dagger(t,f_\alpha)\tilde{a}_\alpha^\dagger(t,h_\alpha)\psi\rangle=\langle\varphi,\tilde{a}_\alpha^\dagger(t,h_\alpha)\Phi_\alpha^\dagger(t,f_\alpha)\psi\rangle. \tag{3.57}$$

(iii) *For* $f_\alpha\succ h_{j,\alpha}$, $j=1,\ldots,n$,

$$\langle\varphi,\Phi_\alpha^\dagger(t,f_\alpha)\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega\rangle=\langle\varphi,\tilde{a}_\alpha^\dagger(t,f_\alpha)\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega\rangle. \tag{3.58}$$

Proof: One just has to apply the order by order technique developed in Ref. 29. The latter heavily relied on the ZF algebra satisfied by the creation and annihilation operators. Here, one must take care in addition of the many contributions of the defect generators but it is remarkable that the RT algebra satisfied by the bulk and defect operators leads to the same results (using the support requirements of the smearing functions and the conditions $g\succ 0$, $\eta\succ 0$, all the defect contributions vanish). One realizes in these manipulations, especially in (3.58), that the contribu-

tions of Φ, $\Phi^\dagger$ on $\tilde{\mathcal{D}}_0^{n,\alpha}$ are carried by the zeroth order corresponding to the linear problem (it is the Fourier transform of a, $a^\dagger$). ■

Lemma 3.5: Given $\varphi_\alpha \in \tilde{\mathcal{D}}_0^{n,\alpha}$, $\psi_\alpha \in \tilde{\mathcal{D}}_0^{n+1,\alpha}$ *and* $f_\alpha \in C_0^\infty(\mathbb{R}^\alpha)$, *the quadratic form (3.51) satisfies the following boundedness condition:*

$$|\langle \varphi_\alpha, \Phi_\alpha(t,f_\alpha)\psi_\alpha\rangle| \leqslant (n+1)\|f_\alpha\|\,\|\varphi_\alpha\|\,\|\psi_\alpha\|. \tag{3.59}$$

Proof: The proof is similar to that given in Ref. 32 and uses lemmas 3.2 and 3.4(i). ■

From the Riesz lemma and theorem 3.1, we conclude that $\Phi_\alpha(t,f_\alpha):\mathcal{H}^{(n+1)}\to\mathcal{H}^{(n)}$ is a bounded operator for any $n\geqslant 0$. Thus, it defines an operator on the common invariant domain $\mathcal{D}$. The same holds for $\Phi_\alpha^\dagger(t,f_\alpha)$, $\mathcal{H}^{(n)}\to H^{(n+1)}$ by (3.55). We can therefore collect our results in the following theorem.

Theorem 3.6: $\Phi(t,f)$, $\Phi^\dagger(t,f):\mathcal{D}\to\mathcal{D}$ *are Hermitian conjugate, linear operators and satisfy*

$$\Phi(t,f)\Omega = 0, \quad \Phi^\dagger(t,f)\Omega = \tilde{a}^\dagger(t,f)\Omega. \tag{3.60}$$

Finally, we will have a *nonrelativistic quantum field* if we prove the canonical commutation relations for Φ, $\Phi^\dagger$.

Theorem 3.7: $\{\Phi(t,f),\Phi^\dagger(t,f), f\in\mathcal{C}\}$ *realize a Fock representation of the equal time canonical commutation relations on* $\mathcal{D}$,

$$[\Phi(t,f_1),\Phi(t,f_2)] = 0 = [\Phi^\dagger(t,f_1),\Phi^\dagger(t,f_2)], \tag{3.61}$$

$$[\Phi(t,f_1),\Phi^\dagger(t,f_2)] = \langle f_1,f_2\rangle. \tag{3.62}$$

Proof: We know that it suffices to compute the commutators on $\tilde{\mathcal{D}}_0^{n,+}$ or $\tilde{\mathcal{D}}_0^{n,-}$ for arbitrary n and then extend the results by continuity to $\mathcal{H}^{(n)}$ and by linearity to $\mathcal{D}$. From theorem 3.6, we get that (i)–(iii) of lemma 3.4 hold as operator equalities. Let us start with the first commutator. It is made out of four parts,

$$\begin{aligned}[\Phi(t,f_1),\Phi(t,f_2)] = {}& [\Phi_+(t,f_{1,+}),\Phi_+(t,f_{2,+})] + [\Phi_+(t,f_{1,+}),\Phi_-(t,f_{2,-})] + [\Phi_-(t,f_{1,-}),\Phi_+(t,f_{2,+})] \\ & + [\Phi_-(t,f_{1,-}),\Phi_-(t,f_{2,-})].\end{aligned} \tag{3.63}$$

The first and fourth parts of the right-hand side are easily seen to be zero from (i) of lemma 3.4 One has for $\alpha=\pm$,

$$\begin{aligned}\Phi_\alpha(t,f_{1,\alpha})\Phi_\alpha(t,f_{2,\alpha})\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega = {}& \sum_{j=1}^{n}\sum_{\substack{k=1\\k\neq j}}^{n}\langle f_{2,\alpha},h_{j,\alpha}\rangle\langle f_{1,\alpha},h_{k,\alpha}\rangle\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots \\ & \times\widehat{\tilde{a}_\alpha^\dagger(t,h_{j,\alpha})}\cdots\widehat{\tilde{a}_\alpha^\dagger(t,h_{k,\alpha})}\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega,\end{aligned} \tag{3.64}$$

which is symmetric under the exchange of f_1 and f_2 implying the vanishing of the commutators. As for the mixed terms, one can check that

$$\Phi_\alpha(t,f_{i,\alpha})\tilde{a}_{-\alpha}^\dagger(t,h_{1,-\alpha})\cdots\tilde{a}_{-\alpha}^\dagger(t,h_{n,-\alpha})\Omega = 0, \quad i=1,2 \tag{3.65}$$

implying the vanishing of the second and third commutators on $\tilde{\mathcal{D}}_0^{n,-\alpha}$ and hence on $\mathcal{D}$. Now the vanishing of $[\Phi^\dagger(t,f_1),\Phi^\dagger(t,f_2)]$ on $\mathcal{D}$ is obtained by Hermitian conjugation. This proves (3.61).

Equation (3.62) is obtained as follows. Again, we split the commutator into four parts. Now given a state in $\tilde{\mathcal{D}}_0^{n,\alpha}$, we assume $h_{k,\alpha}\succ f_{2,\alpha}\succ h_{k+1,\alpha}$ for some k and using lemma 3.4, we compute for $\alpha=\pm$,

$$\Phi_\alpha(t,f_{1,\alpha})\Phi_\alpha^\dagger(t,f_{2,\alpha})\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega=\langle f_{1,\alpha},f_{2,\alpha}\rangle\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega+\mathfrak{S} \tag{3.66}$$

and

$$\Phi_\alpha^\dagger(t,f_{2,\alpha})\Phi_\alpha(t,f_{1,\alpha})\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega=\mathfrak{S}, \tag{3.67}$$

where $\mathfrak{S}$ is

$$\sum_{j=1}^{n}\langle f_{1,\alpha},h_{j,\alpha}\rangle\tilde{a}_\alpha^\dagger(t,h_{1,\alpha})\cdots\widehat{\tilde{a}_\alpha^\dagger(t,h_{j,\alpha})}\cdots\tilde{a}_\alpha^\dagger(t,h_{k,\alpha})\tilde{a}_\alpha^\dagger(t,f_{2,\alpha})\tilde{a}_\alpha^\dagger(t,h_{k+1,\alpha})\cdots\tilde{a}_\alpha^\dagger(t,h_{n,\alpha})\Omega.$$

This gives

$$[\Phi_+(t,f_{1,+}),\Phi_+^\dagger(t,f_{2,+})]+[\Phi_-(t,f_{1,-}),\Phi_-^\dagger(t,f_{2,-})]=\langle f_{1,+},f_{2,+}\rangle+\langle f_{1,-},f_{2,-}\rangle=\langle f_1,f_2\rangle, \tag{3.68}$$

i.e., the desired contribution. It is then straightforward using (3.65) to verify that the mixed terms do not contribute

$$[\Phi_+(t,f_{1,+}),\Phi_-^\dagger(t,f_{2,-})]=[\Phi_-(t,f_{1,-}),\Phi_+^\dagger(t,f_{2,+})]=0.$$

■

Now we prove that Ω is cyclic with respect to $\Phi^\dagger$ and that $\Phi(t,x)$ is the solution of the quantum nonlinear Schrödinger equation with impurity. Extending the partial ordering $\succ$ to functions in $\mathcal{C}$ as follows:

$$\text{for } f,g\in\mathcal{C},\quad f\succ g\Leftrightarrow f_\alpha\succ g_\alpha,\quad \alpha=\pm, \tag{3.69}$$

one can prove the following theorems.

Theorem 3.8: *The space*

$$\mathcal{H}_0^{(n)}=\text{vect}\{\Phi^\dagger(t,f_1)\cdots\Phi^\dagger(t,f_n)\Omega;\quad f_i\in\mathcal{C},\quad i=1,\ldots,n,\quad f_n\succ\ldots\succ f_1\} \tag{3.70}$$

is dense in $\mathcal{H}^{(n)}$.

Proof: Let $\varphi^{(n)}\in\mathcal{H}^{(n)}$ and suppose

$$\langle\varphi^{(n)},\Phi^\dagger(t,f_1)\cdots\Phi^\dagger(t,f_n)\Omega\rangle=0,\quad \forall f_n\succ\cdots\succ f_1.$$

Then, it is true in particular for $f_{i,-}=0$, $i=1,\ldots,n$ but in that case, we have

$$\Phi^\dagger(t,f_1)\cdots\Phi^\dagger(t,f_n)\Omega=\tilde{a}_+^\dagger(t,f_{n,+})\cdots\tilde{a}_+^\dagger(t,f_{1,+})\Omega$$

which implies $\varphi^{(n)}=0$ since $\tilde{\mathcal{D}}_0^{n,+}$ is dense in $\mathcal{H}^{(n)}$. ■

Theorem 3.9: *The quantum field* Φ *is solution of the quantum nonlinear Schrödinger equation with impurity, i.e., it satisfies*

$$(i\partial_t+\partial_x^2)\langle\varphi,\Phi(t,x)\psi\rangle=2g\langle\varphi,{:}\Phi\Phi^\dagger\Phi{:}(t,x)\psi\rangle \tag{3.71}$$

and the following boundary conditions:

$$\lim_{x\to0^+}\langle\varphi,\{\Phi_+(t,x)-\Phi_-(t,-x)\}\psi\rangle=0, \tag{3.72}$$

$$\lim_{x\to0^+}\partial_x\langle\varphi,\{\Phi_+(t,x)+\Phi_-(t,-x)\}\psi\rangle=2\eta\lim_{x\to0}\langle\varphi,\Phi(t,x)\psi\rangle, \tag{3.73}$$

$$\lim_{x\to\pm\infty}\langle\varphi,\Phi(t,x)\psi\rangle=0, \tag{3.74}$$

for any $\varphi, \psi \in \mathcal{D}$.

Proof: Inspired by the classical case, we split the field as follows:

$$\Phi(t,x) = \theta(x)\Phi_+(t,x) + \theta(-x)\Phi_-(t,x). \tag{3.75}$$

The main difficulty here is to specify a normal ordering prescription for the analog of the cubic term. We adopt the prescription detailed in Ref. 32 for the normal ordering denoted $:\cdots:$ and apply it to Φ_α, $\alpha=\pm$. Then following Ref. 32 (theorem 5), one gets that the quantum field Φ_α is solution of the nonlinear Schrödinger equation on the half-line $\mathbb{R}^\alpha$: for all $\varphi, \psi \in \mathcal{D}$,

$$(i\partial_t + \partial_x^2)\langle \varphi, \Phi_\alpha(t,x)\psi\rangle = 2g\langle \varphi, :\Phi_\alpha \Phi_\alpha^\dagger \Phi_\alpha:(t,x)\psi\rangle. \tag{3.76}$$

The situation is now similar to the classical case and we have to check the quantum analog of (2.12)–(2.14). The idea lies again in realizing that Eqs. (3.72)–(3.74) can be cast into a zeroth-order/linear problem. Following the line of argument of Ref. 32 (theorem 6), one shows that given $\varphi, \psi \in \mathcal{D}$, there exists $\chi \in \mathcal{H}^{(1)}$ such that $\langle \varphi, \Phi(t,f)\psi\rangle = \langle \Omega, \Phi(t,f)\chi\rangle$ and χ is independent of f. This gives in particular $\langle \varphi, \Phi_\alpha(t,f_\alpha)\psi\rangle = \langle \Omega, \Phi_\alpha(t,f_\alpha)\chi\rangle$, $\alpha=\pm$ and we can compute

$$\langle \varphi, \Phi_\alpha(t,x)\psi\rangle = \langle \tilde{a}_\alpha^\dagger(t,x)\Omega, \chi\rangle = \int_{\mathbb{R}} \frac{dp}{2\pi} e^{ipx - ip^2 t}\chi_\alpha(p). \tag{3.77}$$

Then, Eqs. (3.72) and (3.73) are easily obtained using the property (3.21) satisfied by χ. Finally, since $\chi_\alpha \in L^2(\mathbb{R})$, $\langle \varphi, \Phi_\alpha(t,x)\psi\rangle$ as a function of x is also in $L^2(\mathbb{R})$ and therefore vanishes at infinity. Noting that $\lim_{x\to\pm\infty}\langle \varphi, \Phi(t,x)\psi\rangle = \lim_{x\to\pm\infty}\langle \varphi, \Phi_\pm(t,x)\psi\rangle$, we get (3.74). ■

We have finally achieved the goal of this section: we have explicitly constructed off-shell local fields for the quantum nonlinear Schrödinger system on the line in the presence of a transmitting and reflecting impurity. As mentioned in Ref. 7, this remained a challenging open problem for which we brought an answer here. In other words, the quantum inverse scattering method remains valid in the presence of an impurity provided that the ZF algebra is replaced by the RT algebra.

IV. SCATTERING THEORY

Scattering theory in the presence of an impurity was studied on general grounds in Ref. 7 by introducing the RT algebra which, being a generalization of the ZF and boundary algebras, is believed to prove fundamental also in the study of off-shell correlations functions and symmetries for $1+1$-dimensional integrable systems with impurity.

In this section, we aim at giving some credit to this in the context of the nonlinear Schrödinger model. Indeed from the above results, we can get some insight in the correlations functions of the theory. The correlations functions vanish unless they involve the same number of Φ and $\Phi^\dagger$ and for a given $2n$-point function, we need at most the first $(n-1)$-order terms in the Rosales expansion of the field. This reads

$$\begin{aligned}&\langle \Omega, \Phi(t_1,x_1)\cdots\Phi(t_n,x_n)\Phi^\dagger(t_{n+1},x_{n+1})\cdots\Phi^\dagger(t_{2n},x_{2n})\Omega\rangle \\ &\quad = \sum_{\substack{K\leqslant n-1 \\ L\leqslant n-1}} g^{K+L}\langle \Omega, \Phi^{(k_1)}(t_1,x_1)\cdots\Phi^{(k_n)}(t_n,x_n)\Phi^{\dagger(l_1)}(t_{n+1},x_{n+1})\cdots\Phi^{\dagger(l_n)}(t_{2n},x_{2n})\Omega\rangle,\end{aligned} \tag{4.1}$$

where $K=\sum_{i=1}^n k_i$ and $L=\sum_{i=1}^n l_i$ and the sum runs over all n-uplets $(k_1,\ldots,k_n)$, $(l_1,\ldots,l_n)\in\mathbb{Z}_+^n$ such that $K,L\leqslant n-1$.

One has, for example (with $t_{12}=t_1-t_2$, $x_{12}=x_1-x_2$, and $\tilde{x}_{12}=x_1+x_2$),

$$\langle\Omega,\Phi(t_1,x_1)\Phi^*(t_2,x_2)\Omega\rangle = \int_{-\infty}^{+\infty}\frac{\mathrm{d}p}{2\pi}e^{-ip^2t_{12}}\{\theta(x_1)\theta(x_2)[e^{ipx_{12}}+R(p)e^{ip\tilde{x}_{12}}]+\theta(-x_1)\theta(-x_2)[e^{ipx_{12}} + \overline{R}(p)e^{ip\tilde{x}_{12}}]+\theta(x_1)\theta(-x_2)T(p)e^{ipx_{12}}+\theta(-x_1)\theta(x_2)\overline{T}(p)e^{ipx_{12}}\}. \tag{4.2}$$

More importantly, using the Haag–Ruelle approach suitably, we can relate off-shell and asymptotic theories and, doing so, fill the gap of our quantum field theory. Indeed, on the one hand, we know from Ref. 7 that the Fock representation of the RT algebra generates the asymptotic states of a general integrable theory with impurity with corresponding *S*-matrix. On the other hand, in this paper we constructed off-shell local time-dependent fields whose behavior as $t\to\pm\infty$ we would like to know.

A. Asymptotic theory

The first step is to characterize wave packets for the free Schrödinger equation which take into account the presence of the impurity at $x=0$. We adopt the following setup. For $\mathfrak{f}\in C_0^\infty(\mathbb{R})$, we define

$$f^t(x) = \int_{\mathbb{R}}\frac{\mathrm{d}p}{2\pi}\mathfrak{f}(p)e^{ipx-ip^2t}. \tag{4.3}$$

We transpose the partial ordering (3.35) to functions of the variable p.

Definition 4.1: Given $n,m\geqslant 1$, consider two sets of functions

$$\mathfrak{H}_n=\{\mathfrak{h}_{i,\alpha_i}\in C_0^\infty(\mathbb{R}^{\alpha_i}),\quad i=1,\ldots,n\}\quad\text{and}\quad \mathfrak{G}_m=\{\mathfrak{g}_{i,\beta_i}\in C_0^\infty(\mathbb{R}^{-\beta_i}),\quad i=1,\ldots,m\}, \tag{4.4}$$

where the functions obey the following order prescriptions:

$$\mathfrak{h}_{1,\alpha_1}\succ\cdots\succ\mathfrak{h}_{n,\alpha_n},\quad \mathfrak{g}_{m,\beta_m}\succ\cdots\succ\mathfrak{g}_{1,\beta_1}. \tag{4.5}$$

We also define

$$h^\theta_{i,\alpha_i}(x)=\theta(\alpha_i x)h^t_{i,\alpha_i}(x),\quad g^\theta_{i,\beta_i}(x)=\theta(\beta_i x)g^t_{i,\beta_i}(x). \tag{4.6}$$

By construction, $h^\theta_{i,\alpha_i}(x)$ represent wave packets in $\mathbb{R}^{\alpha_i}$ moving away from the impurity towards $\alpha_i\infty$ while $g^\theta_{i,\beta_i}(x)$ represent wave packets in $\mathbb{R}^{\beta_i}$ moving towards the impurity. One already understands that they will be relevant for the so-called "out" and "in" states, respectively. In fact, this is the main theorem of this section for which we need some preliminary results.

From the preceding section, we know the exchange and commutation properties of $\Phi^\dagger$ and $\tilde{a}^\dagger$ smeared with ordered functions in the variable x. Here, our wave packets were constructed from ordered functions in p but we made no assumption as to their ordering in x. Therefore, we must include all the possibilities and this requires the use of the permutation group of n elements $\mathfrak{S}_n$. For $\sigma\in\mathfrak{S}_n$, $\pi\in\mathfrak{S}_m$, $n,m\geqslant 2$, we introduce

$$\theta^\sigma_h(\alpha_1x_1,\ldots,\alpha_nx_n)=\prod_{\substack{i,j=1\\ i<j}}^{n}\theta(\alpha_{\sigma_i}x_{\sigma_i}-\alpha_{\sigma_j}x_{\sigma_j}), \tag{4.7}$$

$$\theta^\pi_g(\beta_1x_1,\ldots,\beta_mx_m)=\prod_{\substack{i,j=1\\ i>j}}^{m}\theta(\beta_{\pi_i}x_{\pi_i}-\beta_{\pi_j}x_{\pi_j}), \tag{4.8}$$

satisfying

$$\sum_{\sigma\in\mathfrak{S}_n}\theta_h^\sigma(\alpha_1x_1,\ldots,\alpha_nx_n)=1=\sum_{\pi\in\mathfrak{S}_m}\theta_g^\pi(\beta_1x_1,\ldots,\beta_mx_m). \tag{4.9}$$

Lemma 4.2: Given any two sets of functions in $\mathfrak{H}_n$ and $\mathfrak{G}_m$,

(i) *The following limits hold:*

$$\lim_{t\to+\infty}\|h^\theta_{1,\alpha_1}\otimes\cdots\otimes h^\theta_{n,\alpha_n}-h^t_{1,\alpha_1}\otimes\cdots\otimes h^t_{n,\alpha_n}\|=0,$$

$$\lim_{t\to-\infty}\|g^\theta_{1,\beta_1}\otimes\cdots\otimes g^\theta_{m,\beta_m}-g^t_{1,\beta_1}\otimes\cdots\otimes g^t_{m,\beta_m}\|=0. \tag{4.10}$$

(ii) *Let e_n be the identity of $\mathfrak{S}_n$ and let us define*

$$H^\sigma_{\alpha_1\cdots\alpha_n}(x_1,\ldots,x_n)=h^\theta_{1,\alpha_1}(x_1)\cdots h^\theta_{n,\alpha_n}(x_n)\theta_h^\sigma(\alpha_1x_1,\ldots,\alpha_nx_n),$$

$$G^\pi_{\beta_1\cdots\beta_m}(x_1,\ldots,x_m)=g^\theta_{1,\beta_1}(x_1)\cdots g^\theta_{m,\beta_m}(x_m)\theta_g^\pi(\beta_1x_1,\ldots,\beta_mx_m). \tag{4.11}$$

Then

$$\lim_{t\to+\infty}\|H^\sigma_{\alpha_1\cdots\alpha_n}\|=0,\quad \lim_{t\to-\infty}\|G^\pi_{\beta_1\cdots\beta_m}\|=0\quad \textit{for all } \sigma\neq e_n,\quad \pi\neq e_m. \tag{4.12}$$

(iii) *The following estimate is valid for any $F\in L^2(\mathbb{R}^n)$,*

$$\left\|\int_{\mathbb{R}^n}\mathrm{d}x_1\cdots\mathrm{d}x_nF(x_1,\ldots,x_n)\tilde a^\dagger_{\alpha_1}(t,x_1)\cdots\tilde a^\dagger_{\alpha_n}(t,x_n)\right\|\leqslant\sqrt{n!}\|F\|. \tag{4.13}$$

Proof: The ideas are the same as those detailed in Ref. 32 from theorem 7 onwards and rest especially on the use of the weak limit

$$\lim_{t\to\pm\infty}\frac{e^{itk}}{k\pm i\varepsilon}=0. \tag{4.14}$$

We just stress again that in our case all the above holds thanks to the use of the RT algebra and by paying careful attention to the support conditions encoded in (4.5). ■

We are now in position to identify the asymptotic behavior of the field as $t\to\pm\infty$.

Theorem 4.3: *The following limits hold in the strong sense in the Fock space $\mathcal{F}$*:

$$\lim_{t\to+\infty}\Phi^\dagger(t,h^\theta_{1,\alpha_1})\cdots\Phi^\dagger(t,h^\theta_{n,\alpha_n})\Omega=a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega, \tag{4.15}$$

$$\lim_{t\to-\infty}\Phi^\dagger(t,g^\theta_{1,\beta_1})\cdots\Phi^\dagger(t,g^\theta_{m,\beta_m})\Omega=a^\dagger_{\beta_1}(\mathfrak{g}_{1,\beta_1})\cdots a^\dagger_{\beta_m}(\mathfrak{g}_{m,\beta_m})\Omega. \tag{4.16}$$

Proof: We note first that from (3.75) one gets $\Phi^\dagger(t,h^\theta_{i,\alpha_i})=\Phi^\dagger_{\alpha_i}(t,h^\theta_{i,\alpha_i})$ and $\Phi^\dagger(t,g^\theta_{i,\beta_i})=\Phi^\dagger_{\beta_i}(t,g^\theta_{i,\beta_i})$ so that

$$\Phi^\dagger(t,h^\theta_{i,\alpha_i})\Omega=\tilde a^\dagger_{\alpha_i}(t,h^\theta_{i,\alpha_i})\Omega\quad\text{and }\Phi^\dagger(t,g^\theta_{i,\beta_i})\Omega=\tilde a^\dagger_{\beta_i}(t,g^\theta_{i,\beta_i})\Omega. \tag{4.17}$$

Moreover, for $\mathfrak{f}_\alpha\in C_0^\infty(\mathbb{R}^\alpha)$, one has

$$a^\dagger_\alpha(\mathfrak{f}_\alpha)=\tilde a^\dagger_\alpha(t,f^t_\alpha). \tag{4.18}$$

Collecting all this, theorem 4.3 is proved for $n=m=1$ using (i), and (iii) of lemma (4.2),

$$\|\Phi^\dagger(t,f^\theta_\alpha)\Omega - a^\dagger_\alpha(\mathfrak{f}_\alpha)\Omega\| = \|\tilde{a}^\dagger_\alpha(t,f^\theta_\alpha)\Omega - \tilde{a}^\dagger_\alpha(t,f^t_\alpha)\Omega\| \leqslant \|f^\theta_\alpha - f^t_\alpha\|, \tag{4.19}$$

$\mathfrak{f}$ playing the role of $\mathfrak{h}$ or $\mathfrak{g}$. Now we want to compute the left-hand sides of Eqs. (4.15) and (4.16) for $n,m \geqslant 2$. We give details for Eq. (4.15),

$$\begin{aligned}\Phi^\dagger(t,h^\theta_{1,\alpha_1})\cdots\Phi^\dagger(t,h^\theta_{n,\alpha_n})\Omega &= \sum_{\sigma\in\mathfrak{S}_n}\int_{\mathbb{R}^n} dx_1\cdots dx_n\, H^\sigma_{\alpha_1\cdots\alpha_n}(x_1,\ldots,x_n)\Phi^\dagger_{\alpha_1}(t,x_1)\cdots\Phi^\dagger_{\alpha_n}(t,x_n)\Omega\\ &= \sum_{\sigma\in\mathfrak{S}_n}\int_{\mathbb{R}^n} dx_1\cdots dx_n\, H^\sigma_{\alpha_1\cdots\alpha_n}(x_1,\ldots,x_n)\tilde{a}^\dagger_{\alpha_{\sigma_1}}(t,x_{\alpha_{\sigma_1}})\cdots\tilde{a}^\dagger_{\alpha_{\sigma_n}}(t,x_{\alpha_{\sigma_n}})\Omega\\ &= \tilde{a}^\dagger_{\alpha_1}(t,h^\theta_{1,\alpha_1})\cdots\tilde{a}^\dagger_{\alpha_n}(t,h^\theta_{n,\alpha_n})\Omega + \sum_{\substack{\sigma\in\mathfrak{S}_n\\ \sigma\neq e_n}}\int_{\mathbb{R}^n} dx_1\cdots dx_n\, H^\sigma_{\alpha_1\cdots\alpha_n}(x_1,\ldots,x_n)\\ &\quad\times\{\tilde{a}^\dagger_{\alpha_{\sigma_1}}(t,x_{\alpha_{\sigma_1}})\cdots\tilde{a}^\dagger_{\alpha_{\sigma_n}}(t,x_{\alpha_{\sigma_n}})\Omega - \tilde{a}^\dagger_{\alpha_1}(t,h^\theta_{1,\alpha_1})\cdots\tilde{a}^\dagger_{\alpha_n}(t,h^\theta_{n,\alpha_n})\Omega\},\end{aligned} \tag{4.20}$$

where we used point (iii) of lemma 3.4 and (3.61) for $\Phi^\dagger$ in the second equality. Applying (4.13) then gives

$$\begin{aligned}\|\Phi^\dagger(t,h^\theta_{1,\alpha_1})\cdots\Phi^\dagger(t,h^\theta_{n,\alpha_n})\Omega - a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega\| &\leqslant \sqrt{n!}\|h^\theta_{1,\alpha_1}\otimes\cdots\otimes h^\theta_{n,\alpha_n} - h^t_{1,\alpha_1}\otimes\cdots\\ &\otimes h^t_{n,\alpha_n}\| + 2\sqrt{n!}\sum_{\substack{\sigma\in\mathfrak{S}_n\\ \sigma\neq e_n}}\|H^\sigma_{\alpha_1\cdots\alpha_n}\|,\end{aligned} \tag{4.21}$$

implying (4.15) by points (i)–(ii) of lemma 4.2 Similar computations give

$$\begin{aligned}\|\Phi^\dagger(t,g^\theta_{1,\beta_1})\cdots\Phi^\dagger(t,g^\theta_{m,\beta_m})\Omega - a^\dagger_{\beta_1}(\mathfrak{g}_{1,\beta_1})\cdots a^\dagger_{\beta_m}(\mathfrak{g}_{m,\beta_m})\Omega\| &\leqslant \sqrt{m!}\|g^\theta_{1,\beta_1}\otimes\cdots\otimes g^\theta_{m,\beta_m} - g^t_{1,\beta_1}\\ &\otimes\cdots\otimes g^t_{m,\beta_m}\| + 2\sqrt{m!}\sum_{\substack{\pi\in\mathfrak{S}_m\\ \neq e_m}}\|G^\pi_{\beta_1\cdots\beta_m}\|,\end{aligned} \tag{4.22}$$

proving (4.16). ■

B. Scattering matrix

Now that we have identified the natural "free" dynamics approached by our interacting field as $t\to\pm\infty$, we are left with the verification of asymptotic completeness allowing the construction of a unitary S-matrix. We emphasize here that our "in" and "out" spaces are slightly different from those exhibited in Ref. 7 because of our ordering involving absolute values, so that we must recheck their properties.

Proposition 4.4: Let

$$\mathcal{F}^{\text{in}} = \text{vect}\{\Omega, a^\dagger_{\beta_1}(\mathfrak{g}_{1,\beta_1})\cdots a^\dagger_{\beta_m}(\mathfrak{g}_{m,\beta_m})\Omega,\ \beta_i = \pm,\ i=1,\ldots,m,\ m\geqslant 1\}, \tag{4.23}$$

$$\mathcal{F}^{\text{out}} = \text{vect}\{\Omega, a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega,\ \alpha_i = \pm,\ i=1,\ldots,n,\ n\geqslant 1\}, \tag{4.24}$$

where $\mathfrak{h}_{i,\alpha_i}$ *and* $\mathfrak{g}_{j,\beta_j}$ *run over* $\mathfrak{H}_n$ *and* $\mathfrak{G}_m$.

Then, $\mathcal{F}^{\text{in}}$ *and* $\mathcal{F}^{\text{out}}$ *are separately dense in* $\mathcal{F}$.

Proof: We deal with $\mathcal{F}^{\text{in}}$. Again, it is sufficient to consider the matrix element,

$$A_{t,\varphi,\beta_1\cdots\beta_p}(p_1,\ldots,p_m)=\langle\varphi^{(n)},a^\dagger_{\beta_1}(t,p_1)\cdots a^\dagger_{\beta_m}(t,p_m)\Omega\rangle, \tag{4.25}$$

where $\varphi^{(n)}\in\mathcal{H}^{(n)}$ is arbitrary and to show that

$$A_{t,\varphi,\beta_1\cdots\beta_p}(p_1,\ldots,p_m)=0,\quad \forall\,|p_1|<\cdots<|p_m|,\quad p_i\in\mathbb{R}^{-\beta_i},\quad \beta_i=\pm,\quad i=1,\ldots,m \tag{4.26}$$

implies $\varphi^{(n)}=0$. From the cyclicity of Ω with respect to $a^\dagger$, (4.26) gives

$$\varphi^{(n)}_{\beta_1\cdots\beta_p}(p_1,\ldots,p_m)=0,\quad \forall\,|p_1|<\cdots<|p_m|,\quad p_i\in\mathbb{R}^{-\beta_i},\quad \beta_i=\pm,\quad i=1,\ldots,m \tag{4.27}$$

and in view of the properties of $\varphi^{(n)}\in\mathcal{H}^{(n)}$, this implies in turn

$$\varphi^{(n)}_{\beta_1\cdots\beta_p}(p_1,\ldots,p_m)=0,\quad \forall\,p_i\in\mathbb{R},\quad \beta_i=\pm,\quad i=1,\ldots,m, \tag{4.28}$$

i.e., $\varphi^{(n)}=0$. The case of $\mathcal{F}^{\text{out}}$ is similar. ■

We turn to the definition of the scattering operator **S** of our theory.

Proposition 4.5: Take functions in $\mathfrak{H}_n$ and let $\mathbf{S}$: $\mathcal{F}^{\text{out}}\to\mathcal{F}^{\text{in}}$ *act as follows:*

$$\mathbf{S}\Omega=\Omega\quad \textit{and}\quad \mathbf{S}{:}\,a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega\mapsto a^\dagger_{\alpha_n}(\hat{\mathfrak{h}}_{n,\alpha_n})\cdots a^\dagger_{\alpha_1}(\hat{\mathfrak{h}}_{1,\alpha_1})\Omega \tag{4.29}$$

$$\textit{where}\quad \hat{\mathfrak{h}}_{i,\alpha_i}(p)=\mathfrak{h}_{i,\alpha_i}(-p)\in\mathfrak{G}_n. \tag{4.30}$$

Then **S** *is invertible and* $\mathbf{S}$, $\mathbf{S}^{-1}$ *are unitary operators acting on* $\mathcal{F}$.

Proof: From the definitions (4.29) and (4.30), one deduces immediately that $\mathbf{S}^{-1}$ is well defined. Then, it is straightforward, albeit lengthy, to check that

$$\begin{aligned}&\langle\mathbf{S}a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega,\mathbf{S}a^\dagger_{\gamma_1}(\mathfrak{f}_{1,\gamma_1})\cdots a^\dagger_{\gamma_n}(\mathfrak{f}_{n,\gamma_n})\Omega\rangle\\&\quad=\langle a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega,a^\dagger_{\gamma_1}(\mathfrak{f}_{1,\gamma_1})\cdots a^\dagger_{\gamma_n}(\mathfrak{f}_{n,\gamma_n})\Omega\rangle.\end{aligned} \tag{4.31}$$

In evaluating the left-hand side, one just has to notice that all the contributions coming from the defect generators vanish due to the support properties of the smearing functions and one is left with what would be obtained by using the ZF algebra. Then, it is just a matter of changing the variables into their opposite to get the right-hand side.

Next, following the line of argument given in Ref. 19, one extends **S** to $\mathcal{F}^{\text{out}}$ by linearity, preserving unitarity. This gives rise to bounded linear operators which one can uniquely extend by continuity to the whole of $\mathcal{F}$. We note that this last step is allowed by the asymptotic completeness property satisfied by $\mathcal{F}^{\text{out}}$ and $\mathcal{F}^{\text{in}}$ (cf. Proposition 4.4). The case of $\mathbf{S}^{-1}$ is similar. ■

Refering now to Ref. 7 we finish the description of our scattering theory by defining the correspondence between in and out states and the asymptotic states identified in theorem 4.3 (correspondence already anticipated in our calling $\mathcal{F}^{\text{out}}$ and $\mathcal{F}^{\text{in}}$ the "in" and "out" spaces),

$$|\mathfrak{g}_{1,\beta_1};\ldots;\mathfrak{g}_{m,\beta_m}\rangle^{\text{in}}=a^\dagger_{\beta_1}(\mathfrak{g}_{1,\beta_1})\cdots a^\dagger_{\beta_m}(\mathfrak{g}_{m,\beta_m})\Omega, \tag{4.32}$$

$$|\mathfrak{h}_{1,\alpha_1};\ldots;\mathfrak{h}_{n,\alpha_n}\rangle^{\text{out}}=a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega. \tag{4.33}$$

Transition amplitudes are therefore easily computable from

$$ {}^{\text{out}}\langle \mathfrak{h}_{1,\alpha_1};\ldots;\mathfrak{h}_{n,\alpha_n}|\mathfrak{g}_{1,\beta_1};\ldots;\mathfrak{g}_{m,\beta_m}\rangle^{\text{in}} = \langle a^\dagger_{\alpha_1}(\mathfrak{h}_{1,\alpha_1})\cdots a^\dagger_{\alpha_n}(\mathfrak{h}_{n,\alpha_n})\Omega, a^\dagger_{\beta_1}(\mathfrak{g}_{1,\beta_1})\cdots a^\dagger_{\beta_m}(\mathfrak{g}_{m,\beta_m})\Omega\rangle \tag{4.34} $$

and using (3.27), (3.8), (3.13), (3.15), and (3.23). One recovers for transition amplitudes that they vanish unless $n=m$ as expected for an integrable system where particle production does not occur. As an example, we derive in our context the one and two particle transition amplitudes obtained in Ref. 6. We start with the computation of the correlators,

$$ \langle a^\dagger_\alpha(p)\Omega, a^\dagger_\beta(q)\Omega\rangle = \delta^\beta_\alpha\delta(p-q) + \epsilon^\beta_\alpha\delta(p-q)T(\alpha p) + \delta^\beta_\alpha\delta(p+q)R(\alpha p) \tag{4.35} $$

and

$$ \begin{aligned}
&\langle a^\dagger_{\alpha_1}(p_1)a^\dagger_{\alpha_2}(p_2)\Omega, a^\dagger_{\beta_1}(q_1)a^\dagger_{\beta_2}(q_2)\Omega\rangle \\
&\quad = S(\alpha_1p_1-\beta_1q_1)[\delta^{\beta_1}_{\alpha_2}+\epsilon^{\beta_1}_{\alpha_2}T(\alpha_2p_2)][\delta^{\beta_2}_{\alpha_1}+\epsilon^{\beta_2}_{\alpha_1}T(\alpha_1p_1)] \\
&\qquad \times \delta(p_2-q_1)\delta(p_1-q_2) + S(\alpha_1p_1-\beta_1q_1)[\delta^{\beta_1}_{\alpha_2}R(\alpha_2p_2)][\delta^{\beta_2}_{\alpha_1}+\epsilon^{\beta_2}_{\alpha_1}T(\alpha_1p_1)] \\
&\qquad \times \delta(p_2+q_1)\delta(p_1-q_2) + S(\alpha_1p_1-\beta_1q_1)[\delta^{\beta_1}_{\alpha_2}+\epsilon^{\beta_1}_{\alpha_2}T(\alpha_2p_2)][\delta^{\beta_2}_{\alpha_1}R(\alpha_1p_1)]\delta(p_2-q_1)\delta(p_1+q_2) \\
&\qquad + S(\alpha_1p_1-\beta_1q_1)[\delta^{\beta_1}_{\alpha_2}R(\alpha_2p_2)][\delta^{\beta_2}_{\alpha_1}R(\alpha_1p_1)]\delta(p_2+q_1)\delta(p_1+q_2) \\
&\qquad + [\delta^{\beta_1}_{\alpha_1}+S(\alpha_1p_1-\beta_2q_2)S(\alpha_1p_1+\beta_2q_2)\epsilon^{\beta_1}_{\alpha_1}T(\alpha_1p_1)][\delta^{\beta_2}_{\alpha_2}+\epsilon^{\beta_2}_{\alpha_2}T(\alpha_2p_2)]\delta(p_1-q_1)\delta(p_2-q_2) \\
&\qquad + S(\alpha_1p_1-\beta_2q_2)S(\alpha_1p_1+\beta_2q_2)[\delta^{\beta_1}_{\alpha_1}R(\alpha_1p_1)][\delta^{\beta_2}_{\alpha_2}+\epsilon^{\beta_2}_{\alpha_2}T(\alpha_2p_2)]\delta(p_1+q_1)\delta(p_2-q_2) \\
&\qquad + [\delta^{\beta_1}_{\alpha_1}+S(\alpha_1p_1-\beta_2q_2)S(\alpha_1p_1+\beta_2q_2)\epsilon^{\beta_1}_{\alpha_1}T(\alpha_1p_1)][\delta^{\beta_2}_{\alpha_2}R(\alpha_2p_2)]\delta(p_1-q_1)\delta(p_2+q_2) \\
&\qquad + S(\alpha_1p_1-\beta_2q_2)S(\alpha_1p_1+\beta_2q_2)[\delta^{\beta_1}_{\alpha_1}R(\alpha_1p_1)][\delta^{\beta_2}_{\alpha_2}R(\alpha_2p_2)]\delta(p_1+q_1)\delta(p_2+q_2)
\end{aligned} \tag{4.36} $$

We note that the result for the two-particle correlator differs from that obtained in Ref. 6 by the appearance of two S coefficients in the four last terms. This is due to the fact that we started with a more general RT algebra where the defect generators do not necessarily obey the linear relations used in Ref. 6. For the one-particle amplitudes, there are two possibilities according to the relative signs of the in and out states

$$ {}^{\text{out}}\langle \mathfrak{h}_\pm, \mathfrak{g}_\pm\rangle^{\text{in}} = \begin{cases} \displaystyle\int_0^\infty \frac{dp}{2\pi}\overline{\mathfrak{h}}_+(p)R(p)\mathfrak{g}_+(-p), \\ \displaystyle\int_{-\infty}^0 \frac{dp}{2\pi}\overline{\mathfrak{h}}_-(p)R(-p)\mathfrak{g}_-(-p), \end{cases} \tag{4.37} $$

$$ {}^{\text{out}}\langle \mathfrak{h}_\pm|\mathfrak{g}_\mp\rangle^{\text{in}} = \begin{cases} \displaystyle\int_0^\infty \frac{dp}{2\pi}\overline{\mathfrak{h}}_+(p)T(p)\mathfrak{g}_-(p), \\ \displaystyle\int_{-\infty}^0 \frac{dp}{2\pi}\overline{\mathfrak{h}}_-(p)T(-p)\mathfrak{g}_+(p). \end{cases} \tag{4.38} $$

One clearly sees the particle-impurity interaction through the reflection coefficient R for a final and an initial state on the same half-line and through the transmission coefficient T otherwise, as expected. The particle–particle interaction through the bulk interaction coefficient S shows up in the 2^4 different two-particle amplitudes. As an illustration, we compute four such amplitudes gathered into two generic expressions:

$$
{}^{\text{out}}\langle \mathfrak{h}_{1,\pm};\mathfrak{h}_{2,\pm}|\mathfrak{g}_{1,\pm};\mathfrak{g}_{2,\pm}\rangle^{\text{in}} = \int_{\mathbb{R}^\pm}\frac{dp_1}{2\pi}\int_{\mathbb{R}^\pm}\frac{dp_2}{2\pi}(\overline{\mathfrak{h}}_{1,\pm}(p_1)\overline{\mathfrak{h}}_{2,\pm}(p_2)R(\pm p_2)S(\pm p_1 \pm p_2)R(\pm p_1)\mathfrak{g}_{1,\pm}(-p_2)
$$

$$
\times\mathfrak{g}_{2,\pm}(-p_1) + \overline{\mathfrak{h}}_{1,\pm}(p_1)\overline{\mathfrak{h}}_{2,\pm}(p_2)R(\pm p_1)S(\pm p_1 \pm p_2)S(\pm p_1 \mp p_2)R(\pm p_2)
$$

$$
\times\mathfrak{g}_{1,\pm}(-p_1)\mathfrak{g}_{2,\pm}(-p_2)) \tag{4.39}
$$

and

$$
{}^{\text{out}}\langle \mathfrak{h}_{1,\pm};\mathfrak{h}_{2,\pm}|\mathfrak{g}_{1,\pm};\mathfrak{g}_{2,\mp}\rangle^{\text{in}} = \int_{\mathbb{R}^\pm}\frac{dp_1}{2\pi}\int_{\mathbb{R}^\pm}\frac{dp_2}{2\pi}(\overline{\mathfrak{h}}_{1,\pm}(p_1)\overline{\mathfrak{h}}_{2,\pm}(p_2)R(\pm p_2)S(\pm p_1 \pm p_2)T(\pm p_1)
$$

$$
\times\mathfrak{g}_{1,\pm}(-p_2)\mathfrak{g}_{2,\mp}(p_1) + \overline{\mathfrak{h}}_{1,\pm}(p_1)\overline{\mathfrak{h}}_{2,\pm}(p_2)R(\pm p_1)
$$

$$
\times S(\pm p_1 \pm p_2)S(\pm p_1 \mp p_2)T(\pm p_2)\mathfrak{g}_{1,\pm}(-p_1)\mathfrak{g}_{2,\mp}(p_2)). \tag{4.40}
$$

More complex transition amplitudes contain the same building blocks namely R, T, and S, which shows that the corresponding processes involve a succession of particle-impurity and particle–particle interactions as expected from the factorized scattering occurring in this integrable model.

V. DISCUSSION AND CONCLUSIONS

We have analyzed above the NLS model interacting with a δ-type impurity, establising the exact classical and quantum solutions. We have shown that an appropriate RT algebra and its Fock representation allow to construct not only the scattering operator, but also the off-shell quantum field $\Phi(t,x)$. As already mentioned in the introduction, these results can be extended[33] to a whole class of point-like defects, substituting (3.72) and (3.73) by the impurity boundary conditions

$$
\lim_{x\downarrow 0}\begin{pmatrix} \langle\varphi,\Phi(t,x)\psi\rangle \\ \partial_x\langle\varphi,\Phi(t,x)\psi\rangle \end{pmatrix} = \alpha\begin{pmatrix} a & b \\ c & d \end{pmatrix}\lim_{x\uparrow 0}\begin{pmatrix} \langle\varphi,\Phi(t,x)\psi\rangle \\ \partial_x\langle\varphi,\Phi(t,x)\psi\rangle \end{pmatrix}, \tag{5.1}
$$

where

$$
\{a,\ldots,d\in\mathbb{R},\ \alpha\in\mathbb{C}: ad-bc=1,\ \overline{\alpha}\alpha=1,\}. \tag{5.2}
$$

In absence of impurity bound states, namely in the domain

$$
a+d+\sqrt{(a-d)^2+4}\leqslant 0, \quad b<0,
$$

$$
c(a+d)^{-1}\geqslant 0, \quad b=0, \tag{5.3}
$$

$$
a+d-\sqrt{(a-d)^2+4}\geqslant 0, \quad b>0,
$$

one can treat the model closely following the δ-impurity case, because the corresponding reflection and transmission matrices $\mathcal{R}$ and $\mathcal{T}$ have the same analytic properties as (3.18).

We would like to comment finally on the symmetry content of the solution derived in the paper. It is quite obvious that impurities break down Galilean (Lorentz) invariance of the *total* scattering matrix **S**. However, since the *bulk* scattering matrix $\mathcal{S}$ describes the scattering away from the impurity, some authors[1–5] have assumed that $\mathcal{S}$ preserves these symmetries and that the breaking in **S** is generated exclusively by the reflection and transmission coefficients $\mathcal{R}$ and $\mathcal{T}$. This assumption however, combined with the conditions of factorized scattering, implies[1,5] that $\mathcal{S}$ is constant, which is too restrictive. In fact, one is left with a few systems of limited physical interest. In order to avoid this negative result, a consistent factorized scattering theory was developed in Refs. 6 and 7, which does not necessarily assume that $\mathcal{S}$ is Galilean (Lorentz) invariant. Since the impurity NLS model considered above is the first concrete application of this framework with nontrivial bulk scattering, the lesson from it is quite instructive. Focusing on $\mathcal{S}$ (3.2), we see

that Galilean invariance is broken by the entries which describe the scattering of two incoming particles localized for $t\to-\infty$ on the different half-lines $\mathbb{R}_-$ and $\mathbb{R}_+$ respectively. Indeed, these entries depend on k_1+k_2 and not on k_1-k_2. An intuitive explanation for this breaking is that before such particles scatter, one of them must necessarily cross the impurity. The nontrivial transmission is therefore the origin of the symmetry breaking in $\mathcal{S}$. This conclusion agrees with the observation that in systems which allow only reflection (e.g., models on the half-line), one can have[14–19] both Galilean (Lorentz) invariant and nonconstant bulk scattering matrices.

The issue of internal symmetries in the presence of impurities has been partially addressed in Refs. 8 and 11. In particular, the role of the reflection and transmission elements of the RT algebra as symmetry generators has been established. However, this question deserves further investigation. It will be interesting in this respect to extend the analysis[38] of the SU(N)–NLS model on the half-line to the impurity case. Work is in progress on this aspect.

Let us conclude by observing that the concept of RT algebra indeed represents a powerful tool for solving the NLS model with impurities. We are currently exploring the possibility to apply this algebraic framework also to the quantization of other integrable systems with defects.

APPENDIX A: PROOF OF THEOREM 2.2

First, notice that (2.12) and (2.13) translate into

$$\lim_{x\to0^+}\{\Phi_+(t,x)-\Phi_-(t,-x)\}=0, \tag{A1}$$

$$\lim_{x\to0^+}\{(\partial_x\Phi_+)(t,x)-(\partial_x\Phi_-)(t,-x)\}-2\eta\Phi(t,0)=0, \tag{A2}$$

which we are going to check order by order in the Rosales expansion. The idea is to introduce the one-to-one correspondence

$$\beta_\pm(p)=\tfrac{1}{2}\{\lambda_+(p)\pm\lambda_-(-p)\},\quad p\in\mathbb{R} \tag{A3}$$

and it is not difficult to check that

$$\beta_\alpha(p)=B_\alpha(p)\beta_\alpha(-p),\quad \text{with } B_\alpha(p)=\alpha\frac{p-i\alpha\eta}{p+i\eta},\quad \alpha=\pm. \tag{A4}$$

Take $n=0$ corresponding to the linear problem. One gets

$$\lim_{x\to0^+}\{\Phi_+^{(0)}(t,x)-\Phi_-^{(0)}(t,-x)\}=\int_{\mathbb{R}}\frac{dp}{2\pi}\beta_-(p)e^{-ip^2t},$$

$$\lim_{x\to0^+}\{(\partial_x\Phi_+^{(0)})(t,x)-(\partial_x\Phi_-^{(0)})(t,-x)\}-2\eta\Phi^{(0)}(t,0)=\int_{\mathbb{R}}\frac{dp}{2\pi}(ip-\eta)\beta_+(p)e^{-ip^2t},$$

which vanish using the properties (A4). It is interesting to note that the time-dependent phase e^{-ip^2t}, being even in p, does not play any role in the vanishing of the previous expressions. It will be the same in the following as we shall see.

For $n\geqslant1$, we start by changing variables in the Rosales expansion according to $(p_1,\ldots,p_n,q_n,\ldots,q_0)\to(k_1,\ldots,k_{2n-1},-k_{2n}\ldots,-k_0)$ and we use the one-to-one correspondence (A3) to rewrite the left-hand side of (A1) as

$$\lim_{x\to 0^+}\{\Phi_+^{(n)}(0,x)-\Phi_-^{(n)}(0,-x)\}=\sum_{\alpha_0,\ldots,\alpha_{2n}=\pm}\left(1-\prod_{i=0}^{2n}\alpha_i\right)\int_{\mathbb{R}^{2n+1}}\prod_{i=0}^{2n}\frac{dk_i}{2\pi}\overline{\beta}_{\alpha_1}(k_1)\cdots\overline{\beta}_{\alpha_{2n-1}}(k_{2n-1})$$
$$\times\beta_{\alpha_{2n}}(-k_{2n})\cdots\beta_{\alpha_0}(-k_0)\frac{e^{-i\Sigma_{j=0}^{2n}k_j^2t}}{\prod_{j=1}^{2n}(k_j+k_{j-1})}. \tag{A5}$$

In view of the linear case, we "B_α-symmetrize" the integrand of the previous integral for each k_i. Introducing

$$B_\alpha^\sigma(p)=\begin{cases}1 & \text{for } \sigma=+,\\ B_\alpha(p) & \text{for } \sigma=-,\end{cases} \tag{A6}$$

this reads

$$\frac{1}{2^{2n+1}}\sum_{\sigma_0,\ldots,\sigma_{2n}=\pm}\frac{B_{\alpha_1}^{\sigma_1}(k_1)\cdots B_{\alpha_{2n-1}}^{\sigma_{2n-1}}(k_{2n-1})B_{\alpha_{2n}}^{\sigma_{2n}}(-k_{2n})\cdots B_{\alpha_0}^{\sigma_0}(-k_0)}{\prod_{j=1}^{2n}(\sigma_jk_j+\sigma_{j-1}k_{j-1})}\overline{\beta}_{\alpha_1}(k_1)\cdots\overline{\beta}_{\alpha_{2n-1}}(k_{2n-1})$$
$$\times\beta_{\alpha_{2n}}(-k_{2n})\cdots\beta_{\alpha_0}(-k_0)e^{-i\Sigma_{j=0}^{2n}k_j^2t}$$

which we rewrite as

$$\frac{1}{2^{2n+1}}\sum_{\sigma_0,\ldots,\sigma_{2n}=\pm}B_{\alpha_1}^{\sigma_1}(k_1)\cdots B_{\alpha_{2n-1}}^{\sigma_{2n-1}}(k_{2n-1})B_{\alpha_{2n}}^{\sigma_{2n}}(-k_{2n})\cdots B_{\alpha_0}^{\sigma_0}(-k_0)\prod_{j=1}^{2n}(\sigma_{j-1}k_{j-1}-\sigma_jk_j)$$
$$\times\frac{\overline{\beta}_{\alpha_1}(k_1)\cdots\overline{\beta}_{\alpha_{2n-1}}(k_{2n-1})\beta_{\alpha_{2n}}(-k_{2n})\cdots\beta_{\alpha_0}(-k_0)}{\prod_{j=1}^{2n}(k_{j-1}^{2n}-k_j^2)}e^{-i\Sigma_{j=0}^{2n}k_j^2t}.$$

Let us concentrate on the part depending on the σ's. Developing explicitly the sum over σ_{2n}, one gets

$$\frac{1}{2^{2n+1}}\sum_{\sigma_0,\ldots,\sigma_{2n-1}=\pm}B_{\alpha_1}^{\sigma_1}(k_1)\cdots B_{\alpha_{2n-1}}^{\sigma_{2n-1}}(k_{2n-1})B_{\alpha_{2n-2}}^{\sigma_{2n-2}}(-k_{2n-2})\cdots B_{\alpha_0}^{\sigma_0}(-k_0)\prod_{j=1}^{2n-1}(\sigma_{j-1}k_{j-1}-\sigma_jk_j)$$
$$\times\left(\delta_{\alpha_{2n},+}\frac{2k_{2n}}{k_{2n}+i\eta}-\delta_{\alpha_{2n},-}2k_{2n}\right)$$

Collecting all the pieces depending on k_{2n}, one gets a function proportional to

$$\frac{k_{2n}}{k_{2n-2}^2-k_{2n}^2}\left(\frac{\beta_+(-k_{2n})}{k_{2n}+i\eta}-\beta_-(-k_{2n})\right). \tag{A7}$$

Now taking μ_+,μ_- as in (2.20) it is not hard to see that the function in parentheses in (A7) is identically zero, implying the vanishing of (A5).

The case of the jump condition is treated in complete analogy. Indeed, in evaluating the term proportional to η in (A2) in terms of $\beta_\pm$, all one must do is to replace $(1-\Pi_{i=0}^{2n}\alpha_i)$ in (A5) by $(1+\Pi_{i=0}^{2n}\alpha_i)$. The rest of the argument implies therefore that

$$\Phi^{(n)}(0,0)=0, \quad n\geqslant 1. \tag{A8}$$

As for the term involving derivatives of the field, an analogous treatment produces the following integrand:

$$\frac{1}{2^{2n+1}}\sum_{\sigma_0,\ldots,\sigma_{2n}=\pm} B^{\sigma_1}_{\alpha_1}(k_1)\cdots B^{\sigma_{2n-1}}_{\alpha_{2n-1}}(k_{2n-1})B^{\sigma_{2n}}_{\alpha_{2n}}(-k_{2n})\cdots B^{\sigma_0}_{\alpha_0}(-k_0)\prod_{j=1}^{2n}(\sigma_{j-1}k_{j-1}-\sigma_j k_j)$$
$$\times\left(\sum_{j=0}^{2n} i\sigma_j k_j\right)\frac{\overline{\beta}_{\alpha_1}(k_1)\cdots\overline{\beta}_{\alpha_{2n-1}}(k_{2n-1})\beta_{\alpha_{2n}}(-k_{2n})\cdots\beta_{\alpha_0}(-k_0)}{\prod_{j=1}^{2n}(k_{j-1}^2-k_j^2)}e^{-i\Sigma_{j=0}^{2n}k_j^2 t}.$$

This time, one must develop the sum for σ_{2n} and σ_{2n-1}. This produces the function (A7) but in the variable k_{2n-1} and we know it vanishes. This leads to

$$\lim_{x\to 0^+}\{(\partial_x\Phi_+^{(n)})(0,x)-(\partial_x\Phi_-^{(n)})(0,-x)\}=0, \quad n\geqslant 1. \tag{A9}$$

As already mentioned, we see that the continuity and the jump condition of the field hold for any time t. Put another way, they are conserved in time and this is due to the dispersion relation of the free Schrödinger equation (being quadratic in k_j, it is not affected by all the symmetrizations $k_j\to -k_j$ involved in the proof).

It is remarkable that the jump condition actually decouples for the nonlinear terms ($n\geqslant 1$) as seen from (A8) and (A9). This is also true for the continuity which, combined with (A8) shows that

$$\Phi_-^{(n)}(0,0)=\Phi_+^{(n)}(0,0)=0, \quad n\geqslant 1.$$

■

APPENDIX B: EXPLICIT FORM OF THE ACTION OF THE CREATION OPERATOR

The projector $P^{(n)}$ is constructed in Ref. 7 in terms of the generators of the Weyl group associated to the root system of the classical Lie algebra B_n and of their representation on $\mathcal{L}^{\otimes n}$. In our context, we get for $f\in\mathcal{C}$ and $\varphi^{(n-1)}\in\mathcal{H}^{(n-1)}$,

$$[a^\dagger(f)\varphi]^{(n)}_{\alpha_1\cdots\alpha_n}(p_1,\ldots,p_n)=\frac{1}{2\sqrt{n}}\sum_{k=1}^{n}S(\alpha_{k-1}p_{k-1}-\alpha_k p_k)\cdots S(\alpha_1 p_1-\alpha_k p_k)(f_{\alpha_k}(p_k)$$
$$+C_k(\alpha_1 p_1,\ldots,\alpha_n p_n)[T(\alpha_k p_k)f_{-\alpha_k}(p_k)+R(\alpha_k p_k)f_{\alpha_k}(-p_k)])$$
$$\times\varphi^{(n-1)}_{\alpha_1\cdots\hat{\alpha_k}\cdots\alpha_n}(p_1,\ldots,p_n), \tag{B1}$$

where we have defined

$$C_k(p_1,\ldots,p_n)=S(p_k-p_1)\cdots S(\widehat{p_k-p_k})\cdots S(p_k-p_n)S(p_n+p_k)\cdots S(\widehat{p_k+p_k})\cdots S(p_1+p_k).$$

All the hatted symbols must be omitted.

One recognizes the reflected and transmitted structure inside the square brackets of (B1) which, combined with all the S matrices, ensures the properties (3.21) and (3.22) required for the functions of $\mathcal{H}^{(n)}$.

We construct the local and nonlocal conserved densities for the Camassa–Holm equation by solving a suitable Riccati equation. We also define a Kadomtsev–Petviashvili extension for the local Camassa–Holm hierarchy. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1888568]

I. INTRODUCTION

Since its introduction in Ref. 1 as a model for shallow water waves, the Camassa–Holm equation

$$u_t - u_{xxt} = 6u_x u - 4u_{xx}u - 2uu_{xxx} \tag{1}$$

has been the subject of a great number of papers. In particular, some of them (Refs. 4,7, and 9, just to cite a few) have been devoted to investigate its bi-Hamiltonian structure and its relation with other nonlinear partial differential equations living on the same phase space, namely the Korteweg–de Vries (KdV) equation, the Hunter–Saxton equation,[3] and the Harry–Dym (HD) equation.[5] It is well known how to use the bi-Hamiltonian structure of the KdV equation to construct the whole corresponding hierarchy (see, e.g., Ref. 8). This structure has been used in Ref. 2 to relate in a geometrical way the KdV hierarchy with the celebrated Kadomtsev–Petviashvili (KP) hierarchy. [In this paper by "KP hierarchy" we mean the Sato form, in terms of pseudodifferential operators, of the KP hierarchy. This is a hierarchy of $(1+1)$ evolution equations for infinitely many fields.] The same results have been found in Ref. 11 for the HD equation, recovering in this way the KP extension of the Harry–Dym hierarchy presented in Ref. 10.

The aim of this paper is to develop an analogous theory for the CH equation as well. More precisely, we show how the bi-Hamiltonian approach to the CH allows us to write a Riccati equation whose solutions give rise to the conserved densities of the CH equation. As it is well known, there are two hierarchies of such conserved quantities. The first one contains the Camassa–Holm equation, and its Hamiltonian densities are nonlocal, while the other one is formed by local densities. (To the best of our knowledge, and according to Ref. 6, there is no sound proof of the existence of an infinite number of members of the nonlocal hierarchy. In this paper we give such a proof.) Moreover we show that the local CH hierarchy can be embedded in a wider hierarchy in an infinite number of fields, exactly like the KdV equation can be included in the KP hierarchy.

The paper is organized as follows. In the next section we use the bi-Hamiltonian method to find a Riccati equation that allows us to construct the two above-mentioned hierarchies of con-

served quantities. In the third and last section we show—using the technique of the Faà di Bruno polynomials—how the local CH hierarchy can be framed in a more general hierarchy which plays the same role that the KP hierarchy does in the KdV case.

II. THE CONSERVED DENSITIES

It is well known that the CH equation (1) is a bi-Hamiltonian system on the infinite dimensional space $C^\infty(S^1,\mathbb{R})$ of C^∞ functions from the circle to the real line, with respect to the Poisson tensors,

$$P_0 = \tfrac{1}{2}\partial_x - \tfrac{1}{2}\partial_x^3, \quad P_1 = -(m\partial_x + \partial_x m),$$

where m is defined by $m=(1-\partial_x^2)u$. In this section we construct the positive and negative CH hierarchies using the so-called method of the Casimir of the Poisson pencil. This means that we look for Casimirs of the Poisson pencil $P_\lambda = P_0 - \lambda P_1$, i.e., for functionals $H(\lambda)$ whose differentials $v(\lambda)$ belong to the kernel of P_λ. The coefficients of the Laurent expansion of any such Casimir $H(\lambda)=\Sigma_{k=-\infty}^{+\infty} H_k \lambda^{-k}$ provide indeed a set of functionals satisfying the Lenard–Magri recursion relation

$$P_0\, \mathrm{d}H_k = P_1\, \mathrm{d}H_{k+1}$$

and thus in involution with respect to both Poisson structures (see, e.g., Ref. 8).

The key point to determine $v(\lambda)$ is to notice that

$$vP_\lambda v = v\left(\tfrac{1}{2}v_x - \tfrac{1}{2}v_{xxx} + 2\lambda m v_x + \lambda m_x v\right) = \left(\tfrac{1}{4}v^2 - \tfrac{1}{2}v_{xx}v + \tfrac{1}{4}v_x^2 + \lambda m v^2\right)_x. \tag{2}$$

This result is a direct consequence of the fact that $\int vP_\lambda v$ is the antisymmetric action of the 2-tensor P_λ on the pair (v,v). The condition $P_\lambda v(\lambda)=0$ is thus equivalent to

$$\tfrac{1}{4}v^2 - \tfrac{1}{2}v_{xx}v + \tfrac{1}{4}v_x^2 + \lambda m v^2 = f(m,\lambda), \tag{3}$$

where $f(m,\lambda)$ satisfies $f_x=0$. It turns out that v is an exact 1-form if f does not depend on m. Without loss of generality, we can set $f(\lambda)=\lambda/4$. Then Eq. (3) can be set in the useful Riccati form

$$h_x + h^2 = \tfrac{1}{4} + z^2 m \tag{4}$$

through the transformation

$$-v_x + 2vh = z, \tag{5}$$

where $z^2=\lambda$. Let us verify that $v(\lambda)$ is an exact 1-form:

$$\langle v, \dot{m}\rangle \overset{(4)}{=} \int_{S^1} v z^{-2}(\dot{h}_x + 2h\dot{h})\mathrm{d}x \overset{(5)}{=} \frac{1}{z^2}\int_{S^1}(-v_x + 2vh)\dot{h}\,\mathrm{d}x = \frac{1}{z}\frac{\mathrm{d}}{\mathrm{d}t}\int_{S^1} h\,\mathrm{d}x, \tag{6}$$

so that the potential of $v(\lambda)$ is given by $H=z^{-1}\int_{S^1} h\,\mathrm{d}x$. In the next two sections we will solve the Riccati equation (4) using a formal development for the function h. We will find a first solution of the form $h(z)=\Sigma_{i=-1}^{\infty} h_i z^{-i}$, where the h_i are functions of m and its x derivatives. This solution gives rise to the local (often called also negative) CH hierarchy, starting from a Casimir of P_1. The second solution has the form $k(z)=\Sigma_{i=0}^{\infty} k_i z^{-i}$, where the k_i are now nonlocal densities. They constitutes the usual (nonlocal, positive) CH hierarchy, which the CH equation belongs to. In other words, we will deal with two possible different choices of the essential singularity of the solutions of the Riccati equation (4).

A. The local CH hierarchy

In this case the Laurent expansion of the density of Hamiltonians is

$$h(z) = h_{-1}z + h_0 + \frac{h_1}{z} + \frac{h_2}{z^2} + \cdots = h_{-1}z + h_0 + \sum_{i=1}^{\infty} \frac{h_i}{z^i}, \tag{7}$$

where the maximum degree of the positive term is established by (4).

If we substitute this expansion in (4) we get

$$\sum_{i=-2}^{\infty} \left(\left(h_{i_x} + \sum_{j=-1}^{i+1} h_{i-j}h_j \right) \frac{1}{z^i} \right) = \frac{1}{4} + z^2 m. \tag{8}$$

Then the obtained system can be solved in a purely algebraic way by equating the terms with the same degree in z,

$$z^2, \quad h_{-1}^2 = m, \quad h_{-1} = \sqrt{m},$$

$$z^1, \quad h_{-1x} + 2h_0h_{-1} = 0, \quad h_0 = (\ln(m^{-1/4}))_x,$$

$$z^0, \quad h_{0x} + h_0^2 + 2h_1h_{-1} = \tfrac{1}{4}, \quad h_1 = \frac{1}{8\sqrt{m}} - \frac{1}{8}\frac{m_{xx}}{\sqrt{m^3}} + \frac{5}{32}\frac{m_x^2}{\sqrt{m^5}},$$

$$z^{-1}, \quad h_{1x} + 2h_0h_1 + 2h_2h_{-1} = 0, \quad h_2 = \left(-\frac{1}{16m} + \frac{1}{16}\frac{m_{xx}}{m^2} + \frac{5}{64}\frac{m_x^2}{m^3} \right)_x,$$

and so on. It can be shown that the even densities are x derivatives, so that $H = z^{-1}\int_{S^1} h\, \mathrm{d}x$ is actually a Laurent series in λ:

$$H(\lambda) = \sum_{i=0}^{+\infty} H_{2i}\lambda^{-i}.$$

If j is even, we call X_j the Hamiltonian vector field associated with $H_j = \int_{S^1} h_{j-1}\, \mathrm{d}x$ by means of the Poisson operator P_0. By construction, X_j is the Hamiltonian vector field associated with H_{j+2} by means of P_1. The first nontrivial equation of the hierarchy, corresponding to X_0, is

$$\frac{\partial m}{\partial t_0} = P_0\, \mathrm{d}H_0 = (\partial_x - \partial_x^3)\frac{1}{4\sqrt{m}} = -\frac{1}{8}\frac{m_x}{\sqrt{m^3}} - \frac{1}{8}\frac{m_{xxx}}{\sqrt{m^3}} + \frac{9}{16}\frac{m_{xx}m_x}{\sqrt{m^5}} - \frac{15}{32}\frac{m_x^3}{\sqrt{m^7}} = P_1\, \mathrm{d}H_2. \tag{9}$$

B. The nonlocal CH hierarchy

In this case the Laurent expansion of the solution $k(z)$ of the Riccati equations (4) is

$$k(z) = k_0 + k_{-1}z + k_{-2}z^2 + k_{-3}z^3 + \cdots = \sum_{i=0}^{+\infty} k_{-i}z^i. \tag{10}$$

Substituting it in (4), we obtain

$$\sum_{i=0}^{\infty} \left(\left(k_{-i_x} + \sum_{j=0}^{i} k_{-j}k_{j-1} \right) z^i \right) = \frac{1}{4} + z^2 m. \tag{11}$$

Exactly as before, we can find a recursive solution of (11) comparing the terms of the same degree on both sides of the equation. However, in the present case this requires to solve at any step a differential equation. This fact is responsible for the presence of nonlocal quantities. The first equation to be considered is that related to the coefficient of z^0,

$$k_{0x} + k_0^2 = \tfrac{1}{4}.$$

It is easily checked that the only periodic solutions of this equation are the constant solutions $k_0 = \pm\frac{1}{2}$. Let us choose the positive constant solution. Next, the coefficient of z^1 gives

$$k_{-1x} + 2k_0 k_{-1} = 0$$

or, using $k_0 = \frac{1}{2}$,

$$(1 + \partial_x)k_{-1} = 0.$$

This linear equation is solved by $k_{-1} = c\exp(-x)$, where c is a constant. But again among them the only solution which lies in $C^\infty(S^1, \mathbb{R})$ is the trivial one, $k_{-1} = 0$. More generally, the operator $1 + \partial_x$ is invertible in $C^\infty(S^1, \mathbb{R})$. The unique solution of

$$(1 + \partial_x)k = f(x)$$

of period 1 is indeed explicitly given by

$$k(x) = \int_0^x e^{y-x} f(y)\mathrm{d}y + \frac{1}{e-1}\int_0^1 e^{y-x} f(y)\mathrm{d}y.$$

From $k_{-1} = 0$ one can immediately show that $k_{-2n-1} = 0$ for all $n \geqslant 0$. In fact, k_{-2n-1} appears for the first time in the coefficient of z^{n+1},

$$k_{-2n-1_x} + k_{-2n-1} + 2\sum_{i=1}^{n} k_{-2i}k_{-2(n-i)-1} = 0,$$

and this allows us to prove by recursion that all the odd terms in the Laurent series $k(z)$ are zero. Using the remaining equations,

$$z^2, \quad k_{-2x} + 2k_0 k_{-2} + k_{-1}^2 = m,$$

$$z^4, \quad k_{-4x} + 2k_0 k_{-4} + 2k_{-1}k_{-3} + k_{-2}^2 = 0,$$

$$z^6, \quad k_{-6x} + 2k_0 k_{-6} + 2k_{-1}k_{-5} + k_{-3}^2 + 2k_{-2}k_{-4} = 0,$$

$$\cdots, \quad \cdots,$$

it is now simple to find the even terms,

$$k_{-2} = (1 + \partial_x)^{-1} m,$$

$$k_{-4} = -(1 + \partial_x)^{-1}((1 + \partial_x)^{-1} m)^2,$$

$$k_{-6} = 2(1 + \partial_x)^{-1}((1 + \partial_x)^{-1} \cdot ((1 + \partial_x)^{-1} m)^2 (1 + \partial_x)^{-1} m)$$

$$\cdots = \cdots.$$

Thanks to the invertibility of the operator $1 + \partial_x$ in the space of C^∞ periodic functions, we can conclude that there is an infinite sequence of (increasingly nonlocal) densities k_{-2i}, giving rise to a set of functionals in involution with respect to both Poisson brackets. More precisely, let $K(\lambda) = \int_{S^1} k\, ax$ be the Casimir of the Poisson pencil constructed with k. Then $K(\lambda) = \frac{1}{4} + \sum_{j=1}^{\infty} K_{-2j}\lambda^j$, with $K_{-2j} = \int_{S^1} k_{-2j}\, \mathrm{d}x$. We call X_j the Hamiltonian vector field associated with K_j by means of the

Poisson operator P_1. By construction, X_j is the Hamiltonian vector field associated with K_{j-2} by means of P_0.

Since $k_{-2x}+k_{-2}=m$, we have that $K_{-2}=\int_{S^1}k_{-2}\,dx=\int_{S^1}m\,dx$, so that the first equation of the hierarchy is $m_{t_{-2}}=P_1\,dK_{-2}=-m_x$. In order to write the second vector field, we recall that $k_{-4x}+k_{-4}+k_{-2}^2=0$ and therefore

$$K_{-4}=\int_{S^1}k_{-4}\,dx=-\int_{S^1}k_{-2}^2\,dx=-\int_{S^1}((1+\partial_x)^{-1}m)^2\,dx.$$

This functional becomes local after the usual change of variables $m=u-u_{xx}$, that is invertible in the space of C^∞ periodic functions because it is the composition of $1+\partial_x$ and $1-\partial_x$. Its inverse is explicitly given by

$$u(x)=\int_0^x m(y)\sinh(y-x)dy+\frac{1}{2\sinh\frac{1}{2}}\int_0^1 m(y)\cosh\left(y-x-\frac{1}{2}\right)dy.$$

In terms of u we have that $K_{-4}=-\int_{S^1}(u^2+u_x^2)dx$, so that

$$\frac{\partial m}{\partial t_{-4}}=P_1\,dK_{-4}=-(m\partial_x+\partial_x m)(1-\partial_x^2)^{-1}(-2u+2u_{xx})=4mu_x+2m_xu, \tag{12}$$

that is, with $t_{-4}=t$,

$$u_t-u_{xxt}=6u_xu-4u_{xx}u_x-2uu_{xxx}, \tag{13}$$

which is the standard Camassa–Holm equation with null critical velocity term. The next symmetry of the hierarchy is related to the Hamiltonian $K_{-6}=\int_{S^1}k_{-6}=2\int_{S^1}(u^3+uu_x^2)dx$, which, using (5) to compute dK_{-6}, gives

$$\frac{\partial m}{\partial t_{-6}}=P_1\,dK_{-6}=-(m\partial_x+\partial_x m)(1-\partial_x^2)^{-1}(6u^2-2u_x^2-4uu_{xx}).$$

We remark that, due to the Lenard–Magri recursion relations, the equation (13) can be obtained also as $\partial m/\partial t_{-4}=P_0\,dK_{-6}$.

III. KP EXTENSION OF THE LOCAL CH HIERARCHY

In Ref. 2 it has been shown how to generate, from a bi-Hamiltonian viewpoint, the KP hierarchy starting from the KdV hierarchy. The same procedure has been performed in Ref. 11, where the KP extension of the Harry–Dym hierarchy (already found in Ref. 10) has been recovered. The idea is quite simple and can be successfully applied to the local CH hierarchy, as we do in this section.

In Sec. II A we have found a map $m\mapsto h(m)$, where $h(m)$ is the unique solution of the Riccati equation (4) with the asymptotic expansion (7). Since the coefficients of $h(m)$ are the densities of the Hamiltonians of the hierarchy, the time derivatives of $h(m)$ must be an x derivative, that is,

$$\frac{\partial h}{\partial t_s}=\partial_x H^{(s)},\quad s=0,2,\ldots,$$

for suitable currents $H^{(s)}$. They can be explicitly constructed after noticing that the vector fields of the hierarchy are not only bi-Hamiltonian, but they are Hamiltonian with respect to every Poisson structure of the pencil. Indeed, one can immediately see that

$$\frac{\partial h}{\partial t_{2s}} = P_\lambda(\lambda^s \, \mathrm{d}H(\lambda))_{\mathrm{reg}} = P_\lambda\left(\sum_{r=0}^{s} \mathrm{d}H_{2r}\lambda^{s-r}\right), \tag{14}$$

where "reg" stands for the regular part in the Laurent expansion. Moreover, using (4) the Poisson pencil P_λ can be factorized in the following way:

$$P_\lambda = -\tfrac{1}{2}(\partial_x + 2h)\partial_x(\partial_x - 2h).$$

Substituting it in the derivative with respect to t_{2s} of (4), we obtain

$$\lambda^{-1}(\partial_x + 2h)h_{t_{2s}} = -\tfrac{1}{2}(\partial_x + 2h)\partial_x(\partial_x - 2h)(\lambda^s \, \mathrm{d}H(\lambda))_{\mathrm{reg}}.$$

From the previous equation, due to the particular form of the z development of h, it follows that the continuity equation

$$\frac{\partial h}{\partial t_{2s}} = \partial_x\left(-\frac{\lambda}{2}(\partial_x - 2h)(\lambda^s \, \mathrm{d}H(\lambda))_{\mathrm{reg}}\right) \tag{15}$$

holds true. Therefore, the currents $H^{(2s)}$ we are looking for are given by

$$H^{(2s)} = -\frac{\lambda}{2}(\partial_x - 2h)(\lambda^s \, \mathrm{d}H(\lambda))_{\mathrm{reg}} = -\frac{\lambda}{2}(\lambda^s v(\lambda)_x)_{\mathrm{reg}} + h\lambda(\lambda^s v(\lambda))_{\mathrm{reg}}. \tag{16}$$

The next step is to realize that the currents $H^{(s)}$, where s is even, can be obtained directly from a Laurent series h of the form (7), without using the Riccati equation (4). We start with the preliminary consideration that they can be written in two equivalent ways,

$$H^{(s)} = \sum_{i=0}^{s}\left(-\frac{1}{2}v_{i,x}(z^{s-i+2}) + v_i(z^{s-i+2}h)\right) \tag{17}$$

and

$$\begin{aligned} H^{(s)} &= -\frac{1}{2}(\partial_x - 2h)(z^{s+2} \, \mathrm{d}H(z) - z^2(z^s \, \mathrm{d}H(z))_{\mathrm{sing}}) = \frac{1}{2}z^{s+2}(-v_x + 2hv) - \frac{z^2}{2}(\partial_x - 2h)(z^s v)_{\mathrm{sing}} \\ &\overset{(5)}{=} \frac{1}{2}z^{s+3} - \frac{z^2}{2}(\partial_x - 2h)(z^s v)_{\mathrm{sing}}, \end{aligned} \tag{18}$$

where with "sing" we mean the singular part of the expansion in z. Equation (18), using (4), gives the regular asymptotic behavior of the currents, that is, $(H^{(s)})_{\mathrm{reg}} = \frac{1}{2}z^{s+3} + O(z)$. On the other hand, Eq. (17) implies that the currents belong to a particular vector space H_h, which can be constructed using only the Hamiltonian density h. It is defined as the linear span over the functions $C^\infty(S^1, \mathbb{R})$ of the Faà di Bruno polynomials $h^{(n)} = (\partial_x + h)^n z^2$, with $n \geqslant 0$, $h^{(0)} = z^2$.

Proposition 3.1: The currents $H^{(2s)}$, with $s \geqslant 0$, are elements of H_h.

Proof: Thanks to the representation (17), it suffices to show that z^{2i} and $z^{2i}h$ are elements of H_h for all $i \geqslant 1$. First of all, $z^2 = h^{(0)} \in H_h$ and $z^2 h = h^{(1)} \in H_h$ by definition of H_h. Moreover, the Riccati equation multiplied by z^2,

$$z^2(h_x + h^2) = \frac{z^2}{4} + z^4 m, \tag{19}$$

shows that $z^4 = (1/m)\left(h^{(2)} - \frac{1}{4}h^{(0)}\right) \in H_h$. Now, acting with $(\partial_x + h)$ on both sides of (19), we can show that $z^4 h \in H_h$. More generally, acting with $(\partial_x + h)^n$, we prove that $z^2(H_h) \subset H_h$, and this concludes the proof. □

At this point it is not difficult to see that the current $H^{(s)}$ can be characterized in a unique way by the following properties:

(1) $H^{(s)}=\frac{1}{2}z^{s+3}+O(z)$,
(2) $H^{(s)}\in H_h$.

Therefore, we can assume that h is an arbitrary Laurent series of the form

$$h(z)=h_{-1}z+\sum_{i=0}^{+\infty}\frac{h_i}{z^i}, \tag{20}$$

where the coefficients h_i are not constrained by the Riccati equation, and we can define the currents $H^{(s)}$, for all $s\geqslant 0$, imposing the two above-mentioned properties. Then we define the s-th equation of the *local KP–CH hierarchy* as

$$\frac{\partial h}{\partial t_s}=\partial_x H^{(s)},\quad s\geqslant 0. \tag{21}$$

It is an evolution equation in an infinite number of fields given by the coefficients $h_{-1},h_0,h_1,\ldots$ of h.

In order to write these equations one must compute the first Faà di Bruno polynomials,

$$h^{(0)}=z^2,$$

$$h^{(1)}=h_{-1}z^3+h_0z^2+h_1z+\cdots,$$

$$h^{(2)}=(h_{-1}^2)z^4+(h_{-1x}+2h_{-1}h_0)z^3+(h_{0x}+h_0^2+2h_{-1}h_1)z^2+(h_{1x}+2h_{-1}h_2+2h_0h_1)z+\cdots,$$

$$h^{(3)}=\cdots.$$

Then the first currents are given by

$$H^{(0)}=\frac{1}{2h_{-1}}h^{(1)}-\frac{h_0}{2h_{-1}}h^{(0)}=\frac{1}{2}z^3+\frac{h_1}{2h_{-1}}z+\cdots,$$

$$\begin{aligned}H^{(1)}&=\frac{1}{2h_{-1}^2}h^{(2)}-\left(\frac{h_{-1x}}{2h_{-1}^3}+\frac{h_0}{h_{-1}^2}\right)h^{(1)}-\left(\frac{h_{0x}}{2h_{-1}^2}+\frac{h_0^2}{2h_{-1}^2}+\frac{h_1}{h_{-1}}-\frac{h_{-1x}h_0}{2h_{-1}^3}-\frac{h_{-1}h_0^2}{h_{-1}^3}\right)h^{(0)}\\&=\frac{1}{2}z^4+\left(\frac{h_{-1x}}{2h_{-1}^2}+\frac{h_2}{h_{-1}}+\frac{h_1h_0}{h_{-1}^2}-\frac{h_{-1x}h_1}{2h_{-1}^3}-\frac{h_0h_1}{h_{-1}^2}\right)z+\cdots,\end{aligned}$$

$$H^{(2)}=\cdots.$$

To recover the local CH hierarchy, one must impose on h the constraint given by the Riccati equation (4). It entails that all the fields h_i can be written in terms of m and its x derivatives. Thus the local KP–CH hierarchy (21) reduces to the local CH hierarchy. This reduction can be interpreted, like in the KdV and HD cases, as a stationary reduction. Indeed, the Riccati equation and the very definition of the currents imply that the current $H^{(1)}$ is equal to $z^4/2$ and therefore that t_1 is a stationary time. From Proposition 3.1 it also follows that all the odd times are stationary.

ACKNOWLEDGMENTS

The authors would like to thank Gregorio Falqui and Franco Magri for interesting and useful discussions on the bi-Hamiltonian properties of the Camassa–Holm hierarchy. (Received 15 March 2004; accepted 30 November 2004; published online 15 March 2005)

The theory of the separation of variables for the null Hamilton–Jacobi equation $\mathcal{H}=0$ is systematically revisited and based on Levi–Civita separability conditions with Lagrangian multipliers. The separation of the null equation is shown to be equivalent to the ordinary separation of the image of the original Hamiltonian under a generalized Jacobi–Maupertuis transformation. The general results are applied to the special but fundamental case of the orthogonal separation of a natural Hamiltonian with a fixed value of the energy. The separation is then related to conditions which extend those of Stäckel and Kalnins and Miller (for the null geodesic case) and it is characterized by the existence of conformal Killing two-tensors of special kind. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1862325]

I. INTRODUCTION

The aim of this paper is to propose a general approach to the theory of variable separation for the *null* Hamilton–Jacobi equation (HJE)

$$\mathcal{H}(\underline{q},\underline{p})=0, \quad \underline{q}=(q^i), \quad \underline{p}=(p_i), \quad p_i=\frac{\partial W}{\partial q^i}.$$

This approach is based on a suitable definition of separation (Sec. II), whose geometrical content (Sec. III) is related to special integrable Lagrangian distributions on the cotangent bundle T^*Q, of coordinates $(\underline{q},\underline{p})$. By the Hadamard lemma, the integrability conditions of these special distributions lead in Sec. IV to *Levi–Civita separability conditions with Lagrangian multipliers* (Theorem 4.1), which are a natural extension of the classical Levi–Civita conditions,[24] and from which we derive two characterizations of the separation of the null HJE. The first one (Theorem 4.2) asserts that the separation occurs in a given coordinate system if and only if the ordinary Levi–Civita equations are satisfied on the surface $\mathcal{H}=0$; the second one (Theorem 4.3) asserts that the separation occurs if and only if there exists a function $\Lambda(\underline{q},\underline{p})\neq 0$ such that the ordinary Levi–Civita equations are satisfied by the *conformal Hamiltonian* $\mathcal{H}/\Lambda$. The passage from a Hamiltonian $\mathcal{H}$ to a conformal Hamiltonian $\mathcal{H}/\Lambda$ is an extension of the so-called *Jacobi* (or *Maupertuis*) *transformation* for natural Hamiltonians,[9,16,23,28,31,33] recalled and discussed in Sec. VI.

We apply these general results to the analysis of particular cases of Hamiltonians. In Sec. V we consider the so-called *homogeneous formalism* in time-dependent mechanics and get a rigorous proof of a known property of the separation in the time-dependent HJE.[15] In Sec. VI we consider a natural Hamiltonian in orthogonal coordinates, $H=\frac{1}{2}g^{ii}p_i^2+V(\underline{q})$ and the corresponding HJE with a fixed value E of the energy,

$$\mathcal{H}(\underline{q},\underline{p}) \doteq \tfrac{1}{2}g^{ii}p_i^2+V(\underline{q})-E=0.$$

From a general theorem (Theorem 6.1) concerned with the separation of this equation, we derive three theorems (Theorems 6.3, 6.4, and 6.5) characterizing the separation for the following three special cases,

$$V=0, \quad E\neq 0, \quad \text{non-null geodesics},$$

$$V=0, \quad E=0, \quad \text{null geodesics},$$

$$V-E\neq 0, \quad \text{dynamical trajectories with total energy } E.$$

The case of null geodesics occurs, of course, for indefinite metric tensors. In Sec. VII we analyze the intrinsic framework of the theorems stated in Sec. VI, by considering special kinds of conformal Killing tensors and by introducing the notion of conformal involution. The first integrals and the separated equations are examined in Sec. VIII. In Sec. IX we consider the two-dimensional case. We renounce here to deal with the nonorthogonal separation for natural Hamiltonians, which is currently under investigation within the general framework presented in this paper. All this work is also made in the perspective of application to the theory of the ordinary multiplicative separation and of the *R*-separation for the second-order differential equations of mathematical physics (Laplace, Helmholtz, Poisson, Schrödinger equations).[20,22] As possible applications of the present theory we mention: (i) The integration of the equations of the null geodesics in general relativity theory,[11] (ii) The integration of dynamical systems which are Hamiltonian only on single hypersurfaces of the phase space.

II. DEFINITION OF SEPARATED COMPLETE SOLUTION OF THE NULL HJE

Let Q be a real n-dimensional differentiable manifold and $\mathcal{H}$ be a smooth real-valued function on the cotangent bundle T^*Q. Let $\underline{q}=(q^i)$ be local coordinates on an open subset $U\subseteq Q$ and $(\underline{q},\underline{p})=(q^i,p_i)$ the corresponding standard canonical coordinates on T^*Q. In the following, ∂_i and ∂^i will denote the partial derivative with respect to q^i and p_i, respectively.

We restrict our analysis to the open set $\mathcal{O}\subseteq T^*U\subseteq T^*Q$, where $\partial^i\mathcal{H}\neq 0$ for all $i=1,\ldots,n$, assuming that it is not empty. In this open set we have $\mathrm{d}\mathcal{H}\neq 0$, so that any equation of the kind $\mathcal{H}(\underline{q},\underline{p})=h$, $h\in\mathbb{R}$, defines a set $\mathcal{E}_h$ that, if not empty, is a submanifold of codimension 1. In particular, we focus on the submanifold $\mathcal{E}_0$ described by equation $\mathcal{H}=0$.

We consider the HJE for $h=0$,

$$\mathcal{H}\left(\underline{q},\frac{\partial W}{\partial \underline{q}}\right)=0, \tag{2.1}$$

and two definitions of complete solution.

Definition 2.1: An *internal complete solution* of the HJE (2.1) is a solution $W^I(\underline{q},c_\alpha)$ depending on $n-1$ parameters (c_α) such that the following completeness condition is satisfied:

$$\operatorname{rank}\left[\frac{\partial^2 W^I}{\partial q^i\,\partial c_\alpha}\right]=n-1. \tag{2.2}$$

An *extended complete solution* of the HJE (2.1) is a function $W^E(\underline{q},\underline{c})$ depending on n real parameters $\underline{c}=(c_i)$ satisfying the completeness condition

$$\det\left[\frac{\partial^2 W^E}{\partial q^i\,\partial c_j}\right]\neq 0 \tag{2.3}$$

for all admissible values of $(\underline{q},\underline{c})$, and satisfying Eq. (2.1) for all $\underline{c}$ belonging to a suitable $n-1$-dimensional submanifold of $\mathbb{R}^n$ (see Remark 2.1 below) or (up to a transformation of $\underline{c}$) for $c_n=0$.

The geometrical meaning of these two definitions is the following. An internal complete solution W^I defines a Lagrangian foliation $\mathcal{L}^I$ of the submanifold $\mathcal{E}_0$, Fig. 1(a), via equations $p_i=\partial_i W^I$. Each Lagrangian submanifold $L_{(c_\alpha)}\in\mathcal{L}^I$ is parametrized by the value of the $n-1$ parameters (c_α).

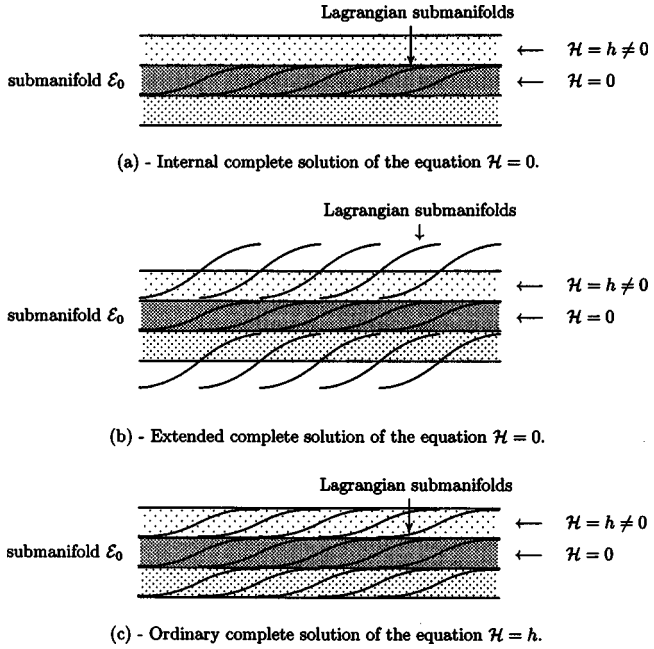

FIG. 1. The geometry of the three definitions of complete solution.

An extended complete solution W^E defines a Lagrangian foliation $\mathcal{L}^E$ on an open neighborhood of T^*Q via equations $p_i = \partial_i W^E$. Each Lagrangian submanifold $L_{(c_i)} \in \mathcal{L}^E$ is parametrized by the value of the n parameters $\underline{c} = (c_i)$. This foliation is compatible with the submanifold $\mathcal{E}_0$, in the sense that it is reducible to a foliation of $\mathcal{E}_0$, Fig. 1(b).

Remark 2.1: The quotient set $\mathcal{C}$ of the foliation $\mathcal{L}^E$ is locally a n-dimensional manifold with coordinates (c_i). The restriction $\mathcal{L}^I$ of $\mathcal{L}^E$ to $\mathcal{E}_0$ is a submanifold $\mathcal{S} \subset \mathcal{C}$ of dimension $n-1$. Then $\mathcal{S}$ is locally defined by an equation $h(c_i) = 0$ with $\mathrm{d}h \,|\, \mathcal{S} \neq 0$. Up to a transformation $(c_i) \leftrightarrow (c_i')$ we can find coordinates adapted to $\mathcal{S}$ such that equation $h(c_i) = 0$ is replaced by $c_n' = 0$. This means that for a suitable choice of the parameters appearing in a W^E equation (2.1) is satisfied for $c_n = 0$.

Remark 2.2: In general, the foliation generated by a W^E may be not reducible to the submanifolds $\mathcal{E}_h$ with $h \neq 0$. When it is reducible to each $\mathcal{E}_h$, then we have an *ordinary complete solution*, Fig. 1(c), of the HJE

$$\mathcal{H}\left(\underline{q}, \frac{\partial W}{\partial \underline{q}}\right) = h. \tag{2.4}$$

The following proposition shows that the two definitions of internal and extended complete solutions are, in a sense, equivalent.

Proposition 2.1: Equation (2.1) *admits an internal complete solution* W^I *if and only if it admits an extended complete solution* W^E.

Proof: Let W^I be an internal complete solution. By the completeness condition (2.2), we know that there exist $n-1$ linearly independent columns in the matrix $\partial^2 W^I / \partial q^i \partial c_\alpha$. Thus, we can assume without loss of generality that

$$\det\left[\frac{\partial^2 W^I}{\partial q^\beta \partial c_\alpha}\right] \neq 0, \quad \alpha, \beta = 1, \ldots, n-1.$$

Then, the function

$$W^E(\underline{q},\underline{c}) = W^I(\underline{q},c_\alpha) + c_n q^n, \quad \underline{c} = (c_i) = (c_\alpha, c_n) \tag{2.5}$$

is an extended complete solution: the completeness condition (2.3) is satisfied. Conversely, if W^E is an extended complete solution, then the function $W^I = W^E|_{c_n=0}$ is an internal complete solution. ■

Now we adapt the above-given definitions to a particular class of complete solutions:

Definition 2.2: An *internal separated solution* of the HJE (2.1) is an internal complete solution $W^I(\underline{q},c_\alpha)$ of the form

$$W^I(\underline{q},c_\alpha) = \sum_{i=1}^{n} W_i^I(q^i,c_\alpha). \tag{2.6}$$

An *extended separated solution* of the HJE (2.1) is an extended complete solution $W^E(\underline{q},\underline{c})$ of the form

$$W^E(\underline{q},\underline{c}) = \sum_{i=1}^{n} W_i^E(q^i,\underline{c}). \tag{2.7}$$

It is obvious that the additive separation is preserved in the passage from a W^E to a W^I. However, it is remarkable that it is also preserved in the inverse passage, from a W^I to a W^E, due to the particular form of formula (2.5). Hence, from Proposition 2.1 it follows that

Proposition 2.2: Equation (2.1) *admits an internal separated solution* W^I *in a coordinate system* $\underline{q}=(q^i)$ *if and only if it admits an extended separated solution* W^E *in the same coordinates.*

The equivalence proved in Proposition 2.2 leads to the following definition of separability for $\mathcal{H}=0$:

Definition 2.3: The null HJE (2.1) is *separable* in the coordinates $\underline{q}=(q^i)$ if it admits an internal separated solution or, equivalently, if it admits an extended separated solution.

Remark 2.3: The definition of *internal separated solution* given here, i.e., depending on $n-1$ constant parameters satisfying the completeness condition (2.2), is that commonly adopted in the literature. See, e.g., Ref. 17, p. 107. However, the use of a second, although equivalent, definition of separation (Proposition 2.2) is essential for a complete development of the present theory. Indeed, as will be shown in Sec. IV, the definition of *extended separated solution* allows the characterization of the separability for the null HJE (2.1) by means of Lagrangian multipliers.

III. SPECIAL DISTRIBUTIONS RELATED TO THE SEPARATION

In order to give necessary and sufficient conditions for the existence of separated solutions it is convenient to give a geometrical interpretation of the separation in terms of complete integrability of a special kind of first-order differential systems. This interpretation is related to the concept of separated connection on a cotangent bundle.[5]

With a coordinate system $\underline{q}=(q^i)$ on Q we associate n differential operators on functions on T^*Q of the kind

$$D_i = \partial_i + R_i(\underline{q},\underline{p})\partial^i, \tag{3.1}$$

where R_i are assigned functions on T^*Q. The vector fields D_i on T^*Q are pointwise independent and transversal to the fibers. Thus, they span a regular distribution $\Delta \subset TT^*U$ of rank n transversal to the fibers: this means that at each point $x \in T^*U$ they span an n-dimensional subspace $\Delta_x \subset T_x(T^*U)$ which is transversal to the vertical vectors of TT^*U. We say that the vector fields D_i are the generators of Δ.

With the same functions R_i entering (3.1) we associate the first-order normal differential system

$$\partial_i p_j = \delta_{ij} R_i(\underline{q},\underline{p}) \tag{3.2}$$

and we remark as follows,

(i) Any integral manifold L of Δ, i.e., a submanifold $L \subset T^*U$ such that $T_x L = \Delta_x$ for all $x \in L$, is locally described by equations

$$p_i = \varphi_i(\underline{q}), \tag{3.3}$$

where the functions φ_i are solutions of system (3.2). Indeed, since Δ is transversal to the fibers, any integral manifold L of Δ is an n-dimensional submanifold transversal to the fibers, thus locally described by equations of the kind (3.3). Moreover, by definition of integral manifold, the generators D_i are tangent to L, so that equations $D_j(p_i - \varphi_i(\underline{q})) = 0$ are satisfied on L. This implies $0 = D_j(p_i - \varphi_i(\underline{q})) = (\partial_j + R_j\partial^j)(p_i - \varphi_i(\underline{q})) = -\partial_j\varphi_i + R_j\delta_{ij}$. This shows that the functions (3.3) satisfy the differential system (3.2).

(ii) Any integral manifold L is a Lagrangian submanifold, since the distribution Δ spanned by D_i is Lagrangian with respect to the canonical symplectic form $\omega = \mathrm{d}p_k \wedge \mathrm{d}q^k$. Indeed, we have

$$\omega(D_i,D_j) = (\mathrm{d}p_k \wedge \mathrm{d}q^k)(D_i,D_j) = \langle D_i, \mathrm{d}p_k\rangle\langle D_j, \mathrm{d}q^k\rangle - \langle D_j, \mathrm{d}p_k\rangle\langle D_i, \mathrm{d}q^k\rangle = R_i\delta_j^i - R_j\delta_i^j = 0.$$

This shows that Δ is an isotropic distribution. Being of rank n, it is a Lagrangian distribution.

(iii) Any Lagrangian submanifold L transversal to the fibers of T^*Q admits local generating functions, i.e., functions $W(\underline{q})$ such that L is described by equations $p_i = \partial_i W$. If L is an integral manifold of the distribution Δ, then $p_i = \partial_i W$ must be a solution of system (3.2). It follows that for $i \neq j$, $\partial_i\partial_j W = 0$, i.e.,

$$W(\underline{q}) = \sum_{i=1}^{n} W_i(q^i). \tag{3.4}$$

(iv) The Lie brackets of the generators D_i are vertical vectors, i.e., vectors tangent to the fibers of T^*Q. Indeed,

$$\begin{aligned}[D_i,D_j] &= [\partial_i + R_i\partial^i, \partial_j + R_j\partial^j] \\ &= \partial_i\partial_j + \partial_i R_j\partial^j + R_j\partial_i\partial^j + R_i\partial^i\partial_j + R_i\partial^i R_j\partial^j + R_i R_j\partial^i\partial^j - \partial_j\partial_i - \partial_j R_i\partial^i - R_i\partial_j\partial^i - R_j\partial^j\partial_i \\ &\quad - R_j\partial^j R_i\partial^i - R_j R_i\partial^j\partial^j = (\partial_i R_j + R_i\partial^i R_j)\partial^j - (\partial_j R_i + R_j\partial^j R_i)\partial^i.\end{aligned}$$

It follows that

$$[D_i,D_j] = D_i R_j\partial^j - D_j R_i\partial^i, \tag{3.5}$$

being

$$\partial_i R_j + R_i\partial^i R_j = D_i R_j. \tag{3.6}$$

Hence, Δ is completely integrable if and only if the generators commute, $[D_i,D_j] = 0$, i.e., if and only if

$$D_i R_j = 0, \quad i \neq j. \tag{3.7}$$

So far we have no links with the HJE $\mathcal{H} = 0$. Now we introduce the function $\mathcal{H}$.

(v) The distribution Δ, when restricted to the points of $\mathcal{E}_0$, gives rise to a distribution Δ_0 on $\mathcal{E}_0$ if and only if the generators are tangent to $\mathcal{E}_0$, and this happens if and only if

$$D_i\mathcal{H}|_{\mathcal{E}_0} = (\partial_i\mathcal{H} + R_i\partial^i\mathcal{H})|_{\mathcal{E}_0} = 0. \tag{3.8}$$

In this case we say that Δ is reducible to $\mathcal{E}_0$ and a well-known property of the Lie bracket tells us that

$$[D_i|\mathcal{E}_0, D_j|\mathcal{E}_0] = [D_i, D_j]|\mathcal{E}_0. \tag{3.9}$$

It follows that the reduced distribution Δ_0 is integrable if and only if

$$D_i R_j|\mathcal{E}_0 = 0, \quad i \neq j. \tag{3.10}$$

Theorem 3.1: *The HJE* (2.1) *admits an extended separated solution in the coordinate system* $\underline{q}$ *if and only if there exist n functions* $R_i(\underline{q},\underline{p})$ *satisfying one of the following equivalent conditions:* (a) *The distribution* Δ *spanned by the generators* (3.1) *is completely integrable and reducible to a distribution* Δ_0 *on* $\mathcal{E}_0$. (b) *Conditions* (3.7) and (3.8) *are satisfied*:

$$\partial_i R_j + R_i \partial^i R_j = 0, \quad i \neq j, \quad (\partial_i \mathcal{H} + R_i \partial^i \mathcal{H})|_{\mathcal{E}_0} = 0. \tag{3.11}$$

Proof: Conditions (a) and (b) are clearly equivalent because of the remarks above. Let $W^E(\underline{q},\underline{c})$ be an extended separated solution. The completeness condition (2.3) means that $(\underline{q},\underline{c})$ are local noncanonical coordinates of T^*Q. Thus, the functions $R_i = \partial_i^2 W^E(\underline{q},\underline{c})$ are well defined on an open subset of T^*Q. Then we consider the separable connection Δ with generators

$$D_i = \partial_i + \partial_i^2 W^E \partial^i.$$

The integral manifolds of Δ are locally described by equations $p_i = \partial_i W^E(\underline{q},\underline{c})$ and, due to the completeness condition (2.3), we get the complete integrability of Δ. Moreover, since for $c_n = 0$, W^E is a solution of (2.1), the generators are tangent to $\mathcal{E}_0$. Conversely, assume that functions R_i exist satisfying (3.11). Then the distribution Δ is completely integrable and the integral manifolds are generated by a separated solution $W^E(\underline{q},\underline{c})$ parametrized by n parameters $\underline{c} = (c_i)$. Since the integral manifolds form a foliation, there is only one integral manifold $L_{\underline{c}}$ containing a given point. This means that equations $p_i = \partial_i W^E$ must be solvable with respect to $\underline{c}$. This is equivalent to the completeness condition (2.3). ■

Theorem 3.2: *The HJE* (2.1) *admits an internal separated solution in the coordinate system* $\underline{q}$ *if and only if there exist functions* $R_i(\underline{q},\underline{p})$ *such that* (a) *the distribution* Δ *spanned by the generators* (3.1) *is reducible to a distribution* Δ_0 *on* $\mathcal{E}_0$ *and this reduced distribution is completely integrable, i.e., such that* (b) *conditions* (3.8) and (3.10) *are satisfied*:

$$(\partial_i \mathcal{H} + R_i \partial^i \mathcal{H})|_{\mathcal{E}_0} = 0, \quad (\partial_i R_j + R_i \partial^i R_j)|_{\mathcal{E}_0} = 0, \quad i \neq j \tag{3.12}$$

Proof: The equivalence between conditions (a) and (b) follows from the above remarks. Let W^I be an internal separated solution. Then, by Proposition 2.2, we can construct an extended separated solution W^E in the same coordinates. Hence, by Theorem 3.1, there exist functions R_i satisfying (3.11). It is clear that these functions R_i satisfy (3.12). Conversely, we consider functions R_i satisfying (3.12) which are associated with a distribution Δ reducible to a completely integrable distribution Δ_0 on $\mathcal{E}_0$. The integral manifolds of Δ_0 are generated by a separated solution $W^I(\underline{q},c_\alpha)$ parametrized by $n-1$ parameters (c_α). Since they form a foliation $\mathcal{L}^I \subseteq \mathcal{E}_0$, there is only one integral manifold containing a given point $p \in \mathcal{E}_0$. This means that equations $p_i = \partial_i W^I$ are solvable with respect to c_α so that the completeness condition (2.2) holds. ■

Remark 3.1: We know from Proposition 2.2 that the existence of a separated solution W^I is equivalent to the existence of a separated solution W^E. However, this does not mean that the functions R_i entering Theorem 3.1 and Theorem 3.2 are the same functions. Indeed, it is obvious that functions R_i satisfying (3.11) also satisfy (3.12); but functions R_i satisfying (3.12) may not satisfy (3.11).

IV. THE LEVI–CIVITA SEPARABILITY CONDITIONS WITH LAGRANGIAN MULTIPLIERS

The ordinary separation of the HJE $\mathcal{H} = h$ (2.4) is characterized by the Levi–Civita equations,[24]

$$\partial_i\mathcal{H}\partial_j\mathcal{H}\partial^i\partial^j\mathcal{H} + \partial^i\mathcal{H}\partial^j\mathcal{H}\partial_i\partial_j\mathcal{H} - \partial_i\mathcal{H}\partial^j\mathcal{H}\partial^i\partial_j\mathcal{H} - \partial^i\mathcal{H}\partial_j\mathcal{H}\partial_i\partial^j\mathcal{H} = 0, \quad i \neq j. \tag{4.1}$$

We want to write similar differential equations characterizing the separation of the null HJE $\mathcal{H}=0$ (2.1). For this reason, we look for differential systems equivalent to the conditions (3.11) and (3.12), respectively. Since these conditions are differential conditions restricted to a submanifold, we base our approach on the Hadamard lemma (cf. Ref. 1, for the one-dimensional case).

Lemma 4.1: Let $f(\underline{x},y)$ *be a smooth* (C^∞) *function on an open subset* U of $\mathbb{R}^{m+1}$ *such that* $f(\underline{x},0)=0$. *Then there exists a smooth function* $\lambda(\underline{x},y)$ *such that* $f(\underline{x},y)=y\lambda(\underline{x},y)$.

Proof: The function $\lambda(\underline{x},y)$ is defined by

$$\lambda(\underline{x},y) = \int_0^1 \frac{\partial f}{\partial y}(\underline{x},ty)\mathrm{d}t. \tag{4.2}$$

Indeed we have

$$y\int_0^1 \frac{\partial f}{\partial y}(\underline{x},ty)\mathrm{d}t = \int_0^1 \frac{\partial f}{\partial y}(\underline{x},ty)y\ \mathrm{d}t = \int_0^y \frac{\partial f}{\partial y}(\underline{x},u)\mathrm{d}u = f(\underline{x},y) - f(\underline{x},0) = f(\underline{x},y).$$

The function defined by (4.2) is smooth. ■

We use Hadamard's lemma in the following form.

Lemma 4.2: A smooth function F *on* T^*Q *which vanishes on the submanifold* $\mathcal{E}_0$ *defined by equation* $\mathcal{H}=0$ *is of the form*

$$F = \mathcal{H}\lambda, \tag{4.3}$$

where λ *is a suitable function on* T^*Q.

Proof: Since $\mathcal{E}_0$ is a submanifold of codimension 1, and $\mathrm{d}\mathcal{H}\neq 0$, we can consider local coordinates $(\underline{x},y)$ on T^*Q, such that $\mathcal{E}_0$ is locally defined by equation $y=\mathcal{H}=0$. Then, by applying Lemma 4.1 to the function $F=F(\underline{x},y)$, there exists a smooth function $\lambda(\underline{x},y)$ such that $F=y\lambda$, i.e., a smooth function $\lambda(\underline{q},\underline{p})$ such that (4.3) holds. ■

Due to Lemma 4.2, and recalling our assumption $\partial^i\mathcal{H}\neq 0$, we can reformulate Theorems 3.1 and 3.2 as follows.

Proposition 4.1: The HJE (2.1) *admits an extended separated solution in the coordinates* $\underline{q}=(q^i)$ *if and only if there exist* n *functions* $\lambda_i(\underline{q},\underline{p})$ *such that equations*

$$\partial_i R_j + R_i\partial^i R_j = 0, \quad i \neq j, \tag{4.4}$$

are satisfied for

$$R_i \doteq -\frac{\partial_i\mathcal{H} - \lambda_i\mathcal{H}}{\partial^i\mathcal{H}}. \tag{4.5}$$

Proof: It is sufficient to examine the second equation (3.11). Due to Lemma 4.2, this is equivalent to the existence of functions λ_i on T^*Q such that

$$\partial_i\mathcal{H} + R_i\partial^i\mathcal{H} = \lambda_i\mathcal{H}. \tag{4.6}$$

Then we get for R_i the expression (4.5). ■

Proposition 4.2: The HJE (2.1) *admits an internal separated solution in the coordinates* $\underline{q}=(q^i)$ *if and only if there exist functions* $\lambda_i(\underline{q},\underline{p})$ *and* $\mu_{ij}(\underline{q},\underline{p})$ *such that equations*

$$\partial_i R_j + R_i\partial^i R_j = \mu_{ij}\mathcal{H}, \quad i \neq j, \tag{4.7}$$

are satisfied for R_i *given by* (4.5),

$$R_i \doteq -\frac{\partial_i\mathcal{H} - \lambda_i\mathcal{H}}{\partial^i\mathcal{H}}.$$

Proof: By recalling the proof of Proposition 4.1, the first equation (3.12) means that R_i must have the form (4.5). Moreover, due to Lemma 4.2, the second equation (3.12) is equivalent to the existence of functions μ_{ij} on T^*Q such that (4.7) holds

.■

We remark that the additional functions λ_i and μ_{ij} play the role of Lagrangian multipliers. Now we are able to state three effective criteria for the separability (Definition 2.3) of the null HJE.

Theorem 4.1: The HJE $\mathcal{H}=0$ (2.1) *is separable in the coordinates* $\underline{q}=(q^i)$ *if and only if there exist n functions* $\underline{\lambda}=(\lambda_k)$ *on* T^*Q *such that equations*

$$L_{ij}(\mathcal{H};\underline{\lambda}) \doteq L_{ij}(\mathcal{H}) + \mathcal{H}[\lambda_i(\partial^j\mathcal{H}\partial^i\partial_j\mathcal{H} - \partial_j\mathcal{H}\partial^i\partial^j\mathcal{H}) + \lambda_j(\partial^j\mathcal{H}\partial_i\partial^j\mathcal{H} - \partial^i\partial^j\mathcal{H}\partial_i\mathcal{H}) + \lambda_i\lambda_j(\mathcal{H}\partial^i\partial^j\mathcal{H} - \partial^i\mathcal{H}\partial^j\mathcal{H}) - \partial_j\lambda_i\partial^i\mathcal{H}\partial^j\mathcal{H} + \partial^j\lambda_i(\partial_j\mathcal{H}\partial^i\mathcal{H} - \lambda_j\mathcal{H}\partial^i\mathcal{H})] = 0 \quad (4.8)$$

are satisfied for $i \neq j$, *where*

$$L_{ij}(\mathcal{H}) \doteq \partial_i\mathcal{H}\partial_j\mathcal{H}\partial^i\partial^j\mathcal{H} + \partial^i\mathcal{H}\partial^j\mathcal{H}\partial_i\partial_j\mathcal{H} - \partial_i\mathcal{H}\partial^j\mathcal{H}\partial^i\partial_j\mathcal{H} - \partial^i\mathcal{H}\partial_j\mathcal{H}\partial_i\partial^j\mathcal{H}. \quad (4.9)$$

We call equations (4.8), $L_{ij}(\mathcal{H},\underline{\lambda})=0$, the *Levi–Civita conditions with Lagrangian multipliers.*

Proof: By Proposition 4.1, the HJE (2.1) is separable if and only if there exist functions λ_i on T^*Q such that equations (4.4) and (4.5) hold. Due to the expression of R_i given by (4.5), the left-hand side D_iR_j of (4.4) becomes

$$D_iR_j = -\frac{1}{\partial^j\mathcal{H}(\partial^j\mathcal{H})^2}L_{ij}(\mathcal{H};\underline{\lambda}), \quad (4.10)$$

so that equations (4.4) are equivalent to equations (4.8). ■

Remark 4.1: For all $\lambda_i=0$, the expression (4.5) reduces to

$$R_i = -\frac{\partial_i\mathcal{H}}{\partial^i\mathcal{H}}, \quad (4.11)$$

and (4.8) become the usual Levi–Civita conditions (4.1). Conditions (4.8) are more general than (4.1). Indeed, equations (4.1) are satisfied if and only if for R_i given by (4.11) we have $D_iR_j=0$, i.e., if and only if the associated distribution Δ is completely integrable on an open subset of T^*Q and reducible to every $\mathcal{E}_h$, that is if and only if there exists an ordinary complete solution of equation $\mathcal{H}=h$ (2.4).

Remark 4.2: Equations (4.8) can be written in the form $L_{ij}(\mathcal{H})=P_{ij}(\underline{q},\underline{p})\mathcal{H}$. This is just a special case [corresponding to a first order PDE $\mathcal{H}(\underline{q},\underline{p})=0$] of a general equation written by Kalnins and Miller in their theory of the variable separation for partial differential equations [Eq. (1.25) of Ref. 26, or Eq. (1.17) of Ref. 21]. In fact, equation $L_{ij}(\mathcal{H})=\mathcal{H}P_{ij}$ is considered as a *definition* of a so-called regular separation of equation $\mathcal{H}=0$. Instead, in our approach it is a consequence of the definitions of separation given in Sec. II and rigorously proved by means of the Hadamard lemma, as shown by the following.

Theorem 4.2: *The HJE* $\mathcal{H}=0$ (2.1) *is separable in the coordinates* $\underline{q}=(q^i)$ *if and only if the Levi–Civita conditions* $L_{ij}(\mathcal{H})=0$ *are satisfied for* $\mathcal{H}=0$, *that is on the submanifold* $\mathcal{E}_0$,

$$L_{ij}(\mathcal{H})|_{\mathcal{E}_0} = 0. \quad (4.12)$$

Proof: The Levi–Civita conditions with Lagrangian multipliers (4.8) obviously imply $L_{ij}(\mathcal{H})=0$ for $\mathcal{H}=0$. Conversely, assume that (4.12) holds. Then, by Lemma 4.2, there exist functions ν_{ij} such that $L_{ij}(\mathcal{H})=\nu_{ij}\mathcal{H}$. If we set

$$\mu_{ij} = -\frac{1}{\partial^i \mathcal{H}(\partial^j \mathcal{H})^2}\nu_{ij},$$

and $\lambda_i = 0$, then due to (4.10) we get that equations (4.5) and (4.7) are satisfied, and due to Proposition 4.2 the HJE admits an internal separated solution. ■

We remark that conditions (4.12) do not involve Lagrangian multipliers.

Remark 4.3: When the functions R_i are given by (4.5), the generators D_i become

$$D_i = \partial_i - \frac{\partial_i \mathcal{H} - \lambda_i \mathcal{H}}{\partial^j \mathcal{H}}\,\partial^i. \tag{4.13}$$

Then, the Levi–Civita conditions with Lagrangian multipliers (4.8) can be written in the form

$$L_{ij}(\mathcal{H};\lambda_k) = L_{ij}(\mathcal{H}) + \mathcal{H}[\lambda_i(\partial^j \mathcal{H}\partial^i\partial_j \mathcal{H} - \partial_j \mathcal{H}\partial^i\partial^j \mathcal{H}) + \lambda_j(\partial^i \mathcal{H}\partial_i\partial^j \mathcal{H} - \partial^i\partial^j \mathcal{H}\partial_i \mathcal{H}) + \lambda_i\lambda_j(\mathcal{H}\partial^i\partial^j \mathcal{H} - \partial^i \mathcal{H}\partial^j \mathcal{H}) - D_j\lambda_i\partial^i \mathcal{H}\partial^j \mathcal{H}] = 0. \tag{4.14}$$

It is a remarkable fact that the Levi–Civita separability conditions with Lagrangian multipliers λ_i are equivalent to differential conditions involving a single undetermined function Λ on T^*Q and that these new conditions are the ordinary Levi–Civita separability conditions, but with respect to a modified Hamiltonian, $\mathcal{J} = \mathcal{H}/\Lambda$.

Theorem 4.3: *The HJE* $\mathcal{H} = 0$ (2.1) *is separable in the coordinates* $\underline{q} = (q^i)$ *if and only if there exists a nowhere vanishing function* $\Lambda = \Lambda(\underline{q}, \underline{p})$ *such that for any* $i \neq j$,

$$L_{ij}\left(\frac{\mathcal{H}}{\Lambda}\right) = 0. \tag{4.15}$$

Proof: The Levi–Civita equations with Lagrangian multipliers (4.14) are not symmetric in the indices (i,j), due to the last term. By taking their skew-symmetric part, we obtain equations

$$\partial^i \mathcal{H}\partial^j \mathcal{H} D_j\lambda_i = \partial^i \mathcal{H}\partial^j \mathcal{H} D_i\lambda_j, \tag{4.16}$$

which are necessary conditions for the solvability of (4.14). Since D_i and D_j commute, it follows that (4.16) are locally equivalent to the existence of a function $F(\underline{q}, \underline{p})$ such that

$$\lambda_i = D_i F. \tag{4.17}$$

Indeed, the commutation condition $[D_i, D_j] = 0$ is equivalent to the existence of local coordinates (x^i, y^j) such that $D_i = \partial/\partial y^i$. Hence, equations (4.16) become equivalent to $\partial\lambda_i/\partial y^j = \partial\lambda_j/\partial y^i$. By considering the coordinates (x^i) as independent parameters, this is locally equivalent to the existence of a function $F(\underline{x}, \underline{y})$ such that $\lambda_i = \partial F/\partial y^i$, and we get (4.17). However, it turns out to be more convenient to replace the function F in (4.17) with $F = \ln|\Lambda|$, where $\Lambda(\underline{q}, \underline{p})$ is a nowhere vanishing function, so that

$$\lambda_i = \tfrac{1}{\Lambda} D_i \Lambda. \tag{4.18}$$

Then, by inserting (4.18) in (4.5), we obtain

$$R_i = -\frac{\partial_i \mathcal{H}}{\partial^j \mathcal{H}} + \frac{1}{\Lambda} D_i \Lambda \frac{\mathcal{H}}{\partial^j \mathcal{H}},$$

and, by (4.13),

$$R_i = -\frac{\partial_i \mathcal{H}}{\partial^j \mathcal{H}} + \frac{1}{\Lambda}(\partial_i \Lambda + R_i \partial^j \Lambda)\frac{\mathcal{H}}{\partial^j \mathcal{H}}.$$

By solving this equation with respect to R_i, we find

$$R_i = -\frac{\Lambda\partial_i\mathcal{H} - \mathcal{H}\partial_i\Lambda}{\Lambda\partial^i\mathcal{H} - \mathcal{H}\partial^i\Lambda}, \tag{4.19}$$

that is

$$R_i = -\frac{\partial_i(\mathcal{H}/\Lambda)}{\partial^i(\mathcal{H}/\Lambda)}. \tag{4.20}$$

Hence, for the functions (4.20) the complete integrability conditions (4.4) become the Levi–Civita conditions (4.15) for the new Hamiltonian $\mathcal{J}=\mathcal{H}/\Lambda$. ■

Remark 4.4: The explicit expression of the n Lagrangian multipliers λ_i in terms of Λ is

$$\lambda_i = \frac{\{\mathcal{H},\Lambda\}_i}{\Lambda\partial^i\mathcal{H} - \mathcal{H}\partial^i\Lambda}, \tag{4.21}$$

where $\{\mathcal{H},\Lambda\}_i \doteq \partial^i\mathcal{H}\partial_i\Lambda - \partial^i\Lambda\partial_i\mathcal{H}$. Indeed, by (4.20), the generators D_i become

$$D_i = \partial_i - \frac{\partial_i(\mathcal{H}/\Lambda)}{\partial^i(\mathcal{H}/\Lambda)}\partial^i.$$

In particular, using (4.19), the Lagrangian multipliers (4.18) become

$$\lambda_i = \frac{\partial^i\mathcal{H}\partial_i\Lambda - \partial^i\Lambda\partial_i\mathcal{H}}{\Lambda\partial^i\mathcal{H} - \mathcal{H}\partial^i\Lambda},$$

that is (4.21).

We call the function

$$\mathcal{J} = \frac{\mathcal{H}}{\Lambda} \tag{4.22}$$

the *conformal Hamiltonian* associated to $\mathcal{H}$ and the function Λ the conformal factor. The link between the two Hamiltonian vector fields $\mathbf{X}_\mathcal{H}$ and $\mathbf{X}_\mathcal{J}$ generated by the Hamiltonians $\mathcal{H}$ and $\mathcal{J}$, respectively, is given by the following.

Proposition 4.3: On the submanifold $\mathcal{E}_0$ the vector fields $\mathbf{X}_\mathcal{H}$ and $\mathbf{X}_\mathcal{J}$ are parallel and differ by the factor Λ,

$$(\Lambda X_\mathcal{J})|_{\mathcal{E}_0} = X_\mathcal{H}|_{\mathcal{E}_0} \tag{4.23}$$

so that the corresponding affine parameters t and $\bar{t}$ are related by equation

$$\mathrm{d}\bar{t} = \Lambda\,\mathrm{d}t. \tag{4.24}$$

Proof: Let ω be the symplectic form on T^*Q. Then,

$$i_{\mathbf{X}_\mathcal{J}}\omega = -\,\mathrm{d}\mathcal{J} = \tfrac{1}{\Lambda^2}\mathcal{H}\,\mathrm{d}\Lambda - \tfrac{1}{\Lambda}\mathrm{d}\mathcal{H}, \quad i_{\mathbf{X}_\mathcal{H}}\omega = -\,\mathrm{d}\mathcal{H}. \tag{4.25}$$

By eliminating $\mathrm{d}\mathcal{H}$ in these two equations we get the single equation $\Lambda i_{\mathbf{X}_\mathcal{J}}\omega - d\ln|\Lambda|\mathcal{H} = i_{\mathbf{X}_\mathcal{H}}\omega$, which is equivalent to

$$i_{(\mathbf{X}_\mathcal{H}-\Lambda\mathbf{X}_\mathcal{J})}\omega = \frac{\mathcal{H}}{\Lambda}\mathrm{d}\Lambda. \tag{4.26}$$

By (4.26), for $\mathcal{H}=0$ the Hamiltonian vector field $(\mathbf{X}_\mathcal{H}-\Lambda\mathbf{X}_\mathcal{J})$ vanishes and we get (4.23). If t and $\bar{t}$ are the affine parameters of $\mathbf{X}_\mathcal{H}$ and $\mathbf{X}_\mathcal{J}$, respectively, then by (4.23), we find that (4.24) holds on $\mathcal{E}_0$. ■

Theorem 4.4: *If we know a complete solution of the HJE $\mathcal{J}=h$ for the conformal Hamiltonian*

(4.22), *then for* $h=0$ *we get the orbits on* $\mathcal{E}_0$ *of the Hamiltonian vector field* $\mathbf{X}_{\mathcal{H}}$.

Proof: According to Proposition 4.3, on $\mathcal{E}_0$, the integral curves of the vector fields $\mathbf{X}_{\mathcal{H}}$ and $\mathbf{X}_{\mathcal{J}}$ coincide, up to the reparametrization given by (4.24). Since $\mathcal{H}=0$ means $\mathcal{J}=0$, by inserting the condition $h=0$ in a complete solution of the HJE $\mathcal{J}=h$, we get the orbits of the field $\mathbf{X}_{\mathcal{H}}$ on the hypersurface $\mathcal{H}=0$. ■

Remark 4.5: We recall that a first integral of a Hamiltonian $\mathcal{H}$ is a function F on T^*Q which is constant on the integral curves of $\mathbf{X}_{\mathcal{H}}$ and that this is equivalent to the condition $\mathbf{X}_{\mathcal{H}}F=0$ or $\{\mathcal{H},F\}=0$. We call isoenergetic first integral of a function $\mathcal{H}$ any function F which is constant on all the integral curves contained in a submanifold $\mathcal{H}=h$ for some values of $h\in\mathbb{R}$. Due to the Hadamard lemma, this is equivalent to the existence of a function ϕ such that $\{\mathcal{H},F\}=\phi(\mathcal{H}-h)$. Of course, any ordinary first integral is a special kind of isoenergetic first integral. If $h=0$ we call F a *null first integral* of $\mathcal{H}$: it is characterized by equation

$$\{\mathcal{H},F\}=\phi\mathcal{H}. \tag{4.27}$$

By (4.23), it follows that any first integral F of $\mathbf{X}_{\mathcal{J}}$ is a null first integral of $\mathbf{X}_{\mathcal{H}}$. In Sec. VIII we shall use this definition.

Remark 4.6: Let the Hamiltonian $\mathcal{H}$ be of the form $\mathcal{H}=H+\Lambda$. In this case we can consider a particular conformal Hamiltonian $J=H/\Lambda$. We call the Hamiltonian J the *generalized Jacobi transform* of $\mathcal{H}$. According to Theorem 4.4, we get that the orbits of $\mathcal{H}$ on the hypersurface $\mathcal{H}=0$ coincide with the orbits of J on $J=1$. Moreover, by (4.24), the generalized Jacobi transform can be considered[33] as a transformation on the cotangent bundle $T^*\overline{Q}$ of the extended configuration manifold $\overline{Q}=\mathbb{R}\times Q$ which is a canonical transformation only on the hypersurface $p_0+\mathcal{H}=0$.

V. A FIRST APPLICATION: THE SEPARATION FOR TIME-DEPENDENT HAMILTONIANS

Let $H(t,q)$ be a time-dependent Hamiltonian, that is a function on the $(n+1)$-dimensional manifold $\overline{Q}=\mathbb{R}\times Q$ (the extended configuration manifold). The well-known HJE associated with a time-dependent system is

$$\frac{\partial W}{\partial t}+H\left(t,q^i,\frac{\partial W}{\partial q^i}\right)=0. \tag{5.1}$$

In the so-called homogeneous formalism, this is equivalent to consider on the cotangent bundle $T^*\overline{Q}$, with coordinates $(q^A,p_A)=(q^0,q^i,p_0,p_i)$, the function

$$\mathcal{H}(q^A,p_A)=p_0+H(q^A,p_i), \tag{5.2}$$

whose corresponding equation $\mathcal{H}=0$ is (5.1) (with $q^0=t$). We have the separation of variables of (5.1) on the hypersurface $\mathcal{H}=0$ if and only if the Levi–Civita conditions $L_{AB}(\mathcal{H})=0 (A\neq B=0,\ldots,n)$ are satisfied on $\mathcal{E}_0$, that is for

$$p_0=-H(q^A,p_i). \tag{5.3}$$

The Levi–Civita equations $L_{AB}(\mathcal{H})=0$ for the Hamiltonian (5.2) become

$$L_{ij}(\mathcal{H})=L_{ij}(H),\quad L_{i0}(\mathcal{H})=\partial^j H\partial_i\partial_0 H-\partial_i H\partial^j\partial_0 H\quad (i,j=1,\ldots,n). \tag{5.4}$$

It is remarkable the fact that, due to (5.3) and since equations (5.4) do not contain p_0, we have

$$L_{AB}(\mathcal{H})|\mathcal{E}_0=0\quad\Leftrightarrow\quad L_{AB}(\mathcal{H})=0.$$

Thus, in this case we have the perfect equivalence between the separation of the HJE $\mathcal{H}=h$ of the kind (2.4) and the separation of variables for the single equation $\mathcal{H}=0$ of the kind (2.1). Then, in order to have the separability for the HJE (5.1) we need that the following conditions be satisfied:

$$L_{ij}(H)=0,\quad \partial^j H\partial_i\partial_0 H-\partial_i H\partial^j\partial_0 H=0\quad (i\ \text{n.s.}). \tag{5.5}$$

Remark 5.1: Equations (5.5) implies that the T^*Q-Poisson bracket of the functions H and $\partial_0 H$ vanishes,

$$\{H, \partial_0 H\}_{T^*Q} = \partial^i H \partial_i \partial_0 H - \partial_i H \partial^i \partial_0 H = 0.$$

Remark 5.2: If conditions (5.5) hold, then the Levi–Civita conditions with $n+1$ Lagrangian multipliers $L_{AB}(\mathcal{H}; \lambda_C) = 0$ are satisfied for $\lambda_C = 0 (C = 0, \ldots, n)$ or, equivalently, conditions (4.15) hold for $\Lambda = 1$.

Remark 5.3: Equations (5.5) are the Levi–Civita separability conditions for the time-dependent case proposed by Forbat.[15] However, the proof given by Forbat is unsatisfactory. Indeed, it is based on the fact that, assuming that the equation (5.1) admits a complete solution of the form $W = W_0(t, \underline{c}) + \Sigma_i W_i(q^i, \underline{c})$, by differentiating (5.1) with respect to a coordinate q^i, we get equations

$$\partial^i H \partial_i p_i + \partial_i H = 0 \tag{5.6}$$

(no summation on the index i). By solving (5.6) with respect to $\partial_i p_i$, we obtain the system

$$\partial_j p_i = \delta_{ij} R_i, \quad R_i = -\frac{\partial_i H}{\partial^i H}, \tag{5.7}$$

whose integrability conditions are (5.5). However, equations (5.6) are derivable also from equation $\mathcal{H} = h$, where h is any constant, not only from equation $\mathcal{H} = 0$. In other words, in considering the integrability conditions of system (5.7) one is actually considering the separation of all equations $\mathcal{H} = h = \text{const}$, which is not in general equivalent to the separation of the single equation $\mathcal{H} = 0$, as we have seen in the preceding sections.

VI. THE ORTHOGONAL SEPARATION FOR NATURAL HAMILTONIANS

Let us apply the general theory so far developed to the special but fundamental case of a natural Hamiltonian $H = G + V$ in orthogonal coordinates,

$$H(\underline{q}, \underline{p}) = \tfrac{1}{2} g^{ii} p_i^2 + V(\underline{q}).$$

With an orthogonal metric $\mathbf{G} = (g^{ii})$ we associate differential operators $S_{ij}(A)$ on functions $A(\underline{q})$,

$$S_{ij}(A) \doteq \partial_i \partial_j A - \partial_j \ln|g^{ii}| \partial_i A - \partial_i \ln|g^{jj}| \partial_j A = \partial_i \partial_j A - \frac{1}{g^{ii}} \partial_j g^{ii} \partial_i A - \frac{1}{g^{jj}} \partial_i g^{jj} \partial_j A,$$

which we call *Stäckel operators*. The indices (i, j) are assumed to be distinct and not summed (n.s.). In the following the condition "$i \neq j$ n.s." referred to an operator S_{ij} will be understood. We know (see, e.g., Ref. 3) that g^{kk} is a Stäckel metric if and only if

$$S_{ij}(g^{kk}) = 0, \tag{6.1}$$

and that a potential V is separable in these coordinates if and only if $S_{ij}(V) = 0$. Indeed, for a natural Hamiltonian in orthogonal coordinates the Levi–Civita equations become

$$L_{ij}(H) = g^{ii} g^{jj} p_i p_j \left(\tfrac{1}{2} S_{ij}(g^{kk}) p_k^2 + S_{ij}(V) \right) = 0, \tag{6.2}$$

and they are satisfied if and only if $\frac{1}{2} S_{ij}(g^{kk}) p_k^2 + S_{ij}(V) = 0$. For the operators S_{ij} the following rules hold:

$$S_{ij}(c) = 0, \quad c \in \mathbb{R},$$

$$S_{ij}(A + B) = S_{ij}(A) + S_{ij}(B),$$

$$S_{ij}(AB) = AS_{ij}(B) + BS_{ij}(A) + \partial_i A \partial_j B + \partial_j A \partial_i B,$$

$$S_{ij}(A^{-1}) = 2A^{-3}\partial_i A \partial_j A - A^{-2}S_{ij}(A). \tag{6.3}$$

The Stäckel operators $\bar{S}_{ij}$ corresponding to a conformal orthogonal metric $\bar{g}^{ii}=(1/\sigma)g^{ii}$ obey rules (6.3) and

$$\bar{S}_{ij}(A) = S_{ij}(A) - \sigma^{-3}(\partial_i \sigma \partial_j A + \partial_i A \partial_j \sigma),$$

$$\bar{S}_{ij}(\bar{g}^{kk}) = \sigma^{-1}S_{ij}(g^{kk}) - g^{kk}\sigma^{-2}S_{ij}(\sigma) = \frac{g^{kk}}{\sigma}\left(\frac{1}{g^{kk}}S_{ij}(g^{kk}) - \frac{1}{\sigma}S_{ij}(\sigma)\right). \tag{6.4}$$

Remark 6.1: From the second equation (6.4), by setting $\sigma=g^{11},\ldots,g^{nn}$, we derive the following theorem due to Kalnins and Miller, Ref. 20, Lemma 1: *If* (g^{ii}) *is a Stäckel metric then all metrics* $(g^{ii}/g^{11}),\ldots,(g^{ii}/g^{nn})$ *are Stäckel metrics*. We recall also Lemma 2 of Ref. 20: *An orthogonal metric* (g^{ii}) *is conformal to a Stäckel metric if and only if* g^{ii}/g^{jj}*, for any fixed value of the index* j*, is a Stäckel metric*. Indeed, this follows from Lemma 1 and the fact that for any conformal metric $\bar{g}^{ii}$ we have $\bar{g}^{ii}/\bar{g}^{ij}=g^{ii}/g^{jj}$. Note that equation (6.1) are equivalent to equations

$$\partial_{ij}^2 \ln|g_{ii}| - \partial_i \ln|g_{kk}|\partial_j \ln|g_{ii}| + \partial_i \ln|g_{jj}|\partial_j \ln|g_{kk}| + \partial_j \ln|g_{ii}|\partial_i \ln|g_{kk}| = 0.$$

With the substitution $g_{ii}=e_i H_i^2$, $e_i=\pm 1$, they coincide with the equations given by Eisenhart (Ref. 14, Appendix 13).

Let us apply the results of Sec. IV to the function

$$\mathcal{H} = \tfrac{1}{2}g^{ii}p_i^2 + V - E, \quad E \in \mathbb{R}.$$

Theorem 6.1: *The HJE*

$$\tfrac{1}{2}g^{ii}p_i^2 + V - E = 0, \tag{6.5}$$

is separable in the orthogonal coordinates (q^i)*, for a fixed value* $E\in\mathbb{R}$*, if and only if equations*

$$\frac{1}{g^{hh}}S_{ij}(g^{hh}) = \frac{1}{g^{kk}}S_{ij}(g^{kk}), \quad S_{ij}(V) = \frac{V-E}{g^{hh}}S_{ij}(g^{hh}), \tag{6.6}$$

are satisfied for all indices h*,* k *and* $i\neq j$.

Proof: Due to Theorem 4.2, a necessary and sufficient condition for the separation of $\mathcal{H}=0$ is that the Levi–Civita conditions be satisfied when restricted to the submanifold $\mathcal{E}_0$, that is for $\mathcal{H}=0$. By (6.5), equation $\mathcal{H}=0$ is equivalent to

$$p_1^2 = -\sum_{k=2}^{n}\frac{g^{kk}}{g^{11}}p_k^2 + \frac{2}{g^{11}}(E-V). \tag{6.7}$$

Thus, by (6.2) and (6.7), we get

$$L_{ij}(\mathcal{H})|_{\mathcal{E}_0} = g^{ii}g^{jj}p_i p_j\left(\frac{1}{2}\sum_{k=2}^{n}S_{ij}(g^{kk})p_k^2 + S_{ij}(V) - \frac{1}{2}S_{ij}(g^{11})\sum_{k=2}^{n}\frac{g^{kk}}{g^{11}}p_k^2 + \frac{S_{ij}(g^{11})}{g^{11}}(E-V)\right). \tag{6.8}$$

Functions (6.8) vanish if and only if

$$\frac{1}{2}\sum_{k=2}^{n}\left[S_{ij}(g^{kk})-\frac{g^{kk}}{g^{11}}S_{ij}(g^{11})\right]p_k^2-S_{ij}(E-V)-\frac{S_{ij}(g^{11})}{g^{11}}(E-V)=0. \tag{6.9}$$

Since conditions (6.9) must be satisfied for all values of $p_2,\ldots,p_n$, they are equivalent to

$$S_{ij}(g^{kk})-\frac{g^{kk}}{g^{11}}S_{ij}(g^{11})=0,\quad S_{ij}(E-V)-\frac{E-V}{g^{11}}S_{ij}(g^{11})=0,$$

hence to (6.6). ■

The first equations (6.6) mean that the functions $(1/g^{hh})S_{ij}(g^{hh})$ do not depend on the choice of the index h. This is a necessary condition for the separability of equation (6.5), which has the following equivalent formulation.

Theorem 6.2: *The necessary condition for the separability of the HJE* (6.5)

$$\frac{1}{g^{hh}}S_{ij}(g^{hh})=\frac{1}{g^{kk}}S_{ij}(g^{kk})\quad \textit{for all indices } h,\ k \textit{ and } i\neq j, \tag{6.10}$$

is equivalent to the existence of a function $\sigma\neq 0$ *such that the conformal metric* $\bar{g}^{ii}=g^{ii}/\sigma$ *is a Stäckel metric,*

$$\bar{S}_{ij}(\bar{g}^{kk})=0. \tag{6.11}$$

Proof: (i) If such a function σ exists, then by the second equation (6.4) we derive $(1/g^{kk})S_{ij}(g^{kk})=(1/\sigma)S_{ij}(\sigma)$. Hence, (6.10) follows. (ii) Conversely, assume that (6.10) holds. If we choose $\sigma=g^{11}$ then from the second equation (6.4) we get $\bar{S}_{ij}(\bar{g}^{kk})=0$. ■

Remark 6.2: From this proof it follows that condition (6.10) is verified if and only if (6.11) is satisfied with $\sigma=g^{jj}$ for any arbitrary choice of the index j.

This theorem suggests the following.

Definition 6.1: We call *conformal separable coordinates* orthogonal coordinates $\underline{q}=(q^i)$ for which conditions (6.10) or (6.11) hold.

Remark 6.3: A special class of orthogonal conformal separable coordinates is that for which $g^{ii}=c^i\sigma(\underline{q})$, $c^i\in\mathbb{R}$. In this case the components of the orthogonal conformal metric are $c^i=g^{ii}/\sigma$ = constant; hence, they are obviously of the Stäckel type. Up to a rescaling of the coordinates we can reduce to the case $g^{ii}=\pm\sigma$, according to the signature of the metric. Note that in this case the original metric (g^{ii}) is conformally flat. Orthogonal coordinates for which $g^{ii}=g^{jj}$ are called isothermal.

Now we apply Theorem 6.1 to the following three special cases:

$V=0,\quad E\neq 0,$	non-null geodesics,
$V=0,\quad E=0,$	null geodesics,
$V-E\neq 0,$	dynamical trajectories with total energy E.

The results for the null geodesics case date back to Stäckel[32] (see also Ref. 20).

Theorem 6.3: *The HJE* $\frac{1}{2}g^{ii}p_i^2=E$ *with a fixed value* $E\neq 0$, *is separable in orthogonal coordinates* (q^i) *if and only if* (g^{ii}) *is a Stäckel metric, i.e., if and only if it is separable in the ordinary sense for all values of* E.

Proof: For $V=0$ the second equation (6.6) gives $S_{ij}(g^{kk})=0$. ■

Theorem 6.4: *The HJE of the null geodesics*

$$g^{ii}p_i^2=0 \tag{6.12}$$

is separable in the orthogonal coordinates (q^i) *if and only if these coordinates are conformal separable.*

Proof: For $V=0$ and $E=0$ the second equations (6.6) are trivially satisfied, so that only the first equations characterize the separation. ■

Theorem 6.5: *The HJE*

$$\tfrac{1}{2}g^{ii}p_i^2 + V - E = 0 \quad (V - E \neq 0), \tag{6.13}$$

is separable if and only if the conformal metric

$$\bar{g}^{ii} = \frac{1}{E - V}g^{ii} \tag{6.14}$$

is a Stäckel metric, or equivalently, if and only if for all indices h, k and $i \neq j$,

$$\frac{1}{g^{kk}}S_{ij}(g^{kk}) = \frac{1}{V - E}S_{ij}(V). \tag{6.15}$$

This means that the coordinates are conformal separable, according to Definition 6.1, but the conformal factor σ must be equal to the function $V-E$.

Proof: For $V-E \neq 0$ system (6.6) is equivalent to (6.15). Moreover, let us consider the conformal metric (6.14) and the associated Stäckel operators $\bar{S}_{ij}$. From the second formula (6.4) with $\sigma = E - V$, we get

$$\bar{S}_{ij}(\bar{g}^{kk}) = \frac{1}{E - V}S_{ij}(g^{kk}) - \frac{g^{kk}}{(E - V)^2}S_{ij}(E - V).$$

Thus, $\bar{S}_{ij}(\bar{g}^{kk}) = 0$ is equivalent to (6.15). ■

Remark 6.4: The metric $\bar{g}^{ii} = (E-V)^{-1}g^{ii}$ is called the *Jacobi metric* or action metric (see, e.g., Ref. 33 and the references cited therein) of the natural Hamiltonian $H = G + V$ for the fixed value E of the total energy. Then, Theorem 6.5 can be reformulated as follows

Theorem 6.6: *The HJE* (6.13) *is separable if and only if the corresponding Jacobi metric is a Stäckel metric.*

We adapt to the Jacobi metric the considerations about the conformal Hamiltonians stated in Proposition 4.3 and Theorem 4.4.

With a natural Hamiltonian $H = G + V = \frac{1}{2}g^{ij}p_ip_j + V$ and a fixed value of the energy $E \in \mathbb{R}$ we associate two Hamiltonians,

$$H_E = \tfrac{1}{2}g^{ij}p_ip_j + V - E, \quad J_E = \tfrac{1}{2}\frac{g^{ij}}{E-V}p_ip_j.$$

The passage from the natural Hamiltonian $H = G + V$ to the geodesic Hamiltonian J_E is called Jacobi transformation[16,28,30] or Maupertuis transformation.[9,33]

Let $\mathbf{X}_H$ be the Hamiltonian vector field generated by H (it coincides with that generated by H_E) and $\mathbf{X}_J$ the Hamiltonian vector field generated by J_E. Adapting to these cases Proposition 4.3, Theorem 4.4, and Remark 4.5, we get the following.

Theorem 6.7: *Assume that equation $H_E = 0$ (i.e., $J_E = 1$) defines a regular hypersurface of T^*Q. Then* (i) *on this hypersurface the Hamiltonian vector fields $\mathbf{X}_H$ and $\mathbf{X}_J$ are parallel,*

$$(E - V)\mathbf{X}_J = \mathbf{X}_H, \tag{6.16}$$

and outside this surface the difference $(E-V)\mathbf{X}_J - \mathbf{X}_H$ is a vertical vector field. (ii) *On $H_E = 0$ the integral curves of the vector fields $\mathbf{X}_H$ and $\mathbf{X}_J$ coincide, up to a reparametrization, and the affine parameters t and $\bar{t}$ of $\mathbf{X}_H$ and $\mathbf{X}_J$, respectively, are related by $\mathrm{d}\bar{t} = (E-V)\mathrm{d}t$.* (iii) *Any first integral F of $\mathbf{X}_J$ is constant along the integral curves of $\mathbf{X}_H$ contained on $H_E = 0$.* (iv) *If a complete solution of the geodesic HJE $J_E = h$ is known, then for $h = 1$ we get the orbits of the field $\mathbf{X}_H$ on the hypersurface $H_E = 0$.*

Proof: By (4.23), we get (6.16). Moreover, due to (4.26), we have that $\mathbf{X}_H - (E-V)\mathbf{X}_J$ is vertical outside the hypersurface $H_E = 0$, since it is generated by the function $\Lambda = E - V$ which is constant along the fibers. ■

Hence, as a corollary of Theorem 6.6, we have the following.

Theorem 6.8: *The orthogonal separation (in the ordinary sense) of the geodesic HJE $J_E=h$ is equivalent to the orthogonal separation of the HJE $H_E=0$ for a fixed value E of the energy. For $h=1$ we get the orbits corresponding to the integral curves of $\mathbf{X}_H$ with total energy E.*

Remark 6.5: Equation (6.15) shows that $S_{ij}(V)=0$ if and only if $S_{ij}(g^{kk})=0$. These two conditions characterize the orthogonal Stäckel separation for a natural Hamiltonian. In this case the Jacobi metric is a Stäckel metric for all values of E. From (6.15) it follows also that if the conformal Jacobi metric (6.14) is a Stäckel metric for two distinct values $E_1 \neq E_2$ of the energy, then it is a Stäckel metric for all values of E. Indeed, from (6.15) written for $E=E_1$ and $E=E_2$ it follows that

$$\frac{1}{V-E_1}S_{ij}(V) = \frac{1}{V-E_2}S_{ij}(V).$$

Thus, $S_{ij}(V)=0$, so that also $S_{ij}(g^{kk})=0$. As a consequence, we have the following.

Theorem 6.9: *The HJE* (6.13) *is separable for two distinct values of the energy E if and only if it is separable in the ordinary sense.*

Remark 6.6: According to Theorem 6.9, we have that if a natural Hamiltonian $H=G+V$ is not separable in the ordinary sense, then there exists at most one value of the energy E such that $H=E$ is separable.

Remark 6.7: For a natural Hamiltonian in orthogonal coordinates the Lagrangian multipliers λ_i or the function Λ, involved in Theorems 4.1 and 4.3, respectively, which in general are functions on T^*Q, are necessarily constant along the fibers, i.e., they reduce in this case to functions on Q.

We conclude this section with the formulation of Theorems 6.2 and 6.3 in terms of Stäckel matrices. We recall that an orthogonal metric is a Stäckel metric if and only if it is a row of the inverse of a Stäckel matrix $\mathbf{S}=[\varphi_i^{(j)}(q^i)]$. By applying this definition to the general conformal metric $\overline{g}^{ii}=g^{ii}/\sigma$ and to the Jacobi metric (6.14) we get the following.

Theorem 6.10: (i) *Coordinates (q^i) are conformal separable if and only if there exists a Stäckel matrix $\mathbf{S}=[\varphi_i^{(j)}(q^i)]$ such that*

$$\frac{g^{ii}}{\varphi^i_{(n)}} = \frac{g^{jj}}{\varphi^j_{(n)}}, \tag{6.17}$$

where $[\varphi^i_{(j)}]=\mathbf{S}^{-1}$. (ii) *The Jacobi metric* (6.14) *is a Stäckel metric if and only if there exists a Stäckel matrix $\mathbf{S}=[\varphi_i^{(j)}(q^i)]$ such that* (6.17) *holds and moreover,*

$$E - V = \sum_i \varphi_i^{(n)} g^{ii}. \tag{6.18}$$

Proof: We have

$$\exists \sigma \left| \frac{g^{ii}}{\sigma} = \varphi^i_{(n)} \Leftrightarrow \frac{g^{ii}}{\varphi^i_{(n)}} = \frac{g^{jj}}{\varphi^j_{(n)}}, \right.$$

$$\frac{g^{ii}}{E-V} = \varphi^i_{(n)} \Leftrightarrow \frac{g^{ii}}{\varphi^i_{(n)}} = \frac{g^{jj}}{\varphi^j_{(n)}} \wedge E - V = \sum_i \varphi_i^{(n)} g^{ii}. \qquad \blacksquare$$

Remark 6.8: Let us denote by M^i_j the cofactor of $\varphi^{(i)}_j$. We have $\det \mathbf{S} = \Sigma_i \varphi_i^{(n)} M_i^n$ and

$$\varphi^i_{(n)} = \frac{M_i^n}{\det \mathbf{S}}.$$

Hence, (6.17) is equivalent to

$$\frac{g^{ii}}{M_i^n} = \cdots = \frac{g^{jj}}{M_j^n}.$$

We observe that in these conditions, only the first $n-1$ columns of the Stäckel matrix are involved, while the last column is involved only in the expression (6.18) of $E-V$. Hence, in the characterization of the null geodesic separation only a rectangular $n\times(n-1)$ Stäckel matrix is involved,

$$\begin{bmatrix} \varphi_1^{(1)} & \cdots & \varphi_1^{(n-1)} \\ \vdots & \vdots & \vdots \\ \varphi_n^{(1)} & \cdots & \varphi_n^{(n-1)} \end{bmatrix}.$$

VII. THE INTRINSIC CHARACTERIZATION OF THE ORTHOGONAL SEPARATION

Theorems 6.4 and 6.5 show that the separation of variables of the HJE for the null geodesics and for a fixed value of the energy is equivalent to the ordinary complete orthogonal separation of a conformal (contravariant) metric

$$\overline{\mathbf{G}} = \frac{1}{\sigma}\mathbf{G},$$

where $\overline{\mathbf{G}}=(\overline{g}^{ii})$, $\mathbf{G}=(g^{ii})$ and σ is a nowhere vanishing function on Q. In these two cases we have, respectively,

$$\sigma = \text{a suitable function on } Q \quad \text{for the null geodesics},$$

$$\sigma = E - V \quad \text{for the Jacobi metric}.$$

Since the ordinary geodesic separation can be characterized by means of Killing tensors (KT's), in both cases we are led to consider KT's of a conformal metric. A basic well known property is the following.

Proposition 7.1: A symmetric two-tensor $\mathbf{K}$ *is a KT for the conformal metric* $\overline{\mathbf{G}}=(1/\sigma)\mathbf{G}$ *i.e.*,

$$[\overline{\mathbf{G}},\mathbf{K}] = 0 \ (\Leftrightarrow \{P_{\overline{\mathbf{G}}}, P_{\mathbf{K}}\} = 0), \tag{7.1}$$

if and only if

$$[\mathbf{G},\mathbf{K}] = -\frac{2}{\sigma}\mathbf{K}\nabla\,\sigma\odot\mathbf{G} \quad \left(\Leftrightarrow \{P_{\mathbf{G}}, P_{\mathbf{K}}\} = -\frac{2}{\sigma}P_{\mathbf{K}\nabla\sigma}P_{\mathbf{G}}\right). \tag{7.2}$$

Notation: Here we denote by $[\cdot,\cdot]$ the Lie–Schouten bracket of contravariant symmetric tensors and by $\odot$ the symmetric tensor product. If we consider the homogeneous polynomial functions $P_{\mathbf{K}}$ on T^*Q associated with contravariant symmetric tensors $\mathbf{K}=(K^{i\cdots j})$ on Q, then this bracket is defined by $P_{[\mathbf{K}_1,\mathbf{K}_2]}=\{P_{\mathbf{K}_1}, P_{\mathbf{K}_2}\}$ and the symmetric product by $P_{\mathbf{K}_1\odot\mathbf{K}_2}=P_{\mathbf{K}_1}P_{\mathbf{K}_2}$. We say that $\mathbf{K}_1$ and $\mathbf{K}_2$ are in involution if $[\mathbf{K}_1,\mathbf{K}_2]=0$. We denote by $\mathbf{KX}$ the image of a vector field $\mathbf{X}$ by $\mathbf{K}$ interpreted as a (1,1) tensor.

Proof of Proposition 7.1: The equivalence of (7.1) and (7.2) is proved by the following calculation:

$$[\overline{\mathbf{G}},\mathbf{K}] = \left[\frac{1}{\sigma}\odot\mathbf{G},\mathbf{K}\right] = \frac{1}{\sigma}\odot[\mathbf{G},\mathbf{K}] + \left[\frac{1}{\sigma},\mathbf{K}\right]\odot\mathbf{G}$$
$$= \frac{1}{\sigma}[\mathbf{G},\mathbf{K}] - 2\mathbf{K}\nabla\frac{1}{\sigma}\odot\mathbf{G} = \frac{1}{\sigma}\left([\mathbf{G},\mathbf{K}] + \frac{2}{\sigma}\mathbf{K}\nabla\,\sigma\odot\mathbf{G}\right). \qquad \blacksquare$$

A symmetric two-tensor **K** is a conformal Killing tensor (CKT) if there exists a vector field **C** such that

$$[\mathbf{G},\mathbf{K}] = 2\mathbf{C}\odot\mathbf{G} \ (\Leftrightarrow\{P_{\mathbf{G}},P_{\mathbf{K}}\} = 2P_{\mathbf{C}}P_{\mathbf{G}}). \tag{7.3}$$

We say that **K** is a CKT of *gradient type* if there exists a function U such that $\mathbf{C}=\nabla U$. We say that **K** is a CKT of *self-gradient type* if $\mathbf{C}=\mathbf{K}\nabla U$.

We remark that in Proposition 7.1 the tensor **K** is a CKT of self-gradient type with respect to the metric **G** with $U=-\ln|\sigma|$.

Remark 7.1: The eigenvectors of **K** in Proposition 7.1 are the same with respect both metrics $\overline{\mathbf{G}}$ and **G**. If $\overline{\rho}^i$ are the eigenvalues of **K** with respect to $\overline{\mathbf{G}}$, then the eigenvalues with respect to **G** are

$$\rho^i = \frac{\overline{\rho}^i}{\sigma}. \tag{7.4}$$

If the eigenvalues are simple with respect to $\overline{\mathbf{G}}$, then they are also simple with respect to **G**.

Remark 7.2: Tensors of the kind $f\mathbf{G}$ are at the same time CKT's of gradient type (with $\mathbf{C}=\nabla f$, i.e., $U=f$) and of self-gradient type (with $\mathbf{C}=f\mathbf{G}\nabla \ln f$, i.e., $U=\ln f$).

Definition 7.1: Two CKT's **K** and $\mathbf{K}'$ are said to be *equivalent* if $\mathbf{K}'=\mathbf{K}+f\mathbf{G}$ for some function f.

Equivalent CKT's have the same eigenvectors. We shall be interested in equivalence classes of this kind. In any equivalence class there exists a trace-free representative, so that only trace-free CKT's are considered by some authors.[20,29,34]

As shown by the following proposition, in some special case a CKT **K** is equivalent to a tensor $\mathbf{K}'$ of self-gradient type (hence, a KT of a conformal metric).

Proposition 7.2: (i) *A CKT* **K** *which is diagonalized in orthogonal coordinates is equivalent to a CKT* $\mathbf{K}'$ *of self-gradient type.* (ii) *For any given orthogonal coordinate system there exists a function U such that any CKT* **K** *diagonalized in these coordinates is equivalent to a CKT* $\mathbf{K}'$ *of self-gradient type such that* $[\mathbf{G},\mathbf{K}']=2\mathbf{K}'\nabla U\odot\mathbf{G}$, *i.e., to a KT of the conformal metric* $\overline{\mathbf{G}}=e^U\mathbf{G}$. (iii) *The n functions* $U_k=-\ln|g^{kk}|$ *satisfy item (ii).*

Proof: If $g^{ij}=0$ and $K^{ij}=0$ for $i\neq j$, then $K^{ii}=\rho^i g^{ii}$ and Eq. (7.3) is equivalent to

$$\partial_i\rho^j = (\rho^i-\rho^j)\partial_i \ln g^{jj} + \partial_i\rho^i, \quad C_i = \partial_i\rho^i. \tag{7.5}$$

Let us take the tensor $\mathbf{K}'=\mathbf{K}-\rho^n\mathbf{G}$ with eigenvalues $\rho'^i=\rho^i-\rho^n$. By using (7.5) we get

$$\partial_i\rho'^j = (\rho'^i-\rho'^j)\partial_i \ln|g^{jj}| - \rho'^i\partial_i \ln|g^{nn}|.$$

This shows that $\mathbf{K}'$ is a CKT with $C'_i=-\rho'^i\partial_i\ln|g^{nn}|$, hence of self-gradient type with $U=-\ln|g^{nn}|$ and a KT for the conformal metric $\mathbf{G}/g^{nn}$. We remark that U does not depend on **K** but only on the given coordinates. ■

In the following two sections we give intrinsic versions of Theorems 6.4 and 6.5, respectively, for the case considered in Theorem 6.3 the intrinsic characterizations are just that of the ordinary orthogonal separation.[4,18] We shall use the following.

Definition 7.2: A (conformal) Killing two-tensor with simple eigenvalues and normal eigenvectors is called *characteristic (conformal) Killing tensor*.

A. The orthogonal separation of the null geodesics

A first characterization is related to the existence of a single CKT.

Theorem 7.1: *The HJE* (6.12) *for the null geodesics is separable in orthogonal coordinates if and only if on Q there exists a characteristic CKT* **K**.

Proof: According to the intrinsic characterization of the orthogonal separation of a geodesic Hamiltonian,[4,18] a metric $\overline{\mathbf{G}}$ is orthogonally separable if and only if it admits a KT **K**, $[\overline{\mathbf{G}},\mathbf{K}]=0$, with simple eigenvalues and normal eigenvectors. Since $\overline{\mathbf{G}}=\mathbf{G}/\sigma$, due to Proposition 7.1, this

is equivalent to the existence of a characteristic CKT satisfying equation (7.2). Proposition 7.2 shows that this is equivalent to the existence of a characteristic CKT without any other condition. ■

Remark 7.3: Theorem 7.1 was first stated by Kalnins and Miller (Ref. 20, Theorem 1, Sec. II with a different proof, not involving the use of self-gradient CKT's.

A second characterization is related to n CKT's.

Theorem 7.2: *The HJE* (6.12) *for the null geodesics is separable in orthogonal coordinates if and only if on Q there exist n CKT's* $(\mathbf{K}_i)=(\mathbf{K}_1,\mathbf{K}_2,\ldots,\mathbf{K}_n)$, (i) *pointwise independent,* (ii) *with common eigenvectors,* (iii) *in involution.*

Proof: By Theorem 8.8 of Ref. 7 the common eigenvectors are normal. There exists orthogonal coordinate systems in which all the tensors are diagonalized. Then, the pointwise independence implies the existence of a linear combination (with constant coefficients) $\mathbf{K}=c^i\mathbf{K}_i$ with simple eigenvalues. This is a conformal characteristic tensor. Then we apply Theorem 7.1. Conversely, since the separation of (6.12) is equivalent to the ordinary separation of a conformal metric $\overline{\mathbf{G}}=\mathbf{G}/\sigma$, there exist n KT's $\mathbf{K}_i$ for the conformal metric satisfying (i), (ii), (iii). Due to Proposition 7.1, these tensors are CKT's for $\mathbf{G}$. ■

Remark 7.4: In the intrinsic characterization of the ordinary orthogonal separation in terms of n independent KT's (in involution), the metric $\mathbf{G}$ may be one of them. On the contrary, in Theorem 7.2 none CKT's $\mathbf{K}_i$ can be the metric. Indeed, if one of the $\mathbf{K}_i$ is the metric, then condition (iii) implies that all $\mathbf{K}_i$ are KT's and we reduce to the ordinary orthogonal separation. In other words, the metric cannot belong to the linear space generated by the $\mathbf{K}_i$ (by linear combinations with constant coefficients). However,

Proposition 7.3: Given, n CKT's $\mathbf{K}_i$ *with common normal eigenvectors, there exist a linear combination with constant coefficients and a function f such that* $c^i\mathbf{K}_i=f\mathbf{G}$.

Proof: We apply the second part of Proposition 7.2. Then, there are equivalent CKT's of self-gradient type $\mathbf{K}_i'=\mathbf{K}_i+f_i\mathbf{G}$ with the same function U. They are KT's of the metric $e^U\mathbf{G}=\overline{\mathbf{G}}$ with common normal eigenvectors. Thus, there exists a linear combination with constant coefficients such that $c^i\mathbf{K}_i'=\overline{\mathbf{G}}$. It follows that $c^i\mathbf{K}_i=-c^if_i\mathbf{G}+e^U\mathbf{G}=f\mathbf{G}$ with $f=e^U-c^if_i$.■

A third characterization of the separability for (6.12) involves $n-1$ CKT's.

Theorem 7.3: *The HJE* (6.12) *for the null geodesics is separable in orthogonal coordinates if and only if on Q there exist* $n-1$ *CKT's* $(\mathbf{K}_\alpha)=(\mathbf{K}_1,\mathbf{K}_2,\ldots,\mathbf{K}_{n-1})$ *with* (i) *common normal eigenvectors (i.e., all simultaneously diagonalizable in orthogonal coordinates) and such that* (ii) $\mathbf{G},\mathbf{K}_1,\mathbf{K}_2,\ldots,\mathbf{K}_{n-1}$ *are pointwise independent.*

Proof: Due to the pointwise independence of the tensors, there exists a linear combination with constant coefficients having distinct eigenvalues, i.e., which is a characteristic CKT and by Theorem 7.1 we have the separation of variables for (6.12) Conversely, if (6.12) is separable, then the conformal metric $\overline{\mathbf{G}}$ is separable and there exists $n-1$ tensors $(\mathbf{K}_\alpha)$ which are (a) KT's with respect to $\overline{\mathbf{G}}$, (b) with common normal eigenvectors, and such that (c) $(\overline{\mathbf{G}},\mathbf{K}_1,\mathbf{K}_2,\ldots,\mathbf{K}_{n-1})$ are pointwise independent. Hence, $\mathbf{K}_\alpha$ satisfy (i), (ii), and (iii). ■

This theorem is a slightly modified version of Theorem 2, Sec. II of Ref. 20. In general, a set of tensors $(\mathbf{K}_\alpha)$ satisfying the hypotheses of Theorem 7.3 may not be in involution. However,

Proposition 7.4: The tensors $(\mathbf{K}_\alpha)$ *in Theorem 7.3 are equivalent to CKT's in involution.*

Proof: First of all we remark that also the tensors $\mathbf{K}_\alpha+f_\alpha\mathbf{G}$ satisfy the hypotheses of Theorem 7.3, for any choice of the $n-1$ nonzero functions f_α. By using equations (7.5), we see that two CKT's $\mathbf{K}_\alpha$, $\mathbf{K}_\beta$ (diagonalized in orthogonal coordinates) are in involution if and only if for all indices i,

$$\frac{C_{\alpha i}}{\rho_\alpha^i}=\frac{C_{\beta i}}{\rho_\beta^i}\quad(\alpha,\beta\in\{1,\ldots,n-1\}),\tag{7.6}$$

where ρ_α^i are the eigenvalues of $\mathbf{K}_\alpha$ and $C_{\alpha i}$ are the covariant components of the vector fields $\mathbf{C}_\alpha$ satisfying $[\mathbf{G},\mathbf{K}_\alpha]=2\mathbf{C}_\alpha\odot\mathbf{G}$. Condition (7.6) is not preserved by replacing the tensors by equivalent ones. Moreover, by Proposition 7.2 (ii), $\mathbf{K}_\alpha$ are equivalent to CKT's $\mathbf{K}_\alpha'$ of self-gradient type

with the same function U. By Proposition 7.1, $\mathbf{K}'_\alpha$ are KT's of the conformal metric $e^U\mathbf{G}$, having common normal eigenvectors. Hence, they are in involution. ■

There is an alternative formulation of Theorem 7.3, still involving $n-1$ CKT's, due to Kalnins and Miller (Ref. 20, Theorem 4, Sec. II):

Theorem 7.4: *The HJE* (6.12) *for the null geodesics is separable in orthogonal coordinates if and only if on Q there exist* $n-1$ *CKT's* $(\mathbf{K}_\alpha)=(\mathbf{K}_1,\mathbf{K}_2,\ldots,\mathbf{K}_{n-1})$ (i) *with common eigenvectors,* (ii) *in involution and such that* (iii) $\mathbf{G},\mathbf{K}_1,\mathbf{K}_2,\ldots,\mathbf{K}_{n-1}$ *are pointwise independent.*

We give here a proof which is based on the following general characterization of the integrability of frames, which is an extension of that given in Ref. 7, Theorem 8, Sec. VIII.

Theorem 7.5: *Let* $(\mathbf{X}_i)$ *a frame on Q. Let* $(\mathbf{K}_a)$ *be n contravariant symmetric two-tensors* (i) *pointwise independent,* (ii) *simultaneously diagonalized in the frame* $(\mathbf{X}_i)$ *and such that* (iii) *for each* $a\neq b$ *there exists a vector field* $\mathbf{C}_{ab}$ *and a symmetric two tensor* $\mathbf{M}_{ab}$ *diagonalized in the frame* $(\mathbf{X}_i)$ *such that*

$$\{P(\mathbf{K}_a),P(\mathbf{K}_b)\}=2P(\mathbf{C}_{ab})P(\mathbf{M}_{ab}). \tag{7.7}$$

Then, the frame is integrable and all the two-tensors are simultaneously diagonalized in a same coordinate system.

We recall (cf. Ref. 7) that (I) a frame is called *integrable* if for each index i the distribution Δ_i spanned by the vectors $(\mathbf{X}_1,\ldots,\mathbf{X}_{i-1},\mathbf{X}_{i+1},\ldots,\mathbf{X}_n)$ is completely integrable; (II) a frame is integrable if and only if the distributions Δ_{ij} spanned by pairs of vectors $(\mathbf{X}_i,\mathbf{X}_j)$ are completely integrable; (III) a frame is integrable if and only if there exist local coordinates (q^i) such that $\mathbf{X}_i=f_i\partial/\partial q^i$, where f_i are nowhere vanishing functions.

Proof: Let us set $[\mathbf{X}_i,\mathbf{X}_j]=\Omega_{ij}^h\mathbf{X}_h$, $\Omega_{ij}^h=-\Omega_{ji}^h$, $P(\mathbf{X}_i)=x_i$, so that $\{x_i,f\}=\langle\mathbf{X}_i,\mathrm{d}f\rangle$, $\{x_i,x_j\}=P([\mathbf{X}_i,\mathbf{X}_j])=\Omega_{ij}^hx_h$. Assumptions (ii) and (iii) mean that $\mathbf{K}_a=K_a^i\mathbf{X}_i\odot\mathbf{X}_i$, $\mathbf{M}=M^i\mathbf{X}_i\odot\mathbf{X}_i$. By recalling the calculation of Ref. 7, Sec. VIII, we have

$$\{P(\mathbf{K}_a),P(\mathbf{K}_b)\}=2\big(2K_a^iK_b^h\Omega_{ih}^j+(K_a^i\langle\mathbf{X}_i,\mathrm{d}K_b^k\rangle-K_b^i\langle\mathbf{X}_i,\mathrm{d}K_a^k\rangle)\delta_k^h\delta_k^j\big)x_ix_hx_j.$$

Being $2P(\mathbf{C}_{ab})P(\mathbf{M}_{ab})=2C_{ab}^kx_kM_{ab}^lx_l^2=2C_{ab}^kM_{ab}^lx_kx_l^2$, from Eq. (7.7) it follows that

$$\big(2K_a^iK_b^h\Omega_{ih}^j+(K_a^i\langle\mathbf{X}_i,\mathrm{d}K_b^k\rangle-K_b^i\langle\mathbf{X}_i,\mathrm{d}K_a^k\rangle-C_{ab}^iM_{ab}^k)\delta_k^h\delta_k^j\big)x_ix_hx_j=0.$$

This is a homogeneous polynomial equation which must be identically satisfied for all values of the variables (p_k), i.e., for all values of the variables (x_i), since $x_i=P(\mathbf{X}_i)=X_i^kp_k$, and $\det[X_i^k]\neq0$. Thus, all coefficients vanish. In particular, the coefficient of $x_1x_2x_3$ (as well as for all possible choices of three distinct indices) gives rise to equation

$$K_a^1K_b^2\Omega_{12}^3+K_a^1K_b^3\Omega_{13}^2+K_a^2K_b^3\Omega_{23}^1+K_a^2K_b^1\Omega_{21}^3+K_a^3K_b^1\Omega_{31}^2+K_a^3K_b^2\Omega_{32}^1=0.$$

From now on the proof is the same of Theorem 8.8 of Ref. 7. ■

Proof of Theorem 7.4: The tensors $(\mathbf{K}_a)=(\mathbf{G},\mathbf{K}_\alpha)$ fulfill the assumptions of Theorem 7.5. In particular, Eqs. (7.7) become

$$\{P(\mathbf{K}_\alpha),P(\mathbf{K}_\beta)\}=0,\quad \{P(\mathbf{K}_\alpha),P(\mathbf{G})\}=2P(\mathbf{C}_\alpha)P(\mathbf{G}).$$

Hence, the common eigenvectors are normal. ■

A final important remark is that Theorems 7.2 and 7.4 can be derived from more general statements.

Definition 7.2: We say that two symmetric two-tensors $\mathbf{K}_1$ and $\mathbf{K}_2$ on a Riemannian manifold are in conformal involution if there exists a vector field $\mathbf{C}_{12}$ such that

$$[\mathbf{K}_1,\mathbf{K}_2]=2\mathbf{C}_{12}\odot\mathbf{G}\quad(\Leftrightarrow\{P_{\mathbf{K}_1},P_{\mathbf{K}_2}\}=2P_{\mathbf{C}_{12}}P_{\mathbf{G}}). \tag{7.8}$$

Theorem 7.6: *The HJE* (6.12) *for the null geodesics is separable in orthogonal coordinates if and only if on Q there exist n CKT's* $(\mathbf{K}_i)=(\mathbf{K}_0,\mathbf{K}_1,\ldots,\mathbf{K}_{n-1})$ (i) *pointwise independent,* (ii) *with common eigenvectors and* (iii) *in conformal involution.*

Proof: The common eigenvectors are normal, since equation (7.8) is a particular case of (7.7). Item (i) implies the existence of a linear combination $\mathbf{K}=c^i\mathbf{K}_i$ with simple eigenvalues. Then we apply Theorem 7.1. Conversely, due to Theorem 7.2, the separation implies the existence of independent CKT's $\mathbf{K}_i$ satisfying (7.8) with $\mathbf{C}_{ij}=0$. ■

Remark 7.5: Theorem 7.6 is in perfect analogy with the intrinsic characterization of the ordinary orthogonal separation in terms of *n* independent KT's in involution: it is enough to cancel the word "conformal." This shows that the notion of conformal involution is a natural and useful extension of the ordinary involution.

Proposition 7.5: All CKT's diagonalized in orthogonal coordinates (q^i) *are in conformal involution.*

Proof: According to Proposition 7.2, two tensors $\mathbf{K}_1$, $\mathbf{K}_2$ diagonalized in (q^i) are equivalent to two KT's $\mathbf{K}_1'=\mathbf{K}_1-\rho_1^n\mathbf{G}$, $\mathbf{K}_2'=\mathbf{K}_2-\rho_2^n\mathbf{G}$ of the conformal metric $\overline{\mathbf{G}}=\mathbf{G}/g^{nn}$. Two simultaneously diagonalized KT's are in involution (Ref. 4, Sec. II). Hence,

$$[\mathbf{K}_1,\mathbf{K}_2]=[\mathbf{K}_1'+\rho_1^n\mathbf{G},\mathbf{K}_2'+\rho_2^n\mathbf{G}]=2(\mathbf{K}_1\nabla\rho_2^n-\mathbf{K}_2\nabla\rho_1^n)\odot\mathbf{G}.$$

■

Remark 7.6: As a consequence of this proposition, for two CKT's simultaneously diagonalized in orthogonal coordinates equation (7.7), $[\mathbf{K}_1,\mathbf{K}_2]=2\mathbf{C}_{12}\odot\mathbf{M}_{12}$, implies $\mathbf{M}_{12}=\mathbf{G}$, thus the conformal involution (7.8). In other words, in Theorem 7.6 by replacing the conformal involution conditions (iii), $[\mathbf{K}_i,\mathbf{K}_j]=2\mathbf{C}_{ij}\odot\mathbf{G}$ with $[\mathbf{K}_i,\mathbf{K}_j]=2\mathbf{C}_{ij}\odot\mathbf{M}_{ij}$ we do not get an extension of the theorem.

Remark 7.7: The CKT's $\mathbf{K}_i$ of Theorem 7.6 generate an *n*-dimensional space $\mathcal{K}$ of CKT's in conformal involution which are simultaneously diagonalized in orthogonal coordinates. We call such a space a *conformal Killing–Stäckel space* (CKS space). The existence of such a space is necessary and sufficient for the orthogonal separation of the null geodesic HJE. However, since properties (i), (ii), and (iii) in this theorem are invariant with respect to the equivalence transformations $\mathbf{K}_i\rightarrow\mathbf{K}_i'=\mathbf{K}_i+f_i\mathbf{G}$, there are infinitely many CKS-spaces $\mathcal{K}'$ associated with $\mathcal{K}$, corresponding to any choice of the functions f_i, having the same properties and diagonalized in the same coordinates. We remark that (I) each CKS space contain a tensor of the kind $f\mathbf{G}$ (i.e., a symmetric tensor with *n* coinciding eigenvalues). (II) There exists a CKS space which contains the metric tensor $\mathbf{G}$. Property (I) follows from Proposition 7.3. To prove (II), starting from the given $\mathbf{K}_i$, according to Proposition 7.3, we can find a linear combination such that $c^i\mathbf{K}_i=f\mathbf{G}$. Thus, if $c^0\neq 0$, we replace $\mathbf{K}_0$ by the equivalent tensor $\mathbf{K}_0'=\mathbf{K}_0+[(1-f)/c^0]\mathbf{G}$. Then the CKS space generated by $(\mathbf{K}_0',\mathbf{K}_1,\ldots,\mathbf{K}_{n-1})$ contains the metric $\mathbf{G}=c^0\mathbf{K}_0'+c^1\mathbf{K}_1+\cdots+c^{n-1}\mathbf{K}_{n-1}$. A consequence of these remarks is that we can reformulate Theorem 7.6 assuming that the metric tensor $\mathbf{G}$ is one of the $\mathbf{K}_i$. This shows that Theorem 7.4 follows from Theorem 7.6.

B. The orthogonal separation for $E-V\neq 0$

Theorem 7.7: *The HJE* (6.13) *for a fixed value E of the energy and for* $E-V\neq 0$ *is separable in orthogonal coordinates if and only if on Q there exists a characteristic CKT* $\mathbf{K}$ *such that*

$$[\mathbf{G},\mathbf{K}]=\frac{2}{E-V}\mathbf{K}\nabla V\odot\mathbf{G} \tag{7.9}$$

or, equivalently, if and only if there exist a function f and a characteristic CKT $\mathbf{K}'$ *such that*

$$[\mathbf{G},\mathbf{K}']=\frac{2}{E-V}(\mathbf{K}'\nabla V+\nabla f)\odot\mathbf{G}. \tag{7.10}$$

Proof: The proof of the first part of this statement follows the same pattern of that of Theorem 7.1, with $\sigma=E-V$. Moreover, if we find a characteristic CKT $\mathbf{K}'$ satisfying (7.10), then the equivalent tensor $\mathbf{K}=\mathbf{K}'-[f/(E-V)]\mathbf{G}$ satisfies condition (7.9). ■

Theorem 7.8: *The HJE (6.13) for a fixed value E of the energy and for* $E-V\neq 0$ *is separable*

in orthogonal coordinates if and only if on Q there exist n CKT's $(\mathbf{K}_i)=(\mathbf{K}_0,\mathbf{K}_1,\ldots,\mathbf{K}_{n-1})$ *(i) pointwise independent, (ii) with common eigenvectors, (iii) in conformal involution and such that*

$$[\mathbf{G},\mathbf{K}_i]=\frac{2}{E-V}(\mathbf{K}_i\nabla V+\nabla f_i)\odot\mathbf{G} \tag{7.11}$$

with suitable functions f_i.

Proof: Due to Theorem 7.5 and item (iii) the common eigenvectors are normal. Items (i) and (ii) imply the existence of a CKT with simple eigenvalues satisfying (7.10). Then we apply Theorem 7.7. Conversely, if (6.13) is separable, then the Jacobi metric $\overline{\mathbf{G}}=\mathbf{G}/(E-V)$ is separable. This means that there exists n KT's $\mathbf{K}_i$ for $\overline{\mathbf{G}}$, pointwise independent, with common eigenvectors, in involution, hence in conformal involution. Recalling Proposition 7.1, we have

$$[\mathbf{G},\mathbf{K}_i]=\tfrac{2}{E-V}\mathbf{K}_i\nabla V\odot\mathbf{G}.$$

This is a particular case of (7.11). ■

Remark 7.8: This theorem shows that, in other words, the orthogonal separation of the Jacobi metric is equivalent to the existence of a CKS space satisfying the additional condition (7.11). We observe that we can always modify the basis $(\mathbf{K}_i)$ in order to include the metric tensor $\mathbf{G}$. Due to Proposition 7.2, there exist a function f and n real numbers c^i not all equal to zero, such that $f\mathbf{G}=\Sigma_i c^i\mathbf{K}_i$. Up to a reordering of the tensors, we can suppose that $c^0\neq 0$. Then, $(\mathbf{G},\mathbf{K}_\alpha)=(\mathbf{G},\mathbf{K}_1,\ldots,\mathbf{K}_{n-1})$ satisfy items (ii), (iii) and are pointwise independent,

$$\det\begin{bmatrix} g^{ii} \\ K^{ii}_\alpha \end{bmatrix}=\frac{1}{f}\det\begin{bmatrix} c^jK^{ii}_j \\ K^{ii}_\alpha \end{bmatrix}=\sum_{\beta=1}^{n-1}\frac{c^\beta}{f}\det\begin{bmatrix} K^{ii}_\beta \\ K^{ii}_\alpha \end{bmatrix}+\frac{c^0}{f}\det\begin{bmatrix} K^{ii}_0 \\ K^{ii}_\alpha \end{bmatrix}=\frac{c^0}{f}\det[K^{ii}_j]\neq 0.$$

VIII. SEPARATED EQUATIONS

Summarizing the results of Sec. VII A, we have five intrinsic characterizations of the orthogonal separation of the null geodesic HJE: Theorem 7.1 (involving a single characteristic CKT), Theorem 7.2 (involving n CKT's in involution), Theorem 7.3 (involving $n-1$ simultaneously diagonalized CKT's), Theorem 7.4 (involving $n-1$ CKT's in involution), and Theorem 7.6 (involving n CKT's in conformal involution). We show how, for each one of these characterizations, we can reduce the HJE to separated ordinary differential equations. This reduction involves the use of Stäckel matrices. As shown in Ref. 2, we can state the following.

Lemma 8.1: Let $(F_i)=(F_1,\ldots,F_n)$ *be n independent functions of the form* $F_i=\varphi^j_{(i)}p_j^2$. *They are in involution if and only if the matrix* $[\varphi^j_{(i)}]$ *is the inverse of a Stäckel matrix* $\mathbf{S}=[\varphi^{(j)}_i]$.

Proof: We prove this statement in a direct way, without any reference with the known links between Stäckel matrices and the orthogonal separation. The condition

$$\{F_i,F_h\}=2(\varphi^k_{(i)}\partial_k\varphi^j_{(h)}-\varphi^k_{(h)}\partial_k\varphi^j_{(i)})p_kp_j^2=0$$

is equivalent to equations

$$\varphi^k_{(i)}\partial_k\varphi^j_{(h)}=\varphi^k_{(h)}\partial_k\varphi^j_{(i)},\quad k\ \text{n.s.} \tag{8.1}$$

(i) Multiplying by $\varphi^{(i)}_l$ and summing over i, we get the equivalent system $\delta^k_l\partial_k\varphi^{(h)}_j=-\varphi^k_{(h)}\Sigma_i\varphi^j_{(i)}\partial_k\varphi^{(i)}_l$. For $k\neq l$, $\varphi^k_{(h)}\Sigma_i\varphi^j_{(i)}\partial_k\varphi^{(i)}_l=0$. For any fixed index k there always exists an index h such that $\varphi^k_{(h)}\neq 0$. It follows that $\Sigma_i\varphi^j_{(i)}\partial_k\varphi^{(i)}_l=0$. And this is equivalent to $\partial_k\varphi^{(i)}_l=0$, for $k\neq l$. (ii) Conversely, let $[\varphi^{(j)}_i]$ be a Stäckel matrix. By applying ∂_k to equation $\varphi^i_{(h)}\varphi^{(l)}_i=\delta^l_h$, we get $\Sigma_i(\varphi^{(l)}_i\partial_k\varphi^i_{(h)})+\varphi^k_{(h)}\partial_k\varphi^{(l)}_k=0$. Let us multiply by $\varphi^j_{(l)}$ and sum over the index l; we get $\partial_k\varphi^j_{(h)}-\varphi^k_{(h)}\Sigma_l\varphi^{(l)}_k\partial_k\varphi^j_{(l)}=0$. If we multiply by $\varphi^k_{(i)}$ without summing over k, then we find $\varphi^k_{(i)}\partial_k\varphi^j_{(h)}=\varphi^k_{(i)}\varphi^k_{(h)}\Sigma_l\varphi^{(l)}_k\partial_k\varphi^j_{(l)}$. This shows that $\varphi^k_{(i)}\partial_k\varphi^j_{(h)}$ is symmetric with respect to the indices (i,h). Thus,

(8.1) is proved. ■

Case of Theorem 7.2: Let $(\mathbf{K}_i)$ be n CKT's satisfying the conditions of this theorem. The functions $F_i = K_i^{jj} p_j^2$ fulfill Lemma 8.1. Hence, $\varphi^j_{(i)} \doteq K_i^{jj}$ form the inverse $\mathbf{S}^{-1}$ of a Stäckel matrix. Moreover, since they are CKT's, see (7.3), we have $\{P_{\mathbf{G}}, F_i\} = 2P_{\mathbf{C}_i} P_{\mathbf{G}}$, where $P_{\mathbf{G}} = g^{ii} p_i^2$. This shows that F_i *are null first integrals* of the null geodesics [cf. (4.27)]. Since F_i are independent and in involution, equations

$$F_i(\underline{q}, \underline{p}) \doteq K_i^{jj} p_j^2 = c_i \tag{8.2}$$

describe a Lagrangian foliation on an open subset of T^*Q which is compatible with the submanifold of equation $g^{ii} p_i^2 = 0$ (see Sec. II). This foliation is the geometrical counterpart of an extended complete solution of the null HJE. This complete solution is separable. Indeed, by solving equations (8.2), $\varphi^j_{(i)} p_j^2 = c_i$, we get the separated equations

$$p_j^2 = \varphi_j^{(i)} c_i. \tag{8.3}$$

Case of Theorem 7.3: Let $(\mathbf{K}_\alpha) = (\mathbf{K}_1, \ldots, \mathbf{K}_{n-1})$ be $n-1$ CKT's satisfying the conditions of this theorem. They are diagonalized in orthogonal coordinates. Let us consider the diagonalized tensors $\mathbf{K}'_\alpha = \mathbf{K}_\alpha - \rho_\alpha^n \mathbf{G}$, where ρ_α^n are the last eigenvalues of $\mathbf{K}_\alpha$. Since $\rho_\alpha^n = K_\alpha^{nn}/g^{nn}$, the diagonal components of $\mathbf{K}'_\alpha$ are

$$K_\alpha^{jj} - K_\alpha^{nn} \frac{g^{jj}}{g^{nn}}. \tag{8.4}$$

By recalling the proof of Proposition 7.2, all $\mathbf{K}'_\alpha$ are KT's of the conformal metric $\mathbf{G}/g^{nn}$, simultaneously diagonalized, hence in involution. As a consequence, the $n-1$ functions

$$F_\alpha \doteq \left(K_\alpha^{jj} - K_\alpha^{nn} \frac{g^{jj}}{g^{nn}} \right) p_j^2$$

are null first integrals in involution of the null geodesics. Moreover, the function

$$F_n \doteq \frac{g^{jj}}{g^{nn}} p_j^2$$

is a further null first integral in involution. These n first integrals in involution are independent because of item (ii) of Theorem 7.3. Thus, due to Lemma 8.1, the functions

$$\varphi^j_{(\alpha)} \doteq K_\alpha^{jj} - K_\alpha^{nn} \frac{g^{jj}}{g^{nn}}, \quad \varphi^j_{(n)} \doteq \frac{g^{jj}}{g^{nn}},$$

form the inverse of a Stäckel matrix. It follows that equations

$$F_\alpha = \varphi^j_{(\alpha)} p_j^2 = c_\alpha, \quad F_n = \varphi^j_{(n)} p_j^2 = 0, \tag{8.5}$$

define a Lagrangian foliation of the submanifold $g^{ii} p_i^2 = 0$, which is the geometrical counterpart of an internal complete solution of the null HJE. This complete solution is separable. Indeed, by solving equations (8.5), $\varphi^j_{(i)} p_j^2 = c_i$, with $c_n = 0$, we get separated equations of the kind (8.3), but with $n-1$ constant parameters (c_α),

$$p_j^2 = \varphi_j^{(\alpha)} c_\alpha. \tag{8.6}$$

This result is in agreement with Remark 6.8.

Case of Theorem 7.4: The procedure is the same as for the case of Theorem 7.3.

Case of Theorem 7.6: Let $(\mathbf{K}_i)$ be n CKT's satisfying the conditions of this theorem. By recalling Remark 7.7, we can always find a linear (constant coefficients) combination such that $a^i \mathbf{K}_i = f\mathbf{G}$. When the constants a^i and the function f are determined, assuming (up to a reordering)

that $a^0 \neq 0$, we can replace $\mathbf{K}_0$ by $\mathbf{G}$, and we are in the case of Theorem 7.3.

Case of Theorem 7.1: We point out that Theorem 7.1 is convenient for characterizing the separation, since it involves only a single CKT. However, in order to get separated equations (involving a Stäckel matrix) we need to know $n-1$ CKT's. Let ρ^i be the eigenvalues of the given characteristic CKT $\mathbf{K}$. According to Proposition 7.2, the tensor $\widetilde{\mathbf{K}}=\mathbf{K}-\rho^n\mathbf{G}$ is a characteristic KT for the conformal metric $\overline{\mathbf{G}}=\mathbf{G}/g^{nn}$ (instead of the last one n, we can choose any other index). As it is well known, any characteristic KT generates a n-space of KT's simultaneously diagonalized in orthogonal coordinates, whose eigenvalues $\overline{\rho}^i$ with respect to the metric $\overline{\mathbf{G}}$ satisfy the Killing–Eisenhart equations

$$\partial_i \overline{\rho}^j = (\overline{\rho}^i - \overline{\rho}^j)\partial_i \ln \overline{g}^{jj} \tag{8.7}$$

which form a complete integrable system. Since $\overline{\rho}^j=(\rho^j-\rho^n)g^{nn}$, we observe that for the given tensor $\widetilde{\mathbf{K}}$ we have $\overline{\rho}^n=0$. We observe that, following Kalnins and Miller,[20] if we set $\mu^i=\rho^i-\rho^n$, then from (8.7) we obtain equations

$$\partial_i \mu^j = (\mu^i - \mu^j)\partial_i \ln g^{jj} - \mu^i \partial_i \ln g^{nn},$$

which summarize Eqs. (2.8) of Ref. 20. Let us take n independent solutions $\overline{\rho}_i^j$ of system (8.7) with $\overline{\rho}_n^j=1$ for all j. The corresponding tensors $\mathbf{K}_i$ of components $K_i^{jj}=\overline{\rho}_i^j g^{jj}/g^{nn}$ are independent KT's for $\overline{\mathbf{G}}$ such that $\mathbf{K}_n=\overline{\mathbf{G}}$. This means that

$$\varphi_{(i)}^j = K_i^{jj} = \overline{\rho}_i^j g^{jj}/g^{nn}$$

form the inverse of a Stäckel matrix and equations $\varphi_{(i)}^j p_j^2 = c_i$ are equivalent to the separated equations $p_j^2=\varphi_j^{(i)}c_i$. This gives an extended separated solution. For $c_n=0$ we get the null geodesics.

Finally, let us consider the case of $E-V\neq 0$.

Case of Theorem 7.8: Let $(\mathbf{K}_i)=(\mathbf{K}_0,\ldots,\mathbf{K}_{n-1})$ be n CKT's satisfying the conditions of this theorem. By recalling the proof of Theorem 7.7, if we perform the equivalence transformation $\widetilde{\mathbf{K}}_i=\mathbf{K}_i-[f_i/(E-V)]\mathbf{G}$ we get n KT's of the Jacobi metric $\overline{\mathbf{G}}=\mathbf{G}/(E-V)$, characterizing its orthogonal separation. Then the functions $\varphi_{(i)}^j=K_i^{jj}-f_i/(E-V)$ form the inverse of a Stäckel matrix. By solving equations $\varphi_{(i)}^j p_j^2=c_i$, we get the separated equations

$$p_j^2 = \varphi_j^{(i)} c_i \tag{8.8}$$

thus, a complete separated solution of the HJE,

$$(E-V)^{-1} g^{ii} p_i^2 = 2h. \tag{8.9}$$

The separated solution following from (8.8) is an extended separated solution of the HJE $\frac{1}{2}g^{ii}p_i^2 = E-V$ with the fixed value E of the energy. By substituting in (8.9) the expressions of p_j given by (8.8), we get an equation of the kind $h=h(c_i)$. It follows that for $h=1$ we get equation $h(c_i)=1$. When the constants c_i satisfy this equation we get an internal separated solution of the HJE for the given value E of the energy.

Case of Theorem 7.7: If we have a characteristic CKT tensor $\mathbf{K}'$ satisfying (7.10), then $\mathbf{K}=\mathbf{K}'-[f/(E-V)]\mathbf{G}$ is characteristic KT of the Jacobi metric $\overline{\mathbf{G}}=\mathbf{G}/(E-V)$. System (8.7) with $\overline{g}^{jj}=g^{jj}/(E-V)$ is completely integrable and provides n independent solutions $\overline{\rho}_i^j$ with $\overline{\rho}_n^j=1$ for all j. With such a solution we define the inverse of a Stäckel matrix by setting $\varphi_{(i)}^j=\overline{\rho}_i^j g^{jj}/(E-V)$. Then, by solving equations $\varphi_{(i)}^j p_j^2=c_i$ we get separated equations which define an extended separated solution. By setting $c_n=1$ we get an internal separated solution. We remark that in both cases the Stäckel matrices depend on the value E.

IX. THE TWO-DIMENSIONAL CASE

A two-dimensional Riemannian manifold is always conformally flat. The link between the conformal separation in two dimensions, the analytical functions and the CKT's is examined in Ref. 28, and used for generalizing a result of Ref. 25. We show here how some known results follow from the general theory developed in the preceding sections.

We can write the most general 2×2 Stäckel matrix in two variables in the form

$$\mathbf{S}=\begin{bmatrix}\phi_1(q^1) & \psi_1(q^1)\\ \phi_2(q^2) & \psi_2(q^2)\end{bmatrix},\quad \phi_1\psi_2-\phi_2\psi_1\neq 0. \tag{9.1}$$

The inverse matrix is

$$\mathbf{S}^{-1}=\frac{1}{\phi_1\psi_2-\phi_2\psi_1}\begin{bmatrix}\psi_2 & -\psi_1\\ -\phi_2 & \phi_1\end{bmatrix}. \tag{9.2}$$

The components $\bar{g}^{ii}$ of a separable orthogonal metric $\overline{\mathbf{G}}$ and of the associated KT $\mathbf{K}$ are given by the second and the first line of $\mathbf{S}^{-1}$,

$$[\bar{g}^{11},\bar{g}^{22}]=\frac{1}{\phi_1\psi_2-\psi_1\phi_2}[-\phi_2,\phi_1],\quad [K^{11},K^{22}]=\frac{1}{\phi_1\psi_2-\psi_1\phi_2}[\psi_2,-\psi_1].$$

Then Theorem 6.10 implies the following.

Theorem 9.1: (i) *The HJE of the null geodesics* (6.12) *is separable in the orthogonal coordinates* (q^1,q^2) *if and only if there exist two nowhere vanishing functions* $\xi_1(q^1)$ *and* $\xi_2(q^2)$ *such that*

$$\frac{g^{11}}{g^{22}}=\frac{\xi_1}{\xi_2}. \tag{9.3}$$

(ii) *The HJE* (6.13), *for a fixed value of* E *and for* $E-V\neq 0$, *is separable in the orthogonal coordinates* (q^1,q^2) *if and only if there exist four functions* $(\xi_1(q^1),\xi_2(q^2),\psi_1(q^1),\psi_2(q^2))$, *with*

$$\frac{\psi_2}{\xi_1}+\frac{\psi_1}{\xi_2}\neq 0, \tag{9.4}$$

such that (9.3) *holds and moreover*,

$$E-V=\psi_1 g^{11}+\psi_2 g^{22}. \tag{9.5}$$

Proof: From (6.17) and (9.2) it follows that there exist functions $\phi_1(q^1)$ and $\phi_2(q^2)$ such that $g^{11}/g^{22}=-\phi_2/\phi_1$. The functions ξ_i of the statement are then given by $\xi_1=1/\phi_1$ and $\xi_2=-1/\phi_2$. Formula (9.5) follows from (6.18) and (9.1). Condition (9.4) is the regularity condition of the Stäckel matrix (9.1). ■

From Theorem 9.1 it follows that on a two-dimensional Riemannian manifold, orthogonal coordinates (q^1,q^2) are conformal separable coordinates if and only if the ratio g^{11}/g^{22} has the form (9.3), which is equivalent to say that g^{11}/g^{22} is a product of two functions depending only on q^1 and q^2, respectively. In Remark 6.3 we have seen that coordinates satisfying $g^{ii}=c^i\sigma(\underline{q})$ $(c^i\in\mathbb{R})$ are conformal separable. The following theorem shows that in fact any two-dimensional conformal separable system is of this kind.

Theorem 9.2: *On a two-dimensional manifold an orthogonal coordinate system is conformal separable if and only if, up to a rescaling,*

$$g^{11}=\pm g^{22}. \tag{9.6}$$

Proof: According to Remark 6.3, if (9.6) holds, then the coordinates are conformal separable. Conversely, assume that (9.3) holds. Then $g_{11}=\rho/\xi_1$, $g_{22}=\rho/\xi_2$, and

$$ds^2 = g_{11}(dq^1)^2 + g_{22}(dq^2)^2 = \rho\left(\frac{(dq^1)^2}{\xi_1} + \frac{(dq^2)^2}{\xi_2}\right).$$

In the coordinates $(\tilde{q}^i)$ defined by the rescaling $d\tilde{q}^i = |\xi_i|^{-1/2}\, dq^i$ we have $ds^2 = \rho(e_1(d\tilde{q}^1)^2 + e_2(d\tilde{q}^2)^2)$, where $e_i = \mathrm{sign}(\xi_i)$. It follows that $\tilde{g}_{ii} = \rho e_i$. ■

Remark 9.1: If (9.6) holds, from (9.3) and (9.5) it follows that $\xi_2 = \pm\xi_1 = \text{constant}$ and $E - V = (\psi_1 \pm \psi_2)g^{11}$. Then the Stäckel matrix (9.1) and its inverse (9.2) have the form

$$\mathbf{S} = \begin{bmatrix} c & \psi_1(q^1) \\ \mp c & \psi_2(q^2) \end{bmatrix}, \quad \psi_2 \pm \psi_1 \neq 0, \quad \mathbf{S}^{-1} = \frac{1}{c(\psi_2 \pm \psi_1)} \begin{bmatrix} \psi_2 & -\psi_1 \\ \pm c & c \end{bmatrix}.$$

Let us consider the particular case of the Euclidean plane $\mathbb{E}_2$, with Cartesian coordinates (x,y). We recall the following (see, e.g., Ref. 28).

Proposition 9.1: *If $f(z) = u(x,y) + iv(x,y)$, $z = x + iy$, is a non constant analytic function, then in the open domain where $\nabla u \neq 0$ the real and the imaginary parts define conformal separable coordinates $q^1 = u(x,y)$ and $q^2 = v(x,y)$ such that $g^{11} = g^{22}$.*

Proof: From the Cauchy–Riemann conditions

$$u_x = v_y, \quad u_y = -v_x \tag{9.7}$$

(the suffixes denote the partial derivatives) it follows that

$$g^{12} = u_x v_x + u_y v_y = 0, \quad g^{11} = (u_x)^2 + (u_y)^2 = (v_y)^2 + (v_x)^2 = g^{22}. \tag{9.8}$$

Then we apply Remark 9.1. The coordinate transformation is singular at those points where the partial derivatives (9.7) vanish, since

$$\det\begin{bmatrix} u_x & v_x \\ u_y & v_y \end{bmatrix} = u_x v_y - v_x u_y = (u_x)^2 + (u_y)^2 .$$ ■

By applying Theorem 9.2, we prove the converse of Proposition 9.1.

Proposition 9.2: *Up to a rescaling, every conformal separable system of the Euclidean plane is generated by a nonconstant analytic function.*

*Proof:*According to Theorem 9.2, we can rescale a conformal separable coordinate system in order to have $g^{11} = g^{22}$ and such that the corresponding coordinate transformation satisfies (9.8). The solutions of (9.8) are

$$\begin{aligned} u_x &= v_y, & u_x &= -v_y, \\ u_y &= -v_x, & u_y &= v_x, \end{aligned}$$

which are the Cauchy–Riemann conditions for $f = u(x,y) + iv(x,y)$ or $\tilde{f} = v(x,y) + iu(x,y)$. Hence the coordinates are generated by an analytic function. ■

Remark 9.2: The real and imaginary part of a given analytic function are both harmonic functions on $\mathbb{R}^2$, i.e., solutions of the Laplace equation in the plane $\Delta u = 0$. Conversely, each harmonic function $u(x,y)$ can be chosen as real part of an analytic function. The corresponding imaginary part $v(x,y)$ is determined up to an additive constant.

Remark 9.3: It is possible to associate with every harmonic function a class of potentials, depending on two real parameters a, b, which are separable for a single value of the energy. The conformal separable coordinates and the suitable value of E depend on (a,b). Let $u(x,y)$ be a harmonic function. Then, the functions $\tilde{u} = u + ax + by$, $a,b \in \mathbb{R}$ are harmonic. According to Remark 9.2, we construct a coordinate transformation

$$q^1 = q^1(x,y) = \tilde{u}, \quad q^2 = q^2(x,y) = \tilde{v},$$

with $\tilde{v}$ such that $\tilde{u} + i\tilde{v}$ is analytic. For these coordinates we have

$$g^{11} = g^{22} = \left(\frac{\partial \tilde{u}}{\partial x}\right)^2 + \left(\frac{\partial \tilde{u}}{\partial y}\right)^2.$$

Hence, (q^1, q^2) are conformal separable coordinates compatible with a natural Hamiltonian $H = G + V$ for a fixed value of the energy E if and only if

$$E - V = (\psi_1(q^1) + \psi_2(q^2))g^{11}. \tag{9.9}$$

In particular, the case $E - V = g^{11}$ is satisfied by choosing $E = a^2 + b^2$ and

$$V(x,y) = \left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2 + 2a\frac{\partial u}{\partial x} + 2b\frac{\partial u}{\partial y}. \tag{9.10}$$

In the following example we consider a dynamical system with a scalar potential depending on a single parameter a, which is a special case of the potential (9.10) obtained by considering $b = 0$ in the preceding discussion.

Example 9.1: In $\mathbb{E}_2$ let us consider the potential

$$V(x,y) = -\frac{2ax + 1}{x^2 + y^2},$$

where (x,y) are Cartesian coordinates and a is a real parameter. By examining the separability condition

$$\mathrm{d}(\mathbf{K}\,\mathrm{d}V) = 0, \tag{9.11}$$

where $\mathbf{K}$ is a generic KT of the Euclidean plane (see Ref. 6 for the details of this technique), we find that, for $a \neq 0$, (9.11) is satisfied only for $\mathbf{K} = \mathbf{G}$ (the metric tensor). Thus, for $a \neq 0$, V is not separable in $\mathbb{E}_2$. However, for any value of $a \neq 0$ there is a suitable value of the energy E, such that the HJE $G + V - E = 0$ is separable in a conformal coordinate system depending on a. Let us consider

$$q^1 = \log\sqrt{x^2 + y^2} + ax = \log \varrho + a\varrho \cos \vartheta, \quad q^2 = \arctan\left(\frac{y}{x}\right) + k\pi + ay = \vartheta + a\varrho \sin \theta.$$

With respect to these coordinates we have

$$g^{11}(q^1,q^2) = g^{22}(q^1,q^2) = \frac{x^2}{(x^2 + y^2)^2} + a^2 + \frac{2ax}{x^2 + y^2} + \frac{y^2}{(x^2 + y^2)^2} = \frac{2ax + 1}{x^2 + y^2} + a^2.$$

Thus, (q^1, q^2) are conformally separable. Moreover, since for $E = a^2$ we get $E - V = g^{11}$, which is of the form (9.9), we have the separation of variables for the fixed value of the energy $E = a^2$. Now we solve the HJE and the corresponding dynamical system. We construct the Stäckel matrix $\mathbf{S}$ associated with (q^1, q^2). By applying to this special case (9.3), (9.4), and (9.9), we have

$$\xi_1 = 1 = \xi_2, \quad \psi_1 = 1, \quad \psi_2 = 0,$$

so that the Stäckel matrix and its inverse are

$$\mathbf{S} = \begin{bmatrix} 1 & 1 \\ -1 & 0 \end{bmatrix}, \quad \mathbf{S}^{-1} = \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix}.$$

A basis of the conformal Killing–Stäckel space is

$$\mathbf{G} = \frac{\partial}{\partial q^1} \otimes \frac{\partial}{\partial q^1} + \frac{\partial}{\partial q^2} \otimes \frac{\partial}{\partial q^2}, \quad \mathbf{K} = \frac{\partial}{\partial q^2} \otimes \frac{\partial}{\partial q^2}.$$

With respect to the new coordinates, the natural Hamiltonian

$$\mathcal{H} = \frac{1}{2}p_x^2 + \frac{1}{2}p_y^2 - \frac{2ax+1}{x^2+y^2} - a^2$$

becomes the geodesic Hamiltonian $J_E = \frac{1}{2}p_1^2 + \frac{1}{2}p_2^2$. The quadratic first integral is $H_K = \frac{1}{2}p_2^2$. The separated equations are given by the system

$$\begin{array}{ll} J_E = h, & \\ H_K = c, & \end{array} \Leftrightarrow \begin{array}{l} \frac{1}{2}p_1^2 + \frac{1}{2}p_2^2 = h, \\ \frac{1}{2}p_2^2 = c, \end{array} \Leftrightarrow \begin{array}{l} p_1^2 = 2(h-c), \\ p_2^2 = 2c. \end{array}$$

The constants have to fulfill the conditions $0 \leqslant c \leqslant h$. The integral curves of the Hamilton equations are

$$p_1 = \pm\sqrt{2(h-c)}, \quad p_2 = \pm\sqrt{2c}, \quad q^1 = \pm\sqrt{2(h-c)}t + q_0^1, \quad q^2 = \pm\sqrt{2c}t + q_0^2,$$

and their orbits are described by the equation

$$q^1 - q_0^1 = \pm\sqrt{\frac{h-c}{c}}(q^2 - q_0^2).$$

For $h=1$, we have the orbits of $\mathcal{H}=0$, i.e., of the natural Hamiltonian with potential V and energy $E=a^2$, parametrized by $c \in (0,1)$. In Cartesian coordinates the orbits are given by

$$\log\sqrt{x^2+y^2} + ax = \pm\sqrt{\frac{1-c}{c}}\left[\arctan\left(\frac{y}{x}\right) + k\pi + ay\right] + d$$

and in polar coordinates (ϱ, ϑ) by

$$\log\varrho + a\varrho\cos\vartheta = \pm\sqrt{\frac{1-c}{c}}(\vartheta + a\varrho\sin\theta) + d,$$

where $d = q_0^1 \pm \sqrt{[1-c/c]}q_0^2$ is a constant depending on the initial point.

Remark 9.4: For $n>2$ it is no longer possible to relate conformal separable coordinates with analytic functions, as for the case $n=2$. However, it can be seen that the orthogonal coordinate systems which allow the R-separation of the Laplace equation in n-dimensional manifolds with constant curvature, obtained by different methods,[8,10,17,19,27] and known in the Euclidean three-space as confocal cyclides[12,13] are all conformal separable coordinates according to our Definition 6.1. This fact exhibits the deep relation between the R-separation and the separation of the HJE with a fixed value of the energy developed in this paper. Indeed, both conformal separable and R-separable coordinates are characterized by CKT's (see, e.g., Ref. 20). A further analysis of this link is in progress.

(Received 12 February 2004; accepted 3 December 2004; published online 25 March 2005)

In this paper we study equations of magnetic hydrodynamics with a stress tensor. We interpret this system as the generalized Euler equation associated with an Abelian extension of the Lie algebra of vector fields with a nontrivial 2-cocycle. We use the Lie algebra approach to prove the energy conservation law and the conservation of cross-helicity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1857065]

I. INTRODUCTION

Magnetic hydrodynamics (MHD) describes evolution of a fluid or plasma, carrying a magnetic field. This theory is used to model the processes in the Solar corona,[22] as well as to design tokamaks.[14] There are numerous books treating various aspects of the subject, see e.g., Refs. 9 and 20.

The MHD equations are derived from the Euler equation of motion of an incompressible fluid and the Maxwell's electrodynamics equations, and describe evolution of a fluid with the velocity vector field $\mathbf{v}$ and the magnetic field $\mathbf{B}$,

$$\frac{\partial \mathbf{v}}{\partial t} = -(\mathbf{v}\cdot\nabla)\mathbf{v} + (\mathbf{B}\cdot\nabla)\mathbf{B} - \nabla p,$$

$$\frac{\partial \mathbf{B}}{\partial t} = -\{\mathbf{v},\mathbf{B}\},$$

$$\operatorname{div}(\mathbf{v}) = 0, \quad \operatorname{div}(\mathbf{B}) = 0. \tag{1.1}$$

In this paper we study another system of PDEs, where we add extra terms into the evolution equation for the velocity,

$$\frac{\partial \mathbf{v}}{\partial t} = -(\mathbf{v}\cdot\nabla)\mathbf{v} + (\mathbf{B}\cdot\nabla)\mathbf{B} + \sum_{i,j} \frac{\partial B_i}{\partial x_j}\nabla\frac{\partial v_j}{\partial x_i} - \nabla p. \tag{1.2}$$

The additional terms here are of the third degree in derivatives and one can draw certain parallels between (1.2) and the Korteweg–de Vries equation,

$$u_t = uu_x + u_{xxx}. \tag{1.3}$$

We interpret the extra terms in (1.2) as a contribution of a stress tensor,

$$T_{ki} = \sum_j \frac{\partial B_i}{\partial x_j}\frac{\partial v_j}{\partial x_k}. \tag{1.4}$$

This stress tensor is not symmetric, which indicates that the particles of the fluid should possess electric or magnetic momentum.

[a)]Electronic mail: billig@math.carleton.ca

In spite of the additional higher-order terms, the new system of PDEs retains many features of the original system. In particular, we show that it still admits the Alfvén wave solutions.

We follow an approach developed by Arnold to give an interpretation of the MHD equations with the stress tensor as a generalized Euler equation. A generalized Euler equation is an equation for the geodesics on a (possibly infinite-dimensional) Lie group supplied with a Riemannian structure. This equation describes the evolution of a tangent vector of the geodesic in the Lie algebra of the Lie group (see Sec. III for details).

The Lie algebra that corresponds to the MHD equations with the stress tensor is an Abelian extension $\mathfrak{g}(\tau)$ of the Lie algebra of the divergence zero vector fields twisted with a nontrivial 2-cocycle τ. This Lie algebra was studied in the framework of the representation theory of the toroidal Lie algebras and the cocycle plays a prominent role there.

Infinite-dimensional groups associated with Abelian extensions of the Lie algebra of vector fields are discussed in Ref. 8.

The Lie algebra $\mathfrak{g}(\tau)$ has nice properties and this translates into nice properties of the PDEs. In particular we establish the energy conservation law and the cross-helicity conservation for MHD with the stress tensor.

Ovsienko and Khesin showed in Ref. 21 that the generalized Euler equation for the Lie algebra of vector fields on a circle yields the nonlinear wave equation $u_t = uu_x$, while incorporation of the Virasoro cocycle into the Lie algebra leads to the Korteweg–de Vries equation (1.3). In a way, the present paper may be viewed as a higher-dimensional generalization of Ref. 21.

The paper is organized as follows: in Sec. II we discuss the properties of the system (1.2), derive the expression for the stress tensor, list the conservation laws and describe the Alfvén wave solutions. In Sec. III we review the generalized Euler equation for an arbitrary Lie algebra and we apply this method in Sec. IV to an Abelian extension of the Lie algebra of the divergence zero vector fields, deriving (1.2), and establishing the conservation laws in a purely algebraic way.

II. MAGNETIC HYDRODYNAMICS WITH A STRESS TENSOR AND ITS PROPERTIES

Evolution of an incompressible fluid carrying a magnetic field is given by the equations of magnetic hydrodynamics (MHD),

$$\frac{\partial \mathbf{v}}{\partial t} = -(\mathbf{v}\cdot\nabla)\mathbf{v} + (\mathbf{B}\cdot\nabla)\mathbf{B} - \nabla p,$$

$$\frac{\partial \mathbf{B}}{\partial t} = -\{\mathbf{v},\mathbf{B}\},$$

$$\operatorname{div}(\mathbf{v}) = 0, \quad \operatorname{div}(\mathbf{B}) = 0. \tag{2.1}$$

Here $\mathbf{B}$ is the magnetic field, $\mathbf{v}$ is the velocity vector field of the fluid, and p (pressure) is an auxiliary function which is chosen in such a way that the equation $\operatorname{div}(\mathbf{v})=0$ is satisfied. The formal dot product $\mathbf{v}\cdot\nabla$ represents the differential operator

$$\mathbf{v}\cdot\nabla = \sum_j v_j \frac{\partial}{\partial x_j}.$$

The Poisson (Lie) bracket $\{\mathbf{v},\mathbf{B}\}$ of two vector fields $\mathbf{v}=\Sigma_j v_j(x)(\partial/\partial x_j)$ and $\mathbf{B}=\Sigma_j B_j(x)(\partial/\partial x_j)$ is given by

$$\{\mathbf{v},\mathbf{B}\} = \operatorname{ad}(\mathbf{v})\mathbf{B} = (\mathbf{v}\cdot\nabla)\mathbf{B} - (\mathbf{B}\cdot\nabla)\mathbf{v} = \sum_j \left(v_j \frac{\partial \mathbf{B}}{\partial x_j} - B_j \frac{\partial \mathbf{v}}{\partial x_j} \right).$$

In the three-dimensional space, the first equation in (2.1) may be also written as

$$\frac{\partial \mathbf{v}}{\partial t} = \mathbf{v} \times \operatorname{curl}(\mathbf{v}) + \operatorname{curl}(\mathbf{B}) \times \mathbf{B} - \nabla p.$$

For a conducting medium, the curl of the magnetic field is equal to the electric current (Ampère's law), and so the expression curl $(\mathbf{B}) \times \mathbf{B}$ represents the Lorentz force, with which the magnetic field acts on the current.

The configuration space for a flow of an incompressible fluid is the group of volume-preserving diffeomorphisms. In his remarkable paper,[2] Arnold interpreted the Euler equation for an ideal fluid as the geodesic equation on this Lie group. The geodesic equation describes the evolution of the tangent vector of the geodesic curve, and this tangent vector belongs to the Lie algebra, which is the Lie algebra SVect of the divergence zero vector fields, in case of the group of volume preserving diffeomorphisms.

Using Arnold's method, Vishik and Dolzhanskii[24] (see also Ref. 17) showed that the MHD equations (2.1) also may be interpreted as a geodesic equation for a certain infinite-dimensional Lie group. The Lie algebra that is used to write this equation is the semidirect product

$$\mathrm{SVect} \oplus \Omega^1/\mathrm{d}\Omega^0$$

of the Lie algebra of divergence zero vector fields SVect with its dual space—the factor $\Omega^1/\mathrm{d}\Omega^0$ of the differential 1-forms modulo the exact 1-forms. We review this construction in detail in Sec. III.

The Lie algebra that is associated with the MHD equations,

$$\mathfrak{g} = \mathrm{SVect} \oplus \Omega^1/\mathrm{d}\Omega^0,$$

has recently attracted much interest in representation theory. It turns out that representations of $\mathfrak{g}$ may be used for constructing modules for toroidal Lie algebras (see, e.g., Refs. 5, 6, and 11). It was also discovered that this Lie algebra has an important deformation—the Lie bracket in $\mathfrak{g}$ may be twisted with a Virasoro-like 2-cocycle τ. The twisted Lie algebra $\mathfrak{g}(\tau)$ still has nice properties, and its representation theory is even better than for $\mathfrak{g}$ itself.

In this paper we study the system of PDEs that comes from the geodesic equation for $\mathfrak{g}(\tau)$. In Sec. IV we show that this Lie algebra yields the following system of PDEs:

$$\frac{\partial \mathbf{v}}{\partial t} = -(\mathbf{v} \cdot \nabla)\mathbf{v} + (\mathbf{B} \cdot \nabla)\mathbf{B} + \sum_{i,j} \frac{\partial B_i}{\partial x_j} \nabla \frac{\partial v_j}{\partial x_i} - \nabla p,$$

$$\frac{\partial \mathbf{B}}{\partial t} = -\{\mathbf{v}, \mathbf{B}\},$$

$$\operatorname{div}(\mathbf{v}) = 0, \quad \operatorname{div}(\mathbf{B}) = 0. \tag{2.2}$$

Let us discuss the properties of this system of PDEs.

First of all, we note that the new term

$$\sum_{i,j} \frac{\partial B_i}{\partial x_j} \nabla \frac{\partial v_j}{\partial x_i} = \sum_{i,j} \frac{\partial^2}{\partial x_i \, \partial x_j} (B_i \nabla v_j) \tag{2.3}$$

can also be written as

$$-\sum_{i,j} \frac{\partial v_j}{\partial x_i} \nabla \frac{\partial B_i}{\partial x_j}, \tag{2.3$'$}$$

since the difference of the two expressions is the gradient of $\Sigma_{i,j}(\partial v_j/\partial x_i)(\partial B_i/\partial x_j)$ and may be absorbed into ∇p.

It is curious to note here that in the one-dimensional case the passage from the Lie algebra of vector fields to the Virasoro algebra leads to the transition from the nonlinear wave equation

$$u_t = uu_x$$

to the Korteweg–de Vries equation

$$u_t = uu_x + u_{xxx},$$

as shown by Ovsienko and Khesin in Ref. 21.

Just like the dispersion term u_{xxx} in the KdV, the new term $\Sigma_{i,j}(\partial B_i/\partial x_j)\nabla(\partial v_j/\mathrm{d}x_i)$ that we get in (2.2) has a triple derivative in x.

Next we are going to show that (2.2) describes magnetic hydrodynamics with a *stress tensor*. Indeed, for a stress tensor T_{ki}, the equations on the velocity field in (2.1) will become (see, e.g., Sec. 1.7 in Ref. 23)

$$\frac{\partial v_k}{\partial t} = -(\mathbf{v}\cdot\nabla)v_k + (\mathbf{B}\cdot\nabla)B_k + \sum_i \frac{\partial T_{ki}}{\partial x_i} - \frac{\partial p}{\partial x_k}. \tag{2.4}$$

Proposition 1: The system (2.2) describes magnetic hydrodynamics with a stress tensor. The stress tensor T_{ki} may be written as

$$T_{ki} = \sum_j \frac{\partial B_i}{\partial x_j}\frac{\partial v_j}{\partial x_k} \tag{2.5}$$

or as

$$T'_{ki} = -\sum_j \frac{\partial v_i}{\partial x_j}\frac{\partial B_j}{\partial x_k} \tag{2.5$'$}$$

or as a linear combination $\alpha T_{ki} + \beta T'_{ki}$ with $\alpha+\beta=1$.

Proof: We will prove the statement of the Proposition for tensor T_{ki} given by (2.5). We write the contribution in (2.4) from the stress tensor (2.5),

$$\sum_i \frac{\partial T_{ki}}{\partial x_i} = \sum_{i,j} \frac{\partial^2 B_i}{\partial x_i\,\partial x_j}\frac{\partial v_j}{\partial x_k} + \sum_{i,j}\frac{\partial B_i}{\partial x_j}\frac{\partial^2 v_j}{\partial x_i\,\partial x_k}.$$

Since $\mathrm{div}(\mathbf{B})=0$, the first term on the right-hand side vanishes, and we get precisely the first equation from (2.2).

The stress tensor (2.5′) will yield the additional term written in the form (2.3′). The proof in this case is completely analogous.

We point out that the stress tensors we obtain here are not symmetric, $T_{ki}\neq T_{ik}$. In a typical situation in hydrodynamics, stress tensor is symmetric. The derivation of the symmetry of a stress tensor is based on the consideration of the angular momentum for an infinitesimal region of the fluid. Provided that the external force does not cause angular acceleration of individual particles of the fluid, the stress tensor must be symmetric. However, this need not to be the case if there is a force acting on polarized fluid particles (see discussion in Sec. 1.3 in Ref. 4 or Chap. 8 in Ref. 23). The asymmetry of stress tensor (2.5) indicates that the particles of the fluid are polar, i.e., possess electric or magnetic momentum. The derivation of the stress tensor from the first principles is rather delicate (see, e.g., Chap. 7 in Ref. 23), and this paper does not describe precisely the physical situations when the stress tensors (2.5) and (2.5′) would occur.

Introduction of the term (2.3) which has the third order in derivatives, into the equations will clearly change the behavior of the solutions in a substantial way. It is quite surprising that the conservation laws of magnetic hydrodynamics still hold for the system (2.2).

Our next goal is to study the conservation laws for magnetic hydrodynamics with the stress tensor (2.2). However before we do that, let us discuss the class of solutions that we consider here.

We require that the functions $v_i(x), B_i(x)$ are defined in a domain $D \subset \mathbb{R}^n$ and belong to the intersection of the Sobolev spaces $\cap_{k=1}^{\infty} H_0^k(D)$. We recall that the space $H_0^k(D)$ is the closure in the Sobolev space $H^k(D)$ of the functions of class C^k with compact support (see, e.g., Ref. 1). This will ensure that all functions and their partial derivatives of all orders are square-integrable [belong to $L^2(D)$] and satisfy the vanishing conditions on the boundary of D (if D is unbounded this means that at infinity the functions go to zero faster than the inverse of any polynomial). Choosing this class of functions will allow us to carry out integration by parts with the boundary term vanishing.

Alternatively, we may consider periodic boundary conditions, as it is often done in turbulence theory.

There are several conserved quantities for the MHD system—mass, momentum, magnetic helicity, as well as energy and cross-helicity. It turns out that all of these are also conserved for the MHD with the stress tensor. Since we consider the case of an incompressible fluid, the conservation of mass (volume) holds trivially. The derivation of the conservation of magnetic helicity involves only the evolution equation on magnetic field **B**, and is exactly the same for both systems. Let us prove the conservation of momentum for the new system.

Proposition 2: The total momentum is a conserved quantity for the MHD system with the stress tensor (2.2),

$$\int_D \mathbf{v}(x) \mathrm{d}V \equiv \text{const}.$$

Proof: With the help of Proposition 1, we can write the first equation using the divergence operator,

$$\frac{\partial v_k}{\partial t} = \sum_i \frac{\partial}{\partial x_i}(-v_i v_k + B_i B_k + T_{ki} - p\delta_{ki}).$$

By the divergence theorem, we get

$$\frac{\partial}{\partial t}\int_D v_k(x) \mathrm{d}V = \oint_{\partial D} R_{ki} \mathbf{e}_i \cdot \mathrm{d}\mathbf{n},$$

where R is a 2-tensor

$$R_{ki} = -v_i v_k + B_i B_k + T_{ki} - p\delta_{ki},$$

n denotes the unit outward normal vector, and $\mathbf{e}_i$'s are the standard basis vectors. Since the vector fields we consider vanish on the boundary of D, the last integral is zero.

Next we state the corresponding theorem for the conservation of energy and the cross-helicity conservation.

Theorem 3: The system (2.2) of magnetic hydrodynamics with stress tensor (2.5) in a domain $D \subset \mathbb{R}^n$ with appropriate boundary conditions (see discussion above) has the following two first integrals:

$$\int_D \sum_i v_i(x)^2 + \sum_i B_i(x)^2 \, \mathrm{d}V \equiv \text{const} \quad \text{(energy conservation)} \tag{2.6}$$

and

$$\int_D \sum_i v_i(x) B_i(x) \mathrm{d}V \equiv \text{const (cross-helicity conservation)}. \tag{2.7}$$

We will give the proof of this theorem in Sec. IV. These conservation laws will be derived from the properties of the Lie algebra $\mathfrak{g}(\tau)$.

It is interesting to note that unlike the case of the Navier–Stokes equation, introduction of the stress tensor in (2.2) does not lead to the dissipation of energy, and the energy conservation law still holds.

For the topological interpretation of helicity and cross-helicity, see Refs. 18 and 19.

In the conclusion of this section we show that system (2.2) admits Alfvén wave solutions.

Alfvén waves solutions are obtained as a perturbation of a steady-state constant solution $\mathbf{v}(x)=0, \mathbf{B}(x)=\mathbf{B}_0$. If we take an expansion $\mathbf{v}=\tilde{\mathbf{v}}(x), \mathbf{B}=\mathbf{B}_0+\tilde{\mathbf{B}}(x)$ near this equilibrium state, we will get the following system:

$$\frac{\partial \tilde{\mathbf{v}}}{\partial t} = -(\tilde{\mathbf{v}}\cdot\nabla)\tilde{\mathbf{v}} + (\mathbf{B}_0\cdot\nabla)\tilde{\mathbf{B}} + (\tilde{\mathbf{B}}\cdot\nabla)\tilde{\mathbf{B}} + \sum_{i,j}\frac{\partial \tilde{B}_i}{\partial x_j}\nabla\frac{\partial \tilde{v}_j}{\partial x_i} - \nabla p,$$

$$\frac{\partial \tilde{\mathbf{B}}}{\partial t} = -(\tilde{\mathbf{v}}\cdot\nabla)\tilde{\mathbf{B}} + (\mathbf{B}_0\cdot\nabla)\tilde{\mathbf{v}} + (\tilde{\mathbf{B}}\cdot\nabla)\tilde{\mathbf{v}},$$

$$\operatorname{div}(\tilde{\mathbf{v}}) = 0, \quad \operatorname{div}(\tilde{\mathbf{B}}) = 0. \tag{2.8}$$

Next we set $\tilde{\mathbf{B}}=\tilde{\mathbf{v}}$. In this case the term $\Sigma_{i,j}(\partial\tilde{B}_i/\partial x_j)\nabla(\partial\tilde{v}_j/\partial x_i)$ is a gradient of $\Sigma_{i,j}(\partial\tilde{v}_i/\partial x_j)\times(\partial\tilde{v}_j/\partial x_i)$, and we can eliminate it by setting

$$p = \sum_{i,j}\frac{\partial \tilde{v}_i}{\partial x_j}\frac{\partial \tilde{v}_j}{\partial x_i}. \tag{2.9}$$

Now the first two equations in (2.8) reduce to a single equation

$$\frac{\partial \tilde{\mathbf{v}}}{\partial t} = (\mathbf{B}_0\cdot\nabla)\tilde{\mathbf{v}}. \tag{2.10}$$

Finally, by taking an arbitrary divergence zero vector field $\mathbf{w}(x)$, we can construct a solution of (2.8),

$$\tilde{\mathbf{v}}(x,t) = \mathbf{w}(x+\mathbf{B}_0 t).$$

This traveling wave solution is called the Alfvén wave. The only difference with the classical MHD system (2.1) is the change of the pressure term (2.9).

III. GENERALIZED EULER EQUATION

In this section we are going to review the geodesic equation approach to hydrodynamics developed by Arnold. In the key paper,[2] Arnold gave an interpretation of the Euler equation for an incompressible ideal fluid

$$\frac{\partial \mathbf{v}}{\partial t} = -(\mathbf{v}\cdot\nabla)\mathbf{v} - \nabla p,$$

$$\operatorname{div}(\mathbf{v}) = 0, \tag{3.1}$$

from the perspective of infinite-dimensional Lie groups. He showed that the Euler equation may be interpreted as the geodesic equation on the group of diffeomorphisms, where the Riemannian structure on the group is given by the energy functional.

We will describe this approach here following Ref. 3.

Let G be a Lie group (possibly infinite-dimensional), and let $\mathfrak{g}$ be its Lie algebra. Consider a map from $\mathfrak{g}$ to its dual

$$A\colon \mathfrak{g} \to \mathfrak{g}^* \quad \text{(inertia operator)},$$

such that it defines a positive-definite symmetric bilinear form on $\mathfrak{g}$,

$$\langle X|Y\rangle = \tfrac{1}{2}A(X)Y + \tfrac{1}{2}A(Y)X, \quad X,Y \in \mathfrak{g}.$$

The corresponding quadratic form $\langle X|X\rangle = A(X)X$ is called the energy functional.

The Lie algebra $\mathfrak{g}$ acts on its dual space via the coadjoint action,

$$(\mathrm{ad}^*(X)u)(Y) = -u([X,Y]) \quad \text{for } X,Y \in \mathfrak{g},\ u \in \mathfrak{g}^*.$$

We assume that the space $A(\mathfrak{g})$ is invariant under the coadjoint action, and we make a convention that in what follows $\mathfrak{g}^*$ stands for $A(\mathfrak{g})$ [this is a slight abuse of notations since in the infinite-dimensional case $A(\mathfrak{g})$ is typically smaller than the formal dual of $\mathfrak{g}$]. Since the kernel of A is trivial [otherwise, the quadratic form $\langle X|X\rangle = A(X)X$ is not positive-definite], then with the above convention the operator A is invertible.

The bilinear form $\langle\cdot|\cdot\rangle$ may be left-translated from $\mathfrak{g} = T_e(G)$ to the tangent spaces at all points of G. This gives a Riemannian structure on G, and allows us to consider the geodesics on this group.

Next we are going to write the equation for the geodesics on G, which describes the evolution of the tangent vector $X \in \mathfrak{g}$ to the geodesic curve. It turns out however, that it is easier to write the evolution equation for the covector $u = A(X) \in \mathfrak{g}^*$ rather than for X itself. The generalized Euler equation is the evolution equation for $u = A(X)$ which is written using the coadjoint action [see (6.4) in Ref. 3]

$$u_t = -\mathrm{ad}^*(A^{-1}u)u. \tag{3.2}$$

When $G = \mathrm{SO}(3)$ this equation turns into the equations of motion of a rigid body with a fixed point.

Let us discuss equation (3.2) in the context of fluid dynamics. Evolution of an incompressible fluid in domain $D \subset \mathbb{R}^n$ from time 0 to time t is given by a volume-preserving diffeomorphism of D. Thus the group of the volume preserving diffeomorphisms $G = \mathrm{SDiff}(D)$ is the configuration space for this motion. The Lie algebra of the group $\mathrm{SDiff}(D)$ is the Lie algebra of the divergence zero vector fields $\mathrm{SVect}(D)$. As the energy functional we take the kinetic energy,

$$\left\langle \sum_i v_i(x)\ \frac{\partial}{\partial x_i} \middle| \sum_i v_i(x)\frac{\partial}{\partial x_i} \right\rangle = \int_D \sum_i v_i(x)^2\, \mathrm{d}V. \tag{3.3}$$

The dual space for the divergence zero vector fields is the factor space of differential 1-forms of D by exact 1-forms,

$$\mathrm{SVect}(D)^* = \Omega^1(D)/\mathrm{d}\Omega^0(D).$$

The pairing between $\mathrm{SVect}(D)$ and $\Omega^1(D)/\mathrm{d}\Omega^0(D)$ is given by the integral

$$\sum_j w_j(x)\mathrm{d}x_j\left(\sum_i v_i(x)\frac{\partial}{\partial x_i}\right) = \int_D \sum_j w_j(x)v_j(x)\mathrm{d}V. \tag{3.4}$$

It is easy to check that exact 1-forms vanish on the divergence zero vector fields, and so the value of the integral on the right-hand side is independent of the choice of a representative in a class of 1-forms modulo $\mathrm{d}\Omega^0(D)$.

The inertia operator

$$A\colon \mathrm{SVect}(D) \to \Omega^1(D)/\mathrm{d}\Omega^0(D)$$

that corresponds to the energy functional (3.3) is written as follows:

$$A\left(\sum_i v_i(x)\frac{\partial}{\partial x_i}\right)=\sum_i v_i(x)\mathrm{d}x_i.$$

It is possible to check that in these settings, Eq. (3.2) turns into the Euler equations of motion of an ideal fluid.

Ebin and Marsden[10] used this interpretation of the Euler equations to prove existence of solutions for the motion of an ideal fluid for small times. A variational approach to the generalized Euler equation is presented in Ref. 16.

The equations of the magnetic hydrodynamics (2.1) can also be obtained as a special case of the generalized Euler equation (3.2). To construct the corresponding Lie algebra we take the Lie algebra SVect(D) together with its dual space,

$$\mathfrak{g}=\mathrm{SVect}(D)\oplus\Omega^1(D)/\mathrm{d}\Omega^0(D).$$

The Lie bracket of two 1-forms is set to be zero. The Lie bracket of two vector fields is defined in the usual way,

$$\left[\sum_i v_i(x)\frac{\partial}{\partial x_i},\sum_j w_j(x)\frac{\partial}{\partial x_j}\right]=\sum_{i,j} v_i\frac{\partial w_j}{\partial x_i}\frac{\partial}{\partial x_j}-w_j\frac{\partial v_i}{\partial x_j}\frac{\partial}{\partial x_i},\tag{3.5}$$

and the Lie bracket of a vector field with a 1-form is given by the Lie derivative,

$$\left[\sum_i v_i(x)\frac{\partial}{\partial x_i},\sum_j w_j(x)\mathrm{d}x_j\right]=\sum_{i,j} v_i\frac{\partial w_j}{\partial x_i}\mathrm{d}x_j+\sum_j w_j\mathrm{d}(v_j).\tag{3.6}$$

It is easy to see that the space $\mathrm{d}\Omega^0(D)$ is invariant under the Lie derivative action, so the above formula may be taken modulo $\mathrm{d}\Omega^0(D)$.

The Lie algebra $\mathfrak{g}$ is a semidirect product of SVect(D) with its module $\Omega^1(D)/\mathrm{d}\Omega^0(D)$. The space $\Omega^1(D)/\mathrm{d}\Omega^0(D)$ forms an Abelian ideal in $\mathfrak{g}$.

A really important feature of the Lie algebra $\mathfrak{g}$ is the existence of an invariant symmetric nondegenerate bilinear form. In contrast, the Lie algebra SVect does not possess such a form. The invariant form on $\mathfrak{g}$ is defined as follows [cf. (3.4)]:

$$\left(\sum_i v_i(x)\ \ \frac{\partial}{\partial x_i}\middle|\sum_j w_j(x)\mathrm{d}x_j\right)=\int_D\sum_i v_i(x)w_i(x)\mathrm{d}V,$$

$$\left(\sum_i v_i(x)\ \ \frac{\partial}{\partial x_i}\middle|\sum_j w_j(x)\frac{\partial}{\partial x_j}\right)=0,\quad\left(\sum_i v_i(x)\mathrm{d}x_i\middle|\sum_j w_j(x)\mathrm{d}x_j\right)=0.\tag{3.7}$$

One can verify that the bilinear form (3.7) satisfies the invariance property,

$$([X,Y]|Z)=(X|[Y,Z])\quad\text{for all } X,Y,Z\in\mathfrak{g}.$$

We can use this form to identify each element $X\in\mathfrak{g}$ with a linear functional $(X|\cdot)$ in $\mathfrak{g}^*$. It is well known that when the bilinear form that is used to identify $\mathfrak{g}^*$ with $\mathfrak{g}$, is invariant and nondegenerate, the coadjoint action becomes isomorphic to the adjoint action. In this case the generalized Euler equation takes the following form:

$$X_t=-\mathrm{ad}(A^{-1}X)X,\tag{3.8}$$

where now $X\in\mathfrak{g}$ and the inertia operator A now maps $\mathfrak{g}$ to $\mathfrak{g}$.

The generalized Euler equation (3.8) yields the equations of magnetic hydrodynamics (2.1) if we choose A to be the following involution on $\mathfrak{g}$:

$$A\left(\sum_i v_i(x)\frac{\partial}{\partial x_i}\right) = \sum_i v_i(x)\mathrm{d}x_i,$$

$$A\left(\sum_i w_i(x)\mathrm{d}x_i\right) = \sum_i w_i(x)\frac{\partial}{\partial x_i}. \tag{3.9}$$

Note that in the second equality we choose a (unique) representative in a class modulo $\mathrm{d}\Omega^0$ satisfying $\Sigma_i(\partial w_i/\partial x_i)=0$, so that the right-hand side is a divergence zero vector field.

We see that the inertia operator (3.9) satisfies $A^{-1}=A$, and the energy functional $(AX|X)$ for $X=\Sigma_i v_i(x)(\partial/\partial x_i)+\Sigma_i w_i(x)\mathrm{d}x_i \in \mathfrak{g}$ is given by the integral

$$\int_D \sum_i v_i(x)^2 + \sum_i w_i(x)^2 \,\mathrm{d}V. \tag{3.10}$$

The Lie algebra

$$\mathfrak{g} = \mathrm{Svect} \oplus \Omega^1/\mathrm{d}\Omega^0$$

appears in the study of toroidal Lie algebras (Refs. 5–7, 11, and 15). The representations of $\mathfrak{g}$ are an essential ingredient for constructing the representation theory of toroidal Lie algebras. It was discovered however that $\mathfrak{g}$ admits a nontrivial deformation with a $\Omega^1/\mathrm{d}\Omega^0$-valued 2-cocycle on SVect, and one gets a better representation theory for the deformed algebra than for $\mathfrak{g}$ itself.

In the next section we will describe this deformation of $\mathfrak{g}$ and study the associated generalized Euler equation.

IV. ABELIAN EXTENSIONS OF THE LIE ALGEBRA OF VECTOR FIELDS

In the preceding section we have constructed a semidirect product $\mathfrak{g}$ of the Lie algebra of divergence zero vector fields with $\Omega^1/\mathrm{d}\Omega^0$. It turns out that on the same vector space

$$\mathfrak{g} = \mathrm{Svect} \oplus \Omega^1/\mathrm{d}\Omega^0$$

we may deform the Lie bracket in a nontrivial way. When we define the Lie bracket of two vector fields, we are going to add to the right-hand side of (3.5) a correction term which has value in $\Omega^1(D)/\mathrm{d}\Omega^0(D)$,

$$\left[\sum_i v_i(x)\frac{\partial}{\partial x_i}, \sum_j w_j(x)\frac{\partial}{\partial x_j}\right] = \sum_{i,j}\left(v_i\frac{\partial w_j}{\partial x_i}\frac{\partial}{\partial x_j} - w_j\frac{\partial v_i}{\partial x_j}\frac{\partial}{\partial x_i}\right) + \tau\left(\sum_i v_i(x)\frac{\partial}{\partial x_i}, \sum_j w_j(x)\frac{\partial}{\partial x_j}\right). \tag{4.1}$$

In order to get a Lie bracket, τ must be a 2-cocycle on $\mathrm{SVect}(D)$ with values in $\Omega^1(D)/\mathrm{d}\Omega^0(D)$.

The following cocycle plays an important role in the representation theory:

$$\tau\left(\sum_i v_i(x)\frac{\partial}{\partial x_i}, \sum_j w_j(x)\frac{\partial}{\partial x_j}\right) = \sum_{i,j}\frac{\partial v_i}{\partial x_j}\mathrm{d}\left(\frac{\partial w_j}{\partial x_i}\right). \tag{4.2}$$

This cocycle may be viewed as a higher-dimensional generalization of the Virasoro cocycle. Just as the Virasoro cocycle, it has a triple derivative in x, and in fact (4.2) reducès to the Virasoro cocycle for the Lie algebra of vector fields on a circle.

The cocycle τ can be constructed using Gelfand–Fuks cohomology.[12,13] In its explicit form it first appeared in Ref. 11 in the context of the representation theory of toroidal Lie algebras.

We will denote the Lie algebra with the Lie bracket deformed by the cocycle τ by $\mathfrak{g}(\tau)$. Note that

$$\mathfrak{g}(\tau) = \mathrm{Svect}(D) \oplus \Omega^1(D)/\mathrm{d}\Omega^0(D)$$

is no longer a semidirect product, but the subspace $\Omega^1(D)/\mathrm{d}\Omega^0(D)$ still forms an Abelian ideal. As before, the action of $\mathrm{Svect}(D)$ on $\Omega^1(D)/\mathrm{d}\Omega^0(D)$ is given by the Lie derivative formula (3.6).

Proposition 4: The bilinear form on $\mathfrak{g}(\tau)$ given by (3.7) is invariant.

Proof: We need to establish the invariance property,

$$([X,Y]|Z) = (X|[Y,Z]).$$

There are three nontrivial cases to be considered,

(i) $X, Y \in \mathrm{Svect}(D), Z \in \Omega^1(D)/\mathrm{d}\Omega^0(D)$,
(ii) $X, Z \in \mathrm{SVect}(D), Y \in \Omega^1(D)/\mathrm{d}\Omega^0(D)$,
(iii) $X, Y, Z \in \mathrm{SVect}(D)$.

We will verify the invariance only for the last case, since only this case will involve the cocycle τ, and leave the first two cases as an exercise to the reader.

Suppose

$$X = \sum_i u_i \frac{\partial}{\partial x_i}, \quad Y = \sum_j v_j \frac{\partial}{\partial x_j}, \quad Z = \sum_k w_k \frac{\partial}{\partial x_k}.$$

Since $(\mathrm{SVect}|\mathrm{SVect}) = 0$, then we get that $([X,Y]|Z) = (\tau(X,Y)|Z)$ and $(X|[Y,Z]) = (X|\tau(Y,Z))$.

We have

$$([X,Y]|Z) = \left(\sum_{i,j,s} \frac{\partial u_i}{\partial x_j} \frac{\partial^2 v_j}{\partial x_i \partial x_s} \mathrm{d}x_s \middle| \sum_k w_k \frac{\partial}{\partial x_k} \right) = \int_D \sum_{i,j,k} w_k \frac{\partial u_i}{\partial x_j} \frac{\partial^2 v_j}{\partial x_i \partial x_k} \mathrm{d}V.$$

Integrating by parts and using the fact that $\Sigma_i (\partial u_i / \partial x_i) = 0$, we get

$$([X,Y]|Z) = -\int_D \sum_{i,j,k} \frac{\partial w_k}{\partial x_i} \frac{\partial u_i}{\partial x_j} \frac{\partial v_j}{\partial x_k} \mathrm{d}V.$$

On the other hand,

$$(X|\tau(Y,Z)) = \left(\sum_i u_i \frac{\partial}{\partial x_i} \middle| \sum_{j,k,s} \frac{\partial v_j}{\partial x_k} \frac{\partial^2 w_k}{\partial x_j \mathrm{d}x_s} \mathrm{d}x_s \right) = \int_D \sum_{i,j,k} u_i \frac{\partial v_j}{\partial x_k} \frac{\partial^2 w_k}{\partial x_j \mathrm{d}x_i} \mathrm{d}V = -\int_D \sum_{i,j,k} \frac{\partial u_i}{\partial x_j} \frac{\partial v_j}{\partial x_k} \frac{\partial w_k}{\partial x_i} \mathrm{d}V.$$

This proves the invariance property $([X,Y]|Z) = (X|[Y,Z])$ in case (iii).

Now we are going to prove the following theorem.

Theorem 5: The generalized Euler equation

$$X_t = -[AX, X] \tag{4.3}$$

for the Lie algebra $\mathfrak{g}(\tau)$ with the inertia operator A given by (3.9) yields the equations of magnetic hydrodynamics with asymmetric stress tensor (2.2).

Proof: We write

$$X = \sum_i B_i \frac{\partial}{\partial x_i} + \sum_j v_j \, \mathrm{d}x_j.$$

We will fix representatives of classes of 1-forms modulo $\mathrm{d}\Omega^0(D)$ by imposing a condition $\Sigma_j (\partial v_j / \partial x_j) = 0$. Then we have

$$AX = \sum_j v_j \frac{\partial}{\partial x_j} + \sum_i B_i \, \mathrm{d}x_i$$

and

$$[X,AX] = \sum_{i,j} B_i \frac{\partial v_j}{\partial x_i} \frac{\partial}{\partial x_j} - \sum_{i,j} v_j \frac{\partial B_i}{\partial x_j} \frac{\partial}{\partial x_i} + \sum_{i,j,k} \frac{\partial B_i}{\partial x_j} \frac{\partial^2 v_j}{\partial x_i \partial x_k} \mathrm{d}x_k + \sum_{i,j} B_i \frac{\partial B_j}{\partial x_i} \mathrm{d}x_j + \sum_i B_i d(B_i)$$
$$- \sum_{i,j} v_i \frac{\partial v_j}{\partial x_i} \mathrm{d}x_j - \sum_i v_i d(v_i).$$

Note that the terms $B_i d(B_i) = \frac{1}{2} d(B_i^2)$ and $v_i d(v_i) = \frac{1}{2} d(v_i^2)$ are full differentials and thus may be dropped.

Substituting the obtained expression into the generalized Euler equation (4.3) and collecting terms at $\mathrm{d}x_j, \partial/\partial x_j$, and taking into account that equality of 1-forms is taken modulo $\mathrm{d}\Omega^0(D)$, we get the following system of PDEs:

$$\frac{\partial v_j}{\partial t} = - \sum_i v_i \frac{\partial v_j}{\partial x_i} + \sum_i B_i \frac{\partial B_j}{\partial x_i} + \sum_{i,k} \frac{\partial B_i}{\partial x_k} \frac{\partial^2 v_k}{\partial x_i \partial x_j} - \frac{\partial p}{\partial x_j},$$

$$\frac{\partial B_j}{\partial t} = - \sum_i \left(v_i \frac{\partial B_j}{\partial x_i} - B_i \frac{\partial v_j}{\partial x_i} \right),$$

$$\sum_j \frac{\partial v_j}{\partial x_j} = 0, \quad \sum_j \frac{\partial B_j}{\partial x_j} = 0.$$

Rewriting this system in a vector form with the vector fields we get (2.2).

Finally let us prove Theorem 3 and establish the energy and the cross-helicity conservation laws for MHD equations with the stress tensor (2.2). We will in fact obtain Theorem 3 as a corollary of the following.

Theorem 6: Let $\mathfrak{g}$ be a Lie algebra with a nondegenerate symmetric invariant bilinear form $(\cdot|\cdot)$. Let A be an involution of $\mathfrak{g}$ preserving the invariant form

$$A\colon \mathfrak{g} \to \mathfrak{g}, \quad A^2 = \mathrm{Id}, \quad (AX|AY) = (X|Y) \quad \text{for all } X, Y \in \mathfrak{g}.$$

Then the generalized Euler equation $X_t = -[AX, X]$ has the following two first integrals:

$$(AX|X) \equiv \mathrm{const} \tag{4.4}$$

and

$$(X|X) \equiv \mathrm{const}. \tag{4.5}$$

Proof: Let us evaluate $(\partial/\partial t)(AX|X)$,

$$\frac{\partial}{\partial t}(AX|X) = (AX_t|X) + (AX|X_t).$$

Taking into account that $(X|Y) = (AX|AY)$ and $A^2 = \mathrm{Id}$, we get that $(AX_t|X) = (A^2 X_t|AX) = (X_t|AX)$. Thus

$$\frac{\partial}{\partial t}(AX|X) = 2(AX|X_t).$$

Substituting the right-hand side of the generalized Euler equation for X_t we obtain

$$\frac{\partial}{\partial t}(AX|X) = -2(AX|[AX,X]).$$

By invariance of the form we get

$$(AX|[AX,X]) = ([AX,AX]|X) = 0.$$

Thus $(\partial/\partial t)(AX|X)=0$ and (4.4) is established.

The second conservation law (4.5) is obtained in a similar way,

$$\frac{\partial}{\partial t}(X|X) = 2(X_t|X) = -2([AX,X]|X) = -2(AX|[X,X]) = 0.$$

This completes the proof of Theorem 6.

Note that for (4.5) we may drop the requirements that A preserves the invariant form and is an involution.

We obtain Theorem 3 as an immediate corollary to the previous theorem, noting that the bilinear form (3.7) on $\mathfrak{g}(\tau)$ is invariant by Proposition 4 and the inertia operator (3.9) is an involution and preserves this form.

We can see that for

$$X = \sum_i B_i \frac{\partial}{\partial x_i} + \sum_j v_j \, \mathrm{d}x_j,$$

the first integral (4.4) becomes the energy conservation law

$$(AX|X) = \int_D \sum_i v_i(x)^2 + \sum_i B_i(x)^2 \, \mathrm{d}V \equiv \text{const},$$

and (4.5) becomes the cross-helicity conservation,

$$(X|X) = 2\int_D \sum_i v_i(x) B_i(x) \mathrm{d}V \equiv \text{const}.$$

ACKNOWLEDGMENTS

A special class in vanishing helicity ideal flows

The derivation of a Lagrangian invariant so-called *spirality* is reviewed through the Lagrangian coordinates. The value of the spirality is fixed up to a gauge transformation. The helicity conservation follows directly from this invariant. Among all ideal flows with zero helicity in a domain of flow frozen into the fluid motion, a special class is introduced. This special topological class has the possibility to transform its spirality to be identically zero everywhere in the domain. For those simply connected domains of motion, a necessary and a sufficient condition is presented for these zero spirality flows. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1860592]

I. INTRODUCTION

Hydrodynamics has been a very nice laboratory to observe many interesting physical and mathematical phenomena. Various mathematical theories such as PDEs, dynamical systems, turbulence, functional analysis, geometry, topology, etc., are being widely extended to give as complete as possible description for fluid dynamics equations.

Among these topics, the geometrical study, especially for ideal flows, is a very useful tool to analyze fluid flows. In this approach the invariants of the fluid motion have been found to highly simplify the complicated behavior of nonlinear flows. (see, for example, Moffatt, 1990). Perhaps the most ramifications of topological investigations nest in vortex dynamics in ideal fluids as well as magnetic fields in conductor plasmas. The conservation of the helicity is a fine topological character of motions. This constant was first understood and interpreted in vortex and magnetic fields by Moffatt (1969). However, the conservation of helicity was known even by Kelvin from the 19th century (see Moffatt, 1990).

The helicity is practically a measure for the wrapping and winding of field lines inside each other. This quantity is concerned with the so-called writhing number or linking number of two closed curves in three-space. Historically, as cited by Cantarella *et al.* (2001), Gauss in 1833 discussed the linking number of two separate closed curves. Later, Woltjer (1958, Calugareanu in 1959–1961), Moffatt in (1969), and Fuller in (1971) developed this subject (see these references in Cantarella *et al.* 2000, 2001). Further progressions in this material within various points of view were achieved by many people such as Arnold (1974), Berger and Field (1984), Yoshida and Giga (1990), Freedman and He (1991), Laurence and Avellaneda (1991), Moffatt and Ricca (1992), Ricca and Moffatt (1992), Chui and Moffatt (1995), and Cantarella *et al.* (2000–2002).

Vortex Lagrangian invariants reveal a number of special symmetries in ideal fluids. Here the purpose of the present article is concentrated on the helicity. For other kinds of symmetries and invariants the reader can, for instance, refer to Lamb (1932), Tagor and Treve (1982), Salmon

[a)]Electronic mail: eshraghi@theory.ipm.ac.ir

(1988), Sagdeef, Tur, and Yanovsky (1990), and references therein), Troshkin (1995), Zakharov and Kuznetsov (1997), Kuznetsov and Ruban (1998, 2000), Arnold and Khesin (1998), and Kuznetsov (2002).

The conservation of helicity is a result of a Lagrangian invariant named *Spirality*. A nonrelativistic version of spirality for incompressible flow can be found in the book of Marchioro and Pulvirenti (1994), although this fact has been studied both analytically (Tur and Yanovsky, 1993) and numerically (see, for example, Russo and Smereca, 1999, and many references therein). A more detailed derivation for the spirality in relativistic fluids is presented by the first author (see Eshraghi, 2003). We will review this invariant in this paper in Lagrangian description to give the helicity conservation. The aim of this paper is to notice the important relation of spirality with the topology of vortex field. We will consider a zero helicity flow in a volume surrounded by a surface everywhere tangent to vortex lines. The sustained vanishing helicity as will be shown can naturally result in the existence of a special class of such flows. In this special class the invariant spirality can be chosen to be *identically zero* among the moving (with fluid) volume.

There is a feeling (even not so clear) that this invariant may play some role in the difficult debate of "finite time singularity" in vortex dynamics. It seems that the singularity cannot happen by any arbitrary initial conditions. Only some of the initial flows may result in a singularity at a finite future time. In other words, the singularity is probably hidden in the topology of the initial flow. We still have no obvious clue, but hope that the study of spirality may help us to discover a topological (invariant) character of initially smooth flows that possess the potential of creating singularity in later times.

II. SPIRALITY AND HELICITY CONSERVATION

Let us recall the Lagrangian coordinates which are suitable for invariance properties in ideal fluids. Although many solutions of hydrodynamic systems are mostly explained in terms of Eulerian variables, there exist some interesting solutions requesting a Lagrangian description (see Yakubovich and Zenkovich, 2001). If a fluid particle at time t is at the position $\mathbf{X}$ while initially (at $t=0$) was at the position $\mathbf{a}$, one can take $\mathbf{X}$ as a function of $\mathbf{a}$ and t and vice versa. Hence

$$\mathbf{X} = \mathbf{X}(\mathbf{a}, t), \qquad \dot{\mathbf{X}} = \mathbf{v}, \tag{1}$$

where $\mathbf{v}$ is the fluid velocity. In an isentropic (where entropy is constant), or barotropic (where the pressure is only function of density), or incompressible flow, the equation of motion reads

$$\dot{\mathbf{v}} = \ddot{\mathbf{X}} = -\nabla w, \quad \nabla = \left(\frac{\partial}{\partial X_1}, \frac{\partial}{\partial X_2}, \frac{\partial}{\partial X_3}\right). \tag{2}$$

The function w is the enthalpy or heat function per unit mass of the fluid element. For the incompressible case w must be simply replaced by $P/\rho_\circ$ where P and $\rho_\circ$ are the pressure and the constant density, respectively.

Consider now the jth component of Eq. (1) and multiply it by $(\partial X_j/\partial a_i)$ and sum over j. It is easily obtained that

$$\left(\frac{\partial \mathbf{u}}{\partial t}\right)_{\mathbf{a}} = \frac{\mathrm{d}\mathbf{u}}{\mathrm{d}t} = -\nabla_{\mathbf{a}}(w - v^2/2), \tag{3}$$

where

$$u_i \equiv v_j \frac{\partial X_j}{\partial a_i}, \quad \nabla_{\mathbf{a}} = \left(\frac{\partial}{\partial a_1}, \frac{\partial}{\partial a_2}, \frac{\partial}{\partial a_3}\right). \tag{4}$$

A formal solution for Eq. (3) is

$$\mathbf{u}(\mathbf{a},t) = \mathbf{u}_\circ(\mathbf{a}) + \nabla_\mathbf{a}\varphi, \tag{5}$$

with

$$\frac{\mathrm{d}\varphi}{\mathrm{d}t} = -(w - v^2/2) + f(t).$$

Here $f(t)$ is an arbitrary function of time only which we can put to zero. So

$$\frac{\mathrm{d}\varphi}{\mathrm{d}t} = v^2/2 - w, \tag{6}$$

with the assumed initial condition

$$\varphi_{t=0} \equiv 0. \tag{7}$$

An inverse transformation of Eq. (5) yields

$$\mathbf{v} = u_{\circ j}(\mathbf{a})\,\boldsymbol{\nabla}\, a_j + \boldsymbol{\nabla}\,\varphi, \quad (\mathbf{a} = \mathbf{a}(\mathbf{X},t))$$

or we define a vector function $\boldsymbol{\gamma}$,

$$\boldsymbol{\gamma} \equiv \mathbf{v} - \boldsymbol{\nabla}\,\varphi = u_{\circ j}(\mathbf{a})\,\boldsymbol{\nabla}\, a_j. \tag{8}$$

Then

$$\boldsymbol{\nabla} \times \boldsymbol{\gamma} = \boldsymbol{\nabla} \times \mathbf{v} \equiv \boldsymbol{\omega}.$$

The vector $\boldsymbol{\gamma}$ in Eq. (8) is the same as the impulse density function corresponding to the geometrical gauge introduced in the literature (see, for example, Russo and Smereca, 1999).

It follows from Eq. (8) that

$$\boldsymbol{\gamma}\cdot\boldsymbol{\omega} = \boldsymbol{\gamma}\cdot\boldsymbol{\nabla} \times \boldsymbol{\gamma} = (u_{\circ i}\,\boldsymbol{\nabla}\, a_i)\cdot[\boldsymbol{\nabla} u_{\circ j} \times \boldsymbol{\nabla}\, a_j] = \boldsymbol{\gamma}\cdot\boldsymbol{\omega} = \det\left(\frac{\partial a_m}{\partial X_n}\right) u_{\circ i}\frac{\partial u_{\circ j}}{\partial a_k}\epsilon_{ikj}.$$

By use of the well-known relation $\det(\partial a_m/\partial X_n) = \rho/\rho_\circ$ we obtain a Lagrangian invariant so-called "spirality" which we denote by "Sp:"

$$\mathrm{Sp}(\mathbf{a}) \equiv \frac{\boldsymbol{\gamma}\cdot\boldsymbol{\omega}}{\rho} = \rho_\circ^{-1}(\mathbf{a})\epsilon_{ikj}u_{\circ i}(\mathbf{a})\frac{\partial u_{\circ j}(\mathbf{a})}{\partial a_k}. \tag{9}$$

The invariance of the spirality is also easily visible through the Eulerian variables which we do not review it here. The reader can find it in Marchioro and Pulvirenti (1994).

Now let us realize the relation between spirality and helicity. Consider a fluid volume Ω_t frozen into the fluid motion. This volume contains a constant amount of mass. At $t=0$ this domain was $\Omega_\circ$. If its boundary $\partial\Omega_\circ$ was everywhere tangent to vortex lines $\boldsymbol{\omega}_\circ(\mathbf{a})$, it remains so for any future time t because of the frozenness of vortex lines in ideal flows. Therefore

$$\boldsymbol{\omega}\cdot\mathbf{n}\big|_{\partial\Omega_t} = 0, \tag{10}$$

where $\mathbf{n}$ is the unit vector normal to the surface $\partial\Omega_t$.

The conservation of the helicity $\mathcal{H}$ of the domain Ω_t easily follows from Eqs. (8) and (10) and the fact that $\boldsymbol{\nabla}\cdot\boldsymbol{\omega}=0$. Hence,

$$\mathcal{H} \equiv \int_{\Omega_t} \boldsymbol{\omega}\cdot\mathbf{v}\mathrm{d}^3X = \int_{\Omega_t} \boldsymbol{\omega}\cdot\boldsymbol{\gamma}\mathrm{d}^3X = \int_{\Omega_\circ} \mathrm{Sp}(\mathbf{a})\rho_\circ(\mathbf{a})\mathrm{d}^3a = \mathrm{const}. \tag{11}$$

Equation (6) admits a simple gauge transformation

$$\varphi \to \tilde{\varphi} = \varphi + \varphi_\circ(\mathbf{a}), \tag{12}$$

where $\varphi_\circ(\mathbf{a})$ is an arbitrary differentiable function of $\mathbf{a}$ only. This transformation clearly changes the value of the spirality at each point but does not change the helicity which is the result of the frozenness of vortex lines

$$\frac{\boldsymbol{\omega}}{\rho} = \left(\frac{\boldsymbol{\omega}_\circ}{\rho_\circ} \cdot \boldsymbol{\nabla}_\mathbf{a}\right)\mathbf{X}.$$

The new (invariant) spirality $\widetilde{\mathrm{Sp}}(\mathbf{a})$ after the gauge transformation (12) is

$$\widetilde{\mathrm{Sp}}(\mathbf{a}) = \frac{\boldsymbol{\omega}}{\rho} \cdot (\mathbf{v} - \boldsymbol{\nabla}\tilde{\varphi}) = \frac{\boldsymbol{\omega}_\circ}{\rho_\circ} \cdot (\mathbf{v}_\circ - \boldsymbol{\nabla}_\mathbf{a}\varphi_\circ), \tag{13}$$

in which Eq. (7) and the invariance of spirality were taken. Thus, by the gauge transformation (12) the helicity remains unchanged while the spirality takes new invariant values. In the next section, the case of zero helicity will be studied.

III. SPECIAL TOPOLOGY DUE TO ZERO SPIRALITY

Assume the helicity in Ω_t vanishes,

$$\mathcal{H} = \int_{\Omega_t} \boldsymbol{\omega} \cdot (\mathbf{v} - \boldsymbol{\nabla}\varphi)\mathrm{d}^3X = \int_{\Omega_\circ} \boldsymbol{\omega}_\circ \cdot (\mathbf{v}_\circ - 0)\mathrm{d}^3a = 0. \tag{14}$$

The total spirality also vanishes according to Eq. (11). As was shown, the transformation (12) leaves the total spirality and so the helicity unchanged. A natural question arises here: *For what kinds of flows one can find a suitable function* $\varphi_\circ(\mathbf{a})$ *such that the new spirality* $\widetilde{\mathrm{Sp}}$ *identically vanishes throughout* $\Omega_\circ$ *and so* Ω_t*?* In other words, we want to reveal a special class of zero helicity in which the spirality can be brought to zero identically:

$$\widetilde{\mathrm{Sp}}(\mathbf{a}) \equiv 0, \tag{15}$$

with $\widetilde{\mathrm{Sp}}(\mathbf{a})$ given by Eq. (13). It is enough to study this property in the initial configuration in $\Omega\circ$. In this paper we want to notice to the topological meaning of the property (15) which imposes a strong restriction among all zero-helicity flows. Although a complete description of the problem seems to be difficult and complicated, in some special cases there exist some viable statements.

Before starting the topological study we would like to mention an important point. The property (15) may contain a significant relation with finite time singularity. In this singularity the vorticity $\boldsymbol{\omega}$ is supposed to become infinite at some finite point and finite time while initially it was smooth. Due to the invariance of the spirality since it can be transformed to zero by Eq. (15), everywhere $\boldsymbol{\gamma}$ can be perpendicular to the vorticity. It means that in this case there is more freedom for $\boldsymbol{\gamma}$, i.e., there is no restriction on its singularity or smoothness. If the spirality cannot be transformed to zero, then it must have a finite invariant value by initial conditions. Starting from a smooth initial point and following the fluid trajectory, assume at a finite point and time a singularity occurs, i.e., $\boldsymbol{\omega}$ becomes infinite. In this case the component of $\boldsymbol{\gamma}$ which is parallel to $\boldsymbol{\omega}$ must necessarily go to zero in order to compensate the singularity of vorticity. This means that we have some restriction on $\boldsymbol{\gamma}$. To conclude we say that if the spirality can be *identically* transformed to zero everywhere, then the possibility of a singularity occurring at some point seems to be increased compared with the case when the spirality cannot be globally zero.

Let us come back to our geometrical consideration. We restrict our consideration to a *simply connected domain* for $\Omega_\circ$. In this geometry one may find a *necessary* condition and also a *sufficient* condition separately for Eq. (15). We emphasize that we still do not know a complete geometrical description for this property and only give one necessary and one sufficient condition which must be studied very carefully.

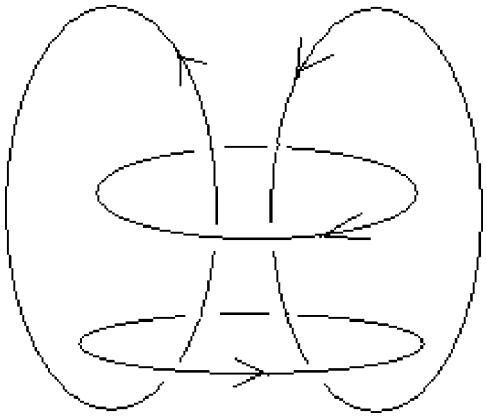

FIG. 1. Four nonzero vortex rings with zero helicity and zero spirality.

A necessary condition. Assume in the simply connected set $\Omega_\circ$ some closed vortex lines of $\boldsymbol{\omega}_\circ$ exist such that everywhere on these lines vorticity does not vanish. Let the closed curve $C_\circ$ be such a field line of $\boldsymbol{\omega}_\circ$, i.e.,

$$|\boldsymbol{\omega}_\circ(\mathbf{a})|_{C_\circ} \neq 0, \quad \frac{\boldsymbol{\omega}_\circ}{|\boldsymbol{\omega}_\circ|} = \frac{\mathrm{d}\mathbf{l}}{|\mathrm{d}\mathbf{l}|} \text{ on } C_\circ. \tag{16}$$

Let us substitute the right side of Eq. (13) into Eq. (15) and then divide it by $|\boldsymbol{\omega}_\circ(\mathbf{a})|$ for points on the closed curve $C_\circ$. The integration over this curve yields

$$\oint_{C_\circ} \mathbf{v}_\circ \cdot \mathrm{d}\mathbf{l} = \oint_{C_\circ} (\boldsymbol{\nabla}_\mathbf{a}\varphi_\circ) \cdot \mathrm{d}\mathbf{l} = 0. \tag{17}$$

By the use of Stokes theorem for a surface $\Sigma_\circ$ surrounded by $C_\circ$ (entirely inside $\Omega_\circ$) we obtain

$$\int_{\Sigma_\circ} \boldsymbol{\omega}_\circ \cdot \mathrm{d}\mathbf{S} = 0. \tag{18}$$

Therefore, if the spirality vanishes everywhere then the "total flux" of vortex lines across any closed nonzero vortex line must vanish. Of course this does not imply that the closed vortex lines have no link inside each other. They wrap inside one another but for each such closed curve, various links cancel provided the total link (flux) is zero. This fact is consistent with the zero helicity but, of course, the inverse is not necessarily true: If the helicity is zero, one can imagine some of closed vortex lines having nonzero fluxes inside but the sum of all these nonzero fluxes must be zero. To feel this difference in topologies, we consider only four nonzero vortex rings such that their helicity is zero. If Eq. (15) holds then necessarily Eq. (18) holds across each of these four nonzero vortex rings. The situation is shown in Fig. 1. We see that across each vortex ring, two opposite vortex lines pass and so the total flux of vorticity passing through each vortex ring is zero and also the helicity is zero. On the other hand, in Fig. 2 these four vortex rings have again zero helicity but the flux across each ring is not zero. It means that Eq. (18) imposes a significant restriction on the topology of vortex rings. However the general situation is much more complicated and requests a careful study.

It is very vital here to recall that the problem of the existence of a function $\varphi_\circ$ is a *global* existence and not a local one. Indeed, "locally" one can "always" use the Clebsh variables λ, μ, and $\tilde{\varphi}$ such that

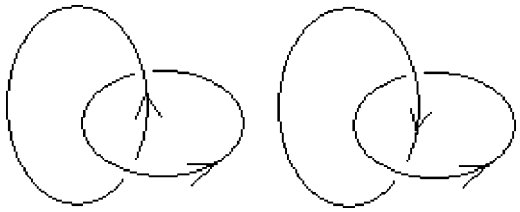

FIG. 2. Four nonzero vortex rings with zero helicity but nonzero spirality.

$$\mathbf{v} = \frac{\lambda}{\rho}\nabla\mu + \nabla\tilde{\varphi}, \tag{19}$$

from which Eq. (15) follows (but only locally). If there is no closed vortex lines in $\Omega_\circ$ (and so in Ω_t) the Clebsh variables globally exist and so the spirality can be chosen to be identically zero.

A sufficient condition. Again consider the simply connected domain $\Omega_\circ$. According to the "decomposition theorem," any smooth vector field defined on $\Omega_\circ$ can be represented as the sum of a divergence free and tangent to the boundary vector field, and a gradient field (i.e., the field which is the gradient of some smooth scalar function). See, for example, Marchioro and Pulvirenti (1994) or Gallavotti (2002). A more general decomposition applicable even for nonsimply connected domains is the "Hodge decomposition theorem" accessible, for example, in Cantarella *et al.* (2000–2002) or Schwarz (1995).

Let us apply the decomposition theorem to the initial velocity field $\mathbf{v}_\circ$. This field can be *uniquely* decomposed as

$$\mathbf{v}_\circ(\mathbf{a}) = \mathbf{w}_\circ(\mathbf{a}) + \nabla_{\mathbf{a}}\phi_\circ(\mathbf{a}), \tag{20}$$

where the unique vector $\mathbf{w}_\circ(\mathbf{a})$ satisfies

$$\begin{aligned} \nabla_{\mathbf{a}}\cdot\mathbf{w}_\circ &= 0 \quad \text{in } \Omega_\circ, \\ \mathbf{w}_\circ\cdot\mathbf{n}_\circ &= 0 \quad \text{on } \partial\Omega_\circ \end{aligned} \tag{21}$$

and $\phi_\circ$ is unique up to a constant.

A sufficient condition for Eq. (15) is then to have

$$\mathbf{w}_\circ\cdot\nabla_{\mathbf{a}}\times\mathbf{w}_\circ = \mathbf{w}_\circ\cdot\boldsymbol{\omega}_\circ = 0. \tag{22}$$

If the above condition is found in the initial velocity field, then it is enough to put

$$\varphi_\circ = \phi_\circ. \tag{23}$$

The condition (22) is equivalent to the *local* integrability of the vector field $\mathbf{w}_\circ$. This is the result of the "Frobenius theorem" (see Arnold, 1988, or more generally Yang, 1992). It is valuable to emphasize the feature of "local" integrability of $\mathbf{w}_\circ$. This means that if one looks for some surfaces everywhere normal to $\mathbf{w}_\circ$, i.e.,

$$\mathbf{w}_\circ\cdot d\mathbf{a} = 0, \tag{24}$$

then the above equation is integrable and there exists locally a surface $\mu=0$ on which Eq. (24) holds. This means that locally one can write

$$\mathbf{w}_\circ = \frac{\lambda}{\rho}(\mathbf{a})\boldsymbol{\nabla}_\mathbf{a}\mu, \tag{25}$$

which is the consequence of the Lagrangian invariance of the local Clebsh variables λ/ρ and μ. Since according to Eqs. (4), (5), and (7) we have $\mathbf{u}_\circ = \mathbf{v}_\circ$, then, regarding Eqs. (25), (20), and (23) one finds

$$\mathbf{u}_\circ = \frac{\lambda}{\rho}(\mathbf{a})\boldsymbol{\nabla}_\mathbf{a}\mu + \nabla_\mathbf{a}\varphi_\circ. \tag{26}$$

The first term on the right-hand side of the above equation holds "locally" while the last term is valid "globally" throughout $\Omega_\circ$. Indeed, since the vector field $\mathbf{w}_\circ$ is divergence free, its field lines may become closed curves. We know that topologically for a smooth closed curve like $\mathbf{w}_\circ$ we cannot find any "global" scalar function which its level surfaces are everywhere normal to $\mathbf{w}_\circ$. Hence, in this case there is not any "global" scalar function $\mu(\mathbf{a})$ on the entire domain of $\Omega_\circ$ such that the surface $\mu(\mathbf{a}) = \text{const}$ be everywhere normal to $\mathbf{w}_\circ$. Finally substitution of Eq. (26) into Eq. (8) reproduces the Clebsh representation (19).

We summarize our sufficient condition, Eq. (22), in a global sense or equivalently, Eq. (25) in a local sense only. If this is fulfilled, then the spirality can "globally" (identically) transformed to zero [Eq. (15) holds] provided the gauge transformation (12) is based on the unique "global" function $\varphi_\circ = \phi_\circ$.

IV. SUMMARY

In the present note we reviewed a nonfamous Lagrangian invariant so-called spirality. This invariant, which depends on the Bernoulli's potential and Weber transformation, may have significant geometrical and topological features. In particular, we hope the spirality may be helpful in understanding those topological invariants which may have the potential to create singularity in future finite times. It seems that if the spirality can be globally zero, the possibility for the creation of a singularity will increase relative to the other case.

The conservation of helicity, which is a well-known law, can also be obtained by the invariance of the spirality mentioned in Marchioro and Pulvirenti (1994) and also Eshraghi (2003). A gauge transformation for the spirality was given which leaves the helicity unchanged. Then, in the case of vanishing helicity in a co-moving domain of fluid motion whose boundary was tangent to vortex lines, we studied a special class of zero spirality. In other words, we tried to discover the geometrical meaning of such a flow in which one can change the spirality to be identically zero inside the mentioned domain. We considered a simply connected domain of fluid motion with zero helicity. For such a domain a necessary and a sufficient condition for the possibility of zero spirality was introduced.

The necessary condition says that across any closed nonzero vortex line (if any) inside the domain, the total flux (link) of other vortex lines must vanish. This means that there can exist some links or wrapping of vortex lines around each other but for any of them all links cancel and the total link vanishes.

The sufficient condition was derived through the global nature of the decomposition theorem. By this theorem we could decompose the initial velocity field as the sum of a unique global divergence free and tangent to the boundary plus a unique global gradient field. It was shown that if the divergence free field is locally integrable, then the spirality can globally be brought to zero everywhere.

However, the spirality "locally," always can become zero. This is the direct result of the Clebsh variables. We saw under the situation of the sufficient condition that the local invariant Clebsh variables λ/ρ and μ can also represent the divergence free (and tangent to the boundary) component of the initial velocity field. Hence, in this case the invariant Clebsh variables λ/ρ and μ are only local while $\tilde{\varphi}$ turns out to be global.

A Bethe–Ansatz study of a self-dual Z_N spin model is undertaken for even spin system. One must solve a coupled system of Bethe–Ansatz equations (BAE) involving zeroes of two families of transfer matrices. A numerical study on finite size lattices is done for identification of elementary excitations over the ferromagnetic and antiferromagnetic ground states. The free energies for both ferromagnetic and antiferromagnetic ground states and dispersion relation for elementary excitations are found. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1847708]

I. INTRODUCTION

The present model was first proposed in 1982 by Fateev and Zamolodchikov[1] as a two-dimensional self-dual Z_N lattice model with nearest neighbor spin-spin interaction. Baxter, Bazhanov, and Perk[2] discovered a set of functional equations involving families of chiral Potts (CP) transfer matrices. Fateev–Zamolodchikov model (FZM) was shown to be a nonchiral self-dual limit of chiral Potts.[3,4] The chiral Potts transfer matrix functional equations were used to obtain transcendental equations (Bethe Ansatz equations)[5] for the zeroes of the transfer matrices for the present problem.[3,4] In the general FZM model the Bethe Ansatz equations (BAE) are coupled involving two automorphically connected families of transfer matrices as in the CP case.[2] In the odd spin case these families are connected by simple transformations and the BAEs greatly simplify and decouple requiring us to solve only one set of equations.[4] For this odd spin case alone, Albertini obtained the ferromagnetic ground state.[6] A unified treatment for the ground state of odd and even spin FZM can be found in a previous work.[4] For $N=4$ FZM a comprehensive study has been done. This includes determination of exact energy values and central charge,[7] and completeness and classification of Bethe states.[8] The present work demonstrates the study of these Bethe equations in both ferromagnetic and antiferromagnetic cases for finding the free energy and elementary excitations.

In a generic situation for the Fateev–Zamolodchikov model (to be specific we shall use the even spin case) we obtained coupled Bethe–Ansatz equations,

$$\prod_{k=1}^{L_{Uq}} \frac{\sinh(\lambda_j - \overline{\lambda_k} - i\gamma)}{\sinh(\lambda_j - \overline{\lambda_k} + i\gamma)} = (-1)^{M+1}\left[\frac{\sinh 2(\lambda_j + is\gamma)}{\sinh 2(\lambda_j - is\gamma)}\right]^{2M}, \tag{1}$$

a)Electronic mail: subho@juphys.ernet.in

$$\prod_{k=1}^{L_q} \frac{\sinh(\overline{\lambda_j} - \lambda_k - i\gamma)}{\sinh(\overline{\lambda_j} - \lambda_k + i\gamma)} = (-1)^{M+1}, \tag{2}$$

where $\{\lambda_j\}$ and $\{\overline{\lambda_j}\}$ are the spectral variables for transfer matrices T_q and T_{U_q}, respectively and $\gamma = \pi/2N$ and $s = \frac{1}{2}$.

The first equation is quite similar to the generic case of the Bethe equation. However it involves zeroes of two different transfer matrices $(\lambda, \overline{\lambda})$ that are coupled further by a second equation whose form is quite unique.

The generic case of the most commonly encountered Bethe Ansatz equation looks like

$$\prod_{k=1}^{L} \frac{\sinh(\lambda_j - \lambda_k - i\gamma)}{\sinh(\lambda_j - \lambda_k + i\gamma)} = (-)^{M+1} \left[\frac{\sinh(\lambda_j - iS\gamma)}{\sinh(\lambda_j + iS\gamma)} \right]^{2M},$$

where S is the spin and γ is the anisotropy parameter of the model. In Bethe's original paper,[5] he studied the case $\gamma \to \infty$, where the hyperbolic functions reduce to rational ones. Note that in the generic case we have only one type of λ_j as opposed to two species of λ_j and $\overline{\lambda_j}$ as they appear in the present problem.

The standard procedure of calculating the physical quantities, e.g., the energy spectrum, dispersion curves, free energy, is to assume that the solutions for the Bethe equation are given by the string hypothesis. Starting with the work of Bethe there has been a great deal of study in these complex solutions of BAE. They appear in the form,

$$\lambda_{\alpha,k}^{(n,\nu)} = \lambda_{\alpha}^{(n,\nu)} + \frac{\gamma}{2}(n + 1 - 2k)i + \frac{(1-\nu)\pi}{4}i + \delta_{\alpha,k}^{(n,\nu)}, \quad k = 1, 2, \ldots, n,$$

where $\lambda_{\alpha}^{(n,\nu)}$ is the real part, n is its length, k runs from 0 through n labelling the root. The coefficient ν takes on the value (+1) (positive parity) or (−1) (negative parity); $\delta_{\alpha,k}^{(n,\nu)}$ vanishes regularly as $M \to \infty$.

However Bethe himself realized that for large M not all solutions of BAE are of the form (above) with $\lim_{M\to\infty} \mathrm{Im}(\delta) = 0$. Modern work for the case of $\lim_{M\to\infty} \mathrm{Im}(\delta) \neq 0$ was initiated by Destri and Lowenstein and Woynarovich who introduced the definition of narrow pairs for $\lim_{M\to\infty} \mathrm{Im}(\delta) < 0$ and wide pairs for $\lim_{M\to\infty} \mathrm{Im}(\delta) > 0$ and was furthered by Avdeev and Dörfel[9,10] who introduced three classes for $\lim_{M\to\infty} \mathrm{Im}(\delta)$. It is clear that none of the existing approaches to BAE for S integer or half-integer is sufficiently refined to answer the reality or completeness question for the Hamiltonian.

In the general spin hypothesis framework one obtains equations for the centers of the strings by multiplying the Bethe Ansatz equations over different members of the same string and then taking the logarithm of the resulting equation. This yields

$$\frac{1}{2\pi}\Theta_j^{(1)}(\lambda_\alpha^j) - \frac{1}{2\pi M}\sum_k \sum_{\beta=1}^{M^{(k)}} \Theta_{jk}^{(2)}(\lambda_\alpha^{(j)} - \lambda_\beta^{(k)}) = \frac{I_\alpha^{(j)}}{M},$$

where $M^{(k)}$ is the number of k-strings and

$$\Theta_j^{(1)}(\lambda) = 2\sum_{\ell=1}^{n_j} \phi(\lambda, n_j + 2s - 2\ell + 1, \nu_j),$$

$$\Theta_{jk}(\lambda) = \phi(\lambda, n_j + n_k, \nu_j\nu_k) + \phi(\lambda, |n_j - n_k|, \nu_j\nu_k) + \sum_{\ell=1}^{\min(n_j,n_k)-1} 2\phi(\lambda, |n_j - n_k| + 2\ell, \nu_j\nu_k),$$

and

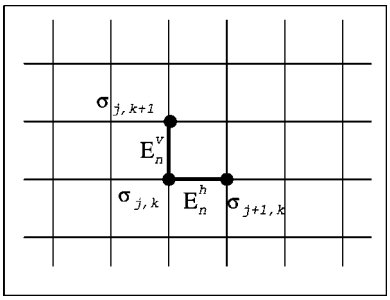

FIG. 1. Fateev–Zamolodchikov model on a square lattice.

$$\phi(\lambda,n,\nu)=\begin{cases}2\nu\arctan\left(\cot\left(\dfrac{n\gamma}{2}\right)^{\nu}\tanh(\lambda)\right),\\ 0 \text{ if } n\gamma=q\pi, \quad q\in Z.\end{cases}$$

In certain cases, e.g., δ-function Bose gas, it can be proved that the solutions are real, and no such multiplying of string components is necessary.[11] In such cases, the integers designating the branches of logarithms uniquely characterize the states and may be viewed as quantum numbers for the states. A monotonic relation is shown to exist between the integers and the values of the spectral variable $\lambda_{\alpha}^{(n,v)}$. In almost all subsequent work in the field this unique characterization of states by integers and their monotonic relation to solutions have been assumed. In few cases some counting argument is attempted[5,12–15] to justify this assumption. In the $N\to\infty$ limit, after introducing the concept of density of string centers, one obtains a coupled set of integral equations. These equations are manipulated to calculate the energies of the ground state and low lying excited states. For the spin 4 system, complete classification of Bethe states, and exact calculation for finite and infinite systems is already known.[7,8]

In the present problem, we had to deal with a doubly coupled set of integral equations; two sets of coupled equations both involving zeroes of two types of transfer matrices. However linearity of the equations made it possible to solve for the ground state and elementary excitations by the Fourier transform method. A study of the classification of roots is undertaken. However one must keep track of the added complexity of having to handle T_q and T_{U_q} simultaneously. One can identify the ground state and elementary excitations on the basis of this numerical study. The excitation spectrum and dispersion relations can hence be calculated.

II. FATEEV–ZAMOLODCHIKOV MODEL

Fateev and Zamolodchikov proposed in 1982 a two-dimensional self-dual Z_N lattice spin model with nearest neighbor interaction. They obtained this model as the self-dual[16] solution of the star-triangle relations.[17]

A general Z_N model can be defined as follows. On a two-dimensional rectangular lattice the lattice sites are occupied by a spin variable z which takes its values in the group Z_N $[z^N=1]$. If one designates the sites on the lattice by a two-dimensional integer-valued vector x, one can write down the partition function of the statistical Z_N model with nearest neighbor interaction as

$$Z=\sum_{\{z\}}\prod_{\mathbf{x}}\prod_{\sigma=\pm}w^{(\sigma)}(z(\mathbf{x}),z(\mathbf{x}+\boldsymbol{\epsilon}_{\delta})), \tag{3}$$

where the sum runs over all values of the variable z in every site of the lattice. The functions w^{σ}, $(\sigma=\pm1)$ are the weight functions corresponding to the interaction between spins on the neighboring sites of the lattice in horizontal $(\sigma=1)$ and vertical $(\sigma=-1)$ directions, respectively. The vectors $\boldsymbol{\epsilon}_1=(1,0)$ and $\boldsymbol{\epsilon}_{-1}=(0,1)$ are the basis vectors of the lattice (see Fig. 1).

In the absence of external fields, the most general interaction between two neighboring spins after appropriate normalization is given by

$$w^{(\sigma)}(z_1,z_2) = 1 + \sum_{i=1}^{N-1} x_i^{(\sigma)} \cdot (z_1 z_2^{\star})^i, \tag{4}$$

where superscript * denotes complex conjugate. Reality of $w^{(\sigma)}(z_1,z_2)$ imposes on the parameters the following restriction:

$$x_i^{(\sigma)} = x_{N-i}^{(\sigma)}. \tag{5}$$

The dual transformation of the statistical weights are given by

$$\tilde{x}_i^{(\sigma)} = \left(1 + \sum_{k=1}^{N-1} x_k^{(-\sigma)} \omega^{ki}\right)\left(1 + \sum_{k=1}^{N-1} x_k^{(-\sigma)}\right)^{-1}, \tag{6}$$

where $\omega = \exp(2\pi i/N)$. The region of self-duality is then given by

$$\tilde{x}_i^{(\sigma)} = x_i^{(\sigma)}. \tag{7}$$

Let the parameters $x_i^{(\sigma)}$ be represented by a family of functions $W_i(\alpha)$ of auxiliary parameter $\alpha \in \mathcal{C}$,

$$x_i^{(1)} = W_i(\alpha), \quad x_i^{(-1)} = W_i(\pi - \alpha). \tag{8}$$

The star-triangle relation[18,19] on $x_i(\alpha)$,

$$\sum_{k=0}^{N-1} W_{n_1-k}(\alpha) W_{n_2-k}(\pi - \alpha - \alpha') W_{n_3-k}(\alpha') = c(\alpha,\alpha') W_{n_2-n_3}(\pi - \alpha) W_{n_1-n_3}(\alpha + \alpha') W_{n_1-n_2}(\pi - \alpha'). \tag{9}$$

The particular solution of Eq. (9) that possesses the self-duality property, e.g., Eq. (7), is given by

$$W_0 = 1, \quad W_n(\alpha) = \prod_{k=0}^{n-1} \frac{\sin[\pi k/N + \alpha/2N]}{\sin[\pi(k+1)/N - \alpha/2N]}. \tag{10}$$

Denoting $x_n^{(1)} = W(n|u)$ and $x_n^{(-1)} = \bar{W}(n|u)$ we get

$$\frac{W(n|u)}{W(0|u)} = \prod_{j=1}^{n} \frac{\sin(\pi j/N - \pi/2N - u)}{\sin(\pi j/N - \pi/2N + u)}, \tag{11}$$

$$\frac{\bar{W}(n|u)}{\bar{W}(0|u)} = \prod_{j=1}^{n} \frac{\sin(\pi j/N - \pi/N + u)}{\sin(\pi j/N - u)}. \tag{12}$$

We adopt the normalization $W(0|u) = \bar{W}(0|u) = 1$. The "physical region" defined by non-negative real Boltzmann weights (BW), is given by $u \in [0, \pi/2N[$. For $N=2,3$ Eq. (11) and Eq. (12) simply reduce to the self-dual critical Potts model. For $N=4$ it gives a particular case of critical Ashkin–Teller model. Fateev and Zamolodchikov propose that for $N=5,7$ the solution describes the critical bifurcation points in the phase diagram of Alcaraz and Koberle.[20]

III. CHIRAL–POTTS MODEL AND CONNECTION TO FZM

On the sites of a two-dimensional lattice of size $\mathcal{M} \times \mathcal{N}$ denoted by two-dimensional vector (j,k) with integer entries, we place Z_N spins $\sigma_{j,k}$. The spins $\sigma_{j,k}$ are classical variables satisfying

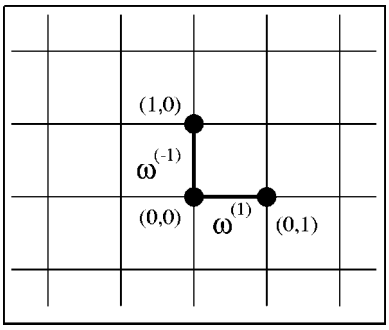

FIG. 2. Square lattice chiral Potts model.

$$\sigma_{j,k}^{N} = 1,$$

i.e., $\sigma_{j,k} = \omega^{\nu}$, $\nu \in \{0,1,2,\ldots,N-1\}$ where ω is the complex Nth root of unity with the minimum argument,

$$\omega = e^{2\pi i/N}.$$

The energy corresponding to a given configuration of spins $\{\sigma_{j,k}\}$ is

$$\mathcal{E} = -\sum_{\{j,k\}} \sum_{n=1}^{N-1} \{E_n^h \cdot (\sigma_{j,k}\sigma_{j,k+1}^{\star})^n + E_n^v \cdot (\sigma_{j,k}\sigma_{j+1,k}^{\star})^n\}.$$

Row index j runs over 1 to $\mathcal{M}$ and column index k runs over 1 to $\mathcal{N}$ with periodic boundary condition in both directions implied (see Fig. 2).

In chiral Potts a subspace of the coupling parameters (E_n^h, E_n^v) is chosen which has a built-in handedness, or phase. The energy of a nearest neighbor pair is chosen as

$$\mathcal{E}_{\text{pair}}^{h,v}(\sigma_1,\sigma_2) = -\sum_{n=1}^{N-1} E_n^{h,v} \cdot (\sigma_1\sigma_2^{\star})^n,$$

where $E_n^{h,v} = |E_n^{h,v}| \cdot e^{i\delta_n}$. The local Boltzmann weights (BW) can now be easily defined as

$$W^{h,v}(n) = e^{(1/k_B T)\sum_{j=1}^{N-1} E_j^{h,v}\omega^{jn}}.$$

Let us denote two adjacent row configurations by $\{l\}$ and $\{l'\}$ (l corresponds to the lower row), where

$$\{l\} = \{\omega^{l_j} | j = 1(1)\mathcal{N} \text{ and } l_j \in 0,1,\ldots,N-1\}.$$

The row to row transfer matrix is given by

$$T_{\{l\},\{l'\}} = \prod_{j=1}^{\mathcal{N}} W^h(l_j - l'_{j+1}) \cdot W^v(l_j - l'_j).$$

It has been shown by several authors[1,21–23] that the transfer matrices corresponding to the interaction parameters belonging to the chiral Potts submanifold commute,

$$[T, T'] = 0.$$

The self-dual chiral Potts model is given by BWs,

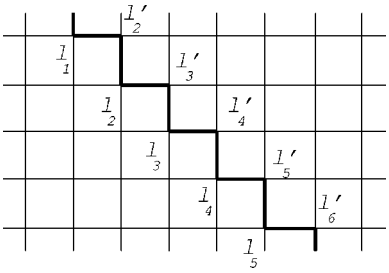

FIG. 3. Transfer matrix $T_{\{l\},\{l'\}}$.

$$\frac{W_{pq}(n)}{W_{pq}(0)} = \prod_{j=1}^{n} \frac{b_q - \omega^j a_p}{b_p - \omega^j a_q}, \tag{13}$$

$$\frac{\overline{W}_{pq}(n)}{\overline{W}_{pq}(0)} = \prod_{j=1}^{n} \frac{\omega a_p - \omega^j a_q}{b_q - \omega^j b_p}, \tag{14}$$

where $\omega = \exp(2\pi i/N)$ and the paired complex variables $(a,b) \in \mathcal{C}^2$ satisfy the constraint

$$a_x^N + b_x^N = \kappa, \tag{15}$$

$\kappa \in [0,1]$, and $x = p$ or q. In the nonchiral limit, when $\kappa = 0$, we can parametrize (a_x, b_x) in Eq. (15) as

$$a_x = e^{2ix}, \quad b_x = \omega^{1/2} e^{2ix}. \tag{16}$$

Defining $u = q - p$ Eq. (13) and Eq. (14) reduce to Eq. (11) and Eq. (12). However we retain suffixes (p,q) in the Boltzmann weights $W_{pq}(n|u)$ and $\overline{W}_{pq}(n|u)$ to signify that these BWs are obtained from the chiral Potts BWs defined in terms of p and q variables.

The transfer matrix for the FZM can be constructed from the BWs as

$$T_{p,q}^{\mathrm{n},\mathrm{n}'}(u) = \prod_{k=1}^{M} \overline{W}_{pq}(n_k - n_k'|u) W_{pq}(n_k - n_{k+1}'|u), \tag{17}$$

where M is the number of sites in each row and periodic boundary condition is implied (see Fig. 3). These transfer matrices for different spectral variable u form a commuting set. This can be argued from the fact that these transfer matrices come as a limit of CP transfer matrix, which are known to be commuting. A more direct argument would be that Fateev and Zamolodchikov obtained FZM BWs as solutions of star-triangle relation, and hence the transfer matrix constructed out of them should commute,

$$[T(u), T(u')] = 0 \ \forall \ u, u' \in C. \tag{18}$$

Transfer matrix $T(u)$ reduces to identity operator for $u \to 0$. An expansion of $T(u)$ gives us the associated spin chain Hamiltonian H,

$$T(u) = 1 - Mu \sum_{n=1}^{N-1} \frac{1}{\sin(n\pi/N)} - uH + O(u^2), \tag{19}$$

$$H = -\sum_{k=1}^{M}\sum_{n=1}^{N-1}\frac{1}{\sin(n\pi/N)}(X_k^n + Z_k^n Z_{k+1}^{-n}), \tag{20}$$

where X and Z are defined as

$$X_k|n_1\cdots n_k\cdots n_M\rangle = |n_1\cdots n_k+1\cdots n_M\rangle \bmod N,$$

$$Z_k|n_1\cdots n_k\cdots n_M\rangle = \omega^{n_k}|n_1\cdots n_k\cdots n_M\rangle.$$

Equations (19) and (20) imply that each Hamiltonian commutes with all the transfer matrices and their associated Hamiltonians. Thus it has an infinite set of conserved charges in involution. However only a subset of them, whose number is equal to the degrees of freedom of the system, are independent.

In order to obtain the zeros of the eigenvalues of the transfer matrix T_q, we will use functional equations connecting T_q with its automorphically conjugate partners. Thus it is important to understand the relevant automorphisms of the constraint Eq. (15). It has been claimed in the preceding section that the transfer matrices constructed out of CP BWs, Eq. (13) and Eq. (14), commute as long as they satisfy Eq. (15). For any $(a,b)\in\mathcal{C}^2$ satisfying the above relations there exist other complex pairs connected to them which satisfy the same relation. Two such automorphic relations of importance are

$$R(a,b) = (b,\omega a), \quad U(a,b) = (\omega a, b). \tag{21}$$

It is rather straightforward to check

$$a_{Rx}^N + b_{Rx}^N = \kappa, \quad a_{Ux}^N + b_{Ux}^N = \kappa$$

from the relation

$$a_x^N + b_x^N = \kappa.$$

If one makes an attempt to go over from CP BWs to FZM BWs through a limiting process, one gets the following relations for W_{pRq}, $\overline{W}_{pRq}$, W_{pUq}, and $\overline{W}_{pUq}$:

$$\frac{W_{pRq}(n|u)}{W_{pRq}(0|u)} = \prod_{k=1}^{n}\frac{\sin(\pi k/N - \pi/N - u)}{\sin(\pi k/N + u)}, \tag{22}$$

$$\frac{\overline{W}_{pRq}(n|u)}{\overline{W}_{pRq}(0|u)} = \prod_{k=1}^{n}\frac{\sin(\pi k/N - \pi/2N + u)}{\sin(\pi k/N - \pi/2N - u)}, \tag{23}$$

$$\frac{W_{pUq}(n|u)}{W_{pUq}(0|u)} = e^{-\imath\pi n/N}\prod_{k=1}^{n}\frac{\sin(\pi k/N - \pi/2N - u)}{\sin(\pi k/N + \pi/2N + u)}, \tag{24}$$

$$\frac{\overline{W}_{pUq}(n|u)}{\overline{W}_{pUq}(0|u)} = e^{\imath\pi n/N}\prod_{k=1}^{n}\frac{\sin(\pi k/N + u)}{\sin(\pi k/N - u)}. \tag{25}$$

Thus in the nonchiral limit, $T_q \to T_q(u)$ and $T_{Rq} \to T_q(u+\pi/2N)$. There is no simple relation between T_q and T_{Uq} though. However, we do feel that there must exist some nontrivial mapping between T_q and T_{Uq} whose understanding will unravel the connection between the zeroes of T_q and T_{U_q} and will give the satisfactory derivation of completeness of states.

IV. BETHE ANSATZ TYPE EQUATIONS FOR THE EVEN *N* FZM

We define the normalized transfer matrices by removing their denominators,

$$T_q^N(u) = [g_q(u)\overline{g_q}(u)]^M T_q(u),$$

where

$$g_q(u) = \prod_{j=1}^{N/2} \sin\left(\frac{\pi j}{N} - \frac{\pi}{2N} + u\right), \quad \overline{g_q}(u) = \prod_{j=1}^{N/2} \sin\left(\frac{\pi j}{N} - u\right).$$

One must note that the superscript in T_q^N denotes "normalize" and is not related to the spin quantum number N. Each entry of $T_q^N(u)$ is a product of NM sines and it has the general form

$$\prod_{k=1}^{NM} (c_k^{(1)} e^{iu} + c_k^{(2)} e^{-iu}).$$

The calculation of this section goes in the same spirit as that of odd N case. Hence we only quote the results,

$$\Lambda_{Q=0}(u) = \left[\frac{g_q(0)\overline{g_q}(0)}{g_q(u)\overline{g_q}(u)}\right]^M \prod_{k=1}^{L} \frac{\sin(u - v_k)}{\sin v_k},$$
$$L = A + B = NM. \tag{26}$$

The normalization has been fixed by $T_q(0) = 1_{id}$.

The momentum (P) is given by

$$e^{iP} = \Lambda_Q\left(u = \frac{\pi}{2N}\right) = \left[\frac{g_q(0)\overline{g_q}(0)}{g_q\left(\frac{\pi}{2N}\right)\overline{g_q}\left(\frac{\pi}{2N}\right)}\right]^M \prod_{k=1}^{L} \frac{\sin\left(\frac{\pi}{2N} - v_k\right)}{\sin v_k}. \tag{27}$$

Now we turn to the sectors $Q \neq 0$, and the symmetry under charge conjugation allows us to consider the sectors $Q = 1, 2, \ldots, (N-1)/2$ only. While we have not been able to obtain a proof like the one given above, one can show that, in the sector Q,

$$\text{(a) } A, B \leqslant \frac{NM}{2} - Q, \quad Q = 1, 2, \cdots, \frac{N}{2},$$

$$\text{(b) } A, B \geqslant \frac{NM}{2} - \frac{N}{2}.$$

Following similar argument as before, we arrive at

$$A = B = \frac{NM}{2} - Q.$$

The reader must be warned that this conclusion lacks rigor just like in the case of N odd. The factorization in terms of sines can be carried out without the appearance of a phase $(e^{2iu})^{\pm(B-A)}$. We assume this to be true also for the others Q sectors, and arrive at the general form

$$\Lambda_Q(u) = \left[\frac{g_q(0)\overline{g_q}(0)}{g_q(u)\overline{g_q}(u)}\right]^M \prod_{k=1}^{L} \frac{\sin(u-v_k)}{\sin v_k},$$
$$L = NM - 2Q, \quad Q = 0,1,\cdots\frac{N}{2}, \quad \Lambda_{N-Q}(u) = \Lambda_Q(u). \tag{28}$$

From this, the eigenvalue of H is easily found to be

$$E = \sum_{k=1}^{L} \cot v_k - 2M\sum_{j=1}^{N/2} \cot(\pi j/N). \tag{29}$$

The momentum (P) is given by

$$e^{iP} = \Lambda_Q\left(u = \frac{\pi}{2N}\right) = \left[\frac{g_q(0)\overline{g_q}(0)}{g_q\left(\frac{\pi}{2N}\right)\overline{g_q}\left(\frac{\pi}{2N}\right)}\right]^M \prod_{k=1}^{L} \frac{\sin\left(\frac{\pi}{2N} - v_k\right)}{\sin v_k}. \tag{30}$$

We shall use the set of functional equations for the eigenvalues of transfer matrices of chiral Potts derived by Baxter, Bazhanov, and Perk.[2,24] This functional relation appears in Ref. 2 as Eq. (4.40) and has the following form:

$$\widetilde{T}_{\overline{q}} = \sum_{m=0}^{N-1} c_{m,q} T^{-1}_{U^m q} T_q T^{-1}_{U^{m+1}q} X^{-m-1}, \tag{31}$$

where $\widetilde{T} = TS$, $\overline{q} = (a_{\overline{q}}, b_{\overline{q}}) = UR^{-1}(a_q, b_q)$, and

$$c_{m,q} = \left(\left(\prod_{j=0}^{m-1} \frac{b_p - \omega^{j+1}a_q}{a_p - \omega^j a_q}\right)\cdot\left(\prod_{j=m+1}^{N-1} \frac{\omega(a_p - \omega^j a_q)}{b_p - \omega^{j+1}a_q}\right)\cdot\left(\frac{N(b_q - b_p)(b_p - a_q)}{a_p b_p - \omega^m a_q b_q}\right)\right)^M,$$

$$\widetilde{T}_{\overline{q}} = \sum_{s=0}^{(N/2)-1} (c_{2s,q} T^{-1}_{U^{2s}q} T_q T^{-1}_{U^{2s+1}q} X^{-2s-1}) + \sum_{s=0}^{(N/2)-1} (c_{2s+1,q} T^{-1}_{U^{2s+1}q} T_q T^{-1}_{U^{2s+2}q} X^{-2s-2})$$
$$= \sum_{s=0}^{(N/2)-1} \left(\frac{c_{2s,q}}{A_{s,q}A_{s,q'}} \cdot T^{-1}_{R^{2s}q} T_q T^{-1}_{R^{2s}(Uq)} X^{-1} + \frac{c_{2s+1,q}}{A_{s,q'}A_{s+1,q}} \cdot T^{-1}_{R^{2s}(Uq)} T_q T^{-1}_{R^{2s+2}q} X^{-1}\right).$$

Define

$$p_{2s} = \frac{c_{2s,q}}{A_{s,q}A_{s,q'}}, \quad d_{2s+1} = \frac{c_{2s+1,q}}{A_{s,q'}A_{s+1,q}}.$$

The independent inverse factors of $T_{R^{2s}q}$ and $T_{R^{2s}(Uq)}$ are considered, and both sides of the above equation are multiplied by the appropriate common factor so as to get rid of inverses of transfer matrix. The appropriate factor is

$$X\prod_{j=1}^{N/2} T_{R^{2j}q} \prod_{j=0}^{(N/2)-1} T_{R^{2j}(Uq)}. \tag{32}$$

After multiplying we get

$$X\cdot\tilde{T}_{\bar{q}}\cdot\prod_{j=1}^{N/2}T_{R^{2j}q}T_{R^{2(j-1)}(Uq)}=\sum_{s=0}^{(N/2)-1}\left(p_{2s}\prod_{\substack{j=0\\ j\neq s}}^{N/2}T_{R^{2j}q}\cdot\prod_{\substack{j=0\\ j\neq s}}^{(N/2)-1}T_{R^{2j}(Uq)}+d_{2s+1}\prod_{\substack{j=0\\ j\neq (s+1)}}^{N/2}T_{R^{2j}q}\cdot\prod_{\substack{j=0\\ j\neq s}}^{(N/2)-1}T_{R^{2j}(Uq)}\right). \tag{33}$$

If one expresses $T_{p,q}$ and $T_{p,Uq}$ in terms of a complex parameter u, where $u=q-p$ as $k\to 0$,

$$\begin{gathered}T_q\to T_q,\quad T_{Uq}\to T_{Uq}(u),\\ T_{R^{2k}q}\to T_q\left(u+\frac{k\pi}{N}\right),\quad T_{R^{2k}(Uq)}\to T_{(Uq)}\left(u+\frac{k\pi}{N}\right),\end{gathered} \tag{34}$$

with this parametrization we get

$$X\cdot\tilde{T}_{\bar{q}}\cdot\prod_{j=1}^{N/2}T_q\left(u+\frac{\pi j}{N}\right)\cdot\prod_{j=0}^{(N/2)-1}T_{Uq}\left(u+\frac{\pi j}{N}\right)=\sum_{s=0}^{(N/2)-1}\left(p_{2s}\prod_{\substack{j=0\\ j\neq s}}^{N/2}T_q\left(u+\frac{\pi j}{N}\right)\prod_{\substack{j=0\\ j\neq s}}^{(N/2)-1}T_{Uq}\left(u+\frac{\pi j}{N}\right)+d_{2s+1}\prod_{\substack{j=0\\ j\neq s+1}}^{N/2}T_q\left(u+\frac{\pi j}{N}\right)\prod_{\substack{j=0\\ j\neq s}}^{(N/2)-1}T_{Uq}\left(u+\frac{\pi j}{N}\right)\right). \tag{35}$$

Let v be a zero of T_q, i.e., $T_q(v)=0$, then whenever $u=v-\pi k/N$, $T_q(u+\pi k/N)=0$. Thus for $u=v-\pi k/N\ k\in\{1,2,\ldots,(N/2)-1\}$ all but two terms vanish,

$$p_{2k}\prod_{\substack{j=0\\ j\neq k}}^{N/2}T_q\left(u+\frac{\pi j}{N}\right)\prod_{\substack{j=0\\ j\neq k}}^{(N/2)-1}T_{Uq}\left(u+\frac{\pi j}{N}\right)+d_{2k-1}\prod_{\substack{j=0\\ j\neq k}}^{N/2}T_q\left(u+\frac{\pi j}{N}\right)\prod_{\substack{j=0\\ j\neq k-1}}^{(N/2)-1}T_{Uq}\left(u+\frac{\pi j}{N}\right)=0. \tag{36}$$

Cancelling the common factors we get

$$p_{2k}(u)\cdot T_{Uq}\left(u+\frac{\pi k}{N}-\frac{\pi}{N}\right)+d_{2k-1}(u)\cdot T_{Uq}\left(u+\frac{\pi k}{N}\right)=0 \tag{37}$$

whence

$$\frac{T_{Uq}(v)}{T_{Uq}\left(v-\frac{\pi}{N}\right)}=-\frac{p_{2k}\left(v-\frac{\pi k}{N}\right)}{d_{2k-1}\left(v-\frac{\pi k}{N}\right)}. \tag{38}$$

Recalling the expression for T_{Uq},

$$\prod_{j=1}^{L_{Uq}}\frac{\sin(v_i-\bar{v_j})}{\sin\left(v_i-\bar{v_j}-\frac{\pi}{N}\right)}=-\left(\frac{g_{Uq}(v_i)\cdot\bar{g}_{Uq}(v_i)}{g_{Uq}\left(v_i-\frac{\pi}{N}\right)\cdot\bar{g}_{Uq}\left(v_i-\frac{\pi}{N}\right)}\right)^M\cdot\frac{p_{2k}\left(v_i-\frac{\pi k}{N}\right)}{d_{2k-1}\left(v_i-\frac{\pi k}{N}\right)}. \tag{39}$$

The ratio of g_{Uq}'s can be obtained as

$$g_{Uq}(v_i) = \prod_{j=1}^{(N/2)-1} \sin\left(\frac{\pi j}{N} + \frac{\pi}{2N} + v_i\right), \quad g_{Uq}\left(v_i - \frac{\pi}{N}\right) = \prod_{j=0}^{(N/2)-2} \sin\left(\frac{\pi j}{N} + \frac{\pi}{2N} + v_i\right),$$

$$\frac{g_{Uq}(v_i)}{g_{Uq}\left(v_i - \frac{\pi}{N}\right)} = \frac{\sin\left(\frac{\pi}{2} - \frac{\pi}{N} + \frac{\pi}{2N} + v_i\right)}{\sin\left(0 + \frac{\pi}{2N} + v_i\right)} = \frac{\cos\left(v_i - \frac{\pi}{2N}\right)}{\sin\left(v_i + \frac{\pi}{2N}\right)}. \tag{40}$$

Similarly the ratios of $\overline{g}_{Uq}$ is found as

$$\overline{g}_{Uq}(v_i) = \prod_{j=1}^{(N/2)-1} \sin\left(\frac{\pi j}{N} - v_i\right), \quad \overline{g}_{Uq}\left(v_i - \frac{\pi}{N}\right) = \prod_{j=2}^{N/2} \sin\left(\frac{\pi j}{N} - v_i\right),$$

$$\frac{\overline{g}_{Uq}(v_i)}{\overline{g}_{Uq}\left(v_i - \frac{\pi}{N}\right)} = \frac{\sin\left(\frac{\pi}{N} - v_i\right)}{\sin\left(\frac{\pi}{2} - v_i\right)} = (-1) \cdot \frac{\sin\left(v_i + \frac{\pi}{N}\right)}{\cos(v_i)}. \tag{41}$$

Using these results for the ratios of g_{Uq} and those of (p_{2k}/d_{2k-1}) we finally get the Bethe equations[5]

$$\prod_{j=1}^{L_{Uq}} \frac{\sin(v_i - \overline{v_j})}{\sin\left(v_i - \overline{v_j} - \frac{\pi}{N}\right)} = (-1)^{M+1}\left[\frac{\sin 2\left(v_i - \frac{\pi}{2N}\right)}{\sin(2v_i)}\right]^{2M}. \tag{42}$$

Let $\overline{v}$ be a zero of T_{Uq}, i.e., $T_{Uq}(\overline{v})=0$, then whenever $u=\overline{v}-\pi k/N$, $T_q(u+\pi k/N)=0$. For $u=\overline{v}-\pi k/N$ $k \in \{1,2,\ldots,(N/2)-1\}$ all but two terms vanish

$$p_{2k} \prod_{\substack{j=0 \\ j \neq k}}^{N/2} T_q\left(u + \frac{\pi j}{N}\right) \prod_{\substack{j=0 \\ j \neq k}}^{(N/2)-1} T_{Uq}\left(u + \frac{\pi j}{N}\right) + d_{2k+1} \prod_{\substack{j=0 \\ j \neq k+1}}^{N/2} T_q\left(u + \frac{\pi j}{N}\right) \prod_{\substack{j=0 \\ j \neq k}}^{(N/2)-1} T_{Uq}\left(u + \frac{\pi j}{N}\right) = 0. \tag{43}$$

Cancelling the common factors we get

$$p_{2k}(u) \cdot T_q\left(u + \frac{\pi k}{N} + \frac{\pi}{N}\right) + d_{2k+1}(u) \cdot T_q\left(u + \frac{\pi k}{N}\right) = 0,$$

$$\frac{T_q(\overline{v})}{T_q\left(\overline{v} + \frac{\pi}{N}\right)} = -\frac{p_{2k}\left(\overline{v} - \frac{\pi k}{N}\right)}{d_{2k+1}\left(\overline{v} - \frac{\pi k}{N}\right)}. \tag{44}$$

The ratios of g_q's can be obtained as

$$g_q(\overline{v_i}) = \prod_{j=1}^{N/2} \sin\left(\frac{\pi j}{N} - \frac{\pi}{2N} + \overline{v_i}\right), \quad g_q\left(\overline{v_i} + \frac{\pi}{N}\right) = \prod_{j=2}^{(N/2)+1} \sin\left(\frac{\pi j}{N} - \frac{\pi}{2N} + \overline{v_i}\right),$$

$$\frac{g_q(\overline{v_i})}{g_q\left(\overline{v_i} + \frac{\pi}{N}\right)} = \frac{\sin\left(\frac{\pi}{N} - \frac{\pi}{2N} + \overline{v_i}\right)}{\sin\left(\frac{\pi}{N} + \frac{\pi}{N} + \overline{v_i}\right)} = \frac{\sin\left(\overline{v_i} + \frac{\pi}{2N}\right)}{\cos\left(\overline{v_i} + \frac{\pi}{2N}\right)}. \tag{45}$$

Similarly the ratios of $\overline{g_q}$'s is found as

$$\overline{g_q}(\overline{v_i}) = \prod_{j=1}^{N/2} \sin\left(\frac{\pi j}{N} - \overline{v_i}\right), \quad \overline{g_q}\left(\overline{v_i} + \frac{\pi}{N}\right) = \prod_{j=0}^{(N/2)-1} \sin\left(\frac{\pi j}{N} - \overline{v_i}\right),$$

$$\frac{\overline{g_q}(\overline{v_i})}{\overline{g_q}\left(\overline{v_i} + \frac{\pi}{N}\right)} = \frac{\sin\left(\frac{\pi}{2} - \overline{v_i}\right)}{\sin(0 - v_i)} = (-1) \cdot \frac{\cos(\overline{v_i})}{\sin(\overline{v_i})}. \tag{46}$$

Using these results for the ratios of g_q and those of p_{2k}/d_{2k+1} we finally get

$$\prod_{j=1}^{L_q} \frac{\sin(\overline{v_i} - v_j)}{\sin\left(\overline{v_i} - v_j + \frac{\pi}{N}\right)} = (-1)^{M+1}.$$

In order to cast the BAE's for the even case in a simpler (and standard) form, we make a change of variables.

$$v_j = i\lambda_j + \frac{\pi}{4N}, \quad \overline{v_j} = i\overline{\lambda_j} - \frac{\pi}{4N}. \tag{47}$$

The BAE's in terms of these new variables are

$$\prod_{k=1}^{L_{Uq}} \frac{\sinh(\lambda_j - \overline{\lambda_k} - i\gamma)}{\sinh(\lambda_j - \overline{\lambda_k} + i\gamma)} = (-1)^{M+1}\left[\frac{\sinh 2(\lambda_j + is\gamma)}{\sinh 2(\lambda_j - is\gamma)}\right]^{2M}, \tag{48}$$

$$\prod_{k=1}^{L_q} \frac{\sinh(\overline{\lambda_j} - \lambda_k - i\gamma)}{\sinh(\overline{\lambda_j} - \lambda_k + i\gamma)} = (-1)^{M+1}, \tag{49}$$

where $\gamma = \pi/2N$ and $s = \frac{1}{2}$. From the numerical study for even spin BAE's, it was found that λ_j's are related to one another. In fact

$$\forall \lambda_j \, \exists \, \lambda_j + i\pi/2 \bmod(\pi). \tag{50}$$

This allows us to group λ_j such that $\lambda_j \in [-\pi/4, \pi/4]$. Using transformation rules for the hyperbolic functions one can rewrite the expressions in terms of a new variable $\chi_j = 2\lambda_j$. The left-hand side (LHS) of BAE(1) becomes

$$\prod_{k=1}^{L_{Uq}/2} \frac{\sinh(\lambda_j - \overline{\lambda}_k - i\gamma)}{\sinh(\lambda_j - \overline{\lambda}_k + i\gamma)} \cdot \frac{\sinh\left(\lambda_j - \overline{\lambda}_k - i\gamma - \frac{i\pi}{2}\right)}{\sinh\left(\lambda_j - \overline{\lambda}_k + i\gamma - \frac{i\pi}{2}\right)} = \prod_{k=1}^{L_{Uq}/2} \frac{\sinh 2(\lambda_j - \overline{\lambda}_k - i\gamma)}{\sinh 2(\lambda_j - \overline{\lambda}_k + i\gamma)}$$

$$= \prod_{k=1}^{L_{Uq}/2} \frac{\sinh(\chi_j - \overline{\chi}_k - 2i\gamma)}{\sinh(\chi_j - \overline{\chi}_k + 2i\gamma)}. \tag{51}$$

The right-hand side (RHS) of BAE(1) is rewritten in terms of variables χ_j,

$$(-1)^{M+1}\left(\frac{\sinh(\chi_j + 2is\gamma)}{\sinh(\chi_j - 2is\gamma)}\right)^{2M} = (-1)^{M+1}\left(\frac{\sinh(\chi_j + i\gamma)}{\sinh(\chi_j - i\gamma)}\right)^{2M}, \quad \text{since } s = \tfrac{1}{2}. \tag{52}$$

A similar transformation is done for BAE(2). Hence the BAE equations become

$$\prod_{k=1}^{L_{Uq}/2} \frac{\sinh(\chi_j - \overline{\chi}_k - 2i\gamma)}{\sinh(\chi_j - \overline{\chi}_k + 2i\gamma)} = (-1)^{M+1}\left(\frac{\sinh(\chi_j + i\gamma)}{\sinh(\chi_j - i\gamma)}\right)^{2M}, \tag{53}$$

$$\prod_{k=1}^{L_q/2} \frac{\sinh(\overline{\chi}_j - \chi_k - 2i\gamma)}{\sinh(\overline{\chi}_j - \chi_k + 2i\gamma)} = (-1)^{M+1}. \tag{54}$$

The eigenvalues $\Lambda_Q(u)$ of the transfer matrix are given in terms of these zeroes χ_j's as[3]

$$\Lambda_Q(u) = \left[\frac{g_q(0)\overline{g}_q(0)}{g_q(u)\overline{g}_q(u)}\right]^M \prod_{k=1}^{L/2} \frac{\sin\left(2u - i\chi_k - \frac{\pi}{2N}\right)}{\sin\left(i\chi_k + \frac{\pi}{2N}\right)}, \tag{55}$$

where

$$g_q(u) = \prod_{j=1}^{N/2} \sin\left(\frac{\pi j}{N} - \frac{\pi}{2N} + u\right), \quad \overline{g}_q(u) = \prod_{j=1}^{N/2} \sin\left(\frac{\pi j}{N} - u\right). \tag{56}$$

V. STUDY OF FINITE SIZE SYSTEMS

The BAE in the present model differs from the standard form. The sign in front of γ on the right hand side of BAE(1) is reversed. That is to say that the RHS is equal to the inverse of what usually is known to be the RHS. The second of the coupled pair, BAE(2) is even more striking. Though the LHS is still coupled, the RHS is independent of the spectral variable. Understanding the real significance of these peculiarities can help enormously in solving the problem.

The transfer matrix for the FZM is constructed from the FZM Boltzmann weights (BW) as

$$T_q^{\mathbf{n},\mathbf{n}'}(u) = T_{p,q}^{\mathbf{n},\mathbf{n}'}(u) = \prod_{k=1}^{M} \overline{W}_{pq}(n_k - n'_k|u)W_{pq}(n_k - n'_{k+1}|u), \tag{57}$$

where M is the number of sites in each row and periodic boundary condition is implied. These transfer matrices for different spectral variable u form a commuting family. Transfer matrix acts on vectors defined in terms of spin indices along a row (or diagonal)[3] or the spin configuration $\mathbf{n} = |n_1, n_2, \ldots, n_M\rangle$.

There is an associated transfer matrix $T_{p,Uq}$ which corresponds to a conjugate set of Boltzmann weights,[4]

$$T_{Uq}^{\mathbf{n},\mathbf{n}'}(u) = T_{p,Uq}^{\mathbf{n},\mathbf{n}'}(u) = \prod_{k=1}^{M} \overline{W}_{pUq}(n_k - n'_k|u)W_{pUq}(n_k - n'_{k+1}|u). \tag{58}$$

The shift or translation operator $\hat{S}$ is defined by its action on a state function or spin configuration $\mathbf{n}=|n_1,n_2,\ldots,n_M\rangle$.

$$\hat{S}|n_1,n_2,n_3,\ldots,n_M\rangle = |n_M,n_1,n_2,\ldots,n_{M-1}\rangle. \tag{59}$$

Momentum P is defined in terms of the shift operator as

$$e^{iP} = \hat{S}^{-1}.$$

The z-component of spin operator $\hat{Z}_k$ and spin raising operator $\hat{X}_k$ corresponding to a given lattice site (k) are defined by their action on a state function or spin configuration as $\mathbf{n}=|n_1,n_2,\ldots,n_M\rangle$, $n_k=0,1,\ldots,N-1$.

$$\hat{X}_k|n_1\cdots n_k\cdots n_M\rangle = |n_1\cdots n_k+1\cdots n_M\rangle \mathrm{mod}(N),$$

$$\hat{Z}_k|n_1\cdots n_k\cdots n_M\rangle = \omega^{n_k}|n_1\cdots n_k\cdots n_M\rangle.$$

The global spin raising operator is given by

$$\hat{X} = \prod_{k=1}^{M} \hat{X}_k.$$

The spin Q is defined in terms of $\hat{X}$ as

$$e^{iQ} = \hat{X}^{-1}.$$

$T_{p,q}(u)$ and $T_{p,Uq}(u)$ commute with $\hat{S}$, $\hat{Z}_k$, and $\hat{X}$. Hence it is possible to make a spin and momentum sectorwise study of the problem.

The roots of the BAE are studied by computing the eigenvalues of the transfer matrices as meromorphic functions of $x=e^{\lambda}$. Since the transfer matrices with different spectral parameter λ commute, their eigenvectors are independent of the spectral parameter. Hence by taking a specific value of the spectral parameter one can determine the eigenvectors numerically by diagonalizing the finite size transfer matrix. From the definition of the eigenvalue equation one can express the eigenvalues as meromorphic functions of x, as the entries of transfer matrix are polynomials in x and the eigenvectors are vectors with numerical (independent of x) entries.

However the problem being coupled, one needs to simultaneously diagonalize T_q and T_{Uq} or in other words find the eigenvalues corresponding to simultaneous eigenvectors of T_q and T_{Uq}. This fact by itself introduces a significantly higher level of difficulty over other numerical simulation of similar type (noncoupled eqns.), e.g., chiral Potts.[25] Coupled BAE and any simultaneous eigenvalue problem (eigenvalues corresponding to simultaneous eigenvectors) results in the same generic problem in computer algorithm. One must develop efficient optimized codes for tackling this.

A detailed numerical study for chains of length $M \leqslant 8$ was done in Ref. 3. The main observations of this numerical study are as follows:

(i) 1-string with both parities, $(1,v)$, $v=(\pm 1)$,
(ii) even length strings with positive parities, $(n,+)$, $n=2,4,\ldots,N$,
(iii) nonstring solutions $\mathrm{Im}(\lambda) \sim \pm \pi/3$.

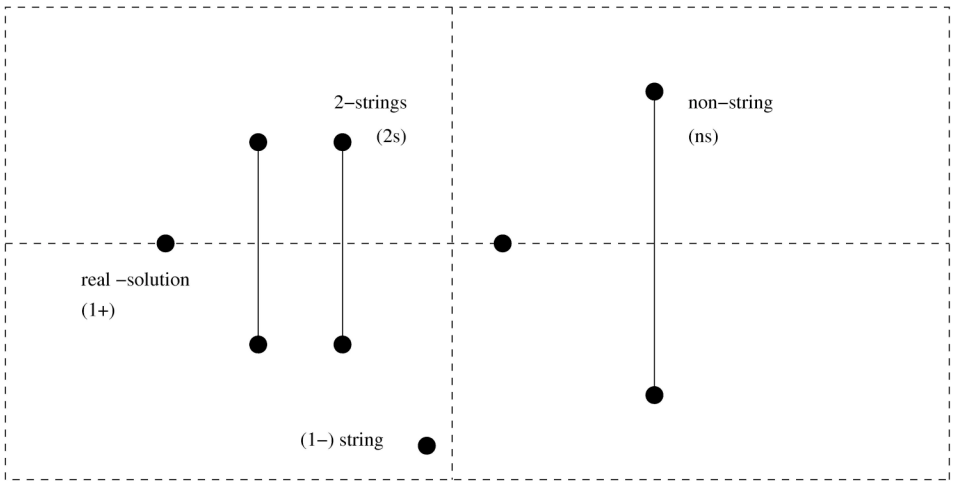

FIG. 4. String and nonstring solutions for BAE.

The ferromagnetic ground state is a filled band of 2-strings, and the excitations consist of $(1+)$, $(1-)$, etc. The antiferromagnetic ground state on the other hand is a filled band of $(1,\pm)$ and excitations are 2-strings with positive parity (see Fig. 4).

It is remarkable that a good deal of insight into the nature of string solutions can be obtained from finite systems of rather small size. The 2-strings are easily identified as having imaginary parts close to $\pi/4$. One can also identify the real roots and roots with negative parity $\mathrm{Im}(\lambda)=\pi/2$. There are roots whose imaginary parts are not well approximated by $\pi/2$ or $\pi/4$. These roots do not seem to systematically approach the 2-string value as $M\to\infty$. These roots are classified as nonstrings. For space limitation $M=2$ and $M=3$ figures are presented in this paper. The imaginary parts of the nonstring (ns) roots are

BAE in the variable χ. The content or the type of root is identified in column three. Column four gives the corresponding integer that appears in the BAE. In column five the energy calculated for the corresponding eigenvalue for transfer matrix is given.

VI. FREE ENERGY IN THE FERROMAGNETIC CASE FOR *N* EVEN

From the numerical study one can identify that the ferromagnetic (FM) ground state corresponds to a filled band of $N/2$ strings of positive parity for T_q and a filled band of 1-string of negative parity for T_{Uq}. This vector always falls in the $P=0$ sector as is expected. A further study up to eight sites reveals that this remains true.

The LHS of the first of Bethe Ansatz equations, BAE(1), is given by

$$\prod_{k=1}^{L_{Uq/2}} \frac{\sinh(\chi_j-\overline{\chi_k}-2i\gamma)}{\sinh(\chi_j-\overline{\chi_k}+2i\gamma)} = (-1)^{M+1}\left[\frac{\sinh(\chi_j+\gamma i)}{\sinh(\chi_j-\gamma i)}\right]^{2M}. \tag{60}$$

For the ferromagnetic case we made the assumption that the ground state corresponds to $N/2$ strings with positive parity for T_q and 1-strings of negative parity for T_{Uq},

$$\chi_{\alpha,v}^{n,l} = \chi_\alpha^n + 2\gamma(n+1-2l)i, \tag{61}$$

$$\overline{\chi}_{\alpha,v}^{n,l} = \overline{\chi}_\alpha^n - \frac{i\pi}{2}. \tag{62}$$

Define x and $\overline{x}$ by $\chi=2\gamma x$ and $\overline{\chi}=2\gamma\overline{x}$. If $M^{(n)}$ denotes the number of n-strings, we get for the left-hand side (LHS) of the BAE(1),

$$\prod_{l=1}^{n} \frac{\sinh 2\gamma(x_\alpha^n-\overline{x_\beta}+(n+1-2l)i-i-p_0 i)}{\sinh 2\gamma(x_\alpha^n-\overline{x_\beta}+(n+1-2l)i+i-p_0 i)} = \frac{\sinh 2\gamma(x_\alpha^n-\overline{x_\beta}-ni-p_0 i)}{\sinh 2\gamma(x_\alpha^n-\overline{x_\beta}+ni-p_0 i)}.$$

Taking product over the string elements of χ_α the first BAE becomes decoupled and is given in terms of the variables for T_q alone,

$$(-1)^{(M+1)n}\left[\prod_{l=1}^{n}\frac{\sinh 2\gamma\left(x_\alpha^n+\left(n+1-2l+\frac{1}{2}\right)i\right)}{\sinh 2\gamma\left(x_\alpha^n-\left(n+1-2l+\frac{1}{2}\right)i\right)}\right]^{2M}=(-1)^{M+1}. \tag{63}$$

After multiplying for the elements of a string, the second BAE becomes

$$\prod_{k=1}^{L_q/2}\prod_{l=1}^{n}\frac{\sinh 2\gamma(\overline{x_\alpha}-x_\beta^n-(n+1-2l)i-i-p_0 i)}{\sinh 2\gamma(\overline{x_\alpha}-x_\beta^n-(n+1-2l)i+i-p_0 i)}=(-1)^{(M+1)+(nL_q/2)}. \tag{64}$$

Thus we have only one set of BAE which involves the zeros of the transfer matrix T_q. From the above equation taking natural logarithm of both sides we get

$$2M\sum_{l=1}^{n} i\cdot\ln\left(\frac{\sinh\left(\chi_\alpha+2\gamma\left(n+1-2l+\frac{1}{2}\right)\right)}{\sinh\left(\chi_\alpha-a\gamma\left(n+1-2l+\frac{1}{2}\right)\right)}\right)=\pi I_\alpha.$$

Defining the density of string centers for the zeros of T_q by

$$\rho(\chi)=\lim_{M\to\infty}\frac{1}{M(\chi_{k+1}-\chi_k)} \tag{65}$$

we get

$$\rho(\chi)=\frac{1}{\pi}\Theta_{(N/2,+)}^{(1)'}(\chi), \tag{66}$$

where

$$\Theta^{(1)}_{(N/2,+)}(\chi) \doteq \sum_{l=1}^{n} 2\phi\left(\chi, n+\frac{1}{2}-2l, +\right)$$

and prime on $\Theta^{(1)}_{(N/2,+)}(\chi)$ denotes differentiation with respect to the variable χ. Here the function ϕ, as defined by Takahashi and Suzuki[26] is

$$\phi(x,n,v) \doteq i\cdot\ln(g(x,n,v)), \quad g(x,n,v) \doteq \frac{\sinh 2\gamma(x+ni+p_0 i)}{\sinh 2\gamma(x-ni+p_0 i)}.$$

Evaluating the sum over l in the Fourier space,

$$\tilde{\Theta}^{(1)'}_{(N/2,+)}(k) = 2\pi\frac{\sinh\left(\frac{\pi k}{2}-\frac{\pi k}{2N}\right)}{\sinh\left(\frac{\pi k}{N}\right)}, \tag{67}$$

$$\tilde{\rho}(k) = 4\frac{\sinh\left(\frac{\pi k}{2}-\frac{\pi k}{2N}\right)}{\sinh\left(\frac{\pi k}{N}\right)}. \tag{68}$$

By inverse Fourier transform we get

$$\rho(\chi) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \mathrm{d}k\, e^{-ik\chi}\tilde{\rho}(k).$$

The free energy for the ferromagnetic ground state is defined as

$$f_0(u) \doteq \lim_{M\to\infty}\left(-\frac{1}{M}\ln\Lambda_0(u)\right) = \prod_{\alpha=1}^{M^{N/2}}\prod_{l=1}^{N/2}\frac{\sin(2u-i\chi_\alpha+x(l))}{\sin(i\chi_\alpha-x(l))}.$$

Replacing the summation by an integral over the symmetrically placed string centers,

$$f_0(u) = -\frac{1}{2}\int_{-\infty}^{\infty}\mathrm{d}\chi\,\rho(\chi)\sum_{l=1}^{N/2}\ln\left(\frac{\cosh(2\chi)-\cos(4u+2x(l))}{\cosh(2\chi)-\cos(2x(l))}\right). \tag{69}$$

Transforming to the Fourier space and utilizing the expression and properties of $\tilde{\rho}(k)$ we get

$$f_0(u) = \int_{-\infty}^{\infty}\frac{4\mathrm{d}k}{k}\frac{\sinh\left(k\pi-\frac{k\pi}{N}\right)\sinh(2ku)\sinh\left(2ku-k\pi-\frac{k\pi}{N}\right)}{\sinh^2\left(\frac{2k\pi}{N}\right)}. \tag{70}$$

VII. EXCITATION ON FM GROUND STATE

We have seen in the preceding section that the FM ground state is given by a filled band of $(2s)$ strings. Consider the $Z_{(2s)}(\chi)$ function. In the general case it should look like

$$Z_{(2s)}(\chi) = \frac{1}{2\pi}\Theta^{(1)}_{(2s)}(\chi) - \frac{1}{2\pi M}\sum_k\sum_{\beta=1}^{M^{(k)}}\Theta^{(2)}_{(2s,k)}(\chi-\chi^k_\beta). \tag{71}$$

The density of $(2s)$ vacancies is given by

$$\sigma_{(2s)}(\chi) \doteq -Z'_{(2s)}(\chi). \tag{72}$$

The vacancy density and the density of $(2s)$ particles is related by

$$\sigma_{(2s)}(\chi) = \rho_{(2s)}(\chi) + \frac{1}{M}\sum_{\beta=1}^{M_h^{(2s)}} \delta(\chi - \chi_\beta^{(2s)h}), \tag{73}$$

where $\chi_\beta^{(2s)h}$ are the position of the holes.

Thus

$$-\sigma_{(2s)}(\chi) = \frac{1}{2\pi}\Theta'^{(1)}_{(2s)}(\chi) - \frac{1}{2\pi M}\sum_{k\neq(2s)}\sum_{\beta=1}^{M^{(k)}} \Theta'^{(2)}_{(2s,k)}(\chi - \chi_\beta^k) - \frac{1}{2\pi}\int \Theta'^{(2)}_{(2s,2s)}(\chi-\mu)\mathrm{d}\mu$$
$$+ \frac{1}{2\pi M}\sum_{h=1}^{M_h^{(2s)}} \Theta'^{(2)}_{(2s,2s)}(\chi - \chi_\beta^{(2s)h}). \tag{74}$$

The above equation can be interpreted as a collection of terms contributing to $(2s)$-ground state, $(2s)$-holes and excited particles $\sigma_{(2s)} = \sigma^{(0)}_{(2s)} + \sigma^{(h)}_{(2s)} + \Sigma_j \sigma^{(j)}_{(2s)}$ where $\sigma^{(0)}_{(2s)}$ is the same as $\rho_{(2s)}$ of the last section.

The expressions for energy (E) and momentum (P) are

$$E = \sum_{k=1}^{L/2} \cot\left(i\chi_k + \frac{\pi}{2N}\right) - 2M\sum_{k=1}^{N/2} \cot\left(\frac{\pi k}{N}\right), \tag{75}$$

$$e^{iP} = \prod_{k=1}^{L/2} \frac{\sinh\left(\chi_k + \frac{i\pi}{2N}\right)}{\sinh\left(\chi_k - \frac{i\pi}{2N}\right)}. \tag{76}$$

We obtain the energy of a state designated by a given set of strings

$$E = \sum_{\substack{k \\ \text{strings}}} \sum_{\beta=1}^{M^{(k)}} \epsilon_k(\chi_\beta^{(k)}) = \int \mathrm{d}\chi\, \sigma_{(2s)}(\chi)\epsilon_{(2s)}(\chi) - \sum_{\beta=1}^{M_h^{(2s)}} \epsilon_{(2s)}(\chi_\beta^{(2s)h}) + \sum_{\substack{k \\ k\neq(2S)}} \sum_{\beta=1}^{M^{(k)}} \epsilon(\chi_\beta^{(k)}). \tag{77}$$

The bare energies for n-string with parity v is easily obtained

$$\epsilon_{(n,v)}(\chi_\alpha) = \sum_{k=1}^{n} \cot\left(i\chi_{k,\alpha}^{(n,v)} + \frac{\pi}{2N}\right) = \sum_{k=1}^{n} \cot\left(i\chi_\alpha^{(n,v)} - 2\gamma(n+1-2k) - \frac{\pi}{4}(1-v) + \frac{\pi}{2N}\right)$$
$$= \sum_{k=1}^{n} \tan\left(\frac{\pi}{2} - i\chi_\alpha^{(n,v)} + 2\gamma(n+1-2k) + \frac{\pi}{4}(1-v) - \frac{\pi}{2N}\right).$$

One can separate the real and imaginary parts of this expression. This helps in determining whether we require additional constraints on rapidities χ_j to ensure reality of the total energy.

Numerical study showed that there exist several spurious solutions and only a subset of them, corresponding to a specific choice of counting numbers $I_\alpha^{(j)}$, is admissible. Nonstring solutions exist, however they are not as numerous. From the numerical study we make the assumption that the elementary excitations over the FM [a sea of $(2s)$-strings] are (a) a pair of $(1+)$ strings, and (b) $(1+)$ and $(1-)$ strings.

The FM ground state is a filled band of $(2s)$ strings. The density of ground state energy is

$$e_0 = \lim_{M\to\infty} \frac{E_0}{M} = \int d\chi\, \rho_{(2s)}(\chi)\epsilon_{(2s)}(\lambda) - 2\sum_{k=1}^{(N-1)/2} \cot\left(\frac{\pi k}{N}\right). \tag{78}$$

The observed correlation between the integers suggest that the rapidities corresponding to $(2s)$ and (a) should be connected allowing cancellation of the imaginary part of the total energy,

$$\mathrm{Im}[\epsilon_{(2s)}] = \mathrm{Im}[\epsilon_{(a)}]. \tag{79}$$

It can be shown that, $\mathrm{Im}[\epsilon_{(2s)}]=\mathrm{Im}[\epsilon_{(a)}]$ and $\mathrm{Re}[\epsilon_{(2s)}]=-\mathrm{Re}[\epsilon_{(a)}]$.

$$\mathrm{Re}[\epsilon_{(a)}(\chi)] = \frac{4}{\cosh(4\chi)}. \tag{80}$$

Similar argument holds for (b)-type excitations, where $\mathrm{Im}[\epsilon_{(2s)}]=\mathrm{Im}[\epsilon_{(b)}]$ and $\mathrm{Re}[\epsilon_{(2s)}]=-\mathrm{Re}[\epsilon_{(b)}]$.

$$\mathrm{Re}[\epsilon_{(b)}(\chi)] = \frac{4}{\cosh(4\chi)}. \tag{81}$$

One should note that the dressed energy and bare energy are equal since the function coupling the ground state density to excited states $\Theta^{(2)}_{(j,k)}$ is zero for $j=(2s)$. Thus we arrive at

$$E = E_0 + \sum_{\beta=1}^{M^{(a)}} 2\epsilon_{(a)}(\chi^{(a)}_\beta) + \sum_{\beta=1}^{M^{(b)}} 2\epsilon_{(b)}(\chi^{(b)}_\beta), \tag{82}$$

where E_0 is the ground state energy.

We now turn to the calculation of momentum. The momentum associated with a string of length j and parity v is found to be

$$p_{(1+)}(\chi) = -\tfrac{1}{2}\Theta^{(1)}_{(1+)}(\chi),$$

$$p_{(j)}(\chi) = -\tfrac{1}{2}\Theta^{(1)}_{(j)}(\chi) \quad \text{for } j \neq (1+), \tag{83}$$

whence

$$p_{(a)}(\chi) = p_{(b)}(\chi) = 2\arctan\left(\tanh\left(\frac{\chi}{2}\right)\right) + \pi. \tag{84}$$

These expressions are similar to the ones for nonstring excitations in the anti-ferromagnetic case for odd spin FZM. We get the dispersion relations for elementary excitations over the ferromagnetic ground state as

$$\epsilon_{(a)}(p) = 4\sin\left(\frac{p}{2}\right),$$

$$\epsilon_{(b)}(p) = 4\sin\left(\frac{p}{2}\right). \tag{85}$$

VIII. FREE ENERGY IN THE ANTIFERROMAGNETIC CASE FOR *N* EVEN

From the numerical study for finite lattices it was apparent that the antiferromagnetic (AFM) ground-state corresponds to a filled band of real roots for both T_q and T_{Uq}. In other words the AFM ground state is a filled sea of $(1,+)$ strings for both families of transfer matrices.

The AFM ground state corresponds to real roots for both families of transfer matrices. Hence we consider the natural logarithm of both sides of BAE's. From BAE(1) we get

$$\sum_{k=1}^{L_{Uq}/2} i \ln\left(\frac{\sinh(\chi_j - \overline{\chi_k} - 2i\gamma)}{\sinh(\chi_j - \overline{\chi_k} + 2i\gamma)}\right) = 2M \cdot i \ln\left(\frac{\sinh(\chi_j + i\gamma)}{\sinh(\chi_j - i\gamma)}\right) + 2\pi I_j \tag{86}$$

with standard definition of $\rho_1(\chi)$ and $\rho_2(\chi)$,

$$\rho_1(\chi_\alpha) = \frac{1}{\pi}\Theta_1^{(1)'}(\chi_\alpha) - \frac{1}{2M\pi}\sum_{\beta=1}^{\overline{M}} \Theta_1^{(2)'}(\chi_\alpha - \overline{\chi_\beta}) = \frac{1}{\pi}\Theta_1^{(1)'}(\chi_\alpha) - \frac{1}{2M\pi}\int_{-\infty}^{+\infty} d\overline{\mu}\Theta_1^{(2)'}(\chi - \overline{\mu})\rho_1(\overline{\mu}). \tag{87}$$

From BAE(2) we get

$$\sum_{k=1}^{L_q/2} i \ln\left(\frac{\sinh(\overline{\chi_j} - \chi_k - 2i\gamma)}{\sinh(\overline{\chi_j} - \chi_k + 2i\gamma)}\right) = 2\pi\overline{I_j}. \tag{88}$$

In the continuum limit $M \to \infty$ we get

$$\rho_2(\overline{\chi}) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} d\mu\, \Theta_2^{(2)'}(\overline{\chi_\alpha} - \mu)\rho_1(\mu). \tag{89}$$

The above pair of BAE is solved as before by the Fourier transform method,

$$\tilde{\rho}_1(k) = \frac{1}{\pi}\tilde{\Theta}_1^{(1)'}(k) - \frac{1}{2\pi}\tilde{\Theta}_1^{(2)'}(k)\tilde{\rho}_2(k), \tag{90}$$

$$\tilde{\rho}_2(k) = \frac{1}{2\pi}\tilde{\Theta}_2^{(2)'}(k)\tilde{\rho}_1(k). \tag{91}$$

From the above two equations,

$$\tilde{\rho}_1(k) = \frac{\sinh\left(\frac{\pi k}{2}\right) \cdot \sinh\left(\frac{\pi k}{2} - \frac{\pi k}{2N}\right)}{\sinh\left(\frac{\pi k}{N}\right) \cdot \sinh\left(\pi k + \frac{\pi k}{N}\right)}. \tag{92}$$

Following a similar procedure as shown in detail in the ferromagnetic case, the free energy for the antiferromagnetic case is obtained as

$$f = \frac{1}{2}\int_{-\infty}^{+\infty} \frac{dk}{k}\frac{\tilde{\rho}_1(2k)}{\sinh(\pi k)}\left[\cosh k\left(\pi - 4u - \frac{\pi}{N}\right) - \cosh k\left(\pi - \frac{\pi}{N}\right)\right]. \tag{93}$$

Substituting for $\tilde{\rho}_1(2k)$,

$$f = \frac{1}{2}\int_{-\infty}^{+\infty} \frac{dk}{k} \frac{\sinh\left(\pi k - \frac{\pi k}{N}\right)}{\sinh\left(\frac{2\pi k}{N}\right) \cdot \sinh\left(2\pi k + \frac{2\pi k}{N}\right)} \cdot \cosh k\left(\pi - 4u - \frac{\pi}{N}\right)$$

$$- \int_{-\infty}^{+\infty} \frac{dk}{k} \frac{\sinh\left(\pi k - \frac{\pi k}{N}\right)}{\sinh\left(\frac{2\pi k}{N}\right) \cdot \sinh\left(2\pi k + \frac{2\pi k}{N}\right)} \cdot \cosh k\left(\pi - \frac{\pi}{N}\right). \tag{94}$$

IX. EXCITATION ON AFM GROUND STATE

In the case of AFM, the ground state is a filled band of $(1+)$. The results of the preceding section suggest that excitations appear as $(2s)$ strings when a hole is created in the $(1+)$ sea. Consider the $Z_{(1+)}(\chi)$ function. In the general case it should look like

$$Z_{(1+)}(\chi) = \frac{1}{2\pi}\Theta^{(1)}_{(1+)}(\chi) - \frac{1}{2\pi M}\sum_k \sum_{\beta=1}^{M^{(k)}} \Theta^{(2)}_{(1+,k)}(\chi - \chi^k_\beta). \tag{95}$$

The density of $(1+)$ vacancies is given by

$$\sigma_{(1+)}(\chi) \doteq - Z'_{(1+)}(\chi). \tag{96}$$

The vacancy density $\sigma_{(1+)}(\chi)$ and the density of $(1+)$ particles $\rho_{(1+)}(\chi)$ is related by

$$\sigma_{(1+)}(\chi) = \rho_{(1+)}(\chi) + \frac{1}{M}\sum_{\beta=1}^{M_h^{(1+)}} \delta(\chi - \chi^{(1+)h}_\beta), \tag{97}$$

where $\chi^{(1+)h}_\beta$ are the position of the holes.

Thus

$$- \sigma_{(1+)}(\chi) = \frac{1}{2\pi}\Theta^{(1)\prime}_{(1+)}(\chi) - \frac{1}{2\pi M}\sum_{k\neq(1+)} \sum_{\beta=1}^{M^{(k)}} \Theta^{(2)\prime}_{(1+,k)}(\chi - \chi^k_\beta) - \frac{1}{2\pi}\int \Theta^{(2)\prime}_{(1+,1+)}(\chi - \mu)d\mu$$

$$+ \frac{1}{2\pi M}\sum_{\beta=1}^{M_h^{(1+)}} \Theta^{(2)\prime}_{(1+,1+)}(\chi - \chi^{(1+)h}_\beta). \tag{98}$$

The above equation can be interpreted as a collection of terms contributing to $(1+)$ ground state, $(1+)$ holes and excited particles over the ground state sea of $(1+)$ string. $\sigma_{(1+)} = \sigma^{(0)}_{(1+)} + \sigma^{(h)}_{(1+)} + \Sigma_j \sigma^{(j)}_{(1+)}$, where $\sigma^{(0)}_{(1+)}$ is the same as $\rho_{(1+)}$ of the last section.

We obtain the energy of a state designated by a given set of strings $\{k\}$, having $M^{(k)}$ strings of type (k) with string centers at $\chi^{(k)}_\beta$,

$$E = \sum_{\substack{k \\ \text{strings}}} \sum_{\beta=1}^{M^{(k)}} \epsilon_k(\chi^{(k)}_\beta) = \int d\chi\, \sigma_{(1+)}(\chi)\epsilon_{(1+)}(\chi) - \sum_{\beta=1}^{M_h^{(1+)}} \epsilon_{(1+)}(\chi^{(1+)h}_\beta) + \sum_{\substack{k \\ k\neq(1+)}} \sum_{\beta=1}^{M^{(k)}} \epsilon(\chi^{(k)}_\beta). \tag{99}$$

From the numerical study we can make the assumption that the elementary excitations over the AFM ground state, which is a sea of $(1+)$-strings, is given by a set of $(2s)$ strings.

The density of ground state energy for the AFM case is given by

$$e_0 = \lim_{M\to\infty} \frac{E_0}{M} = \int d\chi\, \rho_{(1+)}(\chi)\epsilon_{(1+)}(\lambda) - 2\sum_{k=1}^{(N-1)/2} \cot\left(\frac{\pi k}{N}\right). \tag{100}$$

Total energy is real since the imaginary part of the energy contribution from holes cancel the imaginary part of the energy of excitation, i.e., $\mathrm{Im}[\epsilon_{(2s)}]=\mathrm{Im}[\epsilon_{(1+)}]$. The real parts are given by

$$\mathrm{Re}[\epsilon_{(2s)}(\chi)] = \mathrm{Re}[\epsilon_{(1+)h}(\chi)]. \tag{101}$$

In this case also, the dressed energy equals the bare energy. As before, we will denote by $\epsilon_{(2s)} \times(\chi_\beta^{(2s)})$ its real part. The total energy is given by

$$E = E_0 + \sum_{\beta=1}^{M^{(2s)}} 2\epsilon_{(2s)}(\chi_\beta^{(2s)}), \tag{102}$$

where E_0 is the ground state energy.

We now turn to the calculation of momentum. The momentum associated with a string of length j and parity v is found to be

$$p_{(1+)}(\chi) = -\tfrac{1}{2}\Theta_{(1+)}^{(1)}(\chi), \tag{103}$$

$$p_{(j)}(\chi) = -\tfrac{1}{2}\Theta_{(j)}^{(1)}(\chi) \quad \text{for } j \neq (1+), \tag{104}$$

whence

$$p_{(2s)}(\chi) = 2\arctan\left(\tanh\left(\frac{\chi}{2}\right)\right). \tag{105}$$

If one keeps in mind the fact that the correlation of χ's demand an additional π for the creation of $(1+)$ hole, we can derive the dispersion relation

$$\epsilon_{(2s)}(p) = 4\sin\left(\frac{p}{2}\right). \tag{106}$$

.

(Received 23 April 2004; accepted 12 October 2004; published online 14 March 2005)

We utilize a diagrammatic notation for invariant tensors to construct the Young projection operators for the irreducible representations of the unitary group U(n), prove their uniqueness, idempotency, and orthogonality, and rederive the formula for their dimensions. We show that all U(n) invariant scalars ($3n-j$ coefficients) can be constructed and evaluated diagrammatically from these U(n) Young projection operators. We prove that the values of all U(n) $3n-j$ coefficients are proportional to the dimension of the maximal representation in the coefficient, with the proportionality factor fully determined by its S_k symmetric group value. We also derive a family of new sum rules for the $3-j$ and $6-j$ coefficients, and discuss relations that follow from the negative dimensionality theorem. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1832753]

I. INTRODUCTION

Symmetries are beautiful, and theoretical physics is replete with them, but there comes a time when a calculation must be done. Innumerable calculations in high-energy physics, nuclear physics, atomic physics, and quantum chemistry require construction of irreducible many-particle states (irreps), decomposition of Kronecker products of such states into irreps, and evaluations of group theoretical weights (Wigner $3n-j$ symbols, reduced matrix elements, quantum field theory "vacuum bubbles"). At such times effective calculational methods gain in appreciation.

In his 1841 fundamental paper[1] on the determinants today known as "Jacobians," Jacobi initiated the theory of irreps of the symmetric group S_k. Schur used the S_k irreps to develop the representation theory of GL($n;\mathbb{C}$) in his 1901 dissertation,[2] and already by 1903 the Young tableaux[3,4] came into use as a powerful tool for reduction of both S_k and GL($n;\mathbb{C}$) representations. In quantum theory the group of choice[5] is the unitary group U(n), rather than the general linear group GL($n;\mathbb{C}$). Today this theory forms the core of the representation theory of both discrete and continuous groups, described in many excellent textbooks.[6–17]

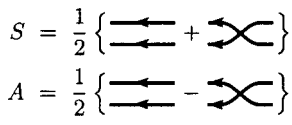
Here we transcribe the theory of the Young projection operators into a form particularly well suited to particle physics calculations, and show that the diagrammatic methods of Ref. 18 can be profitably employed in explicit construction of U(n) multiparticle states, and evaluation of the associated $3n-j$ coefficients.

In diagrammatic notation tensor objects are manipulated without any explicit indices. Diagrammatic evaluation rules are intuitive and relations between tensors can often be grasped visually. Take as an example the reduction of a two-index tensor T_{ij} into symmetric and antisymmetric parts, $T=(S+A)T$, where

$$ST_{ij} = \tfrac{1}{2}(\mathbb{I} + (12))T_{ij}$$

$$AT_{ij} = \tfrac{1}{2}(\mathbb{I} - (12))T_{ij},$$

and $\mathbb{I}$ and (12) denote the identity and the index transposition. Diagrammatically, the two projection operators are drawn as



(1)

It is clear at a glance that S symmetrizes and A antisymmetrizes the two tensor indices. Here we shall construct such projection operator for tensors of any rank.

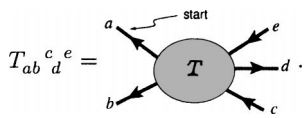
Penrose's papers are the first (known to the authors) to cast the Young projection operators into a diagrammatic form. Here we use Penrose diagrammatic notation for symmetrization operators,[19] Levi–Civita tensors[20] and "strand networks."[21] For several specific, few-particle examples, diagrammatic Young projection operators were constructed by Canning,[22] Mandula,[23] and Stedman.[24] A diagrammatic construction of the U(n) Young projection operators for *any* Young tableau was outlined in Ref. 25, without proofs. Here we present the method in detail, as well as the proof that the Young projection operators so constructed are unique.[26] The other new results are a proof that every U(n) $3n-j$ coefficient is proportional to the dimension of the largest irrep within the $3n-j$ diagram, and several sum rules for U(n) $3-j$ and $6-j$ coefficients.

The paper is organized as follows. The diagrammatic notation for tensors is reviewed in Sec. II and the Young tableaux in Sec. III. This material is standard and the reader is referred to any of the above cited monographs for further details. In Sec. IV we construct diagrammatic Young projection operators for U(n), and give formulas for the normalizations and the dimensions of U(n) irreps. In Sec. V we recast the Clebsch–Gordan recoupling relations into a diagrammatic form, and show that—somewhat surprisingly—the values of all U(n) $3n-j$ coefficients follow from the representation theory for the symmetric group S_k alone. The $3n-j$ coefficients for U(n) are constructed from the Young projection operators and evaluated by diagrammatic methods in Sec. V B. We derive a family of new sum rules for U(n) $3n-j$ coefficients in Sec. V C. In Sec. VI we briefly discuss the case of SU(n) and mixed multiparticle antiparticle states. In Sec. VII we state and prove the negative dimensionality theorem for U(n). Not only does this proof provide an example of the power of diagrammatic methods, but the theorem also simplifies certain group theoretic calculations. We summarize our results in Sec. VIII.

The key, but lengthy original result presented in this paper, the proof of the uniqueness, completeness, and orthogonality of the Young projection operators[26] is relegated to the appendix.

II. DIAGRAMMATIC NOTATION

In the diagrammatic notation[18] an invariant tensor is drawn as a "blob" with a leg representing each index. An arrow indicates whether it is an upper or lower index; lower index arrows always point away from the blob whereas upper index arrows point into the blob. The index legs are ordered in the counterclockwise direction around the blob, and if the indices are not cyclic there must be an indication of where to start, for example,



An internal line in a diagram implies a sum over the corresponding index: matrix multiplication is drawn as

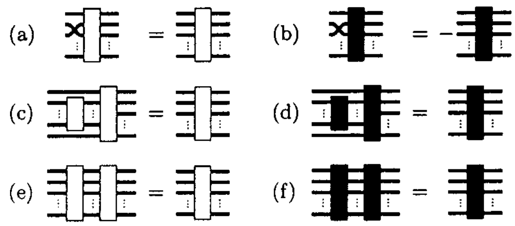


FIG. 1. Properties of the diagrammatic symmetrization and antisymmetrization operators.

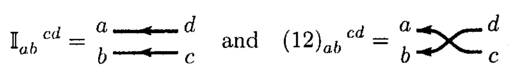
where the index b can be omitted, as indeed can all other "dummy" indices. The Kronecker delta is drawn as

$$\delta^a_b = b \longleftarrow a \quad a,b = 1,2,\ldots,n,$$

and its trace—the dimension of the representation—is drawn as a closed loop,

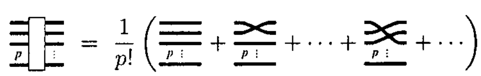
$$= \delta^a_a = n\,. \tag{2}$$

Index permutations can be drawn in terms of Kronecker deltas. For example, the symmetric group S_2 acting on two indices consists of the identity element $\mathbb{I}_{ab}{}^{cd} = \delta^d_a \delta^c_b$ and the transposition $(12)\,_{ab}{}^{cd} = \delta^c_a \delta^d_b$. In the diagrammatic notation these operators are drawn as

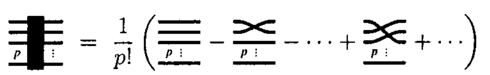


Symmetrization of p indices is achieved by adding all permutations σ of p indices, $S = (1/p!)\Sigma_{\sigma\in S_p}\, \delta^{a_1}_{\sigma(b1}\ldots\delta^{a_p}_{b_p)}$. Similarly, the operator$A = (1/p!)\Sigma_{\sigma\in S_p} \operatorname{sgn}(\sigma)\; \delta^{a_p}_{\sigma(b_1}\ldots\delta^{a_1}_{b_p)}$ (with a minus − for odd permutations) antisymmetrizes p indices. Combinations of symmetrizers S and antisymmetrizers A are collectively referred to as *symmetry operators*.

In the diagrammatic notation we write the symmetrizers and the antisymmetrizers of *length p* as[19]

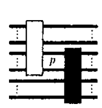


(3)



(4)

In order to streamline the notation we shall neglect the arrows whenever this leads to no confusion. Basic properties of the symmetry operators are listed in Fig. 1: A symmetrizer is invariant under any permutation of its legs, rule (a). The antisymmetrizer changes sign under odd permutations, rule (b). A symmetrizer connected by more than one line to an antisymmetrizer is zero by rules (a) and (b),



$$= 0, \quad p \geq 2\,. \tag{5}$$

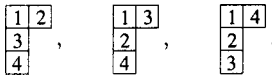
Recursive identities for the (anti)symmetrizers are given in (A5) and (A4).

III. YOUNG TABLEAUX

Partition k identical boxes into D subsets, and let λ_m, $m=1,2,\ldots,D$, be the number of boxes in the subsets ordered so that $\lambda_1 \geqslant \lambda_2 \cdots \geqslant \lambda_D \geqslant 1$. Then the partition $\lambda=[\lambda_1,\lambda_2,\cdots,\lambda_D]$ fulfills $\Sigma_{m=1}^{D}\lambda_m=k$. The diagram obtained by drawing the D rows of boxes on top of each other, left aligned, starting with λ_1 at the top, is called a *Young diagram* Y.

Inserting each number from the set $\{1,\ldots,k\}$ into a box of a Young diagram Y in such a way that numbers increase when reading a column from top to bottom and numbers do not decrease when reading a row from left to right yields a *Young tableau* Y_a. The subscript a labels different tableaux derived from a given Young diagram, i.e., different admissible ways of inserting the numbers into the boxes. A *standard tableau* is a k-box Young tableau constructed by inserting the numbers $1,\ldots,k$ according to the above rules, but using each number exactly once.

As an example, three distinct standard tableaux,



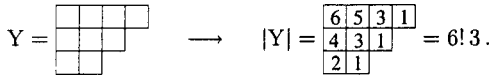
are obtained from the four-box Young diagram with partition $\lambda=[2,1,1]$.

A. Symmetric group S_k

Young diagrams label the irreps of the symmetric group S_k. A k-box Young diagram Y corresponds to an irrep of S_k, and Δ_λ, the dimension of the irrep λ, is the number of standard tableaux Y_a that can be constructed from the Young diagram Y. From the above example we see that the irrep $\lambda=[2,1,1]$ of S_4 is three dimensional. The formula for the dimension Δ_Y of the irrep of S_k corresponding to the Young diagram Y is

$$\Delta_Y = \frac{k!}{|Y|}. \tag{6}$$

The number $|Y|$ is computed using a "hook" rule: Enter into each box of the Young diagram the number of boxes below and to the left of the box, including the box itself. Then $|Y|$ is the product of the numbers in all the boxes. For instance,



The hook rule (6) was first proved surprisingly late, in 1954, by Frame, de B. Robinson, and Thrall.[27] Various proofs can be found in Refs.[15,16,28–31]; in particular, see Sagan[32] and references therein.

B. Representations of U(n)

While every Young diagram labels an irrep of S_k, every standard tableau labels an irrep of U(n). The dimension d_Y of an irrep labeled by the Young diagram Y equals the number of Young tableaux Y_a that can be obtained from Y by inserting numbers from the set $\{1,2,\ldots,n\}$ such that the numbers increase in each column and do not decrease in each row.

For example, for SU (2) the partition [2] corresponds to a three-dimensional irrep with tableaux $\boxed{1}\boxed{1}$, $\boxed{1}\boxed{2}$, and $\boxed{2}\boxed{2}$, and the partition [1, 1] corresponds to a one-dimensional irrep with one tableau, $\begin{array}{|c|}\hline 1\\\hline 2\\\hline\end{array}$. Similarly, one can check that for SU (3), the partition [2] is six dimensional and the partition [1, 1] is three dimensional. We shall derive the dimension formula for any irrep of U(n) in Sec. IV C.

IV. YOUNG PROJECTION OPERATORS

We now present a diagrammatic method for construction of Young projection operators. A combinatorial version of these operators was given by van der Waerden,[33] who credited von Neumann. There are many other versions in the literature, all of them illustrating the fundamental theorem of 't Hooft and Veltman:[34] combinatorics cannot be taught. What follows might aid those who think visually.

A. The group algebra

Our goal is to construct the projection operators such as (1) for any irrep of S_k. We need to construct a basis set of invariant tensors, multiply them by scalars, add and subtract them, and multiply a tensor by another tensor. The necessary framework is provided by the notion of *group algebra*.

The elements $\sigma \in S_k$ of the symmetric group S_k form a basis of a $k!$-dimensional vector space V of elements

$$s = \sum_{\sigma \in S_k} s_\sigma \sigma \in V, \tag{7}$$

where s_σ are the components of the vector s in the given basis. If s, $t \in V$ have components (s_σ) and (t_σ), we define the product of s and t as the vector st in V with components $(st)_\sigma = \Sigma_{\tau \in S_k} s_\tau t_{\tau^{-1}\sigma}$. This multiplication is associative because it relies on the associative group operation. Since V is closed under the multiplication the elements of V form an associative algebra—the *group algebra* of S_k. Acting on an element $s \in V$ with any group element maps s to another element in the algebra, hence this map gives a $k!$-dimensional matrix representation of the group algebra, the *regular representation*. Note that the matrices of any representation μ of the group is also a basis for representation of the algebra: Let $D^\mu(\sigma)$ denote a (possibly reducible) representation of S_k. The group algebra of S_k in the representation μ then consists of elements

$$D^\mu(\mathrm{s}) = \sum_{\sigma \in S_k} \mathrm{s}_\sigma D^\mu(\sigma) \in V,$$

where s is given by (7). The minimal left-ideals V_λ of the group algebra (i.e., $sV_\lambda = V_\lambda$ for all $s \in V$, and V_λ has no proper subideals) are the proper invariant subspaces corresponding to the irreps of the symmetric group S_k.

The regular representation is reducible and each irrep appears Δ_λ times in the reduction, where Δ_λ is the dimension of the subspace V_λ corresponding to the irrep λ. This gives the well-known relation between the order of the symmetric group $|S_k| = k!$ (the dimension of the regular representation) and the dimensions of the irreps,

$$|S_k| = \sum_{\text{irreps } \lambda} \Delta_\lambda^2.$$

Using (6) and the fact that the Young diagrams label the irreps of S_k, we have

$$1 = k! \sum_{(k)} \frac{1}{|\mathrm{Y}|^2}, \tag{8}$$

where the sum is over all Young diagrams with k boxes. We shall use this relation to determine the normalization of Young projection operators in the Appendix.

The reduction of the regular representation of S_k gives a completeness relation

$$\mathbb{I} = \sum_{(k)} P_{\mathrm{Y}}$$

into projection operators

$$P_{\mathrm{Y}} = \sum_{\mathrm{Y}_a \in \mathrm{Y}} P_{\mathrm{Y}_a}.$$

The sum is over all Young tableaux derived from the Young diagram Y. Each P_{Y_a}. projects onto the corresponding invariant subspace V_{Y_a}. For each Y there are Δ_{Y} such projection operators (corresponding to the Δ_{Y} possible standard arrangements of the diagram) and each of these project onto one of the Δ_{Y} invariant subspaces V_{Y} of the reduction of the regular representation. It follows that the projection operators are orthogonal and that they constitute a complete set.

B. Diagrammatic Young projection operators

We now generalize (1), the S_2 projection operators expressed in terms of Kronecker deltas, to Young projection operator for any S_k.

The Kronecker delta is invariant under unitary transformations, $\delta^b_a = (U^\dagger)_a{}^{a'} \delta^{b'}_{a'} U_{b'}{}^b$, $U \in \mathrm{U}(n)$, and so is any combination of Kronecker deltas, such as the symmetrizers of Fig. 1. Since these operators constitute a complete set, any U(n) invariant tensor built from Kronecker deltas can be written in terms of symmetrizers and antisymmetrizers. In particular, the invariance of the Kronecker delta under U(n) transformations implies that the same symmetry group operators which project the irreps of S_k also yield the irreps of U(n).

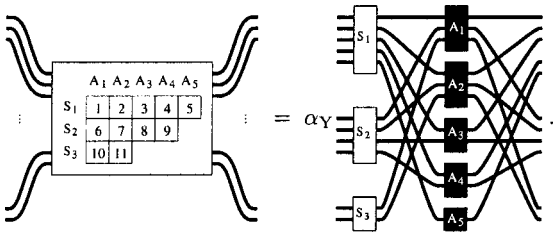
The simplest examples of Young projection operators are those associated with the Young tableaux consisting of either one row or one column. The corresponding Young projection operators are simply the symmetrizers (3) or the antisymmetrizers (4), respectively. As projection operators for S_k, the symmetrizer projects onto the one-dimensional subspace corresponding to the fully symmetric representation, and the antisymmetrizer projects onto the alternating representation.

A Young projection operator for a mixed symmetry Young tableau will here be constructed by first antisymmetrizing subsets of indices, and then symmetrizing other subsets of indices; which subsets are dictated by the form of the Young tableau, as will be explained shortly. Schematically,

$P_{\mathrm{Y}_a} = \alpha_{\mathrm{Y}}$  ,

where α_{Y} is a normalization constant (defined below) ensuring that the operators are idempotent, $P_{\mathrm{Y}_a} P_{\mathrm{Y}_b} = \delta_{ab} P_{\mathrm{Y}_a}$. This particular form of projection operators is by no means unique—Young projection operators symmetric under transposition are constructed in Ref. 18—but is particularly convenient for explicit computations

Let Y_a be a k-box standard tableau. Arrange a set of symmetrizers corresponding to the rows in Y_a, and to the right of this arrange a set of antisymmetrizers corresponding to the columns in Y_a. For a Young diagram Y with s rows and t columns we label the rows $\mathrm{S}_1, \mathrm{S}_2, \ldots, \mathrm{S}_s$ and to the columns $\mathrm{A}_1, \mathrm{A}_2, \ldots, \mathrm{A}_t$. Each symmetry operator in P_{Y_a} is associated with a row/column in Y_a, hence we label a symmetry operator after the corresponding row/column, for example



Let the lines numbered 1 to k enter the symmetrizers as described by the numbers in the boxes in the standard tableau and connect the set of symmetrizers to the set of antisymmetrizers in a nonvanishing way, avoiding multiple intermediate lines prohibited by (5). Finally, arrange the lines coming out of the antisymmetrizers such that if the lines all passed straight through the symmetry operators, they would exit in the same order as they entered.

We shall denote by Δ_Y the dimensions of irreps of S_k, and by d_Y the dimensions of irreps of U(n). Let $|S_i|$ or $|A_i|$ denote the number of boxes within a row or column, respectively. Thus $|A_i|$ also denotes the number of lines entering the antisymmetrizer A_i, and similarly for the symmetrizers. The normalization constant α_Y is given by

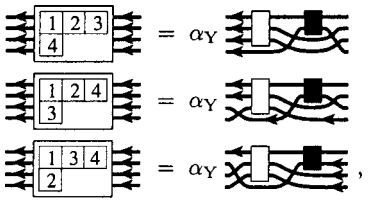
$$\alpha_Y = \frac{\Pi_{i=1}^{s}|S_i|!\Pi_{j=1}^{t}|A_j|!}{|Y|},$$

where $|Y|$ is related through (6) to Δ_Y, the dimension of irrep Y of S_k, and is a hook rule S_k combinatoric number. The normalization depends only on the shape of the Young diagram, not the particular tableau. The Young projection operators

(1) are *idempotent*, $P_Y^2 = P_Y$;
(2) are *orthogonal*: if Y and Z are two distinct standard tableaux, then $P_Y P_Z = P_Z P_Y = 0$; and
(3) constitute a *complete set*, $\mathbb{I} = \Sigma P_Y$, where the sum is over all standard tableaux Ywith k boxes.

The projections are unique up to an overall sign. By construction, the identity element always appears as a term in the expansion of the symmetry operators of the Young projection operators—the overall sign is fixed by requiring that the identity element comes with a positive coefficient. The diagrammatic proof that the above rules indeed assign a unique projection operator to each standard tableaux is the central result of this paper; as it would impede the flow of our argument at this point, it is placed in the Appendix.

Example: The Young diagram corresponding to the partition $[3,1]$ tells us to use one symmetrizer of length three, one of length one, one antisymmetrizer of length two, and two of length one. There are three distinct standard tableaux, each corresponding to a projection operator



where α_Y is the normalization constant. The symmetry operators of unit width need not be drawn explicitly. We have $|Y| = 8$, $|S_1| = 3$, $|S_2| = 1$, $|A_1| = 2$, etc., yielding the normalization $\alpha_Y = 3/2$.

C. Dimensions of U(n) irreps

The dimension d_Y of a U(n) irrep is computed by taking the trace of the corresponding Young projection operator, $d_Y = \mathrm{tr}\, P_Y$. The trace can be evaluated by expanding the symmetry operators using (3) and (4). By (2), each closed line is worth n, so d_Y is a polynomial in n of degree k.

Example: The dimension of a three-index Young projection operator,

d_Y =  (9)

$$= \frac{1}{3}(n^3 + n^2 - n^2 - n) = \frac{n(n^2-1)}{3}. \tag{10}$$

Such brute expansion is unnecessarily laborious: The dimension of the irrep labeled by Y is

$$d_Y = \frac{f_Y(n)}{|Y|}, \tag{11}$$

where $f_Y(n)$ is the polynomial in n obtained from the Young diagram Y by multiplying the numbers written in the boxes of Y, according to the following rules: (A) The upper left box contains an n. (B) The numbers in a row increase by 1 when reading from left to right. (C) The numbers in a column decrease by 1 when reading from top to bottom. Hence, if k is the number of boxes in Y, $f_Y(n)$ is a polynomial in n of degree k. The dimension formula (11) is well known, see for instance Ref. 11.

In the example (10), we have $f_Y(n)=n(n-1)(n+1)$ and $|Y|=3$, giving $d_Y=n(n^2-1)/3$.

Example: For $Y=[4,2,1]$ we have

$$d_Y = \begin{array}{|c|c|c|c|} \hline n & n+1 & n+2 & n+3 \\ \hline n-1 & n & & \\ \cline{1-2} n-2 & & & \\ \cline{1-1} \hline 6 & 4 & 2 & 1 \\ \hline 3 & 1 & & \\ \cline{1-2} 1 & & & \\ \cline{1-1} \end{array} = \frac{n^2(n^2-1)(n^2-4)(n+3)}{144}.$$

A diagrammatic proof of the U(n) dimension formula (11) is given in the Appendix.

Diagrammatically, the number $f_Y(n)$ is the number of n-color colorings of the strand network corresponding to tr P_Y, see, for example, Ref. 18.

D. Examples

We present examples to illustrate decomposition of reducible representation into irreps using the diagrammatic projection operators.

The Young diagram $\square$ corresponds to the fundamental n-dimensional irrep of U(n). As we saw in (1), the direct product of two of these n-dimensional representations is a n^2-dimensional reducible representation,

$\square \otimes \square$ =  (12)

 (13)

$$n^2 = \frac{n(n+1)}{2} + \frac{n(n-1)}{2}. \tag{14}$$

Equation (12) shows the decomposition of the reducible representation in terms of Young diagrams, and (13) gives the corresponding projection operators. Tracing (13) yields the dimensions (14) of the irreps.

The first nontrivial example is the reduction of the three-index tensor Young projection operators, listed in Fig. 2. Further examples can be found in Ref. 18.

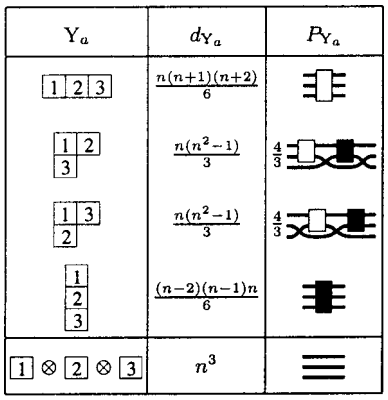


FIG. 2. Reduction of a three-index tensor. Bottom row; the direct product of three unit tableaux, the sum of dimensions, and the projection operators completeness sum.

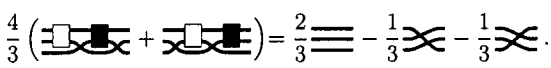
The four projectors are orthogonal by inspection. In order to verify the completeness, expand first the two three-index projection operators of mixed symmetry,



(15)

In the sum of the fully symmetric and the fully antisymmetric tensors all the odd permutations cancel, and we are left with

(16)

Adding (15) and (16) we find

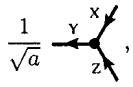
verifying the completeness relation.

Acting with any permutation on the fully symmetric or antisymmetric projection operators gives ± 1 times the projection operator (see Fig. 1). For projection operators of mixed symmetry the action of a permutation is not as simple, because the permutations will mix the spaces corresponding to the different tableaux. Here we shall need only the action of a permutation within a $3n-j$ coefficient, and, as we shall show below, in this case the result will again be simple, a factor ± 1 or 0.

V. RECOUPLING RELATIONS

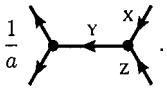
In the spirit of Feynman diagrams, group theoretic weights with all indices contracted can be drawn as "vacuum bubbles." We now show that for U(n) any such vacuum bubble can be evaluated diagrammatically, either directly, as a $3n-j$ coefficient, or following a reduction to $3-j$ and $6-j$ coefficients. The exposition of this section follows closely Ref. 18; the reader can find there more details, as well as the precise relationship between our $3-j$ and $6-j$ coefficients, and the Wigner $3-j$ and $6-j$ symbols.[35]

The decomposition of a many-particle state can be implemented sequentially, decomposing two-particle states at each step. The Clebsch–Gordan coefficients for $X \otimes Z \rightarrow Y$ can be drawn as *3-vertices*,

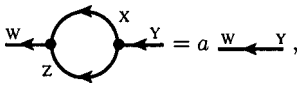


(17)

where $1/\sqrt{a}$ is an (arbitrary) normalization constant. The projection operators for $X\otimes Z\to Y\to X\otimes Z$ can be drawn as

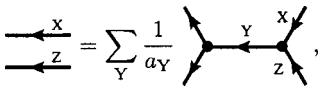


The orthogonality of irreps implies W=Y in



(18)

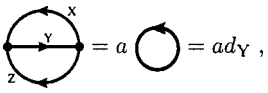
and the completeness relation can be drawn as



(19)

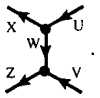
where the sum is over all irreps contained in $X\otimes Z$.

The normalization constant a can be computed by tracing (18),

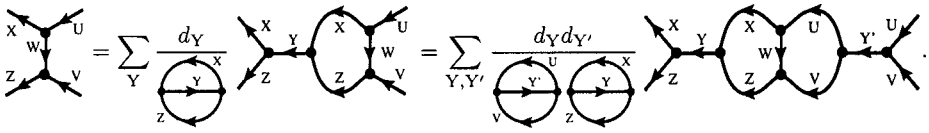


where d_Y is the dimension of the representation Y. The vacuum bubble on the left-hand side is called a $3-j$ coefficient. More generally, vacuum bubbles with n lines are called $n-j$ coefficients.

Let particles in representations U and V interact by exchanging a particle in the representation W, with the final state particles in the representations X and Z,



Applying the completeness relation (19) repeatedly yields



By the orthogonality of irreps $Y=Y'$, and we obtain the *recoupling relation*

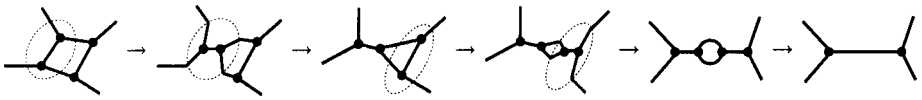


FIG. 3. A reduction of a 4-vertex loop to a sum of "tree" tensors, weighted by products of $3-j$ and $6-j$ coefficients.

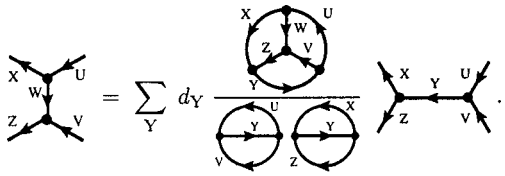
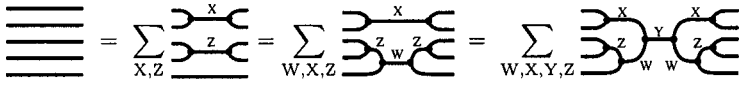


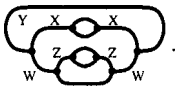
(20)

The "Mercedes" vacuum bubbles in the numerators are called $6-j$ coefficients. *Any* arbitrarily complicated vacuum bubble can be reduced to $3-j$ and $6-j$ coefficients by recursive use of the recoupling relation (20). For instance, a four-vertex loop can be reduced to a two-vertex loop by repeated application of the recoupling relations as sketched in Fig. 3.

Another, more explicit example of a sequence of recouplings, is the following step-by-step reduction of a five-particle state:



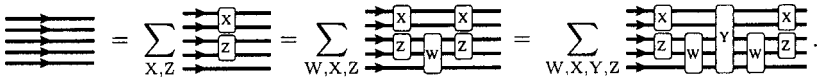
(for brevity we omit the normalization factors here). Taking the trace of both sides leads to $12-j$ coefficients of the form



(21)

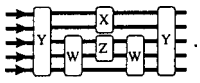
A. U(n) recoupling relations

Due to the overall particle number conservation (we consider no "antiparticle" states here), for U(n) the above five-particle recoupling flow takes a very specific form in terms of Young projection operators,



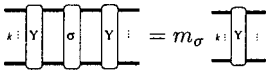
More generally, we can visualize any sequence of U(n) pairwise Clebsch–Gordan reductions as a flow with lines joining into thicker and thicker projection operators, always ending in a maximal P_Y which spans across all lines.

In the trace (21) we can use the idempotency of the projection operators to double the maximal Young projection operator P_Y, and sandwich by it all smaller projection operators,



(22)

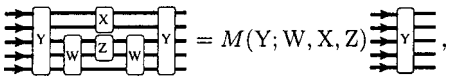
From uniqueness of the connection between the symmetry operators (see the Appendix I) we have for any permutation $\sigma \in S_k$



(23)

where $m_\sigma = 0, \pm 1$. Expressions like (22) can be evaluated by expanding the projection operators

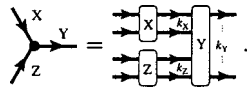
P_W, P_X, P_Z and determining the value of m_σ of (23) for each permutation σ of the expansion. The result is



where the factor $M(\mathrm{Y};\mathrm{W},\mathrm{X},\mathrm{Z})$ *does not depend* on n and is determined by a purely symmetric group calculation. Several examples follow.

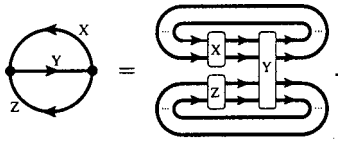
B. Evaluation of 3*n*-*j* coefficients

Let X, Y, and Z be irreps of U(n). In terms of the Young projection operators P_X, P_Y, and P_Z, a U(n) three-vertex (17) is obtained by tying together the three Young projection operators,



(24)

The number of particles is conserved (the multiparticle states constructed here consist only of particles, no "antiparticles"): $k_X+k_Z=k_Y$. A $3-j$ coefficient constructed from the vertex (24) is then

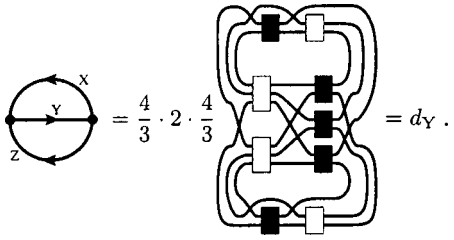


(25)

As an example, take

$$\mathrm{X}=\begin{array}{|c|c|}\hline 1&2\\\hline 3\\\cline{1-1}\end{array}\,,\quad \mathrm{Y}=\begin{array}{|c|c|c|}\hline 1&2&4\\\hline 3&5&6\\\cline{1-3}\end{array}\,,\qquad \text{and}\qquad \mathrm{Z}=\begin{array}{|c|c|}\hline 4&5\\\hline 6\\\cline{1-1}\end{array}\,.$$

Then

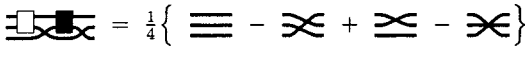


(26)

In principle the value of such $3-j$ coefficient can be computed by expanding out all symmetry operators, but that is not recommended as the number of terms in such expansions grows combinatorially with the total number of boxes in the Young diagram Y. Instead, the answer—in this case $d_Y=(n^2-1)n^2(n+1)(n+2)/144$— is obtained as follows.

In general, the $3-j$ coefficients (25) can be evaluated by expanding the projections P_X and P_Z and determing the value of m_σ in (23) for each permutation σ of the expansion.

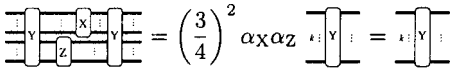
As an example, consider the $3-j$ coefficient (26). With P_Y as in (26) we find



$$m_\sigma(P_X): \quad +1 \quad 0 \quad +1 \quad -1$$

$$m_\sigma(P_Z): \quad +1 \quad -1 \quad 0 \quad -1\,,$$

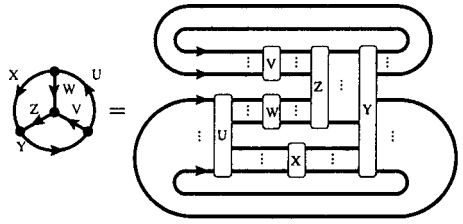
hence



and the value of the $3-j$ is d_{Y} as claimed in (26). That the eigenvalue happens to be 1 is an accident—in tabulations of $3-j$ coefficients[26] it takes a range of values.

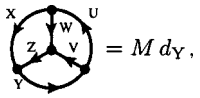
The relation (23) implies that the value of any U(n) $3-j$ coefficient (25) is $M(\mathrm{Y};\mathrm{X},\mathrm{Z})d_{\mathrm{Y}}$, where d_{Y} is the dimension of the maximal irrep Y.

A $6-j$ coefficient is composed of the three-vertex (17) and the other three-vertex in the projection operator (24), with all arrows reversed. A general U(n) $6-j$ coefficient has the form



(27)

Using the relation (23) we immediately see that



(28)

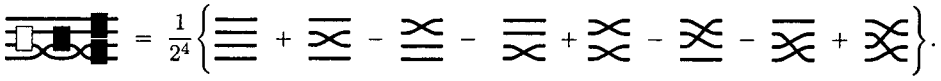
where M is a pure symmetric group $S_{k\mathrm{Y}}$ number, independent of U(n); it is surprising that the only vestige of U(n) is the fact that the value of a $6-j$ coefficient is proportional to the dimension d_{Y} of its largest projection operator.

Example: Consider the $6-j$ constructed from the Young tableaux,

$$\mathrm{U}=\begin{array}{|c|c|}\hline 2&3\\\hline 4\\\cline{1-1}\end{array},\quad \mathrm{V}=\begin{array}{|c|}\hline 1\\\cline{1-1}\end{array},\quad \mathrm{W}=\begin{array}{|c|}\hline 2\\\cline{1-1}\end{array},$$

$$\mathrm{X}=\begin{array}{|c|}\hline 3\\\hline 4\\\cline{1-1}\end{array},\quad \mathrm{Y}=\begin{array}{|c|c|}\hline 1&3\\\hline 2\\\cline{1-1}4\\\cline{1-1}\end{array},\quad \mathrm{Z}=\begin{array}{|c|}\hline 1\\\hline 2\\\cline{1-1}\end{array}.$$

Using the idempotency we can double the projection P_{Y} and sandwich the other operators, as in (22). Several terms cancel in the expansion of the sandwiched operator, and we left with

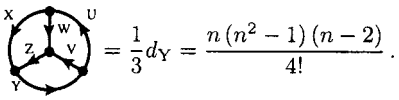


m_σ : +1 0 −1 0 0 −1 0 +1

We have listed the symmetry factors m_σ of (23) for each of the permutations σ sandwiched between the projection operators P_{Y}. We find that in this example the symmetric group factor M of (28) is

$$M=\frac{4}{2^4}\alpha_{\mathrm{U}}\alpha_{\mathrm{V}}\alpha_{\mathrm{W}}\alpha_{\mathrm{X}}\alpha_{\mathrm{Z}}=\frac{1}{3},$$

so the value of the $6-j$ is



The method generalizes to evaluations of any $3n-j$ coefficients of U(n).

C. Sum rules

Let Y be a standard tableau with k_Y boxes, and let Λ be the set of all standard tableaux with one or more boxes (exclude the trivial $k=0$ representation). Then the $3-j$ coefficients obey the sum rule

$$\sum_{X,Z\in\Lambda}$$  $$= (k_Y-1)d_Y. \tag{29}$$

The sum is finite, because the $3-j$ is nonvanishing only if the number of boxes in X and Z add up to k_Y, and this happens only for a finite number of tableaux.

To prove (29), recall that the Young projection operators constitute a complete set, $\Sigma_{X\in\Lambda_k}P_X=\mathbb{I}$, where $\mathbb{I}$ is the $k\times k$ unit matrix and Λ_k the set of all standard tableaux of Young diagrams with k boxes. Hence

$$\sum_{X,Z\in\Lambda}$$  $$= \sum_{k_X=1}^{k_Y-1} \sum_{\substack{X\in\Lambda_{k_X}\\ Z\in\Lambda_{k_Y-k_X}}}$$ 
$$= \sum_{k_X=1}^{k_Y-1}$$  $$= \sum_{k_X=1}^{k_Y-1} d_Y = (k_Y-1)d_Y\,.$$

This sum rule offers a useful cross-check on tabulations of $3-j$ values, see for instance Ref. 26.

There is a similar sum rule for the $6-j$ coefficients,

$$\sum_{X,Z,U,V,W\in\Lambda}$$  $$= \frac{1}{2}(k_Y-1)(k_Y-2)\,d_Y\,. \tag{30}$$

Referring to the $6-j$ (27), let k_U be the number of boxes in the Young diagram U, k_X be the number of boxes in X, etc., and let k_Y be given. From (27) we see that k_X takes values between 1 and k_Y-2 and k_Z takes values between 2 and k_Y-1, subject to the constraint $k_X+k_Z=k_Y$. We now sum over all tableaux U, V, and W keeping k_Y, k_X, and k_Z fixed. Note that k_V can take values 1,…, k_Z-1. Using completeness we find

$$\sum_{U,V,W\in\Lambda}$$  $$= \sum_{k_V=1}^{k_Z-1} \sum_{V\in\Lambda_{k_V}} \sum_{W\in\Lambda_{k_Z-k_V}} \sum_{U\in\Lambda_{k_Y-k_V}}$$

 $$= (k_Z-1)$$  .

Now sum over all tableaux X and Z to find

$$\sum_{X,Z,U,V,W\in\Lambda}$$  $$= \sum_{k_Z=2}^{k_Y-1}(k_Z-1) \sum_{Z\in\Lambda_{k_Z}} \sum_{X\in\Lambda_{k_Y-k_Z}}$$  $$= \frac{1}{2}(k_Y-1)(k_Y-2)\,d_Y$$

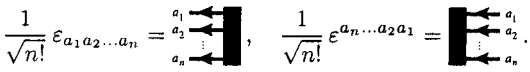
verifying the sum rule (30) for $6-j$ coefficients.

VI. SU(N) AND ITS ADJOINT REPRESENTATION

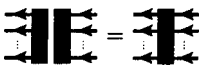
The SU(n) group elements satisfy det U=1, so SU(n) has an additional invariant, the Levi–Civita tensor

$$\epsilon_{a_1 a_2 \cdots an} = U_{a_1}{}^{a_1'} U_{a_2}{}^{a_2'} \cdots U_{a_n}{}^{a_n'} \epsilon_{a_1' a_2' \cdots a_n'}.$$

In the diagrammatic notation the Levi–Civita tensors can be drawn as[20]

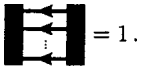


They satisfy

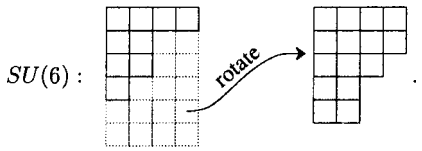


(31)

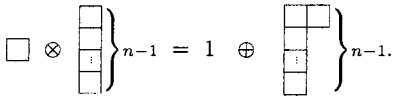
(Levi–Civita projects an n-particle state onto a single, one-dimensional, singlet representation), and are correctly normalized,



The Young diagrams for SU(n) cannot contain more than n rows, since at most n indices can be antisymmetrized. By contraction with the Levi-Civita tensor, a column with k boxes can be converted into a column of $n-k$ boxes: this operation associates to each irrep the *conjugate* irrep. The Young diagram corresponding to the irrep is the *conjugate* Young diagram constructed from the missing pieces needed to complete the rectangle of n rows. For example, the conjugate of the irrep corresponding to the partition [4, 2, 2, 1] of SU(6) has the partition [4, 4, 3, 2, 2]:

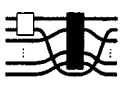


The Levi–Civita tensor converts an antisymmetrized collection of $n-1$ "in" indices, an ($n-1$)-particle state, into 1 "out" index: a single antiparticle state $\overline{\square}$, the conjugate of the fundamental representation $\square$ single particle state. The corresponding Young diagram is a single column of $n-1$ boxes. The product of the fundamental representation and the conjugate representation of SU(n) decomposes into a singlet and the adjoint representation,



In the notation introduced in Sec. IV, the Young projection operator for the adjoint representation A is drawn as

$$P_A = \frac{2(n-1)}{n}$$



Using P_A and the definition (24) of the three-vertex, SU(n) group theory weights involving quarks, antiquarks, and gluons can be calculated by expansion of the symmetry operators or by application of the recoupling relation. When the adjoint representation plays a key role, as it does in gauge theories, it is wisest to abandon the above construction of all irreps by Clebsch–Gordan reductions of multiparticle states, and build the theory by taking a single particle and a single antiparticle as the fundamental building blocks. A much richer theory, beyond the scope of this paper follows,

leading to a diagrammatic construction of representations of all simple Lie groups, the classical as well as the exceptional. The reader is referred to Ref. 18 for the full exposition.

VII. NEGATIVE DIMENSIONS

We conclude by a brief discussion of implications of the $n \to -n$ duality[18,36] of U(n) invariant scalars.

Any SU(n) invariant tensor is built from Kronecker deltas and Levi–Civita tensors. A scalar is a tensor object with all indices contracted, so in the diagrammatic notation a scalar is a diagram with no external legs, a vacuum bubble. Thus, in scalars Levi–Civita tensors can appear only in pairs (the lines must end somewhere), and by (31) the Levi–Civita tensors combine to antisymmetrizers. Consequently both U(n) and SU(n) invariant scalars are all built only from symmetrizers and antisymmetrizers.

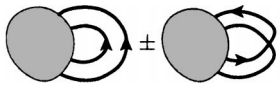
Expanding all symmetry operators in a U(n) vacuum bubble gives a sum of entangled loops. Each loop is worth n, so each term in the sum is a power of n, and therefore a U(n) invariant scalar is a polynomial in n.

The negative dimensionality theorem[18,36] for U(n) states that interchanging symmetrizers and antisymmetrizers in U(n) invariant scalar is equivalent (up to an overall sign) to substituting $n \to -n$ in the polynomial, which is the value of the scalar. We write this

$$\overline{\mathrm{U}(n)} = \mathrm{U}(-n).$$

The bar symbolizes the interchange of symmetrizers and antisymmetrizers.

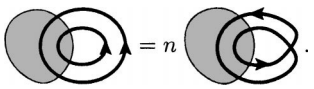
The terms in the expansion of all symmetry operators in a U(n) vacuum bubble can be arranged in pairs that only differ by one crossing,



(32)

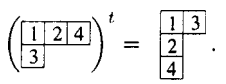
with $\pm$ depending on whether the crossing is due to symmetrization $(+)$ or antisymmetrization $(-)$. The gray blobs symbolize the tangle of lines common to the two terms.

If the two arcs outside the gray blob of the first term of (32) belong to separate loops, then in the second term they will belong to the same loop. The two terms thus differ only by a factor of n: schematically,



Likewise, if the arcs in the first term belong to the same loop then in the second term they will belong to two separate loops. In this case the first term is $1/n$ times the second term. In either case the ratio of the two terms is an odd power of n. Interchanging symmetrizers and antisymmetrizers in a U(n) vacuum bubble changes the sign in (32). Up to an overall sign the result is the same as substituting $n \to -n$. This proves the theorem.

Consider now the implications for the dimension formulas and the values of $3n-j$ coefficients. The dimension of an irrep of U(n) is the trace of the Young projection operator, a vacuum bubble diagram built from symmetrizers and antisymmetrizers. Applying the negative dimensionality theorem we get $d_{Y^t}(n) = d_Y(-n)$, where Y^t is the *transpose* Y^t of the standard Young tableau Y obtained by interchanging rows and columns (reflection across the diagonal). For instance [3, 1] is the transpose of [2, 1, 1],



As an example, note the $n \to -n$ dualities in the dimension formulas of Fig. 2.

Now for standard tableaux X, Y, and Z, compare the diagram of the $3-j$ constructed from X, Y, and Z to that constructed from X^t, Z^t, and Y^t. The diagrams are related by a reflection in a vertical line, reversal of all the arrows on the lines, and interchange of symmetrizers and antisymmetrizers. The first two operations do not change the value of the diagram, hence the values of the two diagrams are again related by $n \leftrightarrow -n$ (and possibly an overall sign; this sign is fixed by requiring that the highest power of n comes with a positive coefficient). Hence in tabulation it is sufficient to calculate approximately half of all $3-j$'s. The $3-j$ sum rule (29) provides a cross-check.

The two $6-j$ coefficients

are related by a reflection in a vertical line, reversal of all the arrows on the lines, and interchange of symmetrizers and antisymmetrizers—this can be seen by writing out the $6-j$ coefficients in terms of the Young projection operators as in (27). By the negative dimensionality theorem, the values of the two $6-j$ coefficients are therefore again related by $n \leftrightarrow -n$.

VIII. SUMMARY

We have presented a diagrammatic method for construction of correctly normalized Young projection operators for U(n). These projection operators in diagrammatic form are useful for explicit evaluation of group theoretic quantities such as the $3n-j$ coefficients. Using the recoupling relations, all U(n) invariant scalars can be reduced to expressions involving only terms of $3-j$ and $6-j$ coefficients and the dimensionalities of the representations. Our main results are as follows:

(i) Diagrammatic Young projection operators for tensors (multiparticle states) with given symmetry properties; a diagrammatic proof of their uniqueness, completeness, and orthogonality.
(ii) U(n) invariant scalars may be expressed in terms of the Young projection operators, and their values computed by diagrammatic expansions.
(iii) U(n) $3-j$ and $6-j$ coefficients constructed from the three-vertex defined in (24) have simple n-dependencies: they are proportional to the dimension of the maximal irrep projection operator that spans over all multiparticle indices.
(iv) The negative dimensionality theorem applies to all U(n) invariant scalars, in particular the $3n-j$ coefficients and the dimensions of the irreps of U(n).
(v) The sum rules (29) and (30) for $3-j$ and $6-j$ coefficients afford useful cross-checks of $3n-j$ tabulations.

APPENDIX: DIAGRAMMATIC YOUNG PROJECTION OPERATORS: THE PROOFS

In this appendix we prove the properties of the Young projection operators stated above in Sec. IV.

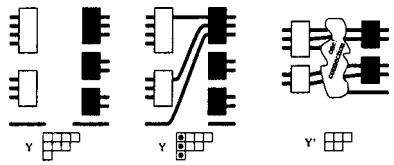

FIG. 4. There is a unique (up to an overall sign) connection between the symmetrizers and the antisymmetrizers, so the Young projection operators are well defined by the construction procedure explained in the text. The figure shows the principles of the proof. The dots on the middle Young diagram mark boxes that correspond to contracted lines.

Uniqueness

We show that the Young projection operators P_{Y} are well defined by proving the existence and uniqueness (up to an overall sign) of a nonvanishing connection between the symmetrizers and antisymmetrizers in P_{Y}.

The proof is by induction over the number of columns t in the Young diagram Y; the principles are illustrated in Fig. 4. For $t=1$ the Young projection operator consists of one antisymmetrizer of length s and s symmetrizers of length 1, and clearly the connection can only be made in one way, up to an overall sign, see Fig. 1(b).

Assume the result to hold for Young projection operators derived from Young diagrams with $t-1$ columns. Let Y be a Young diagram with t columns. The lines from A_1 in P_{Y} must connect to different symmetrizers for the connection to be nonzero. Since there are exactly $|\mathrm{A}_1|$ symmetrizers in P_{Y}, this can be done in essentially one way, since which line goes to which symmetrizer is only a matter of an overall sign, and where a line enters a symmetrizer is irrelevant due to Fig. 1(a).

After having connected A_1, connecting the symmetry operators in the rest of P_{Y} is the problem of connecting symmetrizers to antisymmetrizers in the Young projection operator $P_{\mathrm{Y}'}$, where Y′ is the Young diagram obtained from Y by slicing off the first column. Thus Y′ has $k-1$ columns, so by the induction hypothesis the rest of the symmetry operators in P_{Y} can be connected in exactly one nonvanishing way (up to an overall sign).

Orthogonality

If Y_a and Y_b denote standard tableaux derived from the same Young diagram Y, then $P_{\mathrm{Y}_a}P_{\mathrm{Y}_b}=P_{\mathrm{Y}_b}P_{\mathrm{Y}_a}=\delta_{ab}P^2_{\mathrm{Y}_a}$, since there is a permutation of the lines connecting the symmetry operators of Y with those of Z and by uniqueness of the nonzero connection the result is either $P^2_{\mathrm{Y}_a}$ (if $\mathrm{Y}_a=\mathrm{Y}_b$) or (if $\mathrm{Y}_a\neq\mathrm{Y}_b$).

Next, consider two different Young diagrams Y and Z with the same number of boxes. Since at least one column must be bigger in (say) Y than in Z and the p lines from the corresponding antisymmetrizer must connect to different symmetrizers, it is not possible to make a nonzero connection between the antisymmetrizers of P_{Y_a} to the symmetrizers in P_z, where subscripts a and b denote any standard tableaux of Y and Z. Hence $P_{\mathrm{Y}_a}P_{\mathrm{Z}_b}=0$, and by a similar argument $P_{\mathrm{Z}_b}P_{\mathrm{Y}_a}=0$.

Normalization and completeness

We now derive the formula for the normalization factor α_{Y} such that the Young projection operators are idempotent, $P^2_{\mathrm{Y}_a}=P_{\mathrm{Y}_a}$. By the normalization of the symmetry operators, Young projection operators corresponding to fully symmetric or antisymmetric Young tableaux will be idempotent with $\alpha_{\mathrm{Y}}=1$.

Diagrammatically $P^2_{\mathrm{Y}a}$ is simply P_{Y_a} connected to P_{Y_a}, hence it may be viewed as a set of *outer* symmetry operators connected by a set of *inner* symmetry operators. Expanding all the inner symmetry operators and using the uniqueness of the nonzero connection between the symmetrizers and antisymmetrizers of the Young projection operators, we find that each term in the expansion is

either 0 or a copy of P_{Y_a}. For a Young diagram with s rows and t columns there will be a factor of $1/|S_i|!(1/|A_j|!)$ from the expansion of each inner (anti)symmetrizer, so we find

$$P_{Y_a}^2 = \alpha_{Y_a}^2$$
$$= \frac{\alpha_{Y_a}^2}{\prod_{i=1}^{s}|S_i|!\prod_{j=1}^{t}|A_j|!}\sum_{\sigma}\sigma$$
$$= \alpha_{Y_a}\frac{\kappa_Y}{\prod_{i=1}^{s}|S_i|!\prod_{j=1}^{t}|A_j|!}P_{Y_a},$$

where the sum is over permutation σ from the expansion of the inner symmetry operators. Note that by the uniqueness of the connection between the symmetrizers and antisymmetrizers, the constant κ_Y is independent of which tableau gives rise to the projection, and consequently the normalization constant α_Y depends only on the Young diagram and not the tableau.

For a given k, consider the Young projection operators P_{Y_a} corresponding to all the k-box Young tableaux. Since the operators P_{Y_a} are orthogonal and in one-to-one correspondence with the Young tableaux, it follows from the discussion in Sec. IV A that there are no other operators of k lines orthogonal to this set. Hence the P_{Y_a}'s form a complete set, so that

$$\mathbb{I} = \sum_{Y_a} P_{Y_a}. \tag{A1}$$

Expanding the projections the identity appears only once, so we have

$$P_{Y_a} = \alpha_Y \frac{1}{\prod_{i=1}^{s}|S_i|!\prod_{j=1}^{t}|A_j|!}\left(\underline{\equiv}_{p} + \ldots\right),$$

and using this, equation (A1) states

$$\underline{\equiv}_{p} = \left(k!\sum_{Y}\frac{\alpha_Y/|Y|}{\prod_{i=1}^{s}|S_i|!\prod_{j=1}^{t}|A_j|!}\right)\underline{\equiv}_{p} \tag{A2}$$

since all permutation different from the identity must cancel. When changing the sum from a sum over the tableaux to a sum over the Young diagrams we use that α_Y depends only on the diagram and that there are $\Delta_Y = k!/|Y|$ k-standard tableaux for a given diagram. Choosing

$$\alpha_Y = \frac{\Pi_{i=1}^{s}|S_i|!\Pi_{j=1}^{t}|A_j|!}{|Y|}, \tag{A3}$$

the factor on the right-hand side of (A2) is 1 by (8).

Since the choice of normalization (A3) gives the completeness relation (A1), it follows that it also gives idempotent operators, multiplying by P_{Z_b} on both sides of (A1) and using orthogonality, we find $P_{Z_b} = P_{Z_b}^2$ for any Young tableau Z_b.

Dimensionality

To prove the dimension formula (11) we need the identities

$$\underline{\equiv}_{p}\,| = \frac{1}{p}\left(\underline{\equiv}_{p-1}| + (p-1)\,\underline{\equiv}_{p-1}\right) \tag{A4}$$

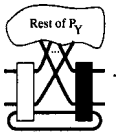
and

$$\underline{\equiv}_{p}\,| = \frac{1}{p}\left(\underline{\equiv}_{p-1}| - (p-1)\,\underline{\equiv}_{p-1}\right) \tag{A5}$$

given in Ref. 18. For Young tableaux with a single row or column, the dimension formula can be derived directly using the relations (A4) and (A5).

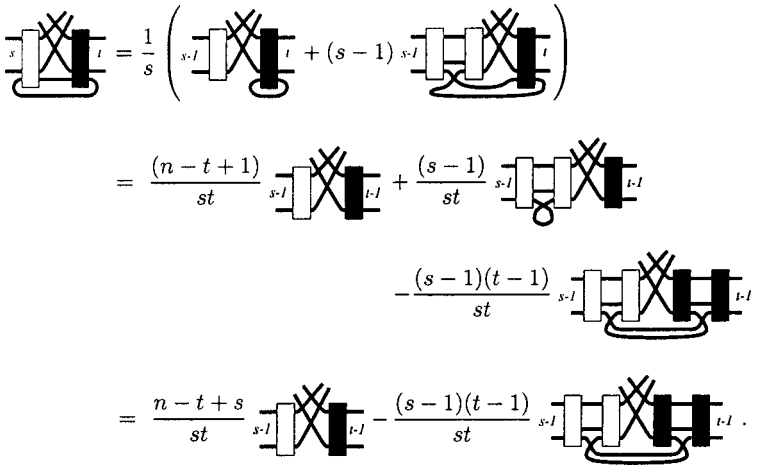
Let Y be a standard tableau with k boxes, and Y′ the standard Young tableau obtained from it by removing the box containing k. Draw the Young projection operators corresponding to Y and Y′ and note that P_{Y} with the "last" line traced is proportional to $P_{\mathrm{Y}'}$.

Quite generally the contraction of the last line will look like



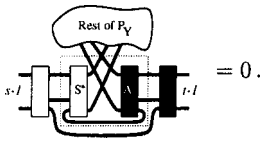
(A6)

Using (A4) and (A5) we have



Inserting this into (A6) we see that the first term is proportional to the projection operator $P_{\mathrm{Y}'}$

The second term vanishes,



If we ignore the internal structure within the dotted box we see that this is exactly of the form of $P_{\mathrm{Y}'}$, except that the "last" symmetrizers and antisymmetrizers are connected by a line. There is a unique nonvanishing way of connecting the symmetrizers and antisymmetrizers in $P_{\mathrm{Y}'}$, and the "last" symmetrizer and antisymmetrizer are not connected in this, as they correspond to a row and column with no common box in the Young tableau. Therefore every term obtained from the expansion of the dotted box must vanish.

The dimensionality formula follows by induction on the number of boxes in the Young diagrams with the dimension of a single box Young diagram being n. Let Y be a Young diagram with p boxes. We assume that the dimensionality formula is valid for any Young diagram with $p-1$ boxes. With $P_{\mathrm{Y}'}$ obtained from P_{Y} as above, we have (using the above calculation and writing D_{Y} for the diagrammatic part of P_{Y})

$$\dim P_{\mathrm{Y}} = \alpha_{\mathrm{Y}}\ \mathrm{tr}\ D_{\mathrm{Y}} = \frac{n-t+s}{st}\alpha_{\mathrm{Y}}\ \mathrm{tr}\ D_{\mathrm{Y}'} = (n-t+s)\alpha_{Y'}\frac{|\mathrm{Y}'|}{|\mathrm{Y}|}\mathrm{tr}\ D_{\mathrm{Y}'} = (n-t+s)\frac{f_{\mathrm{Y}'}}{|\mathrm{Y}|} = \frac{f_{\mathrm{Y}}}{|\mathrm{Y}|}.$$

This completes the proof of the dimensionality formula (11).

(Received 30 November 2004; accepted 14 January 2005; published online 15 March 2005)

We introduce notions of equivalence of conservation laws with respect to Lie symmetry groups for fixed systems of differential equations and with respect to equivalence groups or sets of admissible transformations for classes of such systems. We also revise the notion of linear dependence of conservation laws and define the notion of local dependence of potentials. To construct conservation laws, we develop and apply the most direct method which is effective to use in the case of two independent variables. Admitting possibility of dependence of conserved vectors on a number of potentials, we generalize the iteration procedure proposed by Bluman and Doran-Wu for finding nonlocal (potential) conservation laws. As an example, we completely classify potential conservation laws (including arbitrary order local ones) of diffusion-convection equations with respect to the equivalence group and construct an exhaustive list of locally inequivalent potential systems corresponding to these equations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1865813]

I. INTRODUCTION

After Noether's remarkable paper[30] had become well known, a number of authors[21,31,38,40] searched for conservation laws using the symmetry approach based on the Noether's results. In view of the generalized Noether's theorem,[31] there exists one-to-one correspondence between the nontrivial generalized variational symmetries of some functional and the nontrivial conservation laws of the associated Euler–Lagrange equations, and any such symmetry is a generalized symmetry of the Euler–Lagrange equations.

The Noether's approach has a number of advantages. It reduces construction of conservation laws to finding symmetries for which there exist a number of well-developed methods, and complete description of necessary symmetry properties is known for a lot of systems of differential equations. However, this approach can be applied only to Euler–Lagrange equations that form normal systems and admit symmetry groups satisfying an additional "variational" property of leaving the variational integral invariant in some sense.[31] The latter requirements lead to restriction of class of systems that could be investigated in such way.

At the same time, the definition of conservation laws itself gives rise to a method of finding conservation laws. Technique of calculations used in the framework of this method is similar to the classical Lie method yielding symmetries of differential equations.[20] As mentioned in the above reference, such algorithmic possibility was first employed by Laplace[27] for derivation of the well-known Laplace vector of the two-body Kepler problem. Following tradition from group analysis of differential equations, we may call this method *direct* and distinguish four versions of it, depending on the way of taking into account systems under investigation. (See, e.g., Refs. 4, 5, 8, and 23 and Sec. IV of this paper for more details as well as Ref. 44 for comparison of the

[a]Electronic mail: rop@imath.kiev.ua
[b]Electronic mail: ivanova@imath.kiev.ua

versions and their realizations in computer algebra programs.) In the present paper we use the most direct version based on immediate solving of determining equations for conserved vectors of conservations laws on the solution manifolds of investigated systems.

Let us note that there exist other approaches for construction of conservation laws which differ from the Noether's or above direct ones, are based on exploitation of symmetry properties of differential equations and can be applied to non-Lagrangian systems. Thus, Fushchych and Nikitin[17] proposed to calculate directly bilinear combinations of solutions of motion equations, which are conserved in time by virtue of symmetries of these equations. It is possible in such way to find conservation laws corresponding to nongeometric symmetries. In the recent work[2] a purely algebraic formula has been derived for generating conservation laws of systems of differential equations that possess a scaling invariance.

To classify conservation laws, instead of the usual equivalence relation on their set (more exactly, on the set of conserved vectors) we propose to use the natural and more general notions of equivalences of conservation laws with respect to Lie symmetry groups for fixed systems of differential equations and with respect to equivalence groups or sets of admissible point (or contact) transformations for classes of such systems. Results of classification up to these equivalences are more comprehensible, especially, if a whole class of systems is studied and blend with the framework of group analysis.

Bluman and Doran-Wu[8] proposed an ingenious procedure of branching iterations for finding nonlocal (potential) conservation laws of diffusion equations. Namely, on each iteration they use a conservation law from the previous iteration (one conservation law for one iteration) to introduce a potential and to construct the extended potential system. Then they study local conservation laws of the potential system, which are, generally speaking, nonlocal (potential) conservation laws for the initial equation. To the best of our knowledge, it was the first paper where the idea of hierarchy of potential systems and associated conservation laws is presented in an explicit form.

We generalize the iteration procedure by Bluman and Doran-Wu, admitting dependence of conserved vectors on different number (from one to the maximum possible that) of new potentials on each iteration. The idea of a similar approach was adduced by Wahlquist and Estabrook[43] and was formalized in the form of notion of *universal Abelian covering* of differential equations.[10,36,42] Such approach naturally results in the questions on some independence of employed potentials. That is why, in this paper we consider definition of linear dependence of conservation laws in detail and define the notion of local dependence of potentials.

Therefore, in the first part of the paper we propose some technique and discuss the classification problem for conservation laws in general. The ultimate goal of the second part is to present an exhaustive classification of potential conservation laws in a quite difficult and interesting case. As an illustration of the proposed technique, we choose the class of diffusion-convection equations

$$u_t = (A(u)u_x)_x + B(u)u_x, \tag{1}$$

where $A=A(u)$ and $B=B(u)$ are arbitrary smooth functions of u, $A(u)\neq 0$. Symmetry properties of (1) were considered by a number of authors,[13,32,45] however the complete and strong group classification of (1) was first presented in our recent work[34] [see also references therein for more details about symmetry analysis of classes intersecting class (1)].

Studying conservation laws of equations (1) was started from linear equations.[38] Dorodnitsyn and Svirshchevskii[12] (see also Ref. 20) completely investigated the local conservation laws for reaction-diffusion equations $u_t=(A(u)u_x)_x+C(u)$. The first-order local conservation laws of equations (1) were constructed by Kara and Mahomed.[24] Developing results of Bluman and Doran-Wu[8] obtained for the case $B=0$, Ivanova[22] classified the first-order local conservation laws for equations (1) with respect to the equivalence group and constructed potential conservation laws of the first level. Namely, she made two steps of the iteration procedure, looking, in the second step, for the first-order local conservation laws of the potential systems obtained after the first step.

In the present work we exhaustively classify, with respect to the corresponding equivalence group, the local conservation laws of an arbitrary order, find the simplest and general potential

conservation laws and construct locally inequivalent potential systems of equations (1). All possible steps of the branching iterations procedure are done, and admission of dependence of conserved vectors on a number of potentials is of fundamental importance for completing iterations. We obtain the following eight inequivalent cases of equations (1) having different sets of potential conservation laws:

(i) the general case (the parameter-functions A and B are arbitrary);
(ii) three cases with an arbitrary value of A and a special value of B ($B=0; B=A; B=\int A\,\mathrm{d}u + uA$);
(iii) three corresponding linearizable equations ($A=u^{-2}, B=0; A=B=u^{-2}; A=1, B=2u$) and
(iv) the linear heat equation ($A=1, B=0$).

The latter case takes on special significance in our consideration since investigation of the linearizable equations having infinite series of potential conservation laws is reduced to this case and the nonlinearizable equations from class (1) have at the most two independent conservation laws.

Our paper is organized as follows. First (Sec. II) we give a basic theoretical background, following the spirit of Olver's book.[31] We recall the notions of equivalence of conserved vectors and characteristics with respect to the triviality relation and discuss properties of the space of conserved vectors and the space of characteristics. This naturally results in the notions of linear dependence of conservation laws and local dependence of potentials (Secs. IV and V). In Sec. III we introduce the notions of equivalence of conservation laws with respect to Lie symmetry groups for fixed systems of differential equations and equivalence groups or sets of admissible point (or contact) transformations for classes of such systems. We emphasize the possibility of solving classification problems for conservation laws with respect to the above equivalences similarly to usual group classification problems for differential equations. In Sec. IV we adduce different versions of the direct method of construction of conservation laws, emphasizing the most direct one and combining it with classification up to symmetry or equivalence groups. Since the two-dimensional case is special for construction of potential systems we describe it in more detail in Sec. V.

Then we apply the theoretical background given in the previous sections to investigation of diffusion-convection equations from class (1). The local conservation laws of (1) are classified with respect to the corresponding equivalence group in Sec. VI. In Sec. VII we construct simplest potential conservation laws and analyze connections between them using potential equivalence transformations. The subject of Sec. VIII is the description of general potential conservation laws of the linear heat equation. In Sec. IX we complete studying potential conservation laws of diffusion-convection equations and adduce the hierarchy of conservation laws obtained in our framework. In the same section we give an exhaustive list of locally inequivalent potential systems of equations (1). The obtained results can be interpreted as construction of universal Abelian covering for the whole class of diffusion-convection equations.

II. BASIC DEFINITIONS AND STATEMENTS

Let $\mathcal{L}$ be a system $L(x,u_{(\rho)})=0$ of l differential equations $L^1=0,\dots,L^l=0$ for m unknown functions $u=(u^1,\dots,u^m)$ of n independent variables $x=(x_1,\dots,x_n)$. Here $u_{(\rho)}$ denotes the set of all the derivatives of the functions u with respect to x of order no greater than ρ, including u as the derivatives of the zero order. Let $\mathcal{L}_{(k)}$ denote the set of all algebraically independent differential consequences that have, as differential equations, orders no greater than k. We identify $\mathcal{L}_{(k)}$ with the manifold determined by $\mathcal{L}_{(k)}$ in the jet space $J^{(k)}$.

Definition 1: A *conservation law* of the system $\mathcal{L}$ is a divergence expression $\mathrm{Div}\,F:=D_iF^i$ which vanishes for all solutions of $\mathcal{L}$: $\mathrm{Div}\,F|_{\mathcal{L}}=0$. The n-tuple $F=(F^1(x,u_{(r)}),\dots,F^n(x,u_{(r)}))$ is called a *conserved vector* of this (local) conservation law.

In Definition 1 and below $D_i=D_{x_i}$ denotes the operator of total differentiation with respect to the variable x_i, i.e., $D_i=\partial_{x_i}+u^a_{\alpha,i}\partial_{u^a_\alpha}$, where u^a_α and $u^a_{\alpha,i}$ stand for the variables in jet spaces, which

correspond to derivatives $\partial^{|\alpha|}u/\partial x_1^{\alpha_1}\cdots\partial x_n^{\alpha_n}$ and $\partial u^a_\alpha/\partial x_i$, $\alpha=(\alpha_1,\dots,\alpha_n)$, $\alpha_i\in\mathbb{N}\cup\{0\}$, $|\alpha|:=\alpha_1+\cdots+\alpha_n$. We use the summation convention for repeated indices and assume any function as its zero-order derivative. The notation $V|_{\mathcal{L}}$ means that values of V are considered only on solutions of the system $\mathcal{L}$.

Definition 2: A conserved vector F is called *trivial* if

$$F^i=\hat{F}^i+\check{F}^i,\quad i=\overline{1,n},$$

where $\hat{F}^i$ and $\check{F}^i$ are, likewise F^i, functions of x and derivatives of u (i.e., differential functions), $\hat{F}^i$ vanish on the solutions of $\mathcal{L}$ and the n-tuple $\check{F}=(\check{F}^1,\dots,\check{F}^n)$ is a null divergence (i.e., its divergence vanishes identically).

The triviality concerning the vanishing conserved vectors on solutions of the system can be easily eliminated by confining on the manifold of the system, taking into account all its necessary differential consequences.

A characterization of all null divergences is given by the following lemma (see, e.g., Ref. 31).

Lemma 1: The n-tuple $F=(F^1,\dots,F^n)$, $n\geqslant 2$, *is a null divergence* ($\mathrm{Div}\,F\equiv 0$) *iff there exist smooth functions* v^{ij} $(i,j=\overline{1,n})$ *of x and derivatives of u, such that* $v^{ij}=-v^{ji}$ *and* $F^i=D_jv^{ij}$.

The functions v^{ij} are called *potentials* corresponding to the null divergence F. If $n=1$ any null divergence is constant.

Definition 3: Two conserved vectors F and F' are called *equivalent* if the vector-function $F'-F$ is a trivial conserved vector.

By the latter definition any trivial conserved vector is equivalent to the vanishing one. For any system $\mathcal{L}$ of differential equations the set $\mathrm{CV}(\mathcal{L})$ of conserved vectors of its conservation laws is a linear space, and the subset $\mathrm{CV}_0(\mathcal{L})$ of trivial conserved vectors is a linear subspace in $\mathrm{CV}(\mathcal{L})$. The factor space $\mathrm{CL}(\mathcal{L})=\mathrm{CV}(\mathcal{L})/\mathrm{CV}_0(\mathcal{L})$ coincides with the set of equivalence classes of $\mathrm{CV}(\mathcal{L})$ with respect to the equivalence relation adduced in Definition 3. We can identify elements of $\mathrm{CL}(\mathcal{L})$ with conservation laws and call $\mathrm{CL}(\mathcal{L})$ also as *the space of conservation laws* of $\mathcal{L}$ (see, e.g., Ref. 46). That is why we assume description of the set of conservation laws as finding $\mathrm{CL}(\mathcal{L})$ that is equivalent to construction of either a basis if $\dim\mathrm{CL}(\mathcal{L})<\infty$ or a system of generatrices in the infinite dimensional case, and we will additionally identify elements from $\mathrm{CL}(\mathcal{L})$ with their representatives in $\mathrm{CV}(\mathcal{L})$. In contrast to the order r_F of a conserved vector F as the maximal order of derivatives explicitly appearing in F, the *order of a conservation law* as an element $\mathcal{F}$ from $\mathrm{CL}(\mathcal{L})$ is called $\min\{r_F\,|\,F\in\mathrm{CV}(\mathcal{L})\text{corresponds to }\mathcal{F}\}$. Under linear dependence of conservation laws we understand linear dependence of corresponding elements in $\mathrm{CL}(\mathcal{L})$.

Definition 4: Conservation laws of a system $\mathcal{L}$ are called *linearly dependent* if a linear combination of them has a trivial conserved vector.

Note 1: Sometimes other definitions of equivalence of conservation laws are used.[16]

Let the system $\mathcal{L}$ be totally nondegenerate.[31] Then application of the Hadamard lemma to the definition of conservation law and integrating by parts imply that the left-hand side of any conservation law of $\mathcal{L}$ can always be presented up to the equivalence relation as a linear combination of left-hand side of independent equations from $\mathcal{L}$ with coefficients λ^μ being functions on a suitable jet space $J^{(k)}$,

$$\mathrm{Div}\,F=\lambda^\mu L^\mu. \tag{2}$$

Here the order k is determined by $\mathcal{L}$ and the allowable order of conservation laws, $\mu=\overline{1,l}$.

Definition 5: Formula (2) and the l-tuple $\lambda=(\lambda^1,\dots,\lambda^l)$ are called the *characteristic form* and the *characteristic* of the conservation law $\mathrm{Div}\,F=0$ correspondingly.

The characteristic λ is *trivial* if it vanishes for all solutions of $\mathcal{L}$. Since $\mathcal{L}$ is nondegenerate, the characteristics λ and $\tilde{\lambda}$ satisfy (2) for the same F and, therefore, are called *equivalent* iff $\lambda-\tilde{\lambda}$ is a trivial characteristic. Similarly to conserved vectors, the set $\mathrm{Ch}(\mathcal{L})$ of characteristics corresponding to conservation laws of the system $\mathcal{L}$ is a linear space, and the subset $\mathrm{Ch}_0(\mathcal{L})$ of trivial characteristics is a linear subspace in $\mathrm{Ch}(\mathcal{L})$. The factor space $\mathrm{Ch}_f(\mathcal{L})=\mathrm{Ch}(\mathcal{L})/\mathrm{Ch}_0(\mathcal{L})$ coincides

with the set of equivalence classes of $\mathrm{Ch}(\mathcal{L})$ with respect to the above characteristic equivalence relation.

The following result[31] forms the cornerstone for the methods of studying conservation laws, which are based on formula (2), including the Noether theorem and the direct method by Anco and Bluman.[4,5]

Theorem 1: (Ref. 31) *Let $\mathcal{L}$ be a normal, totally nondegenerate system of differential equations. Then representation of conservation laws of $\mathcal{L}$ in the characteristic form (2) generates a one-to-one linear mapping between* $\mathrm{CL}(\mathcal{L})$ *and* $\mathrm{Ch}_f(\mathcal{L})$.

Using properties of total divergences, we can exclude the conserved vector F from (2) and obtain a condition for the characteristic λ only. Namely, a differential function f is a total divergence, i.e., $f=\mathrm{Div}\,F$ for some n-tuple F of differential functions iff $\mathsf{E}(f)=0$. Hereafter the Euler operator $\mathsf{E}=(\mathsf{E}^1,\dots,\mathsf{E}^m)$ is the m-tuple of differential operators

$$\mathsf{E}^a=(-D)^\alpha\partial_{u^a_\alpha},\quad a=\overline{1,m},$$

where $\alpha=(\alpha_1,\dots,\alpha_n)$ runs the multi-indices set $(\alpha_i\in\mathbb{N}\cup\{0\})$, $(-D)^\alpha=(-D_1)^{\alpha_1}\cdots(-D_m)^{\alpha_m}$. Therefore, action of the Euler operator on (2) results to the equation

$$\mathsf{E}(\lambda^\mu L^\mu)=\mathsf{D}^*_\lambda(L)+\mathsf{D}^*_L(\lambda)=0, \tag{3}$$

which is a necessary and sufficient condition on characteristics of conservation laws for the system $\mathcal{L}$. The matrix differential operators D^*_λ and D^*_L are the adjoints of the Fréchet derivatives D_λ and D_L, i.e.,

$$\mathsf{D}^*_\lambda(L)=\left((-D)^\alpha\left(\frac{\partial\lambda^\mu}{\partial u^a_\alpha}L^\mu\right)\right),\quad \mathsf{D}^*_L(\lambda)=\left((-D)^\alpha\left(\frac{\partial L^\mu}{\partial u^a_\alpha}\lambda^\mu\right)\right).$$

Since $\mathsf{D}^*_\lambda(L)=0$ automatically on solutions of $\mathcal{L}$ then Eq. (3) implies a necessary condition for λ to belong to $\mathrm{Ch}(\mathcal{L})$:

$$\mathsf{D}^*_L(\lambda)|_{\mathcal{L}}=0. \tag{4}$$

Condition (4) can be considered as adjoint to the criteria $\mathsf{D}_L(\eta)|_{\mathcal{L}}=0$ for infinitesimal invariance of $\mathcal{L}$ with respect to evolutionary vector field having the characteristic $\eta=(\eta^1,\dots,\eta^m)$. That is why solutions of (4) are sometimes called *cosymmetries*[7,36] or *adjoint symmetries*.[5]

By writing $\mathcal{L}$ in Cauchy–Kovalevskaya form (which is always possible since $\mathcal{L}$ is normal), system (3) can be split on the solution manifold of $\mathcal{L}$ to get determining equations for λ^μ formulated entirely on the solution manifold of $\mathcal{L}$. These equations include the adjoint symmetry condition (4) and certain adjoint-linearization equations.[5] As stated in Ref. 2, one only needs to find adjoint symmetries of $\mathcal{L}$ [i.e., solutions of (4)] in order to obtain conservation laws whenever $\mathcal{L}$ possesses a scaling symmetry.

III. EQUIVALENCE OF CONSERVATION LAWS

We can essentially simplify and order classification of conservation laws, taking into account additionally symmetry transformations of a system or equivalence transformations of a whole class of systems. Such problem is similar to one of group classification of differential equations.

Proposition 1: Any point transformation g maps a class of equations in the conserved form into itself. More exactly, the transformation g: $\tilde{x}=x_g(x,u)$, $\tilde{u}=u_g(x,u)$ prolonged to the jet space $J^{(r)}$ transforms the equation $D_iF^i=0$ to the equation $D_iF^i_g=0$. The transformed conserved vector F_g is determined by the formula

$$F^i_g(\tilde{x},\tilde{u}_{(r)})=\frac{D_{x_j}\tilde{x}_i}{|D_x\tilde{x}|}F^j(x,u_{(r)}),\quad \text{i.e., } F_g(\tilde{x},\tilde{u}_{(r)})=\frac{1}{|D_x\tilde{x}|}(D_x\tilde{x})F(x,u_{(r)}) \tag{5}$$

in the matrix notions. Here $|D_x\tilde{x}|$ is the determinant of the matrix $D_x\tilde{x}=(D_{x_j}\tilde{x}_i)$.

Note 2: In the case of one dependent variable ($m=1$) g can be a contact transformation: $\tilde{x}=x_g(x,u_{(1)})$, $\tilde{u}_{(1)}=u_{g(1)}(x,u_{(1)})$. Similar notes are also true for the statements below.

Definition 6: Let G be a symmetry group of the system $\mathcal{L}$. Two conservation laws with the conserved vectors F and F' are called *G-equivalent* if there exists a transformation $g\in G$ such that the conserved vectors F_g and F' are equivalent in the sense of Definition 3.

Any transformation $g\in G$ induces a linear one-to-one mapping g_* in $\mathrm{CV}(\mathcal{L})$, transforms trivial conserved vectors only to trivial ones [i.e., $\mathrm{CV}_0(\mathcal{L})$ is invariant with respect to g_*] and therefore induces a linear one-to-one mapping g_f in $\mathrm{CL}(\mathcal{L})$. It is obvious that g_f preserves linear (in)dependence of elements in $\mathrm{CL}(\mathcal{L})$ and maps a basis (a set of generatrices) of $\mathrm{CL}(\mathcal{L})$ in a basis (a set of generatrices) of the same space. In such way we can consider the G-equivalence relation of conservation laws as well determined on $\mathrm{CL}(\mathcal{L})$ and use it to classify conservation laws.

Proposition 2: If the system $\mathcal{L}$ admits a one-parameter group of transformations then the infinitesimal generator $X=\xi^i\partial_i+\eta^a\partial_{u^a}$ of this group can be used for construction of new conservation laws from known ones. Namely, differentiating Eq. (5) with respect to the parameter ε and taking the value $\varepsilon=0$, we obtain the new conserved vector

$$\tilde{F}^i=-X_{(r)}F^i+(D_j\xi^j)F^j-(D_j\xi^j)F^i. \tag{6}$$

Here $X_{(r)}$ denotes the rth prolongation[31,33] of the operator X.

Note 3: Formula (6) can be directly extended to generalized symmetry operators (see, for example, Refs. 6 and 24). A similar statement for generalized symmetry operators in evolutionary form ($\xi^i=0$) was known earlier.[19,31] It was used by Khamitova[25] to introduce a notion of basis of conservation laws as a set which generates a whole set of conservation laws with action of generalized symmetry operators and operation of linear combination.

Proposition 3: Any point transformation g between systems $\mathcal{L}$ and $\tilde{\mathcal{L}}$ induces a linear one-to-one mapping g_* from $\mathrm{CV}(\mathcal{L})$ into $\mathrm{CV}(\tilde{\mathcal{L}})$, which maps $\mathrm{CV}_0(\mathcal{L})$ into $\mathrm{CV}_0(\tilde{\mathcal{L}})$ and generates a linear one-to-one mapping g_f from $\mathrm{CL}(\mathcal{L})$ into $\mathrm{CL}(\tilde{\mathcal{L}})$.

Corollary 1: Any point transformation g between systems $\mathcal{L}$ and $\tilde{\mathcal{L}}$ induces a linear one-to-one mapping $\hat{g}_f$ from $\mathrm{Ch}_f(\mathcal{L})$ into $\mathrm{Ch}_f(\tilde{\mathcal{L}})$.

It is possible to obtain an explicit formula for correspondence between characteristics of $\mathcal{L}$ and $\tilde{\mathcal{L}}$. Let $\tilde{\mathcal{L}}^\mu=\Lambda^{\mu\nu}\mathcal{L}^\nu$, where $\Lambda^{\mu\nu}=\Lambda^{\mu\nu\alpha}D^\alpha$, $\Lambda^{\mu\nu\alpha}$ are differential functions, $\alpha=(\alpha_1,\dots,\alpha_n)$ runs the multi-indices set ($\alpha_i\in\mathbb{N}\cup\{0\}$), $\mu,\ \nu=\overline{1,l}$. Then

$$\lambda^\mu=\Lambda^{\nu\mu*}(|D_x\tilde{x}|\tilde{\lambda}^\nu).$$

Here $\Lambda^{\nu\mu*}=(-D)^\alpha\cdot\Lambda^{\mu\nu\alpha}$ is the adjoint to the operator $\Lambda^{\nu\mu}$. For a number of cases, e.g., if $\mathcal{L}$ and $\tilde{\mathcal{L}}$ are single partial differential equations ($l=1$), the operators $\Lambda^{\mu\nu}$ are simply differential functions (i.e., $\Lambda^{\mu\nu\alpha}=0$ for $|\alpha|>0$) and, therefore, $\Lambda^{\nu\mu*}=\Lambda^{\mu\nu}$.

Consider the class $\mathcal{L}|_S$ of systems $L(x,u_{(\rho)},\theta(x,u_{(\rho)}))=0$ parametrized with the parameter-functions $\theta=\theta(x,u_{(\rho)})$. Here L is a tuple of fixed functions of x, $u_{(\rho)}$ and θ. θ denotes the tuple of arbitrary (parametric) functions $\theta(x,u_{(\rho)})=(\theta^1(x,u_{(\rho)}),\dots,\theta^k(x,u_{(\rho)}))$ satisfying the condition $S(x,u_{(\rho)},\theta_{(q)}(x,u_{(\rho)}))=0$. This condition consists of differential equations on θ, where x and $u_{(\rho)}$ play the role of independent variables and $\theta_{(q)}$ stands for the set of all the partial derivatives of θ of order no greater than q. In what follows we call the functions θ arbitrary elements. Denote the local transformations group preserving the form of systems from $\mathcal{L}|_S$ as $G^\sim=G^\sim(L,S)$.

Consider the set $P=P(L,S)$ of all pairs each of which consists of a system from $\mathcal{L}|_S$ and a conservation law of this system. In view of Proposition 3, action of transformations from $G^\sim$ together with the pure equivalence relation of conserved vectors naturally generates an equivalence relation on P. Classification of conservation laws with respect to $G^\sim$ will be understood as classification in P with respect to the above equivalence relation. This problem can be investigated in the way that is similar to group classification in classes of systems of differential equations. Namely, we construct first the conservation laws that are defined for all values of the arbitrary

elements. (The corresponding conserved vectors may depend on the arbitrary elements.) Then we classify, with respect to the equivalence group, arbitrary elements for each of that the system admits additional conservation laws.

In an analogous way we also can introduce an equivalence relation on P generated by all admissible point or contact transformations (called also form-preserving ones[26]) in pairs of equations from $\mathcal{L}|_S$.

Note 4: It can be easily shown that all the above equivalences are indeed equivalence relations.

IV. DIRECT ITERATION METHOD OF FINDING CONSERVATION LAWS

To construct conservation laws of a system $\mathcal{L}$ of differential equations, we iterate a modification of the most *direct method* based on Definition 1. More precisely, the algorithm is as follows.

Zeroth iteration: At first we construct local conservation laws of $\mathcal{L}$. We fix an (arbitrary) order r of conserved vectors under consideration. Then we introduce local coordinates ("unconstrained variables") on the manifold $\mathcal{L}_{(r+1)}$ determined by the system $\mathcal{L}$ and its differential consequences in $J^{(r+1)}$. The other ("constrained") variables of $J^{(r+1)}$ are expressed via unconstrained ones by means of using the equations of $\mathcal{L}_{(r+1)}$. We substitute the expressions for constrained variables into a conservation law and split the obtained condition with respect to the unconstrained variables. This procedure results in a first-order linear system of determining equations for conserved vectors. Solving the determining equations up to the usual equivalence relation on $\mathrm{CV}(\mathcal{L})$, we obtain complete description of local conservation laws of $\mathcal{L}$. To classify conservation laws in easier and more systematic way (especially for classes of systems of differential equations), instead of usual equivalence we use the introduced above equivalence with respect to symmetry or equivalence transformations. (See Sec. VI for examples.)

First iteration: After applying Lemma 1 to constructed conservation laws on the set of solutions of $\mathcal{L}=\mathcal{L}^0$, we introduce potentials as additional dependent variables and attach the equations connecting the potentials with components of corresponding conserved vectors to $\mathcal{L}^0$. (If $n>2$ the attached equations of such kind form an underdetermined system with respect to the potentials. Therefore, we can also attach gauge conditions on the potentials to $\mathcal{L}^0$. See discussion on gauge freedom in potential systems and necessity of gauge conditions in paper.[3])

We must use linear independent conservation laws since otherwise the introduced potentials will be *dependent* in the following sense: there exists a linear combination of the potential tuples, which is, for some $r' \in \mathbb{N}$, a tuple of functions of x and $u_{(r')}$ only.

Then we exclude the unnecessary equations (i.e., the equations that are dependent on equations of $\mathcal{L}^0$ and attached equations simultaneously) from the extended (potential) system $\mathcal{L}^1$ which will be called a *potential system of the first level*. Any conservation law of $\mathcal{L}^0$ is one of $\mathcal{L}^1$. We iterate the above procedure of the direct method for $\mathcal{L}^1$ to find its conservation laws which are linear independent with ones from the previous iteration and will be called *potential conservation laws of the first level*.

Further iterations: We make iterations while it is possible [i.e., the iteration procedure has to be stopped if all the conservation laws of a *potential system* $\mathcal{L}^{k+1}$ *of the* $(k+1)$*th level* are linear dependent with the ones of $\mathcal{L}^k$] or construct infinite chains of conservation laws by means of induction. This process may yield *purely potential* conservation laws of the initial system $\mathcal{L}$, which are linear independent with local conservation laws and, therefore, depend explicitly on potential variables.

Any conservation law from the previous step of iteration procedure will be a conservation law for the next step and vice versa; conservation laws which are obtained on the next step and depend only on variables of the previous step are linear dependent with conservation laws from the previous step. It is also obvious that the conservation laws used for construction of a potential system of the next level are trivial on the manifold of this system.

Since gauge conditions on potentials can be chosen in many different ways, exhaustive realization of iterations is improbable in the case $n>2$.

The procedure of exclusion of constrained variables (which are described above in detail only for the zeroth iteration) is called in classical group analysis as "confining to the manifold of $\mathcal{L}$." Taking into account $\mathcal{L}$ in the above way, we automatically eliminate the ambiguity connected with vanishing conserved vectors on the solutions of $\mathcal{L}$. However, the second kind of ambiguity arising via existence of null divergences is preserved, and it is the main reason of difficulties in realization of this algorithm with symbolic computation systems.[44]

To find conservation laws on each step of iteration procedure, one can apply other methods which are based on the characteristic form (2) or its consequences (3) and (4). These methods are also called as direct.[4,5] Following Ref. 44, for convenience we will numerate them as the second, third, and fourth versions of the direct method in contrast to the above first one. They are close to the symmetry group method by Noether since in the case of Euler–Lagrange equations the coefficients λ^a are nothing else than Noether's characteristics. Taking into account the equivalence relation on $\mathrm{Ch}(\mathcal{L})$, one can assume during calculations that characteristics depend only on unconstrained variables.

In the second version of the direct method the representation (2) is regarded as an equation defined on an open subset of $J^{(k)}$ with respect to conserved vectors and characteristics simultaneously.

In the framework of the third version, sought quantities are characteristics only. Determining Eq. (3) is defined on an open subset of $J^{(k)}$. Conserved vectors are reconstructed from known characteristics via explicit integral formulas. An algorithm of this (third) version of the direct method was developed for Cauchy–Kovalevskaya systems by Anco and Bluman[4,5] (see also Refs. 31 and 46 for a theoretical background).

The fourth version is based on Eq. (4) which is defined on the manifold $\mathcal{L}$ and is only a necessary condition on characteristic of conservation laws. Therefore, one has to choose characteristics from the set of adjoint symmetries using additional conditions. Such approach was used by Bluman and Doran-Wu[8] for studying conservation laws of diffusion equations.

Each from four above versions of the direct method has its advantages and disadvantages. A detailed comparative analysis of all the versions and their realizations in computer algebra programs are given by Wolf.[44]

Prototypes and sources of a number of above ideas can be found in Ref. 28.

V. TWO-DIMENSIONAL CASE

The case of two independent variables is singular, in particular, with respect to possible (constant) indeterminacy after introduction of potentials and high effectiveness of application of potential symmetries. That is why we consider some notions connected with conservation laws in this case separately. We denote independent variables as t (the time variable) and x (the space one). Any local conservation law has the form

$$D_t F(t,x,u_{(r)}) + D_x G(t,x,u_{(r)}) = 0. \tag{7}$$

Here D_t and D_x are the operators of the total differentiation with respect to t and x. F and G are called the *conserved density* and the *flux* of the conservation law correspondingly.

Two conserved vectors (F,G) and (F',G') are *equivalent* if there exist such functions $\hat{F}$, $\hat{G}$, and H of t, x, and derivatives of u that $\hat{F}$ and $\hat{G}$ vanish on $\mathcal{L}_{(k)}$ for some k and

$$F' = F + \hat{F} + D_x H, \quad G' = G + \hat{G} - D_t H. \tag{8}$$

Any conservation law (7) of $\mathcal{L}$ allows us to deduce the new dependent (potential) variable v by means of the equations

$$v_x = F, \quad v_t = -G. \tag{9}$$

To construct a number of potentials in one step, we must use a set of linear independent conservation laws (see the preceding section) since otherwise the potentials will be dependent in the

following sense: there exists a linear combination of the potentials, which is, for some $r' \in \mathbb{N}$, a function of t, x, and $u_{(r')}$ only.

In the case of two independent variables we can also introduce the more general notion of potential dependence.

Definition 7: The potentials $v^1, \dots, v^p$ are called *locally dependent on the set of solution of the system* $\mathcal{L}$ (or, briefly speaking, *dependent*) if there exist $r' \in \mathbb{N}$ and a function H of the variables t, x, $u_{(r')}, v^1, \dots, v^p$ such that $H(t,x,u_{(r')},v^1,\dots,v^p)=0$ for any solution $(u,v^1,\dots,v^p)$ of the united system determining the set of potentials $v^1,\dots,v^p$.

Proof of local dependence or independence of potentials for general classes of differential equations is difficult since it is closely connected with precise description of possible structure of conservation laws. An example of such proof for diffusion-convection equations is presented below.

In the case of single equation $\mathcal{L}$, equations of form (9) combine into the complete potential system since $\mathcal{L}$ is a differential consequence of (9). As a rule, systems of such kind admit a number of nontrivial symmetries and so they are of great interest.

Equations (5) and (9) imply the following statement.

Proposition 4: Any point transformation connecting two systems $\mathcal{L}$ and $\widetilde{\mathcal{L}}$ of PDEs with two independent variables generates a one-to-one mapping between the sets of potential systems, which correspond to $\mathcal{L}$ and $\widetilde{\mathcal{L}}$. Generation is made via trivial prolongation on the space of introduced potential variables, i.e., we can assume that the potentials are not transformed.

Corollary 2: The Lie symmetry group of a system $\mathcal{L}$ *of differential equations generates an equivalence group on the set of potential systems corresponding to* $\mathcal{L}$.

Corollary 3: Let $\hat{\mathcal{L}}|_S$ *be the set of all potential systems constructed for systems from the class* $\mathcal{L}|_S$ *with their construction laws. Action of transformations from* $G^{\sim}(L,S)$ *together with the equivalence relation of potentials naturally generates an equivalence relation on* $\hat{\mathcal{L}}|_S$.

Note 5: Proposition 4 and its corollaries imply that the equivalence group for a class of systems or the symmetry group for single system can be prolonged to potential variables for any step of the direct iteration procedure. It is natural the prolonged equivalence groups are used to classify possible conservation laws and potential systems in each iteration. Additional equivalences which exist in some subclasses of the class or arise after introducing potential variables can be used for deeper analysis of connections between conservation laws.

VI. LOCAL CONSERVATION LAWS OF DIFFUSION-CONVECTION EQUATIONS

To classify the conservation laws of equations from class (1) we have to start our investigation from finding equivalence transformations. Application of the direct method to class (1) allows us to find the complete equivalence group $G^{\sim}$ including the both continuous and discrete transformations. The following statement is true.

Theorem 2: (Refs. 34 and 35) *Any transformation from* $G^{\sim}$ *has the form*

$$\tilde{t} = \varepsilon_4 t + \varepsilon_1, \quad \tilde{x} = \varepsilon_5 x + \varepsilon_7 t + \varepsilon_2, \quad \tilde{u} = \varepsilon_6 u + \varepsilon_3, \quad \tilde{A} = \varepsilon_4^{-1}\varepsilon_5^2 A, \quad \tilde{B} = \varepsilon_4^{-1}\varepsilon_5 B - \varepsilon_7,$$

where $\varepsilon_1,\dots,\varepsilon_7$ *are arbitrary constants,* $\varepsilon_4\varepsilon_5\varepsilon_6 \neq 0$.

The kernel of Lie symmetry group of equations from class (1) is the group of the transformations which are common for all of these equations. We denote it as G^{ker}. Via trivial prolongation on the arbitrary elements A and B, G^{ker} is isomorphic to a normal subgroup of $G^{\sim}$.

Theorem 3: G^{ker} *is formed by the transformations*

$$\tilde{t} = t + \varepsilon_1, \quad \tilde{x} = x + \varepsilon_2, \quad \tilde{u} = u,$$

where ε_1 *and* ε_2 *are arbitrary constants*.

First we search the conservation laws of equations from class (1) in the form (7).

Lemma 2: Any local conservation law of any equation from class (1) *has the first order.*

Moreover, up to equivalence on conserved vectors one can assume that the density depending on t, x, and u and the flux depending on t, x, u, and u_x.

Proof: Considering conservation laws on the manifold of Eq. (1) and its differential consequences, we can assume that F and G depend only on t, x, and $u_k=\partial^k u/\partial x^k$, $k=\overline{0,r'}$, where $r' \leqslant 2r$. We expand the total derivatives in (7) and take into account differential consequences of the form $u_{tj}=D_x^{j+2}\int A+D_x^{j+1}\int B$, where $\int A=\int A(u)\mathrm{d}u$, $\int B=\int B(u)\mathrm{d}u$, $j=\overline{0,r'}$. As a result we obtain the following condition:

$$F_t+F_{u_j}\left(D_x^{j+2}\int A+D_x^{j+1}\int B\right)+G_x+G_{u_j}u_{j+1}=0. \tag{10}$$

Let us decompose (10) with respect to the highest derivatives u_j. So, the coefficients of $u_{r'+2}$ and $u_{r'+1}$ give the equations $F_{u_{r'}}=0$, $G_{u_{r'}}+AF_{u_{r'-1}}=0$ that result in

$$F=\hat{F},\quad G=-Au_{r'}\hat{F}_{u_{r'-1}}+\hat{G},$$

where $\hat{F}$ and $\hat{G}$ are functions of $t,x,u,u_1,\dots,u_{r'-1}$. Then, after selecting the terms containing $u_{r'}^2$, we obtain that $-A\hat{F}_{u_{r'-1}u_{r'-1}}=0$. It yields that $\hat{F}=\check{F}^1u_{r'-1}+\check{F}^0$, where $\check{F}^1$ and $\check{F}^0$ depend only on $t,x,u,u_1,\dots,u_{r'-2}$.

Consider the conserved vector with the density $\widetilde{F}=F-D_xH$ and the flux $\widetilde{G}=G+D_tH$, where $H=\int\check{F}^1\mathrm{d}u_{r'-2}$. This conserved vector is equivalent to the initial one, and

$$\widetilde{F}=\widetilde{F}(t,x,u,u_1,\dots,u_{r'-2}),\quad \widetilde{G}=\widetilde{G}(t,x,u,u_1,\dots,u_{r'-1}).$$

Iterating this procedure a necessary number of times, we obtain the lemma statement. ■

Note 6: A similar statement is true for an arbitrary $(1+1)$-dimensional evolution equation $\mathcal{L}$ of the even order $r=2\overline{r},\overline{r}\in\mathbb{N}$.[1,19] For example,[19] for any conservation law of $\mathcal{L}$ we can assume up to equivalence of conserved vectors that F and G depend only on t, x and derivatives of u with respect to x, and the maximal order of derivatives in F is not greater than $\overline{r}$.

Lemma 2 gives a stronger result for a more restricted class of equations. In the above proof we specially use the most direct method to demonstrate its effectiveness in quite general cases. This proof can be easily extended to other classes of $(1+1)$-dimensional evolution equations of odd orders and potential systems corresponding to equations from class (1) (see the proof of Lemma 3).

Theorem 4: *Any equation from class* (1) *has the conservation law* (7) *where*

$$(1)\quad F=u,\quad G=-Au_x-\int B. \tag{11}$$

A complete list of $G^{\sim}$-inequivalent equations (1) *having additional* [*i.e., linear independent with* (11)] *conservation laws is exhausted by the following ones:*

$$(2)\quad \forall A,\quad B=0:\quad F=xu,\quad G=\int A-xAu_x, \tag{12}$$

$$(3)\quad \forall A,\quad B=A:\quad F=(e^x+\varepsilon)u,\quad G=-(e^x+\varepsilon)Au_x-\varepsilon\int A, \tag{13}$$

$$(4)\quad A=1,\quad B=0:\quad F=\alpha u,\quad G=\alpha_x u-\alpha u_x, \tag{14}$$

where $\varepsilon\in\{0,\pm1\}\bmod G^{\sim}$, $\int A=\int A(u)\mathrm{d}u$, $\int B=\int B(u)\mathrm{d}u$, $\alpha=\alpha(t,x)$ is an arbitrary solution of the linear heat equation $\alpha_t+\alpha_{xx}=0$. (*Together with values A and B we also adduce complete lists of densities and the fluxes of additional conservation laws.*)

Proof: In view of Lemma 2, we can assume at once that $F=F(t,x,u)$ and $G=G(t,x,u,u_x)$. Let us substitute the expression for u_t deduced from (1) into (7) and decompose the obtained equation with respect to u_{xx}. The coefficient of u_{xx} gives the equation $AF_u+G_{u_x}=0$, therefore $G=-AF_u u_x+G^1(t,x,u)$. Taking into account the latter expression for G and splitting the rest of Eq. (7) with respect to the powers of u_x, we obtain the system of PDEs on the functions F and G^1 of the form

$$F_{uu}=0, \quad BF_u-AF_{ux}+G^1_u=0, \quad F_t+G^1_x=0. \tag{15}$$

Solving the first two equations of (15) yields

$$F=F^1(t,x)u+F^0(t,x), \quad G^1=F^1_x\int A-F^1\int B+G^0(t,x). \tag{16}$$

In further consideration the major role is played by the equation $AF_{uxx}-BF_{ux}+F_{ut}=0$ that is a differential consequence of system (15) and can be rewritten as

$$AF^1_{xx}-BF^1_x+F^1_t=0.$$

Indeed, it is the unique classifying condition for this problem. There exist four different possibilities for values A and B. In all cases we obtain the equation $F^0_t+G^0_x=0$. Therefore, up to conservation laws equivalence we can assume $F^0=G^0=0$. Moreover, the function $F^1=\text{const}$ is a solution of the classifying condition in the general case. This solution corresponds to the conservation laws of case 1. Only conservation laws of such kind exist for all admissible values of arbitrary elements A and B. Then we classify special values of A and B for which Eq. (1) possesses additional conservation laws.

(1) $B\notin\langle A,1\rangle$. Then $F^1_x=0$, $F^1_t=0$ that gives contradiction with the assumption $F^1\neq\text{const}$.
(2) $A\notin\langle 1\rangle$, $B\in\langle 1\rangle$. Then $B=0 \bmod G^\sim$ and $F^1_{xx}=0$, $F^1_t=0$, i.e., $F^1=x \bmod G^\sim$ (case 2).
(3) $B\in\langle A,1\rangle$, $A,B\notin\langle 1\rangle$. Then $B=A \bmod G^\sim$ and $F^1_{xx}+F^1_x=0$, $F^1_t=0$, i.e., $F^1=e^x+\varepsilon \bmod G^\sim$, where $\varepsilon\in\{0,\pm 1\}$ (case 3).
(4) A, $B\in\langle 1\rangle$. Therefore, $A=1$, $B=0 \bmod G^\sim$, and $F^1_t+F^1_{xx}=0$ (case 4). ■

Note 7: It follows from the proof that we can assume $(A,B)\neq\text{const}$ in cases 1, 2, and 3. [If $(A,B)=\text{const}$ cases 1, 2, and 3 are included in case 4 for different values of α.]

Using the conservation laws adduced in Theorem 4, we can introduce potentials for different values of the parameter functions A and B and construct the corresponding potential systems (cases 1–4 of Table I). The important question for our consideration is whether the introduced potentials are locally independent in the sense of Definition 7. If we know the precise structure of conservation laws the answer is almost obvious.

Theorem 5: *For any equation* (1) *potentials are locally dependent on the equation manifold iff the corresponding conservation laws are linear dependent.*

Proof: Since the direct statement of the theorem is obvious (see Sec. V), we prove only the inverse statement, using the rule of contraries. Suppose that potentials $v^0,\dots,v^p$ introduced with (independent) conservation laws of cases 1–4 are locally dependent. The vanishing p means local triviality of v^0 as a potential, i.e., v^0 can be expressed in terms of local variables and the corresponding conservation law is trivial. That is why it is sufficient to investigate only the special cases when the number of independent conservation laws is greater than 1. Therefore, $p=1$ if either $B=0$ or $B=A$ and $p\in\mathbb{N}/\{0\}$ for the linear heat equation.

Without loss of generality we can assume that there exist $r\in\mathbb{N}$ and a fixed function V of $t,x,\overline{v}=(v^1,\dots,v^p)$ and $u_{(r)}$ that $v^0=V(t,x,\overline{v},u_{(r)})$ for any solution of the united system determining the whole set of potentials $v^0,\dots,v^p$. Taking into account equation (1) and its differential consequences, we can assume that V depends only on t, x, $\overline{v}$, and $u_k=\partial^k u/\partial x^k$, $k=\overline{0,r'}$, where $r'\leqslant 2r$. Let us apply the operator D_x to the condition $v^0=V(t,x,\overline{v},u,u_1,\dots,u_{r'})$: $v^0_x=V_x+V_{v^s}v^s_x+V_{u^k}u_{k+1}$. (Hereafter the index s takes the values from 1 to p.) Since in any case under consideration $v^s_x=f^s u$ for some functions f^s of t and x, we can split the differentiated condition with respect

TABLE I. Conservation laws and potential systems of convection-diffusion equations.[a]

N	A	B	F	G	Potential system
1	$\forall$	$\forall$	u	$-Au_x-\int B$	$v_x=u,\ v_t=Au_x+\int B$
1.1	$\forall$	0	v	$-\int A$	$v_x=u,\ w_x=v,\ w_t=\int A$
1.2	$\forall$	A	$e^x v$	$-e^x\int A$	$v_x=u,\ w_x=e^x v,\ w_t=e^x\int A$
1.3	$\forall$	$\int A+uA$	e^v	$-e^v\int A$	$v_x=u,\ w_x=e^v,\ w_t=e^v\int A$

4.1	1	0	$(\beta/\alpha)_x v$	$-\alpha(\beta/\alpha)_x u-(\beta/\alpha)_t v$	$v_x=\alpha u,$ $w_x=(\beta/\alpha)_x v,\ w_t=\alpha(\beta/\alpha)_x u+(\beta/\alpha)_t v$

[a]Here $\varepsilon\in\{0,\pm1\}$, $\int A=\int A(u)\mathrm{d}u$, $\int B=\int B(u)\mathrm{d}u$; $\alpha(t,x)$, $\beta(t,x)$, and $\alpha(t,v)$ are arbitrary solutions of the linear heat equation $(\alpha_t+\alpha_{xx}=0,\beta_t+\beta_{xx}=0,\sigma_t+\sigma_{vv}=0)$. In case 1.3 we assume $\int B=u\int A$ for a conservation law to have the adduced form.

to u_k step-by-step in the reverse sequence, beginning with the major derivative. As a result, we obtain $V_{u^k}=0$, $V_x=0$, and $f^0=V_{v^s}f^s$, i.e., the functions $f^0,\dots,f^p$ are linear dependent. This gives a contradiction with the supposition that the conservation laws are independent. ■

VII. SIMPLEST POTENTIAL CONSERVATION LAWS OF DIFFUSION-CONVECTION EQUATIONS

Let us investigate local conservation laws of potential systems 1–4 from Table I, which have the form

$$D_t F(t,x,u_{(r)},v_{(r)})+D_x G(t,x,u_{(r)},v_{(r)})=0. \tag{17}$$

These laws can be considered as nonlocal (*potential*) conservation laws of equations from class (1). We assume them as simplest potential conservation laws since the corresponding potential systems are constructed from the initial equation (1) with one conservation law only.

We classify conservation laws up to the equivalence relation with respect to the transformation group $G^{\sim}_{\mathrm{pr}}$ which is a result of the trivial prolongation of the group $G^{\sim}$ from Theorem 2 to the space of the potential v.

Lemma 3: Any conservation law of form (17) *for each of systems* 1–4 *from Table I has the zero order, i.e., it is equivalent to a law with a conserved density F and a flux G that are independent on the (nonzero order) derivatives of u and v.*

Proof: Consider any from the systems 1–4. Taking it and its differential consequences into account, we can exclude dependence of F and G on all (nonzero order) derivatives of v and the derivatives of u containing differentiation with respect to t. The remaining part of the proof is completely similar to the one of Lemma 2. ■

In an analogous to proof of Theorem 4 and more cumbersome way we prove the following statement.

Theorem 6: *A complete set of* $G^{\sim}_{\mathrm{pr}}$*-inequivalent conservation laws of form* (17) *for equations from class* (1) *is presented in Table I with a double numeration of cases.*

Note 8: To prove Theorem 6 we use all independent differential consequences of correspondent potential systems. In Table I for the double numerated potential systems we omit equations containing v_t since they are only differential consequences of equations of these systems.

Let us analyze connections between conservation laws and ones between potential systems, which arise due to additional (including purely potential) equivalence transformations in some special cases. Below we assume $A \notin \{1, u^{-2}\}$ mod $G^{\sim}$ as a general value of A.

General case: Equation (1) in the general case has the unique linear independent local conservation law (case 1) with the conserved vectors $(F^1, G^1) = (u, -Au_x)$. All conservation laws of the corresponding potential system

$$v^1_x = u, \quad v^1_t = Au_x + \int B, \tag{18}$$

are trivial, i.e., in our framework equation (1) of the general form admits only trivial potential conservation laws.

$B=0$: Any equation of such form has two linear independent local conservation laws (cases 1 and 2) with the conserved vectors $(F^1, G^1) = (u, -Au_x)$ and $(F^2, G^2) = (xu, \int A - xAu_x)$, and any conservation law is G^{ker}-equivalent to one of them. Using these conservation laws, we can introduce two potentials v^1 and v^2, where

$$v^1_x = u, \quad v^1_t = Au_x, \tag{19}$$

$$v^2_x = xu, \quad v^2_t = xAu_x - \int A. \tag{20}$$

Equations (19) and (20) considered separately form two potential systems for equation (1) with vanishing B in unknown functions (u, v^1) and (u, v^2) correspondingly. The third potential system is formed by Eqs. (19) and (20) simultaneously, and three functions u, v^1, and v^2 are assumed as unknown. Each from systems (19) and (20) has one linear independent local conservation law (cases 1.1 and 2.1). These conservation laws with conserved vectors $(F^{11}, G^{11}) = (v^1, -\int A)$ and $(F^{21}, G^{21}) = (x^{-2}v^2, -x^{-1}\int A)$ are simplest potential conservation laws for Eq. (1) with vanishing B and allow us to introduce "second-level" potentials w^1 and w^2. As a result, we obtain two potential systems of the next level,

$$v^1_x = u, \quad w^1_x = v^1, \quad w^1_t = \int A, \tag{21}$$

$$v^2_x = xu, \quad w^2_x = x^{-2}v^2, \quad w^2_t = x^{-1}\int A. \tag{22}$$

At the same time, the simplest potential conservation laws are trivial on the solution manifold of the united system (19) and (20) since

$$F^{11} = D_x(xv^1 - v^2), \quad G^{11} = -D_t(xv^1 - v^2),$$

$$F^{21} = D_x(v^1 - x^{-1}v^2), \quad G^{21} = -D_t(v^1 - x^{-1}v^2).$$

Moreover $w^1 = xv^1 - v^2$, $w^2 = v^1 - x^{-1}v^2$, i.e., system (21), system (22), and united system (19) and (20) are point equivalent. It implies that really system (19) and (20) is generated by only three independent equations. (We can choose, e.g., the equation $v^1_x = u$, $v^2_x = xu$, $xv^1_t - v^2_t = \int A$.) Although system (21) formally belongs to the second level, it is the most convenient for further investigation since it has the simplest form.

$B=A$: This case is analyzed in the similar way to the previous one. Any equation with $B=A$ has the two-dimensional space of local conservation laws. Up to G^{ker}-equivalence, we have two possibilities for conserved vectors (cases 1 and 3),

$$(F^1,G^1)=\left(u,-Au_x-\int A\right)\quad\text{and}\quad(F^3,G^3)=\left((e^x+\varepsilon)u,-(e^x+\varepsilon)Au_x-\varepsilon\int A\right).$$

Using these conservation laws, we can introduce two potentials v^1 and v^3, where

$$v^1_x=u,\quad v^1_t=Au_x+\int A, \tag{23}$$

$$v^3_x=(e^x+\varepsilon)u,\quad v^3_t=(e^x+\varepsilon)Au_x+\varepsilon\int A. \tag{24}$$

Equations (23) and (24) considered separately form two potential systems for Eq. (1) with $B=A$ in unknown functions (u,v^1) and (u,v^3) correspondingly. The third potential system is formed by Eqs. (23) and (24) simultaneously, and three functions u, v^1, and v^3 are assumed as unknown. Each from systems (23) and (24) has one linear independent local conservation law (cases 1.2 and 3.1). These conservation laws with conserved vectors

$$(F^{12},G^{12})=\left(e^xv^1,-e^x\int A\right)$$

and

$$(F^{31},G^{31})=\left(\frac{e^x}{(e^x+\varepsilon)^2}v^3,-\frac{e^x}{e^x+\varepsilon}\int A\right)$$

are simplest potential conservation laws for Eq. (1) with $B=A$ and allow us to introduce "second-level" potentials w^1 and w^3. As a result, we obtain two potential systems of the next level,

$$v^1_x=u,\quad w^1_x=e^xv^1,\quad w^1_t=e^x\int A, \tag{25}$$

$$v^3_x=(e^x+\varepsilon)u,\quad w^3_x=\frac{e^x}{(e^x+\varepsilon)^2}v^3,\quad w^3_t=\frac{e^x}{e^x+\varepsilon}\int A. \tag{26}$$

At the same time, the simplest potential conservation laws are trivial on the solution manifold of the united system (23) and (24) since

$$F^{12}=D_x((e^x+\varepsilon)v^1-v^3),\quad G^{12}=-D_t((e^x+\varepsilon)v^1-v^3),$$

$$F^{31}=D_x\left(v^1-\frac{v^3}{e^x+\varepsilon}\right),\quad G^{31}=-D_t\left(v^1-\frac{v^3}{e^x+\varepsilon}\right).$$

Moreover

$$w^1=(e^x+\varepsilon)v^1-v^3,\quad w^3=v^1-\frac{v^3}{e^x+\varepsilon},$$

i.e., system (25), system (26), and united system (23) and (24) are point equivalent. It implies that really system (23) and (24) is generated by only three independent equations. [We can choose, e.g., the equation $v^1_x=u$, $v^3_x=(e^x+\varepsilon)u$, $(e^x+\varepsilon)v^1_t-v^3_t=e^x\int A$.] Although system (25) formally belongs to the second level, it is the most convenient for further investigation since it has the simplest form.

$B=\int A+uA$: The initial potential system in case 1.3 is reduced to case 1.2 by means of the hodograph transformation

$$\tilde{t} = t, \quad \tilde{x} = v, \quad \tilde{v} = x, \quad \tilde{u} = u^{-1}, \quad \tilde{A} = u^{-2}A, \tag{27}$$

and the conservation law 1.3 is transformed to the local one of case 3 where $\varepsilon = 0$. The same transformation extended to the potential w as $\tilde{w} = -w + ve^x$ also reduces the potential system 1.3 to 1.2.

Linearizable equations: It is well known[9,11,14,15,18,39,41] that equations (1) $G^{\sim}$-equivalent to ones of cases 1.4, 1.5, and 1.6 are linearized by a nonlocal (so-called potential equivalence[29,35]) transformations to the linear heat equation. That is why these equations stand out against the other diffusion-convection equations with having an infinite number of linear independent purely potential conservation laws.

The u^{-2}-diffusion equation $u_t = (u^{-2}u_x)_x$ is reduced to the linear heat equation[9] by the hodograph transformation (27). More exactly, (27) is a local transformation between the corresponding potential systems $v_x = u$, $v_t = u^{-2}u_x$ and $v_x = u$, $v_t = u_x$ constructed by means of using the "common" conservation law (case 1). The u^{-2}-diffusion equation has, as a subcase of the case $B = 0$, two linear independent local conservation laws with the conserved vectors

$$F^1 = u, \quad G^1 = -u^{-2}u_x, \tag{28}$$

$$F^2 = xu, \quad G^2 = -xu^{-2}u_x - u^{-1} \tag{29}$$

(cases 1 and 2 of Table I) and the infinite series of potential conservation laws (case 1.4) additionally. Under the action of hodograph transformation (27) the conservation law with conserved vector (28) is transformed to the trivial one of the linear heat equation with the conserved vector (1, 0). And vice versa, the conservation law of the linear heat equation corresponding to the value $\alpha = 1$ (case 4) is transformed by (27) to the trivial one of the u^{-2}-diffusion equation with the conserved vector (1, 0). The conservation law with conserved vector (29) is trivial on the manifold of potential system constructed by means of (28), is equivalent to the one from case 1.4 with $\sigma = 1$ and is transformed to case 4.1, where $\alpha = 1$ and $\beta = x$. Case 1.4 is reduced by (27) to case 4, where $\alpha = \sigma$.

Since the equation $u_t = (u^{-2}u_x)_x + u^{-2}u_x$ is reduced to the u^{-2}-diffusion equation by the local transformation $\tilde{t} = t$, $\tilde{x} = e^x$, $\tilde{u} = e^{-x}u$, its conservation laws are connected with ones of the linear heat equation in a way which is similar to the previous case.

The potential systems $\tilde{v}_{\tilde{x}} = \tilde{u}$, $\tilde{v}_{\tilde{t}} = \tilde{u}_{\tilde{x}} + \tilde{u}^2$, and $v_x = u$, $v_t = u_x$ constructed with the "common" conservation law for the Burgers equation $u_t = u_{xx} + 2uu_x$ and the linear heat equation $u_t = u_{xx}$ are connected via the transformation $t = \tilde{t}$, $x = \tilde{x}$, $u = \tilde{u}e^{\tilde{v}}$, $v = e^{\tilde{v}}$. (Here the tilde variables correspond to the Burgers equation.) Let us note that really the famous Cole–Hopf transformation[11,18] (first found in Ref. 15) linearizes the Burgers equation to the "potential" heat equation $v_t = v_{xx}$.[29,35] The Burgers equation has the "common" local conservation law (case 1) and the infinite series of simplest potential conservation laws (case 1.6). The above transformation between the potential systems induces the one-to-one mapping preserving α between the infinite series 1.6 and the one 4 of the "potential" heat equation $v_t = v_{xx}$. Then, the conservation law of form 4 with the function $\tilde{\alpha}$ for the "potential" heat equation $v_t = v_{xx}$ is equivalent to the one with the function α for the heat equation $u_t = u_{xx}$, where $\tilde{\alpha} = \alpha_x$. The conservation law of case 1 for the Burgers equation is trivial on the manifold of the corresponding potential system and is mapped to trivial one of the system $v_x = u$, $v_t = u_x$.

Linear heat equation: The linear heat equation $u_t = u_{xx}$ has an infinite dimensional space of local conservation laws,[12] which is generated by conserved vectors of the form $(F^\alpha, G^\alpha) = (\alpha u, \alpha_x u - \alpha u_x)$, where $\alpha = \alpha(t,x)$ is an arbitrary solution of the backward linear heat equation $\alpha_t + \alpha_{xx} = 0$. Using a fixed conservation law of such form, we can introduce the potential v^α, where

$$v^\alpha_x = \alpha u, \quad v^\alpha_t = \alpha u_x - \alpha_x u. \tag{30}$$

System (30) has one infinite series of conservation laws (case 4.1) with conserved vectors

$$(F^{\alpha\beta},G^{\alpha\beta})=\left(\left(\frac{\beta}{\alpha}\right)_x v^\alpha,-\alpha\left(\frac{\beta}{\alpha}\right)_x u-\left(\frac{\beta}{\alpha}\right)_t v^\alpha\right), \tag{31}$$

where $\beta=\beta(t,x)$ is an arbitrary solution of the backward linear heat equation $\beta_t+\beta_{xx}=0$. These conservation laws are simplest potential ones for the linear heat equation and allow us to introduce "second-level" potentials $w^{\alpha\beta}$. As a result, we obtain potential systems of the next level,

$$v^\alpha_x=\alpha u,\quad w^{\alpha\beta}_x=\left(\frac{\beta}{\alpha}\right)_x v^\alpha,\quad w^{\alpha\beta}_t=\alpha\left(\frac{\beta}{\alpha}\right)_x u+\left(\frac{\beta}{\alpha}\right)_t v^\alpha. \tag{32}$$

Consider the system

$$v^\alpha_x=\alpha u,\quad v^\alpha_t=\alpha u_x-\alpha_x u,\quad v^\beta_x=\beta u,\quad v^\beta_t=\beta u_x-\beta_x u \tag{33}$$

that is the union of two potential systems of form (30) corresponding to the local conservation laws with the conserved vectors (F^α,G^α) and (F^β,G^β). In a similar way to the previous cases we can state that the second-level potential conservation law with conserved vector (31) is trivial on the solution manifold of system (33) since

$$F^{\alpha\beta}=D_x\left(\frac{\beta}{\alpha}v^\alpha-v^\beta\right)\quad\text{and}\quad G^{\alpha\beta}=-D_t\left(\frac{\beta}{\alpha}v^\alpha-v^\beta\right).$$

Moreover, systems (32) and (33) are connected via the local substitution

$$w^{\alpha\beta}=\frac{\beta}{\alpha}v^\alpha-v^\beta.$$

It implies that really system (33) is generated by only three independent equations. We can choose, e.g., the equations

$$v^\alpha_x=\alpha u,\quad v^\beta_x=\beta u,\quad \frac{\beta}{\alpha}v^\alpha_t-v^\beta_t=\alpha\left(\frac{\beta}{\alpha}\right)_x u.$$

As a result of our analysis, we can formulate the following statement.

Theorem 7: *For any nonlinearized equation* (1) *and the linear heat equation the potential systems of the second level, which are constructed by means of using single conservation law of the simplest potential systems, are equivalent to first-level potential systems obtained with pairs of conservation laws.*

VIII. POTENTIAL CONSERVATION LAWS OF LINEAR HEAT EQUATION

With respect to $G^{\sim}$-equivalence the linear heat equation is the unique linear equation in class (1). Investigation of its general potential conservation laws plays the major role in classification of potential conservation laws for linearizable equations in class (1) and, therefore, for whole class (1). (The simplest potential conservation laws are studied in the preceding section.)

As proved in Theorem 4, the linear heat equation has the infinite series of local conservation laws. Fixing an arbitrary $p\in\mathbb{N}$ and choosing p linear independent solutions $\overline{\alpha}=(\alpha^1,\dots,\alpha^p)$ of the backward linear heat equation, we obtain p linear independent conservation laws with the conserved vectors $(F^s,G^s)=(\alpha^s u,\alpha^s_x u-\alpha^s u_x)$. (Hereafter $s=\overline{1,p}$.) In view of Theorem 5 the potentials $\overline{v}=(v^1,\dots,v^p)$ introduced with these conservation laws by the formulas

$$v^s_x=\alpha^s u,\quad v^s_t=\alpha^s u_x-\alpha^s_x u \tag{34}$$

are independent in the sense of Definition 7.

For the linear heat equation the complete set of first level potential conservation laws is indeed the union set of conservation laws of systems (34) corresponding to all possible values of p and p-tuples $\overline{\alpha}$. The following theorem is true.

Theorem 8: *Any local conservation law of system* (34) *is equivalent on the manifold of system* (34) *to a local conservation law of the linear heat equation.*

Corollary 4: For the linear heat equation potential conservation laws of any level are equivalent to local ones on the manifolds of the corresponding potential systems, and potentials of any level are locally expressed via local variables t, x, $u_{(r)}$ *(for some* r*) and potentials of the first lèvel only.*

We present the proof of Theorem 8 as the chain of simple and nice lemmas.

Lemma 4: Any local conservation law of system (34) *is equivalent to that with the conserved vector* $(Ku, K_x u - Ku_x)$ *where the function* $K=K(t,x,\overline{v})$ *is determined by the system*

$$K_t + K_{xx} = 0, \quad \alpha^s K_{xv^s} - \alpha^s_x K_{v^s} = 0. \tag{35}$$

Proof: Consider a local conservation law of system (34) in the most general form, where the conserved vector is a vector-function of t, x and derivatives of the functions u and v^s from the zero order up to some finite one. Taking into account system (34) and its differential consequences, we can exclude dependence of the conserved vector on all (nonzero order) derivatives of v^s and the derivatives of u containing differentiation with respect to t. Similarly to Lemma 2 we can prove that the reduced conserved vector (F,G) does not depend on (nonzero order) derivatives of u and, moreover, $F=F(t,x,\overline{v})$, $G=-\alpha^s F_{v^s}(t,x,\overline{v})u+G^0(t,x,\overline{v})$. The functions F and G^0 satisfy the system

$$\alpha^s \alpha^{s'} F_{v^s v^{s'}} = 0, \quad \alpha^s G^0_{v^s} = 2\alpha^s_x F_{v^s} + \alpha^s F_{xv^s}, \quad F_t + G^0_x = 0.$$

Let us pass on to the equivalent conserved vector $(\widetilde{F},\widetilde{G})$, where $\widetilde{F}=F+D_x H$, $\widetilde{G}=G-D_t H$, and $H=H(t,x,\overline{v})$ is a solution of the equations $H_x=-F$, $H_t=G$. (The variables v^s is assumed as parameters in the latter equations.) Then $\widetilde{F}=Ku$, $\widetilde{G}=K_x u-Ku_x$. The function $K=\alpha^s H_{v^s}$ depends on t, x, and $\overline{v}$ and satisfies system (35). ■

Lemma 5: Let the solutions $\alpha^s=\alpha^s(t,x)$ *and* $\beta^s=\beta^s(t,x)$ *of the (backward) linear heat equation satisfy the additional condition* $\alpha^s_x\beta^s-\alpha^s\beta^s_x=0$. *Then for any* $i,j\in\mathbb{N}$,

$$\alpha^s_i\beta^s_j - \alpha^s_j\beta^s_i = 0. \tag{36}$$

Hereafter the subscripts i *and* j denote the *ith and jth order derivatives with respect to* x.

Proof: We make the proof by means of mathematical induction with respect to the value $i+j$. Equation (36) is trivial for $i+j=0$, coincides with the additional condition for $i+j=1$ and is obtained from this condition by means of differentiation with respect to x if $i+j=2$. Let us suppose that the lemma's statement is true if $i+j=m-1$ and $i+j=m$ and prove it for $i+j=m+1$. Acting on Eq. (36) where $i+j=m-1$ with the operator $\partial_t+\partial_{xx}$ and taking into account the conditions $\alpha^s_t+\alpha^s_{xx}=0$ and $\beta^s_t+\beta^s_{xx}=0$, we obtain the equation $\alpha^s_{i+1}\beta^s_{j+1}-\alpha^s_{j+1}\beta^s_{i+1}=0$. Therefore, the statement is true for $i'+j'=m+1$, $1\leqslant i',j'\leqslant m$ $(i'=i+1, j'=j+1)$. It remains to perform the proof in the case $i'=m+1$, $j'=0$ (or equivalently $i'=0$, $j'=m+1$). For these values of i' and j' the statement is produced by subtracting the induced above equation $\alpha^s_m\beta^s_1-\alpha^s_1\beta^s_m=0$ from the results of differentiation of Eq. (36) where $i=m$, $j=0$ with respect to x. ■

Let $W(\varphi^1,\dots,\varphi^l)$ denotes the Wronskian of the functions $\varphi^1,\dots,\varphi^l$ with respect to the variable x, i.e., $W(\varphi^1,\dots,\varphi^l)=\det(\varphi^j_i)^l_{i,j=1}$.

Lemma 6: The solutions $\varphi^1=\varphi^1(t,x),\dots,\varphi^l=\varphi^l(t,x)$ *of a linear evolution equation* $L\varphi=0$ *are linear dependent iff* $W(\varphi^1,\dots,\varphi^l)=0$.

Proof: Since the equation $L\varphi=0$ is linear and evolution the operator L is the sum of ∂_t and linear differential operator with respect to x with the coefficients depending on t and x. If the functions $\varphi^1,\dots,\varphi^l$ are linear dependent then the equality $W(\varphi^1,\dots,\varphi^l)=0$ is obvious. Let us prove the inverse statement.

In the case $l=2$ the condition $W(\varphi^1,\varphi^2)=0$ implies $\varphi^2=C\varphi^1$, where C is a smooth function of t. Acting on the latter equality with the operator L, we obtain $C_t\varphi^1=0$, i.e., $C=\text{const}$ or $\varphi^1=0$. In any case the functions φ^1 and φ^2 are linear dependent.

Suppose $W(\varphi^1,\dots,\varphi^l)=0$. Without loss of generality we can assume $W(\varphi^1,\dots,\varphi^{l-1})\neq 0$. (Otherwise we consider a less value of l.) Then $\varphi^l=C^k\varphi^k$, where C^k are smooth functions of t and the superscript k runs from 1 to $l-1$. Action of the operator L on the latter equality results in the equation $C^k_t\varphi^k=0$ that implies, in view of the condition $W(\varphi^1,\dots,\varphi^{l-1})\neq 0$, $C^k=\text{const}$. It gives the Lemma's statement. ■

Lemma 7: If $\alpha^s_i\beta^s_j-\alpha^s_j\beta^s_i=0$ *for* $0\leqslant i<j\leqslant p$ *then* $W(\alpha^1,\dots,\alpha^p,\beta^{s'})=0$ *for any* s'.

Proof: Let $M^{s'}_{ij}$ denote the $(p-1)$th order minor of $W(\overline{\alpha},\beta^{s'})$, which is obtained by means of deletion of s'th and $(p+1)$th columns corresponding to the functions $\alpha^{s'}$ and $\beta^{s'}$ and ith and jth rows. Let us multiply the equation $\alpha^s_i\beta^s_j-\alpha^s_j\beta^s_i=0$ by $(-1)^{i+j+s'+p+1}M^{s'}_{ij}$ and convolve with respect to the indices i and j. In view of the Laplace theorem on determinant expansion we obtain $W(\overline{\alpha}|_{\alpha^s\rightsquigarrow\alpha^{s'}},\beta^s)=0$. Here the sign "$\rightsquigarrow$" means that the function α^s is substituted instead of the function $\alpha^{s'}$ and we have summation over the index s. The lemma's statement easily follows from the latter equation since for any fixed $s\neq s'$ we have $W(\overline{\alpha}|_{\alpha^s\rightsquigarrow\alpha^{s'}},\beta^s)=0$. ■

Lemma 8: The general solution of system (35) *can be presented in the form*

$$K=\alpha^sH_{v^s}+\beta^0, \tag{37}$$

where H *is an arbitrary smooth function of* $\overline{v}$, $\beta^0=\beta^0(t,x)$ *is an arbitrary solution of the backward linear heat equation.*

Proof: In view of Lemma 4 the functions α^s and $\beta^s=K_{v^s}$ satisfy the conditions of Lemma 5 and, therefore, the ones of Lemma 7, and the variables $\overline{v}$ are assumed as parameters. Since α^s are linear independent it implies $K_{v^\sigma}=C^{\sigma s}\alpha^s$, where $C^{\sigma s}$ are smooth functions of the variables $\overline{v}$ only. Hereafter the indices s, σ, and ς run from 1 to p. The expressions for the cross derivatives $K_{v^\sigma v^\varsigma}=C^{\sigma s}_{v^\varsigma}\alpha^s=C^{\varsigma s}_{v^\sigma}\alpha^s$ result in the equation $C^{\sigma s}_{v^\varsigma}=C^{\varsigma s}_{v^\sigma}$ which can be easily integrated, $C^{\sigma s}=P^s_{v^\sigma}$ for some smooth function P^s of the variables $\overline{v}$. Substituting the expressions for $C^{\sigma s}$ in the equations on K and integrating, we obtain $K=\alpha^sP^s+\beta^0$, where $\beta^0=\beta^0(t,x)$ is a solution of the backward heat equation. The latter equality and the equation $\alpha^sK_{xv^s}-\alpha^s_xK_{v^s}=0$ together imply the equation $(\alpha^\sigma_x\alpha^\varsigma-\alpha^\sigma\alpha^\varsigma_x)(P^\varsigma_{v^\sigma}-P^\sigma_{v^\varsigma})=0$. Analogously to Lemma 7 we can state for any $i,j\in\mathbb{N}$

$$(\alpha^\sigma_i\alpha^\varsigma_j-\alpha^\sigma_j\alpha^\varsigma_i)(P^\varsigma_{v^\sigma}-P^\sigma_{v^\varsigma})=0. \tag{38}$$

Let $M^{\sigma'\varsigma'}_{ij}$ denote the $(p-2)$th order minor of $W(\overline{\alpha})$, which is obtained by means of deletion of σ'th and ς'th columns corresponding to the functions $\alpha^{\sigma'}$ and $\alpha^{\varsigma'}$ and ith and jth rows. Let us multiply the Eq. (38) by $(-1)^{i+j+\sigma'+\varsigma'}M^{\sigma'\varsigma'}_{ij}$ and convolve with respect to the indices i and j. In view of the Laplace theorem on determinant expansion we obtain

$$W(\overline{\alpha}|_{\alpha^\sigma\rightsquigarrow\alpha^{\sigma'},\alpha^\varsigma\rightsquigarrow\alpha^{\varsigma'}})(P^\varsigma_{v^\sigma}-P^\sigma_{v^\varsigma})=0. \tag{39}$$

Here the sign "$\rightsquigarrow$" means that the functions α^σ and α^ς is substituted instead of the function $\alpha^{\sigma'}$ and α^ς correspondingly and we have summation over the indices σ and ς. For any fixed $\sigma\neq\sigma'$ and $\varsigma\neq\varsigma'$ we have $W(\overline{\alpha}|_{\alpha^\sigma\rightsquigarrow\alpha^{\sigma'},\alpha^\varsigma\rightsquigarrow\alpha^{\varsigma'}})=0$. Since $W(\overline{\alpha})\neq 0$ in view of linear independence of the functions α^s, Eq. (39) implies $P^{\varsigma'}_{v^{\sigma'}}-P^{\sigma'}_{v^{\varsigma'}}=0$, i.e., $P^s=H_{v^s}$ for some smooth function H of $\overline{v}$. ■

In view of Lemma 8 the conserved vector (Ku,K_xu-Ku_x) from Lemma 4 has the form $(\beta^0u+D_xH,\beta^0_xu-\beta^0u_x-D_tH)$.

The proof of Theorem 8 is completed.

IX. POTENTIAL CONSERVATION LAWS OF NONLINEAR DIFFUSION-CONVECTION EQUATIONS

More general potential conservation laws than simplest ones are admissible only if the investigated system has

(i) either more than one linear independent local conservation laws (and, therefore, we can introduce a number of different potentials for the first iteration step),

(ii) or nontrivial simplest potential conservation laws.

As shown in Sec. VII, it is possible in class (1) only for special values of the parameter functions A and B. In view of results of Sec. VII for the linearizable equations and Theorem 8, we can formulate the following statement.

Theorem 9: *For any linearizable equation from class* (1) *all potential conservation laws of the second level are equivalent on the manifold of the corresponding potential systems to potential conservation laws of the first level.*

To investigate completely the potential conservation laws of equations from class (1), it remains to study the subclasses with $B=0$ and $B=A$, equations from which have two independent local conservation laws, and the subclass $B=\int A+uA$ reduced to $B=A$ by means of potential equivalence transformations.

Theorem 10: *All potential conservation laws of any equation from class* (1) *with* $B=0$ *or* $B=A$ *are trivial on the manifold of the united potential system* (19), (20) *and united potential system* (23), (24) *constructed with pairs of independent local conservation laws.*

Proof: Consider the united system (19) and (20) [or (23) and (24)]. (Below we write down the differences of the second case with the first one in brackets.) Similarly to Lemma 3, we can assume without loss of generality that $F=F(t,x,v^1,v^2)$ and $G=G(t,x,u,v^1,v^2)$. Let us split the equation $D_tF+D_xG=0$ on the manifold determining by the united system. Integration of one from the obtained equations results in the following expression for the flux G: $G=-(QF)\int A+G^0$, where $G^0=G^0(t,x,v^1,v^2)$ and $Q=\partial_{v^1}+x\partial_{v^2}$ $(Q=\partial_{v^1}+e^x\partial_{v^2})$. The other equations form the system on the functions F and G^0,

$$Q^2F=0, \quad QG^0=0, \quad F_t+G^0_x=0, \quad (QF)_x+F_{v^2}=0 \quad [(QF)_x-F_{v^1}=0].$$

Therefore, $F=F^1v^1+F^0$, and F^1, F^0, and G^0 are functions of t, $y=x$ and $\omega=xv^1-v^2$ $(\omega=e^xv^1-v^2)$ for which $F^0_\omega=F^1_y$, $F^1_t=-G^0_\omega$, $F^0_t=-G^0_y$. The latter system implies existence of such function $H=H(t,y,\omega)$ that $F^1=H_\omega$ $(F^1=e^xH_\omega)$, $F^0=H_y$, $G^0=-H_t$. Then, $F=D_xH$, $G=-D_tH$, i.e., the conservation law is trivial. ■

As shown above, there exists the following chain of local transformations between potential systems: $1.3\leftrightarrow 1.2\leftrightarrow$ (23) and (24), i.e., system 1.3 is locally equivalent to system (23) and (24). In view of this fact and Theorem 10 we obtain the following statement.

Theorem 11: *On the manifold of the potential system 1.3 all potential conservation laws of any equation from class* (1) *with* $B=\int A+uA$ *are trivial.*

Summarizing the above results, we note that up to $G^{\sim}$-equivalence the hierarchy of conservation laws (including local ones) for diffusion-convection equations (1) has the following form:

(i) the "common" local conservation law (case 1) for arbitrary values of the parameter functions A and B;
(ii) two independent local conservation laws if $B=0$ (cases 1 and 2) or $B=A$ (cases 1 and 3);
(iii) one "common" local conservation law (case 1) and one simplest potential that (case 1.3) if $B=\int A+uA$;
(iv) the infinite series of local conservation laws (case 4) for the linear heat equation;
(v) one "common" local conservation law (case 1) and the infinite series of simplest potential conservation laws (case 1.6) for the Burgers equation;
(vi) two independent local conservation laws for the u^{-2}-diffusion equation (cases 1 and 2) and the equation $u_t=(u^{-2}u_x)_x+u^{-2}u_x$ (cases 1 and 3) as subcases of $B=0$ and $B=A$ and the infinite series of simplest potential conservation laws (cases 1.4 and 1.5) additionally.

Note 9: Above we did not consider in an explicit form action of transformations from Lie symmetry groups on conservation laws of corresponding equations or potential systems. For the majority of cases this action is quite trivial. For example, we use translations with respect to x to normalize the constant ε in case 3. In case 2 the same translations result in adding the "common" conservation law to the special one of this case.

A nonobvious connection between independent conservation laws can be established only for

$A=u^{-4/3}$, $B=0$ (case 1 and case 2) by means of the transformation $\tilde{t}=t$, $\tilde{x}=1-x^{-1}$, $\tilde{u}=x^3u$ from the Lie symmetry group of the corresponding equation. This fact was first discovered in Ref. 24 in the framework of the "operator" approach. It should be mentioned that the values $A=u^{-4/3}$, $B=0$ give rise to the equation which distinguishes from nonlinear diffusion-convection equations (1) by singular Lie symmetry properties.

The Lie symmetry group $\mathcal{G}_-$ of the linear heat equation contains infinite dimensional normal subgroup $\mathcal{G}_-^0$ formed by the linear superposition transformations $\tilde{u}=u+f(t,x)$, where $f=f(t,x)$ is an arbitrary solution of the same equation. Up to the equivalence relation, transformations from $\mathcal{G}_-^0$ act identically on the set of conservation laws of case 4. Action of the finite dimensional factor group $\mathcal{G}_-/\mathcal{G}_-^0$ on this set induces the analogous factor group $\mathcal{G}_+/\mathcal{G}_+^0$ on the set of solutions of the backward linear heat equation, which is varied over by the parameter-function α.

The hierarchy of conservation laws generates the complete set of locally inequivalent potential systems for the class under consideration:

(i) "common" potential system (18) (case 1);
(ii) additional simplest potential systems (20) (case 2) or (24) (case 3) if $B=0$ or $B=A$ correspondingly;
(iii) second level potential systems (21) (case 1.1) and (25) (case 1.2) (which are really equivalent to the united potential systems of the first level) if $B=0$ or $B=A$ correspondingly;
(iv) system (34) with arbitrary number of locally independent potentials for the linear heat equation.

Potential symmetries arising for equations (1) from cases 1 and 1.1 of Table I were studied by Sophocleous.[37] Complete investigation of the potential system (18) (case 1) with the symmetry point of view was carried out in Ref. 35.

X. CONCLUSION

The notions and methods proposed in the paper are simple and effective tools for investigation of both local and pure potential conservation laws. They can be applied to a wide range of physically interesting systems of differential equations. At the same time, there exist a number of unresolved problems, in particular, on determining the number of necessary iterations for construction of an exhaustive list of independent potential conservation laws or on connections of our framework with Wahlquist–Estabrook prolongation structures.[43] We hope to consider these problems in the near future.

The adduced results for diffusion-convection equations can be developed and generalized in a number of directions. So, studying different kinds of symmetries (Lie, nonclassical, generalized ones) of constructed potential systems, we may obtain the corresponding kinds of potential symmetries (usual potential, nonclassical potential, generalized potential ones). Let us note that investigation of generalized symmetries is natural for potential systems, since potentials introduced with equivalent conservation laws are related, in general, via transformations depending on derivatives of local dependent variables. Analogously, local equivalence transformations between potential systems constructed for different initial equations result in nonlocal (potential) equivalence transformations for the class under consideration. In such way it is possible to find new connections between well-studied diffusion-convection equations.[35] We believe that the same approach can be used for investigation of wider classes of differential equations, e.g., variable coefficient diffusion-convection equations. We also plan to study conservation laws of more general structure (e.g., ones with pseudopotentials).

The spectral action for Moyal planes

Victor Gayral[a),b)] and Bruno Iochum[a),c)]
Centre de Physique Théorique, CNRS-Luminy, Case 907, 13288 Marseille Cedex 9, France[d)]

(Received 30 June 2004; accepted 17 November 2004; published online 18 March 2005)

Extending a result of Vassilevich, we obtain the asymptotic expansion for the trace of a spatially regularized heat operator $L^{\Theta}(f)e^{-t\Delta^{\Theta}}$, where Δ^{Θ} is a generalized Laplacian defined with Moyal products and $L^{\Theta}(f)$ is Moyal left multiplication. The Moyal planes corresponding to any skewsymmetric matrix Θ being spectral triples, the spectral action introduced in noncommutative geometry by Chamseddine and Connes is computed. This result generalizes the Connes–Lott action previously computed by Gayral for symplectic Θ. © *2005 American Institute of Physics*. [DOI: 10.1063/1.1855401]

I. INTRODUCTION

Since few years, the interest in noncommutative field theory has been renewed in many works. The noncommutative space is quite often of Moyal type, involving either noncommutative tori or Moyal planes (see Refs. 19 and 33 for recent reviews).

Historically, Moyal[39] has tried to build quantum mechanics with a statistical point of view using a phase space approach. Actually, his idea was that the formalism of quantum theory allows to derive the phase space distributions $F(p,q)$ when a theory of functions of noncommuting observables is specified conversely. This type of consideration was initiated by Wigner[54] with a formula for $F(p,q)$ using Fourier transform and for canonical conjugate coordinates and momenta by Weyl[52] with group theoretical motivations. A noncommutative star product was previously explicitly given by Groenewold.[29] In fact, the use of quantification by deformation[1,42] has been intensively investigated since it yields a continuous path between classical and quantum mechanics. In the meantime, the Weyl–Wigner quantification process was also interesting for the pseudodifferential operators theory.[22] The Seiberg–Witten[44] map allows to go from ordinary to noncommutative gauge field theory and the replacement of the ordinary commutative product of functions by the Moyal noncommutative one is now ubiquitous in string theory where the effective low energy theory of D-branes with B-field background lives in a noncommutative space.

The mathematical background of these different developments for quantization within noncommutative geometry[8,9,28,48] where noncommutative tori[7,41] play an important role,[12] includes the construction of new spectral triples,[3,13,14,16,24] and more generally the theory of pseudodifferential operators,[18,45] the construction of star product,[26,34] integrable systems, etc. For reviews on these topics, see Refs. 9, 28, 35, 37, and 38.

It has been proposed for a long time[46,55] that the noncommutative space–time is a quantum effect of gravity and that this could provide some hints for the regularization of quantum field theory. Naturally, many types of action have been proposed and here we choose the spectral action introduced by Chamseddine and Connes[5,6] in a proper noncommutative geometry setting. Since a similar action was derived in Refs. 23 and 24 following a prescription by Connes and Lott,[15] it is

interesting to quote the differences. In Ref. 6, the idea is to recover the usual action of the standard model of particle physics from purely gravitational considerations; more precisely to define the bosonic action by $\mathrm{Tr}(\phi(\mathcal{D}^2/\Lambda^2))$ while the fermionic action is simply $\langle\psi,\mathcal{D}\psi\rangle$ where $\mathcal{D}$ is the Dirac operator, Λ is an energy scale cutoff and ϕ is a smooth positive function. So Chamseddine and Connes recovered the Einstein plus Yang–Mills and Weyl actions including of course the spin 1 bosons, but also the part induced by the Higgs fields of spin 0. The action functional computed in Refs. 23 and 24 is defined by $\mathrm{Tr}^+(F^2\mathcal{D}^{-d})$ where F is the field strength curvature of a vector potential and Tr^+ is a Dixmier trace which pins down the leading term of logarithmic divergence in the usual trace of F^2.

Here we choose for the manifold the Moyal plane $\mathbb{R}^{2m}$ with flat curvature, technically viewed as an algebra $(\mathcal{S}(\mathbb{R}^{2m}),\star_\theta)$ for the Moyal product $\star_\theta$ ($\mathcal{S}$ is the Schwartz space) and as Dirac operator, the usual one $-i(\partial_\mu+L^\Theta(\omega_\mu))\otimes\gamma^\mu$ but where the connection ω acts by Moyal left multiplication $L^\Theta(\omega)$ on the usual Hilbert space of L^2-sections of the trivial spinor bundle spinors $\mathcal{H}=L^2(\mathbb{R}^{2m})\otimes\mathbb{C}^{2^m}$. In Ref. 24, this algebra and one of its unitizations is proved to be a real spectral triple of spectral dimension $2m$. So this case completely fits the requirements and the computation of $\mathrm{Tr}(\phi(\mathcal{D}/\Lambda))$ is possible using a standard heat kernel technique. The not so surprisingly result is that one recovers the usual commutative action where all commutative products have been replaced by the Moyal ones.

Despite the fact that this computation is made here in Euclidean signature and with no real gravity, the main interest is that all the algebraic and analytical difficulties are overcome and that it is the first example of spectral action for a not almost commutative spectral triple. Since the Dirac operator has a noncompact resolvent, a spatial regularization by the multiplication of a function f in the algebra is introduced to get the tracability of $L^\Theta(f)e^{-t\Delta^\Theta}$ where Δ^Θ is the generalized Moyal Laplacian. Of course, the choice of a regularization is arbitrary and one could prefer for instance a soliton one,[36] when one wants to avoid, before the limit, the renormalization problems set in by UV/IR mixing.

After some reminders on the role of the Moyalology for spectral triples in Sec. II, we establish the main result, and then, give the important technical details on the heat kernel computation in Sec. III. Section IV is just an application to the case of Moyal planes which ends with a few remarks on the difficulties with nonflat cases.

II. MOYAL SPECTRAL TRIPLES AND SPECTRAL ACTION

A. Moyal analysis

In this section, the very basic tools on Moyal analysis are recalled and we refer to Ref. 24 for a review. The Moyal product comes from the phase space formulation of flat quantum mechanics, that is a deformation of the associative algebra structure of a suitable family of functions on $\mathbb{R}^{2m}$ with pointwise product in the direction of the flat Poisson bracket $\{.,.\}_P$. More precisely, if we denote by W the Weyl map which assigns Schwartz functions on $\mathbb{R}^{2m}$ say, to bounded operators on $L^2(\mathbb{R}^m)$, the Moyal product $\star_\theta$ is constructed in order to obtain a $*$-algebra homomorphism

$$W:\mathcal{S}(\mathbb{R}^{2m})\to\mathcal{L}(L^2(\mathbb{R}^m)),\quad W(f\star_\theta g)=W(f)W(g).$$

This leads us to

$$(f\star_\theta g)(x):=(\pi\theta)^{-2m}\int\int_{\mathbb{R}^{2m}\times\mathbb{R}^{2m}} f(y)g(z)e^{(2i/\theta)(x-y)\cdot S(x-z)}d^{2m}yd^{2m}z, \tag{1}$$

where

$$S := \begin{pmatrix} 0 & 1_m \\ -1_m & 0 \end{pmatrix}$$

comes from the canonical symplectic structure of $\mathbb{R}^{2m} = T^*\mathbb{R}^m$ and $\theta \in \mathbb{R}_+^*$ is the deformation parameter.

Actually, one can define Moyal products on $\mathcal{S}(\mathbb{R}^n)$, n even or odd, independently of any symplectic structure. In those cases, it is any real skewsymmetric matrix Θ which defines the deformation directions. Generic Moyal products are then defined by

$$(f \star_\Theta g)(x) := (2\pi)^{-n} \int_{\mathbb{R}^n \times \mathbb{R}^n} e^{i\xi(x-y)} f\left(x - \tfrac{1}{2}\Theta\xi\right) g(y) d^n y d^n \xi. \tag{2}$$

To fix notations and avoid to refer to the odd or even case, n will be an integer equal to the plane dimension and m will be the integer part of $n/2$.

This formula shows that the theory of pseudodifferential operators on $\mathbb{R}^n$ (Refs. 31 and 45) is suitable for the analysis of left and right Moyal multiplication operators $L^\Theta(f)$ and $R^\Theta(f)$ defined by $L^\Theta(f)\psi := f \star_\theta \psi$ and $\mathbb{R}^\Theta(f)\psi := \psi \star_\theta f$. In particular their symbols are

$$\sigma[L^\Theta(f)](\xi, x) = f\left(x - \tfrac{1}{2}\Theta\xi\right), \quad \sigma[R^\Theta(f)](\xi, x) = f\left(x + \tfrac{1}{2}\Theta\xi\right). \tag{3}$$

On coordinate functions x^μ, $\mu = 1, \ldots, n$, generic Moyal products formally define a generalized Heisenberg Lie algebra structure,

$$[x^\mu, x^\nu]_{\star_\Theta} = i\Theta^{\mu\nu} 1.$$

This equality can have a precise analytical meaning if we work with Moyal products on some tempered distribution spaces,[27,47] and is obvious from the asymptotic expansion of Moyal products,

$$f \star_\Theta g \sim \sum_{\alpha \in \mathbb{N}^n} \left(\frac{i}{2}\right)^{|\alpha|} \frac{1}{\alpha!} \frac{\partial f}{\partial x^\alpha} \frac{\partial g}{\partial (\Theta x)^\alpha}. \tag{4}$$

This expansion can be heuristically derived from (2) by a Taylor expansion of $\sigma[L^\Theta(f)](\xi, x)$ "near" x, for a more rigorous approach see Ref. 20. Moyal products satisfy a few useful algebraic equalities (see Ref. 24 for a review); in particular the Leibniz rule is satisfied, the integral is a faithful trace and the complex conjugation is an involution,

$$\partial^\mu (f \star_\Theta g) = \partial^\mu f \star_\Theta g + f \star_\Theta \partial^\mu g, \tag{5}$$

$$\int (f \star_\Theta g)(x) d^n x = \int f(x) g(x) d^n x, \tag{6}$$

$$(f \star_\Theta g)^* = g^* \star_\Theta f^*. \tag{7}$$

These properties allow to prove that $\mathcal{B}_\Theta := (\mathcal{S}(\mathbb{R}^n), \star_\theta)$ is an associative and involutive Fréchet algebra with a jointly continuous product.

For Θ symplectic, hence $n = 2m$, it is proved in Refs. 27 and 47 that $(L^2(\mathbb{R}^{2m}), \star_\theta)$ is an associative Banach algebra, and we have shown in Ref. 24 that $(\mathcal{D}_{L^2}(\mathbb{R}^{2m}), \star_\theta)$ is also an *-algebra with a jointly continuous product, $\mathcal{D}_{L^2}(\mathbb{R}^{2m})$ being the space of smooth functions, having all their derivatives in $L^2(\mathbb{R}^{2m})$ endowed with the Fréchet topology of L^2-convergence for all derivatives. For the nonunital spectral triple point of view (see below), one needs also to choose a unitization for these algebras. Reference 24 it is studied that unital *-algebra $(\mathcal{O}_0(\mathbb{R}^{2m}), \star_\theta)$, where $\mathcal{O}_0(\mathbb{R}^{2m})$ consists in smooth bounded functions with bounded derivatives, with the topology given by the family of seminorms $\{p_\alpha\}_{\alpha \in \mathbb{N}^{2N}}$, $p_\alpha(f) := \|\partial^\alpha f\|_\infty$.

For generic Moyal products, $(\mathcal{S}(\mathbb{R}^n),\star_\theta)$, $(\mathcal{D}_{L^2}(\mathbb{R}^n),\star_\theta)$, $(\mathcal{O}_0(\mathbb{R}^n),\star_\theta)$ are also Fréchet algebras. Actually this statement comes from the algebra structure of $\mathcal{S}(\mathbb{R}^n)$, $\mathcal{D}_{L^2}(\mathbb{R}^n)$, $\mathcal{O}_0(\mathbb{R}^n)$ with pointwise product as well as with Moyal one, and because any Moyal product splits into a symplectic Moyal product and a pointwise one denoted by a point (Ref. 42, Proposition 2.7 and Corollary 2.8): Namely, $f\star_\theta g(x)=f(x).g(x)$ when $\Theta=0$, so if the matrix Θ is decomposed as the direct sum of a symplectic one θ of dimension $2m$ and the zero matrix of dimension $n-2m$, then $(\mathcal{S}(\mathbb{R}^n),\star_\theta)\cong(\mathcal{S}(\mathbb{R}^{2m}),\star_\theta)\hat{\otimes}(\mathcal{S}(\mathbb{R}^{n-2m}),.)$. Remark in particular that $\mathcal{S}(\mathbb{R}^n)$ and $\mathcal{O}_0(\mathbb{R}^n)$ are algebras for pointwise product while for $\mathcal{D}_{L^2}(\mathbb{R}^n)$ this is a consequence of the inclusion $\mathcal{D}_{L^2}(\mathbb{R}^n)\subset\mathcal{O}_0(\mathbb{R}^n)$.[43]

A *spectral triple* $(\mathcal{A},\tilde{\mathcal{A}},\mathcal{H},\mathcal{D},J,\chi)$ (a noncommutative generalization of a Riemannian spin manifold) consists of an algebra $\mathcal{A}$, a suitable one of its unitizations $\tilde{\mathcal{A}}\supset\mathcal{A}$ (for the analog of the noncompact case) both faithfully represented by bounded operators on a separable Hilbert space $\mathcal{H}$ (the representation is denoted by π), together with an unbounded self-adjoint operator $\mathcal{D}$ such that $\pi(a)(\mathcal{D}+\lambda)^{-1}$ is a compact operator for all $a\in\mathcal{A}$ and λ in the resolvent of $\mathcal{D}$ and such that the commutators $[\mathcal{D},\pi(a)]$ for all $a\in\tilde{\mathcal{A}}$ extend to bounded operators. J and χ are, respectively, antiunitary and unitary operators with commutation relations depending on the dimension of the triple. These data must moreover fulfill a set of axioms (see Refs. 10 and 24).

It is shown in Ref. 24 that symplectic Moyal planes yield nonunital spectral triples if we choose $\mathcal{A}=(\mathcal{D}_{L^2}(\mathbb{R}^{2m}),\star_\theta)$, $\tilde{\mathcal{A}}=(\mathcal{O}_0(\mathbb{R}^{2m}),\star_\theta)$, represented by the diagonal left regular representation $\pi^\theta(f):=L^\theta(f)\otimes 1_{2^m}$ on the Hilbert space of L^2-sections of the trivial spinor bundle $\mathcal{H}=L^2(\mathbb{R}^{2m})\otimes\mathbb{C}^{2^N}$, and for $\mathcal{D}$, the flat Dirac operator $\not{\partial}:=-i\partial_\mu\otimes\gamma^\mu$ where γ^μ are the Clifford matrices associated to $(\mathbb{R}^{2m},\eta)$ with η the standard Euclidean metric of $\mathbb{R}^{2m}$.

B. Main result

The *action functional* or Connes–Lott action[15] associated with this spectral triple gives the noncommutative Yang–Mills action for symplectic Moyal products,

$$\mathrm{YM}(\alpha)=c\int F^{\mu\nu}\star_\theta F_{\mu\nu}d^{2m}x, \tag{8}$$

where α is a universal represented connection,

$$\alpha\in\tilde{\pi}^\theta(\{a_0\delta a_1:a_0,a_1\in\mathcal{B}_\theta\})=\{\pi^\theta(a_0)[\not{\partial},\pi^\theta(a_1)]:a_0,a_1\in\mathcal{B}_\theta\},$$

and F is its curvature, $F^{\mu\nu}=\partial^\mu A^\nu-\partial^\nu A^\mu+[A^\mu,A^\nu]_{\star_\theta}$ and A^μ being defined by $\alpha=L^\theta(A_\mu)\otimes\gamma^\mu$. This result comes from the Junk computation[23] and the following result.[24]

Theorem 2.1: *For $f\in\mathcal{S}(\mathbb{R}^{2m})$, the compact operator $\pi^\theta(f)(\not{D}^2+\varepsilon^2)^{-m}$ lies in $\mathcal{L}^{(1,\infty)}(\mathcal{H})$ and any of its Dixmier traces Tr_ω is independent of the positive number ε. More precisely we have,*

$$\mathrm{Tr}_\omega(\pi^\theta(f)(\not{D}^2+\varepsilon^2)^{-m})=\frac{2^m\Omega_{2m}}{2m(2\pi)^{2m}}\int f(x)d^{2m}x, \tag{9}$$

where $\mathcal{L}^{(1,\infty)}(\mathcal{H})$ is the ideal of compact operators whose kth singular values satisfy $\mu_k(T)=O(k^{-1})$ and Ω_{2m} is the hyper-area of the unit sphere in $\mathbb{R}^{2m}$.

For generic Moyal products, $[(\mathcal{D}_{L^2}(\mathbb{R}^n),\star_\theta),(\mathcal{O}_0(\mathbb{R}^n),\star_\theta),L^2(\mathbb{R}^n)\otimes\mathbb{C}^{2^m},\not{\partial}]$ yields also a nonunital spectral triple, but the Connes–Lott action computation is not obvious because the computation of (8) was basis dependent.

Let Δ^Θ be a *noncommutative generalized Laplacian* associated with Moyal products,

$$\Delta^\Theta:=-(\eta^{\mu\nu}(\partial_\mu+L^\Theta(\omega_\mu))(\partial_\nu+L^\Theta(\omega_\nu))+L^\Theta(E))\otimes 1_{2^m},$$

$$\Delta^{\Theta} =: \Delta_r^{\Theta} \otimes 1_{2^m} \tag{10}$$

acting on the Hilbert space $\mathcal{H}=L^2(\mathbb{R}^n)\otimes\mathbb{C}^{2^m}:=\mathcal{H}_r\otimes\mathbb{C}^{2^m}$, where $\omega_\mu^*=-\omega_\mu$ and E are in $\mathcal{O}_0(\mathbb{R}^n)$. From now on, let $\mathcal{B}_\Theta:=(\mathcal{S}(\mathbb{R}^n),\star_\theta)$ acting on $\mathcal{H}$ by the diagonal left regular representation $\pi^\Theta(.):=L^\Theta(.)\otimes 1_{2^m}$.

For $f\in\mathcal{B}_\Theta$, $L^\Theta(f)e^{-t\Delta^\Theta}$ will be called *spatially regularized heat operator* associated with the generalized Laplacian Δ^Θ.

The following is the main result.

Theorem 2.2: *Let* Δ^θ *be as in* (10) *and* $f\in\mathcal{B}_\Theta$. *Then* $\mathrm{Tr}(\pi^\Theta(f)e^{-t\Delta^\Theta})$ *has an asymptotic expansion*

$$\mathrm{Tr}(\pi^\Theta(f)e^{-t\Delta^\Theta}) \underset{t\to 0}{\sim} 2^m\left(\frac{1}{4\pi t}\right)^{n/2}\sum_{l\in\mathbb{N}} t^l\int_{\mathbb{R}^n} f(x)\tilde{a}_{2l}(x)d^nx, \tag{11}$$

where

$$\tilde{a}_0(x)=1,$$

$$\tilde{a}_2(x)=E(x),$$

$$\tilde{a}_4(x)=\tfrac{1}{2}E\star_\Theta E(x)+\tfrac{1}{6}\eta^{\mu\nu}E_{;\mu\nu}(x)+\tfrac{1}{12}\Omega^{\mu\nu}\star_\Theta\Omega_{\mu\nu}(x),$$

$$\begin{aligned}\tilde{a}_6(x)=&\tfrac{1}{6}E\star_\Theta E\star_\Theta E(x)+\tfrac{1}{12}\eta^{\mu\nu}E_{;\mu}\star_\Theta E_{;\nu}(x)+\tfrac{1}{6}\eta^{\mu\nu}E\star_\Theta E_{;\mu\nu}(x)+\tfrac{1}{60}\eta^{\mu\nu}\eta^{\rho\sigma}E_{;\mu\nu\rho\sigma}(x)\\&+\tfrac{1}{12}E\star_\Theta\Omega^{\mu\nu}\star_\Theta\Omega_{\mu\nu}(x)+\tfrac{1}{45}\eta^{\rho\sigma}\Omega^{\mu\nu}_{;\rho}\star_\Theta\Omega_{\mu\nu;\sigma}(x)+\tfrac{1}{180}\eta^{\rho\sigma}\Omega^{\mu\nu}_{;\nu}\star_\Theta\Omega_{\mu\rho;\sigma}(x)\\&+\tfrac{1}{30}\eta^{\rho\sigma}\Omega^{\mu\nu}\star_\Theta\Omega_{\mu\nu;\rho\sigma}-\tfrac{1}{30}\Omega^{\mu\nu}\star_\Theta\Omega_{\nu\rho}\star_\Theta\Omega^\rho_\mu(x),\end{aligned}$$

where $g_{;\mu}:=\partial_\mu g+[\omega_\mu,g]_{\star_\theta}$ *and* $\Omega_{\mu\nu}:=\partial_\mu\omega_\nu-\partial_\nu\omega_\mu+[\omega_\mu,\omega_\nu]_{\star_\theta}$ *is the curvature of the connection* ω.

III. HEAT KERNEL EXPANSION FOR MOYAL GENERALIZED LAPLACIANS

We will first discuss the heat kernel expansion for Laplace type operators associated with Moyal products, for NC planes as well as for NC tori. This section generalizes Vassilevich's result[50] in two directions: first the Moyal products are defined by their integral form as opposed to differential or formal Moyal products (4) and second they are taken over the whole plane $\mathbb{R}^n$ and not only on NC tori. This noncompact situation generates some analytical difficulties.

We use the standard one-parameter semigroup theory of e^{-tA} where A is a positive (unbounded) operator and $t\in\mathbb{R}^+$. Let $\mathcal{H}$ be a separable Hilbert space. We denote by $\mathcal{B}(\mathcal{H})$ the set of bounded operators on $\mathcal{H}$, by $\mathcal{K}(\mathcal{H})$ the compact one's and by $\mathcal{L}^p(\mathcal{H})$ the pth Schatten class.

If we assume that A is a non-negative self-adjoint operator on $\mathcal{H}$, then e^{-zA} is holomorphic for $\Re(z)>0$ and $\|e^{-zA}\|\leqslant 1$ (Ref. 32, Example 1.25, p. 493).[56] With $\mathcal{R}_A(z):=(z-A)^{-1}$ denoting the resolvent of A, one can use the holomorphic functional calculus,

$$e^{-tA}=\frac{1}{2i\pi}\int_\Gamma e^{-tz}\mathcal{R}_A(z)\mathrm{d}z, \tag{12}$$

where Γ is a positively oriented (possibly infinite) closed curve containing the spectrum of A.

Lemma 3.1: Let B be a bounded operator and A be a non-negative densely defined generator of a holomorphic semigroup such that $B\mathcal{R}_A(z)^l\in\mathcal{L}^1(\mathcal{H})$ *for some* $z\notin\mathrm{Spect}(A)$. *Then for* $t>0$, Be^{-tA} *is trace-class*.

Proof: For some $z_0\notin\mathrm{Spect}(A)$, the semigroup property together with the first resolvent equation and (12) gives

$$Be^{-tA} = B(e^{-(t/l)A})^l = B\mathcal{R}_A(z_0)^l\left(\frac{1}{2i\pi}\int_\Gamma e^{-(t/l)z}(1+(z-z_0)\mathbb{R}_A(z))\mathrm{d}z\right)^l.$$

This concludes the proof because $\|\mathcal{R}_A(z)\| \leqslant M/|z|$ for all z with $\Re(z)>0$, thus

$$\int_\Gamma e^{-(t/l)\Re(z)}(1+|z-z_0|\|\mathcal{R}_A(z)\|)|\mathrm{d}z| < \infty.$$

■

Since we are interested in the small t-asymptotic expansion of $\mathrm{Tr}(Be^{-tA})$, recall the following definition.

Let $\{f_n\}_n$ be a sequence of functions such that $f_n(t)\neq 0$ for $t\neq 0$ and $f_{n+1}(t)=o(f_n(t))$ as $t\to 0$. A function f has the *asymptotic expansion* $f(t)\sim_{t\to 0}\Sigma_{n=0}^{\infty}a_n f_n(t)$, when for each $k\in\mathbb{N}$, $f(t)=\Sigma_{n=0}^{k}a_n f_n(t)+O(f_{k+1}(t))$ as $t\to 0$.

A. Heat kernel expansion for Moyal planes

We will first show that $L^\Theta(f)e^{-t\Delta_r^\Theta}$ is trace-class for $t\in\mathbb{R}_+^*$, then we will show that its trace has a small t-asymptotic expansion:

$$\mathrm{Tr}(L^\Theta(f)e^{-t\Delta_r^\Theta})\sim_{t\to 0}\left(\frac{1}{4\pi t}\right)^{n/2}\sum_{l\in\mathbb{N}}t^l\int_{\mathbb{R}^n}f(x)\tilde{a}_{2l}(x)d^nx,$$

where the local invariants $\tilde{a}_l$ are built from the universal (represented) connection ω_μ, the (non-local) endomorphism E and their covariant derivative (in the adjoint representation) $\partial_\mu+L^\Theta(\omega_\mu)-R^\Theta(\omega_\mu)$.

We will prove that $L^\Theta(f)e^{-t\Delta_r^\Theta}$ is trace-class by two approaches. The first uses semigroup theory results while the second will be based on pseudodifferential operator (ΨDO) techniques, which is more in the spirit of Ref. 24.

Theorem 3.2: *Let $f\in\mathcal{S}(\mathbb{R}^n)$, ω_μ, $E\in\mathcal{O}_0(\mathbb{R}^n)$ with $\omega_\mu^*=-\omega_\mu$ and $E=-g^*\star_\theta g$ for some $g\in\mathcal{O}_0(\mathbb{R}^n)$. Then, for all $t>0$ the spatially regularized heat operator associated with Δ^Θ defined in* (10) *is trace-class.*

First proof of Theorem 3.2: Because $(L^\Theta(g))^*=L^\Theta(g^*)$, $\Im(g)=0$ implies $L^\Theta(g)$ is self-adjoint, so Δ^Θ is positive. Thanks to Lemma 3.1, it is enough to prove that $L^\Theta(f)R_{\Delta_r^\Theta}(z)^l$ is trace-class for $l>n/2$.

Let us anticipate further notations to see that Δ^Θ is a squared covariant Dirac operator:

$$\Delta^\Theta = \not{\partial}_\omega^2 - B,$$

$$\not{\partial}_\omega := -i(\partial_\mu + L^\Theta(\omega_\mu))\otimes\gamma^\mu,$$

and $B := L^\Theta(E)\otimes 1_{2^m} - L^\Theta(\partial_\mu(\omega_\nu)-\omega_\mu\star_\theta\omega_\nu)\otimes(\eta^{\mu\nu}1_{2^m}-\gamma^\nu\gamma^\mu)$ is bounded.

Assume first that $l=1$, $z=-1$, $B=0$. Using the notations $\pi^\Theta(\omega):=L^\Theta(\omega_\mu)\otimes\gamma^\mu$, $\pi^\Theta(\not{\partial}(f)) := L^\Theta(\partial_\mu f)\otimes\gamma^\mu$ and the fact that all $f\in\mathcal{S}(\mathbb{R}^n)$ factorizes as $f=f_1\star_\theta f_2$, for some $f_1, f_2\in\mathcal{S}(\mathbb{R}^n)$ (Ref. 24, Proposition 2.7), one gets

$$\begin{aligned}\pi^\Theta(f)\mathcal{R}_{\Delta^\Theta}(-1) &= -\pi^\Theta(f)\frac{1}{\not{\partial}-i}\left(1-\pi^\Theta(\omega)\frac{1}{\not{\partial}_\omega-i}\right)\frac{1}{\not{\partial}_\omega+i}\\ &= -\pi^\Theta(f_1)\frac{1}{\not{\partial}-i}\pi^\Theta(f_2)\left(1-\pi^\Theta(\omega)\frac{1}{\not{\partial}_\omega-i}\right)\frac{1}{\not{\partial}_\omega+i}\\ &\quad -\pi^\Theta(f_1)\frac{1}{\not{\partial}-i}\pi^\Theta(\not{\partial}(f_2))\frac{1}{\not{\partial}-i}\left(1-\pi^\Theta(\omega)\frac{1}{\not{\partial}_\omega-i}\right)\frac{1}{\not{\partial}_\omega+i}\end{aligned}$$

$$= -\pi^{\Theta}(f_1)\frac{1}{\not\partial - i}\pi^{\Theta}(f_2)\frac{1}{\not\partial + i}\left(1 - \pi^{\Theta}(\omega)\frac{1}{\not\partial_{\omega} + i}\right)$$
$$+ \pi^{\Theta}(f_1)\frac{1}{\not\partial - i}\pi^{\Theta}\ (f_2)\star_{\Theta}\omega)\frac{1}{\not\partial - i}\left(1 - \pi^{\Theta}(\omega)\frac{1}{\not\partial_{\omega} - i}\right)\frac{1}{\not\partial_{\omega} + i}$$
$$- \pi^{\Theta}(f_1)\frac{1}{\not\partial - i}\pi^{\Theta}(\not\partial(f_2)\star_{\Theta}\omega)\frac{1}{\not\partial - i}\left(1 - \pi^{\Theta}(\omega)\frac{1}{\not\partial_{\omega} - i}\right)\frac{1}{\not\partial_{\omega} + i}.$$

By (Ref. 24, Lemmata 4.5 and 4.14), $\pi^{\Theta}(g)\mathcal{R}_{\not\partial}(i)\pi^{\Theta}(h)\mathcal{R}_{\not\partial}(i) \in \mathcal{L}^p(\mathcal{H})$ whenever $g, h \in \mathcal{S}(\mathbb{R}^n)$ and $p > n/2$. The boundness of $\pi^{\Theta}(\omega)$ and $\mathcal{R}_{\not\partial_{\omega}}(z)$ then yields $\pi^{\Theta}(f)\mathcal{R}_{\Delta^{\Theta}}(-1) \in \mathcal{L}^p(\mathcal{H})$ for the same p. For $l \geqslant 1$, repeat this algorithm using $(A+C)^{-1} = A^{-1}(1 - CA^{-1}(\cdots(1 - C(A+C)^{-1})\cdots))$ up to order l.

The case with nonzero B is obtained using the same trick,

$$\pi^{\Theta}(f)\mathcal{R}_{\Delta^{\Theta}}(-1) = \pi^{\Theta}(f)\mathcal{R}_{\not\partial^2_{\omega}}(-1)(1 - B\mathcal{R}_{\Delta^{\Theta}}(-1)).$$

The first resolvent equation implies the same result for any z instead of -1 in the resolvent set of $\mathrm{Spect}(\Delta^{\Theta})$. ■

The second proof, which is based on a functional calculus for ΨDO,[18] needs the following definition of ΨDO classes relevant for Moyal analysis (Shubin[45] or GLS[30] symbol classes).

Definition 3.3: Let $S^{\rho,\lambda}$ be the Shubin or GLS symbol class

$$S^{\rho,\lambda} := \{\sigma \in \mathcal{C}^{\infty}(\mathbb{R}^{2n}) : \forall\ \alpha, \beta \in \mathbb{N}^n,\ \exists\ C_{\alpha\beta} \in \mathbb{R}^+ | \partial_x^{\alpha}\partial_{\xi}^{\beta}\sigma(\xi, x)|,$$

$$\leqslant C_{\alpha,\beta}(1 + |x|^2)^{(\rho - |\alpha|)/2}(1 + |\xi|^2)^{(\lambda - |\beta|)/2}$$

and let $\Psi^{\rho,\lambda} := \{A \in \Psi\mathrm{DO} : \sigma[A] \in S^{\rho,\lambda}\}$ be the associated ΨDO class.

Actually, $S^{\rho,\lambda}$ fits into the general Hörmander symbol classes (see Ref. 31, Chap. XVIII) $S(m, g)$ with order function $m(\xi, x) = (1 + |x|^2)^{\rho/2}(1 + |\xi|^2)^{\lambda/2}$ and slowly varying metric $g_{\xi,x} = (1 + |\xi|^2)^{-1}|\mathrm{d}\xi|^2 + (1 + |x|^2)^{-1}|\mathrm{d}x|^2$.

Second proof of Theorem 3.2: First, Eq. (3) and the product formula for ΨDOs allows us to compute the symbol of Δ_r^{θ},

$$\sigma[\Delta_r^{\theta}](\xi, x) = \eta^{\mu\nu}\xi_{\mu}\xi_{\nu} + 2i\omega_{\mu}\left(x - \tfrac{1}{2}\Theta\xi\right)\xi_{\nu} - \partial_{\mu}\omega_{\nu}\left(x - \tfrac{1}{2}\Theta\xi\right) - \omega_{\nu}\star_{\Theta}\omega_{\nu}\left(x - \tfrac{1}{2}\Theta\xi\right) - E\left(x - \tfrac{1}{2}\Theta\xi\right),$$

and because $\omega_{\mu}, E \in \mathcal{O}_0(\mathbb{R}^n)$, Δ_r^{θ} lies in $\Psi^{0,2}$.

Let $\{f_N\}_{N\in\mathbb{N}}$ be the family of smooth compactly supported functions defined by $f_N(x) := \chi_N(x)e^{-x}$, where $0 \leqslant \chi_N \leqslant 1$, $\chi_N \in \mathcal{C}_c^{\infty}(\mathbb{R})$ with $\chi_N(x) = 0$ for $x \in]-\infty, -\epsilon] \cup [N, +\infty[$ for a fixed $\epsilon > 0$ and $\chi_N(x) = 1$ for $x \in [0, N - \epsilon]$. First, Ref. 18, Theorem 8.7 yields $f_N(t\Delta_r^{\theta}) \in \Psi^{0,-\infty}$, and basic estimates (see Ref. 24, Sec. 2.4 for details) gives $L^{\Theta}(f) \in \Psi^{-\infty,0}$ for all $f \in \mathcal{S}(\mathbb{R}^n)$. Then, by Ref. 31 Lemma 18.4.3 one obtains $L^{\Theta}(f)f_N(t\Delta_r^{\Theta}) \in \Psi^{-\infty,-\infty}$ and its symbol is in $\mathcal{S}(\mathbb{R}^{2n})$. Therefore,

$$C := \sum_{|\alpha|+|\beta|\leqslant 2n+1} \|\partial_x^{\alpha}\partial_{\xi}^{\beta}\sigma[L^{\Theta}(f)f_N(t\Delta_r^{\Theta})]\|_1$$

$$\leqslant \sum_{|\alpha|+|\beta|\leqslant 2n+1} C_{\alpha,\beta}\int (1 + |x|^2)^{(-l-|\alpha|)/2}(1 + |\xi|^2)^{(-k-|\beta|)/2} d^n x d^n \xi,$$

for some $C_{\alpha,\beta} < \infty$ and all $l, k \in \mathbb{N}$, hence $C < \infty$. Finally, Ref. 18, Theorem 9.4 shows $L^{\Theta}(f)f_N(t\Delta_r^{\Theta})$ is trace-class for all $N \in \mathbb{N}$. Looking at the estimates in the proof of Ref. 18, Theorem 8.7, one can find constants $C_{\alpha,\beta}$ independent of N (because e^{-x} is rapidly decreasing when $x \to +\infty$, the right support of f_N plays no role), therefore one obtains that $L^{\Theta}(f)f_N(t\Delta_r^{\Theta})$ is trace-class uniformly in N.

To finish the proof, it remains to show that s-lim $L^{\Theta}(f)f_N(t\Delta_r^{\Theta}) = L^{\Theta}(f)e^{-t\Delta_r^{\Theta}}$, because Ref. 17, Proposition 2 will ensure that $L^{\Theta}(f)e^{-t\Delta_r^{\Theta}}$ is trace-class for all $t > 0$.

Let $\phi \in \mathcal{H}$ and E_λ be the spectral family of Δ_r^Θ, then

$$\|(\chi_N(\Delta_r^\Theta)-1)\phi\|_2^2 = \langle\phi|(\chi_N(\Delta_r^\Theta)-1)^2\phi\rangle$$
$$= \int_{\mathrm{Spect}(\Delta_r^\Theta)} (\chi_N(\lambda)-1)^2 d\langle\phi|E_\lambda\phi\rangle \leqslant \int_{\mathrm{Spect}(\Delta_r^\theta)} d\langle\phi|E_\lambda\phi\rangle = \langle\phi|\phi\rangle.$$

Hence by dominated convergence and with $\phi = e^{-t\Delta_r^\Theta}\psi$,

$$\lim_{N\to\infty}\|(\chi_N(\Delta_r^\Theta)-1)e^{-t\Delta_r^\Theta}\psi\|_2^2 = \lim_{N\to\infty}\int_{\mathrm{Spect}(\Delta_r^\Theta)} (\chi_N(\lambda)-1)^2 d\langle e^{-t\Delta_r^\Theta}\psi, E_\lambda e^{-t\Delta_r^\Theta}\psi\rangle$$
$$= \int_{\mathrm{Spect}(\Delta_r^\theta)} \lim_{N\to\infty}(\chi_N(\lambda)-1)^2 d\langle e^{-t\Delta_r^\Theta}\psi, E_\lambda e^{-t\Delta_r^\Theta}\psi\rangle = 0,$$

where the last equality comes from $\mathrm{Spect}(\Delta_r^\Theta)\subset\mathbb{R}^+$. ∎

We now come to the computation of the exponential of Δ^Θ following a Vassilevich's idea.[50]

Proof of Theorem 2.2: Let

$$X := 2L^\Theta(\omega_\mu)\partial^\mu + L^\Theta(\partial_\mu\omega^\mu) + L^\Theta(\omega_\mu \star_\Theta \omega^\mu) + L^\Theta(E)$$

$$Y := -\partial_\mu\partial^\mu,$$

so $\Delta_r^\Theta = Y - X$ and the Baker–Campbell–Hausdorff (BCH) formula

$$e^T e^S = e^{T+S+1/2[T,S]+1/12[T,[T,S]]+1/12[S,[S,T]]-1/48[T,[S,[T,S]]]+\cdots},$$

allows to write

$$e^{-t\Delta_r^\Theta} = e^{tX+1/2t^2[X,Y]+1/12t^3[X,[X,Y]]-1/6t^3[Y,[X,Y]]-1/48t^4[X,[Y,[X,Y]]]+1/48t^4[Y,[Y,[X,Y]]]+\cdots}e^{-tY}.$$

In order to obtain a power expansion when t goes to zero, the strategy is to expand the first exponential, to compute the commutators, to reorganize the sequence and finally to write down the explicit symbol of those ΨDO's. The trace will be simply taken by integrating them with respect to $(\xi,x)\in\mathbb{R}^{2n}$. Actually, the reorganization in homogeneous terms in powers of t is slightly more elaborate than a simple exponential expansion. All the operators coming from this expansion are of the type $L^\Theta(g)\partial^\alpha$, $\alpha\in\mathbb{N}^n$, for some $g\in\mathcal{B}_\Theta$. Some terms will give no contributions to the trace since $\int\xi_1^{\alpha_1}\cdots\xi_n^{\alpha_n}e^{-t|\xi|^2}d^n\xi = \Pi_i^n\frac{1}{2}(1+(-1)^{\alpha_i})\Gamma[(n+1)/2]t^{-(\alpha_i+1)/2}$ is zero when at least one of the α_i is odd, and when they are all even, $|\alpha| = \Sigma_i^n\alpha_i = 2l$ is even and we get

$$\int_{\mathbb{R}^n}\xi_{\mu_1}\cdots\xi_{\mu_{2l}}e^{-t|\xi|^2}d^n\xi = \left(\frac{\pi}{t}\right)^{n/2}(2t)^{-l}\sum_{\sigma\in S_{2l}}\frac{1}{2^l l!}\delta_{\sigma(\mu_1)\sigma(\mu_2)}\cdots\delta_{\sigma(\mu_{2l-1})\sigma(\mu_{2l})},$$

where σ runs over the permutation group S_{2l} of $2l$ elements. So, in the reorganization of the power series, we must keep in mind that $t^l L^\Theta(g)\partial^\alpha$ is effectively a term of order $t^{l-|\alpha|/2}$ [independently of the $(\pi/t)^{n/2}$ term]. Moreover, to obtain the asymptotic expansion up to order l say, we must use the BCH formula up to order $2l-1$. The order of the BCH formula is defined as the number of commutators in the expansion. The term with higher degree derivatives coming from the BCH formula at order l is

$$[t\partial^2,[t\partial^2,\ldots,[t\partial^2,tL^\Theta(g)\partial]\cdots]] \propto t^{l+1}L^\Theta(h)\partial^{l+1},$$

for some $h\in\mathcal{B}_\Theta$, which yields a term of order $t^{(l+1)/2}$.

Let us show how it works up to order one. We must use the BCH formula up to order one also, $e^{-t\Delta_r^\Theta} = e^{tX-tY} = e^{tX+\frac{1}{2}[tX,tY]+\cdots}e^{-tY}$, and

$$
\begin{aligned}
[tX,tY] &= t^2[\partial_\nu\partial^\nu, 2L^\Theta(\omega_\mu)\partial^\mu + L^\Theta(\partial_\mu\omega^\mu) + L^\Theta(\omega_\mu \star_\Theta \omega^\mu) + L^\Theta(E)] \\
&= t^2(2L^\Theta(\partial_\nu\partial^\nu\omega_\mu)\partial^\mu + 4L^\Theta(\partial_\nu\omega_\mu)\partial^\mu\partial^\nu + L^\Theta(\partial_\nu\partial^\nu\partial_\mu\omega^\mu) + 2L^\Theta(\partial_\nu\partial_\mu\omega^\mu)\partial^\nu \\
&\quad + L^\Theta(\partial_\nu\partial^\nu(\omega_\mu\star_\Theta\omega^\mu)) + 2L^\Theta(\partial_\nu(\omega_\mu\star_\Theta\omega^\mu))\partial^\nu + L^\Theta(\partial_\nu\partial^\nu E) + 2L^\Theta(\partial_\nu E)\partial^\nu) \\
&= 4t^2L^\Theta(\partial_\nu\omega_\mu)\partial^\mu\partial^\nu + O(t^2),
\end{aligned}
$$

hence

$$
\begin{aligned}
L^\Theta(f)e^{-t\Delta_r^\Theta} &= L^\Theta(f)e^{t(2L^\Theta(\omega_\mu)\partial^\mu + L^\Theta(\partial_\mu\omega^\mu) + L^\Theta(\omega_\mu\star_\Theta\omega^\mu) + L^\Theta(E)) + 2t^2L^\Theta(\partial_\nu\omega_\mu)\partial^\mu\partial^\nu + \cdots}e^{t\partial_\mu\partial^\mu} \\
&= L^\Theta(f)(1 + t(2L^\Theta(\omega_\mu)\partial^\mu + L^\Theta(\partial_\mu\omega^\mu) + L^\Theta(\omega_\mu\star_\Theta\omega^\mu) + L^\Theta(E)) \\
&\quad + 2t^2(L^\Theta(\partial_\nu\omega_\mu)\partial^\mu\partial^\nu + L^\Theta(\omega_\mu\star_\Theta\omega_\nu)\partial^\mu\partial^\nu) + O(t^2))e^{t\partial_\mu\partial^\mu},
\end{aligned}
$$

where the last t^2-term comes from e^{tX}. So, by (3),

$$
\begin{aligned}
\sigma[L^\Theta(f)e^{-t\Delta_r^\Theta}](\xi,x) &= \Big(f\Big(x-\tfrac{1}{2}\Theta\xi\Big) + t\Big(2f\star_\Theta\omega_\mu\Big(x-\tfrac{1}{2}\Theta\xi\Big)(-i\xi)^\mu + f\star_\Theta\partial_\mu\omega^\mu\Big(x-\tfrac{1}{2}\Theta\xi\Big) \\
&\quad + f\star_\Theta\omega_\mu\star_\Theta\omega^\mu\Big(x-\tfrac{1}{2}\Theta\xi\Big) + f\star_\Theta E\Big(x-\tfrac{1}{2}\Theta\xi\Big)\Big) + 2t^2\Big(f\star_\Theta\partial_\nu\omega_\mu\Big(x-\tfrac{1}{2}\Theta\xi\Big) \\
&\quad \times(-i\xi)^\mu(-i\xi)^\nu + f\star_\Theta\omega_\mu\star_\Theta\omega_\nu\Big(x-\tfrac{1}{2}\Theta\xi\Big)(-i\xi)^\mu(-i\xi)^\nu\Big) + O(t^2)\Big)e^{-t\xi_\mu\xi^\mu}.
\end{aligned}
$$

Finally, it remains to integrate $\sigma[L^\Theta(f)e^{-t\Delta_r^\Theta}](\xi,x)$. By the translation $x\to x+\frac{1}{2}\Theta\xi$, one obtains,

$$
\begin{aligned}
\mathrm{Tr}(L^\Theta(f)e^{-t\Delta_r^\Theta}) &= (2\pi)^{-n}\int\int (f(x) + t(2f\star_\Theta\omega_\mu(x)(-i\xi)^\mu + f\star_\Theta\partial_\mu\omega^\mu(x) + f\star_\Theta\omega_\mu\star_\Theta\omega^\mu(x) \\
&\quad + f\star_\Theta E(x)) + 2t^2(f\star_\Theta\partial_\nu\omega_\mu(x)(-i\xi)^\mu(-i\xi)^\nu + f\star_\Theta\omega_\mu\star_\Theta\omega_\nu(x) \\
&\quad \times(-i\xi)^\mu(-i\xi)^\nu))e^{-t\xi_\mu\xi^\mu}d^nxd^n\xi + O(t^{(n/2)+2}) \\
&= (4\pi t)^{-n/2}\int f(x)(1 + t(\partial_\mu\omega^\mu(x) + \omega_\mu\star_\Theta\omega^\mu(x) + E(x) - \partial_\mu\omega^\mu(x) \\
&\quad - \omega_\mu\star_\Theta\omega^\mu(x)))d^nx + O(t^{-(n/2)+2}) \\
&= (4\pi t)^{-n/2}\int f(x)(1 + tE(x))d^nx + O(t^{-n/2+2}).
\end{aligned}
$$

The higher order terms can be obtained by similar computations, that is to say, one generically gets

$$
L^\Theta(f)e^{-t\Delta_r^\Theta} \sim_{t\to 0} L^\Theta(f)\Bigg(\sum_{l\in\mathbb{N}} t^l \sum_{\alpha\in\mathbb{N}^n,|\alpha|\leqslant l} L^\Theta(g_{\alpha,l})t^{|\alpha|/2}\partial^\alpha\Bigg)e^{t\partial_\mu\partial^\mu},
$$

for some $g_{\alpha,l}\in\mathcal{B}_\Theta$, and where we have corrected the power series in t by the order of derivatives, with respect to the previous discussion. Here $\sim$ means asymptotic expansion with respect to the trace-norm topology,

$$
\Bigg\| L^\Theta(f)e^{-t\Delta_r^\Theta} - L^\Theta(f)\Bigg(\sum_{l\leqslant N} t^l \sum_{\alpha\in\mathbb{N}^n,|\alpha|\leqslant l} L^\Theta(g_{\alpha,l})t^{|\alpha|/2}\partial^\alpha\Bigg)e^{t\partial_\mu\partial^\mu}\Bigg\|_1 = O(t^{N+1}),
$$

convergence of the sequence being warranted by Theorem 3.2.

This concludes the proof of Theorem 2.2 since in (11) we get the coefficient $\mathrm{Tr}(1_{\mathbb{C}^{2^m}})$. ■

Remark 3.4: This systematic computation also yields that the other coefficients $\tilde{a}_{2l}$, $l>3$ have the same canonical form, that is Moyal products replace pointwise ones everywhere.

We will use this asymptotic expansion to compute the spectral action, but it can also be used to compute counterterms and anomalies in noncommutative quantum field theory [see the recent review (Ref. 51) and the quoted references].

B. Heat kernel expansion for NC tori in Moyal (re)presentation

Let $\mathcal{A}_\Theta$ be the smooth algebra of Schwartz (rapidly decreasing) linear combination of the plane waves $\{e^{ik.x}\}_{k\in\mathbb{Z}^n}$ endowed with Moyal product,

$$\mathcal{A}_\Theta = \left(\left\{\sum_{k\in\mathbb{Z}^n} c_k e^{ik.x} : (c_k) \in \mathcal{S}(\mathbb{Z}^n)\right\}, \star_\Theta\right).$$

$\mathcal{A}_\Theta$ closes to an algebra and represents the NC n-tori,

$$e^{ik.x}\star_\Theta e^{iq.x} = e^{-ik.\Theta q} e^{iq.x}\star_\Theta e^{ik.x}, \tag{13}$$

this canonical commutation relation of the NC n-tori coming from the straightforward computation (here Fourier modes are viewed as tempered distributions):

$$e^{ik.x}\star_\Theta e^{iq.x} = (2\pi)^{-n}\int\int_{\mathbb{R}^n\times\mathbb{R}^n} e^{i\xi.(x-y)} e^{ik.(x-1/2\Theta\xi)} e^{iq.y} d^n\xi d^n y = e^{-i1/2k.\Theta q} e^{i(k+q).x}.$$

One can build a unital spectral triple associated to this algebra,[11,28] with $\mathcal{H}=L^2(\mathbb{T}^n)\otimes\mathbb{C}^{2^m}$ the squared integrable sections of the trivial spinor bundle over $\mathbb{T}^n$, and $\mathcal{D}=\partial\!\!\!/$ the flat Dirac operator. $\mathcal{A}_\Theta$ is again represented on bounded operators by the left regular representation $\pi^\Theta(a)\psi = L^\Theta(a)\otimes 1_{2^m}\psi = a\star_\Theta\psi$, for $a\in\mathcal{A}_\Theta$, $\psi\in\mathcal{H}$. Actually, this construction is equivalent to the GNS representation associated to the state given by the canonical trace τ of $\mathcal{A}_\Theta$: when $a(x)=\Sigma_{k\in\mathbb{Z}^n} c_k e^{ik.x} \in \mathcal{A}_\Theta$,

$$\tau(a) := c_0 = \int_{\mathbb{T}^n} a(x) d^n x.$$

Let again Δ^Θ be the noncommutative generalized Laplacian defined in (10) acting now on $\mathcal{H} := L^2(\mathbb{T}^n)\otimes\mathbb{C}^{2^m}$, where $\omega_\mu^* = -\omega_\mu$ and $E\leqslant 0$ are in $\mathcal{A}_\Theta$.

We will first show that in the NC-tori cases, $e^{-t\Delta^\Theta}$ is trace-class for $t\in\mathbb{R}_+^*$ is a direct consequence of the compactness of $\mathcal{R}_\Delta^\Theta(z) := (\Delta^\Theta - z)^{-1}$. Then, thanks to the preceding section, it will be straightforward to show that its trace has a small-t asymptotic expansion (11) where the local invariants $\tilde{a}_l$ are the same as in the Moyal plane case, but with $f=1$.

Theorem 3.5: *Let Δ^Θ be as in (10), then $e^{-t\Delta^\Theta}$ is trace-class for all $t\in\mathbb{R}_+^*$.*

Proof: The proof is simpler than for the Moyal plane. Clearly, $\mathcal{R}_\theta(z)\in\mathcal{L}^p(\mathcal{H})$, $p>n$, and so $\mathcal{R}_{\Delta\Theta}(z)\in\mathcal{L}^{p/2}(\mathcal{H})$ (use the same trick as in the proof of Theorem 3.2). Then Theorem 3.1 yields $e^{-t\Delta^\Theta} = (e^{-t(2/p)\Delta^\Theta})^{p/2} \in \mathcal{L}^1(\mathcal{H})$. ∎

For the computation of the small-t expansion, because all algebraic properties (mainly Leibniz rule) used in the preceding section work as well as for the tori, we also obtain

$$e^{-t\Delta^\Theta} \underset{t\to 0}{\sim} \sum_{l\in\mathbb{N}} t^l \left(\sum_{\alpha\in\mathbb{N}^n, |\alpha|\leqslant l} L^\Theta(g_{\alpha,l}) t^{|\alpha|/2}\partial^\alpha\right) e^{t\partial_\mu\partial^\mu},$$

where $g_{\alpha,l}\in\mathcal{A}_\Theta$ are the same as for the Moyal plane case except that now $f=1$. So the trace has the small-t expansion,

$$\begin{aligned}\mathrm{Tr}(e^{-t\Delta^\Theta}) &= 2^m(2\pi)^{-n}\int_{\mathbb{T}^n} d^n x \int_{\mathbb{R}^n} \sigma[e^{-t\Delta^\Theta}](\xi,x) d^n\xi \\ &\underset{t\to 0}{\sim} \frac{2^m}{(2\pi)^n}\int_{\mathbb{T}^n} d^n x \int_{\mathbb{R}^n} \sum_{l\in\mathbb{N}} t^l \left(\sum_{\alpha\in\mathbb{N}^n, |\alpha|\leqslant l} g_{\alpha,l}\left(x - \frac{1}{2}\Theta\xi\right) t^{|\alpha|/2}(-i\xi)^\alpha\right) e^{-t|\xi|^2} d^n\xi.\end{aligned}$$

Now, expanding $g_{\alpha,l}$ in Fourier modes and using

$$\int_{\mathbb{T}^n} e^{ik(x-(1/2)\Theta\xi)} d^n x = e^{-ik1/2\Theta\xi}\delta_{k,0} = \delta_{k,0},$$

we directly obtain the following result.

Theorem 3.6: *Let* Δ^{Θ} *be as in (10), then*

$$\mathrm{Tr}(e^{-t\Delta^{\Theta}}) \underset{t\to 0}{\sim} 2^m \left(\frac{1}{4\pi t}\right)^{n/2} \sum_{l\in\mathbb{N}} t^l \int_{\mathbb{T}^n} \tilde{a}_{2l}(x) d^n x,$$

where the $\tilde{a}_{2l}(x)$ *are given in Theorem 2.2.*

IV. THE SPECTRAL ACTION

A. Spectral action for nonunital spectral triples

For a unital spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$, Chamseddine and Connes[5,6] proposed a definition of a physical action which depends only on the spectrum of the covariant $\mathcal{D}$-operator (the spectral action principle),

$$S(\mathcal{D},A) := \mathrm{Tr}(\phi(\mathcal{D}_A^2/\Lambda^2)), \tag{14}$$

where $\mathcal{D}_A$ is the covariant "Dirac" operator $\mathcal{D}_A := \mathcal{D}+A+\epsilon JAJ^{-1}$, A is a universal represented 1-form $A\in\tilde{\pi}(\Omega^1\mathcal{A})$, $\tilde{\pi}$ being the lifted representation on the whole differential algebra $\Omega^{\cdot}\mathcal{A}$ $(\tilde{\pi}(a_0\delta a_1\cdots\delta a_p) := \pi(a_0)[\mathcal{D},\pi(a_1)]\cdots[\mathcal{D},\pi(a_p)], a_i\in\mathcal{A}, i=1,\ldots,p)$, J is the real structure of the triple (the charge conjugation for spinors in the commutative case), ϕ a suitable cutoff function, Λ a mass scale and $\epsilon\in\{+1,-1\}$ depending upon the dimension. Any positive smooth function ϕ mimicking the step function $\chi_{[0,1]}$ was initially used in Refs. 5 and 6 and in Ref. 21, sufficient conditions on ϕ have been detailed. Since in the unital case, $\mathcal{D}$ has compact resolvent and likewise for the perturbed $\mathcal{D}_A$ by Theorem 3.5, $\phi(\mathcal{D}_A^2/\Lambda^2)$ is trace-class as long as ϕ decreases fast enough; for instance $r^{n-1}\phi(r^2)\in L^1(\mathbb{R}^+)$ is a sufficient condition for a spectral triple with spectral dimension equal to n.

Let us be more explicit about the covariant "Dirac" operator $\mathcal{D}_A$. The starting point is the analogy between the invariance group of a gauge theory on a Riemannian manifold M coupled with general relativity, $G=U\rtimes\mathrm{Diff}(M)$ and the group of automorphism of an algebra $\mathcal{A}$ which splits into its inner and outer part $\mathrm{Aut}(\mathcal{A})=\mathrm{Int}(\mathcal{A})\rtimes\mathrm{Out}(\mathcal{A})$, with the following exact (group) sequence:

$$1\to U\to G\to \mathrm{Diff}(M)\to 1,$$

$$1\to \mathrm{Int}(\mathcal{A})\to \mathrm{Aut}(\mathcal{A})\to \mathrm{Out}(\mathcal{A})\to 1.$$

In particular, if we choose $\mathcal{A}=\mathcal{C}^\infty(M,M_n(\mathbb{C}))\cong\mathcal{C}^\infty(M)\otimes M_n(\mathbb{C})$, $n>1$, the two constructions coincide: $\mathrm{Out}(\mathcal{A})=\mathrm{Diff}(M)$, $\mathrm{Int}(\mathcal{A})=\mathcal{C}^\infty(M,\mathrm{SU}_n/\mathbb{Z}_n)$. The natural invariance group for an action defined on a spectral triple must be the automorphism group of the algebra. In order to retrieve a gauge theory with spin matter when $\mathcal{A}$ is almost commutative that is $\mathcal{A}=\mathcal{C}^\infty(M)\otimes A_F$ [where A_F is a finite algebra such as $\mathbb{H}\oplus\mathbb{C}\oplus M_3(\mathbb{C})$ for the standard model of particle physics (Refs. 2, 5, and 6)], we must represent $\mathrm{Aut}(\mathcal{A})$ in the fermionic Hilbert space $\mathcal{H}$. In particular, we must lift $\mathrm{Int}(\mathcal{A})$ to the unitary group $\mathcal{U}(\mathcal{H})$ of the bounded operators on $\mathcal{H}$,

$$\mathcal{U}(\mathcal{A})\ni u\mapsto \sigma(u)=\pi(u)J\pi(u)J^{-1}\in\mathcal{U}(\mathcal{H}).$$

For NC tori, Moyal planes and some almost-commutative geometries, this is the adjoint representation, $\pi(u)J\pi(u)J^{-1}\psi = u\star_\Theta\psi\star_\Theta u^*$, $\psi\in\mathcal{H}$. Under this transformation, $\mathcal{D}$ transforms as

$$\mathcal{D} \to \sigma(u)\mathcal{D}\sigma(u)^{-1} = \mathcal{D} + \pi(u)[\mathcal{D}, \pi(u^*)] + \epsilon J\pi(u)[\mathcal{D}, \pi(u^*)]J^{-1}, \tag{15}$$

where ϵ comes from commutation relations $\mathcal{D}J = \epsilon J\mathcal{D}$, $\epsilon \in \{+1, -1\}$ [(see Refs. 10 and 28 for a table of signs)]. The sign ϵ in Eq. (15) is actually wrong in most of the literature, however the computations linked with physics models are unaffected because $\epsilon = 1$ in the zero and four-dimensional cases. Hence $\mathcal{D}_A \to \mathcal{D}_{A'}$ with $A' = \pi(u)A\pi(u^*) + \pi(u)[\mathcal{D}, \pi(u^*)]$ transforms covariantly.

For almost commutative geometry $\mathcal{C}^\infty(M) \otimes A_F$, in particular for the standard model, with $\mathcal{D} = \not{D} \otimes 1_{\mathcal{H}_F}$ and the curved Dirac operator $\not{D} = -ie^\mu{}_a \gamma^a(\partial_\mu + \omega_\mu)$, ω being the spin connection on M, $S(\mathcal{D}, A)$ is asymptotically computable by heat kernel techniques. We may note that $\not{D}_A^2$ can be written as a generalized Laplacian, $\not{D}_A^2 = P$ with $P = -(g^{\mu\nu}(\partial_\mu + \omega_\mu)(\partial_\nu + \omega_\nu) + E)$, where $g^{\mu\nu}$ is the metric tensor, now ω_μ is a connection containing spin and Yang–Mills part and E is an endomorphism of the fiber bundle, on whose sections P acts. One can formally show,[5,6] expanding ϕ in Taylor series, that $S(\mathcal{D}, A)$ is linked to the Seeley–DeWitt coefficients $a_k(P, x)$ of the trace of the heat operator on a n-dimensional manifold,

$$\mathrm{Tr}(e^{-tP}) \underset{t \to 0}{\sim} (4\pi)^{-n/2} \sum_{l \in \mathbb{N}} t^{(l-n)/2} \int_M a_l(P, x)\mathrm{dvol}(x), \tag{16}$$

where $\mathrm{dvol}(x)$ is the Riemannian volume form, by the relation between zeta function and trace of the heat operator[25]

$$\zeta_P(s) := \mathrm{Tr}(P^{-s}) = \frac{1}{\Gamma(s)} \int_0^\infty t^{s-1}\, \mathrm{Tr}(e^{-tP})\mathrm{d}t. \tag{17}$$

On a manifold without boundary $a_l(P, x) = 0$, l odd, therefore in the four-dimensional case, this yields,

$$S(\not{D} \otimes 1_{A_F}, A) = (4\pi)^{-2} \sum_{l=0}^{2} \Lambda^{4-2l} \phi_{2l} \int_M a_{2l}(P, x)\mathrm{dvol}(x) + O(\Lambda^{-2}), \tag{18}$$

where

$$\phi_0 = \int_0^\infty \phi(t)t\, \mathrm{d}t, \quad \phi_2 = \int_0^\infty \phi(t)\mathrm{d}t, \quad \phi_{2(2l+2)} = (-1)^l \phi^{(l)}(0), \quad l \geqslant 0. \tag{19}$$

A less formal, derivation of this relation with precise constraints on ϕ can be found in Refs. 21 and 40. For M still four dimensional and $A_F = \mathbb{H} \oplus \mathbb{C} \oplus M_3(\mathbb{C})$, the spectral action yields a unification of the Einstein plus Weyl gravity and the standard model including the Higgs sector and its spontaneous symmetry breaking (see Refs. 2, 5, and 6). There is no restriction for an arbitrary dimension but the coefficients (19) will be slightly different, as we will see below for the Moyal plane.

Remark 4.1: The relation (17), links also the Dixmier trace with the heat kernel expansion, and therefore the Connes–Lott action (8) with the spectral action as explained in Sec. IV C.

For the nonunital case, since $\mathcal{D}$ has no longer a compact resolvent, we invoke a *spatial regularization* ρ to define the spectral action. Like the energy regularization ϕ, ρ is a positive function rapidly decreasing, in the almost commutative case, and must be generically an element of the algebra $\mathcal{A}$.

Definition 4.2: For a nonunital spectral triple $(\mathcal{A}, \tilde{\mathcal{A}}, \mathcal{H}, \mathcal{D})$ of spectral dimension n, the *spectral action* is

$$S(\mathcal{D}, A, \rho) := \mathrm{Tr}_{\mathcal{H}}(\pi(\rho)\phi(\mathcal{D}_A^2/\Lambda^2)), \tag{20}$$

where as in the unital case, $\mathcal{D}_A = \mathcal{D} + A + \epsilon JAJ^{-1}$ ($\epsilon \in \{+1, -1\}$ depending on n), and $A \in \Omega^1_{\mathcal{D}}(\tilde{\mathcal{A}})$ is now a represented self-adjoint 1-form of the unitized algebra, $A = \Sigma_{i \in I} \pi(b_0^i)[\mathcal{D}, \pi(b_1^i)]$, for I a

finite set, b_0^i, $b_1^i \in \tilde{\mathcal{A}}$, $0 \leqslant \rho \in \mathcal{A}$ and moreover $0 \leqslant \phi$, Λ are as in the unital case.

Remark 4.3: (i) This definition gives more importance to the choice of the unitization. The 1-form A is now constructed from $\tilde{\mathcal{A}}$, and all the symmetry considerations discussed previously occur now for the unitized algebra. This is important because unitaries in the algebra are necessary to express gauge invariance, $S(\mathcal{D},A,\rho)$ is gauge invariant that is invariant under the lifted inner automorphism implemented by the unitary operator $\pi(u)J\pi(u)J^{-1}$ and now the regularization ρ transforms also

$$A \to uAu^* + u[\mathcal{D},u^*],$$

$$\rho \to u\rho u^*.$$

(ii) The positivity of ρ and ϕ is necessary in order to get a positive action.

(iii) Other regularizations are possible. For instance, $\phi(\mathcal{D}_A^2\pi(\rho)^{-1})$ where $\rho \in \mathcal{S}$ is a strictly positive function also give rise to trace-class operators for Moyal planes, but the asymptotic expansion is still unmanageable.

Let us show how it works for an almost commutative geometry associated with a boundaryless noncompact smooth manifold M. In this case, we still work with $\mathcal{A}=\mathcal{C}_c^\infty(M)\otimes A_F$. The operator ρe^{-tP}, $t \in \mathbb{R}_+^*$, is trace-class, for $\rho \in \mathcal{C}_c^\infty(M)$ viewed as a pointwise multiplication operator and P being a generalized Laplacian (ΨDO operator of order two with metric tensor as coefficient of the leading symbol). In this case the formula (17) has an analog,

$$\zeta_{\rho,P}(s) := \mathrm{Tr}(\rho P^{-s}) = \frac{1}{\Gamma(s)}\int_0^\infty t^{s-1}\,\mathrm{Tr}(\rho e^{-tP})\mathrm{d}t, \tag{21}$$

one obtains, for $P=(\not{D}+A+\epsilon JAJ^{-1})^2$,

$$S(\not{D}\otimes 1_{A_F},A) = (4\pi)^{-n/2}\sum_{l=0}^{m}\Lambda^{n-2l}\phi_{2l}\int_M a_{2l}(P,x)\rho(x)\mathrm{dvol}(x) + O(\Lambda^{n-2(m+1)}),$$

where a_{2l} are still the Seeley–DeWitt coefficients which are now only locally integrable while $a_{2l}(P,x)\rho(x)$ are globally integrable (see Ref. 49). The coefficients ϕ_{2l} have the form (19) in the four-dimensional case, and their values in any dimension n is now computed for Moyal planes.

B. The case of the Moyal plane

Actually, the relation (21) is quite general, that is for any bounded operator S and any operator T such that ST^{-s} is trace-class, we have

$$\zeta_{S,T}(s) := \mathrm{Tr}(ST^{-s}) = \frac{1}{\Gamma(s)}\int_0^\infty t^{s-1}\,\mathrm{Tr}(Se^{-tT})\mathrm{d}t. \tag{22}$$

With this relation and the result of Sec. III, one can derive the spectral action for Moyal planes. However in order to obtain more directly the form of the coefficients ϕ_{2k} in any dimension, we will derive it by Laplace transform techniques such as in Ref. 40 (see Ref. 53 for details on Laplace transform). We assume that the function ϕ has the following property:

$$\phi \in \mathcal{C}^\infty(\mathbb{R}^+) \text{ is the Laplace transform of } \hat{\psi} \in \mathcal{S}(\mathbb{R}^+) := \{g \in \mathcal{S}: g(x) = 0, x \leqslant 0\}. \tag{23}$$

Thus, any function with this property has necessarily an analytic extension on the right complex plane and is a Laplace transform. Consequently, any m-differentiable function ψ such that $\psi^{(m)} = \phi$ is the Laplace transform of a function $\hat{\psi}$ and by differentiation, it satisfies

$$\phi(z) = \psi^{(m)}(z) = (-1)^m \int_0^\infty e^{-sz} s^m \hat{\psi}(s)\mathrm{d}s, \quad \Re z > 0.$$

With Δ^Θ defined in (10), using $\phi(\Delta_r^\Theta) = (-1)^m \int_0^\infty e^{-s\Delta_r^\Theta} s^m \hat{\psi}(s)\mathrm{d}s$ and the positivity of $\rho = g^* \star_\Theta g$, $g \in \mathcal{B}_\Theta$, we get

$$\mathrm{Tr}(L^\Theta(\rho)\phi(\Delta_r^\Theta/\Lambda^2)) = (-1)^m \,\mathrm{Tr}\left(L^\Theta(g) \int_0^\infty e^{-t\Delta_r^\Theta/\Lambda^2} t^m \hat{\psi}(t)\mathrm{d}t \, L^\Theta(g^*) \right).$$

Let $\{\Phi_p\}_{p\in\mathbb{N}}$ be any orthonormal basis of $\mathcal{H}_r$ and let $0 \leqslant B_t := L^\Theta(g) e^{-t\Delta_r^\Theta/\Lambda^2} L^\Theta(g^*)$, then

$$\mathrm{Tr}(L^\Theta(\rho)\phi(\Delta_r^\Theta/\Lambda^2)) = \lim_{N\to\infty} \int_0^\infty \sum_{p\leqslant N} \langle \Phi_p, B_t \Phi_p \rangle t^m \hat{\psi}(t)\mathrm{d}t \leqslant \lim_{N\to\infty} \int_0^\infty \|B_t\|_1 t^m \hat{\psi}(t)\mathrm{d}t = \int_0^\infty \|B_t\|_1 t^m \hat{\psi}(t)\mathrm{d}t.$$

Let us estimate $\|B_t\|_1$. For $t > \epsilon$ with a fixed arbitrary small ϵ, we have

$$\|B_t\|_1 = \|L^\Theta(g) e^{-t\Delta_r^\Theta/2\Lambda^2}\|_2^2 \leqslant \|L^\Theta(g) e^{-\epsilon\Delta_r^\Theta/2\Lambda^2}\|_2^2 \|e^{-(t-\epsilon)\Delta_r^\Theta/2\Lambda^2}\|.$$

But, $(t-\epsilon)\Delta_r^\Theta$ being positive, we have $\|e^{-(t-\epsilon)\Delta_r^\Theta/2\Lambda^2}\| \leqslant 1$. Hence for $t > \epsilon$, $\|B_t\|_1 \leqslant C$ uniformly in t. For $t \leqslant \epsilon$, our previous computation shows that $\|B_t\|_1 = O(t^{-n/2})$. Hence $\mathrm{Tr}(\int_0^\infty B_t t^m \hat{\psi}(t)\mathrm{d}t) < \infty$, so by dominated convergence one obtains

$$\begin{aligned}
\mathrm{Tr}(L^\Theta(\rho)\phi(\Delta_r^\Theta/\Lambda^2)) &= (-1)^m \int_0^\infty \mathrm{Tr}(L^\Theta(\rho) e^{-t\Delta_r^\Theta/\Lambda^2}) t^m \hat{\psi}(t)\mathrm{d}t \\
&= (-1)^m (4\pi)^{-n/2} \int_0^\infty \sum_{l=0}^m \Lambda^{n-2l} t^{m+l-n/2} \hat{\psi}(t)\mathrm{d}t \int_{\mathbb{R}^n} \rho \star_\Theta \tilde{a}_{2l}(x) d^n x + O(\Lambda^{n-2(m+1)}) \\
&= (4\pi)^{-n/2} \sum_{l=0}^m \Lambda^{n-2l} \phi_{2l} \int_{\mathbb{R}^n} \rho \star_\Theta \tilde{a}_{2l}(x) d^n x + O(\Lambda^{n-2(m+1)}),
\end{aligned}$$

where ϕ_{2l} is now defined by

$$\phi_{2l} := (-1)^m \int_0^\infty t^{m+l-n/2} \hat{\psi}(t)\mathrm{d}t. \tag{24}$$

When $n = 2m$ is even, ϕ_{2l} has the more familiar form of (19),

$$\phi_{2l} = \begin{cases} \dfrac{1}{\Gamma(m-l)} \displaystyle\int_0^\infty \phi(t) t^{m-1-l}\,\mathrm{d}t & \text{for } l = 0, \ldots, m-1, \\ (-1)^l \phi^{(l-m)}(0) & \text{for } l = m, \ldots, n. \end{cases} \tag{25}$$

For n odd, the coefficients ϕ_{2l} have less explicit forms because they invoke fractional derivatives of ϕ, so in this case, it is better to stick to definition (24).

Let us summarize.

Theorem 4.4: *Let $\rho \in \mathcal{S}(\mathbb{R}^n)$, $A = -iL^\Theta(A_\mu) \otimes \gamma^\mu$, $A_\mu^* = -A_\mu \in \mathcal{O}_0(\mathbb{R}^n)$, $\phi \in \mathcal{C}^\infty(\mathbb{R}^+)$ be a positive function satisfying condition (23) and $\not{b}_A = \not{b} + A$. Then $L^\Theta(\rho)\phi(\not{b}_A^2/\Lambda^2)$ is trace-class. Moreover, the following expansion of the spectral action holds:*

$$S(\not{b}, A, \rho) = 2^m (4\pi)^{-n/2} \sum_{l=0}^m \Lambda^{n-2l} \phi_{2l} \int_{\mathbb{R}^n} \rho(x) \tilde{a}_{2l}(x) d^n x + O(\Lambda^{n-2(m+1)}),$$

where the ϕ_{2l} are defined in (24) or (25) depending on the dimension and the $\tilde{a}_{2l}(x)$ are given in Theorem 2.2 with the following replacement in (10):

$$L^{\Theta}(\omega_{\mu}) \to L^{\Theta}(A_{\mu}),$$

$$L^{\Theta}(E) \otimes 1_{2^m} \to (L^{\Theta}(\partial_{\mu}A_{\nu}) + L^{\Theta}(A_{\mu} \star_{\Theta} A_{\nu})) \otimes \tfrac{1}{2}(\gamma^{\mu}\gamma^{\nu} - \gamma^{\nu}\gamma^{\mu}).$$

Moreover, all terms in $\tilde{a}_{2l}$ linear in E are zero.

Proof: This follows from $\gamma^{\mu}\gamma^{\nu} = \eta^{\mu\nu} + \frac{1}{2}(\gamma^{\mu}\gamma^{\nu} - \gamma^{\nu}\gamma^{\mu})$, so all linear terms in E are of zero trace. ■

Remark 4.5: When the Dirac operator is symmetrized, $\mathcal{D}_A = \mathcal{D} + A + \epsilon JAJ^{-1}$, one must replace $L^{\Theta}(A_{\mu})$ by $L^{\Theta}(A_{\mu}) - R^{\Theta}(A_{\mu})$ since $\epsilon J(L^{\Theta}(A_{\mu}) \otimes \gamma^{\mu})J^{-1} = R^{\Theta}(A_{\mu}^{*}) \otimes \gamma^{\mu}$. So, the behavior in t of different terms like $\mathrm{Tr}(L^{\Theta}(f)R^{\Theta}(g)(-i\partial)^{\alpha}e^{t\partial_{\mu}\partial^{\mu}})$ must be computed. More precisely, since

$$\sigma[L^{\Theta}(f)R^{\Theta}(g)](\xi, x) = (2\pi)^{-n} \int e^{i(\eta-\xi).(x-y)} f\left(x - \tfrac{1}{2}\Theta\eta\right) g\left(y + \tfrac{1}{2}\Theta\xi\right) d^n y d^n \eta,$$

we have

$$\begin{aligned}\mathrm{Tr}(L^{\Theta}(f)R^{\Theta}(g)(-i\partial)^{\alpha}e^{t\partial_{\mu}\partial^{\mu}}) &= \int \sigma[L^{\Theta}(f)R^{\Theta}(g)(-i\partial)^{\alpha}e^{t\partial_{\mu}\partial^{\mu}}](\xi, x) d^n x d^n \xi \\ &= \int f\left(x - \tfrac{1}{2}\Theta\xi\right) g\left(x + \tfrac{1}{2}\Theta\xi\right) \xi^{\alpha} e^{-t|\xi|^2} d^n x d^n \xi,\end{aligned}$$

the translation invariance $x \to x + \frac{1}{2}\Theta\xi$ crucially used in the proof of Theorem 2.2 now fails. This point is related to the UV/IR mixings and must be clarified.

C. Connes–Lott versus Chamseddine–Connes actions

In order to compare this result with the Connes–Lott action computation of the four-dimensional Moyal plane,[23] up to negative order terms with respect to the mass scale Λ, we obtain

$$S(\phi, A, \rho) = \frac{1}{4\pi^2}\left(\Lambda^4 \phi_0 \int_{\mathbb{R}^4} \rho(x) d^4x + \frac{\phi(0)}{6} \int_{\mathbb{R}^4} \rho(x) F^{\mu\nu} \star_{\Theta} F_{\mu\nu}(x) d^4x\right) + O(\Lambda^{-2}),$$

where $F^{\mu\nu} := \partial^{\mu}A^{\nu} - \partial^{\nu}A^{\mu} + [A^{\mu}, A^{\nu}]_{\star_{\Theta}}$.

If we choose the characteristic function $\rho = \chi_V$ of a bounded subset $V \subset \mathbb{R}^4 (\chi_V \notin \mathcal{S}(\mathbb{R}^4))$, property (6) yields

$$S(\phi, A, \chi_V) = \frac{1}{4\pi^2}\left(\Lambda^4 \phi_0 \int_V d^4x + \frac{\phi(0)}{6} \int_V F^{\mu\nu} \star_{\Theta} F_{\mu\nu}(x) d^4x\right) + O(\Lambda^{-2}), \tag{26}$$

which, modulo a cosmological term, is the spatially localized noncommutative Yang–Mills action. This expression must be compared with the four-dimensional Connes–Lott one (8) for Θ symplectic, hence $\star_{\Theta} = \star_{\Theta}$,

$$\mathrm{YM}(\alpha) = -\frac{1}{4g^2} \int F^{\mu\nu} \star_{\Theta} F_{\mu\nu}(x) d^4x.$$

This action is slightly different from (26), because property (6), together with the absence of ρ gives

$$\mathrm{YM}(\alpha) = -\frac{1}{4g^2} \int F^{\mu\nu}(x) F_{\mu\nu}(x) d^4x.$$

For the noncommutative tori, we have also a similar result, with the spectral action in the unital case ($\rho = 1$),

$$S(\not{b},A)\sim_{\Lambda\to\infty}2^m(4\pi)^{-n/2}\sum_{k\in\mathbb{N}}\Lambda^{n-2k}\phi_{2k}\int_{\mathbb{T}^n}\tilde{a}_{2k}(x)d^nx,$$

which also yields for $n=4$,

$$S(\not{b},A)=\frac{1}{4\pi^2}\left(\Lambda^4\phi_0+\frac{\phi(0)}{6}\int_{\mathbb{T}^4}F^{\mu\nu}\star_\Theta F_{\mu\nu}(x)d^4x\right)+O(\Lambda^{-2}).$$

D. Towards a gravitational degree of freedom

One can ask about adding gravitational degrees of freedom for Moyal planes or NC tori. For instance, the results of Sec. III also work with a nonconstant metric $g^{\mu\nu}(x)$. More precisely, Theorem 3.2 is still true if we replace in (10), Δ^Θ by the square of

$$-ie_a^\mu(\partial_\mu+\omega_\mu+L^\Theta(A_\mu))\otimes\gamma^a,$$

where e_a^μ and ω_μ are bounded functions. Here, the pointwise and Moyal products are mixed, but in this case, computation of the trace of its regularized semigroup can be done, at least in principle, with the same techniques but it will be highly less easy.

However, this construction is meaningless from a spectral triple point of view. A nonflat Dirac operator over $\mathbb{R}^n$, $\not{D}=-ie_a^\mu(x)\gamma^a(\partial_\mu+\omega_\mu(x))$, ω_μ being the spin connection, will violate most of the axioms describing spectral triples, for instance,

$$[\not{D},\pi^\Theta(f)]=-i\gamma^a([e_a^\mu\omega_\mu,\pi^\Theta(f)]+e_a^\mu\pi^\Theta(\partial_\mu f)+[e_a^\mu,\pi^\Theta(f)]\partial_\mu).$$

So, for $f\in\mathcal{B}_\Theta$, $[\not{D},\pi^\Theta(f)]$ can be extended to a bounded operator only if $[e_a^\mu,\pi^\Theta(f)]=0$. This condition can be satisfied for instance by a n-dimensional Riemannian manifold (M,g) endowed with an isometric action of $\mathbb{R}^l$, $l\geqslant 2$ (periodic or not). This is actually the Connes–Landi isospectral deformations.[13,14] Those cases, admit nontrivial fluctuations of the metric (in some sense for the untwisted directions). Since the only invariant metric on $\mathbb{R}^n$ or $\mathbb{T}^n$ by the natural action of $\mathbb{R}^n$ is the flat one and this is the geometrical obstruction to deal with nonflat Moyal planes (see Ref. 4).

(Received 12 September 2004; accepted 28 January 2005; published online 21 March 2005)

We explore the relationship between the integrability of nonsemilinear partial differential equations and formal Dirichlet series solutions. To this end we consider a variety of integrable and nonintegrable differential equations. We also demonstrate that such series solutions are a natural extension to the nonlinear case of those obtained by basic solution techniques for linear ordinary differential equations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1879083]

I. INTRODUCTION

One class of completely integrable partial differential equations (PDEs) that has long been of interest is that of nonsemilinear PDEs; see for example Refs. 1–4. However, nonsemilinear PDEs, when compared with other classes of PDE, present certain problems. One is that many such equations, even if completely integrable, fail the Painlevé test.[5] In other words, there is no simple test of integrability that can be applied directly to such PDEs.

In two recent papers[6,7] it has been suggested that, instead of classifiying equations using Painlevé expansions, a classification using Dirichlet series might be used. It was noted that, for two particular classes of nonsemilinear PDEs, the only equations admitting such series solutions are transformable back onto the only known completely integrable PDEs within those classes. One aim of the present paper is to explore these ideas still further, and to this end we consider a variety of nonsemilinear PDEs, both integrable and nonintegrable, in $1+1$ and multidimensions. For a discussion of integrability in multidimensions, see e.g., Refs. 8 and 9.

However, despite the apparent link between Dirichlet series and integrability—at least in the case of particular examples, or for certain classes of equations—it would be imprudent to claim a hard and fast connection. Indeed, we show here that the existence of Dirichlet series solutions is not sufficient for integrability; the question of necessity remains open. A precise description of the uncertainties in the current state of the art can be found in the concluding Secs. VII and VIII.

A second aim of the present paper is to provide an understanding of our technique as a method of constructing series solutions. We find that instead of a comparison with Painlevé analysis, it is more profitable to consider a comparison with solution techniques for linear ordinary differential equations (ODEs). It turns out that the important feature is that of having multilinear terms that are dominant over other terms in the equation. We explain our ideas within the context not only of the PDEs considered but also using ODE examples which help to make clear the connection between Dirichlet series solutions for nonlinear equations and basic solution techniques for linear ODEs. We note that Dirichlet series solutions for nonlinear ODEs have been considered before (see, e.g., Ref. 10), although this connection with the linear case does not seem to have been remarked upon.

II. DIRICHLET SERIES: AN ODE EXAMPLE

In this section we recall some basic facts about Dirichlet series, and illustrate our ideas using a simple ODE example. A Dirichlet series is a series of the form

$$\sum_{j=0}^{\infty} a_j e^{-\lambda_j x}, \tag{1}$$

where $\{\lambda_j\}$ is a strictly monotonic increasing sequence of real numbers (only a finite number of which are negative), unbounded above, and $x, a_j \in \mathbb{C}$. We recall that a Dirichlet series, if convergent for $x=x_0$, is then also convergent for all x with $\mathrm{Re}(x) > \mathrm{Re}(x_0)$, and uniformly convergent for all x with $|\arg(x-x_0)| \leqslant \theta$, for any fixed θ, $0 < \theta < \pi/2$. That is, in general, convergence is in right half-planes, and uniform convergence is in sectors. For further details, see e.g., Ref. 11. Clearly, $x \to -x$ allows us to define Dirichlet-type series convergent in left half-planes; more generally, a rotation $x \to e^{i\varphi} x$ $(-\pi < \varphi \leqslant \pi)$ allows us to define Dirichlet-type series convergent in skewed half-planes,

$$\sum_{j=0}^{\infty} a_j e^{\mu_j x}, \tag{2}$$

where $\mu_j = -\lambda_j e^{i\varphi}$ is a sequence of points lying on a half-line in the complex plane. We will refer to any series of the form (2) as a Dirichlet series, or standard Dirichlet series when we wish to distinguish between a series (2) and generalizations thereof.

We note that Dirichlet series appear to be used little in the study of solutions of differential equations. The reason for this is presumably that, in comparison to power series (Taylor or Laurent), relatively few functions, and so also relatively few solutions of differential equations, can be expressed as Dirichlet series; there is in fact no reason why a given function should have such an expression. Thus, in general, in order to represent solutions of differential equations, Dirichlet series need modification, and those cases where this is not necessary are therefore very special. Indeed, in any half-plane of convergence, a Dirichlet series sums to an analytic function of x. We return to these considerations later (see Sec. VI).

We now illustrate the basic ideas underlying our approach using as an example the ODE,

$$B[V] \equiv VV_{xxx} + 2V_x V_{xx} - 3VV_x + V - V_{xx} = 0. \tag{3}$$

We first seek a leading order term for our Dirichlet series,

$$V \sim V_0 e^{px}, \quad V_0 \neq 0, \quad \text{constant}. \tag{4}$$

Substituting into the dominant (quadratic) terms gives

$$VV_{xxx} + 2V_x V_{xx} - 3VV_x \sim 3p(p^2-1)V_0^2 e^{2px}, \tag{5}$$

and so we may take $p = \pm 1$ or $p = 0$. However in this last case the quadratic terms are not dominant over the linear terms, and so we are left with $p = \pm 1$.

We take $p = -1$, and seek to determine which coefficients in our putative Dirichlet series will be arbitrary, using a substitution of the form

$$V \sim V_0 e^{-x} + V_j e^{(j-1)x}, \tag{6}$$

which allows us to determine the coefficient of V_j in the recursion relation by which the coefficients of our Dirichlet series are determined. We thus obtain that this recursion relation is of the form

$$j(j-2)(j-3)V_j = R_j(V_{j-1}, V_{j-2}, \ldots, V_0), \tag{7}$$

for some function R_j, and so we have arbitrary coefficients at $j=0,2,3$. We therefore seek a solution of our ODE as

$$V = e^{-x}\sum_{j=0}^{\infty} V_j e^{jx}, \tag{8}$$

where all V_j are constant. We note in passing that if instead of x in the series (8), we write $x-\tilde{x}$, for some constant $\tilde{x}$, we can always absorb the factor $e^{-j\tilde{x}}$ into the coefficient V_j.

Substitution of the series (8) into our ODE yields

$$B[V] = e^{-2x}\sum_{j=0}^{\infty} B_j e^{jx} = 0, \tag{9}$$

and so a sequence of equations $B_j=0$ for the coefficients V_j. Here,

$$B_0 = 0, \tag{10}$$

$$B_1 = 2V_0V_1, \tag{11}$$

$$B_2 = V_1, \tag{12}$$

$$B_3 = -2V_1V_2, \tag{13}$$

$$B_4 = 8V_0V_4 + 2V_1V_3 - 3V_3. \tag{14}$$

Thus we see that V_0 is left arbitrary and that, at $j=1$, since we assume $V_0 \neq 0$, V_1 is determined as $V_1=0$. At $j=2$, V_2 is not determined, and we have the compatibility condition $R_2=0$ (i.e., $B_2=0$), satisfied since $V_1=0$. Similarly at $j=3$, where V_3 is left undetermined, we must have $R_3=0$ (i.e., $B_3=0$), again satisfied since $V_1=0$. The equations $B_j=0$, $j\geqslant 4$, then determine all subsequent coefficients V_j, $j=4,5,6,\ldots$, in terms of V_0, V_2, and V_3. Our ODE therefore admits, at least formally, a Dirichlet series solution. We note that, if one of the conditions at $j=2$ or $j=3$ had not been satisfied, then we would have had to modify the series solution by the inclusion of powers of x. Examples of differential equations where such modifications are needed will be presented later.

We note that for the choice $p=1$, the fact that we have a Dirichlet series solution of the form

$$V = e^{x}\sum_{j=-\infty}^{0} \tilde{V}_j e^{jx}, \tag{15}$$

with $\tilde{V}_0$, $\tilde{V}_{-2}$, and $\tilde{V}_{-3}$ arbitrary, follows immediately from the observation that our ODE admits the discrete symmetry $(V,x)\rightarrow(-V,-x)$.

Thus our ODE admits formal Dirichlet series solutions. These are constructed by first identifying a leading order, determined by the terms of highest nonlinearity, and then checking that compatibility conditions—which arise when coefficients are left arbitrary—are satisfied. It is the construction of such series solutions that we will explore in later sections. We will also consider variations of our approach, i.e., series solutions of a more general form than the standard Dirichlet series (2).

The above ODE example, however, also ties in with the other main theme of our paper, which is integrability: the ODE (3) is integrable, having the Lax pair

$$\phi_{xx} = \tfrac{1}{4}[1-\mu(V_{xx}-V)]\phi, \tag{16}$$

$$\phi_\mu = \left(\frac{V}{\mu} - \frac{2}{\mu^2}\right)\phi_x - \frac{1}{2}\frac{V_x}{\mu}\phi. \tag{17}$$

It was the existence of Dirichlet series solutions for integrable PDEs that motivated the work in Refs. 6 and 7. Here we have an integrable ODE which also admits formal Dirichlet series solutions. In fact the ODE (3) can be obtained from the classification in Ref. 7. It can also be obtained[12] as a similarity reduction of the now famous Fuchsteiner–Fokas–Camassa–Holm (FFCH) equation,[13,14]

$$UU_{xxx} + 2U_xU_{xx} - 3UU_x + U_{xxt} - U_t - 2\kappa U_x = 0. \tag{18}$$

It is to this question of integrability to which we now turn. We consider Dirichlet series solutions for PDEs, as well as modifications of such for equations where compatibility conditions are not satisfied. Perhaps the best way to begin is to summarize briefly the results of Refs. 6 and 7. This we now do.

III. DIRICHLET SERIES FOR PDEs

In Ref. 12, the Painlevé analysis of the class of nonsemilinear PDEs

$$F \equiv F_1 + F_2 = 0, \tag{19}$$

where

$$F_1 = UU_{xxx} + \beta U_xU_{xx} - p^2(\beta + 1)UU_x, \tag{20}$$

$$F_2 = \epsilon U_{xxt} - U_t - 2\kappa U_x, \tag{21}$$

was considered. It was shown that no equation in this class survived the combination of the Painlevé ODE (Ref. 15) and PDE (Ref. 16) tests. In particular, since the FFCH equation is contained in this class, the drawbacks of Painlevé analysis for certain classes of equations—as first observed by Weiss for the Dym equation[5]—were confirmed. It also led to the question, posed in Ref. 12, of how many other equations in this class are actually integrable, in spite of not passing the Painlevé tests.

Remarkably, it turns out that the class of equations (19) does contain another completely integrable PDE, namely the Degasperis–Procesi (DP) equation,[17]

$$UU_{xxx} + 3U_xU_{xx} - 4UU_x + U_{xxt} - U_t = 0. \tag{22}$$

Further, as is clear from the results presented in Ref. 12, this PDE also fails to survive the Painlevé tests: in fact, this PDE admits the weak Painlevé expansion

$$U = -\psi'(t) + \phi^{1/2}(x,t)\sum_{j=0}^{\infty} U_{j/2}(t)\phi^{j/2}(x,t), \quad \phi(x,t) = x + \psi(t), \tag{23}$$

where ψ, U_0, and U_1 are three arbitrary functions of t. This then highlights the need for some simple and directly applicable test—analogous to the Painlevé tests—capable of identifying completely integrable differential equations in such a class.

We note that a partial answer to the question of which PDEs in the class (19) are completely integrable has been given in Ref. 18, as follows. First we observe that in the case $p \neq 0$ we may assume, without loss of generality, that $p=1$ (in the later sections of this paper we prefer to include the parameter p—as did the authors of Ref. 12—so that the known equations in the class (19) can be taken in standard form). That is, when $p \neq 0$, an appropriate rescaling yields

$$UU_{xxx} + \beta U_x U_{xx} - (\beta + 1)UU_x + \hat{\epsilon} U_{xxt} - U_t - 2\kappa U_x = 0, \tag{24}$$

where $\hat{\epsilon} = p^2 \epsilon$. If in addition we have $(\beta+1)\hat{\epsilon} \neq 1$, we may use a Galilean transformation to set $\kappa = 0$.[12] Of the resulting equations,

$$UU_{xxx} + \beta U_x U_{xx} - (\beta + 1)UU_x + \hat{\epsilon} U_{xxt} - U_t = 0, \tag{25}$$

it was shown in Ref. 18 that in the special case $\hat{\epsilon} = 1$, only those having $\beta = 2$ or $\beta = 3$ are completely integrable. This relied on a quasilocal extension of the symmetry approach, so that in this case $\hat{\epsilon} = 1$, (25) is expressed in evolution form using the operator $\Delta = (1 - \partial^2/\partial x^2)^{-1}$, with higher symmetries containing nestings of Δ. The case $\beta = 2$ corresponds to the FFCH equation, and $\beta = 3$ to the DP equation.

However, as indicated above, one of our aims here is to explore the relationship between a simple property of solutions, easily testable for a much wider class of equations, i.e., their expression as formal Dirichlet series, and integrability. It was with this aim in mind that in Refs. 6 and 7 the following class of equations was considered:

$$E \equiv E_1 + E_2 = 0, \tag{26}$$

where

$$E_1 = UU_{xxx} + \beta U_x U_{xx} - (\beta + 1)UU_x \tag{27}$$

and

$$\begin{aligned} E_2 = {} & a(t) + b(t)U + c_0(t)U_x + c_1(t)U_t + d_0(t)U_{xx} + d_1(t)U_{xt} + d_2(t)U_{tt} \\ & + e_0(t)U_{xxx} + e_1(t)U_{xxt} + e_2(t)U_{xtt} + e_3(t)U_{ttt}, \end{aligned} \tag{28}$$

i.e., where E_1 consists of quadratic terms equivalent to those of (19) for $p \neq 0$, and E_2 consists of all possible linear terms up to and including third derivatives.

Motivated by the observation that not only does the FFCH equation (18) admit the exact solution[12]

$$U = f(t)e^{-x} - \kappa + g(t)e^{x}, \tag{29}$$

but also a generalization having the form of a Dirichlet series,

$$U = e^{-x} \sum_{j=0}^{\infty} U_j(t) e^{jx}, \tag{30}$$

where U_0, U_2, and U_3 are three arbitrary functions of t, it was shown in Refs. 6 and 7 that for each of the choices $\beta = 2$ and $\beta = 3$ in (26), the only equations admitting Dirichlet series solutions can be transformed back onto the only known integrable equation within that class (FFCH and DP, respectively). These results suggest a connection between Dirichlet series solutions and certain classes of integrable equations.

We note that the construction of a Dirichlet series solution such as (30), here for the FFCH equation, proceeds in the same way as in the ODE case: we have dominant and nondominant terms (E_1 and E_2, respectively), the former determining the leading order behavior and also which coefficients are left arbitrary. We then have compatibility conditions to be satisfied, in order that our solution remains a series in powers of exponentials only. When a compatibility condition is not satisfied the series has to be modified by the inclusion of powers of x (higher and higher powers for higher powers of e^x). We also note that if instead of x in (30) we have $x - \eta(t)$, we can always absorb the factor $e^{-j\eta(t)}$ into the coefficient $U_j(t)$.

In order to explore the connection between Dirichlet series solutions and integrability, we consider the construction of Dirichlet series solutions for a wide variety of PDEs. We begin in Sec. IV with various examples of PDEs in the class (19). For example, we will see in Sec. IV A that the

Fornberg–Whitham equation[21] does not admit Dirichlet series solutions, and so this PDE differs in this respect from the integrable FFCH and DP equations; this example also allows us to illustrate the modification of a putative Dirichlet series solution with powers of x in the case of failed compatibility conditions. We will also see that in the case $\hat{\epsilon}=1$, all equations in the class (25) admit Dirichlet series solutions for all integer $\beta \geqslant 2$, and thus while there is indeed a strong connection between Dirichlet series solutions and integrability, the admission of Dirichlet series solutions is not sufficient for integrability. In Sec. V we give further examples of integrable PDEs, but in multidimensions rather than 1+1, that admit Dirichlet series solutions. In Sec. VI we consider some technical points, such as convergence, and the connection between our approach and basic solution techniques for linear ODEs; we also consider more general Dirichlet-type series, but find that even integrable equations may require that such nonstandard Dirichlet series solutions be modified by including powers of x. We return to a discussion of the connection between integrability and Dirichlet series solutions in Sec. VII; a summary of our conclusions is given in Sec. VIII.

IV. EXAMPLES IN 1+1 DIMENSIONS

A. The Fornberg–Whitham equation

In this section we consider the Fornberg–Whitham (FW) equation,[19–21]

$$G[U] \equiv UU_{xxx} + 3U_xU_{xx} - UU_x + U_{xxt} - U_t - U_x = 0, \tag{31}$$

which corresponds to the parameter choice $(\epsilon, p^2, \beta, \kappa) = \left(1, \frac{1}{4}, 3, \frac{1}{2}\right)$ in Eq. (19).

We begin by seeking a leading order term for our Dirichlet series,

$$U \sim U_0(t)e^{px}, \quad U_0(t) \neq 0. \tag{32}$$

Substitution into the quadratic terms of the equation gives

$$UU_{xxx} + 3U_xU_{xx} - UU_x \sim p(4p^2 - 1)U_0^2 e^{2px} \tag{33}$$

and so we have the possible leading order (dominant) behaviors $U \sim U_0(t)e^{\pm(1/2)x}$. Corresponding to these leading order behaviors we obtain the recursion relations

$$j(j \pm 1)(j \pm 2)U_j = R_j, \tag{34}$$

for the coefficients of our Dirichlet series, where R_j is now a function not only of previous coefficients but also of their derivatives. Thus, corresponding respectively to the cases $p=-\frac{1}{2}$ and $p=\frac{1}{2}$, we seek solutions of the form

$$U = e^{-(1/2)x}\sum_{2j=0}^{\infty} U_j(t)e^{jx} = e^{-(1/2)x}(U_0(t) + U_{1/2}(t)e^{1/2x} + U_1(t)e^{x} + \cdots), \tag{35}$$

where the coefficients U_0, U_1, and U_2 will be left arbitrary, and

$$U = e^{1/2x}\sum_{2j=-\infty}^{0} U_j(t)e^{jx} = e^{1/2x}(U_0(t) + U_{-(1/2)}(t)e^{-(1/2)x} + U_{-1}(t)e^{-x} + \cdots), \tag{36}$$

where the coefficients U_0, U_{-1}, and U_{-2} will be left arbitrary.

Here we consider the case $p=-\frac{1}{2}$. Substitution of (35) into (31) yields

$$G[U] = e^{-x}\sum_{2j=0}^{\infty} G_j e^{jx} = 0, \tag{37}$$

where

$$G_0 = 0, \tag{38}$$

$$G_{1/2} = \tfrac{1}{8}(4U_0 + 3U_0U_{1/2} - 6U_0'), \tag{39}$$

$$G_1 = -U_{1/2}', \tag{40}$$

$$G_{3/2} = -\tfrac{1}{8}(4U_1 + 3U_{1/2}U_1 + 3U_0U_{3/2} + 6U_1'), \tag{41}$$

$$G_2 = -U_{3/2}, \tag{42}$$

and $'$ is used to denote derivatives with respect to t. We see that U_0 is left arbitrary, and that $U_{1/2}$ is determined by the equation $G_{1/2}=0$ as

$$U_{1/2} = -\frac{4}{3} + 2\frac{U_0'}{U_0}. \tag{43}$$

The equation $G_1=0$ does not determine U_1, which is left arbitrary. However, we have the compatibility condition $U_{1/2}'=0$, a condition not satisfied for arbitrary U_0. Moreover, we see that even if we were to have a satisfied compatibility condition at $j=1$, we would still have another compatibility condition to be satisfied at $j=2$. That is, the FW equation does not admit Dirichlet series solutions of the form (35).

The series (35), in order to satisfy the FW equation, needs to be modified by the inclusion of powers of x. Thus, instead of (35), we seek a solution of the form

$$\begin{aligned} U = e^{-(1/2)x}&(U_0 + U_{1/2}e^{(1/2)x} + (U_{1,0} + U_{1,1}x)e^{x} + (U_{3/2,0} + U_{3/2,1}x)e^{(3/2)x} \\ &+ (U_{2,0} + U_{2,1}x + U_{2,2}x^2)e^{2x} + (U_{5/2,0} + U_{5/2,1}x + U_{5/2,2}x^2)e^{(5/2)x} + \cdots), \end{aligned} \tag{44}$$

where as before all coefficients are functions of t. Substitution into (31) then gives

$$G[U] = e^{-x}\sum_{2j=0}^{\infty} \tilde{G}_j e^{jx} = 0, \tag{45}$$

where each $\tilde{G}_j$ is now polynomial in x:

$$\tilde{G}_0 = 0, \tag{46}$$

$$\tilde{G}_{1/2} = \tfrac{1}{8}(4U_0 + 3U_0U_{1/2} - 6U_0'), \tag{47}$$

$$\tilde{G}_1 = -U_0U_{1,1} - U_{1/2}', \tag{48}$$

$$\begin{aligned} \tilde{G}_{3/2} = &-\tfrac{1}{8}[4U_1 + 3U_{1/2}U_{1,0} + 8U_{1,1} + 2U_{1/2}U_{1,1} + 3U_0U_{3/2,0} + 2U_0U_{3/2,1} \\ &+ 6U_{1,0}' - 8U_{1,1}'] - \tfrac{1}{8}[4U_{1,1} + 3U_{1/2}U_{1,1} + 3U_0U_{3/2,1} + 6U_{1,1}']x, \end{aligned} \tag{49}$$

$$\begin{aligned} \tilde{G}_2 = &[2U_{1,0}U_{1,1} + 3U_{1,1}^2 - U_{3/2,0} - U_{3/2,1} + 2U_{1/2}U_{3/2,1} + 2U_0U_{2,1} \\ &+ 6U_0U_{2,2} + 2U_{3/2,1}'] + [2U_{1,1}^2 - U_{3/2,1} + 4U_0U_{2,2}]x, \end{aligned} \tag{50}$$

with $\tilde{G}_{5/2}$ being quadratic in x.

We see, as before, that U_0 is arbitrary, and that $U_{1/2}$ is determined by $\tilde{G}_{1/2}=0$ to be as given in (43). However at $j=1$, $U_{1,0}$ is left arbitrary, and $\tilde{G}_1=0$ determines the coefficient $U_{1,1}$. At j

$=3/2$, the equation $\tilde{G}_{3/2}=0$ determines both $U_{3/2,1}$ and $U_{3/2,0}$. Then at $j=2$, $U_{2,0}$ is left arbitrary and the equation $\tilde{G}_2=0$ determines $U_{2,2}$ and $U_{2,1}$. The equation $\tilde{G}_{5/2}=0$ determines the three coefficients $U_{5/2,2}$, $U_{5/2,1}$, and $U_{5/2,0}$. Our modified series therefore contains three arbitrary coefficients, U_0, $U_{1,0}$, and $U_{2,0}$. We thus see how a putative Dirichlet series needs to be modified in the case of failed compatibility conditions, so that the modified series satisfies the PDE/ODE and contains the predicted number of arbitrary coefficients. In Sec. VI we explain this modification process in terms of basic solution techniques for linear ODEs.

We now briefly remark on an alternative procedure which allows us to obtain a solution of the FW equation of the form (35), albeit not containing three arbitrary functions of t. This can be done by insisting that the compatibility conditions (40) and (42) be satisfied: (40) requires that $(\log(U_0))''=0$, and so $U_0=ae^{bt}$ for some arbitrary $a,b\in\mathbb{C}$; (42) then requires that $(\log(U_1))'=-b$, and so $U_1=ce^{-bt}$ for some arbitrary $c\in\mathbb{C}$. Thus for these choices of U_0 and U_1 we have a solution of the form (35) containing one arbitrary function of t, namely U_2. In the special case $U_2=0$ this infinite series becomes finite to give the exact solution $U=ae^{-(1/2)(x-2bt)}+\left(2b-\frac{4}{3}\right)+ce^{(1/2)(x-2bt)}$, as obtained in Ref. 12.

B. The Rosenau–Hyman equation

We now consider the Rosenau–Hyman (RH) equation,[22]

$$H[U]\equiv UU_{xxx}+3U_xU_{xx}+UU_x-U_t=0, \tag{51}$$

which corresponds to the parameter choice $(\epsilon,p^2,\beta,\kappa)=\left(0,-\frac{1}{4},3,0\right)$ in Eq. (19).

Proceeding as for the FW equation, we obtain the leading order or dominant behaviors $U\sim U_0(t)e^{\pm(i/2)x}$, and the corresponding recursion relations

$$j(j\pm i)(j\pm 2i)U_j=R_j \tag{52}$$

for the coefficients of our Dirichlet series, where R_j is a function of previous coefficients and their derivatives. Thus, corresponding respectively to the cases $p=-(i/2)$ and $p=i/2$, we seek solutions of the form

$$U=e^{-(i/2)x}\sum_{2k=0}^{\infty}U_k(t)e^{kix}=e^{-(i/2)x}(U_0(t)+U_{1/2}(t)e^{(i/2)x}+U_1(t)e^{ix}+\cdots), \tag{53}$$

where U_0, U_1, and U_2 (corresponding to $j=0,i,2i$) will be left arbitrary, and

$$U=e^{(i/2)x}\sum_{2k=-\infty}^{0}U_k(t)e^{kix}=e^{(i/2)x}(U_0(t)+U_{-(1/2)}(t)e^{-(i/2)x}+U_{-1}(t)e^{-ix}+\cdots), \tag{54}$$

where U_0, U_{-1}, and U_{-2} (corresponding to $j=0,-i,-2i$) will be left arbitrary.

Here we consider the case $p=-(i/2)$. Substitution of (53) into (51) yields

$$H[U]=e^{-ix}\sum_{2k=0}^{\infty}H_ke^{kix}=0, \tag{55}$$

where

$$H_0=0, \tag{56}$$

$$H_{1/2}=-\tfrac{1}{8}i(3U_0U_{1/2}-8iU_0'), \tag{57}$$

$$H_1=-U_{1/2}', \tag{58}$$

$$H_{3/2} = \tfrac{1}{8} i(3U_{1/2}U_1 + 3U_0U_{3/2} + 8iU_1'), \tag{59}$$

$$H_2 = -U_{3/2}'. \tag{60}$$

Thus U_0 is left arbitrary, and $U_{1/2}$ is determined by the equation $H_{1/2}=0$ as

$$U_{1/2} = \frac{8}{3} i \frac{U_0'}{U_0}. \tag{61}$$

Then U_1 is left arbitrary, with compatibility condition $H_1=0$, or $U_{1/2}'=0$; this condition is not satisfied for arbitrary U_0. Further—as for the FW equation—even if this condition at $j=i$ were to be satisfied, we would still have another compatibility condition, $H_2=0$, to be satisfied at $j=2i$. Thus we see that the RH equation does not admit Dirichlet series solutions of the form (53).

The series (53), in order to satisfy the RH equation, needs to be modified by the inclusion of powers of x. Thus, instead of (53), we seek a solution of the form

$$\begin{aligned} U = e^{-(i/2)x}(U_0 + U_{1/2}e^{i/2x} + (U_{1,0} + U_{1,1}x)e^{ix} + (U_{3/2,0} + U_{3/2,1}x)e^{(3i/2)x} \\ + (U_{2,0} + U_{2,1}x + U_{2,2}x^2)e^{2ix} + (U_{5/2,0} + U_{5/2,1}x + U_{5/2,2}x^2)e^{(5i/2)x} + \cdots), \end{aligned} \tag{62}$$

where as before all coefficients are functions of t. Substituting into (51), we find that U_0, $U_{1,0}$, and $U_{2,0}$ are left arbitrary with all other coefficients in our series determined in terms of these three.

Once again, as for the FW equation, we can also obtain a solution of the RH equation of the form (53) but depending on less than three arbitrary functions of t, by insisting that the compatibility conditions (58) and (60) be satisfied. Condition (58) requires that $(\log(U_0))''=0$, and so $U_0=ae^{bt}$ for some arbitrary $a,b\in\mathbb{C}$. Then condition (60) requires that $U_1''-b^2U_1=0$, and so $U_1=ce^{-bt}+de^{bt}$ for some arbitrary $c,d\in\mathbb{C}$. For these choices of U_0 and U_1 we have a solution of the form (53) containing one arbitrary function of t, U_2. In the special case $U_2=0$ and $d=0$ this infinite series self-truncates to give the exact solution $U=ae^{-(i/2)(x+2bit)}+\frac{8}{3}bi+ce^{(i/2)(x+2bit)}$, as obtained in Ref. 12.

C. A further example in 1+1 dimensions

In Secs. IV A and IV B we have seen that the FW and RH equations fail to admit Dirichlet series solutions. In this they therefore differ from the completely integrable FFCH and DP equations. Of course, in general, the integrability of a nonsemilinear PDE not admitting (standard) Dirichlet series solutions remains an open question.

In this section we will see that it is not always the case that a nonintegrable equation fails to admit Dirichlet series solutions. That is, the admission of Dirichlet series solutions is not sufficient for integrability. In order to show this we will consider in this section a special case of the class of equations (19), namely those that can be put in the form (25) with $\hat{\epsilon}=1$, and in addition with β an integer $\geqslant 2$,

$$K[U] \equiv UU_{xxx} + \beta U_xU_{xx} - (\beta+1)UU_x + U_{xxt} - U_t = 0. \tag{63}$$

We know from Ref. 18 that only those equations (63) having $\beta=2$ or $\beta=3$ are completely integrable. However, as we will see, all equations (63) admit Dirichlet series solutions. We note that the FW and RH equations are not included in the class (63): for the FW equation, we cannot remove the U_x term, and in any case—as also for the RH equation—we do not have $\hat{\epsilon}=p^2\epsilon=1$ (see Sec. III).

Seeking a leading order behavior for a possible Dirichlet series solution of (63) leads to $U \sim U_0(t)e^{\pm x}$, with corresponding recursion relations

$$j(j\pm 2)(j\pm\beta\pm 1)U_j = R_j, \tag{64}$$

where R_j is a function of previous coefficients and their derivatives.

Here we consider the case $U \sim U_0(t)e^{-x}$. We claim that each equation in the class (63) has a Dirichlet series solution of the form

$$U = U_0(t)e^{-x} + U_2(t)e^{x} + \sum_{j=\beta+1}^{\infty} U_j(t)e^{(j-1)x}, \tag{65}$$

with U_0, U_2, and $U_{\beta+1}$ arbitrary. In order to show this, we substitute (65) into (63) to obtain

$$K[U] = e^{-2x}\sum_{j=0}^{\infty} K_j e^{jx} = 0, \tag{66}$$

and show that each K_j, for $j \leqslant \beta+1$, is identically zero. That is, we need to prove that (66) is in fact

$$K[U] = e^{-2x}\sum_{j=\beta+2}^{\infty} K_j e^{jx} = 0. \tag{67}$$

If this is so, then for $j \geqslant \beta+2$, each equation $K_j=0$ will determine U_j in terms of U_0, U_2, and $U_{\beta+1}$.

Our discussion of this example is simplified by the fact that all equations in class (63) can be written in the factorized form,[12]

$$K[U] = \left(U\frac{\partial}{\partial x} + \beta U_x + \frac{\partial}{\partial t}\right)(U_{xx} - U) = 0. \tag{68}$$

Setting

$$U = U_0(t)e^{-x} + U_2(t)e^{x} + U_{\beta+1}(t)e^{\beta x} + U_{\beta+2}(t)e^{(\beta+1)x} + \cdots, \tag{69}$$

we therefore calculate

$$U_{xx} - U = (\beta^2 - 1)U_{\beta+1}(t)e^{\beta x} + (\beta^2 + 2\beta)U_{\beta+2}(t)e^{(\beta+1)x} + \cdots, \tag{70}$$

and thus obtain

$$K[U] = [(\beta^2 + 2\beta)U_0(t)U_{\beta+2}(t) + (\beta^2 - 1)U'_{\beta+1}(t)]e^{\beta x} + \cdots = K_{\beta+2}e^{\beta x} + \cdots, \tag{71}$$

as required [compare with (67)].

Thus we see that all equations in the class (63) admit formal Dirichlet series solutions of the form (65). It then follows, using the discrete symmetry $(x,t) \to (-x,-t)$ of (63), that these equations also admit formal Dirichlet series of the form

$$U = \widetilde{U}_0(t)e^{x} + \widetilde{U}_{-2}(t)e^{-x} + \sum_{j=-\infty}^{-(\beta+1)} \widetilde{U}_j(t)e^{(j+1)x} \tag{72}$$

$$= \widetilde{U}_0(t)e^{x} + \widetilde{U}_{-2}(t)e^{-x} + \widetilde{U}_{-(\beta+1)}e^{-\beta x} + \widetilde{U}_{-(\beta+2)}e^{-(\beta+1)x} + \cdots, \tag{73}$$

where $\overline{U_0}(t)$, $\widetilde{U}_{-2}(t)$, and $\widetilde{U}_{-(\beta+1)}$ are arbitrary, and where all other coefficients in the series are determined in terms of these three.

V. EXAMPLES IN MULTIDIMENSIONS

A. The Kraenkel–Zenchuk system

We now turn to an example of a completely integrable PDE in multidimensions, namely the Kraenkel–Zenchuk (KZ) system,[23–25]

$$L_1 \equiv -m_t + um_x + 2mu_x = 0, \tag{74}$$

$$L_2 \equiv mu_y + u_x - u_{xx} - 2p_x = 0, \tag{75}$$

$$L_3 \equiv m^2 p_y + mp_x + mp_{xx} - pm_x - p_x m_x = 0, \tag{76}$$

which constitutes an extension of the FFCH equation to $2+1$ dimensions. This system fails the Painlevé PDE test: in fact it admits weak Painlevé expansions.[26] It thus behaves similarly to the FFCH and DP equations (see, respectively, Ref. 12 and Sec. III). Here we see that this system admits Dirichlet series solutions.

For this system, we find corresponding to the leading order behavior

$$u \sim u_0(y,t)e^{-x}, \quad m \sim m_0(y,t)e^{2x}, \quad p \sim p_0(y,t)e^{-x}, \tag{77}$$

where $p_0 = u_0$, and u_0 and m_0 are arbitrary, the recursion relation

$$\mathbf{J}\begin{pmatrix} u_j \\ m_j \\ p_j \end{pmatrix} \equiv \begin{pmatrix} 2jm_0 & ju_0 & 0 \\ -(j-2)(j-1) & 0 & -2(j-1) \\ 0 & 0 & j(j-3)m_0 \end{pmatrix}\begin{pmatrix} u_j \\ m_j \\ p_j \end{pmatrix} = \begin{pmatrix} R_{1j} \\ R_{2j} \\ R_{3j} \end{pmatrix}, \tag{78}$$

where R_{1j}, R_{2j}, and R_{3j} are functions of previous coefficients and their derivatives. Arbitrary coefficients will enter our expansions at values of j satisfying

$$\det \mathbf{J} = 0, \quad \text{i.e.,} \quad j^2(j-1)(j-2)(j-3) = 0. \tag{79}$$

At $j=0$, the two arbitrary coefficients are u_0 and m_0, as noted previously.

We therefore seek a Dirichlet series solution of the KZ system of the form

$$u = e^{-x}\sum_{j=0}^{\infty} u_j e^{jx}, \quad m = e^{2x}\sum_{j=0}^{\infty} m_j e^{jx}, \quad p = e^{-x}\sum_{j=0}^{\infty} p_j e^{jx}, \tag{80}$$

with $p_0 = u_0$. Substitution into the KZ system yields

$$L_1 = e^{x}\sum_{j=0}^{\infty} L_{1j}e^{jx} = 0, \quad L_2 = e^{-x}\sum_{j=0}^{\infty} L_{2j}e^{jx} = 0, \quad L_3 = e^{x}\sum_{j=0}^{\infty} L_{3j}e^{jx} = 0, \tag{81}$$

where L_{10}, L_{20}, and L_{30} are identically zero, and where of course for $j \geqslant 1$ [compare (78)], we have $(L_{1j}, L_{2j}, L_{3j})^T = \mathbf{J}(j)(u_j, m_j, p_j)^T - (R_{1j}, R_{2j}, R_{3j})^T$.

At $j=1$, we see from (78) that one of the coefficients u_1 or m_1 will be left arbitrary, and that we have as corresponding compatibility condition $L_{21}=0$. This compatibility condition is satisfied. We then use the equation $L_{31}=0$ to determine p_1, and $L_{11}=0$ to determine m_1, leaving u_1 arbitrary. At $j=2$, we see from (78) that one of u_2 or m_2 will be left arbitrary, and that the corresponding compatibility condition is $m_0 L_{22} - L_{32} = 0$. This condition is satisfied. We then use the equation $L_{32}=0$ to determine p_2, and $L_{12}=0$ to determine m_2, leaving u_2 arbitrary. At $j=3$, we see that one of the coefficients u_3, m_3, or p_3 will be left arbitrary, and that the corresponding compatibility condition is $L_{33}=0$. Again, the compatibility condition is satisfied. We then use the equation $L_{23}=0$ to determine p_3, and $L_{13}=0$ to determine m_3, leaving u_3 arbitrary. All coefficients in the series (81) are then determined in terms of the five arbitrary coefficients u_0, m_0, u_1, u_2, and u_3. This number of arbitrary coefficients is consistent with the order of the KZ system (see also Ref. 26). Thus we see that we have another example of a weak Painlevé but completely integrable system which admits Dirichlet series solutions.

B. A further example in 2+1 dimensions

Here we consider an alternative generalization of the FFCH equation to $2+1$ dimensions, one based on a nonisospectral scattering problem: discussions of such scattering problems can be found for example in Refs. 27–29, as well as in Refs. 8 and 9. This completely integrable equation,

$$M[U] \equiv \tfrac{1}{2}U_{xxxx}U_y + U_{xxx}U_{xy} - \tfrac{1}{2}U_{xx}U_y - U_{xy}U_x + U_{xxxt} - U_{xt} = 0, \tag{82}$$

was given in Ref. 30. The reduction

$$U(x,y,t) = W(z,\tau), \quad z = x + y, \quad \tau = \tfrac{1}{2}t, \tag{83}$$

yields the FFCH equation in W_z, with $\kappa = 0$ (which is anyway equivalent to the case $\kappa \neq 0$; see Sec. III).

We note in passing that Eq. (82) admits a solution in the form of a weak Painlevé expansion,

$$U = U_{(-5/3)} - \frac{1}{\psi_y}(2\psi_t + U_{(-5/3),y})\phi + \phi^{5/3}\sum_{j=0}^{\infty} U_{j/3}\phi^{j/3}, \tag{84}$$

where all coefficients $U_{(-5/3)}, U_0, U_{1/3}, U_{2/3}, \ldots$ are functions of (y,t), and $\phi = x + \psi(y,t)$.

The expansion (84) contains four arbitrary functions $(U_{(-5/3)}, \psi, U_0, U_{2/3})$ of (y,t), corresponding to the resonances $-5/3, -1, 0, 2/3$, respectively. We note that for this equation the negative resonance at $-5/3$ can be catered for by introducing an extra coefficient at constant level (i.e., at level ϕ^0); for a further example where this can be done we refer to Ref. 26. We also remark that the term at level ϕ in (84) is an additional lower order term which corrects the balancing of terms in the leading order analysis. Further examples of the use of such an additional term, although at constant level rather than level ϕ, can be found in Ref. 12, as well as in Refs. 26 and 31; see also the weak Painlevé expansion for the DP equation given in Sec. III.

We now turn to the construction of Dirichlet series solutions for Eq. (82). Proceeding as in previous sections, we obtain for Eq. (82) the leading order behaviors $U \sim U_0(y,t)e^{\pm x}$, with corresponding recursion relations

$$j(j \pm 1)(j \pm 2)(j \pm 3)U_j = R_j, \tag{85}$$

where R_j is a function of previous coefficients and their derivatives.

Let us consider the case $U \sim U_0(y,t)e^{-x}$, corresponding to which we seek a Dirichlet series solution

$$U = e^{-x}\sum_{j=0}^{\infty} U_j(y,t)e^{jx}, \tag{86}$$

where the coefficients U_0, U_1, U_2, and U_3 will be left arbitrary. Substitution of (86) into (82) yields

$$M[U] = e^{-2x}\sum_{j=0}^{\infty} M_j e^{jx}, \tag{87}$$

where M_0, M_1, M_2, and M_3 are all identically zero. Thus we see that all compatibility conditions are satisfied, and that Eq. (82) does indeed admit formal Dirichlet series solutions of the form (86), with U_0, U_1, U_2, and U_3 arbitrary, and all other coefficients determined in terms of these four.

It then follows, using the discrete symmetry $(x,t) \to (-x,-t)$ of Eq. (82), that this equation also admits formal Dirichlet series solutions of the form

$$U = e^x \sum_{j=-\infty}^{0} \tilde{U}_j(y,t) e^{jx}. \tag{88}$$

Thus Eq. (82) provides a further example of a completely integrable PDE, again in $2+1$ dimensions, which admits formal Dirichlet series solutions.

VI. TECHNICAL CONSIDERATIONS

In previous sections we have considered the construction of formal Dirichlet series solutions of a certain form, with coefficients determined recursively by linear algebraic equations (thus in the present paper we do not consider series having coefficients determined by a sequence of differential equations), for a wide variety of differential equations. We now turn to some technical points related to such series solutions, including how our approach can be understood as an extension of basic solution techniques for linear ODEs.

A. Convergence

We have not, for the examples presented in earlier sections, considered the convergence or otherwise of the Dirichlet series solutions constructed. Here—rather than considering general approaches to proving convergence—we present a simple ODE example which shows us that such series solutions can be convergent, in which case they do give meaningful information about the behavior of solutions. In particular, we see that a Dirichlet series solution may indeed turn out to represent a solution which is analytic in some half-plane (see comments in Sec. II). This is in turn related to a second motivation behind the discussion in this section, which is the question of whether Dirichlet series are not, for certain equations, better suited to the representation of solutions than Painlevé expansions.

We consider the ODE

$$N[U] \equiv UU_{xx} - 2U_x^2 + UU_x = 0, \tag{89}$$

for which we obtain the leading order behaviors $U \sim U_0 e^{px}$ (U_0 constant), with $p=1$ or $p=0$. We note that here, in the absence of any additional linear terms, the choice $p=0$ is allowed.

Corresponding to $p=1$, i.e., $U \sim U_0 e^x$, we obtain the recursion relation

$$j(j-1)U_j = R_j \tag{90}$$

for the coefficients of our Dirichlet series, where R_j is a function of previous coefficients. In this case we therefore seek a Dirichlet series solution

$$U = e^x \sum_{j=0}^{\infty} U_j e^{jx}. \tag{91}$$

Substitution into (89) yields

$$N[U] = e^{2x} \sum_{j=0}^{\infty} N_j e^{jx}, \tag{92}$$

where N_0 and N_1 are identically zero. Thus we obtain a formal Dirichlet series solution (91), with U_0 and U_1 arbitrary and all other coefficients determined in terms of these two.

Meanwhile, for the case $p=0$, i.e. $U \sim \tilde{U}_0$, we obtain the recursion relation

$$j(j+1)\tilde{U}_j = R_j \tag{93}$$

for the coefficients of our Dirichlet series, R_j being a function of previous coefficients. We now therefore seek a Dirichlet series solution

$$U = \sum_{j=-\infty}^{0} \tilde{U}_j e^{jx}. \tag{94}$$

Substitution into our Eq. (89) yields

$$N[U] = \sum_{j=-\infty}^{0} \tilde{N}_j e^{jx}, \tag{95}$$

where $\tilde{N}_0$ and $\tilde{N}_{-1}$ are identically zero. We therefore obtain a formal Dirichlet series solution (94), with $\tilde{U}_0$ and $\tilde{U}_{-1}$ arbitrary, and all other coefficients determined in terms of these two.

Each of the series solutions (91) and (94) is in fact summable. The ODE (89) has the general solution

$$U = \frac{Ae^x}{B - e^x}, \tag{96}$$

where A, $B \in \mathbb{C}$ are two arbitrary constants of integration. This function can be represented by the Dirichlet series

$$U = e^x \sum_{j=0}^{\infty} \left(\frac{A}{B^{j+1}} \right) e^{jx}, \tag{97}$$

for $\mathrm{Re}(x) < \log|B|$, and also by the Dirichlet series

$$U = \sum_{j=-\infty}^{0} \left(\frac{-A}{B^j} \right) e^{jx}, \tag{98}$$

for $\mathrm{Re}(x) > \log|B|$. We can identify (97) with (91), with $U_0 = A/B$ and $U_1 = A/B^2$, and thus conclude that (91) is convergent to a solution analytic in the left half-plane $\mathrm{Re}(x) < \log|U_0/U_1|$. Similarly, we can identify (98) with (94), with $\tilde{U}_0 = -A$ and $\tilde{U}_{-1} = -AB$. Thus we see that (94) is convergent to a solution analytic in the right half-plane $\mathrm{Re}(x) > \log|\tilde{U}_{-1}/\tilde{U}_0|$.

The function (96) is of course analytic except for simple poles spaced at intervals of 2π along the line $\mathrm{Re}(x) = \log|B|$. The general solution of the ODE (89) therefore has no movable branched singularities, and so has the Painlevé property. We note that since these poles are at $x = \log|B| + i \arg B$, their locations depend on the value of (one of) the constants of integration, and so they are movable. The two Dirichlet series represent the function (96) on either side of this line of poles. Thus our Dirichlet series solutions seem to be much more suited to the representation of the general solution of this ODE than the usual Painlevé expansion, which would only give a solution convergent in a punctured disk of radius 2π, centered at a pole (although it is this last that gives information about the nature of the singularities).

B. Linear and multilinear differential equations

We have developed a method of seeking solutions in the form of Dirichlet series for differential equations having a set of constant-coefficient multilinear terms, illustrated using examples where these terms are quadratic, or bilinear; we use these terms to determine possible leading orders. However, the simplest example where our approach can be applied is that of the constant-coefficient linear ODE,

$$\left(\prod_{j=1}^{N} (D - \mu_j)^{n_j} \right) U = f(x), \quad D = \frac{d}{dx}, \tag{99}$$

where $n_j \in \mathbb{N}$ and $\mu_j \in \mathbb{C}$, and where for our purposes it is sufficient to assume that

$$f(x) = \sum_{j=1}^{N} P_j(x) e^{\mu_j x}, \tag{100}$$

for some polynomials P_j of x. In the case where all $n_j = 1$ and all $P_j(x) \equiv 0$, the general solution of this ODE consists of a linear combination of terms $e^{\mu_j x}$,

$$U = \sum_{j=1}^{N} A_j e^{\mu_j x}, \quad A_j \in \mathbb{C}. \tag{101}$$

If the constants μ_j lie on a line in the complex plane [of course, since the equation is linear, the general solution (101) can always be decomposed into a sum of solutions U_k, where this is true for each U_k], this solution can be understood as a *finite* Dirichlet series [compare (2)]. Such a Dirichlet series, when some $n_j > 1$, or some $P_j(x) \not\equiv 0$, needs, in order to give the general solution of the ODE, to be modified by the inclusion of powers of x; in the language used earlier, we would say that in the case where some $P_j(x) \not\equiv 0$ we have a failed compatibility condition at the resonance μ_j. The use of infinite Dirichlet series represents the extension of such basic solution techniques for linear ODEs to nonlinear differential equations.

C. Doubly infinite series

Here we simply comment that Dirichlet-type series of a more general form than the standard Dirichlet series (2) may be used to represent solutions of differential equations. For example, the ODE

$$P[U] \equiv U_{xx} + 3e^x U U_x - U_x + e^{2x} U^3 = 0 \tag{102}$$

has the general solution

$$U = \frac{1}{e^x - A} + \frac{1}{e^x - B}, \tag{103}$$

which—assuming $|A| < |B|$—can be represented by the series

$$U = e^{-x} \sum_{j=-\infty}^{\infty} U_j e^{jx} \tag{104}$$

for $\log|A| < \mathrm{Re}(x) < \log|B|$, where

$$U_j = \begin{cases} 1/A^j & j \leqslant 0, \\ -1/B^j, & j > 0. \end{cases} \tag{105}$$

Thus we have a representation of the general solution of the ODE (102) as a doubly infinite series, which is convergent in the strip $\log|A| < \mathrm{Re}(x) < \log|B|$, rather than in a half-plane.

The general solution (103) of Eq. (102) is analytic except for simple poles, and so this equation has the Painlevé property. There are two families of simple poles, spaced at intervals of 2π along the lines $\mathrm{Re}(x) = \log|A|$ and $\mathrm{Re}(x) = \log|B|$; since the locations of these poles, at $x = \log|A| + i \arg A$ and $x = \log|B| + i \arg B$, depend on the constants of integration, they are movable. The series (104) provides a representation of the general solution in the strip between these two lines of poles. Clearly, in addition to (104), we also have the Dirichlet series solutions

$$U = \sum_{j=0}^{\infty} \left(-\frac{1}{A^{j+1}} - \frac{1}{B^{j+1}} \right) e^{jx} \tag{106}$$

and

$$U = e^{-x} \sum_{j=-\infty}^{0} \left(\frac{1}{A^j} + \frac{1}{B^j} \right) e^{jx}, \tag{107}$$

convergent for $\mathrm{Re}(x) < \log|A|$ and $\mathrm{Re}(x) > \log|B|$, respectively. Together, the three series solutions given above provide representations of the general solution of Eq. (102) in all the complex plane except on the two lines $\mathrm{Re}(x) = \log|A|$ and $\mathrm{Re}(x) = \log|B|$. As with our previous example discussed in Sec. VI A, such series solutions appear to be much more suited to representing the general solution of this ODE than would be the usual Painlevé expansion. Of course, this is because of the form of the general solution; as remarked in Sec. I, there is no reason why the general solution of any given ODE should admit such a representation. However, for this ODE, such series seem more appropriate than Taylor or Laurent series. We also note that this example demonstrates the possibility of seeking Dirichlet-type series solutions when we have nonautonomous dominant terms.

D. A perturbative technique

In all of our examples so far, except for the ODE discussed in Sec. VI A, we have excluded from consideration the leading order behavior $p=0$, on the grounds that the terms of highest nonlinearity are then no longer dominant over the other terms in the equation. However, the possibility of $p=0$ occurring as a leading order behavior is one that needs to be taken into account. Here we consider two examples, one an ODE and one a PDE: we find that even for integrable differential equations it may happen that series solutions in terms of exponentials require modification by the inclusion of power of x. Our results are obtained using a perturbative approach.

1. An ODE example

Here we consider the ODE

$$Q[U] \equiv UU_{xxx} + 2U_xU_{xx} - 3UU_x = 0, \tag{108}$$

which consists of the quadratic terms of the FFCH equation, and also of the ODE (3). As mentioned in Sec. II, $p=0$ occurs as a possible leading order behavior of solutions of this ODE (in addition to $p=\pm 1$ and corresponding to these the series obtained from those of FFCH via the reduction $\partial/\partial t=0$ and $\kappa=0$). For this choice $p=0$, we obtain the recursion relation

$$j(j^2-3)U_j = R_j, \tag{109}$$

and so we have resonances at $j=0, \pm\sqrt{3}$. Corresponding to this leading order behavior, we find that we can construct a Dirichlet series solution of the form

$$U = U_0 + U_{\sqrt{3}}e^{\sqrt{3}x} + U_{2\sqrt{3}}e^{2\sqrt{3}x} + U_{3\sqrt{3}}e^{3\sqrt{3}x}\cdots, \tag{110}$$

where U_0 and $U_{\sqrt{3}}$ are arbitrary constants, and with all remaining coefficients (constants) being determined in terms of these two. It then follows, from the discrete symmetry $x \to -x$ of the ODE (3), that we also have a Dirichlet series solution

$$U = U_0 + U_{-\sqrt{3}}e^{-\sqrt{3}x} + U_{-2\sqrt{3}}e^{-2\sqrt{3}x} + U_{-3\sqrt{3}}e^{-3\sqrt{3}x} + \cdots, \tag{111}$$

this having the same coefficients as the Dirichlet series solution (110).

However, in order to construct a solution of our third order ODE containing three arbitrary constants—one for each resonance—a different approach needs to be used. Thus we consider a perturbation about the constant solution $U=U_0$,

$$U = U_0 + \epsilon V + \epsilon^2 W + \epsilon^3 Z + \cdots, \tag{112}$$

which then gives a sequence of ODEs, the first three of which are

$$U_0(V_{xxx} - 3V_x) = 0, \tag{113}$$

$$U_0(W_{xxx} - 3W_x) = 3VV_x - 2V_xV_{xx} - VV_{xxx}, \tag{114}$$

$$U_0(Z_{xxx} - 3Z_x) = 3WV_x + 3W_xV - 2W_{xx}V_x - 2W_xV_{xx} - WV_{xxx} - W_{xxx}V. \tag{115}$$

As a solution of (113) we take

$$V = V_{-\sqrt{3}}e^{-\sqrt{3}x} + V_{\sqrt{3}}e^{\sqrt{3}x}, \tag{116}$$

where $V_{-\sqrt{3}}$ and $V_{\sqrt{3}}$ are two arbitrary constants corresponding to the resonances $j=\pm\sqrt{3}$ (we already have an arbitrary constant corresponding to the resonance $j=0$ at order ϵ^0). For this choice of V, we then take as solution of Eq. (114)

$$W = W_{-2\sqrt{3}}e^{-2\sqrt{3}x} + W_{2\sqrt{3}}e^{2\sqrt{3}x}, \tag{117}$$

where $W_{-2\sqrt{3}}$ and $W_{2\sqrt{3}}$ are determined as

$$W_{-2\sqrt{3}} = -\frac{1}{3}\frac{(V_{-\sqrt{3}})^2}{U_0}, \quad W_{2\sqrt{3}} = -\frac{1}{3}\frac{(V_{\sqrt{3}})^2}{U_0}, \tag{118}$$

and where, since we already have three arbitrary coefficients in (112), we do not include any further such here. Then as a solution of Eq. (115) we take

$$Z = Z_{-3\sqrt{3}}e^{-3\sqrt{3}x} + Z_{-\sqrt{3}}xe^{-\sqrt{3}x} + Z_{\sqrt{3}}xe^{\sqrt{3}x} + Z_{3\sqrt{3}}e^{3\sqrt{3}x}, \tag{119}$$

whose four coefficients, determined in terms of U_0, $V_{-\sqrt{3}}$ and $V_{\sqrt{3}}$, are in the general case nonzero. We note that, formally, since at each order of ϵ we need to introduce higher powers of $e^{\pm\sqrt{3}x}$, our perturbation results in a doubly infinite series. We see from the above that, at order ϵ^3, we need to introduce powers of x into (112).

2. A PDE example

We now consider the following nonsemilinear PDE:

$$R[U] \equiv U_{xxxx}U_t + 2U_{xxx}U_{xt} - U_{xx}U_t - 2U_xU_{xt} = 0, \tag{120}$$

which corresponds to the reduction $\partial/\partial t=0$ (with y then relabelled as t) of Eq. (82). In the absence of additional linear terms, in addition to $p=\pm 1$ and the corresponding series obtained by reduction from those in Sec. V B, $p=0$ is a possible leading order behavior. Corresponding to this choice $p=0$, we obtain the recursion relation

$$j^2(j^2-1)U_j = R_j, \tag{121}$$

and so the resonances $j=0,0,\pm 1$. Proceeding as in the previous section, we take

$$U = U_0 + \epsilon V + \epsilon^2 W + \cdots, \tag{122}$$

i.e., we make a perturbation about the solution $U=U_0(t)$. We thus obtain a sequence of PDEs, the first two of which are

$$U_0'(V_{xxxx} - V_{xx}) = 0, \tag{123}$$

$$U_0'(W_{xxxx} - W_{xx}) = -V_{xxxx}V_t - 2V_{xxx}V_{xt} + V_{xx}V_t + 2V_xV_{xt}. \tag{124}$$

As solution of the first of the above, we take

$$V = V_{-1}(t)e^{-x} + V_0(t)x + V_1(t)e^{x}, \tag{125}$$

where V_{-1}, V_0, and V_1 are three arbitrary functions of t, and as solution of the second

$$W = W_{-1}(t)xe^{-x} + W_0(t)x^2 + W_1(t)xe^{x}, \tag{126}$$

where

$$W_{-1} = \frac{V_0 V_{-1}'}{U_0'}, \quad W_0 = -\frac{V_0 V_0'}{U_0'}, \quad W_1 = \frac{V_0 V_1'}{U_0'}. \tag{127}$$

Thus we have four arbitrary functions of t (U_0, V_{-1}, V_0, and V_1), one corresponding to each of the resonances $j=0,0,\pm 1$. We see that for this example, consideration of the case $p=0$ leads to the introduction of powers of x in our perturbation expansion, basically because of the double resonance at $j=0$. Given that the PDE (120) is completely integrable—it has the Lax pair

$$\psi_{xx} = \tfrac{1}{4}[1 - \lambda(U_{xxx} - U_x)]\psi, \tag{128}$$

$$\psi_t = \tfrac{1}{2}\lambda U_t \psi_x - \tfrac{1}{4}\lambda U_{xt}\psi, \tag{129}$$

—this then implies that needing to modify such a formal series solution with powers of x is not enough to claim non-integrability. However, as we will see in Sec. VII, for some PDEs we can establish a direct link between needing to modify a (standard) Dirichlet series solution in this way and their apparent nonintegrability.

VII. DISCUSSION: DIRICHLET SERIES AND INTEGRABILITY

One of the main aims of this paper has been to explore, for nonsemilinear PDEs, the connection between integrability and Dirichlet series solutions. Our motivation was the work in Refs. 6 and 7 where not only was it observed that the FFCH and DP equations admit standard Dirichlet series solutions, but also that, for certain classes of PDEs, the only equations admitting such solutions were transformable back onto the only known completely integrable PDEs within those classes. Here we have given other examples of completely integrable nonsemilinear PDEs, both in $1+1$ and multidimensions, which admit standard Dirichlet series solutions.

However, we have also seen that nonintegrable PDEs may admit Dirichlet series solutions; that is, the admission of Dirichlet series solutions is not sufficient for integrability. This result might be as expected, since such series—even if convergent—provide only partial information about the behavior of solutions. Thus, the techniques explored here should be regarded as being *complementary* to known techniques (e.g., Painlevé analysis, and the use of hodograph transformations). [The ODE (3), for example, while admitting standard Dirichlet series solutions, also has branched solutions; we have the weak Painlevé expansion $V=(x-x_0)^{2/3}\Sigma_{j=0}^{\infty}V_{j/3}(x-x_0)^{j/3}$, where x_0, V_0, and $V_{2/3}$ are arbitrary. Consideration of the function

$$U = \frac{1}{(e^x - A)^{1/2}}$$

is also instructive.]

We have also seen, using a perturbative approach, that generalized Dirichlet series solutions of integrable PDEs may require modification by the inclusion of powers of x; examples include Eq. (120), as well as, by implication from the results of Sec. VI D 1, the FFCH equation. Strictly speaking, this tells us that the admission of Dirichlet series solutions (allowing here, as we should, such more general formulations within our definition) is not a necessary condition for integrability. Of course, there is no reason to expect a simple relationship between integrability and Dirichlet series, especially given the well known problems that equations of the type being considered here present for other integrability tests, e.g. for the Painlevé tests. However, it may also be that we should, as in the previous papers on classification using Dirichlet series,[6,7] restrict our attention to

standard Dirichlet series; it is certainly the case that in Refs. 6 and 7 the use of standard Dirichlet series isolated what were essentially the FFCH and DP equations. (Of course, a complete classification of integrable equations in the classes considered in Refs. 6 and 7 remains an open problem.)

We conclude this section with an example where modification by powers of x of a standard Dirichlet series solution can be directly related to the apparent nonintegrability of a PDE, although of course in general the integrability of a nonsemilinear PDE not admitting such Dirichlet series solutions remains an open question. This PDE is the x-derivative of the FFCH equation,

$$S[U] \equiv (UU_{xxx} + 2U_xU_{xx} - 3UU_x + U_{xxt} - U_t - 2\kappa U_x)_x = 0, \tag{130}$$

and has for the leading order behaviors $U \sim U_0(t)e^{\pm x}$ the recursion relations

$$j(j \pm 2)^2(j \pm 3)U_j = R_j, \tag{131}$$

and so resonances $j = 0, \mp 2, \mp 2, \mp 3$. We know from our results for the FFCH equation that, corresponding to the leading order behavior $U \sim U_0(t)e^{-x}$, the PDE (130) has a standard Dirichlet series solution

$$U = e^{-x}\sum_{j=0}^{\infty} U_j(t)e^{jx}, \tag{132}$$

with U_0, U_2, and U_3 arbitrary. However, because of the double resonance at $j=2$, this solution needs to be modified. As a solution of Eq. (130) we therefore obtain

$$\begin{aligned} U = e^{-x}(&U_0(t) + U_1(t)e^x + (U_{2,0}(t) + U_{2,1}(t)x)e^{2x} + (U_{3,0}(t) + U_{3,1}(t)x)e^{3x} \\ &+ (U_{4,0}(t) + U_{4,1}(t)x)e^{4x} + (U_{5,0}(t) + U_{5,1}(t)x + U_{5,2}(t)x^2)e^{5x} + \cdots), \end{aligned} \tag{133}$$

where now U_0, $U_{2,0}$, $U_{2,1}$, and $U_{3,0}$ are arbitrary. Thus we see that we need to modify our standard Dirichlet series solution by including powers of x. [Similarly for the series corresponding to the leading order behavior $U \sim U_0(t)e^x$; alternatively we may use in (133) the discrete symmetry $(x,t) \to (-x,-t)$ of Eq. (130).]

The extra resonance at $j=2$, when compared to the leading order behavior $U \sim U_0(t)e^{-x}$ of the FFCH equation, arises because of the overall x-derivative in Eq. (130). Meanwhile, the travelling wave reduction $U(x,t) = W(z) - m$, $z = x + mt$, yields the ODE

$$WW_{zzz} + 2W_zW_{zz} - 3WW_z - \alpha W_z + \beta = 0, \tag{134}$$

where the constant α is defined as $\alpha = 2\kappa - 2m$, and β is a constant of integration. A nonlinear time transformation (following Ref. 32) then yields an ODE which does not have the Painlevé property, in contrast to the case of the FFCH equation itself discussed in Ref. 32. This is then suggestive of the nonintegrability of Eq. (130); for details see Ref. 31, where a $2+1$-dimensional version of this PDE is considered. The reason why the ODE obtained from Eq. (134) does not have the Painlevé property is because of the constant of integration β, which arises precisely because of the overall x-derivative in Eq. (130). Thus we see that the inclusion of powers of x in the standard Dirichlet series solution (132)—to obtain the modified Dirichlet series solution (133)—can be directly related to the apparent nonintegrability of the PDE (130). It is worth recalling here that the x-derivative of the completely integrable modified Korteweg–de Vries equation, $(U_t - U_{xxx} + 6U^2U_x)_x = 0$, fails the Weiss–Tabor–Carnevale Painlevé test,[16] and so is presumably nonintegrable.

VIII. CONCLUSIONS

Our main conclusions are as follows:

(1) For certain classes of equations, there is a strong connection between standard Dirichlet series solutions and integrability. This follows from Refs. 6 and 7, and from our results for the integrable and nonintegrable equations discussed here.
(2) This connection is, however, difficult to unravel: standard Dirichlet series solutions are not sufficient for integrability and, despite the results presented here, we remain at this stage reluctant to claim necessity.
(3) For some equations, Dirichlet-type series give useful representations of solutions. However, information about singularities enters such series in a nontrivial way. Thus we regard our approach as complementary to known techniques, e.g., Painlevé analysis (to study singularities) or hodograph transformations.

(Received 30 October 2004; accepted 20 January 2005; published online 22 March 2005)

We study the dynamics of a one-dimensional Bloch electron subjected to a constant electric field. The periodic potential is supposed to be less singular than the δ-like potential (Dirac comb). We give a rigorous proof of Ao's result that for a large class of initial conditions (high momentum regime) there is no localization in momentum space. The proof is based on the mathematical substantiation of the two simplifying assumptions made in physical literature: the transitions between far away bands can be neglected and the transitions at the quasicrossing can be described by Landau–Zener-type formulas. Using the connection between the above model and the driven quantum ring (DQR) shown by Avron and Nemirovski, our results imply the increase of energy for weakly singular such DQR and appropiate initial conditions. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1870732]

I. INTRODUCTION

The dynamics of Bloch electrons (i.e., electrons subjected to a periodic potential) in the presence of a homogeneous electric field is among those topics that appeared since the beginning of the quantum theory of the solid state physics but are still alive today for both mathematical and physical reasons; in particular the emergence of superlattices leads to interesting physics (see, e.g., Ref. 31).

The dynamics of an electron in one dimension subjected to a periodic potential $V_{\mathrm{per}}(x)$ and a constant electric field $E=-eF$ is described by the time-dependent Schrödinger equation,

$$i\hbar\frac{\partial\psi}{\partial t}(x,t)=H^{\mathrm{SW}}\psi(x,t)=\left(-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}-eFx+V_{\mathrm{per}}(x)\right)\psi(x,t), \tag{1.1}$$

where H^{SW} is the so-called Stark–Wannier Hamiltonian.

There is a large body of mathematically oriented literature about spectral properties of the Stark–Wannier Hamiltonian (especially concerning the Stark–Wannier ladder problem; see Refs. 8,9,10,22,24 and references therein). In particular the spectrum has been proved to be absolutely continuous for twice differentiable potentials[7] and recently, results about the nature of the spectrum were obtained for more singular potentials.[4,13,16,17,26]

On the contrary, at the rigorous level there are by far fewer results concerning the dynamics generated by H^{SW}. Of course, as well known, the results about spectral properties of H^{SW} lead to results about dynamics but they either concern finite (albeit long) intervals of time[24,25] or are only qualitative. As an example we mention the results of Avron and Nemirovski[5] on driven quantum

rings. They first proved the nice result that there is a close connection between driven quantum rings and Stark–Wannier Hamiltonians. Then, using this connection and the fact mentioned above that the spectrum of H^{SW} is absolutely continuous for twice differentiable potentials they proved that the energy of a smoothly driven quantum ring grows indefinitely as $t\to\infty$ for arbitrary initial conditions.

At the physical level the dynamics generated by H^{SW} has been thoroughly studied (using the temporal gauge representation) both by analytical and numerical methods. Due to the difficulty of the problem two main assumptions are made.

(1) The only interband transitions considered are the ones between neighboring bands (the so-called Zener tunneling process[33] through avoided crossings); all the others are considered sufficiently small to be neglected.
(2) The transition probabilities can be computed approximatively via Landau–Zener type formulae.

Based on earlier developements,[12] the consequences of these assumptions were exhaustively discussed by Ao.[2] More precisely, writing the evolution at arbitrary times as a product of evolutions over half Bloch periods and using for the last ones the "scattering matrix" between adjacent bands given by Blatter and Browne[12] he reduced the original problem to a discrete dynamics, amenable to numerical and analytical study. The main result coming from his analysis is that for potentials more regular than the Dirac comb and a large class of initial conditions there is a propagating front for the Bloch electron (in other words it will escape at infinity). The Dirac comb is a critical border, one could have either propagation or localization (respectively, pure point, continuous spectrum spectrum or even mixed cases) depending upon the electric field strength and some resonance conditions.

At the rigorous level the existence of a propagating front (with quantitative estimates) for a large class of initial conditions as well as some spectral consequences has been recently proved in Ref. 3 for potentials more regular than the L^2_{loc} class.

The aim of this paper is to provide a rigorous justification of the simplifying assumptions (1) and (2) above in order to substantiate from the mathematical point of view at least a part of Ao's analysis. We do it for a class of periodic potentials whose Fourier coefficients, $\hat{V}(n)$, satisfy $|\hat{V}(n)|<\mathrm{const}|n|^{-r}$ for all $r>0$. Notice however that the results of Secs. III and IV are even valid for $r>-\frac{1}{2}$.

The need for a rigorous control comes from the fact that even if the errors involved in the assumptions (1) and (2) are "small" over a half Bloch period they acummulate during a long time evolution to the point of making irrelevant the approximate computation based on the discrete dynamics.

The problem turned out to be fairly complex for two reasons. First we are dealing with singular periodic potentials which leads to a definition in the form sense of the gauged Hamiltonian $\tilde{H}^{\mathrm{SW}}$ and second, we want to control the evolution over infinite intervals of time which demands a very good control of the errors involved.

The results in this paper allows us to prove the existence of a propagating front (which in turn implies the existence of continuous spectrum for H^{SW}) up to the Dirac comb [which corresponds to $\hat{V}(n)=1$ and is known as notoriously difficult]. Actually the Dirac comb case remains open, although it is not clear for us whether the present approach could provide as well some results in this case.

The plan of the paper is as follows. Section II contains the preliminaries: the direct integral representation of the Stark–Wannier Hamiltonian in the temporal gauge, the periodicity in time properties of the fiber Hamiltonian and the reduction to the one Bloch period. All that is done for $\tilde{H}^{\mathrm{SW}}$ defined as a quadratic form sum. Section II contains in addition a key technical estimate (Lemma 2.3) used many times in the following sections. Since the proof is technical and somehow long it was moved to the Appendix.

Section III contains the first main result of our paper (Theorem 3.1) saying that the transitions

over a half Bloch period, between far-away bands [neglected by assumption (1) in the physical literature] can be controlled by adiabatic techniques. The idea is that in adiabatic perturbation theory the relevant parameter is ε/Δ, where ε is the slowness parameter and Δ is the spectral gap. In our case it is the gap that grows with energy making thus the adiabatic machinery effective.

After the far-away decoupling in Sec. III we come to the "in-band" dynamics, i.e., to Zener transitions through quasicrossings at high energies. The task of computing this dynamics has been taken again and again in the physical literature. It consists in solving a 2×2 system of first order ordinary differential equations over a finite interval of time. There are two problems here. The first is that the coefficients are taken as given by a low order almost degenerate pertubation theory without any control of the reminder. Second, the obtained "Zener model" is solved over an infinite period of time. We cope with the first problem by using the reduction theory in Sec. IV to obtain an effective Hamiltonian (Theorem 4.1). Then we integrate the system over one-half period by the use of Dyson series; we compute the first two terms in Sec. V and estimate the remainder in the Appendix. The resulting "transfer matrix" is given in Theorem 5.1. We expect the results mentioned above to give a lot of information on spectral and dynamical properties of the Stark–Wannier (SW) and driven quantum ring models for fairly singular potentials. As an example in Sec. VI the results in the preceding sections are assembled to prove the Ao's statement about the the existence of a propagating front. As direct side consequences we obtain (see Corollary 6.4) that for $r>0$ the continuous spectrum of H^{SW} is not empty (see however the recent paper of Perelman[26] for a better result in this direction), that for a large class of initial conditions the energy of the DQR increases like t^2 (see Corollary 6.5) and that there is no localization in momentum space (see Corollary 6.6).

In the Appendix we state for convenience the Sz-Nagÿ transformation matrix. In order to make the reading of the paper easier we start each section by simply stating the theorems and lemmas, their proofs being provided later.

II. PRELIMINARIES

As already said in the introduction we are interested in the evolution given by the Stark–Wannier operator. For simplicity we normalize $e=\hbar=2m=1$. Moreover since the results we are going to prove along the paper do not depend upon the electric field strength, we set $F=1$. Accordingly the Stark–Wannier Hamiltonian writes

$$H^{\mathrm{SW}} = -\frac{d^2}{\mathrm{d}x^2} - x + V_{\mathrm{per}}, \tag{2.1}$$

where V_{per} is a real periodic potential with periodicity $a=2\pi$. Under these assumptions the quantity $2\pi\hbar/aF$, the so-called Bloch period, is equal to 1.

Let us define

$$\tilde{U}^{\mathrm{SW}}(t,s) := G(t)e^{-i(t-s)H^{\mathrm{SW}}}G(s)^*, \tag{2.2}$$

where $G(t)$ is the temporal gauge,

$$G(t)\psi(x,t) := e^{-ixt}\psi(x,t) =: \tilde{\psi}(x,t). \tag{2.3}$$

Actually $G(t)$ has the role of a boost to a free falling frame that eliminates the field. Then using (2.2) and (2.3) one has by direct computation,

$$i\frac{d}{\mathrm{d}t}\tilde{U}^{\mathrm{SW}}(t,s) = \left(\left(-i\frac{d}{\mathrm{d}x}+t\right)^2 + V_{\mathrm{per}}(x)\right)\tilde{U}^{\mathrm{SW}}(t,s) =: \tilde{H}^{\mathrm{SW}}(t)\tilde{U}^{\mathrm{SW}}(t,s).$$

As is well known the periodicity of V_{per} allows a direct integral representation for $\tilde{H}^{\mathrm{SW}}(t)$ via the Fourier–Bloch transform[28] which maps unitarily the space $L^2(\mathbb{R})$ onto $L^2([0,1),\mathrm{d}k,l^2(\mathbb{Z}))$,

$$(S\psi)(k,n) = \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} e^{-inx}\left\{\sum_{\gamma\in\mathbb{Z}} e^{-ik(x+2\pi\gamma)}\psi(x+2\pi\gamma)\right\}\mathrm{d}x. \tag{2.4}$$

Note that $(S\psi)(k,n)=(\mathcal{F}\psi)(k+n)$ where $\mathcal{F}$ is the Fourier transform. In this representation $\tilde{H}^{\mathrm{SW}}(t)$ reads as

$$S\tilde{H}^{\mathrm{SW}}(t)S^* = \int_{[0,1)}^{\oplus} H(k,t)\mathrm{d}k, \tag{2.5}$$

with the fiber Hamiltonian

$$H(k,t) \coloneqq H_0(k,t) + V. \tag{2.6}$$

We remark that $H(0,t)$ coincide with the Hamiltonian of the DQR when written in the Fourier representation (see, e.g., Ref. 5) so all the results below on the evolution $U(t,s)$, generated by $H(0,t)$ apply (see the Corollary 6.5 below) to the DQR problem. The unperturbed Hamiltonian $H_0(k,t)$ has a simple spectral representation

$$H_0(k,t) = \sum_{n\in\mathbb{Z}} E_{n,0}(k,t)P_{n,0}(k), \tag{2.7}$$

where

$$E_{n,0}(k,t) = (n+k+t)^2 \tag{2.8}$$

and $P_{n,0}(k)\coloneqq P_{n,0}$ is the projection on the nth vector, φ_n, from the canonical basis in $l^2(\mathbb{Z})$,

$$\varphi_{n,0}(m) = \delta_{n,m}. \tag{2.9}$$

The perturbation V is given by the following convolution in $l^2(\mathbb{Z})$:

$$(V\phi)(k,m) = \sum_{n\in\mathbb{Z}} \hat{V}(m-n)\phi(k,n), \tag{2.10}$$

$\hat{V}(n)$ being the Fourier coefficients of V_{per}. Since V_{per} is real we have $\hat{V}(n)=\overline{\hat{V}}(-n)$. Moreover we can choose $\hat{V}(0)=0$ (this amounts for a shift in the energy scale). We characterize different classes of perturbations by the norm

$$\|V\|_r \coloneqq \sup_{n\in\mathbb{Z}}\langle n\rangle^r|\hat{V}(n)| < \infty, \quad \langle n\rangle \coloneqq \sqrt{1+n^2} \quad r\in\mathbb{R}. \tag{2.11}$$

Notice that when r gets smaller and smaller, $\hat{V}(n)$ are allowed to decrease slower hence $V_{\mathrm{per}}(x)$ is more and more singular. Actually $V_{\mathrm{per}}(x)$ is to be considered as a tempered distribution on the one-dimensional torus $\mathbb{T}$ such that its Fourier series satisfies $\|V\|_r<\infty$. For $r>0$, $V_{\mathrm{per}}(x)$ is realized as an usual function while $r=0$ corresponds to δ-like potentials. For $r>\frac{1}{2}$, $V_{\mathrm{per}}(x)$ is square integrable over the unit cell, and then as well known,[28] V is $H_0(k,t)$ bounded with relative bound zero. As a consequence, by the Kato–Rellich theorem,[28] $H(k,t)$ is self-adjoint on the (time independent) domain of $H_0(k,t)$:

$$\mathcal{D}(H_0(k,t)) = \mathcal{H}^2 = \{\phi(n)|\langle n\rangle^2\phi(n) \in l^2(\mathbb{Z})\}. \tag{2.12}$$

In addition, the existence of a strongly continuous evolution $U(k;t,s)$, generated by $H(k,t)$ is assured by standard results (see Ref. 32 and Theorem X.70 in Ref. 27). We are mainly interested in the case of more singular potentials corresponding to $r\leqslant\frac{1}{2}$ and here the problem is more involved since as one can easily see [take, for example, $\hat{V}(n)=\langle n\rangle^{-1/2}$] V is no more $H_0(k,t)$ bounded. Notice that the time independent form domain of $H_0(k,t)$ is $\mathcal{Q}(H_0(k,t))=\mathcal{H}^1$

$=\{\phi(n)\,|\,\langle n\rangle\phi(n)\in l^2(\mathbb{Z})\}$. Then one can use the theory of Hamiltonians defined as quadratic forms.[27] More precisely, from

$$R_0(z,k,t) := \sum_{n\in\mathbb{Z}} \frac{P_{n,0}}{E_{n,0}(k,t)-z} \tag{2.13}$$

let us define

$$|R_0(z,k,t)|^{1/2} = \sum_{n\in\mathbb{Z}} \frac{P_{n,0}}{|E_{n,0}(k,t)-z|^{1/2}} \tag{2.14}$$

and

$$R_0(z,k,t)^{1/2} = \sum_{n\in\mathbb{Z}} \frac{\mathrm{sgn}(E_{n,0}(k,t)-z)P_{n,0}}{|E_{n,0}(k,t)-z|^{1/2}}. \tag{2.15}$$

Then $R_0(z,k,t)=R_0(z,k,t)^{1/2}|R_0(z,k,t)|^{1/2}$. The following operator, defined for $z\notin\sigma(H_0(k,t))$ will appear many times along the paper:

$$K(z,k,t) := |R_0(z,k,t)|^{1/2} V R_0(z,k,t)^{1/2}. \tag{2.16}$$

The fact that V is $H_0(k,t)$-bounded in the form sense with relative bound zero is implied by the following lemma.

Lemma 2.1: Let $r>-\frac{1}{2}$. Then uniformly in t and k,

$$\lim_{a\to\infty}\|K(-a^2,k,t)\| = 0. \tag{2.17}$$

As a consequence one can use the KLMN theorem[27] to define $H(k,t)$ as a form sum with form domain $\mathcal{H}^1$. The associated quadratic form is

$$\mathcal{H}^1 \ni \phi \to \sum_n |(n+k+t)\phi(k,n)|^2 + \sum_{m,n\in\mathbb{Z}} \hat{V}(m-n)\overline{\phi}(k,m)\phi(k,n). \tag{2.18}$$

Due to Lemma 2.1 one can write a useful formula for $R(z,k,t):=(H(k,t)-z)^{-1}$. Indeed, for sufficiently large a

$$R(-a^2,k,t) = R_0(-a^2,k,t)^{1/2}(1+K(-a^2,k,t))^{-1}|R_0(-a^2,k,t)|^{1/2}, \tag{2.19}$$

one has by analytic continuation

$$R(z,k,t) = R_0(z,k,t)^{1/2}(1+K(z,k,t))^{-1}|R_0(z,k,t)|^{1/2}. \tag{2.20}$$

Since $|R_0(z,k,t)|^{1/2}$ is compact, it follows from (2.19) that $R(z,k,t)$ is compact which implies (see Ref. 28) that the spectrum of $H(k,t)$ is discrete. In what concerns the evolution $U(k,s,t)$ generated by $H(k,t)$, as a corollary of Theorem 2.27 in Ref. 29 one has the following result assuring the existence of $U(k;s,t)$ in the weak sense.

Lemma 2.2: Let $\mathcal{H}^{-1}$ denote the space of continuous linear forms on $\mathcal{H}^1$. Then for every $\phi(k,0)\in H^1$ it exists a unique function $\phi(k,\cdot):\mathbb{R}\to H^1$ such that

(i) *$\mathbb{R}\ni t\to(\phi(k,t),\psi)$ is continuous for any $\psi\in H^{-1}$,*

(ii) *for every $f\in\mathcal{H}^1$,*

$$\frac{1}{i}\frac{d}{dt}(\phi(k,t),f) + (\phi(k,t),H(k,t)f) = 0.$$

(iii) *The map $U(k,t,s):\phi(k,s)\to\phi(k,t)$ is isometric and its extension by continuity is unitary in $l^2(\mathbb{Z})$.*

From (2.2) and (2.5) and Lemma 2.2 we can write the following formula for the Stark–Wannier evolution

$$e^{-i(t-s)H^{\mathrm{SW}}} = G(t)^* S^* \int_{[0,1)}^{\oplus} U(k,t,s)\mathrm{d}k\, SG(s), \tag{2.21}$$

so the study of $e^{-i(t-s)H^{\mathrm{SW}}}$ is reduced to the study of the family of evolutions $U(k,t,s)$ in $l^2(\mathbb{Z})$ generated by $H(k,t)$, and the rest of the paper will be devoted to this problem. From (2.6)–(2.10) it follows that $H(k,t)=H(0,k+t)$ and then

$$U(k,t,s) = U(0,k+t,k+s), \tag{2.22}$$

which means that one can restrict the analysis to the fiber $k=0$, and from now on we omit to write k when it is taken to be zero, e.g., $H(k=0,t)=H(t)$, $E_{n,0}(k=0,t)=E_{n,0}(t)$, etc. The next remark is that although $H(t)$ is not periodic in t there is a hidden periodicity. More precisely if T is the shift operator in $l^2(\mathbb{Z})$,

$$(T\psi)(n) = \psi(n-1) \tag{2.23}$$

then by direct computation one can see that

$$TH(k,t+1)T^* = H(k,t), \tag{2.24}$$

which in turn implies

$$U(t+1,s+1) = T^* U(t,s) T. \tag{2.25}$$

The analysis of $U(t,s)$ can be restricted to one period. We take the basic period to be the union of two half-periods,

$$t \in I_0 \cup I_1, \quad I_0 = \left[-\tfrac{1}{4},\tfrac{1}{4}\right), \quad I_1 = \left[\tfrac{1}{4},\tfrac{3}{4}\right). \tag{2.26}$$

Let us consider now in more detail the spectral properties of $H_0(t)$ and $H(t)$. We remark that when $t \in I_0 \cup I_1$, $H_0(t)$ has degeneracies at the points $t=0$ and $t=\frac{1}{2}$. Actually the splitting of one period into two half-periods is due to the existence of two points per period where $H_0(t)$ has degeneracies. Since the latter play a key role in the dynamics (due to the Zener transitions) the above structure suggests to describe $\sigma(H_0(t))$ inside I_l, $l=0,1$ as a union of pairs of eigenvalues that cross at $t=0$ and $t=\frac{1}{2}$. We define (see Fig. 1)

$$\sigma_{m,0}(t) \coloneqq E_{m-1,0}(t) \cup E_{-(m-1),0}(t) \quad \text{for } m \geqslant 1, \quad t \in I_0, \tag{2.27}$$

$$\tilde{\sigma}_{m,0}(t) \coloneqq E_{m-1,0}(t) \cup E_{-m,0}(t) \quad \text{for } m \geqslant 1, \quad t \in I_1, \tag{2.28}$$

so that $\sigma(H_0(t))=\cup_{m\geqslant 1}\sigma_{m,0}(t)$, $\sigma(H_0(t))=\cup_{m\geqslant 1}\tilde{\sigma}_{m,0}(t)$ on I_0 and I_1, respectively. An alternative way of labelling the eigenvalues of $H_0(t)$ is to count them in the increasing order

$$E_1^0(t) \leqslant E_2^0(t) \leqslant E_3^0(t) \cdots, \quad t \in \mathbb{R}. \tag{2.29}$$

Of course the two labellings are related, for a fixed α and a given t there exists an $n_\alpha(t)$ such that

$$E_\alpha^0(t) = E_{n_\alpha(t),0}(t) \quad \text{and } P_\alpha^0(t) = P_{n_\alpha(t),0}. \tag{2.30}$$

Let $t \in \left[-\frac{1}{2},0\right)+(N/2)$ with $N=0,1,2,\ldots$. Then the correspondence between α and $n_\alpha(t)$ is given as follows:

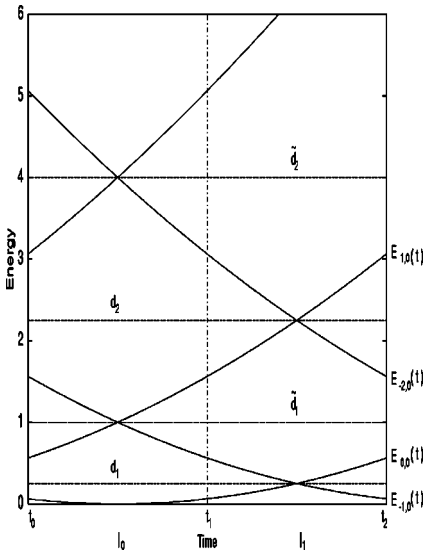

FIG. 1. The first eigenvalues of the free Hamiltonian $H_0(t)$ as a function of time and the horizontal lines $d_m, \tilde{d}_m$ used in Lemma 2.3. The intervals I_0 and I_1 are also marked.

$$n_\alpha(t) = \begin{cases} \dfrac{\alpha - N}{2} & \text{if } N \text{ and } \alpha \text{ have the same parity,} \\ -\dfrac{\alpha + N - 1}{2} & \text{if } N \text{ and } \alpha \text{ have different parities.} \end{cases} \tag{2.31}$$

With this labelling one has

$$\sigma_{1,0}(t) = E_1^0(t), \quad \sigma_{m,0}(t) = E_{2m-2}^0 \cup E_{2m-1}^0 \quad \text{for } t \in I_0, \tag{2.32}$$

$$\tilde{\sigma}_{m,0}(t) = E_{2m-1}^0 \cup E_{2m}^0 \quad \text{for } t \in I_1. \tag{2.33}$$

The spectral projections of $H_0(t)$ corresponding to $\sigma_{m,0}(t)$ and $\tilde{\sigma}_{m,0}(t)$ are denoted $Q_{m,0}$ and $\tilde{Q}_{m,0}$,

$$Q_{1,0} = P_{0,0}, \quad Q_{m,0} = P_{m-1,0} + P_{-(m-1),0} \quad \text{for } t \in I_0, \tag{2.34}$$

$$\tilde{Q}_{m,0} = P_{m-1,0} + P_{-m,0} \quad \text{for } t \in I_1. \tag{2.35}$$

By construction, for any $m = 1, 2, \ldots$ and $t \in I_0$, $\sigma_{m,0}(t)$ are well separated. Similarly, for $t \in I_1$ $\tilde{\sigma}_{m,0}(t)$ are well separated,

$$\inf_{t \in I_0} \operatorname{dist}(\sigma_{m,0}(t), \sigma_{m+1,0}(t)) = m - \tfrac{1}{2},$$

$$\inf_{t \in I_1} \operatorname{dist}(\tilde{\sigma}_{m,0}(t), \tilde{\sigma}_{m+1,0}(t)) = m. \tag{2.36}$$

Moreover, at the end of the interval I_0, the two eigenvalues composing $\sigma_{m,0}(t)$ [with the exception of $\sigma_{1,0}(t)$ which consists in just one eigenvalue] are well separated, e.g.,

$$E^0_{2m-1}\left(-\tfrac{1}{4}\right) - E^0_{2m-2}\left(-\tfrac{1}{4}\right) = m - 1. \tag{2.37}$$

The same is true for the two eigenvalues composing $\tilde{\sigma}_{m,0}(t)$. We come now to the spectral properties of $H(t)$.

Since $K\left(n+\frac{1}{2},t\right)$ tends to zero as n tends to infinity, uniformly with respect to t the analytic perturbation theory of type *B*, see Ref. 15, Chap. VII, works here as long as $r > -\frac{1}{2}$. More precisely if we label the eigenvalues of $H(t)$ in increasing order $E_\alpha(t)$, $\alpha = 1,\ldots$ then $\lim_{\alpha\to\infty}(E_\alpha(t) - E^0_\alpha(t)) = 0$. In addition for $t \neq 0, \frac{1}{2}$, when all the eigenvalues are nondegenerate the corresponding spectral projections $P_\alpha(t)$ are close the unperturbed ones, $\lim_{\alpha\to\infty}\|P_\alpha(t) - P^0_\alpha(t)\| = 0$. In the following $\varphi_\alpha(t)$ denotes the eigenfunction of $H(t)$ corresponding to the eigenvalue $E_\alpha(t)$.

Let

$$\Gamma_m = \left\{\left(m - \tfrac{1}{2}\right)^2 + iy | y \in \mathbb{R}\right\}, \quad \tilde{\Gamma}_m = \{m^2 + iy | y \in \mathbb{R}\} \quad m = 1,2,\ldots \tag{2.38}$$

be vertical lines in the energy plane. In what follows, each time a quantity will be bounded from above by a positive constant, this will be denoted by C, while for the lower bounds we denote it c.

The main estimates, used many times along the paper are contained in the following.

Lemma 2.3: Let $A < \infty$. Then for each $r > -\frac{1}{2}$ there exists a constant C_V independent of m and a positive integer N_r such that for any $m > N_r$ the following estimate holds:

$$\sup_{t\in I_0}\left(\sup_{z\in\Gamma_m}\|K(z,t)\| + \int_{\Gamma_m}\|R_0(z,t)\|\cdot\|K(z,t)\|dy\right) + \sup_{t\in I_1}\left(\sup_{z\in\tilde{\Gamma}_m}\|K(z,t)\| + \int_{\tilde{\Gamma}_m}\|R_0(z,t)\|\cdot\|K(z,t)\|dy\right)$$
$$+ \max_{t=-1/4,1/4}\left(\sup_{z\in\Gamma_m\cup\tilde{\Gamma}_m}\|K(z,t)\| + \int_{\Gamma_m\cup\tilde{\Gamma}_m}\|R_0(z,t)\|\cdot\|K(z,t)\|dy\right) \leqslant C_V b(m), \tag{2.39}$$

where

$$b(m) := \frac{\log^2\langle 4m-1\rangle}{\langle m\rangle^{1+\min\{0,2r\}}}. \tag{2.40}$$

Also one has

$$\lim_{y\to\infty}\sup_{t\in I_0}\sup_{x\leqslant A}\|K(x+iy,t)\| = 0. \tag{2.41}$$

Let $m > 1$, $d_m := \left(m-\frac{1}{2}\right)^2$, $\tilde{d}_m := m^2$ and γ_m, $\tilde{\gamma}_m$ be closed finite contours that intersect the real axis in and only in d_m, d_{m-1} and $\tilde{d}_m$, $\tilde{d}_{m-1}$ [for example, γ_m can be a square of length $8(m-1)$]. Then there exist an absolute constant C such that

$$\sup_{t\in I_0}\sup_{z\in\gamma_m}\|K(z,t)\| \leqslant C\|K(d_m,0)\|, \tag{2.42}$$

$$\sup_{t\in I_1}\sup_{z\in\tilde{\gamma}_m}\|K(z,t)\| \leqslant C\|K(\tilde{d}_m,0)\|. \tag{2.43}$$

Due to the above lemma we are able to give upper bounds of the type $(C_V\langle b(m)\rangle)^N$. In the following we shall say that a quantity A is of order $(\mathcal{O}_r(\langle b(m)\rangle)^N)$ if it obeys the estimate $\|A\| \leqslant (C_V\langle b(m)\rangle)^N$. The subscript r reminds us the dependence on $\|V\|_r$. We notice that the third line in (2.39) follows at once from the estimates of the first and the second lines. As we have said, the proof of the lemma is postponed to the Appendix.

Now we are ready to spell the spectral properties of $H(t)$. We shall consider only $t \in I_0$; the results and the proofs for $t \in I_1$, with the appropiate identifications, are the same. The first remark

is that there exists an m^* such that for any $m>m^*$ the norm of $K(z,t)$ is smaller than $\frac{1}{2}$. Second, for all $t\in I_0$ $d_m\in\rho(H(t))$ and for all $t\in I_1$ $\tilde{d}_m\in\rho(H(t))$. Moreover, $\tilde{d}_m\in\rho(H(-\frac{1}{4}))$.

Corollary 2.4: Let $m>m^*$. Then

$$\min\{\inf_{t\in I_0}\operatorname{dist}(d_m,\sigma(H(t))),\inf_{t\in I_1}\operatorname{dist}(\tilde{d}_m,\sigma(H(t)))\}\geqslant cm. \tag{2.44}$$

Let $Q_m(t)$ the spectral projection associated to $\sigma_m(t)=(d_{m-1},d_m)\cap\sigma(H(t))$. Then one has the following.

Corollary 2.5: For m sufficiently large or V small enough

$$\sup_{t\in I_0}\|Q_m(t)-Q_{m,0}\|\leqslant C_V b(m). \tag{2.45}$$

Let for $\alpha=2m-2,2m-1$ [see (2.31)],

$$P_\alpha^0\left(-\tfrac{1}{4}\right)=P_{n_\alpha(-1/4),0},\quad \varphi_\alpha^0\left(-\tfrac{1}{4}\right)=\varphi_{n_\alpha(-1/4),0}, \tag{2.46}$$

and $P_{2m-2}\left(-\frac{1}{4}\right)$, $P_{2m-1}\left(-\frac{1}{4}\right)$ the spectral projections of $H\left(-\frac{1}{4}\right)$ corresponding to the intervals $(d_{m-1},\tilde{d}_{m-1})$ and $(\tilde{d}_{m-1},d_m)$, respectively. Then the following estimate holds.

Corollary 2.6: Let $\alpha=2m-2,2m-1$. Then for $m>m^*$,

$$\left\|P_\alpha\left(-\tfrac{1}{4}\right)-P_\alpha^0\left(-\tfrac{1}{4}\right)\right\|\leqslant C_V b(m). \tag{2.47}$$

For sufficiently large m, by Sz-Nagÿ lemma (see the Appendix), $P_\alpha\left(-\frac{1}{4}\right)$ and $P_\alpha^0\left(-\frac{1}{4}\right)$ are unitarily equivalent so that $H\left(-\frac{1}{4}\right)$ has nondegenerate eigenvalues in $(d_{m-1},\tilde{d}_{m-1})$ and $(\tilde{d}_{m-1},d_m)$, respectively. They are denoted by $E_{2m-2}\left(-\frac{1}{4}\right)$ and $E_{2m-1}\left(-\frac{1}{4}\right)$. Moreover, if $N_\alpha\left(-\frac{1}{4}\right)$ is the Sz-Nagÿ transformation corresponding to the pair $P_\alpha\left(-\frac{1}{4}\right)$, $P_\alpha^0\left(-\frac{1}{4}\right)$ then

$$\varphi_\alpha\left(-\tfrac{1}{4}\right)=N_\alpha\left(-\tfrac{1}{4}\right)\varphi_\alpha^0\left(-\tfrac{1}{4}\right) \tag{2.48}$$

are eigenvectors of $H\left(-\frac{1}{4}\right)$ corresponding to $E_\alpha\left(-\frac{1}{4}\right)$. We say that an eigenbasis $\{\varphi_\alpha\left(-\frac{1}{4}\right)\}_{\alpha=1}^\infty$ of $H\left(-\frac{1}{4}\right)$ is a canonical one if for sufficiently large α (such that all the above construction works) $\varphi_\alpha\left(-\frac{1}{4}\right)$ is given by (2.48). In the same way one constructs canonical bases for $t=\frac{1}{4}$. For $t_l:=-\frac{1}{4}+(l/2)$, $l=2,3,\ldots$ the canonical bases are provided by [see (2.24)]

$$T\varphi_\alpha(t_l+1)=\varphi_\alpha(t_l). \tag{2.49}$$

Before going to the proofs let us write the reduction to one period formula (2.25) in the canonical basis.

Lemma 2.7: Let l be even, $t_0=-\frac{1}{4}$, $t_l=t_0+(l/2)$. Then for α and β sufficiently large

$$\langle\varphi_\alpha(t_l+1),U(t_l+1,t_l)\varphi_\beta(t_l)\rangle=\langle\varphi_\alpha(t_2),U(t_2,t_0)\varphi_\beta(t_0)\rangle. \tag{2.50}$$

Now we present the proofs for the lemmas and corollaries given above.

Proof of Lemma 2.1: We estimate the Hilbert–Schmidt norm of $K(-a^2,k,t)$,

$$\begin{aligned}\|K(-a^2,k,t)\|^2\leqslant\|K(-a^2,k,t)\|_{\mathrm{HS}}^2&\leqslant\|V\|_r^2\sum_{m,n\in\mathbb{Z}}\frac{1}{(m+k+t)^2+a^2}\langle m-n\rangle^{-2r}\frac{1}{(n+k+t)^2+a^2}\\&\leqslant\|V\|_r^2\left(\frac{\sqrt{5}}{2}\right)^{\max\{-2r,0\}}\sum_{m\in\mathbb{Z}}\frac{\langle m\rangle^{\max\{-2r,0\}}}{(m+k+t)^2+a^2},\end{aligned}$$

where in the last line we used the inequality

$$\langle m-n\rangle^{-2r} \leqslant \left(\frac{\sqrt{5}}{2}\langle m\rangle\langle n\rangle\right)^{\max\{-2r,0\}}. \tag{2.51}$$

Then the above series is convergent for $r>-\frac{1}{2}$ and the lemma is proved using the Lebesque dominated convergence theorem. □

Proof of Corollary 2.4: $R(d_m,t)$ can be written as

$$R(d_m,t) = |R_0(d_m,t)|^{\frac{1}{2}}(1+K(d_m,t))^{-1}R_0(d_m,t)^{\frac{1}{2}}. \tag{2.52}$$

Taking into account that $\mathrm{dist}(d_m,\sigma(H_0(t))) \geqslant cm$ one obtains from (2.52),

$$\|R(d_m,t)\| \leqslant 2\||R_0(d_m,t)|^{1/2}\|\cdot\|R_0(d_m,t)^{1/2}\| = 2\|R_0(d_m,t)\| \leqslant 2(Cm)^{-1}, \tag{2.53}$$

which implies $\inf_{t\in I_0}\mathrm{dist}(d_m,\sigma(H(t))) \geqslant cm$. The proof of the inequality $\mathrm{dist}\left(\tilde{d}_m,\sigma\left(H\left(-\frac{1}{4}\right)\right)\right) \geqslant Cm/2$ is similar. □

Proof of Corollary 2.5: By perturbation theory

$$Q_m(t)-Q_{m,0} = -\frac{i}{2\pi}\int_{\gamma_m} R_0(z,t)^{1/2}K(z,t)(1+K(z,t))^{-1}|R_0(z,t)|^{1/2}\,\mathrm{d}z.$$

Taking the norms, using that $\oint_{\gamma_m}\|R_0(z,t)\|\mathrm{d}z \leqslant C$ the estimate (2.45) follows from (2.42) and (2.39).

Proof of Corollary 2.6: Similar to the proof of Corollary 2.5. □

Proof of Lemma 2.7: Direct computation using (2.25), (2.48), and (2.49). □

III. THE ADIABATIC THEOREM

As already said in the introduction our first task is to show that at high energies the most important "interband transitions" during a half Bloch period are the so-called Zener transitions, namely the ones between neighboring bands [e.g., on I_0 between $E_{2m-2}(t)$ and $E_{2m-1}(t)$]. This is nothing else but to claim that for $t,s\in I_0$ the subspace $Q_m(t)\mathcal{H}$ is almost invariant under the evolution $U(t,s)$. In this section we construct adiabatic evolutions $U_m^A(t,t_0)$ and $\tilde{U}_m^A(t,t_1)$ on I_0 and I_1, respectively, satisfying

$$U_m^A(t,t_0)Q_m(t_0)\mathcal{H} = Q_m(t)\mathcal{H}, \quad t\in I_0, \tag{3.1}$$

$$\tilde{U}_m^A(t,t_1)\tilde{Q}_m(t_1)\mathcal{H} = \tilde{Q}_m(t)\mathcal{H}, \quad t\in I_1, \tag{3.2}$$

and prove that they are close to $U(t,t_0)$ and $U(t,t_1)$, respectively. We consider first the half Bloch period I_0 and at the end indicate the changes for I_1. Let

$$Q_m^+(t) := \sum_{j=m+1}^{\infty} Q_j(t), \quad Q_m^-(t) := \sum_{j=1}^{m-1} Q_j(t), \quad t\in I_0, \tag{3.3}$$

and define $H_m^A(t)$ by

$$H_m^A(t) := H(t)-X_m(t) =: H(t) - iQ_m^+(t)\dot{Q}_m^+(t) - iQ_m(t)\dot{Q}_m(t) - iQ_m^-(t)\dot{Q}_m^-(t). \tag{3.4}$$

It turns out (see the proof of Lemma 3.4 below) that $X_m(t)$ are bounded hence $H_m^A(t)$ are self-adjoint on $\mathcal{D}(H(t))$. The adiabatic evolution $U_m^A(t,t_0)$ generated by $H_m^A(t)$ will be defined as the solution (in the weak sense, as in Lemma 2.2) of the equation

$$i\frac{d}{dt}U_m^A(t,t_0) = H_m^A(t)U_m^A(t,t_0), \quad U_m^A(t_0,t_0) = 1. \tag{3.5}$$

As in the case of standard adiabatic theorem of quantum mechanics, $U_m^A(t,t_0)$ has the intertwining property

$$Q_m(t) = U_m^A(t,t_0)Q_m(t_0)U_m^A(t,t_0)^*, \quad Q_m^{\pm}(t) = U_m^A(t,t_0)Q_m^{\pm}(t_0)U_m^A(t,t_0)^*, \tag{3.6}$$

i.e., the families of subspaces $Q_m(t)\mathcal{H}$, $Q_m^{\pm}(t)\mathcal{H}$ are invariant under $U_m^A(t,t_0)$. The proof is standard (Krein–Kato lemma[15,18,23]). For $t \in I_1$ one constructs in a similar way $\tilde{U}_m^A(t,t_1)$ by replacing $Q_j(t)$ by $\tilde{Q}_j(t)$. The main result of this section is to show that $U_m^A(t,t_0)$ and $U(t,t_0)$ are close.

Theorem 3.1: *For any $r > -\frac{1}{2}$ and m sufficiently large or $\|V\|_r$ small enough it holds,*

$$\sup_{t\in I_0}\|U(t,t_0) - U_m^A(t,t_0)\| \leqslant C_V b(m)\langle m\rangle^{-1}, \tag{3.7}$$

$$\sup_{t\in I_1}\|U(t,t_1) - \tilde{U}_m^A(t,t_1)\| \leqslant C_V b(m)\langle m\rangle^{-1}, \tag{3.8}$$

where C_V is a constant that depends on V and $b(m)$ was introduced in Lemma 2.3.

The basic steps of the proof are the standard ones but we must check the relevant estimates. Define

$$\Omega_m(t,t_0) := U_m^A(t,t_0)^* U(t,t_0), \tag{3.9}$$

and notice that $\|\Omega_m(t,t_0)-1\| = \|U_m^A(t,t_0) - U(t,t_0)\|$, so one is left with the estimation of $\|\Omega_m(t,t_0)-1\|$. Since a direct estimation of

$$i(\Omega_m(t,t_0) - 1) = \int_{t_0}^{t} \mathrm{d}s\; U_m^A(s,t_0)^* X_m(s) U_m^A(s,t_0)\Omega_m(s,t_0) \tag{3.10}$$

would give (see Lemma 3.4) a bound of order $\mathcal{O}_r(b(m))$, which is not accurate enough for the error estimates in the long time behavior we must follow the proof of the standard adiabatic theorem[6] and make "an integration by parts." More precisely we have the following.

Lemma 3.2: $X_m(t)$ can be written in the form (we omit for simplicity the time dependence),

$$X_m = [H, Y_m], \tag{3.11}$$

with

$$Y_m = \frac{1}{2\pi}\oint_{\gamma_m^-} \mathrm{d}z\, R(z)\{Q_m^- \dot{Q}_m^- - Q_m^+ \dot{Q}_m^+ Q_m^-\}R(z) + \frac{1}{2\pi}\oint_{\gamma_m} \mathrm{d}z\, R(z)\{Q_m \dot{Q}_m - Q_m^+ \dot{Q}_m^+ Q_m\}R(z). \tag{3.12}$$

Here γ_m^- is a closed contour around $\sigma(Q_m^- H(t))$. Now the integration by parts will give $\|\Omega_m(t,t_0)-1\|$ in terms of Y_m.

Lemma 3.3: If t belongs to I_0 the following estimate holds:

$$\|\,\Omega_m(t,t_0) - 1)\| \leqslant \|Y_m(t)\| + \|Y_m(t_0)\| + \int_{t_0}^{t} \mathrm{d}s(\|X_m(s)Y_m(s)\| + \|\dot{Y}_m(s)\|), \tag{3.13}$$

so we are left with verifying (3.11)–(3.13) and to estimate the norms in (3.13). The basic estimation is contained in the following.

Lemma 3.4: For m sufficiently large

$$\sup_{t\in I_0}(\|\dot{Q}_m(t)\| + \|\dot{Q}_m^-(t)\| + \|\dot{Q}_m^+(t)\|) \leqslant C_V b(m). \tag{3.14}$$

Notice that since $Q_m^+(t)=1-Q_m(t)-Q_m^-(t)$, we must only estimate $\|\dot{Q}_m(t)\|$ and $\|\dot{Q}_m^-(t)\|$. Taking Lemma 3.4 for granted we give now the proofs of Lemmas 3.2 and 3.3.

Proof of Lemma 3.2: Since by Lemma 3.4 $X_m(t)$ is bounded

$$\sup_{t\in I_0}\|X_m(t)\| \leqslant C_V b(m) \tag{3.15}$$

and in addition [remember that for an orthogonal projection valued function $E(t)$ $E(t)\dot{E}(t)E(t)=0$] $X_m(t)$ is off-diagonal with respect to the decomposition $\mathcal{H}=Q_m^+(t)\mathcal{H}\oplus Q_m\mathcal{H}\oplus Q_m^-\mathcal{H}$ one obtains $Y_m(t)$ as the solution of the commutator equation (3.11) by using Theorem 9.3 in Ref. 11. Actually one can verify that (3.12) solves (3.11) by straightforward computation. □

Proof of Lemma 3.3: We omit for simplicity the index m and the time dependence. Using the identity [see (3.11)]

$$i\frac{d}{dt}(U^{A^*}YU^A) = U^{A^*}\{i\dot{Y} - X + [X,Y]\}U^A$$

and replacing $U^{A^*}XU^A$ in (3.10) one has

$$\begin{aligned} i(\Omega-1) &= \int_{t_0}^t ds\left\{-i\frac{d}{ds}(U^{A^*}YU^A) + U^{A^*}[X,Y]U^A + iU^{A^*}\dot{Y}U^A\right\}\Omega \\ &= \int_{t_0}^t ds\left\{-i\frac{d}{ds}(U^{A^*}YU^A\Omega) + iU^{A^*}YU^A\dot{\Omega} + U^{A^*}[X,Y]U^A\Omega + iU^{A^*}\dot{Y}U^A\Omega\right\} \\ &= -iU^{A^*}YU^A\Omega|_{t_0}^t + \int_{t_0}^t ds\, U^{A^*}\{XY + i\dot{Y}\}U^A\Omega \end{aligned}$$

which in norm gives the claimed result. □

Proof of Lemma 3.4: We give detailed calculations only for $\dot{Q}_m^-(t)$. Computing Q_m perturbatively, using the identity $\dot{R}(z,t)=-R(z,t)\dot{H}(t)R(z,t)$ one has

$$\dot{Q}_m^-(t) = \frac{i}{2\pi}\oint_{\gamma_m^-} dz\{R_0(z)\dot{H}_0R_0(z)VR(z) + R_0(z)VR(z)\dot{H}R(z)\},$$

where we omited the explicit t dependence. To go further with the estimates we deform first γ_m^- to $\gamma_m^-(L) := \gamma_{m-1}(L)\cup\gamma'_{m-1}(L)\cup\gamma''_{m-1}(L)\cup\gamma_0(L)$ with

$$\gamma_{m-1}(L) := \{d_{m-1} + iy | y\in[-L,L]\}, \tag{3.16}$$

$$\gamma'_{m-1}(L) := \{x + iL | x\in[-L,d_{m-1}]\}, \tag{3.17}$$

$$\gamma''_{m-1}(L) := \{x - iL | x\in[-L,d_{m-1}]\}, \tag{3.18}$$

$$\gamma_0(L) := \{-L + iy | y\in[-L,L]\}, \tag{3.19}$$

and then use the estimate (2.41) to show that the only integral that survives from γ_m^- in the limit $L\to\infty$ is the one on Γ_{m-1} [notice that $\lim_{L\to\infty}\gamma_{m-1}(L)=\Gamma_{m-1}$]. Using the polar decomposition of $R_0(z)$ and the resolvent equation for $R(z)$ it follows that

$$\|\dot{Q}_m^-(t)\| \leqslant \frac{1}{2\pi}\oint_{\Gamma_{m-1}} |\mathrm{d}z|\|R_0(z)\|\|K(z)\| \cdot \||R_0(z)|^{1/2}\dot{H}_0 R_0(z)^{1/2}\| \cdot \|(1+K(z))^{-1}\| + \frac{1}{2\pi}\oint_{\Gamma_{m-1}} |\mathrm{d}z|\|R_0(z)\|$$
$$\times \|K(z)\| \cdot \||R_0(z)|^{1/2}\dot{H}_0 R_0(z)^{1/2}\| \cdot \|(1+K(z))^{-1}\|^2.$$

We note that the quantity $|R_0(z,t)^{1/2}|\dot{H}_0(t)R_0(z,t)^{1/2}$ is uniformly bounded on Γ_{m-1} (namely this quantity is bounded in norm by a constant). Indeed,

$$\sup_{t\in I_0}\sup_{z\in\Gamma_{m-1}} \|R_0(z,t)^{1/2}\dot{H}_0(t)|R_0(z,t)|^{1/2}\| = \sup_{t\in I_0}\sup_{y\in\mathbb{R}}\sup_{m'\in\mathbb{Z}} \left|\frac{2(m'+t)}{(m'+t)^2 - d_{m-1} - iy}\right| \leqslant C.$$

Then using Lemma 2.3 and the inequality $\|(1+K)\|^{-1} \leqslant (1-\|K\|)^{-1}$ one obtains

$$\sup_{t\in I_0}\|\dot{Q}_m^-(t)\| \leqslant C_V b(m-1). \tag{3.20}$$

Since $b(m-1) \leqslant Cb(m)$ we proved the claimed result on $\dot{Q}_m^-(t)$. The estimate of $\dot{Q}_m(t)$ goes along the same line, by deforming the closed contour around $\sigma(Q_m(t)H)$, γ_m, to $\Gamma_{m-1}\cup\Gamma_m$. The lemma is now proved. □

We turn now to the estimations of the norms in the right-hand side (rhs) of (3.13). For $X_m(t)$ Lemma 3.4 gives

$$\sup_{t\in I_0}\|X_m(t)\| \leqslant C_V b(m), \tag{3.21}$$

while for $Y_m(t)$ we write

$$\|Y_m(t)\| \leqslant \frac{1}{2\pi}(\|\dot{Q}_m^-(t)\| + \|\dot{Q}_m^+(t)\|)\int_{\Gamma_{m-1}} \mathrm{d}z\|R(z,t)\|^2 + \frac{1}{2\pi}(\|\dot{Q}_m(t)\| + \|\dot{Q}_m^+(t)\|)\int_{\Gamma_{m-1}\cup\Gamma_m} \mathrm{d}z\|R(z,t)\|^2. \tag{3.22}$$

Now for example [use again the estimate of $K(z,t)$ on $\Gamma_{m-1}\cup\Gamma_m$]

$$\sup_{t\in I_0}\int_{\Gamma_{m-1}\cup\Gamma_m} |\mathrm{d}z|\|R(z,t)\|^2 \leqslant C\sup_{t\in I_0}\int_{\Gamma_{m-1}\cup\Gamma_m} |\mathrm{d}z|\|R_0(z,t)\|^2 = \sup_{t\in I_0}\sup_{m'\in\mathbb{Z}}\int_{-\infty}^{\infty}\left\{\frac{\mathrm{d}y}{[E_{m',0}(t)-d_{m-1}]^2+y^2}\right.$$
$$\left. + \frac{\mathrm{d}y}{[E_{m',0}(t)-\mathrm{d}_m]^2+y^2}\right\} \leqslant C\langle m\rangle^{-1},$$

which together with Lemma 3.4 gives

$$\sup_{t\in I_0}\|Y_m(t)\| \leqslant C_V b(m)\langle m\rangle^{-1}. \tag{3.23}$$

Obviously, $Y_m(t_0)$ satisfies the same estimate. To estimate $\|\dot{Y}_m(t)\|$ one observes first that it involves estimates on $\ddot{Q}_m^-(t)$, $\ddot{Q}_m^+(t)$, and $\ddot{Q}_m(t)$. In what concerns $\ddot{Q}_m^-(t)$, we perform all the derivatives involved and estimate the various terms that appear. After a long but straightforward calculation one can check that the estimates for these terms involve only powers of $(1+K(z,t))^{-1}$, $R_0(z,t)^{1/2}\dot{H}_0(t)|R_0(z,t)|^{1/2}$, and the integral of $\|R_0(z,t)^{1/2}\|^2 \cdot \|K(z,t)\|$ on Γ_{m-1} which was already estimated in Lemma 2.3. The result is

$$\sup_{t\in I_0}\|\ddot{Q}_m^-(t)\| \leqslant C_V b(m). \tag{3.24}$$

The same estimate is satisfied by $\ddot{Q}_m(t)$ and then

$$\sup_{t\in I_0}\|\dot{Y}(t)\| \leqslant C_V b(m)\langle m\rangle^{-1}. \tag{3.25}$$

The last term to be considered is $X_m(t)Y_m(t)$ which gives a better estimate

$$\sup_{t\in I_0}\|X_m(t)Y_m(t)\| \leqslant C_V^2 b(m)^2\langle m\rangle^{-1}. \tag{3.26}$$

Collecting (3.13), (3.21), (3.23), (3.25), and (3.26) one obtains the first estimate from Theorem 3.1. For $\tilde{U}_m^A(t,t_0)$ the computations and estimations are similar as above, the only difference being that the contour of integration $\tilde{\Gamma}_m$ is slightly different, i.e., it is shifted upwards with $\frac{1}{2}$ with respect to Γ_m. As a consequence all the estimations will be improved with $\frac{1}{2}$, in the sense that $b(m) \to b\left(m+\frac{1}{2}\right)$. Thus there is no loss if we write

$$\sup_{t\in I_1}\|U(t,t_0) - \tilde{U}_m^A(t,t_0)\| \leqslant C_V b(m)\langle m\rangle^{-1}. \tag{3.27}$$

The proof of Theorem 3.1 is done. □

IV. THE ADIABATIC EVOLUTION. THE EFFECTIVE HAMILTONIAN

As shown in Theorem 3.1 the true evolution over the half-periods I_0 and I_1 is well approximated, in the limit of large m, by the adiabatic evolutions U_m^A and $\tilde{U}_m^A$. The next step is to compute, up to small controllable errors, U_m^A when restricted to $Q_m(t)\mathcal{H}$ and $\tilde{U}_m^A$ when restricted to $\tilde{Q}_m(t)\mathcal{H}$. In what follows we consider explicitly only U_m^A over I_0 and give the similar results for $\tilde{U}_m^A$ over I_1.

Before entering the computation of U_m^A let us show that, when restricted to $Q_m(t)\mathcal{H}$, U_m^A is nothing but the simplified dynamics in Ref. 2 obtained by keeping only the couplings between almost touching bands. Indeed, consider an initial wave function $\psi_m(s) \in Q_m(s)\mathcal{H}$, $s \in I_0$. Then, as far as $t \in I_0$, the adiabatic vector $\psi_m^A(t) := U_m^A(t,s)\psi_m(s) \in Q_m(t)\mathcal{H}$ and it can be written as

$$\psi_m^A(t) = \sum_{j=1}^{2} c_j(t)\varphi_{\alpha_j}(t), \quad \alpha_1 = 2m-2, \quad \alpha_2 = 2m-1, \tag{4.1}$$

where $\varphi_{\alpha_j}(t)$ are eigenfunctions of $H(t)$ corresponding to the eigenvalues from $\sigma(H(t))$ [one can assume that for $t=t_0$ or $t=t_1$, $\varphi_{\alpha_j}(t)$ coincide with the canonical eigenfunctions constructed in Sec. II]. Plugging the decomposition (4.1) into the Schrödinger equation for $\psi_m^A(t)$ (see Sec. III),

$$i\frac{d}{dt}\psi_m^A(t) = H_m^A(t)\psi_m^A(t) = (H(t) - X_m(t))\psi_m^A(t), \tag{4.2}$$

taking the scalar product with $\varphi_{\alpha_l}(t)$ and using the fact that $X_m(t)$ is off diagonal i.e., $Q_m(t)X_m(t)Q_m(t)=0$, one obtains

$$i\frac{d}{dt}c_l(t) = c_l(t)E_{\alpha_l}(t) + \sum_{j=1}^{2}\chi_{l,j}(t)c_j(t), \tag{4.3}$$

where

$$\chi_{l,j}(t) := -i\left\langle \varphi_{\alpha_l}(t), \frac{d}{dt}\varphi_{\alpha_j}(t)\right\rangle \tag{4.4}$$

which is nothing but the equation given in Ao's paper.

To compute U_m^A amounts then to solve the 2×2 system (4.3) and this problem has been considered many times (see Refs. 2,12,19,20 and references therein) in the physical literature. The trouble with (4.3) is that $\chi_{l,j}(t)$ are not easy to compute up to a controlled error in the limit $m \to \infty$ since due to the existence of quasicrossings one must deal with almost degenerate perturba-

tion theory. To our knowledge the earlier papers take for $\chi_{l,j}(t)$ a low order perturbation theory formula, but never controlled the rest. We avoid this difficulty by using the reduction theory which is the standard tool in analytic perturbation theory[15] and was as well extended to other contexts, in particular for adiabatic perturbation theory (see, e.g., Refs. 21,23 and references therein). More precisely, for m sufficiently large (see Corollary 2.2) $\|Q_m(t)-Q_{m,0}\|<1$ and then (see the Appendix) one can write the Sz-Nagÿ transformation matrix corresponding to the pair $Q_m(t), Q_{m,0}$,

$$Q_m(t) = W_m(t)Q_{m,0}W_m(t)^*. \tag{4.5}$$

Then if one defines for $t,s \in I_0$,

$$\mathcal{U}_m(t,s) := W_m(t)^* U_m^A(t,s)W_m(s), \tag{4.6}$$

it can be checked by straightforward calculation that

$$i\frac{\mathrm{d}\mathcal{U}_m(t,s)}{\mathrm{d}t} = (i\dot{W}_m(t)^* W_m(t) + W_m(t)^* H_m^A(t)W_m(t))\mathcal{U}_m(t,s) \tag{4.7}$$

and that

$$[Q_{m,0},\mathcal{U}_m(t,s)] = 0. \tag{4.8}$$

As a consequence if by definition

$$\mathcal{U}_{\mathrm{eff},m}(t,s) := Q_{m,0}\mathcal{U}_m(t,s)Q_{m,0} \tag{4.9}$$

then $\mathcal{U}_{\mathrm{eff},m}(t,s)$ satisfies (as operators in $Q_{m,0}\mathcal{H}$) the equation of motion

$$i\frac{d\mathcal{U}_{\mathrm{eff},m}(t,s)}{\mathrm{d}t} = Q_{m,0}(i\dot{W}_m(t)^* W_m(t) + W_m(t)^* H(t)W_m(t))Q_{m,0}\mathcal{U}_{\mathrm{eff},m}(t,s) =: H_{\mathrm{eff},m}(t)\mathcal{U}_{\mathrm{eff},m}(t,s). \tag{4.10}$$

Going backwards, once $\mathcal{U}_{\mathrm{eff},m}(t,s)$ is known one can recover $U_m^A(t,s)$ when restricted to $Q_m(t_0)\mathcal{H}$,

$$U_m^A(t,t_0)Q_m(t_0) = W_m(t)\mathcal{U}_{\mathrm{eff},m}(t,t_0)W_m(t_0)^* Q_m(t_0). \tag{4.11}$$

The point of the reduction theory outlined above is that we can compute $H_{\mathrm{eff},m}(t)$ up to a controlled error.

Theorem 4.1: *For sufficiently large m,*

$$H_{\mathrm{eff},m}(t) = Q_{m,0}(H_0(t)+V)Q_{m,0} + \tfrac{1}{2}Q_{m,0}(\hat{E}_{m,1}(t)V + V\hat{E}_{m,1}(t))Q_{m,0} + \Delta H_{\mathrm{eff},m}(t), \tag{4.12}$$

where

$$\hat{E}_{m,1}(t) := \frac{1}{2\pi i}\oint_{\gamma_m} \mathrm{d}z\, R_0(z,t)VR_0(z,t) \tag{4.13}$$

and

$$\sup_{t\in I_0}\|\Delta H_{\mathrm{eff},m}(t)\| \leqslant C_V\langle m\rangle b(m)^3. \tag{4.14}$$

We prove the theorem in a few lemmas, each lemma giving an estimate for different terms that appear in $H_{\mathrm{eff},m}(t)$. In the proofs we shall use several results of the perturbation theory. As well known, $Q_m(t)$ has the following expansion:

$$Q_m(t) = \sum_{j=0}^{N} \hat{E}_{m,j}(t) + E_{m,N+1}(t), \tag{4.15}$$

with

$$\hat{E}_{m,j}(t) := \frac{(-1)^j i}{2\pi} \oint_{\gamma_m} \mathrm{d}z\, R_0(z,t)(VR_0(z,t))^j, \tag{4.16}$$

$$E_{m,j}(t) := \frac{(-1)^j i}{2\pi} \oint_{\gamma_m} \mathrm{d}z (R_0(z,t)V)^j R(z,t). \tag{4.17}$$

Using the identity $Q_m(t) = (Q_m(t))^2$ one can easily check the following relations:

$$Q_{m,0}\hat{E}_{m,1}(t)Q_{m,0} = 0, \tag{4.18}$$

$$Q_{m,0}\hat{E}_{m,2}(t)Q_{m,0} = -Q_{m,0}\hat{E}^2_{m,1}(t)Q_{m,0}, \tag{4.19}$$

$$[H_0(t), \hat{E}_{m,1}(t)] = -[V, Q_{m,0}]. \tag{4.20}$$

Moreover, $E_{m,j}(t)$ and its derivatives obey the estimates

$$\sup_{t\in I_0} \|E_{m,j}(t)\| \leqslant C_V(b(m))^j, \tag{4.21}$$

$$\sup_{t\in I_0} \|\dot{E}_{m,j}(t)\| \leqslant C_V(j+1)(b(m))^j. \tag{4.22}$$

To see (4.21) we deform the contour γ_m into $\Gamma_{m-1} \cup \Gamma_m$ and write

$$\begin{aligned}\sup_{t\in I_0} \|E_{m,j}(t)\| &= \frac{1}{2\pi} \sup_{t\in I_0} \left\| \int_{\Gamma_{m-1}\cup\Gamma_m} \mathrm{d}z |R_0(z,t)|^{1/2} (K(z,t))^j (1+K(z,t))^{-1} R_0(z,t)^{1/2} \right\| \\ &\leqslant \frac{2}{2\pi} \sup_{t\in I_0} \sup_{z\in\Gamma_{m-1}\cup\Gamma_m} \|(K(z,t))^{j-1}\| \int_{\Gamma_{m-1}\cup\Gamma_m} |\mathrm{d}z| \|R_0(z,t)^{1/2}\|^2 \|K(z,t)\| \leqslant C_V(b(m))^j,\end{aligned}$$

where in the last line we used Lemma 2.3. The estimate (4.22) is obtained in the same way. We remark without giving details that $\hat{E}_{m,j}$ and $\dot{\hat{E}}_{m,j}$ verify the same estimates as $E_{m,j}$ and $\dot{E}_{m,j}$. Now we list the estimates for the various term appearing in $H_{\mathrm{eff},m}$.

Lemma 4.2: The first term in the effective Hamiltonian obeys the following estimate:

$$\sup_{t\in I_0} \|Q_{m,0}\dot{W}_m(t)^* W_m(t) Q_{m,0}\| \leqslant C_V \langle m\rangle b(m)^3. \tag{4.23}$$

Lemma 4.3: The second term is estimated as follows:

$$Q_0 W_m^*(t) H_0(t) W_m(t) Q_0 = Q_0 H_0(t) Q_0 - \tfrac{1}{2}\{Q_0 V \hat{E}_{m,1}(t) Q_0 + Q_0 \hat{E}_{m,1}(t) V Q_0\} + \mathcal{O}_r(\langle m\rangle b(m)^3). \tag{4.24}$$

Lemma 4.4: The last term gives

$$Q_0 W(t)^*_m V W_m(t) Q_0 = Q_0 V Q_0 + Q_0(V\hat{E}_{m,1}(t) + \hat{E}_{m,1}(t)V)Q_0 + \mathcal{O}_r(\langle m\rangle (b(m))^3). \tag{4.25}$$

Combining now Lemmas 4.2, 4.3, and 4.4 one obtains the explicit form of the effective Hamiltonian as given in Theorem 4.1. When proving the lemmas we skip for simplicity the index m and the time dependence of $W_m(t)$, $E_{m,1}(t)$, $Q_m(t)$, and other related quantities.

Proof of Lemma 4.2: We shall use the fact that E_1, $\hat{E}_1$, and E_2 are symmetric hence in particular $\partial_t(1-E_1^2)^{-1/2}$ is also symmetric. As we have said it is easy to see that

$$E_1 = \mathcal{O}_r(b(m)), \quad \hat{E}_1 = \mathcal{O}_r(b(m)), \quad E_2 = \mathcal{O}_r(b^2(m)).$$

Denoting $L := (1-E_1^2)^{-1/2} =: 1+M := 1+E_1^2F$ one has

$$WQ_0 = LQQ_0, \quad Q_0\dot{W}^* = Q_0\dot{Q}L + Q_0Q\dot{L}$$

and

$$M = \mathcal{O}_r(b^2(m)).$$

Actually by writing $L^2 = 1+\tilde{N}$ we obtain

$$Q_0\dot{W}^*WQ_0 = \tfrac{1}{2}Q_0(\dot{W}^*W - W^*\dot{W})Q_0 = \tfrac{1}{2}Q_0(\dot{Q}L^2Q - QL^2\dot{Q})Q_0 + \tfrac{1}{2}Q_0Q[\dot{L},L]QQ_0 = \tfrac{1}{2}Q_0[\dot{Q},Q]Q_0$$
$$+ \tfrac{1}{2}Q_0(\dot{Q}\tilde{N}Q - Q\tilde{N}\dot{Q})Q_0 + \tfrac{1}{2}Q_0Q[\dot{\tilde{N}},\tilde{N}]QQ_0 = \tfrac{1}{2}Q_0[\dot{Q},Q]Q_0 + \mathcal{O}_r(b^3(m))$$

where we used that $\tilde{N}$ and $\dot{\tilde{N}}$ are of $\mathcal{O}_r(b^2(m))$ and $\dot{Q} = \mathcal{O}_r(b(m))$. Now one should use the expansion $Q = Q_0 + \hat{E}_1 + E_2$ and the property $Q_0\hat{E}_1Q_0 = 0$,

$$Q_0[\dot{Q},Q]Q_0 = Q_0[\dot{\hat{E}}_1 + \dot{E}_2, Q_0 + \hat{E}_1 + E_2]Q_0 = Q_0[\dot{\hat{E}}_1, \hat{E}_1]Q_0 + \mathcal{O}_r(b^3(m)).$$

The last thing to be done is to show that $Q_0[\dot{\hat{E}}_1, \hat{E}_1]Q_0 = 0$. This follows by writing explicitly $\hat{E}_1$ (that is, by using residue theorem) and by direct calculation. □

Proof of Lemma 4.3: The idea behind the proof is to write

$$Q_0W^*H_0WQ_0 = Q_0W^*\hat{H}_0WQ_0 + (m-1)^2Q_0 \tag{4.26}$$

with $\hat{H}_0 := H_0 - (m-1)^2Q_0$ and to estimate the first term. As $W = (1+E_1^2F)(QQ_0 + (1-Q)(1-Q_0))$ then

$$WQ_0 = QQ_0 + E_1^2FQQ_0 \tag{4.27}$$

from where

$$Q_0W^*\hat{H}_0WQ_0 = Q_0Q\hat{H}_0QQ_0 + Q_0Q(\hat{H}_0E_1^2F + \text{h.c.}) + Q_0QFE_1^2\hat{H}_0E_1^2FQQ_0.$$

We start by estimating the last term

$$\sup_{t\in I_0}\|FE_1^2\hat{H}_0E_1^2F\| \leqslant \text{ct}\|E_1^2\| \cdot \|E_1\hat{H}_0E_1\|, \tag{4.28}$$

which requires an estimate on $E_1\hat{H}_0E_1$. To obtain it we shall use

$$\sup_{t\in I_0}\sup_{z,z'\in\Gamma_{m-1}\cup\Gamma_m}\|R_0(z',t)^{1/2}\hat{H}_0R_0(z,t)^{1/2}\| \leqslant C. \tag{4.29}$$

It follows from this that

$$\sup_{t\in I_0}\|E_1\hat{H}_0E_1\| = \sup_{t\in I_0}\Big\|\frac{1}{2\pi^2}\oint_{\gamma_m}\oint_{\gamma_m} \mathrm{d}z\,\mathrm{d}z' R_0(z,t)^{1/2}(1+K(z,t))^{-1}K(z,t)$$
$$\cdot |R_0(z,t)|^{1/2}\hat{H}_0|R_0(z',t)|^{1/2}K(z',t)(1+K(z',t))^{-1}|R_0(z',t)|^{1/2}$$
$$\leqslant C\oint_{\gamma_m}|\mathrm{d}z|\|R_0(z,t)^{1/2}\|\|K(z,t)\|\cdot\oint_{\gamma_m}|\mathrm{d}z'|\|R_0(z',t)^{1/2}\|\|K(z',t)\|\leqslant C_V\langle m\rangle b(m)^2.$$

Then the term $FE_1^2\hat{H}_0E_1^2F$ turns out to be of order $\mathcal{O}_r(\langle m\rangle b(m)^4)$ and can be disregarded. We continue the estimations with $Q_0QFE_1^2\hat{H}_0QQ_0$ using the perturbation theory up to E_1 (i.e., $Q=Q_0+E_1$):

$$Q_0QFE_1^2\hat{H}_0QQ_0 = Q_0FE_1^2\hat{H}_0Q_0 + Q_0FE_1^2\hat{H}_0E_1Q_0 + Q_0E_1FE_1^2\hat{H}_0E_1Q_0 + Q_0E_1FE_1^2\hat{H}_0Q_0.$$

The second and the third terms in the above equation are simply estimated using the bounds on E_1 and $E_1\hat{H}_0E_1$. For the fourth term we have to estimate instead $Q_0\hat{H}_0E_1$. Following the same steps as in the estimation of $E_1\hat{H}_0E_1$ we arrive at

$$\sup_{t\in I_0}\|Q_0\hat{H}_0E_1(t)\| = \sup_{t\in I_0}\left\|\frac{1}{2\pi^2}\oint_{\gamma_m}\oint_{\gamma_m}\mathrm{d}z\,\mathrm{d}z'\,R_0(z,t)\hat{H}_0(t)R_0\,(z',t)V(z',t))R(z',t)\right\|\leqslant C_V\langle m\rangle b(m). \tag{4.30}$$

In the similar way one can prove a more general result that will be used below, namely

$$\sup_{t\in I_0}\|Q_0\hat{H}_0E_j\|\leqslant C_V\langle m\rangle(b(m))^j. \tag{4.31}$$

It follows then from (4.30) that

$$\sup_{t\in I_0}\|Q_0E_1FE_1^2\hat{H}_0Q_0\|\leqslant C\|E_1\|^2\|E_1\hat{H}_0Q_0\|\leqslant C_V\langle m\rangle(b(m))^3.$$

Hence a preliminar result is

$$Q_0W^*\hat{H}_0WQ_0 = Q_0Q\hat{H}_0QQ_0 + Q_0Q(FE_1^2\hat{H}_0 + \hat{H}_0E_1^2F)QQ_0 + \mathcal{O}_r(\langle m\rangle(b(m))^3). \tag{4.32}$$

To go further we shall use that $F=\frac{1}{2}+E_1^2G$ (G and its derivatives being again uniformly bounded). Then

$$Q_0QFE_1^2\hat{H}_0QQ_0 = \tfrac{1}{2}Q_0QE_1^2\hat{H}_0QQ_0 + Q_0QE_1^2GE_1^2\hat{H}_0QQ_0$$

and the last term is of order $\mathcal{O}_r(\langle m\rangle(b(m))^4)$. In what concerns $Q_0QE_1^2\hat{H}_0QQ_0$ one should use the perturbation theory up to E_1,

$$Q_0QE_1^2\hat{H}_0QQ_0 = Q_0E_1^2\hat{H}_0Q_0 + \mathcal{O}_r(\langle m\rangle(b(m))^3) \tag{4.33}$$

so finally

$$Q_0W^*\hat{H}_0WQ_0 = Q_0\hat{H}_0Q_0 + Q_0(\hat{H}_0E_1 + E_1\hat{H}_0)Q_0 + \tfrac{1}{2}Q_0(\hat{H}_0E_1^2 + E_1^2\hat{H}_0)Q_0$$
$$+ Q_0E_1\hat{H}_0E_1Q_0 + \mathcal{O}_r(\langle m\rangle(b(m))^3).$$

In the following we shall use the expansion $E_1=\hat{E}_1+\cdots+\hat{E}_N+E_{N+1}$ for suitable N and the estimate (4.31), in such a way that the terms containing E_{N+1} are small. It turns out that in order to estimate the third and the fourth terms it is sufficient to go up to E_2. When plugging this expansion in $Q_0\hat{H}_0E_1^2Q_0$ and $Q_0E_1\hat{H}_0E_1Q_0$ several new terms will appear ($Q_0\hat{H}_0\hat{E}_1E_2Q_0$, $Q_0\hat{E}_1\hat{H}_0E_2$, and

$Q_0E_2\hat{H}_0E_2$). All of them are easily estimated in the same way as before and the result is

$$Q_0\hat{H}_0E_1^2Q_0 = Q_0\hat{H}_0\hat{E}_1^2Q_0 + \mathcal{O}_r(\langle m\rangle(b(m))^3),$$

$$Q_0E_1\hat{H}_0E_1Q_0 = Q_0\hat{E}_1\hat{H}_0\hat{E}_1 + \mathcal{O}_r(\langle m\rangle(b(m))^3). \tag{4.34}$$

For the first term we must go up to E_3 with the expansion. Using (4.31) and the identity (4.18) we arrive at

$$Q_0\hat{H}_0E_1Q_0 = Q_0\hat{H}_0\hat{E}_2Q_0 + \mathcal{O}_r(\langle m\rangle(b(m))^3). \tag{4.35}$$

Moreover, using (4.19) we can replace $Q_0\hat{E}_2Q_0$ and write

$$\begin{aligned} Q_0W^*H_0WQ_0 &= Q_0\hat{H}_0 + Q_0(n_0-1)^2 - \tfrac{1}{2}Q_0(\hat{H}_0\hat{E}_1^2 + \hat{E}_1^2\hat{H}_0)Q_0 + \tfrac{1}{2}(Q_0\hat{E}_1\hat{H}_0\hat{E}_1Q_0 + Q_0\hat{E}_1\hat{H}_0\hat{E}_1Q_0) \\ &\quad + \mathcal{O}_r(\langle m\rangle(b(m))^3) = Q_0H_0 + \tfrac{1}{2}(Q_0[\hat{E}_1,\hat{H}_0]\hat{E}_1Q_0 + Q_0\hat{E}_1[\hat{H}_0,\hat{E}_1]) + \mathcal{O}_r(\langle m\rangle(b(m))^3) \\ &= Q_0H_0Q_0 - \tfrac{1}{2}\{Q_0V\hat{E}_1Q_0 + Q_0\hat{E}_1VQ_0\} + \mathcal{O}_r(\langle m\rangle(b(m))^3). \end{aligned} \tag{4.36}$$

In the last line we used (4.20). The lemma is now proved. □

Proof of Lemma 4.4: Using (4.27) and $Q=Q_0+E_1$ it results

$$\begin{aligned} Q_0W(t)^*VW(t)Q_0 &= Q_0VQ_0 + Q_0(E_1V+VE_1)Q_0 + Q_0E_1VE_1Q_0 + Q_0(Q_0+E_1)(VE_1^2F + FE_1^2V)(Q_0 \\ &\quad + E_1)Q_0 + Q_0(Q_0+E_1)FE_1(E_1VE_1)E_1F(Q_0+E_1)Q_0. \end{aligned}$$

Let us first show that the last three terms are small. To see this we need estimates on E_1VE_1 and Q_0VE_1. For E_1VE_1 one has

$$\begin{aligned} E_1VE_1 = -\frac{1}{2\pi^2}\oint_{\gamma_m}\oint_{\gamma_m} \mathrm{d}z\,\mathrm{d}z'\, R_0(z,t)^{1/2}K(z,t)(1+K(z,t))^{-1}\cdot|R_0(z,t)|^{1/2}VR_0(z',t)^{1/2} \\ \times K(z',t)(1+K(z',t))^{-1}|R_0(z',t)|^{1/2}. \end{aligned} \tag{4.37}$$

Now observe that

$$\sup_{t\in I_0}\sup_{z\in\gamma_m}\sup_{z'\in\gamma_m}\||R_0(z,t)|^{1/2}VR_0(z',t)^{1/2}\| \leqslant C_Vb(m). \tag{4.38}$$

Then using the fact that $l(\gamma_m)\sim\langle m\rangle$,

$$\sup_{t\in I_0}\|E_1VE_1\| \leqslant C_V\langle m\rangle(b(m))^3. \tag{4.39}$$

In what concerns Q_0VE_1 we have

$$\sup_{t\in I_0}\|Q_0VE_1\| = \frac{1}{2\pi}\left\|\oint_{\gamma_m}\oint_{\gamma_m}\mathrm{d}z\,\mathrm{d}z'\,R_0(z,t)VR_0(z',t)VR(z',t)\right\| \leqslant C_V\langle m\rangle(b(m))^2. \tag{4.40}$$

The estimates (4.39) and (4.40) used in $Q_0W(t)^*VW(t)Q_0$ suffices to prove that the last three terms are of order $\mathcal{O}_r(\langle m\rangle(b(m))^3)$. We arrived thus at

$$Q_0W^*VWQ_0 = Q_0VQ_0 + Q_0(VE_1+E_1V)Q_0 + \mathcal{O}_r(\langle m\rangle(b(m))^3).$$

As for the remaining term $Q_0E_1VQ_0$ we shall write it more carefully by writing

$$Q_0E_1VQ_0 = Q_0(\hat{E}_1+E_2)VQ_0. \tag{4.41}$$

Finally, $Q_0E_2VQ_0$ is found to be of order $\mathcal{O}_r(\langle m\rangle(b(m))^3)$ and the lemma is finished. □

For $\tilde{H}_{\mathrm{eff},m}$ the computations and estimations are similar as above the difference appearing again due to the different integration contour. We can then conclude that

$$\tilde{H}_{\mathrm{eff},m}(t) = \tilde{Q}_{m,0}(H_0(t) + V)\tilde{Q}_{m,0} + \tfrac{1}{2}\tilde{Q}_{m,0}(\hat{E}_{m,1}(t)V + V\hat{E}_{m,1}(t))\tilde{Q}_{m,0} + \Delta\tilde{H}_{\mathrm{eff},m}(t),$$

where $\hat{E}_{m,1}(t)$ is now the first order term from the pertubative expansion for $\tilde{Q}_m(t)$ and the remainder $\Delta\tilde{H}_{\mathrm{eff},m}(t)$ is of the same order as in Theorem 4.2.

V. THE ADIABATIC EVOLUTION. THE TRANSITION AMPLITUDES

We shall use now the effective Hamiltonian obtained in the preceding section to compute $U_m^A(t_1,t_0)$ and $\tilde{U}_m^A(t_2,t_1)$ when restricted to $Q_m(t_0)\mathcal{H}$ and $\tilde{Q}_m(t_1)\mathcal{H}$, respectively, up to an error which remains small after taking the sum over m from some sufficiently large n_0 to infinity. This amounts to the computation of the 2×2 transfer matrices $\mathcal{S}^m(t_1,t_0): Q_m(t_0)\mathcal{H} \to Q_m(t_1)\mathcal{H}$ and $\tilde{\mathcal{S}}^m(t_2,t_1): \tilde{Q}_m(t_1)\mathcal{H} \to \tilde{Q}_m(t_2)\mathcal{H}$ (remember that $t_0=-\frac{1}{4}$, $t_1=\frac{1}{4}$, $t_2=\frac{3}{4}$). They are in turn related to the effective evolutions $U_{\mathrm{eff},m}$ and $\tilde{U}_{\mathrm{eff},m}$ (see Sec. IV) by the unitary transformations that rotate the proper basis of $Q_m(t)\mathcal{H}$ and $\tilde{Q}_m(t)\mathcal{H}$ to the canonical ones in $Q_{m,0}\mathcal{H}$ and $\tilde{Q}_{m,0}\mathcal{H}$. The coefficients of these transformations are easily estimated thus one is left with the calculation of the effective evolutions. The strategy goes as follows: We start from the effective Hamiltonians introduced in Sec. IV and use Dyson techniques. Along the Dyson expansions new effective Hamiltonians appear as well as additional error terms which we carefully count. The final Hamiltonian has a nice simple structure: it decomposes into a free diagonal time-dependent part and an off-diagonal time independent perturbation. Its associated evolution leads to the Landau–Zener formulas similar to the ones obtained by Browne and Lenstra. The rigorous form of the above discussion is the main result of this section and is contained in the following.

Theorem 5.1: *Let $r>-\frac{1}{2}$, m sufficiently large and define the transfer matrices*

$$\mathcal{S}^m(t_1,t_0) = \begin{pmatrix} \mathcal{S}^m_{2m-1,2m-2}(t_1,t_0) & \mathcal{S}^m_{2m-1,2m-1}(t_1,t_0) \\ \mathcal{S}^m_{2m-2,2m-2}(t_1,t_0) & \mathcal{S}^m_{2m-2,2m-1}(t_1,t_0) \end{pmatrix}, \tag{5.1}$$

$$\tilde{\mathcal{S}}^m(t_2,t_1) = \begin{pmatrix} \tilde{\mathcal{S}}^m_{2m,2m-1}(t_2,t_1) & \tilde{\mathcal{S}}^m_{2m,2m}(t_2,t_1) \\ \tilde{\mathcal{S}}^m_{2m-1,2m-1}(t_2,t_1) & \tilde{\mathcal{S}}^m_{2m-1,2m}(t_2,t_1) \end{pmatrix}, \tag{5.2}$$

with

$$\mathcal{S}^m_{i,j}(t_1,t_0) := \langle \varphi_i(t_1), U_m^A(t_1,t_0)\varphi_j(t_0)\rangle, \quad i,j = 2m-2, 2m-1 \tag{5.3}$$

$$\tilde{\mathcal{S}}^m_{i,j}(t_2,t_1) := \langle \varphi_i(t_2), \tilde{U}_m^A(t_2,t_1)\varphi_j(t_1)\rangle, \quad i,j = 2m-1, 2m. \tag{5.4}$$

Then

$$\mathcal{S}^m(t_1,t_0) = e^{-i\theta_m(t_1,t_0)}\begin{pmatrix} \alpha_{2m-2}(t_1,t_0) & -\overline{\beta}_{2m-2}(t_1,t_0) \\ \beta_{2m-2}(t_1,t_0) & \alpha'_{2m-2}(t_1,t_0) \end{pmatrix} + \mathcal{R}_{\mathrm{eff},m}, \tag{5.5}$$

$$\tilde{\mathcal{S}}^m(t_2,t_1) = e^{-i\tilde{\theta}_m(t_2,t_1)}\begin{pmatrix} \tilde{\alpha}_{2m-1}(t_2,t_1) & -\bar{\tilde{\beta}}_{2m-1}(t_2,t_1) \\ \tilde{\beta}_{2m-1}(t_2,t_1) & \tilde{\alpha}'_{2m-1}(t_2,t_1) \end{pmatrix} + \mathcal{R}_{\mathrm{eff},m}, \tag{5.6}$$

with

$$\mathcal{R}_{\mathrm{eff},m} = \mathcal{O}_r\left(\frac{\log^8\langle m\rangle}{\langle m\rangle^{\min\{2+8r,3/2+5r,3/2+r,2\}}}\right) \quad \text{as } m\to\infty \tag{5.7}$$

and the following notations (we list below only the quantities related to $\mathcal{S}^m$; the ones corresponding to $\widetilde{\mathcal{S}}^m$ are discussed at the end of this section):

$$\alpha_{2m-2}(t_1,t_0) := 1 - \frac{|\hat{V}(2(m-1))|^2}{m-1} c_{2,m}(t_1,t_0) - i\omega_{1,m}(t_1,t_0), \tag{5.8}$$

$$\alpha'_{2m-2}(t_1,t_0) := 1 - \frac{|\hat{V}(2(m-1))|^2}{m-1} c_{2,m}(t_1,t_0) - i\omega_{2,m}(t_1,t_0), \tag{5.9}$$

$$\beta_{2m-2}(t_1,t_0) := \frac{\overline{\hat{V}(2(m-1))}}{\sqrt{m-1}} c_{1,m}(t_1,t_0) - i\lambda_m(t_1,t_0) - \frac{\overline{2\hat{V}(2(m-1))}}{m-1}, \tag{5.10}$$

$$c_{1,m}(t_1,t_0) := -(i+1)\frac{\sqrt{\pi}}{2} e^{i(m-1)/8} \operatorname{erf}\left(\frac{i+1}{4}\sqrt{m-1}\right), \tag{5.11}$$

$$c_{2,m}(t_1,t_0) := \frac{\pi}{4}\left|\operatorname{erf}\left(\frac{i-1}{4}\sqrt{m-1}\right)\right|^2, \tag{5.12}$$

$$\theta_m(t_1,t_0) := \int_{t_0}^{t_1} \mathrm{d}s((m-1)^2 + s^2),$$

$$\lambda_m(t_1,t_0) := \int_{t_0}^{t_1} \mathrm{d}s\, \overline{\Delta}_m(s) e^{-2i(m-1)(s^2-t_0^2)}, \tag{5.13}$$

$$\omega_{1,m}(t_1,t_0) := \int_{t_0}^{t_1} \mathrm{d}s \frac{1}{2}\langle \varphi_{m-1,0}, (V\hat{E}_1(t) + \hat{E}_1(t)V)\varphi_{m-1,0}\rangle =: \int_{t_0}^{t_1} \mathrm{d}s\, \gamma_{1,m}(s) \tag{5.14}$$

$$\omega_{2,m}(t_1,t_0) := \int_{t_0}^{t_1} \mathrm{d}s \frac{1}{2}\langle \varphi_{-(m-1),0}, (V\hat{E}_1(t) + \hat{E}_1(t)V)\varphi_{-(m-1),0}\rangle =: \int_{t_0}^{t_1} \mathrm{d}s\, \gamma_{2,m}(s), \tag{5.15}$$

$$\Delta_m(t) := \tfrac{1}{2}\langle \varphi_{m-1,0}, (V\hat{E}_1(t) + \hat{E}_1(t)V)\varphi_{-(m-1),0}\rangle. \tag{5.16}$$

Here $\operatorname{erf}(z)$ *is the error function (see Ref. 1):*

$$\operatorname{erf}(z) := \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2}\, \mathrm{d}t. \tag{5.17}$$

Remark: Although the above estimates are valid for $r > -\frac{1}{2}$ the bound on the error terms gets small as m tends to infinity only for $r > -\frac{1}{4}$ and is summable with respect to m only for $r > -\frac{1}{10}$ (these facts can be noticed from the behavior of the error term $\mathcal{R}_{\mathrm{eff},m}$).

Proof: We shall consider only $S^m_{i,j}$; the proof for $\widetilde{S}^m_{i,j}$ is similar. From (2.48) and (4.11):

$$S^m_{i,j}(t_1,t_0) = \sum_{k,l=2m-2,2m-1} \overline{c}^m_{k,i}(t_1)\mathcal{U}_{\mathrm{eff},m;k,l}(t_1,t_0)c^m_{l,j}(t_0), \tag{5.18}$$

where $\varphi^0_\alpha(t_\beta) = \varphi_{n_\alpha,0}(t_\beta)$ [see (2.30)] and we introduced the coefficients

$$c^m_{i,k}(t_p) := \langle \varphi^0_i(t_p), W_m(t_p)^* N_k(t_p) \varphi^0_k(t_p) \rangle, \quad p = 0,1 \tag{5.19}$$

and

$$\mathcal{U}_{\mathrm{eff},m;k,l}(t_1,t_0) := \langle \varphi^0_k(t_1), \mathcal{U}_{\mathrm{eff},m}(t_1,t_0) \varphi^0_l(t_0) \rangle. \tag{5.20}$$

The estimation of the coefficients $c^m_{i,k}(t_p)$ is easy and reads as follows.

Lemma 5.2: For m large enough and $r > -\frac{1}{2}$ *one has*

$$c^m_{\alpha,\beta}(t_p) = \delta_{\alpha,\beta} + \frac{\langle \varphi^0_\alpha(t_p), V\varphi^0_\beta(t_p) \rangle}{E^0_\beta(t_p) - E^0_\alpha(t_p)} (1 - \delta_{\alpha,\beta}) + \mathcal{O}_r(b^2(m)) \quad \text{as } m \to \infty. \tag{5.21}$$

The estimation of $\mathcal{U}_{\mathrm{eff},m}$ is more involved and the result is summarized in the following.

Lemma 5.3: For m large enough and $r > -\frac{1}{2}$ *the effective evolution is given by*

$$\mathcal{U}_{\mathrm{eff},m;i,j}(t_1,t_0) = \mathcal{S}^m_{ij}(t_1,t_0) + e^{-i\theta_m(t_1,t_0)} v_m + \mathcal{R}_{\mathrm{eff},m} \quad \text{as } m \to \infty \tag{5.22}$$

with

$$v_m := \begin{pmatrix} 0 & -\dfrac{2\hat{V}(2(m-1))}{m-1} \\ \dfrac{2\hat{V}(2(m-1))}{m-1} & 0 \end{pmatrix}. \tag{5.23}$$

The proof of Theorem 5.1 requires only straightforward calculations using (5.18), (5.21), and (5.22).

Proof of Lemma 5.2: Write [see (4.16) and (4.17)]

$$Q_m(t_p) - Q^0_m(t_p) = \hat{E}_{m,1}(t_p) + E_{m,2}(t_p), \tag{5.24}$$

and in the same way

$$P_\alpha(t_p) - P^0_\alpha(t_p) = -\frac{i}{2\pi} \int_{C_\alpha} \mathrm{d}z\, R_0(z,t_p) V R_0(z,t_p) + \frac{i}{2\pi} \int_{C_\alpha} \mathrm{d}z\, R_0(z,t_p) V R(z,t_p) V R_0(z,t_p) =: \hat{e}_{\alpha,1}(t_p) + e_{\alpha,2}(t_p), \quad p = 0,1 \tag{5.25}$$

with $C_{2m-2} = \Gamma_{m-1} \cup \tilde{\Gamma}_{m-1}$ and $C_{2m-1} = \tilde{\Gamma}_{m-1} \cup \Gamma_m$, i.e., C_α is a countour which contains only one eigenvalue of $H_0(t_p)$ namely $E^0_\alpha(t_p)$. By Lemma 2.3 (see also Sec. IV) one has

$$\|\hat{E}_{m,1}(t_p)\| + \|\hat{e}_{\alpha,1}(t_p)\| \leqslant C_V b(m), \tag{5.26}$$

$$\|E_{m,2}(t_p)\| + \|e_{\alpha,2}(t_p)\| \leqslant C_V b(m)^2. \tag{5.27}$$

Then using the expansion in the Sz-Nagÿ formula, (5.26) and (5.27), and the fact that for $\alpha = 2m-2$, $2m-1$ we have $Q_{m,0} P^0_\alpha(t_p) = P^0_\alpha(t_p) Q_{m,0} = P^0_\alpha(t_p)$ and $P^0_\alpha(t_p) \varphi^0_\alpha(t_p) = \varphi^0_\alpha(t_p)$ it follows that up to errors of order $\mathcal{O}_r b(m)^2$,

$$c^m_{\alpha,\beta}(t_p) = \langle \varphi^0_\alpha(t_p), (1 + \hat{E}_{m,1}(t_p) + \hat{e}_{\beta,1}(t_p)) \varphi^0_\beta(t_p) \rangle. \tag{5.28}$$

Since $Q_{m,0} \hat{E}_{m,1}(t_p) Q_{m,0} = P^0_\beta(t_p) \hat{e}_{\beta,1}(t_p) P^0_\beta(t_p) = 0$ one gets finally

$$|c^m_{\alpha,\beta}(t_p) - \delta_{\alpha,\beta} - \langle \varphi^0_\alpha(t_p), \hat{e}_{\beta,1}(t_p) \varphi^0_\beta(t_p) (1 - \delta_{\alpha,\beta}) \rangle| \leqslant C_V b(m)^2 \tag{5.29}$$

and computing the third term on the left-hand side (lhs) of (5.29) by residues theorem we obtain the needed result. □

Proof of Lemma 5.3: First remark that due to Theorem 4.1 one can write

$$H_{\mathrm{eff},m}(t) = h_{\mathrm{eff},m}(t) + \Delta H_{\mathrm{eff},m}(t), \tag{5.30}$$

where

$$h_{\mathrm{eff},m}(t) = Q_{m,0}(H_0(t) + V)Q_{m,0} + \tfrac{1}{2}Q_{m,0}(\hat{E}_{m,1}(t)V + V\hat{E}_{m,1}(t))Q_{m,0}. \tag{5.31}$$

Denote then by $\mathcal{U}^0_{\mathrm{eff},m}(t,t_0)$ the evolution associated to $h_{\mathrm{eff},m}(t)$ having the equation of motion

$$i\frac{d}{dt}\mathcal{U}^0_{\mathrm{eff},m}(t,t_0) = h_{\mathrm{eff},m}(t)\mathcal{U}^0_{\mathrm{eff},m}(t,t_0), \quad \mathcal{U}^0_{\mathrm{eff},m}(t_0,t_0) = 1. \tag{5.32}$$

The usual estimation for $\Omega_{\mathrm{eff},m}(t,t_0) := \mathcal{U}^0_{\mathrm{eff},m}(t,t_0)^*\mathcal{U}_{\mathrm{eff},m}(t,t_0)$ gives

$$\sup_{t\in I_0}\|\Omega_{\mathrm{eff},m}(t,t_0) - 1\| \leqslant \frac{1}{2}\sup_{t\in I_0}\|\Delta H_{\mathrm{eff},m}(s)\| \leqslant C_V\langle m\rangle b(m)^3.$$

Hence

$$\mathcal{U}_{\mathrm{eff},m}(t,t_0) = \mathcal{U}^0_{\mathrm{eff},m}(t,t_0) + \mathcal{O}_r(\langle m\rangle b(m)^3) \quad \text{as } m\to\infty. \tag{5.33}$$

We continue the computation of $\mathcal{U}^0_{\mathrm{eff},m}(t,t_0)$ by further decomposing $h_{\mathrm{eff},m}(t)$ into a "free" part

$$H_{P,m}(t) := Q_{m,0}(H_0(t) + V)Q_{m,0} \tag{5.34}$$

and a perturbation

$$B_m(t) := \tfrac{1}{2}Q_{m,0}(\hat{E}_{m,1}(t)V + V\hat{E}_{m,1}(t))Q_{m,0}. \tag{5.35}$$

Remark first that $H_{P,m}(t)$ has a simple matrix form in the eigenbasis of $H_0(t)$ that can be explicitly written taking into account that $Q_{m,0} = P_{m-1,0} + P_{-(m-1),0}$. Second one notes that it is possible to eliminate a diagonal term from $H_{P,m}(t)$ by writing

$$\mathcal{U}^0_{\mathrm{eff},m}(t_1,t_0) := \exp\left(-i\int_{t_0}^{t_1}((m-1)^2 + s^2)\mathrm{d}s\right)\hat{\mathcal{U}}_{\mathrm{eff},m}(t_1,t_0), \tag{5.36}$$

where $\hat{\mathcal{U}}_{\mathrm{eff},m}(t,t_0)$ satisfies the equation

$$i\frac{d}{dt}\hat{\mathcal{U}}_{\mathrm{eff},m}(t,t_0) = (\hat{H}_{P,m}(t) + B_m(t))\hat{\mathcal{U}}_{\mathrm{eff},m}(t,t_0), \quad \hat{\mathcal{U}}_{\mathrm{eff},m}(t_0,t_0) = 1, \tag{5.37}$$

and

$$\hat{H}_{P,m}(t) = \begin{pmatrix} 2(m-1)t & \hat{V}(2(m-1)) \\ \hat{V}(2(m-1)) & -2(m-1)t \end{pmatrix}. \tag{5.38}$$

Now let $\hat{\mathcal{U}}_{P,m}(t,t_0)$ be the evolution generated by $\hat{H}_{P,m}(t)$ and

$$\hat{\Omega}_{P,m}(t_1,t_0) = \hat{\mathcal{U}}_{P,m}(t_1,t_0)^*\hat{\mathcal{U}}_{m,\mathrm{eff}}(t_1,t_0). \tag{5.39}$$

We write the Dyson expansion for $\hat{\Omega}_{P,m}$ with the remainder of order 2,

$$\hat{\Omega}_{P,m}(t_1,t_0) = 1 + (-i)\int_{t_0}^{t_1} \mathrm{d}s_1\, B_m^{\mathrm{int}}(s_1) + (-i)^2 \int_{t_0}^{t_1} \mathrm{d}s_1\, B_m^{\mathrm{int}}(s_1) \int_{t_0}^{s_1} \mathrm{d}s_2\, B_m^{\mathrm{int}}(s_2)\hat{\Omega}_{P,m}(s_2,t_0), \tag{5.40}$$

where $B_m^{\mathrm{int}}(t) = \hat{\mathcal{U}}_{P,m}(t,t_0)^* B_m(t)\hat{\mathcal{U}}_{P,m}(t,t_0)$. Observe first that $\sup_{t\in I_0} B_m(t) = \mathcal{O}_r(\langle m\rangle b(m)^2)$ as $m \to \infty$ [this follows from the estimate on $Q_{m,0}V\hat{E}_1(t)$ which is the same as the one from Eq. (4.40)]. Then

$$\sup_{t\in I_0} \left\| \int_{t_0}^{t_1} \mathrm{d}s_1\, B_m^{\mathrm{int}}(s_1) \int_{t_0}^{s_1} \mathrm{d}s_2\, B_m^{\mathrm{int}}(s_2)\hat{\Omega}_{P,m}(s_2,t_0) \right\| \leqslant \frac{1}{4}(\sup_{t\in I_0}\|B_m(t)\|)^2 = \mathcal{O}_r((\langle m\rangle b(m)^2)^2) \quad \text{as } m \to \infty. \tag{5.41}$$

In conclusion, at this level of approximation from (5.39) we have

$$\hat{\mathcal{U}}_{\mathrm{eff},m}(t_1,t_0) = \hat{\mathcal{U}}_{P,m}(t_1,t_0)\left[1 - i\int_{t_0}^{t_1} \mathrm{d}s\, B_m^{\mathrm{int}}(s)\right] + \mathcal{O}_r((\langle m\rangle b(m)^2)^2) \quad \text{as } m \to \infty. \tag{5.42}$$

Thus we have reduced the problem at hand to the computation of $\hat{\mathcal{U}}_{P,m}(t_1,t_0)$ and of the contribution of B_m^{int}. Now we write $\hat{H}_{P,m}(t)$ in the form $\hat{H}_{P,m}(t) = \hat{H}_{P,m}^0(t) + \hat{V}_P$, where

$$\hat{H}_{P,m}^0(t) = \begin{pmatrix} 2(m-1)t & 0 \\ 0 & -2(m-1)t \end{pmatrix}, \quad \hat{V}_P = \begin{pmatrix} 0 & \hat{V}(2(m-1)) \\ \overline{\hat{V}(2(m-1))} & 0 \end{pmatrix}.$$

Let $\hat{\mathcal{U}}_{P,m}^0$ be the evolution generated by $\hat{H}_{P,m}^0$,

$$\hat{\mathcal{U}}_{P,m}^0(t,t_0) = \begin{pmatrix} e^{-i(m-1)(t^2-t_0^2)} & 0 \\ 0 & e^{i(m-1)(t^2-t_0^2)} \end{pmatrix}. \tag{5.43}$$

By defining all the "effective" Hamiltonians above we ended with a time-independent perturbation $\hat{V}_P$ (which is precisely the one considered in the physical literature[2,12]). Writing the Dyson expansion with the remainder of order 3 for $\hat{\Omega}_{P,m}^0(t_1,t_0) = \hat{\mathcal{U}}_{P,m}^0(t_1,t_0)^*\hat{\mathcal{U}}_{P,m}(t_1,t_0)$,

$$\begin{aligned}\hat{\Omega}_{P,m}^0(t_1,t_0) &= 1 + (-i)\int_{t_0}^{t_1} \mathrm{d}s_1\, \hat{V}_P(s_1) + (-i)^2 \int_{t_0}^{t_1} \mathrm{d}s_1\, \hat{V}_P(s_1) \int_{t_0}^{s_1} \mathrm{d}s_2\, \hat{V}_P(s_2) \\ &\quad + (-i)^3 \int_{t_0}^{t_1} \mathrm{d}s_1\, \hat{V}_P(s_1) \int_{t_0}^{s_1} \mathrm{d}s_2\, \hat{V}_P(s_2) \int_{t_0}^{s_2} \mathrm{d}s_3\, \hat{V}_P(s_3)\hat{\Omega}_{P,m}^0(s_3,t_0) \\ &:= 1 + \hat{\Omega}_{P,m}^{0,(1)}(t_1,t_0) + \hat{\Omega}_{P,m}^{0,(2)}(t_1,t_0) + \mathcal{R}_3, \end{aligned} \tag{5.44}$$

where $\hat{V}_P(t) = \hat{\mathcal{U}}_{P,m}^0(t,t_0)^*\hat{V}_P\hat{\mathcal{U}}_{P,m}^0(t,t_0)$. We compute explicitely the first and second order terms while the remainder $\mathcal{R}_3$ is estimated using Eq. (A28) from the Appendix. That is, we use (A45) for $p=3$ which gives, with m large enough

$$\|\mathcal{R}_3\| \leqslant C_{m_0}\|V\|_r^3 \frac{\log^2\langle m\rangle}{\langle m\rangle^{3/2+3r}}. \tag{5.45}$$

As for the first two terms in the Dyson expansion by direct computation we have

$$\sum_{k=0}^{2}\hat{\Omega}_{P,m}^{0,(k)}(t_1,t_0)=\begin{pmatrix}1-\dfrac{|\hat{V}(2(m-1))|^2}{m-1}c_{2,m}(t_1,t_0) & -\dfrac{\hat{V}(2(m-1))}{\sqrt{m-1}}\overline{c_{1,m}(t_1,t_0)}\\ \dfrac{\overline{\hat{V}(2(m-1))}}{\sqrt{m-1}}c_{1,m}(t_1,t_0) & 1-\dfrac{|\hat{V}(2(m-1))|^2}{m-1}c_{2,m}(t_1,t_0)\end{pmatrix}, \tag{5.46}$$

with $c_{1,m}(t_1,t_0)$ and $c_{2,m}(t_1,t_0)$ as introduced in Theorem 5.1.

The expression (5.46) together with the estimate (5.45) allow to compute approximately $\hat{\mathcal{U}}_{P,m}$ with the help of the following formula for $B_m(t)$ [see (5.35) and (5.14)–(5.16)]:

$$B_m(t)=\begin{pmatrix}\gamma_{1,m}(t) & \Delta_m(t)\\ \overline{\Delta}_m(t) & \gamma_{2,m}(t)\end{pmatrix}. \tag{5.47}$$

Later on we shall need the the following expansion of B_m^{int}:

$$B_m^{\mathrm{int}}(t)=\hat{\mathcal{U}}_{P,m}(t,t_0)^*B_m(t)\hat{\mathcal{U}}_{P,m}(t,t_0)=\left(\hat{\mathcal{U}}_{P,m}^0(t,t_0)\left(1+(-i)\int_{t_0}^{t}\mathrm{d}s\ \hat{V}_P(s)\hat{\Omega}_{P,m}^0(s,t_0)\right)\right)^*B_m(s)\hat{\mathcal{U}}_{P,m}^0(t,t_0)$$
$$\times\left(1+(-i)\int_{t_0}^{t}\mathrm{d}s\ \hat{V}_P(s)\hat{\Omega}_{P,m}^0(s,t_0)\right).$$

The term $(-i)\int_{t_0}^{t}\mathrm{d}s\ \hat{V}_P(s)\hat{\Omega}_{P,m}^0(s,t_0)$ is actually the remainder of order 1 from the Dyson expansion of $\hat{\Omega}_{P,m}^0(s,t_0)$. Consequently we denote this quantity $\mathcal{R}_1$ and estimate it by (A45) (for m large enough) as

$$\|\mathcal{R}_1\|\leqslant C_{m_0}\|V\|_r\frac{\log\langle m\rangle}{\langle m\rangle^{1/2+r}}. \tag{5.48}$$

Using that $B_m(t)=\mathcal{O}_r((b(m))^2\langle m\rangle)$ and (5.48) we have

$$B_m^{\mathrm{int}}(t)=\hat{\mathcal{U}}_{P,m}^0(t,t_0)^*B_m(t)\hat{\mathcal{U}}_{P,m}^0(t,t_0)+\mathcal{O}_r\left(\frac{\log^5\langle m\rangle}{\langle m\rangle^{\min\{3/2+r,3/2+5r\}}}\right)\quad\text{as } m\to\infty. \tag{5.49}$$

To write down $\mathcal{U}_{\mathrm{eff},m}(t_1,t_0)$ we use (5.33), (5.36), (5.39), (5.41), (5.43), (5.44), (5.46), and (5.49),

$$\mathcal{U}_{\mathrm{eff},m}(t_1,t_0)=e^{-i\theta_m(t_1,t_0)}\begin{pmatrix}1-\dfrac{|\hat{V}(2(m-1))|^2}{m-1}c_{2,m}(t_1,t_0) & -\dfrac{\hat{V}(2(m-1))}{\sqrt{m-1}}\overline{c_{1,m}(t_1,t_0)}\\ \dfrac{\overline{\hat{V}(2(m-1))}}{\sqrt{m-1}}\overline{c_{1,m}}(t_1,t_0) & 1-\dfrac{|\hat{V}(2(m-1))|^2}{m-1}c_{2,m}(t_1,t_0)\end{pmatrix}$$
$$-i\begin{pmatrix}\omega_{1,m} & \overline{\lambda_m}\\ \lambda_m & \omega_{2,m}\end{pmatrix}+\mathcal{R}_{\mathrm{eff},m}. \tag{5.50}$$

The remainder $\mathcal{R}_{\mathrm{eff},m}$ takes into account all the errors involved during the computation of the effective evolution in the subspace $Q_m\mathcal{H}$,

$$\|\mathcal{R}_{\mathrm{eff},m}\|\leqslant 2\|\mathcal{R}_1\|\cdot\|B_m\|+\|\mathcal{R}_3\|+\|\ B_m)\|^2+\|\Delta H_{\mathrm{eff},m}\|=\mathcal{O}_r\left(\frac{\log^8\langle m\rangle}{\langle m\rangle^{\min\{2+8r,3/2+5r,3/2+r,2\}}}\right). \tag{5.51}$$

Making the necessary identifications in (5.50) one finds that this expression coincides with the one given in Lemma 5.3 which is now proven. □

Remark 5.4: Let us justify why we kept explicitly the matrix elements of $B_m(t)$ in the effective

evolution. First we point out, without giving details, that one can obtain sharp estimates on Δ_m and γ's as in Eqs. (10) and (11) from Ref. 3, namely ($j=1,2$)

$$\sup_{t\in I_0}|\Delta_m(t)| \leqslant \frac{C\|V\|_r^2}{\langle m\rangle^{1+r}}, \quad \sup_{t\in I_0}|\gamma_{j,m}(t)| \leqslant \frac{C\|V\|_r^2}{\langle m\rangle^{\min\{2,1+2r\}}}. \tag{5.52}$$

Second, observe that from these estimates one cannot conclude that the diagonal contribution of $B_m(t)$ is smaller that the second terms from the Landau–Zener coefficients α_{2m-2}, α'_{2m-2}.

To obtain $\tilde{\mathcal{U}}_{\mathrm{eff},m}(t_2,t_1)$ we must follow the same steps as above, using the effective Hamiltonian $\tilde{H}_{\mathrm{eff},m}$. Without giving explicit calculations we summarize the results and the notations. Up to errors of order $\mathcal{O}_r(\langle m\rangle^{\min\{2,2+8r\}})$ as $m\to\infty$,

$$\tilde{\mathcal{U}}_{\mathrm{eff},m}(t_2,t_1) = e^{-i\tilde{\theta}_m(t_2,t_1)}\begin{pmatrix} 1-\dfrac{|\hat{V}(2m-1)|^2}{m-\frac{1}{2}}\tilde{c}_{2,m}(t_2,t_1) & -\dfrac{\hat{V}(2m-1)}{\sqrt{m-\frac{1}{2}}}\,\overline{\tilde{c}_{1,m}(t_2,t_1)}) \\ \dfrac{\overline{\hat{V}(2m-1)}}{\sqrt{m-\frac{1}{2}}}\tilde{c}_{1,m}(t_2,t_1) & 1-\dfrac{|\hat{V}(2m-1)|^2}{m+\frac{1}{2}}\tilde{c}_{2,m}(t_2,t_1) \end{pmatrix} - ie^{-i\tilde{\theta}_m(t_2,t_1)} \times \begin{pmatrix} \tilde{\omega}_{1,m}(t_2,t_1) & \overline{\tilde{\lambda}_m(t_2,t_1)} \\ \tilde{\lambda}_m(t_2,t_1) & \tilde{\omega}_{2,m}(t_2,t_1) \end{pmatrix} \tag{5.53}$$

the phase $\tilde{\theta}_m$ coeficients $\tilde{c}_i(m)$ being related to the ones of $\mathcal{U}_{\mathrm{eff},m}(t_1,t_0)$ by the relations

$$\tilde{\theta}_m(t_2,t_1) = \theta_{m+1/2}(t_1,t_0), \tag{5.54}$$

$$\tilde{c}_{i,m}(t_2,t_1) = c_{i,m+1/2}(t_1,t_0), \quad i=1,2. \tag{5.55}$$

$\tilde{\lambda}_m(t_2,t_1)$ and $\tilde{\gamma}_{1,m}(t)$ are to be computed in the same way as $\lambda_m(t_1,t_0)$ and $\gamma_m(t_1,t_0)$ [replace $\varphi_{-(m-1),0}$ with $\varphi_{-m,0}$ and $\hat{E}_{m,1}(t)$ with $\tilde{\hat{E}}_{m,1}(t)$ associated to $\tilde{Q}_m(t)$]. Finally,

$$\tilde{\alpha}_{2m-1}(t_2,t_1) := 1-\frac{|\hat{V}(2m-1)|^2}{m-\frac{1}{2}}\tilde{c}_{2,m}(t_2,t_1) - i\tilde{\omega}_{1,m}(t_2,t_1), \tag{5.56}$$

$$\tilde{\beta}_{2m-1} := \frac{\overline{\hat{V}(2m-1)}}{\sqrt{m-\frac{1}{2}}}\tilde{c}_{1,m}(t_2,t_1) - i\tilde{\lambda}_m(t_2,t_1). \tag{5.57}$$

The proof of Theorem 5.1 is finished. □

VI. THE LONG TIME BEHAVIOR. SPECTRAL PROPERTIES

The last part of this work is concerned with the long time behavior of the Bloch electron. Suppose that at the time $t_0=-\frac{1}{4}$ the electron is in a given band [say $E_{2n_0-2}(t_0)$ for n_0 fixed] and its wave function $\psi(t_0)=\varphi_{2n_0-2}(t_0)$ [let us recall that $\varphi_i(t)$ is the eigenfunction of $H(t)$ which corresponds to the eigenvalue $E_i(t)$]. We are interested in obtaining some quantitative information about $\psi(t_N)=U(t_N,t_0)\psi(t_0)$ where $t_N=t_0+(N/2)$, particular attention being payed to the case when N goes to infinity.

To answer these questions we proceed as follows: the complete evolution $U(t_N,t_0)$ is written as a product of one-period evolutions $U(t_l+1,t_l)$ each of them being then reduced to the first period $I_0\cup I_1$ by using (2.25). Then we use Theorem 3.1 to approximate the one-period evolution by the adiabatic evolutions which were written explicitly (in suitable subspaces) in Theorem 5.1. As pointed out by Ao it is of particular interest to establish how far the electron goes in the energy

space, otherwise stated, to say up to what band it is accelerated by the electric field. Because in the neighbor band approximation the electron can jump during one-half period only up to the next band it is clear that after N-half periods the uppermost reachable band is $E_{2n_0-2+N}(t_N)$. Its eigenfunction $\varphi_{2n_0-2+N}(t_N)$ is related to $\varphi_{2n_0-2+N}(t_0)$ by the shift operator T [see (2.49)]. The long time behavior of the Bloch electron is described in the following theorem.

Theorem 6.1: *Let $r>0$ and n_0 sufficiently large. Define the so-called propagating front,*[2]

$$\mathcal{P}(N) := |\langle \varphi_{2n_0-2+N}(t_N), U(t_N,t_0)\varphi_{2n_0-2}(t_0)\rangle|^2. \tag{6.1}$$

Then

$$\liminf_{N\to\infty} \mathcal{P}(N) = \exp\left\{ -2\sum_{l=0}^{\infty} \frac{|\hat{V}(2n_0+l-2)|^2}{n_0+(l/2)-1} c_{2,n_0+(l/2)}(t_1,t_0) \right\} \times (1+\mathcal{R}), \tag{6.2}$$

with

$$|\mathcal{R}| \leqslant \sum_{l=0}^{\infty} \frac{C_V}{\left\langle n_0 + l - \frac{1}{2}\right\rangle^{1+2r}} + \frac{C_V \log^8\langle n_0\rangle}{\langle n_0\rangle^{\min\{1+8r,1/2+5r,1/2+r,1\}}} \exp\left(\sum_{l=0}^{\infty} \frac{C_V}{\langle n_0+(l/2)-1\rangle^{1+2r}} \right). \tag{6.3}$$

As one may guess we need first a more explicit form for the scalar product in Eq. (6.1). Consequently a preliminary result is the following.

Lemma 6.2: For $r>-\frac{1}{10}$, n_0 sufficiently large and N even one gets

$$\langle \varphi_{2n_0+N-2}(t_N), U(t_N,t_0)\varphi_{2n_0-2}(t_0)\rangle = \prod_{l=0}^{(N/2)-1} e^{-i(\tilde{\theta}_{n_0+l}(t_2,t_1)+\theta_{n_0+l}(t_1,t_0))} \tilde{\alpha}_{2(n_0+l)-1}(t_2,t_1)\alpha_{2(n_0+l)-2}(t_1,t_0) + \mathcal{R}(N), \tag{6.4}$$

where the remainder $\mathcal{R}(N)$ satisfy the estimate

$$|\mathcal{R}(N)| \leqslant \frac{C_V \log^8\langle n_0\rangle}{\langle n_0\rangle^{\min\{1+8r,1/2+5r,1/2+r,1\}}}. \tag{6.5}$$

A similar expression holds for N odd.

Proof: The idea is to factorize $U(t_N,t_0)$ into one-period evolutions and to use the adiabatic theorem for a suitable index m of the two-dimensional projector $Q_m(t)$ or $\tilde{Q}_m(t)$. By the telescoping sum rule,

$$\prod_{l=0}^{n} a_l - \prod_{l=0}^{n} b_l = \sum_{l'=0}^{n} \prod_{l=l'+1}^{n} a_l (a_{l'} - b_{l'}) \prod_{l=0}^{l'-1} b_l$$

one has

$$U(t_N,t_0) = \prod_{l=0}^{(N/2)-1} U(t_{2l+2},t_{2l+1})U(t_{2l+1},t_{2l}) =: \prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}(t_{2l+2},t_{2l+1})U^A_{n_0+l}(t_{2l+1},t_{2l}) + \mathcal{R}_{\mathrm{ad}}(N). \tag{6.6}$$

The property $T^* U(t,s)T = U(t+1,s+1)$ leads to

$$\mathcal{R}_{\mathrm{ad}}(N) := \sum_{l=0}^{(N/2)-1} U(t_N,t_{2l+2})(T^*)^l(\ U(t_2,t_0)) - \tilde{U}^A_{n_0+l}(t_2,t_1)U^A_{n_0+l}(t_1,t_0))T^l \times \prod_{k=0}^{l-1}(T^*)^k\tilde{U}^A_{n_0+k}(t_2,t_1)U^A_{n_0+k}(t_1,t_0)T^k.$$

We pass now to the estimation of $\mathcal{R}_{\mathrm{ad}}(N)$. Clearly due to the presence of many unitarities one gets at once from the adiabatic theorem,

$$\|\mathcal{R}_{\mathrm{ad}}(N)\| \leqslant \sum_{l=0}^{(N/2)-1} \|U(t_2,t_0) - \tilde{U}^A_{n_0+l}(t_2,t_1)U^A_{n_0+l}(t_1,t_0)\| \leqslant \sum_{l=0}^{(N/2)-1} \|U(t_2,t_1) - \tilde{U}^A_{n_0+l}(t_2,t_1)\| + \|U(t_1,t_0) - U^A_{n_0+l}(t_1,t_0)\| \leqslant \sum_{l=0}^{(N/2)-1} 2C_V b(n_0+l)\langle n_0+l\rangle^{-1}.$$

We concentrate on the following term:

$$\begin{aligned}
&\prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}(t_{2l+2},t_{2l+1})U^A_{n_0+l}(t_{2l+1},t_{2l})P_{2n_0-2}(t_0)\\
&\quad= \sum_{j_{N/2}=1}^{\infty} P_{j_{N/2}}(t_N) \prod_{l=0}^{(N/2)-1} \left(\tilde{U}^A_{n_0+l}(t_{2l+2},t_{2l+1}) \sum_{\tilde{j}_l=1}^{\infty} P_{\tilde{j}_l}(t_{2l+1})U^A_{n_0+l}(t_{2l+1},t_{2l}) \sum_{j_l=1}^{\infty} P_{j_l}(t_{2l}) \right) P_{2n_0-2}(t_0)\\
&\quad= \sum_{j_{N/2},j_{(N/2)-1},\tilde{j}_{(N/2)-1},\ldots,j_0,\tilde{j}_0} P_{j_{N/2}}(t_N)\\
&\qquad\times \left(\prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}(t_{2l+2},t_{2l+1})P_{\tilde{j}_l}(t_{2l+1})U^A_{n_0+l}(t_{2l+1},t_{2l})P_{j_l}(t_{2l}) \right) P_{2n_0-2}(t_0),
\end{aligned}$$

where all the j indices run for the moment from 1 to ∞. However since U^A_n and $\tilde{U}^A_n$ leave invariant Ran Q_n and Ran $\tilde{Q}_n$ and since for any $l \in \mathbb{Z}$

$$Q_n(t_l) = P_{2n-2}(t_l) + P_{2n-1}(t_l),$$

$$\tilde{Q}_n(t_l) = P_{2n-1}(t_l) + P_{2n}(t_l),$$

we know that the only indices which contribute are the ones of the set J_{2n_0-2} where we define J_n as follows:

$$J_n := \{(j_{N/2},\tilde{j}_{(N/2)-1},j_{(N/2)-1},\ldots,\tilde{j}_0,j_0),\quad j_0 = 2n_0-2,\quad \forall\, l,\quad \tilde{j}_l = j_l \text{ or } j_l+1;\quad j_{l+1} = \tilde{j}_l \text{ or } \tilde{j}_l+1\}.$$

Then (we drop the times variables in U^A and $\tilde{U}^A$ since their values are clear from the context)

$$\left(\prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}U^A_{n_0+l} \right) P_{2n_0-2} = \sum_{J_{2n_0-2}} P_{j_{N/2}} \prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}P_{\tilde{j}_l}U^A_{n_0+l}P_{j_l}.$$

Clearly if we force $j_{N/2}$ to be equal to $2n_0+N-2$ by multiplying on the left by P_{2n_0+N-2} it remains only one "path" in this sum. Using (2.25), (2.49), (5.3), and (5.4) one may write

$$\begin{aligned}
&\left\langle \varphi_{2n_0+N-2}(t_N),\ \prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}(t_{2l+2},t_{2l+1})U^A_{n_0+l}(t_{2l+1},t_{2l})\varphi_{2n_0-2}(t_0)\right\rangle = \left\langle \varphi_{2n_0+N-2}(t_N), P_{2n_0+N-2}(t_N)\right.\\
&\quad\left.\times \prod_{l=0}^{(N/2)-1} \tilde{U}^A_{n_0+l}(t_{2l+2},t_{2l+1})P_{2n_0+2l-1}(t_{2l+1})U^A_{n_0+l}(t_{2l+1},t_{2l})P_{2n_0+2l-2}(t_{2l})\varphi_{2n_0-2}(t_0)\right\rangle\\
&= \left\langle \varphi_{2n_0+N-2}(t_2), T^{(N/2)-1}P_{2n_0+N-2}(t_N)\right.\\
&\quad\left.\times \prod_{l=0}^{(N/2)-1} (T^*)^l\tilde{U}^A_{n_0+l}(t_2,t_1)P_{2n_0+2l-1}(t_1)U^A_{n_0+l}(t_1,t_0)P_{2n_0+2l-2}(t_0)T^l\varphi_{2n_0-2}(t_0)\right\rangle\\
&= \prod_{l=0}^{(N/2)-1} \tilde{S}^{n_0+l}_{2n_0+2l,2n_0+2l-1}(t_2,t_1)S^{n_0+l}_{2n_0+2l-1,2n_0+2l-2}(t_1,t_0)\\
&=: \prod_{l=0}^{(N/2)-1} e^{-i\tilde{\theta}_{n_0+l}(t_2,t_1)}\tilde{\alpha}_{2n_0+2l-1}(t_2,t_1)e^{-i\theta_{n_0+l}(t_1,t_0)}\alpha_{2n_0+2l-2}(t_1,t_0) + \mathcal{R}_{\mathrm{eff}}(N),
\end{aligned}$$

where

$$\begin{aligned}
|\mathcal{R}_{\mathrm{eff}}(N)| &\leqslant \sum_{l=0}^{(N/2)-1} (2|\mathcal{R}_{\mathrm{eff},n_0+l}| + |R_{\mathrm{eff},n_0+l}|^2) \leqslant \sum_{l=0}^{\infty} (2|\mathcal{R}_{\mathrm{eff},n_0+l}| + |\mathcal{R}_{\mathrm{eff},n_0+l}|^2)\\
&= \frac{C_V \log^8\langle n_0\rangle}{\langle n_0\rangle^{\min\{1+8r,1/2+5r,1/2+r,1\}}}.
\end{aligned}$$

Defining

$$\mathcal{R}(N) := \mathcal{R}_{\mathrm{eff}}(N) + \langle \varphi_{2n_0+N-2}, \mathcal{R}_{\mathrm{ad}}(N)\varphi_{2n_0-2}\rangle \tag{6.7}$$

the lemma follows immediately from the estimates of $\mathcal{R}_{\mathrm{ad}}(N)$ and $\mathcal{R}_{\mathrm{eff}}(N)$. □

Proof of Theorem 6.1: Let

$$\mathcal{A}(N) := \prod_{l=0}^{(N/2)-1} e^{-i(\tilde{\theta}_{n_0+l}(t_2,t_1)+\theta_{n_0+l}(t_1,t_0))}\tilde{\alpha}_{2n_0+2l-1}(t_2,t_1)\alpha_{2n_0+2l-2}(t_1,t_0). \tag{6.8}$$

Then by Lemma 6.2 the propagating front reads as

$$\mathcal{P}(N) = |\mathcal{A}(N)|^2 \cdot \left|1 + \frac{\mathcal{R}(N)}{\mathcal{A}(N)}\right|^2. \tag{6.9}$$

Replacing $\alpha_{2m-2}(t_1,t_0)$ and $\tilde{\alpha}_{2m-1}(t_2,t_1)$ for $m=n_0+k$ it follows that (we omit the time arguments for the simplicity of writing)

$$\begin{aligned}
|\mathcal{A}(N)| = \prod_{l=0}^{(N/2)-1} |\tilde{\alpha}_{2n_0+2l-1}\alpha_{2n_0+2l-2}| &= \prod_{l=0}^{(N/2)-1} \left(\left(1 - \frac{|\hat{V}(2n_0+2l-1)|^2}{n_0+l-\frac{1}{2}}\tilde{c}_{2,n_0+l}\right)^2 + \tilde{\omega}^2_{1,n_0+l}\right)^{1/2}\\
&\quad\times \left(\left(1 - \frac{|\hat{V}(2(n_0+l-1))|^2}{n_0+l-1}c_{2,n_0+l}\right)^2 + \omega^2_{1,n_0+l}\right)^{1/2}\\
&= \exp\left\{\frac{1}{2}\sum_{l=0}^{(N/2)-1} \log\left(\left(1 - \frac{|\hat{V}(2n_0+2l-1)|^2}{n_0+l-\frac{1}{2}}\tilde{c}_{2,n_0+l}\right)^2 + \tilde{\omega}^2_{1,n_0+l}\right)\right\}
\end{aligned}$$

$$\times \exp\left\{\frac{1}{2}\sum_{l=0}^{(N/2)-1}\log\left(\left(1-\frac{|\hat{V}(2(n_0+l-1))|^2}{n_0+l-1}c_{2,n_0+l}\right)^2+\omega_{1,n_0+l}^2\right)\right\}$$

$$=\exp\left\{-\sum_{l=0}^{N-1}\frac{|\hat{V}(2n_0+l-2)|^2}{n_0+\frac{l}{2}-1}c_{2,n_0+(l/2)}\right\}$$

$$\times\left(1+\mathcal{O}\left(\sum_{l=0}^{\infty}\frac{1}{\langle n_0+l-\frac{1}{2}\rangle^{1+2r}}\right)\right),$$

where we used estimates of the following type (similar bounds are found for the sums containing ω_{1,n_0+l}^2 and $\tilde{\omega}_{1,n_0+l}^2$) and the relation $\tilde{c}_{i,m}(t_2,t_1)=c_{i,m+1/2}(t_1,t_0)$:

$$\sum_{l=0}^{(N/2)-1}\left|\frac{|\hat{V}(2n_0+2l-1)|^2}{n_0+l-\frac{1}{2}}\tilde{c}_{2,n_0+l}\right|\leqslant\sum_{l=0}^{\infty}\left|\frac{C_V}{\langle n_0+l-\frac{1}{2}\rangle^{1+2r}}\right|.$$

Thus

$$\lim_{N\to\infty}\left|\frac{\mathcal{R}(N)}{\mathcal{A}(N)}\right|=:|\mathcal{R}|\leqslant\frac{C_V\log^8\langle n_0\rangle}{\langle n_0\rangle^{\min\{1+8r,1/2+5r,1/2+r,1\}}}\exp\left(\sum_{l=0}^{\infty}\frac{C_V}{\langle n_0+(l/2)-1\rangle^{1+2r}}\right).$$

The proof of the theorem is done. □

Remark 6.3: Since as long as $r>0$ the series that appears in Eq. (6.2) both in the exponential and in the error term converges the propagating front does not vanish in the limit $N\to\infty$. This means that the electron is always accelerated and it escapes at infinity *in the energy space*, provided that it is initially prepared in a band with sufficient energy. Thus we recovered rigorously the Ao's result. We end the paper with a result on the spectral properties of the Stark–Wannier operator.

Corollary 6.4: For $r>0$ one has $\sigma_{\mathrm{cont}}(H^{\mathrm{SW}})\neq\emptyset$.

Proof of Corollary 6.4: Let $\phi\in\mathcal{H}_{\mathrm{pp}}(H^{\mathrm{SW}})$ and Π_N a family of bounded operators that goes strongly to zero when $N\to\infty$. Then it is known (see Ref. 14) that

$$\lim_{N\to\infty}\sup_{\pm t>0}\left\|\Pi_N e^{-itH^{\mathrm{SW}}}\phi\right\|=0.$$

In particular, for $t_N:=t_0+(N/2)$,

$$\lim_{N\to\infty}\left\|\Pi_N e^{-i(t_N-t_0)H^{\mathrm{SW}}}\phi\right\|=0. \tag{6.10}$$

The strategy of the proof consists in writing $\Pi_N e^{-i(t_N-t_0)H^{\mathrm{SW}}}\phi$ in the Fourier–Bloch representation and then to express the result in terms of the propagating front $\mathcal{P}(N)$ which was computed in Theorem 6.1. Using (2.21), writing [see (2.22)]

$$U(k,t_N,t_0)=U(0,t_N+k,t_0+k)=:U(t_N+k,t_0+k)=U(t_N+k,t_N)U(t_N,t_0)U(t_0,t_0+k)$$

and choosing

$$\phi:=e^{it_0X}S^*\left(\int_{[0,1)}^{\oplus}\mathrm{d}k\,U(t_0,t_0+k)\varphi_{2n_0-2}(t_0)\right) \tag{6.11}$$

one has

$$\|\Pi_N e^{-i(t_N-t_0)H^{\mathrm{SW}}}\phi\| = \left\| Se^{-it_N X}\Pi_N e^{it_N X}S^*\left(\int_{[0,1)}^{\oplus} \mathrm{d}k\, U(t_N+k,t_N)U(t_N,t_0)\varphi_{2n_0-2}(t_0)\right)\right\|.$$

Now we choose Π_N such that

$$Se^{-it_N X}\Pi_N e^{it_N X}S^*\left(\int_{[0,1)}^{\oplus} \mathrm{d}k\, U(t_N+k,t_N)\right) = \left(\int_{[0,1)}^{\oplus} \mathrm{d}k\, P_{2n_0-2+N}(t_N)\right). \tag{6.12}$$

Let us show that Π_N goes strongly to zero as N goes to infinity. Using the identity

$$Se^{-inX}S^* = \mathrm{id}\otimes T^{-n}, \quad \forall\, n\in\mathbb{Z} \tag{6.13}$$

it turns out that Π_N is given by

$$\Pi_N := e^{it_N X}S^*\left(\int_{[0,1)}^{\oplus} \mathrm{d}k\, P_{2n_0-2+N}(t_N)U(t_N,t_N+k)\right)Se^{-it_N X} = e^{it_0 X}S^*\left(\int_{[0,1)}^{\oplus} \mathrm{d}k\, T^{N/2}P_{2n_0-2+N}(t_N)U(t_N,t_N+k)T^{-(N/2)}\right)Se^{-it_0 X} = e^{it_0 X}S^*\left(\int_{[0,1)}^{\oplus} \mathrm{d}k\, P_{2n_0-2+N}(t_0)U(t_0,t_0+k)\right)Se^{-it_0 X}.$$

Then clearly

$$s-\lim_{N\to\infty}\Pi_N = 0.$$

Finally observe that from (6.11) and (6.12)

$$\|\Pi_N e^{-i(t_N-t_0)H^{\mathrm{SW}}}\phi\|^2 = \|P_{2n_0-2+N}(t_N)U(t_N,t_0)\varphi_{2n_0-2}(t_0)\|^2 = \mathcal{P}(N).$$

However, from Theorem 6.1 we know that for n_0 sufficiently large and $r>0$ the propagating front $\mathcal{P}(N)$ does not vanish when $N\to\infty$ so ϕ must have a part in $\mathcal{H}_{\mathrm{cont}}(H^{\mathrm{SW}})$. □

When applied to the driven quantum ring problem the existence of a propagating front gives the following at once.

Corollary 6.5: Let $r>0$ and $\varphi\left(t_0=-\frac{1}{4}\right)=\varphi_{2n_0-2}(t_0)$, $\varphi[t_N=t_0+(N/2)]=U(t_N,t_0)\varphi(t_0)$. Then

$$\langle\varphi(t_N),H(t)\varphi(t_N)\rangle \geqslant \left(1+\mathcal{O}_r\left(\frac{1}{\langle n_0\rangle^r}\right)\right)\cdot t^2. \tag{6.14}$$

We end this section of applications by showing that there is no localization in momentum space for appropriate initial conditions.

Corollary 6.6: Let $F_D(I)$ be the spectral projection of $D:=-i\partial_x$ on the interval $I:=[n_0,n_0+1)$. Then for all V such that $r>0$ one has

$$\lim_{n_0\to\infty}\lim_{N\to\infty}\|F_D(I+t_N)e^{-i(t_n-t_0)H^{\mathrm{SW}}}F_D(I+t_0)\| = 1.$$

Proof: One can check that SDS^* is simply the multiplication by $k+n$; thus $SF_D(I)S^*=1\otimes P_{n_0,0}$. One has successively

$$\|F_D(I+t_N)e^{-i(t_N-t_0)H^{\mathrm{SW}}}F_D(I+t_0)\| = \left\| F_D(I+t_N)e^{it_N X}S^*\int_{[0,1)}^{\oplus}\mathrm{d}k\, U(t_N+k,t_0+k)Se^{-it_0 X}F_D(I+t_0)\right\| \quad [\text{see (2.21)}]$$

$$= \left\| Se^{-it_N X}F_D(I+t_N)e^{it_N X}S^*\int_{[0,1)}^{\oplus}\mathrm{d}k\, U(t_N+k,t_0+k)Se^{-it_0 X}F_D(I$$

$$
\begin{aligned}
&+ t_0)e^{it_0X}S^*\Big\| \\
&= \left\| SF_D(I)S^\star \int_{[0,1)}^{\oplus} \mathrm{d}k\, U(t_N + k, t_0 + k) SF_D(I)S^\star \right\| \\
&= \left\| 1 \otimes P_{n_0,0} \int_{[0,1)}^{\oplus} \mathrm{d}k\, U(t_N + k, t_0 + k) 1 \otimes P_{n_0,0} \right\| = \sup_{k\in[0,1)} \\
&\quad \times \| \times P_{n_0,0} U(t_N + k, t_0 + k) P_{n_0,0} \| \geqslant \| P_{n_0,0} U(t_N, t_0) P_{n_0,0} \| \\
&= \| P^0_{2n_0+N}(t_N) U(t_N, t_0) P^0_{2n_0+N}(t_0) \| \quad [\text{see (2.30)}] \\
&= \| P_{2n_0+N}(t_N) U(t_N, t_0) P_{2n_0+N}(t_0) \| + \mathcal{O}_r(b(n_0 + 1)) \\
&\quad (\text{see Corollary 2.6}) \\
&= \mathcal{P}(N + 1) + \mathcal{O}_r(b(n_0 + 1)).
\end{aligned}
$$

Using Theorem 6.1, the rest is now clear. □

APPENDIX

The key estimate

Proof of Lemma 2.3: In the following we shall use the notation $\alpha := \max\{0, -r\}$. We start by estimating $\sup_{t\in I_0} \sup_{z\in\Gamma_m} \|K((d_m + iy), t)\|$,

$$
\begin{aligned}
\sup_{t\in I_0} \sup_{z\in\Gamma_m} \|K((d_m + iy), t)\|_{\mathrm{HS}} &\leqslant \|V\|_r \left(\frac{\sqrt{5}}{2}\right)^{\alpha} \sup_{t\in I_0} \sum_{n\in\mathbb{Z}} \frac{\langle n\rangle^{2\alpha}}{|(n + t)^2 - d_m - iy|} \\
&\leqslant \|V\|_r \left(\frac{\sqrt{5}}{2}\right)^{\alpha} \sup_{t\in I_0} \sum_{n\in\mathbb{Z}} \frac{\langle n\rangle^{2\alpha}}{|(n + t)^2 - d_m|} \leqslant 4\|V\|_r \left(\frac{\sqrt{5}}{2}\right)^{\alpha} \sum_{n\in\mathbb{Z}} \frac{\langle n\rangle^{2\alpha}}{|n^2 - d_m|} \\
&= \|V\|_r \left(\frac{\sqrt{5}}{2}\right)^{\alpha} \left\{ \frac{1}{d_m} + 2 \sum_{n\geqslant 1} \frac{\langle n\rangle^{2\alpha}}{|n^2 - d_m|} \right\} \qquad \text{(A1)}
\end{aligned}
$$

where the time dependence of $K((d_m + iy), t)$ was eliminated by using the inequality (proved below)

$$
\sup_{t\in I_0} |(n + t)^2 - d_m| \geqslant \tfrac{1}{4}|n^2 - d_m|. \qquad \text{(A2)}
$$

The next step is to estimate the sum from the rhs of (A1). Let us assume that $m > 1$ (the particular case $m = 1$ will be discussed separately). Then approximating the sum with integrals one has

$$\sum_{n\geqslant 1}\frac{\langle m\rangle^{2\alpha}}{|n^2-d_m|}\leqslant\int_1^{m-1}\frac{\langle x\rangle^{2\alpha}}{d_m-x^2}\mathrm{d}x+\frac{\langle m-1\rangle^{2\alpha}}{\frac{1}{2}\left(2m-\frac{3}{2}\right)}+\frac{\langle m\rangle^{2\alpha}}{m-\frac{1}{4}}+\int_m^{\infty}\frac{\langle x\rangle^{2\alpha}}{x^2-d_m}=:S_1+S_2+S_3+S_4. \tag{A3}$$

Since $\langle x\rangle$ is an increasing function we can estimate the term S_1 as follows:

$$S_1\leqslant\langle m-1\rangle^{2\alpha}\int_1^{m-1}\frac{\mathrm{d}x}{d_m-x^2}=\frac{\langle m-1\rangle^{2\alpha}}{2\sqrt{d_m}}\log\left(\frac{\sqrt{d_m}+m-1}{\sqrt{d_m}-(m-1)}\cdot\frac{\sqrt{d_m}-1}{\sqrt{d_m}+1}\right)\leqslant\frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}}\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right). \tag{A4}$$

To obtain the last line we used the following estimate (valid for $m\geqslant 2$):

$$\frac{\sqrt{d_m}+m-1}{\sqrt{d_m}-(m-1)}\cdot\frac{\sqrt{d_m}-1}{\sqrt{d_m}+1}=\frac{2m-\frac{3}{2}}{\frac{1}{2}}\cdot\frac{m-\frac{3}{2}}{m+\frac{1}{2}}\leqslant\frac{2m-\frac{1}{2}}{\frac{1}{2}}=\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}.$$

The next two terms are easier,

$$S_2\leqslant\frac{12}{5\log 7}\cdot\frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}}\cdot\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right), \tag{A5}$$

$$S_3\leqslant\frac{12}{7\log 7}\cdot\frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}}\cdot\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right). \tag{A6}$$

We give some details only for S_2. First we write

$$S_2=\frac{\langle m-1\rangle^{2\alpha}}{\frac{1}{2}\left(2m-\frac{3}{2}\right)}\leqslant\frac{\langle m\rangle^{2\alpha}}{\frac{1}{2}\left(2m-\frac{3}{2}\right)}\cdot\frac{\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right)}{2\sqrt{d_m}}\cdot\frac{2\sqrt{d_m}}{\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right)}.$$

Then use

$$\frac{2\sqrt{d_m}}{\frac{1}{2}\left(2m-\frac{3}{2}\right)}=\frac{4\left(m-\frac{1}{2}\right)}{2m-\frac{3}{2}}=2\cdot\frac{m-\frac{1}{2}}{m-\frac{3}{4}}\leqslant\frac{12}{5}$$

and

$$\frac{1}{\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right)}=\frac{1}{\log\left(\frac{2m-\frac{1}{2}}{\frac{1}{2}}\right)}\leqslant\frac{1}{\log 7}.$$

To estimate S_4 we make an integration by parts,

$$\begin{aligned}S_4=\int_m^{\infty}\frac{(1+x^2)^{\alpha}}{x^2-d_m}&=\left[\frac{(1+x^2)^{\alpha}}{2\sqrt{d_m}}\log\left(\frac{x-\sqrt{d_m}}{x+\sqrt{d_m}}\right)\right]_m^{\infty}-\frac{\alpha}{\sqrt{d_m}}\int_m^{\infty}\mathrm{d}x\,x(1+x^2)^{\alpha-1}\log\left(\frac{x-\sqrt{d_m}}{x+\sqrt{d_m}}\right)\\&\leqslant\frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}}\log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right)+\frac{\alpha}{\sqrt{d_m}}\left(\sup_{x\geqslant m}x\log\left(\frac{x+\sqrt{d_m}}{x-\sqrt{d_m}}\right)\right)\int_m^{\infty}x^{2(\alpha-1)}\,\mathrm{d}x.\end{aligned}$$

The supremum above is computed by simply noticing that the function $f(x):=x\log[(x+a)/(x-a)]$ is decreasing on (a,∞). Indeed, its first two derivatives are given by

$$f'(x) = \log\left(\frac{x+a}{x-a}\right) + \frac{2xa}{a^2-x^2} \to 0 \quad \text{if } x \to \infty,$$

$$f''(x) = \frac{4a^3}{(a^2-x^2)^2}.$$

Hence

$$S_4 \leqslant \frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}} \log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right) + \frac{\alpha}{1-2\alpha}\frac{\langle m\rangle^{2\alpha}}{\sqrt{d_m}} \log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right) = \frac{1}{2(1-2\alpha)} \cdot \frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}} \cdot \log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right). \tag{A7}$$

Now taking into account that

$$\frac{1}{d_m} \leqslant \frac{4}{3\log 7} \frac{\langle m\rangle^{2\alpha}}{2\sqrt{d_m}} \log\left(\frac{m+\sqrt{d_m}}{m-\sqrt{d_m}}\right), \tag{A8}$$

and that $2\sqrt{d_m} \geqslant (3/\sqrt{5})\langle m\rangle$ we collect all the estimates (A4)–(A7) and plug them into (A1)

$$\sup_{t\in I_0}\sup_{z\in\Gamma_m} \|K((d_m+iy),t)\| \leqslant \|V\|_r \frac{4\sqrt{5}}{3}\left(\frac{\sqrt{5}}{2}\right)^{\alpha} \cdot \frac{9-6\alpha}{1-2\alpha} \frac{\log(4m-1)}{\langle m\rangle^{1-2\alpha}} := C_V \frac{\log(4m-1)}{\langle m\rangle^{1+\min\{0,2r\}}}. \tag{A9}$$

Note that the constant C_V depends on r and has a pathological behavior at $r=-\frac{1}{2}$. We treat now the case $m=1$. This term contains actually only the terms of the type S_3 and S_4, so that

$$\sup_{t\in I_0}\sup_{z\in\Gamma_1} \|K((d_1+iy),t)\| \leqslant \|V\|_r \left(\frac{\sqrt{5}}{2}\right)^{\alpha} \left\{ \frac{1}{d_1} + 2\sum_{n\geqslant 1} \frac{\langle 1\rangle^{2\alpha}}{|n^2-d_1|} \right\}$$

and

$$\sum_{n\geqslant 1}^{\infty} \frac{\langle n\rangle^{2\alpha}}{\left|n^2-\frac{1}{4}\right|} \leqslant \frac{4\langle 1\rangle^{2\alpha}}{3} + \int_2^{\infty} \frac{\langle x\rangle^{2\alpha}}{x^2-\frac{1}{4}}.$$

This leads to

$$\sup_{t\in I_0}\sup_{z\in\Gamma_1} \|K((d_1+iy),t)\| \leqslant \|V\|_r \left(\frac{\sqrt{5}}{2}\right)^{\alpha} \left(4 + \frac{8\langle 1\rangle^{2\alpha}}{3} + \frac{\langle 1\rangle^{2\alpha}}{1-2\alpha}\log 3\right) \leqslant C_V \frac{\log 3}{\langle 1\rangle^{1+\min\{0,2r\}}}. \tag{A10}$$

Inspecting (A9) and (A10) it is clear that one has for any $m \geqslant 1$,

$$\sup_{t\in I_0}\sup_{z\in\Gamma_m} \|K((d_m+iy),t)\| \leqslant C_V \frac{\log(4m-1)}{\langle m\rangle^{1+\min\{0,2r\}}}. \tag{A11}$$

From this estimate one can identify m^* such that for any $m > m^*$ we have $\sup_{t\in I_0}\sup_{z\in\Gamma_m}\|K((d_m+iy),t)\| \leqslant 1$.

Now we turn to the estimation of $\sup_{t\in I_0}\int_{\Gamma_m}\|R_0(z,t)\|\cdot\|K(z,t)\|\mathrm{d}y$. The resolvent is easily estimated as

$$\|R_0(z,t)\| \leqslant \frac{1}{\sqrt{A^2+y^2}}, \tag{A12}$$

where we introduced the notation $A := (m-\frac{1}{2})^2-(m-\frac{3}{4})^2$. Since $\sup_{t\in I_0}\|K(z,t)\| \leqslant 4\|K(z,0)\|_{\mathrm{HS}}$ we have

$$\begin{aligned}
\sup_{t\in I_0}\int_{\Gamma_m}\|R_0(z,t)\|\cdot\|K(z,t)\|\mathrm{d}y &\leqslant 4\|V\|_r\left(\frac{\sqrt{5}}{2}\right)^{\alpha}\int_{-\infty}^{\infty}\mathrm{d}y\frac{1}{\sqrt{A^2+y^2}}\left(\sum_{n_1\in\mathbb{Z}}\frac{\langle n_1\rangle^{2\alpha}}{\sqrt{B_{n_1}^2+y^2}}\cdot\sum_{n_2\in\mathbb{Z}}\frac{\langle n_2\rangle^{2\alpha}}{\sqrt{B_{n_2}^2+y^2}}\right)^{1/2}\\
&\leqslant 4\|V\|_r\left(\frac{\sqrt{5}}{2}\right)^{\alpha}\left(\int_{-\infty}^{\infty}\mathrm{d}y\sum_{n_1\in\mathbb{Z}}\frac{\langle n_1\rangle^{2\alpha}}{\sqrt{A^2+y^2}\sqrt{B_{n_1}^2+y^2}}\right)^{1/2}\\
&\quad\cdot\left(\int_{-\infty}^{\infty}\mathrm{d}y\sum_{n_2\in\mathbb{Z}}\frac{\langle n_2\rangle^{2\alpha}}{\sqrt{A^2+y^2}\sqrt{B_{n_2}^2+y^2}}\right)^{1/2}\quad\text{by Cauchy – Schwartz}\\
&= 4\|V\|_r\left(\frac{\sqrt{5}}{2}\right)^{\alpha}\sum_{n\in\mathbb{Z}}\langle n\rangle^{2\alpha}\int_{-\infty}^{\infty}\frac{\mathrm{d}y}{\sqrt{A^2+y^2}\sqrt{B_n^2+y^2}}\\
&:= 4\|V\|_r\left(\frac{\sqrt{5}}{2}\right)^{\alpha}\sum_{n\in\mathbb{Z}}\langle n\rangle^{2\alpha}I(A,B_n).
\end{aligned}$$

In the above calculation we used as well the notation

$$B_n := n^2 - d_m. \tag{A13}$$

The integral $I(A,B_n)$ is estimated as follows (in our case $B_n > A$ always):

$$\begin{aligned}
I(A,B_n) &\leqslant \frac{1}{B_n^{1-\delta}}\int_{-\infty}^{\infty}\mathrm{d}y\frac{1}{\sqrt{A^2+y^2}\cdot(A^2+y^2)^{\delta/2}} = \frac{1}{A^{\delta}B_n^{1-\delta}}\int_{-\infty}^{\infty}\mathrm{d}p\frac{1}{(1+p^2)^{(1+\delta)/2}}\\
&= \frac{1}{A^{\delta}B_n^{1-\delta}}\cdot\frac{\sqrt{\pi}\Gamma(\delta/2)}{\Gamma((1+\delta)/2)} = \frac{C_{\delta}}{A^{\delta}B_n^{1-\delta}},
\end{aligned}$$

where we made the substitution $p=y/A$. On the other hand, B_n obeys the following estimate:

$$B_n = |n^2 - d_m| \leqslant \max\{n^2, d_m\} \leqslant \max\{\langle n\rangle^2, \langle d_m\rangle^2\} \leqslant \langle n\rangle^2\langle d_m\rangle^2 \tag{A14}$$

from where

$$I(A,B_n) \leqslant C_{\delta}\frac{\langle n\rangle^{2\delta}\langle d_m\rangle^{2\delta}}{A^{\delta}B_n}. \tag{A15}$$

Using the fact that the function $g(m) := \langle d_m\rangle^2/A\langle n\rangle$ is decreasing so that $\max_{m\in\mathbb{Z}} g(m) = g(0) = 4$ one has $\langle d_m\rangle^{2\delta}/A^{\delta} \leqslant 4\langle m\rangle^{2\delta}$. Thus

$$\sup_{t\in I_0}\int_{\Gamma_m}\|R_0(z,t)\|\cdot\|K(z,t)\|\mathrm{d}y \leqslant 16\|V\|_r\left(\frac{\sqrt{5}}{2}\right)^{\alpha}C_{\delta}\langle m\rangle^{2\delta}\sum_{n\in\mathbb{Z}}\frac{\langle n\rangle^{2(\alpha+\delta)}}{|n^2-d_m|} \leqslant C_V C_{\delta}\frac{\langle m\rangle^{4\delta}\log(4m-1)}{\langle m\rangle^{1+\min\{0,2r\}}},$$

$$0 < \delta < \frac{1}{4} - \frac{\alpha}{2}. \tag{A16}$$

The last condition on δ assures that the rhs vanishes in the limit $m\to\infty$. We further optimize the result by using the inequality

$$C(\delta) \leqslant \frac{3}{\delta} \tag{A17}$$

and taking

$$\delta = \frac{1}{4\log\langle m\rangle} < \frac{1}{4} - \frac{\alpha}{2}, \tag{A18}$$

from where it follows that $\langle m\rangle \geqslant e^{1/(1-2\alpha)}$ and

$$\delta^{-1}\langle m\rangle^{4\delta} = 4e\log\langle m\rangle. \tag{A19}$$

Then

$$\sup_{t\in I_0}\int_{\Gamma_m}\|R_0(z,t)\|\cdot\|K(z,t)\|\mathrm{d}y \leqslant C_V\frac{\log^2(4m-1)}{\langle m\rangle^{\min\{1,1+2r\}}}. \tag{A20}$$

The estimates (A11) and (A20) lead to

$$\sup_{t\in I_0}\left(\sup_{z\in\tilde{\Gamma}_m}\|K(z,t)\| + \int_{\Gamma_m}\|R_0(z,t)\|\cdot\|K(z,t)\|\mathrm{d}y\right) \leqslant C_V\frac{\log^2\langle 4m-1\rangle}{\langle m\rangle^{\min\{1,1+2r\}}}. \tag{A21}$$

In what concerns the estimates on $\tilde{\Gamma}_m$ one must follow the same steps as above, the result being that m is pushed to $m+\frac{1}{2}$. Since $\langle m+\frac{1}{2}\rangle \leqslant \sqrt{2}\langle m\rangle$ and $\log(4m+1) \leqslant 2\log(4m-1)$ one can work only with $b(m)$. To prove (2.41) and (2.42) one must use the first resolvent identity,

$$\|K(z,t)\| \leqslant \|K(d_m,t)\|\cdot\left\|\frac{R_0(z,t)}{R_0(d_m,t)}\right\| \leqslant \|K(d_m,t)\|\left(1+\frac{|z-d_m|}{\inf_{z\in\gamma_m}\mathrm{dist}(z,\sigma(H_0(t)))}\right).$$

Since

$$\sup_{z\in\gamma_n}|z-d_m| = \sqrt{5}(m-1)$$

$$\inf_{t\in I_0}\inf_{z\in\gamma_m}\mathrm{dist}(z,\sigma(H_0(t))) \leqslant \tfrac{1}{4}\left(2m-\tfrac{11}{4}\right)$$

from where (2.42) follows. Finally let us prove (A2),

$$\begin{aligned}
\inf_{t\in I_0}\inf_{n\in\mathbb{Z}}\left|\frac{(n+t)^2-d_m}{n^2-d_m}\right| &= \inf_{t\in I_0}\inf_{n\in\mathbb{Z}}\left|\frac{(n+t)-\sqrt{d_m}}{n-\sqrt{d_m}}\right|\left|\frac{(n+t)+\sqrt{d_m}}{n+\sqrt{d_m}}\right| \\
&\geqslant \inf_{t\in I_0}\inf_{n\in\mathbb{Z}}\left|\frac{(n+t)-\sqrt{d_m}}{n-\sqrt{d_m}}\right|\inf_{t\in I_0}\inf_{n\in\mathbb{Z}}\left|\frac{(n+t)+\sqrt{d_m}}{n+\sqrt{d_m}}\right| \\
&= \inf_{t\in I_0}\inf_{n\in\mathbb{Z}}\left|1+\frac{t}{n-\sqrt{d_m}}\right|\inf_{t\in I_0}\inf_{n\in\mathbb{Z}}\left|1+\frac{t}{n+\sqrt{d_m}}\right| \\
&\geqslant \left(1-\sup_{t\in I_0}\sup_{n\in\mathbb{Z}}\left|\frac{t}{n-\sqrt{d_m}}\right|\right)\left(1-\sup_{t\in I_0}\sup_{n\in\mathbb{Z}}\left|\frac{t}{n+\sqrt{d_m}}\right|\right) \\
&\geqslant \left(1-\sup_{n\in\mathbb{Z}}\left|\frac{\frac{1}{4}}{n-\sqrt{d_m}}\right|\right)\left(1-\sup_{n\in\mathbb{Z}}\left|\frac{\frac{1}{4}}{n+\sqrt{d_m}}\right|\right) = \left(1-\frac{1}{4\,\mathrm{dist}(\sqrt{d_m},\mathbb{Z})}\right)^2 = \frac{1}{4}.
\end{aligned}$$

The proof of Lemma 2.3 is finished. □

The Sz-Nagÿ transformation

For convenience we give here the well known[15,30] Sz-Nagÿ lemma on unitary equivalence of orthogonal projections.

Lemma 7.2.1: Let P,Q be orthogonal projections in a Hilbert space $\mathcal{H}$ satisfying

$$\|P-Q\|<1 \tag{A22}$$

If U is defined by

$$U=(1-(P-Q)^2)^{-1/2}(PQ+(1-P)(1-Q)), \tag{A23}$$

then

$$U^*=U^{-1} \tag{A24}$$

and

$$P=UQU^*. \tag{A25}$$

Notice also that

$$(1-(P-Q)^2)^{-1/2}=1+\sum_{j\geqslant 1}\frac{(2j-1)!!}{j!2^j}(P-Q)^{2j}. \tag{A26}$$

The remainder of order *p* for the Dyson series

In this section we review a method to estimate the remainder of order p for the Dyson series of $\hat{\Omega}_{P,m}$ encountered in Sec. V. Let $\mathcal{E}$ be the space of C^∞ operator-valued functions on I_0 taking values in $\mathcal{B}(\mathbb{C}^2)$. Thus $\forall X\in\mathcal{E}$, $\forall l\in\mathbb{N}$

$$\|X\|_\infty := \sup_{t\in I_0}\|\partial_t^l X(t)\|<\infty, \tag{A27}$$

since I_0 is compact and $t\to\partial_t^l X(t)$ is continuous. We define the operator $K:\mathcal{E}\to\mathcal{E}$ by the following relation:

$$(KX)(t) := -i\int_{t_0}^{t}\hat{V}_P(s)X(s)\mathrm{d}s,\quad \hat{V}_P(t) := \begin{pmatrix}0 & b(t)\\ \overline{b(t)} & 0\end{pmatrix}, \tag{A28}$$

where $b(t):=\hat{V}(2(m-1))e^{2i(m-1)(t^2-t_0^2)}$. The Dyson series with remainder of order p reads as

$$\hat{\Omega}^0_{P,m}(t_1,t_0)=\sum_{k=0}^{m-1}K^k(t)\mathrm{id}+K^m(t)\hat{\Omega}^0_{P,n_0}(t_1,t_0). \tag{A29}$$

Here K^k denotes $K\circ K\circ\cdots\circ K$ k times. We start by proving a technical lemma.

Lemma 7.3.1: Let $a:=m-1$. Then for all $X\in\mathcal{E}$ it holds

$$\|KX\|_\infty\leqslant\frac{|b|}{\sqrt{a}}2\sqrt{6}\|X\|_\infty+|b|\frac{\log\left(\frac{\sqrt{a}}{2\sqrt{6}}\vee 1\right)}{a}\|\dot{X}\|_\infty, \tag{A30}$$

where we used the notation $m\vee n:=\max\{m,n\}$.

Proof: We shall use the canonical basis in $\mathcal{B}(\mathbb{C}^2)$ which reads as follows:

$$\Pi_{1,1} := \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \Pi_{2,2} := \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad \Pi_{1,2} := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \Pi_{2,1} := \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}. \tag{A31}$$

Also, let χ_-, χ_0 et χ_+ be the characteristic functions corresponding to the intervals $[-\frac{1}{4}, -\varepsilon]$, $[-\varepsilon, \varepsilon]$ and $[\varepsilon, \frac{1}{4}]$ where $0 < \varepsilon < \frac{1}{4}$. Then we have

$$KX = K\chi_- X + K\chi_0 X + K\chi_+ X. \tag{A32}$$

One gets immediately

$$\|K\chi_0 X\|_\infty \leqslant 2\varepsilon |b| \|X\|_\infty. \tag{A33}$$

For $K\chi_\pm X$ we use the identity $K\chi_\pm X = K\chi_\pm \Pi_{1,1} X + K\chi_\pm \Pi_{2,2} X$. We shall treat in detail only the term $K\chi_- \Pi_{2,2} X$, the estimates for the remaining parts being completely similar. Then with the notation $m \wedge n := \min\{m, n\}$ we have

$$(K\chi_- \Pi_{2,2} X)(t) = -i \int_{t_0}^{t\wedge -\varepsilon} b(s) \Pi_{1,2} X(s) \mathrm{d}s = -\int_{t_0}^{t\wedge -\varepsilon} 4ias b(s) \frac{\Pi_{1,2} X(s)}{4as} \mathrm{d}s = -\left[\frac{b(s) \Pi_{1,2} X(s)}{4as} \right]_{t_0}^{t\wedge -\varepsilon} + \int_{t_0}^{t\wedge -\varepsilon} b(s) \partial_s \left(\frac{\Pi_{1,2} X(s)}{4as} \right) \mathrm{d}s,$$

since $\dot{b}(s) = 4ias b(s)$. The first term is estimated as follows:

$$\left\| \left[b(s) \frac{\Pi_{1,2} X(s)}{4as} \right]_{t_0}^{t\wedge -\varepsilon} \right\| \leqslant \frac{|b|}{2a\varepsilon} \|\Pi_{1,2} X\|_\infty. \tag{A34}$$

For the second term,

$$\int_{t_0}^{t\wedge -\varepsilon} b(s) \partial_s \left(\frac{\Pi_{1,2} X(s)}{4as} \right) \mathrm{d}s = \int_{t_0}^{t\wedge -\varepsilon} b(s) \left(-\frac{\Pi_{1,2} X(s)}{4as^2} + \frac{\Pi_{1,2} \dot{X}(s)}{4as} \right) \mathrm{d}s, \tag{A35}$$

and consequently

$$\left\| \int_{t_0}^{t\wedge -\varepsilon} b(s) \partial_s \left(\frac{\Pi_{1,2} X(s)}{4as} \right) \mathrm{d}s \right\| \leqslant \|\Pi_{1,2} X\|_\infty \int_{t_0}^{-\varepsilon} \frac{|b|}{4as^2} \mathrm{d}s + \|\Pi_{1,2} \dot{X}\|_\infty \int_{t_0}^{-\varepsilon} \frac{|b|}{4a|s|} \mathrm{d}s \leqslant \frac{|b|}{4a\varepsilon} \|\Pi_{1,2} X\|_\infty - \frac{|b| \log(4\varepsilon)}{4a} \|\Pi_{1,2} \dot{X}\|_\infty.$$

Finally we find

$$\|KX\|_\infty \leqslant |b| \left(\left(2\varepsilon + \frac{1}{a\varepsilon} \right) \|X\|_\infty - \frac{\log(4\varepsilon)}{a} \|\dot{X}\|_\infty \right) \tag{A36}$$

and choosing $\varepsilon = \sqrt{3}(2a)^{-1/2} \wedge \frac{1}{4}$ we arrive at the announced result. □

Using Lemma 7.3.1 and the identity $(d/\mathrm{d}t)(K^{p-1}X)(t) = \hat{V}(t)(K^{p-2}X)(t)$ one can get the general result,

$$\text{if } p \geqslant 2, \quad \|K^p X\|_\infty \leqslant \frac{|b|}{\sqrt{a}} c \|K^{p-1} X\|_\infty + |b| \frac{\log \frac{\sqrt{a}}{c}}{a} \|\hat{V} K^{p-2} X\|_\infty \leqslant A \|K^{p-1} X\|_\infty + B \|K^{p-2} X\|_\infty, \tag{A37}$$

with the notations

$$c = 2\sqrt{6}, \quad A := \frac{|b|}{\sqrt{a}}c, \quad B = |b|^2 \frac{\log \frac{\sqrt{a}}{c} \vee 1}{a}.$$

By looking at the expansion of $\Omega^0_{P,m}(t_1,t_0)$ it is clear that we must solve (A37) in the case $X = \Omega^0_{P,m}$. However, in order to estimate as well $\hat{\Omega}^{0,(p)}_{P,m}$ the case $X=1$ would be also usual. We consider then the following two sequences for $\forall p \geqslant 2$:

$$x_p^{(k)} = Ax_{p-1}^{(k)} + Bx_{p-2}^{(k)} \quad \text{with} \quad x_0^{(k)} = 1 \quad \text{and} \quad x_1^{(k)} \text{ given}. \tag{A38}$$

Here $k=1,2$ labels the considered case, namely $x_p^{(1)} = \|K^p\|$ and $x_p^{(2)} = \|K_p \hat{\Omega}^0_{P,m}\|$. We know that x_p is a linear combination of two geometric series $p \to r_\pm^p$. More explicitly $x_p = \alpha_+ r_+^p + \alpha_- r_-^p$ where $r_\pm$ are the solutions of the characteristic equation $r^2 - Ar - B = 0$. Denoting with $\Delta := \sqrt{A^2+4B}$ one finds

$$r_\pm = \frac{A \pm \sqrt{\Delta}}{2}. \tag{A39}$$

The coefficients of the linear combination $\alpha_\pm$ are solutions of the equation

$$\begin{pmatrix} 1 & 1 \\ r_+ & r_- \end{pmatrix} \begin{pmatrix} \alpha_+ \\ \alpha_- \end{pmatrix} = \begin{pmatrix} x_0 \\ x_1 \end{pmatrix} \Leftrightarrow \alpha_\pm = \pm \frac{x_1 - r_\mp x_0}{\sqrt{\Delta}}. \tag{A40}$$

Now for the case 1 we have by direct calculation $\alpha_\pm^{(1)} = r_\pm / \sqrt{\Delta}$ and then

$$x_p^{(1)} = \frac{r_+^{p+1} - r_-^{p+1}}{\sqrt{\Delta}} = \sum_{k=0}^{p} r_+^k r_-^{p-k} = r_+^p \sum_{k=0}^{p} \left(\frac{r_-}{r_+}\right)^{p-k}.$$

For the second case we use the superposition principle. Let y the sequence defined by the relation as x with the initial conditions $y_0 = 0$ et $y_1 = B$. Then we have $x^{(2)} = x^{(1)} + y$. Since $y_p = \beta_+ r_+^p + \beta_- r_-^p$ with $\beta_\pm = \pm B\Delta^{-1/2}$ one has

$$x_p^{(2)} = x_p^{(1)} + \frac{B}{\sqrt{\Delta}}(r_+^p - r_-^p) = x_p^{(1)} + B\sum_{k=0}^{p-1} r_+^k r_-^{p-k}.$$

We proceed to the estimates by noticing that $|r_-| < r_+$ which allows to write

$$\left| \sum_{k=0}^{p} r_+^k r_-^{p-k} \right| = \left| r_+^p \sum_{k=0}^{p} \left(\frac{r_-}{r_+}\right)^{p-k} \right| \leqslant r_+^p \frac{1}{1 - \frac{|r_-|}{r_+}} = \frac{r_+^{p+1}}{r_+ - |r_-|} = \frac{r_+^{p+1}}{A}$$

and consequently

$$|x_p^{(1)}| \leqslant \frac{r_+^{p+1}}{A}, \quad |x_p^{(2)}| \leqslant \frac{r_+^{p+1}}{A} + \frac{B}{A} r_+^p. \tag{A41}$$

Using these results we obtain

$$\|K^p \,\mathrm{id}\| \leqslant \frac{r_+}{A} r_+^p \leqslant \left(1 + \frac{\sqrt{B}}{A}\right) B^{p/2} \left(1 + \frac{A}{\sqrt{B}}\right)^p, \tag{A42}$$

where

$$\frac{\sqrt{B}}{A} = \frac{1}{4\sqrt{3}}\left(\log\left(\frac{a}{24}\vee 1\right)\right)^{1/2}.$$

The estimate on $x_p^{(2)}$ gives

$$\|K^p\hat{\Omega}^0_{P,m}\| \leqslant \frac{r_+^{p+1}}{A} + \frac{B}{A}r_+^p \leqslant \left(1+\frac{\sqrt{B}}{A}+\frac{B}{A}\right)B^{p/2}\left(1+\frac{A}{\sqrt{B}}\right), \tag{A43}$$

where

$$\frac{B}{A} = \frac{1}{4\sqrt{6}}\frac{|b|}{\sqrt{a}}\log\left(\frac{a}{24}\vee 1\right).$$

Therefore we have proved the following.

Theorem 7.3.2: *Let $\hat{\mathcal{U}}_{P,m}$ and $\hat{\mathcal{U}}^0_{P,m}$ as defined in Sec. V $a=m-1$ and $b=\hat{V}(2(m-1))$. Then there exists m_0 and a constant C_{m_0} such that the Dyson series for $\hat{\Omega}^0_{P,m}(t,t_0)=\hat{\mathcal{U}}^0_{P,m}(t,t_0)^*\hat{\mathcal{U}}^0_{P,m}$ converges uniformly with respect to t for every $t\in I_0$ and that for any $m>m_0$ one has the following estimate:*

$$\|\hat{\Omega}^{0,(p)}_{P,m}\|_\infty \leqslant C_{m_0}|b|^p\sqrt{\log a}\left(\frac{\log a}{a}\right)^{p/2}. \tag{A44}$$

The remainder of order p satisfy the estimate

$$\|K^p\hat{\Omega}^0_{P,m}\|_\infty \leqslant 2C_{m_0}|b|^p\sqrt{\log a}\left(\frac{\log a}{a}\right)^{p/2}. \tag{A45}$$

It is demonstrated that Burgers equations, which are often believed to describe dissipative systems, are non-Lagrangian. Following Bateman's analysis of damped harmonic oscillator an action is defined to look for a Lagrangian representation for equations in the Burgers hierarchy. The associated higher-order Lagrangian densities are found to be degenerate such that the Hamiltonian structure could be studied by a repackaging of Ostrogradski formalism and Dirac's theory of constraints. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1852700]

The Burgers equation

$$u_t = u_{xx} + 2uu_x, \quad u = u(x,t) \tag{1}$$

represents the simplest nonlinear evolution equation that can be regarded as a one-dimensional reduction of the Navier–Stokes equation.[1] This equation is dissipative and does not support soliton solutions. However, it appears in many applicative contexts including the study of acoustics and shock waves.[2] Its solvability was discovered before the introduction of the spectral transform method.[3] For example, the Cole–Hopf transformation[4]

$$u = \frac{\phi_x}{\phi}, \quad \phi = \phi(x,t) \tag{2}$$

was found to map the equation in (1) into the integrable linear diffusion equation

$$\phi_t = \phi_{xx}. \tag{3}$$

It is of interest to note that (1) represents the first nontrivial flow of the hierarchy written as[5]

$$u_{t_{n+1}} = \partial(\partial + u)^n u, \quad \partial = \frac{\partial}{\partial x} \tag{4}$$

with t_{n+1}, the commutative time. For (4), an equation similar to that in (3) is given by

$$\phi_{t_{n+1}} = \partial^{n+1}\phi. \tag{5}$$

Taflin[6] first observed that (1) can be written in the Hamiltonian form[7] and that it has an infinite number of constants of the motion in involution. A similar study was carried out by Tasso[8] for the third-order Burgers equation. In each of these studies the canonical structure was derived with particular attention to the linear equation as given in (5). Moreover, there was no explicit reference

[a)]Electronic mail: binoy123@sancharnet.in

to Lagrangians to construct the Hamiltonian densities. The object of the present work is to provide an *ab initio* approach for the canonical or Hamiltonian structure of Burgers equations. We shall present all results with particular emphasis on the third-order equation. This is however, no loss of generalization because the method derived by us is applicable to any equation in the hierarchy. We shall begin by solving the inverse problem of variational calculus to construct an appropriate Lagrangian and then Hamiltonize this equation to get the relevant Poisson structure. The following gives a brief outline for the inverse variational problem as given by Helmholtz.[9]

Let $P[\zeta]=P(x,\zeta^n)\epsilon\mathcal{A}^r$ be an r-tuple of differential functions. The Fréchet derivative of P is the differential operator $D_P:\mathcal{A}^q\rightarrow\mathcal{A}^r$ and is defined as

$$D_P(Q) = \left.\frac{d}{d\epsilon}\right|_{\epsilon=0} P[\zeta + \epsilon Q(\zeta)] \tag{6}$$

for any $Q\epsilon\mathcal{A}^q$. The Helmholtz condition[9] asserts that P is the Euler–Lagrange expression for some variational problem if D_P is self-adjoint. Once the existence of a Lagrangian is guaranteed, the expression for it can be constructed by using a homotopy formula.[10] The solution given by Helmholtz is very neat, from the wider perspective of determining which systems of differential equations arise from variational principle. However, there are situations where the Helmholtz solution may turn out to be somewhat unsatisfactory. For example, if D_P is not self-adjoint for a system of differential equations, we have to stop by inferring that the system is non-Lagrangian. In the following, we first show that Burgers equation does not satisfy the Helmholtz condition and then try to construct a Lagrangian by taking recourse to the celebrated work of Bateman.[11]

The third-order equation is given by

$$u_t = u_{3x} + 3u^2u_x + 3uu_{2x} + 3u_x^2, \quad u = u(x,t). \tag{7}$$

To study the inverse problem for nonlinear evolution equations it is convenient to work with an integral of u

$$w(x,t) = \int_x^\infty \mathrm{d}y\, u(y,t) \tag{8}$$

rather than u itself; w is often called a potential function. In terms of this dependent variable, (7) reads

$$w_{xt} = w_{4x} + 3w_x^2w_{2x} - 3w_{2x}^2 - 3w_xw_{3x}. \tag{9}$$

Equivalently,

$$w_t = w_{3x} + w_x^3 - 3w_xw_{2x}. \tag{10}$$

For (9) we write the Euler–Lagrange expression as

$$P[w] = w_{4x} + 3w_x^2w_{2x} - 3w_{2x}^2 - 3w_xw_{3x}. \tag{11}$$

From (6) and (11)

$$D_P = D_{4x} + 6w_xw_{2x}D_x + 3w_x^2D_{2x} - 3w_xD_{3x} - 3w_{3x}D_x - 6w_{2x}D_{2x},$$
$$D_{nx} = \left(\frac{d}{dx}\right)^n. \tag{12}$$

To construct the adjoint operator D_P^* corresponding to (12) we write D_P as

$$D_P = \sum_{j=1}^{4} P_j(w) D_{jx} \tag{13}$$

and make use of the definition

$$D_P^* = \sum_{j=1}^{4} (-D)_{jx} P_j(w). \tag{14}$$

This gives

$$D_P^* = D_{4x} + 6w_x w_{2x} D_x + 3w_x^2 D_{2x} + 3w_{2x} D_{2x} + 3w_x D_{3x}. \tag{15}$$

From (12) and (15) we see that $D_P \neq D_P^*$. This tells us that the Burgers equation (7) or (10) is non-Lagrangian. The same is true for any member of the hierarchy. Thus it remains an interesting curiosity to find a Lagrangian from which we could get the Burgers equation using an action principle. To achieve this, we remember that, being weakly nonlinear the equations of the Burgers hierarchy are dissipative. In particle dynamics Bateman[11] allowed for an additional equation of motion to write an explicitly time independent Lagrangian for the damped harmonic oscillator. In particular, the Lagrangian

$$L = \dot{x}\dot{y} + \tfrac{1}{2}\lambda(x\dot{y} - \dot{x}y) - w^2 xy \tag{16}$$

was found to give two equations of motion

$$\ddot{x} + \lambda\dot{x} + w^2 x = 0 \quad \text{and } \ddot{y} - \lambda\dot{y} + w^2 y = 0, \tag{17}$$

where w is the natural frequency of the oscillator and λ, the damping constant. Therefore, following Bateman, we introduce an ansatz,

$$\mathcal{L} = \frac{1}{2}(w_t v_x + w_x v_t) + (w_{2x} \quad F_1 \quad F_2 \quad \cdots \quad F_{m-1}) \begin{pmatrix} (-1)^{n-1} v_{(n-1)x} \\ G_1 \\ G_2 \\ \cdots \\ G_{m-1} \end{pmatrix} \tag{18}$$

with $v = v(x,t)$ and $G_i = -v_x$, $i = 1, 2, \ldots, m-1$ to define a Lagrangian density $\mathcal{L}$. In writing (18), we assumed that the nth equation in the Burgers hierarchy written in terms of $w(x,t)$ can be expressed as

$$w_t = w_{nx} + \sum_{i=1}^{m-1} F_i. \tag{19}$$

We demand that the Lagrangian density in (18) should satisfy the following lemmas.

Lemma 1: $\mathcal{L}$ *via* an appropriate action principle gives equations in the Burgers hierarchy.

Lemma 2: $\mathcal{L}$ introduces a set of new equations coupled with the original Burgers equations.

Proof of Lemma 1: The potential function w and v which enter in (18) can be used to obtain equations of the Burgers hierarchy from an action principle. For this purpose, we consider

$$\delta I = 0, \quad I = \int \mathcal{L}\, dx\, dt. \tag{20}$$

To make the proof transparent we consider the third order equation. Comparing (10) and (19) we have

$$F_1 = w_x^3 \quad \text{and } F_2 = -3w_x w_{2x}, \tag{21}$$

such that

$$\mathcal{L} = \tfrac{1}{2}(w_t v_x + w_x v_t) + w_{2x} v_{2x} - w_x^3 v_x + 3w_x w_{2x} v_x. \tag{22}$$

The Euler–Lagrange equation from (20) can be written in the form

$$\frac{\delta \mathcal{L}}{\delta \psi} - \frac{d}{\mathrm{d}t}\left(\frac{\partial \mathcal{L}}{\partial \psi_t}\right) = 0 \tag{23}$$

with the variational derivative

$$\frac{\delta}{\delta \psi} = \frac{\partial}{\partial \psi} - \frac{d}{\mathrm{d}x}\frac{\partial}{\partial \psi_x} + \frac{d^2}{\mathrm{d}x^2}\frac{\partial}{\partial \psi_{2x}} - \cdots . \tag{24}$$

For the Lagrangian in (22), the function $\psi(x,t)$ is either $v(x,t)$ or $w(x,t)$. Choosing $\psi(x,t) = v(x,t)$ we get from (22) and (23) the third order Burgers equation in (10). This is true for any member of the hierarchy.

Proof of Lemma 2: For $\psi(x,t) = w(x,t)$, the Euler–Lagrange equation gives

$$v_t = v_{3x} + 3w_x^2 v_x + 3w_x v_{2x}. \tag{25}$$

This equation is coupled with (10) verifying our demand in Lemma 2. An equation similar to (25) can be obtained for each member of the hierarchy.

We shall now recast the equation of the Burgers hierarchy into canonical form and obtain an explicit expression for the exact Hamiltonian. We do this with particular emphasis on the Lagrangian in (22). This Lagrangian density is first order in time and higher order in the space variable. In the context of particle dynamics similar Lagrangians are often called higher-order Lagrangians. Euler[12] first investigated the variational problem in which the integral implied in the definition of action depends on higher derivatives of the generalized coordinates. The standard procedure for Hamiltonizing a higher-order Lagrangian is due to Ostrogradaski[13] who proceeded by introducing a set of new variables such that one could finally work with an effective first-order action to arrive at the canonical structure. We closely follow this procedure to deal with the Lagrangian density in (22).

In view of the above, we rewrite (22) using

$$w_{2x} v_{2x} = (w_x v_{2x} + v_x w_{2x})_x - w_{2x} v_{2x} - w_x v_{3x} - v_x w_{3x} \tag{26}$$

such that

$$\mathcal{L} = \tfrac{1}{2}(w_t v_x + v_t w_x) - w_{2x} v_{2x} - w_x v_{3x} - v_x w_{3x} - w_x^3 v_x - 3w_x w_{2x} v_x. \tag{27}$$

Here, we have omitted the trivial gauge term $(w_x v_{2x} + v_x w_{2x})_x$. We reduce the action to first order by introducing a set of constraints

$$\theta - w_{2x} = 0 \quad \text{and } \eta - v_{2x} = 0. \tag{28}$$

From (27) and (28) we have

$$\mathcal{L} = \tfrac{1}{2}(w_t v_x + v_t w_x) - \eta\theta - w_x \eta_x - v_x \theta_x - w_x^3 v_x - 3w_x v_x \theta. \tag{29}$$

The Lagrangian density in (29) is degenerate because the associated Hessian is zero. Degenerate Lagrangians are Hamiltonized by using the Dirac's machinery[14] which is supposed to introduce a set of new constraints to consistently define the Hamiltonian density. To pass from the Lagrangian to the Hamiltonian formulation of the problem we introduce the canonical momentum densities

$$\pi_w = \frac{\partial \mathcal{L}}{\partial w_t} = \frac{1}{2} v_x,$$

$$\pi_v = \frac{\partial \mathcal{L}}{\partial v_t} = \frac{1}{2} w_x,$$

$$\pi_\theta = \frac{\partial \mathcal{L}}{\partial \theta_t} = 0, \tag{30}$$

$$\pi_\eta = \frac{\partial \mathcal{L}}{\partial \eta_t} = 0.$$

These momenta cannot be inverted for velocities. This represents a characteristic feature of degenerate Lagrangians. In the Dirac's machinery one proceeds by defining the primary constraints through the weak equations

$$c_1 = \pi_w - \tfrac{1}{2} v_x \approx 0,$$

$$c_2 = \pi_v - \tfrac{1}{2} w_x \approx 0,$$

$$c_3 = \pi_\theta \approx 0, \tag{31}$$

$$c_4 = \pi_\eta \approx 0.$$

These equations play a role in the Poisson bracket formalism of Hamiltonian mechanics. The sign "$\approx$" implies that we should not use these constraints before working out the Poisson brackets chracterizing the dynamical evolution of the system. In other words, all Poisson brackets occurring in the theory must be worked out before we make use of (31). In Dirac's theory, the total Hamiltonian of the system is given by

$$H = \int \mathcal{H}\, dx, \quad \mathcal{H} = \mathcal{H}_0 + \mathcal{H}', \tag{32}$$

where $\mathcal{H}_0$ is the free part of the Hamiltonian density determined by the usual Legendre transformation and we have

$$\mathcal{H}_0 = \eta\theta + w_x \eta_x + v_x \theta_x + w_x^3 v_x + 3 w_x v_x \theta. \tag{33}$$

The interaction part $\mathcal{H}'$ is an arbitrary linear combination of the constraints such that the total Hamiltonian could give the correct equations of motion with the usual Poisson brackets. Thus, we write

$$\mathcal{H}' = \beta c_1 + \gamma c_2 + \sigma c_3 + \rho c_4, \tag{34}$$

where β, γ, σ, and ρ are undetermined multipliers. In order for the Hamiltonian formulation of dynamics to be consistent it is not only necessary that the positions and momenta evolve in a manner which respects the constraints, but it is also necessary that the constraints themselves have dynamics. Thus one must require that

$$\frac{dc_i}{dt} = [c_i, H] \approx 0 \tag{35}$$

and this requirement will determine the multipliers provided there are no further constraints in the problem.

Using the canonical Poisson brackets of the w, v, θ, and η fields written as

$$\begin{aligned} [w(x), \pi_w(x')] &= \delta(x - x'), \\ [v(x), \pi_v(x')] &= \delta(x - x'), \\ [\theta(x), \pi_\theta(x')] &= \delta(x - x'), \\ [\eta(x), \pi_\eta(x')] &= \delta(x - x') \end{aligned} \tag{36}$$

we have found the following Poisson brackets given by

$$\begin{aligned} [c_1, H] &= [\gamma - \eta_x - 3w_x^2 v_x - 3v_x\theta]_x, \\ [c_2, H] &= -[\beta + \theta_x + 3w_x\theta + w_x^3]_x, \\ [c_3, H] &= [\eta - v_{2x} + 3w_x v_x], \\ [c_4, H] &= [\theta - w_{2x}]. \end{aligned} \tag{37}$$

It is clear that the last two Poisson brackets in (37) cannot be made to vanish by any choice of the multipliers. This implies that there are secondary constraints in the theory. We introduce these constraints as

$$\begin{aligned} c_5 &= \eta - v_{2x} + 3w_x v_x \approx 0, \\ c_6 &= \theta - w_{2x} \approx 0. \end{aligned} \tag{38}$$

The constraints c_5 and c_6 must be incorporated in the total Hamiltonian to get the correct dynamics of the system. Thus we replace (34) by

$$\mathcal{H}' = \beta c_1 + \gamma c_2 + \sigma c_3 + \rho c_4 + \mu c_5 + \xi c_6 \tag{39}$$

with μ and ξ as additional multipliers. In order to check that if there are further constraints in the problem we have again calculated the following Poisson brackets:

$$\begin{aligned} [c_1, H] &= [\gamma - 3\mu v_x - \xi_x - \eta_x - w_x^2 v_x - 3v_x\theta]_x, \\ [c_2, H] &= -[\beta + \mu_x + 3w_x\mu + \theta_x + 3w_x\theta + w_x^3]_x, \\ [c_3, H] &= [\xi + \eta - v_{2x} + 3w_x v_x], \\ [c_4, H] &= [\mu + \theta - w_{2x}], \\ [c_5, H] &= [(\gamma_x + 3v_x\beta + 3w_x\gamma)_x - \rho], \end{aligned} \tag{40}$$

$$[c_6, H] = [\beta_{2x} - \sigma].$$

These Poisson brackets can be made to vanish by choosing the Lagrange's multipliers

$$\begin{aligned}
\beta &= -(w_{3x} + 3w_x w_{2x} + w_x^3), \\
\gamma &= (v_{3x} + w_x^2 v_x - 3w_x v_{2x}), \\
\sigma &= (w_{3x} + 3w_x w_{2x} + w_x^3)_{xx}, \\
\rho &= (v_{4x} - 3w_{2x}v_{2x} - 3w_{3x}v_x - 7w_x w_{2x} v_x - 8w_x^2 v_{2x}), \\
\mu &= (w_{2x} - \theta), \\
\xi &= (v_{2x} - \eta - 3w_x v_x).
\end{aligned} \tag{41}$$

Equations (41) indicate that $c_1 - c_6$ exhaust all constraints of the problem. Thus from (31), (33), (38), (39), and (41) we write the total Hamiltonian density in the form

$$\begin{aligned}
\mathcal{H} = {} & 2w_{2x}\eta - 2w_{2x}v_{2x} + \tfrac{15}{2} w_x w_{2x} v_x - \eta\theta + 2v_{2x}\theta - 3w_x v_x \theta + w_x \eta_x + v_x \theta_x + w_x^3 v_x + \tfrac{1}{2} w_{3x} v_x - \tfrac{1}{2} w_x v_{3x} \\
& + \tfrac{3}{2} w_x^2 v_{2x} - (w_{3x} + 3w_x w_{2x} + w_x^3)\pi_w + (v_{3x} + w_x^2 v_x - 3w_x v_{2x})\pi_v - (w_{3x} + 3w_x w_{2x} + w_x^3)_{xx}\pi_\theta \\
& + (v_{4x} - 3w_{2x}v_{2x} - 3w_{3x}v_x - 7w_x w_{2x} v_x - 8w_x^2 v_{2x})\pi_\eta.
\end{aligned} \tag{42}$$

It is straightforward to verify that each Poisson brackets $[\pi_\omega, H]$, $[\pi_v, H]$, $[\pi_\theta, H]$, and $[\pi_\eta, H]$, reproduces the Burgers equation in (10).

Let us now identify those constraints that are physically important for the dynamics of the system. In order that we must divide the constraints into first and second class irrespective of whether they are primary, secondary or tertiary. The constraints are called first class if they have vanishing Poisson brackets with all the rest, that is

$$[c_i, c_j] = 0, \quad i, j = 1, \cdots, 6 \tag{43}$$

otherwise the constraints are called second class. The first-class constraints are related, at least to some extent, to the gauge properties of the system while the second-class constraints are associated with the appearance of unphysical degrees of freedom in the theory. Thus, it is clear that these two classes play a fundamentally distinct role in the canonical analysis. We have found that the Poisson brackets involving all c's are zero except for $[c_i, c_j]$, $i=1, j=2,5$; $[c_i, c_j]$, $i=2, j=5$; $[c_i, c_j]$, $i=3, j=6$; and $[c_i, c_j]$, $i=4, j=5$. The existence of these nonvanishing Poisson brackets can be used to see that all constraints of the problem are second class. Moreover, by introducing Dirac brackets to write the equation of motion one can eventually eliminate all second-class constraints from the theory. This means that all weak equations now becomes strong, such that all c's are now strong zeros. This is precisely, the reason why the zero-order Hamiltonian when substituted in the canonical equation of Zakharov and Faddeev, and Gardner[7] gives the equation of motion. In the present case, we can make use of

$$\omega_t = \frac{\delta \mathcal{H}_0}{\delta v_x} \quad \text{and} \quad v_t = \frac{\delta \mathcal{H}_0}{\delta \omega_x} \tag{44}$$

to get (10) and (25). We conclude by noting the following.

The heat equation in (2) is an instructive case of an integrable equation since it is easier to find a Lagrangian structure[15] for this equation. Moreover, using the Cole–Hopf coordinate transformation, one can map structures (Lagrangian or Hamiltonian) of the heat equation into those of the potential Burgers equation. This viewpoint has been advocated by Hojman and his collaborators in

a number of publications.[16] However, the results cannot be applied directly to investigate the canonical structure. In the present work we exploited the similarity between physical effects described by Burgers equations and equations of the damped harmonic oscillator to define an action that gives an uncomplicated expression for a degenerate Lagrangian density $\mathcal{L}$ which is first order in time. Faddeev and Jackiw[17] found that one must refrain from viewing a Lagrangian that is linear in first order time derivatives as necessarily describing a constrained system. Despite that we used Dirac's machinery to derive the Hamiltonian structure presumably because our Lagrangian analytically represents a set of coupled equations which might also follow from a Lagrangian which is nonlinear in the first derivatives in time.[18]

Conditional expectations associated with quantum states

Gerd Niestegge
Zillertalstrasse 39, D-81373 Muenchen, Germany

(Received 23 November 2004; accepted 3 January 2005; published online 23 March 2005)

An extension of the conditional expectations (those under a given subalgebra of events and not the simple ones under a single event) from the classical to the quantum case is presented. In the classical case, the conditional expectations always exist; in the quantum case, however, they exist only if a certain weak compatibility criterion is satisfied. This compatibility criterion was introduced among others in a recent paper by the author. Then, state-independent conditional expectations and quantum Markov processes are studied. A classical Markov process is a probability measure, together with a system of random variables, satisfying the Markov property and can equivalently be described by a system of Markovian kernels (often forming a semigroup). This equivalence is partly extended to quantum probabilities. It is shown that a dynamical (semi)group can be derived from a given system of quantum observables satisfying the Markov property, and the group generators are studied. The results are presented in the framework of Jordan operator algebras, and a very general type of observables (including the usual real-valued observables or self-adjoint operators) is considered. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1861275]

I. INTRODUCTION

A classical Markov process is a probability measure together with a system of random variables, satisfying the Markov property (which characterizes a certain memorilessness of the process). A classical Markov process can equivalently be described by a system of Markovian kernels forming a semigroup when the process is stationary.

The quantum analogues of probability measures, random variables and Markovian kernels are the states, observables and unital positive linear maps. A quantum Markov process is usually modeled as a semigroup of unital positive linear maps on a W^*-algebra (von Neumann algebra). The major result of the present paper is the derivation of such a semigroup from a stochastic process given as a quantum state together with a system of observables, satisfying a certain directed weak compatibility criterion, the Markov property and the stationarity criterion. This partly extends the classical equivalence between stationary Markov processes and semigroups of Markovian kernels to the quantum case. As in the classical case, the major tools are the Radon–Nikodym theorem and conditional expectations, the extension of which to the quantum case is a major result of the present paper.

The quantum probabilities are considered in the general framework of Jordan operator algebras, particularly the so-called JBW algebras. A justification for this is given in Ref. 10. An observable then becomes a homomorphism between such algebras. A classical random variable can be considered an observable on a classical space with values in a classical space. A real-valued quantum observable (spectral measure of a self-adjoint operator) can be considered an observable on a nonclassical quantum space with values in a classical space (the real numbers). This paper, however, uses the most general type, i.e., an observable on a nonclassical quantum space with values in a nonclassical quantum space; this is a homomorphism between two nonassociative Jordan operator algebras.

A *Jordan algebra* [4] is a linear space $\mathcal{A}$ equipped with a (nonassociative) commutative product $\circ$ satisfying $X\circ(Y\circ X^2)=(X\circ Y)\circ X^2$ for all $X,Y\in\mathcal{A}$. A *JB algebra* [4] is a real Jordan algebra $\mathcal{A}$ that

is a Banach space with a norm satisfying $\|X\circ Y\|\leqslant\|X\|\,\|Y\|$, $\|X^2\|=\|X\|^2$, and $\|X^2\|\leqslant\|X^2+Y^2\|$ for all $X,Y\in\mathcal{A}$. The subset $\mathcal{A}_+:=\{X^2|X\in\mathcal{A}\}$ of a JB algebra $\mathcal{A}$ is a closed convex cone, and a partial ordering is defined via $X\leqslant Y\Leftrightarrow Y-X\in\mathcal{A}_+$. For idempotent elements E and F, $E\leqslant F$ is equivalent to $E\circ F=E$. A linear functional $\mu:\mathcal{A}\to\mathbb{R}$ is called *positive* if $\mu(X)\geqslant 0$ for $X\in\mathcal{A}_+$. A positive linear functional μ is bounded with $\|\mu\|=\mu(\mathbb{I})$ and is called a *state* if $\mu(\mathbb{I})=1$; μ is *faithful* means that $\mu(X)=0$ with $X\geqslant 0$ implies that $X=0$. A linear map V from a JB algebra $\mathcal{A}$ to another JB algebra is *positive* if $V(X)\geqslant 0$ for $X\geqslant 0$. A JB algebra which is the dual of a Banach space is a *JBW algebra*. [4] A JBW algebra has a unit denoted by $\mathbb{I}$ and is generated by its idempotent elements called *events*; the event $E':=\mathbb{I}-E$ is the *negation* of the event E. Two events E and F are *orthogonal* if $E\circ F=0$. The spectral decomposition theorem each element of a JBW algebra.

The *conditional probability* $\mu(F|E)$ of an event F under another event E in a state μ with $\mu(E)>0$ has been introduced in Ref. 9, where it has been shown that $\mu(F|E)=\mu(\{E,F,E\})/\mu(E)$. Note that the *triple product* $\{\ ,\ ,\ \}$ in a Jordan algebra is defined as follows: $\{X,Y,Z\}=X\circ(Y\circ Z)-Y\circ(Z\circ X)+Z\circ(X\circ Y)$. For some pairs of events E and F, the conditional probability $\mu(F|E)$ does not depend on the underlying state μ and is then denoted by $\mathbb{P}(F|E)$.

Generally, the equation $\mu(F)=\mu(F|E)\mu(E)+\mu(F|E')\mu(E')$ or the equivalent equation $\mu(\{E,F,E\})=\mu(E\circ F)$ does not hold; if it does, we write $E\underset{\mu}{\to}F$. This is a weak state-dependent directed compatibility criterion that has been introduced in Ref. 11 and is always fulfilled in classical probability theory. Several stronger forms of compatibility exist, e.g., the event E and F are called *compatible* if $E\underset{\mu}{\to}F$ and$F\underset{\mu}{\to}F$ both hold for all states μ; in this case, E and F *operator-commute*. [4] With a JBW subalgebra $\mathcal{A}_1$ of $\mathcal{A}$, we write $\mathcal{A}_1\underset{\mu}{\to}F$ if $E\underset{\mu}{\to}F$ holds for each event E in $\mathcal{A}_1$, and with two JBW subalgebras $\mathcal{A}_1$ and $\mathcal{A}_2$ of $\mathcal{A}$, we write $\mathcal{A}_1\underset{\mu}{\to}\mathcal{A}_2$ if $E\underset{\mu}{\to}F$ each event E in $\mathcal{A}_1$ and each event F in $\mathcal{A}_2$. We shall later see that the condition $\mathcal{A}_1\underset{\mu}{\to}F$ ensures the existence of a reasonable conditional expectation of F under $\mathcal{A}_1$ in the state μ. This condition is satisfied, e.g., when $\mathcal{A}_1$ and F operator-commute, or when $\mathcal{A}$ is the tensor product [11] of $\mathcal{A}_1$ and $\mathcal{A}_2$ with $F\in\mathcal{A}_2$, or when μ is a trace state.[13]

A linear map (state, homomorphism, observable) on a JBW algebra $\mathcal{A}$ is called *normal* if it is continuous with respect to the weak topology on $\mathcal{A}$ generated by its predual. Normal linear maps are completely additive for any orthogonal family of events. The paper restricts to the study of normal states and normal observables although it would be desirable to include σ-additive states and standard observables that are σ-additive and not necessarily normal, but then some methods needed from the theory of JBW algebras would not apply (see also Sec. VII).

The paper is organized as follows: In Secs. II and III, some results that are well known for C^*-/W^*-algebras are extended to the Jordan operator algebras for later use; these are Kadison's generalized Schwarz inequality and Sakai's Radon–Nikodym theorem. The extension of conditional expectations and Markov processes to the quantum case is introduced in Secs. IV and V, respectively. It is shown that a semigroup of positive linear maps is associated with each such Markov process. Finally the generator of this semigroup is studied in Sec. VI.

Although the motivation for the work presented here primarily stems from a quantum probability model proposed in Refs. 9–11, the paper is written in such a way that most of it can be understood without knowledge of that quantum probability model. However, some knowledge of Jordan operator algebras is required, and the monograph Ref. 4 is recommended as an excellent reference.

II. THE GENERALIZED SCHWARZ INEQUALITY

The following lemma will be needed to prove the generalized Schwarz inequality for positive linear maps between JB algebras.

Lemma 2.1: *Let* $X_1,\ldots,X_n$ *be n positive elements in a JB algebra* $\mathcal{A}$ *with unit* $\mathbb{I}$ *such that* $\Sigma_{k=1}^n X_k\leqslant\mathbb{I}$ *and* $s_1,\ldots,s_n\in\mathbb{R}$. *Then*

$$\left(\sum_{k=1}^{n} s_k X_k\right)^2 \leqslant \sum_{k=1}^{n} s_k^2 X_k.$$

Proof: Let φ be a state on $\mathcal{A}$. On the direct sum of n copies of $\mathcal{A}$ we consider the positive–semidefinite inner product

$$\langle Y|Z\rangle := \sum_{k=1}^{n} \varphi(\{Y_k, X_k, Z_k\})$$

for $Y = Y_1 \oplus \cdots \oplus Y_n$ and $Z = Z_1 \oplus \cdots \oplus Z_n$ with $Y_k, Z_k \in \mathcal{A}$. Then the Cauchy–Schwarz inequality holds (note that $\{Y_k, X_k, Y_k\} \geqslant 0$ for $Y_k, X_k \in \mathcal{A}$ with $X_k \geqslant 0$) and, selecting $Y_k := s_k \mathbb{I}$ for $k = 1, \ldots, n$ and

$$Z_1 := \cdots := Z_n := \sum_{k=1}^{n} s_k X_k,$$

we get

$$\left(\varphi\left(\left(\sum_{k=1}^{n} s_k X_k\right)^2\right)\right)^2 = \langle Y|Z\rangle^2 \leqslant \langle Y|Y\rangle\langle Z|Z\rangle = \varphi\left(\sum_{k=1}^{n} s_k^2 X_k\right)\varphi\left(\left\{Z_1, \sum_{k=1}^{n} X_k, Z_1\right\}\right)$$
$$\leqslant \varphi\left(\sum_{k=1}^{n} s_k^2 X_k\right)\varphi(Z_1^2) = \varphi\left(\sum_{k=1}^{n} s_k^2 X_k\right)\varphi\left(\left(\sum_{k=1}^{n} s_k X_k\right)^2\right).$$

Hence

$$\varphi\left(\left(\sum_{K=1}^{n} s_k X_k\right)^2\right) \leqslant \varphi\left(\sum_{K=1}^{n} s_k^2 X_k\right)$$

and, since this every state φ, the lemma is proved.

The following proposition now provides the extension of Kadison's generalized Schwarz inequality for positive maps between C*-algebras[5] to the more general case of positive maps between JB algebras.

Proposition 2.2: *Let V be a positive linear map from a unital JB algebra $\mathcal{M}$ to a unital JB algebra $\mathcal{N}$ with $V(\mathbb{I}) = \mathbb{I}$. Then $(V(X))^2 \leqslant V(X^2)$ for every $X \in \mathcal{M}$.*

Proof: First, we assume that $\mathcal{M}$ is a JBW algebra[4] and that X has the shape $X = \Sigma_{k=1}^{n} s_k E_k$ with pairwise orthogonal idempotent elements $E_1, \ldots, E_n \in \mathcal{A}$ and $s_1, \ldots, s_n \in \mathbb{R}$. Then $0 \leqslant V(E_k)$ for $k = 1, \ldots, n$ and $\Sigma V(E_k) \leqslant \mathbb{I}$ such that we can apply Lemma 2.1 obtaining

$$(V(X))^2 = \left(\sum_{k=1}^{n} s_k V(E_k)\right)^2 \leqslant \sum_{k=1}^{n} s_k^2 V(E_k) = V\left(\sum_{k=1}^{n} s_k^2 E_k\right) = V(X^2).$$

Since, due to the spectral theorem, every $X \in \mathcal{M}$ can be approximated in the norm topology by a sequence of elements having the above special shape and since a positive linear map is automatically norm continuous, $(V(X))^2 \leqslant V(X^2)$ every $X \in \mathcal{M}$.

We now assume that $\mathcal{M}$ is a JB algebra. Then the double dual spaces $\mathcal{M}^{**}$ and $\mathcal{N}^{**}$ are JBW algebras containing $\mathcal{M}$ and $\mathcal{N}$, respectively, as subalgebras,[4] such that Proposition 2.2 follows by applying the above to the map $V^{**}: \mathcal{M}^{**} \to \mathcal{N}^{**}$.

Corollary 2.3: *Let V be a bijective positive linear map from a unital JB algebra $\mathcal{M}$ to a unital JB algebra $\mathcal{N}$ with $V(\mathbb{I}) = \mathbb{I}$ such that V^{-1} is positive as well. Then V is a muliplicative homomorphism.*

Proof: $(V(X))^2 \leqslant V(X^2)$ for every $X \in \mathcal{M}$ and $(V^{-1}(Y))^2 \leqslant V^{-1}(Y^2)$ for every $Y \in \mathcal{N}$. Hence with $Y = V(X): X^2 \leqslant V^{-1}((V(X)^2)$. Then, since V is positive, $V(X^2) \leqslant (V(X))^2$. Therefore, $V(X^2) = (V(X))^2$.

The identity $2A\circ B=(A+B^2)-A^2-B^2$ for $A,B\in\mathcal{M}$ finally implies that V is multiplicative.

III. THE RADON–NIKODYM THEOREM

We shall now extend one of Sakai's Radon–Nikodym theorems[14] from W^*-algebras to JBW algebras. Since all methods needed for the proof of the W^*-case are available in the JBW case as well, the proofs are quite similar in these two cases.

Theorem 3.1: *Let $\mathcal{A}$ be a JBW algebra and let ν, μ be two positive normal linear functionals on $\mathcal{A}$ with $\nu\leqslant\mu$. Then, there is an element $Y\in\mathcal{A}$ with $0\leqslant Y\leqslant\mathbb{I}$ such that $\nu(Z)=\mu(Y\circ Z)$ all $Z\in\mathcal{A}$.*

Proof: For $X\in\mathcal{A}$ we define μ_X via $\mu_X(Z):=\mu(X\circ Z)$ for $Z\in\mathcal{A}$ and consider the set $K:\{\mu_X|X\in\mathcal{A},0\leqslant X\leqslant\mathbb{I}\}$ which is a nonempty convex subset of the predual $\mathcal{A}_*$ of $\mathcal{A}$. Moreover, K is compact with respect to the weak topology on $\mathcal{A}_*$ that is generated by $\mathcal{A}$. Note that $\{X\in\mathcal{A},0\leqslant X\leqslant\mathbb{I}\}$ is compact and that the multiplication operation with one element fixed is continuous with respect to the weak topology on $\mathcal{A}$ generated by $\mathcal{A}_*$.

All we must show is that $\nu\in K$. We assume that $\nu\notin K$. From the Hahn–Banach theorem it then follows that there is an element $A\in\mathcal{A}$ and a real number r such that $\nu(A)>r$ and $\mu_X(A)\leqslant r$ for $X\in\mathcal{A}$ with $0\leqslant X\leqslant\mathbb{I}$. Now let F be the support of the positive part A_+ of A; these are defined as follows: with $A=\int\lambda\ dE_\lambda$ being the spectral decomposition of A, $A_+:=\int_{[0,\infty]}\lambda\ dE_\lambda$ and $F:=\int_{[0,\infty]}dE_\lambda$. Then $r\geqslant\mu_F(A)=\mu(F\circ A)=\mu(A_+)\geqslant\nu(A_+)\geqslant\nu(A)$, which contradicts $\nu(A)>r$.

IV. CONDITIONAL EXPECTATIONS

Let $\mathcal{A}$ be a JBW algebra and $\mathcal{A}_0$ a JBW subalgebra of $\mathcal{A}$ with $\mathbb{I}\in\mathcal{A}_0$. Let μ be a normal state on $\mathcal{A}$ and $X\in\mathcal{A}$ with $0\leqslant X\leqslant\mathbb{I}$.

Definition 4.1: *An element $Y\in\mathcal{A}_0$ such that $\mu(\{E,X,E\})=\mu(Y\circ E)$ all events E in $\mathcal{A}_0$ is called a conditional expectation of X under $\mathcal{A}_0$ in the state μ.*

If F is an event in $\mathcal{A}$ and if Y is a conditional expectation of F under $\mathcal{A}_0$ in the state μ, we get that $\mu(F|E)\mu(E)=\mu(Y\circ E)$ all events E in $\mathcal{A}_0$.

Lemma 4.2: *If a conditional expectation exists for $X\in\mathcal{A}$ with $0\leqslant X\leqslant\mathbb{I}$, then there is a least one conditional expectation Y with $0\leqslant Y\leqslant\mathbb{I}$.*

Proof: Let $Z\in\mathcal{A}_0$ be a conditional expectation with $Z=\int\lambda\ dE_\lambda$ being its spectral decomposition, and define

$$Z_-:=-\int_{(-\infty,0)}\lambda\ dE_\lambda,\quad Y:=\int_{[0,\infty]}\lambda\ dE_\lambda,\quad \text{and } E_0:=\int_{(-\infty,0)}dE_\lambda.$$

Then $Z_-,Y,E_0\in\mathcal{A}_0$. Hence $0\leqslant\mu(\{E_0,X,E_0\})=\mu(Z\circ E_0)=-\mu(Z_-)\leqslant 0$, i.e., $\mu(Z_-)=0$. Since $0\leqslant Z_-$, we get $\mu(Z_-^2)=0$, and the Cauchy–Schwarz inequality for states implies that $\mu(Z_-\circ E)=0$ for all events E in $\mathcal{A}_0$. Therefore $\mu(\{E,X,E\})=\mu(Z\circ E)=\mu((Z_-+Y)\circ E)=\mu(Y\circ E)$ for all events E in $\mathcal{A}_0$, i.e., Y is a positive conditional expectation of X. Repeating now the same procedure for the conditional expectation $\mathbb{I}-Y$ of $\mathbb{I}-X$ finally yields a conditional expectation Y with $0\leqslant Y\leqslant\mathbb{I}$.

Theorem 4.3: (i) *A conditional expectation of X under $\mathcal{A}_0$ in the state μ exists if and only if $\mathcal{A}_0\underset{\mu}{\rightarrow}X$ holds* [*i.e., $\mu(\{E,X,E\}=\mu(E\circ X))$ for all events $E\in\mathcal{A}_0$*].

(ii) If $\mathcal{A}_0\underset{\mu}{\rightarrow}X$ *holds and if the restriction of μ to $\mathcal{A}_0$ is faithful, then there is one and only one conditional expectation of X under $\mathcal{A}_0$ in the state μ* [*which shall be denoted by $\mu(X|\mathcal{A}_0)$ in the remaining part of this paper*].

Proof: (i) Let Y be a conditional expectation of X under $\mathcal{A}_0$ in the state μ, and let E be an event in $\mathcal{A}_0$. Then $\mu(X)=\mu(Y)=\mu(Y\circ E)+\mu(Y\circ E')=\mu(\{E,X,E\})+\mu(\{E',X,E'\})=\mu(X)-2\mu(X\circ E)+2\mu(\{E,X,E\})$, where the last equality follows from the identity $\{E',X,E'\}=X-2X\circ E+\{E,X,E\}$. Therefore $\mu(\{E,X,E\})=\mu(X\circ E)$.

Now let $\mathcal{A}_0\underset{\mu}{\rightarrow}X$ hold. We then define $\nu(Z):=\mu(X\circ Z)$ for $Z\in\mathcal{A}_0$; ν is a normal linear functional on $\mathcal{A}_0$. Due to the condition $\mathcal{A}_0\underset{\mu}{\rightarrow}X$, we have $0\leqslant\nu(E)\leqslant\mu(E)$ for all events E in $\mathcal{A}_0$.

Therefore $0 \leqslant \nu \leqslant \mu$ on $\mathcal{A}_0$. From the Radon–Nikodym theorem we get an element $Y \in \mathcal{A}_0$ with $0 \leqslant Y \leqslant \mathbb{I}$ such that $\nu(Z) = \mu(Y \circ Z)$ for all $Z \in \mathcal{A}_0$. Finally, we get that $\mu(Y \circ E) = \mu(X \circ E) = \mu(\{E,X,E\})$ the events E in $\mathcal{A}_0$, where we have again used the assumption $\mathcal{A}_0 \underset{\mu}{\rightarrow} X$. Thus, Y is a conditional expectation of X under $\mathcal{A}_0$ in the state μ.

(ii) Now let μ be faithful on $\mathcal{A}_0$ and $Y_1, Y_2 \in \mathcal{A}_0$ with $0 \leqslant Y_1, Y_2 \leqslant \mathbb{I}$ such that $\mu(\{E,X,E\}) = \mu(Y_1 \circ E) = \mu(Y_2 \circ E)$ for all events $E \in \mathcal{A}_0$. Then $\mu((Y_1 - Y_2) \circ E) = 0$ for all events $E \in \mathcal{A}_0$ and, since $\mathcal{A}_0$ is the closed linear hull of its events, we get $\mu((Y_1 - Y_2) \circ Z) = 0$ for all $Z \in \mathcal{A}_0$. Hence $\mu((Y_1 - Y_2)^2) = 0$. The faithfulness now implies that $(Y_1 - Y_2)^2 = 0$. Therefore $Y_1 = Y_2$.

Let the restriction of μ to $\mathcal{A}_0$ be faithful, and let $\mathcal{A}_0 \underset{\mu}{\rightarrow} X, X_1, X_2$ hold with $X, X_1, X_2 \in \mathcal{A}, 0 \leqslant X, X_1, X_2 \leqslant \mathbb{I}$. Lemma 4.2 implies that $0 \leqslant \mu(X|\mathcal{A}_0) \leqslant \mathbb{I}$. Obviously we have $\mu(0|\mathcal{A}_0) = 0$, $\mu(\mathbb{I}|\mathcal{A}_0) = \mathbb{I}$, and $\mu(\alpha X_1 + (1-\alpha)X_2|\mathcal{A}_0) = \alpha\mu(X_1|\mathcal{A}_0) + (1-\alpha)\mu(X_2|\mathcal{A}_0)$ for $0 \leqslant \alpha \leqslant 1$. Moreover, $\mu(\mu(X|\mathcal{A}_0)|\mathcal{A}_1) = \mu(X|\mathcal{A}_1)$ holds for any other JBW subalgebra $\mathcal{A}_1 \subseteq \mathcal{A}_0$ with $\mathcal{A}_1 \underset{\mu}{\rightarrow} \mu(X|\mathcal{A}_0)$.

The faithfulness of μ on $\mathcal{A}_0$ is not really a strong restriction; moving over from $\mathcal{A}$ to the JBW algebra $\{D,\mathcal{A},D\}$ with D being the support of μ, one could even assume that μ is faithful on $\mathcal{A}$. Note that the support is the smallest event E with $\mu(E) = 1$, which exists for normal states.

We are now in a position to extend the concept of the state-independent conditional probabilities [$\mathbb{P}(F|E)$; see Ref. 9] to the conditional expectations. If $\mu(X|\mathcal{A}_0) = \nu(X|\mathcal{A}_0)$ all normal states μ, ν on $\mathcal{A}$, which are faithful on $\mathcal{A}_0$ and satisfy $\mathcal{A}_0 \underset{\mu}{\rightarrow} X$ and $\mathcal{A}_0 \underset{\nu}{\rightarrow} X$, respectively, and if at least one such state exists, this state-independent conditional expectation is denoted by $\mathbb{E}(X|\mathcal{A}_0)$. The conditional expectations $\mu(F|\mathcal{A}_0)$ and $\mathbb{E}(F|\mathcal{A}_0)$ are elements in $\mathcal{A}_0$ while $\mu(F|E)$ and $\mathbb{P}(F|E)$ are real numbers for events E and F in $\mathcal{A}$. If E_n is a finite or infinite sequence of mutually orthogonal events in $\mathcal{A}$ with $\Sigma E_n = \mathbb{I}$ and $0 < \mu(E_n) < 1$ for each n, if $\mathcal{A}_0$ is the subalgebra generated by the E_n, and if $\mathcal{A}_0 \underset{\mu}{\rightarrow} F$ holds, we get $\mu(F|\mathcal{A}_0) = \Sigma\mu(F|E_n)E_n$. If, moreover, the E_n are atoms,[9] $\mathbb{E}(F|\mathcal{A}_0)$ exists and $\mathbb{E}(F|\mathcal{A}_0) = \Sigma\mathbb{P}(F|E_n)E_n$.

With $R: \mathcal{M} \rightarrow \mathcal{A}$ being a normal observable, i.e., a JBW-homomorphism from another JBW algebra $\mathcal{M}$ to $\mathcal{A}$, $R(\mathcal{M})$ is a JBW subalgebra of $\mathcal{A}$. If $R(\mathcal{M}) \underset{\mu}{\rightarrow} X$ and if μ is faithful on $R(\mathcal{M})$, $\mu(X|R(\mathcal{M})) \in R(\mathcal{M})$ is also denoted by $\mu(X|R)$ [or by $\mathbb{E}(X|R)$ in the case of independence of the particular state]. If R is injective, there is one and only one element $V_{R,\mu}(X) \in \mathcal{M}$ with $\mu(X|R) = RV_{R,\mu}(X)$. Then $0 \leqslant V_{R,\mu}(X) \leqslant \mathbb{I}$.

We now assume that $\mathcal{A}_1$ is a further subalgebra of $\mathcal{A}$ such that $\mathcal{A}_0 \underset{\mu}{\rightarrow} \mathcal{A}_1$ (i.e., $E \underset{\mu}{\rightarrow} X$ all events E in $\mathcal{A}_0$ and all $X \in \mathcal{A}_1$) or $R(\mathcal{M}) \underset{\mu}{\rightarrow} \mathcal{A}_1$. Then the maps $X \rightarrow \mu(X|\mathcal{A}_0), X \rightarrow \mu(X|R)$, and $X \rightarrow V_{R,\mu}(X)$ [possibly also $X \rightarrow \mathbb{E}(X|\mathcal{A}_0)$ and $X \rightarrow \mathbb{E}(X|R)$] are convex normal maps from the positive unit ball of $\mathcal{A}_1$ to the positive unit ball of $\mathcal{A}_0, R(\mathcal{M})$, and $\mathcal{M}$, respectively. Therefore, each of these maps has a unique extension to a positive normal linear map from $\mathcal{A}_1$ to $\mathcal{A}_0$, $R(\mathcal{M})$, and $\mathcal{M}$, respectively. Thus, $\mu(X|\mathcal{A}_0), \mu(X|R)$, and $V_{R,\mu}(X)$ [possibly also $\mathbb{E}(X|\mathcal{A}_0)$ and $\mathbb{E}(X|R)$] are defined for all $X \in \mathcal{A}_1$.

Differing from the notation used here, a positive linear map $\pi: \mathcal{A} \rightarrow \mathcal{A}_0, X \rightarrow \pi(X)$ with $\mathcal{A}_0 \subseteq \mathcal{A}_1$, $\pi = \pi^2$ and $\pi(\mathbb{I}) = \mathbb{I}$ is sometimes called a conditional expectation (e.g., Refs. 2 and 14); in Ref. 4, it is shown that then $\pi(X \circ Y) = \pi(X) \circ Y$ for $X \in \mathcal{A}$ and $Y \in \mathcal{A}_0$. If $\mathcal{A}$ is a JBW algebra with a faithful trace state (e.g., a JBW algebra with a finite dimension, or a type II_1 factor), then it follows from Theorem 4.3 that a positive linear map $\pi: \mathcal{A} \rightarrow \mathcal{A}$ with $\pi = \pi^2$, $\pi(\mathbb{I}) = \mathbb{I}$, and $\pi(\mathcal{A}) = \mathcal{A}_0$ exists for each JBW subalgebra $\mathcal{A}_0 \subseteq \mathcal{A}$; note that, with μ being a trace state, $E \underset{\mu}{\rightarrow} F$ all events E and F in $\mathcal{A}$, and define $\pi(X) := \mu(X|\mathcal{A}_0)$ for $X \in \mathcal{A}$.

V. THE MARKOV PROCESS

Let $\mathcal{A}$ be a JBW algebra. Let $R_s: \mathcal{M}_s \rightarrow \mathcal{A} (s \in S)$ be a family of normal observables with $\mathcal{M}_s$ being further JBW algebras. Typical examples of the index set S are intervals, e.g., $[0,\infty]$ or $[-\infty,\infty]$, the integers or the non-negative integers $\{0,1,2,\ldots\}$. The JBW subalgebra of $\mathcal{A}$ that is generated by $\cup_{s' \leqslant s} R_{s'}(\mathcal{M}_{s'})$ is denoted by $\mathcal{A}_{\leqslant s}$ for $s \in S$.

Definition 5.1: *The family of normal observables* $R_s (s \in S)$ *together with a faithful normal*

state μ on $\mathcal{A}$ is now called a normal Markov process if

(i) $\mathcal{A}_{\leqslant s} \underset{\mu}{\rightarrow} R_{s'}(\mathcal{M}_{s'})$ *for* $s<s'$, *and*

(ii) $\mu(X|\mathcal{A}_{\leqslant s})=\mu(X|R_s)$ *for* $s<s'$ *and* $X \in R_{s'}(\mathcal{M}_{s'})$ *both hold.*

Condition (i) is a weak directed compatibility criterion for the family of observables $R_s(s \in S)$ under the fixed state μ. Within classical probability theory, it is meaningless, since generally holding. Condition (ii) is the Markov property, meaning that a Markov process is memoryless; the future behavior of the process after time s depends only on its behavior at time s and not on the process history before time s.

We now assume a normal Markov process with each $R_s(s \in S)$ being injective; then $V_{R_s,\mu}(R_{s'}(Y)) \in \mathcal{M}_s$ for $Y \in \mathcal{M}_{s'}$ and $s<s'$ (see Sec. IV). Hence, the composition $V_{s,s'}:=V_{R_s,\mu}R_{s'}$ is a positive normal map $\mathcal{M}_{s'} \rightarrow \mathcal{M}_s$ with $V_{s,s'}(\mathbb{I})=\mathbb{I}$. Keep in mind that the $V_{s,s'}$ depend on the underlying state μ, although this is not shown in the nomenclature.

Theorem 5.2:(i) $\mu^{R_s}(V_{s,s'}(Y))=\mu^{R_{s'}}(Y)$ *for* $Y \in \mathcal{M}_{s'}$ and $s<s'$; *i.e., $V_{s,s'}$ transfers the probability distribution of R_s on $\mathcal{M}_s$ into the one of $R_{s'}$ on $\mathcal{M}_{s'}$. Note that μ^R with $\mu^R(E):=\mu(R(E))$ is the distribution of the observable R in the state μ.* (ii) $V_{s,s'}V_{s',s''}=V_{s,s''}$ for $s,s',s'' \in S$ with $s<s'<s''$.

Proof: (i) $\mu^{R_s}(V_{s,s'}(Y))=\mu((R_sV_{R_s,\mu}R_{s'})(Y))=\mu(\mu(R_{s'}(Y)|R_s))=\mu(R_{s'}(Y))=\mu^{R_{s'}}(Y)$. (ii) Let $X \in R_{s''}(\mathcal{M}_{s''})$. Note that $\mathcal{A}_{\leqslant s} \underset{\mu}{\rightarrow} \mu(X|R_{s'})=\mu(X|A_{\leqslant s'})$. Therefore $\mu(X|R_s)=\mu(X|\mathcal{A}_{\leqslant s})=\mu(\mu(X|\mathcal{A}_{\leqslant s'})|\mathcal{A}_{\leqslant s})=\mu(\mu(X|R_{s'})|\mathcal{A}_{\leqslant s})=\mu(\mu(X|R_{s'})|R_s)$, where the Markov property has been applied several times. With $X=R_{s''}(Y)$ we get $(R_sV_{R_s,\mu}R_{s''})(Y)=(R_sV_{R_s,\mu}R_{s'}V_{R_{s'},\mu}R_{s''})(Y)$ for all $Y \in M_{s''}$ and, due to the injectivity of R_s, $V_{R_s,\mu}R_{s''}=V_{R_s,\mu}R_{s'}V_{R_{s'},\mu}R_{s''}$. The left-hand side of this last equation is identical with $V_{s,s''}$ and the right-hand side is identical with $V_{s,s'}V_{s',s''}$.

Part (ii) of the theorem is the quantum version of the Chapman–Kolmogorov equation in classical probability theory. It holds if the Markov property is satisfied. Part (i) is valid more generally [i.e., if $R_s(\mathcal{M}_s) \rightarrow \mu\ R_{s'}(\mathcal{M}_{s'})$ is satisfied for $s<s'$]. The approach to Markov processes, presented here, is very similar to the one in classical mathematical probability theory (e.g., Ref. 8). The adaptation to the quantum case becomes possible due to the compatibility criterion (i) in Definition 5.1. The faithfulness of the underlying state μ and the injectivity of the R_s are technical assumptions to avoid the difficulties involved with the μ-almost-everywhere equivalence classes that are used in mathematical probability theory. Some further discussion of the assumptions will follow in the concluding remarks.

We call a Markov process *reversible*, if each $V_{s,s'}$ has an inverse $V_{s,s'}^{-1}$, and if this inverse is a positive map. Then $V_{s,s'}^{-1}$ transfers the probability distribution of $R_{s'}$ on $\mathcal{M}_{s'}$ into the one of R_s on $\mathcal{M}_s$. Without $V_{s,s'}^{-1}$ being positive, it would not transfer states to states, but to linear functionals that are not necessarily positive. The generalized Schwarz inequality (Corollary 2.3) implies that the $V_{s,s'}$ are multiplicative isomorphisms in the case of a reversible Markov process.

VI. THE DYNAMICAL GROUP AND ITS GENERATOR

We now assume a Markov process such that each $R_s(s \in S)$ is injective and $\mathcal{M}_s=\mathcal{M}$ for all s. Let $\mathrm{Aut}(\mathcal{M})$ denote the automorphism group of $\mathcal{M}$ and let $\mathrm{Pos}(\mathcal{M})$ be the set of all positive normal linear maps from $\mathcal{M}$ to $\mathcal{M}$ that map the unit element to itself; $\mathrm{Pos}(\mathcal{M})$ is a semigroup, but an inverse need not exist for an element of $\mathrm{Pos}(\mathcal{M})$. The $V_{s,s'}$ now lie in $\mathrm{Pos}(\mathcal{M})$, and if the Markov process is reversible, they lie in $\mathrm{Aut}(\mathcal{M})$.

With the index set S being one of the sets $(-\infty,\infty)$, $[0,\infty)$, $\{0,1,2,\ldots\}$ or $\{\ldots,-1,0,1,2\ldots\}$ and with $\mathcal{M}_s=\mathcal{M}$ for all $s \in S$, we call a Markov process *stationary*, if $\mu(R_{s'}(Y)|R_s)=\mu(R_{t'}(Y)|R_t)$ for $s'-s=t'-t$ ($s,t \in S$, $s<s'$, $t<t'$, and $Y \in \mathcal{M}$). Then $V_{s,s'}=V_{t,t'}$ for $s'-s=t'-t$, and we can define $V_{t,t'}=:V_{t'-t}$. For these V_t we have $V_sV_t=V_{s+t}$. Note that $V_{s,s}(s=s')$ as well as $V_0(t=0)$ have not been defined so far, and we now define $V_{s,s}$ and V_0 to be the identity map on $\mathcal{M}$. Thus, with $S=[0,\infty)$ and a stationary Markov process, the V_t form a dynamical semigroup in

$\mathrm{Pos}(\mathcal{M})$; with $S=(-\infty,\infty)$ and a stationary and reversible Markov process, the V_t form a dynamical group in $\mathrm{Aut}(\mathcal{M})$.

We shall now briefly consider the generators of such groups, but will not go into the technical details of the different kinds of convergence, since most of it is well known—if not for JBW algebras, then at least for the C^*-/W^*-algebras. If

$$L:\ \frac{d}{dt}V_t\bigg|_{t=0}$$

exists (convergence in some sense assumed) for a stationary Markov process, L is a linear operator $\mathcal{M}\to\mathcal{M}$ (or possibly defined only on a dense subset of $\mathcal{M}$) and the following differential equation holds:

$$\frac{d}{dt}V_t = LV_t.$$

Then $V_t=\exp(tL)$. L is called the *generator* of the dynamical (semi)group V_t. From the generalized Schwarz inequality we get for $Y\in\mathcal{M}$,

$$V_t(Y^2)-Y^2 \geqslant (V_t(Y))^2-Y^2 = (V_t(Y)+Y)\circ(V_t(Y)-Y)$$

and therefore (note that V_0 is the identity)

$$L(Y^2)=\frac{d}{dt}V_t(Y^2)\bigg|_{t=0}=\lim_{t\downarrow 0}\frac{1}{t}(V_t(Y^2)-Y^2)\geqslant\lim_{t\downarrow 0}(V_t(Y)+Y)\circ\lim_{t\downarrow 0}\frac{1}{t}(V_t(Y)-Y)=2Y\circ L(Y).$$

In the reversible case, each "$\geqslant$" can be replaced by "=" (Corollary 2.3). Then $L(Y^2)=2Y\circ L(Y)$ for $Y\in\mathcal{M}$. Linear maps L satisfying this equation are called *derivations*. We call a linear map L satisfying $L(Y^2)\geqslant 2Y\circ L(Y)$ for $Y\in\mathcal{M}$ a *dissipation*.

Thus, we have shown that the generator of the dynamical group associated with a stationary Markov process is a dissipation, and is a derivation if the Markov process is stationary and reversible. With $\mathcal{M}$ being the self-adjoint part of a W^*-algebra and with the inner derivation $L(X):=i[H,X]$ for $X\in\mathcal{M}$ [with some $H\in\mathcal{M}$], we get

$$\frac{d}{dt}V_t(X)=i[H,V_t(X)] \text{ and } V_t(X)=e^{itH}Xe^{-itH}.$$

This provides the Schrödinger equation and its solution as a very special case of a more general approach.

Derivations on C^*-algebras are studied in Refs. 2 and 1. The above definition of a dissipation differs from the dissipations studied in Refs. 1 and 3. In Ref. 1, a linear map δ on a *-subalgebra $\mathcal{A}_0$ of a C^*-algebra, satisfying $\delta(X^*X)\leqslant\delta(X^*)X+X^*\delta(X)$ for $X\in\mathcal{A}_0$, is called a dissipation. This implies, but is not equivalent to $\delta(X^2)\leqslant\delta(X)X+X\delta(X)=2X\circ\delta(X)$ for all self-adjoint X in $\mathcal{A}_0$. Other authors use the reversed inequality $\delta(X^*X)\geqslant\delta(X^*)X+X^*\delta(X)$ for the definition of a dissipation. Note that our definition is based on this reversed inequality which, moreover, is required to hold for the self-adjoint elements only (which form the JB algebra).

Note that other authors immediately define a quantum Markov process as a pair consisting of a W^*-algebra and a dynamical semigroup of (completely) positive normal maps on this W^*-algebra, without starting from a stochastic process given as a family of observables and implicitly assuming the stationarity.

VII. CONCLUDING REMARKS

The concept of the classical conditional expectations has been extended to the quantum case, using the framework of Jordan operator algebras. An important condition for the existence of the conditional expectations is given by a certain weak compatibility criterion that was introduced

earlier in Ref. 11. With these concepts, it has been possible to partly extend the classical equivalence between two different ways of describing a Markov process to the quantum case. Starting from a Markov process given as a family of observables, we have derived the positive maps $V_{s,s'}$. In classical probability theory, the reverse is also possible; a Markov process consisting of a family of random variables can be reconstructed from a system of Markovian kernels by using the concept of product σ-algebras. The problem of finding a satisfying analogue of these product σ-algebras for the quantum case has been addressed, but only partly been solved in Ref. 11.

The appropriate framework for this approach to quantum Markov processes are Jordan operator algebras, but neither the only norm-complete JB algebras nor the weakly complete JBW algebras are really satisfying. The JB algebras do not contain sufficiently many idempotent elements (quantum events). If the theory is based upon JBW algebras (as here in this paper), an important example, the algebra consisting of the measurable real-valued functions on a measurable space (the real-valued random variables of classical probability theory) is ruled out. This algebra can be embedded in a JBW algebra (even in a W^*-algebra,[7]) however, one is rather reluctant to work with this abstractly constructed JBW algebra instead of the well-understood algebra of measurable real functions. What is needed is a theory of monotone-sequentially complete JB algebras, similar to the one of the monotone-sequentially complete C^*-algebras studied by Kadison,[6] Kehlet,[7] and Pedersen.[12] This theory must include a Gleason-type theorem and a Radon–Nikodym theorem for σ-additive states. The Gleason-type theorem is needed for proving that unique conditional probabilities exist for σ-additive states defined on the system of events (as done for the JBW case in Ref. 9), and the Radon–Nikodym theorem is required for showing that the conditional expectations exist for the σ-additive states.

(Received 18 May 2004; accepted 10 January 2005; published online 24 March 2005)

Landscape paradigm is ubiquitous in physics and other natural sciences, but it has to be supplemented with both quantitative and qualitatively meaningful tools for analyzing the topography of a given landscape. We here consider dynamic explorations of the relief and introduce as basic topographic features "wells of duration T and altitude y." We determine an intrinsic exploration mechanism governing the evolutions from an initial state in the well up to its rim in a prescribed time, whose finite-difference approximations on finite grids yield a constructive algorithm for determining the wells. Our main results are thus (i) a quantitative characterization of landscape topography rooted in a dynamic exploration of the landscape, (ii) an alternative to stochastic gradient dynamics for performing such an exploration, (iii) a constructive access to the wells, and (iv) the determination of some bare dynamic features inherent to the landscape. The mathematical tools used here are not familiar in physics: They come from set-valued analysis (differential calculus of set-valued maps and differential inclusions) and viability theory (capture basins of targets under evolutionary systems) that have been developed during the last two decades; we therefore propose a minimal Appendix exposing them at the end of this paper to bridge the possible gap. © *2005 American Institute of Physics.*

I. INTRODUCTION

A. The landscape paradigm in natural sciences

The general notion of landscape is encountered in many different domains, for instance in physics, neural networks (Hopfield nets[22]) and learning processes, molecular biology,[13,19] ecology and evolutionary biology,[23] or optimization problems, to cite but a few. From the mathematical viewpoint, a *landscape* is simply a function $V: X \mapsto \mathbb{R} \cup \{+\infty\}$ (more precisely, an extended[30] function since it might take infinite values $+\infty$) associating a real value $V(x)$ to each state $x \in X$ of the system. From a physical viewpoint, the status and definition of V strongly depend on the scale at which the system is described, reflecting in the choice of the space of states X.

Let us give some examples to sustain our exposition. In statistical physics and molecular biology, $V(x)$ can be the *energy landscape* if x is the (high-dimensional) microscopic configuration of the considered system: atomic coordinates in a glass,[15] spin orientations in a spin glass,[17] tridimensional conformation of the hundred or more amino acids forming a protein,[18] spatial positions of bead centers in a granular medium.[16] It can also be a (mesoscopic) *free energy landscape* if x is the value of a (low-dimensional) order parameter describing the global state of the system: spatially average density, overall magnetization, conformational parameter(s) for a macromolecule (as, for instance, its radius of gyration). At a still more macroscopic level, x can be

a)Electronic mail: J.P.Aubin@wanadoo.fr
b)Electronic mail: lesne@lptl.jussieu.fr

a reaction coordinate measuring the progress along a path representing some transformation of the system and inscribed on an *effective energy landscape*. In quite different contexts, cost functions encountered in optimization problems are close analogs to energy landscapes,[2] whereas fitness landscapes encountered in ecology and evolutionary biology can be cast in the frame of free or effective energy landscapes, up to a sign change (namely, by considering the opposite of the fitness). (See Ref. 28 for an introductory review.)

Energy or free energy landscapes are currently exploited in stochastic gradient methods accounting for the interplay between thermal motion and interaction forces (effective forces in the case of a free energy landscape) deriving from the potential $x \mapsto V(x)$. In complex systems (glasses, spin glasses, proteins, for instance) the landscape V typically presents a large number of local optima around which the solution of a stochastic gradient method is trapped and travels a long time before going away and visiting other local minima. This dynamical behavior has been advocated by Giorgio Parisi to encapsulate a meaning of complexity and rugged landscapes are often seen as a mark of complex systems. (See, for instance, Ref. 25.)

Although the landscape $V(x)$ is thus endowed with different status and interpretations in varying contexts, understanding and controlling the system behavior requires in any case a quantitative knowledge of the landscape topography. It is thus of the utmost importance to design efficient tools allowing a dynamical analysis of local minima of such a function $x \mapsto V(x)$. We emphasize that it is not just an academic issue since actual energy or free energy landscapes of real systems are available through either of the following:

(i) a *theoretical access* from first principles (e.g., molecular interactions, spin–spin interactions) and/or modeling hypotheses, allowing us to write an explicit formula for $V(x)$;
(ii) an *experimental access*, for instance, for proteins (indirect kinetic or spectral measurements) (Ref. 19);
(iii) a *numerical access*, either through molecular dynamics at an atomic scale, yielding the energy landscape, either through Monte Carlo sampling of the configuration space according to the Boltzmann distribution, yielding free energy landscapes for the relevant order parameter(s) of the system.[20]

B. Dynamical analysis of a landscape topography

Here we propose a theoretical and algorithmic analysis allowing us to determine quantitatively the landscape relief of a function V, e.g., location of wells, location and heights of the barriers associated with a given dynamics for exploring the landscape.[31] It gives access to a hierarchical picture of the landscape and allows us to determine the nesting of wells and barriers at different scales.

Given a dynamic exploration mechanism (such as a stochastic gradient dynamics), we define the "wells of velocity λ, duration T, and altitude y" as the sets of initial states $x \in X$ "below the level y," i.e., $V(x) \leqslant y$, from which at least one evolution governed by the exploration mechanism, and of velocity bounded by λ, reaches the rim y of the well at the prescribed time T. When the well is not empty, we then evidence intrinsic dynamics governing the evolutions from an initial state of the well up to its rim y at prescribed time T. This intrinsic exploration mechanism is characterized from *the time derivative of the well, regarded as a set-valued map associated with the prescribed duration T and the altitude y the elements of the well*. Both the wells and their intrinsic exploration mechanism can be approximated by finite-difference approximations on finite grids, *which allows us to implement a constructive algorithm*.

In this study we offer an alternative to stochastic gradient-type exploration mechanisms. In quite a similar way of thought, second-order exploration mechanisms of the graph of an energy landscape function has been proposed in Ref. 1. Here we suggest starting the landscape exploration with a universal mechanism, independent of the energy function, allowing us to look at any possible velocity with prescribed norm λ and retaining its intrinsic exploration dynamics as a good candidate for a dynamical system exploring the given energy landscape. The stochastic gradient

method is thus replaced by a differential inclusion involving the time derivative of the well, but allowing in the same spirit the system state to escape the trap of local minima, while being quantitatively influenced by their depth.

The mathematical tools we use are quite novel in physics: They come from set-valued analysis (differential calculus of set-valued maps and differential inclusions) and viability theory (capture basins of targets under evolutionary systems) that have been developed during the last two decades.

The resulting quantitative topographic description by wells rooted in a constructive dynamic exploration of the landscape and the associated determination of the statistical properties of its relief can then be exploited for the following:

(1) *performing a quantitative characterization of the landscape*, for comparison or classification purposes. It allows us to investigate bifurcations, more currently called phase transitions in many-particle systems (Ref. 24);
(2) *providing a quantitative access to the landscape hierarchical structure* and allowing us to estimate its ruggedness, which yields a tentative measure of the system complexity;
(3) *defining macrostates and macroscopic variables* to be used in coarse-grained descriptions of the system. The relevance of such an approach is to provide an intrinsic determination of macrostates, founded upon the identification of macroscopic features with slow modes and slowly evolving properties (Ref. 21).

Outline of the paper. In Sec. II, we shall define wells, introduce some mathematical features of their relief, and reformulate their characterization in terms of the "capture basin of a target," a key concept of viability theory that finds here an unexpected, yet natural, application. In Sec. III, we present the algorithm allowing us to construct explicitly these wells and the intrinsic exploration mechanism on which it is based. In Sec. IV, we introduce the notion of complete wells, matching more closely with physical landscape features. After a conclusive summary in Sec. V, the essential notions of viability theory needed for this paper are presented in an Appendix. ■

II. WELLS OF AN ENERGY LANDSCAPE

A. An efficient alternative to stochastic exploration

In order to provide both a quantitatively meaningful and quantitative topographic analysis of a landscape V on a space X, we introduce "wells of duration T and depth y." Given a dynamical system, allowing upward steps of velocity bounded by a parameter λ, these wells are the sets $\mathbf{P}_V(\lambda;t,y)$ of initial states "below the level y" [i.e., of states $x \in X$ such that $V(x) \leqslant y$] from which at least one[32] evolution reaches the upper level y (what we call the *rim of the well*) at time T. In other words, given some tolerance λ allowing upwards exploration, and some level y, the wells and their depth might be dynamically (the experimentally meaningful and operational way) determined according to the trapping time T.

For exploratory purposes, here we implement an alternative to stochastic gradient dynamics and replace stochastic differential equations encountered in physics by differential inclusions of the form[33]

$$\forall t \geqslant 0, \quad x'(t) \in F(\lambda;x(t)),$$

where $x \rightsquigarrow F(\lambda;x(t))$ is some set-valued function on X [i.e., $F(\lambda;x)$ is a subset of X] parametrized by a parameter $\lambda \in \mathbb{R}$. Compared to a differential equation, the solution of a differential inclusion is less constrained since the full specification of the derivative $x'(t)$ at each time t is replaced by a constraint on the region $F(\lambda;x(t))$, where it has to lie. Such a tolerance is highly valuable and quite realistic in the modeling of an actual system, since the experimentally available knowledge about its dynamics generally provides only bounds (or more generally viability constraints) on the kinetic rates, rather than explicit pointwise expressions of these rates as a function of the system state. These bounds might nevertheless vary with the system state $x(t)$, hence defining a specific

set $F(\lambda; x(t))$at each time t. For instance, in the case when the function V is differentiable, a close analog to stochastic gradient dynamics is provided by

$$x'(t) \in -\nabla V(x(t)) + \lambda B,$$

where B denotes the unit ball of the finite-dimensional vector space X. Indeed, the gradient dynamics $x'(t) = -\nabla V(x(t))$ governs evolutions decreasing along the function V, but stopping at the first encountered local minimum. To overcome this stalling situation, a natural idea is to perturb the gradient equation either by a stochastic noise, as currently implemented in simulated annealing methods, or, as we suggest here, by a "*tychastic*" one. Indeed, differential inclusion $x'(t) \in -\nabla V(x(t)) + \lambda B$ is the "tychastic version" of the stochastic differential equation $dx = -\nabla V(x(t))dt + \lambda\, dW(t)$ (see Ref. 8 for the links between stochastic and tychastic viability).

However, we have to overcome the fact that the function V is usually not differentiable, if obtained through experimental measures or simulations and no longer analytically defined. Hence the concept of gradient disappears (when the observable or simulated configuration space is discrete), or has to be approximated by gradients of functions interpolating in one way or another the experimental data. Any method allowing to bypass these obstacles and to deal with graphs of such functions may be worthy of being investigated.

Another suggestion is to leave open the choice of the directions of exploration by looking for any way to climb the landscape V to reach a given level y at a given time T. For that purpose, we can choose $F(\lambda; x) := \lambda B$, stating that any velocity of norm λ is *a priori* an eligible candidate to apply for such a mission. We shall provide below the way of further selecting the most efficient (subset of) velocity(ies), i.e., achieving the most thoroughly and the most efficiently from a numerical viewpoint the quantitative exploration of the landscape relief. The same type of strategy has been used in previous works for constructing an algorithm that is also of relevance for landscapes. This so-called Montagnes Russes Algorithm converges to global minima of an extended function jumping over local minima, which amounts to using the gradient algorithm to the smallest of the exponential Lyapunov functions above the energy function for the differential inclusion $x'(t) \in \lambda B$. (See Refs. 10 and 11.) But whereas this algorithm was devoted to the search of global minima, we are here looking for exploratory tools providing a complete hierarchical picture of the landscape.

B. Definition and characterization of wells

From now on, we assume that the set-valued map $x \rightsquigarrow F(\lambda; x)$ governing the exploration dynamics is given. We denote by $y \in \mathbb{R}$ the altitude of the well we wish to study. $y = 0$ is set through the (arbitrary) choice of a base level (or, if known and finite, by the lower bound on V). Usually, the relevant altitudes are the values of the *local maxima* or *saddle points* of the function V. We shall associate with it the concept of well $\mathbf{P}(\lambda; T, y)$ of duration T and altitude y defined as follows.

Definition II.1: Consider an extended function $V: X \mapsto \mathbb{R} \cup \{+\infty\}$ and a differential inclusion

$$\forall\, t \geqslant 0, \quad x'(t) \in F(\lambda; x(t)).$$

Denote by

$$\mathbf{S}(V, y) := \{x \in X \text{ such that } V(x) \leqslant y\} \text{ and } \mathbf{S}_0(V, y) := \{x \in X \text{ such that } V(x) = y\}$$

the level sets of the function V and by $\mathcal{S}_\lambda(x)$ the set of solutions to the above differential inclusion starting at x. The well $\mathbf{P}_V(\lambda; T, y) \subset \mathbf{S}(V; y)$ of duration T and altitude y of the function V is defined by the set of initial states $x \in \mathbf{S}(V; y)$ such that there exists at least one solution $x_\lambda(\cdot) \in \mathcal{S}_\lambda(x)$ such that

$$\text{(i) } V(x_\lambda(T)) = y,$$

$$\text{(ii)}\ \ \forall\, t \in [0,T], \quad V(x_\lambda(t)) \leqslant y.$$

We observe that $\mathbf{P}_V(\lambda;0,y)=\mathbf{S}_0(V,y):=\{x\in X \text{ such that } V(x)=y\}$. In other words, the well $\mathbf{P}_V(\lambda;T,y)$ is the set of initial conditions x in the well from which there exists at least one evolution $x_\lambda(\cdot)$ staying below the level y during a duration T and reaching the level y at exactly time T. This does not exclude the fact that for some earlier time $t^*\leqslant T$ (or some later time $t^*\geqslant T$), the evolution reaches the level y. This just means that x belongs to the intersection $\mathbf{P}_V(\lambda;T,y)\cap\mathbf{P}_V(\lambda;t^*,y)$ of wells of several durations. This point can be made more explicit: considering the initial state x of the system as a variable and the time to reach the level y as the result, we can define the *reaching function* $(\lambda,x,y)\mapsto\xi(\lambda,x,y)$ by

$$\xi(\lambda,x,y) := \inf_{x\in\mathbf{P}_V(\lambda;T,y)} T,$$

providing the first instant when one evolution starting from x reaches the level y.

We can also regard the same object by introducing the set-valued map $(\lambda;T,x)\rightsquigarrow\mathbf{P}_V^{-1}(\lambda;T,x)$ associated with the parameter λ, the duration T, and the initial state x the altitude y of the well, the rim of which can be reached at time T by at least one evolution governed by differential inclusion $x'(t)\in F(\lambda;x(t))$.

Turning back to the initial definition, the *maximal depth* $\delta_V(\lambda;T,y)$ of the well $\mathbf{P}_V(\lambda;T,y)$ is defined by

$$\delta_V(\lambda;T,y) := \sup_{x\in\mathbf{P}_V(\lambda;T,y)} (y - V(x)).$$

The knowledge of the wells provides some physical characteristics of the landscape V, thus bridging the above mathematical definitions with a more traditional description of landscapes. We observe, for instance, that $\xi(\lambda,x,y)$ is the *escape time* for the given dynamics, also called the *first passage time*, from above a barrier of top y when the velocity is bounded by λ. Its inverse $[\xi(\lambda,x,y)]^{-1}$ has the meaning of a kinetic constant.

Denoting $\Omega_V(\lambda;T,y)$ the number of the connected components of well $\mathbf{P}_V(\lambda;T,y)$, its logarithm is the *configurational entropy*. (See Refs. 29 and 16 for its meaning and use in physics, respectively, for glasses and granular media):

$$\sigma_V(\lambda;T,y) := \log(\Omega_V(\lambda;T,y)).$$

In summary, what we are basically looking for is the subset of (x,y,λ,T) such that either $x\in\mathbf{P}_y(\lambda;T,y)$ or $T>\xi(\lambda;x,y)$ or $y\in\mathbf{P}_V^{-1}(\lambda;T,x)$. As detailed in the next section, we shall give a mathematical characterization of this set as a "capture basin of a target under an auxiliary system," allowing us to implement a constructive algorithm. We choose here the representation of this set through the above concept of well $x\in\mathbf{P}_V(\lambda;T,y)$.

C. Viability characterization of wells

The next step of our investigation is to translate the above topographically meaningful features in terms of capture basins for which many properties have been established and constructive algorithms are available (See the Appendix and for further details, Refs. 3–6.)

Proposition II.2: Consider an extended function $V:X\mapsto\mathbb{R}\cup\{+\infty\}$ and a differential inclusion

$$\forall\, t\geqslant 0, \quad x'(t)\in F(\lambda;x(t)).$$

We associate with it the auxiliary system of differential inclusions

$$\text{(i)}\ x'(t)\in F(\lambda(t);x(t)),$$

$$\text{(ii)}\ y'(t)=0,$$

$$\text{(iii)}\ \lambda'(t) = 0,$$

$$\text{(iv)}\ \tau'(t) = -1 \tag{1}$$

the constrained set $\mathcal{K}$ and the target $\mathcal{C}$ defined by

$$\mathcal{K} := \mathcal{E}_p(V) \times \mathbb{R}_+ \times \mathbb{R}_+ \text{ and } \mathcal{C} := \text{Graph}(V) \times \mathbb{R}_+ \times \{0\},$$

where Graph(V) and $\mathcal{E}p(V) \subset X \times \mathbb{R} \cup \{+\infty\}$ are, respectively, the graph and epigraph of V (see the Appendix for a precise definition). Then

$$\mathbf{P}_V(\lambda; T, y) = \{x \in X \text{ such that } (x, y, \lambda, T) \in \text{Capt}_{(1)}(\mathcal{K}, \mathcal{C})\},$$

where $\text{Capt}_{(1)}(\mathcal{K}, \mathcal{C})$ is the capture basin of the target $\mathcal{C}$ under evolutionary system (1) and under the constraint of remaining in $\mathcal{K}$ (see Definition A.2 below).

Proof: Indeed, to say that $(x, y, \lambda, T) \in \text{Capt}_{(1)}(\mathcal{K}, \mathcal{C})$ amounts to saying that there exist one evolution $x_\lambda(\cdot) \in \mathcal{S}_\lambda(x)$ and a time $t^\star \geqslant 0$ such that the associated auxiliary evolution,

$$t \to (x(t), y(t); \lambda(t); \tau(t)) = (x(t), y, \lambda, T - t),$$

starting from (x, y, λ, T) at $t=0$, reaches the target $\mathcal{C}$ at time $t^\star$ while staying meanwhile in $\mathcal{K}$:

$$\text{(i)}\ (x(t^\star), y, \lambda, T - t^\star) \in \mathcal{C},$$

$$\text{(ii)}\ \forall\, t \in [0, t^\star], \quad (x(t), \lambda, y, T - t) \in \mathcal{K}.$$

The first condition is equivalent to both equations $t^\star = T$ and $V(x(T)) = y$. The second equation means that for every $t \in [0, T]$, $V(x(t)) \leqslant y$. These are the very properties stating that x belongs to the well $\mathbf{P}_V(\lambda; T, y)$, or, equivalently, that $\xi(\lambda; x, y) \leqslant T$. ■

Therefore, the graph of the set-valued map $(\lambda, T, y) \rightsquigarrow \mathbf{P}_V(\lambda; T, y)$ inherits the properties of capture basins. For instance, it can be shown (using Theorem A.6 given in the Appendix) that the well satisfies a kind of dynamical programming principle that can be stated in the following way:

Proposition II.3: The set-valued map $\mathbf{P}_V$ is the unique set-valued map $(\lambda, T, y) \rightsquigarrow \mathbf{P}(\lambda; T, y)$ satisfying the initial condition

$$\mathbf{P}(\lambda; 0, y) := \mathbf{S}_0(V, y) := \{x \in X \text{ such that } V(x) = y\}$$

the constraints

$$\mathbf{P}(\lambda; T, y) \subset \mathbf{S}(V; y)$$

and the "tracking property:" for any $x \in \mathbf{P}(\lambda; T, y)$, any evolution $x_\lambda(\cdot) \in \mathcal{S}_\lambda(x)$ starting from x at time 0 climbing the well until it reaches the rim at time T satisfies

$$\text{(i)}\ \forall\, t \in [0, T], \quad x(t) \in \mathbf{P}(\lambda; T - t, y),$$

$$\text{(ii)}\ \forall\, s \geqslant T \text{ such that } \forall\, t \in [T, s], \quad V(x(t)) \leqslant y, \quad \text{then } x(t) \in \mathbf{P}(\lambda; t - T, y).$$

D. Time derivative of the well as an *a posteriori* exploratory dynamical system

Since we have related the well of a landscape function to capture basins, the basic viability theorems provide tangential characterization of the wells, allowing us to find the underlying dynamical system governing the evolutions of differential inclusion climbing the wells up to their rims. This can be done to the price of using differential calculus of set-valued maps (invented in

the beginning of the 1980s for this purpose): Knowing the "derivatives" with respect to time of the set-valued map $t \rightsquigarrow \mathbf{P}_V(\lambda;t,y)$ (see Definition A.10 for a rigorous definition), we obtain an intrinsic exploration mechanism of the well.

Proposition II.4: For any $x \in \mathbf{P}_V(\lambda;T,y)$, those evolutions $x_\lambda(\cdot) \in \mathcal{S}_\lambda(x)$ starting at x and climbing the well $\mathbf{P}_V(\lambda;T,y)$ in the sense that $V(x_\lambda(t)) \leqslant y$ for any $t \in [0,T]$ and $V(x_\lambda(T)) = y$ are governed by differential inclusion

$$x'(t) \in -\frac{\partial \mathbf{P}_V(\lambda;T-t,y)}{\partial t} \cap F(\lambda;x(t)).$$

In particular, taking for initial exploration mechanism the set-valued map $F(\lambda;x) := \lambda B$ independent of the energy function V instead of exploration mechanisms $F(\lambda;x) := -\nabla V(x(t)) + \lambda B$ already dependent of V, we obtain a more intrinsic exploration mechanism.

Theorem A.12 stated in the Appendix gives a technically precise meaning to this symbolic statement. In other words, the underlying dynamical system governing the evolutions climbing the wells up to their rims is the set of velocities $v \in F(\lambda;x)$ pointing to the time derivative of the well in order to climb it from $-T$ to 0 in order to reach the rim of the well at altitude y. The associated mathematical problem to comfort this intuitive result starts with the definition of the time derivative and the proof of this result is based on results of viability theory. Let us just mention the following informal version of Theorem A.12 stated in the Appendix:

Proposition II.5: The set-valued map $\mathbf{P}_V$ is the unique "Frankowska solution to the partial differential inclusion"

$$\forall t > 0, x \in \mathbf{P}(\lambda;T,y), \quad 0 \in \frac{\partial \mathbf{P}(\lambda;T,y)}{\partial t} + F(\lambda;x)$$

satisfying the initial condition

$$\mathbf{P}(\lambda;0,y) := \mathbf{S}_0(V,y) := \{x \in X \text{ such that } V(x) = y\}$$

and the constraints

$$\mathbf{P}(\lambda;T,y) \subset \mathbf{S}(V;y).$$

We propose now to check the same statement in the discrete case, which allows us to define an algorithm providing the wells under discrete dynamics and the exploratory mechanisms.

III. THE SAINT-PIERRE CAPTURE BASIN ALGORITHM

The Saint-Pierre Capture Basin Algorithm provides both the set-valued map $\mathbf{P}_V$ and for any $x \in \mathbf{P}_V(\lambda;T,y)$, the evolutions climbing the well up to its rim under a given duration.

Let us consider any discrete time approximation $\Phi(\lambda;x)$ of $F(\lambda;x)$ governing the evolution of sequences $\vec{x} \in \vec{\mathcal{S}}_\lambda(x)$, governed by

$$x_{n+1} \in \Phi(\lambda;x_n).$$

[For instance, $\Phi(x): x + hF_h(\lambda;x)$, where h is a time step and F_h is an approximation of F in the sense that the graph of F_h converges to the graph of F in the Painlevé–Kuratowski sense]. The discrete version of a well defined by Definition II.1 for continuous time systems becomes as follows:

Definition III.1: Consider an extended function $V: X \mapsto \mathbb{R} \cup \{+\infty\}$ and a set-valued map $(\lambda,x) \rightsquigarrow \Phi(\lambda;x)$. The discrete time well $\vec{\mathbf{P}}_V(\lambda;N,y) \subset \mathbf{S}(V;y)$ of duration T and depth y of the function V is the subset of initial states $x \in \mathbf{S}(V;y)$ such that there exists one sequence $\vec{x} \in \mathcal{S}_\lambda(x)$ such that

$$\text{(i) } V(x_N) = y,$$

$$\text{(ii)}\ \ \forall\, n \in \{0,N\}, \quad V(x_n) \leqslant y.$$

In the discrete time, we obtain the intrinsic exploration mechanism under mere inspection:

Proposition III.2: Knowing the well $\vec{\mathbf{P}}_V$, the discrete dynamical system

$$x_{n+1} \in \Phi(\lambda; x_n) \cap \vec{\mathbf{P}}_V(\lambda; N-n, y)$$

governs the evolutions starting from $x \in \vec{\mathbf{P}}_V(\lambda; N, y)$ and arriving at step N at some $x_N \in \vec{\mathbf{P}}_V(\lambda; 0, y) = \mathbf{S}_0(V, y)$ of the rim of the well $\vec{\mathbf{P}}_V(\lambda; N, y)$.

In the discrete case, the discrete well is obtained by the Capture Basin Algorithm:

Proposition III.3: The Saint-Pierre Capture Basin Algorithm yields the discrete well as the intersection of the following subsets defined recursively by

$$\text{(i)}\ \vec{\mathbf{P}}_V(\lambda; 0, y) = \mathbf{S}_0(V, y),$$

$$\text{(ii)}\ \ \forall\, N \geqslant 0, \quad \vec{\mathbf{P}}_V(\lambda; N+1, y) = \Phi(\lambda; \cdot)^{-1}(\vec{\mathbf{P}}_V(\lambda; N, y)) \cap \mathbf{S}(V, y).$$

When $\Phi(\lambda; x) := x + \lambda B$, this algorithm can be written

$$\text{(i)}\ \vec{\mathbf{P}}_V(\lambda; 0, y) = \mathbf{S}_0(V, y),$$

$$\text{(ii)}\ \ \forall\, N \geqslant 0, \quad \vec{\mathbf{P}}_V(\lambda; N+1, y) = (\vec{\mathbf{P}}_V(\lambda; N, y) + \lambda B) \cap \mathbf{S}(V, y).$$

Proof: Indeed, we introduce the auxiliary system Ψ by

$$\Psi(x, y, \lambda, \tau) := \Phi(\lambda, x) \times \{y\} \times \{\lambda\} \times \{\tau - 1\},$$

governing the evolution of the sequence:

$$\begin{aligned} &\text{(i)}\ x_{n+1} \in \Phi(\lambda; x_n), \\ &\text{(ii)}\ y_{n+1} = y_n, \\ &\text{(iii)}\ \lambda_{n+1} = \lambda_n, \\ &\text{(iv)}\ \tau_{n+1} = \tau_n - 1, \end{aligned} \tag{2}$$

and the constrained set $\mathcal{K}$ and the target $\mathcal{C}$ defined by

$$\mathcal{K} := \mathcal{E}p(V) \times \mathbb{R}_+ \times \mathbb{R}_+ \quad \text{and} \quad \mathcal{C} := \text{Graph}(V) \times \mathbb{R}_+ \times \{0\}.$$

Then one can prove as in the continuous time case that

$$\vec{\mathbf{P}}_V(\lambda; N, y) = \{x \in X, \quad \text{such that} \quad (x, y, \lambda, N) \in \text{Capt}_{(2)}(\mathcal{K}, \mathcal{C})\},$$

where the subscript (2) in $\text{Capt}_{(2)}(\mathcal{K}, \mathcal{C})$ refers to the discrete evolutionary system (2).

The capture basin algorithm defines recursively a sequence of subsets $\mathcal{C}_n$ starting at $\mathcal{C}_0$ by

$$\mathcal{C}_{n+1} := \mathcal{K} \cap (\mathcal{C}_n \cup \Psi^{-1}(\mathcal{C}_n)),$$

which converges to the capture basin $\text{Capt}_{(2)}(\mathcal{K}, \mathcal{C})$. ■

One can prove that whenever the discrete map $x \rightsquigarrow \Phi_h(x) := x + hF_h(\lambda; x)$ is a time discretization of the differential inclusion $x'(t) \in F(\lambda; x(t))$, the graph of the discrete well converges to the graph of the well in the Kuratowski–Painlevé sense (see Refs. 26 and 27 and see Ref. 14, among other references).

IV. COMPLETE WELLS

The concept of well we proposed in Definition II.1 is not restrictive enough to match its physical counterpart, in the sense that it does not require that all evolutions starting from a point of a well $\mathbf{P}_V(\lambda;T,y)$ to remain below the rim of the well before time T while one of them at least reaches its rim at time T.

Definition IV.1: Consider an extended function $V:X\mapsto\mathbb{R}\cup\{+\infty\}$ and a differential inclusion

$$\forall t\geqslant 0,\quad x'(t)\in F(\lambda;x(t)).$$

The complete well $\mathbf{W}_V(\lambda;T,y)\subset\mathbf{P}(V;y)$ of duration T and depth y of the function V is defined by the set of initial states $x\in\mathbf{S}(V;y)$ such that

(i) all solutions $x_\lambda(\cdot)\in\mathcal{S}_\lambda(x)$ satisfy

$$\forall t\in[0,T],\quad V(x_\lambda(t))\leqslant y$$

(ii) at least one solution $x_\lambda(\cdot)\in\mathcal{S}_\lambda(x)$ satisfies

$$V(x_\lambda(T))=y.$$

The complete wells can be characterized in terms of absorption and capture basins. (See, for instance, Refs. 3–6.)

Proposition IV.2: Consider an extended function $V:X\mapsto\mathbb{R}\cup\{+\infty\}$ and a differential inclusion

$$\forall t\geqslant 0,\quad x'(t)\in F(\lambda;x(t)).$$

We associate with it the auxiliary system of differential inclusions (1). The constrained set $\mathcal{K}$ and the targets $\mathcal{C}$ and $\mathcal{D}$ are defined by

$$\mathcal{K}:=\mathcal{E}_p(V)\times\mathbb{R}_+\times\mathbb{R}_+ \text{ and } \mathcal{C}:=\mathrm{Graph}(V)\times\mathbb{R}_+\times\{0\}$$

and

$$\mathcal{D}:=\mathcal{E}_p(V)\times\mathbb{R}_+\times\{0\}.$$

Then

$$\mathbf{W}_V(\lambda;T,y)=\{x\in X \text{ such that } (x,y,\lambda,T)\in\mathrm{Capt}_{(1)}(\mathcal{K},\mathcal{C})\cap\mathrm{Abs}_{(1)}(\mathcal{K},\mathcal{D})\}.$$

Proof: Indeed, to say that $(x,y,\lambda,T)\in\mathrm{Capt}_{(1)}(\mathcal{K},\mathcal{C})\cap\mathrm{Abs}_{(1)}(\mathcal{K},\mathcal{D})$ amounts to saying the following:

(1) $(x,y,\lambda,T)\in\mathrm{Capt}_{(1)}(\mathcal{K},\mathcal{C})$, and thus, as we have seen, that $x\in\mathbf{P}_V(\lambda;T,y)$.

(2) $(x,y,\lambda,T)\in\mathrm{Abs}_{(1)}(\mathcal{K},\mathcal{D})$ means that for all evolutions $x_\lambda(\cdot)\in\mathcal{S}_\lambda(x)$, there exists a time $t^\star\geqslant 0$ such that the associated auxiliary evolutions,

$$t\rightarrow(x(t),y(t);\lambda(t);\pi(t))=(x(t),y,\lambda,T-t),$$

starting from (x,y,λ,T) at $t=0$ reaches the target $\mathcal{D}$ at time $t^\star$ while staying, meanwhile, in $\mathcal{K}$:

$$\text{(i) } (x(t^\star),y,\lambda,T-t^\star)\in\mathcal{D},$$

$$\text{(ii) } \forall\, t\in[0,t^\star],\quad (x(t),\lambda,y,T-t)\in\mathcal{K}.$$

The first condition is equivalent to both equation $t^\star=T$ and inequality $V(x(T))\leqslant y$. The second equation means that for every $t\in[0,T]$, $V(x(t))\leqslant y$.

These are the two properties stating that x belongs to the well $\mathbf{W}_V(\lambda;T,y)$. ■

V. CONCLUSIONS

Our objective in this investigation was to build exploration dynamics of a landscape V associating with a bound λ on the velocities of the exploration mechanism, a duration T, and an altitude y:

(1) The set $\mathbf{P}_V(\lambda;T,y)$ of initial states x below altitude y from which starts at least one evolution climbing the landscape in order to reach the altitude y at exactly the prescribed time T; altitude y might be either a reference level, thus providing access to the depth of the well, or chosen among the values of local maxima of the landscape function, thus providing access to the height of the barriers separating the well from the other ones.

(2) An underlying dynamical system governing the evolutions climbing the wells up to their rims the velocities of the exploration mechanism are consistently chosen among

$$x'(t) \in -\frac{\partial \mathbf{P}_V(\lambda;T-t,y)}{\partial t}.$$

Hence, the exploration mechanism is no longer an external stochastic modification of the gradient equation, but an intrinsic set-valued method involving the time derivative of the well.

This dynamic description of landscape topography has then been reformulated in the framework of viability theory, which provides a constructive algorithm to characterize quantitatively the landscape, built as an intrinsic exploration mechanism of energy landscapes; this mechanism could be either a perturbed gradient method or a universal mechanism independent of the energy function. The more refined notion of complete well, introduced in Sec. IV, allows us to bridge still more our mathematical definitions and exploration with the current landscape paradigm. As discussed in the Introduction (Sec. I B), our results can then be exploited for taxinomic purposes, to investigate phase transitions, to quantify the landscape hierarchical structure. It also proposes an alternative to standard stochastic gradient methods, namely differential inclusions, in modeling dynamics associated with an experimentally determined landscape.

APPENDIX: ELEMENTS OF VIABILITY THEORY

Let X be a finite-dimensional vector space. A *set-valued map* $F:X \rightsquigarrow X$ associates to any $x \in X$ a subset $F(x) \subset X$. The set-valued map F generates the evolutionary system $\mathcal{S}_F:X \rightsquigarrow \mathcal{C}(0,\infty;X)$ associating with any initial state $x_0 \in X$ the set $\mathcal{S}_F(x_0) \subset \mathcal{C}(0,\infty;X)$ of solutions to *differential inclusion* $x'(t) \in F(x(t))$ starting at x_0. We denote by

$$\mathrm{Graph}(F) := \{(x,y) \in X \times Y | y \in F(x)\} \subset X \times Y,$$

the *graph* of a set-valued map $F:X \rightsquigarrow Y$ and $\mathrm{Dom}(F) := \{x \in X | F(x) \neq \emptyset\}$ its *domain*.

We shall say that a subset $K \subset X$ *is locally viable under* F (or under $\mathcal{S}_F$) if from every $x \in K$ starts *at least one* solution $x(\cdot)$ to the differential inclusion $x' \in F(x)$ *viable in* K on the nonempty interval $[0,T_x[$ in the sense

$$\forall\, t \in [0,T_x[, \quad x(t) \in K,$$

and that K is *viable* if we can take $T_x = +\infty$ for any $x \in K$. Most of the results of viability theory are true whenever we assume that the dynamics are Marchaud:

Definition A.1: We shall say that the set-valued map $F:X \rightsquigarrow Y$ is a Marchaud map if

(i) the graph of F is closed in $X \times Y$,
(ii) the values of $F(x)$ of F are convex subsets of Y,
(iii) the growth of F is linear: $\exists c > 0 \,|\, \forall x \in X,\ \|F(x)\| := \sup_{v \in F(x)} \|v\| \leqslant c(\|x\| + 1)$.

We shall say that F is λ-Lipschitz if (set-valued extension of the standard Lipschitz property)

$$\forall x, x' \in X, \quad F(x) \subset F(x') + \lambda \|x - x'\| B,$$

where B is the unit ball in Y.

We shall also need some other prerequisites from the Viability Theory: among which capture and absorption basins.

Definition A.2: Let $C \subset K \subset X$ be two subsets, C being regarded as a target, K as a constrained set. The subset $\mathrm{Capt}_F(K, C)$ of initial states $x_0 \in K$ such that C is reached in finite time, without leaving K, by at least one solution $x(\cdot) \in \mathcal{S}_F(x_0)$ starting at x_0 is called the viable-capture basin of C in K (the solution might eventually leave K, but only after having reached C). The subset $\mathrm{Abs}_F(K, C)$ of initial states $x_0 \in K$ such that ***all evolutions*** $x(\cdot) \in \mathcal{S}_F(x_0)$ starting at x_0 are viable in K until they reach C in finite time is called the absorption basin of K with target C.

Obviously $\mathrm{Abs}_F(K, C) \subset \mathrm{Capt}_F(K, C)$. We recall the following result (Ref. 7) of bilateral fixed point property:

Theorem A.3: The viable-capture basin $\mathrm{Capt}(K, C)$ of a target C viability being with respect to the constrained set K) is the unique subset D satisfying $C \subset D \subset K$ and

$$D = \mathrm{Capt}_F(K, D) = \mathrm{Capt}_F(D, C)$$

and the absorption basin of K with target C is the unique subset A satisfying $C \subset A \subset K$ and

$$A = \mathrm{Abs}_F(A, C) = \mathrm{Abs}_F(K, A).$$

We also recall backward invariance:

Definition A.4: The subset K is locally backward invariant under F if for every $t_0 \in]0, +\infty[$, $x \in K$, for all solutions $x(\cdot)$ to the differential inclusion $x' \in F(x)$ arriving at x at time t_0, there exists a time $s \in [0, t_0[$ (depending on the solution) such that $x(\cdot)$ is viable in K on the interval $[s, t_0]$. The subset K is backward invariant under F if we can take $s = 0$ for all solutions.

It is straightforward to check that backward evolutions $\theta \to z(\theta) = x(t_0 - \theta)$ are solutions of the differential inclusion $z'(\theta) \in -F(z(\theta))$ with initial condition $z(0) = x(t_0)$; we call them *backward solutions* (starting from $x(t_0)$ at time $\theta = 0$). It is noted that the (local) backward invariance of K is stronger than (local) viability of K under this backward evolution, since *all* solutions starting in a backward invariant subset K remain in K for a finite time (depending on each considered solution in case of the local version of the property), whereas the (local) viability of K only requires that for each point $x \in K$, at least *one* solution is (locally) viable in K.

We also introduce a weaker notion: A subset $D \subset K$ is *locally backward invariant relatively* to K if all backward solutions starting from D and viable in K (i.e. remaining in K for a finite time) are actually viable in D (i.e., remain in D for a finite time).

Definition A.5: A subset $R \subset X$ is a repeller under F if all solutions starting from R leave R in finite time.

Hence, R is not viable, but this does not exclude local viability. It is, moreover, obvious that any subset of a repeller is itself a repeller.

We can derive the following characterization of capture basin (see Ref. 4):

Theorem A.6: Let us assume that F is Marchaud and that the subsets $C \subset K$ and K are closed. If $K \backslash C$ is a repeller (this is for instance the case when K itself is a repeller), then the viable-capture basin $\mathrm{Capt}_F(K, C)$ of the target C under F is the unique closed subset D satisfying $C \subset D \subset K$ and[34]

(i) $D \backslash C$ is locally viable under F,
(ii) D is locally backward invariant relatively to K.

Definition A.7: The contingent cone $T_L(x)$ to $L \subset X$ at $x \in L$ is the set (obviously a closed cone)

of directions $v \in X$ such that there exist sequences $h_n > 0$ converging to 0 and v_n converging to v satisfying $x + h_n v_n \in L$ for every n (see, for instance, Ref. 9).

For instance, if L is a differentiable manifold in X, $T_L(x)$ coincides with the tangent space to L at point x. If the interior of L is nonempty, then $T_L(x) = X$ for any $x \in \mathrm{Int}(L)$.

We introduce the following Frankowska property that we need for deriving the system of Hamilton–Jacobi–Bellman equations of which the well is a solution:

Definition A.8: Let us consider a set-valued map $F: X \rightsquigarrow X$ and two subsets $C \subset K$ and K. We shall say that a subset D between C and K (i.e., $C \subset D \subset K$) satisfies the Frankowska property with respect to F if

$$\text{(i)} \quad \forall\, x \in D \setminus C, \quad F(x) \cap T_D(x) \neq \emptyset,$$

$$\text{(ii)} \quad \forall\, x \in D \text{ such that (Ref. 35) } -F(x) \cap T_K(x) \neq \emptyset \text{ then } -F(x) \subset T_D(x). \tag{A1}$$

When K is assumed further to be locally backward invariant (then $-F(x) \subset T_K(x)$ for any $x \in K$) the above conditions (A1) boil down to

$$\text{(i)} \quad \forall\, x \in D \setminus C, \quad F(x) \cap T_D(x) \neq \emptyset,$$

$$\text{(ii)} \quad \forall\, x \in D, \quad -F(x) \subset T_D(x) \tag{A2}$$

[The minus sign in front of F arises when considering backward evolution, governed by the differential inclusion, $z'(\theta) \in -F(z(\theta))$.]

Theorem A.6 and the Viability[36] and Invariance Theorems imply

Theorem A.9: Let us assume that F is Marchaud, that K and $C \subset K$ are closed subsets, and that $K \setminus C$ is a repeller. Then the capture basin $\mathrm{Capt}_F(K, C)$ is

(1) the largest closed subset D satisfying $C \subset D \subset K$ and

$$\forall x \in D \setminus C, \quad F(x) \cap T_D(x) \neq \emptyset. \tag{A3}$$

Furthermore, the evolutions $x(\cdot) \in \mathcal{S}_F(x)$ viable in K until they reach C are governed by the differential inclusion

$$x'(t) \in F(x(t)) \cap T_D(x(t)).$$

(It roughly means that these trajectories point into D or are taugent to D at any point where they reach the boundary of D, thus ensuring their viability until they reach C.)

(2) if F is Lipschitz, the unique closed subset D satisfying the Frankowska property (A1).

The absorption basin $\mathrm{Abs}_F(K, C)$ is the largest closed subset D satisfying $C \subset D \subset K$ and

$$\forall x \in D \setminus C, \quad F(x) \subset T_D(x). \tag{A4}$$

We shall apply Theorem A.9 to the case when subsets $K := \mathrm{Graph}(F)$ and $C := \mathrm{Graph}(H)$ are graphs of set-valued maps from X to X and when we decide to regard D as the graph of a set-valued map $G: \mathbb{R} \times X \rightsquigarrow Y$. We then interpret the contingent cone to the graph as the graph of the contingent derivative. We obtain set-valued solutions to systems of Hamilton–Jacobi inclusions that this unknown function G should satisfy in order that its graph yields the desired capture basin. We refer to Refs. 5 and 6, Ref. 12, and their references for more details on this topic. Here, we recall the definition of contingent derivative of a set-valued map and translate Theorem A.9 in the framework of wells.

Definition A.10: Let us consider a set-valued map $G: \mathbb{R} \times X \rightsquigarrow Y$. The graph of the contingent derivative $DG(t, x, y)$ (a set-valued map defined from $\mathbf{R} \times X$ to Y) at a point $(t, x, y) \in \mathrm{Graph}(G)$ is equal to the contingent cone to the graph of G at (t, x, y):

$$T_{\mathrm{Graph}(G)}(t, x, y) = \mathrm{Graph}(DG(t, x, y)).$$

Consequently, to say that $w \in Y$ belongs to the contingent derivative $DG(t,x,y)(\pm 1,v)$ of G at (t,x,y) in the direction $(\pm 1,v) \in \mathbf{R} \times X$ means that

$$\liminf_{h \to 0+, v' \to v} d\left(w, \frac{G(t \pm h, x + hv') - y}{h}\right) = 0,$$

where d is any distance in Y. Since the contingent cone is a closed subset, the graph of a contingent derivative is always closed and positively homogeneous (this is what remains of the required linearity of the derivative in classical analysis, but, fortunately, we can survive pretty well without linearity).

When $g: \mathbf{R} \times X \mapsto Y$ is single-valued, we set $Dg(t,x) := Dg(t,x,g(t,x))$. We see at once that $Dg(t,x)(\pm 1,v) = \pm \partial g(t,x)/\partial t + \partial g(t,x)/\partial x \cdot v$ whenever g is differentiable at (t,x). The above definition (A.10) generalizes to set-valued maps a property obviously valid for differentiable maps, hence provides a consistent extension of the differentiation to set-valued maps, coinciding with the plain notion for smooth single-valued maps. Moreover, it is to note that when g is Lipschitz on a neighborhood of (t,x) and when the dimension of X is finite, the domain of $Dg(t,x)$ is not empty. Furthermore, the Rademacher Theorem stating that a locally Lipschitz single-valued map is almost everywhere differentiable implies that $x \rightsquigarrow Dg(t,x)$ is almost everywhere single valued. However, in this case, equality $Dg(t,x)(-1,-v) = -Dg(t,x)(1,v)$ is not true in general. We refer to Ref. 9 for more details.

Remark: This is how Fermat defined in 1637 the derivative of a function as the slope of the tangent to its graph. Leibniz and Newton provided the characterization in terms of limits of difference quotients. Here, too, *the graph of the contingent derivative* $DG(t,x,y)$ *is the upper Painlevé–Kuratowski limit of the graphs of difference quotients* $\nabla_h G(t,x,y)$ of G at $(t,x,y) \in \mathrm{Graph}(G)$, defined by

$$(\lambda, v) \mapsto \nabla_h G(t,x,y)(\lambda, v) := \frac{G(t + \lambda h, x + hv) - y}{h}.$$

Indeed, we observe that

$$\mathrm{Graph}(\nabla_h G(t,x,y)) = \frac{\mathrm{Graph}(G) - (t,x,y)}{h} (\subset \mathbf{R} \times X \times Y),$$

so that the contingent cone to the graph of G, being the upper limit of the graphs of the difference quotients, is equal by definition to the graph of the upper graphical limit of the difference quotients.

The strong requirement of pointwise convergence of differential quotients involved in the usual derivatives can be weakened in (at least) two ways, each way sacrificing different groups of properties of these usual derivatives.

(i) *Distributional derivatives:* Fix the direction v and take the limit of the function $x \mapsto \nabla_h g(x)(v)$ in the weaker sense of distributions. The limit $D_v g$ may then be a distribution, and no longer a single-valued map. However, it coincides with the usual limit $(D_v g(x) = Dg(x) \cdot v)$ when g is Gâteaux differentiable. Moreover, one can define difference quotients of distributions, take their limit, and thus, differentiate distributions.
Distributions are no longer functions or maps defined on $\mathbf{R}^n$, so these distributional derivatives lose the pointwise character of functions and maps; on the other hand, this generalization retains the linearity of the operator $g \mapsto D_v g$, mandatory for using the theory of linear operator for solving partial differential equations.

(ii) *Graphical derivatives:* Fix the point x and take the limit of the function $v \mapsto \nabla_h g(x)(v)$ in the weaker sense of graphical convergence (the graph of the graphical limit being by definition the Painlevé–Kuratowski upper limit of the graphs). The limit $Dg(x)$ may then be a set-valued map, and no longer a single-valued map. However, it coincides with the usual limit when g is Gâteaux differentiable. Moreover, one can define difference quotients of

set-valued maps, take their graphical limit, and thus differentiate set-valued maps. These graphical derivatives keep the pointwise character of functions and maps, mandatory for implementing the Fermat Rule, proving inverse function theorems under constraints or using Lyapunov functions, for instance, but lose the linearity of the map $g \mapsto Dg(x)$.

In both cases, the approaches are similar: They use (different) convergences *weaker than the pointwise convergence* for increasing the possibility for the difference quotients to converge. But the price to pay is the loss of some properties by passing to these weaker limits (the pointwise character for distributional derivatives, the linearity of the differential operator for graphical derivatives). ■

Proposition II.2 related the graph of the well to the capture basin $P_v(\lambda;T,y) = \{x \in X \text{ such that } (x,y,\lambda,T) \in \text{Capt}_1(\mathcal{KC})\}$ under system (A1):

$$\begin{aligned} &\text{(i) } x'(t) \in F(\lambda(t);x(t)),\\ &\text{(ii) } y'(t) = 0,\\ &\text{(iii) } \lambda'(t) = 0,\\ &\text{(iv) } \tau'(t) = -1. \end{aligned} \tag{A1'}$$

At this point, we need to introduce the concepts of epigraph and epiderivative of extended numerical functions:

Definition A.11: Let $V: X \mapsto \mathbb{R} \cup \{+\infty\}$ be an extended function. Its epigraph $\mathcal{E}p(V)$ is the set of pairs $(x,y) \in X \times \mathbb{R}$ satisfying $V(x) \leqslant y$ [thus $\mathcal{E}p(V) \subset X \times \mathbf{R}$]. The contingent epiderivative $D_\uparrow V(x): X \mapsto \overline{\mathbb{R}}$ is defined through the relation

$$\mathcal{E}p(D_\uparrow V(x)) := T_{\mathcal{E}p(V)}(x, V(x)).$$

We can check that $D_\uparrow V(x)$ consistently coincide with the usual derivative $DV(x)$ when V is differentiable in x, and that for any $v \in X$,

$$D_\uparrow V(x)(v) = \liminf_{h \to 0+, v' \to v} \frac{V(x+hv') - V(x)}{h}$$

is a generalized limit of differential quotients.

We deduce from Proposition II.2 and Theorem A.9 the following characterization of the well as the unique solution to an initial-value problem of a partial differential inclusion satisfying viability constraints:

Theorem A.12: Assume that the set-valued map F is Marchaud and that the function V is continuous. Then the well $\mathbf{P}_V: \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R} \rightsquigarrow X$ is the largest set-valued map $\mathbf{P}: \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R} \rightsquigarrow X$ solution to the partial differential inclusion

$$\forall x \in \mathbf{P}(\lambda;T,y), \quad F(\lambda;x) \cap D\mathbf{P}(\lambda;T,y,x)(0,-1,0) \neq \emptyset$$

the initial condition

$$\mathbf{P}(\lambda;0,y) = \mathbf{S}_0(V,y)$$

and the viability constraint

$$\mathbf{P}(\lambda;T,y) \subset \mathbf{S}(V,y).$$

Furthermore, if F is Lipschitz, this solution is the unique solution satisfying

(i) $\forall x \in \mathbf{P}(\lambda;T,y)$, $F(\lambda;x) \cap D\mathbf{P}(\lambda;T,y,x)(0,-1,0) \neq \emptyset$,

(ii) $\forall x \in \mathbf{P}(\lambda;T,y)$ such that $\inf_{v \in F(\lambda;x)} D_{\uparrow}V(x)(-v) \leqslant 0$ then $-F(\lambda;x) \subset D\mathbf{P}(\lambda;T,y,x)(0,+1,0)$.

Proof: Theorem A.9 implies that the graph of the well $\mathbf{P}_V : \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R} \rightsquigarrow X$, once transformed by the permutation $(\lambda,\tau,y,x) \to (x,y,\lambda,\tau)$ of the coordinates, is the largest subset $\mathcal{D}$ between $\mathcal{C}$ and $\mathcal{K}$ (i.e., $\mathcal{C} \subset \mathcal{D} \subset \mathcal{K} \subset X \times \mathbb{R} \times \mathbb{R}_+ \times \mathbb{R}_+$), such that

$$\forall (x,y,\lambda,\tau), \quad (F(\lambda;x) \times \{0\} \times \{0\} \times \{-1\}) \cap T_{\mathcal{D}}(x,y,\lambda,\tau) \neq \emptyset.$$

This amounts to saying that the well $\mathbf{P}_V$ is the largest set-valued map $\mathbf{P}$ satisfying the initial condition $\mathbf{P}(\lambda;0,y) = \mathbf{S}_0(V,y)$, the constraint $\mathbf{P}(\lambda;T,y) \subset \mathbf{S}(V,y)$, and the contingent solution to the partial differential inclusion,

$$\forall x \in \mathbf{P}(\lambda;T,y), \quad F(\lambda;x) \cap D\mathbf{P}(\lambda;T,y,x)(0,-1,0) \neq \emptyset,$$

and that the evolutions $[t \mapsto (\lambda, T-t, y, x(t))]$ viable in the well until they reach its rim are governed by the differential inclusion

$$(0,-1,0,x'(t)) \in (\{0\} \times \{-1\} \times \{0\} \times F(\lambda;x(t))) \cap \mathrm{Graph}(D\mathbf{P}_V(\lambda;T-t,y,x(t))(0,-1,0)).$$

This can be written as

$$x'(t) \in F(\lambda;x(t)) \cap D\mathbf{P}_V(\lambda;T-t,y,x(t))(0,-1,0).$$

This is what we meant symbolically above as

$$x'(t) \in F(\lambda;x(t)) \cap -\frac{\partial \mathbf{P}_V(\lambda;T-t,y)}{\partial t}.$$

When F is Lipschitz [this is the case when $F(\lambda;x) := \lambda B$ (where B is the unit ball in X)], the graph of the well $\mathbf{P}_V$ (after permutation of the coordinates as above) is the unique subset $\mathcal{D}$, satisfying

$$\forall (x,y,\lambda,\tau), \quad (F(\lambda;x) \times \{0\} \times \{0\} \times \{-1\}) \cap T_{\mathcal{D}}(x,y,\lambda,\tau) \neq \emptyset,$$

and, whenever $(-F(\lambda;x) \times \{0\} \times \{0\} \times \{+1\}) \cap T_{\mathcal{K}}(x,y,\lambda,\tau) \neq \emptyset$, then

$$(-F(\lambda;x) \times \{0\} \times \{0\} \times \{+1\}) \subset T_{\mathcal{D}}(x,y,\lambda,\tau).$$

Thanks to the definition of the contingent epiderivative and the fact that $\mathcal{K} := \mathcal{E}p(V) \times \mathbb{R}_+ \times \mathbb{R}_+$, we infer that

$$(-v,0,0,+1) \in T_{\mathcal{D}}(x,y,\lambda,\tau),$$

if and only if $D_{\uparrow}V(x)(-v) \leqslant 0$. This concludes the proof. ■

[30] We call V an "extended function" in the sense that it can take the value $+\infty$. This allows us to encapsulate state constraints $x \in K$ [where K is the subset of "viable" (acceptable, feasible) states] in the definition of the extended function, equal to $+\infty$ outside K. A well-known example in physics is hard-core interaction potential.
[31] Care has to be taken not to confuse exploration mechanism (valid whatever the interpretation of V is) and actual evolution (whose modeling is indissociable from the status and definition of V). We here mainly consider exploration dynamics. Only at the end of the paper, it is suggested that the intrinsic exploration mechanism determined in Sec. III could be a relevant alternative to stochastic gradient dynamics for modeling actual dynamic features of the system.
[32] or, if needed, all evolutions.
[33] At odds with stochastic models currently used in physics, differential inclusions provide another way to translate uncertainty in mathematical terms. A full corpus of results have been steadily accumulated since their introduction in the early 1930s by Marchaud and Zaremba, and next, by the Polish and Russian schools, around Ważewski and Filippov, who laid the foundations of the mathematical theory of differential inclusions after the 1950s. The confrontation of evolutions governed by differential inclusion and viability constraints for reaching targets in finite time began in the early 1980s to provide regulation maps and feedbacks. Their use for translating mathematically uncertainty "against nature" as an alternative to stochastic differential equations began at the same period, but is taking a new start when it was realized recently that they yield much more general results than the stochastic paradigm: Differential inclusions allow us to represent uncertainty by state-dependent maps. As a name needed to refer to such a viewpoint and to underline its difference with stochastic differential equations, we called these *tychastic systems* when the velocities depend upon both the state and a parameter that is called "tyche" [meaning "chance" in classical Greek, from the Goddess Tyche of (good and bad) fortune], which play the role of perturbations or disturbances on which actors and decision makers have no control. Tyches could in fact have been more plainly called "random variables" if this vocabulary were not already confiscated by probabilists. This is why we borrow the term of *tychastic evolution* to the American philosopher Charles Peirce who introduced it in a paper published in 1893 *under the title "Evolutionary love:" "Three modes of evolution have thus been brought before us: evolution by fortuitous variation, evolution by mechanical necessity, and evolution by creative love. We may term them tychastic evolution, or tychasm, anancastic evolution, or anancasm, and agapastic evolution, or agapasm.*
[34] The subset $K \backslash C$ denotes the intersection of K and the complement of C, i.e., is the set of elements of K that do not belong to C.
[35] This is always satisfied when $x \in \mathrm{Int}(K)$.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 043509 (2005)

Partial fractions expansions and identities for products of Bessel functions

Mathew D. Rogers
Department of Mathematics, University of British Columbia, Vancouver, BC, Canada V6T-1Z2

(Received 11 July 2004; accepted 8 December 2004; published online 28 March 2005)

We derive several partial fractions expansions for products of Bessel functions, and use them to prove algebraic relationships between infinite series involving squares of Bessel functions. We also give formulas for the Taylor series coefficients of the zeros of Bessel functions, when the zeros are regarded as functions of the order x of $J_x(y)$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1866222]

I. INTRODUCTION

In this paper we derive several partial fractions expansions for products of Bessel functions, the simplest of which is given by

$$J_x(y)J_{-x}(y)\frac{\pi}{\sin(\pi x)} = \sum_{n=-\infty}^{\infty} \frac{J_n^2(y)}{n+x}.$$

These formulas, which are presented in Sec. II, allow us to easily characterize $J_x(y)J_{-x}(y)$ as a function of x. Surprisingly, these sorts of identities are generally overlooked in the modern literature on Bessel functions.

We can apply these formulas to study the zeros of Bessel functions. Let $\nu_k(x)$ denote the kth zero of $J_x(y)$. In Sec. IV we recursively compute the Taylor series coefficients of $\nu_k(x)$ at the half-integers. In Sec. V we discuss computing the Taylor series at zero and the positive integers. The form that we give for the coefficients is interesting because they are expressed as polynomials in functions defined by series of squares of Bessel functions.

Besides appearing in the Taylor series coefficients of $\nu_k(x)$, functions like

$$\mu_k(y) = \sum_{n=1}^{\infty} \frac{J_n^2(y)}{n^k}, \quad \beta_k(y) = \sum_{n=-\infty}^{\infty} \frac{J_n^2(y)}{(2n+1)^k},$$

obey a bewildering variety of identities and algebraic relations. In Secs. IV, V, and VII we prove many interesting formulas involving these functions. We also present several associated open problems at the end of Secs. IV–VI.

Throughout this paper we will assume the usual differentiation and addition formulas for Bessel functions,

$$2\frac{x}{y}J_x(y) = J_{x-1}(y) + J_{x+1}(y),$$

$$2\frac{d}{dy}J_x(y) = J_{x-1}(y) - J_{x+1}(y).$$

We will also employ a standard Wronskian relation,

$$J_{x-1}(y)J_{-x}(y) + J_{1-x}(y)J_x(y) = \frac{2\sin(\pi x)}{\pi y}.$$

II. IDENTITIES AND PARTIAL FRACTIONS EXPANSIONS FOR BESSEL FUNCTIONS

The Bessel function of the first kind of order x is defined by the infinite series

$$J_x(y) = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!\Gamma(n+x+1)}\left(\frac{y}{2}\right)^{2n+x}, \tag{2.1}$$

where $\Gamma(x)$ is the usual gamma function.

We will use the following three partial fractions expansions throughout this paper.

Proposition 2.1: The following formulas hold for all $y \in \mathbf{C}$ and for all $x \notin \mathbf{Z}$,

$$J_x(y) = \frac{\left(\frac{y}{2}\right)^x}{\Gamma(x)} \sum_{n=0}^{\infty} \frac{J_n(y)}{n!} \frac{\left(\frac{y}{2}\right)^n}{n+x}, \tag{2.2}$$

$$J_x(y)J_{-x}(y)\frac{\pi}{\sin(\pi x)} = \sum_{n=-\infty}^{\infty} \frac{J_n^2(y)}{n+x}, \tag{2.3}$$

$$J_x(y)J_{1-x}(y)\frac{\pi}{\sin(\pi x)} = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(y)}{n+x}. \tag{2.4}$$

Equation (2.2) has a long history. It appears in several 19th century and 20th century books, including Lommel,[2] Schafheitlin,[4] and Watson (Ref. 5, p.143). From (2.2) one can easily derive Lommel's expression for $Y_0(z)$,

$$Y_0(z) = \frac{2}{\pi}(\log(z/2) + \gamma)J_0(z) + \frac{2}{\pi}\sum_{n=1}^{\infty} \frac{J_n(z)}{n!} \frac{\left(\frac{z}{2}\right)^n}{n}. \tag{2.5}$$

The function $Y_0(z)$ is a Bessel function of the second kind (Ref. 5, p.64).

Equations (2.3) and (2.4) seem to be omitted from the modern literature, as well as all of the easily accessible 19th century books. Considering their relative simplicity, it seems unlikely that 19th century mathematicians would have missed them. In fact, the following integral (Ref. 1, p.756)

$$\int_0^{\pi/2} \cos(2xu)J_0(2y\cos(u))\mathrm{d}u = \frac{\pi}{2}J_x(y)J_{-x}(y) \tag{2.6}$$

is exactly equivalent to Eq. (2.3).

We have found a particularly simple way to prove formulas (2.3) and (2.4) that is worth relating.

Proof: Lommel proves Eq. (2.2) in Ref. 2. We can also prove this result by applying the following elementary partial fractions expansion to Eq. (2.1):

$$\frac{n!}{x(x+1)(x+2)\cdots(x+n)} = \sum_{j=0}^{n} \frac{(-1)^j}{j+x}\binom{n}{j}.$$

To prove Eq. (2.4) we will use the reflection formula for the gamma function,

$$\Gamma(x)\Gamma(1-x)=\frac{\pi}{\sin(\pi x)},$$

and we will apply formula (2.2) several times. Proceeding with the proof,

$$J_x(y)J_{1-x}(y)\frac{\pi}{\sin(\pi x)}=(J_x(y)\Gamma(x))(J_{1-x}(y)\Gamma(1-x))=\left(\sum_{n=0}^{\infty}\frac{J_n(y)}{n!}\frac{\left(\frac{y}{2}\right)^{n+x}}{n+x}\right)\left(\sum_{m=0}^{\infty}\frac{J_m(y)}{m!}\frac{\left(\frac{y}{2}\right)^{m+1-x}}{m+1-x}\right)$$

$$=\sum_{n\geqslant 0,m\geqslant 0}^{\infty}\frac{J_n(y)J_m(y)}{n!m!}\frac{\left(\frac{y}{2}\right)^{n+m+1}}{(n+x)(m+1-x)}$$

$$=\sum_{n\geqslant 0,m\geqslant 0}^{\infty}\frac{J_n(y)J_m(y)}{n!m!}\frac{\left(\frac{y}{2}\right)^{n+m+1}}{n+m+1}\left(\frac{1}{n+x}+\frac{1}{m+1-x}\right).$$

Next split the sum into two pieces, then rearrange the order of summation to get

$$=\sum_{n=0}^{\infty}\frac{J_n(y)}{n!(n+x)}\left(\sum_{m=0}^{\infty}\frac{J_m(y)}{m!}\frac{\left(\frac{y}{2}\right)^{n+m+1}}{n+m+1}\right)+\sum_{m=0}^{\infty}\frac{J_m(y)}{m!(m+1-x)}\left(\sum_{n=0}^{\infty}\frac{J_n(y)}{n!}\frac{\left(\frac{y}{2}\right)^{n+m+1}}{n+m+1}\right).$$

Observe that the two nested sums in the preceding equation are just special cases of Eq. (2.2). Substituting the appropriate expressions we have

$$=\sum_{n=0}^{\infty}\frac{J_n(y)}{n!(n+x)}\Gamma(n+1)J_{n+1}(y)+\sum_{m=0}^{\infty}\frac{J_m(y)}{m!(m+1-x)}\Gamma(m+1)J_{m+1}(y)$$

$$=\sum_{n=0}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}+\sum_{m=0}^{\infty}\frac{J_m(y)J_{m+1}(y)}{m+1-x}.$$

Now let $m+1=-n$, and change the indices of summation on the right-hand sum to get

$$=\sum_{n=0}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}+\sum_{n=-1}^{-\infty}\frac{J_{-n-1}(y)J_{-n}(y)}{-n-x}.$$

Finally, recall that if $m\in\mathbf{Z}$ then $J_{-m}(y)=(-1)^m J_m(y)$. Substituting this relation into the preceding equation yields

$$=\sum_{n=0}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}+\sum_{n=-1}^{-\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}=\sum_{n=-\infty}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x},$$

completing the proof of (2.4).

The proof of Eq. (2.3) is nearly identical to the above proof, except that slightly more care must be taken when combining the partial fractions expansions for $J_x(y)$ and $J_{-x}(y)$. ■

Proposition 2.2: The infinite sums appearing in Proposition 2.1 are related as follows:

$$\left(\sum_{n=-\infty}^{\infty}\frac{J_n^2(y)}{n+x}\right)\left(\sum_{n=-\infty}^{\infty}\frac{J_n^2(y)}{n+1-x}\right)=\frac{2}{y}\left(\sum_{n=-\infty}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}\right)-\left(\sum_{n=-\infty}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}\right)^2,\qquad(2.7)$$

$$\sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(y)}{n+x} = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(y)}{n+1-x}, \tag{2.8}$$

$$\left(\sum_{n=0}^{\infty} \frac{J_n(y)}{n!}\frac{\left(\frac{y}{2}\right)^n}{n+x}\right)\left(\sum_{n=0}^{\infty} \frac{J_n(y)}{n!}\frac{\left(\frac{y}{2}\right)^{n+1}}{n+1-x}\right) = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(y)}{n+x}, \tag{2.9}$$

$$\left(\sum_{n=0}^{\infty} \frac{J_n(y)}{n!}\frac{\left(\frac{y}{2}\right)^n}{n+x}\right)\left(\sum_{n=0}^{\infty} \frac{J_n(y)}{n!}\frac{\left(\frac{y}{2}\right)^n}{n-x}\right) = \frac{-1}{x}\sum_{n=-\infty}^{\infty} \frac{J_n^2(y)}{n+x}. \tag{2.10}$$

Proof: Equations (2.8)–(2.10) follow trivially from Proposition 2.1.

Equation (2.7) is a simple consequence of the Wronskian relation for Bessel functions,

$$J_{x-1}(y)J_{-x}(y) + J_{1-x}(y)J_x(y) = \frac{2\sin(\pi x)}{\pi y}.$$

We will prove (2.7) as follows. Observe from Proposition 2.1 that the left-hand side (LHS) of Eq. (2.7) is given by

$$\text{LHS} = J_x(y)J_{1-x}(y)J_{x-1}(y)J_{-x}(y)\left(\frac{\pi}{\sin(\pi x)}\right)^2,$$

and the right-hand side (RHS) is given by

$$\text{RHS} = J_x(y)J_{1-x}(y)\left(\frac{\pi}{\sin(\pi x)}\right)^2\left(\frac{2\sin(\pi x)}{\pi y} - J_x(y)J_{1-x}(y)\right).$$

Apply the Wronskian relation to the RHS to see that LHS=RHS, which establishes (2.7). ■

Of course these are not the only partial fractions expansions available for Bessel functions. There are multitudes of ways to generalize these results. We state several generalizations in the next proposition.

Proposition 2.3: If x, y, and z are complex numbers such that $x \notin \mathbf{Z}$, *then*

$$\frac{\pi}{\sin(\pi x)}J_{z-x}(y)J_{x-z}(y) = \sum_{n=-\infty}^{\infty} (-1)^n \frac{J_{z+n}(y)J_{-z-n}(y)}{x+n}, \tag{2.11}$$

$$\frac{\pi}{\sin(\pi x)}J_x(y)J_{-x}(z) = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_n(z)}{n+x}\left(\frac{y}{z}\right)^{n+x}, \tag{2.12}$$

$$\frac{\pi}{\sin(\pi x)}J_x(y)J_{1-x}(z) = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(z)}{n+x}\left(\frac{y}{z}\right)^{n+x}. \tag{2.13}$$

Suppose that $x_1+x_2+x_3=1$, *then*

$$J_{x_1}(y)J_{x_2}(y)J_{x_3}(y)\Gamma(x_1)\Gamma(x_2)\Gamma(x_3) = \sum_{n\geq 0, m\geq 0} J_n(y)J_m(y)J_{n+m+1}(y)\binom{n+m}{m}\left(\frac{1}{(n+x_1)(m+x_2)} + \frac{1}{(n+x_1)(m+x_3)} + \frac{1}{(n+x_2)(m+x_3)}\right). \tag{2.14}$$

Letting $x_1=x_2=x_3=\frac{1}{3}$ in Eq. (2.14) yields an interesting double series for $(J_{1/3}(y))^3$,

$$(J_{1/3}(y))^3 = \frac{1}{\Gamma^3(4/3)} \sum_{n\geqslant 0, m\geqslant 0}^{\infty} \frac{J_n(y)J_m(y)J_{n+m+1}(y)}{(3n+1)(3m+1)} \binom{n+m}{m}. \tag{2.15}$$

III. PROPERTIES OF THE FUNCTION $\nu_k(x)$

We will give a brief description of the function $\nu_k(x)$, and then prove a new form for the differential equation that $\nu_k(x)$ satisfies. Throughout this section we will assume that $x \in \mathbf{R}$.

It is well known that $J_x(y)$ has infinitely many real zeros, and a finite number of complex zeros. We can regard the zeros of $J_x(y)$ as functions of the order x.

Definition 3.1: Let $\nu_k(x)$ *denote the* kth *real zero of* $J_x(y)$ *to the right of* x. *Then* $J_x(\nu_k(x)) = 0$ *for all* x.

It can be shown that $\nu_k(x)$ is continuous and differentiable for all $x \in \mathbf{R}\backslash\{-1,-2,\ldots\}$. In fact, it is well known that $\nu_k(x)$ satisfies transcendental differential equations. Nicholson's differential equation (Ref. 5, p. 508) is given by

$$\nu_k'(x) = -2\nu_k(x)\int_0^{\infty} K_0(2\nu_k(x)\sinh(t))e^{-2xt}\,dt, \tag{3.1}$$

and is valid provided that $x \notin \{-1,-2,\ldots\}$. The negative integers must be excluded from the domain of $\nu_k(x)$, because $\nu_k(x)$ is discontinuous at each of these points. These discontinuities occur because new solution curves of $J_x(y)=0$ come into existence when $x \in \{-1,-2,\ldots\}$. Watson provides a nice illustration (Ref. 5, p. 510) of this phenomenon.

The form of the differential equation that we are interested in follows almost directly from formula (2.3). Proposition 3.2 will allow us to express derivatives of $\nu_k(x)$ in terms of infinite series that obey interesting algebraic relations [see Theorem 4.7 and Eq. (4.24)].

Proposition 3.2: If $x \notin \{-1,-2,\ldots\}$, *then* $\nu_k(x)$ *satisfies the differential equation*

$$\nu_k'(x) = \frac{\nu_k(x)}{2} \sum_{n=-\infty}^{\infty} \frac{J_n^2(\nu_k(x))}{(n+x)^2}. \tag{3.2}$$

Proof: This proof is quite standard (Ref. 5, p. 507). By the definition of $\nu_k(x)$, and by formula (2.3) we have

$$0 = \sum_{n=-\infty}^{\infty} \frac{J_n^2(\nu_k(x))}{n+x}.$$

Now assume that x is not a negative integer, and take the derivative of each side to show that

$$0 = -\sum_{n=-\infty}^{\infty} \frac{J_n^2(\nu_k(x))}{(n+x)^2} + \nu_k'(x)\frac{d}{d\nu}\sum_{n=-\infty}^{\infty} \frac{J_n^2(\nu_k(x))}{(n+x)}.$$

Substituting Eq. (2.3) for the sum on the right-hand side we find that

$$0 = -\sum_{n=-\infty}^{\infty} \frac{J_n^2(\nu_k(x))}{(n+x)^2} + \nu_k'(x)\frac{\pi}{\sin(\pi x)}\frac{d}{d\nu}(J_x(\nu_k(x))J_{-x}(\nu_k(x))). \tag{3.3}$$

Now expand and simplify $d/d\nu(J_x(\nu_k(x))J_{-x}(\nu_k(x)))$ as follows:

$$\frac{\mathrm{d}}{\mathrm{d}\nu}(J_x(\nu_k(x))J_{-x}(\nu_k(x))) = \frac{J_{x-1}(\nu_k(x)) - J_{x+1}(\nu_k(x))}{2}J_{-x}(\nu_k(x)) + J_x(\nu_k(x))\frac{\mathrm{d}}{\mathrm{d}\nu}(J_{-x}(\nu_k(x)))$$

$$= \frac{J_{x-1}(\nu_k(x)) - J_{x+1}(\nu_k(x))}{2}J_{-x}(\nu_k(x)) + 0.$$

If $\nu_k(x) \neq 0$, then the Bessel function addition formula shows that $J_{x+1}(\nu_k(x)) = -J_{x-1}(\nu_k(x))$. Since the only x values for which we may have $\nu_k(x) = 0$ are the negative integers (Ref. 5, p. 510), the initial assumption that $x \notin \{-1, -2, \ldots\}$ satisfies this condition. Therefore we obtain

$$\frac{\mathrm{d}}{\mathrm{d}\nu}(J_x(\nu_k(x))J_{-x}(\nu_k(x))) = J_{x-1}(\nu_k(x))J_{-x}(\nu_k(x)).$$

The Wronskian relation shows that

$$J_{x-1}(\nu_k(x))J_{-x}(\nu_k(x)) = \frac{2\sin(\pi x)}{\pi\nu_k(x)},$$

which allows us to evaluate $(\mathrm{d}/\mathrm{d}\nu)(J_x(\nu_k(x))J_{-x}(\nu_k(x)))$ in a simple form,

$$\frac{\mathrm{d}}{\mathrm{d}\nu}(J_x(\nu_k(x))J_{-x}(\nu_k(x))) = \frac{2\sin(\pi x)}{\pi\nu_k(x)}.$$

Substituting this final result into Eq. (3.3) completes the proof. ■

For more technical results about the zeros of Bessel functions, Muldoon's paper[3] provides an excellent list of references.

IV. THE TAYLOR SERIES FOR $\nu_k(x)$ AT THE HALF-INTEGERS

In this section we will give a recursive formula for computing the derivatives of $\nu_k(x)$ at the half-integers. The resulting Taylor series converge relatively slowly, however the form that we give for the coefficients is very interesting. We show that the Taylor coefficients can always be expressed in terms of polynomials of entire functions. The entire functions in question are defined by summations of reciprocal powers of integers, with squares of Bessel functions in the numerators.

Definition 4.1: Let k be an integer, and define $\beta_k(y)$ and $d_k(y)$ by

$$\beta_k(y) = \sum_{n=-\infty}^{\infty} \frac{J_n^2(y)}{(2n+1)^k},$$

$$d_k(y) = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(y)}{(2n+1)^k}.$$

Also define the more general function

$$\beta_k^{(a,b)}(y) = \sum_{n=-\infty}^{\infty} \frac{J_{n+a}(y)J_{n+b}(y)}{(2n+1)^k}.$$

Proposition 4.2: The functions $\beta_k(y)$ and $d_k(y)$ have the following elementary properties:

$$\beta_0(y) = 1, \tag{4.1}$$

$$\beta_1(y) = \frac{\sin(2y)}{2y}, \tag{4.2}$$

$$\beta_2(y) = \frac{1}{2y}\int_0^{2y} \frac{\sin(z)}{z} dz, \tag{4.3}$$

$$d_{2k}(y) = 0 \quad \text{if } k \geqslant 0 \text{ is an integer}, \tag{4.4}$$

$$d_1(y) = \frac{1-\cos(2y)}{2y}. \tag{4.5}$$

Since (4.5) will be used later, we note that it follows from (2.4).

As a simple corollary to Proposition 4.2 we can obtain formulas for $1/\pi$. Here are two examples,

$$\frac{1}{\pi} = \frac{1}{2}\sum_{n=-\infty}^{\infty} \frac{J_n^2\left(\frac{\pi}{4}\right)}{2n+1}, \tag{4.6}$$

$$\frac{1}{\pi} = \frac{4}{9}\sum_{n=-\infty}^{\infty} \frac{J_n\left(\frac{\pi}{3}\right)J_{n+1}\left(\frac{\pi}{3}\right)}{2n+1}. \tag{4.7}$$

Proposition 4.3: Let $k \geqslant 1$ be an integer, then $\beta_k^{(a,b)}(y)$ has the following elementary properties for every pair $(a,b) \in \mathbf{Z}^2$:

$$\beta_k^{(a,b)}(y) = \frac{1}{y}\beta_{k-1}^{(a-1,b)}(y) + \frac{2a-3}{y}\beta_k^{(a-1,b)}(y) - \beta_k^{(a-2,b)}(y), \tag{4.8}$$

$$\beta_k^{(a,b)}(y) = \beta_k^{(b,a)}(y), \tag{4.9}$$

$$\beta_0^{(a,b)}(y) = \begin{cases} 1 & \text{if } a = b, \\ 0 & \text{if } a \neq b, \end{cases} \tag{4.10}$$

$$\beta_k^{(0,0)}(y) = \beta_k(y), \tag{4.11}$$

$$\beta_k^{(0,1)}(y) = d_k(y), \tag{4.12}$$

$$\beta_k^{(1,1)}(y) = (-1)^k \beta_k(y). \tag{4.13}$$

Proposition 4.3 establishes linear dependencies between $\beta_k^{(a,b)}(y)$, $\beta_k(y)$, and $d_k(y)$ for all $(a,b) \in \mathbf{Z}^2$. To express $\beta_k^{(a,b)}(y)$ in terms of $d_m(y)$'s and $\beta_m(y)$'s, use the recursion formula (4.8) while applying formula (4.10) as many times as necessary. For example, we can show that

$$\beta_k^{(-1,-1)}(y) = \left(\frac{1}{y^2} + (-1)^k\right)\beta_k(y) - \frac{2}{y^2}\beta_{k-1}(y) + \frac{1}{y^2}\beta_{k-2}(y) - \frac{2}{y}d_{k-1}(y) + \frac{2}{y}d_k(y). \tag{4.14}$$

The next proposition shows that $d_k(y)$ can always be written as a polynomial in $\beta_m(y)$'s for $m \leqslant k$, and the elementary functions. As a result we can always express $\beta_k^{(a,b)}(y)$ as a polynomial in $\beta_2(y), \beta_3(y), \ldots, \beta_k(y)$, and elementary functions.

Proposition 4.4: We can calculate $d_{2n+1}(y)$ recursively using the following formula:

$$\frac{\cos(2y)}{y}d_{2n+1}(y)=\sum_{k=1}^{2n-1}d_{k+1}(y)d_{2n+1-k}(y)+\sum_{k=0}^{2n}(-1)^k\beta_{k+1}(y)\beta_{2n+1-k}(y). \tag{4.15}$$

Proof: We will use Eq. (2.7) to prove this result. First observe that a slight rearrangement of (2.7) yields

$$\left(\sum_{n=-\infty}^{\infty}\frac{J_n^2(y)}{n+x}\right)\left(\sum_{n=-\infty}^{\infty}\frac{J_n^2(y)}{n+1-x}\right)=\frac{1}{y^2}-\left(\frac{1}{y}-\sum_{n=-\infty}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}\right)^2. \tag{4.16}$$

If $|x-\frac{1}{2}|<\frac{1}{2}$, then we can expand each infinite series about $x=1/2$ to obtain

$$\sum_{n=-\infty}^{\infty}\frac{J_n^2(y)}{n+x}=\sum_{k=0}^{\infty}(-1)^k2^{k+1}\beta_{k+1}(y)(x-1/2)^k,$$

$$\sum_{n=-\infty}^{\infty}\frac{J_n^2(y)}{n+1-x}=\sum_{k=0}^{\infty}2^{k+1}\beta_{k+1}(y)(x-1/2)^k,$$

$$\sum_{n=-\infty}^{\infty}\frac{J_n(y)J_{n+1}(y)}{n+x}=\sum_{k=0}^{\infty}2^{2k+1}d_{2k+1}(y)(x-1/2)^{2k}.$$

Substituting these formulas into (4.16), then collecting the series coefficients on each side of the equality proves Eq. (4.15). ■

Applying Proposition 4.4 yields the following evaluations of $d_3(y)$ and $d_5(y)$:

$$d_3(y)=\tan(2y)\beta_3(y)-\frac{y}{\cos(2y)}\beta_2^2(y), \tag{4.17}$$

$$d_5(y)=\tan(2y)\beta_5(y)-\frac{2y}{\cos(2y)}\beta_4(y)\beta_2(y)+\frac{y}{\cos^3(2y)}\beta_3^2(y)-2y^2\frac{\sin(2y)}{\cos^3(2y)}\beta_3(y)\beta_2^2(y)$$
$$+\frac{y^3}{\cos^3(2y)}\beta_2^4(y). \tag{4.18}$$

Now that we have shown how to write $d_k(y)$ and $\beta_k^{(a,b)}(y)$ in terms of $\beta_k(y)$, it is necessary to justify the claim that all of these functions are entire. Considering the fact that formula (4.17) contains multiple terms involving $1/\cos(2y)$, this claim is not obvious.

Theorem 4.5: *The functions $\beta_k(y)$, $d_k(y)$, and $\beta_k^{(a,b)}(y)$ are entire functions for all $k\geqslant 0$, and for all $(a,b)\in\mathbf{Z}^2$.*

Proof: Let $E_k(y)$ denote the kth Euler polynomial. Recall that $E_k(y)$ is a kth degree polynomial with generating function

$$\frac{2e^{yt}}{e^t+1}=\sum_{k=0}^{\infty}E_k(y)\frac{t^k}{k!}.$$

Then for all $k\geqslant 0$, and for all $(a,b)\in\mathbf{Z}^2$, we have the following representation of $\beta_{k+1}^{(a,b)}(y)$:

$$\beta_{k+1}^{(a,b)}(y)=(-1)^a\frac{\pi^k}{k!}\int_0^{\pi/2}\cos\left((a+b-1)z+\frac{\pi k}{2}\right)J_{b-a}(2y\cos z)E_k\left(\frac{1}{2}+\frac{z}{\pi}\right)dz. \tag{4.19}$$

Equation (4.19) expresses $\beta_k^{(a,b)}(y)$ as a finite integral of entire functions, so we conclude that $\beta_k^{(a,b)}(y)$ is entire for all $k \geqslant 1$ and for all $(a,b) \in \mathbf{Z}^2$. The $k=0$ case is clear from Eq. (4.10). This also proves that $\beta_k(y)$ and $d_k(y)$ are entire, since they are just special cases of $\beta_k^{(a,b)}(y)$. Recall that $\beta_k(y) = \beta_k^{(0,0)}(y)$ and $d_k(y) = \beta_k^{(0,1)}(y)$.

The proof of Eq. (4.19) is an exercise that we will leave to the reader. ■

The next proposition shows that $(d/dy)\beta_k(y)$ and $(d/dy)d_k(y)$ are just linear combinations of $d_k(y)$, $\beta_k(y)$, and $\beta_{k-1}(y)$ (with coefficients involving y and $1/y$). While Proposition 4.4 allows us to eliminate the notation $d_k(y)$, the convenience of working with linear differential equations justifies its continued use.

Proposition 4.6: The derivatives of $\beta_k(y)$ and $d_k(y)$ are related as follows:

$$\frac{\mathrm{d}}{\mathrm{d}y}(y\beta_k(y)) = \beta_{k-1}(y) - (1-(-1)^k)yd_k(y),$$

$$\frac{\mathrm{d}}{\mathrm{d}y}(yd_k(y)) = (1-(-1)^k)y\beta_k(y). \tag{4.20}$$

Proposition 4.6 allows us to reformulate our study of $\beta_k(y)$ and $d_k(y)$ from a differential equations perspective. By substituting the appropriate formulas for $d_k(y)$ into Eq. (4.20), we can express derivatives of $y\beta_k(y)$ as polynomials in $\beta_2(y), \beta_3(y), \ldots, \beta_k(y)$ and the elementary functions. For example, if we plug (4.17) into (4.20) we find

$$\frac{\mathrm{d}}{\mathrm{d}y}(y\beta_3(y)) = \beta_2(y) - 2\tan(2y)y\beta_3(y) + 2\sec(2y)(y\beta_2(y))^2. \tag{4.21}$$

Solving this resulting system of nonlinear differential equations will naturally lead to some very complicated integrals. To solve Eq. (4.21) for $\beta_3(y)$, multiply each side by $\sec(2y)$ and collect the terms involving $\beta_3(y)$ to get

$$\frac{\mathrm{d}}{\mathrm{d}y}\left(\frac{y\beta_3(y)}{\cos(2y)}\right) = \frac{\beta_2(y)}{\cos(2y)} + 2\left(\frac{y\beta_2(y)}{\cos(2y)}\right)^2. \tag{4.22}$$

Now integrate each side from 0 to y, restricting $|y| < \pi/4$ to avoid the poles of $\sec(2y)$. Therefore if $|y| < \pi/4$,

$$\beta_3(y) = \frac{\cos(2y)}{y}\int_0^y \frac{\beta_2(u)}{\cos(2u)} + 2\left(\frac{u\beta_2(u)}{\cos(2u)}\right)^2 \mathrm{d}u. \tag{4.23}$$

It might be of some interest to try to generalize the system of linear differential equations presented in (4.20). For example, can we perturb the coefficients, but still find a reduction to a first order system of equations? It appears (after some effort) that the equations in (4.20), combined with the initial conditions $\{\beta_0(y)=1, d_0(y)=0, \beta_k(0)=1, d_k(0)=0\}$ are not easily generalized.

Next we will establish a recursive formula for generating the Taylor series coefficients of $\nu_k(x)$ about $x = r+1/2$ where $r \in \mathbf{Z}$.

Theorem 4.7: *Let r be any integer, then we may compute the Taylor series for $\nu_k(x)$ about $x=r+1/2$. The derivatives of $\nu_k(x)$ can be computed recursively using*

$$\nu_k^{(n+1)}(r+1/2) = \sum_{m=0}^{n} 2^{m+1}(m+1)!\binom{n}{m}\frac{\mathrm{d}^{n-m}}{\mathrm{d}x^{n-m}}\left[\nu_k(x)\beta_{m+2}^{(r+1,r+1)}(\nu_k(x))\right]_{x=r+1/2}.$$

Since $J_{r+1/2}(y)$ can always be written in terms of elementary functions, $\nu_k(r+1/2)$ is always the root of an elementary function. The selection of k determines which zero of $J_x(y)$ that $\nu_k(x)$ will pass through.

TABLE I. Table of the first five positive zeros of $J_0(y)$. The approximations were calculated using Eq. (4.24).

Zero number	Exact zero	Approximate zero
1	2.4048…	2.4094…
2	5.5200…	5.5217…
3	8.6537…	8.6545…
4	11.7915…	11.7919…
5	14.9309…	14.9312…

To compute the Taylor series for $\nu_k(x)$ about $x=1/2$, apply Theorem 4.7 with $r=0$. Since $J_{1/2}(y)=(2/\pi y)^{\frac{1}{2}}\sin(y)$, the kth zero of $J_{1/2}(y)$ to the right-hand side of $x=1/2$ is just πk, therefore $\nu_k(1/2)=\pi k$. Computing the first few terms in our series, we get

$$\nu_k(x)=\pi k+2\pi k\beta_2(\pi k)(x-1/2)-8\pi k\beta_3(\pi k)\frac{(x-1/2)^2}{2!}+(48\pi k\beta_4(\pi k)-64\pi^3k^3\beta_2^3(\pi k)$$
$$-24\pi k\beta_2^2(\pi k))\frac{(x-1/2)^3}{3!}+\cdots. \tag{4.24}$$

Since $\nu_k(x)$ is not analytic at $x=-1$, Eq. (4.24) converges for $-1<x<2$. We can approximate the first few zeros of $J_0(y)$ using (4.24). As Table I illustrates, this series converges very slowly.

We will pose three open problems to conclude this section.

Open question 1: It is easy to see that if $m\geqslant 0$ is an integer, then $\nu_k^{(m)}(1/2)$ is a polynomial in the elements $\pi k,\beta_2(\pi k),\beta_3(\pi k),\ldots,\beta_{m+1}(\pi k)$. Thus $\nu_k^{(m)}(1/2)$ can be expressed as a polynomial in πk and the derivatives of $J_x(\pi k)J_{-x}(\pi k)[\pi/\sin(\pi x)]$ at $x=1/2$. Based on this evidence, we might conjecture the existence of a "nice" function $f(x,y,z)$, such that

$$\nu_k(x)=f\left(x,\pi k,\frac{\pi}{\sin(\pi x)}J_x(\pi k)J_{-x}(\pi k)\right). \tag{4.25}$$

It would be highly desirable to prove the existence of such a function, as it would give an exact solution of $J_x(y)=0$.

Open question 2: Are the elements of the set $\{y,\cos(2y),\beta_2(y),\beta_3(y),\ldots\}$ algebraically independent? For example, can $\beta_3(y)$ be expressed in terms of $\beta_2(y)$ and trigonometric functions?

This is not a trivial question. Using Eq. (4.17) we easily see that if $n\geqslant 0$ is an integer,

$$\beta_3\left((2n+1)\frac{\pi}{4}\right)=(-1)^n(2n+1)\frac{\pi}{4}\beta_2^2\left((2n+1)\frac{\pi}{4}\right). \tag{4.26}$$

This shows that $\beta_3(y)$ can be expressed in terms of $\beta_2(y)$ at certain discrete points. Whether or not this indicates more general algebraic relations remains unanswered.

Open question 3: Is it possible to simplify the recurrence relation given in Theorem 4.7? In other words, can we generate $\nu_k^{(m)}(1/2)$ in a way that does not involve taking derivatives?

V. THE TAYLOR SERIES FOR $\nu_k(x)$ AT THE INTEGERS

In general, calculating the Taylor series for $\nu_k(x)$ at the integers is far more challenging than computing the Taylor series at the half-integers. Recall that $\nu_k(x)$ is discontinuous when $x\in\{-1,-2,\}$, so it only makes sense to calculate a Taylor series for $x\in\{0,1,2,\ldots\}$. The main difficulty lies in the fact that

$$\nu_k'(x) = \frac{\nu_k(x)}{2} \sum_{n=-\infty}^{\infty} \frac{J_n^2(\nu_k(x))}{(n+x)^2}$$

has removable singularities at $x=0,1,2,\ldots$. This gives rise to polynomial rather than linear relationships between derivatives of $\nu_k(x)$. To illustrate this point, we will calculate the first Taylor polynomial of $\nu_k(x)$ at zero.

Proposition 5.1: The first Taylor polynomial of $\nu_k(x)$ at zero is given by

$$\nu_k(x) = \nu_k(0) + \frac{x}{2\nu_k(0)J_1^2(\nu_k(0))} + O(x^2). \tag{5.1}$$

Proof: We simply need to show that $\nu_k'(0)$ has the correct form, and consequently Eq. (5.1) really is the first Taylor polynomial of $\nu_k(x)$ at zero.

Applying Proposition 3.2, we obtain the following relation for $\nu_k'(0)$:

$$\frac{\nu_k'(0)}{\nu_k(0)} = \frac{1}{2}\lim_{x\to 0}\left(\frac{J_0^2(\nu_k(x))}{x^2}\right) + \frac{1}{2}\sum_{\substack{n=-\infty \\ n\neq 0}}^{\infty} \frac{J_n^2(\nu_k(0))}{n^2} = \frac{1}{2}J_1^2(\nu_k(0))(\nu_k'(0))^2 + \sum_{n=1}^{\infty} \frac{J_n^2(\nu_k(0))}{n^2}.$$

We will use Eq. (5.4) to simplify this expression. By letting $y \to \nu_k(0)$ in (5.4), we can show that

$$\sum_{n=1}^{\infty} \frac{J_n^2(\nu_k(0))}{n^2} = \frac{1}{2\nu_k^2(0)J_1^2(\nu_k(0))}. \tag{5.2}$$

Eliminating this infinite series and solving the resulting quadratic equation for $\nu_k'(0)$, we arrive at the simple formula

$$\nu_k'(0) = \frac{1}{2\nu_k(0)J_1^2(\nu_k(0))}. \tag{5.3}$$

The fact that we can use Eq. (5.2) to prove such a simple expression for $\nu_k'(0)$ is a minor miracle. The fact that we must solve a quadratic equation for $\nu_k'(0)$ illustrates why we should not expect to find a simple recursive formula like that in Theorem 4.7 to compute $\nu_k^{(m)}(0)$. ■

When we are computing higher derivatives of $\nu_k(x)$ at integer points, we will encounter the following three functions:

$$\mu_k(y) = \sum_{n=1}^{\infty} \frac{J_n^2(y)}{n^k},$$

$$\eta_k(y) = \sum_{n=1}^{\infty} \frac{J_{n+1}^2(y)}{n^k},$$

$$\rho_k(y) = \sum_{n=1}^{\infty} \frac{J_n(y)J_{n+1}(y)}{n^k}.$$

In Proposition 4.4 we showed that $d_k(y)$ is expressible in terms of $\beta_j(y)$'s and the elementary functions. Unfortunately such strong relationships are probably not possible between $\mu_k(y)$, $\eta_k(y)$, and $\rho_k(y)$. The strongest relationships that we have found allow us to eliminate $\rho_k(y)$ if k is even. It is not too difficult to show that

$$\rho_2(y) = -\frac{(J_0^2(y)-1)^2}{4y^2J_0(y)J_1(y)} + \frac{\mu_1(y)}{y} - \frac{J_0(y)}{J_1(y)}\frac{\rho_1(y)}{y} + \frac{1}{2}\frac{J_1(y)}{J_0(y)}\mu_2(y) + \frac{1}{2}\frac{J_0(y)}{J_1(y)}\eta_2(y). \tag{5.4}$$

Equation (5.4) was critical in our computation of the first Taylor polynomial of $\nu_k(x)$ at $x=0$. We will state the more general case in the next proposition.

Proposition 5.2: Define a_n, b_n, and c_n *as follows:*

$$a_n = \begin{cases} J_0(y)J_1(y) & \text{if } n=-1, \\ -\dfrac{J_0^2(y)}{y} & \text{if } n=0, \\ \dfrac{2}{y}\mu_n(y) - (1-(-1)^n)\rho_{n+1}(y) & \text{if } n \geqslant 1, \end{cases}$$

$$b_n = \begin{cases} J_0^2(y) & \text{if } n=-1, \\ -(1-(-1)^n)\mu_{n+1}(y) & \text{if } n \geqslant 0, \end{cases}$$

$$c_n = \begin{cases} -J_1^2(y) & \text{if } n=-1, \\ \dfrac{2}{y}J_0(y)J_1(y) & \text{if } n=0, \\ (1-(-1)^n)\eta_{n+1}(y) + \dfrac{4}{y^2}\mu_{n-1}(y) - \dfrac{4}{y}\rho_n(y) & \text{if } n \geqslant 1. \end{cases}$$

Then for $n=0,1,2\ldots$,

$$\sum_{k=-1}^{n+1} c_k b_{n-k} = \frac{\delta_{n0}}{y^2} - \sum_{k=-1}^{n+1} a_k a_{n-k}, \tag{5.5}$$

where

$$\delta_{n0} = \begin{cases} 1 & \text{if } n=0, \\ 0 & \text{otherwise}. \end{cases}$$

If n is odd, then Eq. (5.5) is trivial. When n is even, we obtain nontrivial relationships between $\eta_j(y)$*'s,* $\rho_j(y)$*'s, and* $\mu_j(y)$*'s. The case where* $n=0$ *yields Eq. (5.4).*

If we let $n=2$, Eq. (5.5) yields the complicated formula

$$\begin{aligned} 0 = {} & \frac{2}{y^2}\mu_1^2(y) - 2\left(\frac{1-J_0^2(y)}{y^2}\right)\mu_2(y) + 2\frac{J_0(y)J_1(y)}{y}\mu_3(y) + J_1^2(y)\mu_4(y) - 2\mu_2(y)\eta_2(y) + J_0^2(y)\eta_4(y) \\ & + \frac{4}{y}\mu_2(y)\rho_1(y) - \frac{4}{y}\mu_1(y)\rho_2(y) + 2\rho_2^2(y) - 2\frac{J_0^2(y)}{y}\rho_3(y) - 2J_0(y)J_1(y)\rho_4(y). \end{aligned} \tag{5.6}$$

To conclude this section, we will list a couple of interesting open questions about $\mu_k(y)$, $\eta_k(y)$, and $\rho_k(y)$.

Open question 4: Is it possible to find explicit expressions for $\mu_1(y)$, $\eta_1(y)$, and $\rho_1(y)$ in terms of known functions? It seems likely that these functions are somehow related to Bessel functions of the first and second kinds. Formulas similar to Eq. (4.2) and (4.5) would be desirable.

Open question 5: Do more nontrivial algebraic relations exist between $\mu_k(y)$, $\eta_k(y)$, and $\rho_k(y)$? This question is probably very hard, given the difficulty of working with these particular functions.

VI. A CONNECTION TO THE RIEMANN ZETA FUNCTION, AND FURTHER REMARKS ABOUT SERIES OF SQUARES OF BESSEL FUNCTIONS

The functions that we have considered so far, $\{\beta_k(y), d_k(y), \beta_k^{(a,b)}(y), \mu_k(y), \eta_k(y), \rho_k(y)\}$, are particularly nice. Besides their various algebraic relations and differentiation formulas, they are sums over products of Bessel functions of integer order. As a result, integrals like

$$\frac{1}{2} = \int_0^\infty J_n(y)J_{n+1}(y)\mathrm{d}y \quad \text{if } n \in \mathbf{Z} \text{ and } n \geqslant 0, \tag{6.1}$$

naturally connect them to the Riemann zeta function (Ref. 1, p. 1102).

Applying formula (6.1) to $d_k(y)$, it is easy to see that for $k=1,2,3,\ldots$,

$$\left(1 - \frac{1}{2^{2k+1}}\right)\zeta(2k+1) = \int_0^\infty d_{2k+1}(y)\mathrm{d}y. \tag{6.2}$$

Setting $k=1$ gives the following integral for $\zeta(3)$:

$$\frac{7}{8}\zeta(3) = \int_0^\infty d_3(y)\mathrm{d}y = \int_0^\infty (\tan(2y)\beta_3(y) - y\sec(2y)\beta_2^2(y))\mathrm{d}y.$$

A simple integration by parts generates another nontrivial integral for $\zeta(3)$. In general we can use the algebraic relations between our functions to find many complicated integrals for π and the odd values of the Riemann zeta function. Perhaps additional knowledge about the $\beta_k(y)$'s will yield some useful information about $\zeta(3), \zeta(5), \ldots$ (unfortunately this is probably too much to hope for).

Since the entire paper (up to this point) discusses functions defined by infinite series of squares of Bessel functions, we pose the following general question: What functions can be expressed in such a form?

As an example, we evaluated $\beta_2(y)$ in terms of the sine integral in formula (4.3). This expansion converges rapidly, and provides an example of a useful special function expressible by a series of squares of Bessel functions. We can also derive a similar expression for the cosine integral,

$$\int_0^{2y} \frac{1-\cos(z)}{z}\mathrm{d}z = 4\sum_{n=1}^{\infty} J_n^2(y)\sum_{k=0}^{n-1}\frac{1}{2k+1}. \tag{6.3}$$

Proof: We can prove (6.3) by showing that the derivatives of each side of the equation are equal, and by showing that the equation holds when $y=0$.

It is trivial to show that (6.3) holds when $y=0$, since both sides of the equation vanish. Therefore we just have to show that

$$\frac{1-\cos(2y)}{y} = 4\frac{d}{\mathrm{d}y}\left(\sum_{n=1}^{\infty} J_n^2(y)\sum_{k=0}^{n-1}\frac{1}{2k+1}\right).$$

Observe that this sum converges uniformly whenever $y \in \mathbf{R}$, so we may interchange summation and differentiation. Therefore if $y \in \mathbf{R}$,

$$\begin{aligned} 4\frac{d}{\mathrm{d}y}\left(\sum_{n=1}^{\infty} J_n^2(y)\sum_{k=0}^{n-1}\frac{1}{2k+1}\right) &= 4\sum_{n=1}^{\infty}\frac{d}{\mathrm{d}y}(J_n^2(y))\sum_{k=0}^{n-1}\frac{1}{2k+1} \\ &= 4\sum_{n=1}^{\infty}(J_{n-1}(y)J_n(y) - J_n(y)J_{n+1}(y))\sum_{k=0}^{n-1}\frac{1}{2k+1}. \end{aligned}$$

Now break the sum into two pieces, and combine the two pieces so that the inner sums telescope,

$$
\begin{aligned}
&= 4\sum_{n=1}^{\infty} J_{n-1}(y)J_n(y)\sum_{k=0}^{n-1}\frac{1}{2k+1} - 4\sum_{n=1}^{\infty} J_n(y)J_{n+1}(y)\sum_{k=0}^{n-1}\frac{1}{2k+1} \\
&= 4\sum_{n=0}^{\infty} J_n(y)J_{n+1}(y)\sum_{k=0}^{n}\frac{1}{2k+1} - 4\sum_{n=1}^{\infty} J_n(y)J_{n+1}(y)\sum_{k=0}^{n-1}\frac{1}{2k+1} \\
&= 4\sum_{n=0}^{\infty} J_n(y)J_{n+1}(y)\left(\sum_{k=0}^{n}\frac{1}{2k+1} - \sum_{k=0}^{n-1}\frac{1}{2k+1}\right) = 4\sum_{n=0}^{\infty}\frac{J_n(y)J_{n+1}(y)}{2n+1}.
\end{aligned}
$$

Using the fact that $J_{-n}(y) = (-1)^n J_n(y)$ [as in the proof of Eq. (2.4)], this becomes

$$
2\sum_{n=-\infty}^{\infty}\frac{J_n(y)J_{n+1}(y)}{2n+1} = \frac{1-\cos(2y)}{y}
$$

by Eq. (4.5). ■

In the next theorem we state Gegenbauer's result from the 1870s, namely that any even function with a Taylor series at zero can be written as a sum of squares of Bessel functions (Ref. 5, p. 525). The form that we give for this theorem is slightly different from Watson's statement, but is sufficient for our purposes.

Theorem 6.1: *(Gegenbauer) Suppose that $f(z)$ is an even function that is analytic at zero, or equivalently suppose that $f(z)$ is even and has a Taylor series at zero. Let*

$$
f(z) = \sum_{n=0}^{\infty}\frac{f^{(2n)}(0)}{(2n)!}z^{2n}.
$$

Then the following representation holds for $f(z)$:

$$
f(z) = \sum_{n=0}^{\infty} a_n J_n^2(z),
$$

where a_n is given by

$$
a_n = \begin{cases} f(0) & \text{if } n = 0, \\ 2n\displaystyle\sum_{k=0}^{n}\frac{\binom{n+k}{2k}}{n+k}\frac{2^{2k}}{\binom{2k}{k}}f^{(2k)}(0) & \text{if } n \geqslant 1. \end{cases}
$$

This formula relating a_n and $f^{(2n)}(0)$ can be inverted to give

$$
f^{(2n)}(0) = \frac{(-1)^n}{2^{2n}}\binom{2n}{n}\sum_{k=0}^{n}(-1)^k a_k\binom{2n}{n+k}.
$$

If we apply Theorem 6.1 to appropriately chosen hypergeometric functions, we can obtain a variety of "nice" series of squares of Bessel functions. Examples include

$$
\sum_{n=0}^{\infty}(-1)^n\frac{(2n)!}{n!^3}\frac{\left(\frac{y}{2}\right)^{2n}}{(x)_n} = J_0^2(y) + 2\sum_{n=1}^{\infty}(-1)^n\frac{(1-x)_n}{(x)_n}J_n^2(y), \tag{6.4}
$$

$$\sum_{n=0}^{\infty}(-1)^n\binom{2n}{n}\binom{2n-x}{n-x}\frac{\left(\frac{y}{2}\right)^{2n}}{(2n)!}=\sum_{n=0}^{\infty}\frac{(x)_n}{n!}J_n^2(y), \tag{6.5}$$

where $(x)_n=x(x+1)\cdots(x+n-1)$.

Open question 6: An interesting question associated with Theorem 6.1 is to find a "nice" expression for the Taylor series coefficients of $\mu_k(y)$ when k is an odd integer. It is easy to show that the Taylor series coefficients of $\beta_k(y)$, $d_k(y)$, and $\mu_{2k}(y)$ can always be expressed in terms of harmonic numbers. If we let

$$\lambda_n^{(j)}=\sum_{m=0}^{n}\frac{1}{(2m+1)^j},\quad H_n^{(j)}=\sum_{m=1}^{n}\frac{1}{m^j},$$

then we can obtain series expansions including

$$\beta_3(y)=\sum_{n=0}^{\infty}(-1)^n\lambda_n^{(2)}\frac{(2y)^{2n}}{(2n+1)!}, \tag{6.6}$$

$$\mu_4(y)=\sum_{n=1}^{\infty}(-1)^{n+1}\left(\frac{H_n^{(4)}+(H_n^{(2)})^2}{4}\right)\binom{2n}{n}\frac{\left(\frac{y}{2}\right)^{2n}}{n!^2}, \tag{6.7}$$

$$d_5(y)=\sum_{n=0}^{\infty}(-1)^n\left(\frac{\lambda_n^{(4)}+(\lambda_n^{(2)})^2}{2}\right)\frac{(2y)^{2n}}{(2n+2)!}. \tag{6.8}$$

A simple application of Theorem 6.1 shows that trying to find nice Taylor series coefficients for $\{\mu_3(y),\mu_5(y),\ldots\}$ is equivalent to reducing

$$r_n^{(j)}=\sum_{m=1}^{n}\frac{(-1)^{m+1}}{m^j}\binom{2n}{n+m},$$

into "some nice form" when $j>1$ is an odd integer.

In the case of $\mu_1(y)$, we can show that if A_n is the alternating harmonic series,

$$A_n=\sum_{k=1}^{n}\frac{(-1)^{k+1}}{k},$$

then we must have

$$\mu_1(y)=\sum_{n=1}^{\infty}(-1)^{n+1}A_{2n}\binom{2n}{n}\frac{\left(\frac{y}{2}\right)^{2n}}{n!^2}. \tag{6.9}$$

Generalizing this result has proven surprisingly difficult.

VII. MORE REPRESENTATIONS OF $\beta_k(y)$ AND $d_k(y)$ IN TERMS OF INFINITE SERIES

The functions $\beta_k(y)$ and $d_k(y)$ possess many representations in terms of infinite integrals and infinite series. Since $\beta_k(y)$ and $d_k(y)$ are just the derivatives with respect to order of products of Bessel functions, every one of the legions of representations for Bessel functions will yield formulas for $\beta_k(y)$ and $d_k(y)$. In this section we will present a few of the most visually appealing and useful formulas that we have encountered.

Our first formula expresses $d_k(y)$ in terms of sums running over the Bessel functions of half-integer order. This is noteworthy since the Bessel functions of half-integer order reduce to polynomials in $1/\pi$ whenever $y \to \pi k$.

Let $\alpha_n(y)$ be defined by

$$\alpha_n(y) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k^n} J_{1/2+k}(y) J_{1/2-k}(y), \tag{7.1}$$

and let B_j denote the Bernoulli numbers (Ref. 1, p. 1107). Then for $n \geqslant 1$,

$$d_{2n-1}(y) = \frac{4(4^n-1)}{(2n)!}|B_{2n}|\pi^{2n-2}\frac{\sin^2(y)}{y} + \frac{1}{4^{n-1}}\sum_{j=1}^{n-1}\frac{4^j(4^j-1)}{(2j)!}|B_{2j}|\pi^{2j-1}\alpha_{2n-2j}(y). \tag{7.2}$$

Equation (7.2) yields the following relation when $n=2$:

$$d_3(y) = \frac{\pi^2}{12}\frac{\sin^2(y)}{y} + \frac{\pi}{4}\alpha_2(y). \tag{7.3}$$

A second family of formulas can be obtained from Eqs. (2.9) and (2.10). We can decompose $\beta_k(y)$ and $d_k(y)$ in terms of two sets of functions defined by a modified Neumann series. Define $g_k(y)$ and $h_k(y)$ by

$$g_k(y) = \sum_{n=0}^{\infty} \frac{J_n(y)\left(\frac{y}{2}\right)^n}{n!(2n+1)^k}, \tag{7.4}$$

$$h_k(y) = \sum_{n=0}^{\infty} \frac{J_{n+1}(y)\left(\frac{y}{2}\right)^n}{n!(2n+1)^k}. \tag{7.5}$$

It is easy to see from Eq. (2.2) that $g_k(y)$ and $h_k(y)$ can be written compactly as

$$g_k(y) = \frac{(-1)^{k-1}}{2^k(k-1)!}\frac{\mathrm{d}^{k-1}}{\mathrm{d}x^{k-1}}\left[\left(\frac{2}{y}\right)^x \Gamma(x)J_x(y)\right]_{x=1/2} \quad \text{if } k \geqslant 1, \tag{7.6}$$

$$h_k(y) = \frac{-1}{2^k(k-1)!}\frac{\mathrm{d}^{k-1}}{\mathrm{d}x^{k-1}}\left[\left(\frac{2}{y}\right)^{1-x} \Gamma(1-x)J_{-x}(y)\right]_{x=1/2} \quad \text{if } k \geqslant 2. \tag{7.7}$$

We can prove the following formulas for $\beta_k(y)$ and $d_k(y)$:

$$d_{2n+1}(y) = 2h_{2n+1}(y) - y\sum_{m=0}^{2n}(-1)^m h_{m+1}(y)h_{2n+1-m}(y), \tag{7.8}$$

$$d_{2n+1}(y) = y\sum_{m=0}^{2n}(-1)^m g_{m+1}(y)g_{2n+1-m}(y), \tag{7.9}$$

$$\beta_n(y) = g_n(y) - y\sum_{m=0}^{n}(-1)^m h_{m+1}(y)g_{n-m}(y). \tag{7.10}$$

By combining these three formulas we can find a wide variety of relations between $\beta_k(y)$, $d_k(y)$, $h_k(y)$, and $g_k(y)$. We will use the following elementary evaluations of $g_0(y)$, $g_1(y)$, $h_0(y)$, and $h_1(y)$,

$$g_0(y) = 1, \quad g_1(y) = \frac{\sin(y)}{y}, \tag{7.11}$$

$$h_0(y) = \frac{y}{2}, \quad h_1(y) = \frac{1 - \cos(y)}{y}. \tag{7.12}$$

Examples of identities include

$$h_2(y)\sin(y) + g_2(y)\cos(y) = \beta_2(y), \tag{7.13}$$

$$h_3(y)\sin(y) + g_3(y)\cos(y) = \frac{1}{\sin(2y)}(d_3(y) + 2y\cos(y)g_2(y)\beta_2(y) - y\beta_2^2(y)), \tag{7.14}$$

$$h_4(y)\sin(y) + g_4(y)\cos(y) = \beta_4(y) + y(g_2(y)h_3(y) - h_2(y)g_3(y)). \tag{7.15}$$

Unfortunately, it seems to be impossible to express $g_k(y)$ or $h_k(y)$ only in terms of $\beta_k(y)$'s. This is not especially surprising, since we would not intuitively expect to find strong relationships between the derivatives of $J_x(y)$ and the derivatives of $J_x(y)J_{-x}(y)$. Interestingly enough however, it may be possible to express $g_k(y)$ in terms of $\beta_k(y)$'s at certain arguments. An example follows easily from Eq. (7.13),

$$g_2(\pi k) = (-1)^k \beta_2(\pi k) \quad \text{for } k \in \mathbf{Z}. \tag{7.16}$$

A third class of identities can be derived from Eqs. (2.12) and (2.13). While we have not explored this avenue in depth, we have derived a few noteworthy formulas. If we let

$$F_k(y,z) = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_n(z)}{(2n+1)^k}\left(\frac{y}{z}\right)^n,$$

$$G_k(y,z) = \sum_{n=-\infty}^{\infty} \frac{J_n(y)J_{n+1}(z)}{(2n+1)^k}\left(\frac{y}{z}\right)^n,$$

then examples of identities include

$$d_3(y) = -\left(\frac{\pi}{2}\right)^2 \beta_2^2\left(\frac{\pi}{2}\right)\frac{\sin^2(y)}{y} - yG_2^2\left(y, \frac{\pi}{2}\right) + 2\sin(y)G_3\left(y, \frac{\pi}{2}\right), \tag{7.17}$$

$$\frac{\sin(2z)}{2z}\beta_2(y) + \frac{\sin(2y)}{2y}\beta_2(z) = \frac{\sin(z)}{z}\cos(y)F_2(y,z) + \frac{\sin(y)}{y}\cos(z)F_2(z,y). \tag{7.18}$$

VIII. CONCLUSION

It would be particularly nice to see solutions to some of the open problems presented in this paper. A solution of question 4 could potentially yield a rapidly converging series for $Y_0(z)$, while a solution for question 3 would simplify Theorem 4.7. Such results would be quite useful.

It might also be interesting to generalize the results of Secs. II, IV, and V to other special functions. For example, while it is possible to generate a differential equation similar to Eq. (3.2) for the zeros of ${}_2F_1\left(\begin{matrix}a,1-a\\c\end{matrix}\middle| x\right)$, it is not immediately clear that this will yield a nice series similar to Eq. (4.24) for the zeros of this hypergeometric function.

ACKNOWLEDGMENTS

The author would like to thank his advisor, David Boyd, for the useful discussions about the zeros of analytic functions, and for his help with this paper. The author thanks Chris Duarte for his careful reading of this paper, and for suggesting several improvements.

We devise a new simple loop algebra $\tilde{G}_M$ and an isospectral problem. By making use of the Tu scheme, the multicomponent generalized Kaup–Newell hierarchy is obtained. Furthermore, an expanding loop algebra $\tilde{F}_M$ of the loop algebra $\tilde{G}_M$ is presented. Based on $\tilde{F}_M$, the multicomponent integrable couplings system with two arbitrary functions of the multicomponent generalized Kaup–Newell hierarchy are worked out. The method can be applied to other nonlinear evolution equations hierarchy. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1866220]

I. INTRODUCTION

Searching for new integrable hierarchies of soliton equations is an important and interesting topic in soliton theory. Various efficient approaches have been developed to get many integrable systems such as AKNS hierarchy, Kaup–Newell hierarchy, Schrödinger system, and so on.[1–24] As far as the multicomponent integrable hierarchies are concerned, there have been developments such as in Refs. 13 and 14. Ma and Zhou once also gave the multicomponent AKNS hierarchies by using generalized Tu scheme in Ref. 15. In Refs. 16–18, a simple and efficient method for generating multicomponent integrable hierarchies was proposed. Constructing a new simple loop algebra and designing an isospectral problem of multicomponent hierarchy of soliton equations become a key step in this method. Although using the loop algebra in Refs. 16–18 can produce many multicomponent integrable hierarchies, it is not suitable for seeking the multicomponent generalized Kaup–Newell hierarchy.[10,11] In this paper, a new loop algebra $\tilde{G}_M$ is first constructed, and then an isospectral problem is designed. By employing Tu scheme,[6–19] the multicomponent generalized Kaup–Newell hierarchy is worked out. In addition, an expanding loop algebra $\tilde{F}_M$ of the loop algebra $\tilde{G}_M$ is presented, which is devoted to deducing the integrable couplings of the multicomponent generalized Kaup–Newell hierarchy.

In Refs. 10 and 11, we investigated the isospectral problem,

[a)]Electronic mail: xiatc@yahoo.com.cn
[b)]Electronic mail: faneg@fudan.edu.cn

$$\varphi_x = U\varphi, \quad U = \begin{pmatrix} -\lambda^2 + \beta qr & \lambda q \\ \lambda r & \lambda^2 - \beta qr \end{pmatrix}, \quad \lambda_t = 0. \tag{1}$$

Where β is an arbitrary constant. When $\beta=0$, problem (1) reduces to the Kaup–Newell spectral problem. We obtained the generalized Kaup–Newell hierarchy and established its multi-Hamiltonian structure by using Tu scheme,

$$u_t = \begin{pmatrix} q \\ r \end{pmatrix}_t = J\frac{\delta H_n}{\delta u} = JL\frac{\delta H_{n-1}}{\delta u} = JL^n\frac{\delta H_0}{\delta u}, \quad n = 1,2, \ldots .$$

It is interesting the hierarchy is related to seven well-known nonlinear evolution equations such as Kaup–Newell equations, Chen–Lee–Liu equations, Gerdjikov equation and Kundu type equation, etc.[11,12] In this paper, we would like to extend the hierarchy to the multicomponent generalized Kaup–Newell integrable hierarchy in the Lax sense. Finally, we shall obtain the multicomponent integrable couplings with two arbitrary functions of the multicomponent generalized Kaup–Newell integrable hierarchy based on a new loop algebra $\tilde{F}_M$.

II. A NEW LOOP ALGEBRA

If $G_M=\{a=(a_{ij})_{M\times 3}=(a_1,a_2,a_3)\}$ denotes a set of matrices, where M is a positive integer, $a_i(i=1,2,3)$ is the ith column of the matrix a. Then G_M is a linear space.

Let $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_M)^T$, $\beta=(\beta_1,\beta_2,\ldots,\beta_M)^T$, and define their product $\alpha*\beta=\beta*\alpha=(\alpha_1\beta_1,\alpha_2\beta_2,\ldots,\alpha_M\beta_M)^T$. If $a=(a_1,a_2,a_3)$, $b=(b_1,b_2,b_3)\in\tilde{G}_M$, a commutation operation for G_M is defined as

$$[a,b] = (a_2 * b_3 - a_3 * b_2, 2(a_1 * b_2 - a_2 * b_1), 2(a_3 * b_1 - a_1 * b_3)), \tag{2}$$

It is easy to verify that the operation (2) is linear and antisymmetric. For $\forall a,b,c\in G_M$, we can also verify that

$$[[a,b],c] + [[b,c],a] + [[c,a],b] = 0, \tag{3}$$

i.e., Jacobian identity holds. Therefore, G_M with the operation (2) becomes a Lie algebra. A corresponding loop algebra $\tilde{G}_M$ is defined as

$$\tilde{G}_M = \{a\lambda^n, a \in G_M, n = 0, \pm 1, \pm 2, \ldots\},$$

with a commutation operation defined as

$$[a\lambda^m, b\lambda^n] = [a,b]\lambda^{m+n}, \quad \forall\, a,b \in \tilde{G}_M. \tag{4}$$

Since $\tilde{G}_1$ is equal to $\tilde{A}_1$ in Refs. 21 and 22, we conclude that $\tilde{G}_M$ is an extension of the loop algebra $\tilde{A}_1$. We also find that $\tilde{G}_M$ has two features, (i) the commutation operation is simple and straightforward, as that in the loop algebra $\tilde{A}_1$; (ii) by means of $\tilde{G}_M$, we proceed to a simple calculation to be able to obtain various multicomponent integral systems.

Considering linear is spectral problem as follows:

$$\phi_x = [U,\phi], \quad \lambda_t = 0, \phi, U, \quad V \in \tilde{G}_M,$$

$$\phi_t = [V,\phi], \tag{5}$$

whose compatibility gives rise to

$$\phi_{xt} = [U_t,\phi] + [U,[V,\phi]] = \phi_{tx} = [V_x,\phi] + [V,[U,\phi]],$$

that is

$$[U_t,\phi]-[V_x,\phi]+[U,[V,\phi]]+[V,[U,\phi]]=0. \tag{6}$$

By employing (3), the formula (5) can be written as

$$[U_t,\phi]-[V_x,\phi]+[[U,V],\phi]=0. \tag{7}$$

Since ϕ is arbitrary, a condition of (7) holds if and only if the following equation does:

$$U_t-V_x+[U,V]=0. \tag{8}$$

Hence, the compatibility of (7) leads to a zero-curvature equation (8).

III. THE MULTICOMPONENT GENERALIZED KAUP–NEWELL HIERARCHY

We consider an is spectral problem

$$\phi_x=[U,\phi],\quad \lambda_t=0,\quad U=(-\lambda^2 I_M+\beta q*r,\lambda q*I_M,\lambda r*I_M), \tag{9}$$

where

$$I_M=\begin{pmatrix}1\\1\\\cdots\\1\end{pmatrix}_{M\times 1},\quad q=(q_1,q_2,\ldots,q_M)^T,\quad r=(r_1,r_2,\ldots r_M)^T.$$

Let

$$V=\sum_{m=0}^{\infty}(a(0,m),\lambda b(1,m),\lambda c(1,m))\lambda^{-2m},$$

where $a(0,m)=(a_{m1}^{(0)},\ldots,a_{mM}^{(0)})^T$, $b(1,m)=(b_{m1}^{(1)},\ldots,b_{mM}^{(1)})^T$, $c(1,m)=(c_{m1}^{(1)},\ldots,c_{mM}^{(1)})^T$. Solving the stationary zero curvature equation

$$V_x=[U,V], \tag{10}$$

gives

$$\begin{aligned}
&a_x(0,m)=q*c(1,m+1)-r*b(1,m+1),\\
&b_x(1,m)=-2b_m(1,m+1)+2\beta q*r*b(1,m)-2q*a(0,m),\\
&c_x(1,m)=2r*a(0,m)+2c(1,m+1)-2\beta q*r*c(1,m),\\
&a(1,m+1)=b(0,m)=c(0,m)=0,\\
&b(1,0)=c(1,0)=0,a(0,0)=\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_M)\neq 0,\\
&c(1,1)=-\alpha*r,b(1,1)=-\alpha*q.
\end{aligned} \tag{11, 12}$$

Where $\alpha_i(i=1,2,\ldots,M)$ are constants.

Denoting $V_+^{(n)}=\Sigma_{m=0}^{n}(a(0,m),\lambda b(1,m),\lambda c(1,m))\lambda^{2n-2m}$, $V_-^{(n)}=\lambda^{2n}V-V_+^{(n)}$, then Eq. (7) can be written as

$$-V_{+x}^{(n)}+[U,V_+^{(n)}]=V_{-x}^{(n)}-[U,V_-^{(n)}]. \tag{13}$$

A direct calculation reads

$$-V_{+x}^{(n)}+[U,V_{+}^{(n)}]=(a_x(0,n+1),b_x(1,n+1)-2\beta q*r*b(1,n+1),c_x(1,n+1)+2\beta q*r*c(1,n+1))$$

Again taking

$$\Delta_n=(\beta(\partial^{-1}q*c_x(1,n+1)+r*b_x(1,n+1))+2\beta^2\partial^{-1}q*r*(q*c(1,n+1)-r*b(1,n+1)),0,0),$$

$$V^{(n)}=V_{+}^{(n)}+\Delta_n,$$

the zero curvature equation

$$U_t-V_x^{(n)}+[U,V^{(n)}]=0,$$

gives rise to the Lax integrable hierarchy

$$u_t=\begin{pmatrix}q\\r\end{pmatrix}_t=J'L'^{n-1}\begin{pmatrix}-\alpha*r\\-\alpha*q\end{pmatrix},\tag{14}$$

with

$$J'=\begin{pmatrix}J_{11}&J_{12}\\J_{21}&J_{22}\end{pmatrix},$$

where

$$J_{11}=2\beta q*\partial^{-1}q*\partial+4\beta^2q*\partial^{-1}q^2*r*,$$

$$J_{12}=\partial-2\beta q*r*+2\beta q*\partial^{-1}r*\partial-4\beta^2q*\partial^{-1}q*r^2*,$$

$$J_{21}=\partial+2\beta q*r*-2\beta r*\partial^{-1}q*\partial-4\beta^2r*\partial^{-1}r*q^2*,$$

$$J_{22}=-2\beta r*\partial^{-1}r*\partial-4\beta^2r*\partial^{-1}q*r^2*,$$

$$L'=\frac{1}{2}\begin{pmatrix}L_{11}&L_{12}\\L_{21}&L_{22}\end{pmatrix},$$

$$L_{11}=\partial-2\beta r*\partial^{-1}q^2*r*-r*\partial^{-1}q*\partial+2\beta q*r*,$$

$$L_{12}=2\beta r*\partial^{-1}q*r^2*-r*\partial^{-1}r*\partial,$$

$$L_{21}=-2\beta q*\partial^{-1}q^2*r*-q*\partial^{-1}q*\partial,$$

$$L_{22}=-\partial+2\beta q*\partial^{-1}q*r^2*-q*\partial^{-1}r*\partial+2\beta q*r*.$$

Let us see some special cases of our multicomponent hierarchy (14).

When $M=1$, the system (14) is just the the generalized Kaup–Newell hierarchy.[10,11] When $M>1$, the system (14) is the multicomponent generalized Kaup–Newell hierarchy.

The first system ($m=1$, $\alpha=-1$) in hierarchy (14) is the following coupled system:

$$q_t=b(1,n+1)_x-2\beta qrb(1,n+1)+2q\Delta_n,$$

$$r_t = c(1,n+1)_x - 2\beta qrc(1,n+1) - 2r\Delta_n. \tag{15}$$

Where Δ_n is given by

$$\Delta_n = (\beta(\partial^{-1}qc_x(1,n+1) + rb_x(1,n+1)) + 2\beta^2\partial^{-1}qr(qc(1,n+1) - rb(1,n+1)),0,0).$$

$$c(1,2) = \tfrac{1}{2}r_x - \tfrac{1}{2}(1-2\beta)r^2q; b(1,2) = -\tfrac{1}{2}q_x - \tfrac{1}{2}(1-2\beta)q^2r.$$

Taking $n=1$ and substituting $c(1,2)$, $b(1,2)$, Δ_n into system (15), we have

$$q_t = -\tfrac{1}{2}q_{xx} - \tfrac{1}{2}(q^2r)_x - 2\beta q(qr)_x - \tfrac{1}{2}\beta q^3r^2,$$

$$r_t = \tfrac{1}{2}r_{xx} - \tfrac{1}{2}(r^2q)_x - 2\beta r(qr)_x - \tfrac{1}{2}\beta q^2r^3,$$

which is just a generalized coupled derivative Schrödinger system in Ref. 11. Other kinds of equations can be obtained from system (15) in the cases when $n=2,\ldots$, we just omit them here.

IV. THE MULTICOMPONENT INTEGRABLE COUPLINGS SYSTEM

Set

$$F_M = \{a = (a_{ij})_{M\times 5} = (a_1,a_2,a_3,a_4,a_5)\}, \tag{16}$$

with a commutation operation defined as

$$[a,b] = (a_2 * b_3 - a_3 * b_2, 2(a_1 * b_2 - a_2 * b_1), 2(a_3 * b_1 - a_1 * b_3)), a_1 * b_4 - a_4 * b_1 + a_1 * b_5 - a_5 * b_1,$$

$$a_1 * b_5 - a_5 * b_1 + a_4 * b_1 - a_1 * b_4). \tag{17}$$

Then F_M is a Lie algebra. A corresponding loop algebra $\tilde{F}_M$ is defined as

$$\tilde{F}_M = \{a\lambda^n, a \in F_M, n = 0, \pm 1, \pm 2, \ldots\}, \tag{18}$$

with a commutation operation defined as

$$[a\lambda^m, b\lambda^n] = [a,b]\lambda^{m+n}, \forall\, a,b \in F_M. \tag{19}$$

Denote

$$\tilde{F}_M(1) = \{(a_1,a_2,a_3,0,0)\lambda^n\},$$

$$\tilde{F}_M(2) = \{(0,0,0,a_4,a_5)\lambda^n\},$$

then (i) $\tilde{F}_M = \tilde{F}_M(1) \oplus \tilde{F}_M(2)$, $\tilde{F}_M(1) \cong \tilde{G}_M$; (ii) $[\tilde{F}_M(1), \tilde{F}_M(2)] \subset \tilde{F}_M(2)$. Based on $\tilde{F}_M$, we consider an isospectral problem,

$$\phi_x = [U,\phi], \lambda_t = 0, U = (-\lambda^2 I_M + \beta u_1 * u_2, \lambda u_1 * I_M, \lambda u_2 * I_M, \lambda u_3 * I_M, \lambda u_4 * I_M), \tag{20}$$

where $u_i = (u_{i1}, u_{i2}, \ldots, u_{iM})^T$, $i=1,2,3,4$. Let $V = \Sigma_{m=0}^{n}(a_m, b_m, c_m, d_m, f_m)\lambda^{-2m}$. Solving the equation similar to (10) gives

$$a_x(0,m) = u_1 * c(1,m+1) - u_2 * b(1,m+1),$$

$$b_x(1,m) = -2b_m(1,m+1) + 2\beta * u_1 * u_2 * b(1,m) - 2u_1 * a(0,m),$$

$$c_x(1,m) = 2u_2 * a(0,m) + 2c(1,m+1) - 2\beta u_1 * u_2 * c(1,m),$$

$$d_x(1,n) = -d(1,n+1) + \beta * u_1 * u_2 * d(1,n) + \beta * u_1 * u_2 * f(1,n) - u_3 * a(0,n) - f(1,n+1) - u_4 * a(0,n),$$

$$f_x(1,n) = -f(1,n+1) + \beta * u_1 * u_2 * f(1,n) - \beta * u_1 * u_2 * d(1,n) - u_4 * a(0,n) + d(1,n+1) + u_3 * a(0,n),$$

$$a(1,m+1) = b(0,m) = c(0,m) = d(0,m) = f(0,m) = 0,$$

$$b(1,0) = c(1,0) = 0,\ a(0,0) = \alpha = (\alpha_1, \alpha_2, \ldots, \alpha_M) \neq 0,$$

$$c(1,1) = -\alpha * u_2,\ b(1,1) = -\alpha * u_1,\ d(1,1) = -\alpha * u_3,\ f(1,1) = -\alpha * u_4. \tag{21}$$

Taking

$$\Delta_n = (\beta * (\partial^{-1} u_1 * c_x(1,n+1) + u_2 * b_x(1,n+1)) + 2\beta^2 \partial^{-1} u_1 * u_2 * (u_1 * c(1,n+1) - u_2 * b(1,n+1)), 0, 0, \delta_{1n}, \delta_{2n}),$$

$$V^{(n)} = V_+^{(n)} + \Delta_n, \tag{22}$$

where δ_{1n}, δ_{2n} are arbitrary multicomponent functions of $u_i (i=1,2,3,4)$, therefore according to the zero curvature equation, we have following multicomponent integrable couplings of hierarchy of the multicomponent generalized Kaup–Newell hierarchy with two arbitrary functions:

$$u_t = \begin{pmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{pmatrix}_{t_n} = \begin{pmatrix} J_{11} * c(1,n+1) + J_{12} * b(1,n+1) \\ J_{21} * c(1,n+1) + J_{22} * b(1,n+1) \\ H_1 * \\ H_2 * \end{pmatrix}, \tag{23}$$

where

$$J_{11} = 2\beta * u_1 * \partial^{-1} u_1 * \partial + 4\beta^2 * u_1 * \partial^{-1} u_1^2 * u_2,$$

$$J_{12} = \partial - 2\beta * u_1 * u_2 + 2\beta * u_1 * \partial^{-1} r * \partial - 4\beta^2 u_1 * \partial^{-1} u_1 * u_2^2,$$

$$J_{21} = \partial + 2\beta * u_1 * u_2 - 2\beta * u_2 * \partial^{-1} u_1 * \partial - 4\beta^2 u_2 * \partial^{-1} u_2 * u_1^2,$$

$$J_{22} = -2\beta * u_2 * \partial^{-1} u_2 * \partial - 4\beta^2 * u_2 * \partial^{-1} u_1 * u_2^2,$$

$$H_1 = d_x(1,n+1) - \beta * u_1 * u_2 * d(1,n+1) - \beta * u_1 * u_2 * f(1,n+1) + (u_3 + u_4) * \Delta_n + \delta_{1nx} - \beta * u_1 * u_2 * \delta_{1n} - \beta * u_1 * u_2 * \delta_{2n},$$

$$H_2 = f_x(1,n+1) - \beta * u_1 * u_2 * f(1,n+1) + \beta * u_1 * u_2 * d(1,n+1) + (u_4 - u_3) * \Delta_n + \delta_{2nx} + \beta * u_1 * u_2 * \delta_{1n} - \beta * u_1 * u_2 * \delta_{2n}. \tag{24}$$

which have the Lax pair,

$$\phi_x = U\phi, \quad \phi_{t_n} = V^{(n)}\phi, \tag{25}$$

where U and $V^{(n)}$ satisty (9) and (22), respectively.

In particular, when taking $\delta_{1n}=\delta_{2n}=0$, from (23), we have

$$u_t = \begin{pmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{pmatrix}_t = \begin{pmatrix} J_{11}* & J_{12}* & 0 & 0 \\ J_{21}* & J_{22}* & 0 & 0 \\ J_{31}* & J_{32}* & \partial-\beta*u_1*u_2* & -\beta*u_1*u_2* \\ J_{41}* & J_{42}* & \beta*u_1*u_2* & \partial-\beta*u_1*u_2* \end{pmatrix} \begin{pmatrix} c(1,n+1) \\ b(1,n+1) \\ d(1,n+1) \\ f(1,n+1) \end{pmatrix} = J \begin{pmatrix} c(1,n+1) \\ b(1,n+1) \\ d(1,n+1) \\ f(1,n+1) \end{pmatrix}, \tag{26}$$

where $J_{ij}(i,j=1,2)$ comes from Eq. (24),

$$J_{31} = (u_3+u_4)*(\beta*\partial^{-1}u_1*\partial+2\beta^2*\partial^{-1}u_1^2*u_2),$$

$$J_{32} = (u_3+u_4)*(\beta*\partial^{-1}u_2*\partial-2\beta^2*\partial^{-1}u_2^2*u_1),$$

$$J_{41} = (u_4-u_3)*(\beta*\partial^{-1}u_1*\partial+2\beta^2*\partial^{-1}u_1^2*u_2),$$

$$J_{42} = (u_4-u_3)*(\beta*\partial^{-1}u_2*\partial-2\beta^2*\partial^{-1}u_2^2*u_1).$$

From (21), a recurrence operator is presented

$$L = \begin{pmatrix} L_{11}* & L_{12}* & 0 & 0 \\ L_{21}* & L_{22}* & 0 & 0 \\ L_{31}* & L_{32}* & \beta*u_1*u_2*-\frac{1}{2}\partial & \frac{1}{2}\partial \\ L_{41}* & L_{42}* & \beta*u_1*u_2*-\frac{1}{2}\partial & -\frac{1}{2}\partial \end{pmatrix},$$

with

$$L_{11} = \partial-2\beta*u_2*\partial^{-1}u_1^2*u_2-u_2*\partial^{-1}u_1*\partial+2\beta*u_1*u_2,$$

$$L_{12} = 2\beta*u_2*\partial^{-1}u_1*u_2^2-u_2*\partial^{-1}r*\partial,$$

$$L_{21} = -2\beta*u_1*\partial^{-1}u_1^2*u_2-u_1*\partial^{-1}u_1*\partial,$$

$$L_{22} = -\partial+2\beta*u_1*\partial^{-1}u_1*u_2^2-u_1*\partial^{-1}u_2*\partial+2\beta*u_1*u_2,$$

$$L_{31} = -u_3\partial^{-1}\left(\beta*u_1^2*u_2+\tfrac{1}{2}u_1*\partial\right),$$

$$L_{32} = -u_3\partial^{-1}\left(-\beta*u_2^2*u_1+\tfrac{1}{2}u_2*\partial\right),$$

$$L_{41} = -u_4\partial^{-1}\left(\beta*u_1^2*u_2+\tfrac{1}{2}u_1*\partial\right),$$

$$L_{42} = -u_4\partial^{-1}\left(-\beta*u_2^2*u_1+\tfrac{1}{2}u_2*\partial\right).$$

Thus, Eq. (23) can be written as

$$u_t = \begin{pmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{pmatrix}_t = JL^n \begin{pmatrix} -\alpha * u_2 \\ -\alpha * u_1 \\ -\alpha * u_3 \\ -\alpha * u_4 \end{pmatrix}. \tag{27}$$

When $M=1$, the system (27) is the integrable coupling of the generalized Kaup–Newell hierarchy.[10] When $M>1$, the (27) is the multicomponent integrable coupling of the multicomponent generalized Kaup–Newell hierarchy.

V. CONCLUSION AND REMARK

In this paper, a new loop algebra $\tilde{F}_M$ and Tu scheme are proposed to construct a multicomponent integrable couplings with two arbitrary functions of the multicomponent generalized Kaup–Newell hierarchy. It was shown that the obtained integrable couplings is integrable in the Lax sense and contains two arbitrary functions of old potentials (u_1,u_2) and new potentials (u_3,u_4) which are different from those in Refs. 16–18. Searching for new and multicomponent integrable systems is an important and difficult topic in integrable theory. It is obvious that the proposed method in this paper provides an efficient approach and a guideline to find new and multicomponent integrable systems. The loop algebra presented here can be used to other known integrable hierarchies of soliton equation for generating the multicomponent systems. But there are two open problems. How to improve the loop algebra $\tilde{F}_M$ such that the obtained multicomponent hierarchies are Liouville integrable and possess Hamiltonian structures? How to extend the proposed method for constructing integrable couplings of nonisospectral problem and corresponding evolution equation hierarchy? These problems are worthwhile studying in the future.

(Received 29 March 2004; accepted 17 January 2005; published online 29 March 2005)

We consider type II superstring compactifications on the singular Spin(7) manifold constructed as a cone on SU(3)/U(1). Based on a toric realization of the projective space $\mathbb{C}\mathbf{P}^2$, we discuss how the manifold can be viewed as three intersecting Calabi–Yau conifolds. The geometric transition of the manifold is then addressed in this setting. The construction is readily extended to higher dimensions where we speculate on possible higher-dimensional geometric transitions. Armed with the toric description of the Spin(7) manifold; we discuss a brane/flux duality in both type II superstring theories compactified on this manifold. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1873038]

I. INTRODUCTION

Calabi–Yau conifold transitions in superstring compactifications have been studied intensively over the last couple of years. These transitions have become a standard tool in understanding large N dualities. An example of such a duality is the equivalence of the SU(N) Chern–Simons theory on $\mathbf{S}^3$ for large N, and the closed topological strings on the resolved conifold.[1] A further example has been obtained by embedding these results in type IIA superstring theory.[2] In particular, the scenario with N $D6$-branes wrapped around the $\mathbf{S}^3$ of the deformed conifold $T^*\mathbf{S}^3$ for large N has been found to be equivalent to type IIA superstrings on the resolved conifold with N units of $R-R$ two-form fluxes through $\mathbf{S}^2$. The latter thus gives the strong-coupling description of the weak-coupling physics of the former.[1] This result has been lifted to the 11-dimensional M-theory[3] where it corresponds to a so-called flop duality in M-theory compactified on a manifold with G_2 holonomy, for short, a G_2 manifold.

Quite recently, similar studies have been done in three dimensions using either type IIA superstring compactification on a G_2 manifold,[4,5] or M-theory compactified on a Spin(7) manifold.[5] This Spin(7) manifold is constructed as a cone on SU(3)/U(1). Upon reduction of the M-theory case to 10 dimensions, the original geometric transition involving a collapsing $\mathbf{S}^5$ and a growing $\mathbb{C}\mathbf{P}^2$ may be interpreted as a transition between two phases described by wrapped $D6$-branes or $R-R$ fluxes, respectively.

An objective of the present work is to continue the study of geometric transitions and brane/flux dualities in lower dimensions. We shall thus consider type II superstrings propagating on the same Spin(7) manifold as above. By comparison with the known results for the Calabi–Yau conifold transition, in particular, we conjecture new brane/flux dualities in two dimensions. The type IIA and type IIB superstrings are treated separately, and we find that the resulting gauge theories in two dimensions have only one supercharge each, so that $\mathcal{N}=1/2$ in both cases.

The present study utilizes a toric geometry description of the Spin(7) manifold. We find that the manifold can be viewed as three intersecting Calabi–Yau conifolds associated to a triangular toric diagram. This result offers a picture for understanding the topology-changing transition of the Spin(7) manifold. It also allows us to discuss the aforementioned brane/flux transition based on an analysis of type II superstrings on the individual Calabi–Yau conifolds.

Our toric description of the Spin(7) manifold may be extended to higher-dimensional manifolds thus suggesting that (generalized) geometric transitions may play a role in higher dimensions as well. We propose an explicit hierarchy of pairs of geometries related by such transitions.

The remaining part of this paper is organized as follows. In Sec. II, we use toric geometry to discuss the Calabi–Yau conifold transition and its extension to the Spin(7) manifold, and speculate on a further generalization to higher dimensions. We then turn to compactifications of superstrings in Sec. III. Since our analysis is based on the toric description of the Spin(7) manifold, our results are deduced from similar results on compactifications on Calabi–Yau conifolds. The associated brane/flux dualities are discussed separately for type IIA and type IIB superstring propagations. Section IV contains some concluding remarks.

II. TORIC GEOMETRY AND GEOMETRIC TRANSITIONS

A. Projective spaces and odd-dimensional spheres

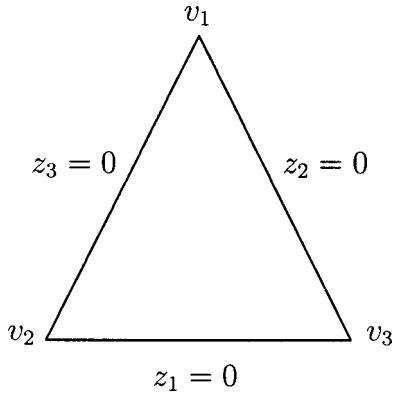
As a description of projective spaces in terms of toric geometry lies at the heart of our study of superstring compactifications, we shall review it here. Odd-dimensional (real) spheres are equally important in our analysis and are therefore also discussed here.

The simplest (complex) projective space is $\mathbb{C}\mathbf{P}^1$ with a toric U(1) action having two fixed points, v_1 and v_2, corresponding to the North and South poles, respectively, of the (real) two-sphere $\mathbf{S}^2 \sim \mathbb{C}\mathbf{P}^1$. In this way, $\mathbb{C}\mathbf{P}^1$ may be viewed as the interval $[v_1, v_2]$,

$$v_1 \text{———} v_2 \tag{1}$$

referred to as the toric diagram, with a circle on top which vanishes at the endpoints v_1 and v_2.

Embedded in $\mathbb{C}^3$, $\mathbb{C}\mathbf{P}^2$ may be described as the space of three complex numbers (z_1, z_2, z_3) not all zero, modulo the identification $(z_1, z_2, z_3) \sim (\lambda z_1, \lambda z_2, \lambda z_3)$ for all nonzero $\lambda \in \mathbb{C}$. Alternatively, $\mathbb{C}\mathbf{P}^2$ is the (complex) two-dimensional space with a toric $U(1)^2$ action with three fixed points, v_1, v_2, and v_3. Its toric diagram is the triangle $(v_1 v_2 v_3)$



(2)

describing the intersection of three $\mathbb{C}\mathbf{P}^1$'s. Each of the three edges, $[v_1, v_2]$, $[v_2, v_3]$, and $[v_3, v_1]$, is characterized by the vanishing of one of the homogeneous coordinates, $z_3 = 0$, $z_1 = 0$ or $z_2 = 0$, respectively. Each edge is stable under the action of a subgroup of $U(1)^2$—two of them being the two U(1) factors, while the third subgroup is the diagonal one. This toric realization of $\mathbb{C}\mathbf{P}^2$ can be viewed as the triangle $(v_1 v_2 v_3)$ with a torus, $\mathbf{T}^2$, on top which collapses to a circle at an edge and to a point at a vertex.

This representation is readily extended to the n-dimensional projective space $\mathbb{C}\mathbf{P}^n$ where we have a $\mathbf{T}^n$ fibration over an n-dimensional simplex (regular polytope), see Ref. 6, for example. In

this case, the $\mathbf{T}^n$ collapses to a $\mathbf{T}^{n-1}$ on each of the n faces of the simplex, and to a $\mathbf{T}^{n-2}$ on each of the $(n-2)$-dimensional intersections of these faces, etc. We recall that $\mathbb{C}\mathbf{P}^n$ is defined similarly to $\mathbb{C}\mathbf{P}^2$ in terms of $n+1$ homogeneous coordinates modulo the identification $(z_1,\ldots,z_{n+1}) \sim (\lambda z_1,\ldots,\lambda z_{n+1})$.

The odd-dimensional (real) spheres admit a similar description. The one-sphere, for example, is trivially realized as a $\mathbf{T}^1 \sim \mathbf{S}^1$ over the zero-simplex—a point. The three-sphere may be realized as a $\mathbf{T}^2$ over a one-simplex—a line segment as the one in (1). This may be extended to the $(2n+1)$-dimensional sphere $\mathbf{S}^{2n+1}$ which may be described as a $\mathbf{T}^{n+1}$ over an n-simplex. Of particular interest is the five-sphere $\mathbf{S}^5$ which in this way may be realized as the triangle (2) with a $\mathbf{T}^3$ on top (whereas $\mathbb{C}\mathbf{P}^2$ had a $\mathbf{T}^2$ on top). It is stressed that it is for $n=1$ only that the even-dimensional sphere $\mathbf{S}^{2n}$ is equivalent to $\mathbb{C}\mathbf{P}^n$.

To illustrate this toric description of odd-dimensional spheres, let us add a couple of comments on $\mathbf{S}^5$ realized as a $\mathbf{T}^3$ over a triangle. As in (2), an edge of the triangle corresponds to the vanishing of one of the three complex coordinates of the embedding space $\mathbb{C}^3$. Each edge of the triangle (2) is stable under the action of one of the three U(1) factors of $\mathrm{U}(1)^3$ associated to $\mathbf{T}^3$. The three-torus itself collapses to a two-torus $\mathbf{T}^2$ at an edge and to a circle at a vertex. We may thus view $\mathbf{S}^5$ as three intersecting three-spheres over the triangle (2). As opposed to the toric description of $\mathbb{C}\mathbf{P}^2$ as a $\mathbf{T}^2$ over a triangle, the diagonal U(1) of $\mathrm{U}(1)^3$ in the $\mathbf{S}^5$ description has no fixed points. This is natural from the realization of $\mathbb{C}\mathbf{P}^2$ as $\mathbf{S}^5$ modulo U(1).

B. Calabi–Yau conifold

We shall also make use of the noncompact Calabi–Yau threefold defined in $\mathbb{C}^4$ by the equation

$$uv - xy = 0. \tag{3}$$

It may be viewed as the singular cone on the five-dimensional base $\mathbf{S}^2 \times \mathbf{S}^3$ and is therefore referred to as the Calabi–Yau conifold. The singularity is located at the origin and may be turned into a regular point by blowing it up. There are basically two ways of doing that, referred to as resolution and deformation, respectively. Resolving the singularity consists in replacing the singular point by a $\mathbb{C}\mathbf{P}^1$. In this way, the local geometry is given by an $O(-1)+O(-1)$ bundle over $\mathbb{C}\mathbf{P}^1$. The smooth manifold thus obtained is called the resolved conifold and is of topology $\mathbb{R}^4 \times \mathbb{C}\mathbf{P}^1$. In the case of complex deformation, the conifold singularity is removed by modifying the defining algebraic equation (3) by introducing the complex parameter μ,

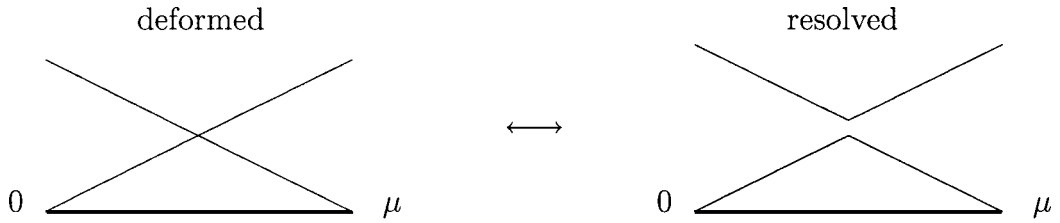
$$uv - xy = \mu, \tag{4}$$

while keeping the Kähler structure. The origin is thereby replaced by $\mathbf{S}^3$, and the local geometry is given by $T^*\mathbf{S}^3$ of topology $\mathbb{R}^3 \times \mathbf{S}^3$. This is called the deformed conifold and is related to the resolved conifold by the so-called conifold transition.

This conifold transition admits a representation in toric geometry, where it can be understood as an enhancement or breaking, respectively, of the toric circle actions. On the one hand, the $O(-1)+O(-1)$ bundle over $\mathbb{C}\mathbf{P}^1$ has only one toric U(1) action, identified with the toric action on $\mathbb{C}\mathbf{P}^1$ itself, while the deformed conifold $T^*\mathbf{S}^3$ has a toric $\mathrm{U}(1)^2$ action since the spherical part can be viewed as a $\mathbf{T}^2$ over a line segment. Referring to (4), the torus is generated by the two U(1) actions

$$(u,v) \to (e^{i\theta_1}u, e^{-i\theta_1}v), \quad (x,y) \to (e^{i\theta_2}x, e^{-i\theta_2}y) \tag{5}$$

with θ_i real. Thus, the blown-up $\mathbf{S}^3$ may be described by the complex interval $[0,\mu]$ with the two circles parametrized by θ_i on top, where $\mathbf{S}^1(\theta_1)$ collapses to a point at μ while $\mathbf{S}^1(\theta_2)$ collapses to a point at 0. The transition occurs when one of these circles refrains from collapsing while the other one collapses at both interval endpoints. This breaks the toric $\mathrm{U}(1)^2$ action to U(1), and the missing U(1) symmetry has become a real line (over $\mathbb{C}\mathbf{P}^1$). The resulting geometry is thus the resolved conifold. The following picture may help to illustrate this transition which can go in both directions:



(6)

The top, thin and piecewise straight line in the resolved part of (6) corresponds to the extra $\mathbb{R}$ while the remaining three thin lines (the two straight lines in the deformed part, and the lower, thin and piecewise straight line segment in the resolved part) indicate the U(1)'s. The two thick line segments represent the underlying interval.

A somewhat pragmatic way of viewing the conifold transition is based on the conical structure of the conifold itself as a cone on $\mathbf{S}^2 \times \mathbf{S}^3$. As described in Ref. 4, an n-dimensional cone on an $(n-1)$-dimensional compact space Y with metric $\mathrm{d}\Omega^2$ has metric

$$\mathrm{d}s^2 = \mathrm{d}r^2 + r^2\,\mathrm{d}\Omega^2. \tag{7}$$

It has a singularity at the origin unless $Y = \mathbf{S}^{n-1}$ and $\mathrm{d}\Omega^2$ is the standard round metric. In that case the cone corresponds to $\mathbb{R}^n$. Now, the deformed conifold is obtained by pulling the conical structure off of the $\mathbf{S}^3$ factor in the base, while maintaining it on the $\mathbf{S}^2$ factor. The latter is then equivalent to $\mathbb{R}^3$ and we have recovered the $\mathbb{R}^3 \times \mathbf{S}^3$ structure of the deformed conifold. The resolved conifold is obtained in a similar way by pulling off the conical structure of the $\mathbf{S}^2$ factor.

C. Spin(7) manifolds

Here we shall present a picture for understanding the topology-changing geometric transition of the Spin(7) manifold discussed in Ref. 5 and alluded to in Sec. I. First we recall that a Spin(7) manifold is a real eight-dimensional Riemannian manifold with holonomy group Spin(7). As in the case of Calabi–Yau and G_2 manifolds, there are several such geometries.[7] The example we shall be interested in may be described as a singular real cone over the seven-dimensional Aloff–Wallach (coset) space SU(3)/U(1). It was argued in Ref. 5 that there are two ways of blowing up the singularity, replacing the singularity by either $\mathbb{C}\mathbf{P}^2$ or $\mathbf{S}^5$. The resulting smooth Spin(7) manifolds have topologies,

$$\text{resolution,} \quad \text{Spin}(7){:}\mathbb{R}^4 \times \mathbb{C}\mathbf{P}^2 \quad (\text{Calabi} - \text{Yau,} \quad \mathbb{R}^4 \times \mathbb{C}\mathbf{P}^1) \tag{8}$$

and

$$\text{deformation,} \quad \text{Spin}(7){:}\mathbb{R}^3 \times \mathbf{S}^5 \quad (\text{Calabi} - \text{Yau,} \quad \mathbb{R}^3 \times \mathbf{S}^3), \tag{9}$$

and are referred to as resolution and deformation, respectively, due to the similarity with the Calabi–Yau conifold discussed above [and indicated in (8) and (9)].

Our aim here is to re-address the transition between these two manifolds using toric geometry. As described in the following, the basic idea is to view the singular Spin(7) manifold [the real cone on SU(3)/U(1)] as three intersecting Calabi–Yau conifolds associated to the triangular toric diagram (2). To reach this picture, we first recall that a deformed Spin(7) manifold is obtained by blowing up an $\mathbf{S}^5$, while a resolved Spin(7) manifold is obtained by blowing up a $\mathbb{C}\mathbf{P}^2$. Deformed and resolved conifolds, on the other hand, are obtained by blowing up an $\mathbf{S}^3$ or a $\mathbb{C}\mathbf{P}^1$, respectively. Since an $\mathbf{S}^5$ may be represented by three intersecting three-spheres, while $\mathbb{C}\mathbf{P}^2$ may be represented by three intersecting two-spheres, we thus see that the deformed and resolved Spin(7) manifolds correspond to three intersecting conifolds being deformed or resolved, respectively.

To recapitulate this, let us consider $\mathbb{C}^3$ parametrized by (z_1, z_2, z_3). A five-sphere is obtained by imposing the constraint

$$|z_1|^2 + |z_2|^2 + |z_3|^2 = r \tag{10}$$

(with r real and positive), while the additional identification

$$(z_1, z_2, z_3) \sim (e^{i\theta} z_1, e^{i\theta} z_2, e^{i\theta} z_3) \tag{11}$$

(with θ real) will turn it into a $\mathbb{C}\mathbf{P}^2$. In either case, r measures the size. With both conditions imposed, we can obtain the three resolved Calabi–Yau conifolds

$$\mathbb{R}^4 \times \mathbb{C}\mathbf{P}^1 (z_k = 0), \quad k = 1,2,3 \tag{12}$$

embedded in $\mathbb{R}^4 \times \mathbb{C}^3$, simply by setting one of the coordinates equal to 0. With reference to the triangle (2), this means that the resolution of the Spin(7) singularity reached by blowing up a $\mathbb{C}\mathbf{P}^2$ may be described by three intersecting resolved conifolds over the triangle (2). Likewise, the deformation of the Spin(7) singularity constructed by blowing up an $\mathbf{S}^5$ may be realized as three intersecting deformed Calabi–Yau conifolds

$$\mathbb{R}^3 \times \mathbf{S}^3 (z_k = 0), \quad k = 1,2,3 \tag{13}$$

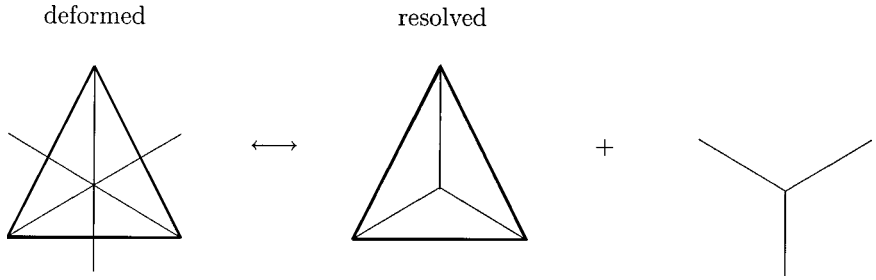
over the same triangle. This description is thus based on our toric representation of $\mathbf{S}^5$ as a $\mathbf{T}^3$ over a triangle. As already mentioned, this construction collapses to a $\mathbf{T}^2$ over an edge for $z_k = 0$ where $k = 1$, 2 or 3, and it is recalled that the resulting $\mathbf{T}^2$ over a line segment corresponds to $\mathbf{S}^3$.

Since the basic intersection of the deformed or resolved conifolds is governed by the constituent three- or two-spheres, one may describe the intersection of the conifolds by the intersection matrices associated to $\mathbf{S}^5$ or $\mathbb{C}\mathbf{P}^2$, respectively. They read

$$M_{\text{def}} = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{pmatrix}, \quad M_{\text{res}} = \begin{pmatrix} -2 & 1 & 1 \\ 1 & -2 & 1 \\ 1 & 1 & -2 \end{pmatrix}. \tag{14}$$

We emphasize that the Spin(7) transition in our picture is accompanied by Calabi–Yau conifold transitions. In the transition from the resolved Spin(7) manifold (8) to the deformed one (9), for example, this indicates that the collapsing $\mathbb{C}\mathbf{P}^2$ and its constituent two-spheres are replaced by $\mathbf{S}^5$ and its constituent three-spheres. This is at the core of the dualities in the phase transition of the compactified superstrings to be discussed below.

One may attempt to illustrate the geometric transitions of Spin(7) manifolds by generalizing (6). The following proposal extends readily to higher dimensions (see below), and reads



(15)

The configuration to the left is a representation of the $\mathbf{S}^5$ part of the deformed Spin(7) manifold, in which the three thin lines represent the three U(1) factors. The counting is less obvious to the right of the arrow, as the triangular part represents the $\mathbb{C}\mathbf{P}^2$ part of the resolved Spin(7) manifold. The inscribed three-vertex in thin line segments thus corresponds to two U(1) factors only. The three-vertex to the far right represents the extra $\mathbb{R}$ in the resolved scenario (8).

The Spin(7) transition may be viewed as taking place when passing a particular point while moving along a particular curve in the moduli space of Spin(7) manifolds. The point corresponds to the singular Spin(7) manifold, whereas the remaining points on the curve are associated to the deformed and resolved Spin(7) manifolds. In one direction away from the singular point, the

points correspond to the deformed manifolds with the size r of the blown-up $\mathbf{S}^5$ parametrizing that part of the curve. Likewise, the other direction away from the singular point is parametrized by the size r of the blown-up $\mathbb{C}\mathbf{P}^2$ in the resolved Spin(7) manifold. The singular point is shared as it is reached from either side when the relevant r vanishes, $r=0$.

In the interpretation of the Spin(7) manifold as three intersecting Calabi–Yau manifolds over a triangle, we see that the Spin(7) transition corresponds to all three Calabi–Yau manifolds undergoing simultaneous conifold transitions. We find it an interesting problem to understand the geometries associated to individual conifold transitions and hope to report on it elsewhere. Our graphic representation (15) [and (6)] does not seem to shed light on this as it is based on the transition of the full blow-ups, i.e., $\mathbf{S}^5$ and $\mathbb{C}\mathbf{P}^2$, and not on their constituent three- and two-spheres.

D. On possible extensions

It seems possible to extend our previous analysis of the Spin(7) manifold in terms of intersecting Calabi–Yau manifolds to higher dimensions. To this end, let us consider the complex $(n+1)$-dimensional space $\mathbb{C}^{n+1}$ parametrized by $(z_1,\ldots,z_{n+1})$. A $(2n+1)$-dimensional sphere is obtained by imposing the constraint

$$\sum_{j=1}^{n+1} |z_j|^2 = r \tag{16}$$

(with r real and positive), while the additional identification

$$(z_1,\ldots,z_{n+1}) \sim (e^{i\theta}z_1,\ldots,e^{i\theta}z_{n+1}) \tag{17}$$

(with θ real) will turn it into $\mathbb{C}\mathbf{P}^n$. In either case, r measures the size of the resulting space. Since $\mathbf{S}^{2n+1}$ can be described as a $\mathbf{T}^{n+1}$ over an n-simplex it supports a toric $\mathrm{U}(1)^{n+1}$ action whereas $\mathbb{C}\mathbf{P}^n$ (which may be realized as a $\mathbf{T}^n$ over an n-simplex) admits a toric $\mathrm{U}(1)^n$ action. The additional U(1) is the one used in the identification (17). As in the picture (6), we are thus expecting that a geometric transition can take place, replacing a U(1) by the one-dimensional real line $\mathbb{R}$. Since the U(1) is associated to one of the $\mathbf{S}^1$ factors of $\mathbf{T}^{n+1}$, the transition essentially amounts to replacing $\mathbf{T}^{n+1}$ by $\mathbf{T}^n\times\mathbb{R}$. Our interest is in real fibrations over the spaces $\mathbf{S}^{2n+1}$ and $\mathbb{C}\mathbf{P}^n$ so the relevant geometric transitions would read

$$\text{(deformed)}\quad \mathbb{R}^m\times\mathbf{S}^{2n+1} \leftrightarrow \mathbb{R}^{m+1}\times\mathbb{C}\mathbf{P}^n \quad \text{(resolved)}. \tag{18}$$

With $m=3$, we expect to be able to describe the transition (18) in terms of Calabi–Yau conifolds. Using arguments similar to the Spin(7) example above, this generalized geometric transition should be related to $\frac{1}{2}n(n+1)$ intersecting conifolds over the n-simplex, where the number of conifolds is equal to the number of one-dimensional edges of the simplex. One should also expect to be able to describe the transition in terms of $\frac{1}{6}n(n^2-1)$ intersecting Spin(7) manifolds over the n-simplex, where the number of them is equal to the number of two-dimensional faces of the simplex. We hope to address this further elsewhere.

The extension of the transition picture (15) to higher dimensions is based on $\mathbb{C}\mathbf{P}^n$ and $\mathbf{S}^{2n+1}$ admitting descriptions as $\mathbf{T}^n$ and $\mathbf{T}^{n+1}$ fibrations, respectively, over an n-simplex. One chooses an extra point different from the $n+1$ vertices of the n-simplex in such a way that any subset of $q<n+2$ nodes out of the total of $n+2$ points gives rise to a $(q-1)$-simplex. A natural choice is the center of the original (regular) n-simplex. To represent $\mathbf{S}^{2n+1}$, one then draws thin lines from the vertices through this extra point, where the thin lines represent the U(1) factors of $\mathrm{U}(1)^{n+1}$, cf. (15). The projective counterpart, $\mathbb{C}\mathbf{P}^n$, is represented by ending these thin lines at the common point, resulting in an $(n+1)$-vertex inscribed in the n-simplex. This inscribed vertex corresponds to $\mathrm{U}(1)^n$. Finally, the real line $\mathbb{R}$ may be represented by a free $(n+1)$-vertex, and the graphical representation of the transition (18) is a higher-dimensional version of (15).

The conifold analysis based on the toric variety $\mathbb{C}\mathbf{P}^2$ could alternatively be extended by blowing up some generic points. With the number of points restricted as $k=1,2,3$, this defines a so-called toric del Pezzo surface denoted dP_k. The blowing up consists in replacing a point by $\mathbb{C}\mathbf{P}^1$ with a line segment as its toric diagram. The full del Pezzo surface will thus have a polygon with $k+3$ legs as its toric diagram.

III. TYPE II SUPERSTRING COMPACTIFICATIONS

A. Compactification on conifold

Based on the Calabi–Yau conifold transition discussed above, Gopakumar and Vafa have argued that the SU(N) Chern–Simons theory on $\mathbf{S}^3$ for large N is dual to topological strings on the resolved conifold.[1] In this way, the 't Hooft expansion of the Chern–Simons free energy has been shown to be in agreement, for all genera, with the topological string amplitudes on the resolved conifold. This duality has subsequently been embedded in type IIA superstring theory,[2] where it was proposed that N $D6$-branes wrapped around the three-sphere of the deformed conifold is equivalent (for large N) to type IIA superstrings on the resolved conifold with the $D6$-branes replaced by N units of $R-R$ two-form fluxes through the two-sphere ($\mathbf{S}^2\sim\mathbb{C}\mathbf{P}^1$) in the resolved conifold. This duality thus offers a way of understanding the same physics at strong coupling.

The mirror version in type IIB superstring theory of this duality states that the scenario with N $D5$-branes wrapped around the two-sphere in the resolved conifold, is equivalent (for large N) to three-form fluxes through the $\mathbf{S}^3$ of the deformed conifold. This has been generalized to other Calabi–Yau threefolds where the blown-up geometries involve several $\mathbb{C}\mathbf{P}^1$'s.[8–14]

The large N duality in type IIA superstring theory has also been lifted to M-theory[3,4] (see also Ref. 15) where it is known to give a so-called flop duality. Unlike the duality in string theory, the phase transition here is smooth and does not correspond to a topology-changing geometric transition.

B. Compactification on Spin(7) manifold and brane/flux duality

Based on the results on superstrings compactified on Calabi–Yau threefolds and our toric description of the geometric transition of the Spin(7) manifolds, we now consider the two-dimensional gauge theories obtained by compactifying type II superstrings on these Spin(7) manifolds. The idea is to study the consequences of adding N wrapped D-branes to the setup before letting the manifold undergo the geometric transition. In the transition from the resolved to the deformed Spin(7) manifold, we initially have D-branes wrapping $\mathbb{C}\mathbf{P}^2$ (and its constituent two-spheres). We conjecture that they are replaced, under the transition, by $R-R$ fluxes through $\mathbf{S}^5$ (and its constituent three-spheres). Similarly in the transition from deformed to resolved Spin(7) manifolds, we conjecture that D-branes wrapped around $\mathbf{S}^5$ (and its constituent three-spheres) are replaced by $R-R$ fluxes through $\mathbb{C}\mathbf{P}^2$ (and its constituent two-spheres). The kind of D-branes involved and the more detailed phase transition depend on which type II superstrings are propagating on the Spin(7) manifolds. In the following we shall therefore consider type IIA and type IIB separately. We find that they lead to different brane/flux dualities.

1. Duality in type IIB superstring theory

We start by considering type IIB superstrings on the resolved Spin(7) manifold (8). Since the type IIB theory does not support four-forms, one considers $D5$-branes wrapped around $\mathbb{C}\mathbf{P}^2$. A two-dimensional U(N) gauge model can be obtained by wrapping N $D5$-branes on $\mathbb{C}\mathbf{P}^2$. The volume of $\mathbb{C}\mathbf{P}^2$ described by r (10) is proportional to the inverse of the gauge coupling squared. This two-dimensional model has only one supercharge so $\mathcal{N}=1/2$. Now, when the manifold undergoes the geometric transition to the deformed Spin(7) manifold (9), the N $D5$-branes disappear and we expect a dual physics with N units of $R-R$ three-fluxes through the compact three-cycles, $\mathbf{S}^3$, in the intersecting Calabi–Yau threefolds. These fluxes could be accompanied by some

NS–NS fluxes through the noncompact dual three-cycles in the six-dimensional deformed conifolds. In order to handle the associated divergent integrals, one would have to introduce a cutoff to regulate the infinity.[9]

2. Duality in type IIA superstring theory

Here we start with type IIA superstrings on the deformed Spin(7) manifold (9). In this case, a two-dimensional U(N) gauge theory can be obtained by wrapping N $D6$-branes around $\mathbf{S}^5$. As above, this gauge model has only one supercharge, so again $\mathcal{N}=1/2$. At the transition point, the $D6$-branes disappear and are replaced by $R-R$ two-form fluxes through the two-spheres embedded in $\mathbb{C}\mathbf{P}^2$ in the resolved Spin(7) manifold (8).

One could wonder if there is an M-theory interpretation of this type IIA transition. Let us therefore consider a nine-dimensional manifold X_9 with a U(1) isometry. M-theory compactified on X_9 is then equivalent to type IIA superstrings compactified on $X_9/\mathrm{U}(1)$. We start with the resolved Spin(7) manifold (8) and identify the extra eleventh compact dimension of M-theory with the $\mathbf{S}^1$ that generates (11). In this way, the extra M-theory circle becomes the fiber in the definition of $\mathbf{S}^5$ as an $\mathbf{S}^1$ fibration over $\mathbb{C}\mathbf{P}^2$. We thus end up with an $\mathbb{R}^4$ bundle over $\mathbf{S}^5$ as the compactification space in M-theory. As a consequence, the moduli space of M-theory on such a background is parametrized by the real parameter r defining the volume of $\mathbf{S}^5$ (10), and cannot be complexified by the C field. Starting with the resolved Spin(7) manifold, on the other hand, the eleventh M-theory dimension is obtained by extending $\mathbb{R}^3$ to $\mathbb{R}^4$ with the isometry being a trivial U(1) action on the fiber $\mathbb{R}^4$. Using arguments similar to those in Ref. 3, we conjecture that this lift to M-theory gives rise to a (smooth) flop transition in the $\mathbb{R}^4$ bundle over $\mathbf{S}^5$ where a five-sphere collapses and is replaced by a five-sphere. In our scenario, however, the physics resulting from the type IIA superstring compactification undergoes a singular phase transition.

IV. DISCUSSION

Based on toric geometry, we have studied geometric transitions of Spin(7) manifolds. Our framework allowed us to discuss extensions to higher dimensions. It also made it possible to address straightforwardly type II superstring compactifications on Spin(7) manifolds, from which some brane/flux dualities were extrapolated.

Our work opens up for further studies. One interesting problem is to understand better the geometries involved in our proposal for higher-dimensional geometric transitions. Another question is related to the toric description of the Spin(7) manifolds as intersecting Calabi–Yau threefolds over a triangle where the Spin(7) transition corresponds to three simultaneous conifold transitions. A natural question concerns the geometries associated to individual conifold transitions. Of potential importance to superstring and M-theory compactifications, one should then study what the physical implications of such transitions would be. It would also be interesting to understand the link between our results and the ones in Ref. 16 based on string compactifications on Calabi–Yau fourfolds. One approach to this problem could be to consider the Spin(7) manifold as a Calabi–Yau fourfold modulo an involution, thus ensuring the same number of supersymmetries. We hope to report elsewhere on these open problems.

(Received 18 January 2005; accepted 26 January 2005; published online 29 March 2005)

We complete the classification of almost commutative geometries from a particle physics point of view given by Iochum, Schücker, and Stephan, J. Math. Phys. (to be published). Four missing Krajewski diagrams will be presented after a short introduction into irreducible, nondegenerate spectral triples. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1876873]

I. INTRODUCTION

Alain Connes' noncommutative geometry[1–4] allows in an elegant way to unify gravity and the standard model of particle physics. A central role in this formalism is played by almost commutative spectral triples $(\mathcal{A},\mathcal{H},\mathcal{D})$ which decompose into an external and an internal, finite dimensional component. The external part encodes a compact four-dimensional Euclidian space–time and the internal one corresponds to a discrete 0-dimensional Kaluza–Klein space, determining the particle content of the theory. Via the spectral action[5] one recovers the Einstein–Hilbert action combined with the bosonic action of a Yang–Mills–Higgs (YMH) theory. Since the set of allowed YMH theories is determined by the possible internal, finite dimensional spectral triples, we will restrict ourselves to this part. The standard model of particle physics is the most prominent example in this context.

Real, finite dimensional spectral triples have been completely classified by Krajewski[6] and Paschke and Sitarz.[7] A classification of almost commutative geometries from a physical point of view was given in Ref. 8. The spectral triples were required to be irreducible and nondegenerate, in the sense that the Hilbert space was chosen to be as small as possible with nondegenerate fermion masses. Heavy use was made of Krajewski's diagrammatic method, which will be described briefly below. The main obstacle in finding all physically relevant almost commutative spectral triples is the sheer mass of diagrams which must be considered. Since this is a purely combinatorial problem it is convenient to let a computer do the tedious task. The cases of one and two matrix algebras can still be done by hand. But already three algebras produce hundreds of diagrams and one easily loses sight.

Therefore we developed an algorithm to calculate these diagrams and used the known results from Ref. 8 to test and calibrate the program. The main goal was to extend the calculations to more than three algebras, where we expect thousands of possible irreducible spectral triples. During the calibration it turned out that four diagrams were overlooked in the case of three algebras. To complete the proof we will present these four missing diagrams and their models in this paper. The algorithm to compute the diagrams and the results for the case of four algebras will be presented elsewhere.

In Sec. II we give some basic definitions and briefly introduce Krajewski diagrams and irreducible, nondegenerate spectral triples. The missing diagrams for three algebras are presented in Sec. III.

II. BASIC DEFINITIONS, IRREDUCIBILITY, AND NONDEGENERACY

In this section we give the necessary basic definitions for a classification of almost commutative geometries from a particle physics point of view. As mentioned above only the 0-dimensional part will be taken into account, so we restrict ourselves to real, S^0-real, finite spectral triples $(\mathcal{A},\mathcal{H},\mathcal{D},J,\epsilon,\chi)$. The algebra $\mathcal{A}$ is a finite sum of matrix algebras $\mathcal{A}=\oplus_{i=1}^{N} M_{n_i}(\mathbb{K}_i)$ with $\mathbb{K}_i=\mathbb{R}$, $\mathbb{C}$, $\mathbb{H}$, where $\mathbb{H}$ denotes the quaternions. A faithful representation ρ of $\mathcal{A}$ is given on the finite dimensional Hilbert space $\mathcal{H}$. The Dirac operator $\mathcal{D}$ is a self-adjoint operator on $\mathcal{H}$ and plays the role of the fermionic mass matrix. J is an antiunitary involution, $J^2=1$, and is interpreted as the charge conjugation operator of particle physics. The S^0-real structure ϵ is a unitary involution, $\epsilon^2=1$. Its eigenstates with eigenvalue +1 are the particle states, eigenvalue −1 indicates antiparticle states. The chirality χ as well is a unitary involution, $\chi^2=1$, whose eigenstates with eigenvalue $+1(-1)$ are interpreted as right (left) particle states. These operators are required to fulfill Connes' axioms for spectral triples:

(i)
$$[J,\mathcal{D}]=[J,\chi]=[\epsilon,\chi]=[\epsilon,\mathcal{D}]=0, \quad \epsilon J=-J\epsilon, \quad \mathcal{D}\chi=-\chi\mathcal{D},$$

$$[\chi,\rho(a)]=[\epsilon,\rho(a)]=[\rho(a),J\rho(b)J^{-1}]=[[\mathcal{D},\rho(a)],J\rho(b)J^{-1}]=0,\ \forall\, a,b\in\mathcal{A}.$$

(ii) The chirality can be written as a finite sum $\chi=\Sigma_i\rho(a_i)J\rho(b_i)J^{-1}$. This condition is called *orientability*.

(iii) The intersection form $\cap_{ij}:=\mathrm{tr}(\chi\rho(p_i)J\rho(p_j)J^{-1})$ is nondegenerate, $\det\cap\neq 0$. The p_i are minimal rank projections in $\mathcal{A}$. This condition is called *Poincaré duality*.

Now the Hilbert space $\mathcal{H}$ and the representation ρ decompose with respect to the eigenvalues of ϵ and χ into left and right, particle and antiparticle spinors and representations,

$$\mathcal{H}=\mathcal{H}_L\oplus\mathcal{H}_R\oplus\mathcal{H}_L^c\oplus\mathcal{H}_R^c, \quad \rho=\rho_L\oplus\rho_R\oplus\overline{\rho_L^c}\oplus\overline{\rho_R^c}.$$

In this representation the Dirac operator has the form

$$\mathcal{D}=\begin{pmatrix} 0 & \mathcal{M} & 0 & 0 \\ \mathcal{M}^* & 0 & 0 & 0 \\ 0 & 0 & 0 & \overline{\mathcal{M}} \\ 0 & 0 & \overline{\mathcal{M}^*} & 0 \end{pmatrix},$$

where $\mathcal{M}$ is the fermionic mass matrix connecting the left-handed and the right-handed fermions.

Connes' axioms, the decomposition of the Hilbert space, the representation and the Dirac operator allow a diagrammatic dipiction. As was shown in Refs. 6,8 this can be boiled down to simple arrows, which encode the intersection form and the fermionic mass matrix. From this information all the ingredients of the spectral triple can be recovered. For our purpose a simple arrow and a double arrow are sufficient. The arrows always point from right fermions (positive chirality) to left fermions (negative chirality). We may also restrict ourselves to the particle part, since the information of the antiparticle part is included by transposing the particle part. We will adopt the conventions of Ref. 8.

The *fluctuation* ${}^f\mathcal{D}$ of the Dirac operator $\mathcal{D}$ is given by a finite collection f of real numbers r_j and algebra automorphisms $\sigma_j\in\mathrm{Aut}(\mathcal{A})^e$ lifted to the Hilbert space $\mathcal{H}$ such that

$$^f\mathcal{D} := \sum_j r_j L(\sigma_j)\mathcal{D}L(\sigma_j)^{-1}, \quad r_j \in \mathbb{R}, \quad \sigma_j \in \mathrm{Aut}(\mathcal{A})^e,$$

where the Lift is given by

$$L(\sigma) = \rho(u)J\rho(u)J^{-1}.$$

The spectral action of this almost commutative spectral triple reduced to the finite part is a functional on the vector space of all fluctuated, finite Dirac operators,

$$V(^f\mathcal{D}) = \lambda\ \mathrm{tr}\left[(^f\mathcal{D})^4\right] - \frac{\mu^2}{2}\ \mathrm{tr}\left[(^f\mathcal{D})^2\right],$$

where λ and μ are positive constants.[1,9] Our task is to find the minima $\hat{}^f\mathcal{D}$ of this action and their spectra.

To classify the almost commutative spectral triples we will impose some extra conditions as in Ref. 8. We will require the spectral triples to be irreducible and nondegenerate according to the following definitions.

Definition 2.1: (i) A spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ is *degenerate* if the kernel of $\mathcal{D}$ contains a nontrivial subspace of the complex Hilbert space $\mathcal{H}$ invariant under the representation ρ on $\mathcal{H}$ of the real algebra $\mathcal{A}$.

(ii) A nondegenerate spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ is *reducible* if there is a proper subspace $\mathcal{H}_0 \subset \mathcal{H}$ invariant under the algebra $\rho(\mathcal{A})$ such that $(\mathcal{A},\mathcal{H}_0,\mathcal{D}|_{\mathcal{H}_0})$ is a nondegenerate spectral triple. If the triple is real, S^0-real and even, we require the subspace $\mathcal{H}_0$ to also be invariant under the real structure J, the S^0-real structure ϵ and under the chirality χ such that the triple $(\mathcal{A},\mathcal{H}_0,\mathcal{D}|_{\mathcal{H}_0})$ is again real, S^0-real and even.

Definition 2.2: The irreducible spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ is *dynamically nondegenerate* if all minima $\hat{}^f\mathcal{D}$ of the action $V(^f\mathcal{D})$ define a nondegenerate spectral triple $(\mathcal{A},\mathcal{H},\hat{}^f\mathcal{D})$ and if the spectra of all minima have no degeneracies other than the three kinematical degeneracies: left–right, particle–antiparticle, and color. Of course in the massless case there is no left–right degeneracy. We also suppose that the color degeneracies are protected by the little group. By this we mean that all eigenvectors of $\hat{}^f\mathcal{D}$ corresponding to the same eigenvalue are in a common orbit of the little group (and scalar multiplication and charge conjugation).

In physicists' language nondegeneracy excludes all models with pairwise equal fermion masses up to color degeneracy. Irreducibility tells us that the Krajewski diagrams, which we must find must not contain more arrows than strictly necessary to satisfy Connes' axioms, especially the Poincaré duality. The last requirement of Definition 2.2 means noncommutative color groups are unbroken. It ensures that the corresponding mass degeneracies are protected from quantum corrections.

III. THE MISSING DIAGRAMS

In this section we will present the diagrams missing in the proof for three algebras in Ref. 8. For every diagram only one representative model will be given. All the other models can be obtained by simply exchanging left with right and particles with antiparticles. On the diagrammatic side this is equivalent to changing the directions of all arrows or reflecting the diagram on its diagonal. Permutations of the algebras in the diagrams are neglected as well, since they lead to the same physical models with a different order of the particles. For every diagram there are several ways to connect the algebras by arrows in accordance with the consistency conditions of Table 1 in Ref. 6. With respect to this, the four diagrams are all computed in the same way and they all fall in the same way. The possibilities of complex conjugating an algebra representation are limited and yield no essentially new models. It should be obvious from the diagrams whether the matrix algebras are complex, real, or quaternionic. In all other cases the choice of the field will

not affect the calculations, so we will not specify the algebras explicitly. For the four missing diagrams, $\mathcal{A}_1$, $\mathcal{A}_2$, $\mathcal{A}_3$ denote the algebras, a, b, c their generic elements and k, ℓ, p the respective size of the matrices.

Diagram 1 yields the representation

$$\rho_L(a,b,c)=\begin{pmatrix} b\otimes 1_k & 0 & 0\\ 0 & c\otimes 1_k & 0\\ 0 & 0 & b\otimes 1_p\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} \overline{a}\otimes 1_k & 0 & 0\\ 0 & \overline{b}\otimes 1_k & 0\\ 0 & 0 & a\otimes 1_p\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 & 0\\ 0 & 1_p\otimes a & 0\\ 0 & 0 & 1_\ell\otimes \overline{c}\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_k\otimes a & 0 & 0\\ 0 & 1_\ell\otimes a & 0\\ 0 & 0 & 1_p\otimes \overline{c}\end{pmatrix}.$$

The mass matrix is

$$\mathcal{M}=\begin{pmatrix} M_1\otimes 1_k & 0 & 0\\ 0 & M_2\otimes 1_k & 0\\ 0 & 0 & M_3\otimes 1_p\end{pmatrix},\quad M_1,M_3\in M_{k\times\ell}(\mathbb{C}),\quad M_2\in M_{p\times\ell}(\mathbb{C}),$$

where all three algebras are $M_n(\mathbb{C})$. The fluctuations are

$${}^fM_1=\sum_j r_j v_j M_1 \overline{u_j}^{-1},\quad u_j\in U(\mathcal{A}_1),\quad v_j\in U(\mathcal{A}_2),$$

$${}^fM_2=\sum_j r_j w_j M_2 \overline{v_j}^{-1},\quad w_j\in U(\mathcal{A}_3),$$

$${}^fM_3=\sum_j r_j v_j M_3 u_j^{-1},$$

and the action $V(C_1,C_2,C_3)$ is, with $C_i:={}^fM_i^*{}^fM_i$ equal to

$$4k\left[\lambda\,\mathrm{tr}(C_1)^2-\tfrac{1}{2}\mu^2\,\mathrm{tr}(C_1)\right]+4k\left[\lambda\,\mathrm{tr}(C_2)^2-\tfrac{1}{2}\mu^2\,\mathrm{tr}(C_2)\right]+4p\left[\lambda\,\mathrm{tr}(C_3)^2-\tfrac{1}{2}\mu^2\,\mathrm{tr}(C_3)\right].$$

Counting neutrinos and imposing broken color to be commutative leaves only one case, $k=\ell=p=1$. The fluctuations decouple the ${}^fM_i$ so it is always possible to reach the absolute minimum of the Higgs potential and the triple is degenerate.

Diagram 2 falls in the same way.

Diagram 3 is degenerate in the commutative case and exhibits mass relations in the noncommutative case. The calculation runs along the lines of diagram 8 in Ref. 8.

Diagram 4 yields the representation

$$\rho_L(a,b,c)=\begin{pmatrix} c\otimes 1_k & 0\\ 0 & a\otimes 1_\ell\end{pmatrix},\quad \rho_R(a,b,c)=\begin{pmatrix} \overline{b}\otimes 1_k & 0 & 0\\ 0 & \overline{b}\otimes 1_k & 0\\ 0 & 0 & c\otimes 1_\ell\end{pmatrix},$$

$$\rho_L^c(a,b,c)=\begin{pmatrix} 1_p\otimes a & 0\\ 0 & 1_k\otimes b\end{pmatrix},\quad \rho_R^c(a,b,c)=\begin{pmatrix} 1_\ell\otimes a & 0 & 0\\ 0 & 1_\ell\otimes a & 0\\ 0 & 0 & 1_p\otimes b\end{pmatrix},$$

with possible complex conjugations here and there. The mass matrix is

$$\mathcal{M} = \begin{pmatrix} M_1 \otimes 1_k & M_2 \otimes 1_k & 0 \\ 0 & 0 & M_3 \otimes 1_\ell \end{pmatrix}, \quad M_1, M_2 \in M_{p\times\ell}(\mathbb{C}), \quad M_3 \in M_{k\times p}(\mathbb{C}).$$

The fluctuations are

$$^fM_1 = \sum_j r_j w_j M_1 \overline{v_j}^{-1}, \quad w_j \in U(\mathcal{A}_3), \quad v_j \in U(\mathcal{A}_2),$$

$$^fM_2 = \sum_j r_j w_j M_2 \overline{v_j}^{-1},$$

$$^fM_3 = \sum_j r_j u_j M_3 w_j^{-1}, \quad u_j \in U(\mathcal{A}_1),$$

and the action is

$$V(C_1, C_2, C_3) = 4k\left[\lambda\ \mathrm{tr}(C_1 + C_2)^2 - \tfrac{1}{2}\mu^2\ \mathrm{tr}(C_1 + C_2)\right] + 4p\left[\lambda\ \mathrm{tr}(C_3)^2 - \tfrac{1}{2}\mu^2\ \mathrm{tr}(C_3)\right].$$

The neutrino count and broken color imply $k=\ell=1$ and $p=1$ or $p=2$. The case $k=\ell=p=1$ is obviously degenerate.

For $k=\ell=1$, $p=2$ we have one neutrino. $^fM_3$ fluctuates independently and can be pushed into the absolute minimum of the Higgs potential. Let us set $^fM_1$ and $^fM_2$ into one matrix

$$^fM_{1,2} = \sum_j r_j w_j (M_1, M_2) \begin{pmatrix} \overline{v_j}^{-1} & 0 \\ 0 & \overline{v_j}^{-1} \end{pmatrix}.$$

Since the $\overline{v_j}^{-1} \in \mathbb{C}$ they commute with (M_1, M_2) and so

$$^fM_{1,2} = C(M_1, M_2),$$

where $C \in M_{2\times 2}(\mathbb{C})$ is an arbitrary matrix. M_1 must be linearly independent of M_2 because otherwise they would produce a second neutrino. It follows that (M_1, M_2) is invertible and we can choose C to be its inverse. In this way we reach the absolute minimum of the Higgs potential and the triple is degenerate.

IV. CONCLUSION

The new models discovered with help of the computer complete the proof for up to three algebras given in Ref. 8. We did not find anything of interest from the particle physics point of view but we gained confidence in our algorithm and it seems sensible to compute the case with four algebras.

Homogeneous superspaces arising from the general linear supergroup are studied within a Hopf algebraic framework. Spherical functions on homogeneous superspaces are introduced, and the structures of the superalgebras of the spherical functions on classes of homogeneous superspaces are described explicitly. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1868859]

I. INTRODUCTION

We study spherical functions on homogeneous superspaces arising from the complex general linear supergroup. This is the first part of our endeavour to develop a theory of spherical functions on Lie supergroups[8,13] and quantum supergroups.[12,28] The theory of spherical functions on ordinary Lie groups has long reached its maturity (see, e.g., Ref. 26). There also exists extensive literature on spherical functions[9,18,14,3,17] on quantum symmetric spaces.[10,17,3,4,11] However, little seems to be known about spherical functions on Lie supergroups, let alone those on quantum supergroups. On the other hand, supersymmetry and its quantum analogue have become an integral part of modern mathematical physics, and have also permeated many areas of pure mathematics. A good understanding of spherical functions on Lie supergroups and quantum supergroups should facilitate practical means for studying the dynamics of physical systems with classical or quantum supersymmetries.

We choose to work within a Hopf superalgebraic framework to study homogeneous superspaces, as it can incorporate both the Lie supergroup (as defined by Kostant[8]) and quantum supergroup[12,28] cases. Our methodology is similar to that adopted in the literature on quantum homogeneous spaces.[10,17,3,4,11] The starting point is the universal enveloping algebra $\mathrm{U}(\mathfrak{g})$ of the general linear superalgebra $\mathfrak{g}=\mathfrak{gl}(m|n,\mathbb{C})$, which is a cocommutative Hopf superalgebra.[15] A $\mathbb{Z}_2$-graded subalgebra $\mathbb{C}(G)$ (see Definition 3.1) of the dual of the universal enveloping algebra acquires a Hopf superalgebra structure, from which the general linear supergroup can be reconstructed[21] in a manner similar to the Tanakan–Krein theory for compact Lie groups. The universal enveloping algebra admits many Hopf $*$-superalgebra structures, each corresponding to a real form $\mathfrak{g}^{\sigma,\sqrt{i}}$ (see Sec. IV A for definition) of $\mathfrak{g}$. Each Hopf $*$-superalgebra structure θ of $\mathrm{U}(\mathfrak{g})$ induces a Hopf $*$-superalgebraic structure on $\mathbb{C}(G)$. We fix the θ corresponding to one of the compact real forms of $\mathfrak{g}$ [see Eq. (4.3)]. Let $\mathfrak{p}\subset\mathfrak{g}$ be a parabolic subalgebra with Levi factor $\mathfrak{l}$, and let $\mathfrak{k}=\mathfrak{l}\cap\mathfrak{g}^{\sigma,\sqrt{i}}$ be the real form of $\mathfrak{l}$. Then the $*$-subalgebra $\mathbb{C}(K\backslash G)$ of $\mathbb{C}(G)$ invariant with respect to $\mathfrak{k}$ under the left translation defines a homogeneous superspace[12] in the spirit of noncommutative geometry.[2] We shall call this superalgebra the superalgebra of functions on the homogeneous superspace. Next we consider the subspace $\mathbb{C}(K\backslash G/K)$ of $\mathbb{C}(K\backslash G)$ consisting of elements that are

a)Electronic mail: rzhang@maths.usyd.edu.au
b)Electronic mail: ymzou@uwm.edu

invariant with respect to $\mathfrak{k}$ under the right translation. It can be shown that $\mathbb{C}(K\backslash G/K)$ forms a $*$-superalgebra, which will be referred to as the superalgebra of spherical functions on the homogeneous superspace.

Our aim in the present paper is to understand the structures of the superalgebras $\mathbb{C}(K\backslash G)$ and $\mathbb{C}(K\backslash G/K)$. The main results obtained are Theorem 4.2, Lemma 4.5, and Lemma 4.6, which give explicit descriptions of the superalgebra of functions on the homogeneous superspace and the superalgebra of spherical functions. In the case of a homogeneous superspace associated to a maximal rank reductive subgroup of a compact real form of the general linear supergroup, the superalgebra of spherical functions is either the polynomial algebra in one variable or a quotient thereof (Theorems 5.1 and 5.2).

Recall that the space of functions on an ordinary Lie group has another natural algebraic structure with the multiplication defined by convolution. In this context, the counter parts of $\mathbb{C}(K\backslash G)$ and $\mathbb{C}(K\backslash G/K)$ form subalgebras under convolution, where the analogue of $\mathbb{C}(K\backslash G/K)$ is the celebrated Hecke algebra.[26] The Hecke algebras associated with Riemannian symmetric spaces are commutative, and their elements provide the invariant integral operators acting on functions on the symmetric spaces. It is an important problem to develop a theory for such Hecke algebras in the Lie supergroup context, and to investigate properties of supersymmetric spaces from the viewpoint of Hecke algebras. We plan to do this in a future publication, as the problem requires in-depth investigations into the analytical theory of Lie supergroups.

The organization of the paper is as follows. In Sec. II we provide some preliminary material on the complex general linear superalgebra and its invariant theory. In Sec. III we discuss the Hopf superalgebra of functions on the general linear supergroup, and explain how the general linear supergroup itself can be extracted from this Hopf superalgebra.[21] The material in this section is not all new, but it forms the basis for the study of homogeneous superspaces and spherical functions in later sections. Sections IV and V contain the main results of the paper. In Sec. IV A we discuss real forms of the complex general linear superalgebra and general linear supergroup from a Hopf algebraic point of view. The material presented here is largely new, and we believe it to be interesting in its own right. In Sec. IV B we explain the notion of homogeneous superspaces in a Hopf algebraic setting, and in Sec. IV C we investigate the superalgebras of spherical functions on the homogeneous superspaces. In Sec. V we analyze in detail the superalgebras of spherical functions on the projective superspace and other symmetric superspaces arising from maximal rank subgroups of real forms of the general linear supergroup.

II. PRELIMINARIES ON $\mathfrak{gl}(m|n,\mathbb{C})$

We present some background material on the universal enveloping superalgebra of the general linear Lie superalgebra, which will be used later. General references are Refs. 6 and 19.

We shall work on the complex number field $\mathbb{C}$ for simplicity. Let W be a superspace, i.e., a $\mathbb{Z}_2$-graded vector space $W=W_{\bar{0}}\oplus W_{\bar{1}}$, where $W_{\bar{0}}$ and $W_{\bar{1}}$ are the even and odd subspaces, respectively. The elements of $W_{\bar{0}}\cup W_{\bar{1}}$ will be called homogeneous. Define a map $[\ ]: W_{\bar{0}}\cup W_{\bar{1}}\to\mathbb{Z}_2$ by $[w]=\alpha$ if $w\in W_\alpha$. (Quite generally, whenever a symbol like $[w]$ appears in the sequel, it is tacitly assumed that the element w is homogeneous.) The dual superspace ($\mathbb{Z}_2$-graded dual vector space) of W will be denoted by W^*, and the dual space pairing $W^*\otimes W\to\mathbb{C}$ by $\langle,\rangle$.

Denote by $\mathfrak{g}$ the Lie superalgebra $\mathfrak{gl}(m|n,\mathbb{C})$. A standard basis for $\mathfrak{g}$ is $\{E_{ab}|a,b\in\mathbf{I}\}$, where $\mathbf{I}=\{1,2,\ldots,m+n\}$ The element E_{ab} belongs to $\mathfrak{g}_{\bar{1}}$ if $a\leqslant m<b$, or $b\leqslant m<a$, and belongs to $\mathfrak{g}_{\bar{0}}$ otherwise. For convenience, we define the map

$$[\ ]:\mathbf{I}\to\mathbb{Z}_2 \text{ by } [a]=\begin{cases}\bar{0} & \text{if } a\leqslant m,\\ \bar{1} & \text{if } a>m.\end{cases}$$

Then $[E_{ab}]=[a]+[b]$. The supercommutation relations of the Lie superalgebra are given for the basis elements by

$$[E_{ab},E_{cd}] = E_{ad}\delta_{bc} - (-1)^{([a]-[b])([c]-[d])}E_{cb}\delta_{ad}.$$

As usual, we choose the Cartan subalgebra $\mathfrak{h} = \oplus_a \mathbb{C}E_{aa}$. Let $\{\epsilon_a | a \in \mathbf{I}\}$ be the basis of $\mathfrak{h}^*$ such that $\epsilon_a(E_{bb}) = \delta_{ab}$. The space h^* is equipped with a bilinear form $(,):\mathfrak{h}^* \times \mathfrak{h}^* \to \mathbb{C}$ such that $(\epsilon_a, \epsilon_b) = (-1)^{[a]}\delta_{ab}$. The roots of $\mathfrak{g}$ are $\epsilon_a - \epsilon_b$, $a \neq b$, where $\epsilon_a - \epsilon_b$ is even if $[a]+[b]=\overline{0}$ and odd otherwise. We choose as positive roots the elements of $\{\epsilon_a - \epsilon_b | a < b\}$, and as simple roots the elements of $\{\epsilon_a - \epsilon_{a+1} | a < m+n\}$.

The enveloping algebra $\mathrm{U}(\mathfrak{gl}(m|n,\mathbb{C}))$ of $\mathfrak{gl}(m|n,\mathbb{C})$ will be denoted by $\mathrm{U}(\mathfrak{g})$. We shall always regard $\mathfrak{g}$ as embedded in $\mathrm{U}(\mathfrak{g})$ in the natural way. As is well known, $\mathrm{U}(\mathfrak{g})$ forms a $\mathbb{Z}_2$-graded cocommutative Hopf algebra (i.e., a Hopf superalgebra) in the sense of Ref. 15, with

$$\text{comultiplication, } \Delta : \mathrm{U}(\mathfrak{g}) \to \mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g}), \quad \Delta(X) = X \otimes 1 + 1 \otimes X, \quad X \in \mathfrak{g},$$

$$\text{counit, } \quad \epsilon : \mathrm{U}(\mathfrak{g}) \to \mathbb{C}, \quad \epsilon(X) = 0, \quad X \in \mathfrak{g},$$

$$\text{antipode, } \quad S : \mathrm{U}(\mathfrak{g}) \to \mathrm{U}(\mathfrak{g}), \quad S(X) = -X, \quad X \in \mathfrak{g}.$$

In particular, this Hopf superalgebra structure allows us to introduce a natural left $\mathrm{U}(\mathfrak{g})$-module structure on the dual superspace W^* of any left $\mathrm{U}(\mathfrak{g})$-module W, with the $\mathrm{U}(\mathfrak{g})$-action given by

$$U(\mathfrak{g}) \otimes W^* \to W^*, \quad x \otimes \overline{w} \mapsto x\overline{w},$$

$$\langle x\overline{w}, v\rangle := (-1)^{[x][w]}\langle \overline{w}, S(x)v\rangle, \quad \forall\, v \in W.$$

As it stands, the last equation only makes sense for homogeneous $\overline{w} \in W^*$ and homogeneous $x \in \mathrm{U}(\mathfrak{g})$, but it can be extended to all elements of W^* and $\mathrm{U}(\mathfrak{g})$ linearly.

We shall denote by L_λ the irreducible left $\mathrm{U}(\mathfrak{g})$-module with highest weight $\lambda \in \mathfrak{h}^*$. The module L_λ is finite-dimensional if and only if λ is dominant,[7,19] i.e.,

$$2(\lambda, \epsilon_a - \epsilon_{a+1})/(\epsilon_a - \epsilon_{a+1}, \epsilon_a - \epsilon_{a+1}) \in \mathbb{Z}_+ \quad \forall\, a \neq m. \tag{2.1}$$

A basic problem in the representation theory of Lie superalgebras is to understand the weight space decompositions of the finite dimensional irreducible representations. However, the problem turned out to be unexpectedly difficult, resisting solution for some 20 years. Only a few years ago, Serganova[22] succeeded in developing an algorithm to compute formal characters of irreducible representations.

Of particular importance to us here is the contravariant vector module $V = L_{\epsilon_1}$ of $\mathfrak{g}$. It has the standard basis $\{v_a | a \in \mathbf{I}\}$ such that $E_{ab}v_c = \delta_{bc}v_a$, where v_a is even if $a \leqslant m$, and odd otherwise. The dual module V^* of V is the covariant vector module with highest weight $-\epsilon_{m+n}$. It has a basis $\{\overline{v_a} | a \in \mathbf{I}\}$ dual to the standard basis of V, i.e., $\langle \overline{v_a}, v_b\rangle = \delta_{ab}$. The action of $\mathfrak{g}$ on V^* is given by

$$E_{ab}\overline{v_c} = -(-1)^{[a]+[a][b]}\delta_{ac}\overline{v_b}. \tag{2.2}$$

As the antipode of $\mathrm{U}(\mathfrak{g})$ is of order two, there is a $\mathrm{U}(\mathfrak{g})$-module isomorphism between V and its double dual $V^{**} := (V^*)^*$,

$$V \cong V^{**}, \quad v \mapsto v^{**},$$

$$\langle v^{**}, \overline{w}\rangle = (-1)^{[v]}\langle \overline{w}, v\rangle, \quad \forall\, \overline{w} \in V^*.$$

Remark 2.1: (Reference 27) For all $d > 0$, $V^{\otimes d}$ is a semisimple $\mathrm{U}(\mathfrak{g})$-module, which does not contain any one-dimensional submodule.

Let $\mathfrak{S}_d$ be the symmetric group on d letters. There exists a natural action ρ_d of $\mathfrak{S}_d$ on $V^{\otimes d}$ defined in the following way. Let s_i denote the permutation $(i, i+1)$. Then

$$\rho_d(s_i)(v_{a_1} \otimes \cdots \otimes v_{a_{i-1}} \otimes v_{a_i} \otimes v_{a_{i+1}} \otimes v_{a_{i+2}} \cdots \otimes v_{a_d})$$
$$= (-1)^{[a_i][a_{i+1}]} v_{a_1} \otimes \cdots \otimes v_{a_{i-1}} \otimes v_{a_{i+1}} \otimes v_{a_i} \otimes v_{a_{i+2}} \cdots \otimes v_{a_d}.$$

Let us denote by t^d the representation of $\mathrm{U}(\mathfrak{g})$ in $V^{\otimes d}$, and denote by $\mathbb{C}\mathfrak{S}_d$ the group algebra of $\mathfrak{S}_d$. The following result was first proven by Sergeev[24,25] (see Ref. 1 for a detailed treatment).

Theorem 2.1: *The superalgebras* $t^d(\mathrm{U}(\mathfrak{g}))$ *and* $\rho_d(\mathbb{C}\mathfrak{S}_d)$ *are mutual centralizers in* $\mathrm{End}_{\mathbb{C}}(V^{\otimes d})$.

Let W be a finite dimensional $\mathrm{U}(\mathfrak{g})$-module. Let $\pi: \mathrm{U}(\mathfrak{g}) \to \mathrm{End}_{\mathbb{C}}(\mathrm{W})$ be the $\mathrm{U}(\mathfrak{g})$-representation furnished by W. Then $\mathrm{End}_{\mathbb{C}}(\mathrm{W})$ acquires a natural $\mathrm{U}(\mathfrak{g})$-module structure under the action

$$\mathrm{U}(\mathfrak{g}) \otimes \mathrm{End}_{\mathbb{C}}(\mathrm{W}) \to \mathrm{End}_{\mathbb{C}}(\mathrm{W}), \quad x \otimes \phi \mapsto \mathrm{Ad}_x(\phi),$$

$$\mathrm{Ad}_x(\phi) := \sum_{(x)} (-1)^{[x_{(2)}][\phi]} \pi(x_{(1)}) \phi \pi(S(x_{(2)})) \ ,$$

where we have used Sweedler's notation $\Delta(x) = \Sigma_{(x)} x_{(1)} \otimes x_{(2)}$ for the comultiplication of $x \in \mathrm{U}(\mathfrak{g})$. There exists the natural isomorphism $j: W \otimes W^* \cong \mathrm{End}_{\mathbb{C}}(\mathrm{W})$ of $\mathrm{U}(\mathfrak{g})$ modules defined, for any $u \otimes \overline{v} \in W \otimes W^*$ and $w \in W$, by

$$j(u \otimes \overline{v})(w) = \langle \overline{v}, w \rangle u.$$

For any $\mathrm{U}(\mathfrak{g})$-module M, we use the notation $(M)^{\mathrm{U}(\mathfrak{g})}$ to denote the invariant submodule

$$(M)^{\mathrm{U}(\mathfrak{g})} := \{w \in M | xw = \epsilon(x)w, \quad \forall\, x \in \mathrm{U}(\mathfrak{g})\}.$$

We have

$$(W \otimes W^*)^{\mathrm{U}(\mathfrak{g})} \cong \mathrm{End}_{\mathrm{U}(\mathfrak{g})}(\mathrm{W}) := \{\phi \in \mathrm{End}_{\mathbb{C}}(W) | \mathrm{Ad}_x(\phi) = \epsilon(x)\phi, \forall\, x \in \mathrm{U}(\mathfrak{g})\}. \tag{2.3}$$

Consider $V^{\otimes k} \otimes (V^*)^{\otimes \ell}$ as a $\mathrm{U}(\mathfrak{g})$-module, where the $\mathrm{U}(\mathfrak{g})$-action is defined by using the comultiplication. The element $Z = \Sigma_a E_{aa}$ acts on $V^{\otimes k} \otimes (V^*)^{\otimes \ell}$ by $(k-\ell)\mathrm{id}$. This immediately shows that

$$(V^{\otimes k} \otimes (V^*)^{\otimes \ell})^{\mathrm{U}(\mathfrak{g})} = \{0\} \quad \text{if } k \neq \ell. \tag{2.4}$$

As $(V^{\otimes d})^* \cong (V^*)^{\otimes d}$, we have the $\mathrm{U}(\mathfrak{g})$-module isomorphism

$$j: V^{\otimes d} \otimes (V^*)^{\otimes d} \to \mathrm{End}_{\mathbb{C}}(V^{\otimes d}).$$

It follows from Theorem 2.1 that the even subspace of $(V^{\otimes d} \otimes (V^*)^{\otimes d})^{\mathrm{U}(\mathfrak{g})}$ is isomorphic to $j^{-1} \circ \rho_d(\mathbb{C}\mathfrak{S}_d)$. Let $\mathfrak{g}_{\overline{0}} = \mathfrak{gl}(m) \oplus \mathfrak{gl}(n)$ be the maximal even subalgebra of $\mathfrak{g}$. Both V and V^* naturally restrict to $\mathfrak{g}_{\overline{0}}$-modules. By using Weyl's first fundamental theorem for the invariant theory of the general linear group,[5] we easily prove that $(V^{\otimes d} \otimes (V^*)^{\otimes d})^{\mathrm{U}(\mathfrak{g}_{\overline{0}})}$ is contained in the even subspace of $V^{\otimes d} \otimes (V^*)^{\otimes d}$. Since

$$(V^{\otimes d} \otimes (V^*)^{\otimes d})^{\mathrm{U}(\mathfrak{g}_{\overline{0}})} \supset (V^{\otimes d} \otimes (V^*)^{\otimes d})^{\mathrm{U}(\mathfrak{g})},$$

we have

$$(V^{\otimes d} \otimes (V^*)^{\otimes d})^{\mathrm{U}(\mathfrak{g})} = j^{-1} \circ \rho_d(\mathbb{C}\mathfrak{S}_d). \tag{2.5}$$

This result may be stated more explicitly as follows.

Theorem 2.2: (Reference 25) *The vector space* $(V^{\otimes d} \otimes (V^*)^{\otimes d})^{\mathrm{U}(\mathfrak{g})}$ *is spanned by the following elements:*

$$\sum_{a_1,\ldots,a_d} \mathrm{sgn}(\sigma, a_1, \ldots, a_d) \otimes v_{a_{\sigma(1)}} \otimes v_{a_{\sigma(2)}} \otimes \ \ldots \ \otimes v_{a_{\sigma(d)}} \otimes \overline{v}_{a_d} \otimes \overline{v}_{a_{d-1}} \otimes \ \ldots \overline{v}_{a_1}, \quad \forall\, \sigma \in \mathfrak{S}_d, \tag{2.6}$$

where $\mathrm{sgn}(\sigma,a_1,\ldots,a_d)$ *is a sign factor which is determined by the restriction of* σ *on the subset of odd indices in* $\{a_1,\ldots,a_d\}$ *in such a way that if the restriction is even then* $\mathrm{sgn}(\sigma,a_1,\ldots,a_d)$ *is* 1 *and* -1 *otherwise*.

We shall refer to both Theorems 2.1 and 2.2 as the first fundamental theorem of the invariant theory of the general linear supergroup.

III. SUPERALGEBRAS OF FUNCTIONS ON THE GENERAL LINEAR SUPERGROUP

We examine properties of the Hopf superalgebra of regular functions on the general linear supergroup in this section. The material presented here is of critical importance for setting up the framework for studying spherical functions. Some of the material can be extracted from Refs. 20 and 21.

Let $\mathrm{U}(\mathfrak{g})^0 := \{f \in \mathrm{U}(\mathfrak{g})^* \,|\, \ker f$ contains a cofinite $\mathbb{Z}_2$- graded ideal of $\mathrm{U}(\mathfrak{g})\}$ be the finite dual[16] of the universal enveloping algebra $\mathrm{U}(\mathfrak{g})$ of $\mathfrak{g}$. Standard Hopf algebra theory[15,16] asserts that the Hopf superalgebra structure of $\mathrm{U}(\mathfrak{g})$ induces a Hopf superalgebra structure on $\mathrm{U}(\mathfrak{g})^0$. Denote by $m_\circ$, $\Delta_\circ$, $\epsilon_\circ$, and $S_\circ$ the multiplication, comultiplication, counit, and antipode of $\mathrm{U}(\mathfrak{g})^0$, respectively. The maps are defined for all $f,\ \mathfrak{g} \in \mathrm{U}(\mathfrak{g})^0$, and $a,\ b \in \mathrm{U}(\mathfrak{g})$, by

$$\langle m_\circ(f \otimes g), a\rangle = \langle f \otimes g, \Delta(a)\rangle,$$

$$\langle \Delta_\circ(f), a \otimes b\rangle = \langle f, ab\rangle,$$

$$\langle S_\circ(f), a\rangle = \langle f, S(a)\rangle,$$

and $\mathbb{1}_{\mathrm{U}(\mathfrak{g})^0} = \epsilon$, $\epsilon_\circ = \mathbb{1}_{\mathrm{U}(\mathfrak{g})}$. Because $\mathrm{U}(\mathfrak{g})$ is supercocommutative, $\mathrm{U}(\mathfrak{g})^0$ is supercommutative. Recall that $S^2 = \mathrm{id}$ and hence also $S_\circ^2 = \mathrm{id}$. For convenience, we shall drop the subscript 0 from the notations for the multiplication, comultiplication, and antipode of $\mathrm{U}(\mathfrak{g})^0$.

Let π be a $\mathrm{U}(\mathfrak{g})$-representation of dimension $d < \infty$. Now for any $x \in \mathrm{U}(\mathfrak{g})$, $\pi(x)$ is a $d \times d$-matrix. We define a set of elements $\pi_{ij} \in \mathrm{U}(\mathfrak{g})^*$, $i,j = 1,2,\ldots,d$, by

$$\pi(x) = (\pi_{ij}(x))_{i,j=1}^{d}, \quad \forall\, x \in \mathrm{U}(\mathfrak{g}).$$

The π_{ij} will be called the matrix elements of π. It is easy to see that the matrix elements of every finite-dimensional representation of $\mathrm{U}(\mathfrak{g})$ belong to $\mathrm{U}(\mathfrak{g})^0$. Conversely, $\mathrm{U}(\mathfrak{g})^0$ is spanned by the matrix elements of all the finite-dimensional representations of $\mathrm{U}(\mathfrak{g})$. To see this, we only need to consider an arbitrary nonzero element $f \in \mathrm{U}(\mathfrak{g})^0$. Let Ker be a graded cofinite ideal of $\mathrm{U}(\mathfrak{g})$ contained in the kernel of f. Then $\mathrm{U}(\mathfrak{g})/\mathrm{Ker}$ forms a left $\mathrm{U}(\mathfrak{g})$-module,

$$\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})/\mathrm{Ker} \to \mathrm{U}(\mathfrak{g})/\mathrm{Ker},$$

$$y \otimes (x + \mathrm{Ker}) \mapsto yx + \mathrm{Ker}.$$

Let $\{x_i + \mathrm{Ker}\}$ be a basis of $\mathrm{U}(\mathfrak{g})/\mathrm{Ker}$, and denote by f_{ij} the matrix elements of the associated representation relative to this basis. Choose a set of complex numbers $c_i \in \mathbb{C}$ such that $\mathbb{1}_{\mathrm{U}(\mathfrak{g})} + \mathrm{Ker} = \Sigma_i c_i x_i + \mathrm{Ker}$, where the set $\mathbb{1}_{\mathrm{U}(\mathfrak{g})} + \mathrm{Ker}$ is not contained in the kernel of f since $f \neq 0$. Then $f = \Sigma_{i,j} c_i \langle f, x_j\rangle f_{ji}$.

We denote by t the $\mathrm{U}(\mathfrak{g})$-representation associated with the contravariant vector module $V = L_{\epsilon_1}$ in the standard basis, and denote its matrix elements by $t_{ab} \in \mathrm{U}(\mathfrak{g})^0$, $a,b \in \mathbf{I}$, where t_{ab} is even if $[a]+[b] = \overline{0}$, and odd otherwise. Note that

$$t_{ab}(E_{cd}) = \delta_{ac}\delta_{bd}.$$

Denote by $\overline{t}$ the covariant vector representation of $\mathrm{U}(\mathfrak{g})$ relative to the basis $\{\overline{v_a} \,|\, a \in \mathbf{I}\}$. Let $\overline{t_{ab}} \in \mathrm{U}(\mathfrak{g})^0$, $a,b \in \mathbf{I}$, be the matrix elements of $\overline{t}$. Then

$$\overline{t}_{ab}(E_{cd}) = -(-1)^{[a][b]+[b]}\delta_{bc}\delta_{ad}.$$

Note that $\overline{t}_{ab}$ is even if $[a]+[b]=\overline{0}$, and odd otherwise.

Definition 3.1: (Reference 20) Let $\mathbb{C}(G)$ be the subsuperalgebra of $\mathrm{U}(\mathfrak{g})^0$ generated by $\{t_{ab}, \overline{t}_{ab} | a, b \in \mathbf{I}\}$.

The following relations hold in $\mathbb{C}(G)$:

$$\sum_c t_{ac}\overline{t}_{bc}(-1)^{[c][a]+[b]} = \delta_{ab}, \quad \sum_c \overline{t}_{ca}t_{cb}(-1)^{[b][c]+[c]} = \delta_{ab}, \tag{3.1}$$

because t and $\overline{t}$ are dual representations of $\mathrm{U}(\mathfrak{g})$. More precisely, the first relation states that the canonical tensor $\Sigma_c v_c \otimes \overline{v}_c \in V \otimes V^*$ is $\mathrm{U}(\mathfrak{g})$-invariant, while the second relation means that the dual pairing $\langle , \rangle$: $V^* \otimes V \to \mathbb{C}$ is a $\mathrm{U}(\mathfrak{g})$-module homomorphism.

$\mathbb{C}(G)$ has a bisuperalgebra structure, with the comultiplication defined by

$$\Delta(t_{ab}) = \sum_{c \in \mathbf{I}} (-1)^{([c]-[a])([c]-[b])} t_{ac} \otimes t_{cb},$$

$$\Delta(\overline{t}_{ab}) = \sum_{c \in \mathbf{I}} (-1)^{([c]-[a])([c]-[b])} \overline{t}_{ac} \otimes \overline{t}_{cb}.$$

Let us also denote by S the antipode of $\mathrm{U}(\mathfrak{g})^0$. By using the definition of dual modules we can show that

$$S(t_{ab}) = (-1)^{[a][b]+[a]}\overline{t}_{ba}, \quad S(\overline{t}_{ab}) = (-1)^{[a][b]+[b]} t_{ba}. \tag{3.2}$$

The following result was proven in Ref. 20.

Proposition 3.1: (Reference 20) *(1)* $\mathbb{C}(G)$ *forms a Hopf sub-superalgebra of* $\mathrm{U}(\mathfrak{g})^0$. *(2)* $\mathbb{C}(G)$ *is dense in* $\mathrm{U}(\mathfrak{g})^*$ *in the following sense: for every nonzero element* $x \in \mathrm{U}(\mathfrak{g})$, *there exists some* $f \in \mathbb{C}(G)$ *such that* $\langle f, x \rangle \neq 0$.

Let Λ denote a finite-dimensional Grassmann algebra. Recall that the general linear supergroup $\mathrm{GL}(m|n, \Lambda)$ over Λ is the group of even invertible $(m+n)\times(m+n)$-matrices with entries in Λ. It was shown in Ref. 21 that $\mathrm{GL}(m|n, \Lambda)$ can be reconstructed from $\mathbb{C}(G)$ in the following way. The $\mathbb{Z}_2$-graded vector space $\mathrm{Hom}_{\mathbb{C}}(\mathbb{C}(G), \Lambda)$ has a natural superalgebra structure, with the multiplication defined for any ϕ and ψ by

$$(\phi\psi)(f) \coloneqq \sum_{(f)} (-1)^{[f_{(1)}][\psi]} \phi(f_{(1)}) \psi(f_{(2)}), \quad \forall f \in \mathbb{C}(G), \tag{3.3}$$

where we have used Sweedler's notation expressing the comultiplication $\Delta(f)$ of any $f \in \mathbb{C}(G)$ by $\Sigma_{(f)} f_{(1)} \otimes f_{(2)}$.

Theorem 3.1: (Reference 21) *Let* $G_{\mathbb{C}} \coloneqq \{$*superalgebra homomorphisms* $\mathbb{C}(G) \to \Lambda\}$. *Then with the multiplication defined by (3.3), the set* $G_{\mathbb{C}}$ *forms a group, which is isomorphic to* $\mathrm{GL}(m|n, \Lambda)$.

We shall not repeat the proof of the theorem here, but merely point out that the inverse α^{-1} of any element $\alpha \in G_{\mathbb{C}}$ is given by $\alpha^{-1}(f) = \alpha(S(f))$, for all $f \in \mathbb{C}(G)$.

We shall refer to the elements of $\mathbb{C}(G)$ as the regular functions on the general linear supergroup. We now consider their properties. Note that there exists two natural left actions dR and dL of $\mathrm{U}(\mathfrak{g})$ on $\mathbb{C}(G)$, respectively, corresponding to the left and right translations. For all $x \in \mathrm{U}(\mathfrak{g})$, $f \in \mathbb{C}(G)$,

$$\mathrm{d}R_x(f) = \sum_{(f)} (-1)^{[x][f]} f_{(1)} \langle f_{(2)}, x \rangle,$$

$$\mathrm{d}L_x(f) = \sum_{(f)} (-1)^{[x]} \langle f_{(1)}, S(x) \rangle f_{(2)}. \tag{3.4}$$

Equivalently, the equations in (3.4) can be rewritten in the form

$$\langle \mathrm{d}R_x(f), y \rangle = (-1)^{[x]([f]+[y])} \langle f, yx \rangle, \quad \langle \mathrm{d}L_x(f), y \rangle = (-1)^{[x][f]} \langle f, S(x)y \rangle, \tag{3.5}$$

for all $x, y \in \mathrm{U}(\mathfrak{g})$ and $f \in \mathbb{C}(G)$. Straightforward calculations show that each of $\mathrm{d}L$ and $\mathrm{d}R$ indeed converts $\mathbb{C}(G)$ into a (graded) left $\mathrm{U}(\mathfrak{g})$-module. With respect to this module structure the product map of $\mathbb{C}(G)$ is a $\mathrm{U}(\mathfrak{g})$-module homomorphism, and the unit element of $\mathbb{C}(G)$ is $\mathrm{U}(\mathfrak{g})$-invariant. Take $\mathrm{d}L$ as an example, we have

$$\sum_{(x)} (-1)^{[x_{(2)}][f]} \mathrm{d}L_{x_{(1)}}(f) \otimes \mathrm{d}L_{x_{(1)}}(g) \mapsto \mathrm{d}L_x(fg), \quad \forall\, f, g \in \mathrm{U}(\mathfrak{g})^0, \quad x \in \mathrm{U}(\mathfrak{g}),$$

$$\mathrm{d}L_x(\epsilon) = \epsilon(x)\epsilon, \quad \forall\, x \in \mathrm{U}(\mathfrak{g}). \tag{3.6}$$

This is saying that each of the actions $\mathrm{d}L$ and $\mathrm{d}R$ converts $\mathbb{C}(G)$ into a left $\mathrm{U}(\mathfrak{g})$-module superalgebra.[16] The two actions supercommute as can be easily checked. Thus $\mathbb{C}(G)$ forms a left $\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})$-module algebra, with the action

$$(x \otimes y) f = \mathrm{d}L_x\, \mathrm{d}R_y(f), \quad \forall\, x, y \in \mathrm{U}(\mathfrak{g}), \quad f \in \mathbb{C}(G).$$

The fact that the product map in $\mathbb{C}(G)$ is a module homomorphism means that the operators $\mathrm{d}R_x$ and $\mathrm{d}L_x$ behave as some sort of generalized superderivations. In particular, if $x \in \mathfrak{g}$, they are superderivations.

To better understand the structure of $\mathbb{C}(G)$, we let $X = V \otimes V^*$ and $\overline{X} = V^* \otimes V$. Using the standard bases of V and V^* we manufacture the bases $\{x_{ab} := v_b \otimes \overline{v_a}\}$ and $\{\overline{x_{ab}} := \overline{v_b} \otimes v_a\}$ for X and $\overline{X}$, respectively. Denote by $\mathbb{C}[X, \overline{X}]$ the $\mathbb{Z}_2$-graded symmetric algebra of $X \oplus \overline{X}$. Then $\mathbb{C}[X, \overline{X}]$ as an associative superalgebra can be described more explicitly as generated by x_{ab}, $\overline{x_{ab}}$, $a, b \in \mathbf{I}$, subject to the relations

$$x_{ab} x_{cd} = (-1)^{([b]-[a])([d]-[c])} x_{cd} x_{ab},$$

$$x_{ab} \overline{x_{cd}} = (-1)^{([b]-[a])([c]-[d])} \overline{x_{cd}} x_{ab},$$

$$\overline{x_{ab}}\, \overline{x_{cd}} = (-1)^{([a]-[b])([c]-[d])} \overline{x_{cd}}\, \overline{x_{ab}}.$$

The generators x_{ab} and $\overline{x_{ab}}$ are even if $[a]+[b]=\overline{0}$, and odd otherwise. Stated differently, the $2(m^2+n^2)$ even generators generate a polynomial algebra, the $4mn$ odd generators generate a Grassmann algebra with the standard grading, and $\mathbb{C}[X, \overline{X}]$ is the tensor product of the two. Let $\mathcal{J}$ be the (graded) ideal of $\mathbb{C}[X, \overline{X}]$ generated by the following elements:

$$\sum_c x_{ac} \overline{x_{bc}} (-1)^{[c][a]+[b]} - \delta_{ab}, \quad \sum_c \overline{x_{ca}} x_{cb} (-1)^{[b][c]+[c]} - \delta_{ab}, \quad a, b \in \mathbf{I}. \tag{3.7}$$

We have the following theorem.

Theorem 3.2: (Reference 20) *The assignments* $x_{ab} \mapsto t_{ab}$, $\overline{x_{ab}} \mapsto \overline{t_{ab}}$, $a, b \in \mathbf{I}$ *specify a well-defined superalgebra isomorphism* $j: \mathbb{C}[X, \overline{X}]/\mathcal{J} \to \mathbb{C}(G)$.

Define two left $\mathrm{U}(\mathfrak{g})$-actions on $X \oplus \overline{X}$,

$$\Phi: \mathrm{U}(\mathfrak{g}) \otimes (X \oplus \overline{X}) \to X \oplus \overline{X}, \quad u \otimes w \mapsto \Phi(u) w,$$

$$\Psi: \mathrm{U}(\mathfrak{g}) \otimes (X \oplus \overline{X}) \to X \oplus \overline{X}, \quad u \otimes w \mapsto \Psi(u)w,$$

by

$$\Phi(u)(v_b \otimes \overline{v_a}) = (-1)^{[u]} uv_b \otimes \overline{v_a},$$

$$\Psi(u)(v_b \otimes \overline{v_a}) = (-1)^{[u][b]} v_b \otimes u\overline{v_a},$$

$$\Phi(u)(\overline{v_b} \otimes v_a) = (-1)^{[u]} u\overline{v_b} \otimes v_a,$$

$$\Psi(u)(\overline{v_b} \otimes v_a) = (-1)^{[u]([u]+[b])} \overline{v_b} \otimes uv_a, \quad u \in \mathrm{U}(\mathfrak{g}).$$

These actions supercommute, and can both be extended to left $\mathrm{U}(\mathfrak{g})$-actions on $\mathbb{C}[X, \overline{X}]$ by

$$\Phi(x)(p_1 p_2) = \sum (-1)^{[x_{(2)}][p_1]} (\Phi(x_{(1)})p_1)(\Phi(x_{(2)})p_2),$$

$$\Psi(x)(p_1 p_2) = \sum (-1)^{[x_{(2)}][p_1]} (\Psi(x_{(1)})p_1)(\Psi(x_{(2)})p_2),$$

where $p_1, p_2 \in \mathbb{C}[X, \overline{X}]$ and $x \in \mathrm{U}(\mathfrak{g})$. This gives rise to a $\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})$-module algebra structure on $\mathbb{C}[X, \overline{X}]$. Note that the $\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})$-action leaves the ideal $\mathcal{J}$ invariant. Thus we have the following proposition.

Proposition 3.2: *The map* $j: \mathbb{C}[X, \overline{X}]/\mathcal{J} \to \mathbb{C}(G)$ *of Theorem 2 is a* $\mathrm{U}(\mathfrak{g}) \otimes \mathrm{U}(\mathfrak{g})$*-module algebra isomorphism, with*

$$j((\Psi(x) \otimes \Phi(y))p) = (\mathrm{d}L_x \otimes \mathrm{d}R_y) j(p), \quad \forall\, x, y \in \mathrm{U}(\mathfrak{g}), \quad p \in \mathbb{C}[X, \overline{X}].$$

IV. HOMOGENEOUS SUPERSPACES AND SPHERICAL FUNCTIONS

Recall the following well-known fact in the context of classical homogeneous spaces: if H is a compact semisimple Lie group, and $H_{\mathbb{C}}$ is its complexification, then for any parabolic subgroup Q of $H_{\mathbb{C}}$, we have $H_{\mathbb{C}}/Q = H/R$, where R is the intersection of the Levi factor of Q with H. We shall imitate this construction in the algebraic setting for Lie supergroups. For this we need to discuss real forms of the complex general linear superalgebra and the general linear supergroup.

A. Real forms

Let us begin by briefly discussing the notion of Hopf $*$-superalgebras.[28] A $*$-superalgebraic structure on an associative superalgebra A is a conjugate linear anti-involution θ: $A \to A$: for all $x, y \in A$, $c, c' \in \mathbb{C}$,

$$\theta(cx + c'y) = \overline{c}\theta(x) + \overline{c'}\theta(y), \quad \theta(xy) = \theta(y)\theta(x), \quad \theta^2(x) = x.$$

Note that the second equation does not involve any sign factors as one would normally expect of superalgebras. We shall sometimes use the notation (A, θ) for the $*$-superalgebra A with the $*$-structure θ. Let (B, θ_1) be another associative $*$-superalgebra. Now $A \otimes B$ has a natural superalgebra structure, with the multiplication defined for any $a, a' \in A$ and $b, b' \in B$ by

$$(a \otimes b)(a' \otimes b') = (-1)^{[b][a']} aa' \otimes bb',$$

where $(-1)^{[b][a']}$ is the usual sign factor required for exchanging positions of odd elements. Furthermore, the following conjugate linear map,

$$\theta\star\theta_1: a\otimes b \mapsto (1\otimes\theta_1(b))(\theta(a)\otimes 1) = (-1)^{[a][b]}\theta(a)\otimes\theta_1(b), \tag{4.1}$$

defines a $*$-superalgebraic structure on $A\otimes B$.

Let us assume that A is a Hopf superalgebra with comultiplication Δ, counit ϵ and antipode S. If the $*$-superalgebraic structure θ satisfies

$$(\theta\star\theta)\Delta = \Delta\theta, \quad \theta\epsilon = \epsilon\theta,$$

then A is called a Hopf $*$-superalgebra. Now

$$\sigma := S\theta$$

satisfies $\sigma^2 = id_A$, as follows from the definition of the antipode.

Let A^0 denote the finite dual of A, which has a natural Hopf superalgebraic structure. We shall still use Δ and S to, respectively, denote the comultiplication and antipode of A^0, but write its counit as ϵ_o. If A is a Hopf $*$-superalgebra with the Hopf $*$-superalgebraic structure θ, then $\sigma = S\theta$ induces a map $\omega: A^0\to A^0$ defined for any $f\in A^0$ by

$$\langle\omega(f),x\rangle = \overline{\langle f,\sigma(x)\rangle}, \quad \forall\, x\in A. \tag{4.2}$$

Lemma 4.1: The map $\omega: A^0\to A^0$ defined by (4.2) gives rise to a Hopf $*$-superalgebraic structure on A^0.

Proof: It is clear that ω is conjugate linear. Also, $\sigma^2 = \mathrm{id}_A$ implies $\omega^2 = \mathrm{id}_{A^0}$. For all $f,g\in A^0$, $x,y\in A$, we have

$$\begin{aligned}\langle\omega(fg),x\rangle &= \overline{\langle fg,\sigma(x)\rangle} = \overline{\langle f\otimes g,(S\otimes S)(\theta\star\theta)\Delta'(x)\rangle}\\ &= (-1)^{[f][g]}\langle\omega(f)\otimes\omega(g),\Delta'(x)\rangle = \langle\omega(g)\omega(f),x\rangle,\end{aligned}$$

that is, $\omega(fg)=\omega(g)\omega(f)$. Define $\omega\star\omega$ as in (4.1), we have

$$\begin{aligned}\langle(\omega\star\omega)\Delta(f),x\otimes y\rangle &= (-1)^{[x][y]}\overline{\langle\Delta(f),\sigma(x)\otimes\sigma(y)\rangle} = \overline{\langle f,\sigma(xy)\rangle}\\ &= \langle\omega(f),xy\rangle = \langle\Delta\omega(f),x\otimes y\rangle,\end{aligned}$$

that is $(\omega\star\omega)\Delta(f)=\Delta\omega(f)$. It is easy to show that ω also satisfies all the other minor requirements to qualify as a Hopf $*$-superalgebraic structure on A^0. ■

The universal enveloping algebra of the general linear superalgebra admits many Hopf $*$-superalgebraic structures. Let us fix one Hopf $*$-superalgebraic structure θ: $\mathrm{U}(\mathfrak{g})\to\mathrm{U}(\mathfrak{g})$ here. As $\mathfrak{g}$ is canonically embedded in $\mathrm{U}(\mathfrak{g})$, the restriction of θ to $\mathfrak{g}$ defines a conjugate anti-involution of the Lie superalgebra. Let $\mathfrak{g}_0^{\sigma}$ and $\mathfrak{g}_1^{\sigma}$ be the fixed point sets of $\mathfrak{g}_0$ and $\mathfrak{g}_1$ under σ, respectively. Let $\mathfrak{g}^{\sigma,\sqrt{i}}\subset\mathfrak{g}$ be the real span of $\mathfrak{g}_0^{\sigma}\cup\sqrt{i}\mathfrak{g}_1^{\sigma}$. Then $\mathfrak{g}^{\sigma,\sqrt{i}}$ forms a real Lie superalgebra, which is a real form of $\mathfrak{g}$. However, note that the σ-invariants of $\mathfrak{g}$ do not form a real subalgebra of $\mathfrak{g}$ if $\mathfrak{g}_1^{\sigma}$ is nontrivial. This is the reason for us to consider $\mathfrak{g}^{\sigma,\sqrt{i}}$ instead.

Denote by $\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}})$ the real universal enveloping algebra of $\mathfrak{g}^{\sigma,\sqrt{i}}$, which is embedded in $\mathrm{U}(\mathfrak{g})$ in the natural way. Furthermore,

$$\mathrm{U}(\mathfrak{g}) = \mathbb{C}\otimes_{\mathbb{R}}\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}}).$$

By Lemma 4.1, the Hopf $*$-superalgebraic structure θ induces a Hopf $*$-superalgebraic structure ω: $\mathbb{C}(G)\to\mathbb{C}(G)$ on $\mathbb{C}(G)$. By using the embedding of the real associative superalgebra $\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}})$ in $\mathrm{U}(\mathfrak{g})$, we can see that $f\in\mathbb{C}(G)$ vanishes if and only if $\langle f,x\rangle=0$, for all $x\in\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}})$. Therefore elements of $\mathbb{C}(G)$ can be considered as complex valued functionals on the real superalgebra $\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}})$. From this point of view, we should interpret $\mathbb{C}(G)$ as the $*$-superalgebra of functions on some real supergroup G. Now let us make this discussion more precise.

Let Λ be the complex Grassmann algebra introduced in Sec. III. Let $^-: \Lambda\to\Lambda$ be a complex conjugation operation on supernumbers [i.e., $(\Lambda, ^-)$ is a $*$-superalgebra]. Theorem 3.1 shows that

all the superalgebra homomorphisms $\mathbb{C}(G)\to\Lambda$ form a supergroup G_{C}, which is isomorphic to $\mathrm{GL}(m|n,\Lambda)$. A homomorphism α: $\mathbb{C}(G)\to\Lambda$ will be called a $*$-superalgebra homomorphism if it preserves the $*$-superalgebraic structures in the sense that $\alpha(\omega(f))=\overline{\alpha(f)}$, for all $f\in\mathbb{C}(G)$. The following result can be easily proven.

Lemma 4.2: If an element α of G_{C} is a $*$-superalgebra homomorphism, then its inverse is also a $*$-superalgebra homomorphism. The product of any two $*$-superalgebra homomorphisms in G_{C} is again a $*$-superalgebra homomorphism.

Proof: We shall prove the first statement only. The second one can be shown in a similar way. Recall that the inverse of $\alpha\in G_{\mathrm{C}}$ is defined by

$$\langle\alpha^{-1},f\rangle=\langle\alpha,S(f)\rangle,\quad\forall\, f\in\mathbb{C}(G).$$

Now if α is a $*$-superalgebra homomorphism, then for all $f\in\mathbb{C}(G)$,

$$\langle\alpha^{-1},\omega(f)\rangle=\langle\alpha,S\omega(f)\rangle=\overline{\langle\alpha,S(f)\rangle}=\overline{\langle\alpha^{-1},f\rangle}.$$

This shows that α^{-1} is indeed a $*$-superalgebra homomorphism. ■

Introduce the map $\check{\theta}$: $G_{\mathrm{C}}\to G_{\mathrm{C}}$ defined by

$$\langle\check{\theta}(\alpha),f\rangle=\overline{\langle\alpha,\omega S(f)\rangle},\quad\forall\, f\in\mathbb{C}(G).$$

We need to show that the image of $\check{\theta}$ indeed lies in G_{C}. For any $f,g\in\mathbb{C}(G)$, we have

$$\begin{aligned}\langle\check{\theta}(\alpha),fg\rangle&=(-1)^{[f][g]}\overline{\langle\alpha,\omega S(f)\omega S(g)\rangle}\\&=(-1)^{[f][g]}\overline{\langle\alpha\otimes\alpha,\omega S(f)\otimes\omega S(g)\rangle}\\&=(-1)^{[f][g]}\overline{\langle\alpha,\omega S(f)\rangle\langle\alpha,\omega S(g)\rangle}\\&=\overline{\langle\alpha,\omega S(g)\rangle\langle\alpha,\omega S(f)\rangle}\\&=\overline{\langle\alpha,\omega S(f)\rangle}\cdot\overline{\langle\alpha,\omega S(g)\rangle}\\&=\langle\check{\theta}(\alpha),f\rangle\langle\check{\theta}(\alpha),g\rangle.\end{aligned}$$

Therefore, $\check{\theta}(\alpha)$ is a superalgebra homomorphism from $\mathbb{C}(G)$ to Λ, thus is indeed an element of G_{C}.

Definition 4.1: $G:=\{*\text{-superalgebra homomorphism }\mathbb{C}(G)\to\Lambda\}$.

Theorem 4.1: *G forms a subgroup of G_{C}. Furthermore, $\check{\theta}(\alpha)=\alpha^{-1}$ for all $\alpha\in G$.*

Proof: The fact that G forms a subgroup immediately follows from the above lemma. If $\alpha\in G$, we have

$$\begin{aligned}\langle\check{\theta}(\alpha),f\rangle&=\overline{\langle\alpha,\omega S(f)\rangle}=\langle\alpha,S(f)\rangle\\&=\langle\alpha^{-1},S(f)\rangle,\quad\forall\, f\in\mathbb{C}(G).\end{aligned}$$

This confirms the second claim. ■

B. Spherical functions on homogeneous superspaces

Hereafter we fix a Hopf $*$-superalgebraic structure θ for $\mathrm{U}(\mathfrak{g})$, which is defined for all the generators by

$$\theta:E_{ab}\mapsto E_{ba}.\tag{4.3}$$

The associated real form $\mathfrak{gl}(m|n;\mathbb{C})^{\sigma,\sqrt{i}}$ of the general linear superalgebra is one of the compact real forms of the general linear superalgebra, which probably deserves the notation $\mathfrak{u}(m|n)$ because it contains the maximal even subalgebra $\mathfrak{u}(m)\oplus\mathfrak{u}(n)$. (The unitarizable representations of this compact real form comprise the tensor powers of the natural representation, while the unita-

rizable representations of the other compact real form are the duals of these representations.[27]) Direct calculations can show that the Hopf $*$-superalgebraic structure on $\mathbb{C}(G)$ induced by θ is given by

$$\omega(t_{ab}) = (-1)^{[b]([a]+[b])}\overline{t_{ab}}, \quad \omega(\overline{t_{ab}}) = (-1)^{[b]([a]+[b])}t_{ab}. \tag{4.4}$$

The real supergroup G has body $\mathrm{U}(m)\times\mathrm{U}(n)$.

Let $\mathfrak{p}$ be a parabolic subalgebra of $\mathfrak{g}$ with Levi factor $\mathfrak{l}$. Let $\mathfrak{k}=\mathfrak{l}^{\sigma,\sqrt{i}}$ be the real form of $\mathfrak{l}$, which is a subalgebra of $\mathfrak{g}^{\sigma,\sqrt{i}}$. Denote by $\mathrm{U}^{\mathbb{R}}(\mathfrak{k})$ the universal enveloping algebra of $\mathfrak{k}$ over $\mathbb{R}$. Note that $\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}})$ inherits a real Hopf superalgebra structure from $\mathrm{U}(\mathfrak{g})$, and $\mathrm{U}^{\mathbb{R}}(\mathfrak{k})$ inherits a real Hopf superalgebra structure from $\mathrm{U}^{\mathbb{R}}(\mathfrak{g}^{\sigma,\sqrt{i}})$. Let us introduce the following definition.

Definition 4.2:

$$\mathbb{C}(K\backslash G) := \{f \in \mathbb{C}(G) | \mathrm{d}L_k(f) = \epsilon(k)f, \forall\, k \in \mathrm{U}^{\mathbb{R}}(\mathfrak{k})\}. \tag{4.5}$$

Note the following obvious fact, which will be used immediately below:

$$\mathbb{C}(K\backslash G) := \{f \in \mathbb{C}(G) | \mathrm{d}L_k(f) = \epsilon(k)f, \forall\, k \in \mathrm{U}(\mathfrak{l})\}. \tag{4.6}$$

We have the following lemma.

Lemma 4.3: $\mathbb{C}(K\backslash G)$ *forms a* $*$*-subalgebra of* $\mathbb{C}(G)$*, which is also a left coideal of* $\mathbb{C}(G)$.

Proof: Since $\mathrm{U}(\mathfrak{l})$ is a Hopf subalgebra of $\mathrm{U}(\mathfrak{g})$, we have $\Delta(k)=\Sigma_{(k)}k_{(1)}\otimes k_{(2)} \in \mathrm{U}(\mathfrak{l})\otimes\mathrm{U}(\mathfrak{l})$ for all $k\in\mathrm{U}(\mathfrak{l})$. If $a,b\in\mathbb{C}(K\backslash G)$, then by (4.6),

$$\begin{aligned}
\mathrm{d}L_k(ab) &= \sum (-1)^{[a_{(2)}][b_{(1)}]+[k]}\langle a_{(1)}b_{(1)}, S(k)\rangle a_{(2)}b_{(2)} \\
&= \sum (-1)^{[a_{(2)}][k_{(1)}]+[k]}\langle a_{(1)}, S(k_{(2)})\rangle b_{(1)}, S(k_{(1)})a_{(2)}b_{(2)} \\
&= \sum (-1)^{[k]}\epsilon(k_{(1)})\langle a_{(1)}, S(k_{(2)})\rangle a_{(2)}b = \epsilon(k)ab, \quad \forall\, k \in \mathrm{U}(\mathfrak{l}).
\end{aligned}$$

Thus $ab\in\mathbb{C}(K\backslash G)$.

Given any $f\in\mathbb{C}(K\backslash G)$, we have $\mathrm{d}L_k(\omega(f))=\omega(\mathrm{d}L_{\theta(k)}(f))(-1)^{[k]([k]+[f])}$ for all $k\in\mathrm{U}(\mathfrak{l})$. As $\mathrm{U}(\mathfrak{l})$ is θ invariant, we have $\mathrm{d}L_{\theta(k)}(f)=\overline{\epsilon(k)}f$. Thus

$$\mathrm{d}L_k(\omega(f)) = \epsilon(k)\omega(f), \quad \forall\, k \in \mathrm{U}(\mathfrak{l}).$$

Also, a straightforward calculation shows that

$$(\mathrm{d}L_k \otimes \mathrm{id})\Delta(f) = \epsilon(k)\Delta(f), \quad \forall\, k \in \mathrm{U}(\mathfrak{l}).$$

Thus $\mathbb{C}(K\backslash G)$ is a left coideal. This completes the proof. ■

The subalgebra $\mathbb{C}(K\backslash G)$ consists of the elements of $\mathbb{C}(G)$ which are invariant with respect to $\mathrm{U}^{\mathbb{R}}(\mathfrak{k})$ under left translation. Following the general philosophy of noncommutative geometry,[2] we may take the viewpoint that $\mathbb{C}(K\backslash G)$ defines an algebraic homogeneous superspace.[12] We shall refer to $\mathbb{C}(K\backslash G)$ as the superalgebra of functions on the homogeneous superspace. Also a word about the notation $\mathbb{C}(K\backslash G)$: here K is used to indicate some real subsupergroup of G with Lie superalgebra $\mathfrak{k}$.

Remark 4.1: Since $\mathbb{C}(G)$ and $\mathbb{C}(K\backslash G)$ are all $*$-superalgebras, their elements are in general not holomorphic functions on the supergroup. This is a particularly welcome fact, as it indicates that our construction can lead to analogues of compact complex super manifolds like projective superspaces. As is well known from the Gelfand–Naimark theorem, the continuous functions on a compact manifold determine the manifold completely, even when the manifold is complex, where all the holomorphic functions are constants.

Remark 4.2: In the quantum group context, one usually considers left or right coideal subalgebras of the algebra of functions[10,17,3,11] in the place of $\mathbb{C}(K\backslash G)$. By Lemma 4.3 $\mathbb{C}(K\backslash G)$ forms a left coideal subalgebra of $\mathbb{C}(G)$.

Because the two left actions dR and dL of U($\mathfrak{g}$) on $\mathbb{C}(G)$ supercommute, the subalgebra $\mathbb{C}(K\backslash G)$ of $\mathbb{C}(G)$ forms a left module algebra over U($\mathfrak{g}$) under the action dR. We shall study the dR(U$^{\mathbb{R}}(\mathfrak{k})$)-invariant subspace of $\mathbb{C}(K\backslash G)$. Let us first generalize the definition of zonal spherical functions[26] to the supergroup setting. We shall refer to elements of the following space as spherical functions on the homogeneous superspace.

Definition 4.3:

$$\mathbb{C}(K\setminus G/K) := \{f \in \mathbb{C}(K\setminus G) \big| \mathrm{d}R_k(f) = \epsilon(k) f, \quad \forall\, k \in \mathrm{U}^{\mathbb{R}}(\mathfrak{k})\}. \tag{4.7}$$

Similar arguments as those in the proof of Lemma 4.3 show the following.

Lemma 4.4: The subspace $\mathbb{C}(K\backslash G/K)$ *forms a* $*$*-subalgebra of* $\mathbb{C}(K\backslash G)$. Obviously

$$\mathbb{C}(K\setminus G/K) = \{f \in \mathbb{C}(K\setminus G) \big| \mathrm{d}R_x(f) = \epsilon(x) f, \forall\, x \in \mathrm{U}(\mathfrak{l})\}, \tag{4.8}$$

where $\mathfrak{l}$ is the complexification of $\mathfrak{k}$. The fact will be used in the next section to prove Theorem 4.2.

C. Structure of superalgebra of spherical functions

Let $\mathfrak{l}$ be a reductive subalgebra of $\mathfrak{g}$ generated by E_{aa}, $a \in \mathbf{I}$, and $E_{c,c+1}$, $E_{c+1,c}$ with c belonging to some proper subset of $\mathbf{I}\backslash\{m+n\}$. As in the last section, we let

$$\mathfrak{k} = \mathfrak{l}^{\sigma,\sqrt{i}}.$$

See Remark 4.3 for further discussions on this choice of $\mathfrak{k}$. The main result here is Theorem 4.2, which enables us to obtain the superalgebras $\mathbb{C}(K\backslash G)$ and $\mathbb{C}(K\backslash G/K)$ from the invariants of $\mathbb{C}[X,\overline{X}]$. An explicit description of the generators of these superalgebras will also be given in Lemmas 4.5 and 4.6.

Theorem 4.2: *When* $\mathfrak{k}=\mathfrak{l}^{\sigma,\sqrt{i}}$, *we have*

$$\begin{aligned} \mathbb{C}(K\setminus G) &= \{j(p) \big| p \in \mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))}\}, \\ \mathbb{C}(K\setminus G/K) &= \{j(p) \big| p \in \mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))}\}. \end{aligned} \tag{4.9}$$

The remainder of this section is devoted to the proof of Theorem 4.2. The proof is carried out in two steps. We first show that the theorem holds when $\mathfrak{l}=\mathfrak{k}_{\mathbb{C}}$ is even, that is, when $\mathfrak{l}$ is a reductive Lie subalgebra of $\mathfrak{g}$. Then we use this fact to prove the general case. In the process of proving the theorem, we also establish Lemmas 4.5 and 4.6. We mention that Eqs. (4.6) and (4.8) will be used repeatedly in the proof without further warning.

1. Proof of Theorem 4.2 for $\mathfrak{l}$ *even*

In this case we can find a set of positive integers k_i, $i=1,2,\ldots,r,r+1,\ldots,s$ such that $\Sigma_{i=1}^{r}k_i=m$, $\Sigma_{j=r+1}^{s}k_j=n$, and $\mathfrak{l}=\oplus_{i=1}^{s}\mathfrak{gl}(k_i)$. More explicitly,

$$\mathfrak{l} = \left\{ \begin{pmatrix} A_1 & & 0 \\ & \ddots & \\ 0 & & A_s \end{pmatrix} \Big| A_i \in \mathfrak{gl}(k_i) \right\} \subset \mathfrak{g}.$$

Proposition 3.2 implies the following short exact sequence:

$$0 \to \mathcal{J} \to \mathbb{C}[X,\overline{X}] \xrightarrow{\mathcal{J}} \mathbb{C}(G) \to 0$$

in the category of U($\mathfrak{l}$)$\otimes$U($\mathfrak{l}$)-module superalgebras. Since the various U($\mathfrak{l}$) and U($\mathfrak{l}$)$\otimes$U($\mathfrak{l}$) actions on $\mathcal{J}$, $\mathbb{C}[X,\overline{X}]$ and $\mathbb{C}(G)$ are all semisimple, we have the following short exact sequences of U($\mathfrak{l}$)$\otimes$U($\mathfrak{l}$)-modules:

$$0 \to \mathcal{J}^{\Psi(\mathrm{U}(\mathfrak{l}))} \to \mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))} \to \mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l})}} \to 0, 0 \to \mathcal{J}^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))} \to \mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))}$$
$$\to \mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l})}\otimes\mathrm{d}R_{\mathrm{U}(\mathfrak{l})}} \to 0,$$

where $\mathbb{C}(K\backslash G)=\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l})}}$ and $\mathbb{C}(K\backslash G/K)=\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l})}\otimes\mathrm{d}R_{\mathrm{U}(\mathfrak{l})}}$. These are also short exact sequences of $\mathrm{U}(\mathfrak{l})\otimes\mathrm{U}(\mathfrak{l})$-module algebras, thus they imply the claims of Theorem 4.2 in the case under consideration.

Let us now describe the algebras $\mathbb{C}(K\backslash G)$ and $\mathbb{C}(K\backslash G/K)$ more carefully. Set $l_i=\Sigma_{t=1}^{i}k_t$. Recall that $\mathbb{C}[X,\overline{X}]$ is the symmetric algebra in $X\oplus\overline{X}$ where $X=V\otimes\overline{V}$ and $\overline{X}=\overline{V}\otimes V$. Restricted to a $\mathrm{U}(\mathfrak{l})$-module, V decomposes into

$$V=\oplus_{i=1}^{s}V_i^{(k_i)}.$$

The ideal $\mathfrak{gl}(k_i)$ of $\mathfrak{l}$ acts on $V_i^{(k_i)}$ by the natural representation, and acts on all other submodules trivially. There is also an analogous decomposition of the restriction of $\overline{V}$ to a $\mathrm{U}(\mathfrak{l})$-module. By applying the first fundamental theorem of the invariant theory of the general linear group,[5] we obtain that the subalgebra $\mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))}$ of $\mathbb{C}[X,\overline{X}]$ is generated by

$$\hat{C}_{ab}^{(i)} := \sum_{c=1+l_{i-1}}^{l_i} x_{ca}\overline{x_{cb}}, \quad i=1,2,\ldots,s, \quad a,b\in\mathbf{I}.$$

It then immediately follows that $\mathbb{C}(K\backslash G)$ is generated by

$$C_{ab}^{(i)} := j(\hat{C}_{ab}^{(i)}) = \sum_{c=1+l_{i-1}}^{l_i} t_{ca}\overline{t_{cb}}, \quad i=1,2,\ldots,s, \quad a,b\in\mathbf{I}.$$

Note that the $C_{ab}^{(i)}$ are not algebraically independent, for example, for $a,b\in\mathbf{I}$ the following hold:

$$\sum_{i=1}^{s} C_{ab}^{(i)}(-1)^{[l_i]}=\delta_{ab}, \quad \sum_{a=1}^{m+n} C_{ab}^{(i)}=k_i. \tag{4.10}$$

Thus the elements of the set $\{C_{ab}^{(i)}\,|\,i\neq s; a,b\in\mathbf{I}\}$ can also generate $\mathbb{C}(K\backslash G)$. By using the fact that t_{ab} and $\overline{t_{cd}}$ supercommute, one can verify the following proposition easily.

Proposition 4.1: We have

$$C_{ab}^{(i)}C_{cd}^{(j)}=(-1)^{([a]+[b])([c]+[d])}C_{cd}^{(j)}C_{ab}^{(i)}, \tag{4.11}$$

in particular, if $[a]+[b]=1$ *then* $(C_{ab}^{(i)})^2=0$. *Thus for fixed i, there is an onto algebra homomorphism* $\mathbb{C}[X]\to\langle C_{ab}^{(i)}\,|\,a,b\in\mathbf{I}\rangle$, *where* $\mathbb{C}[X]$ *is the subalgebra of* $\mathbb{C}[X,\overline{X}]$ *generated by X, and* $\langle C_{ab}^{(i)}\,|\,a,b\in\mathbf{I}\rangle$ *is the subalgebra of* $\mathbb{C}(K\backslash G)$ *generated by* $\{C_{ab}^{(i)}\,|\,a,b\in\mathbf{I}\}$.

In a similar way we can show that $\mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))}$ is generated by

$$\hat{C}^{(i,j)} := \sum_{a=1+l_{j-1}}^{l_j}\sum_{c=1+l_{i-1}}^{l_i} x_{ca}\overline{x_{ca}}, \quad i,j=1,2,\ldots,s,$$

and $\mathbb{C}(K\backslash G/K)$ is generated by

$$C^{(i,j)} := j(\hat{C}^{(i,j)}) = \sum_{a=1+l_{j-1}}^{l_j}\sum_{c=1+l_{i-1}}^{l_i} t_{ca}\overline{t_{ca}}, \quad i,j=1,2,\ldots,s.$$

Again, the $C^{(i,j)}$ are not algebraically independent, for example,

$$\sum_{i=1}^{s} C^{(i,j)}(-1)^{[l_i]} = k_j, \quad \sum_{j=1}^{s} C^{(i,j)}(-1)^{[l_j]} = k_i. \tag{4.12}$$

Thus the elements of the set $\{C^{(i,j)} | i, j \neq r\}$ generate $\mathbb{C}(K\backslash G/K)$.

2. Proof of Theorem 4.2 for generic $\mathfrak{l}$

The most general form of $\mathfrak{l}$ is as follows. There exists a set of positive integers k_i as in the last section such that

$$\mathfrak{l} = (\oplus_{i=1}^{r-1} \mathfrak{gl}(k_i)) \oplus \mathfrak{gl}(k_r|k_{r+1}) \oplus (\oplus_{j=r+2}^{s} \mathfrak{gl}(k_j)).$$

More explicitly, we have

$$\mathfrak{l} = \left\{ \begin{pmatrix} \ddots & & & & 0 \\ & A_{r-1} & & & \\ & & B & & \\ & & & A_{r+2} & \\ 0 & & & & \ddots \\ & & & & & A_s \end{pmatrix} \middle| \begin{array}{lcl} A_i & \in & \mathfrak{gl}(k_i), \\ B & \in & \mathfrak{gl}(k_r|k_{r+1}) \end{array} \right\}.$$

Note that $\mathfrak{l}$ contains the maximal even subalgebra $\mathfrak{l}_0 = \oplus_{i=1}^{s} \mathfrak{gl}(k_i)$.

We first consider the subalgebra $\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}}$ of $\mathbb{C}(G)$. By using results of the last section, we can immediately see that $\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}}$ is generated by the elements of $\{C_{ab}^{(i)} | i \neq r; a, b \in \mathbf{I}\}$. Now

$$\mathbb{C}(K \setminus G) = \{f \in \mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}} | \mathrm{d}L_{E_{mm+1}}(f) = \mathrm{d}L_{E_{m+1,m}}(f) = 0\}.$$

We shall show that $\mathbb{C}(K\backslash G)$ is generated by $\{C_{ab}^{(i)} | i \neq r, r+1; a, b \in \mathbf{I}\}$.

Note that all the elements of $\{C_{ab}^{(i)} | i \neq r; a, b \in \mathbf{I}\}$ are annihilated by $\mathrm{d}L_{E_{mm+1}}$ and $\mathrm{d}L_{E_{m+1,m}}$ except for $C_{ab}^{(r+1)}$, for which we have

$$\mathrm{d}L_{E_{mm+1}}(C_{ab}^{(r+1)}) = -(-1)^{[a]+[b]} t_{m+1,a} \overline{t}_{mb}, \tag{4.13}$$

$$\mathrm{d}L_{E_{m+1,m}}(C_{ab}^{(r+1)}) = -(-1)^{[a]+[b]} t_{ma} \overline{t}_{m+1,b}, \quad a, b \in \mathbf{I}. \tag{4.14}$$

Note that as a $\mathrm{U}(\mathfrak{g})$-module, $\mathbb{C}(G)$ has a filtration defined by the degrees of the polynomials in the t_{ab} and the $\overline{t}_{ab}$, and the filtration on the $\mathrm{U}(\mathfrak{l}_0)$-module $\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}}$ defined by the degrees of the polynomials in the $\{C_{ab}^{(i)} | i \neq r; a, b \in \mathbf{I}\}$ is compatible with this filtration. Thus in order to find those $f \in \mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}}$ such that $\mathrm{d}L_{E_{mm+1}}(f) = L_{E_{m+1,m}}(f) = 0$, by passing through to the associated graded modules defined by these filtrations if necessary, we may assume that f is homogeneous of degree μ in the elements of $\{C_{ab}^{(i)} | i \neq r; a, b \in \mathbf{I}\}$. We consider an element $f \in \mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}}$ as a polynomial in $\{C_{ab}^{(r+1)} | a, b \in \mathbf{I}\}$ with coefficients being polynomials in $\{C_{ab}^{(i)} | i \neq r, r+1; a, b \in \mathbf{I}\}$. Set $C_{ab} = C_{ab}^{(r+1)}$ $(a, b \in \mathbf{I})$. Then by Proposition 4.1, the subalgebra $\langle C_{ab} | a, b \in \mathbf{I}\rangle$ has a basis consists of elements of the form

$$C_{a_1 b_1}^{p_1} \cdots C_{a_s b_s}^{p_s} C_{c_1 d_1} \cdots C_{c_t d_t}, \tag{4.15}$$

with $[a_i] + [b_i] = 0 (1 \leqslant i \leqslant s)$, $[c_j] + [d_j] = 1 (1 \leqslant j \leqslant t)$, and $p_i \geqslant 0 (1 \leqslant i \leqslant s)$ are integers. Extend such a basis of $\langle C_{ab} | a, b \in I\rangle$ to a homogeneous basis $\mathbf{B}$ of $\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}(\mathfrak{l}_0)}}$, so that the elements of $\mathbf{B}$ are of the form

$$CC_{a_1b_1}^{p_1}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots C_{c_td_t}, \tag{4.16}$$

where C is a monomial in $\{C_{ab}^{(i)}|i\neq r,r+1;a,b\in\mathbf{I}\}$. Now let us write $f=\Sigma_{0\leqslant k\leqslant\mu}f_k$, where f_k is a linear combination of the basis elements of (4.16) such that $\Sigma_i p_i+t=k$ and $\deg(C)+k=\deg(f)$. The action of E_{mm+1} (similarly for E_{m+1m}) on the elements of (4.5) can be computed by using (4.13), and we have

$$\begin{aligned}\mathrm{d}L_{E_{mm+1}}(C_{a_1b_1}^{p_1}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots C_{c_td_t}) &= -\sum_{i=1}^{s}(-1)^t p_i C_{a_1b_1}^{p_1}\cdots C_{a_ib_i}^{p_i-1}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots C_{c_td_t}t_{m+1a_i}\overline{t}_{mb_i}\\ &\quad + C_{a_1b_1}^{p_1}\cdots C_{a_sb_s}^{p_s}\sum_{j=1}^{t}(-1)^j C_{c_1d_1}\cdots\hat{C}_{c_jd_j}\cdots C_{c_td_t}t_{m+1c_j}\overline{t}_{md_j}.\end{aligned} \tag{4.17}$$

Since the product map of $\mathbb{C}(G)$ is a $\mathrm{U}(\mathfrak{g})$-module homomorphism [see (3.6)], by (4.17) the action of E_{mm+1} on the elements of (4.16) is given by

$$\begin{aligned}&\mathrm{d}L_{E_{mm+1}}(CC_{a_1b_1}^{p_1}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots C_{c_td_t})\\ &\quad=-(-1)^{[C]}C\sum_{i=1}^{s}(-1)^t p_i C_{a_1b_1}^{p_1}\cdots C_{a_ib_i}^{p_i-1}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots C_{c_td_t}t_{m+1a_i}\overline{t}_{mb_i}\\ &\quad+(-1)^{[C]}CC_{a_1b_1}^{p_1}\cdots C_{a_sb_s}^{p_s}\sum_{j=1}^{t}(-1)^j C_{c_1d_1}\cdots\hat{C}_{c_jd_j}\cdots C_{c_td_t}t_{m+1c_j}\overline{t}_{md_j},\end{aligned} \tag{4.18}$$

where $\hat{C}_{c_jd_j}$ means that the factor $C_{c_jd_j}$ is omitted.

For an element x of the form (4.16), let $x'(ab)$ be

$$CC_{a_1b_1}^{p_1}\cdots C_{a_{i-1}b_{i-1}}^{p_{i-1}}C_{a_ib_i}^{p_i-1}C_{a_{i+1}b_{i+1}}^{p_{i+1}}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots C_{c_td_t},$$

or

$$CC_{a_1b_1}^{p_1}\cdots C_{a_sb_s}^{p_s}C_{c_1d_1}\cdots\hat{C}_{c_jd_j}\cdots C_{c_td_t},$$

depending on whether $(ab)=(a_ib_i)$ or $(ab)=(c_jd_j)$.

Let us make some observations. First note that since

$$\langle m_\circ(h\otimes g),a\rangle=\langle h\otimes g,\Delta(a)\rangle,\quad h,g\in U(\mathfrak{g})^0,\quad a\in U(\mathfrak{g}),$$

if $\{b_i|1\leqslant i\leqslant\ell\}\subset\mathbb{C}(G)$ is a set of linearly independent functions which are constants on $U(\mathfrak{k}_0)$ and $\{t_{m+1a}\overline{t}_{mb}|a,b\in\mathbf{J}\subset\mathbf{I}\}$ is linearly independent, then the set $\{b_it_{m+1a}\overline{t}_{mb}|1\leqslant i\leqslant\ell,a,b\in\mathbf{J}\}$ is linearly independent. Then note that if $S_{cd}\subset\mathbf{B}$ with C_{cd} appearing in every element for a fixed pair c and d, then the set

$$S'_{cd}=\{x'(cd)|x\in S_{cd}\}$$

is linearly independent. In fact the elements of S_{cd} and $C_{cd}S'_{cd}$ are the same up to signs. Finally note that the only relation among the elements in $\{t_{m+1a}\overline{t}_{mb}|a,b\in\mathbf{I}\}$ is [see (3.1)]

$$\sum_{a\in I}t_{m+1a}\overline{t}_{ma}(-1)^{[a]}=\sum_{1\leqslant a\leqslant m}t_{m+1a}\overline{t}_{ma}-\sum_{m+1\leqslant a\leqslant m+n}t_{m+1a}\overline{t}_{ma}=0,$$

and this relation can only come from (via the map $\mathrm{d}L_{E_{mm+1}}$)

$$\sum_{1\leqslant a\leqslant m} C_{aa} - \sum_{m+1\leqslant a\leqslant m+n} C_{aa} = \sum_{1\leqslant a\leqslant m} \sum_{c=m+1}^{l_{r+1}} t_{ca}\overline{t_{ca}} - \sum_{m+1\leqslant a\leqslant m+n} \sum_{c=m+1}^{l_{r+1}} t_{ca}\overline{t_{ca}} = -k_{r+1},$$

i.e., a constant.

These observations together with (4.18) imply that $\mathrm{d}L_{E_{mm+1}}(f)=\mathrm{d}L_{E_{m+1,m}}(f)=0$ if and only if $f=f_0$, i.e., f is independent of $C_{ab}^{(r+1)}(a,b\in\mathbf{I})$. Therefore, we have the following.

Lemma 4.5: $\mathbb{C}(K\backslash G)$ *is generated by the elements of*

$$\{C_{ab}^{(i)} | i\neq r,r+1;a,b\in\mathbf{I}\}. \tag{4.19}$$

By Theorem 2.1 and the first fundamental theorem of the invariant theory of the general linear group, $\mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))}$ is generated by $\hat{C}_{ab}^{(i)}(i\neq r,r+1;a,b\in\mathbf{I})$, and $\hat{C}_{ab}^{(r)}-\hat{C}_{ab}^{(r+1)}(a,b\in\mathbf{I})$. We have $j(\hat{C}_{ab}^{(i)})=C_{ab}^{(i)}(i\neq r,r+1;a,b\in\mathbf{I})$, which yield all the elements of (4.19). This establishes the short exact sequence

$$0\rightarrow\mathcal{J}^{\Psi(\mathrm{U}(\mathfrak{l}))}\rightarrow\mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))}\rightarrow\mathbb{C}(K\setminus G)\rightarrow 0$$

of $\mathrm{U}(\mathfrak{l})\otimes\mathrm{U}(\mathfrak{l})$-module algebras, thus proves the first claim of Theorem 4.2.

Let us now consider the subalgebra $\mathbb{C}(K\backslash G)^{\mathrm{d}R_{\mathrm{U}(\mathfrak{l}_0)}}$ of $\mathbb{C}(K\backslash G)$, which is generated by the elements of the set $\{C^{(i,j)}|i\neq r,r+1;j\neq r\}$, as follows from results of the last section. Among all the elements of this set, only $C^{(i,r+1)}$ are not annihilated by $\mathrm{d}R_{E_{mm+1}}$ and $\mathrm{d}R_{E_{m+1,m}}$. Thus similar to the case of the left action, we can prove that $f\in\mathbb{C}(K\backslash G)^{\mathrm{d}R_{\mathrm{U}(\mathfrak{l}_0)}}$ satisfies $\mathrm{d}R_{E_{mm+1}}(f)=0$ and $\mathrm{d}R_{E_{m+1,m}}(f)=0$ if and only if it is independent of the $C^{(i,r+1)}(i\neq r,r+1)$. Observe that

$$\mathbb{C}(K\setminus G/K)=\{f\in\mathbb{C}(K\setminus G)^{\mathrm{d}R_{\mathrm{U}(\mathfrak{l}_0)}}|\mathrm{d}R_{E_{mm+1}}(f)=\mathrm{d}R_{E_{m+1,m}}(f)=0\}.$$

We have

Lemma 4.6: $\mathbb{C}(K\backslash G/K)$ *is generated by the elements of*

$$\{C^{(i,j)}|i,j\neq r,r+1\}. \tag{4.20}$$

By Theorem 2.1 and the first fundamental theorem of the invariant theory of the general linear group, $\mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))}$ is generated by

$$\hat{C}^{(i,j)},\hat{C}^{(r,j)}-\hat{C}^{(r+1,j)},\hat{C}^{(i,r)}-\hat{C}^{(i,r+1)},\quad i,j\neq r,r+1,\quad a,b\in\mathbf{I},$$

and since

$$j(\{\hat{C}^{(i,j)}|i,j\neq r,r+1\})=\{C^{(i,j)}|i,j\neq r,r+1\},$$

we have the following short exact sequence of $\mathrm{U}(\mathfrak{l})\otimes\mathrm{U}(\mathfrak{l})$-module algebras:

$$0\rightarrow\mathcal{J}^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))}\rightarrow\mathbb{C}[X,\overline{X}]^{\Psi(\mathrm{U}(\mathfrak{l}))\otimes\Phi(\mathrm{U}(\mathfrak{l}))}\rightarrow\mathbb{C}(K\setminus G/K)\rightarrow 0,$$

which is equivalent to the second claim of Theorem 4.2.

Remark 4.3: Geometric homogeneous superspaces have been studied since the 1970s, see, for example, Refs. 8 and 13. Symmetric superspaces were also classified by Serganova in Ref. 23 at the level of Lie superalgebras. In relation to our algebraic definition of homogeneous superspaces, one may ask the following question. Let P be the parabolic subgroup of $\mathrm{GL}(m|n,\Lambda)$ with Lie superalgebra $\mathfrak{p}$. We have the homogeneous superspace $\mathrm{GL}(m|n,\Lambda)/P$ (understood as a left coset of P). Now let $\mathfrak{l}$ be the Levi factor of $\mathfrak{p}$ and take $\mathfrak{k}=\mathfrak{l}^{\sigma,\sqrt{\tilde{i}}}$, with θ being the Hopf $*$-superalgebraic structure of $\mathrm{U}(\mathfrak{g})$ corresponding to the compact real form of the general linear superalgebra [defined by (4.3)]. Then the question is whether the homogeneous superspace determined by $\mathbb{C}(K\backslash G)$ is the same as $\mathrm{GL}(m|n,\Lambda)/P$ in some appropriate sense. We expect the answer to be

affirmative, but have not been able to locate a reference, which addresses any form of the question, in the literature on supergeometry.

V. SPHERICAL FUNCTIONS ON $\mathbb{C}(K\backslash G)$ WITH MAXIMAL RANK K

We keep notations from the last section. In particular, we fix the $*$-structure θ of $\mathrm{U}(\mathfrak{g})$ given by (4.3), which corresponds to the real form $\mathfrak{u}(m|n)$ for the general linear superalgebra. We use $\mathfrak{l}$ to denote the Levi factor of a parabolic subalgebra of $\mathfrak{g}$, and set $\mathfrak{k}=\mathfrak{l}^{\sigma,\sqrt{i}}$. The homogeneous superspaces studied in this section are all examples of symmetric superspaces in the sense of Ref. 22 (see Tables 2 and 3 in Ref. 23).

A. The case with $\mathfrak{k}=\mathfrak{u}(m|n-1)\oplus\mathfrak{u}(1)$

We first examine in some detail the spherical functions on the homogeneous superspace corresponding to $\mathfrak{k}=\mathfrak{u}(m|n-1)\oplus\mathfrak{u}(1)$, where the complexification $\mathfrak{l}$ of $\mathfrak{k}$ is the subalgebra of $\mathfrak{g}$ spanned by the elements E_{ij}, $i,j\in\mathbf{I}\backslash\{m+n\}$, and $E_{m+n,m+n}$. But before discussing the superalgebra $\mathbb{C}(K\backslash G)$, let us introduce the following superalgebra.

Definition 5.1: $\mathbb{C}(\mathbb{S}^{2n-1|2m}):=\mathbb{C}(G)^{\mathrm{d}L_{\mathrm{U}^{\mathbb{R}}(\mathfrak{u}(m|n-1))}}$ relative to $\mathfrak{u}(m|n-1)\subset\mathfrak{k}$.

More explicitly,

$$\mathbb{C}(\mathbb{S}^{2n-1|2m})=\{f\in\mathbb{C}(G)|\mathrm{d}L_k(f)=\epsilon(k)f,\ \forall\, k\in\mathrm{U}^{\mathbb{R}}(\mathfrak{u}(m|n-1))\}.$$

We can modify the analysis of Sec. IV C to construct $\mathbb{C}(\mathbb{S}^{2n-1|2m})$. With the help of Theorem 2.1 for $\mathfrak{gl}(m|n-1)$, we can show that $\mathbb{C}(\mathbb{S}^{2n-1|2m})$ is generated by

$$z_a:=t_{m+n,a},\quad \overline{z_a}:=\overline{t}_{m+n,a},$$

$$Q_{ab}:=\sum_{c<m+n}\overline{t}_{ca}t_{cb}(-1)^{[b][c]+[c]},\quad a\in\mathbf{I},$$

where z_a and $\overline{z_a}$ are odd if $a\leqslant m$, and even otherwise. The defining relations of $\mathbb{C}(G)$ imply $Q_{ab}=\delta_{ab}\mathbb{1}-z_a\overline{z}_b(-1)^{[b]}$. Thus the z_a and $\overline{z_a}$ generate $\mathbb{C}(\mathbb{S}^{2n-1|2m})$ by themselves. We have the following result.

Lemma 5.1: The subalgebra of $\mathbb{C}(\mathbb{S}^{2n-1|2m})$ *of* $\mathbb{C}(G)$ *is generated by* z_a, $\overline{z_a}$, $a\in\mathbf{I}$, *which satisfy the following relation:*

$$\sum_{a\in\mathbf{I}}\overline{z_a}z_a=\mathbb{1}. \tag{5.1}$$

Remark 5.1: The notation suggests $\mathbb{C}(\mathbb{S}^{2n-1|2m})$ be the superalgebra of functions on the supersphere. This can be understood as follows. Under the $*$-map ω defined by (4.4), we have

$$\omega(z_a)=\overline{z_a},\quad \omega(\overline{z_a})=z_a.$$

Thus we may interpret $\overline{z_a}$ as the complex conjugate of z_a, and this indeed makes perfect sense when z_a and $\overline{z_a}$ are regarded as functions on G (see Sec. IV A). Thus Eq. (5.1) defines a supersphere in analogy with the embedding of a supersphere $\mathbb{S}^{2n-1|2m}$ in $\mathbb{C}^{n|m}$. This also indicates the importance of the $*$-structure in determining the underlying supermanifold of $\mathbb{C}(K\backslash G)$.

Remark 5.2: When $\mathfrak{k}=\mathfrak{u}(m|n-1)\oplus\mathfrak{u}(1)$, we have $\mathbb{C}(K\backslash G)=\mathbb{C}(\mathbb{S}^{2n-1|2m})^{\mathrm{d}L_{\mathfrak{u}(1)}}$. This superalgebra embedding $\mathbb{C}(K\backslash G)\hookrightarrow\mathbb{C}(\mathbb{S}^{2n-1|2m})$ corresponds to a projection from $\mathbb{S}^{2n-1|m}$ to the symmetric superspace, which is the supergeneralization of the Hopf map $\mathbb{S}^{2n-1}\to\mathbb{CP}^{n-1}$. Therefore, we shall regard the symmetric superspace associated with $\mathbb{C}(K\backslash G)$ as an algebraic analogue of the projective superspace $\mathbb{CP}^{n-1|m}$.

We denote $\mathbb{C}(K\backslash G)$ by $\mathbb{C}(\mathbb{P}^{n-1|m})$ when $\mathfrak{k}=\mathfrak{u}(m|n-1)\oplus\mathfrak{u}(1)$. Lemma 5.1 immediately leads to the following result.

Lemma 5.2: The superalgebra $\mathbb{C}(\mathbb{P}^{n-1|m})$ *is the* $*$*-subalgebra of* $\mathbb{C}(\mathbb{S}^{2n-1|2m})$ *generated by the quadratic elements* $z_a\overline{z_b}$, $a,b\in\mathbf{I}$.

Proof: Since for all a, $\mathrm{d}L_{E_{m+n,m+n}}z_a=z_a$, and $\mathrm{d}L_{E_{m+n,m+n}}\overline{z_a}=-\overline{z_a}$, any $\mathrm{d}L_{\mathfrak{u}(1)}$-invariant element of $\mathbb{C}(\mathbb{S}^{2n-1|2m})$ must be a polynomial in $z_a\overline{z_b}$, $a,b\in\mathbf{I}$. This result can also be obtained in a more direct way by using Theorem 4.2. ■

Remark 5.3: We should emphasize that elements of $\mathbb{C}(\mathbb{P}^{n-1|m})$ are functions on the projective superspace that are not holomorphic in general because $\mathbb{C}(\mathbb{P}^{n-1|m})$ is a $*$-superalgebra.

Now we use Theorem 4.2 to extract the algebra $\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathrm{R}}(\mathfrak{k})}}$ of spherical functions on the projective superspace. Let $z:=z_{m+n}$ and $\overline{z}=\overline{z_{m+n}}$. We have the following.

Theorem 5.1: *The algebra of the spherical functions on the projective superspace is generated by* $r:=z\overline{z}$ *as a* $*$*-subalgebra of* $\mathbb{C}(\mathbb{P}^{n-1|m})$. *When* $n>1$, *the spherical functions form a polynomial algebra in one variable. When* $n=1$, *we have* $(1-r)^{m+1}=0$.

Proof: It is an immediate consequence of Theorem 4.2 that the algebra $\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathrm{R}}(\mathfrak{k})}}$ of the spherical functions on the projective superspace is indeed generated by the single element r.

When $n=1$, all the z_c, $\overline{z_c}$, $c\leqslant m$, are odd. Thus the $(m+1)$th power of $1-r=\Sigma_{c\leqslant m}z_c\overline{z_c}$ vanishes identically.

To study the case with $n>1$, we first analyze $\mathbb{C}[\mathrm{GL}_n]$, the algebra generated by the matrix elements of the contravariant and covariant vector representations of $\mathfrak{gl}(n)$. Let $\mathfrak{q}=\mathfrak{gl}(n-1)\oplus\mathfrak{gl}(1)$ be the subalgebra of $\mathfrak{gl}(n)$ embedded block diagonally. Set $A=\mathbb{C}[\mathrm{GL}_n]^{\mathrm{d}L_{\mathrm{U}(\mathfrak{q})}\otimes\mathrm{d}R_{\mathrm{U}(\mathfrak{q})}}$. Recall that $\mathbb{C}[\mathrm{GL}_n]$ is semisimple as a left module $\mathrm{U}(\mathfrak{q})$-module under the action $\mathrm{d}L_{\mathrm{U}(\mathfrak{q})}\otimes\mathrm{d}R_{\mathrm{U}(\mathfrak{q})}$. There exists a surjective $\mathrm{d}L_{\mathrm{U}(\mathfrak{q})}\otimes\mathrm{d}R_{\mathrm{U}(\mathfrak{l})}$-module map $\psi:\mathbb{C}[\mathrm{GL}_n]\to\mathrm{A}$. Let $\psi^*,(\mathrm{id}-\psi)^*:\mathrm{U}(\mathfrak{gl}(n))\to\mathrm{U}(\mathfrak{gl}(n))$ be vector space maps defined by

$$\langle f,(\mathrm{id}-\psi)^*(u)\rangle=\langle(\mathrm{id}-\psi)(f),u\rangle,$$

$$\langle f,\psi^*(u)\rangle=\langle\psi(f),u\rangle,\quad\forall\, u\in\mathfrak{gl}(n),\ f\in\mathbb{C}[\mathrm{GL}_n].$$

Since the dual space pairing between $\mathbb{C}[\mathrm{GL}_n]$ and $\mathrm{U}(\mathfrak{gl}(n))$ is nondegenerate, there is a nondegenerate pairing between A and $\psi^*(\mathrm{U}(\mathfrak{gl}(n)))$. Now as vector spaces,

$$\psi^*(\mathrm{U}(\mathfrak{gl}(n)))\cong\mathrm{U}(\mathfrak{gl}(n))/(\mathfrak{q}\mathrm{U}(\mathfrak{gl}(n))+\mathrm{U}(\mathfrak{gl}(n))\mathfrak{q}),$$

where the right-hand side is clearly infinite dimensional. This in particular implies that the subalgebra A of $\mathbb{C}[\mathrm{GL}_n]$ is infinite dimensional.

Let $\zeta:\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathrm{R}}(\mathfrak{k})}}\to\mathbb{C}[\mathrm{GL}_n]$ be the map defined for any $f\in\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathrm{R}}(\mathfrak{k})}}$ and $u\in\mathrm{U}(\mathfrak{gl}(n))$ by $\langle\zeta(f),u\rangle=\langle\zeta(f),i(u)\rangle$, where i is the canonical embedding $\mathrm{U}(\mathfrak{gl}(n))\subset\mathrm{U}(\mathfrak{g})$. Then ζ is an algebra homomorphism, and we have

$$\zeta(\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathrm{R}}(\mathfrak{e})}})=A.$$

If there existed a nontrivial polynomial $P(r)$ in r which was identically zero as an element of $\mathbb{C}(\mathbb{P}^{n-1|m})$, then $\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathrm{R}}(\mathfrak{k})}}$ would have to be finite dimensional over $\mathbb{C}$. This contradicts the fact that A is an infinite dimensional algebra. ■

Let us now study the action of a generalized Laplacian operator on the spherical functions. Recall that the quadratic Casimir of $\mathrm{U}(\mathfrak{g})$ can be expressed as $c=\Sigma_{a,b=1}^{m+n}(-1)^{[b]}E_{ab}E_{ba}$. For any $f\in\mathbb{C}(K\backslash G/K)$, we have $\mathrm{d}R_X\,\mathrm{d}R_c(f)=\mathrm{d}R_c\,\mathrm{d}R_X(f)=0$, $\forall X\in\mathfrak{l}$. That is $\mathrm{d}R_c(f)\in\mathbb{C}(K\backslash G/K)$. Consider the following generalized Laplacian operator on the homogeneous superspace:

$$\nabla^2=-\sum_{i=1}^{m+n-1}E_{i,m+n}E_{m+n,i}.$$

Then the actions of $\mathrm{d}R_{\nabla^2}$ and $\frac{1}{2}\mathrm{d}R_c$ coincide on $\mathbb{C}(K\backslash G/K)$. Thus $\mathrm{d}R_{\nabla^2}$ also maps $\mathbb{C}(K\backslash G/K)$ to itself.

In the case of the projective superspace, we can show that

$$\mathrm{d}R_{\nabla^2}(r^k) = kr^{k-1}[(m-n-k+1)r+k], \quad k=0,1,\ldots . \tag{5.2}$$

Let us now consider eigenfunctions of $\mathrm{d}R_{\nabla^2}$ in $\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathbb{R}}(\mathfrak{k})}}$. Things turn out to be quite different for $m-n+1\leqslant 0$ and $m-n+1>0$.

(1) If $m-n+1\leqslant 0$, there exists an eigenfunction $\theta_k \in \mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathbb{R}}(\mathfrak{k})}}$ of $\mathrm{d}R_{\nabla^2}$ for each $k\in\mathbb{Z}_+$ with $\mathrm{d}R_{\nabla^2}(\theta_k)=k(m-n-k+1)\theta_k$, where

$$\theta_k = \sum_{i=0}^{k} (-1)^i \binom{n-m+2k-2}{i} \binom{k}{i}^2 (i!)^2 r^{k-i}. \tag{5.3}$$

Furthermore, the θ_k, $k\in\mathbb{Z}_+$, span $\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathbb{R}}(\mathfrak{k})}}$.

(2) If $m-n+1>0$, we let $L=m-n+1$, and denote by $[L/2]$ the largest integer $\leqslant L/2$. Then there exists an eigenfunction $\theta_k \in \mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathbb{R}}(\mathfrak{k})}}$ of $\mathrm{d}R_{\nabla^2}$ for each non-negative integer k satisfying either $k\leqslant[L/2]$ or $k>L$ with $\mathrm{d}R_{\nabla^2}$-eigenvalue $k(L-k)$, where the θ_k are still given by (5.3). However, the θ_k's do not span $\mathbb{C}(\mathbb{P}^{n-1|m})^{\mathrm{d}R_{\mathrm{U}^{\mathbb{R}}(\mathfrak{k})}}$.

Note that if $m-n+1>0$, the operator $\mathrm{d}R_{\nabla^2}$ is not diagonalizable over $\mathbb{C}(K\backslash G/K)$. The simplest illustration comes from the case with $L=1$, where $\mathbb{C}(K\backslash G/K)$ is the direct sum of $\{a+br \,|\, a,b\in\mathbb{C}\}$ and $\oplus_{k>1}\mathbb{C}\theta_k(r)$. While acting diagonally on the latter subspace, $\mathrm{d}R_{\nabla^2}$ acts on the former subspace by $\mathrm{d}R_{\nabla^2}(a+br)=b$.

Remark 5.4: $\mathbb{C}(G)$ is not semisimple with respect to $\mathrm{d}R_{\mathrm{U}(\mathfrak{g})}$. There exist $\mathrm{d}R_{\mathrm{U}(\mathfrak{g})}$-submodules of $\mathbb{C}(G)$ on which $\mathrm{d}R_c$ cannot be diagonalized. Therefore, $\mathrm{d}R_{\nabla^2}$ is not diagonalizable on $\mathbb{C}(K\backslash G/K)$ in general, and case (2) shows this fact.

B. The other maximal rank *K* cases

We assume that both m and n are greater than 2 in this section, and consider the maximal rank K's that correspond to the subalgebras $\mathfrak{k}_{n,k}:=\mathfrak{l}_{n,k}^{\sigma,\sqrt{\imath}}$ and $\mathfrak{k}_{m,k}:=\mathfrak{l}_{m,k}^{\sigma,\sqrt{\imath}}$, where

$$\mathfrak{l}_{n,k} = \mathfrak{gl}(m|n-k)\oplus\mathfrak{gl}(k), \quad 0<k\leqslant n,$$

$$\mathfrak{l}_{m,k} = \mathfrak{gl}(k)\oplus\mathfrak{gl}(m-k|n), \quad 0<k\leqslant m.$$

For the subalgebra $\mathfrak{k}_{n,k}$, by Theorem 4.1, the corresponding homogeneous superspace $\mathbb{C}(K_{n,k}\backslash G)$ is generated by

$$C_{ab} = \sum_{c=m+n-k+1}^{m+n} t_{ca}\overline{t_{cb}}, \quad a,b\in\mathbf{I}.$$

Note that $[c]=1$. As in Theorem 5.1, we can show that $\mathbb{C}[C_{ab}]$ forms a polynomial algebra in one variable if $[a]=[b]=1$; and if $[a]=[b]=0$, then $(C_{ab})^{k+1}=0$ and $(C_{ab})^k\neq 0$. Recall that by Proposition 4.1, we always have $(C_{ab})^2=0$ if $[a]+[b]=1$. The subalgebra of spherical functions $\mathbb{C}[K_{n,k}\backslash G/K_{n,k}]$ is generated by

$$C = \sum_{c,a=m+n-k+1}^{m+n} t_{ca}\overline{t_{ca}},$$

and forms a polynomial algebra in one variable. Similarly, for $\mathfrak{k}_{m,k}$, the symmetric superspace $\mathbb{C}(K_{m,k}\backslash G)$ is generated by

$$C_{ab} = \sum_{c=1}^{k} t_{ca}\overline{t_{cb}}, \quad a,b \in \mathbf{I}.$$

If $[a]=[b]=0$, then $\mathbb{C}[C_{ab}]$ forms a polynomial algebra in one variable, and if $[a]=[b]=1$, then $(C_{ab})^{k+1}=0$ and $(C_{ab})^{k}\neq 0$. The subalgebra of spherical functions $\mathbb{C}(K_{m,k}\backslash G/K_{m,k})$ is generated by

$$C = \sum_{c,a=1}^{k} t_{ca}\overline{t_{ca}},$$

as a polynomial algebra. To summarize, we have

Theorem 5.2: (1) *If $m\leqslant n$, then there is an onto algebra homomorphism,*

$$\phi:\mathbb{C}(K_{n,k}\backslash G) \rightarrow \mathbb{C}(K_{m,k}\backslash G)$$

which induces an isomorphism $\mathbb{C}(K_{n,k}\backslash G/K_{n,k})\rightarrow\mathbb{C}(K_{m,k}\backslash G/K_{m,k})$.

(2) *For each $1\leqslant k<n$, there is an onto algebra homomorphism,*

$$\phi_{k+1,k}:\mathbb{C}(K_{n,k+1}\backslash G) \rightarrow \mathbb{C}(K_{m,k}\backslash G)$$

which induces an isomorphism $\mathbb{C}(K_{n,k+1}\backslash G/K_{n,k+1})\rightarrow\mathbb{C}(K_{n,k}\backslash G/K_{n,k})$.

Proof: For (1), we just need to note that any relation among the C_{ab} holds for both algebras by symmetry. For (2), let the generators of $\mathbb{C}(K_{n,k}\backslash G)$ described above be $C_{ab}(k)$ $(a,b\in\mathbf{I}, 1\leqslant k\leqslant n)$, and define $\phi_{k+1,k}:\mathbb{C}(K_{n,k+1}\backslash G)\rightarrow\mathbb{C}(K_{m,k}\backslash G)$ by $\phi_{k+1,k}(C_{ab}(k+1))=[(k+1)/k]C_{ab}(k)$. ■

Scattering amplitude and scattering phase for the Schrödinger equation with strong magnetic field

Laurent Michel[a)]
Institut Gallilée, Département de Mathématiques, Universite Paris XIII, 93430 Villetaneuse, France

(Received 18 October 2004; accepted 14 January 2005; published online 30 March 2005)

In this paper we consider the Schrödinger equation with constant magnetic field of strength $b>0$ in all dimension. We study the behavior of the scattering amplitude and the scattering phase when the parameter b goes to infinity and the energy is far from the Landau levels. © *2005 American Institute of Physics.*

I. INTRODUCTION

In this paper, we are interested in the Schrödinger equation with magnetic field

$$i\partial_t\psi = H(b)\psi,$$

where $H(b)=H_0(b)+V(x)$ with $V\in L^\infty(\mathbb{R}^n)$ and

$$H_0(b) = |i\nabla_x - bA(x)|^2. \tag{1}$$

Here, $A:\mathbb{R}^n\to\mathbb{R}^n$ is the magnetic potential and b is a strictly positive real parameter. Our aim is to study the scattering matrix associate to the pair $(H(b),H_0(b))$. In order to lighten the notations we drop the parameter b and write H instead of $H(b)$. There is a wide literature dealing with the Schrödinger equation with magnetic field (see for instance Refs. 2, 7, and 14 for general properties dealing with our problem). In this paper, we consider the case where the magnetic field is constant. More precisely, denoting $A(x)=(A_1(x),\dots,A_n(x))$ with $A_j:\mathbb{R}^n\to\mathbb{R}$, $j=1,\dots,n$, the magnetic field B can be identified with the antisymmetric matrix $B(x)=(\partial_{x_i}A_j(x)-\partial_{x_j}A_i(x))_{i,j}$. Here, we consider the case where the magnetic field $B(x)$ does not depend on x. Regarding B as an antisymmetric linear map on $\mathbb{R}^n$, we set $2d=\dim \mathrm{Ran}\, B$ and $k=n-2d=\dim \mathrm{Ker}\, B$. As we are interested in the case where $B\neq 0$, we suppose that $d\neq 0$. On the other hand, as we study scattering problems we do not consider the case $n=2d$ where the spectrum of H_0 is pure point. Hence, we suppose that $k=n-2d\neq 0$. Under this assumption there exists Cartesian coordinates in which the reference Hamiltonian takes the form

$$H_0 = \sum_{j=1}^{d}\left[(i\partial_{x_{2j-1}} - b\mu_j x_{2j})^2 + (i\partial_{x2j} + b\mu_j x_{2j-1})^2\right] - \Delta_{x\|},$$

where $x=(x_1,x_2,\dots,x_{2d-1},x_{2d},x_\|)=(x_\perp,x_\|)\in\mathbb{R}^{2d}\times\mathbb{R}^{n-2d}$ and $\mu_1,\dots,\mu_d$ are strictly positive real numbers (see Ref. 14 for details). Under suitable assumptions on V, it is well known (see Ref. 2) that the scattering operator $\mathbf{S}=\mathbf{S}(b)$ associated to the pair (H_0,H) is well defined. Our aim is to describe this operator when the parameter b goes to infinity.

Before going further, let us recall some works concerning such problems. First, we would like to mention some results concerning the scattering matrix in the case where $A(x)$ is a long range potential [i.e., $A(x)$ decreases faster than $|x|^{-\rho}$ for some $\rho>0$ when $|x|$ goes to infinity]. In that

a)Electronic mail: michel@math.univ-paris13.fr

case, there is a scattering theory for the pair $(H,-\Delta)$ (cf. Refs. 10, 13, 16, and 18) and it is possible to describe the behavior of the scattering amplitude in the high energy limit (cf. the work of Nicoleau[12]).

On the other hand, there are some recent works of Bruneau–Pushnitski–Raikov[5] and Bruneau–Dimassi,[4] concerning the Schrödinger equation with constant magnetic field. In Ref. 5, the authors study the spectral shift function associate to this equation in dimension 3 and they describe its behavior in several asymptotic regimes. In particular, they investigate deeply the case where b goes to infinity and the distance from the energy to the set of Landau levels behaves as b. There are also some works of Kostrykin–Kvitsinsky–Mekuyriev,[8] where the authors study partial scattering matrix in dimension 3 near the Landau levels (b being fixed). Moreover, in Ref. 8 the authors make some symmetry assumption on the potential V. Here, we would like to treat the case of general potential in dimension n in the asymptotic regime considered in Ref. 5.

First, we need to give an exact definition of the scattering amplitude in the present situation. Let us consider the Schrödinger operator with constant magnetic field in dimension $2d$,

$$\hat{H}_0 = \sum_{j=1}^{d} [(i\partial_{x_{2j-1}} - b\mu_j x_{2j})^2 + (i\partial_{x_{2j}} + b\mu_j x_{2j-1})^2] \tag{2}$$

acting on $L^2(\mathbb{R}^{2d})$. As $\mu_1 \cdots \mu_d \neq 0$, it is well known that the spectrum of $\hat{H}_0$ is pure point.[2] For $q=(q_1,\ldots,q_d)\in\mathbb{N}^d$ we denote $\Lambda_q=(2_{q1}+1)\mu_1+\cdots+(2q_d+1)\mu_d$, so that the spectrum of $\hat{H}_0$ is given by the sequence of Landau levels

$$\mathbb{L} = \sigma(\hat{H}_0) = \sigma_{pp}(\hat{H}_0) = \{b\Lambda_q, q \in \mathbb{N}^d\}.$$

In particular, the bottom of the spectrum is given by $b\Lambda_0=b(\mu_1+\cdots+\mu_d)$. Let us denote by $\Upsilon_q \subset L^2(\mathbb{R}^{2d})$ the eigenspace associated to the eigenvalue $b\Lambda_q$ and $\Pi_q: L^2(\mathbb{R}^{2d}) \to \Upsilon_q$ the corresponding projector. Denoting $L^2_\alpha(\mathbb{R}^{n-2d})=\{f\in L^2(\mathbb{R}^{n-2d}); \langle x_\parallel\rangle^\alpha f \in L^2(\mathbb{R}^{n-2d})\}$; we define $\tilde{\mathcal{F}}_0(\lambda): L^2_\alpha(\mathbb{R}^{n-2d}) \to L^2(S^{n-2d-1})$ by

$$\tilde{\mathcal{F}}_0(\lambda)\varphi(\xi) = \frac{\lambda^{(n-2d-2)/4}}{\sqrt{2}(2\pi)^{(n-2d)/2}} \int_{\mathbb{R}^{n-2d}} e^{-i\sqrt{\lambda}\langle x,\xi\rangle}\varphi(a)\mathrm{d}x,$$

and we set

$$\mathcal{F}_0(\lambda): L^2(\mathbb{R}^{2d}, L^2_\alpha(\mathbb{R}^{n-2d})) \to L^2(\mathbb{R}^{2d}\times S^{n-2d-1}),$$

$$\varphi \mapsto \sum_{b\Lambda_q \leqslant \lambda} \Pi_q \otimes \tilde{\mathcal{F}}_0(\lambda - b\Lambda_q)\varphi.$$

Let us introduce the space

$$L^\infty_\alpha(\mathbb{R}^n) = \{u: \mathbb{R}^n \to \mathbb{R}, \langle x_\parallel\rangle^\alpha u \in L^\infty(\mathbb{R}^n)\}$$

and for $u\in L^\infty_\alpha(\mathbb{R}^n)$ let us set $\|u\|_{\infty,\alpha}=\|\langle x_\parallel\rangle^\alpha u\|_{L^\infty}$. The assumption that we make on the potential V is the following.

Assumption 1: We assume that $V(x_\parallel,x_\perp)=V^\infty(x_\parallel)+W(x_\parallel,x_\perp)$ with V^∞ and W in $L^\infty_\rho(\mathbb{R}^n)$ for some $\rho>1$, $V^\infty \geqslant 0$ and $\sup\{|W(n)|, 1\times 1 \geqslant R\} \to 0$ when $R\to+\infty$.

It follows from the general results of Ref. 2 that under this assumption the wave operators associated to the pair (H_0,H) exist and are complete. Therefore, the scattering operator $\mathbf{S}(b)$ is well defined and by the mean of $\mathcal{F}_0$, we can define the scattering matrix. More precisely, recall that the absolute continuous spectrum of H_0 is $\sigma_{ac}(H_0)=]b\Lambda_0,+\infty[$. Then for all $\lambda > b\Lambda_0$ there exists

$$S(\lambda,b): L^2(\mathbb{R}^{2d}\times S^{n-2d-1}) \to L^2(\mathbb{R}^{2d}\times S^{n-2d-1})$$

such that

$$S(\lambda,b)\mathcal{F}_0(\lambda) = \mathcal{F}_0(\lambda)\mathbf{S}(b).$$

Let us denote $\mathcal{H}_\alpha = L^2(\mathbb{R}^n, \langle x_\| \rangle^\alpha \, dx)$ and $\|\cdot\|_{\mathcal{H}_\alpha}$ the corresponding norm. Our first result gives a representation formula for the scattering matrix very similar to that obtained for the Schrödinger equation.[1]

Theorem 1: *Suppose that Assumption 1 is satisfied and denote by $\sigma_{pp}(H)$ the point spectrum of H. Then, for all $\lambda \in]b\Lambda_0, +\infty[\setminus (L \cup \sigma_{pp}(H))$, one has*

$$S(\lambda,b) - Id = -2i\pi\mathcal{F}_0(\lambda)V(x)\mathcal{F}_0(\lambda)^* + 2i\pi\mathcal{F}_0(\lambda)V(x)R(\lambda+i0)V(x)\mathcal{F}_0(\lambda)^*, \tag{3}$$

where

$$R(\lambda+i0) = \lim_{\mu\to 0^+} (H-\lambda-i\mu)^{-1}$$

exists in the space $\mathcal{L}(\mathcal{H}_\alpha, \mathcal{H}_{-\alpha})$ for $\alpha > 1/2$.

Remark 1.1: In the case where the potential V is compactly supported with respect to the variable $x_\|$, the scattering matrix takes a form that could be interesting for other applications. More precisely, suppose that $V \in L^\infty(\mathbb{R}^n)$ and there exists a compact $K \subset \mathbb{R}^{n-2d}$ such that $\forall x_\| \notin K$, $V(.,x_\|) = 0$. Let χ_1, $\chi_2 \in C_0^\infty(\mathbb{R}^{n-2d})$ such that $\chi_1 = 1$ in a neighborhood of K and $\chi_2 = 1$ on supp χ_1. *Then, using some ingrations by parts, it is not hard to prove that*

$$S(\lambda,b) - Id = -2i\pi\mathcal{F}_0(\lambda)[\Delta_{x_\|}, \chi_1]R(\lambda+i0)[\Delta_{x_\|}, \chi_2]\mathcal{F}_0(\lambda)^*.$$

Using Theorem 1, we can describe the behavior of $S(\lambda,b)$. Let us set $T(\lambda,b) = S(\lambda,b) - Id$, then $T(\lambda,b)$ has a kernel

$$(\omega,\omega') \in S^{n-2d-1} \times S^{n-2d-1} \mapsto T(\omega,\omega',\lambda,b) \in \mathcal{L}(L^2(R^{2d})).$$

Denote by $\hat{V}^\|$ the partial Fourier transform of V with respect to the variable $x_\|$. We need to introduce two additional assumptions.

Assumption 2: We suppose that $V \in L^\infty_\rho(\mathbb{R}^n)$ for some $\rho > n - 2d$, and that $\hat{V}^\| \in L^\infty_r(\mathbb{R}^n)$ for some $r > 0$.

Assumption 3: We suppose that $\hat{V}^\| \in C^1(\mathbb{R}^n)$ and that $\sup_{\mathbb{R}^n} |\partial_{x_\perp} \hat{V}^\|| < \infty$.

Now we are in position to state our main result on the scattering amplitude. In the following we denote

$$\tilde{\mathbb{L}} = \{\Lambda_q, q \in \mathbb{N}^d\} = b^{-1}\mathbb{L}.$$

and

$$\tilde{Q}(\mathcal{E}) = \{q \in \mathbb{N}^d; \Lambda_q \leqslant \mathcal{E}\},$$

which is a finite set, thanks to the fact that $\mu_1, \ldots, \mu_d > 0$. In this paper we denote by $\|\cdot\|$ the L^2 norm and the norm on the space of linear bounded operators on L^2. We have the following theorem.

Theorem 2: *Suppose that Assumptions 1 and 2 are satisfied and let $\lambda > b\Lambda$.*

(i) *Denote $\delta := dist(\lambda, \mathbb{L})$ and suppose that $\delta > \|V\|_{\infty,\rho}$, then*

$$\sup_{(\omega,\omega')\epsilon S^{n-2d-1}\times S^{n-2d-1}} \left\| T(\omega,\omega',\lambda,b) + \frac{i}{2(2\pi)^{n-2d+1}} \sum_{b\Lambda_q \leqslant \lambda} (\lambda - b\Lambda_q)^{(n-2d-2)/2} \Pi_q \hat{V}^{\|}(x_\perp, \sqrt{\lambda - b\Lambda_q} \times(\omega-\omega'))\Pi_q \right\| \leqslant C\lambda b^{-1} \delta^{[n-2d-2-\min(1,r)]/2}, \tag{4}$$

where C depends only on $\|\hat{V}^{\|}\|_{\infty,r}$ *and* $\|V\|_{\infty,\rho}$.

(ii) *We suppose additionally that Assumption 3 is satisfied. Let* $\mathcal{E} \in]\Lambda_0, +\infty[\setminus \tilde{\mathbb{L}}$ *and* $\Delta \subset \mathbb{R}$ *be a bounded interval. When b tends to infinity, one has*

$$\sup_{(\omega,\omega')\epsilon S^{n-2d-1}\times S^{n-2d-1}} \sup_{\lambda\in\Delta} \left\| T(\omega,\omega',\mathcal{E}b+\lambda,b) + \frac{ib^{(n-2d-2)/2}}{2(2\pi)^{n-2d+1}} \sum_{q\in\tilde{Q}(\mathcal{E})} \beta_q^{n-2d-2} \hat{V}^{\|}(x_\perp, b^{1/2}\beta_q(\omega - \omega'))\Pi_q \right\| \leqslant C b^{[n-2d-2-\min(1,r)]/2}, \tag{5}$$

where

$$\beta_q = (\mathcal{E} - \Lambda_q)^{1/2} = (\mathcal{E} - \mu_1 q_1 - \cdots - \mu_d q_d)^{1/2}. \tag{6}$$

From this theorem we can also deduce the following inverse scattering result.

Corollary 1.2: Suppose that V_1, V_2 *satisfy Assumptions* 1, 2, *and* 3. *Assume that the associate scattering operators* S_1 *and* S_2 *are equal. Then* $V_1 = V_2$.

We can also use the representation formula of Theorem 1 to study the scattering phase $s(\lambda,b)$ associate to the pair (H,H_0). Let us recall briefly how to define this function. Assume that the operator $T(\lambda,b)$ is trace class. Then the determinant $\det(I+T(\lambda,b))$ is well defined. Moreover, $S(\lambda,b)$ being unitary, this determinant is of modulus 1 so that the function $s(.,b)$ can be defined modulo 2π by

$$\det S(\lambda,b) = e^{-2i\pi s(\lambda,b)}. \tag{7}$$

Assume additionally that for b large enough, $\|T(\lambda,b)\| < 1$ uniformly with respect to λ. Then $s(\lambda,b) = (-1/2i\pi)\ln \det S(\lambda,b)$ can be determined uniquely by the following process. Consider the function

$$f{:}\sigma \in [0,1] \mapsto \det(I+\sigma T) \in \mathbb{C}$$

which is holomorphic with respect to σ. From the assumption $\|T\| < 1$ we deduce that the spectrum of T is contained in $]-1,1[$ and the function f is nonvanishing. Therefore, the function $\ln(f)$ such that $\ln(f)(0) = 0$ is uniquely defined and it follows that $s = \ln(f)(1) = (1/2i\pi)\ln \det(I+T)$ is well defined. Moreover, by construction, we have

$$2i\pi s(\lambda,b) = \int_0^1 \frac{\mathrm{d}}{\mathrm{d}\sigma} \ln(\det(Id + \sigma T(\lambda,b)))\mathrm{d}\sigma = \int_0^1 \mathrm{tr}\,(T(\lambda,b)(Id+\sigma T(\lambda,b))^{-1})\mathrm{d}\sigma. \tag{8}$$

Before we state our results, let us recall the link between the scattering phase $s(\lambda,b)$ and the spectral shift function $\xi(\lambda,b)$ (in short SSF). Assume that the difference $(H+\lambda_0)^{-\gamma} - (H_0+\lambda_0)^{-\gamma}$ is trace class for some $\lambda_0, \gamma > 0$ large enough [for instance, if $\langle x\rangle^{\delta/2} V \in L^2(\mathbb{R}^n)$ with $\delta > n$, this assumption is satisfied in view of Theorem XI.21 of Ref. 15 and the diamagnetic inequality]. Therefore, the spectral shift function can be defined (see Refs. 17 and 9) in the sense of distribution by:

$$\langle \xi'(.,b)\,.\,f\rangle = \mathrm{tr}(f(H) - f(H_0)), \quad \forall\, f \in C_0^\infty(\mathbb{R})$$

and $\xi(\lambda,b)=0$ for λ below the infimum spectrum of H. Moreover, we know from the Birman–Krein theory (see Refs. 3 and 17) that

$$\det S(\lambda,b) = e^{-2i\pi\xi(\lambda,b)}. \tag{9}$$

Comparing Eqs. (9) and (7), it follows that $\xi(\lambda,b)=s(\lambda,b)+c(\lambda,b)$ with $c(\lambda,b)\in\mathbb{Z}$. In Ref. 5, Bruneau, Pushnitski, and Raikov studied the asymptotics of $\xi(\lambda,b)$ far from the Landau levels. In the two next theorems we lead such a study for the scattering phase.

Theorem 3: *Suppose that Assumption 1 is satisfied and that* $V\in L^1(\mathbb{R}^n)$. *Let* $\mathcal{E}\in\,]\Lambda_0, +\infty[\backslash\widetilde{\mathbb{L}}$ *and* $\Delta\subset\mathbb{R}$ *be a bounded interval. When* $b\to+\infty$, *one has* $\sup_{\lambda\in\Delta}\|T(\mathcal{E}b+\lambda)\|\leqslant Cb^{-1/2}$ *and the scattering phase defined by (8) satisfies*

$$\sup_{\lambda\in\Delta}\left| s(\mathcal{E}b+\lambda,b) + b^{(n-2)/2}\frac{mes(S^{n-2d-1})}{2(2\pi)^{n-2d+1}}\sum_{q\in\widetilde{Q}(\mathcal{E})}\beta_q^{n-2d-1}\int_{\mathbb{R}^n}V(x)\mathrm{d}x\right| = \mathcal{O}(b^{(n-3)/2}), \tag{10}$$

where β_q *is given by (6) and* $mes(S^{n-2d-1})$ *denotes the Lebesgue measure of* S^{n-2d-1}.

Let us remark that in the asymptotic regime that we consider the scattering phase and the spectral shift function differ from a constant independent on λ and b. Indeed, it is clear that these functions are continuous far from the Landau levels. Hence, for $\mathcal{E}\in\,]\Lambda_0,+\infty[\backslash\widetilde{\mathbb{L}}$, the function $c(\mathcal{E}b+\lambda,b)$ is continuous with respect to $(\lambda,b)\in\Delta\times\,]b_0,+\infty[$ for b_0 large enough. As it takes its values in $\mathbb{Z}$ it follows that c is constant. Therefore, it follows from (10) that under the preceding assumptions we have

$$\sup_{\lambda\in\Delta}\left| \xi(\mathcal{E}b+\lambda,b) + b^{(n-2)/2}\frac{mes(S^{n-2d-1})}{2(2\pi)^{n-2d+1}}\sum_{q\in\widetilde{Q}(\mathcal{E})}\beta_q^{n-2d-1}\int_{\mathbb{R}^n}V(x)\mathrm{d}x\right| = \mathcal{O}(b^{(n-3)/2}).$$

Remark that this result generalizes Theorem 2.1 of Ref. 5 in several directions. First it holds in all dimension whereas Bruneau, Pushnitski, and Raikov work in dimension 3. Moreover, it needs less regularity on the potential. Let us also remark that the method we use to prove it is completely different from that of Ref. 5 as it stands on the study of the scattering phase. However, we can notice that for $n=3$, we obtain the same asymptotics than in Ref. 5.

Using this representation, we can also give a complete asymptotics expansion of scattering phase. For a sake of simplicity, we formulate the theorem only in the case $n=3$ (and hence we can suppose that $\mu_1=1$), but the proof is the same in the case where $n=2d+1$. We also prove the Theorem for V in the Schwartz class whereas it certainly holds for more general C^∞ potentials going to zero at infinity as well as their derivatives.

Theorem 4: *Suppose that* $V\in\mathcal{S}(\mathbb{R}^3)$. *Let* $\mathcal{E}\in\mathbb{R}_+^*\backslash\{2q+1, q\in\mathbb{N}\}$ *and* $\Delta\subset\mathbb{R}$ *be a bounded interval. There exists a sequence of coefficients* $(a_j(\lambda,\mathcal{E},V))_{j\in\mathbb{N}}$ *such that one has the following expansion when* $b\to+\infty$:

$$\sup_{\lambda\in\Delta}\left| s(\mathcal{E}b+\lambda,b) - b^{\frac{1}{2}}\sum_{j=0}^{\infty}a_j(\lambda,\mathcal{E},V)b^{-j}\right| = \mathcal{O}(b^{-\infty}). \tag{11}$$

Moreover, the coefficients a_j *can be computed explicitly. Setting* $\gamma_j(\mathcal{E})=\sum_{q=1}^{[(\varepsilon-1)]/2}(\mathcal{E}-2q-1)^{-\frac{1}{2}-j}$, *one has*

$$a_0(\lambda,\mathcal{E},V) = -\frac{\gamma_0(\mathcal{E})}{4\pi^2}\int_{\mathbb{R}^3}V(x)\mathrm{d}x,$$

$$a_1(\lambda,\mathcal{E},V)=\frac{\gamma_1(\mathcal{E})}{16\pi^2}\left(2\lambda\int_{\mathbb{R}^3}V(x)\mathrm{d}x-\int_{\mathbb{R}^3}V(x)^2\,\mathrm{d}x\right).$$

The plan of the paper is the following. In the next section we use the spectral resolution of H_0 to obtain a representation formula for the scattering matrix. In Sec. III, we study the scattering amplitude whereas the results concerning the scattering phase are proved in Sec. IV.

II. REPRESENTATION OF THE SCATTERING MATRIX

In this section, we recall some basic facts on the spectral resolution of H_0 and the limiting absorption principle and we prove Theorem 1. Let us denote $\partial\widetilde{E}_0/\partial\lambda:L^2(\mathbb{R}^{n-2d})\to L^2(\mathbb{R}^{n-2d})$ the spectral resolution of $-\Delta_{x_\parallel}$ on $\mathbb{R}^{n-2d}$. Then, it is well known that the spectral resolution of H_0 is given by

$$\frac{\partial E_0}{\partial\lambda}=\sum_{b\Lambda_q\leqslant\lambda}\Pi_q\otimes\frac{\partial\widetilde{E}_0}{\partial\lambda}(\lambda-\Lambda_q). \tag{12}$$

Moreover, one knows that $\partial\widetilde{E}_0/\partial\lambda=\widetilde{\mathcal{F}}_0(\lambda)^*\widetilde{\mathcal{F}}_0(\lambda)$ so that (12) yields

$$\frac{\partial E_0}{\partial\lambda}=\mathcal{F}_0(\lambda)^*\mathcal{F}_0(\lambda). \tag{13}$$

For $z\in\mathbb{C}$ with $\mathrm{Im}\,z\neq 0$, we set $R_0(z)=(H_0-z)^{-1}$ and $R(z)=(H-z)^{-1}$ which are holomorphic with respect to $z\in\mathbb{C}\backslash\mathbb{R}$. We denote by $\sigma_{pp}(H)$, the point spectrum of H. The following proposition gives the limiting absorption principle for the operators H_0 and H.

Proposition 2.1: (i) *Assume that* $\lambda\in]b\Lambda_0,+\infty[\backslash\mathbb{L}$, *then the following limit exists in the space of bounded operators* $\mathcal{L}(\mathcal{H}_\alpha,\mathcal{H}_{-\alpha})$ *for any* $\alpha>1/2$:

$$R_0(\lambda\pm i0)=\lim_{\mu\to0^+}R_0(\lambda\pm i\mu).$$

(ii) *Suppose that Assumption* 1 *is satisfied and that* $\lambda\in\mathbb{R}_+^*\backslash(\sigma_{pp}(H)\cup\mathbb{L})$, *then there exists*

$$R(\lambda\pm i0)=\lim_{\mu\to0^+}R(\lambda\pm i\mu)$$

in $\mathcal{L}(\mathcal{H}_\alpha,\mathcal{H}_{-\alpha})$ *for any* $\alpha>1/2$.

Proof: Using (12), it is clear that for all $z\in\mathbb{C}\backslash\mathbb{R}$, one has

$$R_0(z)=\sum_{q\in\mathbb{N}^d}\Pi_q\otimes(-\Delta_{x_\parallel}-(z-b\Lambda_q))^{-1}, \tag{14}$$

where the series converges in $\mathcal{L}(\mathcal{H}_\alpha,\mathcal{H}_{-\alpha})$ for any $\alpha>1/2$. Assume that $\lambda\in]b\Lambda_0,+\infty[\backslash\mathbb{L}$, then

$$R_0(\lambda\pm i\mu)=\sum_{b\Lambda_q\leqslant\lambda}\Pi_q\otimes(-\Delta_{x_\parallel}-(\lambda\pm i\mu-b\Lambda_q))^{-1}+W(\lambda\pm i\mu),$$

with

$$\|W(\lambda\pm i\mu)-W(\lambda\pm i\mu')\|^2\leqslant C|\mu-\mu'|^2\sum_{b\Lambda_q\geqslant\lambda}\|\Pi_q\otimes Id\|^2\leqslant C|\mu-\mu'|^2. \tag{15}$$

Moreover, using the limiting absorption principle for the free Laplacian on $\mathbb{R}^{n-2d}$ it is clear that for any $\lambda\in]b\Lambda_0,+\infty[\backslash\mathbb{L}$, there exists

$$\lim_{\mu\to 0^+}\sum_{b\Lambda_q\leqslant\lambda}\Pi_q\otimes(-\Delta_{x_\parallel}-(\lambda\pm i\mu-b\Lambda_q))^{-1}$$

and the proof of (i) is complete.

The proof of (ii) is very close to the proof of Agmon[1] for Schrödinger operator. For $\mathrm{Im}\, z>0$, let us denote $R_\infty(z)=(H_0+V^\infty-z)^{-1}$. The potential V^∞ being independent on $x_\perp$, it commutes with the projectors Π_q so that

$$\forall\,\mathrm{Im}\, z>0,\ R_\infty(z)=\sum_{q\in\mathbb{N}^d}\Pi_q\otimes(-\Delta_{x_\parallel}+V^\infty(x_\parallel)-(z-b\Lambda_q))^{-1}.$$

As V^∞ is non negative the spectrum of $-\Delta_{x_\parallel}+V^\infty$ is contained in $\mathbb{R}^+$ and we deduce from the limiting absorption principle for the Schrödinger operator that for any $\lambda\in]b\Lambda_0,+\infty[\backslash\mathbb{L}$,

$$R_\infty(\lambda\pm i0)=\lim_{\mu\to 0+}R_\infty(\lambda\pm i\mu)=\sum_{b\Lambda_q\leqslant\lambda}\Pi_q\otimes(-\Delta_{x_\parallel}+V^\infty-(\lambda\pm i0-b\Lambda_q))^{-1}$$

exists in $\mathcal{L}(\mathcal{H}_\alpha,\mathcal{H}_{-\alpha})$. Now for $\mathrm{Im}\ z>0$ we can write

$$R(z)=R_\infty(z)(Id+WR_\infty(z))^{-1}$$

As in Ref. 1, the only thing we have to check is that for all $z\in\mathbb{C}$ with $\mathrm{Im}\,(z)\geqslant 0$, $K(z)=W(x)R_\infty(z)$ is compact from $\mathcal{H}_\alpha$ into $\mathcal{H}_\alpha$ for some $\alpha>1/2$. On the other hand,

$$K(z)=W(x)R_0(z)(Id-V^\infty R_\infty(z))$$

and it follows from the limiting absorption principle for $R^\infty(z)$ that $(Id-V^\infty R_\infty(z))$ can be continued to $\mathrm{Im}\, z\geqslant 0$ into a bound operator on $\mathcal{H}_\alpha$ for $1/2<\alpha<\rho/2$. Hence the proof is reduced to show that $W R_0(z)$ is compact from $\mathcal{H}_\alpha$ into $\mathcal{H}_\alpha$. Using the diamagnetic inequality (see Ref. 14, Lemma 2.1), the compactness of $K(z)$ is a straightforward consequence of the same property for the Schrödinger operator.

In the next proposition we recall some estimates of the resolvent proved in Ref. 5.

Proposition 2.2: (i) *Assume that* $\lambda\in]b\Lambda_0,+\infty[\backslash\mathbb{L}$, *then*

$$\|\langle x_\parallel\rangle^{-\alpha}R_0(\lambda\pm i0)\langle x_\parallel\rangle^{-\alpha}\|\leqslant\frac{C}{dist(\lambda,\mathbb{L})^{1/2}},\ \forall\ \alpha>1/2.$$

(ii) *Suppose that Assumption 1 is verified and that* $\lambda\in]b\Lambda_0,+\infty[$ *satisfies* $dist(\lambda,\mathbb{L})>\|V\|_{\infty,\rho}$. *Then* $\lambda\notin\sigma_{pp}(H)$ *and*

$$\|\langle x_\parallel\rangle^{-\alpha}R(\lambda\pm i0)\langle x_\parallel\rangle^{-\alpha}\|\leqslant\frac{C}{dist(\lambda,\mathbb{L})^{1/2}},\ \forall\ 1/2<\alpha<\rho/2.$$

Proof: The point (i) is a direct consequence of the well-known high-energy estimates of the resolvent of the Schrödinger equation. The claim (ii) follows easily from Birman–Schwinger principle and from the following formula:

$$R(\lambda\pm i0)=R_0(\lambda\pm i0)(Id+V\,R_0(\lambda\pm i0))^{-1}.$$

■

Now, we are in position to give the proof of Theorem 1 which is an adaptation of the demonstration given in the case of the Schrödinger operator (cf. Ref. 6). We start with a simple lemma.

Lemma 2.3: Suppose that $\lambda\in]b\Lambda_0,+\infty[\backslash\mathbb{L}$, *then*

$$R_0(\lambda+i0)-R_0(\lambda-i0)=2i\pi\mathcal{F}_0(\lambda)^*\mathcal{F}_0(\lambda).$$

Proof: The proof is based on the fact that this result holds for the Schrödinger operator,

$$\forall \lambda > 0, (-\Delta_{x_\parallel} - \lambda - i0)^{-1} - (-\Delta_{x_\parallel} - \lambda + i0)^{-1} = 2i\pi \tilde{\mathcal{F}}_0(\lambda)^* \tilde{\mathcal{F}}_0(\lambda). \tag{16}$$

On the other hand, for $\lambda \in]b\Lambda_0, +\infty[\backslash \mathbb{L}$, it follows from (15) that

$$R_0(\lambda + i0) - R_0(\lambda - i0) = \sum_{b\Lambda_q \leqslant \lambda} (-\Delta_{x_\parallel} - \lambda + b\Lambda_q - i0)^{-1} \otimes \Pi_q - (-\Delta_{x_\parallel} - \lambda + b\Lambda_q + i0)^{-1} \otimes \Pi_q.$$

Using (16), we obtain

$$R_0(\lambda + i0) - R_0(\lambda - i0) = 2i\pi \sum_{b\Lambda_q \leqslant \lambda} \tilde{\mathcal{F}}_0(\lambda)^* \tilde{\mathcal{F}}_0(\lambda) \otimes \Pi_q = 2i\pi \mathcal{F}_0(\lambda)^* \mathcal{F}_0(\lambda),$$

and the proof is complete. ■

Using this lemma, we can prove Theorem 1. Let us denote $W_\pm$ the wave operators for the pair (H, H_0) and take f, g in the absolute continuous subspace of H_0. Then

$$\begin{aligned}\langle (\mathbf{S} - Id) f, g\rangle &= \langle (W_- - W_+) f, W_+ g\rangle \\ &= -i \int_{-\infty}^{+\infty} \langle e^{itH} V(x) e^{-itH_0} f, W_+ g\rangle \mathrm{d}t = -i \int_{-\infty}^{+\infty} \langle V(x) e^{-itH_0} f, W_+ e^{-itH_0} g\rangle \mathrm{d}t.\end{aligned}$$

Moreover, one knows that

$$W_+ - Id = i \int_0^{+\infty} e^{i\sigma H} V(x) e^{-i\sigma H_0} \mathrm{d}\sigma.$$

Therefore,

$$\begin{aligned}\langle (\mathbf{S} - Id) f, g\rangle &= i \int_0^{+\infty} i \int_{-\infty}^{+\infty} \langle V(x) e^{-i\tau H_0} f, e^{i\sigma H} V(x) e^{-i(\sigma+\tau)H_0} g\rangle \mathrm{d}\tau \, \mathrm{d}\sigma - i \int_{-\infty}^{+\infty} \langle V(x) e^{-itH_0} f, e^{-itH_0} g\rangle \mathrm{d}t \\ &= \lim_{\mu, \mu' \to 0^+} i \int_0^{+\infty} e^{-\mu\sigma} i \int_{-\infty}^{+\infty} e^{-\mu'|\tau|} \langle e^{i(\sigma+\tau)H_0} V(x) e^{-i\sigma H} V(x) e^{-i\tau H_0} f, g\rangle \mathrm{d}\tau \\ &\quad \times \mathrm{d}\sigma - i \int_{-\infty}^{+\infty} e^{-\mu'|\tau|} \langle V(x) e^{-itH_0} f, e^{-itH_0} g\rangle \mathrm{d}t \\ &= \lim_{\mu, \mu' \to 0} i \int_0^{+\infty} e^{-\mu\sigma} i \int_{-\infty}^{+\infty} e^{-\mu'|\tau|} \int_{b\Lambda_0}^{+\infty} \langle \mathcal{F}_0(\lambda) V(x) e^{-i\sigma(H-\lambda)} V(x) e^{-i\tau(H_0-\lambda)} f, \mathcal{F}_0(\lambda) g\rangle \, \mathrm{d}\lambda \\ &\quad \times \mathrm{d}\tau \, \mathrm{d}\sigma - i \int_{-\infty}^{+\infty} e^{-\mu'|\tau|} \int_{b\Lambda_0}^{+\infty} \langle \mathcal{F}_0(\lambda) V(x) e^{-it(H_0-\lambda)} f, \mathcal{F}_0(\lambda) g\rangle \mathrm{d}\lambda \, \mathrm{d}t \\ &= \lim_{\mu' \to 0^+} i \int_{-\infty}^{+\infty} e^{-\mu'|\tau|} \int_{b\Lambda_0}^{+\infty} \langle \mathcal{F}_0(\lambda) V(x) R(\lambda + i0) V(x) e^{-i\tau(H_0-\lambda)} f, \mathcal{F}_0(\lambda) g\rangle \mathrm{d}\lambda \, \mathrm{d}\tau \\ &\quad - i \int_{-\infty}^{+\infty} e^{-\mu'|\tau|} \int_{b\Lambda_0}^{+\infty} \langle \mathcal{F}_0(\lambda) V(x) e^{-it(H_0-\lambda)} f, \mathcal{F}_0(\lambda) g\rangle \mathrm{d}\lambda \, \mathrm{d}t \\ &= \int_{b\Lambda_0}^{+\infty} \langle \mathcal{F}_0(\lambda) V(x) R(\lambda + i0) V(x) (R_0(\lambda + i0) - R_0(\lambda - i0)) f, \mathcal{F}_0(\lambda) g\rangle \mathrm{d}\lambda \, \mathrm{d}\tau \\ &\quad - \int_{b\Lambda_0}^{+\infty} \langle \mathcal{F}_0(\lambda) V(x) (R_0(\lambda + i0) - R_0(\lambda - i0)) f, \mathcal{F}_0(\lambda) g\rangle \mathrm{d}\lambda \, \mathrm{d}t.\end{aligned}$$

Using Lemma 2.3, we obtain

$$\langle(\mathbf{S}-Id)f,g\rangle = 2i\pi\int_{b\Lambda_0}^{+\infty}\langle\mathcal{F}_0(\lambda)V(x)R(\lambda+i0)V(x)\mathcal{F}_0(\lambda)^*\mathcal{F}_0(\lambda)f,\mathcal{F}_0(\lambda)g\rangle \mathrm{d}\lambda\ \mathrm{d}\tau$$
$$-2i\pi\int_{b\Lambda_0}^{+\infty}\langle\mathcal{F}_0(\lambda)V(x)\mathcal{F}_0(\lambda)^*\mathcal{F}_0(\lambda)f,\mathcal{F}_0(\lambda)g\rangle \mathrm{d}\lambda\ \mathrm{d}t$$

and the proof of Theorem 1 is complete. ■

III. SCATTERING AMPLITUDE IN STRONG MAGNETIC FIELD

In this section, we prove Theorem 2. The first step is to write the scattering amplitude under a convenient form. Let us denote by $\langle .,.\rangle_{L^2(\mathbb{R}^{n-2d})}$ the scalar product on $L^2(\mathbb{R}^{n-2d})$. From Theorem 1 and Assumption 2, it is clear that for $\lambda\in]b\Lambda_0,+\infty[\setminus(\mathbb{L}\cup\sigma_{pp}(H))$, $T(\omega,\omega',\lambda,b)$ can be decomposed into $T=T_1+T_2$ with

$$T_1(\omega,\omega',\lambda,b) = -\frac{i\pi}{(2\pi)^{n-2d}}\sum_{b\Lambda_p\leqslant\lambda}\sum_{b\Lambda_p\leqslant\lambda}(\lambda-b\Lambda_q)^{(n-2d-2)/4}(\lambda-b\Lambda_p)^{(n-2d-2)/4}$$
$$\times\Pi_p\langle V(x_{\perp},.)e^{i\sqrt{\lambda-b\Lambda_q}\langle .,\omega'\rangle},e^{i\sqrt{\lambda-b\Lambda_p}\langle .,\omega\rangle}\rangle_{L^2(\mathbb{R}^{n-2d})}\Pi_q$$

and

$$T_2(\omega,\omega',\lambda,b) = \frac{i\pi}{(2\pi)^{n-2d}}\sum_{b\Lambda_p\leqslant\lambda}\sum_{b\Lambda_q\leqslant\lambda}(\lambda-b\Lambda_q)^{(n-2d-2)/4}(\lambda-b\Lambda_p)^{(n-2d-2)/4}$$
$$\times\int_{\mathbb{R}^{n-2d}}\Pi_p V(x_{\perp},x_{\|})e^{-i\sqrt{\lambda-b\Lambda_p}\langle x_{\|},\omega\rangle}R(\lambda+i0)V(x_{\perp},x_{\|})e^{i\sqrt{\lambda-b\Lambda_q}\langle x_{\|},\omega'\rangle}\Pi_q\mathrm{d}x_{\|},$$

where the last integral converges in the space of bounded operator on $L^2(\mathbb{R}^{2d})$. From Proposition 2.2, it follows that for $\delta>\|V\|_{\infty,\rho}$,

$$\|T_2(\omega,\omega',\lambda,b)\|\leqslant C\delta^{-1/2}\sum_{b\Lambda_q\leqslant\lambda}(\lambda-b\Lambda_q)^{(n-2d-2)/2}\|V\|_{\infty,\rho}^2\leqslant C\lambda\|V\|_{\infty,\rho}^2 b^{-1}\delta^{(n-2d-3)/2},$$

where the constant C does not depend on ω and ω'. It remains to treat the term T_1. Suppose that $p\neq q$. As $\hat{V}^{\|}\in L^{\infty}_r(\mathbb{R}^n)$, then

$$\sup_{(\omega,\omega')\in S^{n-2d-1}\times S^{n-2d-1}}\left|\langle V(x_{\perp},.)e^{i\sqrt{\lambda-b\Lambda_q}\langle .,\omega'\rangle},e^{i\sqrt{\lambda-b\Lambda_p}\langle .,\omega\rangle}\rangle_{L^2(\mathbb{R}^{n-2d})}\right|$$
$$=\sup_{(\omega,\omega')\in S^{n-2d-1}\times S^{n-2d-1}}\left|\hat{V}^{\|}(x_{\perp},\sqrt{\lambda-b\Lambda_p}\omega-\sqrt{\lambda-b\Lambda_q}\omega')\right|$$
$$\leqslant C\|\hat{V}^{\|}\|_{\infty,r}\sup_{(\omega,\omega')\in S^{n-2d-1}\times S^{n-2d-1}}\left|\sqrt{\lambda-b\Lambda_p}\omega-\sqrt{\lambda-b\Lambda_q}\omega'\right|^{-r}\leqslant C\|\hat{V}^{\|}\|_{\infty,r}\delta^{-r/2}. \tag{17}$$

Therefore,

$$\sup_{(\omega,\omega')\in S^{n-2d-1}\times S^{n-2d-1}}\left\|T_1(\omega,\omega',\lambda,b)+\frac{i\pi}{(2\pi)^{n-2d}}\sum_{b\Lambda_q\leqslant\lambda}(\lambda-b\Lambda_q)^{(n-2d-2)/2}\Pi_q\hat{V}^{\|}(x_{\perp},\sqrt{\lambda-b\Lambda_q}(\omega\right.$$
$$\left.-\omega'))\Pi_q\right\|\leqslant C\|\hat{V}^{\|}\|_{\infty,r}\lambda b^{-1}\delta^{[n-2d-2-\min(1,r)]/2} \tag{18}$$

and the proof of (i) is complete.

Let us prove (ii). Starting from (4) at the energy $\mathcal{E}b+\lambda$, we get

$$T(\omega,\omega',\mathcal{E}b+\lambda,b)=\frac{-i\pi}{(2\pi)^{n-2d}}b^{(n-2d-2)/2}\sum_{q\in\tilde{Q}(\mathcal{E})}\beta_q^{n-2d-2}\Pi_q\hat{V}^{\|}\Big(x_\perp,b^{\frac{1}{2}}\beta_q(\omega-\omega')\Big)\Pi_q + \mathcal{O}(b^{[n-2d-2-\min(1,r)]})/2.$$

On the other hand, we know from Lemma 9.1 in Ref. 5 that

$$\|(1-\Pi_q)\hat{V}^{\|}\Big(.,b^{\frac{1}{2}}\beta_q(\omega-\omega')\Big)\Pi_q\|\leqslant Cqb^{-1/2}\sup_{x\in\mathbb{R}^n}|\partial_{x_\perp}\hat{V}^{\|}|.$$

Combining these estimates, we obtain the result claimed in (ii).

Finally, let us give the proof of Corollary 1.2. Suppose that $S_1=S_2$, then $T_1=T_2$ and for all $\mathcal{E}\notin\tilde{\mathbb{L}}$, $b>0$ and $(\omega,\omega')\in S^{n-2d-1}\times S^{n-2d-1}$, we have

$$T_1(\omega,\omega',\mathcal{E}b,b)=T_2(\omega,\omega',\mathcal{E}b,b).$$

It follows from Theorem 2 that

$$\sum_{q\in\tilde{Q}(\mathcal{E})}\beta_q^{n-2d-2}\hat{W}^{\|}(x_\perp,b^{1/2}\beta_q(\omega-\omega'))\Pi_q=\mathcal{O}(b^{-[\min(1,r)]/2}),$$

where $W=V_1-V_2$. Now, let $\xi\in\mathbb{R}^{n-2d}$, then for all $b>0$ there exists $\omega,\omega'\in S^{n-2d-1}$ such that $b^{1/2}(\omega-\omega')=\xi$. Therefore,

$$\sum_{q\in\tilde{Q}(\mathcal{E})}\beta_q^{n-2d-2}\hat{W}^{2}(x_\perp,\beta_q\xi)\Pi_q=\mathcal{O}(b^{-[\min(1,r)]/2}),$$

and taking the limit when b tends to infinity, we obtain

$$\sum_{q\in\tilde{Q}(\mathcal{E})}\beta_q^{n-2d-2}\hat{W}^{2}(x_\perp,\beta_q\xi)\Pi_q=0.$$

Moreover, this equality holds for all $\mathcal{E}\notin\tilde{\mathbb{L}}$, so that for all $q\in\mathbb{N}^d$, the map $x_\perp\mapsto\hat{W}^{\|}(x_\perp,-\beta_q\xi)$ belongs to $(\mathrm{Im}\,\Pi_q)^\perp$. As $L^2(\mathbb{R}^{2d})=\oplus_{q\in\mathbb{N}^d}\mathrm{Im}\,\Pi_q$, it follows that $\hat{W}^{\|}$ vanishes identically and the proof is complete. ■

IV. ASYMPTOTICS OF THE SCATTERING PHASE

In this section, we prove Theorems 3 and 4. Starting from formula (8), we must show that the operator $T=T(\mathcal{E}b+\lambda,b)$, $\mathcal{E}\notin\tilde{\mathbb{L}}$ is trace class and to obtain convenient estimates on $\|T\|$. For this purpose, we recall that

$$T(\mathcal{E}b+\lambda,b)=-2i\pi\mathcal{F}_0(\mathcal{E}b+\lambda)V(x)\mathcal{F}_0(\mathcal{E}b+\lambda)^*+2i\pi\mathcal{F}_0(\mathcal{E}b+\lambda)V(x)\times R(\mathcal{E}b+\lambda+i0)V(x)\mathcal{F}_0(\mathcal{E}b+\lambda)^*.$$

Moreover, as $\mathcal{E}\notin\tilde{\mathbb{L}}$, Proposition 2.2 shows that $\|\langle x_\|\rangle^{-\alpha}R_0(\mathcal{E}b+\lambda+i0)\langle x_\|\rangle^{-\alpha}\|$ is bounded by $b^{-1/2}$. Using Assumption 1, the resolvent

$$R(\mathcal{E}b+\lambda+i0)=R_0(\mathcal{E}b+\lambda+i0)(Id+V\,R_0(\mathcal{E}b+\lambda+i0))^{-1}$$

can expand in powers of $V\,R_0$. Combining this argument with the formula giving $\mathcal{F}_0$, it follows that for $L\in\mathbb{N}$,

$$T(\mathcal{E}b+\lambda,b)=\sum_{l=0}^{L}\sum_{q\in\tilde{Q}(\mathcal{E})}T_{q,l}(\mathcal{E}b+\lambda,b)+\mathcal{O}(\|T_{q,L+1}(\mathcal{E}b+\lambda,b)\|_1), \tag{19}$$

where for $l\in\mathbb{N}$ we have defined

$$T_{q,l}(\mathcal{E}b+\lambda,b)=(-1)^{l+1}2i\pi\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)(V(x)R_0(\mathcal{E}b+\lambda+i0))^lV(x)\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)^* \tag{20}$$

and

$$\forall E>b\Lambda_q,\quad \mathcal{F}_{q,0}(E)=\Pi_q\otimes\tilde{\mathcal{F}}_0(E-b\Lambda_q). \tag{21}$$

Let us denote by S^1 the space of trace class operators on $L^2(\mathbb{R}^{2d}\times S^{n-2d-1})$ and by $\|.\|_1$ the corresponding norm. For $A\in S^1$, we denote by tr A the trace of A. With these notations, we have the following lemma.

Lemma 4.1: Suppose that V satisfies Assumption 1. Let $\mathcal{E}\in]\Lambda_0+\infty[\setminus\tilde{\mathbb{L}}$ *and* $\Delta\subset\mathbb{R}$ *be a bounded interval. When b tends to infinity, one has*

(i) $\forall\epsilon>0$,

$$\sup_{\lambda\in\Delta}\|T_{q,l}(\mathcal{E}b+\lambda,b)\|_{L^2(\mathbb{R}^{2d}\times S^{n-2d-1}),L^2(\mathbb{R}^{2d}\times S^{n-2d-1})}\leqslant Cb^{-\frac{3}{4}-\frac{1}{2}+\epsilon},$$

$$\sup_{\lambda\in\Delta}\|T(\mathcal{E}b+\lambda,b)\|_{L^2(\mathbb{R}^{2d}\times S^{n-2d-1}),L^2(\mathbb{R}^{2d}\times S^{n-2d-1})}\leqslant Cb^{-\frac{3}{4}+\epsilon}.$$

(ii) *Suppose additionally that* $V\in L^1(\mathbb{R}^n)$. For *b large enough,* $T_{q,l}(\mathcal{E}b+\lambda,b)$ *and* $T(\mathcal{E}b+\lambda,b)$ *are trace class and*

$$\sup_{\lambda\in\Delta}\|T_{q,l}(\mathcal{E}b+\lambda,b)\|_1\leqslant Cb^{(n-2-l)/2},\quad \sup_{\lambda\in\Delta}\|T(\mathcal{E}b+\lambda,b)\|_1\leqslant Cb^{(n-2)/2}.$$

Proof: Let us start with the point (i). We start by estimating the operator $\mathcal{F}^*_{q,0}(\mathcal{E}b+\lambda)$ which is bounded from $L^2(S^{n-2d-1}\times\mathbb{R}^{2d})$ into $L^2_{-\beta}(\mathbb{R}^{n-2d},L^2(\mathbb{R}^{2d}))$ for all $\beta>\frac{1}{2}$. Moreover, for all $\beta>\frac{1}{2}$ and $\varphi\in L^2(S^{n-2d-1})$, we have

$$\begin{aligned}\|\tilde{\mathcal{F}}_0(\lambda)^*\varphi\|^2_{L^2_{-\beta}}&=\lambda^{(n-2d-2)/2}\int_{\mathbb{R}^{n-2d}}\langle x\rangle^{-\beta}\left|\int_{S^{n-2d-1}}e^{i\sqrt{\lambda}x\omega}\mathrm{d}\omega\right|^2\mathrm{d}x\\&=\lambda^{-1}\int_{\mathbb{R}^{n-2d}}\langle\lambda^{-1/2}x\rangle^{-\beta}\left|\int_{S^{n-2d-1}}e^{ix\omega}d\omega\right|^2\mathrm{d}x\leqslant C\lambda^{(\beta/2)-1}\|\mathcal{F}_0(1)^*\varphi\|^2_{L^2_{-\beta}}\\&\leqslant C\lambda^{(\beta/2)-1}\|\varphi\|^2_{L^2(S^{n-2d-1})}.\end{aligned}$$

From this estimate, one deduces easily that for all $\beta>1/2$,

$$\begin{aligned}\|\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)\|_\beta&:=\|\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)\|_{L^2_\beta(\mathbb{R}^{n-2d},L^2(\mathbb{R}^{2d})),L^2(S^{n-2d-1}\times\mathbb{R}^{2d})}\\&=\|\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)^*\|_{L^2(S^{n-2d-1}\times\mathbb{R}^{2d}),L^2_{-\beta}(\mathbb{R}^{n-2d},L^2(\mathbb{R}^{2d}))}\\&\leqslant C(\mathcal{E}b+\lambda-b\Lambda_q)^{(\beta-2)/4}.\end{aligned} \tag{22}$$

It follows from this estimate, Assumption 1, formula (20) and Proposition 2.2 that for $\epsilon>0$,

$$\begin{aligned}\|T_{q,l}(b)\|_{L^2(\mathbb{R}^{2d}\times S^{n-2d-1}),L^2(\mathbb{R}^{2d}\times S^{n-2d-1})}&\\ \leqslant C\|\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)\|^2_{1/2+\epsilon}\times\|V(R_0(\mathcal{E}b+\lambda)V)^l\|_{L^2_{-1/2-\epsilon}(\mathbb{R}^{n-2d},L^2(\mathbb{R}^{2d})),L^2_{1/2+\epsilon}(\mathbb{R}^{n-2d},L^2(\mathbb{R}^{2d}))}&\\ \leqslant b^{-\frac{3}{4}-\frac{1}{2}+\epsilon}.&\end{aligned}\tag{23}$$

This achieves to prove the first estimate of (i). The second one then follows by Eq. (19).

Let us prove (ii). Thanks to the resolvent estimates of Proposition 2.2, it suffices to show that the operator $|V|^{\frac{1}{2}}\mathcal{F}_{q,0}(\lambda)^*: L^2(S^{n-2d-1}\times\mathbb{R}^{2d})\to L^2(\mathbb{R}^{2n})$ belongs to the Hilbert–Schmidt class and that

$$\||V|^{\frac{1}{2}}\mathcal{F}_{q,0}(\mathcal{E}b+\lambda)\|_2\leqslant Cb^{(n-2)/4},\tag{24}$$

where $\|.\|_2$ denotes the Hilbert–Schmidt norm. For $q=(q_1,\ldots,q_d)\in\mathbb{N}^d$, let us denote by $K_q(y_\perp,x_\perp)$ the kernel of Π_q and by $\sigma(.,.)$ the symplectic form on $\mathbb{R}^{2d}$. We have

$$K_q(y_\perp,x_\perp)=\frac{b^d}{2\pi}\exp\left(-\frac{b}{4}[|y_\perp-x_\perp|^2+2i\sigma(y_\perp,x_\perp)]\right)L_q(y_\perp,x_\perp,b),\tag{25}$$

with

$$L_q(y_\perp,x_\perp,b)=\prod_{j=1}^d\tilde{L}_{q_j-1}\left(\frac{b}{2}|y_{\perp,j}-x_{\perp,j}|^2\right),$$

where for $s\in\mathbb{N}$, $\tilde{L}_s$ is the Laguerre polynomial of order s (see Ref. 14 for more details). With these notations, the kernel $N(x_\perp,x_\parallel,x'_\perp,\omega)$ of $|V|^{\frac{1}{2}}\mathcal{F}_{q,0}(\lambda)^*$ satisfies

$$\begin{aligned}N(x_\perp,x_\parallel,x'_\perp,\omega)&=(\mathcal{E}b+\lambda-b\Lambda_q)^{(n-2d-2)/4}|V|^{\frac{1}{2}}K_q(x_\perp,x'_\perp)e^{-i\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}\langle x_\parallel,\omega\rangle}\\&=\mathcal{O}(b^{(n-2d-2)/4})|V|^{\frac{1}{2}}K_q(x_\perp,x'_\perp)e^{-i\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}\langle x_\parallel,\omega\rangle}\end{aligned}$$

and

$$\begin{aligned}\|N\|^2_{L^2(\mathbb{R}^n\times\mathbb{R}^{2d}\times S^{n-2d-1})}&=\mathcal{O}(b^{(n+2d-2)/2})\int_{\mathbb{R}^{2d}\times\mathbb{R}^{n-2d}\times\mathbb{R}^{2d}\times S^{n-2d-1}}|V(x_\perp,x_\parallel)|e^{-(b/2)|x_\perp-x'_\perp|^2}\\&\quad\times\left|L_q\left(\frac{b}{2}|x_\perp-x'_\perp|^2\right)\right|^2\mathrm{d}x_\perp\mathrm{d}x_\parallel\mathrm{d}x'_\perp\mathrm{d}\omega\\&\leqslant Cb^{(n+2d-2)/2}\int_{\mathbb{R}^{2d}\times\mathbb{R}^{n-2d}\times\mathbb{R}^{2d}}|V(x_\perp,x_\parallel)|e^{-(b/2)|x_\perp-x'_\perp|^2}\\&\quad\times\left|L_q\left(\frac{b}{2}|x_\perp-x'_\perp|^2\right)\right|^2\mathrm{d}x'_\perp\mathrm{d}x_\parallel\mathrm{d}x_\perp.\end{aligned}$$

By change of variable, it comes

$$\begin{aligned}\|N\|^2_{L^2(\mathbb{R}^n\times\mathbb{R}^{2d}\times S^{n-2d-1})}&\leqslant Cb^{(n+2d-2)/2}\int_{\mathbb{R}^{2d}\times\mathbb{R}^{n-2d}\times\mathbb{R}^{2d}}|V(x_\perp,x_\parallel)|e^{-b|x_\perp-x'_\perp|^2}\mathrm{d}x'_\perp\mathrm{d}x_\parallel\mathrm{d}x_\perp\\&\leqslant Cb^{(n+2d-2)/2}\int_{\mathbb{R}^n}|V(x)|\mathrm{d}x\int_{\mathbb{R}^{2d}}e^{-|x'_\perp|^2}\mathrm{d}x'_\perp\leqslant Cb^{(n-2)/2}\end{aligned}$$

which proves (24). Using (24) and Proposition 2.2, it comes

$$\|T_{q,l}(\mathcal{E}b+\lambda)\|_1 \leqslant Cb^{(n-2-l)/2}$$

and the proof of (ii) is complete. ■

From this lemma, we know that $\|T(\mathcal{E}b+\lambda,b)\|<1$ and by Taylor expansion, we deduce from (8) that for $N\in\mathbb{N}$

$$2i\pi s(\mathcal{E}b+\lambda,b)=\sum_{k=0}^{N}\frac{(-1)^k}{k+1}\mathrm{tr}(T(\mathcal{E}b+\lambda,b)^{k+1})+\mathcal{O}(\|T(\mathcal{E}b+\lambda,b)^{N+2}\|_1). \tag{26}$$

Hence, we must show that for $k\in\mathbb{N}$, $\mathrm{tr}(T(\mathcal{E}b+\lambda,b)^k)$ admits an expansion in powers of $b^{1/2}$. Using the fact that for $p\neq q$, $\Pi_p\Pi_q=0$, we deduce from Eq. (19) that

$$\mathrm{tr}(T(\mathcal{E}b+\lambda,b)^k)=\sum_{q\in\tilde{Q}(\mathcal{E})}\mathrm{tr}\left(\sum_{l=0}^{L}T_{q,l}(\mathcal{E}b+\lambda,b)\right)^k+\mathcal{O}(\|T_{q,L+1}^k(\mathcal{E}b+\lambda,b)\|_1). \tag{27}$$

At this point of the calculus, we can either continue the expansion to get a complete asymptotics or we can stop the expansion at the first order to prove Theorem 3. Indeed, it follows from Lemma 4.1 that the remainder terms in Eqs. (26) and (27) satisfy

$$\|T_{q,L+1}^N(\mathcal{E}b+\lambda,b)\|_1=\mathcal{O}(b^{[n-1-N(L+2)]/2}) \text{ and } \|T(\mathcal{E}b+\lambda,b)^{N+2}\|_1=\mathcal{O}(b^{(n-N-3)/2}).$$

Therefore, Eqs. (26) and (19) yield

$$s(\mathcal{E}b+\lambda,b)=\frac{1}{2i\pi}\sum_{q\in\tilde{Q}(\mathcal{E})}\mathrm{tr}(T_{q,0}(\mathcal{E}b+\lambda,b))+\mathcal{O}(b^{(n-3)/2}). \tag{28}$$

On the other hand, a standard calculation shows that the kernel $N_{q,0}$ of $T_{q,0}(\mathcal{E}b+\lambda,b)$ is given by

$$N_{q,0}(\omega',x_\perp',\omega,x_\perp)=-\frac{i\pi}{(2\pi)^{n-2d}}(\mathcal{E}b+\lambda-b\Lambda_q)^{(n-2d-2)/2}K_q(x_\perp,x_\perp')\hat{V}^{\|}(x_\perp,\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}(\omega-\omega')).$$

Using (25), it follows that

$$\begin{aligned}\mathrm{tr}(T_{q,0}(\mathcal{E}b+\lambda,b))&=\int_{S^{n-2d-1}\times\mathbb{R}^{2d}}N_{q,0}(\omega,x_\perp,\omega,x_\perp)\mathrm{d}x_\perp\mathrm{d}\omega\\&=-\frac{i\pi}{(2\pi)^{n-2d+1}}b^d(\mathcal{E}b+\lambda-b\Lambda_q)^{(n-2d-2)/2}\int_{S^{n-2d-1}\times\mathbb{R}^{2d}}\hat{V}^{\|}(x_\perp,0)\mathrm{d}x_\perp\mathrm{d}\omega\\&=-\frac{i\pi\ mes(S^{n-2d-1})}{(2\pi)^{n-2d+1}}\int_{\mathbb{R}^n}V(x)\mathrm{d}x(b^{(n-2)/2}(\mathcal{E}-\Lambda_q)^{(n-2d-2)/2}+\mathcal{O}(b^{(n-4)/2})).\end{aligned}$$

Combining this equation with (28), we obtain the result claimed in Theorem 3.

The end of the paper is devoted to the proof of Theorem 4. We must show that for all $N\in\mathbb{N}^*$ and all $(l_1,\ldots,l_N)\in\mathbb{N}^N,(k_1,\ldots,k_N)\in\mathbb{N}^N$,

$$\mathrm{tr}(T_{q,l_1}^{k_1}\cdots T_{q,l_N}^{k_N})$$

admits an asymptotic expansion in powers of $b^{1/2}$. For this purpose, we work directly on the kernel of these operators that we expand with respect to b. For $V\in\mathcal{S}(\mathbb{R})$, let us denote $\hat{V}$ its Fourier transform. The two next lemmas permit us to obtain an expansion of the kernel of $T_{q,l_1}^{k_1}\cdots T_{q,l_N}^{k_N}$ by mean of the expansion of each term of the product.

Lemma 4.2. Let V_1, $V_2\in\mathcal{S}(\mathbb{R})$ *and for* ω, $\omega'\in\{\pm1\}$, $\lambda>0$ *let*

$$W(\lambda,\omega,\omega') = \sum_{\theta\in\{\pm 1\}} \hat{V}_1(\sqrt{\lambda}(\omega-\theta))\hat{V}_2(\sqrt{\lambda}(\theta-\omega')).$$

Then, there exists $V\in\mathcal{S}(\mathbb{R})$ *such that*

$$W(\lambda,\omega,\omega') = \hat{V}(\sqrt{\lambda}(\omega-\omega')) + \mathcal{O}(\lambda^{-\infty}),$$

when $\lambda\to+\infty$.

Proof: From the properties of the Fourier transform, it is clear that

$$W(\lambda,\omega,\omega') = \begin{cases} (\int V_1(x)\mathrm{d}x)(\int V_2(x)\mathrm{d}x) + \mathcal{O}(\lambda^{-\infty}) & \text{if} \quad \omega=\omega', \\ \mathcal{O}(\lambda^{-\infty}) & \text{if} \quad \omega\neq\omega'. \end{cases}$$

Let us set

$$V(x) = \left(\int V_2(y)\mathrm{d}y\right)V_1(x),$$

then it is clear that

$$W(\lambda,\omega,\omega') = \hat{V}(\sqrt{\lambda}(\omega-\omega')) + \mathcal{O}(\lambda^{-\infty}).$$

■

Lemma 4.3: Let $V\in\mathcal{S}(\mathbb{R})$ *and for* $l\in\mathbb{N}^*$, $\omega,\omega'\in\{\pm 1\}$, $\lambda>0$ *let*

$$W(\lambda,\omega,\omega') = \int e^{i\sqrt{\lambda}(|x_1-x_2|+\ldots+|x_l-x_{l+1}|+x_{l+1}\omega-x_1\omega')}V(x_1)\cdots V(x_{l+1})\mathrm{d}x_1\cdots\mathrm{d}x_{l+1}.$$

Then, there exists a sequence $(V_j)_{j\in\mathbb{N}}$ *of potentials in* $\mathcal{S}(\mathbb{R})$ *such that*

$$W(\lambda,\omega,\omega') = \sum_{j=0}^{+\infty}(i\sqrt{\lambda})^{-j}\hat{V}_j(\sqrt{\lambda}(\omega-\omega')).$$

Proof: The integral being absolutely convergent, we have

$$W(\lambda,\omega,\omega') = \int_{\mathbb{R}} e^{i\sqrt{\lambda}(\omega-\omega')y}V(y)\tilde{V}(y)\mathrm{d}y,$$

with

$$\tilde{V}(y) = \int_{\mathbb{R}} e^{i\sqrt{\lambda}(|x|-x\omega')}V(x+y)\mathrm{d}x.$$

Moreover,

$$\begin{aligned}\tilde{V}(y) &= \int_0^{+\infty} V(\omega' x+y)\mathrm{d}x + \int_{-\infty}^0 e^{-2i\sqrt{\lambda}x}V(\omega' x+y)\mathrm{d}x \\ &= V_0(y) - \frac{1}{2i\sqrt{\lambda}}[e^{-2i\sqrt{\lambda}x}V(\omega' x+y)]_{x=-\infty}^{x=0} + \frac{\omega'}{2i\sqrt{\lambda}}\int_{-\infty}^0 e^{-2i\sqrt{\lambda}x}V'(\omega' x+y)\mathrm{d}y \\ &= \tilde{V}_0(y) + \lambda^{-1/2}\tilde{V}_1(y) + \frac{\omega'}{2i\sqrt{\lambda}}\int_{-\infty}^0 e^{-2i\sqrt{\lambda}x}V'(\omega' x+y)\mathrm{d}y,\end{aligned}$$

with $\tilde{V}_0(y)=\int_0^{+\infty}V(\omega' x+y)\mathrm{d}x$ and $\tilde{V}_1(y)=(i/2)V(y)$. In particular, $\tilde{V}_0$ and $\tilde{V}_1$ are C^∞ functions whose derivatives are bounded at all orders. Integrating by parts N times, we obtain

$$\tilde{V}(y) = \tilde{V}_0(y) + \sum_{j=1}^{N} \lambda^{-j/2} \frac{\omega'^{j-1}}{(2i)^j} V^{(j-1)}(y) + \mathcal{O}(\lambda^{-N-1}).$$

Let us set $\tilde{V}_j(y) = [\omega'^{j-1}/(2i)^j] V^{(j-1)}(y)$, then

$$W(\lambda, \omega, \omega') = \sum_{j=0}^{N} \lambda^{-j/2} \int_{\mathbb{R}} e^{i\sqrt{\lambda}(\omega-\omega')y} V(y) \tilde{V}_j(y) \mathrm{d}y + \mathcal{O}(\lambda^{-N-1}) = \sum_{j=0}^{N} \lambda^{-j/2} \hat{V}_j(\sqrt{\lambda}(\omega - \omega')) + \mathcal{O}(\lambda^{-N-1}),$$

with $V_j(y) = V(y)\tilde{V}_j(y)$. As $V \in \mathcal{S}(\mathbb{R})$ and for $j \geqslant 0$, $\tilde{V}_j$ and their derivatives are bounded, it is clear that $V_j \in \mathcal{S}(\mathbb{R})$ and the proof is complete. ■

Now, we give the proof of Theorem 4. Thanks to Eqs. (26) and (27), it suffices to prove that for all $N \in \mathbb{N}^*$ and all $l = (l_1, \ldots, l_N) \in \mathbb{N}^N$, $k = (k_1, \ldots, k_N) \in \mathbb{N}^N$,

$$\mathrm{tr}(T_{q,l_1}^{k_1} \cdots T_{q,l_N}^{k_N})$$

admits an asymptotic expansion in powers of $b^{1/2}$. For this purpose, we will simply show that the kernel of $T_{q,l_1}^{k_1} \cdots T_{q,l_N}^{k_N}$ admits such an expansion. Let us start with $T_{q,l_j}^{k_j}$, $j \in \{1, \ldots, N\}$. Recall that

$$T_{q,l_j}(\mathcal{E}b + \lambda, b) = (-1)^{l_j+1} 2i\pi \mathcal{F}_{q,0}(\mathcal{E}b + \lambda)(V(x)R_0(\mathcal{E}b + \lambda + i0))^{l_j} V(x) \mathcal{F}_{q,0}(\mathcal{E}b + \lambda)^*.$$

Moreover, it is well known (see Ref. 11) that for $E > 0$, the resolvent $[-(\mathrm{d}^2/\mathrm{d}x^2) - E - i0]^{-1}$ has a kernel $N_0(x, y)$ given by

$$N_0(x, y) = \frac{1}{2i\sqrt{E}} e^{i\sqrt{E}|x-y|}.$$

Therefore, the kernel of T_{q,l_j} takes the form

$$N_{q,l_j}(\omega, \omega', x_\perp, x'_\perp) = \frac{(-1)^{l_j+1}}{(2i\sqrt{\mathcal{E}b + \lambda - b\Lambda_q})^{l_j+1}} K_q(x_\perp, x'_\perp) \int e^{i\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}(|x_1-x_2|+\cdots+|x_{l_j}-x_{l_j+1}|+x_{l_j+1}\omega-x_1\omega')} \times V(x_\perp, x_1) \cdots V(x_\perp, x_{l_j+1}) \mathrm{d}x_1 \cdots \mathrm{d}x_{l_j+1}. \tag{29}$$

By Lemma 4.3 applied in the variable $x_\parallel$, we obtain the following expansion:

$$N_{q,l_j}(\omega, \omega', x_\perp, x'_\perp) = K_q(x_\perp, x'_\perp)(i\sqrt{b})^{-l_j-1} \sum_{m=0}^{+\infty} (i\sqrt{b})^{-m} \hat{V}^{\parallel}_{m,q,l_j}(x_\perp, \sqrt{\mathcal{E}b + \lambda - b\Lambda_q}(\omega - \omega')),$$

with $V_{m,q,lj} \in \mathbf{S}(\mathbb{R}^3)$. Using Lemma 4.2, it comes that the kernel N_{q,l_j,k_j} of $T_{q,l_j}^{k_j}$ has the expansion

$$N_{q,l_j,k_j}(\omega, \omega', x_\perp, x'_\perp) = K_q(x_\perp, x'_\perp)(i\sqrt{b})^{-l_j-1} \sum_{m=0}^{+\infty} (i\sqrt{b})^{-m} \hat{V}^{\parallel}_{m,q,l,k}(x_\perp, \sqrt{\mathcal{E}b + \lambda - b\Lambda_q}(\omega - \omega')),$$

with $V_{m,q,l_j,k_j} \in \mathbf{S}(\mathbb{R}^3)$. Next, using again Lemma 4.2, it follows by induction that $T_{q,l_1}^{k_1} \cdots T_{q,l_N}^{k_N}$ has a kernel $N_{q,l,k}(\omega, \omega', x_\perp, x'_\perp)$ which admits an expansion in powers of $ib^{-1/2}$,

$$N_{q,l,k}(\omega, \omega', x_\perp, x'_\perp) = (i\sqrt{b})^{-|l|-N} \sum_{m=0}^{+\infty} (i\sqrt{b})^{-m} \hat{V}^{\parallel}_{m,q,l,k}(x_\perp, \sqrt{\mathcal{E}b + \lambda - b\Lambda_q}(\omega - \omega')) K_q(x_\perp, x'_\perp),$$

where $|l| := l_1 + \cdots + l_N$. Hence, we get

$$\mathrm{tr}(T_{q,l_1}^{k_1}\dots T_{q,l_N}^{k_N}) = \sum_{\omega=\pm1}\int_{\mathbb{R}^2} N_{q,l,k}(\omega,\omega,x_\perp,x_\perp)\mathrm{d}x_\perp = 2(i\sqrt{b})^{-|l|-N}\sum_{m=0}^{+\infty}(i\sqrt{b})^{-m}\int_{\mathbb{R}^2}\hat{V}^{\|}_{m,q,l,k}(x_\perp,0)\mathrm{d}x_\perp$$

$$= 2(i\sqrt{b})^{-|l|-N}\sum_{m=0}^{+\infty}(i\sqrt{b})^{-m}\int_{\mathbb{R}^3} V_{m,q,l,k}(x)\mathrm{d}x$$

and the proof of Theorem 4 is almost complete. Indeed, we have shown that there exists a sequence $(\alpha_j)_{j\in\mathbb{N}}$ of real numbers such that

$$s(\mathcal{E}b+\lambda,b) = \frac{1}{2i\pi}b^{(n-2)/2}\sum_{j=0}^{+\infty}\alpha_j(\mathcal{E},\lambda)(i\sqrt{b})^{-j}.$$

Hence, we must prove that for $j\in\mathbb{N}$, $\alpha_{2j}=0$. For this purpose, let us remark that $S(\lambda,b)$ being unitary, $s(\mathcal{E}b+\lambda,b)$ is real valued. Therefore, the coefficients α_{2j}, $j\in\mathbb{N}$ vanish and the proof of expansion (11) is complete.

It remains to compute the coefficients a_0 and a_1. From Eqs. (26) and (27) and Lemma 4.1 we deduce that

$$s(\mathcal{E}b+\lambda,b) = \frac{1}{2i\pi}\sum_{q=0}^{[(\mathcal{E}-1)/2]}\sum_{k=0}^{2}\frac{(-1)^k}{k+1}\mathrm{tr}\left(\sum_{l=0}^{2}T_{q,l}(\mathcal{E}b+\lambda,b)\right)^{k+1}+\mathcal{O}(b^{-1}).$$

Using again Lemma 4.1, we obtain

$$s(\mathcal{E}b+\lambda,b) = \frac{1}{2i\pi}\sum_{q=0}^{[(\mathcal{E}-1)/2]}\left(\mathrm{tr}\,T_{q,0}+\mathrm{tr}\,T_{q,1}+\mathrm{tr}\,T_{q,2}-\frac{1}{2}\mathrm{tr}\,T_{q,0}^2-\mathrm{tr}\,T_{q,0}T_{q,1}+\frac{1}{3}\mathrm{tr}\,T_{q,0}^3\right)+\mathcal{O}(b^{-1}), \tag{30}$$

and we must compute all the terms of the sum. From the proof of Theorem 3 with $n=3$, $d=1$, we deduce that

$$\mathrm{tr}(T_{q,0}(\mathcal{E}b+\lambda,b)) = -\frac{2i\pi}{4\pi^2}\int_{\mathbb{R}^3}V(x)\mathrm{d}x\left(b^{\frac{1}{2}}(\mathcal{E}-2q-1)^{-\frac{1}{2}}-\frac{\lambda}{2}b^{-\frac{1}{2}}(\mathcal{E}-2q-1)^{-\frac{3}{2}}\right)+\mathcal{O}\left(b^{-\frac{3}{2}}\right).$$

By similar computations, we prove that

$$\mathrm{tr}(T_{q,0}^2(\mathcal{E}b+\lambda,b)) = -\frac{1}{4\pi(\mathcal{E}-2q-1)}\left(\int V(x)\mathrm{d}x\right)^2+\mathcal{O}(b^{-1})$$

and

$$\mathrm{tr}(T_{q,0}^3(\mathcal{E}b+\lambda,b)) = \frac{i(\mathcal{E}-2q-1)^{-3/2}}{8\pi}b^{-1/2}\left(\int V(x)\mathrm{d}x\right)^3+\mathcal{O}(b^{-1}).$$

Let us compute $\mathrm{tr}(T_{q,1})$. It follows from Eq. (29) that

$$\mathrm{tr}(T_{q,1}(\mathcal{E}b+\lambda,b)) = \frac{-b}{8\pi(\mathcal{E}b+\lambda-b\Lambda_q)}\sum_{\omega=\pm1}\int e^{i\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}(|x_1-x_2|+\omega(x_1-x_2))}V(x_\perp,x_1)V(x_\perp,x_2)\mathrm{d}x_1\mathrm{d}x_2\mathrm{d}x_\perp$$

$$= \frac{-1}{8\pi(\mathcal{E}-2q-1)}\int(1+e^{2i\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}(|x_1-x_2|)})V(x_\perp,x_1)V(x_\perp,x_2)\mathrm{d}x_1\mathrm{d}x_2\mathrm{d}x_\perp$$

$$+\mathcal{O}(b^{-1}) = \frac{-1}{8\pi(\mathcal{E}-2q-1)}\left(\int V(x)\mathrm{d}x\right)^2$$

$$-\frac{2}{8\pi(\mathcal{E}-2q-1)}\int_{x_1\leqslant x_2} e^{2i\sqrt{\mathcal{E}b+\lambda-1\Lambda_q}(x_2-x_1)}V(x_\perp,x_1)V(x_\perp,x_2)\mathrm{d}x_1\mathrm{d}x_2\mathrm{d}x_\perp$$
$$+\mathcal{O}(b^{-1}).$$

Integrating by parts with respect to x_1, we obtain

$$\mathrm{tr}(T_{q,1}(\mathcal{E}b+\lambda,b)) = \frac{-1}{8\pi(\mathcal{E}-2q-1)}\left(\left(\int V(x)\mathrm{d}x\right)^2+\frac{i}{\sqrt{\mathcal{E}b+\lambda-b\Lambda_q}}\int V(x)^2\mathrm{d}x\right)+\mathcal{O}(b^{-1})$$
$$= \frac{-1}{8\pi(\mathcal{E}-2q-1)}\left(\left(\int V(x)\mathrm{d}x\right)^2-\frac{ib^{-1/2}}{8\pi(\mathcal{E}-2q-1)^{3/2}}\int V(x)^2\mathrm{d}x\right)+\mathcal{O}(b^{-1}).$$

The computations of $\mathrm{tr}(T_{q,2})$ and $\mathrm{tr}(T_{q,0}T_{q,1})$ are similar to the preceding ones. We find

$$\mathrm{tr}(T_{q,0}(\mathcal{E}b+\lambda,b)T_{q,1}(\mathcal{E}b+\lambda,b)) = \frac{i(\mathcal{E}-2q-1)^{-3/2}}{16\pi}b^{-1/2}\left(\int V(x)\mathrm{d}x\right)^3+\mathcal{O}(b^{-1})$$

and

$$\mathrm{tr}(T_{q,2}(\mathcal{E}b+\lambda,b)) = \frac{i(\mathcal{E}-2q-1)^{-3/2}}{48\pi}b^{-1/2}\left(\int V(x)\mathrm{d}x\right)^3+\mathcal{O}(b^{-1}).$$

Combining these equations with (30), we obtain

$$s(\mathcal{E}b+\lambda,b) = -\frac{\gamma_0(\mathcal{E})}{4\pi^2}b^{1/2}\left(\int V(x)\mathrm{d}x\right)+\frac{\lambda\gamma_1(\mathcal{E})}{8\pi^2}b^{-1/2}\left(\int V(x)\mathrm{d}x\right)$$
$$-\frac{\gamma_1(\mathcal{E})}{16\pi^2}b^{-1/2}\left(\int V(x)^2\mathrm{d}x\right)+\mathcal{O}(b^{-1})$$

with

$$\gamma_j(\mathcal{E}) = \sum_{q=0}^{[(\mathcal{E}-1)/2]}(\mathcal{E}-2q-1)^{-1/2-j}.$$

This completes the proof of Theorem 4. ■

To conclude, let us notice that Theorem 4 could be generalized to the case $n-2d>1$ by using stationary phase method in the variable $x_\parallel$. Nevertheless, there are some difficulties due to degenerate phases.

(Received 13 October 2004; accepted 2 December 2004; published online 31 March 2005)

We study the inviscid limit, $\mu \to 0$, of the stochastic viscous Burgers equation, for the velocity field $v^\mu(x,t)$, $t>0$, $x \in \mathbb{R}^d$, $(\partial v^\mu/\partial t)+(v^\mu \cdot \nabla)v^\mu = -\nabla c(x,t) - \epsilon \nabla k(x,t)\dot{W}_t + (\mu^2/2)\Delta v^\mu$, for small ϵ, with $v^\mu(x,0) \equiv \nabla S_0(x)$ for some given S_0, $\dot{W}_t$ representing white noise. Here we use the Hopf–Cole transformation, $v^\mu = -\mu^2 \nabla \ln u^\mu$, where u^μ satisfies the stochastic heat equation of Stratonovich-type and the Feynmac–Kac Truman–Zhao formula for u^μ, where $\mathrm{d}u_t^\mu(x) = [(\mu^2/2)\Delta u_t^\mu(x) + \mu^{-2}c(x,t)u_t^\mu(x)]\mathrm{d}t + \epsilon\mu^{-2}k(x,t)u_t^\mu(x) \circ \mathrm{d}W_t$, with $u_0^\mu(x) = T_0(x) \times \exp(-S_0(x)/\mu^2)$, S_0 as before and T_0 a smooth positive function. In an earlier paper, Davies, Truman, and Zhao [J. Math. Phys. **43**, 3293 (2002)], an exact solution of the stochastic viscous Burgers equation was used to show how the formal "blow-up" of the Burgers velocity field occurs on *random shockwaves* for the $v^{\mu=0}$ solution of Burgers equation coinciding with the caustics of a corresponding Hamiltonian system with classical flow map Φ. Moreover, the $u^{\mu=0}$ solution of the stochastic heat equation has its *wavefront* determined by the behavior of the Hamilton principal function of the corresponding stochastic mechanics. This led in particular to the level surface of the minimizing Hamilton–Jacobi function developing cusps at points corresponding to points of intersection of the corresponding prelevel surface with the precaustic, "pre" denoting the preimage under Φ determined algebraically. These results were primarily of a geometrical nature. In this paper we consider small ϵ and derive the shape of the random shockwave for the inviscid limit of the stochastic Burgers velocity field and also give the equation determining the random wavefront for the stochastic heat equation both correct to first order in ϵ. In the case $c(x,t) = \frac{1}{2}x^T\Omega^2 x$, $\nabla k(x,t) = -a(t)$, we obtain the exact random shockwave and prove that its shape is unchanged by the addition of noise, it merely being displaced by a random Brownian vector $N(t)$. By exploiting the Jacobi fields for this problem we obtain the large time limit of the distribution of the Burgers fluid velocity for noises which have infinite time averages, such as almost periodic ones. Here resonance with the underlying $\epsilon = 0$ classical problem has an important effect. Imitating these results for the case of a periodic underlying classical problem perturbed by small noise, arming ourselves with some detailed estimates for Green's functions enables us to make generalizations. In the stochastic case we have also the possibility of "infinitely rapid" changes in the number of cusps on the minimizing level surface of the Hamilton–Jacobi function. This will engender stochastic turbulence in the Burgers velocity field and, due to its stochasticity, may be of an "intermittent" nature. There is no analog of this in the deterministic case. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1850836]

I. INTRODUCTION

Stochastic Burgers equations have attracted a considerable amount of attention in recent years, e.g., Refs. 2, 4, 7, 11, 12, 16, 20–24, 35, 41, 37, and 39. See also Refs. 3, 5, 18, and 30 for related works. Burgers equations have been used to give models of turbulence (see especially Ref. 11) and to model the large scale structure of the universe.[34] Here we shall be interested in what has come to be called Burgulence. Primarily we show how a knowledge of Jacobi fields, and the geometry of the level surfaces of a Hamilton–Jacobi function and the associated caustic surface can be used in determining the behavior of the velocity field of the viscous Burgers fluid in the inviscid limit. The presence of viscosity provides access to a range of powerful analytical methods.

Consider the stochastic viscous Burgers equation for the velocity field $v^\mu = v^\mu(x,t)$, $x \in \mathbb{R}^d$, $t > 0$, small $\epsilon \in \mathbb{R}$,

$$\frac{\partial v^\mu}{\partial t} + (v^\mu \cdot \nabla) v^\mu = \frac{\mu^2}{2}\Delta v^\mu - \nabla c(x) - \epsilon \nabla k(x,t)\dot{W}_t,$$

with initial velocity $v^\mu(x,0) = \nabla S_0(x) + O(\mu^2)$ where μ^2 is the coefficient of viscosity. Here c, k, and S_0 are C^2 functions and W_t is a Wiener process on the probability space $\{\Omega, \mathcal{F}, P\}$. The corresponding heat equation for $u^\mu = u^\mu(x,t)$ is the Stratonovich equation

$$\frac{\partial u^\mu}{\partial t} = \frac{\mu^2}{2}\Delta u^\mu + \frac{1}{\mu^2}c(x)u^\mu + \frac{\epsilon}{\mu^2}k(x,t)u^\mu \circ \dot{W}_t,$$

$$u^\mu(x,0) = T_0(x)\exp(-S_0(x)/\mu^2),$$

where T_0 is a smooth positive function, the square root of the initial Burgers fluid density.

The connection between u^μ and v^μ is the Hopf–Cole logarithmic transformation $v^\mu = -\mu^2 \nabla \ln u^\mu$. Our studies are driven by an interest in the blow-up of $v^0(x,t)$ where

$$v^0(x,t) = \lim_{\mu \to 0} v^\mu(x,t).$$

We seek an understanding of the advent of discontinuities in v^0 and the large time limit of its probability density. In particular we show how for small, almost periodic noise resonating with the underlying classical problem there is no invariant measure.

It is this correspondence with the stochastic heat equation that enables us to appeal to asymptotic methods in our study of the viscous Burgers fluid. Moreover, these methods highlight the importance of the stochastic dynamical flow and the stochastic Hamilton–Jacobi function in determining the behavior of solutions. With this in mind we would expect, from the work of Donsker, Freidlin *et al.*,[19,17,41] that we have as $\mu \to 0$,

$$-\mu^2 \ln u^\mu(x,t) \to \inf_{x_0}[A(x_0,x,t) + S_0(x_0)] = S(x,t), \tag{1.1}$$

with

$$A(x_0,x,t) = \inf_{\substack{X(s) \\ X(0)=x_0 \\ X(t)=x}} A[X],$$

where $A[X]$ is the stochastic action

[a]Electronic mail: i.m.davies@swansea.ac.uk
[b]Electronic mail: a.truman@swansea.ac.uk
[c]Electronic mail: h.zhao@lboro.ac.uk

$$A[X] = \frac{1}{2}\int_0^t |\dot{X}^2(s)|\mathrm{d}s - \int_0^t c(X(s))\mathrm{d}s - \epsilon\int_0^t k(X(s),s)\mathrm{d}W_s$$

and

$$\mathcal{A}(x_0,x,t) = A(x_0,x,t) + S_0(x_0).$$

We shall assume that $\tilde{x}_0(x,t)$ the minimizer of $\mathcal{A}(x_0,x,t)$ is unique. Note that we require absolute continuity of X (cf. Davies and Truman[9] and references therein) and we will have $\dot{X}$ continuous almost surely. Then $S(x,t)$ is the minimizing solution of the stochastic Hamilton–Jacobi equation

$$\mathrm{d}S_t + \frac{|\nabla S|^2}{2}\mathrm{d}t + c(x)\mathrm{d}t + \epsilon k(x,t)\mathrm{d}W_t = 0, \quad S(x,0) = S_0(x).$$

So $S(x,t)$ is Hamilton's principal function for a stochastic classical mechanical path $X(s)$, satisfying the second order stochastic differential equation

$$\mathrm{d}\dot{X}(s) + \nabla c(X(s))\mathrm{d}s + \epsilon\nabla k(X(s),s)\mathrm{d}W_s = 0, \quad s \in (0,t),$$

with

$$X(0) = x_0, \quad \dot{X}(0) = \nabla S_0(x_0),$$

where $x_0 = x_0(x,t)$ is determined by the boundary condition $X(t) = x$. Here we finally have to set $x_0 = \tilde{x}_0(x,t)$ to get the minimizing S.

When $x_0(x,t)$ above is unique, the solutions of the stochastic heat equation and the viscous stochastic Burgers equation, cf. Ref. 41, for each $m \geqslant 0$ are, respectively,

$$u_t^\mu(x) = \exp\left\{-\mu^{-2}\sum_{j=0}^{m}\mu^{2j}S_j(x,t)\right\}\mathbb{E}\exp\left\{-\frac{\mu^{2m}}{2}\int_0^t \Delta S_m(y_s^\mu, t-s)\mathrm{d}s\right.$$
$$\left. + \frac{1}{2}\sum_{j=m+1}^{2m}\mu^{2(j-1)}\sum_{\substack{0\leqslant i_1,i_2\leqslant m\\ i_1+i_2=j}}\int_0^t \nabla S_{i_1}\cdot\nabla S_{i_2}(y_s^\mu, t-s)\mathrm{d}s\right\},$$

$$v^\mu(x,t) = \sum_{j=0}^{m}\mu^{2j}v_j(x,t) - \mu^2\nabla\ln\mathbb{E}\left\{\exp\left\{-\frac{\mu^{2m}}{2}\int_0^t \nabla\cdot v_m(y_s^\mu, t-s)\mathrm{d}s\right.\right.$$
$$\left.\left. + \frac{1}{2}\sum_{j=m+1}^{2m}\mu^{2(j-1)}\sum_{\substack{0\leqslant i_1,i_2\leqslant m\\ i_1+i_2=j}}\int_0^t v_{i_1}\cdot v_{i_2}(y_s^\mu, t-s)\mathrm{d}s\right\}\right\},$$

where $v_j(x,t) = \nabla S_j(x,t)$ is known explicitly for $j = 0,1,2,\ldots$ (see Truman and Zhao[41]).

Note that each second factor in the expectation is of the form $(1+O(\mu^{2m}))$ and the first factor gives the expansion up to μ^{2m-2} for each m. The S_j satisfy the stochastic Hamilton–Jacobi equations

$$\frac{\partial S_j}{\partial t} + \frac{1}{2} \sum_{\substack{i_1, i_2 \geqslant 0 \\ i_1 + i_2 = j}} \nabla S_{i_1} \cdot \nabla S_{i_2} = \frac{1}{2} \Delta S_{j-1},$$

for $j=0,1,2,\ldots$, with the convention $\frac{1}{2}\Delta S_{-1} = -c - \epsilon k \dot{W}_t$, $\dot{W}_t$ being white noise and the Nelson diffusion process y_s^μ satisfying

$$\mathrm{d}y_s^\mu = \mu \mathrm{d}B_s - \nabla \sum_{j=0}^{m} \mu^{2j} S_j(y_s^\mu, t-s)\mathrm{d}s, \quad y_0^\mu = x, \quad B_s \text{ is BM}.$$

It is important to note that S_1, and hence all S_j, are T_0 dependent, cf. Ref. 41. Formally, we are using $S^\mu \sim \Sigma_{j=0}^{\infty} \mu^{2j} S_j$ where S^μ is the solution of the viscous stochastic Hamilton–Jacobi equation,

$$\mathrm{d}S^\mu + \tfrac{1}{2} |\nabla S^\mu|^2 \, \mathrm{d}t + c \, \mathrm{d}t + \epsilon k \, \mathrm{d}W_t = \tfrac{1}{2} \mu^2 \Delta S^\mu \, \mathrm{d}t.$$

Changes in the degree of nonuniqueness of $x_0(x,t)$ is associated with discontinuities in $v^0(x,t)$ and $u^0(x,t)$ and this occurs when infinitely many paths $X(s)$ focus in zero volume centered at x. For nondegenerate critical paths $X(\cdot)$, when the multiplicity of $x_0(x,t)$, $n=n(x,t)$, is finite so that for a given x and t the set of possible initial positions x_0 is $\{x_0^1(x,t), x_0^2(x,t), \ldots, x_0^n(x,t)\}$, we can deduce that

$$u^\mu(x,t) \sim \sum_{i=1}^{n} \theta_i \exp\{-S_0^i(x,t)/\mu^2\},$$

where

$$S_0^i(x,t) = S_0(x_0^i(x,t)) + A(x_0^i(x,t), x, t)$$

for $i=1,2,\ldots,n$ and θ_i is an asymptotic series in μ^2 associated with $x_0^i(x,t)$ as above. (The detailed structure of θ_i may be developed by drawing on the papers of Davies and Truman,[8,9] Ellis and Rosen[13–15] and Truman and Zhao.[41]) Needless to say the dominant term in the above comes from $\tilde{x}_0(x,t)$ the minimizing $x_0(x,t)$ so that

$$S(x,t) = \min_{i=1,2,\ldots,n} S_0^i(x,t)$$

in line with the results of Freidlin *et al.*[19,17] Here we assume, unless stated otherwise, that the minimizer $\tilde{x}_0(x,t)$ is unique. The caustic, where the focusing of the paths $X(s)$ occurs, is important since $u^0(x,t)$ can switch discontinuously from being exponentially large to exponentially small as we cross parts of the caustic. This is because two of the $x_0^i(x,t)$ can coalesce and then disappear causing the minimizing S_0^i to disappear.

In this paper we develop inequalities showing how closely related the stochastic caustic and wavefront are to their classical dynamical counterparts for small noise. Once again the classical dynamical structures guide the arguments and we state our results for the caustic in terms of the classical path X^0, the stochastic path X^ϵ and their near neighbor $\tilde{X}^\epsilon$. We also derive inequalities relating ∇X^0, ∇X^ϵ, and $\nabla \tilde{X}^\epsilon$. For small noise, the stochastic wavefront is shown to lie within an ϵ neighborhood of the classical wavefront by utilizing the solution of the matrix Jacobi equation, the Green's function, to construct the appropriate estimates. Our main theorems (3.5 and 4.6) relate to the nonexistence of an invariant measure for the small noise stochastic Burgers equation when there is resonance between the underlying classical mechanical problem and the almost periodic noise. It is here that we use the detailed properties of Jacobi fields, developed by imitating more or less standard results for the linear harmonic oscillator.

II. STOCHASTIC DYNAMICS, H_t AND C_t

We now define our main structures and state without proof some of the key results from our earlier paper.[10] The familiar objects from classical dynamics are easily recognizable.

Define $A(x_0,p_0,t)$, the stochastic action, to be

$$\frac{1}{2}\int_0^t |\dot{X}(s)|^2\,\mathrm{d}s - \int_0^t [c(X(s))\mathrm{d}s + \epsilon k(X(s),s)\mathrm{d}W_s], \quad \text{a.s.},$$

with $X(s)=X(s,x_0,p_0)$ satisfying

$$\mathrm{d}\dot{X}(s) = -\nabla c(X(s))\mathrm{d}s - \epsilon\nabla k(X(s),s)\mathrm{d}W_s,$$

$s\in[0,t]$, $X(0)=x_0$, $\dot{X}(0)=p_0$, x_0, $p_0\in\mathbb{R}^d$. We shall assume that the minimizing $X(s)$ satisfying $X(t)=x$ and $\dot{X}(0)=\nabla S_0(X(0))$ is unique in any space with $\dot{X}$ continuous, where we assume as usual that $X(s)$ is $\mathcal{F}_s$ measurable. Later on we must consider Poisson brackets $\{X(s),X(u)\}_{x_0,p_0}$ with respect to x_0, p_0 variables which we suppress. We also allow for p_0 to be an as yet unspecified function of x_0 such as $\nabla S_0(x_0)$.

Then, for ∇c, ∇k Lipschitz, with Hessians $\nabla^2 c$, $\nabla^2 k$ and all second derivatives with respect to space variables of c and k bounded, according to Kunita,[27] $\partial X(s)/\partial x_0^\alpha$ satisfies

$$\frac{d}{\mathrm{d}s}\left(\frac{\partial X(s)}{\partial x_0^\alpha}\right) = \frac{\partial \dot{X}(0)}{\partial x_0^\alpha} - \int_0^s \left[\nabla^2 c(X(r))\frac{\partial X(r)}{\partial x_0^\alpha}\mathrm{d}r + \epsilon\nabla^2 k(X(r),r)\frac{\partial X(r)}{\partial x_0^\alpha}\mathrm{d}W_r\right].$$

Moreover,

$$\dot{X}(s) = \dot{X}(0) - \int_0^s [\nabla c(X(r))\mathrm{d}r + \epsilon\nabla k(X(r),r)\mathrm{d}W_r]. \tag{2.1}$$

Define the random map $\Phi_s:\mathbb{R}^d\to\mathbb{R}^d$ corresponding to the classical flow by the second order stochastic differential equation

$$d_s\dot{\Phi}_s = -\nabla c(\Phi_s)\mathrm{d}s - \epsilon\nabla k(\Phi_s,s)\mathrm{d}W_s,$$

with $\Phi_0=I$ and $\dot{\Phi}_0=\nabla S_0$.

We then have $X(s)=\Phi_s\Phi_t^{-1}x$, where we accept that $x_0(x,t)=\Phi_t^{-1}x$ may not be necessarily unique. Given some regularity, the global inverse function theorem gives a caustic time $T(\omega)$ $\times(>0)$ such that, for $s<T(\omega)$, Φ_s is a random diffeomorphism.[40] So for $t<T(\omega)$, $x_0(x,t)$ is unique. Therefore, as we shall see,

$$v^0(x,t) = \dot{\Phi}_t\Phi_t^{-1}x = \nabla S(x,t)$$

is a formal solution of Burgers equation with $\mu=0$, which is well defined up to the caustic time $T(\omega)$.

Lemma 2.1: Assume S_0, $c\in C^2$ and $k\in C^{2,0}$, ∇c, ∇k are Lipschitz, with Hessians $\nabla^2 c$, $\nabla^2 k$ and all second derivatives with respect to space variables of c and k bounded. If $\dot{X}(s)$ satisfies Eq. (2.1) *and we have p_0, possibly x_0 dependent, then almost surely*

$$\frac{\partial A}{\partial x_0^\alpha}(x_0,p_0,t) = \dot{X}(t)\cdot\frac{\partial X(t)}{\partial x_0^\alpha} - \dot{X}_\alpha(0).$$

Remark 2.1: Observe that, if we fix $X(t)$ independently of x_0, we obtain almost surely

$$\frac{\partial A}{\partial x_0^\alpha}(x_0,p_0,t) = -\dot{X}_\alpha(0),$$

for $\alpha=1,2,\ldots,d$.

Let $X(s,x_0,x)=X(s,x_0,p_0)|_{p_0=p(x_0,x,t)}$ where $p_0=p(x_0,x,t)$ is the (assumed unique) random minimizer of $A(x_0,p_0,t)$ with $X(t,x_0,p_0)=x$.

Remark 2.2: Here we need the maps $\mathbb{R}^d \to \mathbb{R}^d$ defined by $p_0 \mapsto X(x_0,p_0,t)$, for fixed t, for each $x_0 \in \mathbb{R}^d$ to be onto with probability one (cf. Kolokoltsov *et al.*[26,25]).

Set $A(x_0,x,t)=A(x_0,p_0,t)|_{p_0=p(x_0,x,t)}$ and define Hamilton's principal function corresponding to the initial momentum $\nabla S_0(x_0)$ to be

$$\mathcal{A}(x_0,x,t) = A(x_0,x,t) + S_0(x_0).$$

Then

$$\frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t) = 0 \quad \text{for } \alpha = 1,2,\ldots,d \Rightarrow \dot{X}(0) = \nabla S_0(X(0))$$

which defines the classical flow map Φ.

We define a prelevel surface of Hamilton's principal function for real constant c by eliminating x between the equations

$$\mathcal{A}(x_0,x,t) = c \quad \text{and} \quad \frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t) = 0,$$

$\alpha=1,2,\ldots,d$, and a level surface H_t by eliminating x_0. We denote the prelevel surface by $\Phi_t^{-1}H_t$. Similarly we define the caustic C_t and the precaustic $\Phi_t^{-1}C_t$ by eliminating x_0 or x between

$$\mathrm{Det}\left(\frac{\partial^2 \mathcal{A}}{\partial {x_0}^2}(x_0,x,t)\right) = 0 \quad \text{and} \quad \frac{\partial \mathcal{A}}{\partial x_0^\alpha}(x_0,x,t) = 0,$$

$\alpha=1,2,\ldots,d$.

Remark 2.3: Note that $\Phi_t^{-1}H_t$ (and $\Phi_t^{-1}C_t$) are determined by taking algebraic inverse images, i.e., by eliminating x above. Those are not necessarily the same as the topological inverse images $\Phi_t^{-1}(H_t)$ and $\Phi_t^{-1}(C_t)$. In fact as we shall demonstrate $\Phi_t^{-1}C_t \neq \Phi_t^{-1}(C_t)$.

We shall need.

Lemma 2.2: The classical flow map $x=\Phi_t(x_0)$ is a differentiable map from $\Phi_t^{-1}H_t$ to H_t with Fréchet derivative

$$D\Phi_t(x_0) = \left(-\frac{\partial^2 \mathcal{A}}{\partial x\, \partial x_0}(x_0,x,t)\right)^{-1}\left(\frac{\partial^2 \mathcal{A}}{\partial {x_0}^2}(x_0,x,t)\right),$$

if $\mathcal{A}$ is C^3 in space derivatives.

In the next section we investigate the linear harmonic oscillator case in detail. This will provide us with the main ideas for the proofs of our general results.

III. HARMONIC OSCILLATOR WELLS WITH NOISE

The stochastic harmonic oscillator was studied by Albeverio *et al.*,[1] Markus and Weerasinghe,[28] and McKean.[29] The stochastic Mehler formula was first obtained by Truman and Zhao[38–40] and later using different techniques by Truman and Zastawniak.[36]

Consider $v=v(x,t)$, $x \in \mathbb{R}^d$, $t \in \mathbb{R}^+$, satisfying

$$dv + (v \cdot \nabla)v\ dt = -\Omega^2 x\ dt - \epsilon \nabla k(x,t) dW_t, \tag{3.1}$$

with $v(x,0) = \nabla S_0(x)$, i.e., v is Burgers velocity field for the perturbed harmonic oscillator potential

$$c(x) = \tfrac{1}{2} x^T \Omega^2 x,$$

where Ω^2 is a positive definite, real, symmetric matrix. Here the perturbing potential is the white noise term $k_t(x)\dot{W}_t$, with real valued $k_t(x) = k(x,t) \in C^{2,1}(\mathbb{R}^d, \mathbb{R}^+)$ and W_t is one-dimensional Brownian motion on the probability space $\{\Omega, \mathcal{F}, P\}$. The corresponding stochastic mechanics is

$$d_s \dot{X}^\epsilon(s) + \Omega^2 X^\epsilon(s) ds = -\epsilon \nabla k(X^\epsilon(s), s) dW_s, \tag{3.2}$$

with

$$X^\epsilon(0)(x_0) = x_0,$$

$$\dot{X}^\epsilon(0)(x_0) = \nabla S_0(x_0).$$

Here x_0 must be chosen such that

$$X^\epsilon(t)(x_0) = x,$$

for fixed t and x in $v^\mu(x,t)$ and to minimize $\mathcal{A}(x_0, x, t)$, the choice being unique.

When $\epsilon = 0$, we have a harmonic oscillator, which defines the classical flow map Φ_s^0,

$$X^0(s) = \Phi_s^0 x_0 = \cos(\Omega s) x_0 + \sin(\Omega s) \Omega^{-1} \nabla S_0(x_0), \tag{3.3}$$

Ω being the obvious positive square root of Ω^2.

Note that the solution $X^\epsilon(s)$ of (3.2) can be found explicitly as follows: provided $\nabla k(\cdot, s) = -a(s)$, is independent of spatial variables. We obtain in matrix notation

$$X^\epsilon(s) = \cos(\Omega s) x_0 + \sin(\Omega s) \Omega^{-1} \nabla S_0(x_0) + \epsilon \int_0^s \sin(\Omega(s-u)) \Omega^{-1} a(u) dW_u. \tag{3.4}$$

It therefore turns out that

$$X^\epsilon(s) - \epsilon \int_0^s \sin(\Omega(s-u)) \Omega^{-1} a(u) dW_u = \Phi_s^0 x_0. \tag{3.5}$$

The following simple result for shockwaves in a random environment is an easy corollary of the above computations.

Theorem 3.1: *At time t, let* $\Delta_t^0(x_0) = \mathrm{Det}(\partial X^0(t) / \partial x_0) = \mathrm{Det}(\nabla_{x_0} \Phi_t^0 x_0) = 0$ *be the equation of the precaustic in* x_0*, where* Φ_t^0 *is the classical flow map for the harmonic oscillator without noise and let* $x = \Phi_t x_0$*. Eliminating* y_0*, let the corresponding equation at time t in* $y = \Phi_t y_0$ *be*

$$\Delta_t^0((\Phi_t^0)^{-1}(y)) = 0.$$

Then, if $\nabla k(x,t) = -a(t)$*, independent of x, the random shockwave in the presence of noise at time t has equation*

$$\Delta_t^0((\Phi_t^0)^{-1}(y + \epsilon N(t))) = 0,$$

where $N(t)$ *is the random vector*

$$N(t) = \int_0^t \Omega^{-1} \sin(\Omega(t-s)) a(s) dW_s.$$

Remark 3.1: In this case the noise leaves the shape of the shockwaves unchanged merely displacing them by a random vector $-N(t)$.

Remark 3.2: Needless to say $N(t)$ satisfies the second order stochastic differential equation

$$\mathrm{d}\dot{N}_t + \Omega^2 N_t \,\mathrm{d}t = a(t)\mathrm{d}W_t,$$

where $N(0)=0$, $\dot{N}(0)=0$.

We need the following lemma, a simple one-dimensional result.

Lemma 3.2: Let $a(\cdot)\in C^1(\mathbb{R}^+)$ be bounded, with $\lim_{t\to\infty} t^{-1/2}a(t)=0$, and let the infinite time average

$$\lim_{t\to\infty} t^{-1}\int_0^t a^2(u)\mathrm{d}u = M(a^2) > 0.$$

Then, if $d(a^2(u))/\mathrm{d}u \in L^1(\mathbb{R}^+)$, the leading behavior of the noise term

$$N(t) = \int_0^t \Omega^{-1}\sin(\Omega(t-s))a(s)\mathrm{d}W_s,$$

as $t\to\infty$ is given almost surely by

$$N(t) \sim \Omega^{-1}M^{\frac{1}{2}}(a^2)(\sin(\Omega t)B^c(t) - \cos(\Omega t)B^s(t)),$$

where B^c and B^s are normalized $BM(\mathbb{R})$ processes B, with $\mathbb{E}(B^2(t))=t$, correlated by

$$\mathbb{E}(B^c(t)B^s(u)) = \int_0^{\tau_c(t)\wedge\tau_s(u)} a^2(r)\cos(\Omega r)\sin(\Omega r)\mathrm{d}r,$$

with

$$\tau_c(t) = \inf\left\{ s>0 : \int_0^s a^2(u)\cos^2(\Omega u)\mathrm{d}u = t \right\},$$

$$\tau_s(t) = \inf\left\{ s>0 : \int_0^s a^2(u)\sin^2(\Omega u)\mathrm{d}u = t \right\}.$$

Proof: We need McKean's result on time changed Brownian motion (see p. 29 of McKean[29]). Now

$$\int_0^t a^2(u)\cos^2(\Omega u)\mathrm{d}u = \frac{1}{2}\int_0^t (1+\cos(2\Omega u))a^2(u)\mathrm{d}u$$

and

$$t^{-1}\int_0^t \cos(2\Omega u)a^2(u)\mathrm{d}u = \frac{1}{2\Omega t}\left(a^2(t)\sin(2\Omega t) - \int_0^t \sin(2\Omega u)\frac{d}{\mathrm{d}u}(a^2(u))\mathrm{d}u \right) \to 0,$$

as $t\to\infty$. ∎

If we now work in Cartesian axes relative to which Ω is diagonal, $\Omega_{ij}=\Omega_i\delta_{ij}$, $\Omega_i>0$, for $i,j=1,2,\ldots,d$, we can deduce a vector version of the last lemma.

Lemma 3.3: Working in coordinates in which Ω is diagonal and $N(t)=(N_1(t),\ldots,N_d(t))$, we obtain the behavior as $t\to\infty$,

$$N_i(t) \sim \Omega_i^{-1}M^{\frac{1}{2}}(a_i^2)(\sin(\Omega_i t)B^{c_i}(t) - \cos(\Omega_i t)B^{s_i}(t)),$$

for $i=1,\ldots,d$, *where the* B^{c_i}, B^{s_i} *are normalized correlated* $BM(\mathbb{R})$ *processes with*

$$\mathbb{E}(B^{c_i}(t)B^{s_j}(u)) = \int_0^{\tau_{c_i}(t)\wedge\tau_{s_j}(u)} a_i(r)a_j(r)\cos(\Omega_i r)\sin(\Omega_j r)\mathrm{d}r,$$

together with similar results for $\mathbb{E}(B^{c_i}(t)B^{c_j}(u))$ *and* $\mathbb{E}(B^{s_i}(t)B^{s_j}(u))$.

Remark 3.3: The above results hold for any finite value of ϵ, no matter how large. This gives the leading behavior of $N(t)$ as $t\to\infty$ in terms of the Jacobi fields of the zero noise problem and thence the large time behavior of $v^0(x,t)$ and $X^\epsilon(x,t)$ and their sample paths. The Jacobi fields are also important in understanding the small noise processes, as we see in the next section.

Example: We now illustrate the development of the semicubical parabolic shockwave with respect to time for the velocity field of a Burgers' fluid with initial velocity $(xy, x^2/2)$ in a harmonic well with $V(x,y)=(x^2+\omega^2y^2)/2$. The effect of noise here is to superimpose on the deterministic movement of the cusp caustic a Brownian motion. Let us just consider the deterministic case. It is easy to see

$$\Phi_t\begin{pmatrix}x_0\\ y_0\end{pmatrix} = \begin{pmatrix} x_0\cos t + x_0y_0\sin t \\ y_0\cos\omega t + \dfrac{1}{2\omega}x_0^2\sin\omega t\end{pmatrix}. \tag{3.6}$$

So

$$\Delta_t^0(x_0,y_0) = \det\begin{pmatrix}\cos t + y_0\sin t, & x_0\sin t\\ \omega^{-1}x_0\sin\omega t, & \cos\omega t\end{pmatrix} = \cos\omega t\cos t + y_0\cos\omega t\sin t - \omega^{-1}x_0^2\sin t\sin\omega t. \tag{3.7}$$

The precaustic is then given by $\Delta_t^0(x_0,y_0)=0$. The caustic is obtained by mapping the precaustic under the map Φ_t. If ω is rational then the deterministic motion of the cusp is periodic as is the deterministic part of v_t^0. The equation is then given by

$$8(y\csc\omega t + \cot t\cot\omega t)^3\omega = 27x^2\cot^2\omega t\csc^2 t. \tag{3.8}$$

The periodic motion of the cusp can be seen in Fig. 1 where we plot a succession of caustics for the case $\omega=3/2$. Time increases from left to right and top to bottom. Many more illustrations of this periodic behavior can be found in the Ph.D. thesis of Reynolds.[31]

We continue to investigate Burgers equation in $\mathbb{R}^d$, Eqs. (3.1) and (3.2), where $\nabla k(x,u) = -a(u)$ is independent of x and $\int_0^t |a(u)|^2\,\mathrm{d}u<\infty$. The key elementary lemma here is the following.

Lemma 3.4: *Let* $\dot X^\epsilon(t)-\dot X^0(t)=\dot N(t)=\epsilon\int_0^t\cos[\Omega(t-u)]a(u)\mathrm{d}W_u$. *Then, working in a coordinate system in which* Ω^2 *is diagonal,* $\dot N(t)$ *has mean zero and is Gaussian with covariance,*

$$\begin{aligned}A_{ij}^{-1}(t) &= \mathbb{E}[\dot N_i(t)\dot N_j(t)]\\ &= \frac{\epsilon^2}{4}\sum_{\pm}\left\{\cos((\Omega_i\pm\Omega_j)t)\int_0^t\cos((\Omega_i\pm\Omega_j)u)a_i(u)a_j(u)\mathrm{d}u\right.\\ &\quad\left.+\sin((\Omega_i\pm\Omega_j)t)\int_0^t\sin((\Omega_i\pm\Omega_j)u)a_i(u)a_j(u)\mathrm{d}u\right\},\quad t>0.\end{aligned}$$

Proof: The point is that, if $0=s_0<s_1<\cdots<s_{n+1}=t$ is a partition of $[0,t]$,

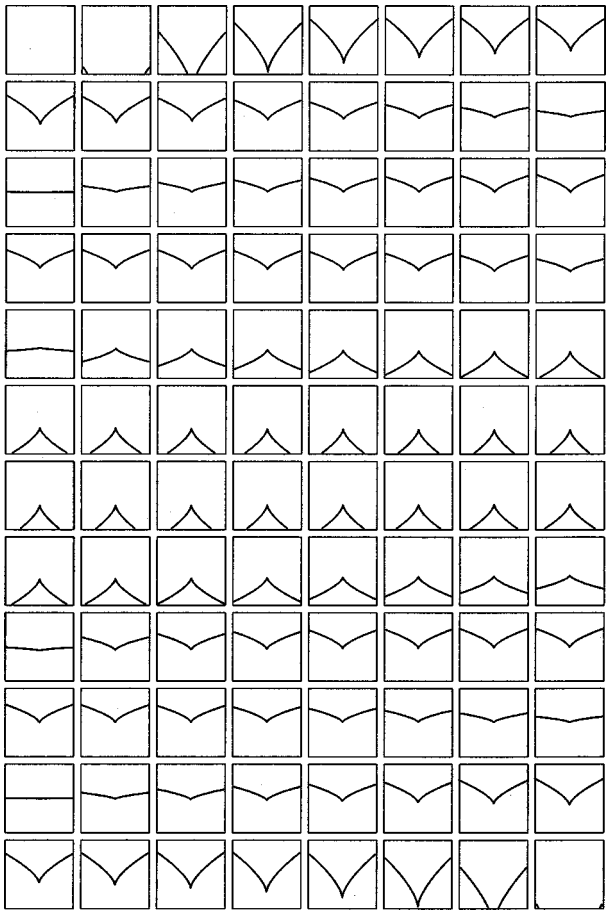

FIG. 1. Periodic motion of caustic.

$$\dot{N}_i(t) = \lim \sum_j \cos[\Omega_i(t - s_j)] a_i(s_j)[W(s_{j+1}) - W(s_j)]$$

exhibits $\dot{N}(t)$ as the limit of a sum of independent Gaussians. So for each t $\dot{N}(t)$ is Gaussian with mean and covariance as above. ■

A strikingly simple result emerges if we assume that $a(\cdot)$ is almost periodic in the sense that in our coordinate system $a(s)=(a_1(s),a_2(s),\ldots,a_d(s))$, where each a_j is almost periodic. [The class of almost periodic functions is a natural generalization of periodic functions in that they can be realized as uniform limits of trigonometric polynomials and if f is almost periodic $\lim_{t\uparrow\infty} t^{-1}\int_{t_0}^{t_0+t} f(s)\mathrm{d}s = M(f)$ exists, the class being closed under addition and multiplication.] When $a(\cdot)$ is almost periodic in our setup we refer to almost periodic white noise forces. The possibility of resonance between the almost periodic noise and the restraining harmonic oscillator force affects the long time behavior of the Burgers fluid.

Theorem 3.5: *For almost periodic white noise forces, for underlying harmonic oscillator potentials, the inviscid limit of Burgers fluid velocity* $v^0(x,t)$ *satisfies*

$$\mathbb{E}(v^0(x,t)) = \dot{X}^0(x,t) = \cos(\Omega t)\tilde{x}_0(x,t) + \Omega^{-1} \sin(\Omega t)\, \nabla S_0(\tilde{x}_0(x,t)),$$

where $\tilde{x}_0(x,t)$ *is the minimizer (assumed to be unique) of the deterministic* $\mathcal{A}(x_0,x,t)$. *Moreover,*

$$\mathbb{P}((v^0(x,t) - \dot{X}^0(x,t)) \in \mathrm{d}v) = \exp\left(-\frac{v^T A(t) v}{2}\right)(2\pi)^{-d/2}(\det A)^{-1/2}\, \mathrm{d}v,$$

where the matrix $A^{-1}(t)$ is specified above. In particular as $t\sim\infty$ we obtain

$$t^{-1}A_{ij}^{-1}(t) = t^{-1}\mathbb{E}[(v_i^0(x,t) - \dot{X}_i^0(x,t))(v_j^0(x,t) - \dot{X}_j^0(x,t))]$$
$$\sim \frac{\epsilon^2}{4}\sum_{\pm}\{\cos((\Omega_i \pm \Omega_j)t)M[\cos((\Omega_i \pm \Omega_j)\cdot)a_i(\cdot)a_j(\cdot)]$$
$$+ \sin((\Omega_i \pm \Omega_j)t)M[\sin((\Omega_i \pm \Omega_j)\cdot)a_i(\cdot)a_j(\cdot)]\},$$

where M denotes the infinite time average.

Proof: The proof is a simple consequence of the properties of almost periodic functions.[6] ■

Remark 3.4: (i) The ensemble average of the Burgers fluid velocity $\mathbb{E}(v^0(x,t))$ inherits the singularity structure of $\dot{X}^0(x,t)$ with caustics depending on the initial velocity field ∇S_0.

(ii) The distribution of Burgers fluid velocity depends only on the forces in this harmonic oscillator case.

(iii) Evidently, if there is resonance between the noise and the harmonic oscillator forces, there is no invariant measure for this problem as expected.

We emphasize here that the above results are true for any value of $\epsilon > 0$. We see in the next section to what extent the above results generalize to the nonlinear setting for small noise. Our main results will require new detailed estimates for this problem.

IV. GENERAL POTENTIALS WITH SMALL NOISE PERTURBATION

Having considered a special case in the preceding section we now demonstrate for small noise the closeness of the stochastic X_t, C_t, and H_t to their deterministic counterparts for more general potentials. Let X^ϵ, with ϵ highlighted, satisfy

$$d\dot{X}^\epsilon(x_0,s) = -\nabla c(X^\epsilon(x_0,s))ds - \epsilon\nabla k(X^\epsilon(x_0,s))dW_s, \tag{4.1}$$

with $X^\epsilon(x_0,0)=x_0$ and $\dot{X}^\epsilon(x_0,0)=\nabla S_0(x_0)$, for $0<s<t$. Abusing notation, let $X^0(x_0,s)=\Phi_s x_0$ be the deterministic version, where $\epsilon=0$, and let $\mathcal{G}$ be given by $\mathcal{G}_{ij}(x_0,s,u)=\{X_i^0(u),X_j^0(s)\}\theta(s-u)$, the first term being the Poisson bracket, the second a Heaviside function. The following elementary lemma is key.

Lemma 4.1: With X^0 defined as above, $\mathcal{G}$ satisfies the matrix Jacobi equation

$$\left(\frac{d^2}{ds^2} + \nabla^2 c(X^0(x_0,s))\right)\mathcal{G} = 0, \mathcal{G}(x_0,s_+,s) = 0, \quad \frac{d\mathcal{G}}{ds}(x_0,s,u)\bigg|_{s=u_+} = I.$$

Furthermore, $(\partial/\partial x_0^i)\mathcal{G}(x_0,s,u)$ satisfies

$$\frac{d^2}{ds^2}\frac{\partial}{\partial x_0^i}\mathcal{G}(x_0,s,u) + \sum_{j=1}^{n}\frac{\partial}{\partial X_j^0}\nabla^2 c(X^0(x_0,s))\left(\frac{\partial}{\partial x_0^i}X_j^0(x_0,s)\right)\mathcal{G}(x_0,s,u) + \nabla^2 c(X^0(x_0,s))\frac{\partial}{\partial x_0^i}\mathcal{G}(x_0,s,u) = 0 \tag{4.2}$$

and

$$\nabla_{x_0^i}\mathcal{G}(x_0,s_+,s) = 0, \qquad \frac{d}{ds}\nabla_{x_0^i}\mathcal{G}(x_0,s,u)\bigg|_{s=u_+} = 0. \tag{4.3}$$

Proof: A trivial computation using the properties of Poisson brackets. ■

We now come to one of our main results.

Theorem 4.2: *Subject to certain conditions on the continuity and boundedness of c and k and their derivatives, define*

$$\tilde{X}^{\epsilon}(x_0,s) = \Phi_s x_0 - \epsilon \int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0) \mathrm{d}W_u,$$

for $s \in [0,t]$. *Then there exists a constant* $M>0$ *such that for any* $\delta>0$ *and sufficiently small* $\epsilon>0$,

$$P\{\epsilon^{-\frac{3}{2}} |X^{\epsilon}(x_0,s) - \tilde{X}^{\epsilon}(x_0,s)| > \delta, \quad some \quad s \in [0,t]\} < \frac{M\epsilon^2}{\delta^4}, \tag{4.4}$$

and

$$P\{\epsilon^{-\frac{3}{2}} |\nabla X^{\epsilon}(x_0,s) - \nabla \tilde{X}^{\epsilon}(x_0,s)| > \delta, \quad \text{some} \quad s \in [0,t]\} < \frac{M\epsilon}{\delta^2}. \tag{4.5}$$

We have $X^{\epsilon}(x_0,s) - \tilde{X}^{\epsilon}(x_0,s) = o(\epsilon^{3/2})$, $\nabla X^{\epsilon}(x_0,s) - \nabla \tilde{X}^{\epsilon}(x_0,s) = \circ(\epsilon^{3/2})$ *as* $\epsilon \to 0$ *in probability.*

Proof: (i) We first prove (4.4). From the definition of $\tilde{X}^{\epsilon}(x_0,s)$ and Lemma 4.1, it is easy to see

$$\dot{\tilde{X}}^{\epsilon}(x_0,s) = \dot{\Phi}_s x_0 - \epsilon \int_0^s \frac{\partial}{\partial s} \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0) \mathrm{d}W_u, \quad s \in [0,t].$$

Differentiating with respect to s again we have

$$\begin{aligned}
\mathrm{d}\dot{\tilde{X}}^{\epsilon}(x_0,s) &= -\, \nabla\, c(\Phi_s x_0)\mathrm{d}s - \epsilon \nabla\, k(\Phi_s x_0)\mathrm{d}W_s - \epsilon \int_0^s \frac{\partial^2}{\partial s^2} \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\, \mathrm{d}s \\
&= -\, \nabla\, c(\Phi_s x_0)\mathrm{d}s + \left(\nabla^2 c(\Phi_s x_0)\epsilon \int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)\mathrm{d}s - \epsilon \nabla\, k(\Phi_s x_0)\mathrm{d}W_s.
\end{aligned}$$

It turns out that by Taylor's theorem, there exist ξ_1 and ξ_2 such that for $0 \leqslant s \leqslant t$,

$$\begin{aligned}
\mathrm{d}\dot{\tilde{X}}^{\epsilon}(x_0,s) = &-\, \nabla\, c\left(\Phi_s x_0 - \epsilon \int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)\mathrm{d}s \\
&- \epsilon \nabla\, k\left(\Phi_s x_0 - \epsilon \int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)\mathrm{d}W_s + \epsilon^2 \sum_{i,j=1}^{d} \frac{\partial^2}{\partial \xi_1^i \xi_1^j}\, \nabla\, c(\xi_1) \\
&\times \left(\int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)_i \left(\int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)_j \mathrm{d}s + \epsilon^2 \nabla^2 k(\xi_2) \\
&\times \left(\int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)\mathrm{d}W_s \\
= &-\, \nabla\, c(\tilde{X}^{\epsilon}(x_0,s))\mathrm{d}s - \epsilon \nabla_{\tilde{X}^0} k(\tilde{X}^{\epsilon}(x_0,s))\mathrm{d}W_s + \epsilon^2 N_1(s)\mathrm{d}s + \epsilon^2 N_2(s)\mathrm{d}W_s.
\end{aligned}$$

Here N_1 and N_2 are given by

$$\begin{aligned}
N_1(s) &= \sum_{i,j=1}^{d} \frac{\partial^2}{\partial \xi_1^i \xi_1^j}\, \nabla\, c(\xi_1) \left(\int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)_i \left(\int_0^s \mathcal{G}(x_0,s,u)\, \nabla\, k(\Phi_u x_0)\mathrm{d}W_u \right)_j, \\
N_2(s) &= \nabla^2 k(\xi_2) \int_0^s \mathcal{G}(x_0,s,u) \nabla_{X^0} k(\Phi_u x_0)\mathrm{d}W_u.
\end{aligned} \tag{4.6}$$

Now it is easy to see that

$$\begin{aligned}\tilde{X}^{\epsilon}(x_0,s) &= x_0 - s\,\nabla S_0(x_0) - \int_0^s \int_0^r \nabla c(\tilde{X}^{\epsilon}(x_0,u))\mathrm{d}u\ \mathrm{d}r - \epsilon \int_0^s \int_0^r \nabla k(\tilde{X}^{\epsilon}(x_0,u))\mathrm{d}W_u\ \mathrm{d}r \\ &\quad + \epsilon^2 \int_0^s \int_0^r N_1(u)\mathrm{d}u\ \mathrm{d}r + \epsilon^2 \int_0^s \int_0^r N_2(u)\mathrm{d}W_u\ \mathrm{d}r \\ &= x_0 - s\,\nabla S_0(x_0) - \int_0^s (s-r)\,\nabla c(\tilde{X}^{\epsilon}(x_0,r))\mathrm{d}r - \epsilon \int_0^s (s-r)\,\nabla k(\tilde{X}^{\epsilon}(x_0,r))\mathrm{d}W_r \\ &\quad + \epsilon^2 \int_0^s (s-r)N_1(r)\mathrm{d}r + \epsilon^2 \int_0^s (s-r)N_2(r)\mathrm{d}W_r. \end{aligned} \tag{4.7}$$

On the other hand, the solution of (4.1) can be represented by

$$X^{\epsilon}(x_0,s) = x_0 - s\,\nabla S_0(x_0) - \int_0^s (s-r)\,\nabla c(X^{\epsilon}(x_0,r))\mathrm{d}r - \epsilon \int_0^s (s-r)\,\nabla k(X^{\epsilon}(x_0,r))\mathrm{d}W_r. \tag{4.8}$$

Therefore it turns out that there exists $M_1 > 0$ such that

$$\begin{aligned}|\tilde{X}^{\epsilon}(x_0,s) - X^{\epsilon}(x_0,s)|^4 &= \Bigg| - \int_0^s (s-r)(\nabla c(\tilde{X}^{\epsilon}(x_0,r)) - \nabla c(X^{\epsilon}(x_0,r)))\mathrm{d}r - \epsilon \int_0^s (s-r)(\nabla k(\tilde{X}^{\epsilon}(x_0,r)) \\ &\quad - \nabla k(X^{\epsilon}(r)))\mathrm{d}W_r + \epsilon^2 \int_0^s (s-r)N_1(r)\mathrm{d}r + \epsilon^2 \int_0^s (s-r)N_2(r)\mathrm{d}W_r \Bigg|^4 \\ &\leqslant M_1 \Big| \int_0^s (s-r)(\nabla c(\tilde{X}^{\epsilon}(x_0,r)) - \nabla c(X^{\epsilon}(x_0,r)))\mathrm{d}r\Big|^4 + M_1\epsilon^4 \Big| \int_0^s (s-r) \\ &\quad \times (\nabla k(\tilde{X}^{\epsilon}(x_0,r)) - \nabla k(X^{\epsilon}(x_0,r)))\mathrm{d}W_r\Big|^4 + M_1\epsilon^8 \Big| \int_0^s (s-r)N_1(r) \\ &\quad \times \mathrm{d}r\Big|^4 + M_1\epsilon^8 \Big| \int_0^s (s-r)N_2(r)\mathrm{d}W_r\Big|^4. \end{aligned} \tag{4.9}$$

Now using Hölder's inequality, $E(\int_0^s f(r)\mathrm{d}W_r)^4 \leqslant M_2 s \int_0^s Ef^4(r)\mathrm{d}r$ for a constant $M_2 > 0$, and the Lipschitz continuity we have

$$\begin{aligned}E \sup_{0\leqslant s\leqslant t} |\tilde{X}^{\epsilon}(x_0,s) - X^{\epsilon}(x_0,s)|^4 &\leqslant M_1 \left(\int_0^s (s-r)^{\frac{4}{3}}\mathrm{d}r \right)^3 E \int_0^s \sup_{0\leqslant r\leqslant s} |\nabla c(\tilde{X}^{\epsilon}(x_0,r)) - \nabla c(X^{\epsilon}(x_0,r))|^4\ \mathrm{d}r \\ &\quad + M_1 M_2 \epsilon^4 s \int_0^s (s-r)^4 E \sup_{0\leqslant r\leqslant s} |\nabla k(\tilde{X}^{\epsilon}(x_0,r)) - \nabla k(X^{\epsilon}(r))|^4\ \mathrm{d}r \\ &\quad + M_1\epsilon^8 \left(\int_0^s (s-r)^{\frac{4}{3}}\ \mathrm{d}r \right)^3 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_1(r)|^4\ \mathrm{d}r + M_1 M_2 \epsilon^8 s \\ &\quad \times \int_0^s (s-r)^4 E \sup_{0\leqslant r\leqslant s} |N_2(r)|^4\ \mathrm{d}r \\ &\leqslant M_3 s^7 L^4 \int_0^s E \sup_{0\leqslant r\leqslant s} |\tilde{X}^{\epsilon}(x_0,r) - X^{\epsilon}(x_0,r)|^4\ \mathrm{d}r + M_3 s^4 \epsilon^4 L^4 \end{aligned}$$

$$\times \int_0^s E \sup_{0\leqslant r\leqslant s} |\tilde{X}^\epsilon(x_0,r) - X^\epsilon(r)|^4 \, \mathrm{d}r + M_3 \epsilon^8 s^7 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_1(r)|^4 \mathrm{d}r$$

$$+ M_3 s^4 \epsilon^8 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_2(r)|^4 \, \mathrm{d}r. \tag{4.10}$$

Here L is a Lipschitz constant of ∇c and ∇k and M_3 is a constant. But using inequality $E(\int_0^s f(r)\mathrm{d}W_r)^8 \leqslant M_4 s^{4/3} \int_0^s E(f(r))^8 \mathrm{d}r$ for a $M_4 > 0$, and taking $M_5 = n \max_{l,\xi_1,\xi_2}\{|\text{eigenvalue of the Hessian}(\nabla^2(\nabla_l c(\xi_1)))|, |\text{ eigenvalue of the Hessian } (\nabla^2(k(\xi_2)))|\}$, then

$$E \sup_{0\leqslant s\leqslant t} |N_1(r)|^4 \leqslant M_4 M_5 r^{\frac{4}{3}} \int_0^r \sup_{0\leqslant r\leqslant s} < \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0), \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) >^4 \, \mathrm{d}u \leqslant M_6 r^{\frac{4}{3}}, \tag{4.11}$$

and

$$E \sup_{0\leqslant s\leqslant t} (N_2(r))^4 = M_4 M_2 r \int_0^r \sup_{0\leqslant r\leqslant s} < \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0), G(x_0,s,u) \nabla k(\Phi_u x_0) >^2 \, \mathrm{d}u \leqslant M_6 r. \tag{4.12}$$

Here $M_6 > 0$ is a constant.

It follows from (4.10) that there exists $M_7 > 0$ such that

$$E \sup_{0\leqslant s\leqslant t} (\tilde{X}^\epsilon(x_0,s) - X^\epsilon(x_0,s))^4 \leqslant M_3 s^7 L^4 \int_0^s E \sup_{0\leqslant r\leqslant s} (\tilde{X}^\epsilon(x_0,r) - X^\epsilon(x_0,r))^4 \, \mathrm{d}r$$

$$+ M_3 s^4 \epsilon^4 L^4 \int_0^s E \sup_{0\leqslant r\leqslant s} (\tilde{X}^\epsilon(x_0,r) - X^\epsilon(x_0,r))^4 \, \mathrm{d}r + M_7 s^{\frac{28}{3}} \epsilon^8 + M_7 s^6 \epsilon^8. \tag{4.13}$$

By using the Gronwall inequality we know that for $0 \leqslant s \leqslant t$,

$$E \sup_{0\leqslant s\leqslant t} (\tilde{X}^\epsilon(x_0,s) - X^\epsilon(x_0,s))^4 \leqslant M \epsilon^8, \tag{4.14}$$

for a constant $M > 0$. Then (4.4) follows from the Chebyshev inequality. Following a similar method, one can prove that $0 \leqslant s \leqslant t$,

$$E \sup_{0\leqslant s\leqslant t} (X(x_0,s))^4 \leqslant M, \tag{4.15}$$

for a constant $M > 0$.

(ii) Now we prove (4.5). Denote $\nabla_i = \partial / \partial x_0^i$. From the definition of $\tilde{X}^\epsilon(x_0,s)$ we know

$$\nabla_i \tilde{X}^\epsilon(x_0,s) = \nabla_i \Phi_s x_0 - \epsilon \int_0^s \mathcal{G}(x_0,s,u) \nabla^2 k(\Phi_u x_0) \nabla_i \Phi_u x_0 \, \mathrm{d}W_u - \epsilon \int_0^s \nabla_i \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) \mathrm{d}W_u.$$

Thus, applying Lemma 4.1 again we have

$$\frac{d}{\mathrm{d}s}\nabla_i\tilde{X}^{\epsilon}(x_0,s) = \nabla_i\dot{\Phi}_s x_0 - \epsilon\int_0^s \frac{\partial}{\partial s}\mathcal{G}(x_0,s,u)\nabla^2 k(\Phi_u x_0)\nabla_i\Phi_u x_0\ \mathrm{d}W_u$$

$$-\epsilon\int_0^s \frac{\partial}{\partial s}\nabla_i\mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u.$$

Then differentiating again and using Lemma 4.1 we have

$$\begin{aligned}
d\frac{d}{\mathrm{d}s}\nabla_i\tilde{X}^{\epsilon}(x_0,s) &= -\nabla^2 c(\Phi_s x_0)(\nabla_i\Phi_s x_0)\mathrm{d}s - \epsilon\nabla^2 k(\Phi_s x_0)(\nabla_i\Phi_s x_0)\mathrm{d}W_s \\
&\quad -\epsilon\int_0^s \frac{\partial^2}{\partial s^2}\mathcal{G}(x_0,s,u)\nabla^2 k(\Phi_u x_0)\nabla_i\Phi_u x_0\ \mathrm{d}W_u\ \mathrm{d}s \\
&\quad -\epsilon\int_0^s \left(\frac{\partial^2}{\partial s^2}\nabla_i\mathcal{G}(x_0,s,u)\right)\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\ \mathrm{d}s \\
&= -\nabla^2 c(\Phi_s x_0)(\nabla_i\Phi_s x_0)\mathrm{d}s + \nabla^2 c(\Phi_s x_0)\epsilon\int_0^s \mathcal{G}(x_0,s,u)\nabla^2 k(\Phi_u x_0)\nabla_i\Phi_u x_0 \\
&\quad \times\mathrm{d}W_u\ \mathrm{d}s + \sum_{j=1}^{d}\frac{\partial}{\partial X_j}\nabla^2 c(\Phi_s x_0)(\nabla_i\Phi_s^j x_0)\epsilon\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\ \mathrm{d}s \\
&\quad + \nabla^2 c(\Phi_s x_0)\epsilon\int_0^s (\nabla_i\mathcal{G}(x_0,s,u))\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\ \mathrm{d}s - \epsilon\nabla^2 k(\Phi_s x_0)(\nabla_i\Phi_s x_0)\mathrm{d}W_s \\
&= -\nabla^2 c(\Phi_s x_0)\nabla_i\tilde{X}^{\epsilon}(x_0,s)\mathrm{d}s + \sum_{j=1}^{d}\frac{\partial}{\partial X_j}\nabla^2 c(\Phi_s x_0)(\nabla_i\Phi_s^j x_0)\epsilon \\
&\quad \times\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\ \mathrm{d}s - \epsilon\nabla^2 k(\Phi_s x_0)(\nabla_i\Phi_s x_0)\mathrm{d}W_s.
\end{aligned}$$

Now using Taylor's theorem we know that there exist ξ_3 and ξ_4 such that

$$\begin{aligned}
d\frac{d}{\mathrm{d}s}\nabla_i\tilde{X}^{\epsilon}(x_0,s) &= -\nabla^2 c\left(\Phi_s x_0 - \epsilon\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)\nabla_i\tilde{X}^{\epsilon}(x_0,s)\mathrm{d}s \\
&\quad -\epsilon\nabla^2 k\left(\Phi_s x_0 - \epsilon\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)\nabla_i\tilde{X}^{\epsilon}(x_0,s)\mathrm{d}W_s \\
&\quad -\epsilon^2\sum_{j=1}^{d}\frac{\partial}{\partial X_j}\nabla^2 c(\Phi_s x_0)\left[\int_0^s \mathcal{G}(x_0,s,u)\nabla^2 k(\Phi_u x_0)\nabla_i X^0(x_0,u)\mathrm{d}W_u\right. \\
&\quad \left.+\int_0^s \nabla_i\mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right]\times\left(\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_j\mathrm{d}s \\
&\quad +\epsilon^2\sum_j\sum_l (\nabla_{\xi_3^j}\nabla_{\xi_3^l}\nabla^2 c(\xi_3))\left(\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_j \\
&\quad \times\left(\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_l\nabla_i\tilde{X}^{\epsilon}(x_0,s)\mathrm{d}s - \epsilon^2\sum_j \nabla_{\xi_4^j}\nabla^2 k(\xi_4) \\
&\quad \times\left(\int_0^s \mathcal{G}(x_0,s,u)\ \nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_j\nabla_i(\tilde{X}^{\epsilon}(x_0,s))\mathrm{d}W_s \\
&= -\nabla^2 c(\tilde{X}^{\epsilon}(x_0,s))\nabla_i\tilde{X}^{\epsilon}(x_0,s)\mathrm{d}s - \epsilon\nabla^2 k(\tilde{X}^{\epsilon}(x_0,s))\nabla_i\tilde{X}^{\epsilon}(x_0,s)\mathrm{d}W_s
\end{aligned}$$

$$+ \epsilon^2 N_3(s)\mathrm{d}s + \epsilon^2 N_4(s)\mathrm{d}W_s, \quad s \in [0,t].$$

Here N_3 and N_4 are given by

$$\begin{aligned} N_3(s) = &- \sum_{j=1}^{d} \frac{\partial}{\partial X_j} \nabla^2 c(\Phi_s x_0) \Bigg[\int_0^s \mathcal{G}(x_0,s,u) \nabla^2 k(\Phi_u x_0) \nabla_i X^0(x_0,u) \mathrm{d}W_u \\ &+ \int_0^s \nabla_i \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) \mathrm{d}W_u \Bigg] \Bigg(\int_0^s \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) \mathrm{d}W_u \Bigg)_j + \sum_j \sum_l (\nabla_{\xi_3^{lj}} \nabla_{\xi_3^{jl}} c''(\xi_3)) \\ &\times \Bigg(\int_0^s \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) \mathrm{d}W_u \Bigg)_j \Bigg(\int_0^s \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) \mathrm{d}W_u \Bigg)_l \nabla_i \tilde{X}^\epsilon(x_0,s), \\ N_4(s) = &- \sum_j \nabla_{\xi_4^{jj}} \nabla^2 k(\xi_4) \Bigg(\int_0^s \mathcal{G}(x_0,s,u) \nabla k(\Phi_u x_0) \mathrm{d}W_u \Bigg)_j \nabla_i \tilde{X}^\epsilon(x_0,s). \end{aligned} \tag{4.16}$$

Using the Fubini theorem, it is easy to see that

$$\begin{aligned} \nabla_i \tilde{X}^\epsilon(x_0,s) &= e_i - s\nabla_i \nabla S_0(x_0) - \int_0^s \int_0^r \nabla^2 c(\tilde{X}^\epsilon(x_0,u))\mathrm{d}u \nabla_i \tilde{X}^\epsilon(x_0,r)\mathrm{d}r - \epsilon \int_0^s \int_0^r \nabla^2 k(\tilde{X}^\epsilon(x_0,u)) \\ &\quad \times \mathrm{d}W_u \nabla_i \tilde{X}^\epsilon(x_0,r)\mathrm{d}r + \epsilon^2 \int_0^s \int_0^r N_3(u)\mathrm{d}u \, \mathrm{d}r + \epsilon^2 \int_0^s \int_0^r N_4(u)\mathrm{d}W_u \, \mathrm{d}r \\ &= e_i - s\nabla_i \nabla S_0(x_0) - \int_0^s (s-r)\nabla^2 c(\tilde{X}^\epsilon(x_0,r)) \nabla_i \tilde{X}^\epsilon(x_0,r)\mathrm{d}r \\ &\quad - \epsilon \int_0^s (s-r)\nabla^2 k(\tilde{X}^\epsilon(x_0,r)) \nabla_i \tilde{X}^\epsilon(x_0,r)\mathrm{d}W_r \\ &\quad + \epsilon^2 \int_0^s (s-r) N_3(r)\mathrm{d}r + \epsilon^2 \int_0^s (s-r) N_4(r)\mathrm{d}W_r. \end{aligned} \tag{4.17}$$

Here $e_i = (0,0,\ldots,0,1,0,\ldots,0)$.

On the other hand, differentiating (4.8) we have

$$\begin{aligned} \nabla_i X^\epsilon(x_0,s) &= e_i - s\nabla_i \nabla S_0(x_0) - \int_0^s (s-r)\nabla^2 c(X^\epsilon(x_0,r))(\nabla_i X^\epsilon(x_0,r))\mathrm{d}r - \epsilon \int_0^s (s-r)\nabla^2 k(X^\epsilon(x_0,r)) \\ &\quad \times (\nabla_i X^\epsilon(x_0,r))\mathrm{d}W_r. \end{aligned} \tag{4.18}$$

Note here $\nabla_i \nabla S_0, \nabla^2 c, \nabla^2 k$ are bounded. So it is easy to prove there exists $M_1 > 0$ such that

$$E \sup_{0\leqslant s\leqslant t} |\nabla_i X^\epsilon(x_0,s)|^4 \leqslant M_1. \tag{4.19}$$

Therefore it turns out that

$$\begin{aligned}|\nabla_i \tilde{X}^\epsilon(x_0,s) - \nabla_i X^\epsilon(x_0,s)|^2 = \Bigg| &- \int_0^s (s-r)(\nabla^2 c(X^\epsilon(x_0,r)) - \nabla^2 c(\tilde{X}^\epsilon(x_0,r)))\nabla_i X^\epsilon(x_0,r)\mathrm{d}r - \int_0^s (s-r) \\ &\times (\nabla^2 c(\tilde{X}^\epsilon(x_0,r))(\nabla_i X^\epsilon(x_0,r) - \nabla_i \tilde{X}^\epsilon(x_0,r))\mathrm{d}r - \epsilon \int_0^s (s-r)(\nabla^2 k(X^\epsilon(x_0,r)) \\ &- \nabla^2 k(\tilde{X}^\epsilon(x_0,r)))\nabla_i X^\epsilon(x_0,r)\mathrm{d}W_r - \epsilon \int_0^s (s-r)\nabla^2 k(\tilde{X}^\epsilon(x_0,r)(\nabla_i X^\epsilon(x_0,r)) \\ &- \nabla_i \tilde{X}^\epsilon(x_0,r))\mathrm{d}W_r + \epsilon^2 \int_0^s (s-r)N_3(r)\mathrm{d}r + \epsilon^2 \int_0^s (s-r)N_4(r)\mathrm{d}W_r \Bigg|^2. \end{aligned} \tag{4.20}$$

This leads to, for any $0\leqslant s\leqslant t$,

$$\begin{aligned}E \sup_{0\leqslant s\leqslant t} |\nabla_i \tilde{X}^\epsilon(x_0,s) - \nabla_i X^\epsilon(x_0,s)|^2 \leqslant\ & 6E \sup_{0\leqslant s\leqslant t} \left| \int_0^s (s-r)(\nabla^2 c(\tilde{X}^\epsilon(x_0,r)) - \nabla^2 c(X^\epsilon(x_0,r)))\nabla_i X^\epsilon(x_0,r)\mathrm{d}r \right|^2 \\ &+ 6E \sup_{0\leqslant s\leqslant t} \left| \int_0^s (s-r)(\nabla^2 c(\tilde{X}^\epsilon(x_0,r))(\nabla_i X^\epsilon(x_0,r) - \nabla_i \tilde{X}^\epsilon(x_0,r))\mathrm{d}r \right|^2 \\ &+ 6\epsilon^2 E \sup_{0\leqslant s\leqslant t} \Bigg| \int_0^s (s-r)(\nabla^2 k(\tilde{X}^\epsilon(x_0,r)) \\ &- \nabla^2 k(X^\epsilon(r)))\nabla_i X^\epsilon(x_0,r)\mathrm{d}W_r \Bigg|^2 + 6\epsilon^2 E \sup_{0\leqslant s\leqslant t} \Bigg| \int_0^s (s \\ &- r)\nabla^2 k(\tilde{X}^\epsilon(x_0,r))(\nabla_i X^\epsilon(x_0,r) - \nabla_i X^\epsilon(x_0,r))\mathrm{d}W_r \Bigg|^2 \\ &+ 6\epsilon^4 E \sup_{0\leqslant s\leqslant t} \left| \int_0^s (s-r)N_3(r)\mathrm{d}r \right|^2 + 6\epsilon^4 E \sup_{0\leqslant s\leqslant t} \Bigg| \int_0^s (s \\ &- r)N_4(r)\mathrm{d}W_r \Bigg|^2. \end{aligned} \tag{4.21}$$

Denote by $M_2 = \sup_{x\in\mathbb{R}^d}\{|\text{eigenvalue of } \nabla^2 c(x))|, |\text{eigenvalue of } \nabla^2 k(x))|\}$ and by L the Lipschitz constant of $\nabla^2 c$ and $\nabla^2 k$. So by the Hölder inequality and the Lipschitz continuity we have

$$\begin{aligned}&E \sup_{0\leqslant s\leqslant t} |\nabla_i \tilde{X}^\epsilon(x_0,s) - \nabla_i X^\epsilon(x_0,s)|^2 \\ &\quad\leqslant 6E \sup_{0\leqslant s\leqslant t} \int_0^s (s-r)^2 |\nabla^2 c(\tilde{X}^\epsilon(x_0,r)) - \nabla^2 c(X^\epsilon(x_0,r))|^2 \mathrm{d}r \\ &\quad\quad\times \int_0^s |\nabla_i X^\epsilon(x_0,r)|^2\ \mathrm{d}r + 6E \sup_{0\leqslant s\leqslant t} \int_0^s (s-r)^2\ \mathrm{d}r \\ &\quad\quad\times \int_0^s |\nabla^2 c(\tilde{X}^\epsilon(x_0,r))(\nabla_i X^\epsilon(x_0,r) - \nabla_i \tilde{X}^\epsilon(x_0,r))|^2\ \mathrm{d}r + 6\epsilon^2 E \sup_{0\leqslant s\leqslant t} \int_0^s (s-r)^2 |\nabla^2 k(\tilde{X}^\epsilon(x_0,r))\end{aligned}$$

$$
\begin{aligned}
&- \nabla^2 k(X^\epsilon(r)))\nabla_i X^\epsilon(x_0,r)^2\,\mathrm{d}r + 6\epsilon^2 E \sup_{0\leqslant s\leqslant t}\int_0^s (s-r)^2 |\nabla^2 k(\widetilde{X}^\epsilon(x_0,r))(\nabla_i X^\epsilon(x_0,r) - \nabla_i \widetilde{X}^\epsilon(x_0,r))|^2\,\mathrm{d}r \\
&+ 6\epsilon^4 E \sup_{0\leqslant s\leqslant t}\int_0^s (s-r)^2\,\mathrm{d}r \int_0^s |N_3(r)|^2\,\mathrm{d}r + 6\epsilon^4 E \sup_{0\leqslant s\leqslant t}\int_0^s (s-r)^2 |N_4(r)|^2\,\mathrm{d}r \leqslant 6\Bigg\{ E \sup_{0\leqslant s\leqslant t}\Bigg(\int_0^s (s \\
&- r)^2 |\nabla^2 c(\widetilde{X}^\epsilon(x_0,r)) - \nabla^2 c(X^\epsilon(x_0,r))|^2\,\mathrm{d}r\Bigg)^2\Bigg\}^{1/2} \times \Bigg\{ E \sup_{0\leqslant s\leqslant t}\Bigg(\int_0^s (\nabla_i X^\epsilon(x_0,r))^2\,\mathrm{d}r\Bigg)^2\Bigg\}^{1/2} \\
&+ 2M_2 s^3 \int_0^s E \sup_{0\leqslant r\leqslant s} |\nabla_i X^\epsilon(x_0,r) - \nabla_i X^\epsilon(x_0,r)|^2\,\mathrm{d}r + 6\epsilon^2 \\
&\times \int_0^s (s-r)^2 \{E \sup_{0\leqslant r\leqslant s} (\nabla^2 k(\widetilde{X}^\epsilon(x_0,r)) - \nabla^2 k(X^\epsilon(r)))^4\}^{1/2} \{E \sup_{0\leqslant r\leqslant s} (\nabla_i X^\epsilon(x_0,r))^4\}^{1/2}\,\mathrm{d}r \\
&+ 6\epsilon^2 M_2 s^2 E \int_0^s E \sup_{0\leqslant r\leqslant s} (\nabla_i X^\epsilon(x_0,r) - \nabla_i \widetilde{X}^\epsilon(x_0,r))^2\,\mathrm{d}r + 2\epsilon^4 s^3 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_3(r)|^2\,\mathrm{d}r \\
&+ 6s^2\epsilon^4 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_4(r)|^2\,\mathrm{d}r. \qquad (4.22)
\end{aligned}
$$

This leads to

$$
\begin{aligned}
E \sup_{0\leqslant s\leqslant t} |\nabla_i \widetilde{X}^\epsilon(x_0,s) - \nabla_i X^\epsilon(x_0,s)|^2 \leqslant 6L^2 &\Bigg\{ \int_0^s (s-r)^4\,\mathrm{d}r \int_0^s E \sup_{0\leqslant r\leqslant s} |\widetilde{X}^\epsilon(x_0,r) - X^\epsilon(x_0,r)|^4\,\mathrm{d}r \Bigg\}^{1/2} \\
&\times \Bigg\{ \int_0^s E \sup_{0\leqslant r\leqslant s} |\nabla_i X^\epsilon(x_0,r)|^4\,\mathrm{d}r \Bigg\}^{1/2} + 6L^2\epsilon^2 \int_0^s (s-r)^2 \\
&\times \{E \sup_{0\leqslant r\leqslant s} |\widetilde{X}^\epsilon(x_0,r) - X^\epsilon(r)|^4\}^{1/2} \times \{E \sup_{0\leqslant r\leqslant s} |\nabla_i X^\epsilon(x_0,r)|^4\}^{1/2}\,\mathrm{d}r \\
&+ 2M_2 s^3 \int_0^s E|\nabla_i X^\epsilon(x_0,r) - \nabla_i \widetilde{X}^\epsilon(x_0,r)|^2\,\mathrm{d}r \\
&+ 6\epsilon^2 M_2 s^2 \int_0^s E \sup_{0\leqslant r\leqslant s} |\nabla_i X^\epsilon(x_0,r) - \nabla_i \widetilde{X}^\epsilon(x_0,r))^2\,\mathrm{d}r \\
&+ 2\epsilon^4 s^3 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_3(r)|^2\,\mathrm{d}r + 6s^2\epsilon^4 \int_0^s E \sup_{0\leqslant r\leqslant s} |N_4(r)|^2\,\mathrm{d}r. \qquad (4.23)
\end{aligned}
$$

Note (4.19). Similar to the estimate of N_1 and N_2, we can prove that there exists $M_3 > 0$ such that

$$
E \sup_{0\leqslant s\leqslant t} |N_3(r)|^2 \leqslant M_3 < \infty \qquad (4.24)
$$

and

$$
E \sup_{0\leqslant s\leqslant t} |N_4(r)|^2 \leqslant M_3 < \infty. \qquad (4.25)
$$

It follows from (4.14) and (4.23)–(4.25) that there exists $M_4 > 0$ such that

$$E \sup_{0\leqslant s\leqslant t} |\nabla_i \tilde{X}^\epsilon(x_0,s) - \nabla_i X^\epsilon(x_0,s)|^2 \leqslant M_4 s^3 \int_0^s E \sup_{0\leqslant r\leqslant s} |\nabla_i \tilde{X}^\epsilon(x_0,r) - \nabla_i X^\epsilon(x_0,r)|^2 \, dr + M_4 \epsilon^2 \int_0^s E \sup_{0\leqslant r\leqslant s} |\nabla_i \tilde{X}^\epsilon(x_0,r) - \nabla_i X^\epsilon(x_0,r)|^2 \, dr + M_4 \epsilon^4. \tag{4.26}$$

By using the Gronwall inequality we know that

$$E \sup_{0\leqslant s\leqslant t} |\nabla_i \tilde{X}^\epsilon(x_0,s) - \nabla_i X^\epsilon(x_0,s)|^2 \leqslant M\epsilon^4, \tag{4.27}$$

for a constant $M>0$. Then (4.5) follows from Chebyshev inequality. ■

A. Behavior of the caustic

Define for any given $0\leqslant T<\infty$,

$$\Omega_0 = \{\omega \in \Omega: \epsilon^{-\frac{3}{2}} \sup_{x_0\in\mathbb{R}^d} |\nabla X^\epsilon(x_0,s) - \nabla \tilde{X}^\epsilon(x_0,s)| < \delta \text{ for all } s \in [0,T]\}.$$

Then from Theorem 4.2

$$P\{\Omega_0\} > 1 - \frac{M\epsilon}{\delta^2}.$$

Now we define for each $\omega \in \Omega_0$.

In the case of the caustic C_t we define

$$\mathcal{D}^\epsilon_{\text{pre}} = \{(t,x_0): \text{Det } \nabla_{x_0} X^\epsilon_t(x_0) \neq 0, 0 \leqslant t \leqslant T\},$$

$$\mathcal{D}_{\text{pre}} = \{(t,x_0): \text{Det } \nabla_{x_0} \Phi_t x_0 \neq 0, 0 \leqslant t \leqslant T\}.$$

Lemma 4.3: As $\epsilon\to 0$, $[0,T]\times\mathbb{R}^d - \mathcal{D}^\epsilon_{\text{pre}} \to [0,T]\times\mathbb{R}^d - \mathcal{D}_{\text{pre}}$ *in probability for any given* $T>0$. *That is to say the precaustic surface of the stochastic dynamics converges to the precaustic surface of the classical mechanics as* $\epsilon\to 0$ *in probability*.

Proof: From Lemma 4.1, *it is easy to see that for each* $\omega \in \Omega_0$,

$$\nabla_{x_0} X^\epsilon(x_0,s) = \nabla \Phi_s x_0 - \epsilon \int_0^s \mathcal{G}(x_0,s,u) \nabla^2 k(\Phi_u x_0) \nabla_{x_0} \Phi_u x_0 \, dW_u + o(\epsilon).$$

So if $\text{Det}(\nabla\Phi_s x_0) \neq 0$, then for sufficiently small ϵ, $\text{Det}(\nabla X^\epsilon(x_0,s)) \neq 0$. That is to say, $D^\epsilon_{\text{pre}} \to D_{\text{pre}}$ as $\epsilon\to 0$ in probability. So as $\epsilon\to 0$, $[0,T]\times\mathbb{R}^d - \mathcal{D}^\epsilon_{\text{pre}} \to [0,T]\times\mathbb{R}^d - \mathcal{D}_{\text{pre}}$ in probability. ■

Theorem 4.4: *Denote for any given* $T>0$,

$$\mathcal{D}^\epsilon = \{(t,x): \text{Det } (\nabla (X^\epsilon)^{-1}_t x) \neq 0, 0 \leqslant t \leqslant T\},$$

$$\mathcal{D} = \{(t,x): \text{Det}(\nabla \Phi^{-1}_t x) \neq 0, 0 \leqslant t \leqslant T\}.$$

Then $[0,T]\times\mathbb{R}^d - \mathcal{D}^\epsilon \to [0,T]\times\mathbb{R}^d - \mathcal{D}$, *as* $\epsilon\to 0$. *That is to say the caustic surface of the stochastic dynamics with noise converges in probability to the caustic surface of the classical mechanics without noise as* $\epsilon\to 0$.

Proof: Denote by $\mathcal{D}^\epsilon_{\text{pre}}(s)$ a projection of $\mathcal{D}^\epsilon_{\text{pre}}$ on $\mathbb{R}^d$ such that $(s, \mathcal{D}^\epsilon_{\text{pre}}(s)) \subset \mathcal{D}^\epsilon_{\text{pre}}$. So

$$\mathcal{D}^\epsilon = \{(s, X_s^\epsilon(\mathcal{D}_{\text{pre}}^\epsilon(s)), \text{all } s\}. \tag{4.28}$$

But

$$X_s^\epsilon(\mathcal{D}_{\text{pre}}^\epsilon(s)) = X_s(\mathcal{D}_{\text{pre}}^\epsilon(s)) + (X_s^\epsilon(\mathcal{D}_{\text{pre}}^\epsilon(s)) - X_s(\mathcal{D}_{\text{pre}}^\epsilon(s))). \tag{4.29}$$

But from Lemma 4.1 and Lemma 4.3, as $\epsilon \to 0$ in probability,

$$X_s(\mathcal{D}_{\text{pre}}^\epsilon(s)) \to X_s(\mathcal{D}_{\text{pre}}(s)) \tag{4.30}$$

and

$$X_s^\epsilon(\mathcal{D}_{\text{pre}}^\epsilon(s)) - X_s(\mathcal{D}_{\text{pre}}^\epsilon(s)) \to 0. \tag{4.31}$$

Therefore $X_s^\epsilon(\mathcal{D}_{\text{pre}}^\epsilon(s)) \to X_s(\mathcal{D}_{\text{pre}}^\epsilon(s))$, i.e., $\mathcal{D}^\epsilon(s) \to \mathcal{D}(s)$. So $\mathcal{D}^\epsilon \to \mathcal{D}$. ■

B. Behavior of the wavefront

To characterize the wavefront H_t we must consider the Hamilton principal function $S^\epsilon(x,t)$ where we have, once again, emphasized the ϵ dependence.

Theorem 4.5: *Let ϕ_s be the minimizer of*

$$\frac{1}{2}\int_0^t |\dot{\phi}_s|^2 \, \mathrm{d}s + S_0(\phi_t) - \int_0^t c(\phi_s)\mathrm{d}s,$$

satisfying $\phi_t = x$ and ϕ_s^ϵ be the minimizer of $\frac{1}{2}\int_0^t |\dot{\phi}_s^\epsilon|^2 \, \mathrm{d}s + S_0(\phi_t^\epsilon) - \int_0^t c(\phi_s^\epsilon)\mathrm{d}s - \epsilon\int_0^t k(\phi_s^\epsilon)\mathrm{d}W_s$, satisfying $\phi_t^\epsilon = x$ for almost all $\omega \in \Omega$. Then we have for almost all $\omega \in \Omega$

$$S(x,t) - \epsilon\int_0^t k(\phi_s^\epsilon)\mathrm{d}W_s \leqslant S^\epsilon(x,t) \leqslant S(x,t) - \epsilon\int_0^t k(\phi_s)\mathrm{d}W_s. \tag{4.32}$$

In particular, as $\epsilon \to 0$, $S^\epsilon(x,t) \to S(x,t)$ a.s.

Furthermore, for the classical mechanics, assume there exists a unique x_0 for fixed t and x such that $\Phi_t x_0 = x$. The random wavefront for the heat equation has (x,t) equation

$$S^0(x,t) = \epsilon\int_0^t k(\Phi_s x_0)\mathrm{d}W_s + o(\epsilon),$$

where $S^0(x,t)$ is Hamilton's principal function for the path $X^0(x,t)(s)$.

Proof: By the definition of ϕ_s and ϕ_s^ϵ, it is easy to see for almost all ω,

$$\frac{1}{2}\int_0^t |\dot{\phi}_s^\epsilon|^2 \, \mathrm{d}s + S_0(\phi_t^\epsilon) - \int_0^t c(\phi_s^\epsilon)\mathrm{d}s \geqslant \frac{1}{2}\int_0^t |\dot{\phi}_s|^2 \, \mathrm{d}s + S_0(\phi_t) - \int_0^t c(\phi_s)\mathrm{d}s, \tag{4.33}$$

and

$$\begin{aligned}\frac{1}{2}\int_0^t |\dot{\phi}_s|^2 \, \mathrm{d}s + S_0(\phi_t) - \int_0^t c(\phi_s)\mathrm{d}s - \epsilon\int_0^t k(\phi_s)\mathrm{d}W_s \\ \geqslant \frac{1}{2}\int_0^t |\dot{\phi}_s^\epsilon|^2 \, \mathrm{d}s + S_0(\phi_t^\epsilon) - \int_0^t c(\phi_s^\epsilon)\mathrm{d}s - \epsilon\int_0^t k(\phi_s^\epsilon)\mathrm{d}W_s.\end{aligned} \tag{4.34}$$

It turns out that

$$\frac{1}{2}\int_0^t |\dot{\phi}_s|^2 \, \mathrm{d}s + S_0(\phi_t) - \int_0^t c(\phi_s)\mathrm{d}s - \epsilon \int_0^t k(\phi_s)\mathrm{d}W_s$$
$$\geqslant \frac{1}{2}\int_0^t |\dot{\phi}^\epsilon_s|^2 \, \mathrm{d}s + S_0(\phi^\epsilon_t) - \int_0^t c(\phi^\epsilon_s)\mathrm{d}s - \epsilon \int_0^t k(\phi^\epsilon_s)\mathrm{d}W_s$$
$$\geqslant \frac{1}{2}\int_0^t |\dot{\phi}_s|^2 \, \mathrm{d}s + S_0(\phi_t) - \int_0^t c(\phi_s)\mathrm{d}s - \epsilon \int_0^t k(\phi^\epsilon_s)\mathrm{d}W_s. \tag{4.35}$$

That is (4.32). Denote

$$\Omega_1 = \left\{ \omega \in \Omega : \epsilon \sup_{0\leqslant t\leqslant T} \left| \int_0^t k(\phi_s)\mathrm{d}W_s \right| \leqslant \delta \right\}, \tag{4.36}$$

and

$$\Omega_2 = \left\{ \omega \in \Omega : \epsilon \sup_{0\leqslant t\leqslant T} \left| \int_0^t k(\phi^\epsilon_s)\mathrm{d}W_s \right| \leqslant \delta \right\}. \tag{4.37}$$

But it is easy to see that

$$P\{\Omega_1\} \geqslant P\left\{ \epsilon \int_0^t k(\phi_s)\mathrm{d}W_s - \frac{\delta\epsilon^2}{2\epsilon^2 \max_x k^2(x)T} \int_0^t k^2(\phi_s)\mathrm{d}s \leqslant \frac{1}{2}\delta \right\} \geqslant 1 - e^{-[\delta^2/2\epsilon^2 \max_x k^2(x)T]}. \tag{4.38}$$

Similarly

$$P\{\Omega_2\} \geqslant 1 - e^{-[\delta^2/2\epsilon^2 \max_x k^2(x)T]}. \tag{4.39}$$

So for $\omega \in \Omega_1 \cap \Omega_2$,

$$S(x,t) - \delta \leqslant S^\epsilon(x,t) \leqslant S(x,t) + \delta. \tag{4.40}$$

From this, it is easy to conclude as $\epsilon \to 0$, $S^\epsilon(x,t) \to S(x,t)$ almost surely. Now we assume that there exists a unique minimizer $x_0 = x_0(x,t)$ for fixed t and x such that $\Phi_t x_0 = x$. Consider the solution of the Hamilton–Jacobi equation for $\mathcal{L}(q,\dot{q}) = \dot{q}^2/2 + c(q)$,

$$S(x,t) = S_0(x_0(x,t)) + \int_0^t \mathcal{L}(q(s),\dot{q}(s))\mathrm{d}s|_{q=q_0},$$

where q_0 is $X_0(s) = \Phi_s x_0(x,t)$. Here S satisfies the Hamilton–Jacobi equation

$$\frac{\partial S}{\partial t} + \frac{1}{2}|\nabla S|^2 + c(x) = 0 \text{ and } S(x,0) = S_0(x). \tag{4.41}$$

Consider

$$\delta q(s) = \Phi_s x_0(x + \epsilon \int_0^t \mathcal{G}(x_0,t,u) \, \nabla \, k(\Phi_u x_0)\mathrm{d}W_u, t) - \epsilon \int_0^s \mathcal{G}(x_0,s,u) \, \nabla \, k(\Phi_u x_0)\mathrm{d}W_u - \Phi_s x_0(x,t).$$

By Taylor's theorem, there exists ξ such that

$$\delta q(s) = \left(\frac{\partial}{\partial x_0}\Phi_s x_0\right)\frac{\partial}{\partial x}x_0(x,t)\left(\epsilon\int_0^t \mathcal{G}(x_0,t,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)$$
$$+\sum_{i,j,l=1}^{d}\left[\sum_{k=1}^{d}(\nabla_k\nabla_l\Phi_s x_0(\xi,t))\frac{\partial}{\partial\xi_i}x_0^k(\xi,t)\frac{\partial}{\partial\xi_j}x_0^l(\xi,t)+(\nabla_l\Phi_s x_0(\xi,t))\frac{\partial^2}{\partial\xi_i\xi_j}x_0^l(\xi,t)\right]$$
$$\times\left(\epsilon\int_0^t \mathcal{G}(x_0,t,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_i\left(\epsilon\int_0^t \mathcal{G}(x_0,t,u)\,\nabla\, k(\Phi_u x_0)dW_u\right)_j$$
$$-\epsilon\int_0^s \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u,$$

and computing $\dot{q}(s)$ gives

$$\delta\dot{q}(s) = \left(\frac{\partial}{\partial x_0}\right)\dot{\Phi}_s x_0\frac{\partial}{\partial x}x_0(x,t)\left(\epsilon\int_0^t \mathcal{G}(t,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)$$
$$+\sum_{i,j,l=1}^{d}\left[\sum_{k=1}^{d}(\nabla_k\nabla_l\dot{\Phi}_s x_0(\xi,t))\frac{\partial}{\partial\xi_i}x_0^k(\xi,t)\frac{\partial}{\partial\xi_j}x_0^l(\xi,t)+(\nabla_l\dot{\Phi}_s x_0(\xi,t))\frac{\partial^2}{\partial\xi_i\xi_j}x_0^l(\xi,t)\right]$$
$$\times\left(\epsilon\int_0^t \mathcal{G}(x_0,t,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_i\left(\epsilon\int_0^t \mathcal{G}(x_0,t,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_j$$
$$-\epsilon\int_0^s \frac{\partial}{\partial s}\mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u.$$

Therefore, as required,

$$\delta\dot{q}(s) = \frac{d}{\mathrm{d}s}\delta q(s). \tag{4.42}$$

We see by definition that

$$\delta q(t) = 0, \tag{4.43}$$

$$\delta q(0) = x_0\left(x+\epsilon\int_0^t \mathcal{G}(x_0,t,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u, t\right) - x_0(x,t). \tag{4.44}$$

Define

$$\Omega_3 = \left\{\sup_{\substack{x_0\in\mathbb{R}^d\\ 0\leqslant s\leqslant t}}\epsilon^{1/2}\left|\int_0^s \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right| \leqslant \delta\right\}. \tag{4.45}$$

It is easy to see that

$$P\{\Omega_3\} > 1 - e^{-[\delta^2/2\epsilon\sup_{x_0\in\mathbb{R}^d}\int_0^T(\mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0))^2\ \mathrm{d}u]}. \tag{4.46}$$

Then for each $\omega\in\Omega_3$ there exists ξ_1 such that,

$$\delta q(0) = \frac{\partial}{\partial x} x_0(x,t)\left(\epsilon \int_0^t \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right) + \sum_{i,j=1}^{d} \frac{\partial^2}{\partial \xi_i\, \partial\, \xi_j} x_0(\xi_1,t)$$
$$\times\left(\epsilon \int_0^t \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_i \left(\epsilon \int_0^t \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)_j$$
$$= \frac{\partial}{\partial x} x_0(x,t)\left(\epsilon \int_0^t \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right) + o(\epsilon). \tag{4.47}$$

Now we have

$$\delta S = \left\langle \left(\frac{\partial}{x_0} S_0\right), \left(\frac{\partial x_0}{\partial x}\right)\left(\epsilon \int_0^t \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)\right\rangle + \delta A. \tag{4.48}$$

And,

$$\delta A \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s + \int_0^t \mathcal{L}(q_0+\delta q_0, \dot{q}_0 + \delta\dot{q}_0)\mathrm{d}s - \int_0^t \mathcal{L}(q_0,\dot{q}_0)\mathrm{d}s$$
$$= \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s + \int_0^t \left(\frac{\partial \mathcal{L}}{\partial q}\delta q_0 + \frac{\partial \mathcal{L}}{\partial \dot{q}}\delta\dot{q}_0\right)\mathrm{d}s$$
$$= \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s + \left[\frac{\partial \mathcal{L}}{\partial \dot{q}}\delta q_0\right]_{s=0}^{s=t} + \int_0^t \left(\frac{\partial \mathcal{L}}{\partial q} - \frac{d}{\mathrm{d}s}\left(\frac{\partial \mathcal{L}}{\partial \dot{q}}\right)\right)\delta q_0\ \mathrm{d}s$$
$$= \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s - \langle \dot{q}(0), \delta q(0)\rangle. \tag{4.49}$$

It turns out that for each $\omega \in \Omega_3$,

$$\delta A = \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s - \left\langle \nabla S_0(x_0), \frac{\partial}{\partial x} x_0(x,t)\left(\epsilon \int_0^t \mathcal{G}(x_0,s,u)\,\nabla\, k(\Phi_u x_0)\mathrm{d}W_u\right)\right\rangle + o(\epsilon). \tag{4.50}$$

Therefore for each $\omega \in \Omega_3$,

$$\delta S = \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s + o(\epsilon). \tag{4.51}$$

The wavefront, for each $\omega \in \Omega_3$, satisfies

$$S(x,t) = \epsilon \int_0^t k(\Phi_s x_0)\mathrm{d}W_s + o(\epsilon). \tag{4.52}$$

■

C. Large time behavior for almost periodic small noise

Our Theorem 4.2 shows that for small noise $\dot{\tilde{X}}^\epsilon(x,t)$ is close to the actual solution of our problem in the inviscid limit. Also, we have an exact expression for $\tilde{X}^\epsilon$ in terms of the Jacobi fields for $\tilde{X}^0$, If we now assume that $\nabla k(x,s) = -a(s)$ is independent of x, we can define $\dot{\tilde{X}}^\epsilon(x,t)$ and

$\tilde{X}^{\epsilon}(x,t)$ in the same way as we did for the harmonic oscillator and, since we are working only to first order in ϵ, the $x^0(x,t)$'s are just the deterministic ones. It is therefore not surprising that there is an analog of Theorem 3.5.

Theorem 4.6: *Assume that* $\tilde{X}^0(x,t)$ *is periodic together with its Jacobi fields* $\partial\tilde{X}^0/\partial\gamma_0^{\alpha}$, $\alpha = 1,2,\ldots,2d$ *where* $\gamma_0=(x_0,p_0)^T$. *Then, if* $\int_0^t |a(s)|^2\,\mathrm{d}s<\infty$, *dropping* $\sim$, *the ensemble average is given by*

$$\mathbb{E}(\dot{\tilde{X}}^{\epsilon}(x,t)) = \dot{\tilde{X}}^0(x,t) = \dot{X}^0(x,t).$$

Moreover,

$$\mathbb{P}((\dot{\tilde{X}}^{\epsilon}(x,t) - \dot{X}^0(x,t)) \in \mathrm{d}v) = \exp\left(-\frac{v^T A(t) v}{2}\right)(2\pi)^{-d/2}(\det A)^{-1/2}\,\mathrm{d}v,$$

where the $d\times d$ *matrix* $A^{-1}(t)$ *is given by*

$$A^{-1}_{ii'}(t) = \epsilon^2 \int_0^t \frac{\partial X_i^0(u)}{\partial \gamma_0^{\alpha}} a_j(u) \frac{\partial X_{i'}^0(u)}{\partial \gamma_0^{\alpha'}} a_{j'}(u)\mathrm{d}u\; J_{\alpha\beta} J_{\alpha'\beta'} \frac{\partial \dot{X}_j^0(t)}{\partial \gamma_0^{\beta}} \frac{\partial \dot{X}_{j'}^0(t)}{\partial \gamma_0^{\beta'}},$$

$i,i'=1,2,\ldots,d$, *where* J *is the complex structure and the summation convention is enforced. In particular, if* $a(\cdot)$ *is almost periodic, with the above product almost periodic uniformly in* (x_0,p_0) *in a compact set* K,

$$t^{-1}A^{-1}_{ii'}(t) \sim \epsilon^2 M\left(\frac{\partial X_i^0}{\partial \gamma_0^{\alpha}} a_j \frac{\partial X_{i'}^0}{\partial \gamma_0^{\alpha'}} a_{j'}\right) J_{\alpha\beta} J_{\alpha'\beta'} \frac{\partial \dot{X}_j^0(t)}{\partial \gamma_0^{\beta}} \frac{\partial \dot{X}_{j'}^0(t)}{\partial \gamma_0^{\beta'}},$$

where M *denotes the infinite time average.*

Proof: This is a simple rewrite of the proof of Theorem 3.5. We need uniform almost periodicity because at the last step we must set $p_0=\nabla S_0(x_0)$ and $x_0=\tilde{x}_0(x,t)$ the minimizer (assumed unique) of $\mathcal{A}(x_0,x,t)$. We tacitly assume that $(\tilde{x}_0(x,t), \nabla S_0(\tilde{x}_0(x,t))) \in K$, our compact set. ■

Remark 4.1: The remarks after Theorem 3.5 are all relevant here save that the distribution of the Burgers fluid velocity now depends on the initial conditions. This distribution is in fact discontinuous across the cool part of the caustic because $\tilde{x}_0(x,t)$ jumps as we cross this part of the caustic, making the Jacobi fields jump here as well. The periodic behavior is in $\partial\dot{X}_j^0(t)/\partial\gamma_0^{\beta}$ and the resonance which is relevant is that between the zero noise Jacobi fields $\partial X_i^0/\partial\gamma_0^{\alpha}$ and the almost periodic noise term a. As expected the resonance destroys any possibility of an invariant measure existing. When the infinite time averages above are all zero the invariant measure should exist for a suitable restricted class of initial conditions.

D. Archetypal example with some illustrations

Having discussed the properties of the surfaces C_t and H_t we now illustrate what is perhaps the archetypal case with $S_0(x_0,y_0)=x_0^2y_0/2$ and zero potentials.

Figure 2 illustrates the critical case $\mathcal{A}=0$ where the precaustic is a parabola and the prelevel surface consists of an ellipse and a line pair. The zero prelevel surface has equation

$$x_0^2\left(\frac{\left(y_0+\frac{1}{2t}\right)^2}{\left(\frac{1}{2t}\right)^2} + \frac{x_0^2}{\left(\frac{1}{t}\right)^2} - 1\right) = 0,$$

and the precaustic has equation

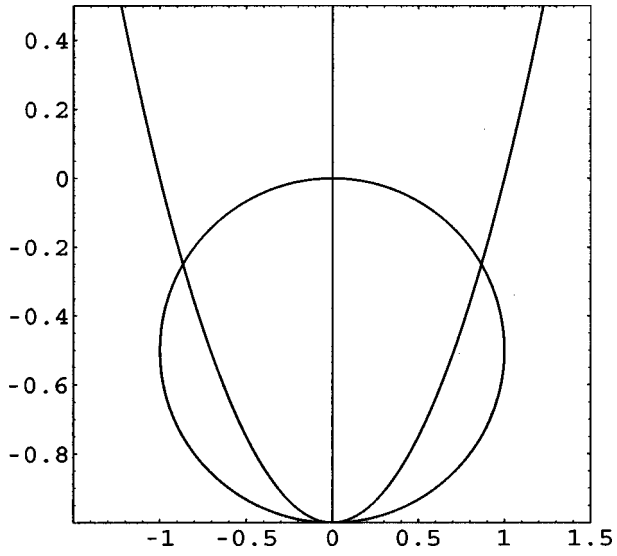

FIG. 2. Precaustic and prelevel surface.

$$1 + ty_0 = t^2 x_0^2.$$

We now map $(x,y)=\Phi_t(x_0,y_0)$ to obtain the hypocycloid tricorn

$$x = \frac{\cos\,\theta(1+\sin\,\theta)}{2t}, \quad y = \frac{\sin\,\theta(1-\sin\,\theta)}{2t}, \tag{4.53}$$

for $0 \leqslant \theta < 2\pi$, as the zero level surface at time t for the heat equation and semicubical parabolic cusp

$$8(yt+1)^3 = 27t^2x^2, \tag{4.54}$$

as the caustic at time t for the corresponding Burgers velocity field. Figure 3 illustrates the level surface H_t and the caustic C_t. The number of solutions $x_0(x,t)$ is also indicated for the three different regions (within, on and outwith the semicubical parabola). In this case $x_0(x,t)$ is the point $(a, y-ta^2/2)$ where $a \in \mathbb{R}$ satisfies the cubic $t^2a^3/2 - a(1+ty) + x = 0$ and $\tilde{x}_0(x,t)$ corresponds to the value of a minimizing $a^2(t^3a^4/8 - ta^3(1+4ty)/8 + y(1+ty)/2)$. We note that the vanishing of the

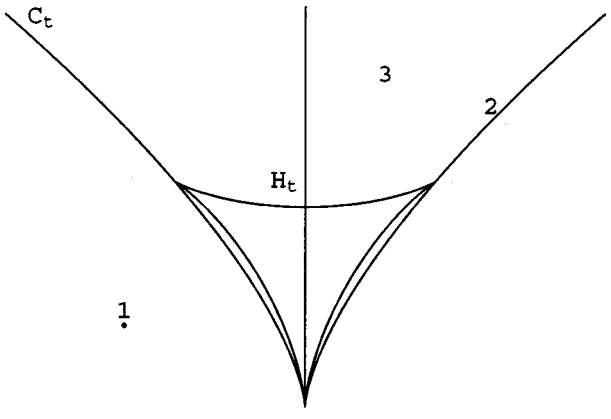

FIG. 3. Cusp and tricorn.

discriminant of the cubic for a defines the cusp caustic and that it can be shown that $\tilde{x}_0(x,t)$ jumps on crossing this caustic and nowhere else.

We now consider the stochastic case at $t=1$ where $\epsilon=\frac{1}{10}$ and $k(x,y,t)=x$. Figures 4 and 5 illustrate the case where we have $\mathcal{A}=0$.

Figures 6 and 7 illustrate the case of $\mathcal{A}=-\frac{1}{64}$.

We refrain from presenting a gallery of two- and three-dimensional images herein but such can be found in the recent doctoral theses of Reynolds and Reynolds.[31,32]

V. SINGULARITIES AND INTERMITTENCE OF TURBULENCE

We have analyzed the stochastic Burgers equation for small noise and shown how for our initial conditions resonance between the almost periodic noise and the underlying deterministic problem destroys any possibility of the existence of an invariant measure. We have also seen how for small noise the ensemble average and the distribution of the Burgers velocity inherit the singularity structure of the underlying Hamiltonian system, in particular the way that the caustics and shockwaves are still relevant.This is the main object lesson of the present work. These results rely heavily on our exact analysis of the harmonic oscillator and free cases.

Previously we detailed the caustic wavefront interaction in both the classical and stochastic case by appealing to geometrical properties of the Hamiltonian system. Now we have detailed information about these stochastic caustic wavefront structures in terms of the classical structures, at least in the case of small ϵ.

We now emphasize that new features emerge if one tries to use the above ideas to analyze the "intermittence" of stochastic turbulence as opposed to deterministic turbulence. The reason for the sharp contrast between stochastic and deterministic turbulence can already be seen here if we associate turbulent behavior with (an infinitely rapid) change in the number of cusped curves on the minimizing level surface of the Hamilton–Jacobi function. The times t when this occurs are just the times when the prelevel surfaces *touch* the precaustic. The times t when this number of curves changes in the deterministic case are simply the zeros of a deterministic function ζ, usually isolated zeros.

In the stochastic case ζ is a stochastic process whose zeros usually form a perfect set, i.e., an infinite set containing no isolated points. At these times the number of cusped curves changes with infinite frequency because of the infinitely rapid oscillation of the stochastic process ζ. This is in line with what one would expect for turbulent behavior. When the stochastic process ζ is *recurrent* this turbulent behavior is "intermittent" so that the scale of turbulent fluctuations varies in a random periodic way.

For example, in the two-dimensional case of $c\equiv 0$, $k_t(x,y)\equiv x$ and $S_0(x_0,y_0)=f(x_0)+g(x_0)y_0$, where f,g,f', and g' are zero at $x_0=a$, $g''(a)\neq 0$, the turbulent times t at which $n_c(t)$, the number of cusps on the zero prelevel surface of the Hamilton–Jacobi function changes are the zeros of the stochastic turbulence process ζ,

$$\zeta(t) = -a\epsilon W_t + \epsilon^2 W_t \int_0^t W_s \mathrm{d}s - \frac{\epsilon^2}{2}\int_0^t W_s^2 \mathrm{d}s.$$

The turbulence appears at the point $\Phi_t(a,-[(1+tf''(a))/tg''(a)]$ where $(a,-[(1+tf''(a))/tg''(a)]$ is a point on the precaustic with equation

$$y_0 = \frac{-1+t^2(g'(x_0))^2 - tf''(x_0)}{tg''(x_0)}.$$

Now $\{t:\zeta(t)=0\}$ is a perfect set and $\zeta(t)$ is recurrent to 0, while $\zeta_c(t)=\zeta(t)-c$ has exactly the same properties. Zeros of $\zeta_c(t)$ are times at which the number of cusps on the c prelevel surface of the Hamilton–Jacobi function changes (see Reynolds, Truman, and Williams[33]).

We may also introduce a singularity periodic in the (x_0,y_0) coordinates.

Lemma 5.1: Consider the initial function $S_0(x_0,y_0)=f(x_0)+g(x_0)\gamma(y_0)$. If f,f',g,g' are zero at

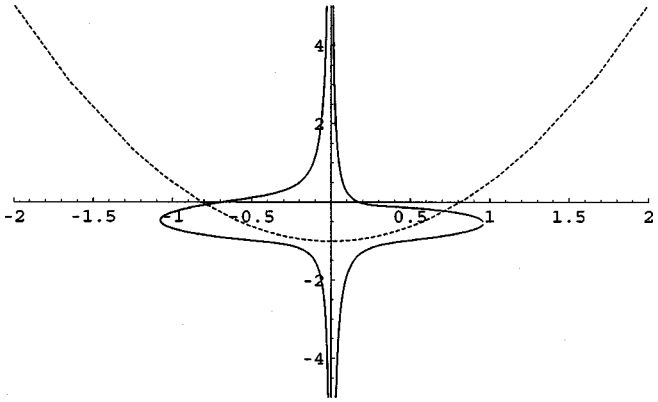

FIG. 4. Stochastic precaustic and prelevel surface.

α_i for $i=1,2,\ldots,n$ and $g''(\alpha_i)\neq 0$ then the zero precurves will touch at

$$\left(\alpha_i, \gamma^{-1}\left(\frac{-1-tf''(\alpha_i)}{tg''(\alpha_i)}\right)\right),$$

for $i=1,2,\ldots,n$ if γ is invertible.

Proof: The precurves meet at solutions x_0 of $F_0(x_0,t)=0$ where

$$F_0(x_0,t)=\frac{t}{2}(f'+g'\gamma(y_0(x_0)))^2+\frac{t}{2}g^2\gamma'(y_0(x_0))^2+f+g\gamma(y_0(x_0)),$$

and $y_0(x_0)$ is the precaustic. Now

$$\frac{\partial F_0}{\partial x_0}(x_0,t)=t(f'+g'\gamma(y_0(x_0)))\frac{\partial}{\partial x_0}(f'+g'\gamma(y_0(x_0)))+tgg'\gamma'(y_0(x_0))^2$$
$$+tg^2\gamma'(y_0(x_0))\gamma''(y_0(x_0))y_0'(x_0)+f'+g'\gamma(y_0(x_0))+g\gamma'(y_0(x_0))y_0'(x_0),$$

so that clearly $F_0(\alpha_i,t)=0$ and $\partial F_0/\partial x_0|_{x_0=\alpha_i}=0$. Hence the precurves will touch at $(\alpha_i,y_0(\alpha_i))$ where $y_0(x_0)$ is the precaustic. However in this case the precaustic is given by

$$(1+t(f''+g''\gamma(y_0)))(1+tg\gamma''(y_0))-t^2g'^2\gamma'(y_0)^2=0,$$

so that at $x_0=\alpha_i$

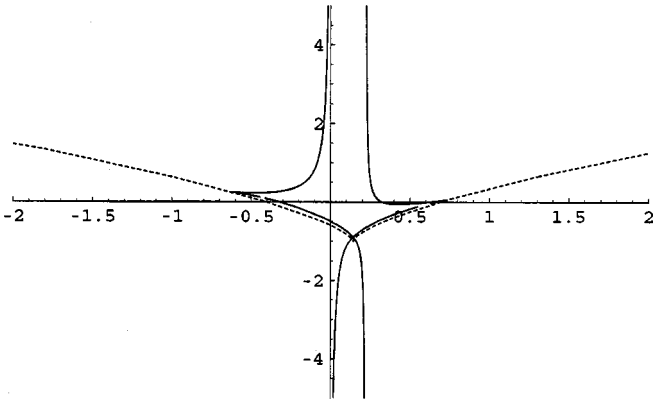

FIG. 5. Stochastic caustic and level surface.

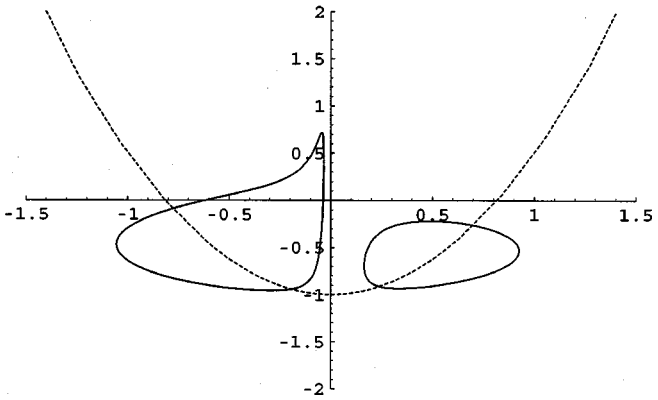

FIG. 6. Stochastic precaustic and prelevel surface.

$$\gamma(y_0) = \frac{-1 - tf''(\alpha_i)}{tg''(\alpha_i)}.$$

Hence

$$y_0(\alpha_i) = \gamma^{-1}\left(\frac{-1 - tf''(\alpha_i)}{tg''(\alpha_i)}\right).$$

■

Corollary 5.2: If $S_0(x_0,y_0) = f(x_0) + g(x_0)\gamma(y_0)$ *where* γ *is a periodic function with period* b *and* f, g, f', g' *are zero at* α_i *for* $i = 1,2,\ldots,n$ *while* $g''(\alpha_i) \neq 0$ *then the precurves will touch at*

$$(x_0,y_0) = \left(\alpha_i, \gamma^{-1}\left(\frac{-1 - tf''(\alpha_i)}{tg''(\alpha_i)}\right) + lb\right),$$

for $l \in \mathbb{Z}$ *and* $i = 1,2,\ldots,n$.

In order to obtain a periodic cusp singularity we set $\gamma(\cdot) := (b/2\pi)\sin(2\pi/b\cdot)$, where $b > 0$, so that γ has period b and $\gamma(y) \sim y$ for $y \sim 0$. Clearly if we take $f \equiv 0$ and $g(x_0) := (a^2/2\pi^2)\sin^2(\pi x_0/a)$ then f, g, f', and g' are zero at $x_0 = ka$ $(k \in \mathbb{Z})$ and $g''(ka) = 1$. Moreover

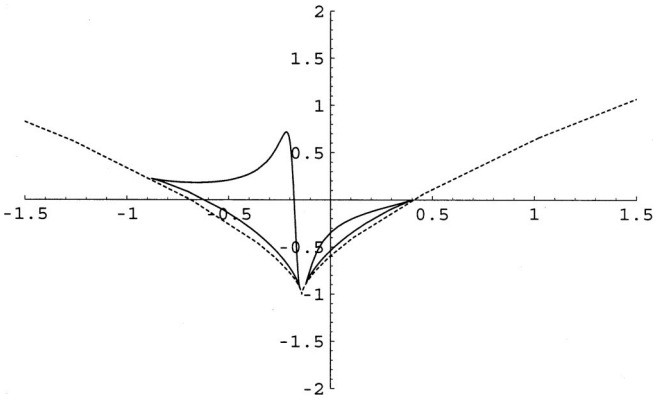

FIG. 7. Stochastic caustic and level surface.

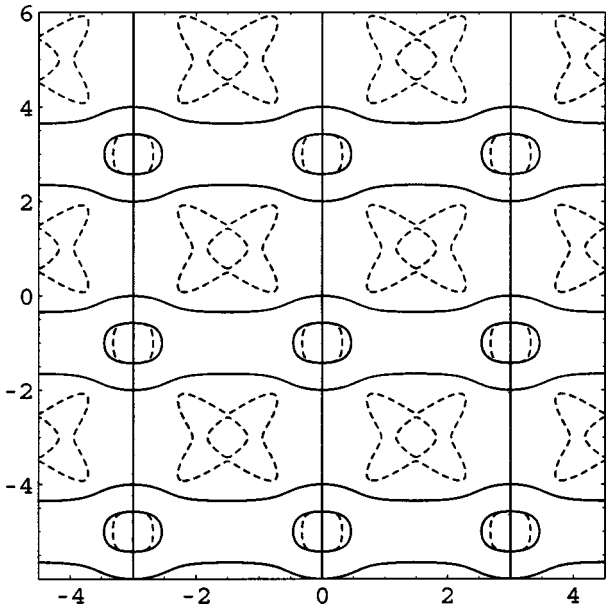

FIG. 8. Periodic zero prelevel surface and precaustic.

$$\gamma^{-1}\left(\frac{-1-tf''(ka)}{tg''(ka)}\right)=\gamma^{-1}\left(-\frac{1}{t}\right)=\frac{b}{2\pi}\arcsin\left(-\frac{2\pi}{bt}\right),$$

which exists if $b\geqslant 2\pi/t$. Since the conditions of Corollary 5.2 are satisfied we obtain the following proposition.

Proposition 5.3: Consider the initial function $S_0(x_0,y_0)=(a^2b/4\pi^3)\sin^2(\pi x_0/a)\sin(2\pi y_0/b)$. *If* $b\geqslant 2\pi/t$ *then the precurves will touch at*

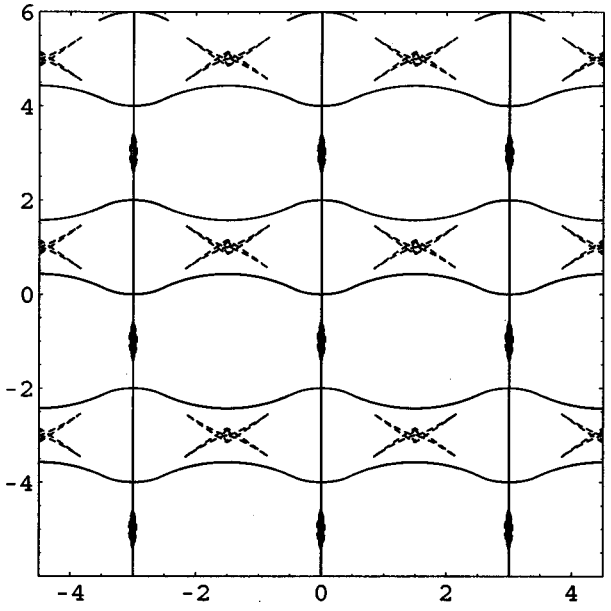

FIG. 9. Periodic zero level surface and caustic.

$$(x_0,y_0) = \left(ka, \frac{b}{2\pi} \arcsin\left(-\frac{2\pi}{bt} \right) + lb \right),$$

for $k,l \in \mathbb{Z}$.

In Figs. 8 and 9 we have shown the precurves and image curves, respectively, where $a=3$, $b=4$, and $t=2$ so that $b \geqslant 2\pi/t$.

We shall not pursue the notion of periodic singularities any further, but suffice to say many examples may be easily created.

Hence, the second object lesson of the present study is that the number of cusped curves on the wavefront will change infinitely rapidly in the stochastic case when the presurfaces touch and that this behavior will recur in a random periodic way if the stochastic process ζ is recurrent. This is the "intermittence" of stochastic turbulence in our model. There is no analog of this for the deterministic Burgers equation.

We hope to investigate these phenomena in more detail in a future paper.

On the asymptotics of some large Hankel determinants generated by Fisher–Hartwig symbols defined on the real line

T. M. Garoni[a)]
Institute for Mathematics and its Applications, University of Minnesota, Minneapolis, Minnesota 55455-0436

(Received 8 November 2004; accepted 19 January 2005; published online 5 April 2005)

We investigate the asymptotics of Hankel determinants of the form $\det_{j,k=0}^{N-1}[\int_\Omega dx\ \omega_N(x)\Pi_{i=1}^m|\mu_i-x|^{2q_i}x^{j+k}]$ as $N\to\infty$ with q and μ fixed, where Ω is an infinite subinterval of $\mathbb{R}$ and $\omega_N(x)$ is a positive weight on Ω. Such objects are natural analogs of Toeplitz determinants generated by Fisher–Hartwig symbols, and arise in random matrix theory in the investigation of certain expectations involving random characteristic polynomials. The reduced density matrices of certain one-dimensional systems of trapped impenetrable bosons can also be expressed in terms of Hankel determinants of this form. We focus on the specific cases of scaled Hermite and Laguerre weights. We compute the asymptotics by using a duality formula expressing the $N\times N$ Hankel determinant as a $2(q_1+\cdots+q_m)$-fold integral, which is valid when each q_i is natural. We thus verify, for such q, a recent conjecture of Forrester and Frankel derived using a log-gas argument. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1867981]

I. INTRODUCTION

Consider the multiple integral

$$H_{M,N,m,q}(\mu):=\int_\Omega \omega_N(z_1)dz_1\cdots\int_\Omega \omega_N(z_M)dz_M|\Delta_M(z)|^2\prod_{l=1}^{M}\prod_{i=1}^{m}|\mu_i-z_l|^{2q_i}, \tag{1}$$

where

$$q:=(q_1,\ldots,q_m),\quad \mu:=(\mu_1,\ldots,\mu_m), \tag{2}$$

$\omega_N(z)$ is a nonzero and continuous weight function, possibly depending on a parameter N, and

$$\Delta_M(z):=\det_{j,k=1}^{M}(z_k^{j-1})=\prod_{1\leqslant j<k\leqslant M}(z_k-z_j) \tag{3}$$

is the Vandermonde determinant. As a notational convenience we also define

$$H_{M,N}:=H_{M,N,0,}(\cdot) \tag{4}$$

$$=\int_\Omega \omega_N(z_1)dz_1\cdots\int_\Omega \omega_N(z_M)dz_M|\Delta_M(z)|^2. \tag{5}$$

a)Electronic mail: garoni@ima.umn.edu; URL: http://www.ima.umn.edu/~garoni

It is known that M-fold integrals of the form (1) can be identified with the determinant of an $M \times M$ matrix. Expanding the Vandermonde determinants in terms of sums over permutations, and simplifying appropriately, we find

$$H_{M,N,m,q}(\mu) = M! \det_{j,k=0}^{M-1} \left[\int_\Omega \mathrm{d}z \, a(z) z^j (z^*)^k \right], \tag{6}$$

where z^* denotes the complex conjugate of z, and

$$a(z) := \omega_N(z) \prod_{i=1}^{m} |\mu_i - z|^{2q_i}. \tag{7}$$

When $\Omega \subseteq \mathbb{R}$, Eq. (6) becomes

$$H_{M,N,m,q}(\mu) = M! \det_{j,k=0}^{M-1} [a_{j+k}], \tag{8}$$

where

$$a_n := \int_\Omega \mathrm{d}z \, a(z) z^n. \tag{9}$$

One says that the determinant (8) is *generated* by the function (7).

Since the entries in the determinant (8) are of the form a_{j+k}, we have thus identified the multiple integral (1), when $\Omega \subseteq \mathbb{R}$, with a Hankel determinant. Had we instead taken Ω to be $\mathbb{T}$, the unit circle in $\mathbb{C}$, then according to (6) the entries of the determinant would be a_{j-k}, and we would thus obtain a Toeplitz determinant. [It is conventional when discussing such Toeplitz determinants to set $z = e^{i\theta}$ and to define a_n as the integral of $a(z)z^n$ with respect to $\mathrm{d}\theta$ rather than $\mathrm{d}z$. This merely introduces the nonzero factor $ie^{i\theta}$ which is easily absorbed into the definition of $a(z)$, and so such technicalities are not relevant to our discussion here.]

When $z \in \mathbb{T}$, functions of the form (7) are known as *Fisher–Hartwig symbols*[1] (although we remark that they are not the most general examples of Fisher–Hartwig symbols). By extension, we can describe the Hankel determinant (8) as being generated by a Fisher–Hartwig symbol which is defined on the real line.

The asymptotic analysis of Toeplitz determinants generated by Fisher–Hartwig symbols is a fascinating and well studied subject (see, e.g., Ref. 1 and references therein), and rigorous results which describe the large M asymptotic behavior of Toeplitz determinants generated by symbols of the form (7) are known.[2] There are a number of important physical applications of such determinants (see, e.g., Refs. 3–5). It is often the case, as we discuss presently, that the quantity appearing in applications is actually the integral (1) rather than the determinant directly, and when $\Omega \subseteq \mathbb{R}$ we are naturally lead to Hankel determinants generated by the symbol (7). We discuss below a number of physical applications in which the asymptotics of such Hankel determinants is of interest. A rigorous treatment of these asymptotics is an open problem, however a conjectured form for the large M asymptotics has recently been reported by Forrester and Frankel in Ref. 5. Very recently, the $m=1$ case of this conjecture has been verified when $\Omega = \mathbb{R}$ and $\omega_N(x)$ is a Hermite weight, by using a Riemann–Hilbert approach.[6] In the present work we verify the conjecture of Forrester and Frankel when $\omega_N(z)$ is either a Hermite or Laguerre weight for any $m \in \mathbb{N}$, when each $q_i \in \mathbb{N}$.

A. Random matrix theory

The multiple integral (1) has a natural interpretation in random matrix theory. Let us consider the ensemble of random matrices with joint eigenvalue probability density function (pdf) given by

$$P_{M,N}(x) := \frac{1}{H_{M,N}} |\Delta_M(x)|^2 \prod_{l=1}^{M} \omega_N(x_l), \tag{10}$$

and whose eigenvalues lie in Ω. When $\Omega = \mathbb{R}$, concrete examples of such ensembles include the ubiquitous Gaussian unitary ensemble (GUE), corresponding to $\omega_N(x) = \exp(-2Nx^2)$, as well as more general unitary ensembles (UE), corresponding to $\omega_N(x) = \exp(-NV(x))$ with $V(x)$ an arbitrary polynomial of even degree with positive leading coefficient (see, e.g., Ref. 7). When $\Omega = (0, \infty)$ an important example is the Laguerre unitary ensemble (LUE), corresponding to $\omega_N(x) = x^\alpha \exp(-4Nx)$, which includes Wishart matrices and the Chiral GUE as special cases (the latter after a straightforward change of variables; see, e.g., Ref. 8). Setting $x = e^{i\theta}$ and $\omega_N(x) = 1$ in (10) we obtain the joint pdf for the eigenphases $\theta_l \in [0, 2\pi]$ of the ensemble of random unitary matrices with Haar measure, often called the circular unitary ensemble (CUE). For the purpose of computing expectations, the CUE is equivalent to (10) with $\Omega = \mathbb{T}$ and $\omega_N(z) = 1/iz$.

If we denote the characteristic polynomial of the $M \times M$ matrix X, with eigenvalues $x_1, \ldots, x_M$, by

$$\mathcal{Z}_M(\mu_i) := \det(\mu_i I - X) = \prod_{l=1}^{M} (\mu_i - x_l), \tag{11}$$

then (1) corresponds to the following expectation involving the absolute value of such characteristic polynomials:

$$\left\langle \prod_{i=1}^{m} |\mathcal{Z}_M(\mu_i)|^{2q_i} \right\rangle_{P_{M,N}} = \frac{H_{M,N,m,q}(\mu)}{H_{M,N}}, \tag{12}$$

where the expectation on the left-hand side of (12) is with respect to the joint eigenvalue pdf (10). The case $M = N$ is generally the case of interest.

From (6) we see that expectations of characteristic polynomials of the form appearing in (12) are characterized by a determinant generated by the symbol (7); when $\Omega \subseteq \mathbb{R}$, it is a Hankel determinant, and when $\Omega = \mathbb{T}$ it is a Toeplitz determinant.

A sizable literature on the correlations of products and ratios of characteristic polynomials of random matrices from various ensembles has emerged in recent years, see, e.g., Refs. 9–16, and significant progress has been made in the understanding of such objects. Such quantities have applications in diverse fields including number theory, quantum chaos, and many-body quantum mechanics. These works consider either exact algebraic relations that are valid for finite N, or the large N asymptotics in the usual universal microscopic scaling limits. We shall be interested not in scaling limits, but in the limit of large N with μ fixed. Investigations of objects of the form (12) in this limit have been reported in Refs. 5 and 17.

B. Impenetrable bosons

A compelling physical motivation for investigating multiple integrals of the form (1) arises from a consideration of certain one-dimensional many-body systems of impenetrable bosons. By impenetrability we simply mean that we require the wave function to vanish whenever two bosons occupy the same point in space. Such systems have been receiving renewed theoretical interest recently due to the possibility of their experimental realization in the near future using ultracold systems of atomic bosons confined in elongated traps; see, e.g., Refs. 18 and 19. Systems of impenetrable bosons with certain specific boundary conditions are known to have ground state wave functions of the form

$$\psi(x_1,\ldots,x_M) = \frac{1}{\sqrt{C_M}}\prod_{l=1}^{M}\sqrt{g_N(x_l)}\,|\Delta_M[f(x_1),\ldots,f(x_M)]|, \quad x_1,\ldots,x_M \in D \subseteq \mathbb{R}, \tag{13}$$

see, e.g., Refs. 20 and 21. Specifically, systems with periodic, Dirichlet, or Neumann boundary conditions have wave functions of this form, as do systems confined in an harmonic well. Of these, the harmonically confined system is perhaps the most relevant to current experiments.

It is worth emphasizing that the introduction of such zero-range infinite-strength interactions establishes a correspondence between impenetrable bosons and a corresponding system of free fermions, a fact first noted in Ref. 22, and this is one of the primary reasons for current experimental interest in such systems. Indeed, for the specific systems mentioned above, were it not for the absolute value surrounding the Vandermonde determinant, (13) would define the wave function for a system of free fermions. This fact implies that certain quantities such as the energy spectrum and the particle density are identical in the impenetrable boson system and its corresponding free fermion system. Quantities which depend on the phase of the wave function however will clearly differ significantly between these two systems.

One such quantity, of great significance, is the n-body density matrix, which for a system of $N+n$ particles is defined as

$$\rho_{N+n}^{(n)}(x_1,y_1,\ldots,x_n,y_n) := \binom{N+n}{n}\int_D \mathrm{d}\xi_1 \cdots \int_D \mathrm{d}\xi_N\, \psi(x_1,\ldots,x_n,\xi_1,\ldots,\xi_N)\psi^*(y_1,\ldots,y_n,\xi_1,\ldots,\xi_N). \tag{14}$$

A key observation is that wave functions of the form (13) admit the factorization

$$\begin{aligned}\psi(x_1,\ldots,x_n,\xi_1,\ldots,\xi_N) = {} & \sqrt{\frac{C_N}{C_{N+n}}}\prod_{l=1}^{n}\sqrt{g_N(x_l)}\,|\Delta_n[f(x_1),\ldots,f(x_n)]| \\ & \times \prod_{l=1}^{N}\prod_{i=1}^{n}|f(x_i)-f(\xi_l)|\cdot\psi(\xi_1,\ldots,\xi_N),\end{aligned} \tag{15}$$

and inserting (15) into (14) yields

$$\begin{aligned}\rho_{N+n}^{(n)}(x_1,y_1,\ldots,x_n,y_n) = {} & \binom{N+n}{N}\prod_{i=1}^{n}\sqrt{g_N(x_i)g_N(y_i)}\,|\Delta_n[f(x_1),\ldots,f(x_n)]\Delta_n[f(y_1),\ldots,f(y_n)]| \\ & \times \frac{1}{H_{N+n,N}}\,H_{N,N,2n,q}(f(x_1),\ldots,f(x_n),f(y_1),\ldots,f(y_n))|_{q=(1/2,\ldots,1/2)},\end{aligned} \tag{16}$$

where in the definition of $H_{N,N,2n,q}$ and $H_{N+n,N}$ we have $\Omega = f(D)$ and

$$\omega_N(z) = g_N(f^{-1}(z))\frac{\mathrm{d}f^{-1}}{\mathrm{d}z}(z). \tag{17}$$

For the four specific systems mentioned below (13), this $\omega_N(z)$ given in (17) is well defined, nonzero and continuous.

Hence, from (6) we see that $\rho_{N+n}^{(n)}$ is characterized by a determinant generated by the symbol (7). For systems subject to periodic boundary conditions this determinant will be a Toeplitz determinant,[23,24] whereas for systems confined by an harmonic well it will be a Hankel determinant.[24] Indeed, this link between density matrices for impenetrable bosons and Toeplitz determinants generated by Fisher–Hartwig symbols was originally one of the key motivations for investigating the asymptotics of such Toeplitz determinants.[3,4,23] In light of the possible future experimental realization of finite one-dimensional harmonically trapped systems of impenetrable bosons, an important theoretical question is the behavior of the corresponding density matrices

when N is large and $x_1, y_1, \ldots, x_n, y_n$ are fixed. This then provides a direct physical motivation for investigating the large N asymptotics of $N \times N$ Hankel determinants generated by symbols of the form (7).

Perhaps the most important quantity is the one-body density matrix. The asymptotics of the one-body density matrix for a system with periodic boundary conditions can be rigorously established from the asymptotics of the corresponding Toeplitz determinant. The leading order behavior of the one-body density matrix in the case of harmonic confinement was deduced in Ref. 24 using log-gas arguments, and has been recovered in Ref. 25 using a rather more direct, yet still nonrigorous, approach. The asymptotics of the one-body density matrix in the Dirichlet/Neumann case was deduced in Ref. 17, again by log-gas arguments, and has now been rigorously proved in Ref. 5, by making use of recent results in Refs. 26 and 27.

We conclude our discussion of impenetrable bosons by noting the correspondence between the joint eigenvalue pdf (10) and the wave function (13). The correspondence between the joint eigenvalue pdf (10) and the wave function for a system of free fermions is well known.[28] The correspondence between impenetrable bosons and random matrices was first noted by Sutherland,[29] between systems of impenetrable bosons with periodic boundary conditions and the CUE; see also Ref. 30. The correspondence between impenetrable bosons with Dirichlet or Neumann boundary conditions and the Jacobi unitary ensembles (JUE) was discussed in Refs. 17 and 20, and a similar interpretation for the LUE was noted in Ref. 5. Again, the most interesting case from an experimental perspective is the correspondence between the GUE and systems of impenetrable bosons confined in an harmonic well, and this particular system has been the focus of considerable recent theoretical study, see, e.g., Refs. 24, 25, and 31 and references therein.

C. Asymptotics of Hankel determinants

The asymptotics of large Toeplitz and Hankel determinants has been of long standing interest to mathematicians. For Toeplitz determinants generated by well behaved symbols, very precise asymptotic results are given by the Szegö limit theorems (see, e.g., Refs. 1 and 32). Toeplitz determinants generated by the symbol (7) are not amenable to the Szegö limit theorems however since (7) has zeros. Inspired in part by applications to impenetrable bosons Lenard[4,23] (see also Ref. 3) conjectured the asymptotics of Toeplitz determinants generated by symbols of the form (7), and this conjecture was subsequently proved by Widom.[2] The asymptotic behavior of Toeplitz determinants generated by (7), as well as more general Fisher–Hartwig symbols, is now well understood (see, e.g., Ref. 1). Analogously, the asymptotic behavior of large Hankel determinants generated by functions defined on $\Omega \subseteq \mathbb{R}$ has also been the subject of study. This problem was addressed by Szegö[33] and also Hirschman[34] with Ω a finite interval (see also Ref. 32). In the context of the UE and LUE of random matrix theory, as well as in the context of trapped systems of impenetrable bosons, we are interested in case where Ω is infinite, and recently Basor *et al.*[35] have considered the asymptotics of Hankel determinants generated by symbols defined on $\Omega = (0, \infty)$. However, a key restriction in these works is that the symbol be nowhere zero, and hence they do not apply to determinants generated by (7). Forrester and Frankel[5] have recently conjectured the asymptotic behavior of Hankel determinants generated by symbols of the form (7) defined on $\Omega \subseteq \mathbb{R}$. Complete and rigorous proofs of their conjectures remains an open problem. As mentioned above, a rigorous proof for the $m=1$ case when $\Omega = \mathbb{R}$ and $\omega_N(x)$ is a Hermite weight has very recently been reported in Ref. 6.

Specifically, Forrester and Frankel[5] consider the behavior of the ratio

$$\mathcal{H}_{N,m,q}(\mu) := \frac{H_{N,N,m,q}(\mu)}{H_{N+|q|,N}}, \tag{18}$$

where

$$|q| := q_1 + \cdots + q_m, \tag{19}$$

as $N \to \infty$ with μ and q fixed. Amongst other results, they consider the case $\omega_N(x) = e^{-NV(x)}$ with either $\Omega = \mathbb{R}$ or $\Omega = (0, \infty)$. For a particular choice of such $\omega_N(x)$ and Ω there corresponds the quantity $\rho(x)$, which, with $P_{N,N}$ defined as in (10), equals the limit of

$$\int_{\Omega^{N-1}} P_{N,N}(x, x_2, \ldots, x_N) \mathrm{d}x_2 \cdots \mathrm{d}x_N \tag{20}$$

as $N \to \infty$ with x held fixed; i.e., $\rho(x)$ is the limiting expected eigenvalue density of the ensemble of random matrices defined by $P_{N,N}$. We note that $\rho(x)$ is non-negative and has compact support. In what follows int(supp ρ) denotes the interior of the support of $\rho(x)$. For a detailed discussion of $\rho(x)$, and a number of other very interesting alternative characterizations of $\rho(x)$, the reader is referred to Ref. 7. The conjecture reported in Ref. 5 (in our notation) is the following.

Conjecture (Forrester–Frankel): *Let* $m, N \in \mathbb{N}$, $q \in (-1/2, \infty)^m$ *and* $\mu_1, \ldots, \mu_m \in \mathrm{int}(\mathrm{supp}\, \rho)$, *where* $\rho(x)$ *is defined as above. Furthermore, suppose either* $\Omega = \mathbb{R}$ *or* $\Omega = (0, \infty)$, *and take* $\omega_N(x) = e^{-NV(x)}$ *where* $V(x)$ *is a polynomial which is independent of* N *and which has positive leading coefficient and no zeros in* Ω. *Then*

$$\mathcal{H}_{N,m,q}(\mu) = N^{\sum_{i=1}^{m}(q_i^2 - q_i)} \prod_{i=1}^{m} [\omega_N(\mu_i)]^{-q_i} \prod_{i=1}^{m} \frac{G^2(q_i + 1)}{G(2q_i + 1)} (2\pi)^{q_i^2 - q_i}$$
$$\times \prod_{1 \leqslant j < k \leqslant m} |\mu_k - \mu_j|^{-2q_j q_k} \prod_{i=1}^{m} [\rho(\mu_i)]^{q_i^2} [1 + o(1)]. \tag{21}$$

Here and in the sequel G refers to Barnes' G-function.[36]

Despite first appearances, the structure of (21) is actually quite simple. Note that the only ensemble dependent quantities on the right-hand side are $\rho(x)$ and $\omega_N(x)$, and that the dependence of $\mathcal{H}_{M,m,q}(\mu)$ on these two quantities is universal. The other quantities on the right-hand side are truly universal. We note that the factor $G^2(q_i+1)/G(2q_i+1)$ occurs also in the asymptotics of Toeplitz determinants generated by Fisher–Hartwig symbols,[2] and has been discussed in the context of moments of random characteristic polynomials.[9,10] We should note that the actual conjecture reported in Ref. 5 is slightly more general than (21), but (21) is sufficient for our purposes.

As an aside, we remark that the ratio appearing in (16) is precisely of the form (18) and so the asymptotic behavior of all the n-body density matrices for a system of harmonically confined impenetrable bosons follows directly from (21).

The present paper focuses on two classical cases already mentioned, the case of the Hermite weight, corresponding to the GUE, and the case of the Laguerre weight, corresponding to the LUE. In the Hermite case

$$\omega_N(x) = e^{-2Nx^2}, \quad \Omega = \mathbb{R}, \quad \rho(\mu) = \frac{2}{\pi}\sqrt{1 - \mu^2}, \quad \mathrm{supp}(\rho) = [-1, 1], \tag{22}$$

and in the Laguerre case

$$\omega_N(x) = x^{\alpha} e^{-4Nx}, \quad \Omega = (0, \infty), \quad \rho(\mu) = \frac{2}{\pi}\sqrt{\frac{1}{\mu} - 1}, \quad \mathrm{supp}(\rho) = [0, 1]. \tag{23}$$

The conjecture reported in Ref. 5 was deduced by considering the specific examples of the Hermite and Laguerre cases, to find the general form in terms of $\rho(x)$ and $\omega_N(x)$. The asymptotics for these two cases was deduced by using the log-gas analogy to conjecture a factorization of (18), computing the asymptotics of each factor when the q_i were natural, and then conjecturing an analytic continuation to real q_i.

In this work we show how (21) can be proved rigorously for the Hermite and Laguerre cases, when each q_i is natural, by using a duality formula derived from a general result in Ref. 9. By a *duality* formula we mean an equation identifying the N-fold integral $\mathcal{H}_{N,m,q}(\mu)$ with a $2|q|$ - fold integral. Our results clarify the origin of the factors appearing in (21). A similar approach has been used in Ref. 25 to investigate a particular special case when the weight was of Hermite type, in the context of trapped impenetrable bosons.

Section II contains a discussion of the duality formula. Due to the similar nature of the Laguerre and Hermite cases, they can both be derived simultaneously. Section III then discusses the asymptotic analysis of the $2|q|$ - fold integral obtained from the duality formula by means of the saddle point method. We show how to deduce the general form of all terms and explicitly simplify the leading order term, and thus verify the conjecture (21) for the Hermite and Laguerre cases when each q_i is natural.

II. DUALITY FORMULA

Let us define

$$F_{K,N}(\lambda_1,\ldots,\lambda_K) := \frac{1}{\Delta_K(\lambda_1,\ldots,\lambda_K)} \det_{j,k=1}^{K} \pi_{N+j-1}^{(N)}(\lambda_k), \tag{24}$$

where $\{\pi_k^{(N)}\}_{k=0}^{\infty}$ are the monic orthogonal polynomials corresponding to $\omega_N(x)$ and Ω; i.e., they are uniquely defined by the following two conditions:

$$\int_\Omega \omega_N(x)\mathrm{d}x\ \pi_j^{(N)}(x)\pi_k^{(N)}(x) = 0, \quad j \neq k, \tag{25}$$

$$\pi_j^{(N)}(x) = x^j + O(x^{j-1}). \tag{26}$$

For the Hermite and Laguerre cases, the $\pi_{N+j-1}^{(N)}(x)$ can be expressed in terms of the standard Hermite and Laguerre polynomials found in Szegö's classic book[37] as follows:

$$\pi_{N+j-1}^{(N)}(x) = \begin{cases} 2^{-3(N+j-1)/2} N^{-(N+j-1)/2} H_{N+j-1}(\sqrt{2N}x), & \text{Hermite,} \\ (-1)^{N+j-1}(N+j-1)!(4N)^{-N-j+1} L_{N+j-1}^{(\alpha)}(4Nx), & \text{Laguerre.} \end{cases} \tag{27}$$

According to Brézin and Hikami,[9] we have the following very useful identity:

$$F_{K,N}(\lambda_1,\ldots,\lambda_K) = \frac{1}{H_{N,N}} \int_\Omega \omega_N(x_1)\mathrm{d}x_1 \cdots \int_\Omega \omega_N(x_N)\mathrm{d}x_N\, \Delta_N^2(x) \prod_{l=1}^{N}\prod_{i=1}^{K}(\lambda_i - x_l). \tag{28}$$

If we restrict ourselves to $q \in \mathbb{N}^m$ and set

$$K = 2q_1 + \cdots + 2q_m = 2|q|, \tag{29}$$

we can consider the confluent limit

$$\lim_{*} := \lim_{\lambda_{\pi(m)+2q_m}\to\mu_m} \cdots \lim_{\lambda_{\pi(m)+1}\to\mu_m} \cdots \lim_{\lambda_{2q_1+2q_2}\to\mu_2} \cdots \lim_{\lambda_{2q_1+1}\to\mu_2} \lim_{\lambda_{2q_1}\to\mu_1} \cdots \lim_{\lambda_1\to\mu_1}, \tag{30}$$

where

$$\pi(i) := \sum_{l=1}^{i-1} 2q_l. \tag{31}$$

Taking the limit (30) of both sides of (28), and using the elementary fact that $(\mu_i - x_l)^{2q_i} = |\mu_i - x_l|^{2q_i}$ when q_i is an integer and μ_i and x_l are real, we thus obtain

$$\lim_{*} F_{K,N}(\lambda_1,\ldots,\lambda_K) = \frac{H_{N,N,m,q}(\mu)}{H_{N,N}}, \tag{32}$$

and therefore

$$\mathcal{H}_{N,m,q}(\mu) = \frac{H_{N,N}}{H_{N+|q|,N}} \lim_{*} F_{K,N}(\lambda_1,\ldots,\lambda_K), \quad q \in \mathbb{N}^m. \tag{33}$$

This is the key relation we need to derive the duality formula for $\mathcal{H}_{N,m,q}(\mu)$, all that remains is to take the confluent limit of $F_{K,N}$.

For later convenience, we set

$$\pi^{(N)}_{N+j-1}(x) = \zeta_N(x) r_{N+j-1}(x). \tag{34}$$

If we insert (34) into (24) and take the limit (30), then by factoring the Vandermonde determinant we obtain

$$\begin{aligned}\lim_{*} F_{K,N}(\lambda_1,\ldots,\lambda_K) = \lim_{*} \prod_{1\leqslant j<k\leqslant m} \prod_{l_k=1}^{2q_k} \prod_{l_j=1}^{2q_j} (\lambda_{\tau(k)+l_k} - \lambda_{\tau(j)+l_j})^{-1} \prod_{j=1}^{K} \zeta_N(\lambda_j) \\ \times \lim_{*} \prod_{i=1}^{m} \Delta^{-1}_{2q_i}(\lambda_{\tau(i)+1},\ldots,\lambda_{\tau(i+1)}) \det_{j,k=1}^{K} r_{N+j-1}(\lambda_k)\end{aligned} \tag{35}$$

$$= \prod_{1\leqslant j<k\leqslant m} (\mu_k - \mu_j)^{-4q_k q_j} \prod_{i=1}^{m} \zeta_N^{2q_i}(\mu_i) \lim_{*} \prod_{i=1}^{m} \Delta^{-1}_{2q_i}(\lambda_{\tau(i)+1},\ldots,\lambda_{\tau(i+1)}) \det_{j,k=1}^{K} r_{N+j-1}(\lambda_k). \tag{36}$$

To compute the remaining limit in (36) we can use the following.

Lemma 1: Let $\mathbf{c}(\lambda)$ *denote a column vector with* $\tau(m+1)$ *entries, then for* $i=1,2,\ldots,m$

$$\begin{aligned}&\lim_{\lambda_{\tau(i)+2q_i}\to\mu_i} \cdots \lim_{\lambda_{\tau(i)+1}\to\mu_i} \frac{1}{\Delta_{2q_i}(\lambda_{\tau(i)+1},\ldots,\lambda_{\tau(i)+2q_i})} \\ &\quad \times G(2q_i+1)\det[\mathbf{c}(\lambda_1)\cdots\mathbf{c}(\lambda_{\tau(i)+1})\cdots\mathbf{c}(\lambda_{\tau(i)+2q_i})\cdots\mathbf{c}(\lambda_{\tau(m+1)})] \\ &= \det\left[\mathbf{c}(\lambda_1)\cdots\mathrm{c}(\lambda_{\tau(i)})\mathbf{c}(\mu_i)\frac{\mathrm{d}}{\mathrm{d}\mu_i}\mathbf{c}(\mu_i)\cdots\frac{\mathrm{d}^{2q_i-1}}{\mathrm{d}\mu_i^{2q_i-1}}\mathbf{c}(\mu_i)\mathbf{c}(\lambda_{\tau(i+1)+1})\cdots\mathbf{c}(\lambda_{\tau(m+1)})\right],\end{aligned} \tag{37}$$

where G is Barnes' G-function.

Proof: This is easily proven by induction using L'Hôpital's rule, and recalling the identity

$$\prod_{l=1}^{n} \Gamma(l) = G(n+2). \tag{38}$$

■

Applying Lemma 1 to (36) independently for each set $\{\lambda_{\tau(i)+1},\ldots,\lambda_{\tau(i)+2q_i}\}$ with $i=1,2,\ldots,m$, results in

$$\lim_{*} F_{K,N}(\lambda_1,\ldots,\lambda_K) = \prod_{1\leqslant j<k\leqslant m}(\mu_k-\mu_j)^{-4q_kq_j}\prod_{i=1}^{m}\frac{\zeta_N^{2q_i}(\mu_i)}{G(2q_i+1)}\det_{\substack{1\leqslant l_i\leqslant 2q_i\\ 1\leqslant i\leqslant m\\ 1\leqslant j\leqslant 2|q|}}\left[\frac{\mathrm{d}^{l_i-1}}{\mathrm{d}\mu_i^{l_i-1}}r_{N+j-1}(\mu_i)\right]. \tag{39}$$

In (39) the columns of the determinant are ordered such that one starts with $i=1$, writes out the $2q_1$ columns depending on l_1, and then moves to $i=2$, etc. We remark that we have now already obtained one of the two Barnes G-function factors that appear in (21).

The special property possessed by the Hermite and Laguerre polynomials that allows us to derive a duality formula for $\mathcal{H}_{N,m,q}(\mu)$ for the specific weights (22) and (23) is that they can be expressed in terms of contour integrals. Indeed, by suitably massaging the standard results in Szegö's book[37] we find

$$\pi_{N+j-1}^{(N)}(\mu_i) = \begin{cases} c_j(N)e^{2N\mu_i^2}\displaystyle\int_{\mathcal{C}}\mathrm{d}z\, e^{-2Nz\mu_i+Nz^2/2}z^{N+j-1}, & \text{Hermite},\\ c_j(N)\displaystyle\int_{\mathcal{C}}\mathrm{d}z\, e^{-2Nz\mu_i}\frac{(z+2)^{N+\alpha}}{z^{N+1}}\left(\frac{1}{z}+\frac{1}{2}\right)^{j-1}, & \text{Laguerre}, \end{cases} \tag{40}$$

$$c_j(N) = \begin{cases} \sqrt{\dfrac{2N}{\pi}}\dfrac{1}{i2^{N+j}}, & \text{Hermite},\\ (-1)^{N+j-1}\dfrac{(N+j-1)!}{N^{N+j-1}}\dfrac{1}{2^{2N+j+\alpha}\pi i}, & \text{Laguerre}, \end{cases} \tag{41}$$

where in the Hermite case the contour $\mathcal{C}$ lies along the imaginary axis and is oriented from $-i\infty$ to $+i\infty$, and in the Laguerre case $\mathcal{C}$ is a closed positively oriented contour which encircles the origin but does not contain the point $z=-2$.

It is now straightforward to compute the derivatives required in (39) from the contour integrals in (40). Defining

$$\zeta_N(\mu_i) = \begin{cases} e^{2N\mu_i^2}, & \text{Hermite},\\ 1, & \text{Laguerre}, \end{cases} \tag{42}$$

and recalling the definition (34) we obtain

$$\frac{\mathrm{d}^{l_i-1}}{\mathrm{d}\mu_i^{l_i-1}}r_{N+j-1}(\mu_i) = c_j(N)d_{l_i}(N)\int_{\mathcal{C}}\mathrm{d}z\, e^{-NS(z,\mu_i)}u(z)z^{l_i-1}[z^{\delta}+c]^{j-1}, \tag{43}$$

where

$$S(z,\mu_i) := \begin{cases} 2\mu_i z-\log(z)-\dfrac{z^2}{2}, & \text{Hermite},\\ 2\mu_i z+\log(z)-\log(z+2), & \text{Laguerre}, \end{cases} \tag{44}$$

$$u(z) := \begin{cases} 1, & \text{Hermite},\\ \dfrac{(z+2)^{\alpha}}{z}, & \text{Laguerre}, \end{cases} \tag{45}$$

$$d_{l_i}(N) := (-2N)^{l_i-1}, \tag{46}$$

and where $\delta=\pm 1$ and $c=0,1/2$ in the Hermite and Laguerre cases, respectively.

Our task now is to simplify the determinant appearing in (39) by using the contour integral (43). This is achieved by the following lemma.

Lemma 2: If $q \in \mathbb{N}^m$, *and* $\delta = \pm 1$, *and we define*

$$b_{\delta,q_i}(z) := \begin{cases} 1, & \delta = +1, \\ iz^{1-2q_i}, & \delta = -1, \end{cases} \tag{47}$$

then

$$\begin{aligned} &\det_{\substack{1\leqslant l_i\leqslant 2q_i \\ 1\leqslant i\leqslant m \\ 1\leqslant j\leqslant 2|q|}} \left[\int_{\mathcal{C}} \mathrm{d}z_{\tau(i)+l_i} e^{-NS(z_{\tau(i)+l_i},\mu_i)} u(z_{\tau(i)+l_i}) z_{\tau(i)+l_i}^{l_i-1} [z_{\tau(i)+l_i}^{\delta} + c]^{j-1} \right] \\ &\quad = \prod_{i=1}^{m} \frac{1}{\Gamma(2q_i+1)} \prod_{i=1}^{m} \prod_{l_i=\tau(i)+1}^{\tau(i+1)} \int_{\mathcal{C}} \mathrm{d}z_{l_i} e^{-NS(z_{l_i},\mu_i)} u(z_{l_i}) b_{\delta,q_i}(z_{l_i}) \prod_{i=1}^{m} \Delta_{2q_i}^2(z_{\tau(i)+1},\ldots,z_{\tau(i+1)}) \\ &\qquad \times \prod_{1\leqslant j<k\leqslant m} \prod_{l_k=\tau(k)+1}^{\tau(k+1)} \prod_{l_j=\tau(j)+1}^{\tau(j+1)} (z_{l_k}^{\delta} - z_{l_j}^{\delta}). \end{aligned} \tag{48}$$

Proof: We start with the identity

$$\begin{aligned} &\det_{\substack{1\leqslant l_i\leqslant 2q_i \\ 1\leqslant i\leqslant m \\ 1\leqslant j\leqslant 2|q|}} \left[\int \mathrm{d}z_{\tau(i)+l_i} g_{l_i}(z_{\tau(i)+l_i},\mu_i) [f(z_{\tau(i)+l_i})]^{j-1} \right] \\ &\quad = \prod_{i=1}^{m} \prod_{l_i=1}^{2q_i} \int \mathrm{d}z_{\tau(i)+l_i} g_{l_i}(z_{\tau(i)+l_i},\mu_i) \Delta_{2|q|}(f(z_1),\ldots,f(z_{2|q|})), \end{aligned} \tag{49}$$

which is valid for arbitrary integrable functions $f(z)$ and $g_{l_i}(z,\mu_i)$. If we apply (49) to the left-hand side (LHS) of (48) and use the elementary fact that

$$\Delta_n(z_1+c, z_2+c, \ldots, z_n+c) = \Delta_n(z_1, z_2, \ldots, z_n), \tag{50}$$

we obtain

$$\text{LHS of (48)} = \prod_{i=1}^{m} \prod_{l_i=1}^{2q_i} \int_{\mathcal{C}} \mathrm{d}z_{\tau(i)+l_i} z_{\tau(i)+l_i}^{l_i-1} \prod_{i=1}^{m} \prod_{l_i=\tau(i)+1}^{\tau(i+1)} e^{-NS(z_{l_i},\mu_i)} u(z_{l_i}) \cdot \Delta_{2|q|}(z_1^{\delta},\ldots,z_{2|q|}^{\delta}). \tag{51}$$

To proceed further we first note the following two useful identities.

Lemma 3: If $f(z_1,\ldots,z_{2|q|})$ *is a totally antisymmetric function of each set of variables* $\{z_{\tau(i)+1},\ldots,z_{\tau(i+1)}\}$, *for* $i = 1,2,\ldots,m$, *then*

$$\begin{aligned} &\prod_{i=1}^{m} \prod_{l_i=1}^{2q_i} \int \mathrm{d}z_{\tau(i)+l_i} z_{\tau(i)+l_i}^{l_i-1} f(z_1,\ldots,z_{2|q|}) \\ &\quad = \prod_{i=1}^{m} \frac{1}{\Gamma(2q_i+1)} \prod_{i=1}^{m} \left(\prod_{l_i=\tau(i)+1}^{\tau(i+1)} \int \mathrm{d}z_{l_i} \right) \Delta_{2q_i}(z_{\tau(i)+1},\ldots,z_{\tau(i+1)}) \cdot f(z_1,\ldots,z_{2|q|}). \end{aligned} \tag{52}$$

Proof: By expanding the Vandermonde determinant and then rearranging the order of integrations we see that

$$\prod_{i=1}^{m}\left(\prod_{l_i=\tau(i)+1}^{\tau(i+1)}\int \mathrm{d}z_{l_i}\right)\Delta_{2q_i}(z_{\tau(i)+1},\ldots,z_{\tau(i+1)})\cdot f(\ldots,z_{\tau(i)+1},\ldots,z_{\tau(i)+2q_i},\ldots)$$
$$=\prod_{i=1}^{m}\sum_{\sigma_i\in S_{2q_i}}\prod_{l_i=1}^{2q_i}\int \mathrm{d}z_{\tau(i)+\sigma_i(l_i)}z_{\tau(i)+\sigma_i(l_i)}^{l_i-1}(-1)^{\sigma_i}\cdot f(\ldots,z_{\tau(i)+1},\ldots,z_{\tau(i)+2q_i},\ldots), \tag{53}$$

and the antisymmetry of f then implies that the right-hand side of (53) equals

$$\prod_{i=1}^{m}\sum_{\sigma_i\in S_{2q_i}}\prod_{l_i=1}^{2q_i}\int \mathrm{d}z_{\tau(i)+\sigma_i(l_i)}\,z_{\tau(i)+\sigma_i(l_i)}^{l_i-1}\cdot f(\ldots,z_{\tau(i)+\sigma_i(1)},\ldots,z_{\tau(i)+\sigma_i(2q_i)},\ldots)$$
$$=\prod_{i=1}^{m}\sum_{\sigma_i\in S_{2q_i}}\prod_{l_i=1}^{2q_i}\int \mathrm{d}z_{\tau(i)+l_i}\,z_{\tau(i)+l_i}^{l_i-1}\cdot f(\ldots,z_{\tau(i)+1},\ldots,z_{\tau(i)+2q_i},\ldots), \tag{54}$$

where the last equality follows by simply relabeling integration variables. The stated result is now immediate. ■

Lemma 4: With q, δ and $b_{\delta,q_i}(z)$ as defined in Lemma 2 we have

$$\Delta_{2q_i}(z_1^{\delta},\ldots,z_{2q_i}^{\delta})\Delta_{2q_i}(z_1,\ldots,z_{2q_i})=\prod_{l=1}^{2q_i}b_{\delta,q_i}(z_l)\cdot\Delta_{2q_i}^2(z_1,\ldots,z_{2q_i}). \tag{55}$$

Proof: When $\delta=1$ there is nothing to prove, so take $\delta=-1$. Then

$$\Delta_{2q_i}(z_1^{\delta},\ldots,z_{2q_i}^{\delta})\Delta_{2q_i}(z_1,\ldots,z_{2q_i})=\prod_{1\leqslant j<k\leqslant 2q_i}\frac{(z_j-z_k)(z_k-z_j)}{z_jz_k} \tag{56}$$

$$=(-1)^{2q_i^2+q_i}\prod_{1\leqslant j<k\leqslant 2q_i}\frac{1}{z_jz_k}\cdot\Delta_{2q_i}^2(z_1,\ldots,z_{2q_i}) \tag{57}$$

$$=\prod_{l=1}^{2q_i}iz_l^{1-2q_i}\cdot\Delta_{2q_i}^2(z_1,\ldots,z_{2q_i}). \tag{58}$$

■

Armed with Lemmas 3 and 4 the proof of Lemma 2 follows at once. Applying Lemma 3 to (51) results in

$$\text{LHS of (48)}=\prod_{i=1}^{m}\frac{1}{\Gamma(2q_i+1)}\prod_{i=1}^{m}\left(\prod_{l_i=\tau(i)+1}^{\tau(i+1)}\int_{\mathcal{C}}\mathrm{d}z_{l_i}\right)\Delta_{2q_i}(z_{\tau(i)+1},\ldots,z_{\tau(i+1)})$$
$$\times\prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i+1)}e^{-NS(z_{l_i},\mu_i)}u(z_{l_i})\cdot\Delta_{2|q|}(z_1^{\delta},\ldots,z_{2|q|}^{\delta}) \tag{59}$$

$$=\prod_{i=1}^{m}\frac{1}{\Gamma(2q_i+1)}\prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i+1)}\int_{\mathcal{C}}\mathrm{d}z_{l_i}\,e^{-NS(z_{l_i},\mu_i)}u(z_{l_i})\prod_{i=1}^{m}\Delta_{2q_i}(z_{\tau(i)+1}^{\delta},\ldots,z_{\tau(i+1)}^{\delta})\Delta_{2q_i}(z_{\tau(i)+1},\ldots,z_{\tau(i+1)})$$
$$\times\prod_{1\leqslant j<k\leqslant m}\prod_{l_k=\tau(k)+1}^{\tau(k+1)}\prod_{l_j=\tau(j)+1}^{\tau(j+1)}(z_{l_k}^{\delta}-z_{l_j}^{\delta}). \tag{60}$$

Applying Lemma 4 to the right-hand side of (60) produces the stated result. ■

Now we substitute (43) into (39), factor out the constants $c_j(N)$ and $d_{l_i}(N)$ from the determinant, and apply Lemma 2 to finally obtain the following.

Proposition 1:

$$\mathcal{H}_{N,m,q}(\mu) = h_{N,m,q}\prod_{i=1}^{m}\frac{1}{G(2q_i+1)\Gamma(2q_i+1)}\prod_{i=1}^{m}\zeta_N^{2q_i}(\mu_i)\prod_{1\leqslant j<k\leqslant m}(\mu_k-\mu_j)^{-4q_jq_k}\cdot I_{N,m,q}(\mu), \tag{61}$$

where

$$\begin{aligned} I_{N,m,q}(\mu) \coloneqq & \prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i+1)}\int_{\mathcal{C}}\mathrm{d}z_{l_i}\, e^{-NS(z_{l_i},\mu_i)}\Delta_{2q_i}^2(z_{\tau(i)+1},\ldots,z_{\tau(i+1)}) \\ & \times\prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i+1)} g_{q_i}(z_{l_i})\prod_{1\leqslant j<k\leqslant m}\prod_{l_k=\tau(k)+1}^{\tau(k+1)}\prod_{l_j=\tau(j)+1}^{\tau(j+1)}(z_{l_k}^{\delta}-z_{l_j}^{\delta}), \end{aligned} \tag{62}$$

the function $g_{q_i}(z)$ *is*

$$g_{q_i}(z) \coloneqq u(z)b_{\delta,q_i}(z) \tag{63}$$

$$= \begin{cases} 1, & \text{Hermite}, \\ i\dfrac{(z+2)^{\alpha}}{z^{2q_i}}, & \text{Laguerre}, \end{cases} \tag{64}$$

and

$$h_{N,m,q} \coloneqq \prod_{j=1}^{\tau(m+1)} c_j(N)\prod_{i=1}^{m}\prod_{l_i=1}^{2q_i} d_{l_i}(N)\cdot\frac{H_{N,N}}{H_{N+|q|,N}}. \tag{65}$$

Proposition 1 is an exact duality formula when $q\in\mathbb{N}^m$, expressing the N-fold integral $\mathcal{H}_{N,m,q}(\mu)$ in terms of the $2|q|$-fold integral $I_{N,m,q}(\mu)$. This allows us to compute the large N asymptotics of $\mathcal{H}_{N,m,q}(\mu)$ by computing the large N asymptotics of $I_{N,m,q}(\mu)$, and the latter can be obtained by using the saddle point method. This is the subject of Sec. III.

The prefactor $h_{N,m,q}$ defined in (65) can be expressed in terms of the Barnes' G-function by using known results for the Selberg integral, see, e.g., Refs. 8 and 28, and the asymptotics can then be obtained from the known asymptotics of Barnes' G-function.[38] We obtain

$$h_{N,m,q} = \begin{cases} 2^{-|q|^2-3|q|/2+\sum_{i=1}^{m}2q_i^2}\pi^{-3|q|/2}N^{\sum_{i=1}^{m}2q_i^2+|q|^2/2+|q|N}\dfrac{G(N+2)}{G(N+|q|+2)}, & \text{Hermite}, \\ (-1)^{|q|}2^{-2|q|+\sum_{i=1}^{m}2q_i^2}\pi^{-2|q|}N^{(\alpha-|q|)|q|+\sum_{i=1}^{m}2q_i^2} & \\ \times\dfrac{G(N+2)}{G(N+1)}\dfrac{G(N+\alpha+1)}{G(N+\alpha+|q|+1)}\dfrac{G(N+2|q|+1)}{G(N+|q|+2)}, & \text{Laguerre}, \end{cases} \tag{66}$$

$$= \begin{cases} N^{\sum_{i=1}^{m}(2q_i^2-q_i)}e^{|q|N}2^{-|q|^2}\displaystyle\prod_{i=1}^{m}2^{2q_i^2-2q_i}\pi^{-2q_i}\left[1+O\left(\frac{1}{N}\right)\right], & \text{Hermite}, \\ N^{\sum_{i=1}^{m}(2q_i^2-q_i)}\displaystyle\prod_{i=1}^{m}(-1)^{q_i}2^{2q_i^2-2q_i}\pi^{-2q_i}\left[1+O\left(\frac{1}{N}\right)\right], & \text{Laguerre}. \end{cases} \tag{67}$$

It will be useful in Sec. III for us to introduce the notation

$$h_{N,m,q} = N^{\sum_{i=1}^{m}(2q_i^2-q_i)} h_0 \left[1 + O\left(\frac{1}{N}\right)\right], \tag{68}$$

where

$$h_0 := \begin{cases} e^{|q|N} 2^{-|q|^2} \prod_{i=1}^{m} 2^{2q_i^2-2q_i} \pi^{-2q_i}, & \text{Hermite}, \\ \prod_{i=1}^{m} (-1)^{q_i} 2^{2q_i^2-2q_i} \pi^{-2q_i}, & \text{Laguerre}. \end{cases} \tag{69}$$

III. ASYMPTOTICS

Now we begin the task of computing the large N asymptotics of the integral $I_{N,m,q}(\mu)$ for fixed μ and q. Since the only appearance that N makes in (62) is in the exponent of $e^{-NS(z,\mu_i)}$, this problem is a natural candidate for the saddle point method.

In both the Hermite and Laguerre cases, the function $S(z,\mu_i)$ has two saddle points, $z_{+,i}$ and its complex conjugate $z_{+,i}^*$. Explicitly

$$z_{+,i} = \begin{cases} \mu_i + i\sqrt{1-\mu_i^2}, & \text{Hermite}, \\ -1 + i\sqrt{\dfrac{1}{\mu_i} - 1}, & \text{Laguerre}. \end{cases} \tag{70}$$

It is worth noting that in both cases

$$\mathrm{Im}\{z_{+,i}\} = \frac{\pi}{2}\rho(\mu_i), \tag{71}$$

where $\rho(\mu_i)$ is as defined in (22) and (23), for the Hermite and Laguerre cases, respectively. Both saddle points are of equal importance, since

$$\mathrm{Re}\{S(z_{+,i},\mu_i)\} = \mathrm{Re}\{S(z_{+,i}^*,\mu_i)\}, \tag{72}$$

and we deform the contour $\mathcal{C}$ through both of them.

Let us denote the subset of the contour in neighborhoods of $z_{+,i}$ and $z_{+,i}^*$ by $\Omega_{+,i}$ and $\Omega_{-,i}$, respectively, and the complement of the union of these two neighborhoods in $\mathcal{C}$ by $\mathcal{C}_s$, so that

$$\mathcal{C} = \mathcal{C}_s \cup \Omega_{+,i} \cup \Omega_{-,i}. \tag{73}$$

By deforming $\mathcal{C}$ appropriately, the dominant contribution of each integral comes from $\Omega_{+,i}$ and $\Omega_{-,i}$, and the standard arguments of the saddle point method lead to

$$\begin{aligned} I_{N,m,q}(\mu) = {} & \prod_{i=1}^{m} \prod_{l_i=\tau(i)+1}^{\tau(i+1)} \left(\int_{\Omega_{+,i}} \mathrm{d}z_{l_i} + \int_{\Omega_{-,i}} \mathrm{d}z_{l_i} \right) e^{-NS(z_{l_i},\mu_i)} \cdot \Delta_{2q_i}^2(z_{\tau(i)+1},\ldots,z_{\tau(i+1)}) \\ & \times \prod_{i=1}^{m} \prod_{l_i=\tau(i)+1}^{\tau(i+1)} g_{q_i}(z_{l_i}) \prod_{1\le j<k\le m} \prod_{l_k=\tau(k)+1}^{\tau(k+1)} \prod_{l_j=\tau(j)+1}^{\tau(j+1)} (z_{l_k}^{\delta} - z_{l_j}^{\delta}) + \prod_{i=1}^{m} e^{-2q_i N \,\mathrm{Re}\{S_i\}} \cdot O(e^{-\varepsilon N}), \end{aligned} \tag{74}$$

for suitably small $\varepsilon > 0$, where we have defined

$$S_i := S(z_{+,i},\mu_i) = S(z_{+,i}^*,\mu_i)^*. \tag{75}$$

We would now like to expand out the $2|q|$-fold composition of the sum of the two integrals appearing in (74). To achieve this, we first note that the integrand in (74) is totally symmetric in each set of variables $\{z_{\tau(i)+1},\ldots,z_{\tau(i+1)}\}$, for $i=1,2,\ldots,m$. With this in mind we can then apply the following elementary result.

Lemma 5: If $f(z_1,\ldots,z_{\tau(i)+1},\ldots,z_{\tau(i+1)},\ldots,z_{\tau(m+1)})$ *is a totally symmetric function of the variables* $\{z_{\tau(i)+1},\ldots,z_{\tau(i+1)}\}$, *then*

$$\prod_{l_i=\tau(i)+1}^{\tau(i+1)}\left(\int_{\Omega_{+,i}}dz_{l_i}+\int_{\Omega_{-,i}}dz_{l_i}\right)f(z_1,\ldots,z_{\tau(i)+1},\ldots,z_{\tau(i+1)},\ldots,z_{\tau(m+1)})$$
$$=\sum_{n_i=0}^{2q_i}\binom{2q_i}{n_i}\prod_{l_i=\tau(i)+1}^{\tau(i)+n_i}\int_{\Omega_{+,i}}dz_{l_i}\prod_{l_i=\tau(i)+n_i+1}^{\tau(i+1)}\int_{\Omega_{-,i}}dz_{l_i}\,f(z_1,\ldots,z_{\tau(i)+1},\ldots,z_{\tau(i+1)},\ldots,z_{\tau(m+1)}). \quad (76)$$

Proof: All terms in the expansion with n_i integrals over $\Omega_{+,i}$ can be seen to be equal by swapping the order of the integrations, permuting the arguments of f in $\{z_{\tau(i)+1},\ldots,z_{\tau(i+1)}\}$, and then relabeling the integration variables appropriately. ■

Applying Lemma 5 to (74) results in

$$I_{N,m,q}(\mu)=\prod_{i=1}^{m}\sum_{n_i=0}^{2q_i}\binom{2q_i}{n_i}\prod_{l_i=\tau(i)+1}^{\tau(i)+n_i}\int_{\Omega_{+,i}}dz_{l_i}\prod_{l_i=\tau(i)+n_i+1}^{\tau(i+1)}\int_{\Omega_{-,i}}dz_{l_i}\prod_{i=1}^{m}\left(\prod_{l_i=\tau(i)+1}^{\tau(i+1)}e^{-NS(z_{l_i},\mu_i)}g_{q_i}(z_{l_i})\right)$$
$$\times\Delta_{2q_i}^2(z_{\tau(i)+1},\ldots,z_{\tau(i+1)})\cdot\prod_{1\leqslant j<k\leqslant m}\prod_{l_k=\tau(k)+1}^{\tau(k+1)}\prod_{l_j=\tau(j)+1}^{\tau(j+1)}(z_{l_k}^{\delta}-z_{l_j}^{\delta})+\prod_{i=1}^{m}e^{-2q_iN\,\mathrm{Re}\{S_i\}}\cdot O(e^{-\varepsilon N}). \quad (77)$$

Now let us parametrize the integration variables in (77) so that the paths $\Omega_{\pm,i}$ become line segments (of length 2η say), centered at $z_{+,i}$ and $z_{+,i}^*$, respectively, and lying along the direction of steepest descent

$$z_{l_i}=\begin{cases}z_{+,i}+e^{i\theta_i}t_{l_i}, & \tau(i)+1\leqslant l_i\leqslant\tau(i)+n_i,\\ z_{+,i}^*+e^{-i\theta_i}t_{l_i}, & \tau(i)+n_i+1\leqslant l_i\leqslant\tau(i)+2q_i.\end{cases} \quad (78)$$

The angles θ_i are chosen in the usual way so that with

$$a_i:=\frac{S''(z_{+,i},\mu_i)}{2}e^{2i\theta_i}=\frac{S''(z_{+,i}^*,\mu_i)}{2}e^{-2i\theta_i} \quad (79)$$

we have $a_i\in(0,\infty)$, and so

$$a_it_{l_i}^2=\frac{S''(z_{+,i},\mu_i)}{2}(z_{l_i}-z_{+,i})^2=\frac{S''(z_{+,i}^*,\mu_i)}{2}(z_{l_i}-z_{+,i}^*)^2, \quad (80)$$

with $t_{l_i}\in[-\eta,\eta]$. With this convention the integrals through $z_{+,i}$ are oriented in the negative direction, and we will compensate for this by introducing the explicit factor $(-1)^{n_i}$. Explicitly, since

$$\frac{S''(z_{+,i},\mu_i)}{2}=\begin{cases}\dfrac{\pi}{2}\rho(\mu_i)e^{i(\mathrm{Arcsin}(\mu_i)+\pi)}, & \text{Hermite},\\ \pi\mu_i^2\rho(\mu_i)e^{-i\pi/2}, & \text{Laguerre},\end{cases} \quad (81)$$

we obtain

$$\theta_i = \begin{cases} \dfrac{\pi - \operatorname{Arcsin}(\mu_i)}{2}, & \text{Hermite}, \\ \dfrac{\pi}{4}, & \text{Laguerre}, \end{cases} \tag{82}$$

$$a_i = \begin{cases} \dfrac{\pi}{2}\rho(\mu_i), & \text{Hermite}, \\ \pi\mu_i^2\rho(\mu_i), & \text{Laguerre}. \end{cases} \tag{83}$$

Note that $a_i > 0$ when $\mu_i \in \operatorname{int}(\operatorname{supp}\rho)$.

In making the change of variables (78) in (77), it is convenient to introduce the following definitions:

$$\phi_{N,i} := 4q_i\theta_i + 2N\,\mathrm{Im}\{S_i\}, \tag{84}$$

$$\varphi_i(t_{l_i}) := \sum_{k=1}^{\infty} \frac{2}{S''(z_{+,i},\mu_i)} \frac{S^{(k+2)}(z_{+,i},\mu_i)}{(k+2)!} (z_{l_i} - z_{+,i})^k|_{z_{l_i}=z_{+,i}+e^{i\theta_i}t_{l_i}}, \tag{85}$$

$$\Phi_n(t) := \prod_{i=1}^{m} \prod_{l_i=\tau(i)+1}^{\tau(i)+n_i} e^{-Na_it_{l_i}^2\varphi_i(t_{l_i})} \prod_{l_i=\tau(i)+n_i+1}^{\tau(i+1)} e^{-Na_it_{l_i}^2\varphi_i^*(t_{l_i})}, \tag{86}$$

$$G_n(t) := \prod_{i=1}^{m} \prod_{l_i=\tau(i)+1}^{\tau(i+1)} g_{q_i}(z_{l_i})|_{\bigstar}, \tag{87}$$

$$D_n(t) := \prod_{i=1}^{m} \prod_{k_i=\tau(i)+n_i+1}^{\tau(i+1)} \prod_{j_i=\tau(i)+1}^{\tau(i)+n_i} (z_{k_i} - z_{j_i})^2|_{\bigstar}, \tag{88}$$

$$H_n(t) := \prod_{1\le j<k\le m} \prod_{l_k=\tau(k)+1}^{\tau(k+1)} \prod_{l_j=\tau(j)+1}^{\tau(j+1)} (z_{l_k}^{\delta} - z_{l_j}^{\delta})|_{\bigstar}, \tag{89}$$

$$F_n(t) := G_n(t)D_n(t)H_n(t), \tag{90}$$

where $\bigstar$ on the right-hand sides of (87)–(89) refers to the change of variables (78), and $n := (n_1,\ldots,n_m)$. We also define the (unnormalized) integral operator

$$\mathbb{E}_{r,p}^{(i)} := \prod_{l_i=\tau(i)+r}^{\tau(i)+p} \int_{-\eta}^{\eta} \mathrm{d}t_{l_i}\, e^{-Na_it_{l_i}^2} \Delta_{p-r+1}^2(t_{\tau(i)+r},\ldots,t_{\tau(i)+p}). \tag{91}$$

Armed with these definitions, we see that since

$$\begin{aligned} &\Delta_{n_i}^2(z_{\tau(i)+1},\ldots,z_{\tau(i)+n_i})\Delta_{2q_i-n_i}^2(z_{\tau(i)+n_i+1},\ldots,z_{\tau(i)+2q_i}) \prod_{l_i=\tau(i)+1}^{\tau(i+1)} \mathrm{d}z_{l_i} \\ &= e^{i4q_i(q_i-n_i)\theta_i}\Delta_{n_i}^2(t_{\tau(i)+1},\ldots,t_{\tau(i)+n_i})\Delta_{2q_i-n_i}^2(t_{\tau(i)+n_i+1},\ldots,t_{\tau(i)+2q_i}) \prod_{l_i=\tau(i)+1}^{\tau(i+1)} \mathrm{d}t_{l_i}, \end{aligned} \tag{92}$$

and

$$\prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i+1)} e^{-NS(z_{l_i},\mu_i)} = \prod_{i=1}^{m} e^{-2q_iN\,\mathrm{Re}\{S_i\}}\prod_{i=1}^{m} e^{2i(q_i-n_i)N\,\mathrm{Im}\{S_i\}}\prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i+1)} e^{-Na_it_{l_i}^2}\Phi_n(t), \tag{93}$$

we arrive at the following more compact expression for $I_{N,m,q}(\mu)$:

$$I_{N,m,q}(\mu) = \prod_{i=1}^{m} e^{-2q_iN\,\mathrm{Re}\{S_i\}}\left[\prod_{i=1}^{m}\sum_{n_i=0}^{2q_i}\binom{2q_i}{n_i}(-1)^{n_i}e^{i(q_i-n_i)\phi_{N,i}}\mathbb{I}_{1,n_i}^{(i)}\mathbb{I}_{n_i+1,2q_i}^{(i)}\Phi_n(t)F_n(t)+O(e^{-\varepsilon N})\right]. \tag{94}$$

The factor $(-1)^{n_i}$ results from the fact that we traversed the line through $z_{+,i}$ in the negative direction, whereas the line through $z_{+,i}^*$ is traversed in the positive direction.

To obtain an asymptotic expansion of $I_{N,m,q}(\mu)$ from (94) we proceed in direct analogy with the one-dimensional saddle point method (see, e.g., Ref. 39) and introduce the following generalization of $\Phi_n(t)$:

$$\Phi_n(t,u) := \prod_{i=1}^{m}\prod_{l_i=\tau(i)+1}^{\tau(i)+n_i} e^{u_{l_i}\varphi_i(t_{l_i})}\prod_{l_i=\tau(i)+n_i+1}^{\tau(i+1)} e^{u_{l_i}\varphi_i^*(t_{l_i})}, \tag{95}$$

where $u\in\mathbb{R}^{2|q|}$. For convenience we also introduce the function

$$Q_n(t,u) := \Phi_n(t,u)F_n(t), \tag{96}$$

so that with

$$u_{l_i} = -Na_it_{l_i}^2 \quad \text{for each } 1\leqslant l_i\leqslant 2|q|, \tag{97}$$

we have

$$Q_n(t,\{-Na_it_{l_i}^2\}) = \Phi_n(t)F_n(t). \tag{98}$$

Let us suppose for the present that u is some arbitrary fixed parameter independent of t, and consider the kth degree Taylor polynomial of $Q_n(t,u)$ as a function of $t\in\mathbb{R}^{2|q|}$,

$$Q_n(t,u) = \sum_{0\leqslant|\alpha|\leqslant k}\frac{1}{\alpha!}\left[\frac{\partial^{\alpha_1}}{\partial t_1^{\alpha_1}}\cdots\frac{\partial^{\alpha_{2|q|}}}{\partial t_{2|q|}^{\alpha_{2|q|}}}Q_n(t,u)\right|_{t=0}\Bigg]t^{\alpha}+O(t^{\alpha})\big|_{|\alpha|=k+1}, \tag{99}$$

where $\alpha\in\mathbb{Z}_{\geqslant 0}^{2|q|}$ and we use the standard notations $\alpha!=\alpha_1!\cdots\alpha_{2|q|}!$ and $t^{\alpha}=t_1^{\alpha_1}\cdots t_{2|q|}^{\alpha_{2|q|}}$ and $|\alpha|=\alpha_1+\cdots+\alpha_{2|q|}$.

If in (99) we now choose u according to (97) we obtain

$$Q_n(t,\{-Na_it_{l_i}^2\}) = \sum_{0\leqslant|\alpha|\leqslant k}\frac{1}{\alpha!}\left[\frac{\partial^{\alpha_1}}{\partial t_1^{\alpha_1}}\cdots\frac{\partial^{\alpha_{2|q|}}}{\partial t_{2|q|}^{\alpha_{2|q|}}}\Phi_n(t,u)F_n(t)\right|_{t=0}\Bigg]\Bigg|_{\{u_{l_i}=-Na_it_{l_i}^2\}}t^{\alpha}+O(t^{\alpha})\big|_{|\alpha|=k+1}, \tag{100}$$

where we emphasize that the partial derivatives with respect to t on the right-hand side of (100) are performed with u fixed *before* making the substitution (97). The effect of constructing the Taylor series in this way is that when (100) is substituted into (94) and the integrations are performed, each term corresponding to a given value of $|\alpha|$ in (100) will have the same N dependence. To see this we need to consider the asymptotics of the integral operator (91) acting on a general monomial, which can be deduced simply by scaling N out of the integral. We thus deduce that

$$\prod_{i=1}^{m} \mathbb{E}^{(i)}_{1,n_i} \mathbb{E}^{(i)}_{n_i+1,2q_i} t^{\alpha} = O\left(N^{-\sum_{i=1}^{m} q_i^2 - \sum_{i=1}^{m} (n_i - q_i)^2 - |\alpha|/2}\right). \tag{101}$$

As a direct consequence of (101), we see that with $u_{l_i} = -a_i N t_{l_i}^2$ for each $1 \leqslant l_i \leqslant 2|q|$, we have

$$\prod_{i=1}^{m} \mathbb{E}^{(i)}_{1,n_i} \mathbb{E}^{(i)}_{n_i+1,2q_i} t^{\alpha} u^{\alpha'} = O\left(N^{-\sum_{i=1}^{m} q_i^2 - \sum_{i=1}^{m} (n_i - q_i)^2 - |\alpha|/2}\right) \tag{102}$$

for any $\alpha_1', \ldots, \alpha_{2|q|}' \in \mathbb{N}$; i.e., the left-hand sides of (101) and (102) have precisely the same asymptotic dependence on N. From (95) its clear that when computing the partial derivatives of $\Phi_n(t,u)F_n(t)$ for a given $|\alpha|$ various powers of u will appear, which after the substitution (97) will mean we need to calculate quantities of the form (102). However (101) and (102) tell us that all such quantities have the same N dependence. This would not be the case if we had just naively constructed the Taylor polynomial of $\Phi_n(t)F_n(t)$. We remark that since the symmetry of the integral operator (91) implies t^{α} is annihilated whenever $|\alpha|$ is odd, only integer powers of $1/N$ actually appear in the asymptotic expansion of $I_{N,m,q}(\mu)$, despite the appearance of $|\alpha|/2$ in the exponent in (102).

As a result of the expression (102) we can see that the dominant term in the asymptotic expansion of (94) occurs when both $n_i = q_i$ for all $i = 1, \ldots, m$, and $|\alpha| = 0$ in the Taylor expansion (100). In general, the coefficient of the term which is of order $1/N^k$ relative to the leading term is composed of all terms for which

$$\sum_{i=1}^{m} (n_i - q_i)^2 + \frac{|\alpha|}{2} = k. \tag{103}$$

If we are interested only in retaining the leading term the preceding arguments imply that

$$I_{N,m,q}(\mu) = \prod_{i=1}^{m} \frac{e^{-2q_i N \mathrm{Re}\{S_i\}}}{N^{q_i^2}} \cdot I_0 \left[1 + O\left(\frac{1}{N}\right)\right], \tag{104}$$

where the coefficient I_0 depends on μ and q but is independent of N. To obtain the explicit form of I_0 we first note that, since $\Phi_n(0) = 1$, we have

$$\mathbb{E}^{(i)}_{r+1,r+p} \Phi_n(0) F_n(0) = \frac{1}{N^{p^2/2}} F_n(0) Z_p(a_i) + O(e^{-\eta^2 a_i N}), \tag{105}$$

where

$$Z_p(a_i) := \int_{\mathbb{R}^p} \mathrm{d}^p x \, \Delta_p^2(x) \prod_{l=1}^{p} e^{-a_i x_l^2} \tag{106}$$

$$= \left(\frac{\pi}{2^{p-1}}\right)^{p/2} \frac{G(p+2)}{a_i^{p^2/2}}. \tag{107}$$

The quantity $Z_p(a_i)$ is the normalization of the joint eigenvalue pdf of the GUE and can be expressed in terms of the Selberg integral; see Refs. 8 and 28. If we substitute (100) into (94) and take the leading term, which corresponds to $\Sigma_{i=1}^{m} (n_i - q_i)^2 + |\alpha|/2 = 0$, then applying (105) we find that

$$I_0 = \prod_{i=1}^{m} \binom{2q_i}{q_i} (-1)^{q_i} Z_{q_i}^2(a_i) \cdot F_q(0). \tag{108}$$

The explicit form of $F_q(0)$ can be obtained from the following results:

$$D_q(0) = (-1)^{|q|}\pi^{\sum_{i=1}^m 2q_i^2}\prod_{i=1}^m \rho^{2q_i^2}(\mu_i), \tag{109}$$

$$G_q(0) = \begin{cases} 1, & \text{Hermite}, \\ \displaystyle\prod_{i=1}^m (-1)^{q_i}\mu_i^{2q_i^2}\mu_i^{-\alpha q_i}, & \text{Laguerre}, \end{cases} \tag{110}$$

$$H_q(0) = \prod_{1\leqslant j<k\leqslant m}(\mu_k-\mu_j)^{2q_jq_k} \times \begin{cases} 2^{|q|^{2-\sum_{i=1}^m q_i^2}}, & \text{Hermite}, \\ 1, & \text{Laguerre}. \end{cases} \tag{111}$$

Now let us put together what we have learned about the asymptotic behavior of $I_{N,m,q}(\mu)$ to describe the asymptotic behavior of $\mathcal{H}_{N,m,q}(\mu)$ when $q\in\mathbb{N}^m$. To this end, we substitute (109) into (108), then (108) into (104), and finally substitute (104) and (68) into (61), to obtain

$$\begin{aligned}\mathcal{H}_{N,m,q}(\mu) = {} & N^{\sum_{i=1}^m q_i(q_i-1)}\prod_{i=1}^m \frac{G^2(q_i+1)}{G(2q_i+1)}2^{-q_i^2+q_i}\pi^{2q_i^2+q_i}\rho^{2q_i^2}(\mu_i)\prod_{1\leqslant j<k\leqslant m}(\mu_k-\mu_j)^{-4q_jq_k} \\ & \times\prod_{i=1}^m e^{-2q_iN\,\mathrm{Re}\{S_i\}}\zeta_N^{2q_i}(\mu_i)a_i^{-q_i^2}\cdot G_q(0)H_q(0)\cdot h_0\left[1+O\left(\frac{1}{N}\right)\right].\end{aligned} \tag{112}$$

Using the explicit forms for $G_q(0)$ and $H_q(0)$, given by (110) and (111), respectively, one can easily verify that for both the Hermite and Laguerre cases we have the following identity:

$$\begin{aligned}\prod_{i=1}^m e^{-2q_iN\,\mathrm{Re}\{S_i\}}\zeta_N^{2q_i}(\mu_i)a_i^{-q_i^2}\cdot G_q(0)H_q(0)\cdot h_0 = {} & \prod_{i=1}^m \omega_N^{-q_i}(\mu_i)\rho^{-q_i^2}(\mu_i)2^{2q_i^2-2q_i}\pi^{-q_i^2-2q_i} \\ & \times\prod_{1\leqslant j<k\leqslant m}(\mu_k-\mu_j)^{2q_jq_k}.\end{aligned} \tag{113}$$

Inserting the identity (113) into (112) we finally obtain

$$\begin{aligned}\mathcal{H}_{N,m,q}(\mu) = {} & N^{\sum_{i=1}^m (q_i^2-q_i)}\prod_{i=1}^m [\omega_N(\mu_i)]^{-q_i}\prod_{i=1}^m \frac{G^2(q_i+1)}{G(2q_i+1)}(2\pi)^{q_i^2-q_i} \\ & \times\prod_{1\leqslant j<k\leqslant m}|\mu_k-\mu_j|^{-2q_jq_k}\prod_{l=1}^m [\rho(\mu_i)]^{q_i^2}\left[1+O\left(\frac{1}{N}\right)\right],\end{aligned} \tag{114}$$

which does indeed recover (21).

We emphasize that the derivation we have presented for (114) is entirely rigorous for $q\in\mathbb{N}^m$ for any $m\in\mathbb{N}$, thus verifying the legitimacy of the log-gas procedure used in Ref. 5 for the Hermite and Laguerre cases, for such q.

Exact solutions of two complementary one-dimensional quantum many-body systems on the half-line

Martin Hallnäs and Edwin Langmann
Mathematical Physics, KTH Physics, AlbaNova, SE-106 91 Stockholm, Sweden

(Received 14 April 2004; accepted 9 December 2004; published online 6 April 2005)

We consider two particular one-dimensional quantum many-body systems with local interactions related to the root system C_N. Both models describe identical particles moving on the half-line with nontrivial boundary conditions at the origin, but in the first model the particles interact with the delta interaction while in the second via a particular momentum dependent interaction commonly known as delta-prime interaction. We show that the Bethe ansatz solution of the delta-interaction model is consistent even for the general case where the particles are distinguishable, whereas for the delta-prime interaction it only is consistent and nontrivial in the fermion case. We also establish a duality between the bosonic delta- and the fermionic delta-prime model, and we elaborate on the physical interpretations of these models. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1865320]

I. INTRODUCTION

Quantum mechanical models with interactions are, in general, very difficult to solve, but there exist a few important cases where exact solutions are available, allowing them to be understood completely. A prominent example is the delta interaction in one dimension which, in the simplest two-particle case, is defined by the Hamiltonian

$$H = -\partial_x^2 + c\,\delta(x), \tag{1}$$

where c is a real coupling constant and $x \in \mathbb{R}$ the relative coordinate of the two particles, $x = x_1 - x_2$. This latter model is popular because it allows for an explicit solution by simple means: since the delta interaction is restricted to $x=0$, it only manifests itself in the nontrivial boundary conditions for eigenfunctions $\psi(x)$ of H [we use the notation $\psi(\pm 0) \equiv \lim_{\varepsilon \downarrow 0} \psi(\pm\varepsilon)$, and similarly for the derivative ψ'],

$$\begin{aligned} \psi(+0) &= \psi(-0), \\ \psi'(+0) - \psi'(-0) &= c\,\psi(+0), \end{aligned} \tag{2}$$

and these can easily be accounted for. The natural generalization of this model to an arbitrary number N of identical particles defines a prominent exactly solvable quantum many-body system which, in the boson case, was solved by Lieb and Liniger[1] (see also Ref. 2) and, in the general case of distinguishable particles, by Yang[3] in a seminal paper where the Yang–Baxter relations first appeared.

Interactions localized at points have been studied extensively using the mathematical theory of defect indices; see Refs. 4–6 and references therein. From these studies it is well known that the delta interaction is only one of many possible local interactions, and that in general such interaction can be characterized by four real coupling parameters. One prominent example of such an interaction, often referred to as delta-prime interaction,[7,8] is defined by the following boundary conditions:

$$\psi'(+0) = \psi'(-0),$$
$$\psi(+0) - \psi(-0) = 4\lambda\psi'(+0), \tag{3}$$

with a real parameter λ. Recently it was shown that these latter boundary conditions arise also from the following formal Hamiltonian:

$$H = -\partial_x^2 + 4\lambda\partial_x\delta(x)\partial_x, \tag{4}$$

where the second term has a physical interpretation as a local interaction depending also on the momentum $\hat{p} = -i\partial_x$ (Ref. 9); see Sec. III A. This interpretation of the boundary conditions in Eq. (3) has the advantage that it does not require an infinite coupling constant renormalization as is the case with the usual one.[7,8] [Note that the coupling constant $\tilde{\lambda}$ in the formal Hamiltonian $-\partial_x^2 + \tilde{\lambda}\delta'(x)$ is dimensionless, whereas the parameter λ in Eq. (3) has the dimension of a length, consistent with Eq. (4). We feel that this former mismatch of physical dimensions is a strong argument in favor of our interpretation.] We will therefore refer to the boundary conditions in Eq. (3) as $\hat{p}\delta\hat{p}$ interaction (see Ref. 10 for yet another interpretation). The N-body generalization of this model is exactly solvable by the Bethe ansatz in the indistinguishable particle case when the particles are either bosons or fermions but, different from the delta-interaction case, not in the general case of distinguishable particles[9] (see also Refs. 5 and 11–13). Still, this model is complementary to the model with the delta interactions for at least three different reasons: first, for indistinguishable particles the delta-interaction model is known to be interesting only for bosons (since the delta interaction is trivial on fermion wave functions), whereas the $\hat{p}\delta\hat{p}$ interaction is trivial for bosons and nontrivial for fermions.[4] Second, while the delta-interaction model for bosons can be obtained as the nonrelativistic limit of the quantum sine Gordon model, the $\hat{p}\delta\hat{p}$-interaction model for fermions naturally arises as the nonrelativistic limit of the massive Thirring model.[9] Third, there exists an interesting weak coupling duality between the fermionic $\hat{p}\delta\hat{p}$-interaction model and the bosonic delta-interaction model.[12]

As is well-known, exactly solvable many-body systems of particles moving on the full real line are naturally associated with the root system A_{N-1}, and they often allow for extensions to other root systems such that the exact solubility is preserved.[14] An early example was given by Gaudin who solved the C_N root system variant of the delta-interaction model for bosons[15] (see also Ref. 16), while the general case of this model for arbitrary root systems and distinguishable particles was treated by Sutherland.[17] As pointed out by Cherednik,[18] models related to the root system C_N describe interacting particles on the half-line, and the exact solubility requires the so-called reflection equation to be added to the Yang–Baxter relations. The reflection equation has played a central role in many exactly solvable systems with a boundary; see, e.g., Refs. 19 and 20.

In this paper we consider the Bethe ansatz solution of the C_N versions of the models discussed above. Similarly as for the A_{N-1} case, we find that the delta-interaction model is exactly solvable in this way even for distinguishable particles, but for the model with momentum independent interactions we obtain its exact solution only for indistinguishable particles. We also elaborate on the physical interpretation of these models as describing particles on the half-line with nontrivial boundary conditions at the origin.

To be more specific, the models we discuss in the paper can be formally defined by the following Hamiltonians:

$$H = -\sum_{j=1}^{N}\partial_{x_j}^2 + 2c_1\sum_{j<k}[\delta(x_j - x_k) + \delta(x_j + x_k)] + c_2\sum_{j=1}^{N}\delta(x_j) \tag{5}$$

(delta interactions) and

$$H = -\sum_{j=1}^{N} \partial_{x_j}^2 + 2\lambda_1 \sum_{j<k} [(\partial_{x_j} - \partial_{x_k})\delta(x_j - x_k)(\partial_{x_j} - \partial_{x_k}) + (\partial_{x_j} + \partial_{x_k})\delta(x_j + x_k)(\partial_{x_j} + \partial_{x_k})]$$
$$+ 4\lambda_2 \sum_{j=1}^{N} \partial_{x_j}\delta(x_j)\partial_{x_j} \tag{6}$$

($\hat{p}\delta\hat{p}$ interactions). For simplicity we assume all coupling constants positive so that there are no bound states. Mathematically, the model in Eq. (5) is the C_N variant of the model solved by Yang,[3] and Eq. (6) defines the C_N variant of the model discussed in Ref. 9.

The plan of the rest of this paper is as follows. In Sec. II we consider the C_N delta-interaction model, starting by deriving the boundary conditions and thus turning the Schrödinger equation $H\psi = E\psi$ into a well-defined mathematical problem. We proceed to the Bethe ansatz solution of this model where the Yang–Baxter relations and the reflection equation play a central role. We conclude the section by elaborating on the physical interpretation of this model. In Sec. III we discuss the C_N variant of the $\hat{p}\delta\hat{p}$-interaction model, in large part paralleling our discussion for the delta interaction in Sec. II. We also present a duality relation between the fermionic $\hat{p}\delta\hat{p}$-interaction model and the bosonic delta-interaction model. Appendix A gives some details on the verification of the Yang–Baxter relations and the reflection equation. Appendix B contains a few mathematical facts about the Weyl group of the root system C_N, and Appendix C gives some details on the physical interpretation of these models.

II. DELTA INTERACTION

In this section we provide the exact solution of the C_N delta interaction in the case of distinguishable particles and elaborate on its physical interpretation.

A. Boundary conditions

The Hamiltonian (5) defining the C_N delta-interaction model is only formal, and to determine its eigenfunctions we must first convert it into a set of boundary conditions.

For completeness we start by discussing the Hamiltonian H in Eq. (1), which can be regarded also as the one-particle case of the Hamiltonian in Eq. (5), $N=1$. The first step in finding the eigenfunctions ψ of H is to note that the equation $H\psi = E\psi$ for all x is equivalent to $-\psi'' = E\psi$ for $x \neq 0$ together with the boundary conditions in Eq. (2). These boundary conditions are obtained by integrating the equation $H\psi = E\psi$, i.e., $-\psi''(x) + c\,\delta(x)\psi(0) = E\psi(x)$, twice, first from $x = -\varepsilon$ to $x > 0$ and then once more from $x = -\varepsilon$ to $x = \varepsilon$ yields the first condition in Eq. (2) in the limit $\varepsilon \downarrow 0$, and integrating from $x = -\varepsilon$ to $x = \varepsilon$ yields the second condition in Eq. (2) in the same limit. Thus in this case there are two regions free of interactions, $x < 0$ and $x > 0$, linked to each other by the boundary condition in Eq. (2) at $x = 0$.

For general N, the interaction terms of the Hamiltonian H in Eq. (5) are restricted to $x_j = \pm x_k$ and $x_j = 0$ for $1 \leqslant j < k \leqslant N$, and the eigenfunctions ψ of H therefore obey the equation

$$\left(\sum_{j=1}^{N} \partial_{x_j}^2 + E\right)\psi(x_1, \ldots, x_N) = 0 \quad \text{for } x_j \neq \pm x_k \text{ and } x_j \neq 0, \tag{7}$$

and for each of the boundaries of the interaction free regions one gets a pair of boundary conditions similarly to the ones for $N=1$,

$$\psi|_{x_j = \pm x_k + 0} = \psi|_{x_j = \pm x_k - 0},$$

$$(\partial_{x_j} - \partial_{x_k})\psi|_{x_j = \pm x_k + 0} - (\partial_{x_j} - \partial_{x_k})\psi|_{x_j = \pm x_k - 0} = 2c_1\, \psi|_{x_j = \pm x_k - 0}, \tag{8a}$$

$$\psi|_{x_j = +0} = \psi|_{x_j = -0},$$

$$\partial_{x_j}\psi|_{x_j=0} - \partial_{x_j}\psi|_{x_j=-0} = c_2\,\psi|_{x_j=+0} \tag{8b}$$

(these conditions are obtained by a straightforward generalization of the $N=1$ argument above, using $\partial_{x_j} \pm \partial_{x_k} = 2\partial_{x_j \pm x_k}$).

Obviously there are now many more regions free of interactions. One such region is $0 < x_1 < x_2 < \cdots < x_N$, and all others can be obtained from this one by permuting the particle labels, $j \to pj$ with $p \in S_N$ (=permutation group), and/or reflecting some of the coordinates, $x_j \to -x_j$. Thus all regions free of interactions can be characterized as follows:

$$0 < \sigma_1 x_{p1} < \sigma_2 x_{p2} < \cdots < \sigma_N x_{pN} < \infty, \tag{9}$$

where $\sigma_j = \pm 1$ and $p \in S_N$; we will refer to these regions as *wedges*. It is important to note that they can be labeled by elements Q in the group

$$W_N := (\mathbb{Z}/2\mathbb{Z})^N \rtimes S_N, \tag{10}$$

where the first factor corresponds to the reflections while the second factor corresponds to the permutations of the coordinates,

$$x_{Qj} = \sigma_j x_{pj} \quad \text{for } Q = (\sigma_1, \ldots, \sigma_N; p) \in W_N \text{ with } \sigma_j \in \{\pm 1\} \text{ and } p \in S_N. \tag{11}$$

In the sequel we will therefore use the following convenient notation for the wedges:

$$\Delta_Q, \quad 0 < x_{Q1} < x_{Q2} < \cdots < x_{QN} \tag{12}$$

with $Q \in W_N$. It is interesting to note that the group W_N is isomorphic to the Weyl group of the root system C_N; see, e.g., Ref. 21.

B. Bethe ansatz

Using the boundary conditions deduced in the preceding section we now proceed to determine all eigenfunctions of the C_N delta interaction, starting by recalling the physical motivation of the Bethe ansatz below. For that we first consider the Hamiltonian H in Eq. (1). In this case there are eigenfunctions $\psi(x) = \exp(ikx)$ for $x < 0$ which are equal to a particular linear combination of $\exp(ikx)$ and $\exp(-ikx)$ for $x > 0$. This can be interpreted as scattering by the delta interaction $\propto \delta(x)$ where a plane wave is partly transmitted and partly reflected. Regarding H in Eq. (1) as a two particle Hamiltonian with $x = x_1 - x_2$ the relative coordinate and $k = (k_1 - k_2)/2$ the relative momentum, we can interpret this very fact as scattering of a plane wave solution $\exp(ik_1x_1 + ik_2x_2)$ into a linear combination of this wave and another one where the particle momenta k_1 and k_2 are exchanged, $\exp(ik_2x_1 + ik_1x_2)$. This suggests that an eigenfunction ψ of the N-particle Hamiltonian in Eq. (5) which is equal to a plane wave $\exp(i\Sigma_{j=1}^N k_j x_j)$ in one wedge Δ_Q (12) will be transformed into a linear combination of plane waves $\exp(i\Sigma_{j=0}^N \tilde{k}_j x_j)$ in any other wedge where $\tilde{k}_j = \sigma_j k_{pj}$, with $\sigma_j = \pm 1$ resulting from the interactions $\propto \delta(x_j)$ which can invert momenta, $k_j \to -k_j$, and $p \in S_N$ resulting from the interactions $\propto \delta(x_j - x_\ell)$ which can interchange momenta, $k_j \leftrightarrow k_\ell$.

We thus see that the group in Eq. (10) naturally appears again, $\tilde{k}_j = k_{Pj}$ for some $P \in W_N$, and the discussion above suggests the following Bethe ansatz for the eigenfunctions of the Hamiltonian H in Eq. (5):

$$\psi(x) = \sum_{P \in W_N} A_P(Q) e^{ik_P \cdot x_Q} \quad \text{for } 0 < x_{Q1} < x_{Q2} < \cdots < x_{QN} \tag{13}$$

with $x = (x_1, \ldots, x_N)$ and $k_P \cdot x_Q \equiv \Sigma_{j=1}^N k_{Pj} x_{Qj}$, for all $Q \in W_N$. The corresponding eigenvalue is obviously $E = \Sigma_{j=1}^N k_j^2$.

One now has to take into account the boundary conditions in (8a) and (8b). For each $Q \in W_N$, the wedge Δ_Q (12) participates in N boundaries, $x_{Qi} = x_{Q(i+1)}$ for $i = 1, 2, \ldots (N-1)$ and $x_{Q1} = 0$, and for each of these boundaries we will get two conditions. More specifically, the boundary

at $x_{Qi}=x_{Q(i+1)}$ is between the wedges Δ_Q and Δ_{QT_i} where $T_i \in W_N$ is the transposition interchanging i and $(i+1)$, and the conditions implied by Eq. (8a) for $j=Qi$ and $k=Q(i+1)$ are

$$\begin{aligned} A_P(Q) + A_{PT_i}(Q) &= A_P(QT_i) + A_{PT_i}(QT_i) \\ i(k_{Pi} - k_{P(i+1)})[A_{PT_i}(QT_i) - A_P(QT_i) + A_{PT_i}(Q) - A_P(Q)] &= 2c_1[A_P(Q) + A_{PT_i}(Q)]. \end{aligned} \tag{14a}$$

The boundary at $x_{Q1}=0$ is between the wedges Δ_Q and Δ_{QR_1} with $R_1 \in W_N$ the reflection of the first argument, i.e., $x_{R_1 j}=x_j$ for $j\neq 1$ and $-x_j$ for $j=1$, and the conditions at $x_{Q1}=0$ implied by Eq. (8b) for $j=Q1$ are

$$\begin{aligned} A_P(Q) + A_{PR_1}(Q) &= A_P(QR_1) + A_{PR_1}(QR_1) \\ ik_{P1}[A_P(Q) - A_{PR_1}(Q) + A_P(QR_1) - A_{PR_1}(QR_1)] &= c_2[A_P(QR_1) + A_{PR_1}(QR_1)]. \end{aligned} \tag{14b}$$

We thus have $2N(2^N N!)^2$ linear, homogeneous equations for the $(2^N N!)^2$ coefficients $A_P(Q)$. The following beautiful argument due to Yang[3] shows that this system of equations has enough nontrivial solutions and, at the same time, gives a recipe to compute all the $A_P(Q)$.

For that it is important to note that W_N plays a third role, defining

$$(\hat{R})_{Q,Q'} = \delta_{Q',QR} \tag{15}$$

one can write

$$A_P(QR) = \sum_{Q' \in W_N} (\hat{R})_{Q,Q'} A_P(Q') = (\hat{R}A_P)(Q), \tag{16}$$

where the first equality is a trivial consequence of the definition, and in the second we interpret $(\hat{R})_{Q,Q'}$ as elements of an $n\times n$ matrix $\hat{R}$ with $n=2^N N!$ the rank of W_N. These matrices obviously define a representation $R\to\hat{R}$ of W_N acting on the coefficients $A_P(Q)$. It is worth noting that this is identical with the so-called (right) regular representation of W_N.

We can therefore insert $A_{PT_i}(QT_i)=(\hat{T}_i A_{PT_i})(Q)$ in Eq. (14a), and by a simple computation show that these latter equations are equivalent to

$$A_P = Y_i(k_{P(i+1)} - k_{Pi})A_{PT_i}, \tag{17}$$

where we have introduced the operator

$$Y_i(u) = \frac{iu\hat{T}_i + c_1\hat{I}}{iu - c_1} \tag{18}$$

and interpret A_P as a vector with $2^N N!$ elements $A_P(Q)$. In the same way we can rewrite the conditions in Eq. (14b) using $A_{PR_1}(QR_1)=(\hat{R}_1 A_{PR_1})(Q)$,

$$A_P = Z(2k_{P1})A_{PR_1} \tag{19}$$

with the operator

$$Z(u) = \frac{iu\hat{R}_1 + c_2\hat{I}}{iu - c_2}. \tag{20}$$

It is known that the group W_N is generated by the reflection R_1 and the transpositions T_i (see, e.g., p. 21 in Ref. 22). Thus one can use the identities in Eqs. (17), (19), and (16) to calculate recursively all coefficients $A_P(Q)$ from $A_I(I)$ using the operators Z and Y_i above. It is important to note that there is a possible inconsistency arising from the fact that the representation of an

element P in W_N as a product of the T_i's and R_1 is not unique. However, any two such representations can be converted into each other by using the defining relations of the group W_N,

$$T_iT_i = 1, \quad T_iT_j = T_jT_i \quad \text{for } |i-j| > 1,$$
$$T_iT_{i+1}T_i = T_{i+1}T_iT_{i+1}, \tag{21a}$$

$$R_1R_1 = 1, \quad R_1T_i = T_iR_1 \quad \text{for } i > 1,$$
$$R_1T_1R_1T_1 = T_1R_1T_1R_1. \tag{21b}$$

Thus no inconsistency can arise provided that

$$A_{PT_iT_i}(Q) = A_P(Q), \quad A_{PT_iT_j}(Q) = A_{PT_jT_i}(Q) \quad \text{for } |i-j| > 1,$$
$$A_{PT_iT_{i+1}T_i}(Q) = A_{PT_{i+1}T_iT_{i+1}}(Q), \tag{22a}$$

$$A_{PR_1R_1}(Q) = A_P(Q), \quad A_{PR_1T_i}(Q) = A_{PT_iR_1}(Q) \text{ for } i > 1,$$
$$A_{PR_1T_1R_1T_1}(Q) = A_{PT_1R_1T_1R_1}(Q) \tag{22b}$$

for all P, $Q \in W_N$. Using the recursion relations (17) and (19) one finds that these conditions hold true if and only if the following operator relations are fulfilled:

$$Y_i(-u)Y_i(u) = I, \quad Y_i(u)Y_j(v) = Y_j(v)Y_i(u) \quad \text{for } |i-j| > 1,$$
$$Y_i(v)Y_{i+1}(u+v)Y_i(u) = Y_{i+1}(u)Y_i(u+v)Y_{i+1}(v), \tag{23a}$$

$$Z(-u)Z(u) = I, \quad Z(u)Y_i(v) = Y_i(v)Z(u) \quad \text{for } i > 1,$$
$$Z(2v)Y_1(u+v)Z(2u)Y_1(u-v) = Y_1(u-v)Z(2u)Y_1(u+v)Z(2v) \tag{23b}$$

for all real u and v. The validity of this system of equations is necessary and sufficient in order for the Bethe ansatz above to be consistent and the model at hand to be exactly solvable. The first three relations are the so-called Yang–Baxter relations, and the last one is the reflection equation. The validity of these relations for arbitrary $\hat{T}_i$ and $\hat{R}_1$ can be checked by straightforward but somewhat tedious computations (of course, the validity of the Yang–Baxter relation in this case is known since a long time,[3] and this seems to be the case also for the reflection equation,[17,19] but for completeness we provide the essential steps in the verification in Appendix A 1).

Thus the Bethe ansatz (13) is consistent even in the general case of distinguishable particles, and we can calculate all coefficients A_P from A_I using the recursion relation

$$A_P = \mathcal{W}_P(k)A_I, \tag{24}$$

where $\mathcal{W}_P(k)$ is a product of the operators $Y_i(k_{P(i+1)} - k_{Pi})$ and $Z(2k_{P1})$ obtained by using repeatedly (17) and (19).

Interesting special cases of this solution are when the particles are indistinguishable, i.e., when the particles are fermions of bosons. In the former case $\hat{T}_i = -I$, and Eq. (18) implies $Y_i(u) = -I$ independent of the coupling constant c_1. This shows that the delta interaction is trivial for fermions. In the boson case we have $\hat{T}_i = +I$, and $Y_i(u)$ is a nontrivial phase. As discussed in more detail below, there are two different boson cases with different physical interpretations, namely $\hat{R}_1 = -I$ and $\hat{R}_1 = +I$.

C. Physical interpretation

As is well known, the C_N delta-interaction model describes interacting particles on the half-line with particular boundary conditions at the origin.[18] However, the general solution of the C_N delta-interaction model without any restrictions includes many more eigenfunctions than any model on the half-line, and the relation between these models is therefore not completely obvious. In this section we discuss the relation of these models in more detail. We also give a physical interpretation of the boundary conditions which occur as limits of particular external potentials restricting the particles to the half-line.

As discussed in Appendix B, in any irrep of the group W_N the reflections R_j of the particle coordinate x_j are represented either by $\hat{R}_j = +1$ or -1. For simplicity we now discuss in more detail the cases where all $\hat{R}_j$ are the same, either $+1$ or -1, which from a physical point of view are the most interesting ones. As discussed in Appendix B, these irreps of W_N can be rather easily understood since they are related in a simple way to irreps of S_N. Thus we can impose the following restriction on the eigenfunctions ψ of the Hamiltonian in Eq. (5),

$$(\hat{R}_j\psi)(x_1, \ldots, x_j, \ldots, x_N) \equiv \psi(x_1, \ldots, -x_j, \ldots, x_N) = \pm\, \psi(x_1, \ldots, x_j, \ldots, x_N). \tag{25}$$

With that assumption we can restrict ourselves to $x_j > 0$, and the boundary conditions in Eq. (8a) and Eq. (8b) reduce to

$$\begin{gathered} \psi|_{x_j=x_k+0} = \psi|_{x_j=x_k-0}, \\ (\partial_{x_j} - \partial_{x_k})\, \psi|_{x_j=x_k+0} - (\partial_{x_j} - \partial_{x_k})\, \psi|_{x_j=x_k-0} = 2c_1\, \psi|_{x_j=x_k+0}, \end{gathered} \tag{26a}$$

and

$$\begin{gathered} 2\partial_{x_j}\, \psi|_{x_j=+0} = c_2\, \psi|_{x_j=+0} \quad \text{for } \hat{R}_j = +1, \\ \psi|_{x_j=+0} = 0 \quad \text{for } \hat{R}_j = -1, \end{gathered} \tag{26b}$$

respectively. These are exactly the boundary conditions obtained from the Hamiltonian

$$H_0 = -\sum_{j=1}^{N} \partial_{x_j}^2 + 2c_1 \sum_{j<k} \delta(x_j - x_k) \tag{27}$$

describing particles on the half-line, $x_j > 0$, and the boundary conditions at the origin given in Eq. (26b).

It is also interesting to note that these later boundary conditions are obtained by allowing the particles to move on the full line, $x_j \in \mathbb{R}$, and adding a particular external potential $\Sigma_j V(x_j)$ to the Hamiltonian in Eq. (27) which effectively constrains the particles to the half-line $x_j > 0$. To be specific, these potentials are given by

$$V(x) = \begin{cases} V_0\Theta(-x) + (c_2/2 - \sqrt{V_0})\,\delta(x) & \text{if } \hat{R}_j = +1, \\ V_0\Theta(-x) & \text{if } \hat{R}_j = -1, \end{cases} \tag{28}$$

where $\Theta(-x)$ is the Heaviside function (equal to one for $x < 0$ and zero otherwise), and one must take the strong coupling limit $V_0 \to \infty$, as shown in Appendix C, in this latter limit the eigenfunctions of the Hamiltonian $H_0 + \Sigma_j V(x_j)$ on the full line, $x_j \in \mathbb{R}$, coincide with the ones of H_0 on the half-line, $x_j > 0$, and the boundary conditions in Eq. (26b).

As already mentioned, the most important cases in applications are the ones we have considered here, i.e., where all the $\hat{R}_j$ are the same. Nevertheless it would be of interest to consider the implications of allowing the $\hat{R}_j$ to take on different values, in effect dividing the particles into two groups distinguished by their interactions with the boundary.

III. LOCAL MOMENTUM-DEPENDENT INTERACTION

In this section we discuss the model with local momentum dependent interactions defined by the Hamiltonian in Eq. (6). While most of our discussion is in parallel with the one for the delta-interaction model in the preceding section, we find that the Bethe ansatz is consistent only in case of indistinguishable particles. We also present a duality relation between the fermionic variant of the model with local momentum dependent interactions and the bosonic delta-interaction model discussed in the preceding section.

A. Boundary conditions

Since this interaction is not as familiar as the delta interaction we give a somewhat more detailed discussion of how to turn the eigenvalue equation of the formal Hamiltonian in Eq. (6) into a well-defined mathematical problem in terms of boundary conditions. We stress that we give this argument only to substantiate our physical interpretation of the model we consider, and that one also could *define* the model in terms of the boundary conditions in Eqs. (30a) and (30b) below, as is often done for this type of models.[4,5] However, it seems that the results in Ref. 23 provide a framework making our formal computations mathematically precise.

To explain our method we start by considering the formal eigenvalue equation $H\psi=E\psi$ for the $N=1$ Hamiltonian in Eq. (4), i.e.,

$$-\psi''(x)+4\lambda\delta'(x)\psi'(0)=E\psi(x) \tag{29}$$

since $\partial_x\delta(x)\partial_x\psi(x)=\partial_x[\delta(x)\psi'(x)]$. It is important to note that the wave function $\psi(x)$ is not continuous at the singular point $x=0$, but we interpret $\psi'(0)$ as $\lim_{\varepsilon\downarrow 0}[\psi'(\varepsilon)+\psi'(-\varepsilon)]/2$ which is well defined. This amounts to a particular renormalization of this singular interaction; see Ref. 9 for a more detailed discussion on this. For $x\neq 0$ Eq. (29) again reduces to $-\psi''=E\psi$. To deduce the boundary conditions at $x=0$ we integrate Eq. (29) from $x=-\varepsilon$ to ε, and taking the limit $\varepsilon\downarrow 0$ we obtain the first condition in Eq. (3). Integrating Eq. (29) from $x=-\varepsilon$ to $x>0$ and then once more from $x=-\varepsilon$ to ε and taking the limit $\varepsilon\downarrow 0$ yields the second condition in Eq. (3).

It is straightforward to generalize this argument to the N-particle case: consider the formal eigenvalue equation $H\psi=E\psi$ for the Hamiltonian in Eq. (6) and treat each singular point $x_j=\pm x_k$ and $x_j=0$ separately, similarly as for the $N=1$ Hamiltonian above. For the singular points $x_j=0$ the argument is identical to the one for the $N=1$ case above. For any other singular point $x_j=\pm x_k$ we introduce new coordinates $y=x_j\mp x_k$ and $z=x_j\pm x_k$ in the vicinity of this point so that $H=-2(\partial_y^2+\partial_z^2+4\lambda_1\partial_y\delta(y)\partial_y+4\lambda_1\partial_z\delta(z)\partial_z)+\cdots$ where the dots represent terms which remain nonsingular as $y\to 0$, and then one can treat the singular point $y=0$ as explained in the $N=1$ case above.

Thus, we find that the eigenfunctions ψ of the Hamiltonian in Eq. (6) are determined by Eq. (7) together with the boundary conditions

$$\begin{aligned}
&(\partial_{x_j}-\partial_{x_k})\,\psi|_{x_j=\pm x_k+0}=(\partial_{x_j}-\partial_{x_k})\,\psi|_{x_j=\pm x_k-0},\\
&\psi|_{x_j=\pm x_k+0}-\psi|_{x_j=\pm x_k-0}=2\lambda_1(\partial_{x_j}-\partial_{x_k})\,\psi|_{x_j=\pm x_k-0},\\
&\partial_{x_j}\psi|_{x_j=+0}=\partial_{x_j}\psi|_{x_j=-0},
\end{aligned} \tag{30a}$$

$$\psi|_{x_j=+0} - \psi|_{x_j=-0} = 4\lambda_2 \partial_{x_j} \psi|_{x_j=+0}, \tag{30b}$$

where we used $2\partial_{x_j \mp x_k} = \partial_{x_j} \mp \partial_{x_k}$.

B. Bethe ansatz

We now discuss the Bethe ansatz for the eigenfunctions of the Hamiltonian H defined in Eq. (6). Obviously much of what we said for the delta-interaction case carries over straightforwardly to the present case. Due to the different boundary conditions in Eqs. (30a) and (30b), Eqs. (14a) and (14b) are changed to

$$\begin{aligned} &i(k_{Pi} - k_{P(i+1)})[A_{PT_i}(QT_i) - A_P(QT_i)] = i(k_{Pi} - k_{P(i+1)})[A_P(Q) - A_{PT_i}(Q)] \\ &A_P(QT_i) + A_{PT_i}(QT_i) - A_P(Q) - A_{PT_i}(Q) = 2\lambda_1 i(k_{Pi} - k_{P(i+1)})[A_P(Q) - A_{PT_i}(Q)], \end{aligned} \tag{31a}$$

$$\begin{aligned} &ik_{P1}[A_P(Q) - A_{PR_1}(Q)] = ik_{P1}[A_{PR_1}(QR_1) - A_P(QR_1)] \\ &A_P(Q) + A_{PR_1}(Q) - A_P(QR_1) - A_{PR_1}(QR_1) = 4\lambda_2 ik_{P1}[A_P(QR_1) - A_{PR_1}(QR_1)]. \end{aligned} \tag{31b}$$

We now also use Eq. (16) to convert these equations into the recursion relations

$$A_P = Y_i(k_{P_{i+1}} - k_{P_i}) A_{PT_i}, \tag{32}$$

and similarly

$$A_P = Z(2k_{P_1}) A_{PR_1}, \tag{33}$$

where now

$$Y_i(u) = \frac{iu\hat{I} - 1/\lambda_1 T_i}{iu - 1/\lambda_1} \tag{34}$$

and

$$Z(u) = \frac{iu\hat{I} - 1/\lambda_2 \hat{R}_1}{iu - 1/\lambda_2}. \tag{35}$$

As in the delta-interaction case these relations allow to recursively compute all coefficients A_P in terms of A_I, and the conditions for the absence of inconsistencies are identical to (22a) and (22b) of the delta-interaction case, leading to the Yang–Baxter relations (23a) and reflection equation (23b) but now with the operators (34) and (35). In contrast to the delta-interaction case, we find that these consistency relations are fulfilled only if $\hat{T}_i = \pm I$ for all i (see Appendix A 2 for details). We thus conclude that *the Bethe ansatz is consistent only if the particles are indistinguishable, i.e., A_I is chosen such that either $\hat{T}_i = I$ or $\hat{T}_i = -I$*, and in these two cases we can compute all coefficients A_P from A_I as

$$A_P = \mathcal{W}_P(k) A_I, \tag{36}$$

where $\mathcal{W}_P(k)$ is a product of operators $Y_i(k_{P_{i+1}} - k_{P_i})$ and $Z(2k_{P_1})$ in Eqs. (34) and (35) obtained by using repeatedly (32) and (33).

For $\hat{T}_i = +I$ we get from Eq. (34) that $Y_i(u) = I$ independent of λ_1, and we conclude that *the momentum-dependent interaction is trivial for bosons*. However, for $\hat{T}_i = -I$ (fermions) the $Y_i(u)$ are nontrivial phases. There are two different fermion cases, namely $\hat{R}_1 = \pm I$.

C. Duality

It is interesting to note that there exists a simple duality relation between the fermionic $\hat{p}\delta\hat{p}$-model and the bosonic C_N delta-interaction model discussed in Sec. II. Since the operators $Y_i(u)$ and $Z(u)$ for the latter model are identical with the ones of the fermionic $\hat{p}\delta\hat{p}$-model upon the substitution $\lambda_1 \to 1/c_1$ and $\lambda_2 \to 1/c_2$ [compare Eqs. (18) and (20) for $\hat{T}_i = \hat{R}_1 = +I$ and Eqs. (34) and (35) for $\hat{T}_i = \hat{R}_1 = -1$], Eqs. (24) and (36) imply that

$$A_P^{\delta}|_{\hat{T}_i=\hat{R}_1=+I} = A_P^{\hat{p}\delta\hat{p}}|_{\hat{T}_i=\hat{R}_1=-I,\lambda_1\to 1/c_1,\lambda_2\to 1/c_2}, \tag{37}$$

where A_P^{δ} are the coefficients of Sec. II B and $A_P^{\hat{p}\delta\hat{p}}$ the ones in Sec. III B. This implies that *the bosonic wave functions of the delta-model in Sec. II B and the fermionic wave functions of the $\hat{p}\delta\hat{p}$-model in Sec. III B are identical when restricted to the fundamental wedge*

$$\Delta_I, \quad 0 < x_1 < x_2 < \cdots < x_N, \tag{38}$$

provided that the coupling constants of these models are related as follows:

$$\lambda_1 = \frac{1}{c_1} \quad \textit{and } \lambda_2 = \frac{1}{c_2}. \tag{39}$$

This can be seen also more directly, assuming that the eigenfunction ψ of the Hamiltonian in Eq. (5) is bosonic, $\hat{T}_i = \hat{R}_1 = I$, it is enough to determine it in the fundamental wedge. Moreover, the continuity conditions in Eqs. (8a) and (8b) are fulfilled automatically for boson wave functions, whereas the conditions on the derivatives simplify to

$$\begin{gathered}(\partial_{x_j} - \partial_{x_{j+1}} - c_1)\ \psi|_{x_j=x_k+0} = 0, \\ (2\partial_{x_j} - c_2)\ \psi|_{x_j=+0} = 0\end{gathered} \tag{40}$$

for all x in the fundamental wedge. In a similar manner one finds that the fermionic eigenfunctions of the Hamiltonian in Eq. (6), $\hat{T}_i = \hat{R}_1 = -I$, are determined by the very same conditions in Eq. (40) with $c_{1,2}$ replaced by $1/\lambda_{1,2}$.

This generalizes the duality previously observed in the A_{N-1} case[9,12] to the C_N case.

D. Physical interpretation

As in the delta-interaction case, one can restrict the eigenfunctions ψ of the Hamiltonian in Eq. (6) by imposing the conditions in Eq. (25), reducing the boundary conditions in Eqs. (30a) and (30b) to

$$\begin{gathered}(\partial_{x_j} - \partial_{x_k})\ \psi|_{x_j=x_k+0} = (\partial_{x_j} - \partial_{x_k})\ \psi|_{x_j=x_k-0}, \\ \psi|_{x_j=x_k+0} - \psi|_{x_j=x_k-0} = 2\lambda_1(\partial_{x_j} - \partial_{x_k})\ \psi|_{x_j=x_k+0}\end{gathered} \tag{41a}$$

and

$$\begin{gathered}\partial_{x_j}\ \psi|_{x_j=+0} = 0 \quad \text{for } \hat{R}_j = +1, \\ \psi|_{x_j=+0} = 2\lambda_2\partial_{x_j}\ \psi|_{x_j=+0} \quad \text{for } \hat{R}_j = -1,\end{gathered} \tag{41b}$$

where $x_j > 0$. This shows that the eigenfunctions of the C_N Hamiltonian in Eq. (6) with the restriction in Eq. (25) are identical to the ones of the A_{N-1} Hamiltonian,

$$H_0 = -\sum_{j=1}^{N} \partial_{x_j}^2 + 2\lambda_1 \sum_{j<k} (\partial_{x_j} - \partial_{x_k}) \delta(x_j - x_k)(\partial_{x_j} - \partial_{x_k}), \tag{42}$$

restricted to the half-line, $x_j > 0$, and the boundary conditions at the origin given in Eq. (41b).

Moreover, as shown in Appendix C 2, the eigenfunctions ψ above restricted to $x_j > 0$ become identical to the ones of the Hamiltonian $H_0 + \Sigma_j V(x_j)$ on the full real line, $x_j \in \mathbb{R}$, with an external potential

$$V(x) = \begin{cases} V_0 \Theta(-x) + \sqrt{V_0} \partial_x \delta(x) \partial_x & \text{if } \hat{R}_j = +1, \\ V_0 \Theta(-x) + 2\lambda_2 \partial_x \delta(x) \partial_x & \text{if } \hat{R}_j = -1 \end{cases} \tag{43}$$

in the limit $V_0 \to \infty$.

IV. CONCLUDING REMARK

As discussed in the Introduction, there exists a four-parameter family of local interactions,[4] and the delta- and $\hat{p}\delta\hat{p}$ interactions only correspond to one-parameter subfamilies each. It is therefore natural to ask, what about the other local interactions? Are there other cases leading to exactly solvable models? It is thus interesting to note that there is a simple physical interpretation of the four-parameter family of local interactions which seems very natural to us but seems different from the one commonly used,[4,10] in the simplest case they correspond to the following generalization of the Hamiltonians in Eqs. (1) and (4):

$$H = -\partial_x^2 + c\,\delta(x) + 4\lambda \partial_x \delta(x) \partial_x + 2(\gamma + i\eta) \partial_x \delta(x) - 2(\gamma - i\eta) \delta(x) \partial_x, \tag{44}$$

which obviously is the most general hermitian Hamiltonian with interactions localized at $x = 0$ and containing only derivatives up to second order (higher derivatives than that do not lead to physically acceptable boundary conditions). This Hamiltonian is formally self-adjoint for arbitrary real parameters c, λ, γ, η, and it indeed corresponds to the well-known four-parameter family of local interactions mentioned above[24] (see also Ref. 23 and Sec. II.1 in Ref. 6). All these models have natural generalizations to the A_{N-1} many-body case, but only the following cases are exactly solvable by the coordinate Bethe ansatz even for distinguishable particles: $(c, 1/c, 0, 0)$ and $(c, 0, 0, \eta)$, for arbitrary real c and η (Ref. 24) (see also Refs. 5, 13, and 25). It is important to note that the many-body generalization of the Hamiltonian in Eq. (44) describes identical particles only if $\gamma = \eta = 0$, and the proof of this latter result therefore requires an extension of Yang's method of solution[3] to models of non-identical particles.[24] We conjecture that similar results hold true for the corresponding C_N models.

ACKNOWLEDGMENTS

The authors would like to thank Harald Grosse, Jouko Mickelsson, and Cornelius Paufler for helpful discussions and P. Kurasov for pointing out Refs. 13, 23, and 25. E.L. was supported in part by the Swedish Science Research Council (VR) and the Göran Gustafsson Foundation.

APPENDIX A: VERIFICATION OF CONSISTENCY RELATIONS

In this appendix we sketch the verification of the consistency relations in Eqs. (23a) and (23b) (Yang–Baxter relations and the reflection equation).

1. Delta interaction

We start by writing the operators Y_i in the following way:

$$Y_i(u) = a(u)\hat{I} + b(u)\hat{T}_i, \tag{A1}$$

where

$$a(u) = \frac{c_1}{iu - c_1}, \quad b(u) = \frac{iu}{iu - c_1}. \tag{A2}$$

Inserting this expression into the equations in (23a) results in a number of relations between the coefficients $a(u)$ and $b(u)$, one for each equation and different permutation operator. Most of them are trivially fulfilled, but the following ones are nontrivial:

$$\begin{aligned} a(-u)a(u) + b(-u)b(u) &= 1, \\ a(-u)b(u) + b(-u)a(u) &= 0, \end{aligned} \tag{A3}$$

and

$$b(v)a(u+v)a(u) + a(v)a(u+v)b(u) = a(u)b(u+v)a(v). \tag{A4}$$

Inserting $a(u)$ and $b(u)$ from Eq. (A2) they can be verified by straightforward calculations. To verify Eq. (23b) we write the operator Z as

$$Z(u) = \tilde{a}(u)\hat{I} + \tilde{b}(u)\hat{R}_1, \tag{A5}$$

where

$$\tilde{a}(u) = \frac{c_2}{iu - c_2}, \quad \tilde{b}(u) = \frac{iu}{iu - c_2}. \tag{A6}$$

Substituting this and Eq. (A1) into the equations in (23b) leads to the following nontrivial relation:

$$\begin{aligned} &\tilde{b}(2v)b(u+v)\tilde{a}(2u)a(u-v) + \tilde{b}(2v)a(u+v)\tilde{a}(2u)b(u-v) + \tilde{a}(2v)a(u+v)\tilde{b}(2u)b(u-v) \\ &\quad = a(u-v)\tilde{b}(2u)b(u+v)\tilde{a}(2v) \end{aligned} \tag{A7}$$

in addition to

$$\begin{aligned} \tilde{a}(-u)\tilde{a}(u) + \tilde{b}(-u)\tilde{b}(u) &= 1, \\ \tilde{a}(-u)\tilde{b}(u) + \tilde{b}(-u)\tilde{a}(u) &= 0, \end{aligned} \tag{A8}$$

the validity of which follow from straightforward calculations.

We conclude that the Bethe ansatz is consistent even for distinguishable particles.

2. Local momentum-dependent interaction

In this case we get $Y_i(u)$ as in Eq. (A1) but with

$$a(u) = \frac{iu}{iu - 1/\lambda_1}, \quad b(u) = \frac{-1/\lambda_1}{iu - 1/\lambda_1}. \tag{A9}$$

With that the two equations in (A3) hold true but the equation in (A4) does not. We therefore conclude that *the Bethe ansatz is not consistent for distinguishable particles.*

For indistinguishable particles we have $\hat{T}_i = \pm I$ and the Yang–Baxter relations in Eq. (23a) are trivially fulfilled. Moreover, in this case it is also easy to check that the relations (23b) hold true for $\hat{R}_1 = \pm I$.

We conclude that the Bethe ansatz is consistent in the indistinguishable particle case but not in general.

APPENDIX B: REPRESENTATIONS OF THE GROUP W_N

In this appendix we discuss the irreducible representations of the group $W_N \equiv (\mathbb{Z}/2\mathbb{Z})^N \rtimes S_N$. In particular we will show the following.

Fact: There exists a set of irreducible representations of W_N isomorphic to the irreducible representations $\chi_\pm \otimes \rho$, where $\chi_\pm$ is a character (irreducible representation) of the (normal) abelian subgroup $(\mathbb{Z}/2\mathbb{Z})^N$ such that $\chi_\pm(R_j) = \pm 1$ for all $j = 1, 2, \ldots, N$ (same sign for all j) and ρ is an arbitrary irreducible representation of the permutation group S_N.

To show this we will use the notion of induced representations, following Sec. 8.2 of Ref. 26. We start by determining the group of characters $X = \mathrm{Hom}((\mathbb{Z}/2\mathbb{Z})^N, \mathbb{C})$ of the subgroup $(\mathbb{Z}/2\mathbb{Z})^N$. The fact that it is generated by the reflections R_j obeying the relations (see, e.g., p. 21 in Ref. 22)

$$R_j^2 = I, \quad j = 1, 2, \ldots, N \tag{B1}$$

implies that the characters $\chi \in X$ are functions such that

$$\chi(R_j) = e^{in_j\pi}, \quad n_j \in \mathbb{Z} \tag{B2}$$

for all $j = 1, 2, \ldots, N$. The group W_N acts on these characters by

$$(w\chi)(R) = \chi(w^{-1}Rw), \quad \forall\, w \in W_N, \chi \in X, R \in (\mathbb{Z}/2\mathbb{Z})^N. \tag{B3}$$

We now determine the orbits of the action of S_N in X, represented by a set χ_i where $i \in X/S_N$. Using the fact that the adjoint action of S_N permutes the reflections R_j, $T_{jk}R_jT_{jk} = R_k$ with T_{jk} the transposition interchanging j and k, we conclude that the orbits of S_N in X can be represented by the characters

$$\chi_k(R_j) = \begin{cases} 1, & j > k, \\ -1, & j \leqslant k, \end{cases} \tag{B4}$$

where $j, k = 1, 2, \ldots, N$. For each i let $(S_N)_i$ be that subgroup of S_N consisting of all $P \in S_N$ such that $P\chi_i = \chi_i$, and let further $\widetilde{W}_i = (\mathbb{Z}/2\mathbb{Z})^N \cdot (S_N)_i$. The structure of χ_i implies that $(S_N)_i = S_i \times S_{N-i}$. The character χ_i can be extended to all of $\widetilde{W}_i$ by setting

$$\chi_i(RP) = \chi(R), \quad R \in (\mathbb{Z}/2\mathbb{Z})^N,\ P \in (S_N)_i. \tag{B5}$$

Now let ρ_i be an irreducible representation of $(S_N)_i$ and combine it with the canonical projection $\widetilde{W}_i \to (S_N)_i$ to yield an irreducible representation $\widetilde{\rho}_i$ of $\widetilde{W}_i$. By taking the tensor product of χ_i and $\widetilde{\rho}_i$ we can now construct a set of irreducible representations $\chi_i \otimes \rho_i$ of $\widetilde{W}_i$. We denote the corresponding induced representation of the whole of W_N by θ_{i,ρ_i}. It follows from Proposition 25 in Ref. 26 that all irreducible representations of W_N are isomorphic to such a representation θ_{i,ρ_i}. In particular setting $i = 0$ and $i = N$ we arrive at the claim stated in the "Fact" at the beginning of the section.

APPENDIX C: PHYSICAL INTERPRETATION OF BOUNDARY CONDITIONS

In this appendix we substantiate the physical interpretations of the boundary conditions of the C_N models given in Secs. II and III in the main text.

1. Delta interaction

We first recall the eigenfunctions ψ of the one particle Hamiltonian in Eq. (1). Since this Hamiltonian is invariant under the reflection $x \to -x$ these eigenfunctions can be chosen such that $\psi(x) = \pm\psi(-x) \equiv \psi_\pm(x)$, and they can be computed using the ansatz

$$\psi_{\pm}(x) = \begin{cases} e^{-ikx} + A_{\pm}e^{ikx} & \text{for } x > 0, \\ \pm(e^{ikx} + A_{\pm}e^{-ikx}) & \text{for } x < 0, \end{cases} \tag{C1}$$

and the boundary conditions in Eq. (2) determine the constants $A_{\pm}$ as follows:

$$A_{+} = \frac{ik + c/2}{ik - c/2}, \quad A_{-} = -1 \tag{C2}$$

with A_{-} being independent of c corresponding to the fact that the delta interaction is trivial (i.e., invisible) for fermions. Obviously, these eigenfunctions obey

$$-\psi_{+}''(x) = k^2\psi_{+}(x) \quad \text{for } x > 0 \text{ and } \psi_{+}'(+0) = (c/2)\psi_{+}(+0) \tag{C3}$$

and

$$-\psi_{-}''(x) = k^2\psi_{-}(x) \quad \text{for } x > 0 \text{ and } \psi_{-}(+0) = 0, \tag{C4}$$

which is the simplest nontrivial case $N=1$ of the general relation between the C_N model and the A_{N-1} model discussed in Sec. II C.

We now show that these eigenfunctions $\psi_{\pm}(x)$ for $x>0$ are identical to the ones of the Hamiltonians,

$$H_{\pm} = -\partial_x^2 + V_0\Theta(-x) + g_{\pm}\delta(x), \tag{C5}$$

with

$$g_{+} = c/2 - \sqrt{V_0} \quad \text{and } g_{-} = 0 \tag{C6}$$

in the limit $V_0 \to \infty$. To show this we determine the eigenfunctions $\phi_{\pm}$ of $H_{\pm}$ with the ansatz

$$\phi_{\pm} = \begin{cases} e^{-ikx} + B_{\pm}e^{ikx} & \text{for } x > 0, \\ C_{\pm}e^{\omega x} & \text{for } x < 0, \end{cases} \tag{C7}$$

and by straightforward computations we find that

$$B_{\pm} = \frac{ik + (\omega + g_{\pm})}{ik - (\omega + g_{\pm})} \quad \text{and } \omega = \sqrt{V_0 - k^2} \tag{C8}$$

for $V_0 > k^2$. We thus see that

$$A_{\pm} = \lim_{V_0 \to \infty} B_{\pm} \tag{C9}$$

provided that $g_{\pm}$ are chosen as in Eq. (C6). This shows that the eigenfunctions ϕ_{+} of the Hamiltonian H_{+} on the full line in the limit $V_0 \to \infty$ become equal to $\psi_{+}(x)$ for $x>0$ (and zero otherwise), and similarly for ϕ_{-}, ψ_{-} and H_{-}.

This computation substantiates the physical interpretation of the C_N model in case $N=1$. However, since this interpretation only involves the boundary conditions at $x_j=0$ which are not affected by the interparticle interactions, this argument immediately generalizes to the $N>1$ particle case.

2. Local momentum dependent interaction

The discussion for the Hamiltonian in Eq. (4) is completely analogous to the one for the Hamiltonian in Eq. (1) given above, and we therefore only write down the formulas that change.

Equation (C1) determining the even and odd eigenfunctions $\psi_{\pm}$ remains the same but A_{+} and A_{-} are (essentially) interchanged,

$$A_+ = 1, \quad A_- = \frac{ik + 1/2\lambda}{ik - 1/2\lambda}, \tag{C10}$$

where now the boson eigenfunction is unaffected by the interaction. Moreover, these eigenfunctions solve the following problems on the half-axis:

$$-\psi_+''(x) = k^2\psi_+(x) \quad \text{for } x > 0 \text{ and } \psi_+'(+0) = 0 \tag{C11}$$

and

$$-\psi_-''(x) = k^2\psi_-(x) \quad \text{for } x > 0 \text{ and } \psi_-'(+0) = 2\lambda\psi_-(+0). \tag{C12}$$

The physical interpretation of these boundary conditions is provided by the following Hamiltonians with external fields:

$$H_\pm = -\partial_x^2 + V_0\Theta(-x) + \tilde{g}_\pm\partial_x\delta(x)\partial_x \tag{C13}$$

which has eigenfunctions as in Eq. (C7) but with

$$B_\pm = \frac{ik + \omega/(1 + \omega\tilde{g}_\pm)}{ik - \omega/(1 + \omega\tilde{g}_\pm)} \quad \text{and } \omega = \sqrt{V_0 - k^2}, \tag{C14}$$

which converge to $A_\pm$ for $V_0 \to \infty$ provided that, for example,

$$\tilde{g}_+ = \sqrt{V_0} \quad \text{and } \tilde{g}_- = 2\lambda. \tag{C15}$$

(Received 7 October 2004; accepted 18 January 2005; published online 6 April 2005)

The question of controllability is investigated for a quantum control system in which the Hamiltonian operator components carry explicit time dependence which is not under the control of an external agent. We consider the general situation in which the state moves in an infinite-dimensional Hilbert space, a drift term is present, and the operators driving the state evolution may be unbounded. However, considerations are restricted by the assumption that there exists an analytic domain, dense in the state space, on which solutions of the controlled Schrödinger equation may be expressed globally in exponential form. The issue of controllability then naturally focuses on the ability to steer the quantum state on a finite-dimensional submanifold of the unit sphere in Hilbert space—and thus on analytic controllability. A relatively straightforward strategy allows the extension of Lie-algebraic conditions for strong analytic controllability derived earlier for the simpler, time-independent system in which the drift Hamiltonian and the interaction Hamiltonian have no intrinsic time dependence. Enlarging the state space by one dimension corresponding to the time variable, we construct an augmented control system that can be treated as time independent. Methods developed by Kunita can then be implemented to establish controllability conditions for the one-dimension-reduced system defined by the original time-dependent Schrödinger control problem. The applicability of the resulting theorem is illustrated with selected examples. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1867979]

I. INTRODUCTION

Over the last two decades, quantum control has played an important part in theoretical and experimental progress toward the realization of laser control of chemical reactions and the development of quantum computers.[1–13] Essential to this contribution has been the integration of concepts and mathematical results from control engineering with the fundamental principles of quantum theory.

Geometric control, a treatment of differential equations rooted in differential geometry, unitary groups, and Lie algebras, provides a natural mathematical basis for quantum control theory. Explicitly or implicitly, its elements[14] pervade the manipulation of quantum states in both traditional and novel technologies. Indeed, the field of nuclear magnetic resonance (NMR) is largely

[a]Electronic mail: lancb@bc.edu; to whom correspondence should be addressed.
[b]Electronic mail: tarn@wuauto.wustl.edu
[c]Electronic mail: chi@math.wustl.edu
[d]Electronic mail: jwc@wuphys.wustl.edu

concerned with geometric control of collections of interacting nuclear spins.[12,15–17] Geometric control is also a key ingredient in the theory of quantum computation, figuring prominently in the works of Lloyd,[18] Deutsch, Barenco, and Ekert,[19] Akulin, Gershkovich, and Harel.[20]

In particular, Lloyd[18] was among the first to establish that almost all quantum logic gates are universal. More precisely, if one has available a gate that can operate on two qubits, plus a single-qubit operation, then an arbitrary unitary transformation on the variables of the system can be performed with arbitrary precision by implementing a finite sequence of local operations. Clark[21] and Ramakrishna *et al.*[22] and Ramakrishna and Rabitz[23] called attention to the close relationship between open-loop geometric quantum control methods and the application of quantum logic gates.[18,19]

Following Ref. 23, let us consider the differential system

$$\frac{\mathrm{d}X(t)}{\mathrm{d}t} = AX(t) + \sum_{i=1}^{m} B_i X(t) u_i(t), \quad X(0) = I, \tag{1}$$

which arises both in quantum computing and molecular control. Here, X is a $N \times N$ unitary matrix (I being the corresponding identity matrix), the matrices A and B_i, $i=1,\ldots,m$ are $N \times N$ skew-Hermitian, and the functions $u_i(t)$ are controls. This equation is the law of motion of the evolution operators which govern time development of the N-dimensional vector representing a pure state of the system in its N-dimensional Hilbert space. A necessary and sufficient condition for (1) to be controllable is that the set of all matrices generated by A, B_i, $i=1,\ldots,m$, and their commutators (i.e., the Lie algebra generated by A and B_i) equals the set of all $N \times N$ skew-Hermitian matrices. Additionally, when this condition is met, any X can be attained through some choice among the controls $u_i(t)$ restricted to piecewise-constant functions of time. In fact, the formulation adopted by Lloyd[18] in his universality proof corresponds to the special case $A=0$ and $m=2$ of system (1). Already in the 1970s, Sussmann and Jurdjevic[24,25] applied Lie-group theory to obtain rigorous results on controllability for finite-dimensional control problems corresponding to (1).

Quantum computation has mostly concerned itself with the manipulation of discrete systems with finite-dimensional state spaces. However, the fundamental quantum observables representing position and momentum, and functions thereof, are continuous in nature. In view of recent developments in quantum error correction[26–28] and quantum teleportation[29,30] of continuous variables, the potential of quantum computation over continuous variables warrants serious investigation, thus reopening issues of controllability on infinite-dimensional Hilbert spaces. Continuous quantum computers may in fact be able to perform some tasks more efficiently than their discrete counterparts.

As early as 1983, Huang, Tarn, and Clark (HTC)[5,31] proved a basic theorem on strong analytic controllability of quantum systems. This theorem explicitly embraces the case of quantum systems whose observables are continuous quantum variables acting on an infinite-dimensional state space, but the essential finite-dimensional results may be extracted as special cases. Because of the difficulties caused by infinite dimensionality and the unboundedness of operators, an analytic domain in the sense of Nelson[32] was introduced to deal with domain problems[5,31] and maintain key features of the application of Lie algebraic methods to finite-dimensional problems.

Infinite-dimensional control systems have been widely if not systematically studied outside the quantum context. Brockett[14] addressed the problem of realization of infinite-dimensional bilinear systems. Sakawa[33] introduced a method for design of finite-dimensional $\mathcal{H}_\infty$ controllers for diffusion systems with bounded input and output operators by using residual model filters. Keulen[34] designed infinite-dimensional $\mathcal{H}_\infty$ controllers for infinite-dimensional systems with bounded input and output operators by using the solutions to two kinds of Riccati equations in an infinite-dimensional space. Based on gap topology, Morris[35] constructed finite-dimensional $\mathcal{H}_\infty$ controllers for infinite-dimensional systems with bounded input and output operators. Morris[36] also showed that approximations of Galerkin type can be used to design controllers for an infinite-dimensional system. Costa and Kubrusly[37] derived necessary and sufficient conditions for existence of a state feedback controller that stabilizes a discrete-time infinite-dimensional stochastic

bilinear system and ensures that the influence of the additive disturbance on the output is smaller than some prescribed bound. In Ref. 38, optimizability and estimatability for infinite-dimensional linear systems are investigated; also, a theorem on the equivalence of input-output stability and exponential stability of well-posed infinite-dimensional linear systems is established. In Ref. 39, the Hilbert-space generalization of the circle criterion is used for finite-dimensional controller design of unstable infinite-dimensional systems. There is also literature on absolute stability problems and open-loop stability problems in infinite-dimensional systems.[40–44] In addition, the spectral factorization problem plays a central role in designing feedback control for the linear quadratic optimal control problem in infinite-dimensional state-space systems.[45–48] In contrast to this body of work, very little has been published on controllability for time-dependent infinite-dimensional quantum control systems.

In the microscopic world ruled by quantum mechanics, most interesting phenomena involve change, and all real-world quantum systems are influenced to a greater or lesser extent by interactions with their environments. The environment changes with time, so the Hamiltonians used to describe these open quantum systems are explicitly time dependent, as in Refs. 49 and 50. Tailored time-dependent perturbations are used to improve system performance[49] in high-resolution NMR spectroscopy, where versatile decoupling techniques are available to manipulate the overall spin Hamiltonian.[16] Colegrave and Abdalla studied quantum systems with a time-dependent mass to investigate the field intensities in a Fabry–Perot cavity.[51] They suggested possible applications to solid-state physics and quantum field theory.[52] Remaud and Hernandez[53] found that a time-dependent mass parameter offers a means of simulating input or removal of energy from the system. Implementation of controls on these time-dependent quantum systems requires guidance from mathematical studies of controllability for time-dependent Hamiltonian operators. Although the HTC theorem deals with controllability in infinite-dimensional Hilbert space, it is restricted to time-independent operators. This paper explores a more general case. We seek an extension of the HTC theorem that is applicable both to time-independent and time-dependent quantum systems, as well as to systems with discrete or continuous operators acting on finite- or infinite-dimensional state spaces.

Since this paper is aimed at an interdisciplinary readership that includes pure quantum theorists as well as control engineers, it is well to draw a clear distinction between time dependence of the system arising solely from influences that are directly under the control of an external, purposeful agent, and time dependence that is intrinsic to the physical system either in isolation or as embedded in a natural environment. In the accepted terminology of control theory, which we adopt, the former case defines a time-independent control system, and the latter, a time-dependent system. The issue of controllability has received considerable attention in the time-independent situation so identified (e.g., in Refs. 5, 8, 12, and 22); whereas relevant results for the time-dependent case are very limited.

The time-dependent quantum control problem that we shall address is stated formally in Sec. II. To cope with the unboundedness of operators involved in the Schrödinger equation, an analytic domain is introduced in Sec. III, such that solutions of the Schrödinger equation can be expressed globally in exponential form on this domain. In Sec. IV, we define an augmented system in a space enlarged by one dimension, enabling its description within the framework of time-independent control systems. Following the pattern of Kunita's proof[54] of strong controllability of a time-independent system, we then establish conditions for controllability of this kind for the one-dimension-reduced system defined by the original time-dependent Schrödinger equation. Three illustrative applications of the theorem are presented in Sec. V, and our findings are reviewed in Sec. VI.

II. PROBLEM FORMULATION

The following quantum control system is derived by applying the geometric quantization method[55] to a classical bilinear control system:[31,56]

$$i\hbar\frac{\partial}{\partial t}\psi(t) = \left[H_0'(t) + \sum_l u_l(t)H_l'(t)\right]\psi(t),$$
$$\psi(t_0) = \psi_0. \tag{2}$$

Here, $H_0'(t)$, and the $H_l'(t)$ with $l=1,2,\ldots,r$, are Hermitian operators on a unit sphere $S_{\mathcal{H}}$ of Hilbert space, the $u_l(t)$, $l=1,\ldots,r$ are restricted to piecewise-constant real functions of time, and $\psi(t)$ denotes a quantum state belonging to $S_{\mathcal{H}}$. In physical language, H_0' is the unperturbed or autonomous Hamiltonian, and the H_l' are interaction Hamiltonians. It is the coefficients $u_l(t)$ that are subject to purposeful control by an agent external to the system, within the specified class of functions. Setting $\hbar=1$ and dividing $H_0'(t)$ and the $H_l'(t)$ by i, we arrive at a more familiar control form,

$$\frac{\partial}{\partial t}\psi(t) = \left[H_0(t) + \sum_l u_l(t)H_l(t)\right]\psi(t),$$
$$\psi(t_0) = \psi_0 \in S_{\mathcal{H}}, \tag{3}$$

where the $H_i(t)$, $i=0,1,2,\ldots,r$, are skew-Hermitian operators on $S_{\mathcal{H}}$. From the standpoint of systems engineering, $H_0(t)$ is called the drift term in Eq. (3) because no control function directly modifies its action. Importantly, we depart from previous studies of quantum controllability in allowing the Hamiltonian operators $H_i(t)$ to their own carry explicit time dependence, which is assumed to be inherent in the physical structure of the system and therefore beyond the control of any external agent. The operators $H_i(t)$ are the counterparts of the structural matrices involved in standard formulations of linear control theory.

For the system (3), we know from arguments presented in Ref. 5 that the transitivity of states on $S_{\mathcal{H}}$ requires an infinite sequence of control manipulations within the control set $\{u_l(t)\}$ of piecewise-constant real functions. Clearly, such a process is strictly meaningless in practice, although under certain conditions it may be possible to find a finite series of control operations that approach the desired target state arbitrarily closely. Even so, we are naturally directed to consider the issue of controllability on a *finite-dimensional* submanifold of the unit sphere $S_{\mathcal{H}}$, for which in turn a finite-dimensional tangent space is generated by $H_0(t)\psi(t),\ldots,H_r(t)\psi(t)$.

Accordingly, our attention focuses on a finite-dimensional submanifold $M\subset S_{\mathcal{H}}$, on which the following dynamics prevail:

$$\frac{\partial}{\partial t}\psi(t) = \left[H_0(t) + \sum_l u_l(t)H_l(t)\right]\psi(t),$$
$$\psi(t_0) = \psi_0, \quad \psi(t) \in M, \quad \forall\, t \geqslant t_0. \tag{4}$$

Thus, instead of studying controllability on $S_{\mathcal{H}}$, we consider controllability on $M\subset S_{\mathcal{H}}$. On the submanifold M, the inherited topology of $S_{\mathcal{H}}$ still applies; hence it is paracompact and connected.

For system (4), we have available a set of vector fields $O(M)$ composed of skew-Hermitian operators on M with Lie algebra defined by $O(M)=\mathcal{L}\{H_0,\ldots,H_r\}$. Let V be a subset of $O(M)$. The Lie algebra generated by V is denoted by $\mathcal{L}(V)$. The restriction of $\mathcal{L}(V)$ to a point ψ on M, which is a tangent subspace of TM_ψ at ψ, is written as

$$\mathcal{L}(V)(\psi) = \{Y(\psi)\,|\,Y \in \mathcal{L}(V)\} \subset TM_\psi, \tag{5}$$

while

$$\tilde{\mathcal{L}}(V) = \{\mathcal{L}(V)(\psi) | \psi \in M\} \tag{6}$$

defines an involutive differential system. A vector field X is said to belong to $\tilde{\mathcal{L}}(V)$ if $X(\psi) \in \tilde{\mathcal{L}}(V)(\psi)$ holds for all $\psi \in M$.

III. SELECTING THE DOMAIN

Recognizing that operators in quantum mechanics are in general unbounded, we need to find a domain on which exponentiations of the operators entering the system (4) converge. To this end, we introduce the so-called analytic domain conceived by Nelson,[32] a dense domain invariant under the action of the operators in system (3). The solution of the Schrödinger equation can be expressed globally in exponential form on this domain, which is also invariant under the action of the exponentiations of the operators H_i.

Definition III.1: If H is an operator on the state space $\mathcal{H}$, we call an element ω of $\mathcal{H}$ an analytic vector for H in case the series expansion of $\exp(Ht)\omega$ *has a positive radius of absolute convergence, that is, provided*

$$\sum_{n=0}^{\infty} \frac{\|H^n \omega\|}{n!} s^n < \infty \tag{7}$$

for some $s > 0$.

If H is a bounded operator, then every vector in $\mathcal{H}$ is trivially an analytic vector for H.

The corresponding definition of analytic vectors for a Lie algebra of operators runs as follows.[32,57]

Definition III.2: A vector $\omega \in \mathcal{H}$ is said to be an analytic vector for the whole Lie algebra $\mathcal{L}$ if for some $s > 0$ and some linear basis $\{H_1, \ldots, H_d\}$ of the Lie algebra, the series

$$\sum_{n=0}^{\infty} \frac{1}{n!} \sum_{1 \leqslant i_1, \ldots, i_n \leqslant d} \|H_{i_1} \cdots H_{i_n} \omega\| s^n \tag{8}$$

is absolutely convergent.

The concept of analytic vectors is especially useful for our purposes, since for certain types of unbounded operators they form a dense set in the Hilbert space. In fact, the set of all analytic vectors for a Lie algebra $\mathcal{L}$ forms an analytic domain in the following sense.[32,57]

Definition III.3: Let $\mathcal{L}$ be the Lie algebra generated by the skew-Hermitian operators $H_0, \ldots, H_r$ on a unit sphere $S_{\mathcal{H}}$ of Hilbert space. An analytic domain $\mathcal{D}_A$ is said to exist for the H_i, $i = 0, 1, \ldots r$, if (i) there exists a common dense invariant subspace $\mathcal{D}_A \subset \mathcal{H}$ on which the corresponding unitary Lie group G can be expressed locally in exponential form with Lie algebra $\mathcal{L}$, (ii) $\mathcal{D}_A$ is invariant under G and *$\mathcal{L}$, and (iii) on $\mathcal{D}_A$, elements of G can be extended globally to all $t \in \mathbb{R}^+$.*

We now state Nelson's fundamental theorem, which provides conditions under which a Lie algebra $\mathcal{L}$ defined by a set of skew-Hermitian operators can be associated with a unitary group G having $\mathcal{L}$ as its Lie algebra.

Theorem III.1: (Nelson) Let $\mathcal{L}$ be a Lie algebra of skew-Hermitian operators in a Hilbert space $\mathcal{H}$ which have a common invariant dense domain $\mathcal{D}_A$. Let $X_1, \ldots, X_d$ be an operator basis for $\mathcal{L}$. If $T = X_1^2 + \cdots + X_d^2$ is essentially self-adjoint, then there is a unique unitary group G in $\mathcal{H}$ with Lie algebra $\mathcal{L}$. Let $\overline{T}$ denote the unique self-adjoint extension of T. Then the analytic vectors of $\overline{T}$ are analytic vectors for the whole Lie algebra $\mathcal{L}$ and form a set invariant under G and dense in $\mathcal{H}$.

Accordingly, on the analytic domain $\mathcal{D}_A$, the Lie algebra and its unitary Lie group are related through the familiar exponential formula. The Lie algebra is composed of skew-Hermitian operators which are vector fields defined on $\mathcal{D}_A \cap S_{\mathcal{H}}$. By property (iii) of the Definition III.3 of the analytic domain, these vector fields on $\mathcal{D}_A \cap S_{\mathcal{H}}$ are complete. Moreover, owing to the skew-

Hermiticity of the operators H_i of system (3), the corresponding transformation groups, taking a given state on $S_{\mathcal{H}}$ to another state on $S_{\mathcal{H}}$, are unitary. This feature guarantees preservation of the norm of quantum states, as required for the statistical interpretation of quantum mechanics.

In fact, Nelson's theorem only provides sufficient conditions for the important properties it yields. With this in mind, we shall assume an analytic domain $\mathcal{D}_A$ exists *without* explicitly imposing the conditions stated in this theorem, a stance also adopted in Ref. 5. This strategy clearly implies that the existence of such a domain must be established explicitly prior to application of the controllability results to be derived in the following sections.

We are now prepared to adapt the concept of controllability to problems involving unbounded operators.

Definition III.4: For system (3), if $\mathcal{D}_A$ exists for $\mathcal{L}$, and if for any ψ_0 and $\psi_f \in \mathcal{D}_A \cap S_{\mathcal{H}}$ there exist control functions $u_1(t), \ldots, u_r(t)$, and a time t_f (respectively, $\forall t_f$) such that the solution of control system (3) satisfies $\psi(t_0)=\psi_0$, $\psi(t_f)=\psi_f$, and $\psi(t) \in \mathcal{D}_A \cap S_{\mathcal{H}}$, where $t_0 \leqslant t \leqslant t_f$, then the system is called analytically controllable (*respectively strongly analytically controllable*) *on $S_{\mathcal{H}}$; moreover we then say that the corresponding unitary Lie group is analytically transitive on $S_{\mathcal{H}}$.*

As has been argued, the more pertinent concept is controllability on the submanifold M of $S_{\mathcal{H}}$. By assumption, $M \cap \mathcal{D}_A$ is dense in M, while $\dim(M \cap \mathcal{D}_A) = \dim M = m$. Denoting the tangent space of $M \cap \mathcal{D}_A$ at ψ by $TM_\psi = \mathcal{L}\{H_0, \ldots, H_r\}(\psi)$, the tangent bundle of the system (4) is given by $T(M \cap \mathcal{D}_A) = \cup_{\psi \in M \cap \mathcal{D}_A} TM_\psi$.

Let $R_t(\psi)$ denote the set of all points that are reachable from ψ at time t. The set $R(\psi) = \cup_{t>t_0} R_t(\psi)$ is then reachable from ψ at some time greater than t_0. We say that system (4) is analytically controllable on M if $R(\psi) = M \cap \mathcal{D}_A$, $\forall\, \psi \in M \cap \mathcal{D}_A$, and that the system is strongly analytically controllable on M if $R_t(\psi) = M \cap \mathcal{D}_A$, $\forall\, t > t_0$, $\forall\, \psi \in M \cap \mathcal{D}_A$.

IV. CONTROLLABILITY OF TIME-DEPENDENT QUANTUM CONTROL SYSTEMS

A. Reformulation as a time-independent augmented system

Most of the methods developed for determining controllability of time-independent bilinear or nonlinear systems[5,31,58–61] cannot be applied directly to the time-dependent bilinear control problem studied here, since these approaches rely upon the following property. Let $Y_t(\varphi)$ be an integral curve of the time-independent tangent vector Y starting from point φ and $t \in [t_0, t_0 + t_f]$, and let $cY_t(\varphi)$ be an integral curve of the tangent vector cY starting from φ and $t \in [t_0, t_0 + t_f/|c|]$; then the integral curves $Y_t(\varphi)$ and $cY_t(\varphi)$ coincide. This property holds for all time-independent tangent vectors, but it generally fails for time-dependent tangent vectors.

However, recognizing that this feature has been instrumental to controllability proofs for nonlinear systems, we recast the system (4) as a time-independent problem so that it can once again be exploited. Reformulation of the original problem is accomplished by regarding the time variable t as an additional parameter in the specification of the system state, supplementing the state vector ψ. Thus the state of the extended system is expressed as

$$\xi = \begin{pmatrix} t + t_0 \\ \psi \end{pmatrix}. \tag{9}$$

Making the corresponding extension of the manifold M, we form an augmented $(m+1)$-dimensional manifold defined by

$$N = \begin{Bmatrix} \mathbb{R} \\ M \cap \mathcal{D}_A \end{Bmatrix}, \tag{10}$$

where $\mathbb{R}$ is the real line. Next we define augmented vector fields W_l by

$$W_0(\xi) = \begin{bmatrix} 1 \\ H_0(t + t_0)\psi(t + t_0) \end{bmatrix},$$

$$W_l(\xi) = \begin{bmatrix} 0 \\ H_l(t+t_0)\psi(t+t_0) \end{bmatrix}, \tag{11}$$

with $l=1,2,\ldots,r$. Obviously, the W_l, with $l=0,1,\ldots,r$, depend on both t and ψ, i.e., the W_l now depend on the state ξ defined by Eq. (9).

The time-dependent control system (4) has thereby been reformulated as an augmented system of time-independent form. Explicitly,

$$\frac{\partial \xi(t)}{\partial t} = \left[W_0(\xi) + \sum_l u_l(t) W_l(\xi) \right],$$

$$\xi(0) = \eta = \begin{pmatrix} t_0 \\ \psi(t_0) \end{pmatrix} = \begin{pmatrix} t_0 \\ \psi_0 \end{pmatrix}, \tag{12}$$

$$\forall t \geqslant 0, \quad \psi_0 \in M \cap \mathcal{D}_A, \quad \xi \in N,$$

where N is the $n=(m+1)$-dimensional manifold constructed in Eq. (10) and M is now viewed as a one-dimension-reduced manifold of the augmented system. As always, the controls $u_l(t)$, with $l=1,\ldots,r$, are piecewise-constant real functions of time t.

It is convenient to employ $t+t_0$ instead of t in definitions (9) and (11), thereby setting the starting time at zero for the augmented system (12). Since the latter system is time-independent by construction, this can be done without affecting its trajectory. Thus, if the time for the augmented system is t, then the time for the original system (4) is $t+t_0$. Standard differential equation techniques can evidently be employed to analyze the behavior of the augmented system on the manifold N, and the results will reflect the behavior of the original system on manifold M.

We note peripherally that system (12) is in a decomposed form in the sense of Ref. 59, where several theorems were developed for decomposition of nonlinear control systems. However, these theorems do not specify reachable sets, so they cannot be applied here to obtain controllability results.

Reachable sets $\hat{R}_t(\eta)$ and $\hat{R}(\eta)$ are defined for the augmented system (12) in just the same manner as for system (4). From the work of Huang, Tarn, and Clark[5] based on the results of Chow,[62] Sussmann and Jurdjevic,[24] and Kunita,[54,58] it is to be expected that the issue of analytic controllability will hinge on the relationships among certain Lie algebras generated by the vector fields involved in the control system (4) or its augmented counterpart (12). For the latter problem, these Lie algebras are specified by $\hat{\mathcal{A}}=\mathcal{L}\{W_0,\ldots,W_r\}$, $\hat{\mathcal{B}}=\mathcal{L}\{W_1,\ldots,W_r\}$, and $\hat{\mathcal{C}}=\mathcal{L}\{\mathrm{ad}^m_{W_0}W_l, l=1,\ldots,r, m=0,\ldots,\infty\}$. By definition, $\mathrm{ad}^m_{W_0}W_l$ is built from repeated commutators of W_0, present in $\hat{\mathcal{A}}$ but not $\hat{\mathcal{B}}$, with any and all of the W_l present in $\hat{\mathcal{A}}$ or $\hat{\mathcal{B}}$; clearly,

$$\hat{\mathcal{B}} \subset \hat{\mathcal{C}} \subset \hat{\mathcal{A}}. \tag{13}$$

For future reference we note (in particular) that the restriction of $\hat{\mathcal{B}}$ to a point ψ on N, which is a tangent subspace of TN_ψ at ψ, is written as

$$\hat{\mathcal{B}}(\psi) = \{Y(\psi) | Y \in \hat{\mathcal{B}}\} \subset TN_\psi, \tag{14}$$

and in turn that

$$\widetilde{\hat{\mathcal{B}}} = \{\hat{\mathcal{B}}(\psi) | \psi \in N\} \tag{15}$$

is an involutive differential system.

B. Controllability of the augmented system

We must still face the situation that standard controllability results,[5,31,58–61] derived for time-independent systems, cannot be carried over directly to our problem as reformulated in the preceding section, since derivation of these results employs the vector-space property of the tangent space. Specifically, it is required that if Y is an acceptable tangent vector, then so is cY, where c is an arbitrary constant. But in our case, once the first component of a tangent vector of the augmented manifold is fixed at unity, it is not possible for both Y and cY, with $c \neq 1$, to be available tangent vectors. However, with the aid of a result of Kunita,[54] we may nevertheless establish one-dimension-reduced controllability of the augmented system; that is, we may prove strong analytic controllability of the original system since it is not necessary to control the time dimension.

First, let us identify certain properties of the reachable set $\hat{R}_t(\eta)$ that will be useful in proving strong analytic controllability.

Theorem IV.1: (References 24 and 25) *Assume that the Lie algebra $\hat{C}$ is locally finitely generated, and let $I(\eta)$ be the maximal connected integral manifold of $\hat{C}$ containing the point η. Then $\hat{R}_t(\eta) \subset \alpha_t^0(I(\eta))$, where α_t^0 is the integral curve whose vector field is W_0. Furthermore, the interior of $\hat{R}_t(\eta)$ with respect to the topology of $\alpha_t^0(I(\eta))$ is dense in $\hat{R}_t(\eta)$.*

In the rest of this section, we systematically develop the principal result of the paper, namely, under suitable conditions the reachable set of the augmented system (12) at time t, $\hat{R}_t(\eta)$, is equal to $\alpha_t^0(I(\eta))$. We begin by establishing a key relationship between the interior of the reachable set $\hat{R}_t(\eta)$ of the augmented system at time t and the interior of its closure, through the following lemma.

Lemma IV.2:

$$\text{int}(\text{cl}\,\hat{R}_t(\eta)) = \text{int}\,\hat{R}_t(\eta). \tag{16}$$

Proof: Let $\chi \in \text{int}(\text{cl}\,\hat{R}_t(\eta))$ and let $S_\epsilon(\chi)$ be the set of all χ' such that χ is reachable from χ' within time $\epsilon > 0$. Then $S_\epsilon(\chi)$ is the reachable set within time $\epsilon > 0$ for the dual control system

$$\frac{\partial v}{\partial t} = -\left[W_0(v) + \sum_l u_l(t) W_l(v) \right]. \tag{17}$$

Theorem IV.1 implies that $\text{int}\,S_\epsilon(\chi)$ is dense in $\text{cl}\,S_\epsilon(\chi)$, and $\text{int}\,\hat{R}_t(\eta)$ is dense in $\text{cl}\,\hat{R}_t(\eta)$. Since $\chi \in \text{cl}\,S_\epsilon(\chi)$, we know that

$$\text{cl}\,S_\epsilon(\chi) \cap \text{int}(\text{cl}\,\hat{R}_t(\eta)) \neq \varnothing \tag{18}$$

and hence that

$$\text{int}\,S_\epsilon(\chi) \cap \text{int}(\text{cl}\,\hat{R}_t(\eta)) \cap \hat{R}_t(\eta) \neq \varnothing\,. \tag{19}$$

If ζ belongs to the latter intersection, then ζ is reachable from η using time t, and χ is reachable from ζ in elapsed time less than or equal to ϵ. Therefore, χ is reachable from η in elapsed time between t and $t+\epsilon$. This argument holds for any $t > 0$ and any $\epsilon > 0$. Letting $\epsilon \to 0$, we conclude that χ is reachable from η in time t, so $\chi \in \hat{R}_t(\eta)$. Thus,

$$\text{int}(\text{cl}\,\hat{R}_t(\eta)) \subset \hat{R}_t(\eta) \Rightarrow \text{int}(\text{cl}\,\hat{R}_t(\eta)) \subset \text{int}\,\hat{R}_t(\eta).$$

But clearly $\text{int}\,\hat{R}_t(\eta) \subset \text{int}(\text{cl}\,\hat{R}_t(\eta))$ and the statement (18) follows.

From the control-theoretic perspective, the drift term is undesirable because no control is present to influence or remove its effect. It is therefore of strategic value to consider a suitably modified control system, called the auxiliary system, that will serve as a bridge to an effective controllability analysis of the augmented system. Let $e_0, e_1, \ldots, e_r$ be unit vectors in $\mathbb{R}^{r+1}$; in

particular, let $e_i=(0,\ldots,0,1,0,\ldots,0)$, in which only the $(i+1)$th element is unity and the others are zero. Denote by $\mathcal{U}_0$ the set of controls $u(t)=(u_0(t),\ldots,u_r(t))$ composed of piecewise-constant functions $u_i(t)$ taking the values $e_0,\pm e_1,\ldots,\pm e_r$ only. Consider then the control system expressed in the form

$$\frac{\partial \xi}{\partial t} = u_0(t)W_0(\xi) + \sum_l u_l(t)W_l(\xi), \quad \xi(t_0) = \eta, \tag{20}$$

where $u(t)\in\mathcal{U}_0$. The solution of this system may be written as

$$\alpha_t = \alpha_{t_k}^{i_k}\cdots\alpha_{t_j}^{i_j}\cdots\alpha_{t_1}^{i_1}, \tag{21}$$

where k is a positive integer and where $\alpha_{t_j}^{i_j}$ is the integral curve of W_{i_j} with $i_j=0,1,\ldots,r$, $j=1,\ldots,k$, and k a positive integer. The times t_j satisfy $t_j\geqslant 0$ if $i_j=0$, otherwise, $t_j\in\mathbb{R}$. We denote by $\hat{R}_t^0(\eta)$ the reachable set of the auxiliary system corresponding to the total time t since time zero, over which the control function $u_0(\cdot)$ is nonzero; the reachable set of the auxiliary system is then $\hat{R}^0(\eta)=\cup_{t>0}\hat{R}_t^0(\eta)$. Theorem IV.1 is valid for this control system.[24]

The following notations are convenient:

Exp $\hat{\mathcal{L}}$=the group of diffeomorphisms generated by the α_t^i, $t\in\mathbb{R}$, $i=0,\ldots,r$, where α_t^i is an integral curve of W_i,

$(\text{Exp}\,\hat{\mathcal{L}})_+$=the semigroup of diffeomorphisms generated by α_t^0, $t\geqslant 0$, and the α_t^l, with $t\in\mathbb{R}$ and $l=1,\ldots,r$,

$(\text{Exp}\,\hat{\mathcal{L}})_t$=the subset of $(\text{Exp}\,\hat{\mathcal{L}})_+$ generated by $\alpha_{t_k}^{i_k}\cdot\cdots\cdot\alpha_{t_1}^{i_1}$, with $\Sigma_{j=1}^k t_j\cdot 1_{\{i_j=0\}}=t$.

To clarify the meaning of the last line, we note that when the index j is such that $i_j=0$, we have $u_0=1$ (and all the other $u_i=0$), so W_0 is "turned on" and does play a role as an active vector field or tangent vector. Conversely, for indices j such that $i_j\neq 0$, the factor u_0 multiplying W_0 in system (20) vanishes, and W_0 plays no role. The sum appearing in the definition of $(\text{Exp}\,\hat{\mathcal{L}})_t$ gives the total time over which W_0 is active in the system dynamics.

From Chow's theorem,[24,62] it is known that the group Exp $\hat{\mathcal{L}}$ acts transitively on the manifold N when $\dim\hat{\mathcal{L}}\{W_0,W_1,\ldots,W_r\}=\dim N$, i.e., we know that $\{\alpha(\eta)\,|\,\alpha\in\text{Exp}\,\hat{\mathcal{L}}\}=N$ for any $\eta\in N$. On the other hand, the reachable set at time t for the auxiliary system (20) is $\hat{R}_t^0(\eta)=\{\alpha(\eta)\,|\,\alpha\in(\text{Exp}\,\hat{\mathcal{L}})_t\}$. (It is to be noted that in the present context t is the total time over which W_0 has been active since time zero, which is generally not equal to the actual elapsed time, since W_0 may be turned off over certain intervals.)

Lemma IV.3:

$$\text{cl}\,\hat{R}_t(\eta) = \text{cl}\,\hat{R}_t^0(\eta). \tag{22}$$

We may gain intuitive understanding of this lemma by analyzing a simple example.

Example: Let us compare the control system

$$\frac{d}{dt}\begin{pmatrix}x\\y\end{pmatrix} = \begin{pmatrix}1\\0\end{pmatrix} + u\begin{pmatrix}0\\1\end{pmatrix}, \tag{23}$$

wherein $u\in\mathbb{R}$, with the system

$$\frac{d}{dt}\begin{pmatrix}x\\y\end{pmatrix} = u_0\begin{pmatrix}1\\0\end{pmatrix} + u_1\begin{pmatrix}0\\1\end{pmatrix}, \tag{24}$$

wherein $(u_0,u_1)\in\{(0,\pm 1),(1,0)\}$. Clearly, the first of these corresponds to the augmented system, and the second to the auxiliary system. Let $\hat{R}_t(\eta)$ and $\hat{R}_t^0(\eta)$ denote, respectively, the reachable sets of systems (23) and (24), starting from the state η. While stopping short of rigorous argument,

explicit computation will be used to reveal the pertinent relationship between $\mathrm{cl}\,\hat{R}_t(\eta)$ and $\mathrm{cl}\,\hat{R}_t^0(\eta)$.

First consider the integral curve

$$\alpha_t(\eta) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}_{t_1} \cdot \begin{pmatrix} 0 \\ -1 \end{pmatrix}_{t_2} \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t} \in \hat{R}_t^0(\eta), \tag{25}$$

and for $n=1,2,3,\ldots$ form a series of integral curves $\beta_t^n(\eta) \in \hat{R}_t(\eta)$ defined by

$$\beta_t^n(\eta) = \left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + n\begin{pmatrix} 0 \\ 1 \end{pmatrix}\right)_{t_1/n} \cdot \left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + n\begin{pmatrix} 0 \\ -1 \end{pmatrix}\right)_{t_2/n} \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t-(t_1/n)-(t_2/n)}. \tag{26}$$

As n goes to ∞, we find

$$\beta_t^n(\eta) \to \begin{pmatrix} 0 \\ 1 \end{pmatrix}_{t_1} \cdot \begin{pmatrix} 0 \\ -1 \end{pmatrix}_{t_2} \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t}, \tag{27}$$

that is, $\beta_t^n(\eta) \to \alpha_t(\eta)$. Hence $\alpha_t(\eta) \in \mathrm{cl}\,\hat{R}_t(\eta)$.

On the other hand, consider

$$\beta_t(\eta) = \left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + m_1\begin{pmatrix} 0 \\ 1 \end{pmatrix}\right)_{t_1} \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t_2} \cdot \left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + m_2\begin{pmatrix} 0 \\ -1 \end{pmatrix}\right)_{t_3} \in \hat{R}_t(\eta), \tag{28}$$

where m_1, $m_2 \in \mathbb{R}$ and $t=t_1+t_2+t_3$, and construct

$$\alpha_1^n = \left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t_1/n} \cdot m_1\begin{pmatrix} 0 \\ 1 \end{pmatrix}_{t_1/n}\right]^n, \tag{29}$$

again for $n=1,2,3,\ldots$. Applying the Baker–Campbell–Hausdorff formula, it is straightforward to show that

$$\lim_{n\to\infty} \alpha_1^n = \lim_{n\to\infty}\left\{\left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + m_1\begin{pmatrix} 0 \\ 1 \end{pmatrix}\right)_{t_1} + \frac{t_1^2}{2n} m_1\left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix}\right] + O\left(\frac{1}{n^2}\right)\right\} = \left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + m_1\begin{pmatrix} 0 \\ 1 \end{pmatrix}\right)_{t_1}. \tag{30}$$

Similarly, let

$$\alpha_3^n = \left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t_3/n} \cdot m_2\begin{pmatrix} 0 \\ -1 \end{pmatrix}_{t_3/n}\right]^n \tag{31}$$

and employ the Baker–Campbell–Hausdorff formula to obtain

$$\lim_{n\to\infty} \alpha_3^n = \lim_{n\to\infty}\left\{\left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + m_2\begin{pmatrix} 0 \\ -1 \end{pmatrix}\right)_{t_3} + \frac{t_3^2}{2n} m_2\left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ -1 \end{pmatrix}\right] + O\left(\frac{1}{n^2}\right)\right\} = \left(\begin{pmatrix} 1 \\ 0 \end{pmatrix} + m_2\begin{pmatrix} 0 \\ -1 \end{pmatrix}\right)_{t_3}. \tag{32}$$

Obviously

$$\alpha_1^n \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix}_{t_2} \cdot \alpha_3^n \in \hat{R}_t^0(\eta), \tag{33}$$

and we find that

$$\lim_{n\to\infty} \alpha_1^n\left(\begin{pmatrix}1\\0\end{pmatrix}_{t_2}\right)\alpha_3^n = \left(\left(\begin{pmatrix}1\\0\end{pmatrix} + m_1\begin{pmatrix}0\\1\end{pmatrix}\right)_{t_1} \cdot \begin{pmatrix}1\\0\end{pmatrix}_{t_2} \cdot \left(\begin{pmatrix}1\\0\end{pmatrix} + m_2\begin{pmatrix}0\\-1\end{pmatrix}\right)_{t_3} = \beta_t(\eta). \tag{34}$$

Therefore $\beta_t(\eta) \in \mathrm{cl}\,\hat{R}_t^0(\eta)$.

Now let us proceed with the proof of Lemma IV.3, showing first that $\mathrm{cl}\,\hat{R}_t^0(\eta) \subseteq \mathrm{cl}\,\hat{R}_t(\eta)$. Consider that $\alpha_t(\eta) \in \hat{R}_t^0(\eta)$ is expressible in the form of $\alpha_{t_k}^{i_k} \cdots \alpha_{t_1}^{i_1}(\eta)$, where $t = \Sigma_{j=1}^k t_j \cdot 1_{\{i_j=0\}}$. With the guidance of the example above, a sequence of controls $u^{(n)}(\cdot)$ associated with the diffeomorphism of this form is constructed as follows. For an arbitrary positive integer n such that $nt_m \geqslant \Sigma_{i_j\neq 0}|t_j|$, where m is the last subscript j such that $i_j = 0$, let

$$t_m^{(n)} = t_m - \frac{\sum_{i_j\neq 0}|t_j|}{n}. \tag{35}$$

Define real numbers $s_1^{(n)}, \ldots, s_k^{(n)}$, ordered so that $0 \leqslant s_1^{(n)} \leqslant s_2^{(n)} \leqslant \cdots \leqslant s_k^{(n)}$, by

$$\begin{aligned} s_1^{(n)} &= |t_1| \quad \text{if } i_1 = 0, \\ &= \frac{1}{n}|t_1| \quad \text{if } i_1 \neq 0, \\ s_{j\geqslant 2}^{(n)} &= s_{j-1}^{(n)} + |t_j^{(n)}| \quad \text{if last } j \text{ with } i_j = 0, \\ &= s_{j-1}^{(n)} + |t_j| \quad \text{if other } j \text{ with } i_j = 0, \\ &= s_{j-1}^{(n)} + \frac{1}{n}|t_j| \quad \text{if } i_j \neq 0. \end{aligned} \tag{36}$$

Further, let

$$\begin{aligned} u^{(n)}(\tau) &= n \cdot \mathrm{sgn}(t_j) e_{i_j} \quad \text{if } s_{j-1}^{(n)} \leqslant \tau \leqslant s_j^{(n)} \text{ and } i_j \neq 0, \\ &= 0 \quad \text{if } s_{j-1}^{(n)} \leqslant \tau \leqslant s_j^{(n)} \text{ and } i_j = 0, \\ &= 0 \quad \text{if } \tau \geqslant s_k^{(n)}, \end{aligned} \tag{37}$$

where $e_1, \ldots, e_r$ are unit vectors in $\mathbb{R}^r$. The solution $\beta_t^{(n)}$ of the system (12) associated with the control $u^{(n)}(\cdot)$ may be written

$$\beta_{s_k^{(n)}}^{(n)} = \beta_{|t_k|}^{n,i_k} \cdots \beta_{|t_1|}^{n,i_1} \in \hat{R}_t(\eta), \tag{38}$$

where $\beta_{|\tau|}^{n,i_j}$ is the integral curve of W_0 if $i_j = 0$, or the integral curve of $W_0 + n \cdot \mathrm{sgn}(\tau) W_{i_j}$ if $i_j \neq 0$, i.e.,

$$\begin{aligned} \beta_{|\tau|}^{n,i_j} &= (W_0)_\tau \quad \text{if } i_j = 0, \\ &= (W_0 + n \cdot \mathrm{sgn}(\tau) W_{i_j})_{|\tau|/n} \quad \text{if } i_j \neq 0. \end{aligned} \tag{39}$$

We note that $(W_0 + n \cdot \mathrm{sgn}(\tau) W_{i_j})_{|\tau|/n}$ and $[(1/n)W_0 + \mathrm{sgn}(\tau) W_{i_j}]_{|\tau|}$ describe the same integral curve on N, by virtue of the time-invariance property of system (12). Obviously, $\beta_{|t_p|}^{n,i_j} \to \alpha_{t_p}^{i_j}$ as $n \to \infty$. On the other hand,

$$s_k^{(n)} = \sum_j t_j \cdot 1_{\{i_j=0\}} - \frac{\sum_l |t_l| \cdot 1_{\{i_l \neq 0\}}}{n} + \frac{\sum_l |t_l| \cdot 1_{\{i_l \neq 0\}}}{n} = t. \tag{40}$$

Thus, as $n \to \infty$ we obtain

$$\beta^{(n)}_{s_k^{(n)}}(\eta) \to \alpha^{i_k}_{t_k} \cdots \alpha^{i_1}_{t_1}(\eta) = \alpha_t(\eta), \tag{41}$$

and hence $\alpha_t(\eta) \in \mathrm{cl}\, \hat{R}_t(\eta)$. Because $\alpha_t(\eta)$ is an arbitrary element in $\hat{R}^0_t(\eta)$, it follows that $\hat{R}^0_t(\eta) \subseteq \mathrm{cl}\, \hat{R}_t(\eta)$, and since $\mathrm{cl}\, \hat{R}_t(\eta)$ is closed, it follows in turn that $\mathrm{cl}\, \hat{R}^0_t(\eta) \subseteq \mathrm{cl}\, \hat{R}_t(\eta)$.

Next we show $\mathrm{cl}\, \hat{R}_t(\eta) \subseteq \mathrm{cl}\, \hat{R}^0_t(\eta)$. Consider $\beta(\eta) \in \hat{R}_t(\eta)$ of the form of $\beta^{c_k}_{u_k} \cdot \cdots \cdot \beta^{c_1}_{u_1}(\eta)$, with $\beta^{c_j}_{u_j} = \exp u_j(W_0 + c_j^1 W_1 + \cdots + c_j^r W_r)$ and $c_j = (c_j^1, \ldots, c_j^r)$. Here, c_j^l is the control applied to W_l during time period u_j, so c_j is the control set applied to $W_1, \ldots, W_r$ during the corresponding time interval u_j, with $u_j \in \mathbb{R}^+$ and $c_j^l \in \mathbb{R}$. For each $\beta^{c_j}_{u_j}$, $j = 1, \ldots, k$, take α_j^n in the form

$$\alpha_j^n = \left[\exp \frac{u_j}{n}(c_j^1 W_1) \cdots \exp \frac{u_j}{n}(c_j^r W_r) \exp \frac{u_j}{n} W_0 \right]^n. \tag{42}$$

Invoking the Baker–Campbell–Hausdorff formula,[63] we write

$$\begin{aligned} \lim_{n\to\infty} \alpha_j^n &= \lim_{n\to\infty} \left[\exp \frac{u_j}{n}(c_j^1 W_1) \cdots \exp \frac{u_j}{n}(c_j^r W_r) \cdot \exp \frac{u_j}{n} W_0 \right]^n \\ &= \lim_{n\to\infty} \exp \left[u_j(W_0 + c_j^1 W_1 + \cdots + c_j^r W_r) + \sum_{0 \leq p,q \leq r} \frac{u_j^2}{2n} c_j^p c_j^q [W_p, W_q] + O\left(\frac{1}{n^2}\right) \right] \\ &= \exp u_j(W_0 + c_j^1 W_1 + \cdots + c_j^r W_r) = \beta^{c_j}_{u_j}. \end{aligned} \tag{43}$$

Constructing $\alpha_1^n \cdots \alpha_k^n \in \hat{R}^0_t(\eta)$ we then obtain

$$\lim_{n\to\infty} \alpha_k^n \cdots \alpha_1^n(\eta) = \beta^{c_k}_{u_k} \cdots \beta^{c_1}_{r_1}(\eta) = \beta(\eta), \tag{44}$$

so that $\beta(\eta) \in \mathrm{cl}\, \hat{R}^0_t(\eta)$. Since $\beta(\eta)$ is an arbitrary element of $\hat{R}_t(\eta)$, we arrive at $\hat{R}_t(\eta) \subseteq \mathrm{cl}\, \hat{R}^0_t(\eta)$ and hence $\mathrm{cl}\, \hat{R}_t(\eta) \subseteq \mathrm{cl}\, \hat{R}^0_t(\eta)$. We conclude that $\mathrm{cl}\, \hat{R}_t(\eta) = \mathrm{cl}\, \hat{R}^0_t(\eta)$.

The time t labeling these reachable sets is to be interpreted as the time interval over which the control operation represented by W_0 is in effect, or "turned on." In fact, W_0 is necessarily *always* "on" in the augmented system, so the total time elapsing in the augmented system is the same as the time interval over which W_0 is turned on; hence the reachable sets $\hat{R}_t$ corresponding to these two times are identical. Of course, the same coincidence does not hold for the auxiliary system. However, this is immaterial, since the auxiliary system was only introduced to exploit the key relationship (22). Further, we may observe that the reachable set $\hat{R}^0_t(\eta)$ of system (20), with the control $u(t) = (u_0(t), \ldots, u_r(t))$ assuming values $(e_0, \pm e_1, \ldots, \pm e_r)$, is the same as the corresponding set for which the control $u(t)$ assumes the values $e_0, \pm c e_1, \ldots, \pm c e_r$, with $c \in \mathbb{R}^+$.

Since we can take advantage of the result (22) in this manner, it is clearly preferable to study the properties of $\hat{R}^0_t(\eta)$. The auxiliary system is easier to control, and the state at time t can be expressed as a composition of integral curves of W_i in the same style as Eq. (21). To do so, let the set of subscripts j with $i_j = 0$ be written as $\{p, \ldots, q, s\}$ in increasing order, of course with $t_p + \cdots + t_q + t_s = t$. Then we have

$$\alpha_t = (\alpha_{t_k}^{i_k} \cdots \alpha_{t_{s+1}}^{i_{s+1}}) \cdot (\alpha_{t_s}^0 \cdot \alpha_{t_{s-1}}^{i_{s-1}} \cdot \alpha_{-t_s}^0) \cdot (\alpha_{t_s}^0 \cdot \alpha_{t_{s-2}}^{i_{s-2}} \cdot \alpha_{-t_s}^0) \cdots (\alpha_{t_s+t_q}^0 \cdot \alpha_{t_{q-1}}^{i_{q-1}} \cdot \alpha_{-(t_s+t_q)}^0)$$
$$\cdot (\alpha_{t_s+t_q}^0 \cdot \alpha_{t_{q-2}}^{i_{q-2}} \cdot \alpha_{-(t_s+t_q)}^0) \cdots (\alpha_{t_s+t_q+\cdots+t_p}^0 \cdot \alpha_{t_{p-1}}^{i_{p-1}} \cdot \alpha_{-(t_s+t_q+\cdots+t_p)}^0) \cdots (\alpha_{t_s+t_q+\ldots+t_p}^0 \cdot \alpha_{t_1}^{i_1}$$
$$\cdot \alpha_{-(t_s+t_q+\ldots+t_p)}^0) \cdot \alpha_t^0 = \beta_0(\alpha_{t_k}^{i_k}) \cdots \beta_0(\alpha_{t_{s+1}}^{i_{s+1}}) \cdot \beta_{t_s}(\alpha_{t_{s-1}}^{i_{s-1}})$$
$$\cdot \beta_{t_s}(\alpha_{t_{s-2}}^{i_{s-2}}) \cdots \beta_{t_s+t_q}(\alpha_{t_{q-1}}^{i_{q-1}}) \cdot \beta_{t_s+t_q}(\alpha_{t_{q-2}}^{i_{q-2}}) \cdots \beta_t(\alpha_{t_{p-1}}^{i_{p-1}}) \cdots \beta_t(\alpha_{t_1}^{i_1}) \cdot \alpha_t^0, \tag{45}$$

where $\beta_t(\gamma) = \alpha_t^0 \cdot \gamma \cdot \alpha_{-t}^0$. This analysis stimulates us to define the following three sets of diffeomorphisms:

Exp $\hat{\mathcal{B}}$ = the group generated by α_t^l, $t \in \mathbb{R}$, $l = 1, \ldots, r$, where α_t^l is the integral curve whose vector field is W_l,

$$F_t = \cup_{k=1}^{\infty} \{\beta_{t_k}(\gamma_k) \cdot \cdots \cdot \beta_{t_1}(\gamma_1) \,|\, \gamma_j \in \text{Exp}\, \hat{\mathcal{B}}, 0 \leqslant t_k \leqslant \cdots \leqslant t_1 = t\},$$

$$G_t = \cup_{k=1}^{\infty} \{\beta_{t_k}(\gamma_k) \cdot \cdots \cdot \beta_{t_1}(\gamma_1) \,|\, \gamma_j \in \text{Exp}\, \hat{\mathcal{B}}, \min_j t_j \geqslant 0, \max_j t_j = t\}.$$

.

By construction,

$$\hat{R}_t^0(\eta) = F_t \alpha_t^0(\eta). \tag{46}$$

We observe that F_t is a semigroup of diffeomorphisms included in the group G_t, whose properties are established in the following lemma.

Lemma IV.4: First, the set G_t is a group. Furthermore, if $\dim \hat{\mathcal{C}}(\eta) = n - 1 = m$ *holds for all* $\eta \in N$, *then* $\{\alpha(\eta) \,|\, \alpha \in G_t\} = \alpha_t^0(I(\alpha_{-t}^0(\eta)))$ *is true for all* η, *where* $I(\nu)$ *is the maximal connected integral manifold containing* $\nu \in N$, *whose associated Lie algebra is* $\hat{\mathcal{C}}$.

Proof: For $\alpha_1, \alpha_2 \in G_t$, it is easily seen that $\alpha_1 \cdot \alpha_2 \in G_t$. Writing $\alpha \in G_t$ as $\alpha = \beta_{t_k}(\gamma_k) \cdot \cdots \cdot \beta_{t_1}(\gamma_1)$, we also see that $\alpha^{-1} = \beta_{t_1}(\gamma_1^{-1}) \cdot \cdots \cdot \beta_{t_k}(\gamma_k^{-1})$. Therefore G_t is a group.

Now, denote the set $\{\alpha(\eta) \,|\, \alpha \in G_t\}$ by $B_t(\eta)$. It is straightforward to show that (i) $B_t(\eta) = B_t(\xi)$ if $\xi \in B_t(\eta)$ and (ii) $B_t(\eta) \cap B_t(\xi) = \varnothing$ if $\xi \notin B_t(\eta)$.[54] We can demonstrate that (iii) $\eta \in \text{int}\, B_t(\eta)$ under the topology of $\alpha_t^0(I(\alpha_{-t}^0(\eta)))$ as follows. By definition, $\hat{R}_t^0(\eta)$ is the reachable set for the system (20). By the same reasoning that leads to Eq. (46), we have $\hat{R}_t^0(\alpha_{-t}^0(\eta)) \subset B_t(\eta)$ because $\hat{R}_t^0(\alpha_{-t}^0(\eta)) = F_t \cdot \alpha_t^0 \cdot \alpha_{-t}^0(\eta)$. Since $\hat{R}_t^0(\alpha_{-t}^0(\eta))$ has a nonempty interior with respect to the topology of $\alpha_t^0(I(\alpha_{-t}^0(\eta)))$ by Theorem IV.1, we see that $B_t(\eta)$ contains a non-null open set U. Given $\mu \in U$, choose $\alpha \in G_t$ such that $\alpha(\eta) = \mu$. Since α is a continuous map, $\alpha^{-1}(U)$ is an open set containing η.

In fact, $\alpha^{-1}(U)$ is included in $B_t(\eta)$. We know that G_t is a group, so $\alpha^{-1} \in G_t$ if $\alpha \in G_t$. Letting $\zeta \in \alpha^{-1}(U)$, we can find $\chi \in U$, such that $\chi = \alpha(\zeta) \in U \subset B_t(\eta)$ and also $\chi \in B_t(\zeta)$. By properties (i) and (ii), we obtain $\chi \in B_t(\zeta) \cap B_t(\eta) \neq \varnothing$. Hence $B_t(\zeta) = B_t(\eta)$ and $\zeta \in B_t(\eta)$. Accordingly, $\alpha^{-1}(U) \subset B_t(\eta)$ and $\eta \in \text{int}\, B_t(\eta)$ under the topology of $\alpha_t^0(I(\alpha_{-t}^0(\eta)))$.

The properties (i)–(iii) imply that $B_t(\eta)$ is maximally connected and open under the topology of $\alpha_t^0(I(\alpha_{-t}^0(\eta)))$. Thus we have $B_t(\eta) = \alpha_t^0(I(\alpha_{-t}^0(\eta)))$ for all $t > 0$ and $\eta \in N$. In addition, it is seen that $B_t(\eta) = \alpha_t^0(I(\alpha_{-t}^0(\eta))) = \left(\begin{smallmatrix} t_0 \\ M \cap \mathcal{D}_A \end{smallmatrix}\right)$. The proof of Lemma IV.4 is now complete.

Based on Lemmas IV.3 and IV.4, we could conclude that $\text{cl}\, \hat{R}_t(\alpha_{-t}^0(\eta)) = \alpha_t^0(I(\alpha_{-t}^0(\eta)))$ if we could establish that $F_t = G_t$. The following proof takes a slightly different path. Let Exp $\widetilde{\hat{\mathcal{B}}}$ denote the group of diffeomorphisms generated by all one parameter groups of transformations with respect to vector fields belonging to $\widetilde{\hat{\mathcal{B}}}$. The sets $\widetilde{F_t}$ and $\widetilde{G_t}$ are defined in the same way as F_t and G_t, i.e., via Eq. (17), but with Exp $\widetilde{\hat{\mathcal{B}}}$ entering in place of Exp $\hat{\mathcal{B}}$.

Obviously, $F_t \subset \widetilde{F_t}$ and $G_t \subset \widetilde{G_t}$ hold. We shall now establish that $\widetilde{F_t} = \widetilde{G_t}$.

Lemma IV.5: Let X be a complete vector field belonging to $\tilde{\tilde{\mathcal{B}}}$, *and let* γ_t *be the one-parameter group of transformations generated by X. Assume* $[\hat{\mathcal{B}},\hat{\mathcal{C}}](\eta)\subset\hat{\mathcal{B}}(\eta)$ *is satisfied for all* η. *Then* $\mathrm{d}\beta_s(\gamma_t)$ *is an isomorphism between* $\hat{\mathcal{B}}(\eta)$ *and* $\hat{\mathcal{B}}(\beta_s(\gamma_t)(\eta))$ *for each* η, *and* $\tilde{F}_t=\tilde{G}_t$ *is true for all* $t>0$.

Proof: Since $\beta_s(\gamma_{t_1})\cdot\beta_s(\gamma_{t_2})=\beta_s(\gamma_{t_1+t_2})$ holds, we have $\mathrm{d}\beta_s(\gamma_{t_1+t_2})=\mathrm{d}\beta_s(\gamma_{t_1})\cdot\mathrm{d}\beta_s(\gamma_{t_2})$. Hence it is enough to prove the lemma's assertion for sufficiently small $|t|$. Let $Y_{t,s}=\mathrm{d}\beta_s(\gamma_t)Z$, where $Z\in\tilde{\tilde{\mathcal{B}}}$. For each value of s, $\beta_s(\gamma_t)$ with $t\in R$ is the one parameter group of transformations generated by $\mathrm{d}\alpha_s^0 X$, while

$$\frac{\partial Y_{t,s}}{\partial t}=-\mathrm{d}\beta_s(\gamma_t)[\mathrm{d}\alpha_s^0 X,Z]=\mathrm{d}\beta_s(\gamma_t)[Z,\mathrm{d}\alpha_s^0 X]. \tag{47}$$

Therefore $[Z,\mathrm{d}\alpha_s^0 X]\in\tilde{\tilde{\mathcal{B}}}$ by assumption, because $\mathrm{d}\alpha_s^0 X$ belongs to $\tilde{\tilde{\mathcal{C}}}=\{\hat{\mathcal{C}}(\eta)\,|\,\eta\in N\}$.[64,65]

Now we fix a point η of N and a value of $s\in R$. Let $Z^1,\ldots,Z^n$ provide a basis of $\hat{\mathcal{B}}$ in an open neighborhood U of η. Then there exist C^∞ functions f_{ij} on U such that $[Z^i,\mathrm{d}\alpha_s^0 X]=\Sigma_{j=1}^n f_{ij}Z^j$ holds in U. Let ϵ be a positive number such that $\beta_s(\gamma_t)(\eta)\in U$ for $|t|<\epsilon$, noting that $\beta_s(\gamma_t)$ is a continuous map of t and $\beta_s(\gamma_0)(\eta)=\eta$. Then $\mathrm{d}\beta_s(\gamma_t)[Z^i,\mathrm{d}\alpha_s^0 X]=\Sigma_{j=1}^n f_{ij}\,\mathrm{d}\beta_s(\gamma_t)Z^j$ for $|t|<\epsilon$. Set $V^j(t)=\mathrm{d}\beta_s(\gamma_t)Z^j$. Then $V^j(t)$, with $|t|<\epsilon$, satisfies the linear differential equation

$$\frac{\mathrm{d}V^j(t)}{\mathrm{d}t}=\sum_{j=1}^n f_{jk}V^k(t)\quad j=1,\ldots,n. \tag{48}$$

The solution $V^j(t)$ can be written as $V^j(t)=\Sigma_{k=1}^n g_{jk}(t)V^k(0)$, where (g_{jk}) is a regular matrix. Also, we have $V^k(0)\in\hat{\mathcal{B}}(\eta)$ and $V^k(t)\in\hat{\mathcal{B}}(\beta_s(\gamma_t))(\eta)$. The map $\mathrm{d}\beta_s(\gamma_t):\hat{\mathcal{B}}(\eta)\to\hat{\mathcal{B}}(\beta_s(\gamma_t))(\eta)$ is bijective because (g_{jk}) is a regular matrix. Moreover, $\mathrm{d}\beta_s(\gamma_t)$ retains the structure of the Lie bracket with respect to $\mathrm{d}\alpha_s^0 X$. This establishes that $\mathrm{d}\beta_s(\gamma_t)$ is an isomorphism between $\hat{\mathcal{B}}(\eta)$ and $\hat{\mathcal{B}}(\beta_s(\gamma_t))(\eta)$ for $|t|<\epsilon$. Since $\gamma_t'\equiv\beta_s(\alpha)\cdot\gamma_t\cdot\beta_s(\alpha)^{-1}$ (with s fixed) is a one-parameter group of transformations generated by $\mathrm{d}\beta_s(\alpha)X$ and $\mathrm{d}\beta_s(\alpha)X$ belongs to $\tilde{\tilde{\mathcal{B}}}$, we know γ_t' (with $t\in R$) belongs to $\mathrm{Exp}\,\tilde{\tilde{\mathcal{B}}}$. But $\mathrm{Exp}\,\tilde{\tilde{\mathcal{B}}}$ is generated by all such γ_t, so we arrive at the relationship

$$\beta_t(\alpha)(\mathrm{Exp}\,\tilde{\tilde{\mathcal{B}}})\beta_t(\alpha)^{-1}\subset\mathrm{Exp}\,\tilde{\tilde{\mathcal{B}}}\quad\text{for }\alpha\in\tilde{\tilde{\mathcal{B}}}. \tag{49}$$

Let α be any element of $\tilde{G}_t$, written as

$$\alpha=\beta_{t_k}(\gamma_k)\cdot\cdots\cdot\beta_{t_1}(\gamma_1),\quad t_l\geqslant 0,\quad \max_l t_l=t. \tag{50}$$

By induction we can prove that there exist $\tilde{\gamma}_k,\ldots,\tilde{\gamma}_1$ of $\mathrm{Exp}\,\tilde{\tilde{\mathcal{B}}}$ and $0\leqslant s_k\leqslant\cdots\leqslant s_1=t$ such that

$$\beta_{t_k}(\gamma_k)\cdot\cdots\cdot\beta_{t_1}(\gamma_1)=\beta_{s_k}(\tilde{\gamma}_k)\cdot\cdots\cdot\beta_{s_1}(\tilde{\gamma}_1). \tag{51}$$

Here we only consider the case $k=2$. If $t_2\leqslant t_1$, there is no need for proof. Suppose $t_2>t_1$, and set $t_3=t_2-t_1$. Then we may write $\beta_{t_2}(\gamma_2)\cdot\beta_{t_1}(\gamma_1)=\beta_{t_1}(\beta_{t_3}(\gamma_2)\cdot\gamma_1)$. By relationship (49), there exists $\tilde{\gamma}_1$ of $\mathrm{Exp}\,\tilde{\tilde{\mathcal{B}}}$ such that $\beta_{t_3}(\gamma_2)\cdot\gamma_1\cdot\beta_{t_3}(\gamma_2)^{-1}=\tilde{\gamma}_1$, i.e., $\beta_{t_3}(\gamma_2)\cdot\gamma_1=\tilde{\gamma}_1\cdot\beta_{t_3}(\gamma_2)$. This implies

$$\beta_{t_2}(\gamma_2)\cdot\beta_{t_1}(\gamma_1)=\beta_{t_1}(\beta_{t_3}(\gamma_2)\cdot\gamma_1)=\beta_{t_1}(\tilde{\gamma}_1\cdot\beta_{t_3}(\gamma_2))=\beta_{t_1}(\tilde{\gamma}_1)\cdot\beta_{t_2}(\gamma_2). \tag{52}$$

More detailed proofs may be found in Refs. 54 and 66.

Theorem IV.6: *Suppose that* $\dim\hat{\mathcal{C}}(\eta)=n-1=m$ *holds for all* $\eta\in N$, *and suppose that* $[\hat{\mathcal{B}},\hat{\mathcal{C}}](\eta)\subset\hat{\mathcal{B}}(\eta)$ *holds for all* η. *Let* $I(\eta)$ *be the maximally connected integral manifold containing* η *whose corresponding Lie algebra is* $\hat{\mathcal{C}}$. *Then* $\alpha_t^0(I(\eta))=\hat{R}_t(\eta)$.

Proof: Clearly we have $\{\alpha\alpha_t^0(\eta)\,|\,\alpha\in F_t\}\subset\{\alpha\alpha_t^0(\eta)\,|\,\alpha\in\widetilde{F}_t\}$. In fact, the closures of these two sets coincide. Since $\widetilde{F}_t=\widetilde{G}_t\supset G_t$, it is seen that

$$\begin{aligned}\mathrm{cl}\,\hat{R}_t^0(\eta) &= \mathrm{cl}\{\alpha\alpha_t^0(\eta)|\alpha\in F_t\}\\ &= \mathrm{cl}\{\alpha\alpha_t^0(\eta)|\alpha\in\widetilde{F}_t\}\\ &= \mathrm{cl}\{\alpha\alpha_t^0(\eta)|\alpha\in\widetilde{G}_t\}\quad\text{(by Lemma IV.5)}\\ &= \mathrm{cl}\;\alpha_t^0(I(\alpha_{-t}^0(\alpha_t^0(\eta))))\quad\text{(by Lemma IV.4)}\\ &= \mathrm{cl}\;\alpha_t^0(I(\eta)).\end{aligned}\tag{53}$$

But Lemma IV.3 tells us that $\mathrm{cl}\,\hat{R}_t^0(\eta)=\mathrm{cl}\,\hat{R}_t(\eta)$, so we obtain $\mathrm{cl}\,\hat{R}_t(\eta)=\mathrm{cl}\;\alpha_t^0(I(\eta))$. From Lemma IV.2 we know that $\mathrm{int}\,\hat{R}_t(\eta)=\mathrm{int}(\mathrm{cl}\,\hat{R}_t(\eta))$, which implies $\mathrm{int}\hat{R}_t(\eta)=\alpha_t^0(I(\eta))$ under the topology of $\alpha_t^0(I(\eta))$. Finally, $\hat{R}_t(\eta)\subset\alpha_t^0(I(\eta))$ by Theorem IV.1, and we arrive at $\hat{R}_t(\eta)=\alpha_t^0(I(\eta))$.

C. Strong analytic controllability of the actual system

In Sec. IV B, we investigated the reachable set at time t of the time-independent augmented system formed by enlarging the state space to include an extra dimension corresponding to the variable t. Now we return to the original quantum control system (4) to discover conditions under which it is strongly analytically controllable.

Theorem IV.7: *For the control system defined by Eq. (4), let*

$$\begin{aligned}&\mathcal{B}(t)=\mathcal{L}\{H_1(t),\ldots,H_r(t)\},\\ &B_1(t)=-[H_0(t),\mathcal{B}(t)]+\frac{\partial}{\partial t}\mathcal{B}(t),\quad\ldots,\\ &B_n(t)=-[H_0(t),B_{n-1}(t)]+\frac{\partial}{\partial t}B_{n-1}(t),\quad\ldots,\\ &\mathcal{C}(t)=\mathcal{L}\{\mathcal{B}(t),B_1(t),\ldots,B_n(t),\ldots\}.\end{aligned}\tag{54}$$

Suppose $\dim\mathcal{C}(t)\psi(t)=m$ *holds for all* $\psi\in M\cap\mathcal{D}_A$, *and* $[\mathcal{B},\mathcal{C}](t)\subset\mathcal{B}(t)$ *is the case for all* t. *Then the time-dependent quantum control system (4) is strongly analytically controllable.*

Proof: We apply Theorem IV.6 to the augmented control system (12). To do so, we need to examine the Lie algebras $\hat{\mathcal{B}}$ and $\hat{\mathcal{C}}$ for this problem. For economy of expression, we sometimes omit the t argument in the following steps. For $\hat{\mathcal{B}}$ we readily find

$$\hat{\mathcal{B}}=\mathcal{L}\{W_1,\ldots,W_r\}=\mathcal{L}\left\{\begin{pmatrix}0\\H_1(t)\end{pmatrix},\ldots,\begin{pmatrix}0\\H_r(t)\end{pmatrix}\right\}\psi(t)=\begin{pmatrix}0\\\mathcal{L}\{H_1(t),\ldots,H_r(t)\}\end{pmatrix}\psi(t)=\begin{pmatrix}0\\\mathcal{B}(t)\psi(t)\end{pmatrix}.\tag{55}$$

Next let us construct $\hat{\mathcal{C}}$. For any

$$W(\eta)=W(t,\psi)=\begin{pmatrix}0\\H(t)\psi(t)\end{pmatrix}\in\hat{\mathcal{B}},\tag{56}$$

where $\eta\in N$, we have

$$\begin{aligned}\mathrm{ad}_{W_0} W &= [W_0, W] = \left[\begin{pmatrix} 1 \\ H_0(t)\psi(t) \end{pmatrix}, \begin{pmatrix} 0 \\ H(t)\psi(t) \end{pmatrix}\right] \\ &= \frac{\partial \begin{pmatrix} 0 \\ H(t)\psi(t) \end{pmatrix}}{\partial(t,\psi)} \begin{pmatrix} 1 \\ H_0(t)\psi(t) \end{pmatrix} - \frac{\partial \begin{pmatrix} 1 \\ H_0(t)\psi(t) \end{pmatrix}}{\partial(t,\psi)} \begin{pmatrix} 0 \\ H(t)\psi(t) \end{pmatrix} \\ &= \begin{Bmatrix} 0 \\ -[H_0, H] + \partial H/\partial t \end{Bmatrix} \psi(t). \end{aligned} \tag{57}$$

Similarly,

$$\mathrm{ad}_{W_0} \hat{\mathcal{B}} = \begin{pmatrix} 0 \\ -[H_0, \mathcal{B}] + \partial \mathcal{B}/\partial t \end{pmatrix} \psi(t). \tag{58}$$

Setting $B_1 = -[H_0, \mathcal{B}] + \partial \mathcal{B}/\partial t$, we may then derive

$$\mathrm{ad}^2_{W_0} \hat{\mathcal{B}} = \mathrm{ad}_{W_0} \mathrm{ad}_{W_0} \hat{\mathcal{B}} = \mathrm{ad}_{W_0} \begin{pmatrix} 0 \\ B_1\psi(t) \end{pmatrix} = \begin{pmatrix} 0 \\ -[H_0, B_1] + \partial B_1/\partial t \end{pmatrix} \psi(t). \tag{59}$$

Continuing in this fashion with

$$B_n = -[H_0, B_{n-1}] + \partial B_{n-1}/\partial t \tag{60}$$

for $n = 2, 3, \ldots$, we find

$$\mathrm{ad}^n_{W_0} \hat{\mathcal{B}} = \begin{pmatrix} 0 \\ -[H_0, B_{n-1}] + \dfrac{\partial B_{n-1}}{\partial t} \end{pmatrix} \psi(t) = \begin{pmatrix} 0 \\ B_n\psi(t) \end{pmatrix}. \tag{61}$$

Thus

$$\begin{aligned}\hat{\mathcal{C}} &= \mathcal{L}\{\hat{\mathcal{B}}, \mathrm{ad}_{W_0} \hat{\mathcal{B}}, \ldots, \mathrm{ad}^n_{W_0} \hat{\mathcal{B}}, \ldots\} \\ &= \mathcal{L}\left\{\begin{pmatrix} 0 \\ \mathcal{B}(t)\psi(t) \end{pmatrix}, \begin{pmatrix} 0 \\ B_1(t)\psi(t) \end{pmatrix}, \ldots, \begin{pmatrix} 0 \\ B_n(t)\psi(t) \end{pmatrix}, \ldots\right\} \\ &= \begin{pmatrix} 0 \\ \mathcal{L}\{\mathcal{B}(t), B_1(t), \ldots, B_n(t), \ldots\}\psi(t) \end{pmatrix} = \begin{pmatrix} 0 \\ \mathcal{C}(t)\psi(t) \end{pmatrix}. \end{aligned} \tag{62}$$

From the assumption that $[\mathcal{B}, \mathcal{C}](t) \subset \mathcal{B}(t)$, $\forall(t)$, we have

$$[\mathcal{B}, \mathcal{C}](t)\psi(t) \subset \mathcal{B}(t)\psi(t), \forall\,(t). \tag{63}$$

Hence

$$\left[\begin{pmatrix} 0 \\ \mathcal{B}\psi \end{pmatrix}, \begin{pmatrix} 0 \\ \mathcal{C}\psi \end{pmatrix}\right] \subset \begin{pmatrix} 0 \\ \mathcal{B}\psi \end{pmatrix}, \tag{64}$$

so that $[\hat{\mathcal{B}}, \hat{\mathcal{C}}](\eta) \subset \hat{\mathcal{B}}(\eta)$, $\forall\, \eta \in N$.

By assumption, $\dim \mathcal{C}(t)\psi(t) = m$, $\forall\, \psi \in M \cap \mathcal{D}_A$, which implies that $\dim \hat{\mathcal{C}}(\eta) = m = n - 1$ holds for all $\eta \in N$. According to Theorem IV.6, $\alpha^0_t(I(\eta)) = \hat{\mathcal{R}}_t(\eta)$, $\forall\, t > 0$, and since $\alpha^0_t(I(\alpha^0_{-t}(\eta))) = \begin{pmatrix} t_0 \\ M \cap \mathcal{D}_A \end{pmatrix}$, we obtain $\alpha^0_t(I(\eta)) = \begin{pmatrix} t+t_0 \\ M \cap \mathcal{D}_A \end{pmatrix}$.

Let $\pi: N \to M \cap \mathcal{D}_A$ be the projection map that in effect annihilates the time dimension of the augmented problem corresponding to the variable t, and brings us back to the original control

system. In fact, the extension and projection maps mediate a one-to-one correspondence between the states of the augmented system and those of the original system. The simplicity of this relationship stems from the fact that t is a strictly increasing variable.

To reiterate our strategy: We have dealt with the explicit time dependence of the original control problem by adding an extra dimension to its state space, such that, as viewed in the augmented space, the augmented control problem is time independent. After analyzing controllability within this extension, the results are projected to the original space by removing the extra time dimension, recovering the exact states of the original system.

Accordingly, $\pi(\alpha_t^0(I(\eta)))=M\cap\mathcal{D}_A$, while $\pi\hat{R}_t(\eta)=R_{t+t_0}(\psi)$, $\forall\,\psi\in M\cap\mathcal{D}_A$ and $\forall t>0$. Hence $R_t(\psi)=M\cap\mathcal{D}_A$, $\forall\,t>t_0$, and the system (4) is strongly analytically controllable on M.

We may note that upon introducing the Lie algebra $\mathcal{A}(t)=\mathcal{L}\{H_0(t),H_1(t),\ldots,H_r(t)\}$, it is readily established from property (13) that $\mathcal{B}\subset\mathcal{C}\subset\mathcal{A}$ for all t.

To complete the formal analysis, we state two corollaries that devolve immediately from Theorem IV.7.

Corollary IV.8: *From the operators H_i entering control system (4), form the Lie algebras $\mathcal{B}=\mathcal{L}\{H_1,\ldots,H_r\}$ and $\mathcal{C}=\mathcal{L}\{\mathcal{B},\mathrm{ad}_{H_0}\mathcal{B},\ldots,\mathrm{ad}_{H_0}^n\mathcal{B},\ldots\}$. Suppose that the H_i do not possess explicit dependence on the time t, that* $\dim\mathcal{C}\psi(t)=m$ *holds for all $\psi\in M\cap\mathcal{D}_A$, and that $[\mathcal{B},\mathcal{C}]\subset\mathcal{B}$ is satisfied. Then the time-invariant system (4) is strongly analytically controllable.*

Corollary IV.9: *For the control system (4), form the Lie algebra $\mathcal{B}(t)=\mathcal{L}(H_1(t),\ldots,H_r(t))$, and suppose that* $\dim\mathcal{B}(t)\psi(t)=m$ *holds for all $\psi\in M\cap\mathcal{D}_A$. Then system (4) is strongly analytically controllable.*

The latter corollary follows because $[\mathcal{B},\mathcal{C}](t)\subset\mathcal{B}(t)$ must hold, once $\dim\mathcal{B}(t)\psi(t)=m$.

V. EXAMPLES OF STRONG ANALYTIC CONTROLLABILITY

In this section, we present three examples that meet the criteria for analytic controllability enunciated in Theorem IV.7. The examples selected are relevant to problems of interest in mathematical physics or engineering applications of quantum mechanics.

Example 1: The strong analytic controllability theorem can be applied to the simple degenerate parametric oscillator, a problem of importance in physics and engineering. Introducing an appropriate effective Hamiltonian allows the corresponding control system to be written in the form[67]

$$i\frac{\partial}{\partial t}\psi=\left\{\omega(t)a^\dagger a+\frac{1}{2}\chi(t)[e^{-2i\omega t}(a^\dagger)^2+e^{2i\omega t}a^2]\right\}\psi. \tag{65}$$

Here $a^\dagger$ and a represent, in turn, the creation and annihilation operators of the pump mode of frequency $\omega(t)$, while $\chi(t)$ is the time-dependent coupling function related to the second-order nonlinear susceptibility of the pumped medium. We may consider $\omega(t)$ and $\chi(t)$ as control functions playing the role of the u_l in Eq. (4), since they are real and can be adjusted to piecewise-constant functions of time t, outside the system itself.

Following Refs. 68–71, we define the operators

$$K_+=\tfrac{1}{2}(a^\dagger)^2,\quad K_-=\tfrac{1}{2}a^2,\quad K_0=\tfrac{1}{2}(a^\dagger a+aa^\dagger), \tag{66}$$

which satisfy the commutation relations of SU (1, 1), thus

$$[K_0,K_\pm]=\pm K_\pm,\quad [K_+,K_-]=-2K_0. \tag{67}$$

Setting

$$H_0=-iK_0, \tag{68}$$

$$H_1=-\frac{i}{2}[e^{-2i\omega t}K_+ + e^{2i\omega t}K_-], \tag{69}$$

$$H_2 = \tfrac{1}{2}[e^{-2i\omega t}K_+ - e^{2i\omega t}K_-], \tag{70}$$

the control system (65) may be written in the more familiar form

$$\frac{\partial}{\partial t}\psi = [\omega(t)H_0 + \chi(t)H_1(t)]\psi. \tag{71}$$

The skew-Hermitian operators H_0, H_1, and H_2 satisfy the commutation relations

$$[H_0,H_1] = -H_2, \quad [H_0,H_2] = H_1, \quad [H_1,H_2] = H_0. \tag{72}$$

We observe that the system (71) does not have a drift term in the usual sense, because the factor $\omega(t)$ can be manipulated externally. We also see immediately that $\mathcal{A}=\mathcal{B}=\mathcal{C}=\mathcal{L}\{H_0,H_1,H_2\}$, and the second condition of Theorem IV.7 is obviated. In addition, H_0 has eigenvectors $|mk\rangle$, with $m=0,1,\ldots$ and $k=1/4,\ 3/4$, which span an analytic domain $\mathcal{D}_A$.[69,71] Consequently, we can choose a manifold M such that $\dim \mathcal{C}\psi = \dim M$, $\forall \psi \in \mathcal{D}_A \cap M$. All conditions of Theorem IV.7 being met, the system (65) is strongly analytically controllable on M.

Example 2: Defining $Q = i\partial_t + \partial_{x_1x_1} + \partial_{x_2x_2}$, the Schrödinger equation for a free particle moving in two spatial dimensions may be expressed simply as $Qu=0$. Determination of the maximal symmetry algebra of this equation leads to the following set of nine operators, which form the basis of a nine-dimensional complex Lie algebra:[72]

$$\begin{gathered} K_2 = -t^2\partial_t - t(x_1\partial_{x_1} + x_2\partial_{x_2}) - t + (i/4)(x_1^2 + x_2^2), \quad K_{-2} = \partial_t, \quad P_j = \partial_{x_j}, \\ B_j = -t\partial_{x_j} + ix_j/2, \quad J = x_1\partial_{x_2} - x_2\partial_{x_1}, \quad E = i, \quad D = x_1\partial_{x_1} + x_2\partial_{x_2} + 2t\partial_t + 1, \end{gathered} \tag{73}$$

with $j=1,2$. Of immediate concern is the real Lie algebra spanned by this basis, i.e., the Schrödinger algebra, which has, as alternative basis, the operators B_j, P_j, and E (yielding the five-dimensional Weyl algebra), plus the operator J and the three operators defined by $L_1=D$, $L_2=K_2+K_{-2}$, and $L_3=K_{-2}-K_2$. The pertinent nonvanishing commutators are specified by[72]

$$\begin{gathered} [L_1,L_2] = -2L_3, \quad [L_3,L_1] = 2L_2, \quad [L_2,L_3] = 2L_1, \quad [L_1,B_j] = B_j, \quad [L_1,P_j] = -P_j, \\ [P_j,J] = (-1)^{j+1}P_l, \quad [B_j,J] = (-1)^{j+1}B_l, \quad [L_2,B_j] = -P_j, \quad [L_3,B_j] = -P_j, \quad [L_2,P_j] = B_j, \\ [L_3,P_j] = -B_j, \quad [P_j,B_j] = E/2, \end{gathered} \tag{74}$$

where $j,\ l=1,\ 2,\ j\neq l$.

Now we consider the controllability of the system

$$\frac{\partial}{\partial t}\psi = [L_2 + u_1(t)L_1 + u_2(t)L_3 + u_3(t)P_1 + u_4(t)J]\psi. \tag{75}$$

In this case there is a time-dependent drift term in the vector field driving ψ. The relations (74) imply the equalities $\mathcal{B}=\mathcal{C}=\mathcal{L}\{L_1,L_2,L_3,P_1,P_2,B_1,B_2,J,E\}$, while the required analytic domain $\mathcal{D}_{\mathcal{A}}$ is furnished by the span of the eigenfunctions $\psi_{n,m}$ of L_3. These take the explicit, time-dependent form[72]

$$\begin{aligned} \psi_{n,m} &= (2^{m+n+1}\pi n!m!)^{-1/2}\exp[i\pi(m+n-1)/2] \\ &\quad \times \exp\left[\frac{(v_1^2+v_2^2)(1-iv_3)}{4}\right]\left(\frac{v_3+i}{v_3-i}\right)^{(m+n)/2} \times \frac{H_m(v_1/\sqrt{2})H_n(v_2/\sqrt{2})}{v_3-i}, \end{aligned} \tag{76}$$

where $x_1=v_1(1+v_3^2)^{1/2}$, $x_2=v_2(1+v_3^2)^{1/2}$, and $t=v_3$. It follows as before that the system (75) is strongly analytically controllable.

Example 3: A quantum control system with position-dependent effective mass $m=(2Ax)^{-1}$ has been described by the time-dependent Schrödinger equation[73]

$$i\frac{\partial}{\partial t}\psi=[iBI_0+u_1(t)A(t)I_0I_-+iu_2(t)C]\psi, \tag{77}$$

where B, $C\in\mathbb{R}$, and $A(t)$, is a real function of time t but in general not piecewise constant. The operators I_0 and $I_\pm$, which are independent of time, provide a basis for an SU(1, 1) algebra, and have the concrete realization

$$I_-=-\partial_x,\quad I_0=x\partial_x+1,\quad I_+=x^2\partial_x+2x, \tag{78}$$

which satisfies the commutative relations

$$[I_0,I_\pm]=\pm I_\pm,\quad [I_-,I_+]=-2I_0. \tag{79}$$

This effective-mass problem arises in the study of semiconductor heterostructures and, more generally, of inhomogeneous crystals.[74] In the semiconductor application, the effective mass of a carrier depends spatially on the graded composition of the semiconductor alloys used in the barrier and well regions of the microstructures.[75]

The wave functions of the stationary states of Eq. (77) can be written as

$$\begin{aligned}\psi_E(t,x)=&\frac{1}{\sqrt{2\pi}}\exp\left\{-iE\int_0^t B(\sigma)\mathrm{d}\sigma+\int_0^t\left[-C(\sigma)-\frac{1}{2}B(\sigma)\right]\mathrm{d}\sigma\right\}\\&\times\exp\{-a_1(t)(x\partial_{xx}+\partial_x)\}x^{-iE-1/2}=\frac{1}{\sqrt{2\pi}}\exp\left\{-iE\int_0^t B(\sigma)\mathrm{d}\sigma+\int_0^t\left[-C(\sigma)\right.\right.\\&\left.\left.-\frac{1}{2}B(\sigma)\right]\mathrm{d}\sigma\right\}\\&\times\sum_{n=0}^{\infty}\prod_{l=0}^{n}\left(iB(t)E+\frac{1}{2}+l\right)^2[-a_1(t)]^n\times\frac{x^{-iE-n-1/2}}{n!}.\end{aligned} \tag{80}$$

These eigenfunctions span the analytic domain relevant to Theorem IV.7.

Let us define

$$H_0=BI_0+u_2(t)C,\quad H_1=-iA(t)I_0I_-, \tag{81}$$

where we take $u_2(t)=-B/2C$. Equation (77) can be recast as the control system,

$$\frac{\partial}{\partial t}\psi=[H_0+u_1(t)H_1]\psi. \tag{82}$$

Here the drift term is time independent. Using the commutation relations (79), we obtain $[H_0,H_1]=-BH_1$. Obviously, $\mathcal{B}=\mathcal{C}\subset\mathcal{A}$, so $[\mathcal{B},\mathcal{C}]=\mathcal{B}$. Choosing a manifold M such that $\dim M=\dim \mathcal{C}\psi$ for all $\psi\in M$, we are assured that system (77) is strongly analytically controllable.

VI. CONCLUSIONS

In this paper, we have formulated the time-dependent quantum control problem and studied its controllability. Acknowledging the unbounded nature of operators commonly involved in quantum control systems, our analysis has been predicated on the existence of an analytic domain[32] on which exponentiations of such operators are guaranteed to converge. Within this framework, we have extended the established treatment of time-independent quantum control problems by introducing an augmented system described in a state space that is enlarged by one dimension, yet embodies the true dynamics of the original system. With the aid of techniques and results devel-

oped by Kunita,[54,58] we are able to explicate the one-dimension-reduced controllability of the augmented system. Projection onto the original state space then yields a proof of the analytic controllability of the original time-dependent quantum control system, under conditions similar to those required in the time-independent case. The theorem so established has been illustrated with examples drawn from mathematical physics and systems engineering.

Control aspects of holonomic quantum computation

Dennis Lucarelli
The Johns Hopkins University, Applied Physics Laboratory, Laurel, Maryland 20723-6099

(Received 15 October 2003; accepted 2 February 2005; published online 8 April 2005)

A unifying framework for the control of quantum systems with non-Abelian holonomy is presented. It is shown that, from a control theoretic point of view, holonomic quantum computation can be treated as a control system evolving on a principal fiber bundle. An extension of methods developed for these classical systems may be applied to quantum holonomic systems to obtain insight into the control properties of such systems and to construct control algorithms for two established examples of the computing paradigm. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1888028]

I. INTRODUCTION

Geometric phases have long been a source of fascination and insight into classical and quantum physical theories.[1] In recent years, they have proven to be useful in describing the dynamics and control of certain nonholonomic mechanical systems with symmetry.[2] Inspired by the appearance of geometric phases in biology, engineers have sought to create motion in machines via cyclic variations in *shape space*. These endeavors[3–6] and the characterization of optimal trajectories[7–10] remain active areas of research.

Most recently, the quantum geometric phase has been realized as a way of constructing logic gates in a quantum computer.[11] Holonomic quantum computation (HQC) employs non-Abelian geometric phases (holonomies) for the purpose of quantum information processing. Here we present a unified framework for the control of quantum holonomic systems with applications to quantum computing by casting the model as a control system evolving on a principal bundle. The integration of control theoretic ideas into the HQC paradigm sharpens existing results for these systems and reveals computational techniques for solving two separate but related fundamental problems in quantum computing. First, the well known conditions for determining universal quantum computation must be translated to the holonomic framework. The determination of universality, however, is existential in nature and generally not constructive. Quantum logic gate synthesis or constructive controllability is the process of determining from the system dynamics the construction or concatenation from available transformations some desired dynamic transformation of the state. This latter task is required for executing quantum algorithms. Both of these issues have subtleties in the holonomic framework not encountered in the usual *dynamical* approach to quantum computing.

Since the introduction of this approach to quantum computing,[11] there has been considerable interest from the research community in proposing physical systems capable of performing HQC[12–19] and exploring its mathematical foundations.[20–30] This paper draws on much of this work to provide a characterization of the problem, introduce computational techniques, and present results for two classes of control architectures related to HQC. In particular, we state simple conditions for determining the holonomy group of a principal fiber bundle with connection. These conditions, well known and reported elsewhere,[8,5,27] circumvent the difficulties in directly applying the Ambrose–Singer theorem which was originally stated as the technique for determining universality of HQC. For quantum holonomy groups of dimension greater than 3, a direct application of Ambrose–Singer essentially neglects the contribution of nested Lie brackets of lifted vector fields, however these vector fields can provide new transformations available for manipulating quantum information. From the product bundle representing single qubit rotations and two

qubit interactions, conditions for universality can then be derived. Having established the decisive condition for determining universality, we explore the difficult inverse problem associated to constructing holonomies. Namely, given a desired holonomy what is the loop in parameter space that generates it? In principal, this information is sufficient for the experimentalist to construct particular holonomies in the laboratory. For the the $\mathbf{CP}^n$ model, holonomic logic gate synthesis has been successfully treated by a numerical optimization scheme in Refs. 29 and 28. Moreover, Ref. 28 refines the method to minimize the length of the loop in parameter space. Since the parameters must be driven sufficiently slowly for the adiabatic approximation to hold, minimizing length also minimizes the time to construct the logic gate. This criterion is perhaps relevant for combatting decoherence. Logic gate synthesis has also been treated analytically in Ref. 30, however these loops are characterized in the Grassmann manifold and not in parameter space. Characterizations of length minimizing loops can also be found in Refs. 8 and 9.

We apply the theory to two well studied models of HQC. We provide a complete analysis of the so-called *optical holonomic computer*.[21–26] We extend the results of Ref. 27 by carrying out the universality analysis and explicitly characterizing a parametric loop that can be employed to construct an arbitrary two-qubit logic gate. These results surmount a negative result reported for this model.[22] In a similar manner, we use the Cartan decomposition of the unitary group to solve the constructive controllability problem for holonomic systems involving a conditional Berry phase. To the best of our knowledge, aside from the $\mathbf{CP}^n$ model, the two control models treated here encompass all proposed holonomic computing schemes.

This paper is organized as follows: In Sec. II, following Ref. 22 the geometry of holonomic quantum computation is reviewed. Also in Sec. II, we introduce the product bundle describing single qubit holonomies and two qubit interaction holonomies and state conditions for universal holonomic quantum computation. In Sec. III, we introduce methods for solving the path ordered integral associated with logic gate synthesis in the holonomic framework. The main contributions of the paper are contained in Sec. IV, where we apply the theory of the preceding sections.

II. HOLONOMIC QUANTUM COMPUTATION

If a quantum state undergoes adiabatic evolution subject to a periodic Hamiltonian, it acquires a phase after one complete cycle. Berry's surprising discovery[31] was that, in addition to the well-known dynamical phase associated to the evolution, there is a phase of purely geometric origin. Berry's phase was then understood as the holonomy or geometric phase corresponding to a principal bundle with connection over a parameter space.[32] This phenomenon has been generalized in a variety of ways, most notably to nonadiabatic evolutions[33] and to degenerate systems possessing a non-Abelian phase factor.[34]

A. Preliminaries

We construct a family of degenerate Hamiltonians parametrized by elements of a parameter space M that govern the quantum dynamics. To allow for the possibility of a countably infinite dimensional Hilbert space, we consider universal classifying bundles. For further details see Refs. 22, 24, 35, and 36.

Let $\mathcal{H}$ be a separable (possibly infinite dimensional) Hilbert space, and define the manifolds

$$\mathrm{St}_k(\mathcal{H}) = \{V = (|v_1\rangle, \ldots, |v_k\rangle) \in \mathcal{H} \times \cdots \times \mathcal{H} | V^\dagger V = \mathbf{1}\}, \tag{1}$$

$$\mathrm{Gr}_k(\mathcal{H}) = \{X \in B(\mathcal{H}) | X^2 = X, X^\dagger = X, \mathrm{tr}\, X = n\}. \tag{2}$$

where $B(\mathcal{H})$ denotes the set of bounded linear operators on $\mathcal{H}$. These manifolds are known as the (universal) Stiefel and Grassmann manifolds, respectively. The space Gr_k is also known as a *classifying space* and can be defined as the union of Grassmann manifolds,[35]

$$\mathrm{Gr}_k(\mathcal{H}) \equiv \bigcup_{n=k}^{\infty} \mathrm{Gr}_{k,n}(\mathcal{H}). \tag{3}$$

Denote this $\mathrm{U}(k)$-bundle by P_k. Note that when $\mathcal{H} \cong \mathbb{C}^n$ and the system has a k-dimensional degeneracy, the bundle of interest is the more familiar $\mathrm{U}(k)$-bundle $\mathrm{St}_{k,n}(\mathbb{C}^n) \to \mathrm{Gr}_{k,n}(\mathbb{C}^n)$ which can be written in terms of homogeneous spaces as

$$\frac{\mathrm{U}(n)}{\mathrm{U}(n-k)} \to \frac{\mathrm{U}(n)}{\mathrm{U}(n-k) \times \mathrm{U}(k)}. \tag{4}$$

We continue with the infinite dimensional case with the understanding that the development specializes to this case when $\mathcal{H}$ is finite dimensional.

Let M be a finite dimensional parameter space and suppose the classifying map $\Pi_k: M \to \mathrm{Gr}_k$ (to be defined below) is given. Then form the pullback bundle $Q_k = \Pi_k^* P_k$,

$$\begin{array}{ccc} Q_k & \to & \mathrm{St}_k(\mathcal{H}) \\ \downarrow & & \downarrow \\ M & \overset{\Pi_k}{\to} & \mathrm{Gr}_k(\mathcal{H}). \end{array} \tag{5}$$

Let H_0 be a Hamilonian with a k-dimensional degeneracy spanned by the orthogonal basis $\{|v_j\rangle_{j=1}^k\}$. To simplify notation, let the degenerate eigenvalue be 0. In holonomic quantum computation, the degenerate subspaces of H_0 encode the quantum information. Suppose we have at our disposal a set of $\mathrm{U}(k)$ unitary transformations

$$\{W_1(x), W_2(x), \ldots, W_m(x)\} \tag{6}$$

parametrized by the base coordinate x. These are the (exponentiated) analogues of *control Hamiltonians*. Setting

$$\mathcal{U}_k(x) = \prod_j W_j(x), \tag{7}$$

we obtain the isospectral family of Hamiltonians given by

$$\mathcal{O}(H_0) \equiv \mathcal{U}_k(x) H_0 \mathcal{U}_k^\dagger(x). \tag{8}$$

In the adiabatic approximation, the adjoint orbit $\mathcal{O}(H_0)$ forms a family of Hamiltonians that govern the system since there are no energy level crossings. The classifying map is then defined as

$$\Pi_k(x) \equiv \mathcal{U}_k(x) \left(\sum_{j=1}^k |v_j\rangle\langle v_j| \right) \mathcal{U}_k^\dagger(x). \tag{9}$$

B. Control systems on principal fiber bundles

In general, let Q be a principal fiber bundle with structure group G over a base manifold M. Recall that a *connection* on Q defines a G-invariant distribution $\mathbb{H}$ such that $T_qQ = \mathbb{H}_q \oplus \mathbb{V}_q$, where $\mathbb{V}_q \equiv T_q(\mathcal{O}(q)) \cong \mathfrak{g}$ (the Lie algebra of G). Alternatively, a connection can be characterized by an Ad-equivariant $\mathfrak{g}$-valued one-form $\mathcal{A}$ on Q such that $\mathcal{A} \cdot \xi_q = \xi$, where ξ_q is the infinitesimal generator of the group action and $\xi \in \mathfrak{g}$. The horizontal subspace at a point $q \in Q$ is then defined as the kernel $\mathbb{H}_q = \{v_q | \mathcal{A} \cdot v_q = 0\}$. The local connection one-form, A, is defined with respect to a *local section* σ by $A \equiv \sigma^* \mathcal{A}$. Using Ad-equivariance and the fact that $\mathcal{A}$ is the identity on vertical vectors, we can obtain the local connection form in terms of the base variables only[35,37]

$$\mathcal{A} \cdot \dot{q} = \mathrm{Ad}_g(g^{-1}\dot{g} + A(x) \cdot \dot{x}). \tag{10}$$

We note that the term $g^{-1}\dot{g}$ is in the Lie algebra $\mathfrak{g}$, by interpreting $g^{-1}\dot{g}$ as the lifted action of g^{-1} on $\dot{g} \in T_g G$. Restricting the connection $\mathcal{A}$ to act on horizontal vectors yields an equation for the evolution of the group elements given by

$$g^{-1}\dot{g} = -A(x) \cdot \dot{x}. \tag{11}$$

Returning to the quantum setting, we note that the canonical connection on the bundle Q_k is given by $A_{wz} \equiv \mathcal{U}_k^{-1}\, \mathrm{d}\mathcal{U}_k$, The matrix elements of the connection form are given by

$$A^{\overline{vv}}_{x_\mu} \equiv \langle \overline{v} | \mathcal{U}_k^\dagger(x) \frac{\partial}{\partial x_\mu} \mathcal{U}_k(x) | v \rangle. \tag{12}$$

This is commonly known as the Wilczek–Zee connection.[34]

Assuming direct control over the base variables, we may interpret the quantum control system as a *control system evolving on a principal bundle* and write it locally as

$$g^{-1}\dot{g} = -A_{wz}(x) \cdot \dot{x},$$

$$\dot{x} = u, \tag{13}$$

where u is a vector of control inputs describing the controlled evolution in parameter space.

A formal solution to this system of equations corresponding to a particular path in parameter space is given by the *path ordered* integral

$$\mathbf{P} \exp \int_\gamma -A_{wz}\, \mathrm{d}x. \tag{14}$$

When γ is a closed curve in M, then $\mathbf{P} \exp \oint_\gamma -A_{wz}\, \mathrm{d}x$ lies in G and is known as the *holonomy* of γ. It is well known that the set of all such group elements taken over the set of closed curves in M is a subgroup of G and is known as the *holonomy group*. In *holonomic quantum computation*, quantum logic gates are implemented by holonomies acting on the degenerate subspaces.

C. Universality

A control system evolving on a principal fiber bundle is said to be *locally controllable* if any group element can be implemented on the state of the system. In the context of quantum computing, a system with this property is said to be (exactly) *universal*.[38] This property is a fundamental requirement for building a quantum processor. As is well known, in the usual dynamical approach to quantum computing (as opposed to the geometric approach addressed here), the Lie algebra generated by the system Hamiltonian and the control Hamiltonians determines the universality of the system. For an N qubit system, it is sufficient for this Lie algebra to span $\mathfrak{su}(2^n)$. We now show how these statements translate to the holonomic framework.

Let X^h denote the horizontal lift of a vector field X on M. This is the unique vector on TQ such that $T\pi(X^h) = X$ where π is the projection $\pi: Q \to M$. Then the *curvature* can be defined as a $\mathfrak{g}$-valued 2-form on Q given by

$$\mathcal{A}([X^h_{i_2}, X^h_{i_1}]) = -\mathcal{F}(X^h_{i_2}, X^h_{i_1}), \tag{15}$$

where $[\cdot,\cdot]$ denotes the Lie bracket on TQ. Thus evaluating the curvature determines the vertical component of the Lie bracket of horizontal vectors. Let $f: Q \to \mathfrak{g}$ be an Ad-equivariant function on Q, then

$$\mathcal{A}([X^h, f]) = -\mathrm{d}\mathcal{A}(X^h, f) + X^h(\mathcal{A}(f)) + f(\mathcal{A}(X^h)) \tag{16}$$

$$= X^h f, \tag{17}$$

since the function f is $\mathfrak{g}$-valued and $d\mathcal{A}(\cdot,\cdot)$ is zero if either argument is vertical.[35] Using the correspondence between covariant derivatives of the associated adjoint bundle and Lie derivatives of Ad-equivariant functions,[39] we obtain

$$\mathcal{A}([X^h, f]) = X^h f = D_{X^h} f. \tag{18}$$

Now, the curvature is an Ad-equivariant function on Q, so setting $\mathcal{F}=f$ and using the previous expression (18) to evaluate iterated Lie brackets of horizontally lifted vector fields, we can obtain the corollary to the well-known *Chow–Rashevski* theorem from control theory.[9]

Theorem 1: *(Ambrose–Singer–Chow–Rashevski) The system (13) is locally controllable at* $q \in Q$ *if the curvature* $F(X_{i_1}, X_{i_2})$ *and all of its covariant derivatives* $D_{X_{i_k}} \cdots D_{X_{i_3}} F(X_{i_1}, X_{i_2})$ *evaluated at the point* $x = \pi(q)$ *span the entire Lie algebra of* G.

Some remarks are in order. Following Ref. 9, we refer to the theorem as *Ambrose–Singer–Chow–Rashevski* since it can be considered to be a corollary to the *Ambrose–Singer*[39] theorem from the theory of holonomy. We note also that we have stated the theorem in terms of base vector fields and the local curvature. All the necessary ingredients of the theorem, although not explicitly stated, can be found in Ref. 39. In fact, the *infinitesimal holonomy algebra* is spanned by elements of the form

$$X^h_{i_k} \cdot X^h_{i_{k-1}} \cdots X^h_{i_3} \cdot \mathcal{F}(X^h_{i_1}, X^h_{i_2}). \tag{19}$$

We can then use the correspondence (18) to relate this to covariant derivatives of the associated adjoint bundle. This statement is used in our applications, since in some holonomic quantum computation problems the relevant holonomy algebra does not span the entire Lie algebra. However, it does contain *nonlocal* operations which together with holonomies corresponding to *local* operations do indeed span the entire Lie algebra. This is the usual local/nonlocal analysis often encountered in quantum information science.

For the purposes of building a quantum processor, the quantum information is stored in the $\mathbb{C}^2$ vector bundle associated to Q^2 and single qubit rotations are performed by SU (2) holonomies acting on the fiber $\mathbb{C}^2$. Interactions among qubits are modeled as SU (4) holonomies acting on the fibers of the vector bundle associated to Q^4.

Thus we may treat the control problems separately and form the product bundle (and its pullbacks)

$$\begin{array}{ccccccc} \cdots & \mathrm{St}_2(\mathcal{H}_i) & \times & \mathrm{St}_4(\cdots \otimes \mathcal{H}_i \otimes \mathcal{H}_j \otimes \cdots) & \times & \mathrm{St}_2(\mathcal{H}_j) & \cdots \\ & \downarrow & & \downarrow & & \downarrow & \\ \cdots & \mathrm{Gr}_2(\mathcal{H}_i) & \times & (\mathrm{Gr}_4)^{\mathrm{int}}(\cdots \otimes \mathcal{H}_i \otimes \mathcal{H}_j \otimes \cdots) & \times & \mathrm{Gr}_2(\mathcal{H}_j) & \cdots . \end{array} \tag{20}$$

To set notation, let

$$I_x = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad I_y = \frac{1}{2}\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad I_z = \frac{1}{2}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \mathbf{1} = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}. \tag{21}$$

We define the *local algebra* generated by the elements

$$I_{k1} = I_k \otimes \mathbf{1}, \quad I_{k2} = \mathbf{1} \otimes I_k, \tag{22}$$

where $k \in \{x, y, z\}$ The local algebra is the Lie algebra corresponding to the *local group* SU(2) $\otimes$ SU(2).

To conclude exact universality (controllability) of the system, one should compute the *control Lie algebra* with the constituent holonomy algebras. For example, in the two-qubit system, compute the Lie algebra generated by $\mathfrak{su}(2) \otimes \mathbf{1}, \mathbf{1} \otimes \mathfrak{su}(2)$ and the interaction holonomy algebra $\mathfrak{hol}_{\mathrm{int}}$ associated with the bundle $\mathrm{St}_4(\mathcal{H}_i \otimes \mathcal{H}_j) \to (\mathrm{Gr}_4)^{\mathrm{int}}(\mathcal{H}_i \otimes \mathcal{H}_j)$. In the generic case, the control Lie

algebra will generate $\mathfrak{su}(4)$ provided that $\mathrm{Hol}_{\mathrm{int}}$ is not isomorphic to the local group or is trivial.

Theorem 2: *The two-qubit holonomic system is exactly universal if the Lie algebra generated by the local algebra and* $\mathfrak{hol}_{\mathrm{int}}$ *spans* $\mathfrak{su}(4)$.

III. CONSTUCTIVE CONTROLLABILITY

Having established conditions for determining universality in HQC, we now present various ways of solving or approximating the solution to the path ordered integral arising for the differential equation defining the group displacement

$$g^{-1}\dot{g} = -A(x)\cdot\dot{x}. \tag{23}$$

For control systems on principal bundles, this equation describes the group transformation obtained from a controlled cyclic variation of the parameters in the base manifold. Recall, that we assume direct access and complete controllability over the base variables. We endeavor to ascertain the desired group transformation resulting from a particular choice of loop in the base space. This is the notion of constructive controllability in the context of a control system on a principal bundle. In HQC these procedures provide explicit methods for logic gate synthesis. This requires dealing with the path ordered integral obtained from (23).

A. Path ordered integral

We define the path ordered integral as a product integral. Let γ be a curve in the base manifold M and let x^μ be local coordinates. We may express the local connection form A in terms of coordinates as

$$A(x) = A_\mu(x)\mathrm{d}x^\mu. \tag{24}$$

The curve γ is parametrized by an intrinsic parameter s, which is naturally considered to be time. In terms of s, A takes the form

$$A_\mu(x(s))\mathrm{d}x^\mu = A(s)\mathrm{d}s, \tag{25}$$

where

$$A(s) \equiv A_\mu(x(s))\frac{\mathrm{d}x^\mu(s)}{\mathrm{d}s}. \tag{26}$$

Let $[s_0, s_T]$ be a real interval over which the curve γ is defined. Consider a partition of the interval $P=\{s_0, s_1, \ldots, s_n\}$ such that $\Delta s_k = s_k - s_{k-1}$ and $s_n = s_T$. Then path ordering operator may be defined as

$$\mathbf{P}\exp\int_\gamma -A(s)\mathrm{d}s \equiv \lim_{n\to\infty}\prod_{s_0}^{s_n}\exp(-A(s_k)\Delta s_k). \tag{27}$$

This definition clearly shows the dependence on the ordering of the exponentials and the difficulties associated with its solution, given that we are naturally interested in the case where the relevant group is non-Abelian. When G is Abelian, then one can directly integrate the connection coefficients and apply the usual exponential operator.

B. Abelian substructures

A common technique in holonomic quantum computation for tackling the integral (27) is to restrict the class of loops and exploit Abelian substructures in the connection components.[12,21] The strategy is briefly described as follows. Choose a particular 2-manifold of M spanned by the

coordinates (σ,τ) such that the associated connection components commute, that is $[A_\sigma,A_\tau]=0$ but for which the local curvature form is not identically zero. For these restricted loops the path ordering in (27) can be avoided and the line integral

$$\oint_\gamma A(x)\mathrm{d}x = \oint_\gamma (A_\sigma\,\mathrm{d}\sigma + A_\tau\,\mathrm{d}\tau) \tag{28}$$

can be integrated directly and exponentiated.

Alternatively, one can use a non-Abelian Stokes theorem[40] for evaluating holonomies corresponding to curves lying in a 2-submanifold of parameter space.

C. Averaging

The exact results of the preceding section were accompanied by restrictions on the set of loops available to the controller or by exploiting Abelian substructures in the connection components. Here we review local approximations that can be used for any system evolving on a principal bundle.

In Ref. 41, Leonard and Krishnaprasad developed approximate control algorithms for left invariant control systems on Lie groups of the form

$$g^{-1}\dot{g} = \epsilon U(t) \tag{29}$$

where ϵ is a (small) parameter and $U(t)=T_\alpha u^\alpha(t)$ for a basis $\{T_\alpha\}$ of $\mathfrak{g}$. They employ a Magnus expansion for a representation of the solution

$$g(t) = g(0)\exp(\xi(t)) \tag{30}$$

given by

$$\xi(t) = \epsilon\int_0^t U(\tau)\mathrm{d}\tau + \frac{\epsilon^2}{2}\int_0^t [\tilde{U}(\tau),U(\tau)]\mathrm{d}\tau + \frac{\epsilon^3}{4}\int_0^t\left[\int_0^\tau [\tilde{U}(\sigma),U(\sigma)]\mathrm{d}\sigma,U(\tau)\right]\mathrm{d}\tau + \cdots, \tag{31}$$

where $\tilde{U}(t)$ is the effective input "averaged" over the time period.[41]

Radford and Burdick have generalized this expansion for systems evolving on principal bundles.[5] Let $\gamma:[0,T]\to M$ be a closed curve in the base space parametrized by $x\in M$, then it is shown in Ref. 5 that the holonomy associated to γ can be locally approximated by

$$g(T) = g(0)\exp(\xi(\gamma)), \tag{32}$$

where

$$\xi(\gamma) = -\frac{1}{2}F(X_i,X_j)\int_\gamma \mathrm{d}x_i\,\mathrm{d}x_j + \frac{1}{3}D_{X_i}(F(X_j,X_k))\int_\gamma \mathrm{d}x_i\,\mathrm{d}x_j\,\mathrm{d}x_k + \cdots. \tag{33}$$

Here $F(X_i,X_j)$ is the local curvature form evaluated on the base coordinate vectors $X_i=\partial/\partial_{x_i}$ evaluated at $\gamma(0)$, $D_{\partial/\partial_{x_i}}$ is the covariant derivative of the curvature along the base coordinate vector ∂/∂_{x_i} and the area integrals are defined by

$$\mathcal{I}_{x_ix_jx_k} = \int_\gamma \mathrm{d}x_i\,\mathrm{d}x_j\,\mathrm{d}x_k \equiv \int_0^T\int_0^{t_k}\int_0^{t_j}\dot{x}^i(t_i)\mathrm{d}t_i\,\dot{x}^j(t_j)\mathrm{d}t_j\,\dot{x}^k(t_k)\mathrm{d}t_k. \tag{34}$$

Higher order terms are given by higher order covariant derivatives of the curvature. This is plausible given expression (33) and the fact that iterated Lie brackets of horizontally lifted vector fields appear as covariant derivatives of the curvature.

IV. APPLICATIONS

In this section we apply the results of the preceding sections. We first review the $\mathbf{CP}^n$ model of quantum holonomy. This was the original system discovered by Wilczek and Zee[34] and subsequently proposed as a model for HQC. We then consider two very different models of quantum holonomic systems. Holonomic quantum computation with squeezed coherent states has a rich interaction holonomy group that can be exploited to obtain contructive controllability algorithms. On the other hand, quantum computation based on the conditional phase shift has become the dominant control strategy for a wide range of holonomic quantum computing schemes. We will see that the interaction holonomy for systems of this type is quite limited yet powerful enough for universal computation and constructive algorithms.

A. The $\mathbf{CP}^n$ model

The $\mathbf{CP}^n$ (Ref. 11) model gives a concrete example illustrating how non-Abelian holonomies can occur in highly degenerate systems. In this model, we assume that the Hilbert space $\mathcal{H}$ is finite dimensional from the outset. That is, we have the isomorphism $\mathcal{H}\cong\mathbb{C}^{n+1}=\{|\alpha\rangle\}_{\alpha=1}^{n+1}$. We further assume an n-dimensional degenerate subspace with eigenvalue 0. We may write the degenerate Hamiltonian H_0 as

$$H_0=\epsilon|n+1\rangle\langle n+1|=\begin{pmatrix}0 & 0 & \cdots & 0\\ 0 & \ddots & 0 & 0\\ \vdots & & \ddots & \\ 0 & 0 & 0 & \epsilon\end{pmatrix}. \tag{35}$$

Let $\{\mathcal{T}_{j,n+1}(x)\}_{j=1}^{l}$ denote a basis of $\mathfrak{u}(n)$ parametrized by $x\in M$ embedded in $\mathfrak{u}(n+1)$ and let $\mathcal{U}_n=\Pi_j^l\exp(\mathcal{T}_{j,n+1}(x))$. Given these control operations, it is perhaps not surprising that the holonomy group can be shown to be $\mathrm{U}(n)$ by considering the curvature coefficients only (and not its covariant derivatives).[34,11]. We have the isomorphism

$$\mathcal{O}(H_0)\cong\frac{\mathrm{U}(n+1)}{\mathrm{U}(n)\times\mathrm{U}(1)}\cong\frac{\mathrm{SU}(n+1)}{\mathrm{U}(n)}\cong\mathbf{CP}^n. \tag{36}$$

This system requires control over $2n=\dim_{\mathbb{R}}\mathbf{CP}^n$ real parameters to control an n-level system. For high dimensional systems, this may be an unrealistic requirement.

B. Squeezed coherent states

In this section we revisit the mathematical foundations of *holonomic quantum computation with squeezed coherent states*. There is considerable literature already on this model,[12,21–23,25,26] here we exploit the methods of geometric control. Originally, this model was proposed in the context of quantum optics[12] with displacers and squeezers operating on coherent laser beams in a nonlinear Kerr medium and thus known as the optical holonomic computer. However, other physical systems have quantum states that may be displaced and squeezed. As far as the control analysis is concerned, these systems are identical. Pachos has recently adapted the model to perform trapped ion quantum computation.[16] We, therefore, refer to this model generically as *holonomic quantum computation with squeezed coherent states*.

1. Harmonic oscillator

Recall that the commutation relations of the creation, annihilation, and number operator $N\equiv a^\dagger a$, are given by

$$[N,a^\dagger]=a^\dagger,\quad [N,a]=a,\quad [a,a^\dagger]=\mathbf{1}. \tag{37}$$

The underlying Hilbert space $\mathcal{H}$ is a Fock space and takes the form

$$\mathcal{H} = \{|n\rangle, \alpha \in \mathbf{N} \cup 0\}. \tag{38}$$

The creation and annihilation operators act on $\mathcal{H}$ according to

$$a|n\rangle = \sqrt{n}|n-1\rangle, \quad a^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle, \quad a|0\rangle = 0. \tag{39}$$

Thus a and $a^\dagger$ create and destroy quanta.

Since we are interested in the two-qubit system, we will use the subscript i to distinguish the creation and annihilation corresponding to the ith field of the harmonic oscillator. That is, we set $N_i = a_i^\dagger a_i$ and

$$a_1 = a \otimes \mathbf{1}, \quad a_1^\dagger = a^\dagger \otimes \mathbf{1}, \tag{40}$$

$$a_2 = \mathbf{1} \otimes a, \quad a_2^\dagger = \mathbf{1} \otimes a^\dagger. \tag{41}$$

To provide a concrete example, we will use the degenerate Hamiltonian

$$H^i = N_i(N_i - 1) \tag{42}$$

to encode the ith qubit in the degenerate subspace $\{|0_i\rangle, |1_i\rangle\}$ and

$$H^{12} = N_1(N_1 - 1) + N_2(N_2 - 1) \tag{43}$$

to obtain controlled interactions on the computation basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$ where $|ij\rangle = |i\rangle \otimes |j\rangle$. In the optics context, this Hamiltonian corresponds (up to a constant) to placing lasers in a nonlinear Kerr medium.[12,21] However, the form of the degenerate Hamiltonian does not affect the control analysis. For our purposes, it is used only to encode the quantum information. With slight modification of some constants, the results in this section apply to the trapped ion model proposed in Ref. 16.

2. Single qubit

We consider first single qubit rotations. Consider the eigenvalue problem for a single creation operator. The state $|\alpha\rangle$ can be written in terms of the basis $\{|n\rangle\}$,

$$|\alpha\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} |n\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n a^{\dagger n}}{n!} |0\rangle. \tag{44}$$

Which is equal to

$$|\alpha\rangle = e^{-|\alpha|^2/2} e^{\alpha a^\dagger} |0\rangle \tag{45}$$

and allows for the definition of the *displacement operator*

$$|\alpha\rangle = D(\alpha) = e^{-|\alpha|^2/2} e^{\alpha a^\dagger} e^{-\alpha^* a} |0\rangle. \tag{46}$$

Note that the introduction of $e^{-\alpha^* a}$ does nothing since $a|0\rangle = |0\rangle$ By using the Campbell–Baker–Hausdorff formula and noting that $[\alpha a^\dagger, -\alpha^* a] = |\alpha|^2$, we may write

$$|\alpha\rangle = D(\alpha)|0\rangle = e^{\alpha a^\dagger - \alpha^* a}|0\rangle. \tag{47}$$

We see that the displacement operator creates a coherent state $|\alpha\rangle$ from the vacuum state $|0\rangle$. In HQC with squeezed coherent states, the displacement operator will be a control operator. The other transformation we have at our disposal is the *squeezing operator*, $S(\beta)$, defined by

$$S(\beta) = e^{\beta \Lambda_+ - \beta^* \Lambda_-}, \tag{48}$$

where

$$\Lambda_+ \equiv \tfrac{1}{2}a^{\dagger 2}, \quad \Lambda_- \equiv \tfrac{1}{2}a^2. \tag{49}$$

If we define,

$$\Lambda_3 \equiv \tfrac{1}{4}(aa^\dagger + a^\dagger a), \tag{50}$$

then we have the commutation relations,

$$[\Lambda_3, \Lambda_+] = \Lambda_+, \quad [\Lambda_3, \Lambda_-] = -\Lambda_-, \quad [\Lambda_+, \Lambda_-] = 2\Lambda_3. \tag{51}$$

These are the commutation relations for $\mathfrak{su}(1,1)$; thus we see that the squeeze operator is a representation of the noncompact group SU(1, 1). With these two unitary transformations, we form the product

$$\mathcal{U}_2(\alpha, \beta) = D(\alpha)S(\beta) \tag{52}$$

and the isospectral family of Hamiltonians

$$\mathcal{U}_2(\alpha, \beta)H^i\mathcal{U}_2^\dagger(\alpha, \beta). \tag{53}$$

The holonomy group for the single qubit system has been shown to be U(2).[12,21–23] Thus we have complete control over the single qubit.

3. Two qubit

To obtain universality over the entire quantum register it suffices to show nontrivial U(4) transformations on the computational basis and check the control Lie algebra. Analogously to the single qubit case, we employ displacement and squeeze operators as our control operations. Let

$$J_+ = a^\dagger{}_1 a_2, \quad J_- = a^\dagger{}_2 a_1, \quad J_3 = \tfrac{1}{2}(a^\dagger{}_1 a_1 - a^\dagger{}_2 a_2). \tag{54}$$

These generate SU(2) with the commutation relations,

$$[J_3, J_+] = J_+, \quad [J_3, J_-] = -J_-, \quad [J_+, J_-] = 2J_3. \tag{55}$$

The two-mode displacement operator is defined as

$$N(\xi) = \exp(\xi a_1^\dagger a_2 - \overline{\xi} a_1 a_2^\dagger). \tag{56}$$

Similarly, we may define the two-mode squeeze operator as a representation of SU(1, 1). Let

$$K_+ = a^\dagger{}_1 a^\dagger{}_2, \quad K_- = a_1 a_2, \quad K_3 = \tfrac{1}{2}(a^\dagger{}_1 a_1 + a^\dagger{}_2 a_2), \tag{57}$$

and

$$[K_3, K_+] = K_+, \quad [K_3, K_-] = -K_-, \quad [K_+, K_-] = -2K_3. \tag{58}$$

The two-mode squeeze operator is defined as

$$M(\zeta) = \exp(\zeta a_1^\dagger a_2^\dagger - \overline{\zeta} a_1 a_2), \tag{59}$$

where $\xi, \zeta \in \mathbf{C}$. Set

$$\mathcal{U}_4 = N(\xi)M(\zeta). \tag{60}$$

Setting $\zeta = r_2 e^{i\theta_2}$ and $\xi = r_3 e^{i\theta_3}$ and we obtain the two-qubit connection coefficients[21] listed in Appendix A. The interaction holonomy algebra spans $\mathfrak{su}(2) \times \mathfrak{su}(2) \times \mathfrak{u}(1)$ (Ref. 27) (also listed in Appendix B). Higher order covariant derivatives do not yield independent group directions. The matrices in $\mathfrak{hol}_{\text{int}}$ sit in $\mathfrak{u}(4)$ in a manner that allows for nonlocal U(4) transformations on the computational basis. By the reduction theorem for connections,[39] the connection is reducible to a

$\mathrm{su}(2)\times\mathrm{su}(2)\times\mathrm{u}(1)$-valued connection and we may reduce the total space to $\mathrm{St}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2)$. To determine the reduced base manifold, we form the quotient

$$\frac{\mathrm{U}(4)}{\mathrm{SU}(2)\times\mathrm{SU}(2)\times\mathrm{U}(1)}\cong\frac{\mathrm{SU}(4)}{\mathrm{SU}(2)\times\mathrm{SU}(2)}\cong S\,\mathrm{Gr}_{2,4}\equiv(\mathrm{Gr}_{2,4})^{\mathrm{int}}. \tag{61}$$

In a similar manner, we can reduce the bundles $\mathrm{St}_2(\mathcal{H}_i)\mapsto\mathrm{Gr}_2(\mathcal{H}_i)$ corresponding to the single qubit rotations. The U(2) holonomies act in the product space $\mathcal{H}_1\otimes\mathcal{H}_2$ as $\mathrm{U}(2)\otimes\mathbf{1}$ and $\mathbf{1}\otimes\mathrm{U}(2)$. The bundles reduce to $\mathrm{St}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2)\mapsto\mathrm{Gr}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2)$. For the full two-qubit system, we have the reduced product bundle,

$$\begin{array}{ccccc}\mathrm{St}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2) & \times & \mathrm{St}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2) & \times & \mathrm{St}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2)\\ \downarrow & & \downarrow & & \downarrow\\ \mathrm{Gr}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2) & \times & (\mathrm{Gr}_{2,4})^{\mathrm{int}}(\mathcal{H}_1\otimes\mathcal{H}_2) & \times & \mathrm{Gr}_{2,4}(\mathcal{H}_1\otimes\mathcal{H}_2).\end{array} \tag{62}$$

4. Control algebra

To be complete, we will now demonstrate that all of SU(4) may be obtained from the single qubit rotations and the two-qubit transformations above. Of course, as we have mentioned earlier, this is generically true provided the two-qubit holonomy group is not isomorphic to the local group. Nonetheless, it is useful to go though the computations.

From the single qubit analysis, we know that we can perform local transformations of the form $\mathrm{SU}(2)\otimes\mathrm{SU}(2)$. To simplify matters further, we use linear combinations of the two-qubit curvature forms and covariant derivatives and consider only

$$\{F_{r_2r_3},F_{r_2\theta_3},F_{r_3\theta_3},D_{\partial/\partial\theta_2}F_{r_2\theta_2},\tilde{D}_{\partial/\partial r_2}F_{r_2\theta_2}\}, \tag{63}$$

where

$$\tilde{D}_{\partial/\partial r_2}F_{r_2\theta_2}=\begin{pmatrix}0&0&0&-e^{-i\theta_2}\\0&0&0&0\\0&0&0&0\\-e^{i\theta_2}&0&0&0\end{pmatrix}4i\sinh 2r_2. \tag{64}$$

From this set of matrices and the local algebra (22), we may build a set of holonomic transformations spanning $\mathfrak{su}(4)$. After taking iterated brackets from these sets, we find that one choice of spanning elements is given by

$$\mathfrak{su}(4)=\{\mathcal{C}_1\cup\mathcal{C}_2\cup\mathcal{C}_3\}, \tag{65}$$

where $\mathcal{C}_1=\{I_{x1},I_{y1},I_{z1},I_{x2},I_{y2},I_{z2}\}$ and

$$\mathcal{C}_2=\{F_{r_2r_3},F_{r_2r\theta_3},D_{\partial/\partial\theta_2}F_{r_2\theta_2},\tilde{D}_{\partial/\partial r_2}F_{r_2\theta_2}\},$$

$$\mathcal{C}_3=\{[I_{x1},F_{r_2r_3}],[I_{x1},F_{r_2\theta_3}],[I_{x2},F_{r_2r_3}],[I_{x2},F_{r_2\theta_3}],[[I_{x1},F_{r_2r_3}],I_{x2}]\}.$$

Please see Appendix C for the matrix representation of these elements.

5. An approximate holonomy in the Cartan subalgebra of $\mathfrak{su}(4)$

In the preceding section, we showed that it is indeed *possible* to create holonomic transformations spanning the full unitary group on two qubits. This was not a constructive procedure. In this section, we show that by using a combination of the methods in the preceding sections, we can solve the logic gate synthesis problem completely. We use the local expansion of the holonomy

procedure to construct an element in the Cartan subalgebra of $\mathfrak{su}(4)$ and use the Cartan decomposition of SU(4) to obtain the result.

The Cartan decomposition of the unitary groups is a powerful technique that has been used for constructing quantum control algorithms,[42,43] deriving time optimal control laws for quantum spin systems[44] and understanding the entanglement content of two-qubit unitaries,[45,46] Here we review the decomposition for the purposes of constructing control algorithms.

Let K denote a closed and compact subgroup of a Lie group G. Assume that $\mathfrak{g}$ admits a vector space decomposition,

$$\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}, \tag{66}$$

where $\mathfrak{k}$ is the Lie algebra of K and $\mathfrak{p}$ is vector space orthogonal to $\mathfrak{k}$ with respect to a biinvariant metric $\langle \cdot, \cdot \rangle$ on $\mathfrak{g}$. Further assume that $\mathfrak{k}$ and $\mathfrak{p}$ satisfy the following commutation relations:

$$[\mathfrak{k},\mathfrak{k}] \subset \mathfrak{k}, \quad [\mathfrak{p},\mathfrak{p}] \subset \mathfrak{k}, \quad [\mathfrak{p},\mathfrak{k}] \subset \mathfrak{p}. \tag{67}$$

We refer to a this decomposition as a Cartan decompostion of the Lie algebra $\mathfrak{g}$.

Let $\mathfrak{a}$ denote a maximal Abelian subalgebra contained in $\mathfrak{p}$. The algebra $\mathfrak{a}$ is often called the *Cartan subalgebra* of $\mathfrak{g}$. Then one can write G as

$$G = KAK, \tag{68}$$

where $A = \exp(\mathfrak{a})$.

In a two-qubit system, interactions among the qubits are modeled by the products

$$I_{kl} = 2I_k \otimes I_l, \tag{69}$$

where $k,l \in \{x,y,z\}$. For example,

$$I_{yy} = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}. \tag{70}$$

The Cartan decomposition of $\mathfrak{su}(4)$ is given by

$$\mathfrak{k} = i\{I_{x1}, I_{y1}, I_{z1}, I_{x2}, I_{y2}, I_{z2}\}, \tag{71}$$

$$\mathfrak{p} = i\{I_{xx}, I_{xy}, I_{xz}, I_{yx}, I_{yy}, I_{yz}, I_{zx}, I_{zy}, I_{zz}\}, \tag{72}$$

$$\mathfrak{a} = i\{I_{xx}, I_{yy}, I_{zz}\}. \tag{73}$$

Thus we can write any $g \in \mathrm{SU}(4)$ as

$$g = K_1 \exp(-i\phi_1 I_{xx} - i\phi_2 I_{yy} - i\phi_3 I_{zz}) K_2, \tag{74}$$

where ϕ_j is a real parameter and $K_j \in \mathrm{SU}(2) \otimes \mathrm{SU}(2)$.

By inspection of the two-qubit curvature forms and their covariant derivatives, it seems possible that I_{yy} can be obtained by linear combinations of the elements,

$$\{F_{r_2\theta_2}, F_{r_2\theta_3}, D_{\partial/\partial r_2} F_{r_2\theta_2}, D_{\partial/\partial r_2} F_{r_2\theta_3}\}. \tag{75}$$

Equivalently, I_{yy} is contained in the real span of

$$\left[\frac{\partial^h}{\partial x_k},\left[\frac{\partial^h}{\partial x_{k-1}},\cdots\left[\frac{\partial^h}{\partial x_2},\frac{\partial^h}{\partial x_1}\right]\right]\cdots\right], \tag{76}$$

where $x \in \{r_2, \theta_2, \theta_3\}$.

We therefore choose a candidate loop, γ^*, of the form

$$\theta_2(t) = \theta_2(0) + \Theta_2 \sin(t), \tag{77}$$

$$r_2(t) = r_2(0) + R_2 \cos(t) - R_2, \tag{78}$$

$$\theta_3(t) = \theta_3(0) + \Theta_3 \sin(nt), \quad n \neq 1, \tag{79}$$

$$r_3 = \text{const.}, \tag{80}$$

with the parameters $\{n, r_2(0), \theta_2(0), \theta_3(0), R_2; \Theta_2, \Theta_3\}$ to be determined. We compute the integrals appearing in the expansion (33), with the period $T=2\pi$ and choose some parameters to yield the expressions,

$$F_{r_2\theta_2} \cdot \mathcal{I}_{r_2\theta_2} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix} 2i \sinh 2r_2(0) \cdot R_2\Theta_2\pi, \tag{81}$$

$$F_{r_2\theta_3}\big|_{\theta_3(0)=\pi} \cdot \mathcal{I}_{r_2\theta_3} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} i \sin 2r_3 \sinh 2r_2(0) \cdot \frac{R_2\Theta_3 \sin 2n\pi}{n^2-1}, \tag{82}$$

$$D_{\partial/\partial r_2} F_{\theta_3 r_2}\big|_{\theta_3(0)=\pi} \cdot \mathcal{I}_{r_2\theta_3 r_2} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} 2i \sin 2r_3 \cosh 2r_2(0) \cdot \frac{-6R_2^2\Theta_3 \sin 2n\pi}{n^4-5n^2+4}, \tag{83}$$

$$\begin{aligned} D_{\partial/\partial r_2} F_{r_2\theta_2}\big|_{\theta_2(0)=0} \cdot \mathcal{I}_{r_2 r_2 \theta_2} = & \begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix} 4i \sinh 2r_2(0) \cdot 2\Theta_2 R_2^2 \pi \\ & + \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix} 4i \cosh 2r_2(0) \cdot 2\Theta_2 R_2^2 \pi. \end{aligned} \tag{84}$$

We also have,

$$\mathcal{I}_{\theta_2 r_2 \theta_2} = 0, \tag{85}$$

$$F_{\theta_2\theta_3} = 0, \tag{86}$$

$$D_{\partial/\partial\theta_3} F_{r_2\theta_2} = 0, \tag{87}$$

$$D_{\partial/\partial\theta_3} F_{r_2\theta_3}|_{r_3(0)=\pi/4} = 0, \tag{88}$$

$$F_{r_2\theta_2} \cdot \mathcal{I}_{r_2\theta_2} = F_{\theta_2 r_2} \cdot \mathcal{I}_{\theta_2 r_2}, \tag{89}$$

$$F_{r_2\theta_3}|_{\theta_3(0)=\pi} \cdot \mathcal{I}_{r_2\theta_3} = F_{\theta_3 r_2}|_{\theta_3(0)=\pi} \cdot \mathcal{I}_{\theta_3 r_2}, \tag{90}$$

$$-2D_{\partial/\partial r_2} F_{r_2\theta_3}|_{\theta_3(0)=\pi} \cdot \mathcal{I}_{r_2 r_2\theta_3} = D_{\partial/\partial r_2} F_{\theta_3 r_2}|_{\theta_3(0)=\pi} \cdot \mathcal{I}_{r_2\theta_3 r_2}, \tag{91}$$

$$2D_{\partial/\partial r_2} F_{\theta_2 r_2}|_{\theta_2(0)=0} \cdot \mathcal{I}_{r_2\theta_2 r_2} = D_{\partial/\partial r_2} F_{r_2\theta_2}|_{\theta_2(0)=0} \cdot \mathcal{I}_{r_2 r_2\theta_2}. \tag{92}$$

The strategy now is to choose parameters so that the $F_{r_2\theta_2}$ terms kill the terms along the diagonal in the expressions $D_{\partial/\partial r_2} F_{r_2\theta_2}$ and $D_{\partial/\partial r_2} F_{\theta_2 r_2}$. Then, with those parameters chosen, we choose the rest of the parameters so that the remaining terms combine to yield $-i\theta I_{yy}$, where θ is a free parameter. Remembering to include the coefficients in the expansion, the first objective leads to the following equation:

$$r_2(0) = -\tfrac{1}{2} \operatorname{arctanh}(2R_2). \tag{93}$$

Setting $\Theta_2 = \Theta_3 = \theta$, and substituting the preceding equation defining $r_2(0)$ and R_2, the second objective yields

$$R_2 = -\frac{\sin 2n\pi}{4\pi(n^2 - 4)}. \tag{94}$$

If n is chosen so that (94) is nonzero and (93) is well defined, the loop γ^* determines the holonomy (up to third order)

$$\Gamma(\gamma^*) = \exp(-i\theta I_{yy}), \tag{95}$$

where θ is a free parameter.

Loops generating single qubit SU(2) holonomies can be characterized by *abelianizing* the dynamics.[21] Thus with this single two-qubit holonomy, we can construct any SU(4) transformation on the computational basis. To see this, recall that any SU(4) transformation may be written with the Cartan decomposition

$$g = K_1 \exp(-i\theta_1 I_{xx} - i\theta_2 I_{yy} - i\theta_3 I_{zz}) K_2, \tag{96}$$

where $K_j \in \mathrm{SU}(2) \otimes \mathrm{SU}(2)$.

We may obtain the transformations $\exp(-i\theta_1 I_{xx})$ and $\exp(-i\theta_1 I_{zz})$ by noting that

$$K_z^{-1}\left(\frac{\pi}{2}\right) \exp(-i\theta I_{yy}) K_z\left(\frac{\pi}{2}\right) = \exp(-i\theta I_{xx}), \tag{97}$$

$$K_x\left(\frac{\pi}{2}\right) \exp(-i\theta I_{yy}) K_x^{-1}\left(\frac{\pi}{2}\right) = \exp(-i\theta I_{zz}), \tag{98}$$

where

$$K_z(\theta) = \exp(-i\theta I_{z1}) \exp(-i\theta I_{z2}), \tag{99}$$

$$K_x(\theta) = \exp(-i\theta I_{x1})\exp(-i\theta I_{x2}). \tag{100}$$

Thus any $g \in \mathrm{SU}(4)$ can be approximated up to third order by

$$g = K_1 K_z^{-1}\left(\frac{\pi}{2}\right)\Gamma(\gamma^*)K_z\left(\frac{\pi}{2}\right)\Gamma(\gamma^*)K_x\left(\frac{\pi}{2}\right)\Gamma(\gamma^*)K_x^{-1}\left(\frac{\pi}{2}\right)K_2. \tag{101}$$

One can also use the *abelianization* procedure of the preceding section to construct a holonomy of the form[12,21]

$$\tilde{U} = \frac{1}{\sqrt{2}}\begin{pmatrix} \sqrt{2} & 0 & 0 & 0 \\ 0 & 1 & -i & 0 \\ 0 & -i & 1 & 0 \\ 0 & 0 & 0 & \sqrt{2} \end{pmatrix}. \tag{102}$$

One can then show that the Lie algebra element $\tilde{\xi}$ such that $\exp(\tilde{\xi}) = \tilde{U}$ along with the local algebra generates $\mathfrak{su}(4)$ under repeated bracketing. Thus $\tilde{U}$ is a so-called *universal logic gate*. However, this procedure does not give a prescription for building an arbitrary SU(4) transformation.

C. Conditional Berry phases

An interesting hybrid scheme to quantum computing involving *dynamical* SU(2) rotations and conditional Berry phases has been realized as a universal set of gates for several physical systems proposed for quantum computing. To date, there have been HQC implementations using this control paradigm with NMR,[13] trapped ions,[14] neutral atoms,[15] semiconductor nanostructures,[17] and Josephson junction networks.[18,19] We refer the reader to the literature for a description of the physical systems underlying these proposed quantum computing schemes.

Here we are interested in the control strategy of the experimentalist with the gates available in systems of this type. Namely, how does one build an arbitrary unitary transformation on two coupled qubits given only single qubit rotations and the conditional phase shift? It is perhaps surprising that indeed this is possible and one can entangle qubits with only the conditional phase shift as the nonlocal operation. We note that in these systems, the calculation of the geometric phase is trivial since one is able to exploit Abelian substructures in the case of the SU(2) phases and the Abelian Berry phase may be computed with the standard version of Stokes theorem.

Since the conditional phase gate is not an element of SU(4), we employ a Cartan decomposition of U(4). To this end, recall the notation of the preceding section and note that the real span of the sets

$$\mathfrak{k} = i\{I_{x1}, I_{y1}, I_{z1}, I_{x2}, I_{y2}, I_{z2}\}, \tag{103}$$

$$\mathfrak{p} = i\{\mathbf{1}_4, I_{xx}, I_{yy}, I_{zz}, I_{xy}, I_{xz}, I_{yx}, I_{yz}, I_{zx}, I_{zy}\} \tag{104}$$

form a basis of $\mathfrak{u}(4)$ in the tensor product representation. Moreover, one can check the commutation relations (67) to confirm that the set forms a Cartan decomposition of $\mathfrak{u}(4)$ where $\mathfrak{u}(4) = \mathfrak{k} \oplus \mathfrak{p}$. Since the maximal Abelian subalgebra $\mathfrak{a}$ contained in $\mathfrak{p}$ is just

$$\mathfrak{a} = i\{\mathbf{1}_4, I_{xx}, I_{yy}, I_{zz}\}, \tag{105}$$

we obtain the decomposition for any $G \in \mathrm{U}(4)$,

$$G = K_1 \exp(-i\phi_0 \mathbf{1}_4 - i\phi_1 I_{xx} - i\phi_2 I_{yy} - i\phi_3 I_{zz}) K_2, \tag{106}$$

where $\phi_i \in \mathbb{R}$ and $K_j \in K = \mathrm{SU}(2) \otimes \mathrm{SU}(2)$.

1. Control algorithms

Proceeding along the lines of Refs. 42, 44, and 43, we develop control algorithms with single qubit rotations and the conditional phase shift. The action of the conditional phase shift of the computational basis is as follows:

$$U_\phi|00\rangle = |00\rangle, \quad U_\phi|01\rangle = |01\rangle, \tag{107}$$

$$U_\phi|10\rangle = |10\rangle, \quad U_\phi|11\rangle = e^{-i\phi}|11\rangle. \tag{108}$$

Under the isomorphism $C^2 \otimes C^2 \cong C^4$, the conditional phase shift can be written as

$$U_\phi = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & e^{-i\phi} \end{pmatrix}. \tag{109}$$

In terms of the basis (104) we can write

$$U_\phi = \exp\left(-i\frac{\phi}{2}(2\mathbf{1}_4 + I_{zz} - (I_{z1} + I_{z2}))\right). \tag{110}$$

Let

$$\tilde{K}_z = \exp\left(-i\frac{\phi}{4}(I_{z1} + I_{z2})\right), \tag{111}$$

since

$$[2\mathbf{1}_4, I_{zi}] = [I_{zz}, I_{zi}] = 0, \tag{112}$$

we have

$$\tilde{K}_z U_{\phi/2} = \exp\left(-i\frac{\phi}{4}(I_{z1} + I_{z2})\right) \cdot \exp\left(-i\frac{\phi}{4}(2\mathbf{1}_4 + I_{zz} - (I_{z1} + I_{z2}))\right) = \exp\left(-i\frac{\phi}{4}(2\mathbf{1}_4 + I_{zz})\right). \tag{113}$$

Let

$$K_j(\theta) = \exp(-i\theta I_{j1})\exp(-i\theta I_{j2}) \in K \tag{114}$$

for $j \in \{x, y\}$ and $\theta \in \mathbb{R}$ is a real parameter. We have the commutation relations,

$$[-i(I_{z1} + I_{z2}), -i(2\mathbf{1}_4 + I_{zz})] = [-i(I_{z1} + I_{z2}), -iI_{zz}] \tag{115}$$

and

$$[-iI_{zz}, [-i(I_{j1} + I_{j2}), -iI_{zz}]] = -i(I_{j1} + I_{j2}). \tag{116}$$

Thus by the Campbell–Baker–Hausdorff formula, we obtain

$$K_j(\theta)\tilde{K}_z U_{\phi/2} K_j^{-1}(\theta) = K_j(\theta)\exp\left(-i\frac{\phi}{4}(2\mathbf{1}_4 + I_{zz})\right)K_j^{-1}(\theta) \tag{117}$$

$$= \exp\left(- i\frac{\phi}{4}(2\mathbf{1}_4 + I_{zz}\cos(\theta) + [(-iI_{j1} - iI_{j2}), -iI_{zz}]\sin(\theta))\right). \tag{118}$$

We employ a π rotation to achieve the necessary decoupling. Using the preceding expression we get

$$K_j(\pi)\tilde{K}_z U_{\phi/2} K_j^{-1}(\pi) = K_j(\pi)\exp\left(- i\frac{\phi}{4}(2\mathbf{1}_4 + I_{zz})\right)K_j^{-1}(\pi) \tag{119}$$

$$= \exp\left(- i\frac{\phi}{4}(2\mathbf{1}_4 - I_{zz})\right). \tag{120}$$

So we obtain

$$\tilde{K}_z U_{\phi/2} \cdot K_j(\pi)\tilde{K}_z U_{\phi/2} K_j^{-1}(\pi) = \exp(-i\phi\mathbf{1}_4). \tag{121}$$

Similarly,

$$\tilde{K}'_z U_{\phi} \cdot K_j(\pi)\tilde{K}'_z U_{-\phi} K_j^{-1}(\pi) = \exp(-i\phi I_{zz}), \tag{122}$$

where $\tilde{K}'_z = \exp(-i(\phi/2)(I_{z1} + I_{z2}))$.

Finally, by noting that for

$$K_x(\theta) = \exp(-i\theta I_{x1})\exp(-i\theta I_{x2}) \tag{123}$$

$$K_y(\theta) = \exp(-i\theta I_{y1})\exp(-i\theta I_{y1}), \tag{124}$$

we have

$$K_y\left(\frac{\pi}{2}\right)\exp(-i\phi I_{zz})K_y^{-1}\left(\frac{\pi}{2}\right) = \exp(-i\phi I_{xx}), \tag{125}$$

$$K_x^{-1}\left(\frac{\pi}{2}\right)\exp(-i\phi I_{zz})K_x\left(\frac{\pi}{2}\right) = \exp(-i\phi I_{yy}). \tag{126}$$

Using (125) and (126), we can construct the desired decomposition for any $G \in \mathrm{U}(4)$,

$$G = K_1 \cdot \exp(-i\phi_0\mathbf{1}_4 - i\phi_1 I_{xx} - i\phi_2 I_{yy} - i\phi_3 I_{zz}) \cdot K_2 \tag{127}$$

$$= K_1 \cdot \exp(-i\phi_0\mathbf{1}_4) \cdot K_y\left(\frac{\pi}{2}\right)\exp(-i\phi_1 I_{zz})K_y^{-1}\left(\frac{\pi}{2}\right) \cdot$$

$$\times K_x^{-1}\left(\frac{\pi}{2}\right)\exp(-i\phi_2 I_{zz})K_x\left(\frac{\pi}{2}\right) \cdot \exp(-i\phi_3 I_{zz}) \cdot K_2. \tag{128}$$

This can now be written in terms of just elements of $\mathrm{SU}(2) \otimes \mathrm{SU}(2)$ and the conditional phase shift U_ϕ,

$$G = K_1 \cdot \tilde{K}_z U_{\phi_0/2} K_j(\pi)\tilde{K}_z U_{\phi_0/2} K_j^{-1}(\pi) \cdot K_y\left(\frac{\pi}{2}\right)\tilde{K}'_z U_{\phi_1} K_j(\pi)\tilde{K}'_z U_{-\phi_1} K_j^{-1}(\pi) K_y^{-1}\left(\frac{\pi}{2}\right) \cdot K_x^{-1}\left(\frac{\pi}{2}\right) \cdot \tilde{K}'_z$$

$$\times U_{\phi_2} K_j(\pi)\tilde{K}'_z U_{-\phi_2} K_j^{-1}(\pi) K_x\left(\frac{\pi}{2}\right)\tilde{K}'_z U_{\phi_3} K_j(\pi)\tilde{K}'_z U_{-\phi_3} K_j^{-1}(\pi) \cdot K_2. \tag{129}$$

Given the freedom of choosing j in K_j this sequence can be simplified somewhat. For example,

choose $j=y$ in the product $K_j^{-1}(\pi)\cdot K_y(\pi/2)$ to obtain $K_j^{-1}(\pi)\cdot K_y(\pi/2)=K_y(-\pi)\cdot K_y(\pi/2)=K_y(-\pi/2)$. Using this substitution and two others, the decomposition simplifies to

$$G = K_1\cdot\tilde{K}_z U_{\phi_0/2} K_j(\pi)\tilde{K}_z U_{\phi_0/2} K_y\left(-\frac{\pi}{2}\right)\tilde{K}_z' U_{\phi_1} K_j(\pi)\tilde{K}_z' U_{-\phi_1} K_y\left(-\frac{3\pi}{2}\right)K_x^{-1}\left(\frac{\pi}{2}\right)\tilde{K}_z' U_{\phi_2}$$

$$\times K_j(\pi)\tilde{K}_z' U_{-\phi_2}\cdot K_x\left(-\frac{\pi}{2}\right)\cdot\tilde{K}_z' U_{\phi_3} K_j(\pi)\tilde{K}_z' U_{-\phi_3} K_j^{-1}(\pi)\cdot K_2. \tag{130}$$

Finally, absorbing $\tilde{K}_z$ and $K_j^{-1}(\pi)$ into K_1 and K_2, respectively, we get

$$G = K_1 U_{\phi_0/2} K_j(\pi)\tilde{K}_z U_{\phi_0/2} K_y\left(\frac{\pi}{2}\right)\tilde{K}_z' U_{\phi_1} K_j(\pi)\tilde{K}_z' U_{-\phi_1} K_y\left(-\frac{3\pi}{2}\right)K_x^{-1}\left(\frac{\pi}{2}\right)\tilde{K}_z' U_{\phi_2} K_j(\pi)$$

$$\times\tilde{K}_z' U_{-\phi_2}\cdot K_x\left(-\frac{\pi}{2}\right)\tilde{K}_z' U_{\phi_3} K_j(\pi)\tilde{K}_z' U_{-\phi_3} K_2. \tag{131}$$

Some remarks are appropriate. This sequence of unitary transformations is exact and a precise prescription for building any U(4) logic gate with just local operations and the conditional phase shift. We make no claim that this decomposition is optimal with respect to number of elements nor time. In the holonomic framework, time optimality is constrained by the adiabatic requirement. In this case, one should then focus primarily on minimizing the number of loops necessary to build an arbitrary gate.

V. CONCLUSION

In this paper, we have considered holonomic quantum computation from a control theoretic point of view. A general framework for the control analysis is obtained by casting the relevant problems as control systems evolving on principal fiber bundles. We have applied this framework to two well established models of the computing scheme. To the best of our knowledge, all holonomic computing schemes proposed thus far fall into one of the two models considered here. From a control perspective, an interesting avenue for future work would be extending these ideas to the control of molecular systems in the Born–Oppenheimer approximation (as mentioned in Ref. 11). Holonomies can be realized in this regime[36] and it is reasonable to expect that a similar analysis can be carried out for these systems. However, a direct application of the methods proposed here will not suffice since the control parameters themselves are quantum degrees of freedom and therefore possess a nontrivial uncontrolled evolution of their own. In other words, the state equations analogous to those considered here (13) will be coupled quantum control problems.

Stability of three unit charges: Necessary conditions

D. K. Gridnev,[a] C. Greiner, and W. Greiner
Institut für Theoretische Physik, Robert-Mayer-Str. 8-10, D-60325 Frankfurt am Main, Germany

(Received 2 July 2004; accepted 13 January 2005; published online 12 April 2005)

We consider the stability of three Coulomb charges $\{+1,-1,-1\}$ with finite masses in the framework of nonrelativistic quantum mechanics. A simple physical condition on masses is derived to guarantee the absence of bound states below the dissociation thresholds. In particular this proves that certain negative muonic ions are unstable, thus extending the old result of Thirring to the actual values of all masses. The proof is done by reducing the initial problem to the question of binding of one particle in some effective potential. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1873039]

I. INTRODUCTION

The stability of three particles with pure Coulomb forces is an old and extensively studied problem, this is to explain why certain ions and molecules stay as a whole and some dissociate into a bound pair and a single particle. Under stability of the Hamiltonian H we shall understand the existence of a bound state with the energy strictly less than $\inf \sigma_{\mathrm{ess}}(H)$, i.e., a stationary state below all dissociation thresholds. As a quantum system three particles with Coulomb interactions demonstrate interesting behavior. It is known that three charges $\{1+\varepsilon,-1,-1\}$ for any $\varepsilon>0$ form the system, which is stable regardless of mass values. However at $\varepsilon=0$ the situation abruptly changes and due to the screening effect not all systems remain stable. The typical example is the unstable muonic hydrogen ion $p\mu^{-}e^{-}$, where the heavy muon is tightly bound to the proton and screens the positive charge for the electron. This interesting effect is well studied, in particular it has been proved[1] that for equal dissociation thresholds the system remains stable (Refs. 2 and 3 explain very well how stability depends on masses and charges).

Among the instability proofs for three unit charges the most appealing is that of Thirring,[4] which does not require any numerical calculations. Thirring considered a negative hydrogen ion with an infinitely heavy proton, and proved that such a negative ion is unstable when its second negatively charged particle is lighter than electron by a factor larger than π (π can be replaced[3,5] with a better constant 1.57). In his method Thirring exploited the fact that the ground state in the hydrogen atom is substantially separated from other states in its spectrum (the nondegenerate energy levels have $1/n^2$ dependence), and thus its role becomes emphasized. This suggests an idea to move the problem to the space spanned by the projector $P_0=|\phi_0\rangle\langle\phi_0|\otimes 1$, where ϕ_0 is the ground state of hydrogen. After estimating the part of the repulsion, which is present in this space, the problem reduces to checking the binding of one particle in some effective potential. The contribution from the attractive interaction term coming from additional particle is easy to treat because it commutes with P_0. Yet this is no longer true if one considers particles of finite mass or any system of four particles.

Thirring's bound was improved[2] and it was shown that the muonic ion $p\mu^{-}e^{-}$ is unstable for actual values of all masses. However this extension [Eq. (24) in Ref. 2] is weak in the sense that it fails when the second particle is heavy compared to other particles. (For a physical example, it does not prove that the ion $\mu^{-}pe^{+}$ is unstable, yet we shall prove it here.) This extension still uses

[a]Electronic mail: dima_gridnev@yahoo.com

Thirring's treatment of repulsion and it is unclear how one could extend it to four particles. Armour[6] with his method proved the instability of such systems as positron-hydrogen-atom e^-pe^+ and μ^-pe^+, but this method requires certain numerical assistance. It is also based on the separation of variables in the problem of two fixed centers, which makes it inapplicable to four particles because the variables do not separate even in the case of three fixed centers.

Here we follow the Thirring's idea but the nucleus does not have to be infinitely heavy. The derived physical condition restricts the ratio of Jacobi masses, which makes the system stable. It can be used in conjunction with Thirring's result and convexity properties of stability curve[2] for a reasonable determination of stability area free from any numerics. The present method has an important advantage in that it admits generalization to four particles. It should be mentioned that both Thirring's method and the new one share the same deficiency, namely, they are not applicable when the dissociation thresholds in the system are close or equal (e.g., when two like charges have equal masses). In particular, using such methods one cannot prove the "overheating" effect, when a system with charges $\{+1,-q,-q\}$ and equal masses loses its binding for some $q>1$. Nowadays various charged particles are produced in laboratories and it is, of course, of interest to know the principles behind formation of exotic atoms or molecules. All this motivates the present analysis.

II. FROM THREE PARTICLES TO ONE IN EFFECTIVE POTENTIAL

Let m_i, q_i, $\mathbf{r}_i \in \mathbb{R}^3$ denote masses, charges, and position vectors of particles $i=1,2,3$. We set $q_1=+1$ and $q_{2,3}=-1$, and the interactions between the particles are $V_{ik}=q_iq_k/|\mathbf{r}_i-\mathbf{r}_k|$. We enumerate the particles in such a way, that the particles (1,2) form the lowest dissociation threshold. The stability problem with Coulomb interactions is invariant with respect to scaling all masses,[2] so we can set $\hbar=1$. We separate the center of mass motion in the Jacobi frame[7] setting $\mathbf{x}=\mathbf{r}_1-\mathbf{r}_2$ and $\mathbf{y}=\mathbf{r}_3-\mathbf{r}_1+a\mathbf{x}$, where $a=m_2/(m_1+m_2)$ is the mass parameter invariant with respect to mass scaling. The reduced masses and Jacobi momenta are, respectively, $\mu_x=m_1m_2/(m_1+m_2)$, $\mu_y=m_3(m_1+m_2)/(m_1+m_2+m_3)$, and $p_{x,y}=-i\nabla_{x,y}$. It is convenient to scale all masses so that $\mu_x=2$. (In Sec. IV we shall rescale them back.) The Hamiltonian for the system on the tensor product space $L_2(\mathbb{R}^3)\otimes L_2(\mathbb{R}^3)$ is

$$H = h_{12}\otimes 1 + 1\otimes\frac{p_y^2}{2\mu_y} + W,$$

where

$$W = V_{13}+V_{23} = -\frac{1}{|a\mathbf{x}-\mathbf{y}|}+\frac{1}{|(1-a)\mathbf{x}+\mathbf{y}|} \tag{1}$$

and $h_{12}=p_x^2/4-1/x$ is the Hamiltonian of the pair of particles (1,2) (notation x is used instead of $|\mathbf{x}|$). The ground state wave function of h_{12} is $\phi_0=\sqrt{8/\pi}\exp(-2x)$ so that $h_{12}\phi_0=-\phi_0$. The Hamiltonian H is self-adjoint on $\mathcal{D}(H)=H^2(\mathbb{R}^6)$ (square integrable functions having partial derivatives up to the second order in the weak distributional sense) and by the HVZ theorem $\sigma_{\mathrm{ess}}(H)=[-1,\infty)$. We split positive and negative parts of W by introducing $W_-:=(|W|-W)/2$ and $W_+:=(-W)_-=(|W|+W)/2$ and we have $W=W_+-W_-$, where $W_\pm\geqslant 0$. Instead of H we shall consider the Hamiltonian

$$\tilde{H} = h_{12}\otimes 1 + 1\otimes\frac{p_y^2}{2\mu_y} - W_-. \tag{2}$$

Note that the part W_- can also be expressed as

$$W_- = -(V_{13}+V_{23}F(\mathbf{x},\mathbf{y})), \tag{3}$$

where $F=1$ when $|V_{13}|\geqslant|V_{23}|$ and $F=|V_{13}|/|V_{23}|$ when $|V_{13}|\leqslant|V_{23}|$, and we have $0\leqslant F\leqslant 1$. Because $\|V_{23}F\phi\|\leqslant\|V_{23}\phi\|$ we can directly apply Kato's theorem[8] on self-adjointness of atomic

Hamiltonians and find out that $\tilde{H}$ is self-adjoint on $\mathcal{D}(\tilde{H})=\mathcal{D}(H)$. We cannot though directly apply the HVZ theorem to locate $\inf \sigma_{\mathrm{ess}}(\tilde{H})$ but we observe that the following inequality holds $(H-V_{23})\leqslant\tilde{H}\leqslant H$. Here $(H-V_{23})$ is the original Hamiltonian without repulsion, which is bounded from below and by the HVZ theorem $\inf \sigma_{\mathrm{ess}}(H-V_{23})=-1$. Thus from the min–max principle[8] we get $\inf \sigma_{\mathrm{ess}}(\tilde{H})=-1$.

Now let us assume that H is stable, i.e., H has a bound state with the energy less than -1. Because $\tilde{H}\leqslant H$ from the variational principle we conclude that $\tilde{H}$ also has a bound state $\Psi\in\mathcal{D}(H)$ with the energy below $\inf \sigma_{\mathrm{ess}}(\tilde{H})=-1$ which means

$$\tilde{H}\Psi=-(-1-\delta)\Psi, \tag{4}$$

where $\delta>0$ is the extra binding energy. Let us introduce a projection operator $P_0=|\phi_0\rangle\langle\phi_0|\otimes 1$ $(P_0:\mathcal{D}(H)\to\mathcal{D}(H))$ and set $\eta:=P_0\Psi$ and $\xi:=(1-P_0)\Psi$, where obviously $\eta\perp\xi$ and $\Psi=\eta+\xi$ and $\eta,\ \xi\in\mathcal{D}(H)$. Taking the scalar product of each side of (4) with η and ξ we obtain

$$\left\langle \eta\left| 1\otimes\frac{p_y^2}{2\mu_y}-W_-\right|\eta\right\rangle-\langle\eta|W_-|\xi\rangle=-\delta\|\eta\|^2, \tag{5}$$

$$\langle\xi|h_{12}\otimes 1|\xi\rangle+\left\langle \xi\left| 1\otimes\frac{p_y^2}{2\mu_y}-W_-\right|\xi\right\rangle-\langle\xi|W_-|\eta\rangle=(-1-\delta)\|\xi\|^2, \tag{6}$$

where we have used $\langle\eta|1\otimes p_y^2|\xi\rangle=0$ because P_0 and $1\otimes p_y^2$ commute. We shall assume that $\|\eta\|$, $\|\xi\|\neq 0$ (we shall get rid of this assumption in Theorem 1), then we are free to choose such normalization of Ψ that $\|\xi\|=1$.

From the bound spectrum of h_{12} we have[4] $h_{12}\otimes 1\geqslant -P_0-1/4(1-P_0)$, hence for the first term in (6) we get the bound $\langle\xi|h_{12}\otimes 1|\xi\rangle\geqslant -1/4$. Introducing two non-negative constants $\alpha:=\sqrt{\langle\eta|W_-|\eta\rangle}$ and $\beta:=\sqrt{\langle\xi|W_-|\xi\rangle}$ we get by virtue of the Schwarz inequality $|\langle\xi|W_-|\eta\rangle|\leqslant\alpha\beta$. Now we can rewrite Eqs. (5) and (6) to obtain the main pair of inequalities,

$$\left\langle \eta\left| 1\otimes\frac{p_y^2}{2\mu_y}-W_-\right|\eta\right\rangle-\alpha\beta<0, \tag{7}$$

$$\left\langle \xi\left| 1\otimes\frac{p_y^2}{2\mu_y}-W_-\right|\xi\right\rangle-\alpha\beta<-\frac{3}{4}. \tag{8}$$

Using the second inequality we shall find $\max \beta/\alpha$ and by substituting this value into (7) we shall formulate the stability condition.

Lemma 1: Suppose that Eq. (8) holds and $\mu_y<3/2$, then the following inequality is true:

$$\beta<\left(\sqrt{\frac{3}{2\mu_y}}-1\right)^{-1}\alpha. \tag{9}$$

Proof: First, let us show that for $A\geqslant 0$,

$$\inf_{\substack{\chi\in\mathcal{D}(H)\\ \|\chi\|=1}}\left\langle \chi\left| 1\otimes\frac{p_y^2}{2\mu_y}-AW_-\right|\chi\right\rangle\geqslant-\frac{A^2\mu_y}{2}. \tag{10}$$

It suffices to prove this for $\chi\in C_0^\infty(\mathbb{R}^6)$. Using (3) from the variational principle we get

$$\left\langle \chi \left| 1 \otimes \frac{p_y^2}{2\mu_y} - AW_- \right| \chi \right\rangle \geqslant \int d\mathbf{x} \int d\mathbf{y}\, \chi^*(\mathbf{x},\mathbf{y}) \left(\frac{p_y^2}{2\mu_y} - \frac{A}{|a\mathbf{x}-y|} \right) \chi(\mathbf{x},\mathbf{y})$$

$$\geqslant -\frac{A^2\mu_y}{2} \int d\mathbf{x} \int d\mathbf{y} |\chi|^2(\mathbf{x}, a\mathbf{x}+\mathbf{y}) = -\frac{A^2\mu_y}{2} \|\chi\|^2 \tag{11}$$

from which (10) follows and where we have used the explicit expression for the ground state energy of the hydrogen atom. [Using an appropriate set of trial functions it is easy to show that there is an equality sign in (10), but we do not need this for our purposes]. Now using (10) we obtain the following chain of inequalities:

$$\inf_{\substack{\xi \in \mathcal{D}(H) \\ \|\xi\|=1 \\ \langle \xi | W_- | \xi \rangle = \beta^2}} \left\langle \xi \left| 1 \otimes \frac{p_y^2}{2\mu_y} - W_- \right| \xi \right\rangle = \max_{\lambda \geqslant -1} \inf_{\substack{\xi \in \mathcal{D}(H) \\ \|\xi\|=1 \\ \langle \xi | W_- | \xi \rangle = \beta^2}} \left(\left\langle \xi \left| 1 \otimes \frac{p_y^2}{2\mu_y} - (\lambda+1) W_- \right| \xi \right\rangle + \lambda\beta^2 \right)$$

$$\geqslant \max_{\lambda \geqslant -1} \inf_{\substack{\xi \in \mathcal{D}(H) \\ \|\xi\|=1}} \left(\left\langle \xi \left| 1 \otimes \frac{p_y^2}{2\mu_y} - (\lambda+1) W_- \right| \xi \right\rangle + \lambda\beta^2 \right)$$

$$\geqslant \max_{\lambda \geqslant -1} (\lambda\beta^2 - (\lambda+1)^2 \mu_y/2) = \frac{\beta^4}{2\mu_y} - \beta^2.$$

Substituting this result into (8) and setting $\alpha = s\beta$ we obtain

$$\frac{\beta^4}{2\mu_y} - (s+1)\beta^2 < -\frac{3}{4}. \tag{12}$$

Now simply minimizing the left-hand side of (12) over β^2 we obtain the lower bound on s, which gives us Eq. (9). ■

It is worth noting that the relation in the lemma is a version of the uncertainty principle, when β^2 grows, the kinetic energy term grows faster like β^4. Let us introduce an effective potential $V_{\text{eff}}(y) := \int d\mathbf{x} |\phi_0|^2 W_-$. We formulate the result as follows.

Theorem 1: *If the system of three charges is stable and* $\mu_y < 3/2$ *then the particle with mass* μ_y *must have a bound state in the potential* $-(1+(\sqrt{3/2\mu_y}-1)^{-1})V_{\text{eff}}$.

Proof: We have $\|\eta\|, \|\xi\| \neq 0$. The function η has the factorized form $\eta = \phi_0(\mathbf{x}) f(\mathbf{y})$, where $f \in H^2(\mathbb{R}^3)$, $\|f\| \neq 0$. By substituting (9) into (7) and using expressions for α^2 and η we get the necessary condition for stability

$$\left\langle f \left| \frac{p_y^2}{2\mu_y} - (1+(\sqrt{3/2\mu_y}-1)^{-1}) V_{\text{eff}} \right| f \right\rangle < 0. \tag{13}$$

In the next section we shall study $V_{\text{eff}}(y)$ and show that it is a continuous function decaying like $1/y^2$. Inequality (13) means that a particle having mass μ_y has a bound state in this potential.

Now let us complete the proof considering the case when either $\xi = 0$ or $\eta = 0$. If $\xi = 0$ we have $\beta = 0$ and substituting this into (7) we get a condition more stringent than Eq. (13). If $\eta = 0$ we have $\|\xi\| = 1$ and $\alpha = 0$, substituting this into (8) and using (10) for $\mu_y < 3/2$ results in the contradiction. ■

III. BINDING IN EFFECTIVE POTENTIAL

In this section we shall analyze the effective potential and find out at which values of the coupling constant λ the Hamiltonian $p_y^2 - \lambda V_{\text{eff}}$ may have bound states. It turns out that the effective potential in our case has a nonphysical term, which is a long-range attraction of the type $1/y^2$. This nonphysical behavior stems from cutting off the positive part of the potential and results in the infinite number of bound states at the point of binding (that is why it is meant nonphysical).

But as it is well known since the result of Hilbert and Courant,[9] even this long-range attraction does not guarantee binding, for $\lambda \max_y y^2 V_{\text{eff}}(y) \leqslant 1/4$ the inequality $p_y^2 - \lambda V_{\text{eff}} \geqslant 0$ holds, i.e., no binding occurs (see also the proof in Ref. 8, Vol. 2). Thus the nontrivial critical coupling constant exists, and we must determine it. On the other hand, in such potentials short-range repulsive terms do not play any role for binding.[10] It would be of interest to get rid of this nonphysical behavior in the future (pay attention that the Thirring's effective potential[4] behaves at infinity like $1/y^3$!).

To calculate V_{eff} we must cut off the positive part of W. From (1) $W \leqslant 0$ is equivalent to $\cos\theta \geqslant x/(\omega y)$, where $\omega = (a-1/2)^{-1}$ and $\cos\theta = \mathbf{x}\cdot\mathbf{y}/xy$. We shall consider separately two cases $a > 1/2$ and $a \leqslant 1/2$.

A. Case when $a > 1/2$

The integration is simpler in this case. After direct integration in spherical coordinates over the area where $\cos\theta \geqslant x/(\omega y)$ we obtain

$$V_{\text{eff}}(y) = 16y^2 \int_0^{\omega} \mathrm{d}s\, s e^{-4sy} \left(\frac{\sqrt{a(1-a)s^2+1}}{a(1-a)} - \frac{|as-1|}{a} - \frac{(1-a)s+1}{1-a} \right)$$
$$= \frac{16y^2}{a(1-a)} \int_0^{\omega} \mathrm{d}s\, s e^{-4sy} (\sqrt{a(1-a)s^2+1} - 1) + U, \tag{14}$$

where

$$U = 32y^2 \int_{1/a}^{\omega} \mathrm{d}s\, s e^{-4sy} (1/a - s) < 0. \tag{15}$$

Now we do not have to carry out integration in (15), it is enough to see that it is a short-range repulsion, which does not play a role in our case. To calculate the first term in (14) we use $\sqrt{a(1-a)s^2+1} \leqslant 1 + a(1-a)s^2/2$ to get

$$V_{\text{eff}} < 8y^2 \int_0^{\omega} \mathrm{d}s\, s^3 e^{-4sy} < \frac{3}{16y^2}, \tag{16}$$

where after the integration we have dropped the short-range negative terms. Finally, we have $p_y^2 - \lambda V_{\text{eff}} \geqslant p_y^2 - \lambda(3/16)y^{-2}$. The following inequality[8] holds $p_y^2 - (1/4)y^{-2} \geqslant 0$. Thus in the case of binding, i.e., when such f exists that $\langle f | p_y^2 - \lambda V_{\text{eff}} | f \rangle < 0$, we must have $\lambda > 4/3$. Comparing this with (13) we obtain that three charges form an unstable system if $\mu_y < 3/2$ and

$$2\mu_y (1 + (\sqrt{3/2\mu_y} - 1)^{-1}) < 4/3. \tag{17}$$

Solving this simple inequality tells us that the system is unstable when $\mu_y < 2(11 - 2\sqrt{10})/27 \simeq 0.3463$.

B. Case when $a \leqslant 1/2$

First let us take $a < 1/2$. We shall write $W(a)$ instead of W to point out the dependence on parameter a. We can alleviate the integration noting that $W(a) = -W(1-a)$, thus we have $W_-(a) = (-W(1-a))_- = W_+(1-a) = W(1-a) + W_-(1-a)$. From this we conclude $V_{\text{eff}}(a) = -\overline{W}(a) + V_{\text{eff}}(1-a)$. The additional integral $\overline{W}(a) := \int \mathrm{d}\mathbf{x} |\phi_0|^2 W$ is easy to calculate and $V_{\text{eff}}(1-a)$ for $a < 1/2$ we have already calculated. We obtain

$$-\overline{W}(a) = 16y^2 \int_0^\infty ds\, e^{-4sy} s\left(\left(\frac{1}{a} - \frac{1}{1-a}\right) + \left|s - \frac{1}{1-a}\right| - \left|s - \frac{1}{a}\right|\right)$$

$$= 32y^2 \int_{1/(1-a)}^{1/a} ds\, e^{-4sy}\left(s^2 - \frac{s}{1-a}\right) + 32y^2 \int_{1/a}^\infty ds\, e^{-4sy} s\left(\frac{1}{a} - \frac{1}{1-a}\right). \tag{18}$$

Using (14) and (15) and approximation for the square root $\sqrt{a(1-a)s^2+1} \leqslant 1 + a(1-a)s^2/2$ gives us

$$V_{\text{eff}}(1-a) \leqslant 8y^2 \int_0^{-\omega} ds\, s^3 e^{-4sy} + 32y^2 \int_{1/(1-a)}^{-\omega} ds\, e^{-4sy}\left(\frac{s}{1-a} - s^2\right). \tag{19}$$

Summing (18) and (19) and calculating the integrals explicitly gives us the following expression for $a < 1/2$:

$$V_{\text{eff}} < \frac{3}{16y^2} - e^{-4y/a}\left[\frac{8(1-a)y}{a^2} + 2\frac{2-a}{a} + \frac{1}{y}\right]$$

$$- e^{4\omega y}\left[-2y\omega(\omega+2)^2 + (3\omega/2+1)(\omega+2) - \frac{1}{y}(3\omega/4+1) + \frac{3}{16y^2}\right]. \tag{20}$$

For $a < 1/2$ we have $\omega < -2$, and it is easily seen that all terms in square brackets are positive (this leads again to short-range potentials), meaning that $V_{\text{eff}} < (3/16)y^{-2}$, which gives the same condition for stability as (17). We do not consider explicitly $a = 1/2$, it is done analogously and also results in (17).

IV. SUMMARY

We have initially scaled all masses $m_i \to 2m_i/\mu_x$, making $\mu_x = 2$. Now rescaling it back we get through (17) that the system of three charges is unstable if $\mu_y/\mu_x < (11 - 2\sqrt{10})/27 \simeq 0.1732$. In the case of infinitely heavy nucleus this is $m_3/m_2 < 0.1732$, which is worse than the refined[2,5] Thirring's estimate $m_3/m_2 < 1/1.57$. The accuracy is lost at the point of cutting the positive part of the potential, which induces a long-range attraction. However this is more than enough to prove that the muonic ions $p\mu^- e^-$ or $\mu^- p e^+$ are unstable for the actual values of all three masses. The case of four unit charges $\{+1, +1, -1, -1\}$ is treated similarly but the calculations are more involved[11] and results would be published elsewhere. Let us also stress that the obtained condition is physical. Both Jacobi masses determine Bohr radii for the particle orbits, the orbit within the pair of particles (1,2) and the orbit for the third particle in the field of this pair with respect to the pair's center of mass. If the orbit of one negative particle is outdistanced then the attraction from the positive charge is screened off by the other negative particle and the system becomes unbound.

Strict deformation quantization for a particle in a magnetic field

Marius Măntoiu[a] and Radu Purice[b]
Institute of Mathematics "Simion Stoilow" of the Romanian Academy, P.O. Box 1-764, Bucarest, RO-014700, Romania

(Received 7 December 2004; accepted 8 February 2005; published online 12 April 2005)

Recently, we introduced a mathematical framework for the quantization of a particle in a variable magnetic field. It consists in a modified form of the Weyl pseudodifferential calculus and a C^*-algebraic setting, these two points of view being isomorphic in a suitable sense. In the present paper we leave Planck's constant vary, showing that one gets a strict deformation quantization in the sense of Rieffel. In the limit $\hbar \to 0$ one recovers a Poisson algebra induced by a symplectic form defined in terms of the magnetic field. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1887922]

I. INTRODUCTION

The present paper treats the semiclassical limit of the mathematical formalism describing a quantum, nonrelativistic particle without internal structure, placed in a variable magnetic field. The limit is considered in the precise sense of Rieffel's axioms (cf. Refs. 8,22,23), involving C^*-algebras. This setting is widely called *strict* quantization, to distinguish it from the version in terms of formal series (see Ref. 1, for example). It consists of several ingredients, which we outline here very briefly, referring to Sec. II for a detailed discussion.

(1) One needs first a natural family of classical observables. It is admitted that this should form a Poisson algebra $\mathfrak{A}$, which is roughly a real associative and commutative algebra endowed with a compatible Poisson bracket. This structure describes the classical physical system.

(2) For non-null values of Planck's constant $\hbar$, one must define C^*-algebras of quantum observables $\mathfrak{C}^\hbar$.

(3) It must be shown that for $\hbar \to 0$ "the quantum structure converges to the classical one." This is described precisely by Rieffel's system of axioms or some of its versions.

If a certain extra technical condition is verified, allowing to define on classical observables a family of "deformed products" indexed by $\hbar$, one speaks of *strict deformation quantization*.

In our case, a particle without spin moving in the N-dimensional configuration space $\mathbb{R}^N$ and placed under the influence of an external variable magnetic field, the natural Poisson algebra is well known. The observables are smooth functions defined on the phase space $\Xi := \mathbb{R}^{2N}$, the associative product is defined pointwise and the Poisson bracket is induced by the canonical symplectic form on Ξ, to which we add a magnetic contribution.[6,16] This is described in Sec. III.

Quite surprisingly, the algebras of quantum observables for this system were defined and developed only recently. One reason could be that the canonical variables in the magnetic case (the components of the position and those of the magnetic momentum) satisfy complicated commutation relations, that must be taken into account when defining more general observables as functions of these basic ones. The intensive use of *constant* magnetic fields and (or) special observables that are *quadratic* with respect to the momenta have also played a certain role. The setting which is correct (at least in our opinion) appeared in Refs. 6,7 and 13 (a pseudodifferential point

[a]Electronic mail: marius.mantoiu@imar.ro
[b]Electronic mail: radu.purice@imar.ro

of view) and in Refs. 12 and 14 (C^*-algebras). The right attitude can also be found in Ref. 11, but undeveloped and stated for a very particular case; it seems that it has been largely unnoticed. The critical point is *gauge invariance*: when several equivalent vector potentials corresponding to a given magnetic field are used in defining observables, the results should be connected by simple unitary equivalences. But to achieve this, one has to be very careful in defining the precise form of the observables as well as the composition laws to which they are submitted. We shall explain all these in Sec. IV.

In Sec. V we state our main theorem. It asserts that under certain hypothesis, to a magnetic field and to an Abelian algebra of "configurational observables" one can associate naturally a strict deformation quantization.

Sections VI–VIII are devoted to the proof of the main result. The three nontrivial axioms are verified separately. The Rieffel condition and the von Neumann condition follow from the results of Refs. 18 and 20 (Secs. VI and VII). Nevertheless, we also give a direct elementary proof for the von Neumann condition similar with that given for the Dirac condition (Secs. VII and VIII).

This paper is addressed also to people that do not have deformation quantization as their main skill. The system we treat has a certain physical interest (this is not always the case in this field). Thus we decided to avoid technical complications and to leave more general situations to subsequent works. In particular, we hope to be able to say something on strict deformation quantization by twisted groupoids (see Refs. 8–10 and 17, and references therein for the untwisted case), which should include the present work as a particular instance. A pure state quantization would also be an interesting topic.

Both in classical and in quantum theory one works with "real" observables. For any space $\mathcal{E}$ of complex functions we denote by $\mathcal{E}_{\mathbb{R}}$ the subspace of $\mathbb{R}$-valued elements in $\mathcal{E}$. For instance, $C^\infty(P)_{\mathbb{R}}$ will be the family of real C^∞ functions on the smooth manifold P. If $\mathfrak{C}$ is a C^*-algebra, we set $\mathfrak{C}_{\mathbb{R}}$ for the set of self-adjoint elements of $\mathfrak{C}$. Some other notations: If Y is a locally compact group we denote by $C(Y)$ the $*$-algebra of all continuous complex functions on Y. $BC(Y), BC_u(Y), C_0(Y)$ mean respectively "bounded and continuous," "bounded and uniformly continuous," and "continuous and small at infinity." If $\mathcal{H}$ is a Hilbert space, $K(\mathcal{H})$ will be the set of all compact operators in $\mathcal{H}$, forming an ideal in the C^*-algebra $B(\mathcal{H})$ of all the linear, bounded operators on $\mathcal{H}$. The unitary operators form the group $\mathcal{U}(\mathcal{H})$.

II. THE AXIOMS

We describe here Rieffel's framework for strict quantization. There are several versions of his axioms; we choose to work with the system of axioms which appears in Ref. 8, to which we also refer to for many other details. The starting point is a "classical algebra of observables" described by a Poisson algebra.

Definition 1.1: A Poisson algebra *is a triple* $(\mathfrak{A}, \circ, \{\cdot,\cdot\})$, *where* $\mathfrak{A}$ *is a real vector space,* $\circ, \{\cdot,\cdot\}$ *are bilinear maps* : $\mathfrak{A}\times\mathfrak{A}\to\mathfrak{A}$ *such that* $\circ$ *is associative and commutative,* $\{\cdot,\cdot\}$ *is antisymmetric and for each* $\varphi\in\mathfrak{A}$, $\{\varphi,\cdot\}$ *is a derivation both with respect to* $\circ$ *and to* $\{\cdot,\cdot\}$. *Thus, aside bilinearity, the two maps satisfy for all* $\varphi,\psi,\rho\in\mathfrak{A}$.

(i) $\psi\circ\varphi=\varphi\circ\psi$, $(\psi\circ\varphi)\circ\rho=\psi\circ(\varphi\circ\rho)$,
(ii) $\{\psi,\varphi\}=-\{\varphi,\psi\}$,
(iii) $\{\varphi,\psi\circ\rho\}=\psi\circ\{\varphi,\rho\}+\{\varphi,\psi\}\circ\rho$ (Leibnitz rule),
(iv) $\{\varphi,\{\psi,\rho\}\}=\{\{\varphi,\psi\},\rho\}+\{\psi,\{\varphi,\rho\}\}$ (Jacobi's identity).

The elements of $\mathfrak{A}$ are interpreted as observables of a classical description of a physical system. For each $\varphi\in\mathfrak{A}$ and each value $\hbar\neq 0$ of Planck's constant, one would like to have an object $\mathcal{Q}^\hbar(\varphi)$ representing the same observable in a quantum description of the system. One also hopes that the algebraic structure of the quantum observables should converge to the classical picture described by the Poisson algebra, in some suitable norm $\|\cdot\|_\hbar$ depending continuously of $\hbar$. This might be seen as a precise mathematical form of Bohr's correspondence principle.

A systematic justification of the next definitions may be found in Ref. 8. Note that usually in $\mathfrak{A}$ many classical observables are "unbounded;" the use of norms forces us to apply quantization only to certain subfamilies $\mathfrak{A}_0$ of $\mathfrak{A}$.

Definition 1.2: Let $\mathfrak{A}_0$ *be a Poisson algebra which is densely contained in the self-adjoint part* $\mathfrak{C}^0_{\mathbb{R}}$ *of an Abelian* C^**-algebra* $\mathfrak{C}^0$. A strict quantization of the Poisson algebra $(\mathfrak{A}_0, \circ, \{\cdot,\cdot\})$ *is a family of maps* $(\mathcal{Q}^\hbar : \mathfrak{A}_0 \to \mathfrak{C}^\hbar_{\mathbb{R}})_{\hbar \in I}$, *where we have the following:*

(i) *I is a subset of the real axis, for which the origin is an accumulation point contained in I.*

(ii) $\mathfrak{C}^\hbar$ *is a* C^**-algebra, with product and norm denoted, respectively, by* $\#^\hbar$ *and* $\|\cdot\|_\hbar$. *For* $\varphi^\hbar, \psi^\hbar \in \mathfrak{C}^\hbar_{\mathbb{R}}$ *(the self-adjoint part of* $\mathfrak{C}^\hbar$*) we set* $\varphi^\hbar \star^\hbar \psi^\hbar := \frac{1}{2}(\varphi^\hbar \#^\hbar \psi^\hbar + \psi^\hbar \#^\hbar \varphi^\hbar)$ (a Jordan product) *and* $\{\varphi^\hbar, \psi^\hbar\}_\hbar := (1/i\hbar)(\varphi^\hbar \#^\hbar \psi^\hbar - \psi^\hbar \#^\hbar \varphi^\hbar)$.

(iii) $\mathcal{Q}^\hbar : \mathfrak{A}_0 \to \mathfrak{C}^\hbar_{\mathbb{R}}$ *is* $\mathbb{R}$*-linear for each* $\hbar$ *and* $\mathcal{Q}^0$ *is just the inclusion map, and the following axioms are fulfilled:*

(a) *RIEFFEL'S CONDITION: For* $\varphi \in \mathfrak{A}_0$, *the map* $I \ni \hbar \to \|\mathcal{Q}^\hbar(\varphi)\|_\hbar \in \mathbb{R}_+$ *is continuous.*

(b) *VON NEUMANN CONDITION: For* $\varphi, \psi \in \mathfrak{A}_0$, $\|\mathcal{Q}^\hbar(\varphi) \star^\hbar \mathcal{Q}^\hbar(\psi) - \mathcal{Q}^\hbar(\varphi \circ \psi)\|_\hbar \to 0$ *when* $\hbar \to 0$.

(c) *DIRAC'S CONDITION: For* $\varphi, \psi \in \mathfrak{A}_0$, $\|\{\mathcal{Q}^\hbar(\varphi), \mathcal{Q}^\hbar(\psi)\}_\hbar - \mathcal{Q}^\hbar(\{\varphi, \psi\})\|_\hbar \to 0$ *when* $\hbar \to 0$.

(d) *COMPLETENESS:* $\mathcal{Q}^\hbar(\mathfrak{A}_0)$ *is dense in* $\mathfrak{C}^\hbar_{\mathbb{R}}$ *for all* $\hbar \in I$.

The word "strict" was coined by Rieffel in order to distinguish his framework from the (deformation) quantization defined in terms of formal series. Usually Poisson algebras are function spaces.

Definition 1.3: We call Poisson manifold *a smooth manifold M so that on* $C^\infty(M)_{\mathbb{R}}$ *a bracket* $\{\cdot,\cdot\}$ *is given such that, denoting by* $\circ$ *the pointwise multiplication, the triple* $(C^\infty(M)_{\mathbb{R}}, \circ, \{\cdot,\cdot\})$ *is a Poisson algebra.*

When M is not compact, $C^\infty(M)_{\mathbb{R}}$ is a very large, unnormed space. In quantization one deals with suitable families of smooth bounded observables.

Definition 1.4: A strict quantization of the Poisson manifold *M means the choice of a Poisson subalgebra* $\mathfrak{A}_0$ *of* $C^\infty(M)_{\mathbb{R}}$ *composed of bounded functions and a strict quantization of this Poisson subalgebra.*

One should be aware that the linear maps $\mathcal{Q}^\hbar$ tend to behave as morphisms only in the asymptotic limit $\hbar \to 0$. But under favorable circumstances (fulfilled rather often, but by no means always) they may serve to define modified products on $\mathfrak{C}^0$. In this case, one really is allowed to think in terms of "deformed products."

Definition 1.5: A strict quantization $(\mathcal{Q}^\hbar : \mathfrak{A}_0 \to \mathfrak{C}^\hbar_{\mathbb{R}})_{\hbar \in I}$ *is called* a strict deformation quantization *if for each* $\hbar$, $\mathcal{Q}^\hbar(\mathfrak{A}_0)$ *is a subalgebra of* $\mathfrak{C}^\hbar_{\mathbb{R}}$ *and* $\mathcal{Q}^\hbar$ *is injective.*

In such a case, for any $\hbar$, one defines $\#^\hbar : \mathfrak{A}_0 \times \mathfrak{A}_0 \to \mathfrak{A}_0$ such that $\mathcal{Q}^\hbar(\varphi \#^\hbar \psi) = \mathcal{Q}^\hbar(\varphi) \#^\hbar \mathcal{Q}^\hbar(\psi)$ for all $\varphi, \psi \in \mathfrak{A}_0$. The notational ambiguity is deliberate.

Remark: We shall briefly comment upon an alternative definition for *strict deformation quantization of a Poisson algebra* $\mathfrak{A}_0$, in the spirit of Rieffel's approach.[21–23] The maps $\mathcal{Q}^\hbar$ being injective (see Definition 1.5), we may identify all the algebras $\mathcal{Q}^\hbar[\mathfrak{A}_0]$ and consider the different C^*-algebras $\mathfrak{C}^\hbar$ as completions for different C^*-norms $\|.\|_\hbar$ of the same *-algebra $\mathbb{C} \otimes \mathfrak{A}_0$. We denote by $\overline{\mathbb{C} \otimes \mathfrak{A}_0}$ the completion taken with respect to the C^*-norm $|||.||| := \sup_{\hbar \in I} \|.\|_\hbar$. Then we may define a strict deformation quantization of the Poisson algebra $\mathfrak{A}_0$, as a family $\{\mathfrak{C}^\hbar\}_{\hbar \in I}$ of C^*-algebras (with products $\#^\hbar$ and C^*-norms $\|.\|_\hbar$) such that

(1) $\mathfrak{C}^0$ is Abelian;

(2) $\mathbb{C} \otimes \mathfrak{A}_0$ is dense in $\mathfrak{C}^\hbar$ for any $\hbar \in I$;

(3) the triple $(I, \{\mathfrak{C}^\hbar\}_{\hbar \in I}, \Gamma)$, with $\Gamma := C(I; \overline{\mathbb{C} \otimes \mathfrak{A}_0})$, defines a *a continuous field of* C^**-algebras*, cf. Ref. 5;

(4) (the Dirac condition) for any φ and ψ in $\mathfrak{A}_0$ we have

$$\lim_{\hbar\to 0}\left\|\frac{1}{i\hbar}(\varphi\#^{\hbar}\psi-\psi\#^{\hbar}\varphi)-\{\varphi,\psi\}\right\|_{\hbar}=0.$$

In fact our proof in this paper may be seen to give such a structure.

III. THE MAGNETIC POISSON ALGEBRA

For the convenience of the reader, we start by recalling briefly the way a symplectic manifold acquires a canonical Poisson structure. For a differentiable manifold M we denote by $C^\infty(M)$ the vector space of smooth real functions on M, by $\chi(M)$ the $C^\infty(M)$-module of vector fields on M and by $\Omega^k(M)$ the $C^\infty(M)$-module of k-forms on M (i.e., C^∞ sections of the fibre bundle of antisymetric k-linear forms $\Lambda^k_m M$ on $\mathbb{T}_m M$, the tangent space of M at $m\in M$). One has $\Omega^0(M)=C^\infty(M)$. We denote by $\mathrm{d}:\Omega^k(M)\to\Omega^{k+1}(M)$ the exterior differential. A symplectic form on M is just a closed nondegenerate 2-form $\Sigma\in\Omega^2(M)$.

It follows easily from the axioms that the bracket $\{\cdot,\cdot\}$ of any Poisson manifold M is given by *a Poisson bivector*. This means that one has $\{f,g\}=w(\mathrm{d}f,\mathrm{d}g)$ for all $f,\ g\in C^\infty(M)$, where $w:\Omega^1(M)\times\Omega^1(M)\to C^\infty(M)$ is bilinear, antisymmetric and satisfies an extra condition connected to the Jacobi identity (see Refs. 8 or 24 for details). The symplectic form will lead to such a Poisson bivector in a specific way. Being a nondegenerate bilinear form on each tangent space, Σ defines a $C^\infty(M)$-linear isomorphism $\beta:\Omega^1(M)\to\chi(M)$, $\theta(v):=\Sigma_m(\beta_m(\theta),v)$, $\forall(\theta,v)\in\mathbb{T}^*_m M\times\mathbb{T}_m M$. Then one defines

$$\{f,g\}_\Sigma:=\Sigma[\beta(\mathrm{d}f),\beta(\mathrm{d}g)], \tag{1}$$

so in this case the Poisson bivector is given by $w_\Sigma=\Sigma\circ(\beta\times\beta)$. One checks easily that, in this way, M becomes a Poisson manifold and we denote by $\mathcal{P}_0(M)$ the algebra $C^\infty(M)_{\mathbb{R}}$ endowed with the pointwise multiplication and the above canonical Poisson bracket.

We come back to our specific situation. The configuration space of our particle without internal structure is the space $X:=\mathbb{R}^N$, with elements q,x,y,z. The subsequent presence of a magnetic field demands $N\geqslant 2$. We denote by $X^\star$ the dual of the vector space X, with elements p,k,l and by $(x,p)\mapsto x\cdot p$ the duality between X and $X^\star$.

The phase-space of the system is the cotangent bundle $\mathbb{T}^*X$ of X, often denoted by Ξ and identified with the direct sum $X\times X^\star$ (by identifying all the fibers with $X^\star$, using the action through translations). Typical vectors in Ξ are $\xi=(q,p)$ or $\eta=(x,k)$. All the tangent spaces $\mathbb{T}_\xi(\Xi)$ will be identified with Ξ and all the cotangent spaces $\mathbb{T}^*_\xi(\Xi)$ will be viewed as $\Xi^\star$ and, furthermore, as $X^\star\times X$. On Ξ we have the canonical (constant) symplectic form defined by

$$\sigma:\Xi\times\Xi\to\mathbb{R},\quad \sigma[(x,k),(y,l)]:=y\cdot k-x\cdot l.$$

This structure is adequate for the description of the particle whith no magnetic field. When a magnetic field is present, this can be taken into account by a change in the symplectic structure, cf. Ref. 16.

We thus consider a special class of flat symplectic manifolds, representing perturbations of the above symplectic space and associated to a general (regular) magnetic field on X. In fact such *a magnetic field is described by a closed 2-form* $B\in\Omega^2(X)$. Starting with the canonical projection $\pi:\Xi\cong X\times X^\star\to X$, we define canonically an injection $\widetilde{\pi}_2:\Omega^2(X)\to\Omega^2(\Xi)$. Thus we get a new symplectic form σ_B on Ξ as the sum $\sigma_B:=\sigma+\widetilde{\pi}_2 B$, i.e.,

$$(\sigma_B)_{(q,p)}[(x,k),(y,l)]:=\sigma[(x,k),(y,l)]+(\widetilde{\pi}_2 B)_{(q,p)}[(x,k),(y,l)]=y\cdot k-x\cdot l+B_q(x,y).$$

Being the sum of two closed forms, this 2-form is closed. It is also nondegenerate, thus it is a symplectic form on Ξ. Then (1) gives

$$\{f,g\}_B \equiv \{f,g\}_{\sigma_B} = \sigma_B[\beta(\mathrm{d}f),\beta(\mathrm{d}g)],$$

so we badly need an explicit formula for β. Let us denote by $\langle\cdot,\cdot\rangle$ the duality between Ξ and $\Xi^\star$. The inverse $\beta_\xi^{-1}:\Xi\to\Xi^\star$ is defined, for $\xi=(q,p)$, $\eta=(x,k)$, $\zeta=(y,l)\in\Xi$, by

$$(\sigma_B)_{(q,p)}[(x,k),(y,l)] \equiv y\cdot k - x\cdot l + x\cdot \overline{B_q} y = \langle (x,k), \beta_{(q,p)}^{-1}(y,l)\rangle,$$

where $\overline{B_q}:X\to X^\star$ is the linear, antisymmetric operator defined by $B_q(x,y)=x\cdot\overline{B_q}y$, $\forall x,y\in X$. It follows easily that β^{-1} can be set in matrix form,

$$\beta_\xi^{-1} = \begin{pmatrix} \overline{B_q} & -1_{X^*} \\ 1_X & 0 \end{pmatrix} : X\times X^\star \to X^\star \times X,$$

which leads to the next matrix form of β_ξ,

$$\beta_\xi = \begin{pmatrix} 0 & 1_X \\ -1_{X^*} & \overline{B_q} \end{pmatrix} : X^\star \times X \to X\times X^\star.$$

Thus, writting $\mathrm{d}_\xi h = (\mathrm{d}_\xi^X h, \mathrm{d}_\xi^{X^\star} h)$, one gets

$$\{f,g\}_B(\xi) = \mathrm{d}_\xi^X f\cdot \mathrm{d}_\xi^{X^\star} g - \mathrm{d}_\xi^X g\cdot \mathrm{d}_\xi^{X^\star} f + B_q(\mathrm{d}_\xi^X f, \mathrm{d}_\xi^X g).$$

Using coordinates, one has $\mathrm{d}_\xi^X h = \Sigma_{j=1}^N (\partial_{p_j} h)(\xi)\mathrm{d}p_j$ and $\mathrm{d}_\xi^{X^\star} h = \Sigma_{j=1}^N (\partial_{q_j} h)(\xi)\mathrm{d}q_j$ [recall that $\mathrm{d}p_j \in (X^\star)^\star \equiv X$]. We get finally

$$\{f,g\}_B = \sum_{j=1}^N (\partial_{p_j} f\ \partial_{q_j} g - \partial_{q_j} f\ \partial_{p_j} g) + \sum_{j,k=1}^N B_{jk}(\cdot)\partial_{p_j} f\ \partial_{p_k} g. \tag{2}$$

We shall denote by $\mathcal{P}_B(\Xi)$ the Poisson algebra $C^\infty(\Xi)_\mathbb{R}$ endowed with the pointwise multiplication and the Poisson bracket $\{\cdot,\cdot\}_B$ given in (2). The different descriptions of the quantum observable algebras in the next section asks also for a partial Fourier transformed version of this Poisson algebra. This will be explained in Sec. V under favorable circumstances.

IV. THE QUANTUM MAGNETIC OBSERVABLES; THE C^*-ALGEBRAS FOR $\hbar\neq 0$

We are placed in the framework of the preceding section, but for most of the constructions the smoothness assumption on B will be useless. We assume for the moment only that B is continuous.

We present first a pseudodifferential approach to the magnetic quantum system, following Refs. 6,7, and 13. No C^*-algebras are in sight for the moment. We choose some vector potential A corresponding to the magnetic field B ($\mathrm{d}A=B$). It also can be chosen continuous; think of the transversal gauge for example. The vector potential is used to define a representation of some explicitely gauge invariant structure. Only this one will be used in the process of quantization.

Let us fix some value $\hbar\neq 0$ for the Planck constant. We would like to justify the construction of a correspondence $f\mapsto \mathfrak{Op}_A^\hbar(f)$ between (suitable) complex functions defined on the phase space Ξ and operators. To the function $(q,p)\mapsto q_j$ one wants to assign the operator Q_j of multiplication with q_j [i.e., $(Q_j u)(q) := q_j u(q)$] and to $(q,p)\mapsto p_j$ we associate the first-order differential operator $\Pi_{A,j}^\hbar := \hbar P_j - A_j(Q) = -i\hbar\partial_j - A_j$. The difficulty of defining a functional calculus $f\mapsto \mathfrak{Op}_A^\hbar(f) \equiv f(Q,\Pi_A^\hbar)$ for these $2N$ operators comes from their high degree of noncommutativity,

$$i[Q_j,Q_k]=0,\quad i[\Pi_{A,j}^\hbar, Q_k] = \hbar\delta_{j,k},\quad i[\Pi_{A,j}^\hbar,\Pi_{A,k}^\hbar] = \hbar B_{kj}(Q),\quad j,k=1,\ldots,N.$$

A convenient global form of these canonical commutation relations may be given in terms of *the magnetic Weyl system*. Recall the unitary group $(e^{iQ\cdot p})_{p\in X^\star}$ of the position as well as *the magnetic translations* $(U_A^\hbar(q) := e^{iq\cdot\Pi_A^\hbar})_{q\in X}$, given explicitly in the Hilbert space $\mathcal{H} := L^2(X)$ by

$$U_A^\hbar(q) = e^{-(i/\hbar)\Gamma_A([Q,Q+\hbar q])} e^{iq\cdot\hbar P}, \tag{3}$$

where $\Gamma_A([q',q'+\hbar q]) := \int_{[q',q'+\hbar q]} A$ is the circulation of the vector potential A along the segment

$$[q',q'+\hbar q] := \{q'+t\hbar q | t \in [0,1]\}.$$

The family $(U_A^\hbar(q))_{q\in X}$ satisfies

$$U_A^\hbar(q)U_A^\hbar(q') = \omega_B^\hbar(Q;q,q')U_A^\hbar(q+q'), \quad q,q' \in X,$$

where we set

$$\omega_B^\hbar(q_0;q,q') := e^{-(i/\hbar)\Gamma_B(\langle q_0,q_0+\hbar q,q_0+\hbar q+\hbar q'\rangle)}$$

and

$$\Gamma_B(\langle q_0,x,y\rangle) := \int_{\langle q_0,x,y\rangle} B$$

is the flux of B through the triangle $\langle q_0,x,y\rangle$ defined by the points q_0,x, and y. Now the magnetic Weyl system is the family $(W_A^\hbar(q,p))_{(q,p)\in\Xi}$ of unitary operators in $\mathcal{H}$ given by

$$W_A^\hbar(q,p) := e^{-i\sigma((q,p),(Q,\Pi_A^\hbar))} = e^{-i(Q+(\hbar/2)q)\cdot p} e^{-(i/\hbar)\Gamma_A([Q,Q+\hbar q])} e^{iq\cdot\hbar P}$$

and it satisfies for all (q,p), $(q',p') \in \Xi$,

$$W_A^\hbar(q,p)W_A^\hbar(q',p') = e^{(i/2)\sigma((q,p),(q',p'))}\omega_B^\hbar(Q;q,q')W_A^\hbar(q+q',p+p').$$

To construct $\mathfrak{Op}_A^\hbar(f) \equiv f(Q,\Pi_A^\hbar))$ one does not dispose of a spectral theorem. Having the functional calculus with a C_0 group in mind and having faith in the ability of the magnetic Weyl system to take into account the way $(Q_1,\dots,Q_N;\ \Pi_{A,1}^\hbar,\dots,\Pi_{A,N}^\hbar)$ fail to commute, one proposes

$$\mathfrak{Op}_A^\hbar(f) := \int_\Xi \mathrm{d}\xi (\mathfrak{F}_\Xi f)(\xi) W_A^\hbar(\xi),$$

where by $\mathfrak{F}_\Xi$ we denote the symplectic Fourier transform

$$(\mathfrak{F}_\Xi f)(\xi) := \int_\Xi \mathrm{d}\eta\, e^{-i\sigma(\xi,\eta)} f(\eta).$$

A suitable choice of the Haar measures on $X, X^\star$ and Ξ leads to the exact form of the formulas above, with no numerical factors in front of the integrals.

Some simple replacements lead to the following expression for the action of these operators on vectors $u \in L^2(X)$:

$$[\mathfrak{Op}_A^\hbar(f)u](x) = \hbar^{-N}\int_X\int_{X^\star} \mathrm{d}y\,\mathrm{d}k\, e^{(i/\hbar)(x-y)\cdot k} e^{-(i/\hbar)\Gamma_A([x,y])} f\left(\frac{x+y}{2},k\right) u(y). \tag{4}$$

To have $\mathfrak{Op}_A^\hbar(f)\mathfrak{Op}_A^\hbar(g) = \mathfrak{Op}_A^\hbar(f\circ^\hbar g)$ and $\mathfrak{Op}_A^\hbar(f)^* = \mathfrak{Op}_A^\hbar(f^{\circ^\hbar})$, one sets $f^{\circ^\hbar}(q,p) := \overline{f(q,p)}$ (independent of $\hbar$ or B) and

$$(f\circ^\hbar g)(\xi) := (2/\hbar)^{2N}\int_\Xi \mathrm{d}\eta \int_\Xi \mathrm{d}\zeta\, e^{-2(i/\hbar)\sigma(\xi-\eta,\xi-\zeta)} e^{-(i/\hbar)\Gamma_B(\langle q-y+x,x-q+y,y-x+q\rangle)} f(\eta)g(\zeta). \tag{5}$$

The composition law $\circ^\hbar \equiv \circ_B^\hbar$ depends only on the magnetic field and not on the choice of some vector potential.

Obviously, for $B=0$ and $A=0$ the above formulas reproduce the well-known formulas of the pseudodifferential calculus in Weyl form. In Ref. 13 they are studied in detail, their gauge-invariance is underlined and a rigorous meaning of them and of some of their extensions are outlined. See also Refs. 6,7 for other developments and for nice geometrical interpretations. We shall come back to this *magnetic Weyl calculus* after an excursion into twisted crossed product algebras.

The input for a crossed product is a locally compact group X acting on a C^*-algebra $\mathcal{A}$. One constructs a larger C^*-algebra $\mathcal{A}\rtimes X$ containing both $\mathcal{A}$ and a unitary representation of X, with a prescribed commutation rule between elements of these two sets. When a 2-cocycle of the group (with values in the unitary group of the algebra) is also given and when "unitary representation" is replaced by "projective representation" in some suitable generalized sense, then one gets a twisted crossed product. We shall be pragmatic and introduce only the object of strict interest for our situation in a somewhat ad hoc manner. In Ref. 12 and especially in Ref. 14 we give a more detailed description. The abstract theory of twisted crossed products was developed in Refs. 4,19,20.

So, let us start by remarking that $X=\mathbb{R}^N$ is indeed a locally compact second countable group. We shall call *admissible* C^*-algebra $\mathcal{A}$ composed of bounded, uniformly continuous complex functions on X which contains $C_0(X)$ and is invariant under translations, $a\in\mathcal{A}$, $x\in X$ imply $a(\cdot+x)\in\mathcal{A}$. Thus, for any $\hbar\neq 0$, one can define the continuous action of X by automorphisms of $\mathcal{A}$,

$$\theta^\hbar: X\to \mathrm{Aut}(\mathcal{A}),\quad [\theta^\hbar_x(a)](y) := a(y+\hbar x).$$

$\theta^\hbar$ is a group morphism and the maps $X\ni x\mapsto\theta^\hbar_x(a)\in\mathcal{A}$, $a\in\mathcal{A}$ are all continuous. Let us recall the function

$$(q,x,y)\mapsto \omega^\hbar_B(q;x,y) := e^{-(i/\hbar)\Gamma_B(\langle q,q+\hbar x,q+\hbar x+\hbar y\rangle)},$$

which governs the multiplication property of the magnetic translations. It can be interpreted as a map

$$\omega^\hbar_B: X\times X\to C(X;\mathbb{T}),\quad [\omega^\hbar_B(x,y)](q) := \omega^\hbar_B(q;x,y)$$

with values in the set of continuous functions on X taking values in the 1-torus $\mathbb{T}:=\{z\in\mathbb{C}\,|\,|z|=1\}$. It is easy to see that $\omega^\hbar_B$ satisfies *the 2-cocycle condition*

$$\omega^\hbar_B(x,y)\omega^\hbar_B(x+y,z)=\theta^\hbar_x[\omega^\hbar_B(y,z)]\omega^\hbar_B(x,y+z),\quad \forall\, x,y,z\in X,$$

easy to check with Stokes' theorem, since $\mathrm{d}B=0$. It is also *normalized*, i.e.,

$$\omega^\hbar_B(x,0)=1=\omega^\hbar_B(0,x),\quad \forall\, x\in X.$$

We have shown in Ref. 14 how to impose conditions on B in order to have a good connection between $\omega^\hbar_B$ and the admissible C^*-algebra $\mathcal{A}$. Let us denote by $S_\mathcal{A}$ the Gelfand spectrum of $\mathcal{A}$ (the space of characters with the pointwise convergence topology). Our assumptions on $\mathcal{A}$ imply that X can be identified with a dense subset of the locally compact space $S_\mathcal{A}$. We say that a continuous function on X is *of class* $\mathcal{A}$ if it extends to a continuous function on $S_\mathcal{A}$. The C^*-algebra $\mathcal{A}$ is unital iff $S_\mathcal{A}$ is compact (thus a compactification of X) and in this case "continuous" means also "bounded;" in the nonunital case many unbounded functions are allowed. If the components B_{jk} of the magnetic field are of class $\mathcal{A}$ the mapping $X\times X\ni(x,y)\mapsto\omega^\hbar_B(\cdot;x,y)\in C(S_\mathcal{A};\mathbb{T})$ is well defined and continuous with respect to the topology of uniform convergence on compact subsets of $S_\mathcal{A}$. [Note that $C(S_\mathcal{A};\mathbb{T})$ is exactly the unitary group $\mathcal{UM}(\mathcal{A})$ of the multiplier algebra of $\mathcal{A}$.] These are the needed conditions to call $(\theta^\hbar,\omega^\hbar_B)$ *a twisted action of* X *on* $\mathcal{A}$ and to make the quadruplet $(\mathcal{A},\theta^\hbar,\omega^\hbar_B,X)$ a particular case of *a twisted* C^**-dynamical system*. These are also conditions under which one can perform the construction of the twisted crossed product C^*-algebra that we now explain.

Consider first the Banach space $L^1(X;\mathcal{A})$ with the norm $\|\varphi\|_1 := \int_X \mathrm{d}x \|\varphi\|_{\mathcal{A}}$. As a rule, its elements will be considered as functions of two variables: $[\varphi(x)](q) \equiv \varphi(q;x)$, thus $\|\varphi\|_1 = \int_X \mathrm{d}x \sup_{q\in X}|\varphi(q;x)|$. We can introduce an involution by $\varphi^{\diamond}(q;x) := \varphi(q;-x)$ and a composition law

$$(\varphi \diamond^{\hbar} \psi)(q;x) := \int_X \mathrm{d}y\, \varphi\left(q - \frac{\hbar}{2}(x-y);y\right)\psi\left(q+\frac{\hbar}{2}y;x-y\right)e^{-(i/\hbar)\Gamma_B(\langle q-(\hbar/2)x,q-(\hbar/2)x+\hbar y,q+(\hbar/2)x\rangle)} \tag{6}$$

(we leave to the reader the task of suppressing the variable q and introducing the objects $\theta^{\hbar}$ and $\omega_B^{\hbar}$ in the right places to get a more abstract version of this formula). Endowed with this structure $L^1(X;\mathcal{A})$ is a Banach*-algebra.

Its enveloping C^*-algebra will be called *the twisted crossed product of* $\mathcal{A}$ *by the twisted action* $(\theta^{\hbar},\omega_B^{\hbar})$ *of* X. A comprehensive but awkward notation would be $\mathcal{A}\rtimes_{\theta^{\hbar}}^{\omega_B^{\hbar}}X$, which we abbreviate to $\mathfrak{C}_{\mathcal{A}}^{\hbar}$, insisting on its dependence on $\hbar$ and $\mathcal{A}$, the magnetic field B being fixed. We recall that $\mathfrak{C}_{\mathcal{A}}^{\hbar}$ is the completion of $L^1(X;\mathcal{A})$ under the C^*-norm,

$$\|\varphi\|_{\hbar} := \sup\{\|\pi(\varphi)\|_{B(\mathcal{H})} | \pi: L^1(X;\mathcal{A}) \to B(\mathcal{H}) \text{ representation}\}.$$

The main reason for $\mathfrak{C}_{\mathcal{A}}^{\hbar}$ to exist is the fact that its nondegenerate representations are in a one-to-one correspondence with *covariant representations* of the twisted C^*-dynamical system $(\mathcal{A},\theta^{\hbar},\omega_B^{\hbar},X)$, i.e., with triples $(\mathcal{H},r,U)$, where $\mathcal{H}$ is a Hilbert space, r is a nondegenerate representation of $\mathcal{A}$ and U is a strongly continuous map from X to the family of unitary operators on $\mathcal{H}$ satisfying for all x, $y\in X$ and $a\in\mathcal{A}$,

$$U(x)U(y) = r[\omega_B^{\hbar}(x,y)]U(x+y) \quad \text{and } U(x)r(a)U(x)^* = r[\theta_x^{\hbar}(a)]. \tag{7}$$

We shall use this for a single case, that of *the Schrödinger covariant representation* $(L^2(X),r,U_A^{\hbar})$ *associated to the vector potential* A (with $\mathrm{d}A=B$). Here $r:\mathcal{A}\to B[L^2(X)]$ is the usual representation of functions in $\mathcal{A}$ by multiplication operators [$r(a)\equiv a(Q)$ by a previous notation] and $U_B^{\hbar}$ has been introduced at (3). It is easy in this case to check (7) and to view it as another way to codify the commutation relations between positions and magnetic momenta. In fact this is the root of the close connection (see below) between $\mathfrak{C}_{\mathcal{A}}^{\hbar}$ and the magnetic pseudodifferential calculus sketched above. The representation of $\mathfrak{C}_{\mathcal{A}}^{\hbar}$ corresponding to $(L^2(X),r,U_A^{\hbar})$ is given (by abstract principles) by

$$\mathfrak{Rep}_A^{\hbar}(\varphi) := \int_X \mathrm{d}x\, r[\theta_{x/2}^{\hbar}(\varphi(x))]U_A^{\hbar}(x),$$

which gives for $\varphi\in L^1(X;\mathcal{A})$ and $u\in L^2(X)$,

$$[\mathfrak{Rep}_A^{\hbar}(\varphi)u](x) = \hbar^{-N}\int_X \mathrm{d}y\, e^{(i/\hbar)\Gamma_A([x,y])}\varphi\left(\frac{x+y}{2},\frac{y-x}{\hbar}\right)u(y). \tag{8}$$

By comparing (8) with (4) one sees that, at least formally, $\mathfrak{Rep}_A^{\hbar}$ and $\mathfrak{Op}_A^{\hbar}$ are connected to each other by a partial Fourier transformation, $\mathfrak{Op}_A^{\hbar}(f) = \mathfrak{Rep}_A^{\hbar}[\mathbb{F}(f)]$, with $\mathbb{F} := 1\otimes\mathcal{F}$ and $(\mathcal{F}b)(x) := \int_{X^*}\mathrm{d}k\, e^{-ix\cdot k}b(k)$ whenever it makes sense. It follows that the composition laws $\circ^{\hbar}$ and $\diamond^{\hbar}$ are intertwined by $\mathbb{F}$, i.e., $f\circ^{\hbar}g = \mathbb{F}^{-1}[(\mathbb{F}f)\diamond^{\hbar}(\mathbb{F}g)]$, as can also be checked by a direct calculation. We refer to Ref. 14 for details on the rigorous meaning of these connections in nontrivial cases. We do not need it here since actually all our verifications in Secs. VI–VIII are done in the setting of twisted crossed products. One defines the C^*-algebra $\mathfrak{B}_{\mathcal{A}}^{\hbar} := \mathbb{F}^{-1}\mathfrak{C}_{\mathcal{A}}^{\hbar}$. On suitable dense subsets of $\mathfrak{B}_{\mathcal{A}}^{\hbar}$ we are entitled to use (5) as it stands.

V. THE MAIN RESULT

In Sec. III, assuming that the components of our magnetic field B are C^∞ functions on $X=\mathbb{R}^N$, we endowed the space $C^\infty(\Xi)_\mathbb{R}$ of real smooth functions on the phase-space $\Xi=X\times X^\star$ with a B-dependent Poisson algebra structure, called $\mathcal{P}_B(\Xi)$. On the other hand, in Sec. IV we constructed for each $\hbar\in(0,1]$ a C^*-algebra $\mathfrak{B}_\mathcal{A}^\hbar$, which is the partial Fourier transform of the twisted crossed product C^*-algebra $\mathfrak{C}_\mathcal{A}^\hbar$ defined by the twisted action $(\theta^\hbar,\omega_B^\hbar)$ of X on the admissible C^*-algebra $\mathcal{A}$; we had to use the assumption that the components B_{jk} are functions of class $\mathcal{A}$.

In order to construct now a strict deformation quantization we must study the conditions to be imposed to the magnetic field in connection with the choice of the Poisson subalgebra $\mathfrak{A}_0$ of $\mathcal{P}_B(\Xi)$.

We recall that $\mathfrak{C}_\mathcal{A}^\hbar$ is a C^*-completion of the Banach*-algebra $L^1(X;\mathcal{A})$; the structure depends on $\hbar$ and B. Then for any subspace $\mathcal{A}_0$ of $\mathcal{A}$ and any subspace $\mathcal{S}$ of $L^1(X)$, the algebraic tensor product $\mathcal{A}_0\odot\mathcal{S}$ (finite combination of simple tensors) is a subspace of $L^1(X;\mathcal{A})$, thus also of $\mathfrak{C}_\mathcal{A}^\hbar$. The partial Fourier transformed version $\mathbb{F}^{-1}[\mathcal{A}_0\odot\mathcal{S}]=\mathcal{A}_0\odot\mathcal{F}^{-1}\mathcal{S}$ will be a subspace of $\mathbb{F}^{-1}[L^1(X;\mathcal{A})]$ and, therefore, a subspace of $\mathfrak{B}_\mathcal{A}^\hbar$. Note that $\mathcal{A}_0\odot\mathcal{F}^{-1}\mathcal{S}$ is also contained in $\mathcal{A}\odot C_0(X^\star)$, thus it is composed of complex functions defined on the phase space Ξ. If one also requires that $\mathcal{A}_0\subset C^\infty(X)$ and $\mathcal{F}^{-1}\mathcal{S}\subset C^\infty(X^\star)$, then $\mathcal{A}_0\odot\mathcal{F}^{-1}\mathcal{S}\subset C^\infty(\Xi)$ and both the classical and the quantum formalisms hold on $\mathcal{A}_0\odot\mathcal{F}^{-1}\mathcal{S}$. In fact several choices for $\mathcal{A}_0$ and $\mathcal{S}$ are available, their success hanging on the assumptions we impose on the magnetic field. With severe contraints on B one hopes to quantize larger classes of classical symbols. We shall study a simple, convenient situation; the reader could work out other cases for himself. We define $\mathcal{A}^\infty:=\{a\in\mathcal{A}\cap C^\infty(X)\,|\,\partial^\alpha a\in\mathcal{A},\forall\,\alpha\in\mathbb{N}^N\}$; it is a subspace of $\mathcal{A}\cap BC^\infty(X)$. Take $\mathcal{A}_0=\mathcal{A}^\infty$ and $\mathcal{S}=\mathcal{S}(X)$, the Schwartz space of functions on X which have rapidly decaying derivatives of any order. Then $\mathcal{F}^{-1}\mathcal{S}=\mathcal{S}(X^\star)$ is the Schwartz space defined on $X^\star$.

We also consider $\mathcal{S}(X^\star;\mathcal{A}^\infty)$, the space of functions $X^\star\ni p\mapsto f(p)\in\mathcal{A}^\infty$ such that for any l, $m\in\mathbb{N}$,

$$\|f\|_{l,m}:=\max\{\sup_{p\in X^\star}\|p^\alpha(\partial^\beta f)(p)\|_\mathcal{A}\;||\alpha|\leqslant l,|\beta|\leqslant m\}<\infty.$$

We remark that

$$\mathcal{S}(X^\star;\mathcal{A}^\infty)\subset C^\infty(\Xi)\cap\mathbb{F}^{-1}\{L^1(X;\mathcal{A})\}.$$

Then we have the following evident statement.

Proposition 4.1: Suppose that the components of the magnetic field B belong to $\mathcal{A}^\infty$. Then $\mathcal{S}(X^\star;\mathcal{A}^\infty)_\mathbb{R}$ is a Poisson subalgebra of $\mathcal{P}_B(\Xi)$ and a dense subset of the self-adjoint part of the Abelian C^*-algebra $\mathcal{A}\otimes C_0(X^\star)$.

We can now state the following.

Theorem 4.2: (Main result) *Assume that the components of the magnetic field B belong to $\mathcal{A}^\infty$. Then the family of injections $(\mathcal{S}(X^\star;\mathcal{A}^\infty)_\mathbb{R}\hookrightarrow\mathfrak{B}_\mathcal{A}^\hbar)_{\hbar\in[0,1]}$ is a strict deformation quantization (cf. Definitions 1.2 and 1.5).*

As seen in Sec. IV, one may say that $\mathfrak{B}_\mathcal{A}^\hbar$ is a C^*-algebra of (magnetic) pseudodifferential symbols and its represented versions $\mathfrak{Op}_A^\hbar(\mathfrak{B}_\mathcal{A}^\hbar)\subset B(L^2(X))$ are C^*-algebras of magnetic pseudodifferential operators. It will be more convenient to work in the other realization, that of twisted crossed products. There are two reasons.

(1) There exist results of Refs. 18 and 20 on continuous fields of twisted crossed products which lead almost immediately to Rieffel's condition.
(2) In the twisted crossed product formalism one disposes of the simple norm $\|\cdot\|_1$, which will be very convenient in checking the axioms of von Neumann and Dirac. Thus we state now a variant of Theorem 4.2; these two results are equivalent by the isomorphisms defined by the partial Fourier transformation. We need first to rewrite the magnetic Poisson structure. On $\mathcal{S}(X;\mathcal{A})$ (obvious definition) we set by transport of structure

$$\varphi \diamond^0 \psi := \mathbb{F}[(\mathbb{F}^{-1}\varphi)(\mathbb{F}^{-1}\psi)] \quad \text{and} \quad \{\varphi,\psi\}^B := \mathbb{F}[\{\mathbb{F}^{-1}\varphi,\mathbb{F}^{-1}\psi\}_B], \quad \varphi,\psi \in \mathcal{S}(X;\mathcal{A}).$$

A simple direct calculation gives

$$(\varphi \diamond^0 \psi)(q;x) = \int_X \mathrm{d}y\, \varphi(q;y)\psi(q;x-y); \tag{9}$$

$\diamond^0$ is pointwise multiplication in the first variable and convolution in the second. Slightly more effort is needed to prove that

$$\{\varphi,\psi\}^B = -i\sum_{j=1}^{N}[(Q_j^{(2)}\varphi)\diamond^0(\partial_j^{(1)}\psi) - (\partial_j^{(1)}\varphi)\diamond^0(Q_j^{(2)}\psi)] - \sum_{j,k=1}^{N} B_{jk}(\cdot)(Q_j^{(2)}\varphi)\diamond^0(Q_k^{(2)}\psi), \tag{10}$$

where $(Q_j^{(2)}\rho)(q;x) := x_j\rho(q;x)$ and $(\partial_j^{(1)}\rho)(q;x) = (\partial/\partial q_j)\rho(q;x)$.

Let us denote by $C^*(X)$ the group C^*-algebra of X; it is the enveloping C^*-algebra of $L^1(X)$, the convolution Banach*-algebra of X. It is isomorphic to $C_0(X^\star)$ by an extension of the Fourier transformation; thus the spectrum of $C^*(X)$ is homeomorphic to $X^\star$. Note that the twisted crossed product $\mathfrak{C}_{\mathcal{A}}^{\hbar} = \mathcal{A} \rtimes_{\theta^{\hbar}}^{\omega_{\hbar}^B} X$ collapses to $\mathcal{A}\otimes C^*(X)$ for $\hbar = 0$.

Proposition 4.3: Suppose that the components of the magnetic field B belong to $\mathcal{A}^\infty$; then the vector space $\mathcal{S}(X;\mathcal{A}^\infty)_{\mathbb{R}} = \mathbb{F}[\mathcal{S}(X^\star;\mathcal{A}^\infty)]_{\mathbb{R}}$ is a Poisson algebra for the composition laws (9) and (10). It is also dense in the self-adjoint part of the Abelian C^*-algebra $\mathcal{A}\otimes C^*(X)$.

The partial Fourier transformed version of our main result reads as follows.

Theorem 4.4: *Assume that the components of the magnetic field B belong to $\mathcal{A}^\infty$; then the family of injections $(\mathcal{S}(X;\mathcal{A}^\infty)_{\mathbb{R}} \hookrightarrow (\mathfrak{C}_{\mathcal{A}}^{\hbar})_{\mathbb{R}})_{\hbar\in[0,1]}$ is a strict deformation quantization (cf. Definitions 1.2 and 1.5).*

The completeness condition is obvious, $\mathcal{S}(X;\mathcal{A}^\infty)$ is dense in $(L^1(X;\mathcal{A}),\|\cdot\|_1)$, $L^1(X;\mathcal{A})$ is dense in $(\mathfrak{C}_{\mathcal{A}}^{\hbar},\|\cdot\|_{\hbar})$ and one has $\|\cdot\|_1 \leqslant \|\cdot\|_{\hbar}$. The conditions of Definition 1.5 are also clearly satisfied. We still must verify the conditions (a), (b), and (c) of Definition 1.2. This will be done in the next sections.

Remark: It would be in the spirit of many works in strict deformation quantization to consider only the case $\mathcal{A} = C_0(X)$. Since in this case $\mathfrak{C}_{C_0(X)}^{\hbar}$ is isomorphic to $K[L^2(X)]$, the C^*-algebra of all compact operators on $L^2(X)$ [cf. Ref. 14, Proposition 2.17 (b)], in fact one works with a field of C^*-algebras with two types of fibers: $C_0(\Xi)$ for $\hbar = 0$ and $K[L^2(X)]$ for $\hbar \neq 0$. We think that both the twisted crossed product $\mathfrak{C}_{\mathcal{A}}^{\hbar}$ and the pseudodifferential formalism are useful for arbitrary, admissible $\mathcal{A}$. In Ref. 15 it is shown how to calculate the essential spectrum and how to get localization results for generalized Schrödinger operators with anisotropic potentials and magnetic fields. The anisotropy is taken into account by the abelian algebra $\mathcal{A}$ and exploiting the structure of its spectrum is the key of the proofs.

Remark: Let us point out that if the spectrum of $\mathcal{A}$ is compact (and that is always the case in the applications to quantum Hamiltonians, where we expect $\mathcal{A}$ to have a unit), then the components of the magnetic field B being of type $\mathcal{A}$ evidently imply that they are bounded and uniformly continuous. Thus, in this case the requirement that the components of B are of class $\mathcal{A}^\infty$ [i.e., they are of class $C^\infty(X)$ and together with all their derivatives admit continuous extensions to the spectrum of $\mathcal{A}$] is rather optimal. If we allow the spectrum of $\mathcal{A}$ to be noncompact, then we can allow unbounded magnetic fields with components of class $\mathcal{A}$ but we must replace $\mathcal{A}^\infty$ with $\mathcal{A}_{\mathrm{c}}^\infty$ the subalgebra of elements of $\mathcal{A}^\infty$ that have compact support (with respect to the spectrum of $\mathcal{A}$).

An important technical ingredient in our proof relies on a result saying roughly that, under certain conditions, the twisted crossed product of a group with the sectional algebra of a C^*-bundle is the sectional algebra of a C^*-bundle of twisted crossed products. This can be found in Refs. 18 and 20; techniques of Refs. 3 and 21 are also relevant here. For us the most convenient reference is Ref. 18, from which we quote slightly reformulated the definition and the result below.

Definition 4.5: A continuous C^*-bundle *is a triple* $\mathbf{A}=(I,\{\mathcal{A}^\hbar\}_{\hbar\in I},\Gamma_0(\mathbf{A}))$, *where* I *is a Hausdorff, locally compact space,* $\mathcal{A}^\hbar$ *is a* C^**-algebra with norm* $\|\cdot\|_\hbar$ *and* $\Gamma_0(\mathbf{A})$ *a* C^**-algebra of sections such that*

(i) *for any* $\hbar\in I$, $\{F(\hbar)\,|\,F\in\Gamma_0(\mathbf{A})\}=\mathcal{A}^\hbar$,
(ii) *for any* $F\in\Gamma_0(\mathbf{A})$, *the map* $\hbar\mapsto\|F_\hbar\|_\hbar$ *belongs to* $C_0(I)$,
(iii) $\Gamma_0(\mathbf{A})$ *is a* $C_0(I)$*-module: if* $F\in\Gamma_0(\mathbf{A})$ *and* $\nu\in C_0(I)$, *then* νF *(defined pointwise) also belongs to* $\Gamma_0(\mathbf{A})$.

In fact the arguments in Ref. 20 show that the separability condition in their definition of the twisted crossed product is needed only in studying the structure of the group of cocycles. Thus, for our developments of the functional calculus with magnetic fields, we can consider a slightly general definition for twisted crossed products by eliminating the separability condition, and as the proof in Ref. 18 is still valid, we have in fact the theorem cited below.

Theorem 4.6: [Nielsen, 1996 (Ref. 18)] *Let* $\mathbf{A}$ *be a continuous* C^**-bundle*. . *Let* (Θ,Ω) *be a twisted action of an amenable, second countable locally compact group* X *on* $\Gamma_0(\mathbf{A})$ *by* $C_0(I)$*-automorphisms. Then there exists a continuous* C^**-bundle* $\mathbf{C}=(I,\{\mathcal{C}^\hbar\}_{\hbar\in I},\Gamma_0(\mathbf{C}))$ *such that*

(i) *for any* $\hbar\in I$, $\mathcal{C}^\hbar=\mathcal{A}^\hbar\rtimes^{w^\hbar}_{t^\hbar}X$, *where* $t^\hbar_x:X\to\mathrm{Aut}(\mathcal{A}^\hbar)$, $t^\hbar_x[F(\hbar)]:=[\Theta_x(F)](\hbar)$, $\forall x\in X$, $\forall F\in\Gamma_0(\mathbf{A})$ *and* $w^\hbar:X\times X\to\mathcal{UM}(\mathcal{A}^\hbar)$, $w^\hbar(x,y):=[\Omega(x,y)](\hbar)$, $\forall x,y\in X$,
(ii) *the map* $[(\chi\Phi)(\hbar)](x)=[\Phi(x)](\hbar)$, $\forall\hbar\in I$, $\forall x\in X$ *extends from* $C_c(X;\Gamma_0(A))$*to an isomorphism* $\chi:\Gamma_0(\mathbf{A})\rtimes^\Omega_\Theta X\to\Gamma_0(\mathbf{C})$ *such that for every* $\Phi\in L^1(X;\Gamma_0(\mathbf{A}))$ *one has* $(\chi\Phi)(\hbar)\in L^1(X;\mathcal{A}^\hbar)$.

VI. RIEFFEL'S CONDITION

We are placed in the framework of Sec. IV. We start by constructing a twisted action on a large C^*-algebra, consisting of functions depending both on the variables $\hbar\in[0,1]$ and $q\in X\equiv\mathbb{R}^N$. The same strategy has been used in Ref. 2 for the rotation algebras (which are also twisted crossed products) in order to explore the regularity of the spectrum of certain finite-difference operators, the parameter $\hbar$ being replaced there by the strength of a (discrete) magnetic field.

We consider first the C^*-bundle $\mathbf{A}=(I,\{\mathcal{A}^\hbar\}_{\hbar\in I},\Gamma_0(\mathbf{A}))$, where $I:=[0,1]$ is compact, $\mathcal{A}^\hbar:=\mathcal{A}$ (our admissible C^*-algebra) for all $\hbar$ and $\Gamma_0(\mathbf{A}):=C(I;\mathcal{A})$. One checks easily that $\mathbf{A}$ is indeed a continuous C^*-bundle. Note that the Gelfand spectrum of the C^*-algebra $C(I;\mathcal{A})$ is homeomorphic to $I\times S_\mathcal{A}$, where $S_\mathcal{A}$ is the spectrum of $\mathcal{A}$. Recalling the twisted actions $\{(\theta^\hbar,\omega^\hbar_B)\,|\,\hbar\in I\}$ of Sec. IV, one defines for all $\hbar\in I$, $q,x,y\in X$ and $F\in C(I;\mathcal{A})$,

$$\Theta:X\to\mathrm{Aut}[C(I;\mathcal{A})],\quad(\Theta_xF)(\hbar):=\theta^\hbar_x[F(\hbar)],\tag{11}$$

$$\Omega_B:X\times X\to C(I\times S_\mathcal{A};\mathbb{T}),\quad[\Omega_B(x,y)](\hbar,q):=\omega^\hbar_B(q;x,y).\tag{12}$$

By using notations as $[F(\hbar)](q)\equiv F(\hbar,q)$ [the elements of $C(I;\mathcal{A})\cong C(I\times S_\mathcal{A})$ may be seen as functions on $I\times X$], (11) can be rewritten $(\Theta_xF)(\hbar,q)=F(\hbar,q+\hbar x)$. The group $X=\mathbb{R}^N$, being Abelian, is amenable. Then it is easy to verify that $(C(I;\mathcal{A}),\Theta,\Omega_B,X)$ is a twisted C^*-dynamical system and that $\Theta_x(\nu F)=\nu\Theta_x(F)$ for all $x\in X$, $\nu\in C(I)$ and $F\in C(I;\mathcal{A})$, as required by Theorem 4.6.

To apply Theorem 4.6, one must compute first the twisted actions $\{(t^\hbar,w^\hbar)\,|\,\hbar\in I\}$ associated to (Θ,Ω_B). It easily comes out that $t^\hbar=\theta^\hbar$ and $w^\hbar=\omega^\hbar_B$; just use the explicit formulas. Thus the C^*-algebras $\mathcal{C}^\hbar$, the fibers of the continuous C^*-bundle $\mathbf{C}$, coincide (respectively) with the C^*-algebras $\mathfrak{C}^\hbar_\mathcal{A}$ defined in Sec. IV. To show that the map $\hbar\mapsto\|\varphi\|_\hbar$ is continuous for any $\varphi\in\mathcal{A}^\infty\odot\mathcal{S}(X)$, by the axiom (ii) of a continuous C^*-bundle, one has just to prove that any element $\varphi\in S(X;\mathcal{A}^\infty)$ defines a (constant) section belonging to $\Gamma_0(\mathbf{C})$. This is obvious even for $\varphi\in L^1(X;\mathcal{A})$, since the isomorphism χ just intertwines the variables $\hbar$ and x.

VII. THE VON NEUMANN CONDITION

We have to show that, for fixed $\varphi,\ \psi\in\mathcal{S}(X;\mathcal{A}^\infty)_{\mathbb{R}}$ we have

$$\lim_{\hbar\to 0}\|\tfrac{1}{2}(\varphi\diamondsuit^{\hbar}\psi+\psi\diamondsuit^{\hbar}\varphi)-\varphi\diamondsuit^{0}\psi\|_{\hbar}=0.$$

The operations $\diamondsuit^{\hbar}$ and $\diamondsuit^{0}$ are defined, respectively, at (6) and (9). Taking into account that $\|\cdot\|_{\hbar}\leqslant\|\cdot\|_1$ and by the triangle inequality, it is enough to prove

$$\lim_{\hbar\to 0}\|\varphi\diamondsuit^{\hbar}\psi-\varphi\diamondsuit^{0}\psi\|_1=0. \tag{13}$$

By standard arguments one can approach any function in $L^1(X;\Gamma_0(\mathbf{A}),$ in L^1-norm, with a continuous function with compact support, and show that (using the notations of Theorem 4.6)

$$\chi[L^1(X;\Gamma_0(\mathbf{A}))]=C(I;L^1(X,\mathcal{A})).$$

For any function $\varphi\in L^1(X;\mathcal{A})$ let us denote by $\varphi_\circ\in C(I;L^1(X;\mathcal{A})$ the constant function $\varphi_\circ(\hbar):=\varphi,\ \forall\hbar\in I$ and by $\widetilde{\varphi}\in L^1(X;C(I;\mathcal{A}))$ the function taking constant values $[\widetilde{\varphi}(x)](\hbar):=\varphi(x),\ \forall\hbar\in I$. Let us also remark that any constant function in $C(I;L^1(X;\mathcal{A}))$ is of the form $\varphi_\circ=\chi[\widetilde{\varphi}]$ for some $\varphi\in L^1(X;\mathcal{A})$. We denote by # the product in $\Gamma_0(\mathbf{A})\rtimes^{\Omega}_{\Theta}X$ and by $\diamondsuit$ the product in $\Gamma_0(\mathbf{C})$. Then for fixed $\varphi,\ \psi\in\mathcal{S}(X;\mathcal{A}^\infty)_{\mathbb{R}}\subset L^1(X;\mathcal{A})$, one has

$$[\varphi_\circ\diamondsuit\psi_\circ](\hbar)=\chi[\widetilde{\varphi}\#\widetilde{\psi}](\hbar)$$

and thus $\varphi_\circ\diamondsuit\psi_\circ\in C(I;L^1(X;\mathcal{A}))$. As a direct consequence, if we set $\mathbf{\Psi}(\varphi,\psi):=\varphi_\circ\diamondsuit\psi_\circ-(\varphi\diamondsuit^{0}\psi)_\circ\in C(I;L^1(X;\mathcal{A})$ we get

$$\lim_{\hbar\to 0}\|\mathbf{\Psi}(\varphi,\psi)(\hbar)-\mathbf{\Psi}(\varphi,\psi)(0)\|_1=0.$$

But

$$\mathbf{\Psi}(\varphi,\psi)(0)=(\varphi_\circ\diamondsuit\psi_\circ)(0)-(\varphi\diamondsuit^{0}\psi)_\circ(0)=\varphi\diamondsuit^{0}\psi-\varphi\diamondsuit^{0}\psi=0$$

so that

$$\|\varphi\diamondsuit^{\hbar}\psi-\varphi\diamondsuit^{0}\psi\|_{\hbar}=\|\mathbf{\Psi}(\varphi,\psi)(\hbar)\|_{\hbar}\leqslant\|\mathbf{\Psi}(\varphi,\psi)(\hbar)\|_1\underset{\hbar\to 0}{\longrightarrow}0$$

and thus we have got the von Neumann condition.

An alternative direct proof by elementary arguments can be given by studying the exponent of the cocycle appearing in the definition of $\diamondsuit^{\hbar}$,

$$-\frac{i}{\hbar}\Gamma_B\left(\left\langle q-\frac{\hbar}{2}x,q-\frac{\hbar}{2}x+\hbar y,q+\frac{\hbar}{2}x\right\rangle\right)=-\frac{i}{\hbar}\int_{\langle q-(\hbar/2)x,q-(\hbar/2)x+\hbar y,q+(\hbar/2)x\rangle}B.$$

Consider a parametrization for the triangle $\langle q-(\hbar/2)x,q-(\hbar/2)x+\hbar y,q+(\hbar/2)x\rangle$,

$$\left\langle q-\frac{\hbar}{2}x,q-\frac{\hbar}{2}x+\hbar y,q+\frac{\hbar}{2}x\right\rangle=\kappa_{q,(x,y)}[\Delta_2]$$

where $\Delta_2:=\{(t,s)\in\mathbb{R}^2\,|\,0\leqslant t\leqslant 1,0\leqslant s\leqslant t\}$ and

$$\kappa_{q,(x,y)}(t,s):=q-\frac{\hbar}{2}x+t\hbar y+s\hbar(x-y)=q+\left(s-\frac{1}{2}\right)\hbar x+(t-s)\hbar y.$$

Thus, by denoting e_t and e_s the tangent vectors corresponding to the two coordinate functions of $\mathbb{R}^2$, we have

$$\int_{\kappa[\Delta_2]} B = \int_{\Delta_2} \kappa^* B = \int_0^1 \mathrm{d}t \int_0^t \mathrm{d}s (\kappa^* B)(e_t, e_s).$$

An obvious calculation gives

$$(\kappa^* B)(e_t, e_s) = \sum_{j,k} B(\kappa_{q,(x,y)}(t,s)) \frac{\partial \kappa_j}{\partial t} \frac{\partial \kappa_k}{\partial s}$$

and thus we have

$$-\frac{i}{\hbar}\Gamma_B(\kappa_{q,(x,y)}[\Delta_2]) = -i\hbar \sum_{j,k} y_j (x-y)_k \int_0^1 \mathrm{d}t \int_0^t \mathrm{d}s\, B_{jk}\left[q + \left(s - \frac{1}{2}\right)\hbar x + (t-s)\hbar y\right]$$
$$=: -i\hbar \Omega_B(q,x,y;\hbar). \tag{14}$$

Now let us come back to (13) and estimate

$$\|\varphi \diamondsuit^{\hbar} \psi - \varphi \diamondsuit^{0} \psi\|_1 \leqslant \int_X \mathrm{d}x \int_X \mathrm{d}y \sup_{q \in X} \left| \varphi\left(q - \frac{\hbar}{2}(x-y); y\right) \psi\left(q + \frac{\hbar}{2} y; x - y\right) e^{-i\hbar \Omega_B(q,x,y;\hbar)} \right.$$
$$\left. - \varphi(q;y)\psi(q;x-y) \right|. \tag{15}$$

It is easy to see that the integral is bounded by the expression

$$2\left(\sup_{q \in X} \sup_{y \in X} \langle y \rangle^m \varphi(q;y)\right)\left(\sup_{q \in X} \sup_{x \in X} \langle x \rangle^m \psi(q;x)\right)\left(\int_X \mathrm{d}x \langle x \rangle^{-m}\right)^2,$$

that is finite and not depending of $\hbar$ for any $m > N$. On the other hand, the integrand in (15) is convergent pointwise to zero when $\hbar$ goes to 0, as can be seen after writing the inequality

$$\sup_{q \in X} \left| \varphi\left(q - \frac{\hbar}{2}(x-y); y\right) \psi\left(q + \frac{\hbar}{2} y; x - y\right) e^{-i\hbar \Omega_B(q,x,y;\hbar)} - \varphi(q;y)\psi(q;x-y) \right| \leqslant \left(\sup_{q \in X} \left| \varphi\left(q - \frac{\hbar}{2}(x \right.\right.\right.$$
$$\left.\left.\left. - y); y\right) - \varphi(q;y) \right|\right)\left(\sup_{q \in X} \left| \psi\left(q + \frac{\hbar}{2} y; x - y\right) \right|\right) + \left(\sup_{q \in X} |\varphi(q;y)|\right)\left(\sup_{q \in X} \left| \psi\left(q + \frac{\hbar}{2} y; x - y\right) \right.\right.$$
$$\left.\left. - \psi(q;x-y) \right|\right) + \left(\sup_{q \in X} |\varphi(q;y)\psi(q;x-y)|\right)\left(\sup_{q \in X} |e^{-i\hbar \Omega_B(q,x,y;\hbar)} - 1|\right).$$

For the first two lines we use the fact that φ and ψ belong to $\mathcal{S}(X;\mathcal{A}^\infty) \subset BC^\infty(X \times X)$. For the third one, the hypothesis that the components of the magnetic field are in $\mathcal{A}^\infty \subset BC^\infty(X)$ implies that for any $(x,y) \in X^2$ we have $\sup_{q \in X} |\Omega_B(q,x,y;\hbar)| \leqslant C(x,y)$ uniformly in $\hbar$. Thus $\sup_{q \in X} |\exp\{-i\hbar\Omega(q,x,y;\hbar)\} - 1|$ converges to 0 for $\hbar \to 0$.

VIII. THE DIRAC CONDITION

We need only to prove that the following convergence holds:

$$\left\| \frac{1}{i\hbar}(\varphi \diamondsuit^{\hbar} \psi - \psi \diamondsuit^{\hbar} \varphi) - \{\varphi, \psi\}_B \right\|_{1^{\hbar \to 0}} \to 0. \tag{16}$$

For that we shall need the exact form of the first order term in $\hbar$ of $\varphi \diamondsuit^{\hbar} \psi - \psi \diamondsuit^{\hbar} \varphi$. We use Taylor developments

$$\varphi\left(q-\frac{\hbar}{2}(x-y);y\right)=\varphi(q;y)-\frac{\hbar}{2}\sum_{j=1}^{N}(x_j-y_j)\int_0^1 \mathrm{d}s(\partial_j^{(1)}\varphi)\left(q-s\frac{\hbar}{2}(x-y);y\right)$$

and

$$\psi\left(q+\frac{\hbar}{2}y;x-y\right)=\psi(q;x-y)+\frac{\hbar}{2}\sum_{j=1}^{N}y_j\int_0^1 \mathrm{d}s(\partial_j^{(1)}\psi)\left(q+s\frac{\hbar}{2}y;x-y\right).$$

For $\rho\in\mathcal{S}(X;\mathcal{A}^\infty)$, $z\in X$ and $(q,x)\in X^2$ we shall use the notation $\nabla^{(1)}\rho$ for the gradient with respect to the first variable in $X\times X$ and set

$$(\mathfrak{L}_z^{\pm}\rho)(q;x):=\frac{1}{2}z\cdot\int_0^1 \mathrm{d}s(\nabla^{(1)}\rho)\left(q\pm s\frac{\hbar}{2}z;x\right). \tag{17}$$

Note that we have

$$\lim_{\hbar\to 0}(\mathfrak{L}_z^{\pm}\varphi)(q;x)=\tfrac{1}{2}z\cdot(\nabla^{(1)}\varphi)(q;x). \tag{18}$$

Then the Taylor developments above read

$$\varphi\left(q-\frac{\hbar}{2}(x-y);y\right)=\varphi(q;y)-\hbar(\mathfrak{L}_{x-y}^{-}\varphi)(q;y)$$

and

$$\psi\left(q+\frac{\hbar}{2}y;x-y\right)=\psi(q;x-y)+\hbar(\mathfrak{L}_{y}^{+}\varphi)(q;x-y).$$

Moreover, the assumption that $B_{jk}\in\mathcal{A}^\infty\subset BC^\infty(X)$ implies that for any x, $y\in X$, the function $X\times[0,1]\ni(q,\hbar)\mapsto\Omega_B(q,x,y;\hbar)\in\mathbb{R}$ is bounded and uniformly continuous. Thus, if we denote

$$R_B(q,x,y;\hbar):=\frac{1}{\hbar}(e^{-i\hbar\Omega_B(q,x,y;\hbar)}-e^{-i\hbar\Omega_B(q,x,y,0)}), \tag{19}$$

we get $\lim_{\hbar\to 0}|R_B(q,x,y;\hbar)|=0$.

Setting everything together we obtain

$$\begin{aligned}(\varphi\diamondsuit^{\hbar}\psi-\psi\diamondsuit^{\hbar}\varphi)(q;x)=&\int_X \mathrm{d}y[(1-\hbar\mathfrak{L}_{x-y}^{-})\varphi](q;y)[(1+\hbar\mathfrak{L}_{y}^{+})\psi](q;x-y)[e^{-i\hbar\Omega_B(q,x,y;0)}\\&+\hbar R_B(q,x,y;\hbar)]-\int_X \mathrm{d}y[(1-\hbar\mathfrak{L}_{x-y}^{-})\psi](q;y)[(1+\hbar\mathfrak{L}_{y}^{+})\varphi](q;x-y)\\&\times[e^{-i\hbar\Omega_B(q,x,y;0)}+\hbar R_B(q,x,y;\hbar)]=\int_X \mathrm{d}y\ \varphi(q,y)\psi(q;x-y)[e^{-i\hbar\Omega_B(q,x,y;0)}\\&-e^{-i\hbar\Omega_B(q,x,x-y;0)}]+\hbar\int_X \mathrm{d}y\ \varphi(q;y)[(\mathfrak{L}_{y}^{+}+\mathfrak{L}_{y}^{-})\psi](q;x-y)\\&-\hbar\int_X \mathrm{d}y[(\mathfrak{L}_{x-y}^{+}+\mathfrak{L}_{x-y}^{-})\varphi](q;y)\psi(q;x-y)+o(\hbar),\end{aligned}$$

where for obtaining the second identity, we have changed an integration variable from y to $x-y$. By using (18) and some simple arguments we get

$$(\varphi \diamond^{\hbar} \psi - \psi \diamond^{\hbar} \varphi)(q;x) = -i\hbar \sum_{j,k} B_{jk}(q) \int_X \mathrm{d}y\, y_j \varphi(q;y)(x-y)_k \psi(q;x-y)$$
$$+ \hbar \int_X \mathrm{d}y [y\varphi(q;y) \cdot (\nabla^{(1)}\psi)(q;x-y) - (\nabla^{(1)}\varphi)(q;y) \cdot (x-y)\psi(q;x-y)]$$
$$+ o(\hbar).$$

The result is now straightforward by the explicit form of the bracket $\{\cdot, \cdot\}^B$ and of the composition law $\diamond^0$.

ACKNOWLEDGMENTS

A large part of this work has been completed while the authors visited the University of Geneva and the authors express their gratitude to Professor Werner Amrein for his kind hospitality and the stimulating discussions. By means of complex representation and real representation of a quaternion matrix, this paper studies the problem of diagonalization of a quaternion matrix, gives two algebraic methods for diagonalization of quaternion matrices in quaternionic quantum theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1896386]

I. INTRODUCTION

In the study of quaternionic quantum mechanics and quantum fields,[1–3] the theory of diagonalization of quaternion matrices plays an important role. In practical calculation and applications in quaternionic quantum theory, one meets a problem of finding a nonsingular quaternion matrix S and reducing a quaternion matrix A to a diagonal matrix by a transformation of the form $A \to S^{-1}AS$. Because of the noncommutation of quaternions and the standard complex mathematical methods of resolution break down, the problem is more difficults. In Refs. 4 and 5, the authors discussed the problem of diagonalization of quaternion matrices, and gave a practical rule for diagonalization of quaternion matrices. In Ref. 6, by means of complex representation and companion vector, we studied the problems the eigenvalues and eigenvectors for a quaternion matrix, and derived an algorithm for the eigenvalues and eigenvectors for a quaternion matrix in quaternionic quantum theory. In this paper, by means of complex representation and real representation of a quaternion matrix, we study the problem of diagonalization of a quaternion matrix in two ways, give two algebraic methods for diagonalization of quaternion matrices in quaternionic quantum theory.

Let $\mathbf{R}$ denote the real number field, $\mathbf{C}$ the complex number field, $\mathbf{Q}=\mathbf{R}\oplus\mathbf{R}i\oplus\mathbf{R}j\oplus\mathbf{R}k$ the quaternion field, where $i^2=j^2=k^2=-1$, $ij=-ji=k$. For any matrix A, A^T and $\overline{A}$ denote the transpose and conjugate of A, respectively. $\mathbf{F}^{m\times n}$ denotes the set of $m\times n$ matrices on a field $\mathbf{F}$. $A\sim B$ means that A is similar to B for $A,B\in\mathbf{C}^{n\times n}$.

II. COMPLEX REPRESENTATION OF A QUATERNION MATRIX

For any quaternion matrix $A=B_1+B_2i+B_3j+B_4k\in\mathbf{Q}^{m\times n}$, $i^2=j^2=k^2=-1$, $ij=-ji=k$, $B_l\in\mathbf{R}^{m\times n}(l=1,2,3,4)$, A can be uniquely expressed as $A=(B_1+B_2i)+(B_3+B_4i)j=A_1+A_2j$, $A_1,A_2\in\mathbf{C}^{m\times n}$. It is easy to verify that for any $A\in\mathbf{C}^{m\times n}$, we have $Aj=j\overline{A}$, and $jAj=-A$. Define

$$A^f=\begin{bmatrix} A_1 & A_2 \\ -\overline{A_2} & \overline{A_1} \end{bmatrix}\in\mathbf{C}^{2m\times 2n}, \tag{2.1}$$

the complex matrix A^f is known as complex representation of the matrix A.

Let A, $B\in\mathbf{Q}^{m\times n}$, $C\in\mathbf{Q}^{n\times s}$, $a\in\mathbf{R}$, $P_t=\begin{pmatrix} I_t & 0 \\ 0 & -I_t \end{pmatrix}$, $Q_t=\begin{pmatrix} 0 & -I_t \\ I_t & 0 \end{pmatrix}$, I_t be $t\times t$ identity matrix. Then $P_t^2=I_{2t}$, $Q_tQ_t^T=I_{2t}$. By the definition of complex representation we easily get the following results:

a)Electronic mail: tsjemail@163.com

$$(A+B)^f = A^f + B^f, \quad (aA)^f = aA^f, \tag{2.2}$$

$$(AC)^f = A^f C^f, \tag{2.3}$$

$$\overline{A^f} = Q_m^T A^f Q_n. \tag{2.4}$$

For $A \in \mathbf{Q}^{n\times n}$, clearly by (2.3) the quaternion matrix A is nonsingular if and only if the complex representation A^f is nonsingular, and $(A^{-1})^f = (A^f)^{-1}$.

For $A \in \mathbf{Q}^{n\times n}$ and $\mathbf{x} \in \mathbf{C}^{2n\times 1}$, if $A^f\mathbf{x} = \lambda\mathbf{x}$, then by (2.4),

$$\overline{A^f}\overline{\mathbf{x}} = \overline{\lambda}\overline{\mathbf{x}} \Leftrightarrow A^f(Q_n^T\overline{\mathbf{x}}) = \overline{\lambda}(Q_n^T\overline{\mathbf{x}}), \tag{2.5}$$

clearly two vectors $\mathbf{x}$ and $Q_n^T\overline{\mathbf{x}}$ are linearly independent. Therefore the following result comes immediately from (2.5).

Proposition 2.1: Let $A \in \mathbf{Q}^{n\times n}$. Then the complex eigenvalues of complex representation A^f appear in conjugate pairs.

III. COMPLEX REPRESENTATION METHOD

In this section, we derive a technique for diagonalization of a quaternion matrix by means of complex representation in quaternionic quantum theory.

Let $A \in \mathbf{Q}^{n\times n}$, and A^f be the complex representation of quaternion matrix A.

If A is a diagonalizable matrix, then there exists a nonsingular quaternion matrix S such that $AS = SJ$, $J = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$, in which λ_t is an eigenvalue of quaternion matrix A. By Ref. 6, Lemma 3.1 let $\lambda_t = a_t + b_t i$ with real number a_t, b_t and $\mathrm{Im}\,\lambda_t \geqslant 0$, we have

$$A^f S^f = S^f J^f = S^f \begin{bmatrix} J & 0 \\ 0 & \overline{J} \end{bmatrix}, \tag{3.1}$$

therefore the complex representation A^f is diagonalizable.

Conversely, if complex representation A^f is diagonalizable, by Proposition 2.1 let all eigenvalues of A^f be $\lambda_1, \overline{\lambda_1}, \lambda_2, \overline{\lambda_2}, \ldots, \lambda_n, \overline{\lambda_n}$,in which $\mathrm{Im}\,\lambda_t \geqslant 0$, $t = 1, 2, \ldots, n$, and T be a nonsingular complex matrix such that

$$T^{-1}A^f T = \begin{bmatrix} J & 0 \\ 0 & \overline{J} \end{bmatrix} = J^f \Leftrightarrow A^f T = TJ^f, \tag{3.2}$$

where $J = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$. By (2.4), the equation (3.2) is equivalent to

$$\overline{A^f}\overline{T} = \overline{TJ^f} \Leftrightarrow A^f(Q_n^T\overline{T}Q_n) = (Q_n^T\overline{T}Q_n)J^f. \tag{3.3}$$

Combine (3.2) and (3.3) there exists a nonzero matrix $\hat{T}$ such that

$$A^f\hat{T} = \hat{T}J^f, \tag{3.4}$$

where $\hat{T} = \frac{1}{2}(T + Q_n^T\overline{T}Q_n)$. Let

$$T = \begin{bmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{bmatrix}, \tag{3.5}$$

where $T_{kl} \in \mathbf{C}^{n\times n}$. It is easy to get by direct calculation

$$\hat{T} = \begin{bmatrix} \hat{T}_1 & \hat{T}_2 \\ -\overline{\hat{T}}_2 & \overline{\hat{T}}_1 \end{bmatrix}, \tag{3.6}$$

where

$$\hat{T}_1 = \tfrac{1}{2}(T_{11} + \overline{T}_{22}), \quad \hat{T}_2 = \tfrac{1}{2}(T_{12} - \overline{T}_{21}). \tag{3.7}$$

From (3.6) construct a quaternion matrix

$$S = \hat{T}_1 + \hat{T}_2 j = \frac{1}{2}(I_n, -jI_n)\hat{T}\begin{bmatrix} I_n \\ jI_n \end{bmatrix}. \tag{3.8}$$

Clearly $S^f = \hat{T}$. Therefore (3.4) is equivalent to

$$A^f S^f = S^f J^f \Leftrightarrow AS = SJ. \tag{3.9}$$

Finally for any two complex numbers k_1, k_2, since

$$\begin{bmatrix} \hat{T}_1 & \hat{T}_2 \\ -\overline{\hat{T}}_2 & \overline{\hat{T}}_1 \end{bmatrix}\begin{bmatrix} k_1 \\ k_2 \end{bmatrix} = 0 \Leftrightarrow \begin{bmatrix} k_1 & k_2 \\ \overline{k}_2 & -\overline{k}_1 \end{bmatrix}\begin{bmatrix} \hat{T}_1 \\ \hat{T}_2 \end{bmatrix} = 0. \tag{3.10}$$

Clearly if $(k_1, k_2) \neq (0,0)$, then the equation (3.10) has only zero solution, $\hat{T}_1 = 0$, $\hat{T}_2 = 0$, i.e., $\hat{T} = 0$, a contradiction. Therefore nonzero $\hat{T}$ is nonsingular complex matrix, and from $S^f = \hat{T}$ we know that S is nonsingular quaternion matrix.

From the statement above we get the following result.

Theorem 3.1: Let $A \in \mathbf{Q}^{n\times n}$. Then A is a diagonalizable quaternion matrix if and only if A^f is a diagonalizable complex matrix, in which case, if A^f is a diagonalizable matrix and let all eigenvalues of A^f be $\lambda_1, \overline{\lambda}_1, \lambda_2, \overline{\lambda}_2, \ldots, \lambda_n, \overline{\lambda}_n$, in which $\mathrm{Im}\,\lambda_t \geqslant 0$, $t = 1, 2, \ldots, n$, and T be a nonsingular matrix such that

$$T^{-1}A^f T = \begin{bmatrix} J & 0 \\ 0 & \overline{J} \end{bmatrix} = J^f \Leftrightarrow A^f T = TJ^f,$$

where $J = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$. Let

$$S = \frac{1}{4}(I_n, -jI_n)(T + Q_n^{-1}\overline{T}Q_n)\begin{bmatrix} I_n \\ jI_n \end{bmatrix}. \tag{3.11}$$

Then S is a nonsingular quaternion matrix and $S^{-1}AS = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$.

The proof of Theorem 3.1 is constructive. Theorem 3.1 turns the problem of diagonalization of a quaternion matrix into that of corresponding complex representation matrix by means of complex representation of a quaternion matrix. When a quaternion matrix is a diagonalizable matrix, it gives a formula algorithm for the diagonalization of the quaternion matrix by the formula (3.11).

Example: Let

$$A = \begin{bmatrix} 2i & -2j & j+k \\ -k & 2 & -1 \\ -j & 1-i & 1 \end{bmatrix}.$$

Is quaternion matrix A a diagonalizable matrix? If A is a diagonalizable matrix, then find a nonsingular quaternion matrix S such that $S^{-1}AS$ is a diagonal matrix.

Solution: It is easy to get by (2.1) that the complex representation A^f of quaternion matrix A is

$$A^f = \begin{bmatrix} 2i & 0 & 0 & 0 & -2 & 1+i \\ 0 & 2 & -1 & -i & 0 & 0 \\ 0 & 1-i & 1 & -1 & 0 & 0 \\ 0 & 2 & -1+i & -2i & 0 & 0 \\ -i & 0 & 0 & 0 & 2 & -1 \\ 1 & 0 & 0 & 0 & 1+i & 1 \end{bmatrix},$$

and $|xI_{2n}-A^f|=(x-1)^2(x-1-i)^2(x-1+i)^2$. Therefore the eigenvalues λ of A^f are 1, 1, $1+i$, $1+i$, $1-i$, $1-i$.

For $\lambda=1$, find two corresponding linearly independent eigenvectors by solving equation $(\lambda I_6-A^f)\mathbf{x}=0$, $\alpha_1=(1+i,0,0,0,-1,-i)^T$, $\alpha_2=(0,1,-i,1-i,0,0)^T$; for $\lambda=1+i$, find two corresponding linearly independent eigenvectors $\alpha_3=(i,0,0,0,-1,i)^T$, $\alpha_4=(i,0,0,0,0,1)^T$; and for $\lambda=1-i$, $\alpha_5=(0,1,i,-i,0,0)^T$, $\alpha_6=(0,0,-1,-i,0,0)^T$ are corresponding linearly independent eigenvectors.

Let $T=(\alpha_1,\alpha_3,\alpha_4,\alpha_2,\alpha_5,\alpha_6)$. Then T is a nonsingular matrix and

$$T^{-1}A^fT=\operatorname{diag}(J,\overline{J})=J^f,$$

where $J=\operatorname{diag}(1,1+i,1+i)$. Therefore A^f is diagonalizable, and then by Theorem 3.1 A is diagonalizable. Construct a quaternion matrix S by (3.11),

$$S=\frac{1}{4}(I_3,-jI_3)(T+Q_3^T\overline{T}Q_3)\begin{bmatrix} I_3 \\ jI_3 \end{bmatrix}=\begin{bmatrix} 1+i & i & i \\ j & j & 0 \\ -k & k & -j \end{bmatrix},$$

then S is a nonsingular quaternion matrix and such that

$$S^{-1}AS=\operatorname{diag}(1,1+i,1+i).$$

IV. REAL REPRESENTATION OF A QUATERNION MATRIX

For any quaternion matrix $A=A_1+A_2i+A_3j+A_4k\in\mathbf{Q}^{m\times n}$, $A_l\in\mathbf{R}^{m\times n}(l=1,2,3,4)$, define

$$A^f=\begin{bmatrix} A_1 & -A_2 & -A_3 & -A_4 \\ A_2 & A_1 & -A_4 & A_3 \\ A_3 & A_4 & A_1 & -A_2 \\ A_4 & -A_3 & A_2 & A_1 \end{bmatrix}\in\mathbf{R}^{4m\times 4n}, \tag{4.1}$$

the real matrix A^f is known as real representation of the quaternion matrix A.

Let

$$P_t=\begin{bmatrix} I_t & 0 & 0 & 0 \\ 0 & -I_t & 0 & 0 \\ 0 & 0 & I_t & 0 \\ 0 & 0 & 0 & -I_t \end{bmatrix},\quad Q_t=\begin{bmatrix} 0 & -I_t & 0 & 0 \\ I_t & 0 & 0 & 0 \\ 0 & 0 & 0 & I_t \\ 0 & 0 & -I_t & 0 \end{bmatrix},$$

$$R_t=\begin{bmatrix} 0 & 0 & 0 & -I_t \\ 0 & 0 & I_t & 0 \\ 0 & -I_t & 0 & 0 \\ I_t & 0 & 0 & 0 \end{bmatrix},\quad S_t=\begin{bmatrix} 0 & 0 & -I_t & 0 \\ 0 & 0 & 0 & -I_t \\ I_t & 0 & 0 & 0 \\ 0 & I_t & 0 & 0 \end{bmatrix}.$$

Then P_t,Q_t,R_t,S_t are unitary matrices, and

$$Q_t^2 = R_t^2 = S_t^2 = Q_t R_t S_t = -1. \tag{4.2}$$

Let $A, B \in \mathbf{Q}^{m\times n}$, $C \in \mathbf{Q}^{n\times s}$, $a \in \mathbf{R}$. By the definition of real representation we easily get the following results:

$$(A+B)^f = A^f + B^f, (aA)^f = aA^f, \tag{4.3}$$

$$(AC)^f = A^f C^f, \tag{4.4}$$

$$Q_m^T A^f Q_n = A^f, \tag{4.5}$$

$$R_m^T A^f R_n = A^f, \tag{4.6}$$

$$S_m^T A^f S_n = A^f. \tag{4.7}$$

Clearly, from (4.4) we know that the quaternion matrix A is nonsingular if and only if real representation matrix A^f is nonsingular, and $(A^{-1})^f = (A^f)^{-1}$.

For $A \in \mathbf{Q}^{n\times n}$ and $\mathbf{x} \in \mathbf{C}^{4n\times 1}$, if $A^f\mathbf{x} = \lambda\mathbf{x}$, then by (4.5)–(4.7) we have

$$A^f(Q_n^T\mathbf{x}) = \lambda(Q_n^T\mathbf{x}), \quad A^f(R_n^T\mathbf{x}) = \lambda(R_n^T\mathbf{x}), \quad A^f(S_n^T\mathbf{x}) = \lambda(S_n^T\mathbf{x}). \tag{4.8}$$

On the one hand, let λ be a real number, we may choose $\mathbf{x} \in \mathbf{R}^{4n\times 1}$, and from (4.8) we easily verify that $\mathbf{x}, Q_n^T\mathbf{x}, R_n^T\mathbf{x}, S_n^T\mathbf{x}$ are linearly independent. This means that real eigenvalues of A^f appear in fours. On the other hand, let λ be an imaginary number. If there exist three complex numbers k_1, k_2, k_3 such that $\mathbf{x} = k_1 Q_n^T\mathbf{x} = k_2 R_n^T\mathbf{x} = k_3 S_n^T\mathbf{x}$, then by (4.2) we easily know that $k_1^2 = k_2^2 = k_3^2 = k_1 k_2 k_3 = -1$, this is a contradiction. Without loss generality suppose that $\mathbf{x}, Q_n^T\mathbf{x}$ are linearly independent, and clearly $\mathbf{x}, Q_n^T\overline{\mathbf{x}}$ are also linearly independent, by (4.5) we have

$$A^f\mathbf{x} = \lambda\mathbf{x}, \quad A^f(Q_n^T\mathbf{x}) = \lambda(Q_n^T\mathbf{x}), \tag{4.9}$$

$$A^f\mathbf{x} = \lambda\mathbf{x}, \quad A^f(Q_n^T\overline{\mathbf{x}}) = \overline{\lambda}(Q_n^T\overline{\mathbf{x}}). \tag{4.10}$$

Therefore (4.9) and (4.10) mean that the imaginary eigenvalues of real representation A^f appear in pairs and in conjugate pairs.

Form the statement above we obtain the following result.

Proposition 4.1: Let $A \in \mathbf{Q}^{n\times n}$. Then the real eigenvalues of real representation A^f appear in fours; the imaginary eigenvalues of real representation A^f appear in pairs and in conjugate pairs. In other words, the complex eigenvalues of real representation A^f appear in double conjugate pairs, i.e., the complex eigenvalues of the $4n\times 4n$ real matrix A^f appear in the form

$$\lambda_1, \lambda_1, \lambda_2, \lambda_2, \ldots, \lambda_n, \lambda_n,$$

$$\overline{\lambda_1}, \overline{\lambda_1}, \overline{\lambda_2}, \overline{\lambda_2}, \ldots, \overline{\lambda_n}, \overline{\lambda_n}.$$

V. REAL REPRESENTATION METHOD

In this section, we discuss an analogue of technique for diagonalization of a quaternion matrix by means of real representation in quaternionic quantum theory.

For $A \in \mathbf{Q}^{n\times n}$, if A is a diagonalizable matrix, there exists a nonsingular quaternion matrix S such that

$$S^{-1}AS = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n), \tag{5.1}$$

in which λ_t is an eigenvalue of quaternion matrix A, $t=1,2,\ldots,n$. By Ref. 6, Lemma 3.1 we may let $\lambda_t = a_t + b_t i$ with $\mathrm{Im}\,\lambda_t \geqslant 0$. Let $J=\mathrm{diag}(\lambda_1,\lambda_2,\ldots,\lambda_n)=J_1+J_2 i$, in which $J_1=\mathrm{diag}(a_1,a_2,\ldots,a_n)$ and $J_2=\mathrm{diag}(b_1,b_2,\ldots,b_n)$. Then

$$(S^f)^{-1}A^f S^f = J^f = \begin{bmatrix} J_1 & -J_2 & 0 & 0 \\ J_2 & J_1 & 0 & 0 \\ 0 & 0 & J_1 & -J_2 \\ 0 & 0 & J_2 & J_1 \end{bmatrix}. \tag{5.2}$$

Therefore by the fact that

$$\begin{bmatrix} 1 & 1 \\ -i & i \end{bmatrix}^{-1} \begin{bmatrix} a_t & -b_t \\ b_t & a_t \end{bmatrix} \begin{bmatrix} 1 & 1 \\ -i & i \end{bmatrix} = \begin{bmatrix} a_t + b_t i & 0 \\ 0 & a_t - b_t i \end{bmatrix}$$

we have

$$A^f \sim J^f \sim \begin{bmatrix} a_1 & -b_1 & & & 0 \\ b_1 & a_1 & & & \\ & & \ddots & & \\ & & & a_n & -b_n \\ 0 & & & b_n & a_n \end{bmatrix} \oplus \begin{bmatrix} a_1 & -b_1 & & & 0 \\ b_1 & a_1 & & & \\ & & \ddots & & \\ & & & a_n & -b_n \\ 0 & & & b_n & a_n \end{bmatrix} \sim \begin{bmatrix} \lambda_1 & 0 & & & 0 \\ 0 & \overline{\lambda_1} & & & \\ & & \ddots & & \\ & & & \lambda_n & 0 \\ 0 & & & 0 & \overline{\lambda_n} \end{bmatrix}$$
$$\oplus \begin{bmatrix} \lambda_1 & 0 & & & 0 \\ 0 & \overline{\lambda_1} & & & \\ & & \ddots & & \\ & & & \lambda_n & 0 \\ 0 & & & 0 & \overline{\lambda_n} \end{bmatrix}. \tag{5.3}$$

That is the real representation A^f is diagonalizable.

Conversely, if real representation A^f is diagonalizable, by Proposition 4.1, (5.2) and (5.3) there exists a nonsingular complex matrix T such that

$$T^{-1}A^f T = J^f \Leftrightarrow A^f T = TJ^f, \tag{5.4}$$

where $J=\mathrm{diag}(\lambda_1,\lambda_2,\ldots,\lambda_n)$, and $\lambda_t = a_t + b_t i$ with $\mathrm{Im}\,\lambda_t \geqslant 0$, $t=1,2,\ldots,n$.

Let

$$T = \begin{bmatrix} T_{11} & T_{12} & T_{13} & T_{14} \\ T_{21} & T_{22} & T_{23} & T_{24} \\ T_{31} & T_{32} & T_{33} & T_{34} \\ T_{41} & T_{42} & T_{43} & T_{44} \end{bmatrix}, \tag{5.5}$$

where $T_{kl} \in \mathbf{C}^{n\times n}$. By (4.5)–(4.7) and (5.4) we have

$$A^f \overline{T} = \overline{T} J^f,$$

$$A^f (Q_n^T \overline{T} Q_n) = (Q_n^T \overline{T} Q_n) J^f,$$

$$A^f (R_n^T \overline{T} R_n) = (R_n^T \overline{T} R_n) J^f,$$

$$A^f(S_n^T\overline{T}S_n) = (S_n^T\overline{T}S_n)J^f, \tag{5.6}$$

let $\hat{T}=\frac{1}{4}(\overline{T}+Q_n^T\overline{T}Q_n+R_n^T\overline{T}R_n+S_n^T\overline{T}S_n)$, then clearly $\hat{T}$ is nonzero complex matrix and with

$$A^f\hat{T} = \hat{T}J^f. \tag{5.7}$$

It is easy to get by direct calculation

$$\hat{T} = \begin{bmatrix} \hat{T}_1 & -\hat{T}_2 & -\hat{T}_3 & -\hat{T}_4 \\ \hat{T}_2 & \hat{T}_1 & -\hat{T}_4 & \hat{T}_3 \\ \hat{T}_3 & \hat{T}_4 & \hat{T}_1 & -\hat{T}_2 \\ \hat{T}_4 & -\hat{T}_3 & \hat{T}_2 & \hat{T}_1 \end{bmatrix}, \tag{5.8}$$

where

$$\hat{T}_1 = \tfrac{1}{4}(\overline{T}_{11} + \overline{T}_{22} + \overline{T}_{44} + \overline{T}_{33}), \quad \hat{T}_2 = \tfrac{1}{4}(\overline{T}_{21} - \overline{T}_{12} - \overline{T}_{34} + \overline{T}_{43}),$$

$$\hat{T}_3 = \tfrac{1}{4}(\overline{T}_{31} - \overline{T}_{42} + \overline{T}_{24} - \overline{T}_{13}), \quad \hat{T}_4 = \tfrac{1}{4}(\overline{T}_{41} + \overline{T}_{32} - \overline{T}_{14} - \overline{T}_{23}).$$

From (5.8) construct a quaternion matrix,

$$S = \hat{T}_1 + \hat{T}_2 i + \hat{T}_3 j + \hat{T}_4 k = \frac{1}{4}(I_n, iI_n, jI_n, kI_n)\hat{T}\begin{bmatrix} I_n \\ -iI_n \\ -jI_n \\ -kI_n \end{bmatrix}. \tag{5.9}$$

Clearly $S^f=\hat{T}$, and by (4.4) and (5.7) we have $AS=SJ$. Similarly in Sec. III, we can also prove that S is nonsingular quaternion matrix, therefore A is a diagonalizable matrix.

The following result comes immediately from the statement above.

Theorem 5.1: Let $A \in \mathbf{Q}^{n\times n}$. Then A is a diagonalizable quaternion matrix if and only if real representation A^f is a diagonalizable real matrix, in which case, if A^f is a diagonalizable matrix and let complex eigenvalues of the $4n\times 4n$ real matrix A^f are in the form

$$\lambda_1, \lambda_1, \lambda_2, \lambda_2, \ldots, \lambda_n, \lambda_n,$$

$$\overline{\lambda_1}, \overline{\lambda_1}, \overline{\lambda_2}, \overline{\lambda_2}, \ldots, \overline{\lambda_n}, \overline{\lambda_n},$$

where $\operatorname{Im}\lambda_t \geqslant 0$, $t=1,2,\ldots,n$. Then

$$A^f \sim \begin{bmatrix} \lambda_1 & 0 & & & 0 \\ 0 & \overline{\lambda_1} & & & \\ & & \ddots & & \\ & & & \lambda_n & 0 \\ 0 & & & 0 & \overline{\lambda_n} \end{bmatrix} \oplus \begin{bmatrix} \lambda_1 & 0 & & & 0 \\ 0 & \overline{\lambda_1} & & & \\ & & \ddots & & \\ & & & \lambda_n & 0 \\ 0 & & & 0 & \overline{\lambda_n} \end{bmatrix} \sim J^f,$$

where $J=\operatorname{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$. Let T be a nonsingular complex matrix such that

$$T^{-1}A^fT = J^f \Leftrightarrow A^fT = TJ^f.$$

Construct a quaternion matrix

$$S = \frac{1}{16}(I_n, iI_n, jI_n, kI_n)(\overline{T} + Q_n^T \overline{T} Q_n + R_n^T \overline{T} R_n + S_n^T \overline{T} S_n) \begin{bmatrix} I_n \\ -iI_n \\ -jI_n \\ -kI_n \end{bmatrix}. \tag{5.10}$$

Then S is nonsingular and $S^{-1}AS = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$.

The proof of Theorem 5.2 is also constructive. Theorem 5.2 turns the problem of diagonalization of a quaternion matrix into that of corresponding real representation matrix by means of real representation of a quaternion matrix. When a quaternion matrix is a diagonalizable matrix, it gives a formula algorithm for the diagonalization of the quaternion matrix by the formula (5.10).

Symmetric informationally complete–positive operator valued measures and the extended Clifford group

D. M. Appleby[a)]
Department of Physics, Queen Mary University of London, London E1 4NS, United Kingdom

(Received 17 January 2005; accepted 28 February 2005; published online 19 April 2005)

We describe the structure of the extended Clifford group [defined to be the group consisting of all operators, unitary and antiunitary, which normalize the generalized Pauli group (or Weyl–Heisenberg group as it is often called)]. We also obtain a number of results concerning the structure of the Clifford group proper (i.e., the group consisting just of the unitary operators which normalize the generalized Pauli group). We then investigate the action of the extended Clifford group operators on symmetric informationally complete–positive operator valued measures (or SIC–POVMs) covariant relative to the action of the generalized Pauli group. We show that each of the fiducial vectors which has been constructed so far (including all the vectors constructed numerically by Renes *et al.*) is an eigenvector of one of a special class of order 3 Clifford unitaries. This suggests a strengthening of a conjecture of Zauner's. We give a complete characterization of the orbits and stability groups in dimensions 2–7. Finally, we show that the problem of constructing fiducial vectors may be expected to simplify in the infinite sequence of dimensions 7,13,19,21,31,… . We illustrate this point by constructing exact expressions for fiducial vectors in dimensions 7 and 19. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1896384]

I. INTRODUCTION

The statistics of an arbitrary quantum measurement are described by a positive operator valued measure, or POVM (Davies,[1] Busch *et al.*,[2] Peres,[3] Nielsen and Chuang[4] and references cited therein). Suppose the measurement has only a finite number of distinct outcomes. Then the corresponding POVM assigns to each outcome i the positive operator $\hat{E}_i$ with the property that $\mathrm{Tr}(\hat{E}_i\hat{\rho})$ is the probability of obtaining outcome i (where $\hat{\rho}$ is the density operator). Since $\Sigma_i \mathrm{Tr}(\hat{E}_i\hat{\rho})=1$ for all $\hat{\rho}$ we must have $\Sigma_i \hat{E}_i=1$.

A POVM is said to be *informationally complete* if the probabilities $\mathrm{Tr}(\hat{E}_i\hat{\rho})$ uniquely determine the density operator $\hat{\rho}$. The concept of informational completeness is originally due to Prugovečki[5] (also see Busch,[6] Busch *et al.*,[2] d'Ariano *et al.*,[7] Flammia *et al.*,[8] Finkelstein,[9] and references cited therein). It has an obvious relevance to the problem of quantum state determination. It also plays an important role in the Caves *et al.*[10–13] Bayesian approach to the interpretation of quantum mechanics, and in Hardy's[14,15] proposed axiomatization.

Suppose the Hilbert space has finite dimension d. Then it is easily seen that an informationally complete POVM must contain at least d^2 distinct operators $\hat{E}_i$. An informationally complete POVM is said to be *symmetric informationally complete* (or SIC) if it contains exactly this minimal number of distinct operators and if, in addition,

(1) $\lambda\hat{E}_i$ is a one-dimensional projector for all i and some fixed constant λ,

a)Electronic mail: d.m.appleby@qmul.ac.uk

(2) the overlap $\mathrm{Tr}(\hat{E}_i\hat{E}_j)$ is the same for every pair of distinct labels i,j.

It is straightforward to show that this is equivalent to the requirement that, for each i,

$$\hat{E}_i = \frac{1}{d}|\psi_i\rangle\langle\psi_i|, \tag{1}$$

where the d^2 vectors $|\psi_i\rangle$ satisfy

$$|\langle\psi_i|\psi_j\rangle| = \begin{cases} 1, & i = j, \\ \dfrac{1}{\sqrt{d+1}}, & i \neq j. \end{cases} \tag{2}$$

SIC–POVMs were introduced in a dissertation by Zauner,[16] and in Renes *et al.*[17] Wootters,[18] Bengtsson and Ericsson,[19,20] and Grassl[21] have made further contributions. There appear to be some intimate connections with the theory of mutually unbiased bases,[18,22,23] finite affine planes,[18–20] and polytopes.[19,20]

If SIC–POVMs existed in every finite dimension (or, failing that, in a sufficiently large set of finite dimensions) they would constitute a naturally distinguished class of POVMs which might be expected to have many interesting applications to quantum tomography, cryptography, and information theory generally. They would also be obvious candidates for the "fiducial" or "standard" POVMs featuring in the work of Fuchs[13] and Hardy.[14,15]

The question consequently arises, is it in fact true that SIC–POVMs exist in every finite dimension? The answer to this question is still unknown. Analytic solutions to Eqs. (2) have been constructed in dimensions 2, 3, 4, 5, 6, and 8. Moreover Renes *et al.*[17] have constructed numerical solutions in dimensions 5 to 45 (the actual vectors can be downloaded from their website[24]). So one may plausibly speculate that SIC–POVMs exist in every finite dimension. But it has not been proved.

With one exception, the SIC–POVMs which have so far been explicitly described in the literature are all covariant under the action of the generalized Pauli group (or Weyl–Heisenberg group, as it is often called). (The exception being the solution in dimension 8 described in Zauner's thesis.[16] Renes *et al.*[17] also mention that they have constructed numerical solutions which are covariant under the action of other groups, but they do not give any details.) It is therefore natural to investigate their behavior under the action of the extended Clifford group. The Clifford group proper is defined to be the normalizer of the generalized Pauli group, considered as a subgroup of $\mathrm{U}(d)$ (the group consisting of all unitary operators in dimension d). It is relevant to a number of areas of quantum information theory, and it has been extensively discussed in the literature.[25–31] Its relevance to the SIC–POVM problem has been stressed by Grassl.[21] As Grassl notes, it is related to the Jacobi group,[32] which has attracted some notice in the pure mathematical literature. We define the extended Clifford group to be the group which results when the Clifford group is enlarged, so as to include all *anti*unitary operators which normalize the generalized Pauli group. As we will see, this enlargement is essential if one wants to achieve a full understanding of the SIC–POVM problem.

In Secs. II–IV we give a self-contained account of the structure of the extended Clifford group. In the course of this discussion we obtain a number of results concerning the structure of the Clifford group proper which, to the best of our knowledge, have not previously appeared in the literature and which may be of some independent interest.

In Sec. V we define and establish some of the properties of a function we call the Clifford trace. We also identify a distinguished class of order 3 Clifford unitaries for which the Clifford trace$=-1$. We refer to these as *canonical* order 3 unitaries.

In Sec. VI we analyze the vectors constructed numerically by Renes *et al.*[17] (RBSC in the sequel) in dimension 5–45. We show that each of them is an eigenvector of a canonical order 3 Clifford unitary. This suggests the conjecture, that *every* GP fiducial vector is an eigenvector of a canonical order 3 unitary. We also show that, with one exception, the stability group of each RBSC

vector is order 3 (the exception being dimension 7, where the stability group is order 6).

In Sec. VII we show that RBSC's results also support a strengthened version of a conjecture of Zauner's[16] (also see Grassl[21]).

In Sec. VIII we use RBSC's numerical data, regarding the total number of fiducial vectors in dimensions 2–7, to give a complete characterization of the orbits and stability groups in dimensions 2–7. Our results show that in each of these dimensions *every* fiducial vector covariant under the action of the generalized Pauli group is an eigenvector of a canonical order 3 Clifford unitary. We also identify the total number of distinct orbits. It was already known[16,17,21] that there are infinitely many orbits in dimension 3, and one orbit in dimensions 2 and 6. We show that there is, likewise, only one orbit in dimensions 4 and 5, but two distinct orbits in dimension 7. We also construct exact expressions for two fiducial vectors in dimension 7 (one on each of the two distinct orbits).

RBSC's numerical data may suggest that, after dimension 7, the stability group of every fiducial vector has order 3. In Sec. IX we show that there is at least one exception to that putative rule by constructing an exact expression for a fiducial vector in dimension 19 for which the stability group has order $\geqslant 18$.

Our construction of exact solutions in dimensions 7 and 19 was facilitated by the fact that in these dimensions there exist canonical order 3 unitaries having a particularly simple form. In Sec. X we show that a similar simplification occurs in every dimension d for which (a) d has at least one prime factor $=1 \pmod 3$, (b) d has no prime factors $=2 \pmod 3$, and (c) d is not divisible by 9. In other words, it happens when $d=7,13,19,21,31,\ldots$.

II. FIDUCIAL VECTORS FOR THE GENERALIZED PAULI GROUP

The SIC–POVMs which have been constructed to date all have a certain group covariance property. Let G be a finite group having d^2 elements, and suppose we have an injective map $g \rightarrow \hat{U}_g$ which associates to each $g \in G$ a unitary operator $\hat{U}_g$ acting on d-dimensional Hilbert space. Suppose that for all g, g',

$$\hat{U}_g \hat{U}_{g'} = e^{i\xi_{gg'}} \hat{U}_{gg'}, \tag{3}$$

where $e^{i\xi_{gg'}}$ is a phase [so the map defines a group homomorphism of G into the quotient group $\mathrm{U}(d)/\mathrm{U}_c(d)$, where $\mathrm{U}_c(d)$ is the center of $\mathrm{U}(d)$]. (In other words it defines a projective representation of the group G. Such representations also play an important role in the theory of "nice" error bases.[33–35]) Finally (and this, of course, is the difficult part) suppose we can find a vector $|\psi\rangle \in \mathbb{C}^d$ such that $\langle\psi|\psi\rangle = 1$ and

$$|\langle\psi|\hat{U}_g|\psi\rangle| = \frac{1}{\sqrt{d+1}} \tag{4}$$

for all $g \neq e$ (e being the identity of G). Then the assignment

$$\hat{E}_g = \frac{1}{d}\hat{U}_g|\psi\rangle\langle\psi|\hat{U}_g^\dagger \tag{5}$$

defines a SIC–POVM on $\mathbb{C}^d$. The vector $|\psi\rangle$ is said to be a *fiducial vector*.

To date attention has been largely focussed on the case $G=(\mathbb{Z}_d)^2$, where $\mathbb{Z}_d$ is the set of integers 0,1, …, $d-1$ under addition *modulo d* (although there is numerical evidence that fiducial vectors exist for other choices of group[17]). That is also the case on which we will focus here.

To construct a suitable map $(\mathbb{Z}_d)^2 \rightarrow \mathrm{U}(d)$, let $|e_0\rangle, |e_1\rangle, \ldots |e_{d-1}\rangle$ be an orthonormal basis for $\mathbb{C}^d$, and let $\hat{T}$ be the operator defined by

$$\hat{T}|e_r\rangle = \omega^r|e_r\rangle, \tag{6}$$

where $\omega = e^{2\pi i/d}$. Let $\hat{S}$ be the shift operator

$$\hat{S}|e_r\rangle = \begin{cases} |e_{r+1}\rangle & r = 0,1,\ldots,d-2, \\ |e_0\rangle & r = d-1. \end{cases} \tag{7}$$

Then define, for each pair of integers $\mathbf{p}=(p_1,p_2)\in\mathbb{Z}^2$,

$$\hat{D}_{\mathbf{p}} = \tau^{p_1 p_2}\hat{S}^{p_1}\hat{T}^{p_2}, \tag{8}$$

where $\tau=-e^{\pi i/d}$ (the minus sign means that $\tau^{d^2}=1$ for all d, thereby simplifying some of the formulas needed in the sequel). We have, for all $\mathbf{p},\mathbf{q}\in\mathbb{Z}^2$,

$$\hat{D}_{\mathbf{p}}^{\dagger} = \hat{D}_{-\mathbf{p}}, \tag{9}$$

$$\hat{D}_{\mathbf{p}}\hat{D}_{\mathbf{q}} = \tau^{\langle \mathbf{p},\mathbf{q}\rangle}\hat{D}_{\mathbf{p}+\mathbf{q}}, \tag{10}$$

and

$$\hat{D}_{\mathbf{p}+\mathrm{d}\mathbf{q}} = \begin{cases} \hat{D}_{\mathbf{p}} & \text{if } d \text{ is odd}, \\ (-1)^{\langle \mathbf{p},\mathbf{q}\rangle}\hat{D}_{\mathbf{p}} & \text{if } d \text{ is even}, \end{cases} \tag{11}$$

where $\langle \mathbf{p},\mathbf{q}\rangle$ is the symplectic form

$$\langle \mathbf{p},\mathbf{q}\rangle = p_2 q_1 - p_1 q_2. \tag{12}$$

Consequently the map $\mathbf{p}\in(\mathbb{Z}_d)^2\to\hat{D}_{\mathbf{p}}\in \mathrm{U}(d)$ has all the required properties. The operators $\hat{D}_{\mathbf{p}}$ are sometimes called generalized Pauli matrices. So we will say that a vector $|\psi\rangle\in\mathbb{C}^d$ is a generalized Pauli fiducial vector, or *GP fiducial vector* for short, if it is a fiducial vector relative to the action of these operators, i.e., if $\langle\psi|\psi\rangle=1$ and

$$|\langle\psi|\hat{D}_{\mathbf{p}}|\psi\rangle| = \frac{1}{\sqrt{d+1}} \tag{13}$$

for every $\mathbf{p}\in\mathbb{Z}^2\neq\mathbf{0}(\mathrm{mod}\ d)$.

The set of operators $\hat{D}_{\mathbf{p}}$ is not a group. However, it becomes a group if we allow each $\hat{D}_{\mathbf{p}}$ to be multiplied by an arbitrary phase. We will refer to the group $\mathrm{GP}(d)=\{e^{i\xi}\hat{D}_{\mathbf{p}}:\xi\in\mathbb{R},\mathbf{p}\in\mathbb{Z}^2\}$ so obtained as the generalized Pauli group. **(**Also known as the Weyl–Heisenberg group. Our definition is, perhaps, slightly unconventional. It would be more usual to define $\mathrm{GP}(d)=\{\tau^n\hat{D}_{\mathbf{p}}:n\in\mathbb{Z},\mathbf{p}\in\mathbb{Z}^2\}$—i.e., the subgroup generated by the operators $\hat{D}_{\mathbf{p}}$. It appears to us that our definition, and our corresponding definition of the group $\mathrm{C}(d)$ (see below), make the analysis (slightly) simpler. It will be observed that on our definitions $\mathrm{GP}(d)$ and $\mathrm{C}(d)$ are both infinite. For some purposes this might be considered a disadvantage. However, in this paper we are really only interested in the groups which result when the phases are factored out. Consequently, it makes no important difference whether one adopts our definitions [on which $\mathrm{GP}(d)$ and $\mathrm{C}(d)$ are infinite] or the more conventional definitions (on which they are finite).**)**

We now want to investigate the normalizer of $\mathrm{GP}(d)$, i.e., the group $\mathrm{C}(d)$ consisting of all unitary operators $\hat{U}\in\mathrm{U}(d)$ with the property

$$\hat{U}\,\mathrm{GP}(d)\hat{U}^{\dagger} = \mathrm{GP}(d). \tag{14}$$

The significance of this group for us is that it generates automorphisms of $\mathrm{GP}(d)$ according to the prescription

$$\hat{P}\to\hat{U}\hat{P}\hat{U}^{\dagger}. \tag{15}$$

Consequently, if $|\psi\rangle$ is a GP fiducial vector, then so is $\hat{U}|\psi\rangle$ for every $\hat{U}\in\mathrm{C}(d)$.

The group $\mathrm{C}(d)$ is known as the Clifford group, and has been extensively discussed in the literature.[25–31] Its relevance to the SIC–POVM problem has been stressed by Grassl.[21] However, none of these accounts derive all the results needed for our analysis of the RBSC vectors. In the interests of readability we give a unified treatment in the next section.

III. THE CLIFFORD GROUP: STRUCTURE, AND CALCULATION OF THE UNITARIES

We begin with some definitions. Let

$$\overline{d} = \begin{cases} d & \text{if } d \text{ is odd,} \\ 2d & \text{if } d \text{ is even.} \end{cases} \tag{16}$$

Let $\mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ be the group consisting of all 2×2 matrices,

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}, \tag{17}$$

such that $\alpha,\beta,\gamma,\delta \in \mathbb{Z}_{\overline{d}}$ and $\alpha\delta-\beta\gamma=1 \pmod{\overline{d}}$. Note that inverses exist in this group because the condition $\alpha\delta-\beta\gamma=1 \pmod{\overline{d}}$ implies

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}\begin{pmatrix} \delta & -\beta \\ -\gamma & \alpha \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \tag{18}$$

in arithmetic *modulo* $\overline{d}$.

We then have the following.

Lemma 1: For each unitary operator $\hat{U} \in \mathrm{C}(d)$ *there exists a matrix* $F \in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ *and a vector* $\boldsymbol{\chi} \in (\mathbb{Z}_d)^2$ *such that*

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}} \tag{19}$$

for all $\mathbf{p} \in \mathbb{Z}^2$ *(where* $\omega=\tau^2=e^{2\pi i/d}$*, as before).*

Proof: If $\hat{U} \in \mathrm{C}(d)$ it is immediate that there exist functions f and g such that

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = e^{ig(\mathbf{p})}\hat{D}_{f(\mathbf{p})} \tag{20}$$

for all $\mathbf{p} \in \mathbb{Z}^2$. It follows from Eq. (10) that

$$(e^{ig(\mathbf{p})}\hat{D}_{f(\mathbf{p})})(e^{ig(\mathbf{q})}\hat{D}_{f(\mathbf{q})}) = \tau^{\langle \mathbf{p},\mathbf{q}\rangle}(e^{ig(\mathbf{p}+\mathbf{q})}\hat{D}_{f(\mathbf{p}+\mathbf{q})}) \tag{21}$$

for all $\mathbf{p},\mathbf{q} \in \mathbb{Z}^2$. Consequently

$$e^{i(g(\mathbf{p})+g(\mathbf{q}))}\tau^{\langle f(\mathbf{p}),f(\mathbf{q})\rangle}\hat{D}_{f(\mathbf{p})+f(\mathbf{q})} = e^{ig(\mathbf{p}+\mathbf{q})}\tau^{\langle \mathbf{p},\mathbf{q}\rangle}\hat{D}_{f(\mathbf{p}+\mathbf{q})} \tag{22}$$

which implies $f(\mathbf{p}+\mathbf{q})=f(\mathbf{p})+f(\mathbf{q})(\mathrm{mod}\, d)$. We may therefore write

$$f(\mathbf{p}) = F'\mathbf{p} + \mathrm{d}h(\mathbf{p}) \tag{23}$$

for some matrix F' and function h. Inserting this expression in Eq. (20) gives, in view of Eq. (11),

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = e^{ig(\mathbf{p})}\hat{D}_{F'\mathbf{p}+\mathrm{d}h(\mathbf{p})} = \begin{cases} e^{ig(\mathbf{p})}\hat{D}_{F'\mathbf{p}}, & d \text{ odd} \\ e^{ig(\mathbf{p})}(-1)^{\langle \mathbf{p},h(\mathbf{p})\rangle}\hat{D}_{F'\mathbf{p}}, & d \text{ even.} \end{cases} \tag{24}$$

With the appropriate definition of g' this means

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = e^{ig'(\mathbf{p})}\hat{D}_{F'\mathbf{p}} \tag{25}$$

for all $\mathbf{p}$. Repeating the argument which led to Eq. (22) we find

$$e^{ig'(\mathbf{p}+\mathbf{q})-g'(\mathbf{p})-g'(\mathbf{q})}\tau^{\langle \mathbf{p},\mathbf{q}\rangle-\langle F'\mathbf{p},F'\mathbf{q}\rangle} = 1. \tag{26}$$

Interchanging $\mathbf{p}$ and $\mathbf{q}$ gives

$$e^{ig'(\mathbf{p}+\mathbf{q})-g'(\mathbf{p})-g'(\mathbf{q})}\tau^{-\langle \mathbf{p},\mathbf{q}\rangle+\langle F'\mathbf{p},F'\mathbf{q}\rangle} = 1, \tag{27}$$

We consequently require

$$\omega^{\langle \mathbf{p},\mathbf{q}\rangle-\langle F'\mathbf{p},F'\mathbf{q}\rangle} = \tau^{2(\langle \mathbf{p},\mathbf{q}\rangle-\langle F'\mathbf{p},F'\mathbf{q}\rangle)} = 1 \tag{28}$$

for all $\mathbf{p},\mathbf{q}$. It is readily verified that $\langle F'\mathbf{p},F'\mathbf{q}\rangle = (\mathrm{Det}\, F')\langle \mathbf{p},\mathbf{q}\rangle$. We must therefore have

$$\mathrm{Det}\, F' = 1 (\mathrm{mod}\, d). \tag{29}$$

If d is odd, or if d is even and $\mathrm{Det}\, F' = 1 (\mathrm{mod}\, \overline{d})$, we can find a matrix $F \in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ such that $F = F' (\mathrm{mod}\, \overline{d})$. It then follows from Eq. (11) that $\hat{D}_{F\mathbf{p}} = \hat{D}_{F'\mathbf{p}}$ for all $\mathbf{p}$.

Suppose, on the other hand, d is even and $\mathrm{Det}\, F' \neq 1 (\mathrm{mod}\, \overline{d})$. Then $\mathrm{Det}\, F' = d+1 (\mathrm{mod}\, \overline{d})$. Write

$$F' = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}. \tag{30}$$

We know $\alpha\delta - \beta\gamma = \mathrm{Det}\, F'$ is odd. So either α, δ are both odd, or else β, γ are both odd. If α, δ are both odd let

$$\Delta = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \tag{31}$$

while if β, γ are both odd let

$$\Delta = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}. \tag{32}$$

Then $\mathrm{Det}(F' + \mathrm{d}\Delta) = 1 (\mathrm{mod}\, \overline{d})$. We can therefore choose a matrix $F \in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ such that $F = F' + \mathrm{d}\Delta (\mathrm{mod}\, \overline{d})$. Inserting this expression in Eq. (25) we have, in view of Eq. (11),

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = e^{ig'(\mathbf{p})}\hat{D}_{(F-\mathrm{d}\Delta)\mathbf{p}} = e^{ig'(\mathbf{p})}(-1)^{\langle F\mathbf{p},\Delta\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}}. \tag{33}$$

We conclude that there is, in every case, a function g'' and a matrix $F \in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ such that

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = e^{ig''(\mathbf{p})}\hat{D}_{F\mathbf{p}} \tag{34}$$

for all $\mathbf{p}$.

It remains to establish the form of the function g''. We note, first of all, that it follows from Eqs. (8) and (10) that

$$(\hat{D}_{\mathbf{p}})^d = \hat{D}_{\mathrm{d}\mathbf{p}} = \tau^{d^2 p_1 p_2}\hat{S}^{\mathrm{d}p_1}\hat{T}^{\mathrm{d}p_2} = 1 \tag{35}$$

for all $\mathbf{p}$ (because $\hat{S}^d = \hat{T}^d = \tau^{d^2} = 1$). Consequently,

$$1 = \hat{U}(\hat{D}_{\mathbf{p}})^d\hat{U}^\dagger = (\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^\dagger)^d = e^{i\,dg''(\mathbf{p})}(\hat{D}_{F\mathbf{p}})^d = e^{i\,dg''(\mathbf{p})} \tag{36}$$

for all $\mathbf{p}$. We must therefore have $e^{ig''(\mathbf{p})} = \omega^{\tilde{g}(\mathbf{p})}$ for some function $\tilde{g}$ taking values in $\mathbb{Z}_d$. Repeating the argument which led to Eq. (26) we find

$$\omega^{\tilde{g}(\mathbf{p}+\mathbf{q})-\tilde{g}(\mathbf{p})-\tilde{g}(\mathbf{q})}\tau^{\langle\mathbf{p},\mathbf{q}\rangle-\langle F\mathbf{p},F\mathbf{q}\rangle} = 1. \tag{37}$$

We have $\langle\mathbf{p},\mathbf{q}\rangle - \langle F\mathbf{p},F\mathbf{q}\rangle = (1-\mathrm{Det}\,F)\langle\mathbf{p},\mathbf{q}\rangle = 0 \pmod{\overline{d}}$. Consequently, $\tau^{\langle\mathbf{p},\mathbf{q}\rangle-\langle F\mathbf{p},F\mathbf{q}\rangle'} = 1$ (because $\tau^{\overline{d}} = 1$) and so

$$\tilde{g}(\mathbf{p}+\mathbf{q}) = \tilde{g}(\mathbf{p}) + \tilde{g}(\mathbf{q}) (\mathrm{mod}\, d) \tag{38}$$

for all $\mathbf{p},\mathbf{q}$. This implies $\tilde{g}(\mathbf{p}) = \langle\boldsymbol{\chi}',\mathbf{p}\rangle \pmod d$ for all $\mathbf{p}$ some fixed $\boldsymbol{\chi}' \in (\mathbb{Z}_d)^2$. Setting $\boldsymbol{\chi} = F\boldsymbol{\chi}'$, and using the fact that $\langle F^{-1}\boldsymbol{\chi},\mathbf{p}\rangle = \langle\boldsymbol{\chi},F\mathbf{p}\rangle \pmod d$ we conclude

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^\dagger = \omega^{\langle\boldsymbol{\chi},F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}} \tag{39}$$

for all $\mathbf{p}$. □

We now want to prove the converse of Lemma 1. That is, we want to prove that, for each pair $F \in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ and $\boldsymbol{\chi} \in (\mathbb{Z}_d)^2$ there is a corresponding operator $\hat{U} \in \mathrm{C}(d)$. We also want to derive an explicit expression for the operator $\hat{U}$ (this has, in effect, already been done by Hostens *et al.*;[29] however, the formulas we derive are different, and better adapted to the questions addressed in this paper).

We begin by focussing on a special class of matrices F. Let $[n_1,n_2,\ldots,n_r]$ denote the GCD (greatest common divisor) of the integers $n_1,n_2,\ldots,n_r$. We define the class of *prime matrices* to be the set of all matrices

$$F = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \tag{40}$$

$\in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$ such that $[\beta,\overline{d}] = 1$ (so that β has a multiplicative inverse in $\mathbb{Z}_{\overline{d}}$). We then have the following.

Lemma 2: Let

$$F = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \tag{41}$$

be a prime matrix $\in \mathrm{SL}(2,\mathbb{Z}_{\overline{d}})$. *Let*

$$\hat{V}_F = \frac{1}{\sqrt{d}}\sum_{r,s=0}^{d-1}\tau^{\beta^{-1}(\alpha s^2-2rs+\delta r^2)}|e_r\rangle\langle e_s| \tag{42}$$

[where $\beta^{-1} \in \mathbb{Z}_{\overline{d}}$ *is such that* $\beta^{-1}\beta = 1 \pmod{\overline{d}}$*]. Then* $\hat{V}_F$ *is a unitary operator* $\in \mathrm{C}(d)$ *such that*

$$\hat{V}_F\hat{D}_{\mathbf{p}}\hat{V}_F^\dagger = \hat{D}_{F\mathbf{p}} \tag{43}$$

for all $\mathbf{p}$.

Proof: Let

$$\hat{S}' = \hat{D}_{(\alpha,\gamma)} \quad \text{and } \hat{T}' = \hat{D}_{(\beta,\delta)}. \tag{44}$$

We proceed by constructing a complete set of eigenvectors for $\hat{T}'$. It turns out that $\hat{S}'$ is the shift operator for these eigenvectors. It is then straightforward to verify that $\hat{V}_F$ has the stated property.

Define

$$|f_0\rangle = \frac{1}{\sqrt{d}} \sum_{r=0}^{d-1} (\hat{T}')^r |e_0\rangle. \tag{45}$$

It follows from Eq. (35) that $(\hat{T}')^d = 1$. Consequently

$$\hat{T}'|f_0\rangle = |f_0\rangle. \tag{46}$$

It follows from Eq. (10) that $\hat{T}'\hat{S}' = \omega \hat{S}'\hat{T}'$. So we can obtain a complete set of eigenvectors by laddering. Specifically, let

$$|f_r\rangle = (\hat{S}')^r |f_0\rangle \tag{47}$$

for $r = 1, \ldots, d-1$. Then

$$\hat{T}'|f_r\rangle = \omega^r |f_r\rangle \tag{48}$$

for all r. Since $(\hat{S}')^d = 1$ [as follows from Eq. (35)] we also have

$$\hat{S}'|f_r\rangle = |f_{r \oplus_d 1}\rangle \tag{49}$$

for all r (where $\oplus_d$ signifies addition *modulo d*).

We next show that the vectors $|f_r\rangle$ are orthonormal. It follows from Eqs. (6)–(8) and (10) that

$$(\hat{T}')^r |e_0\rangle = \hat{D}_{(r\beta, r\delta)} |e_0\rangle = \tau^{\beta\delta r^2} \hat{S}^{\beta r} |e_0\rangle \tag{50}$$

and consequently

$$|f_0\rangle = \left(\frac{1}{\sqrt{d}} \sum_{r=0}^{d-1} \tau^{\beta\delta r^2} \hat{S}^{\beta r} \right) |e_0\rangle = \left(\frac{1}{\sqrt{d}} \sum_{r=0}^{d-1} \tau^{\beta^{-1}\delta(\beta r)^2} \hat{S}^{\beta r} \right) |e_0\rangle \tag{51}$$

(where we have used the fact that $\tau^{\overline{d}} = 1$). We need to be careful at this point, due to the fact that congruence *modulo d* need not imply congruence *modulo* $\overline{d}$. Let q_r be the quotient of βr on division by d, and let t_r be the remainder. So $\beta r = q_r d + t_r$ and

$$|f_0\rangle = \left(\frac{1}{\sqrt{d}} \sum_{r=0}^{d-1} \tau^{\beta^{-1}\delta(q_r d + t_r)^2} \hat{S}^{q_r d + t_r} \right) |e_0\rangle. \tag{52}$$

We have

$$\hat{S}^{q_r d + t_r} = \hat{S}^{t_r} \tag{53}$$

and

$$\tau^{\beta^{-1}\delta(q_r d + t_r)^2} = \tau^{\beta^{-1}\delta(t_r^2 + 2d q_r t_r + d^2 t_r^2)} = \tau^{\beta^{-1}\delta t_r^2} \tag{54}$$

(because $\tau^{2d} = \tau^{d^2} = 1$). Consequently

$$|f_0\rangle = \left(\frac{1}{\sqrt{d}} \sum_{r=0}^{d-1} \tau^{\beta^{-1}\delta t_r^2} \hat{S}^{t_r} \right) |e_0\rangle = \frac{1}{\sqrt{d}} \sum_{r=0}^{d-1} \tau^{\beta^{-1}\delta t_r^2} |e_{t_r}\rangle. \tag{55}$$

The fact that $[\beta, \overline{d}] = 1$ implies that $[\beta, d] = 1$. It follows that, as r runs over the integers $0, 1, \ldots, d-1$, so does t_r (though not necessarily in the same order). Consequently

$$|f_0\rangle = \frac{1}{\sqrt{d}} \sum_{t=0}^{d-1} \tau^{\beta^{-1}\delta t^2} |e_t\rangle. \tag{56}$$

It follows that

$$\langle f_r | f_r \rangle = \langle f_0 | (\hat{S}')^{-r} (\hat{S}')^r | f_0 \rangle = \langle f_0 | f_0 \rangle = 1. \tag{57}$$

The fact that $\langle f_r | f_s \rangle = 0$ when $r \neq s$ is an immediate consequence of the fact that $|f_r\rangle, |f_s\rangle$ are eigenvectors of $\hat{T}'$ corresponding to different eigenvalues. We conclude that

$$\langle f_r | f_s \rangle = \delta_{rs} \tag{58}$$

as claimed.

We now want to calculate an explicit formula for $|f_r\rangle$ when $r > 0$. It follows from previous results that

$$|f_r\rangle = \hat{D}_{r\alpha, r\gamma} |f_0\rangle = \frac{1}{\sqrt{d}} \sum_{t=0}^{d-1} \tau^{\beta^{-1}\delta t^2 + \alpha\gamma r^2 + 2\gamma r t} (\hat{S})^{r\alpha} |e_t\rangle. \tag{59}$$

By an argument similar to the one leading to Eq. (56) we deduce

$$|f_r\rangle = \frac{1}{\sqrt{d}} \sum_{t=0}^{d-1} \tau^{\beta^{-1}\delta(t-\alpha r)^2 + \alpha\gamma r^2 + 2\gamma r(t-\alpha r)} |e_t\rangle \tag{60}$$

$$= \frac{1}{\sqrt{d}} \sum_{t=0}^{d-1} \tau^{\beta^{-1}(\delta t^2 - 2rt + \alpha r^2)} |e_t\rangle \tag{61}$$

[since $\alpha\delta - \beta\gamma = 1 \pmod{\overline{d}}$]. Comparing with Eq. (42) we see that

$$\hat{V}_F = \sum_{r=0}^{d-1} |f_r\rangle\langle e_r| \tag{62}$$

which shows that $\hat{V}_F$ is unitary. Moreover,

$$\hat{V}_F \hat{T} \hat{V}_F^\dagger |f_r\rangle = \hat{V}_F \hat{T} |e_r\rangle = \omega^r |f_r\rangle \tag{63}$$

for all r. Comparing with Eq. (48) we deduce $\hat{V}_F \hat{T} \hat{V}_F^\dagger = \hat{T}'$. Similarly $\hat{V}_F \hat{S} \hat{V}_F^\dagger = \hat{S}'$. Hence

$$\hat{V}_F \hat{D}_{\mathbf{p}} \hat{V}_F^\dagger = \tau^{p_1 p_2} \hat{V}_F \hat{S}^{p_1} \hat{T}^{p_2} \hat{V}_F^\dagger \tag{64}$$

$$= \tau^{p_1 p_2} \hat{D}_{\alpha p_1, \gamma p_1} \hat{D}_{\beta p_2, \delta p_2} \tag{65}$$

$$= \tau^{(1-\beta\gamma+\alpha\delta) p_1 p_2} \hat{D}_{F\mathbf{p}} \tag{66}$$

$$= \hat{D}_{F\mathbf{p}} \tag{67}$$

for all $\mathbf{p}$. □

To extend this result to the case of an arbitary matrix $\in \mathrm{SL}(2, \mathbb{Z}_{\overline{d}})$ we need the following decomposition lemma, which states that every nonprime matrix can be written as the product of two prime matrices.

Lemma 3: Let

$$F = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \tag{68}$$

be a nonprime matrix $\in \mathrm{SL}(2, \mathbb{Z}_{\overline{d}})$. *Then there exists an integer x such that* $\delta + x\beta$ *is nonzero and* $[\delta + x\beta, \overline{d}] = 1$. *Let x be any integer having that property, and let*

$$F_1 = \begin{pmatrix} 0 & -1 \\ 1 & x \end{pmatrix}, \tag{69}$$

$$F_2 = \begin{pmatrix} \gamma + x\alpha & \delta + x\beta \\ -\alpha & -\beta \end{pmatrix}. \tag{70}$$

Then F_1, F_2 *are prime matrices* $\in \mathrm{SL}(2, \mathbb{Z}_{\overline{d}})$ *such that*

$$F = F_1 F_2. \tag{71}$$

Proof: Suppose, to begin with, that β, δ are both nonzero. Let $k = [\beta, \delta]$. We then have

$$\beta = k\beta_0, \tag{72}$$

$$\delta = k\delta_0, \tag{73}$$

where $[\beta_0, \delta_0] = 1$. We also have $[k, \overline{d}] = 1$ [because $\alpha\delta - \beta\gamma = 1 (\mathrm{mod}\, \overline{d})$]. The fact that β_0, δ_0 are relatively prime means we can use Dirichlet's theorem (see, for example, Nathanson[36] or Rose[37]) to deduce that the sequence

$$\delta_0,\ (\delta_0 + \beta_0),\ (\delta_0 + 2\beta_0),\ \ldots \tag{74}$$

contains infinitely many primes. Consequently, there exists an integer x such that $\delta_0 + x\beta_0 \neq 0$ and $[\delta_0 + x\beta_0, \overline{d}] = 1$. The fact that $k \neq 0$ and $[k, \overline{d}] = 1$ then implies that $\delta + x\beta \neq 0$ and $[\delta + x\beta, \overline{d}] = 1$. The claim is now immediate.

It remains to consider the case when β, δ are not both nonzero. If $\delta = 0$ the fact that $\det F = 1 (\mathrm{mod}\, \overline{d})$ would imply that $\beta \neq 0$ and $[\beta, \overline{d}] = 1$—contrary to the assumption that the matrix F is nonprime. Suppose, on the other hand, that $\beta = 0$. Then the fact that $\det F = 1 (\mathrm{mod}\, \overline{d})$ implies that $\delta \neq 0$ and $[\delta, \overline{d}] = 1$. So the claim is true for every choice of x. □

We can now deduce the following converse of Lemma 1.

Lemma 4: Let $(F, \boldsymbol{\chi})$ *be any pair* $\in \mathrm{SL}(2, \mathbb{Z}_{\overline{d}}) \times (\mathbb{Z}_d)^2$. *If F is a prime matrix define*

$$\hat{U} = \hat{D}_{\boldsymbol{\chi}} \hat{V}_F \tag{75}$$

[where $\hat{V}_F$ *is the operator defined by Eq. (42)]. If F is nonprime choose two prime matrices* F_1, F_2 *such that* $F = F_1 F_2$ *(the existence of such matrices being guaranteed by Lemma 3), and define*

$$\hat{U} = \hat{D}_{\boldsymbol{\chi}} \hat{V}_{F_1} \hat{V}_{F_2} \tag{76}$$

[where $\hat{V}_{F_1}, \hat{V}_{F_2}$ *are the operators defined by Eq. (42)]. Then*

$$\hat{U} \hat{D}_{\mathbf{p}} \hat{U}^\dagger = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p} \rangle} \hat{D}_{F\mathbf{p}} \tag{77}$$

for all $\mathbf{p} \in \mathbb{Z}^2$.

Proof: The claim is an immediate consequence of Eqs. (9) and (10) and Lemma 2. □

If $\hat{U}, \hat{U}'$ differ by a phase, so that $\hat{U}' = e^{i\theta} \hat{U}$, they have the same action on the generalized Pauli group,

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \hat{U}'\hat{D}_{\mathbf{p}}\hat{U}'^{\dagger} \tag{78}$$

for all $\mathbf{p}$. So the object of real interest is not the Clifford group itself, but the group $\mathrm{C}(d)/\mathrm{I}(d)$ which results when the phases are factored out. Here $\mathrm{I}(d)$ is the subgroup consisting of all operators of the form $e^{i\theta}\hat{I}$, where $\hat{I}$ is the identity operator and $\theta \in \mathbb{R}$. The elements of $\mathrm{C}(d)/\mathrm{I}(d)$ are often called *Clifford operations.*

Let $\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2$ be the canonical semidirect product of $\mathrm{SL}(2,\mathbb{Z}_d)$ and $(\mathbb{Z}_d)^2$, i.e., the group which results when the set $\mathrm{SL}(2,\mathbb{Z}_d) \times (\mathbb{Z}_d)^2$ is equipped with the composition rule

$$(F_1, \boldsymbol{\chi}_1) \circ (F_2, \boldsymbol{\chi}_2) = (F_1 F_2, \boldsymbol{\chi}_1 + F_1 \boldsymbol{\chi}_2). \tag{79}$$

Then we have the following structure theorem, which states that $\mathrm{C}(d)/\mathrm{I}(d)$ is naturally isomorphic to $\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2$ when d is odd, and naturally isomorphic to a quotient group of $\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2$ when d is even.

Theorem 1: *There exists a unique surjective homomorphism,*

$$f{:}\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2 \to \mathrm{C}(d)/\mathrm{I}(d) \tag{80}$$

with the property $\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}}$ *for each* $\hat{U} \in f(F, \boldsymbol{\chi})$ *and all* $\mathbf{p} \in \mathbb{Z}^2$.

If d is odd f is an isomorphism. If d is even the kernel of f is the subgroup $K_f \subseteq \mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2$ *consisting of the* 8 *elements of the form*

$$\left(\begin{pmatrix} 1+rd & sd \\ td & 1+rd \end{pmatrix}, \begin{pmatrix} sd/2 \\ td/2 \end{pmatrix} \right), \tag{81}$$

where $r, s, t = 0$ *or* 1.

Proof: An operator $\hat{U} \in \mathrm{C}(d)$ has the property

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \hat{D}_{\mathbf{p}} \tag{82}$$

for all $\mathbf{p}$ if and only if it is a multiple of the identity (due to the irreducibility of the projective representation $\mathbf{p} \to \hat{D}_{\mathbf{p}}$, and Schur's lemma). So it follows from results already proved that there is exactly one surjective map,

$$f{:}\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2 \to \mathrm{C}(d)/\mathrm{I}(d) \tag{83}$$

such that $\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}}$ for each $\hat{U} \in f(F, \boldsymbol{\chi})$ and all $\mathbf{p} \in \mathbb{Z}^2$. The fact that f is actually a homomorphism is then an immediate consequence of the definitions.

Let K_f be the kernel of f. Then $(F, \boldsymbol{\chi}) \in K_f$ if and only if

$$\omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}} = \hat{D}_{\mathbf{p}} \tag{84}$$

for all $\mathbf{p}$. For that to be true we must have $F = 1 (\mathrm{mod}\, d)$. If d is odd this implies $\hat{D}_{F\mathbf{p}} = \hat{D}_{\mathbf{p}}$ for all $\mathbf{p}$. Equation (84) then becomes $\omega^{\langle \boldsymbol{\chi}, \mathbf{p}\rangle} = 1$ for all $\mathbf{p}$, implying $\boldsymbol{\chi} = (0\ 0)$. So the kernel is trivial, and f is an isomorphism as claimed.

Suppose, on the other hand, that d is even. The condition $F = 1 (\mathrm{mod}\, d)$ then implies that $F = 1 + \mathrm{d}\Delta$, where Δ is a matrix of the form

$$\Delta = \begin{pmatrix} r_1 & s \\ t & r_2 \end{pmatrix} \tag{85}$$

with $r_1, r_2, s, t = 0$ or 1. Inserting this expression in Eq. (84) we find, in view of Eqs. (9)–(11), that $(F, \boldsymbol{\chi}) \in K_f$ if and only if

$$1 = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}}\hat{D}_{-\mathbf{p}} = \omega^{\langle \boldsymbol{\chi},\mathbf{p}\rangle}\tau^{d\langle \mathbf{p},\Delta\mathbf{p}\rangle} \tag{86}$$

for all $\mathbf{p}$. After rearranging the condition

$$\omega^{\chi_2 p_1 - \chi_1 p_2} = (-1)^{(r_1-r_2)p_1p_2 - tp_1^2 + sp_2^2} = (-1)^{(r_1-r_2)p_1p_2 + tp_1 - sp_2} \tag{87}$$

for all $\mathbf{p}$. This is true if and only if $r_1 = r_2$, $\chi_1 = sd/2$, and $\chi_2 = td/2$. □

We conclude with a result concerning the order of the group $\mathrm{C}(d)/\mathrm{I}(d)$ which will be needed later on. Let $\nu(n,d)$ be the number of distinct ordered pairs $(x,y) \in (\mathbb{Z}_d)^2$ such that $xy = n \pmod d$. We then have the following.

Lemma 5: The order of the group $\mathrm{C}(d)/\mathrm{I}(d)$ *is*

$$|\mathrm{C}(d)/\mathrm{I}(d)| = d^2\left(\sum_{n=0}^{d-1} \nu(n,d)\,\nu(n+1,d)\right). \tag{88}$$

If d is a prime number this reduces to

$$|\mathrm{C}(d)/\mathrm{I}(d)| = d^3(d^2-1). \tag{89}$$

Proof: We begin by showing that $\mathrm{C}(d)/\mathrm{I}(d)$ and $\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2$ have the same cardinality when considered as *sets*. This is true for all d, notwithstanding the fact that when d is even $\mathrm{C}(d)/\mathrm{I}(d)$ and $\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2$ are not naturally isomorphic as *groups*.

The statement is immediate when d is odd. Suppose, on the other hand, that d is even. Let $g:\mathrm{SL}(2,\mathbb{Z}_{2d}) \to \mathrm{SL}(2,\mathbb{Z}_d)$ be the natural homomorphism defined by

$$g:\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \mapsto \begin{pmatrix} [\alpha]_d & [\beta]_d \\ [\gamma]_d & [\delta]_d \end{pmatrix}, \tag{90}$$

where $[x]_d$ denotes the residue class of x *modulo* d. It is easily seen that d is surjective. In fact, consider arbitrary

$$F = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \mathrm{SL}(2,\mathbb{Z}_d). \tag{91}$$

Then $\alpha\delta - \beta\gamma = 1 + nd$ for some integer n. If n is even then $F \in \mathrm{SL}(2,\mathbb{Z}_{\bar{d}})$ and $F = g(F)$. Suppose, on the other hand, that n is odd. Then either α or β is odd. If α is odd $F = g(F')$ where

$$F' = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta + d \end{pmatrix} \in \mathrm{SL}(2,\mathbb{Z}_{\bar{d}}) \tag{92}$$

while if β is odd $F = g(F'')$ where

$$F'' = \begin{pmatrix} \alpha & \beta \\ \gamma + d & \delta \end{pmatrix} \in \mathrm{SL}(2,\mathbb{Z}_{\bar{d}}). \tag{93}$$

Now let K_g be the kernel of g. A matrix $F \in K_g$ if and only if

$$F = \begin{pmatrix} 1 + r_1 d & sd \\ td & 1 + r_2 d \end{pmatrix}, \tag{94}$$

where $r_1, r_2, s, t = 0$ or 1 and $(1+r_1d)(1+r_2d) - std^2 = 1 \pmod{2d}$. We have

$$(1 + r_1 d)(1 + r_2 d) - std^2 = 1 + (r_1 + r_2)d \pmod{2d} \tag{95}$$

[bearing in mind that d is even, so $d^2 = 0 \pmod{2d}$]. We therefore require $r_1 = r_2$. It follows that K_g consists of the eight matrices of the form

$$\begin{pmatrix} 1+rd & sd \\ td & 1+rd \end{pmatrix}, \tag{96}$$

where $r,s,t=0$ or 1. The fact that g is surjective and $|K_g|=8$ implies $|\mathrm{SL}(2,\mathbb{Z}_{2d})|=8|\mathrm{SL}(2,\mathbb{Z}_d)|$. In view of Theorem 1 this means

$$|\mathrm{C}(d)/\mathrm{I}(d)| = \tfrac{1}{8}|\mathrm{SL}(2,\mathbb{Z}_{2d})||(\mathbb{Z}_d)^2| = |\mathrm{SL}(2,\mathbb{Z}_d)||(\mathbb{Z}_d)^2| = |\mathrm{SL}(2,\mathbb{Z}_d) \ltimes (\mathbb{Z}_d)^2| \tag{97}$$

as claimed.

We have shown that $|\mathrm{C}(d)/\mathrm{I}(d)|=|\mathrm{SL}(2,\mathbb{Z}_d)\ltimes(\mathbb{Z}_d)^2|=d^2|\mathrm{SL}(2,\mathbb{Z}_d)|$ for all d, odd or even. It remains to calculate $|\mathrm{SL}(2,\mathbb{Z}_d)|$. For each $n\in\mathbb{Z}_d$ let $M_n\subseteq\mathrm{SL}(2,\mathbb{Z}_d)$ be the set of matrices

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \tag{98}$$

for which $\alpha\delta=n+1(\mathrm{mod}\,d)$ and $\beta\gamma=n(\mathrm{mod}\,d)$. The sets M_n are disjoint. Moreover, $\mathrm{SL}(2,\mathbb{Z}_d)=\cup_{n=0}^{d-1}M_n$ and $|M_n|=\nu(n,d)\nu(n+1,d)$. It follows that

$$|\mathrm{SL}(2,\mathbb{Z}_d)| = \sum_{n=0}^{d-1} \nu(n,d)\nu(n+1,d). \tag{99}$$

Equation (88) is now immediate.

If d is a prime number

$$\nu(n,d) = \begin{cases} 2d-1 & \text{if } n=0 \ (\mathrm{mod}\,d), \\ d-1 & \text{otherwise} \end{cases} \tag{100}$$

implying

$$\sum_{n=0}^{d-1} \nu(n,d)\nu(n+1,d) = d(d^2-1). \tag{101}$$

Equation (89) is now immediate. □

IV. THE EXTENDED CLIFFORD GROUP

It can be seen from Eqs. (6)–(8) and (13) that, if $|\psi\rangle=\Sigma_{r=0}^{d-1}\psi_r|e_r\rangle$ is a GP fiducial vector, then so is the vector $|\psi^*\rangle=\Sigma_{r=0}^{d-1}\psi_r^*|e_r\rangle$ obtained by complex conjugation. So to make the analysis complete we need to consider automorphisms of GP(d) which are generated by antiunitary operators.

An antilinear operator is a map $\hat{L}:\mathbb{C}^d\to\mathbb{C}^d$ with the property

$$\hat{L}(\alpha|\phi\rangle+\beta|\psi\rangle) = \alpha^*\hat{L}|\phi\rangle + \beta^*\hat{L}|\psi\rangle \tag{102}$$

for all $|\phi\rangle,|\psi\rangle\in\mathbb{C}^d$ and all $\alpha,\beta\in\mathbb{C}$. The adjoint $\hat{L}^\dagger$ is defined to be the unique antilinear operator with the property

$$\langle\phi|\hat{L}^\dagger|\psi\rangle = \langle\psi|\hat{L}|\phi\rangle \tag{103}$$

for all $|\phi\rangle,|\psi\rangle\in\mathbb{C}^d$. [The existence and uniqueness of $\hat{L}^\dagger$ can be established by a variant of the argument which establishes the existence and uniqueness of the adjoint of a linear operator (see, for example, Greub[38]). Alternatively, one can exploit the operator $\hat{J}$ defined in Eq. (106). If $\hat{L}$ is antilinear then $\hat{L}\hat{J}$ is linear. So there exists a unique operator $(\hat{L}\hat{J})^\dagger$ with the property $\langle\phi|(\hat{L}\hat{J})^\dagger|\psi\rangle=(\langle\psi|(\hat{L}\hat{J})|\phi\rangle)^*$ for all $|\phi\rangle,|\psi\rangle$. It follows from the definition of $\hat{J}$ that $\langle\phi|\hat{J}|\psi\rangle=\langle\psi|\hat{J}|\phi\rangle$ for all $|\phi\rangle,|\psi\rangle$. It is now straightforward to confirm that, if one defines $\hat{L}^\dagger=\hat{J}(\hat{L}\hat{J})^\dagger$, then $\hat{L}^\dagger$ satisfies Eq. (103) for all $|\phi\rangle,|\psi\rangle$, and, furthermore, that there is no other operator with that

property.] An operator $\hat{U}$ is said to be antiunitary if it is antilinear and $\hat{U}^\dagger\hat{U}=1$ (or, equivalently, $\hat{U}\hat{U}^\dagger=1$).

We now define the *extended Clifford Group* to be the group $\mathrm{EC}(d)$ consisting of all unitary or antiunitary operators $\hat{U}$ having the property

$$\hat{U}\,\mathrm{GP}(d)\hat{U}^\dagger=\mathrm{GP}(d). \tag{104}$$

Let us also define $\mathrm{ESL}(2,\mathbb{Z}_{\bar{d}})$ to be the group consisting of all 2×2 matrices

$$\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} \tag{105}$$

such that $\alpha,\beta,\gamma,\delta\in\mathbb{Z}_{\bar{d}}$ and $\alpha\delta-\beta\gamma=\pm 1(\mathrm{mod}\,\bar{d})$. In the last section we showed that there is a natural homomorphism $f:\mathrm{SL}(2,\mathbb{Z}_{\bar{d}})\ltimes(\mathbb{Z}_d)^2\to\mathrm{C}(d)/\mathrm{I}(d)$. We are going to show that this extends to a natural homomorphism $f_E:\mathrm{ESL}(2,\mathbb{Z}_{\bar{d}})\ltimes(\mathbb{Z}_d)^2\to\mathrm{EC}(d)/\mathrm{I}(d)$.

Let $\hat{J}$ be the antilinear operator which replaces components in the standard basis with their complex conjugates,

$$\hat{J}:\sum_{r=0}^{d-1}\psi_r|e_r\rangle\mapsto\sum_{r=0}^{d-1}\psi_r^*|e_r\rangle. \tag{106}$$

Clearly $\hat{J}^\dagger=\hat{J}$ and $\hat{J}^\dagger\hat{J}=\hat{J}^2=1$. So $\hat{J}$ is an antiunitary operator. Furthermore, it follows from Eqs. (6)–(8) that

$$\hat{J}\hat{D}_{\mathbf{p}}\hat{J}^\dagger=\hat{D}_{\tilde{J}\mathbf{p}} \tag{107}$$

for all $\mathbf{p}$, where

$$\tilde{J}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{108}$$

So $\hat{J}\in\mathrm{EC}(d)$. Note that $\mathrm{Det}\,\tilde{J}=-1(\mathrm{mod}\,\bar{d})$, so $\tilde{J}\in\mathrm{ESL}(2,\mathbb{Z}_{\bar{d}})$.

Now let $\mathrm{C}^*(d)$ be the set of antiunitary operators $\in\mathrm{EC}(d)$ [so $\mathrm{EC}(d)$ is the disjoint union $\mathrm{EC}(d)=\mathrm{C}(d)\cup\mathrm{C}^*(d)$]. The mapping $\hat{U}\mapsto\hat{J}\hat{U}$ defines a bijective correspondence between $\mathrm{C}^*(d)$ and $\mathrm{C}(d)$. We can use this to prove the following extension of Theorem 1.

Theorem 2: *There is a unique surjective homomorphism,*

$$f_E:\mathrm{ESL}(2,\mathbb{Z}_{\bar{d}})\ltimes(\mathbb{Z}_d)^2\to\mathrm{EC}(d)/\mathrm{I}(d) \tag{109}$$

such that, for each $(F,\boldsymbol{\chi})\in\mathrm{ESL}(2,\mathbb{Z}_{\bar{d}})\ltimes(\mathbb{Z}_d)^2$ *and* $\hat{U}\in f_E(F,\boldsymbol{\chi})$,

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^\dagger=\omega^{\langle\boldsymbol{\chi},F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}} \tag{110}$$

for all $\mathbf{p}$. $\hat{U}$ *is unitary if* $\mathrm{Det}\,F=1(\mathit{mod}\,\bar{d})$ *and antiunitary if* $\mathrm{Det}\,F=-1(\mathit{mod}\,\bar{d})$. f_E *extends the homomorphism* f *defined in Theorem 1, and has the same kernel. So* f_E *is an isomorphism if* d *is odd, while if* d *is even its kernel is the subgroup* K_f *defined in Theorem 1.*

Proof: Let $\hat{U}$ be an arbitrary antiunitary operator $\in\mathrm{C}^*(d)$. The fact that $\hat{J},\hat{U}$ are both antiunitary means that $\hat{J}\hat{U}$ is unitary. So $\hat{J}\hat{U}\in\mathrm{C}(d)$. It then follows from Theorem 1 that there exists $(F',\boldsymbol{\chi}')\in\mathrm{SL}(2,\mathbb{Z}_{\bar{d}})\ltimes(\mathbb{Z}_d)^2$ such that

$$(\hat{J}\hat{U})\hat{D}_{\mathbf{p}}(\hat{J}\hat{U})^\dagger=\omega^{\langle\boldsymbol{\chi}',F'\mathbf{p}\rangle}\hat{D}_{F'\mathbf{p}} \tag{111}$$

for all $\mathbf{p}$. Define $F=\tilde{J}F'$ and $\boldsymbol{\chi}=\tilde{J}\boldsymbol{\chi}'$. In view of Eq. (107), and the fact that $\hat{J}^2=1$, we deduce

$$\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \hat{J}(\hat{J}\hat{U})\hat{D}_{\mathbf{p}}(\hat{J}\hat{U})^{\dagger}\hat{J}^{\dagger} = \omega^{-\langle \boldsymbol{\chi}', F'\mathbf{p}\rangle}\hat{D}_{\tilde{J}F'\mathbf{p}} = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}} \tag{112}$$

for all $\mathbf{p}$ (where we have used the fact that $\langle \boldsymbol{\xi}, \boldsymbol{\eta}\rangle = -\langle \tilde{J}\boldsymbol{\xi}, \tilde{J}\boldsymbol{\eta}\rangle$ for all $\boldsymbol{\xi}, \boldsymbol{\eta}$). We have $\mathrm{Det}(F) = (\mathrm{Det}\, J)(\mathrm{Det}\, F') = -1$, so $(F, \boldsymbol{\chi}) \in \mathrm{ESL}(2, \mathbb{Z}_{\bar{d}}) \ltimes (\mathbb{Z}_d)^2$.

Reversing the argument we deduce the converse proposition, for each $(F, \boldsymbol{\chi}) \in \mathrm{ESL}(2, \mathbb{Z}_{\bar{d}}) \ltimes (\mathbb{Z}_d)^2$, there exists $\hat{U} \in \mathrm{EC}(d)$ such that $\hat{U}\hat{D}_{\mathbf{p}}\hat{U}^{\dagger} = \omega^{\langle \boldsymbol{\chi}, F\mathbf{p}\rangle}\hat{D}_{F\mathbf{p}}$ for all $\mathbf{p}$. The fact that an operator commutes with $\hat{D}_{\mathbf{p}}$ for all $\mathbf{p}$ if and only if it is a multiple of the identity means that $\hat{U}$ is unique up to a phase.

This establishes the existence and uniqueness of the homomorphism f_E. The proof of the remaining statements is straightforward, and is left to the reader. □

Finally, we have the following result which, together with Lemma 5, enables us to calculate the order of $\mathrm{EC}(d)/\mathrm{I}(d)$.

Lemma 6:

$$\left|\mathrm{EC}(d)/\mathrm{I}(d)\right| = 2\left|\mathrm{C}(d)/\mathrm{I}(d)\right| \tag{113}$$

for all d.

Proof: The map

$$\hat{U}\mathrm{I}(d) \mapsto \hat{J}\hat{U}\mathrm{I}(d) \tag{114}$$

defines a bijective correspondence between $\mathrm{C}^*(d)/\mathrm{I}(d)$ and $\mathrm{C}(d)/\mathrm{I}(d)$. So the set $\mathrm{C}^*(d)/\mathrm{I}(d)$ contains the same number of elements as $\mathrm{C}(d)/\mathrm{I}(d)$. The statement is now immediate. □

V. THE CLIFFORD TRACE

We now define the Clifford trace. The significance of this function for us is that every GP fiducial vector which has been constructed to date is an eigenvector of a Clifford unitary having Clifford trace $=-1$.

Let $[F, \boldsymbol{\chi}] \in \mathrm{EC}(d)/\mathrm{I}(d)$ be the image of $(F, \boldsymbol{\chi})$ under the homomorphism f_E defined in Theorem 2. We refer to $[F, \boldsymbol{\chi}]$ as an extended Clifford operation [or Clifford operation if it $\in \mathrm{C}(d)/\mathrm{I}(d)$]. The operators $\in [F, \boldsymbol{\chi}]$ only differ by a phase. It is therefore convenient to adopt a terminology which blurs the distinction between the operation $[F, \boldsymbol{\chi}]$ and the operators $\hat{U} \in [F, \boldsymbol{\chi}]$. In particular, we will adopt the convention that properties which hold for each $\hat{U} \in [F, \boldsymbol{\chi}]$ may also be attributed to $[F, \boldsymbol{\chi}]$. Thus, we will say that $[F, \boldsymbol{\chi}]$ is unitary (respectively antiunitary) if the operators $\hat{U} \in [F, \boldsymbol{\chi}]$ are unitary (respectively, antiunitary). Similarly, we will say that $|\psi\rangle \in \mathbb{C}^d$ is an eigenvector of $[F, \boldsymbol{\chi}]$ if it is an eigenvector of the operators $\hat{U} \in [F, \boldsymbol{\chi}]$.

It is easily verified that $\mathrm{Tr}(F_1) = \mathrm{Tr}(F_2) \pmod{d}$ whenever $[F_1, \boldsymbol{\chi}_1] = [F_2, \boldsymbol{\chi}_2]$ [note that it is not necessarily true that $\mathrm{Tr}(F_1) = \mathrm{Tr}(F_2) \pmod{\bar{d}}$ if d is even]. We therefore obtain a well-defined function $\mathrm{EC}(d)/\mathrm{I}(d) \to \mathbb{Z}_d$ if we assign to each operation $[F, \boldsymbol{\chi}]$ the value $\mathrm{Tr}(F) \pmod{d}$. We obtain a function $\mathrm{EC}(d) \to \mathbb{Z}_d$ by assigning to each $\hat{U} \in [F, \boldsymbol{\chi}]$ the value $\mathrm{Tr}(F) \pmod{d}$. We use the term "Clifford trace" to refer to either of these functions. (The Clifford trace is a modular character in the case when d is prime. For the theory of modular representations see, for example, Serre.[39])

We now prove the main result of this section, which states that there is a connection between the order of a Clifford operation and its Clifford trace.

Lemma 7: Let $[F, \boldsymbol{\chi}] \in \mathrm{C}(d)/\mathrm{I}(d)$, *where d is any* dimension $\neq 3$. *Then* $[F, \boldsymbol{\chi}]$ *is of order* 3 *if* $\mathrm{Tr}(F) = -1 \ (mod\ d)$.

Let $[F, \boldsymbol{\chi}] \in \mathrm{C}(d)/\mathrm{I}(d)$, *where d is any* prime dimension $\neq 3$. *Then the stronger statement is true,* $[F, \boldsymbol{\chi}]$ *is of order* 3 *if and only if* $\mathrm{Tr}(F) = -1 \ (mod\ d)$.

Remark: The restriction to operations $\in \mathrm{C}(d)/\mathrm{I}(d)$ is essential (because if $[F, \boldsymbol{\chi}]$ is antiunitary its order must be even).

Proof: Let $[F, \boldsymbol{\chi}] \in \mathrm{C}(d)/\mathrm{I}(d)$, and let $\kappa = \mathrm{Tr}(F)$. Then, taking into account the fact that $\mathrm{Det}(F) = 1 \pmod{\bar{d}}$, it is straightforward to show

$$F^2 = \kappa F - 1 \pmod{\overline{d}} \tag{115}$$

implying

$$F^3 = (\kappa^2 - 1)F - \kappa \pmod{\overline{d}}, \tag{116}$$

$$1 + F + F^2 = (\kappa + 1)F \pmod{\overline{d}}. \tag{117}$$

Now suppose that $\kappa = -1 \pmod{d}$. Then there are three possibilities, (a) d is odd; (b) d is even and $\kappa = -1 \pmod{\overline{d}}$; (c) d is even and $\kappa = -1 + d \pmod{\overline{d}}$. In case (a) or (b) we have

$$F^3 = 1 \pmod{\overline{d}}, \tag{118}$$

$$1 + F + F^2 = 0 \pmod{\overline{d}}, \tag{119}$$

while in case (c) we have $\kappa^2 - 1 = d^2 - 2d = 0 \pmod{\overline{d}}$, and consequently

$$F^3 = \begin{pmatrix} 1+d & 0 \\ 0 & 1+d \end{pmatrix} \pmod{\overline{d}}, \tag{120}$$

$$1 + F + F^2 = 0 \pmod{d}. \tag{121}$$

Referring to the definition of K_f (see Theorem 1) we deduce that, in every case,

$$(F, \boldsymbol{\chi})^3 = (F^3, (1 + F + F^2)\boldsymbol{\chi}) \in K_f \tag{122}$$

implying that $[F, \boldsymbol{\chi}]^3 = [1, \mathbf{0}]$. It remains to show that neither $[F, \boldsymbol{\chi}]$ nor $[F, \boldsymbol{\chi}]^2 = [1, \mathbf{0}]$. To see that $[F, \boldsymbol{\chi}] \neq [1, \mathbf{0}]$ observe that the contrary would imply $-1 = \kappa = \mathrm{Tr}(1) = 2 \pmod{d}$, which is not possible given that $d \neq 3$. Similarly, if $[F, \boldsymbol{\chi}]^2 = [1, \mathbf{0}]$ it would follow [taking the trace on both sides of Eq. (115)] that $2 = \kappa^2 - 2 = -1 \pmod{d}$, contrary to the assumption that $d \neq 3$. We conclude that $[F, \boldsymbol{\chi}]$ is of order 3, as claimed.

To prove the second part of the lemma suppose that d is a prime number $\neq 3$ and $[F, \boldsymbol{\chi}]$ is of order 3. Then $(F^3, (1 + F + F^2)\boldsymbol{\chi}) \in K_f$, implying $F^3 = 1 \pmod{d}$. In view of Eq. (116) this means

$$(\kappa + 1)((\kappa - 1)F - 1) = 0 \pmod{d}. \tag{123}$$

We now proceed by *reductio ad absurdum*. Suppose that $\kappa \neq -1 \pmod{d}$. Then Eq. (123) and the fact that d is prime implies

$$(\kappa - 1)F = 1 \pmod{d}. \tag{124}$$

Taking the trace on both sides gives $(\kappa + 1)(\kappa - 2) = 0 \pmod{d}$ implying $\kappa = 2 \pmod{d}$. Substituting this value into Eq. (124) we deduce $F = 1 \pmod{d}$, implying $F^2 = 1 \pmod{\overline{d}}$ and $F^3 = F \pmod{\overline{d}}$. So

$$(F, 3\boldsymbol{\chi}) = (F, \boldsymbol{\chi})^3 \in K_f \tag{125}$$

implying $(F, \boldsymbol{\chi}) \in K_f$. But that would mean $[F, \boldsymbol{\chi}]$ is of order 1, contrary to assumption. We conclude that $\kappa = -1 \pmod{d}$, as claimed. □

The result does not hold when $d = 3$ because then the identity has Clifford trace $= -1$. It is, however, easily verified that in dimension 3 (as in every other prime dimension) every order 3 Clifford operation has Clifford trace $= -1$.

If d is not a prime number there may exist order 3 Clifford operations for which the Clifford trace $\neq -1$. Consider, for example,

$$[F,\boldsymbol{\chi}]=\left[\begin{pmatrix}5 & 4\\ 2 & -3\end{pmatrix},\begin{pmatrix}-4\\ 5\end{pmatrix}\right]\in \mathrm{C}(6)/\mathrm{I}(6). \tag{126}$$

Then $[F,\boldsymbol{\chi}]$ is of order 3 yet $\mathrm{Tr}(F)=2 \pmod 6$.

Because these results will play an important role in the following it is convenient to introduce some terminology. We will say that an operation $[F,\boldsymbol{\chi}]\in \mathrm{C}(d)/\mathrm{I}(d)$ is a *canonical* order 3 unitary if

(a) $\mathrm{Tr}(F)=-1 \pmod d$,
(b) F is not the identity matrix.

Note that the second stipulation is only needed because of the possibility that $d=3$. If $d\neq 3$ an operation $[F,\boldsymbol{\chi}]\in \mathrm{C}(d)/\mathrm{I}(d)$ is a canonical order 3 unitary if and only if $\mathrm{Tr}(F)=-1 \pmod d$.

VI. THE RBSC VECTORS

For $5\leqslant d\leqslant 45$ RBSC[17,24] have constructed GP fiducial vectors numerically. In this section we examine the behavior of these vectors under the action of the extended Clifford group. In particular we show that each of them is an eigenvector of a canonical order 3 Clifford unitary. This suggests the following.

Conjecture A: GP fiducial vectors exist in every finite dimension. Furthermore, every such vector is an eigenvector of a canonical order 3 unitary.

Conjecture A is related to a conjecture of Zauner's. Let

$$[Z,\mathbf{0}]=\left[\begin{pmatrix}0 & -1\\ 1 & -1\end{pmatrix},\begin{pmatrix}0\\ 0\end{pmatrix}\right]. \tag{127}$$

It will be observed that $[Z,\mathbf{0}]$ is defined, and $\in \mathrm{C}(d)/\mathrm{I}(d)$, for every dimension d, and that it is canonical order 3. Zauner[16] has conjectured the following.

Conjecture B: In each dimension d there exists a GP fiducial vector which is an eigenvector of $[Z,\mathbf{0}]$.

In Sec. VII we will see that RBSC's numerical data also provides further support for Conjecture B.

Let $|\psi_d\rangle$ be the RBSC vector in dimension d. In Table I we list, for each value of d, a unitary Clifford operation $[F_d,\boldsymbol{\chi}_d]$ having $|\psi_d\rangle$ as one of its eigenvectors (to the precision that RBSC's numerical data permits). It will be seen that, in every case, $\mathrm{Tr}(F_d)=-1 \pmod d$, implying that $[F_d,\boldsymbol{\chi}_d]$ is canonical order 3. Clearly, $|\psi_d\rangle$ is also an eigenvector of $[F_d,\boldsymbol{\chi}_d]^2$. Moreover, $[F_d,\boldsymbol{\chi}_d]^2$ also has Clifford trace$=-1$. $[F_d,\boldsymbol{\chi}_d]$ and $[F_d,\boldsymbol{\chi}_d]^2$ are, however, the only trace -1 unitary Clifford operations of which $|\psi_d\rangle$ is an eigenvector (to the stated degree of precision).

In Table I we also list (n_{d1},n_{d2},n_{d3}), the dimensions of the three eigenspaces of $[F_d,\boldsymbol{\chi}_d]$, and n_d, the dimension of the particular eigenspace to which $|\psi_d\rangle$ belongs. It will be seen that, with one exception, $|\psi_d\rangle$ always belongs to an eigenspace of highest dimension (the exception being $d=17$, where $|\psi_d\rangle$ belongs to the eigenspace of *lowest* dimension).

We used a computer algebra package (*Mathematica*) to construct the table. To illustrate the method employed we give a detailed description for the case $d=5$. We begin with the observation that, if $|\psi_5\rangle$ is an eigenvector of $[F,\boldsymbol{\chi}]$, then

$$\langle\psi_5|\hat{D}_{\mathbf{p}}|\psi_5\rangle=e^{(2\pi i/5)\langle\boldsymbol{\chi},F\mathbf{p}\rangle}\langle\psi_5|\hat{D}_{F\mathbf{p}}|\psi_5\rangle \tag{128}$$

for all $\mathbf{p}$. So, using the value of $|\psi_5\rangle$ which is available on RBSC's website,[24] we look for values of $\mathbf{p},\mathbf{q}$ such that

TABLE I. For each d the RBSC vector $|\psi_d\rangle$ is an eigenvector of the unitary operation $[F_d, \boldsymbol{\chi}_d]$. Note that in every case $\mathrm{Tr}\, F_d = -1$, implying that $[F_d, \boldsymbol{\chi}_d]$ is canonical order 3. (n_{d1}, n_{d2}, n_{d3}) are the dimensions of the three eigenspaces of $[F_d, \boldsymbol{\chi}_d]$, and n_d is the dimension of the eigenspace to which $|\psi_d\rangle$ belongs. Note that $n_d = \max(n_{d1}, n_{d2}, n_{d3})$, with the single exception of $d=17$.

$$\frac{5}{2\pi}(\arg(\langle\psi_5|\hat{D}_{\mathbf{p}}|\psi_5\rangle) - \arg(\langle\psi_5|\hat{D}_{\mathbf{q}}|\psi_5\rangle)) \tag{129}$$

is an (approximate) integer. We find that if $\mathbf{p}=(1,0)$ this is only true when $\mathbf{q}=(1,0)$, $(-1,1)$ or $(0,-1)$ (mod 5), and that if $\mathbf{p}=(0,1)$ it is only true when $\mathbf{q}=(0,1)$, $(-1,0)$ or $(1,-1)$ (mod 5). Taking account of the requirement $\mathrm{Det}(F)=1$ (mod 5) we deduce that the only candidates are (apart from the identity)

$$[F_5,\boldsymbol{\chi}_5] = \left[\begin{pmatrix}-1 & -1\\ 1 & 0\end{pmatrix},\begin{pmatrix}2\\ 2\end{pmatrix}\right] \tag{130}$$

and its square, $[F_5,\boldsymbol{\chi}_5]^2$. To check that $|\psi_5\rangle$ actually is an eigenvector of $[F_5,\boldsymbol{\chi}_5]$ we observe that F_5 is a prime matrix. So in view of Lemma 4 we have the following explicit formula for the $\hat{U}\in[F_5,\boldsymbol{\chi}_5]$:

$$\hat{U} = \frac{1}{\sqrt{5}}e^{i\theta}\hat{D}_{(2,2)}\left(\sum_{r,s=0}^{4} e^{-(4\pi i/5)s(s+2r)}|e_r\rangle\langle e_s|\right) \tag{131}$$

$e^{i\theta}$ being an arbitrary phase. Suppose we choose $\theta=7\pi/15$. Then we find $\hat{U}^3=1$ and

$$\|(\hat{U}-1)|\psi_5\rangle\|^2 = 0 \tag{132}$$

to machine precision. This confirms that $|\psi_5\rangle$ is indeed an eigenvector of $[F_5,\boldsymbol{\chi}_5]$. To calculate the dimensions of the eigenspaces define, for $r=0,\pm1$ (and with the same choice of θ),

$$\hat{P}_r = \tfrac{1}{3}(1 + e^{-2r\pi i/3}\hat{U} + e^{2r\pi i/3}\hat{U}^2). \tag{133}$$

Then $\hat{P}_r$ projects onto the eigenspace of $\hat{U}$ with eigenvalue $e^{2r\pi i/3}$. We find

$$\mathrm{Tr}(\hat{P}_r) = \begin{cases}1, & r=1,\\ 2, & r=-1 \text{ or } 0,\end{cases} \tag{134}$$

implying that the dimensions of the eigenspaces are 1,2,2, and that $|\psi_5\rangle$ is in one of the eigenspaces with dimension 2.

In dimensions 6–45 the calculation goes through in essentially the same way. The calculation is, however, slightly more complicated when d is even, due to the fact that we must then require $\mathrm{Det}\,F_d=1$ (mod $2d$). Note, also, that when $d=6$, 21, 24, 28 or 36 the matrix F_d is nonprime, so we must use the decomposition of Lemma 3.

This method also enables us to establish (to the precision that RBSC's numerical data permits) the full stability group of $|\psi_d\rangle$, i.e., the set of all operations (unitary or antiunitary) $\in \mathrm{EC}(d)/I(d)$ of which $|\psi_d\rangle$ is an eigenvector. It turns out that, with one exception, the stability group is the order 3 cyclic subgroup generated by $[F_d,\boldsymbol{\chi}_d]$. The exception is dimension 7, where the stability group is the order 6 cyclic subgroup generated by the antiunitary operation

10	$\begin{pmatrix}3&1\\-7&-2\end{pmatrix}$	$\begin{pmatrix}2\\4\end{pmatrix}$	24	$\begin{pmatrix}0&1\\-1&-1\end{pmatrix}$	$\begin{pmatrix}3\\0\end{pmatrix}$	38	$\begin{pmatrix}0&1\\-1&-5\end{pmatrix}$	$\begin{pmatrix}-6\\16\end{pmatrix}$
11	$\begin{pmatrix}1&1\\2&3\end{pmatrix}$	$\begin{pmatrix}0\\5\end{pmatrix}$	25	$\begin{pmatrix}1&0\\6&1\end{pmatrix}$	$\begin{pmatrix}3\\4\end{pmatrix}$	39	$\begin{pmatrix}7&2\\2&6\end{pmatrix}$	$\begin{pmatrix}17\\14\end{pmatrix}$
12	$\begin{pmatrix}0&1\\-1&-3\end{pmatrix}$	$\begin{pmatrix}3\\2\end{pmatrix}$	26	$\begin{pmatrix}9&0\\11&-23\end{pmatrix}$	$\begin{pmatrix}2\\-7\end{pmatrix}$	40	$\begin{pmatrix}27&1\\14&-35\end{pmatrix}$	$\begin{pmatrix}-19\\2\end{pmatrix}$
13	$\begin{pmatrix}4&2\\5&6\end{pmatrix}$	$\begin{pmatrix}-6\\-5\end{pmatrix}$	27	$\begin{pmatrix}1&0\\10&-1\end{pmatrix}$	$\begin{pmatrix}-4\\7\end{pmatrix}$	41	$\begin{pmatrix}18&0\\-5&16\end{pmatrix}$	$\begin{pmatrix}1\\-15\end{pmatrix}$
14	$\begin{pmatrix}0&1\\-1&-1\end{pmatrix}$	$\begin{pmatrix}-4\\3\end{pmatrix}$	28	$\begin{pmatrix}12&1\\-25&26\end{pmatrix}$	$\begin{pmatrix}-6\\-8\end{pmatrix}$	42	$\begin{pmatrix}2&1\\11&-36\end{pmatrix}$	$\begin{pmatrix}8\\7\end{pmatrix}$
15	$\begin{pmatrix}1&0\\5&-1\end{pmatrix}$	$\begin{pmatrix}0\\7\end{pmatrix}$	29	$\begin{pmatrix}11&0\\-2&8\end{pmatrix}$	$\begin{pmatrix}-4\\-2\end{pmatrix}$	43	$\begin{pmatrix}8&1\\-16&-18\end{pmatrix}$	$\begin{pmatrix}14\\16\end{pmatrix}$
16	$\begin{pmatrix}3&1\\-11&-14\end{pmatrix}$	$\begin{pmatrix}5\\8\end{pmatrix}$	30	$\begin{pmatrix}10&1\\29&3\end{pmatrix}$	$\begin{pmatrix}12\\1\end{pmatrix}$	44	$\begin{pmatrix}7&1\\-37&20\end{pmatrix}$	$\begin{pmatrix}6\\19\end{pmatrix}$
17	$\begin{pmatrix}1&1\\2&3\end{pmatrix}$	$\begin{pmatrix}8\\-4\end{pmatrix}$	31	$\begin{pmatrix}11&0\\6&-14\end{pmatrix}$	$\begin{pmatrix}-5\\4\end{pmatrix}$	45	$\begin{pmatrix}1&0\\20&1\end{pmatrix}$	$\begin{pmatrix}14\\-6\end{pmatrix}$
18	$\begin{pmatrix}2&1\\7&-14\end{pmatrix}$	$\begin{pmatrix}-3\\3\end{pmatrix}$	32	$\begin{pmatrix}27&1\\-8&-5\end{pmatrix}$	$\begin{pmatrix}13\\-15\end{pmatrix}$			

$$[A_7,\boldsymbol{\xi}_7]=\left[\begin{pmatrix}2&-1\\-1&0\end{pmatrix},\begin{pmatrix}1\\1\end{pmatrix}\right]. \tag{135}$$

Note that $[A_7,\boldsymbol{\xi}_7]^2=[F_7,\boldsymbol{\chi}_7]$.

VII. ZAUNER'S CONJECTURE

In the preceding section we saw that RBSC's numerical results support Conjecture A. Their results also support Conjecture B, i.e., Zauner's conjecture, that in each dimension d there exists a GP fiducial vector which is an eigenvector of $[Z,\mathbf{0}]$.

In fact, for each $5\leqslant d\leqslant 45$ let $[L_d,\boldsymbol{\eta}_d]$ be the operation specified in Table II. It is easily verified that

TABLE III. Stability groups in dimensions 2–7. In every case the stability group includes an order 3 cyclic subgroup generated by a unitary operation having Clifford trace $=-1$.

	Stability group		
Dimension	Type	Order	Number of orbits
2	Non-Abelian	6	1
3	Non-Abelian	6	∞
	Non-Abelian	12	1
	Non-Abelian	48	1
4	Cyclic	6	1
5	Cyclic	3	1
6	Cyclic	3	1
7	Cyclic	3	1
	Cyclic	6	1

$$[L_d, \boldsymbol{\eta}_d][F_d, \boldsymbol{\chi}_d][L_d, \boldsymbol{\eta}_d]^{-1} = [Z, \mathbf{0}]. \tag{136}$$

This means that if $\hat{U} \in [L_d, \boldsymbol{\eta}_d]$, and if $|\psi_d\rangle$ is the RBSC vector in dimension d, then $\hat{U}|\psi_d\rangle$ is a GP fiducial vector which is an eigenvector of $[Z, \mathbf{0}]$. Conjecture B is thus confirmed numerically for every dimension $\leqslant 45$. This suggests the following.

Conjecture C: GP fiducial vectors exist in every finite dimension. Furthermore, every such vector is an eigenvector of a canonical order 3 unitary which is conjugate to $[Z, \mathbf{0}]$.

Conjecture C is clearly stronger than Conjecture B. It also implies Conjecture A.

An operation conjugate to $[Z, \mathbf{0}]$ is automatically a canonical order 3 unitary. It would be interesting to know whether the converse is also true, i.e., whether every canonical order 3 unitary is conjugate to $[Z, \mathbf{0}]$. If that were not the case Conjecture C would be strictly stronger than Conjecture A.

VIII. DIMENSIONS 2–7: VECTORS, ORBITS, AND STABILITY GROUPS

In dimensions 2–7 RBSC made a numerical search, in an attempt to find the total number of GP fiducial vectors. On the assumption that their search was exhaustive we use their data to calculate, for dimensions 2–7, the number of distinct orbits under the action of the extended Clifford group. We also calculate the order of the stability group corresponding to each orbit. Our results are tabulated in Table III. They confirm that in dimensions 2–7 *every* GP fiducial vector is an eigenvector of a canonical order 3 Clifford unitary (in agreement with Conjecture A). We incidentally give exact expressions for two of the GP fiducial vectors in dimension 7 (one on each of the two distinct orbits).

The calculations on which these statements are based are somewhat lengthy, and there is not the space to reproduce them here. We therefore confine ourselves to summarizing the end results, which it is straightforward (albeit tedious) to confirm with the help of (for example) *Mathematica*.

Dimension 2: Exact solutions in dimension 2 have been obtained by Zauner[16] and RBSC.[17] In dimension 2 the GP fiducial vectors all lie on a single orbit of the extended Clifford group. Consider the GP fiducial vector

$$|\psi_2\rangle = \sqrt{(3+\sqrt{3})/6}|e_0\rangle + e^{i\pi/4}\sqrt{(3-\sqrt{3})/6}|e_1\rangle. \tag{137}$$

The stability group of $|\psi_2\rangle$ is the order 6, non-Abelian subgroup of $\mathrm{EC}(2)/\mathrm{I}(2)$ generated by the unitary operation

$$[F_2,\mathbf{0}]=\left[\begin{pmatrix}0 & 1\\ -1 & -1\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right] \tag{138}$$

and the antiunitary operation

$$[A_2,\mathbf{0}]=\left[\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right]. \tag{139}$$

Note that $[F_2,\mathbf{0}]$ is canonical order 3. It follows from Lemmas 5 and 6 that $|\mathrm{EC}(2)/\mathrm{I}(2)|=48$. So the orbit consists of $48/6=8$ fiducial vectors (identifying vectors which only differ by a phase), constituting two distinct SIC–POVM's (as described by RBSC).

Dimension 3: Exact solutions in dimension 3 have been obtained by Zauner[16] and RBSC.[17] We saw in Sec. V that dimension 3 is unusual in that it is the only dimension for which the identity operator has Clifford trace $=-1$. It seems to be unusual in another respect also, for it is the only case presently known where the GP fiducial vectors constitute infinitely many distinct orbits of the extended Clifford group.

Consider the one parameter family of GP fiducial vectors

$$|\psi_3(t)\rangle=\frac{1}{\sqrt{2}}(e^{-it}|e_1\rangle-e^{it}|e_2\rangle). \tag{140}$$

The complete set of GP fiducial vectors is obtained by acting on the vectors $|\psi_3(t)\rangle$ with elements of EC(3).

Let $\hat{T}$ and $\hat{J}$ be the operators defined by Eqs. (6) and (106), respectively. Then

$$\hat{T}|\psi_3(t)\rangle=-\left|\psi_3\left(t+\frac{\pi}{3}\right)\right\rangle \quad \text{and} \quad \hat{J}|\psi_3(t)\rangle=|\psi_3(-t)\rangle. \tag{141}$$

So $|\psi_3(t)\rangle$ and $|\psi_3(t')\rangle$ are on the same orbit if $t'=(n\pi/3)\pm t$ for some integer n. At the cost of rather more computational effort one can show that this condition is not only sufficient but also necessary for $|\psi_3(t)\rangle$ and $|\psi_3(t')\rangle$ to be on the same orbit. So for each distinct orbit there is exactly one value of $t\in[0,\pi/6]$ such that $|\psi_3(t)\rangle$ is on the orbit.

As Zauner[16] has previously shown, there are three kinds of orbit, a set of infinitely many generic orbits corresponding to values of t in the interior of the interval $[0,\pi/6]$, and two exceptional orbits corresponding to the two endpoints $t=0$ and $\pi/6$.

The stability group of the exceptional vector $|\psi_3(0)\rangle$ consists of all 48 operations of the form $[F,\mathbf{0}]$, where F is any element of $\mathrm{ESL}(2,\mathbf{Z}_3)$. The orbit thus consists of $432/48=9$ fiducial vectors, constituting a single SIC–POVM.

The stability group of the exceptional vector $|\psi_3(\pi/6)\rangle$ is the order 12 non-Abelian subgroup of $\mathrm{EC}(3)/\mathrm{I}(3)$ generated by the unitary operation

$$[F_3,\boldsymbol{\chi}_3]=\left[\begin{pmatrix}-1 & 0\\ -1 & -1\end{pmatrix},\begin{pmatrix}0\\1\end{pmatrix}\right] \tag{142}$$

and the antiunitary operation

$$[A_3,\boldsymbol{\chi}_3]=\left[\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\begin{pmatrix}0\\1\end{pmatrix}\right]. \tag{143}$$

Note that

$$[F_3,\boldsymbol{\chi}_3]^2=\left[\begin{pmatrix}1 & 0\\ -1 & 1\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right] \tag{144}$$

is canonical order 3. The orbit thus consists of $432/12=36$ fiducial vectors, constituting four distinct SIC–POVMs.

The stability group of a generic vector $|\psi_3(t)\rangle$ with $0<t<\pi/6$ is the order 6 non-Abelian subgroup generated by the unitary operation

$$[F_3,\boldsymbol{\chi}_3]^2=\left[\begin{pmatrix}1&0\\-1&1\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right] \tag{145}$$

and the antiunitary operation

$$[F_3,\boldsymbol{\chi}_3]\circ[A_3,\boldsymbol{\chi}_3]=\left[\begin{pmatrix}-1&0\\-1&1\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right]. \tag{146}$$

The orbit thus consists of $432/6=72$ fiducial vectors, constituting eight distinct SIC–POVMs.

Dimension 4: The vector

$$|\psi_4\rangle=\sqrt{\frac{5-\sqrt{5}}{40}}\Bigg(2\cos\frac{\pi}{8}|e_0\rangle+i(e^{-i\pi/8}+(2+\sqrt{5})^{1/2}e^{i\pi/8})|e_1\rangle+2i\sin\frac{\pi}{8}|e_2\rangle$$
$$+i(e^{-i\pi/8}-(2+\sqrt{5})^{1/2}e^{i\pi/8})|e_3\rangle\Bigg) \tag{147}$$

is a GP fiducial vector in dimension 4, as discovered by Zauner[16] and RBSC.[17]

In Zauner's notation $|\psi_4\rangle$ is the vector

$$e^{-i\pi/8}(X\psi_{1a}+\rho^3Y\psi_{1b}). \tag{148}$$

In RBSC's notation it is the vector

$$r_0|e_0\rangle+r_+e^{i\theta_+}|e_1\rangle+r_1e^{i\theta_1}|e_2\rangle+r_-e^{i\theta_-}|e_3\rangle \tag{149}$$

for the case $n=j=m=1$ and $k=0$ [note, however, that there is a typographical error in RBSC,[17] their expression for r_0 should read $r_0=\sqrt{(1-1/\sqrt{5})/(2\sqrt{2-\sqrt{2}})}$].

The stability group of $|\psi_4\rangle$ is the order 6 cyclic subgroup of EC(4)/I(4) generated by the antiunitary operation

$$[A_4,\boldsymbol{\chi}_4]=\left[\begin{pmatrix}-1&1\\-1&2\end{pmatrix},\begin{pmatrix}2\\0\end{pmatrix}\right]. \tag{150}$$

Note that

$$[A_4,\boldsymbol{\chi}_4]^2=\left[\begin{pmatrix}0&1\\-1&3\end{pmatrix},\begin{pmatrix}0\\2\end{pmatrix}\right]=\left[\begin{pmatrix}0&1\\-1&-1\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right] \tag{151}$$

is canonical order 3 [where we used Eq. (81) to obtain the last expression on the right-hand side].

It follows from Lemmas 5 and 6 that the group EC(4)/I(4) is of order 1536. So the orbit generated by $|\psi_4\rangle$ contains $1536/6=256$ fiducial vectors, constituting $256/16=16$ SIC–POVMs. RBSC's numerical search found a total of 16 SIC–POVMs in dimension 4. If their search was exhaustive, it would follow that the fiducial vectors all lie on a single orbit of the extended Clifford group.

Dimension 5: Let $|\psi_5\rangle$ be RBSC's numerical vector in dimension 5. We noted in the preceding section that the stability group of $|\psi_5\rangle$ is of order 3. It follows from Lemmas 5 and 6 that the group EC(5)/I(5) is of order 6000. So the orbit generated by $|\psi_5\rangle$ contains $6000/3=2000$ fiducial vectors, constituting $2000/25=80$ SIC–POVMs. RBSC found a total of 80 SIC–POVMs in dimension 5. If their search was exhaustive, it would follow that the fiducial vectors all lie on a single orbit of the extended Clifford group.

Note that Zauner's analytic solution in dimension 5 (on p. 63 of his thesis[16]) can be used to give exact expressions for each of the vectors on the orbit.

Dimension 6: Let $|\psi_6\rangle$ be RBSC's numerical vector in dimension 6. We noted in the preceding

section that the stability group of $|\psi_6\rangle$ is of order 3. It follows from Lemmas 5 and 6 that the group EC(6)/I(6) is of order 10 368. So the orbit generated by $|\psi_6\rangle$ contains $10\,368/3=3456$ fiducial vectors, constituting $3456/36=96$ SIC–POVMs. RBSC found a total of 96 SIC–POVMs in dimension 5. If their search was exhaustive, it would follow that the fiducial vectors all lie on a single orbit of the extended Clifford group (in agreement with Grassl's[21] analysis, based on his exact solution in dimension 6).

Note that Grassl's[21] analytic solution can be used to give exact expressions for each of the vectors on the orbit.

Dimension 7: Let $|\psi_7\rangle$ be RBSC's numerical vector in dimension 7. We noted in the last section that the stability group of $|\psi_7\rangle$ is of order 6. It follows from Lemmas 5 and 6 that the group EC(6)/I(6) is of order 32 928. So the orbit generated by $|\psi_7\rangle$ contains $32\,928/6=5488$ fiducial vectors, constituting $5488/49=112$ SIC–POVMs. However, RBSC found 336 SIC–POVMs in dimension 7. This indicates the existence of at least one other orbit.

The search for the additional orbit or orbits is facilitated by the fact that in dimension 7 there exists a canonical order 3 Clifford unitary for which the F matrix is diagonal, namely

$$[F_7',\mathbf{0}]=\left[\begin{pmatrix}-3 & 0\\ 0 & 2\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right]. \tag{152}$$

The fact that F_7' is diagonal means that the $\hat{U}\in[F_7',\mathbf{0}]$ are permutation matrices. Specifically

$$\hat{U}=e^{i\theta}\sum_{r=0}^{6}|e_{4r}\rangle\langle e_r| \tag{153}$$

for every $\hat{U}\in[F_7',\mathbf{0}]$ (where $e^{i\theta}$ is an arbitrary phase, and where we have used the decomposition described in Lemma 3). This considerably simplifies the calculations. We will also have occasion to consider the antiunitary operation

$$[A_7',\mathbf{0}]=\left[\begin{pmatrix}-2 & 0\\ 0 & -3\end{pmatrix},\begin{pmatrix}0\\0\end{pmatrix}\right] \tag{154}$$

which is a square root of $[F_7',\mathbf{0}]$.

We look for eigenvectors of $[F_7',\mathbf{0}]$. Let

$$l_r=\begin{cases}1 & \text{if } r=1,\,2 \text{ or } 4,\\ -1 & \text{if } r=3,\,5 \text{ or } 6.\end{cases} \tag{155}$$

Also let

$$a_0=\frac{1}{2}\left(\sqrt{\frac{1}{4-\sqrt{2}}}+i\sqrt{\frac{4-\sqrt{2}}{2}}\right),\quad a_1=\frac{1}{4}\sqrt{\frac{8-5\sqrt{2}}{7}},\quad a_2=2^{-7/4} \tag{156}$$

and

$$b_0=\sqrt{\frac{2+3\sqrt{2}}{14}},\quad b_1=\sqrt{\frac{4-\sqrt{2}}{28}},\quad \theta=\cos^{-1}\left(-\frac{\sqrt{\sqrt{2}+1}}{2}\right). \tag{157}$$

Then define

$$|\psi_7'\rangle=a_0|e_0\rangle-\sum_{r=1}^{6}(a_1+l_r a_2)|e_r\rangle, \tag{158}$$

$$|\psi_7''\rangle = b_0|e_0\rangle + \sum_{r=1}^{6} b_1 e^{il_r\theta}|e_r\rangle. \tag{159}$$

It is readily confirmed that $|\psi_7'\rangle$ and $|\psi_7''\rangle$ are both GP fiducial vectors. The stability group of $|\psi_7'\rangle$ is the order 3 subgroup generated by $[F_7', \mathbf{0}]$, while the stability group of $|\psi_7''\rangle$ is the order 6 subgroup generated by $[A_7', \mathbf{0}]$. Since the stability groups are nonisomorphic the orbits generated by $|\psi_7'\rangle$ and $|\psi_7''\rangle$ are disjoint. The orbit generated by $|\psi_7'\rangle$ contains $32\,928/3 = 10\,976$ fiducial vectors, constituting $10\,976/49 = 224$ SIC–POVMs. The orbit generated by $|\psi_7''\rangle$ contains 5488 fiducial vectors, constituting a further 112 SIC–POVMs. This accounts for all 336 of the SIC–POVMs identified by RBSC. If we assume that RBSC's search was exhaustive it would follow that there are no other orbits, apart from these two.

For the sake of completeness let us note that

$$|\psi_7\rangle = \hat{U}|\psi_7''\rangle, \tag{160}$$

where $|\psi_7\rangle$ is RBSC's numerical vector and $\hat{U}$ is a unitary operator

$$\hat{U} \in \left[\begin{pmatrix} 1 & 1 \\ -3 & -2 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right]. \tag{161}$$

Finally, let us remark that l_r is the Legendre symbol (see, e.g., Nathanson[36] or Rose[37])

$$l_r = \left(\frac{r}{7} \right). \tag{162}$$

It has the important property that $l_{rs} = l_r l_s$ for all $r, s \in \mathbb{Z}$.

IX. A FIDUCIAL VECTOR IN DIMENSION 19

In Sec. VI we saw that, apart from the solution in dimension 7, RBSC's numerical solutions in dimensions 5–45 all have stability group of order 3. This might encourage one to speculate that when $d > 7$ the stability group is *always* of order 3. In this section we show that there is at least one exception to that putative rule, by constructing a GP fiducial vector in dimension 19 for which the stability group has order $\geqslant 18$.

The vector we construct is an eigenvector of the order 18 antiunitary operation

$$[A_{19}', \mathbf{0}] = \left[\begin{pmatrix} -9 & 0 \\ 0 & -2 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right] \in \mathrm{EC}(19)/\mathrm{I}(19). \tag{163}$$

Note that

$$[F_{19}', \mathbf{0}] = [A_{19}', \mathbf{0}]^6 = \left[\begin{pmatrix} -8 & 0 \\ 0 & 7 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right] \tag{164}$$

is canonical order 3.

The construction is similar to our construction of the vector $|\psi_7''\rangle$ in the last section. Let l_r' be the Legendre symbol

$$l_r' = \left(\frac{r}{19} \right) = \begin{cases} 1 & \text{if } r = 1, 4, 5, 6, 7, 9, 11, 16 \text{ or } 17, \\ -1 & \text{if } r = 2, 3, 8, 10, 12, 13, 14, 15 \text{ or } 18, \end{cases} \tag{165}$$

and let

$$b_0' = \sqrt{\frac{5+9\sqrt{5}}{95}}, \quad b_1' = \sqrt{\frac{10-\sqrt{5}}{190}}, \quad \theta' = \cos^{-1}\left(\sqrt{\frac{\sqrt{5}-1}{8}}\right). \tag{166}$$

Then define

$$|\psi_{19}'\rangle = b_0'|e_0\rangle + \sum_{r=1}^{18} b_1' e^{il_r'\theta'}|e_r\rangle. \tag{167}$$

It is readily confirmed that $|\psi_{19}'\rangle$ is a GP fiducial vector, and an eigenvector of $[A_{19}', \mathbf{0}]$.

Observe that the orbit generated by $|\psi_{19}'\rangle$ is disjoint from the orbit generated by RBSC's numerical vector $|\psi_{19}\rangle$ (because the stability groups are nonisomorphic). It follows that there are at least two distinct orbits in dimension 19.

X. DIAGONALIZING THE *F* MATRIX

Our construction of the exact solutions $|\psi_7'\rangle$, $|\psi_7''\rangle$, and $|\psi_{19}'\rangle$ in Eqs. (158), (159), and (167) was facilitated by the fact that in dimensions 7 and 19 there exist canonical order 3 unitaries for which the corresponding F matrix is diagonal. It is natural to ask in what other dimensions that is true. The theorem proved below answers that question.

We will need the following lemma.

Lemma 8: Let p be a prime number $=1 \pmod 3$, *and let n be any* integer $\geqslant 1$. *Then there exists an integer* α *such that*

$$\alpha^2 + \alpha + 1 = 0 \pmod{p^n}. \tag{168}$$

Proof: The proof relies heavily on the theory of primitive roots, as described in (for example) Chap. 3 of Nathanson[36] or Chap. 5 of Rose.[37] Let ϕ be Euler's phi, or totient function [so for every integer $x \geqslant 1$, $\phi(x)$ is the number of integers y in the range $1 \leqslant y < x$ which are relatively prime to x]. Then there exists a single positive integer g such that for every integer $m \geqslant 1$ the multiplicative order of g, considered as an element of $\mathbb{Z}_{p^m}$, is $\phi(p^m) = (p-1)p^{m-1}$ (see, for example, Nathanson,[36] p. 93, or Rose,[37] p. 91). The fact that $p = 1 \pmod 3$ means $p = 3k+1$ for some integer $k \geqslant 1$. Define

$$\alpha = g^{kp^{n-1}}. \tag{169}$$

It is then immediate that

$$\alpha^3 = g^{\phi(p^n)} = 1 \pmod{p^n}. \tag{170}$$

It is also true that $\alpha - 1$ is relatively prime to p. Suppose that were not the case. It would then follow from the definition of α, and the fact that g is a primitive root *modulo p*, that

$$kp^{n-1} = l(p-1) - 3kl \tag{171}$$

for some integer $l \geqslant 1$. That, however, is impossible since p is not a multiple of 3.

The fact that $\alpha - 1$ is relatively prime to p means that there exists an integer β such that

$$\beta(\alpha - 1) = 1 \pmod{p^n}. \tag{172}$$

It now follows from Eqs. (170) and (172) that

$$\alpha^2 + \alpha + 1 = \beta(\alpha^3 - 1) = 0 \pmod{p^n}. \tag{173}$$

□

We are now in a position to prove our main result.

Theorem 3: *There exists a canonical order 3 unitary* $[F, \boldsymbol{\chi}] \in \mathrm{C}(d)/\mathrm{I}(d)$ *for which the matrix F is diagonal if and only if each of the following is true:*

(1) *d has at least one* prime divisor $= 1$ (*mod* 3).

(2) *d has no* prime divisors $=2$ (*mod* 3).
(3) *d is not divisible by* 9.

Remark: So there exist canonical order 3 unitaries $[F,\boldsymbol{\chi}]$ for which F is diagonal in dimension 7,13,19,21,31,37,39,43,49, … .

Proof: We begin by proving sufficiency. Suppose that conditions (1), (2), and (3) are all true. Then we have, for some $t \geqslant 1$,

$$d = 3^{n_0} p_1^{n_1} \cdots p_t^{n_t}, \tag{174}$$

where the p_i are distinct prime numbers $=1 \pmod 3$, where the integer $n_0 = 0$ or 1, and where the integers $n_1, \ldots, n_t$ are all $\geqslant 1$. It follows from Lemma 8 that there exist integers $\alpha_1, \ldots, \alpha_t$ such that

$$\alpha_i^2 + \alpha_i + 1 = 0 \pmod{p_i^{n_i}} \tag{175}$$

for $i = 1, \ldots, t$. We now use the Chinese remainder theorem (see, for example, Nathanson[36] or Rose[37]) to deduce that there exists a single integer α such that

$$\alpha = 1 \pmod 3 \tag{176}$$

and

$$\alpha = \alpha_i \pmod{p_i^{n_i}} \tag{177}$$

for $i = 1, \ldots, t$. We then have

$$\alpha^2 + \alpha + 1 = 0 \pmod d \tag{178}$$

implying that the matrix

$$F = \begin{pmatrix} \alpha & 0 \\ 0 & -\alpha - 1 \end{pmatrix} \tag{179}$$

$\in \mathrm{SL}(2, \mathbb{Z}_d)$ (bearing in mind that d is odd). Moreover, $\mathrm{Tr}(F) = -1 \pmod d$. Since $d \neq 3$ we conclude that $[F,\boldsymbol{\chi}]$ is a canonical order 3 unitary for all $\boldsymbol{\chi} \in (\mathbb{Z}_d)^2$. This proves sufficiency.

To prove necessity suppose

$$F = \begin{pmatrix} \alpha & 0 \\ 0 & \delta \end{pmatrix} \in \mathrm{SL}(2, \mathbb{Z}_d) \tag{180}$$

is such that $[F,\boldsymbol{\chi}]$ is canonical order 3 for some $\boldsymbol{\chi} \in (\mathbb{Z}_d)^2$. Then $\alpha + \delta = -1 \pmod d$, implying

$$\alpha^2 + \alpha + 1 = 0 \pmod d, \tag{181}$$

$$\alpha^3 = 1 \pmod d \tag{182}$$

[in view of the fact that $\alpha\delta = 1 \pmod d$].

To show that d has no prime divisors $=2 \pmod 3$ assume the contrary. It would then follow from Eqs. (181) and (182) that

$$\alpha^2 + \alpha + 1 = 0 \pmod p, \tag{183}$$

$$\alpha^3 = 1 \pmod p \tag{184}$$

for some prime number $p = 2 \pmod 3$. Let r be a primitive root of p and let $k \in \mathbb{Z}$ be such that $0 \leqslant k < p-1$ and $\alpha = r^k \pmod p$ (see, for example, Nathanson[36] or Rose[37]). Then Eq. (184) implies $r^{3k} = 1 \pmod p$ which, in view of the fact that r is a primitive root, means $3k = l(p-1)$ for some $l \in \mathbb{Z}$. The fact that $0 \leqslant k < p-1$ implies $0 \leqslant l < 3$. Taking into account the fact that $p-1$ is not

divisible by 3 [because $p=2 \pmod 3$] we deduce that $l=0$. But then $k=0$, implying $\alpha = 1 \pmod p$. In view of Eq. (183) this means $3=0 \pmod p$, which is a contradiction.

To prove that d is not divisible by 9 we again proceed by *reductio ad absurdum*. Suppose that d were divisible by 9. It would then follow from Eq. (181) that

$$\alpha^2 + \alpha + 1 = 0 \pmod 9. \tag{185}$$

However, it is easily verified (by explicit enumeration) that this equation has no solutions.

Finally, suppose that d had no prime divisors $=1 \pmod 3$. In view of the results just proved it would follow that $d=3$. But if $d=3$, Eq. (181) implies $\alpha=1 \pmod 3$. Taking into account the requirement $\alpha\delta=\det F=1 \pmod 3$ this means $\delta=1 \pmod 3$. But then F is the identity matrix, which contradicts the assumption that $[F,\boldsymbol{\chi}]$ is a canonical order 3 unitary. We conclude that d must have at least one prime divisor $=1 \pmod 3$. □

XI. CONCLUSION

RBSC conclude their paper by saying "a rigorous proof of existence of SIC–POVMs in all finite dimensions seems tantalizingly close, yet remains somehow distant." That well expresses our own perception of the matter. While working on this problem we have several times had the sense that the crucial discovery lay just round the corner, only to find that our hopes were illusory. We make our results public in the hope that they may, nevertheless, contain a few clues, which will help to take us further forward.

In particular it seems to us that significant progress would be made if it could be established whether it is in fact true that every GP fiducial vector is an eigenvector of a canonical order 3 unitary. Also, if that is the case, one would like to know exactly *why* it is the case.

ACKNOWLEDGMENTS

The author is grateful to Chris Fuchs for exciting his interest in this problem. The author is also grateful to him and to Paul Busch, Barry Rhule, and Rüdiger Schack for numerous inspiring discussions about POVMs in particular, and the mysteries of quantum mechanics in general. Finally, the author is grateful to Markus Grassl, Gerhard Zauner, and Alexander Vlasov for some very helpful comments regarding the first version of this paper.

In the Mandelstam–Tamm version of the time-energy uncertainty principle Δt denotes the infimum of time intervals that elapse before the change in the mean of any observable has the same magnitude as its standard deviation. We clarify this interpretation, and show that the infimum is achieved for certain observables and thus that this famous inequality is actually an equality. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1897164]

I. INTRODUCTION

The time-energy uncertainty principle (TEUP) has many versions.[1–8] In one of its standard forms, due to Mandelstam and Tamm[9] [we follow the formulation in Messiah's book (Ref. 1, pp. 319–320)], Δt represents the infimum of times that must pass for the change in the mean of some observable to be comparable in size to the standard deviation of that observable at the initial time. TEUP asserts that this time is greater than or equal to Planck's constant $\hbar$ divided by twice the standard deviation of the energy observable at the initial time.

In this note we clarify the meaning of the symbol Δt. We strive for exactness and introduce notions of *dynamic uncertainty per unit time* and *static uncertainty* to aid our discussion. Indeed, as we shall explain, Δt is only in a crude sense a lower bound for the time needed for significant change to occur, and is more accurately regarded as the infimum of the absolute ratio of static uncertainty to dynamic uncertainty per unit time among observables satisfying technical conditions which ensure that this ratio is properly defined. Moreover, there are observables (corresponding even to bounded operators) for which this infimum is actually achieved, and thus the Mandelstam–Tamm inequality is an equality. Defined for a given Hamiltonian and a given initial state, Δt is a characteristic time for measurable change to occur in a system. The observables used to observe such change, as one might expect, are ones that measure the component of the time derivative of the state perpendicular to the initial state.

An alternative view of the TEUP, taken in quantum estimation theory, is that Δt is the standard error of an estimate for the time at which some quantum event occurs, and the Mandelstam–Tamm inequality is a special case of a quantum Cramer–Rao inequality.[10–12] The time in quantum mechanics thus appears to be interpreted not as a variable but as a fixed parameter to be estimated as parameters are estimated in classical statistics. In our discussion here we adopt instead the traditional Newtonian view of time.

II. PRELIMINARIES

As is customary, we identify an observable with a self-adjoint operator A on the Hilbert space containing the state vectors ψ. For convenience neither positive operator valued measures nor

a)Electronic mail: john.e.gray@navy.mil
b)Author to whom correspondence should be addressed. Electronic mail: vogt@math.georgetown.edu

density matrices are considered. The inner product $\langle,\rangle$ in the Hilbert space is assumed to be linear in the first variable, conjugate linear in the second. We will be careful to point out domain restrictions in our discussion.

The mean, or the expected value, of an observable A for the state ψ is given by

$$\mu_\psi(A) = \langle A(\psi), \psi\rangle, \tag{1}$$

while the standard deviation of the observable A is

$$\Delta_\psi A = \|(A - \mu_\psi(A)I)(\psi)\|. \tag{2}$$

The mean and standard deviation are defined if and only if ψ is in the domain of the operator A, denoted by $D(A)$. Furthermore, a state ψ is an eigenstate of the operator A iff ψ is in $D(A)$ and $\Delta_\psi A = 0$.

Although the mean of an observable may appear to be a specialized notion of limited value, it actually includes the full range of quantum-mechanical probability considerations. If $P_A(\ )$ is the projection-valued measure associated with the self-adjoint operator A, then for any Borel subset I of the real numbers $P_A(I)$ is a bounded observable (in fact an orthogonal projection onto a closed subspace) and $\mu_\psi(P_A(I))$ is the probability that a measurement of the observable A when the state is ψ yields a value in the set I. As we vary I, we obtain the probability distribution for the observable A. Thus, means incorporate all of the probability theory, and no domain questions arise since ψ is always in $D(P_A(I))$.

The Cauchy–Schwarz inequality, applied to (2) for observables A and B, takes the form

$$\begin{aligned}\Delta_\psi A \Delta_\psi B &\geqslant \tfrac{1}{2}|\langle (A - \mu_\psi(A)I)(\psi), (B - \mu_\psi(B)I)(\psi)\rangle - \langle (B - \mu_\psi(B)I)(\psi), (A - \mu_\psi(A)I)(\psi)\rangle| \\ &= \tfrac{1}{2}|\langle A(\psi), B(\psi)\rangle - \langle B(\psi), A(\psi)\rangle) = |\mathrm{Im}(\langle A(\psi), B(\psi)\rangle|,\end{aligned} \tag{3}$$

where ψ is in $D(A) \cap D(B)$. If ψ is in the set $D = \{\psi: \psi$ is in $D(A) \cap D(B), A(\psi)$ is in $D(B)$, and $B(\psi)$ is in $D(A)\}$, then (3) can be rewritten as

$$\Delta_\psi A \Delta_\psi B \geqslant \tfrac{1}{2}|\langle i(AB - BA)(\psi), \psi\rangle| = \tfrac{1}{2}|\mu_\psi([A,B])|, \tag{4}$$

where in general $[A,B] = i(AB - BA)$ defines a unique self-adjoint operator, the commutator of A and B, whose domain $D([A,B])$ contains the subspace D.

III. THE MANDELSTAM–TAMM TEUP

Fundamental to quantum mechanics is an evolution of the state between measurements described by the Schrödinger equation

$$i\hbar \frac{\mathrm{d}\psi}{\mathrm{d}t} = H(\psi), \tag{5}$$

where H is the energy observable of the system, called its *Hamiltonian*. For simplicity we assume H is time independent. The state at time t is given by $\psi(t) = \exp(-it/\hbar)H(\psi)$ where $\psi(0) = \psi$ is the state at time 0, and $\{\exp(-it/\hbar)H: t \in \mathcal{R}\}$ is a one-parameter group of unitary operators generated by H. Since the statistics are contained in ψ, the statistics also must evolve.

Although the wave function $\psi(t)$ is defined for all t, the existence of derivatives depends upon whether ψ is in the (dense) domain of the energy operator H, and, if we are taking the derivative of the mean of some observable, in the domain of the associated operator A. The time derivative of the mean of an observable A at time $t = 0$ is given by

$$\frac{\mathrm{d}}{\mathrm{d}t}(\mu_\psi(A)) = \frac{\mathrm{d}}{\mathrm{d}t}(\langle A(\psi(t)), \psi(t)\rangle)$$

$$= \lim_{t\to 0} \frac{1}{t}(\langle A(\psi(t)), \psi(t)\rangle - \langle A(\psi), \psi\rangle)$$

$$= \lim_{t\to 0}\left(\left\langle \frac{\psi(t)-\psi}{t}, A(\psi(t)-\psi)\right\rangle + \left\langle \frac{\psi(t)-\psi}{t}, A(\psi)\right\rangle + \left\langle A(\psi), \frac{\psi(t)-\psi}{t}\right\rangle\right)$$

$$= 0 + \frac{-i}{\hbar}(\langle H(\psi), A(\psi)\rangle - \langle A(\psi), H(\psi)\rangle) = \frac{2}{\hbar}\,\mathrm{Im}(\langle H(\psi), A(\psi)\rangle). \tag{6}$$

For these equations to be valid we assume that

$$\psi \text{ is in } D(H), \tag{7a}$$

$$\psi(t) \text{ is in } D(A) \text{ for } t \text{ near } 0, \text{ and} \tag{7b}$$

$$\langle \psi(t)-\psi, A(\psi(t)-\psi)\rangle = o(t). \tag{7c}$$

Conditions (7a) and (7b) are plausible requirements, but (7c) is less so. The notation $o(t^\delta)$ describes any scalar quantity $q(t)$ such that $\lim_{t\to 0} q(t)/t^\delta = 0$. If (7a) holds, then $\|\psi(t)-\psi\| = o(t^{1-\epsilon})$ for any $\epsilon > 0$, but since A may be unbounded, (7c) is not guaranteed[1].

Proposition: Suppose (7a) holds. It follows that

(i) if A is bounded, then (7b) and (7c) hold;
(ii) if (7b) holds, A is semibounded, and $(\mathrm{d}/\mathrm{d}t)(\mu_\psi(A))$ exists as a two-sided derivative, then (7c) holds; and
(iii) if (7b) holds and $\{A(\psi(t)) : |t| < \epsilon\}$ is a bounded set for some $\epsilon > 0$, then (7c) holds.

Proof: If A is bounded, $D(A)$ is the whole Hilbert space and the expression in (7c) is $o(t^{2(1-\epsilon)})$ for small ϵ and *a fortiori* $o(t)$, which establishes (i).

In (ii), since $(\mathrm{d}/\mathrm{d}t)(\mu_\psi(A))$ exists, $\lim_{t\to 0}(1/t)\langle \psi(t)-\psi, A(\psi(t)-\psi)\rangle = p$ for some scalar p. Since A is semibounded, $\langle \theta, A(\theta) - c\theta\rangle \geq 0$ for some real number c and all vectors θ in $D(A)$ (or else $-A$ satisfies such an inequality and the same argument can be applied to $-A$). Since $\lim_{t\to 0}(1/t)\langle \psi(t)-\psi, c(\psi(t)-\psi)\rangle = 0$, it follows that for t converging to 0^+, $p \geq 0$; while for t converging to 0^-, $p \leq 0$; and so $p = 0$.

To establish (iii), let $M = \sup\{\|A(\psi(t))\| : |t| < \epsilon\}$. Given $\epsilon_1 > 0$, choose $\delta_1 > 0$ in $(0, \epsilon)$ so that if $|t| < \delta_1$ then $\|\{[\psi(t)-\psi]/t\} + (i/\hbar)H(\psi)\| < \epsilon_1/6M$. Choose θ in the dense domain $D(A)$ so that $\|\theta + (i/\hbar)H(\psi)\| < \epsilon_1/6M$, and choose $\delta_2 \leq \delta_1$ so that for $|t| < \delta_2$, $\|\psi(t)-\psi\| < \epsilon_1/(3(\|A(\theta)\|+1))$. Then for $|t| < \delta_2$,

$$\left|\frac{\langle \psi(t)-\psi, A(\psi(t)-\psi)\rangle}{t}\right| \leq \left|\left\langle \frac{\psi(t)-\psi}{t} + \frac{i}{\hbar}H(\psi), A(\psi(t)-\psi)\right\rangle\right| + \left|\left\langle \frac{i}{\hbar}H(\psi) + \theta, A(\psi(t)-\psi)\right\rangle\right|$$

$$+ |\langle \theta, A(\psi(t)-\psi)\rangle| < \frac{\epsilon_1}{6M}\cdot 2M + \frac{\epsilon_1}{6M}\cdot 2M + \frac{\epsilon_1}{3} = \epsilon_1.$$

This establishes (7c). ■

[1]We have not found examples of self-adjoint operators H, A and a state ψ for which (7a) and (7b) hold but not (7c). The following may perhaps suggest an example. In the Hilbert space $l_2(\mathcal{N})$, define a sequence of vectors $\{a_k : k \geq 1\}$ by $a_k(n) = 1/(kn^{3/4})$ for $n \leq k^2$, $a_k(n) = 0$ else, and let A be the number operator satisfying $A(a_k)(n) = na_k(n)$ for $k, n \geq 1$. Then $\{a_k\}$ is analogous to $\{\psi(t)-\psi\}$, with t replaced by $1/k$. Moreover $\lim_{k\to\infty} ka_k = c$ where $c(n) = 1/n^{3/4}$ for $n \geq 1$, and $\lim_{k\to\infty}\langle ka_k, A(a_k)\rangle = 2$.

If in addition to (7), we assume that $A(\psi)$ is in $D(H)$, $H(\psi)$ is in $D(A)$, and $[H,A]$ exists, then we can rewrite (6) as $(\mathrm{d}/\mathrm{d}t)\mu_\psi(A)=(1/\hbar)\mu_\psi([H,A])$.

If ψ is an eigenvector of the energy operator, then $H(\psi)=c\psi$ for some real number c. For any time interval $[0,t]$ during which Schrödinger evolution occurs, $\psi(t)=[\exp(-ict/\hbar)](\psi)$ and the state remains unchanged since wave functions that differ by a scalar multiple represent the same state. If $A(\psi)$ is defined, then so is $A(\psi(t))$ in this case, and

$$\langle H(\psi(t)),A(\psi(t))\rangle = c\langle \psi(t),A(\psi(t))\rangle = c\mu_{\psi(t)}(A) \tag{8}$$

has imaginary part equal to zero. Thus, by (6), $\langle A(\psi(t)),\psi(t)\rangle$ stays constant. This follows directly because

$$\langle A(\psi(t)),\psi(t)\rangle = \left\langle A\left(\exp\frac{-ict}{\hbar}\right)(\psi),\left(\exp\frac{-ict}{\hbar}\right)(\psi)\right\rangle \equiv \langle A(\psi),\psi\rangle. \tag{9}$$

Since all bounded observables, including orthogonal projections, have constant means, the statistics associated with every observable remain constant in time. This is a familiar property of the evolution of energy eigenstates.

In any case we can combine (3) and (6), with $B=H$, to obtain

$$\Delta_\psi A\Delta_\psi H \geqslant \frac{\hbar}{2}\left|\frac{\mathrm{d}}{\mathrm{d}t}\mu_\psi(A)\right|. \tag{10}$$

Instead of regarding $\Delta_\psi A$ as the standard deviation, we choose to call it the *static uncertainty* of the observable A when the state is ψ. This label emphasizes that $\Delta_\psi A$ is a measure of the variability of A at a given time. The quantity $(\mathrm{d}/\mathrm{d}t)\mu_\psi(A)$ is the *dynamic uncertainty per unit time*: it measures the variability of the central value of A per unit time. Typically in one unit of time the value of $\mu_\psi(A)$ changes by approximately $(\mathrm{d}/\mathrm{d}t)\mu_\psi(A)\cdot 1$. Thus it is quite natural (after Messiah) to make the following definition when ψ is a unit vector in $D(H)$ that is not an eigenvector of H,

$$\Delta_\psi t \overset{\text{def}}{=} \inf_A\left\{\frac{\Delta_\psi A}{\left|\frac{\mathrm{d}}{\mathrm{d}t}\mu_\psi(A)\right|}: A \text{ self-adjoint}, A \text{ satisfies (7)}, \text{and} \frac{\mathrm{d}}{\mathrm{d}t}\mu_\psi(A)\neq 0\right\}. \tag{11}$$

If ψ is an eigenvector of H, then the denominator in (11) is always zero, thus no observable varies in time. Thinking of $\Delta_\psi t$ as infinity in this case makes sense.

The quantity $\Delta_\psi t$ is, roughly speaking, the minimum time required for the dynamic uncertainty in some observable to achieve the same magnitude as its static uncertainty, the minimum time interval until the evolution of the state introduces variation large enough to match the intrinsic variability at the initial time.

This description is only approximate for multiple reasons. The conditions in (7) may not be fulfilled. In addition, the dynamics are described by a linear approximation to $\mu_{\psi(t)}(A)$, namely, $\mu_{\psi(0)}(A)+(\mathrm{d}/\mathrm{d}t)(\mu_{\psi(t)}(A))|_{t=0}(t-0)$. Observables A for which $(\mathrm{d}/\mathrm{d}t)(\mu_{\psi(t)}(A))|_{t=0}$ equals zero and a second or higher order approximation might be relevant are excluded from consideration. This happens whenever ψ is an eigenvector of A, for then $\Delta_\psi A=0$ and by (10) $(\mathrm{d}/\mathrm{d}t)\mu_\psi(A)=0$. Also ignored is the possibility that linear approximation is not accurate over the time interval of interest, short as it may be, because, say, the first derivative changes very rapidly. Finally, although changes in the mean of a variable are important, we cannot argue that they are the only significant measures of change as time passes or that any change smaller than one standard deviation is truly negligible. In fact, if the observable is taken to be $P_A(I)$, the mean $\langle P_A(I)\psi,\psi\rangle=p$ is the probability that A lies in the Borel set I, and the standard deviation or static uncertainty is $\sqrt{p-p^2}$, a number that is larger than p for $p<\frac{1}{2}$. Messiah (Ref. 1, pp. 319–320) calls $\Delta_\psi t$ "the characteristic time of evolution." This formulation recommends itself since it does not promise too much. The precise meaning of $\Delta_\psi t$ is given by (11).

The existence of observables A satisfying the conditions in (11) is established below, so that the definition is not vacuous.

Assuming such observables exist, by combining (11) with inequality (10), we obtain

$$\Delta_\psi t \Delta_\psi H \geqslant \frac{\hbar}{2} \tag{12}$$

for all unit vectors ψ in $D(H)$ that are not eigenvectors of H. This is the TEUP (Ref. 1, pp. 319–320).

The quantity $\Delta_\psi t$ depends not only on the state ψ but also on the time evolution of ψ, that is, on the particular Hamiltonian H that governs the evolution of the state. Furthermore, (11) and (6) imply that

$$\begin{aligned}\Delta_\psi t &\geqslant \inf_A \left\{ \frac{\hbar \Delta_\psi A}{2|\mathrm{Im}(\langle H(\psi), A(\psi)\rangle)|} : A \text{ self-adjoint}, \psi \in D(A), \mathrm{Im}(\langle H(\psi), A(\psi)\rangle) \neq 0 \right\} \\ &\geqslant \inf_\theta \left\{ \frac{\hbar \| \theta - \langle \theta, \psi\rangle \psi \|}{2|\mathrm{Im}(\langle H(\psi), \theta\rangle)|} : \theta \text{ a vector}, \mathrm{Im}(\langle \psi, \theta\rangle) = 0 \neq \mathrm{Im}(\langle H(\psi), \theta\rangle) \right\}. \end{aligned} \tag{13}$$

To obtain (13), we have replaced the time derivative of the mean in (11) by its value in (6), and then replaced $A(\psi)$ by a vector θ. Since the infimum in (11) and those in (13) are effectively over progressively larger sets, the inequalities are as indicated. The theorem below establishes that these inequalities are in fact equalities.

Theorem: Let ψ be a unit vector in $D(H)$ that is not an eigenvector of H. Then

$$\Delta_\psi t \Delta_\psi H = \frac{\hbar}{2}. \tag{14}$$

Furthermore, the infimum $\Delta_\psi t$ is achieved precisely for self-adjoint operators A satisfying (7) and taking ψ to $\alpha\psi + i\beta PH(\psi)$ where P is the orthogonal projection of the Hilbert space to the subspace $(\mathrm{span}\{\psi\})^\perp$, and α and β are real numbers with β nonzero.

Remarks: The theorem tells us that $\Delta_\psi t = \hbar/2\Delta_\psi H$. It also tells us that there are three kinds of observables A, (i) those for which the absolute ratio of static uncertainty to dynamic uncertainty per unit time is undefined [i.e., (7) fails or $\mathrm{d}/\mathrm{d}t\mu_\psi(A) = 0$], (ii) those for which this ratio is larger than $\Delta_\psi t$, and (iii) those for which the ratio equals $\Delta_\psi t$. The theorem also characterizes the third kind of observable.

Before proceeding to the proof, we establish the existence of observables for which the absolute ratio is defined. If θ is any vector such that $\langle \psi, \theta\rangle$ is real, then there always exist self-adjoint operators A that take the unit vector ψ to θ. Indeed, for an arbitrary Hilbert space vector ψ', A may always be defined by $A(\psi') =^{\mathrm{def}} \langle \psi', P(\theta)\rangle \psi + \langle \psi', \psi\rangle \theta + BP(\psi')$, where B is a self-adjoint operator defined on the Hilbert subspace $(\mathrm{span}\{\psi\})^\perp$. It is straightforward to verify that A is self-adjoint if and only if B is, and A is bounded if and only if B is.

Now take θ to satisfy $\mathrm{Im}(\langle H(\psi), \theta\rangle) \neq 0$. Then corresponding operators A exist with $A(\psi) = \theta$. So the two infima on the right-hand side of (13) are over the same set and hence are equal. If B is taken to be a bounded operator on $(\mathrm{span}\{\psi\})^\perp$, then A is bounded. This implies that A satisfies (7). Hence $\Delta_\psi t$ is well defined.

If θ is chosen as in the theorem [i.e., $\theta = \alpha\psi + i\beta PH(\psi)$, with α and β real and β nonzero], then $\langle \theta, \psi\rangle = \alpha$ is real and $\langle H(\psi), \theta\rangle = \alpha\langle H(\psi), \psi\rangle - i\beta\langle H(\psi), PH(\psi)\rangle$, so that $\mathrm{Im}(\langle H(\psi), \theta\rangle) = -\beta\|PH(\psi)\|^2 \neq 0$ since ψ is not an eigenvector of H. A self-adjoint operator A taking ψ to θ exists, constructed as in the preceding paragraphs, and if B is taken to be bounded, A satisfies (7). Thus operators A fitting the description in the theorem exist. In particular, a simple example of such an operator A is obtained by setting $B = 0$, $\alpha = 0$, and $\beta = 1/\|PH(\psi)\|$. Then

$$A(\psi') = \langle \psi', e^+ \rangle e^+ - \langle \psi', e^- \rangle e^-, \tag{15}$$

where

$$e^{\pm} = \frac{1}{\sqrt{2}} \left(i \frac{PH(\psi)}{\|PH(\psi)\|} \pm \psi \right). \tag{16}$$

This choice of A is bounded and has the discrete spectrum $\sigma(A) = \{1, -1, 0\}$ and corresponding eigenspaces span$\{e^+\}$, span$\{e^-\}$, and (span$\{e^+, e^-\}$)$^\perp$. In fact $\psi(t) = \exp(-it/\hbar)H(\psi)$ is in the range space of A, i.e., span$\{e^+, e^-\}$, to first order in t.

Proof: We establish that the infimum in the last expression in (13) is a minimum. Then the remarks above show that the previous expressions in (13) are also infimized since θ gives rise to a self-adjoint operator A such that $A(\psi) = \theta$ and A even can be chosen to satisfy (7) (for example, take A to be globally defined and thus bounded).

Write θ in (13) in the form $\theta = \alpha\psi + \gamma PH(\psi) + \psi'$, where ψ' is taken to be orthogonal to ψ and $PH(\psi)$, and α and γ are unknown scalars. Since we require in (13) that $\mathrm{Im}(\langle \psi, \theta \rangle) = 0 \neq \mathrm{Im}(\langle H(\psi), \theta \rangle)$, then α must be real and

$$\begin{aligned} \mathrm{Im}(\langle H(\psi), \theta \rangle) &= \mathrm{Im}(\langle H(\psi), \gamma PH(\psi) \rangle) \\ &= \mathrm{Im}(\overline{\gamma})(\|PH(\psi)\|^2) = \mathrm{Im}(\overline{\gamma})(\|H(\psi) - \langle H(\psi), \psi \rangle \psi\|^2) = \mathrm{Im}(\overline{\gamma})(\Delta_\psi H)^2. \end{aligned} \tag{17}$$

So γ cannot be real.

The ratio inside the final set of braces in (13) (with $\hbar/2$ omitted) is

$$\frac{\|\theta - \langle \theta, \psi \rangle \psi\|}{|\mathrm{Im}(\langle H(\psi), \theta \rangle)|} = \frac{\sqrt{|\gamma|^2 (\Delta_\psi H)^2 + \|\psi'\|^2}}{|\mathrm{Im}(\overline{\gamma})| (\Delta_\psi H)^2} \geqslant \frac{1}{\Delta_\psi H} \tag{18}$$

and equality holds if and only if ψ' is the zero vector and γ is a nonzero pure imaginary number $i\beta$. ■

The above proof establishes the TEUP, and even transforms it into an equality. The quantity $\Delta_\psi t = \hbar/2\Delta_\psi H$ depends on both ψ and H, and can be thought of as a kind of fundamental unit of time for the given state and evolutionary law. In any shorter time interval, with the caveats noted earlier, there is no appreciable distinction between dynamics and statics. Since $\hbar$ is small, this unit is usually small, but in some cases (states that are approximate eigenvectors of the energy observable) it can be large and the system is in a metastable state.

Certain observables allow one to achieve the infimum $\Delta_\psi t$, and allow us, so to speak, to detect the temporal change in statistics. These observables take ψ to $\alpha\psi + i\beta PH(\psi)$, and the significant part of this (set $\beta = -1/\hbar$ and $\alpha = 0$) is merely $(-i/\hbar)PH(\psi) = P(\mathrm{d}\psi/\mathrm{d}t)$, the projection of the time derivative of ψ perpendicular to ψ. From this perspective the TEUP, despite its assured perennial interest, appears almost trivial, the time required to detect change is the time τ required for the dynamic uncertainty of such an observable A to achieve the same magnitude as its static uncertainty. A moment's computation shows that the static uncertainty is

$$\begin{aligned} \Delta_\psi A = \|A(\psi) - \langle A(\psi), \psi \rangle \psi\| &= \left\| P\left(\frac{\mathrm{d}}{\mathrm{d}t}\psi\right) - \left\langle P\left(\frac{\mathrm{d}}{\mathrm{d}t}\psi\right), \psi \right\rangle \psi \right\| \\ &= \left\| P\left(\frac{\mathrm{d}}{\mathrm{d}t}\psi\right) \right\| = \frac{1}{\hbar}\|PH(\psi)\| = \frac{1}{\hbar}\|H(\psi) - \langle H(\psi), \psi \rangle \psi\| = \frac{1}{\hbar}\Delta_\psi H \end{aligned}$$

and by (6)

$$\frac{\mathrm{d}}{\mathrm{d}t}\mu_\psi(A) = \frac{2}{\hbar}\,\mathrm{Im}(\langle H(\psi), A(\psi)\rangle) = \frac{2}{\hbar}\,\mathrm{Im}\left(\left\langle H(\psi), P\left(\frac{\mathrm{d}}{\mathrm{d}t}\psi\right)\right\rangle\right)$$

$$= \frac{2}{\hbar}\,\mathrm{Im}\left(\frac{-i}{\hbar}\langle H(\psi), PH(\psi)\rangle\right) = \frac{2}{\hbar^2}\|PH(\psi)\|^2 = \frac{2}{\hbar^2}(\Delta_\psi H)^2.$$

Since $\tau\times(2/\hbar^2)(\Delta_\psi H)^2 = |(1/\hbar)\Delta_\psi H|$, we find that $\tau = \hbar/2\Delta_\psi H$.

IV. AFTERWORD

An alternative to the TEUP discussed here is the *half-life* version, in which Δt is an estimate of the time that must elapse before there is a 50% probability that the state is orthogonal to the original state. Pfeifer and Fröhlich[8] propose six different variants of the half-life TEUP. Allcock[2–4] and Wigner[5] have also proposed versions of the TEUP. Their treatments are somewhat obscure since they do not establish square integrability of the wave function with respect to time. Quantum estimation theory, as already mentioned, yields a quantum Cramer–Rao inequality which has the form of a general TEUP.

Busch[13] proposes three useful notions of time: (1)laboratory or clock or external time, (2) dynamic or internal time, and (3) observable or event time. TEUPs can be formulated in terms of each.

Indeed, multiple versions and interpretations of the TEUP should be accepted as a fact of life. The product of time and energy has the same units as Planck's celebrated constant, and it should not be surprising to find that significant time intervals and energy intervals derived from a variety of physical scenarios can be related to $\hbar$.

The status of Δt in the Mandelstam–Tamm TEUP and most other TEUPs is quite different from that of Δx in Heisenberg's uncertainty principle. An important part of the program of relativistic quantum mechanics is to establish the comparability and equal footing of space and time. However, the Mandelstam–Tamm and half-life version of the TEUP, and the equality established in this paper, are actually obstacles to achieving this objective. Time here is clock time and is the parameter of the unitary group of state evolution generated by the Hamiltonian. The quantity $\Delta_\psi t$ is not the standard deviation of an observable, but is the infimum of the ratio of static uncertainty to dynamic uncertainty per unit time, with the caveats noted above.

ACKNOWLEDGMENT

The authors thank Dan Parks for helpful comments on this work, and note that he has developed yet another version of the TEUP in the context of weak energy.[14]

(Received 14 December 2004; accepted 14 February 2005; published online 29 April 2005)

There exists an example of a set of 40 projective lines in eight-dimensional Hilbert space producing a Kochen–Specker-type contradiction. This set corresponds to a known no-hidden variables argument due to Mermin. In the present paper it is proved that this set admits a finite saturation, i.e., an extension up to a finite set with the following property: every subset of pairwise orthogonal projective lines has a completion, i.e., is contained in at least one subset of eight pairwise orthogonal projective lines. An explicit description of such an extension consisting of 120 projective lines is given. The idea to saturate the set of projective lines related to Mermin's example together with the possibility to have a finite saturation allow to find the corresponding group of symmetry. This group is described explicitely and is shown to be generated by reflections. The natural action of the mentioned group on the set of all subsets of pairwise orthogonal projective lines of the mentioned extension is investigated. In particular, the restriction of this action to complete subsets is shown to have only four orbits, which have a natural characterization in terms of the construction of the saturation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1887923]

I. INTRODUCTION

The analysis of the foundations of quantum theory has two important results, (1) Bell's inequalities; (2) Kochen–Specker theorem. Both of them show that in quantum mechanics a statistical model of a physical experiment may not admit a realization by way of a probability space $(\Omega,\mathcal{F},P)$. The first result shows, that even if one assumes the existence of a measurable space $(\Omega,\mathcal{F})$, one might not be able to consruct a probability measure P. The second result shows that the assumption about the existence of $(\Omega,\mathcal{F})$ may itself be contradictory.

The Bell–Kochen–Specker theory[2,5] restricts itself to considering the measuring devices with only two possible indications. In this case the problem cocerning the existence of $(\Omega,\mathcal{F})$ reduces to a problem about coloring projective lines in a finite dimensional Hilbert space. It is possible to reformulate this problem as follows.[8] Let $\mathcal{H}$ be a Hilbert space over $\mathbb{C}$ of finite dimension $n := \dim_{\mathbb{C}} \mathcal{H}$. Suppose one is given a family of $m \in \mathbb{N}$ orthonormal bases in $\mathcal{H}$: $\{e_i^{(\alpha)}\}_{i=1}^{n}$, $\alpha=\overline{1,m}$. Choose from each basis an element $e_{i_\alpha}^{(\alpha)}$, $\alpha=\overline{1,m}$, and look at the inner products $(e_{i_\alpha}^{(\alpha)}, e_{i_\beta}^{(\beta)})$, $\alpha,\beta=\overline{1,m}$. Is it always possible to make this choice in such a way, that for all α and β the inner product of $e_{i_\alpha}^{(\alpha)}$ and $e_{i_\beta}^{(\beta)}$ does not vanish, i.e., the (projective) lines $\mathbb{C}e_{i_\alpha}^{(\alpha)}$ and $\mathbb{C}e_{i_\beta}^{(\beta)}$ are *not* orthogonal?

One says that a collection of projective lines $\{\mathbb{C}e_i^{(\alpha)}\}_{i,\alpha}$ produces a *Kochen–Specker-type con-*

tradiction if the answer to the formulated question is "No." The original construction by Kochen and Specker in the proof of their theorem generates the first example of this contradiction. Since then several other examples of this type have been found, in particular Refs. 7, 6, 9, 4, and 1. In the present paper we analyze one of them—the example coming from the proof of a no-hidden-variables theorem given by Mermin.[6] Note, that the latter example can be related to the discussion of Einstein–Podolsky–Rosen paradox and Bell's theorem in Ref. 3.

The original construction of Kochen and Specker is quite sophisticated. This is determined by the fact that the authors work in a three-dimensional space. The construction of Mermin and the corresponding proof are much more simple, but the space is eight-dimensional. To be exact, the original paper of Mermin is written in terms of operators on a Hilbert space and the reformulation in terms of projective lines is due to Kernaghan and Peres.[4] In general, the latter consists in the following. One defines a set of 40 projective lines in $\mathbb{C}^8$. The corresponding description is explicit and quite simple. If one views the elements of $\mathbb{C}^8$ as columns of eight complex numbers, then it is possible to represent each of the 40 projective lines by a column with entries 0, 1 or −1. Thus in fact the projective lines can even be viewed as real. The corresponding Kochen–Specker contradiction is then established by some simple arithmetic argument. The link with the Mermin's formulation is as follows. The described set splits into five distinct tuples, each containing eight pairwise orthogonal projective lines. Identifying $\mathbb{C}^8$ with $(\mathbb{C}^2)^{\otimes 3}$ and interpreting each of the five tuples as coming from an orthonormal basis corresponding to some complete set of pairwise commuting orthogonal projectors, one arrives at five complete sets playing a key role in Ref. 6.

There is another well-known example—the "Penrose dodecahedron"—studied in detail by Zimba and Penrose in Ref. 9. In this case one again makes use of 40 projective lines, but this time in $\mathbb{C}^4$. In the corresponding construction one considers a dodecahedron and associates in a certain way to each of its 20 vertices two projective lines in $\mathbb{C}^4$. The whole construction has the symmetry group of a dodecahedron, which naturally acts on the resulting set of 40 projective lines. Comparing the examples of Penrose and of Mermin, it is natural to ask, what can one say about the symmetry of Mermin's example? An additional motivation for this is given by the two examples described in Ref. 1 which also have a high degree of symmetry. One of them is associated to a 120 cell (a four-dimensional analog of dodecahedron), and the other to a 600 cell (a four-dimensional analog of icosahedron). It turns out, that despite of the fact that the projective lines in Mermin's case look quite simple, an answer to this question, as was mentioned in Ref. 4, presents a problem. Its possible solution constitutes the subject of the present paper.

II. SATURATED KOCHEN–SPECKER

Let A denote a set of projective lines in Hilbert space $\mathcal{H}$, $\dim_{\mathbb{C}} \mathcal{H}=n<\infty$. The set A is called *saturated* with respect to orthogonality relation $\perp$ if any of its subsets $B\subset A$ of pairwise orthogonal projective lines can be embedded into a subset $C\subset A$ of n pairwise orthogonal projective lines. Denote $\mathcal{P}_{\perp}(A):=\{B\subset A \,|\, \forall x,y\in B: x\neq y \Rightarrow x\perp y\}$. Denote $C(A):=\{B\in\mathcal{P}_{\perp}(A)\,|\,\#B=n\}$. The elements of $C(A)$ will be called *complete* subsets of A. Note that $\mathcal{P}_{\perp}(A)$ contains an empty set and all subsets of cardinality 1. Note that if A produces a Kochen–Specker contradiction, then $C(A)$ is not empty.

If one looks at the mentioned example of Mermin, one observes that the corresponding set is *not* saturated with respect to $\perp$. Intuitively, a saturated set should have a higher degree of symmetry than an unsaturated part of it [an example of a saturated set is the set $\mathbb{P}(\mathcal{H})$ of *all* projective lines in $\mathcal{H}$]. This leads to the idea of how to investigate the symmetry of Mermin's example. One may try to add projective lines to the given set so that to get a saturated set. After that it makes sense to proceed with the symmetry. Naively, such an attempt should look as follows. One takes a subset of pairwise orthogonal lines, tries to find a complete set containing it, and in case there is no such one, invents several other pairwise orthogonal projective lines to make it complete. These new projective lines are added to the initial set, and the whole process is repeated until one reaches a saturation. At each step one solves the problem for the chosen subset, but at the same time one may create other subsets of pairwise orthogonal elements which require a completion. It means, that *a priori* the described algorythm is not even finite.

In the next section we are going to describe a *finite* set A of projective lines in $\mathcal{H}$, $\dim_{\mathbb{C}} \mathcal{H} = 8$, with the following properties: (1) A is saturated with respect to $\perp$; (2) A contains a set of Mermin–Kernaghan–Peres projective lines and due to this, in particular, produces a Kochen–Specker-type contradiction; (3) *every* element of A can be represented by a column with each of the eight entries being 0, 1 or -1.

After that we proceed with the study of the symmetry of the set A. One looks at $Bij(A)$—a group of all bijections of A, and denotes by $Bij_{\perp}(A)$ its subgroup consisting of all bijections which respect the orthogonality relation $\perp$. The set $C(A)$ naturally splits into four disjoint subsets denoted as $C_k(A)$, $k=1,2,4,8$, as will be explained below. We describe a subgroup $\mathcal{G}$ in $Bij_{\perp}(A)$ by giving explicit formulas for a set of its generators and prove, that this group has an action on $C(A)$ such that $C_k(A)$'s conicide with its orbits. It means that one can take any element of $C_k(A)$ and then generate all the other complete subsets belonging $C_k(A)$ by applying the elements of this group. This allows to describe the symmetry of Mermin's example.

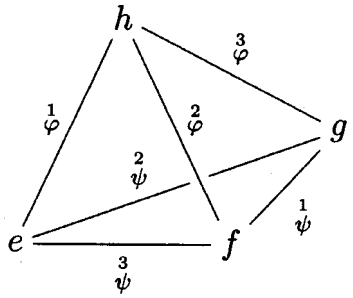
III. 120 PROJECTIVE LINES

We shall now describe a set A which will later be proved to be a saturated extension of Mermin's example. Set $\mathcal{H} := \mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$. Recall that one has denoted the set of all projective lines in $\mathcal{H}$ by $\mathbb{P}(\mathcal{H})$. Let V denote a set of four symbols, $V=\{e,f,g,h\}$. We are going to describe a map

$$\xi: \mathcal{P}(V)^{\times} := \mathcal{P}(V) \setminus \{\varnothing\} \to C(\mathbb{P}(\mathcal{H})),$$

such that $\forall U, U' \in \mathcal{P}(V)^{\times}: U \neq U' \Rightarrow \xi(U) \cap \xi(U') = \varnothing$. Note that the latter in particular implies that ξ is injective. Since $\#\mathcal{P}(V)^{\times} = 15$ and $\dim_{\mathbb{C}}(\mathcal{H}) = 8$, the union of all the sets from the image of ξ must yield 120 projective lines. This will produce the set A.

The set $\mathcal{P}(V)^{\times}$ may be visualized as a tetrahedron with vertices labeled as e, f, g, and h. Considering the subsets of V, one identifies the vertices with the subsets of cardinality 1, the edges with subsets of cardinality 2, faces with subsets of cardinality 3, and the body of the tetrahedron with V. Assign to the edges of this graph labels of the form $\overset{\omega}{\varphi}$ or $\overset{\omega}{\psi}$ where φ and ψ are two symbols and ω is a number 1, 2 or 3. Require, that the edges associated to the same vertex have different numbers ω. This defines the labelling of the edges of the graph up to a permutation of labels of vertices. Without loss of generality, one may choose and fix the labeling as shown in



(1)

Note that this tetrahedron appears in Ref. 8.

Choose an arbitrary orthonormal basis $\{\varphi_\alpha\}_{\alpha=0,1}$ in $\mathbb{C}^2$. It will be convenient to view the possible values 0 and 1 of the index α as elements of the group $\mathbb{Z}_2$ with the group operation written additively (addition modulo 2). Consider a matrix $u := \|u(\alpha,\beta)\|_{\alpha,\beta\in\mathbb{Z}_2}$ with entries $u(\alpha,\beta) = -1$ if $(\alpha,\beta) = (1,1)$ and $u(\alpha,\beta) = 1$ otherwise. Note that it can be viewed as a character matrix of $\mathbb{Z}_2$. There exist the following properties:

$$(1) \quad u(\alpha,\beta) = u(\beta,\alpha) \in \mathbb{R},$$

$$(2)\quad \sum_{\beta} u(\alpha,\beta)u(\beta,\gamma) = 2\delta_{\alpha,\gamma},$$

$$(3)\quad u(\alpha,1+\alpha) = 1, \tag{2}$$

$$(4)\quad u(\alpha,\beta+\gamma) = u(\alpha,\beta)u(\alpha,\gamma),$$

where α, β, γ run over $\mathbb{Z}_2$. Denote $u^{\beta}_{\alpha} := u(\alpha,\beta)/\sqrt{2}$ and define another orthonormal basis $\{\psi_\alpha\}_\alpha$ in $\mathbb{C}^2$: $\psi_\alpha := \Sigma_\beta u^{\beta}_{\alpha}\varphi_\beta$.

We shall associate to the mentioned graph and a fixed choice of an orthonormal basis $\{\varphi_\alpha\}_\alpha$ a set A of 120 projective lines in $\mathcal{H}$ expressed via the functions φ_α and the matrix u. It means that there will be a complete set associated to every vertex of the graph (this gives four complete sets), to every edge (this gives six more complete sets), to every face (this gives four complete sets) and to the whole tetrahedron (this gives one complete set). In what follows we use the notation: write $\hat{e}$ instead of $\{e\}$ to refer to a vertex, write ef instead of $\{e,f\}$ to denote an edge, write efg or $\overline{h}$ to denote the face $\{e,f,g\}$, and write $efgh$ instead of $\{e,f,g,h\}$.

Let us start with the description of the complete sets corresponding to vertices. Denote a set of all edges having a common vertex $v \in V$ by E_v, and consider a set

$$S_{\hat{v}} := \mathrm{Maps}(E_v \to \mathbb{Z}_2), \quad v \in V.$$

This set is not empty and contains eight elements. Take any v, say $v=e$, and take any $\sigma \in S_{\hat{e}}$. The labels of the edges eh, eg, and ef from E_e are of the form φ^1, ψ^2, and ψ^3, respectively. Associate to this fact a vector $\Psi^{(e)}_{\sigma} := \varphi_{\sigma(eh)} \otimes \psi_{\sigma(eg)} \otimes \psi_{\sigma(ef)}$. The vectors $\Psi^{(v)}_{\sigma}$ for other $v \in V$ are defined in a similar way. As a result one gets for every vertex v an orthonormal basis $\{\Psi^{(v)}_{\sigma}\}_{\sigma\in S_{\hat{v}}}$. Denote $\Psi^{v}_{\sigma} := \mathbb{C}\Psi^{(v)}_{\sigma}$. It follows, that one has four complete sets of projective lines associated to each vertex. One defines $\xi(\hat{v}) := \{\Psi^{v}_{\sigma}\}_{\sigma\in S_{\hat{v}}}$, $v \in V$.

The complete sets associated to edges make use of a slightly more sophisticated indexing. We denote by $E := \{ef, eg, eh, fg, fh, gh\}$ the set of all edges. To define a complete set of projective lines corresponding to an edge, one first takes an arbitrary *ordered* pair of two distinct vertices (v,w). Let z and t denote the remaining two vertices of the graph. Consider a disjoint union of a one-element set $\{vw\}$ and a two-element set $\{z,t\}$ and denote

$$K_{vw} := \mathrm{Maps}(\{vw\} \sqcup \{z,t\} \to \mathbb{Z}_2).$$

Note, that $\#K_{vw}=8$. The complete set of projective lines corresponding to the edge vw will be indexed by the elements of K_{vw}. Take $v=e$, $w=f$ and take arbitrary $\varkappa \in K_{ef}$. Recall that the labels of the edges eh, eg, and ef from E_e are of the form φ^1, ψ^2, and ψ^3, respectively. Denote

$$X^{(e\to f)}_{\varkappa} := \sum_{\alpha,\mu\in\mathbb{Z}_2} u^{\mu}_{\alpha} u^{\varkappa(h)}_{\alpha} u^{\varkappa(g)}_{\mu} \varphi_\alpha \otimes \psi_\mu \otimes \psi_{\varkappa(ef)}.$$

One defines the vectors $X^{(v\to w)}_{\varkappa}$, $\varkappa \in K_{vw}$, corresponding to every ordered pair (v,w), $v \neq w$, in a similar way. Using the properties of the matrix u, one can prove that

(1) the vectors $X^{(v\to w)}_{\varkappa}$, $\varkappa \in K_{vw}$, are pairwise orthogonal,
(2) the projective lines $\mathbb{C}X^{(v\to w)}_{\varkappa}$ and $\mathbb{C}X^{(w\to v)}_{\varkappa}$ coincide.

The latter fact motivates the notation $X^{vw}_{\varkappa} := \mathbb{C}X^{(v\to w)}_{\varkappa}$. The first fact implies, that $\{X^{vw}_{\varkappa}\}_{\varkappa\in K_{vw}}$ is a complete set of projective lines. It follows, that one gets six complete sets of projective lines associated to each edge of the graph. One defines $\xi(\epsilon) := \{X^{\epsilon}_{\varkappa}\}_{\varkappa\in K_{\epsilon}}$, $\epsilon \in E$.

Let us construct the complete sets associated to faces of the tetrahedron. Actually, every face is determined by an opposite vertex of the tetrahedron, and in this sense the complete sets to be constructed can be viewed as associated to vertices. It is simply natural to view them as associated to faces since the role of complete sets associated to vertices is already occupied. Denote

$$R_{\overline{v}} := \mathrm{Maps}(E \setminus E_v \to \mathbb{Z}_2), \quad v \in V.$$

This set is not empty, contains eight elements, and moreover, there is a natural bijection $\nu_v : R_{\overline{v}} \xrightarrow{\sim} S_{\hat{v}}$ established by the formula $\nu_v(\rho)(vw) = \rho(zt)$, where z and t are the vertices complementing $\{v, w\}$ up to V. If there is no risk of confusion, we write ρ^* instead of $\nu_v(\rho)$, $\rho \in R_{\overline{v}}$, as well as σ^* instead of $\nu_v^{-1}(\sigma)$, $\sigma \in S_{\overline{v}}$. Now take $v = e$ and any $\rho \in R_{\overline{e}}$. Recall that the labels of the edges eh, eg, and ef from E_e are of the form φ^1, ψ^2, and ψ^3, respectively. Denote

$$\Phi_\rho^{(e \to f)} := \sum_{\alpha, \mu \in \mathbb{Z}_2} u_\alpha^{\rho^*(eh)+\rho^*(ef)} u_\mu^{\rho^*(eg)+\rho^*(ef)} \varphi_\alpha \otimes \psi_\mu \otimes \psi_{\Delta_\rho + \alpha + \mu},$$

where $\Delta_\rho := \Sigma_{\epsilon \in E \setminus E_e} \rho(\epsilon)$. The vectors $\Phi_\rho^{(v \to w)}$ corresponding to other choices of $v, w \in V, v \neq w$ are defined in a similar way. The properties of the matrix u imply that the vectors $\Phi_\rho^{(v \to w)}, \rho \in R_{\overline{v}}$, are pairwise orthogonal and that $\mathbb{C}\Phi_\rho^{(v \to w)}$ does not depend on the choice of w. Denote, $\Phi_\rho^v := \mathbb{C}\Phi_\rho^{(v \to w)}$. It follows, that to every face $\overline{v}$ one associates a complete set of projective lines $\{\Phi_\rho^v\}_{\rho \in R_{\overline{v}}}$. One defines $\xi(\overline{v}) := \{\Phi_\rho^v\}_{\rho \in R_{\overline{v}}}$, $v \in V$.

Let us finally associate a complete set of projective lines to the whole tetrahedron. Denote

$$\Lambda := \left\{ \pi : V \to \mathbb{Z}_2 \middle| \sum_{v \in V} \pi(v) = 1 \right\}.$$

Note, that $\#\Lambda = 8$. Take an *ordered* pair $(e, f) \in V \times V$. Recall that the labels of the edges eh, eg, and ef from E_e are of the form φ^1, ψ^2, and ψ^3, respectively,

$$F_\pi^{(e \to f)} := \sum_{\alpha, \mu \in \mathbb{Z}_2} u_{\pi(h)}^{\pi(g)+\mu} u_\alpha^{\pi(g)+\mu} \varphi_\alpha \otimes \psi_\mu \otimes \psi_{\pi(e)+\alpha+\mu}.$$

Note, that using the properties of the matrix u one can prove that the expression $u_a^{m+\mu} u_\alpha^{m+\mu}$ remains invariant under the transposition $(a, \alpha) \rightleftarrows (m, \mu)$. The vectors $F_\pi^{(u \to v)}$ corresponding to other ordered pairs are defined in a similar way. Using the properties of u, one can prove, that

(1) the vectors $F_\pi^{(v \to w)}$, $\pi \in \Lambda$, are pairwise orthogonal,
(2) the projective line $\mathbb{C}F_\pi^{(v \to w)}$ does not depend on the choice of the ordered pair (v, w).

The latter fact motivates the notation $F_\pi := \mathbb{C}F_\pi^{(v \to w)}$. The first fact implies, that $\{F_\pi\}_{\pi \in \Lambda}$ is a complete set of projective lines. One defines $\xi(efgh) := \{F_\pi\}_{\pi \in \Lambda}$. This completes the definition of ξ.

Note that the projective lines of the form Ψ_σ^v and F_π have been introduced in Ref. 8, but the set $\{F_\pi\}_\pi$ was not viewed as a complete set associated to the whole tetrahedron (1), since the projective lines of the form $X_\varkappa^{vw}$ and Φ_ρ^v did not exist. One can find the calculations illustrating the mentioned properties of F_π in Ref. 8. The definition of $X_\varkappa^{vw}$ and Φ_ρ^v is new.

Now we have a map $\xi : \mathcal{P}(V)^\times \to C(\mathbb{P}(\mathcal{H}))$. One verifies, that all the described projective lines are distinct. It means, that one gets 15 disjoint complete sets of projective lines in $\mathcal{H}$, for every vertex $v \in V$ a set $\{\Psi_\sigma^v\}_{\sigma \in S_{\hat{v}}}$; for every edge $\epsilon \in E$ a set $\{X_\varkappa^\epsilon\}_{\varkappa \in K_\epsilon}$; for every face $\overline{v}$, $v \in V$, a set $\{\Phi_\rho^v\}_{\rho \in R_{\overline{v}}}$; and for the whole tetrahedron a set $\{F_\pi\}_{\pi \in \Lambda}$. The set $A := \sqcup_{U \in Im(\xi)} U$ has a cardinality $\#A = 120$. We claim, that the set A is saturated with respect to the orthogonality relation $\perp$ and produces a Kochen–Specker-type contradiction.

IV. RELATIONS BETWEEN THE PROJECTIVE LINES

Let us describe the orthogonality relations between the elements of the set A. All these relations follow from the properties (2) of the matrix u. Recall that if $\rho \in R_{\overline{v}}$, then one denotes by ρ^* its image under the natural bijection $\nu_v : R_{\overline{v}} \xrightarrow{\sim} S_{\hat{v}}$. Simillarly, if $\sigma \in S_{\hat{v}}$, one writes σ^* instead of

$\nu_v^{-1}(\sigma) \in R_{\bar{v}}$. If $\sigma \in S_{\hat{v}}$, let $\nabla_\sigma := \Sigma_{\epsilon \in E_v} \sigma(\epsilon)$. If $\varkappa \in K_{\boldsymbol{\epsilon}}$, say $\boldsymbol{\epsilon} = ef$, then let $\tilde{\varkappa}$ denote an element of K_{ef} defined by $\tilde{\varkappa}(ef) = 1 + \varkappa(ef) + \varkappa(g) + \varkappa(h)$, $\tilde{\varkappa}(g) = \varkappa(h)$, $\tilde{\varkappa}(h) = \varkappa(g)$. For other $\boldsymbol{\epsilon}$ the notation $\tilde{\varkappa}$ for $\varkappa \in K_{\boldsymbol{\epsilon}}$ is defined in a similar way. Note that $\rho^{**} = \rho$, $\sigma^{**} = \sigma$, and $\tilde{\tilde{\varkappa}} = \varkappa$.

We explicitly describe part of the relations. The others are obtained by permutation of the symbols e, f, g, and h,

(1) $\Psi^e_\sigma \perp \Psi^e_{\sigma'}$ iff $\sigma(\cdot) \neq \sigma'(\cdot)$,
(2) $\Psi^e_\sigma \perp \Psi^f_{\sigma_1}$ iff $\sigma(ef) = 1 + \sigma_1(ef)$,
(3) $\Phi^e_\rho \perp \Phi^e_{\rho'}$ iff $\rho^*(\cdot) \neq \rho'^*(\cdot)$,
(4) $\Phi^e_\rho \perp \Phi^f_{\rho_1}$ iff $\rho^*(ef) = 1 + \rho_1^*(ef)$,
(5) $X^{ef}_\varkappa \perp X^{ef}_{\varkappa'}$ iff $\varkappa(\cdot) \neq \varkappa'(\cdot)$,
(6) $X^{ef}_\varkappa \perp X^{eg}_{\varkappa_1}$ iff $\varkappa(ef) + \varkappa(h) = 1 + \varkappa_1(eg) + \varkappa_1(h)$,
(7) $X^{ef}_\varkappa \perp X^{gh}_{\varkappa_1}$ iff $\varkappa(g) + \varkappa(h) = \varkappa_1(e) + \varkappa_1(f)$,
(8) $F_\pi \perp F_{\pi'}$ iff $\pi(\cdot) \neq \pi'(\cdot)$,
(9) $\Psi^e_\sigma \perp \Phi^e_\rho$ iff $\nabla_\sigma = 1 + \nabla_{\rho^*}$,
(10) $\Psi^e_\sigma \perp \Phi^f_\rho$ iff $\nabla_\sigma + \sigma(ef) = 1 + \nabla_{\rho^*} + \rho^*(ef)$,
(11) $\Psi^e_\sigma \perp X^{ef}_\varkappa$ iff $\sigma(ef) = 1 + \varkappa(ef)$,
(12) $\Psi^e_\sigma \perp X^{fg}_\varkappa$ iff $\sigma(ef) + \sigma(eg) = 1 + \tilde{\varkappa}(e)$,
(13) $\Phi^e_\rho \perp X^{ef}_\varkappa$ iff $\rho^*(ef) = 1 + \tilde{\varkappa}(ef)$,
(14) $\Phi^e_\rho \perp X^{fg}_\varkappa$ iff $\rho^*(ef) + \rho^*(eg) = 1 + \varkappa(e)$,
(15) $\Psi^e_\sigma \perp F_\pi$ iff $\nabla_\sigma = 1 + \pi(e)$,
(16) $\Phi^e_\rho \perp F_\pi$ iff $\nabla_{\rho^*} = 1 + \pi(e)$,
(17) $X^{ef}_\varkappa \perp F_\pi$ iff $\varkappa(g) + \varkappa(h) = 1 + \pi(g) + \pi(h)$.

Note, that there is no 1 in the formula (7). Note that these relations have a self-duality property. Namely, the condition for orthogonality in (5) is equivalent to $\tilde{\varkappa}(\cdot) \neq \tilde{\varkappa}'(\cdot)$, the condition in (6) is equivalent to $\tilde{\varkappa}(ef) + \tilde{\varkappa}(h) = 1 + \tilde{\varkappa_1}(eg) + \tilde{\varkappa_1}(h)$, the condition in (7) is equivalent to $\tilde{\varkappa}(g) + \tilde{\varkappa}(h) = \tilde{\varkappa_1}(e) + \tilde{\varkappa_1}(f)$, and the condition in (17) is equivalent to $\tilde{\varkappa}(g) + \tilde{\varkappa}(h) = 1 + \pi(g) + \pi(h)$. It follows, that if one has a set of pairwise orthogonal projective lines of the form $\{\Psi^{v_i}_{\sigma_i}\}_{i \in I} \cup \{X^{\epsilon_j}_{\varkappa_j}\}_{j \in J} \cup \{\Phi^{w_l}_{\rho_l}\}_{l \in L} \cup \{F_{\pi_m}\}_{m \in M}$, where I, J, L, M are some index sets, $v_i, w_l \in V$, $\boldsymbol{\epsilon}_j \in E$, then by replacing $\Psi^{v_i}_{\sigma_i}$ with $\Phi^{v_i}_{\sigma_i^*}$, $\Phi^{w_l}_{\rho_l}$ with $\Psi^{w_l}_{\rho_l^*}$ and $X^{\epsilon_j}_{\varkappa_j}$ with $X^{\bar{\epsilon}_j}_{\tilde{\varkappa}_j}$, one obtains a set of projective lines $\{\Phi^{v_i}_{\sigma_i^*}\}_{i \in I} \cup \{X^{\epsilon_j}_{\tilde{\varkappa}_j}\}_{j \in J} \cup \{\Psi^{w_l}_{\rho_l^*}\}_{l \in L} \cup \{F_{\pi_m}\}_{m \in M}$, which are still pairwise orthogonal. It follows, that one has a map $\delta: A \to A$, $\delta^2 = id$, which respects the orthogonality relation $\perp$. Call $\delta \in Bij_\perp(A)$ the *duality map*.

V. LINK TO MERMIN'S EXAMPLE

Let us prove that the set A produces a Kochen–Specker-type contradiction and establish the link with the example of Mermin. Denote

$$\Gamma(A) := \{\phi: C(A) \to A \,|\, \forall\, B \in C(A): \phi(B) \in B\},$$

$$\Delta(A) := \{\phi \in \Gamma(A) \,|\, \forall\, B, B' \in C(A): B \neq B' \Rightarrow \neg\, (\phi(B) \perp \phi(B'))\}.$$
