V. THE BONDI ENERGY FORMULA

The aim of this section is to implement the strategy of the preceding section for an asymptotic translation symmetry in even space–time dimensions $d>4$, i.e., to show that a generator $\mathcal{H}_\xi$ exists for such a symmetry, and to derive an expression for this generator. We will take this $\mathcal{H}_\xi$ as the definition of the Bondi energy momentum (Bondi energy, for short) in space–times of even dimension $d>4$.

The crucial issue regarding the existence of a generator conjugate to asymptotic symmetries is whether the symplectic current ω has a (finite) restriction to $\mathscr{I}$and whether there exists, under our choice of boundary conditions, a potential Θ for the pull-back (50) of the symplectic current density to $\mathscr{I}$, i.e., a Θ satisfying (40). We now examine these issues.

We fix the conformal factor Ω once and for all, so that, if $(\tilde{M},\tilde{g}_{ab})$ is an asymptotically flat space–time, then $g_{ab}=\Omega^2\tilde{g}_{ab}$ satisfies Eqs. (69) with this fixed choice of Ω. Consider a solution $\delta\tilde{g}_{ab}$ of the linearized field equations that preserves asymptotic flatness to first order. Then the quantities $\tau_{ab}=\Omega^{-(d-6)/2}\delta\tilde{g}_{ab}$, $\tau_a=\Omega^{-1}\tau_{ab}n^b$ are finite and smooth at $\mathscr{I}$and $\tau_a{}^a$ and $n^a\tau_a$ vanish at $\mathscr{I}$. We substitute these relations into the definition of the symplectic current, use the relation (20) between the physical and unphysical derivative, the relation

$$\tilde{\epsilon}_{s_1\cdots s_d} = \Omega^{-d}\epsilon_{s_1\cdots s_d} \tag{47}$$

between the physical and unphysical volume element, and evaluate at $\mathscr{I}$. After some algebra, we find the simple result

$$\omega_{s_1\cdots s_d} = \frac{1}{32\pi G}(\tau_1^{bc}\nabla^m\tau_{2bc} - \tau_2^{bc}\nabla^m\tau_{1bc})\epsilon_{ma_1\cdots a_{d-1}} + O(\Omega), \tag{48}$$

noticing that this is finite at $\mathscr{I}$ (this formula is valid only in $d>4$). This expression can be rewritten somewhat more conveniently introducing a $(d-1)$-form ${}^{(d-1)}\boldsymbol{\epsilon}$ by the formula

$${}^{(d)}\boldsymbol{\epsilon}_{ma_1\cdots a_{d-1}} = d\cdot n_{[m}\,{}^{(d-1)}\boldsymbol{\epsilon}_{a_1\cdots a_{d-1}]} = (n\wedge{}^{(d-1)}\boldsymbol{\epsilon})_{ma_1\cdots a_{d-1}}, \tag{49}$$

where we have set a superscript on the quantities in order to indicate the degree of the form. [Note that ${}^{(d-1)}\boldsymbol{\epsilon}$ is only defined up to the addition of a $(d-1)$-form of the form $n\wedge{}^{(d-2)}\phi$, where ${}^{(d-2)}\phi$ is arbitrary. The addition of such a form does however not make any difference in the formulas given above.] The pull-back to $\mathscr{I}$ of the symplectic current $(d-1)$-form ω can then be written as

$$\zeta^*\,\omega_{a_1\cdots a_{d-1}} = \frac{1}{32\pi G}(\tau_1^{bc}n^m\nabla_m\tau_{2bc} - \tau_2^{bc}n^m\nabla_m\tau_{1bc})\epsilon_{a_1\cdots a_{d-1}}, \tag{50}$$

where ζ^* denotes the pull-back of a covariant tensor field to $\mathscr{I}$. Thus, it follows from this expression that the pull-back of the symplectic current form to $\mathscr{I}$ is finite and smooth for any linear perturbation preserving our asymptotic flatness condition.

We next look for a potential Θ for (50). The subsequent calculations are somewhat simplified using the tensor S_{ab} defined by the equation

$$R_{abcd} = C_{abcd} + g_{a[c} S_{d]b} - g_{b[c} S_{d]a} \tag{51}$$

in terms of the unphysical Riemann tensor and Weyl tensor. It can be expressed in terms of the unphysical Ricci tensor by

$$S_{ab} = \frac{2}{(d-2)} R_{ab} - \frac{1}{(d-1)(d-2)} R g_{ab}. \tag{52}$$

Using the relation (21) between the physical and unphysical Ricci tensor, we find that Einstein's equation for the physical Ricci tensor takes the form

$$\Omega S_{ab} + 2\nabla_a n_b - f g_{ab} = 0 \tag{53}$$

in terms of the tensor S_{ab}, where we remember the shorthand $f = \Omega^{-1} n^a n_a = O(1)$. We now take the variation of Eq. (53) with respect to a linearized solution of the field equations that preserves asymptotic flatness to first order (remembering $\delta\Omega = 0$ since Ω is rigidly fixed) and substitute the definition of τ_{ab} and τ_b. Using the formulas

$$\delta f = -\Omega^{(d-2)/2} \tau_a n^a, \tag{54}$$

$$\delta(\nabla_a n_b) = \Omega^{(d-2)/2} \left(-\frac{d}{2} n_{(a} \tau_{b)} + \frac{d}{4} f \tau_{ab} + \frac{1}{2} n^c \nabla_c \tau_{ab} - \Omega \nabla_{(a} \tau_{b)} - \frac{1}{2} \Omega S_{c(a} \tau_{b)}{}^{c} \right), \tag{55}$$

we find the result

$$\Omega^{-(d-4)/2} \delta S_{ab} = d \cdot n_{(a} \tau_{b)} - n^c \nabla_c \tau_{ab} - \frac{(d-2)}{2} f \tau_{ab} + \Omega (2\nabla_{(a} \tau_{b)} + S_{c(a} \tau_{b)}{}^{c} - \Omega^{-1} \tau_c n^c g_{ab}), \tag{56}$$

and we note that the right-hand side of this equation is manifestly finite at $\mathscr{I}$ and that the fourth term on the right side is of order Ω. It follows from this relation, together with the relation $\tau_{ab} n^b = O(\Omega)$, that the pull-back of the symplectic current density at $\mathscr{I}$, Eq. (50), can be written as

$$\zeta * \omega_{a_1 \cdots a_{d-1}} = \frac{1}{32\pi G} \Omega^{-(d-4)/2} (\tau_2^{cd} \delta_1 S_{cd} - \tau_1^{cd} \delta_2 S_{cd}) \epsilon_{a_1 \cdots a_{d-1}}. \tag{57}$$

To construct the desired potential, Θ, for Eq. (57), we note that our asymptotic flatness conditions (3) and (4) imply that (we note that the second relation is in general false in $d = 4$)

$$S_{ab} - \overline{S}_{ab} = O(\Omega^{(d-4)/2}), \quad S_m{}^m - \overline{S}_m{}^m = O(\Omega^{(d-2)/2}), \quad f - \overline{f} = O(\Omega^{d/2}). \tag{58}$$

By construction, the restriction of the symplectic form to $\mathscr{I}$, Eq. (57), only depends on the physical metric $\tilde{g}_{ab}$ and its variations, but not on how we have chosen to write them in terms of an unphysical metric g_{ab} and a conformal factor Ω, as long as g_{ab} and $\overline{g}_{ab}$ are smooth at $\mathscr{I}$. We now take advantage of this fact by choosing a conformal factor so that the background metric (2) is flat in a neighborhood of $\mathscr{I}$, i.e., $\overline{S}_{ab} = 0$, and such that $\overline{f} = \text{const}$ there. This is possible, at least locally in a neighborhood of any open subset of $\mathscr{I}^+$, respectively, $\mathscr{I}^-$ with compact closure not intersecting spatial infinity (see Appendix B for details). Consequently, by Eq. (58), in such a gauge we have

$$S_{ab} = O(\Omega^{(d-4)/2}), \quad S_m{}^m = O(\Omega^{(d-2)/2}), \quad f = \text{const} + O(\Omega^{d/2}). \tag{59}$$

Choose any smooth covector field l_a on M with the property that $l_a l^a = 0$, $n^a l_a = +1$ at $\mathscr{I}$, set

$$q_{ab} = g_{ab} - 2 n_{(a} l_{b)} \tag{60}$$

and define the "news tensor" by

$$N_{ab} = \zeta^* (\Omega^{-(d-4)/2} q^m{}_a q^n{}_b S_{mn}) \quad (\text{assuming } d > 4), \tag{61}$$

where ζ^* denotes the pull-back to $\mathscr{I}$. By definition, N_{ab} is a well-defined smooth tensor field at $\mathscr{I}$ with vanishing trace. Using the identity

$$S_{ab} n^b + \nabla_a f = 0, \tag{62}$$

one sees that N_{ab} is independent of the particular choice of l^a. A symplectic potential Θ at $\mathscr{I}$ with the desired properties is now given by

$$\Theta_{a_1 \cdots a_{d-1}} \equiv \frac{1}{32\pi G} \tau^{cd} N_{cd} \epsilon_{a_1 \cdots a_{d-1}}. \tag{63}$$

While the restriction of the symplectic form ω to $\mathscr{I}$ [see Eq. (57)] only depends on the physical metric and its perturbation, but not on the particular choice of the conformal factor Ω and unphysical metric (although the latter were used to obtain a convenient form for ω), this need not be the case for Θ, as the latter is a potential for ω and therefore only unique up to a "total variation" $\delta\Pi$. We therefore must investigate the behavior of Θ under "conformal gauge changes." If we change the conformal factor to $\Omega' = k\Omega$ with some smooth k, then, since the physical metric is to remain unchanged, the unphysical metric changes by $g'_{ab} = k^2 g_{ab}$, and likewise the background metric changes as $\overline{g}'_{ab} = k^2 \overline{g}_{ab}$. The quantities S_{ab}, n^a, f change in the following way:

$$n^{a\prime} = k^{-1} n^a + k^{-2} \Omega \nabla^a k,$$

$$S'_{ab} = S_{ab} + 2k^{-1} \nabla_a \nabla_b k - k^{-2} g_{ab} (\nabla_m k) \nabla^m k, \tag{64}$$

$$f' = k^{-1} f + 2k^{-2} n^a \nabla_a k + k^{-3} (\nabla^a k) \nabla_a k \tag{65}$$

with similar formulas for the background quantities $\overline{S}_{ab}$, $\overline{n}^a$, $\overline{f}$. In order to arrive at the above formula for Θ, we assumed that we were in a gauge such that $S_{ab} = 0$, and such that $\overline{f} = \text{const}$. Since we have thereby already partially fixed the gauge, we need to demand that k be such that $\overline{S}'_{ab} = 0$ and such that $\overline{f}' = \text{const}$. Inserting these formulas, we find that for such k,

$$\Theta' = \Theta + \delta\Pi, \tag{66}$$

where Π is the $(d-1)$-form on $\mathscr{I}$ defined by

$$\Pi_{a_1 \cdots a_{d-1}} = \frac{(d-2)}{2^6 \pi G} \Omega^{-(d-2)} k^{-1} n^b (\nabla_b k) (g - \overline{g})_{cd} q^{ce} q^{df} (g - \overline{g})_{ef} \epsilon_{a_1 \cdots a_{d-1}}. \tag{67}$$

Since $\delta\Pi$ is not vanishing at $\mathscr{I}$, this means that the definition of Θ is not completely independent upon how the physical metric is written as $\Omega^2 \tilde{g}_{ab} = g_{ab}$, respectively, how the Minkowski metric is written as $\Omega^2 \tilde{\eta}_{ab} = \overline{g}_{ab}$ in terms of a conformal background metric, with $\overline{S}_{ab} = 0$ and $\overline{f} = \text{const}$. We resolve this gauge ambiguity by choosing a representer $\overline{g}_{ab}$ in the conformal class of the Einstein static universe which has

$$\overline{f} = 0, \quad \overline{\nabla}_a \overline{n}^b = 0, \quad \overline{S}_{ab} = 0 \quad \text{near } \mathscr{I}, \tag{68}$$

where $\overline{\nabla}_a$ denotes the derivative operator associated with $\overline{g}_{ab}$. It can be seen that $\Pi = 0$ for any further gauge change preserving this gauge condition, i.e., that Θ is now defined in a gauge invariant way. We will stick with this gauge choice for the remainder of the paper. It follows from these gauge conditions that

$$f = O(\Omega^{d/2}), \quad \nabla_a n_b = O(\Omega^{(d-2)/2}). \tag{69}$$

Some further explanations concerning this gauge choice are provided in Appendix B.

By the general analysis reviewed in the last section we infer that generators $\mathcal{H}_\xi$ associated with asymptotic symmetries ξ^a exist in d-dimensional general relativity with our choice of asymptotic flatness conditions, and that analysis instructs us to define $\mathcal{H}_\xi$ by

$$\delta\mathcal{H}_\xi = \int_B (\delta Q_\xi - \xi \cdot \theta) + \frac{1}{32\pi G}\int_B \tau^{ab} N_{ab} \xi \cdot {}^{(d-1)}\boldsymbol{\epsilon}, \tag{70}$$

where Q_ξ and θ were defined in Eqs. (42) and (34).

Formulas (70) and (63) are also correct in $d=4$ (for a derivation, see Ref. 14), provided that N_{ab} is given by the usual definition of the news tensor in four dimensions, $N_{ab}=\zeta^*(q^m{}_a q^n{}_b S_{mn}) - \rho_{ab}$, instead of Eq. (61). Here, ρ_{ab} is the uniquely determined symmetric tensor on $\mathscr{I}$ provided by Theorem 5 of Ref. 10, whose precise form depends on the chosen gauge.

Plugging the expression (63) for the symplectic potential into the flux formula, Eq. (44), and setting as above $\chi_{ab}=\Omega^{-(d-6)/2}\pounds_{\tilde{\xi}}\tilde{g}_{ab}$ we get the following expression for the flux associated with an asymptotic symmetry ξ^a through a segment $\mathcal{S}$ of $\mathscr{I}$:

$$F_\xi = \frac{1}{32\pi G}\int_{\mathcal{S}} \chi^{cd} N_{cd}{}^{(d-1)}\boldsymbol{\epsilon}, \tag{71}$$

noting that this is finite on account of our definition of an asymptotic symmetry, see Eqs. (10).

Having established the existence of a generator $\mathcal{H}_\xi$, we now discuss its uniqueness. The definition of $\mathcal{H}_\xi$ depends on the choice of Θ, which is itself only unique up to the addition of a $(d-1)$-form on $\mathscr{I}$ of the form δW, where W is an arbitrary $(d-1)$-form on $\mathscr{I}$ that is locally constructed out of the physical metric, the physical Riemann tensor and its derivatives, and Ω. The change $\Omega \to \lambda\Omega$ and $g_{ab} \to \lambda^2 g_{ab}$ with λ a constant will keep the physical metric fixed and preserve (69), so gauge invariance requires that $W \to W$ under this change of the unphysical metric and the conformal factor. [This requirement is met by our definition (63) of Θ.] Moreover, the symplectic potential Θ defined in (63) has the property that it vanishes whenever the news tensor, N_{ab}, vanishes. A vanishing news tensor indicates the absence of radiation (at least in four dimensions), and our definition (63) for Θ has the property that it vanishes when $N_{ab}=0$, thereby implying by Eq. (44) that the flux also vanishes whenever the news vanishes. It is natural to demand that any reasonable definition of Θ, and hence the flux, vanishes when the news is zero, which in turn leads to the requirement that $W=0$ whenever $N_{ab}=0$. If W has furthermore an analytic dependence on the (physical) metric, then we claim that these requirements imply that $W=0$, and hence that Θ is unique.

In order to see that this is indeed true, it is useful to introduce the "scaling dimension"[10] of a tensor $L^{a\cdots b}{}_{c\cdots d}$ with u upper indices and l lower indices that is constructed out of the unphysical metric and Ω. We say that such a tensor has scaling dimension s if $L^{a\cdots b}{}_{c\cdots d} \to \lambda^{s-u+l} L^{a\cdots b}{}_{c\cdots d}$ under a change $\Omega \to \lambda\Omega$ and $g_{ab} \to \lambda^2 g_{ab}$. It follows from this definition that the scaling dimension does not depend on the position of the indices and is additive under the tensor product. The dimension of g_{ab} is 0, the dimension of Ω is +1, the dimension of the Riemann tensor is −2 and each derivative decreases the dimension by 1, which implies that the dimension of n_a is 0. By assumption, the $(d-1)$ form

$$W_{ab\cdots c} = Y(\Omega, g_{ab}, n_a, \ldots, (\nabla_m)^r n_a, R_{abcd}, \ldots, (\nabla_m)^t R_{abcd})^{(d-1)}\boldsymbol{\epsilon}_{ab\cdots c} \tag{72}$$

has scaling dimension $-(d-1)$. Therefore, since ${}^{(d-1)}\boldsymbol{\epsilon}$ has scaling dimension 0, Y must have scaling dimension $-(d-1)$. Using Einstein's equation to eliminate covariant derivatives of n_a in terms of covariant derivatives or S_{ab}, and using Eq. (51) to eliminate the Riemann tensor in favor of C_{abcd} and S_{ab}, we can write a term in Y schematically in the form

$$\Omega^v (n_a)^l \prod_{i=1}^{r} (\nabla_m)^{s_i} (\Omega^{-(d-4)/2} S_{ab}) \prod_{j=1}^{u} (\nabla_m)^{t_j} (\Omega^{-(d-6)/2} C_{abcd}), \tag{73}$$

where we have suppressed contractions with the metric g_{ab} to lighten the notation. The scaling dimension of this term must be equal to $-(d-1)$, which implies that

$$\sum_i s_i + \frac{d}{2} r + \sum_j t_j + \frac{(d-2)}{2} u - v = d - 1. \tag{74}$$

Since the expressions $\Omega^{-(d-4)/2} S_{ab}$ and $\Omega^{-(d-6)/2} C_{abcd}$ are smooth at $\mathscr{I}$ as a consequence of our definition of asymptotic flatness, the expression (73) can be nonvanishing at $\mathscr{I}$ if and only if $v \leqslant 0$ (note that $v < 0$ is allowed, since the other terms appearing in the above expression could vanish at $\mathscr{I}$). Furthermore, $\Omega^{-(d-4)/2} S_{ab}$ vanishes at $\mathscr{I}$ if and only if the news vanishes at $\mathscr{I}$. Therefore, since we want Y to vanish whenever $N_{ab} = 0$, we must have $r > 0$. On the other hand, Eq. (74) implies that $r \leqslant 1$, so $r = 1$. We now analyze the remaining cases: When $r = 1$ and $u = 0$, then the term (73) looks schematically like

$$\Omega^v (n_a)^l (\nabla_m)^s (\Omega^{-(d-4)/2} S_{ab}), \tag{75}$$

with $s - v = (d-2)/2$. This term must vanish when the news vanishes and hence when $\Omega^{-(d-4)/2} S_{ab}$, but not necessarily its derivatives, vanishes at $\mathscr{I}$. This implies $s = 0$ and hence $v = -(d-2)/2$, so we need contractions of n_a with itself to get a term that is finite at $\mathscr{I}$. But contractions of n_a with itself give a power of at least $\Omega^{(d+2)/2}$, therefore terms of the form Eq. (75) cannot occur. The only remaining nontrivial case is $r = 1$ and $u = 1$. In this case, we must have $s_i = t_j = v = 0$ and the term (73) must take the form $\Omega^{-(d-5)} C_{abcd} S^{ac} n^b n^d$. But this term vanishes at $\mathscr{I}$, by Eq. (A14) in the appendix. We have therefore shown that $W = 0$ and hence that the symplectic potential Θ given by Eq. (63) is unique under the above assumptions.

We now consider the flux for the special case of "translational" asymptotic symmetries ξ^a. These are distinguished by the fact that the restriction of ξ^a to $\mathscr{I}$ is proportional to n^a, i.e., $\xi^a = \alpha n^a + \Omega k^a$, for some k^a, smooth at $\mathscr{I}$. A vector field ξ^a is an asymptotic symmetry if and only if the tensor $\chi_{ab} = \Omega^{-(d-6)/2} \pounds_\xi \tilde{g}_{ab}$ satisfies Eqs. (10). If we substitute this form of ξ^a into Eqs. (10), we see that $k^a = -\nabla^a \alpha$ at $\mathscr{I}$. Let us therefore make the ansatz

$$\xi^a = \alpha n^a - \Omega \nabla^a \alpha. \tag{76}$$

For which α is this an asymptotic symmetry? Inserting (76) into χ_{ab}, we find that

$$\chi_{ab} = 2\Omega^{-(d-4)/2} (-\nabla_a \nabla_b \alpha + \Omega^{-1} \alpha \nabla_a n_b + \Omega^{-1} g_{ab} n^c \nabla_c \alpha). \tag{77}$$

Using that $\nabla_a n_b = O(\Omega^{(d-2)/2})$ in our gauge choice [see Eq. (69)] we see that χ_{ab} is finite at $\mathscr{I}$ if and only if α satisfies

$$\nabla_a \nabla_b \alpha - \Omega^{-1} g_{ab} n^c \nabla_c \alpha = O(\Omega^{(d-4)/2}). \tag{78}$$

Dotting n^a into Eq. (77), and using that $f = O(\Omega^{d/2})$ in our gauge choice, we see that $\chi_{ab} n^b = O(\Omega)$ if and only if

$$\nabla^b (\Omega^{-1} n^a \nabla_a \alpha) = O(\Omega^{(d-4)/2}). \tag{79}$$

Contracting this once more into n^a, we see that $\chi_{ab} n^a n^b = O(\Omega^2)$ if

$$\Omega^{-1} n^b \nabla_b (\Omega^{-1} n^a \nabla_a \alpha) = O(\Omega^{(d-4)/2}). \tag{80}$$

In $d > 4$, an asymptotic symmetry must furthermore satisfy $\chi^a{}_a = O(\Omega)$. However, this condition actually automatically follows for any asymptotic symmetry ξ^a once $\chi_{ab} = O(1)$, $\chi_{ab} n^b = O(\Omega)$, $\chi_{ab} n^a n^b = O(\Omega^2)$ are satisfied. To see this, we note that since $\delta \tilde{g}_{ab} = \pounds_\xi \tilde{g}_{ab}$ satisfies the linearized Einstein equation, the tensor χ_{ab} satisfies Eq. (22) (with $\tau_{ab} = \chi_{ab}$ in that equation).

Multiplying Eq. (22) by Ω, we see that the only remaining singular term on the right-hand side is given by a constant that is nonzero for $d \neq 4$, times $\Omega^{-1} n_a n_b \chi_c{}^c$, which implies that $\chi_a{}^a = O(\Omega)$ when $d > 4$. Thus, if Eqs. (78), (79), and (80) hold, then the vector field $\xi^a = \alpha n^a - \Omega \nabla^a \alpha$ is an symptotic symmetry.

The above conditions on α can be understood as follows. In $d=4$ dimensions, conditions (78) and (79) together imply that α must be constant along the null generators of $\mathscr{I}$, whereas condition (80) gives a restriction on how α is defined off of $\mathscr{I}$. Hence, α is essentially an arbitrary function on a given cross section of $\mathscr{I}$, which is propagated along the null generator to the other cross sections. The corresponding symmetries are commonly referred to as "supertranslations." They comprise the ordinary "pure" translations, as well as an additional infinite set of mutually commuting so-called "angle dependent" translations. In $d > 4$, the above conditions are more restrictive than in $d=4$ and are analyzed in Appendix C. There are now only d linearly independent admissible functions α up to correction terms which essentially do not affect the restriction of χ_{ab} to $\mathscr{I}$, in the sense that the correction terms do not make a contribution to the flux. The translational asymptotic symmetries associated with these choices of α correspond to the d translational Killing fields in Minkowski space–time. There is no direct analog of the angle dependent translations in higher dimensions. The asymptotic translations with $\alpha \geqslant 0$ correspond precisely to the future directed ($\alpha \geqslant 0$ means that $\xi^a = \alpha n^a$ is the future pointing near $\mathscr{I}^+$) timelike or null translational Killing fields in Minkowski space–time.

Let us calculate the flux when $\xi^a = \alpha n^a - \Omega \nabla^a \alpha$ is an asymptotic future directed time translation, i.e., $\alpha \geqslant 0$. Using Einstein's equation (53) to eliminate the term proportional to $\nabla_a n_b$ in Eq. (77) in favor of S_{ab}, we can bring χ_{ab} into the form

$$\chi_{ab} = -\Omega^{-(d-4)/2}(2\nabla_a \nabla_b \alpha + \alpha S_{ab} - 2\Omega^{-1} g_{ab} n^c \nabla_c \alpha - \alpha \Omega^{-1} f g_{ab}). \tag{81}$$

Substituting it into the flux formula, Eq. (71), one finds

$$F_\xi = -\frac{1}{32\pi G}\int_{\mathcal{S}} \alpha N^{cd} N_{cd}{}^{(d-1)} \boldsymbol{\epsilon} \leqslant 0. \tag{82}$$

This shows that the flux of energy (defined via *any* future directed asymptotic time translation) through $\mathscr{I}$ is always negative, i.e., that the energy radiated away by the system is always positive.

The generators $\mathcal{H}_\xi$ are determined, in principle, by the defining relation Eq. (70) and the requirement that $\mathcal{H}_\xi = 0$ on Minkowski space–time. If ξ^a is not a translation, i.e., if ξ^a is tangent to some cross section B of $\mathscr{I}$, then the term involving Θ vanishes in the expression for the variation of $\mathcal{H}_\xi$, Eq. (70), and an explicit expression for $\mathcal{H}_\xi$ can be derived in basically the same manner as in four dimensions, see Ref. 14. We will not discuss this case here but focus on the case when ξ^a is a translation for the rest of this section.

In that case, the defining relation (70) is not useful to actually find the expression for the generators $\mathcal{H}_\xi$, although the right-hand side of that equation is, of course, explicitly known. Indeed, in Ref. 14, an explicit expression for $\mathcal{H}_\xi$ in $d=4$ was found by verifying that relation (70) is satisfied by a known expression for the Bondi energy previously given by Geroch.[10] Such a candidate expression is, of course, not available in $d > 4$, since this is precisely what we are actually looking for in the first place. We therefore proceed by a different route, restricting ourselves for simplicity first to the case of the asymptotic translation $\xi^a = \alpha n^a$, with α a constant.

Consider the $(d-1)$-form $\Theta(\tilde{g}; \pounds_{\alpha n}\tilde{g})$ on $\mathscr{I}$ that is given by the integrand of the flux integral, Eq. (82). We extend this to a $(d-1)$-form that is defined on the entire unphysical space–time M by setting

$$\Theta_{s_1 \cdots s_{d-1}} = \frac{1}{32\pi G}\alpha \Omega^{-(d-4)}(S_{ab} S_{cd} q^{ac} q^{bd}) \boldsymbol{\epsilon}_{s_1 \cdots s_{d-1}}. \tag{83}$$

Define the vector field

$$P^a \equiv \frac{\alpha}{8(d-3)\pi G}\Omega^{-(d-4)}(S_{de}q^{ce}q^{d[b}\,n^{\,a]}\nabla_b l_c - \Omega^{-1}C^{abcd}n_b l_c n_d), \tag{84}$$

in the interior of the space–time, where l_a is any smooth vector field such that $l_a l^a = 0$ and $n^a l_a = 1$ on $\mathscr{I}$ and such that relations (A2) are satisfied. We show in the Appendix that

$$\nabla^a P_a = \frac{1}{32\pi G}\alpha\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} + O(\Omega), \tag{85}$$

and it can be verified directly from the definition of P^a that $P^a n_a = O(\Omega^2)$. Next, define the $(d-2)$-form μ by[22]

$$\mu_{a_1\cdots a_{d-2}} = \epsilon_{a_1\cdots a_{d-2}cd}l^c P^d = \tfrac{1}{2}[*(l\wedge P)]_{a_1\cdots a_{d-2}}. \tag{86}$$

Then it follows that

$$\begin{aligned}(\mathrm{d}\mu)_{a_1\cdots a_{d-1}} &= 2\nabla_m(P^{[m}\,l^{\,n]})\epsilon_{na_1\cdots a_{d-1}}\\ &= 2n_n\nabla_m(P^{[m}\,l^{\,n]})\epsilon_{a_1\cdots a_{d-1}} - 2(d-1)\nabla_m(P^{[m}\,l^{\,n]})n_{[a_1}\,\epsilon_{\,|n|a_2\cdots a_{d-1}]}\\ &= (\nabla_m P^m)\epsilon_{a_1\cdots a_{d-1}} - 2(d-1)\nabla_m(P^{[m}\,l^{\,n]})n_{[a_1}\,\epsilon_{\,|n|a_2\cdots a_{d-1}]} + O(\Omega)\\ &= (\Theta + \mathrm{d}\Omega\wedge\varphi)_{a_1\cdots a_{d-1}} + O(\Omega),\end{aligned} \tag{87}$$

where $\epsilon_{a_1\cdots a_{d-1}}$ is as in Eq. (49), where it has been used that $P^a n_a = O(\Omega^2)$, and where we have set $\varphi_{a_1\cdots a_{d-2}} = 2\nabla_m(P^{[m}\,l^{\,n]})\epsilon_{na_1\cdots a_{d-2}}$.

Consider now a segment $\mathcal{S}$ of $\mathscr{I}$ bounded by cross sections B_1 and B_2, and a sequence of smooth $(d-1)$-surfaces $\mathcal{S}_i$ of constant Ω that approach $\mathcal{S}$. Using Eqs. (44) and (87), we can write the flux through the segment $\mathcal{S}$ as follows:

$$F_{\alpha n} = \lim_{i\to\infty}\int_{\mathcal{S}_i}\Theta(\tilde{g},\pounds_{\alpha n}\tilde{g}) = \lim_{i\to\infty}\int_{\mathcal{S}_i}(\mathrm{d}\mu - \mathrm{d}\Omega\wedge\varphi) = \lim_{i\to\infty}\left(\int_{(\partial\mathcal{S}_i)_2}\mu - \int_{(\partial\mathcal{S}_i)_1}\mu\right), \tag{88}$$

where we have used Stoke's theorem and where we have written $(\partial\mathcal{S}_i)_1$ for the connected component of the boundary approaching B_1 and $(\partial\mathcal{S}_i)_2$ for the connected component of the boundary approaching B_2. **(**A subtlety arises from the fact that the gauge that we are working in [chosen such that Eq. (69) holds] is actually not defined on all of $\mathscr{I}$, but only on $\mathscr{I}$ minus a single generator, see Appendix B. Therefore, there also should appear another "boundary term" in Eq. (88) corresponding to that single generator. However, it can be seen that this term does not make a contribution by passing to a suitable gauge which is defined on all of $\mathscr{I}$, and by transforming the expression for μ accordingly using formulas very similar to those given on pp. 50 and 51 of Ref. 9. An example is worked out in Appendix B. Similar remarks apply to other formulas below.**)** Now take the variation of this equation and substitute the variation of the flux formula (43), $\delta F_{\alpha n} = \delta\mathcal{H}_{\alpha n}(B_1) - \delta\mathcal{H}_{\alpha n}(B_2)$. This gives

$$\delta\mathcal{H}_{\alpha n}(B_1) - \delta\mathcal{H}_{\alpha n}(B_2) = \lim_{i\to\infty}\left(\delta\int_{(\partial\mathcal{S}_i)_2}\mu - \delta\int_{(\partial\mathcal{S}_i)_1}\mu\right). \tag{89}$$

Consider a variation of the metric that vanishes in a neighborhood of *some* cross section of $\mathscr{I}$, in addition to satisfying the linearized equations of motion and the linearized conditions of asymptotic flatness. Then it follows from Eq. (89) that for such a variation,

$$\delta\mathcal{H}_{\alpha n}(B) = \delta\int_B\mu \tag{90}$$

for *any* cross section B of $\mathscr{I}$, where the integral on the right-hand side is defined by the limit of the

corresponding integrals over $(d-2)$-surfaces of constant Ω that smoothly approach B from the interior of the space–time. [This shows in particular that the right-hand side of Eq. (90) (defined via this limiting procedure) is actually finite. This is not obvious from the definition since P^a as well as its variation is *not* manifestly finite at $\mathscr{I}$ in $d>4$. Indeed, the Weyl term in the definition of P^a can only be shown to make a contribution of order $O(\Omega^{-(d-4)/2})$ using our asymptotic flatness conditions.] Next, consider a variation that is pure gauge, $\delta\tilde{g}_{ab}=\pounds_\eta\tilde{g}_{ab}$, for some asymptotic symmetry η^a. For such a variation, we have

$$\delta\int_B \mu=\int_B \pounds_\eta\mu=\int_B [\mathrm{d}(\eta\cdot\mu)+\eta\cdot \mathrm{d}\mu]=\int_B \eta\cdot\Theta(\tilde{g};\pounds_{\alpha n}\tilde{g}), \tag{91}$$

where the integrals are defined by a limiting procedure as above. We now show that $\delta\mathcal{H}_{\alpha n}(B)$ for this variation is also given by the right-hand side of the above equation. For this, we consider the one-parameter family of diffeomorphisms Φ_t generated by η^a which maps points in $\mathscr{I}$ to points in $\mathscr{I}$. If $\Phi_t^* B$ is the cross section of $\mathscr{I}$ obtained from B by applying this diffeomorphism, and if $\mathcal{S}_t$ is the segment of $\mathscr{I}$ bounded by these two cross sections, then we have

$$\delta\mathcal{H}_{\alpha n}(B)=\lim_{t\to 0}\frac{1}{t}[\mathcal{H}_{\alpha n}(B)-\mathcal{H}_{\alpha n}(\Phi_t^* B)]=\lim_{t\to 0}\frac{1}{t}\int_{\mathcal{S}_t}\Theta(\tilde{g};\pounds_{\alpha n}\tilde{g})=\int_B \eta\cdot\Theta(\tilde{g};\pounds_{\alpha n}\tilde{g}), \tag{92}$$

for the variation $\delta\tilde{g}_{ab}=\pounds_\eta\tilde{g}_{ab}$, where we have used the flux formula Eq. (44) in the second line, and where we have used that $\Theta(\tilde{g};\pounds_{\alpha n}\tilde{g})$ is smooth at $\mathscr{I}$ in the third line. Hence, we conclude that Eq. (90) also holds for any variation of the form $\delta\tilde{g}_{ab}=\pounds_\eta\tilde{g}_{ab}$. Consider now a variation with compact support K on some Cauchy surface which satisfies the linearized field equations and the linearized conditions of asymptotic flatness. Then it follows from the arguments given in Sec. III that such a variation can be written as a sum $\delta\tilde{g}_{ab}+\pounds_\eta\tilde{g}_{ab}$, where η^a is some asymptotic symmetry and where $\delta\tilde{g}_{ab}$ has support in $J^+(K)\cup J^-(K)$. It follows that there exist cross sections B^+ of $\mathscr{I}^+$ and B^- of $\mathscr{I}^-$ such that $\delta\tilde{g}_{ab}$ vanishes in a neighborhood of B^+ and B^-. By the arguments already given, Eq. (90) therefore holds for any variation which has compact support on some Cauchy surface. Consequently, Eq. (90) will also hold for any variation such that the corresponding fields τ_{ab}, τ_a and their first (unphysical) derivatives can be approximated near B by the corresponding fields for a sequence of variations that have compact support on a Cauchy surface. We believe that all variations that satisfy the linearized equations of motion and the linearized conditions of asymptotic flatness can be approximated in this way. Assuming that this is true, it follows that Eq. (90) holds for all variations.

We have $\int_B\overline{\mu}=0$ for our background geometry, since we are in a gauge in which $\overline{g}_{ab}$ is flat in a neighborhood of $\mathscr{I}$, therefore $\overline{\mu}=0$ in a neighborhood of $\mathscr{I}$. Therefore, modulo the proof of the approximation property mentioned in the last paragraph, we have shown that

$$\mathcal{H}_\xi=\int_B \mu=\frac{1}{2}\int_B *(l\wedge P) \tag{93}$$

for asymptotic time translations, $\xi^a=\alpha n^a$, where P^a is given by Eq. (84). This is our expression for the Bondi energy of an asymptotically flat space–time in d dimensions.

Our expression for the Bondi energy is independent of the particular choice of l_a with the properties (A2): Consider another l'_a with the same properties as l_a, and set $x_a=l_a-l'_a$. Then x_a satisfies the relations $\nabla_b x_a=O(\Omega^{(d-4)/2})$, $n_a x^a=O(\Omega^{d/2})$, and $l^a x_a=O(\Omega^{(d-2)/2})$. Consider the antisymmetric tensor field X^{ab} defined by

$$X^{ab}=\frac{1}{8(d-3)\pi G}\alpha\Omega^{-(d-4)}S_{ef}q^{ed}q^{f[a}n^{b]}x_d. \tag{94}$$

Then it can be seen, using formulas (A2), (69), and (A6), that $X^{ab}n_b=O(\Omega)$, and

$$P'^a = P^a + \nabla_b X^{ab} + O(\Omega). \tag{95}$$

Consider now a sequence of embedded $(d-2)$-surfaces that are smoothly embedded into M and which approach a cross section B of $\mathscr{I}$ as $i \to \infty$. Without loss of generality we may assume that $\Omega = \text{const}$ on each of these surfaces, so that n^a is one of the normals to the surfaces. Let u^a be another normal so that the field $n^{[a} u^{b]}$ is a binormal, meaning that $\epsilon_{a_1 \cdots a_{d-2}} = \zeta_i^*(n^{[m} u^{n]} \epsilon_{mna_1 \cdots a_{d-2}})$ is equal to the $(d-2)$-volume form induced by g_{ab} on each of these surfaces, where ζ_i^* denotes the pull-back to B_i. Then from Eq. (95), we get

$$\begin{aligned}\zeta_i^*(\mu - \mu')_{a_1 \cdots a_{d-2}} = {} & \tfrac{3}{2}\zeta_i^* \nabla_q (X^{[qm} l^{n]}) \epsilon_{mna_2 \cdots a_{d-2}} - \zeta_i^*(\tfrac{3}{2} X^{[mq} \nabla_q l^{n]} + \tfrac{1}{2} l^q \nabla_q X^{mn} \\ & + P'^{[m} x^{n]}) n_m u_n \epsilon_{a_1 \cdots a_{d-2}}.\end{aligned} \tag{96}$$

But the terms in the last line are all of $O(\Omega)$, since $X^{ab} = O(\Omega^{(d-4)/2})$, $X^{ab} n_b = O(\Omega^2)$, $P^a n_a = O(\Omega^2)$, and since $x^a n_a = O(\Omega^{d/2})$, $n^b \nabla_a l_b = O(\Omega^{(d-2)/2})$ by Eqs. (A2). This shows that, in differential forms notation,

$$\zeta_i^*(\mu - \mu') = -\tfrac{1}{3}\zeta_i^*\{\mathrm{d}[*(X \wedge l)]\} + O(\Omega), \tag{97}$$

and therefore, by Stoke's theorem, that

$$\int_B \mu - \int_B \mu' = \lim_{i \to \infty} \int_{B_i} (-\tfrac{1}{3}\mathrm{d}[*(X \wedge l)] + O(\Omega)) = 0, \tag{98}$$

since B_i has no boundary. Thus, our definition (93) of the Bondi energy does not depend on our choice of l_a.

Substituting our expression (84) for P^a into Eq. (93), using the definition of S_{ab} together with the fact that $S_m{}^m = O(\Omega^{(d-2)/2})$, we can express $\mathcal{H}_\xi$ by the final formula

$$\mathcal{H}_\xi = \frac{1}{8(d-3)\pi G} \int_B \alpha \Omega^{-(d-4)} \left(\frac{1}{(d-2)} R_{ab} q^{ac} q^{bd} (\nabla_c l_d) n^e l^f - \Omega^{-1} l^{[e} C^{f]bcd} n_b l_c n_d \right) \epsilon_{efa_1 \cdots a_{d-2}}. \tag{99}$$

This formula holds for the special translation $\xi^a = \alpha n^a$, with $\alpha = \text{const}$. The above arguments and calculations can be generalized to arbitrary (null) translations, $\xi^a = \alpha n^a - \Omega \nabla^a \alpha$. One now finds the formula

$$\begin{aligned}\mathcal{H}_\xi = {} & \frac{1}{8(d-3)\pi G} \int_B \Omega^{-(d-4)} \left(\frac{1}{(d-2)} R_{ab} q^{ac} q^{bd} (\nabla_c l_d) \xi^e l^f \right. \\ & \left. - \Omega^{-1} \alpha^{-1} (l^{[e} - v \alpha^{-1} \nabla^{[e} \alpha) C^{f]bcd} \xi_b (l_c - v \alpha^{-1} \nabla_c \alpha) \xi_d \right) \epsilon_{efa_1 \cdots a_{d-2}},\end{aligned} \tag{100}$$

where v is a function such that $\nabla_a v = l_a$. It can be verified again that this expression does not depend on the particular choice of l_a. Formula (100) can alternatively be derived by noting that any null translation ξ^a can be obtained from n^a by applying an asymptotic symmetry ϕ to the latter, $\xi^a = \phi * n^a$. Since the Bondi energy for the vector field ξ^a and metric $\tilde{g}_{ab}$ evaluated at B is equal to the Bondi energy for $n^a = \xi^{a\prime} = \phi^{-1} * \xi^a$ and metric $\tilde{g}'_{ab} = \phi^{-1} * \tilde{g}_{ab}$ evaluated at the cross section $B' = \phi(B)$, one can obtain the Bondi energy for ξ^a by applying Eq. (99) to the metric $\tilde{g}'_{ab}$ and the cross section B'. The above expression (100) is then obtained using the formulas $\phi * g'_{ab} = \alpha^{-2} g_{ab}$, $\phi * \Omega = \alpha^{-1}\Omega$, $\phi * l^{a\prime} = \alpha l^a - v \nabla^a \alpha$, $\phi * n^{a\prime} = \alpha n^a - \Omega \nabla^a \alpha$, as well as our asymptotic flatness conditions.

Equation (100) is the main result of our paper. It holds in the gauge defined in (68). The corresponding formula for other choices of the background geometry $\bar{g}_{ab}$ can be obtained by applying the corresponding gauge transformation to our formula. In the case $d=4$, formula (100)

is not correct. An expression in $d=4$ has been given by Geroch.[10] It involves, among other things, the news tensor (given by $N_{ab}=S_{ab}-\rho_{ab}$ in $d=4$), instead of the unphysical Ricci tensor.

The first and second term in the integrand of (100) can be roughly interpreted as follows: the second term is the "Coulomb part" of the Weyl tensor (multiplied by suitable powers of Ω), and represents the "pure Coulomb contribution" to the Bondi energy. The first term represents contributions from gravitational radiation; it follows from Eq. (A2) given in Appendix A that it vanishes if and only if the news tensor, N_{ab}, and hence the flux, vanishes. In four dimensions, it can be proven[10] that the news tensor, and hence the radiative contribution to the Bondi energy, always vanishes in stationary space–times. It would be interesting to see whether an analog of this result holds in d dimensions.

In the d-dimensional analog of Schwarzschild space–time given by the line element (5), the Bondi energy is evaluated as follows. The term involving R_{ab} in our expression (100) for the Bondi energy does not contribute, showing that there is no radiative contribution to the Bondi energy. The Coulomb contribution is found to be $\Omega^{-(d-3)}C^{abcd}l_a n_b l_c n_d = c(d-2)(d-3)/4$ at $\mathscr{I}$. Normalizing α so that $\alpha n^a - \Omega\nabla^a\alpha$ is equal to the timelike Killing field t^a of the metric (5) at infinity gives

$$\mathcal{H}_{\alpha n} = \frac{c(d-2)A_{d-2}}{16\pi G} \quad \left(= \frac{c}{2G} \text{ in four dimensions}\right), \tag{101}$$

where A_{d-2} is the area of the unit sphere S^{d-2}. This coincides with the ADM mass of the space–time (5) (given, e.g., in Ref. 20), as we expect.

VI. CONCLUSIONS

We have given a geometrical definition of the asymptotic flatness at null infinity in space–times of even dimension d greater than four within the framework of conformal infinity. Our definition was shown to be stable against perturbations to linear order and was shown to be stringent enough to allow one to define the total energy of the system viewed from null infinity as the generator conjugate to an asymptotic time translation. We proposed to take this notion of energy as the natural generalization of the Bondi energy to higher dimensions. Our definitions of asymptotic flatness and the Bondi energy differ qualitatively from the corresponding definitions in $d=4$; although the asymptotic structure of null infinity in higher dimensions parallels that in four dimensions in some ways, the latter seems to be a rather special case on the whole compared to general $d>4$.

Our definitions and constructions related to asymptotic flatness and Bondi energy do not work in odd space–time dimensions, essentially because the unphysical metric seems to have insufficient regularity properties at null infinity in that case. The case of odd dimensional theories of gravity therefore remains open. Apart from this issue, the analysis given in this paper could be generalized in two obvious ways: (1) by including matter fields, and (2) by admitting higher derivative terms such as the square of the scalar curvature in the gravitational action.

With regard to the first possibility, one would first have to formulate appropriate asymptotic conditions on the matter fields, which in practice would presumably be found by performing a perturbation analysis. We expect the analysis given in Sec. III of this paper to generalize straightforwardly to include conformally invariant fields such as a conformally coupled scalar field, or an Abelian p-form gauge field A [with Lagrangian density $L=\mathrm{d}A\wedge *(\mathrm{d}A)$] in $d=2p+2$ space–time dimensions. This kind of analysis should also still work for other (nonconformally invariant) massless fields. For massive fields a different kind of analysis is probably needed, although we expect on physical grounds that these fields have the best (i.e., exponential) drop off behavior at null infinity. Altogether, we expect that the asymptotic conditions for the combined metric and matter fields are given by the conditions given in Sec. II for the metric, plus a condition of the form $T_{ab}=O(\Omega^s)$ for the stress energy of the matter fields, where s is a suitable number. With these conditions in place, a derivation of the Bondi energy can presumably be given in close parallel to our analysis in Sec. V.

With regard to the second possibility, it is much less clear to us what the likely asymptotic conditions on the gravitational fields might be in that case, or even how they depend on the actual form of the Lagrangian. In fact, it is not even clear to us that there will generically be *any* reasonable definition of asymptotic flatness that is stable under linear perturbations. Moreover, the linearized equations will now have more derivatives and are therefore presumably harder to analyze than the linearized Einstein's equations. One may ignore the issue of stability and simply try to repeat the analysis of this paper and Ref. 14 using the asymptotic flatness conditions of Sec. II which have been shown to work for general relativity. However, even though an expression for the Bondi energy might be found in this way, its physical significance would be far from clear under these circumstances.

ACKNOWLEDGMENTS

The authors would like to thank Bob Wald for discussions, especially with regard to the definition of asymptotic flatness in higher dimensions. The authors also thank Gary Gibbons for conversations. The authors benefited from talks and conversations during the YITP workshop, YITP-W-02-19 on "Extra dimensions and Braneworld" held at the Yukawa Institute for Theoretical Physics at Kyoto University. One of the authors (A.I.) thanks the Enrico Fermi Institute for hospitality. APPENDIX A: DERIVATION OF EQUATION (84)

In this appendix we derive expression (84) for P^a as a solution to the equation

$$\nabla^a P_a = \frac{1}{32\pi G}\alpha\Omega^{-(d-4)} S_{ab}S_{cd}q^{ac}q^{bd} + O(\Omega). \tag{A1}$$

It follows from Eqs. (3) and (4) that the covector l_a can be chosen in such a way that the following conditions are satisfied:

$$\nabla_a l_b = O(\Omega^{(d-4)/2}), \quad l^a l_a = O(\Omega^{(d-2)/2}), \quad l_a n^a = 1 + O(\Omega^{d/2}) \tag{A2}$$

[for example, take $l_a = g_{ab}\overline{l^b}$, where $\overline{l^a}$ is a vector field on $\overline{M}$ such that $\overline{g_{ab}}\,\overline{l^a}\,\overline{l^b} = \overline{\nabla_a}\,\overline{l^b} = 0$ and $\overline{l^a}(\mathrm{d}\Omega)_a = 1$ in a neighborhood of $\partial\overline{M}$]. We assume from now on that l_a has been chosen in this way.

From the defining relation for S_{ab}, together with Eq. (62), we have

$$2n^a\nabla_{[a}\nabla_{b]}l_c = R_{abcd}n^a l^d = C_{abcd}n^a l^d + \tfrac{1}{2}S_{db}n_c l^d - \tfrac{1}{2}S_{cb} - \tfrac{1}{2}l_b\nabla_c f + \tfrac{1}{2}g_{bc}l^d\nabla_d f. \tag{A3}$$

Contracting this equation with $S_{de}q^{bd}q^{ce}$, and making use of the relations $S_{ab}n^b = -\nabla_a f$, $\nabla_a f = \kappa n_a$, $\kappa = O(\Omega^{(d-2)/2})$ and Eq. (A2), gives

$$\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} = -4\Omega^{-(d-4)}n^a(\nabla_{[a}\nabla_{b]}l_c)S_{de}q^{bd}q^{ce} + 2\Omega^{-(d-4)}C_{abcf}n^a l^f S_{de}q^{bd}q^{ce} + O(\Omega). \tag{A4}$$

Thus, the task is to show that the right-hand side of this equation can be written as a constant times the divergence of P^a, plus terms of order Ω.

We now evaluate the right-hand side of Eq. (A4) up to order Ω, proceeding term by term and make heavy use of the drop-off conditions, Eq. (A2) and (69). For the second term in Eq. (A4) containing the Weyl tensor, we have, using the symmetry of the Weyl tensor $C_{abcd} = C_{cdab}$,

$$
\begin{aligned}
2\Omega^{-(d-4)}C_{abcf}n^a l^f S_{de}q^{bd}q^{ce} &= 2\Omega^{-(d-4)+1}(\nabla_{[c}S_{f]b})l^f S_{de}q^{bd}q^{ce} \\
&= 2\Omega\nabla_{[c}(\Omega^{-(d-4)/2}S_{f]b})l^f q^{cd}q^{be}(\Omega^{-(d-4)/2}S_{de}) \\
&\quad + (d-4)\Omega^{-(d-4)}n_{[c}S_{f]b}l^f q^{cd}q^{be}S_{de} \\
&= -\frac{(d-4)}{2}\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} + O(\Omega),
\end{aligned} \tag{A5}
$$

where the identity [compare Eq. (9) of Ref. 10]

$$
\Omega\nabla_{[a}S_{b]c} + C_{abcd}n^d = 0 \tag{A6}
$$

has been used in the first line. Note that the term (A5) is of order Ω in four dimensions, in accordance with the fact that by Theorem 11 of Ref. 10, the unphysical Weyl tensor vanishes at $\mathscr{I}$ in four dimensions. We next turn to the first term on the right-hand side of Eq. (A4). This can be written as

$$
\begin{aligned}
-4\Omega^{-(d-4)}n^a(\nabla_{[a}\nabla_{b]}l_c)S_{de}q^{bd}q^{ce} &= -4\nabla_a(\Omega^{-(d-4)}S_{de}q^{ce}q^{d[b}n^{a]}\nabla_b l_c) \\
&\quad + 4\Omega^{-(d-4)}(\nabla_a S_{de})q^{ce}q^{d[b}n^{a]}\nabla_b l_c + O(\Omega).
\end{aligned} \tag{A7}
$$

In the second term on the right-hand side, we may replace $\nabla_a S_{ed}$ by the expression $2\nabla_{[a}S_{e]d}$, because

$$
\begin{aligned}
\Omega^{-(d-4)}(\nabla_e S_{ad})q^{ce}q^{d[b}n^{a]}\nabla_b l_c &= \tfrac{1}{2}\Omega^{-(d-4)}[(\nabla_e\nabla_d f)q^{db}q^{ce} - (\nabla_e S_m{}^m)q^{ce}n^b \\
&\quad - 2\nabla_e(l^a\nabla_a f)q^{ce}n^b]\nabla_b l_c + O(\Omega) = O(\Omega),
\end{aligned} \tag{A8}
$$

where we have used that

$$
\nabla_a S_m{}^m = \nabla_m S_a{}^m \tag{A9}
$$

by the Bianchi identities, that $S_m{}^m = O(\Omega^{(d-2)/2})$ and that $\nabla_a f = \kappa n_a$, $\kappa = O(\Omega^{(d-2)/2})$. We can now apply the identity (A6) to write the right-hand side of Eq. (A7) as

$$
\begin{aligned}
&= -4\nabla_a(\Omega^{-(d-4)}S_{de}q^{ce}q^{d[b}n^{a]}\nabla_b l_c) - 8\Omega^{-(d-3)}C_{aedf}q^{ce}q^{d[b}n^{a]}n^f\nabla_b l_c + O(\Omega) \\
&= -4\nabla_a(\Omega^{-(d-4)}S_{de}q^{ce}q^{d[b}n^{a]}\nabla_b l_c) - 4\Omega^{-(d-3)}C_{aedf}n^a n^f\nabla^d l^e \\
&\quad + 4\Omega^{-(d-3)}C_{aedf}n^a n^f l^e n^c\nabla^d l_c + O(\Omega) \\
&= -4\nabla_a(\Omega^{-(d-4)}S_{de}q^{ce}q^{d[b}n^{a]}\nabla_b l_c) \\
&\quad + 4\nabla^d(\Omega^{-(d-3)}C_{dfea}n^f l^e n^a) + 4\Omega^{-(d-3)}C_{aedf}n^a n^f l^e n^c\nabla^d l_c \\
&\quad + 4\Omega^{-(d-3)}C_{aedf}l^e n^f\nabla^d n^a + O(\Omega),
\end{aligned} \tag{A10}
$$

where we have used the tracelessness and symmetries of the Weyl tensor and Eqs. (A2) and (69) in the second line, and where we have used [compare Eq. (12) of Ref. 10]

$$
\Omega\nabla^d C_{abcd} + C_{abcd}n^d = 0 \tag{A11}
$$

in the third line. Using Einstein's equation (53), the last term in the last line of Eq. (A10) is seen to be equal to $+2\Omega^{-(d-4)}C_{adef}n^a l^f S^{de}$, up to terms of order Ω. Using Eqs. (A5) and (A6), this term can be further rewritten as

$$
\begin{aligned}
2\Omega^{-(d-4)}C_{adef}n^a l^f S^{de} &= 2\Omega^{-(d-4)}C_{adef}n^a l^f S_{bc}q^{bd}q^{ec} + 2\Omega^{-(d-4)+1}(\nabla_{[e}S_{f]d})l^f n^e l^c q^{bd}S_{bc} \\
&\quad - 2\Omega^{-(d-4)+1}(\nabla_{[e}S_{f]d})l^f l^d q^{ec}\nabla_c f \\
&= -\frac{(d-4)}{2}\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} + \Omega^{-(d-4)+1}(n^e\nabla_e S_{df})l^f l^c q^{bd}S_{bc} \\
&\quad - \Omega^{-(d-4)+1}(\nabla_f S_{de})n^e l^f l^c q^{bd}S_{bc} + O(\Omega) \\
&= -\frac{(d-4)}{2}\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} + \Omega^{-(d-4)+1}(\nabla_f\nabla_d f + S_{de}\nabla_f n^e)l^f l^c q^{bd}S_{bc} + O(\Omega) \\
&= -\frac{(d-4)}{2}\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} + O(\Omega). \qquad \text{(A12)}
\end{aligned}
$$

The term $+4\Omega^{-(d-3)}C_{aedf}n^a n^f l^e n^c \nabla^d l_c$ on the right-hand side of Eq. (A10) can be seen to be of order Ω by using the identities

$$
n^c\nabla^d l_c = \nabla^d(n^c l_c) - (\nabla^d n^c)l_c = O(\Omega^{(d-2)/2}), \qquad \text{(A13)}
$$

$$
C_{aedf}n^a n^f = -\frac{\Omega}{2}(n^a\nabla_a S_{ed} + \nabla_e\nabla_d f + (\nabla_e n^a)S_{ad}) = O(\Omega^{(d-2)/2}). \qquad \text{(A14)}
$$

Substituting now Eqs. (A10) and (A5) back into Eq. (A4), we obtain

$$
-(d-3)\Omega^{-(d-4)}S_{ab}S_{cd}q^{ac}q^{bd} = 4\nabla_a[\Omega^{-(d-4)}(S_{de}q^{ce}q^{d[b}n^{a]}\nabla_b l_c - \Omega^{-1}C^{abcd}n_b l_c n_d)] + O(\Omega), \qquad \text{(A15)}
$$

from which Eq. (A1) follows immedliately.

APPENDIX B: CONFORMAL GAUGE CHOICES

In this appendix we review transformations related to the conformal completion of Minkowski space–time, thereby eludicating our gauge choice (68) for the background geometry. Let us denote by x^μ the usual Cartesian coordinates of Minkowski space–time $(\mathbb{R}^d, \tilde{\eta}_{ab})$. Introducing the radial coordinate

$$
r = \sqrt{\sum_{\mu=1}^{d-1}(x^\mu)^2} \qquad \text{(B1)}
$$

and $t = x^0$, the Minkowski metric can be rewritten as

$$
\mathrm{d}\tilde{s}^2 = -\mathrm{d}t^2 + \mathrm{d}r^2 + r^2\,\mathrm{d}\sigma^2 = \Omega^{-2}\{-\mathrm{d}T^2 + \mathrm{d}\psi^2 + \sin^2\psi\,\mathrm{d}\sigma^2\}, \qquad \text{(B2)}
$$

where $\mathrm{d}\sigma^2$ is the line element of the unit sphere S^{d-2}, and where

$$
\Omega = 2\cos\frac{T+\psi}{2}\cos\frac{T-\psi}{2}. \qquad \text{(B3)}
$$

The coordinates T, ψ are defined by

$$
\frac{T+\psi}{2} = \tan^{-1}(t+r), \quad \frac{T-\psi}{2} = \tan^{-1}(t-r). \qquad \text{(B4)}
$$

We view these relations as a map λ from the portion $\bar{M} = \{-\pi < T \pm \psi < \pi, \psi \geqslant 0\}$ of the Einstein static universe $\mathbb{R}\times S^{d-1}$ to Minkowski space–time $\mathbb{R}^d$. In other words,

$$\overline{g}_{ab} = \Omega^2 \lambda * \tilde{\eta}_{ab}, \tag{B5}$$

where $\overline{g}_{ab}$ is the metric of the Einstein static universe. The boundary of $\overline{M}$ corresponds to the conformal infinity of Minkowski space–time. It is naturally divided into future/past timelike infinity, future/past null infinity $\mathscr{I}^{\pm}$, and spatial infinity. The conformal factor Ω is well defined and smooth in a neighborhood of the null infinities $\mathscr{I}$, and vanishes there. The metric $\overline{g}_{ab}$ is conformally flat (implying $\overline{C}_{abcd}=0$), but not flat, $\overline{S}_{ab} \neq 0$.

If we change

$$\overline{g}_{ab} \to k^2 \overline{g}_{ab}, \quad \Omega \to k\Omega, \tag{B6}$$

with k a nonvanishing smooth scalar function defined in a neighborhood of $\overline{M}$ in the Einstein static universe which does not vanish at $\mathscr{I}$, then the physical metric remains unchanged, and the unphysical metric and the conformal factor remain smooth at $\mathscr{I}$. One may use this gauge freedom to make suitable "gauge choices" for the unphysical metric, and we will now discuss some of the choices that are being made in the main part of the paper. Let B be a cross section of, say future, null infinity which does not intersect spatial infinity. Then it is possible to choose Ω so that $\overline{g}_{ab}$ is Minkowskian in an open neighborhood of B not intersecting spatial infinity. This can be seen as follows.

Any neighborhood of the indicated form is contained in the causal future of some point in the interior of the space–time, which of course, corresponds to the interior of a future directed light cone V^+, whose apex we may assume to be at the origin,

$$V^+ = \{x^\mu | x^\mu x_\mu < 0, x^0 > 0\}. \tag{B7}$$

A conformal factor, Ω, defined on V^+ such that $\overline{g}_{ab}$ is flat and Minkowskian and such that the gauge condition (68) is satisfied can be constructed as follows. Consider the map ϕ,

$$\phi: x^\mu \to x'^\mu = \frac{a^\mu + b^\mu x^\lambda x_\lambda + 2q^{\mu\nu} x_\nu}{2b^\nu x_\nu},$$

$$a^\mu = (1,-1,0,\ldots,0), \quad b^\mu = (1,1,0,\ldots,0), \quad q^{\mu\nu} = \eta^{\mu\nu} + a^{(\mu} b^{\nu)}, \tag{B8}$$

which maps points of the interior of V^+ bijectively into points in the "right wedge" W of Minkowski space–time

$$W = \{x^\mu | x^1 \geqslant |x^0|\}. \tag{B9}$$

The portion of $\mathscr{I}^+$ lying in the causal future of V^+ corresponds, under the map ϕ, to the "upper horizon" of W, defined by $\partial W^+ = \{x^\mu | b^\mu x_\mu = 0, x^0 > 0\}$. The cross section of $\mathscr{I}^+$ corresponding to the light rays outgoing from the apex of V_+ corresponds to the "edge" $(x^0=0=x^1)$ of the wedge, whereas the light rays themselves are represented by the null curves generated by $a^\mu(\partial/\partial x^\mu)^a$ on the "lower horizon" of W, given by $\partial W^- = \{x^\mu | a^\mu x_\mu = 0, x^0 < 0\}$. We find that this map ϕ is a conformal isometry of Minkowski space–time with conformal factor

$$\Omega = b_\mu x^\mu, \tag{B10}$$

i.e., the background metric $\overline{g}_{ab} = \Omega^2 \phi * \tilde{\eta}_{ab}$ is Minkowskian. The quantities $\overline{f}, \overline{n}^a$ associated with this choice of conformal factor are

$$\overline{f} = 0, \quad \overline{n}^a = b^\mu \left(\frac{\partial}{\partial x^\mu} \right)^a, \quad \overline{\nabla}_a \overline{n}^b = 0. \tag{B11}$$

Thus, the conformal transformation (B8) with conformal factor (B10) satisifies our gauge condition (68).

An awkward feature of the map ϕ is that it is not globally defined on the boundary of V^+, for the single null generator corresponding to $x'^\mu = \lambda b^\mu$, $\lambda > 0$ of the boundary of V^+ is mapped to infinity. Consequently, there is also a single corresponding generator of $\mathscr{I}^+$ which is not represented as a corresponding generator of ∂W^+, or, stated differently, is mapped to the null generator at infinity of the upper horizon ∂W^+ (corresponding to $b_\mu x^\mu = 0$, $x^0 > 0$ but $x^{\mu=2,\ldots,d-1} \to \pm\infty$). Consequently, the cross sections of $\mathscr{I}^+$ within the causal future of V^+ now correspond to noncompact cross sections of the upper horizon of W (of topolgy $\mathbb{R}^{d-2}$). This feature of the conformal embedding ϕ has the undesirable consequence that the integrals in Sec. V over cross sections of $\mathscr{I}^+$ inside V^+ are now integrals over a noncompact set and therefore the convergence issue must be addressed. An example of such an integral is $\int_{\mathcal{S}} \Theta$, where Θ is the symplectic potential $(d-1)$-form introduced in Eq. (63), and where $\mathcal{S}$ is a segment of $\mathscr{I}^+$. We will now explain how the convergence issue is dealt with in this example.

For this purpose, it is useful to introduce another conformal transformation:

$$\psi: x^\mu \to x'^\mu = \frac{(x+t)^\nu (x+t)_\nu t^\mu + 2(x+t)^\mu}{(x-t)^\lambda (x-t)_\lambda}, \quad t^\mu = (1,0,0,\ldots,0), \tag{B12}$$

which maps points in V^+ into points of the interior of a double cone K of Minkowski space–time,

$$K = \{ x^\mu \,|\, |x^0| + r \leqslant 1 \}. \tag{B13}$$

This map also provides a conformal isometry of Minkowski space–time with conformal factor

$$\Omega' = -(x-t)^\mu (x-t)_\mu, \tag{B14}$$

rendering the metric $\overline{g'}_{ab} = \Omega'^2 \psi^* \tilde{\eta}_{ab}$ Minkowskian in the portion of space–time corresponding to the interior of the future light cone V^+. The derivative operator $\overline{\nabla'}_a$ compatible with $\overline{g'}_{ab} = \Omega'^2 \psi^* \tilde{\eta}_{ab}$ is simply equal to the coordinate derivative operator $\partial/\partial x^\mu$ associated with Cartesian coordinates. The portion of $\mathscr{I}^+$ that can be reached from within V^+ corresponds precisely to the points x^μ in K such that $\Omega' = 0$, i.e., the "upper cap" of the double cone K, defined by $\partial K^+ = \{x^\mu \,|\, x^0 + r = 1, x^0 > 0\}$. Future timelike infinity corresponds to the apex $x^\mu = t^\mu$ of the upper cap. The apex of V^+ corresponds to the apex of the lower cap of K given by $x^\mu = -t^\mu$, and the light rays going out from the apex of V_+ correspond to the null generators of the lower cap, ∂K^-, of K. We should note that this choice of conformal factor Ω' does not satisfy our gauge condition (68), as the quantities $\overline{n'}^a, \overline{f'}$ associated with Ω' satisfy

$$\overline{f'} = 4, \quad \overline{n'}^a = -2(x-t)^\mu \left(\frac{\partial}{\partial x^\mu}\right)^a, \quad \overline{\nabla'}_a \overline{n'}^b = -2\delta_a{}^b. \tag{B15}$$

The advantage of the conformal transformation (B12) with conformal factor Ω' is however that it preserves the compactness of cross sections of $\mathscr{I}^+$. In fact, the cross section of $\mathscr{I}^+$ corresponding to the outgoing light rays from the apex of V^+ is represented by the "belt" of K ($x^0 = 0, r = 1$), and all other cross sections to the future of this particular one are given by cross sections of the upper cap, and are therefore topological spheres.

We compose the two maps ϕ and ψ to the map $\sigma = \phi \circ \psi^{-1}: K \to W$. Under the map σ the set ∂W^+ is identified with the upper cap ∂K^+ of the double cone K. If we denote $\overline{g}_{ab}$ the Minkowskian metric of W, then under this map, $\overline{g}_{ab}$ gets mapped to the metric $k^{-2}\overline{g'}_{ab}$, where $\overline{g'}_{ab}$ is the Minkowskian metric on K, and where k is calculated to be

$$k = (x - t + b)^\mu (x - t + b)_\mu. \tag{B16}$$

The conformal factor k vanishes on the single null generator emanating from future timelike infinity (represented by the point $x^\mu = t^\mu$ of ∂K^+) parallel to b^μ. This generator corresponds to the generator at infinity in ∂W^+ under the map σ, and the vanishing of k on this generator is a reflection of this fact. (In other words, ∂K^+ is the comactification of ∂W^+).

Returning to the example integral, let $\mathcal{S}$ be a segment of $\mathscr{I}^+$, viewed as a subset of the upper horizon ∂W^+ of W, with noncompact cross sections, i.e., $\mathcal{S}$ has topology $\mathbb{R}^{d-2}\times I$, where I is a compact interval. Let $\mathcal{S}'$ be the segment of ∂K^+ corresponding to $\mathcal{S}$ under σ, i.e., $\sigma(\mathcal{S}')=\mathcal{S}$. Then $\mathcal{S}'$ has compact cross sections homeomorphic to $\mathcal{S}^{d-2}$ as ∂K^+ does. By Eq. (66) the symplectic form satisfies

$$\int_{\mathcal{S}} \Theta = \int_{\mathcal{S}'} \Theta' + \delta \int_{\mathcal{S}'} \Pi', \tag{B17}$$

where Θ' is given in terms of $\Omega' = k^{-1}\sigma^*\Omega$, $g'_{ab} = k^2\sigma^* g_{ab}$, and $\tau'_{ab} = k^{(d-2)/2}\sigma^*\tau_{ab}$ by a formula analogous to (63), and where Π' is given by Eq. (67). Using that $n'^a = -2(x^\mu - t^\mu)(\partial/\partial x^\mu)^a$ by Eq. (B15), as well as the above expression (B16) for the conformal factor k, one immediately finds that

$$k^{-1} n'^a \nabla'_a k = -2 \tag{B18}$$

at points of ∂K^+. Inserting this into the definition of Π', one gets

$$\Pi' = \frac{(d-2)}{2^5 \pi G} \Omega'^{-(d-2)} (g' - \overline{g}')_{cd} q'^{ce} q'^{df} (g' - \overline{g}')_{ef}{}^{(d-1)} \boldsymbol{\epsilon}'. \tag{B19}$$

Now Π' and Θ' are finite at $\mathscr{I}$ as a result of our asymptotic flatness conditions, and the integrals on the right-hand side of Eq. (B17) are over a compact set, $\mathcal{S}'$ of $\mathscr{I}$ (viewed as a subset of the upper cap ∂K^+ via the map σ). This shows that the integral of the symplectic potential over $\mathcal{S}$ appearing on the left-hand side of Eq. (B17) is convergent. The same kind of argument can be made for other integrals appearing in Sec. V.

APPENDIX C: ASYMPTOTIC TRANSLATIONS

We finally discuss the space of translational asymptotic symmetries ξ^a of the form $\xi^a = \alpha n^a - \Omega \nabla^a \alpha$ in $d>4$ dimensions. As discussed in Sec. V, in order for such a vector field to be an asymptotic symmetry, we must satisfy Eqs. (78), (79), and (80) which we here repeat for convenience,

$$\nabla_a \nabla_b \alpha - \Omega^{-1} g_{ab} n^c \nabla_c \alpha = O(\Omega^{(d-4)/2}), \tag{C1}$$

$$\nabla^b (\Omega^{-1} n^a \nabla_a \alpha) = O(\Omega^{(d-4)/2}), \tag{C2}$$

$$\Omega^{-1} n^b \nabla_b (\Omega^{-1} n^a \nabla_a \alpha) = O(\Omega^{(d-4)/2}). \tag{C3}$$

These equations hold in any conformal gauge choice satisfying Eq. (68). Actually, by our asymptotic flatness conditions, if these conditions are satisfied for one given asymptotically flat metric, they are satsified for any asymptotically flat metric [satisfying our gauge choice (68)]. In order to analyze these equations, we may therefore choose g_{ab} to be equal to our Minkowskian background metric $\overline{g}_{ab} = \Omega^2 \phi^* \tilde{\eta}_{ab}$, where ϕ is the conformal map $V_+ \to W$ defined in Eq. (B8), and where the conformal factor is defined in Eq. (B10). The derivative operator $\overline{\nabla}_a$ is then given by the coordinate derivative operator $\partial/\partial x^\mu$, and the associated quantity $\overline{n^a}$ is given by b^μ in Cartesian coordinates. Inserting these expressions and going to Cartesian coordinates, Eqs. (C1), (C2), and (C3) become, respectively,

$$\partial_\mu \partial_\nu \alpha + 2\eta_{\mu\nu} w^{-1} \partial_v \alpha = O(w^{(d-4)/2}), \tag{C4}$$

$$\partial_\mu (w^{-1} \partial_v \alpha) = O(w^{(d-4)/2}), \tag{C5}$$

$$w^{-1}\partial_v(w^{-1}\partial_v\alpha) = O(w^{(d-4)/2}), \tag{C6}$$

where we have now set $w=x^0-x^1$ and $v=x^0+x^1$, and where we remember that the location of null infinity corresponds to $\Omega=-w=0$ in our gauge.

Let us first check that the timelike translational Killing vector fields

$$\tau^a = \tau^\mu\left(\frac{\partial}{\partial x^\mu}\right)^a, \quad \tau^\mu = (\tau^0, \tau^1, \ldots, \tau^{d-1}) = \text{const} \tag{C7}$$

in Minkowski space–time give rise to solutions of Eqs. (C4). Under the identification provided by the map ϕ, these vector fields correspond to

$$\xi^a = \phi * \tau^a = (\alpha b^\mu - \Omega\partial^\mu\alpha)\left(\frac{\partial}{\partial x^\mu}\right)^a = \alpha\overline{n}^a - \Omega\overline{\nabla}^a\alpha, \tag{C8}$$

where

$$\alpha = \tfrac{1}{2}(b^\lambda\tau_\lambda x^\mu x_\mu + 2q_{\mu\nu}\tau^\mu x^\nu + a^\mu\tau_\mu). \tag{C9}$$

By construction, since ϕ is a conformal isometry of Minkowski space–time, we must have

$$\partial_\mu\partial_\nu\alpha + 2\eta_{\mu\nu}w^{-1}\partial_v\alpha = 0, \tag{C10}$$

which can also be verified explicitly. This shows Eq. (C4), and the other equations (C5) and (C6) follow by dotting b^μ into this equation. It is not difficult to see that (in $d>4$), any other solution α to Eqs. (C4), (C5), and (C6) is given by

$$\alpha = \alpha_0 + O(\Omega^{d/2}), \tag{C11}$$

where α_0 is given by Eq. (C9). Inserting this into the definition of χ_{ab}, Eq. (77), we see that

$$\chi_{ab} = \chi_{0ab} + O(1)n_a n_b + O(\Omega), \tag{C12}$$

where χ_{0ab} is defined by Eq. (77), with α replaced by α_0. Now the integrand of the flux associated with an asymptotic symmetry is given by [see Eq. (71)] $N_{ab}\chi^{ab}$ up to numerical factors, and $N_{ab}n^b=0$. Thus, the second term in Eq. (C12) does not contribute to the flux. This shows that the α_0 given by Eq. (C9) are essentially the only solutions to Eqs. (C4), in the sense that any other solution will give rise to the same flux. Hence, the vector space of infinitesimal asymptotic translations is d dimensional in $d>4$, consists of the vector fields $\xi^a=\alpha n^a-\Omega\nabla^a\alpha$, with α given by Eq. (C9) in the gauge that we are working in.

Let us finally characterize the α corresponding to a future directed timelike translational Killing fields τ^μ of Minkowski space–time. A point x^μ of $\mathscr{I}^+$ corresponds to a point on ∂W^+ under the map ϕ, so we have $b^\mu x_\mu=0$ and $x^\lambda x_\lambda = q_{\mu\nu}x^\mu x^\nu$ for such points. Also, since τ^μ is future pointing timelike, we have $a^\mu\tau_\mu b^\nu\tau_\nu > q_{\mu\nu}\tau^\mu\tau^\nu$. Using this, and the inequality obtained by expanding out the relation

$$0 \leqslant q_{\mu\nu}[(b^\lambda\tau_\lambda)^{-1/2}\tau^\mu + (b^\lambda\tau_\lambda)^{1/2}x^\mu][(b^\sigma\tau_\sigma)^{-1/2}\tau^\nu + (b^\sigma\tau_\sigma)^{1/2}x^\nu], \tag{C13}$$

one easily finds that $\alpha>0$ on ∂W^+. Conversely, if τ^μ is such that $\alpha>0$ on ∂W^+, then one sees by the same argument that it must be future directed timelike. Thus, future directed timelike translational Killing fields correspond to asymptotic symmetries ξ^a with $\alpha>0$ on $\mathscr{I}^+$.

We investigate conserved quantities of periodic box-ball systems (PBBS) with arbitrary kinds of balls and box capacity greater than or equal to 1. We introduce the notion of nonintersecting paths on the two dimensional array of boxes, and give a combinatorial formula for the conserved quantities of the generalized PBBS using these paths. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1842354]

I. INTRODUCTION

The box-ball system (BBS) is a reinterpretation of a soliton cellular automaton proposed by Takahashi–Satsuma[1] as a dynamical system of balls in a one dimensional array of boxes.[2] Hence, the BBS shows both a feature of cellular automata (CA) and that of solitons.

CAs are mathematical idealizations of physical systems in which space and time are discrete, and physical quantities take on a finite set of discrete values. The CAs were originally introduced by von Neumann and Ulam as a possible idealization of biological systems, with the particular purpose of modeling biological self-reproduction. Physical systems containing many discrete elements with local interactions are often conveniently modeled as the CAs. Many biological systems have been modeled by the CAs. The CAs have also been used to study problems in number theory and their applications to tapestry design. The CAs play an important role in various fields like these.

On the other hand, the notion of a soliton arose from a peculiar solution of partial differential equations.[3,4] Actually, the system in which solitons exist has continuous and smooth mathematical structures, such as an inverse scattering method, a pseudodifferential operator, an algebraic manifold, an infinite-dimensional Lie group and so on. Because of these rich structures, the soliton systems play an important role in various fields of mathematics and physics.

The reason why the BBS has these two completely different features is well explained by the notion of ultradiscretization.[5] Ultradiscretization is a limiting procedure through which we can construct piecewise linear equations or CAs from continuous equations. By taking the ultradiscrete limit, the rich mathematical structures of soliton systems are introduced to the CAs. On the other hand, the useful properties of the CAs for computer simulation are introduced to the continuous systems by inverse ultradiscretization. Using this limiting procedure, the BBSs are obtained from

$$N = 6,\ M = 2,\ \theta_1 = \theta_2 = \theta_4 = 3,\ \theta_3 = 2,\ \theta_5 = \theta_6 = 1.$$

FIG. 1. Time evolution rule for the PBBS.

the soliton equations (the KdV equation and the Toda equation).[6,7] Thus the BBS has N soliton solutions and an infinite number of conserved quantities and the BBS is called an "integrable" CA.

The periodic box-ball system (PBBS) is the BBS in which the updating rule is extended to be compatible with a periodic boundary condition.[8] Let us consider a one-dimensional array of N boxes. A periodic boundary condition is imposed by assuming that the Nth box is adjacent to the first one. (We may imagine that the boxes are arranged in a circle.) In the generalized PBBS (gPBBS), the capacity of the nth ($1 \leqslant n \leqslant N$) box is denoted by a positive integer θ_n, and we suppose that there are M kinds of balls distinguished by an integer index j ($1 \leqslant j \leqslant M$). When ${}^{\forall}n\,\theta_n = 1$ and $M = 1$, the gPBBS coincides with the PBBS. Then, the rule for the time evolution of the gPBBS from time step t to $t+1$ is given as follows:

(1) At each box, create the same number of copies of the balls with index 1.
(2) Choose one of the copies arbitrarily and move it to the nearest box with an available space to the right of it.
(3) Choose one of the remaining copies and move it to the nearest available box on the right of it.
(4) Repeat the above procedure until all the copies have been moved.
(5) Delete all the original balls with index 1.
(6) Perform the same procedure for the balls with index 2.
(7) Repeat this procedure successively until all of the balls are moved.

An example of the time evolution of the gPBBS according to this rule is shown in Fig. 1.

In Ref. 9, we have established an algorithm to construct the conserved quantities of the gPBBS by means of the ultradiscretization of the nonautonomous discrete KP (ndKP) equation.[10] Using this algorithm, we obtain an expression for the conserved quantities of the gPBBS in the

case of one kind of balls ($M=1$). We have also proved that, when box capacities are all one, our conserved quantities for $M=1$ coincide with those described by the Young diagram.[11]

In this paper, using a path description and the results obtained in Ref. 9, we investigate the conserved quantities of the gPBBS for arbitrary M. In Sec. II, we derive the path description of the characteristic polynomial of a particular matrix. In Sec. III, we briefly summarize the results of Ref. 9, which we will use in the subsequent sections. In Sec. IV, we treat the ndKP equation which corresponds to the gPBBS. We shall obtain an explicit expression for the conserved quantities of the ndKP equation. Using the results in Sec. IV, we construct the conserved quantities of the gPBBS in Sec. V. In Sec. VI, we discuss algebraic aspects of the gPBBS with respect to the affine Weyl group and the crystals of quantum affine algebra. Section VII is devoted to concluding remarks.

II. PATH DESCRIPTION OF CHARACTERISTIC POLYNOMIAL FOR A PARTICULAR MATRIX

For a particular matrix A which contains a parameter μ in the upper half elements, we give a combinatorial description for coefficients of the characteristic polynomial $\det(\lambda I-A)$ in λ and μ in terms of nonintersecting paths (Theorem II.1). The result will be used in the subsequent sections to obtain a combinatorial formula for conserved quantities of the gPBBS.

We denote by S_X the set of all permutations of elements in $X\subset\{1,2,\ldots,N\}$. Let A be an arbitrary $N\times N$ matrix, and $A_{n,m}$ denote the (n,m) element of A. The characteristic polynomial of A is

$$\begin{aligned}\det(\lambda I-A) &= \sum_{\sigma\in S_{\{1,2,\ldots,N\}}} \operatorname{sgn}(\sigma)\prod_{i=1}^{N}(\lambda\delta_{i,\sigma(i)}-A_{i,\sigma(i)})\\ &= \sum_{k=0}^{N}(-1)^{N-k}\lambda^{k}\sum_{\substack{X\subset\{1,2,\ldots,N\}\\ \sharp X=N-k}}\sum_{\sigma\in S_X}\operatorname{sgn}(\sigma)\prod_{i\in X}A_{i,\sigma(i)},\end{aligned}$$

where $\delta_{n,m}$ is Kronecker's delta. For $J\subset X$, we set

$$S_X^J := \left\{\sigma\in S_X \,\middle|\, \begin{array}{ll} i<\sigma(i) & (i\in J),\\ i\geqslant\sigma(i) & (i\in X-J).\end{array}\right\}.$$

Since

$$S_X=\bigcup_{j=0}^{N}\bigcup_{\substack{J\subset X\\ \sharp J=j}} S_X^J \quad \text{(disjoint)},$$

we have

$$\begin{aligned}\det(\lambda I-A) &= \sum_{k=0}^{N}(-1)^{N-k}\lambda^{k}\sum_{\substack{X\subset\{1,2,\ldots,N\}\\ \sharp X=N-k}}\sum_{j=0}^{N-k}\sum_{\substack{J\subset X\\ \sharp J=j}}\sum_{\sigma\in S_X^J}\operatorname{sgn}(\sigma)\prod_{i\in X}A_{i,\sigma(i)}\\ &= \sum_{k=0}^{N}(-1)^{N-k}\lambda^{k}\sum_{j=0}^{N-k}\sum_{\substack{X\subset\{1,2,\ldots,N\}\\ \sharp X=N-k}}\sum_{\substack{J\subset X\\ \sharp J=j}}\sum_{\sigma\in S_X^J}\operatorname{sgn}(\sigma)\left(\prod_{i\in J}A_{i,\sigma(i)}\right)\left(\prod_{i\in X-J}A_{i,\sigma(i)}\right). \qquad (1)\end{aligned}$$

Now we assume

$$A = (D_0 - \Upsilon)(D_1 - \Upsilon)\cdots(D_M - \Upsilon), \tag{2}$$

where $D_i = \mathrm{diag}(x_{1,i}, x_{2,i}, \ldots, x_{N,i})$ $(i = 0, 1, \ldots, M)$ and

$$\Upsilon := \begin{bmatrix} & & & & \mu \\ 1 & & & & \\ & 1 & & & \\ & & \ddots & & \\ & & & 1 & \end{bmatrix}.$$

If we set $D_i^{(0)} := D_i$ and $D_i^{(r)} := \mathrm{diag}(x_{N-r+1,i}, x_{N-r+2,i}, \ldots, x_{N,i}, x_{1,i}, \ldots, x_{N-r,i})$ for $0 < r < N$, we have $D_i^{(r+1)}\Upsilon = \Upsilon D_i^{(r)}$. Hereafter, for $i = 0$, we define $\Sigma_{c_1<c_2<\cdots<c_i}\cdots := 1$. Then

$$A = \sum_{\ell=0}^{M+1} (-1)^\ell \left(\sum_{\substack{0\le h_1<h_2<\cdots \\ \cdots<h_{M-\ell+1}\le M}} D_{h_1}^{(h_1)} D_{h_2}^{(h_2-1)} \cdots D_{h_{M-\ell+1}}^{(h_{M-\ell+1}-M+\ell)} \right) \Upsilon^\ell.$$

We assume $M+1 < N$. The (n,m) element of A is the following.

(i) if $m = n$, $x_{n,0}x_{n,1}\cdots x_{n,M}$;
(ii) if $m = N+n-\ell$ $(\ell = 1, 2, \ldots, M)$,

$$(-1)^\ell \mu \sum_{\substack{0\le h_1<h_2<\cdots \\ \cdots<h_{M-\ell+1}\le M}} \prod_{i=1}^{M-\ell+1} x_{n-h_i+i-1,h_i};$$

(ii′) if $m = n-\ell$ $(\ell = 1, 2, \ldots, M)$,

$$(-1)^\ell \sum_{\substack{0\le h_1<h_2<\cdots \\ \cdots<h_{M-\ell+1}\le M}} \prod_{i=1}^{M-\ell+1} x_{n-h_i+i-1,h_i};$$

(iii) if $m = N+n-M-1$, $(-1)^{M+1}\mu$;
(iii′) if $m = n-M-1$, $(-1)^{M+1}$;
(iv) otherwise, 0.

Hence, from (1), we have

$$\begin{aligned} \det(\lambda I - A) = \sum_{k=0}^{N} (-1)^{N-k} \lambda^k \sum_{j=0}^{N-k} \mu^j \sum_{\substack{X\subset\{1,2,\ldots,N\} \\ \sharp X = N-k}} \sum_{\substack{J\subset X \\ \sharp J = j}} \sum_{\sigma\in S_X^J} \mathrm{sgn}(\sigma) \\ \times \left(\prod_{n\in J} \left(\sum_{\substack{0\le h_1<h_2<\cdots \\ \cdots<h_{M-N-n+\sigma(n)+1}\le M}} \prod_{i=1}^{M-N-n+\sigma(n)+1} x_{n-h_i+i-1,h_i} \right) \right) \\ \times \left(\prod_{n\in X-J} \left(\sum_{\substack{0\le h_1<h_2<\cdots \\ \cdots<h_{M-n+\sigma(n)+1}\le M}} \prod_{i=1}^{M-n+\sigma(n)+1} x_{n-h_i+i-1,h_i} \right) \right). \end{aligned} \tag{3}$$

A combinatorial description of the coefficients is possible.

By $C_{N,M+1}$ we denote the $N\times(M+1)$ boxes in Fig. 2 and by (n,m)-box the box at the nth column in the $(m+1)$th row. We assume that the Nth column is adjacent to the first one.

Let a and b be column indices $(a, b = 1, 2, \ldots, N)$. A *path* connecting the *initial point a* and the

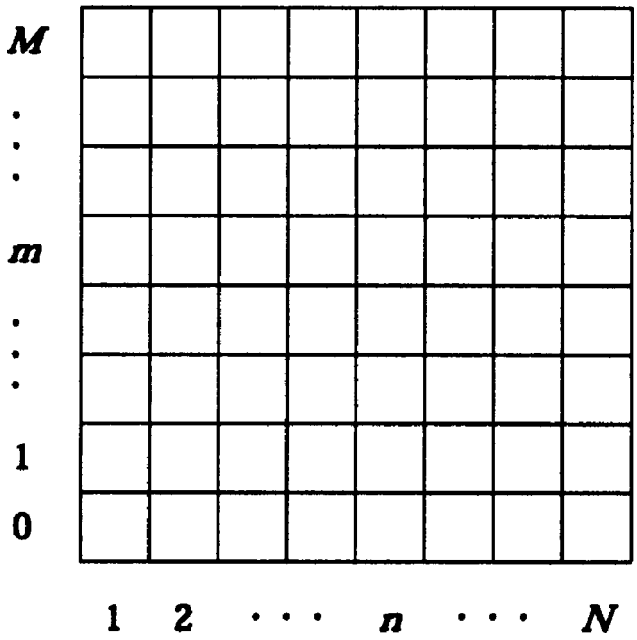

FIG. 2. $N\times(M+1)$ boxes.

end point b is a (continuous) polygonal line from the initial point *a* to the end point *b* which consists of (i), (ii) or (iii) in Fig. 3 locally; here by the initial point *a* we mean the middle point of the south edge of $(a,0)$-box and by the end point *b* the middle point of the north edge of (b,M)-box. For example, the left-hand part in Fig. 4 shows a path connecting the initial point 1 and the end point 1, and the right-hand part shows a path from 5 to 2.

There is a natural correspondence between $\Pi_{i=1}^{M-\ell+1}x_{n-h_i+i-1,h_i}$ $(0\leqslant h_1<h_2<\cdots<h_{M-\ell+1}\leqslant M)$ and a path on $C_{N,M+1}$. To put it concretely, we draw the line (i) on $(n-h_i+i-1,h_i)$-box $(i=1,2,\ldots,M-\ell+1)$; for each r, $h_i<r<h_{i+1}$, we draw the line (ii) on $(n+i-r,r)$-box and the line (iii) on $(n+i-r-1,r)$-box where $h_0=-1$ and $h_{M-\ell+2}=M+1$; then we obtain a path. For example, for $N=8$ and $M=5$, $x_{1,0}x_{1,1}x_{1,2}x_{1,3}x_{1,4}x_{1,5}$ and $x_{5,0}x_{4,2}x_{2,5}$ correspond to paths in Fig. 4, respectively.

Let $X=\{d_1,d_2,\ldots,d_{N-k}\}$ $(1\leqslant d_1<d_2<\cdots<d_{N-k}\leqslant N)$; we denote by $\mathcal{P}(d;\sigma)$ the set of all paths which connect the initial point d and the end point $\sigma(d)$ $(d\in X,\ \sigma\in S_X$; cf. Fig. 5). Define $\xi_{n,m}:\mathcal{P}(d;\sigma)\to\{x_{n,m},1\}$ as

$$\xi_{n,m}(P):=\begin{cases}x_{n,m} & (P \text{ has the vertical line on the}(n,m)\text{-box of } C_{N,M+1}),\\ 1 & (\text{otherwise}),\end{cases} \tag{4}$$

where $P\in\mathcal{P}(d;\sigma)$. Then, we obtain

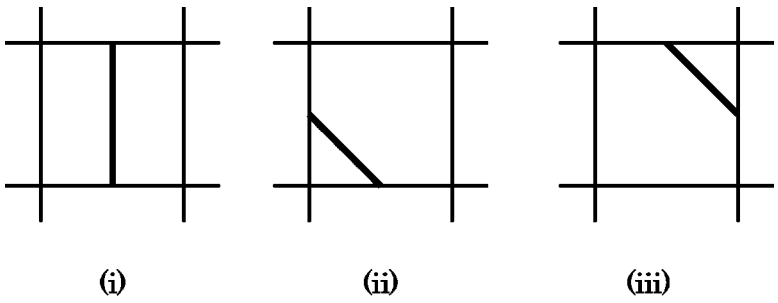

FIG. 3. A line can pass through a box in three possible ways.

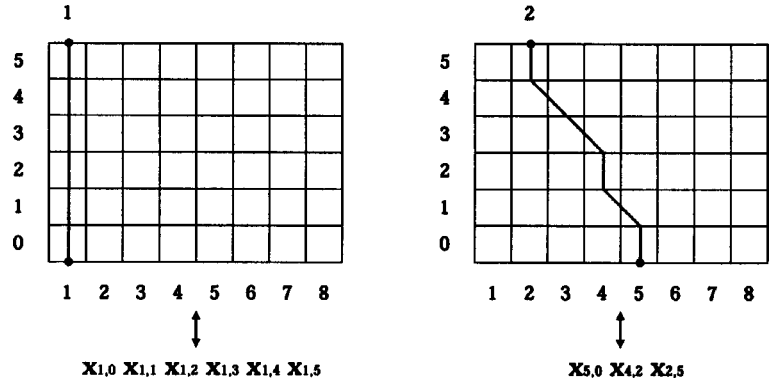

FIG. 4. Paths corresponding to $x_{1,0}x_{1,1}x_{1,2}x_{1,3}x_{1,4}x_{1,5}$ and $x_{5,0}x_{4,2}x_{2,5}$.

$$\sum_{\substack{X\subset\{1,2,\ldots,N\}\\ \sharp X=N-k}}\sum_{\substack{J\subset X\\ \sharp J=j}}\sum_{\sigma\in S_X^J}\operatorname{sgn}(\sigma)\left(\prod_{n\in J}\left(\sum_{\substack{0\leqslant h_1<h_2<\cdots\\ \cdots<h_{M-N-n+\sigma(n)+1}\leqslant M}}\prod_{i=1}^{M-N-n+\sigma(n)+1}x_{n-h_i+i-1,h_i}\right)\right)$$
$$\times\left(\prod_{n\in X-J}\left(\sum_{\substack{0\leqslant h_1<h_2<\cdots\\ \cdots<h_{M-n+\sigma(n)+1}\leqslant M}}\prod_{i=1}^{M-n+\sigma(n)+1}x_{n-h_i+i-1,h_i}\right)\right)$$
$$=\sum_{\substack{1\leqslant d_1<d_2<\cdots\\ \cdots<d_{N-k}\leqslant N}}\sum_{\substack{J\subset X\\ \sharp J=j}}\sum_{\sigma\in S_X^J}\sum_{P_1\in\mathcal{P}(d_1;\sigma)}\cdots\sum_{P_{N-k}\in\mathcal{P}(d_{N-k};\sigma)}\operatorname{sgn}(\sigma)\prod_{i=1}^{N-k}\prod_{n=1}^{N}\prod_{m=0}^{M}\xi_{n,m}(P_i). \tag{5}$$

If we draw $N-k$ paths $P_1\in\mathcal{P}(d_1;\sigma),\ldots,P_{N-k}\in\mathcal{P}(d_{N-k};\sigma)$ on $C_{N,M+1}$, some paths may go

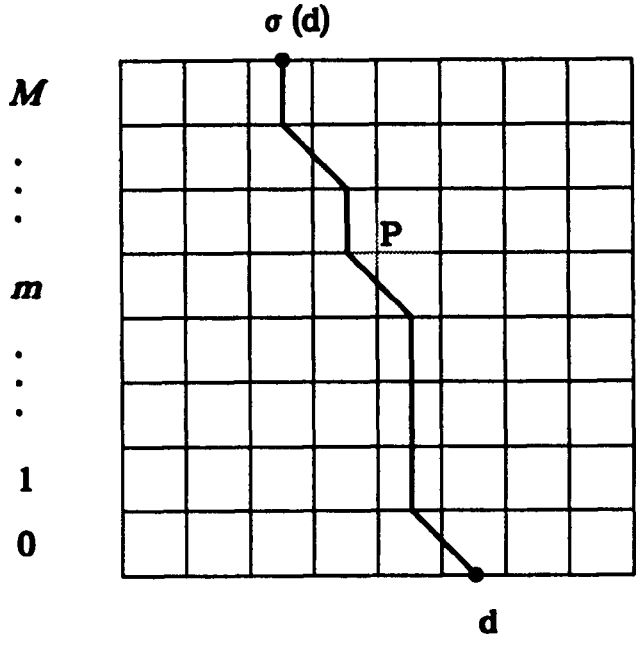

FIG. 5. A path $P\in\mathcal{P}(d;\sigma)$.

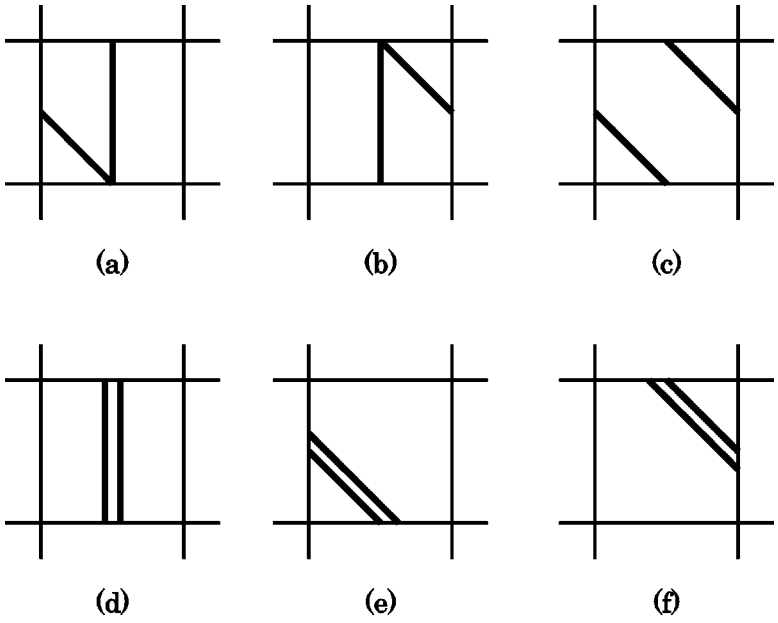

FIG. 6. Two lines can pass through a box in six possible ways.

through the same box (cf. Fig. 6). When two paths pass through a single box, there are six possible states as shown in Fig. 6. Except for the state (c) in Fig. 6, the lines touch each other. When the lines touch each other, we say that the lines *intersect*.

Now we show that, in (5), terms corresponding to intersecting paths cancel out. Let $P_{i_1} \in \mathcal{P}(d_{i_1};\sigma)$ and $P_{i_2} \in \mathcal{P}(d_{i_2};\sigma)$ be paths which intersect $(i_1 < i_2)$. Then at some box, the state (a) occurs as in the left-hand part of Fig. 7. Let P'_{i_1} and P'_{i_2} denote new paths constructed from P_{i_1} and P_{i_2} by exchanging lines in the box as shown in Fig. 7, where $P'_{i_1} \in \mathcal{P}(d_{i_1};\sigma')$, $P'_{i_2} \in \mathcal{P}(d_{i_2};\sigma')$ and

$$\sigma' = \begin{pmatrix} d_1 & \cdots & d_{i_1} & \cdots & d_{i_2} & \cdots & d_{N-k} \\ \sigma(d_1) & \cdots & \sigma(d_{i_2}) & \cdots & \sigma(d_{i_1}) & \cdots & \sigma(d_{N-k}) \end{pmatrix}.$$

Since $\mathrm{sgn}(\sigma) = -\mathrm{sgn}(\sigma')$ and $\xi_{n,m}(P'_{i_1})\xi_{n,m}(P'_{i_2}) = \xi_{n,m}(P_{i_1})\xi_{n,m}(P_{i_2})$ for any $P_i \in \mathcal{P}(d_i;\sigma)$ $(i \neq i_1, i_2)$, the terms corresponding to $(P_1, \ldots, P_{i_1}, \ldots, P_{i_2}, \ldots, P_{N-k})$ and $(P_1, \ldots, P'_{i_1}, \ldots, P'_{i_2}, \ldots, P_{N-k})$ cancel each other out in (5).

If any two of $P_1, \ldots, P_{N-k}$ do not intersect, we say that the paths are nonintersecting. Hence only terms corresponding to nonintersecting paths contribute to (5).

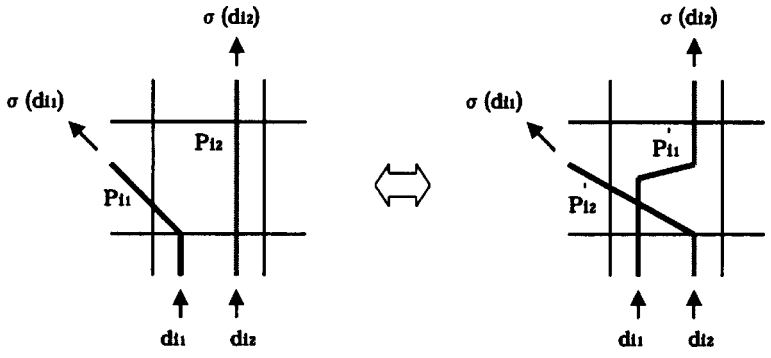

FIG. 7. Definition of P'_{i_1} and P'_{i_2}.

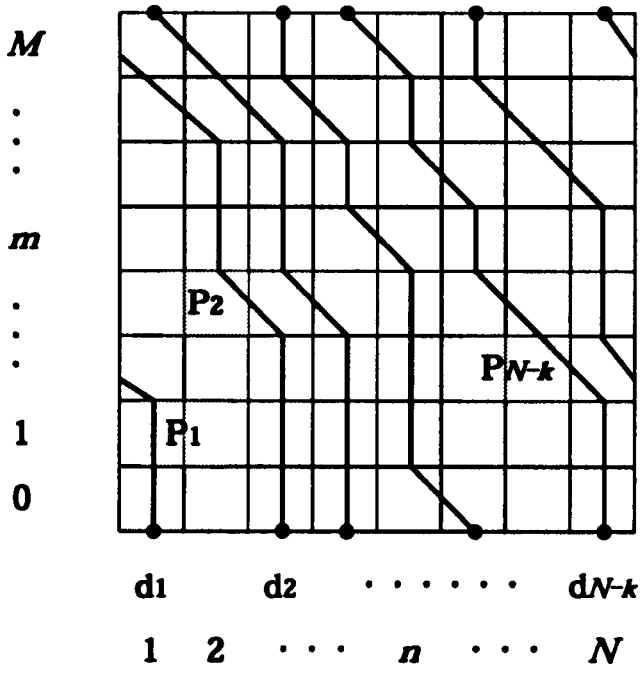

FIG. 8. Nonintersecting paths $P_1, \ldots, P_{N-k}$.

When $P_1, \ldots, P_{N-k}$ are nonintersecting $[P_1 \in \mathcal{P}(d_1;\sigma), \ldots, P_{N-k} \in \mathcal{P}(d_{N-k};\sigma)$ and $\sigma \in S_X^J, \sharp J = j]$,

$$\sigma(d_i) = \begin{cases} d_{i-j} & (i-j \geqslant 1), \\ d_{N+i-j} & (i-j \leqslant 0) \end{cases}$$

(cf. Fig. 8 and Fig. 9), and therefore $\mathrm{sgn}(\sigma) = (-1)^{j(N-k-1)}$.

In (3), the upper bound of the summation over j is $\{[(N-k)/N](M+1)\}$ where $[\ell]$ denotes the largest integer which does not exceed ℓ.

From (3) and (5), we obtain the following theorem.

Theorem II.1: *For A defined in (2), it holds that*

$$\det(\lambda I - A) = \sum_{k=0}^{N} (-1)^{N-k} \lambda^k \sum_{j=0}^{[(N-k)(M+1)/N]} (-1)^{j(N-k-1)} \mu^j \sum_{\substack{1 \leqslant d_1 < d_2 < \cdots \\ \cdots < d_{N-k} \leqslant N}} \sum_{\substack{(P_1,\ldots,P_{N-k}) \\ \in \mathcal{P}^{(j)}(d_1,\ldots,d_{N-k})}} \prod_{i=1}^{N-k} \prod_{n=1}^{N} \prod_{m=0}^{M} \xi_{n,m}(P_i),$$

where $\xi_{n,m}$ *are defined in (4) and*

$$\mathcal{P}^{(j)}(d_1, \ldots, d_{N-k}) := \left\{ (P_1, \ldots, P_{N-k}) \;\middle|\; \begin{array}{l} P_i \text{ connects the initial point } d_i \text{ and the} \\ \text{end point } d_{N+i-j} (1 \leqslant i \leqslant j); P_i \\ \text{connects } d_i \text{ and } d_{i-j} (j < i \leqslant N-k). \\ \text{Any two of them are nonintersecting} \end{array} \right\}. \tag{6}$$

■

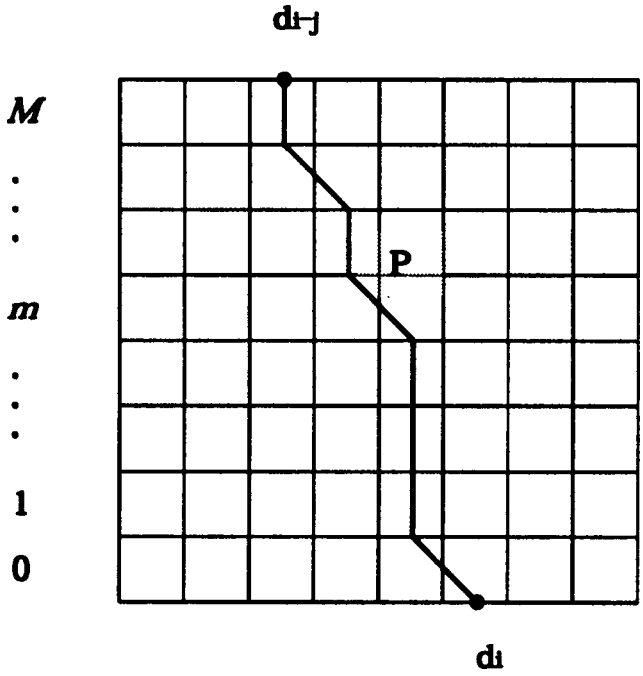

FIG. 9. A path $P \in \mathcal{P}(d_i;\sigma)$, $\sigma \in S_X^J$, $\sharp J=j$, which connects d_i and $\sigma(d_i)=d_{i-j}$.

III. gPBBS AND ndKP EQUATION

We briefly summarize the results obtained in Ref. 9 to fix the notations used in the subsequent sections.

A. gPBBS and its equation of motion

In order to describe the dynamics of the gPBBS, we introduce a new independent variable s ($s \in \mathbb{Z}$). As any integer s can be uniquely expressed as $s=Mt+j$ ($t \in \mathbb{Z}, 1 \leqslant j \leqslant M$), we denote by u_n^s the number of balls with index $j \equiv s \bmod M$ in the nth box at time step $t=[(s-1)/M]$, where $[x]$ denotes the largest integer which does not exceed x. In other words, the new *time* variable s is a refinement of the original time, indicating explicitly when balls with index j move.

We assume that θ_n and u_n^s satisfy the relation

$$\sum_{n=1}^{N} \theta_n - \sum_{j=1}^{M} \sum_{n=1}^{N} u_n^j \geqslant \sum_{n=1}^{N} u_n^k \quad (k=1,2,\ldots,M). \tag{7}$$

The first and second terms of the left-hand side of (7) represent the number of spaces and the number of balls in the gPBBS, respectively, hence the left-hand side is the total number of free spaces of the gPBBS. The right-hand side of (7) is the number of balls with index k. Thus (7) requires the total number of free spaces of the gPBBS to be larger than the number of copies of any type of ball in the time evolution process.

Let us consider the process at time s, i.e., the movement of the balls with index j at time step t where $s=Mt+j$; we often use s instead of j, i.e., we treat the indices modulo M. If we define κ_n^s, which denotes the number of spaces of the nth box at s, by

$$\kappa_n^s := \theta_n - (u_n^s + u_n^{s-1} + \cdots + u_n^{s-M+1}),$$

condition (7) is rewritten as

$$\sum_{n=1}^{N} \kappa_n^s \geqslant \sum_{n=1}^{N} u_n^{s-M+k} \quad (k=1,2,\ldots,M).$$

Theorem III.1 (Ref. 9): *The time evolution of the gPBBS is described by an ultradiscrete equation,*

$$u_n^{s+1} - \kappa_n^s = \max_{k=1,\ldots,N}\left[\sum_{j=1}^{k} u_{n-j}^{s-M+1} - \kappa_{n-j+1}^s\right] - \max\left[0, \max_{k=1,\ldots,N-1}\left[\sum_{j=1}^{k} u_{n-j}^{s-M+1} - \kappa_{n-j+1}^s\right]\right]. \tag{8}$$

■

B. From ndKP equation to gPBBS

The ndKP equation is obtained from the generating formula of the KP hierarchy.[12,13] It is given as

$$(b(m)-c(n))\tau(l+1,m,n)\tau(l,m+1,n+1) + (c(n)-a(l))\tau(l,m+1,n)\tau(l+1,m,n+1) + (a(l) - b(m))\tau(l,m,n+1)\tau(l+1,m+1,n) = 0, \tag{9}$$

where l, m, $n \in \mathbb{Z}$ are independent variables, the tau function $\tau: \mathbb{Z}\times\mathbb{Z}\times\mathbb{Z}\to\mathbb{R}$ (or $\mathbb{C}$) is dependent variable and the coefficients $a(l)$, $b(m)$, $c(n)$ are arbitrary functions which depend on the independent variables l, m, n, respectively.

In order to relate the ndKP equation to the gPBBS, we take $a(l)=0$, $b(m)=1$, $c(n)=1+\delta_n$ and impose the following constraint on $\tau(l,m,n)$:

$$\tau(l,m,n) = \tau(l-M, m-1, n).$$

If we define $\sigma_n^s := \tau(s-1,0,n)$, (9) turns into

$$\frac{\sigma_{n+1}^{s+M-1}\sigma_{n+1}^{s}}{\sigma_{n+1}^{s+M}\sigma_{n+1}^{s-1}} - (1+\delta_{n+1})\frac{\sigma_n^{s-1}\sigma_{n+1}^{s}}{\sigma_{n+1}^{s-1}\sigma_n^s} = -\delta_{n+1}\frac{\sigma_n^{s+M}\sigma_{n+1}^{s}}{\sigma_n^s\sigma_{n+1}^{s+M}}. \tag{10}$$

Furthermore, we define U_n^s and K_n^s as

$$U_n^s := \frac{\sigma_{n+1}^s\sigma_n^{s+1}}{(1+\delta_{n+1})\sigma_n^s\sigma_{n+1}^{s+1}}, \quad \frac{1}{K_n^s} = \delta_{n+1}\cdot\prod_{j=1}^{M} U_n^{s-j+1}$$

and impose the following periodic condition on U_n^s:

$$U_n^s = U_{n+N}^s. \tag{11}$$

Then, from (10), we have

$$\frac{U_n^{s+1}}{K_n^s} = \frac{\displaystyle\sum_{k=1}^{N}\prod_{j=1}^{k}\frac{U_{n-j}^{s-M+1}}{K_{n-j+1}^s}}{\displaystyle 1+\sum_{k=1}^{N-1}\prod_{j=1}^{k}\frac{U_{n-j}^{s-M+1}}{K_{n-j+1}^s}}. \tag{12}$$

To take the ultradiscrete limit, we set $U_n^s = e^{u_n^s/\epsilon}$, $K_n^s = e^{\kappa_n^s/\epsilon}$, $1/\delta_{n+1} = e^{\theta_n/\epsilon}$. Then, we found the following.

Theorem III.2 (Ref. 9): *The ultradiscrete limit of the constrained ndKP equation with the periodic boundary condition [i.e., (11) and (12)] coincides with the time evolution equation of the gPBBS (8).* ■

IV. CONSERVED QUANTITIES OF ndKP EQUATION

In Ref. 9 we derived the Lax representation for the ndKP equation when it has period N in the spatial variable n. In short, the equation (12) is equivalent to the matrix equation

$$\tilde{M}(s)L(M;s) = L(M;s-1)\tilde{M}(s),$$

where $\tilde{M}(s) = G_{U;s} - \tilde{\Upsilon}$,

$$L(M;s) = (-G_{K;s} + \tilde{\Upsilon})(G_{U;s-M+1} - \tilde{\Upsilon})(G_{U;s-M+2} - \tilde{\Upsilon}) \cdots (G_{U;s} - \tilde{\Upsilon}), \tag{13}$$

$G_{K;s} = \mathrm{diag}(1/K_1^s, 1/K_2^s, \ldots, 1/K_N^s)$, $G_{U;s} = \mathrm{diag}(1/U_1^s, 1/U_2^s, \ldots, 1/U_N^s)$, and

$$\tilde{\Upsilon} := \begin{bmatrix} & & & & (1+\delta_N)\cdot\eta \\ 1+\delta_1 & & & & \\ & 1+\delta_2 & & & \\ & & \ddots & & \\ & & & 1+\delta_{N-1} & \end{bmatrix};$$

here, η is an arbitrary parameter.

This means

$$\det(\lambda I + L(M;s)) = \det(\lambda I + L(M;s-1));$$

therefore, the coefficients e_k of the characteristic polynomial

$$\det(\lambda I + L(M;s)) = \lambda^N + e_{N-1}\lambda^{N-1} + e_{N-2}\lambda^{N-2} + \cdots + e_1\lambda + e_0$$

are conserved in time s. Furthermore, since η is arbitrary and e_k contain η, if we define $e_k^{[j]}$ by

$$e_k = \sum_j e_k^{[j]} \eta^j, \tag{14}$$

then $e_k^{[j]}$ are also conserved.

Let $\Delta := \Pi_{i=1}^N (1+\delta_i)$,

$$\Upsilon := \begin{bmatrix} & & & & \eta\Delta \\ 1 & & & & \\ & 1 & & & \\ & & \ddots & & \\ & & & 1 & \end{bmatrix},$$

and $D_\delta := \mathrm{diag}(1, 1+\delta_1, (1+\delta_1)(1+\delta_2), \ldots, \Pi_{i=1}^{N-1}(1+\delta_i))$. Since $\Upsilon = (D_\delta)^{-1}\tilde{\Upsilon}D_\delta$ we have (Ref. 9)

$$\det(\lambda I + L(M;s)) = \det(\lambda I + L_0(M;s)), \tag{15}$$

where

$$L_0(M;s) := (-G_{K;s} + \Upsilon)(G_{U;s-M+1} - \Upsilon)(G_{U;s-M+2} - \Upsilon) \cdots (G_{U;s} - \Upsilon).$$

From Theorem II.1, we obtain a combinatorial formula for $e_k^{[j]}$ immediately.

Theorem IV.1: *Set*

$$x_{n,0} = \frac{1}{K_n^s}, \quad x_{n,m} = \frac{1}{U_n^{s-M+m}} \quad (m \neq 0)$$

in (4) and set $\mu = \eta\Delta$. *Then, for* $k = 0, 1, \ldots, N$ *and* $j = 0, 1, \ldots, [(N-k)(M+1)/N]$, *it holds that*

$$e_k^{[j]} = (-1)^{\ell(k,j)}\Delta^j \sum_{\substack{1\leqslant d_1<d_2<\cdots \\ \cdots<d_{N-k}\leqslant N}} \sum_{(P_1,\ldots,P_{N-k}) \atop \in \mathcal{P}^{(j)}(d_1,\ldots,d_{N-k})} \prod_{i=1}^{N-k}\prod_{n=1}^{N}\prod_{m=0}^{M} \xi_{n,m}(P_i),$$

where $\ell(k,j) := (j+1)N-(k+j+kj)$. ■

V. CONSERVED QUANTITIES OF gPBBS

Using the results in Sec. IV, we construct the conserved quantities of the gPBBS.

For $k=0,1,\ldots,N$ and $j=0,1,\ldots,[(N-k)(M+1)/N]$, the ultradiscrete limit of $e_k^{[j]}$ is

$$ue_k^{[j]} := -\lim_{\epsilon\to+0}\epsilon\log((-1)^{\ell(k,j)}e_k^{[j]}) = -\lim_{\epsilon\to+0}\epsilon\log\left(\Delta^j \sum_{\substack{1\leqslant d_1<d_2<\cdots \\ \cdots<d_{N-k}\leqslant N}} \sum_{(P_1,\ldots,P_{N-k}) \atop \in \mathcal{P}^{(j)}(d_1,\ldots,d_{N-k})} \prod_{i=1}^{N-k}\prod_{n=1}^{N}\prod_{m=0}^{M} \xi_{n,m}(P_i)\right).$$

Since θ_n is the capacity of the nth box,

$$\lim_{\epsilon\to+0}\epsilon\log\Delta^j = j\cdot\lim_{\epsilon\to+0}\epsilon\log\prod_{j=1}^{N}(1+e^{-\theta_j/\epsilon}) = j\cdot\sum_{j=1}^{N}\max[0,-\theta_j] = 0.$$

Therefore, from Theorem IV.1, $ue_k^{[j]}$ is given by the following.

Theorem V.1: *Set*

$$x_{n,0} = \kappa_n^s, \quad x_{n,m} = u_n^{s-M+m}\ (m\neq 0)$$

in (4). Then, for $k=0,1,\ldots,N$ *and* $j=0,1,\ldots,[(N-k)(M+1)/N]$, *it holds that*

$$ue_k^{[j]} = \min_{\substack{1\leqslant d_1<d_2<\cdots \\ \cdots<d_{N-k}\leqslant N}}\left[\min_{(P_1,\ldots,P_{N-k}) \atop \in \mathcal{P}^{(j)}(d_1,\ldots,d_{N-k})}\left[\sum_{i=1}^{N-k}\sum_{n=1}^{N}\sum_{m=0}^{M}\xi_{n,m}(P_i)\right]\right].$$

■

Remark V.1: The conserved quantity $ue_k^{[0]}$ $(0\leqslant k\leqslant N)$ *is trivial. Since* $j=0$, *all paths are vertical lines. Hence we have*

$$ue_k^{[0]} = \min_{\substack{1\leqslant d_1<d_2<\cdots \\ \cdots<d_{N-k}\leqslant N}}\left[\sum_{i=1}^{N-k}\left(\kappa_{d_i}^s + \sum_{m=1}^{M}u_{d_i}^{s-M+m}\right)\right] = \min_{\substack{1\leqslant d_1<d_2<\cdots \\ \cdots<d_{N-k}\leqslant N}}\left[\sum_{i=1}^{N-k}\theta_{d_i}\right].$$

As θ_n *is the capacity of the nth box,* $ue_k^{[0]}$ *does not depend on the time steps. So we are not interested in them.*

Remark V.2: Once we obtain all quantities that are conserved in variable s, we are to have all quantities that are conserved in the original time variable t. The reasoning is as follows: Assume that A_1 *is a conserved quantity of the gPBBS; this means* $A_1=A_1(s)$ *has period M in s.* [*Since equation of motion (8) is Mth order in s,* $A_1(s)$ *is written as*

$$A_1(s) = F(u_1^s,\ldots,u_N^s,u_1^{s-1},\ldots,u_N^{s-1},\ldots,u_1^{s-M+1},\ldots,u_N^{s-M+1})$$

by some function F.] *Let* $A_j(s)=A_1(s+j-1)$ $(j=2,3,\ldots)$; *they all have period M in s. By definition* $A_j(s+1)=A_{j+1}(s)$ $(j=1,2,\ldots)$, *and, since* $A_1(s)$ *has period M,* $A_M(s+1)=A_1((s+1)+M-1)=A_1(s+M)=A_1(s)$; *hence, symmetric polynomials of* $A_1(s),\ldots,A_M(s)$ *are conserved in s. More explicitly, let* $S_k(s)$ *be the kth elementary symmetric polynomial of* $A_1(s),\ldots,A_M(s)$; *then, we have M quantities* $S_1(s),\ldots,S_M(s)$ *that are conserved in s. Conversely, once we know the elementary symmetric polynomials* $S_1(s),\ldots,S_M(s)$ *of* $A_1(s),\ldots,A_M(s)$, *we can obtain* $A_1(s),\ldots,A_M(s)$. *Therefore, the statement follows.*

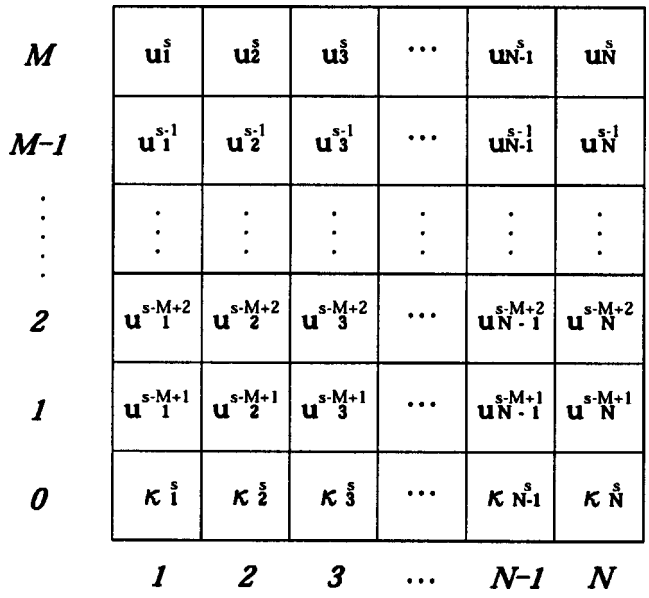

FIG. 10. Associate values κ_n^s, $u_n^s, \ldots, u_n^{s-M+1}$ with boxes of $C_{N,M+1}$.

An easy way to read off $\Sigma_{i=1}^{N-k}\Sigma_{n=1}^{N}\Sigma_{m=0}^{M}\xi_{n,m}(P_i)$ is as follows: Associate values κ_n^s, $u_n^s, \ldots, u_n^{s-M+1}$ with boxes of $C_{N,M+1}$ as shown in Fig. 10. For $(P_1, \ldots, P_{N-k}) \in \mathcal{P}^{(j)}(d_1, \ldots, d_{N-k})$, summing up the values corresponding to the vertical lines of the paths, we get the value $\Sigma_{i=1}^{N-k}\Sigma_{n=1}^{N}\Sigma_{m=0}^{M}\xi_{n,m}(P_i)$.

Example V.1: For a state in Fig. 11 $(N=10, M=5)$*, we obtain a table in Fig. 12. For paths shown in Fig. 13,*

$$\sum_{i=1}^{N-k}\sum_{n=1}^{N}\sum_{m=0}^{M}\xi_{n,m}(P_i) = (0+0+1)+(0+1+0+0)+(0+0+0+0)+(0+1+0)+(0+0+1)$$
$$+(0+1+0)+(1+0)=6.$$

Occasionally these paths minimize $\Sigma_{i=1}^{N-k}\Sigma_{n=1}^{N}\Sigma_{m=0}^{M}\xi_{n,m}(P_i)$*; thus,* $ue_3^{[2]}$ *is* 6.

VI. DISCUSSION

In this section we discuss some algebraic aspects of the gPBBS. The time evolution of the gPBBS is decomposed into a product of transformations, each of which is a representation of the generators of the affine Weyl group $\widetilde{W}(A_M^{(1)})$. Furthermore a state of the gPBBS is naturally identified with a vector of a tensor product of the crystals $U_q'(A_M^{(1)})$, and a time evolution pattern is interpreted as twisted lattices of the crystals $U_q'(A_{N-1}^{(1)})$ whose Boltzmann weights are determined by the combinatorial R matrices.

A. Affine Weyl group and gPBBS

Let $\mathcal{T}$ be the set of $N\times(M+1)$ rectangular tableaux with integer entries, and $s_\ell(\ell\in\mathbb{Z}/(M+1)\mathbb{Z})$ and π be mappings: $\mathcal{T}\to\mathcal{T}$. For a tableau

$$Y=\begin{array}{|c|c|c|c|}\hline y_{1,M} & y_{2,M} & \cdots & y_{N,M}\\ \hline \vdots & \vdots & \cdots & \vdots\\ \hline y_{1,1} & y_{2,1} & \cdots & y_{N,1}\\ \hline y_{1,0} & y_{2,0} & \cdots & y_{N,0}\\ \hline\end{array},$$

these mappings are given as

$$s_\ell(Y)=\begin{array}{|c|c|c|c|}\hline s_\ell(y_{1,M}) & s_\ell(y_{2,M}) & \cdots & s_\ell(y_{N,M})\\ \hline \vdots & \vdots & \cdots & \vdots\\ \hline s_\ell(y_{1,1}) & s_\ell(y_{2,1}) & \cdots & s_\ell(y_{N,1})\\ \hline s_\ell(y_{1,0}) & s_\ell(y_{2,0}) & \cdots & s_\ell(y_{N,0})\\ \hline\end{array},$$

$$\pi(Y)=\begin{array}{|c|c|c|c|}\hline \pi(y_{1,M}) & \pi(y_{2,M}) & \cdots & \pi(y_{N,M})\\ \hline \vdots & \vdots & \cdots & \vdots\\ \hline \pi(y_{1,1}) & \pi(y_{2,1}) & \cdots & \pi(y_{N,1})\\ \hline \pi(y_{1,0}) & \pi(y_{2,0}) & \cdots & \pi(y_{N,0})\\ \hline\end{array},$$

where

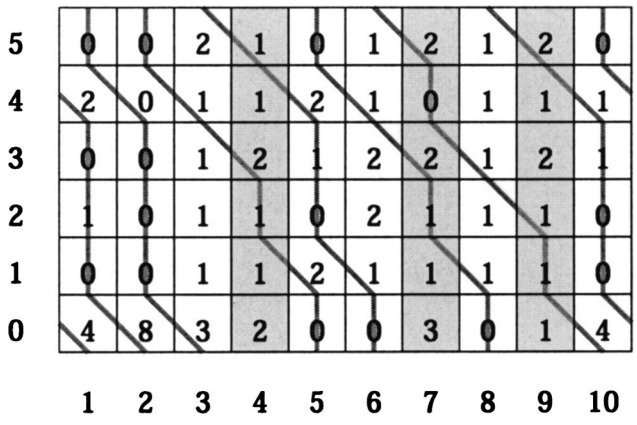

FIG. 13. Paths (see text).

$$s_\ell(y_{n,m}) = y_{n,m+1} + Q_{n,m} - Q_{n-1,m} \quad (m \equiv \ell \bmod M+1),$$

$$s_\ell(y_{n,m+1}) = y_{n,m} + Q_{n-1,m} - Q_{n,m} \quad (m \equiv \ell \bmod M+1),$$

$$s_\ell(y_{n,m}) = y_{n,m} \quad (m \neq \ell, \ell+1 \bmod M+1),$$

$$\pi(y_{n,m}) = y_{n,m+1},$$

and

$$Q_{n,m} = \max_{1 \leqslant h \leqslant N} \left[\sum_{k=1}^{h-1} y_{n+k,m+1} + \sum_{k=h+1}^{N} y_{n+k,m} \right].$$

Here we extend the indices n,m of $y_{n,m}$ for $n,m \in \mathbb{Z}$ by the condition $y_{n+N,m}=y_{n,m+M+1}=y_{n,m}$.

The following theorem is proved by direct calculations.

Theorem VI.1 (Refs. 14 and 15): *The mappings* s_ℓ $(\ell \in \mathbb{Z}/(M+1)\mathbb{Z})$ *and* π *defined as above give a realization of the affine Weyl group* $\tilde{W}(A_M^{(1)})$. ■

Remark VI.1: The affine Weyl group $\tilde{W}(A_{n-1}^{(1)})$ *is defined as the group generated by the simple reflections* $s_0, s_1, \ldots, s_{n-1}$ *and diagram rotation* π *subject to the fundamental relations*

$$s_i^2 = 1,$$

$$s_i s_j = s_j s_i \quad (j \neq i, i \pm 1 \bmod n),$$

$$s_i s_j s_i = s_j s_i s_j \quad (j \equiv i \pm 1 \bmod n),$$

$$\pi s_i = s_{i+1} \pi,$$

where we understand the indices for s_i *as elements of* $\mathbb{Z}/(M+1)\mathbb{Z}$.

When we set

$$y_{n,0} = \kappa_n^s, \quad y_{n,m} = u_n^{s-M+m} \quad (m \neq 0), \tag{16}$$

we get the following theorem which gives a relation between the gPBBS and the affine Weyl group.

Theorem VI.2: $\pi s_{M-1} s_{M-2} \cdots s_0$ *gives the time evolution which concerns the original time*

variable t, i.e.,

$$\pi s_{M-1}s_{M-2}\cdots s_0 \begin{pmatrix} u_1^s & u_2^s & \cdots & u_N^s \\ \vdots & \vdots & \cdots & \vdots \\ u_1^{s-M+1} & u_2^{s-M+1} & \cdots & u_N^{s-M+1} \\ \kappa_1^s & \kappa_2^s & \cdots & \kappa_N^s \end{pmatrix} = \begin{pmatrix} u_1^{s+M} & u_2^{s+M} & \cdots & u_N^{s+M} \\ \vdots & \vdots & \cdots & \vdots \\ u_1^{s+1} & u_2^{s+1} & \cdots & u_N^{s+1} \\ \kappa_1^{s+M} & \kappa_2^{s+M} & \cdots & \kappa_N^{s+M} \end{pmatrix}$$

. ■

The proof goes as follows.

The equation of motion (8) is

$$u_n^{s+1} = u_n^{s-M+1} + Q_{n-1,0} - Q_{n,0}.$$

This means

$$s_0(\kappa_n^s) = u_n^{s+1},$$

and

$$s_0(u_n^{s-M+1}) = \kappa_n^s + Q_{n-1,0} - Q_{n,0} = \kappa_n^s + u_n^{s+1} - u_n^{s-M+1};$$

in the gPBBS, κ_n^s denotes the number of spaces of the nth box at s, and u_n^{s+1}, u_n^{s-M+1} denote the numbers of balls which come in the nth box and get out the nth box from time step s to $s+1$, respectively; hence

$$s_0(u_n^{s-M+1}) = \kappa_n^{s+1}.$$

Therefore

$$s_0 \begin{pmatrix} u_1^s & u_2^s & \cdots & u_N^s \\ \vdots & \vdots & \cdots & \vdots \\ u_1^{s-M+1} & u_2^{s-M+1} & \cdots & u_N^{s-M+1} \\ \kappa_1^s & \kappa_2^s & \cdots & \kappa_N^s \end{pmatrix} = \begin{pmatrix} u_1^s & u_2^s & \cdots & u_N^s \\ \vdots & \vdots & \cdots & \vdots \\ s_0(u_1^{s-M+1}) & s_0(u_2^{s-M+1}) & \cdots & s_0(u_N^{s-M+1}) \\ s_0(\kappa_1^s) & s_0(\kappa_2^s) & \cdots & s_0(\kappa_N^s) \end{pmatrix}$$

$$= \begin{pmatrix} u_1^s & u_2^s & \cdots & u_N^s \\ \vdots & \vdots & \cdots & \vdots \\ \kappa_1^{s+1} & \kappa_2^{s+1} & \cdots & \kappa_N^{s+1} \\ u_1^{s+1} & u_2^{s+1} & \cdots & u_N^{s+1} \end{pmatrix}.$$

Repeating the above procedure, we obtain

$$s_{M-1}s_{M-2}\cdots s_0 \begin{pmatrix} u_1^s & u_2^s & \cdots & u_N^s \\ \vdots & \vdots & \cdots & \vdots \\ u_1^{s-M+1} & u_2^{s-M+1} & \cdots & u_N^{s-M+1} \\ \kappa_1^s & \kappa_2^s & \cdots & \kappa_N^s \end{pmatrix} = \begin{pmatrix} \kappa_1^{s+M} & \kappa_2^{s+M} & \cdots & \kappa_N^{s+M} \\ u_1^{s+M} & u_2^{s+M} & \cdots & u_N^{s+M} \\ \vdots & \vdots & \cdots & \vdots \\ u_1^{s+1} & u_2^{s+1} & \cdots & u_N^{s+1} \end{pmatrix}.$$

Finally, applying π upon it immediately gives Theorem VI.2.

B. gPBBS as twisted crystal lattice

The BBSs can be reformulated as integrable lattice models at temperature zero from viewpoint of the crystal theory and the combinatorial R matrix.[16,17] The PBBS with one kind of ball and box capacity one has also been reformulated into two types of lattice models, a periodic $A_1^{(1)}$ crystal lattice and a twisted $A_{N-1}^{(1)}$ crystal chain, where N denotes the number of the boxes in the system.[8] It is straightforward to extend this result to the case of the gPBBS. In this section, we will briefly show how the gPBBS is reinterpreted as some integrable lattice systems. Since the proofs for the statements below are almost the same as those in Ref. 8, we will omit them here.

Let B_k be the classical crystal of $U_q'(A_M^{(1)})$ corresponding to the k-fold symmetric tensor representation of $U_q(A_M)$. As a set it consists of the single row semistandard tableaux of length k on letters $\{1,2,\ldots,M+1\}$,

$$B_k := \left\{ \boxed{i_1}\boxed{i_2}\boxed{\cdots}\boxed{i_k} \;\middle|\; 1 \le i_1 \le i_2 \le \cdots \le i_k \le M+1 \right\}.$$

An element b

$$b = \boxed{i_1}\boxed{i_2}\boxed{\cdots}\boxed{i_k} \in B_k$$

is also denoted as a series of $M+1$ integers $b \equiv (x^{(M+1)}, x^{(M)}, \ldots, x^{(2)}, x^{(1)})$, where $x^{(j)}$ is the number of letters j in b. A state $|\psi\rangle_t$ of the gPBBS is naturally identified with

$$|\psi\rangle_t \cong b_1^t \otimes b_2^t \otimes \cdots \otimes b_N^t \in B_{\theta_1} \otimes B_{\theta_2} \otimes \cdots \otimes B_{\theta_N},$$

where

$$b_n^t = (\kappa_n^s, u_n^{s-M+1}, u_n^{s-M+2}, \ldots, u_n^s) \quad (n = 1,2,\ldots,N).$$

For the BBS without the periodic boundary condition, time evolution is given by the isomorphism induced by the combinatorial R matrices,

$$\mathcal{T}: B_\infty \otimes (B_{\theta_1} \otimes B_{\theta_2} \otimes \cdots \otimes B_{\theta_N}) \to (B_{\theta_1} \otimes B_{\theta_2} \otimes \cdots \otimes B_{\theta_N}) \otimes B_\infty,$$

$$\mathcal{T}: |\{0\}\rangle \otimes |\psi\rangle_t \to |\psi\rangle_{t+1} \otimes |\{0\}\rangle,$$

where $|\{0\}\rangle$ is the highest weight vector of B_∞. For the gPBBS, by taking the trace of the auxiliary state in B_∞, $T := \mathrm{Tr}_{B\infty}\,\mathcal{T}$, we have the time evolution

$$T: B_{\theta_1} \otimes B_{\theta_2} \otimes \cdots \otimes B_{\theta_N} \to B_{\theta_1} \otimes B_{\theta_2} \otimes \cdots \otimes B_{\theta_N},$$

$$T: |\psi\rangle_t \to |\psi\rangle_{t+1}.$$

As the $A_1^{(1)}$ crystal, the operator T maps $|\psi\rangle_t$ to the unique tensor product of $A_M^{(1)}$ crystal that exactly corresponds to the state of the gPBBS at $t+1$.

The gPBBS is also reformulated as a twisted lattice of M vertical axes in terms of $A_{N-1}^{(1)}$ crystals. In this case, a state $|\psi\rangle_t$ is identified

$$|\psi\rangle_t \cong b_\kappa^t \otimes (b_{u_1}^t \otimes b_{u_2}^t \otimes \cdots \otimes b_{u_M}^t) \in B_k \otimes (B_{n_1} \otimes B_{n_2} \otimes \cdots \otimes B_{n_M}),$$

where

$$b_\kappa^t = (\kappa_N^s, \kappa_{N-1}^s, \ldots, \kappa_1^s),$$

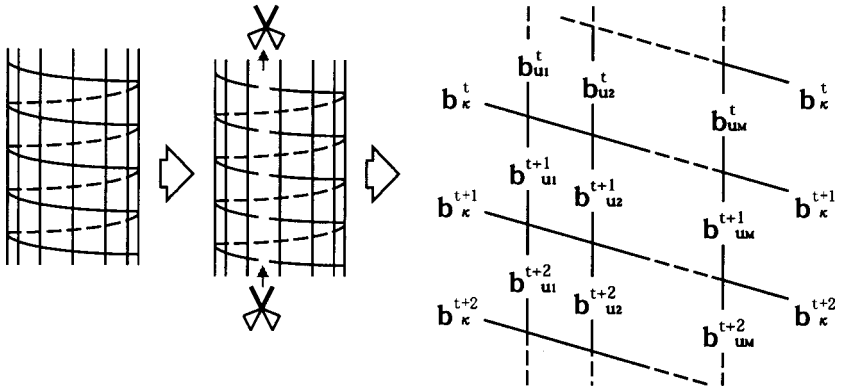

FIG. 14. The twisted crystal lattice associated with the gPBBS.

$$b^t_{u_j} = (u_N^{s-M+j}, u_{N-1}^{s-M+j}, \ldots, u_1^{s-M+j}) \quad (j = 1,2, \ldots, M),$$

$k := \Sigma_{n=1}^N \kappa_n^s$ and $n_j := \Sigma_{n=1}^N u_n^{s-M+j}$. The time evolution is determined by the isomorphism induced by the combinatorial R-matrix for $A_{N-1}^{(1)}$ crystal,

$$b^t_\kappa \otimes (b^t_{u_1} \otimes b^t_{u_2} \otimes \cdots \otimes b^t_{u_M}) \cong (b^{t+1}_{u_1} \otimes b^{t+1}_{u_2} \otimes \cdots \otimes b^{t+1}_{u_M}) \otimes b^{t+1}_\kappa.$$

In Fig. 14, we schematically show the twisted crystal lattice associated with the gPBBS.

VII. CONCLUDING REMARKS

In this paper, using a path description of the characteristic polynomial of particular matrices and an algorithm to construct the conserved quantities using the Lax representation of the ndKP equation, we showed explicit form of the conserved quantities of the gPBBS. Relations to the affine Weyl group action and the crystal theory were also clarified. An advantage to reformulate the PBBS as crystal lattices is that we can extend it to the crystals associated with other root systems.

Since the gPBBS is composed of a finite number of boxes and balls, it can only take on a finite number of patterns. Hence its trajectory is always periodic and a fundamental cycle, i.e., the shortest period of the periodic motion, exists for any given initial state. In the case where the box capacity is one everywhere and only one kind of ball exists, the formula used to calculate the fundamental cycle is explicitly obtained using the conserved quantities and some rescaling properties of the states.[18] Hence, using the results in this paper, we may get the formula to calculate the fundamental cycle for the gPBBS, which is a problem we wish to address in the future.

A revised model for diffusion induced segregation processes

T. Blesgen[a)]
Max-Planck-Institute for Mathematics in the Sciences, Inselstraße 22-26, 04103 Leipzig, Germany

(Received 25 October 2004; accepted 1 November 2004; published online 2 February 2005)

A mathematical model for chalcopyrite disease within sphalerite is developed. As one main result, by analyzing the system enthalpy, correct expressions for the reaction terms in a system undergoing phase transitions are worked out. For the resulting equations, the thermodynamical validity is shown and the existence of a unique solution is proved. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1840292]

I. INTRODUCTION

In the present work we are concerned with diffusion-induced segregation (DIS) phenomena. This class is characterized by segregation processes that can only take place after a sufficient amount of a diffusor has penetrated the crystal. We will exemplary study the so-called chalcopyrite disease within sphalerite, which is a well-known and extensively discussed problem arising in geology and a particular example of DIS, but the techniques developed here apply as well for other DIS phenomena.

In Ref. 3 a first model for chalcopyrite disease has been developed, Ref. 4 discusses related ternary systems. Reference 3 also provides references to the mineralogical experiments and illuminates the physical background. But as a deeper thermodynamical analysis in this paper reveals, the reaction terms chosen in this first model are only approximately true and will in general depend on the phase parameter (the function χ introduced later on). The principles worked out are quite general and will apply whenever reactions and phase transitions take place simultaneously. The presentation is completed by showing existence and uniqueness of the solutions.

II. DERIVATION OF THE REVISED MODEL

Let us consider the following reaction diffusion equations:

$$\partial_t c_i = \mathrm{div}(J_i) + r_i = \left(\sum_l \frac{\partial}{\partial x_l} J_{i,l} \right) + r_i, \quad i = 1, \ldots, 4. \tag{1}$$

In (1), $c_i = c_i(x,t)$ denotes the relative number of species i, $i = 1, \ldots, 4$ per available lattice point at time t and space point $x \in \Omega$, Ω a (time-independent) domain in $\mathbb{R}^D$, $1 \leqslant D \leqslant 3$. By $T_0 > 0$ we denote a stop time and by $\Omega_{T_0} := \Omega \times (0, T_0)$ a cylinder in space–time.

We introduce the notations

$$c_1 \approx \mathrm{Fe}^{3+}, \quad c_2 \approx \mathrm{Fe}^{2+}, \quad c_3 \approx \mathrm{Cu}^{+}, \quad c_4 \approx \mathrm{Zn}^{2+}, \quad c_5 \approx \text{vacancies}.$$

c_1 satisfies $c_1 = N_{\mathrm{Fe}}^{3+} / N_{\mathrm{Me}}$, where $N_{\mathrm{Fe}^{3+}}$ is the number of Fe^{3+} atoms and N_{Me} is the number of metal ion sites. Similar relationships hold for c_2, c_3, and c_4. It is an essential property of this formulation that there is no equation for c_5, but the vacancy concentration is obtained implicitly by the conservation of mass

a)Electronic mail: blesgen@mis.mpg.de

$$c_5 = 1 - \sum_{i=1}^{4} c_i.$$

In (1), r_i denote the reaction terms and J_i the fluxes of metal ions of species i. The reaction terms model the jumps of the electrons. A first ansatz is $r=(r_1,-r_1,0,0)$ and [see (22) below for explanation]

$$r_1 = k(c_2^2 - \kappa c_1 c_e),$$

where $k>0$ and $k\kappa>0$ are the reaction rates and c_e denotes the electron concentration. If we assume that all sulfur places are occupied by S^{2-}, by the condition of electric neutrality we can compute

$$c_e = 2 - 3c_1 - 2c_2 - c_3 - 2c_4 = 2 - 2(c_1 + c_2 + c_3 + c_4) - c_1 + c_3 = 2c_5 - c_1 + c_3. \tag{2}$$

In the presence of phase transitions the reaction rates may not be chosen to be constants, as we shall see below.

Onsager's postulate,[11,12] states that each thermodynamic flux is linearly related to every thermodynamic force. Since in our case the thermodynamic forces are the negative chemical potential gradients, we obtain the phenomenological equations, see Ref. 9, p. 137,

$$J_i = \sum_{j=1}^{4} L_{ij} \nabla \mu_j, \quad 1 \leqslant i \leqslant 4, \tag{3}$$

with a constant mobility matrix L. The Onsager reciprocity law,[9,11,12] states that L must be symmetric which we assume in the following. To simplify the existence theory we will further assume in the sequel that L is positive definite. By

$$\mu_j = \frac{\partial f}{\partial c_j}$$

we denote the chemical potential.

In this work the temperature T is held constant reflecting the situation of the mineralogical experiments. Let f denote the Helmholtz free energy density of the system, which is the convex hull of the free energy density of f_1, f_2 with f_1 for chalcopyrite, f_2 for sphalerite. Hence, the two different phases or lattice orders are characterized by two different free energies, and f is the convex hull of f_1 and f_2.

For order-disorder phase transitions, we make the first ansatz

$$f_l = f_l(c) = k_B T \sum_{i=1}^{5} \beta_i^l c_i \ln c_i + \sum_{i=1}^{3} E_i c_i + \left(\sum_{i=1}^{4} \alpha_i c_i \right)^2, \quad l = 1,2. \tag{4}$$

The elastic coefficients α_i do not change for both phases, only the β_i^l differ. The convex terms $c_i \ln c_i$ are motivated by considerations from statistical mechanics on the system entropy by counting the different configurations. The term $\Sigma_{i=1}^{3} E_i c_i$ refers to the system enthalpy and is a consequence of the presence of the Fe reaction. It will be discussed in the subsequent section.

The expression $(\Sigma_{i=1}^{4} \alpha_i c_i)^2$ is a consequence of Hooke's law. The constants α_i correspond to the ion radii and measure the volume response when replacing Zn^{2+} by other metal ions. In (4), the β_i^1, β_i^2 are positive constants and k_B is the Boltzmann constant.

Equation (4) is a very reasonable term for a numerical computation, since (4) implies infinite slope of Df_l if one component c_j approaches 0 or 1. This guarantees, see Ref. 13,

$$c_j \in (0,1) \quad \text{in } \Omega, t > 0 \tag{5}$$

and c_j has physical meaning. As there is no maximum principle for systems of equations, without the logarithmic terms in (4), Condition (5) may be violated even if $c_j \in (0,1)$ holds for $t=0$.

At this stage, a control mechanism for the segregation process is introduced. The following principle is well known. Let $\chi = \chi(x,t) \in [0,1]$ be a function that measures the volume fraction of the chalcopyrite phase; e.g., $\chi(x_0,t_0)=0$ means that for $t=t_0$ in $x_0 \in \Omega$ only the sphalerite phase is present, $\chi(x_0,t_0)=\frac{1}{2}$ that the system is in x_0 in an intermediate state with no dominant phase.

Let $\gamma > 0$ be a small constant, denoting the square of the thickness of the interface between the sphalerite and chalcopyrite phase. We define the density of the mixing entropy s_M by

$$s_M(\chi) = W(\chi) + \frac{\gamma}{2}|\nabla \chi|^2, \tag{6}$$

with the double-well potential

$$W(\chi) := \chi \ln \chi + (1-\chi)\ln(1-\chi). \tag{7}$$

Since $f := \mathrm{conv}(f_1, f_2)$, we will consider f as the convex combination of f_1 and f_2. Because s_M is subtracted from the entropy density s, the thermodynamic relation $f=e-Ts$ thus implies

$$f(c,\chi) := \chi f_1(c) + (1-\chi) f_2(c) + T s_M(\chi). \tag{8}$$

The phase parameter χ is governed by the modified Allen–Cahn equation

$$\tau \partial_t \chi = -\partial_\chi \left(\frac{f}{T}\right) = \gamma \Delta \chi - \omega(c,\chi), \tag{9}$$

where $\gamma\Delta\chi$ comes from the first variation of $-\int_\Omega (\gamma/2)|\nabla\chi|^2$ with respect to χ and τ is a scaling parameter to adjust the different time scales between mass diffusion and growing of the chalcopyrite phase. The driving force ω in (9) is given by

$$\omega(c,\chi) := \ln\left(\frac{\chi}{1-\chi}\right) + m(c). \tag{10}$$

The value $m(c)$ accounts for the growing of chalcopyrite in copper rich regions and is gained implicitly by $\tau\partial_t\chi = -\partial_\chi(f/T)$. Since so far the final formula for f has not been derived, we will postpone the discussion of this term and of the mechanism responsible for the growing of chalcopyrite in copper rich regions. The final definition of ω is given in (29).

III. AN ENTHALPY PRINCIPLE FOR A PURELY REACTIVE SYSTEM

We want to incorporate the electron jumps by including reaction terms in the model. The reactions are represented in the free energy by enthalpic terms. To understand the nature of these enthalpic terms, we consider a purely reactive system without diffusion and derive general properties of reactive systems.

Let the domain Ω comprise of substances A, B, C, and D subject to the reactions

$$A + B \overset{r_+}{\rightarrow} C + D,$$

$$A + B \overset{r_-}{\leftarrow} C + D.$$

Let $\tilde{c}_1$, $\tilde{c}_2$, $\tilde{c}_3$, and $\tilde{c}_4$ denote the concentration of substances A, B, C, and D where we assume

$$\sum_{i=1}^{4} \tilde{c}_i = 1. \tag{11}$$

In the language of partial differential equations, these reactions can be written as, see Ref. 8,

$$\partial_t \tilde{c}_1 = \partial_t \tilde{c}_2 = - r_+ \tilde{c}_1 \tilde{c}_2 + r_- \tilde{c}_3 \tilde{c}_4,$$

$$\partial_t \tilde{c}_3 = \partial_t \tilde{c}_4 = + r_+ \tilde{c}_1 \tilde{c}_2 - r_- \tilde{c}_3 \tilde{c}_4. \tag{12}$$

From statistical mechanics we infer

$$r_+ = \exp\left(\frac{\tilde{E}_1 + \tilde{E}_2 - \tilde{E}_S}{k_B T} \right),$$

$$r_- = \exp\left(\frac{\tilde{E}_3 + \tilde{E}_4 - \tilde{E}_S}{k_B T} \right), \tag{13}$$

where $\tilde{E}_1 + \tilde{E}_2$ is the energy level before the reaction $A + B \to C + D$, $\tilde{E}_3 + \tilde{E}_4$ the energy level after the reaction. $\tilde{E}_S$ is the activation energy or sattle point energy that must be exceeded to start the reaction.

For the free energy we make the ansatz

$$\tilde{F}(\tilde{c}) = \int_\Omega k_B T \sum_{i=1}^{4} \tilde{c}_i \left(\ln \tilde{c}_i + \frac{\tilde{E}_i}{k_B T} \right). \tag{14}$$

Now we will show the following properties of $\tilde{F}$:

$$\partial_t \tilde{F}(\tilde{c}(t)) = 0 \quad \text{iff } \partial_t \tilde{c}_i = 0,\ 1 \leqslant i \leqslant 4, \tag{15}$$

$$\partial_t \tilde{F}(\tilde{c}(t)) \leqslant 0, \tag{16}$$

$$\tilde{F}(\tilde{c}(t)) \text{ is critical} \quad \text{iff } \partial_t \tilde{c}(t) = 0. \tag{17}$$

In order to show (15) and (16), after setting

$$R := - r_+ \tilde{c}_1 \tilde{c}_2 + r_- \tilde{c}_3 \tilde{c}_4 = \partial_t \tilde{c}_1 = \partial_t \tilde{c}_2 = - \partial_t \tilde{c}_3 = - \partial_t \tilde{c}_4,$$

elementary computations yield

$$\partial_t \tilde{F}(\tilde{c}) = \int_\Omega k_B T R \left[\ln\left(\frac{\tilde{c}_1 \tilde{c}_2}{\tilde{c}_3 \tilde{c}_4} \right) + \frac{\tilde{E}_1 + \tilde{E}_2 - \tilde{E}_S}{k_B T} - \frac{\tilde{E}_3 + \tilde{E}_4 - \tilde{E}_S}{k_B T} \right] = \int_\Omega k_B T R \ln\left[\left(\frac{\tilde{c}_1 \tilde{c}_2}{\tilde{c}_3 \tilde{c}_4} \right) \left(\frac{r_+}{r_-} \right) \right]. \tag{18}$$

We observe

$$\ln\left(\frac{\tilde{c}_1 \tilde{c}_2 r_+}{\tilde{c}_3 \tilde{c}_4 r_-} \right) = 0 \quad \text{iff } \tilde{c}_1 \tilde{c}_2 r_+ = \tilde{c}_3 \tilde{c}_4 r_-$$

and together with (18) we find (15). Equation (18) directly implies the free energy inequality (16). To see this, let us consider the following two mutual exclusive cases:

$$\text{(A)} \quad R \geqslant 0 \Leftrightarrow \tilde{c}_3\tilde{c}_4 r_- \geqslant \tilde{c}_1\tilde{c}_2 r_+ \Leftrightarrow \ln\left(\frac{\tilde{c}_1\tilde{c}_2 r_+}{\tilde{c}_3\tilde{c}_4 r_-}\right) \leqslant 0,$$

$$\text{(B)} \quad R < 0 \Leftrightarrow \tilde{c}_3\tilde{c}_4 r_- < \tilde{c}_1\tilde{c}_2 r_+ \Leftrightarrow \ln\left(\frac{\tilde{c}_1\tilde{c}_2 r_+}{\tilde{c}_3\tilde{c}_4 r_-}\right) > 0.$$

This discussion reveals the natural structure of the problem,

$$[\ln(\tilde{c}_1\tilde{c}_2 r_+) - \ln(\tilde{c}_3\tilde{c}_4 r_-)](\tilde{c}_3\tilde{c}_4 r_- - \tilde{c}_1\tilde{c}_2 r_+) \leqslant 0, \tag{19}$$

from which we unconditionally infer $\partial_t \tilde{F}(\tilde{c}(t)) \leqslant 0$. We see that the canonical structure of the problem goes along with the ansatz of the free energy.

A critical point $\tilde{c}$ of $\tilde{F}$ is characterized by

$$\ln \tilde{c}_l + \frac{\tilde{E}_l}{k_B T} + 1 = 0 \quad \text{for } 1 \leqslant l \leqslant 4. \tag{20}$$

This implies $\partial_t \tilde{c}_i = 0$, $1 \leqslant i \leqslant 4$ because from (20) it follows with (13)

$$\ln(\tilde{c}_1\tilde{c}_2 r_+) = -2,$$

$$\ln(\tilde{c}_3\tilde{c}_4 r_-) = -2,$$

and when subtracting the last two identities we find

$$\ln\left(\frac{\tilde{c}_1\tilde{c}_2 r_+}{\tilde{c}_3\tilde{c}_4 r_-}\right) = 0.$$

This implies at once $\partial_t \tilde{c}_i = 0$, $1 \leqslant i \leqslant 4$. The other implication in (17) is shown similarly.

IV. DERIVATION OF THE COMPLETE MODEL

Equation (19) reveals the underlying structure of reaction–diffusion equations which allows to discuss the reaction terms and give a complete description of the model. The swift jumps of the electrons are integrated into the model by two reactions,

$$\mathrm{Fe}^{2+} \overset{k}{\rightarrow} \mathrm{Fe}^{3+} + e^-,$$

$$\mathrm{Fe}^{2+} \overset{\kappa k}{\leftarrow} \mathrm{Fe}^{3+} + e^-. \tag{21}$$

Here, e^- is a free lattice electron and k, κk are reaction rates. A formula for c_e has already been found with (2).

The standard approach to model reactions (21) analogous to Eq. (12) is

$$r_1 = k(c_2^2 - \kappa c_1 c_e). \tag{22}$$

The principles leading to (22) are carefully explained in Ref. 8. But as we will show, (22) is wrong in our case as the rates will depend on χ! With the knowledge of (19) we can obtain a consistent formulation of r that generalizes (22). In this generalization, the rates will depend on χ.

To perfectly adjust the model, we first remind that the oxidation of Fe is caused by swift shifts of the electrons and occurs thus much faster than any other process, i.e., faster than diffusion. Hence, it is reasonable to assume that this oxidation is instantaneous. Thus we will replace the equation for c_1 by a stationary elliptic equation.

Second, due to electric neutrality, we postulate

$$c_5 = \tfrac{1}{2} c_1. \tag{23}$$

This condition was found experimentally in Ref. 2 long before a mathematical model had been developed. Equation (23) is the key to finding a consistent formulation for the reaction term. There is one difficulty here because (23) tells us that the movement of the vacancies is on the same fast time scale as the movement of the free electrons. We will bypass this problem by demanding $\partial_t c_5 = 0$ in the derivation of the reaction term in (27). All crystallographic measurements verify relation (23), but the quick electron jumps are beyond the resolution horizon of todays methods

As the main consequence of (2) and (23) we find

$$c_e = c_3. \tag{24}$$

To end up with the reaction terms having the structure of (19), the logarithms must have the same factors. Hence we assume

$$\beta_1^l + \frac{\beta_5^l}{2} = \beta_2^l = \beta_3^l = \beta_4^l =: b^l, \quad l = 1,2.$$

The final form of the free energy (4) is thus

$$f_l(c) = k_B T b^l \sum_{i=1}^{4} c_i \ln c_i + \sum_{i=1}^{3} c_i E_i + \left(\sum_{i=1}^{4} \alpha_i c_i \right)^2, \quad l = 1,2. \tag{25}$$

Combined, (8) and (25) define the free energy,

$$F(c,\chi) = \int_\Omega f(c,\chi) = \int_\Omega \left[k_B T b_\chi \left(\sum_{i=1}^{4} c_i \ln c_i \right) + \sum_{i=1}^{3} c_i E_i + \left(\sum_{i=1}^{4} \alpha_i c_i \right)^2 + \frac{\gamma T}{2} |\nabla \chi|^2 + TW(\chi) \right]. \tag{26}$$

Here we introduced the abbreviation $b_\chi := \chi b^1 + (1-\chi) b^2$. The rates fulfill

$$r_+ = k\kappa = \exp\left(\frac{E_1 + E_3 + E_S}{k_B T} \right), \quad r_- = k = \exp\left(\frac{2E_2 - E_S}{k_B T} \right).$$

We can give a quick motivation for the correct reaction term by considering again a purely reactive system, this time with phase changes. If we consider the oxidation process alone (without diffusion) we have

$$\partial_t c_4 = \partial_t c_5 = 0 \tag{27}$$

and from $\partial_t c_1 = \partial_t c_3$ and $\Sigma_{i=1}^5 c_i = 1$ we infer $\partial_t c_2 = -2\partial_t c_1$. With these constraints we compute $\partial_t F(c(t), \chi(t))$ for the free energy (26), where we can drop $(\Sigma_{i=1}^4 \alpha_i c_i)^2$ (the estimation of this term is possible as in Sec. V). We find

$$\begin{aligned} \partial_t F(c(t),\chi(t)) &= \int_\Omega \left[k_B T b_\chi \partial_t c_1 \ln\left(\frac{c_1 c_3}{c_2^2} \right) + \frac{E_1 + E_3 - E_S}{k_B T} - \frac{2E_2 - E_S}{k_B T} - (\partial_t \chi)^2 \right] \\ &= \int_\Omega \left[k_B T b_\chi \partial_t c_1 \ln\left(\frac{c_1 c_3 (r_+)^{1/b_\chi}}{c_2^2 (r_-)^{1/b_\chi}} \right) - (\partial_t \chi)^2 \right]. \end{aligned}$$

The consistent form of the reaction term that replaces (22) is hence

$$r_1 = r_3 = -\tfrac{1}{2} r_2 = (k)^{1/b_\chi} (c_2^2 - \kappa^{1/b_\chi} c_1 c_3), \quad r_4 = 0. \tag{28}$$

b^1 and b^2 should be in the magnitude of 1 and for $b^1 = b^2$ there would be no χ dependence. For $b^1 = b^2 = 1$ we fall back to standard formulas of r.

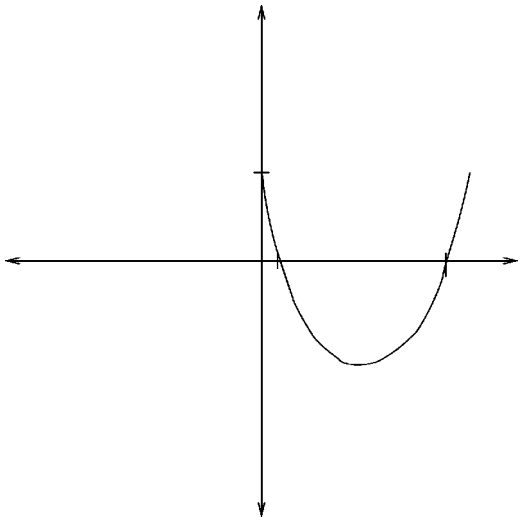

FIG. 1. Plot of $m(c_3)$.

It remains to discuss the control mechanism for the chalcopyrite phase. Equation (26) together with $\tau\partial_t\chi = -\partial_\chi(f/T) = \gamma\Delta\chi - \omega(c,\chi)$ gives rise to setting

$$\omega(c,\chi) = W'(\chi) + k_B(b^2 - b^1)\left(\sum_{i=1}^{4} c_i \ln c_i + \overline{\alpha}\right). \tag{29}$$

Here, $\overline{\alpha} > 0$ is a temperature-dependent constant. Additive constants occur in (26) because one can only measure the change δF of F when varying a quantity q, commonly temperature or volume, within some interval (q_0, q_1), finding the expression $\int_{q_0}^{q_1}\delta F$ for F. Frequently, we will set $\overline{\alpha} := \ln 3$.

To understand the principle of the control mechanism, we first freeze c_1, c_2, and c_4 and consider for constants $\alpha > 0$, $\beta > 0$, see Fig. 1,

$$\omega(c_3,\chi) = W'(\chi) + m(c_3),$$

$$m(c_3) = \beta c_3 \ln c_3 + \alpha.$$

The mechanism thus obtained is similar to the one commonly used in phase field models, where c_3 plays the role of temperature. From convexity of $m(c_3)$ and from the magnitude of α and β, we get the existence of $x_1, x_2 \in (0,1)$, $x_1 < x_2$ with $m(c_3) > 0$ for $c_3 \in (0,x_1) \cup (x_2,1)$ and $m(c_3) < 0$ for $c_3 \in (x_1,x_2)$. Consequently for $c_3 < x_1$, the sphalerite phase is preferred, whereas for $x_1 < c_3 < x_2$, chalcopyrite can form. In practice, the branch $c_3 > x_2$ is never reached, and the chalcopyrite phase once it has formed does not destabilize at a later time.

Expression (29) is symmetric with respect to the variables $c_1, \ldots, c_4$ and so the mechanism just explained also applies for the other variables. Yet there is unsymmetry which comes from the initial values for c. If we consider Fig. 1 again, this time imagining it as a function of c_1, then due to $c_1(t=0)$ one will stay in the part $(0,x_1)$. Hence, the reason why c_3 is mainly responsible for controlling the chalcopyrite disease is caused by the size of initial values $c(t=0)$. Now, the derivation of the model is complete.

Find for $t \geqslant 0$ the vector (c_1,c_2,c_3,c_4), χ such that in $\Omega \subset \mathbb{R}^D$ for $t > 0$,

$$0 = \operatorname{div}\left(\sum_{j=1}^{4} L_{1j}\nabla\mu_j\right) + k^{1/b_\chi}(c_2^2 - (\kappa)^{1/b_\chi}c_1c_3),$$

$$\partial_t c_i = \operatorname{div}\left(\sum_{j=1}^{4} L_{ij} \nabla \mu_j\right) + r_i(c,\chi), \quad i = 2,3,4,$$

$$\mu_i = \frac{\partial f}{\partial c_i}(c,\chi), \quad 1 \leqslant i \leqslant 4,$$

$$\tau \partial_t \chi = \gamma \Delta \chi - \omega(c,\chi),$$

and for $t=0$, $x \in \Omega$,

$$c_i(x,0) = c_{0i}(x), \quad i = 2,3,4,$$

$$\chi(x,0) = \chi_0(x),$$

and for $t>0$, $x \in \partial\Omega$,

$$c_i = g_i, \quad 1 \leqslant i \leqslant 4,$$

$$\mu_i = h_i, \quad 1 \leqslant i \leqslant 4 \tag{30}$$

with given Dirichlet data $g=(g_1,\ldots,g_4)$ *and* $h=(h_1,\ldots,h_4)$ *defined on* $\partial\Omega$.

V. THE FREE ENERGY INEQUALITY

We will show the thermodynamical correctness of system (30) under isothermal conditions, where the approximating elliptic equation is replaced by the original time-dependent formulation. It is suitable to reformulate (30),

$$\partial_t c + \operatorname{div}(J) = r, \tag{31}$$

$$\tau \partial_t \chi = -\frac{\partial f}{\partial \chi}, \tag{32}$$

where

$$J = -L \nabla \mu$$

and r is defined by (28). An application of the chain rule yields

$$\frac{d}{dt} f(c,\chi) = \sum_{j=1}^{4} \frac{\partial f}{\partial c_j} \partial_t c_j + \frac{\partial f}{\partial \chi} \partial_t \chi. \tag{33}$$

From (33) we learn that we must test the equation for c_i with $\partial f/\partial c_i = \mu_i$, $1 \leqslant i \leqslant 4$ and Eq. (32) with $\partial f/\partial \chi$. After integrating over Ω, one integration by parts we obtain

$$\frac{d}{dt}\int_\Omega f(c,\chi) - \int_\Omega \left(\sum_{j=1}^{4} \mu_j r_j + \sum_{j=1}^{4} \nabla \mu_j \cdot J_j + \frac{\partial f}{\partial \chi}\partial_t \chi\right) + \int_{\partial\Omega} \sum_{j=1}^{4} \mu_j J_j \cdot \vec{\nu} = 0. \tag{34}$$

This is the constitutive equality for the Helmholtz free energy density f.

To recast (34) as an inequality, we have that the matrix L is positive definite,

$$\sum_{j=1}^{4} \nabla \mu_j \cdot J_j = -L \nabla \mu : \nabla \mu \leqslant 0. \tag{35}$$

Additionally, by (32), we have $(\partial f/\partial \chi)\partial_t \chi = -\tau(\partial_t \chi)^2 \leqslant 0$. It remains to show

$$\int_\Omega \sum_{j=1}^{4} \mu_j r_j \leqslant 0. \tag{36}$$

We exploit the particular form of r and f and structure (19). Let $Q(c) := \Sigma_{i=1}^{4} \alpha_i c_i$. Since $r_1 = r_3 = -\frac{1}{2} r_2$, $r_4 = 0$ we have

$$\begin{aligned}
\int_\Omega \sum_{j=1}^{4} \mu_j r_j &= \int_\Omega (\mu_1 - 2\mu_2 + \mu_3) r_1 \\
&= \int_\Omega \left\{ k_B T b_\chi \left[\ln\left(\frac{c_1 c_3}{c_2^2} \right) + \frac{E_1 + E_3 - E_S}{k_B T b_\chi} - \frac{2E_2 - E_S}{k_B T b_\chi} \right] + 2(\alpha_1 - 2\alpha_2 + \alpha_3) Q(c) \right\} r_1 \\
&= \int_\Omega \left[k_B T b_\chi \ln\left(\frac{c_1 c_3 (r_+)^{1/b_\chi}}{c_2^2 (r_-)^{1/b_\chi}} \right) + 2(\alpha_1 - \alpha_2 + \alpha_3) Q(c) \right] r_1.
\end{aligned}$$

The first term can be estimated analogous to (19),

$$\int_\Omega k_B T b_\chi \ln\left(\frac{c_1 c_3 (r_+)^{1/b_\chi}}{c_2^2 (r_-)^{1/b_\chi}} \right) r_1 \leqslant 0 \tag{37}$$

but to estimate $\int_\Omega 2(\alpha_1 - 2\alpha_2 + \alpha_3) Q(c) r_1$ additional considerations are necessary. The logarithmic form (26) of the free energy guarantees $c_i > 0$ in Ω_{T_0} for $t > 0$ if this is true for $t = 0$. In Sec. VI a rigorous proof of this statement will be given. Hence we obtain $Q(c) > 0$ in Ω_{T_0}. Let

$$\sigma_1 := \sup_{x \in \Omega} c_1(x,0), \quad \sigma_2 := \inf_{x \in \Omega} c_{02}(x), \quad \sigma_3 := \sup_{x \in \Omega} c_{03}(x), \tag{38}$$

where σ_1, σ_2, σ_3 are positive constants. By the parabolic maximum principle,[13] as for fixed c_2, c_3, χ the mapping $c_1 \mapsto r_1(c, \chi)$ decreases as c_1 increases, and (now for fixed c_1, c_3, χ) $c_2 \mapsto r_1(c, \chi)$ increases and finally $c_3 \mapsto r_1(c, \chi)$ decreases, we have $\sigma_1 = \sup_{\overline{\Omega_{T_0}}} c_1$, $\sigma_2 = \inf_{\overline{\Omega_{T_0}}} c_2$, and $\sigma_3 = \sup_{\overline{\Omega_{T_0}}} c_3$.

Now a sufficient condition for $r_1 > 0$ in Ω_{T_0} is

$$\kappa^{1/b_\chi} < \frac{\sigma_2^2}{\sigma_1 \sigma_3}. \tag{39}$$

We remark that in the crystallographic measurements, the ratio constant κ never exceeded a value of 0.07 (otherwise the matrix becomes unstable). For an estimate of the volume term we require

$$\alpha_1 - 2\alpha_2 + \alpha_3 < 0. \tag{40}$$

This is a condition on the ion radii of Fe^{3+}, Fe^{2+}, and Cu^{+} and fulfilled in nature, see Table I.

Together with $r_1 > 0$ and the above estimate this shows $\int_\Omega 2(\alpha_1 - 2\alpha_2 + \alpha_3) Q(c) r_1 < 0$. Hence, (36) is proved and we have shown the *constitutive free energy inequality*

$$\frac{d}{dt} \int_\Omega f(c(t), \chi(t)) + \int_{\partial\Omega} \sum_{j=1}^{4} \mu_j J_j \cdot \vec{\nu} \leqslant 0. \tag{41}$$

In a thermodynamically closed system the fluxes on $\partial\Omega$ disappear. Hence we impose as condition on the Dirichlet data,

TABLE I. Values of sulfide crystal radii taken from Ref. 10.

Symbol	Species	Ion radius
α_1	Fe^{3+}	0.555 Å
α_2	Fe^{2+}	0.660 Å
α_3	Cu^{+}	0.635 Å
α_4	Zn^{2+}	0.640 Å

$$h_i = 0, \quad 1 \leqslant i \leqslant 4.$$

Instead we could impose the Neumann boundary conditions $\partial_\nu \mu_j = 0$, $1 \leqslant j \leqslant 4$ on $\partial\Omega$.

VI. EXISTENCE OF WEAK SOLUTIONS FOR POLYNOMIAL FREE ENERGY

The rest of the paper is devoted to the proof of global existence and uniqueness of a solution to the sharp interface model (30) with classical Dirichlet boundary conditions, i.e., $g=h=0$, and with the elliptic equation in (30) replaced by the original parabolic equation. The proof of existence is done in three steps. An additional (and artificial) surface energy term $\int_\Omega (\lambda/2)|\nabla c|^2$ is added to the free energy functional leading to a diffuse interface model. This term is necessary to guarantee the existence of a minimizer (Lemma 1). The first part is contained in Secs. VII–XIII and discusses the case of polynomial free energies for this diffuse interface model. Then we generalize to logarithmic free energies and finally the limit $\lambda \searrow 0$ is carried out. Some of the techniques used in the following sections were developed for the Cahn–Hilliard model, we mainly refer to Refs. 5, 6, and 1, and in particular Ref. 7.

VII. PRELIMINARIES

In what follows, $f = f(c,\chi)$ denotes the free energy density without the surface energy terms $(\gamma/2)|\nabla \chi|^2 + (\lambda/2)|\nabla c|^2$. C will denote generic constants that can change from estimate to estimate. With the additional surface term the model is the following.

Find for $t \geqslant 0$ the vector (c,μ,χ) such that in $\Omega_{T_0} := \Omega \times (0,T_0)$,

$$\partial_t c = \operatorname{div}(L \nabla \mu) + r(c,\chi),$$

$$\mu(c,\chi) = \frac{\partial f}{\partial c}(c,\chi) - \lambda \Delta c,$$

$$\tau \partial_t \chi = \gamma \Delta \chi - \omega(c,\chi)$$

and for $t=0$ in Ω,

$$c(\cdot,0) = c_0(\cdot), \quad \chi(\cdot,0) = \chi_0(\cdot)$$

and for $t>0$ in $\partial\Omega$,

$$c_i = \mu_i = 0, \quad 1 \leqslant i \leqslant 4. \tag{42}$$

$T_0 > 0$ denotes the stop time, $\omega = \partial_\chi f$, and $r(c,\chi)$ is given by (28).

Now, let us collect general properties of the model and some necessary tools that will be needed in the sequel. As a consequence of the assumed relation (23) the concentration vector c lies in the simplex

$$c \in \Sigma := \{d = (d_1, \ldots, d_4) \in \mathbb{R}^4 | \tfrac{3}{2} d_1 + d_2 + d_3 + d_4 = 1\}. \tag{43}$$

We do not propose $0 \leqslant c_i \leqslant 1$ in Ω because for the polynomial free energies considered here this is simply not true. This is one of the reasons why logarithmic free energies are introduced later on. Let

$$X_1 := \{c \in H_0^{1,2}(\Omega;\mathbb{R}^4) \| c \in \Sigma \text{ almost everywhere}\},$$

$$X_2 := H^{1,2}(\Omega;\mathbb{R}).$$

Since we have (classical) Dirichlet boundary conditions for the equations of conservation of mass, we consider the space of test functions,

$$Y := H_0^{1,2}(\Omega;\mathbb{R}^4)$$

and its dual

$$\mathcal{D} := (H_0^{1,2}(\Omega;\mathbb{R}^4))' = H^{-1,2}(\Omega;\mathbb{R}^4).$$

Let us now consider the mapping $\mathcal{L}(\mu): Y \to \mathcal{D}$ corresponding to $\mu \mapsto -\mathrm{div}(L \nabla \mu)$ with Dirichlet boundary conditions, defined by

$$\mathcal{L}(\mu)(\zeta) := \int_\Omega L \nabla \mu : \nabla \zeta.$$

To simplify the argumentation later we will need the inverse $\mathcal{G}$ of $\mathcal{L}$. The existence of $\mathcal{G}$ is derived from the Poincaré inequality and the Lax-Milgram theorem, since L is positive definite. From this we find that $\mathcal{G}$ is positive definite, self-adjoint, injective, and compact. Hence we have

$$(L \nabla \mathcal{G} v, \nabla \zeta)_{L^2} = (\zeta, v) \quad \text{for all } \zeta \in Y \text{ and } v \in \mathcal{D}.$$

We define for $v_1, v_2 \in \mathcal{D}$ the L scalar product by

$$(v_1, v_2)_L := (L \nabla \mathcal{G} v_1, L \nabla \mathcal{G} v_2)_{L^2}$$

with the corresponding norm

$$\|v\|_L := \sqrt{(v,v)_L}.$$

Functions $v \in Y$ canonically define an element in Y and consequently $(\cdot,\cdot)_L$ and $\|\cdot\|_L$ are as well defined for elements in Y.

With the help of Young's inequality we find for $\delta > 0$ and all $d \in Y$,

$$\|d\|_{L^2} = (L \nabla \mathcal{G} d, \nabla d)_{L^2} \leqslant \|L^{1/2} \nabla \mathcal{G} d\|_{L^2} \|L^{1/2} \nabla d\|_{L^2} \leqslant \frac{C_L}{\delta} \|d\|_L^2 + \delta \|\nabla d\|_{L^2}^2, \tag{44}$$

where C_L is a positive constant depending on L.

The Green's function $\mathcal{G}$ allows to rewrite the conservation of mass equations as

$$\mathcal{G}(\partial_t c - r(c,\chi)) = \mu := \left(\frac{\partial f}{\partial c_j}\right)_{1 \leqslant j \leqslant 4}. \tag{45}$$

VIII. THE WEAK FORMULATION OF THE PROBLEM

We call a triple $(c,\mu,\chi) \in L^2(0,T_0;H_0^{1,2}(\Omega;\mathbb{R}^4)) \times L^2(0,T_0;H_0^{1,2}(\Omega;\mathbb{R}^4)) \times L^2(0,T_0;H^{1,2}(\Omega;\mathbb{R}))$ with $r(c,\chi)$, $\omega(c,\chi) \in L^1(\Omega_{T_0})$ a *weak solution* of (42) if

$$-\int_{\Omega_{T_0}} \partial_t \xi \cdot (c - c_0) + \int_{\Omega_{T_0}} L \nabla \mu : \nabla \xi - \int_{\Omega_{T_0}} r(c,\chi)\xi = 0 \tag{46}$$

for all $\xi \in L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$ with $\partial_t \xi \in L^2(\Omega_{T_0})$, $\xi(T_0)=0$, and

$$\int_{\Omega_{T_0}} \mu \cdot \eta = \int_{\Omega_{T_0}} \left(\frac{\partial f}{\partial c}(c) \cdot \eta + \lambda \nabla c \cdot \nabla \eta \right) \tag{47}$$

for all $\eta \in L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4)) \cap L^\infty(\Omega_{T_0};\mathbb{R}^4)$, and

$$-\int_{\Omega_{T_0}} \tau \partial_t \zeta (\chi - \chi_0) + \int_{\Omega_{T_0}} \gamma \nabla \chi \cdot \nabla \zeta - \int_{\Omega_{T_0}} \omega(c,\chi)\zeta = 0 \tag{48}$$

for all $\zeta \in L^2(0,T_0;H^1(\Omega;\mathbb{R}))$ with $\partial_t \zeta \in L^2(\Omega_{T_0})$, $\zeta(T_0)=0$.

IX. A SEMI-IMPLICIT TIME DISCRETIZATION

We fix an $M \in \mathbb{N}$ and set $h := T_0/M$. For $m \geqslant 1$ and given $(c^{m-1},\mu^{m-1},\chi^{m-1}) \in H_0^{1,2}(\Omega;\mathbb{R}^4) \times H_0^{1,2}(\Omega,\mathbb{R}^4) \times H^{1,2}(\Omega;\mathbb{R})$,

$$\frac{c^m - c^{m-1}}{h} = \operatorname{div}(L \nabla \mu^m) + r(c^{m-1},\chi^{m-1}),$$

$$\mu^m = \frac{\partial f}{\partial c}(c^m,\chi^m) - \lambda \Delta c^m, \tag{49}$$

$$\tau \frac{\chi^m - \chi^{m-1}}{h} = \gamma \Delta \chi^m + \omega(c^m,\chi^m)$$

defines the implicit time discretization of system (42) except for the reaction term r that has been treated explicitly. Therefore, we call the resulting scheme semi-implicit. In (49), $\omega(c,\chi) = \partial_\chi f(c,\chi)$ and for the subsequent sections, let $r^{m-1} := r(c^{m-1},\chi^{m-1})$.

X. STRUCTURAL ASSUMPTIONS

In order to be able to establish the existence of weak solutions in the sense of Sec. VIII, the following assumptions are made.

(A1) $\Omega \subset \mathbb{R}^D$ is a bounded domain with Lipschitz boundary.

(A2) The free energy density f can be written as

$$f(c,\chi) = f^1(c,\chi) + f^2(c,\chi) \quad \text{for all } c \in \mathbb{R}^4, \quad \chi \in \mathbb{R}$$

with f^1, $f^2 \in C^1(\mathbb{R}^4 \times \mathbb{R};\mathbb{R})$ and $f^1(\cdot,\chi)$ convex for every $\chi \in \mathbb{R}$, $f^1(c,\cdot)$ convex for every $c \in \mathbb{R}^4$. Furthermore, we have the following:

(A2.1) $f^1 \geqslant 0$.

(A2.2) There exists a constant $C_1 > 0$ such that

$$|\partial_c f^2(c,\chi)| \leqslant C_1(|c| + 1) \quad \text{for all } c \in \Sigma, \chi \in \mathbb{R},$$

$$|\partial_\chi f^2(c,\chi)| \leqslant C_1(|\chi| + 1) \quad \text{for all } c \in \Sigma, \chi \in \mathbb{R}.$$

(A2.3) For all $\delta > 0$ there exists a constant $C_\delta > 0$ such that

$$|\partial_c f^1(c,\chi)| + |\partial_\chi f^1(c,\chi)| \leqslant \delta f^1(c,\chi) + C_\delta \quad \text{for all } c \in \Sigma,\ \chi \in \mathbb{R}.$$

(A3) The initial data (c_0,χ_0) fulfills

$$f(c_0,\chi_0)<\infty,\quad \omega(c_0,\chi_0)<\infty.$$

(A4.1) The diffusion tensor L is symmetric and positive definite.

(A4.2) $\gamma>0$ is a constant, $0<\lambda<\lambda_0$ where λ_0 is a small constant such that the estimate $\partial_t F\leqslant 0$ is valid.

(A5) The reaction term r is chosen in correspondence to f such that

$$\int_\Omega \mu\cdot r\leqslant 0. \tag{50}$$

(A6) The coefficients $\alpha_i>0$ satisfy condition (40). Furthermore $0<\kappa\leqslant 1$, $k>0$ and $0<b^1$, $b^2\leqslant 1$. The initial values c_0 of c and κ, b^1, b^2 fulfill [compare with (39)].

$$\kappa^{1/\max(b^1,b^2)}<\frac{\sigma_2^2}{\sigma_1\sigma_3}. \tag{51}$$

By assumption (A2) any polynomial growth is allowed for f^1, whereas exponential growth is not. For the nonconvex part, sublinear growth of $\partial_c f^2$ in c and $\partial_\chi f^2$ in χ is prescribed.

If we approximate a logarithmic free energy function f by a polynomial, we also must replace the reaction term by a suitable approximation. This is the gist of (A5). In Sec. XV it is shown how a suitable r can be constructed for approximations f^δ of f.

If one chooses $\lambda>0$ small enough, one can guarantee $\partial_t F(c(t),\chi(t))\leqslant 0$ because then the term with the possibly wrong sign $\lambda\Delta c r_1$ can be compensated by $(\alpha_1-2\alpha_2+\alpha_3)Q(c)r_1(c)<0$. From now on we assume without further stating that the assumptions (A1)–(A6) hold.

XI. EXISTENCE OF SOLUTIONS TO THE TIME DISCRETE SCHEME

For the treatment of the diffuse interface model we introduce the energy functional

$$F(c,\chi):=\int_\Omega\left(f(c,\chi)+\frac{\lambda}{2}|\nabla c|^2+\frac{\gamma}{2}|\nabla\chi|^2\right). \tag{52}$$

Additionally, for each time step m in the semi-implicit time discretization (49), given step size $h>0$ and given (c^{m-1},χ^{m-1}) we define the discrete energy functional

$$F^{m,h}(c,\chi):=F(c,\chi)+\frac{1}{2h}\|c-c^{m-1}-hr^{m-1}\|_L^2+\frac{\tau}{2h}\|\chi-\chi^{m-1}\|_{L^2}^2. \tag{53}$$

Lemma 1: Let $(c^{m-1},\chi^{m-1})\in X_1\times X_2$ *be given. Then for* $0<h<\min\{\tau/2C_1,\lambda/8C_1^2C_L\}$ *the functional* $F^{m,h}$ *possesses a minimizer in* $X_1\times X_2$.

Proof: We will show that $F^{m,h}$ is coercive and weakly lower semicontinuous. Using assumptions (A2.1) and (A2.2) we find

$$\begin{aligned}
&F^{m,h}(c,\chi)\\
&\quad\geqslant\frac{\lambda}{2}\|\nabla c\|_{L^2}^2+\frac{\gamma}{2}\|\nabla\chi\|_{L^2}^2-C_1(\|c\|_{L^2}^2+\|\chi\|_{L^2}^2)-C+\frac{1}{2h}(\|c-c^{m-1}-hr^{m-1}\|_L^2+\tau\|\chi-\chi^{m-1}\|_{L^2}^2)\\
&\quad\geqslant\left(\frac{\lambda}{2}-\delta C_1\right)\|\nabla c\|_{L^2}^2+\left(\frac{1}{2h}-\frac{C_1C_L}{\delta}\right)\|c-c^{m-1}-hr^{m-1}\|_L^2+\frac{\gamma}{2}\|\nabla\chi\|_{L^2}^2\\
&\qquad\times\left(\frac{\tau}{2h}-C_1\right)\|\chi-\chi^{m-1}\|_{L^2}^2-C,
\end{aligned}$$

where in the second estimate (44) was used and $C=C(c^{m-1},\chi^{m-1},r)$. Now, for $0<h$

$<\min\{\tau/2C_1, \lambda/8C_1^2C_L\}$ by choosing $\delta=\lambda/4C_1$, we conclude with the help of the Poincaré inequality that $F^{m,h}$ is coercive on $X_1\times X_2$. Let

$$d := \inf\{F^{m,h}(c,\chi)|c \in X_1,\ \chi \in X_2\}, \quad d<\infty.$$

If we now consider a minimizing sequence $(c_l,\chi_l)_{l\in\mathbb{N}}\subset X_1\times X_2$ with $F^{m,h}(c_l,\chi_l)\to d$, the coercivity of $F^{m,h}$ implies the boundedness of (c_l,χ_l) uniformly in l. Passing to a subsequence if necessary, by the reflexivity of $X_1\times X_2$ we may assume

$$(c_l,\chi_l)\to(c,\chi)\in X_1\times X_2 \quad \text{for } l\to\infty$$

and by Rellich's theorem or Sobolev's imbedding theorem,

$$(c_l,\chi_l)\to(c,\chi)\in L^2(\Omega,\mathbb{R}^4)\times L^2(\Omega,\mathbb{R}) \quad \text{for } l\to\infty$$

and $(c_l,\chi_l)\to(c,\chi)$ a.e. in Ω.

To verify the weak lower semicontinuity of $F^{m,h}$ in $X_1\times X_2$ we first remark that this is true for all convex terms. For $\int_\Omega f^1(c,\chi)$ this follows from assumption (A2) and for $\int_\Omega f^2(c,\chi)$ from (A2.2) and the dominated convergence theorem of Lebesgue. This implies $F^{m,h}(c,\chi)\leqslant\liminf_{l\to\infty}F^{m,h}(c_l,\chi_l)$. ■

Lemma 2: The minimizer (c^m,χ^m) *of* $F^{m,h}$ *fulfills*

$$\int_\Omega \frac{c^m-c^{m-1}}{h}\cdot\xi+\int_\Omega L\nabla\mu^m:\nabla\xi=\int_\Omega r^{m-1}\xi \quad \textit{for all } \xi\in Y, \tag{54}$$

$$\int_\Omega(\lambda\nabla c^m\cdot\nabla\eta+\partial_c f(c^m,\chi^m)\cdot\eta)=\int_\Omega\mu^m\cdot\eta \quad \textit{for } \eta\in Y\cap L^\infty(\Omega;\mathbb{R}^4), \tag{55}$$

$$\int_\Omega\left[\tau\frac{\chi^m-\chi^{m-1}}{h}+\omega(c^m,\chi^m)\right]\zeta+\int_\Omega\gamma\nabla\chi^m\cdot\nabla\zeta=0 \quad \textit{for } \zeta\in H^1(\Omega). \tag{56}$$

Here,

$$\mu^m=\mathcal{G}\left(\frac{c^m-c^{m-1}}{h}-r^{m-1}\right).$$

Proof: We choose directions $\xi\in Y\cap L^\infty(\Omega;\mathbb{R}^4)$, $\zeta\in X_2\cap L^\infty(\Omega;\mathbb{R})$ and determine the variations of $F^{m,h}(c,\chi)$ with respect to c and χ for ξ, ζ. We start with the variation with respect to c, i.e.,

$$\lim_{s\to0}((F^{m,h}(c^m+s\xi,\chi^m)-F^{m,h}(c^m,\chi^m))s^{-1}). \tag{57}$$

Since f^1 is convex in c, we have

$$f^1(c^m,\chi^m)\geqslant f^1(c^m+s\xi,\chi^m)-s\partial_c f^1(c^m+s\xi,\chi^m)\cdot\xi.$$

This implies

$$f^1(c^m+s\xi,\chi^m)\leqslant f^1(c^m,\chi^m)+|s\partial_c f^1(c^m+s\xi,\chi^m)|\|\xi\|_{L^\infty}\leqslant f^1(c^m,\chi^m)+|s|f^1(c^m+s\xi,\chi^m)\|\xi\|_{L^\infty}+C|s|.$$

The last is by assumption (A2.3) with $\delta=1$. Hence, for s small enough,

$$\left|\frac{f^1(c^m+s\xi,\chi^m)-f^1(c^m,\chi^m)}{s}\right|\leqslant C(f^1(c^m,\chi^m)+1).$$

Assumption (A2.2) and Lebesgue's dominated convergence theorem imply

$$\lim_{s\to 0}\frac{1}{s}\left(\int_\Omega f(c^m+s\xi,\chi^m)-f(c^m,\chi^m)\right)=\int_\Omega \partial_c f(c^m,\chi^m)\cdot\xi.$$

The variation of the quadratic form $c\mapsto(1/2h)\|c^m-c^{m-1}-hr^{m-1}\|_L^2$ yields

$$\lim_{s\to 0}[s^{-1}(2h)^{-1}(\|c^m+s\xi-c^{m-1}-hr^{m-1}\|_L^2-\|c^m-c^{m-1}-hr^{m-1}\|_L^2)]$$
$$=\left(\frac{c^m-c^{m-1}-hr^{m-1}}{h},\xi\right)_L=\left(\mathcal{G}\left(\frac{c^m-c^{m-1}}{h}-r^{m-1}\right),\xi\right)_{L^2}=(\mu^m,\xi)_{L^2}$$

and finally

$$\frac{\lambda}{2}\lim_{s\to 0}\{s^{-1}[(\nabla(c+s\xi),\nabla(c+s\xi))_{L^2}-(\nabla c,\nabla c)_{L^2}]\}=\lambda(\nabla c,\nabla\xi)_{L^2}=-\lambda(\Delta c,\xi)_{L^2}.$$

Hence we obtain (54). The equality (55) follows because (c^m,χ^m) is a minimizer and thus the variation in (57) is 0. To derive (56), we consider the variation of $F^{m,h}(c^m,\chi^m)$ with respect to χ. As before,

$$\lim_{s\to 0}[\tau s^{-1}(2h)^{-1}(\|\chi^m+s\zeta-\chi^{m-1}\|_{L^2}^2-\|\chi^m-\chi^{m-1}\|_{L^2}^2)]=\left(\tau\frac{\chi^m-\chi^{m-1}}{h},\zeta\right)_{L^2}.$$

It remains to prove

$$\lim_{s\to 0}\int_\Omega (f(c^m,\chi^m+s\zeta)-f(c^m,\chi^m))=\int_\Omega \partial_\chi f(c^m,\chi^m)\zeta.$$

This limit can be justified in the same way as (57) and identity (56) follows. ■

XII. UNIFORM ESTIMATES

In the preceding sections we proved the existence of a discrete solution (c^m,μ^m,χ^m) for $1\leqslant m\leqslant M$ and arbitrary $M\in\mathbb{N}$. We define the piecewise constant extension (c_M,μ_M,χ_M) of $(c^m,\mu^m,\chi^m)_{1\leqslant m\leqslant M}$ by

$$(c_M(t),\mu_M(t),\chi_M(t)):=(c_M^m,\mu_M^m,\chi_M^m):=(c^m,\mu^m,\chi^m)\quad\text{for } t\in((m-1)h,mh)$$

and $c_M(0)=c_0$, $\chi_M(0)=\chi_0$, $\mu_M(0)$ obtained from Eq. (55).

The piecewise linear extension $(\overline{c_M},\overline{\mu_M},\overline{\chi_M})$ for $t=[\beta m+(1-\beta)(m-1)]h$ with appropriate $\beta\in[0,1]$ is given by the interpolation

$$(\overline{c_M},\overline{\mu_M},\overline{\chi_M})(t):=\beta(c_M^m,\mu_M^m,\chi_M^m)+(1-\beta)(c_M^{m-1},\mu_M^{m-1},\chi_M^{m-1}).$$

Lemma 3: For sufficiently small h the following a priori estimates are valid.

(a) *For all $M\in\mathbb{N}$ and all $t\in[0,T_0]$ we have the dissipation inequality*

$$F(c_M,\chi_M)(t)+\frac{1}{2}\int_{\Omega_t}(L\nabla\mu_M:\nabla\mu_M+|\partial_t\chi_M|^2)\leqslant F(c_0,\chi_0).$$

(b) *There exists a constant $C>0$ such that*

$$\sup_{0\leqslant t\leqslant T_0}\{\|c_M(t)\|_{H^1}+\|\chi_M(t)\|_{H^1}\}\leqslant C, \tag{58}$$

$$\sup_{0\leqslant t\leqslant T_0}\int_\Omega f^1(c_M(t),\chi_M(t))+\|\nabla\mu_M\|_{L^2(\Omega_{T_0})}+\|\partial_t\chi_M\|_{L^2(\Omega_{T_0})}\leqslant C. \tag{59}$$

Proof: The idea of the proof is to use the decay of $t \mapsto F(c(t),\chi(t))$. Here, a modification of the standard proof becomes necessary which reveals that the treatment of the reaction term in (49) is natural.

As (c^m,χ^m) is minimizer of $F^{m,h}$,

$$F(c^m,\chi^m)+\frac{1}{2h}\|c^m-c^{m-1}-hr^{m-1}\|_L^2+\frac{\tau}{2h}\|\chi^m-\chi^{m-1}\|_{L^2}^2 \leqslant F(c^{m-1}+hr^{m-1},\chi^{m-1}). \tag{60}$$

A direct calculation yields

$$\frac{1}{2h}\|c^m-c^{m-1}-hr^{m-1}\|_L^2=\frac{h}{2}(\nabla\mu^m,L\,\nabla\,\mu^m)_{L^2}.$$

To bring the right-hand side of (60) in a form suitable for recursion, we remark that for sufficiently small h,

$$F(c^{m-1}+hr^{m-1},\chi^{m-1}) \leqslant F(c^{m-1},\chi^{m-1}).$$

This is equivalent to

$$\frac{F(c^{m-1}+hr^{m-1},\chi^{m-1})-F(c^{m-1},\chi^{m-1})}{h} \leqslant 0 \quad \text{for all } h>0.$$

By Lebesgue's dominated convergence theorem, a sufficient condition for the last inequality is $\partial_c F(c^{m-1},\chi^{m-1})\cdot r^{m-1} \leqslant 0$ which holds due to (A5).

By iterating (60) with the estimated right-hand side, we find

$$F(c_M^m,\chi_M^m)+\frac{1}{2}\int_0^{mh}((\nabla\mu_M^m,L\,\nabla\,\mu_M^m)_{L^2}+(\partial_t\chi_M^m,\partial_t\chi_M^m)_{L^2})\mathrm{d}t \leqslant F(c_0,\chi_0).$$

Using the assumptions and with the help of the Poincaré inequality this proves the lemma. ■

We extend c_M by the initial value c_0 of c for $t\in(-h,0]$. Now, for the linear interpolation $\overline{c_M}$ of c_M^m, the Euler–Lagrange equation (54) can be rewritten as

$$\int_\Omega \partial_t\overline{c_M}(t)\cdot\xi+\int_\Omega L\,\nabla\,\mu_M(t):\nabla\,\xi=\int_\Omega r(c_M(t-h),\chi_M(t-h))\cdot\xi \quad \text{for all } \xi\in Y \tag{61}$$

which holds for almost all $t\in(0,T_0)$. Together with the uniform estimates of Lemma 3, (61) allows to show compactness in time.

Lemma 4: There exists a constant $C>0$ such that for all t_1, $t_2\in[0,T_0]$,

$$\|\overline{c_M}(t_2)-\overline{c_M}(t_1)\|_{L^2} \leqslant C|t_2-t_1|^{1/4}.$$

Furthermore, there is a subsequence $(c_M)_{M\in\mathcal{N}}$ and a subsequence $(\mu_M)_{M\in\mathcal{N}}$ with $\mathcal{N}\subset\mathbb{N}$ and there are $c\in L^\infty(0,T_0;Y)$, $\mu\in L^2(0,T_0;Y)$ such that

(i) $\overline{c_M}\to c$ *in* $C^{0,\alpha}([0,T_0];L^2(\Omega;\mathbb{R}^4))$ *for all* $\alpha\in(0,\frac{1}{4})$,
(ii) $c_M\to c$ *in* $L^\infty(0,T_0;L^2(\Omega;\mathbb{R}^4))$,
(iii) $c_M\to c$ *almost everywhere in* Ω_{T_0},
(iv) $c_M\overset{*}{\rightharpoonup}c$ *in* $L^\infty(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$,
(v) $\mu_M\rightharpoonup\mu$ *in* $L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$

as $M\in\mathcal{N}$ *tends to infinity*.

Proof: We test Eq. (61) with $\xi:=\overline{c_M}(t_2)-\overline{c_M}(t_1)$, where t_1, $t_2\in[0,T_0]$ with $t_1<t_2$. After integration in time from t_1 to t_2, we obtain

$$\|\overline{c_M}(t_2)-\overline{c_M}(t_1)\|_{L^2}^2+\int_{t_1}^{t_2}\int_\Omega L\,\nabla\,\mu_M(t):\nabla\,(\overline{c_M}(t_2)-\overline{c_M}(t_1))\mathrm{d}t$$
$$=\int_{t_1}^{t_2}\int_\Omega r(c_M(t-h),\chi_M(t-h))(\overline{c_M}(t_2)-\overline{c_M}(t_1))\mathrm{d}t.$$

The c_M^m are uniformly bounded in Y, therefore the linear interpolants $\overline{c_M}$ are uniformly bounded in $L^\infty(0,T_0;Y)$. Thus we obtain

$$\|\overline{c_M}(t_2)-\overline{c_M}(t_1)\|_{L^2}^2\leqslant C\|\overline{c_M}\|_{L^\infty(H^1)}\int_{t_1}^{t_2}(\|\nabla\,\mu_M(t)\|_{L^2}+\|r(c_M(t-h),\chi_M(t-h))\|_{L^2})\mathrm{d}t$$
$$\leqslant C\|\overline{c_M}\|_{L^\infty(H^1)}[(t_2-t_1)^{1/2}\|\nabla\,\mu\|_{L^2(\Omega_{T_0})}+(t_2-t_1)\|r(c_M,\chi_M)\|_{L^\infty(L^2)}].$$

Employing the *a priori* estimates (58) and (59) we have shown

$$\|\overline{c_M}(t_2)-\overline{c_M}(t_1)\|_{L^2}\leqslant C|t_2-t_1|^{1/4}\quad\text{for all } t_1,t_2\in[0,T_0]$$

for a positive constant C. This is the equicontinuity of $(\overline{c_M})_{M\in\mathbb{N}}$. The boundedness of $(\overline{c_M})$ in $L^\infty(0,T_0;H_0^{1,2}(\Omega))$ and the fact that H^1 is compactly imbedded in L^2 yields (i) as a consequence of the Arzelà–Ascoli theorem. The claims (ii), (iii), and (iv) follow exactly as in Ref. 7. We choose for $t\in[0,T_0]$ values $m\in\{1,\ldots,M\}$ and $\beta\in[0,1]$ such that $t=[\beta m+(1-\beta)(m-1)]h$. From the definition of $\overline{c}$ we get at once

$$\|\overline{c_M}(t)-c_M(t)\|_{L^2}=\|\beta c_M^m+(1-\beta)c_M^{m-1}-c_M^m\|_{L^2}=(1-\beta)\|c_M^m-c_M^{m-1}\|_{L^2}\leqslant Ch^{1/4}.$$

This tends to zero as M becomes infinite. With the help of (i), this proves (ii). Since for a subsequence we have convergence almost everywhere, (iii) is proved, too. Claim (iv) is a direct consequence of estimate (58) which gives the boundedness of c_M in $L^\infty(0,T_0;Y)$.

For the proof of (v) we notice that due to estimate (59), the $(\nabla\mu_M)$ are uniformly bounded in $L^2(\Omega_{T_0})$. By the Poincaré inequality the (μ_M) are uniformly bounded in $L^2(0,T_0;H_0^1(\Omega))$. With the Banach–Alaoglu theorem (v) follows. ■

Lemma 5: For a suitable subsequence $\mathcal{N}\subset\mathbb{N}$, we have

(i) $\overline{\chi_M}\to\chi$ *in* $C^{0,\alpha}([0,T_0];L^2(\Omega))$ *for all* $\alpha\in(0,\frac{1}{2})$,
(ii) $\chi_M\to\chi$ *in* $L^\infty(0,T_0;L^2(\Omega))$,
(iii) $\chi_M\to\chi$ *almost everywhere in* Ω_{T_0},
(iv) $\chi_M\overset{*}{\rightharpoonup}\chi$ *in* $L^\infty(0,T_0;H^1(\Omega))$,
(v) $\partial_c f(c_M,\chi_M)\to\partial_c f(c,\chi)$ *in* $L^1(\Omega_{T_0})$,
(vi) $\partial_\chi f(c_M,\chi_M)\to\partial_\chi f(c,\chi)$ *in* $L^1(\Omega_{T_0})$

as $M\in\mathcal{N}$ tends to infinity.

Proof: Similar to Eq. (61) we can reformulate identity (56) to

$$\tau\int_\Omega\partial_t\overline{\chi_M}(t)\zeta+\int_\Omega\gamma\nabla\,\chi_M(t)\cdot\nabla\,\zeta+\int_\Omega\omega(c_M(t),\chi_M(t))\zeta=0\quad\text{for all }\zeta\in H^1(\Omega)\qquad(62)$$

which holds for almost all $t\in[0,T_0]$.

We test (62) with $\zeta:=\overline{\chi_M}(t_2)-\overline{\chi_M}(t_1)$, where t_1, $t_2\in[0,T_0]$, $t_2>t_1$. After integration in time from t_1 to t_2 we get

$$\tau\|\overline{\chi}_M(t_2)-\overline{\chi}_M(t_1)\|_{L^2}^2+\int_{t_1}^{t_2}\int_\Omega \gamma\nabla\chi_M(t)\cdot\nabla(\overline{\chi}_M(t_2)-\overline{\chi}_M(t_1))\mathrm{d}t+\int_{t_1}^{t_2}\omega(c_M(t),\chi_M(t))(\overline{\chi}_M(t_2)-\overline{\chi}_M(t_1))\mathrm{d}t=0.$$

From the uniform boundedness of $\overline{\chi}_M$ in $L^\infty(0,T_0;H^1(\Omega))$ and in $L^\infty(\Omega_{T_0})$ we obtain

$$\int_{t_1}^{t_2}\int_\Omega \gamma\nabla\chi_M(t)\cdot\nabla(\overline{\chi}_M(t_2)-\overline{\chi}_M(t_1))\mathrm{d}t\leqslant c\|\overline{\chi}_M\|_{L^\infty(H^1)}\int_{t_1}^{t_2}\|\nabla\chi_M(t)\|_{L^2}\mathrm{d}t,$$

$$\int_{t_1}^{t_2}\omega(c_M(t),\chi_M(t))(\overline{\chi}_M(t_2)-\overline{\chi}_M(t_1))\mathrm{d}t\leqslant c\|\overline{\chi}_M\|_{L^\infty(\Omega_{T_0})}\int_{t_1}^{t_2}\omega(c_M(t),\chi_M(t))\mathrm{d}t.$$

With the continuity of ω, these estimates imply

$$\|\overline{\chi}_M(t_2)-\overline{\chi}_M(t_1)\|_{L^2}\leqslant C|t_2-t_1|^{1/2}\quad\text{for all } t_1,t_2\in[0,T_0]$$

and exactly as in Lemma 4 this yields statements (i)–(iv).

In order to prove (v) and (vi), we first notice that by assumption (A2), $\partial_c f$ and $\partial_\chi f$ are continuous functions. Hence, by (iii) and Lemma 4(iii),

$$\partial_c f(c_M,\chi_M)\to\partial_c f(c,\chi)\quad\text{almost everywhere in }\Omega_{T_0},$$

$$\partial_\chi f(c_M,\chi_M)\to\partial_\chi f(c,\chi)\quad\text{almost everywhere in }\Omega_{T_0}.$$

The growth condition of assumption (A2.3) on f^1 now yields that for arbitrary $\delta>0$ and all measurable $E\subset\Omega$,

$$\int_E|\partial_c f^1(c_M,\chi_M)|\leqslant\delta\int_E f^1(c_M,\chi_M)+C_\delta|E|\leqslant\delta C+C_\delta|E|.$$

Therefore, $\int_E|\partial_c f^1(c_M,\chi_M)|\to 0$ as $|E|\to 0$ uniformly in M and by Vitali's theorem, $f^1(c_M,\chi_M)\to f^1(c,\chi)$ in $L^1(\Omega_{T_0})$ as $M\in\mathcal{N}$ tends to infinity. The same result for f^2 follows directly from (A2.2) and the dominated convergence theorem of Lebesgue. The proof of $\partial_\chi f(c_M,\chi_M)\to\partial_\chi f(c,\chi)$ exploiting (A2.3) and (A2.2) is similar. ■

XIII. GLOBAL EXISTENCE OF SOLUTIONS FOR POLYNOMIAL FREE ENERGY

We are now in the position to state one of the main results.

Theorem 1: *Let the assumptions of Sec. X hold. Then, there exists a weak solution* (c,μ,χ) *of the diffuse interface equations in the sense of (46)–(48) such that*

(i) $c\in C^{0,1/4}([0,T_0];L^2(\Omega;\mathbb{R}^4))$,
(ii) $\partial_t c\in L^2(0,T_0;(H_0^1(\Omega;\mathbb{R}^4))')$,
(iii) $\chi\in C^{0,1/2}([0,T_0];L^2(\Omega))$,
(iv) $\partial_t\chi\in L^2(0,T_0;(H_0^1(\Omega))')$.

Proof: We are going to prove that (c,μ,χ) introduced in Lemmata 4 and 5 is the desired weak solution in the sense of (46)–(48). From Eq. (61) we learn

$$-\int_{\Omega_{T_0}}\partial_t\xi(\overline{c_M}-c_0)+\int_{\Omega_{T_0}}L\nabla\mu_M:\nabla\xi+\int_{\Omega_{T_0}}r(c_M,\chi_M)=0$$

for all $\xi\in L^2(0,T_0;Y)$ with $\partial_t\xi\in L^2(\Omega_{T_0})$ and $\xi(T_0)=0$. Passing to the limit $M\to\infty$ together with Lemma 4 this implies (46). Now we show (47). From (55) we see

$$\int_\Omega \lambda \nabla c_M \cdot \nabla \eta + \partial_c f(c_M, \chi_M) \cdot \eta = \int_\Omega \mu_M \cdot \eta \quad \text{for all } \eta \in Y \cap L^\infty(\Omega; \mathbb{R}^4).$$

The convergence of

$$\int_\Omega \lambda c_M \cdot \nabla \eta \to \int_\Omega \lambda c \cdot \nabla \eta$$

as $M \to \infty$ is clear by linearity and the convergence

$$\int_\Omega \partial_c f(c_M, \chi_M) \cdot \eta \to \int_\Omega \partial_c f(c, \chi) \cdot \eta$$

is again evident by Vitali's theorem similar to the proof of Lemma 5 by using the almost everywhere convergence of c_M and χ_M, the growth condition (A2.3), estimate (59) on f^1 and the boundedness of η.

In the same way, we obtain (48) from (62). ■

XIV. UNIQUENESS OF THE DIFFUSE INTERFACE MODEL

To show uniqueness of (42), we use an integration in time method. The proof requires the validity of the free energy inequality and the validity of (A6).

Theorem 2: *The solution (c, μ, χ) of the diffuse interface equations obtained in Theorem 1 is unique in the spaces stated in this theorem.*

Proof: Assume that (c^i, χ^i, μ^i), $i = 1, 2$ are two solutions of system (42). Now, let $c := c^2 - c^1$, $\chi := \chi^2 - \chi^1$, $\mu := \mu^2 - \mu^1$, $r := r(c^2, \chi^2) - r(c^1, \chi^1)$, $\omega := \partial_\chi f(c^2, \chi^2) - \partial_\chi f(c^1, \chi^1)$. The difference (c, χ, μ) solves the weak formulation

$$-\int_{\Omega_{T_0}} \partial_t \xi \cdot c + \int_{\Omega_{T_0}} L \nabla \mu : \nabla \xi - \int_{\Omega_{T_0}} r \cdot \xi = 0, \tag{63}$$

$$\int_{\Omega_{T_0}} [(\partial_c f(c^2, \chi^2) - \partial_c f(c^1, \chi^1)) \cdot \eta + \lambda \nabla c \cdot \nabla \eta] = \int_{\Omega_{T_0}} \mu \cdot \eta, \tag{64}$$

$$-\int_{\Omega_{T_0}} \tau \partial_t \zeta \chi + \int_{\Omega_{T_0}} \gamma \nabla \chi \cdot \nabla \zeta - \int_{\Omega_{T_0}} \omega \cdot \zeta = 0. \tag{65}$$

For given $\eta \in L^2(0, T_0; H_0^1(\Omega, \mathbb{R}^4))$ and $t_0 \in (0, T_0)$ we define

$$\xi(\cdot, t) := \begin{cases} \displaystyle\int_t^{t_0} \eta(\cdot, s)\mathrm{d}s & \text{if } t \leqslant t_0, \\ 0 & \text{if } t > t_0. \end{cases} \tag{66}$$

Using this test function in (63) we find after integration by parts in time

$$\begin{aligned} 0 &= \int_{\Omega_{t_0}} c \cdot \eta + \int_{\Omega_{t_0}} L \nabla \mu : \nabla \left(\int_t^{t_0} \eta(s)\mathrm{d}s \right) - \int_{\Omega_{t_0}} r \cdot \left(\int_t^{t_0} \eta(s)\mathrm{d}s \right) \\ &= \int_{\Omega_{t_0}} c \cdot \eta + \int_{\Omega_{t_0}} L \nabla \left(\int_0^t \mu(s)\mathrm{d}s \right) : \nabla \eta - \int_{\Omega_{t_0}} \left(\int_0^t r(s)\mathrm{d}s \right) \cdot \eta. \end{aligned} \tag{67}$$

This implies

$$\mathcal{G}\left(c-\int_0^t r(s)\mathrm{d}s\right)=-\int_0^t \mu(s)\mathrm{d}s \quad \text{and } \partial_t\mathcal{G}\left(c-\int_0^t r(s)\mathrm{d}s\right)=-\mu.$$

By choosing $\eta:=\mu$ in (67) we obtain

$$0=\int_{\Omega_{t_0}} c\cdot\mu+\int_{\Omega_{t_0}} L\,\nabla\left(\mathcal{G}\left(\int_0^t r(s)\mathrm{d}s-c\right)\right):\nabla\left(\partial_t\mathcal{G}\left(\int_0^t r(s)\mathrm{d}s-c\right)\right)-\int_{\Omega_{t_0}}\left(\int_0^t r(s)\mathrm{d}s\right)\cdot\mu$$

and consequently

$$0=\int_{\Omega_{t_0}} c\cdot\mu+\int_{\Omega} L\,\nabla\,\mathcal{G}\left(\int_0^{t_0} r(s)\mathrm{d}s-c(t_0)\right):\nabla\,\mathcal{G}\left(\int_0^{t_0} r(s)\mathrm{d}s-c(t_0)\right)-\int_{\Omega_{t_0}}\left(\int_0^t r(s)\mathrm{d}s\right)\cdot\mu. \tag{68}$$

In Eq. (64) we test with $\eta:=\chi_{[0,t_0]}c$. Hence we have

$$\int_{\Omega_{t_0}} c\cdot\mu=\int_{\Omega_{t_0}}\lambda|\nabla c|^2+(\partial_c f(c^2,\chi^2)-\partial_c f(c^1,\chi^1))\cdot c. \tag{69}$$

From (68) and (69) we learn

$$\left\|\left(\int_0^{t_0} r\right)-c(t_0)\right\|_L^2+\int_{\Omega_{t_0}}\lambda|\lambda c|^2-\int_{\Omega_{t_0}}\left(\int_0^t r(s)\mathrm{d}s\right)\cdot\mu=-\int_{\Omega_{t_0}}(\partial_c f(c^2,\chi^2)-\partial_c f(c^1,\chi^1))\cdot c. \tag{70}$$

From the free energy estimate we infer that if conditions (40) and (51) and (A4.2) hold (i.e., if $\lambda<\lambda_0$), then

$$\int_{\Omega_{t_0}}\left(\int_0^t r(s)\mathrm{d}s\right)\cdot\mu\leqslant 0. \tag{71}$$

This holds because $r(t)\cdot\mu(t)=r_1(t)(\mu_1(t)-2\mu_2(t)+\mu_3(t))$ and $(\mu_1(t)-2\mu_2(t)+\mu_3(t))<0$, $\int_0^L r(s)\mathrm{d}s\geqslant r_1(t)>0$ for almost every $t\in\Omega_{T_0}$, see Sec. V. Therefore we obtain as a consequence of (70)

$$\lambda\int_{\Omega_{t_0}}|\nabla c|^2\leqslant-\int_{\Omega_{t_0}}(\partial_c f(c^2,\chi^2)-\partial_c f(c^1,\chi^1))\cdot c. \tag{72}$$

In (65) we choose the test function $\mathrm{X}_{[0,t_0]}\chi$ analogous to (66). This leads to

$$\frac{\tau}{\gamma}\int_{\Omega_{t_0}}\chi\eta+\int_{\Omega_{t_0}}\nabla\left(\int_0^t\chi(s)\mathrm{d}s\right):\nabla\,\eta(t)-\frac{1}{\gamma}\int_{\Omega_{t_0}}\eta(t)\int_0^t\omega(s)\mathrm{d}s=0. \tag{73}$$

This implies because of $\chi(0)=0$,

$$(-\Delta)^{-1}\left(\frac{\tau}{\gamma}\chi-\frac{1}{\gamma}\int_0^t\omega(s)\mathrm{d}s\right)=-\int_0^t\chi(s)\mathrm{d}s,$$

$$\partial_t(-\Delta)^{-1}\left(\frac{\tau}{\gamma}\chi-\frac{1}{\gamma}\int_0^t\omega(s)\mathrm{d}s\right)=-\chi(t).$$

We set $\eta:=\chi$ in (73). As in the treatment of Eq. (63) this yields

$$0 = \gamma\tau\int_{\Omega_{t_0}} |\chi|^2 + \left\| \tau\chi(t_0) - \left(\int_0^{t_0} \omega(s) \right) \right\|_{L^2}^2 - \gamma \int_{\Omega_{t_0}} \chi(t) \int_0^t \omega(s)\mathrm{d}s$$

and consequently with Young's inequality

$$\tau\int_{\Omega_{t_0}} |\chi|^2 \leqslant \delta\int_{\Omega_{t_0}} |\chi|^2 + \frac{C}{\delta}\int_{\Omega_{t_0}} \left(\int_0^t \omega(s)\mathrm{d}s \right)^2. \tag{74}$$

Now we add (72) and (74) and find

$$\lambda\int_{\Omega_{t_0}} |\nabla c|^2 + \tau\int_{\Omega_{t_0}} |\chi|^2 \leqslant \delta C\int_{\Omega_{t_0}} (|c|^2 + |\chi|^2) + \frac{C}{\delta}\int_{\Omega_{t_0}} \left(\int_0^t \omega(s)\mathrm{d}s \right)^2 + |\partial_c f(c^2,\chi^2) - \partial_c f(c^1,\chi^1)|^2.$$

For δ small the first integral on the right-hand side can be absorbed on the left. As

$$|\partial_c f(c^2,\chi^2) - \partial_c f(c^1,\chi^1)|^2 + |\partial_\chi f(c^2,\chi^2) - \partial_\chi f(c^1,\chi^1)|^2 \leqslant C_0(|c|^2 + |\chi|^2),$$

where C_0 depends on the Lipschitz constant of $\partial_c f$ and $\partial_\chi f$, we find at last by exploiting the Poincaré inequality

$$\int_{\Omega_{t_0}} (|\nabla c|^2 + |\chi|^2) \leqslant C\int_{\Omega_{t_0}} (|\nabla c|^2 + |\chi|^2) + \int_0^t \int_{\Omega_{t_0}} (|\nabla c|^2 + |\chi|^2).$$

With Gronwall's inequality this finally means $c=\chi=0$ in Ω_{t_0} and with (64) $\mu=0$ in Ω_{t_0}. By repeating the argument, as $t_0>0$, this holds in the whole of Ω_{T_0}. ■

XV. LOGARITHMIC FREE ENERGY

In the following four sections we are going to extend Theorem 1 to logarithmic free energies. The results will in particular be taylor made for the free energy functional considered in definition (8),

$$f(c,\chi) = \chi b^1 \sum_{j=1}^4 c_j \ln c_j + (1-\chi) b^2 \sum_{j=1}^4 c_j \ln c_j + \sum_{i=1}^3 c_i E_i + \left(\sum_{j=1}^4 \alpha_j c_j \right)^2 + TW(\chi). \tag{75}$$

We will use the statements proved for polynomial free energies that can be regarded as a Taylor expansion.

For the proof of $0<c_j<1$, $1\leqslant j\leqslant 4$, we approximate f for $\delta>0$ by some f^δ that fulfills the requirements of Sec. X and find suitable *a priori* estimates that put us in the position to pass to the limit $\delta\to 0$.

The logarithmic form of the free energy guarantees that the concentration vector c lies inside the transformed Gibbs simplex,

$$G := \Sigma \cap \{c \in \mathbb{R}^4 | c_j \geqslant 0 \text{ for } 1 \leqslant j \leqslant 4\}$$

and that $\chi \in (0,1)$. Therefore (c,χ) is physically meaningful.

The assumptions (A2) and (A3) of Sec. X are replaced by the following:

(A2′) f is of the form (75) with constants $\alpha_j>0$, $b^1>0$, $b^2>0$, $T>0$.

(A3′) The initial values $c_0 \in X_1$, $\chi_0 \in X_2$ fulfill $c_0 \in G$, $\chi \in [0,1]$ almost everywhere and

$$\int_\Omega c_{0l} > 0 \quad \text{for } 1 \leqslant l \leqslant 4, \quad \int_\Omega \chi > 0, \quad \int_\Omega (1-\chi) > 0.$$

(A6′) Additional to the conditions in (A6) we demand

$$\kappa^{1/\max(b^1,b^2)} < \frac{1}{e^2}. \tag{76}$$

The assumptions (A1) and (A4) remain unchanged and continue to hold.

To proceed, we define for $d>0$ the convex function

$$\psi(d) := d \ln d$$

and for $\delta>0$ its regularization (defined for $d \in \mathbb{R}$)

$$\psi^\delta(d) := \begin{cases} d \ln d & \text{for } d \geqslant \delta, \\ d \ln \delta - \dfrac{\delta}{2} + \dfrac{d^2}{2\delta} & \text{for } d < \delta. \end{cases}$$

The regularized free energy functional is defined such that $\psi^\delta \in C^2$ and the derivative $(\psi^\delta)'$ is monotone increasing. This ansatz goes back to Ref. 5.

The free energy of the regularized δ-problem is found by replacing $\Sigma_i c_i \ln c_i$ by $\Sigma_i \psi^\delta(c_i)$ in (26). Since the convex combination

$$\overline{f}(c,\chi) := \chi f_1(c) + (1-\chi) f_2(c)$$

would define a nonconvex functional in c if $\chi \notin [0,1]$, we consider the following penalization [$f^\delta = f^{1,\delta} + f^2$, see assumption (A2)]:

$$f^{1,\delta}(c,\chi) := \begin{cases} \chi b^1 \sum\limits_j \psi^\delta(c_j) + (1-\chi) b^2 \sum\limits_j \psi^\delta(c_j) + T[\psi^\delta(\chi) + \psi^\delta(1-\chi)] & \text{if } \chi \in (0,1), \\ +\infty \quad \text{else}, \end{cases}$$

$$f^2(c,\chi) := \left(\sum_{j=1}^4 \alpha_j c_j \right)^2.$$

Due to the expression $\psi^\delta(\chi)+\psi^\delta(1-\chi)$ in the definition of f^δ it is obvious that every minimizer χ fulfills $0<\chi<1$. This is proved rigorously in Lemma 8.

It can be easily checked that the functional $F^{m,h}$ of Sec. XI still has a minimizer (c^m,χ^m) for every m and sufficiently small h. For $\chi \in (0,1)$, $f^{1,\delta}$ is still continuously differentiable. Since $f^{1,\delta}$, f^2 fulfill the assumptions of Sec. X the earlier existence results can be carried over.

The regularization f^δ of f also implies that $\omega(c^\delta,\chi^\delta) = \partial_\chi f^\delta(c^\delta,\chi^\delta)$ depends on δ and therefore we will replace $\omega(c^m,\chi^m)$ in the implicit time discretization (49) by $\omega^\delta(c^m,\chi^m)$ and the weak formulation (48) by

$$-\int_{\Omega_{T_0}} \tau \partial_t \zeta (\chi^\delta - \chi_0) + \int_{\Omega_{T_0}} \gamma \nabla \chi^\delta \cdot \nabla \zeta - \int_{\Omega_{T_0}} \omega^\delta(c^\delta,\chi^\delta)\zeta = 0 \tag{77}$$

for all $\zeta \in L^2(0,T_0;H^1(\Omega;\mathbb{R}))$ with $\partial_t \zeta \in L^2(\Omega_{T_0})$, $\zeta(T_0)=0$. Later we will show that $\omega^\delta(c^\delta,\chi^\delta) \to \omega(c,\chi)$ in $L^1(\Omega_{T_0})$ as $\delta \searrow 0$.

The only assumption that needs further clarification is (A5). In order to verify (50), we must construct an approximation $r^\delta = (r_1^\delta, -r_1^\delta, r_1^\delta, 0)$ of r and must check that

$$\int_\Omega k_B T b_\chi \left[(\psi^\delta)'(c_1) - 2(\psi^\delta)'(c_2) + (\psi^\delta)'(c_3) + \frac{E_1 - 2E_2 + E_3}{k_B T b_\chi} \right] r_1^\delta \leqslant 0.$$

We claim that a good choice for r_1^δ is

$$r_1^\delta(c,\chi) := k^{1/b_\chi}(\max(c_2,\delta)^2 - \kappa^{1/b_\chi}\max(c_1,\delta)\max(c_3,\delta)). \tag{78}$$

To illustrate (78), let us consider three characteristic cases.

Case 1: $c_1 \geqslant \delta$, $c_2 \geqslant \delta$, $c_3 \geqslant \delta$. Apparently $r^\delta = r$, and (50) follows verbatim as in the proof of the free energy inequality in Sec. V.

Case 2: $c_1 < \delta$, $c_2 \geqslant \delta$, $c_3 \geqslant \delta$. From the definition of ψ^δ we find that we must estimate

$$\int_\Omega k_B T b_\chi \left(\ln \delta + \frac{c_1}{\delta} - 2\ln c_2 - 2 + \ln c_3 + 1 + \frac{E_1 + E_3 - 2E_2}{k_B T b_\chi} \right) r_1^\delta$$
$$= \int_\Omega k_B T b_\chi \left[\ln\left(\frac{\delta c_3 \kappa^{1/b_\chi}}{c_2^2} \right) + \frac{c_1}{\delta} - 1 \right] r_1^\delta.$$

The estimate follows now from $[\ln(\delta c_3 \kappa^{1/b_\chi}) - \ln(c_2^2)] r_1^\delta < 0$ and because of $(c_1/\delta) - 1 < 0$ and $r_1^\delta = k^{1/b_\chi}(c_2^2 - \kappa^{1/b_\chi}\delta c_3) > 0$ for δ sufficiently small. We emphasize that we need $r_1^\delta > 0$ in order to have $\int_\Omega (\alpha_1 - 2\alpha_2 + \alpha_3) Q(c^\delta) r_1^\delta < 0$ which allows to compensate the surface energy term for sufficiently small λ.

Case 3: $c_1 < \delta$, $c_2 < \delta$, $c_3 < \delta$. Here we must estimate

$$\int_\Omega k_B T b_\chi \left[\ln\left(\frac{\delta^2}{\delta^2} \right) + \frac{c_1}{\delta} - 2\frac{c_2}{\delta} + \frac{c_3}{\delta} + \frac{E_1 - 2E_2 + E_3}{k_B T b_\chi} \right] r_1^\delta.$$

We observe $r_1^\delta = k^{1/b_\chi}\delta^2(1 - \kappa^{1/b_\chi}) > 0$ due to assumption (A6). Finally

$$\int_\Omega \left(\frac{E_1 - 2E_2 + E_3}{k_B T b_\chi} + \frac{c_1 - 2c_2 + c_3}{\delta} \right) \leqslant \int_\Omega [\ln(\kappa^{1/b_\chi}) + 2] < 0$$

if κ satisfies (76). The remaining cases can be treated similar to case 2.

XVI. UNIFORM ESTIMATES

The following lemma was first stated and proved in Elliott and Luckhaus[5] for logarithmic free energies typical for the Cahn–Hilliard system.

Lemma 6: For $\delta_0 = 1/e$ there exists a $K > 0$ such that for all $\delta \in (0, \delta_0)$,

$$f^\delta(c,\chi) \geqslant -K \text{ for all } c \in \Sigma,\ \chi \in [0,1].$$

Proof: For $\delta_0 < 1/e$ one has $\psi^\delta(d) \geqslant -1/e$ for all $\delta < \delta_0$. As b^l, $T > 0$, the proof is complete.■

Lemma 7: (a) For $\delta \in (0, \delta_0)$ there exists a weak solution $(c^\delta, \mu^\delta, \chi^\delta)$ of (42) with a logarithmic free energy that satisfies (A2′)–(A6′) in the sense of Sec. VIII with (48) replaced by (77).

(b) There exists a constant $C > 0$ independent of δ such that for all $\delta \in (0, \delta_1)$ with some constant $\delta_1 \leqslant \delta_0$

$$\sup_{t \in [0,T_0]} \{ \|c^\delta(t)\|_{H^1} + \|\chi^\delta(t)\|_{H^1} \} \leqslant C,$$

$$\sup_{t \in [0,T_0]} \int_\Omega f^{1,\delta}(c^\delta(t), \chi^\delta(t)) + \|\nabla \mu^\delta\|_{L^2(\Omega_{T_0})} \leqslant C$$

and

$$\|c^\delta(t_2) - c^\delta(t_1)\|_{L^2} \leqslant C|t_2 - t_1|^{1/4},$$

$$\|\chi^\delta(t_2) - \chi^\delta(t_1)\|_{L^2} \leqslant C|t_2 - t_1|^{1/2}$$

for all t_1, $t_2 \in [0, T_0]$.

(c) One can extract subsequences $(c^\delta)_{\delta\in\mathcal{R}}$, $(\mu^\delta)_{\delta\in\mathcal{R}}$ *and* $(\chi^\delta)_{\delta\in\mathcal{R}}$ *where* $\mathcal{R}\subset(0,\delta_1)$ *is a countable set with zero as the only accumulation point such that*

(i) $c^\delta\to c$ *in* $C^{0,\alpha}([0,T_0];L^2(\Omega;\mathbb{R}^4))$ *for all* $\alpha\in\left(0,\frac{1}{4}\right)$,
(ii) $c^\delta\to c$ *almost everywhere in* Ω_{T_0},
(iii) $c^\delta\overset{*}{\rightharpoonup}c$ *in* $L^\infty(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$,
(iv) $\chi^\delta\to\chi$ *in* $C^{0,\alpha}([0,T_0];L^2(\Omega))$ *for all* $\alpha\in\left(0,\frac{1}{2}\right)$,
(v) $\chi^\delta\to\chi$ *almost everywhere in* Ω_{T_0} *and* $0\leqslant\chi^\delta,\ \chi\leqslant 1$ *a.e. in* Ω_{T_0},
(vi) $\chi^\delta\overset{*}{\rightharpoonup}\chi$ *in* $L^\infty(0,T_0;H^1(\Omega))$,
(vii) $\mu^\delta\rightharpoonup\mu$ *in* $L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$

as $\delta\in\mathcal{R}$ *tends to zero.*

Proof: Using Lemma 6, the regularized problem satisfies the assumptions of Sec. X and by Theorem 1, a weak solution for fixed $\delta\in(0,\delta_0)$ exists. This proves (a). The estimates in (b) are a direct consequence of Lemma 3 and Lemma 4, where due to assumption (A4.2) we must choose δ small enough for Lemma 3 to hold. From Lemma 3, it follows that $F^\delta(c_0,\chi_0)$ does not depend on δ, hence the constant on the right-hand side does not depend on δ. (c) is proved by Lemmata 4 and 5. ■

XVII. HIGHER INTEGRABILITY FOR THE LOGARITHMIC FREE ENERGY

Since $\varphi^\delta:=(\psi^\delta)'$ will be singular as $\delta\to 0$ we introduce for $r>0$

$$\varphi_r^\delta(d):=\begin{cases}\varphi^\delta(d)|\varphi^\delta(d)|^{r-1} & \text{if } \varphi^\delta(d)\neq 0,\\ 0 & \text{if } \varphi^\delta(d)=0.\end{cases}$$

By definition, $\varphi_r^\delta\in C^0(\mathbb{R})$.

For $0<r<1$, φ_r^δ is not differentiable at the zero point of φ^δ. To overcome this difficulty, for $\varrho>0$ introduce the function $\varphi_r^{\delta,\varrho}$ with $\varphi_r^{\delta,\varrho}=\varphi_r^\delta$ in $\mathbb{R}\backslash[0,1]$ and define $\varphi_r^{\delta,\varrho}$ in [0, 1] such that $\varphi_r^{\delta,\varrho}$ is a C^1 function, monotone increasing and $\varphi_r^{\delta,\varrho}\to\varphi_r^\delta$ in $C^0(\mathbb{R})$ as $\varrho\searrow 0$.

For the approximation of $\varphi^\delta(\chi^\delta)$ in the modified Allen–Cahn equation it is more suitable to introduce the Dirac sequence

$$\varphi^{\delta,\varepsilon}(x):=(\varphi^\delta * J_\varepsilon)(x):=\varepsilon^{-D}\int_{\mathbb{R}^D}\varphi^\delta(x)J((x-y)/\varepsilon)\mathrm{d}y,$$

where the kernal $J\in C^\infty(B^1(0))$ is a positive smooth polynomial [see assumption (A2)]. As is well known, $\varphi^{\delta,\varepsilon}\in C^\infty$ and $\varphi^{\delta,\varepsilon}\to\varphi^\delta$ in $L^p(\Omega)$ as $\varepsilon\searrow 0$ for any $p\geqslant 1$.

Even though by construction $0<\chi^\delta<1$ almost everywhere, it might still happen that for the limit the sets $\{x\in\Omega\,|\,\chi(x)=0\}$ and $\{x\in\Omega\,|\,\chi(x)=1\}$ have nonzero Lebesgue measure and that the entropic terms in the free energy density become singular. Now we will show that this is not the case.

Lemma 8: There exists a constant $C>0$ *such that for all* $\delta\in(0,\delta_0)$,

(i) $\|\varphi^\delta(c_l^\delta)\|_{L^q(\Omega_{T_0})}\leqslant C$ *for a suitable* $q>1$ *and all* $1\leqslant l\leqslant 4$,
(ii) $\|\varphi^\delta(\chi^\delta)+\varphi^\delta(1-\chi^\delta)\|_{L^2(\Omega_{T_0})}\leqslant C$.

Proof: The weak formulation (47) for the generalized chemical potential is

$$\int_{\Omega_{T_0}} \mu^\delta \cdot \eta = \int_{\Omega_{T_0}} \left\{ \lambda \sum_{l=1}^{4} \nabla c_l^\delta \cdot \nabla \eta_l + 2 \left[\alpha_l \sum_{j=1}^{4} \alpha_j c_j^\delta \right]_{1\leqslant l\leqslant 4} \cdot \eta + \sum_{l=1}^{3} E_l \eta_l \right\}$$
$$+ \int_{\Omega_{T_0}} (\chi^\delta b^1 + (1-\chi^\delta) b^2)[\varphi^\delta(c_l^\delta)]_{1\leqslant l\leqslant 4} \cdot \eta \tag{79}$$

for all $\eta \in L^2(0,T_0;H^1(\Omega;\mathbb{R}^4)) \cap L^\infty(\Omega_{T_0},\mathbb{R}^4)$. We choose $\eta := [\varphi_r^{\delta,\varrho}(c_l^\delta)]_{1\leqslant l\leqslant 4}$ in (79) which is an admissible test function because of the Sobolev imbedding theorem and because $\varphi_r^{\delta,\varrho} \in C^1$. We obtain

$$\int_{\Omega_{T_0}} \sum_{l=1}^{4} \mu_l^\delta \varphi_r^{\delta,\varrho}(c_l^\delta) = + \int_{\Omega_{T_0}} \sum_{l=1}^{4} \varphi_r^{\delta,\varrho}(c_l^\delta) \left(2\alpha_l \sum_{j=1}^{4} \alpha_j c_j^\delta + E_l \right) + \int_{\Omega_{T_0}} \lambda \sum_{l=1}^{4} \nabla c_l^\delta \cdot \nabla \varphi_r^{\delta,\varrho}(c_l^\delta)$$
$$+ \int_{\Omega_{T_0}} \sum_{l=1}^{4} (\chi^\delta b^1 + (1-\chi^\delta) b^2) \varphi^\delta(c_l^\delta) \varphi_r^{\delta,\varrho}(c_l^\delta).$$

In the last formula we set for simplicity $E_4 := 0$. Due to $(\varphi_r^{\delta,\varrho})' \geqslant 0$ we find

$$\int_{\Omega_{T_0}} \lambda \sum_{l=1}^{4} \nabla c_l^\delta \cdot \nabla \varphi_r^{\delta,\varrho}(c_l^\delta) \geqslant 0.$$

This implies

$$\int_{\Omega_{T_0}} \sum_{l=1}^{4} (\chi^\delta b^1 + (1-\chi^\delta) b^2) \ \varphi^\delta(c_l^\delta)) \varphi_r^{\delta,\varrho}(c_l^\delta)$$
$$\leqslant \int_{\Omega_{T_0}} \sum_{l=1}^{4} \mu_l^\delta \varphi_r^{\delta,\varrho}(c_l^\delta) - \int_{\Omega_{T_0}} \sum_{l=1}^{4} \varphi_r^{\delta,\varrho}(c_l^\delta) \left(2\alpha_l \sum_{j=1}^{4} \alpha_j c_j + E_l \right)$$
$$\leqslant C \max_{1\leqslant l\leqslant 4} \|\varphi_r^{\delta,\varrho}(c_l^\delta)\|_{L^2(\Omega_{T_0})} (\|\mu^\delta\|_{L^2(\Omega_{T_0})} + \|c^\delta\|_{L^2(\Omega_{T_0})})$$

where the constant C in the last line depends on $\alpha_1,\ldots,\alpha_4$ and on $E_1,\ldots,E_3$. For $\varrho \searrow 0$ employing Lemma 6 and Lemma 7 this proves

$$\int_{\Omega_{T_0}} \sum_{l=1}^{4} (\chi^\delta b^1 + (1-\chi^\delta) b^2) \varphi^\delta(c_l^\delta) \varphi_r^\delta(c_l^\delta) \leqslant C. \tag{80}$$

A direct computation finally yields

$$\int_{\Omega_{T_0}} \sum_{l=1}^{4} (\chi^\delta b^1 + (1-\chi^\delta) b^2) \ \varphi^\delta(c_l^\delta)) \varphi_r^\delta(c_l^\delta) \geqslant \int_{\Omega_{T_0}} \max_{1\leqslant l\leqslant 4} (\chi^\delta b^1 + (1-\chi^\delta) b^2) |\varphi^\delta(c_l^\delta)|^{r+1}$$
$$\geqslant \int_{\Omega_{T_0}} C \max_{1\leqslant l\leqslant 4} |\varphi^\delta(c_l^\delta)|^{r+1}$$

for a constant $C = C(b^1,b^2)$. The last is possible because $\chi^\delta b^1 + (1-\chi^\delta) b^2 > 0$ almost everywhere in Ω_{T_0}. Together with (80) this proves (i).

Next we consider the weak formulation (77),

$$-\int_{\Omega_{T_0}} \tau\partial_t\zeta(\chi^\delta-\chi_0)+\int_{\Omega_{T_0}}\gamma\nabla\chi^\delta\cdot\nabla\zeta-\int_{\Omega_{T_0}}(b^2-b^1)\sum_{j=1}^{4}\psi^\delta(c_j^\delta)\zeta+\int_{\Omega_{T_0}}T(\varphi^\delta(\chi^\delta)+\varphi^\delta(1-\chi^\delta))\zeta$$
$$=0 \tag{81}$$

of the Allen–Cahn equation. We want to test Eq. (81) with $\zeta:=\varphi^{\delta,\varepsilon}(\chi)+\varphi^{\delta,\varepsilon}(1-\chi)$. Since by Theorem 1 $\chi^\delta\in C^{0,1/2}(0,T_0;L^2(\Omega_{T_0}))$, we can use Fourier theory to formally shift a half-time derivative from ζ to $\chi^\delta-\chi_0$. After this procedure we find with Lemma 7,

$$\int_{\Omega_{T_0}}\tau\partial_t^{1/2}(\varphi^{\delta,\varepsilon}(\chi^\delta)+\varphi^{\delta,\varepsilon}(1-\chi^\delta))\partial_t^{1/2}(\chi^\delta-\chi_0)\leqslant C.$$

To estimate the second integral in (81), we notice

$$\int_{\Omega_{T_0}}\gamma\nabla\chi^\delta\cdot\nabla(\varphi^{\delta,\varepsilon}(\chi^\delta)+\varphi^{\delta,\varepsilon}(1-\chi^\delta))=\int_{\Omega_{T_0}}\gamma|\nabla\chi^\delta|^2[(\varphi^{\delta,\varepsilon})'(\chi^\delta)-(\varphi^{\delta,\varepsilon})'(1-\chi^\delta)].$$

By Lemma 7, χ^δ is bounded in $L^\infty(0,T_0;H^1(\Omega))$ which implies the boundedness of the integral.

If we choose δ sufficiently small in (i) we find $c_j\in(0,1)$ for $1\leqslant j\leqslant 4$, see also the proof of Theorem 3. This guarantees that $\psi^\delta(c_j)$ does not become singular and thus proves the boundedness of the third integral in (81) independently of δ. Finally, we have

$$0\leqslant\int_{\Omega_{T_0}}(\varphi^\delta(\chi^\delta)+\varphi^\delta(1-\chi^\delta))(\varphi^{\delta,\varepsilon}(\chi^\delta)+\varphi^{\delta,\varepsilon}(1-\chi^\delta))\to\|\varphi^\delta(\chi^\delta)+\varphi^\delta(1-\chi^\delta)\|_{L^2(\Omega_{T_0})}\quad\text{as }\varepsilon\searrow 0.$$

By combining these results, (ii) follows. ■

XVIII. GLOBAL EXISTENCE OF SOLUTIONS FOR LOGARITHMIC FREE ENERGIES

Theorem 3: *Let the assumptions of Sec. XV hold. Then there exists a weak solution* (c,μ,χ) *in the sense of Sec. VIII of the diffuse interface equations (42) with logarithmic free energy such that*

(i) $c\in C^{0,1/4}([0,T_0];L^2(\Omega;\mathbb{R}^4))$,
(ii) $\partial_t c\in L^2(0,T_0;(H_0^1(\Omega;\mathbb{R}^4))')$,
(iii) $\chi\in C^{0,1/2}([0,T_0];L^2(\Omega))$,
(iv) $\partial_t\chi\in L^2(0,T_0;(H_0^1(\Omega))')$,
(v) *there exists a* $q>1$ *such that* $\ln c_j\in L^q(\Omega_{T_0})$ *for* $1\leqslant j\leqslant 4$, $\ln\chi$, $\ln(1-\chi)\in L^2(\Omega_{T_0})$ *and in particular* $0<\chi$, $c_j<1$ *a.e.*

Proof: We pass to the limit $\delta\searrow 0$ in the weak formulation (46)–(48) with f defined by (75) and must show that (c,μ,χ) found in Lemma 7 is a solution.

For the limit in (47), the argumentation is an extension to Ref. 7. In particular we must take care of the term

$$\chi^\delta b^1\sum_{j=1}^{4}\varphi^\delta(c_j^\delta)+(1-\chi^\delta)b^2\sum_{j=1}^{4}\varphi^\delta(c_j^\delta). \tag{82}$$

From the almost everywhere convergence of c_l^δ to c_l, Lemma 8(i) and the Lemma of Fatou we find

$$\int_{\Omega_{T_0}}\liminf_{\delta\searrow 0}|\varphi^\delta(c_l^\delta)|^q\leqslant\liminf_{\delta\searrow 0}\int_{\Omega_{T_0}}|\varphi^\delta(c_l^\delta)|^q\leqslant C.$$

Next we will show that

$$\lim_{\delta\searrow 0}\varphi^{\delta}(c_l^{\delta})=\begin{cases}\varphi(c_l) & \text{if } \lim_{\delta\searrow 0} c_l^{\delta}=c_l>0\\ \infty & \text{if } \lim_{\delta\searrow 0} c_l^{\delta}=c_l\leqslant 0\end{cases}, \tag{83}$$

almost everywhere in Ω_{T_0}. For a point $(x,t)\in\Omega_{T_0}$ with $\lim_{\delta\searrow 0} c_l^{\delta}(x,t)=c_l(x,t)>0$, we obtain from $\varphi^{\delta}(d)=\varphi(d)$ for $d\geqslant\delta$ that $\varphi^{\delta}(c^{\delta}(x,t))\to\varphi(c(x,t))$. In the second case of a point $(x,t)\in\Omega_{T_0}$ with $\lim_{\delta\searrow 0} c_l^{\delta}(x,t)=c_l(x,t)\leqslant 0$, we have for δ small enough

$$|\varphi^{\delta}(c_l^{\delta}(x,t))|\geqslant\varphi(\max\{\delta,c_l^{\delta}(x,t)\})\to\infty \quad \text{for } \delta\searrow 0.$$

This proves (83). A similar statement holds for $\psi^{\delta}(\chi^{\delta})$.

From (83) and Lemma 8(i) we deduce $0<c_l<1$ a.e., $\int_{\Omega_{T_0}}|\varphi(c_l)|^q\leqslant C$ and $\varphi^{\delta}(c_l^{\delta})\to\varphi(c_l)$ a.e. With Vitali's theorem we find

$$\varphi^{\delta}(c_l^{\delta})\to\varphi(c_l) \quad \text{in } L^1(\Omega_{T_0}).$$

This allows to pass to the limit in (47).

Let us now consider the limit in (77). The relation $0<c_j<1$ almost everywhere implies $b^l\Sigma_{j=1}^4\psi^{\delta}(c_j^{\delta})\to b^l\Sigma_{j=1}^4\psi(c_j)$, $l=1,2$ almost everywhere in Ω_{T_0} like in the first case of (83). From $\varphi^{\delta}(c_j^{\delta})\in L^q(\Omega_{T_0})$, the uniform boundedness of χ^{δ} and Vitali's theorem we obtain

$$\chi^{\delta}b^1\sum_{j=1}^{4}\psi^{\delta}(c_j^{\delta})\to\chi^{b^1}\sum_{j=1}^{4}\psi(c_j),\quad (1-\chi^{\delta})b^2\sum_{j=1}^{4}\psi^{\delta}(c_j^{\delta})\to(1-\chi)b^2\sum_{j=1}^{4}\psi(c_j)$$

in $L^1(\Omega_{T_0})$ such that

$$\omega^{\delta}(c^{\delta},\chi^{\delta})\to\omega(c,\chi) \quad \text{in } L^1(\Omega_{T_0}) \text{ for } \delta\searrow 0.$$

By repeating the argumentation from above for $\varphi^{\delta}(\chi^{\delta})+\varphi^{\delta}(1-\chi^{\delta})$ we deduce $0<\chi<1$ almost everywhere in Ω_{T_0} which again with the help of Vitali's theorem and Lemma 8(ii) yields

$$\varphi^{\delta}(\chi^{\delta})+\varphi^{\delta}(1-\chi^{\delta})\to\varphi(\chi)+\varphi(1-\chi) \quad \text{in } L^1(\Omega_{T_0}).$$

So we can also pass to the limit in (77). The limit for (46) can be justified in the same way as in the proof of Theorem 1 if we additionally show

$$r^{\delta}(c^{\delta},\chi^{\delta})\to r(c,\chi) \quad \text{in } L^1(\Omega_{T_0}). \tag{84}$$

From the almost everywhere convergence of c_l^{δ} to c_l and $c_l>0$ almost everywhere in Ω_{T_0} we obtain

$$\max(c_l^{\delta},\delta)\to c_l \quad \text{almost everywhere in } \Omega_{T_0},\ \delta\searrow 0,\quad 1\leqslant l\leqslant 3.$$

Since the functions $\chi\mapsto k^{1/b\chi}$ and $\chi\mapsto\kappa^{1/b\chi}$ are in C^1, we find

$$k^{1/b\chi^{\delta}}(\max(c_2^{\delta},\delta)^2-\kappa^{1/b\chi^{\delta}}\max(c_1,\delta)\max(c_3,\delta))\to k^{1/b\chi}(c_2^2-\kappa^{1/b\chi}c_1c_3)$$

almost everywhere in Ω_{T_0} as $\delta\searrow 0$. By Lebesgue's dominated convergence theorem we find (84), because $k^{1/b\chi^{\delta}}\leqslant k^{1/\min(b^1,b^2)}$ almost everywhere in Ω_{T_0} if $k\geqslant 1$, respectively, $k^{1/b\chi^{\delta}}\leqslant k^{1/\max(b^1,b^2)}$ almost everywhere if $k<1$ and the analogous estimate for the κ-term, hence

$$\int_{\Omega_{T_0}}|r_1^{\delta}|\leqslant C\int_{\Omega_{T_0}}(|c_2^2|+|c_1c_3|)$$

for a constant C that depends on κ and k. ■

Uniqueness of the solution to Theorem 3 can be obtained in exactly the same way as in Theorem 2 if we replace (A6) by (A6′).

XIX. THE SHARP INTERFACE MODEL

It remains to perform the limit $\lambda \to 0$. This limit is carried out in the same way as before by showing *a priori* estimates and compactness results.

Lemma 9: (a) For $\lambda \in (0,\lambda_0)$ *there exists a weak solution* $(c^\lambda, \mu^\lambda, \chi^\lambda)$ *of (42) with a logarithmic free energy that satisfies (A2′)–(A6′).*

(b) There is a constant $C>0$ *independent of* λ *such that for all* $\lambda \in (0,\lambda_0)$,

$$\sup_{t\in[0,T_0]} \{\|c^\lambda(t)\|_{H^1} + \|\chi^\lambda(t)\|_{H^1}\} \leqslant C,$$

$$\sup_{t\in[0,T_0]} \int_\Omega f^1(c^\lambda(t),\chi^\lambda(t)) + \|\nabla \mu^\lambda\|_{L^2(\Omega_{T_0})} \leqslant C$$

and for all $t_1, t_2 \in [0,T_0]$

$$\|c^\lambda(t_2) - c^\lambda(t_1)\|_{L^2} \leqslant C|t_2 - t_1|^{1/4},$$

$$\|\chi^\lambda(t_2) - \chi^\lambda(t_1)\|_{L^2} \leqslant C|t_2 - t_1|^{1/2}.$$

(c) One can extract subsequences $(c^\lambda)_{\lambda\in\mathcal{R}}$, $(\mu^\lambda)_{\lambda\in\mathcal{R}}$, *and* $(\chi^\lambda)_{\lambda\in\mathcal{R}}$ *where* $\mathcal{R}\subset(0,\lambda_0)$ *is a countable set with zero as the only accumulation point such that*

(i) $c^\lambda \to c$ *in* $C^{0,\alpha}([0,T_0];L^2(\Omega;\mathbb{R}^4))$ *for all* $\alpha \in (0,\frac{1}{4})$,
(ii) $c^\lambda \to c$ *almost everywhere in* Ω_{T_0},
(iii) $c^\lambda \overset{*}{\rightharpoonup} c$ *in* $L^\infty(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$,
(iv) $\chi^\lambda \to \chi$ *in* $C^{0,\alpha}([0,T_0];L^2(\Omega))$ *for all* $\alpha \in (0,\frac{1}{2})$,
(v) $\chi^\lambda \to \chi$ *almost everywhere in* Ω_{T_0} *and* $0 \leqslant \chi^\lambda$, $\chi \leqslant 1$ *a.e. in* Ω_{T_0},
(vi) $\chi^\lambda \overset{*}{\rightharpoonup} \chi$ *in* $L^\infty(0,T_0;H^1(\Omega))$,
(vii) $\mu^\lambda \rightharpoonup \mu$ *in* $L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$

as $\lambda \in \mathcal{R}$ *tends to zero.*

Proof: By Theorem 3, a weak solution for fixed $\lambda \in (0,\lambda_0)$ exists. This proves (a). The estimates in (b) are a direct consequence of Lemma 7, where due to assumption (A4.2) we must choose $\lambda < \lambda_0$ for Lemma 3 to hold. Since $F^\lambda(c_0,\chi_0)$ can be estimated independently of λ, the constant C on the right-hand side does not depend on λ. (c) is proved by Lemma 7. ■

We make precise what we mean by a weak solution to the sharp interface model. We call a triple $(c,\mu,\chi) \in L^2(0,T_0;H_0^{1,2}(\Omega;\mathbb{R}^4)) \times L^2(0,T_0;H_0^{1,2}(\Omega;\mathbb{R}^4)) \times L^2(0,T_0;H^{1,2}(\Omega;\mathbb{R}))$ with $r(c,\chi)$, $\omega(c,\chi) \in L^1(\Omega_{T_0})$ a *weak solution* of the sharp interface model (30) if

$$-\int_{\Omega_{T_0}} \partial_t \xi \cdot (c - c_0) + \int_{\Omega_{T_0}} L\nabla\mu : \nabla\xi - \int_{\Omega_{T_0}} r(c,\chi)\xi = 0 \tag{85}$$

for all $\xi \in L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4))$ with $\partial_t\xi \in L^2(\Omega_{T_0})$, $\xi(T_0)=0$, and

$$\int_{\Omega_{T_0}} \mu\cdot\eta = \int_{\Omega_{T_0}} \frac{\partial f}{\partial c}(c)\cdot\eta \tag{86}$$

for all $\eta \in L^2(0,T_0;H_0^1(\Omega;\mathbb{R}^4)) \cap L^\infty(\Omega_{T_0};\mathbb{R}^4)$, and

$$-\int_{\Omega_{T_0}} \tau\partial_t\zeta(\chi-\chi_0) + \int_{\Omega_{T_0}} \gamma\nabla\chi\cdot\nabla\zeta - \int_{\Omega_{T_0}} \omega(c,\chi)\zeta = 0 \tag{87}$$

for all $\zeta \in L^2(0,T_0;H^1(\Omega;\mathbb{R}))$ with $\partial_t\zeta \in L^2(\Omega_{T_0})$, $\zeta(T_0)=0$.

Theorem 4: *Let the assumptions of Sec. XV hold. Then, there exists a weak solution* (c,μ,χ) *in the sense of (85) of the sharp interface equations (30) with a logarithmic free energy that satisfies (A2′)–(A6′) such that*

(i) $c \in C^{0,1/4}([0,T_0];L^2(\Omega;\mathbb{R}^4))$,
(ii) $\partial_t c \in L^2(0,T_0;(H_0^1(\Omega;\mathbb{R}^4))')$,
(iii) $\chi \in C^{0,1/2}([0,T_0];L^2(\Omega))$,
(iv) $\partial_t \chi \in L^2(0,T_0;(H_0^1(\Omega))')$,
(v) *there exists a* $q>1$ *such that* $\ln c_j \in L^q(\Omega_{T_0})$ *for* $1 \leqslant j \leqslant 4$, $\ln \chi$, $\ln(1-\chi) \in L^2(\Omega_{T_0})$ *and in particular* $0<\chi,c_j<1$ *a.e.*

Proof: We pass to the limit $\lambda \searrow 0$ in the weak formulation. In order to show that the limit (c,μ,χ) found in Lemma 9 is a solution we must only observe that in (47) $\lambda\Delta\mu \to 0$ in $H_0^{1,2}(\Omega)$ as $\lambda \searrow 0$. ■

Theorem 5: *If* $\partial_c f$, $\partial_\chi f$ *are Lipschitz continuous, the solution* (c,μ,χ) *of the sharp interface equations obtained in Theorem 4 is unique in the spaces stated in this theorem.*

Proof: The proof of Theorem 2 can be reused after sharpening estimate (71). We have according to (A4.2),

$$-\int_{\Omega_{t_0}} \left(\int_0^t r(s)\mathrm{d}s \right) \cdot \mu \geqslant \int_{\Omega_{t_0}} r_1(t)(\mu_1(t) - 2\mu_2(t) + \mu_3(t))$$

$$\geqslant \int_{\Omega_{t_0}} (\alpha_1 - 2\alpha_2 + \alpha_3) Q(c) r_1 \geqslant \lambda \int_{\Omega_{t_0}} |\nabla c|^2$$

for an arbitrary constant $\lambda < \lambda_0$. Then one can proceed with the proof. ■

(Received 11 February 2004; accepted 1 November 2004; published online 18 January 2005)

The position of the singular electromagnetic shock waves arising in the smooth Tamm problem is found. They consist of the Cherenkov shock wave and shock waves arising when the charge velocity coincides with the velocity of light in medium. In the limit of small intervals of accelerated and decelerated motion they are not transformed into the singular electromagnetic shock waves of the original Tamm problem. The reasons for this and the relation of the arising electromagnetic shock waves to the experimental situation are discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1836013]

I. INTRODUCTION

Usually, the radiation of a charge moving uniformly in medium, in a finite space interval is described in the framework of the so-called Tamm problem.[1] In it, a charge being initially at rest exhibits instantaneous acceleration acquiring the velocity v with which it moves uniformly in a finite space interval. Later, a charge exhibits instantaneous deceleration coming to the permanent state of rest. Using some approximations Tamm obtained a remarkably simple formula having a sharp maximum at the Cherenkov angle θ_c defined by $\cos\theta_c = 1/\beta n$ ($\beta = v/c$, n is the medium refractive index). This formula is frequently used for identification of the charge velocity.[2,3] Analytic formulas and numerical results presented in Ref. 4 demonstrate that in realistic conditions the Tamm formula does not work properly. The radiation intensity has a form of plateau [Fig. 1(a)] with intensity bursts at the ends of this plateau [Fig. 1(b)]. It was shown in Ref. 4 that this plateau is the Cherenkov shock wave of finite extension while the intensity bursts were *ad hoc* associated with the shock waves arising when the charge velocity coincides with the velocity of light $c_n = c/n$ in medium. On the other hand, the experimental intensity presented in Ref. 4 had a triangle form (Fig. 2). When evaluating the radiation intensities in the spectral representation (Figs. 1, 5, and 7) we omit the overall factor $(Ze)^2/c$. Thus obtained intensities have the dimension cm^{-1}. The Tamm approximate radiation intensities are highly oscillating functions. To make them more visible, we draw them through their maxima.

The goal of this consideration is to analyze the following questions: (1) how are the shock waves distributed in the original and smooth Tamm problems; (2) how are they manifested in experimental data.

The plan of our exposition is as follows. The mathematical preliminaries are collected in Sec. II. For the pedagogical purposes the derivation of the position of the electromagnetic shock waves in the original Tamm problem is presented in Sec. III. The method for finding the electromagnetic field singularities accompanying the moving charge is exposed in Sec. IV. In Sec. V, the electromagnetic field (EMF) singularities arising in the smooth Tamm problem are found. To our surprise, in the limit of small acceleration and deceleration intervals, the resulted configuration of the

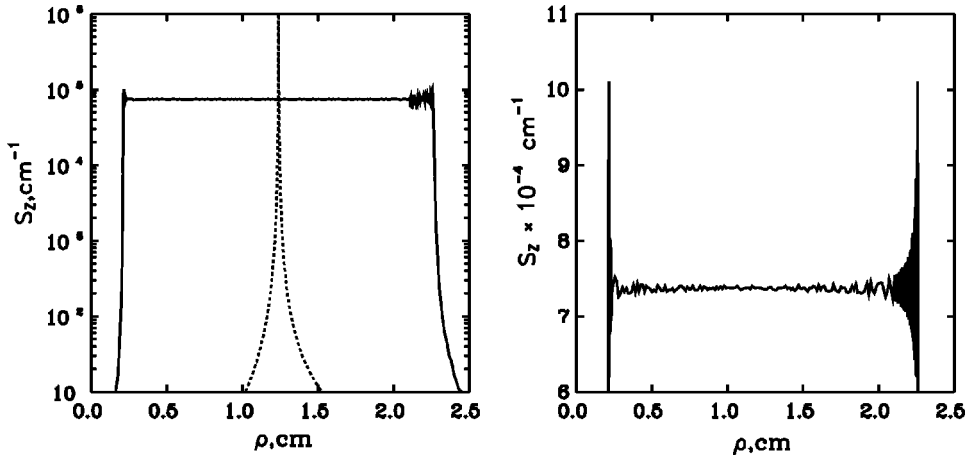

FIG. 1. Spectral radiation intensities corresponding to the charge motion in a finite spatial interval $L=2z_0=2.95$ cm in the plane perpendicular to the motion axis in logarithmic (a) and linear (b) scales. The distance from the end point of the motion interval to the observation plane is 0.3 cm. The dotted curve passes through the peaks of the Tamm approximate intensity. The refractive index of the medium is 1.505, the observed wavelength $\lambda=4\times10^{-5}$ cm, the charge velocity $\beta \approx 0.81$. The plateau corresponds to the Cherenkov shock wave, the intensity bursts at its ends correspond to the shock waves arising at the beginning (right peak) and the end (left peak) of the charge motion.

electromagnetic shock waves does not coincide with that of the original Tamm problem. The reason for this and the relation of the arising electromagnetic shock waves to the experimental radiation intensities are presented in Sec. VI. In the same section, the physical meaning of the smooth Tamm problem and the recommendations for the experimental search of the shock waves associated with the overcoming the light velocity barrier are given. A short resume of the results obtained is given in Sec. VII.

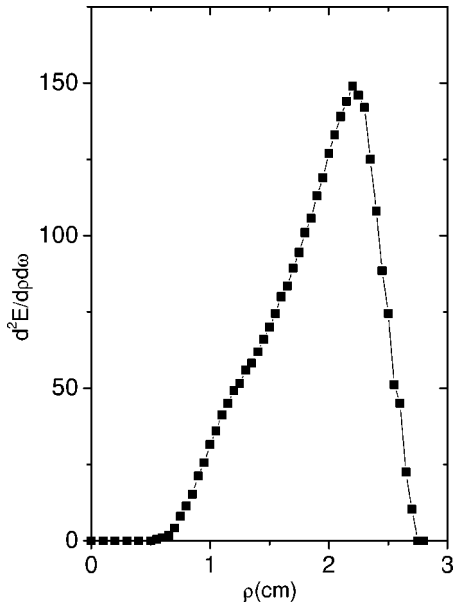

FIG. 2. The experimental radiation intensity (in arbitrary units) for the same parameters as in Fig. 1. One observes the increment of the radiation intensity at $\rho \approx 2.25$ cm which corresponds to the Cherenkov ray emitted from the initial point of the charge motion. No frequency filters were used in this experiment.

II. MATHEMATICAL PRELIMINARIES

Let a pointlike charge move inside the nondispersive medium with polarizabilities ϵ and μ along the given trajectory $\vec{\xi}(t)$. Then its EMF potentials at the observational point (ρ,z) are given by

$$\Phi(\vec{r},t)=\frac{e}{\epsilon}\frac{1}{|R|},\qquad \vec{A}(\vec{r},t)=\frac{e\mu}{c}\frac{\vec{v}}{|R|},\quad \operatorname{div}\vec{A}+\frac{\epsilon\mu}{c}\dot{\Phi}=0,\quad c_n=c/n. \tag{2.1}$$

Here

$$\vec{v}=\left(\frac{\mathrm{d}\vec{\xi}}{\mathrm{d}t}\right)\Bigg|_{t=t'},\quad R=|\vec{r}-\vec{\xi}(t')|-\vec{v}_i(\vec{r}-\vec{\xi}(t'))/c_n.$$

The proper or retarded time t' satisfies the equation

$$c_n(t-t')=|\vec{r}-\vec{\xi}(t')|. \tag{2.2}$$

To preserve the causality, the time t' of the radiation should be smaller than the observational time t. Obviously, t' depends on the coordinates $\vec{r}$, t of the point P at which the EMF is observed. If there are few t' satisfying (2.2), the electromagnetic potentials (2.1) should involve the sum over all these t'.

III. PEDAGOGICAL EXAMPLE: THE ORIGINAL TAMM PROBLEM IN THE ABSENCE OF DISPERSION

In this problem, a charge is at rest at the point $z=-z_0$ of the motion axis up to $t'=-t_0$ ($t_0=z_0/v$). At this instant it exhibits instantaneous acceleration acquiring the velocity v_0. With this velocity the charge moves uniformly up to reaching the point $z=z_0$ at $t'=t_0$. At this instant it exhibits instant deceleration coming to the permanent state of rest. For $t'<-t_0$ and $t'>t_0$ a charge is at rest at the $z=\mp z_0$ points, respectively. The corresponding electric scalar potentials are given by

$$\Phi_1=\frac{e}{r_1}\Theta[r_1-c_n(t+t_0)],\quad \Phi_2=\frac{e}{r_2}\Theta[c_n\ (t-t_0)-r_2)]. \tag{3.1}$$

Here $r_{1,2}=\sqrt{\rho^2+(z\pm z_0)^2}$. It is seen that Φ_1 describes the electrostatic field of charge at rest at $z=-z_0$. It differs from zero outside the sphere BS_1 defined by $r_1\equiv\sqrt{\rho^2+(z+z_0)^2}=c_n(t+t_0)$. Information on the beginning of motion does not reach the points lying outside BS_1. Correspondingly, Φ_2 describes the electrostatic field of charge at rest at $z=z_0$. It differs from zero inside the sphere BS_2 defined by $r_2\equiv\sqrt{\rho^2+(z-z_0)^2}=c_n(t-t_0)$. Information on the end of the charge motion does not reach the points lying inside BS_2.

There are two roots of (2.2) for $-t_0<t'<t_0$,

$$t'_{1,2}=\frac{1}{c_n(\beta_{0n}^2-1)}(\beta_{0n}z-c_nt\pm r_m), \tag{3.2}$$

where $r_m=\sqrt{(z-v_0t)^2+(1-\beta_{0n}^2)\rho^2}$ ($\beta_{0n}=\beta_0n$, $\beta_0=v_0/c$). Imposing the condition $-t_0<t'<t_0$ one finds space–time regions where t'_1 and t'_2 exist. However, at first we define the straight lines L_1 ($z=-z_0+\rho\gamma_{0n}$, $\gamma_{0n}=1/\sqrt{\beta_{0n}^2-1}$) and L_2 ($z=z_0+\rho\gamma_{0n}$) [Fig. 3(a)]. They originate from the $\mp z_0$ points and are inclined at the angle θ_c ($\cos\theta_c=1/\beta_0n$) towards the motion axis. Then, to the left of L_1 ($z<-z_0+\rho\gamma_{0n}$), t'_1 exists between BS_1 and BS_2 ($-t_0+r_1/c_n<t<t_0+r_2/c_n$). Between L_1 and L_2 ($-z_0+\rho\gamma_{0n}<z<z_0+\rho\gamma_{0n}$), t'_1 exists in the space–time region $(z+\rho/\gamma_{0n})/v<t<t_0+r_2/c_n$ which lies between BS_2 and the straight-line segment $z+\rho/\gamma_{0n}=vt$ enclosed between L_1 and L_2 and perpendicular to them. Its normal is inclined at the angle θ_c towards the motion axis. This segment is a piece of the Cherenkov shock wave enclosed between L_1 and L_2.[4,5] We refer to it as CSW. It

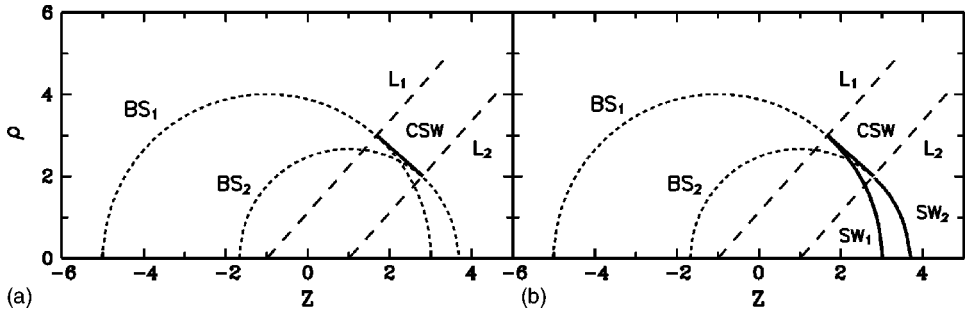

FIG. 3. (a) The position of the shock waves in the original Tamm problem. BS_1 and BS_2 are the bremsstrahlung shock waves emitted at the beginning and the end of motion; CSW (straight thick line) is the finite Cherenkov shock wave; (b) the position of the shock waves in the limiting case of the smooth Tamm problem (see Fig. 4) when the lengths of accelerated and decelerated parts of the charge trajectory tend to zero. The thick curves SW_1 and SW_2 are the shock waves arising at the accelerated and decelerated parts of the charge trajectory, respectively. Due to the instantaneous velocity jumps, SW_1 and SW_2 partly coincide with the BS_1 and BS_2 shock waves, respectively.

corresponds to the plateau shown in Fig. 1. As to t_2', it exists between BS_1 and BS_2 $(t_0+r_2/c_n < t < -t_0+r_1/c_n)$ to the right of L_2 $(z>z_0+\rho\gamma_{0n})$. Between L_1 and L_2 $(-z_0+\rho\gamma_{0n}<z<z_0+\rho\gamma_{0n})$, t_2' differs from zero in the space–time $(z+\rho/\gamma_{0n})/v<t<-t_0+r_1/c_n$ region surrounded by BS_1 and CSW. The space–time region where both t_1' and t_2' differ from zero lies between L_1 and L_2, outside BS_1 and BS_2 and below the CSW. Substituting either t_1' or t_2' into the denominator R entering into (3.1) one finds that $|R|=r_m$. With the account of all this, one finds for the electromagnetic potentials

$$\Phi=\Phi_1+\Phi_2+\Phi_3, \quad A_z=\mu\beta\epsilon\Phi_3, \tag{3.3}$$

$$\begin{aligned}\Phi_3=\frac{e}{\epsilon r_m}\{&\Theta(\rho\gamma_{0n}-z-z_0)\Theta[c_n(t+t_0)-r_1]\Theta[r_2-c_n(t-t_0)]+\Theta(z-z_0-\rho\gamma_{0n})\\&\times\Theta[c_n(t-t_0)-r_2]\Theta[r_1-c_n(t+t_0)]+\Theta(z+z_0-\rho\gamma_{0n})\\&\times\Theta(z_0+\rho\gamma_{0n}-z)\Theta(vt-z-\rho/\gamma_{0n})\times[\Theta(r_2-c_n(t-t_0))+\Theta(r_1-c_n(t+t_0))]\}.\end{aligned}$$

It is seen that $r_m=0$ on the CSW defined by $z+\rho/\gamma_{0n}=vt$ while the electromagnetic potentials are infinite there. There are no other singularities of electromagnetic potentials. However, the EMF strengths have additional delta-type singularities. They are due to the discontinuities of electromagnetic potentials at the boundaries of the BS_1, BS_2, and CSW surfaces.

IV. MOVING SINGULARITIES OF THE ELECTROMAGNETIC FIELD

With the account of (2.2) one finds for R

$$R=c_n(t-t')-\vec{v}(\vec{r}-\vec{\xi}(t'))/c_n. \tag{4.1}$$

We seek the singularities of the EMF potentials for which the denominators R entering into (3.1) disappear,

$$c_n(t-t')-\vec{v}(\vec{r}-\vec{\xi}(t'))/c_n=0.$$

In what follows we limit ourselves to the one-dimensional motion in the positive direction of the z axis. Then

$$c_n(t-t')=v(z-\xi(t'))/c_n=0. \tag{4.2}$$

For this motion $z-\xi(t')>0$. We rewrite (4.1) and (4.2) in the following form:

$$z = \xi(t') + \frac{c_n^2}{v}(t - t'), \quad \rho = \frac{c_n^2(t - t')}{v\gamma_n}. \tag{4.3}$$

Here $\gamma_n = 1/\sqrt{\beta^2 n^2 - 1}$, $\beta = v(t')/c$.

Our procedure reduces to the following one. For the fixed observation time t, we vary t' over the motion interval, evaluate $z(t')$ and $\rho(t')$ and draw the dependence $\rho(z)$ for the fixed t. Due to the axial symmetry of the problem, this curve is in fact the surface on which the electromagnetic potentials are singular. It follows from (4.3) that these singular surfaces exist only if $v > c/n$, that is if the charge velocity is greater than the light velocity in medium. There are other surfaces on which the EMF strengths are singular and which are not described by (4.3). For example, on the surfaces of the bremsstrahlung (BS) shock waves arising at the start or the end of motion, the electromagnetic potentials exhibit finite jumps. The corresponding EMF strengths have δ singularities on these surfaces. In the next section, we demonstrate that for the Tamm problem thus obtained singularities coincide with those found in Sec. III.

Moving singularity of the original Tamm problem: In the time interval $-t_0 < t' < t_0$, $(t_0 = z_0/v_0)$ where a charge moves uniformly with the velocity v_0 equations (4.3) look like

$$\rho = \frac{c_n^2}{v_0\gamma_{0n}}(t - t'), \quad z = v_0 t' + \frac{c_n^2}{v_0}(t - t'). \tag{4.4}$$

Here $\gamma_{0n} = 1/\sqrt{v_0^2/c_n^2 - 1}$. Excluding t' from these equations one finds

$$\rho = (v_0 t - z)\gamma_{0n}, \tag{4.5}$$

where ρ and z are changed in the intervals

$$z_1^0 < z < v_0 t, \quad 0 < \rho < \frac{c_n^2}{v_0\gamma_{0n}}(t + t_0)$$

for $-t_0 < t < t_0$ and

$$z_1^0 < z < z_2^0, \quad \rho_2 < \rho < \rho_1$$

for $t > t_0$. Here

$$z_1^0 = \frac{c^2}{v_0 n^2}(t + t_0) - z_0, \quad \rho_1 = \frac{c^2}{v_0 n^2 \gamma_{0n}}(t + t_0),$$

$$z_2^0 = \frac{c_n^2}{v_0}(t - t_0) + z_0, \quad \rho_2 = \frac{c_n^2}{v_0\gamma_{0n}}(t - t_0).$$

It is seen that for each $t > t_0$ the singular segment (4.5) enclosed between the straight lines L_1 and L_2 is perpendicular to both of them and coincides with the CSW defined in Sec. III. Its normal is inclined at the angle θ_c towards the motion axis. As time goes, it propagates between L_1 and L_2. For $-t_0 < t < t_0$ the CSW is enclosed between the moving charge and the straight line L_1.

V. SMOOTH TAMM PROBLEM

A. Motivation for the smooth Tamm problem

Usually the measurements of the Cherenkov radiation are made in the plane perpendicular to the motion axis. Numerical and analytical calculations[4] made in the framework of the original Tamm problem showed that the spectral radiation intensity has a plateau $\rho_2 < \rho < \rho_1$ with sharp bursts at the end of this plateau. They were *ad hoc* associated with the shock waves arising when the charge velocity coincides with the velocity of light c_n in medium. Since in the original Tamm problem the charge velocity changes instantaneously at the start and the end of motion, the above

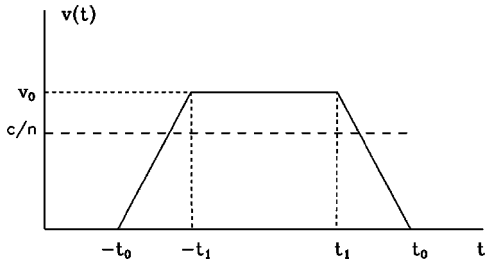

FIG. 4. Schematic presentation of the smooth Tamm problem.

shock waves coincide with bremsstrahlung (BS) shock waves arising at the start and the end of motion. Because of this, we consider the smooth Tamm problem (Fig. 4) in which a charge is at rest up to some instant of time ($t<-t_0$), moves with constant acceleration up to reaching some velocity v_0 ($-t_0<t<-t_1$), moves with this velocity ($-t_1<t<t_1$) and, finally, decelerates down ($t_1<t<t_0$) to reaching the permanent state of rest ($t>t_0$). Since the points where these shock waves are created are separated in space and time, the space–time separation of the resulting shock waves is also to be expected. It was shown in Ref. 6 analytically and numerically that for the semi-infinite accelerated charge motion the resulting configuration of shock waves consists of the BS shock wave and of the indivisible complex consisting of the finite Cherenkov cone and the shock wave closing this cone. Time evolution of the shock waves in the framework of the smooth Tamm problem was studied numerically in Ref. 7. After the termination of the charge motion the resulting configuration of the shock waves presented itself an indivisible complex having the sickle moon form and consisting of two shock waves intersecting the motion axis at the right angle. The following paradoxical result was obtained there: the arising configuration of shock waves does not tend to that of the original Tamm problem when the length along which a charge moves nonuniformly tends to zero. Therefore, a qualitative analysis of the arising situation is needed. In the spectral representation, the smooth Tamm problem was studied in Ref. 8 on the observational sphere of an infinite radius. It was shown that the radiation intensity suddenly drops for the angle greater than the Cherenkov angle θ_c corresponding to the velocity β_0. For $\theta<\theta_c$, the radiation intensity falls more slowly. It was suggested there that such behavior of the radiation intensity in the $\theta<\theta_c$ angular region is due to the shock waves arising when the charge velocity coincides with c_n.

We intend to study the radiation intensities in the $z=$const plane. The typical spectral radiation intensities shown in Fig. 5 have a plateau with a sudden drop at the right of this plateau and with moderate amplitude oscillations at its left. Below, in the framework of the exactly solvable model we show that to the right of this plateau only the nonsingular BS shock waves (associated with the beginning and the end of motion) contribute to the radiation intensity while 2 singular shock waves (arising at the accelerated and decelerated parts of the charge trajectory) contribute to the radiation intensity to the left of this plateau. The intensity oscillations in this region are due to the interference of these shock waves.

B. Analytical consideration

In the smooth Tamm problem a charge is at rest at the spatial point $z=-z_0$ up to an instant $t'=-t_0$. In the space–time interval $-t_0<t'<-t_1$, $-z_0<z<-z_1$ (we refer to this interval as to region 1) it moves with constant acceleration a,

$$\xi(t') = -z_0 + \tfrac{1}{2}a(t'+t_0)^2, \quad v(t') = a(t'+t_0).$$

In the space–time interval $-t_1<t'<t_1$, $-z_1<z<z_1$ (region 2) it moves with the constant velocity v_0,

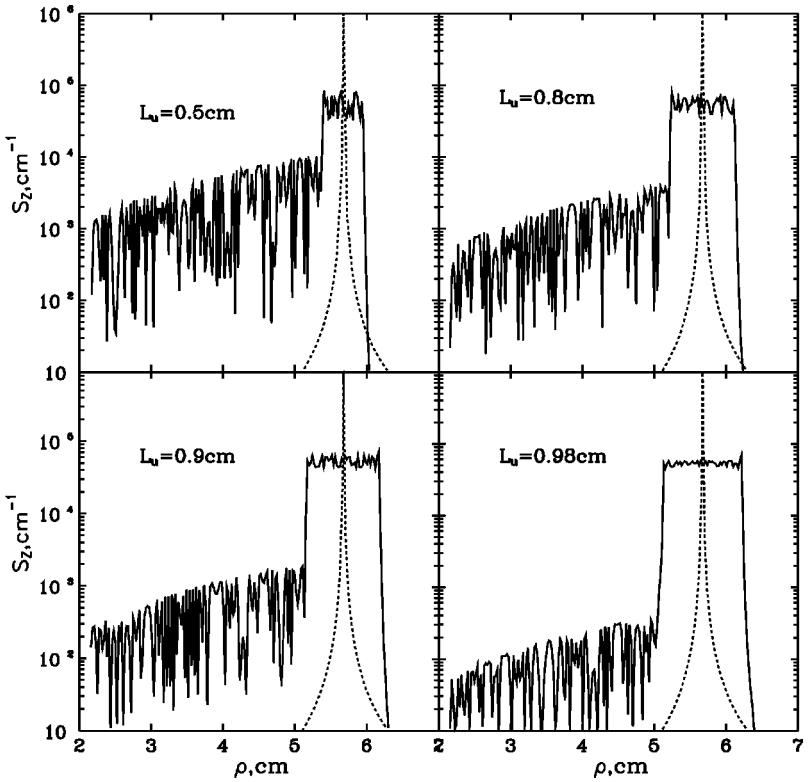

FIG. 5. Spectral radiation intensities for the smooth Tamm problem for various lengths L_u of the charge uniform motion. The total motion interval is 1 cm, the observed wavelength $\lambda = 5.893 \times 10^{-5}$ cm, the medium refractive index $n = 1.512$, the uniform charge velocity $\beta_0 = v_0/c = 1$. The plateau in the radiation intensity corresponds to the CSW in Fig. 6(d). The sudden drop of the radiation intensity to the right of this plateau is due to the absence of the singular shock waves above L_1 [see Fig. 6(d)]. The oscillations of the radiation intensities to the left of the plateau are due to the interference of SW_1 and SW_2 shock waves in the region below L_2. The dotted curves are the Tamm approximate radiation intensities corresponding to the charge uniform motion on the interval L_u.

$$\xi(t') = v_0 t', \quad v(t') = v_0.$$

In the space–time interval $t_1 < t' < t_0$, $z_1 < z < z_0$ (region 3) a charge moves with constant deceleration a down reaching the state of rest at $t = t_0$,

$$\xi(t') = z_0 - \tfrac{1}{2} a (t' - t_0)^2, \quad v(t') = a(t_0 - t').$$

The matching conditions of $\xi(t')$ and $v(t')$ at the $z = \pm z_1$ points define a, t_0, and t_1,

$$a = \frac{v_0^2}{2(z_0 - z_1)}, \quad t_0 = \frac{2z_0 - z_1}{v_0}, \quad t_1 = \frac{z_1}{v_0}.$$

1. Space region 1

In the space region 1 equations (4.3) are

$$z = -z_0 + \frac{1}{2} a (t' + t_0)^2 + \frac{c_n^2}{v}(t - t'), \quad \rho = \frac{c_n^2 (t - t')}{v \gamma_n}, \tag{5.1}$$

where $v = a(t' + t_0)$. It follows from this that the charge velocity coincides with the velocity of light in medium $c_n = c/n$ at $t' = -t_c$, $t_c \equiv t_0 - c_n/a$. At this instant

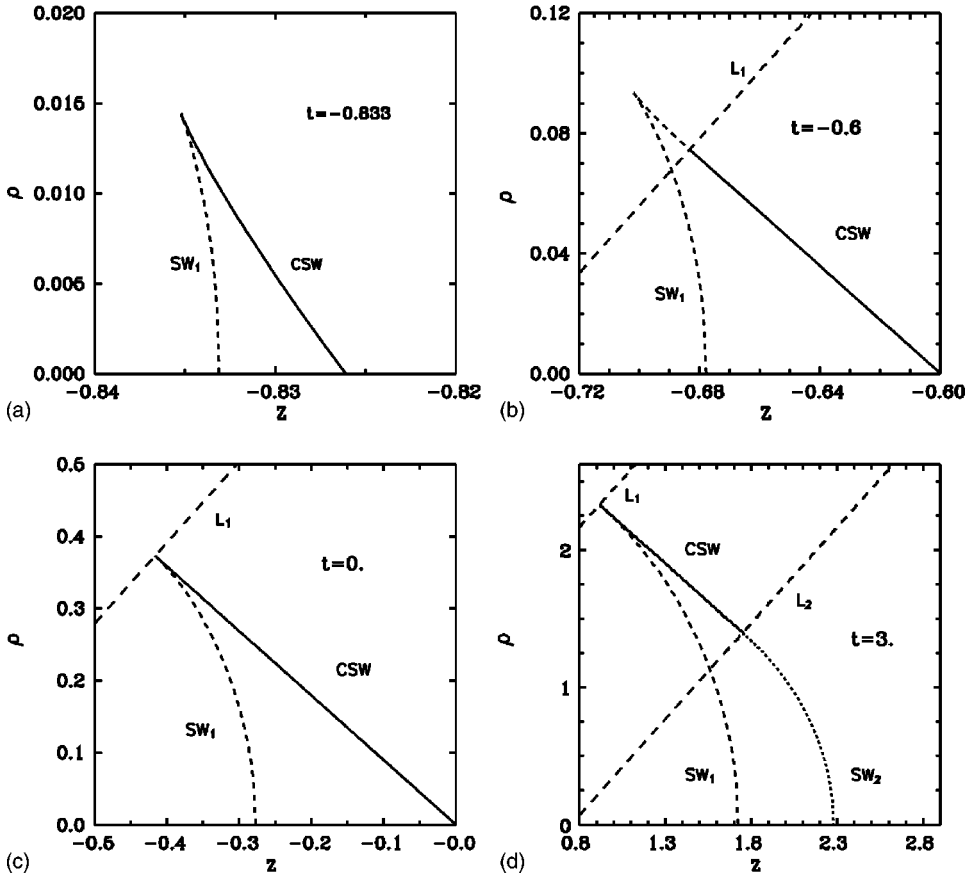

FIG. 6. Shock waves in the smooth Tamm problem. (a), (b), (c) For small and moderate observation times the singularity complex consists of the finite Cherenkov shock wave (CSW) attached to a moving charge and the shock wave SW_1 closing the Cherenkov cone and inclined at the right angle towards the motion axis; (d) for large observation times this complex detaches from a moving charge and propagates with the velocity of light c_n in medium. It consists of the finite CSW and the shock waves SW_1 and SW_2 perpendicular to the motion axis and arising at the accelerated and decelerated parts of the charge trajectory.

$$\rho_c = \rho(t' = -t_c) = 0, \quad z_c^{(1)} = z(t' = -t_c) = c_n t - \left(1 - \frac{1}{\beta_0 n}\right)\left[z_0 - \frac{1}{n\beta_0}(z_0 - z_1)\right]. \tag{5.2}$$

For the observation time t smaller than the time $-t_1$ corresponding to the right boundary of the motion interval 1, $\rho(t')$ has two zeroes (at $t'=t_c$ and $t'=t$). There is a maximum between them [Fig. 6(a)] at

$$t' = t'_m \equiv -t_0 + \left(\frac{c_n}{a}\right)^{2/3}(t + t_0)^{1/3}. \tag{5.3}$$

Obviously, $t_c < t'_m < t$. The corresponding ρ and z are equal to

$$\rho_m = \frac{c_n^2}{a}\left\{\left[\frac{a(t+t_0)}{c_n}\right]^{2/3} - 1\right\}^{3/2}, \quad z_m = -z_0 + \frac{c_n^2}{a}\left\{\frac{3}{2}\left[\frac{a(t+t_0)}{c_n}\right]^{2/3} - 1\right\}. \tag{5.4}$$

This solution coincides with the analytical solution found in Ref. 6 for the semi-infinite motion beginning from the state of rest. The dependence $\rho(z)$ has a moon sicklelike form [Fig. 6(a)]. This complex arises when the charge velocity coincides with the velocity of light c_n in medium. It consists of the curvilinear Cherenkov shock wave CSW attached to a moving charge and the shock

wave closing the Cherenkov cone. As time goes, the dimensions of this complex rise (since a charge moves with the velocity v while SW_1 propagates with the velocity c_n).

For the observation time t greater than the time $-t_1$, ρ has only one zero. It has a maximum if $-t_1<t<-t_0+2(z_0-z_1)v_0/c_n^2$. The corresponding t'_m, ρ_m, and z_m are given by (5.3) and (5.4). In the interval $t'_m<t'<-t_1$, ρ decreases reaching the value

$$\rho_1=\rho(t'=-t_1)=\frac{c_n^2}{v_0\gamma_n}(t+t_1) \tag{5.5}$$

at the boundary point of the motion interval. The corresponding z is equal to

$$\tilde{z}_1=z(t'=-t_1)=\frac{c_n^2}{v_0}(t+t_1)-z_1. \tag{5.6}$$

It is easy to check that z as a function of t' has a minimum at $t'=t'_m$: it decreases from $z_c^{(1)}$ at $t'=-t_c$ down to

$$z_m=-z_0+\frac{c_n^2}{a}\left\{\left[\frac{a(t+t_0)}{c_n}\right]^{2/3}-1\right\} \tag{5.7}$$

at $t'=t'_m$ and then increases up to $\tilde{z}_1$ for $t'=-t_1$ [e.g., Fig. 6(b), dotted line]. For $t>-t_0+2(z_0-z_1)v_0/c_n^2$ there is no maximum of $\rho(t')$ in the space region 1. It rises steadily from 0 for $t'=t_c$ up to ρ_1 given by (5.5) for $t'=-t_1$ [e.g., Fig. 6(c), dotted line]. In particular, $\rho_m=\rho_1$, $z_m=\tilde{z}_1$ for $t=-t_0+2(z_0-z_1)v_0/c_n^2$.

2. Space region 2

In the time interval $-t_1<t'<t_1$ ($t_1=z_1/v_0$) where a charge moves uniformly with the velocity v_0 equations (4.3) look like

$$\rho=\frac{c_n^2}{v_0\gamma_{0n}}(t-t'),\quad z=v_0t'+\frac{c_n^2}{v_0}(t-t'). \tag{5.8}$$

Here $\gamma_{0n}=1/\sqrt{v_0^2/c_n^2-1}$. Excluding t' from these equations one finds

$$\rho=(v_0t-z)\gamma_{0n}, \tag{5.9}$$

where ρ and z change in the intervals

$$\tilde{z}_1<z<v_0t,\quad 0<\rho<\frac{c_n^2}{v_0\gamma_{0n}}(t+t_1)$$

for $-t_1<t<t_1$ and

$$\tilde{z}_1<z<z_2,\quad \rho_2<\rho<\rho_1$$

for $t>t_1$. Here $\tilde{z}_1$ and ρ_1 are the same as above, and

$$z_2=\frac{c_n^2}{v_0}(t-t_1)+z_1,\quad \rho_2=\frac{c_n^2}{v_0\gamma_{0n}}(t-t_1). \tag{5.10}$$

It is seen that for each $t>t_1$ the singular segment (5.9) is enclosed between the straight lines L_1 [$\rho=(z+z_1)/\gamma_{0n}$] and L_2 [$\rho=(z-z_1)/\gamma_{0n}$] originating from the boundary points of the interval 2 and inclined at the angle θ_c ($\cos\theta_c=1/\beta_0 n$) towards the motion axis [Fig. 6(d), solid line]. The singular segment (5.9) is a piece of the Cherenkov shock wave which is enclosed between L_1 and L_2 and perpendicular to both of them. Its normal is inclined at the angle θ_c towards the motion axis. As time goes, it propagates between L_1 and L_2. For $-t_1<t<t_1$ the singular segment (5.9) is enclosed between the moving charge and the straight line L_1 [Fig. 6(c), solid line].

3. Space region 3

In the time interval $t_1 < t' < t_0$ where a charge moves with deceleration a, equations (4.3) look like

$$z = z_0 - \frac{1}{2}a(t' - t_0)^2 + \frac{c_n^2}{v}(t - t'), \quad \rho = \frac{c_n^2(t - t')}{v\gamma_n}, \tag{5.11}$$

where $v = a(t_0 - t')$. The charge velocity changes steadily from v_0 at $t' = t_1$ down to 0 at $t = t_0$. The above singularity surfaces exist only if $c_n < v < v_0$. The charge velocity coincides with the velocity of light in medium $c_n = c/n$ at $t' = t_c$,

$$\rho_c = \rho(t' = t_c) = 0, \quad z_c^{(2)} = z(t' = t_c) = c_n t + \left(1 - \frac{1}{\beta_0 n}\right)\left[z_0 - \frac{1}{\beta_0 n}(z_0 - z_1)\right]. \tag{5.12}$$

The radius $\rho(t')$ vanishes at the position of a moving charge $(t' = t)$ for $t < t_c$ and at $t' = t_c$ for $t > t_c$. It is maximal at the start of the third motion interval $(t' = t_1)$ where

$$\rho(t' = t_1) = \rho_2, \quad z(t' = t_1) = z_2$$

[ρ_2 and z_2 are the same as in (5.10)].

C. Discussion of the results obtained in this section

A complete singular contour composed of its singular pieces defined in the regions 1, 2, and 3 is always closed for the fixed observation time t. In fact, for $-t_c < t < -t_1$ the singular contour lies completely in the region 1. It begins at the point $z = z_c^{(1)}$, $\rho = 0$ and ends at the point $\rho = 0$, $z = -z_0 + a(t + t_0)^2/2$ coinciding with the current charge position [Fig. 6(a)]. For $-t_1 < t < t_1$ the singular contour lies in the regions 1 and 2 [Figs. 6(b) and 6(c)]. Its branch lying in the region 1 begins at the point $z = z_c^{(1)}$, $\rho = 0$ and ends at the point $z = \tilde{z}_1$, $\rho = \rho_1$. Its branch lying in the region 2 begins at the point $z = \tilde{z}_1$, $\rho = \rho_1$ and ends at the point $z = v_0 t$, $\rho = 0$ coinciding with the current charge position. For $t > t_1$ the singular contour lies in the regions 1, 2, and 3 [Fig. 6(d)]. Its branch in region 1 is the same as above. Its branch lying in the region 2 begins at the point $z = \tilde{z}_1$, $\rho = \rho_1$ and ends at the point $z = z_2$, $\rho = \rho_2$. Its branch lying in the region 3 begins at the point $z = z_2$, $\rho = \rho_2$ and ends at the point $z = z_c^{(2)}$, $\rho = 0$.

D. Transition to instantaneous velocity jumps

It is instructive to consider the limit $z_1 \to z_0$ corresponding to the instantaneous velocity jumps at the start and the end of the charge motion. Intuitively it is expected that the original Tamm problem should appear in this limit. Turning to (5.1) we observe that the second term entering into z equals zero in this limit. In fact, it equals

$$\frac{1}{2}a(t' + t_0)^2 = \frac{z_0 - z_1}{\beta^2 n^2}$$

at $t' = -t_c$ and

$$\frac{1}{2}a(t' + t_0)^2 = \frac{z_0 - z_1}{\beta^2 n^2}$$

at $t' = -t_1$. Therefore, in the limit $z_1 \to z_0$ it disappears at the boundaries of the charge motion interval and, therefore, inside this interval since the above term is a monotone function of t'. Then, (5.1) reduces to

$$z = -z_0 + \frac{2(z_0 - z_1)}{\beta_0^2 n^2}\frac{t - t_0}{t' + t_0},$$

$$\rho = \frac{2(z_0 - z_1)}{\beta_0^2 n^2} \frac{t - t_0}{t' + t_0} \left\{ \left[\frac{n\beta_0^2 c(t' + t_0)}{2(z_0 - z_1)} \right]^2 - 1 \right\}^{1/2}. \tag{5.13}$$

On the other hand, we cannot drop the terms with $(z_0 - z_1)$ in (5.13) since the denominator $(t' + t_0)$ is of the same order of smallness. It is seen that $z = z_c^{(1)}$, $\rho = \rho_c^{(1)} = 0$ at $t' = -t_c$ and $z = \tilde{z}_1$, $\rho = \rho_1$ at $t' = -t_1$. Here

$$z_c^{(1)} = c_n t - z_0 \left(1 - \frac{1}{\beta_{0n}} \right), \quad \tilde{z}_1 = \frac{c_n^2}{v_0} t - z_0 \left(1 - \frac{1}{\beta_{0n}^2} \right), \quad \rho_1 = \frac{c_n^2}{v_0 \gamma_{0n}} (t + t_0).$$

It follows from (5.13) that

$$\rho^2 + (z + z_0)^2 = c_n^2 (t + t_0)^2 \tag{5.14}$$

coincides with the equation of the BS shock wave arising at the beginning of the charge motion (BS_1, for short). This singular contour [SW_1 in Fig. 3(b)] begins at the point $z = z_c^{(1)}$, $\rho = \rho_c^{(1)} = 0$ and ends at the point $z = \tilde{z}_1$, $\rho = \rho_1$. It represents the shock wave arising when the charge velocity coincides with the velocity of light in medium at the accelerated part of the charge trajectory.

The fact that SW_1 and BS_1 are described by the same equation (5.14) is physically understandable since both these waves, due to the instantaneous velocity jump, are created at the same instant $t = -t_0$, at the same space point $z = -z_0$, and propagate with the same velocity c_n. It should be noted that the BS_1 shock wave is distributed over the whole sphere (5.14) while the singular shock wave SW_1 fills only its part.

The second part of the singular contour is the Cherenkov shock wave [CSW in Fig. 3(b)] extending from the point $z = \tilde{z}_1$, $\rho = \rho_1$ to the point $z = z_2$, $\rho = \rho_2$. Here

$$z_2 = \frac{c_n^2}{v_0} t + z_0 \left(1 - \frac{1}{\beta_{0n}^2} \right), \quad \rho_2 = \frac{c_n^2}{v_0 \gamma_{0n}} (t - t_0).$$

The third part of the singularity contour [SW_2 in Fig. 3(b)] begins at the point $z = z_2$, $\rho = \rho_2$ and ends at $z = z_c^{(2)}$, $\rho = \rho_c^{(2)} = 0$. Here

$$z_c^{(2)} = c_n t + z_0 \left(1 - \frac{1}{\beta_{0n}} \right).$$

This part of the singularity contour represents the shock wave arising at the decelerated part of the charge trajectory. It is described by the equation

$$\rho^2 + (z - z_0)^2 = c_n^2 (t - t_0)^2 \tag{5.15}$$

coinciding with the equation of the BS_2 shock wave emitted at the end $(t = t_0, z = z_0)$ of a charge motion. Again, the singularity fills only part of the sphere (5.15).

VI. DISCUSSION

Turning to Fig. 5 we observe the existence of the radiation intensity plateau, its sudden drop to the right of the plateau and its moderate decreasing to the left of the plateau. The sudden drop of the radiation intensity to the right of the plateau takes place in the space region where only the nonsingular BS shock waves associated with the beginning and the end of a charge motion exist. In Fig. 6(d), this space region lies above L_1. The plateau corresponds to the space region lying between L_2 and L_1 [Fig. 6(d)] where the singular wave CSW (Cherenkov shock wave) and SW_1 (singular shock wave associated with the transition of the light velocity barrier at the accelerated part of the charge trajectory) exist. The moderate decrease in the radiation intensity to the left of the plateau is due to the existence of SW_1 and SW_2 shock waves (the latter arises at the decelerated part of the charge trajectory). The oscillations of the radiation intensity in this region are due

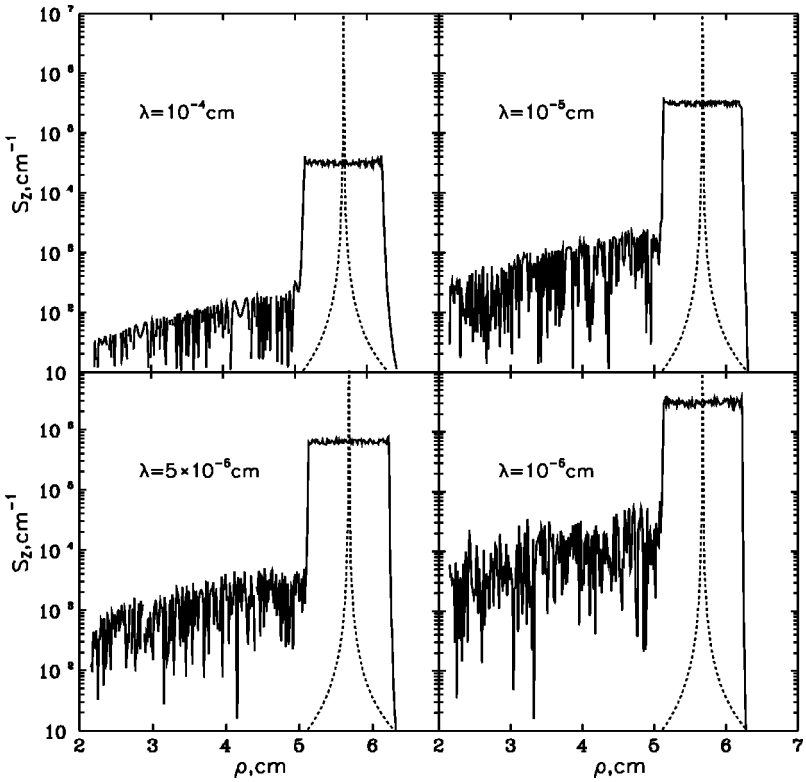

FIG. 7. Spectral radiation intensities for the smooth Tamm problem for the uniform motion interval $L_u=0.98$ cm and various wavelengths λ. Other parameters are the same as in Fig. 5. The radiation intensities rise with the diminishing of λ to the left of the plateau and are very small to the right of the plateau.

to the interference of SW_1 and SW_2. The smallness of oscillations inside the plateau indicates that the contribution of the CSW to the radiation intensity is much larger than that of SW_1.

Now we discuss why the configuration of the shock waves in the limiting case of the smooth Tamm problem [Fig. 3(b)] does not coincide with that of the original Tamm problem [Fig. 3(a)]. It was shown in Ref. 9 that in the spectral representation the radiation intensity (for the fixed observation wavelength) of the smooth Tamm problem transforms into the radiation intensity of the original Tamm problem when the length of the trajectory along which a charge moves nonuniformly tends to zero. Figure 5 supports this claim. However, Figs. 3(a) and 3(b) describe the position of the EMF singularities at the fixed moment of the observational time [or, in other words, Figs. 3(a) and 3(b) correspond to the time representation]. The time and spectral representations of the EMF are related by the Fourier transformation. For an arbitrary small but finite length l of the charge nonuniform motion in the smooth Tamm problem, the contribution of the nonuniform motion to the radiation intensity becomes essential and comparable with the contribution of the uniform motion for high frequencies. This is clearly shown in the last of Refs. 5 and in Ref. 8 and in Fig. 7. Thus, the appearance of additional shock waves in Fig. 3(b) is due to the contribution of high frequencies.

Turning to Fig. 3(b) describing the position of the shock waves in the limiting case of the smooth Tamm problem, we see that three shock waves (BS_1, SW_1, and CSW) are intersected on the straight line L_1. Therefore, the radiation intensity should be large there. Above L_1 (this corresponds to the region lying to the right of the plateau in Fig. 5) only the nonsingular shock waves BS_1 and BS_2 contribute to the radiation intensity. Therefore, the radiation intensity should be very small there. The experimental curve shown in Fig. 2 partly supports these claims.

However, the experimental intensity decreases smoothly in the space region where the theory predicts the existence of plateau. The picture similar to Fig. 2 might be possible if the focusing

devices (their use is wide-spread in the Cherenkov-type experiments) projecting the γ rays emitted at the Cherenkov angle into the narrow Cherenkov ring (and transforming the plateau of the radiation intensity into this ring) were used. However, no focusing lens was used in the experiments discussed in which the Cherenkov light left the radiator along the direction perpendicular to the radiator surface.

There are two possible reasons for the deviation of the theoretical data from the experimental ones. The first of them is the medium dispersion. A charge moving uniformly in medium, in a finite spatial interval, emits all frequencies [contrary to the unbounded charge motion when only the frequencies satisfying the Tamm–Frank radiation condition $\beta n(\omega)>1$ (see, e.g., Ref. 10) are emitted]. In the experiment treated, where no frequency filters were used, the dependence on the frequency enters through the refractive index n of the sample (where a charge moves) and through the spectral sensitivity of the photographic film placed in the observational plane perpendicular to the motion axis. Let the intervals where a charge is accelerated and decelerated be arbitrarily small but finite. For large frequencies the radiation intensity in the space region to the left of the plateau shown in Fig. 7 begins to rise. The resulting radiation intensities are obtained from those presented in Fig. 7 by convoluting them with the spectral sensitivity of the photofilm and integrating over all ω. If the integrand differs from zero for large frequencies, then the arising radiation intensity will resemble the experimental curve of Fig. 2. However, to perform concrete calculations the knowledge of the frequency dependence of the refractive index and the spectral sensitivity of the photofilm is needed. The second reason is due to the finite diameter (0.5 cm) of the proton beam used in experiments described in Ref. 4. The averaging of the radiation intensities over the proton beam diameter leads to their smoothing (and, in particular, to the disappearance of the pronounced peaks at the ends of the Cherenkov plateau).

The transition from the time representation to the spectral one involves the time integration. Since the space regions to which the above shock waves are confined do not depend on time (e.g., CSW is always between L_1 and L_2, etc.), the shock waves are in the same space regions in both representations.

A. The physical meaning of the smooth Tamm problem

Before discussing how the smooth Tamm problem is related to the experimental situation, we recall the usual physical interpretation of the original Tamm problem (see, e.g., Ref. 11). Let the uniformly moving charge move consecutively in vacuum, in dielectric sample and again in vacuum. Since the charge uniformly moving in medium does not radiate if $\beta n<1$ and radiates if $\beta n>1$, the charge passing through the sample is interpreted as a charge instantaneous acceleration at one side of the sample, the instantaneous deceleration at its other side and uniform motion inside the sample. Turning to the physical justification of the smooth Tamm problem, we observe that according to Born,[12] "The assumption on the jump-like transition from one substance to another is a far-reaching idealization. One substance is separated from another by some transition layer in which the dielectric constant changes continuously from ϵ_1 to ϵ_2." Let a charge move uniformly consecutively in vacuum, in a dielectric sample and again in vacuum. A charge begins to radiate with increasing intensity as it moves through the above layer where ϵ changes from ϵ_1 to ϵ_2. Then, in the spirit of the standard interpretation[11] of the original Tamm problem we suggest that the charge uniform motion through this layer is equivalent to its smooth acceleration inside the sample (in both cases βn varies from $\beta n<1$ to $\beta n>1$). That is, the charge passage through the sharp and diffused boundaries is effectively described by its instantaneous and smooth accelerations, respectively.

B. Reflections on the experimental setup

The experiments described in Ref. 4 (performed by Zrelov more than 40 years ago) were not especially designated for the discovering of the shock waves associated with the overcoming of the light velocity barrier (their existence was predicted much later). The following experimental conditions should be fulfilled for the reliable identification of the above shock waves.

(1) The frequency filter should be used. This permits one to escape complications and uncertainties associated with the integration over the frequency spectrum.

(2) The diameter of the charged particles beam should be as small as possible. The radiation intensity peaks associated with the above shock waves will be more pronounced for the thin beam (since the averaging over the beam diameter leads to their smoothing).

(3) No focusing devices (they are frequently used in the Cherenkov-type experiments) projecting the extended Cherenkov radiation into the thin Cherenkov ring should be used.

When these conditions are fulfilled, the observed spectral radiation intensity should resemble those shown in Fig. 7. The peaks of the radiation intensity at the boundaries of the Cherenkov plateau (similar to those shown at the right part of Fig. 1) will certainly indicate the existence of shock waves arising at the light velocity barrier.

VII. CONCLUSION

We briefly summarize the main results obtained.

(1) The position and the time evolution of the electromagnetic singular shock waves in the smooth Tamm problem are found. They consist of the Cherenkov shock wave and the shock waves arising at the accelerated and decelerated parts of the charge trajectory. Theory predicts the existence of the plateau in the spectral radiation intensity (associated with the finite Cherenkov shock wave), its sudden drop to the right of this plateau (associated with the absence of the singular shock waves in this spatial region), and small oscillations to its left (associated with the interference of the shock waves arising at the accelerated and decelerated parts of the charge trajectory).

(2) In the limiting case of the smooth Tamm problem (when the lengths along which a charge moves nonuniformly tend to zero), the resulting configuration of the electromagnetic singular shock waves does not coincide with that of the original Tamm problem (corresponding to the instantaneous velocity jumps at the beginning and the end of the charge motion). This is due to the contribution of high frequencies.

(3) It is studied how the electromagnetic shock waves occurring in the original and smooth Tamm problems reproduce the experimental situation. The recommendations on the performance of experiments aiming to discover shock waves associated with the overcoming of the light velocity barrier are given.

Recently we were aware of the interesting paper[13] in which the Cherenkov waves of the finite width were observed. We associate their finite width with the plateau of the radiation intensities shown in Figs. 1, 5, and 7.

An inequality for the Gibbs mean number of clusters

Camillo Cammarota[a)]
Dipartimento di Matematica, Universitá di Roma "La Sapienza," Piazzale A. Moro 2, 00185 Roma, Italy

(Received 12 October 2004; accepted 12 November 2004; published online 2 February 2005)

The number of percolation clusters for configurations of the Ising model at zero external field and ferromagnetic first neighbors interaction on a general finite graph is considered. The mean number of clusters with respect to the Gibbs measure at any inverse temperature β is proved to be smaller or equal than the one at $\beta=0$. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1845972]

I. INTRODUCTION

Let $G=(V,E)$ be a finite connected graph, of vertexes set V and edges set E. The Gibbs measure on G is the probability measure μ_β on $\Sigma=\{-1,1\}^V$ of weight

$$e^{\beta\Sigma_{\{i,j\}\in E}\,\sigma(i)\sigma(j)}, \quad \sigma\in\Sigma.$$

We denote by $\mathbb{E}^G_{\mu_\beta}$ the mean with respect to this measure. The measure μ_β describes an Ising model with spin variables on vertexes, ferromagnetic interaction on edges, zero external field, and inverse temperature β. Given any configuration $\sigma\in\Sigma$, the + (−) clusters of σ are the maximal connected components of $\sigma^{-1}(+1)$ $(\sigma^{-1}(-1))$. We denote by $C^{+(-)}(\sigma)$ the set of + (−) clusters of σ; the number of + (−) clusters $N^{+(-)}(\sigma)$ is the cardinality of $C^{+(-)}(\sigma)$, also denoted $|C^{+(-)}(\sigma)|$. The number of clusters of σ, denoted $N(\sigma)$, is defined as $N(\sigma)=N^+(\sigma)+N^-(\sigma)$ and obviously one has by symmetry

$$\mathbb{E}^G_{\mu_\beta}(N^+)=\mathbb{E}^G_{\mu_\beta}(N^-).$$

It is useful to consider the family μ_β, $\beta\in[0,\infty]$. One easily recognizes that μ_0 is a Bernoulli measure of parameter $\frac{1}{2}$ and that $\mu_\infty=\frac{1}{2}\delta_+ +\frac{1}{2}\delta_-$, where $\delta_+(\delta_-)$ is the point mass concentrated on the constant +(−) configuration. Consequently one has $\mathbb{E}^G_{\mu_\infty}(N)=1$, while the value of $\mathbb{E}^G_{\mu_0}(N)$ depends on the graph.

The random variable number of clusters plays a central role in percolation theory, and in the case of Bernoulli percolation it has been extensively studied (for a general reference see Ref. 7). We are interested in monotonicity properties with respect to β of the mean number of clusters $\mathbb{E}^G_{\mu_\beta}(N)$, as a particular case of the general problem of monotonicity in β for variables used in percolation theory. As an example, it is an open problem to extend the coexistence of + and − infinite clusters proved in the cubic lattice for the Ising model at β close to 0 (Ref. 5) to a larger range of temperatures.

The Gibbs measure is FKG for fixed temperature (for instance see Ref. 8), but there is not a satisfactory notion of stochastic ordering with respect to temperature. To circumvent this problem one method is to represent the measure on spins by means of a measure on edges configurations. A widespread approach is the random cluster model given by the Fortuin–Kasteleyn representation. For a review we refer to Ref. 8. Since random cluster measures are stochastically ordered in temperature, it is enough to prove that a particular observable in edge representation is monotonic in the partial ordering of these configurations. Using this method some observables related to percolation can be proved to have monotonicity properties.[3,10]

[a)]Electronic mail: cammar@mat.uniroma1.it

However other approaches have been used, and in particular we refer to the group representation of the Ising model, for which a basic reference is Ref. 9. Combining this representation and the notion of stochastic order has been fruitful. In particular some monotonicity properties of local observables can be re-obtained and new ones are proved.[4,6] The main idea is that the Gibbs measure on spins configurations is represented by a measure on edges configurations conditioned to a group, and that conditioned measures are stochastically ordered.

Despite some evident similarities with the random cluster model, one advantage of this approach is that the measure at $\beta=0$ is a delta mass concentrated on the empty configuration on edges. This feature can be exploited to treat a simpler type of problem, i.e., the inequality between the means at $\beta>0$ and at $\beta=0$. In Ref. 2 the mean number of clusters was proved to be smaller at $\beta>0$ than at $\beta=0$, if the graph has degree not greater than 3. In the present paper we prove an extension of this inequality for any degree.

Proposition 1.1: For any graph G the mean number of clusters with respect to the Gibbs measure at inverse temperature $\beta>0$ is less or equal to the one at $\beta=0$,

$$\mathbb{E}^G_{\mu_\beta}(N) \leqslant \mathbb{E}^G_{\mu_0}(N).$$

The main contribution of the present paper essentially consists in reducing the problem for a general graph G to the one for a graph G' with degree not greater than 3. This is achieved using a vertex resolution procedure, similar to the one used in Ref. 11, and conditioning the measure μ_β to a suitable configurations subset Δ. Hence the main ingredients of our proof can be summarized by the following equations:

$$\mathbb{E}^G_{\mu_\beta}(N) = \mathbb{E}^{G'}_{\mu_\beta}(N|\Delta) \leqslant \mathbb{E}^{G'}_{\mu_0}(N|\Delta) = E^G_{\mu_0}(N). \tag{1}$$

The inequality in the middle is an extension of the one proved in Ref. 2 and the external equalities are the result of the resolution procedure. In the present paper we also provide an exposition of the basic elements of the group representation, in order to make the paper self-consistent.

II. VERTEX RESOLUTION

In this section we prove the following lemma.

Lemma 2.1: There is a graph $G'=(V',E')$ with degree not greater than 3 and a subset Δ of $\Sigma'=\{-1,1\}^{V'}$ such that for the number of clusters N the following equation holds:

$$\mathbb{E}^G_{\mu_\beta}(N) = \mathbb{E}^{G'}_{\mu_\beta}(N|\Delta).$$

On the right-hand side there is the conditional expectation with respect to Δ, and the Gibbs measure on G' is defined as the one on G.

Proof: Given a vertex $i \in V$ we denote ∂i the set of the vertexes adjacent to i (first neighbors): the degree of i, denoted $\deg(i)$, is the cardinality of ∂i. For each i we define a set B_i, the resolution of the vertex i, as follows. If $\deg(i)\leqslant 3$, we set $B_i=\{i\}$: if $\deg(i)>3$, the set B_i is defined as a replica of ∂i, and we denote j' the element of B_i which corresponds to j. The new vertexes set is

$$V' = \cup_{i\in V} B_i.$$

In order to define E', we first replace the edges $\{i,j\}\in E$, $j\in\partial i$, by the edges $\{j,j'\}$, $j\in\partial i$. This defines a set of edges on V', called "conduction" edges and denoted E'_C, which are in one to one correspondence with E. We then put in each of the B_i's having cardinality greater than 3 edges such that make it connected; if $B_i=\{k_1,k_2,\ldots,k_n\}$, for instance we choose the edges $\{k_1,k_2\},\ldots,\{k_n,k_1\}$, forming a loop on B_i. We call these "identification" edges and denote them E'_C. The set E' can now be defined as a union of conduction edges E'_C and identification edges E'_I. The vertexes with degree not greater than 3 keep unchanged their degree; the other ones have exactly one conduction edge and two identification edges; hence the degree of G' is at most 3. This formal definition can be made more transparent with the help of Fig. 1.

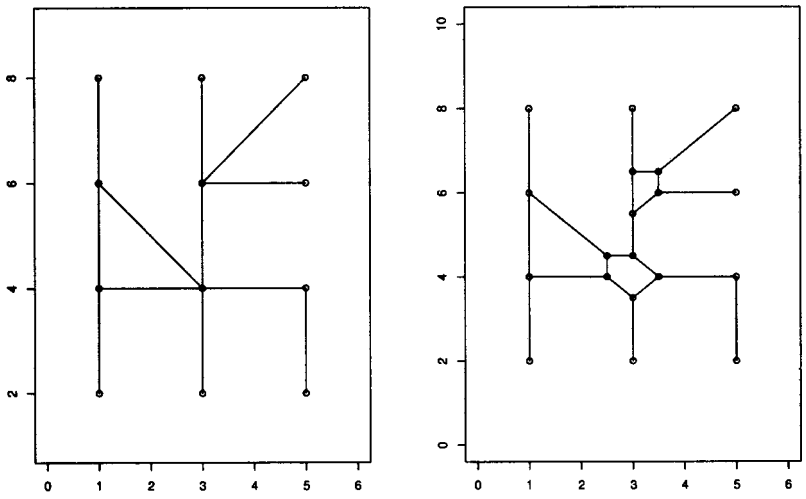

FIG. 1. Resolution procedure applied to the graph on the left, having one vertex of degree 4, of coordinates (3, 6), and one of degree 5, of coordinates (3, 4); on the right the graph obtained after resolution of these vertexes.

For the graph G' the Gibbs measure on $\Sigma'=\{-1,1\}^{V'}$ is formally defined as the one on G, and we use the same notation. We define the identification subset $\Delta\subset\Sigma'$ as the intersection over $i\in V$ of the identification event which forces all spins in B_i to be equal: $\sigma'(k_1)=\cdots=\sigma'(k_n)$. There is a trivial one to one map between configurations spins in Σ and Δ, such that if $\sigma\in\Sigma$ and $\sigma'\in\Delta$ one has $\sigma(i)=\sigma'(k)$, $k\in B_i$. An important consequence of the above definitions is that the number of clusters satisfies the equation

$$N(\sigma)=N(\sigma'). \tag{2}$$

Furthermore the interactions that define the Gibbs weights differ for a constant depending only on the graph,

$$\sum_{\{i,j\}\in E'}\sigma'(i)\sigma'(j)=\sum_{\{i,j\}\in E'_C}\sigma'(i)\sigma'(j)+\sum_{\{i,j\}\in E'_I}\sigma'(i)\sigma'(j)=\sum_{\{i,j\}\in E}\sigma(i)\sigma(j)+\sum_{i\in V,\deg(i)>3}|B_i|,$$

where we have used that conduction edges reproduce exactly E and that each identification edge gives a constant contribution of value 1. This suffices to conclude that conditioned to Δ the mean number of clusters on G' has the same value as the one on G. ■

Remark 1: Identification edges on B_i can be chosen in several ways, subject to the condition that they make B_i connected and that $\deg(j)\leqslant 3$; for instance one of the edges of the loop above defined can be dropped.

Remark 2: Equation (2) may not be true for other percolation variables. Let us consider the cardinality of the (say +) cluster containing a fixed vertex: if $W_k^+(\sigma')$ denotes the + cluster on G' containing the vertex $k\in V'$, where $k\in B_i$ and $\sigma'\in\Delta$, and if $W_k^+(\sigma')$ denotes the corresponding cluster on G, they are related by the nontrivial relationship

$$|W_k^+(\sigma')|=\sum_{j\in W_i^+(\sigma)}|B_j|.$$

III. GROUP REPRESENTATION OF CONDITIONED GIBBS MEASURES

We first discuss the representation of unconditioned Gibbs measures following Ref. 6. Given $\sigma\in\Sigma$ we associate to it the edge configuration $\omega\in\Omega=\{0,1\}^E$, defined as $\omega(i,j)=0$ if $\sigma(i)=\sigma(j)$ and $\omega(i,j)=1$ if $\sigma(i)\neq\sigma(j)$. This defines a map ψ from spins to edges configurations; by symmetry one has $\psi(\sigma)=\psi(-\sigma)$. The range of this map, denoted Γ, can be characterized as the set

of edges configurations such that any loop contains an even number of 1's (this was noticed, for instance, in Ref. 10, but with the opposite coding). A next step is to recognize that this set has a group structure, as a subgroup of Ω.[1] Actually in Ω there is a product defined as

$$\omega_1\omega_2(e) = \omega_1(e) + \omega_2(e) \mod 2, \quad e \in E$$

and the identity is the null element $0(e)=0$, $e \in E$. We call Γ the "parity" group.

The Gibbs weight can be written as

$$e^{\beta|\omega^{-1}(0)|-\beta|\omega^{-1}(1)|}, \quad \omega \in \Gamma.$$

This is the same as the one of a Bernoulli product measure ν_p of parameters p for the 1's and $1-p$ for the 0's, where $p=e^{-\beta}/(e^{\beta}+e^{-\beta})$, conditioned to Γ. Since we are interested in variables invariant with respect to total spin flip, their means with respect to the measure μ_β can be written in terms of means with respect to the Bernoulli measure ν_p conditioned to the subgroup Γ. If X denotes such a variable, both as a function of spins configurations and of edges configurations, we have

$$\mathbb{E}_{\mu_\beta}(X) = \mathbb{E}_{\nu_p}(X|\Gamma). \tag{3}$$

We now consider the general problem of representing the Bernoulli measure ν_p conditioned to a subgroup Θ. We need some definitions. The cylinder of base $A \subset E$, given $\alpha \in \{0,1\}^A$, is

$$K_\alpha^A = \{\omega \in \Omega | \omega(e) = \alpha(e), e \in A\}.$$

We include the case $A=\emptyset$ setting $K_\alpha^\emptyset = \Omega$. In particular one has that K_0^A is a subgroup and K_α^A is a coset for any α. If X is a function on Ω and Θ is a subgroup, we define a function on the subsets of E,

$$X_\Theta(A) = |\Theta \cap K_0^A|^{-1} \sum_{\omega \in \Theta \cap K_0^A} X(\omega). \tag{4}$$

We also introduce a probability measure λ_p^Θ on the subsets of E,

$$\lambda_p^\Theta(A) = \nu_p(\Theta)^{-1}(1-2p)^{|A|}p^{|E\setminus A|}|\Theta \cap K_0^A|. \tag{5}$$

With these notation we have the following.

Proposition 3.1 (Ref. 6): The mean of X with respect to the Bernoulli measure ν_p conditioned to a subgroup Θ can be represented by

$$\mathbb{E}_{\nu_p}(X|\Theta) = \sum_{A \subset E} X_\Theta(A)\lambda_p^\Theta(A). \tag{6}$$

Proof: Denoting for brevity $\omega=\omega^{-1}(1)$ and $\omega^c=\omega^{-1}(0)$ and considering ω as a subset of E, one has

$$\nu_p(\omega) = p^{|\omega|}(1-2p+p)^{|\omega^c|} = \sum_{A \subset \omega^c} (1-2p)^{|A|}p^{|E\setminus A|}.$$

Hence

$$\sum_{\omega \in \Theta} \nu_p(\omega)X(\omega) = \sum_{A \subset E} (1-2p)^{|A|}p^{|E\setminus A|} \sum_{\omega \in \Theta \cap K_0^A} X(\omega)$$

and this concludes the proof. ■

We can now discuss the representation of conditioned Gibbs measures; in particular we are looking for a suitable representation of $\mathbb{E}_{\mu_\beta}^{G'}(N|\Delta)$. We first notice that the image of Δ on edges configurations is a subgroup of Ω'. In particular it is the cylinder $K_0^{E_I'}$ obtained setting 0's on

identification edges of E'; we use the same notation Δ and call it "identification" group. We shall use the following property. Since the representation of the Gibbs measure requires conditioning to the parity group Γ, the representation of the Gibbs measure conditioned to identification group Δ can be achieved conditioning to the intersection of these two groups. We can write

$$\mathbb{E}^{G'}_{\mu_\beta}(N|\Delta) = \mathbb{E}^{G'}_{\nu_p}(N|\Gamma \cap \Delta). \tag{7}$$

Since $\Theta = \Gamma \cap \Delta$ is a group, we can apply Eq. (6) and get

$$\mathbb{E}^{G'}_{\mu_\beta}(N|\Delta) = \sum_{A \subset E} N_\Theta(A) \lambda^\Theta_p(A). \tag{8}$$

We now remark that for $\beta = 0$, i.e., $p = 1/2$, the corresponding measure $\lambda^\Theta_{1/2}$ is a delta mass concentrated on the empty set. Hence,

$$\mathbb{E}^{G'}_{\mu_0}(N|\Delta) = N_\Theta(\emptyset). \tag{9}$$

Hence in order to have

$$\mathbb{E}^{G'}_{\mu_\beta}(N|\Delta) \leqslant E^{G'}_{\mu_0}(N|\Delta) \tag{10}$$

it is sufficient the condition

$$N_\Theta(A) \leqslant N_\Theta(\emptyset), \quad A \subset E'. \tag{11}$$

The next section is devoted to prove this inequality.

IV. A PRUNING TREE ARGUMENT

We shall prove that the function N_Θ over the subsets of E' has the following weak monotonicity property.

Proposition 4.1: For any $A \subset E'$, $A \neq \emptyset$, there is $e \in A$ such that

$$N_\Theta(A) \leqslant N_\Theta(A \setminus e). \tag{12}$$

One easily recognizes that this property is sufficient to give Eq. (11). The case that Θ is the parity group was considered in Ref. 2. Here we recall that proof, adapting it to the present context.

Proof: Equation (12) is equivalent to

$$|\Theta \cap K_0^{A\setminus e}| \sum_{\omega \in \Theta \cap K_0^A} N(\omega) \leqslant |\Theta \cap K_0^A| \sum_{\omega \in \Theta \cap K_0^{A\setminus e}} N(\omega). \tag{13}$$

We use

$$|\Theta \cap K_0^{A\setminus e}| = |\Theta \cap K_{0\,0}^{A\setminus ee}| + |\Theta \cap K_{0\,1}^{A\setminus ee}|$$

and

$$\sum_{\omega \in \Theta \cap K_0^{A\setminus e}} N(\omega) = \sum_{\omega \in \Theta \cap K_{0\,0}^{A\setminus ee}} N(\omega) + \sum_{\omega \in \Theta \cap K_{0\,1}^{A\setminus ee}} N(\omega),$$

and so Eq. (13) is equivalent to

$$|\Theta \cap K_{0\,1}^{A\setminus ee}| \sum_{\omega \in \Theta \cap K_{0\,0}^{A\setminus ee}} N(\omega) \leqslant |\Theta \cap K_{0\,0}^{A\setminus ee}| \sum_{\omega \in \Theta \cap K_{0\,1}^{A\setminus ee}} N(\omega), \tag{14}$$

where we have used $\Theta \cap K_{0\,0}^{A\setminus ee} = \Theta \cap K_0^A$.

If the set $\Theta \cap K_{0\,1}^{A\setminus ee}$ is empty, we define zero the sum extended to it and we have by definition

$$N_\Theta(A) = N_\Theta(A \setminus e).$$

Since $\Theta = \Delta \cap \Gamma$, the set $\Theta \cap K_{0\,1}^{A\setminus ee}$ is empty if the value 1 on the edge e violates the identification or the parity condition. The first case happens if e is an identification edge; the second one if e belongs to a loop of A, since any loop must contain an even numbers of 1's.

If the set $\Theta \cap K_{0\,1}^{A\setminus ee}$ is nonempty, it is a coset of the group $\Theta \cap K_{0\,0}^{A\setminus ee}$ and so it has the same cardinality. Hence Eq. (12) is equivalent to

$$\sum_{\omega \in \Theta \cap K_{0\,0}^{A\setminus ee}} N(\omega) \leqslant \sum_{\omega \in \Theta \cap K_{0\,1}^{A\setminus ee}} N(\omega). \tag{15}$$

From the previous argument we can now suppose that A does not contain loops, i.e., it is union of disjoint trees and we shall prove that pruning any end line e preserves Eq. (12), since Eq. (15) holds. It is convenient to rewrite this equation in spins language, getting

$$\sum_{\sigma \in \Delta \cap K_{=\,=}^{A\setminus ee}} N(\sigma) \leqslant \sum_{\sigma \in \Delta \cap K_{=\,\neq}^{A\setminus ee}} N(\sigma), \tag{16}$$

where the set $K_{=\,\neq}^{A\setminus ee}$ is the spin version of $K_{0\,1}^{A\setminus ee}$. If $e=\{i,j\}$ where j is an endpoint of the tree $T \cup \{j\}$ of A, in order to get Eq. (15) it is sufficient that

$$N(\sigma_{++}^{Tj}) + N(\sigma_{--}^{Tj}) \leqslant N(\sigma_{+-}^{Tj}) + N(\sigma_{-+}^{Tj}), \quad \sigma \in \{-1,1\}^{V' \setminus T \cup \{j\}}, \tag{17}$$

where for instance σ_{+-}^{Tj} denotes the completion of σ with +'s on T and $-$ on j.

We denote for instance by $C_T^+(\sigma)$ and $C_j^+(\sigma)$, respectively, the set of + clusters of σ adjacent to T and j. We have

$$N(\sigma_{++}^{Tj}) = N(\sigma) - \left|C_T^+(\sigma) \cup C_j^+(\sigma)\right| + 1, \tag{18}$$

$$N(\sigma_{+-}^{Tj}) = N(\sigma) - \left|C_T^+(\sigma)\right| + 1 - \left|C_j^+(\sigma)\right| + 1, \tag{19}$$

$$N(\sigma_{--}^{Tj}) = N(\sigma) - \left|C_T^-(\sigma) \cup C_j^-(\sigma)\right| + 1, \tag{20}$$

$$N(\sigma_{-+}^{Tj}) = N(\sigma) - \left|C_T^-(\sigma)\right| + 1 - \left|C_j^+(\sigma)\right| + 1. \tag{21}$$

The first equation, for instance, uses the fact that if one turns on +'s over T and j, the + clusters adjacent to T or to j become a unique cluster. Using in Eq. (17) the above equations we get

$$\left|C_T^+(\sigma) \cap C_j^+(\sigma)\right| + \left|C_T^-(\sigma) \cap C_j^-(\sigma)\right| \leqslant 2. \tag{22}$$

The left-hand side is bounded by the number of vertexes that are simultaneously adjacent to T and j. Since T and j are adjacent and $\deg(j) \leqslant 3$, this number is not greater than 2. This proves Eq. (22) and completes the proof of the proposition. ■

(Received 30 June 2004; accepted 5 October 2004; published online 18 January 2005)

We study the monotonicity under mixing of the scalar curvature for the α-geometries on the simplex of probability vectors. From the results obtained and from numerical data, we are led to some conjectures about quantum α-geometries and Wigner–Yanase–Dyson information. Finally, we show that this last conjecture implies the truth of the Petz conjecture about the monotonicity of the scalar curvature of the Bogoliubov–Kubo–Mori monotone metric. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1834693]

I. INTRODUCTION

The Bogoliubov–Kubo–Mori (BKM) metric is a distinguished element among the monotone metrics which are the quantum analog of Fisher information on the quantum state space.[35,36] In a definite sense BKM metric is the geometry on the state space that is related to von Neumann entropy (say, Umegaki relative entropy). Other well-known elements of this family are the right logarithmic derivative (RLD) metric, the symmetric logarithmic derivative (SLD or Bures) metric, and the Wigner–Yanase–Dyson (WYD) metrics. In Ref. 34 Petz made a conjecture on the scalar curvature of the BKM metric. Many arguments and numerical calculations suggest that the conjecture is true; nevertheless, a complete proof is still missing (see Refs. 3, 4, 12, 24, and 32).

One can state this conjecture in the following way: the BKM scalar curvature is a quantitative measure of symmetry (like entropy), namely it is increasing under mixing. Let us emphasize that it is also possible to relate the conjecture to quantities with direct physical meaning. An equivalent formulation, still due to Petz,[34] is that "…the scalar curvature is an increasing function of the temperature…." Moreover, the asymptotic relation between volume and curvature in Riemannian geometry and Jeffrey's approach to priors in statistics induced Petz to interpret the scalar curvature as the average statistical uncertainty (that should increase under coarse graining; see Ref. 36).

The original motivations given by Petz for the conjecture rely on the truth of the 2×2 case and on some numerical results for the general case. Petz and Sudar observed in Ref. 38 that "…monotonicity of Kubo metric is not surprising because this result is a kind of reformulation of Lieb convexity theorem.[30] However the monotonicity of the scalar curvature seems to be an inequality of new type (provided the conjecture is really true)…." A recent clear reference for Lieb's result and related inequalities can be found in the paper by Ruskai.[40]

The goals of the present paper are the following.

(1) We want to look at "higher mathematics from an elementary point of view." This means that we want to furnish an elementary motivation for the Petz conjecture. We do this by studying

[a)]Electronic-mail: gibilisco@voterra.mat.uniroma2.it
[b)]Electronic-mail: isola@mat.uniroma2.it

the monotonicity of the curvature for α-geometries in the plane. The results obtained in this case are very intuitive if one looks at the unit sphere of the L^p spaces. We conjecture that a similar behavior occurs for α-geometries in higher dimensions and in the noncommutative case, too.

(2) On the basis of the results of point (1) we make a conjecture about the monotonicity of scalar curvature for the WYD metrics. Further, we show that, using a continuity argument, this WYD conjecture would imply the Petz conjecture as a limit case (Theorem 8.1).

(3) We review what is known about monotonicity of scalar curvature for quantum Fisher information. In particular, we emphasize a result on the Bures metric, attributed to Dittmann, according to which the scalar curvature, in this case, is neither Schur-increasing nor Schur-decreasing (see Sec. II for precise definitions). This implies that an example of a monotone metric for which the scalar curvature (or its opposite) is strictly increasing under mixing does not exist yet. Note that Andai (using an integral decomposition of Ref. 15) proved that also in the 2×2 case there exist monotone metrics whose scalar curvature is not monotone.[3]

Finally, let us note that, related to this area, there exist other interesting papers. Some authors have suggested that, when statistical mechanics is geometrized, then the scalar curvature should have important physical meaning (for example, it should be proportional to the inverse of the free energy; see Refs. 8, 9, 25–27, and 39).

II. MAJORIZATION AND SCHUR-INCREASING FUNCTIONS

For the content of this section we refer to Refs. 1, 5–7, and 31.

A. Commutative case

We shall denote by $\mathcal{P}_n$ the manifold of positive vectors of $\mathbb{R}^n$, and by $\mathcal{P}_n^1 \subset \mathcal{P}_n$ the submanifold of density vectors, namely

Definition 2.1:

$$\mathcal{P}_n^1 := \left\{ \rho \in \mathbb{R}^n \middle| \sum_i \rho_i = 1,\ \rho_i > 0 \right\}.$$

We set $e := (1, \ldots, 1)$. The trace of a vector is $\mathrm{Tr}(v) = \Sigma_{i=1}^n v_i$. For an $n \times n$ real matrix, consider the following properties:

(I) $t_{ij} \geqslant 0 \quad i,j = 1, \ldots, n,$
(II) $\Sigma_{i=1}^n t_{ij} = 1 \quad j = 1, \ldots, n,$
(III) $\Sigma_{j=1}^n t_{ij} = 1 \quad i = 1, \ldots, n.$

Definition 2.2:

(a) *T is said to be stochastic if (I),(II) hold*;
(b) *T is said to be doubly stochastic if (I),(II),(III) hold.*

When T is seen as an operator $T: \mathbb{R}^n \to \mathbb{R}^n$ (by $(Tv)_j = \Sigma_{i=1}^n t_{ji} v_i$), then the properties (I),(II),(III) can be written as

(I)′ (positivity preserving) $Tv \geqslant 0$ if $v \geqslant 0$;
(II)′ (trace-preserving) $\mathrm{Tr}(Tv) = \mathrm{Tr}(v) \quad \forall v \in \mathbb{R}^n$;
(III)′ (unital) $Te = e$.

Let $x \in \mathbb{R}^n$ be a vector. We define $x^{\downarrow}$ as a vector with the same components in a decreasing order so that

$$x_1^{\downarrow} \geqslant x_2^{\downarrow} \geqslant \cdots \geqslant x_n^{\downarrow}.$$

Definition 2.3: x is more mixed (more chaotic,…) than y (denoted by $x \succ y$) if and only if

$$x_1^{\downarrow} \leqslant y_1^{\downarrow},$$

$$x_1^{\downarrow} + x_2^{\downarrow} \leqslant y_1^{\downarrow} + y_2^{\downarrow},$$

$$\cdots,$$

$$x_1^{\downarrow} + \cdots + x_{n-1}^{\downarrow} \leqslant y_1^{\downarrow} + \cdots + y_{n-1}^{\downarrow},$$

$$x_1^{\downarrow} + \cdots + x_n^{\downarrow} = y_1^{\downarrow} + \cdots + y_n^{\downarrow}.$$

For example, if $(\rho_1, \ldots, \rho_n)$ is a density vector then

$$\left(\frac{1}{n}, \frac{1}{n}, \ldots, \frac{1}{n}\right) \succ (\rho_1, \ldots, \rho_n) \succ (1,0, \ldots, 0,0).$$

The relation $\succ$ is a preordering but not a partial ordering. If $x \succ y$ and $y \succ x$ then $x = Ty$ for some permutation matrix T.

Theorem 2.1:

$$x \succ y \Leftrightarrow x = Ty \text{ where } T \text{ is doubly stochastic}.$$

Definition 2.4 (see Ref. 31 pp. 14 and 54): A real-valued function f defined on a set $\mathcal{A} \subset \mathbb{R}^n$ is said to be Schur-increasing on $\mathcal{A}$ if

$$x \succ y \text{ on } \mathcal{A} \Rightarrow \quad f(x) \geqslant f(y).$$

If, in addition, $f(x) > f(y)$ whenever $x \succ y$ but x is not a permutation of y, then f is said to be strictly Schur-increasing. Similarly f is said to be Schur-decreasing on $\mathcal{A}$ if

$$x \succ y \text{ on } \mathcal{A} \Rightarrow f(x) \leqslant f(y),$$

and f is strictly Schur-decreasing if strict inequality $f(x) < f(y)$ holds when x is not a permutation of y.

Of course, f is Schur-increasing if and only if $-f$ is Schur-decreasing.

Remark 2.1 (see Ref. 31, p. 54): $\mathcal{A} \subset \mathbb{R}^n$ is symmetric if $x \in \mathcal{A} \Rightarrow \Pi x \in \mathcal{A}$ for all permutations Π. A function f is symmetric on $\mathcal{A}$ if $f(x) = f(\Pi x)$ for all permutations Π. Let $\mathcal{D} := \{x | x_1 \geqslant \cdots \geqslant x_n\}$. If f is symmetric on a symmetric set $\mathcal{A}$ and Schur-increasing on $\mathcal{D} \cap \mathcal{A}$, then f is Schur-increasing on $\mathcal{A}$.

Remark 2.2: Let us consider the following identification $I: (0, \pi/2) \to \mathcal{P}_2^1$ defined by $I(\theta) := (\cos^2\theta, \sin^2\theta)$. Evidently, if $\theta_1, \theta_2 \leqslant \pi/4$, then

$$\theta_1 \leqslant \theta_2 \Leftrightarrow I(\theta_1) \prec I(\theta_2).$$

Any function on $\mathcal{P}_2^1$ can be seen as a function on $(0, \pi/2)$. By abuse of language we shall use the same symbols to denote the two functions. Since $\mathcal{P}_2^1$ is symmetric we have, because of Remark 2.1

Proposition 2.2: A symmetric function f on $\mathcal{P}_2^1$ is Schur-increasing if and only if f is increasing as a function on $(0, \pi/4)$.

B. Noncommutative case

Let M_n be the space of complex $n \times n$ matrices. We shall denote by H_n the real subspace of Hermitian matrices, by $\mathcal{D}_n$ the manifold of strictly positive elements of M_n, and by $\mathcal{D}_n^1 \subset \mathcal{D}_n$ the submanifold of density matrices, namely

Definition 2.5:

$$\mathcal{D}_n^1 := \{\rho \in M^n | \mathrm{Tr}\ \rho = 1,\ \rho > 0\}.$$

If $A \in M_n$, let $\lambda(A)$ be the n-vector of its eigenvalues, arranged in any order with multiplicities counted. If A is Hermitian then $\lambda(A)$ is a real n-vector. Let A, B be Hermitian.

Definition 2.6:

$$A \succ B \Leftrightarrow \lambda(A) > \lambda(B).$$

Definition 2.7: A linear map Φ on M_n is doubly stochastic if it is positive-preserving, trace-preserving, and unital.

Theorem 2.3:

$$A \succ B \Leftrightarrow A = \Phi(B), \textit{where } \Phi \textit{ is doubly stochastic}.$$

Definition 2.8: A real-valued function f defined on a set $\mathcal{A} \subset H_n$ is said to be Schur-increasing on $\mathcal{A}$ if

$$A \succ B \Rightarrow f(A) \geqslant f(B).$$

Similarly, f is said to be Schur-decreasing on $\mathcal{A}$ if

$$A \succ B \Rightarrow f(A) \leqslant f(B).$$

Of course, f is Schur-increasing if and only if $-f$ is Schur-decreasing.

III. PULL-BACK OF DUALITY PAIRINGS

To make the paper self-contained, we recall some constructions from Ref. 18.

Let V, W be vector spaces over $\mathbb{R}$ (or $\mathbb{C}$). One can say that there is a duality pairing if there exists a separating bilinear form

$$\langle \cdot, \cdot \rangle : V \times W \to \mathbb{R}.$$

Let $\mathcal{M}, \mathcal{N}, \widetilde{\mathcal{N}}$ be differentiable manifolds.

Definition 3.1: Suppose we have a pair of immersions (φ, χ), where $\varphi : \mathcal{M} \to \mathcal{N}$ and $\chi : \mathcal{M} \to \widetilde{\mathcal{N}}$, such that a duality pairing exists between $T_{\varphi(\rho)}\mathcal{N}$ and $T_{\chi(\rho)}\widetilde{\mathcal{N}}$ for any $\rho \in \mathcal{M}$. Then, we may pull-back this pairing on $\mathcal{M}$ by defining

$$\langle u, v \rangle_\rho^{\varphi,\chi} := \langle D_\rho \varphi(u), D_\rho \chi(u) \rangle, \quad u, v \in T_\rho \mathcal{M}.$$

The most elementary example is given by the case where $\mathcal{N} = \widetilde{\mathcal{N}}$ is a Riemannian manifold, $\varphi = \chi$, and the duality pairing is just given by the Riemannian scalar product on $T_{\varphi(\rho)}\mathcal{N}$ (this is the pull-back metric induced by the map φ).

A nontrivial example is the following. Let X be a uniformly convex Banach space such that the dual $\widetilde{X}$ is uniformly convex. We denote by $\langle \cdot, \cdot \rangle$ the standard duality pairing between X and $\widetilde{X}$. Let $J : X \to \widetilde{X}$ be the duality mapping, that is J is the differential of the map $v \to \frac{1}{2}\|v\|^2$. $J(v)$ is the unique element of the dual such that $\langle v, J(v) \rangle = \|v\|^2 = \|J(v)\|^2$.

Definition 3.2: Let $\mathcal{M}$ be a manifold. If we have a map $\varphi : \mathcal{M} \to X$ we can consider a dualized pull-back that is a bilinear form defined on the tangent space of $\mathcal{M}$ by

$$\langle A, B \rangle_\rho^\varphi := \langle A, B \rangle_\rho^{\varphi, J \circ \varphi} = \langle D_\rho \varphi(A), D_\rho (J \circ \varphi)(B) \rangle.$$

Example 3.1: For X a Hilbert space, J is the identity, and this is again the definition of pull-back metric induced by the map φ.

In what follows, if $p \in \mathbb{R} \setminus \{0\}$ then $\tilde{p}$ is defined by $(1/p) + (1/\tilde{p}) = 1$. If $p = 1$ then $\tilde{p} = +\infty$.

Example 3.2: Let $(X, \mathcal{F}, \mu)$ be a measure space. If f is a measurable function and $p \in (1, +\infty)$ then $\|f\|_p := (\int |f|^p d\mu)^{1/p}$. Set

$$L^p = L^p(X,\mathcal{F},\mu) = \{f \text{ is measurable and } \|f\|_p < \infty\}.$$

Define N^p as L^p with the norm

$$\|f\|_{N^p} := \frac{\|f\|_p}{p}.$$

Obviously $\tilde{N^p}$ (the dual of N^p) can be identified with $N^{\tilde{p}}$.

Now, suppose that $\rho > 0$ is measurable and $\int \rho = 1$, namely ρ is a strictly positive density. Then, $v = p\rho^{1/p}$ is an element of the unit sphere of N^p and it is easy to see that $J(v) = \tilde{p}\rho^{1/p}$. The family of maps $\rho \to p\rho^{1/p}$ is known as Amari embeddings.

Let $X = \{1, \ldots, n\}$ and let μ be the counting measure. In this case N^p is just $\mathbb{R}^n$ with the norm $\|\cdot\|_p / p$.

Proposition 3.1: Consider the Amari embedding $\varphi: \rho \in \mathcal{P}_n^1 \to p\rho^{1/p} \in N^p$ *for an arbitrary* $p \in (1, +\infty)$. *Then, the bilinear form*

$$\langle A,B\rangle_\rho^\varphi := \langle A,B\rangle_\rho^{\varphi, J\circ\varphi} = \langle D_\rho\varphi(A), D_\rho(J\circ\varphi)(B)\rangle, \quad A,B \in T_\rho\mathcal{P}_n^1,$$

is just the Fisher information.

Proof:

$$\langle D_\rho\varphi(A), D_\rho(J\circ\varphi)(B)\rangle = \int (\rho^{(1/p)-1}A)(\rho^{(1/p)-1}B) = \int \frac{AB}{\rho}.$$

□

The above result can be stated in much greater generality using the machinery of Refs. 19 and 14.

IV. SCALAR CURVATURE OF α-GEOMETRIES

The α-geometries are one of the fundamental objects of information geometry (see Refs. 2 and 20). The study of the monotonicity of their curvatures does not appear in the literature as far as we know. In this section we start such an investigation.

A. The plane case

Definition 4.1: The α*-geometry on* $\mathcal{P}_2^1$ *is the pull-back geometry induced by the map* $A_p(\rho): \mathcal{P}_2^1 \to \mathbb{R}^2$ *defined by*

$$A_p(\rho) := \begin{cases} p\rho^{1/p}, & p \in \mathbb{R}\setminus\{0\}, \\ \log(\rho), & p = \infty, \end{cases}$$

where $p = 2/(1-\alpha)$.

Definition 4.2: We denote by $c_p(\rho)$ *the curvature of the* α*-geometry* [*with* $p = 2/(1-\alpha)$] *at the point* $\rho \in \mathcal{P}_2^1$.

Remark 4.1: For the curvature $c_p(\cdot)$ there are two easy cases:

—if $p = 1$ then $c_p(\cdot) = \text{const} = 0$;

—if $p = 2$ then $c_p(\cdot) = \text{const} = \frac{1}{2}$.

Taking a look at the unit sphere of $\mathbb{R}^2$ with respect to the L^p-norm, one can easily understand the following general result.

Theorem 4.1: *For the function* $c_p(\cdot): \mathcal{P}_2^1 \to R$ *one has the following properties*:

—*if* $p \in (1,2)$ *then* $c_p(\cdot)$ *is a strictly Schur-decreasing function*;

—*if* $p \in (2, +\infty]$ *then* $c_p(\cdot)$ *is a strictly Schur-increasing function.*

Proof: Let us first consider $p \in (1,\infty)$. Then, the α-geometry, $\alpha = (p-2)/p$, on $\mathcal{P}_2^1$ is the geometry of the set

$$\mathcal{B}:=\left\{(x,y)\in\mathbb{R}^2:\left(\frac{x}{p}\right)^p+\left(\frac{y}{p}\right)^p=1,\quad x>0,\quad y>0\right\}.$$

Let us introduce the parametrization

$$x=p(\cos\ \vartheta)^{2/p},\quad y=p(\sin\ \vartheta)^{2/p},\quad 0<\vartheta<\frac{\pi}{2}.$$

Then

$$x'=2(\cos\ \vartheta)^{(2/p)-1}(-\sin\ \vartheta),\quad y'=2(\sin\ \vartheta)^{(2/p)-1}\cos\ \vartheta,$$

$$x''=2(\cos\ \vartheta)^{(2/p)-2}\left(\frac{2}{p}\sin^2\ \vartheta-1\right),\quad y''=2(\sin\ \vartheta)^{(2/p)-2}\left(\frac{2}{p}\cos^2\ \vartheta-1\right).$$

Let us parametrize density vectors as $(\cos^2\ \theta,\sin^2\ \vartheta)$. In this way the curvature of α-geometry at the point ρ, namely $c_p(\rho)$, is

$$\begin{aligned}c_p(\vartheta):&=\frac{|x'y''-x''y'|}{[(x')^2+(y')^2]^{3/2}}=\frac{p-1}{p}\frac{(\sin\ \vartheta\cos\ \vartheta)^{(2/p)+2}}{[(\sin\ \vartheta(\cos\ \vartheta)^{1/p})^4+((\sin\ \vartheta)^{1/p}\cos\ \vartheta)^4]^{3/2}}\\&=\frac{p-1}{p}\left(\frac{1}{2}\right)^{2[1-(2/p)]}\cdot\frac{(\sin 2\vartheta)^{2[1-(2/p)]}}{[(\cos\ \vartheta)^{4/\tilde{p}}+(\sin\ \vartheta)^{4/\tilde{p}}]^{3/2}}=A_p\cdot\frac{g_p(\vartheta)}{f_p(\vartheta)^{\frac{3}{2}}},\end{aligned}$$

where we set

$$A_p:=\frac{p-1}{p}\left(\frac{1}{2}\right)^{2[1-(2/p)]},$$

$$g_p(\vartheta):=(\sin 2\vartheta)^{2-(4/p)},$$

$$f_p(\vartheta):=(\cos\ \vartheta)^{4/\tilde{p}}+(\sin\ \vartheta)^{4/\tilde{p}}.$$

We want to compute the monotonicity properties of c_p with respect to the preordering $>$. We have

$$g_p'(\vartheta):=4(\sin 2\vartheta)^{1-(4/p)}\cdot(\cos\ \vartheta+\sin\ \vartheta)\left(1-\frac{2}{p}\right)(\cos\ \vartheta-\sin\ \vartheta);$$

since $0<\vartheta<\pi/2$, then

$$4(\sin 2\vartheta)^{1-(4/p)}\cdot(\cos\ \vartheta+\sin\ \vartheta)>0,$$

and therefore

$$g_p'(\vartheta)>0\Leftrightarrow\left(1-\frac{2}{p}\right)(\cos\ \vartheta-\sin\ \vartheta)>0.$$

Moreover

$$f_p'(\vartheta)=\frac{4}{\tilde{p}}\sin\ \vartheta\cos\ \vartheta((\sin\ \vartheta)^{(2/\tilde{p})-1}+(\cos\ \vartheta)^{(2/\tilde{p})-1})((\sin\ \vartheta)^{(2/\tilde{p})-1}-(\cos\ \vartheta)^{(2/\tilde{p})-1});$$

again, since $0<\vartheta<\pi/2$, then

$$4\sin\ \vartheta\cos\ \vartheta((\sin\ \vartheta)^{(2/\tilde{p})-1}+(\cos\ \vartheta)^{(2/\tilde{p})-1})>0,$$

and therefore

$$f_p'(\vartheta) > 0 \Leftrightarrow \frac{1}{\tilde{p}}((\sin\ \vartheta)^{(2/\tilde{p})-1} - (\cos\ \vartheta)^{(2/\tilde{p})-1}) > 0.$$

$c_p(\cdot)$ is evidently symmetric on $\mathcal{P}_2^1$ and therefore (because of Proposition 2.2) the fact that the curvature is strictly Schur-increasing (decreasing) is equivalent to the fact that $c_p(\vartheta)$ is strictly increasing (decreasing) for $0<\vartheta<\pi/4$.

We have the following cases:

Case: $1<p<2$.

This implies $1-(2/p)<0, (2/\tilde{p})-1<0$, and therefore

$$g_p'(\vartheta) > 0 \Leftrightarrow \cos\ \vartheta < \sin\ \vartheta \Leftrightarrow \frac{\pi}{4} < \vartheta < \frac{\pi}{2},$$

$$f_p'(\vartheta) > 0 \Leftrightarrow (\sin\ \vartheta)^{(2/\tilde{p})-1} > (\cos\ \vartheta)^{(2/\tilde{p})-1} \Leftrightarrow \sin\ \vartheta < \cos\ \vartheta \Leftrightarrow 0 < \vartheta < \frac{\pi}{4}.$$

Therefore, for $0<\vartheta<\pi/4$, g is decreasing, f is increasing, and $1/f^{3/2}$ is decreasing. This implies that

$$c_p = A_p \frac{g_p}{f_p^{3/2}}$$

is strictly decreasing for $0<\vartheta<\pi/4$.

Case: $2<p<\infty$.

This implies $1-(2/p)>0, (2/\tilde{p})-1>0$, and therefore

$$g_p'(\vartheta) > 0 \Leftrightarrow \cos\ \vartheta > \sin\ \vartheta \Leftrightarrow 0 < \vartheta < \frac{\pi}{4},$$

$$f_p'(\vartheta) > 0 \Leftrightarrow (\sin\ \vartheta)^{(2/\tilde{p})-1} > (\cos\ \vartheta)^{(2/\tilde{p})-1} \Leftrightarrow \sin\ \vartheta > \cos\ \vartheta \Leftrightarrow \frac{\pi}{4} < \vartheta < \frac{\pi}{2}.$$

Therefore, for $0<\vartheta<\pi/4$, g is increasing, f is decreasing, and $1/f^{3/2}$ is increasing. This implies that

$$c_p = A_p \frac{g_p}{f_p^{3/2}}$$

is strictly increasing for $0<\vartheta<\pi/4$.

Case: $p=\infty$.

Use now the following parametrization:

$$x = 2\ \log(\cos\ \theta), \quad y = 2\ \log(\sin\ \theta),$$

for the curve $e^x+e^y=1$. Then

$$x' = -2\frac{\sin\ \theta}{\cos\ \theta}, \quad y' = 2\frac{\cos\ \theta}{\sin\ \theta},$$

$$x'' = \frac{-2}{\cos^2\ \theta}, \quad y'' = \frac{-2}{\sin^2\ \theta},$$

$$c_\infty(\vartheta) := \frac{|x'y'' - x''y'|}{[(x')^2 + (y')^2]^{3/2}} = \frac{(\sin\ \theta \cos\ \theta)^2}{[(\cos\ \theta)^4 + (\sin\ \theta)^4]^{3/2}}$$
$$= \lim_{p\to+\infty} \frac{p-1}{p}\left(\frac{1}{2}\right)^{2[1-(2/p)]} \cdot \frac{(\sin 2\vartheta)^{2[1-(2/p)]}}{[(\cos\ \vartheta)^{4/\tilde{p}} + (\sin\ \vartheta)^{4/\tilde{p}}]^{3/2}}.$$

Note that

$$c_\infty(\vartheta) = \lim_{p\to+\infty} c_p(\theta).$$

If we set

$$g_\infty(\vartheta) := (\sin\ \theta \cos\ \theta)^2, \quad f_\infty(\vartheta) := (\cos\ \theta)^4 + (\sin\ \theta)^4,$$

then

$$g'_\infty(\vartheta) = 2 \sin\ \vartheta \cos\ \vartheta(\cos\ \vartheta + \sin\ \vartheta)(\cos\ \vartheta - \sin\ \vartheta),$$

$$f'_\infty(\vartheta) = 4 \sin\ \vartheta \cos\ \vartheta(\cos\ \vartheta + \sin\ \vartheta)(\sin\ \vartheta - \cos\ \vartheta).$$

This implies

$$g'_\infty(\vartheta) > 0 \Leftrightarrow \cos\ \vartheta > \sin\ \vartheta,$$

$$f'_\infty(\vartheta) > 0 \Leftrightarrow \sin\ \vartheta > \cos\ \vartheta.$$

We have the same situation of the case $2<p<\infty$ and therefore the same conclusion.

This ends the proof. □

Note that we have also

Proposition 4.2: For the function $c_p(\cdot):\mathcal{P}_2^1 \to \mathbb{R}$ *one has the following properties: if* $p \in (-\infty, 0)$ *then* $c_p(\cdot)$ *is strictly Schur-increasing.*

Proof: Since

$$1 - \frac{2}{p} > 0, \quad \frac{2}{\tilde{p}} - 1 > 1 > 0, \quad 0 < \tilde{p} < 1,$$

we have the same situation of the case $2<p<\infty$ in the preceding Theorem 4.1 and therefore the same conclusion. □

If $p \in (0,1)$ then $c_p(\cdot)$ can have an arbitrary behavior (Schur-increasing, Schur-decreasing, neither of the two).

B. The general case

Definition 4.3: The α*-geometry on* $\mathcal{P}_n^1$ *is the pull-back geometry induced by the map* $A_p(\rho):\mathcal{P}_n^1 \to \mathbb{R}^n$ *defined by*

$$A_p(\rho) := \begin{cases} p\rho^{1/p}, & p \in \mathbb{R}\setminus\{0\}, \\ \log(\rho), & p = \infty, \end{cases}$$

where $p = 2/(1-\alpha)$.

Definition 4.4: We denote by $\mathrm{Scal}_p(\rho)$ *the scalar curvature of the* α*-geometry* [*with* $p = (2/(1-\alpha))$] *at the point* $\rho \in \mathcal{P}_n^1$.

Of course the cases $p=1$ (flat geometry) and $p=2$ (geometry of a $(n-1)$-dimensional sphere with radius 2) are easy to study. One has

—if $p=1$ then $\mathrm{Scal}_p(\cdot) = \mathrm{const} = 0$;

—if $p=2$ then $\mathrm{Scal}_p(\cdot) = \mathrm{const} = \frac{1}{4}(n-1)(n-2)$.

Again taking a look at the unit sphere of $\mathbb{R}^n$ equipped with L^p-norm, one can easily understand the following conjecture.

Conjecture 4.1: Suppose $n>2$. *For the function* $\mathrm{Scal}_p(\cdot):\mathcal{P}_n^1\to R$ *one has the following properties:*

—*if* $p\in(1,2)$ *then* $\mathrm{Scal}_p(\cdot)$ *is a strictly Schur-decreasing function*;

—*if* $p\in(2,+\infty]$ *then* $\mathrm{Scal}_p(\cdot)$ *is a strictly Schur-increasing function*.

C. Non-commutative case

Definition 4.5: The α*-geometry on* $\mathcal{D}_n^1$ *is the geometry induced by the pull-back of the map* $A_p(\rho):\mathcal{D}_n^1\to M_n$ *defined by*

$$A_p(\rho):=\begin{cases}p\rho^{1/p}, & p\in\mathbb{R}\setminus\{0\},\\ \log(\rho), & p=\infty,\end{cases}$$

where $p=2/(1-\alpha)$.

Since the commutativity or noncommutativity of the context will always be clear, we perform a little abuse of language in the following definition.

Definition 4.6: We denote by $\mathrm{Scal}_p(\rho)$ *the scalar curvature of the* α*-geometry* [*with* $p=(2/(1-\alpha))$] *at the point* $\rho\in\mathcal{D}_n^1$.

Again, the case $p=1$ (flat geometry) is obvious. The case $p=2$ is known (see Refs. 16 and 17 or Theorem 7.2 below), and we have

—if $p=1$ then $\mathrm{Scal}_p(\cdot)=\mathrm{const}=0$;

—if $p=2$ then $\mathrm{Scal}_p(\cdot)=\mathrm{const}=\frac{1}{4}(n^2-1)(n^2-2)$.

Motivated by the commutative plane case we formulate the following conjecture.

Conjecture 4.2: Suppose $n\geqslant 2$. *For the function* $\mathrm{Scal}_p(\cdot):\mathcal{D}_n^1\to\mathbb{R}$ *one has the following properties:*

—*if* $p\in(1,2)$ *then* $\mathrm{Scal}_p(\cdot)$ *is a strictly Schur-decreasing function*;

—*if* $p\in(2,+\infty]$ *then* $\mathrm{Scal}_p(\cdot)$ *is a strictly Schur-increasing function*.

V. MONOTONE METRICS AND THEIR SCALAR CURVATURES

A commutative Markov morphism $T:\mathbb{R}^n\to\mathbb{R}^m$ is a stochastic map. A noncommutative Markov morphism is a linear map $T:M_n\to M_m$ that is completely positive and trace-preserving (note that in the commutative case complete positivity is equivalent to positivity; see, for example, Ref. 41).

In the commutative case a monotone metric is a family of Riemannian metrics $g=\{g^n\}$ on $\{\mathcal{P}_n^1\}$, $n\in\mathbb{N}$ such that

$$g^m_{T(\rho)}(TX,TX)\leqslant g^n_\rho(X,X)$$

holds for every Markov morphism $T:\mathbb{R}^n\to\mathbb{R}^m$ and all $\rho\in\mathcal{P}_n^1$ and $X\in T_\rho\mathcal{P}_n$.

In perfect analogy, a monotone metric in the noncommutative case is a family of Riemannian metrics $g=\{g^n\}$ on $\{\mathcal{D}_n^1\}$, $n\in\mathbb{N}$ such that

$$g^m_{T(\rho)}(TX,TX)\leqslant g^n_\rho(X,X)$$

holds for every Markov morphism $T:M_n\to M_m$ and all $\rho\in\mathcal{D}_n^1$ and $X\in T_\rho\mathcal{D}_n^1$.

Let us recall that a function $f:(0,\infty)\to\mathbb{R}$ is called an operator monotone if for any $n\in\mathbb{N}$, any A, $B\in M_n$ such that $0\leqslant A\leqslant B$, the inequalities $0\leqslant f(A)\leqslant f(B)$ hold. An operator monotone function is said to be symmetric if $f(x)=xf(x^{-1})$ and normalized if $f(1)=1$. In what follows, by operator monotone we mean normalized symmetric operator monotone. With each operator monotone function f one associates also the so-called Chentsov–Morotzova function

$$c_f(x,y) := \frac{1}{yf\left(\frac{x}{y}\right)} \quad \text{for } x,y>0.$$

Define $L_\rho(A) := \rho A$, and $R_\rho(A) := A\rho$. Since L_ρ, R_ρ commute we may define $c(L_\rho, R_\rho)$. Now, we can state the fundamental theorems about monotone metrics (uniqueness and classification are up to scalars).

Theorem 5.1 (Ref. 10): *There exists a unique monotone metric on $\mathcal{P}_n^1$ given by the Fisher information.*

Theorem 5.2 (Ref. 35): *There exists a bijective correspondence between monotone metrics on $\mathcal{D}_n^1$ and operator monotone functions given by the formula*

$$\langle A,B\rangle_{\rho,f} := \mathrm{Tr}(A\cdot c_f(L_\rho,R_\rho)(B)).$$

To state the general formula for the scalar curvature of a monotone metric we need some auxiliary functions. In what follows $c', (\log c)'$ denote derivatives with respect to the first variable, and $c=c_f$.

$$h_1(x,y,z) := \frac{c(x,y)-zc(x,z)c(y,z)}{(x-z)(y-z)c(x,z)c(y,z)},$$

$$h_2(x,y,z) := \frac{(c(x,z)-c(y,z))^2}{(x-y)^2c(x,y)c(x,z)c(y,z)},$$

$$h_3(x,y,z) := z\frac{(\ln c)'(z,x)-(\ln c)'(z,y)}{x-y},$$

$$h_4(x,y,z) := z(\ln c)'(z,x)(\ln c)'(z,y),$$

$$h := h_1 - \tfrac{1}{2}h_2 + 2h_3 - h_4. \tag{5.1}$$

The functions h_i have no essential singularities if arguments coincide.

Note that $\langle A,B\rangle_\rho^f := \mathrm{Tr}(A\cdot c_f(L_\rho,R_\rho)(B))$ defines a Riemannian metric also over $\mathcal{D}_n$ ($\mathcal{D}_n^1$ is a submanifold of codimension 1). Let $\mathrm{Scal}_f(\rho)$ be the scalar curvature of $(\mathcal{D}_n,\langle\cdot,\cdot\rangle_\rho^f)$ at ρ and $\mathrm{Scal}_f^1(\rho)$ be the scalar curvature of $(\mathcal{D}_n^1,\langle\cdot,\cdot\rangle_\rho^f)$.

Theorem 5.3 (Ref. 12): *Let $\sigma(\rho)$ be the spectrum of ρ. Then*

$$\mathrm{Scal}_f(\rho) = \sum_{x,y,z\in\sigma(\rho)} h(x,y,z) - \sum_{x\in\sigma(\rho)} h(x,x,x),$$

$$\mathrm{Scal}_f^1(\rho) = \mathrm{Scal}_f(\rho) + \tfrac{1}{4}(n^2-1)(n^2-2).$$

These results have the following form in the simplest case (2×2 matrices). From Theorem 5.3 it follows that (see Ref. 3)

Corollary 5.4: If $\rho\in D_2$ has eigenvalues λ_1,λ_2, one has

$$\mathrm{Scal}(\rho) = h(\lambda_1,\lambda_1,\lambda_2) + h(\lambda_1,\lambda_2,\lambda_1) + h(\lambda_2,\lambda_1,\lambda_1) + h(\lambda_2,\lambda_2,\lambda_1) + h(\lambda_2,\lambda_1,\lambda_2) + h(\lambda_1,\lambda_2,\lambda_2) + \tfrac{3}{2}.$$

Theorem 5.5 (Ref. 3): *If $\rho\in D_2$ has eigenvalues λ_1,λ_2, and $a=2\lambda_1-1$, then*

$$r_f(a) := \mathrm{Scal}_f(\rho) = \frac{14(a-1)\left[f'\left(\frac{1-a}{1+a}\right)\right]^2}{(1+a)^3\left[f\left(\frac{1-a}{1+a}\right)\right]^2} + \frac{2(a^2+7a-6)f'\left(\frac{1-a}{1+a}\right)}{(1+a)^2 a f\left(\frac{1-a}{1+a}\right)} + \frac{8(1-a)f''\left(\frac{1-a}{1+a}\right)}{(1+a)^3 f\left(\frac{1-a}{1+a}\right)} + \frac{2(1+a)f\left(\frac{1-a}{1+a}\right)}{a^2} + \frac{3a^3+5a^2+8a-4}{2(1+a)a^2}.$$

VI. THE WYD METRICS

We are going to study a particular class of monotone metrics.

Definition 6.1:

$$f_p(x) := \frac{1}{p\tilde{p}} \cdot \frac{(x-1)^2}{(x^{1/p}-1)(x^{1/\tilde{p}}-1)}, \quad p \in \mathbb{R}\setminus\{0,1\},$$

$$f_1(x) = f_\infty(x) := \frac{x-1}{\log(x)}, \quad p = 1,\infty.$$

Obviously $f_p = f_{\tilde{p}}$ and

$$f_1 = \lim_{p\to 1} f_p = \lim_{p\to\infty} f_p = f_\infty.$$

Theorem 6.1 (Refs. 22 and 23): *The function f_p is operator monotone if and only if $p \in A := (-\infty,-1]\cup\left[\frac{1}{2},+\infty\right]$.*

Note that $p \in A$ if and only if $\alpha \in [-3,3]$.

Definition 6.2: The WYD(p) metric of parameter p is the monotone metric associated with f_p (where $p \in A$).

We have that f_{-1} is the function of the RLD-metric, $f_1 = f_\infty$ is the function of the BKM-metric, and f_2 is the function of the Wigner–Yanase metric.

In what follows $p \in (1,+\infty)$ and we use again the symbol N_p to denote M_n with the norm

$$\|A\|_{N^p} = p^{-1}(\mathrm{Tr}(|A|^p))^{1/p}.$$

All the commutative construction of Example 3.2 goes through. The following Proposition is the noncommutative analogous of Proposition 3.1 (see also Refs. 16, 21, 23, 28, and 37).

Proposition 6.2 (Ref. 18): Let $\varphi: \rho \in \mathcal{D}_n^1 \to p\rho^{1/p} \in N_p$ be the Amari embedding. The dualized pull-back

$$\langle A,B\rangle_\rho^\varphi := \langle A,B\rangle_\rho^{\varphi, J\circ\varphi} = \langle D_\rho\varphi(A), D_\rho(J\circ\varphi)(B)\rangle$$

coincides with the Wigner–Yanase–Dyson information.

VII. KNOWN RESULTS ON MONOTONICITY

In this short section we review what is known about monotonicity of scalar curvature for monotone metrics. This is useful to emphasize that, up to now, no examples exist of a monotone metrics with Schur-increasing (or Schur-decreasing) scalar curvature.

The Bures or SLD metric is the monotone metric associated with the function $f=(1+x)/2$.

Theorem 7.1 (Refs. 11 and 13): *The scalar curvature of SLD metric is neither Schur-increasing nor Schur-decreasing.*

Proof: By Ref. 11 the SLD-metric has a global minimum at the most mixed state for any n. On

the other hand (this is due to Ref. 13), if $\sigma=\mathrm{diag}(\frac{2}{9},\frac{1}{9},\frac{2}{3})$ and $\rho=\mathrm{diag}(\frac{1}{6},\frac{1}{6},\frac{2}{3})$ then $\rho\succ\sigma$. Using Theorem 5.3 one can calculate $\mathrm{Scal}(\sigma)=3078/25>3447/28=\mathrm{Scal}(\rho)$ and so the conclusion follows. □

Theorem 7.2 (Ref. 17): *The scalar curvature of WY metric is a constant equal to* $\frac{1}{4}(n^2-1)\times(n^2-2)$.

VIII. A CONJECTURE ON THE WYD SCALAR CURVATURE AND ITS RELATION TO PETZ CONJECTURE

In this section we want to suggest that a whole family of monotone metrics with Schur-increasing scalar curvature may exist.

Conjecture 8.1: There exist $\varepsilon>0$ *such that for* p *in the interval* $I:=(1,1+\varepsilon)$ *the scalar curvature of the* WYD(p) *metrics is a Schur-increasing function.*

Conjecture 8.2 (Petz conjecture): The scalar curvature of BKM metric is a Schur-increasing function. This can be rephrased as

$$\rho\succ\sigma\Rightarrow \mathrm{Scal}_{f_1}(\rho)\geqslant \mathrm{Scal}_{f_1}(\sigma).$$

The motivations for Conjecture 8.1 are the following. The WYD(p) metrics come from the dualized pull-back of Proposition 6.2. This means that the WYD(p) metrics depend, indeed, on the pair $(p,\tilde{p})$. Note that when p is in the Schur-decreasing region $(1,2)$ we have that $\tilde{p}$ is in the Schur-increasing region $(2,+\infty)$ (Theorem 4.1, Conjectures 4.1, 4.2). When p approaches 1 then $\tilde{p}$ goes to infinity. Near the boundary values $\{1,+\infty\}$ the increasing–decreasing "symmetry" should be broken: in this case WYD(p) geometry comes from a geometry converging to a flat limit ($p\to1$) and a geometry converging to a (conjectured) Schur-increasing scalar curvature ($\tilde{p}\to\infty$).

Theorem 8.1: *If Conjecture 8.1 is true then Conjecture 8.2 (Petz conjecture) is true.*

Proof: For an arbitrary manifold M let us denote by $\mathcal{M}(M)$ the manifold of Riemannian metrics of M. If $\rho\in M$ is fixed and $g\in\mathcal{M}(M)$ then the function $F_\rho(\cdot):\mathcal{M}(M)\to\mathbb{R}$ defined by $F_\rho(g):=\mathrm{Scal}_g(\rho)$ is a smooth function (see Refs. 29 and 33). Identifying f_p with the metric

$$\langle A,B\rangle_{\rho,f_p}:=\mathrm{Tr}(Ac_{f_p}(L_\rho,R_\rho)(B)),$$

we may consider the function $p\to f_p$ as a continuous curve in $\mathcal{M}(\mathcal{D}_n^1)$. This implies that, by composition, the function $p\to\mathrm{Scal}_{f_p}(\rho)$ is a real, continuous function for each $\rho\in\mathcal{D}_n^1$. Suppose now that Conjecture 8.1 is true.

We have for arbitrary $\rho,\sigma\in\mathcal{D}_n^1$, such that $\rho\succ\sigma$

$$\mathrm{Scal}_{f_1}(\rho)=\lim_{p\to1}\mathrm{Scal}_{f_p}(\rho)\geqslant\lim_{p\to1}\mathrm{Scal}_{f_p}(\sigma)=\mathrm{Scal}_{f_1}(\sigma).$$

But, this is precisely the Petz conjecture. □

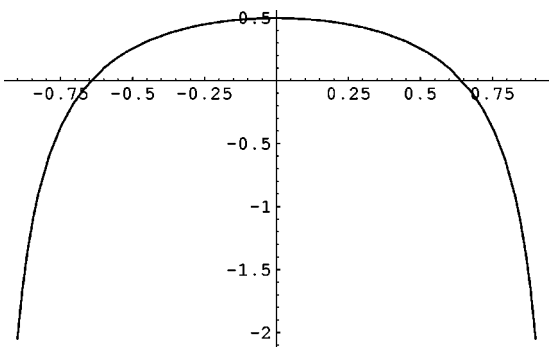

FIG. 1. Case $p=1+10^{-1}$.

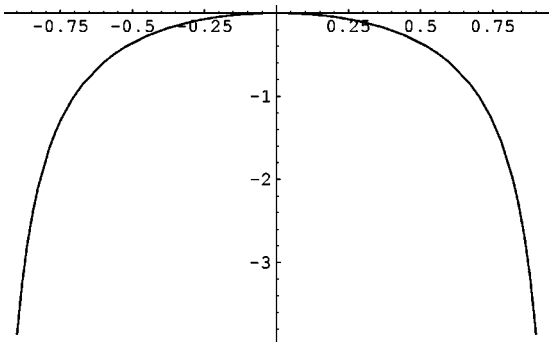

FIG. 2. Case $p=1+10^{-6}$.

A. Numerical results

Conjecture 8.1 would have many consequences. An example is the following theorem.

Theorem 8.2: *Conjecture 8.1 implies that there exists* $\varepsilon>0$ *such that for* $p\in(1,1+\varepsilon)$ *the functions* $r_p:=r_{f_p}$ *of Theorem 5.5 are concave and have their maximum at zero.*

Proof: It follows immediately by Theorem 5.5. □

Using MATHEMATICA, one has the following graphs for the function r_p:

Case $p=1+10^{-1}$; see Fig. 1;

Case $p=1+10^{-6}$; see Fig. 2.

Let us emphasize what we said in the Introduction: a recent result of Andai[3] shows the nontriviality of the above behavior. Indeed, also in the 2×2 case there exist many monotone metrics with nonincreasing scalar curvature.

ACKNOWLEDGMENTS

It is a pleasure to thank J. Dittmann for discussions on the subject and especially for the proof of Theorem 7.1. We are indebted to P. Michor for some references and comments on scalar curvature.

Large-time asymptotics for nonlinear diffusions: the initial-boundary value problem

F. Salvarani and G. Toscani
Dipartimento di Matematica, Università degli Studi di Pavia, Via Ferrata, 1 - 27100 Pavia, Italy

(Received 21 April 2004; accepted 29 September 2004; published online 27 January 2005)

In this paper we investigate the large-time behavior of solutions to the first initial-boundary value problem for the nonlinear diffusion $u_t=(u^m)_{xx}$, $m>0$. In particular, we prove exponential decay of $u(x,t)$ towards its own steady state in L^1-norm for long times and we give an explicit upper bound for the rate of decay. The result is based on a new application of entropy estimates, and on detailed lower bounds for the entropy production in this situation. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1828587]

I. INTRODUCTION

In recent years, entropy dissipation methods (also called *entropy–entropy production* methods) have been successfully applied to reckon decay rates towards equilibrium of weak solutions to Cauchy problems for nonlinear second- and fourth-order parabolic equations and their systems.[1,3,8–10,13,18]

However only rarely, at least to our knowledge, such strategies have been applied to the study of initial-boundary value problems with nonhomogeneous or nonperiodic boundary conditions.[17]

The main reason for this fact relies in the lack of mass conservation, which is one of the main ingredients to handle the problem and to obtain L^1 estimates from the entropy decay by means of Csiszár–Kullback inequalities.[2,12]

An entropy dissipation method to handle almost general Dirichlet boundary conditions will be developed in this paper. Our results show that entropy methods can be fruitfully applied also to initial-boundary value problems with nonhomogeneous Dirichlet boundary conditions.

In more details, we will be concerned with the large-time behavior of the solution to the initial-boundary value problem,

$$u_t(x,t) = [u^m(x,t)]_{xx}, \quad (x,t) \in \Omega \times (0,+\infty), \tag{1}$$

$$u(-L,t) = \varphi_-, \quad u(L,t) = \varphi_+, \tag{2}$$

$$u(x,0) = u_0(x) \tag{3}$$

in $\Omega=(-L,L)$, $L>0$, with $m>0$. The initial data $u_0(x)$ and the boundary conditions φ_+ and φ_- are non-negative real constants satisfying the hypotheses stated in the following definition.

Definition 1.1: The initial and boundary conditions of problem (1)–(3) are said to be admissible if and only if

(1) φ_+ *and* φ_- *are non-negative and* $(\varphi_+ + \varphi_-)>0$*;*
(2) $u_0(x) \in C([-L,L])$ *is a non-negative function which satisfies the compatibility conditions* $u_0(-L)=\varphi_-$ *and* $u_0(L)=\varphi_+$.

While the large-time behavior of solutions to the Cauchy problem for the nonlinear equation (1) was intensively studied for many years (cf. the excellent survey paper of Vázquez[19] and the references therein), the behavior of solutions to the initial-boundary value problem with nonho-

mogenous Dirichlet boundary conditions was less studied (see Refs. 4 and 7; results on the logarithmic nonlinearity can however be found in Ref. 6). Other related results in bounded domains deserve to be referred in. A complete study of the asymptotic behavior of solutions to the initial-Dirichlet problem with homogeneous boundary condition has been recently presented by Vázquez.[20] However, the techniques used there are different from ours. The question of the possible application of the entropy method to the study of the problem treated in Ref. 20 is to our knowledge open in higher dimensions. In dimension one, the analysis of the asymptotic behavior with homogeneous boundary conditions (namely when $\varphi_+ = \varphi_- = 0$) can be performed, by means of the entropy dissipation method, in a rather standard way. We focus therefore our attention only to the case when at least one of the boundary conditions does not vanish.

As we will discuss later on, our method works in the whole range $m > 0$, covering both the fast diffusion equation ($m < 1$) and the porous media equation ($m > 1$).

In order to study the large-time behavior, we shall analyze the time-decay of a suitable relative entropy, where the word "relative" means *relative to the steady state* of Eqs. (1)–(3).

The method introduced in this work, useful to handle second-order diffusions in one dimension, cannot be easily generalized due to a main fact. The entropy associated to the steady state is explicit as the steady state is; in the general case (higher dimensions or higher order diffusions), the steady states are not explicit nor are the entropy functionals. Therefore, the application of the entropy–entropy production method based on the knowledge of the derivative in time of the functional becomes rather difficult.

The results on the large-time behavior will be reached by steps.

The existence and uniqueness theorem for Eqs. (1)–(3) will be stated in Sec. II.

Section III deals with the study of the entropy functional for the same initial-boundary value problem. The sublinear case (i.e., $0 < m \leqslant 1$) and the superlinear case ($m > 1$) lead to different relative entropies, and are treated in a slightly different way. It is interesting to remark that, in the limit $m \to 1$, the entropy functionals of both the superlinear case and the sublinear cases coincide, but the rate of convergence obtained in the linear case as limit of the nonlinear case is worse than the rate obtained from a direct inspection.

The case of strictly positive initial-boundary conditions is considered in Sec. IV, where the rate of decay of the solution towards the steady state is discussed, both in the sublinear case and in the superlinear one.

Finally, the general case of non-negative initial-boundary conditions, obtained by removing the limitation on the data, is studied in Sec. V.

II. MAIN PROPERTIES OF THE SOLUTION

We will start the study of our problem by discussing the well posedness of equations (1)–(3) and the main properties of the solution. Following Ref. 14, the precise characterization of a weak solution to problem (1)–(3) is obtained by the following definition.

Definition 2.1: A function $u(x,t)$ defined on $\overline{\Omega} \times [0,T]$ is a weak solution of problem (1)–(3) if and only if

(1) *$u(x,t)$ is real, non-negative and continuous on $\overline{\Omega} \times [0,T]$;*
(2) *$u(-L,t) = \varphi_-$ and $u(L,t) = \varphi_+$ for all $t \in [0,T]$;*
(3) *$u^m(x,t)$ has a square-integrable generalized derivative with respect to x in $\Omega \times [0,T]$;*
(4) *$u(x,t)$ satisfies the identity*

$$\int_0^T \int_\Omega [(u^m)_x \phi_x - u\phi_t] \mathrm{d}x\, \mathrm{d}t = \int_\Omega \phi(x,0) u_0(x) \mathrm{d}x, \tag{4}$$

for all $\phi \in C(\overline{\Omega} \times [0,T]) \cap H^1(\Omega \times (0,T))$ which vanish for $|x| = L$ and for $t = T$.

The main result of this section is due to Gilding.[14–16] We remark that, as far as the well-posedness of (1)–(3) is concerned, more recent contributions are present in the literature. We refer

in particular to the paper of Bénilan and Touré,[5] where well-posedness is investigated in the framework of the nonlinear semigroup theory. Gilding proved (in a more general form) the following theorem.

Theorem 2.1: *Let us consider the initial-boundary value problem (1)–(3) with admissible (in the sense of Definition 1.1) non-negative initial data* $u(x,0)=u_0(x)\in C(\overline{\Omega})$ *and boundary conditions* $u(-L,t)=\varphi_-$ *and* $u(L,t)=\varphi_+$.

Then problem (1)–(3) has exactly one and only one non-negative weak solution $u(x,t)$.

Moreover, $u(x,t)$ *is a classical solution in a neighborhood of any point* $(x_0,t_0)\in\overline{\Omega}\times[0,T]$ *where* $u(x_0,t_0)>0$.

Finally, if we denote with $u_1(x,t)$ *and* $u_2(x,t)$ *two solutions of Eq. (1) with initial and boundary conditions* $u_{0,1}(x)$, $\varphi_-^{(1)}$, $\varphi_+^{(1)}$ *and* $u_{0,2}(x)$, $\varphi_-^{(2)}$, $\varphi_+^{(2)}$, *respectively,*

$$u_{0,1}(x)\leqslant u_{0,2}(x) \text{ for all } x\in\overline{\Omega}$$

and

$$\varphi_-^{(1)}\leqslant\varphi_-^{(2)},\quad \varphi_+^{(1)}\leqslant\varphi_+^{(2)},$$

imply $u_1(x,t)\leqslant u_2(x,t)$ *for all* $(x,t)\in\overline{\Omega}\times[0,T]$.

The stationary state for problem (1)–(3) can be easily found. We have the following lemma.

Lemma 2.1: Problem (1)–(2) admits one and only one stationary solution. This solution is given by

$$\overline{u^m}(x)=ax+b, \tag{5}$$

where

$$a=\frac{1}{2L}[\varphi_+^m-\varphi_-^m],\quad b=\frac{1}{2}[\varphi_+^m+\varphi_-^m].$$

Proof: The stationary solution of Eqs. (1)–(3) satisfies

$$\overline{u^m}(x)_{xx}=0 \quad \text{in } \Omega, \tag{6}$$

$$\overline{u}(-L)=\varphi_-,\quad \overline{u}(L)=\varphi_+. \tag{7}$$

Integration of (6), together with the use of boundary conditions (7) gives (5). □

Obviously, when $\varphi_+=\varphi_-=0$, we have that $\overline{u}(x)=0$ for all $x\in\overline{\Omega}$. Since this case can be easily solved directly, from now on we will suppose that at least one of the boundary conditions φ_+ or φ_- does not vanish.

III. THE ENTROPY FUNCTIONAL

In order to prove the exponential decay of the solution of problem (1)–(3), we will consider an auxiliary problem and use an entropy monotonicity approach.

We suppose from now on and until the end of Sec. IV that both the initial and boundary conditions are not allowed to take the value zero. If it were the case, we would consider a modified problem, obtained by lifting up the data in a suitable way, as we will see in Sec. V.

Let us define $f=u/\overline{u}$; by the hypotheses on φ_+ and φ_-, $\overline{u}(x)\neq 0$ for all $x\in\Omega$, so that f is always well defined.

It is immediate to show that f satisfies the initial-boundary value problem,

$$\overline{u}f_t=2a(f^m)_x+(ax+b)(f^m)_{xx}, \tag{8}$$

$$f(-L,t)=1,\quad f(L,t)=1, \tag{9}$$

$$f(x,0) = u_0(x)/\overline{u}(x) \tag{10}$$

in Ω.

It will be clear later on that it is convenient to consider separately the two cases $0<m\leqslant 1$ and $m>1$, respectively. Both cases, however, can be treated by studying the time decay of a suitable entropy, defined by the convex functional,

$$H(f) = \int_\Omega \Phi(f)\overline{u}\,\mathrm{d}x, \tag{11}$$

where the convex function Φ, which is defined in the next sections, depends on the case we are considering.

A. The sublinear case

In the sublinear case (i.e., $0<m\leqslant 1$) we consider the convex function Φ given by

$$\Phi(f) = \left[\frac{1}{m(2-m)(3-m)}f^{3-m} - \frac{1}{m(2-m)}f + \frac{1}{m(3-m)}\right]. \tag{12}$$

Note that the linear part of Φ is chosen so that $\Phi(1)=\Phi'(1)=0$.

We prove the following lemma.

Lemma 3.1: Let $u_0(x)$, φ_-, φ_+ be admissible initial-boundary conditions, and moreover be such that φ_-, $\varphi_+>0$ and $u_0(x)$ is strictly positive for all $x\in\Omega$. Then, if $0<m\leqslant 1$, the functional $H(f)$, with $\Phi(f)$ given by (12), is an entropy for problem (8)–(10), that is

$$\frac{\mathrm{d}H(f)}{\mathrm{d}t} = -I(f),$$

where the (non-negative) entropy production $I(f)$ is

$$I(f) = \int_\Omega \overline{u}^m (f_x)^2\,\mathrm{d}x. \tag{13}$$

Proof: Let us multiply both sides of Eq. (8) by $\Phi'(f)$. Integrating over Ω with respect to x, we obtain

$$\int_\Omega \overline{u}\Phi'(f)\frac{\partial f}{\partial t}\mathrm{d}x = \int_\Omega \Phi'(f)(ax+b)(f^m)_{xx}\,\mathrm{d}x.$$

Let us integrate by parts the right-hand side. Thanks to the boundary conditions (9) and to the property $\Phi'(1)=0$ we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \overline{u}\Phi(f)\mathrm{d}x = -\int_\Omega [\overline{u}^m\Phi'(f)]_x (f^m)_x\,\mathrm{d}x = -m\int_\Omega \overline{u}^m\Phi''(f)f^{m-1}(f_x)^2\,\mathrm{d}x.$$

Since $m\Phi''(f)f^{m-1}=1$, the lemma is fully proven. □

B. The superlinear case

In the superlinear case (which corresponds to the choice $m>1$), we introduce the function Φ given by

$$\Phi(f) = \left[\frac{m+f^{m+1}}{m+1} - f\right]. \tag{14}$$

As in the previous case, $\Phi(1)=\Phi'(1)=0$.

We prove the following lemma.

Lemma 3.2: Let $u_0(x)$, φ_-, φ_+ be admissible initial-boundary conditions, and moreover be such that φ_-, $\varphi_+ > 0$ and $u_0(x)$ is strictly positive for all $x \in \Omega$.

Then, if $m > 1$, the functional

$$H(f) = \int_\Omega \Phi(f)\overline{u}\,\mathrm{d}x, \tag{15}$$

where $\Phi(f)$ is given in (14), is an entropy for problem (8)–(10), that is

$$\frac{\mathrm{d}H(f)}{\mathrm{d}t} = -I(f),$$

and the (non-negative) entropy production is

$$I(f) = \int_\Omega \overline{u}^m (f^m)_x^2\,\mathrm{d}x. \tag{16}$$

Proof: Let us multiply both sides of Eq. (8) by $\Phi'(f) = (f^m - 1)$ and integrate over Ω with respect to x,

$$\int_\Omega \overline{u}\Phi'(f)\frac{\partial f}{\partial t}\mathrm{d}x = \int_\Omega \Phi'(f)[2a(f^m)_x + (ax+b)(f^m)_{xx}]\mathrm{d}x.$$

Integrating by parts on the right-hand side, taking into account the boundary conditions (9) and the property $\Phi'(1) = 0$ we obtain

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \overline{u}\Phi(f)\mathrm{d}x &= 2a\int_\Omega (f^m - 1)(f^m)_x\,\mathrm{d}x + \int_\Omega \overline{u}^m (f^m - 1)(f^m)_{xx}\,\mathrm{d}x \\ &= -\int_\Omega (f^m)_x[\overline{u}^m (f^m - 1)]_x \mathrm{d}x = -\int_\Omega \overline{u}^m (f^m)_x^2\,\mathrm{d}x,\end{aligned} \tag{17}$$

which is the thesis of the lemma. □

IV. CONVERGENCE FOR STRICTLY POSITIVE INITIAL DATA

In order to investigate the entropy decay rate, we look now for lower bounds to the entropy production functional

$$I(f) = \int_\Omega \overline{u}^m (f^n)_x^2\,\mathrm{d}x,$$

with $m > 0$ and $n \geqslant 1$. In order to achieve this goal, we prove the following Lemma.

Lemma 4.1: Let f belong to $H^1(\Omega)$, and let $\overline{u}(x)$ be the stationary solution of problem (6)–(7). Then, for any $m > 0$ and $n \geqslant 1$,

$$\int_\Omega \overline{u}^m [(f^n)_x]^2\,\mathrm{d}x \geqslant \frac{1}{16\,L^2} J(\varphi_+, \varphi_-)\left(\int_\Omega |u - \overline{u}|\mathrm{d}x\right)^2,$$

where

$$J(\varphi_+,\varphi_-)=\begin{cases}\dfrac{1}{mL}\left[\dfrac{\varphi_+^m-\varphi_-^m}{\varphi_+^2-\varphi_-^2}\right] & \text{if} \quad \varphi_+\neq\varphi_-,\\ \dfrac{1}{2L}\varphi^{m-2} & \text{if} \quad \varphi_+=\varphi_-=\varphi.\end{cases}$$

Proof: Let us first suppose that $\overline{u}^m$ is nondecreasing. The opposite case can be treated in the same way.

Given any function $g\in H^1(\Omega)$, such that $g(L)=1$,

$$\begin{aligned}\|\overline{u}(g-1)\|_{L^1}&\leqslant\int_{-L}^{L}\overline{u}(x)\int_x^L|g'(y)|\mathrm{d}y\,\mathrm{d}x\leqslant\int_{-L}^{L}\overline{u}(x)^{(2-m)/2}\int_x^L\overline{u}(y)^{m/2}|g'(y)|\mathrm{d}y\,\mathrm{d}x\\&\leqslant\int_{-L}^{L}\overline{u}(x)^{(2-m)/2}\left(\int_x^L\overline{u}(y)^m|g'(y)|^2\,\mathrm{d}y\right)^{1/2}(L-x)^{1/2}\,\mathrm{d}x\\&\leqslant\|\overline{u}^{m/2}g'\|_{L^2}\left(\int_{-L}^{L}\overline{u}(x)^{2-m}\,\mathrm{d}x\right)^{1/2}\left(\int_{-L}^{L}(L-x)\mathrm{d}x\right)^{1/2}.\end{aligned}\tag{18}$$

For any $m>0$, the function $\overline{u}^{2-m}=(ax+b)^{2/m-1}$ is integrable on Ω. If we denote

$$J(\varphi_+,\varphi_-)=\left(\int_\Omega(ax+b)^{2/m-1}\,\mathrm{d}x\right)^{-1},$$

we have in fact that

$$J(\varphi_+,\varphi_-)=\begin{cases}\dfrac{1}{mL}\left[\dfrac{\varphi_+^m-\varphi_-^m}{\varphi_+^2-\varphi_-^2}\right] & \text{if} \quad \varphi_+\neq\varphi_-,\\ \dfrac{1}{2L}\varphi^{m-2} & \text{if} \quad \varphi_+=\varphi_-=\varphi.\end{cases}$$

Hence, (18) implies

$$\int_\Omega\overline{u}(x)^m|g'(x)|^2\,\mathrm{d}x\geqslant\frac{J(\varphi_+,\varphi_-)}{2L^2}\|\overline{u}(g-1)\|_{L^1}^2.\tag{19}$$

Next, if $n\geqslant1$, we have $|r^n-1|\geqslant|r-1|$ for $r\geqslant0$. Consequently,

$$\frac{J(\varphi_+,\varphi_-)}{2L^2}\|\overline{u}(f-1)\|_{L^1}^2\leqslant\frac{J(\varphi_+,\varphi_-)}{2L^2}\|\overline{u}(f^n-1)\|_{L^1}^2\leqslant\int_\Omega\overline{u}(x)^m[(f^n(x))_x]^2\,\mathrm{d}x.\tag{20}$$

□

Remark 4.1: We remark that $J(\varphi_+,\varphi_-)$ is monotone decreasing with respect to m. This is consistent with the fact that we expect a faster convergence towards equilibrium in the fast diffusion case.

Remark 4.2: The proof of Lemma 4.1, which is nothing but the proof of a weighted Poincaré inequality, takes essential advantage from the simple form of the steady state $\overline{u}$. Of course, other proofs can be found in the literature, and the constant could be improved. Recent results on weighted Poincaré inequalities are due to Chua and Wheeden.[11]

In order to obtain a proof of the exponential convergence of the solution $u(x,t)$ to problem (1)–(3) towards its stationary state $\overline{u}(x)$ when $u_0(x)>0$, it remains to show that the relative entropy satisfies an inequality of the Csiszár–Kullback type.[12] This result is contained in the following lemma.

Lemma 4.2: Let $f(x,t)$ be the solution of problem (8)–(10), $\overline{u}(x)$ the solution of problem (6)–(7). Let

$$\xi(m) = \min_{0\leqslant\alpha\leqslant 1} \frac{1-\alpha}{\Phi(\alpha)} + \frac{2}{\Phi''(\alpha)}, \tag{21}$$

where Φ is given by (12) if $m<1$, or by (14) if $m\geqslant 1$. Then the following Csiszár–Kullback-type inequality holds:

$$\int_\Omega \Phi(f)\overline{u}\,\mathrm{d}x \geqslant \frac{\xi(m)}{\int_\Omega \overline{u}\,\mathrm{d}x}\left(\int_\Omega |u-\overline{u}|\mathrm{d}x\right)^2. \tag{22}$$

Proof: First, we note that the function

$$\Psi(r) = \frac{\Phi(r)}{1-r}, \quad 0\leqslant r\leqslant 1,$$

is nonincreasing. Since

$$\Psi'(r) = \frac{\Phi'(r)}{1-r} + \frac{\Phi(r)}{(1-r)^2} = \frac{1}{(1-r)^2}[\Phi'(r)(1-r)+\Phi(r)],$$

it is enough to show that the function $z(r)=\Phi'(r)(1-r)+\Phi(r)$ is nonpositive in the set $0\leqslant r\leqslant 1$. This follows easily considering that $\Phi(1)=0$, while the convexity of Φ implies

$$z'(r) = \Phi''(r)(1-r) \geqslant 0.$$

Fix $\alpha\in(0,1)$. Since Ψ is nonincreasing, and

$$\int_{\{f<\alpha\}} \overline{u}|f-1|\mathrm{d}x \leqslant \left(\int_{\{f<\alpha\}} \overline{u}|f-1|\mathrm{d}x\right)^{1/2}\left(\int_\Omega \overline{u}\,\mathrm{d}x\right)^{1/2},$$

we obtain

$$\int_{\{f<\alpha\}} \overline{u}\Phi(f)\mathrm{d}x \geqslant \Psi(\alpha)\int_{\{f<\alpha\}} \overline{u}|f-1|\mathrm{d}x \geqslant \frac{\Psi(\alpha)}{\|\overline{u}\|_{L^1}}\left(\int_{\{f<\alpha\}} \overline{u}|f-1|\mathrm{d}x\right)^2. \tag{23}$$

On the other hand, since both $\Phi(1)=0$ and $\Phi'(1)=0$, by the monotonicity of Φ'' we have

$$\int_{\{f\geqslant\alpha\}} \overline{u}\Phi(f)\mathrm{d}x = \int_{\{f\geqslant\alpha\}} \overline{u}\frac{(f-1)^2}{2}\Phi''(1+\vartheta(f)(f-1))\mathrm{d}x \geqslant \frac{\Phi''(\alpha)}{2}\int_{\{f\geqslant\alpha\}} \overline{u}(f-1)^2\,\mathrm{d}x$$

$$\geqslant \frac{\Phi''(\alpha)}{2\|\overline{u}\|_{L^1}}\left(\int_{\{f\geqslant\alpha\}} \overline{u}|f-1|\mathrm{d}x\right)^2. \tag{24}$$

Grouping together inequalities (23) and (24) we finally obtain

$$\|u-\overline{u}\|_{L^1}^2 \leqslant 2\left(\int_{\{f<\alpha\}} \overline{u}|f-1|\mathrm{d}x\right)^2 + 2\left(\int_{\{f\geqslant\alpha\}} \overline{u}|f-1|\mathrm{d}x\right)^2 \leqslant 2\|\overline{u}\|_{L^1}\left(\frac{1-\alpha}{\Phi(\alpha)} + \frac{2}{\Phi''(\alpha)}\right)\int_\Omega \overline{u}\Phi(f)\mathrm{d}x. \tag{25}$$

Optimizing with respect to α we conclude the proof. □

The previous results are at the basis of the following theorem.

Theorem 4.3: *Let $u(x,t)$ be the solution of problem (1)–(3), where $u_0(x)$, φ_- and φ_+ are strictly positive, and $H(u_0/\overline{u})$ is bounded. Then $u(x,t)$ decays exponentially fast towards the stationary solution $\overline{u}(x)$ in L^1-norm, and the following bound holds*:

$$\left(\int_\Omega |u-\overline{u}|\mathrm{d}x\right)^2 \leqslant \frac{\int_\Omega \overline{u}\,\mathrm{d}x}{\xi(m)} H(u_0/\overline{u})\exp\left[-\frac{\int_\Omega \overline{u}\,\mathrm{d}x}{16L^2\xi(m)}\left(\int_\Omega \overline{u}^{2/m-1}\,\mathrm{d}x\right)^{-1} t\right]. \tag{26}$$

Proof: In consequence of Lemmas 3.1, 3.2, 4.1, and 4.2 we deduce that

$$\left(\int_\Omega |u-\overline{u}|\mathrm{d}x\right)^2 \leqslant \frac{\int_\Omega \overline{u}\,\mathrm{d}x}{\xi(m)}\left[H(u_0/\overline{u}) - \frac{1}{16L^2}\left(\int_\Omega \overline{u}^{2/m-1}\,\mathrm{d}x\right)^{-1}\int_0^t\left(\int_\Omega |u-\overline{u}|\mathrm{d}x\right)^2 \mathrm{d}t'\right]. \tag{27}$$

Gronwall's lemma then implies (26). □

V. NON-NEGATIVE INITIAL-BOUNDARY CONDITIONS

In this section we briefly sketch the procedure to adopt when the initial and boundary conditions are non-negative only, provided that the stationary solution $\overline{u}(x)$ is not identically zero on $\overline{\Omega}$. This corresponds to suppose that $(\varphi_+ + \varphi_-) > 0$.

We consider two cases. In the first one, the boundary conditions are strictly positive, but the initial data can vanish somewhere on Ω. In the second one we admit the possibility of a vanishing boundary condition in $x=-L$ or in $x=L$.

We note that, while in the former case the result is a simple corollary of Theorem 4.3, in the latter the regularity of the initial data plays an important role.

A. Non-negative initial data

Let $u(x,t)$ be the solution of Eqs. (1)–(3), with admissible non-negative initial datum $u(x,0)$, and boundary conditions $u(-L,t)=\varphi_-$ and $u(L,t)=\varphi_+$ for all $t>0$, such that $u_0(-L)=\varphi_-$ and $u_0(L)=\varphi_+$, where φ_+ and φ_- are strictly positive.

To prove the exponential decay also in this case, we lift up the initial data of a small quantity, depending on a parameter $\varepsilon>0$ and vanishing as $\varepsilon\to 0$, and then pass to the limit.

We denote by $u_\varepsilon(x,t)$ the solution of the lifted problem, where the initial data are

$$u_\varepsilon(x,0) = u_{0,\varepsilon}(x) = u_0(x) + \varepsilon\cos\left(\frac{\pi}{2L}x\right).$$

The corresponding stationary solutions remains unchanged. Thanks to Theorem 4.3,

$$\|u_\varepsilon(x,t)-\overline{u}(x)\|_1^2 \leqslant \frac{\int_\Omega \overline{u}\,\mathrm{d}x}{\xi(m)} H(u_{0,\varepsilon}/\overline{u})\exp\left[-\frac{\int_\Omega \overline{u}\,\mathrm{d}x}{16L^2\xi(m)}\left(\int_\Omega \overline{u}^{2/m-1}\,\mathrm{d}x\right)^{-1} t\right].$$

In the sublinear case,

$$H(u_{0,\varepsilon}/\overline{u}) = \int_\Omega\left[\frac{1}{m(2-m)(3-m)} f_\varepsilon^{3-m} - \frac{1}{m(2-m)} f_\varepsilon + \frac{1}{m(3-m)}\right]\overline{u}\,\mathrm{d}x,$$

with $f_\varepsilon = u_{0,\varepsilon}(x)/\overline{u}$.

Since f_ε decreases as $\varepsilon\to 0^+$, and the integrand is continuous and well defined on $\overline{\Omega}$, we can apply the monotone convergence theorem to obtain

$$\lim_{\varepsilon\to 0^+}\int_\Omega f_\varepsilon^{3-m}\overline{u}\,dx=\int_\Omega\left[\frac{u_0(x)}{\overline{u}}\right]^{3-m}\overline{u}\,dx.$$

The same argument shows that also

$$\lim_{\varepsilon\to 0^+}\int_\Omega f_\varepsilon\overline{u}\,dx=\int_\Omega u_0\,dx.$$

Hence,

$$\lim_{\varepsilon\to 0}H(u_{0,\varepsilon}/\overline{u})=H(u_0/\overline{u}).$$

The superlinear case can be equally treated. We proved the following theorem.

Theorem 5.1: *Let $u(x,t)$ be the solution of problem (1)–(3), where the initial data are admissible, φ_- and φ_+ are strictly positive, and $H(u_0/\overline{u})$ is bounded. Then $u(x,t)$ decays exponentially fast towards the stationary solution $\overline{u}(x)$ in L^1-norm, and bound (26) holds.*

B. Non-negative initial-boundary conditions

More involved is the case when we allow that a boundary condition can be zero, which is the most general situation taken into account in the paper.

In what follows, we will suppose that the vanishing boundary condition is in $x=-L$ (i.e., $\varphi_-=0$); the other case is specular.

Denote by $u(x,t)$ the solution of Eqs. (1)–(3), with admissible initial data $u(x,0)=u_0(x)\geqslant 0$ and boundary conditions $u(-L,t)=0$ and $u(L,t)=\varphi_+$ for all $t>0$, such that $u_0(-L)=0$ and $u_0(L)=\varphi_+$, where $\varphi_+>0$.

Given a positive constant $\varepsilon<\varphi_+$, we introduce a lifted problem where $\varphi_-=\varepsilon$. The corresponding stationary solutions are given by

$$\overline{u}^m(x)=ax+b \text{ and } \overline{u}_\varepsilon^m(x)=a_\varepsilon x+b_\varepsilon,$$

respectively, where

$$a_\varepsilon=\frac{1}{2L}[\varphi_+^m-\varepsilon^m],\quad b_\varepsilon=\frac{1}{2}[\varphi_+^m+\varepsilon^m].$$

Moreover, we lift the initial value $u_0(x)$ in the following way:

$$u_{0,\varepsilon}(x)=\overline{u_\varepsilon}(x)\quad \text{if}\quad -L\leqslant x<-L+\varepsilon,$$

$$u_{0,\varepsilon}(x)=u_\varepsilon^*(x)\quad \text{if}\quad -L+\varepsilon\leqslant x<-L+\varepsilon+\varepsilon^{m+1}.$$

In the above formula $0\leqslant u_\varepsilon^*(x)\leqslant C$ is any function in $C(\overline{\Omega})$ which connects continuously $\overline{u_\varepsilon}(-L+\varepsilon)$ with $u_0(-L+\varepsilon+\varepsilon^{m+1})$. Finally

$$u_{0,\varepsilon}(x)=u_0(x)\quad \text{if}\quad -L+\varepsilon+\varepsilon^{m+1}\leqslant x\leqslant L.$$

Let $u_\varepsilon(x,t)$ be the solution of the lifted problem, with initial data $u_\varepsilon(x,0)=u_{0,\varepsilon}(x)$ and boundary conditions $u_\varepsilon(-L,t)=\varepsilon$ and $u_\varepsilon(L,t)=\varphi_+$, where $\varepsilon>0$. Since $u_\varepsilon(x,t)$ satisfies the conditions of Theorem 5.1, we have immediately that

$$\|u_\varepsilon(x,t)-\overline{u_\varepsilon}(x)\|_1^2 \leqslant \frac{\int_\Omega \overline{u_\varepsilon}\,\mathrm{d}x}{\xi(m)} H(u_{0,\varepsilon}/\overline{u_\varepsilon}) \exp\left[-\frac{\int_\Omega \overline{u_\varepsilon}\,\mathrm{d}x}{16\,L^2\xi(m)}\left(\int_\Omega \overline{u_\varepsilon}^{2/m-1}\,\mathrm{d}x\right)^{-1} t\right].$$

Since all integrals containing $\overline{u_\varepsilon}$ converge to the right limit as $\varepsilon\to 0$, the only problem comes out from the limit of the lifted entropy, which in the superlinear case reads

$$H(u_{0,\varepsilon}/\overline{u_\varepsilon}) = \frac{1}{m+1}\int_\Omega \left(\frac{u_{0,\varepsilon}}{\overline{u_\varepsilon}}\right)^{m+1}\overline{u_\varepsilon}\,\mathrm{d}x - \int_\Omega u_{0,\varepsilon}\,\mathrm{d}x + \frac{m}{m+1}\int_\Omega \overline{u_\varepsilon}\,\mathrm{d}x.$$

The linear part converges to the right limit as $\varepsilon\to 0$. For the nonlinear term, by construction we have the bounds

$$\int_{-L}^{-L+\varepsilon}\left(\frac{u_{0,\varepsilon}}{\overline{u_\varepsilon}}\right)^{m+1}\overline{u_\varepsilon}\,\mathrm{d}x = \int_{-L}^{-L+\varepsilon}\overline{u_\varepsilon}\,\mathrm{d}x \leqslant \varphi_+\varepsilon,$$

and

$$\int_{-L+\varepsilon}^{-L+\varepsilon+\varepsilon^{m+1}}\left(\frac{u_{0,\varepsilon}}{\overline{u_\varepsilon}}\right)^{m+1}\overline{u_\varepsilon}\,\mathrm{d}x \leqslant C^{m+1}\int_{-L+\varepsilon}^{-L+\varepsilon+\varepsilon^{m+1}}\frac{1}{\overline{u_\varepsilon}^m}\mathrm{d}x \leqslant C^{m+1}\varepsilon,$$

where the last inequality follows considering that $\overline{u_\varepsilon}(x)^m \geqslant \varepsilon^m$. Finally, since $\overline{u_\varepsilon}\geqslant\overline{u}$,

$$\int_{-L+\varepsilon+\varepsilon^{m+1}}^{L}\left(\frac{u_{0,\varepsilon}}{\overline{u_\varepsilon}}\right)^{m+1}\overline{u_\varepsilon}\,\mathrm{d}x = \int_{-L+\varepsilon+\varepsilon^{m+1}}^{L}\left(\frac{u_0}{\overline{u}}\right)^{m+1}\overline{u}\left(\frac{\overline{u}}{\overline{u_\varepsilon}}\right)^{m}\mathrm{d}x \leqslant \int_{-L+\varepsilon+\varepsilon^{m+1}}^{L}\left(\frac{u_0}{\overline{u}}\right)^{m+1}\overline{u}\,\mathrm{d}x$$

$$\leqslant \int_{-L}^{L}\left(\frac{u_0}{\overline{u_\varepsilon}}\right)^{m+1}\overline{u}\,\mathrm{d}x.$$

Grouping these inequalities together we obtain the bound

$$H(u_{0,\varepsilon}/\overline{u_\varepsilon}) \leqslant H(u_0/\overline{u}) + o(\varepsilon). \tag{28}$$

On the other hand, Fatou's lemma implies

$$H(u_0/\overline{u}) \leqslant \lim_{\varepsilon\to 0} H(u_{0,\varepsilon}/\overline{u_\varepsilon}).$$

Hence we proved that, for the superlinear case

$$H(u_0/\overline{u}) = \lim_{\varepsilon\to 0} H(u_{0,\varepsilon}/\overline{u_\varepsilon}). \tag{29}$$

Since the sublinear case can be equally treated, the following theorem holds.

Theorem 5.2: *Let $u(x,t)$ be the solution of problem (1)–(3), where the initial data u_0 is admissible, $\varphi_- + \varphi_+ > 0$ and $H(u_0/\overline{u})$ is bounded. Then $u(x,t)$ decays exponentially fast towards the stationary solution $\overline{u}(x)$ in L^1-norm, and bound (26) holds.*

(Received 4 June 2004; accepted 12 October 2004; published online 27 January 2005)

We consider a perturbation of the Fitzhugh–Nagumo equation. The perturbation is proportional to the electric potential across the cell membrane. The purpose of this investigation is to determine the effects of a change in electric potential across the cell membrane. Exact solutions of the perturbed equation are easily obtained from the well-known solutions of the unperturbed Fitzhugh–Nagumo equation. The method of approximate conditional symmetries is used to obtain first-order approximate solutions of the perturbed Fitzhugh-Nagumo equation. The approximate solutions are compared with the exact solutions of the perturbed equation. The exact solutions of the perturbed equation do not indicate a change in the wave front connecting one constant state to another. There is only a proportional increase or decrease in the constant nonzero state. The approximate solutions do show a change in the shape of the wave front connecting two constant states as well as a proportional increase or decrease in the constant nonzero state. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1839276]

I. INTRODUCTION

The Hodgkin–Huxley (HH)[8] model describes the ionic current flows for axonal membranes. The equation is based on data obtained by experimenting on the giant axon of a squid. The HH equation is intractable for analytic investigation. The Fitzhugh–Nagumo (FN) model reduces the complexity of the HH model while maintaining many excitation–propagation phenomena. This FN model is a two variable reaction–diffusion system for nerve-impulse propagation. One variable corresponds to the electric voltage across the cell membrane, also called the fast variable; the other variable corresponds to ion concentration, called the slow variable. The slow variable changes slowly and its coefficient is small. The small variable is set to zero and only the behavior of the fast variables are considered. The resulting model is then described by the nonlinear diffusion equation,

$$u_t = u_{xx} + u(u-a)(1-u), \quad 0 < a < 1, \tag{1}$$

where $u(t,x)$ is the electric potential across the cell membrane. The interested reader is referred to the papers of Fitzhugh[7] and Nagumo[13] for more information on the derivation of (1). The FN equation has also been used in mathematical models in the area of population genetics.[1]

Exact solutions of the unperturbed FN equation (1) are given by

$$u(t,x) = \frac{a\kappa_1 e^{(1/2)(\sqrt{2}ax+a^2t)} + \kappa_2 e^{(1/2)(\sqrt{2}x+t)}}{\kappa_1 e^{(1/2)(\sqrt{2}ax+a^2t)} + \kappa_2 e^{(1/2)(\sqrt{2}x+t)} + \kappa_3 e^{at}}, \tag{2}$$

[a]Electronic mail: ebrahim@cam.wits.ac.za

$$u(t,x) = \frac{1}{1 + \overline{C_1} e^{[(2a-1)t/2] + (x/\sqrt{2})}}, \tag{3}$$

$$u(t,x) = \frac{a}{1 + a\overline{C_3} e^{[(2a-a^2)t/2] + (ax/\sqrt{2})}}, \tag{4}$$

$$u(t,x) = \frac{e^{[(1+a)t/2] + (ax/\sqrt{2}) + \overline{C_5}} - a e^{(x/\sqrt{2}) + a([(1+a)t/2] + \overline{C_5})}}{e^{[(1+a)t/2] + (ax/\sqrt{2}) + \overline{C_5}} - e^{(x/\sqrt{2}) + a([(1+a)t/2] + \overline{C_5})}}, \tag{5}$$

where κ_i, $i=1,2,3$; $\overline{C_1}$, $\overline{C_3}$, and $\overline{C_5}$ are constants. These exact solutions have been determined by Kawahara and Tanaka.[10] These results are also obtained in a more systematic way by Nucci and Clarkson[14] using the nonclassical symmetry method introduced by Bluman and Cole.[3] Further discussions on the use of the nonclassical symmetry method on determining exact solutions of (1) are presented by Clarkson and Mansfield.[5] The nonclassical symmetry approach (also known as the conditional symmetry approach) has been used with much success in obtaining new solutions for differential equations, see, e.g., Refs. 6, 11, and 15–17. These solutions have not been found using Lie's classical approach (see, e.g., Bluman and Kumei[4] and Ibragimov[9]). The solutions (2)–(4) show a wave front connecting two constant states (for the model under consideration in this paper states and electric potentials may be used interchangeably). These states are (0, 1), (1, 0), and (a, 0), respectively. The solution (5) has a singularity at

$$x = x^* = \frac{2\overline{C_5} + t(a+1)}{\sqrt{2}}. \tag{6}$$

In this paper we consider a perturbation of the FN equation where the perturbation is proportional to the electric potential across the cell membrane. The resulting equation is given by

$$u_t = u_{xx} + u(u-a)(1-u) + \epsilon u, \quad 0 < a < 1, \quad \epsilon \ll 1. \tag{7}$$

The approximate equation (7) is solved using the approximate conditional symmetry method of Mahomed and Qu.[12]

II. EXACT SOLUTIONS

We note that the perturbed FN equation (7) can be written in the form

$$u_t = u_{xx} + u(u-a+k)(1-u+k), \quad 0 < a < 1, \quad \epsilon \ll 1, \tag{8}$$

where

$$k = \tfrac{1}{2}((a-1) \pm \sqrt{(a-1)^2 + 4\epsilon}). \tag{9}$$

The expression of the cubic nonlinearity in (8) is not unique. However, the form used is beneficial in this analysis as it indicates the effect of the perturbation on the constant solutions $u=a$ and $u=1$ of the unperturbed FN equation (7). From (8) we note that the stable solution at $u=0$ remains unchanged while two new constant solutions are found, viz.,

$$u = a - k, \quad u = 1 + k. \tag{10}$$

Analytical solutions admitted by (8) are easily found from the solutions (2)–(5) by making the transformations

TABLE I. Symmetries of unperturbed Fitzhugh–Nagumo equation.

	$\tau_0(t,x,u)$	$\xi_0(t,x,u)$	$\eta_0(t,x,u)$	
Case 1	1	$3/\sqrt{2}(u-a+1/3)$	$-\frac{3}{2}(u^3-(a+1)u^2+au)$	(1a)
Case 2	0	1	$1/\sqrt{2}u(u-1)$	(2a)
	0	1	$1/\sqrt{2}u(u-a)$	(2b)
	0	1	$1/\sqrt{2}(u-1)(u-a)$	(2c)

$$a \to a-k, \quad 1 \to 1+k. \tag{11}$$

These transformations do not affect the shape of the wave front connecting two constant states. We will show in the next section that this is not the case when one considers approximate conditional symmetries. The solutions obtained indicate a change in the shape of the wave front. The singularity (6) admitted by (5) is transformed in a similar way. To first order in ϵ we find that the two new constant states are given by

$$u \approx a + \frac{\epsilon}{a-1}, \quad u \approx 1 + \frac{\epsilon}{1-a}. \tag{12}$$

III. APPROXIMATE CONDITIONAL SYMMETRIES

The unperturbed FN equation (1), as is well known, admits the classical Lie point symmetries,

$$Z_1 = \partial_t, \quad Z_2 = \partial_x \tag{13}$$

while it is easy to show that the perturbed FN equation (7) admits the approximate Lie point symmetries (in the sense of Baikov *et al.*[2])

$$W_1 = \partial_t, \quad W_2 = \epsilon\partial_t, \quad W_3 = \partial_x, \quad W_4 = \epsilon\partial_x. \tag{14}$$

The approximate Lie point symmetries (14) of the perturbed FN equation are not true approximate symmetries as they are just a constant multiple of the classical Lie point symmetries of the exact equation. Both the classical and approximate Lie point symmetries lead to the standard traveling wave solutions. Nontrivial symmetries are obtained via the conditional and approximate conditional symmetry approaches.

The conditional symmetries admitted by (1) have been determined by Nucci and Clarkson[14] (see also Clarkson and Mansfield[5]) and are presented in Table I. The generator of these conditional symmetries is written as

$$Y = \tau_0\frac{\partial}{\partial t} + \xi_0\frac{\partial}{\partial x} + \eta_0\frac{\partial}{\partial u}, \tag{15}$$

where the coefficients τ_0, ξ_0, and η_0 are presented in Table I. Solutions admitted by (1) of the form $u=\Phi(t,x)$ are determined from these conditional symmetries by solving the first-order quasilinear partial differential equation,

$$Y(u-\Phi(t,x))\big|_{u=\Phi(t,x)} = 0. \tag{16}$$

These solutions are given by Eqs. (2)–(5).

Using the approach presented by Mahomed and Qu[12] we find the approximate conditional symmetries admitted by (7). The main features of this approach as utilized here can be summarized as follows. An operator $X=X_0+\epsilon X_1$ with

TABLE II. Approximate conditional symmetries of perturbed Fitzhugh–Nagumo equation.

	$\tau(t,x,u;\epsilon)$	$\xi(t,x,u;\epsilon)$	$\eta(t,x,u;\epsilon)$	
Case 1	1	$3/\sqrt{2}(u-a+1/3)$	$-\frac{3}{2}(u^3-(a+1)u^2+au)+\epsilon(\frac{3}{2}u)$	(1b)
Case 2				
(2a)	0	1	$1/\sqrt{2}u(u-1)+\epsilon 1/\sqrt{2}(a-1)u$	(2d)
(2b)	0	1	$1/\sqrt{2}u(u-a)-\epsilon 1/\sqrt{2}(a-1)u$	(2e)
(2c)	0	1	$1/\sqrt{2}(u-1)(u-a)-\epsilon 1/\sqrt{2}$	(2f)

$$X_b = \xi_b^i(x,u)/\partial x^i + \eta_b^\alpha(x,u)/\partial u^\alpha, \quad b = 0,1,$$

is a first-order approximate symmetry generator of an rth-order partial differential equation system $[F]$ perturbed up to order one in the small parameter ϵ, viz.,

$$F^\beta = F_0^\beta(x,u,u_{(1)},\ldots,u_{(r)}) + \epsilon F_1^\beta(x,u,u_{(1)},\ldots,u_{(r)}) = O(\epsilon^2),$$

in which $x=(x^1,x^2,\ldots,x^n)$, $u=(u^1,u^2,\ldots,u^m)$, $u_{(1)},u_{(2)},\ldots,u_{(r)}$ are the collections of partial derivatives up to order r, if

$$X^{[r]}(F^\beta)|_{[W]\cap[F]} = O(\epsilon^2),$$

where

$$X^{[r]} = X_0^{[r]} + \epsilon X_1^{[r]},$$

$$X_b^{[r]} = X_b + \sum_{s=1}^{r} D_{i_1}\cdots D_{i_s}(W_b^\alpha) + \xi_b^j u^\alpha_{ji_1\cdots i_s}\frac{\partial}{\partial u^\alpha_{i_1\cdots i_s}}, \quad b = 0,1,$$

$$W_b^\alpha = \eta_b^\alpha - \xi_b^j u_j^\alpha, \quad \alpha = 1,\ldots,m,$$

and $[W]$ is the surface given by the invariant surface conditions $W_0^\alpha+\epsilon W_1^\alpha=O(\epsilon^2)$ together with

$$D_{i_1}\cdots D_{i_s}[W_0^\alpha + \epsilon W_1^\alpha] = O(\epsilon^2), \quad s = 1,\ldots,r-1.$$

The first order in ϵ approximate conditional symmetries of (7), using the above approach, are presented in Table II.

The generators of the approximate conditional symmetries are written as follows:

$$X = \tau\frac{\partial}{\partial t} + \xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial u}, \tag{17}$$

where the coefficients τ, ξ, and η are presented in Table II. We note from Table II that the perturbation affects only the η terms. To determine approximate solutions,

$$u(t,x) = u_0(t,x) + \epsilon u_1(t,x), \quad \epsilon \ll 1, \tag{18}$$

corresponding to the approximate conditional symmetries indicated in Table II we solve the first-order quasilinear partial differential equation[12]

$$X(u - u_0(t,x) - \epsilon u_1(t,x))|_{u=u_0(t,x)+\epsilon u_1(t,x)} = 0. \tag{19}$$

The resulting first-order quasilinear partial differential equation is separated to first order in the small parameter in ϵ. For each of the cases indicated in Table II we choose the appropriate u_0 from (2)–(5).

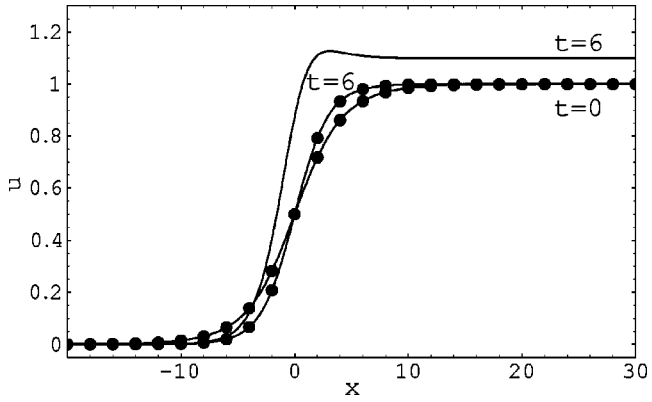

FIG. 1. Plot of the numerical solution $u=u_0+\epsilon u_1$ for case (1b) obtained from the numerical solution of the characteristic equations (22)–(25) and the exact solution (2) (-·-·-·-) of the unperturbed equation on the same system of axes. We have chosen $\epsilon=0.05$, $a=0.5$, and $\kappa_1=\kappa_2=\kappa_3=1$.

For case (1b), we obtain the system of partial differential equations,

$$u_{0_t}+\frac{3}{\sqrt{2}}\left(u_0-\frac{(a+1)}{3}\right)u_{0_x}=-\frac{3}{2}(u_0^3-(a+1)u_0^2+au_0), \tag{20}$$

$$u_{1_t}+\frac{3}{\sqrt{2}}\left(u_0-\frac{(a+1)}{3}\right)u_{1_x}=-\frac{3}{2}(3u_0^2u_1-2(a+1)u_0u_1+au_1-u_0)-\frac{3}{\sqrt{2}}u_1u_{0_x}, \tag{21}$$

where the exact solution of (20) is given by (2). We substitute (2) for u_0 into (21). Unfortunately, we cannot determine an analytical solution to (21). Instead we solve the system (20) and (21) numerically. The characteristic equations for the system (20) and (21) are given by

$$\frac{dt}{ds}=1, \tag{22}$$

$$\frac{dx}{ds}=\frac{3}{\sqrt{2}}\left(u_0-\frac{a+1}{3}\right), \tag{23}$$

$$\frac{du_0}{ds}=-\frac{3}{2}(u_0^3-(a+1)u_0^2+au_0), \tag{24}$$

$$\frac{du_1}{ds}=-\frac{3}{2}(3u_0^2u_1-2(a+1)u_0u_1+au_1-u_0)-\frac{3}{\sqrt{2}}u_1u_{0_x}. \tag{25}$$

We solve the system (22)–(25) numerically subject to

$$t(0,q)=0,\quad x(0,q)=q,\quad u_0(0,q)=F(q),\quad u_1(0,q)=0. \tag{26}$$

$F(q)$ is the initial profile and is obtained from (2) by setting $t=0$. We find that

$$F(q)=\frac{a\kappa_1e^{(1/2)(\sqrt{2}aq)}+\kappa_2e^{(1/2)(\sqrt{2}q)}}{\kappa_1e^{(1/2)(\sqrt{2}aq)}+\kappa_2e^{(1/2)(\sqrt{2}q)}+\kappa_3}. \tag{27}$$

The numerical solution for the perturbed equation and the exact solution for the unperturbed equation are plotted in Fig. 1.

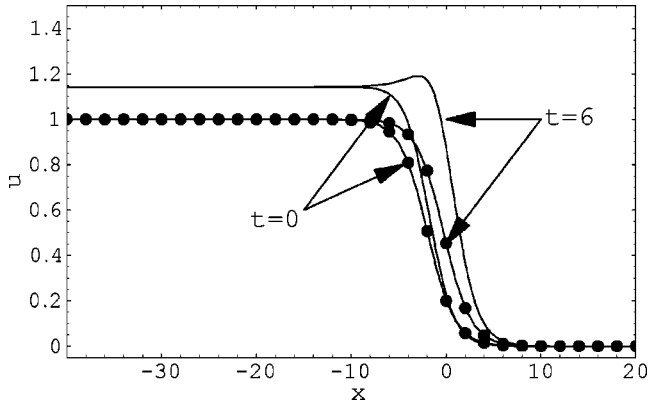

FIG. 2. Plot of the approximate solution $u=u_0+\epsilon u_1$ where u_0 is given by (3) and u_1 is given by (30). The unperturbed solution (3) (-·-·-·-) is plotted on the same system of axes. We have chosen $\epsilon=0.1$, $a=0.3$, $\overline{C}_1=4$, and $\overline{C}_2=5$.

From Fig. 1 we observe that the perturbation has no effect on the zero constant state. The shape of the wave front connecting the zero constant state to the nonzero constant state has changed. The wave front is now steeper and has a pronounced hump. In terms of our model, the hump is indicative of the membrane trying to correct for the perturbation to bring the potential back down to the constant state one. However, the cell is only able to correct this perturbation to a average slightly higher than one.

The system of equations we are required to solve for case (2d) is given by

$$\epsilon^0: u_{0x} - \frac{1}{\sqrt{2}}u_0^2 + \frac{1}{\sqrt{2}}u_0 = 0, \tag{28}$$

$$\epsilon^1: u_{1x} - \sqrt{2}u_0u_1 + \frac{1}{\sqrt{2}}u_1 - \frac{1}{\sqrt{2}(a-1)}u_0 = 0. \tag{29}$$

Substituting in the solution (3) for u_0 we can solve (29) to find that

$$u_1(t,x) = \frac{e^{-t/2}(-2e^{t/2} + e^{at+(x/\sqrt{2})}(2(a-2)\overline{C}_1t + \sqrt{2}\overline{C}_1x + 2(a-1)\overline{C}_2))}{2(a-1)(1+\overline{C}_1e^{(a-(1/2))t+(x/\sqrt{2})})^2}. \tag{30}$$

The approximate solution (18) is plotted in Fig. 2 where u_0 is given by (3) and u_1 is given by (30).

From the solution u_0 given by (3) and u_1 given by (30) we find that

$$\lim_{x\to-\infty} u_0(t,x) = 1, \quad \lim_{x\to\infty} u_0(t,x) = 0 \tag{31}$$

while

$$\lim_{x\to-\infty} (u_0(t,x) + \epsilon u_1(t,x)) = 1 + \frac{\epsilon}{1-a},$$

$$\lim_{x\to\infty} (u_0(t,x) + \epsilon u_1(t,x)) = 0. \tag{32}$$

The system of equations we are required to solve for case (2e) is given by

$$\epsilon^0: u_{0x} - \frac{1}{\sqrt{2}}u_0^2 + \frac{1}{\sqrt{2}}au_0 = 0, \tag{33}$$

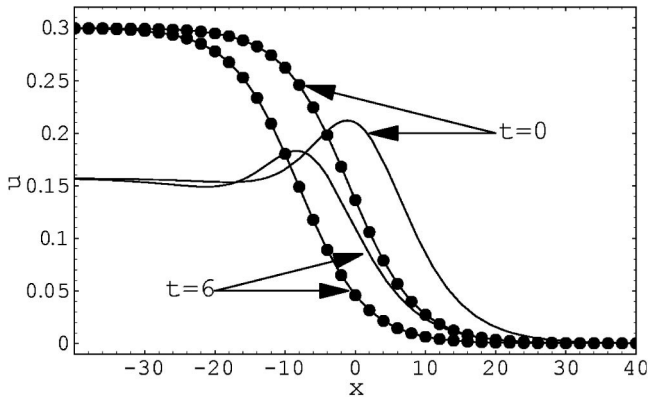

FIG. 3. Plot of the approximate solution $u=u_0+\epsilon u_1$ where u_0 is given by (4) and u_1 is given by (35). The unperturbed solution (4) (-·-·-·-) is plotted on the same system of axes. We have chosen $\epsilon=0.1$, $a=0.3$, $\overline{C_3}=4$, and $\overline{C_4}=5$.

$$\epsilon^1: u_{1x} - \sqrt{2}u_0u_1 + \frac{1}{\sqrt{2}}au_1 + \frac{1}{\sqrt{2}(a-1)}u_0 = 0. \tag{34}$$

Substituting in the solution (4) for u_0 we can solve (34) to find that

$$u_1(t,x) = \frac{1}{2(a-1)(1+a\overline{C_3}e^{[(2a-a^2)t/2]+(ax/\sqrt{2})})^2}(2 - \sqrt{2}a^2e^{[(2a-a^2)t/2]+(ax/\sqrt{2})}x\overline{C_3} + 2e^{[-((-2+a)at)/2]+(ax/\sqrt{2})}$$
$$\times(-a^2t\overline{C_3} + 2a^3t\overline{C_3} - \overline{C_4} + a\overline{C_4})). \tag{35}$$

The approximate solution (18) is plotted in Fig. 3 where u_0 is given by (4) and u_1 is given by (35).

From the solution u_0 given by (4) and u_1 given by (35) we find that

$$\lim_{x\to-\infty} u_0(t,x) = a, \quad \lim_{x\to\infty} u_0(t,x) = 0 \tag{36}$$

while

$$\lim_{x\to-\infty}(u_0(t,x) + \epsilon u_1(t,x)) = a + \frac{\epsilon}{a-1},$$
$$\lim_{x\to\infty}(u_0(t,x) + \epsilon u_1(t,x)) = 0. \tag{37}$$

From Figs. 2 and 3 we observe that the gradient of the wave front has increased. Also, as is indicated in (32) and (37) there is a slight change in the nonzero constant state. In the case of Fig. 2 the potential tends to a nonzero constant state of one as $x\to-\infty$ for the exact solution (3) and $1+\epsilon/(1-a)$ for the perturbed case. While from Fig. 3 we observe that the potential tends to a constant nonzero state of a as $x\to-\infty$ for the exact solution (4) and $a+\epsilon/(a-1)$ for the perturbed case. The zero states are unaffected. We observe the formation of a hump in the wave front. The hump is indicative of the cell membrane trying to correct for the perturbation to bring the potential down to one from $1+\epsilon/(1-a)$ in Fig. 2 and up to a from $a+\epsilon/(a-1)$ in Fig. 3. We note that in Fig. 2 the hump in the perturbed solution grows much larger in size than the unperturbed solution. Also, in Fig. 3, for the parameters given, the perturbed solution becomes negative for larger values of t.

The system of equations we are required to solve for case (2f) is given by

$$\epsilon^0: u_{0x} - \frac{1}{\sqrt{2}}u_0^2 + \frac{1}{\sqrt{2}}(a+1)u_0 - \frac{1}{\sqrt{2}}a = 0, \tag{38}$$

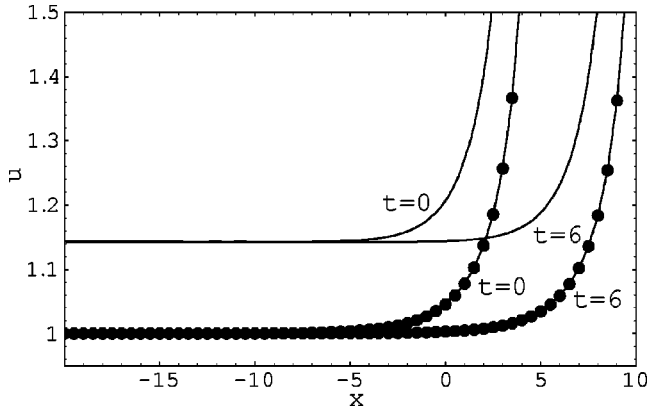

FIG. 4. Plot of the approximate solution $u=u_0+\epsilon u_1$ where u_0 is given by (5) and u_1 is given by (40) on the interval $x \in [-20, x^*]$. The unperturbed solution (5) (-·-·-·-) is plotted on the same system of axes. We have chosen $\overline{C_5}=4$, $\overline{C_6}=5$, $a=0.3$, and $\epsilon=0.1$.

$$\epsilon^1: u_{1x} - \sqrt{2}u_0 u_1 + \frac{1}{\sqrt{2}}(a+1)u_1 + \frac{1}{\sqrt{2}} = 0. \tag{39}$$

Substituting in the solution (5) for u_0 we can solve (39) to find that

$$\begin{aligned} u_1(t,x) = {} & \frac{1}{(a-1)(e^{[(1+a)t/2]+(ax/\sqrt{2})+\overline{C_5}} - e^{(x/\sqrt{2})+a([(1+a)t/2]+\overline{C_5})})^2}[e^{(1+a)^2 t/2}(-e^{[(t-a^2 t+2\sqrt{2}ax+4\overline{C_5})/2]} \\ & + e^{[(a^2-1)t/2]+\sqrt{2}x+2a\overline{C_5}} - (a^2-1)e^{[(1+a)x/\sqrt{2}]+(1+a)\overline{C_5}}t + \sqrt{2}(-1+a)e^{(1+a)(\sqrt{2}x+2\overline{C_5})/2}x \\ & + (a-1)e^{[(1+a)x/\sqrt{2}]}\overline{C_6})]. \end{aligned} \tag{40}$$

We note that (40) also has a singularity at $x=x^*$ where x^* is given by (6). The approximate solution (18) is plotted in Figs. 4 and 5 where u_0 is given by (5) and u_1 is given by (40) on either side of the singularity $x=x^*$.

From the solution u_0 given by (5) and u_1 given by (40) we find that

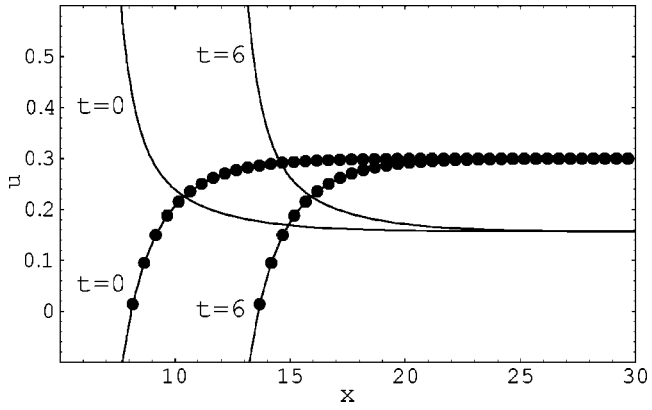

FIG. 5. Plot of the approximate solution $u=u_0+\epsilon u_1$ where u_0 is given by (5) and u_1 is given by (40) on the interval $x \in [x^*, 30]$. The unperturbed solution (5) (-·-·-·-) is plotted on the same system of axes. We have chosen $\overline{C_5}=4$, $\overline{C_6}=5$, $a=0.3$, and $\epsilon=0.1$.

$$\lim_{x\to-\infty} u_0(t,x) = 1, \quad \lim_{x\to\infty} u_0(t,x) = a, \tag{41}$$

while

$$\lim_{x\to-\infty} (u_0(t,x) + \epsilon u_1(t,x)) = 1 + \frac{\epsilon}{1-a},$$
$$\lim_{x\to\infty} (u_0(t,x) + \epsilon u_1(t,x)) = a + \frac{\epsilon}{a-1}. \tag{42}$$

The singular behavior of the solutions for case (2f) destroys the wave front connecting two constant states. However, we note from Figs. 4 and 5 that both the exact and perturbed solutions tend to constant behavior as $x \to \pm\infty$. This solution is not physical in terms of our model of electric potential across a cell membrane.

IV. DISCUSSION

In this paper we have determined approximate solutions for a perturbed Fitzhugh–Nagumo equation where the perturbation is proportional to the electric potential across the cell membrane. This choice of perturbation allows us to write the perturbed equation in an exact form given by (8). The transformations (11) allow us to convert the known solutions of the Fitzhugh–Nagumo equation into exact solutions of the perturbed equation. The physically meaningful solutions represent wave fronts connecting the constant states $(0,1+k)$, $(1+k,0)$, and $(a+k,0)$.

Approximate solutions determined from the approximate conditional symmetries admitted by the perturbed equation (7) were then investigated. The approximate solutions are stable (by the definition of Mahomed and Qu[12]) with one of the solutions having singular behavior. The physically meaningful approximate solutions represent wave fronts joining the constant states $(0,1+\epsilon/(1-a))$, $(1+\epsilon/(1-a),0)$, and $(a+\epsilon/(a-1),0)$. These constant states are just a first-order approximation to the constant states indicated above.

For our investigation into the behavior of the cell membrane it is appropriate to consider only short-time behavior as signals move across the cell membrane in a very short period of time. Over a short time period the difference in the constant states for each of the physically meaningful solutions is given by $|k-\epsilon/(1-a)|$ and $|k-\epsilon/(a-1)|$. We also note a difference in the shape of the wave front connecting the constant states. The approximate solution shows the formation of a hump while the exact solution of the approximate equation shows a smooth transition from one constant state to another.

The difference in the constant state could be used to explain some of the experimental error found when measuring nerve conductivity (see, e.g., Refs. 7 and 13). Also, the formation of the hump is indicative of the cell membrane trying to get down to a constant state given by (12).

A new method of constructing structure equations of Lie symmetry pseudogroups of differential equations, dispensing with explicit solutions of the (infinitesimal) determining systems of the pseudogroups, is presented, and illustrated by the examples of the Kadomtsev–Petviashvili and Korteweg–de Vries equations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1836015]

I. INTRODUCTION

The theory of continuous groups of transformations created by Sophus Lie in the late nineteenth century has evolved to become one of the most important tools for geometric and algebraic study of general nonlinear partial differential equations. Lie himself made no essential distinction between finite-dimensional Lie group actions and infinite-dimensional pseudogroup actions. However, since his time, the two subjects have developed in very different directions. The theoretical foundations of finite-dimensional Lie groups and Lie algebras were well-established in the early twentieth century. In contrast, despite its evident importance in both mathematics and applications, the basic theory for infinite-dimensional Lie pseudogroups remains in relatively primitive shape. Unlike Lie groups, to this day, there is no generally accepted abstract object that represents an infinite-dimensional pseudogroup, and so, like Lie and Cartan,[3] we can only study them in the context of their action on a manifold. This makes the subject considerably more difficult than the finite-dimensional case, and a significant effort has been made in establishing a proper rigorous foundation for pseudogroups.[8,11–13,24,27]

Lie pseudogroups appear in gauge theories, Hamiltonian mechanics, symplectic and Poisson geometry, conformal geometry of surfaces, conformal field theory, and geometry of real hypersurfaces, as symmetry groups of both linear and nonlinear partial differential equations arising in fluid mechanics, solitons, relativity, etc., and as foliation-preserving groups of transformations. In general, a Lie pseudogroup $\mathcal{G}$ is defined in terms of a system $\mathcal{R}$ of (typically nonlinear) differential equations, called its *determining system*, whose solutions are the local diffeomorphisms constituting the pseudogroup. One immediate issue is to determine their local structure, which is usually expressed in the form of Maurer–Cartan structure equations, as in the case of finite-dimensional Lie groups. Both Lie's attempt to use his infinitesimal method based on the infinitesimal determining system obtained by linearizing the determining system, and Cartan's method using intricate recursive prolongation of exterior differential systems are either limited in scope or impractical from the standpoint of applications. Along this line of research in the last decade, Reid *et al.*,[14–16,25,26] developed methods for determining Cartan structure equations of Lie pseudogroups, which depended only on algebraic and differential manipulation, without any integration, of infinitesimal determining systems, hence increasing the feasibility of their computer algebra implementation. Their algorithms were successfully applied to certain types of Lie symmetry pseudo-

[c]Electronic mail: juha@math.oregonstate.edu; URL:http://www.oregonstate.edu/~pohjanpp/

groups of differential equations. A major drawback, however, is that their methods were based on *ad hoc* series expansions and became significantly more complicated, requiring more case-by-case analyses, if they worked at all, when it came to intransitive pseudogroup actions.

More recently, Olver and Pohjanpelto developed a theory[22] where the invariant contact forms on the diffeomorphism jet bundle were interpreted as the Maurer–Cartan forms of the Lie pseudogroup. (For finite-dimensional symmetry groups, Morozov[20] has introduced a related approach based on the method of moving coframes.[7]) As a result, a very efficient method for constructing the structure equations of the Maurer–Cartan forms was discovered. This method bypasses the troublesome process of integrating either the determining system $\mathcal{R}$ or its linearization, or the complicated Cartan prolongation process. Moreover, the algorithm directly applies to completely general Lie pseudogroup actions, whether finite or infinite dimensional, transitive or intransitive, and can be easily implemented in computer algebra systems.

The goal of this paper is to show how to use the method to directly construct structure equations for Lie (point) symmetry pseudogroups of differential equations. Our algorithm works for any general Lie symmetry pseudogroup, and it will also give us better understanding of known local symmetry structures, as well as revealing those of a wide range of differential equations that still wait to be investigated. We also wrote some Mathematica routines to facilitate the computations needed for the implementation of our method on specific differential equations. To illustrate our algorithm, we will use the Kadomtsev–Petviashvili (KP) equation

$$(u_t + \tfrac{3}{2}uu_x + \tfrac{1}{4}u_{xxx})_x + \tfrac{3}{4}\epsilon u_{yy} = 0, \quad \epsilon = \pm 1, \tag{1}$$

and the Korteweg–de Vries (KdV) equation

$$u_t + u_{xxx} + uu_x = 0, \tag{2}$$

both of which are integrable soliton equations, possessing, respectively, infinite- and finite-dimensional Lie symmetry pseudogroups.[1,4–6,17–19]

Let us recall how the classical Lie symmetry method[21] works in the context of the KP equation. Let $M=\mathbb{R}^4$ with coordinates t,x,y,u given by the independent and dependent variables in the differential equation, and let $J^\infty(M,3)$ stand for the jet bundle of equivalence classes of three-dimensional submanifolds $u=f(t,x,y)$ of M under the equivalence relation of infinite-order contact. The infinitesimal symmetry algebra $\mathfrak{g}$ of the KP equation consists of the local vector fields

$$\mathbf{v} = \tau\partial_t + \xi\partial_x + \eta\partial_y + \phi\partial_u \tag{3}$$

on M such that their prolongations $\mathbf{v}^{(\infty)}$ are tangent to the variety in $J^\infty(M,3)$ defined by Eq. (1). This characterizing condition yields the system of partial differential equations

$$\begin{gathered}
\eta_u = 0, \quad \eta_x = 0, \quad \xi_u = 0, \quad \eta_t + \tfrac{3}{2}\epsilon\xi_y = 0, \quad 3\xi_x - \tau_t = 0, \\
\tfrac{3}{2}\phi - \xi_t + u\tau_t = 0, \quad \tfrac{3}{2}\eta_y - \tau_t = 0, \quad \tau_u = 0, \quad \tau_x = 0, \quad \tau_y = 0, \\
\tau_t + \tfrac{3}{2}\phi_u = 0, \quad \tfrac{2}{3}\tau_{tt} - 3\phi_x = 0, \quad \phi_{tx} + \tfrac{3}{2}u\phi_{xx} + \tfrac{1}{4}\phi_{xxxx} + \tfrac{3}{4}\epsilon\phi_{yy} = 0,
\end{gathered} \tag{4}$$

for the coefficient functions of the infinitesimal symmetries $\mathbf{v}$. These equations are the minimal *infinitesimal* (or *linearized*) *determining system* of the Lie symmetry pseudogroup $\mathcal{G}$ of the KP equation. Once the system (4) is completed to involution, all the higher order equations are obtained by differentiation with respect to t,x,y,u. The key point of this paper is to determine the local structure of $\mathcal{G}$ directly from its infinitesimal determining system (4). This setup has an obvious counterpart for the KdV equation (2), too, which, for brevity, we will not elaborate on until the end of the paper.

Our subsequent discussions in the paper are organized in such a way that the results of each section are applied to the case of the KP equation within that section, and, starting from the current section, consistent notation without further comment will be used for the examples. It is worth

emphasizing that both finite-dimensional and infinite-dimensional symmetry pseudogroups are handled, on an equal footing, by precisely the same algorithms to be presented here.

II. MAURER–CARTAN FORMS FOR THE PSEUDOGROUP OF LOCAL DIFFEOMORPHISMS

Let M be a smooth manifold of dimension m, and $\mathcal{D}=\mathcal{D}(M)$ the pseudogroup of local diffeomorphisms on M. For each $0\leqslant n\leqslant\infty$, let $\mathcal{D}^{(n)}=\mathcal{D}^{(n)}(M)$ be the bundle of n-jets of maps in $\mathcal{D}$. The bundle $\mathcal{D}^{(n)}$ is double-fibered over M with fibrations being the source projection

$$\boldsymbol{\sigma}^{(n)}:\mathcal{D}^{(n)}\to M,\quad \boldsymbol{\sigma}^{(n)}(j^n_z\phi)=z,$$

and the target projection

$$\boldsymbol{\tau}^{(n)}:\mathcal{D}^{(n)}\to M,\quad \boldsymbol{\tau}^{(n)}(j^n_z\phi)=\phi(z),$$

where $z\in M$ and $\phi\in\mathcal{D}$. Composition of local diffeomorphisms turns $\mathcal{D}^{(n)}$ into a Lie groupoid with multiplication law

$$(j^n_z\phi)\cdot(j^n_w\psi):=j^n_w(\phi\circ\psi)\quad\text{provided}\quad \boldsymbol{\sigma}^{(n)}(j^n_z\phi)=z=\psi(w)=\boldsymbol{\tau}^{(n)}(j^n_w\psi).$$

Local coordinates of the base space M and the total space $\mathcal{D}^{(n)}$ are denoted by $z=(z^i)$ and $(z,Z^{(n)})=(z^i,Z^a_J)$, respectively, where $Z=(Z^a)$ and Z^a_J, with J a symmetric multi-index, represents the derivative $\partial^J Z^a/\partial z^J$. The natural identification, obtained by viewing maps in terms of their graphs, of $\mathcal{D}^{(\infty)}$ with an open subbundle of the jet bundle $J^\infty(M\times M)$ of infinite jets of local sections of the trivial bundle

$$M\times M\to M,\quad (z,Z)\mapsto z,$$

induces a variational bicomplex structure[2,9,10] on the cotangent bundle $T^*\mathcal{D}^{(\infty)}$, where the horizontal subbundle is spanned by the horizontal forms $\mathrm{d}z^1,\dots,\mathrm{d}z^m$, and the vertical subbundle is spanned by the basic contact forms

$$\Upsilon^a_J:=\mathrm{d}Z^a_J-\sum_{i=1}^m Z^a_{J,i}\,\mathrm{d}z^i,\quad a=1,\dots,m,\quad \#J\geqslant 0.$$

Accordingly, the exterior differential $\mathrm{d}=\mathrm{d}_M+\mathrm{d}_G$ on $\mathcal{D}^{(\infty)}$ splits into the horizontal differential[28] d_M and the contact (or vertical) differential d_G, so that

$$\mathrm{d}F=\mathrm{d}_MF+\mathrm{d}_GF=\sum_{i=1}^m(\mathbb{D}_{z^i}F)\mathrm{d}z^i+\sum_{a=1}^m\sum_{\#J\geqslant 0}(\partial_{Z^a_J}F)\Upsilon^a_J,$$

for any smooth function $F:\mathcal{D}^{(\infty)}\to\mathbb{R}$. Here, $\mathbb{D}_{z^i}$ is the total differential operator with respect to the base coordinate function z^i, and $\partial_{Z^a_J}$ is the partial differential operator with respect to the fiber coordinate function Z^a_J.

Let

$$R_\psi(j^n_z\phi):=(j^n_z\phi)\cdot(j^n_z\psi)^{-1}=j^n_{\psi(z)}(\phi\circ\psi^{-1})$$

denote the right action of the diffeomorphism pseudogroup on its jets. A differential form μ on $D^{(n)}$ is said to be *right-invariant* if $R^*_\psi\mu=\mu$, whenever defined, for all $\psi\in\mathcal{D}$. In particular, the target coordinate functions Z^a are right invariant. Since the right action preserves the splitting of $T^*\mathcal{D}^{(\infty)}$, the horizontal and contact differentials of invariant forms are invariant. Thus,

$$\sigma^a:=\mathrm{d}_MZ^a=\sum_{i=1}^m Z^a_i\,\mathrm{d}z^i,\quad \mu^a:=\mathrm{d}_GZ^a=\Upsilon^a,\quad a=1,\dots,m,$$

are, respectively, *invariant horizontal forms* and *invariant contact forms*. The *invariant differential operators*, denoted $\mathbb{D}_{Z^a}$, are dual to the invariant horizontal forms σ^a, so

$$\mathrm{d}_M F = \sum_{a=1}^{m} (\mathbb{D}_{Z^a} F)\sigma^a \quad \text{for all } F \in C^\infty(\mathcal{D}^{(\infty)}).$$

Lie derivatives of invariant differential forms with respect to the invariant differential operators are invariant. Thus, the *higher order invariant contact forms*,

$$\mu^a_J := \mathbb{D}^J_Z \mu^a := \mathbb{D}_{Zj_1}\mathbb{D}_{Zj_2}\cdots\mathbb{D}_{Zj_k}\mu^a,$$

are obtained by repeated Lie differentiation. As argued in earlier papers,[22,23] these invariant contact forms play the role of the *Maurer–Cartan forms* for $\mathcal{D}$.

Let us present the explicit formulas in the case relevant to the KP equation. Since the KdV case is completely similar, except with one fewer independent variable, it will not be explicitly presented.

KP equation 1: The KP equation has independent variables t,x,y and dependent variable u, which we regard as coordinates on the total space $M=\mathbb{R}^4$. We denote the corresponding local coordinates of the diffeomorphism groupoid $\mathcal{D}^{(\infty)}$ by

$$(t,x,y,u,T,X,Y,U,T_t,T_x,T_y,T_u,X_t,X_x,X_y,X_u,\ldots).$$

The horizontal forms on $\mathcal{D}^{(\infty)}$ are $\mathrm{d}t,\mathrm{d}x,\mathrm{d}y,\mathrm{d}u$, and the contact forms are

$$\Upsilon^t := \mathrm{d}_G T = \mathrm{d}T - T_t\,\mathrm{d}t - T_x\,\mathrm{d}x - T_y\,\mathrm{d}y - T_u\,\mathrm{d}u,$$

$$\Upsilon^x := \mathrm{d}_G X = \mathrm{d}X - X_t\,\mathrm{d}t - X_x\,\mathrm{d}x - X_y\,\mathrm{d}y - X_u\,\mathrm{d}u,$$

$$\Upsilon^y := \mathrm{d}_G Y = \mathrm{d}Y - Y_t\,\mathrm{d}t - Y_x\,\mathrm{d}x - Y_y\,\mathrm{d}y - Y_u\,\mathrm{d}u,$$

$$\Upsilon^u := \mathrm{d}_G U = \mathrm{d}U - U_t\,\mathrm{d}t - U_x\,\mathrm{d}x - U_y\,\mathrm{d}y - U_u\,\mathrm{d}u,$$

$$\Upsilon^t_t := \mathbb{D}_t\Upsilon^t = \mathrm{d}_G T_t = \mathrm{d}T_t - T_{tt}\,\mathrm{d}t - T_{tx}\,\mathrm{d}x - T_{ty}\,\mathrm{d}y - T_{tu}\,\mathrm{d}u,$$

$$\ldots \text{ and, in general,} \quad \Upsilon^a_{h,k,l,n} := \mathbb{D}^h_t\mathbb{D}^k_x\mathbb{D}^l_y\mathbb{D}^n_u\Upsilon^a,$$

where we use a to signify either t, x, y or u, and $h,k,l,n\geqslant 0$, with $\mathbb{D}_t,\mathbb{D}_x,\mathbb{D}_y,\mathbb{D}_u$ denoting the total differential operators. The invariant horizontal forms are

$$\sigma^t := \mathrm{d}_M T = T_t\,\mathrm{d}t + T_x\,\mathrm{d}x + T_y\,\mathrm{d}y + T_u\,\mathrm{d}u,$$

$$\sigma^x := \mathrm{d}_M X = X_t\,\mathrm{d}t + X_x\,\mathrm{d}x + X_y\,\mathrm{d}y + X_u\,\mathrm{d}u,$$

$$\sigma^y := \mathrm{d}_M Y = Y_t\,\mathrm{d}t + Y_x\,\mathrm{d}x + Y_y\,\mathrm{d}y + Y_u\,\mathrm{d}u,$$

$$\sigma^u := \mathrm{d}_M U = U_t\,\mathrm{d}t + U_x\,\mathrm{d}x + U_y\,\mathrm{d}y + U_u\,\mathrm{d}u,$$

and the invariant contact forms are

$$\mu^t := \mathrm{d}_G T = \Upsilon^t, \quad \mu^x := \mathrm{d}_G X = \Upsilon^x, \quad \mu^y := \mathrm{d}_G Y = \Upsilon^y, \quad \mu^u := \mathrm{d}_G U = \Upsilon^u,$$

$$\mu^t_T := \mathbb{D}_T\mu^t, \quad \mu^t_X := \mathbb{D}_X\mu^t, \quad \dots \quad \text{and, in general, } \mu^a_{h,k,l,n} := \mathbb{D}_T^h\mathbb{D}_X^k\mathbb{D}_Y^l\mathbb{D}_U^n\mu^a,$$

where $a=t$, x, y or u, and

$$\begin{bmatrix} \mathbb{D}_T \\ \mathbb{D}_X \\ \mathbb{D}_Y \\ \mathbb{D}_U \end{bmatrix} = \begin{bmatrix} T_t & X_t & Y_t & U_t \\ T_x & X_x & Y_x & U_x \\ T_y & X_y & Y_y & U_y \\ T_u & X_u & Y_u & U_u \end{bmatrix}^{-1} \begin{bmatrix} \mathbb{D}_t \\ \mathbb{D}_x \\ \mathbb{D}_y \\ \mathbb{D}_u \end{bmatrix} \tag{5}$$

are the invariant differential operators.

III. STRUCTURE EQUATIONS OF THE DIFFEOMORPHISM PSEUDOGROUP

The invariant coframe for the diffeomorphism pseudogroup are the invariant horizontal and contact forms σ^a, μ^a_J. The structure equations amount to writing their differentials $\mathrm{d}\sigma^a$, $\mathrm{d}\mu^a_J$ as linear combinations of wedge products of the invariant differential forms. A concise way to write down the structure equations, as first described in an earlier paper,[22] rests on a formal power series expansion.[29] To this end, we define the vector-valued formal power series

$$\mu[\![H]\!] := (\mu^a[\![H]\!]) = \left(\sum_{\#J\geq 0} \frac{1}{J!}\mu^a_J H^J \right) \tag{6}$$

whose coefficients are the invariant contact forms on $\mathcal{D}^{(\infty)}$. In particular, if we set $H=(H^a)=0$ in (6), then $\mu[\![0]\!]=\mu:=(\mu^a)$. The key result, proved in an earlier paper,[22] is that the structure equations of the invariant coframe can be read off from certain matrix identities.

Lemma III.1: Let

$$\nabla\mu[\![H]\!] := \left(\frac{\partial \mu^a[\![H]\!]}{\partial H^b} \right)$$

denote the Jacobian matrix of the vector $\mu[\![H]\!]$ of power series in the variables $H=(H^a)$. Then

$$\mathrm{d}\mu[\![H]\!] = \nabla\mu[\![H]\!] \wedge (\mu[\![H]\!] - \mathrm{d}Z). \tag{7}$$

The structure equations of the invariant horizontal forms are given by

$$\mathrm{d}\sigma = -\,\mathrm{d}\mu, \tag{8}$$

where $\sigma := (\sigma^a)$.

The coefficients of the powers H^J in Eq. (7), along with (8), form the complete system of structure equations for the diffeomorphism pseudogroup $\mathcal{D}$.

KP equation 2: We use the capital letters $H,K,L,N \in \mathbb{R}$ to denote variables for power series. The structure equations for the invariant contact forms on $\mathcal{D}^{(\infty)}$ are given by the identity

$$\mathrm{d}\mu[\![H,K,L,N]\!] = \nabla\mu[\![H,K,L,N]\!] \wedge (\mu[\![H,K,L,N]\!] - \mathrm{d}Z), \tag{9}$$

where

$$\mathrm{d}\mu[\![H,K,L,N]\!] = \sum_{h,k,l,n\geq 0} \frac{H^h K^k L^l N^n}{h!\,k!\,l!\,n!} \begin{bmatrix} \mathrm{d}\mu^t_{h,k,l,n} \\ \mathrm{d}\mu^x_{h,k,l,n} \\ \mathrm{d}\mu^y_{h,k,l,n} \\ \mathrm{d}\mu^u_{h,k,l,n} \end{bmatrix},$$

$$\nabla\mu[\![H,K,L,N]\!] = \sum_{h,k,l,n\geqslant 0} \frac{H^h K^k L^l N^n}{h!\,k!\,l!\,n!} \begin{bmatrix} \mu^t_{h+1,k,l,n} & \mu^t_{h,k+1,l,n} & \mu^t_{h,k,l+1,n} & \mu^t_{h,k,l,n+1} \\ \mu^x_{h+1,k,l,n} & \mu^x_{h,k+1,l,n} & \mu^x_{h,k,l+1,n} & \mu^x_{h,k,l,n+1} \\ \mu^y_{h+1,k,l,n} & \mu^y_{h,k+1,l,n} & \mu^y_{h,k,l+1,n} & \mu^y_{h,k,l,n+1} \\ \mu^u_{h+1,k,l,n} & \mu^u_{h,k+1,l,n} & \mu^u_{h,k,l+1,n} & \mu^u_{h,k,l,n+1} \end{bmatrix},$$

$$\mu[\![H,K,L,N]\!] - \mathrm{d}Z = -\begin{bmatrix} \sigma^t \\ \sigma^x \\ \sigma^y \\ \sigma^u \end{bmatrix} + \sum_{\substack{h,k,l,n\geqslant 0 \\ h+k+l+n\geqslant 1}} \frac{H^h K^k L^l N^n}{h!\,k!\,l!\,n!} \begin{bmatrix} \mu^t_{h,k,l,n} \\ \mu^x_{h,k,l,n} \\ \mu^y_{h,k,l,n} \\ \mu^u_{h,k,l,n} \end{bmatrix}.$$

Once the structure equations for the invariant contact forms are established, those for the invariant horizontal forms are immediately obtained by

$$\begin{bmatrix} \mathrm{d}\sigma^t \\ \mathrm{d}\sigma^x \\ \mathrm{d}\sigma^y \\ \mathrm{d}\sigma^u \end{bmatrix} = -\begin{bmatrix} \mathrm{d}\mu^t \\ \mathrm{d}\mu^x \\ \mathrm{d}\mu^y \\ \mathrm{d}\mu^u \end{bmatrix}.$$

IV. MAURER–CARTAN EQUATIONS FOR LIE SYMMETRY PSEUDOGROUPS

Let $\mathcal{X}=\mathcal{X}(M)$ denote the space of locally defined vector fields

$$\mathbf{v} = \sum_{a=1}^{m} \zeta^a \partial_{z^a}$$

on M, i.e., the space of local sections of its tangent bundle TM. Given a sub-pseudogroup $\mathcal{G}\subset\mathcal{D}$, let $\mathfrak{g}\subset\mathcal{X}$ denote its local Lie algebra of infinitesimal generators, and $\mathfrak{g}^{(n)}$ their jets. With each sufficiently large n, the subbundle $\mathfrak{g}^{(n)}\subset J^nTM$ is characterized by the linearized (or infinitesimal) determining equations

$$L^{(n)}(z^i,\zeta^a_J) = 0 \tag{10}$$

for the pseudogroup $\mathcal{G}$. Here $\zeta^a_J=\partial^J_z\zeta^a$ are the jet coordinates of a vector field $\mathbf{v}$. If $\mathcal{G}$ is the symmetry group of a system of differential equations, then (10) are (the involutive completion of) the usual determining equations obtained through Lie's infinitesimal symmetry method.

A complete, though certainly not minimal, system of invariant differential one-forms for $\mathcal{G}$ is obtained by restricting the invariant coframe $\{\sigma^a,\mu^a_J\}$ to the Lie subgroupoid $\mathcal{G}^{(\infty)}\subset\mathcal{D}^{(\infty)}$ given by the jets of pseudogroup diffeomorphisms. For simplicity, we will not explicitly employ the pull-back notation on these restricted forms. The resulting dependencies among the restricted forms are elucidated by the following theorem.[22]

Theorem IV.1: *The invariant forms μ^a_J on $\mathcal{G}^{(n)}$ satisfy the linear system*

$$L^{(n)}(Z^i,\mu^a_J) = 0 \tag{11}$$

obtained by replacing z^i by Z^i and ζ^a_J by μ^a_J in the linearized determining equations (10).

In accordance with an earlier paper,[22] we refer to (11) as the *lifted determining equations* for the pseudogroup.

Theorem IV.2: *The structure equations of the invariant coframe for a Lie pseudogroup $\mathcal{G}$ are obtained by restricting the diffeomorphism structure equations (7) and (8) to the space of solutions of the lifted determining equations (11).*

Since the target coordinates $Z=(Z^a)$ are right invariant, the individual fibers of the target fibration $\boldsymbol{\tau}^{(n)}:\mathcal{G}^{(n)}\to M$ are invariant under the right-action of $\mathcal{G}$ and, for that matter, $\mathcal{G}^{(n)}$. The

Cartan structure equations of a Lie pseudogroup,[3] are obtained by restricting the invariant coframe to a single fiber $\mathcal{G}^{(n)}|_Z=(\boldsymbol{\tau}^{(n)})^{-1}(Z)$, where $Z\in M$ is fixed. Since $0=\mathrm{d}Z^a=\sigma^a+\mu^a$ when restricted to a fiber $\mathcal{G}^{(n)}|_Z$, we can replace σ^a by $-\mu^a$, and hence only the independent invariant contact forms μ^a_J will appear in the resulting structure equations. For example, if the pseudogroup is defined by the (local) action of a finite-dimensional Lie transformation group G on M, then, under some mild regularity assumptions, $\mathcal{G}^{(n)}\to M$ has the structure of a principal G-bundle for n sufficiently large. Each fiber can be identified with a copy of the Lie group, and the restrictions of the independent invariant contact forms to $\mathcal{G}^{(n)}|_Z\simeq G$ are a system of classical (right-invariant) Maurer–Cartan forms for the group G.

These results form the foundation for a general, intrinsic algorithm for directly determining the structure of the symmetry group of a system of differential equations, as well as the structure of its algebra of differential invariants, as fixed by a choice of a moving frame.[7,9] The key point is that the required computations rely exclusively on linear differential algebra, and so can be readily implemented in any standard symbolic computation package. In this paper, we have concentrated on the first part of the method, the determination of the structure of the symmetry (pseudo)group. The second part, on the structure of the differential invariant algebra and the invariant variational bicomplex[9,10] will be explained in more detail in a subsequent publication.

KP equation 3: Let $\mathcal{G}$ denote the infinite-dimensional symmetry pseudogroup of the KP equation (1). We begin by writing out the lifted determining equations

$$\mu^y_U=0,\quad \mu^y_X=0,\quad \mu^x_U=0,\quad \mu^y_T+\tfrac{3}{2}\epsilon\mu^x_Y=0,\quad 3\mu^x_X-\mu^t_T=0,$$

$$\tfrac{3}{2}\mu^u-\mu^x_T+U\mu^t_T=0,\quad \tfrac{3}{2}\mu^y_Y-\mu^t_T=0,\quad \mu^t_U=0,\quad \mu^t_X=0,\quad \mu^t_Y=0, \tag{12}$$

$$\mu^t_T+\tfrac{3}{2}\mu^u_U=0,\quad \tfrac{2}{3}\mu^t_{TT}-3\mu^u_X=0,\quad \mu^u_{TX}+\tfrac{3}{2}U\mu^u_{XX}+\tfrac{1}{4}\mu^u_{XXXX}+\tfrac{3}{4}\epsilon\mu^u_{YY}=0,$$

and so on, which are obtained from the KP symmetry determining equations (4) by replacing t,x,y,u by T,X,Y,U and τ,ξ,η,ϕ by the invariant contact forms μ^t,μ^x,μ^y,μ^u, respectively. These and their higher order counterparts obtained by Lie differentiation with respect to the invariant differential operators (5) form a complete system of linear dependencies among the invariant contact forms when restricted to the symmetry groupoid $\mathcal{G}^{(\infty)}$.

We solve the lifted system of equations (12) [or, equivalently, the original system (4) of infinitesimal determining equations prior to the lifting] through cross-differentiations and Gaussian elimination to determine the following basis of linearly independent Maurer–Cartan forms,

$$\omega^1:=\mu^t,\quad \omega^2:=\mu^x,\quad \omega^3:=\mu^y,\quad \omega^4:=\mu^u,\quad \omega^5:=\mu^t_T=\mu^t_{1,0,0,0},$$

$$\omega^6:=\mu^y_T=\mu^y_{1,0,0,0},\quad \alpha^i:=\mu^u_{i,0,0,0},\quad \beta^i:=\mu^u_{i-1,1,0,0},\quad \gamma^i:=\mu^u_{i-1,0,1,0}, \tag{13}$$

for $i=1,2,3,\ldots$. For example,

$$\mu^x_T=\tfrac{3}{2}\omega^4+U\omega^5,\quad \mu^t_X=0,\quad \mu^x_X=\tfrac{1}{3}\omega^5,$$

$$\mu^y_X=0,\quad \mu^t_Y=0,\quad \mu^x_Y=-\tfrac{2}{3}\epsilon\omega^6,\quad \mu^y_Y=\tfrac{2}{3}\omega^5,$$

$$\mu^t_U=0,\quad \mu^x_U=0,\quad \mu^y_U=0,\quad \mu^u_U=-\tfrac{2}{3}\omega^5, \tag{14}$$

$$\mu^t_{TT}=\tfrac{9}{2}\beta^1,\quad \mu^x_{TT}=\tfrac{3}{2}\alpha^1+\tfrac{9}{2}U\beta^1,\quad \mu^y_{TT}=-\tfrac{9}{4}\epsilon\gamma^1,$$

$$\mu^t_{TX}=0,\quad \mu^x_{TX}=\tfrac{3}{2}\beta^1,\quad \mu^y_{TX}=0,\quad \mu^t_{TY}=0,\quad \ldots.$$

The independent invariant contact forms (13) together with the restricted invariant horizontal forms $\{\sigma^t, \sigma^x, \sigma^y, \sigma^u\}$ form an invariant coframe on the Lie groupoid $\mathcal{G}^{(\infty)}$. The structure equations of this coframe are obtained by imposing the dependence relation (14) on the structure equations (9) for the full diffeomorphism groupoid $\mathcal{D}^{(\infty)}$. The resulting structure equations are

$$\mathrm{d}\sigma^t = \omega^5 \wedge \sigma^t,$$

$$\mathrm{d}\sigma^x = \tfrac{3}{2}\omega^4 \wedge \sigma^t + U\omega^5 \wedge \sigma^t + \tfrac{1}{3}\omega^5 \wedge \sigma^x - \tfrac{2}{3}\epsilon\omega^6 \wedge \sigma^y,$$

$$\mathrm{d}\sigma^y = \tfrac{2}{3}\omega^5 \wedge \sigma^y + \omega^6 \wedge \sigma^t,$$

$$\mathrm{d}\sigma^u = -\tfrac{2}{3}\omega^5 \wedge \sigma^u + \alpha^1 \wedge \sigma^t + \beta^1 \wedge \sigma^x + \gamma^1 \wedge \sigma^y,$$

$$\mathrm{d}\omega^1 = -\omega^5 \wedge \sigma^t,$$

$$\mathrm{d}\omega^2 = -\tfrac{3}{2}\omega^4 \wedge \sigma^t - U\omega^5 \wedge \sigma^t - \tfrac{1}{3}\omega^5 \wedge \sigma^x + \tfrac{2}{3}\epsilon\omega^6 \wedge \sigma^y,$$

$$\mathrm{d}\omega^3 = -\tfrac{2}{3}\omega^5 \wedge \sigma^y - \omega^6 \wedge \sigma^t,$$

$$\mathrm{d}\omega^4 = \tfrac{2}{3}\omega^5 \wedge \sigma^u - \alpha^1 \wedge \sigma^t - \beta^1 \wedge \sigma^x - \gamma^1 \wedge \sigma^y,$$

$$\mathrm{d}\omega^5 = -\tfrac{9}{2}\beta^1 \wedge \sigma^t,$$

$$\mathrm{d}\omega^6 = -\tfrac{1}{3}\omega^5 \wedge \omega^6 - 3\beta^1 \wedge \sigma^y + \tfrac{9}{4}\epsilon\gamma^1 \wedge \sigma^t,$$

$$\mathrm{d}\alpha^1 = -\tfrac{3}{2}\omega^4 \wedge \beta^1 - \tfrac{5}{3}\omega^5 \wedge \alpha^1 - U\omega^5 \wedge \beta^1 - \omega^6 \wedge \gamma^1 + 3\beta^1 \wedge \sigma^u - \alpha^2 \wedge \sigma^t - \beta^2 \wedge \sigma^x - \gamma^2 \wedge \sigma^y,$$

$$\mathrm{d}\beta^1 = -\omega^5 \wedge \beta^1 - \beta^2 \wedge \sigma^t,$$

$$\mathrm{d}\gamma^1 = -\tfrac{4}{3}\omega^5 \wedge \gamma^1 + \tfrac{2}{3}\epsilon\omega^6 \wedge \beta^1 + \tfrac{4}{3}\epsilon\beta^2 \wedge \sigma^y - \gamma^2 \wedge \sigma^t,$$

$$\mathrm{d}\alpha^2 = -3\omega^4 \wedge \beta^2 - \tfrac{8}{3}\omega^5 \wedge \alpha^2 - 2U\omega^5 \wedge \beta^2 - 2\omega^6 \wedge \gamma^2 + 9\alpha^1 \wedge \beta^1 + 3\beta^2 \wedge \sigma^u - \alpha^3 \wedge \sigma^t - \beta^3 \wedge \sigma^x - \gamma^3 \wedge \sigma^y,$$

$$\mathrm{d}\beta^2 = -2\omega^5 \wedge \beta^2 - \beta^3 \wedge \sigma^t,$$

$$\mathrm{d}\gamma^2 = -\tfrac{7}{3}\omega^5 \wedge \gamma^2 + 2\epsilon\omega^6 \wedge \beta^2 - \tfrac{9}{2}\beta^1 \wedge \gamma^1 - \gamma^3 \wedge \sigma^t + \tfrac{4}{3}\epsilon\beta^3 \wedge \sigma^y, \quad \dots . \tag{15}$$

After restricting the equations (15) to a target fiber $(\boldsymbol{\tau}^{(\infty)})^{-1}(T, X, Y, U)$, i.e., fixing the values of the target coordinates T, X, Y, U, we find the Maurer–Cartan equations for the KP symmetry pseudogroup $\mathcal{G}$ to be

$$\mathrm{d}\omega^1 = -\omega^1 \wedge \omega^5,$$

$$\mathrm{d}\omega^2 = -\tfrac{3}{2}\omega^1 \wedge \omega^4 - U\omega^1 \wedge \omega^5 - \tfrac{1}{3}\omega^2 \wedge \omega^5 + \tfrac{2}{3}\epsilon\omega^3 \wedge \omega^6,$$

$$\mathrm{d}\omega^3 = -\omega^1\wedge\omega^6 - \tfrac{2}{3}\omega^3\wedge\omega^5,$$

$$\mathrm{d}\omega^4 = -\omega^1\wedge\alpha^1 - \omega^2\wedge\beta^1 - \omega^3\wedge\gamma^1 + \tfrac{2}{3}\omega^4\wedge\omega^5,$$

$$\mathrm{d}\omega^5 = -\tfrac{9}{2}\omega^1\wedge\beta^1,$$

$$\mathrm{d}\omega^6 = \tfrac{9}{4}\epsilon\omega^1\wedge\gamma^1 - 3\omega^3\wedge\beta^1 - \tfrac{1}{3}\omega^5\wedge\omega^6,$$

$$\mathrm{d}\alpha^1 = -\omega^1\wedge\alpha^2 - \omega^2\wedge\beta^2 - \omega^3\wedge\gamma^2 + \tfrac{3}{2}\omega^4\wedge\beta^1 - \tfrac{5}{3}\omega^5\wedge\alpha^1 - U\omega^5\wedge\beta^1 - \omega^6\wedge\gamma^1,$$

$$\mathrm{d}\beta^1 = -\omega^1\wedge\beta^2 - \omega^5\wedge\beta^1,$$

$$\mathrm{d}\gamma^1 = -\omega^1\wedge\gamma^2 + \tfrac{4}{3}\epsilon\omega^3\wedge\beta^2 - \tfrac{4}{3}\omega^5\wedge\gamma^1 + \tfrac{2}{3}\epsilon\omega^6\wedge\beta^1,$$

$$\mathrm{d}\alpha^2 = -\omega^1\wedge\alpha^3 - \omega^2\wedge\beta^3 - \omega^3\wedge\gamma^3 - \tfrac{8}{3}\omega^5\wedge\alpha^2 - 2U\omega^5\wedge\beta^2 - 2\omega^6\wedge\gamma^2 + 9\alpha^1\wedge\beta^1,$$

$$\mathrm{d}\beta^2 = -\omega^1\wedge\beta^3 - 2\omega^5\wedge\beta^2,$$

$$\mathrm{d}\gamma^2 = -\omega^1\wedge\gamma^3 + \tfrac{4}{3}\epsilon\omega^3\wedge\beta^3 - \tfrac{7}{3}\omega^5\wedge\gamma^2 + 2\epsilon\omega^6\wedge\beta^2 - \tfrac{9}{2}\beta^1\wedge\gamma^1, \quad \ldots.$$

The structure equations for a slightly different variant of the KP equation obtained by Reid *et al.*,[14–16] involve nine basic Maurer–Cartan forms $\{\boldsymbol{\omega}^i \,|\, i=1,2,\ldots,9\}$. The Maurer–Cartan equations that our algorithm finds for the particular target fiber $U=0$ can be mapped to theirs by the scaling correspondence

$$\omega^3 = \mu^y \mapsto p\boldsymbol{\omega}^1, \quad \omega^2 = \mu^x \mapsto \frac{p^2}{q}\boldsymbol{\omega}^2, \quad \omega^1 = \mu^t \mapsto q\boldsymbol{\omega}^3,$$

$$\omega^4 = \mu^u \mapsto -\frac{p^2}{q^2}\boldsymbol{\omega}^4, \quad \gamma^1 = \mu^u_Y \mapsto -\frac{p}{q^2}\boldsymbol{\omega}^5, \quad \beta^1 = \mu^u_X \mapsto -\frac{1}{q}\boldsymbol{\omega}^6,$$

$$\alpha^1 = \mu^u_T \mapsto -\frac{p^2}{q^3}\boldsymbol{\omega}^7, \quad \omega^5 = \mu^t_T \mapsto -\frac{3}{2}\boldsymbol{\omega}^8, \quad \omega^6 = \mu^y_T \mapsto -\frac{2p}{q}\boldsymbol{\omega}^9,$$

$$\beta^2 = \mu^u_{TX} \mapsto \frac{1}{q^2}\boldsymbol{\pi}^1, \quad \gamma^2 = \mu^u_{TY} \mapsto -\frac{p}{q^3}\boldsymbol{\pi}^2, \quad \alpha^2 = \mu^u_{TT} \mapsto -\frac{p^2}{q^4}\boldsymbol{\pi}^3,$$

where p,q are any nonzero constants. Moreover, the other invariant forms $\{\boldsymbol{\pi}^1,\boldsymbol{\pi}^2,\boldsymbol{\pi}^3\}$ appearing in their list of structure equations will correspond to rescalings of our next three second-order Maurer–Cartan forms $\alpha^2,\beta^2,\gamma^2$.

KdV equation: Now let $\mathcal{G}$ denote the symmetry group of the KdV equation (2). Applying Lie's algorithm, the infinitesimal symmetries $\mathbf{v}=\tau\partial_t+\xi\partial_x+\phi\partial_u$ must satisfy the (minimal) determining equations

$$\xi_u = 0, \quad 3\xi_x - \tau_t = 0, \quad \phi - \xi_t + \tfrac{2}{3}u\tau_t = 0, \quad \tau_u = 0,$$

$$\tau_x = 0, \quad \phi_{uu} = 0, \quad \phi_{xu} = 0, \quad \phi_t + u\phi_x + \phi_{xxx} = 0.$$

When this system is completed to involution, all the higher order equations are obtained by differentiation. The corresponding lifted determining equations are

$$\mu^x_U = 0, \quad 3\mu^x_X - \mu^t_T = 0, \quad \mu^u - \mu^x_T + \tfrac{2}{3}U\mu^t_T = 0, \quad \mu^t_U = 0,$$

$$\mu^t_X = 0, \quad \mu^u_{UU} = 0, \quad \mu^u_{XU} = 0, \quad \mu^u_T + U\mu^u_X + \mu^u_{XXX} = 0,$$

and so on, where the higher-order equations are obtained by repeated Lie differentiation with respect to $\mathbb{D}_T, \mathbb{D}_X, \mathbb{D}_U$. Restricting to the symmetry groupoid $\mathcal{G}^{(\infty)}$, there are precisely four independent invariant contact forms,

$$\omega^1 := \mu^t, \quad \omega^2 := \mu^x, \quad \omega^3 := \mu^u, \quad \omega^4 := \mu^t_T,$$

which reflects the fact that the symmetry group of the KdV equation is a four-dimensional Lie group. The structure equations of the coframe are

$$\mathrm{d}\sigma^t = \omega^4 \wedge \sigma^t,$$

$$\mathrm{d}\sigma^x = \omega^3 \wedge \sigma^t + \tfrac{2}{3}U\omega^4 \wedge \sigma^t + \tfrac{1}{3}\omega^4 \wedge \sigma^x,$$

$$\mathrm{d}\sigma^u = -\tfrac{2}{3}\omega^4 \wedge \sigma^u,$$

$$\mathrm{d}\omega^1 = -\omega^4 \wedge \sigma^t,$$

$$\mathrm{d}\omega^2 = -\omega^3 \wedge \sigma^t - \tfrac{2}{3}U\omega^4 \wedge \sigma^t - \tfrac{1}{3}\omega^4 \wedge \sigma^x,$$

$$\mathrm{d}\omega^3 = \tfrac{2}{3}\omega^4 \wedge \sigma^u,$$

$$\mathrm{d}\omega^4 = 0,$$

where $\sigma^t, \sigma^x, \sigma^u$ are the invariant horizontal forms. The Maurer–Cartan equations for the Lie symmetry group $\mathcal{G}$ are obtained by restricting to a target fiber where T, X, U are fixed, whence

$$\mathrm{d}\omega^1 = -\omega^1 \wedge \omega^4,$$

$$\mathrm{d}\omega^2 = -\omega^1 \wedge \omega^3 - \tfrac{2}{3}U\omega^1 \wedge \omega^4 - \tfrac{1}{3}\omega^2 \wedge \omega^4,$$

$$\mathrm{d}\omega^3 = \tfrac{2}{3}\omega^3 \wedge \omega^4,$$

$$\mathrm{d}\omega^4 = 0.$$

V. DISCUSSION

An efficient method for finding the local structure of Lie symmetry pseudogroups of differential equations was explained, and was demonstrated for the particular cases of the KP and KdV equations. The algorithm can be straightforwardly applied to any system of differential equations, irrespective of whether its symmetry group is finite dimensional or infinite dimensional. To apply our method to other more complicated differential equations, we should optimize our computational procedure and develop more efficient symbolic algebra routines.

The next stage of applications of our method is to develop the moving frame algorithms for pseudogroup actions on submanifolds,[23] which will construct complete systems of differential invariants and invariant differential forms, classify their syzygies and recurrence relations, analyze invariant variational principles,[9,10] and solve equivalence and symmetry problems arising in geometry and physics.

Local and nonlocal symmetries for nonlinear telegraph equation

G. W. Bluman,[a] Temuerchaolu,[b] and R. Sahadevan[c]
Department of Mathematics, University of British Columbia, Vancouver, BC, Canada V6T 1Z2

(Received 18 August 2004; accepted 12 October 2004; published online 2 February 2005)

In this paper, local and nonlocal symmetry classifications are considered for four equivalent nonlinear telegraph equations. A complete potential symmetry classification of a scalar nonlinear telegraph equation is given through the point symmetry classification of a related potential system. Six new classes of equations are shown to admit potential symmetries. The relationships between local (including contact) and nonlocal (potential) symmetries of these equations are explored. A physical example is considered for possible applications of the obtained potential symmetries. © *2005 American Institute of Physics*. [DOI: 10.1063/1.1841481]

I. INTRODUCTION

In Refs. 1–4, an algorithmic procedure has been developed to find nonlocal symmetries (potential symmetries) of partial differential equations (PDEs) to extend the classes of symmetries admitted by PDEs. Various researchers have found examples of PDEs that admit potential symmetries or extended the procedure to find potential systems.[5]

In recent years, there have been several investigations (Refs. 6–8) to find symmetries for nonlinear telegraph equations of the form

$$u_{tt} = [F(u)u_x]_x + [G(u)]_x. \tag{1}$$

PDE (1) is equivalent to the potential system

$$v_x = u_t,$$

$$v_t = F(u)u_x + G(u). \tag{2}$$

In particular, if $(u,v)=(U(x,t),V(x,t))$ solves (2), then $u=U(x,t)$ solves (1). Conversely, for any $u=U(x,t)$ solving (1), there exists a pair of functions $(u,v)=(U(x,t),V(x,t))$ solving (2) with $V(x,t)$ unique to within a constant.

Similarly, the potential system (2) is equivalent to the potential system

$$w_t = v,$$

$$w_x = u, \tag{3}$$

$$v_t = F(u)u_x + G(u),$$

and hence to the potential equation

$$w_{tt} = F(w_x)w_{xx} + G(w_x). \tag{4}$$

In particular, if $u=U(x,t)$ solves (1), then from the integrability conditions associated with (3) there exists a triplet $(u,v,w)=(U(x,t),V(x,t),W(x,t))$ solving system (3) with $w=W(x,t)$ solving (4). Conversely, if $w=W(x,t)$ solves (4), then $(u,v)=(W_x(x,t),W_t(x,t))$ solves (2) and $u=W_x(x,t)$ solves (1).

Consequently, a symmetry of any one of the PDE systems (1)–(4) defines a symmetry of the remaining three equivalent systems. Moreover, due to the relationship connecting these four equivalent systems, it is possible for a local symmetry of any one of these systems to yield a nonlocal symmetry of another one.[9]

Equations related to (1) include the nonlinear heat conduction equation when $F(u)=0$, and the nonlinear inhomogeneous vibrating string equation when $G(u)=0$.

The group properties of the nonlinear heat equation for both the scalar form (1) and the potential system (2) are presented in Ref. 2. The point symmetry classification of the nonlinear wave equation (1) with $G(u)=0$ and $F(u)$ replaced by $F(x,u)$ is discussed in Ref. 6. The complete point symmetry classifications of equation (1) and the equivalent potential equation (4) are given in Refs. 7 and 8, respectively. Some exact solutions of system (2) are given in Ref. 10 for special forms of $F(u)$ and $G(u)$.

Among the equivalent systems (1)–(4), it appears that the potential system (2) arises most directly in physical situations. One physical example directly related to system (2) is represented by the equations of telegraphy of a two-conductor transmission line with v as the current in the conductors, u as the voltage between the conductors, $G(u)$ as the leakage current per unit length, $F(u)$ as the differential capacitance, t as a spatial variable and x as time.[11] Another physical example related to system (2) is the equation of motion of a hyperelastic homogeneous rod whose cross-sectional area varies exponentially along the rod. Here u is the displacement gradient related to the difference between a spatial Eulerian coordinate and a Lagrangian coordinate x, v is the velocity of a particle displaced by this difference, $G(u)$ is essentially the stress tensor, $F(u)=\lambda G'(u)$ for some constant λ, and t is time (see Refs. 12 and 13).

In this paper we give the complete point symmetry classification of the potential system (2) and compare our results with the complete point symmetry classification of the scalar equation (1) included in Ref. 7 and the complete point symmetry classification of the potential equation (4) given in Ref. 8. In particular, we will show the following.

(I) The point symmetry classifications of the scalar equations (1) and (4) are identical, i.e., for any $F(u)$ and $G(u)$, a point symmetry admitted by (1) induces a point symmetry admitted by (4) and vice versa.

(II) For wide classes of $F(u)$ and $G(u)$, there exist point symmetries of the potential system (2) which are nonlocal symmetries of the scalar equation (1).

(III) Each point symmetry of the potential system (2) which is a nonlocal symmetry of (1) yields a contact symmetry of the potential equation (4) that is *not* a point symmetry of (4).

(IV) For all but one particular class of $F(u)$ and $G(u)$, a point symmetry of the scalar equation (1) is a point symmetry of (2).

In Sec. II, we give the set of determining equations for point symmetries of the potential system (2) and the complete potential symmetry classification of the scalar equation (1) related to (2). In Secs. III and IV, we present the complete point symmetry classifications of the scalar equations (1) and (4) given in Refs. 7 and 8, respectively. In Sec. V, we compare the point symmetry classifications of the systems (1), (2), and (4) by proving theorems that yield statements (I)–(IV). The second physical example is considered in Sec. VI. Further comments are given in Sec. VII.

II. POTENTIAL SYMMETRY CLASSIFICATION OF THE SCALAR EQUATION (1)

Consider the potential system (2).

The point symmetry

$$x^* = x + \varepsilon\xi(x,t,u,v) + O(\varepsilon^2),$$

$$t^* = t + \varepsilon\tau(x,t,u,v) + O(\varepsilon^2),$$

$$u^* = u + \varepsilon\eta(x,t,u,v) + O(\varepsilon^2),$$

$$v^* = v + \varepsilon\phi(x,t,u,v) + O(\varepsilon^2), \tag{5}$$

is admitted by system (2) if and only if it satisfies the determining equations,

$$X^{(1)}(v_x - u_t) = 0,$$

$$X^{(1)}(v_t - F(u)u_x - G(u)) = 0, \tag{6}$$

for *any* (u,v) that solves system (2);

$$X = \xi(x,t,u,v)\frac{\partial}{\partial x} + \tau(x,t,u,v)\frac{\partial}{\partial t} + \eta(x,t,u,v)\frac{\partial}{\partial u} + \phi(x,t,u,v)\frac{\partial}{\partial v}$$

is the infinitesimal generator of the point symmetry (5);

$$X^{(1)} = X + \eta^{(1)}\frac{\partial}{\partial u_x} + \eta^{(2)}\frac{\partial}{\partial u_t} + \phi^{(1)}\frac{\partial}{\partial v_x} + \phi^{(2)}\frac{\partial}{\partial v_t},$$

with

$$\eta^{(1)} = \frac{D\eta}{Dx} - \frac{D\xi}{Dx}u_x - \frac{D\tau}{Dx}u_t, \quad \eta^{(2)} = \frac{D\eta}{Dt} - \frac{D\xi}{Dt}u_x - \frac{D\tau}{Dt}u_t,$$

$$\phi^{(1)} = \frac{D\phi}{Dx} - \frac{D\xi}{Dx}v_x - \frac{D\tau}{Dx}v_t, \quad \phi^{(2)} = \frac{D\phi}{Dt} - \frac{D\xi}{Dt}v_x - \frac{D\tau}{Dt}v_t,$$

is the first extension (prolongation) of X;

$$\frac{D}{Dx} = \frac{\partial}{\partial x} + u_x\frac{\partial}{\partial u} + v_x\frac{\partial}{\partial v} + u_{xx}\frac{\partial}{\partial u_x} + u_{xt}\frac{\partial}{\partial u_t} + v_{xx}\frac{\partial}{\partial v_x} + v_{xt}\frac{\partial}{\partial v_t},$$

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + u_t\frac{\partial}{\partial u} + v_t\frac{\partial}{\partial v} + u_{xt}\frac{\partial}{\partial u_x} + u_{tt}\frac{\partial}{\partial u_t} + v_{xt}\frac{\partial}{\partial v_x} + v_{tt}\frac{\partial}{\partial v_t}$$

are total derivative operators. Note that $\eta^{(i)}, \phi^{(i)}$ are functions of x,t,u,v,u_x,u_t,v_x,v_t, $i=1,2$.

The global one-parameter (ε) Lie group of point symmetries associated with (5) is obtained by solving the initial value problem for the first order system of ordinary differential equations (ODEs)

$$\frac{dx^*}{d\varepsilon} = \xi(x^*,t^*,u^*,v^*),$$

$$\frac{dt^*}{d\varepsilon} = \tau(x^*, t^*, u^*, v^*),$$

$$\frac{du^*}{d\varepsilon} = \eta(x^*, t^*, u^*, v^*),$$

$$\frac{dv^*}{d\varepsilon} = \phi(x^*, t^*, u^*, v^*), \tag{7}$$

with $x^* = x$, $t^* = t$, $u^* = u$, $v^* = v$ at $\varepsilon = 0$.

A point symmetry (5) yields a *nonlocal symmetry* of the scalar equation (1) if and only if $\xi_v^2 + \tau_v^2 + \eta_v^2 \neq 0$, i.e., if and only if the infinitesimals ξ, τ, and η have an essential dependence on the potential variable v. Such a nonlocal symmetry is called a *potential symmetry* of scalar equation (1) related to the potential system (2) (for details, see Ref. 3).

The determining equations (6) simplify to

$$\xi_v - \tau_u = 0,$$

$$\eta_u - \phi_v + \xi_x - \tau_t = 0,$$

$$G(u)\eta_v + \eta_t - \phi_x + G(u)\tau_x = 0,$$

$$\xi_u - F(u)\tau_v = 0,$$

$$\phi_u - G(u)\tau_u - F(u)\eta_v = 0,$$

$$G(u)\xi_v + \xi_t - F(u)\tau_x = 0,$$

$$[\phi_v - \tau_t - 2G(u)\tau_v - \eta_u + \xi_x]F(u) - F'(u)\eta = 0,$$

$$[\phi_v - \tau_t - G(u)\tau_v]G(u) - F(u)\eta_x - G'(u)\eta + \phi_t = 0. \tag{8}$$

We now consider the classification problem of finding all $F(u)$, $G(u)$ such that the potential system (2) yields a potential symmetry of (1).

If

$$F(u) = \frac{c}{(au+b)^2}, \quad G(u) = \frac{d}{au+b} + f \tag{9}$$

for arbitrary constants a, b, c, d, f, or if

$$F(u) \text{ is arbitrary}, \quad G(u) = \text{const},$$

then through the potential system (2), the scalar equation admits an infinite number of potential symmetries and the potential system (2) is linearizable by a point transformation (see Refs. 3 and 4).

Various symbolic manipulation algorithms exist to solve the set of determining equations (8) (for example, see Refs. 14 and 15). Using the symmetry manipulation algorithm presented in Ref. 15, one can prove the following results.

Theorem 1: *The scalar equation (1) admits a potential symmetry related to potential system (2) if and only if the functions $F(u)$ and $G(u)$, with $G'(u) \neq 0$, satisfy the system of ODEs,*

$$(c_4u + c_5)F'(u) - 2(c_1 - c_3 - c_2G(u))F(u) = 0, \tag{10}$$

$$(c_4u + c_5)G'(u) + c_2G^2(u) - (c_1 - 2c_3 + c_4)G(u) - c_6 = 0, \tag{11}$$

for any fixed constants $c_1, c_2, \ldots, c_6$ *with* $c_2 \neq 0$.

In the linearizable case (9),

$$c_1 = 0, \quad c_6 = \frac{c_3(c_4 - c_3)}{c_2}.$$

Theorem 2: *For any* $F(u)$, $G(u)$ *satisfying the system of ODEs (10) and (11) with* $c_2 \neq 0$, *the potential system (2) admits the point symmetry (5) with*

$$\xi = c_1x + c_2 \int F(u)\mathrm{d}u,$$

$$\tau = c_3t + c_2v,$$

$$\eta = c_4u + c_5,$$

$$\phi = c_6t + (c_1 - c_3 + c_4)v, \tag{12}$$

and hence the scalar equation (1) admits the corresponding potential symmetry.

Now we find the functions $F(u)$ and $G(u)$ satisfying (10), (11) and the corresponding potential symmetries (12).

Note that the point transformation

$$\overline{x} = ax + b, \quad \overline{t} = ct + d, \quad \overline{u} = \alpha u + \beta, \quad \overline{v} = \gamma v + \rho t$$

for any constants a, b, c, d, α, β, γ, and ρ such that $ac\alpha\gamma \neq 0$ and $a\alpha = c\gamma$ is an equivalence transformation for system (2). Under this transformation, system (2) becomes the equivalent system

$$\overline{v}_{\overline{x}} = \overline{u}_{\overline{t}}, \quad \overline{v}_{\overline{t}} = \overline{F}(\overline{u})\overline{u}_{\overline{x}} + \overline{G}(\overline{u}),$$

where

$$\overline{F}(\overline{u}) = \frac{a\gamma}{c\alpha}F\left(\frac{\overline{u} - \beta}{\alpha}\right)$$

and

$$\overline{G}(\overline{u}) = \frac{\gamma}{c}G\left(\frac{\overline{u} - \beta}{\alpha}\right) + \frac{\rho}{c}.$$

We use such equivalence transformations to simplify the analysis. For example, if $G(u) = a_0(b_0u + c_0)^{d_0} + f_0$, without loss of generality we can assume that $G(u) = u^{d_0}$.

Modulo translations and scalings in u and G, we obtain six distinct classes of ODEs for $F(u)$ and $G(u)$ where scalar equation (1) admits potential symmetries. These six classes of ODEs and their solutions [modulo equivalence classes of $F(u)$ and $G(u)$] are presented in Table I. In Table II for each class we display the corresponding infinitesimals (ξ, τ, η, ϕ) and global group (x^*, t^*, u^*, v^*) obtained from solving the corresponding ODEs (7).

All symmetries presented in Tables I and II are new for each of the equivalent systems (1)–(4). Note that classes 1 and 6 are linearizable[4] if $\beta = 0$ and $\alpha = 1/2$.

TABLE I. Classes of $F(u)$ and $G(u)$ yielding potential symmetries of (1).

Class	ODEs satisfied by $F(u)$ and $G(u)$	$G(u)$	$F(u)$	Relationship between $F(u)$ and $G(u)$
1	$uG'-\alpha(1-G^2)=0$ $uF'-(\beta-1-2\alpha G)F=0$	$(u^{2\alpha}-1)/(u^{2\alpha}+1)$ $(u^{2\alpha}+1)/(u^{2\alpha}-1)$	$4u^{2\alpha+\beta-1}/(u^{2\alpha}+1)^2$ $-4u^{2\alpha+\beta-1}/(u^{2\alpha}-1)^2$	$F(u)=(u^\beta/\alpha)G'(u)$
2	$uG'-\alpha(1+G^2)=0$ $uF'+(1-\beta-2\alpha G)F=0$	$\tan(\alpha \ln u)$	$u^{\beta-1}\sec^2(\alpha \ln u)$	,,
3	$uG'+G^2=0$ $uF'-(\beta-1-2G)F=0$	$(\ln u)^{-1}$	$-u^{\beta-1}(\ln u)^{-2}$	,,
4	$G'-G^2-1=0$ $F'-2(\beta+G)F=0$	$\tan u$	$e^{2\beta u}\sec^2 u$	$F(u)=e^{2\beta u}G'(u)$
5	$G'+G^2-1=0$ $F'-2(\beta-G)F=0$	$\tanh u$ $\coth u$	$e^{2\beta u}\operatorname{sech}^2 u$ $-e^{2\beta u}\operatorname{csch}^2 u$	,,
6	$G'+G^2=0$ $F'-2(\beta-G)F=0$	u^{-1}	$-u^{-2}e^{2\beta u}$	,,

III. POINT SYMMETRY CLASSIFICATION OF THE SCALAR EQUATION (1)

In Ref. 7, Kingston and Sophocleous considered the classification problem of finding all $F(u)$, $G(u)$ such that the scalar equation (1) admits a point symmetry. The point symmetry

$$x^* = x + \varepsilon\xi(x,t,u) + O(\varepsilon^2),$$

TABLE II. Potential symmetries of (1) for each class $[\Gamma(\beta,F,\varepsilon)=\int^{ue^{2\varepsilon}} s^{-(1+\beta)}(\int^s F(x)\mathrm{d}x)\mathrm{d}s,\ \Omega(\beta,F,\varepsilon)=\int^{u+\varepsilon} e^{-2\beta s}(\int^s F(x)\mathrm{d}x)\mathrm{d}s]$.

	Class	Infinitesimals ξ,τ,η,ϕ	Global group
1	$F(u)=4u^{2\alpha+\beta-1}/(u^{2\alpha}+1)^2$ $G(u)=(u^{2\alpha}-1)/(u^{2\alpha}+1)$ or $F(u)=-4u^{2\alpha+\beta-1}/(u^{2\alpha}-1)^2$ $G(u)=(u^{2\alpha}+1)/(u^{2\alpha}-1)$	$\xi=2(\beta x+\alpha\int F(u)\mathrm{d}u)$ $\tau=(\beta+1)t+2\alpha v$ $\eta=2u$ $\phi=2\alpha t+(\beta+1)v$	$x^*=e^{2\beta\varepsilon}[x+\alpha u^\beta(\Gamma(\beta,F,\varepsilon)-\Gamma(\beta,F,0))]$ $t^*=(1/2)e^{(\beta+1)\varepsilon}[(t+v)e^{2\alpha\varepsilon}+(t-v)e^{-2\alpha\varepsilon}]$ $u^*=ue^{2\varepsilon}$ $v^*=(1/2)e^{(\beta+1)\varepsilon}[(t+v)e^{2\alpha\varepsilon}-(t-v)e^{-2\alpha\varepsilon}]$
2	$F(u)=u^{\beta-1}\sec^2(\alpha \ln u)$ $G(u)=\tan(\alpha \ln u)$	$\xi=2(\beta x-\alpha\int F(u)\mathrm{d}u)$ $\tau=(\beta+1)t-2\alpha v$ $\eta=2u$ $\phi=2\alpha t+(\beta+1)v$	$x^*=e^{2\beta\varepsilon}[x-\alpha u^\beta(\Gamma(\beta,F,\varepsilon)-\Gamma(\beta,F,0))]$ $t^*=e^{(\beta+1)\varepsilon}[t\cos 2\alpha\varepsilon-v\sin 2\alpha\varepsilon]$ $u^*=ue^{2\varepsilon}$ $v^*=e^{(\beta+1)\varepsilon}[v\cos 2\alpha\varepsilon+t\sin 2\alpha\varepsilon]$
3	$F(u)=-u^{\beta-1}(\ln u)^{-2}$ $G(u)=(\ln u)^{-1}$	$\xi=2(\beta x+\int F(u)\mathrm{d}u)$ $\tau=(\beta+1)t+2v$ $\eta=2u$ $\phi=(\beta+1)v$	$x^*=e^{2\beta\varepsilon}[x+u^\beta(\Gamma(\beta,F,\varepsilon)-\Gamma(\beta,F,0))]$ $t^*=e^{(\beta+1)\varepsilon}(2v\varepsilon+t)$ $u^*=ue^{2\varepsilon}$ $v^*=ve^{(\beta+1)\varepsilon}$
4	$F(u)=e^{2\beta u}\sec^2 u$ $G(u)=\tan u$	$\xi=2\beta x-\int F(u)\mathrm{d}u$ $\tau=\beta t-v$ $\eta=1$ $\phi=t+\beta v$	$x^*=e^{2\beta\varepsilon}[x-e^{2\beta u}(\Omega(\beta,F,\varepsilon)-\Omega(\beta,F,0))]$ $t^*=e^{\beta\varepsilon}(t\cos\varepsilon-v\sin\varepsilon)$ $u^*=u+\varepsilon$ $v^*=e^{\beta\varepsilon}(v\cos\varepsilon+t\sin\varepsilon)$
5	$F(u)=e^{2\beta u}\operatorname{sech}^2 u$ $G(u)=\tanh u$ or $F(u)=-e^{2\beta u}\operatorname{csch}^2 u$ $G(u)=\coth u$	$\xi=2\beta x+\int F(u)\mathrm{d}u$ $\tau=\beta t+v$ $\eta=1$ $\phi=t+\beta v$	$x^*=e^{2\beta\varepsilon}[x+e^{2\beta u}(\Omega(\beta,F,\varepsilon)-\Omega(\beta,F,0))]$ $t^*=(1/2)e^{\beta\varepsilon}((t+v)e^{\varepsilon}+(t-v)e^{-\varepsilon})$ $u^*=u+\varepsilon$ $v^*=(1/2)e^{\beta\varepsilon}((t+v)e^{\varepsilon}-(t-v)e^{-\varepsilon})$
6	$F(u)=-u^{-2}e^{2\beta u}$ $G(u)=u^{-1}$	$\xi=2\beta x+\int F(u)\mathrm{d}u$ $\tau=\beta t+v$ $\eta=1$ $\phi=\beta v$	$x^*=e^{2\beta\varepsilon}[x+e^{2\beta u}(\Omega(\beta,F,\varepsilon)-\Omega(\beta,F,0))]$ $t^*=e^{\beta\varepsilon}(t+v\varepsilon)$ $u^*=u+\varepsilon$ $v^*=ve^{\beta\varepsilon}$

TABLE III. Classes of $F(u)$ and $G(u)$ yielding point symmetries of (1).

Class	$G(u)$	$F(u)$	Infinitesimals ξ, τ, η
A	e^u	$e^{(\alpha+1)u}$	$\xi=2\alpha x, \tau=(\alpha-1)t, \eta=2$
B	$u^{\alpha+\beta+1}$	u^α	$\xi=2\beta x, \tau=(\alpha+2\beta)t, \eta=-2u$
C	u^{-1}	u^{-2}	Those in class B and $\xi=e^x, \tau=0, \eta=-ue^x$
D	$\ln u$	u^α	$\xi=2(\alpha+1)x, \tau=(\alpha+2)t, \eta=2u$
E	u	$e^{\alpha u}$	$\xi=2\alpha x, \tau=\alpha t, \eta=2$
F	u^{-3}	u^{-4}	Those in class B and $\xi=0, \tau=t^2, \eta=ut$

$$t^* = t + \varepsilon\tau(x,t,u) + O(\varepsilon^2),$$

$$u^* = u + \varepsilon\eta(x,t,u) + O(\varepsilon^2), \tag{13}$$

is admitted by the scalar equation (1) if and only if it satisfies the determining equation

$$X^{(2)}(u_{tt} - (F(u)u_x)_x - G(u)_x) = 0 \tag{14}$$

for any u solving the scalar equation (1);

$$X = \xi(x,t,u)\frac{\partial}{\partial x} + \tau(x,t,u)\frac{\partial}{\partial t} + \eta(x,t,u)\frac{\partial}{\partial u},$$

is the infinitesimal generator of the point symmetry (13); $X^{(2)}$ is the second extension of X.

From (14), the determining equations for $\xi(x,t,u)$, $\tau(x,t,u)$, and $\eta(x,t,u)$ are given by

$$\xi_u = \tau_x = \tau_u = \eta_{uu} = 0,$$

$$\xi_t - F(u)\tau_x = 0,$$

$$2F(u)(\xi_x - \tau_t) - F'(u)\eta = 0,$$

$$\eta_{tt} - F(u)\eta_{xx} - G'(u)\eta_x = 0,$$

$$2\eta_{tu} - \tau_{tt} + F(u)\tau_{xx} + G'(u)\tau_x = 0,$$

$$2F(u)\eta_{xu} + \xi_{tt} - F(u)\xi_{xx} + 2F'(u)\eta_x - G'(u)(\xi_x - 2\tau_t) + G''(u)\eta = 0.$$

For arbitrary $F(u)$ and $G(u)$, clearly each of the equivalent systems (1)–(4) admits translations in $x(\xi=1, \tau=0)$ and $t(\xi=0, \tau=1)$. For specific $F(u)$ and $G(u)$ with $G'(u)\neq 0$, the results are summarized in Table III.

Note that the classes presented in Ref. 7 where $F(u)=1$, $G(u)=e^{\lambda u}$ as well as $F(u)=1$, $G(u)=u^{\lambda+1}$ can be obtained, respectively, by appropriately scaling u in class A and setting $\alpha=0$ in class B.

IV. POINT SYMMETRY CLASSIFICATION OF THE SCALAR EQUATION (4)

In Ref. 8, the authors considered the classification problem of finding all $F(u)$, $G(u)$ such that the scalar equation (4) admits a point symmetry. The point symmetry

$$x^* = x + \varepsilon\xi(x,t,w) + O(\varepsilon^2),$$

TABLE IV. Classes of $F(u)$ and $G(u)$ yielding point symmetries of (4).

Class	$G(u)=G(w_x)$	$F(u)=F(w_x)$	Infinitesimals ξ, τ, η
A	e^u	$e^{(\alpha+1)u}$	$\xi=2\alpha x, \tau=(\alpha-1)t, \Omega=2(\alpha w+x)$
B	$u^{\alpha+\beta+1}$	u^α	$\xi=2\beta x, \tau=(\alpha+2\beta)t, \Omega=2(\beta-1)w$
C	u^{-1}	u^{-2}	Those in class B and $\xi=e^x, \tau=0, \Omega=0$
D	$\ln u$	u^α	$\xi=2(\alpha+1)x, \tau=(\alpha+2)t, \Omega=2(\alpha+2)w+t^2$
E	u	$e^{\alpha u}$	$\xi=2\alpha x, \tau=\alpha t, \Omega=2\alpha w+t^2+2x$
F	u^{-3}	u^{-4}	Those in class B and $\xi=0, \tau=t^2, \Omega=tw$

$$t^* = t + \varepsilon\tau(x,t,w) + O(\varepsilon^2),$$

$$w^* = w + \varepsilon\Omega(x,t,w) + O(\varepsilon^2), \tag{15}$$

is admitted by the scalar equation (4) if and only if it satisfies the determining equation

$$X^{(2)}(w_{tt} - F(w_x)w_{xx} - G(w_x)) = 0$$

for any w solving the scalar equation (4);

$$X = \xi(x,t,w)\frac{\partial}{\partial x} + \tau(x,t,w)\frac{\partial}{\partial t} + \Omega(x,t,w)\frac{\partial}{\partial w},$$

is the infinitesimal generator of the point symmetry (15); $X^{(2)}$ is the second extension of X.

Modulo equivalence transformations, the results presented in Ref. 8 are summarized in Table IV.

V. DISCUSSION OF THE SYMMETRY CLASSIFICATIONS

In this section we prove the statements (I)–(IV) presented in the Introduction through proofs of the following four theorems.

Theorem 3: *The point symmetry classifications of the scalar equations (1) and (4) are identical, i.e., for any $F(u)$ and $G(u)$ a point symmetry admitted by (1) induces a point symmetry admitted by (4) and vice versa.*

Proof: The infinitesimals of a point symmetry of the scalar equation (1) are of the form

$$\xi = \xi(x), \quad \tau = \tau(t), \quad \eta = (f(t) - \xi'(x))u + b$$

for some functions $\xi(x)$, $\tau(t)$, $f(t)$ and constant b. A corresponding point symmetry of the potential scalar equation (4) (with $u=w_x$) must have $\xi=\xi(x)$, $\tau=\tau(t)$, $\Omega=\Omega(x,t,w)$ with $\Omega(x,t,w)$ satisfying

$$\Omega^{x(1)} = \eta$$

in terms of its first extended infinitesimal $\Omega^{x(1)}$, i.e.,

$$\Omega^{x(1)} = \frac{D\Omega}{Dx} - \frac{D\xi}{Dx}w_x - \frac{D\tau}{Dx}w_t = \Omega_x + \Omega_w w_x - \xi'(x)w_x = (f(t) - \xi'(x))w_x + b. \tag{16}$$

Hence from Eq. (16), we must have

$$\Omega_x = b, \quad \Omega_w = f(t).$$

Then it is necessary that

$$\Omega = bx + f(t)w + g(t), \tag{17}$$

for some $g(t)$ in order that a point symmetry of the scalar equation (1) yields a point symmetry of the scalar equation (4). From Tables III and IV, it is easy to check that condition (17) is satisfied for each point symmetry of the scalar equation (4).

Conversely, the infinitesimals of a point symmetry of (4) are of the form

$$\xi = \xi(x), \quad \tau = \tau(t), \quad \Omega = f(t)w + \beta(x,t)$$

for some functions $\xi(x)$, $\tau(t)$, $f(t)$, and $\beta(x,t)$. A corresponding point symmetry of the scalar equation (1) with $u = w_x$ must have

$$\xi = \xi(x), \quad \tau = \tau(t), \quad \eta = \eta(x,t,u).$$

In terms of the first extended infinitesimal $\Omega^{x(1)}$, the infinitesimal $\eta(x,t,u)$ must satisfy

$$\eta = \Omega^{x(1)} = \frac{D\Omega}{Dx} - \frac{D\xi}{Dx}w_x - \frac{D\tau}{Dx}w_t = \Omega_x + \Omega_w w_x - \xi'(x)w_x = \beta_x + (f(t) - \xi'(x))w_x. \tag{18}$$

From Tables III and IV, it is easy to check that condition (18) is satisfied for each point symmetry of (1). ■

Theorem 4: *For each of the six classes of $F(u)$ and $G(u)$ listed in Table I, there exist point symmetries of the potential system (2) which are nonlocal symmetries of the scalar equation (1).*

Proof: Since each point symmetry in Table II has $\tau_v \neq 0$, it follows that for all classes of $F(u)$ and $G(u)$ listed in Table I (also repeated in Table II) there exist point symmetries of the potential system (2) which are nonlocal (potential) symmetries of the scalar equation (1). ■

Note that only the class $F(u) = u^{-2}$, $G(u) = u^{-1}$ is common for Tables I and III. This class is linearizable since it admits potential symmetries leading to the linearization of (2) by a point transformation.[4]

Theorem 5: *Each point symmetry of the potential system (2) which is a nonlocal symmetry of the scalar equation (1) yields a contact symmetry of the potential equation (4) that is* not *a point symmetry of (4).*

Proof: A *contact symmetry* of a PDE with dependent variable w and independent variables x and t is defined by

$$x^* = x + \varepsilon\xi(x,t,w,w_x,w_t) + O(\varepsilon^2),$$

$$t^* = t + \varepsilon\tau(x,t,w,w_x,w_t) + O(\varepsilon^2),$$

$$w^* = w + \varepsilon\Omega(x,t,w,w_x,w_t) + O(\varepsilon^2), \tag{19}$$

if and only if

$$\frac{\partial\Omega}{\partial w_x} = \frac{\partial\xi}{\partial w_x}w_x + \frac{\partial\tau}{\partial w_x}w_t, \quad \frac{\partial\Omega}{\partial w_t} = \frac{\partial\xi}{\partial w_t}w_x + \frac{\partial\tau}{\partial w_t}w_t. \tag{20}$$

Let characteristic function $W = \Omega - \xi w_x - \tau w_t$. A contact symmetry (19) is a point symmetry if and only if

$$\frac{\partial^2 W}{\partial(w_x)^2} = \frac{\partial^2 W}{\partial(w_t)^2} = \frac{\partial^2 W}{\partial w_x \partial w_t} = 0. \tag{21}$$

For details, see Chap. 5 of Ref. 3.

A point symmetry of potential system (2) which is a nonlocal symmetry of the scalar equation (1) (see Table II) is of the form

$$\xi = ax + b\int^{u} F(s)\mathrm{d}s, \quad \tau = ct + dv,$$

$$\eta = fu + g, \quad \phi = ht + kv, \tag{22}$$

for some constants a, b, c, d, f, g, h, and k with $d \neq 0$, $a+f=c+k$.

Solving (20), after using the substitution (22), we find that

$$\Omega(x,t,w,w_x,w_t) = b\int^{w_x} sF(s)\mathrm{d}s + \frac{d}{2}w_t^2 + A(x,t,w) \tag{23}$$

yields a contact symmetry for an arbitrary function $A(x,t,w)$.

Now we find $A(x,t,w)$ so that (23) yields a contact symmetry of the potential equation (4). Since $u=w_x$, $v=w_t$, it follows that we must have

$$\eta = \Omega^{x(1)} = \frac{D\Omega}{Dx} - \frac{D\xi}{Dx}w_x - \frac{D\tau}{Dx}w_t,$$

$$\phi = \Omega^{t(1)} = \frac{D\Omega}{Dt} - \frac{D\xi}{Dt}w_x - \frac{D\tau}{Dt}w_t, \tag{24}$$

in terms of first extended infinitesimals $\Omega^{x(1)}$ and $\Omega^{t(1)}$. After solving the equations (24), we find that $A(x,t,w)=gx+(a+f)w+\frac{1}{2}ht^2$ and hence

$$\xi = ax + b\int^{w_x} F(s)\mathrm{d}s, \quad \tau = ct + dw_t,$$

$$\Omega = b\int^{w_x} sF(s)\mathrm{d}s + \frac{d}{2}w_t^2 + gx + (a+f)w + \frac{1}{2}ht^2, \tag{25}$$

defines a contact symmetry of the scalar potential equation (4). Using condition (21), it is clear that (25) is *not* a point symmetry of (4) since $d \neq 0$. ■

Theorem 6: *A point symmetry of the scalar equation (1) yields a point symmetry of the potential equation (2) if and only if the infinitesimals for $F(u)$ and $G(u)$ belong to classes A–E in Table III.*

Proof: A point symmetry $(\xi(x,t,u), \tau(x,t,u), \eta(x,t,u))$ of the scalar equation (1) yields a point symmetry of (2) if and only if the set of determining equations (8) has a solution for $\phi(x,t,u,v)$. A solution of (8) exists if and only if the six integrability conditions involving the second order mixed partial derivatives of $\phi(x,t,u,v)$ are satisfied. Consequently, it is easy to show that a point symmetry of (1) yields a point symmetry of (2) if and only if it satisfies the additional conditions

$$\tau_{tt} = 0, \quad \eta_{xu} + \xi_{xx} = 0, \quad \eta_{tt} = 0, \quad F'(u)\eta_x - 2F(u)\xi_{xx} = 0. \tag{26}$$

The infinitesimals for classes A–E in Table III satisfy (26) but those for class F do not since here $\tau_{tt} \neq 0$. ■

As a consequence of Theorem 6, we see that the point symmetry $X=t^2(\partial/\partial t)+ut(\partial/\partial u)$ for $G(u)=u^{-3}$, $F(u)=u^{-4}$ yields a *nonlocal symmetry* of the potential system (2).

TABLE V. Physical examples $[F(u)=G'(u)]$ yielding potential symmetries of (1).

	Class	Infinitesimals ξ,τ,η,ϕ	Global group
1.1	$G(u)=(u^{2\alpha}-1)/(u^{2\alpha}+1)$	$\xi=2\alpha((u^{2\alpha}-1)/(u^{2\alpha}+1))$	$x^*=x+\ln((u^{2\alpha}e^{4\alpha\varepsilon}+1)/(u^{2\alpha}+1))-2\alpha\varepsilon$
		$\tau=t+2\alpha v$	$t^*=\frac{1}{2}e^{\varepsilon}[(t+v)e^{2\alpha\varepsilon}+(t-v)e^{-2\alpha\varepsilon}]$
		$\eta=2u$	$u^*=ue^{2\varepsilon}$
		$\phi=2\alpha t+v$	$v^*=\frac{1}{2}e^{\varepsilon}[(t+v)e^{2\alpha\varepsilon}-(t-v)e^{-2\alpha\varepsilon}]$
1.2	$G(u)=(u^{2\alpha}+1)/(u^{2\alpha}-1)$	$\xi=2\alpha((u^{2\alpha}+1)/(u^{2\alpha}-1))$	$x^*=x+\ln\lvert(u^{2\alpha}e^{4\alpha\varepsilon}-1)/(u^{2\alpha}-1)\rvert-2\alpha\varepsilon$
		$\tau=t+2\alpha v$	$t^*=\frac{1}{2}e^{\varepsilon}[(t+v)e^{2\alpha\varepsilon}+(t-v)e^{-2\alpha\varepsilon}]$
		$\eta=2u$	$u^*=ue^{2\varepsilon}$
		$\phi=2\alpha t+v$	$v^*=\frac{1}{2}e^{\varepsilon}[(t+v)e^{2\alpha\varepsilon}-(t-v)e^{-2\alpha\varepsilon}]$
2	$G(u)=\tan(\alpha\ln u)$	$\xi=-2\alpha\tan(\alpha\ln u)$	$x^*=x+\ln\lvert\cos(\alpha(\ln u+2\varepsilon))/\cos(\alpha\ln u)\rvert$
		$\tau=t-2\alpha v$	$t^*=e^{\varepsilon}[t\cos 2\alpha\varepsilon-v\sin 2\alpha\varepsilon]$
		$\eta=2u$	$u^*=ue^{2\varepsilon}$
		$\phi=2\alpha t+v$	$v^*=e^{\varepsilon}[v\cos 2\alpha\varepsilon+t\sin 2\alpha\varepsilon]$
3	$G(u)=(\ln u)^{-1}$	$\xi=2(\ln u)^{-1}$	$x^*=x+\ln\lvert1+2\varepsilon/\ln u\rvert$
		$\tau=t+2v$	$t^*=e^{\varepsilon}(2v\varepsilon+t)$
		$\eta=2u$	$u^*=ue^{2\varepsilon}$
		$\phi=v$	$v^*=ve^{\varepsilon}$
4	$G(u)=\tan u$	$\xi=-\tan u$	$x^*=x+\ln\lvert\cos(u+\varepsilon)/\cos u\rvert$
		$\tau=-v$	$t^*=t\cos\varepsilon-v\sin\varepsilon$
		$\eta=1$	$u^*=u+\varepsilon$
		$\phi=t$	$v^*=v\cos\varepsilon+t\sin\varepsilon$
5.1	$G(u)=\tanh u$	$\xi=\tanh u$	$x^*=x+\ln((e^{2(u+\varepsilon)}+1)/(e^{2u}+1))-\varepsilon$
		$\tau=v$	$t^*=\frac{1}{2}((t+v)e^{\varepsilon}+(t-v)e^{-\varepsilon})$
		$\eta=1$	$u^*=u+\varepsilon$
		$\phi=t$	$v^*=\frac{1}{2}((t+v)e^{\varepsilon}-(t-v)e^{-\varepsilon})$
5.2	$G(u)=\coth u$	$\xi=\coth u$	$x^*=x+\ln\lvert(e^{2(u+\varepsilon)}-1)/(e^{2u}-1)\rvert-\varepsilon$
		$\tau=v$	$t^*=\frac{1}{2}((t+v)e^{\varepsilon}+(t-v)e^{-\varepsilon})$
		$\eta=1$	$u^*=u+\varepsilon$
		$\phi=t$	$v^*=\frac{1}{2}((t+v)e^{\varepsilon}-(t-v)e^{-\varepsilon})$
6	$G(u)=u^{-1}$	$\xi=u^{-1}$	$x^*=x+\ln\lvert1+\varepsilon/u\rvert$
		$\tau=v$	$t^*=t+v\varepsilon$
		$\eta=1$	$u^*=u+\varepsilon$
		$\phi=0$	$v^*=v$

VI. A PHYSICAL EXAMPLE

We now specialize to the situation for the second physical example mentioned in the Introduction. Here $F(u)=\lambda G'(u)$. Consequently, in Tables I and II, we have $\beta=0$ and $\int F(u)\mathrm{d}u=G(u)$. In Table V, we give the corresponding global group for each of the six classes yielding potential symmetries of the scalar equation (1).

After translations and scalings of u and G, class 5 includes bounded monotonic stress tensor functions $G(u)=\alpha\tanh(\beta u+\gamma)$ for arbitrary constants α, β, γ, and δ.

VII. FURTHER DISCUSSION

In this paper we found new symmetries for equivalent telegraph equations (1)–(4). These symmetries can be used to find families of solutions from any given solution and to construct invariant solutions from the invariants of the symmetries or through the direct method discussed in Ref. 3.

In future papers, we will find conservation laws for (1)–(4) through techniques introduced in Refs. 16–18. Systems (1)–(4) are not self-adjoint. Hence a symmetry of (1)–(4) does not yield a conservation law through Noether's theorem.

For the physical case $F(u)=G'(u)$, the second equation in the potential system (2) becomes

$$(e^x v)_t = (e^x G(u))_x.$$

This leads to another equivalent potential system

$$v_x = u_t, \quad w_x = e^x v, \quad w_t = e^x G(u).$$

The problem of finding equivalent potential systems for a given PDE is considered in Refs. 4 and 5.

Finite propagation speed for the Camassa–Holm equation

Adrian Constantin
Department of Mathematics, Lund University, Box 118, SE-221 00 Lund, Sweden

(Received 28 June 2004; accepted 22 October 2004; published online 2 February 2005)

We prove that any classical solution of the Camassa–Holm equation will have compact support if its initial data has this property. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1845603]

I. INTRODUCTION

The Camassa–Holm equation

$$m_t + 2mu_x + m_x u = 0, \quad x \in \mathbb{R}, \quad t > 0, \tag{1}$$

with $m = u - u_{xx}$, was first derived by Fokas and Fuchssteiner[18] as a bi-Hamiltonian system, and then as a model for shallow water waves by Camassa and Holm;[2] see also Refs. 6 and 22 for alternative derivations within the shallow water regime. Equation (1) was also obtained as a model for wave propagation in hyperelastic rods,[16] and shown to describe geodesic flow on the diffeomorphism group of the circle;[24] see also Refs. 11 and 12. The Camassa–Holm equation satisfies the least action principle[11,12] and is an integrable infinite-dimensional Hamiltonian system (for various aspects of the direct/inverse scattering approach and of the direct/inverse spectral problem we refer to Refs. 7, 13, 17–19, 21, and 23). It has both classical solutions that exist for all times as well as smooth solutions which develop singularities in finite time.[3,5,8–10] Note that we can write (1) as

$$u_t - u_{txx} + 3uu_x = 2u_x u_{xx} + uu_{xxx}, \quad t \geqslant 0, \quad x \in \mathbb{R}. \tag{2}$$

The solitary wave solutions of (2) are the peaked waves

$$u_c(x,t) = ce^{|x-ct|}, \quad t \geqslant 0, \quad x \in \mathbb{R},$$

traveling at constant speed $c > 0$, cf. Ref. 2. These peaked waves, called *peakons*, are not classical solutions of (2). They satisfy the conservation law form of the Camassa–Holm equation

$$u_t + uu_x + \partial_x(1 - \partial_x^2)^{-1}(u^2 + \tfrac{1}{2}u_x^2) = 0 \tag{3}$$

(see Refs. 9 and 14). The peakons are solitons, retaining their form and speed through the nonlinear interaction with other peakons (see Refs. 1 and 2). Moreover, the peakons are orbitally stable,[15] i.e., their shape is stable even under perturbations of a more general nature than those occuring through the interaction with other peakons.

This paper is concerned with establishing the finite propagation speed property for the Camassa–Holm equation (1). Due to the nonlocal nature of the conservation law form (3) of the equation, it is not *a priori* clear that a localized initial data $m(x,0)$ (that is, of compact support) will not spread out instantly to the whole spatial domain. Below we will give a simple proof of this property.

II. MAIN RESULTS

Let us first prove the following.

Theorem: *Assume that $m_0:\mathbb{R}\to\mathbb{R}$ is a smooth function with compact support. If $T>0$ is the maximal existence time of the smooth solution $m(x,t)$ to (1) with initial data $m_0(x)$, then for any $t\in[0,T)$ the smooth function $x\mapsto m(x,t)$ has compact support.*

Before proceeding with the proof, a few comments are in order. First of all, the restriction to smooth functions is just for convenience since the same approach will work (the local well-posedness of solutions and other technicalities needed to pursue our approach within this setting are available from the considerations made in Refs. 5 and 9) for initial data in the Sobolev space $H^1(\mathbb{R})$ of square integrable functions with square integrable distributional derivative. It is also well known that the solution of the Camassa–Holm equation inherits at any later time the spatial smoothness of the initial data, measured on a Sobolev space scale with integer index (see Refs. 4 and 9). Finally, we would like to point out that smooth initial data with compact support develop into solutions that might exist for all times or could exhibit singularities in finite time cf. Refs. 3, 5, and 8.

Proof of the theorem: We associate to the solution m with initial data $m(x,0)=m_0(x)$ the family $\{\varphi(\cdot,t)\}_{t\in[0,T)}$ of smooth diffeomorphisms of the line defined by

$$\varphi_t(x,t)=u(\varphi(x,t),t),\quad t\in[0,T), \tag{4}$$

with

$$\varphi(x,0)=x,\quad x\in\mathbb{R}. \tag{5}$$

Using (1), (4), and (5), is easy to check the following identity:

$$m(\varphi(x,t),t)\cdot\varphi_x^2(x,t)=m(x,0),\quad x\in\mathbb{R},\quad t\in[0,T). \tag{6}$$

On the other hand, from (4) and (5) we infer

$$\varphi_x(x,t)=\exp\left(\int_0^t u_x(\varphi(x,s),s)\mathrm{d}s\right),\quad x\in\mathbb{R},\quad t\in[0,T). \tag{7}$$

If m_0 is supported in the compact interval $[a,b]$, since $\varphi_x(x,t)>0$ on $\mathbb{R}\times[0,T)$ in view of (7), we deduce from (6) that $m(x,t)$ has its support in the interval $[\varphi(a,t),\varphi(b,t)]$. This completes the proof. ■

We established that the solutions to the Camassa–Holm equation (1) have finite propagation speed. Since (1) is equivalent to (2), the natural question arises whether this property is captured by the time evolution of the function u. We will now show that this is not the case.

Proposition: *Assume that $u_0:\mathbb{R}\to\mathbb{R}$ is a smooth function with compact support. Let $T>0$ be the maximal existence time of the smooth solution $u(x,t)$ to (2) with initial data $u_0(x)$. If at every $t\in[0,T)$ the smooth function $x\mapsto u(x,t)$ has compact support, then u is identically zero.*

Proof: For $(x,t)\in\mathbb{R}\times[0,T)$, let $m(x,t)=(1-\partial_x^2)u(x,t)$. Clearly $m(x,0)$ has compact support since u_0 does. From our theorem we deduce that for every $t\in[0,T)$ the smooth function $x\mapsto m(x,t)$ is also of compact support. Recall that by the Paley–Wiener theorem,[20,25] an entire analytic function $g(\xi)$ of the complex variable $\xi=\eta+i\zeta$ (with $\eta,\zeta\in\mathbb{R}$) is the Fourier transform $\mathcal{F}_f$ of a smooth function $f:\mathbb{R}\to\mathbb{R}$ with compact support in the ball $\{x\in\mathbb{R}:|x|\leqslant R\}$, where $\mathcal{F}_f(\xi)=\int_{\mathbb{R}}e^{-i\xi x}f(x)\mathrm{d}x$ for $\xi\in\mathbb{C}$, if and only if for every integer $n\geqslant 0$ there is a constant $c_n>0$ so that $|g(\xi)|\leqslant c_n e^{R|\zeta|}/(1+|\xi|)^n$ for all $\xi\in\mathbb{C}$. Notice that

$$\mathcal{F}_m(\xi)=(1+\xi^2)\mathcal{F}_u(\xi),\quad \xi\in\mathbb{C},\quad t\in[0,T). \tag{8}$$

By assumption $u(\cdot,t)$ has compact support at every $t\in[0,T)$. Hence the Paley–Wiener theorem ensures that $\mathcal{F}_u$ and $\mathcal{F}_m$ are entire functions. Then (8) forces $\mathcal{F}_m(\pm i)=0$ at any fixed $t\in[0,T)$, or

$$\int_{\mathbb{R}} e^x m(x,t)\mathrm{d}x = \int_{\mathbb{R}} e^{-x} m(x,t)\mathrm{d}x = 0, \quad t \in [0,T). \tag{9}$$

However, we infer from (1) that for all $t \in (0,T)$,

$$\begin{aligned}
\frac{d}{\mathrm{d}t}\int_{\mathbb{R}} e^x m(x,t)\mathrm{d}x = \int_{\mathbb{R}} e^x m_t \,\mathrm{d}x &= -2\int_{\mathbb{R}} e^x m u_x \,\mathrm{d}x - \int_{\mathbb{R}} e^x m_x u \,\mathrm{d}x \\
&= -\int_{\mathbb{R}} e^x m u_x \,\mathrm{d}x + \int_{\mathbb{R}} e^x m u \,\mathrm{d}x \\
&= -\int_{\mathbb{R}} e^x u u_x \,\mathrm{d}x + \int_{\mathbb{R}} e^x u_x u_{xx} \,\mathrm{d}x + \int_{\mathbb{R}} e^x u^2 \,\mathrm{d}x - \int_{\mathbb{R}} e^x u u_{xx} \,\mathrm{d}x \\
&= -\int_{\mathbb{R}} e^x u u_x \,\mathrm{d}x - \frac{1}{2}\int_{\mathbb{R}} e^x u_x^2 \,\mathrm{d}x + \int_{\mathbb{R}} e^x u^2 \,\mathrm{d}x + \int_{\mathbb{R}} e^x u_x^2 \,\mathrm{d}x \\
&\quad + \int_{\mathbb{R}} e^x u u_x \,\mathrm{d}x
\end{aligned}$$

since all boundary terms obtained after integration by parts vanish as $u(\cdot,t)$ has compact support for every $t \in [0,T)$. Hence

$$\frac{d}{\mathrm{d}t}\int_{\mathbb{R}} e^x m(x,t)\mathrm{d}x = \int_{\mathbb{R}} e^x \left(u^2 + \frac{1}{2}u_x^2\right)\mathrm{d}x, \quad t \in (0,T). \tag{10}$$

But (9) and (10) can hold simultaneously if and only if $u \equiv 0$. The proof is complete. ■

Remark: *If $u_0 \not\equiv 0$ is smooth, the corresponding solution $u(\cdot,t)$ of the Camassa–Holm equation (2) loses instantly the property of having compact support. To prove this statement, we just go through the previous argumentation restricting our attention to an arbitrarily small time interval $[0,\varepsilon)$.*

Recursive calculation of effective potential and variational resummation

Sebastian F. Brandt and Hagen Kleinert
Freie Universität Berlin, Institut für Theoretische Physik, Arnimallee 14, 14195 Berlin, Germany

Axel Pelster
Universität Duisburg-Essen, Campus Essen, Fachbereich Physik, Universitätsstraße 5, 45117 Essen, Germany

(Received 13 July 2004; accepted 7 September 2004; published online 4 February 2005)

We set up a method for a recursive calculation of the effective potential which is applied to a cubic potential with imaginary coupling. The result is resummed using variational perturbation theory, yielding an exponentially fast convergence. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1824212]

I. INTRODUCTION

Perturbation theory is the most commonly used technique for an approximate description of nonexactly solvable systems. However, most perturbation series are divergent and yield acceptable results only after resummation. In recent years, based on a variational approach due to Feynman and Kleinert,[1] a systematic and uniformly convergent *variational perturbation theory* (VPT) has been developed.[2–5] It permits the conversion of divergent weak-coupling into convergent strong-coupling expansions and has been applied successfully in quantum mechanics, quantum statistics, condensed matter physics, and the theory of critical phenomena.

The convergence of VPT has been proved to be exponentially fast,[3,4] and this has been verified for the ground-state energy of different quantum mechanical model systems. If the underlying potential is mirror symmetric, one introduces a trial oscillator whose frequency Ω is regarded as a variational parameter and whose influence is minimized according to the *principle of minimal sensitivity*.[6] In this way, the ground-state energy of the quartic anharmonic oscillator was analyzed up to very high orders in Refs. 7 and 8.

If the potential is not mirror symmetric, the center of fluctuations no longer lies at the origin but at some nonzero place X. In VPT, this situation is accounted for by regarding the nonvanishing center of fluctuations X as a second variational parameter. An extreme example is a complete antisymmetric potential, such as $V(x)=Ax^3$, which for real A does not correspond to a stable system. Interestingly, if the parameter A is chosen to be imaginary, so that there does not exist a classical system at all, the quantum-mechanical system turns out to be well defined, and the spectrum of the Hamilton operator

$$H=-\frac{1}{2}\frac{\partial^2}{\partial x^2}+ix^3 \tag{1}$$

is real and positive. This remarkable property of the non-Hermitian Hamilton operator, found in Refs. 9–13, can be attributed to the fact that it possesses a different symmetry: it is invariant under the combined application of the parity and the time-reversal operation.

In this paper, we apply VPT to the $\mathcal{PT}$-symmetric Hamilton operator (1). In a first naive approach, we ignore the necessary shift X of the center of fluctuations and resum the weak-coupling series of the ground-state energy for the anharmonic oscillator

$$V(x) = \frac{\omega^2}{2}x^2 + igx^3 \tag{2}$$

in the strong-coupling limit. In this limit, the potential (2) reduces to the purely cubic potential of (1). It turns out that the VPT results approach the corresponding numerical value for the ground-state energy of (1) with increasing order, but the rate of convergence is not satisfactory. Afterwards, we allow for a nonvanishing center of fluctuations X by using the effective potential, whose calculation is accomplished by an efficient recursion scheme. This refined approach improves the convergence of the results drastically.

In Sec. II, we derive the weak-coupling series for the ground-state energy of (2) by evaluating connected vacuum diagrams. In Sec. III, we show how this perturbation series can be obtained more efficiently by means of the Bender–Wu recursion method.[14] In Sec. IV, we resum the weak-coupling series for the ground-state energy of (2) by applying VPT and examine the resulting convergence. In Sec. V, we determine the effective potential with the *background method*[15,16] from one-particle irreducible vacuum diagrams. In Sec. VI, we set up new recursion relations for a more efficient calculation of the effective potential. In Sec. VII, we finally treat the resulting expansion with VPT and examine the improved convergence.

II. PERTURBATION THEORY

The perturbation series for the ground-state energy of the anharmonic oscillator (2) can be calculated from connected vacuum diagrams. Up to the fourth order in the coupling constant g, the ground-state energy is given by the Feynman diagrams

$$E = \frac{\hbar\omega}{2} - \lim_{\beta\to\infty}\frac{1}{\beta}\Bigg\{\frac{1}{8}\,\bigcirc\!\!-\!\!\bigcirc + \frac{1}{12}\,\ominus + \frac{1}{24}\,\otimes + \frac{1}{16}\,\oslash + \frac{1}{8}\,\bigcirc\!\!-\!\!\bigcirc\!\!\!\!\bigcirc + \frac{1}{16}\,\bigcirc\!\!-\!\!\bigcirc\!\!-\!\!\bigcirc + \frac{1}{48}\,\curlyvee + \mathcal{O}(g^6)\Bigg\}, \tag{3}$$

with the propagator

$$i \bullet\!\!\!-\!\!\!-\!\!\!\bullet\, j \to G_\omega(\tau_i,\tau_j) = \frac{\hbar}{2\omega}e^{-\omega|\tau_i-\tau_j|} \tag{4}$$

and the vertices

$$\overset{i}{\curlyvee} \to -\frac{6ig}{\hbar}\int_0^{\hbar\beta} \tau_i. \tag{5}$$

Evaluating the Feynman diagrams (3) leads to the following analytical expression for the ground-state energy:

$$E = \hbar\omega\left[\frac{1}{2} + \frac{11g^2\hbar}{8\omega^5} - \frac{465g^4\hbar^2}{32\omega^{10}} + \mathcal{O}(g^6)\right]. \tag{6}$$

Since evaluating Feynman diagrams of higher orders is cumbersome, only low perturbation orders are feasible by this procedure. If we want to study higher orders, we better use the Bender–Wu recursion relations.[14]

k	1	2	3	4	5
ϵ_k	0	$\frac{11}{8}$	0	$-\frac{465}{32}$	0
k	6	7	8	9	10
ϵ_k	$\frac{39\,709}{128}$	0	$-\frac{19\,250\,805}{2048}$	0	$\frac{2\,944\,491\,879}{8192}$

III. BENDER–WU RECURSION RELATIONS

The Schrödinger eigenvalue equation for the anharmonic oscillator (2),

$$-\frac{\hbar^2}{2}\psi''(x)+\left(\frac{\omega^2}{2}x^2+igx^3\right)\psi(x)=E\psi(x), \tag{7}$$

is solved as follows: We write the wave function $\psi(x)$ as

$$\psi(x)=\left(\frac{\omega}{\pi\hbar}\right)^{1/4}\exp\left[-\frac{\hat{x}^2}{2}+\phi(\hat{x})\right], \tag{8}$$

with the abbreviation $\hat{x}=x\sqrt{\omega/\hbar}$, and expand the exponent in powers of the dimensionless coupling constant $\hat{g}=g\sqrt{\hbar/\omega^5}$ by using

$$\phi(\hat{x})=\sum_{k=1}^{\infty}\hat{g}^k\phi_k(\hat{x}). \tag{9}$$

The $\phi_k(\hat{x})$ are expanded in powers of the rescaled coordinate $\hat{x}$,

$$\phi_k(\hat{x})=\sum_{m=1}^{k+2}c_m^{(k)}\hat{x}^m. \tag{10}$$

For the ground-state energy we make the ansatz

$$E=\hbar\omega\left(\frac{1}{2}+\sum_{k=1}^{\infty}\hat{g}^k\epsilon_k\right). \tag{11}$$

Inserting (8)–(11) into (7), we obtain to first order

$$c_1^{(1)}=-i,\quad c_2^{(1)}=0,\quad c_3^{(1)}=-\frac{i}{3},\quad \epsilon_1=0. \tag{12}$$

For $k\geqslant 2$, we find the following recursion relation for the expansion coefficients in (10):

$$c_m^{(k)}=\frac{(m+2)(m+1)}{2m}c_{m+2}^{(k)}+\frac{1}{2m}\sum_{l=1}^{k-1}\sum_{n=1}^{m+1}n(m+2-n)c_n^{(l)}c_{m+2-n}^{(k-l)}, \tag{13}$$

with $c_m^{(k)}\equiv 0$ for $m>k+2$. The expansion coefficients of the ground-state energy follow from

$$\epsilon_k=-c_2^{(k)}-\frac{1}{2}\sum_{l=1}^{k-1}c_1^{(l)}c_1^{(k-l)}. \tag{14}$$

Table I shows the coefficients ϵ_k up to the 10th order. We observe that all odd orders vanish for

symmetry reasons and that the first two even orders agree, indeed, with the earlier result (6).

IV. RESUMMATION OF GROUND-STATE ENERGY

In this section, we consider the strong-coupling limit of the perturbation series (11). Rescaling the coordinate according to $x \to x g^{-1/5}$, the Schrödinger equation (7) becomes

$$-\frac{\hbar^2}{2}\frac{\partial^2}{\partial x^2}\psi(x) + \left(\frac{1}{2}g^{-4/5}\omega^2 x^2 + ix^3\right)\psi(x) = g^{-2/5}E\psi(x). \tag{15}$$

Expanding the wave function and the energy in powers of the coupling constant yields

$$\psi(x) = \psi_0(\hat{x}) + \hat{g}^{-4/5}\psi_1(\hat{x}) + \hat{g}^{-8/5}\psi_2(\hat{x}) + \cdots \tag{16}$$

and

$$E = \hbar\omega\hat{g}^{2/5}(b_0 + \hat{g}^{-4/5}b_1 + \hat{g}^{-8/5}b_2 + \cdots). \tag{17}$$

By considering (15) in the limit $g \to \infty$, we find that the leading strong-coupling coefficient b_0 equals the ground-state energy associated with the Hamilton operator (1). A precise numerical value for this ground-state energy was given by Bender,[9,18]

$$b_0 = 0.762\,851\,773\ \ldots\ . \tag{18}$$

The weak-coupling series (11) is of the form

$$E^{(N)}(\alpha,\omega) = \hbar\omega\left[\frac{1}{2} + \sum_{k=1}^{N}\left(\frac{\hbar\alpha}{\omega^5}\right)^k \epsilon_{2k}\right], \tag{19}$$

with the abbreviation $\alpha = g^2$. Table I suggests that (19) represents a divergent Borel series which is resummable by applying VPT.[2–5] To this end, an artificial parameter is introduced in the perturbation series, which is most easily obtained by Kleinert's square-root trick,

$$\omega \to \Omega\sqrt{1+\alpha r}, \tag{20}$$

with

$$r = \frac{\omega^2 - \Omega^2}{\alpha\Omega^2}. \tag{21}$$

Thus, one replaces the frequency ω in the weak-coupling series (19) according to (20) and re-expands the resulting expression in powers of α up to the order α^N. Afterwards, the auxiliary parameter r is replaced according to (21). The ground-state energy thus becomes dependent on the variational parameter Ω, $E^{(N)}(\alpha,\omega) \to E^{(N)}(\alpha,\omega,\Omega)$. The influence of Ω is then optimized according to the principle of minimal sensitivity,[6] i.e., one approximates the ground-state energy to Nth order by

$$E^{(N)} = E^{(N)}(\alpha,\omega,\Omega^{(N)}), \tag{22}$$

where $\Omega^{(N)}$ denotes that value of the variational parameter for which $E^{(N)}(\alpha,\omega,\Omega)$ has an extremum or a turning point.

Consider, as an example, the weak-coupling series (19) to first order,

$$E^{(1)}(\alpha,\omega) = \frac{\hbar\omega}{2} + \alpha\frac{11\hbar^2}{8\omega^4}. \tag{23}$$

Inserting (20), re-expanding in α to first order, and taking into account (21), we obtain

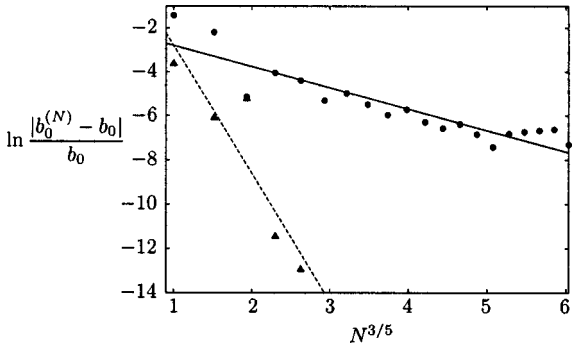

FIG. 1. Convergence of the results for the strong-coupling coefficient b_0 obtained from resummation of the weak-coupling series of the ground-state energy (circles). The resummation involving a variational path average X converges much faster (triangles). The lines represent fits of the respective data to straight lines.

$$E^{(1)}(\alpha,\omega,\Omega) = \frac{\hbar\Omega}{4} + \frac{\hbar\omega^2}{4\Omega} + \alpha\frac{11\hbar^2}{8\Omega^4}. \tag{24}$$

Extremizing this and going to large coupling constants, we obtain the strong-coupling behavior of the variational parameter,

$$\Omega^{(1)} = \omega\hat{\alpha}^{1/5}(\Omega_0^{(1)} + \Omega_1^{(1)}\hat{\alpha}^{-2/5} + \Omega_2^{(1)}\hat{\alpha}^{-4/5} + \cdots), \tag{25}$$

with the abbreviation $\hat{\alpha}=\hat{g}^2$ and the coefficients

$$\Omega_0^{(1)} = \sqrt[5]{22},\ \ \Omega_1^{(1)} = \frac{1}{5\sqrt[5]{22}},\ \ \Omega_2^{(1)} = \frac{1}{25\sqrt[5]{10\,648}},\ \ \ldots\ . \tag{26}$$

Inserting the result (25) and (26) into (24), we obtain the strong-coupling series (17) with the first-order coefficients

$$b_0^{(1)} = \frac{5\sqrt[5]{22}}{16},\quad b_1^{(1)} = \frac{4}{\sqrt[5]{22}},\quad b_2^{(1)} = \frac{-1}{100\sqrt[5]{22}},\quad \ldots\ . \tag{27}$$

The numerical value of the leading strong-coupling coefficient is $b_0^{(1)} \approx 0.5799$. Thus, to first order, the relative deviation of the result from the precise value (18) is

$$\frac{|b_0^{(1)} - b_0|}{b_0} \approx 24\%. \tag{28}$$

Despite this relatively poor agreement, it turns out that the VPT results for $b_0^{(N)}$ in higher orders converge towards the exact value (18). In Refs. 3 and 4 it is proved that VPT in general yields approximations whose relative deviation from the exact value vanishes exponentially. In our case we have

$$\frac{|b_0^{(N)} - b_0|}{b_0} \propto \exp(-CN^{3/5}), \tag{29}$$

where the exponent $3/5$ is determined by the structure of the strong-coupling series (17).

In Fig. 1 the exponential convergence of our variational results is shown up to the 20th order. Fitting the logarithm of the relative deviation to a straight line yields

$$\ln \frac{|b_0^{(N)} - b_0|}{b_0} = -0.96(11)N^{3/5} - 1.83(44). \tag{30}$$

In the following, we show how this exponential convergence is improved drastically by allowing for a shift of the center of fluctuations.

V. DIAGRAMMATIC APPROACH TO EFFECTIVE POTENTIAL

In the presence of a constant external current j, the quantum statistical partition function reads

$$Z(j) := \oint \mathcal{D}x \exp\left\{-\frac{1}{\hbar}\mathcal{A}[x](j)\right\}, \tag{31}$$

where $\mathcal{A}[x](j)$ is the Euclidean action,

$$\mathcal{A}[x](j) = \int_0^{\hbar\beta} \mathrm{d}\tau \left[\frac{1}{2}\dot{x}^2(\tau) + V(x(\tau)) - jx(\tau)\right]. \tag{32}$$

The free energy thus becomes a function of the external current,

$$F(j) = -\frac{1}{\beta}\ln Z(j). \tag{33}$$

The path average,

$$X = \frac{1}{Z(j)}\oint \mathcal{D}x \left[\int_0^{\hbar\beta} \frac{\mathrm{d}\tau}{\hbar\beta} x(\tau)\right] \exp\left\{-\frac{1}{\hbar}\mathcal{A}[x](j)\right\}, \tag{34}$$

then follows from the first derivative of the free energy with respect to the external current:

$$X = -\frac{\partial F(j)}{\partial j}. \tag{35}$$

Assuming that the last identity can be inverted to yield the current j as a function of the average X, one defines the effective potential $V_{\mathrm{eff}}(X)$ as the Legendre transform of the free energy with respect to the external current:

$$V_{\mathrm{eff}}(X) = F(j(X)) + j(X)X. \tag{36}$$

Furthermore, the first derivative of the effective potential gives back the external current j:

$$\frac{\partial V_{\mathrm{eff}}(X)}{\partial X} = j(X). \tag{37}$$

Thus, the free energy $F \equiv F(j=0)$ can be obtained by extremizing the effective potential,

$$F = V_{\mathrm{eff}}(X_e), \tag{38}$$

with

$$\left.\frac{\partial V_{\mathrm{eff}}(X)}{\partial X}\right|_{X=X_e} = 0. \tag{39}$$

In the zero-temperature limit, extremizing the effective potential then yields the ground-state energy.

The effective potential is usually not calculated by performing explicitly the Legendre transformation (36) but by a diagrammatic technique derived via the so-called background method.[15,16] There, the effective potential is expanded in powers of the Planck constant $\hbar$, and the expansion terms are one-particle irreducible vacuum diagrams. The result is

$$V_{\text{eff}}(X) = V(X) + \frac{\hbar}{2}\text{Tr}\ln G^{-1} + V^{(\text{int})}(X), \tag{40}$$

where the trace-log term is given by the ground-state energy of a harmonic oscillator of X-dependent frequency $\tilde{\omega} = \sqrt{V''(X)}$,

$$\frac{\hbar}{2}\text{Tr}\ln G^{-1} = \frac{\hbar\tilde{\omega}}{2}. \tag{41}$$

The interaction term $V^{(\text{int})}(X)$ contains the sum of all one-particle irreducible vacuum diagrams. For the anharmonic oscillator (2), the relevant subset of the diagrams in (3) is

$$V^{(\text{int})}(X) = -\lim_{\beta\to\infty}\frac{1}{\beta}\left\{\frac{1}{12}\ \ominus\ + \frac{1}{24}\ \otimes\ + \frac{1}{16}\ \text{oo}\right\} + \mathcal{O}(\hbar^4). \tag{42}$$

These one-particle irreducible vacuum diagrams are derived most easily by an efficient graphical recursion method.[17] The frequency of the propagators is now given by

$$\tilde{\omega} = \sqrt{\omega^2 + 6igX}. \tag{43}$$

By evaluating the diagrams (42) we obtain

$$V_{\text{eff}}(X) = \frac{\omega^2}{2}X^2 + igX^3 + \frac{\hbar}{2}\sqrt{\omega^2 + 6igX} + \frac{\hbar^2 g^2}{4(\omega^2 + 6igX)^2} - \frac{51\hbar^3 g^4}{32(\omega^2 + 6igX)^{9/2}} + \mathcal{O}(\hbar^4). \tag{44}$$

The ground-state energy of the anharmonic oscillator (2) is found by extremizing the effective potential (44). To this end, we expand the extremal background according to

$$X_e = i(X_0 + \hbar X_1 + \hbar^2 X_2 + \hbar^3 X_3) + \mathcal{O}(\hbar^4). \tag{45}$$

Inserting (45) into the vanishing first derivative of (44) and re-expanding in $\hbar$, we obtain a system of equations which are solved by

$$X_0 = 0, \quad X_1 = -\frac{3g}{2\omega^3}, \quad X_2 = \frac{33g^3}{2\omega^8}. \tag{46}$$

Inserting (45) and (46) into (44) and re-expanding in $\hbar$ yields again the ground-state energy (6).

In order to go to higher orders, we shall now develop a recursion relation for the effective potential.

VI. RECURSIVE APPROACH TO EFFECTIVE POTENTIAL

In the presence of a constant external current j, the Schrödinger eigenvalue equation for the anharmonic oscillator (2) reads

$$-\frac{\hbar^2}{2}\psi''(x) + \left(\frac{\omega^2}{2}x^2 + igx^3 - jx\right)\psi(x) = E\psi(x). \tag{47}$$

Taking into account the Legendre identities (36) and (37), Eq. (47) becomes

$$-\frac{\hbar^2}{2}\psi''(x)+\left(\frac{\omega^2}{2}x^2+igx^3-V'_{\rm eff}(X)x\right)\psi(x)=[V_{\rm eff}(X)-V'_{\rm eff}(X)X]\psi(x). \tag{48}$$

If the coupling constant g vanishes, Eq. (48) is solved by

$$\psi(x)=\mathcal{N}\exp\left(\hat{X}\hat{x}-\frac{\hat{x}^2}{2}\right), \tag{49}$$

$$V_{\rm eff}(X)=\hbar\omega\left(\frac{1}{2}+\frac{\hat{X}}{2}\right), \tag{50}$$

where the path average has been rescaled by the oscillator length, $\hat{X}=X\sqrt{\omega/\hbar}$. For a nonvanishing coupling constant g, we solve the differential equation (48) by the expansions

$$\psi(x)=\mathcal{N}\exp\left[\hat{X}\hat{x}-\frac{\hat{x}^2}{2}+\phi(\hat{x})\right], \tag{51}$$

$$V_{\rm eff}(X)=\hbar\omega\left[\frac{1}{2}+\frac{\hat{X}^2}{2}+\sum_{k=1}^{\infty}\hat{g}^kV_k(\hat{X})\right]. \tag{52}$$

For the correction to the wave function, $\phi(\hat{x})$, we make again the ansatz (9) and (10). Thus, we obtain from (48) for $k=1$,

$$c_1^{(1)}=\frac{i}{2}+2i\hat{X}^2,\ \ c_2^{(1)}=-\frac{i\hat{X}}{2},\ \ c_3^{(1)}=-\frac{i}{3},\ \ V_1(\hat{X})=\frac{3i\hat{X}}{2}+i\hat{X}^3. \tag{53}$$

For $k\geqslant 2$ one finds for $m\geqslant 2$ the following recursion relation for the expansion coefficients of the wave function:

$$c_m^{(k)}=\frac{(m+2)(m+1)}{2m}c_{m+2}^{(k)}+\frac{\hat{X}(m+1)}{m}c_{m+1}^{(k)}+\frac{1}{2m}\sum_{l=1}^{k-1}\sum_{n=1}^{m+1}n(m+2-n)c_n^{(l)}c_{m+2-n}^{(k-l)}, \tag{54}$$

with $c_m^{(k)}\equiv 0$ for $m>k+2$. For $m=1$, we have

$$c_1^{(k)}=3c_3^{(k)}+2\hat{X}c_2^{(k)}+V'_k(\hat{X})+\sum_{l=1}^{k-1}(c_2^{(k-l)}c_1^{(l)}+c_1^{(k-l)}c_2^{(l)}). \tag{55}$$

The expansion coefficients of the effective potential follow from

$$V_k(\hat{X})=-c_2^{(k)}-3\hat{X}c_3^{(k)}-2\hat{X}^2c_2^{(k)}-\hat{X}\sum_{l=1}^{k-1}(c_2^{(k-l)}c_1^{(l)}+c_1^{(k-l)}c_2^{(l)})-\frac{1}{2}\sum_{l=1}^{k-1}c_1^{(l)}c_1^{(k-l)}. \tag{56}$$

Using these results, the effective potential can be determined recursively, yielding an expansion in the coupling constant g,

$$V_{\rm eff}(X)=\frac{\hbar\omega}{2}+\frac{\omega^2}{2}X^2+ig\left(\frac{3\hbar X}{2\omega}+X^3\right)+g^2\frac{\hbar(\hbar+9\omega X^2)}{4\omega^4}$$
$$-ig^3\frac{3\hbar X(4\hbar+9\omega X^2)}{4\omega^6}-g^4\frac{3\hbar(17\hbar^2+288\hbar X^2+270X^4\omega^2)}{32\omega^9}+\mathcal{O}(g^5). \tag{57}$$

This result is in agreement with the expansion of (44) in powers of g and can be carried to higher orders without effort. The expansion coefficients for the $\hbar$-expansion

TABLE II. Expansion coefficients for the effective potential of (2) up to five loops.

l	0	1	2
$V^{(l)}(X)$	$\omega^2X^2/2+igX^3$	$\tilde{\omega}/2$	$g^2/4\tilde{\omega}^4$
l	3	4	5
$V^{(l)}(X)$	$-51g^4/32\tilde{\omega}^9$	$3331g^6/128\tilde{\omega}^{14}$	$-1\,371\,477g^8/2048\tilde{\omega}^{19}$

$$V_{\text{eff}}(X) = \sum_{l=0}^{N} \hbar^l V^{(l)}(X) + \mathcal{O}(\hbar^{N+1}) \tag{58}$$

can then be obtained easily.[19] Iterating the recursion relations (54)–(56) up to the order g^8, we obtain the effective potential up to five loops as shown in Table II.

VII. RESUMMATION OF EFFECTIVE POTENTIAL

We now apply VPT to the loop expansion of the effective potential (58). Since the Planck constant $\hbar$ is now the expansion parameter rather than the coupling constant g, Kleinert's square-root trick will be modified accordingly,

$$\omega \to \Omega\sqrt{1+\hbar r}, \tag{59}$$

with

$$r = \frac{\omega^2 - \Omega^2}{\hbar\Omega^2}. \tag{60}$$

As an example, we consider again the first order

$$V_{\text{eff}}^{(1)}(X) = \frac{\omega^2}{2}X^2 + igX^3 + \frac{\hbar}{2}\sqrt{\omega^2 + 6igX}. \tag{61}$$

After substituting ω according to (59), re-expanding in $\hbar$, and taking into account (60), we obtain

$$V_{\text{eff}}^{(1)}(X,\Omega) = \frac{\omega^2}{2}X^2 + igX^3 + \frac{\hbar}{2}\sqrt{\Omega^2 + 6igX}. \tag{62}$$

In order to calculate an approximation for the ground-state energy, we now optimize in Ω and extremize in X, yielding

$$\frac{\partial}{\partial\Omega}V_{\text{eff}}^{(1)}(X,\Omega)\bigg|_{X=X^{(1)},\Omega=\Omega^{(1)}} = 0, \tag{63}$$

$$\frac{\partial}{\partial X}V_{\text{eff}}^{(1)}(X,\Omega)\bigg|_{X=X^{(1)},\Omega=\Omega^{(1)}} = 0. \tag{64}$$

Equation (63) is solved by

$$\Omega^{(1)} = 0. \tag{65}$$

Afterwards, we obtain from (64),

TABLE III. Variational results for the ground-state energy of (1) compared to the numerical result (18) of Refs. 9 and 18.

1-loop VPT	0.742 751 023
2-loop VPT	0.764 570 478
3-loop VPT	0.758 783 545
4-loop VPT	0.762 843 684
5-loop VPT	0.762 849 959
Numerical	0.762 851 773

$$X^{(1)} + \frac{\omega^2}{3ig} + \frac{\hbar}{2\sqrt{6ig}(X^{(1)})^{3/2}} = 0. \tag{66}$$

This equation allows us to determine the strong-coupling behavior of X,

$$X^{(1)} = -i\hat{g}^{-1/5}\sqrt{\frac{\hbar}{\omega}}(X_0^{(1)} + X_1^{(1)}\hat{g}^{-4/5} + X_2^{(1)}\hat{g}^{-8/5} + \cdots), \tag{67}$$

where the coefficients read

$$X_0^{(1)} = \frac{1}{\sqrt[5]{24}}, \quad X_1^{(1)} = -\frac{2}{15}, \quad X_2^{(1)} = \frac{\sqrt[5]{24}}{75}, \ \ldots \ . \tag{68}$$

Inserting the results (65), (67), and (68) into (62) yields the strong-coupling behavior of the ground-state energy (17), with the new coefficients

$$b_0^{(1)} = \frac{5}{2\sqrt[5]{432}}, \quad b_1^{(1)} = -\frac{1}{4\sqrt[5]{18}}, \quad b_2^{(1)} = \frac{1}{15\sqrt[5]{24}}, \ \ldots \ . \tag{69}$$

The new numerical value of the leading strong-coupling coefficient is $b_0^{(1)} \approx 0.7428$, which is in much better agreement with (18) than the previous value of (27),

$$\frac{|b_0^{(1)} - b_0|}{b_0} \approx 3\%. \tag{70}$$

Thus, the variational path average has led to a significant improvement of the first-order result. Table III summarizes our results for $b_0^{(N)}$ up to the fifth order.

Figure 1 shows the much faster exponential convergence up to the fifth order. A least square fit of the data yields

$$\ln \frac{|b_0^{(N)} - b_0|}{b_0} = -5.8(1.6)N^{3/5} + 3.0(3.0) \tag{71}$$

which is to be compared with (30).

VIII. CONCLUSION AND OUTLOOK

We have developed a recursive technique to determine the effective potential, which is far more efficient than diagrammatic methods. In combination with VPT, this leads to a fast converging determination of the ground-state energy of quantum-mechanical systems with nonmirror symmetric potentials. It will be interesting to analyze in a similar way systems with a coordinate dependent mass term, where only a lowest order effective potential has been calculated so far.[20] Interesting future applications will address the effective potential of ϕ^4 theories in $4-\epsilon$ dimensions to obtain equations of state near to a critical point. A first attempt in this direction is Ref. 21.

(Received 16 August 2004; accepted 17 October 2004; published online 4 February 2005)

By applying the higher order Darboux algorithm to an exactly solvable non-Hermitian $\mathcal{PT}$ symmetric potential, we obtain a hierarchy of new exactly solvable non-Hermitian $\mathcal{PT}$ symmetric potentials with real spectra. It is shown that the symmetry underlying the potentials so generated and the original one is *nonlinear pseudosupersymmetry.* We also show that this formalism can be used to generate a larger class of new solvable potentials when applied to non-Hermitian systems.
 [DOI: 10.1063/1.1843273]

I. INTRODUCTION

There are not many exactly solvable potentials in quantum mechanics. As a result there have always been efforts to enlarge the class of exactly solvable potentials. Some of the different methods which have been used time and again to generate a hierarchy of isospectral potentials are the factorization method of Infeld and Hull,[1] the Darboux algorithm,[2] the method of supersymmetric quantum mechanics (SUSY QM),[3] or the integral transformations of Abraham–Moses–Pursey,[4] etc. Among these methods the Darboux algorithm and the SUSY QM are closely related and these methods have found numerous applications in different areas of theoretical and mathematical physics.[3]

At the same time, the scheme is still narrow as conventional SUSY fails to explain certain phenomena, e.g., the disappearance of the leading Borel singularity of the perturbation correction for the ground state energy of a SUSY theory.[5] In order to explain such behavior and also to widen the scope of SUSY QM, an idea was put forward to extend SUSY to higher orders.[6] We recall that in the conventional intertwining technique, two one-dimensional Schrödinger Hamiltonians H and $\tilde{H}$ are intertwined by means of differential operators L as

$$\tilde{H}L = LH, \quad HL^{\dagger} = L^{\dagger}\tilde{H}. \tag{1}$$

If L is of the first order in derivatives, the standard SUSY QM, with supercharges built of first order Darboux transformation operators, and the factorization method are recovered. On the other hand, if higher order differential operators are involved in the construction of L, it is variously referred to as *polynomial SUSY*,[6] or *nonlinear SUSY*,[7] or *higher order SUSY* (*n-SUSY*),[8,9] or $\mathcal{N}$*-fold SUSY*,[5,10] the study of which has attracted the attention of a lot of researchers in recent times.[5–10] Contrary to standard SUSY, anticommutator of the supercharges no longer coincides with the Hamiltonian in general. Instead, it becomes a polynomial of the Hamiltonian in degree N, and is sometimes referred to as the *Mother Hamiltonian*.[5,10]

[a)]Electronic mail: anjana23@rediffmail.com
[b)]Electronic mail: pinaki@isical.ac.in

Furthermore, the equivalence between an Nth order Darboux transformation and a chain of N first order Darboux transformation is well established.[9] Every chain of N first order Darboux transformation creates a chain of exactly solvable Hamiltonians $h_0 \to h_1 \to \cdots \to h_N$. Hence the intertwining operator $L^{(N)}$ between the initial Hamiltonian h_0 and the final Hamiltonian h_N can always be presented as a product of N first order Darboux transformation operators between every two juxtaposed Hamiltonians $h_0, h_1, \ldots, h_N$,

$$L^{(N)} = L_N L_{N-1} \cdots L_2 L_1, \quad h_p L_p = L_p h_{p-1}, \quad p = 1,2,\ldots,N. \tag{2}$$

In conventional higher order SUSY, h_0 and h_N are essentially self-adjoint Hermitian operators in a Hilbert space, with square integrable eigenfunctions. If all the intermediate potentials $V_1(x)$, $V_2(x), \ldots, V_{N-1}(x)$ are real valued functions in their common domain of definition (a,b), the chain is called *reducible*, and the Nth order Darboux transformation is called *reducible* as well. Additionally, if all the intermediate potentials are free of singularities in (a,b), the chain and the corresponding transformation are called *completely reducible*. When at least one intermediate potential is a complex valued function, the chain and the corresponding transformation are called *irreducible*.

At the same time, non-Hermitian Hamiltonians have made an important place for themselves in the recent development of quantum mechanics, because of their intrinsic interest[11] and possible applications.[12] It is well known by now that a non-Hermitian $\mathcal{PT}$ symmetric Hamiltonian admits real eigenvalues if the eigenfunctions, too, respect the $\mathcal{PT}$ invariance (the so-called unbroken $\mathcal{PT}$ symmetry), whereas the eigenvalues occur as complex conjugate pairs if $\mathcal{PT}$ symmetry is spontaneously broken (in this case the eigenfunctions are no longer $\mathcal{PT}$ invariant). For such non-Hermitian $\mathcal{PT}$ symmetric Hamiltonians,

$$\mathcal{PT}H = H\mathcal{PT}, \tag{3}$$

where $\mathcal{P}$ stands for the *space inversion* operator and $\mathcal{T}$ denotes *time reversal*,

$$\begin{aligned} &\mathcal{P}: \quad x \to -x, \quad p \to -p, \\ &\mathcal{T}: \quad x \to x, \quad p \to -p, \quad i \to -i \end{aligned} \tag{4}$$

The reality of the spectrum may be attributed to the so-called η-pseudo Hermiticity of the non-Hermitian Hamiltonian[13]

$$H^{\dagger} = \eta H \eta^{-1}, \tag{5}$$

where η is a linear, invertible, Hermitian operator. Several non-Hermitian Hamiltonians, whether possessing $\mathcal{PT}$ invariance or not, have been identified as η pseudo-Hermitian under $\eta = e^{-\theta p}$, where θ is real, and $p = -i(d/dx)$, or $\eta = e^{-\phi(x)}$, where $\phi(x)$ is some gaugelike transformation. We note that for $\mathcal{PT}$ symmetric Hamiltonians, η may simply be taken as the parity operator $\mathcal{P}$, whereas for conventional Hermitian Hamiltonians, $\eta = 1$.

Moreover, the square integrability of the wave functions is no longer a prerequisite for non-Hermitian Hamiltonians. Instead, the orthonormalization of the wave function for Hermitian quantum mechanics

$$\int \Psi_m^* \Psi_n \, dx = \delta_{m,n} \tag{6}$$

is replaced by[14]

$$\int [\mathcal{CPT}\Psi_m]\Psi_n \, dx = \delta_{m,n,} \tag{7}$$

where $\mathcal{C}$ plays the role of a linear charge operator, obeying the relationship

$$[\mathcal{C},H]=0, \quad [\mathcal{C},\mathcal{PT}]=0 \tag{8}$$

and has the property $\mathcal{C}^2=1$. In the position representation $\mathcal{C}$ is given as

$$\mathcal{C}(x,y)=\sum_n \psi_n(x)\psi_n(y) \tag{9}$$

and the completeness relation gets modified to

$$\sum_n [\mathcal{CPT}\psi_n(x)]\psi_n(y)=\delta(x-y). \tag{10}$$

While nonlinear SUSY for $N=2$ has been investigated widely for Hermitian Hamiltonians,[5–10] such studies have not been carried out as yet for non-Hermitian Hamiltonians. Motivated by the importance of such systems in the recent development of quantum mechanics, our aim in the present work is to generalize the concept of nonlinear SUSY to include non-Hermitian quantum systems. In analogy with the first order systems, where the partner Hamiltonians $H_\pm$ of non-Hermitian systems were found to be related through *pseudosupersymmetry*,[13,15] it will be shown that the underlying symmetry between the isospectral partners h_0 and h_N is a generalization of $\mathcal{N}$ SUSY and may be called *nonlinear pseudosupersymmetry*. The nature of the intermediate Hamiltonians as well as the corresponding wave functions will also be investigated.

The organization of the paper is as follows. For the sake of completeness, in Sec. II we briefly outline conventional nonlinear SUSY for Hermitian quantum mechanics. In Sec. III we describe a similar framework for non-Hermitian Hamiltonians and show that the underlying symmetry for the potentials produced by higher order Darboux algorithm is nonlinear pseudosupersymmetry. Some explicit examples are given in Secs. IV and V, while Sec. VI is devoted to a conclusion.

II. NONLINEAR SUSY FOR HERMITIAN HAMILTONIANS

In the conventional first order supersymmetric quantum mechanics, if a given solvable Hamiltonian

$$H=-\frac{d^2}{dx^2}+V(x) \tag{11}$$

possesses a discrete spectrum of bound states E_n, $n=0,1,2,\ldots$, together with the square-integrable eigenfunctions $\psi_n(x)$, then a pair of first-order operators L_0 and $L_0^\dagger$ can be constructed from the ground state ψ_0, given by

$$L_0=\frac{d}{dx}+W_0(x), \quad L_0^\dagger=-\frac{d}{dx}+W_0(x), \tag{12}$$

where

$$W_0(x)=-[\ln \psi_0(x)]' \tag{13}$$

such that L_0 and $L_0^\dagger$ play the role of intertwining operators for the initial and final Hamiltonians H and $\tilde{H}$, respectively,

$$\tilde{H}L_0=L_0H, \quad HL_0^\dagger=L_0^\dagger\tilde{H} \tag{14}$$

with

$$H=L_0^\dagger L_0, \quad \tilde{H}=L_0L_0^\dagger. \tag{15}$$

Simple straightforward algebra shows that the partner potentials $V(x)$ and $\tilde{V}(x)$ can be expressed as

$$V(x) = W_0^2(x) - W_0'(x), \tag{16}$$

$$\tilde{V}(x) = W_0^2(x) + W_0'(x) = V(x) + 2W_0'(x). \tag{17}$$

The eigenfunctions $\psi(x)$ and $\tilde{\psi}(x)$ of H and $\tilde{H}$ are interrelated through L_0 and $L_0^\dagger$:

$$L_0\psi_0(x) = 0, \quad L_0(x)\psi_i(x) = \frac{W_{0,i}(x)}{\psi_0(x)}\alpha\,\tilde{\psi}_i(x), \quad L_0^\dagger\tilde{\psi}_i(x)\alpha\,\psi_i(x), \quad i = 1,2,\ldots, \tag{18}$$

where $W_{0,i}(x) = \{\psi_0(x)\psi_i'(x) - \psi_0'(x)\psi_i(x)\}$ is the Wronskian of $\psi_0(x)$ and $\psi_i(x)$. The concise algebraic form of spectral equivalence is given by the superalgebra for the partners H and $\tilde{H}$, and the supercharges Q and $Q^\dagger$,

$$Q = \begin{pmatrix} 0 & L_0 \\ 0 & 0 \end{pmatrix}, \quad Q^\dagger = \begin{pmatrix} 0 & 0 \\ L_0^\dagger & 0 \end{pmatrix}, \tag{19}$$

$$\mathcal{H} = \{Q, Q^\dagger\} = \begin{pmatrix} H & 0 \\ 0 & \tilde{H} \end{pmatrix} = \begin{pmatrix} L_0^\dagger L_0 & 0 \\ 0 & L_0 L_0^\dagger \end{pmatrix} \tag{20}$$

satisfying the relations

$$\{Q,Q\} = \{Q^\dagger, Q^\dagger\} = 0, \quad [Q,\mathcal{H}] = [Q^\dagger,\mathcal{H}] = 0. \tag{21}$$

Thus H and $\tilde{H}$ are isospectral except for the lowest eigenvalue E_0 which is missing in $\tilde{H}$, as $\tilde{\psi}_0$ is not normalizable.

To generalize standard SUSY to higher order, the supercharges are built of higher order intertwining operators.[9] The two Hamiltonians h_0 and h_N are intertwined through an Nth order differential operator $L^{(N)}$, as

$$L^{(N)}h_0 = h_N L^{(N)}, \quad h_0 L^{(N)\dagger} = L^{(N)\dagger} h_N, \tag{22}$$

where h_0 and h_N are self-adjoint operators. The proper eigenfunctions ψ_i of the original Hamiltonian h_0 are known exactly, $h_0\psi_i = E_i\psi_i$. Any such operator $L^{(N)}$ can always be presented in the form known as Crum–Krein formula[16]

$$L^{(N)} = W^{-1}(u_1,u_2,\ldots,u_N)\begin{vmatrix} u_1 & u_2 & \cdots & 1 \\ u'_1 & u'_2 & \cdots & \dfrac{d}{dx} \\ \vdots & \vdots & \ddots & \vdots \\ u_1^{(N)} & u_2^{(N)} & \cdots & \dfrac{d^N}{dx^N} \end{vmatrix}, \tag{23}$$

where $W(u_1,u_2,\ldots,u_N)$ stands for the usual symbol for the Wronskian of the functions $u_1, u_2, \ldots, u_N$. The functions u_i $(i = 1,2,\ldots,N)$ called the transformation functions are eigenfunctions of h_0, $h_0 u_i = \alpha_i u_i$, and they need not necessarily satisfy any physical boundary condition. The final potential has the form

$$V_N(x) = V(x) - 2\frac{d^2}{dx^2}\ln W(u_1, u_2, \ldots, u_N) \tag{24}$$

and will be free of singularities whenever the Wronskian is nodeless, which in turn requires that only consecutive eigenfunctions of h_0 must be considered.[9] The eigenfunctions $\psi(x)$ and $\tilde{\psi}(x)$ of h_0 and h_N are connected by the intertwiners $L^{(N)}$ and $L^{(N)\dagger}$ as

$$\tilde{\psi}_i(x) = L^{(N)}\psi_i(x) = \frac{W_{j,j+1,\ldots,j+N,i}(x)}{W_{j,j+1,\ldots,j+N}(x)}, \tag{25}$$

where $W_{j,j+1,\ldots,j+N,i}(x)$ and $W_{j,j+1,\ldots,j+N}(x)$ are the Wronskians of the eigenfunctions of h_0 associated with the corresponding subindices. Thus if $\psi_i(x)$ is an eigenfunction of h_0 with energy E_i, then $\tilde{\psi}_i(x)$ is an eigenfunction of h_N with the same energy E_i. Evidently

$$L^{(N)}\psi_i = 0, \quad i = 1, 2, \ldots, N. \tag{26}$$

However, for energies E_i $(i=1,2,\ldots,N)$, the corresponding eigenfunctions of h_N,

$$\tilde{\psi}(x)\alpha\frac{\psi(x)}{W_{j,j+1,\ldots,j+N}(x)},$$

have growing asymptotics at both infinities. Consequently, these are not physically acceptable solutions of h_N, and the corresponding eigenvalues E_i $(i=1,2,\ldots,N)$ are excluded from the spectrum of h_N. Thus

$$h_N\tilde{\psi}_E = E\tilde{\psi}_E \tag{27}$$

with the exception of the levels $E=E_i$, $i=1,2,\ldots,N$, which will be absent in the spectrum of the new Hamiltonian h_N, as the corresponding eigenfunctions are not square integrable.

It has already been shown[17] that the operator $L^{(N)}$ can always be presented as a product of N first order Darboux transformation operators between every two Hamiltonians $h_0, h_1, \ldots, h_N$,

$$L^{(N)} = L_N L_{N-1}\cdots L_1, \quad h_p L_p = L_p h_{p-1}, \quad p = 1, 2, \ldots, N. \tag{28}$$

We note that the final Hamiltonian h_N is Hermitian, although some of the intermediate Hamiltonians h_i could be unphysical, e.g., their associated potentials might contain extra singularities that were not present in the initial one. The supercharges Q_N and $Q_N^\dagger$ are constructed as

$$Q_N = \begin{pmatrix} 0 & L^{(N)} \\ 0 & 0 \end{pmatrix}, \quad Q_N^\dagger = \begin{pmatrix} 0 & 0 \\ L^{(N)\dagger} & 0 \end{pmatrix}. \tag{29}$$

Evidently, Q_N and $Q_N^\dagger$ are nilpotent

$$\{Q_N, Q_N\} = \{Q_N^\dagger, Q_N^\dagger\} = 0. \tag{30}$$

The super-Hamiltonian

$$H_N = \begin{pmatrix} h_0 & 0 \\ 0 & h_N \end{pmatrix} \tag{31}$$

satisfies the relations

$$[Q_N, H_N] = [Q_N^\dagger, H_N] = 0. \tag{32}$$

The anticommutator can be generally expressed by a Nth order polynomial $\mathcal{P}_\mathcal{N}$ of the Hamiltonian H_N,

$$\mathcal{H}_N = \{Q_N^\dagger, Q_N\} = \begin{pmatrix} L^{(N)\dagger}L^{(N)} & 0 \\ 0 & L^{(N)}L^{(N)\dagger} \end{pmatrix} = \prod_{k=1}^{N} (H_N - \alpha_k \mathcal{I}), \tag{33}$$

where $\mathcal{I}$ is the 2×2 unit matrix, and

$$L^{(N)\dagger}L^{(N)} = \prod_{k=1}^{N} (h_0 - \alpha_k), \tag{34}$$

$$L^{(N)}L^{(N)\dagger} = \prod_{k=1}^{N} (h_N - \alpha_k). \tag{35}$$

Since the right-hand side of (33) is a polynomial in H_N, it is called nonlinear SUSY or N-fold SUSY. The operator $\mathcal{H}_\mathcal{N}$ is termed as the *Mother Hamiltonian* and satisfies the commutation relations[9]

$$[Q_N, \mathcal{H}_N] = [Q_N^\uparrow, \mathcal{H}_N] = 0. \tag{36}$$

For $N=1$, N-fold SUSY reduces to standard SUSY.

The most widely studied higher order SUSY is for $N=2$,[8,9] where the formalism reduces to

$$L^{(2)} = L_2 L_1, \tag{37}$$

where

$$L_1 = -\partial_x + (\ln u_1)', \quad L_2 = -\partial_x + (\ln v)', \quad v = L_1 u_2, \tag{38}$$

and the isospectral potential turns out to be

$$\tilde{V}_2(x) = V(x) - 2\frac{d^2}{dx^2} \ln W_{j,j+1}(x). \tag{39}$$

III. NONLINEAR PSEUDO-SUSY FOR NON-HERMITIAN HAMILTONIANS

In this section we extend the concept of nonlinear or N-fold supersymmetry to non-Hermitian quantum mechanics. Though the Darboux algorithm and (nonlinear) supersymmetric quantum mechanics are equivalent for Hermitian Hamiltonians, the situation is different for non-Hermitian Hamiltonians. However, intertwining operators $A^{(N)}$ and $B^{(N)}$ can still be constructed with the help of Darboux transformation. Analogous to the case of Hermitian quantum mechanics, it will be shown that once a non-Hermitian Schrödinger potential $V(x)$ is exactly solvable, one can construct an isospectral partner $\tilde{V}_N(x)$ from (24),

$$\tilde{V}_N(x) = V(x) - 2\frac{d^2}{dx^2} \ln W(u_1, u_2, \ldots, u_N), \tag{40}$$

where W stands for the usual symbol for the Wronskian of the functions $u_1, u_2, \ldots, u_N$, which are eigenfunctions of h_0, $h_0 u_i = \alpha_i u_i$. As before the functions $u_i(x)$ may be just formal eigenfunctions. Our aim will be to study the spectrum of the new Hamiltonian in detail, to investigate the nature of the potential and the eigenfunctions, and to determine the symmetry which connects the original Hamiltonian h_0 and the transformed one h_N. For this purpose, we look for two intertwining operators $A^{(N)}$ and $B^{(N)}$ such that

$$A^{(N)}h_0 = h_N A^{(N)}, \quad h_0 B^{(N)} = B^{(N)} h_N, \tag{41}$$

where h_0 and h_N are no longer self-adjoint operators ($h_{0,(N)} \neq h_{0,(N)}^{\dagger}$); on the contrary, to ensure the reality of the spectrum, they are η pseudo-Hermitian,

$$\eta h_{0,(N)} \eta^{-1} = h_{0,(N)}^{\dagger}, \tag{42}$$

where η is a linear, invertible, Hermitian operator. However, the choice of η is not unique. For $\mathcal{PT}$ invariant potentials, a simple representation of η may be given by the parity operator,

$$\eta = \mathcal{P}, \quad \mathcal{P}f(x) = f(-x). \tag{43}$$

It follows that for real potentials, (43) leads to $\eta=1$ so that $B^{(N)}=A^{(N)\dagger}$, thus reproducing the standard result of supersymmetry.

It follows from Eqs. (41) and (42) that the operators $A^{(N)}$ and $B^{(N)}$ are pseudo-adjoint:

$$B^{(N)} = A^{(N)\#} = \eta^{-1} A^{(N)\dagger} \eta. \tag{44}$$

Considering first order Darboux transformation between every two juxtaposed Hamiltonians $h_{0,}h_{1,},\ldots,h_N$, each pair intertwined by first order operators L_k $(k=1,2,\ldots,N)$

$$h_k L_k = L_k h_{k-1,} \quad k = 1,2,3,\ldots,N, \tag{45}$$

$$L_k^{\#} h_k = h_{k-1} L_k^{\#}, \quad k = 1,2,3,\ldots,N, \tag{46}$$

where

$$L_k^{\#} = \eta^{-1} L_k \eta \tag{47}$$

then, analogous to the Hermitian case, the final Hamiltonian h_N is found to be related to the initial (or starting) Hamiltonian h_0 through

$$h_N = L_N L_{N-1} \cdots L_2 L_1 \; h_0 \; L_1^{\#} L_2^{\#} \cdots L_N^{\#} \tag{48}$$

so that the operator $A^{(N)}$ can be represented as a product of the N first order Darboux transformations

$$A^{(N)} = L_N L_{N-1} \cdots L_2 L_1 \tag{49}$$

with its pseudo-adjoint

$$B^{(N)} = A^{(N)\#} = \eta^{-1} L_1 L_2 \cdots L_N \eta = L_1^{\#} \cdots L_{N-1}^{\#} L_N^{\#}. \tag{50}$$

It is worth mentioning here that in contrast to Hermitian quantum mechanics, all the intermediate Hamiltonians h_k are physically acceptable as their associated potentials contain no extra singularities which are not present in the initial potential $V(x)$. This is essentially because the associated eigenfunctions do not have nodes on the real line, and they are normalizable in the sense of Eq. (7).

Thus the initial and the transformed Hamiltonians h_0 and h_N are related by *nonlinear pseudosupersymmetry*. The super-Hamiltonian of this system consists of the pseudosupersymmetric pair of Hamiltonians h_0 and h_N as

$$H_N = \begin{pmatrix} h_0 & 0 \\ 0 & h_N \end{pmatrix}. \tag{51}$$

The supercharges generating this form of pseudosupersymmetry are constructed in the following way:

$$Q_N = \begin{pmatrix} 0 & A^{(N)} \\ 0 & 0 \end{pmatrix}, \quad Q_N^{\#} = \eta^{-1} Q_N^{\dagger} \eta = \begin{pmatrix} 0 & 0 \\ B^{(N)} & 0 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ A^{(N)\#} & 0 \end{pmatrix} \tag{52}$$

so that the supercharge Q_N and its pseudoadjoint $Q_N^{\dagger}$ of standard Hermitian quantum mechanics are replaced by Q_N and its pseudoadjoint $Q_N^{\#}$ for non-Hermitian Hamiltonians. Obviously, Q_N and $Q_N^{\#}$ are nilpotent

$$\{Q_N, Q_N\} = \{Q_N^{\#}, Q_N^{\#}\} = 0 \tag{53}$$

and satisfy the following closed algebra:

$$[Q_N, H_N] = [Q_N^{\#}, H_N] = 0, \tag{54}$$

$$\mathcal{H}_N \equiv \{Q_N^{\#}, Q_N\} = \begin{pmatrix} A^{(N)\#} A^{(N)} & 0 \\ 0 & A^{(N)} A^{(N)\#} \end{pmatrix} = \prod_{k=1}^{N} (H_N - \alpha_k \mathcal{I}), \tag{55}$$

i.e.,

$$A^{(N)\#} A^{(N)} = \prod_{k=1}^{N} (h_0 - \alpha_k), \tag{56}$$

$$A^{(N)} A^{(N)\#} = \prod_{k=1}^{N} (h_N - \alpha_k), \tag{57}$$

and $\mathcal{I}$ is the 2×2 unit matrix. Evidently, if $\psi_i(x)$ is an eigenfunction of h_0 with energy eigenvalue E_i, then $\tilde{\psi}_i(x) = A^{(N)} \psi_i(x)$ is an eigenfunction of h_N with the same energy E_i. However, for $i = 1, 2, \ldots, N$,

$$\tilde{\psi}(x) \alpha \frac{\psi(x)}{W(\psi_1, \psi_2, \ldots, \psi_N)}. \tag{58}$$

Clearly, the eigenfunctions $\tilde{\psi}_i(x)$ $(i = 1, 2, \ldots N)$ of h_N corresponding to the eigenvalues E_i $(i = 1, 2, \ldots, N)$ grow asymptotically, and so cannot be included in the set of solutions of h_N. Consequently, E_i $(i = 1, 2, \ldots, N)$ are excluded from the spectrum of h_N.

Next we note two interesting results which are in contrast to the Hermitian case.

(1) For $\tilde{V}_N(x)$ to be free of singularities, the Wronskian $W(\psi_1, \psi_2, \ldots, \psi_N) = W_{\psi_1, \psi_2, \ldots, \psi_N}(x)$ must be nodeless. In the case of Hermitian potentials, this is guaranteed only when ψ_i, $i = 1, 2, \ldots, N$ represent N consecutive eigenfunctions. However, in the case of generic non-Hermitian potentials, the eigenfunctions $\psi_n(x)$ $(n = 0, 1, 2, \ldots)$ have no nodes on the real line. Consequently, the Wronskian is free of real singularities for any value of $i, j, k, \ldots$, and thus can be used to generate a wider class of isospectral Hamiltonians.

(2) The intermediate Hamiltonians are also physically acceptable, as the corresponding potentials are free of singularities, for the same reason as given above. For example, the first intertwining gives

$$V_1(x) = V(x) - 2 \frac{d^2}{dx^2} \ln \psi_i(x) \tag{59}$$

which is well defined. However, this may not always be true for Hermitian potentials due to the presence of additional singularities in $V_1(x)$, which are not present in $V(x)$.

For the sake of simplicity, in the present work we shall restrict ourselves to second order nonlinear pseudosupersymmetry. Thus if an intertwining operator $A=L_2L_1$ is constructed from the two first order Darboux transformation operators L_1 and L_2, given by

$$L_1 = -\partial_x + (\ln u_i)', \quad L_2 = -\partial_x + (\ln v)', \quad v = L_1 u_j, \tag{60}$$

where u_i and u_j are any two eigenfunctions of the non-Hermitian Hamiltonian h_0, then the transformed isospectral Hamiltonian,

$$h_2 = -\frac{d^2}{dx^2} + \tilde{V}_{i,j}(x) \tag{61}$$

has eigenfunctions

$$\tilde{\psi}_n(x) = \frac{W(\psi_i, \psi_j, \psi_n)}{W(\psi_i, \psi_j)} = -E_n\psi_n + E_i\psi_i\frac{W(\psi_n, \psi_j)}{W(\psi_i, \psi_j)} + E_j\psi_j\frac{W(\psi_i, \psi_n)}{W(\psi_i, \psi_j)}, \tag{62}$$

where

$$\tilde{V}_{i,j}(x) = V(x) - 2\frac{d^2}{dx^2}\ln W(u_i, u_j). \tag{63}$$

The mother Hamiltonian $\mathcal{H}_2$ is constructed from the anticommutator by

$$\mathcal{H}_2 = \{Q_2^{\#}, Q_2\} = \begin{pmatrix} A^{\#}A & 0 \\ 0 & AA^{\#} \end{pmatrix} = \begin{pmatrix} (h_0 - \alpha_1\mathcal{I})(h_0 - \alpha_2\mathcal{I}) & 0 \\ 0 & (h_2 - \alpha_1\mathcal{I})(h_2 - \alpha_2\mathcal{I}) \end{pmatrix}, \tag{64}$$

where $\mathcal{I}$ is 2×2 unit matrix and H_2 is given by (51).

In the following sections we shall investigate this formalism further with the help of explicit examples.

IV. $\mathcal{PT}$ SYMMETRIC OSCILLATOR

In this section we shall apply our formalism to the well-known example of the $\mathcal{PT}$ symmetric oscillator[18]

$$V(x) = (x - i\epsilon)^2 + \frac{\alpha^2 - \frac{1}{4}}{(x - i\epsilon)^2} \tag{65}$$

with eigenfunctions

$$\psi_n(x) = e^{-(1/2)(x - i\epsilon)^2}(x - i\epsilon)^{-q\alpha+1/2}L_n^{-q\alpha}((x - i\epsilon)^2) \tag{66}$$

and eigenvalues

$$E_n = 4n - 2q\alpha + 2, \quad n = 0, 1, 2, \ldots, \tag{67}$$

where $q=\pm 1$ is called the quasiparity.

In this study we shall restrict ourselves to $N=2$ only. If one performs Darboux transformations with two eigenfunctions $\psi_i(x)$ and $\psi_j(x)$ of the potential $V(x)$, corresponding to energies E_i and E_j (i and j need not be consecutive), then the intertwining operators take the form

$$L_1 = -\frac{d}{dx} + \frac{\psi_i'}{\psi_i}, \quad L_1^{\#} = \frac{d}{dx} + \frac{\psi_i'}{\psi_i}, \tag{68}$$

$$L_2 = -\frac{d}{dx} + \frac{W'_{i,j}}{W_{i,j}} - \frac{\psi'_i}{\psi_i}, \quad L_2^{\#} = \frac{d}{dx} + \frac{W'_{i,j}}{W_{i,j}} - \frac{\psi'_i}{\psi_i}, \tag{69}$$

where $W_{i,j}$ is the usual Wronskian given by

$$W_{i,j} = W(\psi_i, \psi_j) = \psi_i(x)\psi'_j(x) - \psi'_i(x)\psi_j(x) \tag{70}$$

and η has been taken as in (43). Replacing the intertwining operators $A^{(2)}$ (and $B^{(2)}$) by A (and B) for simplicity, we obtain

$$A = L_2 L_1 = \frac{d^2}{dx^2} + \beta_{i,j}\frac{d}{dx} - \beta_{i,j}\frac{\psi'_i}{\psi_i} - \frac{\psi''_i}{\psi_i}, \tag{71}$$

$$B = A^{\#} = \eta^{-1}A^{\dagger}\eta = \frac{d^2}{dx^2} - \beta_{i,j}\frac{d}{dx} - \beta_{i,j}\frac{\psi'_i}{\psi_i} - \frac{\psi''_i}{\psi_i} - \beta'_{i,j}, \tag{72}$$

where

$$\beta_{i,j} = -\frac{W'_{i,j}}{W_{i,j}} \tag{73}$$

and η is simply the parity operator $\mathcal{P}$ for $\mathcal{PT}$ symmetric potentials. The new exactly solvable non-Hermitian potential, which is isospectral to the $\mathcal{PT}$ symmetric oscillator in (65), is obtained from

$$\tilde{V}_{i,j}(x) = V(x) - 2\frac{d^2}{dx^2}\ln W_{i,j} \tag{74}$$

with solutions

$$\tilde{\psi}_k(x) = A\psi_k(x). \tag{75}$$

Thus for each set (i,j), one obtains two sets of $\tilde{V}_{i,j}(x)$ because of the presence of quasiparity q. Obviously, $\tilde{\psi}_k(x) = 0$ for $k = i, j$. Thus the new potential so constructed in (74) above, has all the eigenenergies of the original $\mathcal{PT}$ symmetric oscillator except for the levels i, j, which are missing from the spectrum of (74).

For the simplicity of calculations we shall now construct and examine some potentials using low values of i and j in further detail.

A. New potential for $i=1$, $j=2$

Applying the above formalism with the two eigenstates $\psi_1(x)$ and $\psi_2(x)$ of the potential in (65), the Wronskian is found to be

$$W(\psi_1, \psi_2) = c_{12}e^{-(x-i\epsilon)^2}(x - i\epsilon)^{2-2q\alpha}g, \tag{76}$$

where c_{12} is some real constant and

$$g = (1 - q\alpha)(2 - q\alpha) - 2(1 - q\alpha)(x - i\epsilon)^2 + (x - i\epsilon)^4. \tag{77}$$

The intertwining operators A and $A^{\#}$ are obtained from $A = L_2L_1$, $A^{\#} = L_1^{\#}L_2^{\#}$, where

$$L_1 = -\frac{d}{dx} + \frac{\psi'_1}{\psi_1} = -\frac{d}{dx} - (x - i\epsilon) + \frac{-q\alpha + \frac{1}{2}}{(x - i\epsilon)} - \frac{2(x - i\epsilon)}{1 - q\alpha - (x - i\epsilon)^2}, \tag{78}$$

$$L_2 = -\frac{d}{dx} + \frac{d}{dx}\ln(L_1\psi_2) = -\frac{d}{dx} - (x - i\epsilon) + \frac{-q\alpha + \frac{3}{2}}{(x - i\epsilon)} + \frac{2(x - i\epsilon)}{1 - q\alpha - (x - i\epsilon)^2} + \frac{g'}{g}, \tag{79}$$

so that

$$A = \frac{d^2}{dx^2} - \left\{ -2(x - i\epsilon) + \frac{2(1 - q\alpha)}{(x - i\epsilon)} + \frac{g'}{g} \right\} \frac{d}{dx} + (x - i\epsilon)^2 + \frac{(-q\alpha + \frac{1}{2})(-q\alpha + \frac{5}{2})}{(x - i\epsilon)^2} + 2q\alpha - 1$$
$$+ \left\{ -(x - i\epsilon) + \frac{-q\alpha + \frac{1}{2}}{(x - i\epsilon)} - \frac{2(x - i\epsilon)}{1 - q\alpha - (x - 1\epsilon)^2} \right\} \frac{g'}{g}, \tag{80}$$

$$A^{\#} = \frac{d^2}{dx^2} + \left\{ -2(x - i\epsilon) + \frac{2(1 - q\alpha)}{(x - i\epsilon)} + \frac{g'}{g} \right\} \frac{d}{dx} + (x - i\epsilon)^2 + \frac{(-q\alpha + \frac{3}{2})(-q\alpha - \frac{1}{2})}{(x - i\epsilon)^2} + 2q\alpha - 3$$
$$+ \left\{ -(x - i\epsilon) + \frac{-q\alpha + \frac{1}{2}}{(x - 1\epsilon)} - \frac{2(x - i\epsilon)}{1 - q\alpha - (x - i\epsilon)^2} \right\} \frac{g'}{g} + \frac{g''}{g} - \left(\frac{g'}{g}\right)^2. \tag{81}$$

Applying Eq. (74), the new potential isospectral to the one in (65) except for the states corresponding to $\psi_1(x)$ and $\psi_2(x)$, comes out as

$$\tilde{V}_{1,2}(x) = (x - i\epsilon)^2 + \frac{(-q\alpha + \frac{3}{2})(-q\alpha + \frac{5}{2})}{(x - i\epsilon)^2} - 2\frac{g''}{g} + 2\left(\frac{g'}{g}\right)^2 + 4 \tag{82}$$

which has solutions

$$\tilde{\psi}_n(x) = -E_{n+2}\psi_{n+2} + E_1\psi_1 \frac{W(\psi_{n+2}, \psi_2)}{W(\psi_1, \psi_2)} + E_2\psi_2 \frac{W(\psi_1, \psi_{n+2})}{W(\psi_1, \psi_2)} \tag{83}$$

with energy eigenvalues

$$\tilde{E}_n = E_{n+2} = 4n + 10 - 2q\alpha, \quad n = 1, 2, 3, \ldots . \tag{84}$$

The ground state is given by

$$\tilde{\psi}_0(x) = e^{-(1/2)(x - i\epsilon)^2}(x - i\epsilon)^{-q\alpha + 1/2}\left\{ B_1 + \frac{B_2(x - i\epsilon)^2}{g} \right\} \tag{85}$$

with eigenvalue

$$\tilde{E}_0 = E_0 = 2 - 2q\alpha, \tag{86}$$

where B_1 and B_2 are some x, ϵ independent constants. Thus the energies E_1 and E_2 of $V(x)$ are absent in the spectrum of $\tilde{V}_{1,2}(x)$. It can be verified that the eigenfunctions $\tilde{\psi}$ are also $\mathcal{PT}$ invariant, and can be normalized using (7). Furthermore, the supercharges Q_2 and $Q_2^{\#}$, generated from the operators A and $A^{\#}$, satisfy the following algebra :

$$\mathcal{H}_2 = \{Q_2, Q_2^{\#}\} = H_2^2 - 4(4 - q\alpha)H_2 + (6 - 2q\alpha)(10 - 2q\alpha), \tag{87}$$

where H_2 is given by (51). The intermediate potential given by

$$V_1(x) = V(x) - 2\frac{d^2}{dx^2}\ln \psi_1(x) = (x - i\epsilon)^2 + \frac{(-q\alpha + \frac{1}{2})(-q\alpha + \frac{3}{2})}{(x - i\epsilon)^2} + \frac{12}{1 - q\alpha - (x - i\epsilon)^2} - \frac{8(1 - q\alpha)}{\{1 - q\alpha - (x - i\epsilon)^2\}^2} + 4 \tag{88}$$

does not have any singularity on the real line, and hence is physically acceptable as well. By arguments similar to those given above, its ground state eigenfunction is given by

$$\phi_0 = \frac{1}{1 - q\alpha - (x - i\epsilon)^2} e^{-(1/2)(x - i\epsilon)^2} (x - i\epsilon)^{-q\alpha + (3/2)} \tag{89}$$

with energy

$$e_0 = E_0 = 2 - 2q\alpha \tag{90}$$

and the excited states

$$\phi_n = \frac{W(\psi_{n+1}, \psi_1)}{\psi_1} \tag{91}$$

with corresponding energies

$$e_n = E_{n+1} = 4n + 6 - 2q\alpha, \quad n = 1,2,3,\ldots . \tag{92}$$

It is easy to observe that applying (4), both the intermediate and the final potentials (as well as their eigenfunctions) satisfy (3), and hence are $\mathcal{PT}$ invariant, having real spectra.

B. New potentials for *i*=0, *j*=2

In a similar manner, the expressions for the different quantities are obtained as follows:

$$W(\psi_0, \psi_2) = c_{02} e^{-(x - i\epsilon)^2} (x - i\epsilon)^{-2q\alpha + 2} \left\{ \frac{(x - i\epsilon)^2}{2 - q\alpha} - 1 \right\} \tag{93}$$

with c_{02} some real constant

$$L_1 = -\frac{d}{dx} - (x - i\epsilon) + \frac{(-q\alpha + \frac{1}{2})}{(x - i\epsilon)}, \tag{94}$$

$$L_2 = -\frac{d}{dx^2} - (x - i\epsilon) + \frac{(-q\alpha + \frac{3}{2})}{(x - i\epsilon)} + \frac{2(x - i\epsilon)}{\left[(x - i\epsilon)^2 - (2 - q\alpha)\right]}, \tag{95}$$

$$A = \frac{d^2}{dx^2} + 2\left\{ (x - i\epsilon) + \frac{(q\alpha - 1)}{(x - i\epsilon)} - \frac{(x - i\epsilon)}{(x - i\epsilon)^2 - (2 - q\alpha)} \right\} \frac{d}{dx} + (x - i\epsilon)^2 + \frac{(-q\alpha + \frac{1}{2})(-q\alpha + \frac{5}{2})}{(x - i\epsilon)^2} - \frac{3}{(x - i\epsilon)^2 - (2 - q\alpha)} + 2q\alpha - 3, \tag{96}$$

$$A^{\#} = -\frac{d}{dx^2} - 2\left\{ (x - i\epsilon) + \frac{(q\alpha - 1)}{(x - i\epsilon)} + \frac{(x - i\epsilon)}{(x - i\epsilon)^2 - (2 - q\alpha)} \right\} \frac{d}{dx} + (x - i\epsilon)^2 + \frac{(-q\alpha - \frac{1}{2})(-q\alpha + \frac{3}{2})}{(x - i\epsilon)^2} - \frac{5}{\{(x - i\epsilon)^2 - (2 - q\alpha)\}} - \frac{4(-q\alpha + 2)}{\{(x - i\epsilon)^2 - (2 - q\alpha)\}^2} + 2q\alpha - 5. \tag{97}$$

The new potential

$$\tilde{V}_{0,2}(x) = (x - i\epsilon)^2 + \frac{\sigma(\sigma-1)}{(x-i\epsilon)^2} + \frac{4}{(x-i\epsilon)^2 - (2-q\alpha)} + \frac{8(2-q\alpha)}{\{(x-i\epsilon)^2 - (2-q\alpha)\}^2} + 4, \tag{98}$$

where

$$\sigma = -q\alpha + \tfrac{5}{2} \tag{99}$$

is totally different from the initial potential of the $\mathcal{PT}$ symmetric oscillator, yet shares the same spectrum except for the states $n=0$, 2 of the original potential, which are missing in the partner.

The ground state wave function of the Hamiltonian in (98) is given by

$$\tilde{\psi}_0(x) = \left\{ A_1(x-i\epsilon)^2 + A_2 + \frac{A_3}{(x-i\epsilon)^2 - (2-q\alpha)} \right\} e^{-(1/2)(x-i\epsilon)^2} (x-i\epsilon)^{-q\alpha+(1/2)} \tag{100}$$

with ground state energy

$$\tilde{E}_0 = E_1 = 6 - 2q\alpha, \tag{101}$$

where A_1, A_2, A_3 are x-independent constants, while the excited states are obtained from (62)

$$\tilde{\psi}_n = A\psi_{n+2} = -E_{n+2}\psi_{n+2} + E_0\psi_0 \frac{W(\psi_{n+2}, \psi_2)}{W(\psi_0, \psi_2)} + E_2\psi_2 \frac{W(\psi_0, \psi_{n+2})}{W(\psi_0, \psi_2)} \tag{102}$$

with energies

$$\tilde{E}_n = E_{n+2} = 4n + 10 - 2q\alpha, \quad n = 1,2,\ldots . \tag{103}$$

It can also be verified that eigenfunctions $\tilde{\psi}_n(x)$ have correct asymptotic behavior and are also $\mathcal{PT}$ invariant. Consequently, they also satisfy Eq. (7). The intermediate potential is given by

$$V_1(x) = (x-i\epsilon)^2 + \frac{(-q\alpha + \frac{1}{2})(-q\alpha + \frac{3}{2})}{(x-i\epsilon)^2} + 2 \tag{104}$$

which is also physically acceptable. By arguments similar to those given above, its ground state eigenfunction is given by

$$\phi_0 = e^{-(1/2)(x-i\epsilon)^2} (x-i\epsilon)^{-q\alpha+(3/2)} \tag{105}$$

with energy

$$e_0 = 6 - 2q\alpha \tag{106}$$

and excited states

$$\phi_n = \frac{W(\psi_{n+1}, \psi_0)}{\psi_0} \tag{107}$$

with energies

$$e_n = E_{n+1} = 4n + 6 - 2q\alpha, \quad n = 1,2,3,\ldots . \tag{108}$$

Once again, both the intermediate and the final potentials (as well as their eigenfunctions) are $\mathcal{PT}$ invariant, having real spectra.

The supercharges Q_2 and $Q_2^\dagger$ generated from the intertwining operators A and $A^\#$ can be shown to satisfy the following algebra:

$$\mathcal{H}_2 = \{Q_2, Q_2^\#\} = H_2^2 - 4(3-q\alpha)H_2 + (2-q\alpha)(10-2q\alpha) \tag{109}$$

where H_2 is given by (51).

We note that the potentials obtained in this section are unique in the sense that they do not have any counterpart in standard quantum mechanics (i.e., in the Hermitian case).

V. $\mathcal{PT}$ SYMMETRIC SCARF II POTENTIAL

We note that the generalized oscillator problem considered in the last section was made non-Hermitian by an imaginary displacement of the coordinate variable x. However, there are other methods of constructing non-Hermitian models. To see how the formalism described in Sec. III works with such models, in this section we shall study an example, viz., the $\mathcal{PT}$ symmetric non-Hermitian Scarf II potential, which has been $\mathcal{PT}$ symmetrized in a different way. This exactly solvable potential, given by

$$V(x) = -\lambda \operatorname{sech}^2 x - i\mu \operatorname{sech} x \tanh x, \quad \lambda > 0,\ \mu \neq 0 \tag{110}$$

has a discrete spectrum that admits both real as well as complex conjugate energies, depending on the relative strengths of its parameters λ and μ. For $|\mu| \leqslant \lambda + \frac{1}{4}$, the system possesses a real and discrete bound state spectrum, whereas for $|\mu| > \lambda + \frac{1}{4}$, the system exhibits spontaneous $\mathcal{PT}$ symmetry breaking, with complex conjugate pairs of energies. The normalized wave functions for this potential are well known, being given by[15,19]

$$\psi_n(x) = \frac{\Gamma(n - 2p + \frac{1}{2})}{n!\Gamma(\frac{1}{2} - 2p)} z^{-p} (z^*)^{-q} P_n^{-2p-1/2,-2q-1/2}(i \sinh x), \tag{111}$$

where $P_n^{\alpha,\beta}$ are the Jacobi polynomials,[20]

$$P_n^{\alpha,\beta}(i \sinh x) = \frac{\Gamma(n + \alpha + 1)}{\Gamma(n + 1)\Gamma(\alpha + 1)} F(-n, n + \alpha + \beta + 1; \alpha + 1; z) \tag{112}$$

and

$$z = \frac{1 - i \sinh x}{2}, \tag{113}$$

$$p = -\frac{1}{4} \pm \frac{1}{2}\sqrt{\frac{1}{4} + \lambda + \mu} = -\frac{1}{4} \pm \frac{t}{2}, \tag{114}$$

$$q = -\frac{1}{4} \pm \frac{1}{2}\sqrt{\frac{1}{4} + \lambda - \mu} = -\frac{1}{4} \pm \frac{s}{2}. \tag{115}$$

However, for normalization of the wave functions, only the positive sign is allowed in p. The energy spectrum

$$E_n = -(n - p - q)^2, \quad n = 0, 1, 2, \ldots < \left(\frac{s + t - 1}{2}\right) \tag{116}$$

is real and bound for $|\mu| \leqslant \lambda + \frac{1}{4}$, i.e., for real p and q, with two towers characterized by the two values of q.

If the formalism developed above is applied to this example for $N=2$, with states $\psi_0(x)$ and $\psi_2(x)$, then the Wronskian is calculated to be

$$W(\psi_0, \psi_2) = (1 - i \sinh x)^{-2p}(1 + i \sinh x)^{-2q} \cosh x\{-i(p - q) + (p + q - \tfrac{3}{2})\sinh x\} \tag{117}$$

and the intertwining operators A and $A^{\#}$ are given by

$$A = L_2 L_1, \quad A^{\#} = L_1^{\#} L_2^{\#}, \tag{118}$$

where L_1 and L_2 take the form

$$L_1 = -\frac{d}{dx} + \frac{\psi_0'}{\psi_0} = \frac{d}{dx} + i(p-q)\operatorname{sech} x - (p+q)\tanh x, \tag{119}$$

$$\begin{aligned} L_2 = &-\frac{d}{dx} + \frac{W_{0,2}'}{W_{0,2}} - \frac{\psi_0'}{\psi_0} = \frac{d}{dx} + i(p-q)\operatorname{sech} x - (p+q)\tanh x \\ &+ \frac{(-p-q+\frac{3}{2}) + i(p-q)\sinh x + (-2p-2q+3)\sinh^2 x}{i(p-q)\cosh x + (-p-q+\frac{3}{2})\sinh x \cosh x}. \end{aligned} \tag{120}$$

Now using (40) the new potential is found to be

$$\tilde{V}_{0,2}(x) = -\tilde{\lambda}\operatorname{sech}^2 x - i\tilde{\mu}\operatorname{sech} x \tanh x - 2\left(\frac{\sigma^2 \operatorname{sech}^2 x - i\rho\sigma \operatorname{sech} x \tanh x}{(\rho \operatorname{sech} x - i\sigma \tanh x)^2}\right), \tag{121}$$

where

$$\tilde{\lambda} = \lambda - 4p - 4q + 2, \tag{122}$$

$$\tilde{\mu} = \mu - 4p + 4q, \tag{123}$$

$$\lambda = 2(p^2 + q^2) + (p+q), \tag{124}$$

$$\mu = 2(p^2 - q^2) + (p-q), \tag{125}$$

$$\rho = p - q, \tag{126}$$

$$\sigma = -p - q + \tfrac{3}{2}. \tag{127}$$

Once again, the final potential $\tilde{V}_{0,2}(x)$ is also $\mathcal{PT}$ invariant. The eigenfunctions are obtained from (62), with the ground state as

$$\tilde{\psi}_0 = (E_0 - E_1)\psi_1 + (E_2 - E_0)\psi_2 \frac{P_1'}{P_2'} \tag{128}$$

and excited states

$$\tilde{\psi}_n = (E_0 - E_{n+2})\psi_{n+2} + (E_2 - E_0)\psi_2 \frac{P_{n+2}'}{P_2'} \tag{129}$$

where P_n denotes the Jacobi polynomial $P_n^{-2p-1/2-2q-1/2}(i \sinh x)$ and P_n' denotes its derivative with respect to x. It can be shown that for $|\mu| \leqslant \lambda + \frac{1}{4}$, the wave functions $\tilde{\psi}$ are also $\mathcal{PT}$ invariant, and can be normalized following (7). The new potential $\tilde{V}_{0,2}(x)$ has real bound state spectrum given by

$$\tilde{E}_0 = -(1-p-q)^2, \tag{130}$$

$$\tilde{E}_n = -(n+2-p-q)^2, \quad n = 1,2,\ldots, < \left(\frac{s+t-5}{2}\right), \tag{131}$$

and the algebra satisfied by the supercharges turns out to be

$$\mathcal{H}_2 = \{Q_2, Q_2^{\#}\} = H_2^2 + (2 - 2p - 2q)H_2 + (p + q)(p + q - 2), \tag{132}$$

where H_2 is given by (51).

The intermediate potential takes the form

$$V_1(x) = -\tilde{v}_1 \operatorname{sech}^2 x - i\tilde{v}_2 \operatorname{sech} x \tanh x, \tag{133}$$

where

$$\tilde{v}_1 = \lambda - 2(p + q), \tag{134}$$

$$\tilde{v}_2 = \mu - 2(p - q) \tag{135}$$

with eigenfunctions

$$\phi_n = \frac{W(\psi_{n+1}, \psi_0)}{\psi_0} \tag{136}$$

and the corresponding energies

$$e_n = E_{n+1} = -(n + 1 - p - q)^2, \quad n = 0, 1, \ldots, < \left(\frac{s + t - 3}{2}\right). \tag{137}$$

Thus $V_1(x)$ and the corresponding wave functions (136) are also physically acceptable as well as $\mathcal{PT}$ invariant.

VI. CONCLUSIONS

In this paper we have suggested an application of higher order Darboux algorithm to non-Hermitian $\mathcal{PT}$ symmetric potentials. For the sake of definiteness the method has been applied to two specific potentials, namely, the generalized oscillator and the Scarf II potentials and a number of new potentials having nearly the same spectrum as the original ones have been obtained. It may be noted that in each of these cases, starting from a $\mathcal{PT}$ symmetric potential we have obtained new potentials which are again $\mathcal{PT}$ symmetric. In other words the higher order Darboux algorithm does not induce spontaneous $\mathcal{PT}$ symmetry breaking. Among the different cases considered here the one involving nonconsecutive levels deserves special mention. The potentials thus obtained have no Hermitian analogues. Also the intermediate potentials in all the cases are perfectly well behaved since the Darboux algorithm does not introduce any new singularity or break $\mathcal{PT}$ symmetry. Furthermore it has been shown that the symmetry underlying the original and the new potentials is a fusion of *nonlinear SUSY* and $\mathcal{PT}$ symmetry which we call *nonlinear pseudosupersymmetry*. Finally we note that analogous to the study of breaking N-fold supersymmetry,[21] it would be of interest to examine breaking of this new symmetry.

For a very large class of potentials, $V(\vec{x}), \vec{x} \in R^2$, we prove the universality of the low-energy scattering amplitude, $f(\vec{k}', \vec{k})$. The result is $f = \sqrt{\pi/2}(1/\log k) + o(1)/[\log(1/k)]$. The only exceptions occur if V happens to have a zero-energy bound state. Our new result includes as a special subclass the case of rotationally symmetric potentials, $V(|\vec{x}|)$. © *2005 American Institute of Physics.*

I. INTRODUCTION

In a recent paper we proved an interesting universality property for the low-energy scattering limit in two space dimensions.[1] This was done both for massive quantum field theory in 2+1 dimensions, and for nonrelativistic quantum mechanics in two space dimensions for a centrally symmetric force.

The result briefly stated that the S-wave phase shift, $\delta_0(k)$, k being the c.m. momentum, vanishes as $\delta_0 \to c/\log(k/m)$ as $k \to 0$, or in exceptional cases, $\delta_0 = O(k^2)$. The constant, c, is universal, $c = \pi/2$ independent of the dynamics. For potential scattering this kind of universality was first noted in Ref. 2, albeit with an incomplete proof which missed among other things the exceptional class of potentials. For the field theoretic case the result can be found in an earlier paper.[3] But it is buried in a much more general context and its physical significance was not discussed.

Physics in two space dimensions was initially mostly of theoretical and mathematical interest. However, especially in the 5 years since Ref. 1 appeared, we have had several physical, experimentally accessible systems which have two space dimensions. These systems appear in condensed matter physics, and a recent review is given in Ref. 4. We also note more recent theoretical papers by Lieb and Yngvasson[5] and also by Ren.[6] It is important to note that in the condensed matter systems the forces are often not rotationally symmetric and in some cases they are also nonlocal.

In the present paper we return to the nonrelativistic case but treat potentials which have no rotational symmetry, $V \equiv V(\vec{x})$, $\vec{x} \in R^2$. In this case there are no phase shifts, but we obtain the corresponding low-energy result for the full amplitude which agrees with that obtained in the rotationally symmetric case. This is obtained under very general and "reasonable" conditions on

$V(\vec{x})$ which have the following three properties: (a) they are linear in V; (b) they are invariant under a shift of origin; and (c) they include the previously studied case of Ref. 1.

Section II is devoted to preliminaries and definitions, including the Green's function in R^2 and the scattering integral equation.

In Sec. III we study the Fredholm integral equation with the two-dimensional (2D) zero-energy Green's function, $G_0=(1/2\pi)\log|\vec{x}-\vec{y}|$. The main task in this section is to define the general class of potentials, $V(\vec{x})$, to be considered.

In Sec. IV, we consider the Lippmann–Schwinger equation for $k>0$. We prove that, given our class of potentials, then for any real fixed k with $k>0$, this equation has a unique solution, $\psi(\vec{k},\vec{x})$, with $\psi\in C$, where C is the Banach space of continuous functions on R^2 with a sup norm. We also obtain a k-dependent upper bound for $\|\psi\|$, which will prove useful in the succeeding sections.

Section V is devoted to proving that the zero-energy kernel defines a compact operator on C. We also show that even in the case where there exist nontrivial solutions of the homogeneous integral equation with a zero-energy kernel, one still has solutions of the inhomogeneous equation. However these are not unique. This helps in solving the "exceptional case" where ϕ_j, $j=1\ldots,N$, are solutions of the homogeneous equation but with $\int \mathrm{d}^2x\ \phi_j(\vec{x})V(\vec{x})=0$.

We end up with two cases to consider. Case A is where the solution(s) of the inhomogeneous equation, $\tilde{\phi}$, are such that $\int \mathrm{d}^2x\tilde{\phi}(\vec{x})V(\vec{x})\neq 0$. Case B is where the solutions of the inhomogeneous equations satisfy $\int \mathrm{d}^2x\tilde{\phi}(\vec{x})V(\vec{x})=0$.

In Sec. VI we prove the universality of the low-energy scattering amplitude for case A. The result for the full scattering amplitude $f(\vec{k}',\vec{k})$ is $f=-\sqrt{\pi/2}[\log(1/k)]^{-1}+o(1)/(\log k)$. This agrees with our result for the symmetric case given in Ref. 1.

In Sec. VII, we treat the "exceptional case," i.e., mainly case B, and obtain the result $f=o(1)/[\log(1/k)]$. Finally in Sec. VIII we discuss two additional exceptional cases, $\mathrm{A_{II}}$ and $\mathrm{B_I}$.

We briefly discuss the case of nonlocal potentials in Sec. IX. This is limited to giving the class of nonlocal potentials, $W(\vec{x},\vec{y})$, that can be studied by our methods.

Finally, in the last section we give a series of comments and conclusions related to issues raised by this work.

II. NONRELATIVISTIC SCATTERING IN 2D

The free Green's function in two dimensions is given by

$$G(\vec{x},\vec{y}) \equiv \frac{1}{4i}H_0^{(1)}(k|\vec{x}-\vec{y}|), \tag{2.1}$$

where

$$(\nabla^2 + k^2)G(\vec{x},\vec{y}) = \delta^2(\vec{x}-\vec{y}), \tag{2.2}$$

with $\vec{x},\vec{y}\in R^2$, and $H_0^{(1)}$ is the standard Hankel function.

The scattering integral equation is

$$\psi(\vec{k},\vec{x}) = e^{i\vec{k}\cdot\vec{x}} + \frac{1}{4i}\int \mathrm{d}^2y\ H_0^{(1)}(k|\vec{x}-\vec{y}|)V(\vec{y})\psi(\vec{k},\vec{y}). \tag{2.3}$$

The class of noncentral potentials, V, will be specified in the next section.

The asymptotic behavior of ψ for large $|\vec{x}|$ is given by

$$\psi(\vec{k},\vec{x}) \underset{|\vec{x}|\to\infty}{\to} e^{i\vec{k}\cdot\vec{x}} + \frac{i}{\sqrt{k}}f(\vec{k}',\vec{k})\frac{e^{i(kr-\pi/4)}}{\sqrt{r}}, \quad r=|\vec{x}|, \quad \vec{k}'=k\frac{\vec{x}}{|\vec{x}|}. \tag{2.4}$$

Here we have used the large $|z|$ behavior of $H_0^{(1)}(z)$. This leads to

$$G \underset{|\vec{x}-\vec{y}|\to\infty}{\to} \frac{1}{i}\sqrt{\frac{1}{8\pi k|\vec{x}-\vec{y}|}}e^{i(k|\vec{x}-\vec{y}|-\pi/4)}. \tag{2.5}$$

Equation (2.4) defines the scattering amplitude, $f(\vec{k}',\vec{k})$. One should note that in Eq. (2.4) we have chosen a center, i.e., the point $\vec{x}=0$. Unlike the rotationally symmetric case, the definition of f is only unique up to a phase. Shifting the center by $\vec{a}$, $\vec{x}\to\vec{x}+\vec{a}$, the new amplitude differs by a factor $\exp[i(\vec{k}'-\vec{k})\cdot\vec{a}]$. One should note that the forward scattering amplitude is invariant under this shift, as one would expect from the optical theorem. In this paper, we are only interested in the $k\to 0$ limit, which is clearly independent of the choice of a center.

From Eqs. (2.2) and (2.4) we have the standard expression for f,

$$f(\vec{k}',\vec{k}) = -\frac{1}{\sqrt{8\pi}}\int \mathrm{d}^2x\; e^{-i\vec{k}'\cdot\vec{x}}V(\vec{x})\psi(\vec{k},\vec{x}), \tag{2.6}$$

where $|\vec{k}'|=|\vec{k}|$.

The problem we face in this paper originates from the logarithmic singularity of $H_0^{(1)}(z)$ at $z=0$.

We define $R(z)$ by the following:

$$H_0^{(1)}(z) \equiv C_0 + \frac{2i}{\pi}\log z + R(z), \tag{2.7}$$

where

$$C_0 \equiv 1 + \frac{2i}{\pi}[\gamma - \log 2], \tag{2.8}$$

and γ is Euler's constant. For small $|z|$ we have

$$R(z) = O(|z|^2|\log|z||). \tag{2.9}$$

Substituting Eq. (2.7) in (2.3), we obtain

$$\psi(\vec{k},\vec{x}) = e^{i\vec{k}\cdot\vec{x}} + \int \mathrm{d}^2y\left[\frac{\log k|\vec{x}-\vec{y}|}{2\pi} + \frac{C_0}{4i} + \frac{R(k|\vec{x}-\vec{y}|)}{4i}\right]V(\vec{y})\psi(\vec{k},\vec{y}). \tag{2.10}$$

From Eq. (2.7) we also have

$$R(k|\vec{x}|) = H_0^{(1)}(k|\vec{x}|) - \frac{\log k|\vec{x}|}{2\pi} - \frac{C_0}{4i}. \tag{2.11}$$

Using this result, we obtain

$$\psi(\vec{k},\vec{x}) = e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})\left[\frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log|\vec{x}|}{2\pi}\right] + \frac{1}{2\pi}\int \mathrm{d}^2y(\log|\vec{x}-\vec{y}|)V(\vec{y})\psi(\vec{k},\vec{y})$$
$$-\frac{1}{4i}\int [R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)]V(\vec{y})\psi(\vec{k},\vec{y}), \tag{2.12}$$

where F is defined as

$$F(\vec{k}) \equiv \int \mathrm{d}^2y\; V(\vec{y})\psi(\vec{k},\vec{y}). \tag{2.13}$$

We stress that in going from Eq. (2.3)–(2.12) we have made no approximations. We will show in Appendix B that the last term in (2.12) is, for small k, proportional to $[o(1)/|\log k|] \times (\sup_{\vec{y}}|\psi(\vec{k},\vec{y})|)$, and is thus small compared to the preceding term.

It is clear then from Eq. (2.12) that our first task is to study the zero-energy kernel, $K(\vec{x},\vec{y}) = [(1/2\pi)\log|\vec{x}-\vec{y}|]V(\vec{y})$, which is the main term in (2.12). This analysis will also give us the definition of the broadest class of V's that we will investigate.

III. THE ZERO-ENERGY KERNEL AND THE CLASS OF POTENTIALS

In this section we consider the integral equation with the zero-energy Green's function, $G_0 = (1/2\pi)\log|\vec{x}-\vec{y}|$. We use it to define our class of potentials $V(\vec{x})$, essentially as those that lead to a kernel, K, which is bounded on a Banach space of continuous functions on R^2.

We start with

$$\phi(\vec{x}) = 1 + \frac{1}{2\pi}\int d^2y[\log|\vec{x}-\vec{y}|]V(\vec{y})\phi(\vec{y}). \tag{3.1}$$

It is more convenient to deal with functions that have a finite sup norm. We define

$$u(\vec{x}) = \frac{\phi(\vec{x})}{\log(2+|\vec{x}|)}, \tag{3.2}$$

$$u_0(\vec{x}) = \frac{1}{\log(2+|\vec{x}|)}. \tag{3.3}$$

The resulting integral equation is

$$u(\vec{x}) = u_0(\vec{x}) + \int d^2y\ K(\vec{x},\vec{y})u(\vec{y}), \tag{3.4}$$

with

$$K(\vec{x},\vec{y}) = \frac{1}{2\pi}(\log|\vec{x}-\vec{y}|)V(\vec{y})\frac{\log(2+|\vec{y}|)}{\log(2+|\vec{x}|)}. \tag{3.5}$$

The objective is to study Eq. (3.4) for $u \in C$, the Banach space of all bounded continuous functions on R^2. The norm on C is

$$\|u\| = \sup_{\vec{x}\in R^2}|u(\vec{x})|. \tag{3.6}$$

C is complete and convergence in the norm is uniform convergence.

Our task in this section is to define suitable conditions on $V(\vec{x})$ that are needed to guarantee that $K(\vec{x},\vec{y})$ is a bounded operator on C, i.e., we seek some sufficient conditions on $V(\vec{x})$ such that

$$\int d^2y|\log|\vec{x}-\vec{y}|V(\vec{y})|\frac{\log(2+|\vec{y}|)}{\log(2+|\vec{x}|)} < M, \tag{3.7}$$

for all $\vec{x} \in R^2$.

By suitable conditions we mean the following:

(i) the conditions are linear in $|V(\vec{x})|$;
(ii) the conditions are invariant under a shift of origin;
(iii) the conditions are invariant under a scale change;
(iv) the previous symmetrical case of Ref. 1 is included.

Here (iii) implies that k can be replaced by any positive multiple of k. In particular, the k of Sec. II can be replaced by any positive number, an especially convenient choice being 1. To show this explicitly, note that, for $k>0$, there is the following inequality:

$$\frac{2+k|\vec{x}|}{2+|\vec{x}|} \leqslant \max(1,k). \tag{3.8}$$

This inequality implies immediately

$$\log(2+k|\vec{x}|) - \log(2+|\vec{x}|) \leqslant \max(0,\log k)$$

and

$$\log(2+k|\vec{x}|) - \log(2+|\vec{x}|) \leqslant \max\left(\log k, \log\frac{1}{k}\right). \tag{3.9}$$

We prove that the following two conditions are sufficient to guarantee the validity of Eq. (3.7) and hence the boundedness of K,

$$\text{(A)} \quad \int \mathrm{d}^2y |V(\vec{y})| (\log(2+|\vec{y}|))^2 < M \tag{3.10}$$

and

$$\text{(B)} \quad \int_0^1 y \, \mathrm{d}y |\log y| |V(\vec{y})|_R < M, \tag{3.11}$$

where $|V(\vec{y})|_R$ is the rearrangement of $|V(\vec{y})|$.

We remind the reader that the circular decreasing rearrangement of a non-negative function, $f(\vec{x})$, is a decreasing function, $f_R(|\vec{x}|)$, such that

$$\mu[f_R(|\vec{x}|) \geqslant A] = \mu[f(\vec{x}) \geqslant A], \quad \forall A, \tag{3.12}$$

where μ is the Lebesgue measure.

For the proof, we introduce for positive r,

$$\log^+ r = \max(\log r, 0),$$

$$\log^- r = \max(-\log r, 0). \tag{3.13}$$

Hence we have

$$\log r = \log^+ r - \log^- r,$$

$$|\log r| = \log^+ r + \log^- r. \tag{3.14}$$

This splits Eq. (3.7) into two inequalities,

$$\int \mathrm{d}^2y \, \log^+|\vec{x}-\vec{y}| |V(\vec{y})| \frac{\log(2+|\vec{y}|)}{\log(2+|\vec{x}|)} < M \tag{3.15}$$

and

$$\int \mathrm{d}^2y \, \log^-|\vec{x}-\vec{y}| |V(\vec{y})| \frac{\log(2+|\vec{y}|)}{\log(2+|\vec{x}|)} < M. \tag{3.16}$$

We consider Eq. (3.15) first. Fixing $\vec{y}$, we have

$$\max_{\vec{x}} \frac{\log^+|\vec{x}-\vec{y}|}{\log(2+|\vec{x}|)} = \max_{\vec{x}} \frac{\log|\vec{x}-\vec{y}|}{\log(2+|\vec{x}|)} = \max_{\vec{x}} \frac{\log(x+y)}{\log(2+x)}. \tag{3.17}$$

But, for fixed y, the last expression above is monotonic in x. Therefore we obtain

$$\max_{\vec{x}} \frac{\log^+|\vec{x}-\vec{y}|}{\log(2+|\vec{x}|)} \leqslant \frac{\log(2+y)}{\log 2}. \tag{3.18}$$

Hence the inequality (3.15) is satisfied provided that the condition (A), given in Eq. (3.10), is true. One should note that condition (A) is invariant under a change of origin.

Next, we go to the inequality (3.16). Because of the factor $\log^-|\vec{x}-\vec{y}|$, we know that the integrand in (3.15) is zero if $|\vec{x}-\vec{y}|>1$. Hence our domain of integration is such that

$$x-1<y<x+1. \tag{3.19}$$

This gives

$$\log(2+y)<\log(3+x). \tag{3.20}$$

But since $[\log(3+x)/\log(2+x)] \leqslant \log 3/\log 2$, the validity of Eq. (3.16) reduces to

$$\int d^2y \, \log^-|\vec{x}-\vec{y}| \cdot |V(\vec{y})| < \frac{\log 3}{\log 2} M. \tag{3.21}$$

For any $f(\vec{r})$ we denote by $f_R(r)$ the rearrangement of $|f(\vec{r})|$. One has the inequality

$$\int d^2y |f(\vec{y})| \cdot |g(\vec{y})| \leqslant \int d^2y \, f_R(y) g_R(y), \tag{3.22}$$

and using this result

$$\int d^2y \, \log^-|\vec{x}-\vec{y}| \cdot |V(\vec{y})| \leqslant \int d^2y (\log^-|\vec{x}-\vec{y}|)_R \cdot |V(\vec{y})|_R \leqslant \int d^2y (\log^- y)_R \cdot |V(\vec{y})|_R$$

$$\leqslant \int d^2y (\log^- y) |V(\vec{y})|_R. \tag{3.23}$$

But $\log^- y = 0$ for $y>1$, and thus

$$\int_0^1 y \, dy |\log y| |V(\vec{y})|_R \leqslant \frac{\log 3}{\log 2} M. \tag{3.24}$$

This establishes Eq. (3.16), and completes our proof that for potentials, $V(\vec{x})$, satisfying conditions (A) and (B), K is a bounded operator on C.

In Sec. V we prove that K is compact on C, and also prove other important properties of the zero-energy integral equation.

IV. SOLUTIONS OF THE LIPPMANN–SCHWINGER EQUATION FOR $k>0$

We shall now proceed to prove that for our class of potentials the integral equation (2.3), for any fixed real k with $k>0$, has a unique solution, $\psi(\vec{k},\vec{x})$, with $\psi \in C$. The norm of ψ, $\|\psi\|$, will depend on k, but it is bounded for any fixed $k>0$.

The integral equation (2.3) can be written as

$$\psi(\vec{k},\vec{x}) = e^{i\vec{k}\cdot\vec{x}} + \int \mathrm{d}^2 y \tilde{K}(k;\vec{x},\vec{y})\psi(\vec{k},\vec{y}), \tag{4.1}$$

where

$$\tilde{K}(k;\vec{x},\vec{y}) \equiv \frac{1}{4i} H_0^{(1)}(k|\vec{x}-\vec{y}|)V(\vec{y}). \tag{4.2}$$

We first prove the boundedness of $\tilde{K}$.

Lemma 4.1: For any real k, $k>0$, $\tilde{K}$ is a bounded operator on C, with

$$\|\tilde{K}(k)\| < M(k) < \infty, \tag{4.3}$$

where $M(k)=M_1[1+\log(1/k)]$.

Proof: We use the bound on $H_0^{(1)}(\lambda)$,

$$|H_0^{(1)}(\lambda)| \leqslant |H_0^{(1)}(\lambda_0)| + \log^+\left(\frac{\lambda_0}{\lambda}\right). \tag{4.4}$$

This is proved in Appendix A. Hence we have

$$|H_0^{(1)}(k|\vec{x}-\vec{y}|)| < |H_0^{(1)}(k_0|\vec{x}-\vec{y}|)| + \log\frac{k_0}{k}. \tag{4.5}$$

For our case we can set $k_0=1$.

Next, we need the following bounds on $H_0^{(1)}(|\vec{x}-\vec{y}|)$:

$$|H_0^{(1)}(|\vec{x}-\vec{y}|)| < \begin{cases} C_1 + C_2|\log|\vec{x}-\vec{y}|| & \text{for } |\vec{x}-\vec{y}|<1, \\ C_3 & \text{for } |\vec{x}-\vec{y}| \geqslant 1. \end{cases} \tag{4.6}$$

Hence, for any $\chi \in C$, we get

$$\frac{1}{4}\int |H_0^{(1)}(|\vec{x}-\vec{y}|)||V(\vec{y})\chi(\vec{y})|\mathrm{d}^2 y \leqslant \|\chi\|\Bigg[C_1\int_{|\vec{x}-\vec{y}|<1} \mathrm{d}^2 y|V(\vec{y})| + C_2\int_{|\vec{x}-\vec{y}|<1} \mathrm{d}^2 y|\log|\vec{x}-\vec{y}|||V(\vec{y})| + C_3\int_{|\vec{x}-\vec{y}|>1} \mathrm{d}^2 y|V(\vec{y})|\Bigg]. \tag{4.7}$$

But in the preceding section we proved that the middle integral above is bounded.

Hence we have

$$\|\tilde{K}\| = \sup_{\chi\in C}\frac{\|\tilde{K}\chi\|}{\|\chi\|} \leqslant M_1\left(1+\log\frac{1}{k}\right). \tag{4.8}$$

The theorems in textbooks for compact bounded operators on C are usually given for finite domains $|\vec{x}|<\infty$. We use the following lemma which is a generalization of the ones in the textbooks.

Lemma 4.2: Let B be the Banach space of bounded continuous functions on R^m ($m\geqslant 1$) and B_0 the subset of B formed by functions which tend to 0 at infinity. B_0 is a closed subspace of B.

Let Q denote an operator on B satisfying the following three conditions.

(1) For any $g\in B$,

$$(Qg)(x) = \int q(x,y)g(y)\mathrm{d}^m y, \tag{4.9}$$

where q is an L^1 function on $R^m\times R^m$.

(2) $\int|q(x,y)|\mathrm{d}^m y$ exists and is bounded from above by $h(x)$, where h is a continuous positive function which tends to 0 at infinity.

(3) There exists a function η on $[0,a]$ (for some $a>0$) such that $\eta(r)\to 0$ when $r\to 0$, and such that, for every $g\in B$ and every $(x,x')\in R^m\times R^m$ satisfying $|x-x'|\leqslant a$,

$$|Qg(x)-Qg(x')|<\|g\|\,\eta(|x-x'|). \tag{4.10}$$

Then Q is compact from B to B, and in fact from B to B_0.

A proof of this lemma will be given in Appendix B.[7]

Next, we will use Lemma 4.2 to prove the compactness of the operator $\tilde{K}(k)$.

Lemma 4.3: For any fixed real k, $k>0$, the operator $\tilde{K}(k)$ defined by the kernel in Eq. (4.2) is compact on C.

Proof: From Lemma 4.1 the operators, $\tilde{K}(k)$, defined by the kernel

$$\tilde{K}(k;\vec{x},\vec{y})\equiv\frac{1}{4i}H_0^{(1)}(k|\vec{x}-\vec{y}|)V(\vec{y}), \tag{4.11}$$

are, for fixed nonzero k, also bounded operators on C. In addition for any $\vec{x}\in R^2$ we have

$$\int \mathrm{d}^2y|\tilde{K}(k;\vec{x},\vec{y})|\leqslant M<\infty, \tag{4.12}$$

which follows from the boundedness on C. But for large $|\vec{x}|$, $|\vec{x}|\gg 1/k$, we have

$$\int \mathrm{d}^2y|\tilde{K}(k;\vec{x},\vec{y})|=O\left(\frac{1}{\sqrt{|\vec{x}|}}\right). \tag{4.13}$$

This is due to the asymptotic behavior of $H_0^{(1)}(z)$. Hence, we can always find a constant, $M(k)$, such that

$$\int \mathrm{d}^2y|\tilde{K}(k;\vec{x},\vec{y})|\leqslant\frac{M(k)}{\sqrt{1+|\vec{x}|}}, \tag{4.14}$$

for all $\vec{x}\in R^2$.

Thus $\tilde{K}(k)$ satisfies the first condition, i.e., (4.10), of Lemma 4.2 with

$$\tilde{h}(|\vec{x}|)=\frac{M(k)}{\sqrt{1+|\vec{x}|}}. \tag{4.15}$$

To establish the uniform continuity of $f(\vec{x})$, with $f\equiv(\tilde{K}g)(\vec{x})$, we note that, as given in Eq. (2.7),

$$H_0^{(1)}(k|\vec{x}-\vec{y}|)=C_0+\frac{2i}{\pi}\log\, k|\vec{x}-\vec{y}|+R(k|\vec{x}-\vec{y}|), \tag{4.16}$$

and uniform continuity for the kernel $\log|\vec{x}-\vec{y}|V(\vec{y})$ will be established in the next section. The same result for the operator (RV) will be given in Appendix C. Hence, the conditions of Lemma 4.2 are satisfied and therefore $\tilde{K}(k)$ is compact on C for any fixed nonzero k. This completes the proof of Lemma 4.3.

Using the Fredholm alternative we can now assert that a unique solution, $\psi(\vec{k},\vec{x})$, of Eq. (4.1) exists for any fixed $k>0$, unless the homogeneous equation,

$$\psi_0(\vec{k},\vec{x})=(\tilde{K}(k)\psi_0(\vec{k}))(\vec{x}), \tag{4.17}$$

has a nontrivial solution, ψ_0. But one can easily prove that this leads to a contradiction.

Lemma 4.4: For any real fixed k, $k>0$, there is no nontrivial solution, $\psi_0(\vec{k},\vec{x})$, of the equation

$$\psi_0(\vec{k},\vec{x}) = \int \mathrm{d}^2 y \widetilde{K}(k;\vec{x},\vec{y})\psi_0(\vec{k},\vec{y}). \tag{4.18}$$

Proof: Since $\widetilde{K}=(1/4i)H_0^{(1)}(k|\vec{x}-\vec{y}|)V(\vec{y})$, we get for large $k|\vec{x}|$, $|\vec{x}| \gg 1/k$,

$$\psi_0(\vec{k},\vec{x}) = ie^{i(kx-\pi/4)}\left[\frac{\widetilde{f}_0}{\sqrt{kx}} + O\left(\frac{1}{(kx)^{3/2}}\right)\right], \tag{4.19}$$

where

$$\widetilde{f}_0 = -\frac{1}{\sqrt{8\pi}}\int \mathrm{d}^2 y\ e^{-i\vec{k}\cdot\vec{y}}V(\vec{y})\psi_0(\vec{k},\vec{y}), \tag{4.20}$$

with $\vec{k}'/|\vec{k}| = \vec{x}/|\vec{x}|$, and $|\vec{k}'| = |\vec{k}| = k$.

Next, $\psi_0(\vec{k},\vec{x})$ satisfies the Schrödinger equation

$$-\nabla^2\psi_0 + V\psi_0 = k^2\psi_0. \tag{4.21}$$

This leads to

$$\psi_0^*\nabla^2\psi_0 - \psi_0\nabla^2\psi_0^* = 0, \tag{4.22}$$

since V is real. Integrating Eq. (4.22) over a large disk A, we get

$$\int_{\partial A}(\psi_0^*\vec{\nabla}\psi_0 - \psi_0\vec{\nabla}\psi_0^*)\cdot \mathrm{d}\vec{e} = 0, \quad \vec{e} = \vec{x}/|\vec{x}|. \tag{4.23}$$

We note that

$$\vec{\nabla}\left(\frac{e^{i(kx-\pi/4)}}{\sqrt{kx}}\right) = \frac{ike^{i(kx-\pi/4)}}{\sqrt{kx}}\cdot\frac{\vec{x}}{|\vec{x}|} + \frac{\vec{x}}{|\vec{x}|\sqrt{kx}}O(1/x), \tag{4.24}$$

where the $O(1/x)$ factor has no k dependence.

Using the asymptotic expression (4.24) for ψ_0, and substituting in Eq. (4.23), we finally obtain as $|\vec{x}|\to\infty$,

$$2\pi\int \mathrm{d}\theta|\widetilde{f}_0(k,\theta)|^2 = 0. \tag{4.25}$$

This leads to a contradiction and completes the proof of Lemma 4.4.

In conclusion, for our class of potentials, and any $k>0$, a unique solution, $\psi(\vec{k},\vec{x})$, of Eq. (4.1) exists and is in C, i.e.,

$$\|\psi\| = \sup_{\vec{x}}|\psi(\vec{k},\vec{x})| \leqslant M_1(k) < \infty. \tag{4.26}$$

The norm $\|\psi\|$ of course depends on k, and in principle could grow as $k\to 0$.

V. COMPACTNESS OF THE ZERO-ENERGY OPERATOR

We consider the integral equation (3.4),

$$u = u_0 + Ku, \tag{5.1}$$

with $u\in C$, $u_0(x)=1/\log(2+|\vec{x}|)$, and

$$K(\vec{x},\vec{y}) = \frac{1}{2\pi}(\log|\vec{x}-\vec{y}|)\frac{\log(2+|\vec{y}|)}{\log(2+|\vec{x}|)}V(\vec{y}). \tag{5.2}$$

It is easy to check that Lemma 4.2 does not apply to $K(\vec{x},\vec{y})$ because of the large $|\vec{x}|$ behavior of $K(\vec{x},\vec{y})$. This difficulty can be bypassed by writing

$$K \equiv K^{(1)} + B, \tag{5.3}$$

where

$$K^{(1)}(\vec{x},\vec{y}) = \frac{1}{2\pi}\{\log|\vec{x}-\vec{y}| - \log(2+|\vec{x}|)\}\frac{\log(2+|\vec{y}|)}{\log(2+|\vec{x}|)}V(\vec{y}), \tag{5.4}$$

and B is a separable kernel

$$B(\vec{x},\vec{y}) = \frac{1}{2\pi}\log(2+|\vec{y}|)V(\vec{y}). \tag{5.5}$$

Lemma 5.1: $K^{(1)}$ defines a compact operator on C.

Proof: The first condition of Lemma 4.2 applies to $K^{(1)}$. Indeed we have

$$\int |K^{(1)}(\vec{x},\vec{y})|\mathrm{d}^2y \leqslant \tilde{h}(\vec{x}). \tag{5.6}$$

Here $\tilde{h}(|\vec{x}|)=o(1)$ for large x, and $\tilde{h}\to 0$ as $|\vec{x}|\to\infty$. This can be easily shown using the methods of Sec. III.

Next, we must establish uniform continuity as given in inequality (4.10) in Lemma 4.2.

We have, for any $u(\vec{x}) \in C$, the image $w(\vec{x})$ given by

$$w(\vec{x}) = \frac{1}{\log(2+|\vec{x}|)}\int \mathrm{d}^2y[\log|\vec{x}-\vec{y}| - \log(2+|\vec{x}|)]\log(2+|\vec{y}|)V(\vec{y})u(\vec{y}). \tag{5.7}$$

For any $\vec{x}_0$, $\delta>0$, we take the disks,

$$|\vec{x}-\vec{x}_0| \leqslant 2\delta \text{ and } |\vec{x}'-\vec{x}_0| \geqslant 2\delta. \tag{5.8}$$

We want to find a uniform bound on $|w(\vec{x})-w(\vec{x}')|$ which depends only on δ and not on $\vec{x}'$ or $\vec{x}$. Clearly, the second term in the square brackets in (5.7) presents no difficulty and we only need to bound $|\tilde{w}(\vec{x})-\tilde{w}(\vec{x}')|$, where

$$\tilde{w}(\vec{x}) = \frac{1}{2\pi}\frac{1}{\log(2+|\vec{x}|)}\int \mathrm{d}^2y(\log|\vec{x}-\vec{y}|)V(\vec{y})\log(2+|\vec{y}|)u(\vec{y}). \tag{5.9}$$

We can now write

$$\begin{aligned}\tilde{w}(\vec{x}) - \tilde{w}(\vec{x}') = {} & \frac{1}{2\pi}\left[\frac{1}{\log(2+|\vec{x}|)} - \frac{1}{\log(2+|\vec{x}'|)}\right]\int \mathrm{d}^2y(\log|\vec{x}-\vec{y}|)V(\vec{y})\log(2+|\vec{y}|)u(\vec{y}) \\ & + \frac{1}{2\pi}\frac{1}{\log(2+|\vec{x}'|)}\int \mathrm{d}^2y\left(\log\left|\frac{\vec{x}-\vec{y}}{\vec{x}'-\vec{y}}\right|\right)V(\vec{y})\log(2+|\vec{y}|)u(\vec{y}).\end{aligned} \tag{5.10}$$

We treat the two terms in (5.10) separately,

$$\tilde{w}(\vec{x}) - \tilde{w}(\vec{x}') \equiv I_1 + I_2. \tag{5.11}$$

It follows immediately that

$$|I_1| \leqslant \frac{|\vec{x}'|-|\vec{x}|}{(2+|\vec{z}|)[\log(2+|\vec{x}|)]^2}\left|\int \mathrm{d}^2y\ \log|\vec{x}-\vec{y}|V(\vec{y})\log(2+|\vec{y}|)u(\vec{y})\right|, \tag{5.12}$$

where we have assumed $|\vec{x}'|>|\vec{x}|$, and

$$|\vec{x}| < |\vec{z}| < |\vec{x}'|. \tag{5.13}$$

The integral in (5.12) is bounded for $u \in C$, since it is almost identical to the integrals studied in Eqs. (3.7) and (3.10). Thus we have

$$|I_1| \leqslant \frac{|\vec{x}-\vec{x}'|}{2\,\log(2+|\vec{x}|)} \frac{C}{2+|\vec{x}|}. \tag{5.14}$$

For I_2 we introduce two potentials, $V_{x_0,\delta}(\vec{x})$ and $W_{x_0,\delta}(\vec{x})$, such that

$$V_{x_0,\delta} = \begin{cases} V & \text{for } |\vec{x}-\vec{x}_0| \leqslant 2\delta, \\ 0 & \text{for } |\vec{x}-\vec{x}_0| > 2\delta \end{cases} \tag{5.15}$$

and

$$W_{x_0,\delta} = \begin{cases} 0 & \text{for } |\vec{x}-\vec{x}_0| < 2\delta, \\ V & \text{for } |\vec{x}-\vec{x}_0| > 2\delta. \end{cases} \tag{5.16}$$

In terms of these potentials, let

$$I_2 = I_2^{(1)} + I_2^{(2)}, \tag{5.17}$$

where

$$I_2^{(1)} = \frac{1}{2\pi} \frac{1}{\log(2+|\vec{x}'|)} \int \mathrm{d}^2 y \left(\log \left| \frac{\vec{x}-\vec{y}}{\vec{x}'-\vec{y}} \right| \right) W_{x_0,\delta}(\vec{y}) \log(2+|\vec{y}|) u(y) \tag{5.18}$$

and

$$I_2^{(2)} = \frac{1}{2\pi} \frac{1}{\log(2+|\vec{x}'|)} \int d^2 y \left(\log \left| \frac{\vec{x}-\vec{y}}{\vec{x}'-\vec{y}} \right| \right) V_{x_0,\delta}(\vec{y}) \log(2+|\vec{y}|) u(\vec{y}). \tag{5.19}$$

First, we have

$$\begin{aligned} |I_2^{(1)}| &\leqslant \frac{\|u\|}{\log(2+|\vec{x}'|)} \int \mathrm{d}^2 y \left| \log \frac{|\vec{x}-\vec{y}|}{|\vec{x}'-\vec{y}|} \right| |W_{x_0,\delta}(\vec{y})| \log(2+|\vec{y}|) \\ &\leqslant \frac{\|u\|}{\log(2+|\vec{x}'|)} \int d^2 y \left| \left[\log \frac{|\vec{x}'-\vec{y}|+|\vec{x}-\vec{x}'|}{|\vec{x}'-\vec{y}|} + \log \frac{|\vec{x}'-\vec{y}|+|\vec{x}-\vec{x}'|}{|\vec{x}-\vec{y}|} \right] \right| |W_{x_0,\delta}(\vec{y})| \log(2+|\vec{y}|). \end{aligned} \tag{5.20}$$

But in this integral $W_{\vec{x}0,\delta}(\vec{y})$ vanishes for $|\vec{y}-\vec{x}_0| \leqslant 2\delta$. Hence it follows from Eq. (5.9) that our region of integration over $\vec{y}$ is such that

$$|\vec{x}'-\vec{y}| > 2\delta - \delta > \delta,$$

$$|\vec{x}-\vec{y}| > 2\delta > \delta. \tag{5.21}$$

Hence

$$|I_2^{(1)}| \leqslant \frac{C_2}{\log(2+|\vec{x}'|)} \cdot \frac{|\vec{x}-\vec{x}'|}{\delta} \int \mathrm{d}^2 y |V_N(\vec{y})| \log(2+|\vec{y}|) \leqslant \frac{C_2 |\vec{x}-\vec{x}'|}{\delta} \|u\|. \tag{5.22}$$

Next, we estimate $I_2^{(2)}$,

$$|I_2^{(2)}| \leqslant \frac{\|u\|}{\log(2+|\vec{x}'|)} \int \mathrm{d}^2 y \left| \log \frac{|\vec{x}-\vec{y}|}{|\vec{x}'-\vec{y}|} \right| |V_{x0,\delta}(\vec{y})| \log(2+|\vec{y}|). \tag{5.23}$$

If we take $\delta < \frac{1}{3}$, then $|\vec{x}-\vec{y}|$ and $|\vec{x'}-\vec{y}|$ in this integral are both less than 1, and hence

$$|I_2^{(2)}| \leqslant C \int \mathrm{d}^2 y [|\log|\vec{x}-\vec{y}|| + |\log|\vec{x}'-\vec{y}||] |V_{x0,\delta}(\vec{y})| \|u\|. \tag{5.24}$$

We can replace $\log|\vec{x}-\vec{y}|$ and $\log|\vec{x'}-\vec{y}|$ by $\log^-|\vec{x}-\vec{y}|$ and $\log^-|\vec{x'}-\vec{y}|$. Following the same arguments as in Sec. III, we get

$$|I_2^{(2)}| \leqslant C_3 \|u\| \int_0^1 y \, \mathrm{d}y |\log y| |V_{x0,\delta}(\vec{y})|_R. \tag{5.25}$$

Now, $V_{x0,\delta}(\vec{y})$ vanishes outside a disk of radius 2δ. Thus, $|V_{x0,\delta}(\vec{y})|_R = 0$ for $y > 2\delta$. Note also that $|V_{x0,\delta}(\vec{y})| \leqslant |V(\vec{x})|$ which implies that

$$0 \leqslant |V_{x0,\delta}(\vec{y})|_R \leqslant |V(\vec{y})|_R. \tag{5.26}$$

We finally get

$$|I_2^{(2)}| \leqslant \int_0^{2\delta} y \, \mathrm{d}y |\log y| |V(\vec{y})|_R \|u\|. \tag{5.27}$$

The consequence of the above integral allows us to choose δ such that for any small ϵ,

$$\int_0^{2\delta} y \, \mathrm{d}y |\log y| |V(\vec{y})|_R < \epsilon. \tag{5.28}$$

Adding up I_1, $|I_2^{(1)}|$, and $|I_2^{(2)}|$, we obtain

$$|\tilde{w}(\vec{x}) - \tilde{w}(\vec{x}')| \leqslant \left\{ \frac{|\vec{x}| - |\vec{x}'|}{\log(2+|\vec{x}|)(2+|\vec{x}|)} C_1 + \frac{C_2 |\vec{x}-\vec{x}'|}{\log(2+|\vec{x}'|)\delta} + \frac{C_3 \epsilon}{\log(2+|\vec{x}'|)} \right\} \|u\|. \tag{5.29}$$

We can choose now $|\vec{x}-\vec{x}'| < \min(\epsilon/\delta, \delta < 1)$, and hence

$$|\tilde{w}(\vec{x}) - \tilde{w}(\vec{x}')| < \frac{C_4 \epsilon \|u\|}{\log(2+|\vec{x}'|)}. \tag{5.30}$$

This proves the uniform continuity of $\tilde{w}(\vec{x})$ and hence of $w(\vec{x})$. Thus by Lemma 4.2, $K^{(1)}$ is compact. The separable kernel B is compact for our class of V. Hence, since $K = K^{(1)} + B$, the operator, K, is compact on C.

The Fredholm alternative thus holds for K, i.e., either a unique solution of the inhomogeneous equation, (5.1), exists with $u \in C$, and $u_0 = 1/\log(2+|\vec{x}|)$, or there must be at least one solution of the homogeneous equation

$$u_1 = K u_1. \tag{5.31}$$

[From the compactness it follows that, when we have u_j, $j = 1, \ldots, N$ satisfying Eq. (5.31), N is finite.]

Returning to the notation of Eq. (3.1) with $u = \phi/\log(2+|\vec{x}|)$, we have two cases to consider.

(I) A unique solution for Eq. (3.1) exists,

$$\phi = 1 + K_\ell \phi, \tag{5.32}$$

with

$$K_\ell = \frac{1}{2\pi}(\log|\vec{x}-\vec{y}|)V(\vec{y}) \tag{5.33}$$

and

$$|\phi(\vec{x})| \leqslant C\,\log|\vec{x}|, \quad \text{as } |\vec{x}| \to \infty, \quad C \neq 0. \tag{5.34}$$

Otherwise we have the following.

(II) There exist nontrivial, linearly independent, $\phi_j(\vec{x})$, $j=1,\ldots,N$, such that

$$\phi_j = K_\ell \phi_j. \tag{5.35}$$

Case (II) can be divided into two subcases:

$$\int V(\vec{x})\phi_j(\vec{x})\mathrm{d}^2x = V_j \neq 0. \tag{5.36}$$

In this case it is easy to see that if we define

$$\phi_a(x) \equiv -\frac{\phi_j(\vec{x})}{V_j\,\log\,k_1}, \tag{5.37}$$

then

$$\phi_a(\vec{x}) = 1 + \frac{1}{2\pi}\int \mathrm{d}^2y[\log\,k_1|\vec{x}-\vec{y}|]V(\vec{y})\phi_a(\vec{y}), \tag{5.38}$$

which, except for the change of scale, $1 \to k_1$, is essentially the same as Eq. (5.32).

For the second subcase a finite set of ϕ_j's exist, each satisfying the homogeneous equation (5.36) and, in addition,

$$\int \mathrm{d}^2x\; V(\vec{x})\phi_j(\vec{x}) = 0, \quad j = 1,\ldots,N. \tag{5.39}$$

In Appendix D we give a proof of the following theorem.

Theorem 5.1: If the homogeneous equation,

$$\phi(\vec{x}) = \frac{1}{2\pi}\int \mathrm{d}^2y(\log|\vec{x}-\vec{y}|)V(\vec{y})\phi(\vec{y}), \tag{5.40}$$

has nontrivial solutions, ϕ_j, which satisfy

$$\int V(\vec{x})\phi_j(\vec{x})\mathrm{d}^2x = 0, \quad j = 1,\ldots,N, \tag{5.41}$$

then the inhomogeneous integral equation has nonunique solutions, ϕ_a,

$$\phi_a(\vec{x}) = 1 + \frac{1}{2\pi}\int \mathrm{d}^2y(\log|\vec{x}-\vec{y}|)V(\vec{y})\phi_a(\vec{y}), \tag{5.42}$$

where Eq. (5.41) is a necessary and sufficient condition for Eq. (5.42) to hold. Note that this theorem holds whether or not $\int \mathrm{d}^2x\; V(\vec{x})\phi_a(\vec{x})$ is zero.

With this last theorem it becomes clear that we have four cases to consider: $\mathrm{A_I}$, $\mathrm{A_{II}}$, $\mathrm{B_I}$, $\mathrm{B_{II}}$. These are defined as follows.

Case A_I: $\phi = 1 + K_\ell\phi$ has a unique solution, and $\int \mathrm{d}^2x\; V(\vec{x})\phi(\vec{x}) \neq 0$.

Case $\mathrm{A_{II}}$: There exist N linearly independent solutions, $\phi_j(\vec{x})$, $j=1,\ldots,N$, for the homogeneous equation, $\phi_j = K_\ell\phi_j$. But all the ϕ_j satisfy $\int V(\vec{x})\phi_j(\vec{x})\mathrm{d}^2x \neq 0$.

Case B_I: $\phi=1+K_\ell\phi$ has a unique solution but $\int d^2x V(\vec{x})\phi(\vec{x})=0$.

Case B_{II}: The homogeneous equation, $\phi=K_\ell\phi$, has N linearly independent solutions, ϕ_j, $j=1,\ldots,N$, but $\int d^2x\, V(\vec{x})\phi_j(\vec{x})=0$.

One should note that the trivial case $V\equiv 0$ belongs to case B_I, since $\phi=1$ is a unique solution of $\phi=1+K_\ell\phi$ when $V\equiv 0$. One should also note that in both cases A_I and A_{II} we have the bound

$$|\phi(\vec{x})| \leqslant \text{const } \log(2+|\vec{x}|), \tag{5.43}$$

while in cases B_I and B_{II} we have stronger results. In Appendix E we prove that for these two cases $|\phi(\vec{x})|$ is bounded for all $\vec{x}\in R_2$, and more precisely $|\phi|\to 0$ as $|\vec{x}|\to\infty$ in the case B_{II}.

We have referred to these cases as "zero-energy bound states." They are the limits, for a potential $V=g\tilde{V}$, of the trajectories of negative-energy bound states $E_n(g)$, when g decreases to a critical value g_n, where $E_n(g_n)=0$. For $E<0$, the wave functions decrease exponentially, and they cannot approach a solution growing like $\log|\vec{x}|$ for $g=g_n$.

For any $\kappa>0$, $k=i\kappa$, there is a discrete set of couplings, $g_n(\kappa)$, such that a physical bound state exists at $E=-\kappa^2$. Here $(1/g_n(\kappa))$ is an eigenvalue of the homogeneous Lippmann-Schwinger equation (2.3). The discrete nature of $g_n(\kappa)$ follows from the compactness of the operator in (2.3), as does the fact that at each E the degeneracy is finite. But in addition to these general properties, two of the authors (A.M. and T.T.W.) have shown[8] that there exists an explicit bound on the number of zero-energy bound states.

VI. UNIVERSALITY FOR CASE A_I: $\int d^2x\, V(\vec{x})\phi(\vec{x})\neq 0$

Without introducing any approximations we can rewrite our original integral equation for $k>0$, i.e., Eq. (2.3), in the form of Eq. (2.12),

$$\psi(\vec{k},\vec{x}) = e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})\left[\frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log|\vec{x}|}{2\pi}\right] + K_\ell\psi + \Delta_R\psi, \tag{6.1}$$

where F is given in Eq. (2.13),

$$K_\ell(\vec{x},\vec{y}) = \frac{1}{2\pi}(\log|\vec{x}-\vec{y}|)V(\vec{y}) \tag{6.2}$$

and

$$\Delta_R(k;\vec{x},\vec{y}) = -\frac{1}{4i}\{R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)\}V(\vec{y}). \tag{6.3}$$

A unique solution for Eq. (6.1), ψ, exists and $\psi\in C$, with $k>\epsilon>0$. This was proved in Sec. IV, for our class of potentials.

We now introduce a new Banach space, $\mathcal{B}$, with a norm given by

$$\|\phi\|_\ell \equiv \sup_{\vec{x}\in R^2}\left|\frac{\phi(\vec{x})}{\log(2+x)}\right|, \tag{6.4}$$

where ϕ is a continuous function on R^2.

Our first task is to estimate the norm of the operator, Δ_R for small k, where Δ_R is now considered as an operator on $\mathcal{B}$.

In Appendix C, the following is proved.

Theorem 6.1: As a bounded operator on the Banach space $\mathcal{B}$, we have for Δ_R,

$$\|\Delta_R\|_\ell = \epsilon(k), \quad \epsilon(k)=o(1), \quad 0<k\ll 1. \tag{6.5}$$

One should note at this stage the cancellations that occur in Eq. (6.1) for both $x\to\infty$ and $x\to 0$. First, the $(1/2\pi)\log|\vec{x}|$ term in the square brackets is, for $x\to\infty$, exactly cancelled by the contribution of $K_\ell\psi$. Second, for $x\to 0$, the $\log|\vec{x}|$ in the square brackets is cancelled by a $\log|\vec{x}|$ coming from $H_0^{(1)}(k|\vec{x}|)/4i$ for small $|\vec{x}|$.

Our second task is to get a bound on $\|\psi(\vec{k},\vec{x})\|_\ell$.

Lemma 6.1: For any $k>0$, we have the bound

$$\|\psi(\vec{k},\vec{x})\|_\ell \leqslant C_1 + C_2|F(\vec{k})|\left(\log\frac{1}{k}\right). \tag{6.6}$$

Proof: Equation (6.1) may be rearranged as

$$(1-K_\ell-\Delta_R)\psi = e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})B(\vec{k},\vec{x}), \tag{6.7}$$

with

$$B \equiv \frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log|\vec{x}|}{2\pi}. \tag{6.8}$$

Define $I_\ell \equiv (1-K_\ell)^{-1}$. Then,

$$I_\ell(I_\ell^{-1}-\Delta_R)\psi = I_\ell\{e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})B\}, \tag{6.9}$$

or

$$(1-I_\ell\Delta_R)\psi = I_\ell\{e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})B\}. \tag{6.10}$$

We finally obtain

$$\psi = (1-I_\ell\Delta_R)^{-1}I_\ell\{e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})B\} = (I_\ell + I_\ell\Delta_R I_\ell)\{e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})B\} + O(\|\Delta_R\|_\ell^2). \tag{6.11}$$

But, $\|I_\ell\|_\ell \leqslant M$ and

$$\|B\|_\ell \leqslant C_2\left(\log\frac{1}{k}\right) + C_0, \tag{6.12}$$

so that

$$\|\psi\|_\ell \leqslant C_1 + C_2\left(\log\frac{1}{k}\right)|F(\vec{k})|, \tag{6.13}$$

which completes the proof.

Next, we obtain the universal behavior of $F(\vec{k})$ for small k. We take, $\phi(x)$, the solution of the zero-energy integral equation,

$$\phi = 1 + K_\ell\phi, \tag{6.14}$$

which in the case A_I is such that

$$V_0 \equiv \int d^2x\, V(\vec{x})\phi(\vec{x}) \neq 0, \tag{6.15}$$

and thus $\phi(x) = O(\log x)$ for large $|\vec{x}|$. We multiply both sides of Eq. (6.1) by $\phi(\vec{x})V(\vec{x})$ and integrate over d^2x obtaining

$$\int \phi(\vec{x})V(\vec{x})\psi(\vec{k},\vec{x})\mathrm{d}^2x = V_0 + \int \mathrm{d}^2x(e^{i\vec{k}\cdot\vec{x}}-1)V(\vec{x})\phi(\vec{x}) + F(\vec{k})\int \mathrm{d}^2x\ \phi(\vec{x})V(\vec{x})B(\vec{k},\vec{x})$$
$$+\frac{1}{2\pi}\int \mathrm{d}^2x \int \mathrm{d}^2y\ \phi(\vec{x})V(\vec{x})\log|\vec{x}-\vec{y}|V(\vec{y})\psi(\vec{k},\vec{y})$$
$$+\int \mathrm{d}^2x \int \mathrm{d}^2y\ \phi(\vec{x})V(\vec{x})\Delta_R(k;\vec{x},\vec{y})\psi(\vec{k},\vec{y}), \tag{6.16}$$

where $B(\vec{k},\vec{x})$ is given by Eq. (6.8).

Using the integral equation for $\phi(\vec{x})$, we obtain

$$F(\vec{k})[1-X_2] = V_0 + X_1 + X_3, \tag{6.17}$$

where

$$X_1(\vec{k}) \equiv \int \mathrm{d}^2x(e^{i\vec{k}\cdot\vec{x}}-1)V(\vec{x})\phi(\vec{x}),$$

$$X_2(\vec{k}) \equiv \int \mathrm{d}^2x\ B(\vec{k},\vec{x})V(\vec{x})\phi(\vec{x}),$$

$$X_3(\vec{k}) \equiv \int \mathrm{d}^2x \int \mathrm{d}^2y\ \phi(\vec{x})V(\vec{x})\Delta_R(k;\vec{x},\vec{y})\psi(\vec{k},\vec{y}). \tag{6.18}$$

Lemma 6.2: The following estimates hold for small k,

$$X_1(\vec{k}) = o(1)\Big/\left(\log\frac{1}{k}\right), \tag{6.19}$$

$$X_2(\vec{k}) = \frac{1}{2\pi}V_0\log k + \frac{C_0}{4i}V_0 + o(1), \tag{6.20}$$

and

$$|X_3(\vec{k})| = o(1)\left[|F(\vec{k})|\left(\log\frac{1}{k}\right) + C_4\right]. \tag{6.21}$$

Proof: We define $x_0(k)$ as

$$x_0(k) = \frac{1}{k\left(\log\frac{1}{k}\right)^p}, \quad p > 2. \tag{6.22}$$

From Eq. (6.18) it follows that

$$|X_1(\vec{k})| < C_1\left\|\frac{\phi(x)}{\log(2+x)}\right\|\left[\int_{x<x_0(k)} \mathrm{d}^2x|V(\vec{x})|\log(2+x)\left(\frac{1}{\left(\log\frac{1}{k}\right)^p}\right)\right] + 2\int_{x>x_0(k)} \mathrm{d}^2x|V(\vec{x})||\phi(\vec{x})|. \tag{6.23}$$

Thus,

$$|X_1(\vec{k})| \leqslant O\left(\frac{1}{\left(\log\frac{1}{k}\right)^p}\right) + 2\int_{|\vec{x}|>x_0(k)} \mathrm{d}^2x|V(\vec{x})||\phi(\vec{x})|. \tag{6.24}$$

But, $|\phi(\vec{x})| < C\log(2+|\vec{x}|)$, and we get

$$\begin{aligned}\int_{x>x_0(k)} \mathrm{d}^2x|V(\vec{x})||\phi(\vec{x})| &\leqslant C\int_{x>x_0} \mathrm{d}^2x|V(\vec{x})|\log(2+x)\\ &\leqslant \frac{C}{\log(2+x_0(k))}\int_{x>x_0} \mathrm{d}^2x|V(\vec{x})|[\log(2+x)]^2 \leqslant \frac{o(1)}{\log\frac{1}{k}}.\end{aligned} \tag{6.25}$$

Hence Eq. (6.19) holds.

The estimate of X_2 follows again by splitting the region of integration into two parts. For $|\vec{x}| < x_0(k)$,

$$\begin{aligned}B(\vec{k},\vec{x}) &= \frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log x}{2\pi}\\ &= -\frac{1}{2\pi}\left(\log\frac{1}{k}\right) + \frac{C_0}{4i} + o(1);\end{aligned} \tag{6.26}$$

and that gives the main part of the estimate (6.20). The integration over the domain $|\vec{x}| > x_0(k)$ is obviously $o(1)$.

Finally, Lemma 6.1 gives us a bound $\|\psi\|_\ell$ given in Eq. (6.6). This leads to

$$|\psi(\vec{y})| < \left[C_1 + C_2|F(\vec{k})|\left(\log\frac{1}{k}\right)\right]\log(2+y). \tag{6.27}$$

From Appendix C, we have

$$|\Delta_R(\vec{x},\vec{y},\vec{k})| < C\log(1+ky)|V(\vec{y})|. \tag{6.28}$$

Substituting these last two equations in the formula (6.18) for $X_3(\vec{k})$, we get

$$|X_3(\vec{k})| \leqslant \tilde{C}_1\left[|F|\left(\log\frac{1}{k}\right) + \tilde{C}_2\right]\int \mathrm{d}^2x \int \mathrm{d}^2y\, \log(2+x)|V(x)||V(y)|\log(1+ky)\log(2+y). \tag{6.29}$$

By splitting the y integration into two regions, $|\vec{y}| < x_0(k)$ and $|\vec{y}| \geqslant x_0(k)$, with $x_0(k)$ given in Eq. (6.22), one can easily show that

$$\int \mathrm{d}^2y|V(\vec{y})|\log(1+ky)\cdot\log(2+y) = o(1). \tag{6.30}$$

The result given in Eq. (6.21) now follows immediately and Lemma 6.2 is proved.

We now insert our estimates of the X_j, $j=1,2,3$, in Eq. (6.15) and obtain

$$F(\vec{k})\left[1 - \frac{1}{2\pi}V_0\log k - \frac{C_0}{4i}V_0 + o(1)\right] = V_0 + \frac{o(1)}{\log\frac{1}{k}} + o(1)\left[|F(k)|\left(\log\frac{1}{k}\right) + C_4\right]. \tag{6.31}$$

We write

$$|F| = Fe^{i(\arg F)}, \tag{6.32}$$

and obtain

$$F = \frac{V_0 + o(1)}{\left[\left(\frac{1}{2\pi}V_0 + o(1)\right)\left(\log\frac{1}{k}\right) + \left(-\frac{C_0 V_0}{4i} + 1\right) + o(1)\right]}. \tag{6.33}$$

Hence, we finally have for small k,

$$F(\vec{k}) = -\frac{2\pi}{\log k} + \frac{o(1)}{\log\frac{1}{k}}. \tag{6.34}$$

The first important consequence of this result on F is to give a bound on $\|\psi\|_\ell$ which is independent of k and finite. Indeed from Lemma 6.1 and the bound result (6.34), we obtain

$$\|\psi\|_\ell \leqslant M \leqslant \infty. \tag{6.35}$$

The definition of the scattering amplitude, $f(\vec{k}',\vec{k})$, is given in Eq. (2.6), and using the definition of F in Eq. (2.12), we have

$$f(\vec{k}',\vec{k}) = -\frac{1}{\sqrt{8\pi}}F(\vec{k}') - \frac{1}{\sqrt{8\pi}}\int \mathrm{d}^2x(e^{i\vec{k}'\cdot\vec{x}} - 1)V(\vec{x})\psi(\vec{k},\vec{x}). \tag{6.36}$$

But

$$\begin{aligned}\left|\frac{1}{\sqrt{8\pi}}\int \mathrm{d}^2x(e^{i\vec{k}'\cdot\vec{x}} - 1)V(\vec{x})\psi(\vec{k}',\vec{x})\right| &\leqslant C_1\|\psi\|_\ell \int_{|\vec{x}|\leqslant x_0(k)} \mathrm{d}^2x|e^{i\vec{k}'\cdot\vec{x}} - 1||V(\vec{x})|\log(2+x) \\ &\quad + 2M\int_{x\geqslant x_0(k)} \mathrm{d}^2x|V(\vec{x})|\log(2+x) \\ &\leqslant O\left(\frac{1}{\left(\log\frac{1}{k}\right)^p}\right) + \frac{o(1)}{\log\frac{1}{k}}, \quad p > 2. \end{aligned} \tag{6.37}$$

This leads to

$$f = -\frac{1}{\sqrt{8\pi}}F + \frac{o(1)}{\log k}, \tag{6.38}$$

and hence from (6.28) our final universal result,

$$f = -\sqrt{\frac{\pi}{2}}\left(\frac{1}{\log\frac{1}{k}}\right) + \frac{o(1)}{\log k}, \tag{6.39}$$

which agrees with our result for the symmetric case (see Sec. IX).

In closing we prove that in this case

$$\lim_{k\to 0}\psi(\vec{k},\vec{x}) \equiv 0. \tag{6.40}$$

To prove this we return to the rewritten integral equation (6.1),

$$\psi(\vec{k},\vec{x}) = e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})\left[\frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log|\vec{x}|}{2\pi}\right] + K_\ell\psi + \Delta_R\psi. \tag{6.41}$$

The last term vanishes as $k\to 0$. For small $k|\vec{x}|$,

$$H_0^{(1)} = \frac{2i}{\pi}\log\, k|\vec{x}| + C_0 + O(|kx|^2\, \log\, k|\vec{x}|). \tag{6.42}$$

Hence

$$\lim_{k\to 0} F(\vec{k})\left[\frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log|\vec{x}|}{2\pi}\right] = \lim_{k\to 0} F(\vec{k})\left(\frac{\log\, k}{2\pi}\right), \tag{6.43}$$

and given the universality for F, i.e., Eq. (6.28), we get

$$\lim_{k\to 0} F(\vec{k})\left[\frac{H_0^{(1)}(k|\vec{x}|)}{4i} - \frac{\log|\vec{x}|}{2\pi}\right] = -1. \tag{6.44}$$

Thus in the limit we get

$$\psi(0,\vec{x}) = \frac{1}{2\pi}\int \mathrm{d}^2y\, \log|\vec{x}-\vec{y}|V(\vec{y})\psi(0,\vec{y}). \tag{6.45}$$

But we are in the case where no homogeneous solutions exist and (6.45) leads to a contradiction unless

$$\psi(0,\vec{x}) \equiv 0. \tag{6.46}$$

VII. UNIVERSALITY FOR CASE B_{II}: $\int d^2x\, V(\vec{x})\phi(\vec{x}) = 0$

In this section we consider the case B_{II}. This B_{II} case is quite exceptional. As stressed before, if we introduce a coupling parameter replacing V by λV, we have this case for a discrete infinite set of coupling values, λ_q, $q=1,2,\ldots$. The multiplicity of homogeneous solutions for each λ_q is finite. This follows from the compactness of the zero-energy kernel.

In case B_{II} the homogeneous zero-energy equation has N solutions ($N\geqslant 1$), ϕ_j,

$$\phi_j(\vec{x}) = \frac{1}{2\pi}\int \mathrm{d}^2y\, \log|\vec{x}-\vec{y}|V(\vec{y})\phi_j(\vec{y}), \quad j=1,\ldots,N, \tag{7.1}$$

all with

$$\int \mathrm{d}^2x\, V(\vec{x})\phi_j(\vec{x}) = 0. \tag{7.2}$$

From Theorem 5.1, proved in Appendix D, we know that nonunique solutions, $\phi_a(\vec{x})$, of the inhomogeneous equation exist, i.e.,

$$\phi_a(\vec{x}) = 1 + \frac{1}{2\pi}\int \mathrm{d}^2y(\log|\vec{x}-\vec{y}|)V(\vec{y})\phi_a(\vec{y}). \tag{7.3}$$

Here there are two possibilities,

$$\int \mathrm{d}^2x\, V(\vec{x})\phi_a = 0 \tag{7.4}$$

or

$$\int d^2x\, V(\vec{x})\phi_a \neq 0. \tag{7.5}$$

We consider the case (7.4) first.

For small k, $0<k\ll 1$, the solutions $\psi(\vec{k},\vec{x})$ exist and we can write Eq. (6.1) formally as

$$\psi = [e^{i\vec{k}\cdot\vec{x}} + F(\vec{k})B(\vec{k},\vec{x})] + [K_\ell + \Delta_R]\psi. \tag{7.6}$$

Here B is given in (6.28). K_ℓ and Δ_R are operators on the Banach space $\mathcal{B}$, defined in Sec. VI.

We now follow a procedure analogous to that used in Ref. 1, and first introduced by Pais and Wu. The idea is to split Eq. (7.6) into two equations with the same kernel but different inhomogeneous terms. We define $\psi_\alpha(\vec{k},\vec{x})$ and $\psi_\beta(\vec{k},\vec{x})$ as follows:

$$\psi(\vec{k},\vec{x}) \equiv \psi_\alpha(\vec{k},\vec{x}) - \frac{F(\vec{k})}{2\pi}\left(\log\frac{1}{k}\right)\psi_\beta(\vec{k},\vec{x}), \tag{7.7}$$

where now we have two integral equations defining ψ_α and ψ_β,

$$\psi = e^{i\vec{k}\cdot\vec{x}} + (K_\ell + \Delta_R)\psi_\alpha \tag{7.8}$$

and

$$\psi_\beta = -\frac{2\pi B(\vec{k},\vec{x})}{\log\frac{1}{k}} + (K_\ell + \Delta_R)\psi_\beta. \tag{7.9}$$

These last two equations are equivalent to Eq. (7.6).

Note first that both inhomogeneous terms are in $\mathcal{B}$,

$$\|e^{i\vec{k}\cdot\vec{x}}\|_\ell = \frac{1}{\log 2}, \tag{7.10}$$

and from (6.26),

$$\left\| \frac{2\pi B(\vec{k},\vec{x})}{\log\frac{1}{k}} \right\|_\ell \leqslant 1. \tag{7.11}$$

The operators K_ℓ and Δ_R act on $\mathcal{B}$, and we have shown in Sec. VI and Appendix C that $\|\Delta_R\|_\ell = \epsilon(k) = o(1)$ as $k\to 0$. Thus for small k, we have

$$\|K_\ell + \Delta_R\|_\ell = \|K_\ell\|_\ell + o(1) \tag{7.12}$$

and also

$$\lim_{k\to 0}\|K_\ell + \Delta_R\|_\ell = \|K_\ell\|_\ell. \tag{7.13}$$

We can now see the power and significance of the theorem proved in Appendix D. As an operator on $\mathcal{B}$, $(K_\ell+\Delta_R)\to K_\ell$ as $k\to 0$. Thus if $\psi_\alpha(k,x)$, which for $k>0$ is an element of $\mathcal{B}$, remains in $\mathcal{B}$ as $k\to 0$, we will have

$$\psi_\alpha(0,\vec{x}) = 1 + K_\ell\psi_\alpha(0,\vec{x}). \tag{7.14}$$

But without the results of Appendix D, this will be puzzling. However, with those results it follows that, if $\psi_\alpha(0,\vec{x})$ exists,

$$\psi_\alpha(0,\vec{x}) = \phi_a(\vec{x}) + \sum_{j=1}^{N} c_j \phi_j(\vec{x}), \tag{7.15}$$

where $\phi_a = 1 + K_\ell \phi_a$ and $\phi_j = K_\ell \phi_j$. At this stage the c_j's are arbitrary, but we will sketch later how they can be fixed by a perturbative argument.

For any $k > 0$, we know that $\psi(\vec{k},\vec{x})$ exists and is bounded for all $\vec{x}$. It is easy to show that the same holds for both $\psi_\alpha(\vec{k},\vec{x})$ and $\psi_\beta(\vec{k},\vec{x})$. Next, we assert that in any interval $0 < k \leqslant \sigma \ll 1$, and with a fixed $\vec{x}$, the ψ, ψ_α, and ψ_β are continuous functions of k. We now assume that $\psi(0,\vec{x})$ exists. This leads to both $\psi_\alpha(0,\vec{x})$ and $\psi_\beta(0,\vec{x})$ being finite.

With this physical assumption, we now get

$$|\psi_\alpha(\vec{k},\vec{x})| \leqslant C_\alpha(\vec{x}) = \sup_{0 \leqslant k \leqslant \sigma} |\psi_\alpha(\vec{k},\vec{x})| \tag{7.16}$$

and

$$|\psi_\beta(\vec{k},\vec{x})| \leqslant C_\beta(\vec{x}) = \sup_{0 \leqslant k \leqslant \sigma} |\psi_\beta(\vec{k},\vec{x})|. \tag{7.17}$$

Both C_α and C_β are finite for any $\vec{x}$, since there can be no k_0, $0 \leqslant k_0 \leqslant \sigma$, such that the sup above is infinite. That will lead to a contradiction with the statements of the previous paragraph, especially continuity.

It now follows that for any $\vec{x}$,

$$\lim_{k \to 0} |\nabla_R \psi_\alpha| = 0,$$

$$\lim_{k \to 0} |\nabla_R \psi_\beta| = 0. \tag{7.18}$$

Hence we obtain

$$\psi_\alpha(0,\vec{x}) = \tilde{\phi}_\alpha(\vec{x}) = \phi_a + \sum_{j=1}^{N} c_j^{(\alpha)} \phi_j,$$

$$\psi_\beta(0,\vec{x}) = \tilde{\phi}_\beta(\vec{x}) = \phi_a + \sum_{j=1}^{N} c_j^{(\beta)} \phi_j. \tag{7.19}$$

From Appendix E we have the result that both $\tilde{\phi}_\alpha$ and $\tilde{\phi}_\beta$ are bounded by constants for all $\vec{x}$ including $\vec{x} \to \infty$. This fact plus continuity leads to the result that both $C_\alpha(\vec{x})$ and $C_\beta(\vec{x})$ in Eqs. (7.16) and (7.17) are bounded for all $\vec{x}$. Thus for a closed interval $0 \leqslant k \leqslant \sigma \ll 1$, we have

$$|\psi_\alpha(\vec{k},\vec{x})| \leqslant \tilde{C}_\alpha = \sup_{\vec{x} \in R^2} C_\alpha(\vec{x}),$$

$$|\psi_\beta(\vec{k},\vec{x})| \leqslant \tilde{C}_\beta = \sup_{\vec{x} \in R^2} C_\beta(\vec{x}). \tag{7.20}$$

From Eq. (7.7) we have

$$F(\vec{k}) = \int d^2x \; V \psi_\alpha(\vec{k},\vec{x}) - \frac{1}{2\pi}\left(\log\frac{1}{k}\right) F(\vec{k}) \int d^2x \; V(\vec{x}) \psi_\beta(\vec{k},\vec{x}). \tag{7.21}$$

Denoting the integrals above by F_α and F_β, respectively, we get

$$F(\vec{k}) = \frac{F_\alpha(\vec{k})}{1 + \frac{1}{2\pi}\left(\log\frac{1}{k}\right)F_\beta(\vec{k})}. \tag{7.22}$$

We now multiply both sides of Eq. (7.8), i.e., the α-equation, by $\tilde{\phi}_\alpha V$, and integrate. After using the fact that $\tilde{\phi}_\alpha = 1 + K_\ell \tilde{\phi}_\alpha$, and that $\int V(\vec{x})\tilde{\phi}_\alpha(\vec{x})\mathrm{d}^2x = 0$, we obtain as before

$$F_\alpha(\vec{k}) = \int (e^{i\vec{k}\cdot\vec{x}} - 1)V(\vec{x})\tilde{\phi}(\vec{x})\mathrm{d}^2x + Y_\alpha(\vec{k}), \tag{7.23}$$

with

$$Y_\alpha(\vec{k}) = \int \mathrm{d}^2x \int \mathrm{d}^2y\ \tilde{\phi}(\vec{x})\Delta_R(\vec{x},\vec{y},\vec{k})\psi_\alpha(\vec{k},\vec{y}). \tag{7.24}$$

Given the fact that $|\tilde{\phi}_\alpha|$ is bounded (Appendix E), we get

$$\left|\int \mathrm{d}^2x(e^{i\vec{k}\cdot\vec{x}} - 1)V(\vec{x})\tilde{\phi}(\vec{x})\right| = \frac{o(1)}{\left(\log\frac{1}{k}\right)^2}. \tag{7.25}$$

Using the bound given in Appendix C,

$$|\Delta_R(\vec{x},\vec{y},\vec{k})| \leqslant C|V(\vec{y})|\log(1 + ky), \tag{7.26}$$

and the fact that $|\psi_\alpha(\vec{k},\vec{x})|$ is bounded for small k, we get

$$Y_\alpha(\vec{k}) \leqslant C\int \mathrm{d}^2x \int \mathrm{d}^2y|V(\vec{x})\|V(\vec{y})\log(1 + ky)$$

$$\leqslant .9C' \int \mathrm{d}^2y|V(\vec{y})|\log(1 + ky) = \frac{o(1)}{\log\frac{1}{k}}. \tag{7.27}$$

We obtain the last equality by subdividing the d^2y integration into $y < x_0(k)$ and $y > x_0(k)$, as done previously. We finally obtain, as $k \to 0$,

$$F_\alpha(\vec{k}) = \frac{o(1)}{\log\frac{1}{k}}. \tag{7.28}$$

Next, we apply the same trick to Eq. (7.9). We obtain

$$F_\beta = -\frac{2\pi}{\log\frac{1}{k}} \int \mathrm{d}^2x\ \tilde{\phi}_\beta(\vec{x})V(\vec{x})B(\vec{k},\vec{x}) + Y_\beta(\vec{k}), \tag{7.29}$$

where Y_β is given by Eq. (7.24) with $\psi_\alpha \to \psi_\beta$.

The estimate of the first integral in Eq. (7.29) is given by

$$\frac{2\pi}{\log\frac{1}{k}}\int \mathrm{d}^2x\ \tilde{\phi}_\beta(\vec{x})V(\vec{x})B(\vec{k},\vec{x})=\frac{2\pi}{\log\frac{1}{k}}\int \mathrm{d}^2x\ \tilde{\phi}_\beta(\vec{x})V(\vec{x})\left[B(\vec{k},\vec{x})+\frac{1}{2\pi}\log\frac{1}{k}-\frac{C_0}{4i}\right]. \quad (7.30)$$

But from Eq. (6.28) we get

$$\left[B(\vec{k},\vec{x})+\frac{1}{2\pi}\left(\log\frac{1}{k}\right)-\frac{C_0}{4i}\right]=o(1), \quad |\vec{x}|<x_0(k), \quad (7.31)$$

where $x_0(k)$ is given in Eq. (6.24). On the other hand, for $|\vec{x}|>x_0(k)$ we have from (6.28),

$$\left|B(\vec{k},\vec{x})+\frac{1}{2\pi}\left(\log\frac{1}{k}\right)\right|<C\ \log(2+x). \quad (7.32)$$

Splitting the integration domain in (7.30), we finally obtain

$$\frac{2\pi}{\log\frac{1}{k}}\int \mathrm{d}^2x\ \tilde{\phi}_\beta(\vec{x})V(\vec{x})B(\vec{k},\vec{x})=\frac{o(1)}{\log\frac{1}{k}}. \quad (7.33)$$

Hence we get

$$F_\beta=\frac{o(1)}{\log\frac{1}{k}}+Y_\beta(\vec{k}). \quad (7.34)$$

But again, as in Eq. (7.27), we have

$$Y_\beta=\frac{o(1)}{\log\frac{1}{k}}, \quad (7.35)$$

and hence finally

$$F_\beta=\frac{o(1)}{\log\frac{1}{k}} \quad \text{as } k\to 0. \quad (7.36)$$

Substituting our results for F_α and F_β in Eq. (7.22), we get

$$F=\frac{o(1)}{\log\frac{1}{k}} \quad \text{as } k\to 0, \quad (7.37)$$

and a similar result holds for f.

We are left with the case of Eq. (7.5), when

$$V_a\equiv\int \mathrm{d}^2x\ \phi_a(\vec{x})V(\vec{x})\neq 0. \quad (7.38)$$

It is easy to see that in this case we obtain the result of Sec. VI.

Using the same method as above, we get as $k\to 0$,

$$F_\alpha=V_a+o(1),$$

$$F_\beta = V_a + o(1), \tag{7.39}$$

and finally

$$F(\vec{k}) = \frac{V_a + o(1)}{1 + \frac{V_a}{2\pi}\log\frac{1}{k}}$$

$$= \frac{2\pi}{\log\frac{1}{k}} + \frac{o(1)}{\log\frac{1}{k}}. \tag{7.40}$$

This is the same leading term as in the standard case of Sec. VI.

In closing this section we sketch how the coefficients $c_j^{(\alpha)}$ and $c_j^{(\beta)}$ can be determined. We write Eq. (7.8) as

$$\psi_\alpha = f_\alpha + K_\ell \psi_\alpha, \tag{7.41}$$

where

$$f_\alpha \equiv e^{i\vec{k}\cdot\vec{x}} + \Delta_R \psi_\alpha. \tag{7.42}$$

From Appendix D we see that a necessary and sufficient condition for (7.42) to have a solution is

$$\int \phi_j(\vec{x}) V(\vec{x}) f_\alpha(\vec{x}) \mathrm{d}^2x = 0, \quad j = 1, \ldots, N. \tag{7.43}$$

Setting $\psi_\alpha = \tilde{\phi}_\alpha + o(1) = \phi_\alpha + \Sigma_{k=1}^N c_k^{(\alpha)} \phi_k + o(1)$ in Eq. (7.43), and using Eq. (7.44), we obtain

$$\sum_{k=1}^N A_{jk} c_k^{(\alpha)} = \omega_j + \int \mathrm{d}^2x \ \phi_j(\vec{x}) V(\vec{x}) (e^{i\vec{k}\cdot\vec{x}} - 1), \tag{7.44}$$

with

$$A_{jk} \equiv -\int \phi_j(\vec{x}) V(\vec{x}) [\Delta_R \phi_k](\vec{x}) \mathrm{d}^2x,$$

$$\omega_j = \int \phi_j(\vec{x}) V(\vec{x}) [\Delta_R \phi_a](\vec{x}) \mathrm{d}^2x. \tag{7.45}$$

The integral in (7.44) is $o(1)/[\log(1/k)]^2$, while both A_{jk} and ω_j are $O(\|\Delta_R\|_\ell) = o(1)$. Thus to first order in $\|\Delta_R\|_\ell$, the degeneracy can be removed if the matrix A_{jk} has an inverse, and $A^{-1}\vec{\omega}$ will then give $c_k^{(\alpha)}$ for $k = 1, \ldots, N$.

VIII. THE CASES A_{II} AND B_I

We recall that under case A_{II}, we have N solutions, ϕ_j, $j = 1, \ldots, N$, of the homogeneous equation $\phi_j = K_{\ell\phi j}$, with $\int \mathrm{d}^2x \ V(\vec{x}) \phi_j(\vec{x}) \neq 0$. This case depends critically on whether $N = 1$ or $N \geqslant 2$.

For $N = 1$, we can carry out a rescaling of ϕ_j, and define $\hat{\phi}_1$ as

$$\hat{\phi}_1 = -\frac{2\pi\phi_1}{V_1 \log k_1}, \quad V_1 \equiv \int \mathrm{d}^2x \ V(\vec{x}) \phi_1(\vec{x}). \tag{8.1}$$

Then $\hat{\phi}_1(\vec{x})$ is a solution of the inhomogeneous equation

$$\hat{\phi}_1(\vec{x}) = 1 + \frac{1}{2\pi}\int d^2y(\log\, k_1|\vec{x}-\vec{y}|)V(\vec{y})\hat{\phi}(\vec{y}). \tag{8.2}$$

Hence, for $N=1$, case A_{II} will lead to the same result for $f(\vec{k}',\vec{k})$ that was obtained in Sec. VI for the case A_I.

However, for $N\geqslant 2$, we can always take linear combinations of the ϕ_j's, such that

$$\int d^2x\; V(\vec{x})\left(\sum_{j=1}^{N} b_j\phi_j\right) = 0. \tag{8.3}$$

This reduces case A_{II} for $N\geqslant 2$ to the case B_{II} treated in Sec. VII.

In the case B_I one has a unique solution of the inhomogeneous equation, $\phi=1+K_\ell\phi$, but with $\int d^2x\; V(\vec{x})\phi(\vec{x})=0$. In Appendix E we show that in this case $|\phi(\vec{x})|$ is bounded for all $\vec{x}$. The result for F can now be obtained by setting $V_0=0$ in Eq. (6.35), and noting that since $|\phi|$ is bounded,

$$X_1(\vec{k}) = \int d^2x(e^{i\vec{k}\cdot\vec{x}}-1)V(\vec{x})\phi(\vec{x}) = \frac{o(1)}{\left(\log\frac{1}{k}\right)^2}, \tag{8.4}$$

with an additional power of $[\log(1/k)]$ than in Eq. (6.21).

In addition in this case we have

$$X_3(\vec{k}) = o(1)\Big/\left(\log\frac{1}{k}\right). \tag{8.5}$$

The final result for F is then

$$F(\vec{k}) = \frac{o(1)\Big/\left(\log\frac{1}{k}\right)^2}{1+o(1)} = \frac{o(1)}{\left(\log\frac{1}{k}\right)^2}. \tag{8.6}$$

IX. NONLOCAL POTENTIALS

This is the case where the interaction term in the Schrödinger equation is of the form $\int d^2y\; W(\vec{x},\vec{y})\psi(\vec{y})$, replacing the standard local term, $V(\vec{x})\psi(\vec{x})$.

Due to the length of this paper we shall only deal now with the definition of the class of nonlocal potentials, $W(\vec{x},\vec{y})$. More detailed results will be given elsewhere.

The zero-energy integral equation in this case is

$$\phi(\vec{x}) = 1 + \frac{1}{2\pi}\int d^2y\int d^2z(\log|\vec{x}-\vec{y}|)W(\vec{y},\vec{z})\phi(\vec{z}), \tag{9.1}$$

where the norm is given by

$$|\phi| = \sup_{\vec{x}\in R^2}\frac{|\phi(\vec{x})|}{\log(2+|\vec{x}|)}. \tag{9.2}$$

As in the local case we write

$$u \equiv \frac{|\phi(\vec{x})|}{\log(2+|\vec{x}|)}, \tag{9.3}$$

and obtain

$$u(\vec{x}) = u_0(\vec{x}) + \frac{1}{2\pi \log(2+|\vec{x}|)} \int d^2y \int d^2z \, \log|\vec{x}-\vec{y}| W(\vec{y},\vec{z}) \log(2+|\vec{z}|) u(\vec{z}). \tag{9.4}$$

We need conditions on W to guarantee the boundedness of the double integral,

$$I = \frac{1}{\log(2+|\vec{x}|)} \int d^2y \int d^2z (\log|\vec{x}-\vec{y}|) W(\vec{y},\vec{z}) \log(2+|\vec{z}|) u(\vec{z}). \tag{9.5}$$

Using again $\log A = \log^+ A - \log^- A$, we write for $A = |\vec{x}-\vec{y}|$,

$$I = I^+ - I^-. \tag{9.6}$$

We now have

$$|I^+| \leqslant \frac{\|u\|}{\log(2+|\vec{x}|)} \int d^2y \int d^2z \, \log^+|\vec{x}-\vec{y}| |W(\vec{y},\vec{z})| \log(2+|\vec{z}|). \tag{9.7}$$

But

$$\log^+|\vec{x}-\vec{y}| \leqslant \log(2+|\vec{x}|) + \log(2+|\vec{y}|). \tag{9.8}$$

Hence

$$|I^+| \leqslant \|u\| \int d^2y \int d^2z |W(\vec{y},\vec{z})| \log(2+|\vec{z}|) + \frac{\|u\|}{\log(2+|\vec{x}|)} d^2y \int d^2z \, \log(2+|\vec{y}|) \log(2+|\vec{z}|) |W(\vec{y},\vec{z})|. \tag{9.9}$$

This leads to our first condition on W, namely,

$$\text{(A)} \quad \int d^2y \int d^2z \, \log(2+|\vec{y}|) \log(2+|\vec{z}|) |W(\vec{y},\vec{z})| < \infty. \tag{9.10}$$

For I^- we have

$$|I^-| \leqslant \frac{\|u\|}{\log(2+|\vec{x}|)} \int d^2y \int d^2z |\log^-|\vec{x}-\vec{y}|| W(\vec{y},\vec{z})| \log(2+|\vec{z}|). \tag{9.11}$$

Next, one uses the inequality

$$\log(2+|\vec{z}|) \leqslant \log(2+|\vec{y}|) + \log(1+|\vec{y}-\vec{z}|), \tag{9.12}$$

and notes that when $|\vec{x}-\vec{y}| > 1$, $\log^-|\vec{x}-\vec{y}| = 0$. This allows us to write $\log(2+|\vec{y}|) \leqslant C \log(2+|\vec{x}|)$ in Eq. (9.12) when substituted in (9.11). We obtain

$$|I^-| \leqslant \frac{\|u\|}{\log(2+|\vec{x}|)} \int d^2y \int d^2z |\log^-|\vec{x}-\vec{y}|| W(\vec{y},\vec{z})| \log(|1+\vec{y}-\vec{z}|) + C\|u\| \int d^2y \int d^2z |\log^-||\vec{x}-\vec{y}|| W(\vec{y},\vec{z})|. \tag{9.13}$$

We define two decreasing rearrangements,

$$R_W^{(1)}(y) \equiv [\int d^2z |W(\vec{y},\vec{z})| \log(1+|\vec{y}-\vec{z}|)]_R \tag{9.14}$$

and

$$R_W^{(2)}(y) \equiv \left[\int \mathrm{d}^2 z |W(\vec{y},\vec{z})| \right]_R . \tag{9.15}$$

This leads us to two conditions on $R^{(1)}$ and $R^{(2)}$, namely,

$$\mathrm{B}^{(1)}, \quad \int_0^1 y \, \mathrm{d}y |\log y| R_W^{(1)}(y) < \infty \tag{9.16}$$

and

$$\mathrm{B}^{(2)}, \quad \int_0^1 y \, \mathrm{d}y |\log y| R_W^{(2)}(y) < \infty . \tag{9.17}$$

X. MISCELLANEOUS REMARKS

Remark 1: In Ref.1, the next to leading term for the low-energy behavior of the phase shift, $\delta_0(k)$, was given as $O(k^2)$, i.e., $\delta_0 = (\pi/2)(\log k)^{-1} + O(k^2)$. This is true for massive relativistic field theories. It is also certainly true in nonrelativistic potential scattering for rotationally symmetric potentials that are $O(e^{-\mu r})$ for large r with some $\mu > 0$. For potentials that saturate the condition $\int_1^\infty r \, \mathrm{d}r |V(r)| (\log r)^2 < \infty$, the $O(k^2)$ above should be replaced by $o(1)/[\log(1/k)]$. This will remove the inconsistency between Ref. 1 and the present paper.

A similar remark holds for the results in the exceptional case where $\delta_0 = O(k^2)$ is only necessarily true for massive or exponentially decreasing potentials. Otherwise one has $\delta_0 = o(1)/(\log k)$, as in the present case for the full f.

Remark 2: This paper could be significantly shortened and simplified if we were willing to strengthen the condition (A) on $V(\vec{x})$ given by $\int \mathrm{d}^2 x |V(\vec{x})| [\log(2 + |\vec{x}|)]^2 < \infty$. Even changing the power of the log from 2 to $2+\epsilon$ will simplify the proof somewhat. We are however convinced that this condition is the critical one, and in a certain sense we have the optimal result. The difference between the V's for which the $(\log)^2$ integral is convergent and those for which it diverges is apparent in our paper on the number of bound states.[9]

Remark 3: Finally, and indirectly related to the above remark, we must answer the question why we chose to work on a Banach space of wave functions, ϕ, instead of working on a Hilbert space where the elements of the space are $\sqrt{\tilde{V}}\phi$, and $\tilde{V} = V$ where $V(\vec{x}) > 0$, and $\tilde{V} = -V$ otherwise. In fact it can be shown that the nonlinear condition introduced and studied in detail by one of the authors (P.C.S.),

$$\int \mathrm{d}^2 x \int \mathrm{d}^2 y |V(\vec{x})| (\log|\vec{x} - \vec{y}|)^2 |V(\vec{y})| < \infty \tag{10.1}$$

(which gives an L_2 kernel for the zero-energy integral equation), follows from our linear conditions (A) and (B) given in Sec. III, i.e., $\int \mathrm{d}^2 x |V(\vec{x})| [\log(2 + |\vec{x}|)]^2 < \infty$, and $\int \mathrm{d}^2 x |V(\vec{x})|_R \log^- |\vec{x}| < \infty$. Thus conditions (A) and (B) together give a smaller class of potentials.[8]

The reason we use the Banach space approach is also apparent if one reads Sec. VII dealing with the exceptional case, and especially Appendix D.

ACKNOWLEDGMENTS

The authors are indebted to Henri Epstein for several helpful discussions. In addition he provided a much more elegant and general proof for the compactness theorem given in Appendix B. The authors also wish to thank K. Chadan, B. Morariu, and H.-c. Ren for helpful remarks. Two of us, N.N.K. and T.T.W., are grateful to the CERN Theory Division for its kind hospitality. One of us, A.M., also thanks the theory group at Rockefeller University for its hospitality and support. This work was supported in part by the U.S. Department of Energy under Grant No. DE-FG02-91ER40651, Task B, and under Grant No. DE-FG02-84ER40158.

APPENDIX A

In this appendix we prove the bound

$$|H_0^{(1)}(x)| < |H_0^{(1)}(x_0)| + \log^+\left(\frac{x_0}{x}\right). \tag{A1}$$

First we prove

$$|H_0^{(1)}(x)| < \sqrt{\frac{2}{\pi}}\left(\frac{1}{\sqrt{x}}\right). \tag{A2}$$

From Nicholson's formula (Ref.10, p.31),

$$|H_0^{(1)}(x)|^2 = \frac{8}{\pi^2}\int_0^\infty K_0(2x\ \sinh\ t)\mathrm{d}t, \tag{A3}$$

we have

$$|H_0^{(1)}(x)|^2 < \frac{8}{\pi^2}\int_0^\infty K_0(2x\ \sinh\ t)\cosh\ t\ \mathrm{d}t = \frac{8}{\pi^2}\left(\frac{1}{2x}\right)\int_0^\infty K_0(u)\mathrm{d}u. \tag{A4}$$

But, from Ref.10, p.33, $\int_0^\infty K_0(u)\mathrm{d}u = \pi/2$, and this proves the inequality (A2).

Now using the notation of Abramovitz and Stegun,[11]

$$|H_0^{(1)}(x)| \equiv M_0(x), \tag{A5}$$

M_0 satisfies a nonlinear differential equation,

$$x^2M_0'' + xM_0' + x^2M_0 - \frac{4}{\pi^2M_0^3} = 0. \tag{A6}$$

From (A2) it follows that

$$x^2M_0 - \frac{4}{\pi^2M_0^3} < 0. \tag{A7}$$

Hence,

$$x^2M_0'' + xM_0' > 0, \tag{A8}$$

or

$$\frac{d}{\mathrm{d}x}(xM_0') > 0. \tag{A9}$$

This leads to

$$xM_0'(x) \geqslant \lim_{y\to 0}(yM_0'(y)) = -1, \tag{A10}$$

since $M_0(x) \sim -\log\ x$ as $x \to 0$.

For $0 < x < x_0$,

$$M_0(x_0) - M_0(x) = -\int_{x_0}^x M_0'(y)\mathrm{d}y = -\int_{x_0}^x (yM_0'(y))\frac{\mathrm{d}y}{y} > -\int_{x_0}^x \frac{\mathrm{d}y}{y} = -\log\frac{x_0}{x}. \tag{A11}$$

Thus for $x < x_0$,

$$|H_0^{(1)}(x)| < |H_0^{(1)}(x_0)| + \log\frac{x_0}{x}. \tag{A12}$$

But $|H_0^{(1)}(x)|$ is decreasing. This follows from Nicholson's formula since K_0 is also decreasing. Thus we finally obtain the result (A1).

APPENDIX B

A proof of Lemma 4.2 follows.

We use Ascoli's theorem:[7] Any bounded equicontinuous set of functions on a compact metric space is relatively compact in the sup norm topology.

Since B is a metric space, it suffices to prove that any sequence $\{g_n\}_{n=1,2,\ldots}$ in B satisfying $\|g_n\| \leqslant M$, $\forall n$, contains a subsequence $\{g_{n_k}\}_{k=1,2,\ldots}$ such that $\{Qg_{n_k}\}_{k=1,2,\ldots}$ converges in norm, i.e., such that, for every integer $\ell \leqslant 1$ there exists a constant $L_\ell \geqslant 0$ such that

$$k,k' \geqslant L_\ell \Rightarrow \|Qg_{n_k} - Qg_{n_{k'}}\| < 2^\ell. \tag{B1}$$

Let $\{g_n\}_{n=1,2,\ldots}$ be a sequence in B satisfying $\|g_n\| \leqslant M$ for every n. Then $|Qg_n(x)| \leqslant Mh(x)$ for all n and all $x \in R^m$.

Let $R_1 > 0$ be such that $|x| \geqslant R_1 \Rightarrow Mh(x) < 1/8$. Since the ball $B_1 = \{x \in R^m : |x| \leqslant R_1\}$ is compact, and the sequence of the restrictions of the Qg_n to B_1 are equicontinuous, there exists a subsequence $\{g_n^{(1)}\}$ of $\{g_n\}$ and a constant $L_1 > 0$ such that

$$n,n' \geqslant L_1 \Rightarrow |Qg_n^{(1)}(x) - Qg_{n'}^{(1)}(x)| < 1/4, \quad \forall\, x \in B_1, \tag{B2}$$

and hence

$$n,n' \geqslant L_1 \Rightarrow |Qg_n^{(1)}(x) - Qg_{n'}^{(1)}(x)| < 1/2, \quad \forall\, x. \tag{B3}$$

Suppose we have defined, for every integer $p \in [1, \ell-1]$, a subsequence $\{g_n^{(p)}\}$ of $\{g_n\}$ and a constant $L_p > 0$ such that,

if $b > 1$, $\{g_n^{(p)}\}$ is a subsequence of $\{g_n^{(p-1)}\}$, and for all p,

$$n,n' \geqslant L_p \Rightarrow |Qg_n^{(p)}(x) - Qg_{n'}^{(p)}(x)| < 2^{-p}, \quad \forall\, x. \tag{B4}$$

We can then define $\{g_n^\ell\}$ in the same way as in the first step: let R_ℓ be such that $|x| \geqslant R_\ell \Rightarrow Mh(x) < 1/2^{2+\ell}$, and $B_\ell = \{x \in R^m : |x| \leqslant R_\ell\}$. Let $\{g_n^{(\ell)}\}$ be a subsequence of $\{g_n^{\ell-1}\}$ which converges uniformly on B_ℓ, and L_ℓ be a constant such that

$$n,n' \geqslant L_\ell \Rightarrow |Qg_n^{(\ell)}(x) - Qg_{n'}^{(\ell)}(x)| < 1/2^{2+\ell}, \quad \forall\, x \in B_\ell, \tag{B5}$$

and hence

$$n,n' \geqslant L_\ell \Rightarrow |Qg_n^{(\ell)}(x) - Qg_{n'}^{(\ell)}(x)| < 1/2^\ell, \quad \forall\, x. \tag{B6}$$

The sequence $\{Qg_n^{(n)}\}$ is uniformly convergent on the whole space.

APPENDIX C

In this appendix we give a proof of Theorem 6.1 regarding the norm of the operator Δ_R, where

$$\Delta_R(k;\vec{x},\vec{y}) \equiv -\frac{1}{4i}\{R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)\}V(\vec{y}), \tag{C1}$$

and $R(z)$ is defined by

$$R(z) = H_0^{(1)}(z) - C_0 - \frac{2i}{\pi}\log z, \tag{C2}$$

with C_0 given in Eq. (2.8). We want to prove that, as an operator on the Banach space $\mathcal{B}$, $\|\Delta_R\|_\ell$ has a bound for small k, $0<k\ll 1$,

$$\|\Delta_R\|_\ell = o(1). \tag{C3}$$

At the end of this appendix, in Lemma C.1, we will prove the following inequality:

$$|R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)| < C_1 \log(1+k|\vec{y}|). \tag{C4}$$

From Eq. (C1), we have

$$\|\Delta_R\|_\ell \leqslant \sup_x \int \mathrm{d}^2y |R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)||V(\vec{y})|\log(2+y). \tag{C5}$$

Using (C4) we obtain

$$\|\Delta_R\|_\ell \leqslant C_1 \int \mathrm{d}^2y \log(1+k|\vec{y}|)|V(\vec{y})|\log(2+y). \tag{C6}$$

We set

$$y_0(k) = \frac{1}{k(\log k)^2}, \tag{C7}$$

and write

$$\|\Delta_R\|_\ell \leqslant C_1\left\{\int_{|\vec{y}|<y_0} \mathrm{d}^2y \log(1+k|\vec{y}|)|V(\vec{y})|\log(2+y) + \int_{|\vec{y}|>y_0} \mathrm{d}^2y \log(1+k|\vec{y}|)|V(\vec{y})|\log(2+y)\right\}. \tag{C8}$$

This leads to

$$\|\Delta_R\|_\ell \leqslant C_1\left\{\frac{1}{(\log k)^2}\int_{|\vec{y}|<y_0} \log(2+y)|V(\vec{y})|\mathrm{d}^2y + C_2\int_{|\vec{y}|>y_0} [\log(2+|\vec{y}|)]^2|V(y)|\mathrm{d}^2y\right\}. \tag{C9}$$

Since the last integral is convergent over all of R^2, and $y_0(k)\to\infty$ as $k\to 0$, we finally obtain

$$\|\Delta_R\|_\ell \leqslant o(1), \tag{C10}$$

which proves Theorem 6.1.

This result is, in a certain sense, optimal since if we take the special case $\vec{x}=0$, we get for any $\psi\in C$,

$$(\Delta_R\psi)(0) = -\frac{1}{4i}\int \mathrm{d}^2y\, R(k|\vec{y}|)V(\vec{y})\psi(\vec{y}). \tag{C11}$$

By taking a special $V(\vec{y})$,

$$|V(\vec{y})| = \begin{cases} 0, & y\leqslant 1, \\ \dfrac{1}{y^2|\log y|^{3+\epsilon}}, & y>1, \end{cases} \tag{C12}$$

we can easily show that

$$|(\Delta_R\psi)(0)| = O\left(\frac{1}{\left(\log\frac{1}{k}\right)^{1+\epsilon}}\right)\|\psi\|, \tag{C13}$$

for any $\epsilon>0$.

We now prove Eq. (C4).

Lemma C.1:

$$|R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)| < C\,\log(1+k|\vec{y}|). \tag{C14}$$

Proof: The bound given in Eq. (A2) for $|H_0^{(1)}(z)|$ and the definition of $R(z)$ given in (B2) lead us immediately to the following bound on $|R(z)|$:

$$|R(z)| \leqslant \sqrt{\frac{2}{\pi z}} + |C_0| + \frac{2}{\pi}|\log z|. \tag{C15}$$

For small $|z|$ the behavior of the Hankel function gives us

$$|R(z)| \leqslant C|z|^2[|\log z| + 1]. \tag{C16}$$

Combining (C15) and (C16), we get for real $z>0$,

$$|R(z)| < C\,\log(1+|z|), \quad \forall\, z>0. \tag{C17}$$

Next, we want to prove that, for $u>0$ and $v>0$,

$$|R(u) - R(v)| < C\,\log[1+|u-v|]. \tag{C18}$$

We shall do this in two steps. First we will prove that

$$|R(u) - R(v)| < \text{const}\,|u-v|; \tag{C19}$$

then we prove that

$$|R(u) - R(v)| < C_1 + C_2\,\log(1+|u-v|). \tag{C20}$$

On taking the best of (C19) and (C20), and using the fact that

$$\log(1+x) > \frac{x\,\log(1+x_0)}{x_0} \quad \text{for} \quad 0<x<x_0,$$

(C18) follows.

To prove (C19) we proceed as follows. Assuming, without loss of generality, that $v>u>0$, we have,

$$|R(v) - R(u)| = \left|H_0^{(1)}(u) - H_0^{(1)}(v) + \frac{i}{2\pi}\log\frac{v}{u}\right| \leqslant \int_u^v \left|H_1^{(1)}(x) + \frac{i}{2\pi x}\right| \mathrm{d}x, \tag{C21}$$

where we used the property

$$\frac{\mathrm{d}H_0^{(1)}(x)}{\mathrm{d}x} = -H_1^{(1)}(x).$$

The expansion of $H_1^{(1)}(x)$ near $x=0$ is

$$H_1^{(1)}(x) = J_1(x) + i\left[\frac{2}{\pi}J_1(x)\log\frac{\gamma x}{2} - \frac{x}{2\pi}\sum_{\ell=0}^{\infty} c_\ell x^{2\ell} - \frac{1}{2\pi x}\right], \tag{C22}$$

where $\Sigma c_\ell x^{2\ell}$ is an entire function with $c_0=1$. We thus get

$$\left|H_1^{(1)}(x) + \frac{i}{2\pi x}\right| < Ax + Bx|\log x|, \quad x<1. \tag{C23}$$

On the other hand, we have also the bound

$$|H_1^{(1)}(x)| < C\left[\frac{1}{x} + \frac{1}{\sqrt{x}}\right], \tag{C24}$$

which follows from Nicholson's formula for $\nu=1$. Combining (C23) and (C24), we get

$$\left|H_1^{(1)}(x) + \frac{i}{2\pi x}\right| \leqslant \text{const}, \quad \forall\, x>0. \tag{C25}$$

Thus, by integration of (C21),

$$|R(|u|) - R(|v|)| < \text{const}\,|u-v|. \tag{C26}$$

Finally, we need to prove (C20). Here, we distinguish three cases with $v>u>0$.

(i) $v>2$, $u>1$. From Eq. (C21) and from the bound (A2), we obtain

$$|R(u) - R(v)| \leqslant \text{const} + \frac{1}{2\pi}\log\left(\frac{v}{u}\right) \leqslant \text{const} + \frac{1}{2\pi}\log(1+v-u). \tag{C27}$$

(ii) $v>2, u<1$,

$$|R(u) - R(v)| \leqslant C_1 + C_2\,\log(1+v), \tag{C28}$$

which follows from (C17). Hence we have

$$|R(u) - R(v)| \leqslant C_1 + C_2\,\log(1+v-u)\frac{\log 3}{\log 2}. \tag{C29}$$

(iii) $v<2$. Here we get from (C26)

$$|R(|u|) - R(|v|)| \leqslant C_1 + C_2\,\log(1+v-u)\frac{2}{\log 2}. \tag{C30}$$

Finally, we stress that (C19) is exactly sufficient to establish the uniform continuity of the full kernel of the Lippmann–Schwinger equation given in Eq. (6.1). The uniform continuity for $\log|\vec{x}-\vec{y}|V(\vec{y})$ has already been established in the main text. It remains to prove that $\Delta_R(k;\vec{x},\vec{y})$ operating on any $\chi \in C$ leads to a $(\Delta_R\chi)(\vec{x})$ which is uniformly continuous in $\vec{x}$. From (C19) we have

$$|[R(k|\vec{x}|) - R(k|\vec{x}-\vec{y}|)] - [R(k|\vec{x}'|) - R(k|\vec{x}'-\vec{x}|)]| \leqslant \text{const}\, k|\vec{x}-\vec{x}'|, \tag{C31}$$

which is what we need.

APPENDIX D

In this appendix we give a proof of Theorem 5.1 stated in Sec. V. This theorem starts with the case where the zero-energy homogeneous integral equation,

$$\phi(\vec{x}) = \frac{1}{2\pi}\int \mathrm{d}^2y\ \log|\vec{x}-\vec{y}|V(\vec{y})\phi(\vec{y}), \tag{D1}$$

has N nontrivial solutions, $\phi_j(\vec{x})$, $j=1,\ldots,N$, which all satisfy the condition

$$\int \mathrm{d}^2x\ V(\vec{x})\phi_j(\vec{x}) = 0. \tag{D2}$$

It then follows that the inhomogeneous integral equation,

$$\phi(\vec{x}) = 1 + \frac{1}{2\pi}\int \mathrm{d}^2y\ \log|\vec{x}-\vec{y}|V(\vec{y})\phi(\vec{y}), \tag{D3}$$

has a solution, ϕ_a. This solution is of course not unique.

To establish (D3), we first show that (D1) and (D2) imply that

$$\int \mathrm{d}^2x\ V(\vec{x})[\phi_j(\vec{x})]^2 \neq 0. \tag{D4}$$

This result will be proved at the end of this appendix.

The number, N, of linearly independent solutions of (D1) is finite. This follows from Fredholm theory and the compactness of the operator K. We use the notation

$$\phi_0(\vec{x}) = \sum_{j=1}^{N} c_j\phi_j(\vec{x}). \tag{D5}$$

Next, we generalize Eq. (D3) slightly, replacing 1 by $f(x)$,

$$\phi(\vec{x}) = f(\vec{x}) + \frac{1}{2\pi}\int \mathrm{d}^2y\ \log|\vec{x}-\vec{y}|V(\vec{y})\phi(\vec{y}). \tag{D6}$$

We multiply by $\phi_0(\vec{x})V(\vec{x})$ and integrate over $\vec{x}$,

$$\int \phi_0(\vec{x})V(\vec{x})\phi(\vec{x})\mathrm{d}^2x - \int \phi_0(\vec{x})V(\vec{x})f(x)\mathrm{d}^2x = \frac{1}{2\pi}\int \mathrm{d}^2x \int \mathrm{d}^2y\ \phi_0(\vec{x})V(\vec{x})\log|\vec{x}-\vec{y}|V(\vec{y})\phi(\vec{y})$$
$$= \frac{1}{2\pi}\int \mathrm{d}^2y\ \phi(\vec{y})V(\vec{y})\phi_0(\vec{y}). \tag{D7}$$

Therefore if (D1) has a solution, it follows that

$$\int \mathrm{d}^2x\ f(\vec{x})V(\vec{x})\phi_0(\vec{x}) = 0. \tag{D8}$$

In other words, (D2) is a necessary condition.

We proceed to show that (D2) is also sufficient. Of course, (D2) is satisfied for all $\phi_0(\vec{x})$, and for this purpose, we have to be more careful.

Equation (D6) is defined on a Banach space, B. Thus

$$f \in B \quad \text{and } \phi \in B. \tag{D9}$$

We define

$$(K\phi)(\vec{x}) = \frac{1}{2\pi}\int \mathrm{d}^2y\ \log|\vec{x}-\vec{y}|V(\vec{y})\phi(\vec{y}). \tag{D10}$$

The Banach space B is chosen such that K is a compact operator from B to B. Thus we write (D1) and (D6) as

$$\phi = K\phi, \tag{D11}$$

$$\phi = f + K\phi. \tag{D12}$$

Starting with B, we want to define a second Banach space as follows. The elements of B_1 are the equivalence classes, $\{f+\Sigma_{j=1}^{N} c_j\phi_j\}$ in B, where the c_j run over all real numbers. We denote this equivalence class by F, and $F \in B_1$. We verify that B_1 is indeed a Banach space under the norm

$$\|F\|_1 = \min_{c_j}\left\| f + \sum_{j=1}^{N} c_j\phi_j \right\|. \tag{D13}$$

Because the ϕ_j satisfy (D1), K is also an operator from B_1 to B_1. The point is that

$$K\left(f + \sum c_j\phi_j\right) = Kf + \sum_{j=1}^{N} c_jK\phi_j = Kf + \sum_{j=1}^{N} c_j\phi_j, \tag{D14}$$

which satisfies the definition of being an equivalence class. In the second Banach space B_1, (D3) takes the form

$$\Phi = F + K\Phi. \tag{D15}$$

We verify that K is a compact operator from B_1 to B_1. Thus (D15) is a Fredholm equation in B_1.

Next, we apply the Fredholm alternative to (D15). The Banach space B_1 is constructed such that the homogeneous equation,

$$\Phi = K\Phi, \tag{D16}$$

has no nontrivial solutions in B_1. To show this we assume the contrary, i.e., that there is a nontrivial Φ. Translated back to the original Banach space, B, (D16) is

$$\phi = \phi_0 + K\phi, \tag{D17}$$

where ϕ_0 satisfies (D1) and (D2). By (D8), the existence of a solution implies that

$$\int \phi_0(\vec{x})V(\vec{x})\phi_0(\vec{x})\mathrm{d}^2x = 0, \tag{D18}$$

i.e.,

$$\int \mathrm{d}^2x\ V(\vec{x})[\phi_0(\vec{x})]^2 = 0. \tag{D19}$$

But this contradicts (D4). Therefore (D16) cannot have a nontrivial solution.

From the Fredholm alternative, we know that (D15) always has a solution in the Banach space B_1. Translated back to the original space B, this means that

$$\phi = f + \sum_{j=1}^{N} c_j\phi_j + K\phi \tag{D20}$$

has a solution in B for a suitably chosen set of coefficients c_j.

It therefore remains to show that

$$c_j = 0, \quad j = 1, \ldots, N. \tag{D21}$$

To prove this, we again assume the opposite, i.e., not all c_j are zero, or $\phi_0 = \Sigma_{j=1}^{N} c_j \phi_j$ is nontrivial. Then we have both

$$\int [f(\vec{x}) + \phi_0(\vec{x})] V(\vec{x}) \phi_0(\vec{x}) \mathrm{d}^2x = 0 \tag{D22}$$

and

$$\int f(\vec{x}) V(\vec{x}) \phi_0(\vec{x}) \mathrm{d}^2x = 0. \tag{D23}$$

The latter is just (D8). Subtracting (D23) from (D22), we obtain

$$\int V(\vec{x}) [\phi_0(\vec{x})]^2 \, \mathrm{d}^2x = 0. \tag{D24}$$

But this again contradicts (D4).

The conclusion is therefore reached that the necessary and sufficient condition for (D6) to have a solution is (D8), or

$$\int f(\vec{x}) V(\vec{x}) \phi_j(\vec{x}) \mathrm{d}^2x = 0, \quad j = 1, \ldots, N. \tag{D25}$$

It only remains to specialize (D6) to the case $f=1$. Thus the necessary and sufficient condition for (D3) to have a solution is $\int \mathrm{d}^2x \; V(\vec{x}) \phi_j(\vec{x}) = 0$, $j = 1, \ldots, N$.

We are now only left with the task of proving (D4), i.e., that $\int V(\vec{x}) [\phi_0(\vec{x})]^2 \, \mathrm{d}^2x \neq 0$. A zero-energy bound state is characterized by the solution, $\phi_0(\vec{x})$, of the equation

$$\phi_0(\vec{x}) = \frac{1}{2\pi} \int \mathrm{d}^2y \, \log k_0 |\vec{x} - \vec{y}| V(\vec{y}) \phi_0(\vec{y}), \tag{D26}$$

with the condition

$$\int \mathrm{d}^2x \; V(\vec{x}) \phi_0(\vec{x}) = 0. \tag{D27}$$

From (D26) we see that (D27) is independent of the scale k_0. We set $k_0 = 1$. Then, using the Schrödinger equation

$$-\nabla^2 \phi_0 + V(\vec{x}) \phi_0 = 0, \tag{D28}$$

we get, after multiplication by ϕ_0 and integration,

$$-\int_{|\vec{x}| \leqslant R} \mathrm{d}^2x \; \phi_0 \nabla^2 \phi_0 + \int_{|\vec{x}| \leqslant R} \mathrm{d}^2x V(|\vec{x}|) \phi_0(\vec{x})^2 = 0. \tag{D29}$$

Integrating by parts, we get

$$F(R) = \int_{|\vec{x}| < R} |\nabla \phi_0|^2 \mathrm{d}^2x + \int_{|\vec{x}| < R} V(\vec{x}) \phi_0^2(\vec{x}) \mathrm{d}^2x = \int_{|\vec{x}| = R} \mathrm{d}s (\vec{\nabla} \phi_0) \phi_0. \tag{D30}$$

Using polar coordinates, we have

$$\frac{F(R)}{R} = \int \mathrm{d}\theta \ \phi_0(R_1) \ \left. \frac{\partial \phi_0(r,\theta)}{\partial r} \right|_{r=R}. \tag{D31}$$

Taking $R_1 \leqslant R \leqslant R_2$, we obtain

$$\int_{R_1}^{R_2} \frac{F(R)}{R} \mathrm{d}\, R = \frac{1}{2} \int \mathrm{d}\theta [\phi_0^2(R_2,\theta) - \phi_0^2(R_1,\theta)]. \tag{D32}$$

In Appendix E we prove that if (D26) and (D27) hold, then $\int \mathrm{d}\theta \ \phi_0^2(R,\theta) \to 0$ as $R \to \infty$. If this result is true, we then have

$$\int_{R_1}^{R_2} \frac{F(R)}{R} \mathrm{d}\, R \leqslant \text{const}, \quad \forall\, R_2 > R_1 \gg R_0. \tag{D33}$$

Hence using the mean-value theorem, there exists a $\overline{R}$, $R_1 < \overline{R} < R_2$, such that

$$F(\overline{R}) \leqslant \frac{C}{\log(R_2/R_1)}. \tag{D34}$$

Therefore there is a sequence, $\overline{R}_1, \overline{R}_2, \ldots, \overline{R}_j$, such that $F(\overline{R}_j) \to 0$ as $j \to \infty$.

But $\int \mathrm{d}^2x |V| [\phi_0(\vec{x})]^2$ is convergent since $|\phi_0| < \text{const} \log(2+|\vec{x}|)$ for large $|\vec{x}|$. Potentials with $\int \mathrm{d}^2x |V| [\log(2+|\vec{x}|)]^2 < \infty$ belong to our class. Hence we conclude that $\int_{|\vec{x}|<R} V\phi_0^2 \ \mathrm{d}^2x$ has a limit as $R \to \infty$.

On the other hand, the first term on the right-hand side of (D29), i.e., $\int_{|\vec{x}|<R} |\vec{\nabla}\phi_0|^2 \mathrm{d}^2x$, is a monotonically increasing function of R, so it either has a limit as $R \to \infty$ or it tends to $+\infty$. The latter case is in contradiction with the fact that $F(\overline{R}_j) \to 0$ as $j \to \infty$. Therefore, $\int_{|\vec{x}| \leqslant R} \mathrm{d}^2x |\vec{\nabla}\phi|^2$ has a limit as $R \to \infty$, and $F(R)$ has a limit which is identically zero. But, $\int \mathrm{d}^2x |\vec{\nabla}\phi_0|^2 > 0$ strictly, and therefore

$$\int V[\phi_0]^2 \mathrm{d}^2x < 0. \tag{D35}$$

APPENDIX E

In this appendix we prove the following: Given $\phi(\vec{x}) \in \mathcal{B}$ which satisfies the integral equation

$$\phi(\vec{x}) = c_0 + \frac{1}{2\pi} \int \mathrm{d}^2y (\log|\vec{x}-\vec{y}|) V(\vec{y}) \phi(\vec{y}), \tag{E1}$$

with c_0 finite or zero, then if

$$\int \mathrm{d}^2x \ V(\vec{x}) \phi(\vec{x}) = 0, \tag{E2}$$

$|\phi(\vec{x})|$ is uniformly bounded for all $\vec{x} \in R_2$.

We stress first that, as in Appendix D, the $\phi(\vec{x})$ considered here are all in the Banach space $\mathcal{B}$, and hence $\|\phi\|_\ell \leqslant \text{const}$. This means that we have *ab initio* the bound

$$|\phi(\vec{x})| \leqslant C \ \log(2+|\vec{x}|). \tag{E3}$$

Thus to complete the task of this appendix we only have to study the large $|\vec{x}|$ behavior of $|\phi|$.

Using again the notation $\log A = \log^+ A - \log^- A$, we set

$$\frac{1}{2\pi}\int d^2y(\log|\vec{x}-\vec{y}|)V(\vec{y}) \equiv I^+(\vec{x}) - I^-(\vec{x}). \tag{E4}$$

First we prove that

$$I^+(\vec{x}) \to 0, \quad \text{as} \quad |x| \to \infty. \tag{E5}$$

Given (E2) we can write I^+ as

$$I^+(\vec{x}) = \frac{1}{2\pi}\int \mathrm{d}^2y[\log^+|\vec{x}-\vec{y}| - \log(2+|\vec{x}|)]V(\vec{y})\phi(\vec{y}). \tag{E6}$$

We define $y_0(x)$ as

$$y_0 \equiv \frac{x}{\log(2+x)}. \tag{E7}$$

Next, we split the integration in (E6),

$$\begin{aligned}|I^+| \leqslant \frac{1}{2\pi}\int_{y<y_0(x)} \mathrm{d}^2y|\log|\vec{x}-\vec{y}| - \log(2+x)||V(\vec{y})\phi(\vec{y})| \\ + \frac{1}{2\pi}\int_{y>y_0(x)} \mathrm{d}^2y[2\,\log(2+x) + \log(2+y)]|V(\vec{y})\phi(\vec{y})|.\end{aligned} \tag{E8}$$

In the first integral, for x large enough,

$$|\log|\vec{x}-\vec{y}| - \log(2+x)| < \frac{2}{\log(2+x)}. \tag{E9}$$

But as $x \to \infty$,

$$\int_{y<y_0(x)} \mathrm{d}^2y|\log|\vec{x}-\vec{y}| - \log(2+x)||V(\vec{y})||\phi(\vec{y})| \leqslant \frac{C}{\log(2+x)}\int_{y<y_0(x)} \mathrm{d}^2y\|V(y)\|\log(2+y). \tag{E10}$$

Hence the first integral vanishes as $x \to \infty$. The second integral, I_2^+, satisfies

$$|I_2^+(\vec{x})| \leqslant C\int_{y>y_0(x)} \mathrm{d}^2y|V(y)|[\log(2+y)]^2 = o(1), \tag{E11}$$

as $x \to \infty$. Thus Eq. (E5) is proved.

At this stage we have

$$|\phi(\vec{x})| \leqslant C + \frac{1}{2\pi}\int d^2y(\log^-|\vec{x}-\vec{y}|)|V(\vec{y})||\phi(\vec{y})|. \tag{E12}$$

Next, we define $M(r)$ and $B(r)$ as follows:

$$M(r) = \sup_{|\vec{x}|\leqslant r}|\phi(\vec{x})|, \tag{E13}$$

$$B(r) = r \sup_{\rho \leqslant r} \frac{M(\rho)}{\rho} \geqslant M(r). \tag{E14}$$

$B(r)$ exists because $M(r) \leqslant C \log(2+r)$. If $|\phi(\vec{x})|$ grows to infinity as $|\vec{x}| \to \infty$, there must exist a sequence $\vec{x}_1, \vec{x}_2, \ldots, \vec{x}_n$, $|\vec{x}_n| \to \infty$ as $n \to \infty$, where $M(|\vec{x}_n|) = |\phi(\vec{x}_n)|$, and there must be a subsequence $\vec{x}_1', \vec{x}_2', \ldots, \vec{x}_N'$, where

$$B(|\vec{x}_N'|) = M(|\vec{x}_N'|) = |\phi(\vec{x}_N')|. \tag{E15}$$

We take such an $\vec{x}_N'$, and obtain

$$B(|\vec{x}_N'|) \leqslant C + \frac{1}{2\pi} \int \mathrm{d}^2 y (\log^- |\vec{x}_N' - \vec{y}|) |V(\vec{y})| B(|\vec{x}_N'|) \left(\frac{|\vec{x}_N'| + 1}{|\vec{x}_N'|} \right), \tag{E16}$$

where we recall that in the integral

$$|\vec{x}_N'| - 1 \leqslant |\vec{y}| \leqslant |\vec{x}_N'| + 1. \tag{E17}$$

Now we obtain

$$\int \mathrm{d}^2 y \, \log^- |\vec{x}_N' - \vec{y}| V(\vec{y})$$

$$\leqslant \int_{|\vec{z}|<\Delta} (\log^- |\vec{z}|) |V(\vec{z})|_R \, d^2 z + |\log \Delta| \int_{|\vec{y}|>|\vec{x}_N'|-1} |V(\vec{y})| \mathrm{d}^2 y. \tag{E18}$$

The first integral can be made arbitrarily small by taking Δ small enough. Once Δ is fixed we can make the second integral as small as we please by taking $|\vec{x}_N'|$ large enough. Hence we finally have

$$B(|\vec{x}_N'|) \leqslant C + \epsilon B(|\vec{x}_N'|), \tag{E19}$$

with $\epsilon < 1/2$ for $|\vec{x}_N'|$ large enough.

Therefore B is bounded, and it follows that $|\phi|$ is bounded. From this it is easy to see that

$$\int \mathrm{d}^2 y (\log^- |\vec{x} - \vec{y}|) |V(\vec{y})| |\phi(\vec{y})| \to 0, \tag{E20}$$

as $|\vec{x}| \to \infty$, because from (E18),

$$\int \mathrm{d}^2 y (\log^- |\vec{x} - \vec{y}|) |V(\vec{y})| \to 0 \quad \text{as } |\vec{x}| \to \infty. \tag{E21}$$

As a consequence, if in Eq. (E1), $C_0 = 0$, then $|\phi| \to 0$ as $|\vec{x}| \to \infty$.

In the case where $\int \mathrm{d}^2 x \, V(\vec{x}) \phi(\vec{x}) \neq 0$, we have

$$\left| \int d^y \, \log^- |\vec{x} - \vec{y}| V(\vec{y}) \phi(\vec{y}) \right| \leqslant C \, \log(2+x) \int \mathrm{d}^2 y \, \log^- |\vec{x} - \vec{y}| \| V(\vec{y}) \|. \tag{E22}$$

Combining this with (E2) and using Eq. (E21), we get

$$|\phi| \cong \frac{1}{2\pi} \log(2+x) \left| \int \mathrm{d}^2 y \, V(\vec{y}) \phi(\vec{y}) + o(1) \right| \quad \text{for } |\vec{x}| \to \infty. \tag{E23}$$

Sz.-Nagy–Foias theory and Lax–Phillips type semigroups in the description of quantum mechanical resonances

Y. Strauss[a)]
Einstein Institute of Mathematics, The Hebrew University of Jerusalem, Jerusalem 91904, Israel

(Received 29 May 2004; accepted 26 October 2004; published online 8 February 2005)

A quantum mechanical version of the Lax–Phillips scattering theory was recently developed. This theory is a natural framework for the description of quantum unstable systems. However, since the spectrum of the generator of evolution in this theory is unbounded from below, the existing framework does not apply to a large class of quantum mechanical scattering problems. It is shown in this work that the fundamental mathematical structure underlying the Lax–Phillips theory, i.e., the Sz.-Nagy–Foias theory of contraction operators on Hilbert space, can be used for the construction of a formalism in which models associated with a semibounded spectrum may be accomodated. © *2005 American Institute of Physics.*

I. INTRODUCTION

The Lax–Phillips scattering theory[22] was originally devised for the analysis of the scattering of electromagnetic or acoustic waves off compact obstacles; it is most sutible for handling hyperbolic wave equations in which the generator of evolution, or wave group, naturally has a continuous specrum on the whole real line. More recently Sjöstrand and Zworski[33] extended the scope of the Lax–Phillips theory to include more general cases of semibounded, compactly supported, perturbations of the Laplacian in the wave equation. The extended version of the theory plays a role in the ongoing effort in recent years to obtain various upper and lower bounds on the number of resonances.[33,27] The Lax–Phillips theory also plays an important role in geometric analysis where certain problems can be naturally formulated as scattering problems (see Ref. 40 and references therein).

The description of resonances in the framework of the Lax–Phillips theory possess certain properties which may be considered as defining properties of an appropriate description of these objects. Resonances are identified according to their evolution in time under the action of a dynamical semigroup, i.e., the Lax–Phillips semigroup. Specifically, resonances are identified as eigenvalues of the generator of the Lax–Phillips semigroup. In fact, Sjöstrand and Zworski prove in Ref. 33 that in the case of the Lax–Phillips theory, the eigenvalues of the generator of the Lax–Phillips semigroup coincide with the generally accepted identification of resonances with poles of (a generalized form of) the resolvent.

Many recent studies indicate that resonances should formally be treated in the same way as eigenvalues (see Refs. 24 and 40 and references therein). Taking the analogy a step forward it is natural to ask whether it is possible to show that resonances are indeed eigenvalues of an operator closely related to the generator of evolution. This is known to be the case in the procedure of complex scaling[2,4,14,20,31,30,32,15] and the method of rigged Hilbert space.[5,3,19,26,6] For a recent abstract treatment of the problem of resonances along these lines see Ref. 1. The structure of the Lax–Phillips theory is again very appealing in this respect since the Lax–Phillips semigroup is just the projection of the evolution into a subspace of the Hilbert space for the scattering problem.

[a)]Electronic mail: ystrauss@math.huji.ac.il

If we require that the description of resonances would have the properties mentioned above, i.e.,

(I) the time evolution of resonances is given in terms of a continuous, one parameter, contractive semigroup,

$$\mathbf{Z}(t_1)\mathbf{Z}(t_2) = \mathbf{Z}(t_1 + t_2), \quad t_1, t_2 \geqslant 0; \tag{1.1}$$

(II) a resonance is assigned, for each time t, a pure state in a Hilbert space;

then for most scattering problems in quantum mechanics the situation is not as favorable as in the Lax–Phillips theory. In fact, the standard treatment of the time evolution of resonances through the notion of the survival amplitude does not generically yield a semigroup law of evolution even in the pole approximation in which the propagator is approximated by taking only the contributions coming from the scattering poles. This fact becomes evident in the case of multiple scattering poles where the residues of the resolvent at different points in the complex plane are not orthogonal to each other and generate interference effects which destroy the semigroup property.[17] In particular, it is interesting to relate the statements made here to some recent efforts to obtain resonance expansions of propagators[24] and to recent work on time dependent theory of resonances.[23,34,8]

There has been some recent work on a quantum mechanical adaptation of the Lax–Phillips theory. Some progress has been made in Refs. 11, 18, and 10, and in Ref. 37 a general formalism was developed which was subsequently applied to certain simple Lee–Friedrichs type models in relativistic quantum field theory.[35,36] More recently, the general formalism developed in Ref. 37 has been used for the analysis of the Stark effect [Ben Ari and Horwitz, Stark effect in the Lax–Phillips scattering theory (in preparation)]. However, the formalism developed in Ref. 37 essentially retains the original structure of the Lax–Phillips theory and hence it is not suitable for the analysis of a large class of quantum mechanical problems, since the generator of evolution is required to have an unbounded spectrum from below as well as from above. A natural question then arises whether this situation can be amended. One of the goals of this paper is to show that, in a sense, the answer to this question is in the affirmative. More specifically, it is shown that the fundamental mathematical theory underlying the Lax–Phillips structure, i.e., the Sz.-Nagy–Foias theory of contraction operators on Hilbert space,[38] can be used in the description of resonances for problems for which the generator of evolution has a semibounded spectrum.

The purpose of this paper is twofold. First, it is shown in Sec. II below that a formalism analogous to that of the Lax–Phillips scattering theory may be constructed for the description of resonances in scattering problems for which the generator of evolution has a semibounded spectrum. Thus, two "representations" of the problem are defined, analogous to the Lax–Phillips translation representations, in which the evolution of the scattering system is transformed into the analogue of translation, i.e., into a translation semigroup of Toeplitz operators on Hardy space. It is also possible to define an S-matrix, analogous to the Lax–Phillips S-matrix, mapping the incoming "representation" onto the outgoing "representation." Beyond mere analogy, in the formalism developed in Sec. II scattering resonances are defined exactly as in the Lax–Phillips theory, i.e., as eigenvalues of the generator of a Lax–Phillips type semigroup.

The second goal of this paper is to suggest that the tool box of methods available for the analysis of resonance phenomena should include the Sz.-Nagy–Foias theory of contraction operators on Hilbert space and, more generally, the part of operator theory dealing with model operators and decompositions.[21] The Sz.-Nagy–Foias theory of contractions is an important part of the subject of model operators. Let $\mathcal{B}(\mathcal{H})$ be the space of bounded linear operators on a Hilbert space $\mathcal{H}$. An operator is a *model operator* for a class of operators in $\mathcal{B}(\mathcal{H})$ if every operator in that class is similar to a multiple of a part of it (a part of an operator is defined to be the restriction of the operator to an invariant subspace). In the case of contractions on Hilbert space the model operator is the backward shift (see Refs. 28 and 21). If a resonance is characterized by conditions (I) and (II) above it is then quite natural that its description will eventually be given in terms of the model for contractions, i.e., essentially by the restriction of the backward shift to an invariant subspace.

Taking this point of view, the role of the Sz.-Nagy–Foias theory in the structures developed in Sec. II is not surprising and in fact unavoidable.

The rest of this paper is organized as follows: The Lax–Phillips scattering theory is briefly reviewed in Sec. I A. Section I B provides a self-contained, but rather restricted in scope, exposition of the parts of the Sz.-Nagy–Foias theory which are relevant to the rest of the paper. The Sz.-Nagy–Foias theory is thoroughly discussed in Ref. 38. Section I B also describes the way that the Lax–Phillips semigroup can be naturally understood in the context of the Sz.-Nagy–Foias theory. Section II contains the main results in this paper. After a preliminary discussion in Sec. II A, concerning Hilbert space nesting, a formalism enabling the use of the Sz.-Nagy–Foias theory for the description of resonances is developed in Sec. II B. Section III contains some comments on the framework introduced in Sec. II and concluding remarks are found in Sec. IV.

A. The Lax–Phillips scattering theory

This section provides a brief review of the Lax–Phillips scattering theory and establishes some of the notation which is used throughout the rest of this paper.

Consider a Hilbert space $\mathcal{H}$ and an evolution group of unitary operators $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ on $\mathcal{H}$. Suppose that there exists two distinguished subspaces $\mathcal{D}_-$ and $\mathcal{D}_+$ which have the properties that $\mathcal{D}_-$ is orthogonal to $\mathcal{D}_+$ and

$$\begin{aligned} &\mathbf{U}(t)\mathcal{D}_- \subset \mathcal{D}_-, \quad t \leqslant 0, \\ &\mathbf{U}(t)\mathcal{D}_+ \subset \mathcal{D}_+, \quad t \geqslant 0, \\ &\cap_t \mathbf{U}(t)\mathcal{D}_\pm = \{0\}, \\ &\overline{\cup_t \mathbf{U}(t)\mathcal{D}_\pm} = \mathcal{H}. \end{aligned} \tag{1.2.}$$

We call $\mathcal{D}_-$ the *incoming subspace* and $\mathcal{D}_+$ the *outgoing subspace*. $\mathcal{D}_-$ corresponds to incoming waves which do not interact with the target prior to $t=0$ and $\mathcal{D}_+$ corresponds to outgoing waves which do not interact with the target after $t=0$. These properties are reflected in the stability properties of $\mathcal{D}_-$ and $\mathcal{D}_+$ in Eq. (1.2).

Let $L^2_{\mathcal{N}}(\mathbb{R})$ be the space of L^2 functions defined on $\mathbb{R}$ and taking their values in a Hilbert space $\mathcal{N}$. Sinai[7] proved the following theorem.

Theorem 1.1 (Sinai): *If $\mathcal{D}_+$ is an outgoing subspace with respect to a group of unitary operators $\mathbf{U}(t)$, then the Hilbert space $\mathcal{H}$ can be represented isometrically as the Hilbert space of functions $L^2_{\mathcal{N}}(\mathbb{R})$ for some auxiliary Hilbert space $\mathcal{N}$ so that $\mathbf{U}(t)$ goes into translation to the right by t units, and $\mathcal{D}_+$ is mapped onto $L^2_{\mathcal{N}}(\mathbb{R}^+)$. This representation is unique up to an isomorphism of $\mathcal{N}$.*

A representation of this kind is called *outgoing translation representation*. An analogous representation theorem holds for an incoming subspace $\mathcal{D}_-$, i.e., there is a representation in which $\mathcal{H}$ is mapped onto the Hilbert space $L^2_{\mathcal{N}}(\mathbb{R})$, $\mathcal{D}_-$ is mapped onto $L^2_{\mathcal{N}}(\mathbb{R}^-)$ and $\mathbf{U}(t)$ acts as translation to the right by t units. This representation is called the *incoming translation representation*.

For most purposes it is more convenient not to work with the translation representations but with two different representations, called spectral representations. By Fourier transformation of the incoming translation representation and the outgoing translation representation we obtain the *incoming spectral representation* and *outgoing spectral representation*, respectively. According to the Paley–Wiener theorem[25] in the incoming spectral representation, the subspace $\mathcal{D}_-$ is represented by the Hilbert space of functions $H^+_{\mathcal{N}}(\mathbb{R})$ consisting of boundary values on $\mathbb{R}$ of functions in the Hardy space $H^2_{\mathcal{N}}(\Pi)$. Denoting the upper half of the complex plane by Π, the space $H^2_{\mathcal{N}}(\Pi)$ is characterized as the space of analytic vector valued functions on Π, taking their values in the auxiliary Hilbert space $\mathcal{N}$, and such that for any function $f \in H^2_{\mathcal{N}}(\Pi)$ we have

$$\sup_{y>0}\int_{-\infty}^{+\infty}\|f(x+iy)\|_{\mathcal{N}}^2\,dx<C$$

for some constant $C>0$. In the outgoing spectral representation the subspace $\mathcal{D}_+$ is represented, according to the Paley–Wiener theorem, by the function space $H_{\mathcal{N}}^-(\mathbb{R})$ consisting of boundary values of functions in $H_{\mathcal{N}}^2(\overline{\Pi})$, a Hardy space of vector valued functions (taking values in $\mathcal{N}$) on the lower half-plane $\overline{\Pi}$. In the case of scalar valued functions used in the sequel in Sec. II below the same notation will be used but the subscript $\mathcal{N}$ for the auxiliary Hilbert space is omitted.

Let $\mathbf{W}_+$ and $\mathbf{W}_-$ denote the operators that map elements of $\mathcal{H}$ to their outgoing, respectively, incoming, translation representers. We call the operator

$$\mathbf{S}^{L.P}\equiv\mathbf{W}_+\mathbf{W}_-^{-1} \tag{1.3}$$

the *abstract scattering operator* associated with the group $\mathbf{U}(t)$ and the pair of spaces $\mathcal{D}_-$ and $\mathcal{D}_+$. It was proved by Lax and Phillips (LP) that $\mathbf{S}^{\mathrm{LP}}$ is equivalent to the standard definition of the scattering operator. The abstract scattering operator has the following properties:

(a) $\mathbf{S}^{\mathrm{LP}}$ is unitary,
(b) $\mathbf{S}^{\mathrm{LP}}$ commutes with translations,
(c) $\mathbf{S}^{\mathrm{LP}}$ maps $L_{\mathcal{N}}^2(\mathbb{R}^-)$ into itself.

Property (b) is due to the fact that $\mathbf{S}^{\mathrm{LP}}$ is a map between two translation representations. One can understand property (c) by noting that in the incoming translation representation the subspace $\mathcal{D}_-$ is identified with the space of functions $L_{\mathcal{N}}^2(\mathbb{R}^-)$ and in the outgoing translation representation $\mathcal{D}_+$ is represented as $L_{\mathcal{N}}^2(\mathbb{R}^+)$. The orthogonality of $\mathcal{D}_-$ and $\mathcal{D}_+$ then implies that in the outgoing translation representation $\mathcal{D}_-$ is represented by a subspace of $L_{\mathcal{N}}^2(\mathbb{R}^-)$ and property (c) above follows.

Going over to the spectral representations the scattering operator transforms into $\mathcal{S}^{\mathrm{LP}}\equiv\mathbf{F}\mathbf{S}^{\mathrm{LP}}\mathbf{F}^{-1}$, where $\mathbf{F}$ is the Fourier transform operator. Properties (a)–(c) above then imply corresponding properties for $\mathcal{S}^{\mathrm{LP}}$,

(a′) $\mathcal{S}^{\mathrm{LP}}$ is unitary,
(b′) $\mathcal{S}^{\mathrm{LP}}$ commutes with multiplication by scalar functions,
(c′) $\mathcal{S}^{\mathrm{LP}}$ maps $H_{\mathcal{N}}^+(\mathbb{R})$ into itself.

According to a special case of a theorem of Foures and Segal,[12] an operator satisfying properties (a′)–(c′) can be realized as a multiplicative, operator valued function $\mathcal{S}$, such that $\mathcal{S}(\sigma)$ maps $\mathcal{N}$ into $\mathcal{N}$ for each $\sigma\in\mathbb{R}$. This operator valued function satisfies

(a″) $\mathcal{S}(\sigma)$ is the boundary value of an operator valued function $\mathcal{S}(z)$ analytic for $\mathrm{Im}\,z>0$,
(b″) $\|\mathcal{S}(z)\|_{\mathcal{N}}\leqslant 1$ for $\mathrm{Im}\,z>0$,
(c″) $\mathcal{S}(\sigma)$, $\sigma\in\mathbb{R}$ is, pointwise, a unitary operator on the auxiliary Hilbert space $\mathcal{N}$.

Consider the family $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ of operators on $\mathcal{H}$ defined by

$$\mathbf{Z}(t)\equiv\mathbf{P}_+\mathbf{U}(t)\mathbf{P}_-\quad(t\geqslant 0). \tag{1.4}$$

Here $\mathbf{P}_+$ is the orthogonal projection of $\mathcal{H}$ onto the orthogonal complement of $\mathcal{D}_+$ and $\mathbf{P}_-$ is the orthogonal projection of $\mathcal{H}$ onto the orthogonal complement of $\mathcal{D}_-$. Lax and Phillips prove the following theorem.

Theorem 1.2: *The operators* $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ *annihilate* $\mathcal{D}_+$ and $\mathcal{D}_-$, *map the orthogonal complement* $\mathcal{K}=\mathcal{H}\ominus(\mathcal{D}_-\oplus\mathcal{D}_+)$ *into itself, and form a strongly continuous semigroup* [*i.e.* $\mathbf{Z}(t_1)\mathbf{Z}(t_2)=\mathbf{Z}(t_1+t_2)$] *of contraction operators on* $\mathcal{K}$. *Furthermore,* $\mathbf{Z}(t)$ *tends strongly to zero as* $t\to\infty$: $s-\lim_{t\to\infty}\mathbf{Z}(t)x=0$ *for every* x *in* $\mathcal{K}$.

The family of operators $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ is called the Lax–Phillips semigroup. The operator valued

function $\mathcal{S}$, with properties (a″)–(c″) above, is called the Lax–Phillips *S*-matrix. Properties (a″)–(c″) characterize the Lax–Phillips *S*-matrix as an analytic function on the upper half-plane. The analytic continuation of $\mathcal{S}$ to the lower half-plane is given by

$$\mathcal{S}(z) \equiv [\mathcal{S}^*(\overline{z})]^{-1}, \quad \operatorname{Im} z < 0. \tag{1.5}$$

One of the main results of the Lax–Phillips scattering theory is the following theorem.

Theorem 1.3: *Let* $\mathbf{B}$ *denote the generator of the semigroup* $\mathbf{Z}(t)$. *If* $\operatorname{Im}\mu<0$, *then* μ *belongs to the point spectrum of* $\mathbf{B}$ *if and only if* $\mathcal{S}^*(\overline{\mu})$ *has a nontrivial null space*.

This theorem establishes a very important relation between the eigenvalues of the generator $\mathbf{B}$ of the Lax–Phillips semigroup and zeros of the Lax–Phillips *S*-matrix $\mathcal{S}$ in the upper half-plane or poles of the analytic continuation of $\mathcal{S}$ to the lower half-plane.

B. Lax–Phillips theory and Sz.-Nagy–Foias theory of contractions

In this section the structure of the Lax–Phillips theory is put into the context of the more general theory of Sz.-Nagy and Foias concerning contraction operators on Hilbert space.[38]

Consider the Lax–Phillips semigroup $\{\mathbf{Z}(t)\}_{t\geqslant 0}$. According to Theorem 1.2 this semigroup acts nontrivially on the subspace $\mathcal{K}=\mathcal{H}\ominus(\mathcal{D}_-\oplus\mathcal{D}_+)$. For a vector $f\in\mathcal{K}$ and for $t_1,t_2\geqslant 0$ we have

$$\mathbf{Z}(t_1)\mathbf{Z}(t_2)f=\mathbf{P}_+\mathbf{U}(t_1)\mathbf{P}_-\mathbf{Z}(t_2)f=\mathbf{P}_+\mathbf{U}(t_1)\mathbf{Z}(t_2)f=\mathbf{P}_+\mathbf{U}(t_1)\mathbf{P}_+\mathbf{U}(t_2)f. \tag{1.6}$$

The stability properties of the subspace $\mathcal{D}_+$ [Eq. (1.2)] imply the following identity

$$\mathbf{P}_+\mathbf{U}(t)(\mathbf{I}-\mathbf{P}_+)=0, \quad t\geqslant 0. \tag{1.7}$$

Inserting this identity into the right-hand side (rhs) of the previous equation we find, for $f\in\mathcal{K}\oplus\mathcal{D}_-$ and $t_1,t_2\geqslant 0$,

$$\mathbf{P}_+\mathbf{U}(t_1)\mathbf{P}_+\mathbf{U}(t_2)f=\mathbf{P}_+\mathbf{U}(t_1)[(\mathbf{I}-\mathbf{P}_+)+\mathbf{P}_+]\mathbf{U}(t_2)f=\mathbf{P}_+\mathbf{U}(t_1)\mathbf{U}(t_2)f=\mathbf{P}_+\mathbf{U}(t_1+t_2)f. \tag{1.8}$$

We note that, since for $f\in\mathcal{K}$ we have $\mathbf{P}_+\mathbf{U}(t_1+t_2)f=\mathbf{P}_+\mathbf{U}(t_1+t_2)\mathbf{P}_-f=\mathbf{Z}(t_1+t_2)f$, Eq. (1.8) implies the semigroup law. Given a Lax–Phillips structure with an evolution group $\mathbf{U}(t)$ on the Hilbert space $\mathcal{H}$, consider the family of operators $\{\mathbf{T}(t)\}_{t\geqslant 0}$ such that $\mathbf{T}(t)$: $\mathcal{H}\mapsto\mathcal{H}$, $t\geqslant 0$ and

$$\mathbf{T}(t)\equiv\mathbf{P}_+\mathbf{U}(t), \quad t\geqslant 0. \tag{1.9}$$

Each element of this family of operators annihilates the subspace $\mathcal{D}_+$, as can be seen, for example, from Eq. (1.7). By Eq. (1.8) we find that for any vector $f\in\mathcal{D}_-\oplus\mathcal{K}$ we have

$$\mathbf{T}(t_1)\mathbf{T}(t_2)f=\mathbf{T}(t_1+t_2)f, \quad t_1,t_2\geqslant 0 \tag{1.10}$$

and so the family $\{\mathbf{T}(t)\}_{t\geqslant 0}$ forms a one parameter continuous semigroup. We observe from Eq. (1.6) that, for $f\in\mathcal{K}$, we have

$$\mathbf{Z}(t_1)\mathbf{Z}(t_2)f=\mathbf{T}(t_1)\mathbf{T}(t_2)f, \quad t_1,t_2\geqslant 0, \quad f\in\mathcal{K}. \tag{1.11}$$

Consider now the Lax–Phillips outgoing translation representation. Denote the outgoing translation representer of an operator $\mathbf{T}(t)$ from the family defined in Eq. (1.9) by $\widetilde{\mathbf{T}}(t)$. Given any vector valued function $f\in L^2_{\mathcal{N}}(\mathbb{R})$ in the outgoing translation representation we have

$$(\widetilde{\mathbf{T}}(t)f)(s)=\begin{cases} f(s-t), & s\leqslant 0,\\ 0, & s>0,\end{cases} \qquad t\geqslant 0. \tag{1.12}$$

Denote the generator of the semigroup $\{\mathbf{T}(t)\}_{t\geqslant 0}$ by $\mathbf{A}$. It is easy to show that the spectrum of $\mathbf{A}$ is $\sigma(\mathbf{A})=\{\mu\,|\,\operatorname{Im}\mu<0\}$. Denoting the outgoing translation representer of $\mathbf{A}$ by $\widetilde{\mathbf{A}}$, the eigenfunctions of $\widetilde{\mathbf{A}}$ are given by

$$f_{\mu,n}(s)=\begin{cases} e^{i\mu s}n, & s\leqslant 0,\\ 0, & s>0,\end{cases}\qquad \forall\ \mu\ \ \mathrm{Im}\,\mu<0,\quad \forall\ n\in\mathcal{N}, \tag{1.13}$$

where $f_{\mu,n}$ is an eigenfunction of $\tilde{\mathbf{A}}$ with eigenvalue μ.

As mentioned above one usually works in the spectral representations rather than in the translation representations. Hence, we would like to find the representation of the semigroup $\{\mathbf{T}(t)\}_{t\geqslant 0}$ and the eigenfunctions $f_{\mu,n}$ in the outgoing spectral representation. For this we need the definition of a Toeplitz operator on the Hardy space $H^+_{\mathcal{N}}(\mathbb{R})$ (see, for example, Ref. 28 and references therein):

Definition [*Toeplitz operator on* $H^+_{\mathcal{N}}(\mathbb{R})$]: *Let* $W\in L^\infty_{\mathcal{B}(\mathcal{N})}(\mathbb{R})$ [$\mathcal{B}(\mathcal{N})$ *is the space of bounded linear operators on* $\mathcal{N}$]. *Let* P_+ *denote the projection of* $L^2_{\mathcal{N}}(\mathbb{R})$ *on* $H^+_{\mathcal{N}}(\mathbb{R})$. *The operator* $T_W: H^+_{\mathcal{N}}(\mathbb{R})\to H^+_{\mathcal{N}}(\mathbb{R})$ *defined by*

$$T_W f=P_+Wf,\quad f\in H^+_{\mathcal{N}}(\mathbb{R})$$

is called a Toeplitz operator [*on* $H^+_{\mathcal{N}}(\mathbb{R})$] *with symbol W. Here Wf is the operator of pointwise application of W to f i.e.,* $(Wf)(\sigma)=W(\sigma)f(\sigma)$, $\sigma\in\mathbb{R}$.

Define $\{u(t)\}_{t\in\mathbb{R}}$, a family of multiplicative operators on $L^2_{\mathcal{N}}(\mathbb{R})$, by

$$[u(t)f](\sigma)=e^{-i\sigma t}f(\sigma),\quad f\in L^2_{\mathcal{N}}(\mathbb{R}),\quad \sigma\in\mathbb{R}. \tag{1.14}$$

Denote by $\hat{\mathbf{T}}(t)$ the outgoing spectral representer of the semigroup element $\mathbf{T}(t)$. Taking the Fourier transform of Eq. (1.12) and using the definition of a Toeplitz operator we find that $\hat{\mathbf{T}}(t)$ is given by

$$\hat{\mathbf{T}}(t)f=P_+u(t)f=T_{u(t)}f,\quad f\in H^+_N(\mathbb{R}),\quad t\geqslant 0 \tag{1.15}$$

and $\hat{\mathbf{T}}(t)f=0$ for $f\in H^-_{\mathcal{N}}(\mathbb{R})$. The semigroup $\{\mathbf{T}(t)\}_{t\geqslant 0}$ is, therefore, represented in the outgoing spectral representation, by the semigroup of Toeplitz operators on $H^+_{\mathcal{N}}(\mathbb{R})$ with symbols $u(t)$ [and a trivial action on $H^-_{\mathcal{N}}(\mathbb{R})$].

Define the map $\hat{\mathbf{W}}_+:\mathcal{H}\mapsto L^2_{\mathcal{N}}(\mathbb{R})$ by $\hat{\mathbf{W}}_+\equiv\mathbf{F}\mathbf{W}_+$ (recall that $\mathbf{W}_+$ is the map of $\mathcal{H}$ onto the outgoing translation representation and $\mathbf{F}$ is the Fourier transform operator). Then $\hat{\mathbf{W}}_+$ maps $\mathcal{H}$ onto the Lax–Phillips outgoing spectral representation and we can summarize the discussion above by the observation that for any $f\in\mathcal{K}$ we have

$$\hat{\mathbf{W}}_+\mathbf{Z}(t)f=\hat{\mathbf{W}}_+\mathbf{T}(t)f=\hat{\mathbf{T}}(t)f_{\mathrm{out}}=T_{u(t)}f_{\mathrm{out}},\quad t\geqslant 0,\quad f\in\mathcal{K}, \tag{1.16}$$

where $f_{\mathrm{out}}=\hat{\mathbf{W}}_+f$ is the outgoing spectral representer of $f\in\mathcal{K}$. Put differently, letting $\hat{\mathbf{Z}}(t)=\hat{\mathbf{W}}_+\mathbf{Z}(t)\hat{\mathbf{W}}_+^{-1}$ be the outgoing spectral representer of $\mathbf{Z}(t)$ and letting $\hat{\mathcal{K}}=\hat{\mathbf{W}}_+\mathcal{K}$ be the subspace of $L^2_{\mathcal{N}}(\mathbb{R})$ representing $\mathcal{K}$ in the outgoing spectral representation, we have

$$\hat{\mathbf{Z}}(t)=T_{u(t)}|\hat{\mathcal{K}}. \tag{1.17}$$

Taking the Fourier transform of Eq. (1.13) we find that in the outgoing spectral representation the eigenfunctions of the generator $\hat{\mathbf{A}}$ of the semigroup $\{\hat{\mathbf{T}}(t)\}_{t\geqslant 0}=\{T_{u(t)}\}_{t\geqslant 0}$ are given by

$$\hat{f}_{\mu,n}(\sigma)=i\frac{n}{\sigma-\mu}\quad \forall\ \mu\quad \mathrm{Im}\,\mu<0,\quad \forall\ n\in\mathcal{N}. \tag{1.18}$$

Equations (1.17) and (1.18) raise the question of the characterization, out of all of the eigenvectors of the generator of the semigroup $\{T_{u(t)}\}_{t\geqslant 0}$ given in Eq. (1.18), of those which are contained in $\hat{\mathcal{K}}$. These will be the eigenvectors of the Lax–Phillips semigroup. The rest of this section deals with this question.

We start with the observation that following the discussion of the properties of the Lax–Phillips S-matrix in the preceding section we know that the subspace $\hat{\mathcal{K}}$, representing $\mathcal{K} \in \mathcal{H}$ in the outgoing spectral representation, is given by

$$\hat{\mathcal{K}} = H^+_{\mathcal{N}}(\mathbb{R}) \ominus \mathcal{S}H^+_{\mathcal{N}}(\mathbb{R}), \tag{1.19}$$

where $\mathcal{S}$ is an operator valued function with the properties (a″)–(c″) listed in the preceding section. Such a function is identified as belonging to the class of operators on $H^+_{\mathcal{N}}(\Pi)$ known as *inner functions*. Thus we conclude that the representation of an element $\mathbf{Z}(t)$ of the Lax–Phillips semigroup in the outgoing spectral representation is always of the form

$$\hat{\mathbf{Z}}(t) = T_{u(t)}|(H^+_{\mathcal{N}}(\mathbb{R}) \ominus \mathcal{S}H^+_{\mathcal{N}}(\mathbb{R})), \quad t \geqslant 0, \tag{1.20}$$

where $\mathcal{S}$ is some inner function. By a slight abuse of terminology a semigroup of the type of Eq. (1.20) will be called in the rest of this paper a Lax–Phillips semigroup. From Eq. (1.20) we can infer the general form of an element of the adjoint semigroup $\mathbf{Z}^*(t)$. Using the notation of Eq. (1.19) we get

$$\hat{\mathbf{Z}}^*(t) = P_{\hat{\mathcal{K}}}T^*_{u(t)}|\hat{\mathcal{K}} = P_{\hat{\mathcal{K}}}T_{\overline{u}(t)}|\hat{\mathcal{K}}, \quad t \geqslant 0. \tag{1.21}$$

In order to understand the structure described here and the origin of Theorem 1.3, we turn to the Sz.-Nagy–Foias theory of contraction operators on Hilbert space.[38] We start with the observation that the family $\{T_{u(t)}\}_{t\geqslant 0}$ is a continuous semigroup of contraction operators and the adjoint family $\{T^*_{u(t)}\}_{t\geqslant 0}=\{T_{\overline{u}(t)}\}_{t\geqslant 0}$ is also a semigroup of contractions. Moreover, $\{T^*_{u(t)}\}_{t\geqslant 0}$ is an isometric semigroup. It is a basic result of the Sz.-Nagy–Foias theory that the study of continuous semigroups of contractions can be reduced to the study of a single contraction operator. If $\{T(t)\}_{t\geqslant 0}$ is a one parameter continuous semigroup of contractions with generator A defined by

$$Ah = \lim_{t\to 0^+} \frac{1}{t}(T(t) - I)h \tag{1.22}$$

then the study of $\{T(t)\}_{t\geqslant 0}$ reduces to the study of its *cogenerator* T defined by

$$T = \frac{A + I}{A - I}. \tag{1.23}$$

It is easy to show that the cogenerator T is a contraction. The elements of a semigroup $\{T(t)\}_{t\geqslant 0}$ are given in terms of the cogenerator T by

$$T(t) = \exp\left(t\frac{T + I}{T - I}\right). \tag{1.24}$$

Denoting the cogenerator of the semigroup $\{T_{\overline{u}(t)}\}_{t\geqslant 0}$ by $S_T: H^+_{\mathcal{N}}(\mathbb{R}) \to H^+_{\mathcal{N}}(\mathbb{R})$, one finds that

$$(S_T f)(\sigma) = \frac{\sigma - i}{\sigma + i} f(\sigma), \quad \sigma \in \mathbb{R}, \quad f \in H^+_{\mathcal{N}}(\mathbb{R}). \tag{1.25}$$

The cogenerator of $\{T_{\overline{u}(t)}\}_{t\geqslant 0}$ is then identified as the canonical shift operator on $H^+_{\mathcal{N}}(\mathbb{R})$ (see, for example, Ref. 28). By Eq. (1.24) we then have

$$T^*_{u(t)} = T_{\overline{u}(t)} = \exp\left(t\frac{S_T + I}{S_T - I}\right). \tag{1.26}$$

Using Eq. (1.21) we find that

$$\hat{\mathbf{Z}}^*(t) = P_{\hat{\mathcal{K}}} \exp\left(t\frac{S_T + I}{S_T - I}\right)\Big| \hat{\mathcal{K}}. \tag{1.27}$$

Two other important ingredients of the Sz.-Nagy–Foias theory are the notions of *unitary and isometric dilation* of a contraction operator and the *functional calculus for completely nonunitary (cnu) contractions*. A dilation of an operator is defined as follows.

Definition (*dilation*): *Assume that for an operator B on a Hilbert space* $\mathcal{H}$ *and an operator A on a Hilbert space* $\mathcal{H}'$ *the following relations hold:*

(i) $\mathcal{H}$ *is a subspace of* $\mathcal{H}'$,
(ii) $Bx = P_{\mathcal{H}}Ax$ *for all* $x \in \mathcal{H}$, *where* $P_{\mathcal{H}}$ *denotes the orthogonal projection from* $\mathcal{H}'$ *into* $\mathcal{H}$.

We call A a dilation of B if (i) and (ii) hold and if

$$B^n x = P_{\mathcal{H}} A^n x, \quad x \in \mathcal{H}, \quad n = 1,2,3, \ldots . \tag{1.28}$$

Sz.-Nagy and Foias prove (Ref. 38, Chap. I) that for every contraction T on a Hilbert space $\mathcal{H}$ there exists an isometric (and a unitary) dilation V on some Hilbert space $\mathcal{R}$, which is moreover minimal in the sense that

$$\mathcal{R} = \vee_0^\infty V^n \mathcal{H}. \tag{1.29}$$

The minimal isometric dilation is determined up to an isomorphism. The space $\mathcal{H}$ is invariant for V^* and we have

$$TP_{\mathcal{H}} = P_{\mathcal{H}} V, \quad T^* = V^*|\mathcal{H}, \tag{1.30}$$

where $P_{\mathcal{H}}$ denotes the orthogonal projection from $\mathcal{R}$ onto $\mathcal{H}$.

Sz.-Nagy and Foias show (Ref. 38, Chap. III) that the function space $H^\infty(D)$ (D is the open unit disk), regarded as an algebra with an involution under the usual addition and multiplication of functions, can be used to define a *functional calculus for completely nonunitary (cnu) contractions*. By this we mean that, for a cnu contraction T on a Hilbert space $\mathcal{H}$ there exists an algebra homomorphism of $H^\infty(D)$ into $B(\mathcal{H})$ (the space of bounded operators on $\mathcal{H}$). The map providing this homomorphism is defined, for a function $a \in H^\infty(D)$ having the series expansion $a(z) = \Sigma_{n=0}^\infty c_n z^n$, by

$$a(z) = \sum_{n=0}^{\infty} c_n z^n \to a(T) = \lim_{r \to 1^-} a(rT) = \lim_{r \to 1^-} \left(\sum_{n=0}^{\infty} c_n r^n T^n \right).$$

Under this mapping we find, for a function $a \in H^\infty(D)$ and an isometric dilation V of a cnu contraction T, the following relation:

$$a(T)h = P_{\mathcal{H}} a(V)h, \quad h \in \mathcal{H}, \quad a \in H^\infty(D). \tag{1.31}$$

Define

$$T_{\hat{\mathbf{Z}}^*} \equiv P_{\hat{\mathcal{K}}} S_T | \hat{\mathcal{K}}, \tag{1.32}$$

where $\hat{\mathcal{K}} \in H^+(\mathbb{R})$ is defined in Eq. (1.19). The operator $P_{\hat{\mathcal{K}}} S_T | \hat{\mathcal{K}}$ is called a *compression of the shift* into the subspace $\hat{\mathcal{K}}$. It can be shown that, for any inner function $\mathcal{S}$, the shift S_T is an isometric dilation of the compression of S_T into $\hat{\mathcal{K}}$, i.e., it is an isometric dilation of $T_{\hat{\mathbf{Z}}^*}$. Since the function

$$e_t(z) \equiv \exp\left(t\frac{z+1}{z-1}\right) \tag{1.33}$$

is inner, Eq. (1.31) implies that

$$\exp\left(t\frac{T_{\hat{\mathbf{Z}}^*}+I}{T_{\hat{\mathbf{Z}}^*}-I}\right)=P_{\hat{\mathcal{K}}}\exp\left(t\frac{S_T+I}{S_T-I}\right)\Big|\hat{\mathcal{K}}=P_{\hat{\mathcal{K}}}T_{\overline{u}(t)}|\hat{\mathcal{K}}=\hat{\mathbf{Z}}^*(t). \tag{1.34}$$

The operator $T_{\hat{\mathbf{Z}}^*}$ is therefore the cogenerator of the semigroup $\{\hat{\mathbf{Z}}^*(t)\}_{t\geqslant 0}$. Indeed, given the family of functions $\phi_t\in H^\infty(D)$ defined by

$$\phi_t(z)=\frac{z-1+t}{z-1-t},\quad t>0,$$

Sz.-Nagy and Foias prove (Ref. 38, Chap. III, Theorem 8.1) that the cogenerator T of a contractive semigroup $\{T(t)\}_{t\geqslant 0}$ is obtained by

$$T=\lim_{t\to 0^+}\phi_t(T(t))$$

and applying this relation to $\{\hat{\mathbf{Z}}^*(t)\}_{t\geqslant 0}$ we get

$$\lim_{t\to 0^+}\phi_t(\hat{\mathbf{Z}}^*(t))=\lim_{t\to 0^+}\phi_t\circ e_t(T_{\hat{\mathbf{Z}}^*(t)})=\lim_{t\to 0^+}P_{\hat{\mathcal{K}}}\phi_t\circ e_t(S_T)|\hat{\mathcal{K}}=\lim_{t\to 0^+}P_{\hat{\mathcal{K}}}\phi_t(\overline{u}(t))|\hat{\mathcal{K}}=P_{\hat{\mathcal{K}}}S_T|\hat{\mathcal{K}}=T_{\hat{\mathbf{Z}}^*}.$$

We conclude that *the compression of the shift to the subspace $\hat{\mathcal{K}}$ is the cogenerator of the semigroup* $\{\hat{\mathbf{Z}}^*(t)\}_{t\geqslant 0}$ and hence

$$T_{\hat{\mathbf{Z}}^*}=P_{\hat{\mathcal{K}}}S_T|\hat{\mathcal{K}}=\frac{\hat{\mathbf{B}}^*+I}{\hat{\mathbf{B}}^*-I}, \tag{1.35}$$

where $\hat{\mathbf{B}}^*$ is the generator of the semigroup $\{\hat{\mathbf{Z}}^*(t)\}_{t\geqslant 0}$. We note also that, using Eq. (1.30), we obtain

$$T_{\hat{\mathbf{Z}}}=\frac{\hat{\mathbf{B}}+I}{\hat{\mathbf{B}}-I}=S_T^*|\hat{\mathcal{K}}, \tag{1.36}$$

where $\hat{\mathbf{B}}$ is the generator and $T_{\hat{\mathbf{Z}}}$ is the cogenerator of the Lax–Phillips semigroup $\{\mathbf{Z}(t)\}_{t\geqslant 0}$.

For a contraction T on a Hilbert space $\mathcal{H}$ we define the *defect operators* D_T and D_{T^*} by

$$D_T\equiv(I-T^*T)^{1/2},\quad D_{T^*}\equiv(I-TT^*)^{1/2}.$$

The *defect spaces* $\mathcal{D}_T$ and $\mathcal{D}_{T^*}$ are defined by

$$\mathcal{D}_T=\overline{D_T\mathcal{H}},\quad \mathcal{D}_{T^*}=\overline{D_{T^*}\mathcal{H}}.$$

For every complex number λ for which the operator $I-\lambda T^*$ is boundedly invertible, define

$$\Theta_T(\lambda)\equiv\left[-T+\lambda D_{T^*}(I-\lambda T^*)^{-1}D_T\right]|\mathcal{D}_T \tag{1.37}$$

the values of the operator valued function $\Theta_T(\lambda)$ are bounded operators from $\mathcal{D}_T$ into $\mathcal{D}_{T^*}$. When considered on the unit disk D, $\Theta_T(\lambda)$ is a purely contractive, analytic, operator valued function, i.e., it is a contraction from $\mathcal{D}_T$ into $\mathcal{D}_{T^*}$ for every λ in the unit disk. The function $\Theta_T(\lambda)$ is called the *characteristic function of the contraction T* (see Ref. 38, Chap. VI). The main theorem of the Lax–Phillips scattering theory, relating eigenvalues of the generator of the Lax–Phillips semigroup and singularities of the Lax–Phillips *S*-matrix, is then a direct result of the following theorem, proved by Sz.-Nagy and Foias (Ref. 38, Chap. VI, Theorem 4.1).

Theorem 1.4: *Let T be a cnu contraction on $\mathcal{H}$. Denote by α_T the set of points $\mu\in D$ for which the operator $\Theta_T(\mu)$ is not boundedly invertible, together with the points $\mu\in C$ not lying on any of the open arcs of C on which $\Theta_T(\lambda)$ is a unitary operator valued analytic function of λ. Furthermore, denote by α_T^0 the set of points $\mu\in D$ for which $\Theta_T(\lambda)$ is not invertible at all. Then*

$$\sigma(T) = \alpha_T$$

and

$$\sigma_p(T) = \alpha_T^0.$$

Given the cogenerator $T_{\hat{\mathbf{Z}}^*}$ we can define its characteristic function $\Theta_{T_{\hat{\mathbf{Z}}^*}}(\lambda)$ and obtain the spectrum of $T_{\hat{\mathbf{Z}}^*}$ in the closed unit disk through Theorem 1.4. In this particular case the function $\Theta_{T_{\hat{\mathbf{Z}}^*}}$ is an inner function on the unit disk. We can now pass from the unit disk to the upper half-plane by setting

$$\mathcal{S}(z) = \Theta_{T_{\hat{\mathbf{Z}}^*}}\left(\frac{z-i}{z+i}\right), \quad \mathrm{Im}\, z > 0. \tag{1.38}$$

The operator valued function $\mathcal{S}$ on the left-hand side (lhs) of Eq. (1.38) is exactly the inner function appearing in Eq. (1.19) or Eq. (1.20), defining the subspace $\hat{\mathcal{K}} \subset H^+_{\mathcal{N}}(\mathbb{R})$ and identical to the Lax–Phillips *S*-matrix. Theorem 1.4 above then immediately implies Theorem 1.3.

Recapitulating the discussion in this section, we have seen that $\hat{\mathbf{Z}}(t)$, the outgoing spectral representer of an element of the Lax–Phillips semigroup $\mathbf{Z}(t)$, is of the form of a restriction of a Toeplitz operator $T_{u(t)}$ to a subspace $\hat{\mathcal{K}} \subset H^+_{\mathcal{N}}(\mathbb{R})$ given by $\hat{\mathcal{K}} = H^+_{\mathcal{N}}(\mathbb{R}) \ominus \mathcal{S}H^+_{\mathcal{N}}(\mathbb{R})$, for some inner function $\mathcal{S}$. The Lax–Phillips *S*-matrix $\mathcal{S}$ is essentially the characteristic function for the generator $\hat{\mathbf{B}}^*$ of the semigroup $\hat{\mathbf{Z}}^*(t)$. The cogenerator $T_{\hat{\mathbf{Z}}^*}$ of $\hat{\mathbf{Z}}^*(t)$ is identified as a compression of the shift and its characteristic function is an inner function. The correspondence between the points in Π where $\mathcal{S}$ has a nontrivial null space (or poles of the analytic continuation of $\mathcal{S}$ to $\overline{\Pi}$) and eigenvalues of the generator of $\hat{\mathbf{Z}}(t)$ [or $\mathbf{Z}(t)$] then arises from a theorem in operator theory (namely Theorem 1.4 above) relating the points of singularity of the characteristic function for a contraction T to the spectrum of T.

II. DESCRIPTION OF RESONANCES

A. Preliminary discussion

In this section the structures described in Sec. I B are utilized for the description of quantum mechanical resonances. The structures developed below bear general resemblance to the structure of the Lax–Phillips scattering theory. For a given scattering problem an "incoming representation" and an "outgoing representation" are defined, as well as the "*S*-matrix" transforming between the two. The evolution goes in these "representations" into the analogue of translation, i.e., the semigroup of Toeplitz operators $\{T_{u(t)}\}_{t\geq 0}$. Moreover, beyond general resemblance, the framework developed below makes explicit use of the fundamental structures of the Lax–Phillips theory originating from the Sz.-Nagy–Foias theory of contractions. Time evolution of resonances is actually described by a Lax–Phillips type semigroup of the form of Eq. (1.20) and the relation between eigenvalues corresponding to resonances and zeros of the *S*-matrix results from the Sz.-Nagy–Foias theory in the same way as described above in Sec. I B.

The starting point for the developments in this section is a method, proposed by Grossmann,[13] for the description of quantum mechanical resonances through the use of Hilbert space nesting.

Let $\mathcal{H}_0$ and $\mathcal{H}_1$ be (infinitely dimensional, separable) Hilbert spaces. A nesting map of $\mathcal{H}_1$ into $\mathcal{H}_0$ is a linear mapping θ such that

(1) the domain of θ is $\mathcal{H}_1$ and θ is continuous on $\mathcal{H}_1$,
(2) the range of θ is dense in $\mathcal{H}_0$,
(3) θ is one to one.

The adjoint of θ is defined in the usual way by the relation

$$(f,\theta g)_{\mathcal{H}_0} = (\theta^* f, g)_{\mathcal{H}_1} \tag{2.1}$$

θ^* is a nesting map of $\mathcal{H}_0$ into $\mathcal{H}_1$. We note that the properties of the map θ puts it in the class of *quasiaffine transforms* between $\mathcal{H}_1$ and $\mathcal{H}_0$ (see, for example, Refs. 38 and 21). A nested Hilbert space is defined as follows.

Definition (nested Hilbert space): A nested Hilbert space $(\mathcal{H}_1,\mathcal{H}_0,\theta)$ *is defined to be a structure consisting of the two Hilbert spaces* $\mathcal{H}_0$ *and* $\mathcal{H}_1$*, a nesting map* θ *of* $\mathcal{H}_1$ *into* $\mathcal{H}_0$ *and the adjoint nesting map* θ^*.

Given a nested Hilbert space $(\mathcal{H}_1,\mathcal{H}_0,\theta)$ and an operator $\mathbf{A}$ on $\mathcal{H}_0$, Grossmann considereds two types of operators, $\tilde{\mathbf{A}}$ and $\hat{\mathbf{A}}$ defined on $\mathcal{H}_1$. Respectively, these operators are defined to be

$$\tilde{\mathbf{A}} = \theta^* \mathbf{A} \theta \tag{2.2}$$

and

$$\hat{\mathbf{A}} = \theta^{-1} \mathbf{A} \theta. \tag{2.3}$$

We observe that the operator $\hat{\mathbf{A}}$ in Eq. (2.3) is well defined for any operator $\mathbf{A}$ which leaves the range of θ invariant. Let $f \in \mathcal{H}_1$ be in the domain of $\tilde{\mathbf{A}}$. For every $g \in \mathcal{H}_1$ we then have

$$(g,\tilde{\mathbf{A}} f)_{\mathcal{H}_1} = (g,\theta^* \mathbf{A} \theta f)_{\mathcal{H}_1} = (\theta g, \mathbf{A} \theta f)_{\mathcal{H}_0}.$$

We see that matrix elements of $\mathbf{A}$ on the dense set $\theta\mathcal{H}_1 \subset \mathcal{H}_0$ can be calculated as matrix elements of $\tilde{\mathbf{A}}$ on $\mathcal{H}_1$. Put differently, the operator $\tilde{\mathbf{A}}$ on $\mathcal{H}_1$ may be defined through the knowledge of a subset of the matrix elements of $\mathbf{A}$ on $\mathcal{H}_0$. Moreover, if $\mathbf{A}$ is bounded and self-adjoint then $\tilde{\mathbf{A}}$ is also bounded and self-adjoint. Grossmann considers the resolvent $\mathbf{G}(z)=(z-\mathbf{H})^{-1}$ of a scattering Hamiltonian $\mathbf{H}$ and defines through the nesting $(\mathcal{H}_1,\mathcal{H}_0,\theta)$ the operator $\tilde{\mathbf{G}}(z)$ according to Eq. (2.2). Since the matrix elements of $\tilde{\mathbf{G}}(z)$ between elements of $\mathcal{H}_1$ are a subset of the set of matrix elements of $\mathbf{G}(z)$ on $\mathcal{H}_0$, it may happen that $\tilde{\mathbf{G}}(z)$ has a larger domain of analyticity than $\mathbf{G}(z)$. In particular, the domain of analyticity of $\tilde{\mathbf{G}}(z)$ may cross the natural boundary of analyticity of $\mathbf{G}(z)$ along the positive real axis so that it may be possible to reach a second Riemann sheet resonance pole of the resolvent.

The matrix elements of $\hat{\mathbf{A}}$ are, on the other hand, generically different from those of $\mathbf{A}$ due to the different scalar product and, in general, $\hat{\mathbf{A}}$ is neither bounded nor symmetric. It is possible to show that the eigenvalues of $(\hat{\mathbf{A}})^*$ include the "improper" eigenvalues of $\mathbf{A}^*$.

Let $\mathbf{A}$ be a densely defined operator on $\mathcal{H}_0$ such that the operator $(\hat{\mathbf{A}^*})^*$ is also densely defined. A complex number z_0 is defined to be a generalized eigenvalue of $\mathbf{A}$ if there is an element $f \in \mathcal{H}_1$ such that

$$(\hat{\mathbf{A}^*})^* f = z_0 f. \tag{2.4}$$

In particular, it is easy to show that eigenvalues of $\mathbf{A}$ are also eigenvalues of $(\hat{\mathbf{A}^*})^*$.

If in the Hilbert space nesting $(\mathcal{H}_1,\mathcal{H}_0,\theta)$ the map $\theta:\mathcal{H}_1 \mapsto \mathcal{H}_0$ is a contraction then we have a *contractive nesting* of $\mathcal{H}_1$ into $\mathcal{H}_0$. This property of θ *a priori* adds more structure to the resulting framework. A short discussion of this point is found in Sec. III below.

B. Main results

In a similar way to the Lax–Phillips scattering theory, this work centers around three main results: the existence of appropriate incoming and outgoing nesting structures, the existence of a continuous semigroup of contraction operators and the identification of the resonances of the theory, the eigenvalues of the generator of the semigroup, with zeros of the "*S*-matrix" mapping between the incoming and outgoing nesting structures.

Starting with the nesting structures, we have the following theorem.

Theorem 2.1. (outgoing contractive nesting): *Let* $\mathbf{H}_0$ *and* $\mathbf{H}$ *be self-adjoint operators on a Hilbert space* $\mathcal{H}$. *Let* $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ *be the unitary evolution group on* $\mathcal{H}$ *generated by* $\mathbf{H}$ *[i.e.,* $\mathbf{U}(t)=\exp(-i\mathbf{H}t)$*]. Denote by* $\mathcal{H}_{ac}^0$ *and* $\mathcal{H}_{ac}$, *respectively, the absolutely continuous subspaces of* $\mathbf{H}_0$ *and* $\mathbf{H}$. *Assume that the absolutely continuous spectrum of* $\mathbf{H}_0$ *and* $\mathbf{H}$ *has multiplicity one and that it satisfies* $\sigma_{ac}(\mathbf{H}_0)=\sigma_{ac}(\mathbf{H})=\mathbb{R}^+$. *Assume furthermore that the Møller wave operator* $\mathbf{\Omega}^-\equiv\mathbf{\Omega}^-(\mathbf{H}_0,\mathbf{H}):\mathcal{H}_{ac}^0\mapsto\mathcal{H}_{ac}$ *exists and is complete. Then there exists a map* $\hat{\mathbf{\Omega}}_+:\mathcal{H}_{ac}\mapsto H^+(\mathbb{R})$ *such that*

(a) $(\mathcal{H}_{ac},H^+(\mathbb{R}),\hat{\mathbf{\Omega}}_+)$ *is a contractive Hilbert space nesting of* $\mathcal{H}_{ac}$ *into* $H^+(\mathbb{R})$.

(b) *For every* $t\geqslant 0$ *define the Grossmann type operator* $\hat{\mathbf{U}}^*(t):H^+(\mathbb{R})\mapsto H^+(\mathbb{R})$ *according to Eq. (2.3), i.e.,* $\hat{\mathbf{U}}^*(t)=(\hat{\mathbf{\Omega}}_+^*)^{-1}\mathbf{U}^*(t)\hat{\mathbf{\Omega}}_+^*$. *These operators are well defined and, for every* $t\geqslant 0$ *and every* $f\in\mathcal{H}_{ac}$ *we have*

$$\hat{\mathbf{\Omega}}_+\mathbf{U}(t)f=(\widehat{\mathbf{U}^*(t)})^*\hat{\mathbf{\Omega}}_+f=T_{u(t)}f_{\text{out}},\quad t\geqslant 0, \tag{2.5}$$

where $f_{\text{out}}=\hat{\mathbf{\Omega}}_+f$ *and* $T_{u(t)}$ *is the Toeplitz operator with symbol* $u(t)$ *given by Eq. (1.14).*

The nesting $(\mathcal{H}_{ac},H^+(\mathbb{R}),\hat{\mathbf{\Omega}}_+)$ is referred to below as the *outgoing contractive nesting of* $\mathcal{H}_{ac}$. *Remarks:*

(1) It follows from Eq. (2.4) and the discussion above that eigenvalues of $(\widehat{\mathbf{U}^*(t)})^*:H^+(\mathbb{R})\mapsto H^+(\mathbb{R})$, are generalized eigenvalues of $\mathbf{U}(t)$ (for $t\geqslant 0$).

(2) Obviously, the lhs of Eq. (2.5) can be defined for every $t\in(-\infty,\infty)$. Equation (2.5), however, is valid for $t\geqslant 0$.

Proof of Theorem 2.1: At the center of the proof of Theorem 2.1 lie two theorems, proved by Van Winter, that enable us to define a contractive nesting of $L^2(\mathbb{R}^+)$ into $H^+(\mathbb{R})$. Taken together, the following theorems are referred to below as the Van Winter theorem.[39]

Theorem 2.2 (Van Winter): *The class of functions* f *which are analytic, regular in the upper half-plane, and have the property that*

$$\int_0^\infty \mathrm{d}r|f(re^{i\phi})|^2 \tag{2.6}$$

is uniformly bounded in ϕ *for* $0<\phi<\pi$, *is identical to the Hardy class* $H^2(\Pi)$. *For each such* f *there exists a boundary value function* $f(r)$ $(r>0)$ *on* $\mathbb{R}^+$. *The boundary values* $f(r)$ *of functions* $f(re^{i\phi})$ *in* $H^2(\Pi)$ *are dense in* $L^2(\mathbb{R}^+)$.

Theorem 2.3 (Van Winter): *A complex valued function* f *defined on the upper half-plane* Π *is in* $H^2(\Pi)$ *if and only if it is given by an inverse Mellin transform as*

$$f(re^{i\phi})=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}\mathrm{d}s\,E(s)(re^{i\phi})^{-is-1/2} \tag{2.7}$$

for some function $E(s)$ *satisfying*

$$\int_{-\infty}^{+\infty}\mathrm{d}s(1+e^{2\pi s})|E(s)|^2<\infty$$

in this case the Mellin transform of f *is given by*

$$E(s,\phi)=\frac{1}{\sqrt{2\pi}}\int_0^\infty \mathrm{d}r\,f(re^{i\phi})r^{is-1/2}=e^{\phi s-i(\phi/2)}E(s). \tag{2.8}$$

It can be shown[39] that in Eq. (1.8) it is possible to take ϕ to zero, i.e., that if $f(r)$ is the boundary value on $\mathbb{R}^+$ of a function $f(re^{i\phi})$ in $H^2(\Pi)$ then

$$E(s) = \frac{1}{\sqrt{2\pi}} \int_0^\infty \mathrm{d}r\, f(r) r^{is-1/2}. \tag{2.9}$$

By combining Theorem 2.2 and Theorem 2.3 we find that any function in $H^2(\Pi)$ can be reconstructed from its boundary value on the positive real axis. Define $\theta: H^+(\mathbb{R}) \mapsto L^2(\mathbb{R}^+)$ by taking, for each function $f \in H^2(\Pi)$, the restriction to $\mathbb{R}^+$ of the boundary value of f on the real axis. Then θ is one to one and θ^{-1} can be defined. It is also important to note that the Van Winter theorem can be applied to boundary values of Hardy class functions on the negative real axis, a fact which is used below.

Using the Van Winter theorem we easily obtain the following result.

Proposition 2.1: The map $\theta: H^+(\mathbb{R}) \to L^2(\mathbb{R}^+)$ is a contractive nesting map, $(H^+(\mathbb{R}), L^2(\mathbb{R}^+), \theta)$ is a contractive nesting of $H^+(\mathbb{R})$ into $L^2(\mathbb{R}^+)$ and $(L^2(\mathbb{R}^+), H^+(\mathbb{R}), \theta^*)$ is a contractive nesting of $L^2(\mathbb{R}^+)$ into $H^+(\mathbb{R})$.

Proof: From the Van Winter theorem we know that the map θ is injective and that $\theta H^+(\mathbb{R}) \subset L^2(\mathbb{R}^+)$ is dense in $L^2(\mathbb{R}^+)$. Denote by $H^-(\mathbb{R})$ the space of boundary values on $\mathbb{R}$ of functions belonging to $H^2(\overline{\Pi})$ (recall that $\overline{\Pi}$ is the lower half of the complex plane). We have

$$L^2(\mathbb{R}) = H^-(\mathbb{R}) \oplus H^+(\mathbb{R}). \tag{2.10}$$

$H^+(\mathbb{R})$ is then a subspace of $L^2(\mathbb{R})$ and it inherits its scalar product from that of $L^2(\mathbb{R})$. By the definition of θ we have for $f \in H^+(\mathbb{R})$,

$$\|\theta f\|^2_{L^2(\mathbb{R}^+)} = (\theta f, \theta f)_{L^2(\mathbb{R}^+)} < (f,f)_{L^2(\mathbb{R})} = (f,f)_{H^+(\mathbb{R})} = \|f\|^2_{H^+(\mathbb{R})}. \tag{2.11}$$

$\theta: H^+(\mathbb{R}) \mapsto L^2(\mathbb{R}^+)$ is therefore a contraction and $(H^+(\mathbb{R}), L^2(\mathbb{R}^+), \theta)$ is a contractive nesting of $H^+(\mathbb{R})$ into $L^2(\mathbb{R}^+)$. Defining the adjoint map $\theta^*: L^2(\mathbb{R}^+) \mapsto H^+(\mathbb{R})$ through the relation

$$(\theta x, y)_{L^2(\mathbb{R}^+)} = (x, \theta^* y)_{H^+(\mathbb{R})}, \quad x \in H^+(\mathbb{R}), \quad y \in L^2(\mathbb{R}^+) \tag{2.12}$$

we conclude that $(L^2(\mathbb{R}^+), H^+(\mathbb{R}), \theta^*)$ is a contractive nesting of $L^2(\mathbb{R}^+)$ into $H^+(\mathbb{R})$.

■

Consider the spectral (or energy) representation for $\mathbf{H}_0$. The assumption $\sigma_{ac}(\mathbf{H}_0) = \mathbb{R}^+$ (and that the multiplicity is one) leads to the existence of a unitary map $U: \mathcal{H}^0_{ac} \mapsto L^2(\mathbb{R}^+)$ defining a representation of $\mathcal{H}^0_{ac}$ in terms of the space $L^2(\mathbb{R}^+)$. We can now use the unitarity of the Møller wave operator $\mathbf{\Omega}^-: \mathcal{H}^0_{ac} \mapsto \mathcal{H}_{ac}$ and define a unitary map $\mathbf{W}^+: \mathcal{H}_{ac} \mapsto L^2(\mathbb{R}^+)$ by

$$\mathbf{W}^+ \equiv U(\mathbf{\Omega}^-)^*. \tag{2.13}$$

$\mathbf{W}^+$ is a transformation to a spectral representation for $\mathbf{H}|\mathcal{H}_{ac}$. Applying the contractive nesting $(L^2(\mathbb{R}^+), H^+(\mathbb{R}), \theta^*)$ then allows us to define a map

$$\hat{\mathbf{\Omega}}_+: \mathcal{H}_{ac} \mapsto H^+(\mathbb{R})$$

by

$$\hat{\mathbf{\Omega}}_+ \equiv \theta^* \mathbf{W}^+ = \theta^* U (\mathbf{\Omega}^-)^*. \tag{2.14}$$

Since $\mathbf{W}^+$ is unitary and θ^* is a contractive nesting map we find that $(\mathcal{H}_{ac}, H^+(\mathbb{R}), \hat{\mathbf{\Omega}}_+)$ is a contractive nesting of $\mathcal{H}_{ac}$ into $H^+(\mathbb{R})$ and (a) is proved.

Next, we turn to the proof of (b). Assume that the range of $\hat{\mathbf{\Omega}}^*_+$ is invariant for an operator $\mathbf{A}: \mathcal{H}_{ac} \mapsto \mathcal{H}_{ac}$. Then, it is possible to use the nesting $(H^+(\mathbb{R}), \mathcal{H}_{ac}, \hat{\mathbf{\Omega}}^*_+)$ to define the Grossmann type operator $\hat{\mathbf{A}}: H^+(\mathbb{R}) \mapsto H^+(\mathbb{R})$ according to Eq. (2.3), i.e.,

$$\hat{\mathbf{A}} = (\hat{\mathbf{\Omega}}_+^*)^{-1}\mathbf{A}\hat{\mathbf{\Omega}}_+^*. \tag{2.15}$$

The generalized eigenvalues of $\mathbf{A}$ are then eigenvalues of the operator $(\hat{\mathbf{A}^*})^*: H^+(\mathbb{R}) \mapsto H^+(\mathbb{R})$ given by

$$(\hat{\mathbf{A}^*})^* = \hat{\mathbf{\Omega}}_+\mathbf{A}^{**}((\hat{\mathbf{\Omega}}_+^*)^{-1})^*. \tag{2.16}$$

The first equality in Eq. (2.5) results from the following proposition

Proposition 2.2: For any bounded operator $\mathbf{A}: \mathcal{H}_{ac} \mapsto \mathcal{H}_{ac}$ *satisfying* $\mathbf{A}^{**} = \mathbf{A}$ *and such that* $\hat{\mathbf{\Omega}}_+^* H^+(\mathbb{R}) \subset \mathcal{H}_{ac}$ *is invariant for* $\mathbf{A}$*, and for any* $h \in \mathcal{H}_{ac}$ *we have*

$$(\hat{\mathbf{A}^*})^* \hat{\mathbf{\Omega}}_+ h = \hat{\mathbf{\Omega}}_+ \mathbf{A} h.$$

Proof: Since $\hat{\mathbf{\Omega}}_+^*$ is a nesting map of $H^+(\mathbb{R})$ into $\mathcal{H}_{ac}$ the map $(\hat{\mathbf{\Omega}}_+^*)^{-1}$ is defined on the dense set $\hat{\mathbf{\Omega}}_+^* H^+(\mathbb{R}) \subset \mathcal{H}_{ac}$ and we can define the map $((\hat{\mathbf{\Omega}}_+^*)^{-1})^*$ through the relation

$$(g,f)_{H^+(\mathbb{R})} = ((\hat{\mathbf{\Omega}}_+^*)^{-1}\hat{\mathbf{\Omega}}_+^* g, f)_{H^+(\mathbb{R})} = (\hat{\mathbf{\Omega}}_+^* g, ((\hat{\mathbf{\Omega}}_+^*)^{-1})^* f)_{\mathcal{H}_{ac}}$$

which holds for any $f \in D(((\hat{\mathbf{\Omega}}_+^*)^{-1})^*)$ and any $g \in H^+(\mathbb{R})$. It is then true that

$$((\hat{\mathbf{\Omega}}_+^*)^{-1})^* = (\hat{\mathbf{\Omega}}_+^{**})^{-1} = \hat{\mathbf{\Omega}}_+^{-1}. \tag{2.17}$$

From Eq. (2.16) and Eq. (2.17) we conclude that, for any $f \in \hat{\mathbf{\Omega}}_+ \mathcal{H}_{ac}$ we have

$$(\hat{\mathbf{A}^*})^* f = \hat{\mathbf{\Omega}}_+ \mathbf{A}^{**} \hat{\mathbf{\Omega}}_+^{-1} f, \quad f \in \hat{\mathbf{\Omega}}_+ \mathcal{H}_{ac}. \tag{2.18}$$

By the injective property of $\hat{\mathbf{\Omega}}_+$, for any $f \in \hat{\mathbf{\Omega}}_+ \mathcal{H}_{ac}$ there is a unique $h \in \mathcal{H}_{ac}$ such that $f = \hat{\mathbf{\Omega}}_+ h$. Hence, by Eq. (2.18) we have

$$(\hat{\mathbf{A}^*})^* \hat{\mathbf{\Omega}}_+ h = \hat{\mathbf{\Omega}}_+ \mathbf{A}^{**} h, \quad h \in \mathcal{H}_{ac}. \tag{2.19}$$

In particular, if $\mathbf{A}$ satisfies $\mathbf{A}^{**} = \mathbf{A}$ we find that

$$(\hat{\mathbf{A}^*})^* \hat{\mathbf{\Omega}}_+ h = \hat{\mathbf{\Omega}}_+ \mathbf{A} h, \quad h \in \mathcal{H}_{ac}. \tag{2.20}$$

■

It is easy to see that, for $t \geqslant 0$, $\mathbf{U}(t)\hat{\mathbf{\Omega}}_+^* H^+(\mathbb{R}) \subset \hat{\mathbf{\Omega}}_+^* H^+(\mathbb{R})$. Indeed we have

$$\mathbf{U}(t)\hat{\mathbf{\Omega}}_+^* H^+(\mathbb{R}) = \mathbf{U}(t)(\mathbf{W}^+)^* \theta H^+(\mathbb{R}) = (\mathbf{W}^+)^* \overline{u}(t) \theta H^+(\mathbb{R}) \subset (\mathbf{W}^+)^* \theta H^+(\mathbb{R}) = \hat{\mathbf{\Omega}}_+^* H^+(\mathbb{R})$$

hence, we can apply Proposition 2.2 to $\mathbf{U}(t)$ $(t \geqslant 0)$ and obtain the first equality in Eq. (2.5).

In order to prove the second equality in Eq. (2.5) we need to obtain a more explicit expression for the map $\hat{\mathbf{\Omega}}_+$. We have

Proposition 2.3: Define the inclusion map $\mathbf{I}: L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R})$ *by*

$$(\mathbf{I}\phi)(\sigma) = \begin{cases} \phi(\sigma), & \sigma \geqslant 0, \\ 0, & \sigma < 0, \end{cases} \quad \phi \in L^2(\mathbb{R}^+). \tag{2.21}$$

Let $\mathbf{P}_+$ *be the orthogonal projection of* $L^2(\mathbb{R})$ *onto* $H^+(\mathbb{R})$ *and let* $\mathbf{W}^+$ *be the unitary map defined in Eq. (2.13). Then the map* $\hat{\mathbf{\Omega}}_+: \mathcal{H}_{ac} \mapsto H^+(\mathbb{R})$ *is given by*

$$\hat{\mathbf{\Omega}}_+ = \mathbf{P}_+ \mathbf{I} \mathbf{W}^+. \tag{2.22}$$

Proof: We first need an explicit expression for the map θ^*. Regarding $L^2(\mathbb{R}^+)$ as a closed

subspace of $L^2(\mathbb{R})$, the inclusion map $\mathbf{I}: L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R})$ is given by Eq. (2.21). The lhs of Eq. (2.12) can be written then as

$$(\theta x, y)_{L^2(\mathbb{R}^+)} = (\mathbf{I}\theta x, \mathbf{I}y)_{L^2(\mathbb{R})}. \tag{2.23}$$

Making use of the decomposition of $L^2(\mathbb{R})$, Eq. (2.10), we observe that any $y \in L^2(\mathbb{R}^+)$ correspond to the following decompositon into an orthogonal sum:

$$\mathbf{I}y = y_+ + y_-, \quad y_+ \in H^+(\mathbb{R}), \quad y_- \in H^-(\mathbb{R}). \tag{2.24}$$

Equation (2.21) then implies that

$$y_+(\sigma) = -y_-(\sigma), \quad \sigma < 0. \tag{2.25}$$

Inserting the decomposition, Eq. (2.24), into the rhs of Eq. (2.23) we obtain

$$(\theta x, y)_{L^2(\mathbb{R}^+)} = (\mathbf{I}\theta x, y_+ + y_-)_{L^2(\mathbb{R})} = \int_{-\infty}^{+\infty} \mathrm{d}\sigma \overline{(\mathbf{I}\theta x)(\sigma)}(y_+(\sigma) + y_-(\sigma)). \tag{2.26}$$

We can now use Eq. (2.26) to obtain the following identity:

$$\int_{-\infty}^{+\infty} \mathrm{d}\sigma \overline{(\mathbf{I}\theta x)(\sigma)}(y_+(\sigma) + y_-(\sigma)) = \int_{-\infty}^{+\infty} \mathrm{d}\sigma\, \overline{x(\sigma)}(y_+(\sigma) + y_-(\sigma)) = \int_{-\infty}^{+\infty} \mathrm{d}\sigma\, \overline{x(\sigma)} y_+(\sigma) = (x, y_+)_{H^+(\mathbb{R})}, \tag{2.27}$$

where the second equality follows from the orthogonality of $H^+(\mathbb{R})$ and $H^-(\mathbb{R})$. Equations (2.26) and (2.27) imply that

$$(\theta x, y)_{L^2(\mathbb{R}^+)} = (x, y_+)_{H^+(\mathbb{R})}. \tag{2.28}$$

Comparing Eq. (2.12) and Eq. (2.28) we find the desired expression for the map $\theta^*: L^2(\mathbb{R}^+) \mapsto H^+(\mathbb{R})$,

$$\theta^* y = y_+ = \mathbf{P}_+ \mathbf{I} y, \quad y \in L^2(\mathbb{R}^+), \quad y_+ \in H^+(\mathbb{R}). \tag{2.29}$$

Equation (2.14) can now be written in the form

$$\hat{\mathbf{\Omega}}_+ = \mathbf{P}_+ \mathbf{I} \mathbf{W}^+. \tag{2.30}$$

■

Observe that, for any $h \in \mathcal{H}_{ac}$ we have

$$\mathbf{I}\mathbf{W}^+ \mathbf{U}(t) h = \mathbf{I} U \hat{\mathbf{\Omega}}^{-*} \mathbf{U}(t) h = \mathbf{I} U \mathbf{U}_0(t) \hat{\mathbf{\Omega}}^{-*} h = u(t) \mathbf{I} \mathbf{W}^+ h, \tag{2.31}$$

where $u(t)$ is the multiplicative operator defined in Eq. (1.14). Using again the decomposition in Eq. (2.10) we have

$$\mathbf{I}\mathbf{W}^+ h = \mathbf{P}_+ \mathbf{I}\mathbf{W}^+ h + \mathbf{P}_- \mathbf{I}\mathbf{W}^+ h = h_+ + h_-, \tag{2.32}$$

where $h_+ = \mathbf{P}_+ \mathbf{I}\mathbf{W}^+ h = \hat{\mathbf{\Omega}}^+ h$ and $h_- = \mathbf{P}_- \mathbf{I}\mathbf{W}^+ h$. Here $\mathbf{P}_+$ is the projection on $H^+(\mathbb{R})$ defined above and $\mathbf{P}_-: L^2(\mathbb{R}) \mapsto H^-(\mathbb{R})$ is the orthogonal projection of $L^2(\mathbb{R})$ on $H^-(\mathbb{R})$. From Eqs. (2.30)–(2.32) we obtain, for any $h \in \mathcal{H}_{ac}$,

$$\hat{\mathbf{\Omega}}_+ \mathbf{U}(t) h = \mathbf{P}_+ u(t) \mathbf{I}\mathbf{W}^+ h = \mathbf{P}_+ u(t)(h_+ + h_-). \tag{2.33}$$

We conclude the proof of Theorem 2.1 by observing that $H^-(\mathbb{R})$ is stable under the action of $u(t)$ for $t \geqslant 0$. Hence we have $u(t) h_- \in H^-(\mathbb{R})$ and so

$$\hat{\mathbf{\Omega}}_+\mathbf{U}(t)h = \mathbf{P}_+u(t)h_+ = T_{u(t)}\hat{\mathbf{\Omega}}_+h. \tag{2.34}$$

This completes the proof of Theorem 2.1.

■

Theorem 2.1 provides the analogue of the Fourier transform of the representation in Theorem 1.1 in Sec. I, that is, it is the analogue of the outgoing spectral representation of the Lax–Phillips scattering theory. One may think of it as the "outgoing contractive nesting" associated with $\mathcal{H}_{ac}$ and $\mathbf{U}(t)$.

As in the case of the Lax–Phillips theory, there is another nesting structure which may be thought of as the "incoming contractive nesting" associated with $\mathcal{H}_{ac}$ and $\mathbf{U}(t)$. In a similar fashion to Eq. (2.14) we define a contractive nesting map $\hat{\mathbf{\Omega}}_-:\mathcal{H}_{ac}\mapsto H^+(\mathbb{R})$ by

$$\hat{\mathbf{\Omega}}_- \equiv \theta^*\mathbf{W}^- = \theta^*U(\mathbf{\Omega}^+)^*. \tag{2.35}$$

For $\hat{\mathbf{\Omega}}_-$ we have the following theorem.

Theorem 2.4 (incoming contractive nesting): *Let* $\mathbf{H}_0$ *and* $\mathbf{H}$ *be self-adjoint operators on a Hilbert space* $\mathcal{H}$ *and let* $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ *be the unitary evolution group on* $\mathcal{H}$ *generated by* $\mathbf{H}$. *Denote by* $\mathcal{H}_{ac}^0$ *and* $\mathcal{H}_{ac}$, *respectively, the absolutely continuous subspaces of* $\mathbf{H}_0$ *and* $\mathbf{H}$. *Assume that the absolutely continuous spectrum of* $\mathbf{H}_0$ *and* $\mathbf{H}$ *has multiplicity one and that it satisfies* $\sigma_{ac}(\mathbf{H}_0) = \sigma_{ac}(\mathbf{H}) = \mathbb{R}^+$. *Assume furthermore that the Møller wave operator* $\mathbf{\Omega}^+ \equiv \mathbf{\Omega}^+(\mathbf{H}_0,\mathbf{H}):\mathcal{H}_{ac}^0\mapsto\mathcal{H}_{ac}$ *exists and is complete. Then there exists a map* $\hat{\mathbf{\Omega}}_-:\mathcal{H}_{ac}\mapsto H^+(\mathbb{R})$ *such that*

(a) $(\mathcal{H}_{ac}, H^+(\mathbb{R}), \hat{\mathbf{\Omega}}_-)$ *is a contractive Hilbert space nesting of* $\mathcal{H}_{ac}$ *into* $H^+(\mathbb{R})$.

(b) *For every* $t\geqslant 0$ *define the Grossmann type operator* $\hat{\mathbf{U}}^*(t):H^+(\mathbb{R})\mapsto H^+(\mathbb{R})$ *according to Eq. (2.3), i.e.,* $\hat{\mathbf{U}}^*(t) = (\hat{\mathbf{\Omega}}_-^*)^{-1}\mathbf{U}^*(t)\hat{\mathbf{\Omega}}_-^*$. *These operators are well defined and, for every* $t\geqslant 0$ *and every* $f\in\mathcal{H}_{ac}$ *we have*

$$\hat{\mathbf{\Omega}}_-\mathbf{U}(t)f = (\widehat{\mathbf{U}^*(t)})^*\hat{\mathbf{\Omega}}_-f = T_{u(t)}f_{\text{in}}, \quad t\geqslant 0, \tag{2.36}$$

where $f_{\text{in}} = \hat{\mathbf{\Omega}}_-f$ *and* $T_{u(t)}$ *is the Toeplitz operator with symbol* $u(t)$ *given by Eq. (1.14).*

Once the existence of the incoming contractive nesting and the outgoing contractive nesting are established we can turn to the definition of the analogue of the Lax–Phillips S-matrix. Let $f_{\text{in}} = \hat{\mathbf{\Omega}}_-f \in H^+(\mathbb{R})$ be the "incoming nested representer" of an element $f\in\mathcal{H}_{ac}$. Let $f_{\text{out}} = \hat{\mathbf{\Omega}}_+f \in H^+(\mathbb{R})$ be the "outgoing nested representer" of the same element f. We have

$$f_{\text{out}} = \hat{\mathbf{\Omega}}_+\hat{\mathbf{\Omega}}_-^{-1}f_{\text{in}} = \theta^*U(\mathbf{\Omega}^-)^*\mathbf{\Omega}^+U^*(\theta^*)^{-1}f_{\text{in}} = \theta^*U\mathbf{S}U^*(\theta^*)^{-1}f_{\text{in}} = \theta^*\widetilde{\mathbf{S}}(\theta^*)^{-1}f_{\text{in}}, \tag{2.37}$$

where $\mathbf{S} = (\mathbf{\Omega}^-)^*\mathbf{\Omega}^+$ is the scattering operator and $\widetilde{\mathbf{S}}:L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ is defined by $\widetilde{\mathbf{S}} \equiv U\mathbf{S}U^*$. The operator $\widetilde{\mathbf{S}}$ is the representer of $\mathbf{S}$ in the spectral (energy) representation for $\mathbf{H}_0$ and is a multiplicative operator in this representation, i.e.,

$$(\widetilde{\mathbf{S}}f)(E) = \widetilde{\mathbf{S}}(E)f(E), \quad f\in L^2(\mathbb{R}^+).$$

Equation (2.37) provides the definition of the *nested scattering matrix* as follows:

Definition (nested scattering matrix): Let $\mathbf{S} = (\mathbf{\Omega}^-)^*\mathbf{\Omega}^+$ *be the scattering operator associated with* $\mathbf{H}_0$ *and* $\mathbf{H}$. *Let* $\widetilde{\mathbf{S}}:L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ *be given by*

$$\widetilde{\mathbf{S}} \equiv U\mathbf{S}U^*. \tag{2.38}$$

The nested scattering matrix $\mathbf{S}_{\text{nest}}:H^+(\mathbb{R})\mapsto H^+(\mathbb{R})$ *is defined to be*

$$\mathbf{S}_{\text{nest}} \equiv \theta^*\widetilde{\mathbf{S}}(\theta^*)^{-1}. \tag{2.39}$$

Of course, for every $f \in \mathcal{H}_{ac}$ we have $f_{\text{out}} = \mathbf{S}_{\text{nest}} f_{\text{in}}$ where $f_{\text{out}} = \hat{\mathbf{\Omega}}_+ f$ and $f_{\text{in}} = \hat{\mathbf{\Omega}}_- f$. We have the following theorem.

Theorem 2.5: *Consider* $L^2(\mathbb{R}^+)$ *and* $L^2(\mathbb{R}^-)$ *as closed subspaces of* $L^2(\mathbb{R})$. *Denote* $\mathbf{P}_{\mathbb{R}^+}: L^2(\mathbb{R}) \mapsto L^2(\mathbb{R})$ *the orthogonal projection of* $L^2(\mathbb{R})$ *on* $L^2(\mathbb{R}^+)$ *and, similarly,* $\mathbf{P}_{\mathbb{R}^-}: L^2(\mathbb{R}) \mapsto L^2(\mathbb{R})$ *the orthogonal projection of* $L^2(\mathbb{R})$ *on* $L^2(\mathbb{R}^-)$. *Let* $\tilde{\mathbf{S}}$ *be defined as in Eq. (2.38). Then, for every* $f_{\text{in}} \in \hat{\mathbf{\Omega}}_- \mathcal{H}_{ac} \subset H^+(\mathbb{R})$ *we have*

$$[\mathbf{S}_{\text{nest}} f_{\text{in}}](\sigma) = \frac{1}{2\pi} \int_0^\infty \mathrm{d}E \frac{i}{\sigma - E + i0^+} \tilde{\mathbf{S}}(E) [\mathbf{P}_{\mathbb{R}^+} f_{\text{in}}](E) + \frac{1}{4\pi^2} \int_0^\infty \mathrm{d}E \frac{i}{\sigma - E + i0^+} \tilde{\mathbf{S}}(E) \times \left\{ \int_{-\infty}^\infty \mathrm{d}s \int_{-\infty}^0 \mathrm{d}\sigma' [\mathbf{P}_{\mathbb{R}^-} f_{\text{in}}](\sigma') \sigma'^{-is-1/2} E^{is-1/2} \right\}. \tag{2.40}$$

Proof: We need to obtain a realization of the maps θ^* and $(\theta^*)^{-1}$ on the functional level. For θ^* we have the following.

Lemma 2.1: The map $\theta^*: L^2(\mathbb{R}^+) \mapsto H^+(\mathbb{R})$ *is given, for any* $f \in L^2(\mathbb{R}^+)$, *by*

$$(\theta^* f)(\sigma) = \frac{1}{2\pi} \int_0^\infty \mathrm{d}E \frac{i}{\sigma - E + i0^+} f(E).$$

Proof: The starting point is Eq. (2.29). The inclusion map $\mathbf{I}: L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R})$ is realized in a simple way: given a function $f \in L^2_{\mathcal{N}}(\mathbb{R}^+)$, and for any $s \in \mathbb{R}$, we have

$$(\mathbf{I}f)(s) = \int_0^\infty \mathrm{d}E \; \delta(s - E) f(E), \tag{2.41}$$

where $\delta(\cdot)$ is the Dirac delta distribution.

Now for the realization of the projection $\mathbf{P}_+: L^2(\mathbb{R}) \mapsto H^+(\mathbb{R})$. For this we Fourier transform $L^2(\mathbb{R})$ and note that, denoting the Fourier transform operator by $\mathbf{F}$, we have $H^+(i\mathbb{R}) = L^2(\mathbb{R}^+)$ and $\mathbf{F}H^-(\mathbb{R}) = L^2(\mathbb{R}^-)$. For any $f \in L^2(\mathbb{R})$ we therefore obtain

$$\mathbf{P}_+ f = \mathbf{F}^{-1} \mathbf{P}_{\mathbb{R}^+} \mathbf{F} f$$

and hence, for $f \in L^2(\mathbb{R})$

$$(\mathbf{P}_+ f)(\sigma) = \frac{1}{2\pi} \int_{-\infty}^\infty \mathrm{d}t \, e^{i\sigma t} \left(\theta(t) \int_{-\infty}^\infty \mathrm{d}s \, e^{-its} f(s) \right) = \frac{1}{2\pi} \int_{-\infty}^\infty \mathrm{d}s \int_0^\infty \mathrm{d}t \, e^{i(\sigma - s + i0^+)t} f(s) = \frac{1}{2\pi} \int_{-\infty}^\infty \mathrm{d}s \frac{i}{\sigma - s + i0^+} f(s). \tag{2.42}$$

Combining Eq. (2.41) and Eq. (2.42) we get, for $f \in L^2(\mathbb{R}^+)$,

$$(\theta^* f)(\sigma) = (\mathbf{P}_+ \mathbf{I} f)(\sigma) = \frac{1}{2\pi} \int_{-\infty}^\infty \mathrm{d}s \frac{i}{\sigma - s + i0^+} \left[\int_0^\infty \mathrm{d}E \; \delta(s - E) f(E) \right] = \frac{1}{2\pi} \int_0^\infty \mathrm{d}E \frac{i}{\sigma - E + i0^+} f(E). \tag{2.43}$$

■

Next, we need to find an explicit expression for the inverse map $(\theta^*)^{-1}$. We have the following lemma.

Lemma 2.2: The map $(\theta^*)^{-1}: \theta^* L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R}^+)$ *is given, for any* $f \in \theta^* L^2(\mathbb{R}^+)$ *by*

$$[(\theta^*)^{-1} f](E) = [\mathbf{P}_{\mathbb{R}^+} f](E) + \frac{1}{2\pi} \int_{-\infty}^\infty \mathrm{d}s \int_{-\infty}^0 \mathrm{d}\sigma [\mathbf{P}_{\mathbb{R}^-} f](\sigma) \sigma^{-is-1/2} E^{is-1/2},$$

where $E \geqslant 0$, $\mathbf{P}_{\mathbb{R}^+}$ *and* $\mathbf{P}_{\mathbb{R}^-}$ *are the orthogonal projections of* $L^2(\mathbb{R})$ *on* $L^2(\mathbb{R}^+)$ *and* $L^2(\mathbb{R}^-)$, *respectively* [$L^2(\mathbb{R}^+)$ *and* $L^2(\mathbb{R}^-)$ *are considered as subspaces of* $L^2(\mathbb{R})$].

Proof: The procedure for constructing $(\theta^*)^{-1}$ is as follows: Given $y_+ \in H^+(\mathbb{R})$ in the range of θ^*, there is some vector $y \in L^2(\mathbb{R}^+)$ such that $\mathbf{I}y = y_+ + y_-$ [y_- is in $H^-(\mathbb{R})$] and Eq. (2.25) is valid. $y_-(\sigma)$ for $\sigma < 0$ are then the restriction to $\mathbb{R}^-$ of the values of some function $y_- \in H^-(\mathbb{R})$. Van Winter's theorem then implies that $y_- \in H^2(\overline{\Pi})$, and hence also $y_- \in H^-(\mathbb{R})$, can be uniquely reconstructed from its boundary value on the negative real axis. We conclude that, for each y_+ in the range of θ^* we can assign a unique $y_- \in H^-(\mathbb{R})$ such that Eq. (2.25) holds. Therefore, $y = y_+ + y_-$ can be identified with a unique element in $L^2(\mathbb{R}^+)$ corresponding to a given $y_+ \in \theta^* L^2(\mathbb{R}^+)$. This construction defines an inverse $(\theta^*)^{-1}$ such that

$$(\theta^*)^{-1} y_+ = y, \quad y_+ \in \theta^* L^2(\mathbb{R}^+), \quad y \in L^2(\mathbb{R}^+).$$

Observe that the main step in the procedure described above is the construction, through the Van Winter theorem, of a function $f \in H^2(\overline{\Pi})$ from data on the boundary value function of f on the negative real axis $\mathbb{R}^-$.

Given the boundary value function $\theta h \in L^2(\mathbb{R}^+)$ for a function $h \in H^2(\Pi)$, Van Winter's theorem implies that one can reconstruct the function $h \in H^2(\Pi)$ by using an inverse Mellin transform. We first find the Mellin transform

$$E(s) = \frac{1}{\sqrt{2\pi}} \int_0^\infty h(x) x^{is-1/2} \, dx \tag{2.44}$$

and then we reconstruct the analytic function via the inverse Mellin transform as follows:

$$h(re^{i\phi}) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty E(s)(re^{i\phi})^{-is-1/2} \, ds, \quad z = re^{i\phi}, \quad r > 0, \quad 0 \leqslant \phi \leqslant \pi. \tag{2.45}$$

For a function $h \in H^2(\Pi)$, define a new function by $\tilde{h}(z) = \overline{h(\overline{z})}$, $\operatorname{Im} z < 0$. Then $\tilde{h} \in H^2(\overline{\Pi})$. In fact, each function $\tilde{h} \in H^2(\overline{\Pi})$ can be obtained from some function $h \in H^2(\Pi)$ by this procedure. From Eqs. (2.44) and (2.45) we obtain

$$\overline{E}(s) = \frac{1}{\sqrt{2\pi}} \int_0^\infty \overline{h}(x) x^{-is-1/2} \, dx \tag{2.46}$$

and

$$\overline{h(\overline{re^{i\phi}})} = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty \overline{E}(s)(re^{i\phi})^{is-1/2} \, ds, \quad z = re^{i\phi}, \quad r \geqslant 0, \quad -\pi \leqslant \phi \leqslant 0. \tag{2.47}$$

Denoting $\tilde{E}(s) = \overline{E}(s)$ and taking notice of the fact that $\tilde{h}(x) = \overline{h}(x)$ for real x, we can write Eq. (2.46) and Eq. (2.47) in the form

$$\tilde{E}(s) = \frac{1}{\sqrt{2\pi}} \int_0^\infty \tilde{h}(x) x^{-is-1/2} \, dx \tag{2.48}$$

and

$$\tilde{h}(re^{i\phi}) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty \tilde{E}(s)(re^{i\phi})^{is-1/2} \, ds, \quad z = re^{i\phi}, \quad r \geqslant 0, \quad -\pi \leqslant \phi \leqslant 0. \tag{2.49}$$

Using Eq. (2.48) and Eq. (2.49) we can reconstruct a function $\tilde{h} \in H^2(\overline{\Pi})$ from its boundary value function on $\mathbb{R}^+$. This is not quite our goal since we would like to reconstruct the function from its boundary value on the negative real axis $\mathbb{R}^-$. This problem, however, is solved by taking advantage

of the analyticity properties of $\tilde{h}$. Closing a contour integration in the lower half-plane we obtain (s is a real number)

$$\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{0}\tilde{h}(x)x^{-is-1/2}\,dx+\frac{1}{\sqrt{2\pi}}\int_{0}^{\infty}\tilde{h}(x)x^{-is-1/2}\,dx=0$$

and hence

$$\tilde{E}(s)=-\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{0}\tilde{h}(x)x^{-is-1/2}\,dx. \tag{2.50}$$

Using Eq. (2.50) at the rhs of Eq. (2.49) and taking $\phi\to 0$ we obtain

$$\tilde{h}(x)=-\frac{1}{2\pi}\int_{-\infty}^{\infty}ds\int_{-\infty}^{0}dx'\,\tilde{h}(x')x'^{-is-1/2}x^{is-1/2},\quad x>0. \tag{2.51}$$

Given the boundary value on $\mathbb{R}^-$ of a function $\tilde{h}\in H^2(\overline{\Pi})$, Eq. (2.51) enables us to obtain its boundary value on $\mathbb{R}^+$. We can now construct the inverse map $(\theta^*)^{-1}$ according to the procedure described above. Given a function $h_+\in\theta^*L^2(\mathbb{R}^+)$ we have for, $E\geqslant 0$,

$$[(\theta^*)^{-1}h_+](E)=[\mathbf{P}_{\mathbb{R}^+}h_+](E)+\frac{1}{2\pi}\int_{-\infty}^{\infty}ds\int_{-\infty}^{0}d\sigma[\mathbf{P}_{\mathbb{R}^-}h_+](\sigma)\sigma^{-is-1/2}E^{is-1/2}. \tag{2.52}$$

This completes the proof of Lemma 2.2. ■

Equation (2.39), Lemma 2.1 and Lemma 2.2 imply Eq. (2.40) and Theorem 2.5 is proved. ■

Theorem 2.1, Theorem 2.4, and Theorem 2.5 provide the basic nesting structure for the description of quantum mechanical resonances. The fact that for each $t\geqslant 0$ the evolution $\mathbf{U}(t)$ transforms, both in the incoming contractive nesting and in the outgoing contractive nesting, into elements of $\{T_{u(t)}\}_{t\geqslant 0}$, the semigroup of Toeplitz operators on $H^+(\mathbb{R})$, suggests that the Sz.-Nagy–Foias theory, providing the basic mechanism of the Lax–Phillips scattering theory, may be used in the description of resonances. In particular, the Lax–Phillips semigroup in Eq. (1.20) may be used in the description of the time evolution of quantum mechanical resonances and the relation between resonances and second sheet poles of the S-matrix in the lower half-plane (or first sheet zeros of the S-matrix in the upper half-plane) may be shown in some cases to be a result of the Sz.-Nagy–Foias theory of contractions.

The following proposition indicates on the way the Sz.-Nagy–Foias theory may be used.

Proposition 2.4 (H^∞ case): Assume that in Eq. (2.38) $\tilde{\mathbf{S}}$: $L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ *is the boundary value on* $\mathbb{R}^+$ *of some function* $\mathcal{S}\in H^\infty(\Pi)$. *Suppose, furthermore, that* $\mathcal{S}$ *has a single, simple, zero at the point* $z=\overline{\mu}$, $\mathrm{Im}\,\mu<0$ *in* Π. *Let* $f_{\mathrm{in}}=\hat{\mathbf{\Omega}}_-f$ *and* $f_{\mathrm{out}}=\hat{\mathbf{\Omega}}_+f$ *for some* $f\in\mathcal{H}_{ac}$. *We have*

$$f_{\mathrm{out}}(\sigma)=[\mathbf{S}_{\mathrm{nest}}f_{\mathrm{in}}](\sigma)=\frac{\sigma-\overline{\mu}}{\sigma-\mu}[\mathbf{S}'_{\mathrm{nest}}f_{\mathrm{in}}](\sigma)-i2\,\mathrm{Im}\,\mu[\mathbf{P}_-\mathcal{S}'f_{\mathrm{in}}^-](\mu)\frac{1}{\sigma-\mu}, \tag{2.53}$$

where $f_{\mathrm{in}}^-\in H^-(\mathbb{R})$ *is such that* $\mathbf{P}_{\mathbb{R}^-}(f_{\mathrm{in}}+f_{\mathrm{in}}^-)=0$, $\mathbf{S}'_{\mathrm{nest}}=\theta^*\tilde{\mathcal{S}}'(\theta^*)^{-1}$, $\tilde{\mathcal{S}}'$ *is the boundary value on* $\mathbb{R}^+$ *of a function* $\mathcal{S}'\in H^\infty(\Pi)$ *and* $\mathcal{S}'$ *has no zeros in* Π.

Proof: We need first to consider the structure theory of H^p functions on the upper half-plane.[16,9] We have the following definition and subsequent theorem.

Definition (Blaschke product): A Blaschke product on the upper half-plane is an analytic function $b(z)$ *on* Π *of the form*

$$b(z)=\left(\frac{z-i}{z+i}\right)^m\prod_n\frac{|z_n^2+1|}{z_n^2+1}\cdot\frac{z-z_n}{z-\overline{z}_n}, \tag{2.54}$$

here m is a non-negative integer and z_n, $\mathrm{Im}\, z>0$, *are zeros of* $b(\cdot)$ *in* Π, *finite or infinite in number*.

Theorem 2.6: *If* $f\in H^p(\Pi)$ $(0<p\leqslant\infty)$ *and* $f\not\equiv 0$, *then* $f(\cdot)=b(\cdot)g(\cdot)$, *where* $g(\cdot)$ *is a non-vanishing* $H^p(\Pi)$ *function. The boundary value function of* $f(\cdot)$ *on* $\mathbb{R}$ *satisfies* $|g(x)|=|f(x)|$ *a.e.* $(x\in\mathbb{R})$. *The function* $b(\cdot)$ *is a Blaschke product of the form given in Eq. (2.54) and* z_n *are the zeros* $(z_n\neq i)$ *of* f *in* Π.

By the definition of a Blaschke product and Theorem 2.6, if the function $\mathcal{S}\in H^\infty(\Pi)$ has only a single zero in Π then it must be of the form

$$\mathcal{S}(z)=\frac{z-\overline{\mu}}{z-\mu}\mathcal{S}'(z),\quad \mathrm{Im}\, z>0,\quad \mathrm{Im}\,\mu<0, \tag{2.55}$$

where $\mathcal{S}'\in H^\infty(\Pi)$ has no zeros in Π. By assumption $\tilde{\mathbf{S}}$ is the boundary function of $\mathcal{S}$ on $\mathbb{R}^+$ and so

$$\tilde{\mathbf{S}}(E)=\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E),\quad E\geqslant 0. \tag{2.56}$$

Inserting this form of $\tilde{\mathbf{S}}$ into Eq. (2.40) we get

$$\begin{aligned}[\mathbf{S}_{\mathrm{nest}}f_{\mathrm{in}}](\sigma)=&\frac{1}{2\pi}\int_0^\infty \mathrm{d}E\frac{i}{\sigma-E+i0^+}\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E)[\mathbf{P}_{\mathbb{R}^+}f_{\mathrm{in}}](E)+\frac{1}{4\pi^2}\\&\times\int_0^\infty \mathrm{d}E\frac{i}{\sigma-E+i0^+}\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E)\int_{-\infty}^\infty \mathrm{d}s\int_{-\infty}^0 \mathrm{d}\sigma'[\mathbf{P}_{\mathbb{R}^-}f_{\mathrm{in}}](\sigma')\sigma'^{-is-1/2}E^{is-1/2}\end{aligned}$$

in the first integral we can change the integration interval to the negative real axis by using a contour integration in the upper half-plane [we recall that $H^\infty(\Pi)$ can be regarded as an algebra on $H^2(\Pi)$]. We get

$$\begin{aligned}\frac{1}{2\pi}\int_0^\infty \mathrm{d}E\frac{i}{\sigma-E+i0^+}\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E)[\mathbf{P}_{\mathbb{R}^+}f_{\mathrm{in}}](E)=&\frac{\sigma-\overline{\mu}}{\sigma-\mu}\mathcal{S}'(\sigma)f_{\mathrm{in}}(\sigma)\\&-\frac{1}{2\pi}\int_{-\infty}^0 \mathrm{d}E\frac{i}{\sigma-E+i0^+}\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E)[\mathbf{P}_{\mathbb{R}^-}f_{\mathrm{in}}](E).\end{aligned} \tag{2.57}$$

Since $f_{\mathrm{in}}\in\hat{\mathbf{\Omega}}^-\mathcal{H}_{ac}$ it is in the range of θ^* hence (see the proof of Theorem 2.5) there is some function $f_{\mathrm{in}}^-\in H^2(\overline{\Pi})$ such that $\mathbf{P}_{\mathbb{R}^-}(f_{\mathrm{in}}+f_{\mathrm{in}}^-)=0$. Using Eq. (2.51) we obtain

$$[\mathbf{P}_{\mathbb{R}^+}f_{\mathrm{in}}^-](E)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}s\int_{-\infty}^0 \mathrm{d}\sigma'[\mathbf{P}_{\mathbb{R}^-}f_{\mathrm{in}}](\sigma')\sigma'^{-is-1/2}E^{is-1/2},\quad E\geqslant 0. \tag{2.58}$$

Thus we get

$$[\mathbf{S}_{\mathrm{nest}}f_{\mathrm{in}}](\sigma)=\frac{\sigma-\overline{\mu}}{\sigma-\mu}\mathcal{S}'(\sigma)f_{\mathrm{in}}(\sigma)+\frac{1}{2\pi}\int_{-\infty}^\infty \mathrm{d}E\frac{i}{\sigma-E+i0^+}\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E)f_{\mathrm{in}}^-(E). \tag{2.59}$$

For the second term on the rhs of Eq. (2.59) we have the following decomposition:

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dE \frac{i}{\sigma - E + i0^+}\frac{E-\overline{\mu}}{E-\mu}\mathcal{S}'(E)f_{\text{in}}^-(E) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dE \frac{i}{\sigma - E + i0^+}\frac{E-\overline{\mu}}{E-\mu}[(\mathbf{P}_+ + \mathbf{P}_-)\mathcal{S}'f_{\text{in}}^-](E)$$
$$= \frac{\sigma-\overline{\mu}}{\sigma-\mu}[\mathbf{P}_+\mathcal{S}'f_{\text{in}}^-](\sigma) - i2\ \text{Im}\ \mu[\mathbf{P}_-\mathcal{S}'f_{\text{in}}^-](\mu)\frac{1}{\sigma-\mu}. \tag{2.60}$$

The second equality on the rhs of Eq. (2.60) is obtained by making use of the properties of the projections $\mathbf{P}_+$ and $\mathbf{P}_-$ in order to close contour integrals in the upper, respectively, lower half-plane. Taking notice of the fact that $\mathcal{S}'$ is in $H^\infty(\Pi)$ and hence $\mathcal{S}'f_{\text{in}} \in H^+(\mathbb{R})$ we finally obtain

$$[\mathbf{S}_{\text{nest}}f_{\text{in}}](\sigma) = \frac{\sigma-\overline{\mu}}{\sigma-\mu}[\mathbf{P}_+\mathcal{S}'(f_{\text{in}} + f_{\text{in}}^-)](\sigma) - i2\ \text{Im}\ \mu[\mathbf{P}_-\mathcal{S}'f_{\text{in}}^-](\mu)\frac{1}{\sigma-\mu}. \tag{2.61}$$

Moreover, from the procedure for the construction of $(\theta^*)^{-1}$ it follows that $f_{\text{in}} + f_{\text{in}}^- = \mathbf{I}(\theta^*)^{-1}f_{\text{in}}$, so that $\mathbf{P}_+\mathcal{S}'(f_{\text{in}} + f_{\text{in}}^-) = \mathbf{P}_+\mathcal{S}'\mathbf{I}(\theta^*)^{-1}f_{\text{in}} = \mathbf{P}_+\mathbf{I}\tilde{\mathcal{S}}'(\theta^*)^{-1}f_{\text{in}} = \theta^*\tilde{\mathcal{S}}'(\theta^*)^{-1}f_{\text{in}}$ and the proof of Proposition 2.4 is complete.

■

The Blaschke factor B_μ defined by [see Eq. (2.54)]

$$B_\mu(z) = \frac{z-\overline{\mu}}{z-\mu} \tag{2.62}$$

is an inner function, hence we can define the subspace $\hat{\mathcal{K}}_\mu \subset H^+(\mathbb{R})$ by

$$\hat{\mathcal{K}}_\mu \equiv H^+(\mathbb{R}) \ominus B_\mu H^+(\mathbb{R}) \tag{2.63}$$

and the Lax–Phillips semigroup $\{\hat{\mathbf{Z}}(t)\}_{t\in\mathbb{R}^+}$ according to Eq. (1.20), i.e.,

$$\hat{\mathbf{Z}}(t) = T_{u(t)}|\hat{\mathcal{K}}_\mu. \tag{2.64}$$

The dimension of the subspace $\hat{\mathcal{K}}_\mu$ is one and, up to a multiplicative constant, the eigenvector $x_\mu \in \hat{\mathcal{K}}_\mu$ of $\hat{\mathbf{Z}}(t)$ is given by

$$x_\mu(\sigma) = \frac{1}{\sigma-\mu}. \tag{2.65}$$

Equation (2.53) can be written then in the form

$$f_{\text{out}} = B_\mu\mathbf{S}'_{\text{nest}}f_{\text{in}} - i2\ \text{Im}\ \mu[\mathbf{P}_-\mathcal{S}'f_{\text{in}}^-](\mu)x_\mu \tag{2.66}$$

and, using Eq. (2.5) we have, for $t \geqslant 0$,

$$\hat{\mathbf{\Omega}}_+\mathbf{U}(t)f = T_{u(t)}f_{\text{out}} = T_{u(t)}B_\mu\mathbf{S}'_{\text{nest}}f_{\text{in}} - i(2\ \text{Im}\ \mu[\mathbf{P}_-\mathcal{S}'f_{\text{in}}^-](\mu))\hat{\mathbf{Z}}(t)x_\mu$$
$$= T_{u(t)}B_\mu\mathbf{S}'_{\text{nest}}f_{\text{in}} - i(2\ \text{Im}\ \mu[\mathbf{P}_-\mathcal{S}'f_{\text{in}}^-](\mu))e^{-i\mu t}x_\mu. \tag{2.67}$$

Equation (2.67) can be interpreted as implying that in the outgoing nesting "representation" the zero of the *S*-matrix in the upper half-plane corresponds, through the mechanism of the Sz.-Nagy–Foias theory described in Sec. I, to a resonance for which the characteristic, exponentially decaying, evolution in time is given in terms of the action of a Lax–Phillips type semigroup. The resonance state is identified with the eigenvector x_μ of this semigroup. Equation (2.67) clearly exhibits the decomposition, in the nesting space $H^+(\mathbb{R})$, of the state $f_{\text{out}} = \hat{\mathbf{\Omega}}_+ f$ corresponding to an element $f \in \mathcal{H}_{ac}$, into a resonance part and a contribution coming from the subspace in $H^+(\mathbb{R})$ orthogonal to the resonance.

Define

$$\Lambda_{\hat{\mathbf{\Omega}}_+} = \hat{\mathbf{\Omega}}_+^* \hat{\mathbf{\Omega}}_+ \mathcal{H}_{ac} \subset \mathcal{H}_{ac}.$$

The set $\Lambda_{\hat{\mathbf{\Omega}}_+}$ is a linear space in $\mathcal{H}_{ac}$ which is dense in $\mathcal{H}_{ac}$. For an element g in $\Lambda_{\hat{\mathbf{\Omega}}_+}$ there is a unique element $h \in \mathcal{H}_{ac}$ such that $g = \hat{\mathbf{\Omega}}_+^* \hat{\mathbf{\Omega}}_+ h$. Then, for $t \geqslant 0$ and $f, g \in \Lambda_{\hat{\mathbf{\Omega}}_+}$ we have

$$\begin{aligned}(g, \mathbf{U}(t) f)_{\mathcal{H}_{ac}} &= (\hat{\mathbf{\Omega}}_+^* \hat{\mathbf{\Omega}}_+ h, \mathbf{U}(t) f)_{\mathcal{H}_{ac}} = (\hat{\mathbf{\Omega}}_+ h, \hat{\mathbf{\Omega}}_+ \mathbf{U}(t) f)_{H^+(\mathbb{R})} = (h_{\text{out}}, T_{u(t)} f_{\text{out}})_{H^+(\mathbb{R})} \\ &= (h_{\text{out}}, u(t) B_\mu \mathbf{S}'_{\text{nest}} f_{\text{in}})_{H^+(\mathbb{R})} - i2 \text{ Im } \mu [\mathbf{P}_- \mathcal{S}' f_{\text{in}}^-](\mu) (h_{\text{out}}, \hat{\mathbf{Z}}(t) x_\mu)_{H^+(\mathbb{R})} \\ &= (h_{\text{out}}, u(t) B_\mu \mathbf{S}'_{\text{nest}} f_{\text{in}})_{H^+(\mathbb{R})} - i2 \text{ Im } \mu [\mathbf{P}_- \mathcal{S}' f_{\text{in}}^-](\mu) e^{-i\mu t} (h_{\text{out}}, x_\mu)_{H^+(\mathbb{R})}, \end{aligned} \tag{2.68}$$

where $g = \hat{\mathbf{\Omega}}_+^* \hat{\mathbf{\Omega}}_+ h$, $h_{\text{out}} = \hat{\mathbf{\Omega}}_+ h$, and $u(t)$ is the unitary group defined in Eq. (1.14). Thus, on a dense set in $\mathcal{H}_{ac}$, matrix elements of the evolution can be calculated in the outgoing contractive nesting. The example of an H^∞ S-matrix gives a clear demonstration for the possible use of the Sz.-Nagy–Foias theory of contractions in the framework of quantum mechanical scattering problems.

III. COMMENTS—THE CONTRACTIVE CONTAINMENT OF HILBERT SPACES

Consider the following definition of a *bounded and contractive containment* of Hilbert space.[29]

Definition (bounded and contractive containment): If $\mathcal{H}_0$ is a Hilbert space, one says that another Hilbert space $\mathcal{H}_1$ is contained boundedly in $\mathcal{H}_0$ if it is a vector subspace of $\mathcal{H}_0$ and if the inclusion map of it into $\mathcal{H}_0$ is bounded. If the inclusion map is a contraction, one says that $\mathcal{H}_1$ is contained contractively in $\mathcal{H}_0$.

If $\mathbf{A}$ is a bounded operator from the Hilbert space $\mathcal{H}_1$ into the Hilbert space $\mathcal{H}_0$, then we define $\mathcal{M}(\mathbf{A}) \subset \mathcal{H}_0$ to be the range of $\mathbf{A}$ with the Hilbert space structure that makes $\mathbf{A}$ a coisometry from $\mathcal{H}_1$ onto $\mathcal{M}(\mathbf{A})$. Thus if x and y are vectors in $\mathcal{H}_1$ and if they are orthogonal to the kernel of $\mathbf{A}$ then

$$(\mathbf{A}x, \mathbf{A}y)_{\mathcal{M}(\mathbf{A})} = (x, y)_{\mathcal{H}_1}. \tag{3.1}$$

The space $\mathcal{M}(\mathbf{A})$ is contained boundedly in $\mathcal{H}_0$, and if $\mathbf{A}$ is a contraction from $\mathcal{H}_1$ into $\mathcal{H}_0$ then $\mathcal{M}(\mathbf{A})$ is contained contractively in $\mathcal{H}_0$. Every Hilbert space contained boundedly in $\mathcal{H}_0$ is such an operator range, since it is the range of the inclusion map of it into $\mathcal{H}_0$.

Another important notion is that of a *complementary space*.[29] If $\mathbf{A}$: $\mathcal{H}_1 \mapsto \mathcal{H}_0$ is a Hilbert space contraction, then $\mathcal{H}(\mathbf{A}) \equiv \mathcal{M}((1 - \mathbf{A}\mathbf{A}^*)^{1/2}) \subset \mathcal{H}_0$ is called the complementary space of $\mathcal{M}(\mathbf{A})$. If $\mathcal{M}(\mathbf{A})$ is an ordinary subspace, that is, if $\mathbf{A}$ is a partial isometry, then $\mathbf{A}\mathbf{A}^*$ and $1 - \mathbf{A}\mathbf{A}^*$ are complementary orthogonal projections, and $\mathcal{H}(\mathbf{A})$ is the ordinary orthogonal complement of $\mathcal{M}(\mathbf{A})$. If $\mathbf{A}$ is not a partial isometry then the intersection $\mathcal{M}(\mathbf{A}) \cap \mathcal{H}(\mathbf{A})$, called the *overlapping space*,[29] is nontrivial. In this case we have

$$\mathcal{M}(\mathbf{A}) \cap \mathcal{H}(\mathbf{A}) = \mathbf{A}\mathcal{H}(\mathbf{A}^*). \tag{3.2}$$

In addition we have

$$\mathcal{H}_0 = \mathcal{H}(\mathbf{A}) + \mathcal{M}(\mathbf{A}), \tag{3.3}$$

where is Eq. (3.3) vectors in $\mathcal{M}(\mathbf{A})$ and $\mathcal{H}(\mathbf{A})$ are considered as elements of $\mathcal{H}_0$.

Applying the definition above and the subsequent discussion to the nesting structure $(\mathcal{H}_{ac}, H^+(\mathbb{R}), \hat{\mathbf{\Omega}}_+)$ it is clear that $\mathcal{M}(\hat{\mathbf{\Omega}}_+) \subset H^+(\mathbb{R})$ is contractively contained in $H^+(\mathbb{R})$ [of course, the same statement is valid for $\mathcal{M}(\hat{\mathbf{\Omega}}_-) \subset H^+(\mathbb{R})$]. Moreover, since $\hat{\mathbf{\Omega}}_+$: $\mathcal{H}_{ac} \mapsto H^+(\mathbb{R})$ is injective, the scalar product in $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$ defined in Eq. (3.1) can be written in the form

$$(x,y)_{\mathcal{M}(\hat{\mathbf{\Omega}}_+)} \equiv (\hat{\mathbf{\Omega}}_+^{-1}x, \hat{\mathbf{\Omega}}_+^{-1}y)_{\mathcal{H}_{ac}}. \tag{3.4}$$

Regarding $\hat{\mathbf{\Omega}}_+$ as a map from $\mathcal{H}_{ac}$ onto $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$, equipped with the scalar product defined in Eq. (3.4), we find that it is unitary and $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$ is a representation of $\mathcal{H}_{ac}$ [in terms of functions belonging to $H^+(\mathbb{R})$]. Since $\hat{\mathbf{\Omega}}_+$ is a contraction we can construct the complementary space $\mathcal{H}(\hat{\mathbf{\Omega}}_+) \subset H^+(\mathbb{R})$ by

$$\mathcal{H}(\hat{\mathbf{\Omega}}_+) = \mathcal{M}((1 - \hat{\mathbf{\Omega}}_+\hat{\mathbf{\Omega}}_+^*)^{1/2})$$

and Eq. (3.2) and Eq. (3.3) imply that

$$\mathcal{M}(\hat{\mathbf{\Omega}}_+) \cap \mathcal{H}(\hat{\mathbf{\Omega}}_+) = \hat{\mathbf{\Omega}}_+\mathcal{H}(\hat{\mathbf{\Omega}}_+^*) \neq \{0\} \tag{3.5}$$

and

$$H^+(\mathbb{R}) = \mathcal{H}(\hat{\mathbf{\Omega}}_+) + \mathcal{M}(\hat{\mathbf{\Omega}}_+). \tag{3.6}$$

We know that $\hat{\mathbf{\Omega}}_+\mathcal{H}_{ac}$ is dense in $H^+(\mathbb{R})$, hence for any $f \in H^+(\mathbb{R})$ there exists some sequence of elements $\{f_n\}_{n\in N}$, $f_n \in \mathcal{H}_{ac}$ such that

$$\lim_{n\to\infty} \|f - \hat{\mathbf{\Omega}}_+ f_n\|_{H^+(\mathbb{R})} = 0. \tag{3.7}$$

Observe that by the one to one correspondence between $\mathcal{H}_{ac}$ and $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$, the continuity of $\hat{\mathbf{\Omega}}_+$ and its contractive property, if a sequence $\{f_n\}_{n\in N}$ of elements $f_n \in \mathcal{H}_{ac}$ converges to an element $f \in \mathcal{H}_{ac}$ we have

$$\lim_{n\to\infty} \|\hat{\mathbf{\Omega}}_+ f - \hat{\mathbf{\Omega}}_+ f_n\|_{H^+(\mathbb{R})} \leqslant \lim_{n\to\infty} \|f - f_n\|_{\mathcal{M}(\hat{\mathbf{\Omega}}_+)} = \lim_{n\to\infty} \|f - f_n\|_{\mathcal{H}_{ac}} = 0. \tag{3.8}$$

Hence all converging sequences in $\mathcal{H}_{ac}$ correspond, under the mapping $\hat{\mathbf{\Omega}}_+$, to sequences in $H^+(\mathbb{R})$ converging to elements in $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$ *in the topology of the space* $H^+(\mathbb{R})$. Conversly, any element in $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$, regarded as a subset of $H^+(\mathbb{R})$, corresponds (under the mapping by $\hat{\mathbf{\Omega}}_+$) to some sequence converging in $\mathcal{H}_{ac}$. Thus elements in $\mathcal{M}(\hat{\mathbf{\Omega}}_+)$ are associated with the existence of converging sequences in $\mathcal{H}_{ac}$. We conclude that elements in $H^+(\mathbb{R})$ that do not correspond (under the mapping by $\hat{\mathbf{\Omega}}_+$) to any converging sequence in $\mathcal{H}_{ac}$ are all in $\mathcal{H}(\hat{\mathbf{\Omega}}_+)\backslash\mathcal{M}(\hat{\mathbf{\Omega}}_+)$. In particular, resonances, which are not elements of $\mathcal{H}_{ac}$ and do not correspond to any converging sequence in $\mathcal{H}_{ac}$, always belong to the complementary space $\mathcal{H}(\hat{\mathbf{\Omega}}_+)$. In the discussion above of an S-matrix associated with an $H^\infty(\Pi)$ function this observation implies that the subspace $\hat{\mathcal{K}}_\mu$ containing the resonance has the property that $\hat{\mathcal{K}}_\mu \subset \mathcal{H}(\hat{\mathbf{\Omega}}_+)\backslash\hat{\mathbf{\Omega}}_+\mathcal{H}_{ac}$.

IV. CONCLUSIONS

This paper introduces an application of the Sz.-Nagy–Foias theory of contraction operators on Hilbert space for the description of resonances in quantum mechanical scattering problems for which the generator of evolution is bounded from below. This approach is based on the construction, in Sec. II above, of a framework analogous to that of the Lax–Phillips scattering theory. Thus, in this framework there exists an outgoing nesting structure, an incoming nesting structure and a nested S-matrix, which are analogous to the Lax–Phillips translation representations and the Lax–Phillips S-matrix, respectively. In the outgoing and incoming nesting structures the evolution is transformed, for times $t \geqslant 0$ into a continuous semigroup of Toeplitz operators. It was shown that, in the case that the original S-matrix is a bounded analytic function in the upper half-plane, its zeros in the upper half-plane (or poles of its analytic continuation to the lower half-plane) correspond to the existence of a subspace of the nesting space such that the (nested) evolution restricted

to this subspace defines a Lax–Phillips type semigroup providing the typical exponential decay behavior of the resonance. The relation between the zeros of the *S*-matrix and the eigenvalues of the generator of the semigroup are seen to be a result of the Sz.-Nagy–Foias theory of contractions. One may note, furthermore, that the two conditions for an appropriate description of a resonance, set in Sec. I, are formally satisfied. However, the interpretation of the resonance state [the eigenvector x_μ of the generator of the Lax–Phillips type semigroup $\{\hat{\mathbf{Z}}(t)\}_{t\geqslant 0}$ appearing in Eq. (2.68)] merits some additional investigation. The problem of interpretation amounts to the understanding of the contribution of the resonance to observable quantities. Since the resonance state is identified with a well defined closed subspace of the Hardy space, which is a Hilbert space, an appropriate interpretation can be achieved, in principle, by the transfer of the action of operators corresponding to quantum mechanical observables from the original Hilbert space to the Hardy space via the nesting maps. Associating matrix elements of observables to matrix elements of the transformed operators (in a manner similar to the treatment of the evolution in the present paper) should enable for the isolation of the contribution of the resonance. The question of interpretation of the resonance state as well as the natural question regarding the relation of the formalism developed in this paper to standard methods for the description of resonances, such as complex scaling, are best addressed through the analysis of simple concrete models using the framework introduced here and its comparison to the results of analysis by other methods. Such an analysis will be considered elsewhere.

The results presented in this work are limited in two obvious ways. The first is the fact that the nesting structures are constructed for scalar valued functions and the second stems from the fact that the appearance of the Lax–Phillips semigroup was shown under the assumption that the *S*-matrix is the boundary value function on $\mathbb{R}^+$ of an H^∞ function in the upper half-plane. An extension of the nesting framework to the case of an absolutely continuous spectrum of $\mathbf{H}_0$ and $\mathbf{H}$ with finite multiplicity seem to follow in a straightforward way from the framework developed here. More general cases may present additional difficulties.

Concerning the second difficulty raised above, it should be emphasized that the general framework developed in Sec. II, up to and including Theorem 2.5, exist regardless of any particular assumptions on the properties of the original *S*-matrix. More elaborate tools from operator theory may be invoked if more general assumptions, other than the simplifying assumption of an H^∞ *S*-matrix, are made. Possible extensions of the framework presented in this paper, along these lines, will be investigated elsewhere.

A time reversible probabilistic representation of solutions of the (Euclidean) Schrödinger equation in momentum representation is constructed using Lévy processes and bridges. Each diffusion in the position representation is associated with a jump diffusion in the momentum space. Our method can be looked upon as a rigorous version of Feynman's path integral approach. Several examples are studied. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1850178]

I. INTRODUCTION AND NOTATION

Feynman's path integral approach to quantum mechanics can be regarded as an informal reinterpretation of this theory in intrinsically stochastic terms. More than 50 years after its creation,[9] this approach has proved to be deep enough to provide basic insights into an amazing list of physical models, far beyond what could be anticipated originally. However, it is only "informal" because the (complex) probability measures on the various path spaces underlying Feynman's approach do not exist. Of course, a number of mathematical counterparts of such informal probability measures have been known, and used with profit, for a very long time (cf. Refs. 1,18, and references therein for historical perspectives on the issue and, in particular, on the role of the Trotter formula as a kind of alternative). The basic one, for configuration representation, is as old as quantum theory itself: it is Wiener measure, induced by Brownian motion. Its original (sample) path space, also named after Wiener, is of the form

$$\Omega_0 = \{\omega \in C(\mathbb{R}_+;\mathbb{R}^d) : \omega(0) = 0\},$$

and its relation with quantum theory appears in the famous Feynman–Kac formula[19]

$$(e^{-(t/\hbar)H}\chi^*)(q) = \int_{\Omega_0} \chi^*(\omega(t)+q)e^{-(1/\hbar)\int_0^t V(\omega(r)+q)\mathrm{d}r}\,\mathrm{d}P_W(\omega), \tag{1.1}$$

where $H=-(\hbar^2/2)\Delta+V$ is a lower bounded Hamiltonian observable on $L^2(\mathbb{R}^d)$, $V(q)$ a scalar potential, χ^* belongs to the dense domain $\mathcal{D}(H)$ of H in $L^2(\mathbb{R})$, $\hbar$ is the Planck constant, and P_W is the Wiener measure.

It is often more appropriate to consider path spaces on a compact time interval $[0,t]$ instead of $\mathbb{R}_+$, for instance

$$\Omega^{q,t} = \{\omega \in C([0,t];\mathbb{R}^d) : \omega(t) = q\}.$$

Then the Feynman–Kac formula becomes

a)Electronic mail: nprivaul@univ-lr.fr
b)Electronic mail: zambrini@cii.fc.ul.pt

$$(e^{-(t/\hbar)H}\chi^*)(q) = \int_{\Omega^{q,t}} \chi^*(\omega(0)) e^{-(1/\hbar)\int_0^t V(\omega(r))\mathrm{d}r}\, \mathrm{d}P_W(\omega). \tag{1.2}$$

The right-hand side of (1.2) is a legitimate path integral representation of the solution of the Cauchy problem in $L^2(\mathbb{R}^d)$,

$$\begin{aligned} -\hbar \frac{\partial \eta_t^*}{\partial t} &= H\eta_t^*, \\ \eta_0^*(q) &= \chi^*(q), \end{aligned} \tag{1.3}$$

regarded as counterpart of Feynman's one for Schrödinger equation,[10] resulting informally from the "Wick rotation" $t \to -it$ in (1.3). The representation (1.2) is the Euclidean (or imaginary time) viewpoint of Feynman's formula for the wave function ψ, too often considered as the only rigorous one. In relation with the physicists standard manipulations of paths integrals,[27] however, the representation (1.2) is not always appropriate. Indeed, in Feynman's framework, the configuration representation is only one of those where the path integral approach should apply successfully. What are the associated probabilistic counterparts of path integrals in momentum or energy representation, for example? We will really be able to claim that the mathematical content of Feynman's approach is under control when a general probabilistic construction valid in any representation, and providing at once the existence of all underlying probability measures, will be available (at least for a restricted class of potentials). This is, of course, still far from being the case.

Such a general construction would, presumably, also be a great advance to Stochastic Analysis itself[23] since it would provide as well new relations (Euclidean counterparts of quantum unitary transformations) between stochastic processes, or measures, usually regarded as unrelated in probability theory.

A probabilistic counterpart of Feynman's formula in configuration representation, distinct from (1.2), has been introduced in the mid-eighties (cf. Refs. 35,6, and references therein). It is founded on the elementary observation that the Feynman–Kac formula is just a conditional expectation, a concept never defined in quantum mechanics where only absolute expectations appear, and in a very specific manner. Precisely, for the quantum system with the same Hamiltonian as before,

$$\int_A \psi_t(q)\overline{\psi_t}(q)\mathrm{d}q, \tag{1.4}$$

is interpreted as the (unconditional or absolute) probability measure, for this system, to be in the Borelian A at time t, where $\overline{\psi}$ denotes the complex conjugate of the wave function ψ. Of course, the product form of the density in (1.4) is in fact independent of the representation.

Since various probabilistic interpretations of the solutions of (1.3) as conditional expectations are available, (1.4) suggests to look, among those, for a special class of diffusion processes whose absolute probability density is the product of positive solutions η_t^* of (1.3) and of positive solutions η_t of the equation,

$$\begin{aligned} \hbar \frac{\partial \eta_t}{\partial t} &= H\eta_t, \\ \eta_v(q) &= \chi(q), \end{aligned} \tag{1.5}$$

adjoint to (1.3) with respect to the time parameter on a compact time interval, say $t \in I=[r,v]$. Such diffusions are indeed well defined and it can be shown that their qualitative properties are much closer to what is needed to understand Feynman's approach than those of (1.2), cf. Refs. 6,7. In particular, they are time inhomogeneous but still time reversible. The above mentioned product

form of their probability at the time t becomes a mathematical expression of their reversibility (and their Markovian character, actually) since (1.5) can be interpreted as the time reversal of (1.3). In fact, the qualitative properties of these processes are so close to the quantum ones that they allow to understand, for example, fresh aspects of quantum symmetries in Hilbert space, generally ignored.[21,6]

The purpose of this paper is to show that the structure of this probabilistic construction (EQM, or Euclidean quantum mechanics) is preserved in momentum representation, suggesting that this structure is, somehow, independent of the representation. If this is indeed the case, a global mathematical picture of Feynman's path integral approach should be accessible, with a number of exciting consequences, both at the conceptual level of quantum physics and in the infinite dimensional analysis context of (Euclidean) quantum field theory. In this infinite dimensional context, the need for such a unification has been known for a long time in physics and in mathematics (cf. for instance, Refs. 27,13).

As observed by Feynman and Hibbs,[10] Sec. 5.1, it is expected that in momentum representation, the underlying stochastic processes belong to a special class of jump processes. In other words, and in contrast with the configuration representation, the elements ω of the momentum path space cannot be made continuous, in general, but at best continuous on the right.

The organization of our paper is as follows. Section II is devoted to a review of Lévy processes and the use of the Lévy–Khintchine representation to represent potentials. In Sec. III we present a summary of the relations between Lévy processes and pseudodifferential or Hamiltonian operators, and we show how to construct the two adjoint equations corresponding, in momentum representation, to (1.3) and (1.5). What plays the role of the Hamiltonian operator H in (1.3) and (1.5), is now a pseudodifferential operator, denoted by $\hat{H}$, whose explicit form depends, of course, on the scalar potential V in (1.1).

Section IV describes the construction of the new class of reversible diffusions with jumps $\hat{z}_t, t \in I$ (our "momentum process") whose absolute probability density at any time $t \in I$ is a product $\hat{\eta}_t^* \hat{\eta}_t$ of positive solutions of the two adjoint equations above. One way to describe them is to give the two stochastic integro-differential equations solved by $\hat{z}_t, t \in I$, whose coefficients depend exclusively on the two positive solutions $\hat{\eta}_t^*$ and $\hat{\eta}_t$ on I (Euclidean counterparts of the momentum wave function and its complex conjugate). The dual aspect of this construction is fundamental. In particular, two families of σ-algebras (or "filtrations") are necessary, here, for the description of $\hat{z}_t$ in $I=[r,v]$. Let us recall that traditional constructions of stochastic processes require only one such filtration, the nondecreasing family $(\mathcal{P}_t)$, generated by $\hat{z}_t, t \in I$, and describing its past (more precisely the set of all events whose occurrence can result from the observation of $\hat{z}_s, r \leqslant s \leqslant t$). The information about $\mathcal{P}_t$ is contained in the solutions $\hat{\eta}_t^*$ of the Cauchy problem for $\hat{H}$, given a positive initial condition $\hat{\eta}_r^*$. But we will need as well a nonincreasing filtration $\mathcal{F}_t$, describing the future of $\hat{z}_t$ on I. This will correspond to the information included in the solution $\hat{\eta}_t$ of the adjoint PDE, for a positive final condition $\hat{\eta}_v$. Another aspect of this duality can be expressed by saying that the resulting Markovian process $\hat{z}_t, t \in I=[r,v]$, is built from the data of two positive probability densities at the boundary ∂I of our time interval, say π_r and π_v, instead of the traditional initial probability density and a transition function. Our data of π_v is not contradictory, however, because $\hat{z}_t$ is the Markovian representative of a wider class of processes built from $\{\pi_r, \pi_v\}$, called Bernstein (or "local Markov," or "reciprocal," cf. Refs. 6,7) and satisfying the property

$$E[f(\hat{z}_t)|\mathcal{P}_s \vee \mathcal{F}_u] = E[f(\hat{z}_t)|\hat{z}_s, \hat{z}_u], \quad s < t < u, \tag{1.6}$$

for all f bounded measurable, where $E[\cdot|\mathcal{A}]$ denotes the conditional expectation given a σ-algebra $\mathcal{A}$. In other words, the knowledge of all the past $\mathcal{P}_s$ and the future $\mathcal{F}_u$ of the process is irrelevant to compute the conditional expectations; only the boundary values $\hat{z}_s, \hat{z}_u$ matter. Property (1.6) is more general than the Markov property but this one is sufficient for quantum physics, as shown by the product form of the integrand of (1.4).

Sections V and VI describe the dynamics of the momentum process $\hat{z}_t, t \in I$. Here, again, we follow Feynman's approach. His (unpublished) Princeton Ph.D. thesis was entitled "The least

action principle in quantum mechanics" and this principle can be regarded as a stationary phase method in infinite dimension.[1] In our probabilistic context some methods of controlled Markov processes can be adapted to our purpose. They provide a (stochastic) action functional, and in particular a Lagrangian, whose critical points are precisely the diffusion process with jumps constructed in Sec. IV. The method exploits the maximum principle for a class of PDEs which can be interpreted as quantum deformations of the classical Hamilton–Jacobi equation in momentum representation. The equations of motion of Sec. VI are the ones solved by the critical points of the action functional and provide the probabilistic version of the quantum Heisenberg equations in momentum representation. In this sense, the structure of the present construction is, indeed, the same as the one of the reinterpretation of Feynman's approach in configuration representation of Refs. 6 and 35. In particular, the study of the symmetries of this framework (not done here) should have interesting surprises in store as in the configuration representation.[6,33] A number of explicit examples illustrate our construction.

II. LÉVY–KHINTCHINE REPRESENTATION AND POTENTIALS

Let $V:\mathbb{R}^d\to\mathbb{C}$ with $V(0)\geqslant 0$ and such that e^{-tV} is continuous positive definite. In this case the function V admits the Lévy–Khintchine representation

$$V(q)=a+i\langle c,q\rangle+\frac{1}{2}\|q\|^2-\int_{\mathbb{R}^d\setminus\{0\}}(e^{-i\langle q,k\rangle}+i\langle q,k\rangle 1_{\{|k|\leqslant 1\}}-1)\,\nu(\mathrm{d}k), \tag{2.1}$$

where $k\in\mathbb{R}^d$ is called the wave vector, $a,c\in\mathbb{R}^d$, $\langle\cdot,\cdot\rangle$ denotes the scalar product in $\mathbb{R}^d$ with norm $\|\cdot\|$, and ν is a Lévy measure on $\mathbb{R}^d\setminus\{0\}$, i.e., ν satisfies $\int_{\mathbb{R}^d}(\|k\|^2\wedge 1)\,\nu(\mathrm{d}k)<\infty$. Note however that the above hypothesis on V is not satisfied by potentials of the form $V(q)=q^\alpha$ for $\alpha>2$, thus excluding quartic potentials in particular. See, e.g., Refs. 3,29 for background on Lévy processes. A stochastic process ξ_t, $t\geqslant 0$, defined on a probability space $(\Omega,\mathcal{P},P)$ is called a Lévy process if it has right continuous paths starting from the origin and its increments are independent and stationary:

(a) $P(\xi_0=0)=1$,
(b) for all $0\leqslant s\leqslant t$, $\xi_t-\xi_s$ is independent of $\mathcal{P}_s\subset\mathcal{P}$, the past filtration generated by all ξ_r, $r\leqslant s$,
(c) for all $0\leqslant s\leqslant t$, $\xi_t-\xi_s$ is equal in distribution to ξ_{t-s}.

The Lévy process ξ_t of characteristic exponent $V(q)$ is defined by

$$E[e^{-(i/\hbar)\langle\xi_t,q\rangle}]=e^{-(t/\hbar)V(q)},\quad q\in\mathbb{R}^d, \tag{2.2}$$

so that, from now on, the Lévy process ξ_t will have the units of the momentum $p=\hbar k$ and V, of course, the ones of a (potential) energy. Lévy processes form a large class of Markov processes, including the two most commonly used in mathematical physics: Brownian motion and the Poisson process.

The $\mathbb{R}^d$-valued process $\xi_t, t\in\mathbb{R}_+$, admits the following canonical ("Lévy–Itô") decomposition:

$$\xi_t=ct+W_t^\hbar+\int_0^t\int_{\{|k|>1\}}k\mu(\mathrm{d}k,\mathrm{d}s)+\int_0^t\int_{\{0<|k|\leqslant 1\}}k(\mu(\mathrm{d}k,\mathrm{d}s)-\nu(\mathrm{d}k)\mathrm{d}s), \tag{2.3}$$

where $W_t^\hbar=\hbar^{1/2}W_t$ is a Brownian motion with covariance $\hbar$, $\mu(\mathrm{d}k,\mathrm{d}s))$ is a Poisson random measure (or "canonical jump measure") counting the jumps $\Delta\xi_s=\xi_s-\xi_{s^-}$ (where $\xi_{s^-}=\lim_{r\nearrow s}\xi_r$), namely,

$$\mu(\mathrm{d}k,\mathrm{d}s)=\sum_{\Delta\xi_s\neq 0}\delta_{(\Delta\xi_s,s)}(\mathrm{d}k,\mathrm{d}s).$$

Notice that the jump process in (2.3) is independent of $W_t^\hbar$. The first Stieltjes integral in the decomposition (2.3) describes the sum of all large jumps (of size bigger than one) up to time t. It

is called a "compound Poisson process" and is of bounded variation, but may have no finite moments. The Poisson random measure $\mu(\mathrm{d}k,\mathrm{d}s)$ is determined by its compensator

$$\nu(\mathrm{d}k)\mathrm{d}s := E[\mu(\mathrm{d}k,\mathrm{d}s)]. \tag{2.4}$$

As a function of t, the jump process

$$M_t = \int_0^t \int_{\{0<|k|\leqslant 1\}} k(\mu(\mathrm{d}k,\mathrm{d}s) - \nu(\mathrm{d}k)\mathrm{d}s) \tag{2.5}$$

in (2.3) (the "compensated sum of small jumps") is a $\mathcal{P}_t$-martingale, i.e., it satisfies $E[|M_t|]<\infty$, $t\geqslant 0$, and

$$E[M_t|\mathcal{P}_s] = M_s, \quad a.s., \ 0\leqslant s\leqslant t. \tag{2.6}$$

If one takes the absolute expectation, the martingale property (2.6) implies that $t\mapsto E[M_t]$ is constant. A physically interesting example of martingale follows from the definition (2.2) of the characteristic exponent of ξ_t, indeed

$$\exp\left(-\frac{1}{\hbar}(iq\xi_t + tV(q))\right), \quad t>0, \tag{2.7}$$

is a $\mathcal{P}_t$-martingale. It has been shown in Euclidean quantum mechanics that most martingales play, in point of fact, the role of constants of the motion (cf. Refs. 6,21 and references therein).

Remarks:

(1) If $\hbar=0$ the only possible term of unbounded variation paths in (2.3) is the process (2.5) of small jumps. A criterion for bounded variation paths is

$$\int_{\mathbb{R}^d} (|k|\wedge 1)\nu(\mathrm{d}k) < \infty, \tag{2.8}$$

and, in this case, M_t can be decomposed as

$$M_t = \int_0^t \int_{\{0<|k|\leqslant 1\}} k\mu(\mathrm{d}k,\mathrm{d}s) - t\int_{\{|k|\leqslant 1\}} k\nu(\mathrm{d}k), \quad t>0.$$

Condition (2.8) may be verified even when $\nu(\mathbb{R}^d)=\infty$, i.e., when there are infinitely many jumps in any compact time interval. It follows also clearly from (2.1)–(2.3) that the paths $t\mapsto\xi_t$ are continuous if and only $\nu=0$.

(2) A formal expression of the Lévy–Itô decomposition (2.3), used later on when ν is symmetric, is

$$\xi_t = ct + W_t^{\hbar} + \int_0^t \int_{\mathbb{R}^d\setminus\{0\}} k\mu(\mathrm{d}k,\mathrm{d}s), \tag{2.9}$$

but it should be stressed that although the integrals in (2.3) of large and small jumps are convergent, the last term in (2.9) does not make sense in general.

(3) From (2.1) and (2.3) it is clear that, in such a framework, the Brownian motion W_t (in the purely diffusive case) has the characteristic exponent $V(q)=\frac{1}{2}\|q\|^2$. We could say as well that $W_t^{\hbar}$ corresponds to $V(q)=(\hbar/2)\|q\|^2$ but the first version is more natural for our purpose.

(4) Compound Poisson process.

Let Z_n, $n\in\mathbb{N}$, denote a sequence of independent identically distributed $\mathbb{R}^d$-valued random variables with common probability law μ_Z on $\mathbb{R}^d\setminus\{0\}$, and let N_t be a Poisson process with intensity $\gamma>0$, independent of all the Z_n, $n\in\mathbb{N}$. This means that $N_0=0$ and

$$P(N_t = n) = \frac{(\gamma t)^n}{n!} e^{-\gamma t}, \quad n \in \mathbb{N}.$$

Notice that the compensated Poisson process is $\tilde{N}_t = N_t - \gamma t$, so that $E[\tilde{N}_t] = 0$ and $E[\tilde{N}_t^2] = \gamma t$. The compound Poisson process is defined as

$$\xi_t = Z_1 + \cdots + X_{N_t}, \quad t \in \mathbb{R}_+.$$

It is a Lévy process with Lévy measure $\nu = \gamma \mu_Z$. The Lévy–Khintchine representation reduces here to

$$V(q) = \gamma \int_{\mathbb{R}^d \setminus \{0\}} (e^{-iqk} - 1) \mu_Z(\mathrm{d}k).$$

The paths of ξ_t are piecewise constant, and discontinuities occur only at random ("waiting") times

$$T_n = \inf\{t \geqslant 0 : \xi_t = n\}, \quad n \geqslant 1,$$

with $T_0 = 0$, and the jump sizes are random within the range of the Z_n. For example, reducing $\mu_Z(\mathrm{d}k)$, in the above Lévy–Khintchine formula, to $\delta_1(\mathrm{d}k)$, we recover the above elementary Poisson process $\xi_t = N_t$, with jumps of size +1 at each T_n. Those T_n are gamma distributed (see, e.g., Ref. 20), i.e., their probability density has the form

$$\gamma e^{-\gamma s} \frac{(\gamma s)^{n-1}}{(n-1)!} 1_{[0,\infty)}(s).$$

(5) One of the main difficulties in handling Lévy processes is that they can easily be of unbounded variation, i.e.,

$$\sum_{0 \leqslant s \leqslant t} |\Delta \xi_s| = \infty, \quad a.s. \tag{2.10}$$

However it is always true that

$$\sum_{0 \leqslant s \leqslant t} |\Delta \xi_s|^2 < \infty,$$

a.s., and this second property allows to control the problems due to (2.10), see, e.g., Ref. 2.

III. HAMILTONIANS AND PSEUDODIFFERENTIAL OPERATORS

We refer to the survey[15] and to the references therein for the notions summarized in this section on the links between Lévy processes and pseudodifferential operators. In order to proceed with the definition of pseudodifferential operators and the momentum representation, we need to introduce the Fourier transform

$$\mathcal{F}u(p) = \frac{1}{(2\pi\hbar)^{d/2}} \int_{\mathbb{R}^d} e^{-(i/\hbar)\langle p,q \rangle} u(q) \mathrm{d}q, \quad u \in \mathcal{S}(\mathbb{R}^d),$$

and its inverse

$$\mathcal{F}^{-1}v(q) = \frac{1}{(2\pi\hbar)^{d/2}} \int_{\mathbb{R}^d} e^{(i/\hbar)\langle p,q \rangle} v(p) \mathrm{d}p, \quad v \in \mathcal{S}(\mathbb{R}^d).$$

Given any (measurable) classical observable $f : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}$ such that $q \mapsto f(p,q)$ is continuous with polynomial growth, the pseudodifferential operator with symbol $f(p,q)$ is defined as

$$f(p,i\hbar\nabla)u(p) = \frac{1}{(2\pi\hbar)^{d/2}}\int_{\mathbb{R}^d} e^{-(i/\hbar)\langle p,q\rangle} f(p,q)\mathcal{F}^{-1}u(q)\mathrm{d}q$$
$$= \mathcal{F}(f(p,\cdot)\mathcal{F}^{-1}u(\cdot))(p), \quad p \in \mathbb{R}^d, \quad u \in \mathcal{S}(\mathbb{R}^d).$$

In particular, the pseudodifferential operator $V(i\hbar\nabla)$, for V as in (2.1), satisfies

$$V(i\hbar\nabla)u(p) = au(p) - \hbar\langle c, \nabla u\rangle - \frac{\hbar^2}{2}\Delta u - \int_{\mathbb{R}^d}(u(p+\hbar k) - u(p) - \langle \hbar k, \nabla u(p)\rangle 1_{\{|k|\leqslant 1\}})\nu(\mathrm{d}k).$$

Let $(P_t)_{t\in\mathbb{R}_+}$ denote the Markov semigroup associated with the Lévy process $(\xi_t)_{t\in\mathbb{R}_+}$. This means that

$$\begin{aligned} P_t u(p) &= E[u(p+\xi_t)] \\ &= E[(\mathcal{F}\mathcal{F}^{-1}u)(p+\xi_t)] \\ &= \frac{1}{(2\pi\hbar)^{d/2}}\int_{\mathbb{R}^d} E\left[\exp\left(-\frac{i}{\hbar}\langle \xi_t, q\rangle - \frac{i}{\hbar}\langle p,q\rangle\right)\right]\mathcal{F}^{-1}u(q)\mathrm{d}q \\ &= \frac{1}{(2\pi\hbar)^{d/2}}\int_{\mathbb{R}^d} \exp\left(-\frac{t}{\hbar}V(q) - \frac{i}{\hbar}\langle p,q\rangle\right)\mathcal{F}^{-1}u(q)\mathrm{d}q \\ &= \exp\left(-\frac{t}{\hbar}V(i\hbar\nabla)\right)u(p), \quad u \in \mathcal{S}(\mathbb{R}^d), \quad t \in \mathbb{R}_+, \end{aligned}$$

hence the infinitesimal generator of the Markovian semigroup of $(\xi_t)_{t\in\mathbb{R}_+}$ is $-(1/\hbar)V(i\hbar\nabla)$.

We are only interested in real-valued scalar potentials $V(q)$, i.e., the following conditions are assumed to be satisfied from now on:

(H1) the constant c in (2.1) is equal to 0, and

(H2) ν is symmetric with respect to $k \mapsto -k$.

According to (2.1)–(2.3), (H1) says that our basic Lévy process has no constant drift and from (H2) its measure ν is invariant under time reversal, as it should be for any Hamiltonian observable in the class considered now. We shall also assume that the parameter a is zero, i.e., $V(0)=0$, without loss of generality from the physical point of view, since the energy is defined up to an additive constant. Hence, we shall restrict ourselves to V compatible with the Lévy–Khintchine representation

$$V(q) = \frac{1}{2}\|q\|^2 - \int_{\mathbb{R}^d\setminus\{0\}}(e^{-i\langle q,k\rangle} - 1)\nu(\mathrm{d}k), \tag{3.1}$$

and therefore for all $u \in \mathcal{S}(\mathbb{R})$,

$$V(i\hbar\nabla)u(p) = -\frac{\hbar^2}{2}\Delta u(p) - \int_{\mathbb{R}^d}(u(p+k) - u(p))\nu(\mathrm{d}k).$$

Notice that the conditions (H1) and (H2) imply that we could write as well

$$V(q) = \frac{1}{2}\|q\|^2 - \int_0^\infty (\cos(qk) - 1)\nu(\mathrm{d}k).$$

Then we would have

$$V(i\hbar\nabla)u(p) = -\frac{\hbar^2}{2}\Delta u(p) - \frac{1}{2}\int_0^\infty (u(p+\hbar k) - 2u(p) + u(p-\hbar k))\,\nu(\mathrm{d}k). \tag{3.2}$$

Consider any Hamiltonian H of the form

$$H = -\frac{\hbar^2}{2}\Delta_q + V(q) \tag{3.3}$$

and the associated Schrödinger equation in the position representation

$$i\hbar\frac{\partial\Phi}{\partial t}(q,t) = H\Phi(q,t) = -\frac{1}{2}\hbar^2\Delta_q\Phi(q,t) + V(q)\Phi(q,t).$$

The Euclidean version of this equation results from the substitution $t\mapsto it$,

$$\hbar\frac{\partial\eta_t}{\partial t}(q) = H\eta_t(q) = -\frac{1}{2}\hbar^2\Delta_q\eta_t(q) + V(q)\,\eta_t(q), \quad t\in[r,v]. \tag{3.4}$$

The equation adjoint to (3.4) is given by the substitution $t\mapsto -it$,

$$-\hbar\frac{\partial\eta_t^*}{\partial t}(q) = H\eta_t^*(q) = -\frac{1}{2}\hbar^2\Delta_q\eta_t^*(q) + V(q)\,\eta_t^*(q), \quad t\in[r,v]. \tag{3.5}$$

Let us define the Hamiltonian $\hat{H}=\mathcal{F}H\mathcal{F}^{-1}$ in momentum representation, i.e.,

$$\begin{aligned}\hat{H}\hat{\eta}_t(p) &= \mathcal{F}(H\mathcal{F}^{-1}\hat{\eta}_t)(p) = \frac{1}{2}\|p\|^2\hat{\eta}_t(p) + \mathcal{F}(V\mathcal{F}^{-1}\hat{\eta}_t)(p)\\ &= \frac{1}{2}\|p\|^2\hat{\eta}_t(p) + V(i\hbar\nabla)\hat{\eta}_t(p)\\ &= \frac{1}{2}\|p\|^2\hat{\eta}_t(p) - \frac{\hbar^2}{2}\Delta\hat{\eta}_t(p) - \int_{\mathbb{R}^d}(\hat{\eta}_t(p+\hbar k) - \hat{\eta}_t(p))\,\nu(\mathrm{d}k).\end{aligned} \tag{3.6}$$

Using this, the momentum representation of the Euclidean system described by (3.4) becomes

$$\hbar\frac{\partial\hat{\eta}_t}{\partial t}(p) = \hat{H}\hat{\eta}_t(p) = \frac{1}{2}\|p\|^2\hat{\eta}_t(p) + V(i\hbar\nabla)\hat{\eta}_t(p), \tag{3.7}$$

and $\eta, \hat{\eta}$ are linked by the relation $\hat{\eta}_t=\mathcal{F}\eta_t$. Similarly for equation (3.5),

$$-\hbar\frac{\partial\hat{\eta}_t^*}{\partial t}(p) = \hat{H}\hat{\eta}_t^*(p) = \frac{1}{2}\|p\|^2\hat{\eta}_t^*(p) + V(i\hbar\nabla)\hat{\eta}_t^*(p). \tag{3.8}$$

We call (somewhat improperly) integral kernel the kernel $h(t,p,u,\mathrm{d}l)$, $0<t<u$, $p,l\in\mathbb{R}^d$, associated with

$$e^{-(1/\hbar)(u-t)\hat{H}}f(p) = \int_{\mathbb{R}^d} f(l)h(t,p,u,\mathrm{d}l).$$

The following proposition shows how to compute the kernel $h(t,p,u,\mathrm{d}l)$ starting from the law μ_t of the Lévy process ξ_t at time t.

Proposition 3.1: For any $0<t<v$ and $p,l\in\mathbb{R}$ we have

$$h(t,p,u,\mathrm{d}l) = \alpha(u-t,p,l)\mu_{u-t}(-p+\mathrm{d}l), \tag{3.9}$$

where

$$\alpha(u-t,p,l) = E[e^{-(1/2\hbar)\int_0^{u-t}\|p+\xi_\tau\|^2\,\mathrm{d}\tau}\big|\xi_{u-t} = l-p],$$

and $\mu_{u-t}(-p+\mathrm{d}l)$ *denotes the image measure of* μ_{u-t} *under* $l\mapsto l+p$.

Proof: Since $-(1/\hbar)V(i\hbar\nabla)$ is the generator of $(\xi_t)_{t\in[0,u]}$, we have from the Feynman–Kac formula for Markov processes (see, e.g., Sec. III.19 of Ref. 28),

$$e^{-(1/\hbar)(u-t)\hat{H}}f(p) = E[f(\xi_u)e^{-(1/2\hbar)\int_t^u\|\xi_\tau\|^2\,\mathrm{d}\tau}\big|\xi_t = p] = E[f(p+\xi_{u-t})e^{-(1/2\hbar)\int_0^{u-t}\|p+\xi_\tau\|^2\,\mathrm{d}\tau}], \quad t<u,$$

where we used the stationarity of the increments of ξ_t. So, by definition of the integral kernel $h(t,p,u,\mathrm{d}l)$ and the Feynman–Kac formula,

$$\begin{aligned}\int_{\mathbb{R}^d} h(t,p,u,\mathrm{d}l)f(l) &= e^{-(1/\hbar)(u-t)\hat{H}}f(p)\\ &= E[f(\xi_{u-t}+p)e^{-(1/2\hbar)\int_0^{u-t}\|p+\xi_\tau\|^2\,\mathrm{d}\tau}]\\ &= \int_{\mathbb{R}^d} E[f(\xi_{u-t}+p)e^{-(1/2\hbar)\int_0^{u-t}\|p+\xi_\tau\|^2\,\mathrm{d}\tau}\big|\xi_{u-t}=l]\mu_{u-t}(\mathrm{d}l)\\ &= \int_{\mathbb{R}^d} f(p+l)E[e^{-(1/2\hbar)\int_0^{u-t}\|p+\xi_\tau\|^2\,\mathrm{d}\tau}\big|\xi_{u-t}=l]\mu_{u-t}(\mathrm{d}l)\\ &= \int_{\mathbb{R}^d} f(l)E[e^{-(1/2\hbar)\int_0^{u-t}\|p+\xi_\tau\|^2\,\mathrm{d}\tau}\big|\xi_{u-t}=l-p]\mu_{u-t}(-p+\mathrm{d}l).\end{aligned}$$

Consequently we obtain (3.9). ■

We are going to consider five one-dimensional examples in a detailed way, as illustrations of our approach.

Examples:

(1) $V(q)=(1-\cos(\alpha q))$, $\alpha>0$. This case corresponds to

$$\nu(\mathrm{d}k) = \tfrac{1}{2}(\delta_\alpha(\mathrm{d}k) + \delta_{-\alpha}(\mathrm{d}k))$$

in (2.1). By (3.6),

$$\hat{H}u(p) = \tfrac{1}{2}\|p\|^2u(p) - \tfrac{1}{2}\Delta_\alpha u(p),$$

where Δ_α denotes the discretized Laplace operator

$$\Delta_\alpha u(p) = \frac{u(p+\alpha)-2u(p)+u(p-\alpha)}{\alpha^2}.$$

The random jump measure is of the form

$$\mu(\mathrm{d}k,\mathrm{d}s) = \sum_{n=1}^{\infty}\delta_{(\alpha,T_n^1)}(\mathrm{d}k,\mathrm{d}s) + \delta_{(-\alpha,T_n^2)}(\mathrm{d}k,\mathrm{d}s),$$

where $(T_k^1)_{k\geqslant 1}$ and $(T_k^2)_{k\geqslant 1}$ are two independent sequences of Poissonian waiting times, with the same intensity $1/(2\alpha^2)$. The Lévy–Itô decomposition reduces here to the compensated sum of jumps. After introduction of ν and μ as above we find

$$\xi_t = \int_0^t \int_{\mathbb{R}} k(\mu(\mathrm{d}k,\mathrm{d}s) - \nu(\mathrm{d}k)\mathrm{d}s) = \alpha(N_t^1 - N_t^2),$$

where $(N_t^1)_{t\in\mathbb{R}_+}$ and $(N_t^2)_{t\in\mathbb{R}_+}$ are independent standard Poisson processes with intensity $1/(2\alpha^2)$ since (2.5) reduces to a sum, for $k=\pm\alpha$, of all jumps at the waiting times T_n^i, $i=1$, 2, up to the time t. As an illustration, let us check the property (2.4) of the compensator, in this special case. For any integrable f, we have, since T_n^1 and T_n^2 have the same distribution (cf. Remark 2):

$$\begin{aligned}
E\left[\int_0^t \int_{\mathbb{R}} f(k)\mu(\mathrm{d}k,\mathrm{d}s)\right] &= E\left[\sum_{k=1}^{\infty} \int_0^t \int_{\mathbb{R}} f(k)\,\delta_{(\alpha,T_k^1)}(\mathrm{d}k,\mathrm{d}s) + \int_0^t \int_{\mathbb{R}} f(k)\,\delta_{(-\alpha,T_k^2)}(\mathrm{d}k,\mathrm{d}s)\right] \\
&= E\left[\sum_{k=1}^{\infty} f(\alpha)1_{\{T_k^1\leqslant t\}} + f(-\alpha)1_{\{T_k^1\leqslant t\}}\right] \\
&= (f(\alpha)+f(-\alpha))\sum_{k=1}^{\infty} P(T_k^1 \leqslant t) \\
&= \frac{1}{2\alpha^2}(f(\alpha)+f(-\alpha))\sum_{k=1}^{\infty} \int_0^t e^{-s/(2\alpha^2)}\frac{(s/(2\alpha^2))^{k-1}}{(k-1)!}\mathrm{d}s \\
&= \frac{t}{2\alpha^2}(f(\alpha)+f(-\alpha)) = \int_0^t \int_{\mathbb{R}} f(k)\,\nu(\mathrm{d}k)\mathrm{d}s,
\end{aligned}$$

hence $E[\mu(\mathrm{d}k,\mathrm{d}s)] = \nu(\mathrm{d}k)\mathrm{d}s$, as claimed. Here we can compute

$$\begin{aligned}
e^{-(1/\hbar)t\hat{H}}f(p) &= E[f(p+\alpha(N_t^1 - N_t^2))e^{-(1/2\hbar)\int_0^t \|p+\alpha(N_\tau^1 - N_\tau^2)\|^2\,\mathrm{d}\tau}] \\
&= e^{-t}\sum_{k,l\geqslant 0}\left(\frac{1}{2}\right)^{k+l} f(p+\alpha(k-l)) \\
&\quad \times \int_0^t\int_0^{t_k}\cdots\int_0^{t_2}\int_0^t\int_0^{s_l}\cdots\int_0^{s_2} e^{-(1/2\hbar)\int_0^t \|p+\alpha(\sum_{i=1}^{k} i1_{[t_i,t]}(\tau)} \\
&\quad - \sum_{i=j}^{l} i1_{[s_j,t]}(\tau))\|^2\,\mathrm{d}\tau \mathrm{d}s_1\cdots\mathrm{d}s_l\,\mathrm{d}t_1\cdots\mathrm{d}t_k.
\end{aligned}$$

It is generally hard to solve difference equations like (3.7) for $\hat{H}$ given before. As an illustration, let us observe that the solution of its time independent version, namely the stationary equation associated with (3.7),

$$\frac{p^2}{2}u(p) - \frac{1}{2}(u(p+1)+u(p-1)-2u(p)) = Eu(p),$$

is given, for $u(0)=u_0$ and $u(1)=u_1$, by

$$\begin{aligned}
u(p) = &-\frac{(-2)^{p+1}(au_1 - u_1\sqrt{a^2-4} + a^2u_0 - au_0\sqrt{a^2-4} - 2u_0)}{(a-\sqrt{a^2-4})^{p+2}\sqrt{a^2-4}} \\
&+ \frac{(-2)^{p+1}(au_1 + u_1\sqrt{a^2-4} + a^2u_0 + au_0\sqrt{a^2-4} - 2u_0)}{(a+\sqrt{a^2-4})^{p+2}\sqrt{a^2-4}} \\
&+ \frac{(a+\sqrt{a^2-4})^{p+1} + (a-\sqrt{a^2-4})^{p+1}}{(-2)^{p+1}(a+2)^2} + \frac{a-(a+2)(p^2+8p+12)}{(a+2)^2},
\end{aligned}$$

with $a=E+2$ (computation done using the command rsolve in Maple).

(2) Harmonic oscillator: $V(q)=\frac{1}{2}\|q\|^2$. This is the case $\nu(\mathrm{d}k)=0$ in (2.1), and

$$\hat{H}u(p)=\frac{1}{2}\|p\|^2u(p)-\frac{\hbar^2}{2}\Delta u(p).$$

Clearly, the Lévy–Itô decomposition reduces to $\xi_t=W_t^{\hbar}$, i.e., the underlying Lévy process is a Brownian motion (with variance $\hbar$). Notice that this case can be regarded as the limit $\alpha\searrow 0$ of Example 1.

(3) $V(q)=c\|q\|^{\alpha}$, $c>0$, $\alpha\in(0,2]$. Then

$$\nu(\mathrm{d}k)=\begin{cases}0, & \text{when } \alpha=2 \text{(this is the case in Example 2)},\\ \dfrac{c_\alpha}{|k|^{1+\alpha}}\mathrm{d}k, & \text{when } \alpha\neq 2,\end{cases}$$

where $c_\alpha>0$ depends on the value of α. The associated Lévy process is called a "stable process of order α" (and α its "index of stability"). Recall that by (2.2), the existence of moments of order up to $n\geqslant 1$ for ξ_t implies the nth differentiability of $V(q)$ at $q=0$, the converse being true for moments of even order, see, e.g., Ref. 32, Theorem 1, p. 278. In particular, α-stable distributions on $\mathbb{R}$ have finite mean if and only if $\alpha>1$.

Those processes are important because of their rotational invariance (in dimension $d>1$) and also because they are self-similar. Recall that a stochastic process Z_t is self-similar with Hurst index $H>0$ if, $\forall a\geqslant 0$, Z_{at} and a^HZ_t, $t\geqslant 0$, have same finite-dimensional distributions (we refer to Ref. 8 for more about self-similar processes). In particular the stable process $(\xi_t)_{t\geqslant 0}$ of order α is self-similar with Hurst index $1/\alpha$, i.e., we have $\xi_{at}=a^{1/\alpha}\xi_t$, $a\geqslant 0$. For such processes the Hamiltonian (3.6) becomes

$$\hat{H}u(p)=\tfrac{1}{2}\|p\|^2u(p)-c\hbar^{\alpha}\Delta^{\alpha/2}u(p),$$

involving the fractional power of the Laplacian, a highly nonlocal operator, often linked with relativistic Hamiltonians, cf. Ref. 14. When $\alpha=2$, i.e., in the case of the Brownian motion $W_t^{\hbar}$ appearing in (2.3), this scaling property can be traced back to one of the "isovectors" of the symmetry group of the classical heat equation (1.5) for the free Hamiltonian $H_0=-(\hbar^2/2)\Delta$, cf. Ref. 21.

(4) $V(q)=(1/a^2)\log\cosh aq$, $a>0$. The Lévy measure is of the form

$$\nu(\mathrm{d}k)=\frac{1}{2a^2}\frac{\mathrm{d}k}{k\sinh(k\pi/(2a))},$$

see, e.g., Refs. 5,12,30 [note that in Eq. (2) of Ref. 12 as well as in Eq. (4) of Ref. 5, cosh should be replaced by sinh]. Notice that in the limit $a\searrow 0$ this measure reduces to 0, and the potential V becomes the harmonic one of Example 2. The associated process ξ_t is called Meixner process,[24] and its Lévy–Itô decomposition has no diffusive part. Its expectation and variance are, respectively, given by $E[\xi_t]=0$, $E[\xi_t^2]=t$, $t>0$. The corresponding Hamiltonian is

$$\hat{H}u(p)=\frac{1}{2}\|p\|^2u(p)-\frac{1}{2a^2}\int_{\mathbb{R}^d\setminus\{0\}}(u(p+\hbar k)-u(p))\frac{\mathrm{d}k}{k\sinh(k\pi/(2a))}.$$

(5) $V(q)=(1/a^2)\log(1+a^2q^2)$, $a>0$. The Lévy measure

$$\nu(\mathrm{d}k)=\frac{1}{a^2|k|}e^{-|k|/a}\,\mathrm{d}k$$

is one of the (symmetric) variance gamma process (cf., for instance, Ref. 22), whose expectation and variance are, respectively, $E[\xi_t]=0$, $E[\xi_t^2]=2t$, $t>0$. Notice that when the param-

eter a is large the exponential decay of $\nu(\mathrm{d}k)$ is lower around zero and so the probability of large jumps increases. According to Remark 2, the paths of the variance gamma process are of bounded variation. This process has no continuous martingale component but is a pure jump process with infinite number of jumps in any compact time interval. Of course the associated Hamiltonian operator is given by

$$\hat{H}u(p) = \frac{1}{2}\|p\|^2 u(p) - \frac{1}{a^2}\int_{\mathbb{R}\setminus\{0\}} (u(p+\hbar k) - u(p))\frac{e^{-|k|/a}}{|k|}\mathrm{d}k.$$

As in Example 4, this case reduces to the harmonic one when $a \searrow 0$.

Before explaining how the existence of the relevant class of Bernstein processes can be proved, let us introduce some notation and assumptions. In the sequel we make the absolute continuity hypothesis, with an obvious abuse of notation,

$$h(t,p,u,\mathrm{d}l) = h(t,p,u,l)\lambda(\mathrm{d}l), \quad \lambda(\mathrm{d}p) - a\,.\,e\,., \tag{3.10}$$

$0<t<u$, $p,l \in \mathbb{R}^d$, where λ denotes a given reference measure. In particular, for $r \leqslant t \leqslant v$, we have

$$\hat{\eta}_t^*(p) = e^{-(1/\hbar)(t-r)\hat{H}}\hat{\eta}_r^*(p) = \int_{\mathbb{R}^d} \hat{\eta}_r^*(i)h(r,i,t,p)\lambda(\mathrm{d}i)$$

and

$$\hat{\eta}_t(p) = e^{-(1/\hbar)(v-t)\hat{H}}\hat{\eta}_v(p) = \int_{\mathbb{R}^d} \hat{\eta}_v(m)h(t,p,v,m)\lambda(\mathrm{d}m).$$

This condition is satisfied, for example, if

(i) the law of $\xi_t, t>0$, has a density with respect to Lebesgue measure, e.g., in the case of stable processes (see Example 3) and for Lévy processes with Brownian component, or

(ii) $\mu_{t-s}(-j+\mathrm{d}p)$ has a density with respect to $\lambda(\mathrm{d}p), \lambda(\mathrm{d}j)$, a.e. In particular this will follow from Proposition 3.1 if λ is absolutely continuous under the translation $p \mapsto j+p$, $\lambda(\mathrm{d}j)$, a.e., and μ_{t-s} is absolutely continuous with respect to λ,

$$\mu_{t-s}(\mathrm{d}p) = \mu_{t-s}(p)\lambda(\mathrm{d}p).$$

This is the case in particular for the symmetric Poisson process of Example 1 with $\lambda(\mathrm{d}p) = \Sigma_{n=-\infty}^{\infty}\delta_{\alpha\times n}(\mathrm{d}p)$.

Note that we have $h(s,j,t,p) = h(t,p,s,j)$, since $\hat{H}$ that is symmetric with respect to λ.

IV. MOMENTUM REPRESENTATION AND BERNSTEIN–LÉVY PROCESSES

This section summarizes the existence results for Bernstein processes established in Ref. 25. Let $\hat{\eta}_r^*, \hat{\eta}_v : \mathbb{R}^d \to \mathbb{R}_+$ be two λ-a.e. strictly positive initial and final conditions of (1.3) and (1.5), respectively, such that for some $t \in I = [r,v]$, and therefore for any such t,

$$\int_{\mathbb{R}^d} \hat{\eta}_t^*(p)\,\hat{\eta}_t(p)\lambda(\mathrm{d}p) = 1. \tag{4.1}$$

As explained in the introduction, this relation will be interpreted as a Euclidean version of Born's probabilistic interpretation of the wave function in momentum representation. More precisely, and since no specific relation between $\hat{\eta}_t^*$ and $\hat{\eta}_t$ is needed for the last identity to make sense, (4.1) will be regarded as the Euclidean counterpart of the time invariance of any transition amplitudes in Feynman's approach. So the following result shows in particular that, quite in contrast with the

quantum case, this Euclidean (Born) probabilistic interpretation of the wave function in momentum representation is mathematically justifiable.

Theorem 4.1: (Ref. 25) *There exists a* $\mathbb{R}^d$*-valued process* $(\hat{z}_t)_{t\in[r,v]}$ *whose probability density at time* t *with respect to* λ *is precisely given by the product*

$$\rho_t(p) = \hat{\eta}_t^*(p)\,\hat{\eta}_t(p).$$

This process $(\hat{z}_t)_{t\in[r,v]}$ *is both forward and backward Markovian, with forward transition probability kernel, for* $r<s<t<u<v$ *and* $j,p,l\in\mathbb{R}^d$*, given by*

$$\hat{\mathrm{p}}(t,p,u,l) = \frac{\hat{\eta}_u(l)}{\hat{\eta}_t(p)}h(t,p,u,l), \tag{4.2}$$

and backward transition probability kernel

$$\hat{\mathrm{p}}^*(s,j,t,p) = \frac{\hat{\eta}_s^*(j)}{\hat{\eta}_t^*(p)}h(s,j,t,p). \tag{4.3}$$

In particular, the initial and final laws of $(\hat{z}_t)_{t\in[r,v]}$ are of the form

$$\pi_r(\mathrm{d}i) = \hat{\eta}_r(i)\,\hat{\eta}_r^*(i)\lambda(\mathrm{d}i) \quad \text{and } \pi_v(\mathrm{d}m) = \hat{\eta}_v(m)\,\hat{\eta}_v^*(m)\lambda(\mathrm{d}m).$$

In fact, if $h(s,j,t,p)$ is continuous in (j,p) and strictly positive for all $0<s<t$, Theorem 1 of Ref. 4 (see also Theorem 3.2 of Ref. 17, and Theorem 3.4 of Ref. 35) state that given any two strictly positive probability densities $\pi_r(i)$ and $\pi_v(m)$, it is indeed possible to find two strictly positive functions $\hat{\eta}_r^*$, $\hat{\eta}_v:\mathbb{R}^d\to\mathbb{R}_+$ such that

$$\pi_r(i) = \hat{\eta}_r^*(i)\,\hat{\eta}_r(i), \quad \pi_v(m) = \hat{\eta}_v(m)\,\hat{\eta}_v^*(m).$$

A posteriori, $\hat{\eta}_r^*$ and $\hat{\eta}_v$ can, therefore, be interpreted as (positive) initial and final boundary conditions of the two underlying adjoint equations (1.3) and (1.5). The resulting process $(\hat{z}_t)_{t\in[r,v]}$ is a (Markovian) Bernstein process (cf. Ref. 7, for example). As observed in (1.6) this means in particular that

$$P(\hat{z}_t\in\mathrm{d}p|\mathcal{P}_s\vee\mathcal{F}_u) = P(\hat{z}_t\in\mathrm{d}p|\hat{z}_s,\hat{z}_u),$$

and that the joint law $P(\hat{z}_r\in A,\hat{z}_v\in B)$, for A,B two Borelians of $\mathbb{R}^d$, has the special form

$$P(\hat{z}_r\in A,\hat{z}_v\in B) = \int_{A\times B}\hat{\eta}_r^*(i)h(r,i,v,m)\,\hat{\eta}_v(m)\lambda(\mathrm{d}i)\lambda(\mathrm{d}m).$$

Conversely, we also have a uniqueness result, i.e., if $(\hat{z}_t)_{t\in[r,v]}$ is a Markovian Bernstein process with Bernstein kernel $h(s,j,t,\mathrm{d}p,u,l)=P(\hat{z}_t\in\mathrm{d}p\,|\,\hat{z}_s=j,\hat{z}_u=l)$ (cf. Refs. 7,25) such that

$$h(s,j,t,\mathrm{d}p,u,l)h(s,j,u,l) = h(s,j,t,p)h(t,p,u,l)\lambda(\mathrm{d}p),$$

$s\leqslant t\leqslant u$ and $j,p,\ l\in\mathbb{R}^d$, then there exist positive density functions $\hat{\eta}_r^*(i)$ and $\hat{\eta}_v(m)$ such that

$$P(\hat{z}_r\in A,\hat{z}_v\in B) = \int_{A\times B}\hat{\eta}_r^*(i)h(r,i,v,m)\,\hat{\eta}_v(m)\lambda(\mathrm{d}i)\lambda(\mathrm{d}m),$$

see Theorem 7.1 in Ref. 25. The processes $(\hat{z}_t)_{t\in[r,v]}$ resulting from the construction of Theorem 4.1 can be regarded as generalizations of the usual concept of Markovian bridges (cf., for example, Ref. 6 in the more familiar case of diffusion processes), which corresponds to Dirac boundary conditions at the boundary of the time interval $[r,v]$. In contrast, here, we allow for any (λ-a.e. strictly positive) probability densities π_r and π_v. We shall give a description of Markovian bridges of Theorem 4.1 in terms of forward and backward stochastic integro-differential equations driven

by the Lévy process $(\xi_t)_{t\in[r,v]}$ of Sec. II. Let us recall that, for stochastic equations, the analog of classical solutions of integro-differential equations is called a strong solution (in this case the solution is a process). It requires, indeed, strong regularity conditions on the coefficients of the equation, for example Lipschitz conditions for stochastic differential equations. When more general coefficients are needed, there is a concept of weak solution, where one looks for a unique process with the proper set of finite-dimensional distributions (cf. Ref. 16 for instance). Then the solution is a probability measure. Let z_{t^-}, respectively, z_{t^+}, denote the left, respectively, the right, limit of z_t at $t\in[r,v]$.

The proof of the next Proposition 4.2 relies on Lemma 4.3 below, (cf. Ref. 25) which gives the forward and backward generators of the process $(\hat{z}_t)_{t\in I}$ constructed in Theorem 4.1. Indeed, the knowledge of the generators of $(\hat{z}_t)_{t\in I}$ provides the forward and backward representations (4.4) and (4.5) of $(\hat{z}_t)_{t\in I}$ as weak solutions of stochastic integro-differential equations, using Theorem 13.58, Theorem 14.80 of Ref. 16, pp. 438 and 481, and references therein. In order for these representations to hold, we need to assume that the conditions given on p. 434 of Ref. 16 are fulfilled:

(H3) The functions

$$(t,p)\mapsto \int_{\mathbb{R}^d}(1\wedge\|k\|^2)\frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)}\nu(\mathrm{d}k),$$

$$(t,p)\mapsto \int_{\{0<|k|\leqslant 1\}}k\frac{\hat{\eta}_t(p+\hbar k)-\hat{\eta}_t(p)}{\hat{\eta}_t(p)}\nu(\mathrm{d}k),$$

$$(t,p)\mapsto \nabla\ \log\ \hat{\eta}_t(p),$$

(H4) as well as

$$(t,p)\mapsto \int_{\mathbb{R}^d}(1\wedge\|k\|^2)\frac{\hat{\eta}^*_t(p-\hbar k)}{\hat{\eta}^*_t(p)}\nu(\mathrm{d}k),$$

$$(t,p)\mapsto \int_{\{0<|k|\leqslant 1\}}k\frac{\hat{\eta}^*_t(p-\hbar k)-\hat{\eta}^*_t(p)}{\hat{\eta}^*_t(p)}\nu(\mathrm{d}k),$$

$$(t,p)\mapsto \nabla\ \log\ \hat{\eta}^*_t(p),$$

are bounded on compacts of $\mathbb{R}_+\times\mathbb{R}^d$.

Proposition 4.2: *The process $(\hat{z}_t)_{t\in[r,v]}$ is solution, in the weak sense and with respect to the forward filtration $(\mathcal{P}_t)_{t\in[r,v]}$, of*

$$\mathrm{d}\hat{z}_t=\mathrm{d}W^{\hbar}_t+\int_{\mathbb{R}^d}k\mu(\mathrm{d}k,\mathrm{d}t)+\hbar\ \nabla\ \log\ \hat{\eta}_t(\hat{z}_{t^-})\mathrm{d}t, \tag{4.4}$$

under a probability P for which $W^{\hbar}_t$ is a (forward) Brownian motion with variance $\hbar$, and $\mu(\mathrm{d}k,\mathrm{d}s)$ is the canonical point measure with compensator $[\hat{\eta}_t(\hat{z}_{t^-}+\hbar k)/\hat{\eta}_t(\hat{z}_{t^-})]\nu(\mathrm{d}k)\mathrm{d}t$.

In terms of backward differentials, $(\hat{z}_t)_{t\in[r,v]}$ solves weakly, with respect to the decreasing filtration $(\mathcal{F}_t)_{t\in[r,v]}$:

$$\mathrm{d}_*\hat{z}_t = \mathrm{d}_*W_t^{\hbar *} + \int_{\mathbb{R}^d} k\mu_*(\mathrm{d}k,\mathrm{d}t) - \hbar\,\nabla\,\log\,\hat{\eta}_t^*(\hat{z}_{t^+})\mathrm{d}t, \tag{4.5}$$

where $W_t^{\hbar *}$ denotes a backward Brownian motion with variance $\hbar$, and $\mu_*(\mathrm{d}k,\mathrm{d}t)$ is the backward Poisson random measure with compensator $[\hat{\eta}_t^*(\hat{z}_{t^+}-\hbar k)/\hat{\eta}_t^*(\hat{z}_{t^+})]\nu(\mathrm{d}k)\mathrm{d}t$. In (4.4) and (4.5), $(\hat{z}_t)_{t\in[r,v]}$ represents the process (associated with our system in the momentum representation) whose probability density is of the form $\rho_t(p)$, as in Theorem 4.1. Let us define for $f\in\mathcal{S}(\mathbb{R}^d)$ and $g:\mathbb{R}^d\mapsto(0,\infty)$ the integro differential operator $\mathcal{L}_g$ by

$$\mathcal{L}_g f(p) = \frac{\hbar}{2}\Delta f(p) + \frac{1}{\hbar}\int_{\mathbb{R}^d}(f(p+\hbar k)-f(p))\frac{g(p+\hbar k)}{g(p)}\nu(\mathrm{d}k) + \hbar\langle\nabla\,\log g(p),\,\nabla f(p)\rangle. \tag{4.6}$$

The forward and backward generators $\mathcal{L}_{\hat{\eta}_t}$ and $-\mathcal{L}_{\hat{\eta}_t^*}$ of $(\hat{z}_t)_{t\in I}$ are given from the next lemma.

Lemma 4.3: *The kernels* $\hat{\mathrm{p}}(t,p,u,l)$ *and* $\hat{\mathrm{p}}^*(s,j,t,p)$ *defined in* (4.2) and (4.3) *satisfy the partial integro-differential (Kolmogorov forward or Fokker–Planck) equations*

$$\frac{\partial\hat{\mathrm{p}}}{\partial u}(t,p,u,l) = (\mathcal{L}_{\hat{\eta}_u})_l^\dagger\hat{p}(t,p,u,l), \tag{4.7}$$

where † *denotes the adjoint,* $\mathcal{L}_{\hat{\eta}_s}$ *is the forward generator given by*

$$\mathcal{L}_{\hat{\eta}_s} f = \frac{\hbar}{2}\Delta f(p) + \frac{1}{\hbar}\int_{\mathbb{R}^d}(f(p+\hbar k)-f(p))\frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)}\nu(\mathrm{d}k) + \hbar\langle\nabla\,\log\,\hat{\eta}_t(p),\,\nabla f(p)\rangle, \tag{4.8}$$

and

$$\frac{\partial\hat{\mathrm{p}}^*}{\partial s}(s,j,t,p) = -(\mathcal{L}_{\hat{\eta}_s^*})_j^\dagger\hat{\mathrm{p}}(s,j,t,p),$$

where $-\mathcal{L}_{\hat{\eta}_s^*}$ *is the backward generator given by*

$$-\mathcal{L}_{\hat{\eta}_s^*} f = -\frac{\hbar}{2}\Delta f(p) - \frac{1}{\hbar}\int_{\mathbb{R}^d}(f(p+\hbar k)-f(p))\frac{\hat{\eta}_t^*(p+\hbar k)}{\hat{\eta}_t^*(p)}\nu(\mathrm{d}k) - \hbar\langle\nabla\,\log\,\hat{\eta}_t^*(p),\,\nabla f(p)\rangle. \tag{4.9}$$

Let the forward and backward derivative operators D_t and D_t^* be defined informally, on two appropriate domains of real-valued functions f, in terms of the Hamiltonian H and two positive solutions $\hat{\eta}_t$, $\hat{\eta}_t^*$ of (3.7) and (3.8) by

$$D_t f = \frac{1}{\hat{\eta}_t}\left(\frac{\partial}{\partial t} - \frac{1}{\hbar}\hat{H}\right)(\hat{\eta}_t f)$$

and

$$D_t^* f = \frac{1}{\hat{\eta}_t^*}\left(\frac{\partial}{\partial t} + \frac{1}{\hbar}\hat{H}\right)(\hat{\eta}_t^* f).$$

Lemma 4.3 is proved using the following decompositions of D_t and D_t^*, which are straightforward to verify

$$D_t = \frac{\partial}{\partial t} + \mathcal{L}_{\hat{\eta}_t} \quad \text{and } D_t^* = \frac{\partial}{\partial t} - \mathcal{L}_{\hat{\eta}_t^*}. \tag{4.10}$$

Let us observe that for constant f, in particular, these two derivative operators are zero by definition. But many nontrivial functions $f:\mathbb{R}^d\times I\to\mathbb{R}$ in these domains have the same property. For

instance let $(\tilde{\eta}_t)_{t\in[r,v]}$ denote a positive solution of (3.7) on I, distinct from $(\hat{\eta}_t)_{t\in[r,v]}$. Then clearly we have $D_t f=0$ as well when $f=\tilde{\eta}_t/\hat{\eta}_t$.

V. VARIATIONAL CHARACTERIZATION AND LAGRANGIAN

As indicated in the introduction, a natural way to interpret the version of Euclidean quantum mechanics advocated here is as a mathematical counterpart of Feynman's path integral approach. In Feynman's perspective, the variational derivations of the quantum laws of motion (as well as some kinematical characterizations of the paths) is fundamental (cf. Refs. 1,10). We prove in this section and the next one that as far as the dynamics of the momentum representation is concerned, such a variational approach is well defined and provides a characterization of the stochastic process constructed before. More precisely, we will use the approach to stochastic control for jump processes of Refs. 31,11, to obtain a variational characterization of the Markovian Bernstein processes (or reversible diffusions with jumps) considered above. We consider the stochastic control problem $\inf_{\hat{S}} J(t,p;\hat{S})$ with action functional

$$J(t,p;\hat{S}) = E_{(t,p)}\left[\int_t^v \mathcal{L}(\hat{z}(s),\hat{S}_s)\mathrm{d}s - \hbar \log \hat{\eta}_v(\hat{z}(v))\right], \tag{5.1}$$

where $E_{(t,p)}$ denotes the conditional expectation given $\{\hat{z}_t=p\}$, the infimum is taken on the set of control variables made of all measurable scalar functions $\hat{S}_\cdot:\mathbb{R}^d\times\mathbb{R}_+\to\mathbb{R}$, and the integrand $\mathcal{L}(p,\hat{S}_s)$ is defined as

$$\begin{aligned}
\mathcal{L}(p,\hat{S}_s) &= \mathcal{L}_{\exp(\hat{S}_s/\hbar)}\hat{S}_s(p) + e^{-\hat{S}_s(p)/\hbar}\hat{H}e^{\hat{S}_s(p)/\hbar} \\
&= \frac{1}{2}\|p\|^2 + \frac{1}{2}\|\nabla \hat{S}_s(p)\|^2 + \int_{\mathbb{R}^d}\left(1+\left(\frac{\hat{S}_s(p+\hbar k)-\hat{S}_s(p)}{\hbar}-1\right)e^{(\hat{S}_s(p+\hbar k)-\hat{S}_s(p))/\hbar}\right)\nu(\mathrm{d}k) \\
&= \frac{1}{2}\|p\|^2 + \frac{1}{2}\|\nabla \hat{S}_s(p)\|^2 + \int_{\mathbb{R}^d}\frac{\hat{S}_s(p+\hbar k)-\hat{S}_s(p)}{\hbar}e^{(\hat{S}_s(p+\hbar k)-\hat{S}_s(p))/\hbar}\nu(\mathrm{d}k) \\
&\quad - \int_{\mathbb{R}^d}(e^{(\hat{S}_s(p+\hbar k)-\hat{S}_s(p))/\hbar}-1)\nu(\mathrm{d}k).
\end{aligned}$$

In particular, when $\hat{S}_s=\hbar \log \hat{\eta}_s$,

$$\begin{aligned}
\mathcal{L}(p,\hbar \log \hat{\eta}_t) &= \hbar\mathcal{L}_{\hat{\eta}_t}\log \hat{\eta}_t(p) + \frac{1}{\hat{\eta}_t(p)}\hat{H}\hat{\eta}_t(p) = \hbar\mathcal{L}_{\hat{\eta}_t}\log \hat{\eta}_t(p) + \frac{\hbar}{\hat{\eta}_t(p)}\frac{\partial}{\partial t}\hat{\eta}_t(p) = \hbar\mathcal{L}_{\hat{\eta}_t}\log \hat{\eta}_t(p) \\
&\quad + \hbar\frac{\partial}{\partial t}\log \hat{\eta}_t(p) = \hbar D_t \log \hat{\eta}_t(p).
\end{aligned}$$

In other terms we have

$$\begin{aligned}
\mathcal{L}(p,\hbar \log \hat{\eta}_t) &= \frac{1}{2}\|p\|^2 + \frac{\hbar^2}{2}\|\nabla \log \hat{\eta}_t(p)\|^2 + \int_{\mathbb{R}^d}(\log \hat{\eta}_t(p+\hbar k) - \log \hat{\eta}_t(p))\frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)}\nu(\mathrm{d}k) \\
&\quad - \int_{\mathbb{R}^d}\frac{\hat{\eta}_t(p+\hbar k)-\hat{\eta}_t(p)}{\hat{\eta}_t(p)}\nu(\mathrm{d}k).
\end{aligned}$$

Now let us observe that

$$D_t p = \mathcal{L}_{\hat{\eta}_t} p = \hbar \nabla \log \hat{\eta}_t(p) + \int_{\mathbb{R}^d} k \frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)} \nu(\mathrm{d}k).$$

From now on, we will denote by $L(p, D_t p)$ and call Lagrangian, the integrand $\mathcal{L}(p, \hbar \log \hat{\eta}_t)$ of the action functional, when re-expressed in terms of the variables $p, D_t p$. We have, using (3.2) and the expression of $D_t p$,

$$\begin{aligned} L(p, D_t p) = {} & \frac{1}{2}\|p\|^2 + \hbar \left\langle \frac{\nabla \hat{\eta}_t}{\hat{\eta}_t}, D_t p \right\rangle + \frac{V(i\hbar \nabla)\hat{\eta}_t}{\hat{\eta}_t} + \frac{\hbar^2}{2}\frac{\Delta \hat{\eta}_t}{\hat{\eta}_t} - \frac{\hbar^2}{2}\left\| \frac{\nabla \hat{\eta}_t}{\hat{\eta}_t} \right\|^2 \\ & + \int_{\mathbb{R}^d} (\log \hat{\eta}_t(p+\hbar k) - \log \hat{\eta}_t(p)) \frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)} \nu(\mathrm{d}k) \\ & - \hbar \int_{\mathbb{R}^d} \langle k, \nabla \log \hat{\eta}_t(p) \rangle \frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)} \nu(\mathrm{d}k). \end{aligned}$$

By Taylor's formula applied inside the integral term we obtain the Lagrangian

$$\begin{aligned} L(p, D_t p) = {} & \frac{1}{2}\|p\|^2 + \hbar \left\langle \frac{\nabla \hat{\eta}_t}{\hat{\eta}_t}, D_t p \right\rangle + \frac{V(i\hbar \nabla)\hat{\eta}_t}{\hat{\eta}_t} \\ & + \frac{\hbar^2}{2}\Delta \log \hat{\eta}_t(p) \int_{\mathbb{R}^d} (1 + \|k\|^2 + o(\hbar^3)) \frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(p)} \nu(\mathrm{d}k). \end{aligned} \tag{5.2}$$

Let us observe that the action functional for $\hat{S}_s = \hbar \log \hat{\eta}_s$ can be expressed in various equivalent ways,

$$\begin{aligned} J(t,p;\hat{S}) &= E_{(t,p)}\left[\int_t^v D_s \hat{S}_s(\hat{z}_s)\mathrm{d}s - \hbar \log \hat{\eta}_v(\hat{z}(v)) \right] \\ &= E_{(t,p)}\left[\int_t^v \mathcal{L}(\hat{\eta}_t(\hat{z}_s), \hat{S}_s)\mathrm{d}s \right] - E_{(t,p)}[\hbar \log \hat{\eta}_v(\hat{z}_v)] \\ &= E_{(t,p)}[\hat{S}_v(\hat{z}_v) - \hat{S}_t(p) - \hbar \log \hat{\eta}_v(\hat{z}(v))] = E_{(t,p)}\left[\int_t^v \mathrm{d}\hat{S}_s(\hat{z}_s) - \hbar \log \hat{\eta}_v(\hat{z}(v)) \right] \\ &= E_{(t,p)}\left[\int_t^v \nabla \hat{S}_s(\hat{z}_s) \circ \mathrm{d}\hat{z}_s + \int_t^v \int_{\mathbb{R}^d} (\hat{S}_s(\hat{z}_{s^-} + \hbar k) - \hat{S}_s(\hat{z}_{s^-}))\mu(\mathrm{d}k, \mathrm{d}s) \right. \\ &\quad \left. + \int_t^v \frac{\partial}{\partial s}\hat{S}_s(\hat{z}_s)\mathrm{d}s - \hbar \log \hat{\eta}_v(\hat{z}(v)) \right] \\ &= E_{(t,p)}\left[\int_t^v \nabla \hat{S}_s(\hat{z}_s) \circ \mathrm{d}\hat{z}_s + \int_t^v \int_{\mathbb{R}^d} \hat{S}_s(\hat{z}_{s^-} + \hbar k)\nu(\mathrm{d}k)\mathrm{d}s \right. \\ &\quad \left. + \int_t^v \frac{\partial}{\partial s}\hat{S}_s(\hat{z}_s)\mathrm{d}s - \hbar \log \hat{\eta}_v(\hat{z}(v)) \right], \end{aligned}$$

where we have used the extension of Itô's calculus to our diffusions with jumps. The symbol $\circ$ denotes the Fisk–Stratonovich differential (cf., e.g., Ref. 26). Let us show that the diffusion processes with jumps constructed before can also be regarded as minima of a stochastic action functional associated with the starting $\hat{H}$. The infima are taken on all measurable functions $\hat{S}_t : \mathbb{R}^d \to \mathbb{R}$:

Proposition 5.1. *The dynamic programming equation with final boundary condition*

$$\frac{\partial A_t}{\partial t}(p) + \min_{\hat{S}_t}(\mathcal{L}_{\exp(\hat{S}/\hbar)}A_t(p) + L(p,\hat{S}_t)) = 0, \quad A_v = -\hbar \log \hat{\eta}_v, \tag{5.3}$$

associated with the action functional (5.1) *is equivalent to the Hamilton–Jacobi–Bellman equation*

$$\frac{\partial A_t}{\partial t}(p) = -\frac{1}{2}\|p\|^2 - \frac{\hbar}{2}\Delta A_t(p) + \frac{1}{2}\|\nabla A_t(p)\|^2 + \int_{\mathbb{R}^d}(e^{-\hbar^{-1}(A_t(p+\hbar k)-A_t(p))} - 1)\mathrm{d}\nu(k), \quad A_v = -\hbar \log \hat{\eta}_v, \tag{5.4}$$

with solution $A_t = -\hbar \log \hat{\eta}_t$, $r \leqslant t \leqslant v$. *Moreover, in* (5.3), *the minimum in* $\hat{S}_t$ *is attained on* $\hat{S}_t = \hbar \log \hat{\eta}_t$.

Proof: Given $\hat{S}_t$ and A_t two suitable functions, let us define

$$F(p,k) = \frac{A_t(p+\hbar k) - A_t(p)}{\hbar} e^{(\hat{S}_t(p+\hbar k)-\hat{S}_t(p))/\hbar} + \frac{\hat{S}_t(p+\hbar k) - \hat{S}_t(p)}{\hbar} e^{(\hat{S}_t(p+\hbar k)-\hat{S}_t(p))/\hbar}$$
$$- e^{(\hat{S}_t(p+\hbar k)-\hat{S}_t(p))/\hbar} + e^{-(A_t(p+\hbar k)-A_t(p))/\hbar}.$$

We have

$$\begin{aligned}\mathcal{L}(p,\hat{S}_t) + \mathcal{L}_{\exp(\hat{S}_t/\hbar)}A_t(p) - e^{A_t(p)/\hbar}\hat{H}e^{-A_t(p)/\hbar} &= \mathcal{L}_{\exp(\hat{S}_t/\hbar)}(A_t(p) + \hat{S}_t(p)) \\ &\quad + e^{-\hat{S}_t(p)/\hbar}\hat{H}e^{\hat{S}_t(p)/\hbar} - e^{A_t(p)/\hbar}\hat{H}e^{-A_t(p)/\hbar} \\ &= \hbar\int_{\mathbb{R}^d} F(p,k)\,\nu(\mathrm{d}k) + \frac{1}{2}\|\nabla A_t(p) + \nabla \hat{S}_t(p)\|^2 \\ &\geqslant \hbar\int_{\mathbb{R}^d} F(p,k)\,\nu(\mathrm{d}k).\end{aligned}$$

Now, for all $a > 0$,

$$\min_{x\in\mathbb{R}}(xa + a\log a - a + e^{-x}) = 0,$$

hence taking $x = (A_t(p+\hbar k) - A_t(p))/\hbar$ and $a = e^{(\hat{S}_t(p+\hbar k)-\hat{S}_t(p))/\hbar}$, we have $F(p,k) \geqslant 0$, and

$$\mathcal{L}(p,\hat{S}_t) + \mathcal{L}_{\exp(\hat{S}_t/\hbar)}A_t(p) - e^{A_t(p)/\hbar}\hat{H}e^{-A_t(p)/\hbar} \geqslant 0,$$

the minimum (zero) being attained for $\hat{S}_t = -A_t$, i.e.,

$$\min_{\hat{S}_t}(L(p,\hat{S}_t) + \mathcal{L}_{\exp(\hat{S}_t/\hbar)}A_t) = e^{A_t(p)/\hbar}\hat{H}e^{-A_t(p)/\hbar}.$$

The dynamic programming equation (5.3) can be formulated as

$$\frac{\partial A_t}{\partial t} + e^{A_t/\hbar}\hat{H}e^{-A_t/\hbar} = 0,$$

and its solution is $A_t = -\hbar \log \hat{\eta}_t$. Finally, from the relation

$$\frac{1}{\hbar}\Delta A_t = -e^{A_t/\hbar}\Delta e^{-A_t/\hbar} + \frac{1}{\hbar^2}\|\nabla A_t\|^2,$$

we have

$$e^{A_t(p)/\hbar}\hat{H}e^{-A_t(p)/\hbar} = e^{A_t(p)/\hbar}\left(\frac{1}{2}\|p\|^2 e^{-A_t(p)/\hbar} - \frac{\hbar}{2}\Delta e^{-A_t(p)/\hbar} - \int_{\mathbb{R}^d}(e^{-(A_t(p+\hbar k)-A_t(p))/\hbar})\,\nu(\mathrm{d}k)\right)$$

$$= \frac{1}{2}\|p\|^2 + \frac{\hbar}{2}\Delta A_t - \frac{1}{2}\|\nabla A_t\|^2 - \int_{\mathbb{R}^d}(e^{-\hbar^{-1}(A_t(p+\hbar k)-A_t(p))} - 1)\,\nu(\mathrm{d}k),$$

which yields (5.4). ■

In the backward case we consider the action functional time reversed of (5.1),

$$J^*(t,p;\hat{S}^*) = E_{(t,p)}\left[\int_r^t \mathcal{L}(\hat{z}(s),\hat{S}^*)\mathrm{d}s - \hbar\log\hat{\eta}_r^*(\hat{z}(r))\right]. \tag{5.5}$$

Similarly when $\hat{S}_s = \hbar\log\hat{\eta}_s^*$ we verify that

$$\mathcal{L}(p,\hbar\log\hat{\eta}_s^*) = -\hbar D_s^*\log\hat{\eta}_s^*(p),$$

where we have used (4.10) and the backward generator (4.9). Then

$$\begin{aligned}
J^*(t,p;\hat{S}^*) &= -E_{(t,p)}\left[\int_r^t D_s^*\hat{S}_s^*(\hat{z}_s^*)\mathrm{d}s + \hbar\log\hat{\eta}_r^*(\hat{z}(r))\right]\\
&= E_{(t,p)}[\hat{S}_r^*(\hat{z}_r) - \hat{S}_t^*(\hat{z}_t) - \hbar\log\hat{\eta}_r^*(\hat{z}(r))]\\
&= -E_{(t,p)}\left[\int_r^t \mathrm{d}\hat{S}_s^*(\hat{z}_s^*) + \hbar\log\hat{\eta}_r^*(\hat{z}(r))\right]\\
&= -E_{(t,p)}\left[\int_r^t \nabla\hat{S}_s^*(\hat{z}_s) \mp d_*\hat{z}_s^* + \int_r^t\int_{\mathbb{R}^d}(\hat{S}_s^*(\hat{z}_{s^+}+\hbar k) - \hat{S}_s^*(\hat{z}_{s^+}))\mu_*(\mathrm{d}k,\mathrm{d}s)\right.\\
&\quad \left. + \int_r^t \frac{\partial}{\partial s}\hat{S}_s^*(\hat{z}_s^*)\mathrm{d}s + \hbar\log\hat{\eta}_r^*(\hat{z}(r))\right]\\
&= -E_{(t,p)}\left[\int_r^t \nabla\hat{S}_s^*(\hat{z}_s)\mathrm{od}_*\hat{z}_s^* + \int_r^t\int_{\mathbb{R}^d}\hat{S}_s^*(\hat{z}_{s^+}+\hbar k)\,\nu(\mathrm{d}k)\mathrm{d}s + \int_r^t \frac{\partial}{\partial s}\hat{S}_s^*(\hat{z}_s^*)\mathrm{d}s\right.\\
&\quad \left. + \hbar\log\hat{\eta}_r^*(\hat{z}(r))\right].
\end{aligned}$$

With respect to the underlying filtration $\mathcal{F}_t$, the Lagrangian now takes the form

$$L(p,D_t^*p) = \frac{1}{2}\|p\|^2 - \hbar\left\langle\frac{\nabla\hat{\eta}_t^*}{\hat{\eta}_t^*}, D_t^*p\right\rangle + \frac{V(i\hbar\nabla)\hat{\eta}_t^*}{\hat{\eta}_t^*} - \frac{\hbar^2}{2}\Delta\log\hat{\eta}_t^*(p)\int_{\mathbb{R}^d}(1+\|k\|^2 + o(\hbar^3))\frac{\hat{\eta}_t^*(p+\hbar k)}{\hat{\eta}_t^*(p)}\nu(\mathrm{d}k), \tag{5.6}$$

and the following backward version of Proposition 5.1 holds true.

Proposition 5.2: *The backward dynamic programming equation with initial boundary condition*

$$\frac{\partial A_t^*}{\partial t}(p) + \min_{\hat{S}_t^*}(\mathcal{L}_{\exp(\hat{S}^*/\hbar)}A_t^*(p) + L(p,\hat{S}_t^*)) = 0, \quad A_r^* = -\hbar\log\hat{\eta}_r^*, \tag{5.7}$$

associated with (5.5), *is equivalent to the backward Hamilton–Jacobi–Bellman equation*

$$\frac{\partial A_t^*}{\partial t}(p) = \frac{1}{2}\|p\|^2 + \frac{\hbar}{2}\Delta A_t^*(p) - \frac{1}{2}\|\nabla A_t^*(p)\|^2 - \int_{\mathbb{R}^d}(e^{-\hbar^{-1}(A_t^*(p+\hbar k)-A_t^*(p))} - 1)\mathrm{d}\nu(k), \quad A_r^* = -\hbar \log \hat{\eta}_r^*, \tag{5.8}$$

with solution $A_t^* = -\hbar \log \hat{\eta}_t^*$, $r \leqslant t \leqslant v$. *Moreover, in* (5.7), *the minimum in* $\hat{S}_t^*$ *is attained at* $\hat{S}_t^*(p) = \hbar \log \hat{\eta}_t^*(p)$.

Proof: Of course, Propositions 5.1 and 5.2 will not be formally used. The key point is that $\hat{z}_t$, $t \in I$, can be regarded as critical point of a stochastic variational principle. Proposition 5.1 is sufficient since $\hat{z}_t$, $t \in I$, is time reversible in the above mentioned sense. But it is illustrative to show that its critical property takes two slightly different forms with respect to the filtrations $\mathcal{P}_t$ and $\mathcal{F}_t$. So we summarize the $\mathcal{F}_t$ proof only for completeness. We first show that

$$\min_{\hat{S}_t^*}(\mathcal{L}^*_{\exp(\hat{S}_t^*/\hbar)}A_t^*(p) + L(p,\hat{S}_t^*)) = -e^{A_t^*/\hbar}\hat{H}e^{-A_t^*/\hbar}, \tag{5.9}$$

and the minimum is attained for $\hat{S}_t^* = A_t^*$. Let

$$F^*(p,k) = e^{(\hat{S}_t^*(p-\hbar k)-\hat{S}_t^*(p))/\hbar}\frac{A_t^*(p+\hbar k) - A_t^*(p)}{\hbar} + e^{(\hat{S}_t^*(p-\hbar k)-\hat{S}_t^*(p))/\hbar}\frac{f_t^*(p+\hbar k) - f_t^*(p)}{\hbar}$$
$$- e^{(\hat{S}_t^*(p-\hbar k)-\hat{S}_t^*(p))/\hbar} + e^{-(A_t^*(p-\hbar k)-A_t^*(p))/\hbar}.$$

We have

$$L(p,\hat{S}^*) + \mathcal{L}^*_{\exp(\hat{S}_t^*/\hbar)}A_t^*(p) - e^{A_t^*(p)/\hbar}\hat{H}e^{-A_t^*(p)/\hbar} = \hbar\int_{\mathbb{R}^d}F^*(p,k)\nu(\mathrm{d}k) + \frac{1}{2}\|\nabla A_t^*(p) + \nabla \hat{S}_t^*(p)\|^2$$
$$\geqslant \hbar\int_{\mathbb{R}^d}F^*(p,k)\nu(\mathrm{d}k),$$

Proceeding as in the forward case we obtain (5.9) and the dynamic programming equation (5.3) becomes

$$\frac{\partial A_t^*}{\partial t} - e^{A_t^*/\hbar}\hat{H}e^{-A_t^*/\hbar} = 0,$$

with solution $A_t^* = -\hbar \log \hat{\eta}_t^*$. Finally we have

$$e^{A_t^*(p)/\hbar}\hat{H}e^{-A_t^*(p)/\hbar} = \frac{1}{2}\|p\|^2 - e^{A_t^*(p)/\hbar}\left(\frac{\hbar^2}{2}\Delta e^{-A_t^*(p)/\hbar} + \int_{\mathbb{R}^d}(e^{-A_t^*(p+\hbar k)/\hbar} - e^{-A_t^*(p)/\hbar})\nu(\mathrm{d}k)\right)$$
$$= \frac{1}{2}\|p\|^2 + \frac{\hbar}{2}\Delta A_t^*(p) - \frac{1}{2}\|\nabla A_t^*(p)\|^2 - \int_{\mathbb{R}^d}(e^{-\hbar^{-1}(A_t^*(p+\hbar k)-A_t^*(p))} - 1)\nu(\mathrm{d}k),$$

which yields (5.8). ■

The action (5.1), with Lagrangian (5.2) may seen relatively artificial. As a matter of fact, and as Sec. VI will show, they are natural $\hbar$-deformations of their classical (Euclidean) counterparts in momentum representation.

VI. EQUATIONS OF MOTION

We now derive a.s. equations of motion associated with $(\hat{z}_t)_{t\in 1}$. Those equations justify, in a way, our whole strategy, including the variational approach of Sec. V. Here, $(\hat{z}_t)_{t\in[r,v]}$ represents the process associated to our system in momentum representation, and the expectations of the almost sure equations of motion can be interpreted as the probabilistic counterpart of the Ehrenfest

theorem in quantum dynamics of Ref. 6. The forward and backward derivatives defined before as the generators $D_t=(\partial/\partial t)+\mathcal{L}_{\hat{\eta}_t}$ and $D_t^*=(\partial/\partial t)-\mathcal{L}_{\hat{\eta}_t^*}$ have natural probabilistic interpretations as the following limits of conditional expectations, for f regular enough

$$D_t f_t(\hat{z}_t)=\lim_{\Delta t\downarrow 0} E\left[\left.\frac{ft+\Delta t^{(\hat{z}_{t+\Delta t})}-f_t(\hat{z}_t)}{\Delta t}\right|\mathcal{P}_t\right]=E\left[\left.\frac{d}{\mathrm{d}t^+}f_t(\hat{z}_t)\right|\mathcal{P}_t\right], \tag{6.1}$$

and

$$D_t^* f_t(\hat{z}_t)=\lim_{\Delta t\downarrow 0} E\left[\left.\frac{f_t(\hat{z}_t)-f_{t-\Delta t}(\hat{z}_{t-\Delta t})}{\Delta t}\right|\mathcal{F}_t\right]=E\left[\left.\frac{d}{\mathrm{d}t^-}f_t(\hat{z}_t)\right|\mathcal{F}_t\right], \tag{6.2}$$

where $(d/\mathrm{d}t^+)f,(d/\mathrm{d}t^-)f$ denote the right-hand side and left-hand side derivatives corresponding to the formal limits of (6.1) and (6.2) when Planck's constant $\hbar$ is equal to 0. Of course, the expectation E denotes, here, the one with respect to the process $\hat{z}_t$ solving Eqs. (4.4) and (4.5). The definitions (6.1) and (6.2) provide a probabilistic interpretation of M_t, M_t^* such that $D_tM_t=0$ and $D_t^*M_t^*=0$. Indeed, when this happens we have clearly for all $\Delta t>0$,

$$E[M_{t+\Delta t}(\hat{z}_{t+\Delta t})|\mathcal{P}_t]=M_t(\hat{z}_t) \quad \text{and } M_t^*(\hat{z}_t)=E[M_{t-\Delta t}^*(\hat{z}_{t-\Delta t})|\mathcal{F}_t].$$

As indicated after (2.6), the first condition means that $M_t(\hat{z}_t)$ is a $\mathcal{P}_t$-martingale and the second that $M_t^*(\hat{z}_t^*)$ is a $\mathcal{F}_t$-martingale. For instance, $f_t(\hat{z}_t)=\hat{\eta}_t(\hat{z}_t)/\hat{\eta}_t(\hat{z}_t)$, as defined above, is a $\mathcal{P}_t$-martingale.

The relation with quantum dynamics is clearer when expressed in terms of (absolute, in contrast with conditional) expectations. For this purpose it is sufficient to observe the following.

Corollary 6.1: *Under (absolute) expectations and when f_t, D_tf, D_t^*f are integrable we have*

$$\frac{d}{\mathrm{d}t}E[f_t(\hat{z}_t)]=E[D_tf_t(\hat{z}_t)]=E[D_t^*f_t(\hat{z}_t)], \quad f\in\mathcal{S}(\mathbb{R}^{d+1}).$$

Proof: This follows from the Itô formula, written as

$$\mathrm{d}f_t(\hat{z}_t)=D_tf_t(\hat{z}_t)\mathrm{d}t+\langle\nabla f_t(\hat{z}_t),\mathrm{d}W_t^{\hbar}\rangle+\int_{\mathbb{R}^d}(f_t(\hat{z}_{t^-}+\hbar k)-f_t(\hat{z}_{t^-}))\left(\mu(\mathrm{d}k,\mathrm{d}t)-\frac{\hat{\eta}_t(\hat{z}_{t^-}+\hbar k)}{\hat{\eta}_t(\hat{z}_{t^-})}\nu(\mathrm{d}k)\mathrm{d}t\right)$$

and

$$\mathrm{d}_*f(\hat{z}_t)=D_t^*f_t(\hat{z}_t)\mathrm{d}t+\langle\nabla f(\hat{z}_t),\mathrm{d}_*W_t^{\hbar *}\rangle+\int_{\mathbb{R}^d}(f(\hat{z}_{t^+})-f(\hat{z}_{t^+}-\hbar k))\left(\mu_*(\mathrm{d}k,\mathrm{d}t)-\frac{\hat{\eta}_t^*(\hat{z}_{t^+}-\hbar k)}{\hat{\eta}_t^*(\hat{z}_{t^+})}\nu(\mathrm{d}k)\mathrm{d}t\right).$$

■

In the next proposition we make the assumption:

$$\int_{\mathbb{R}^d}\|k\|\nu(\mathrm{d}k)<\infty, \tag{6.3}$$

and let $D_tp_{|p=\hat{z}_t}$ be denoted by $D_t\hat{z}_t$.

Proposition 6.2: *The process $(\hat{z}_t)_{t\in[r,v]}$, critical point of the action functional introduced before Proposition 5.1, solves the almost sure equations of motion,*

$$D_t\left(\hbar\frac{\nabla\hat{\eta}_t}{\hat{\eta}_t}\right)(\hat{z}_t)=\hat{z}_t, \tag{6.4}$$

where ∇ denotes ∇_p except if otherwise specified, and

$$D_t\hat{z}_t=\frac{1}{\hat{\eta}_t(\hat{z}_t)}(-i\nabla_qV)(i\hbar\nabla_p)\hat{\eta}_t(\hat{z}_t). \tag{6.5}$$

Proof: By (3.1),

$$-i\nabla_q V(q) = -iq + \frac{1}{\hbar}\int_{\mathbb{R}^d} k e^{-(i/\hbar)\langle q,k\rangle}\nu(\mathrm{d}k).$$

Therefore

$$(-i\nabla_q V)(i\hbar\,\nabla)\,\hat{\eta}_t(p) = \hbar\,\nabla\,\hat{\eta}_t(p) + \int_{\mathbb{R}^d} k\,\hat{\eta}_t(p+\hbar k)\,\nu(\mathrm{d}k).$$

On the other hand, we have

$$D_t p = \mathcal{L}_{\hat{\eta}_t} p = \hbar\,\nabla\,\log\,\hat{\eta}_t(p) + \int_{\mathbb{R}^d} \hbar k \frac{\hat{\eta}_t(p+\hbar k)}{\hat{\eta}_t(\hbar k)}\nu(\mathrm{d}k)$$

which proves the first relation (6.5). Concerning (6.4) we have

$$D_t\left(\hbar\frac{\nabla\hat{\eta}_t}{\hat{\eta}_t}\right)(p) = \frac{1}{\hat{\eta}_t}\left(\frac{\partial}{\partial t} - \frac{1}{\hbar}\hat{H}\right)(\hbar\,\nabla\,\hat{\eta}_t) = p + \frac{1}{\hat{\eta}_t}\,\nabla\left(\hbar\frac{\partial}{\partial t} - \hat{H}\right)\hat{\eta}_t = p.$$

This relation can also be obtained by differentiation with respect to p of the heat equation for $\hat{\eta}$,

$$\frac{\partial\,\nabla\,\hat{\eta}_t}{\partial t}(p) = \nabla\,\frac{\partial\hat{\eta}_t}{\partial t}(p) = \frac{1}{\hbar}\,\nabla\,\hat{H}\hat{\eta}_t(p) = \frac{1}{\hbar}\hat{H}\,\nabla\,\hat{\eta}_t(p) + p.$$

■

In the backward case, similar calculations yield

$$D_t^*\hat{z}_t = \frac{1}{\hat{\eta}_t^*(\hat{z}_t)}(i\nabla_q\overline{V})(i\hbar\nabla_p)\,\hat{\eta}_t^*(\hat{z}_t), \quad D_t^*\left(\hbar\frac{\nabla\hat{\eta}_t^*}{\hat{\eta}_t^*}\right)(\hat{z}_t) = -\hat{z}_t.$$

Since $D_t \mapsto -D_t^*$ and $p \mapsto -p$ under time reversal, it is clear that these equations are time reversed of (6.5). The (forward) analog of the Newton equation in momentum representation becomes

$$D_t D_t\left(\frac{\nabla\hat{\eta}_t}{\hat{\eta}_t}\right)(\hat{z}_t) = \frac{1}{\hat{\eta}_t(\hat{z}_t)}(-i\nabla_q V)(i\hbar\,\nabla)\,\hat{\eta}_t(\hat{z}_t).$$

If $V(q)=q^2/2$ we obtain $D_t\hat{z}_t=\hbar\nabla\,\log\,\hat{\eta}_t$ and $D_tD_t\hat{z}_t=\hat{z}_t$. This is the purely diffusive case, already known.[6]

Let us come back on the interpretation of what we found and, in particular, on its associated classical limit. In position representation the classical action functional S should be regarded as the integral of the ("reduced") Poincaré–Cartan differential form,

$$\tilde{\omega}_q = p(q,t)\mathrm{d}t - h(q,p(q,t))\mathrm{d}t,$$

where $p=p(q,t)$ denotes the momentum expressed as a function of the position and time and $h=h(q,p(q,t))$ the Hamiltonian observable. This means that the underlying flow is the one associated with the first equation of Hamilton, for our elementary class of $h(q,p)=(\|p\|^2/2)+V(q)$, reduced to the q-variable:

$$\frac{\mathrm{d}q}{\mathrm{d}t} = p(q,t). \tag{6.6}$$

The second Hamilton equation follows from the integrability condition of $\tilde{\omega}_q$. For Lipschitz p, let $s\mapsto q(s)$ be the solution of (6.6) such that $q(t)=q$. Let us denote by $\int^{q,t}\tilde{\omega}_q$ the associated line

integral. When it is locally univocal, this integral defines the action functional, say $S(q,t)$. Then S solves the Hamilton–Jacobi equation,

$$\frac{\partial S}{\partial t} + h(q, \nabla_q S) = 0,$$

whose ∇_q coincides with the above second Hamilton equation. For the momentum representation, the construction is symmetric. Instead of $\tilde{\omega}_q$ we have to consider the reduced form

$$\tilde{\omega}_p = q(p,t)\mathrm{d}p + h(q(p,t),p)\mathrm{d}t$$

whose underlying flow is the one associated with the second equation of Hamilton reduced to its p-variable:

$$\frac{\mathrm{d}p}{\mathrm{d}t} = -\nabla V(q(p,t)).$$

When

$$\hat{S}(p,t) = \int^{p,t} \tilde{\omega}_p$$

makes sense, so does the Hamilton–Jacobi equation,

$$\frac{\partial \hat{S}}{\partial t} + h(-\nabla_p \hat{S}, p) = 0 \tag{6.7}$$

whose gradient ∇_p coincides with the integrability condition of $\tilde{\omega}_p$.

Let us specialize this to our class of elementary Hamiltonians which are classical limits of (3.3). Then the action function becomes

$$\hat{S}(p,t) = \int \left(q(p(s),s)\frac{\mathrm{d}p}{\mathrm{d}s} + h(q(p(s),s),p) \right)\mathrm{d}s = \int \left(\frac{1}{2}p^2 - \nabla_p \hat{S}.\dot{p}(s) + V(-\nabla_p \hat{S}) \right)\mathrm{d}s$$
$$= \int L(p(s),\dot{p}(s))\mathrm{d}s, \tag{6.8}$$

whose integrand defines the Lagrangian L of our system. So, for the elementary class of Hamiltonians H considered here, the equations of motion reduce to

$$\frac{d}{\mathrm{d}t}(-\nabla_p \hat{S}) = p,$$
$$\frac{\mathrm{d}p}{\mathrm{d}t} = -\nabla V(-\nabla_p \hat{S}). \tag{6.9}$$

Now let us compare this with the Lagrangian and a.s. equation of motion obtained for our class of time-reversible processes $\hat{z}_t$ with jumps. First notice that, in the above classical summary, the parameter is the usual ("real") time. In order to obtain the Euclidean counterpart we have to introduce the "Wick rotation" $t \mapsto -it$ seen in Sec. I. It is easy to check that (6.9) can be transformed into

$$\frac{d}{dt}(i\nabla_p \hat{\mathcal{S}}) = ip,$$
$$i\frac{dp}{dt} = -\nabla_q V(i\nabla_p \hat{\mathcal{S}}), \tag{6.10}$$

where $\hat{\mathcal{S}}=\hat{\mathcal{S}}(p,t)$ solves the Euclidean counterpart of the Hamilton–Jacobi equation (6.7). Comparing with (6.5), those equations can be regarded as the quantum deformation of (6.10) when the smooth trajectories $t\mapsto ip(t)$ are replaced by the very irregular ones of our diffusion process with jumps $\hat{z}_t$. Since the classical (strong) time derivative does not make sense anymore, it is natural to replace it by its probabilistic counterpart D_t (6.1) or, regarded as an operator, by (4.10). The role of the classical action function $\hat{S}(p,t)$ is manifestly played, in (6.5), by $A_t(p)=-\hbar \log \hat{\eta}_t(p)$ solving the Hamilton–Jacobi–Bellman equation (5.4). In particular, it is clear from our first equation (6.5) that the position observable is now proportional to $\hbar\nabla \log \hat{\eta}_t(p)=-\nabla A_t(p)$. So the Hamilton–Jacobi–Bellman equation (5.4) is a quantum deformation of the Euclidean version of the classical equation (6.7). The integrand of the action functional, i.e., our Lagrangian $L(p,D_t p)$ defined in (5.2) of Sec. V, is also a (Euclidean) deformation of the classical integrand of (6.8). The main deformation term, of order $o(\hbar^2)$, involves an integral with respect to the Lévy measure $\nu(\mathrm{d}k)$. This "small" term is, however, necessary to validate the variational characterization of the process $\hat{z}_t$ given in Sec. V. Notice that, because of the relation between the action function and the positive solution $\hat{\eta}_t$ of (3.7) (cf. Proposition 5.1) $A_t(p)=-\hbar \log \hat{\eta}_t(p)$, and also the fact that the underlying Lévy measure $\nu(\mathrm{d}k)$ does not depend on the Planck constant $\hbar$, the limit $\hbar\to 0$ of the probabilistic construction is not trivial. In particular, the first term under the integral of the Hamilton–Jacobi–Bellman equation (5.4), which coincides with the factor $\hat{\eta}_t(p+\hbar k)/\hat{\eta}_t(p)$ in the integral term of the forward generator $\mathcal{L}_{\hat{\eta}_t}$ of $\hat{z}_t$, reduces to

$$\int e^{-\hbar\langle(\nabla\hat{\eta}_t/\hat{\eta}_t)(p),k\rangle}\nu(\mathrm{d}k) \to \int e^{\langle\nabla\hat{S}(p),k\rangle}\nu(\mathrm{d}k) \equiv \int e^{-\langle q,k\rangle}\nu(\mathrm{d}k),$$

namely the Laplace transform of ν (or Fourier transform in imaginary time). Indeed, both quantically and classically, the position q is proportional to the gradient of the action. Using this and the representation (3.1) of the classical potential V, one can reinterpret our first order classical equation of motion (6.10) for p as the solution of a deterministic variational principle, limit of the one given in Sec. V, whose "control" $u(k)$ becomes optimal precisely when $u^*(k)=e^{-\langle q,k\rangle}$. Of course, then, the associated classical Lagrangian reduces to the Euclidean version of the one in (6.8) or, equivalently, to the classical limit of $L(p,D_t p)$ as given in Sec. V, for the semiclassical state $\hat{\eta}_t(p)=\exp-(1/\hbar)\hat{\mathcal{S}}_t(p)$. However, since this deterministic variational principle does not seem to have an obvious physical interpretation it will not be given here (cf. Ref. 31).

A number of the properties of these processes remains to be investigated. Many of those known to hold for pure diffusions should survive for the much richer class of diffusions with jumps considered here. In particular, a systematic study of their symmetries, in term of a Noether theorem, on the model of Refs. 33,34, is possible and should provide further information on the general structure of the construction. A more geometrical approach to these symmetries[21] can probably be extended as well to this class. Moreover, the almost sure equations of motion could be more elegantly deduced from an appropriate generalization of the stochastic calculus of variations used in Ref. 7.

(Received 3 August 2004; accepted 21 November 2004; published online 9 February 2005)

In this paper, we consider the problem of the controllability of a finite-dimensional quantum system in both the Schrödinger and interaction pictures. Introducing a Quantum Transfer Graph, we elucidate the role of Lie algebra rank conditions and the complex nature of the control matrices. We analyze the example of a sequentially coupled N-level system: a spin-$\frac{1}{2}$ particle coupled to a finite quantum harmonic oscillator. This models an important physical paradigm of quantum computers—the trapped ion. We describe the control of the finite model obtained, under the right conditions, from the original infinite-dimensional system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1852701]

I. INTRODUCTION

The control and controllability of finite-dimensional quantum systems are of topical interest to the chemical dynamics, coherent control and quantum computing communities.[1–9] Indeed, several methods of proving controllability of quantum systems[3,4,10–13] have been developed from corresponding techniques used in the control of finite-dimensional classical systems. In these treatments, specifically in the graphical methods, the role of the drift (or field-free) Hamiltonian is not obvious. In quantum mechanics, it is fairly standard to use an interaction picture, where the drift term does not appear explicitly in the Schrödinger equation. In these cases, the presence of only one matrix, namely the control matrix in the interaction picture, makes it not amenable to use of the rigorous Lie algebraic method[11] to determine controllability.

In this paper, we present fresh insights into the controllability and control of quantum systems both in the Schrödinger and interaction pictures. We propose a new graphical method—the Quantum Transfer Graph—that will explicitly demonstrate both the roles of the drift and control matrices, and also the importance of considering the control matrix as one with complex entries. Then we analyze a very interesting example of a sequentially coupled N-level system: a spin-$\frac{1}{2}$ particle coupled with a quantum harmonic oscillator. This models an important physical paradigm of quantum computers—the trapped ion. The analysis in this paper expands on our earlier work on the trapped-ion problem (Ref. 17) and illustrates the key role played by the Quantum Transfer Graph in understanding the complex matrices that describe the interactions between the field and the ion. To our knowledge this is the only example of a quantum control problem where the interaction matrices are complex. Our general analysis of a sequentially connected system can also be extended to understanding the control of N-level chain systems used in adiabatic schemes such as STIRAP,[14] as well as the control of transitions between sequentially connected Zeeman states.

II. SCHRÖDINGER PICTURE

The Schrödinger equation for a particle in a static and dynamic potential (in atomic units, wherein $e=m=\hbar=1$) is written as

$$\imath|\dot{\Psi}\rangle = (H_0 + H_I)|\Psi\rangle. \tag{1}$$

Here, H_0 is the Hamiltonian of the particle in the static potential, with a finite number (N) of eigenvalues E_n corresponding to the eigenvectors ϕ_n. The interaction with the time-dependent potential is given by the control Hamiltonian H_I, which includes the time dependence. In general, we consider problems where the time dependence is separable and linear, for example, $H_I = \sum_i u_i(t) * \mu_i$. Here the operator μ_i represents the transition couplings between the various eigenstates of H_0 due to the time-dependent field $u_i(t)$. Unitarity demands that H_0 and H_I be Hermitian. The eigenvalues of H_0 are therefore real. In the control literature, the Schrödinger equation is written equivalently as

$$\dot{X} = \left(A + \sum_i u_i(t) B_i\right) X. \tag{2}$$

In vector representation, X is the state vector, A is the drift matrix, B_i are the control matrices and $u_i(t)$ are controls, generally chosen to be piecewise smooth. In the eigenbasis of H_0, A is $-\imath$ times a real matrix with only diagonal terms. Each matrix B_i is skew-Hermitian. It can, in general, be written as a sum of a $\imath$ times a real symmetric matrix and a skew-symmetric matrix, $B_i = \imath * B_i^S + B_i^K$. More generally, $A, B_i \in \mathfrak{su}(N)$. In most quantum applications considered up to this point[2,4,15] the matrix elements of the B_i are of the form $\imath$ times a symmetric matrix. Consider a special case, where the eigenstates of H_0 are sequentially coupled by control fields $u_i(t)$. It is well known[3,9,11] that a sufficient condition for controllability is that the dimension of the span of the Lie algebra generated by A and the B_i be equal to the dimension of $\mathfrak{su}(n)$. Rather than take the specific values for the matrix elements of the control matrices, B_i, it will be instructive to consider its general structure—a skew-Hermitian, tridiagonal matrix with zero diagonal elements. In the case where B is of the form $\imath$ times a symmetric matrix, this matrix can be decomposed into $N-1$ matrices—simple roots of the Lie algebra $\mathfrak{su}(n)$, as shown below. These matrices represent the nearest-neighbor couplings. We want to elucidate how these nearest-neighbor couplings generate the Lie algebra. Note that we do not have control over each individual coupling. Nevertheless, one can see how decomposing the control matrix into the simple roots is a powerful way to examine the controllability properties of the system.

Using standard notation for a basis of $\mathfrak{su}(N)$, let $e_{i,j}$ denote the matrix with unit ij entry and zeros elsewhere. Define $x_{i,j} = e_{i,j} - e_{j,i}$ and $y_{i,j} = \imath(e_{i,j} + e_{j,i})$. B is decomposed into the $\imath$-times-symmetric roots

$$S_1 = y_{1,2} = \imath \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \tag{3}$$

$$S_2 = y_{2,3}, \tag{4}$$

$$S_3 = y_{3,4}, \tag{5}$$

$$\cdots. \tag{6}$$

The Lie bracket of these roots with each other give the $N-2$ skew-symmetric matrices that represent next-nearest-neighbor coupling as shown below. These matrices form a closed Lie algebra with the matrices from which they were formed, for example, S_1, S_2 and their commutator

$K_N=[S_1,S_2]$ form a Lie subalgebra, similarly for S_2, S_3 and their commutator K_{N+1}, and so on. This generation of alternate symmetric and skew-symmetric elements of the algebra has been observed earlier,[3,13]

$$[S_1,S_2]=x_{1,3}\equiv K_N, \tag{7}$$

$$K_{N+1}=x_{2,4}, \tag{8}$$

$$\cdots. \tag{9}$$

Similarly,

$$[x_{1,3},x_{2,4}]=y_{1,4}\equiv S_{2N-1}. \tag{10}$$

Carrying on in a similar fashion through the matrix that represents the coupling between the first and Nth state (here N is assumed even),

$$S_{N(N-1)/2}=y_{1,N}. \tag{11}$$

It can be shown that the number of linearly independent commutators formed by this set of matrices is $N(N-1)/2$. Thus, the roots of the control Hamiltonian can be used to produce $N(N-1)/2$ independent elements of the algebra.

An interesting observation can be made if the control matrices B_i representing the nearest-neighbor couplings are all skew-symmetric. The Lie algebra generated by these matrices consists of the skew-symmetric matrices, i.e., the symmetric matrices S_n are not generated. These matrices also number $N(N-1)/2$. This is the set of generators for the rotation group $O(N)$, each pairwise coupling representing an independent rotation in N-dimensions.[16]

Thus, if the eigenstates are sequentially connected by the transition matrix elements (usually real), then the Lie algebra generated by the roots of the control terms alone span a space of $N(N-1)/2$. If the drift matrix is strongly regular,[12] it can be decomposed into N linearly independent traceless diagonal matrices $h_i=e_{i,i}-e_{i+1,i+1}$. The Lie brackets formed by the drift matrix and the $N(N-1)/2$ matrices computed above yield another $N(N-1)/2$ matrices of the opposite symmetry. For example, $[A,S_1]$ gives K_1, etc. Thus the total number of linearly independent matrices are $2*N(N-1)/2+N=N^2$, which is sufficient to show controllability.

III. QUANTUM TRANSFER GRAPHS

Graphical methods used to analyze controllability of quantum systems[4,17] are drawn from similar techniques used in the controllability analysis of classical systems.[12] These methods are very elegant. However, they do not bring out two features intrinsic to the controllability of quantum systems—the special role of the drift matrix, and the intrinsically skew-Hermitian nature of the control matrices. To address these issues, we propose that transfer graphs representing the control of quantum systems should be drawn with each eigenstate represented by a double node, representing the real and imaginary parts of the complex wave function. The transition matrix elements are represented by edges of the graph. However, a real matrix element will couple the real part of one state with the real part of the other; and the imaginary part of one state with the imaginary part of the other. A purely imaginary matrix element will couple the real part of one state with the imaginary part of the other. This graph will truly be transitively connected only if the transition matrix elements are complex numbers with both real and imaginary parts. Otherwise the presence of a strongly regular drift matrix (which in time produces a rotation from real to imaginary space) can generate the "missing" elements of the Lie algebra, i.e., complete the transitivity of the Quantum Transfer Graph. These features of Quantum Transfer Graphs are shown in Fig. 1. Other modifications introduced in a recent paper[17] such as ordering the state in energy and the thickness of the edges representing the strength of the couplings are retained.

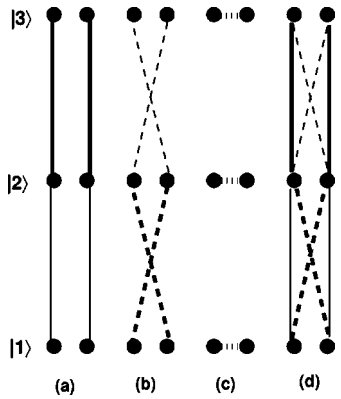

FIG. 1. Features of a Quantum Transfer Graph. Three nondegenerate eigenstates of the field-free Hamiltonian are represented by double nodes, representing the real (left) and imaginary (right) parts of the complex wave function. States that are transitively connected in the classical sense are not necessarily connected when the doublet structure is employed. A control matrix with $\imath$ times symmetric structure connects nodes as shown in (a). A control matrix with real, skew-symmetric structure connects nodes as shown in (b). The drift Hamiltonian causes rotations between the real and imaginary nodes of each eigenstate as in (c). The control matrix with a general complex, skew-Hermitian structure transitively connects the real *and* imaginary parts of the eigenstates as in (d).

IV. CONTROL IN THE INTERACTION PICTURE

In quantum physics, one often uses the interaction picture by making a unitary transformation that is very similar to transforming into the rotating frame in classical physics. Remembering that A is diagonal and $=\imath H_0$, this is carried out as follows:

$$Y = \exp(-At)X, \tag{12}$$

$$\dot{Y} = -A\exp(-At)X + \exp(-At)\dot{X} \tag{13}$$

$$= -A\exp(-At)X + \exp(-At)(A + \sum_i u_i(t)B_i)X \tag{14}$$

$$= \sum_i u_i(t)\exp(-At)B_iX \tag{15}$$

$$= \sum_i u_i(t)\exp(-At)B_i\exp(At)Y \tag{16}$$

$$= \sum_i u_i(t)\left[B_i + \frac{-t}{1!}[A,B_i] + \frac{(-t)^2}{2!}[A,[A,B_i]] + \cdots\right]Y \tag{17}$$

$$= \sum_i u_i(t)\tilde{B}_iY. \tag{18}$$

The transformed state vector Y evolves on an adjoint orbit of $U(n)$ with a span of $N(N-1)$. The last expansion (Baker–Campbell–Hausdorff expansion) contains the Lie algebra formed by the drift and control matrices. In the case that the system is controllable, these matrices span a space of dimension $N(N-1)$. Therefore, the presence of a strongly regular drift matrix, and a transitively

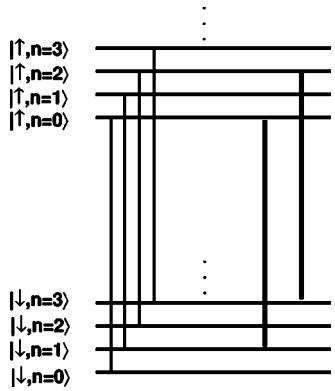

FIG. 2. Trapped-ion quantum states coupled by control fields with frequencies ω_c and ω_r. They cause transitions denoted by solid (carrier) and dashed (red sideband) lines, respectively. By changing the strength of the trap, it is possible to reduce one of the transition strengths to zero, thus truncating the infinitely large Hilbert space.

connected set of eigenstates is sufficient to show controllability. In exactly the same manner, if a set of eigenstates is transitively connected in the interaction picture, and the drift matrix is strongly regular, then these are sufficient conditions to establish controllability as well.

We note that if we have a control matrix that has both symmetric and skew-symmetric parts as in Fig. 1(d), we know that we can generate the $N(N-1)$ elements of the algebra. The Quantum Transfer Graph is transitively connected even without the consideration of the drift matrix. In such a case the demand for the strongly regular drift matrix can be relaxed, and controllability can be shown even with drift matrices that are not strongly regular.[12]

V. SPIN-$\frac{1}{2}$ PARTICLE COUPLED TO FINITE HARMONIC OSCILLATOR

We now apply controllability analysis to a quantum system that is one of the scalable paradigms of a future quantum computer. The system is also interesting from the viewpoint of control, because the control matrices contain both symmetric and skew-symmetric elements. Our analysis can be extended to other systems with sequentially connected eigenstates such as those in N-level STIRAP, and the control of Zeeman states.

In a recent paper,[17] we showed that under certain circumstances, the model of a spin-$\frac{1}{2}$ particle coupled to finite harmonic oscillator is a good representation of a trapped ion with two essential internal states. The spin-$\frac{1}{2}$ model represents a two-level atom with an energy splitting $\hbar\omega_0$, where the frequency $\omega_0/2\pi$ is in the several GHz range. The atomic levels are coupled to the motion of the ion in a harmonic trap.[18] These quantized vibrational energy levels are separated by a frequency $\omega_m/2\pi$ in the MHz range. The Hamiltonian of this system without a control field applied to it (in atomic units) is

$$H_0 = \omega_0 \frac{\sigma_z}{2} + \omega_m \hat{n}. \tag{19}$$

The Pauli operator σ describes the equivalent spin-$\frac{1}{2}$ system, and the operator $\hat{n}$ is the number operator of the quantized simple harmonic oscillator. The eigenstates of the field-free system are characterized by two quantum numbers S_z, and n. When a bichromatic field is applied that causes transitions between states $|\downarrow,n\rangle$ and $|\uparrow,n\rangle$ (carrier transitions), and between states $|\downarrow,n\rangle$ and $|\uparrow,n-1\rangle$ (red sideband transitions), the system is sequentially connected. An important parameter of this system is the Lamb–Dicke parameter η_m that describes the extent of the ion's motion compared to the wavelength of the applied electromagnetic field. It is possible to adjust the strength of the trap (thereby adjusting η_m) such that one of the transition couplings goes to zero, and the state space is truncated to N-levels as shown in Fig. 2.

In the case when the extent of the ion's motion is comparable to the wavelength of the applied field, a matrix element of the control Hamiltonian in the field-free eigenbasis in the interaction picture can be written as[17]

$$\langle S'n'|H_I'|Sn\rangle = \Omega(t)2\ \mathrm{Re}[\langle S'|\sigma_+|S\rangle \otimes \langle n'|\exp(\imath(\eta_m(a_m + a_m^\dagger)))|n\rangle]. \tag{20}$$

The harmonic oscillator part of this matrix element[18] is written as

$$\langle n'|\exp(\imath(\eta_m(a_m + a_m^\dagger)))|n\rangle = \exp(-\eta_m/2)\sqrt{\frac{n_<!}{n_>!}}(\imath\eta_m)^{|n'-n|}L_n^{|n'-n|}(\eta_m^2). \tag{21}$$

The symbol $n_>$ refers to the larger of n and n', and $n_<$ refers to the smaller of n and n'. $L_n^\alpha(x)$ is the associated Laguerre polynomial. When the applied field connects states $|\downarrow,n\rangle$ and $|\uparrow,n\rangle$ (carrier transitions), $n'=n$, and when the applied field connects states $|\downarrow,n\rangle$ and $|\uparrow,n-1\rangle$ (red sideband transitions), $n'=n-1$. The matrix elements are zero for all other values of n'. The strength of the ion trap can be adjusted (thereby adjusting η_m) so that the coupling strength of one of the (red or carrier) transitions becomes zero, the system is transformed into a finite closed subsystem, and a remaining infinite subsystem. For example, if the argument of the Laguerre polynomial η_m^2 is adjusted to 0.527 667 so that $L_6^1(\eta_m^2)=0$, the $|\downarrow,6\rangle$ to $|\uparrow,7\rangle$ transition is turned off.

The truncated finite system is now an N-level sequentially dipole coupled system. The electric field corresponding to the frequencies that cause the carrier and red transitions are dubbed E_c and E_r, respectively. The eigenstates can be ordered as $|\uparrow,0\rangle$, $|\downarrow,0\rangle$, $|\uparrow,1\rangle$, $|\downarrow,1\rangle,\ldots$. The drift Hamiltonian H_0 of this system can be written in matrix form as

$$\begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\
0 & \omega_0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\
0 & 0 & \omega_m & 0 & 0 & 0 & \cdots & 0 & 0 \\
0 & 0 & 0 & \omega_0+\omega_m & 0 & 0 & \cdots & 0 & 0 \\
0 & 0 & 0 & 0 & 2\omega_m & 0 & \cdots & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \omega_0+2\omega_m & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & & \\
0 & 0 & 0 & 0 & 0 & 0 & \cdots & \left(\frac{N}{2}-1\right)\omega_m & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & \cdots & 0 & \omega_0+\left(\frac{N}{2}-1\right)\omega_m
\end{pmatrix}. \tag{22}$$

In the interaction picture, the Schrödinger equation is written as

$$\dot{Y} = (u(t)B_c + v(t)B_r)Y. \tag{23}$$

In general, we can assume that fields $E_c(t)$ and $E_r(t)$ do not have a phase difference between them. Then,

$$u(t) = c_1E_c(t) = 0.25\mu_0\exp(-\eta^2/2)E_c(t), \tag{24}$$

$$v(t) = c_2E_r(t) = 0.25\eta\mu_0\exp(-\eta^2/2)E_r(t), \tag{25}$$

$$B_c = \imath \begin{pmatrix} 0 & L_0(\eta^2) & 0 & 0 & 0 & 0 & \cdots \\ L_0(\eta^2) & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & L_1(\eta^2) & 0 & 0 & \cdots \\ 0 & 0 & L_1(\eta^2) & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & L_2(\eta^2) & \cdots \\ 0 & 0 & 0 & 0 & L_2(\eta^2) & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{26}$$

$$B_r = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & L_0^{(1)}(\eta^2) & 0 & 0 & 0 & \cdots \\ 0 & -L_0^{(1)}(\eta^2) & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & L_1^{(1)}(\eta^2) & 0 & \cdots \\ 0 & 0 & 0 & -L_1^{(1)}(\eta^2) & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 0 & 0 & 0 & 0 & 0 & -L_2^{(1)}(\eta^2) & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}. \tag{27}$$

The associated Laguerre polynomials $L_n^{\alpha}(x)$ can be written as

$$L_n^{\alpha}(x) = \sum_{k=0}^{n} (-1)^k \binom{n+\alpha}{n-k} \frac{x^k}{k!}. \tag{28}$$

The argument of the polynomials is the square of the Lamb–Dicke parameter η which gives a measure of how much the ion moves in the harmonic potential as compared to the wavelength of the light applied. We note that the control matrices for this system are different from the usual control matrices in quantum physics problems. The control matrix $\tilde{B}_c$ has the usual $\imath$ times symmetric structure. The control matrix $\tilde{B}_r$ has a real, skew-symmetric structure. If we take the Lie algebra formed by these two matrices, we get $N(N-1)/2$ independent matrices. As the drift matrix is strongly regular this system is completely controllable. We can further analyze this behavior in a four-dimensional model problem.

A. Example: A model four-dimensional system

Using a simple four-dimensional example,[2,19] we show how the Lie algebra produces successive elements, and spans the space. Consider a general matrix A for a four-dimensional Hilbert space with sequentially coupled eigenstates. In particular, we have

$$A = \begin{pmatrix} a & 0 & 0 & 0 \\ 0 & b & 0 & 0 \\ 0 & 0 & c & 0 \\ 0 & 0 & 0 & d \end{pmatrix}, \tag{29}$$

$$B_c = \imath \begin{pmatrix} 0 & \alpha & 0 & 0 \\ \alpha & 0 & 0 & 0 \\ 0 & 0 & 0 & \gamma \\ 0 & 0 & \gamma & 0 \end{pmatrix}, \tag{30}$$

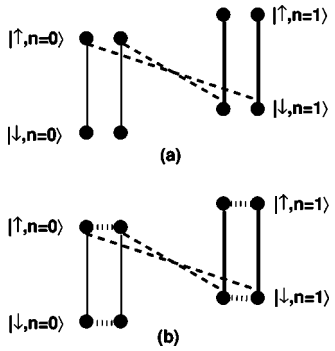

FIG. 3. Quantum Transfer Graph of a model four-level system. Control fields with frequencies ω_c and ω_r cause transitions denoted by solid (carrier) and dashed (red sideband) lines, respectively. The dotted lines in (b) demonstrate the effect of the drift Hamiltonian in rotating between the real and imaginary parts of each eigenfunction.

$$B_r = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & \beta & 0 \\ 0 & -\beta & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{31}$$

Taking the Lie brackets of B_c and B_r, we produce four more linearly independent matrices $C=[B_c,B_r]/\beta$, $D=([B_c,C]-B_r*(\alpha^2+\gamma^2)/b)/(2\alpha\gamma)$, $E=[B_c,D]$, and $F=[E,B_r]/(-\beta)$. Thus the control matrices themselves produce $N(N-1)/2=6$ elements of the Lie algebra. Taking the Lie brackets of these six matrices with the drift matrix A, we get six more independent matrices with the opposite symmetry as the first six. Further Lie brackets of the two sets of six matrices produce the remaining four diagonal traceless matrices into which the strongly regular drift matrix can be decomposed.

B. Graphical analysis

We create a Quantum Transfer Graph to represent and analyze this system. We represent the various eigenstates $|\hat{S},n_m\rangle$ by double-vertices of a graph as shown in Fig. 3. When a resonant electromagnetic field is applied, the coupling between two eigenstates caused by the interaction form the edges. The eigenstates are ordered in energy, and the edges on the graph will represent the matrix elements of the interaction between the eigenstates (not a population flow between them), their thickness qualitatively indicating the strength of the coupling. The carrier field (with frequency ω_c) acting on an ion connects states $|\downarrow n\rangle$ and $|\uparrow n\rangle$. As the coupling matrix consists of real elements, this field connects the real parts to the real parts and the imaginary parts to the imaginary parts. The red sideband field (with frequency ω_r) connects states $|\downarrow n\rangle$ and $|\uparrow n-1\rangle$. Since the coupling matrix consists of imaginary elements, this field connects the real parts to the imaginary parts and vice versa. When both fields are applied simultaneously, we see that the Quantum Transfer Graph splits into two very interesting subgraphs. In the sense of the usual transfer graph,[4,20] all eigenstates are transitively connected. However, we can directly see the role of the drift Hamiltonian in moving this system from one subgraph to the other, and truly making the eigenstates transitively connected.

VI. SPECIFIC CONTROL SCHEME

We now discuss a specific control scheme for the *infinite* system, and show how the Quantum Transfer Graph helps us to describe the roles of the control and drift matrices in this scheme. In 1996, Law and Eberly[21] showed that by using the carrier and red fields *alternately* it is possible to produce arbitrary superpositions of a finite number of harmonic oscillator states. References 22 and 23 show that the same scheme can be used to generate arbitrary finite superposition states in

a spin-$\frac{1}{2}$/harmonic oscillator system. This scheme works by designing a sequence of alternately applied carrier and red sideband fields interspersed with a waiting time (action of the drift) in order to transfer the population from an arbitrary superposition to the ground state of the system $|\downarrow, n=0\rangle$. As seen by the Quantum Transfer Graph in Fig. 3(b), there are many combinations of the drift and control matrices that can be applied in order to get to the ground state (both in the finite and the infinite systems). The optimal combination will be one that time-optimizes the process subject to the constraint on the fields' intensities. This time-optimized Law–Eberly scheme is an interesting avenue for future work. Aspects of the controllability of the infinite-dimensional problem are discussed in related work by the authors.[24]

VII. CONCLUSION

A Quantum Transfer Graph is an effective tool in elucidating the controllability of finite quantum systems both in the Schrödinger and interaction pictures. We have shown the equivalence of sufficient conditions for controllability in both pictures, and explicitly presented the role of the drift matrix. We analyze the example of a sequentially connected N-level system as implemented by suitably designed quantum states of a trapped ion. Showing the mechanism of control, we explain how the specific Law–Eberly control scheme can be efficiently implemented.

Asymptotic of complex hyperbolic geometry and L^2-spectral analysis of Landau-like Hamiltonians

Allal Ghanmi[a] and Ahmed Intissar[b]
Department of Mathematics, Faculty of Sciences, Agdal Mohammed V University, Rabat, Morocco

(Received 13 July 2004; accepted 10 September 2004; published online 11 February 2005)

In this paper we show that the flat Hermitian complex geometry of $\mathbb{C}^n$, $n \geqslant 1$, is approximated by the complex hyperbolic geometry of the Bergman complex balls $\mathbb{B}^n_\rho \subset \mathbb{C}^n$ of radius $\rho > 0$. Furthermore, it will be shown that some elements of the L^2-spectral analysis, such as the spectrum, the L^2-eigenprojector and the resolvent kernels, associated to the so-called Landau-like Hamiltonian $H_{B,\rho}$ on $\mathbb{B}^n_\rho$ give rise to their analogous of the Landau-like Hamiltonian $H_{B,\infty}$ on $\mathbb{C}^n$ by letting ρ tend to infinity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1853505]

I. INTRODUCTION

Let $\mathcal{P}=\{w=x+iy; y>0\}$ be the upper-half plane endowed with the Poincaré metric

$$ds^2(\rho) = \frac{\rho^2}{4}\left(\frac{dx^2+dy^2}{y^2}\right),$$

where ρ is a non-negative real number. The metric $ds^2(\rho)$ is scaled such that the constant scalar curvature of the real hyperbolic plane $\mathcal{P}$ is equal to $-4/\rho^2$.

In Ref. 6, A. Comtet considered one parameter family of magnetic Schrödinger operators (or Maass Laplacians) $H_{B,\rho}$ given on $\mathcal{P}$ by

$$H_{B,\rho} = -4\left\{\frac{y^2}{\rho^2}\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right) - 2iBy\frac{\partial}{\partial x} - B^2\rho^2\right\}, \quad B>0, \tag{1}$$

and discussed some of their asymptotic spectral properties when ρ goes to $+\infty$. In particular, the finite point spectrum in $L^2(\mathcal{P};(\rho^2/4)(dx\,dy/y^2))$ of $H_{B,\rho}$ goes to the Landau levels

$$4B(2l+1), \quad l=0,1,2,\ldots,$$

that correspond to the pure point spectrum in $L^2(\mathbb{R}^2;dxdy)$ of the magnetic Schrödinger operator $H_{B,\infty}$, associated to the vector potential $A=(2By,-2Bx,0)$, given in x,y coordinates by

$$H_{B,\infty} = -\left\{\left(\frac{\partial^2}{\partial x^2}+2iBy\right)^2 + \left(\frac{\partial^2}{\partial y^2}-2iBx\right)^2\right\}$$

or in the complex coordinate $z=x+iy$ as

$$H_{B,\infty} = -4\left\{\frac{\partial^2}{\partial z\,\partial\bar{z}} + B\left(z\frac{\partial}{\partial z}-\bar{z}\frac{\partial}{\partial\bar{z}}\right) - B^2|z|^2\right\}.$$

The operators $H_{B,\rho}$ and $H_{B,\infty}$ (called also Landau Hamiltonians) describe the Hamiltonians of a charged nonrelativistic particle moving under the action of an external uniform magnetic field

[a]Electronic mail: aghanmi@math.net
[b]Electronic mail: intissar@fsr.ac.ma

acting on $\mathcal{P}$ and $\mathbb{R}^2$, respectively. The magnetic Schrödinger operator $H_{B,\rho}$ on $\mathcal{P}$ given by (1) can be intertwined, via Cayley transform, with the Laplacian $H_{B,\rho}$ of the hyperbolic complex disc $\mathbb{B}^1_\rho=\{z\in\mathbb{C};|z|<\rho\}$, which is given in the complex coordinate z of $\mathbb{B}^1_\rho$ by

$$H_{B,\rho}=-4\left(1-\left|\frac{z}{\rho}\right|^2\right)\left\{\left(1-\left|\frac{z}{\rho}\right|^2\right)\frac{\partial^2}{\partial z\,\partial\bar{z}}+B\left(z\frac{\partial}{\partial z}-\bar{z}\frac{\partial}{\partial\bar{z}}\right)\right\}+4B^2|z|^2.$$

Therefore, to have a natural generalization of the above Laplacians $H_{B,\rho}$ and $H_{B,\infty}$ to higher complex dimensions, one may replace the plane $\mathbb{C}$ by the Hermitian complex space $\mathbb{C}^n$, $n\geqslant 1$, and the real hyperbolic disc $\mathbb{B}^1_\rho$ by the Bergman complex ball $\mathbb{B}^n_\rho$ of radius $\rho>0$. Here, the Bergman ball $\mathbb{B}^n_\rho$ will be viewed as the bounded realization of the rank one Hermitian symmetric space of noncompact type [i.e., the complex hyperbolic space $\mathbb{H}^n(\mathbb{C})$] whose holomorphic sectional curvature S_ρ is known to be a negative constant that we will be scaling here to be equal to $-4/\rho^2$. Namely, we can set the following.

Definition 1: Let B be a fixed real number and $\rho>0$. Then

(i) *The Landau-like Hamiltonian $H_{B,\rho}$ on the Bergman ball $\mathbb{B}^n_\rho$ is defined to be equal to*

$$H_{B,\rho}=-4\left(1-\left|\frac{z}{\rho}\right|^2\right)\left\{\sum_{i,j=1}^{n}(\delta_{ij}-\frac{z_i\bar{z}_j}{\rho^2})\frac{\partial^2}{\partial z_i\,\partial\bar{z}_j}+B\sum_{j=1}^{n}\left(z_j\frac{\partial}{\partial z_j}-\bar{z}_j\frac{\partial}{\partial\bar{z}_j}\right)\right\}+4B^2|z|^2.$$

(ii) *The Landau-like Hamiltonian $H_{B,\infty}$ on the Hermitian space $\mathbb{C}^n$ is defined to be equal to*

$$H_{B,\infty}=-4\left\{\sum_{j=1}^{n}\frac{\partial^2}{\partial z_j\,\partial\bar{z}_j}+B\sum_{j=1}^{n}\left(z_j\frac{\partial}{\partial z_j}-\bar{z}_j\frac{\partial}{\partial\bar{z}_j}\right)-B^2|z|^2\right\}.$$

Here we shall note that such Hamiltonians had been considered and studied by many authors in different contexts of both mathematics and physics. Thus, for the unit complex disc case ($n=1$ and $\rho=1$), one can refer to the interest papers (Refs. 14, 17, 8, 18, and 9). And for the unit complex ball ($n\geqslant 2$, $\rho=1$), the reader can refer to the works in Refs. 11, 13, 19, 1, 5, and 3. Also let us note that the operators $H_{B,\infty}$ on $\mathbb{C}^n=\mathbb{R}^{2n}$, which go back to Landau (for $n=1$), play an important role in many different contexts such as Feynman path integral. (in Feynman–Kac formula), oscillatory stochastic integral and theory of lattices electrons in uniform magnetic field. See Bellissard[4] and the rich list of references therein. However, apart Comtet work's[6] for $n=1$ (see also Ref. 7), both Landau-like Hamiltonians $H_{B,\rho}$ and $H_{B,\infty}$ had been studied separately in all previous cited works.

In the present paper, we discuss, when $\rho\to+\infty$, the asymptotic of the Kähler–Bergman geometry on the hyperbolic Bergman balls $\mathbb{B}^n_\rho$ of radius ρ centered at the origin of $\mathbb{C}^n$, $n\geqslant 1$. Further, we follow in spirit Comtet approach to give an analytic treatment which connect many aspect as spectral theory of the Landau-like Hamiltonians $H_{B,\rho}$ on $\mathbb{B}^n_\rho$ (L^2-point spectrum, the L^2-eigenprojectors and the resolvent kernels) to that of the Landau-like Hamiltonians $H_{B,\infty}$ on $\mathbb{C}^n$ ($n\geqslant 1$) by letting ρ go to infinity. Namely, the objective of our work is aimed to show in a rigorous mathematical sense the following statements.

(1) The curved complex hyperbolic geometry of the complex Bergman balls $\mathbb{B}^n_\rho$ of radius $\rho>0$ approximates in a natural intuitive way the flat Hermitian geometry of $\mathbb{C}^n$. This means that all geometrical elements on $\mathbb{B}^n_\rho$ such as the metric ds^2_ρ, the distance d_ρ, the volume form $d\mu_\rho$, the group of motions $G_\rho,\ldots$, converge to their analogous on $\mathbb{C}^n$ when $\rho\to+\infty$; see Table I.

(2) Let

$$\sigma_d(H_{B,\rho})=\left\{4B(2l+n)-4\frac{l(l+n)}{\rho^2};l\in\mathbb{Z}^+,0\leqslant l<B\rho^2-\frac{n}{2}\right\}$$

be the finite set of the point spectrum of the Landau-like Hamiltonian $H_{B,\rho}$ in the Hilbert space $L^2(\mathbb{B}^n_\rho;d\mu_\rho)$. Then obviously we have

TABLE I. Asymptotic of metric and action objects on $\mathbb{B}_\rho^n$.

Metric and action objects on $\mathbb{B}_\rho^n$, $\rho>0$	Their asymptotic on $\mathbb{C}^n=\lim_{\rho\to+\infty}\mathbb{B}_\rho^n$
Hermitian metric ds_ρ^2, $ds_\rho^2=(1-\lvert z/\rho\rvert^2)^{-2}\times\Sigma_{i,j=1}^n((1-\lvert z/\rho\rvert^2)\delta_{i,j}+\bar z_i z_j/\rho^2)dz_j\otimes d\bar z_j$	Euclidean metric ds_∞^2, $ds_\infty^2:=\Sigma_{j=1}^n dz_j\otimes d\bar z_j$
Holomorphic sectional curvature $S_\rho=-4/\rho^2$	Flat curvature $S_\infty=0$
Bergman distance $d_\rho(z,w)$, $\cosh^2(d_\rho(z,w)/\rho)=\lvert\rho^2-\langle z,w\rangle\rvert^2/(\rho^2-\lvert z\rvert^2)(\rho^2-\lvert w\rvert^2)$	Euclidean distance $d_\infty(z,w)d_\infty(z,w):=\lvert z-w\rvert$
Volume form $d\mu_\rho(z)$, $d\mu_\rho(z)=(1-\lvert z/\rho\rvert^2)^{-n-1}\,dm(z)$	Lebesgue form $d\mu_\infty(z)$, $d\mu_\infty(z)=dm(z)$
Kähler 2-form $\Omega_\rho(z)$, $\Omega_\rho(z)=(1-\lvert z/\rho\rvert^2)^{-2}\times\Sigma_{i,j=1}^n((1-\lvert z/\rho\rvert^2)\delta_{i,j}+\bar z_i z_j/\rho^2)dz_i\wedge d\bar z_j$	Kähler 2-form $\Omega_\infty(z)$, $\Omega_\infty(z)=\Sigma_{j=1}^n dz_j\wedge d\bar z_j$
Vector potential $\theta_\rho(z)$, $\theta_\rho(z)=-i(1-\lvert z/\rho\rvert^2)^{-1}\times\Sigma_{j=1}^n(\bar z_j\,dz_j-z_j\,d\bar z_j)$	Vector potential $\theta_\infty(z)$, $\theta_\infty(z)=-i\Sigma_{j=1}^n(\bar z_j\,dz_j-z_j\,d\bar z_j)$
Group of motions G_ρ on $(\mathbb{B}_\rho^n,ds_\rho^2)$, $G_\rho=\{g_\rho=\left(\begin{smallmatrix}A_\rho & B_\rho\\ C_\rho & D_\rho\end{smallmatrix}\right)\in M_{n+1}(\mathbb{C});g_\rho J^{-1}(\rho)g_\rho^*=J^{-1}(\rho),\det(g_\rho)=1\}$	Group of motions G_∞ on $(\mathbb{C}^n,ds_\infty^2)$, $G_\infty=\{g_\infty=\left(\begin{smallmatrix}A & B\\ 0 & (\det A)^{-1}\end{smallmatrix}\right);A\in U(n),B\in\mathbb{C}^n\}$
Homographic action of G_ρ on $\mathbb{B}_\rho^n$, $g_\rho.z=(A_\rho z+B_\rho)\times(C_\rho z+D_\rho)^{-1}$	Affine action of G_∞ on $\mathbb{C}^n$, $g_\infty.z=(\det A)(Az+B)$
Automorphic factor $j_\rho^B(g_\rho,z)$, $B\in\mathbb{R}$, $j_\rho^B(g_\rho,z)=\left(\rho^2-\overline{\langle z,g_\rho^{-1}.0\rangle}/\rho^2-\langle z,g_\rho^{-1}.0\rangle\right)^{B\rho^2}$	Automorphic factor $j_\infty^B(g_\infty,z)$, $\underline{B\in\mathbb{R}}$, $j_\infty^B(g_\infty,z)=e^{B(\langle z,g_\infty^{-1}.0\rangle-\langle z,g_\infty^{-1}.0\rangle)}$

$$\lim_{\rho\mapsto+\infty}\sigma_d(H_{B,\rho})=\{\lambda_l:=4B(2l+n);\quad l=0,1,2,\ldots\},$$

which gives the so-called Landau energy levels for the Landau-like Hamiltonian $H_{B,\infty}$ on $\mathbb{C}^n$. Further, if $K_{l,\rho}^B(z,w)$ denotes the L^2-eigenprojector kernel of the L^2-eigenspace

$$A_l^{2,B}(\mathbb{B}_\rho^n)=\left\{F\in L^2(\mathbb{B}_\rho^n;d\mu_\rho)/H_{B,\rho}F=\left(4B(2l+n)-4\frac{l(l+n)}{\rho^2}\right)F\right\}$$

then $K_{l,\rho}^B(z,w)$ converges, when ρ tends to $+\infty$, to $K_{l,\infty}^B(z,w)$ the L^2-eigenprojector kernel of the L^2-eigenspace

$$A_l^{2,B}(\mathbb{C}^n)=\{F\in L^2(\mathbb{C}^n;dm)/H_{B,\infty}F=4B(2l+n)F\};$$

see Theorem 1.

(3) Appropriately modified, the resolvent kernel of the Landau-like Hamiltonian $H_{B,\rho}$ converges, when $\rho\to+\infty$, to the resolvent kernel of the Landau Hamiltonian $H_{B,\infty}$ (Theorem 2).

Thus the paper is organized as follows: in Sec. II, we show that the Bergman–Kähler geometry on the Bergman balls $\mathbb{B}_\rho^n$ gives rise to the flat geometry of $\mathbb{C}^n$ by letting $\rho\to+\infty$; see Propositions 1 and 2, and Table I. In Sec. III, we give the geometrical realization of the Landau Hamiltonians on both $\mathbb{B}_\rho^n$ and $\mathbb{C}^n$ and we establish some of their invariance properties under the action of the groups of motions; see Proposition 4. In Sec. IV, we recall and we precise some L^2-spectral properties of $H_{B,\rho}$ and $H_{B,\infty}$. Finally, in Sec. V, we give the asymptotic proofs for L^2-spectral analysis of the Landau-like Hamiltonian $H_{B,\rho}$, when $\rho\to+\infty$, such as the L^2-eigenprojector kernels in Theorem 1 and resolvent kernels in Theorem 2.

We conclude this introduction by pointing out that our convergence theorems cannot be obtained just by a simple application of the general theorems in perturbation theory of the operator $H_{B,\rho}$ as in Rauch and Taylor work's.[16] Here the setting is quite different.

II. HERMITIAN STRUCTURE OF $\mathbb{C}^n$ AND BERGMAN–KÄHLER GEOMETRY OF THE BALLS $\mathbb{B}_\rho^n$.

Let $(\mathbb{C}^n,\langle .,.\rangle)$ be the usual n-dimensional Hermitian complex space endowed with its flat Kähler metric ds_∞^2,

$$ds_\infty^2 = \sum_{j=1}^{n} dz_j \otimes d\bar{z}_j. \tag{2}$$

The Euclidean distance $d_\infty(z,w)$ and the volume measure $d\mu_\infty(z)$ associated to ds_∞^2 are given, respectively, by

$$d_\infty(z,w) = |z-w|,$$

$$d\mu_\infty(z) = dm(z) \quad \text{(Usual Lebesgue measure on } \mathbb{C}^n).$$

For ρ fixed in $]0,+\infty[$, let $\mathbb{B}_\rho^n$ be the centered ball in $\mathbb{C}^n$ of radius ρ. That is

$$\mathbb{B}_\rho^n = \{z=(z_1,z_2,\ldots,z_n) \in \mathbb{C}^n;\ |z|^2 = |z_1|^2 + |z_2|^2 + \cdots + |z_n|^2 < \rho^2\}.$$

We equip $\mathbb{B}_\rho^n$ with the scaled Bergman–Kähler metric ds_ρ^2,

$$ds_\rho^2 = \frac{\rho^2}{(\rho^2-|z|^2)^2} \sum_{i,j=1}^{n} \left((\rho^2-|z|^2)\delta_{i,j} + \bar{z}_i z_j\right) dz_i \otimes d\bar{z}_j. \tag{3}$$

The hyperbolic distance $d_\rho(z,w)$ and the volume measure $d\mu_\rho(z)$ associated to ds_ρ^2 on $\mathbb{B}_\rho^n$ are given, respectively, by

$$\cosh^2\left(\frac{d_\rho(z,w)}{\rho}\right) = \frac{|\rho^2 - \langle z,w\rangle|^2}{(\rho^2-|z|^2)(\rho^2-|w|^2)} \tag{4}$$

and

$$d\mu_\rho(z) = \frac{\rho^{2(n+1)}\, dm(z)}{(\rho^2-|z|^2)^{n+1}}.$$

Both $(\mathbb{C}^n, ds_\infty^2)$ and $(\mathbb{B}_\rho^n, ds_\rho^2)$ are complete Kähler manifolds. Further, the holomorphic sectional curvature of $(\mathbb{B}_\rho^n, ds_\rho^2)$ is a negative constant and is equal here to $S_\rho = -4/\rho^2$. Note that $\lim_{\rho\mapsto+\infty} S_\rho = 0$, which corresponds to the flat curvature of $(\mathbb{C}^n, ds_\infty^2)$.

Associated to $(\mathbb{C}^n, ds_\infty^2)$ and $(\mathbb{B}_\rho^n, ds_\rho^2)$ are their groups of motions G_∞ and "G_ρ". The group G_∞ can be represented by the solvable semidirect group $U(n) \ltimes \mathbb{C}^n$, where $U(n)$ denotes the unitary group of $\mathbb{C}^n$ with respect to $\langle .,.\rangle$. The elements $g_\infty \in G_\infty$ can be written as matrices in the form

$$g_\infty = \begin{pmatrix} A & B \\ 0 & (\det A)^{-1} \end{pmatrix}, \quad A \in U(n), \quad B \in \mathbb{C}^n.$$

Also, for fixed $\rho > 0$, the group "G_ρ" of $(\mathbb{B}_\rho^n, ds_\rho^2)$ is essentially isomorphic, as a Lie group, to the complex Lorentz group $SU(n,1)$. But, since we will be varying ρ in $]0,+\infty[$, we need to make the groups "G_ρ" varying smoothly in ρ. To do this let W^∞ be the group of smooth infinite paths in the vector space $M_{n+1}(\mathbb{C})$ of $(n+1)\times(n+1)$ complex matrices of $\mathbb{C}^{n+1}$. That is $W^\infty = \mathcal{C}^\infty(]0,+\infty[, M_{n+1}(\mathbb{C}))$. Instead of W^∞, we consider the following subgroup Σ^∞ of all paths $g \in W^\infty$ "preserving" the nondegenerate Hermitian form J_ρ on $\mathbb{C}^{n+1}$, corresponding to the $(n+1)\times(n+1)$-matrix $J(\rho)$ given by

$$J(\rho) := \begin{pmatrix} I_n & 0 \\ 0 & -\rho^2 \end{pmatrix},$$

such that $\lim_{\rho\to+\infty} g(\rho)$ exists and $\det(g(\rho))=1$ for every fixed $\rho>0$. That is

$$\Sigma^{\infty} = \left\{ g \in W^{\infty}; g^*(\rho)J(\rho)g(\rho) = J(\rho), \lim_{\rho\to+\infty} g(\rho) \text{exists and } \det(g(\rho)) = 1 \right\}.$$

Now, for every fixed $\rho>0$, let G_ρ denote the set of evaluations at ρ of all paths $g\in\Sigma^{\infty}$. That is $G_\rho := \{g(\rho);\quad g\in\Sigma^{\infty}\}$. Then G_ρ is a Lie group of dimension n^2+2n and it can be described as follows:

$$G_\rho = \{g(\rho) \in M_{n+1}(\mathbb{C});\quad g^*(\rho)J(\rho)g(\rho) = J(\rho),\quad \det(g(\rho)) = 1\},$$

or equivalently

$$G_\rho = \{g(\rho) \in M_{n+1}(\mathbb{C});\quad g(\rho)J^{-1}(\rho)g^*(\rho) = J^{-1}(\rho),\quad \det(g(\rho)) = 1\}. \tag{5}$$

Below, we will discuss the asymptotic of the groups G_ρ, when $\rho\to+\infty$. Namely, we have the following proposition.

Proposition 1: (i) Let g be a smooth path in Σ^{∞}. *Then we have* $\lim_{\rho\to+\infty} g(\rho)\in G_\infty = \mathrm{U}(n)\ltimes\mathbb{C}^n$.

(ii) For $g_\infty\in G_\infty$ *there exists at least one path* $g:\rho\mapsto g(\rho)$ *in* Σ^{∞} *such that* $g_\infty=\lim_{\rho\to+\infty} g(\rho)$.

Proof: For (i), we use (5) to see that for every fixed $\rho>0$ the element $g(\rho)=\left(\begin{smallmatrix} A(\rho) & B(\rho) \\ C(\rho) & D(\rho) \end{smallmatrix}\right)\in G_\rho$, satisfies the identity

$$g(\rho)\begin{pmatrix} I_n & 0 \\ 0 & -1/\rho^2 \end{pmatrix} g^*(\rho) = \begin{pmatrix} I_n & 0 \\ 0 & -1/\rho^2 \end{pmatrix}.$$

Therefore, if we set $g_\infty := \lim_{\rho\to+\infty} g(\rho)$, which exists by definition, we see that g_∞ satisfies the identity

$$g_\infty\begin{pmatrix} I_n & 0 \\ 0 & 0 \end{pmatrix} g_\infty^* = \begin{pmatrix} I_n & 0 \\ 0 & 0 \end{pmatrix}. \tag{6}$$

Therefore, writing g_∞ in the form $g_\infty=\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$, where A, B, C, and D are, respectively, the limit when $\rho\to+\infty$ of $A(\rho)$, $B(\rho)$, $C(\rho)$, and $D(\rho)$, we conclude from the identity (6) that A is a unitary matrix and that $C=0$. Finally, since $\det(g_\infty)=\lim_{\rho\to+\infty}\det(g(\rho))=1$, it follows that $D=(\det A)^{-1}$.

Now, for (ii), let us fix $g_\infty=\left(\begin{smallmatrix} A & B \\ 0 & D \end{smallmatrix}\right)\in G_\infty$ and set $B=\left(\begin{smallmatrix} v \\ t+is \end{smallmatrix}\right)$ with $v\in\mathbb{C}^{n-1}$, $n\geqslant 2$, and s, $t\in\mathbb{R}$. Also, for every fixed $\rho>0$, let us consider the matrix

$$g(\rho) = \begin{pmatrix} A & 0 \\ 0 & D \end{pmatrix} \cdot a_t(\rho) \cdot n_{v,s}(\rho), \tag{7}$$

where $a_t(\rho)$ and $n_{v,s}(\rho)$ are given, respectively, by

$$a_t(\rho) = \begin{pmatrix} I_{n-1} & 0 & 0 \\ 0 & \cosh\left(\dfrac{t}{\rho}\right) & \rho\sinh\left(\dfrac{t}{\rho}\right) \\ 0 & \dfrac{1}{\rho}\sinh\left(\dfrac{t}{\rho}\right) & \cosh\left(\dfrac{t}{\rho}\right) \end{pmatrix}$$

and

$$n_{(v,s)}(\rho)=\begin{pmatrix} I_{n-1} & -\dfrac{v}{\rho} & v \\ \dfrac{v^*}{\rho} & 1-\dfrac{|v|^2}{2\rho^2}-\dfrac{is}{\rho} & \dfrac{|v|^2}{2\rho}+is \\ \dfrac{v^*}{\rho^2} & -\dfrac{|v|^2}{2\rho^3}-\dfrac{is}{\rho} & 1+\dfrac{|v|^2}{2\rho^2}+\dfrac{is}{\rho} \end{pmatrix}.$$

Then it is clear from the above explicit formulas, that $a_t(\rho)$ and $n_{v,s}(\rho)$ are smooth paths in $\rho\in]0,+\infty[$. Further, for every fixed $\rho>0$, we can show by direct computation that the matrices $a_t(\rho)$ and $n_{v,s}(\rho)$ are in G_ρ. Hence, the element $g(\rho)$ belongs to G_ρ for all fixed ρ and so the mapping $\rho\mapsto g(\rho)$ is in Σ^∞. Furthermore, using again the explicit expressions involved in the construction of $g(\rho)$ in (7), it becomes easy to check that $\lim_{\rho\to+\infty} g(\rho)=g_\infty$. Thus, the proof of the proposition is completed.

Remark 1: (i) Note that the complex space $\mathbb{C}^n$ as well as the balls $\mathbb{B}_\rho^n$ can be realized as homogeneous spaces. Indeed, for $\mathbb{B}_\rho^n$, we have $\mathbb{B}_\rho^n=G_\rho/K_\rho$, where K_ρ, given by

$$K_\rho=\left\{k(\rho)=\begin{pmatrix} A(\rho) & 0 \\ 0 & (\det A(\rho))^{-1}\end{pmatrix};A(\rho)\in U(n)\ \text{and}\ \lim_{\rho\to+\infty} A(\rho)\ \text{exists}\right\},$$

is the isotropic group at the origin $0\in\mathbb{B}_\rho^n$ of the transitive action of the group G_ρ on $\mathbb{B}_\rho^n$ that is given by

$$g(\rho)\,.\,z=\big(A(\rho)z+B(\rho)\big)\big(C(\rho)z+D(\rho)\big)^{-1}, \tag{8}$$

where we have set $g(\rho)=\left(\begin{smallmatrix} A(\rho) & B(\rho)\\ C(\rho) & D(\rho)\end{smallmatrix}\right)\in G_\rho$, with $A(\rho)\in M_{n,n}(\mathbb{C})$, $B(\rho)\in M_{1,n}(\mathbb{C})$, $C(\rho)\in M_{n,1}(\mathbb{C})$ and $D(\rho)\in\mathbb{C}$ depending smoothly in ρ. In (8) the point $z\in\mathbb{B}_\rho^n$ is viewed as a $(1\times n)$-matrix so that $C(\rho)z+D(\rho)$ is nothing than a complex number.

Similarly we have $\mathbb{C}^n=(\mathrm{U}(n)\ltimes\mathbb{C}^n)/\mathrm{U}(n)$, where the group $G_\infty=\mathrm{U}(n)\ltimes\mathbb{C}^n$ acts on $\mathbb{C}^n$ by

$$g_\infty\,.\,z=\det(A)\big(Az+B\big)\quad\text{for } g_\infty=\begin{pmatrix} A & B\\ 0 & (\det A)^{-1}\end{pmatrix}\in G_\infty. \tag{9}$$

(ii) The actions of the groups G_ρ on $\mathbb{B}_\rho^n$ and G_∞ on $\mathbb{C}^n$, as defined above by (8) and (9), can be extended to smooth complex-valued functions by considering the following transformations:

$$[T_\rho^B(g_\rho)f](z):=j_\rho^B(g_\rho;z)f(g\,.\,z)\quad \textit{for } g_\rho\in G_\rho,\quad f\in C^\infty(\mathbb{B}_\rho^n),\quad z\in\mathbb{B}_\rho^n,$$

$$[T_\infty^B(g_\infty)f](z):=j_\infty^B(g_\infty;z)f(g\,.\,z),\quad \textit{for } g_\infty\in G_\infty,\quad f\in C^\infty(\mathbb{C}^n),\quad z\in\mathbb{C}^n,$$

where the automorphic factors $j_\rho^B(g_\rho;z)$ and $j_\infty^B(g_\infty;z)$ are given, respectively, by

$$j_\rho^B(g_\rho;z):=\left(\frac{\rho^2-\overline{\langle z,g_\rho^{-1}\,.\,0\rangle}}{\rho^2-\langle z,g_\rho^{-1}\,.\,0\rangle}\right)^{B\rho^2}\quad \textit{for } g_\rho\in G_\rho,\quad z\in\mathbb{B}_\rho^n, \tag{10}$$

$$j_\infty^B(g_\infty;z):=e^{B(\langle z,g_\infty^{-1}.0\rangle-\overline{\langle z,g_\infty^{-1}\,.\,0\rangle})}\quad \textit{for } g_\infty\in G_\infty,\quad z\in\mathbb{C}^n. \tag{11}$$

Now, for the limit of the metric objects associated to ds_ρ^2 and the action objects associated to the groups G_ρ on the hyperbolic Bergman ball $\mathbb{B}_\rho^n$, when $\rho\to+\infty$, we have the following.

Proposition 2:

(i) *The Bergman metric ds_ρ^2 converges to the Euclidean metric ds_∞^2 of $\mathbb{C}^n$.*
(ii) *The hyperbolic Bergman distance d_ρ converges to the Euclidean distance d_∞.*
(iii) *Let $g\in\Sigma^\infty$ and $g_\infty=\lim_{\rho\to+\infty} g(\rho)$. Then $\lim_{\rho\to+\infty} j_\rho^B(g(\rho),\cdot)=j_\infty^B(g_\infty,\cdot)$.*

Proof: (i) follows easily from the explicit expressions of the metrics ds_ρ^2 and ds_∞^2 as given in (3) and (2). Just note that the limit $\lim_{\rho\to+\infty} ds_\rho^2 = ds_\infty^2$ means here that for every fixed $z\in\mathbb{C}^n$ and ρ large enough the form $ds_\rho^2(u,v)$ is well defined for every u, v in the tangent space $T_z\mathbb{B}_\rho^n = T_z\mathbb{C}^n = \mathbb{C}^n$, and that we have $\lim_{\rho\to+\infty} ds_\rho^2(u,v) = ds_\infty^2(u,v)$.

To prove (ii) fix $(z,w)\in\mathbb{C}^n\times\mathbb{C}^n$. Then for ρ large enough the Bergman distance $d_\rho(z,w)$ is well defined through the identity (4), i.e.,

$$\cosh^2\left(\frac{d_\rho(z,w)}{\rho}\right) = \frac{|\rho^2 - \langle z,w\rangle|^2}{(\rho^2-|z|^2)(\rho^2-|w|^2)}.$$

Furthermore, using the explicit expression of the inverse function of $\cosh^2(x)$, $x\in[0,+\infty[$, we can rewrite it as follows:

$$d_\rho(z,w) = \frac{\rho}{2}\,\mathrm{Log}\left(1 + 2\sqrt{y-1}\left[\sqrt{y} + \sqrt{y-1}\right]\right), \quad \text{for } y\in[1,+\infty[,$$

where we have set

$$y = y_\rho(z,w) = \frac{|\rho^2 - \langle z,w\rangle|^2}{(\rho^2-|z|^2)(\rho^2-|w|^2)}.$$

Now, after direct computation, we can write $y-1$ in the following form:

$$y - 1 = \frac{\rho^2|z-w|^2}{(\rho^2-|z|^2)(\rho^2-|w|^2)} + \frac{|\langle z,w\rangle|^2 - |z|^2|w|^2}{(\rho^2-|z|^2)(\rho^2-|w|^2)}.$$

Thus, for $z\neq w$ and $\rho\to+\infty$, we have

$$y = 1 + O\left(\frac{1}{\rho^2}\right) \quad \text{and } y-1 = \frac{|z-w|^2}{\rho^2} + O\left(\frac{1}{\rho^2}\right).$$

Hence,

$$\sqrt{y} = 1 + O\left(\frac{1}{\rho}\right) \quad \text{and } \sqrt{y-1} = \frac{|z-w|}{\rho} + O\left(\frac{1}{\rho}\right).$$

Therefore, using the asymptotic of the logarithmic function $\mathrm{Log}(1+x) = x(1+O(x))$ for $x\to 0$, we deduce easily that the limit of $d_\rho(z,w)$ when $\rho\to+\infty$ exists and this limit is equal to $|z-w| =: d_\infty(z,w)$.

For the proof of (iii), it is clear that, for fixed $z\in\mathbb{C}^n$ and ρ large enough, the automorphic factor $j_\rho^B(g_\rho,z)$, $g_\rho = g(\rho)\in G_\rho$, as given in (10), is well defined. Thus, we can write it in the form

$$j_\rho^B(g_\rho,z) = \exp\left\{B\rho^2\left(\mathrm{Log}\left(1 - \frac{\langle z, g_\rho^{-1}.0\rangle}{\rho^2}\right) - \mathrm{Log}\left(1 - \frac{\overline{\langle z, g_\rho^{-1}.0\rangle}}{\rho^2}\right)\right)\right\},$$

where Log is the principal determination of the complex logarithm. But, since $\lim_{\rho\to+\infty} g_\rho\cdot w = g_\infty\cdot w$ for every $w\in K$, where $g_\infty := \lim_{\rho\to+\infty} g_\rho$, we get

$$\lim_{\rho\to+\infty} j_\rho^B(g_\rho,z) = e^{B\left(\langle z, g_\infty^{-1}.0\rangle - \overline{\langle z, g_\infty^{-1}.0\rangle}\right)}.$$

Hence in view of (11), we see that $\lim_{\rho\to+\infty} j_\rho^B(g_\rho,z) = j_\infty^B(g_\infty,z)$. With this we have finished the proof of the proposition.

There are many other geometrical elements of the Bergman–Kähler geometry on $\mathbb{B}_\rho^n$ that converge to their analogous on $\mathbb{C}^n = \lim_{\to}\mathbb{B}_\rho^n$. Table I summarizes the relevant items on $\mathbb{B}_\rho^n$ and $\mathbb{C}^n$ that we will consider in this paper.

Remark 2: The above list of geometrical elements is not exhaustive. Indeed, one can consider

other items such as the three points function $J_\rho^B(z_1,z_2,z_3)$, $z_1,z_2,z_3\in\mathbb{B}_\rho^n$, *defined by*

$$J_\rho^B(z_1,z_2,z_3)=\left(\frac{\rho^2-\langle z_1,z_2\rangle}{\rho^2-\langle z_2,z_1\rangle}\right)^{B\rho^2}\left(\frac{\rho^2-\langle z_2,z_3\rangle}{\rho^2-\langle z_3,z_2\rangle}\right)^{B\rho^2}\left(\frac{\rho^2-\langle z_3,z_1\rangle}{\rho^2-\langle z_1,z_3\rangle}\right)^{B\rho^2}=e^{2iB\mathcal{V}_\rho(z_1,z_2,z_3)},$$

where the three phase point $\mathcal{V}_\rho$ *is given by*

$$\mathcal{V}_\rho(z_1,z_2,z_3)=\rho^2\left[\arg\left(1-\frac{\langle z_1,z_2\rangle}{\rho^2}\right)+\arg\left(1-\frac{\langle z_1,z_2\rangle}{\rho^2}\right)+\arg\left(1-\frac{\langle z_3,z_1\rangle}{\rho^2}\right)\right].$$

Here, $\arg(Z)$ *denotes the principal argument of the complex number* Z. *Then it is easy to check that*

$$\lim_{\rho\mapsto+\infty}\mathcal{V}_\rho(z_1,z_2,z_3)=\mathcal{V}_\infty(z_1,z_2,z_3)=\frac{i}{2}\left[(\langle z_1,z_2\rangle-\overline{\langle z_1,z_2\rangle})+(\langle z_2,z_3\rangle-\overline{\langle z_2,z_3\rangle})+(\langle z_3,z_1\rangle-\overline{\langle z_3,z_1\rangle})\right] \tag{12}$$

for every fixed three points z_1, z_2, z_3 *in* $\mathbb{C}^n$. *In particular, for the case* $n=1$, *the obtained result (12) is geometrically consistent since the three phase points* $\mathcal{V}_\rho(z_1,z_2,z_3)$ *is the area of the geodesic triangle of summits* z_1, z_2, z_3 *in the disc* $\mathbb{B}_\rho^1$ *and that* $\mathcal{V}_\infty(z_1,z_2,z_3)$ *represents the area of the Euclidean triangle of summits* z_1, z_2, z_3 *in* $\mathbb{R}^2=\mathbb{C}$.

III. GEOMETRICAL REALIZATION OF LANDAU-LIKE HAMILTONIANS AND INVARIANCE PROPERTIES

Let $H_{B,\rho}$ be the Landau-like Hamiltonians on the balls $\mathbb{B}_\rho^n$, $\rho\in]0,+\infty]$, as given in Definition 1. Then in this section, we give a geometrical realization of them as Schrödinger operators in the presence of uniform magnetic field on $\mathbb{B}_\rho^n$ and we establish some of their invariance properties.

A. Geometrical realization of the Landau-like Hamiltonians $H_{B,\rho}$

For $\rho\in]0,+\infty]$, let θ_ρ be the real differential 1-form defined by

$$\theta_\rho(z)=i\left(1-\left|\frac{z}{\rho}\right|^2\right)^{-1}\sum_{j=1}^n(\bar{z}_j\,dz_j-z_j\,d\bar{z}_j),\quad z\in\mathbb{B}_\rho^n\quad(i=\sqrt{-1}) \tag{13}$$

and let $\Lambda_c^p(\mathbb{B}_\rho^n)$ denote the space of smooth differential p-forms on $\mathbb{B}_\rho^n$ with compact support. For fixed $B\in\mathbb{R}$, let ∇_ρ^B be the first order differential operator acting on $\Lambda_c^p(\mathbb{B}_\rho^n)$ by

$$\nabla_\rho^B:=d+\sqrt{-1}B\,\mathrm{ext}\,\theta_\rho.$$

Here d is the exterior derivative of differential p-forms and $\mathrm{ext}\,\theta_\rho$ is the operator of exterior left multiplication by θ_ρ. Precisely, $\mathrm{ext}\,\theta_\rho\omega=\theta_\rho\wedge\omega$ for all $\omega\in\Lambda^p(\mathbb{B}_\rho^n)$. Also, let $(\nabla_\rho^B)^*$ denote the formal adjoint of ∇_ρ^B with respect to the Hermitian scalar product

$$(\alpha,\beta)_p=\int_{\mathbb{B}_\rho^n}\alpha\wedge\star\beta,\quad\alpha,\beta\in\Lambda_c^p(\mathbb{B}_\rho^n), \tag{14}$$

where $\star$ denotes the Hodge star operator associated to the appropriate metric on $\mathbb{B}_\rho^n$, $\rho\in]0,+\infty]$. Thus, using the above notations, we fix the following definition.

Definition 2: Let $B\in\mathbb{R}$. *For* $\rho\in]0,+\infty]$ *set*

$$H_{B,\rho}:=(\nabla_\rho^B)^*\nabla_\rho^B \tag{15}$$

acting on the space of smooth functions $\mathcal{C}^\infty(\mathbb{B}_\rho^n)=\Lambda^0(\mathbb{B}_\rho^n)$. *The operators* $H_{B,\rho}$ *will be called Landau-like Hamiltonians of* $\mathbb{B}_\rho^n$ *associated to the vector potential* θ_ρ.

Remark 3: The definition (15) *of the Landau-like Hamiltonians acting on scalar functions can be extended to the case of differential p-forms,* $1\leqslant p\leqslant 2n$, *of* $\mathbb{B}_\rho^n$, $\rho\in]0,+\infty]$, *by considering*

$$H^p_{B,\rho} = (\nabla^B_\rho)^* \nabla^B_\rho + \nabla^B_\rho (\nabla^B_\rho)^*. \tag{16}$$

The following proposition, giving the explicit expressions of the Landau-like Hamiltonians $H_{B,\rho}$, asserts that the Laplacians $H_{B,\rho}$ in Definition 2 is in fact a geometrical realization of those in Definition 1. Namely, we have

Proposition 3: Let B fixed in $\mathbb{R}$. *Then*

(i) The explicit expression of the Landau-like Hamiltonian $H_{B,\rho}$, *(15), in the complex coordinates* $z=(z_1,\ldots,z_n)\in\mathbb{B}^n_\rho$, $\rho\in]0,+\infty[$, *is given by*

$$H_{B,\rho} = -4\left(1-\left|\frac{z}{\rho}\right|^2\right)\left\{\sum_{i,j=1}^n\left(\delta_{ij}-\frac{z_i\bar{z}_j}{\rho^2}\right)\frac{\partial^2}{\partial z_i\,\partial\bar{z}_j}+B\sum_{j=1}^n\left(z_j\frac{\partial}{\partial z_j}-\bar{z}_j\frac{\partial}{\partial\bar{z}_j}\right)\right\}+4B^2|z|^2.$$

(ii) The explicit expression of the Landau-like Hamiltonian $H_{B,\infty}$, (15), *in the complex coordinates* $z=(z_1,\cdots,z_n)\in\mathbb{B}^n_\infty=\mathbb{C}^n$ *is given by*

$$H_{B,\infty} = -4\left\{\sum_{j=1}^n\frac{\partial^2}{\partial z_j\,\partial\bar{z}_j}+B\sum_{j=1}^n\left(z_j\frac{\partial}{\partial z_j}-\bar{z}_j\frac{\partial}{\partial\bar{z}_j}\right)\right\}+4B^2|z|^2.$$

Proof: The proof relies essentially on the construction of the Hodge star operator. For $n=1$ this is easy to handle since in this case the metric ds^2_ρ is conformal to the Euclidean metric $|\mathrm{dz}|^2$ of the disc $\mathbb{B}^1_\rho$ for which we have

$$\star 1=\frac{i}{2}\left(1-\left|\frac{z}{\rho}\right|^2\right)^{-2}\mathrm{dz}\wedge\mathrm{d}\bar{z},\quad \star\mathrm{dz}=i\mathrm{d}\bar{z},\quad \star\mathrm{d}\bar{z}=-i\,\mathrm{dz},\quad \text{and } \star(\mathrm{dz}\wedge\mathrm{d}\bar{z})=2i\left(1-\left|\frac{z}{\rho}\right|^2\right)^2.$$

For $n\geqslant 2$ the Kählerian metric

$$\mathrm{ds}^2_\rho(z)=-\sum_{i,j=1}^n\frac{\partial^2}{\partial z_i\,\partial\bar{z}_j}\mathrm{Log}(\rho^2-|z|^2)\mathrm{dz}_i\otimes\mathrm{d}\bar{z}_j$$

on $\mathbb{B}^n_\rho$ is no more conformal to the Euclidean metric $|\mathrm{dz}|^2=|\mathrm{dz}_1|^2+\cdots+|\mathrm{dz}_n|^2$. Indeed, for $z\in\mathbb{B}^n_\rho$, $z\neq 0$, the eigenvalues of the Hermitian metric ds^2_ρ are explicitly given by

$$\lambda_1(\rho)=\frac{\rho^4}{(\rho^2-|z|^2)^2}\quad\text{and }\lambda_2(\rho)=\frac{\rho^2}{\rho^2-|z|^2}.$$

The first eigenvalue $\lambda_1(\rho)$ is of complex multiplicity one with the vector column z as eigenvector while the eigenvalue $\lambda_2(\rho)$ occurs with $n-1$ multiplicity with eigenspace the hyperplane $z^\perp=\{u\in\mathbb{C}^n;\langle u,z\rangle=0\}$. Thus, using the Gram–Schmidt procedure, we can construct a unitary coframe at the point z of differential 1-forms φ_j, $j=1,2,\ldots,n$, with

$$\varphi_1(z)=\frac{\rho^2\bar{z}_j\,\mathrm{dz}_j}{|z|(\rho^2-|z|^2)}$$

and in which the metric can be written as

$$\mathrm{ds}^2_\rho=\varphi_1(z)\otimes\overline{\varphi}_1(z)+\varphi_2(z)\otimes\overline{\varphi}_2(z)+\cdots+\varphi_n(z)\otimes\overline{\varphi}_n(z),$$

and the vector potential θ_ρ has the form $\theta_\rho(z)=i|z|(\varphi_1(z)-\overline{\varphi_1}(z))$.

Using such coframe, the Hodge star operator, $\star$, can be defined as

$$\varphi_j(z)\wedge\star\varphi_k(z)=\overline{\varphi_j}(z)\wedge\star\overline{\varphi_k}(z)=2\delta_{jk}\,\mathrm{d}\mu_\rho(z),$$

$$\varphi_j(z) \wedge \star\overline{\varphi_k}(z) = \overline{\varphi_j}(z) \wedge \star\varphi_k(z) = 0.$$

Now, using the definition of the Landau-like Hamiltonian $H_{B,\rho}=(\nabla_\rho^B)^*\nabla_\rho^B$, we can write it in the form

$$H_{B,\rho} = \mathrm{d}^*\mathrm{d} + iB(\mathrm{d}^* \text{ ext } \theta_\rho - (\text{ext } \theta_\rho)^*\mathrm{d}) + B^2(\text{ext } \theta_\rho)^*(\text{ext } \theta_\rho). \tag{17}$$

Thus, to obtain explicit differential expression in z of $H_{B,\rho}$ it will be enough to find those of the operators $\mathrm{d}^*\mathrm{d}$, $\mathrm{d}^*(\text{ext } \theta_\rho)$, $(\text{ext } \theta_\rho)^*\mathrm{d}$, and $(\text{ext } \theta_\rho)^*(\text{ext } \theta_\rho)$ acting on functions. For this, recall that the adjoints operators d^* of d and $(\text{ext } \theta_\rho)^*$ of ext θ_ρ with respect to (14) are known to be given, respectively, by

$$\mathrm{d}^* = -\star\mathrm{d}\star \quad \text{and } (\text{ext } \theta_\rho)^* = \star \text{ ext } \theta_\rho\star.$$

Also note that the operator $\mathrm{d}^*\mathrm{d}$ is nothing than the Laplace–Beltrami operator of $(\mathbb{B}_\rho^n, \mathrm{d}s_\rho^2)$, $\rho\in]0,+\infty]$, whose explicit expression in the complex coordinates $z=(z_1,z_2,\ldots,z_n)$ is given by

$$\mathrm{d}^*\mathrm{d} = -4\left(1-\left|\frac{z}{\rho}\right|^2\right)\sum_{i,j=1}^{n}\left(\delta_{ij}-\frac{z_i\bar{z}_j}{\rho^2}\right)\frac{\partial^2}{\partial z_i\,\partial\bar{z}_j}. \tag{18}$$

For the other involved operators occurring in (17), we have the following lemma whose proof can be done by straightforward computation keeping in mind that $\theta_\rho=-i\rho^2(\partial-\bar{\partial})\mathrm{Log}(1-|z/\rho|^2)$; see also Ref. 3.

Lemma 1: *Let f be any smooth function on $\mathbb{B}_\rho^n$ and $z\in\mathbb{B}_\rho^n$. Then we have*

$$(1)\quad \mathrm{d}^*\theta_\rho = 0,$$

$$(2)\quad (\text{ext } \theta_\rho)^*\,\mathrm{d}f(z) = -2i\left(1-\left|\frac{z}{\rho}\right|^2\right)(E-\overline{E})f(z), \tag{19}$$

$$(3)\quad \mathrm{d}^*(\text{ext } \theta_\rho)f(z) = 2i\left(1-\left|\frac{z}{\rho}\right|^2\right)(E-\overline{E})f(z), \tag{20}$$

$$(4)\quad (\text{ext } \theta_\rho)^*(\text{ext } \theta_\rho)f(z) = 4|z|^2 f(z). \tag{21}$$

Hence, by combining (18)–(21), we obtain the desired expression of $H_{B,\rho}$ as stated in (i) of the above proposition.

The explicit expression given in (ii) of $H_{B,\infty}$ on the complex space $\mathbb{C}^n$ can easily be handled since the metric $\mathrm{d}s_\infty^2$ is the Euclidean metric itself.

B. Invariance properties

In below, we establish some invariance properties of the Landau-like Hamiltonians $H_{B,\rho}^p$ acting on p-forms of $\mathbb{B}_\rho^n$, $p=0,1,\ldots,2n$, $\rho\in]0,+\infty]$. To do this remind that the vector potential θ_ρ and the automorphic factor j_ρ^B, are given, respectively, by

$$\theta_\rho(z) = -i\rho^2(\partial-\bar{\partial})\mathrm{Log}(\rho^2-|z|^2), \quad z\in\mathbb{B}_\rho^n, \tag{22}$$

$$j_\rho^B(g;z) := \left(\frac{\rho^2-\overline{\langle z,g^{-1}.0\rangle}}{\rho^2-\langle z,g^{-1}.0\rangle}\right)^{B\rho^2} \quad \text{for } g=g_\rho\in G_\rho, \quad z\in\mathbb{B}_\rho^n, \tag{23}$$

for which we have the following.

Lemma 2: Let $\rho>0$, $g=g_\rho\in G_\rho$, and denote by $g^*\theta_\rho$ the pull-back of the differential 1*-form θ_ρ by the map $z\mapsto g.z$. Then for every $z\in\mathbb{B}_\rho^n$, we have*

$$\text{(i)}\quad (g^*\theta_\rho)(z) = \theta_\rho(z) - i\rho^2 \mathrm{d}\left[\mathrm{Log}\left(\frac{\rho^2 - \overline{\langle z, g^{-1}\cdot 0\rangle}}{\rho^2 - \langle z, g^{-1}\cdot 0\rangle}\right)\right],$$

$$\text{(ii)}\quad \mathrm{d}\left(j_\rho^B(g,z)\right) = B\rho^2 j_\rho^B(g,z)\mathrm{d}\left[\mathrm{Log}\left(\frac{\rho^2 - \overline{\langle z, g^{-1}\cdot 0\rangle}}{\rho^2 - \langle z, g^{-1}\cdot 0\rangle}\right)\right].$$

Proof: Let $g\in G_\rho$ and $z\in\mathbb{B}_\rho^n$. Then using definition of G_ρ, we get the identity

$$\rho^2 - |g\cdot z|^2 = \rho^2\frac{(\rho^2 - |g^{-1}\cdot 0|^2)(\rho^2 - |z|^2)}{|\rho^2 - \langle z, g^{-1}\cdot 0\rangle|^2}.$$

Then using (22) and the fact that the pull-back operation $g^*:\omega\mapsto g^*\omega$ commutes with the operators ∂ and $\bar\partial$ (i.e., $\partial g^* = g^*\partial$ and $\bar\partial g^* = g^*\bar\partial$), it follows that

$$g^*\theta_\rho(z) = \theta_\rho(z) - i\rho^2(\partial - \bar\partial)\mathrm{Log}(|\rho^2 - \langle z, g^{-1}\cdot 0\rangle|^2).$$

But, since $z\mapsto\rho^2 - \langle z, g^{-1}\cdot 0\rangle$ is holomorphic and $\mathrm{d} = \partial + \bar\partial$ it follows

$$(\partial - \bar\partial)\mathrm{Log}(|\rho^2 - \langle z, g^{-1}\cdot 0\rangle|^2) = \mathrm{d}\left[\mathrm{Log}\left(\frac{\rho^2 - \overline{\langle z, g^{-1}\cdot 0\rangle}}{\rho^2 - \langle z, g^{-1}\cdot 0\rangle}\right)\right].$$

Hence, (i) holds. Similarly, a direct computation yields (ii).

Now, let $L^2(\mathbb{B}_\rho^n;\Lambda^p)$ be the Hilbert space obtained as completion of $\Lambda_c^p(\mathbb{B}_\rho^n)$ with respect to (14). For $g = g_\rho\in G_\rho$, let $T_\rho^B(g)$ be the transformation defined by

$$T_\rho^B(g)\omega = j_\rho^B(g,\cdot)g^*(\omega),\quad \omega\in\Lambda_c^p(\mathbb{B}_\rho^n),\quad \rho\in 0,+\infty, \tag{24}$$

where $j_\rho^B(g,\cdot)$ is the automorphic factor as given in (23) and $g^*\omega$ is the pull-back of the differential p-form ω by the biholomorphic mapping $z\mapsto g_\rho\cdot z$. Then T_ρ^B is a projective representation of the group G_ρ on $L^2(\mathbb{B}_\rho^n;\Lambda^p)$. That is

(i) T_ρ^B acts unitary on $L^2(\mathbb{B}_\rho^n;\Lambda^p)$ for every $g\in G_\rho$;

(ii) for all $g_1, g_2\in G_\rho$, we have $T_\rho^B(g_1g_2) = e^{2iB\phi(g_1,g_2)}T_\rho^B(g_2)T_\rho^B(g_1)$, where ϕ is a phase factor given here by

$$\phi(g_1,g_2) = \rho^2\arg\left(1 - \frac{\langle g_1^{-1}\cdot 0, g_2\cdot 0\rangle}{\rho^2}\right).$$

(iii) For each function $f\in L^2(\mathbb{B}_\rho^n;\Lambda^p)$, the map $g\in G_\rho\mapsto T_\rho^B(g)f\in L^2(\mathbb{B}_\rho^n;\Lambda^p)$ is continuous.

Thus the following invariance properties hold.

Proposition 4: Let $B\in\mathbb{R}$ fixed and $g = g_\rho\in G_\rho$ for $\rho\in]0,+\infty]$. Then for $p = 0,1,\ldots,2n$, we have

(i) *The first order differential operators $\nabla_\rho^B = d + \sqrt{-1}\,\mathrm{ext}\,\theta_\rho$ are invariant with respect to the transformations $T_\rho^B(g)$. That is*

$$T_\rho^B(g)\nabla_\rho^B = \nabla_\rho^B T_\rho^B(g).$$

(ii) *The Landau-like Hamiltonians $H_{B,\rho}^p = (\nabla_\rho^B)^*\nabla_\rho^B + \nabla_\rho^B(\nabla_\rho^B)^*$ are also T_ρ^B-invariant. More exactly we have*

$$T_\rho^B(g)H_{B,\rho}^p = H_{B,\rho}^p T_\rho^B(g).$$

Proof: By a direct computation of $\nabla_\rho^B[T_\rho^B(g)\omega]$ in (i) for $g\in G_\rho$, $\omega\in\Lambda_c^p(\mathbb{B}_\rho^n)$ and $z\in\mathbb{B}_\rho^n$, where $T_\rho^B(g)\omega$ is as given in (24), we get

$$\nabla_\rho^B[T_\rho^B(g)\omega]=\nabla_\rho^B[j_\rho^B(g,z)g^*\omega]=\mathrm{d}(j_\rho^B(g,z)g^*\omega)+iBj_\rho^B(g,z)\theta_\rho\wedge g^*\omega$$

$$=j_\rho^B(g,z)\mathrm{d}(g^*\omega)+(\mathrm{d}j_\rho^B(g,z))\wedge g^*\omega+iBj_\rho^B(g,z)\theta_\rho\wedge g^*\omega.$$

Now, using the above lemma and the well known facts that $g^*\mathrm{d}=\mathrm{d}g^*$ and $g^*(\theta\wedge\omega)=g^*\theta\wedge g^*\omega$, we get

$$\nabla_\rho^B[T_\rho^B(g)\omega]=j_\rho^B(g,z)g^*(\mathrm{d}\omega)+B\rho^2j_\rho^B(g,z)\mathrm{d}\left[\mathrm{Log}\left(\frac{\rho^2-\overline{\langle z,g^{-1}.0\rangle}}{\rho^2-\langle z,g^{-1}.0\rangle}\right)\right]\wedge g^*\omega+iBj_\rho^B(g,z)$$
$$\times\left\{g^*\theta_\rho+i\rho^2\mathrm{d}\left[\mathrm{Log}\left(\frac{\rho^2-\overline{\langle z,g^{-1}.0\rangle}}{\rho^2-\langle z,g^{-1}.0\rangle}\right)\right]\right\}\wedge g^*\omega=j_\rho^B(g,z)g^*(\mathrm{d}\omega+iB\theta_\rho\wedge\omega).$$

Hence, we obtain the desired result (i) as cited in the proposition.

Now, for the proof of (ii), we use (i) and the fact that $T_\rho^B(g)$ is unitary, to show that $T_\rho^B(g)$ commutes also with the formal adjoint $(\nabla_\rho^B)^*$. Hence, the invariance property of the Hamiltonian $H_{B,\rho}^p$ with respect to $T_\rho^B(g)$, $g\in G_\rho$, holds and so the proof of the proposition is completed.

IV. BACKGROUND ON L^2-CONCRETE SPECTRAL THEORY OF THE LANDAU-LIKE HAMILTONIANS $H_{B,\rho}$.

In this section, we we recall some well established L^2-spectral properties of $H_{B,\rho}$ for $\rho\in]0,+\infty]$.

A. L^2-spectrum and L^2-eigenfunctions of $H_{B,\rho}$ on $L^2(\mathbb{B}_\rho^n;\mathrm{d}\mu_\rho)$

We start with the following.

Proposition 5: (Spectrum of the Landau-like Hamiltonians). Let $n\geqslant 1$, $B>0$ *and let* $H_{B,\rho}$ *be the Landau-like Hamiltonians on* $\mathbb{B}_\rho^n$ *for* $\rho\in]0,+\infty]$. *Then we have the following.*

(i) For fixed $\rho\in]0,+\infty[$, *the Landau-like Hamiltonian* $H_{B,\rho}$ *is densely defined on the Hilbert space* $L^2(\mathbb{B}_\rho^n;\mathrm{d}\mu_\rho)$ *and admits a unique self-adjoint realization denoted* $H_{B,\rho}$, *whose spectrum on* $L^2(\mathbb{B}_\rho^n;\mathrm{d}\mu_\rho)$ *is given by*

$$\sigma(H_{B,\rho})=\sigma_d(H_{B,\rho})\cup\left[\frac{n^2}{\rho^2}+4B^2\rho^2,+\infty\right],$$

where the finite discrete part $\sigma_d(H_{B,\rho})$ *of the spectrum is given by*

$$\sigma_d(H_{B,\rho})=\left\{\lambda_l(\rho):=4B(2l+n)-4\frac{l(l+n)}{\rho^2};l\in\mathbb{Z}^+,\ 0\leqslant l<B\rho^2-\frac{n}{2}\right\}.$$

Here, each L^2-*eigenvalue* $\lambda_l(\rho)$ *occurs with infinite multiplicity.*

(ii) For $\rho=+\infty$, *the Landau-like Hamiltonian* $H_{B,\infty}$ *is also densely defined on the Hilbert space* $L^2(\mathbb{C}^n;\mathrm{d}m)$ *and admits unique self-adjoint realization. The spectrum* $\sigma(H_{B,\infty})$ *of* $H_{B,\infty}$ *in* $L^2(\mathbb{C}^n;\mathrm{d}m)$ *is reduced only to a pure point spectrum with infinite degenerated multiplicities. More exactly we have*

$$\sigma(H_{B,\infty})=\sigma_d(H_{B,\infty})=\{\lambda_l(\infty):=4B(2l+n);\ l=0,1,2,\ldots\}.$$

Proof: For the proof of assertion (i), the reader can refer, for example, to Refs. 8, 18, and 9 for $n=1$ and to Refs. 19 and 5 for $n\geqslant 2$. The assertion (ii) is well known, in both mathematics and physics literature, as Landau energy levels for Schrödinger operators with uniform magnetic field on $\mathbb{R}^{2n}=\mathbb{C}^n$.

Below, we give concrete characterization of the L^2-eigenfunctions of the Landau-like Hamiltonians $H_{B,\rho}$ acting on $L^2(\mathbb{B}^n_\rho;\mathrm{d}\mu_\rho)$, $\rho\in]0,+\infty]$. Mainly, we have the following.

Proposition 6: Let $B>0$ and $\rho\in]0,+\infty]$.

(i) Let $\rho\in]0,+\infty[$ *such that* $B\rho^2>n/2$ *and* $l\in\mathbb{Z}^+$ *satisfying* $0\leqslant l<B\rho^2-n/2$. *Then any* F *solution of* $H_{B,\rho}F=(4B(2l+n)-4[l(l+n)/\rho^2])F$, *in* $L^2(\mathbb{B}^n_\rho;\mathrm{d}\mu_\rho)$, *can be expanded in* $L^2(\mathbb{B}^n_\rho;\mathrm{d}\mu_\rho)$ *as follows:*

$$F(z)=\left(1-\left|\frac{z}{\rho}\right|^2\right)^{B\rho^2-l}\sum_{p=0}^{+\infty}\sum_{q=0}^{l}{}_2F_1\left(q-l,2B\rho^2+p-l;n+p+q;\left|\frac{z}{\rho}\right|^2\right)h^{pq}_{B,\rho,l}(z,\bar{z}),$$

where $h^{pq}_{B,\rho,l}(z,\bar{z})$ *denotes the harmonic polynomials on* $\mathbb{C}^n$ *that are homogeneous of degree* p *in* z *and degree* q *in* $\bar{z}$ *(see Ref. 10). Furthermore, its norm is given by* $\|F\|^2_{L^2(\mathbb{B}^n_\rho;\,\mathrm{d}\mu_\rho)}=\sum_{p=0}^{+\infty}\sum_{q=0}^{l}\gamma^{n,pq}_{B,\rho}(l)\|h^{pq}_{B,\rho,l}\|^2_{L^2(S^{2n-1})}$ *with*

$$\gamma^{n,pq}_{B,\rho}(l)=\frac{(l-q)!\Gamma^2(n+p+q)}{2\Gamma(n+p+l)}\frac{\rho^{2(n+p+q)}\Gamma(2B\rho^2-n-q-l+1)}{(2B\rho^2-n-2l)\Gamma(2B\rho^2+p-l)}. \tag{25}$$

(ii) For $\rho=+\infty$ *and* $l=0,1,2,\ldots$. *Then any function* F *solution of* $H_{B,\infty}F=4B(2\lambda+n)F$ *in* $L^2(\mathbb{C}^n;\mathrm{d}m)$ *can be expanded as follows:*

$$F(z)=e^{-B|z|^2}\sum_{p=0}^{+\infty}\sum_{q=0}^{l}{}_1F_1(q-l,n+p+q;2B|z|^2)h^{pq}_{B,l}(z,\bar{z}),$$

where its norm is given by

$$\|F\|^2_{L^2(\mathbb{C}^n;\mathrm{d}m)}=\sum_{p=0}^{+\infty}\sum_{q=0}^{l}\gamma^{n,pq}_{B}(l)\|h^{pq}_{B,l}\|^2_{L^2(S^{2n-1})}$$

with

$$\gamma^{n,pq}_{B}(l)=\left(\frac{1}{2B}\right)^{n+p+q}\frac{(l-q)!\Gamma^2(n+p+q)}{2\Gamma(n+p+l)}.$$

Proof: (Sketch of the proof.) For $n=1$, the result in (i) is contained in the works of Elstrodt[8] and Patterson.[18] For $n\geqslant 2$, one can check (i) by the use of the weighted Plancherel formula established in Ref. 19 on the unit Bergman ball.

For the computation of the norm, we use the polar coordinates $z=\rho r\omega$, $0\leqslant r<1$, $\omega\in S^{2n-1}$, and Parseval equality to have

$$\|F\|^2=\|F\|^2_{L^2(\mathbb{B}^n_\rho,d\mu_\rho)}=\sum_{p=0}^{+\infty}\sum_{q=0}^{l}\gamma^{n,pq}_{B,\rho}(l)\|h^{pq}_{B,\rho,l}\|^2_{L^2(S^{2n-1})}.$$

The quantities $\gamma^{n,pq}_{B,\rho}(l)$ are defined by

$$\gamma^{n,pq}_{B,\rho}(l):=\frac{\rho^{2n}}{2}\int_0^1 x^{n+p+q-1}(1-x)^{2(B\rho^2-l)-n-1}\left|{}_2F_1(q-l,2B\rho^2+p-l;n+p+q;x)\right|^2\mathrm{d}x,$$

where we have set $x=r^2$. Then the above integral involving the product of two hypergeometric functions can be computed by applying the following well known identity:

$$ {}_2F_1(-m,b;c;x) = \frac{1}{(c)_m} x^{1-c}(1-x)^{c-b+m}\left(\frac{d}{dx}\right)^m (x^{c+m-1}(1-x)^{b-c}), $$

where m is in $\mathbb{Z}^+$ and $(c)_m = c(c+1)\cdots(c+m-1)$ is the Pochhammer symbol, and using integration by parts and the fact

$$ \left(\frac{d}{dx}\right)^m \left((1-x)^{a+m-1} {}_2F_1(a,b;c;x)\right) = \frac{(-1)^m (a)_m (c-b)_m}{(\gamma)_m} (1-x)^{a-1} {}_2F_1(a+m,b;c+m;x). $$

Thus, we get the norm of F as given by (25).

The result (ii), for $\rho = +\infty$, is well known for Schrödinger operators with constant magnetic field on $\mathbb{R}^{2n} = \mathbb{C}^n$. For the norm the proof is similar to the one given for Theorem 2.1 in Ref. 2.

Remark 4: Note that the bottom eigenvalue $\lambda_0(\rho) = 4Bn$, corresponding to $l = 0$, is independent of ρ. The associated L^2-eigenspace is isomorphic to the usual weighted Bergman–Hilbert space of holomorphic functions on $\mathbb{B}_\rho^n$ that are square integrable with respect to the density $(1 - |z/\rho|^2)^{2B\rho^2 - n - 1}\, dm$,

$$ \left\{ G_\rho(z) \text{ holomorphic}; \int_{\mathbb{B}_\rho^n} |G_\rho(z)|^2 \left(1 - \left|\frac{z}{\rho}\right|^2\right)^{2B\rho^2 - n - 1} dm(z) < +\infty \right\}. $$

Also, the L^2-eigenspace associated to the ground state $4Bn$ of the Landau-like Hamiltonian $H_{B,\infty}$ on $\mathbb{C}^n$ is isometric to the Bargmann–Fock space

$$ \left\{ G: \mathbb{C}^n \to \mathbb{C}, \quad G \text{ entire and } \quad \int_{\mathbb{C}^n} |G(z)|^2 e^{-2B|z|^2}\, dm(z) < +\infty \right\}. $$

B. Explicit formulas for the L^2-eigenprojector kernels for the discrete spectrum of $H_{B,\rho}$

Now, let $B > 0$ and $l \in \mathbb{Z}^+$ be fixed. For $\rho > 0$ such that $\rho^2 > (2l+n)/(2B)$, let $A_l^{2,B}(\mathbb{B}_\rho^n)$ be the following Hilbert space corresponding to the L^2-eigenvalue:

$$ \lambda_l(\rho) = 4B(2l+n) - 4\frac{l(l+n)}{\rho^2} $$

of the Landau-like Hamiltonian $H_{B,\rho}$. That is

$$ A_l^{2,B}(\mathbb{B}_\rho^n) = \left\{ F \in L^2(\mathbb{B}_\rho^n; d\mu_\rho) / H_{B,\rho} F = \left(4B(2l+n) - 4\frac{l(l+n)}{\rho^2}\right) F \right\}. $$

Also, let $A_l^{2,B}(\mathbb{C}^n)$ be the following Hilbert space associated to the L^2-eigenvalue $\lambda_l(\rho) = 4B(2l+n)$ (Landau energy level) of the Landau-like Hamiltonian $H_{B,\infty}$ on $\mathbb{C}^n$,

$$ A_l^{2,B}(\mathbb{C}^n) = \{ F \in L^2(\mathbb{C}^n; dm) / H_{B,\infty} F = 4B(2l+n) F \}. $$

Then one can show that the above Hilbert spaces $A_l^{2,B}(\mathbb{B}_\rho^n)$ and $A_l^{2,B}(\mathbb{C}^n)$ admit L^2-eigenprojector kernels which we denote here, respectively, by $K_{l,\rho}^B(z,w)$ with $z, w \in \mathbb{B}_\rho^n$ and $K_{l,\infty}^B(z,w)$ with $z, w \in \mathbb{C}^n$. Therefore, the following proposition gives the explicit closed expressions of such L^2-eigenprojector kernels. Namely, we have the following.

Proposition 7: Let $B > 0$ fixed. Then we have the following.

(i) For fixed $l \in \mathbb{Z}^+$ such that $0 \leqslant l < B\rho^2 - n/2$, the L^2-eigenprojector kernel $K_{l,\rho}^B(z,w)$ of the L^2-eigenspace $A_l^{2,B}(\mathbb{B}_\rho^n)$ is given in term of the Bergman distance $d_\rho(z,w)$ by the following closed explicit formula:

$$K^B_{l,\rho}(z,w) = A_{n;B;l}(\rho)\left(\frac{\rho^2 - \overline{\langle z,w\rangle}}{\rho^2 - \langle z,w\rangle}\right)^{B\rho^2}\left(\cosh\left(\frac{d_\rho(z,w)}{\rho}\right)\right)^{-2(B\rho^2-l)} \times {}_2F_1\left(-l, 2B\rho^2 - l; n; \tanh^2\left(\frac{d_\rho(z,w)}{\rho}\right)\right), \tag{26}$$

where the constant $A_{n;B;l}(\rho)$ is given explicitly in terms of gamma functions by

$$A_{n;B;l}(\rho) = \frac{1}{\pi^n}\frac{\Gamma(n+l)}{\Gamma(n)l!} \times \frac{(2B\rho^2 - n - 2l)\Gamma(2B\rho^2 - l)}{\rho^{2n}\Gamma(2B\rho^2 - n - l + 1)}. \tag{27}$$

(ii) For $\rho = +\infty$ and $l = 0, 1, 2, \ldots$, the L^2-eigenprojector kernel $K^B_{l,\infty}(z,w)$ of $A^{2,B}_l(\mathbb{C}^n)$ is given by the following explicit closed formula:

$$K^B_{l,\infty}(z,w) = \left(\frac{2B}{\pi}\right)^n \frac{\Gamma(n+l)}{\Gamma(n)l!} e^{B(\langle z,w\rangle - \overline{\langle z,w\rangle})} e^{-B|z-w|^2} {}_1F_1(-l, n; 2B|z-w|^2).$$

Proof: Using the invariance property of the Landau-like Hamiltonians $H_{B,\rho}$ under the action T^B_ρ of the group of motions G_ρ (see Proposition 4), we cheek that the L^2-eigenprojector kernel $K^B_{l,\rho}(z,w)$, $\rho \in]\sqrt{n/2B}, +\infty[$, is G_ρ-invariant which means that we have

$$K^B_{l,\rho}(z,w) = j^B_\rho(g;z)\overline{j^B_\rho(g;w)} K^B_{l,\rho}(g \,.\, z, g \,.\, w)$$

for every $g = g_\rho \in G_\rho$, where $j^B_\rho(g;z)$ is the automorphic factor of g at point z. Hence, we get

$$K^B_{l,\rho}(z,w) = j^B_\rho(g_w;z)\overline{j^B_\rho(g_w;w)} K^B_{l,\rho}(g_w \,.\, z, 0),$$

where g_w is in G_ρ such that $g_w \cdot w = 0$. Now let us note that

$$j^B_\rho(g_w;z)\overline{j^B_\rho(g_w;w)} = j^B_\rho(g_w;z) = \left(\frac{\rho^2 - \overline{\langle z,w\rangle}}{\rho^2 - \langle z,w\rangle}\right)^{B\rho^2}$$

and that the function $z \mapsto K^B_{l,\rho}(z,0)$ is a radial L^2-eigenfunction of $H_{B,\rho}$. Therefore, we get

$$K^B_{l,\rho}(z,0) = \{\gamma^{n,00}_{B,\rho}(l)\}^{-1}\left(1 - \left|\frac{z}{\rho}\right|^2\right)^{B\rho^2 - l} {}_2F_1\left(-l, 2B\rho^2 - l; n; \left|\frac{z}{\rho}\right|^2\right).$$

Here, the factor $\{\gamma^{n,00}_{B,\rho}(l)\}^{-1} =: A_{n;B;l}(\rho)$ is due to the normalization and is given through the formula (25) in which we take $p = q = 0$. Hence, we obtain

$$K^B_{l,\rho}(g_w \,.\, z, 0) = A_{n;B;l}(\rho)\left(1 - \left|\frac{g_w \,.\, z}{\rho}\right|^2\right)^{B\rho^2 - l} {}_2F_1\left(-l, 2\nu\rho^2 - l; n; \left|\frac{g_w \,.\, z}{\rho}\right|^2\right).$$

Next using the fact that

$$1 - \left|\frac{g_w \,.\, z}{\rho}\right|^2 = \frac{(\rho^2 - |z|^2)(\rho^2 - |w|^2)}{|\rho^2 - \langle z,w\rangle|^2},$$

we get the desired result (i) of the above proposition.

The result in (ii) can be obtained in a similar way and the reader can refer, for example, to Ref. 2.

C. Resolvent kernels of $H_{B,\rho}$ on $L^2(\mathbb{B}^n_\rho; d\mu_\rho)$

Fix $\mu \in \mathbb{C}$ and $\rho \in]0, +\infty]$. Then by resolvent kernel $R_{B,\rho}(\mu;z,w)$, z, $w \in \mathbb{B}^n_\rho$, we mean the kernel of the integral operator $R_{B,\rho}(\mu)$ that solves

$$[H_{B,\rho} - h_{B,\rho}(\mu)]R_{B,\rho}(\mu) = I,$$

where I is the identity operator and $h_{B,\rho}(\mu)$ is the complex number given by

$$\begin{aligned} h_{B,\rho}(\mu) &= \frac{\mu^2 + n^2}{\rho^2} + 4B^2\rho^2 \qquad \text{for } \rho \in \ ]0; +\infty[; \\ h_{B,\infty}(\mu) &= \mu =: \mu_\infty \qquad\qquad \text{for } \rho = +\infty. \end{aligned} \tag{28}$$

That is for every $\varphi \in \mathcal{C}_c^\infty(\mathbb{B}_\rho^n)$, we have

$$[R_{B,\rho}(\mu)\varphi](z) = \int_{\mathrm{B}_\rho^n} R_{B,\rho}(\mu; z, w)\varphi(w)\mathrm{d}\mu_\rho(w).$$

More particularly, we seek for $R_{B,\rho}(\mu; z, w)$ such that

(1) $R_{B,\rho}(\mu; z, w)$ is T_ρ^B bi-invariant. That is, for every $g_\rho \in G_\rho$, $\rho \in]0, +\infty]$, we have

$$R_{B,\rho}(\mu; g_\rho \,.\, z, g_\rho \,.\, w) = j_\rho^{-B}(g_\rho, z)\overline{j_\rho^{-B}(g_\rho, w)}R_{B,\rho}(\mu; z, w). \tag{29}$$

(2) $R_{B,\rho}(\mu; z, w)$ is solution of the differential equation

$$[H_{B,\rho} - h_{B,\rho}(\mu)]R_{B,\rho}(\mu; z, w) = \delta_w(z), \tag{30}$$

where $\delta_w(z)$ is the "Dirac density" concentrated at the point w with respect to the volume measure $\mathrm{d}\mu_\rho$ of $\mathbb{B}_\rho^n$. The solution of the above equations (29) and (30) is given by the following proposition.

Proposition 8: Let $B > 0$ *be fixed and* μ, $\mu_\infty \in \mathbb{C}$. *Then we have the following,*

(i) For $\rho \in]0, +\infty[$ *and* $\mu \neq -i(2l + n \pm 2B\rho^2)$ *for* $l = 0, 1, 2, \ldots$, *a resolvent kernel* $R_{B,\rho}(\mu; z, w)$, $z, w \in \mathbb{B}_\rho^n$, *of the Landau-like Hamiltonian* $H_{B,\rho}$ *associated to* $h_{B,\rho}(\mu) := (\mu^2 + n^2)/\rho^2 + 4B^2\rho^2$ *is given explicitly by*

$$\begin{aligned} R_{B,\rho}(\mu; z, w) = C_{B,\rho}^n(\mu)&\left(\frac{\rho^2 - \overline{\langle z, w\rangle}}{\rho^2 - \langle z, w\rangle}\right)^{B\rho^2}\left(\frac{(\rho^2 - |z|^2)(\rho^2 - |w|^2)}{|\rho^2 - \langle z, w\rangle|^2}\right)^{n - i\mu/2} \\ &\times {}_2F_1\left(\frac{n - i\mu}{2} + B\rho^2, \frac{n - i\mu}{2} - B\rho^2; 1 - i\mu; \frac{(\rho^2 - |z|^2)(\rho^2 - |w|^2)}{|\rho^2 - \langle z, w\rangle|^2}\right), \end{aligned}$$

where the constant $C_{B,\rho}^n(\mu)$ *is given by*

$$C_{B,\rho}^n(\mu) = \left(\frac{1}{2\pi^n}\right)\frac{\Gamma\left(\frac{n - i\mu}{2} + B\rho^2\right)\Gamma\left(\frac{n - i\mu}{2} - B\rho^2\right)}{\rho^{2(n-1)}\Gamma(1 - i\mu)}.$$

(ii) *For* $\rho = +\infty$ *and* $\mu_\infty \neq 4B(2l + n)$ *for* $l = 0, 1, 2, \ldots$, *a resolvent kernel* $R_{B,\infty}(\mu_\infty; z, w)$, $z, w \in \mathbb{C}^n$, *of the Landau-like Hamiltonian* $H_{B,\infty}$ *associated to* $h_{B,\infty}(\mu_\infty) := \mu_\infty$ *is given explicitly by*

$$R_{B,\infty}(\mu_\infty; z, w) = \left(\frac{2B}{\pi}\right)^n \frac{\Gamma\left(\frac{n}{2} - \frac{\mu_\infty}{8B}\right)}{4B} \times e^{B(\langle z, w\rangle - \overline{\langle z, w\rangle})}e^{-B|z - w|^2}G\left(\frac{n}{2} - \frac{\mu_\infty}{8B}; n; 2B|z - w|^2\right),$$

where $G(\alpha; \gamma; x)$ *is the degenerate hypergeometric function of the second kind.*[15]

Proof: Proof of (i). Let $\rho \in]0, +\infty[$ be fixed. Since the resolvent kernel $R_{B,\rho}$, we are looking for, is T_ρ^B bi-invariant, it follows that it has the following form:

$$R_{B,\rho}(\mu;z,w)=\left(\frac{\rho^2-\overline{\langle z,w\rangle}}{\rho^2-\langle z,w\rangle}\right)^{B\rho^2}\phi\left(\mu;\frac{d_\rho(z,w)}{\rho}\right),$$

where ϕ is a function of the distance $d_\rho(z,w)$ on $(\mathbb{B}_\rho^n,\mathrm{ds}_\rho^2)$. Using the geodesic polar coordinates $z=\rho\tanh(r/\rho)\omega$, where $r=d_\rho(z,0)$ and $\omega\in S^{2n-1}$, we see that the radial part $\mathrm{rad}(H_{B,\rho})$ of the Landau-like Hamiltonian $H_{B,\rho}$ is given by

$$\mathrm{rad}(H_{B,\rho})=-\left\{\frac{d^2}{\mathrm{d}r^2}+\left([2n-1]\coth\left(\frac{r}{\rho}\right)+\tanh\left(\frac{r}{\rho}\right)\right)\left(\frac{1}{\rho}\right)\frac{d}{\mathrm{d}r}+\frac{4B^2\rho^2}{\cosh^2\left(\frac{r}{\rho}\right)}-4B^2\rho^2\right\}.$$

Hence, the function $\phi(\mu;r/\rho)$ is the irregular solution at the point $r/\rho=0$ of the following ordinary differential equation:

$$\frac{d^2}{\mathrm{d}r^2}+\left([2n-1]\coth\left(\frac{r}{\rho}\right)+\tanh\left(\frac{r}{\rho}\right)\right)\left(\frac{1}{\rho}\right)\frac{d}{\mathrm{d}r}+\frac{4B^2\rho^2}{\cosh^2\left(\frac{r}{\rho}\right)}-4B^2\rho^2+h_{B,\rho}(\mu)=-\delta(r)$$

with $r\geqslant 0$.

Therefore, by making the change $s=r/\rho$ and substituting $h_{B,\rho}(\mu)$ by its value given in (28), we see that the above differential equation reduces to the following ordinary differential equation of Jacobi's type:

$$\frac{d^2}{\mathrm{d}s^2}+\big([2n-1]\coth(s)+\tanh(s)\big)\frac{d}{\mathrm{d}s}+\frac{(2B\rho^2)^2}{\cosh^2(s)}+\mu^2+n^2=0,\quad s>0,$$

whose singular solution is given through the expression

$$[\cosh(s)]^{-(n-i\mu)}{}_2F_1\left(\frac{n-i\mu+2B\rho^2}{2},\frac{n-i\mu-2B\rho^2}{2};1-i\mu;\cosh^{-2}(s)\right). \tag{31}$$

In view of the above explicit singular solution (31), the solution of (29) and (30) is then given by

$$R_{B,\rho}(\mu;z,w)=C_{B,\rho}^n(\mu)\left(\frac{\rho^2-\overline{\langle z,w\rangle}}{\rho^2-\langle z,w\rangle}\right)^{B\rho^2}\left(\cosh\left(\frac{d_\rho(z,w)}{\rho}\right)\right)^{-(n-i\mu)}$$
$$\times{}_2F_1\left(\frac{n-i\mu}{2}+B\rho^2,\frac{n-i\mu}{2}-B\rho^2;1-i\mu;\cosh^{-2}\left(\frac{d_\rho(z,w)}{\rho}\right)\right),$$

where $C_{B,\rho}^n(\mu)$ is a normalization constant that ensures the identity (30). It is given explicitly by

$$C_{B,\rho}^n(\mu)=\left(\frac{1}{2\pi^n\rho^{2(n-1)}}\right)\frac{\Gamma\left(\frac{n-i\mu}{2}-B\rho^2\right)\Gamma\left(\frac{n-i\mu}{2}+B\rho^2\right)}{\Gamma(1-i\mu)}.$$

The proof of (ii) is similar to the first one. Just let mention that the radial part of the Landau-like Hamiltonian $H_{B,\infty}$ is given by

$$-\left\{\frac{d^2}{\mathrm{d}r^2}+\frac{2n-1}{r}\frac{d}{\mathrm{d}r}-4B^2r^2\right\},$$

where $r=|z|$. And using the appropriate change of function

$$R_{B,\infty}(\mu_\infty;r)=e^{-x/2}y(x)$$

with $x=2Br^2$, we see that the ordinary differential equation resulting here is of the following form:

$$xy''(x) + (n - x)y'(x) + \lambda y(x) = \delta(x), \quad x \geqslant 0,$$

whose irregular solution at $x=0$ is the degenerate hypergeometric function of the second kind $G(-\lambda; n; x)$.

V. ASYMPTOTIC OF L^2-SPECTRAL PROPERTIES OF THE LANDAU-LIKE HAMILTONIANS $H_{B,\rho}$

According to (i) of Proposition 6, it is clear that the point spectrum $\sigma_d(H_{B,\rho})$ in $L^2(\mathbb{B}_\rho^n; d\mu_\rho)$ of the Landau-like Hamiltonian $H_{B,\rho}$ on $\mathbb{B}_\rho^n$ converges, when $\rho \to +\infty$, to the "Landau levels" that constitute the point spectrum of the Landau-like Hamiltonian $H_{B,\infty}$ on $\mathbb{C}^n$, which recover, for $n=1$, the Comtet's result[6] as mentioned in the introduction. Whereas the continuous part of the spectrum of $H_{B,\rho}$ becomes empty. In this section, we will be interested in the asymptotic of the L^2-eigenprojector kernels of L^2-eigenspaces of the Landau-like Hamiltonian $H_{B,\rho}$ as well as of their resolvent kernels by letting ρ tend to infinity. Mainly, we show that they give rise to their analogous of $H_{B,\infty}$ on the n-complex space $\mathbb{C}^n$.

A. Asymptotic of the L^2-eigenprojector kernels when ρ tends to $+\infty$

The first main result gives asymptotic of the L^2-eigenprojector kernel $K_{l,\rho}^B(z,w)$ of the Landau-like Hamiltonian $H_{B,\rho}$ on the balls $\mathbb{B}_\rho^n$ when $\rho \to +\infty$. Precisely, we have the following.

Theorem 1: *Let $B>0$, $l \in \mathbb{Z}^+$ fixed, and $K_{l,\rho}^B(z,w)$ and $K_{l,\infty}^B(z,w)$ are, respectively, the L^2-eigenprojector kernels of the L^2-eigenspaces of $H_{B,\rho}$ and $H_{B,\infty}$ corresponding to their point spectrum. Then for every fixed $(z,w) \in \mathbb{C}^n \times \mathbb{C}^n$, we have*

$$\lim_{\rho \to +\infty} K_{l,\rho}^B(z,w) = K_{l,\infty}^B(z,w).$$

Proof: Let $l \in \mathbb{Z}^+$ and $(z,w) \in \mathbb{C}^n \times \mathbb{C}^n$ fixed. Then it is clear, from the established explicit formulas (26) (Proposition 7), that the L^2-eigenprojector kernel $K_{l,\rho}^B(z,w)$ is well defined for every $\rho > \mathrm{Max}(|z|, |w|, \sqrt{(2l+n)/2B})$. Thus according to the explicit expression of the constant $A_{n;B;l}(\rho)$ as given by (27) and using the Binet formula

$$\frac{\Gamma(x+a)}{\Gamma(x+b)} = x^{a-b}\left(1 + O\left(\frac{1}{x}\right)\right)$$

with $x = 2B\rho^2$, $a = -l$, $b = -n-l+1$, we derive easily that we have

$$\lim_{\rho \to +\infty} A_{n;B;l}(\rho) = \left(\frac{2B}{\pi}\right)^n \frac{\Gamma(n+l)}{\Gamma(n)l!}. \tag{32}$$

Also, let us note that we have

$$\lim_{\rho \to +\infty} \left(\frac{\rho^2 - \overline{\langle z,w\rangle}}{\rho^2 - \langle z,w\rangle}\right)^{-B\rho^2} = e^{B(\langle z,w\rangle - \overline{\langle z,w\rangle})} \tag{33}$$

and

$$\lim_{\rho \to +\infty} \left(\cosh\left(\frac{d_\rho(z,w)}{\rho}\right)\right)^{2(B\rho^2 - l)} = \lim_{\rho \to +\infty} \left(\frac{(\rho^2 - |z|^2)(\rho^2 - |w|^2)}{|\rho^2 - \langle z,w\rangle|^2}\right)^{B\rho^2 - l} = e^{-B|z-w|^2}. \tag{34}$$

Next, since

$$\tanh^2\left(\frac{d_\rho(z,w)}{\rho}\right) = 1 - \frac{(\rho^2 - |z|^2)(\rho^2 - |w|^2)}{|\rho^2 - \langle z,w\rangle|^2} \sim \frac{|z-w|^2}{\rho^2}$$

for $\rho \to +\infty$, we conclude by the use of the following standard fact:

$$\lim_{m\mapsto+\infty} {}_2F_1\left(a,m+b;c;\frac{z}{m}\right) = {}_1F_1(a;c;z), \tag{35}$$

that we have

$$\lim_{\rho\mapsto+\infty} {}_2F_1\left(-l,2B\rho^2-l;n;1-\frac{(\rho^2-|z|^2)(\rho^2-|w|^2)}{|\rho^2-\langle z,w\rangle|^2}\right) = {}_1F_1(-l,n;2B|z-w|^2). \tag{36}$$

Thus, from (32)–(34) and (36), we see that

$$\lim_{\rho\mapsto+\infty} K_l^B(\rho;z,w) = \left(\frac{2B}{\pi}\right)^n \frac{\Gamma(n+l)}{\Gamma(n)l!} e^{B(\langle z,w\rangle-\overline{\langle z,w\rangle})} e^{-B|z-w|^2} {}_1F_1(-l,n;2B|z-w|^2).$$

The right-hand side in the above equality is nothing more than the L^2-eigenprojector kernel $K_{l,\infty}^B(z,w)$ of $A_l^{2,B}(\mathbb{C}^n)$ given in (ii) of Proposition 7. This finishes the proof of Theorem 1.

Next, in the following section, we will look for the asymptotic of the resolvent kernels associated to the Landau-like Hamiltonians $H_{B,\rho}$, when $\rho\to+\infty$.

B. Asymptotic of resolvent kernels of $H_{B,\rho}$ when $\rho\to+\infty$

For λ in a suitable region of $\mathbb{C}$, we will be constructing modified T_ρ^B bi-invariant resolvent kernel $R_{B,\rho}(\lambda;z,w)$ solution of the differential equation

$$[H_{B,\rho}-h_{B,\rho}(\lambda)]R_{B,\rho}(\lambda;z,w) = \delta_w(z) \quad \text{with } h_{B,\rho}(\lambda) = 4B(2\lambda+n) - 4\frac{\lambda(\lambda+n)}{\rho^2}.$$

Thus, the solution we seek can be deduced from Proposition 8 by setting $\mu=-i(2\lambda+n-2B\rho^2)$. Namely, we have the following.

Proposition 9: LET $B>0$ and $\lambda\in\mathbb{C}$. Then We have the following. (i) *For fixed $\rho\in]0,+\infty[$ and $\lambda\in\mathbb{C}\setminus(\mathbb{Z}^+\cup 2B\rho^2+\mathbb{Z}^+)$, a resolvent kernel $R_{B,\rho}(\lambda;z,w)$, $z,w\in\mathbb{B}_\rho^n$ with $z\neq w$, of the Landau-like Hamiltonian $H_{B,\rho}$ associated to $h_{B,\rho}(\lambda):=4B(2\lambda+n)-4\lambda(\lambda+n)/\rho^2$ is given explicitly by*

$$R_{B,\rho}(\lambda;z,w) = C_{B,\rho}^n(\lambda)\left(\frac{\rho^2-\overline{\langle z,w\rangle}}{\rho^2-\langle z,w\rangle}\right)^{B\rho^2}\left(\frac{(\rho^2-|z|^2)(\rho^2-|w|^2)}{|\rho^2-\langle z,w\rangle|^2}\right)^{B\rho^2-\lambda}$$
$$\times {}_2F_1\left(-\lambda,2B\rho^2-\lambda;2B\rho^2-2\lambda-n+1;\frac{(\rho^2-|z|^2)(\rho^2-|w|^2)}{|\rho^2-\langle z,w\rangle|^2}\right),$$

where the constant $C_{B,\rho}^n(\lambda)$ is given by

$$C_{B,\rho}^n(\lambda) = \left(\frac{\Gamma(-\lambda)}{2\pi^n}\right)\frac{\Gamma(2B\rho^2-\lambda)}{\rho^{2(n-1)}\Gamma(2B\rho^2-\lambda-n+1)}.$$

(ii) For $\rho=+\infty$ and $\lambda\in\mathbb{C}\setminus\mathbb{Z}^+$, a resolvent kernel $R_{B,\infty}(\lambda;z,w)$, $z,w\in\mathbb{C}^n$ with $z\neq w$, of the Landau-like Hamiltonian $H_{B,\infty}$ associated to $h_{B,\infty}(\lambda):=4B(2\lambda+n)$, is given explicitly by

$$R_{B,\infty}(\lambda;z,w) = \frac{(2B)^{n-1}}{2\pi^n}\Gamma(-\lambda)e^{B(\langle z,w\rangle-\overline{\langle z,w\rangle})}e^{-B|z-w|^2}G(-\lambda;n;2B|z-w|^2).$$

Therefore, we have the following.

Theorem 2: *Let $B>0$ and $\lambda\in\mathbb{C}\setminus\mathbb{R}^+$ be fixed, and $R_{B,\rho}(\lambda;.,.)$ and $R_{B,\infty}(\lambda;.,.)$ be the resolvent kernels of the Landau-like Hamiltonians $H_{B,\rho}$ and $H_{B,\infty}$, respectively. Then for every fixed $(z,w)\in\mathbb{C}^n\times\mathbb{C}^n$ such that $z\neq w$, we have*

$$\lim_{\rho\mapsto+\infty} R_{B,\rho}(\lambda;z,w) = R_{B,\infty}(\lambda;z,w).$$

Proof: Let λ be fixed in $\mathbb{C}\backslash\mathbb{R}^+$. Then without loss of generality, we can assume that $w=0$. Hence, for fixed $z\neq 0$ *in* $\mathbb{C}^n$, the resolvent kernel $R_{B,\rho}(\lambda;z,0)=:R^n_{B,\rho}(\lambda;z)$ simplifies to be given by

$$R^n_{B,\rho}(\lambda;z)=\frac{\Gamma(-\lambda)\Gamma(2B\rho^2-\lambda)}{2\pi^n\rho^{2(n-1)}\Gamma(2B\rho^2-2\lambda-n+1)}\left(1-\left|\frac{z}{\rho}\right|^2\right)^{B\rho^2-\lambda}$$
$$\times{}_2F_1\left(-\lambda,2B\rho^2-\lambda;2B\rho^2-2\lambda-n+1;1-\left|\frac{z}{\rho}\right|^2\right).$$

Further, we may write $R^n_{B,\rho}(\lambda;z)$ as follows:

$$R^n_{B,\rho}(\lambda;z)=\frac{(2B)^{n-1}}{2\pi^n}\Gamma(-\lambda)\left(1-\left|\frac{z}{\rho}\right|^2\right)^{B\rho^2-\lambda}\lim_{\gamma\mapsto n}\phi^{\gamma}_{B,\rho}(\lambda;z),$$

where we have set for γ close to n (and $\gamma\neq n$),

$$\phi^{\gamma}_{B,\rho}(\lambda;z)=\frac{\Gamma(2B\rho^2-\lambda)(2B\rho^2)^{1-\gamma}}{\Gamma(2B\rho^2-2\lambda-\gamma+1)}\times{}_2F_1\left(-\lambda,2B\rho^2-\lambda;2B\rho^2-2\lambda-\gamma+1;1-\left|\frac{z}{\rho}\right|^2\right).$$

Now, by appealing to the hypergeometric identity

$${}_2F_1(a,b;c;x)=\frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}{}_2F_1(a,b;a+b-c+1;1-x)+\frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)}$$
$$\times(1-x)^{c-a-b}{}_2F_1(c-a,c-b;c-a-b+1;1-x),$$

and applying it to the hypergeometric function involved in $\phi^{\gamma}_{B,\rho}(\lambda;z)$ with $a=-\lambda$, $b=2B\rho^2-\lambda$, $c=2B\rho^2-2\lambda-\gamma+1$, and $x=1-|z/\rho|^2$, we see after the use of the duplication formula

$$\Gamma(z)\Gamma(1-z)=\frac{\pi}{\sin\pi z}$$

and easy simplification that the above function $\phi^{\gamma}_{B,\rho}(\lambda;z)$ can be rewritten as a sum in the following form:

$$\phi^{\gamma}_{B,\rho}(\lambda;z)=\frac{\pi}{\sin\pi\gamma}\{\phi^{\gamma,1}_{B,\rho}(\lambda;z)-\phi^{\gamma,2}_{B,\rho}(\lambda;z)\},$$

where

$$\phi^{\gamma,1}_{B,\rho}(\lambda;z)=\frac{\Gamma(2B\rho^2-\lambda)(2B\rho^2)^{1-\gamma}}{\Gamma(2B\rho^2-\lambda-\gamma+1)}\cdot\frac{{}_2F_1\left(-\lambda,2B\rho^2-\lambda;\gamma;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\tag{37}$$

and

$$\phi^{\gamma,2}_{B,\rho}(\lambda;z)=\frac{(2B|z|^2)^{1-\gamma}{}_2F_1\left(2B\rho^2-\lambda-\gamma+1,-\lambda-\gamma+1;2-\gamma;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda)\Gamma(2-\gamma)}.\tag{38}$$

Therefore, since $\phi^{\gamma}_{B,\rho}(\lambda;z)$ and $\phi^{\gamma,j}_{B,\rho}(\lambda;z)$, $j=1,2$, are analytic functions in γ, we see that the singularity in γ produced by $1/(\sin\pi\gamma)$ can be eliminated by applying the Hopital rule and doing so, we end by writing the resolvent kernel $R^n_{B,\rho}(\lambda;z)$ as follows:

$$R^n_{B,\rho}(\lambda;z)=S^{n,1}_{B,\rho}(\lambda;z)-S^{n,2}_{B,\rho}(\lambda;z),$$

where

$$S_{B,\rho}^{n,j}(\lambda;z)=\frac{(-1)^n(2B)^{n-1}}{2\pi^n}\Gamma(-\lambda)\left(1-\left|\frac{z}{\rho}\right|^2\right)^{B\rho^2-\lambda}\frac{d}{d\gamma}[\phi_{B,\rho}^{\gamma,j}(\lambda;z)]_{|_{\gamma=n}},\quad j=1,2.$$

Hence, to obtain the limit of $R_{B,\rho}^n(\lambda;z)$ when $\rho\to+\infty$, we use the following lemma (whose proof will be given later in the Appendix).

Lemma 3: Using the above notations, we have the following.

$$(i)\quad \lim_{\rho\to+\infty}\frac{d}{d\gamma}[\phi_{B,\rho}^{\gamma,1}(\lambda;z)]_{|_{\gamma=n}}=\frac{d}{d\gamma}\left[\frac{{}_1F_1(-\lambda;\gamma;2B|z|^2)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|_{\gamma=n}},$$

$$(ii)\quad \lim_{\rho\to+\infty}\frac{d}{d\gamma}[\phi_{B,\rho}^{\gamma,2}(\lambda;z)]_{|_{\gamma=n}}=\frac{1}{\Gamma(-\lambda)}\frac{d}{d\gamma}\left[(2B|z|^2)^{1-\gamma}\frac{{}_1F_1(-\lambda-\gamma+1;2-\gamma;2B|z|^2)}{\Gamma(2-\gamma)}\right]_{|_{\gamma=n}},$$

where ${}_1F_1(a;c;x)$ *is the confluent hypergeometric function.*

Therefore, using the above lemma and the well established fact

$$\lim_{\rho\to+\infty}\left(1-\left|\frac{z}{\rho}\right|^2\right)^{B\rho^2-\lambda}=e^{-B|z|^2}$$

we conclude that

$$\lim_{\rho\to+\infty}R_{B,\rho}^n(\lambda;z)=(-1)^n\frac{(2B)^{n-1}}{2\pi^n}\Gamma(-\lambda)e^{-B|z|^2}\times\frac{\partial}{\partial\gamma}\left[\frac{{}_1F_1(-\lambda;\gamma;2B|z|^2)}{\Gamma(\gamma)\Gamma(-\lambda-\gamma+1)}-\frac{1}{\Gamma(-\lambda)}(2B|z|^2)^{1-\gamma}\frac{{}_1F_1(-\lambda-\gamma+1;2-\gamma;2B|z|^2)}{\Gamma(2-\gamma)}\right]_{|_{\gamma=n}}.$$

But, since

$$G(\alpha;n;z)=(-1)^n\left\{\frac{\partial}{\partial\gamma}\left[\frac{{}_1F_1(\alpha;\gamma;z)}{\Gamma(\gamma)\Gamma(\alpha-\gamma+1)}\right]_{|_{\gamma=n}}-\frac{1}{\Gamma(\alpha)}\frac{\partial}{\partial\gamma}\left[z^{1-\gamma}\frac{{}_1F_1(\alpha-\gamma+1;2-\gamma;z)}{\Gamma(2-\gamma)}\right]_{|\gamma=n}\right\}.$$

we can rewrite the above limit as

$$\lim_{\rho\to+\infty}R_{B,\rho}^n(\lambda;z)=\frac{(2B)^{n-1}}{2\pi^n}\Gamma(-\lambda)e^{-B|z|^2}G(-\lambda;n;2B|z|^2),\tag{39}$$

where the right-hand side of (39) is nothing more than the resolvent kernel $R_{B,\infty}(\lambda;z,0)$ of $H_{B,\infty}$ associated to the spectral parameter $h_{B,\infty}(\lambda)=4B(2\lambda+n)$. Hence, the proof of the theorem is ended.

Remark 5: The previous theorem is the generalization to $n\geqslant 2$ *of Comtet result's on the asymptotic of the resolvent kernel when* ρ *tends to* $+\infty$. *But, here, we have produced a rigorous proof of this result for* $n\geqslant 1$.

VI. CONCLUDING REMARKS AND COMMENTS

In the preceding sections, we have investigated the asymptotic of the geometrical structure of the hyperbolic balls $\mathbb{B}_\rho^n$ when the radius $\rho\to\infty$ as well as the asymptotic of some aspect of stationary spectral properties (spectrum, L^2-eigenprojector kernels, resolvent kernels) of the so-called Landau-like Hamiltonians acting on functions. And we have shown that they give rise to their analogous of the flat case $\mathbb{C}^n$.

Added to the asymptotic of the stationary spectral analysis of the Landau-like Hamiltonians, they are other aspects of spectral theory related to the Landau-like Hamiltonians such as evolution spectral theory, essentially the heat and wave kernels for which it is likely to investigate their

asymptotic when $\rho \to +\infty$ and to compare the obtained asymptotic formulas (if they exist) to their analogous of the Landau-like Hamiltonians on the flat case $\mathbb{C}^n$. We hope to come back to these matters in the future.

Moreover, in view of the explicit formulas obtained for the Landau Hamiltonians acting on differential 1-forms of the disc, see Ref. 12, which lead to the so-called Pauli Hamiltonians, it seems to be also of interest to discuss and study the concrete spectral analysis of Landau-like Hamiltonians, as defined in (16), acting on differential p-forms, $1 \leqslant p \leqslant n$, as well as their asymptotic. Such Pauli Hamiltonians describes the motion of a nonrelativistic particle with spin $\frac{1}{2}$ under the action of an external uniform magnetic field. Their action on differential 1-forms $\omega = f\,\mathrm{d}z + g\,\mathrm{d}\bar{z}$, identified to the matrix column $\binom{f}{g}$, are given explicitly by

$$H^1_{B,\rho} = \begin{pmatrix} H_{B,\rho} & 0 \\ 0 & \overline{H_{-B,\rho}} \end{pmatrix} - 4B\sigma_3,$$

where

$$H_{B,\rho} = -4\left(1 - \left|\frac{z}{\rho}\right|^2\right)\left\{\left(1 - \left|\frac{z}{\rho}\right|^2\right)\frac{\partial^2}{\partial z\,\partial \bar{z}} + Bz\frac{\partial}{\partial z} - \left(B + \frac{2}{\rho^2}\right)\bar{z}\frac{\partial}{\partial \bar{z}}\right\} + 4B\left(B + \frac{2}{\rho^2}\right)|z|^2.$$

Above $\overline{H_{-B,\rho}}$ is the "complex conjugate" of $H_{-B,\rho}$ and $\sigma_3 = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$ is the third Pauli spin matrix.

All previous considerations can be generalized to the case of the complex projective space $\mathbb{P}^n_\rho(\mathbb{C})$; the compact counterpart of $\mathbb{B}^n_\rho$; whose holomorphic sectional curvature is equal to $+4/\rho^2$. The space $\mathbb{P}^n_\rho(\mathbb{C})$ is endowed with the scaled Fubini-study metric $\widetilde{\mathrm{ds}^2_\rho}$ given in the complex coordinates $z_1, z_2, \ldots, z_n$ of the chart $\mathbb{C}^n$ by

$$\widetilde{\mathrm{ds}^2_\rho} = \left(1 + \left|\frac{z}{\rho}\right|^2\right)^{-2} \sum_{i,j=1}^{n} \left(\left(1 + \left|\frac{z}{\rho}\right|^2\right)\delta_{i,j} - \frac{\bar{z}_i z_j}{\rho^2}\right)\mathrm{d}z_i \otimes \mathrm{d}\bar{z}_j,$$

whose associated invariant Landau-like Hamiltonian is given by

$$\widetilde{H}_{B,\rho} = -4\left(1 + \left|\frac{z}{\rho}\right|^2\right)\left\{\sum_{i,j=1}^{n}\left(\delta_{ij} + \frac{z_i\bar{z}_j}{\rho^2}\right)\frac{\partial^2}{\partial z_i\,\partial \bar{z}_j} + B\sum_{j=1}^{n}\left(z_j\frac{\partial}{\partial z_j} - \bar{z}_j\frac{\partial}{\partial \bar{z}_j}\right)\right\} + 4B^2|z|^2.$$

Thus, the discussion for $\mathbb{P}^n_\rho(\mathbb{C})$ can be carried over in a similar way. The major difference is that the spectrum of $\widetilde{H}_{B,\rho}$ reduces only to the discrete part where their eigenvalues occur with finite multiplicities. We intend to return to this subject in future work.

ACKNOWLEDGMENTS

The authors would like to thank all participants of PDE and Spectral Geometry seminar in Rabat for the meaningful discussions we had on the subject of this paper. The authors are also grateful to Professor S. Gindikin and Professor J. Faraut for reading the paper. The first author (A.G.) would like to thank Professor H. Sami for financial support and encouragement.

APPENDIX (PROOF OF LEMMA 3)

Here, we give the proof of Lemma 3 in the preceding section. For this, we start by the following lemma for series functions.

Lemma 4: Let $u_k(m)$ be a sequence of functions in $m, m > m_0$, satisfying the following assumptions:

(i) $|u_k(m)| < \alpha_k$ *for some* α_k *independent of* $m, m > m_0$, *such that* $\Sigma_{k=0}^{+\infty}\alpha_k < +\infty$.
(ii) *For every fixed* k, *we have* $\lim_{m\to+\infty} u_k(m) = v_k$, *where* $\Sigma_{k=0}^{+\infty}|v_k| < +\infty$. *Then*

$$\lim_{m\mapsto+\infty}\sum_{k=0}^{+\infty}u_k(m)=\sum_{k=0}^{+\infty}\lim_{m\mapsto+\infty}u_k(m).$$

Proof of (i) of Lemma 3: According to (37) and by the use of Leibnitz formula we have

$$\frac{d}{d\gamma}[\phi_{B,\rho}^{\gamma,1}(\lambda;z)]_{|\gamma=n}=I_\rho^1+I_\rho^2,$$

where

$$I_\rho^1=\frac{d}{d\gamma}\left[\frac{\Gamma(2B\rho^2-\lambda)(2B\rho^2)^{1-\gamma}}{\Gamma(2B\rho^2-\lambda-\gamma+1)}\right]_{|\gamma=n}\cdot\frac{{}_2F_1\left(-\lambda,2B\rho^2-\lambda;n;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda-n+1)\Gamma(n)}$$

and

First, we will show that $\lim_{\rho\mapsto+\infty}I_\rho^1=0$. Indeed, the term I_ρ^1 can be written as a product of three factors. Namely, we have

$$I_\rho^1=\frac{\Gamma(2B\rho^2-\lambda)(2B\rho^2)^{1-n}}{\Gamma(2B\rho^2-\lambda-n+1)}\times\{\psi(2B\rho^2-\lambda-n+1)-\mathrm{Log}(2B\rho^2)\}\times\frac{{}_2F_1\left(-\lambda,2B\rho^2-\lambda;n;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda-n+1)\Gamma(n)},$$

where $\psi(z)=\Gamma'(z)/\Gamma(z)$ is the logarithmic derivative of the function $\Gamma(z)$. Then using the Binet formula $\Gamma(x+a)/\Gamma(x+b)=x^{a-b}(1+O(1/x))$ and the fact that

$$\psi(x+b)-\mathrm{Log}(x)=O\left(\frac{1}{x}\right)$$

with $a=-\lambda$, $b=-\lambda-\gamma+1$, $x=2B\rho^2$, we see that we have

$$\lim_{\rho\mapsto+\infty}\frac{\Gamma(2B\rho^2-\lambda)(2B\rho^2)^{1-n}}{\Gamma(2B\rho^2-\lambda-n+1)}=1 \tag{A1}$$

and

$$\lim_{\rho\mapsto+\infty}\{\psi(2B\rho^2-\lambda-n+1)-\mathrm{Log}(2B\rho^2)\}=0.$$

Further, since $\lim_{x\mapsto+\infty}{}_2F_1(a,x+b;c;\xi/x)={}_1F_1(a;c;\xi)$ (Lemma 35), we see that for $a=b=-\lambda$, $x=2B\rho^2$, $c=n$, and $\xi=2B|z|^2$, we have

$$\lim_{\rho\mapsto+\infty}{}_2F_1\left(-\lambda,2B\rho^2-\lambda;n;\left|\frac{z}{\rho}\right|^2\right)={}_1F_1(-\lambda;n;2B|z|^2),$$

which is finite. Hence, we conclude easily that $\lim_{\rho\mapsto+\infty}I_\rho^1=0$.

Therefore, to get (i) of the Lemma 4, we must show that

$$\lim_{\rho\mapsto+\infty}I_\rho^2=\frac{d}{d\gamma}\left[\frac{{}_1F_1(-\lambda;\gamma;2B|z|^2)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|\gamma=n}.$$

To do this let us note that in view of (A1), it follows

$$\lim_{\rho\mapsto+\infty} I_\rho^2 = \lim_{\rho\mapsto+\infty} \frac{d}{d\gamma}\left[\frac{{}_2F_1\left(-\lambda;2B\rho^2-\lambda;\gamma;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|_{\gamma=n}},$$

if the last limit exists. Hence, using the expansion in series of the above involved Gauss hypergeometric function ${}_2F_1$ given by

$${}_2F_1\left(-\lambda,2B\rho^2-\lambda;\gamma;\left|\frac{z}{\rho}\right|^2\right) = \sum_{k=0}^{+\infty} \frac{(-\lambda)_k(2B\rho^2-\lambda)_k}{(\gamma)_k}\cdot\frac{\left(\left|\frac{z}{\rho}\right|^2\right)^k}{k!},$$

where $(\alpha)_k$ is the Pochhammer symbol, we then get

$$\frac{d}{d\gamma}\left[\frac{{}_2F_1\left(-\lambda;2B\rho^2-\lambda;\gamma;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|_{\gamma=n}} = \sum_{k=0}^{+\infty} U_k(\rho),$$

where we have set for every fixed $k\in\mathbb{Z}^+$ and ρ varying in $]0,+\infty[$,

$$U_k(\rho) := (-\lambda)_k \frac{(2B\rho^2-\lambda)_k}{(\rho^2)^k}\frac{d}{d\gamma}\left[\frac{1}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\cdot\frac{1}{(\gamma)_k}\right]_{|_{\gamma=n}}\cdot\frac{(|z|^2)^k}{k!}.$$

At once, one can check easily that for every fixed k, we have

$$\lim_{\rho\mapsto+\infty} U_k(\rho) = (-\lambda)_k \frac{d}{d\gamma}\left[\frac{1}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\cdot\frac{1}{(\gamma)_k}\right]_{|_{\gamma=n}}\cdot\frac{(2B|z|^2)^k}{k!} =: v_k.$$

Thus, proceeding formally, we get

$$\begin{aligned}\lim_{\rho\mapsto+\infty} I_\rho^2 &= \lim_{\rho\mapsto+\infty}\frac{d}{d\gamma}\left[\frac{{}_2F_1\left(-\lambda;2B\rho^2-\lambda;\gamma;\left|\frac{z}{\rho}\right|^2\right)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|_{\gamma=n}}\\ &= \lim_{\rho\mapsto+\infty}\sum_{k=0}^{+\infty} U_k(\rho) = \sum_{k=0}^{+\infty} v_k = \frac{d}{d\gamma}\left[\frac{1}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\sum_{k=0}^{+\infty}\frac{(-\lambda)_k}{(\gamma)_k}\cdot\frac{(2B|z|^2)^k}{k!}\right]_{|_{\gamma=n}}\\ &= \frac{d}{d\gamma}\left[\frac{{}_1F_1(-\lambda;\gamma;2B|z|^2)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|_{\gamma=n}}.\end{aligned}$$

But, to conclude rigorously that

$$\lim_{\rho\mapsto+\infty} I_\rho^2 = \frac{d}{d\gamma}\left[\frac{{}_1F_1(-\lambda;\gamma;2B|z|^2)}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\right]_{|_{\gamma=n}},$$

we apply Lemma 4. For this, we should see that the series $\Sigma_{k=0}^{+\infty}U_k(\rho)$ is absolutely convergent. Indeed, for every fixed k, we have

$$|U_k(\rho)| \leqslant (|\lambda|)_k \frac{(2B\rho^2+|\lambda|)_k}{(\rho^2)^k}\left|\frac{d}{d\gamma}\left[\frac{1}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\cdot\frac{1}{(\gamma)_k}\right]_{|_{\gamma=n}}\right|\cdot\frac{(|z|^2)^k}{k!}.$$

And for fixed α such that $0<\alpha<1$ and arbitrary fixed real number R, $R>0$, set $\rho_0=R/\alpha$. Then since

$$\frac{(2B\rho^2+|\lambda|)_k}{(\rho^2)^k}=\prod_{j=1}^{k}\left(2B+\frac{|\lambda|+j-1}{\rho^2}\right),$$

it follows that for every $\rho>\rho_0=R/\alpha$ (i.e, $1/\rho^2<\alpha^2/R^2$) and fixed k, we have the following estimate:

$$\frac{(2B\rho^2+|\lambda|)_k}{(\rho^2)^k}\leqslant(2B\rho_0^2+|\lambda|)_k\left(\frac{\alpha^2}{R^2}\right)^k. \tag{A2}$$

Also, the factor

$$\left|\frac{d}{\mathrm{d}\gamma}\left[\frac{1}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\cdot\frac{1}{(\gamma)_k}\right]_{|_{\gamma=n}}\right|$$

can be easily estimated. Indeed, we have

$$\left|\frac{d}{\mathrm{d}\gamma}\left[\frac{1}{\Gamma(-\lambda-\gamma+1)\Gamma(\gamma)}\cdot\frac{1}{(\gamma)_k}\right]_{|_{\gamma=n}}\right|\leqslant C(n)(1+k)\frac{1}{(n)_k}. \tag{A3}$$

Setting together the estimates (A2) and (A3), we see that we have

$$|U_k(\rho)|\leqslant C(n)\frac{(|\lambda|)_k(2B\rho_0^2+|\lambda|)_k}{(n)_k}\cdot(1+k)\cdot\frac{(\alpha^2)^k}{k!}=:\alpha_k, \tag{A4}$$

for every $\rho>\rho_0$ and $z\in\mathbb{C}^n$ such that $|z|<R$. Finally, since $0<\alpha<1$, we may use the ratio test to see that the series $\Sigma_{k=0}^{+\infty}\alpha_k$, where α_k is as given in (A4), is convergent.

For the proof of (ii), one can proceed similarly as above [using the expansion in series of the Gauss hypergeometric function ${}_2F_1$ involved in (38) and Leibnitz formula] to split $\lim_{\rho\to+\infty}(d/\mathrm{d}\gamma)[\phi_{B,\rho}^{\gamma,2}(\lambda;z)]_{|_{\gamma=n}}$ as follows:

$$\lim_{\rho\to+\infty}\frac{d}{\mathrm{d}\gamma}[\phi_{B,\rho}^{\gamma,2}(\lambda;z)]_{|_{\gamma=n}}=J_\rho^1+J_\rho^2,$$

where J_ρ^1 and J_ρ^2 are given, respectively, by

$$J_\rho^1=\frac{(2B|z|^2)^{1-n}}{\Gamma(-\lambda)}\sum_{k=0}^{+\infty}\frac{\frac{d}{\mathrm{d}\gamma}[(2B\rho^2-\lambda-\gamma+1)_k]_{|_{\gamma=n}}}{(\rho^2)^k}\cdot\frac{(-\lambda-n+1)_k}{\Gamma(2-n)(2-n)_k}\cdot\frac{(|z|^2)^k}{k!}$$

and

$$J_\rho^2=\sum_{k=0}^{+\infty}\frac{(2B\rho^2-\lambda-n+1)_k}{(\rho^2)^k}\times\frac{d}{\mathrm{d}\gamma}\left[\frac{(2B|z|^2)^{1-\gamma}(-\lambda-\gamma+1)_k}{\Gamma(-\lambda)\Gamma(2-\gamma)}\cdot\frac{1}{(2-\gamma)_k}\right]_{|_{\gamma=n}}\cdot\frac{(|z|^2)^k}{k!}.$$

For every fixed $\lambda\in\mathbb{C}\backslash\mathbb{R}^+$ and $z\in\mathbb{C}\backslash\{0\}$, we have $\lim_{\rho\to+\infty}J_\rho^1=0$. To show this, we use again the Lemma 4 this time for

$$U_k(\rho)=\frac{\frac{d}{\mathrm{d}\gamma}[(2B\rho^2-\lambda-\gamma+1)_k]_{|_{\gamma=n}}}{(\rho^2)^k}\cdot\frac{(-\lambda-n+1)_k}{\Gamma(2-n)(2-n)_k}\cdot\frac{(|z|^2)^k}{k!},$$

$$v_k=\lim_{\rho\to+\infty}U_k(\rho)=0,$$

$$\alpha_k = \frac{1}{\rho^2} C_1(n) \cdot \frac{(|\lambda| + n + 1)_k (2B\rho_0^2 + |\lambda| + n + 1)_k}{(2+n)_k} \cdot k \cdot \frac{(\alpha^2)^k}{k!}.$$

Also, we can show in a similar way (as for I_ρ^2) that

$$\lim_{\rho \mapsto +\infty} J_\rho^2 = \frac{1}{\Gamma(-\lambda)} \frac{d}{d\gamma} \left[(2B|z|^2)^{1-\gamma} \frac{{}_1F_1(-\lambda - \gamma + 1; 2 - \gamma; 2B|z|^2)}{\Gamma(2-\gamma)} \right]_{|\gamma=n}.$$

Here, we apply again the Lemma 4 for

$$U_k(\rho) = \frac{(2B\rho^2 - \lambda - \gamma + 1)_k}{(2B\rho^2)^k} \times \frac{d}{d\gamma} \left[\frac{(2B|z|^2)^{1-\gamma} (-\lambda - \gamma + 1)_k}{\Gamma(-\lambda)\Gamma(2-\gamma)} \cdot \frac{1}{(2-\gamma)_k} \right]_{|\gamma=n} \cdot \frac{(2B|z|^2)^k}{k!},$$

$$v_k = \lim_{\rho \mapsto +\infty} U_k(\rho) = \frac{d}{d\gamma} \left[\frac{(2B|z|^2)^{1-\gamma} (-\lambda - \gamma + 1)_k}{\Gamma(-\lambda)\Gamma(2-\gamma)} \cdot \frac{1}{(2-\gamma)_k} \right]_{|\gamma=n} \cdot \frac{(2B|z|^2)^k}{k!},$$

$$\alpha_k = C_2(n) \cdot \frac{(|\lambda| + n + 1)_k (2B\rho_0^2 + |\lambda| + n + 1)_k}{(2+n)_k} \cdot (1+k) \cdot \frac{(\alpha^2)^k}{k!}.$$

Thus, the proof of Lemma 3 is completed.

Pure point spectrum for the time evolution of a periodically rank-*N* kicked Hamiltonian

James McCaw[a] and B. H. J. McKellar[b]
School of Physics, Research Centre for High Energy Physics, The University of Melbourne, Victoria, 3010, Australia

(Received 29 April 2004; accepted 27 October 2004; published online 14 February 2005)

We find the conditions under which the spectrum of the unitary time evolution operator for a periodically rank-*N* kicked system remains pure point. This stability result allows one to analyze the onset of, or lack of chaos in this class of quantum mechanical systems, extending the results for rank-1 systems produced by Combescure and others. This work includes a number of unitary theorems equivalent to those well known and used in the self-adjoint theory. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1841482]

I. INTRODUCTION

We will derive conditions on the time-periodic perturbations to the base Hamiltonian for the spectrum of the Floquet operator to remain pure point. We consider Hamiltonians of the form

$$H(t) = H_0 + A^* W A \sum_{n=0}^{\infty} \delta(t - nT) \tag{1}$$

where A is bounded, W is self adjoint and H_0 has pure point (discrete) spectrum. The time evolution of such Hamiltonians is of great interest in quantum chaos, and of central importance is the spectral properties of the Floquet operator, defined as

$$V = e^{iA^* WA/\hbar} e^{-iH_0 T/\hbar} \tag{2}$$

which comes directly from considering the time evolution of the kicked system

$$U(t) = \left[\exp\left(-\frac{i}{\hbar} \int_0^t \mathrm{d}t' \; H(t') \right) \right]_+$$

with $H(t')$ given by (1). The spectrum of the Floquet operator is known as the "quasienergy spectrum."

This work is an extension of a result of Combescure.[1] Our results are based on the self-adjoint work by Howland.[2] If we choose A to be a rank-1 perturbation,

$$A = |\psi\rangle\langle\psi|,$$

$$W = \lambda I,$$

we reproduce the work of Combescure.[1] The vector $|\psi\rangle$ is a linear combination of orthonormal basis states, $|\phi_n\rangle$ of the unperturbed Hamiltonian H_0,

[a]Electronic mail: j.mccaw@physics.unimelb.edu.au
[b]Electronic mail: b.mckellar@physics.unimelb.edu.au

$$|\psi\rangle = \sum_{n=0}^{\infty} a_n |\phi_n\rangle. \tag{3}$$

Combescure showed that if $\psi \in l_1(H_0)$, that is if

$$\sum_{n=0}^{\infty} |a_n| < \infty \tag{4}$$

then the quasienergy spectrum remains pure point for almost every perturbation strength λ. We will generalize this result to all finite rank perturbations,

$$A = \sum_{k=1}^{N} A_k = \sum_{k=1}^{N} |\psi_k\rangle\langle\psi_k|,$$

$$W = \sum_{k=1}^{N} \lambda_k |\psi_k\rangle\langle\psi_k|, \tag{5}$$

where $\lambda_k \in \mathbb{R}$ and each vector $|\psi_k\rangle$ is a linear combination of the H_0 basis states, $|\phi_n\rangle$,

$$|\psi_k\rangle = \sum_{n=0}^{\infty} (a_k)_n |\phi_n\rangle. \tag{6}$$

The states $|\psi_k\rangle$ are orthogonal,

$$\langle\psi_k|\psi_l\rangle = \delta_{kl}.$$

The basic result is that if each $|\psi_k\rangle$ is in $l_1(H_0)$, the spectrum of V will remain pure point for almost every perturbation strength.

The perturbation for which we prove that the quasienergy spectrum remains pure point is in fact more general than the finite rank perturbation presented above. The finite rank result is however the motivation for undertaking this work.

Howland[2] showed that the Hamiltonian (1) has a pure point spectrum if the ψ_k's are in $l_1(H_0)$. Here, we follow a similar argument, showing that the continuous part of the spectrum of V is empty, allowing us to conclude that the spectrum of V must be pure point.

Associated with what we have termed the Floquet operator, is the "Floquet Hamiltonian"

$$K = -id/\mathrm{d}t + H(t).$$

It turns out that K provides a different way to access similar information to what we are seeking. Developed in papers by Howland[3–5] and linked to our Floquet operator in Ref. 6 (p. 808), K was introduced, in some part, because directly working with V proved too difficult. The large body of knowledge on self-adjoint operators provides a mature basis for proving theorems about K. As discussed in Ref. 6, the spectrum of K is easily related algebraically to that of V, so results on the spectrum for K and V are equivalent.

Working directly with V, however, as we do here, is valuable in that it gives a transparent, direct insight into the dynamics of the perturbed system $H(t)$. After the completion of this work, which is a unitary equivalent to that of Howland,[2] we discovered that Howland had used his work[2] on the spectrum of self-adjoint operators to obtain similar results to what we do here.[5]

The relationship between our work and Howland's works (Refs. 2 and 5) is similar to the relationship between the self-adjoint rank-1 work of Simon and Wolff[7] and the unitary rank-1 work of Combescure.[1]

The techniques developed in this paper provide new, general theorems applicable to unitary operators and show that it is possible to develop the theory of the spectrum of time evolution operators directly, without need for the techniques of Ref. 3 briefly mentioned here.

A. Motivation

The classical study of chaos is now a well established and flourishing field of research in mathematics and mathematical physics. Chaotic behavior seems to pervade a vast spectrum of dynamical systems, and an appreciation of it is essential for a detailed understanding of such systems. The classic example of the earth's weather patterns always comes to mind when chaos is mentioned.

The microscopic world, however, is not governed by the laws of classical dynamics. In the realm of small quantum numbers the dynamics of a system is governed by the Schrödinger equation. In such systems, the simple and elegant definitions of chaos such as positive Lyapunov exponent, which hold for classical systems, are not applicable. In fact, there is no universally accepted definition of quantum chaos. Some model systems show what many would consider "chaotic behavior," yet there are general arguments made by some[8] to the effect that "quantum chaos" does not exist. Our study of one aspect of "quantum chaos" is motivated by much of this work. Taking note of these uncertainties and conflicting views, two questions arise that are of central importance.

(a) What properties of a quantum mechanical system determine whether or not the corresponding classical system that derives from it will display chaotic behavior?
(b) Are there in fact quantum systems that display chaotic behavior at the quantum level?

The former question is intimately linked to the "correspondence principle" and theories of quantum measurement. Needless to say, this area of fundamental physics is infamous for its interpretational difficulties and seemingly inconsistent behavior.

The latter question too, is the source of much debate in the literature. As in any immature study, quantum chaos is struggling to be self-consistently defined. A wide range of possible definitions and interpretations of what quantum chaos actually is have been put forward, many in direct contradiction with one another. At some stage in the future presumably, we will find a satisfactory criteria for what constitutes quantum chaos. Until then, many attempts to look at particular aspects of the dynamics of quantum systems will be (and have been) made. Some papers, courtesy of their definition of quantum chaos, come to the conclusion that there is no such thing as quantum chaos. That is, they conclude that no quantum system can display chaotic behavior. Other papers, simply as a consequence of a different starting point, come to the conclusion that there are quantum systems that display chaos.

There are general arguments that allow one to categorize the behavior of a quantum system based upon the spectral composition of the quasienergy spectrum. Hence, Combescure's work on the spectrum is relevant to the study of chaos. Our work, by extending the result of Combescure, may allow for the further categorization of classes of Hamiltonian systems as chaotic or otherwise. This is further discussed in the next section.

B. Spectral analysis of operators and a link to chaos

The intuitive definition for the energy spectrum of a quantum system is best seen through example, say the hydrogen atom. The bound states of hydrogen are a countable number of isolated, discrete energies. Each energy corresponds to an eigenvalue of the system and the set of these points makes up the point energy spectrum. The positive energy scattering states form the continuous energy spectrum. Thus, the energy spectrum for the hydrogen system consists of two disjoint parts: the negative energy discrete (or "point") spectrum, and the positive energy continuous spectrum.

For hydrogen, $\sigma_p(H)=\{\alpha_n;\alpha_n\approx -13.6/n^2 \text{ for } n\in\mathbb{N}\}$, and $\sigma_{\text{cont}}(H)=(0,\infty)$.

As another simple example, the harmonic oscillator quantum system has only discrete energy levels, and thus is said to be "pure point." That is, the eigenvectors of the harmonic oscillator form a basis of the Hilbert space.

While these simple examples have shown clearly that we can split the energy spectrum into point and continuous parts, this is not the whole story. The mathematical treatment of operators and measures shows that the spectrum in fact consists of three parts, the point, absolutely continuous and singularly continuous spectrum. For an appreciation of the work that follows, a mathematically rigorous understanding of the spectra is necessary. The introductory chapters in Ref. 9 are essential reading.

One must note that the concept of spectrum is associated with a particular operator. Typically, we talk of the energy spectrum, associated with the Hamiltonian. However, all operators (e.g., Hamiltonian, Floquet, etc.) have a spectrum. A failure to realize this has lead to a number of confused papers (see, for example, Ref. 10) which use results on the spectrum of the Hamiltonian in a discussion of the spectrum of the Floquet operator. With these words of warning, we return to a discussion of the Floquet (or quasienergy) spectrum of a quantum system.

The link between spectral properties and dynamics is an active field of research and is not yet fully understood. The introduction to the paper of Last[11] provides an informative overview of the field and gives details on some of the most relevant theorems and results, including the RAGE theorem (Ref. 12, p. 341, Theorem XI.115). See also Ref. 13 (Ref. 28). Last's paper deals with systems where the Hamiltonian spectrum is of interest. In time-periodic Hamiltonian systems, the spectrum of the Floquet operator takes over that role. Yajima and Kitada[14] show that RAGE like results apply to time-periodic systems, as we have here, and thus an analysis of the Floquet operator spectrum is of interest.

Refering to either the Hamiltonian spectrum or the Floquet spectrum where appropriate, and the appropriate RAGE like theorem, we now comment on the "typical" manifestation of the spectrum. A typical quantum mechanical system does not possess a singularly continuous spectral component and thus, singular continuity is not usually mentioned in texts on quantum mechanics. This however, is not to say that it cannot exist, or that it does not manifest itself in the dynamical behavior of appropriate systems. With an understanding that Milek and Seba meant to refer to the RAGE like theorem in Ref. 14 rather than the RAGE theorem itself, the argument presented in Sec. II of their paper[10] shows that if a system possesses a singularly continuous quasienergy spectrum then its energy growth over time may be characteristic of a classically chaotic system. Thus, establishing the existence or otherwise of singular continuous spectra for the Floquet operator can be seen as of central importance to the question of whether or not a quantum mechanical system is chaotic. It must be noted that the arguments presented by Milek and Seba are acknowledged to be anything but rigorous—a point clearly established by Antoniou and Suchanecki[29,30]

It is with the application of the RAGE like theorem in mind,[14] that we undertook the following work on the analysis of the quasienergy spectrum of the class of Hamiltonians as defined by (1). The aforementioned work by Milek and Seba,[10] utilizing the rank-1 work of Combescure, has shown the manifestation of singularly continuous spectra in numerical simulations of rank-1 kicked rotor quantum systems. The work here has the potential to extend upon this, and provide a rigorous mathematical basis to numerical calculations on the time evolution of higher rank kicked quantum systems.

C. Outline and summary of results

In Sec. II we will present the main theorems of the paper, concerned with establishing when systems of the form given by (1) maintain a pure point quasienergy spectrum. Parallelling Howland's paper[2] on self-adjoint perturbations of pure point Hamiltonians, the key ideas are those of U-finiteness and the absolute continuity of the multiplication operator $\mathbb{V}$. To establish the second of these concepts for our unitary case (remember that we are concerned with the spectral properties of the unitary time evolution operator and not with the spectral properties of the self-adjoint

Hamiltonian itself), we require a modified version of the Putnam–Kato theorem.[15] This, and associated theorems are the topic of Sec. III. Sec. IV uses the results of Secs. II and III to give the final results, which are then discussed in Sec. V.

D. Notation

We inherit our notation directly from the work of Howland.[2] $\mathcal{H}$ and $\mathcal{K}$ will denote Hilbert spaces throughout this paper. They will always be separable. The inner product of two vectors x and y is $\langle x,y\rangle$, and the norm of a vector x is $\|x\|=\langle x,x\rangle^{1/2}$. For an operator $A:\mathcal{H}\to\mathcal{K}$ we define the following:

(i) the domain $D(A)$; the vectors $x\in\mathcal{H}$ for which Ax is defined,
(ii) the range $R(A)=\{y\in\mathcal{K}:y=Ax \text{ for some } x\in\mathcal{H}\}$,
(iii) the kernel $\ker A=\{x\in\mathcal{H}:Ax=0\}$, and
(iv) the operator norm $\|A\|=\sup_{x\in D(A):\|x\|=1}\{\|Ax\|\}$.

For any set $S\in\mathbb{C}$, $\overline{S}$ is the closure of S. If A_n is a sequence of operators, s-lim A_n (also $A_n\to{}^sA$) denotes the strong limit, $\|(A_n-A)g\|\to 0$ for all $g\in\mathcal{H}$. w-lim A_n (also $A_n\to{}^wA$) denotes the weak limit, $|\langle A_ng,f\rangle-\langle Ag,f\rangle|\to 0$ for all $g,f\in\mathcal{H}$. By the Schwartz inequality, the weak limit exists if the condition above is satisfied for $f=g$. We will also have need for the norm limit of an operator, $\|A_n-A\|\to 0$.

For a unitary operator $V=\int e^{-i\theta}E(\mathrm{d}\theta)$ on $\mathcal{H}$, we define for any Borel set S, $E[S]=\int_S E(\mathrm{d}\theta)$. The $E(\mathrm{d}\theta)$ are orthogonal projection operators, i.e., $E^2=E$ and thus

$$\int |f(\theta)|^2E(\mathrm{d}\theta)=\left|\int f(\theta)E(\mathrm{d}\theta)\right|^2.$$

We decompose our operator into its pure point (V^p), singular continuous (V^{sc}) and absolutely continuous (V^{ac}) components. $V^s=V^p+V^{sc}$ is the singular part of the operator V. Similarly, we define the corresponding spectral measures E^p, E^{sc}, E^{ac}, and E^s. For a vector $x\in\mathcal{H}$, m_x is the measure

$$m_x(S)=\langle E(S)x,x\rangle.$$

Again, we define m_x^p, m_x^{sc}, m_x^{ac}, and m_x^s. See Ref. 9, pp. 19–23, for an excellent description of these. By their definition, m_x^p, m_x^{sc}, and m_x^{ac} are mutually singular, so we may write the Hilbert space as a direct sum (i.e., each of the spaces below is invariant)

$$\mathcal{H}=\mathcal{H}_{pp}\oplus\mathcal{H}_{ac}\oplus\mathcal{H}_{sc}.$$

The spectrum of V is $\sigma(V)$, defined by

$$\sigma(V)=\{\alpha\in\mathbb{C}:\alpha I-V \text{ is not invertible}\}.$$

If $Tx=\alpha x$ for some $x\in\mathcal{H}$ and $\alpha\in\mathbb{C}$, then x is an eigenvector, with corresponding eigenvalue α. The closure of the set of α's forms the point spectrum of V,

$$\sigma_p(V)=\overline{\{\alpha:\alpha \text{ an eigenvalue of } V\}}=\sigma(V\restriction\mathcal{H}_p).$$

We say that V is *pure point* if and only if the eigenvectors of V form a basis of $\mathcal{H}$. The absolutely (singularly) continuous spectrum, $\sigma_{ac(sc)}(V)$ is similarly defined by

$$\sigma_{ac(sc)}(V)=\sigma(V\restriction\mathcal{H}_{ac(sc)}).$$

For a complete discussion and analysis of these topics, the most convenient reference is (Ref. 9, pp. 19–23, 188, 230–231) or Ref. 16.

A set $\mathcal{S} \in \mathcal{H}$ is said to reduce an operator A if both $\mathcal{S}$ and its orthocomplement $\mathcal{H} \ominus \mathcal{S}$ are invariant subspaces for A.

A vector ϕ is cyclic for an operator A if and only if finite linear combinations of elements of $\{A^n\phi\}_{n=0}^{\infty}$ are dense in $\mathcal{H}$. This motivates the definition that a set $\mathcal{S}$ is cyclic for $\mathcal{H}$ if and only if the smallest closed reducing subspace of $\mathcal{H}$ containing $\mathcal{S}$ is $\mathcal{H}$.

We will also use some basic set notation. $A \cap B$ and $A \cup B$ are, as usual, the intersection and union of sets A and B, respectively. A^c is the complement of A. $A \sim B$ is $A \cap B^c$. Note that $(A \sim B) \sim C$ is not equal to $A \sim (B \sim C)$, the former being a subset of the latter.

The function $\chi_S(x)$ is the characteristic function for a set S.

II. SPECTRAL PROPERTIES OF THE FLOQUET OPERATOR

Let U be unitary on $\mathcal{H}$ and let $\mathcal{K}$ be an auxiliary Hilbert space. Define the closed operator $A: \mathcal{H} \to \mathcal{K}$, with dense domain $D(A)$. For our purposes, A bounded on $\mathcal{H}$ is adequate. We work with a modification (multiplication by $e^{i\theta}$) of the resolvent of U,

$$F(\theta; U) = (1 - Ue^{i\theta})^{-1}, \tag{7}$$

and define for $\theta \in [0, 2\pi)$, and $\epsilon > 0$ the function $G_\epsilon: \mathcal{K} \to \mathcal{K}$,

$$G_\epsilon(\theta; U, A) = AF^*(\theta_+; U)F(\theta_+; U)A^*, \tag{8}$$

where $\theta_\pm = \theta \pm i\epsilon$. Let J be a subset of $[0, 2\pi)$.

Definition II.1 (*U-finite*): *The operator A is U-finite if and only if the operator* $G_\epsilon(\theta; U, A)$ *has a bounded extension to* $\mathcal{K}$, *and*

$$G(\theta; U, A) = s\text{-}\lim_{\epsilon \downarrow 0} G_\epsilon(\theta; U, A) \tag{9}$$

exists for almost every $\theta \in J$.

We define the function

$$\delta_\epsilon(t) = \frac{1}{2\pi}\left(\sum_{n=0}^{\infty} e^{in(t+i\epsilon)} + \sum_{n=-\infty}^{0} e^{in(t-i\epsilon)} - 1\right) = \frac{1}{2\pi}\frac{1 - e^{-2\epsilon}}{1 - 2e^{-\epsilon}\cos(t) + e^{-2\epsilon}}. \tag{10}$$

The limit as $\epsilon \to 0$ of $\delta_\epsilon(t)$ is a series representation of the δ-function. The proof is based on showing that

$$\lim_{\epsilon \downarrow 0} \int_{-\pi}^{\pi} g(t)\delta_\epsilon(t)\mathrm{d}t = 0,$$

where $g(t) = f(t) - f(0)$ and $f(t)$ is bounded in $(-\pi, \pi)$. One splits the integral into three parts, $\int_{-\pi}^{-\xi} + \int_{-\xi}^{\xi} + \int_{\xi}^{\pi}$. One must assume that $f(t)$ is continuous at $t = 0$ [otherwise $\int f(t)\delta(t)\mathrm{d}t$ is not well defined] so that

$$\forall\, \eta, \exists\, \xi > 0 \text{s.t.} \forall\, t, |t| < \xi \quad \text{we have } |f(t) - f(0)| < \eta.$$

The assumption that $f(t)$ is bounded on $(-\pi, \pi)$ is also required.

The first and third integrals are zero because $\delta_\epsilon(t) \to 0$ for $t \neq 0$ from (10) and the assumption that $g(t)$ is bounded. The second integral from $-\xi$ to ξ is zero by the continuity of $f(t)$ at $t = 0$, the positivity of $\delta_\epsilon(t)$ and Ref. 17, p. 435, (3.792.1).

Given (10) and the spectral decomposition of U, we may write

$$\delta_\epsilon(1 - Ue^{i\theta}) = \int \delta_\epsilon(1 - e^{i(\theta - \theta')})E(\mathrm{d}\theta') = \int \delta_\epsilon(\theta - \theta')E(\mathrm{d}\theta') = \frac{1}{2\pi}(1 - e^{-2\epsilon})F^*(\theta_+; U)F(\theta_+; U). \tag{11}$$

The existence of a nontrivial U-finite operator will have important consequences for the spectrum of the Floquet operator V. We introduce the set

$$N(U,A,J) = \{\theta \in J : s\text{-}\lim_{\epsilon \downarrow 0} G_\epsilon(\theta;U,A) \text{ does not exist}\}$$

of measure zero, which enters the theorem. We will often refer to this set simply as N during proofs.

Theorem II.2: *If A is U-finite on J and $R(A^*)$ is cyclic for U, then*

(a) *U has no absolutely continuous spectrum in J, and*
(b) *the singular spectrum of U in J is supported by $N(U,A,J)$.*

Proof: (a) Following Howland, we note that the absolutely continuous spectral measure, $m_y^{ac}(J)$, is the $\epsilon \to 0$ limit of $\langle \delta_\epsilon(1-Ue^{i\theta})y,y\rangle$ for $\theta \in J$. If $y \in \mathcal{H}$ is in $R(A^*)$, allowing us to write $y=A^*x$ for some $x \in \mathcal{K}$, then

$$\lim_{\epsilon \downarrow 0}\langle \delta_\epsilon(1-Ue^{i\theta})y,y\rangle = \lim_{\epsilon \downarrow 0}\langle \delta_\epsilon(1-Ue^{i\theta})A^*x,A^*x\rangle = \lim_{\epsilon \downarrow 0}\frac{\epsilon(1-\epsilon)}{\pi}\langle G_\epsilon(\theta;U,A)x,x\rangle = 0$$

for almost every $\theta \in J$. The set $\mathcal{Y}$ of vectors y for which $m_y^{ac}(J)=0$ is a closed reducing subspace of $\mathcal{H}$, and by construction contains the cyclic set $R(A^*)$ as a subset. Because $\mathcal{Y}$ is invariant, finite linear combinations of action with U^n leaves us in $\mathcal{Y}$. Due to the cyclicity, these same linear combinations allow us to reach any $y \in \mathcal{H}$. Thus, the set $\mathcal{Y}$ of vectors y with $m_y^{ac}(J)=0$ must be the whole Hilbert space $\mathcal{H}$. So there is no absolutely continuous spectrum of U in J.

(b) A theorem of de la Vallée Pousin [Ref. 18, p. 127, (9.6)] states that the singular part of the spectrum of a function is supported on the set where the derivative is infinite. In our case, this corresponds to finding where $m_y(\mathrm{d}\theta) \to \infty$. We calculate

$$\lim_{\epsilon \downarrow 0}\langle \delta_\epsilon(1-Ue^{i\theta})y,y\rangle = \int \delta(\theta-\theta')\langle E(\mathrm{d}\theta')y,y\rangle = \int \delta(\theta-\theta')m_y(\mathrm{d}\theta') = m_y(\mathrm{d}\theta).$$

Thus, $m_y^s = m_y^{sc} + m_y^{pp}$ is supported on the set where

$$\lim_{\epsilon \downarrow 0}\langle \delta_\epsilon(1-Ue^{i\theta})y,y\rangle = \infty. \tag{12}$$

From the proof to part (a), if $y=A^*x$ then the limit (12) is zero for $\theta \in J$, $\theta \notin N$, so m_y^s in J must be supported by N. The set of vectors y with $m_y^s(J \cap N^c) \equiv m_y^s(J \sim N) = 0$ is closed, invariant and contains $R(A^*)$, so must be $\mathcal{H}$ by the argument above. Thus, the singular spectrum of U is supported on the set N. ■

We now define a new operator, $Q(z):\mathcal{K} \to \mathcal{K}$,

$$Q(z) = A(1-Uz)^{-1}A^*.$$

Note that

$$Q(e^{i\theta_\pm}) = AF(\theta_\pm;U)A^*. \tag{13}$$

$Q(z)$ is clearly well defined for $|z| \neq 1$. Proposition II.3 shows that the definition can be extended to $|z|=1$.

Proposition II.3: Let A be bounded. If $\theta \in J$, but $\theta \notin N(U,A,J)$, then

(a) *the operator $Q(e^{i\theta}) = A(1-Ue^{i\theta})^{-1}A^*$ is bounded on K, and*
(b) *one has s-$\lim_{\epsilon \downarrow 0} Q(e^{\pm i(\theta \pm i\epsilon)}) = Q(e^{\pm i\theta})$.*

Proof: (a) Without loss of generality, take $\theta=0$ $(z=1)$. By Theorem II.2, $e^{-i0} \notin \sigma_p(U)$, so

$(1-Ue^{i0})^{-1}$ exists as a densely defined operator. As A is a bounded operator, it suffices to show that $(1-Ue^{i0})^{-1}A^*$ is bounded. We have

$$\begin{aligned}\|(1-Ue^{i0_+})^{-1}A^*x\|^2 &= \langle F(0_+;U)A^*x, F(0_+;U)A^*x\rangle \\ &= \langle AF^*(0_+;U)F(0_+;U)A^*x, x\rangle \\ &= \langle G_\epsilon(0;U,A)x,x\rangle \leqslant C|x|^2 \text{ (as } \theta \notin N) \end{aligned} \tag{14}$$

for some real constant C. If $y=A^*x$, noting $U=\int e^{-i\theta}E(\mathrm{d}\theta)$, we also have

$$\|(1-Ue^{i0_+})^{-1}A^*x\|^2 = \int \left(\frac{1}{1-e^{-i\theta}e^{-\epsilon}}\right)\left(\frac{1}{1-e^{i\theta}e^{-\epsilon}}\right)\langle E(\mathrm{d}\theta)y,y\rangle.$$

In light of (14), we may safely take ϵ to zero, to obtain

$$\int \left(\frac{1}{1-e^{-i\theta}}\right)\left(\frac{1}{1-e^{i\theta}}\right)\langle E(\mathrm{d}\theta)y,y\rangle \leqslant C\|x\|^2 < \infty. \tag{15}$$

From (15), we have

$$\int \left(\frac{1}{1-e^{-i\theta}}\right)\left(\frac{1}{1-e^{i\theta}}\right)\langle E(\mathrm{d}\theta)y,y\rangle = \langle [1-U]^{-1}y, [1-U]^{-1}y\rangle \leqslant C\|x\|^2 < \infty, \tag{16}$$

so $y \in D[(1-U)^{-1}]$. Thus, $Q(1)=A(1-U)^{-1}A^*$ is defined on all $\mathcal{K}$ and bounded.

(b) For $y \in D((1-U)^{-1})$, we show that the difference between $Q(e^{\pm i(0\pm i\epsilon)})$ and $Q(e^{\pm i0})$ tends to zero as $\epsilon \to 0$. Again, due to the boundedness of A, we need only show that

$$\|((1-Ue^{i0_+})^{-1}-(1-U)^{-1})A^*x\|$$

tends to zero. Consider

$$\begin{aligned}|(1-Ue^{-\epsilon})^{-1}y-(1-U)^{-1}y|^2 &= \int \left|\frac{1}{1-e^{-i\theta}e^{-\epsilon}}-\frac{1}{1-e^{-i\theta}}\right|^2\langle E(\mathrm{d}\theta)y,y\rangle \\ &= \int \left(\frac{(1-e^{-\epsilon})^2}{1-2e^{-\epsilon}\cos\theta+e^{-2\epsilon}}\right)\frac{\langle E(\mathrm{d}\theta)y,y\rangle}{(1-e^{-i\theta})(1-e^{i\theta})}. \end{aligned} \tag{17}$$

The first factor is bounded and tends to zero for $\theta \neq 0$. The second factor is the measure from (15). Clearly, away from the origin, the integral tends to zero. About the origin, we must take some care to show that there is no contribution to the integral.

Using (10), we have

$$\frac{(1-e^{-\epsilon})^2}{1-2e^{-\epsilon}\cos\theta+e^{-2\epsilon}} = \frac{(1-e^{-\epsilon})^2}{1-e^{-2\epsilon}}2\pi\delta_\epsilon(\theta).$$

On substitution into (17), we obtain

$$\frac{(1-e^{-\epsilon})^2}{1-e^{-2\epsilon}}2\pi\int_{-\alpha}^{\alpha}\delta_\epsilon(\theta)\frac{m_y(\mathrm{d}\theta)}{2(1-\cos\theta)} = \frac{(1-e^{-\epsilon})^2}{1-e^{-2\epsilon}}2\pi\int_{-\alpha}^{\alpha}\frac{\mathrm{d}\Theta_\epsilon}{\mathrm{d}\theta}\frac{g_y(\theta)}{2(1-\cos\theta)}\mathrm{d}\theta.$$

The function $\Theta_\epsilon(\theta)=\int\delta_\epsilon(\theta')\mathrm{d}\theta'$ is the step function in the $\epsilon\to 0$ limit. For nonzero ϵ it is positive, monotonic, increasing and bounded by unity. As $\theta \notin N$ we have also written $m_y(\mathrm{d}\theta)=g_y(\theta)\mathrm{d}\theta$ for some well behaved positive function $g_y(\theta)$. By integration by parts (see Ref. 19, p. 32 for existence conditions, which are satisfied) we obtain

$$\frac{(1-e^{-\epsilon})^2}{1-e^{-2\epsilon}}2\pi\left\{\left[\Theta_\epsilon(\theta)\frac{g_y(\theta)}{2(1-\cos\ \theta)}\right]_{-\alpha}^{\alpha}-\int_{-\alpha}^{\alpha}\Theta_\epsilon(\theta)\frac{d}{d\theta}\frac{g_y(\theta)}{2(1-\cos\ \theta)}d\theta\right\}.$$

The first term within the curly braces is clearly some finite value. The second term is less than

$$\int_{-\alpha}^{\alpha}\frac{d}{d\theta}\frac{g_y(\theta)}{2(1-\cos\ \theta)}d\theta=\left[\frac{g_y(\theta)}{2(1-\cos\ \theta)}\right]_{\alpha}^{-\alpha}$$

from the properties of the Θ_ϵ function mentioned above. As with the first term, it is clearly some finite value. Noting that

$$\lim_{\epsilon\downarrow 0}\frac{(1-e^{-\epsilon})^2}{1-e^{-2\epsilon}}=0$$

we see that part (b) follows. ■

Theorem II.4: *Let A be bounded and U-finite on J, with $R(A^*)$ cyclic for U. Let W be bounded and self-adjoint on $\mathcal{K}$, and define the Floquet operator*

$$V=e^{iA^*WA/\hbar}U.$$

We assume that for $|z|\neq 1$, $Q(z)$ is compact, and that $Q(e^{\pm i(\theta\pm i\epsilon)})$ converges to $Q(e^{\pm i\theta})$ in operator norm as $\epsilon\rightarrow 0$ for a.e. θ in J. Define the set

$$M(U,A,J)=\{\theta\in J: Q(e^{\pm i(\theta\pm i0)})\ \textit{does not exist in norm}\}.$$

Then

(a) *V has no absolutely continuous spectrum in J, and*
(b) *the singular continuous part of the spectrum of V in J is supported by the set $N(U,A,J)\cup M(U,A,J)$.*

Proof: (a) For convenience, we write the Floquet operator as

$$V=(1+A^*Z\ A)U,$$

where Z is defined appropriately by requiring $\exp(iA^*WA/\hbar)=1+A^*ZA$. [For the rank-$N$ perturbation case where $W=\Sigma_{k=1}^{N}\lambda_k|\psi_k\rangle\langle\psi_k|$ and $A=\Sigma_{k=1}^{N}|\psi_k\rangle\langle\psi_k|$, we have $Z=\Sigma_{k=1}^{N}(\exp(i\lambda_k/\hbar)-1)|\psi_k\rangle\langle\psi_k|$.]

Noting (7) and (13) allows us to define

$$Q_1=AF(\theta;V)A^*=A(1-Ve^{i\theta})^{-1}A^*.$$

Consider some vector $y'\in\mathcal{H}$. $Ay'=x\in\mathcal{K}$ is defined for such y'. $A^*x=y''$ is some vector in $\mathcal{H}$. The cyclicity of $R(A^*)$ means that action with linear combinations of powers of U on y'' allows us to obtain any $y\in\mathcal{H}$, our original y' being one of them. Thus, we have a construction of A^{-1}, namely, operation with A^* followed by the linear combination of powers of U. As y' was arbitrary, A^{-1} exists for all $y\in\mathcal{H}$. This allows us to introduce $I=A^{-1}A$ in what follows. [The particular choice of A as a projection in (5) does not have an inverse, but we will see in Sec. IV that we can define a subspace of $\mathcal{H}$ on which $R(A^*)$ is cyclic, and apply this theorem.]

We now proceed by use of the resolvent equation,

$$\begin{aligned}Q_1-Q&=A\left\{\frac{1}{1-Ve^{i\theta}}-\frac{1}{1-Ue^{i\theta}}\right\}A^*\\&=A\left\{\frac{1}{1-Ve^{i\theta}}(A^*Z\ AUe^{i\theta})\frac{1}{1-Ue^{i\theta}}\right\}A^*=Q_1(e^{i\theta})Z\ AUA^{-1}e^{i\theta}Q(e^{i\theta}).\end{aligned}\tag{18}$$

Thus, briefly using $L=Z\ AUA^{-1}e^{i\theta}$ for clarity, we have

$$LQ_1 - LQ = LQ_1LQ \Rightarrow (1 + LQ_1)(1 - LQ) = 1$$
$$\Rightarrow 1 + e^{i\theta}Z\,AUA^{-1}Q_1(e^{i\theta}) = [1 - e^{i\theta}Z\,AUA^{-1}Q(e^{i\theta})]^{-1}. \tag{19}$$

Denote by N and M the sets $N(U,A,J)$ and $M(U,A,J)$. If $\theta \in (J \sim N) \sim M$, i.e., $\theta \in J \cap N^c \cap M^c$, and $1 - e^{i\theta}Z\,AUA^{-1}Q(e^{i\theta})$ is not invertible, then the compactness of $-LQ(e^{i\theta})$ [which follows from the compactness of $Q(e^{i(\theta+i\epsilon)})$, the norm convergence of $Q(e^{i(\theta+i\epsilon)})$ and Theorem VI.12 in Ref. 9] allows us to use the Fredholm alternative (Ref. 9, p. 201, Theorem VI.14) to assert that

$$\exists x \in \mathcal{K}, \text{s.t. } [1 - e^{i\theta}Z\,AUA^{-1}Q(e^{i\theta})]x = 0.$$

That is, there is some vector $x \in \mathcal{K}$ which satisfies the equation

$$x - e^{i\theta}Z\,AUA^{-1}A(1 - Ue^{i\theta})^{-1}A^*x = 0. \tag{20}$$

As $\theta \in J \sim N$, by Proposition II.3 $y = A^*x \in D[(1 - Ue^{i\theta})^{-1}]$ so define ϕ as

$$\phi = (1 - Ue^{i\theta})^{-1}A^*x. \tag{21}$$

ϕ is a well-defined vector on $\mathcal{H}$ and we have

$$x = e^{i\theta}Z\,AU\phi.$$

By (21), $x \neq 0$ implies $\phi \neq 0$, so we have

$$(1 - Ue^{i\theta})\phi = A^*x = e^{i\theta}A^*Z\,AU\phi$$

or

$$V\phi = e^{-i\theta}\phi. \tag{22}$$

We conclude that $e^{-i\theta} \in \sigma_p(V)$.

The multiplicity of the eigenvalue is given by the dimension of the kernel of $1 - e^{i\theta}Z\,AUA^{-1}Q$, which is finite by the compactness of Q and Theorem 4.25 of Ref. 20.

Therefore, if $\theta \in J \sim (N \cup M \cup \sigma_p(V))$, which is a set of full Lebesgue measure (that the set M has measure zero is a consequence of Lemma II.5), then the vector

$$x(\epsilon) = [1 + e^{i(\theta+i\epsilon)}Z\,AUA^{-1}Q_1(e^{i(\theta+i\epsilon)})]x \equiv [1 + L_+Q_1(e^{i\theta_+})]x \tag{23}$$

must be bounded in norm as $\epsilon \to 0$ because we have just seen that if it is unbounded, we have an eigenvalue of the operator V. For $y = A^*x \in R(A^*)$, the absolutely continuous spectrum, m_y^{ac} of V is the limit of

$$\langle \delta_\epsilon(1 - Ve^{i\theta})y, y\rangle = \langle A\delta_\epsilon(1 - Ve^{i\theta})A^*x, x\rangle.$$

Our aim is to show that this is zero for all $y \in \mathcal{H}$. We define

$$F_1(\theta) = (1 - Ve^{i\theta})^{-1}, \tag{24}$$

$$F(\theta) = (1 - Ue^{i\theta})^{-1}, \tag{25}$$

and in a similar fashion to (18) and (19), obtain

$$F_1(\theta) = F(\theta)[1 + (V - U)e^{i\theta}F_1(\theta)] \tag{26}$$

and

$$(1 + (V - U)e^{i\theta}F_1(\theta)) = (1 - (V - U)e^{i\theta}F(\theta))^{-1}.$$

Writing $X = V - U$, on substituting (26) into our expression for the δ-function (11) we obtain

$$2\pi\delta_\epsilon(1-Ve^{i\theta}) = (1-e^{-2\epsilon})F_1^*(\theta_+)F_1(\theta_+) = [1+e^{i\theta_+}XF_1(\theta_+)]^* 2\pi\delta_\epsilon(1-Ue^{i\theta})[1+e^{i\theta_+}XF_1(\theta_+)].$$

Substitution of (13) and noting that

$$X = V-U = (1+A^*Z\,A)U - U = A^*Z\,AU$$

gives us

$$\begin{aligned} A\delta_\epsilon(1-Ve^{i\theta})A^* &= A[1+Xe^{i\theta_+}F_1(\theta_+)]^*\delta_\epsilon(1-Ue^{i\theta})[1+Xe^{i\theta_+}F_1(\theta_+)]A^* \\ &= [1+L_+Q_1(\theta_+)]^* A\delta_\epsilon(1-Ue^{i\theta})A^*[1+L_+Q_1(\theta_+)]. \end{aligned}$$

The absolutely continuous spectrum, m_y^{ac} of V is the limit of

$$\begin{aligned} \langle A\delta_\epsilon(1-Ve^{i\theta})A^*x,x\rangle &= \langle [1+L_+Q_1(\theta_+)]^* A\delta_\epsilon(1-Ue^{i\theta})A^*[1+L_+Q_1(\theta_+)]x,x\rangle \\ &= \langle A\delta_\epsilon(1-Ue^{i\theta})A^*x(\epsilon),x(\epsilon)\rangle = \frac{\epsilon(1-\epsilon)}{\pi}\langle G_\epsilon(\theta;U,A)x(\epsilon),x(\epsilon)\rangle \end{aligned} \tag{27}$$

which tends to zero as $\epsilon\to 0$ if both $G_\epsilon(\theta;U,A)$ and $x(\epsilon)$ are bounded. $G_\epsilon(\theta;U,A)$ is bounded as we have $\theta\in J\sim N$ and $x(\epsilon)$ is bounded by (23).

Part (a) follows since $R(A^*)$ cyclic for U implies that $R(A^*)$ is cyclic for V.

(b) Let $N_1=N(V,A,J)$. We have just shown that $\theta\in J\sim(N\cup M\cup\sigma_p(V))$ implies that

$$\frac{\epsilon}{\pi}\langle G_\epsilon(\theta;V,A)x(\epsilon),x(\epsilon)\rangle \to 0 \tag{28}$$

and therefore

$$\langle \delta_\epsilon(1-Ve^{i\theta})y,y\rangle \to 0. \tag{29}$$

If we can infer the strong limit from this weak limit then we have established that $\theta\notin N_1$. We use the result that if $x_n\to^w x$ and $\|x_n\|\to\|x\|$, then $x_n\to^s x$ (Ref. 21, p. 244). Writing G_ϵ and G for $G_\epsilon(\theta;V,A)$ and $G(\theta;V,A)$, and F_ϵ and F for $F(\theta_+;V)$ and $F(\theta;V)$, consider

$$|\|G_\epsilon x\|^2 - \|Gx\|^2| = |\langle (G_\epsilon^2-G^2)x,x\rangle| = |\langle A\{(F_\epsilon^*F_\epsilon - F^*F)A^*AF_\epsilon^*F_\epsilon + F^*FA^*A(F_\epsilon^*F_\epsilon - F^*F)\}A^*x,x\rangle|.$$

If A, F_ϵ, and F are bounded operators, then if $F_\epsilon^*F_\epsilon - F^*F$ tends to zero as $\epsilon\to 0$ we can conclude that the strong limit exists. A short calculation shows that

$$F_\epsilon^*F_\epsilon - F^*F = [(1-e^{-2\epsilon}) - (1-e^{-\epsilon})(Ue^{i\theta}+U^*e^{-i\theta})]F_\epsilon^*F_\epsilon F^*F$$

which trivially tends to zero as $\epsilon\to 0$ given the boundedness of F_ϵ and F. Finally, A is bounded by assumption and (23) shows that $Q_1(\theta_+)$ is a bounded operator as $\epsilon\to 0$ and thus both F_ϵ and F are bounded.

Moving on from (29), we have now established that $N_1\subset N\cup M\cup\sigma_p(V)$ so N_1 must have measure zero, again remembering that we need Lemma II.5 below to prove that M has measure zero. By Theorem II.2, N_1 supports the singular spectrum of V. That is,

$$m^s(N_1^c) = 0,$$

where the set N_1^c is the complement of N_1. As the measure is positive and $m^s=m^{sc}+m^p$, we know that

$$m^{sc}(N_1^c) = 0.$$

Trivially, $(N\cup M)\sim\sigma_p(V)$ contains $N_1\sim\sigma_p(V)$. Thus

$$m^{sc}([N_1\cap\sigma_p(V)^c]^c) = m^{sc}(N_1^c\cup\sigma_p(V)) = m^{sc}(N_1^c) + m^{sc}(\sigma_p(V)) = 0+0 = 0$$

as the (continuous) measure of single points is zero.

The set $N \cup M \cap \sigma_p(V)^c$ must support m^{sc} as $N_1 \cap \sigma_p(V)^c$ is a subset. Therefore

$$m^{sc}([N \cup M \cap \sigma_p(V)^c]^c) = 0.$$

This equals

$$m^{sc}([N \cup M]^c \cup \sigma_p(V)) = m^{sc}([N \cup M]^c) + m^{sc}(\sigma_p(V)) = m^{sc}([N \cup M]^c)$$

so we conclude that the set $N \cup M$ supports the singular continuous part of the spectrum. ■

Theorem II.4 has shown us that V has an empty absolutely continuous component, and that the singular continuous component is supported by the set $N \cup M$, which is independent of λ. We know that N has measure zero, and Lemma II.5 below shows us that M also has measure zero. This will allow us to apply Theorem II.6 to show that the singular continuous spectrum of V is also empty. Thus, with both the *ac* and *sc* spectra empty, we can conclude that V must have pure point spectrum.

Lemma II.5: Let $Q(z)$ be a trace class valued analytic function inside the complex unit circle, with $|z| < 1$. Then for almost every θ,

$$\lim_{\epsilon \downarrow 0} Q(e^{i(\theta + i\epsilon)}) \equiv Q(e^{i(\theta + i0)})$$

exists in the Hilbert–Schmidt norm.

Proof: We parallel the proof of de Branges theorem (see Ref. 22 and pp. 149–150 in Ref. 23). Consider

$$\begin{aligned} Q(e^{i(\theta+i\epsilon)}) + Q^*(e^{i(\theta+i\epsilon)}) &= \int A^* \left\{ \frac{1}{1 - e^{-i(\theta' - \theta)} e^{-\epsilon}} + \frac{1}{1 - e^{i(\theta' - \theta)} e^{-\epsilon}} \right\} AE(\mathrm{d}\theta') \\ &= \int A^* \left\{ \frac{2(1 - e^{-\epsilon} \cos(\theta' - \theta))}{1 + e^{-2\epsilon} - 2e^{-\epsilon} \cos(\theta' - \theta)} \right\} AE(\mathrm{d}\theta'). \end{aligned}$$

The factor within the curly braces is greater than zero for all θ', θ and thus we have

$$Q(e^{i(\theta+i\epsilon)}) + Q^*(e^{i(\theta+i\epsilon)}) \geqslant 0 \quad \forall\, \epsilon \geqslant 0.$$

Therefore, following de Branges,

$$|\det(1 + Q(e^{i(\theta+i\epsilon)}))|^2 \geqslant \det(1 + Q^*(e^{i(\theta+i\epsilon)}) Q(e^{i(\theta+i\epsilon)})) = \prod (1 + |\alpha_n|^2) \geqslant \begin{cases} \sum |\alpha_n|^2 = \|Q(e^{i(\theta+i\epsilon)})\|_{\mathrm{HS}}^2, \\ 1. \end{cases}$$

$\{\alpha_n\}$ are the eigenvalues of Q. From the two bounds on $|\det(1 + Q(e^{i(\theta+i\epsilon)}))|$ above, we obtain

$$\left\| \frac{Q(e^{i(\theta+i\epsilon)})}{\det(1 + Q(e^{i(\theta+i\epsilon)}))} \right\|_{\mathrm{HS}} \leqslant 1 \quad \text{and} \quad \left| \frac{1}{\det(1 + Q(e^{i(\theta+i\epsilon)}))} \right| \leqslant 1.$$

The definition of an analytic operator Ref. 9, p. 189) implies the analyticity of the eigenvalues, and thus the operations of taking the determinant and the Hilbert–Schmidt norm are analytic. Hence, both functions above are analytic and bounded within the complex unit circle ($\epsilon > 0$). Application of Fatou's theorem (Ref. 24, p. 454) establishes the existence in the limit as $\epsilon \to 0$ and hence both functions exist on the boundary almost everywhere. Taking the quotient we establish the existence of $Q(e^{i(\theta+i0)})$ in the Hilbert–Schmidt norm. ■

Let (Ω, μ) be a separable measure space, and

$$V(\lambda) = \int e^{-i\theta} E_\lambda(\mathrm{d}\theta)$$

a measurable family of unitary operators on $\mathcal{H}$. We denote by

$$\mathbb{V} = \int e^{-i\theta}\mathbb{E}(\mathrm{d}\theta)$$

the multiplication operator

$$(\mathbb{V}u)(\lambda) = V(\lambda)u(\lambda)$$

on $L^2(\Omega,\mu;\mathcal{H})$, where $u(\lambda) \in L^2(\Omega,\mu;\mathcal{H})$.

A vector $u(\lambda)$ is an element of $L^2(\Omega,\mu;\mathcal{H})$ if, for $u(\lambda) \in \mathcal{H}$,

$$\int_{-\infty}^{\infty} \|u(\lambda)\|^2 \mathrm{d}\mu < \infty.$$

It is important to note the difference between $V(\lambda)$ acting on $\mathcal{H}$ and $\mathbb{V}$ acting on $L^2(\Omega,\mu;\mathcal{H})$. To obtain our goal of showing that for almost every λ, $V(\lambda)$ has a pure point spectrum, we must show that $\mathbb{V}$ is absolutely continuous as a function of λ on the space $L^2(\Omega,\mu;\mathcal{H})$.

Theorem II.6 is taken directly from Ref. 2. The proof given is, apart from some small notational changes, identical to that in Ref. 2. Due to a number of typographical errors however, we have reproduced the proof here for reference and clarity.

Theorem II.6: *Let $\mathbb{V}$ be absolutely continuous on $L^2(\Omega,\mu;\mathcal{H})$, and assume that there is a fixed set S of Lebesgue measure zero which supports the singular continuous spectrum of $V(\lambda)$ in the interval J for μ-a.e. λ. Then $V(\lambda)$ has no singular continuous spectrum in J for μ-a.e. λ.*

Proof: For fixed $x \in \mathcal{H}$, and any measurable subset Γ of Ω, let $u(\lambda) = \chi_\Gamma(\lambda)x$ be a vector in $L^2(\Omega,\mu;\mathcal{H})$. Then

$$\int_\Gamma |E_\lambda^{sc}[J]x|^2 \mu(\mathrm{d}\lambda) \leqslant \int_\Gamma |E_\lambda[S]x|^2 \mu(\mathrm{d}\lambda)$$

$$= \int |E_\lambda[S]u(\lambda)|^2 \mu(\mathrm{d}\lambda) = \int |\mathbb{E}[S]u(\lambda)|^2 \mu(\mathrm{d}\lambda) = \|\mathbb{E}[S]u(\lambda)\|^2 = 0.$$

$\int_\Gamma |E_\lambda^{sc}[J]x|^2 \mu(\mathrm{d}\lambda) = 0$ implies that $|E_\lambda^{sc}[J]x|^2 = 0$ for μ-a.e. λ. Thus

$$E_\lambda^{sc}[J]x = 0$$

for every $x \in \mathcal{H}$. ■

The application of Theorem II.6 relies on finding a fixed set S of measure zero which supports the singularly continuous spectrum. $S = N \cup M$ is sufficient.

We have now established all the basic requirements for V to be pure point, given U pure point. They are now combined to produce the main theorem of the paper. There is still quite a lot of manipulation to satisfy the condition $\mathbb{V}$ *ac* on $L^2(\mathbb{R};\mathcal{H})$ of Theorem II.6, and this will be the focus for the remainder of Sec. II and III.

Theorem II.7. *Let U and A satisfy the hypotheses of Theorem II.4 and define for $\lambda \in \mathbb{R}$,*

$$V(\lambda) = e^{i\lambda A^* A/\hbar} U.$$

Then $V(\lambda)$ is pure point in J for a.e. λ.

Proof: By Theorem II.4, with $W = \lambda I$, $V(\lambda)$ has no absolutely continuous spectrum in J, and its singularly continuous spectrum is supported on the fixed set $S = N \cup M$. Application of Lemma II.5 shows that S is of measure zero. Theorem II.6 applies and shows that the singular continuous spectrum is empty, if we can show that $\mathbb{V}$ is absolutely continuous on $L^2(\mathbb{R};\mathcal{H})$. We show this in the following sections.

As we have shown that both the absolutely continuous and singular continuous parts of the spectrum are empty, we conclude that $V(\lambda)$ is pure point for almost every $\lambda \in \mathbb{R}$. ■

To show that $\mathbb{V}$ is *ac*, we apply a modified version of the Putnam–Kato theorem which is proved in Sec. III. The unitary Putnam–Kato theorem is the following.

Theorem III.3: *Let V be unitary, and D a self-adjoint bounded operator. If* $C=V[V^*,D]\geqslant 0$, *then V is absolutely continuous on* $R(C^{1/2})$. *Hence, if* $R(C^{1/2})$ *is cyclic for V, then V is absolutely continuous on* $\mathcal{H}$.

We apply this theorem on the space $L^2(\mathbb{R};\mathcal{H})$. A naive application to obtain the desired result is as follows. We slightly change notation and explicitly include the λ dependence of W in our definition of V. If we choose $\mathbb{D}=-i(d/d\lambda)$, with $V=e^{i\lambda A^*WA}U$, we see that

$$-i\frac{dV^*}{d\lambda}=-U^*A^*WAe^{-i\lambda A^*WA}=-V^*A^*WA$$

so that for some $u\in L^2(\mathbb{R};\mathcal{H})$,

$$[\mathbb{V}^*,\mathbb{D}]u=(\mathbb{V}^*\mathbb{D}-\mathbb{D}\mathbb{V}^*)u=-\mathbb{D}\mathbb{V}^*u=i\frac{d}{d\lambda}(V^*u)=\mathbb{V}^*A^*WAu.$$

Therefore,

$$\mathbb{C}=\mathbb{V}[\mathbb{V}^*,\mathbb{D}]=A^*WA.$$

With $W=I$, we obtain $\mathbb{C}=A^*A\geqslant 0$ and thus $R(\mathbb{C}^{1/2})=R(A^*)$ (see the proof to Theorem VI.9 in Ref. 9) is cyclic for V. Hence, $\mathbb{V}$ is *ac* and we satisfy all the requirements of Theorem II.7.

The problem here is that $\mathbb{D}$ is not bounded, and boundedness of $\mathbb{D}$ is essential in the proof of the Putnam–Kato theorem. We use a similar technique as Howland[2] to overcome this issue.

As the norm of A^*A may be scaled however we like, we can rewrite V, for real t as

$$V(t)=e^{ictA^*A}U \tag{30}$$

for some real $c>0$.

Proposition II.8: On $L^2(\mathbb{R};\mathcal{H})$, *consider the unitary multiplication operator* $\mathbb{V}$, *defined by*

$$\mathbb{V}u(t)=V(t)u(t)=e^{ictA^*A}Uu(t)$$

and the bounded self-adjoint operator $\mathbb{D}=-\arctan(p/2)$, *where* $p=-i\mathrm{d}/dt$. *Then* $C=\mathbb{V}[\mathbb{V}^*,D]$ *is positive definite, and* $R(C^{1/2})$ *is cyclic for* $\mathbb{V}$. *Hence, the requirements of Theorem II.7 are fully satisfied.*

Proof: The operator $\mathbb{D}$ on $L^2(\mathbb{R};\mathcal{H})$ is convolution by the Fourier transform of $-\arctan(x/2)$,[2] which is $i\pi t^{-1}e^{-2|t|}$ [Ref. 25, p. 87, (3)]. This is a singular (principal value) integral operator, because $\arctan(p/2)$ does not vanish at infinity. Thus, for $u(t)\in L^2(\mathbb{R};\mathcal{H})$,

$$\mathbb{D}u(t)=i\pi P\int_{-\infty}^{\infty}\frac{e^{-2|t-y|}}{t-y}u(y)\mathrm{d}y$$

and

$$[\mathbb{V}^*,\mathbb{D}]u(t)=i\pi P\int_{-\infty}^{\infty}e^{-2|t-y|}\frac{V^*(t)-V^*(y)}{t-y}u(y)\mathrm{d}y$$

so

$$\mathbb{C}u(t)=\mathbb{V}[\mathbb{V}^*,\mathbb{D}]u(t)=i\pi P\int_{-\infty}^{\infty}e^{-2|t-y|}\frac{1-V(t)V^*(y)}{t-y}u(y)\mathrm{d}y. \tag{31}$$

Inserting our expression (30) for $V(t)$, we obtain

$$\mathbb{C}u(t) = i\pi \int_{-\infty}^{\infty} e^{-2|t-y|} \frac{1 - e^{ic(t-y)A^*A}}{t-y} u(y)\mathrm{d}y$$

$$= i\pi \int_{-\infty}^{\infty} e^{-2|t-y|} \frac{1 - \cos(A^*Ac(t-y)) - i\,\sin(A^*Ac(t-y))}{t-y} u(y)\mathrm{d}y. \tag{32}$$

Note that this is no longer a singular integral. To show that $\mathbb{C}$ is positive, we must show that

$$(u(t), \mathbb{C}u(t)) > 0 \quad \forall\, u(t) \in L^2(\mathbb{R};\mathcal{H}).$$

Note that the inner product on $L^2(\mathbb{R};\mathcal{H})$ is given by

$$(u(t), u'(t)) = \int_{-\infty}^{\infty} u^*(t)u'(t)\mathrm{d}t. \tag{33}$$

We now write our operator A in terms of its spectral components. Please note that λ decomposes A and bears no relation to the strength parameter used at other stages in this paper. When required for clarity, we write $\int_\lambda$ to identify the integral over the variable λ,

$$A = \int \lambda E(\mathrm{d}\lambda).$$

A general vector $u(t)$ may be written

$$u(t) = \int E(\mathrm{d}\lambda)u(t).$$

Then

$$f(A)u(t) = \int f(\lambda)E(\mathrm{d}\lambda)u(t)$$

which implies that we may rewrite (32) as

$$\mathbb{C}u(t) = i\pi \int_{-\infty}^{\infty} \mathrm{d}y \int_{\lambda} e^{-2|t-y|} \frac{1 - e^{ic(t-y)|\lambda|^2}}{t-y} E(\mathrm{d}\lambda)u(y) = \int_{-\infty}^{\infty} \mathrm{d}y \int_{\lambda} \phi_\lambda(t-y)E(\mathrm{d}\lambda)u(y)$$

$$= \int_{\lambda} E(\mathrm{d}\lambda)\mathcal{C}_\lambda(t),$$

where

$$\mathcal{C}_\lambda(t) = \int_{-\infty}^{\infty} \mathrm{d}y \phi_\lambda(t-y)u(y)$$

and we have defined the new function

$$\phi_\lambda(t) = i\pi e^{-2|t|}t^{-1}(1 - e^{ict|\lambda|^2}).$$

By the convolution theorem, note that

$$\tilde{\mathcal{C}}_\lambda(\omega) = \tilde{\phi}_\lambda(\omega)\tilde{u}(\omega),$$

where $\tilde{}$ indicates Fourier transform. Using this decomposition of $u(t)$ and Parseval's theorem, we can now easily write down $(u(t), \mathbb{C}u(t))$. We use $(x,y)_{\mathcal{H}}$ to indicate the inner product on the Hilbert space $\mathcal{H}$, reserving (x,y) for the inner product on $L^2(\mathbb{R};\mathcal{H})$ as in (33).

$$(u(t),\mathbb{C}u(t)) = \int_{-\infty}^{\infty} \mathrm{d}t(u(t),\mathbb{C}u(t))_{\mathcal{H}} = \int_{-\infty}^{\infty} \mathrm{d}t\left(u(t), \int_{\lambda} E(\mathrm{d}\lambda)\mathcal{C}_{\lambda}(t)\right)_{\mathcal{H}}$$
$$= \int_{-\infty}^{\infty} \mathrm{d}t\left(u(t), \int_{\lambda} E(\mathrm{d}\lambda) \int \frac{\mathrm{d}\omega}{2\pi} e^{i\omega t}\tilde{\mathcal{C}}_{\lambda}(\omega)\right)_{\mathcal{H}} = \int_{\lambda} E(\mathrm{d}\lambda) \int \frac{\mathrm{d}\omega}{2\pi} |\tilde{u}_{\lambda}(\omega)|^2 \tilde{\phi}_{\lambda}(\omega).$$

We clearly see that if $\tilde{\phi}_{\lambda}(\omega)$ is positive for all λ, then $\mathbb{C}$ will be positive.

In the following calculation we will find the need to bound $c|\lambda|^2$. The restriction $0 \leqslant c|\lambda|^2 \leqslant 1$ will be employed. We argue that as A^*A is a positive self-adjoint bounded operator we can restrict the integral over λ to (Ref. 26, pp. 262 and 273)

$$A^*A = \int_{-\infty}^{\infty} |\lambda|^2 E(\mathrm{d}\lambda) = \int_{m-0}^{M} |\lambda|^2 E(\mathrm{d}\lambda), \tag{34}$$

where M is the least upper bound and m the greatest lower bound of A^*A. The norm of A^*A is given by $\max(|m|,|M|)$. Thus, if we set

$$c = \frac{1}{\|A^*A\|}$$

then we guarantee each $c|\lambda|^2$ to be less than unity.

Proceeding, the Fourier transform, $\tilde{\phi}_{\lambda}(\omega)$ of

$$\phi_{\lambda}(t) = i\pi e^{-2|t|} t^{-1}[1 - \cos ct|\lambda|^2 - i \sin ct|\lambda|^2] \tag{35}$$

is now calculated. We split (35) into two parts,

$$\phi_{\lambda 1}(t) = i\pi e^{-2|t|} t^{-1}[1 - \cos ct|\lambda|^2], \tag{36}$$

$$\phi_{\lambda 2}(t) = \pi e^{-2|t|} t^{-1} \sin ct|\lambda|^2. \tag{37}$$

The Fourier transform of (36) is

$$\tilde{\phi}_{\lambda 1}(\omega) = i\pi \int_{-\infty}^{\infty} e^{-2|t|} t^{-1}(1 - \cos ct|\lambda|^2) e^{-i\omega t}\, \mathrm{d}t$$
$$= i\pi \left[\int_{0}^{\infty} e^{-2t} t^{-1}(1 - \cos ct|\lambda|^2) e^{-i\omega t}\, \mathrm{d}t + \int_{0}^{\infty} e^{-2t}(-t^{-1})(1 - \cos ct|\lambda|^2) e^{i\omega t}\, \mathrm{d}t \right].$$

Using Ref. 25, p. 157, (59), and setting $S = c|\lambda|^2/(2 + i\omega)$, we obtain

$$\tilde{\phi}_{\lambda 1}(\omega) = \frac{i\pi}{2} \log\left(\frac{1 + S^2}{1 + S^{*2}}\right).$$

The logarithm of a complex number can in general be written as

$$\log(z) = \log(|z|) + i \operatorname{Arg} z$$

so noting that $|(1+S^2)/(1+S^{*2})| = 1$, we see that

$$\tilde{\phi}_{\lambda 1}(\omega) = -\frac{\pi}{2} \operatorname{Arg}\left(\frac{1 + S^2}{1 + S^{*2}}\right) = -\pi \operatorname{Arg}(1 + S^2).$$

With $\kappa = c|\lambda|^2$, the real and imaginary parts of $1 + S^2$ are

TABLE I. Sign of each term in the numerator $n(\omega,\kappa)$ and the denominator $d(\omega,\kappa)$ of (38).

$n(\omega,\kappa)=$	$(4+\omega^2)^2$	$+\kappa\omega(4+\omega^2)^2$	$+\kappa^2(4-\omega^2)$	$-\kappa^3\omega$
$\omega<-2$	$+ve$	$-ve$	$-ve$	$+ve$
$-2<\omega<0$	$+ve$	$-ve$	$+ve$	$+ve$
$0<\omega<2$	$+ve$	$+ve$	$+ve$	$-ve$
$\omega>2$	$+ve$	$+ve$	$-ve$	$-ve$
$d(\omega,\kappa)=$	$(4+\omega^2)^3$	$-2\kappa^2\omega^2(4+\omega^2)$	$-16\kappa^3\omega$	$-\kappa^4(4-\omega^2)$
$\omega<-2$	$+ve$	$-ve$	$+ve$	$+ve$
$-2<\omega<0$	$+ve$	$-ve$	$+ve$	$-ve$
$0<\omega<2$	$+ve$	$-ve$	$-ve$	$-ve$
$\omega>2$	$+ve$	$-ve$	$-ve$	$+ve$

$$\Re(1+S^2)=\frac{(4+\omega^2)^2+\kappa^2(4-\omega^2)}{(4+\omega^2)^2},$$

$$\Im(1+S^2)=\frac{-4\kappa^2\omega}{(4+\omega^2)^2}.$$

With the restriction that $0\leqslant\kappa\leqslant 1$, the real part is positive for all ω and thus $\mathrm{Arg}(z)=\arctan(\Im z/\Re z)$. Thus,

$$\tilde{\phi}_{\lambda 1}(\omega)=-\pi\arctan\left(\frac{\Im(1+S^2)}{\Re(1+S^2)}\right).$$

$\arctan(z)$ is the principal part of $\mathrm{Arctan}(z)$, with range $-\pi/2<\arctan(z)<\pi/2$. The Fourier transform of (37) is similarly calculated using Ref. 25, p. 152, (16), to be

$$\tilde{\phi}_{\lambda 2}(\omega)=\pi[\arctan S+\arctan S^*]=\pi\left[\arctan\left(\frac{c|\lambda|^2}{2+i\omega}\right)+\arctan\left(\frac{c|\lambda|^2}{2-i\omega}\right)\right].$$

Repeated application of the formula $\arctan(z_1)+\arctan(z_2)=\arctan(z_1+z_2/1-z_1z_2)$, valid when $z_1z_2<1$ (true for $0\leqslant\kappa\leqslant 1$), yields (this result is not valid for values of κ larger than around 2, at which point the arctan addition formulas fail—this is a moot point however, as we may trivially restrict κ as already explained)

$$\tilde{\phi}_{\lambda}(\omega)=\tilde{\phi}_{\lambda 1}(\omega)+\tilde{\phi}_{\lambda 2}(\omega)=\pi\arctan\left(\frac{n(\omega,c|\lambda|^2)}{d(\omega,c|\lambda|^2)}\right),\tag{38}$$

where

$$n(\omega,\kappa)=4\kappa[(4+\omega^2)^2+\kappa\omega(4+\omega^2)+\kappa^2(4-\omega^2)-\kappa^3\omega]\tag{39}$$

and

$$d(\omega,\kappa)=(4+\omega^2)^3-2\kappa^2\omega^2(4+\omega^2)-16\kappa^3\omega-\kappa^4(4-\omega^2).\tag{40}$$

One may easily confirm that for $0\leqslant\kappa\leqslant 1$, $n(\omega,\kappa)/d(\omega,\kappa)$ and hence $\tilde{\phi}_{\lambda}(\omega)$ is strictly positive by noting that there are four distinct regions of interest for ω, in which terms in n and d do not change sign. Table I shows these regions and the sign of each term in the region. Note that the global (positive and hence irrelevant) κ factor from (39) is dropped from the numerator for the following discussion.

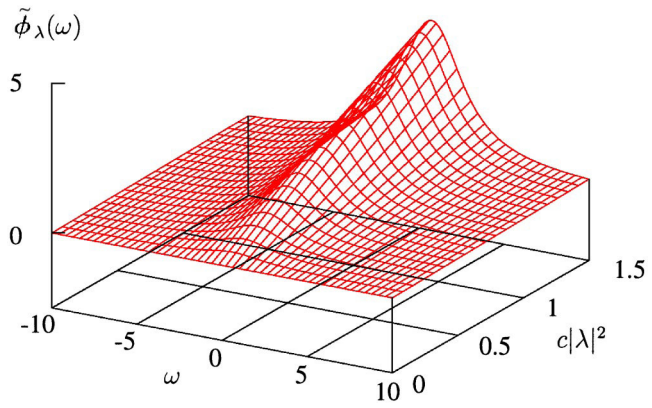

FIG. 1. Plot of $\tilde{\phi}_\lambda(\omega)=\tilde{\phi}_{\lambda 1}(\omega)+\tilde{\phi}_{\lambda 2}(\omega)$, the Fourier transform of $\phi_\lambda(t)=i\pi e^{-2|t|}t^{-1}(1-\cos(ct|\lambda|^2)-i\sin(ct|\lambda|^2))$. $\tilde{\phi}_\lambda(\omega)$ is strictly positive for all ω when $c|\lambda|^2\leqslant 1$.

For each row in the table, we simply need to show that the terms add to produce a strictly positive number. First note that the first column for both the numerator and denominator is independent of κ. To show the positivity of each row, we set all positive κ-dependent terms to zero and then take $\kappa=1$ for the negative terms to maximize their contribution. Expanding out terms, it is then trivially seen in all cases that the first column [$(4+\omega^2)^2$ for the numerator and $(4+\omega^2)^3$ for the denominator] dominates. Thus, no row is negative and we conclude that $\tilde{\phi}_\lambda$ is positive definite.

We have established that the Fourier transform of ϕ_λ is positive definite for $c|\lambda|^2\leqslant 1$. As a visual aid, Fig. 1 shows $\tilde{\phi}_\lambda(\omega)$. The positivity for $c|\lambda|^2\leqslant 1$ is clear.

Thus, $\mathbb{C}$ is strictly positive and $\mathbb{V}$ is absolutely continuous on $R(\mathbb{C}^{1/2})$. As A^*A is a factor of $1-e^{ictA^*A}$ (i.e., A^*A is a factor of $\mathbb{C}$), $R(\mathbb{C}^{1/2})=R(A^*)$. Noting that $R(A^*)$ is cyclic for U and hence cyclic for V, we conclude that $R(\mathbb{C}^{1/2})$ is cyclic for $\mathbb{V}$. Thus, $\mathbb{V}$ is absolutely continuous on $L^2(\mathbb{R};\mathcal{H})$. ■

We have now satisfied all the requirements of Theorem II.7.

III. THE UNITARY PUTNAM–KATO THEOREM

In this section, we will prove a modified version of the Putnam–Kato theorem, as used in the preceding sections. The theorems and proofs follow a similar argument to that of Reed and Simon (Ref. 15, p. 157, Theorem XIII.28) and are motivated by the stroboscopic nature of the kicked Hamiltonian.

Definition III.1. (V-Smooth): Let V be a unitary operator. A is V-smooth if and only if for all $\phi\in\mathcal{H}$, $V(t)\phi\in D(A)$ *for almost every* $t\in\mathbb{R}$ *and for some constant C,*

$$\sum_n \|AV^n\phi\|^2 \leqslant C\|\phi\|^2.$$

Theorem III.2: *If A is V-smooth, then* $\overline{R(A^*)}\subset\mathcal{H}_{ac}(V)$.

Proof: Since $\mathcal{H}_{ac}(V)$ is closed, we need only show $R(A^*)\subset\mathcal{H}_{ac}(V)$. Let $\phi\in D(A^*)$, $\psi=A^*\phi$, and let $d\mu_\psi$ be the spectral measure for V associated with ψ. Define, for the period T in (1),

$$\mathcal{F}_n(T)=\frac{1}{\sqrt{2\pi}}(A^*\phi,[V(T)]^n\psi). \tag{41}$$

We calculate

$$|\mathcal{F}_n| = \frac{1}{\sqrt{2\pi}}|(\phi, AV^n\psi)| \leqslant \frac{1}{\sqrt{2\pi}}\|\phi\|\|AV^n\psi\|.$$

Because A is V-smooth, we see that

$$\sum_n |\mathcal{F}_n|^2 \leqslant \frac{1}{2\pi}\|\phi\|^2 \sum_n \|AV^n\psi\|^2 \leqslant \frac{C}{2\pi}\|\phi\|^2\|\psi\|^2 < \infty.$$

So $\mathcal{F}_n \in L^2(\mathbb{R})$. By the Riesz–Fischer theorem (Ref. 27, pp. 96–97, 4.26 Fourier series), $\mathcal{F}(\theta) = 1/\sqrt{2\pi}\Sigma_n \mathcal{F}_n \bar{e}^{in\theta} \in L^2$.

The spectral resolution of $V[T]$ is

$$V[T] = \int_0^{2\pi} e^{i\theta}\, \mathrm{d}E_T(\theta),$$

so we have

$$(V[T])^n = \int_0^{2\pi} e^{in\theta}\, \mathrm{d}E_T(\theta).$$

Therefore, from (41) we obtain

$$\begin{aligned}\mathcal{F}_n &= \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} (A^*\phi, e^{in\theta}\, \mathrm{d}E(\theta)\psi) \\ &= \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} e^{in\theta}(\psi, \mathrm{d}E(\theta)\psi) \\ &= \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} e^{in\theta}\, \mathrm{d}\mu_\psi(\theta).\end{aligned}$$

Using the inverse of the expression above for $\mathcal{F}(\theta)$ gives

$$\mathcal{F}_n = \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} e^{in\theta}\mathcal{F}(\theta)\mathrm{d}\theta.$$

As we have just shown that $\mathcal{F}(\theta) \in L^2$, $\mathrm{d}\mu_\psi(\theta) = \mathcal{F}(\theta)\mathrm{d}\theta$ is absolutely continuous, which implies that $\psi \in R(A^*)$ is in $\mathcal{H}_{ac}(V)$ and so $\overline{R(A^*)} \subset \mathcal{H}_{ac}(V)$. ■

Theorem III.3 (Unitary Putnam–Kato theorem): *Let V be a unitary operator, and A a self-adjoint bounded operator. If $C = V[V^*, A] \geqslant 0$, then V is absolutely continuous on $R(C^{1/2})$. Hence, if $R(C^{1/2})$ is cyclic for V, then V is absolutely continuous.*

Proof: The discrete time evolution of an operator A is given by

$$\mathcal{F}_n = V^{-n}AV^n.$$

We calculate

$$\mathcal{F}_n - \mathcal{F}_{n-1} = V^{-n}V[V^*, A]V^n \equiv G_n,$$

so

$$\sum_{n=a}^{b}(\phi,G_n\phi)=\sum_{n=a}^{b}(\phi,V^{-n}V[V^*,A]V^n\phi)$$

$$=\sum_{n=a}^{b}(V^n\phi,V[V^*,A]V^n\phi)=\sum_{n=a}^{b}(C^{\frac{1}{2}}V^n\phi,C^{\frac{1}{2}}V^n\phi)=\sum_{n=a}^{b}\|C^{\frac{1}{2}}V^n\phi\|^2,$$

where $C=V[V^*,A]$. We also have

$$\sum_{n=a}^{b}(\phi,G_n\phi)=(\phi,V^{-b}AV^b\phi)-(\phi,V^{-(a-1)}AV^{(a-1)}\phi).$$

Taking the modulus and using the Schwartz inequality, we obtain

$$\sum_{n=a}^{b}\|C^{\frac{1}{2}}V^n\phi\|^2\leqslant 2|(\phi,V^{-b}AV^b\phi)|=2|(V^b\phi,AV^b\phi)|\leqslant 2\|A\|\,\|V^b\phi\|^2=2\|A\|\,\|\phi\|^2<\infty$$

and thus we see that $C^{1/2}$ is V-smooth.

That V is absolutely continuous on $R(C^{1/2})$ follows directly from Theorem III.2. ■

IV. FINITE RANK PERTURBATIONS

Here, we utilize the results of Sec. II to show that perturbations of the form (5) lead to the Floquet operator having pure point spectrum for almost every perturbation strength λ.

We use directly the definition of *strongly H-finite* from Howland.

Definition IV.1 (Strongly H-finite): Let H be a self-adjoint operator on $\mathcal{H}$ with pure point spectrum, ϕ_n a complete orthonormal set of eigenvectors, and $H\phi_n=\alpha_n\phi_n$. A bounded operator $A:\mathcal{H}\to\mathcal{K}$ is strongly H-finite if and only if

$$\sum_{n=1}^{\infty}|A\phi_n|<\infty. \tag{42}$$

If H is thought of as a diagonal matrix on l_2, i.e., $H=\Sigma_n\alpha_n|\phi_n\rangle\langle\phi_n|$, and A as an infinite matrix $\{a_{ij}\}$, i.e., $A=\Sigma_{m,n}a_{mn}|\phi_m\rangle\langle\phi_n|$, then (42) says

$$\sum_n\left[\sum_i|a_{in}|^2\right]^{\frac{1}{2}}<\infty. \tag{43}$$

For our purposes, we need to show that if A is strongly H-finite, then it is U-finite. To satisfy the assumption that Q_ϵ is trace class in Lemma II.5 (and hence also compact in Theorem II.4) we also need to show that A is trace class.

Theorem IV.2: *If A is strongly H-finite, then given $U=e^{iTH/\hbar}$, for the period T in* (1) *and $H\phi_n=\alpha_n\phi_n$,*

(a) *A is trace class, and*
(b) *A is U-finite.*

Proof: (a) Simply consider

$$\mathrm{tr}(A)=\sum_l\langle\phi_l|A|\phi_l\rangle=\sum_l a_{ll}\leqslant\sum_l|a_{ll}|. \tag{44}$$

For each term in the sum (44) we trivially have

$$|a_{ll}| \leqslant \sqrt{\sum_i |a_{il}|^2}$$

and thus (44) is finite so A is trace class.

(b) Noting that

$$U|\phi_n\rangle = e^{iTH/\hbar}|\phi_n\rangle$$

we calculate, by insertion of a complete set of states,

$$\sum_n \langle\phi_n|G_\epsilon(\theta;U,A)|\phi_n\rangle = \sum_n \langle\phi_n|A\frac{1}{(1-U^*e^{-i\theta_-})(1-Ue^{i\theta_+})}A^*|\phi_n\rangle = \sum_m \frac{\langle\phi_m|A^*A|\phi_m\rangle}{|1-e^{-\epsilon}e^{iT\alpha_m/\hbar}e^{i\theta}|^2}.$$

The trace norm is then

$$\text{tr } G_\epsilon(\theta) = \sum_n \frac{|A\phi_n|^2}{|1-e^{-\epsilon}e^{iT\alpha_n/\hbar}e^{i\theta}|^2}.$$

If this is bounded for $\epsilon=0$, then it is trivially bounded for all $\epsilon>0$. By (42) and a slightly modified version of Theorem 3.1 in Ref. 2 this is finite almost everywhere for $\epsilon=0$. Thus the trace norm of G_ϵ exists as $\epsilon\to 0$, which implies that the strong limit of G_ϵ exists and we conclude that A is U-finite. ■

THEOREM IV.3: *Let U be a pure point unitary operator, and let $A_1,\ldots,A_N$ be strongly H-finite. Assume that the A_k's commute with each other. Then for almost every $\lambda=(\lambda_1,\ldots,\lambda_N)$ in $\mathbb{R}^N$,*

$$V(\lambda) = e^{i(\Sigma_{k=1}^N \lambda_k A_k^* A_k)/\hbar}U$$

is pure point.

Proof: This is a trivial modification of Theorem 4.3 in Ref. 2. Let

$$\mathrm{K} = \bigoplus_{k=1}^N \overline{R(A_k)}.$$

The elements of $\mathcal{K}$ are represented as column vectors. Our operator $A:\mathcal{H}\to\mathcal{K}$ is defined, for $y\in\mathcal{H}$, by

$$Ay = \begin{bmatrix} A_1 y \\ \vdots \\ A_N y \end{bmatrix} = \begin{bmatrix} x_1 \\ \vdots \\ x_N \end{bmatrix}$$

and therefore $A^*:\mathcal{K}\to\mathcal{H}$ is given by

$$A^*x = A_1^*x_1 + \cdots + A_N^*x_N.$$

Accordingly, we introduce $G_\epsilon(\theta):\mathcal{K}\to\mathcal{K}$, the matrix equivalent of Eq. (8),

$$G_\epsilon(\theta;U,A) = A[1-U^*e^{-i\theta_-}]^{-1}[1-Ue^{i\theta_+}]^{-1}A^* = \{A_i[1-U^*e^{-i\theta_-}]^{-1}[1-Ue^{i\theta_+}]^{-1}A_j^*\}_{1\leqslant i,j\leqslant N}.$$

The diagonal terms are finite almost everywhere because each A_k is U-finite by Theorem IV.2. The off-diagonal terms are of the form $X_1^*X_2$, and so the Schwartz inequality,

$$|X_1^*X_2|^2 \leqslant \|X_1\|^2\|X_2\|^2$$

ensures that they are finite almost everywhere too. Hence, A is U-finite as every term in the matrix $G_\epsilon(\theta;U,A)$ is almost everywhere finite as $\epsilon\to 0$.

Our Hamiltonian may now be written as

$$H(\lambda) = H_0 + A^* W(\lambda) A \sum_{n=0}^{\infty} \delta(t - nT) \tag{45}$$

and our Floquet operator as

$$V(\lambda) = e^{iA^* W(\lambda) A/\hbar} U,$$

where $W(\lambda) = \mathrm{diag}\{\lambda_k\}$. In this form, the formalism of Sec. II is essentially fully regained, and we proceed to apply Theorems II.2, II.4, II.6, and II.7.

To establish the absolute continuity of the multiplication operator $\mathbb{V}$ on the space $L^2(\mathbb{R}^N; \mathcal{H})$ we proceed as in Proposition II.8.

We write

$$V(t_1, \ldots, t_N) = e^{ic\Sigma_{k=1}^N t_k A_k^* A_k/\hbar} U,$$

define

$$D = -\sum_{k=1}^{N} \arctan(p_k/2),$$

where $p_k = -id/\mathrm{d}t_k$, and compute

$$C = \mathbb{V}[\mathbb{V}^*, D] = \sum_{k=1}^{N} C_k \geqslant 0.$$

In obtaining C as a direct sum of the C_k, we have had to assume that the A_k's commute with each other. This complication comes when considering the term

$$V(t_1, \ldots, t_N) V^*(t_1, \ldots, t_{k-1}, y_k, t_{k+1}, \ldots, t_N)$$

in the equivalent of (31). To obtain the required form of $e^{ic(t_k - y_k)A_k^* A_k}$ we need the A_k's to commute. [This restriction is not required in Howland's self-adjoint work because the summation over k in the Hamiltonian (45) enters directly, rather than in the exponent of V.]

Moving on, each $C_k \geqslant 0$ is equivalent to C in Proposition II.8 and hence positive. Finally, we must show that $R(C^{1/2})$ is cyclic for $\mathbb{V}$. This is no longer trivial as, for each k, while we have $R(C_k^{1/2}) = R(A_k^*)$, the range of A_k^* is not cyclic for U, hence $\mathbb{V}$. To proceed, first note that

$$R(A^*) = \bigcup_k R(A_k^*).$$

Now, as argued in Howland, we can assume that $R(A^*)$ is cyclic for U. To elaborate, define $\mathcal{M}(U, R(A^*))$ to be the smallest closed reducing subspace of $\mathcal{H}$ containing $R(A^*)$. If $R(A^*)$ is not cyclic for U, then $\mathcal{H} \ominus \mathcal{M}$ is not empty. However, as shown below, if $y \in \mathcal{H} \ominus \mathcal{M}$, then $A^* W A y = 0$, so in $\mathcal{H} \ominus \mathcal{M}$, $V(t) = U$ and is therefore pure point trivially. Thus, we can ignore the space $\mathcal{H} \ominus \mathcal{M}$, and restrict our discussion to $\mathcal{M}$—i.e., we may assume $R(A^*)$ cyclic for U.

The above relied upon showing that $A^* W A y = 0$ for $y \in \mathcal{H} \ominus \mathcal{M}$. We now prove this. If $y \in \mathcal{H} \ominus \mathcal{M}$ and $y' \in \mathcal{M}$, then

$$\langle y, y' \rangle = 0.$$

Given $y' \in \mathcal{M}$, there exists an $x \in \mathcal{K}$ such that $y' = A^* x$, so

$$\langle y, A^* x \rangle = 0.$$

That is

$$\langle Ay, x\rangle = 0.$$

This is true for all $x \in \mathcal{K}$. Suppose $y'' \in \mathcal{H}$. Then $WAy'' \in \mathcal{K}$ and so

$$\langle Ay, WAy''\rangle = 0.$$

That is

$$\langle A^*WAy, y''\rangle = 0.$$

As this is true for any $y'' \in \mathcal{H}$, we conclude that $A^*WAy = 0$ on $\mathcal{H} \ominus \mathcal{M}$.

Thus, $R(A^*)$ [with A acting on $L^2(\mathbb{R}^{\mathbb{N}}; \mathcal{H})$] may be assumed cyclic for U, hence cyclic for $\mathbb{V}$.

We must finally show that $R(C^{1/2}) = R(A^*)$. We have

$$R(A^*) = \bigcup_k R(A_k^*) = \bigcup_k R(C_k^{1/2})$$

and

$$R(C) = \bigcup_k R(C_k).$$

As $R(A^*) = R(A^*A)$, $R(C^{1/2}) = R(C)$ and we have shown that $R(C^{1/2}) = R(A^*)$ as required. ■

Finally, we wish to make the connection with our original aim—to show that Hamiltonians of the form

$$H(t) = H_0 + \sum_{k=1}^{N} \lambda_k |\psi_k\rangle\langle\psi_k| \sum_{n=0}^{\infty} \delta(t - nT) \tag{46}$$

have a pure point quasienergy spectrum.

THEOREM IV.4: *Let H_0 be pure point, and define our time dependent Hamiltonian as in* (46). *If $\psi_1, \ldots, \psi_N \in l_1(H_0)$, then for almost every $\lambda = (\lambda_1, \ldots, \lambda_N)$ in $\mathbb{R}^N$, the Floquet operator*

$$V = e^{i(\Sigma_{k=1}^{N} \lambda_k |\psi_k\rangle\langle\psi_k|)/\hbar} U$$

has pure point spectrum.

Proof: This theorem is just a special case of Theorem IV.3 with the A_k's given by $|\psi_k\rangle\langle\psi_k|$. Clearly, the A_k's commute. As Howland shows, $|\psi\rangle\langle\psi|$ is strongly H-finite if and only if $\psi \in l_1(H_0)$. Thus Theorem IV.3 applies and the result follows. ■

V. DISCUSSION OF RESULTS AND POTENTIAL APPLICATIONS

Of fundamental importance in showing that the quasienergy spectrum remains pure point for almost every perturbation strength λ, was the fact that $\psi_k \in l_1(H_0)$. That is, if we write

$$|\psi_k\rangle = \sum_{n=0}^{\infty} (a_k)_n |\phi_n\rangle$$

where the $|\phi_n\rangle$ are the basis states of H_0, then $\psi_k \in l_1(H_0)$ if and only if

$$\sum_{n=0}^{\infty} |(a_k)_n| < \infty.$$

If this requirement is dropped, and we only retain $\psi_k \in l_2(H_0)$, then Theorem 3.1 in Ref. 2 fails and there is the possibility that $V(\lambda)$ will have a nonempty continuous spectrum. It was this fact that Milek and Seba[10] took advantage of in showing that the rank-1 kicked rotor could contain a singularly continuous spectral component under certain conditions on the ratio of the kicking frequency and the fundamental rotor frequency. They analyzed two regimes of the perturbation.

One where $\psi \in l_1(H_0)$, in which case the numerical results clearly showed pure point recurrent behavior, and the other where $\psi \in l_2(H_0)$, but $\psi \notin l_1(H_0)$. In the second case, the authors further proved that the absolutely continuous part of the spectrum was empty, and thus the system contained a singularly continuous spectral component. The numerical results reflected this, with a diffusive type energy growth being observed.

With the generalization of Combescure's work here, namely our Theorem IV.4, it should now be possible to investigate the full class of rank-N kicked Hamiltonians. A sufficient requirement for recurrent behavior has been shown to be $\psi_k \in l_1(H_0)$ and so we must turn our attention to perturbations where this requirement is no longer satisfied.

The challenge will be of course to find systems for which one can show that the absolutely continuous part of the spectrum is empty. Such systems would be candidates for classification as quantum chaotic systems.

(Received 10 November 2003; accepted 21 November 2004; published online 16 February 2005)

We investigate a special case of the Gaudin model related to the superalgebra $osp(1,2)$. We present an exact solution to that system diagonalizing a complete set of commuting observables, and providing the corresponding eigenvectors and eigenvalues. The approach used in this paper is based on the co-algebra symmetry of the model, already known from the Calogero–Gaudin system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1853503]

I. INTRODUCTION

The Gaudin model (sometimes called Gaudin magnet),[1,2] introduced by Gaudin in 1976, is a quantum mechanical system involving long-range spin–spin interaction, described by a set of N Hamiltonians $\mathcal{H}_i$ depending on a set of N arbitrary parameters ϵ_i:

$$\mathcal{H}_i = \sum_{j=1, j\neq i}^{N} \frac{\sigma_i^x\sigma_j^x + \sigma_i^y\sigma_j^y + \sigma_i^z\sigma_j^z}{\epsilon_i - \epsilon_j}, \quad j = 1, \ldots, N. \tag{1.1}$$

Out of the operators (1.1) Gaudin constructed the further operator (dependent also on another set of arbitrary parameters η_i)

$$\mathcal{H}_G = \sum_{i<j} \frac{\eta_i - \eta_j}{\epsilon_i - \epsilon_j}(\sigma_i^x\sigma_j^x + \sigma_i^y\sigma_j^y + \sigma_i^z\sigma_j^z) = \sum_{i=1}^{N} \eta_i\mathcal{H}_i \tag{1.2}$$

selecting it as the Hamiltonian of the system: while $\mathcal{H}_i$ describes just the interaction of the ith spin with all the others, $\mathcal{H}_G$ takes care of the mutual interaction among all spins.

Gaudin showed that the Hamiltonians $\mathcal{H}_i$ commute with each other and constructed their common eigenvectors by the coordinate Bethe ansatz. The algebra corresponding to the observables of the model is a loop-algebra, the so-called "rational Gaudin algebra," whose properties underlie the integrability of the system. Later, this model was studied by Sklyanin through the r-matrix approach[3,4] and quite recently its intimate connections with Richardson's work on "pairing force" Hamiltonians[5] and with BCS model of superconductivity has been unveiled.[6,7]

For the special choice $\eta_i = \epsilon_i \forall\, i$, the Gaudin Hamiltonian (1.2) takes the simpler, parameter independent, form:

$$\mathcal{H}_G = \sum_{i,j} (\sigma_i^x\sigma_j^x + \sigma_i^y\sigma_j^y + \sigma_i^z\sigma_j^z). \tag{1.3}$$

In the following we will always work with the "mean-field" Hamiltonian (1.3) and we will continue to refer to it, a bit improperly, as "Gaudin magnet."

[a)]Electronic mail: ragnisco@fis.uniroma3.it

Using co-algebras, Ballesteros and colleagues developed an alternative approach, shortly denoted as BMR in the following, to construct a second family of commuting observables, independent of the Gaudin set $\{\mathcal{H}_i\}$, but sharing with it the element (1.3) (Refs. 8–10). In Ref. 10 Musso and Ragnisco (MR in the following) performed an exact diagonalization of this alternative family of commuting observables, in the simplest finite-dimensional representation, namely the spin-$\frac{1}{2}$ one. We stress that the existence of two independent complete sets of commuting observables implies that the Hamiltonian (1.3) is maximally superintegrable.

The superalgebra extension of the notion of Gaudin algebra, and of the related r-matrix structure, has been worked out in some remarkable papers (see, for instance, Refs. 11 and 12) where the Gaudin magnet related to orthosymplectic Lie superalgebra $osp(1,2)$ has been constructed and solved through a brilliant generalization of the Bethe ansatz.

In the present paper, our purpose is to extend the BMR approach to the supersymmetric Gaudin magnet associated with the $osp(1,2)$ superalgebra and to find a complete family of commuting observables independent of the set found by the previous authors in the context of the Bethe ansatz. These new observables are in fact a sequence of coproducts of the quadratic Casimir of the algebra $osp(1,2)$. By diagonalizing them, we will construct an exact solution of the model, providing an explicit expression for the associated eigenvectors and eigenvalues, thus proving that the Gaudin magnet related to the superalgebra $osp(1,2)$ is still maximally superintegrable.

The paper is organized as follows. In Sec. II we briefly recall the basic notions on superalgebra $osp(1,2)$, as well as the notion of graded tensor-product multiplication, and define a coproduct enjoying the required homomorphicity properties. Then, we show that, as in the $sl(2)$ case, through the coalgebra approach (Refs. 8 and 13) a completely integrable supersymmetric N-body Hamiltonian system can be derived. In Sec. III we construct the common eigenstates of the observables defined in Sec. II and we derive the eigenvalues associated with the partial Casimir operators of the system $\Delta^{(h)}(C)$ $(h=2,\ldots,N)$ (coproducts of the Casimir), paraphrasing the procedure successfully followed in Ref. 10. Namely, starting from the "total pseudovacuum," we first construct an eigenbasis for the kernel of the global fermionic annihilation operator and then on top of it we build up all the remaining eigenstates by acting with fermionic creation operators. In Sec. IV we restrict ourselves to the case of spin $1/2$ and give the explicit construction of the eigenstates for the three-body case. In Sec. V we briefly introduce a more general Hamiltonian, corresponding to the so-called $t-J$ models,[14] which commutes with the complete family of observables defined in Sec. II and therefore is completely integrable as well. The proof that our set of eigenstates is complete is given in the Appendix but only for the case of spin $1/2$.

II. THE GAUDIN MAGNET RELATED TO THE SUPERALGEBRA *osp*(1,2)

The simplest superalgebra that generalizes $sl(2)$ is the orthosymplectic superalgebra $osp(1,2)$ defined by commutation and anticommutation rules (supercommutation rules). As is well known, the basic extra-ingredient characterizing the supersymmetric case is a grading, which allows one to classify the elements of the algebra in two families, the "bosons" with even degree and the "fermions" with odd degree, and leads to the supercommutation rules. The superalgebra $osp(1,2)$ has five generators, three bosonic ones: H, E^+, E^- and two fermionic ones: F^+, F^-. Its defining relations are the following:[15]

$$[H,E^{\pm}]_- = \pm 2E^{\pm}, \quad [E^+,E^-]_- = H, \tag{2.1}$$

$$[H,F^{\pm}]_- = \pm F^{\pm}, \quad [F^+,F^-]_+ = H, \tag{2.2}$$

$$[E^{\pm},F^{\mp}]_- = -F^{\pm}, \quad [F^{\pm},F^{\pm}]_+ = \pm 2E^{\pm}, \tag{2.3}$$

We immediately see that the operators H, E^+, E^- generate the Lie algebra $sl(2)$. Moreover, as the anticommutation rules entail $(F^{\pm})^2=E^{\pm}$, some authors (see, for instance, Ref. 12) define $osp(1,2)$ only in terms of the three generators $\mathcal{H}$, F^+, F^-.

The Casimir of this algebra is

$$C = H^2 + 2(E^+E^- + E^-E^+) - (F^+F^- - F^-F^+). \tag{2.4}$$

As we shall see in the following, the *N*th coproduct of Casimir gives us the Hamiltonian of the "supersymmetric Gaudin magnet:"

$$\begin{aligned} C_N &= \Delta^{(N)}(C) = [\Delta^{(N)}(H)]^2 + 2[\Delta^{(N)}(E^+), \Delta^{(N)}(E^-)]_+ - [\Delta^{(N)}(F^+), \Delta^{(N)}(F^-)]_- \\ &= \sum_{j\neq i}^{N} \mathbf{S}^i\mathbf{S}^j - F_+^iF_-^j + F_-^iF_+^j + 2Nj\left(j+\frac{1}{2}\right)I \equiv \mathcal{H}_{G_s}, \end{aligned} \tag{2.5}$$

where I is the identity operator, the (positive) integer or half-integer j denotes the spin in each site and $\mathbf{S}^l \equiv (H^l, E_+^l + E_-^l, -i(E_+^l - E_-^l))$.

In passing, we note that a further generalization can be obtained by allowing site-dependent representations $(j_1, \ldots, j_N)$: of course in this case the constant $2Nj\left(j+\frac{1}{2}\right)$ is then replaced by $2\Sigma_{k=1}^{N} j_k\left(j_k+\frac{1}{2}\right)$. However, for the sake of simplicity, we will not deal with this more general case in the present paper.

As in the non-supersymmetric case we pose $C_h = \Delta^{(h)}(C)$, $h = 2, \ldots, N$; a complete set of independent commuting observables is provided by

$$\{\Delta^{(N)}(H), C_2, \ldots, C_N\}. \tag{2.6}$$

The operators $\Delta^{(h)}$, $h = 3, \ldots, N$ are defined through the recursive formula:[8]

$$\Delta^{(h)} = (\Delta^{(h-1)} \otimes id)\Delta^{(2)}, \quad h = 3, \ldots, N, \tag{2.7}$$

where $\Delta^{(2)}$ denotes the coproduct associated with the usual Hopf-algebra structure defined on $U(g)$, the universal enveloping algebra of a given Lie (super)algebra g, namely,

$$\Delta^{(2)}(X) = X \otimes 1 + 1 \otimes X \; \forall \, X \in g. \tag{2.8}$$

For the above construction to hold, yielding complete integrability of the composite system (see Ref. 8), (2.8) has to be a coassociative homomorphism of $osp(1,2)$, that is,

$$[\Delta(a), \Delta(b)]_{S\otimes S} = \Delta([a,b]_S), \quad \forall \, a,b \in S, \tag{2.9}$$

$$(\Delta \otimes id)\Delta = (id \otimes \Delta)\Delta, \tag{2.10}$$

where by $[,]$ we have denoted the supercommutator.

We remark that the above-presented formulas involve tensor-products multiplication, which has to be associative if we want the coproduct to be coassociative. This requires the tensor product to be a suitably graded one. The proper definition for binary tensor products is the following:[15]

$$(a \otimes b)(c \otimes d) = ac \otimes bd(-1)^{\deg(b)\deg(c)}. \tag{2.11}$$

Defining the degree of binary tensor-product in the natural way:

$$\deg(a \otimes b) = \deg(a) + \deg(b) \mod 2 \tag{2.12}$$

we obtain the following equations for three element tensor-products:

$$\begin{aligned} ((a \otimes b) \otimes c)((d \otimes e) \otimes f) &= (a \otimes b)(d \otimes e) \otimes cf(-1)^{\deg(c)\deg(d\otimes e)} \\ &= ad \otimes be \otimes cf(-1)^{\deg(b)\deg(d)+\deg(c)\deg(d)+\deg(c)\deg(e)} \end{aligned} \tag{2.13}$$

and

$$(a \otimes (b \otimes c))(d \otimes (e \otimes f)) = ad \otimes (b \otimes c)(e \otimes f)(-1)^{\deg(b\otimes c)\deg(d)}$$
$$= ad \otimes be \otimes cf(-1)^{\deg(b)\deg(d)+\deg(c)\deg(d)+\deg(c)\deg(e)}. \quad (2.14)$$

As (2.13) and (2.14) coincide, the multiplication between three element tensor-products is associative. We can extend this result to the general case of multiplication between N element tensor-products obtaining

$$(a_1 \otimes a_2 \otimes \ldots \otimes a_N)(b_1 \otimes b_2 \otimes \ldots \otimes b_N) = (-1)^{\sum_{i<j=2}^{N}\deg(a_j)\deg(b_i)}$$
$$\times (a_1 b_1 \otimes a_2 b_2 \otimes \ldots \otimes a_N b_N), \quad \forall\, a_j, b_i \in \mathcal{S}. \quad (2.15)$$

Generalizing (2.12), we define the degree of the N element tensor-product as

$$\deg(a_1 \otimes a_2 \otimes \ldots \otimes a_N) = \deg(a_1) + \deg(a_2) + \ldots + \deg(a_N), \quad \mathrm{mod}\, 2. \quad (2.16)$$

From this definition it follows straight away that the coproduct $\Delta^{(N)}(X_i)$ preserves the degree of the generic operator X_i. In fact we have

$$\Delta^{(N)}(X_i) = X_i \otimes \overbrace{1 \otimes \ldots \otimes 1}^{N-1} + 1 \otimes X_i \otimes \overbrace{1 \otimes \ldots \otimes 1}^{N-2} + \ldots + \overbrace{1 \otimes \ldots \otimes 1}^{N-1} \otimes X_i. \quad (2.17)$$

Hence,

$$\deg(\Delta^{(N)}(X_i)) = \deg(X_i) + (N-1)\deg(1). \quad (2.18)$$

But $\deg(1)=0$, so we obtain

$$\deg(\Delta^{(N)}(X_i)) = \deg(X_i). \quad (2.19)$$

We can immediately see that, as in the case $sl(2)$, a completely integrable supersymmetric N-body Hamiltonian system can be constructed through the BMR approach which yields the complete family of commuting observables (2.6).

III. CONSTRUCTION OF THE SIMULTANEOUS EIGENSTATES IN THE CASE *osp*(1,2)

Our aim is to find the common eigenstates of the observables (2.6), which form a basis for the Hilbert space of the problem. As reference state, the so-called "pseudovacuum," we take the tensor-product of the states annihilated by the single-particle operators F_i^-, namely, the tensor-product of the N single-particle lowest weight vectors $|0\rangle_i$, $i=1,\ldots,N$; as in the nonsupersymmetric case, we denote it as $\Psi(0,0)$.

We will show that the common eigenstates of the family of observables (2.6) take the form

$$\Phi(k; m_l, s_{m_l}; \ldots; 0,0) = [\Delta^{(N)}(F^+)]^{k-m_l}\Psi(m_l, s_{m_l}; \ldots; 0,0), \quad (3.1)$$

where $\Psi(m_l, s_{m_l}; \ldots; 0,0)$ is an element of the basis spanning $\mathrm{Ker}(\Delta^{(s_{m_l})}(F^-))$, obtained through the recursive formula

$$\Psi(m_l, s_{m_l}; \ldots; 0,0) = \sum_{i=0}^{m_l - m_{l-1}} a_i \Delta^{(s_{m_l}-1)}(F^+)^{m_l - m_{l-1} - i}(F^+_{s_{m_l}})^i \Psi(m_{l-1}, s_{m_{l-1}}; \ldots; 0,0) \quad (3.2)$$

$$m_l = 1,2,\ldots,N, \quad s_{m_l} = 2,3,\ldots,N, \quad l = 1,2,\ldots,N-1. \quad (3.3)$$

Paraphrasing the procedure followed in Ref. 9 it is possible to prove that the parameters appearing in (3.1) and (3.3) have to satisfy the inequalities:

$$m_{r-1} < m_r, \quad s_{m_{r-1}} < s_{m_r}, \quad 4j \geqslant m_r - m_{r-1} \geqslant 1,$$

$$s_{m_r} - m_r \geqslant 0, \quad k \leqslant 2N - m_r. \tag{3.4}$$

In (3.3) s_{m_l} indicates the number of sites involved; m_l indicates the total excitation of the system, namely, $m_l - N$ is the eigenvalue of $\Delta^{(N)}(H)$. $F^+_{s_{m_l}}$ is a shorthand for

$$\overbrace{id \otimes \ldots \otimes id}^{s_{m_l}-1} \otimes F^+ \otimes \overbrace{id \otimes \ldots \otimes id}^{N-s_{m_l}}$$

and we also define $\Delta^{(1)}(F^\pm) = F^\pm$.

Up to a normalization constant, the coefficients a_i are determined by

$$\Delta^{(s_{m_l})}(F^-)\Psi(m_l, s_{m_l}; \ldots; 0, 0) = 0. \tag{3.5}$$

In fact, a lengthy but straightforward computation shows that they are given by the recursive relation

$$a_{i+1} = a_i(-1)^{m_l - m_{l-1} - i} \frac{\left[\frac{m_l - m_{l-1} - i}{2}\right] + \frac{1}{2}(1 - (-1)^{m_l - m_{l-1} - i})(m_{l-1} - 2j(s_{m_{l-1}}))}{\left[\frac{i+1}{2}\right] - j(1 - (-1)^{i+1})}. \tag{3.6}$$

Another straightforward computation shows that $\Psi(m_l, s_{m_l}; \ldots; 0, 0)$ are eigenvectors for the operators $\Delta^{(s_{m_l})}(H)$:

$$\Delta^{(s_{m_l})}(H)\Psi(m_l, s_{m_l}; \ldots; 0, 0) = (m_l - s_{m_l})\Psi(m_l, s_{m_l}; \ldots; 0, 0). \tag{3.7}$$

Using Eqs. (3.5) and (3.7) it is not difficult to prove that the states (3.1) are indeed eigenstates of the set of observables (2.6) and then calculate the eigenvalues of the partial Casimir operator C_h. First of all we notice that

$$\Delta^{(N)}(H)\Phi(k; m_l, s_{m_l}; \ldots; 0, 0) = (k - N)\Phi(k; m_l, s_{m_l}; \ldots; 0, 0). \tag{3.8}$$

Now we consider the action of the partial Casimir C_h on the generic state (3.1). Using commutation relations (2.1)–(2.3), we rewrite C_h in the equivalent form:

$$\begin{aligned} C_h &= [\Delta^{(h)}(H)]^2 + 2\Delta^{(h)}(E^+)\Delta^{(h)}(E^-) + 2\Delta^{(h)}(E^-)\Delta^{(h)}(E^+) - \Delta^{(h)}(F^+)\Delta^{(h)}(F^-) + \Delta^{(h)}(F^-)\Delta^{(h)}(F^+) \\ &= [\Delta^{(h)}(H)]^2 + 4\Delta^{(h)}(E^+)\Delta^{(h)}(E^-) - \Delta^{(h)}(H) - 2\Delta^{(h)}(F^+)\Delta^{(h)}(F^-). \end{aligned}$$

As the coproduct is a superalgebra homomorphism, all the partial Casimirs C_h commute with the Nth coproduct of any of the generators, in particular

$$[C_h, \Delta^{(N)}(F^+)] = 0.$$

Thus we only have to worry about the action of the partial Casimir $C_h = \Delta^{(h)}(C)$, $(h = 2, \ldots, N)$ on the states (3.2):

$$\begin{aligned} C_h\Psi(m_l, s_{m_l}; \ldots; 0, 0) = &([\Delta^{(h)}(H)]^2 + 4\Delta^{(h)}(E^+)\Delta^{(h)}(E^-) - \Delta^{(h)}(H) - 2\Delta^{(h)}(F^+)\Delta^{(h)}(F^-)) \\ &\times \left(\sum_{i=0}^{m_l - m_{l-1}} a_i \Delta^{(s_{m_l}-1)}(F^+)^{m_l - m_{l-1} - i}(F^+_{s_{m_l}})^i\right)\Psi(m_{l-1}, s_{m_{l-1}}; \ldots; 0, 0). \end{aligned} \tag{3.9}$$

There are two possibilities: (i) $h \geqslant s_{m_l}$ and (ii) $h < s_{m_l}$.

In case (*i*), we know that

$$\Delta^{(h)}(F^-)\Psi(m_l,s_{m_l};\ldots;0,0)=0\rightarrow\Delta^{(h)}(E^-)\Psi(m_l,s_{m_l};\ldots;0,0)=0$$

and using Eq. (3.7) we obtain

$$C_h\Psi(m_l,s_{m_l};\ldots;0,0)=(h-m_l)(h-(m_l-1))\Psi(m_l,s_{m_l};\ldots;0,0). \tag{3.10}$$

On the other hand, in case (*ii*), the Casimir operator C_h commutes both with $F^+_{(s_{m_l})}$ and with $\Delta^{(s_{m_l}-1)}(F^+)$, so that we obtain

$$C_h\Psi(m_l,s_{m_l};\ldots;0,0)=\left(\sum_{i=0}^{m_l-m_{l-1}}a_i\Delta^{(s_{m_l}-1)}(F^+)^{m_l-m_{l-1}-i}(F^+_{s_{m_l}})^i\right)C_h\Psi(m_{l-1},s_{m_{l-1}};\ldots;0,0). \tag{3.11}$$

Again we have two possibilities: if $h\geqslant s_{m_l-1}$, we have

$$C_h\Psi(m_{l-1},s_{m_{l-1}};\ldots;0,0)=(h-(m_{l-1}))(h-(m_{l-1}-1))\Psi(m_{l-1},s_{m_{l-1}};\ldots;0,0), \tag{3.12}$$

otherwise C_h will work directly on $\Psi(m_{l-2},s_{m_{l-2}};\ldots;0,0)$.

We can proceed in this way until we will find a state $\Psi(m_i,s_{m_i};\ldots;0,0)$ for which we have $h\geqslant s_{m_i}$ (it will always exist, as $s_0=0$).

Then, using equations $\Delta^{(h)}(F^-)\Psi(m_i,s_{m_i},\ldots,0,0)=0$ and (3.7) we obtain

$$C_h\Psi(m_i,s_{m_i};\ldots;0,0)=(h-m_i)(h-(m_i-1))\Psi(m_i,s_{m_i};\ldots;0,0). \tag{3.13}$$

Summarizing,

$$C_h\Phi(k;m_l,s_{m_l};\ldots;0,0)=(h-m_i)(h-(m_i-1))\Phi(k;m_l,s_{m_l};\ldots;0,0), \tag{3.14}$$

where the value of $i\in\{0,1,\ldots,l\}$ is selected by the condition:

$$s_{m_i}\leqslant h<s_{m_{i+1}},\quad s_{m_{l+1}}=N+1. \tag{3.15}$$

IV. THE CASE OF SPIN $\frac{1}{2}$

In the special case $j=\frac{1}{2}$, m_l-m_{l-1} can take two values: 1 or 2. So we have two cases.

Case 1: $m_l-m_{l-1}=1\rightarrow i=0,1$,

$$a_{i+1}=a_i(-1)^{1-i}\frac{\left[\frac{1-i}{2}\right]+\frac{1}{2}(1-(-1)^{1-i})(m_{l-1}-s_{m_l}+1)}{\left[\frac{i+1}{2}\right]-\frac{1}{2}(1-(-1)^{i+1})}, \tag{4.1}$$

$$a_1=a_0(m_{l-1}-s_{m_l}+1). \tag{4.2}$$

Case 2: $m_l-m_{l-1}=2\rightarrow i=0,1,2$,

$$a_{i+1}=a_i(-1)^{i}\frac{\left[\frac{2-i}{2}\right]+\frac{1}{2}(1-(-1)^{i})(m_{l-1}-s_{m_l}+1)}{\left[\frac{i+1}{2}\right]-\frac{1}{2}(1-(-1)^{i+1})}, \tag{4.3}$$

$$a_1=-a_0, \tag{4.4}$$

$$a_2 = -a_1(m_{l-1} - s_{m_l} + 1) = a_0(m_{l-1} - s_{m_l} + 1). \tag{4.5}$$

In both cases, we have the condition

$$s_{m_l} > m_{l-1} + 1. \tag{4.6}$$

Indeed, from (3.4) it follows that $s_{m_l} \geqslant m_{l-1}+1$; however, if equality holds a_0 is the only nonvanishing coefficient, and (3.5) cannot be verified.

We rewrite the simultaneous eigenstates of the set of observables (2.6):

$$\Phi(k; m_l, s_{m_l}; \ldots; 0,0) = [\Delta^{(N)}(F^+)]^{k-m}\Psi(m_l, s_{m_l}; \ldots; 0,0), \tag{4.7}$$

$$N \geqslant s_{m_r} \geqslant m_r, \quad s_{m_r} > s_{m_{r-1}}, \quad m_r > m_{r-1},$$

$$s_{m_r} > m_{r-1} + 1, \quad m_l \leqslant k \leqslant 2N - m_l, \quad m_r - m_{r-1} = 1,2, \tag{4.8}$$

$$\Psi(m_l, s_{m_l}; \ldots; 0,0) = \sum_{i=0}^{m_l - m_{l-1}} a_i \Delta^{(s_{m_l}-1)}(F^+)^{m_l - m_{l-1} - i}(F^+_{s_{m_l}})^i \Psi(m_{l-1}, s_{m_{l-1}}; \ldots; 0,0). \tag{4.9}$$

To construct explicit formulas for the eigenstates we recall that, for spin $\frac{1}{2}$, the fundamental representation is three-dimensional: the $osp(1,2)$ generators read

$$H = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad E^+ = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad E^- = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$
$$F^+ = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \quad F^- = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 1 & 0 & 0 \end{pmatrix}. \tag{4.10}$$

Consequently the vacuum $\Psi(0,0)$ in the spin-$\frac{1}{2}$ representation is

$$\Psi(0,0) = \overbrace{\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \ldots \ldots \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}}^{N} \tag{4.11}$$

Of course, there are three possible single-particle states, namely,

$$\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix},$$

where

$$\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} = F^+ \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$$

denotes the fermionic state and

$$\begin{pmatrix}1\\0\\0\end{pmatrix} = E^{+}\begin{pmatrix}0\\1\\0\end{pmatrix}$$

the bosonic one.

Example: The three-body case: As an example, we give the explicit form of the states (4.9) in the case $N=3$ and for the choice of the normalization parameter $a_0=1$. This is the basis spanning the kernel of $\Delta^{(N)}(F^{-})$:

$$\Psi(0,0) = \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}$$

$$\Psi(1,2;0,0) = \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix},$$

$$\Psi(1,3;0,0) = \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} + \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - 2\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix},$$

$$\Psi(2,2;0,0) = \begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix},$$

$$\Psi(2,3;0,0) = \begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} + \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix} - \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix} - 2\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix},$$

$$\begin{aligned}\Psi(2,3;1,2;0,0) = {} & \begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - 2\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} \\ & - \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix} + \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix},\end{aligned}$$

$$\begin{aligned}\Psi(3,3;1,2;0,0) = {} & \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} - \begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix} - \begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix} + \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix} \\ & + \begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix} - \begin{pmatrix}0\\1\\0\end{pmatrix}\begin{pmatrix}1\\0\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix} - 2\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}.\end{aligned}$$

The remaining 3^3-7 eigenstates are constructed using formula (4.7).

V. A MORE GENERAL HAMILTONIAN

It is easily seen that the basis constructed in Sec. III diagonalizes the more general Hamiltonian $\mathcal{H}$:

$$\mathcal{H} = \lambda\Delta^{(N)}(C_b) + \mu\Delta^{(N)}(C_f), \tag{5.1}$$

which is an arbitrary linear combination of the bosonic and fermionic part of the Gaudin Hamiltonian $\mathcal{H}_{G_s}$, defined in (2.5),

$$\Delta^{(N)}(C) = \Delta^{(N)}(C_b) + \Delta^{(N)}(C_f), \tag{5.2}$$

$$C_b = H^2 + 2(E^+E^- + E^-E^+), \tag{5.3}$$

$$C_f = F^-F^+ - F^+F^-. \tag{5.4}$$

Indeed, $\mathcal{H}$ can be written as

$$\mathcal{H} = \mu\Delta^{(N)}(C) + (\lambda - \mu)\Delta^{(N)}(C_b), \tag{5.5}$$

which obviously commutes with $\Delta^{(h)}(C)$, $(h=2,\ldots,N)$ and $\Delta^{(N)}(H)$. So the complete set of observables

$$\{\Delta^{(N)}(H), C_2, \ldots, C_{N-1}, \mathcal{H}\} \tag{5.6}$$

has the same common eigenstates as the set of observables (2.6). The eigenvalue equation for the more general Hamiltonian $\mathcal{H}$ reads

$$\mathcal{H}\Phi(k;m_l,s_{m-l};\ldots;0,0) = \left(\lambda(N-m_l)(N-(m_l-2)) - \mu(N-m_l) + (\mu-\lambda)(1-(-1)^{k-m_l})\left(N-m_l+\frac{1}{2}\right)\right)\Phi(k;m_l,s_{m_l};\ldots;0,0). \tag{5.7}$$

VI. CONCLUDING REMARKS

A natural generalization of the model presented here will be associated with the q-deformation of the superalgebra $osp(1,2)$ starting from the results first derived by Kulish in the late 1980s, and using the later findings by Lukierski.[16–18] In the coproduct approach integrability of such q-deformed supersymmetric models will follow from the Hopf-algebra structure of $U_q(osp(1,2))$. A further extension is related to the investigation of superalgebras other than $osp(1,2)$, for instance $sl(1,2)$, already introduced within the Bethe ansatz approach.[14,15] Work is progressing in these directions.

APPENDIX

Here we shall prove that our procedure allows one to find all the lowest weight vectors of the representation $(D_{1/2})^N$, i.e., the representation of the N-site chain with spin $\frac{1}{2}$ at each site. These lowest weight vectors are the eigenvectors spanning $\mathrm{Ker}\Delta^{(N)}(F^-)$. In fact the construction of all the common eigenvectors of the set of observables (2.6) consists of two steps. First, we find the "lowest weight vectors" $\Psi(m_l,s_{m_l},\ldots,0,0)$, built up on the "total pseudovacuum" $\Psi(0,0)$. Then we construct all the remaining states by applying $\Delta^{(N)}(F^+)$ repeatedly on $\Psi(m_l,s_{m_l},\ldots,0,0)$. We note that the number of times we can apply $\Delta^{(N)}(F^+)$ on the state $\Psi(m_l,s_{m_l},\ldots,0,0)$ basically depends on the excitation-number m_l and on the magnetization-number k. First of all we notice that it holds:

$$(D_{1/2})^N = (D_{1/2})^{(N-1)} \otimes D_{1/2}. \tag{A1}$$

In general the dimension of $\mathrm{Ker}\Delta^{(N)}(F^-)$ is obtained recurrently from the Clebsch–Gordan series:

$$D_j \otimes D_k = D_{j+k} \oplus \ \ldots \ \oplus D_{|j-k|}, \tag{A2}$$

where $D_{j+k}, \ldots, D_{|j-k|}$ are irreducible representations, each one possessing one lowest weight vector. Thus, the representation $(D_j)^N$ it is associated with a number of lowest weight vectors, which corresponds to the number of irreducible representations appearing in its decomposition.

We have

$$(D_j)^N = \sum_{k=0}^{Nj} c_{j,k}^{(N)} D_k, \quad k = 0, \frac{1}{2}, 1, \ldots, \tag{A3}$$

where $c_{j,k}^{(N)}$ are the appropriate Clebsch-Gordan coefficients.

For $j = \frac{1}{2}$ (A3) obviously becomes

$$(D_{1/2})^N = \sum_{k=0}^{N/2} c_{1/2,k}^{(N)} D_k, \quad k = 0, \frac{1}{2}, 1, \ldots \ . \tag{A4}$$

The dimension of $\mathrm{Ker}\Delta^{(N)}(F^-)$ is given by $\Sigma_{k=0}^{N/2} c_{1/2,k}^{(N)}$. On the other hand (A4) can be written in the form (A1):

$$(D_{1/2})^N = \left(\sum_{k=0}^{(N-1)/2} c_{1/2,k}^{(N-1)} D_k \right) \otimes D_{1/2} = \sum_{k=0}^{(N-1)/2} c_{1/2,k}^{(N-1)} (D_k \otimes D_{1/2}). \tag{A5}$$

Thus, known all the lowest weight vectors of the representation $(D_{1/2})^{N-1}$, by induction we have all the lowest weight vectors of the representation $(D_{1/2})^N$. There are two different cases:

$$D_k \otimes D_{1/2} = D_{1/2}, \quad k = 0. \tag{A6}$$

There is only one lowest weight vector,

$$D_k \otimes D_{1/2} = D_{k-1/2} \oplus D_k \oplus D_{k+1/2}, \quad k \geqslant \tfrac{1}{2}. \tag{A7}$$

We have three lowest weight vectors.

So from the Clebsh–Gordan series we learn that the dimension of $\mathrm{Ker}\Delta^{(N)}(F^-)$ can be obtained recurrently from the dimension of $\mathrm{Ker}\Delta^{(N-1)}(F^-)$, observing that a generic state of the kernel of $\Delta^{(N-1)}(F^-)$ will give rise to one new state of the kernel of $\Delta^{(N)}(F^-)$ for $k=0$ and to three new states otherwise $(k \neq 0)$.

Has our procedure the same starting points and the same properties?

To both questions the answer is affirmative. First, concerning the starting point $(N=2)$, we notice that formula (A1) yields

$$(D_{1/2})^2 = D_0 \oplus D_{1/2} \oplus D_1 \tag{A8}$$

while with our techniques from (4.8), (4.9), and (4.11) we get

$$\Psi(0,0) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix},$$

$$\Psi(1,2;0,0) = \sum_{i=0}^{1} a_i (F_1^+)^{(1-i)} (F_2^+)^i \Psi(0,0) = a_0 F_1^+ \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} + a_1 F_2^+ \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix},$$

$$\Psi(2,2;0,0,0) = \sum_{i=0}^{2} a_i (F_1^+)^{(2-i)} (F_2^+)^i \Psi(0,0)$$

$$= a_0 (F_1^+)^2 \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} + a_1 F_1^+ F_2^+ \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} + a_2 (F_2^+)^2 \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \tag{A9}$$

and from the conditions on the coefficients a_i (4.2), (4.4), and (4.5) we get

$$\Psi(1,2;0,0) = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} - \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix},$$

$$\Psi(2,2;0,0) = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} - \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} - \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

So we have three states according to (A8).

Now we turn to consider the general case. Let $\psi^{(N-1)}(m_l, s_{m_l}, \ldots, 0, 0)$ be a state belonging to $\mathrm{Ker}(\Delta^{(N-1)}(F^-))$: we will obtain a state belonging to $\mathrm{Ker}(\Delta^{(N)}(F^-))$ by tensorizing it with a "spin down" state:

$$\psi^{(N)}(m_l, s_{m_l}, \ldots, 0, 0) = \psi^{(N-1)}(m_l, s_{m_l}, \ldots, 0, 0) \otimes \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}.$$

As $\psi^{(N-1)}(m_l, s_{m_l}, \ldots, 0, 0)$ spans $\mathrm{Ker}(\Delta^{(N-1)}(F^-))$ we get all states belonging to $\mathrm{Ker}(\Delta^{(N)}(F^-))$ having $s_{m_l} < N$. When generating the complementary subspace of $\mathrm{Ker}(\Delta^{(N)}(F^-))$ through our algorithm, we have to consider two different cases:

(1) $\psi^{(N-1)}(m_l, s_{m_l}, \ldots, 0, 0)$ is annihilated by $\Delta^{(N-1)}(H)$. In this case it holds $m_l - N + 1 = 0 \Rightarrow$ no further element of $\mathrm{Ker}(\Delta^{(N)}(F^-))$ can be constructed, as, from (4.6), it would have $s_{m_{l+1}} > N$.

(2) $\psi^{(N-1)}(m_l, s_{m_l}, \ldots, 0, 0)$ does not belong to $\mathrm{Ker}\Delta^{(N-1)}(H)$. it follows that $m_l \leqslant N-2$, and consequently two more states of $\mathrm{Ker}(\Delta^{(N)}(F^-))$ can be constructed, with $(m_{l+1}, s_{m_{l+1}}) = (m_l + 1, N)$ and $(m_{l+1}, s_{m_{l+1}}) = (m_l + 2, N)$, respectively.

Summarizing, we obtain one element of $\mathrm{Ker}(\Delta^{(N)}(F^-))$ starting from each $(N-1)$-particle state of spin 0, and three elements of $\mathrm{Ker}(\Delta^{(N)}(F^-))$ starting from each $(N-1)$-particle state of spin $k > 0$.

JOURNAL OF MATHEMATICAL PHYSICS **46**, 032110 (2005)

Two interacting electrons in a uniform magnetic field and a parabolic potential: The general closed-form solution

B. S. Kandemir
Department of Physics, Faculty of Sciences, Ankara University, 06100 Tandoğan, Ankara, Turkey

(Received 11 August 2004; accepted 6 November 2004; published online 18 February 2005)

We present an analytical analysis of the two-dimensional Schrödinger equation for two interacting electrons subjected to a homogeneous magnetic field and confined by a two-dimensional external parabolic potential. We have found the general closed-form expression for the eigenstates of the problem and its corresponding eigenenergies for particular values of magnetic field and spatial confinement length. The mathematical framework is just based on a rigorous solution of the three-term recursion relation among the coefficients that arises from the series solution of biconfluent Heun (BHE) equation, connected with the radial part of the Schrödinger equation for the internal motion. It is also shown that, by vanishing of Coulomb repulsion strength, the obtained explicit analytical solutions of BHE equation reduces to the well-known polynomials satisfying the associated Laguerre differential equation. Furthermore, in the presence of this interaction, the results are compared with those previously obtained in the literature for first few low-lying states, and are found to be in an exact agreement with them. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1850996]

The study of confined-electron systems is one of the central topics of current theoretical efforts in condensed matter physics, motivated by the recent developments of experimental techniques allowing the creation of ultrasmall nanostructures called quantum dots (QDs).[1–4] Of particular interest are disklike or two-dimensional QDs with two electrons. It is well known that electro-optical properties of such QDs are quite sensitive to the reduction of its dimensionality and to the application of an external magnetic field, and depend strongly on the electron–electron interaction. In recent literature, there exist a large amount of works[5–11] on QDs with two interacting electrons confined in a parabolic potential and/or a magnetic field, wherein a number of approaches, such as exact diagonalization scheme, perturbational and variational methods as well as numerical ones have been successfully applied to this problem. The problem becomes separable by introducing the center-of-mass and internal coordinates. Since the solution of Schrödinger equation for the center-of-mass motion is trivial and simply yields the well-known Fock–Darwin eigenstates,[12,13] the central quantity of interest in the problem therefore arises from the associated radial part of the Schrödinger equation for the relative motion.

From the quantum mechanical point of view, the fact that a system of two interacting Coulomb particles under the influence of a parabolic potential belongs to a class of quasi-exactly-solvable systems is of particular interest in itself. By a quasi-exactly-solvable quantum mechanical problem, it is intended the following: in contrast to the case of standard exactly solvable quantum mechanical problems whose entire spectra can easily be calculated by solving, in general, two-term recursion relations among the coefficients arising from the Frobenius solution to the relevant Schrödinger equation, occurrence of the three-term recursion relations in such problems does not admit an exact solution. Thus, it is only possible to find several eigenvalues and associated eigenstates analytically, under certain circumstances. Introducing accurate group theoretical description of the relevant problem, Turbiner[14] was initially able to show that such a quasi-exact-solvability is purely a consequence of a hidden sl_2 algebraic structure. As discussed in detail by Turbiner, the proof follows immediately from the fact that the eigenvalue equation for the qua-

dratic quasi-exactly-solvable operator constructed from the three generators of sl_2 algebra is directly related to the eigenvalue equation of the relevant problem. Historically, the particular analytical solutions were first found by Verçin[15] in the context of anyon theory, and later by Taut[16] for the two electron case. A different calculation based on the method of factorization was also presented for both Schrödinger and Klein–Gordon equations for a charged particle moving in Coulomb and magnetic fields.[17] There have also been recent other works dealing with this problem.[18–21]

In mathematical physics, the problem is directly linked with the third confluent case of Heun's equation. This equation is, in fact, a generalization of the confluent hypergeometric equation and is called biconfluent Heun equation (BHE).[22] Since it is well-known that, after certain transformations, many Schrödinger equations for a special class of confinement potentials can easily be reduced to BHE, several attempts to solve this equation have been performed in the literature.[23–27] The doubly anharmonic oscillator potential[25] and the potentials of the form $V(r)=\pm Z/r+gr+\lambda r^2$ (Refs. 23, 24, 26, and 27) are the well-known examples of this class of potentials. In particular, the latter (with $\lambda=0$ and with a minus sign) has been studied in the context of nonrelativistic quarkonium model in quantum chromodynamics.[28,29] As can also be easily checked, the problem of interest leads to the same kind of BHE, but with $g=0$ and with a plus sign. To the author's knowledge, so far an exact closed form for the polynomial solutions of this equation has not been achieved.

In this paper, we analyze analytically the two-dimensional (2D) Schrödinger equation for two interacting electrons in a parabolic potential under the influence of a constant, uniform magnetic field perpendicular to the plane of motion. We investigate for the first time its exact general closed form solution by solving the three-term recursion relation among the coefficients arising from the series solutions of the BHE equation. Moreover, we show that, as a particular case, our results reduces to the well-known associated Laguerre polynomials in the absence of the Coulomb interaction between electrons.

The Hamiltonian for a system of two interacting electrons of mass m^* and charge e in two space dimensions subjected to both a uniform magnetic field along the direction perpendicular to the plane and an external parabolic potential is given by

$$H=\sum_{j=1}^{2}\left\{\frac{1}{2m^*}\left[\mathbf{p}(\mathbf{r}_j)+\frac{e}{c}\mathbf{A}(\mathbf{r}_j)\right]^2+U(|\mathbf{r}_j|)\right\}+\frac{e^2}{\epsilon_\infty|\mathbf{r}_1-\mathbf{r}_2|}, \tag{1}$$

where $U(|\mathbf{r}_j|)=(1/2)\,m^*\omega^2\mathbf{r}_j^2$ is the single particle confinement potential, and $\mathbf{A}(\mathbf{r}_j)$ is the vector potential of the magnetic field and will be chosen in the symmetric gauge. It is well known that, by introducing the relative and center-of-mass coordinates, $\mathbf{r}=|\mathbf{r}_1-\mathbf{r}_2|$ and $\mathbf{R}=(\mathbf{r}_1+\mathbf{r}_2)/2$, respectively, Eq. (1) can be decoupled as the sum of two single particle Hamiltonians; one with mass $M=2m^*$ and charge $Q=2e$ and the other with mass $\mu=m^*/2$ and charge $q=e/2$, respectively. The former represents the center-of-mass motion and leads to an eigenvalue equation $H_{2D}(M,\omega)\Psi(\mathbf{R})=E_R\Psi(\mathbf{R})$, wherein H_{2D} is the usual 2D isotropic harmonic oscillator Hamiltonian with frequency ω. Here, ω describes a relation between both strength of magnetic field and the strength of spatial confinement, and is expressed by $\omega_c=QB_0/Mc$ and ω. as $\omega=[\omega_.^2+(\omega_c^2/4)]^{1/2}$. As for the relative motion, we are left with the eigenvalue equation $[H_{2D}(\mu,\omega)+(e^2/\epsilon_\infty|\mathbf{r}|)]\Psi(\mathbf{r})=E_r\Psi(\mathbf{r})$, wherein $H_{2D}(\mu,\omega)$ represent again 2D isotropic harmonic oscillator Hamiltonian with the same frequency ω, but with mass μ. Indeed, for both motion, ω's are the same since $\omega_c=qB_0/\mu c$ is equivalent to eB_0/m^*c as in the case that for the center-of-mass motion. Therefore, by setting $\Psi(\mathbf{r})=e^{im\varphi}R(r)$ due to the cylindrical symmetry of the problem, one can easily obtain the following second-order differential equation for the corresponding radial part of the relative motion

$$\frac{d^2R}{d\rho^2}+\frac{1}{\rho}\frac{dR}{d\rho}-\frac{m^2}{\rho^2}R-\rho^2R-\frac{u}{\rho}R+\tilde{\epsilon}R=0, \tag{2}$$

where $\tilde{\epsilon}=(2E_r-m\hbar\omega_c)/\hbar\omega$, $u=2\mu e^2/\epsilon_\infty\hbar^2\gamma$, $\rho=\gamma r$, $\gamma^2=\mu\omega/\hbar$. The asymptotic behaviors of Eq. (2) at $\rho\to 0$ and $\rho\to\infty$ suggest a solution of the form $R(\rho)=\rho^{\sigma|m|}e^{-\rho^2/2}F(\rho)$ where the function $F(\rho)$ satisfies the differential equation

$$\rho F''+(a-2\rho^2)F'+(d\rho-u)F=0, \tag{3}$$

in which $a=2\sigma|m|+1$ and $d=\tilde{\epsilon}-2(\sigma|m|+1)$. Here, σ takes just $+1$ and -1 values and thus specifies the regular and singular solutions of Eq. (2), respectively, of which only the former one is physically acceptable since the latter diverges at $\rho\to 0$. In fact, Eq. (3) is generally called the biconfluent Heun equation (BHE) in canonical form and its solution is characterized namely by $F(\rho)=N(2\sigma|m|,0,d+2(\sigma|m|+1);\rho)$.[22] The solution of Eq. (3) is obtained through the expansion $F(\rho)=\Sigma_{k=0}^{\infty}A_k\rho^k$ whose coefficients satisfy the following three-term recurrence relation:

$$(k+2)(k+1+a)A_{k+2}=uA_{k+1}-(d-2k)A_k, \tag{4}$$

with $A_0=1$ and $A_1=u/a$. Equation (4) is valid for all values of k greater than and equal to 2. The difficulty in solving Eq. (4) arises from the presence of the Coulomb term u. Without this term, the resulting recurrence relation can easily be solved to construct a series solution of Eq. (3) since all odd coefficients vanish. On the other hand, one can easily express A_{2k} in terms of A_0 by a successive induction, and hence obtains a polynomial of even powers of ρ by just breaking the resulting series off at a certain value of k, say n. However, in the presence of the Coulomb term, studies on Eq. (4) up to now have been restricted to the calculation of the first few terms due to calculational complexities, and could not be able to predict what the general expression for A_k will be. In the present work, by solving A_k's in terms of A_0 and A_1, recursively and taking into account as many terms as we need, and then collecting them together with the same power of ρ, we have achieved to find the general term with ρ^k systematically, and obtained the following infinite series:

$$\begin{aligned}F(\rho)=&\sum_{k=0}^{\infty}\frac{(a-1)!}{k!\,(a+k-1)!}u^k\rho^k-\sum_{k=2}^{\infty}\frac{(a-1)!}{k!\,(a+k-1)!}\sum_{\ell=0}^{k-2}\Theta^{a\ d}(\ell)u^{k-2}\rho^k\\&+\sum_{k=4}^{\infty}\frac{(a-1)!}{k!\,(a+k-1)!}\sum_{\ell=0}^{k-2}\sum_{p>\ell}^{k-3}\Theta^{a\ d}(\ell)\Theta^{a\ d}(p+1)u^{k-4}\rho^k\\&-\sum_{k=6}^{\infty}\frac{(a-1)!}{k!\,(a+k-1)!}\sum_{\ell=0}^{k-2}\sum_{p>\ell}^{k-3}\sum_{r>p}^{k-4}\Theta^{a\ d}(\ell)\Theta^{a\ d}(p+1)\Theta^{a\ d}(r+2)u^{k-6}\rho^k+\cdots,\end{aligned} \tag{5}$$

in which we have defined $\Theta^{a\ d}(\ell)=(\ell+1)(a+\ell)(d-2\ell)$. Equation (5) can easily be rearranged into a more compact form

$$F(\rho)=\sum_{k=0}^{\infty}\frac{(a-1)!}{k!\,(a+k-1)!}\left[u^k-\sum_{s=0(k\geqq 2)}^{[k/2]}(-1)^s u^{k-2s-2}\prod_{t=0}^{s}{\sum_{\ell=0}^{k-t-2}}'\Theta^{a\ d}(\ell+t)\right]\rho^k, \tag{6}$$

where the symbol $[k/2]$ stands for $(k-2)/2$ and $(k-3)/2$ for even and odd k's, respectively. In Eq. (6), the prime above the summation in the square bracket denotes the constraint on summations and implies that only those values of indexes of subsequent summations which satisfy the constraint $\ell>p>r\cdots$ are allowed such that, e.g., for a fixed ℓ, only those values of $\Theta^{a\ d}(p+1)$ in the second sum for which $\ell>p$ will contribute, and so on. Alternatively, it is also possible to write Eq. (5) or equivalently Eq. (6) in the form

$$F(\rho)=\sum_{k=0}^{\infty}\frac{(a-1)!}{k!\,(a+k-1)!}\left[1+\sum_{s=1}^{\infty}(-1)^s\frac{k!\,(a+k-1)!}{(k+2s)!(a+k+2s-1)!}\rho^{2s}\prod_{t=0}^{s-1}\sum_{\ell=0}^{k+2s-t-2}{}'\Theta^{a\ d}(\ell+t)\right]u^k\rho^k. \tag{7}$$

It should be noted that we must have a solution that remains finite as $\rho\to\infty$. Such a solution exists only if the series in Eq. (6) or Eq. (7) are truncated to terminate at a certain value of k to have a finite series. On the other hand, the function $F(\rho)$ becomes a polynomial if and only if the conditions $A_{n+1}=0$ and $d=2n$ are simultaneously fulfilled. Thus, the only solution of Eq. (3) that satisfies these quantization conditions can be finally written as

$$F_{n|m|}(\rho)=\sum_{k=0}^{n}\left[\sum_{s=0(k\geqq 2)}^{[k/2]}\frac{(-1)^s}{k!\,(a)_k}u^{k-2s}\Delta^{a\ n}(k,s)\right]\rho^k. \tag{8}$$

with

$$u^2=\sum_{s=0}^{\|n/2\|}(-1)^s u^{-2s}\prod_{t=0}^{s}\sum_{\ell=0}^{n-t-1}{}'\Theta^{a\ 2n}(\ell+t), \tag{9}$$

where the symbol $\|n/2\|$ stands for $(n-1)/2$ and $(n-2)/2$ for odd and even n's, respectively. In Eq. (8) we have defined a new symbol

$$\Delta^{a\ n}(k,s)=\prod_{t=0}^{s-1}\sum_{\ell=0}^{k-t-2}{}'\Theta^{a\ 2n}(\ell+t),$$

provided that $\Delta^{a\ n}(k,0)=1$, and used the Pochhammer symbol $(a)_k=\Gamma(a+k)/\Gamma(a)$. Therefore, the corresponding energy eigenvalues can be written as $\tilde{\epsilon}_{n\ |m|}=2(n+|m|+1)$. The connection of these eigenvalues with the content of Eq. (9) can be better understood when they are made dimensionless, by expressing them in terms of standard energy and length units, i.e., the effective Bohr radius a_0^* and the Rydberg constant $\mathcal{R}_0^*$. Therefore, one rewrites these eigenvalues and Eq. (9) in the form

$$\bar{E}_r(n,\ |m|)=(n+|m|+1)\bar{\omega}(n,\ |m|)+\frac{m\bar{\omega}_c(n,\ |m|)}{2},$$

$$\bar{\omega}^{-1}(n,\ |m|)=\sum_{s=0}^{\|n/2\|}(-1)^s\bar{\omega}^s(n,\ |m|)\prod_{t=0}^{s}\sum_{\ell=0}^{n-t-1/}\Theta^{a\ 2n}(\ell+t),$$

respectively, where $\bar{E}_r=\bar{E}_r/2\mathcal{R}_0^*$ and $u^2=2\mathcal{R}_0^*/\hbar\omega=1/\bar{\omega}$ are used. Once, a general solution of Eq. (3) has been obtained in the form Eq. (8) together with Eq. (9), one can easily test whether it actually satisfies the differential equation. This can be done by replacing Eq. (8) into Eq. (3), or equivalently by replacing A_k's, which are given by the terms with square brackets in Eq. (8), back into Eq. (4). In the absence of the Coulomb interaction between electrons, i.e., $u=0$, the only nonvanishing term in Eq. (7) is obtained by setting $k=0$, which in fact means that one must retain only the terms with $k=0$, $k=2$, $k=4$, and so on, in Eq. (5). Finally, one finds

$$F(\rho)=1+\sum_{s=1}^{\infty}(-1)^s\frac{(a-1)!}{(2s)!(a+2s-1)!}\prod_{t=0}^{s-1}\sum_{\ell=0}^{2s-t-2\phi}{}'\Theta^{a\ d}(\ell+t)\rho^{2s}. \tag{10}$$

It is also straightforward to verify that the infinite series in Eq. (10) becomes the associated Laguerre polynomials if it terminates at a certain value of s. This is possible if and only if d is an integer, i.e., $d=4n$. This procedure is presented in Appendix A. To check the consistency of our results with those previously obtained in the literature we also give the first few polynomials

together with its associated eigenvalues resulting from Eq. (8) and Eq. (9), respectively, in Appendix B.

In summary, we have explicitly constructed the exact closed-form solution for the problem of two interacting electrons in both uniform magnetic field and external parabolic potential. Besides the polynomial solutions of the problem being obtained from an infinite series for the first time, an alternative representation for the Laguerre polynomials is achieved. The procedure introduced here can easily be extended to its 3D counterpart and can be applied well to the problem of the two- and three-dimensional hydrogen atom in a magnetic field. The results obtained in this paper might also lead to help in understanding the behavior of confined many electron systems under magnetic field, due to the fact that these systems may be considered as interacting pairs. In particular, the present results will be useful in variational and perturbational treatments of the exact spectra of a few particle systems, and thus provide a further insight on discussion of the fractional nature of such systems.

ACKNOWLEDGMENTS

The author would like to thank Professor T. Altanhan and Professor A. Verçin for helpful discussions and comments. Part of the work has been supported by the Scientific and Technical Research Council of Turkey (TUBITAK) under TBAG Project No. 2214 (102T093).

APPENDIX A

Here, we have presented the key steps of how infinite series given by Eq. (10) become the associated Laguerre polynomials if it is terminated. For this purpose, we start with the expansion of the relevant series given by Eq. (10), i.e.,

$$F(\rho) = 1 - \frac{1}{2!\,(a+1)a}\prod_{t=0}^{0}{\sum_{\ell=0}^{0}}'\Theta^{a\ d}(\ell+t)\rho^2 + \frac{1}{4!\,(a+3)(a+2)(a+1)a}\prod_{t=0}^{1}{\sum_{\ell=0}^{2-t}}'\Theta^{a\ d}(\ell+t)\rho^4$$
$$- \frac{1}{6!\,(a+5)(a+4)(a+3)(a+2)(a+1)a}\prod_{t=0}^{2}{\sum_{\ell=0}^{4-t}}'\Theta^{a\ d}(\ell+t)\rho^6 + \cdots . \tag{A1}$$

By using the definition of $\Theta^{a\ d}(\ell)$ and obeying the constraints on each sum, we obtain the following relations for the products in Eq. (A1):

$$\prod_{t=0}^{0}{\sum_{\ell=0}^{0}}'\Theta^{a\ d}(\ell+t) = \Theta^{a\ d}(0) = 1.a.d,$$

$$\prod_{t=0}^{1}{\sum_{\ell=0}^{2-t}}'\Theta^{a\ d}(\ell+t) = \sum_{\ell=0}^{2}\Theta^{a\ d}(\ell)\sum_{p>\ell}^{1}\Theta^{a\ d}(p+1) = \Theta^{a\ d}(0)\Theta^{a\ d}(1) = 1.3.a.(a+2).d.(d-4),$$

$$\prod_{t=0}^{2}{\sum_{\ell=0}^{4-t/}}'\Theta^{a\ d}(\ell+t) = \sum_{\ell=0}^{4}\Theta^{a\ d}(\ell)\sum_{p>\ell}^{3}\Theta^{a\ d}(p+1)\sum_{r>p}^{2}\Theta^{a\ d}(r+2)$$
$$= \Theta^{a\ d}(0)\Theta^{a\ d}(2)\Theta^{a\ d}(4) = 1.3.5.a.(a+2).(a+4).d\,.\,(d-4).(d-8), \tag{A2}$$

Of course, to get an idea about the behavior of the series one can explore more and more terms with products in Eq. (A1), by following the same procedure as used in Eq. (A2). Therefore, by replacing each term in Eq. (A2) back into Eq. (A1) and collecting the resulting terms into a sum again, one can easily find out what the general term of the series is, and then arrives at a more compact series expansion of Eq. (A1),

$$F(\rho) = 1 + \sum_{s=1}^{\infty} (-1)^s \frac{d.(d-4)\cdots(d-4s+4)}{2s\cdots 4.2.(a+2s-1)\cdots(a+1)} \rho^{2s}. \tag{A3}$$

Now, it remains to show that this infinite series is equal to the associated Laguerre polynomials when it is terminated at a certain value of s. For this, we require $d=4n$ which leads to the energy levels $\tilde{\epsilon}_{n\ |m|}=2(|m|+1)+4n$, i.e., $E_r(n,\ |m|)=(2n+|m|+1)\hbar\omega+(m/2)\hbar\omega_c$. Finally, after necessary algebra, one finds the explicit form of the generalized Laguerre polynomials in the form

$$F_{n|m|}(\rho) = \sum_{s=0}^{n} \frac{(-1)^s}{s!} \binom{n+|m|}{n-s} (\rho^2)^s = L_n^{|m|}(\rho^2) = N(2|m|, 0, 4n + 2(|m|+1); \rho),$$

where $\binom{n}{s} = \Gamma(n+1)/s!\,\Gamma(n+1-s)$ are the binomial coefficients. While, without a spatial confinement, the energy levels connected with the function $F_{n|m|}(\rho)$ are the well-known Landau levels, i.e., $E_r(n,\ |m|)=(2n+|m|+m+1)\hbar\omega_c/2$, in the absence of a magnetic field they reproduce the usual energy levels of 2D isotropic oscillator, i.e., $E_r(n,\ |m|)=(2n+|m|+1)\hbar\omega$. .

APPENDIX B

In this appendix, some special results of Eq. (8) together with Eq. (9) have been presented to show that they reproduce the standard results obtained in the literature. First, we start with $n=1$ ($d=2$) which has $\tilde{\epsilon}_{1\ |m|}=2(|m|+1)+2$; so the solution satisfying Eq. (3) is conveniently extracted from Eq. (8) as

$$F_{1\ |m|}(\rho) = \sum_{k=0}^{1} \frac{(a-1)!}{k!\,(a+k-1)!} u^k \rho^k = 1 + \frac{u}{a}\rho \tag{B1}$$

with the corresponding condition on ω, $u^2=1.a.d$ which is calculated from Eq. (9) with the help of the first equality in Eq. (A1). Second, we consider the case $n=2$ ($d=4$), where $\tilde{\epsilon}_{2\ |m|}=2(|m|+1)+4$. For this case, from Eq. (8) we obtain a solution

$$\begin{aligned} F_{2\ |m|} &= \sum_{k=0}^{2} \frac{(a-1)!}{k!\,(a+k-1)!} \left[u^k - \sum_{s=0(k\geqq 2)}^{0} (-1)^s u^{k-2s-2} \prod_{t=0}^{s} \sum_{\ell=0}^{k+2s-t}{}' \Theta^{a\ d}(\ell+t) \right] \rho^k \\ &= 1 + \frac{u}{a}\rho + \frac{1}{2!\,(a+1)a}[u^2 - 1.a.d]\rho^2 \end{aligned} \tag{B2}$$

with $(u^2-1.a.d)-2(a+1)(d-2)=0$, where, again, Eq. (9) has been used here, but together with the help of the second equality in Eq. (A1), besides the first one. We shall finally consider the case $n=3$ ($d=6$), where $\tilde{\epsilon}_{3\ |m|}=2(|m|+1)+6$. In this case, it is straightforward to show that one can easily obtain the following solution:

$$\begin{aligned} F_{3\ |m|} &= \sum_{k=0}^{3} \frac{(a-1)!}{k!(a+k-1)!} \left[u^k - \sum_{s=0(k\geqq 2)}^{[k/2]} (-1)^s u^{k-2s-2} \prod_{t=0}^{s} \sum_{\ell=0}^{k+2s-t}{}' \Theta^{a\ d}(\ell+t) \right] \rho^k \\ &= 1 + \frac{u}{a}\rho + \frac{1}{2!(a+1)a}[u^2 - 1.a.d]\rho^2 + \frac{u}{3!(a+2)(a+1)a}[(u^2 - 1.a.d) - 2(a+1)(d-2)]\rho^3 \end{aligned} \tag{B3}$$

with $u^4=u^2[1.a.d+2(a+1)(d-2)+3(a+2)(d-4)]-1.a.d.3.(a+2)(d-4)$. In the last step of Eq. (B3) we have used again Eq. (A1). All the exact analytical results presented here are in complete agreement with the results obtained in Refs. 15 and 16.

Mathematical Physics/AlbaNova, Royal Institute of Technology, SE-10691 Stockholm, Sweden

(Received 23 July 2004; accepted 13 October 2004; published online 4 February 2005)

We consider bosons on (Euclidean) $\mathbb{R}^4$ that are minimally coupled to an external Yang–Mills field. We compute the logarithmically divergent part of the cutoff regularized quantum effective action of this system. We confirm the known result that this term is proportional to the Yang–Mills action. We use pseudodifferential operator methods throughout to prepare the ground for a generalization of our calculation to the noncommutative four-dimensional Moyal plane $\mathbb{R}^4_\theta$. We also include a detailed comparison of our cutoff regularization to heat kernel techniques. In the case of the noncommutative space, we complement the usual technique of asymptotic expansion in the momentum variable with operator theoretic arguments in order to keep separated quantum from noncommutativity effects. We show that the result from the commutative space $\mathbb{R}^4$ still holds if one replaces all pointwise products by the noncommutative Moyal product. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1839277]

I. INTRODUCTION

In this paper we study the determinant of certain differential operators. Such determinants naturally arise in quantum field theory at the one loop level. As the determinant of an operator on an infinite dimensional Hilbert space is not an *a priori* well-defined object, one must choose some regularization scheme. The latter means generally the choice of a recipe for how to replace the formal expressions by something that is both amenable to a rigorous definition and close in its properties. In our case of the regularization of determinants, a common starting point is the well-known identity

$$\log\det A = \mathrm{Tr}\log A, \tag{1}$$

which holds for (finite dimensional) matrices A. The task is now to give meaning to the trace on the right-hand side, since the operators of interest do not have a finite trace in general. In this paper, we restrict the trace to run over a subspace of our Hilbert space only. Loosely speaking, this subspace is spanned by wave functions that have a momentum expectation value smaller than a certain cutoff Λ. The precise definition will follow below. It is known that the cutoff regularized logarithm of the determinant, now viewed as a function of Λ, contains a term that scales like $\log\Lambda$ for large Λ. This term is closely related to the Wodzicki residue for the operator under consideration, a quantity that is of interest in the study of infinite dimensional geometry, see Ref. 15 for a recent review.

Motivated by the observation[14] that for fermions minimally coupled to an external Yang–Mills field, the logarithmically divergent part of the cutoff regularized logarithm of the determinant of the (massive) Dirac operator is proportional to the corresponding Yang–Mills action, we consider the case of bosons in an external Yang–Mills field on $\mathbb{R}^4$. With our work, we confirmed that the above result also applies to the bosonic case. The former result was proposed to be interpreted in two ways. On the one hand, the spectral action principle[2] states that the spectrum of the Dirac

operator should provide exhaustive information about the complete bare action including the Yang–Mills expression. On the other hand, it is known that the logarithmically divergent part plays a critical role in the selection of the finite part of an effective action because of its behavior under rescaling of the regularization parameter Λ. From the latter viewpoint, it is desirable that the logarithmically divergent term in the regularized effective action produce expressions that occur in the complete bare action already.

To understand the connection between these two interpretations, it is interesting to consider the case of (scalar) bosons coupled to an external Yang–Mills field.

It is generally accepted that space–time might lose its smooth properties at very small scales. One possible mathematical framework for this is noncommutative geometry.[3] We are interested in a particular example, the four-dimensional (4D) Moyal plane,[10] also known as noncommutative flat space $\mathbb{R}^4_\theta$. Roughly speaking, the 4D Moyal plane differs from its Euclidean counterpart $\mathbb{R}^4$ in that there is an uncertainty relation for the simultaneous measurement of coordinates coming from the nonvanishing commutator

$$[x^\mu, x^\nu] = i\Theta^{\mu\nu}.$$

Here x^μ, $\mu = 1, \ldots, 4$ are coordinates of $\mathbb{R}^4$ and Θ is some (antisymmetric) matrix. In this paper we take Θ to be proportional to the constant symplectic matrix, see Eq. (16). We refer to Ref. 5 for a treatment of Lorentz covariant generalization of this equation.

Although the results of our analysis for the case of bosons on the commutative space $\mathbb{R}^4$ are not new and can be found already in deWitt's book,[4] our consistent use of pseudodifferential operator methods technically makes possible the generalization to the noncommutative Moyal plane. We refer to Refs. 18 and 11 for a generalization of heat kernel regularization calculations to the noncommutative torus and the Moyal plane, respectively.

The remainder of this paper is structured as follows. Section II sets up the notation used in our work and states the results in the form of two propositions. Section III provides the necessary tools from the theory of pseudodifferential operators. The proofs of the statements from Sec. II can be found in Secs. IV and V, with detailed calculations postponed to the appendix. Also, Sec. IV contains additional arguments that make contact with the case of fermions on $\mathbb{R}^4$ and to an alternative regularization scheme, the heat kernel regularization. Section VI concludes with what we consider to be the lessons from our calculations.

II. NOTATION AND STATEMENT OF THE RESULTS

We consider the Klein–Gordon operator with minimally coupled external field on the four-dimensional flat Euclidean space $\mathbb{R}^4$, given by

$$\begin{aligned}\Box_A = D_A^\mu D_{A,\mu} = (\partial^\mu + ieA^\mu)(\partial_\mu + ieA_\mu) &= \partial^\mu\partial_\mu + ie\partial^\mu A_\mu + 2ieA^\mu\partial_\mu - e^2A^\mu A_\mu \\ &= \Box_0 + ie\partial^\mu A_\mu + 2ieA^\mu\partial_\mu - e^2A^\mu A_\mu. \qquad (2)\end{aligned}$$

Here, $\mu = 1, \ldots, 4$ are the (Euclidean) indices of $\mathbb{R}^4$, $\partial_\mu = \partial/\partial x^\mu$, and A_μ are gl_N-valued Yang–Mills fields on $\mathbb{R}^4$. The bosonic wave functions are elements of the Hilbert space

$$\mathcal{H} = L^2(\mathbb{R}^4) \otimes \mathbb{C}^N_{\text{color}},$$

where the last factor carries a gl_N representation from the external Yang–Mills fields. As an unbounded operator in $\mathcal{H}$, $\Box_0$ can be defined on smooth functions in $\mathcal{H}$ by its formal expression and then extended to a self-adjoint operator. We assume the Yang–Mills fields A_μ to be regular, i.e., to be smooth and to fall off (together with all their derivatives) at infinity like $|x|^{-2-\epsilon}$, $\epsilon > 0$. The latter assumption ensures that all our spatial integrals below will converge. Also, for regular A_μ, the self-adjoint extension of $\Box_A$ can be computed from that of $\Box_0$. In what follows, we will not distinguish between the formal expression for $\Box_A$ and its self-adjoint extension.

We consider the cutoff regularized logarithm of the determinant of the massive Klein–Gordon operator

$$S_\Lambda(A) := \mathrm{Tr}_\Lambda\left(\log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right) - \log\left(\frac{-\Box_0 + m^2}{\Lambda_0^2}\right)\right), \tag{3}$$

where the cutoff regularized Hilbert space trace Tr_Λ sums over states with momentum bounded by Λ. More precisely, if D is an operator on $\mathcal{H}$ and Tr denotes the operator trace on $\mathcal{H}$, then the cutoff trace is defined by

$$\mathrm{Tr}_\Lambda D := \mathrm{Tr}\{\theta(\Lambda^2 + \Box_0)D\}, \tag{4}$$

where θ is the Heaviside step function. As is well-known, the expression (3) occurs in quantum field theory as the one-loop effective action. Using the formal identity $\log\det = \mathrm{Tr}\log$, it can be viewed as the generalization of the determinant to operators on an infinite-dimensional Hilbert space.

The parameter Λ_0 has been introduced to balance physical dimensions. It also provides a useful tool for cross checking since in the result of our calculations, it should cancel. Moreover, in the definition of the regularized determinant, we have subtracted a term containing the free Klein–Gordon operator as a reference. Whereas this term is needed for turning the expression under the trace into a pseudodifferential operator, it also comes in—at least in the corresponding expression for fermions—when interpreting the determinant as a subsummation of the one loop diagrams in the Feynman path integral.[16]

The regularized determinant (3) has an asymptotic expansion in Λ for large values of Λ as

$$S_\Lambda(A) = c_2(A,m)\Lambda^2 + c_1(A,m)\Lambda^1 + c_{\log}(A,m)\log\Lambda + c_0(A,m) + \cdots, \tag{5}$$

where the dots indicate terms that vanish at least like $1/\Lambda$ in the limit $\Lambda \to \infty$.

We are interested in the coefficient $c_{\log}(A,m) \equiv c_{\log}(A)$.

Proposition II.1: For the regularized determinant $S_\Lambda(A)$ defined as above, the coefficient $c_{\log}(A,m)$ is proportional to the Yang–Mills action of A_μ,

$$c_{\log}(A) = \frac{1}{96\pi^2}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N(F^{\mu\nu}F_{\mu\nu}), \tag{6}$$

where tr_N is the matrix trace in gl_N and the curvature $F_{\mu\nu}$ of A_μ is given by

$$F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu + ie[A_\mu, A_\nu]. \tag{7}$$

The proof is contained in Sec. IV A. Note that the numerical factor in front of $F^{\mu\nu}F_{\mu\nu}$ differs from the one obtained in Ref. 4 Eqs. (24.16), etc., by $\frac{1}{2}$. By the considerations below, this can be understood as coming from the usage of a nongauge invariant regularization for $S_\Lambda(A)$. However, the latter allows a straightforward generalization to the noncommutative Moyal plane.

It is well-known that

$$(\not{D}_A)^2 = \mathbb{1}_4\Box_A - ie\sigma\cdot F, \tag{8}$$

where $\not{D}_A = \gamma^\mu(\partial_\mu + ieA_\mu)$, $\sigma\cdot F = \frac{1}{4}\sigma^{\mu\nu}F_{\mu\nu} = \frac{1}{2}\gamma^\mu\gamma^\nu F_{\mu\nu}$, and γ^μ are the four-dimensional gamma matrices, i.e., 4×4 matrices that satisfy

$$\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2\eta^{\mu\nu}\mathbb{1}_4, \tag{9}$$

$\eta^{\mu\nu}$ being the Euclidean flat metric. Using this identity, we are able to rederive the result of Ref. 14 concerning the determinant of the Dirac operator. This is demonstrated in Sec. IV B. Our

computation has the advantage of avoiding extensive calculations involving the gamma matrices γ^μ.

It is at first sight surprising that the nongauge invariant definition of the determinant yields a gauge invariant logarithmically divergent part. It is therefore natural to consider the manifestly gauge invariant expression

$$\widetilde{S}_\Lambda(A) := \mathrm{Tr}_\Lambda^{\Box_A} \log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right) - \mathrm{Tr}_\Lambda \log\left(\frac{-\Box_0 + m^2}{\Lambda_0^2}\right), \tag{10}$$

where in the first trace, the cutoff is taken with respect to the operator $\Box_A$ rather than $\Box_0$. As before, $\widetilde{S}_\Lambda(A)$ has an asymptotic expansion,

$$\widetilde{S}_\Lambda(A) = \widetilde{c}_2(A,m)\Lambda^2 + \widetilde{c}_1(A,m)\Lambda^1 + \widetilde{c}_{\log}(A,m)\log\Lambda + \widetilde{c}_0(A,m) + \cdots, \tag{11}$$

the dots subsuming terms scaling at least like $1/\Lambda$. A calculation in Sec. IV C reveals that the coefficient$\widetilde{c}_{\log}(A,m) \equiv \widetilde{c}_{\log}(A)$ in (11) equals half of the corresponding expression in $S_\Lambda(A)$,

$$\widetilde{c}_{\log}(A) = \tfrac{1}{2} c_{\log}(A). \tag{12}$$

This result agrees with the one obtained in Ref. 4.

A widely used alternative regularization of the determinant of a differential operator makes use of the ζ-function and the asymptotic expansion of the trace of the heat kernel operator. We want to compare our coefficient with earlier results that have been obtained with these methods[6] [see also the review articles Ref. 1, and references therein]. In this approach, one considers asymptotic expansions for the trace of the heat operator,

$$K(f,D) := \mathrm{Tr}_{L^2}(f e^{-tD}) = t^{-2} a_0(f,D) + t^{-3/2} a_1(f,D) + \cdots + a_4(f,D) + \cdots, \tag{13}$$

for small t, where f is some function on $\mathbb{R}^4$ that serves as a regulator for the spatial integrals. The rightmost dots indicate terms that fall off at least linearly in t. As the heat trace must be integrated on the positive axis together with the function t, the logarithmically divergent contribution to the heat kernel regularized trace is given by the coefficient $a_4(f,D)$. For the comparison of this coefficient to our result, let $c_{(\cdot)}(f,A)$, etc., be the coefficients in the expansion of $S_\Lambda(A)$, now spatially regularized in the same way as $K(f,D)$. In Sec. IV D, it is shown that the coefficient $\widetilde{c}_{\log}(f,A)$ in the asymptotic expansion of $\widetilde{S}_\Lambda(A)$ differs from the corresponding expression obtained via heat kernel regularization methods by a term proportional to m^4,

$$-\widetilde{c}_{\log}(f,A) + \frac{1}{32\pi^2} m^4 \int_{\mathbb{R}^4} \mathrm{d}^4x\, f(x) = a_4\left(f, \frac{-\Box_A + m^2}{\Lambda_0^2}\right). \tag{14}$$

The additional mass term can be traced back to the usage of the reference operator $-\Box_0 + m^2$ in (3). The calculations using the heat operator can be generalized to the noncommutative 4D torus[18] and the noncommutative Moyal plane.[11] The only change one encounters is that in all expressions, the commutative product of functions must be replaced by the noncommutative product $\star$.

The main part of our paper is devoted to the study of the case of the 4D Moyal plane as the underlying (noncommutative) "space." In this case, the algebra of functions on $\mathbb{R}^4$ is furnished with the (noncommutative) Moyal–Weyl product $\star := \star_\Theta$. The latter is defined by the integral formula

$$f \star g(x) = \frac{1}{(2\pi)^4} \int_{\mathbb{R}^4} \int_{\mathbb{R}^4} \mathrm{d}^4y\, \mathrm{d}^4\xi\, e^{i\xi(x-y)} f(x - \tfrac{1}{2}\Theta\xi) g(y), \tag{15}$$

where Θ is a 4×4 matrix defined by

$$\Theta = \theta \begin{pmatrix} 0 & \mathbb{1}_2 \\ -\mathbb{1}_2 & 0 \end{pmatrix} \tag{16}$$

for the real parameter θ. In our calculations we do not use asymptotic expansions of this product in powers of θ.

On the Moyal plane, we consider the generalized Klein–Gordon operator

$$\Box_A^\theta = \partial^\mu \partial_\mu + ie(\partial^\mu A_\mu) \star + 2ieA^\mu \star \partial_\mu - e^2(A^\mu \star A_\mu) \star , \tag{17}$$

where $f\star$ is a short-hand notation for the operator that $\star$-multiplies smooth wave functions in $\mathcal{H}$ from the left by the (smooth) function f. We define $S_\Lambda^\theta(A)$ and $c_{(\cdot)}^\theta(A,m)$ in analogy with the formulas (3) and (5) above. Then, our main result is the following.

Proposition II.2: For minimally coupled bosonic fields on the (noncommutative) 4D Moyal plane, the above formula (6) holds with the commutative products replaced by the noncommutative Moyal–Weyl product, i.e., we have

$$c_{\log}^\theta(A) = \frac{1}{96\pi^2} \int_{\mathbb{R}^4} \mathrm{d}^4x \, \mathrm{tr}_N F^{\theta,\mu\nu} \star F_{\mu\nu}^\theta, \tag{18}$$

where

$$F_{\mu\nu}^\theta = \partial_\mu A_\nu - \partial_\nu A_\mu + e[A_\mu, A_\nu]_\star . \tag{19}$$

III. PSEUDODIFFERENTIAL OPERATOR METHODS

In our work, we deal with a restricted class of *pseudodifferential operators* (ΨDO) which suits our purposes. The statements below may be found in Shubin's book.[17] We consider ΨDOs that act on smooth and compactly supported wave functions u as [$x=(x^\mu)$, $\mu=1,\ldots,4$, and likewise y, p describe points in $\mathbb{R}^4$; $xp=\Sigma_\mu x^\mu p^\mu$ denotes the scalar product, $|x|$ is the length of the vector x]

$$(Au)(x) = \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \int_{\mathbb{R}^4} \mathrm{d}^4y \, \sigma[A](x,p) u(y) e^{ip(x-y)},$$

where the *symbol* $\sigma[A]$ of A is a smooth function that allows an *asymptotic expansion* in p according to

$$\sigma[A](x,p) \sim \sum_{r=0}^{\infty} \sigma_{m-r}[A](x,p).$$

Here, $\sim$ means that for each s, the finite sum $\Sigma_{r=0}^s \sigma_{m-r}[A]$ approximates $\sigma[A]$ up to a function that falls off at most as $|p|^{m-(s+1)}$ for large $|p|$,

$$\left| \partial_x^\alpha \partial_p^\beta \left(\sigma[A](x,p) - \sum_{r=0}^{s} \sigma_{m-r}[A](x,p) \right) \right| \leqslant C_{\alpha\beta} (1+|p|^2)^{[m-(s+1)-|\beta|]/2}$$

for all multi-indices $\alpha=(\alpha_1,\ldots,\alpha_4)$, $\beta=(\beta_1,\ldots,\beta_4)$, where

$$\partial_x^\alpha = \left(\frac{\partial}{\partial x^1}\right)^{\alpha_1} \cdots \left(\frac{\partial}{\partial x^4}\right)^{\alpha_4},$$

$|\alpha| = \alpha_1 + \cdots + \alpha_4$, and $C_{\alpha\beta}$ are constants. The number m above is called the *order* of A. For a given symbol, there are many different asymptotic expansions. One particular choice is the asymptotic

expansion in terms of *homogeneous symbols* $\sigma^h_{m-r}[A]$, i.e., smooth functions that in addition satisfy

$$\sigma^h_{m-r}[A](x,\lambda p) = \lambda^{m-r}\sigma^h_{m-r}[A](x,p) \quad \text{for } |p| = 1,\ \lambda > 1.$$

The first term $\sigma^h_m[A]$ in an asymptotic expansion in homogeneous summands is termed the *principal symbol*.

An asymptotic expansion encodes the information of a given symbol $\sigma[A]$ up to an additive function that falls off in p like a Schwartz test function. This piece of information will be sufficient for our purposes.

While the expansion in homogeneous symbols is appropriate to discuss invariant notions such as the residue of a ΨDO, the expansions obtained from recursion relations in the computation of resolvents of operators are not of this type in general. The two types, however, are related to each other through a finite resummation at every order of the infinite sum.

The action of the ΨDOs considered here can be extended to smooth functions, leading to the useful formula

$$\sigma[A](x,p) = e^{-ixp}Ae^{ixp}.$$

For the product AB of two ΨDOs A and B with respective symbols $\sigma[A]$ and $\sigma[B]$, one has the following asymptotic expansion of the symbol:

$$\sigma[A] * \sigma[B](x,p) = \sigma[AB](x,p) \sim \sum_\alpha \frac{(-i)^{|\alpha|}}{\alpha!}\partial_p^\alpha\sigma[A](x,p)\partial_x^\alpha\sigma[B](x,p), \tag{20}$$

where the sum runs over all 4-indices α and we have used the notation $\alpha! = \alpha_1!\cdots\alpha_4!$. We will use $*$ whenever we mean this product of symbols, in contrast to the noncommutative product $\star$ defined later on.

Interpreting A as an operator in the Hilbert space $L^2(\mathbb{R}^4)\otimes\mathbb{C}^N$, we can compute the trace of A from its symbol according to

$$\mathrm{Tr}(A) = \int_{\mathbb{R}^4}\frac{d^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\ \mathrm{tr}_N\,\sigma[A](x,p),$$

where tr_N denotes the matrix trace over the gl_N-part of the symbol.

For operators A that do not have a (finite) trace, one considers the cutoff trace

$$\mathrm{Tr}_\Lambda(A) = \int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\ \mathrm{tr}_N\,\sigma[A](x,p).$$

Clearly, this coincides with the previous definition of the cutoff regularized trace, Eq. (4).

The above expression has an asymptotic expansion in Λ, as can be seen from the asymptotic expansion of the symbol $\sigma[A]$ in homogeneous symbols. In this case, there appears a term scaling like $\log\Lambda$. On the other hand, the *Wodzicki residue*[19] of the operator A is defined as the angular p-integral and the spatial integral of the coefficient $\sigma^h_{-4}[A]$ in the homogeneous asymptotic expansion,

$$\mathrm{Res}(A) \coloneqq \frac{1}{(2\pi)^4}\int_{|p|=1}\mathrm{d}\Omega_p\int_{\mathbb{R}^4}\mathrm{d}^4x\ \sigma^h_{-4}[A](x,p),$$

whenever the integral exists. It is known that for compact spatial manifolds this quantity determines completely the factor in front of the $\log\Lambda$ term in the asymptotic expansion of $\mathrm{Tr}_\Lambda(A)$. By abuse of notation, and motivated by the above observation, in our calculations we will use the expression $\mathrm{Res}(\cdots)$ to mean the factor in front of the $\log\Lambda$ term in the corresponding cutoff regularized trace.

IV. THE CASE $M=\mathbb{R}^4$

A. The logarithmically divergent part

In this section we compute the logarithmically divergent part of the bosonic effective action on $\mathbb{R}^4$. We define the regularized bosonic action as

$$S_\Lambda(A) := \mathrm{Tr}_\Lambda\left(\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right). \tag{21}$$

We use the following expression for the logarithm:

$$\log(1+a)=\int_0^1 \frac{\mathrm{d}s}{s}(1-(1+sa)^{-1}) \tag{22}$$

and recall the definition for the regularized trace of a pseudodifferential operator

$$\mathrm{Tr}_\Lambda(a) := \int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\sigma[a](x,p) \tag{23}$$

to get

$$\begin{aligned}&\mathrm{Tr}_\Lambda\left(\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right)\\&\quad=-\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\int_0^1\frac{\mathrm{d}s}{s}\mathrm{tr}_N\left(\sigma\left[\left(I+s\left(\frac{-\Box_A+m^2}{\Lambda_0^2}-I\right)\right)^{-1}\right]\right.\\&\qquad\left.-\sigma\left[\left(I+s\left(\frac{-\Box_0+m^2}{\Lambda_0^2}-I\right)\right)^{-1}\right]\right).\end{aligned} \tag{24}$$

As shown in the first section of the Appendix, the symbol of the resolvent of $\Box_A$ must satisfy the following recursion relation:

$$\sigma[(c_1I+c_2\Box_A)^{-1}](p,x)=\frac{1}{c_1-c_2p^2}-\frac{c_2}{c_1-c_2p^2}(\Box_A+2ip_\mu D_A^\mu)\sigma[(c_1I+c_2\Box_A)^{-1}](p,x).$$

Its formal solution is given by

$$\sigma[(c_1I+c_2\Box_A)^{-1}](x,p)=(c_1I+c_2(-p^2+\Box_A+2ip^\mu D_{A\mu}))^{-1}1,$$

which can be understood as defining an asymptotic expansion, see the Appendix for details. In particular, for our values of c_1 and c_2, we derive

$$\sigma\left[\left(I+s\left[\frac{-\Box_A+m^2}{\Lambda_0^2}-I\right]\right)^{-1}\right]\sim\sum_{n=0}^{\infty}\frac{(s/\Lambda_0^2)^n}{\left(1-s+\frac{sm^2}{\Lambda_0^2}+\frac{s}{\Lambda_0^2}p^2\right)^{n+1}}(\Box_A+2ip_\mu D_A^\mu)^n1.$$

Here and in all what follows, the 1 on the right-hand side (rhs) means that the operators $\Box_A$, $D_{A,\mu}$ should be applied to the N-dimensional constant vector.

Inserting this expansion into the integral and noting that the second symbol just cancels the first term in the expansion we then have

$$\mathrm{Tr}_\Lambda\left(\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right)=-\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\sum_{n=1}^{\infty}\frac{1}{\Lambda_0^{2n}}\int_0^1\mathrm{d}s\frac{s^{n-1}}{\left(1+s\left(\frac{p^2+m^2}{\Lambda_0^2}-1\right)\right)^{n+1}}$$
$$\times\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N(\Box_A+2ip_\mu D_A^\mu)^n1. \tag{25}$$

In the first section of the Appendix we will expand explicitly the terms in (25) and pick out the logarithmically diverging ones. Setting all the relevant terms together then gives

$$\begin{aligned}
&\mathrm{Res}\left(\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right)\\
&=-\frac{1}{8\pi^2}m^2\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\Box_A-\frac{1}{16\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\Box_A^2+\frac{1}{8\pi^2}m^2\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\Box_A+\frac{1}{12\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\Box_A^2\\
&\quad+\frac{1}{24\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu\Box_AD_{A\mu}-\frac{1}{48\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N(\Box_A^2+D_A^\nu D_A^\mu D_{A\nu}D_{A\mu}+D_A^\mu\Box_AD_{A\mu})\\
&=\frac{1}{48\pi^2}\left(\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu\Box_AD_{A\mu}-\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\nu D_A^\mu D_{A\nu}D_{A\mu}\right).
\end{aligned}\tag{26}$$

A short calculation shows that the terms under the trace are equal to $(e^2/2)F^{\mu\nu}F_{\mu\nu}$, so we finally get the result

$$\mathrm{Res}\left(\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right)=\frac{e^2}{96\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_NF^{\mu\nu}F_{\mu\nu} \tag{27}$$

which proves Proposition II.1.

B. Comparison with fermion calculations

To incorporate fermions, we have to extend the Hilbert space. We take $\mathcal{H}_{\mathrm{fermion}}=L^2(\mathbb{R}^4)\otimes\mathbb{C}^N_{\mathrm{color}}\otimes\mathbb{C}^4_{\mathrm{spin}}$, where the last factor carries a representation of the Dirac gamma matrixes γ^μ, $\mu=1,\ldots,4$.

We begin by computing the square of the Dirac operator $\not{D}$. First some definitions

$$D_{A\mu}=\partial_\mu+ieA_\mu,$$

$$\not{D}_A=\gamma^\mu(\partial_\mu+ieA_\mu).$$

A short calculation yields the well-known formula

$$(\not{D}_A)^2=\mathbb{1}_4\Box_A+\tfrac{1}{2}\gamma^\mu\gamma^\nu[D_{A\mu},D_{A\nu}]=\mathbb{1}_4\Box_A+ie\sigma\cdot F.$$

Here, $\mathbb{1}_4$ denotes the 4×4 unit matrix and

$$\sigma\cdot F:=\tfrac{1}{4}\sigma^{\mu\nu}F_{\mu\nu}=\tfrac{1}{2}\gamma^\mu\gamma^\nu F_{\mu\nu}$$

for the matrices $\sigma^{\mu\nu}:=[\gamma^\mu,\gamma^\nu]$. We use the above identity to obtain

$$(-i\not{D}_A+im)(-i\not{D}_A-im)=-(\not{D}_A)^2+m^2=-\mathbb{1}_4\Box_A-ie\sigma\cdot F+m^2.$$

Taking the logarithm on both sides, for the left-hand side we arrive at

$$\log\left(\frac{-i\not{D}_A+im}{\Lambda_0}\right)\left(\frac{-i\not{D}_A-im}{\Lambda_0}\right)=\log\left(\frac{-i\not{D}_A+im}{\Lambda_0}\right)+\log\left(\frac{-i\not{D}_A-im}{\Lambda_0}\right),$$

while the right-hand side gives

$$\begin{aligned}\log(-\mathbb{1}_4\Box_A-ie\sigma\cdot F+m^2)&=\log\left(\frac{\mathbb{1}_4(-\Box_A+m^2)}{\Lambda_0^2}\right)\left(\mathbb{1}_4-\frac{ie}{-\Box_A+m^2}\sigma\cdot F\right)\\&=\log\left(\frac{\mathbb{1}_4(-\Box_A+m^2)}{\Lambda_0^2}\right)\\&\quad+\log\left(\mathbb{1}_4-\frac{ie}{-\Box_A+m^2}\sigma\cdot F\right)+\text{commutator terms}.\end{aligned}$$

The extra commutator terms can be computed from the Baker–Campbell–Hausdorff formula.

It is known that on compact manifolds the Wodzicki residue vanishes on commutators.[19] We therefore expect that from the above expression, the commutator terms will not contribute to the logarithmically divergent part of the regularized trace. In the second section of the Appendix it is shown explicitly that this is indeed the case. Rather than using integration-by-parts arguments, this is readily seen from the fact that the $\mathbb{C}_{\text{spin}}$-trace over $\sigma\cdot F$ gives zero. Also, the pertinent contributions from the first two terms of the right-hand side are calculated in the Appendix.

Furthermore, from Langmann's results[14] we know that $\mathrm{Tr}_\Lambda \log[(-i\not{D}_A+im)/\Lambda_0]$ is independent of the sign of m, so we have

$$\begin{aligned}2\,\mathrm{Tr}_\Lambda\log\left(\frac{-i\not{D}_A+im}{\Lambda_0}\right)&=4\,\mathrm{Tr}_\Lambda\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)+\frac{e^2}{16\pi^2}\log\Lambda\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}(\sigma\cdot F)^2\\&\quad+\text{terms finite in }\Lambda,\end{aligned}$$

where the trace tr runs over both the $\mathbb{C}^N_{\text{color}}$ and the $\mathbb{C}^4_{\text{spin}}$ parts. Performing the trace over the γ-matrices yields

$$\mathrm{tr}(\sigma\cdot F)^2=-2\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}.$$

The result is then

$$\begin{aligned}\mathrm{Tr}_\Lambda\log\left(\frac{-i\not{D}_A+im}{\Lambda_0}\right)&=2\,\mathrm{Tr}_\Lambda\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\frac{e^2}{16\pi^2}\log\Lambda\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}+\cdots\\&=\left(\frac{e^2}{48\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}-\frac{e^2}{16\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}\right)\log\Lambda+\cdots\\&=-\frac{e^2}{24\pi^2}\log\Lambda\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}+\text{terms finite in }\Lambda,\end{aligned}$$

in agreement with Ref. 14.

C. Dependence on the regularization scheme

So far we have been looking at the cutoff regularized determinant

$$S_\Lambda(A) = \mathrm{Tr}_\Lambda\left(\log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right) - \log\left(\frac{-\Box_0 + m^2}{\Lambda_0^2}\right)\right). \tag{28}$$

As the cutoff in this regularization is taken with respect to the reference operator $\Box_0$, the above expression is not manifestly gauge invariant. It is thus surprising that the coefficient $c_{\log}(A)$ turns out to be gauge invariant.

One could use the spectral projection with respect to $\Box_A$ instead, but again the resulting expression would fail to be manifestly gauge invariant now because of the reference term $\log[(-\Box_0+m^2)/\Lambda_0^2]$. The latter had to be included to make the calculations tractable by the methods of classical ΨDOs.

Of course, there are gauge invariant regularization schemes such as heat kernel regularization (see the review articles in Ref. 1 for recent developments in this field) readily available. However, cutoff regularized traces seem to be closer to physical intuition.

An acceptable, manifestly gauge invariant expression would be

$$\widetilde{S}_\Lambda(A) := \mathrm{Tr}_\Lambda^{\Box_A} \log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right) - \mathrm{Tr}_\Lambda \log\left(\frac{-\Box_0 + m^2}{\Lambda_0^2}\right), \tag{29}$$

where

$$\mathrm{Tr}_\Lambda^{\Box_A} \log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right) := \mathrm{Tr}\left\{P_\Lambda(\Box_A)\log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right)\right\}$$

is defined using the spectral projections $P_\Lambda(\Box_A) := \theta(\Lambda^2-\Box_A)$ of $\Box_A$, where θ denotes the Heaviside step function that is zero for negative arguments and equal to 1 otherwise. It turns out that $\widetilde{S}_\Lambda(A)$ has an asymptotic expansion as

$$\widetilde{S}_\Lambda(A) = \tilde{c}_2(A)\Lambda^2 + \tilde{c}_1(A)\Lambda + \tilde{c}_{\log}(A)\log\Lambda + \cdots . \tag{30}$$

The dots indicate terms that are finite in the large Λ limit.

In this section we want to compare the coefficient $\tilde{c}_{\log}(A)$ of the logarithmically divergent part in the above expression to the coefficient $c_{\log}(A)$ computed earlier.

A short calculation reveals how to proceed,

$$\begin{aligned}
&\mathrm{Tr}_\Lambda^{\Box_A} \log\frac{-\Box_A + m^2}{\Lambda_0^2} - \mathrm{Tr}_\Lambda^{\Box_0} \log\frac{-\Box_0 + m^2}{\Lambda_0^2} \\
&\quad= \mathrm{Tr}_\Lambda^{\Box_0}\left(\log\frac{-\Box_A + m^2}{\Lambda_0^2} - \log\frac{-\Box_0 + m^2}{\Lambda_0^2}\right) + (\mathrm{Tr}_\Lambda^{\Box_A} - \mathrm{Tr}_\Lambda^{\Box_0})\left(\log\frac{-\Box_A + m^2}{\Lambda_0^2} - \log\frac{-\Box_0 + m^2}{\Lambda_0^2}\right) \\
&\qquad+ (\mathrm{Tr}_\Lambda^{\Box_A} - \mathrm{Tr}_\Lambda^{\Box_0})\log\frac{-\Box_0 + m^2}{\Lambda_0^2}.
\end{aligned} \tag{31}$$

Obviously, the coefficient $\tilde{c}_{\log}(A)$ receives contributions from three different terms, only the first of which is given by $c_{\log}(A)$. From the calculation of the pertinent part in the third term, it will be apparent that the second one in fact does not contribute to $\tilde{c}_{\log}(A)$. For the computation of the third term in (31), however, we must introduce an additional regulator that deals with the noncompactness of $\mathbb{R}^4$. Let f be a smooth, compactly supported function on $\mathbb{R}^4$, interpreted as a multiplication operator on $\mathcal{H}$. Then

$$\mathrm{Tr}\left\{ f\theta(\Lambda^2+\Box_A)\log\frac{-\Box_0+m^2}{\Lambda_0^2}\right\}=\int_{\mathbb{R}^4}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}f(x)\sigma[\theta(\Lambda^2+\Box_A)]\sigma\left[\log\frac{-\Box_0+m^2}{\Lambda_0^2}\right]+\cdots . \tag{32}$$

The dots indicate contributions from the star product of symbols that are uniformly bounded in Λ. Use has been made of the fact that f and $\sigma[\log(-\Box_0+m^2)/\Lambda_0^2]$ are independent of p and x, respectively.

As a next step, we need to derive an asymptotic expansion for the symbol of the theta function. We start with the following sum expression for a smooth approximation of the Heaviside θ function (Ref. 9, p. 248, etc.):

$$\theta_\epsilon(x)=\frac{1}{\epsilon}\sum_{r=-\infty}^{\infty}\frac{e^{i\omega_r 0^+}}{x+i\omega_r}=\frac{e^{-x0^+}}{e^{-x\epsilon}+1},\quad \omega_r=(2r+1)\pi/\epsilon, \tag{33}$$

for $\epsilon>0$. The step function is regained in the limit $\epsilon\to\infty$. Using this equation, we derive an asymptotic expansion for the symbol of $\theta(\Lambda^2+\Box_A)$ as (for details we refer to the third section of the Appendix)

$$\sigma[\theta_\epsilon(\Lambda^2+\Box_A)]=\frac{1}{2\pi i}\int \mathrm{d}z\, e^{iz\epsilon}\sigma\left[\frac{1}{z-i(\Lambda^2+\Box_A)}\right]\sim\sum_{n=0}^{\infty}\frac{1}{n!}\delta_\epsilon^{(n-1)}(\Lambda^2-p^2)(\Box_A+2ip^\mu D_{A\mu})1.$$

As before, for mnemonic purposes, this asymptotic series can be summarized as

$$\sigma[\theta(\Lambda^2+\Box_A)](x,p)=\theta(\Lambda^2-p^2+\Box_A+2ip^\mu D_{A\mu})1, \tag{34}$$

where the x dependence originates from the external fields A.

Combining our results, we find

$$\begin{aligned}&\mathrm{Tr}\left\{ f\theta(\Lambda^2+\Box_A)\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right\}-\mathrm{Tr}\left\{ f\theta(\Lambda^2+\Box_0)\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right\}\\&\quad=\sum_{n=1}^{\infty}\frac{1}{n!}\int_{\mathbb{R}^4}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\, f(x)\delta_\epsilon^{(n-1)}(\Lambda^2-p^2)\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\mathrm{tr}_N\{(\Box_A+2ip^\mu D_{A\mu})^n1\}.\end{aligned}$$

Obviously, we can now drop the regulator f.

For large Λ, the δ_ϵ-functions cancel the radial p-integration. Therefore, the only contributions to the logarithmically divergent part in the above expression can originate from terms where the derivatives of the δ_ϵ-functions exclusively hit the trace under the integral of the measure d^4p but not the factor $\log[(-\Box_0+m^2)/\Lambda_0^2]$. This is only possible as long as $2(n-1)\leqslant 3+n$ (the derivatives of δ_ϵ count twice because of the p^2 in the argument, and the 3 on the rhs comes from the measure d^4p) and hence $n\leqslant 5$. Moreover, since the angular p-integration over an odd number of factors p^μ gives always zero, the $n=5$ term cannot contribute either.

As shown in the Appendix, we can now expand the powers $(\Box_A+2ip^\mu D_{A\mu})^n1$ for $n\leqslant 4$, perform the angular p-integrations, substitute $p^2\to u$ and use partial integration to get rid of the derivatives of the δ_ϵ-functions. We arrive at

$$
\begin{aligned}
&\mathrm{Tr}_{\Lambda}^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_{\Lambda}^{\Box_0}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\frac{1}{16\pi^2}\int_1^\infty du\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta_\epsilon(\Lambda^2-u)u(1-1)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\Box_A 1+\frac{1}{16\pi^2}\int_1^\infty du\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\\
&\qquad\times\delta_\epsilon(\Lambda^2-u)\left(\frac{1}{2}-\frac{2}{3}+\frac{1}{6}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\mathrm{tr}_N\Box_A^2 1+\frac{1}{16\pi^2}\int_1^\infty du\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta_\epsilon(\Lambda^2-u)(-\tfrac{1}{3}+\tfrac{1}{6})\\
&\qquad\times\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N D_A^\mu\Box_A D_{A\mu}1+\frac{1}{16\pi^2}\int_1^\infty du\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\frac{1}{6}\delta_\epsilon(\Lambda^2-u)\\
&\qquad\times\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1+\cdots\\
&\quad=-\frac{1}{96\pi^2}\log\left(\frac{\Lambda^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N D_A^\mu\Box_A D_{A\mu}1\\
&\qquad+\frac{1}{96\pi^2}\log\left(\frac{\Lambda^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1+\cdots\\
&\quad=-\frac{1}{2}\frac{1}{96\pi^2}\log\left(\frac{\Lambda^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}+\cdots,
\end{aligned}
$$

where the dots indicate finite or polynomially divergent contributions.

Finally, we will turn back to the second term in (31). The difference as compared to the previous calculation is that now the symbol of the operator under the traces has an asymptotic expansion that is a power series in $1/p$. Therefore, in contrast to the above, no logarithmically divergent term will occur in a large Λ expansion.

Combining these results with our previous expression for $c_{\log}(A)$, we find

$$
\tilde{c}_{\log}(A)=\frac{1}{2}\frac{1}{96\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\mu\nu}F_{\mu\nu}=\frac{1}{2}c_{\log}(A). \tag{35}
$$

D. Comparison with heat kernel regularization

In this section we want to compare our results with previous ones in the literature[18,11] obtained by heat kernel techniques. For a given differential operator D, we consider the trace of the heat operator for D,

$$
K(t,f,D)=\mathrm{Tr}(fe^{-tD}),
$$

where the auxiliary smooth function $f(x)$ is introduced to make spatial integrals converge on $\mathbb{R}^n$. We write the effective action for D as

$$
S=-\int_0^\infty\frac{\mathrm{d}t}{t}K(t,f,D).
$$

Here the formula $\log\det(D)=\mathrm{Tr}\log(D)$ has been used again together with the following formal expression for the logarithm:

$$\log \lambda = -\int_0^\infty \frac{dt}{t} e^{-t\lambda},$$

which holds up to an (infinite) integration constant.

There is an asymptotic expansion for the heat trace as $t \to 0$ given by

$$\mathrm{Tr}(f e^{-tD}) \sim \sum_{k \geqslant 0} t^{(k-n)/2} a_k(f,D).$$

Next we define the ζ-function for D as follows:

$$\zeta(s,f,D) = \mathrm{Tr}(f D^{-s}).$$

Writing the ζ-function in terms of the heat trace as

$$\zeta(s,f,D) = \frac{1}{\Gamma(s)} \int_0^\infty dt\, t^{s-1} K(t,f,D),$$

we see that $\Gamma(s)\zeta(s,f,D)$ has simple poles at the points $s=(n-k)/2$ and the complex residue at $s=(n-k)/2$ is given by

$$\mathrm{Res}_{s=(n-k)/2}(\Gamma(s)\zeta(s,f,D)) = a_k(f,D). \tag{36}$$

From the asymptotic expansion of the heat trace and the integral formula for the effective action S we see that the logarithmically divergent part is given when $k=n$ so we are interested in computing the coefficient $a_n(f,(-\Box_A+m^2)/\Lambda_0^2)$. In our case $n=4$.

The first task is to compute the ζ-function for the operator $(-\Box_A+m^2)/\Lambda_0^2$. From the definition of the ζ-function we have

$$\zeta\left(s,f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right) = \int_{\mathbb{R}^4} \frac{d^4p}{(2\pi)^4} \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}_N\, \sigma[f] * \sigma\left[\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)^{-s}\right](x,p).$$

We next use the expansion

$$(a+x)^{-s} = \sum_{r=0}^\infty (-1)^r \frac{\Gamma(s+r)}{r!\Gamma(s)} a^{-(r+s)} x^r$$

to write the symbol of $(-\Box_A+m^2)/\Lambda_0^2$ as

$$\sigma\left[\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)^{-s}\right] = \left(\frac{p^2+m^2-\Box_A-2ip^\mu D_{A\mu}}{\Lambda_0^2}\right)^{-s}$$
$$\sim \sum_{r=0}^\infty (-1)^r \frac{\Gamma(s+r)}{r!\Gamma(s)} \Lambda_0^{2s} \frac{1}{p^{2(s+r)}} (m^2-\Box_A-2ip^\mu D_{A\mu})^r 1.$$

Splitting the integration in the ζ-function into two parts we then have

$$\zeta\left(s,f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right) = \int_{|p|\leqslant 1} \frac{d^4p}{(2\pi)^4} \int_{\mathbb{R}^4} d^4x\, f(x) \mathrm{tr}_N\, \sigma\left[\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)^{-s}\right](x,p)$$
$$+ \sum_{r=0}^\infty \frac{(-1)^r\,\Gamma(s+r)}{r!\Gamma(s)} \Lambda_0^{2s} \int_1^\infty |p|^3 d|p| \frac{1}{p^{2(r+s)}} \int_{S^3} \frac{d\Omega_p}{(2\pi)^4} \int_{\mathbb{R}^4} d^4x\, f(x)$$
$$\times \mathrm{tr}_N (m^2-\Box_A-2ip^\mu D_{A\mu})^r 1. \tag{37}$$

Using the fact that under the angular integration odd powers of p give zero we can write

$$\int_{S^3}\frac{d\Omega_\xi}{(2\pi)^4}\int_{\mathbb{R}^4} d^4x\, f(x)\mathrm{tr}_N(m^2-\Box_A-2ip^\mu D_{A\mu})^r 1=\sum_{k=0}^{[r/2]}(-2i)^{2k}p^{2k}\,\mathrm{d}(f,r,2k)$$

for some functions $\mathrm{d}(f,r,2k)$ of f, $\Box_A$ and $D_{A\mu}$ determined from the expansion of $(m^2-\Box_A-2ip^\mu D_{A\mu})^r$. In particular, we have

$$\mathrm{d}(f,0,0)=\frac{1}{8\pi^2}\int_{\mathbb{R}^4} d^4x\, f(x).$$

We then find

$$\zeta\left(s,f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right)=\chi(s)+\sum_{r=0}^{\infty}\frac{(-1)^r\Lambda_0^{2s}\Gamma(s+r)}{r!\Gamma(s)}\int_1^\infty |p|^3\,\mathrm{d}|p|\frac{1}{p^{2(r+s)}}\sum_{t=0}^{[r/2]}(-2i)^{2t}p^{2t}\,\mathrm{d}(f,r,2t),$$

where $\chi(s)$ denotes the first integral in the rhs of (37), a holomorphic function in s. We can evaluate explicitly the p-integral in the above expression to obtain the following formula for the ζ-function:

$$\zeta\left(s,f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right)=\chi(s)+\frac{\Lambda_0^{2s}}{\Gamma(s)}\sum_{r=0}^{\infty}\sum_{t=0}^{[r/2]}\frac{1}{2}\frac{(-1)^{r+t}4^t\Gamma(s+r)}{r!}\frac{1}{s-(2-r+t)}\mathrm{d}(f,r,2t). \tag{38}$$

There are two parts of the ζ-function contributing to the residue at $s=0$; the gamma function $\Gamma(s+r)$ and the poles of $1/[s-(2-r+t)]$. The first one gives a contribution for $r=0$ and the latter one when $r=2+t$. From the summation we see that $t\leqslant r/2$ so it follows that only the terms with $t\leqslant 2$ contribute to the residue:

$$\begin{aligned}a_4\left(f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right)&=\mathrm{Res}_{s=0}\,\Gamma(s)\zeta\left(s,f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right)\\&=\chi(0)-\frac{1}{4}\mathrm{d}(f,0,0)+\sum_{t=0}^{2}\frac{4^t\Gamma(2+t)}{(2+t)!}\frac{1}{2}\mathrm{d}(f,t+2,2t),\end{aligned}$$

where $\chi(0)$ is given by

$$\chi(0)=\frac{1}{(2\pi)^4}\int_{|p|\leqslant 1}d^4p\int_{\mathbb{R}^4}d^4x\,f(x)=\int_0^1|p|^3\,\mathrm{d}|p|\mathrm{d}(f,0,0)=\frac{1}{4}\mathrm{d}(f,0,0).$$

We have thus obtained the following expression for $a_4(f,(-\Box_A+m^2)/\Lambda_0^2)$:

$$a_4\left(f,\frac{-\Box_A+m^2}{\Lambda_0^2}\right)=\sum_{t=0}^{2}\frac{1}{2}\frac{4^t\Gamma(2+t)}{(2+t)!}\mathrm{d}(f,t+2,2t).$$

We now compute directly the logarithmically divergent part of $S_\Lambda(A)$. For this we need the following formula:

$$\sigma\left[\log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)-\log\left(\frac{-\Box+m^2}{\Lambda_0^2}\right)\right]=\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}\frac{1}{p^{2r}}[(m^2-\Box_A-2ip^\mu D_{A\mu})^r-m^{2r}].$$

Note that for this asymptotic expansion, we have divided the recursion formula (A8) differently.

We split the p-integration in the trace into two parts to get

$$\mathrm{Tr}_\Lambda \log\left(f\left(\frac{-\Box_A+m^2}{\Lambda_0^2}-\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\right)$$
$$= \text{finite terms in } \Lambda + \sum_{r=1}^{\infty}\sum_{t=0}^{[r/2]}\frac{(-1)^{r+1}}{r}\int_1^\Lambda |p|^3\,\mathrm{d}|p|\frac{1}{p^{2(r-t)}}(-1)^t 4^t\,\mathrm{d}(f,r,2t)$$
$$-\sum_{r=1}^{\infty}\frac{(-1)^{r+1}}{r}m^{2r}\int_1^\Lambda |p|^3\,\mathrm{d}|p|\frac{1}{p^{2r}}\mathrm{d}(f,0,0).$$

The logarithmically divergent part is then given by

$$c_{\log}(A) = -\sum_{t=0}^{2}4^t\frac{1}{t+2}\mathrm{d}(f,t+2,2t)+\frac{1}{2}m^4\,\mathrm{d}(f,0,0)$$

so we finally have the result

$$-\frac{1}{2}c_{\log}(A)+\frac{1}{4}m^4\,\mathrm{d}(f,0,0)=a_4(f,(-\Box_A+m^2)/\Lambda_0^2).$$

Remarks: (1) The coefficients $\mathrm{d}(f,r,2k)$ defined below Eq. (37) are given by spatial integrals over the $gl(N)$-trace of certain polyomials in the external fields and their derivatives. They can be easily computed by expanding the power on the left-hand side of the defining formula, using the well-known expressions for the angular p-integration of polynomials in p^μ.

(2) Note that the argument relating a_{-4} and $c_{\log}$ did not use the specific form of the coefficients $\mathrm{d}(f,r,2k)$. Therefore, it can be extended to a larger class of operators.

(3) Combining Eqs. (36) and (38), we have a formula for the calculation of the coefficients a_k at hand. In particular, evaluating the function $\chi(s)$ for negative integer s amounts to the computation of the symbol of $(-\Box_A+m^2)^l$ for positive integer powers of l. The latter can be obtained from the formula

$$\sigma[(-\Box_A+m^2)^{l+1}]=(p^2+m^2-\Box_A-2ip_\mu D_A^\mu)\sigma[(-\Box_A+m^2)^l]$$

and the symbol of $-\Box_A+m^2$.

V. GENERALIZATION TO THE MOYAL PLANE

A. The Moyal plane $\mathbb{R}^4_\theta$: generalities

In this section, we want to replace the manifold $\mathbb{R}^4$ by the four-dimensional Moyal plane $\mathbb{R}^4_\theta$, an example of a noncommutative manifold.

For the definition of the latter, one must specify (among other things; see Ref. 3 for the general theory, Ref. 10 for the treatment of the Moyal plane in this context) a (noncommutative) associative algebra $\mathcal{A}$, the elements of which generalize the notion of (smooth) functions on an ordinary manifold. In the case of the 4D Moyal plane, the algebra $\mathcal{A}$ is taken to include the rapidly decaying Schwartz test functions on $\mathbb{R}^4$, while the product of two such elements f, g is given by the integral formula

$$(f\star g)(x)=\frac{1}{(2\pi)^4}\int_{\mathbb{R}^4}\int_{\mathbb{R}^4}\mathrm{d}^4y\,\mathrm{d}^4\xi\,e^{i\xi(x-y)}f(x-\tfrac{1}{2}\Theta\xi)g(y), \tag{39}$$

where Θ is a 4×4 matrix defined by

$$\Theta=\theta\begin{pmatrix}0 & \mathbb{1}_2\\ -\mathbb{1}_2 & 0\end{pmatrix} \tag{40}$$

for the real parameter θ.

The elements of $\mathcal{A}$ act on the Hilbert space $L^2(\mathbb{R}^4)$ by left $\star$-multiplication (see Ref. 8 for an extension of the above formula to distributions). For an element $f \in \mathcal{A}$, we will write the corresponding operator on $L^2(\mathbb{R}^4)$ as $f\star$. From the integral formula (39) of $\star$, we can see that $f\star$ is a ΨDO with the symbol

$$\sigma[f\star\,](x,p) = f(x - \tfrac{1}{2}\Theta p). \tag{41}$$

Note that the asymptotic behavior of f is transferred to the p dependence of the symbol of $f\star$. In particular, for rapidly decaying f, $f\star$ is infinitely smoothing.[10]

A natural class of functions suitable for the Moyal product is the set $\mathcal{P}$ of infinitely differentiable functions f on $\mathbb{R}^4$ such that, for a real number s and for every multi-index α,

$$|(\partial_x^\alpha f)(x)| \leqslant C_\alpha (1 + x^2)^{(s-|\alpha|)/2}, \tag{42}$$

s is called the *order* of f. For $f, g \in \mathcal{P}$ and of order s_1, s_2, respectively, $f\star g$ is again in $\mathcal{P}$ and of order $s_1 + s_2$ (Ref. 12, Sect. 7).

B. Calculation of the logarithmically divergent part

With the commutative product of functions on $\mathbb{R}^4$ replaced by the Moyal product $\star$, Eq. (39), we are led to study the following variant of the Klein–Gordon operator

$$\Box_A^\theta \psi = \partial^\mu \partial_\mu \psi + ie(\partial^\mu A_\mu) \star \psi + 2ieA^\mu \star \partial_\mu \psi - e^2 A^\mu \star A_\mu \star \psi$$

for any rapidly decaying smooth function ψ in the Hilbert space $\mathcal{H} = L^2(\mathbb{R}^4) \otimes \mathbb{C}^N_{\text{color}}$. Here, the matrix valued Yang–Mills fields A_μ are taken to be in the set $\mathcal{P}$ above with order strictly smaller than -4, i.e., to satisfy (42) with $s < -4$.

We will also need the operator $D_{A\mu}^\theta$, defined by

$$D_{A\mu}^\theta \psi = \partial_\mu \psi + ieA_\mu \star \psi, \quad \psi \in \mathcal{S}(\mathbb{R}^4).$$

In analogy with the first section, we consider the cutoff regularized determinant of $(-\Box_A^\theta + m^2)/\Lambda_0^2$,

$$S_\Lambda^\theta(A) := \mathrm{Tr}_\Lambda \left\{ \log \frac{-\Box_A^\theta + m^2}{\Lambda_0^2} - \log \frac{-\Box_0 + m^2}{\Lambda_0^2} \right\}.$$

As before, the trace will be computed from the symbol of $\log[(-\Box_A^\theta + m^2)/\Lambda_0^2]$. For the latter, we will need an expression for the symbol of the resolvent of $\Box_A^\theta$. Again, this will be obtained via a recursion relation.

As explained in the Appendix, we find for $c_1, c_2 \in \mathbb{C}$, $c_1 \cdot c_2 < 0$ or $c_2 = 0$,

$$\sigma[(c_1 + c_2\Box_A^\theta)^{-1}](x,p) = \frac{1}{c_1 - c_2 p^2} - \frac{c_2}{c_1 - c_2 p^2}(\Box^\theta_{A(\cdot - (1/2)\Theta p)} + 2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p)})\sigma[(c_1 + c_2\Box_A^\theta)^{-1}] \times (x,p),$$

where $A\big(\cdot - \frac{1}{2}\Theta p\big)$ is a short-hand notation for the external fields A_μ shifted by $-\frac{1}{2}\Theta p$ in their argument, $A\big(\cdot - \frac{1}{2}\Theta p\big)(x) = A\big(x - \frac{1}{2}\Theta p\big)$. In the derivation of the recursion relation, we have used the identity[13]

$$e^{ip(x-y)} f(x) = [f(\cdot + \tfrac{1}{2}\theta) \star e^{ip(\cdot - y)}](x)$$

and associativity of the Moyal product.

From the recursion relation, one readily obtains the formal expression

$$\sigma[(c_1+c_2\Box_A^\theta)^{-1}](x,p)\sim\sum_{n=0}^{\infty}\frac{(-1)^n}{(c_1-c_2p^2)^{n+1}}(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p)})^n 1.$$

A thorough investigation reveals, however, that an interpretation of this equation as an asymptotic expansion in p would be misleading: The p dependence through the arguments of the external fields $A_\mu\left(x-\frac{1}{2}\Theta p\right)$ is superficial in that it goes away under the spatial integral. Therefore, one must develop different tools to tackle the situation. As shown in the Appendix, the operator R_N defined by the sum of the first N terms in the above series, for N sufficiently large, differs from the operator $(c_1+c_2\Box_A^\theta)^{-1}$ by a trace-class operator only. Hence, for the singular behavior of the cutoff regularized trace, it suffices to consider this operator R_N.

Inserting the expression for the symbol of R_N into the integral formula for the logarithm, Eq. (22), we find

$$S^\theta_\Lambda(A)=-\sum_{n=1}^{N}\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_0^1\frac{\mathrm{d}s}{s}\frac{s^{n-1}}{\left(1+s\left(\frac{p^2+m^2}{\Lambda_0^2}-1\right)\right)^{n+1}}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N(\Box^\theta_{A(\cdot-(1/2)\Theta p)}$$
$$+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})^n 1+\text{terms finite in }\Lambda.$$

Now, for every term in the sum, we can shift the x-integration by $-\frac{1}{2}\Theta p$. After this substitution the contribution to the Λ-behavior is apparent: It is only the first four terms that can contribute to $c^\theta_{\log}(A)$. Moreover, the resulting expression differs from the corresponding $S_\Lambda(A)$, Eq. (25), solely in the appearance of the product $\star$ in place of the commutative product. As the replacement of the latter by the Moyal product does not affect the asymptotic behavior in the variable p, we conclude

$$c^\theta_{\log}(A)=\frac{e^2}{96\pi^2}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N F^{\theta,\mu\nu}\star F^\theta_{\mu\nu},\tag{43}$$

where $F^\theta_{\mu\nu}$ is defined by

$$F^\theta_{\mu\nu}=-ie[D^\theta_{A\mu},D^\theta_{A\nu}].$$

This proves the claim of Proposition II.2.

VI. CONCLUSION

In the first part of our paper, we considered the regularized determinant of the Klein–Gordon operator $\Box_A$ with minimal coupling on $\mathbb{R}^4$. For the regularization, we restricted the Hilbert space trace to run over states of momentum below some cutoff Λ.

Although similar results have been obtained before, we choose to present here an approach that consistently uses the pseudodifferential operator methods to prepare the ground for calculations on a particular noncommutative manifold.

A useful formula for the calculations with symbols of pseudodifferential operators (ΨDO) is given by

$$\sigma[f(\Box_A)](x,p)=f(-p^2+\Box_A+2ip^\mu D_{A\mu})1\tag{44}$$

for any function f of the Klein–Gordon operator $\Box_A$. This formula originates from a recursion relation for the symbol $\sigma[f(\Box_A)]$. It is to be understood as defining an asymptotic expansion of the symbol for large p.

Using this asymptotic expansion we could indeed confirm that the cutoff regularized trace does have an asymptotic expansion in the cutoff Λ as in Eq. (5). Although our approach did not use a manifestly gauge invariant regularization, the term scaling like $\log\Lambda$ in the regularized trace of the logarithm of the massive Klein–Gordon operator was found to be gauge invariant. However, the numerical coefficient in front of this expression differs from that obtained via manifestly gauge

invariant methods[4,11] by a factor of −2, see Eqs. (12) and (14). This difference can be verified through a comparison of our approach to heat kernel regularization. It turns out that this argument does not rely on the particular structure of the operator $\Box_A$, cf. the use of the functions $\mathrm{d}(f,r,2t)$ in Sec. IV D, so we expect it to hold even for more general operators as well. It would be interesting to understand this feature in more detail. Also, we propose a gauge invariant version of the cutoff regularization, Eq. (10), which reproduces the result of Refs. 4 and 11.

Recently, zeta functions have been found to show a pole structure on noncommutative torus[7] that differs from the commutative case. It would be interesting to see a similar effect for the Moyal plane by means of the development in Sec. IV D.

In the second and main part of our work, we considered the generalized Klein–Gordon operator for minimally coupled bosons on the four-dimensional Moyal plane, a particular example for a noncommutative geometry. The difference to the previous case is that now the external Yang–Mills fields act on wave functions by the noncommutative Moyal multiplication. This leads in a natural way to the generalized Klein–Gordon operator $\Box_A^\theta$. As it turns out, the machinery of ΨDOs is still applicable, with (44) generalizing to

$$\sigma[f(\Box_A^\theta)](x,p) = f(-p^2 + \Box^\theta_{A(\cdot-(1/2)\Theta p)} + 2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p)\mu})1. \tag{45}$$

Here, $A\left(\cdot-\frac{1}{2}\Theta p\right)$ denotes the external fields A shifted by the amount $\frac{1}{2}\Theta p$.

From this formula, one might think that the new p-dependence in the external fields leads to an improvement in the decay properties of the symbol for large p. This point of view is however misleading when one wants to draw conclusions for the asymptotic expansion of the regularized trace: By a change of variables, the p-dependence in the external fields disappears under the spatial integral of the trace. This fact comes solely from the noncompactness of $\mathbb{R}^4$. It may be viewed as another manifestation of the UV/IR mixing. A similar effect can be seen for instance in the example of an infinitely smoothing operator on $\mathbb{R}$ that has a nonvanishing trace, see the end of the fourth section of the Appendix. Therefore, on noncompact manifolds (commutative or noncommutative), arguments linking the asymptotic expansion of the regularized trace of an operator to the expansion of its symbol must be taken with caution. For our case, we propose to use the asymptotic expansion in p of the shifted symbol

$$\sigma[f(\Box_A^\theta)](x+\tfrac{1}{2}\Theta p,p)$$

instead. This proposal is justified rigorously by operator theoretic arguments which show that the difference between the original operator and a certain truncation of the asymptotic expansion of the above shifted symbol is trace-class. Hence, it does not contribute to the divergent part of the regularized trace and we can safely exchange the full symbol by its truncation. This argument can even be extended to the commutative case, thereby proving that the coefficient of the $\log\Lambda$ part of the regularized trace is indeed given by the (noncompact) Wodzicki residue. The latter observation now can be used to explain why the expression for $c_{\log}$ is a gauge invariant quantity: Since a gauge transformation conjugates the Klein–Gordon operator by some unitary operator, the fact that $c_{\log}$ is gauge invariant is equivalent to the vanishing of the Wodzicki residue on commutators.

To conclude, we have seen that the methods of ΨDOs are a powerful tool for the investigation of the case studied here, yet they need to be modified in the described way for the case of the noncommutative Moyal plane. It would be interesting to see what modifications are necessary to study the coupling of gravity to the bosons through a varying metric in $\Box_A$. This is presently under investigation.

ACKNOWLEDGMENTS

The authors would like to thank Edwin Langmann for posing the questions that led to Propositions II.1 and II.2, for proposing to consider the gauge invariant expression Eq. (10), and for suggesting to use the representation (33) for the Heaviside step function. The authors would also like to thank Sylvie Paycha for discussions on renormalized traces and for providing them with

Ref. 15, and Jouko Mickelsson for constant interest throughout all stages of the project. One of the authors (C.P.) acknowledges financial support by the German Research Foundation (DFG) under the Emmy Noether Programme.

APPENDIX: DETAILS OF THE COMPUTATIONS

Computation of $c_{\log}(A)$

We are using the following convention for the Klein–Gordon operator:

$$\begin{aligned}\Box_A = D_A^\mu D_{A\mu} = (\partial^\mu + ieA^\mu)(\partial_\mu + ieA_\mu) &= \partial^\mu\partial_\mu + ie\partial^\mu A_\mu + 2ieA_\mu\partial^\mu - e^2A^\mu A_\mu \\ &= \Box_0 + ie\partial^\mu A_\mu + 2ieA_\mu - e^2A^\mu A_\mu. \end{aligned} \tag{A1}$$

Recall the definition of the symbol $\sigma[a]$ of a pseudodifferential operator a:

$$(af)(x) = \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \int_{\mathbb{R}^4} \mathrm{d}^4y\, e^{ip\cdot(x-y)}\sigma[a](p,x)f(y). \tag{A2}$$

In the computation we need the symbol of the resolvent of the Klein–Gordon operator, i.e., of the operator $(c_1I+c_2\Box_A)^{-1}$. To determine an asymptotic expansion for this symbol we start with the following expression:

$$\begin{aligned}(c_1I + c_2\Box_A)af(x) &= c_1I + c_2(\partial^\mu\partial_\mu + ie\partial^\mu A_\mu + 2ieA_\mu\partial^\mu - e^2A^\mu A_\mu) \\ &\quad\times \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \int_{\mathbb{R}^4} \mathrm{d}^4y\, e^{ip\cdot(x-y)}\sigma[a](p,x)f(y) \\ &= \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \int_{\mathbb{R}^4} \mathrm{d}^4y\, e^{ip\cdot(x-y)}(c_1I + c_2(-p^2 - 2eA_\mu p^\mu + \partial^\mu\partial_\mu \\ &\quad + ie\partial^\mu A_\mu + 2ieA_\mu\partial^\mu + 2ip_\mu\partial^\mu - e^2A^\mu A_\mu))\sigma[a](p,x)f(y). \end{aligned} \tag{A3}$$

Next replacing a by $(c_1I+c_2\Box_A)^{-1}a$ we get

$$\begin{aligned}(c_1I + c_2\Box_A)(c_1I + c_2\Box_A)^{-1}af(x) = af(x) &= \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \int_{\mathbb{R}^4} \mathrm{d}^4y\, e^{ip\cdot(x-y)}(c_1I + c_2(-p^2 - 2eA_\mu p^\mu \\ &\quad + \partial^\mu\partial_\mu + ie\partial^\mu A_\mu + 2ieA_\mu\partial^\mu + 2ip_\mu\partial^\mu - e^2A^\mu A_\mu)) \\ &\quad\times\sigma[(c_1I + c_2\Box_A)^{-1}a](p,x)f(y) \\ &= \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \int_{\mathbb{R}^4} \mathrm{d}^4y\, e^{ip\cdot(x-y)}\sigma[a](p,x)f(y). \end{aligned} \tag{A4}$$

So we have

$$\begin{aligned}&(c_1I + c_2(-p^2 - 2eA_\mu p^\mu + \partial^\mu\partial_\mu + ie\partial^\mu A_\mu + 2ieA_\mu\partial^\mu - e^2A^\mu A_\mu + 2ip_\mu\partial^\mu))\sigma[(c_1I + c_2\Box_A)^{-1}a](p,x) \\ &\quad = \sigma[a](p,x) \end{aligned} \tag{A5}$$

which can be written as

$$(c_1 I - c_2 p^2)\sigma[(c_1 I + c_2 \Box_A)^{-1} a](p,x) + c_2(\Box_A + 2ip_\mu D_A^\mu)\sigma[(c_1 I + c_2 \Box_A)^{-1} a](p,x) = \sigma[a](p,x), \tag{A6}$$

giving us the recursive relation

$$\sigma[(c_1 I + c_2 \Box_A)^{-1} a](p,x) = \frac{1}{c_1 - c_2 p^2}\sigma[a](p,x) - \frac{c_2}{c_1 - c_2 p^2}(\Box_A + 2ip_\mu D_A^\mu)\sigma[(c_1 I + c_2 \Box_A)^{-1} a](p,x). \tag{A7}$$

We can now get the desired asymptotic expansion by setting $a=1, \sigma[a]=1$,

$$\sigma[(c_1 I + c_2 \Box_A)^{-1}](p,x) \sim \sum_{n=0}^{\infty} \frac{(-1)^n c_2^n}{(c_1 - c_2 p^2)^{n+1}}(\Box_A + 2ip_\mu D_A^\mu)^n 1. \tag{A8}$$

Next we evaluate explicitly the terms contributing to the logarithmically diverging part in the expansion (25) of the effective action. When taking the angular integrals the following formulas are used:

$$\langle p^\mu p^\nu \rangle = \tfrac{1}{4} p^2 \eta^{\mu\nu},$$

$$\langle p^{\mu_1} p^{\mu_2} p^{\mu_3} p^{\mu_4} \rangle = \tfrac{1}{24} p^4 (\eta^{\mu_1\mu_2}\eta^{\mu_3\mu_4} + \eta^{\mu_1\mu_3}\eta^{\mu_2\mu_4} + \eta^{\mu_1\mu_4}\eta^{\mu_2\mu_3}),$$

where the brackets denote integration over the unit sphere in $\mathbb{R}^4$, that is

$$\langle f(p) \rangle := \frac{1}{2\pi^2}\int_{\mathbb{R}^4} \frac{\mathrm{d}^4 p}{(2\pi)^4}\delta(|p|-1) f(p). \tag{A9}$$

Also the angular integral over an odd number of components p^μ is zero. The s-integrals in the expansion can be evaluated exactly using the formula

$$\int_0^1 \mathrm{d}s \frac{s^{n-1}}{(1+sa)^{n+1}} = \frac{1}{n(1+a)^n} \tag{A10}$$

which holds for $\mathfrak{Re}\, a > 0$. The effective action can now be written as

$$\begin{aligned} &\mathrm{Tr}_\Lambda\left(\log\left(\frac{-\Box_A + m^2}{\Lambda_0^2}\right) - \log\left(\frac{-\Box_0 + m^2}{\Lambda_0^2}\right)\right) \\ &\quad = -\frac{1}{(2\pi)^4}\sum_{n=1}^{\infty}\int_1^\Lambda \mathrm{d}|p||p|^3 \frac{1}{n(p^2+m^2)^n}\int_{\mathbb{R}^4}\mathrm{d}^4 x \int_{S^3}\mathrm{d}\Omega_p \mathrm{tr}_N(\Box_A + 2ip_\mu D_A^\mu)^n 1 + \text{const}, \end{aligned} \tag{A11}$$

where the constant (in Λ) term arises from the integration of the symbol over the region $|p| \leqslant 1$ for which the asymptotic expansion is not valid.

When expanding the integrand in terms of p, the leading term is of the order p^{3-2n} times a term of order at most p^n coming from the angular integration—so the highest order term is of order p^{3-n}. For the terms contributing to logarithmic divergences of the effective action the leading order must be larger than or equal to -1, so the relevant terms in the expansion above are terms of order up to four. To find the parts contributing to the logarithmic divergence we derivate the terms in (A11) with respect to Λ and then pick the terms proportional to $1/\Lambda$. We denote by I_n the nth term in the expansion. Writing the expansions of the first four terms explicitly we then have

$$\frac{\partial I_1}{\partial \Lambda} = -\frac{1}{8\pi^2}\frac{\Lambda^3}{\Lambda_0^2}\frac{\Lambda_0^2}{\Lambda^2+m^2}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A 1 = \frac{1}{8\pi^2}\left(\Lambda - m^2\frac{1}{\Lambda} + O\left(\frac{1}{\Lambda^3}\right)\right)\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A 1,$$

$$\begin{aligned}\frac{\partial I_2}{\partial \Lambda} &= -\frac{1}{8\pi^2}\frac{\Lambda^3}{2(\Lambda^2+m^2)^2}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A^2 1 - \frac{1}{8\pi^2}\frac{\Lambda^5}{(\Lambda^2+m^2)^2}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A 1 \\ &= -\frac{1}{8\pi^2}\frac{1}{2\Lambda}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A^2 1 + \cdots + \frac{1}{8\pi^2}m^2\frac{1}{\Lambda}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A 1 + \cdots,\end{aligned}$$

$$\begin{aligned}\frac{\partial I_3}{\partial \Lambda} &= -\frac{1}{8\pi^2}\frac{\Lambda^3}{3(\Lambda^2+m^2)^3}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{Tr}_N \Box_A^3 + \frac{1}{4\pi^2}\frac{\Lambda^5}{3(\Lambda^2+m^2)^3}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A^2 \\ &\quad + \frac{1}{8\pi^2}\frac{\Lambda^5}{3(\Lambda^2+m^2)^3}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N (D_A^\mu \Box_A D_{A\mu}) \\ &= -\frac{1}{8\pi^2}O\left(\frac{1}{\Lambda^3}\right) + \cdots + \frac{1}{4\pi^2}\frac{1}{3\Lambda}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N \Box_A^2 + \cdots + \frac{1}{8\pi^2}\frac{1}{3\Lambda}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N (D_A^\mu \Box_A D_{A\mu}),\end{aligned}$$

$$\begin{aligned}\frac{\partial I_4}{\partial \Lambda} &= -\frac{1}{8\pi^2}\frac{\Lambda^3}{4(\Lambda^2+m^2)^4}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N\Big(\Box_A^4 - \Lambda^2(3\Box_A^3 + \Box_A D_A^\mu \Box_A D_{A\mu} + D_{A\mu}\Box_A^2 D_{A\mu}) + \frac{2}{3}\Lambda^4(\Box_A^2 \\ &\quad + D_A^\nu D_A^\mu D_{A\nu} D_{A\mu} + D_A^\mu \Box_A D_{A\mu})\Big) \\ &= -\frac{1}{8\pi^2}\frac{2}{3}\frac{1}{4\Lambda}\int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}_N(\Box_A^2 + D_A^\nu D_A^\mu D_{A\nu} D_{A\mu} + D_A^\mu \Box_A D_{A\mu}) + \cdots.\end{aligned}$$

Comparison with fermion calculations

We now compute the traces of the relevant terms in the identity

$$\begin{aligned}\log(-\mathbb{1}_4(\Box_A + m^2) - ie\sigma\cdot F) &= \log\left(\frac{\mathbb{1}_4(-\Box_A + m^2)}{\Lambda_0^2}\right) + \log\left(\mathbb{1}_4 - \frac{ie}{-\Box_A + m^2}\sigma\cdot F\right) \\ &\quad + \frac{1}{2}\left[\log\left(\mathbb{1}_4\frac{-\Box_A + m^2}{\Lambda_0^2}\right), \log\left(\mathbb{1}_4 - \frac{ie}{-\Box_A + m^2}\sigma\cdot F\right)\right] \\ &\quad + \frac{1}{12}\left(\left[\log\left(\mathbb{1}_4\frac{-\Box_A + m^2}{\Lambda_0^2}\right), \left[\log\left(\mathbb{1}_4\frac{-\Box_A + m^2}{\Lambda_0^2}\right),\right.\right.\right. \\ &\quad \left.\left.\left.\log\left(\mathbb{1}_4 - \frac{ie}{-\Box_A + m^2}\sigma\cdot F\right)\right]\right] + \left[\log\left(\mathbb{1}_4 - \frac{ie}{-\Box_A + m^2}\sigma\cdot F\right),\right. \\ &\quad \left.\left.\left[\log\left(\mathbb{1}_4 - \frac{ie}{-\Box_A + m^2}\sigma\cdot F\right), \log\left(\mathbb{1}_4\frac{-\Box_A + m^2}{\Lambda_0^2}\right)\right]\right]\right) + O\left(\frac{1}{\Lambda^5}\right).\end{aligned}$$

The commutator terms come from the Baker–Campbell–Hausdorff formula. Terms that fall off at least as $1/\Lambda^5$ have been suppressed. We find

$$\mathrm{Tr}_\Lambda \log\left(\mathbb{1}_4\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right)\right) = 4\,\mathrm{Tr}_\Lambda \log\left(\frac{-\Box_A+m^2}{\Lambda_0^2}\right),$$

$$\mathrm{Tr}_\Lambda \log\left(\mathbb{1}_4 - \frac{ie}{m^2-\Box_A}\sigma\cdot F\right) = -\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\sum_{n=1}^{\infty}\frac{1}{n}\mathrm{tr}\left(\sigma\left[\frac{ie}{-\Box_A+m^2}\right]*\sigma\cdot F\right)^{*n}.$$

Here, $*$ denotes the product of symbols of two ΨDOs which has the asymptotic expansion (20).

Now using the fact that $\mathrm{tr}\,\sigma\cdot F=0$ and the expansion (A8) for $\sigma[1/(c_1+c_2\Box_A)]$, we get

$$\begin{aligned}
&\mathrm{Tr}_\Lambda \log\left(\mathbb{1}_4 - \frac{ie}{m^2-\Box_A}\sigma\cdot F\right)\\
&\quad= -\frac{1}{2}\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}\left(\sigma\left[\frac{ie}{-\Box_A+m^2}\right]*\sigma\cdot F*\sigma\left[\frac{ie}{-\Box_A+m^2}\right]*\sigma\cdot F\right)+O\left(\frac{1}{\Lambda^5}\right)\\
&\quad= \frac{1}{2}\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\frac{e^2}{(p^2+m^2)^2}\,\mathrm{tr}\,\sigma\cdot F^2+O\left(\frac{1}{\Lambda^5}\right)\\
&\quad= \frac{e^2}{16\pi^2}\log\Lambda\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}\,\sigma\cdot F^2+O(\Lambda^0).
\end{aligned}$$

This provides the results needed in the main text, since, as will be shown below, there are no contributions to the divergent part of the trace that come from the commutator terms. For this, we expand the logarithm in the first commutator term above which gives us

$$\begin{aligned}
&\frac{1}{2}\,\mathrm{Tr}_\Lambda\left[\log\left(\mathbb{1}_4\frac{-\Box_A+m^2}{\Lambda_0^2}\right),\log\left(\mathbb{1}_4-\frac{ie}{-\Box_A+m^2}\sigma\cdot F\right)\right]\\
&\quad=\frac{1}{2}\,\mathrm{Tr}_\Lambda\left[\log\left(\mathbb{1}_4\frac{-\Box_A+m^2}{\Lambda_0^2}\right),\frac{-ie}{-\Box_A+m^2}\sigma\cdot F\right]+\frac{1}{2}\,\mathrm{Tr}_\Lambda\left[\log\left(\mathbb{1}_4\frac{(-\Box_A+m^2)}{\Lambda_0^2}\right),\right.\\
&\qquad\left.-\frac{1}{2}\left(\frac{ie}{-\Box_A+m^2}\sigma\cdot F\right)^2\right]+O\left(\frac{1}{\Lambda^7}\right).
\end{aligned}$$

The first term on the rhs is zero, so we have

$$\begin{aligned}
&\frac{1}{2}\,\mathrm{Tr}_\Lambda\left[\log\left(\frac{\mathbb{1}_4(-\Box_A+m^2)}{\Lambda_0^2}\right),\log\left(\mathbb{1}_4-\frac{ie}{-\Box_A+m^2}\sigma\cdot F\right)\right]\\
&\quad=\frac{1}{4}e^2\,\mathrm{Tr}_\Lambda\left[\log\left(\frac{\mathbb{1}_4(-\Box_A+m^2)}{\Lambda_0^2}\right),\left(\frac{1}{-\Box_A+m^2}\sigma\cdot F\right)^2\right]+O\left(\frac{1}{\Lambda^7}\right).
\end{aligned}$$

Now

$$\begin{aligned}
\sigma\left[\left[\log\left(\mathbb{1}_4\frac{(-\Box_A+m^2)}{\Lambda_0^2}\right),\left(\frac{1}{-\Box_A+m^2}\sigma\cdot F\right)^2\right]\right] &= \left[\log\frac{p^2+m^2}{\Lambda_0^2},\left(\frac{1}{p^2+m^2}\right)^2\sigma\cdot F^2\right]_*+O\left(\frac{1}{\Lambda^6}\right)\\
&= -i\frac{2p^\mu\Lambda_0^2}{p^2+m^2}\left(\frac{1}{p^2+m^2}\right)^2\partial_\mu(\sigma\cdot F^2)+O\left(\frac{1}{\Lambda^6}\right)\\
&= O\left(\frac{1}{\Lambda^5}\right)
\end{aligned}$$

so there is no contribution to the divergent part of the trace.

Next, we turn to the first triple commutator term in the above identity. Counting the powers of p in the pertinent symbols, the leading term should scale like $1/p^4$. However, this term contains a single $\sigma\cdot F$ which gives zero under the trace tr_N. Therefore, one must take one more term in the expansion of

$$\log\left(\mathbb{1}_4 - \frac{ie}{-\Box_A + m^2}\sigma\cdot F\right).$$

The resulting expression then is of order $1/p^6$ and hence can be dropped. Finally the second triple commutator term can be seen to behave as $1/p^6$. In conclusion, we have shown that for the divergent terms of the cutoff regularized trace, all commutator terms can be neglected in the above identity.

Dependence on the regularization scheme

Computation of the symbol of $\theta(\Lambda+\Box_A)$. We start with the following sum expression for the (regularized) θ-function (Ref. 9, p. 248, etc.):

$$\theta_\epsilon(x) = \frac{1}{\epsilon}\sum_{r=-\infty}^{\infty}\frac{e^{i\omega_r 0^+}}{x+i\omega_r} = \frac{e^{-x0^+}}{e^{-x\epsilon}+1}, \quad \omega_r = (2r+1)\pi/\epsilon, \quad \epsilon>0.$$

(This expression is the discretized version of the well-known integral formula

$$\theta(x) = \int_{\mathbb{R}}\frac{\mathrm{d}z}{2\pi i}\frac{e^{iz0^+}}{z-ix}.$$

The latter is regained for $\epsilon\to\infty$.) Differentiation yields

$$\delta_\epsilon^{(n-1)}(x) = \frac{1}{\epsilon}\sum_{r=-\infty}^{\infty}\frac{e^{i\omega_r 0^+}(-1)^n n!}{(x+i\omega_r)^{n+1}}, \quad n=1,2,3,\ldots,$$

for the $(n-1)$th derivative of the (regularized) Dirac δ-function.

Using the above expression, we have

$$\sigma[\theta_\epsilon(\Lambda^2+\Box_A)] = \frac{1}{\epsilon}\sum_{r=-\infty}^{\infty}\sigma\left[\frac{e^{i\omega_r 0^+}}{(\Lambda^2+\Box_A)+i\omega_r}\right].$$

We derived the asymptotic expansion for the symbol of $(c_1 I + c_2\Box_A)^{-1}$ [see Eq. (A8)] to be given by

$$\sigma[(c_1 I + c_2\Box_A)^{-1}](p,x) \sim \sum_{n=0}^{\infty}\frac{(-1)^n c_2^n}{(c_1 - c_2 p^2)^{n+1}}(\Box_A + 2ip_\mu D_A^\mu)^n 1.$$

Using this we get

$$\sigma[\theta_\epsilon(\Lambda+\Box_A)] \sim \frac{1}{\epsilon}\sum_{r=-\infty}^{\infty}\sum_{n=0}^{\infty}\frac{e^{i\omega_r 0^+}(-1)^n}{((\Lambda^2-p^2)+i\omega_r)^{n+1}}(\Box_A + 2ip^\mu D_{A\mu})^n 1.$$

Using the expressions for $\delta_\epsilon^{(n)}$ in the above expansion we finally have

$$\sigma[\theta_\epsilon(\Lambda+\Box_A)] \sim \sum_{n=0}^{\infty}\frac{1}{n!}\delta_\epsilon^{(n-1)}(\Lambda^2-p^2)(\Box_A + 2ip^\mu D_{A\mu})^n 1.$$

Computation of the traces: We can now proceed with the calculation of the trace. From the

remarks in the main section, we know that we can drop the spatial regulator f since terms proportional to the volume of $\mathbb{R}^4$ cancel exactly. We calculate

$$\begin{aligned}
&\mathrm{Tr}_\Lambda^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_\Lambda\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\sum_{n=0}^{\infty}\frac{1}{n!}\int_{|p|\geqslant 1}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\mathrm{d}^4x\;\delta_\epsilon^{(n-1)}(\Lambda^2-p^2)\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\mathrm{tr}_N(\Box_A+2ip^\mu D_{A\mu})^n 1+\cdots\\
&\qquad-\mathrm{Tr}_\Lambda\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\int_{|p|\geqslant 1}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{R^4}\mathrm{d}^4x\;\theta_\epsilon(\Lambda^2-p^2)\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\mathrm{tr}_N 1+\sum_{n=1}^{\infty}\frac{1}{n!}\int_{|p|\geqslant 1}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}\delta_\varepsilon^{(n-1)}(\Lambda^2-p^2)\\
&\qquad\times\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\mathrm{tr}_N(\Box_A+2ip^\mu D_{A\mu})^n 1+\cdots-\mathrm{Tr}_\Lambda\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right),
\end{aligned}$$

where the dots indicate terms that are uniformly bounded in Λ. (In particular, we have split the p-integral in a part over the unit ball and an integral over the rest. The former contributes to the finite part.) Now the first term on the right-hand side matches the last one in the limit $\epsilon\to\infty$. As explained in the main text, we are interested in the terms $n\leqslant 5$ of the sum above. Expanding the pertinent terms and performing the angular p-integrals gives

$$\begin{aligned}
&\mathrm{Tr}_\Lambda^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_\Lambda\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\;p^3\delta(\Lambda^2-p^2)\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\;\mathrm{tr}_N\,\Box_A 1+\frac{1}{2}\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\;p^3\delta^{(1)}(\Lambda^2-p^2)\\
&\qquad\times\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\;\mathrm{tr}_N(\Box_A^2-p^2\Box_A)1+\frac{1}{6}\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\;p^3\delta^{(2)}(\Lambda^2-p^2)\\
&\qquad\times\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\;\mathrm{tr}_N(\Box_A^3-p^2(2\Box_A^2+D_{A\mu}\Box_A D_{A\mu}))1\\
&\qquad+\frac{1}{24}\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\;p^3\delta^{(3)}(\Lambda^2-p^2)\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\;\mathrm{tr}_N\big(\Box_A^4-3p^2\Box_A^3\\
&\qquad-p^2\Box_A D_{A\mu}\Box_A D_A^\mu-p^2 D_{A\mu}\Box_A^2 D_{A\mu}-p^2 D_{A\mu}\Box_A D_A^\mu\Box_A+\tfrac{2}{3}p^4(\Box_A^2\\
&\qquad+D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}+D_A^\mu\Box_A D_{A\mu})\big)1+\cdots\ .
\end{aligned}$$

We have also taken the limit $\epsilon\to\infty$, in which δ_ϵ goes over into the Dirac δ-function.

Gathering terms with equal spatial integral we obtain

$$
\begin{aligned}
&\mathrm{Tr}_{\Lambda}^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_{\Lambda}^{\Box_0}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\,\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\left(p^3\delta(\Lambda^2-p^2)-\frac{1}{2}p^5\delta^{(1)}(\Lambda^2-p^2)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A 1\\
&\qquad+\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\,\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\left(\frac{1}{2}p^3\delta^{(1)}(\Lambda^2-p^2)-\frac{1}{3}p^5\delta^{(2)}(\Lambda^2-p^2)\right.\\
&\qquad\left.+\frac{1}{36}p^7\delta^{(3)}(\Lambda^2-p^2)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A^2 1+\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\,\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\\
&\qquad\times\left(-\frac{1}{6}p^5\delta^{(2)}(\Lambda^2-p^2)+\frac{1}{36}p^7\delta^{(3)}(\Lambda^2-p^2)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu\Box_A D_{A\mu}1\\
&\qquad+\frac{1}{8\pi^2}\int_1^\infty \mathrm{d}p\,\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\frac{1}{36}p^7\delta^{(3)}(\Lambda^2-p^2)\\
&\qquad\times\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1+\frac{1}{8\pi^2}\int_1^\infty dp\,\log\left(\frac{p^2+m^2}{\Lambda_0^2}\right)\left(\frac{1}{6}p^3\delta^{(3)}(\Lambda^2-p^2)\right.\\
&\qquad\left.-\frac{1}{8}p^5\delta^{(4)}(\Lambda^2-p^2)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A^3 1+\cdots\ .
\end{aligned}
$$

Next we make a change of variables $p^2=u$ to get

$$
\begin{aligned}
&\mathrm{Tr}_{\Lambda}^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_{\Lambda}^{\Box_0}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\frac{1}{8\pi^2}\int_1^\infty \frac{\mathrm{d}u}{2}\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\left(u\delta(\Lambda^2-u)-\frac{1}{2}u^2\delta^{(1)}(\Lambda^2-u)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A 1\\
&\qquad+\frac{1}{8\pi^2}\int_1^\infty \frac{\mathrm{d}u}{2}\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\left(\frac{1}{2}u\delta^{(1)}(\Lambda^2-u)-\frac{1}{3}u^2\delta^{(2)}(\Lambda^2-u)\right.\\
&\qquad\left.+\frac{1}{36}u^3\delta^{(3)}(\Lambda^2-u)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A^2 1+\frac{1}{8\pi^2}\int_1^\infty \frac{\mathrm{d}u}{2}\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\\
&\qquad\times\left(-\frac{1}{6}u^2\delta^{(2)}(\Lambda^2-u)+\frac{1}{36}u^3\delta^{(3)}(\Lambda^2-u)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu\Box_A D_{A\mu}1\\
&\qquad+\frac{1}{8\pi^2}\int_1^\infty \frac{\mathrm{d}u}{2}\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\frac{1}{36}u^3\delta^{(3)}(\Lambda^2-u)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1\\
&\qquad+\frac{1}{8\pi^2}\int_0^\infty \frac{\mathrm{d}u}{2}\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\left(\frac{1}{6}u\delta^{(2)}(\Lambda^2-u)-\frac{1}{8}u^2\delta^{(3)}(\Lambda^2-u)\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A^3 1+\cdots\ .
\end{aligned}
$$

Now by integrating by parts and noting that

$$
\frac{\mathrm{d}^k}{\mathrm{d}u^k}\delta(\Lambda^2-u)=(-1)^k\delta^{(k)}(\Lambda^2-u)
$$

we have

$$
\begin{aligned}
&\mathrm{Tr}_{\Lambda}^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_{\Lambda}^{\Box_0}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)\\
&\quad=\frac{1}{16\pi^2}\int_1^\infty \mathrm{d}u\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta(\Lambda^2-u)u(1-1)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A 1\\
&\qquad+\frac{1}{16\pi^2}\int_1^\infty \mathrm{d}u\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta(\Lambda^2-u)\left(\frac{1}{2}-\frac{2}{3}+\frac{1}{6}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,\Box_A^2 1\\
&\qquad+\frac{1}{16\pi^2}\int_1^\infty du\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta(\Lambda^2-u)\left(-\frac{1}{3}+\frac{1}{6}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu\Box_A D_{A\mu}1\\
&\qquad+\frac{1}{16\pi^2}\int_1^\infty \mathrm{d}u\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\frac{1}{6}\delta(\Lambda^2-u)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1+\cdots\\
&\quad=-\frac{1}{16\pi^2}\frac{1}{6}\int_1^\infty \mathrm{d}u\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta(\Lambda^2-u)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{Tr}\,D_A^\mu\Box_A D_{A\mu}1+\frac{1}{16\pi^2}\frac{1}{6}\\
&\qquad\times\int_1^\infty \mathrm{d}u\,\log\left(\frac{u+m^2}{\Lambda_0^2}\right)\delta(\Lambda^2-u)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1+\cdots\\
&\quad=-\frac{1}{96\pi^2}\log\left(\frac{\Lambda^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu\Box_A D_{A\mu}1\\
&\qquad+\frac{1}{96\pi^2}\log\left(\frac{\Lambda^2+m^2}{\Lambda_0^2}\right)\int_{\mathbb{R}^4}\mathrm{d}^4x\,\mathrm{tr}_N\,D_A^\mu D_A^\nu D_{A\mu}D_{A\nu}1+\cdots\,.
\end{aligned}
$$

Recalling that

$$
\mathrm{tr}_N(D_A^\mu\Box_A D_{A\mu}-D_A^\nu D_A^\mu D_{A\nu}D_{A\mu})=\frac{e^2}{2}\,\mathrm{tr}_N\,F^{\mu\nu}F_{\mu\nu}
$$

we finally get

$$
\mathrm{Tr}_{\Lambda}^{\Box_A}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)-\mathrm{Tr}_{\Lambda}^{\Box_0}\log\left(\frac{-\Box_0+m^2}{\Lambda_0^2}\right)=-\frac{1}{2}\frac{1}{96\pi^2}\log\frac{\Lambda}{\Lambda_0}\int_{\mathbb{R}^4}\mathrm{tr}_N\,F^{\mu\nu}F_{\mu\nu}+\cdots\,, \tag{A12}
$$

where again the dots indicate terms that are bounded or polynomial in Λ.

Computation on the Moyal plane

General remarks: The symbol of the operator $c_1+c_2\Box_A^\theta$ is given by

$$
\begin{aligned}
\sigma(x,p)&:=\sigma[c_1+c_2\Box_A^\theta](x,p)\\
&=-p^2-2ep^\mu A_\mu(x-\tfrac{1}{2}\Theta p)+ie(\partial^\mu A_\mu)(x-\tfrac{1}{2}\Theta p)-e^2(A^\mu\star A_\mu)(x-\tfrac{1}{2}\Theta p).
\end{aligned}
$$

From this expression, it is clear that one can bound σ from below by a positive constant and from above by a multiple of p^2 for p^2 greater than a certain constant. Furthermore, the derivatives of σ fall off as long as x is confined to some compact set. Therefore, by Ref. 17, corollary 5.1, there is a ΨDO that inverts $(c_1+c_2\Box_A^\theta)$ up to some infinitely smoothing operator.

Derivation of the recursion relation: As in the first section of this appendix, we start with the following identity for σ:

$$\begin{aligned}\psi(x) &= (c_1 + c_2\Box_A^\theta)(c_1 + c_2\Box_A^\theta)^{-1}\psi(x)\\ &= (c_1 + c_2\Box_A^\theta)\int \frac{\mathrm{d}^4p}{(2\pi)^4}\int \mathrm{d}^4y\, e^{ip(x-y)}\sigma(x,p)\psi(y)\\ &= \int \frac{\mathrm{d}^4p}{(2\pi)^4}\int \mathrm{d}^4y(c_1 + c_2(\partial^\mu\partial_\mu + ie(\partial^\mu A_\mu)\star + 2ieA^\mu\star\partial_\mu - e^2A^\mu\star A_\mu\star))(e^{ip(x-y)}\sigma[(c_1\\ &\quad + c_2\Box_A^\theta)^{-1}](x,p))\psi(y).\end{aligned}$$

To continue we need the following formula:

$$e^{ip(x-y)}\sigma(x,p) = [\sigma(\cdot + \tfrac{1}{2}\Theta p,p)\star e^{ip(\cdot-y)}\chi(\cdot)](x),$$

which can be proved as follows. Using the integral expression for the star product,

$$(f\star g)(x) := (2\pi)^{-4}\int\int e^{i\xi(x-y)}f\left(x - \frac{1}{2}\Theta\xi\right)g(y)\mathrm{d}^4y\,\mathrm{d}^4\xi,$$

we have for a Schwartz test function χ

$$\begin{aligned}\left[\sigma\left(\cdot + \frac{1}{2}\Theta p,p\right)\star e^{ip(\cdot-y)}\chi(\cdot)\right](x) &= \frac{1}{(2\pi)^4}\int\int \mathrm{d}^4\xi\,\mathrm{d}^4z\sigma\left(x - \frac{1}{2}\theta\xi + \frac{1}{2}\Theta p,p\right)e^{ip(z-y)}\chi(z)e^{i\xi(x-z)}\\ &= \frac{1}{(2\pi)^4}\int\int \mathrm{d}^4\xi\,\mathrm{d}^4z\sigma\left(x - \frac{1}{2}\theta\xi + \frac{1}{2}\Theta p,p\right)\chi(z)e^{-iz(\xi-p)}e^{i(\xi x-py)}\\ &= \frac{1}{(2\pi)^2}\int \mathrm{d}^4\xi\,\sigma\left(x - \frac{1}{2}\Theta(\xi-p),p\right)\hat{\chi}(\xi-p)e^{i(\xi x-py)}\\ &= e^{ip(x-y)}\frac{1}{(2\pi)^2}\int \mathrm{d}^4\tilde{\xi}\,\sigma\left(x - \frac{1}{2}\Theta\tilde{\xi},p\right)\hat{\chi}(\tilde{\xi})e^{i\tilde{\xi}x}.\end{aligned}$$

Now in the limit $\chi\to 1$, the Fourier transform $\hat{\chi}$ approximates the delta function. Therefore, in this limit, we obtain the claimed identity. Using this formula in the expression for $\psi(x)$ we get

$$\begin{aligned}\psi(x) &= \int\int \frac{\mathrm{d}^4p\,\mathrm{d}^4y}{(2\pi)^4}(c_1 + c_2(\partial^\mu\partial_\mu + ie(\partial^\mu A_\mu)\star + 2ieA^\mu\star\partial_\mu - e^2A^\mu\star A_\mu\star))(\sigma(x,p)e^{ip(x-y)})\psi(y)\\ &= \int\int \frac{\mathrm{d}^4p\,\mathrm{d}^4y}{(2\pi)^4}(c_1 + c_2(\partial^\mu\partial_\mu + ie(\partial^\mu A_\mu)\star + 2ieA^\mu\star\partial_\mu - e^2A^\mu\star A_\mu\star))\\ &\quad\times\left(\sigma\left(\cdot + \frac{1}{2}\Theta p,p\right)\star e^{ip(\cdot-y)}\right)(x)\psi(y)\\ &= \int\int \frac{\mathrm{d}^4p\,\mathrm{d}^4y}{(2\pi)^4}\Bigg[(c_1 + c_2(\Box_0 + 2ip^\mu\partial_\mu - p^2 + ie(\partial^\mu A_\mu)\star - 2ep^\mu A_\mu\star\\ &\quad + 2ieA^\mu\star\partial_\mu - e^2A^\mu\star A_\mu\star))\sigma\left(\cdot + \frac{1}{2}\Theta p,p\right)\Bigg]\star e^{ip(\cdot-y)}(x)\psi(y)\\ &= \int\int \frac{\mathrm{d}^4p\,\mathrm{d}^4y}{(2\pi)^4}(c_1 + c_2p^2 + c_2(\Box^\theta_{A(\cdot-(1/2)\Theta p)} + 2p^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu}))\sigma(\cdot,p)e^{ip(x-y)}\psi(y),\end{aligned}$$

which gives us

$$1 = (c_1 - c_2p^2 + c_2(\Box^\theta_{A(\cdot-(1/2)\Theta p)} + 2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu}))\sigma[(c_1 + c_2\Box_A^\theta)^{-1}](x,p)$$

or

$$\sigma[(c_1+c_2\Box_A^\theta)^{-1}](x,p)=\frac{1}{c_1-c_2p^2}-\frac{c_2}{c_1-c_2p^2}(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p)})\sigma[(c_1+c_2\Box_A^\theta)^{-1}]\times(x,p). \tag{A13}$$

Derivation of the asymptotic expansion: We set $R:=(c_1+c_2\Box_A^\theta)^{-1}$. As $-\Box_A^\theta$ is a positive operator, R is bounded for $c_1\cdot c_2<0$. Indeed, from

$$\int_{\mathbb{R}^4}\mathrm{d}^4x\,\overline{\psi}(x)(A\star\varphi)(x)=\int_{\mathbb{R}^4}\mathrm{d}^4x(\overline{\psi}\star A\star\varphi)(x)=\int_{\mathbb{R}^4}\mathrm{d}^4x(\overline{\psi}\star A)(x)\varphi(x),$$

which holds for $\psi,A,\varphi\in L^2(\mathbb{R}^4)$ (Ref. 10, lemma 2.10) and $\overline{\overline{A}\star\psi}=\overline{\psi}\star A$ we conclude

$$\langle\psi,A\star\varphi\rangle=\langle\overline{A}\star\psi,\varphi\rangle$$

and hence $(D^\theta_{A\mu})^\dagger=-D^\theta_{A\mu}$. Therefore,

$$\langle\varphi,-\Box_A^\theta\varphi\rangle=\sum_{\mu=1}^4\langle D^\theta_{A\mu}\varphi,D^\theta_{A\mu}\varphi\rangle\geqslant 0.$$

In our case, we have $c_1=1-s+s(m^2/\Lambda_0^2)$ and $c_2=-s/\Lambda_0^2$ for $0\leqslant s\leqslant 1$ which meets the above requirement of $c_1\cdot c_2<0$ for $0<s\leqslant 1$. For $s=0$, we have $c_2=0$, $c_1\neq 0$, and R is a multiple of the identity.

Next, let R_N be the ΨDO defined by the symbol

$$\sigma[R_N](x,p)=\sum_{n=0}^N\frac{(-c_2)^n}{(c_1-c_2p^2)^{n+1}}(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})^n1.$$

We will show that the difference $R-R_N$ is a trace-class operator.

For this, we first apply $c_1+c_2\Box_A^\theta$ from the left to obtain

$$(c_1+c_2\Box_A^\theta)(R-R_N)=1-(c_1+c_2\Box_A^\theta)R_N.$$

Here, 1 denotes the identity operator. We will compute the symbol of the ΨDO on the right-hand side of this equation. On the level of symbols, multiplication of R_N by $c_1+c_2\Box_A^\theta$ from the left amounts to the application of $c_1+c_2(-p^2+\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})$ to $\sigma[R_N]$, cf. the derivation of the recursion relation above. Hence, we find

$$\begin{aligned}\sigma[1-(c_1+c_2\Box_A^\theta)R_N](x,p)&=1-(c_1+c_2(-p^2+\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu}))\sigma[R_N](x,p)\\&=1-(c_1-c_2p^2)\sigma[R_N]-c_2(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})\sigma[R_N]\\&=-\sum_{n=1}^N\frac{(-c_2)^n}{(c_1-c_2p^2)^n}(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})^n1\\&\quad+\sum_{n=0}^N\frac{(-c_2)^{n+1}}{(c_1-c_2p^2)^{n+1}}(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})^{n+1}1\\&=\frac{(-c_2)^{N+1}}{(c_1-c_2p^2)^{N+1}}(\Box^\theta_{A(\cdot-(1/2)\Theta p)}+2ip^\mu D^\theta_{A(\cdot-(1/2)\Theta p),\mu})^{N+1}1.\end{aligned}$$

Let r_N be defined by the last expression,

$$\sigma[r_N](x,p) := \frac{(-c_2)^{N+1}}{(c_1 - c_2 p^2)^{N+1}} (\Box^{\theta}_{A(\cdot - (1/2)\Theta p)} + 2ip^{\mu} D^{\theta}_{A(\cdot - (1/2)\Theta p),\mu})^{N+1} 1.$$

We will show that r_N is a trace-class operator for sufficiently large N. Expanding the power of operators in the symbol $\sigma[r_N]$ yields terms of the form

$$\text{const} \times \frac{1}{(c_1 - c_2 p^2)^{N+1}} \times f_1 \star \cdots \star f_k \left(x - \frac{1}{2}\Theta p \right),$$

$k = 1, \ldots, 2(N+1)$, the f_i denoting the external fields A_μ or derivatives thereof. [We have used the fact that $(f(\cdot - \frac{1}{2}\Theta p) \star g(\cdot - \frac{1}{2}\Theta p))(x) = (f \star g)(x - \frac{1}{2}\Theta p)$.]

As A_μ is in $\mathcal{P}$ and of order $-2-\epsilon$, Moyal multiplication by it increases the decay property of the x-dependent part by 2. On the other hand, differentiation increases it only by 1. Therefore, the leading term of the above type will be the one where N derivatives of $D^{\theta}_{A(\cdot - (1/2)\Theta p),\mu}$ hit a single A_μ. The resulting term can be bounded from above by

$$\text{const} \times \frac{1}{(1+p^2)^{N+1}} \times (p^2)^{N/2} \times \frac{1}{(1 + (x - \frac{1}{2}\Theta p)^2)^{(4+\epsilon+N)/2}}$$

which is integrable in $x-p$ space for sufficiently large N.

Application from the left of the bounded operator R to r_N does not change the property of being trace-class. On the other hand, we find

$$R r_N = R(c_1 + c_2 \Box^{\theta}_A)(R - R_N) = R - R_N.$$

To summarize, if we are interested in the singular behavior of the cutoff regularized trace of R, we may use the symbol $\sigma[R_N]$ for N sufficiently large in the integral formula of the trace. This amounts to the iteration of the recursion relation (A13) N times.

Remarks: It is easy to see that a blind application of the machinery of ΨDO leads astray. As already mentioned in the main text, the symbol of the operator $f\star$ is given by

$$\sigma[f\star](x,p) = f(x - \tfrac{1}{2}\Theta p).$$

Hence, $f\star$ is an infinitely smoothing operator if f is a Schwartz test function. In other words, the noncommutative Klein–Gordon operator $\Box^{\theta}_A$ differs from the free operator $\Box_0$ by an infinitely smoothing operator,

$$\begin{aligned}\sigma[\Box^{\theta}_A](x,p) &= -p^2 - 2ep^{\mu} A_{\mu}(x - \tfrac{1}{2}\Theta p) + ie(\partial^{\mu} A_{\mu})(x - \tfrac{1}{2}\Theta p) - e^2 (A^{\mu} \star A_{\mu})(x - \tfrac{1}{2}\Theta p) \\ &= \sigma[\Box_0](x,p) + \text{smoothing}.\end{aligned}$$

One might therefore expect that the dependence on the fields A of the resolvent R is in the part that is not seen by an asymptotic expansion in p and hence does not contribute to the divergent behavior of the trace. For ΨDOs on *noncompact* manifolds M this line of reasoning must be taken with caution, since there might be additional divergent terms from the x-integration in the trace integral. This is nicely illustrated by the above computation and the following example. Consider the function

$$f(x,p) = e^{-x^2 e^{-p^2} - (1/4)p^2},$$

where x and p are one-dimensional variables. Clearly

$$|\partial_p^{\alpha} \partial_x^{\beta} f(x,p)| \leqslant C_{K,\alpha,\beta} e^{-(1/4)p^2}, \quad x \in K \subset \mathbb{R} \text{ compact}, \ p \in \mathbb{R},$$

hence f defines an infinitely smoothing operator. On the other hand,

$$\int_{\mathbb{R}} \mathrm{d}x\, f(x,p) = \sqrt{\pi} e^{(1/4)p^2},$$

and the operator f does have a diverging trace. Note that in this example, it is the noncompactness that yields the surprise. We conclude that even in the commutative case, the correspondence between the logarithmically divergent part of the trace and the residue needs some additional justification.

In the above calculation, however, the $p-x$ mixing in the arguments of the fields A_μ—which originates from the noncommutativity of the Moyal plane—makes it impossible to distinguish between the asymptotic p-expansion and an (infinitely smoothing) remainder. There, additional arguments are imperative. Observe, however, that our lines of reasoning above can be taken over to the commutative case, thereby solving the raised objection.

Variational two-fermion wave equations in quantum electrodynamics: Muoniumlike systems

Andrei G. Terekidi[a] and Jurij W. Darewych[b]
Department of Physics and Astronomy, York University, Toronto, Ontario, Canada M3J 1P3

(Received 28 May 2004; accepted 17 October 2004; published online 8 February 2005)

We consider a reformulation of quantum electrodynamics in which covariant Green functions are used to solve for the electromagnetic field in terms of the fermion fields. The resulting modified Hamiltonian contains the photon propagator directly. A simple Fock-state variational trial function is used to derive relativistic two-fermion equations variationally from the expectation value of the Hamiltonian of the field theory. The interaction kernel of the equation is shown to be, in essence, the invariant $\mathcal{M}$ matrix in lowest order. Solutions of the two-body equations are presented for muoniumlike systems for small coupling strengths. The results compare well with the observed muonium spectrum, as well as that for hydrogen and muonic hydrogen. Anomalous magnetic moment effects are discussed. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1845602]

I. INTRODUCTION

It has been pointed out in previous publications that various models in quantum field theory (QFT), including quantum electrodynamics (QED), can be reformulated, using mediating-field Green functions, into a form that is particularly convenient for variational calculation.[1,2] This approach was applied to the study of relativistic two-body eigenstates in the scalar Yukawa (Wick–Cutkosky) theory.[3–5] We shall implement such an approach to two-fermion states in QED in this paper.

The Lagrangian of two-fermion fields interacting electromagnetically is ($\hbar=c=1$)

$$\mathcal{L}=\bar{\psi}(x)(i\gamma^{\mu}\partial_{\mu}-m_1-q_1\gamma^{\mu}A_{\mu}(x))\psi(x)+\bar{\phi}(x)(i\gamma^{\mu}\partial_{\mu}-m_2-q_2\gamma^{\mu}A_{\mu}(x))\phi(x)-\tfrac{1}{4}(\partial_{\alpha}A_{\beta}(x)-\partial_{\beta}A_{\alpha}(x))(\partial^{\alpha}A^{\beta}(x)-\partial^{\beta}A^{\alpha}(x)). \tag{1}$$

The corresponding Euler–Lagrange equations of motion are the coupled Dirac–Maxwell equations,

$$(i\gamma^{\mu}\partial_{\mu}-m_1)\psi(x)=q_1\gamma^{\mu}A_{\mu}(x)\psi(x), \tag{2}$$

$$(i\gamma^{\mu}\partial_{\mu}-m_2)\phi(x)=q_2\gamma^{\mu}A_{\mu}(x)\phi(x), \tag{3}$$

and

$$\partial_{\mu}\partial^{\mu}A^{\nu}(x)-\partial^{\nu}\partial_{\mu}A^{\mu}(x)=j^{\nu}(x), \tag{4}$$

where

[a]Electronic mail: terekidi@yorku.ca
[b]Electronic mail: darewych@yorku.ca

$$j^{\nu}(x) = q_1 \overline{\psi}(x) \gamma^{\nu} \psi(x) + q_2 \overline{\phi}(x) \gamma^{\nu} \phi(x). \tag{5}$$

Equations (2)–(4) can be decoupled in part by using the well-known formal solution[6,7] of the Maxwell equation (4), namely

$$A_{\mu}(x) = A^0_{\mu}(x) + \int \mathrm{d}^4x'\, D_{\mu\nu}(x-x') j^{\nu}(x'), \tag{6}$$

where $D_{\mu\nu}(x-x')$ is a Green function (or photon propagator in QFT terminology), defined by

$$\partial_{\alpha}\partial^{\alpha} D_{\mu\nu}(x-x') - \partial_{\mu}\partial^{\alpha} D_{\alpha\nu}(x-x') = g_{\mu\nu}\delta^4(x-x'), \tag{7}$$

and $A^0_{\mu}(x)$ is a solution of the homogeneous (or "free field") equation (4) with $j^{\mu}(x)=0$.

We recall that equation (7) does not define the covariant Green function $D_{\mu\nu}(x-x')$ uniquely. For one thing, one can always add a solution of the homogeneous equation [Eq. (7) with $g_{\mu\nu} \rightarrow 0$]. This allows for a certain freedom in the choice of $D_{\mu\nu}$, as is discussed in standard texts (e.g., Refs. 6 and 7). In practice, the solution of Eq. (7), like that of Eq. (4), requires a choice of gauge. However, we do not need to specify one at this stage.

Substitution of the formal solution (6) into Eqs. (2) and (3) yields the "partly reduced" equations,

$$(i\gamma^{\mu}\partial_{\mu} - m_1)\psi(x) = q_1 \gamma^{\mu}\left(A^0_{\mu}(x) + \int \mathrm{d}^4x'\, D_{\mu\nu}(x-x') j^{\nu}(x') \right)\psi(x), \tag{8}$$

$$(i\gamma^{\mu}\partial_{\mu} - m_2)\phi(x) = q_2 \gamma^{\mu}\left(A^0_{\mu}(x) + \int \mathrm{d}^4x'\, D_{\mu\nu}(x-x') j^{\nu}(x') \right)\phi(x). \tag{9}$$

These are coupled nonlinear Dirac equations. To our knowledge no exact (analytic or numeric) solution of Eqs. (8) and (9) for classical fields have been reported in the literature, though approximate (perturbative) solutions have been discussed by various authors, particularly Barut and co-workers (see Refs. 8 and 9 and citations therein). However, our interest here is in the quantized field theory.

The partially reduced equations (8) and (9) are derivable from the stationary action principle,

$$\delta S[\psi, \phi] = \delta \int \mathrm{d}^4x\, \mathcal{L}_R = 0 \tag{10}$$

with the Lagrangian density

$$\begin{aligned} \mathcal{L}_R = {} & \overline{\psi}(x)(i\gamma^{\mu}\partial_{\mu} - m_1 - q_1\gamma^{\mu}A^0_{\mu}(x))\psi(x) + \overline{\phi}(x)(i\gamma^{\mu}\partial_{\mu} - m_2 - q_2\gamma^{\mu}A^0_{\mu}(x))\phi(x) \\ & - \frac{1}{2}\int \mathrm{d}^4x'\, j^{\mu}(x') D_{\mu\nu}(x-x') j^{\nu}(x) \end{aligned} \tag{11}$$

provided that the Green function is symmetric in the sense that

$$D_{\mu\nu}(x-x') = D_{\mu\nu}(x'-x) \quad \text{and } D_{\mu\nu}(x-x') = D_{\nu\mu}(x-x'). \tag{12}$$

The interaction part of (11) has a somewhat modified structure from that of the usual formulation of QED. Thus, there are two interaction terms. The last term of (11) is a "current–current" interaction which contains the photon propagator sandwiched between the fermionic currents. We shall use this modified formulation together with a variational approach to obtain relativistic few-fermion equations, and to study their bound state solutions.

II. HAMILTONIAN

We shall consider the quantized theory in the equal-time formalism. To this end we write down the Hamiltonian density corresponding to the Lagrangian (11), namely

$$\mathcal{H}_R = \mathcal{H}_0 + \mathcal{H}_1 + \mathcal{H}_{\rm II}, \tag{13}$$

where

$$\mathcal{H}_0 = \psi^\dagger(x)(-i\vec{\alpha}\cdot\nabla + m_1\beta)\psi(x) + \phi^\dagger(x)(-i\vec{\alpha}\cdot\nabla + m_2\beta)\phi(x), \tag{14}$$

$$\mathcal{H}_1 = \frac{1}{2}\int \mathrm{d}^4x'\; j^\mu(x')D_{\mu\nu}(x-x')j^\nu(x), \tag{15}$$

$$\mathcal{H}_{\rm II} = q_1\overline{\psi}(x)\gamma^\mu A^0_\mu(x)\psi(x) + q_2\overline{\phi}(x)\gamma^\mu A^0_\mu(x)\phi(x), \tag{16}$$

and where we have suppressed the kinetic-energy term of the free photon field. We construct a quantized theory by imposing equal-time anticommutation rules for the fermion fields, namely

$$\{\psi_\alpha(\mathbf{x},t),\psi^\dagger_\beta(\mathbf{y},t)\} = \{\phi_\alpha(\mathbf{x},t),\phi^\dagger_\beta(\mathbf{y},t)\} = \delta_{\alpha\beta}\delta^3(\mathbf{x}-\mathbf{y}), \tag{17}$$

and all others vanish. In addition, there are the usual commutation rules for the A^0_μ field, and commutation of the A^0_μ field operators with the ψ and ϕ field operators.

To specify our notation, we quote the Fourier decomposition of the field operators, namely

$$\psi(x) = \sum_s \int \frac{\mathrm{d}^3\mathbf{p}}{(2\pi)^{3/2}}\left(\frac{m_1}{\omega_p}\right)^{1/2}[b_{\mathbf{p}s}u(\mathbf{p},s)e^{-ip\cdot x} + \mathrm{d}^\dagger_{\mathbf{p}s}v(\mathbf{p},s)e^{ip\cdot x}], \tag{18}$$

with $p=p^\mu=(\omega_p,\mathbf{p})$, $\omega_p=\sqrt{m_1^2+\mathbf{p}^2}$ and

$$\phi(x) = \sum_s \int \frac{\mathrm{d}^3\mathbf{p}}{(2\pi)^{3/2}}\left(\frac{m_2}{\Omega_p}\right)^{1/2}[B_{\mathbf{p}s}U(\mathbf{p},s)e^{-ip\cdot x} + D^\dagger_{\mathbf{p}s}V(\mathbf{p},s)e^{ip\cdot x}], \tag{19}$$

with $p=p^\mu=(\Omega_p,\mathbf{p})$, $\Omega_p=\sqrt{m_2^2+\mathbf{p}^2}$. Note that the mass-$m_1$ free-particle Dirac spinors $u(\mathbf{p},s)$, $v(\mathbf{p},s)$ where $(\gamma^\mu\hat{p}_\mu - m_1)u(\mathbf{p},s)=0$, $(\gamma^\mu\hat{p}_\mu + m_1)v(\mathbf{p},s)=0$, are normalized such that

$$\begin{aligned} u^\dagger(\mathbf{p},s)u(\mathbf{p},\sigma) = v^\dagger(\mathbf{p},s)v(\mathbf{p},\sigma) &= \frac{\omega_p}{m_1}\delta_{s\sigma}, \\ u^\dagger(\mathbf{p},s)v(\mathbf{p},\sigma) = v^\dagger(\mathbf{p},s)u(\mathbf{p},\sigma) &= 0. \end{aligned} \tag{20}$$

Analogous properties apply to the mass-m_2 spinors U, V. The creation and destruction operators $b^\dagger$, b of the (free) particles of mass m_1, and $d^\dagger$, d for the corresponding antiparticles, satisfy the usual anticommutation relations. The nonvanishing ones are

$$\{b_{\mathbf{p}s},b^\dagger_{\mathbf{q}\sigma}\} = \{d_{\mathbf{p}s},d^\dagger_{\mathbf{q}\sigma}\} = \delta_{s\sigma}\delta^3(\mathbf{p}-\mathbf{q}). \tag{21}$$

Again, the analogous properties apply to the mass-m_2 operators $B^\dagger$, B, $D^\dagger$, D. As a concrete example, we can think of the mass-m_1 particles as electrons, and the mass-m_2 particles as muons, though any pairs of charged fermions could be considered.

III. VARIATIONAL PRINCIPLE, TWO-FERMION TRIAL STATES AND EQUATIONS

The Hamiltonian formalism of QFT is based on the covariant eigenvalue equation

$$\hat{P}^\mu|\psi\rangle = Q^\mu|\psi\rangle, \tag{22}$$

where $\hat{P}^\mu=(\hat{H},\hat{\mathbf{P}})$ is the energy momentum operator, $Q^\mu=(E,\mathbf{P})$ is the four-vector of energy and momentum, with $E^2-\mathbf{P}^2=M^2$, where M is the invariant mass of the system. There are very few problems in QFT for which exact solution of the $\mu=0$ equation (22) can be written down. In practice, it is necessary to use approximation methods to solve it, such as the widely used covariant perturbation theory or lattice methods. Here we concentrate on the variational approach, which is based on the variational principle

$$\delta\langle\psi|\hat{H}-E|\psi\rangle_{t=0} = 0, \tag{23}$$

which we shall consider in the rest frame, i.e., $\mathbf{P}=0$. Variational solutions are only as good as the trial states that are used. Thus, it is important that the trial states possess as many features of the exact solution as possible. For a system like μ^+e^-, the simplest Fock-space trial state that can be written down in the rest frame is

$$|\psi_{\text{trial}}\rangle = \sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p}) b^\dagger_{\mathbf{p}s_1} D^\dagger_{-\mathbf{p}s_2}|0\rangle, \tag{24}$$

where $F_{s_1s_2}$ are four adjustable functions. We use this trial state to evaluate the matrix elements needed to implement the variational principle (23), that is

$$\langle\psi_{\text{trial}}|:\hat{H}_0-E:|\psi_{\text{trial}}\rangle = \sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F^*_{s_1s_2}(\mathbf{p})F_{s_1s_2}(\mathbf{p})(\omega_p+\Omega_p-E) \tag{25}$$

and

$$\begin{aligned}\langle\psi_{\text{trial}}|:\hat{H}_{\text{I}}:|\psi_{\text{trial}}\rangle = &-\frac{q_1q_2m_1m_2}{(2\pi)^3}\sum_{\sigma_1\sigma_2s_1s_2}\int \frac{\mathrm{d}^3\mathbf{p}\,\mathrm{d}^3\mathbf{q}}{\sqrt{\omega_p\omega_q\Omega_p\Omega_q}}F^*_{s_1s_2}(\mathbf{p})F_{\sigma_1\sigma_2}(\mathbf{q})\overline{u}(\mathbf{p},s_1)\gamma^\mu u(\mathbf{q},\sigma_1)\\ &\times D_{\mu\nu}(p-q)\overline{V}(-\mathbf{q},\sigma_2)\gamma^\nu V(-\mathbf{p},s_2),\end{aligned} \tag{26}$$

where the Fourier transform of the Green function was used,

$$D_{\mu\nu}(x-x') = \int \frac{\mathrm{d}^4k}{(2\pi)^4}D_{\mu\nu}(k)e^{-ik(x-x')}. \tag{27}$$

The Green function $D_{\mu\nu}(p-q)$ consists of two parts

$$D_{\mu\nu}(p-q) = \tfrac{1}{2}(D^{(1)}_{\mu\nu}(p-q)+D^{(2)}_{\mu\nu}(q-p)), \tag{28}$$

where $D^{(1)}_{\mu\nu}(p-q)$ and $D^{(2)}_{\mu\nu}(q-p)$ are the Green functions of particles with masses m_1 and m_2, respectively.

For a particle–antiparticle system like positronium an additional virtual-annihilation interaction term,

$$\overline{u}(\mathbf{p},s_1)\gamma^\mu v(-\mathbf{p},s_2)D_{\mu\nu}(\omega_p)\overline{v}(-\mathbf{q},\sigma_2)\gamma^\nu u(\mathbf{q},\sigma_1) \tag{29}$$

appears in (26).[10] Note that we have normal-order the entire Hamiltonian, since this circumvents the need for mass renormalization which would otherwise arise. Not that there is a difficulty with handling mass renormalization in the present formalism (as shown in various earlier papers; see, for example, Ref. 11 and citations therein). It is simply that we are not interested in mass renormalization here, since it has no effect on the two-body bound state energies that we obtain in this

paper. Furthermore, the approximate trial state (24), which we use in this work, is incapable of sampling loop effects. Thus, the normal ordering of the entire Hamiltonian does not "sweep under the carpet" loop renormalization effects, since none arise at the present level of approximation. Note, also, that $\langle\psi_{\text{trial}}|:\hat{H}_{\text{II}}:|\psi_{\text{trial}}\rangle=0$, that is the variational trial state (24) is insensitive to that part of the interaction Hamiltonian which is linear in $A^0_\mu(x)$. This means that, with the simple anzatz (24) only stable bound states and elastic scattering can be described, but not processes that involve radiation.

The variational principle (23) leads to the following equation;

$$\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}(\omega_p+\Omega_p-E)F_{s_1s_2}(\mathbf{p})\,\delta F^*_{s_1s_2}(\mathbf{p})-\frac{m_1m_2}{(2\pi)^3}\sum_{\sigma_1\sigma_2s_1s_2}\int\frac{\mathrm{d}^3\mathbf{p}\,\mathrm{d}^3\mathbf{q}}{\sqrt{\omega_p\omega_q\Omega_p\Omega_q}}F_{\sigma_1\sigma_2}(\mathbf{q})$$
$$\times(-i)\mathcal{M}^{ope}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})\,\delta F^*_{s_1s_2}(\mathbf{p})=0, \tag{30}$$

where $\mathcal{M}^{ope}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})$ is the usual invariant matrix element corresponding to the one-photon exchange Feynman diagram:

$$\mathcal{M}^{ope}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})=-\overline{u(}\mathbf{p},s_1)(-iq_1\gamma^\mu)u(\mathbf{q},\sigma_1)iD_{\mu\nu}(p-q)\overline{V(}-\mathbf{q},\sigma_2)(-iq_2\gamma^\nu)V(-\mathbf{p},s_2). \tag{31}$$

As mentioned above, for a fermion–antifermion system like positronium we obtain[10] the additional virtual-annihilation term ($q_1=q_2\equiv e$)

$$\mathcal{M}^{ann}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})=\overline{u(}\mathbf{p},s_1)(-ie\gamma^\mu)v(-\mathbf{p},s_2)iD_{\mu\nu}(\omega_p)\overline{v(}-\mathbf{q},\sigma_2)(-ie\gamma^\nu)u(\mathbf{q},\sigma_1). \tag{32}$$

Note that the $\mathcal{M}$-matrix arises naturally in this formalism, that is $\mathcal{M}$ is not put in by hand, nor does its derivation require additional Fock-space terms in the variational trial state (24), as is the case in traditional formulations (e.g., Refs. 12 and 13).

In the nonrelativistic limit, the functions $F_{s_1s_2}$ can be written as

$$F_{s_1s_2}(\mathbf{p})=F(\mathbf{p})\Lambda_{s_1s_2}, \tag{33}$$

where the nonzero elements of Λ_{ij} for total spin singlet ($S=0$) states are $\Lambda_{12}=-\Lambda_{21}=1/\sqrt{2}$, while for the spin triplet ($S=1$) states the nonzero elements are $\Lambda_{11}=1$ for $m_s=+1$, $\Lambda_{12}=\Lambda_{21}=1/\sqrt{2}$ for $m_s=0$, and $\Lambda_{22}=1$ for $m_s=-1$. We use the notation that the subscripts 1 and 2 of Λ correspond to $m_s=1/2$ and $m_s=-1/2$ (or $\uparrow$ and $\downarrow$), respectively. Substituting (33) into (30), multiplying the result by $\Lambda_{s_1s_2}$ and summing over s_1 and s_2, gives the equation

$$(\omega(\mathbf{p})+\Omega(\mathbf{p})-E)F(\mathbf{p})=\frac{1}{(2\pi)^3}\int\mathrm{d}^3\mathbf{q}\,\mathcal{K}(\mathbf{p},\mathbf{q})F(\mathbf{q}), \tag{34}$$

where

$$\mathcal{K}(\mathbf{p},\mathbf{q})=-i\sum_{s_1s_2\sigma_1\sigma_2}\Lambda_{s_1s_2}\mathcal{M}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q})\Lambda_{\sigma_1\sigma_2}. \tag{35}$$

To lowest order in $(|\mathbf{p}|,|\mathbf{q}|)/(m_1,m_2)$ (i.e., in the nonrelativistic limit), the kernel (35) reduces to $\mathcal{K}=q_1q_2/|\mathbf{p}-\mathbf{q}|^2$, and so (34) reduces to the (momentum-space) Schrödinger equation

$$\left(\frac{\mathbf{p}^2}{2m_r}-\varepsilon\right)F(\mathbf{p})=\frac{q_1q_2}{(2\pi)^3}\int\mathrm{d}^3\mathbf{q}\frac{1}{|\mathbf{p}-\mathbf{q}|^2}F(\mathbf{q}), \tag{36}$$

where $\varepsilon=E-M$ and $m_r=m_1m_2/M$, $M=m_1+m_2$. This verifies that the relativistic two-fermion equation (30) has the required nonrelativistic limit.

IV. PARTIAL-WAVE DECOMPOSITION AND CLASSIFICATION OF STATES

In the relativistic case we shall not complete the variational procedure in (30) at this stage to get final equations for the four functions $F_{s_1s_2}$, because they are not independent in general. We require that the trial state must be an eigenstate of the relativistic total angular momentum operator, its projection, and parity. Namely

$$\begin{bmatrix} \hat{\mathbf{J}}^2 \\ \hat{J}_3 \\ \hat{\mathcal{P}} \end{bmatrix} |\psi_{\text{trial}}\rangle = \begin{bmatrix} J(J+1) \\ m_J \\ P \end{bmatrix} |\psi_{\text{trial}}\rangle. \tag{37}$$

For a system like positronium charge conjugation invariance is an additional requirement, that is

$$\hat{\mathcal{C}}|e^+e^-\rangle = C|e^+e^-\rangle, \tag{38}$$

however this does not apply for $m_1 \neq m_2$. Explicit forms for the operators $\hat{\mathbf{J}}^2$, $\hat{J}_3$ are given in Appendix A. The functions $F_{s_1s_2}(\mathbf{p})$ can be written in the general form

$$F_{s_1s_2}(\mathbf{p}) = \sum_{\ell_{s_1s_2}} \sum_{m_{s_1s_2}} f^{\ell_{s_1s_2} m_{s_1s_2}}_{s_1s_2}(p) Y^{m_{s_1s_2}}_{\ell_{s_1s_2}}(\hat{\mathbf{p}}), \tag{39}$$

where $Y^{m_{s_1s_2}}_{\ell_{s_1s_2}}(\hat{\mathbf{p}})$ are the usual spherical harmonics. Here and henceforth we will use the notation $p=|\mathbf{p}|$, etc. (four-vectors will be written as p^μ). The orbital indices $\ell_{s_1s_2}$ and $m_{s_1s_2}$ depend on the spin indices s_1 and s_2 and are specified by Eq. (37). The radial coefficients of expansion (39) $f^{\ell_{s_1s_2} m_{s_1s_2}}_{s_1s_2}(p)$ also depend on the spin variables. Substitution of (39) into (24) and then into (37) leads to two categories of relations among the adjustable functions.

A. Mixed-spin states

In this case $\ell_{s_1s_2} \equiv \ell = J$ and the general solution of the system (37) is

$$F_{s_1s_2}(\mathbf{p}) = C_1 F^{(sg)}_{s_1s_2}(\mathbf{p}) + C_2 F^{(tr)}_{s_1s_2}(\mathbf{p}), \tag{40}$$

where C_1 and C_2 are arbitrary constants. $F^{(sg)}_{s_1s_2}(\mathbf{p})$ and $F^{(tr)}_{s_1s_2}(\mathbf{p})$ are functions, which correspond to pure singlet states with the total spin $S=0$ and triplet states with $S=1$, respectively. The singlet functions have the form

$$F^{(sg)}_{s_1s_2}(\mathbf{p}) = f^{(sg)\ell}_{s_1s_2}(p) Y^{m_{s_1s_2}}_{\ell}(\hat{\mathbf{p}}), \tag{41}$$

where $m_{11}=m_{22}=0$ and $m_{12}=m_{21}=m_J$. The relations between $f^{(sg)J}_{12}(p)$ and $f^{(sg)J}_{21}(p)$ involve the Clebsch–Gordan (CG) coefficients $C^{(sg)m_{s_1s_2}}$, that is

$$f^{(sg)J}_{s_1s_2}(p) = C^{(sg)m_{s_1s_2}} f^J(p), \tag{42}$$

as is shown in Appendix A. We see that the spin and radial variables separate in the sense that the factors $f^{(sg)J}_{s_1s_2}(p)$ have a common radial function $f^J(p)$, that is for the singlet functions we obtain

$$F^{(sg)}_{s_1s_2}(\mathbf{p}) = C^{(sg)m_{s_1s_2}} f^J(p) Y^{m_{s_1s_2}}_J(\hat{\mathbf{p}}). \tag{43}$$

The CG coefficients $C^{(sg)m_{s_1s_2}}$ have a simple form, $C^{(sg)m_{11}}=C^{(sg)m_{22}}=0$, $C^{(sg)m_{12}}=-C^{(sg)m_{21}}=1$ (see Appendix A). Thus the nonzero components of $F^{(sg)}_{s_1s_2}(\mathbf{p})$ are $F^{(sg)}_{\uparrow\downarrow}(\mathbf{p}) \equiv F^{(sg)}_{12}(\mathbf{p})$, $F^{(sg)}_{\downarrow\uparrow}(\mathbf{p}) \equiv F^{(sg)}_{21}(\mathbf{p})$.

The triplet functions have the form

$$F^{(tr)}_{s_1s_2}(\mathbf{p}) = f^{(tr)J}_{s_1s_2}(p) Y_J^{m_{s_1s_2}}(\hat{\mathbf{p}}), \tag{44}$$

where

$$m_{11} = m_J - 1, \quad m_{12} = m_{21} = m_J, \quad m_{22} = m_J + 1. \tag{45}$$

The expressions for $f^{(tr)J}_{s_1s_2}(p)$ involve the CG coefficients $C^{(tr)Jm_s}_{Jm_J}$ for $S=1$ listed in Appendix A, that is

$$f^{(tr)J}_{s_1s_2}(p) = C^{(tr)Jm_s}_{Jm_J} f^{\ell}(p), \tag{46}$$

where the index m_s is defined as

$$m_s = +1, \quad \text{when } m_{s_1s_2} = m_{11},$$

$$m_s = 0, \quad \text{when } m_{s_1s_2} = m_{12} = m_{21}, \tag{47}$$

$$m_s = -1, \quad \text{when } m_{s_1s_2} = m_{22}.$$

Thereupon, the triplet function is

$$F^{(tr)}_{s_1s_2}(\mathbf{p}) = C^{(tr)Jm_s}_{Jm_J} f^J(p) Y_J^{m_{s_1s_2}}(\hat{\mathbf{p}}). \tag{48}$$

We need to note that (43) is true for $J \geqslant 0$, while (48) is true for $J \geqslant 1$. Thus the coefficient C_2 in (40) is zero when $J=0$. In other words, for $J=0$, only the pure singlet state arises. For a system like positronium the requirement (38) decouples the singlet and triplet states for all J. Indeed, the charge conjugation eigenstates are

$$|sg\rangle = \sum_{s_1s_2} C^{(sg)m_{s_1s_2}} \int \mathrm{d}^3\mathbf{p}\, f^J(p) Y_J^{m_J}(\hat{\mathbf{p}}) b^{\dagger}_{\mathbf{p}s_1} d^{\dagger}_{-\mathbf{p}s_2} |0\rangle \tag{49}$$

with $C=(-1)^J$ for the pure singlet states, and

$$|tr\rangle = \sum_{s_1s_2} C^{(tr)Jm_{s_1s_2}}_{Jm_J} \int \mathrm{d}^3\mathbf{p}\, f^J(p) Y_J^{m_J}(\hat{\mathbf{p}}) b^{\dagger}_{\mathbf{p}s_1} d^{\dagger}_{-\mathbf{p}s_2} |0\rangle \tag{50}$$

with $C=(-1)^{J+1}$ for the pure triplet states, as is discussed in Appendix A.

The states (49) and (50) diagonalize the Hamiltonian (13). Thus, for positroniumlike systems, the states can be characterized by the spin quantum number S, and the mixed states (40) separate into singlet states (parastates $S=0$) and triplet states (orthostates $S=1$). For distinct particles ($m_1 \neq m_2$) C is not conserved and there is no separation into pure singlet and triplet states in general. Thus for arbitrary mass ratios we need to diagonalize the expectation value of the Hamiltonian (13) (Appendix E). This can be achieved by the following linear transformation

$$\begin{bmatrix} |sg_q\rangle \\ |tr_q\rangle \end{bmatrix} = \hat{U} \begin{bmatrix} |sg\rangle \\ |tr\rangle \end{bmatrix}, \tag{51}$$

where $\hat{U}$ is the unimodular matrix

$$\hat{U} = \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \tag{52}$$

with components

TABLE I. The quasistate coefficients $C^{(s)Jm_{s_1s_2}}_{Jm_J}$ for $s=s_s, s_t$.

	$m_{11}=m_J-1$	$m_{12}=m_J$	$m_{21}=m_J$	$m_{22}=m_J+1$
s_s	$b\left(\frac{(J+m_J)(J-m_J+1)}{J(J+1)}\right)^{1/2}$	$-b\frac{m_J}{(J(J+1))^{1/2}}+a$	$-b\frac{m_J}{(J(J+1))^{1/2}}-a$	$-b\left(\frac{(J-m_J)(J+m_J+1)}{J(J+1)}\right)^{1/2}$
s_t	$-a\left(\frac{(J+m_J)(J-m_J+1)}{J(J+1)}\right)^{1/2}$	$a\frac{m_J}{(J(J+1))^{1/2}}+b$	$a\frac{m_J}{(J(J+1))^{1/2}}-b$	$a\left(\frac{(J-m_J)(J+m_J+1)}{J(J+1)}\right)^{1/2}$

$$a=\sqrt{\frac{1+\xi}{2}},\quad b=\sqrt{\frac{1-\xi}{2}}, \tag{53}$$

where

$$\xi=(4((m_1-m_2)/(m_1+m_2))^2J(J+1)+1)^{-1/2}. \tag{54}$$

The new states, which diagonalize the expectation value of $\hat{H}$, shall be called quasisinglet $|sg_q\rangle$ and quasitriplet $|tr_q\rangle$ states

$$\begin{aligned}|sg_q\rangle&=\sum_{s_1s_2}C^{(s_s)Jm_{s_1s_2}}_{Jm_J}\int \mathrm{d}^3\mathbf{p}\, f^J(p)Y^{m_J}_J(\hat{\mathbf{p}})b^\dagger_{\mathbf{p}s_1}D^\dagger_{-\mathbf{p}s_2}|0\rangle,\\ |tr_q\rangle&=\sum_{s_1s_2}C^{(s_t)Jm_{s_1s_2}}_{Jm_J}\int \mathrm{d}^3\mathbf{p}\, f^J(p)Y^{m_J}_J(\hat{\mathbf{p}})b^\dagger_{\mathbf{p}s_1}D^\dagger_{-\mathbf{p}s_2}|0\rangle,\end{aligned} \tag{55}$$

where the coefficients $C^{(s_s)Jm_{s_1s_2}}_{Jm_J}$ and $C^{(s_t)Jm_{s_1s_2}}_{Jm_J}$ are listed in Table I, and satisfy the following condition:

$$\sum_{\nu_1\nu_2m_J}(C^{(s_s)Jm_\nu}_{Jm_J})^2=\sum_{\nu_1\nu_2m_J}(C^{(s_t)Jm_\nu}_{Jm_J})^2=2(2J+1). \tag{56}$$

Note that these coefficients differ from CG coefficients, because of the coupled system we are dealing with. Remember that these coupled quasistates arise only for $J>0$. For $J=0$ purely $S=0$ states occur. Quasisinglet and quasitriplet states are both characterized by the same quantum numbers J, m_J and $P=(-1)^{J+1}$. Because of the unimodularity of matrix (52) we can identify quasisinglet and quasitriplet states by quasispin (like isospin) $t=1/2$ with $t_3=\mp 1/2$, which is a new quantum number (or label). However, for our purpose it is more convenient to use the value $s=t_3+1/2$, which gives $s=s_s=0$ or $s=s_t=1$ for quasisinglet and quasitriplet states, respectively. In this case the labels s_s and s_t reflect better the meaning of the indicated quasistates. It is easy to see from (55) and Table I that for positronium the quasistates become true singlet ($b=0$) and triplet ($a=0$) states with different charge conjugation quantum numbers. It is useful to note for subsequent calculations that the coefficients C_1 and C_2 in (40) are $C_1=a$, $C_2=-b$ for quasisinglet states $s=s_s=0$, and $C_1=b$, $C_2=a$ for quasitriplet states $s=s_t=1$.

B. The triplet ℓ-mixing states

These states occur for $\ell_{s_1s_2}\equiv\ell=J\mp 1$ (see Appendix A). The adjustable functions have the form

$$F_{s_1s_2}(\mathbf{p}) = C^{(tr)(J-1)m_s}_{Jm_J} f^{J-1}(p) Y^{m_{s_1s_2}}_{J-1}(\hat{\mathbf{p}}) + C^{(tr)(J+1)m_s}_{Jm_J} f^{J+1}(p) Y^{m_{s_1s_2}}_{J+1}(\hat{\mathbf{p}}), \tag{57}$$

where $m_{s_1s_2}$ are defined in (47), while the coefficients $C^{(tr)(J\mp1)m_s}_{Jm_J}$, which are precisely the CG coefficients, can be found in Appendix A. Expression (57) involves two radial functions $f^{J-1}(p)$ and $f^{J+1}(p)$ which correspond to $\ell = J-1$ and $\ell = J+1$. This reflects the fact that the orbital angular momentum is not conserved and ℓ is not a good quantum number. The system in these states is characterized by J, m_J, and $P=(-1)^J$. In spectroscopic notation, these states are a mixture of $^3(J-1)_J$, and $^3(J+1)_J$ states. The exception is the state with $J=0$, for which the orbital angular momentum is a good quantum number. Indeed, for $J=0$ the function $f^{J-1}(p)$ does not exist (see Appendix A), thus the function $F_{s_1s_2}(\mathbf{p})$ is defined only by the second term in (57). Note that ℓ-mixing states appear for principal quantum number $n \geqslant 3$ only.

V. THE RELATIVISTIC RADIAL EQUATIONS FOR TWO-FERMION SYSTEMS

It is not possible to write a universal two-fermion wave equation, because the adjustable functions have different form for different states. Thus it was important to classify all states of the system before deriving final radial equations. Now we return to the variational equation (30) and replace the functions $F_{s_1s_2}(\mathbf{p})$ by the expression (40) for the quasistates and by (57) for the triplet states. After completing the variational procedure we obtain the following results.

For the states with $\ell = J$, $P=(-1)^{J+1}$ the radial equations are

$$(\omega_p + \Omega_p - E) f^J(p) = \frac{m_1 m_2}{(2\pi)^3} \int \frac{q^2\, dq}{\sqrt{\omega_p \omega_q \Omega_p \Omega_q}} \mathcal{K}(p,q) f^J(q), \tag{58}$$

where the kernel $\mathcal{K}(p,q)$ is defined by invariant $\mathcal{M}$-matrices as follows from (30). For the pure singlet states with $J=0$ the kernel $\mathcal{K}(p,q)$ is

$$\mathcal{K}(p,q) = -\frac{i}{4\pi} \int d\hat{\mathbf{p}}\, d\hat{\mathbf{q}} (\mathcal{M}_{1212}(\mathbf{p},\mathbf{q}) - \mathcal{M}_{1221}(\mathbf{p},\mathbf{q}) - \mathcal{M}_{2112}(\mathbf{p},\mathbf{q}) + \mathcal{M}_{2121}(\mathbf{p},\mathbf{q})). \tag{59}$$

For quasisinglet and quasitriplet states ($J \geqslant 1$) we have

$$\mathcal{K}(p,q) = -i \sum_{s_1s_2\sigma_1\sigma_2 m_J} \int d\hat{\mathbf{p}}\, d\hat{\mathbf{q}}\, C^{(s)s_1s_2\sigma_1\sigma_2}_{Jm_J} \mathcal{M}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q}) Y^{m_J *}_J(\hat{\mathbf{p}}) Y^{m_J}_J(\hat{\mathbf{q}}), \tag{60}$$

where the coefficients $C^{(s)s_1s_2\sigma_1\sigma_2}_{Jm_J}$ are expressed through the coefficients $C^{(s)Jm_{s_1s_2}}_{Jm_J}$,

$$C^{(s)s_1s_2\sigma_1\sigma_2}_{Jm_J} \equiv C^{(s)Jm_{s_1s_2}}_{Jm_J} C^{(s)Jm_{\sigma_1\sigma_2}}_{Jm_J} \Big/ \sum_{\nu_1\nu_2 m_J} (C^{(s)Jm_{\nu_1\nu_2}}_{Jm_J})^2, \tag{61}$$

where $s=s_s$, s_t. In (60) we have summed over m_J, because of the $2J+1$ energy degeneracy.

For the triplet states with $\ell = J \mp 1$, we have two independent radial functions $f^{J-1}(p)$ and $f^{J+1}(p)$. Thus the variational equation (30) leads to a system of coupled equations for $f^{J-1}(p)$ and $f^{J+1}(p)$. It is convenient to write them in matrix form,

$$(\omega_p + \Omega_p - E) \mathbb{F}(p) = \frac{m_1 m_2}{(2\pi)^3} \int \frac{q^2\, dq}{\sqrt{\omega_p \omega_q \Omega_p \Omega_q}} \mathbb{K}(p,q) \mathbb{F}(q), \tag{62}$$

where

$$\mathbb{F}(p) = \begin{bmatrix} f^{J-1}(p) \\ f^{J+1}(p) \end{bmatrix} \tag{63}$$

and

$$\mathbb{K}(p,q) = \begin{bmatrix} \mathcal{K}_{11}(p,q) & \mathcal{K}_{12}(p,q) \\ \mathcal{K}_{21}(p,q) & \mathcal{K}_{22}(p,q) \end{bmatrix}. \tag{64}$$

The kernels $\mathcal{K}_{ij}$ are similar in form to (60), that is

$$\mathcal{K}_{ij}(p,q) = -i \sum_{s_1 s_2 \sigma_1 \sigma_2 m_J} C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J i j} \int \mathrm{d}\hat{\mathbf{p}}\, \mathrm{d}\hat{\mathbf{q}}\, \mathcal{M}_{s_1 s_2 \sigma_1 \sigma_2}(\mathbf{p},\mathbf{q}) Y^{m_{s_1 s_2}\,*}_{\ell_i}(\hat{\mathbf{p}}) Y^{m_{\sigma_1 \sigma_2}}_{\ell_j}(\hat{\mathbf{q}}). \tag{65}$$

However the coefficients $C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J i j}$ are defined by the expression

$$C^{s_1 s_2 \sigma_1 \sigma_2}_{J m_J i j} = C^{(tr)\ell_i m_{s_1 s_2}}_{J m_J} C^{(tr)\ell_j m_{\sigma_1 \sigma_2}}_{J m_J} \Big/ \sum_{s_1 s_2 m_J} (C^{(tr)\ell_i m_s}_{J m_J})^2, \tag{66}$$

where $\ell_1 = J-1$, $\ell_2 = J+1$. The system (62) reduces to a single equation for $f^{J+1}(p)$ when $J=0$, since $f^{J-1}(p)=0$ in that case.

To our knowledge, it is not possible to obtain analytic solutions of the relativistic radial momentum-space equations (58) and (62). Thus one must resort to numerical or other approximation methods. Numerical solutions of such equations are discussed, for example, in Ref. 11, while variational approximations have been employed in Ref. 5. However, in this paper we shall resort to perturbative approximations, in order to verify that our equations agree with known results for positronium to $O(\alpha^4)$. We expect that this must be so, given that the interaction kernels (i.e., momentum-space potentials) of our equations involve the "tree-level" Feynman diagrams only.

Beyond $O(\alpha^4)$ our equations are evidently incomplete. One could, of course, augment them by the addition of invariant matrix elements corresponding to one-loop Feynman diagrams to the existing $\mathcal{M}$-matrices in the kernels of our equations. Indeed such an approach has been used in a similar though not variational treatment of positronium and muonium by Zhang and Koniuk.[14,15] These authors show that the inclusion of single-loop diagrams yields positronium energy eigenstates which are accurate to $O(\alpha^5, \alpha^5 \ln \alpha)$. However such *ad-hoc* augmentation of the kernels would be contrary to the spirit of the present variational treatment, and we shall not pursue it in this work.

VI. THE KERNELS IN SEMIRELATIVISTIC EXPANSION AND THE NONRELATIVISTIC LIMIT

For perturbative solutions of our radial equations, it is necessary to work out expansions of the relevant expressions to first order beyond the nonrelativistic limit. This shall be summarized in the present section. We shall do the calculation in the Coulomb gauge, in which the photon propagator has the form[16]

$$D_{00}(\mathbf{k}) = \frac{1}{\mathbf{k}^2}, \quad D_{0l}(\mathbf{k}) = 0, \quad D_{kl}(k^\mu) = \frac{1}{k^\mu k_\mu}\left(\delta_{kl} - \frac{k_k k_l}{\mathbf{k}^2}\right), \tag{67}$$

where $k^\mu = (\omega_p - \omega_q, \mathbf{p}-\mathbf{q})$.

To expand the amplitudes $\mathcal{M}$ of (31) and (32) up to the lowest nontrivial order of $(p/m)^2$, we take the free-particle spinors to be

$$u(\mathbf{p},i) = \begin{bmatrix} \left(1 + \dfrac{\mathbf{p}^2}{8m^2}\right) \\ \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{2m} \end{bmatrix} \varphi_i, \quad v(\mathbf{p},i) = \begin{bmatrix} \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{2m} \\ \left(1 + \dfrac{\mathbf{p}^2}{8m^2}\right) \end{bmatrix} \chi_i, \tag{68}$$

as discussed in Appendix C. Analogously, the photon propagator takes on the form

$$D_{00}(\mathbf{p}-\mathbf{q}) = \frac{1}{(\mathbf{p}-\mathbf{q})^2}, \quad D_{kl}(\mathbf{p}-\mathbf{q}) \simeq -\frac{1}{(\mathbf{p}-\mathbf{q})^2}\left(\delta_{kl} - \frac{(p-q)_k(p-q)_l}{(\mathbf{p}-\mathbf{q})^2}\right). \tag{69}$$

In this case the total photon propagator (28) coincides with (69). Corresponding calculations give for the orbital part of the $\mathcal{M}$-matrix,

$$\mathcal{M}^{ope(orb)}_{s_1s_2\sigma_1\sigma_2}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{(\mathbf{p}-\mathbf{q})^2}\delta_{s_1\sigma_1}\delta_{s_2\sigma_2} + \frac{iq_1q_2}{m_1m_2}\left(\frac{1}{2}\left(\frac{m_1}{m_2}+\frac{m_2}{m_1}\right)\left(\frac{1}{4}+\frac{\mathbf{q}\cdot\mathbf{p}}{(\mathbf{p}-\mathbf{q})^2}\right) + \frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}\right)\delta_{s_1\sigma_1}\delta_{s_2\sigma_2}. \tag{70}$$

The linear spin terms, which are responsible for spin–orbit interaction, become

$$\mathcal{M}^{ope(s-o)}_{s_1s_2\sigma_1\sigma_2}(\mathbf{q},\mathbf{p}) = -\frac{q_1q_2}{4m_1m_2}\varphi^\dagger_{s_1}\chi^\dagger_{\sigma_2}\left(\left(\frac{m_2}{m_1}+2\right)\vec{\sigma}_1 - \left(\frac{m_1}{m_2}+2\right)\vec{\sigma}_2\right)\cdot\frac{\mathbf{p}\times\mathbf{q}}{(\mathbf{p}-\mathbf{q})^2}\varphi_{\sigma_1}\chi_{s_2}. \tag{71}$$

Here $\vec{\sigma}_1$ and $\vec{\sigma}_2$ are spin matrices of the first and second particles, respectively, which are defined by the following operations: $\vec{\sigma}_1\varphi_{\sigma_1}\chi_{s_2}=(\vec{\sigma}_1\varphi_{\sigma_1})\chi_{s_2}$, $\vec{\sigma}_2\varphi_{\sigma_1}\chi_{s_2}=\varphi_{\sigma_1}(\vec{\sigma}_2\chi_{s_2})$. The quadratic spin terms or spin–spin interaction terms are

$$\mathcal{M}^{ope(s-s)}_{s_1s_2\sigma_1\sigma_2}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{4m_1m_2}\varphi^\dagger_{s_1}\chi^\dagger_{\sigma_2}\left\{-\frac{(\vec{\sigma}_2\cdot(\mathbf{p}-\mathbf{q}))(\vec{\sigma}_1\cdot(\mathbf{p}-\mathbf{q}))}{(\mathbf{p}-\mathbf{q})^2} + (\vec{\sigma}_1\cdot\vec{\sigma}_2)\right\}\varphi_{\sigma_1}\chi_{s_2}. \tag{72}$$

The annihilation contribution, which arises for a particle–antiparticle system,[10] is given by the term

$$\mathcal{M}^{ann}_{s_1s_2\sigma_1\sigma_2}(\mathbf{p},\mathbf{q}) = -\frac{ie^2}{4m^2}\varphi^\dagger_{s_1}\chi^\dagger_{\sigma_2}\{\vec{\sigma}_1\cdot\vec{\sigma}_2\}\varphi_{\sigma_1}\chi_{s_2}, \tag{73}$$

where we have excluded a divergent term, which appears in the Coulomb gauge. In this case $m_1=m_2\equiv m$ and $q_1=q_2\equiv e$ in formulas (70)–(72).

The kernels are calculated from (59), (60), and (65) with (70)–(72). They consist of three parts, namely

$$\mathcal{K}(p,q) = \mathcal{K}^{(orb)}(p,q) + \mathcal{K}^{(s-o)}(p,q) + \mathcal{K}^{(s-s)}(p,q). \tag{74}$$

A. The singlet state ($\ell=J=0$, $P=-1$)

Details of the calculations can be found in Appendix D. We use the notation, $z=(p^2+q^2)/2pq$, and $Q_\lambda(z)$ are the Legendre functions of the second kind.[17] The contributions of the various terms to the kernel are as follows:

Orbital term,

$$\mathcal{K}^{(sgl)(orb)}(p,q) = \frac{2\pi q_1q_2}{pq}Q_0(z) + \frac{\pi q_1q_2}{2m_1m_2}\left(\left(\frac{m_1}{m_2}+\frac{m_2}{m_1}+1\right)\left(\frac{p}{q}+\frac{q}{p}\right)Q_0(z) + 2Q_1(z) - \left(\frac{m_1}{m_2}+\frac{m_2}{m_1}+2\right)\right). \tag{75}$$

Spin–orbit interaction,

$$\mathcal{K}^{(sgl)(s-o)}(p,q) = 0. \tag{76}$$

Spin–spin interaction

$$\mathcal{K}^{(sgl)(s-s)}(p,q) = \frac{2\pi q_1q_2}{m_1m_2}. \tag{77}$$

B. The quasistates [$\ell = J (J \geqslant 1)$, $P = (-1)^{J+1}$, $s = 0,1$]

The contributions of the various terms to the kernel are as follows.
Orbital term,

$$\mathcal{K}^{(orb)}(p,q) = \frac{\pi q_1 q_2}{pq} Q_J(z) + \frac{\pi q_1 q_2}{2m_1 m_2}\left(\left(\frac{m_1}{m_2} + \frac{m_2}{m_1} - (J-1)\right)\left(\frac{p}{q} + \frac{q}{p}\right)Q_J(z) + 2(J+1)Q_{J+1}(z)\right), \tag{78}$$

Spin–orbit interaction,

$$\mathcal{K}^{(s-o)}(p,q) = \frac{\pi q_1 q_2}{2m_1 m_2}\left(-C_2^2\left(\frac{m_1}{m_2} + \frac{m_2}{m_1} + 4\right) + 2C_1 C_2 \sqrt{J(J+1)}\left|\frac{m_2}{m_2} - \frac{m_1}{m_1}\right|\right) \times \frac{1}{2J+1}(Q_{J+1}(z) - Q_{J-1}(z)). \tag{79}$$

Spin–spin interaction,

$$\mathcal{K}^{(s-s)}(p,q) = C_2^2 \frac{\pi q_1 q_2}{2m_1 m_2}\left(\frac{p}{q} + \frac{q}{p}\right)Q_J(z) - C_2^2 \frac{\pi q_1 q_2}{m_1 m_2}\frac{1}{2J+1}\{JQ_{J+1}(z) + (J+1)Q_{J-1}(z)\}, \tag{80}$$

where C_1 and C_2 are defined in Sec. IV.

C. The triplet states [$\ell = J-1 (J \geqslant 1)$, $\ell = J+1 (J \geqslant 0)$, $P = (-1)^J$]

From (65), it follows that the kernels $\mathcal{K}_{12}$ and $\mathcal{K}_{21}$ are responsible for mixing of states with $\ell = J-1$ and $\ell = J+1$. These kernels have the form

$$\mathcal{K}_{12}(p,q) = \mathcal{K}_{21}(p,q) = \frac{\pi q_1 q_2}{5m_1 m_2}\frac{\sqrt{J(J+1)}}{(2J+1)}\left(\frac{p}{q}Q_{J+1}(z) + \frac{q}{p}Q_{J-1}(z) - 2Q_J(z)\right), \tag{81}$$

where only spin–spin interactions contribute. For kernels $\mathcal{K}_{11}$ and $\mathcal{K}_{11}$ we have the following from (65):
Orbital terms,

$$\mathcal{K}_{11}^{(o)}(p,q) = \frac{2\pi q_1 q_2}{pq}Q_{J-1}(z) + \frac{\pi q_1 q_2}{2m_1 m_2}\left(\frac{m_1}{m_2} + \frac{m_2}{m_1} + 2 - J\right)\left(\frac{p}{q} + \frac{q}{p}\right)Q_{J-1}(z) + \frac{\pi q_1 q_2}{m_1 m_2}JQ_J(z) - \frac{\pi q_1 q_2}{2m_1 m_2}\left(\frac{m_1}{m_2} + \frac{m_2}{m_1} + 2\right)\delta_{J,1}, \tag{82}$$

$$\mathcal{K}_{22}^{(o)}(p,q) = \frac{2\pi q_1 q_2}{pq}Q_{J+1}(z_1) + \frac{\pi q_1 q_2}{2m_1 m_2}\left(\frac{m_1}{m_2} + \frac{m_2}{m_1} - J\right)\left(\frac{p}{q} + \frac{q}{p}\right)Q_{J+1}(z_1) + \frac{\pi q_1 q_2}{m_1 m_2}(J+2)Q_{J+2}(z). \tag{83}$$

Spin–orbit interaction,

$$\mathcal{K}_{11}^{(s-o)}(p,q) = \frac{\pi q_1 q_2}{2m_1 m_2}\frac{J-1}{2J-1}\left(\frac{m_2}{m_1} + \frac{m_1}{m_2} + 4\right)(Q_J(z) - Q_{J-2}(z)), \tag{84}$$

$$\mathcal{K}_{22}^{(s-o)}(p,q) = -\frac{\pi q_1 q_2}{2m_1 m_2}\left(\frac{m_2}{m_1} + \frac{m_1}{m_2} + 4\right)\frac{J+2}{2J+3}(Q_{J+2}(z) - Q_J(z)). \tag{85}$$

Spin–spin interaction,

$$\mathcal{K}_{11}^{(s-s)}(p,q)=\frac{\pi q_1 q_2}{2m_1 m_2}\frac{1}{2J+1}\left(\left(\frac{p}{q}+\frac{q}{p}\right)Q_{J-1}(z)-2Q_J(z)\right), \tag{86}$$

$$\mathcal{K}_{22}^{(s-s)}(p,q)=\frac{\pi q_1 q_2}{2m_1 m_2}\frac{1}{2J+3}\left(\left(\frac{p}{q}+\frac{q}{p}\right)Q_{J+1}(z)-2Q_{J+2}(z)\right). \tag{87}$$

Annihilation term (particle–antiparticle system only, with $m_1=m_2=m$, $q_1=q_2=e$),

$$\mathcal{K}^{ann}(p,q)=-\frac{2\pi e^2}{m^2}\delta_{J,1}. \tag{88}$$

We note that in the nonrelativistic limit the only terms that survive are the first terms of the orbital part of the kernels. They have the common form $2\pi q_1 q_2 Q_\ell(z)/pq$, where

$$Q_\ell(z)=\frac{pq}{2\pi}\int\frac{d\hat{\mathbf{q}}\,d\hat{\mathbf{p}}}{(\mathbf{p}-\mathbf{q})^2}Y_\ell^{m_\ell *}(\hat{\mathbf{p}})Y_\ell^{m_\ell}(\hat{\mathbf{q}}). \tag{89}$$

Thus, Eqs. (58) and (62) reduce to the form

$$(\omega_p+\Omega_p-E)f^\ell(p)=\frac{m_1 m_2 q_1 q_2}{\pi\sqrt{\omega_p\Omega_p}p}\int_0^\infty dq\frac{q}{\sqrt{\omega_q\Omega_q}}Q_\ell(z)f^\ell(q). \tag{90}$$

If we expand the relativistic free-particle energy,

$$\omega_p\simeq m_1\left(1+\frac{1}{2}\left(\frac{\mathbf{p}}{m_1}\right)^2\right),\quad \Omega_p\simeq m_2\left(1+\frac{1}{2}\left(\frac{\mathbf{p}}{m_2}\right)^2\right), \tag{91}$$

we obtain the two-particle Schrödinger radial equation in momentum space[18]

$$\left(\frac{\mathbf{p}^2}{2m_r}-\varepsilon\right)f^\ell(p)=\frac{\alpha}{\pi p}\int_0^\infty dq\,qQ_\ell(z)f^\ell(q), \tag{92}$$

where $\alpha=q_1q_2/4\pi$. The solutions of these equations are well known. They are given in Appendix D [formula (D12)].

VII. ENERGY EIGENVALUES AND RELATIVISTIC CORRECTIONS TO $O(\alpha^4)$ FOR ARBITRARY MASS RATIO

The energy eigenvalues $E_{n,J}$ for the states, when $\ell=J$, can be calculated from the equation

$$E\int_0^\infty dp\,p^2 f^J(p)f^J(p)=\int_0^\infty dp\,p^2(\omega_p+\Omega_p)f^J(p)f^J(p) - \frac{m_1m_2}{(2\pi)^3}\int_0^\infty\frac{p^2\,dp}{\sqrt{\omega_p\Omega_p}}\int_0^\infty\frac{q^2\,dq}{\sqrt{\omega_q\Omega_q}}\mathcal{K}(p,q)f^J(p)f^J(q). \tag{93}$$

For the $\ell=J\mp1$ triplet states we have the equation

$$E\int_0^\infty dp\,p^2 f^{\ell_i}(p)f^{\ell_i}(p)=\int_0^\infty dp\,p^2(\omega_p+\Omega_p)f^{\ell_i}(p)f^{\ell_i}(p) - \frac{m_1m_2}{(2\pi)^3}\int_0^\infty\frac{p^2\,dp}{\sqrt{\omega_p\Omega_p}}\int_0^\infty\frac{q^2\,dq}{\sqrt{\omega_q\Omega_q}}\mathcal{K}_{ij}(p,q)f^{\ell_i}(p)f^{\ell_j}(q). \tag{94}$$

To obtain results for E to $O(\alpha^4)$ we use the forms of the kernels expanded to $O(p^2/m^2)$ [expressions (75)–(88)] and replace $f^\ell(p)$ by their nonrelativistic (Schrödinger) form (D12) (see Appendix

D). The most important integrals, which we used for calculating (93) and (94), are given in Appendix D. It has been shown in Ref. 10 that the contribution of the kernels $\mathcal{K}_{12}$ and $\mathcal{K}_{21}$ in (94), which are responsible for coupling of the equations (62), is zero. Thus in the framework of the present approximation, the energy corrections for the triplet states with $\ell=J-1$ and $\ell=J+1$ can be calculated independently. We present the results in the form $\Delta\varepsilon=E+(\alpha^2 m_r/2n^2)-M$, $M=m_1+m_2$, $m_r=m_1m_2/(m_1+m_2)$.

A. Singlet states ($\ell=J=0$, $P=-1$) (which include the ground state)

The kinetic energy corrections,

$$\Delta\varepsilon_n^{(sg)(k)}=-\frac{\alpha^4 m_r}{n^3}\left(1-\frac{3}{8n}\right)\left(1-\frac{3m_r}{M}\right). \tag{95}$$

Orbital energy corrections,

$$\Delta\varepsilon_n^{(sg)(o)}=-\frac{\alpha^4 m_r}{n^3}\left(-\frac{1}{2}+\frac{3m_r}{M}-\frac{m_r}{M}\frac{1}{n}\right). \tag{96}$$

Spin–orbit energy corrections,

$$\Delta\varepsilon_n^{(sg)(s\text{-}o)}=0. \tag{97}$$

Spin–spin energy corrections,

$$\Delta\varepsilon_n^{(sg)(s-s)}=-\frac{\alpha^4 m_r}{n^3}\frac{2m_r}{M}. \tag{98}$$

The total energy corrections,

$$\Delta\varepsilon_n^{(sg)}=-\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2}+\frac{2m_r}{M}-\frac{1}{8n}\left(3-\frac{m_r}{M}\right)\right). \tag{99}$$

B. Quasisinglet, quasitriplet states [$\ell=J(J\geqslant 1)$, $P=(-1)^{J+1}$]

The kinetic energy and orbital energy corrections are common for quasisinglet and quasitriplet states,

$$\Delta\varepsilon_{n,J}^{(k)}=-\frac{\alpha^4 m_r}{2n^3}\left(1-\frac{3m_r}{M}\right)\left(\frac{2}{2J+1}-\frac{3}{4n}\right). \tag{100}$$

Orbital energy corrections,

$$\Delta\varepsilon_{n,J}^{(orb)}=-\frac{\alpha^4 m_r}{n^3}\frac{m_r}{M}\left(\frac{3}{2J+1}-\frac{1}{n}\right). \tag{101}$$

Spin–orbit energy corrections,

$$\Delta\varepsilon_{n,J}^{(s-o)}=\frac{\alpha^4 m_r}{2n^3}\frac{1}{M^2}\frac{-C_2^2((m_1+m_2)^2+2m_1m_2)+2C_1C_2\sqrt{J(J+1)}|m_2^2-m_1^2|}{(2J+1)(J+1)J}. \tag{102}$$

Spin–spin energy corrections,

$$\Delta\varepsilon_{n,J}^{(s-s)}=\frac{\alpha^4 m_r}{n^3}\frac{m_r}{M}\frac{C_2^2}{(2J+1)(J+1)J}. \tag{103}$$

The coefficients C_1 and C_2 are defined here in the same way as in formulas (79) and (80).

Thus, the total energy corrections are

$$\Delta\varepsilon_{n,J,s} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J+1}\left(1+\frac{1\mp\xi^{-1}}{4J(J+1)}\right)-\frac{1}{8n}\left(3-\frac{m_r}{M}\right)\right), \tag{104}$$

where upper and lower signs correspond to quasisinglet $s=s_s=0$ and quasitriplet $s=s_t=1$ states, respectively.

C. Triplet states $[\ell=J-1(J\geqslant 1),\ P=(-1)^J]$

Kinetic energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(k)} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J-1}-\frac{3}{8n}\right)\left(1-\frac{3m_r}{M}\right). \tag{105}$$

Orbital energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(o)} = -\frac{\alpha^4 m_r}{n^3}\left(-\frac{\delta_{J,1}}{2}+\left(\frac{3}{2J-1}-\frac{\delta_{J,1}}{2}-\frac{1}{n}\right)\frac{m_r}{M}\right). \tag{106}$$

Spin–orbit energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(s-o)} = \frac{\alpha^4 m_r}{n^3}\frac{1-\delta_{J,1}}{2J(2J-1)}\left(1+\frac{2m_r}{M}\right). \tag{107}$$

Spin–spin energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(s-s)} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1-\delta_{J,1}}{J(2J+1)(2J-1)}-\frac{2}{3}\delta_{J,1}\right)\frac{m_r}{M}. \tag{108}$$

The total energy corrections,

$$\Delta\varepsilon_{n,J}^{tr} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J-1}\left(1-\frac{1}{2J}-\frac{2m_r}{M}\frac{1}{2J+1}\right)-\frac{1}{8n}\left(3-\frac{m_r}{M}\right)\right). \tag{109}$$

The annihilation term for positroniumlike systems is

$$\Delta\varepsilon_{n}^{(anh)} = \frac{\alpha^4 m}{4n^3}\delta_{J,1}. \tag{110}$$

D. Triplet states $[\ell=J+1(J\geqslant 0),\ P=(-1)^J]$

The kinetic energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(k)} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J+3}-\frac{3}{8n}\right)\left(1-\frac{3m_r}{M}\right). \tag{111}$$

Orbital energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(o)} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{3}{2J+3}-\frac{1}{n}\right)\frac{m_r}{M}. \tag{112}$$

Spin–orbit energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(s-o)} = -\frac{\alpha^4 m_r}{n^3}\frac{1}{2(J+1)(2J+3)}\left(1+\frac{2m_r}{M}\right). \tag{113}$$

Spin–spin energy corrections,

$$\Delta\varepsilon_{n,J}^{(tr)(s-s)} = -\frac{\alpha^4 m_r}{n^3}\frac{1}{(J+1)(2J+3)(2J+1)}\frac{m_r}{M}. \tag{114}$$

The total energy corrections,

$$\Delta\varepsilon_{n,J}^{tr} = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J+3}\left(1+\frac{1}{2(J+1)}+\frac{2m_r}{M}\frac{1}{2J+1}\right)-\frac{1}{8n}\left(3-\frac{m_r}{M}\right)\right). \tag{115}$$

For two equal masses our calculations agree with positronium results.[19] In the limit when one of the masses becomes infinite, say $m_2\to\infty$, the above results reduce to those obtained for a one-electron Dirac equation in a static Coulomb potential [to $O(\alpha^4)$], namely

$$\Delta\varepsilon_{n,j} = -\frac{\alpha^4 m_1}{n^3}\left(\frac{1}{2j+1}-\frac{3}{8n}\right). \tag{116}$$

Indeed, when $m_2\to\infty$ not only the total angular momentum, but also $\mathbf{J}_1^2=(\mathbf{L}_1+\mathbf{S}_1)^2$ and $\mathbf{S}_2^2$ are independently conserved. Thus, in this case, we can replace the quantum number J by $j-1/2$ in (100)–(104) (when $s=0$) and (111)–(115), and by $j+1/2$ in expressions (100)–(104) (when $s=1$) and (105)–(109). In other words,

$$\begin{aligned} &J\to j-1/2 \quad \text{for } |sg_q\rangle \text{ and } |tr_{\ell=J+1}\rangle,\\ &J\to j+1/2 \quad \text{for } |tr_q\rangle \text{ and } |tr_{\ell=J-1}\rangle. \end{aligned} \tag{117}$$

The quantum number $j=|\ell\pm 1/2|$ belongs here to the particle with mass m_1.

The results (99), (104), (109), and (115) agree with the calculations of Connell, based on a quasipotential reduction of the Bethe–Salpeter equation,[20] with those of Hersbach, who used a relativistic Lippman–Schwinger formulation,[21] and with those of Duviryak and Darewych based on a two-fermion Breit equation.[22] Grandy[8] obtained the same results from a perturbative solution of the coupled, nonlinear Dirac equations (8) and (9).

VIII. FINE AND HYPERFINE STRUCTURE: RECOIL EFFECTS

In this section we shall analyze the formulas obtained in the preceding section and we shall apply them to the energy spectra of some exotic atoms. To compare our calculations with experimental data we shall use the standard spectroscopical notation. First of all, it follows from (95)–(97) and (105)–(107) that the difference between the energy levels of $2S$ and $1S$ states (see Fig. 1) is given by formula

$$E(2S)-E(1S) = \frac{3\alpha^2 m_r}{8}+\frac{\alpha^4 m_r}{128}\left(11+15\frac{m_r}{M}\right). \tag{118}$$

Note that the formula (118) ignores hyperfine splitting(HFS), that is we exclude the spin–spin interaction. The fine structure [FS] of the $2P$-state follows similarly from (105)–(107) and (111)–(113), provided that we exclude the spin–spin interaction (108) and (114),

$$\Delta E_{\rm fs}(2P) \equiv E(2P_{3/2})-E(2P_{1/2}) = \frac{\alpha^4 m_r}{32}\left(1+\frac{2m_r}{M}\right). \tag{119}$$

The HFS of $1S_{1/2}$ and $2S_{1/2}$ is obtained from (99) and (109),

$$\Delta E_{\rm hfs}(1S_{1/2}) = \alpha^4 m_r\frac{8m_r}{3M}, \tag{120}$$

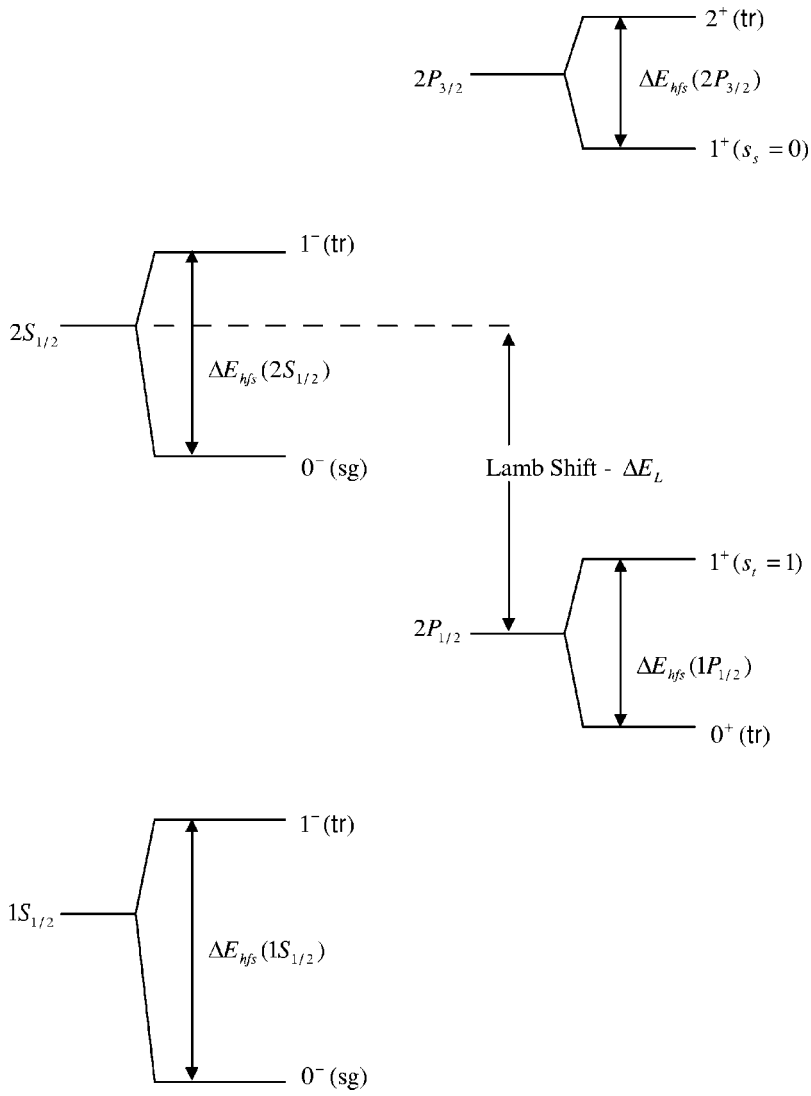

FIG. 1. Energy level diagram of a two-fermion system for $n=1$, 2 shells.

$$\Delta E_{\rm hfs}(2S_{1/2}) = \alpha^4 m_r \frac{m_r}{3M}. \tag{121}$$

Actually this hyperfine splitting, expressions (120) and (121), arises from the difference of spin–spin terms (98) and (108). The formulas (120) and (121) give the usual Fermi splitting.[18]

The HFS of states with $\ell>0$ is more complicated. For each $\ell>0$ we have two sorts of states with different J and s: states with $J=\ell+1$ and $J=\ell$, $s=s_s$ and states with $J=\ell-1$ and $J=\ell$, $s=s_t$. From (104), (109), and (115) we obtain the general HFS formulas for all quantum numbers n, ℓ and for any mass ratio,

$$\Delta E_{\rm hfs}(n,\ell,s_s) \equiv \Delta\varepsilon^{tr}_{n,J=\ell+1} - \Delta\varepsilon_{n,J=\ell,s_s} = \frac{\alpha^4 m_r}{n^3}\frac{1}{2\ell+1}\left(\frac{2\ell+1-\xi^{-1}}{4\ell(\ell+1)} + \frac{2m_r}{M}\frac{1}{2\ell+3}\right), \tag{122}$$

TABLE II. Hyperfine structure in muonium for $n=2$.

μ^+e^-	Experiment (Ref. 24)	Theory (126) and (127)	Theory with a_μ correction
$\Delta E_{\rm hfs}(2P_{1/2})$	186 MHz	185.80 MHz	186.01 MHz
$\Delta E_{\rm hfs}(2P_{3/2})$	74 MHz	74.43 MHz	74.52 MHz

$$\Delta E_{\rm hfs}(n,\ell,s_t) \equiv \Delta\varepsilon_{n,J=\ell,s_t} - \Delta\varepsilon^{tr}_{n,J=\ell-1} = \frac{\alpha^4 m_r}{n^3}\frac{1}{2\ell+1}\left(\frac{2\ell+1-\xi^{-1}}{4\ell(\ell+1)} + \frac{2m_r}{M}\frac{1}{2\ell-1}\right). \quad (123)$$

The quantity ξ is defined by (54), but with the quantum number J replaced by ℓ.

For the particular case when $m_2 \gg m_1$ we obtain from (122) and (123),

$$\Delta E_{\rm hfs}(n,l,s_s) = \frac{\alpha^4 m_1}{n^3}\frac{8(\ell+1)}{(2\ell+1)^2(2\ell+3)}\frac{m_1}{m_2}, \quad (124)$$

$$\Delta E_{\rm hfs}(n,\ell,s_t) = \frac{\alpha^4 m_1}{n^3}\frac{8\ell}{(2\ell+1)^2(2\ell-1)}\frac{m_1}{m_2}, \quad (125)$$

to leading order in m_1/m_2.

The approximate results (124) and (125) are the HFS formulas usually quoted in the literature (e.g., Ref. 18, p. 110, and Ref. 24, p. 836). As mentioned in Sec. VII, in the one-body limit ($m_2 \to \infty$), states with labels s_s and s_t can be characterized by the quantum numbers $j=\ell+1/2$ and $j=\ell-1/2$, respectively. In this one-body picture, the labels s_s and s_t should be replaced by j in the formulas (124) and (125). Note here that, because of the mixed nature of the states $n\ell_{\ell-1/2}(\ell=J, s_t=1)$ and $n\ell_{\ell+1/2}(\ell=J, s_s=0)$, the spin–orbit interaction contributes to the spliting as well. The splitting is largest when $m_1=m_2$ (positronium) and disappears for all states in the one-body limit.

It is easy to get the HFS of $2P_{1/2}$, $2P_{3/2}$ states from (122) and (123):

$$\Delta E_{\rm hfs}(2P_{1/2}) = \alpha^4 m_r\left(\frac{1}{64} - \frac{\xi^{-1}}{192} + \frac{1}{12}\frac{m_r}{M}\right), \quad (126)$$

$$\Delta E_{\rm hfs}(2P_{3/2}) = \alpha^4 m_r\left(\frac{1}{64} - \frac{\xi^{-1}}{192} + \frac{1}{60}\frac{m_r}{M}\right), \quad (127)$$

where $\xi^{-1}=\sqrt{8[(m_1-m_2)/M]^2+1}$. Note that, if we use the pure triplet state instead of the mixed states, we get the following expressions for hyperfine splitting: $E_{\rm hfs}(2P_{1/2})=\alpha^4 m_r\left[\frac{1}{96}+(m_r/12M)\right]$, $E_{\rm hfs}(2P_{3/2})=\alpha^4 m_r\left[\frac{1}{96}+(m_r/60M)\right]$. These give the correct results only for $m_1=m_2$.

The energy level diagram for $n=1$, 2 shells is presented in Fig. 1. Our calculations for FS (119) and HFS (120) and (121) reproduce the well-known result (see, for example, the recent and comprehensive reviews of Refs. 23 and 27). Thus we concentrate here on the discussion of HFS of exited states described by (122) and (123). As already mentioned, formulas (122) and (123) are a consequence of the general formulas (104), (109), and (115), which have been obtained also in Refs. 8 and 20–22. However, to the best of our knowledge, the derivation and analysis of (122) and (123) have never been presented. The results of our calculations of HFS and comparison with experimental data for muonium and hydrogen are summarized in Tables II and III. Because of the absence of experimental data for muonic hydrogen we compare our results with the calculations of Pachucki[28] in Table IV.

Although hydrogen and muonic hydrogen are not strictly leptonic atoms, we can take into account the proton anomalous magnetic moment in the hyperfine splitting in the same phenomenological manner as was done by Barker and Glover.[29] Thus, to get the corrected result for HFS in hydrogen and muonic hydrogen, we multiply the expression for $\Delta E_{\rm hfs}$ by the factor $(1+k_p)$,

TABLE III. Hyperfine structure in hydrogen for $n=2$.

H	Experiment (Refs. 25,26)	Theory (126) and (127)	Theory with k_p correction
$\Delta E_{\mathrm{hfs}}(2P_{1/2})$	59.1721 MHz (Ref. 25)	21.1698 MHz	59.1241 MHz
$\Delta E_{\mathrm{hfs}}(2P_{3/2})$	23.6541 MHz (Ref. 25)	8.4696 MHz	23.6543 MHz

where $k_p=1.792\,847$ is the anomalous magnetic moment of the proton. The last columns in Tables III and IV give the HFS corrected by the factor $(1+k_p)$. The anomalous magnetic moment of the muon is very small, nevertheless for the sake of completeness, we provide the same corrections for muonium, where we use the factor $(1+a_\mu)(a_\mu=0.001\,166)$ to get the result of the last column in Table II from those of the third column. We note that doing so improves the agreement between the calculated and the experimental HFS results in most cases, and dramatically so for hydrogen and muonic hydrogen.

From Tables II and III we see that the calculated $O(\alpha^4)$ results agree with observation remarkably well. Note that if we use the approximate m_1/m_2 expansion formulas (124) and (125), for example, for HFS of $2P_{1/2}$ and $2P_{3/2}$ states we would get, for muonium (with a_μ corrections), the result $\Delta E_{\mathrm{hfs}}(2P_{1/2})=188.50$ MHz, $\Delta E_{\mathrm{hfs}}(2P_{3/2})=75.40$ MHz. These approximate results do not agree as well with observation as the values calculated without the m_1/m_2 expansion, and hence they differ from what we give in the last column of Table II. Note that this difference can be of the same order as the contribution of higher order in α for HFS. Using (124) and (125) for muonic hydrogen gives (with k_p corrections) $\Delta E_{\mathrm{hfs}}(2P_{1/2})=10.47$ meV, $\Delta E_{\mathrm{hfs}}(2P_{3/2})=4.19$ meV. The m_1/m_2 expansion approximation is not significant for hydrogen for which the mass ratio is very small, but it is appreciable for muonium and particularly for muonic hydrogen. Since our results are true for arbitrary mass ratios we can speak here about recoil *effects* rather than about recoil *corrections* to α^4.

IX. CONCLUDING REMARKS

We have used the variational method within the Hamiltonian formalism of QED to derive relativistic momentum-space wave equations for two-fermion systems like muonium. The trial states are chosen to be eigenstates of the total angular momentum operators $\hat{\mathbf{J}}^2, \hat{J}_3$ and parity, as well as charge conjugation for particle–antiparticle systems. A general relativistic reduction of the wave equations to radial form is given for arbitrary masses of the two fermions. For given J there is a single radial equation for total spin zero singlet states, but for spin triplet states there are, in general coupled equations. We have shown how classification of the states follows naturally from the system of eigenvalue equations (37), given our trial state.

It is not possible, as far as we know, to obtain analytic solutions of our relativistic radial equations nor the resulting eigenvalues of the two fermion system that they describe. However, it is possible to obtain $O(\alpha^4)$ corrections to the energy eigenvalues analytically for all states using perturbation theory.

We have compared our calculated results with experiment for hyperfine splitting of low-lying levels in muonium and hydrogen. We find good agreement for muonium, as well as for hydrogen provided that we take into account the anomalous magnetic moment of the proton.

TABLE IV. Hyperfine structure in muonic hydrogen for $n=2$.

μ^-H	Theory (Ref. 27)	Theory (126) and (127)	Theory with k_p correction
$\Delta E_{\mathrm{hfs}}(2P_{1/2})$	7.96 meV	2.79 meV	7.79 meV
$\Delta E_{\mathrm{hfs}}(2P_{3/2})$	3.39 meV	1.16 meV	3.23 meV

The method presented here can be generalized to include effects of higher order in alpha by using dressed propagators in place of the bare propagators. This shall be the subject of a forthcoming work.

APPENDIX A: TOTAL ANGULAR MOMENTUM OPERATOR IN RELATIVISTIC FORM

The total angular momentum operator is defined by the expression

$$\hat{\mathbf{J}} = \int \mathrm{d}^3\mathbf{x}\ \psi^\dagger(x)(\hat{\mathbf{L}} + \hat{\mathbf{S}})\psi(x) + \int \mathrm{d}^3\mathbf{x}\ \phi^\dagger(x)(\hat{\mathbf{L}} + \hat{\mathbf{S}})\phi(x), \tag{A1}$$

where $\hat{\mathbf{L}}$ is the orbital angular momentum and $\hat{\mathbf{S}}$ is the spin operator, $\hat{\mathbf{L}} = \hat{\mathbf{x}} \times \hat{\mathbf{p}}$ and $\hat{\mathbf{S}} = \frac{1}{2}\hat{\vec{\sigma}}$. We use the standard representation for the Pauli matrices,

$$\hat{\vec{\sigma}} = \begin{bmatrix} \vec{\sigma} & 0 \\ 0 & \vec{\sigma} \end{bmatrix}, \tag{A2}$$

$$\sigma_1 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad \sigma_2 = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}, \quad \sigma_3 = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \tag{A3}$$

Using the field operators $\psi(x)$ and $\phi(x)$ in the form (18) and (19), after tedious calculations we obtain the expression for operator $\hat{\mathbf{J}}$. It consists of three parts, two total angular momentum operators of each particle–antiparticle system[10] and the following part, relevant to our considerations:

$$\hat{J}_1 = \int \mathrm{d}^3\mathbf{q} \begin{pmatrix} \hat{L}_{q1}(b^\dagger_{\mathbf{q}\uparrow} b_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}\downarrow} b_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\uparrow} D_{\mathbf{q}\uparrow} + D^\dagger_{\mathbf{q}\downarrow} D_{\mathbf{q}\downarrow}) \\ + \frac{1}{2}(b^\dagger_{\mathbf{q}\uparrow} b_{\mathbf{q}\downarrow} + b^\dagger_{\mathbf{q}\downarrow} b_{\mathbf{q}\uparrow} + D^\dagger_{\mathbf{q}\downarrow} D_{\mathbf{q}\uparrow} + D^\dagger_{\mathbf{q}\uparrow} D_{\mathbf{q}\downarrow}) \end{pmatrix},$$

$$\hat{J}_2 = \int \mathrm{d}^3\mathbf{q} \begin{pmatrix} \hat{L}_{q2}(b^\dagger_{\mathbf{q}\uparrow} b_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}\downarrow} b_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\uparrow} D_{\mathbf{q}\uparrow} + D^\dagger_{\mathbf{q}\downarrow} D_{\mathbf{q}\downarrow}) \\ + \frac{i}{2}(- b^\dagger_{\mathbf{q}\uparrow} b_{\mathbf{q}\downarrow} + b^\dagger_{\mathbf{q}\downarrow} b_{\mathbf{q}\uparrow} - D^\dagger_{\mathbf{q}\uparrow} D_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\downarrow} D_{\mathbf{q}\uparrow}) \end{pmatrix}, \tag{A4}$$

$$\hat{J}_3 = \int \mathrm{d}^3\mathbf{q} \begin{pmatrix} \hat{L}_{q3}(b^\dagger_{\mathbf{q}\uparrow} b_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}\downarrow} b_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\uparrow} D_{\mathbf{q}\uparrow} + D^\dagger_{\mathbf{q}\downarrow} D_{\mathbf{q}\downarrow}) \\ + \frac{1}{2}(b^\dagger_{\mathbf{q}\uparrow} b_{\mathbf{q}\uparrow} - b^\dagger_{\mathbf{q}\downarrow} b_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\uparrow} D_{\mathbf{q}\uparrow} - D^\dagger_{\mathbf{q}\downarrow} D_{\mathbf{q}\downarrow}) \end{pmatrix}.$$

Here $\hat{\mathbf{L}}_q$ is the orbital angular momentum operator in momentum representation,

$$(\hat{\mathbf{L}}_q)_i \equiv \hat{L}_{qi} = -i(\mathbf{q} \times \nabla_q)_i. \tag{A5}$$

Note that these expressions are valid for any t, since the time-dependent phase factors of the form $e^{i\omega_q t}$ cancel out. For the operator $\hat{\mathbf{J}}^2 = \hat{J}_1^2 + \hat{J}_2^2 + \hat{J}_3^2$ we have

$$\hat{\mathbf{J}}^2 = \int \mathrm{d}^3\mathbf{q}\begin{pmatrix} \left(\hat{\mathbf{L}}_q^2 + \frac{3}{4}\right)(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} + D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow}) \\ + \hat{L}_{q-}b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow} + \hat{L}_{q+}b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow} + \hat{L}_{q-}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\downarrow} + \hat{L}_{q+}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\uparrow} \\ + \hat{L}_{q3}(b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\uparrow} - b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\downarrow} + D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} - D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow}) \end{pmatrix}$$

$$+ \frac{1}{2}\int d^3\mathbf{q}'d^3\mathbf{q}\begin{pmatrix} 2\hat{\mathbf{L}}_{q'}\cdot\hat{\mathbf{L}}_q\begin{pmatrix} b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow} \\ + b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow} \end{pmatrix} \\ + \frac{1}{2}(b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} - b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow}) \\ - \frac{1}{2}(b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} - b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow}) \\ + b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\downarrow} \\ + \hat{L}_{q'+}\begin{pmatrix} b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\uparrow} + b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\uparrow} \\ + b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}D^\dagger_{\mathbf{q}'\uparrow}D_{\mathbf{q}'\uparrow} + b^\dagger_{\mathbf{q}\downarrow}b_{\mathbf{q}\uparrow}D^\dagger_{\mathbf{q}'\downarrow}D_{\mathbf{q}'\downarrow} \end{pmatrix} \\ + \hat{L}_{q'-}\begin{pmatrix} b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\downarrow} + b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\downarrow} \\ + b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}D^\dagger_{\mathbf{q}'\uparrow}D_{\mathbf{q}'\uparrow} + b^\dagger_{\mathbf{q}\uparrow}b_{\mathbf{q}\downarrow}D^\dagger_{\mathbf{q}'\downarrow}D_{\mathbf{q}'\downarrow} \end{pmatrix} \\ + (\hat{L}_{q'3} + \hat{L}_{q3})(b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow} - b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow}) \\ - (\hat{L}_{q'3} - \hat{L}_{q3})(b^\dagger_{\mathbf{q}'\uparrow}b_{\mathbf{q}'\uparrow}D^\dagger_{\mathbf{q}\downarrow}D_{\mathbf{q}\downarrow} - b^\dagger_{\mathbf{q}'\downarrow}b_{\mathbf{q}'\downarrow}D^\dagger_{\mathbf{q}\uparrow}D_{\mathbf{q}\uparrow}) \end{pmatrix}, \tag{A6}$$

where

$$\hat{L}_{q+} = \hat{L}_{q1} + i\hat{L}_{q2}, \quad \hat{L}_{q-} = \hat{L}_{q1} - i\hat{L}_{q2}. \tag{A7}$$

The formulas (A4) and (A6) apply to the particle–antiparticle system[10] as well if the operators $D^\dagger$ and D are formally replaced by $d^\dagger$ and d, respectively.

The requirements (37) with trial state in the form of (24) lead to the system of equations $[F_{s_1s_2}(\mathbf{p}) \equiv F_{s_1s_2}]$:

$$\begin{gathered} (\hat{L}_3 + 1)F_{11} = m_J F_{11}, \\ \hat{L}_3 F_{12} = m_J F_{12}, \\ \hat{L}_3 F_{21} = m_J F_{21}, \\ (\hat{L}_3 - 1)F_{22} = m_J F_{22}, \end{gathered} \tag{A8}$$

$$\begin{gathered} (J(J+1) - \hat{\mathbf{L}}^2 - 2 - 2\hat{L}_3)F_{11} = \hat{L}_-(F_{12} + F_{21}), \\ (J(J+1) - \hat{\mathbf{L}}^2 - 1)F_{12} = F_{21} + \hat{L}_+F_{11} + \hat{L}_-F_{22}, \\ (J(J+1) - \hat{\mathbf{L}}^2 - 1)F_{21} = F_{12} + \hat{L}_+F_{11} + \hat{L}_-F_{22}, \end{gathered} \tag{A9}$$

$$(J(J+1)-\hat{\mathbf{L}}^2-2+2\hat{L}_3)F_{22}=\hat{L}_+(F_{12}+F_{21}).$$

After substitution of the functions $F_{s_1s_2}$, Eq. (39), into the system (A8) and (A9) we get

$$m_{12}=m_{21}=m_J,\quad m_{11}=m_J-1,\quad m_{22}=m_J+1, \tag{A10}$$

$$\ell_{11}=\ell_{22}=\ell_{12}=\ell_{21}\equiv\ell, \tag{A11}$$

and

$$(J(J+1)-\ell(\ell+1)-2m_J)f^\ell_{11}(p)=\sqrt{(\ell-m_J+1)(\ell+m_J)}f^\ell_{12}(p)+\sqrt{(\ell-m_J+1)(\ell+m_J)}f^\ell_{21}(p), \tag{A12}$$

$$(J(J+1)-\ell(\ell+1)-1)f^\ell_{12}(p)=f^\ell_{21}(p)+\sqrt{(\ell+m_J)(\ell-m_J+1)}f^\ell_{11}(p)+\sqrt{(\ell-m_J)(\ell+m_J+1)}f^\ell_{22}(p), \tag{A13}$$

$$(J(J+1)-\ell(\ell+1)-1)f^\ell_{21}(p)=f^\ell_{12}(p)+\sqrt{(\ell+m_J)(\ell-m_J+1)}f^\ell_{11}(p)+\sqrt{(\ell-m_J)(\ell+m_J+1)}f^\ell_{22}(p), \tag{A14}$$

$$(J(J+1)-\ell(\ell+1)+2m_J)f^\ell_{22}(p)=\sqrt{(\ell+m_J+1)(\ell-m_J)}f^\ell_{12}(p)+\sqrt{(\ell+m_J+1)(\ell-m_J)}f^\ell_{21}(p). \tag{A15}$$

The solution of this system leads to two categories of relations among the functions $f^\ell_{s_1s_2}(p)$. The first category, which we call the trivial one, is obtained when $f^\ell_{11}(p)=f^\ell_{22}(p)=0$. In this case, as is easy to see from (A12) and (A15), we get $f^\ell_{12}(p)=-f^\ell_{21}(p)$. This solution corresponds to the singlet states of the system with $\ell=J(J\geqslant 0)$ [as follows from (A13) or (A14)]. This simple relation allows us to write the general formula for the components $f^\ell_{s_1s_2}(p)$ in the following form:

$$f^\ell_{s_1s_2}(p)=C^{(sg)m_{s_1s_2}}f^J(p), \tag{A16}$$

where the radial function $f^J(p)$ is common for all components, and the coefficients $C^{(sg)m_{s_1s_2}}$ have the following properties:

$$C^{(sg)m_{11}}=C^{(sg)m_{22}}=0,\quad C^{(sg)m_{21}}=-C^{(sg)m_{12}}=1. \tag{A17}$$

The formulas (A16) and (A17) with the notation $f^\ell_{s_1s_2}(p)\equiv f^{(sg)J}_{s_1s_2}(p)$ make Eq. (42) evident.

The second category corresponds to the triplet states, when $f^\ell_{11}(p), f^\ell_{22}(p)\neq 0$. First of all, it is not difficult to see from (A13) and (A14) that $f^\ell_{12}(p)=f^\ell_{21}(p)\equiv f^\ell(p)$, and after some simple calculations we get for $\ell=J-1(J\geqslant 1)$,

$$(J-m_J)f^{J-1}_{11}(p)=\sqrt{(J-m_J)(J+m_J-1)}f^{J-1}(p), \tag{A18}$$

$$(J+m_J)f^{J-1}_{22}(p)=\sqrt{(J+m_J)(J-m_J-1)}f^{J-1}(p), \tag{A19}$$

for $\ell=J(J\geqslant 1)$,

$$m_Jf^J_{11}(p)=-\sqrt{(J+m_J)(J-m_J+1)}f^J(p), \tag{A20}$$

$$m_Jf^J_{22}(p)=\sqrt{(J-m_J)(J+m_J+1)}f^J(p), \tag{A21}$$

for $\ell=J+1(J\geqslant 0)$,

TABLE V. The CG coefficients for triplet states (total spin $S=1$).

	$m_s=+1$	$m_s=0$	$m_s=-1$
$\ell=J-1$	$\left(\frac{(J+m_J-1)(J+m_J)}{J(2J-1)}\right)^{1/2}$	$\left(\frac{(J-m_J)(J+m_J)}{J(2J-1)}\right)^{1/2}$	$\left(\frac{(J-m_J-1)(J-m_J)}{J(2J-1)}\right)^{1/2}$
$\ell=J$	$-\left(\frac{(J+m_J)(J-m_J+1)}{J(J+1)}\right)^{1/2}$	$\frac{m_J}{(J(J+1))^{1/2}}$	$\left(\frac{(J-m_J)(J+m_J+1)}{J(J+1)}\right)^{1/2}$
$\ell=J+1$	$\left(\frac{(J-m_J+1)(J-m_J+2)}{(J+1)(2J+3)}\right)^{1/2}$	$-\left(\frac{(J-m_J+1)(J+m_J+1)}{(J+1)(2J+3)}\right)^{1/2}$	$\left(\frac{(J+m_J+2)(J+m_J+1)}{(J+1)(2J+3)}\right)^{1/2}$

$$(J+1+m_J)f_{11}^{J+1}(p) = -\sqrt{(J-m_J+2)(J+m_J+1)}\,f^{J+1}(p), \tag{A22}$$

$$(J+1-m_J)f_{22}^{J+1}(p) = -\sqrt{(J-m_J+1)(J+m_J+2)}\,f^{J+1}(p). \tag{A23}$$

It is convenient to introduce the table of coefficients $C_{Jm_J}^{(tr)\ell m_s}$, which represent the relations in (A18)–(A23). (See Table V.)

Thus, we can write the relations between the components $f_{s_1s_2}^{\ell}(p)$ in the compact form

$$f_{s_1s_2}^{\ell}(p) = C_{Jm_J}^{(tr)\ell m_s} f^{\ell}(p). \tag{A24}$$

The coefficients $C_{Jm_J}^{(tr)\ell m_s}$ coincide with the usual Clebsch–Gordan coefficients for total spin $S=1$ except for a factor $\sqrt{2}$ in the denominator. The expression (39) can now be written in an explicit form

$$F_{s_1s_2}(\mathbf{p}) = C_{Jm_J}^{(tr)(J-1)m_s} f^{J-1}(p) Y_{J-1}^{m_{s_1s_2}}(\hat{\mathbf{p}}) + C_{Jm_J}^{(tr)(J)m_s} f^{J}(p) Y_{J}^{m_{s_1s_2}}(\hat{\mathbf{p}}) + C_{Jm_J}^{(tr)(J+1)m_s} f^{J+1}(p) Y_{J+1}^{m_{s_1s_2}}(\hat{\mathbf{p}}). \tag{A25}$$

However, as is shown in Appendix B, the first and third terms have parity $P=(-1)^J$, while the second term has parity $P=(-1)^{J+1}$. Thus, we get the result (57) by suppressing the second term in (A25). The second term in (A25) is associated with the singlet solution (43) for the mixed-spin states, which have the same parity.

APPENDIX B: PARITY AND CHARGE CONJUGATION

We consider the application of the parity operator to the trial state (24),

$$\hat{\mathcal{P}}|\psi_{\text{trial}}\rangle = \sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})\hat{\mathcal{P}}b_{\mathbf{p}s_1}^{\dagger}D_{-\mathbf{p}s_2}^{\dagger}|0\rangle = \sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})\hat{\mathcal{P}}b_{\mathbf{p}s_1}^{\dagger}\hat{\mathcal{P}}^{-1}\hat{\mathcal{P}}D_{-\mathbf{p}s_2}^{\dagger}\hat{\mathcal{P}}^{-1}\hat{\mathcal{P}}|0\rangle. \tag{B1}$$

Making use of the properties

$$\hat{\mathcal{P}}b_{\mathbf{p}s_1}^{\dagger}\hat{\mathcal{P}}^{-1} = \eta^P b_{-\mathbf{p}s_1}^{\dagger}, \quad \hat{\mathcal{P}}D_{-\mathbf{p}s_2}^{\dagger}\hat{\mathcal{P}}^{-1} = -\eta^P D_{\mathbf{p}s_2}^{\dagger}, \quad \hat{\mathcal{P}}|0\rangle = |0\rangle, \tag{B2}$$

where η^P is the intrinsic parity ($(\eta^P)^2=1$), it follows that

$$\begin{aligned}\hat{\mathcal{P}}|\psi_{\text{trial}}\rangle &= \sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})\hat{\mathcal{P}}b_{\mathbf{p}s_1}^{\dagger}D_{-\mathbf{p}s_2}^{\dagger}|0\rangle \\ &= -\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(-\mathbf{p})b_{\mathbf{p}s_1}^{\dagger}D_{-\mathbf{p}s_2}^{\dagger}|0\rangle = P\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})b_{\mathbf{p}s_1}^{\dagger}D_{-\mathbf{p}s_2}^{\dagger}|0\rangle,\end{aligned} \tag{B3}$$

where the parity eigenvalue P depends on the symmetry of $F_{s_1s_2}(p)$ in different states. For the singlet states ($\ell=J$) we get from (43) $F_{s_1s_2}(-p)=(-1)^J F_{s_1s_2}(p)$, so $P=(-1)^{J+1}$. For the triplet states

with $\ell=J$ we get from (48) $F_{s_1s_2}(-p)=(-1)^J F_{s_1s_2}(p)$, so $P=(-1)^{J+1}$. For the triplet states with $\ell=J\pm1$ we get from (57) $F_{s_1s_2}(-p)=(-1)^{J+1}F_{s_1s_2}(p)$, so $P=(-1)^J$.

Charge conjugation is associated with the interchange of the particle and antiparticle. Applying the charge conjugation operator to the trial state of the form (24) we get

$$\hat{C}|\psi_{\text{trial}}\rangle=\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})\hat{C}b^\dagger_{\mathbf{p}s_1}d^\dagger_{-\mathbf{p}s_2}|0\rangle=\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})\hat{C}b^\dagger_{\mathbf{p}s_1}\hat{C}^{-1}\hat{C}d^\dagger_{-\mathbf{p}s_2}\hat{C}^{-1}\hat{C}|0\rangle. \tag{B4}$$

Using the relations

$$\hat{C}b^\dagger_{\mathbf{p}s_1}\hat{C}^{-1}=\eta^C d^\dagger_{\mathbf{p}s_1},\quad \hat{C}d^\dagger_{-\mathbf{p}s_2}\hat{C}^{-1}=\eta^C b^\dagger_{-\mathbf{p}s_2},\quad \hat{C}|0\rangle=|0\rangle, \tag{B5}$$

where $(\eta^C)^2=1$, we obtain

$$\hat{C}|\psi_{\text{trial}}\rangle=-\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_2s_1}(-\mathbf{p})b^\dagger_{\mathbf{p}s_1}d^\dagger_{-\mathbf{p}s_2}|0\rangle=C\sum_{s_1s_2}\int \mathrm{d}^3\mathbf{p}\, F_{s_1s_2}(\mathbf{p})b^\dagger_{\mathbf{p}s_1}d^\dagger_{-\mathbf{p}s_2}|0\rangle, \tag{B6}$$

where the charge conjugation quantum number C depends on the symmetry of $F_{s_1s_2}(p)$ in different states.

For the singlet states ($\ell=J$) we get from (43) $F_{s_2s_1}(-p)=(-1)^{J+1}F_{s_1s_2}(p)$, so $C=(-1)^J$.

For the triplet states with $\ell=J$ we get from (48) $F_{s_2s_1}(-p)=(-1)^J F_{s_1s_2}(p)$, so $C=(-1)^{J+1}$.

For the triplet states with $\ell=J\pm1$ we get from (57) $F_{s_2s_1}(-p)=(-1)^{J+1}F_{s_1s_2}(p)$, so $C=(-1)^J$.

APPENDIX C: EXPANSION OF THE SPINORS AND $\mathcal{M}$-MATRIX ELEMENTS

We recall the form of the particle spinors,

$$u(\mathbf{p},i)=N_{\mathbf{p}}\begin{bmatrix}1\\ \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{\omega_p+m_1}\end{bmatrix}\varphi_i, \tag{C1}$$

where

$$\varphi_1=\begin{bmatrix}1\\0\end{bmatrix},\quad \varphi_2=\begin{bmatrix}0\\1\end{bmatrix},\quad N_{\mathbf{p}}=\sqrt{\frac{\omega_p+m_1}{2m_1}}. \tag{C2}$$

The antiparticle or "positron" representation for the $v_i(p)$ spinors has the form

$$v(\mathbf{p},i)=N_{\mathbf{p}}\begin{bmatrix}\dfrac{(\vec{\sigma}\cdot\mathbf{p})}{\omega_p+m_1}\\ 1\end{bmatrix}\chi_i, \tag{C3}$$

where

$$\chi_1=\begin{bmatrix}0\\1\end{bmatrix},\quad \chi_2=-\begin{bmatrix}1\\0\end{bmatrix}. \tag{C4}$$

The normalization is

$$\overline{u}(\mathbf{p},i)u(\mathbf{p},j)=\delta_{ij},\quad \overline{v}(\mathbf{p},i)v(\mathbf{p},j)=-\delta_{ij}. \tag{C5}$$

Expanding in powers of p/m_1 and keeping the lowest order nontrivial terms,

$$\frac{(\vec{\sigma}\cdot\mathbf{p})}{\omega_p + m_1} \simeq \frac{(\vec{\sigma}\cdot\mathbf{p})}{2m_1}, \tag{C6}$$

$$N_{\mathbf{p}} = \sqrt{\frac{\omega_p + m_1}{2m_1}} \simeq 1 + \frac{\mathbf{p}^2}{8m_1^2}, \tag{C7}$$

we obtain the result

$$u(\mathbf{p},i) \simeq \left(1 + \frac{\mathbf{p}^2}{8m_1^2}\right)\begin{bmatrix} 1 \\ \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{2m_1} \end{bmatrix}\varphi_i = \begin{bmatrix} \left(1 + \dfrac{\mathbf{p}^2}{8m_1^2}\right) \\ \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{2m_1} \end{bmatrix}\varphi_i, \tag{C8}$$

$$v(\mathbf{p},i) \simeq \left(1 + \frac{\mathbf{p}^2}{8m_1^2}\right)\begin{bmatrix} \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{2m_1} \\ 1 \end{bmatrix}\chi_i = \begin{bmatrix} \dfrac{(\vec{\sigma}\cdot\mathbf{p})}{2m_1} \\ \left(1 + \dfrac{\mathbf{p}^2}{8m_1^2}\right) \end{bmatrix}\chi_i. \tag{C9}$$

The M-matrix elements (70)–(73) have the following nonzero components.

Orbital,

$$\begin{aligned}\mathcal{M}^{(orb)}_{1111}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(orb)}_{1212}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(orb)}_{2121}(\mathbf{q},\mathbf{p}) \\ = \mathcal{M}^{(orb)}_{2222}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{(\mathbf{p}-\mathbf{q})^2} + \frac{iq_1q_2}{m_1m_2}\left(\frac{1}{2}\left(\frac{m_1}{m_2} + \frac{m_2}{m_1}\right)\right. \\ \left.\times\left(\frac{1}{4} + \frac{\mathbf{q}\cdot\mathbf{p}}{(\mathbf{p}-\mathbf{q})^2}\right) + \frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}\right),\end{aligned} \tag{C10}$$

Spin–orbit,

$$\mathcal{M}^{(s-o)}_{1111}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{8m_1m_2}\left(\frac{m_2}{m_1} + \frac{m_1}{m_2} + 4\right)\frac{p_-q_+ - p_+q_-}{(\mathbf{p}-\mathbf{q})^2}, \tag{C11}$$

$$\mathcal{M}^{(s-o)}_{2222}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{8m_1m_2}\left(\frac{m_2}{m_1} + \frac{m_1}{m_2} + 4\right)\frac{p_+q_- - p_-q_+}{(\mathbf{p}-\mathbf{q})^2}, \tag{C12}$$

$$\mathcal{M}^{(s-o)}_{1112}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(s-o)}_{2122}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{4m_1m_2}\left(\frac{m_1}{m_2} + 2\right)\frac{p_3q_- - p_-q_3}{(\mathbf{p}-\mathbf{q})^2}, \tag{C13}$$

$$\mathcal{M}^{(s-o)}_{1211}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(s-o)}_{2221}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{4m_1m_2}\left(\frac{m_1}{m_2} + 2\right)\frac{p_+q_3 - p_3q_+}{(\mathbf{p}-\mathbf{q})^2}, \tag{C14}$$

$$\mathcal{M}^{(s-o)}_{1121}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(s-o)}_{1222}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{4m_1m_2}\left(\frac{m_2}{m_1} + 2\right)\frac{p_3q_- - p_-q_3}{(\mathbf{p}-\mathbf{q})^2}, \tag{C15}$$

$$\mathcal{M}^{(s-o)}_{2111}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(s-o)}_{2212}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{4m_1m_2}\left(\frac{m_2}{m_1} + 2\right)\frac{p_+q_3 - p_3q_+}{(\mathbf{p}-\mathbf{q})^2}, \tag{C16}$$

$$\mathcal{M}^{(s-o)}_{1212}(\mathbf{q},\mathbf{p}) = -\mathcal{M}^{(s-o)}_{2121}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{8m_1m_2}\left(\frac{m_2}{m_1}-\frac{m_1}{m_2}\right)\frac{p_-q_+ - p_+q_-}{(\mathbf{p}-\mathbf{q})^2}, \tag{C17}$$

Spin–spin,

$$\mathcal{M}^{(s-s)}_{1111}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(s-s)}_{2222}(\mathbf{q},\mathbf{p}) = -\mathcal{M}^{(s-s)}_{1212}(\mathbf{q},\mathbf{p}) = (\mathcal{M}^{(s-s)}_{2121}(\mathbf{q},\mathbf{p}))^* = \frac{iq_1q_2}{4m_1m_2}\left(\frac{(q_3-p_3)^2}{(\mathbf{q}-\mathbf{p})^2}-1\right), \tag{C18}$$

$$\mathcal{M}^{(s-s)}_{1112}(\mathbf{q},\mathbf{p}) = (\mathcal{M}^{(s-s)}_{2221}(\mathbf{q},\mathbf{p}))^* = -(\mathcal{M}^{(s-s)}_{1211}(\mathbf{q},\mathbf{p}))^* = -\mathcal{M}^{(s-s)}_{2122}(\mathbf{q},\mathbf{p})$$

$$\mathcal{M}^{(s-s)}_{1121}(\mathbf{q},\mathbf{p}) = (\mathcal{M}^{(s-s)}_{2212}(\mathbf{q},\mathbf{p}))^* = -\mathcal{M}^{(s-s)}_{1222}(\mathbf{q},\mathbf{p}) = -(\mathcal{M}^{(s-s)}_{2111}(\mathbf{q},\mathbf{p}))^*$$
$$= \frac{iq_1q_2}{4m_1m_2}\left(\frac{q_-q_3 - p_-q_3 - p_3q_- + p_-p_3}{(\mathbf{q}-\mathbf{p})^2}\right), \tag{C19}$$

$$\mathcal{M}^{(s-s)}_{1122}(\mathbf{q},\mathbf{p}) = -(\mathcal{M}^{(s-s)}_{2211}(\mathbf{q},\mathbf{p}))^* = \frac{iq_1q_2}{4m_1m_2}\frac{q_-^2 - 2q_-p_- + p_-^2}{(\mathbf{q}-\mathbf{p})^2}, \tag{C20}$$

$$\mathcal{M}^{(s-s)}_{1221}(\mathbf{q},\mathbf{p}) = \mathcal{M}^{(s-s)}_{2112}(\mathbf{q},\mathbf{p}) = \frac{iq_1q_2}{4m_1m_2}\left(\frac{q_+q_- - p_+q_- - p_-q_+ + p_+p_-}{(\mathbf{q}-\mathbf{p})^2}-2\right). \tag{C21}$$

Here $p=(p_1,p_2,p_3)$ and

$$p_+ = p_1 + ip_2 = -\sqrt{\frac{8\pi}{3}}pY^1_1(\theta,\varphi), \quad p_- = p_1 - ip_2 = \sqrt{\frac{8\pi}{3}}pY^{-1}_1(\theta,\varphi), \tag{C22}$$

$$p_3 = \sqrt{\frac{4\pi}{3}}pY^0_1(\theta,\varphi). \tag{C23}$$

For a particle–antiparticle system the annihilation components are

$$\mathcal{M}^{anh}_{1111} = \mathcal{M}^{anh}_{2222} = \frac{ie^2}{2m^2}, \tag{C24}$$

$$\mathcal{M}^{anh}_{1212} = \mathcal{M}^{anh}_{1221} = \mathcal{M}^{anh}_{2112} = \mathcal{M}^{anh}_{2121} = \frac{ie^2}{4m^2}. \tag{C25}$$

APPENDIX D: SOME USEFUL EXPRESSIONS, IDENTITIES, AND INTEGRALS

The following expressions and identities are useful for evaluating the M-matrix:

$$\frac{1}{(\mathbf{q}-\mathbf{p})^2} = \frac{2\pi}{|\mathbf{p}|\,|\mathbf{q}|}\sum_\lambda Q_\lambda(z)\sum_{m_\lambda=-\lambda}^{+\lambda} Y^{m_\lambda}_\lambda(\hat{\mathbf{p}})Y^{m_\lambda *}_\lambda(\hat{\mathbf{q}}), \tag{D1}$$

where $z=(p^2+q^2)/2pq$, and $Q_\lambda(z)$ is the Legendre function of the second kind of order λ.[17] Then

$$\frac{((\mathbf{p}-\mathbf{q})\cdot\mathbf{p})^2}{(\mathbf{p}-\mathbf{q})^4} = \frac{\mathbf{p}^2}{(\mathbf{p}-\mathbf{q})^2} - \frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}. \tag{D2}$$

The angular integration in (59), (60), and (65) involves the following integrals:

$$\int \mathrm{d}\hat{\mathbf{p}}\,\mathrm{d}\hat{\mathbf{q}}\,F(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})Y_{J'}^{m_J'}(\hat{\mathbf{q}})Y_{J'}^{m_J*}(\hat{\mathbf{p}}) = 2\pi\delta_{J'J}\delta_{m_J'm_J}\int d(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})F(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})P_J(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}), \tag{D3}$$

$$\int d(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})\frac{\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}}{(\mathbf{p}-\mathbf{q})^2}P_J(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}) = \frac{1}{|\mathbf{p}|\,|\mathbf{q}|}\left(\frac{J+1}{2J+1}Q_{J+1}(z)+\frac{J}{2J+1}Q_{J-1}(z)\right), \tag{D4}$$

$$\int d(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})\frac{(\mathbf{p}\times\mathbf{q})^2}{(\mathbf{p}-\mathbf{q})^4}P_J(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}) = \frac{(J+1)(J+2)}{2(2J+1)}Q_{J+1}(z)-\frac{J(J-1)}{2(2J+1)}Q_{J-1}(z). \tag{D5}$$

Here $F(\hat{\mathbf{p}}\cdot\hat{\mathbf{q}})$ is an arbitrary function of $\hat{\mathbf{p}}\cdot\hat{\mathbf{q}}$, $P_J(x)$ is the Legendre polynomial of order J.

The integrals in the form

$$\int \mathrm{d}\hat{\mathbf{p}}\;Y_J^{m_J*}(\hat{\mathbf{p}})Y_{J'}^{m_J'}(\hat{\mathbf{p}})Y_{J''}^{m_J''}(\hat{\mathbf{p}}) \tag{D6}$$

can be calculated using the Wigner–Eckart theorem.[17]

The calculation of the relativistic energy corrections involves the integrals

$$\int_0^\infty\int_0^\infty \mathrm{d}p\,\mathrm{d}q\,p^2q^2f^J(p)f^J(q) = 2\pi\left(\frac{\alpha m_r}{n}\right)^3\delta_{J,0}, \tag{D7}$$

$$\int_0^\infty\int_0^\infty \mathrm{d}p\,\mathrm{d}q\,pqf^J(p)f^J(q)Q_J(z_1) = \frac{\pi\alpha m_r}{n^2}, \tag{D8}$$

$$\int_0^\infty\int_0^\infty \mathrm{d}p\,\mathrm{d}q\,p^2q^2f^J(p)f^J(q)Q_J(z_1) = \int_0^\infty\int_0^\infty \mathrm{d}p\,\mathrm{d}q\,p^3qf^J(p)f^J(q)Q_J(z_1) = \pi\left(\frac{\alpha m_r}{n}\right)^3\left(\frac{4}{2J+1}-\frac{1}{n}\right), \tag{D9}$$

$$\int_0^\infty\int_0^\infty \mathrm{d}p\,\mathrm{d}q\,p^2q^2f^J(p)f^J(q)Q_{J-1}(z_1) = \pi\left(\frac{\alpha m_r}{n}\right)^3\left(\frac{2}{J}-\frac{1}{n}\right), \tag{D10}$$

$$\int_0^\infty\int_0^\infty \mathrm{d}p\,\mathrm{d}q\,p^2q^2f^J(p)f^J(q)Q_{J+1}(z_1) = \pi\left(\frac{\alpha m_r}{n}\right)^3\left(\frac{2}{J+1}-\frac{1}{n}\right). \tag{D11}$$

Here f^J is the nonrelativistic hydrogenlike radial wave function in momentum space,[18]

$$f^J(p)\equiv f_n^J(p) = \left(\frac{2}{\pi}\frac{(n-J-1)!}{(n+J)!}\right)^{1/2}\frac{n^{J+2}x^J2^{2(J+1)}J!}{(n^2x^2+1)^{J+2}}\mathcal{G}_{n-J-1}^{J+1}\left(\frac{n^2x^2-1}{n^2x^2+1}\right), \tag{D12}$$

where $x=p/(\alpha m_r)$ is a scaled momentum, and $\mathcal{G}_{n-J-1}^{J+1}$ are the Gegenbauer functions.

APPENDIX E: DIAGONALIZATION OF THE EXPECTATION VALUE OF THE HAMILTONIAN

The matrix representation of the perturbing Hamiltonian $\Delta\hat{H}=\hat{H}-\hat{H}_{NR}-M$, in the basis of the states $|sg\rangle, |tr\rangle$ (49) and (50), is ($J\neq 0$),

$$\langle\psi|\Delta\hat{H}|\psi\rangle_{t=0} = [a_{ij}] \quad (i,j=1,2), \tag{E1}$$

where the matrix elements a_{ij} are

$$a_{11} = \langle sg|\Delta\hat{H}|sg\rangle = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J+1} - \left(3 - \frac{m_r}{M}\right)\frac{1}{8n}\right), \tag{E2}$$

$$a_{22} = \langle tr|\Delta\hat{H}|tr\rangle = -\frac{\alpha^4 m_r}{n^3}\left(\frac{1}{2J+1} - \frac{1}{2J(J+1)(2J+1)} - \left(3 - \frac{m_r}{M}\right)\frac{1}{8n}\right), \tag{E3}$$

$$a_{12} = a_{21} = \langle sg|\Delta\hat{H}|tr\rangle = \langle tr|\Delta\hat{H}|sg\rangle = \frac{\alpha^4 m_r}{n^3}\frac{|m_1 - m_2|}{2M}\frac{1}{2J+1}\frac{1}{\sqrt{J(J+1)}}. \tag{E4}$$

Note that, in the case of positronium, the elements a_{11} and a_{22} give the energy corrections for pure singlet and triplet states, respectively. Diagonalization of this matrix leads to (104) with eigenvectors (55).

(Received 21 April 2004; accepted 2 November 2004; published online 10 February 2005)

We study quantum chromodynamics (QCD) on a finite lattice Λ in the Hamiltonian approach. First, we present the field algebra $\mathfrak{A}_\Lambda$ as comprising a gluonic part, with basic building block being the crossed product C^*-algebra $C(G)\otimes_\alpha G$, and a fermionic (CAR-algebra) part generated by the quark fields. By classical arguments, $\mathfrak{A}_\Lambda$ has a unique (up to unitary equivalence) irreducible representation. Next, the algebra $\mathfrak{O}^i_\Lambda$ of internal observables is defined as the algebra of gauge invariant fields, satisfying the Gauss law. In order to take into account correlations of field degrees of freedom inside Λ with the "rest of the world," we must extend $\mathfrak{O}^i_\Lambda$ by tensorizing with the algebra of external gauge invariant operators. This way we construct the full observable algebra $\mathfrak{O}_\Lambda$. It is proved that its irreducible representations are labelled by $\mathbb{Z}_3$-valued boundary flux distributions. Then, it is shown that there exist unitary operators (charge carrying fields), which intertwine between irreducible sectors leading to a classification of irreducible representations in terms of the $\mathbb{Z}_3$-valued global boundary flux. By the global Gauss law, these three inequivalent charge superselection sectors can be labeled in terms of the global color charge (triality) carried by quark fields. Finally, $\mathfrak{O}_\Lambda$ is discussed in terms of generators and relations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1851604]

I. INTRODUCTION

In a series of papers (cf. Refs. 1–6), we have started to analyze the nonperturbative structure of gauge theories, with the final aim being the formulation and investigation of gauge models purely in terms of observables. To start with one should clarify basic structures like that of the field algebra, the observable algebra and the superselection structure of the Hilbert space of physical states. It is well-known that the standard Doplicher–Haag–Roberts theory[7,8] for models, which do not contain massless particles, does not apply here. Nonetheless, there are interesting partial results within the framework of general quantum field theory both for quantum electrodynamics (QED) and for non-Abelian models, see Refs. 9–12.

To approach the problem in a rigorous way, we set the system on a finite (regular cubic) lattice and formulate the model within the Hamiltonian approach. For basic notions concerning lattice gauge theories (including fermions) we refer to Ref. 13 and references therein. Within the finite lattice context, we have analyzed the structure of the observable algebra both for spinorial and scalar QED and we have shown that the physical Hilbert space decomposes into a direct sum of superselection sectors labelled by the total electric charge, see Refs. 1–3. Finally, of course, one wants to construct the continuum limit. In full generality, this is an extremely complicated problem of constructive field theory. However, the results obtained until now suggest that there is some hope, to control the thermodynamic limit, see Ref. 1 for a heuristic discussion. We also mention that for simple toy models, these problems can be solved, see Ref. 14.

In Ref. 4 we have started to investigate quantum chromodynamics (QCD) within the above framework. In particular, we have analyzed the global Gauss law and the notion of global color

charge (triality). Comparing with QED, the notion of global charge in QCD is much more complicated, according to the fact that the local Gauss law is neither built from gauge invariant operators nor is it linear. We have shown that one can extract from the local Gauss equation of QCD a gauge invariant, additive law for operators with eigenvalues in $\mathbb{Z}_3$ [the center of SU(3)]. This implies—as in QED—a gauge invariant conservation law: The global $\mathbb{Z}_3$-valued color charge is equal to the global $\mathbb{Z}_3$-valued gauge invariant color electric flux through the boundary.

We stress that within lattice gauge theories, the above notion of color charge is already implicitly contained in a paper by Kogut and Susskind, see Ref. 15. In particular, Mack[16] used it to propose a certain (heuristic) scheme of color screening and quark confinement, based upon a dynamical Higgs mechanism with Higgs fields built from gluons. For similar ideas we also refer to papers by 't Hooft, see Ref. 17 and references therein. This concept was also used in a paper by Borgs and Seiler,[18] where the confinement problem for Yang–Mills theories with static quark sources at nonzero temperature was discussed.

In the present paper, we continue to investigate lattice QCD as initiated in Ref. 4, with the main topic being the analysis of the observable algebra. Our main result is the proof that all its irreducible representations are labelled by the global charge (triality). For this purpose, we use a special functional analytical framework developed by Woronowicz. To illustrate it, consider the Heisenberg algebra, generated by the canonical commutation relation $[p,q]=-i$, $p^*=p$, $q^*=q$. It is not properly defined unless we impose an appropriately defined "strong commutation rule." In this case, one usually uses the Weyl method which consists in "exponentiating" the commutation relations: $U(t)V(s)=\exp(its)V(s)U(t)$, where $U(t):=\exp(itp)$ and $V(s):=\exp(isq)$. In this context, uniqueness of irreducible representations can be proved and as the observable algebra one can take the algebra $\mathfrak{B}(H)$ of all *bounded* operators acting on the unique (Hilbert) representation space $L^2(\mathbb{R}^1)$.

Unfortunately, this technique does not work in the case of more complicated algebraic relations between the generators of the algebra in question. Already in the case of scalar quantum electrodynamics, the "exponentiation" of complicated algebraic relations defining the observable algebra was impossible (see Ref. 3). The situation is similar to the theory of quantum groups, where a "naive" definition in terms of (in general unbounded) generators and their relations leads to contradictions, as long as one does not find some way to give a precise meaning to the relations in question. One of the most powerful techniques, making it possible to deal even with the most difficult examples of such algebras, was introduced by Woronowicz (see Ref. 19). It enables one to consider algebras defined uniquely in terms of (even *unbounded*) generators and algebraic relations between them. In most cases, the generators themselves *do not belong* to the algebra, but are only *affiliated* with it. Applying this approach to the Heisenberg algebra, yields the algebra of compact operators $\mathfrak{K}(L^2(\mathbb{R}^1))$, whereas p and q are only affiliated with this algebra. The algebra of all bounded operators $\mathfrak{B}(L^2(\mathbb{R}^1))$ is then obtained as the *multiplier algebra* $M(\mathfrak{K}(L^2(\mathbb{R}^1)))$. It may be called *extended* observable algebra.

The fact that bounded operators are not "observables" in the strict sense, but only in the extended sense, whereas unbounded operators like p and q may be called observables in an even more generalized sense, as operators *affiliated* with the observable algebra, can be considered to be a drawback of this approach. But this is the price, which we pay for the rigorous mathematical tractability of the observable algebra. We have earlier used this approach in scalar QED and the present paper is consistently written in this language.

We begin our construction with the algebra $\mathfrak{A}_\Lambda$ of field operators, see Sec. II. Here, the Weyl method would provide an alternative (and, probably, simpler) construction of the algebra. But having in mind the observable algebra, where the Weyl method fails, we use the Woronowicz approach from the very beginning. In this context, we show uniqueness of irreducible representations of $\mathfrak{A}_\Lambda$. Next, we discuss local gauge transformations, the Gauss law and boundary data. In Sec. III, the algebra of internal observables $\mathfrak{O}^i_\Lambda$ is defined as the algebra of gauge invariant fields, satisfying the Gauss law. We show that its irreducible representations are labelled by distributions of color electric fluxes running through the boundary to infinity. It is remarkable that for the very classification of irreducible representations the abstract characterization of $\mathfrak{O}^i_\Lambda$ as the subalgebra,

invariant under the group of local gauge transformations, factorized with respect to the ideal generated by the Gauss law, is sufficient. This is due to the fact that here we work within the compact formulation, which implies that we "stay within" the representation space of the field algebra. This remark does not apply to QED in the noncompact formulation (cf. Refs. 1–3, where the corresponding construction is much more complicated).

In Chap. IV, we extend both the algebra of internal observables $\mathfrak{O}_\Lambda^i$, by adding certain "external observables," and the Hilbert space $\mathcal{H}_\Lambda$, by tensorizing with the Hilbert space of tensors at "external points." By external points we mean endpoints of lattice links connecting the finite lattice Λ with the rest of the world. These external observables enable us to take into account the correlations between the field degrees of freedom contained in Λ and the rest of the world. The algebra obtained this way is called full observable algebra and is denoted by $\mathfrak{O}_\Lambda$. Within this context, we show that different Hilbert space sectors, corresponding to different boundary flux distributions, carry equivalent representations of $\mathfrak{O}_\Lambda$ if and only if their global $\mathbb{Z}_3$-valued flux is the same, with intertwiners given by charge carrying fields (cf. Ref. 20). This reduces the irreducible representations of $\mathfrak{O}_\Lambda$ to three inequivalent sectors, labeled by the $\mathbb{Z}_3$-valued global color electric flux. By the global Gauss law, this flux coincides with the global color charge (triality) carried by the quark fields.

Our proposal to take into account also the external observables is motivated by our strategy to construct the thermodynamical limit of the theory *via* an inductive (respectively, projective) limit procedure for observable algebras (respectively, state spaces). This strategy was discussed in Ref. 1. Physically, it reduces considerably the number of superselection sectors of the theory, which are no longer numbered by the electric flux distribution at the boundary, but only by the global charge. In Sec. IV we thoroughly discuss our motivation for this proposal, which we consider one of the most important ideas of this paper.

Finally, in Sec. V, $\mathfrak{O}_\Lambda$ is discussed in terms of generators and relations. We start with presenting a set of genuine invariants generating $\mathfrak{O}_\Lambda$, which is, however, highly redundant. In the remainder of this section, we use some gauge fixing methods to reduce this set. In this context, a couple of delicate questions arises—all in some sense related to the Gribov problem and to the fact that the underlying classical configuration space has a complicated stratified structure with respect to the gauge group action. A more complete treatment of $\mathfrak{O}_\Lambda$ as an algebra presented by generators and relations will be given in two separate papers, see Refs. 21 and 22.

II. THE FIELD ALGEBRA

A. Basic definitions

We consider QCD in the Hamiltonian framework on a finite regular cubic lattice $\Lambda \subset \mathbb{Z}^3$, with $\mathbb{Z}^3$ being the infinite regular lattice in three dimensions. We denote the lattice boundary by $\partial\Lambda$ and the set of oriented, i-dimensional elements of Λ, respecitively, $\partial\Lambda$, by Λ^i, respectively, $\partial\Lambda^i$, where $i=0,1,2,3$. Such elements are (in increasing order of i) called sites, links, plaquettes, and cubes. Moreover, we denote the set of external links connecting boundary sites of Λ with "the rest of the world" by Λ_∞^1 and the set of endpoints of external links by Λ_∞^0. For the purposes of this paper, we may assume that for each boundary site there is exactly one external link. Then, external links are labeled by boundary sites and we can denote them by (x,∞) with $x \in \partial\Lambda^0$. The set of nonoriented i-dimensional elements will be denoted by $|\Lambda|^i$. If, for instance, $(x,y) \in \Lambda^1$ is an oriented link, then by $|(x,y)| \in |\Lambda|^1$ we mean the corresponding nonoriented link. The same notation applies to $\partial\Lambda^1$ and Λ_∞^1.

The basic fields of lattice QCD are quarks living at lattice sites and gluons living on links, including external links. The field algebra is thus, by definition, the C^*-tensor product of fermionic and bosonic algebras:

$$\mathfrak{A}_\Lambda := \mathfrak{F}_\Lambda \otimes \mathfrak{B}_\Lambda, \tag{2.1}$$

with

$$\mathfrak{F}_\Lambda := \bigotimes_{x\in\Lambda^0} \mathfrak{F}_x \tag{2.2}$$

and

$$\mathfrak{B}_\Lambda := \mathfrak{B}^i_\Lambda \otimes \mathfrak{B}^b_\Lambda = \bigotimes_{|(x,y)|\in|\Lambda|^1} \mathfrak{B}_{|(x,y)|} \bigotimes_{x\in\partial\Lambda^0} \mathfrak{B}_{|(x,\infty)|}. \tag{2.3}$$

Here, $\mathfrak{B}^i_\Lambda$ and $\mathfrak{B}^b_\Lambda$ are the internal and boundary bosonic algebras, respectively. We impose *locality* of the lattice quantum fields by *postulating* that the algebras corresponding to different elements of Λ (anti)commute with each other.

Remark: The bosonic boundary data represent nontrivial color electric flux through the boundary, which—as will be seen later—allows for nontrivial color charge. As will be shown, nontrivial boundary flux is necessary for taking into account correlations of field degrees of freedom inside Λ with the "rest of the world." Even if, for some reasons, the global charge of the Universe vanishes, there is no reason to assume that an arbitrary finite part Λ is also neutral.

The fermionic field algebra $\mathfrak{F}_x$ associated with a lattice site x is the algebra of canonical anticommutation relations (CAR) of quarks at x. The quark field generators are denoted by

$$\Lambda^0 \ni x \to \psi^{aA}(x) \in \mathfrak{F}_x, \tag{2.4}$$

where a stands for bispinorial and (possibly) flavor degrees of freedom and $A=1,2,3$ is the color index corresponding to the fundamental representation of the gauge group $G=\mathrm{SU}(3)$. [In what follows, writing G we have in mind SU(3), but essentially our discussion can be extended to arbitrary compact groups and their representations.] The conjugate quark field is denoted by $\psi^*_{aA}(x)$, where we raise and lower indices by the help of the canonical Hermitian metric tensor g_{AB} in $\mathbb{C}^3$ and the canonical skew-symmetric structure ϵ_{ab} in the spinor space. The only nontrivial canonical anticommutation relations for generators of $\mathfrak{F}_x$ read

$$[\psi^*_{aA}(x), \psi^{bB}(x)]_+ = \delta^B{}_A \delta^b{}_a. \tag{2.5}$$

The bosonic field algebra $\mathfrak{B}_{|(x,y)|}$ associated with the nonoriented link $|(x,y)|$ (where y also stands for ∞), is given in terms of its isomorphic copies $\mathfrak{B}_{(x,y)}$ and $\mathfrak{B}_{(y,x)}$, corresponding to the two orientations of the link (x,y). The algebra $\mathfrak{B}_{(x,y)}$ is generated (in the sense of Woronowicz, as explained below) by matrix elements of the gluonic gauge potential on the link (x,y),

$$\Lambda^1 \ni (x,y) \to U^A{}_B(x,y) \in \mathfrak{C}_{(x,y)}, \tag{2.6}$$

with $\mathfrak{C}_{(x,y)} \cong C(G)$ being the commutative C^*-algebra of continuous functions on G and $A, B=1,2,3$ denoting color indices, and by color electric fields, spanning the Lie algebra $\mathfrak{g}_{(x,y)} \cong \mathrm{su}(3)$. Choosing an orthonormal basis $\{t_i\}$, $i=1,\ldots,8$, of su(3) we denote by $\{E_i(x,y)\}$ the corresponding basis of $\mathfrak{g}_{(x,y)}$,

$$\Lambda^1 \ni (x,y) \to E_i(x,y) := t_i \in \mathfrak{g}_{(x,y)}. \tag{2.7}$$

These elements, satisfying the su(3) commutation relations, generate, in the sense of Woronowicz,[19] the C^*-algebra $\mathfrak{P}_{(x,y)} \cong C^*(G)$ (for the definition see Remark 1 below).

Observe that G acts on $C(G)$ naturally by the left regular representation,

$$\alpha_g(u)(g') := u(g^{-1}g'), \quad u \in C(G). \tag{2.8}$$

Differentiating this relation, we get an action of $e \in \mathrm{su}(3)$ on $u \in C^\infty(G)$ by the corresponding right invariant vector field e^R. Thus, we have a natural commutator between generators of $\mathfrak{P}_{(x,y)}$ and smooth elements of $\mathfrak{C}_{(x,y)}$,

$$i[e,u] := e^R(u). \tag{2.9}$$

Thus, we have a C^*-dynamical system $(\mathfrak{C}_{(x,y)}, G, \alpha)$, with automorphism α given by the left action (2.8). The field algebra $\mathfrak{B}_{(x,y)}$ is, by definition, the corresponding crossed product C^*-algebra,

$$\mathfrak{B}_{(x,y)} := \mathfrak{C}_{(x,y)} \otimes_\alpha G, \tag{2.10}$$

see Refs. 23 and 24 for these notions.

For the convenience of the reader we add a number of comments on the mathematical framework used here.

Remarks:

(1) We give the definition of $C^*(G)$ (cf. Refs. 23 and 25). Take the group algebra of G, which is the space $L^1(G)$ of integrable functions on the group, with convolution providing the product structure. Complete it with respect to the following norm:

$$\|f\| := \sup_\pi \|\pi(f)\|, \tag{2.11}$$

where $f \in L^1(G)$. The supremum is taken over all representations (π, H) of the group and $\pi(f)$ denotes the operator obtained by smearing the corresponding representation in $L^2(G,H)$ over the group with the function f, see Refs. 26 and 25. We stress that $C^*(G)$ is a C^*-algebra without unit. Moreover, its su(3)-generators t_i do not belong to $C^*(G)$, but are only affiliated in the C^*-sense, see Ref. 19.

(2) We define the crossed product algebra $C(G) \otimes_\alpha G$. First take $L^1(G, C(G))$, defined as the *-algebra of $C(G)$-valued L^1-functions on G, with multiplication given by the twisted convolution

$$(z \times w)(g') := \int_G z(g) \alpha_g(w(g^{-1}g'))\mathrm{d}g,$$

involution induced from the *-structure of $C(G)$,

$$z^*(g) = \alpha_g(z(g^{-1})^*),$$

and equipped with the standard L^1-norm. Next, consider all its nondegenerate Hilbert space representations. Finally, $C(G) \otimes_\alpha G \supset L^1(G, C(G))$ is defined as the completion of $L^1(G, C(G))$ in the sup-norm taken over all these representations. This way we obtain a C^*-algebra without unit. This algebra can be viewed as a skew tensor product of $C(G)$ with $C^*(G)$ in the following sense: For each $u \in C(G)$ and $f \in L^1(G)$ denote by $u \otimes f$ the element of $L^1(G, C(G))$ given by $(u \otimes f)(g) := uf(g)$. Then, the linear span of such elements is dense in $L^1(G, C(G))$. It is easily seen that

$$f \to 1 \otimes f \tag{2.12}$$

is an isomorphism onto its image, which enables us to identify $C^*(G)$ with the corresponding subalgebra

$$C^*(G) \subset C(G) \otimes_\alpha G. \tag{2.13}$$

As already noted, the group algebra $C^*(G)$ is a C^*-algebra generated by unbounded elements in the sense of Woronowicz, see Ref. 19. Consequently, $C(G) \otimes_\alpha G$ is of this type, too. It is generated by elements (e, u) fulfilling canonical commutation relations (2.9). We stress that both the (unbounded) su(3)-generators e and the (bounded) generators u do not belong to the algebra, but are only affiliated in the C^*-sense. Moreover, note that—contrary to (2.12)—the mapping $u \to u \otimes 1$ *does not* preserve the algebraic structure of $C(G)$ and, whence, cannot be used to imbed $C(G)$ into $C(G) \otimes_\alpha G$. Hence, $C(G) \nsubseteq C(G) \otimes_\alpha G$, but belongs to its multiplier algebra $M(C(G) \otimes_\alpha G)$. An embedding similar to (2.13) does not hold for a noncompact group G, because here we have to take instead of $C(G)$ the algebra $C_\infty(G)$ of functions

vanishing at infinity, which is an algebra without unit. Thus, the mapping (2.12) does not exist.

(3) Formula (2.9) is a natural generalization of the Heisenberg commutation relation $[p,q]=-i$, describing the Abelian case $G=\mathbb{R}^1$. It corresponds to "canonical quantization" over the phase space

$$T^*(G) \cong \mathfrak{g}^* \times G,$$

with $\mathfrak{g}=\mathrm{su}(3)$ being the Lie algebra of G and $\mathfrak{g}^*$ being the dual space. Quantization applies to functions on $\mathfrak{g}^* \times G$, hence, in particular, to elements of $\mathfrak{g}$. Thus, from the purely algebraic point of view, one would then define $\mathfrak{P}_{(x,y)}$ as the enveloping algebra $\mathfrak{U}(\mathfrak{g})$ of $\mathfrak{g}$, see Ref. 4, yielding for the bosonic field algebra $\mathfrak{B}_{(x,y)}$ the following crossed product structure of Hopf algebras:

$$C^\infty(G) \otimes_\alpha \mathfrak{U}(\mathfrak{g}).$$

This is an example of a Heisenberg double of Hopf algebras, see of Refs. 27 and 28. This choice has, however, substantial drawbacks related to the fact that the operators assigned to the Lie algebra elements e are necessarily unbounded. This is why we choose the functional-analytic framework above, where all fields are compact, hence *bounded* operators in a Hilbert space. We call the algebra (2.10) the algebra of *generalized canonical commutation relations* (CCR) over the group G.

(4) Within the above framework, one can prove a generalization of the classical uniquess theorem by von Neumann,[29] stating that any irreducible representation of the above CCR-algebra is equivalent to the *generalized Schrödinger representation*, acting on the Hilbert space $L^2(G)$ (with respect to the Haar measure). This will be shown in Sec. II B.

The transformation law of elements of $\mathfrak{B}_{(x,y)}$ under the change of the link orientation is derived from the fact that the (classical) G-valued parallel transporter $g(x,y)$ on (x,y) transforms to $g^{-1}(x,y)$ under the change of orientation. This transformation lifts naturally to an isomorphism

$$\mathcal{I}_{(x,y)}: \mathfrak{B}_{(x,y)} \to \mathfrak{B}_{(y,x)} \tag{2.14}$$

of field algebras, defined by

$$\mathcal{I}_{(x,y)}(f) := \check{f}, \quad \mathcal{I}_{(x,y)}(e) := \check{e}, \tag{2.15}$$

where $\check{f}(g) := f(g^{-1})$ and $\check{e}$ is the left invariant vector field on G, generated by $-e$. The bosonic field algebra $\mathfrak{B}_{|(x,y)|}$ is obtained from $\mathfrak{B}_{(x,y)}$ and $\mathfrak{B}_{(y,x)}$ by identifying them via $\mathcal{I}_{(x,y)}$.

Now, we give a full list of relations satisfied by generators of $\mathfrak{B}_{|(x,y)|}$. Being entries of the fundamental representation of SU(3), the generators of $\mathfrak{C}_{(x,y)}$ must fulfill the following conditions:

$$(U^A{}_B(x,y))^* U_A{}^C(x,y) = \delta^C{}_B \mathbf{1}, \tag{2.16}$$

$$\epsilon_{ABC} U^A{}_D(x,y) U^B{}_E(x,y) U^C{}_F(x,y) = \epsilon_{DEF} \mathbf{1}. \tag{2.17}$$

In what follows, we will use the traceless matrix

$$E^A{}_B(x,y) := \sum_i E_i(x,y) t_i{}^A{}_B, \tag{2.18}$$

built from generators of $\mathfrak{P}_{(x,y)}$. Its entries obviously fulfill

$$(E^A{}_B(x,y))^* = E_B{}^A(x,y). \tag{2.19}$$

The transformation law (2.15) of these objects under the change of the link orientation is given by the following relations:

$$U^A{}_B(y,x) = \check{U}^A{}_B(x,y) = (U_B{}^A(x,y))^*, \tag{2.20}$$

$$E^A{}_B(y,x) = \check{E}^A{}_B(x,y) = -U^A{}_D(y,x)U^C{}_B(x,y)E^D{}_C(x,y). \tag{2.21}$$

The su(3)-commutation relations read

$$[E^A{}_B(x,y),E^C{}_D(u,z)] = \delta_{xu}\delta_{yz}(\delta^C{}_B E^A{}_D(x,y) - \delta^A{}_D E^C{}_B(x,y)), \tag{2.22}$$

[formula (2.15) implies that all the components $E^A{}_B(x,y)$ commute with all the components $E^C{}_D(y,x)$, because the left invariant and the right invariant fields on the group commute]. The canonical commutation relations (2.9) take the following form:

$$\begin{aligned} i[E^A{}_B(x,y),U^C{}_D(u,z)] = &+ \delta_{xu}\delta_{yz}\left(\delta^C{}_B U^A{}_D(x,y) - \tfrac{1}{3}\delta^A{}_B U^C{}_D(x,y)\right) \\ &- \delta_{xz}\delta_{yu}\left(\delta^A{}_D U^C{}_B(y,x) - \tfrac{1}{3}\delta^A{}_B U^C{}_D(y,x)\right). \end{aligned} \tag{2.23}$$

To summarize, the field algebra $\mathfrak{A}_\Lambda$, given by (2.1)–(2.3), is a C^*-algebra, generated by elements

$$\{\psi^{aA}(x),\psi^*{}_{aA}(x),U^A{}_B(x,y),E^A{}_B(x,y)\}, \tag{2.24}$$

fulfilling relations (2.16), (2.17), and (2.19)–(2.21), together with canonical (anti)commutation relations (2.5), (2.22), and (2.23).

Remark: According to formula (2.21), the transformation of the color electric field E from (x,y) to (y,x) consists of two steps.

(1) The parallel transport from point x to y by means of the two parallel transporters U, each of them acting appropriately on the two indices of E.
(2) The change of the sign due to the change of the orientation.

In what follows, we always treat $E(x,y)$ as being attached to the site x.

B. Uniqueness of irreducible representations

Here, we prove uniqueness of the generalized canonical commutation relations as announced in Sec. II A.

We use the one-to-one correspondence between nondegenerate representations of crossed products and covariant representations of C^*-dynamical systems, see Ref. 23. Thus, let us consider the following covariant representation of $(C(G),G,\alpha)$ on $L^2(G)$ (with respect to the Haar measure):

(1) Take the representation π of the commutative C^*-algebra $C(G)$ given by multiplication with elements of $C(G)$. This, obviously, a representation by bounded operators on $L^2(G)$.
(2) Consider the left regular (unitary) representation $\hat{\pi}$ of G on $L^2(G)$,

$$(\hat{\pi}(g)\xi)(g') := \xi(g^{-1}g'), \quad \xi \in L^2(G). \tag{2.25}$$

We calculate

$$\begin{aligned} (\hat{\pi}(g)\circ\pi(u)\circ\hat{\pi}(g^{-1}))(\xi)(g') &= ((\pi(u)\circ\hat{\pi}(g^{-1}))(\xi))(g^{-1}g') = u(g^{-1}g')\cdot(\hat{\pi}(g^{-1})(\xi))(g^{-1}g') \\ &= u(g^{-1}g')\cdot\xi(g') = \pi(\alpha_g(u))(\xi)(g'). \end{aligned}$$

This yields

$$\hat{\pi}(g)\circ\pi(u)\circ\hat{\pi}(g^{-1}) = \pi(\alpha_g(u)), \tag{2.26}$$

showing that the pair $(\pi,\hat{\pi})$ defines a *covariant* representation of $(C(G),G,\alpha)$ on $L^2(G)$, indeed.

We call this representation *generalized Schrödinger representation.* Observe that differentiat-

ing relation (2.26) yields the generalized canonical commutation relations (2.9).

Now, consider an arbitrary *covariant* representation $(\rho,\hat{\rho})$ of the the C^*-dynamical system $(C(G),G,\alpha)$, with ρ being a nondegenerate representation of $C(G)$ on a Hilbert space H and $\hat{\rho}$ being a strongly continuous unitary representation of G on H. By the Gelfand–Najmark theorem for commutative C^*-algebras, we have a spectral measure $\mathrm{d}E$ on G, such that

$$\rho(u) = \int u(g)\mathrm{d}E(g), \tag{2.27}$$

for $u\in C(G)$, and by covariance, the pair $(\rho,\hat{\rho})$ also fulfills (2.26). Thus, we get

$$\hat{\rho}(g)\circ\mathrm{d}E(g')\circ\hat{\rho}(g^{-1}) = \mathrm{d}E(gg'). \tag{2.28}$$

We conclude that the spectral measure $\mathrm{d}E$ defines a transitive system of imprimitivity for the representation $\hat{\rho}$ of G based on the group manifold G. Then, the imprimitivity theorem, see Refs. 30 and 31, yields the following.

Theorem 2.1: *Any irreducible representation of* $(C(G),G,\alpha)$ *is equivalent to the generalized Schrödinger representation.*

Remarks:

(1) Disregarding the C^*-context, Theorem 2.1 is a classical result of Mackey, see Ref. 31 and references therein.
(2) Within the C^*-context, there is a formulation of the commutation relations (2.26) for an arbitrary locally compact group in terms of the pentagon equation, which generalizes to quantum groups.[32]

The following statement is a consequence of Theorem 7.7.12 in Ref. 23, but for the reader's convenience we add the proof here.

Lemma 2.2: For any compact Lie group, the generalized Schrödinger representation defines the following isomorphism of C^**-algebras:*

$$C(G)\otimes_{\alpha}G \cong \mathfrak{K}(L^2(G)), \tag{2.29}$$

where $\mathfrak{K}(L^2(G))$ *denotes the algebra of compact operators on* $L^2(G)$.

Proof: Any nondegenerate, irreducible representation of $L^1(G,C(G))$ is equivalent to the following representation in $L^2(G)$:

$$(\pi\times\hat{\pi})(z) = \int \pi(z(g))\hat{\pi}(g)\mathrm{d}g, \tag{2.30}$$

with $z\in L^1(G,C(G))$. This follows from the one-to-one correspondence between nondegenerate representations of $L^1(G,C(G))$ and covariant representations of the C^*-dynamical system $(C(G),G,\alpha)$ (cf. Ref. 23, Proposition 7.6.4) and from the uniqueness theorem above.

Thus, for every $\xi\in L^2(G)$ we have

$$(((\pi\times\hat{\pi})(z))\xi)(h) = \left(\int \pi(z(g))\hat{\pi}(g)\xi\,\mathrm{d}g\right)(h) = \int z(g,h)\xi(g^{-1}h)\mathrm{d}g, \tag{2.31}$$

where we have denoted $(z(g))(h)\equiv z(g,h)$. Note that continuous functions

$$C(G,C(G)) \cong C(G\times G) \subset L^1(G,C(G))$$

form a dense subset. Thus, for algebraically special functions of type $z(g,h)=\overline{x}(g^{-1}h)\cdot y(h)$, with x, $y\in C(G)\subset L^2(G)$, we obtain one-dimensional operators of the following type:

$$(((\pi \times \hat{\pi})(z))\xi)(h) = y(h) \int \bar{x}(g)\xi(g)\mathrm{d}g, \tag{2.32}$$

or, equivalently, in physics notation

$$(\pi \times \hat{\pi})(z) = |y\rangle\langle x|. \tag{2.33}$$

Of course, linear combinations of such elements form a dense subset in $L^1(G, C(G))$ and, thus, also in $C(G) \otimes_\alpha G$. On the other hand, linear combinations of one-dimensional operators exhaust finite dimensional operators and their C^*-closure in the operator norm gives precisely the algebra of all compact operators $\mathfrak{K}(L^2(G))$. ■

Remark:

(1) Consider the isomorphism (2.29). Using the generators (e, u) of $C(G) \otimes_\alpha G$ we built typical elements of $\mathfrak{K}(L^2(G))$ as follows: For any basis $\{t_i\}$, take operators $(1+t_i^2)^{-1}$, which are compact, and multiply them from both sides by any function of matrix elements $U^A{}_B$ (compare with Ref. 19, example 3 of Sec. III).

(2) We stress that Lemma 2.2 holds for noncompact Lie groups, too. In that case, we have to take $x \in C_0(G)$ (function with compact support) and $y \in C_\infty(G)$ (function vanishing at infinity) in the above proof. In particular, for the case of canonical commutation relations $[p, q] = -i$, we take $G = \mathbb{R}^1$ and the above approach yields the algebra $\mathfrak{K}(L^2(\mathbb{R}^1))$. A typical element belonging to this algebra is $(1+q^2)^{-1}(1+p^2)^{-1}(1+q^2)^{-1}$ (compare with Ref. 19, example 4 of Sec. III).

Now, we take the tensor product of generalized Schrödinger representations over all links,

$$\bigotimes_{(x,y)\in\Lambda^1} L^2(\mathcal{C}_{(x,y)}) \bigotimes_{x\in\partial\Lambda^0} L^2(\mathcal{C}_{(x,\infty)}) \cong L^2(\mathcal{C}), \tag{2.34}$$

with

$$\mathcal{C} := \prod_{(x,y)\in\Lambda^1} \mathcal{C}_{(x,y)} \prod_{x\in\partial\Lambda^0} \mathcal{C}_{(x,\infty)}$$

and each of the spaces $\mathcal{C}_{(x,y)}$ being diffeomorphic to the group space of G.

This is, by Theorem 2.1, the unique representation space of the gluonic field algebra $\mathfrak{B}_\Lambda$. Moreover, using the classical uniqueness theorem for CAR-representations by Jordan and Wigner,[33] any representation of fermionic fields is equivalent to the fermionic Fock representation. Consequently, using Lemma 2.2, we get the following.

Corollary 2.3: The field algebra $\mathfrak{A}_\Lambda$ can be identified with the algebra $\mathfrak{K}(H_\Lambda)$ of compact operators on the Hilbert space

$$H_\Lambda = \mathcal{F}(\mathbb{C}^{12N}) \otimes L^2(\mathcal{C}), \tag{2.35}$$

with $\mathcal{F}(\mathbb{C}^{12N})$ denoting the fermionic Fock space generated by $12N$ anticommuting pairs of quark fields.

The subspace $\mathcal{F}(\mathbb{C}^{12N})$ is spanned by vectors

$$\psi^*_{a_1 A_1}(x_1) \cdots \psi^*_{a_n A_n}(x_n)|0\rangle, \tag{2.36}$$

obtained from the fermionic Fock vacuum by the action of quark creation operators. Consequently, any element of H_Λ is a linear combination of these *fermionic* vectors with coefficients being L^2-functions depending on gluonic potentials U.

From the physicists point of view, it might seem to be more natural to choose the whole algebra $\mathfrak{B}(H_\Lambda)$ of all bounded operators as the field algebra. In mathematical terms this means taking the *multiplier algebra*

$$\mathfrak{B}(H_\Lambda) = M(\mathfrak{K}(H_\Lambda))$$

of our field algebra $\mathfrak{K}(H_\Lambda)$. We call $\mathfrak{B}(H_\Lambda)$ *extended field algebra* of our model. Moreover, we denote the set of affiliated elements of the algebra $\mathfrak{K}(H_\Lambda)$ by $(\mathfrak{K}(H_\Lambda))^\eta$. Hence, our approach leads to the triple,

$$\mathfrak{K}(H_\Lambda) \subset \mathfrak{B}(H_\Lambda) \subset (\mathfrak{K}(H_\Lambda))^\eta,$$

which contains physical fields in a (1) restricted, (2) extended, and (3) even more extended sense, but which may all be reconstructed from the first element of the triple. On the level of the observable algebra we will proceed the same way.

The main reason for choosing the above approach, based on $\mathfrak{K}(H_\Lambda)$ and not on $\mathfrak{B}(H_\Lambda)$, is that in this context unbounded generators are structurally related to the field (respectively, observable) algebra, which is defined in terms of algebraic relations between these generators.

C. Gauge transformations and local Gauss law

The group G_Λ of local gauge transformations related to the lattice Λ consists of mappings

$$\Lambda^0 \ni x \to g(x) \in G,$$

which represent internal gauge transformations, and of gauge transformations at external points,

$$\Lambda^0_\infty \ni z \to g(z) \in G.$$

Thus,

$$G_\Lambda := G^i_\Lambda \times G^\infty_\Lambda = \prod_{x\in\Lambda^0} G_x \prod_{z\in\Lambda^0_\infty} G_z, \tag{2.37}$$

with $G_y \cong \mathrm{SU}(3)$, for every y. We denote the corresponding Lie algebra by

$$\mathfrak{g}_\Lambda := \mathfrak{g}^i_\Lambda \oplus \mathfrak{g}^\infty_\Lambda = \bigoplus_{x\in\Lambda^0} \mathfrak{g}_x \oplus \bigoplus_{z\in\Lambda^0_\infty} \mathfrak{g}_z, \tag{2.38}$$

with $\mathfrak{g}_y \cong \mathrm{su}(3)$, for every y.

The group G_Λ acts on the classical configuration space $\mathcal{C}$ as follows:

$$\mathcal{C}_{(x,y)} \ni g(x,y) \to g(x)g(x,y)g(y)^{-1} \in \mathcal{C}_{(x,y)}, \tag{2.39}$$

with $g(x) \in G_x$ and $g(y) \in G_y$. This action lifts naturally to functions on $\mathcal{C}$. Moreover, we have an action of G_x on itself by inner automorphisms. This yields an action of G_Λ by automorphisms on each C^*-dynamical system $(\mathfrak{C}_{(x,y)}, G, \alpha)$ and, therefore, on the gluonic field algebra $\mathfrak{B}_\Lambda$. For generators of $\mathfrak{B}_{(x,y)} \subset \mathfrak{B}_\Lambda$, this action is given by

$$U^A{}_B(x,y) \to g^A{}_C(x) U^C{}_D(x,y) (g^{-1})^D{}_B(y), \tag{2.40}$$

$$E^A{}_B(x,y) \to g^A{}_C(x) E^C{}_D(x,y) (g^{-1})^D{}_B(x), \tag{2.41}$$

with y standing also for ∞. Fermionic generators transform under the fundamental representation:

$$\psi^{aA}(x) \to g^A{}_B(x) \psi^{aB}(x). \tag{2.42}$$

To summarize, the group of local gauge transformation G_Λ acts on the field algebra $\mathfrak{A}_\Lambda$ in a natural way by automorphisms.

It is easy to check that, for $x \in \Lambda^0$, the above automorphisms are generated by the following derivations of the field algebra:

$$\mathcal{G}^A{}_B(x) := \rho^A{}_B(x) - \sum_{y \leftrightarrow x} E^A{}_B(x,y), \tag{2.43}$$

where $y \leftrightarrow x$ means that the sum is taken over all nearest neighbors y of x (with y also standing for ∞), and where

$$\rho^A{}_B(x) = \sum_a \left(\psi^{*aA}(x)\psi^a{}_B(x) - \frac{1}{3}\delta^A{}_B \psi^{*aC}(x)\psi^a{}_C(x) \right) \tag{2.44}$$

is the local matter charge density, fulfilling $\rho^A{}_A(x) = 0$. Observe that both (2.43) and (2.44) satisfy the su(3)-commutation relations separately and that the set $\{\mathcal{G}^A{}_B(x)\}$ of generators spans the Lie algebra $\mathfrak{g}^i_\Lambda$.

The local Gauss law at $x \in \Lambda^0$ reads

$$\sum_{y \leftrightarrow x} E^A{}_B(x,y) = \rho^A{}_B(x), \tag{2.45}$$

meaning that the gauge generator $\mathcal{G}^A{}_B(x)$ defined by formula (2.43) vanishes. Observe that for every $x \in \partial\Lambda^0$, the corresponding boundary flux $E^A{}_B(x,\infty)$ enters the Gauss law. All the Gauss laws at boundary points can thus be easily "solved" by expressing the boundary fluxes in terms of internal fields.

For $z \in \Lambda^0_\infty$, the generator (2.43) of gauge transformations reduces to the boundary flux $E^A{}_B(z,x)$. Nonvanishing of this flux means gauge dependence of the quantum state under the action of $G_z \subset G^\infty_\Lambda$. Neglecting these boundary fluxes means neglecting the possibility that a nontrivial color charge occurs.[4] As will be discussed in Sec. IV A, such a "truncated theory" is not useful as a discrete approximation of the continuum theory. [The continuum limit should be constructed[1] in terms of an inductive (respectively, projective) limit of observable algebras (respectively, quantum states). In this context, "external fluxes" represent the necessary link between any two intersecting lattices belonging to a whole sequence of lattices.]

Remark:

(1) We stress that the Gauss law (2.45) is the lattice counterpart of the "covariant divergence law"

$$D_k E^k \equiv \partial_k E^k + [A_k, E^k] = \rho$$

in the continuum theory. There, the volume integration yields on the left-hand side a standard boundary flux term (by applying Stokes theorem) and an additional volume integral contribution corresponding to the $[A_k, E^k]$-term. In our lattice formulation, the volume integration corresponds to summation over all local Gauss laws. This yields a sum over boundary terms living on external links (x,∞) *and* a volume contribution equal to $E(x,y)+E(y,x)$ on each lattice link. This term mimics the term $[A_k, E^k]$ of the continuum theory, [e.g., it vanishes only if the parallel transporter $U(x,y)$ is trivial, which corresponds to the case $A_k = 0$ in the continuum theory].

(2) We add the "naive" Hamiltonian. Starting from the classical Hamiltonian

$$H = \int \left\{ \frac{1}{4} Tr(E^k(x)E_k(x) + B^k(x)B_k(x)) - \Re(\bar{\psi}(x) i \gamma^k D_k \psi(x)) + \bar{\psi}(x) m \psi(x) \right\} d^3x$$

of continuum QCD, we obtain the following self-adjoint operator acting on the Hilbert space H_Λ of our lattice model:

$$H = \frac{a}{2} \sum_{|(x,y)|\in|\Lambda|^1} E^A{}_B(x,y) E^B{}_A(x,y) + \frac{1}{2g^2 a}\left(\sum_{\sigma\in|\Lambda|^2} U^A{}_A(\partial\sigma) + \text{h.c.} \right)$$
$$+ \frac{a^2}{2} \sum_{|(x,x+\hat{k})|\in|\Lambda|^1} \overline{\psi}_A(x) i\gamma^k U^A{}_B(x,x+\hat{k}) \psi^B(x+\hat{k}) + \text{h.c.} + a^3 \sum_{x\in|\Lambda|^0} \overline{\psi}_A(x) m \psi^A(x), \tag{2.46}$$

where a is the lattice spacing and $\hat{k}$ is the vector of length a in the direction of the kth axis. Here, by $U^A{}_B(\partial\sigma)$ we denote the Wilson loop corresponding to the plaquette σ. By writing "naive" Hamiltonian we mean that we disregard terms, by which H must be supplemented in order to avoid the so-called doubling problem. The dynamical content of this model is based upon this Hamiltonian, which however will not be investigated in the present paper.

III. THE ALGEBRA OF INTERNAL OBSERVABLES

A. Basic definitions

Physical observables, internal relative to Λ, are, by definition, gauge invariant fields respecting the Gauss law. Hence, we must take the subalgebra

$$\mathfrak{A}^{G_\Lambda} \subset \mathfrak{A}_\Lambda$$

of G_Λ-invariant elements of the field algebra $\mathfrak{A}_\Lambda$. This means, in particular, that observables must commute with all gauge generators $\mathcal{G}^A{}_B(x)$.

Moreover, we must impose all relations inherited from the local Gauss laws at all internal lattice sites (*not* including external sites) as defining relations of the observable algebra. This means that the generators $\mathcal{G}^A{}_B(x)$ of G^i_Λ must vanish in all possible gauge-invariant algebraic combinations. Hence, imposing (2.45) at the algebraic (representation-independent) level means that we require vanishing of the ideal $\mathfrak{I}^i_\Lambda \cap \mathfrak{A}^{G_\Lambda}$, with $\mathfrak{I}^i_\Lambda$ being the ideal generated by $\mathfrak{g}^i_\Lambda$. Thus, the algebra $\mathfrak{O}^i_\Lambda$ of internal observables is obtained from $\mathfrak{A}^{G_\Lambda}$ by factorizing with respect to this ideal.

Definition 3.1: The algebra of internal observables relative to Λ *is defined as*

$$\mathfrak{O}^i_\Lambda = \mathfrak{A}^{G_\Lambda}/\{\mathfrak{I}^i_\Lambda \cap \mathfrak{A}^{G_\Lambda}\}, \tag{3.1}$$

where $\mathfrak{A}^{G_\Lambda} \subset \mathfrak{A}_\Lambda$ *is the subalgebra of* G_Λ*-invariant elements of* $\mathfrak{A}_\Lambda$ *and* $\mathfrak{I}^i_\Lambda \subset \mathfrak{A}_\Lambda$ *is the ideal generated by* $\mathfrak{g}^i_\Lambda$*. By the extended algebra of internal observables we mean the multiplier algebra* $M(\mathfrak{O}^i_\Lambda)$.

Remark: The above ideal $\mathfrak{I}^i_\Lambda$ is generated by unbounded elements in the sense of Woronowicz. It is obtained by multiplying its generators $\mathcal{G}^A{}_B(x)$ from both sides by elements of $\mathfrak{A}_\Lambda$ belonging to their common dense domain, e.g., the so-called *smooth* elements (corresponding to C^∞-functions on G).

B. Classification of irreducible representations

By Corollary 2.3, we can identify $\mathfrak{A}_\Lambda$ with the algebra of compact operators acting on the Hilbert space H_Λ, given by (2.35). Under this identification, we have a unitary representation of the gauge group G_Λ on H_Λ and the subalgebra $\mathfrak{A}^{G_\Lambda}$ can be viewed as the commutant $(G_\Lambda)'$ of this representation in $\mathfrak{K}(H_\Lambda)$.

Consider the closed subspace $\mathcal{H}_\Lambda \subset H_\Lambda$ consisting of vectors, which are invariant with respect to internal gauge transformations,

$$\mathcal{H}_\Lambda := \{h \in H_\Lambda | G^i_\Lambda h = h\}. \tag{3.2}$$

Theorem 3.2: *The algebra of internal observables (respectively, extended internal observables) is canonically isomorphic with the algebra of those compact (respectively, bounded) operators on the Hilbert space* $\mathcal{H}_\Lambda$*, which commute with the action of the group* G^∞_Λ*. This means*

$$\mathfrak{O}^i_\Lambda \cong \mathfrak{K}(\mathcal{H}_\Lambda) \cap (G^\infty_\Lambda)'. \tag{3.3}$$

Proof: Consider the direct sum decomposition

$$H_\Lambda = \mathcal{H}_\Lambda \oplus \mathcal{H}^\perp_\Lambda, \tag{3.4}$$

with $\mathcal{H}^\perp_\Lambda$ denoting the orthogonal complement of $\mathcal{H}_\Lambda$. Since the actions of G^i_Λ and G^∞_Λ commute, $\mathcal{H}_\Lambda$ is invariant under the action of G^∞_Λ and, thus, under the full gauge group G_Λ. Consequently, by unitarity of G_Λ, $\mathcal{H}^\perp_\Lambda$ is invariant, too. This implies the following block-diagonal structure of elements of G_Λ with respect to the decomposition (3.4):

$$\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix},$$

with A and B denoting unitary operators on $\mathcal{H}_\Lambda$ and $\mathcal{H}^\perp_\Lambda$, respectively. It can be easily shown that

$$(G_\Lambda)' = \left\{ \begin{pmatrix} C & 0 \\ 0 & D \end{pmatrix} \in \mathfrak{K}(H_\Lambda) : [A,C] = 0 = [B,D], \text{ for all } \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} \in G_\Lambda \right\}. \tag{3.5}$$

Indeed, an arbitrary element $\left(\begin{smallmatrix} C & E \\ F & D \end{smallmatrix}\right)$ belongs to $(G_\Lambda)'$ iff

$$AC = CA, \quad AE = EB, \quad BF = FA, \quad BD = DB,$$

for any $\left(\begin{smallmatrix} A & 0 \\ 0 & B \end{smallmatrix}\right) \in G_\Lambda$. For $\left(\begin{smallmatrix} h \\ 0 \end{smallmatrix}\right) \in \mathcal{H}_\Lambda$ we have $\left(\begin{smallmatrix} 0 \\ Fh \end{smallmatrix}\right) \in \mathcal{H}^\perp_\Lambda$. On the other hand, any element of G^i_Λ has the form $\left(\begin{smallmatrix} \mathbf{1} & 0 \\ 0 & B \end{smallmatrix}\right)$. Thus,

$$\begin{pmatrix} \mathbf{1} & 0 \\ 0 & B \end{pmatrix} \begin{pmatrix} 0 \\ Fh \end{pmatrix} = \begin{pmatrix} 0 \\ BFh \end{pmatrix} = \begin{pmatrix} 0 \\ Fh \end{pmatrix},$$

for all elements of G^i_Λ, yielding $\left(\begin{smallmatrix} 0 \\ Fh \end{smallmatrix}\right) \in \mathcal{H}_\Lambda$. Thus, $Fh = 0$, for all $h \in \mathcal{H}_\Lambda$, implying $F = 0$. In an analogous way one shows $E = 0$. This gives formula (3.5).

We decompose $\left(\begin{smallmatrix} C & 0 \\ 0 & D \end{smallmatrix}\right) = \left(\begin{smallmatrix} C & 0 \\ 0 & 0 \end{smallmatrix}\right) + \left(\begin{smallmatrix} 0 & 0 \\ 0 & D \end{smallmatrix}\right)$. Since the restriction of a compact operator to a closed subspace is compact, we have $\left(\begin{smallmatrix} C & 0 \\ 0 & 0 \end{smallmatrix}\right) \in \mathfrak{K}(\mathcal{H}_\Lambda)$. Moreover, $\left(\begin{smallmatrix} 0 & 0 \\ 0 & D \end{smallmatrix}\right) \in \mathfrak{I}^i_\Lambda$. This yields the direct sum decomposition

$$(G_\Lambda)' = (\mathfrak{K}(\mathcal{H}_\Lambda) \cap (G_\Lambda)') \oplus (\mathfrak{I}^i_\Lambda \cap (G_\Lambda)'). \tag{3.6}$$

Consequently, the algebra of internal observables $\mathfrak{O}^i_\Lambda = (G_\Lambda)' / \{\mathfrak{I}^i_\Lambda \cap (G_\Lambda)'\}$ is represented by the direct sum complement

$$\mathfrak{K}(\mathcal{H}_\Lambda) \cap (G_\Lambda)' = \mathfrak{K}(\mathcal{H}_\Lambda) \cap (G^i_\Lambda)' \cap (G^\infty_\Lambda)'$$

in $(G_\Lambda)'$. Finally, by (3.5) we have that arbitrary elements of $(G^i_\Lambda)'$ have the form $\left(\begin{smallmatrix} C & 0 \\ 0 & D \end{smallmatrix}\right)$, with $C \in \mathfrak{K}(\mathcal{H}_\Lambda)$ and $[D,B] = 0$, for any unitary B acting on $\mathcal{H}^\perp_\Lambda$. Thus, $\mathfrak{K}(\mathcal{H}_\Lambda) \subset (G^i_\Lambda)'$, yielding the isomorphism (3.3). Taking the multiplier algebra of $\mathfrak{K}(\mathcal{H}_\Lambda) \cap (G^\infty_\Lambda)'$ yields $\mathfrak{B}(\mathcal{H}_\Lambda) \cap (G^\infty_\Lambda)'$. ■

To find a presentation of this algebra in terms of generators and relations is a nontrivial task, which will be dealt with in Sec. V. Here, we only stress that obvious observables like Wilson loops are represented in $\mathcal{H}_\Lambda$ as multiplication operators and, therefore, belong to the extended algebra $M(\mathfrak{O}^i_\Lambda)$. It is impossible, to build compact operators from Wilson loops only. For that purpose, one must consider combinations of them with gauge invariant combinations of color electric fields, compare with the Remark after the proof of Lemma 2.2.

Now observe that the restriction of the unitary action of G^∞_Λ to the subspace $\mathcal{H}_\Lambda$ is not irreducible. Thus, $\mathcal{H}_\Lambda$ splits into the direct sum of irreducible subspaces. Each irreducible representation of G_z, $z \in \Lambda^0_\infty$, is labeled by its highest weight (m,n) and is equivalent to the corresponding tensor representation in the space $\mathbb{S}^m_n(\mathbb{C}^3)$ of m-contravariant, n-covariant, traceless and totally symmetric tensors over $\mathbb{C}^3$, endowed with the natural scalar product induced by the scalar product on $\mathbb{C}^3$. Therefore, irreducible representations of G^∞_Λ are labeled by sequences of highest weights

$$(\mathbf{m},\mathbf{n}) = (m_{z_1},\ldots,m_{z_M};n_{z_1},\ldots,n_{z_M}), \tag{3.7}$$

where $(z_1,\ldots,z_M)$ label the lattice external sites. These representations are equivalent to tensor products of representations in spaces $\mathbb{S}^{m_{z_i}}_{n_{z_i}}(\mathbb{C}^3)$. Let us denote by $\mathcal{H}^{(\mathbf{m},\mathbf{n})}_\Lambda$ the sum of all the irreducible subspaces with respect to the action of G^∞_Λ, which carry the same type $(\mathbf{m},\mathbf{n})$. Then we have

$$\mathcal{H}_\Lambda = \oplus\, \mathcal{H}^{(\mathbf{m},\mathbf{n})}_\Lambda. \tag{3.8}$$

Obviously, every subspace of type $(\mathbf{m},\mathbf{n})$ is invariant under the action of the observable algebra,

$$\mathfrak{O}^i_\Lambda \mathcal{H}^{(\mathbf{m},\mathbf{n})}_\Lambda \subset \mathcal{H}^{(\mathbf{m},\mathbf{n})}_\Lambda.$$

This yields the following.

Corollary 3.3: The irreducible representations of $\mathfrak{O}^i_\Lambda$ are labelled by highest weight representations $(\mathbf{m},\mathbf{n})$ of G^∞_Λ. For any $(\mathbf{m},\mathbf{n})$, the corresponding irreducible representation of $\mathfrak{O}^i_\Lambda$ coincides with the algebra of those compact operators on $\mathcal{H}^{(\mathbf{m},\mathbf{n})}_\Lambda$, which commute with the action of the group G^∞_Λ.

We call the pair $(\mathbf{m},\mathbf{n})$ the boundary flux distribution carried by the gluonic field. In the next section, it will become obvious that all distributions $(\mathbf{m},\mathbf{n})$ occur.

C. Explicit description of irreducible representations

Now we give an explicit description of the above irreducible representations, using the explicit form (2.35) of H_Λ. Any element of H_Λ is a linear combination of fermionic vectors (2.36) with coefficients being L^2-functions depending on gluonic potentials U. The invariant subspace $\mathcal{H}_\Lambda \subset H_\Lambda$ is spanned by vectors from H_Λ, which are scalars with respect to G^i_Λ. This means that for every $x \in \Lambda^0$, all the color indices $(A_1,\ldots,A_n)$ of the fermionic state (2.36) must be saturated with the upper indices of either $U^A{}_B(x,y)$ or the canonical tensor $\boldsymbol{\epsilon}^{ABC}$. After such contractions, we are—in general—left with free indices at external points $z_i \in \Lambda^0_\infty$. Finally, such a vector can be multiplied by gauge invariant functions of gluonic potentials U. The general form of such functions is as follows:

$$f([U]) = f(\mathrm{Tr}(U_{\gamma_1}),\ldots,\mathrm{Tr}(U_{\gamma_n})),$$

where f is a function of n scalar variables, each $\gamma=(x_1,x_2,\ldots,x_m)$ is an arbitrary closed lattice path and U_γ is the corresponding *parallel transporter* along γ,

$$U^A_{\gamma B} = U^A{}_{C_2}(x_1,x_2)U^{C_2}{}_{C_3}(x_2,x_3)\cdots U^{C_{m-1}}{}_B(x_{m-1},x_m). \tag{3.9}$$

Let us denote the result of these operations by

$$\boldsymbol{\Psi} = \left(\Psi^{\ldots,A_1,\ldots,A_{m_{z_i}},\ldots}_{\ldots,B_1,\ldots,B_{n_{z_i}},\ldots}\right). \tag{3.10}$$

This is a collection of G^i_Λ-invariant vectors belonging to H_Λ, labeled by tensor indices assigned to external points $z_i \in \Lambda^0_\infty$, i,e., an H_Λ-valued tensor over

$$\mathbb{C}^{3M} = \bigoplus_{z_i \in \Lambda^0_\infty} \mathbb{C}^3_{z_i}.$$

Linear combinations of those elements span the invariant subspace $\mathcal{H}_\Lambda$, with coefficients built from products of tensors

$$t(z_i) = \left(t^{B_1,\ldots,B_{n_{z_i}}}_{A_1,\ldots,A_{m_{z_i}}}(z_i)\right) \in \mathbb{T}^{n_{z_i}}_{m_{z_i}}(\mathbb{C}^3). \tag{3.11}$$

The resulting vector belonging to $\mathcal{H}_\Lambda$ is a scalar obtained by contraction of (3.10) with these tensors,

$$\Psi = \Psi(t(z_1),\ldots,t(z_M)) = t^{B_1,\ldots,B_{n_{z_i}}}_{A_1,\ldots,A_{m_{z_i}}}(z_i)\cdots\Psi^{\ldots,A_1,\ldots,A_{m_{z_i}},\ldots}_{\ldots,B_1,\ldots,B_{n_{z_i}},\ldots}. \tag{3.12}$$

Each of the irreducible components $\mathcal{H}_\Lambda^{(\mathbf{m},\mathbf{n})}$ is composed of combinations (3.12), for which all the tensors $t(z_i)$ are irreducible (symmetric, traceless), i.e., where $t(z_i)\in \mathbb{S}^{n_{z_i}}_{m_{z_i}}(\mathbb{C}^3)\subset \mathbb{T}^{n_{z_i}}_{m_{z_i}}(\mathbb{C}^3)$. If t's are not irreducible, (3.12) is a sum of irreducible components belonging to different weights $(\mathbf{m},\mathbf{n})$, according to the decomposition of tensors $t(z_i)$ into the sum of products of irreducible (symmetric, traceless) tensors with canonical tensors $\delta^A_{\ B}$, ϵ^{ABC} and ϵ_{ABC}.

IV. THE FULL ALGEBRA OF OBSERVABLES

A. Motivation and basic definitions

One of the main perspectives of this work is the construction of the thermodynamical limit of finite lattice QCD. In Ref. 1 we have, in the context of finite lattice QED, outlined a strategy based upon an inductive (respectively, projective) limit procedure for observable algebras (respectively, state spaces). In what follows, we will argue that in order to implement this strategy, we must extend both the algebra of observables $\mathfrak{O}^i_\Lambda$ (by adding certain "external observables") and the Hilbert space $\mathcal{H}_\Lambda$ (by tensorizing with the Hilbert space of tensors at external points). Then, each collection $(\Psi^{\ldots,A_1,\ldots,A_{m_{z_i}},\ldots}_{\ldots,B_1,\ldots,B_{n_{z_i}},\ldots})$ of G^i_Λ-invariant H_Λ-vectors labelled by free indices at external points [see (3.10)] will constitute a physical state.

Thus, let us consider two lattices Λ_1 and Λ_2 which are disjoint $(\Lambda_1\cap\Lambda_2=\emptyset)$ and have a common wall such that their sum $\tilde{\Lambda}=\Lambda_1\cup\Lambda_2$ is also a cubic lattice. If $x\in\Lambda_1$ and $y\in\Lambda_2$ are adjacent points in $\tilde{\Lambda}$, then we identify their external points. This joint external point z may be visualized e.g., as the middle point of the connecting link (x,y). The parallel transporter on (x,y) is defined by

$$U^A_{\ B}(x,y) := U^A_{\ C}(x,z)U^C_{\ B}(z,y). \tag{4.1}$$

Observables internal relative to Λ_1 (respectively, Λ_2) are built, among others, from parallel transporters U_γ along lattice paths γ, which are completely contained in Λ_1 (respectively, Λ_2). On the other hand, there exist observables internal relative to $\tilde{\Lambda}$, built from parallel transporters along paths crossing the set of joint external points. Such observables describe correlations between phenomena occurring in the two disjoint regions Λ_1 and Λ_2. As examples, consider the $\tilde{\Lambda}$-internal observables

$$J^{ab}_\gamma(x,y) := \psi^{*a}_{\ A}(x)U^A_{\gamma B}\psi^{bB}(y),$$

with γ being a path from $x\in\Lambda_1$ to $y\in\Lambda_2$, or observables

$$U_\gamma := U^A_{\gamma A},$$

with γ being a closed path lying partially in Λ_1 and partially in Λ_2. These are operators belonging to the multiplier algebra $M(\mathfrak{O}^i_{\tilde{\Lambda}})$ and, whence, are *observables* in the extended sense. According to the above-mentioned inductive limit procedure, the observable algebra related to $\tilde{\Lambda}$ should be constructed from observables related to Λ_1 and Λ_2. But, in order to construct observables related to $\tilde{\Lambda}$ of the above type (describing correlations), we must admit fields "having free external tensor indices," like $\psi^{*a}_{\ A}(x)U^A_{\gamma_1 C}(x,z)$ and $U^C_{\gamma_2 B}(z,y)\psi^{bB}(y)$, with z being a joint external point. Quantities of this type are usually called "charge carrying fields," they were first introduced by Mandelstam (see Ref. 20).

Observe that charge carrying fields do not act neither on $\mathcal{H}_{\Lambda_1}$ nor on $\mathcal{H}_{\Lambda_2}$. They carry the fundamental (respectively, its contragredient) representation of SU(3) associated with the corre-

sponding external point. Thus, we must extend the Hilbert space $\mathcal{H}_\Lambda$ by tensorizing it with the Hilbert space $\mathbb{T}_\infty$ generated by the fundamental and its contragredient representations of SU(3) associated with all external points,

$$\mathbb{T}_\infty := \bigotimes_{z\in\Lambda^0_\infty} \mathbb{T}(z), \quad \mathbb{T}(z) := \bigoplus_{(m,n)} \mathbb{T}^m_n(z). \tag{4.2}$$

Here, $\mathbb{T}^m_n(z)$ denotes the space of all—not necessarily irreducible—m-contravariant, n-covariant tensors over $\mathbb{C}^3_z$. This way, we are led to consider the Hilbert space $\mathbb{T}_\infty \otimes \mathcal{H}_\Lambda$. The action of the gauge group G^∞_Λ extends in a natural way from $\mathcal{H}_\Lambda$ to this tensor product,

$$T(g)(t\otimes\Psi) := t\otimes(g\cdot\Psi), \quad t\otimes\Psi\in\mathbb{T}_\infty\otimes\mathcal{H}_\Lambda, \quad g\in G^\infty_\Lambda. \tag{4.3}$$

On the other hand, the natural action of G^∞_Λ on $\mathbb{T}_\infty$ can be also extended to this product,

$$R(g)(t\otimes\Psi) := (g\cdot t)\otimes\Psi. \tag{4.4}$$

It is clear that elements of $\mathbb{T}_\infty\otimes\mathcal{H}_\Lambda$ may be represented as "wave functions with free boundary indices," i.e., objects of type (3.10). Indeed, such tensors can be naturally viewed as antilinear mappings

$$\mathbb{T}_\infty \ni s \mapsto (t\otimes\Psi)(s) := (s|t)\Psi \in \mathcal{H}_\Lambda, \tag{4.5}$$

where $(\cdot|\cdot)$ denotes the scalar product in $\mathbb{T}_\infty$. Obviously, wave functions (3.10) are mappings of this type, too.

The above extension of the Hilbert space is necessary if we want to construct the thermodynamical limit of the theory by the above-mentioned projective limit procedure. According to this procedure, physical states related to Λ_1 are obtained from physical states related to $\tilde{\Lambda}$ by applying a projection operator $P_{\Lambda_1,\tilde{\Lambda}}$, which consists in averaging over the degrees of freedom located in Λ_2. More precisely, consider a wave function $\tilde{\psi}\in\mathcal{H}_{\tilde{\Lambda}}$, given by (3.12), take the corresponding projector $|\tilde{\psi}\rangle\langle\tilde{\psi}|$, split all parallel transporters on links joining Λ_1 and Λ_2 according to (4.1), and integrate over all degrees of freedom related to Λ_2 (including those located on external links of Λ_2). The result is a mixed state related to Λ_1, which can be represented as a mixture of pure states, each of them being a $\mathcal{H}_{\Lambda_1}$-valued tensor $\mathbf{\Psi}$ with respect to joint infinities of Λ_1 and Λ_2. In other words, the averaging procedure produces, in general, free indices on the common boundary between Λ_1 and Λ_2. To be consistent, we must admit such free indices from the very beginning.

From the above discussion we see that tensors $t(z)$ occurring in elements $t\otimes\Psi\in\mathbb{T}_\infty\otimes\mathcal{H}_\Lambda$ are not *a priori* given c-number quantities, but quantum averages over external (i.e., contained in Λ_2) degrees of freedom.

There is, however, an additional requirement, which we impose on physical states of the system: the averaging procedure described above should be compatible with gauge transformations. Assume that we average a state $\tilde{\psi}\in\mathcal{H}_{\tilde{\Lambda}}$ over Λ_2, with the parallel transporters on links joining Λ_1 and Λ_2 split according to (4.1). Any gauge transformation g at a common external point z between Λ_1 and Λ_2, acting on $\tilde{\psi}$ can be either implemented by the action of $G^\infty_{\Lambda_1}$ or $G^\infty_{\Lambda_2}$. After averaging over Λ_2, the action of the gauge group $G^\infty_{\Lambda_1}$ is of course still represented by $T(g)$, whereas the action of $G^\infty_{\Lambda_2}$ reduces to $R(g)$ representing gauge transformations in "the rest of the world." But, compatibility of averaging with gauging means that the result of this gauge transformation should not depend upon its implementation. Hence, we postulate

$$T(g)\mathbf{\Psi} = R(g)\mathbf{\Psi}. \tag{4.6}$$

As a result of our discussion, we define the physical Hilbert space as

$$\mathbf{H}_\Lambda := \{\mathbf{\Psi} \in \mathbb{T}_\infty \otimes \mathcal{H}_\Lambda | T(g)\mathbf{\Psi} = R(g)\mathbf{\Psi}, \text{ for any } g \in G_\Lambda^\infty\}, \tag{4.7}$$

with gauge transformation being, according to the above discussion, represented by T. The property (4.6) is obviously not shared by elements, which have partially contracted external indices or indices which do not come from the bosonic wave functions $U(x,\infty)$. To illustrate this, we consider the following examples:

$$\Psi^{\ldots,A_1,\ldots,A_m,\ldots}_{\ldots,B_1,\ldots,B_n,\ldots} r^{B_n}_{A_m}(z) \text{ or } \Psi^{\ldots,A_1,\ldots,A_m,\ldots}_{\ldots,B_1,\ldots,B_n,\ldots} r^{A_{m+1}}_{B_{n+1}}(z), \quad \text{with } r(z) \in \mathbb{T}^1_1(z). \tag{4.8}$$

Thus, (4.6) is fulfilled precisely by elements of type (3.10) having all indices free. Admitting objects of type (4.8) would mean admitting additional degrees of freedom r, which would live at joint external points z and would be relevant for the description of physical states on the lattice $\tilde{\Lambda} = \Lambda_1 \cup \Lambda_2$. In that case, these joint external points could not be removed from $\tilde{\Lambda}$.

Using (4.2), we have

$$\mathbf{H}_\Lambda = \bigoplus_{(\mathbf{m},\mathbf{n})} \mathbf{H}_\Lambda^{(\mathbf{m},\mathbf{n})}. \tag{4.9}$$

Here, $\mathbf{H}_\Lambda^{(\mathbf{m},\mathbf{n})}$ denotes the intersection of $\mathbf{H}_\Lambda$ with $\mathbb{T}_\infty^{(\mathbf{m},\mathbf{n})} \otimes \mathcal{H}_\Lambda$, where

$$\mathbb{T}_\infty^{(\mathbf{m},\mathbf{n})} := \bigotimes_{z \in \Lambda_\infty^0} \mathbb{T}^{m_z}_{n_z}(z) \tag{4.10}$$

is the subspace of tensorial type (m_z, n_z) at each $z \in \Lambda_\infty^0$. Note that, contrary to (3.8), (4.9) is *not* a decomposition into irreducible components.

Next, observe that the scalar products on $\mathbf{H}_\Lambda$ and on $\mathbb{T}_\infty$ induce a natural scalar product on $\mathbf{H}_\Lambda$. Using the representation (3.10), it is given by

$$(\mathbf{\Psi}|\mathbf{\Phi})_{\mathbf{H}_\Lambda} = \left(\Psi^{\ldots,A_1,\ldots,A_{m_{z_i}},\ldots}_{\ldots,B_1,\ldots,B_{n_{z_i}},\ldots} \middle| \Phi^{\ldots,C_1,\ldots,C_{m_{z_i}},\ldots}_{\ldots,D_1,\ldots,D_{n_{z_i}},\ldots} \right)_{H_\Lambda} \times \cdots g_{A_1 C_1} \cdots g_{A_{m_{z_i}} C_{m_{z_i}}} \cdots g^{B_1 D_1} \cdots g^{B_{m_{z_i}} B_{m_{z_i}}} \cdots . \tag{4.11}$$

Tensors with different valences (i.e., having a different number of indices) are, by definition, orthogonal.

We define the full algebra of observables related to Λ as the C^*-algebra of gauge invariant compact operators acting on $\mathbf{H}_\Lambda$,

$$\mathfrak{O}_\Lambda := \mathfrak{K}(\mathbf{H}_\Lambda) \cap (G_\Lambda^\infty)'. \tag{4.12}$$

As before, we define the *extended* full observable algebra as $M(\mathfrak{O}_\Lambda) = \mathfrak{B}(\mathbf{H}_\Lambda) \cap (G_\Lambda^\infty)'$. Consider the algebra $\mathfrak{O}_\Lambda^\infty$ of those compact operators acting on $\mathbb{T}_\infty$, which are invariant with respect to the action of G_Λ^∞. By classical invariant theory, this algebra is generated (in the sense of Woronowicz) by operations of tensorizing or contracting with SU(3)-invariant tensors $\delta^A{}_B$, ϵ^{ABC}, and ϵ_{ABC}, and by projection operators $P^{(\mathbf{m},\mathbf{n})}$ onto $\mathbb{T}_\infty^{(\mathbf{m},\mathbf{n})} \subset \mathbb{T}_\infty$.

Proposition 4.1: The full observable algebra can be characterized as follows:

$$\mathfrak{O}_\Lambda \cong \mathfrak{O}_\Lambda^i \otimes \mathfrak{O}_\Lambda^\infty. \tag{4.13}$$

Proof: Any compact gauge invariant operator A acting on $\mathbf{H}_\Lambda$ can be extended to a gauge invariant operator on the whole tensor product $\mathbb{T}_\infty \otimes \mathcal{H}_\Lambda$, using contractions and tensor products with boundary tensors r in $\mathbb{T}_\infty$, see formula (4.8). More precisely, we set

$$A(C(r \otimes \mathbf{\Psi})) := C(r \otimes A(\mathbf{\Psi})), \tag{4.14}$$

for any tensor $r \in \mathbb{T}_\infty$ and any contraction operator C (the result of the contraction on the right-hand-side vanishes *by definition* if a corresponding index is missing in $A\mathbf{\Psi}$). This way we have proved that

$$\mathfrak{K}(\mathbf{H}_\Lambda) \cap (G_\Lambda^\infty)' \cong \mathfrak{K}(\mathbb{T}_\infty \otimes \mathcal{H}_\Lambda) \cap (G_\Lambda^\infty)'. \tag{4.15}$$

But we have

$$\mathfrak{K}(\mathbb{T}_\infty \otimes \mathcal{H}_\Lambda) \cong \mathfrak{K}(\mathbb{T}_\infty) \otimes \mathfrak{K}(\mathcal{H}_\Lambda), \tag{4.16}$$

and, consequently,

$$\mathfrak{K}(\mathbf{H}_\Lambda) \cap (G_\Lambda^\infty)' \cong \mathfrak{K}(\mathbb{T}_\infty) \otimes (\mathfrak{K}(\mathcal{H}_\Lambda) \cap (G_\Lambda^\infty)') \cong \mathfrak{K}(\mathbb{T}_\infty) \otimes \mathfrak{O}_\Lambda^i. \tag{4.17}$$

Taking again the intersection with $(G_\Lambda^\infty)'$ and implementing it by the representation R yields the thesis. ■

Elements of $\mathfrak{O}_\Lambda^\infty$ representing the rest of the world are called *external observables*.

Adopting the point of view that t occurring in $t \otimes \Psi$ represents the "quantum averages over the external field degrees of freedom," one can argue that the only trace of the action of external observables, which may be seen from Λ, are external gauge invariant operators on $\mathbb{T}_\infty$. Hence, formula (4.13) could be taken as an axiomatic definition of the full observable algebra. The results of the following section show that this approach is equivalent to the one used in the present section.

B. Classification of irreducible representations

Obviously, $\mathbb{T}_\infty$ is not irreducible with respect to the action of $\mathfrak{O}_\Lambda^\infty$. If $t(z) \in \mathbb{T}_n^m(z)$, then its image under this action is a sum of components belonging to $\mathbb{T}_l^k(z)$ with (k,l) fulfilling

$$(m-n) \bmod 3 = (k-l) \bmod 3.$$

We see that the $\mathbb{Z}_3$-valued flux

$$\Phi(z) := (m_z - n_z) \bmod 3 \tag{4.18}$$

through each external link (x,z), $z \in \Lambda_\infty^0$, is conserved under the action of $\mathfrak{O}_\Lambda^\infty$. Let us denote the sequence of $\mathbb{Z}_3$-valued fluxes assigned to all boundary points by

$$\mathbf{\Phi} := (\Phi(z_1), \Phi(z_2), \ldots).$$

In what follows, we call $\mathbf{\Phi}$ boundary flux distribution. Consequently, we define the subspace $\mathbf{H}_\Lambda^{\mathbf{\Phi}} \subset \mathbf{H}_\Lambda$ as the space spanned by those tensors (3.10) which fulfill condition $\Phi(z_i) = (m_{z_i} - n_{z_i}) \bmod 3$. In other words, we set

$$\mathbf{H}_\Lambda^{\mathbf{\Phi}} := \bigoplus_{m(z_i) - n(z_i) \bmod 3 = \Phi(z_i)} \mathbf{H}_\Lambda^{(\mathbf{m},\mathbf{n})}, \tag{4.19}$$

with $\mathbf{H}_\Lambda^{(\mathbf{m},\mathbf{n})}$ given by decomposition (4.9). Obviously, these subspaces are invariant under the action of the full observable algebra $\mathfrak{O}_\Lambda$ and $\mathfrak{O}_\Lambda$ acts irreducibly on each of them. Moreover, the physical Hilbert space $\mathbf{H}_\Lambda$ splits into the direct sum of them,

$$\mathbf{H}_\Lambda = \bigoplus_{\mathbf{\Phi}} \mathbf{H}_\Lambda^{\mathbf{\Phi}}. \tag{4.20}$$

We obviously have the following.

Lemma 4.2: The spaces $\mathbf{H}_\Lambda^{\mathbf{\Phi}}$ *provide all the irreducible representations of the algebra of observables* $\mathfrak{O}_\Lambda$.

We denote the irreducible component of $\mathfrak{O}_\Lambda$ acting on $\mathbf{H}_\Lambda^{\mathbf{\Phi}}$, by $\mathfrak{O}_\Lambda^{\mathbf{\Phi}}$.

Now, we define the global flux associated with a given boundary flux distributions $\mathbf{\Phi}$ setting

$$\mathbf{\Phi}_{\partial\Lambda} := \left(\sum_{z\in\Lambda^0_\infty} \mathbf{\Phi}(z) \right) \mathrm{mod}\, 3. \tag{4.21}$$

Let us denote the total number of gluonic and antigluonic flux lines running through the boundary by

$$m := \sum_{z_i\in\Lambda^0_\infty} m(z_i), \tag{4.22}$$

$$n := \sum_{z_i\in\Lambda^0_\infty} n(z_i). \tag{4.23}$$

Then, we get

$$\Phi_{\partial\Lambda} = (m-n) \mathrm{mod}\, 3. \tag{4.24}$$

Lemma 4.3: The irreducible representations of $\mathfrak{O}_\Lambda$ *in* $\mathbf{H}^{\mathbf{\Phi}}_\Lambda$ *and in* $\mathbf{H}^{\mathbf{\Phi}'}_\Lambda$ *are unitarily equivalent, if and only if* $\mathbf{\Phi}$ *and* $\mathbf{\Phi}'$ *carry the same global flux,*

$$\Phi_{\partial\Lambda} = \Phi'_{\partial\Lambda}.$$

Proof: Suppose that we are given a pair $(\mathbf{\Phi},\mathbf{\Phi}')$ such that $\Phi_{\partial\Lambda}=\Phi'_{\partial\Lambda}$. Then, $\mathbf{H}^{\mathbf{\Phi}}_\Lambda$ is given by (4.19) and, similarly,

$$\mathbf{H}^{\mathbf{\Phi}'}_\Lambda = \bigoplus_{m'(z_i)-n'(z_i)\mathrm{mod}\,3=\Phi'(z_i)} \mathbf{H}^{(\mathbf{m}',\mathrm{n}')}_\Lambda.$$

For $\Phi_{\partial\Lambda}=\Phi'_{\partial\Lambda}$, formula (4.24) implies that we can choose a pair of labels $(\mathbf{m}_0,\mathbf{n}_0)$ and $(\mathbf{m}'_0,\mathbf{n}'_0)$ such that $m_0=m'_0$, $n_0=n'_0$, Acting with tensorial operators $\xi\in\mathfrak{O}^\infty_\Lambda$ (tensorising and contracting with canonical tensors $\delta^A{}_B$, ϵ^{ABC} and ϵ_{ABC}) on $\mathbf{H}^{(\mathbf{m}_0,\mathbf{n}_0)}_\Lambda$ (respectively, $\mathbf{H}^{(\mathbf{m}'_0,\mathbf{n}'_0)}_\Lambda$), we may pass to any other subspace $\mathbf{H}^{(\mathbf{m},\mathbf{n})}_\Lambda$ of $\mathbf{H}^{\Phi}_\Lambda$ (respectively, any other subspace $\mathbf{H}^{(\mathbf{m}',\mathbf{n}')}_\Lambda$ of $\mathbf{H}^{\mathbf{\Phi}'}_\Lambda$). This way we construct a bijection between the two sets $(\mathbf{m},\mathbf{n})$ and $(\mathbf{m}',\mathbf{n}')$ corresponding to $\mathbf{\Phi}$ and $\mathbf{\Phi}'$, preserving the total number of gluonic and antigluonic lines, $m=m'$ and $n=n'$.

We shall construct an intertwining operator between representations on $\mathbf{H}^{\Phi}_\Lambda$ and $\mathbf{H}^{\Phi'}_\Lambda$. For this purpose, we first define a sequence of isometric isomorphisms of Hilbert spaces,

$$\mathbf{U}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})} : \mathbf{H}^{(\mathbf{m},\mathbf{n})}_\Lambda \to \mathbf{H}^{(\mathbf{m}',\mathbf{n}')}_\Lambda$$

corresponding to the above bijection, as follows. We choose two finite families $\{\beta_a\}$ and $\{\gamma_b\}$ of lattice paths in Λ, fulfilling the following conditions:

(i) their starting points x_a and y_b, together with their end points z_a and w_b belong to the boundary $\partial\Lambda$,
(ii) for every $x\in\Lambda^0_\infty$ there are exactly $\Delta n(x) := n(x)-n'(x)$ paths β starting from x if $\Delta n(x) > 0$ and zero otherwise,
(iii) for every $x\in\Lambda^0_\infty$ there are exactly $\Delta m(x) := m(x)-m'(x)$ paths γ ending at x if $\Delta m(x)>0$ and zero otherwise,
(iv) for every $x\in\Lambda^0_\infty$ there are exactly $-\Delta n(x)$ paths β ending at x if $\Delta n(x)<0$ and zero otherwise,
(v) for every $x\in\Lambda^0_\infty$ there are exactly $-\Delta m(x)$ paths γ starting from x if $\Delta m(x)<0$ and zero otherwise.

Now, the action of the operator $\mathbf{U}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})}$ on a vector $\mathbf{\Psi}\in\mathbf{H}^{(\mathbf{m},\mathbf{n})}_\Lambda$ is defined as follows. We multiply the tensor (3.10) by all parallel transporters $U^{B_a}_{\beta_a A_a}$ and $U^{B_b}_{\gamma_b A_b}$, see formula (3.9). Then, we contract all the subsequent upper indices B_a with the corresponding subsequent lower indices B_i of

$\mathbf{\Psi}$ at the starting points of the curves β and all the subsequent lower indices A_b with the corresponding upper indices A_i of $\mathbf{\Psi}$ at the end points of the curves γ. It is easy to see that the inverse (adjoint) operator consists in multiplying $\mathbf{\Psi}$ by the same transporters, but in contracting indices A_a with the corresponding subsequent upper indices A_i of $\mathbf{\Psi}$ at the starting points of the curves β and all the subsequent indices B_b with the corresponding lower indices B_i of $\mathbf{\Psi}$ at the end points of the curves γ. This implies that

$$\mathbf{U}^{*}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})}\mathbf{U}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})} = \mathrm{id} = \mathbf{U}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})}\mathbf{U}^{*}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})}.$$

Organizing the operators $\mathbf{U}_{(\mathbf{m}',\mathbf{n}')(\mathbf{m},\mathbf{n})}$ into a block matrix, we get an isometric isomorphism denoted by

$$\mathbf{U}_{\mathbf{\Phi}'\mathbf{\Phi}}:\mathbf{H}^{\mathbf{\Phi}}_{\Lambda} \to \mathbf{H}^{\mathbf{\Phi}'}_{\Lambda}. \tag{4.25}$$

Next, observe that the action

$$\mathbf{U}^{*}_{\mathbf{\Phi}'\mathbf{\Phi}}\mathfrak{O}^{\mathbf{\Phi}'}_{\Lambda}\mathbf{U}_{\mathbf{\Phi}'\mathbf{\Phi}}:\mathbf{H}^{\mathbf{\Phi}}_{\Lambda} \to \mathbf{H}^{\mathbf{\Phi}}_{\Lambda},$$

defines an irreducible representation of $\mathfrak{O}_\Lambda$ on $\mathbf{H}^{\mathbf{\Phi}}_{\Lambda}$. By Lemma 4.2, this representation must be unitarily equivalent to $\mathfrak{O}^{\mathbf{\Phi}}_{\Lambda}$, i.e., there exists a unitary (intertwining) operator

$$\mathbf{S}:\mathbf{H}^{\mathbf{\Phi}}_{\Lambda} \to \mathbf{H}^{\mathbf{\Phi}}_{\Lambda}, \tag{4.26}$$

such that

$$\mathbf{S}^{*}\mathbf{U}^{*}_{\mathbf{\Phi}'\mathbf{\Phi}}\mathfrak{O}^{\mathbf{\Phi}'}_{\Lambda}\mathbf{U}_{\mathbf{\Phi}'\mathbf{\Phi}}\mathbf{S} = \mathfrak{O}^{\mathbf{\Phi}}_{\Lambda}.$$

It remains to show that equivalent representations yield equal global fluxes: If $\mathbf{H}^{\mathbf{\Phi}}_{\Lambda}$ and $\mathbf{H}^{\mathbf{\Phi}'}_{\Lambda}$ carry equivalent representations, then there exists an intertwiner $\mathbf{V}_{\mathbf{\Phi}'\mathbf{\Phi}}$, such that

$$\Phi'_{\partial\Lambda} = \mathbf{V}_{\mathbf{\Phi}'\mathbf{\Phi}}\Phi_{\partial\Lambda}\mathbf{V}^{-1}_{\mathbf{\Phi}'\mathbf{\Phi}}.$$

But, according to formula (4.24), $\Phi_{\partial\Lambda}$ is a scalar on every irreducible representation space of $\mathfrak{O}_\Lambda$. Thus, it commutes with $\mathbf{V}_{\mathbf{\Phi}'\mathbf{\Phi}}$ yielding $\Phi'_{\partial\Lambda}=\Phi_{\partial\Lambda}$. ■

Theorem 4.4: *There are three inequivalent representations of* $\mathfrak{O}_\Lambda$ *labeled by values of the global flux* $\Phi_{\partial\Lambda}$. *Consequently, the space* $\mathbf{H}_\Lambda$ *splits into the sum of three eigenspaces of* $\Phi_{\partial\Lambda}$

$$\mathbf{H}_\Lambda = \bigoplus_{\lambda=-1,0,1} \mathbf{H}^{\lambda}_{\Lambda}.$$

Each of the spaces $\mathbf{H}^{\lambda}_{\Lambda}$ *is a sum of superselection sectors* $\mathbf{H}^{\mathbf{\Phi}}_{\Lambda}$ *corresponding to all possible distributions* $\mathbf{\Phi}$ *of the global flux* λ. *They carry equivalent representations of* $\mathfrak{O}_\Lambda$.

Anticipating the final result, we call the spaces $\mathbf{H}^{\lambda}_{\Lambda}$ "charge superselection sectors," in contrast to the "boundary-flux-distribution superselection sectors" $\mathbf{H}^{\Phi}_{\Lambda}$. (For an analogous discussion in continuum QED see Ref. 34.)

C. Global color charge and superselection structure

Here we show that, according to the global Gauss law, irreducible representations of $\mathfrak{O}_\Lambda$ are, alternatively, labeled by global color charge (triality), which is carried by the quark fields. We briefly recall the notion of triality and derive the global Gauss law, for details see Ref. 4.

Consider any integrable representation F of the Lie algebra su(3) on a Hilbert space H, i.e., a collection of operators $F^{A}{}_{B}$ in H, fulfilling $F^{A}{}_{A}=0$, $(F^{A}{}_{B})^{*}=F_{B}{}^{A}$, and

$$[F^A{}_B, F^C{}_D] = \delta^C{}_B F^A{}_D - \delta^A{}_D F^C{}_B. \tag{4.27}$$

By (2.22), (2.44), and (2.5), the operators $E^A{}_B(x,y)$ and $\rho^A{}_B(x)$, occurring on both sides of the local Gauss law, are of this type. Integrability means that for each F there exists a unitary representation $G \ni g \to \overline{F}(g) \in B(H)$ of the group G such that F is its derivative. If F_1 and F_2 are two commuting (integrable) representations of su(3), then so is $F_1 + F_2$. Such a collection of operators is an *operator domain* in the sense of Woronowicz, see Ref. 35.

We define an operator function on this domain, i.e., a mapping $F \to \varphi(F)$, which satisfies $\varphi(UFU^{-1}) = U\varphi(F)U^{-1}$ for an arbitrary isometry U, as follows: For any integrable representation F of su(3), consider the corresponding representation $\overline{F}$ of G. Its restriction to the center $\mathcal{Z}$ of G acts as a multiple of the identity on each irreducible subspace H_α of $\overline{F}$,

$$\overline{F}(z)|_{H_\alpha} = \chi^\alpha_F(z) \cdot \mathbf{1}_{H_\alpha}, \quad z \in Z.$$

Obviously, χ^α_F is a character on $\mathcal{Z}$ and, therefore, $(\chi^\alpha_F(z))^3 = 1$. We identify the group of characters on $\mathcal{Z} = \{\zeta \cdot \mathbf{1}_3 | \zeta^3 = 1, \zeta \in \mathbb{C}\}$ with the additive group $\mathbb{Z}_3 \cong \{-1, 0, 1\}$ by assigning to any character χ^α_F a number $k(\alpha) \in \{-1, 0, 1\}$ fulfilling

$$\chi^\alpha_F(\zeta \cdot \mathbf{1}_3) = \zeta^{k(\alpha)}.$$

Hence, there exists a $\mathbb{Z}_3$-valued operator function $F \to \varphi(F)$, defined by

$$\zeta^{\varphi_\alpha(F)} = \chi^\alpha_F(\zeta \cdot \mathbf{1}_3), \tag{4.28}$$

$$\varphi(F) = \sum_\alpha \varphi_\alpha(F) \mathbf{1}_{H_\alpha}. \tag{4.29}$$

Since χ^α_F are characters, we have

$$\varphi(F_1 + F_2) = \varphi(F_1) + \varphi(F_2), \tag{4.30}$$

for F_1 and F_2 commuting. Now, using the equivalence of each irreducible representation α of G with highest weight $(m(\alpha), n(\alpha))$ with the tensor representation in the space $\mathbb{T}^{m(\alpha)}{}_{n(\alpha)}(\mathbb{C}^3)$ of $m(\alpha)$-contravariant, $n(\alpha)$-covariant, completely symmetric and traceless tensors over $\mathbb{C}^3$, we get

$$\chi^\alpha_F(z) = \zeta^{\varphi_\alpha(F)} = \zeta^{m(\alpha) - n(\alpha)}, \tag{4.31}$$

for $z = \zeta \cdot \mathbf{1}_3 \in \mathcal{Z}$. Thus, we have

$$\varphi_\alpha(F) = (m(\alpha) - n(\alpha)) \bmod 3 \tag{4.32}$$

for every irreducible highest weight representation $(m(\alpha), n(\alpha))$. In Ref. 4 we have given an explicit construction of $\varphi(F)$ in terms of Casimir operators of F.

Applying φ to the local Gauss law (2.45) and using additivity (4.30) we obtain a gauge invariant equation for operators with eigenvalues in $\mathbb{Z}_3$,

$$\sum_{y \leftrightarrow x} \varphi(E(x,y)) = \varphi(\rho(x)), \tag{4.33}$$

valid at every lattice site x. The quantity on the right-hand side is the (gauge invariant) local color charge density carried by the quark field.

Using the transformation law (2.15) for $E(x,y)$ under the change of the link orientation and additivity (4.30) of φ, we have for every lattice bond (x,y):

$$\varphi(E(x,y)) + \varphi(E(y,x)) = \varphi(E(x,y)) + \varphi(\check{E}(x,y)) = \varphi(E(x,y) + \check{E}(x,y)), \tag{4.34}$$

because representations E and $\check{E}$ commute. But the following identity holds:

$$\varphi(E(x,y) + \check{E}(x,y)) = 0, \tag{4.35}$$

because both representations have the same irreducible subspaces H_α, with the values of $m(\alpha)$ and $n(\alpha)$ exchanged. [The identity follows also directly from formula (2.21). It implies that the second order Casimirs for E and $\check{E}$ coincide, $K_2(E)=K_2(\check{E})$, whereas $K_3(E)=-K_3(\check{E})$, cf. Ref. 4.]

Now, we take the sum of equations (4.33) over all lattice sites $x\in\Lambda^0$. Due to the above identity, all terms on the left-hand side cancel, except for contributions $\varphi(E(x,\infty))\equiv\varphi(E(x,z))$, $z\in\Lambda^0_\infty$, coming from the boundary. The irreducible subspace $\mathbf{H}^\Phi_\Lambda\subset\mathbf{H}_\Lambda$ characterized by the flux distribution $\mathbf{\Phi}$, see (4.19), is an eigenspace of the gauge invariant operator $\varphi(E(x,z))$, with eigenvalue $(m_z-n_z)\mathrm{mod}\,3=\Phi(z)$, according to formula (4.32). Thus, using (4.21) we obtain

$$\sum_{x\in\partial\Lambda^0} \varphi(E(x,\infty)) = \Phi_{\partial\Lambda}, \tag{4.36}$$

with $\Phi_{\partial\Lambda}$ being the global $\mathbb{Z}_3$-valued boundary flux corresponding to the flux distribution $\mathbf{\Phi}$. On the right-hand side we get the (gauge invariant) global color charge (*triality*), carried by the matter field

$$\mathfrak{t}_\Lambda := \sum_{x\in\Lambda^0} \varphi(\rho(x)). \tag{4.37}$$

Thus, the *global Gauss law* takes the following form:

$$\Phi_{\partial\Lambda} = \mathfrak{t}_\Lambda. \tag{4.38}$$

Both quantities appearing here take eigenvalues in the center $\mathcal{Z}\cong\mathbb{Z}_3$ of G.

Comparing with Theorem 4.4, the global Gauss law yields another, equivalent characterization of irreducible representations of the observable algebra.

Corollary 4.5: The inequivalent representations of $\mathfrak{O}_\Lambda$ are labeled by eigenvalues of global color charge $\mathfrak{t}_\Lambda$.

Remark: We illustrate the main result of this paper. Observe that we can assign to single quark fields [being in the defining representation of SU(3)] triality $+1$ and, consequently to antiquarks -1 (or the other way around). A single lattice gluon field has, of course, triality 0. Now, imagine a state with m quarks and n antiquarks, located in an arbitrary way inside Λ. By additivity of triality, $\mathfrak{t}_\Lambda$ has eigenvalue $m-n\,\mathrm{mod}\,3$ on this state. As discussed already, gauge invariance of states with respect to internal gauge transformations implies that all quark indices inside Λ must be contracted. Basically, this can be done by connecting quark–antiquark pairs *inside* Λ with flux lines built from gluonic parallel transporters and by contracting with canonical tensors $\delta^A{}_B$, ϵ^{ABC}, and ϵ_{ABC}. On the other hand, some of the flux lines starting at a antiquark (or ending at a quark) inside can run through the boundary to end at a quark (or start from an antiquark) *outside* of Λ. By the global Gauss law, the total number of gluonic flux lines minus the number of antigluonic flux lines, calculated modulo 3, is equal to the eigenvalue of triality. But the external quark and antiquark fields are not taken into account by a theory on Λ. After averaging over external fields we are left with the action of external gauge invariant operators $\delta^A{}_B$, ϵ^{ABC} and ϵ_{ABC}. The flux lines running through the boundary may by contracted at points $z\in\Lambda^0_\infty$ with these tensors, eventually leaving either none ($\mathfrak{t}_\Lambda=0$), or one gluonic ($\mathfrak{t}_\Lambda=+1$) or one antigluonic ($\mathfrak{t}_\Lambda=-1$) noncontracted line. These three values of triality correspond to the only possible inequivalent representations of the observable algebra. Thus, in particular, we have rigorously confirmed the heuristic picture, which earlier was taken as a starting point for discussing the quark confinement problem, see e.g., Ref. 16.

V. GENERATORS AND RELATIONS

In this section we wish to find a presentation of the observable algebra in terms of generators and relations, inherited from canonical commutation relations of fields and from the Gauss law. In

order to formulate and to study field dynamics, we rather need a presentation in terms of a set of independent generators. Thus, we wish to solve the Gauss law relations explicitly, to end up with a reduced set of generators and their (anti)commutation relations. We show how to implement this idea by a special gauge fixing procedure based upon the choice of a lattice tree. This procedure leaves us, however, with some discrete gauge freedom. Moreover, we restrict ourselves to the generic stratum of the gauge group action, disregarding all nongeneric strata. But even there, our method works only on a dense subset. These two obstructions to global gauge fixing reflect the Gribov problem, which is well known in the continuum theory, see also Ref. 36 for a discussion of this problem in the Ashtekar theory. Thus, following the gauge fixing idea leads to some delicate problems.

How to overcome these problems will be discussed in separate papers, see Refs. 21 and 22. Instead of trying to fix the gauge, one rather must find a generating set of genuine invariants. Below we show that it is quite easy, to write down a highly redundant set of invariants, but it is very hard to reduce it. If we want to work with genuine invariants we are automatically forced to consider higher order monomials, built from basic bosonic and fermionic fields. These invariants inherit, of course, some (anti)commutation relations, but the algebra generated by them does not close on the linear level. This way interesting new algebras occur. We refer to Ref. 37 for some first remarks on their structure. It turns out that algebras of similar types have been discussed in different areas of mathematical physics throughout the last decade, see the list of references in Ref. 37.

Since the generators of $\mathfrak{O}_\Lambda^\infty$ have been already listed before, it remains to discuss $\mathfrak{O}_\Lambda^i$ in terms of generators and relations.

A. Generators of $\mathfrak{O}_\Lambda^i$

Below, we define a set of generators of $\mathfrak{O}_\Lambda^i$ in terms of gauge-invariant combinations of the fields (U,E,ψ,ψ^*). In the next sections, we will systematically reduce the number of generators to a minimal set.

Theorem 5.1: *The observable algebra $\mathfrak{O}_\Lambda^i$ is generated by the following gauge invariant elements (together with their conjugates):*

$$U_\gamma := U^A_{\gamma A}, \tag{5.1}$$

$$E_\gamma(x,y) := U^A_{\gamma B} E^B{}_A(x,y), \tag{5.2}$$

$$J^{ab}_\gamma(x,y) := \psi^{*a}{}_A(x) U^A_{\gamma B} \psi^{bB}(y), \tag{5.3}$$

$$W^{abc}_{\alpha\beta\gamma}(x,y,z) := \tfrac{1}{6}\epsilon_{ABC} U^A_{\alpha D} U^B_{\beta E} U^C_{\gamma F} \psi^{aD}(x)\psi^{bE}(y)\psi^{cF}(z), \tag{5.4}$$

with γ denoting an arbitrary closed lattice path in formula (5.1), a closed lattice path starting and ending at x in (5.2) and a path from x to y in (5.3). In formula (5.4), α, β and γ are paths starting at some reference point t and ending at x, y, and z, respectively. In formula (5.2), both x and y stand also for ∞.

For the proof see Appendix B.

Note that the observables J^{ab}_γ and $W^{abc}_{\alpha\beta\gamma}$ represent hadronic matter of mesonic and baryonic type. They will play a basic role in future investigations towards a construction of an effective theory of interacting hadrons. Looking at the lattice Hamiltonian, given by (2.46), we see that the kinetic energy E^2 of the gluonic field is given by second Casimirs and its potential energy B^2 is given by Wilson loops U_γ. By the above theorem, the Casimirs can be expressed in terms of the above invariants. It is easy to see that the matter field part is given in terms of J's (which, however, are related with W's *via* nonlinear constraints). At present, it is not quite clear, which parametrization of the Hamiltonian in terms of observables will be the most efficient one for future applications.

B. The reduction idea

The above generating set turns out to be highly redundant. There is a number of nontrivial relations between generators, inherited from the canonical (anti) commutation relations and from the local Gauss laws. Below, we will show how to solve the local Gauss laws explicitly. This will be done by using a technique, based upon the choice of a *lattice tree*. This way we shall prove that $\mathfrak{O}^i_\Lambda$ can be decomposed (in a tree-dependent way) into the tensor product of a gluonic and a matter field part. This presentation of $\mathfrak{O}^i_\Lambda$ can be constructed in two steps:

(1) First we fix a lattice point x_0 and impose gauge invariance with respect to the pointed gauge group at x_0,

$$G^0_\Lambda = G^{i,0}_\Lambda \times G^\infty_\Lambda \tag{5.5}$$

with

$$G^{i,0}_\Lambda = \prod_{x_0 \neq x \in \Lambda^0} G_x. \tag{5.6}$$

Moreover, we implement the Gauss laws at all points $\Lambda^0 \ni x \neq x_0$, i.e., we factorize with respect to the ideal $\mathfrak{I}^0_\Lambda \cap (G^0_\Lambda)'$, with $\mathfrak{I}^0_\Lambda$ being generated by the Lie algebra $\mathfrak{g}^{i,0}_\Lambda \subset \mathfrak{g}^i_\Lambda$ of $G^{i,0}_\Lambda$. This gives the pointed algebra of internal observables,

$$\mathfrak{O}^{i,0}_\Lambda := (G^0_\Lambda)'/\{\mathfrak{I}^0_\Lambda \cap (G^0_\Lambda)'\}. \tag{5.7}$$

(2) Next, we impose on $\mathfrak{O}^{i,0}_\Lambda$ gauge invariance with respect to the residual gauge group G_{x_0}, and factorize with respect to the ideal $\mathfrak{I}_{x_0} \subset \mathfrak{O}^{i,0}_\Lambda$ generated by the local Gauss law at x_0.

Whereas the first step can be performed without any obstructions, in the second step, all the problems mentioned at the beginning of this chapter show up.

Theorem 5.2: *The internal observable algebra can be viewed as follows:*

$$\mathfrak{O}^i_\Lambda \cong (G_{x_0})'/\{\mathfrak{I}_{x_0} \cap (G_{x_0})'\}, \tag{5.8}$$

where $(G_{x_0})'$ and $\mathfrak{I}_{x_0}$ *are considered as subalgebras of* $\mathfrak{O}^{i,0}_\Lambda$.

Proof: Since G_{x_0} commutes with G^0_Λ, we have $(G_\Lambda)' = (G^0_\Lambda)' \cap (G_{x_0})'$. Moreover, the invariant subspaces H^0 and H_{x_0} of $G^{i,0}_\Lambda$ and G_{x_0} are both closed subspaces of H_Λ, whereas $\mathfrak{I}^0_\Lambda$ and $\mathfrak{I}_{x_0}$ are composed of operators vanishing on H^0 and H_{x_0}, respectively. Observe that

$$H^0 \cap H_{x_0} = \mathcal{H}_\Lambda$$

and that the ideal

$$\mathfrak{I}_\Lambda = \mathfrak{I}^0_\Lambda \oplus \mathfrak{I}_{x_0}$$

is composed of those operators which vanish on this intersection. Using completely analogous arguments as in the proof of Theorem 3.2, we obtain

$$\mathfrak{O}^{i,0}_\Lambda = \mathfrak{K}(H^0) \cap (G^\infty_\Lambda)'. \tag{5.9}$$

In the second step we must factorize the commutant $(G_{x_0})'$ of G_{x_0} in $\mathfrak{O}^{i,0}_\Lambda$ with respect to $\mathfrak{I}_{x_0} \cap (G_{x_0})'$. But by (5.9) we have

$$(G_{x_0})' = (G_{x_0})'(\mathfrak{K}(H^0)) \cap (G^\infty_\Lambda)',$$

where $(G_{x_0})'(\mathfrak{K}(H^0))$ is the commutant taken in $\mathfrak{K}(H^0)$. Again, using similar arguments as in the proof of Theorem 3.2, we get

$$(G_{x_0})'/\{\mathfrak{I}_{x_0} \cap (G_{x_0})'\} \cong \mathfrak{K}(\mathcal{H}_\Lambda) \cap (G_\Lambda^\infty)',$$

which is isomorphic to $\mathfrak{O}_\Lambda^i$, by formula (3.3). ■

C. Reduction with respect to pointed gauge transformations

As already mentioned, a convenient way to solve relations between generators is to choose a *tree*, i.e., to assign a unique path connecting any pair of lattice sites. More precisely, a tree is a pair $(x_0, \mathcal{T})$, where x_0 is a distinguished lattice site (called *root*) and $\mathcal{T}$ is a set of lattice links such that for any lattice site x there is exactly one path from x to x_0, with links belonging to $\mathcal{T}$. We denote this path by $\beta(x)$. Consequently, for any pair (x,y) of lattice sites, there is a unique *along tree* path from x to y, equal to $\beta^{-1}(y)\circ\beta(x)$, where $\alpha\circ\beta$ denotes the composition of the two paths (a path obtained by first running through β and next through α) and β^{-1} denotes the path taken with the opposite orientation. This does apply also to external sites, because *external links* are treated as belonging to the tree *a priori*.

To find an explicit set of generators of the pointed observable algebra $\mathfrak{O}_\Lambda^{i,0}$, given by (5.9), we "parallel transport" all generators of the field algebra to the lattice root using the above *along tree* paths. The transported generators feel only gauge transformations at x_0 and, therefore, are invariant with respect to $G_\Lambda^{i,0}$. Hence, $(G_\Lambda^0)'$ is generated by

(1)

$$\{U_{\gamma B}^A, E_{\mathcal{T}B}^A(x,y), \psi_{\mathcal{T}}^{aA}(x), \psi_{\mathcal{T}}^{*aA}(x)\}, \tag{5.10}$$

where γ is an arbitrary closed curve starting and ending at x_0 and

$$E_{\mathcal{T}B}^A(x,y) := U_{\beta(x)C}^A U_{\beta(x)^{-1}B}^D E^C{}_D(x,y), \tag{5.11}$$

$$\psi_{\mathcal{T}}^{aA}(x) := U_{\beta(x)B}^A \psi^{aB}(x), \tag{5.12}$$

with $\beta(x)$ denoting the unique tree path from x to x_0.

(2) Boundary fluxes,

$$E_{\mathcal{T}B}^A(x,\infty) := U_{\beta(x)C}^A U_{\beta(x)^{-1}B}^D E^C{}_D(x,\infty). \tag{5.13}$$

The generating set (5.10) is still enormously redundant. To reduce this redundancy, in a first step, we restrict the admissible paths to the form

$$\gamma(x,y) := \beta(x)\circ(x,y)\circ\beta^{-1}(y). \tag{5.14}$$

We denote

$$U_{\mathcal{T}B}^A(x,y) := U_{\gamma(x,y)B}^A.$$

It is obvious that any $U_{\gamma B}^A$ may be reconstructed from those quantities. Thus,

$$\{U_{\mathcal{T}B}^A(x,y), E_{\mathcal{T}B}^A(x,y), \psi_{\mathcal{T}}^{aA}(x), \psi_{\mathcal{T}}^{*aA}(x)\} \tag{5.15}$$

can be taken, together with boundary fluxes, as a set of generators of $(G_\Lambda^0)'$. The bosonic and fermionic generators fulfill the same commutation relations as generators $U^A{}_B(x,y)$ and $E^A{}_B(x,y)$ (see Sec. II). The local Gauss law can be easily rewritten,

$$\rho_{\mathcal{T}B}^A(x) = \sum_{y\leftrightarrow x} E_{\mathcal{T}B}^A(x,y), \tag{5.16}$$

where $\rho_{\mathcal{T}}$ is given by (2.44) with $\psi^{aA}(x)$ replaced by $\psi_{\mathcal{T}}^{aA}(x)$. However, a nontrivial commutator between $E_{\mathcal{T}B}^A(x,y)$ and the latter occurs.

Next, observe that for any on-tree-link $(x,y)\in\mathcal{T}$ we have

$$U^A_{TB}(x,y) = \delta^A{}_B.$$

Thus, the relevant information is carried by those $U_{\mathcal{T}}$'s, which correspond to off-tree-links $(x,y) \notin \mathcal{T}$. On the other hand, exactly those among the fields $E_{\mathcal{T}}$, which correspond to off-tree-links, may be chosen as independent generators. Indeed, the on-tree $E_{\mathcal{T}}$'s can be calculated by solving the local Gauss law at all the points $x \neq x_0$. Observe that the off-tree $E_{\mathcal{T}}$'s have trivial commutators with $\psi_{\mathcal{T}}$'s. Thus, factorization of $(G^0_\Lambda)'$ with respect to the local Gauss laws at all points $x \neq x_0$ consists in taking only independent internal generators, i.e., those among (5.15), which correspond to off-tree links.

Let us denote the number of lattice sites by N and by L the number of links. Since the number of on-tree links is equal to $N-1$, the number of off-tree links is equal to

$$K = L - N + 1.$$

Enumerate these links setting $(x_i,y_i) =: \ell_i$, where $i=1,\ldots,K$. We have thus the following set of independent generators of $\mathfrak{O}^{i,0}_\Lambda$:

$$\{U^A_{TB}(\ell_i), E^A_{TB}(\ell_i), \psi^{aA}_{\mathcal{T}}(x), \psi^{*aA}_{\mathcal{T}}(x)\}, \tag{5.17}$$

together with the boundary fluxes (5.13). The latter commute with all generators (5.17) and, after the final reduction with respect to G_{x_0}, they will generate the center of the algebra.

Generators (5.17) fulfill canonical (anti)commutation relations, given by formulas (2.22), (2.23), and (2.5). They are all subject to gauge transformations at the tree root x_0. Observe that, since bosonic and fermionic generators commute, we have

$$\mathfrak{O}^{i,0}_\Lambda = \tilde{\mathfrak{O}}^{\mathrm{glu}}_{\mathcal{T}} \otimes \tilde{\mathfrak{O}}^{\mathrm{mat}}_{\mathcal{T}} \otimes \mathfrak{O}^b_\Lambda, \tag{5.18}$$

where $\tilde{\mathfrak{O}}^{\mathrm{glu}}_{\mathcal{T}}$ is the gluonic part generated by $\{U^A_{TB}(\ell_i), E^A_{TB}(\ell_i)\}$ and $\tilde{\mathfrak{O}}^{\mathrm{mat}}_{\mathcal{T}}$ is the matter field part, generated by $\{\psi^{aA}_{\mathcal{T}}(x), \psi^{*aA}_{\mathcal{T}}(x)\}$. According to the above discussion, the gluonic algebra $\tilde{\mathfrak{O}}^{\mathrm{glu}}_{\mathcal{T}}$ is isomorphic to the generalized CCR-algebra over the group G, spanned by K pairs of generators, and $\tilde{\mathfrak{O}}^{\mathrm{mat}}_{\mathcal{T}}$ is isomorphic to the CAR-algebra, generated by $12N$ pairs of anticommuting elements. The subalgebra $\mathfrak{O}^b_\Lambda$ denotes the component generated by boundary fluxes (5.13).

D. Removing the residual gauge freedom

In the first part of this paper we have mentioned that G can be, basically, an arbitrary compact Lie group. Here, we definitely consider $G=\mathrm{SU}(3)$ only. In what follows, we denote the K-fold Cartesian product of G by $\mathbf{G}^K = G \times \cdots \times G$ and elements of $\mathbf{G}^K$ by $\mathbf{g} = (g_1,\ldots,g_K)$.

Let us denote the off-tree variables by

$$E_i = E_{\mathcal{T}}(\ell_i), \quad U_i = U_{\mathcal{T}}(\ell_i), \quad i = 1,\ldots,K.$$

The residual gauge group $G_{x_0} \cong G$ acts on this set of variables by

$$(E_i, U_i) \to (gE_ig^{-1}, gU_ig^{-1}), \tag{5.19}$$

with $g = g(x_0) \in G_{x_0}$. In what follows, we want to fix this residual gauge freedom. Thus, we must consider the action of G on $\mathbf{G}^K$ by inner automorphisms

$$G \times \mathbf{G}^K \ni (h,(g_1,\ldots,g_K)) \mapsto (hg_1h^{-1},\ldots,hg_Kh^{-1}) \in \mathbf{G}^K.$$

We wish to parametrize, by choosing a gauge, the space of equivalence classes of elements of $\mathbf{G}^K$ with respect to this group action, which by abuse of language, will be called $\mathrm{Ad}\,G$. Factorizing with respect to this action, we obtain the orbit space $\mathbf{G}^K/\mathrm{Ad}\,G$. This is a complicated stratified set, which will be more deeply discussed in Ref. 21. Here, we restrict ourselves to the generic orbit type, respectively, the generic stratum $\mathbf{G}^K_{\mathrm{gen}}$, which is an open and dense submanifold in $\mathbf{G}^K$. An element $\mathbf{g} = (g_1,\ldots,g_K) \in \mathbf{G}^K$ belongs to the generic stratum, iff its stabilizer is the center $\mathbb{Z}_3$ of G.

It is quite obvious that **g** belongs to the generic stratum, iff there does not exist any common eigenvector of the matrices $(g_1,\ldots,g_K)$. Moreover, one can show[21] that **g** belongs to the generic stratum, iff there exists a pair (g_i,g_j) or a triple (g_i,g_j,g_k) of elements not possessing any common eigenvector. Using arguments developed in Ref. 36 one can prove that the bundle

$$\pi:\mathbf{G}^K_{\mathrm{gen}} \to \mathbf{G}^K_{\mathrm{gen}}/\mathrm{Ad}\, G$$

is nontrivial, for $K \geqslant 2$. It can be considered as a principal fiber bundle with structure group $G/\mathbb{Z}_3$. Moreover, one can find a system of local trivializations (respectively, local sections) of this bundle, defined over a covering of $\mathbf{G}^K_{\mathrm{gen}}/\mathrm{Ad}\, G$ with open subsets, which are all dense with respect to the natural measure (the one induced by the Haar measure).

Thus, let

$$\mathbf{G}^K_{\mathrm{gen}}/\mathrm{Ad}\, G \supset \mathcal{U} \ni [\mathbf{g}] \to \mathbf{s}([\mathbf{g}]) \equiv (s_1,\ldots,s_K)([\mathbf{g}]) \in \mathbf{G}^K$$

be one of these local sections, with $\mathcal{U}$ being dense in $\mathbf{G}^K_{\mathrm{gen}}/\mathrm{Ad}\, G$. Since Ad G acts (pointwise) on this section, we can fix the gauge by bringing **s** to a special form. Since pairs of group elements being in a nongeneric position form a set of measure zero in $\mathbf{G}^2$, we can—without loss of generality—assume that s_{K-1} and s_K are in generic position on $\mathcal{U}$. That means they have no common eigenvector. Thus, on this neighborhood, we can fix the gauge in two steps: First, we diagonalize s_{K-1} and next we use the stabilizer of this diagonal element to bring s_K to a special form. Since s_{K-1} and s_K have no common eigenvector, this fixes the (remaining) stabilizer gauge completely (up to $\mathbb{Z}_3$). Let us denote the function (which obviously depends only on s_{K-1} and s_K) implementing this gauge transformation by

$$\pi^{-1}(\mathcal{U}) \ni (s_1,\ldots,s_K) \mapsto f(s_1,\ldots,s_K) = f(s_{K-1},s_K) \in G$$

and the local section after gauge fixing by

$$\mathbf{G}^K_{\mathrm{gen}}/\mathrm{Ad}\, G \supset \mathcal{U} \ni [\mathbf{g}] \to \mathbf{f}([\mathbf{g}]) \equiv (f_1,\ldots,f_K)([\mathbf{g}]) \in \mathbf{G}^K, \tag{5.20}$$

with

$$f_i = f(s_{K-1},s_K)\cdot s_i \cdot f(s_{K-1},s_K)^{-1}, \quad i=1,\ldots,K.$$

The section **f** can be made explicit by using a system of local trivializations of G as an SU(2)-principal bundle over S^5. We refer to Ref. 21 for details and to Appendix A for one example of a local section of this bundle.

Suppose that we had started with another section $\tilde{\mathbf{s}}$, related to **s** by a gauge transformation given by $g \in G$. Then, the function $\tilde{f}(s_{K-1},s_K) = f(s_{K-1},s_K)\cdot g^{-1}$ yields the same section **f**. Thus, f is equivariant with respect to gauge transformations,

$$f(g\cdot s_{K-1}\cdot g^{-1}, g\cdot s_K \cdot g^{-1}) = f(s_{K-1},s_K)\cdot g^{-1}, \tag{5.21}$$

and in this sense, we can consider the f_i as being "gauge invariant." It is challenging to parametrize classes $[\mathbf{g}]$ of gauge equivalent configurations more intrinsically, namely in terms of genuine invariants. In Ref. 21 we will prove the following.

Theorem 5.3: *Any function on* $\mathbf{G}^2$ *invariant with respect to the action by inner automorphisms*

$$G \times \mathbf{G}^2 \ni (h,(g_1,g_2)) \mapsto (hg_1h^{-1}, hg_2h^{-1}) \in \mathbf{G}^2$$

can be expressed as a function in the following invariants and their complex conjugates:

$$T_1(g_1,g_2) := tr(g_1),$$

$$T_2(g_1,g_2) := tr(g_2),$$

$$T_3(g_1,g_2) := tr(g_1 g_2),$$

$$T_4(g_1,g_2) := tr(g_1 g_2{}^2),$$

$$T_5(g_1,g_2) := tr(g_1{}^2 g_2{}^2 g_1 g_2) - tr(g_1{}^2 g_2 g_1 g_2{}^2).$$

Moreover, there is one algebraic relation between those invariants such that for given values of T_i, $i=1,\ldots,4$, *there are at most two possible values of* T_5.

By this theorem, it follows that the entries of f_i, $i=K-1$, K, and, therefore, the group elements f_i themselves can be expressed in terms of the above set of invariants,

$$f_i = f_i(T_1(g_{K-1},g_K),\ldots,T_5(g_{K-1},g_K)), \quad i = K-1,K.$$

Since the section **f** parametrizes the gauge orbit space, it is clear that the remaining group elements f_i, $i=1,\ldots,K-2$, can be expressed as a function of traces (5.1), too.

To summarize, applying this special gauge-fixing to a gauge configuration $(U_1,\ldots,U_K)$, with generic (U_{K-1},U_K) corresponding to the pair (x_{K-1},y_{K-1}), (x_K,y_K) of off-tree links, we obtain a local parametrization of its gauge equivalence class by $(\mathfrak{u}_1,\ldots,\mathfrak{u}_K)$ defined by

$$\mathfrak{u}_i := f(U_{K-1},U_K)\cdot U_i \cdot (f(U_{K-1},U_K))^{-1}. \tag{5.22}$$

We denote the indices of these matrices by $r,s,\ldots,\mathfrak{u}_i=\{\mathfrak{u}_i{}^r{}_s\}$, and, consequently, the matrix elements of f by $f=\{f^r{}_A\}$. Then we have

$$\mathfrak{u}_{is}^r = f^r{}_A \cdot U_i^A{}_B \cdot (f^{-1})^B{}_s \tag{5.23}$$

and the gauge transformation (5.21) reads

$$f^r{}_B \to f^r{}_A \cdot (g^{-1})^A{}_B, \tag{5.24}$$

(the color indices $A,B,C,\ldots$ feel gauge transformations, whereas indices $r,s,\ldots$ — assuming the same values 1,2,3—label "gauge-invariant quantities").

By inspecting formula (A1), we see that there are two independent degrees of freedom in the matrix $\mathfrak{u}_{K-1}$ and six independent degrees of freedom in the matrix $\mathfrak{u}_K$. They may be combined into eight degrees of freedom of a single element of G in the following way:

$$\mathfrak{u}_0 := \mathfrak{u}_{K-1}\cdot \mathfrak{u}_K \cdot (\mathfrak{u}_{K-1})^{-1}. \tag{5.25}$$

The above procedure is defined up to a discrete symmetry only. This symmetry arises from the action of the permutation group $S_3 \subset \mathrm{Ad}\,\mathrm{SU}(3)$ on entries of the diagonal matrix $\mathfrak{u}_{K-1} \in T^2 \subset \mathrm{SU}(3)$. To fix this S_3-gauge freedom means choosing for each element of T^2/S_3 a unique representative on the torus T^2. Changing this representative by an even permutation does not change the image of the mapping $(\mathfrak{u}_{K-1},\mathfrak{u}_K)\mapsto \mathfrak{u}_0$ given by (5.25), which *does not cover* the entire group SU(3) but only " half of it." Using also odd permutations we cover a dense subset of SU(3), but then the discrete symmetry $\mathfrak{u}_0 \to \overline{\mathfrak{u}}_0$ must be taken into account.

It can be shown that the decomposition of $\mathfrak{u}_0$ into the above product of elements of special form is unique (up to the discrete symmetry) and both $\mathfrak{u}_{K-1}$ and $\mathfrak{u}_K$ may be reconstructed from $\mathfrak{u}_0$. By the above discussion, we can consider the observable $\mathfrak{u}_0$ as SU(3)-valued, provided we keep the discrete symmetry $\mathfrak{u}_0 \to \overline{\mathfrak{u}}_0$. To summarize, we have shown that, locally, the full information carried by the fields U_i is encoded in $K-1$ elements $\mathfrak{u}_i$, $i=0,\ldots,K-2$, of G, modulo the discrete symmetry just described.

Analogously, we construct K gauge invariant generators

$$\mathfrak{e}_{is}^r = f^r{}_A \cdot E_i^A{}_B \cdot (f^{-1})^B{}_s, \tag{5.26}$$

which have to fulfill the residual Gauss law at x_0. To describe the unconstrained information carried by the fields $\mathfrak{e}_i$, we divide the information contained in $\mathfrak{e}_{K-1}$ and $\mathfrak{e}_K$ (16 gauge invariant

generators) into eight independent generators encoded in the momentum $\mathfrak{e}_0$ canonically conjugate to $\mathfrak{u}_0$ and eight other combinations of $\mathfrak{e}_{K-1}$ and $\mathfrak{e}_K$, which can be reconstructed from the global Gauss law at x_0. More precisely, at each point of the section (5.20), we decompose the pair $(\mathfrak{e}_{K-1},\mathfrak{e}_K)$ into a pair $(\mathfrak{e}^{\|}_{K-1},\mathfrak{e}^{\|}_K)$ of vectors tangent to this section and a pair $(\mathfrak{e}^{\perp}_{K-1},\mathfrak{e}^{\perp}_K)$ of vectors orthogonal to it. Here, orthogonality is of course meant in the sense of the natural scalar product induced by the Killing metric. The tangent components sum up to the momentum $\mathfrak{e}_0$ canonically conjugate to $\mathfrak{u}_0$. More precisely, $\mathfrak{e}_0$ is the image of $(\mathfrak{e}^{\|}_{K-1},\mathfrak{e}^{\|}_K)$ under the tangent mapping of $(\mathfrak{u}_{K-1},\mathfrak{u}_K)\mapsto\mathfrak{u}_0$ given by (5.25). By a simple calculation, we get

$$\mathfrak{e}_0 = (\mathrm{Ad}\,\mathfrak{u}_0^{-1} - 1)\circ\mathrm{Ad}\,\mathfrak{u}_{K-1}(\mathfrak{e}^{\|}_{K-1}) + \mathrm{Ad}\,\mathfrak{u}_{K-1}(\mathfrak{e}^{\|}_K), \tag{5.27}$$

This formula is invertible and enables us to calculate uniquely both $\mathfrak{e}^{\|}_{K-1}$ and $\mathfrak{e}^{\|}_K$ once we know $\mathfrak{e}_0$. On the other hand, the sum $\mathfrak{e}_{K-1}+\mathfrak{e}_K$ is given from the Gauss law. This enables us to calculate $(\mathfrak{u}_{K-1},\mathfrak{u}_K,\mathfrak{e}_{K-1},\mathfrak{e}_K)$ once we know $(\mathfrak{u}_0,\mathfrak{e}_0)$. We end up with $2(K-1)$ independent generators $(\mathfrak{e}_i,\mathfrak{u}_i)$, $i=0,\ldots,K-2$, of the gluonic part of the observable algebra.

It is easy to show that these bosonic generators satisfy the generalized canonical commutation relations over G :

$$[\mathfrak{e}^r_{is},\mathfrak{e}^p_{jq}] = \delta_{ij}(\delta^p{}_s\mathfrak{e}^r_{iq} - \delta^r{}_q\mathfrak{e}^p{}_{is}), \tag{5.28}$$

$$[\mathfrak{e}^r_{is},\mathfrak{u}^p_{jq}] = \delta_{ij}\left(\delta^p{}_s\mathfrak{u}^r_{iq} - \tfrac{1}{3}\delta^r{}_s\mathfrak{u}^p_{iq}\right), \tag{5.29}$$

$$[\mathfrak{u}^r_{is},\mathfrak{u}^p_{jq}] = 0. \tag{5.30}$$

For the fermionic observables, we denote

$$\mathfrak{a}^{ar}(x) := f^r{}_A\psi^{aA}_T(x) = f^r{}_A U^A_{\beta(x)B}\psi^{aB}(x). \tag{5.31}$$

Introducing the joint index $k=(a,r,x)$, $k=1,\ldots,12N$, we get,

$$\mathfrak{a}_k := \mathfrak{a}^{ar}(x). \tag{5.32}$$

Formally, these quantities fulfill the canonical anticommutation relations

$$[\mathfrak{a}^{*k},\mathfrak{a}_l]_+ = \delta^k_l, \tag{5.33}$$

but again, an additional discrete symmetry must be taken into account. This symmetry arises, because the section **f**, given by (5.20), is defined only up to the stabilizer $\mathbb{Z}_3$ of the generic stratum. Observe that this ambiguity does not affect the bosonic quantities $\mathfrak{u}$ and $\mathfrak{e}$, because they are "quadratic" in f.

Let us denote the bosonic (respectively, fermionic) observable algebra part, obtained from $\tilde{\mathfrak{O}}^{\mathrm{glu}}_T$ (respectively, $\tilde{\mathfrak{O}}^{\mathrm{mat}}_T$) after fixing the residual gauge, by $\mathfrak{O}^{\mathrm{glu}}_T$ (respectively $\mathfrak{O}^{\mathrm{mat}}_T$). Then we have

$$\mathfrak{O}_\Lambda = \mathfrak{O}^{\mathrm{glu}}_T \otimes \mathfrak{O}^{\mathrm{mat}}_T \otimes \mathfrak{O}^b_\Lambda \otimes \mathfrak{O}^\infty_\Lambda. \tag{5.34}$$

The above discussion shows that locally (on a dense subset of the generic stratum) and up to discrete symmetries, $\mathfrak{O}^{\mathrm{glu}}_T$ (respectively, $\mathfrak{O}^{\mathrm{mat}}_T$) coincides with the algebra of generalized canonical commutation (respectively, anticommutation) relations for the reduced data $(\mathfrak{u}_i,\mathfrak{e}_i)$, with $i=0$, …, $K-2$ [respectively $(\mathfrak{a}_k,\mathfrak{a}^{*k})$, with $k=1,\ldots,12N$].

As already mentioned at the beginning of this section, a systematic study of $\mathfrak{O}_\Lambda$ as an algebra defined in terms of generators and relations on the level of genuine invariants will be presented in Refs. 21 and 22. In particular, we will show that the fermionic part is generated by the following sesquilinear and trilinear combinations of $\mathfrak{a}_k$ and $\mathfrak{a}^{*k}$:

$$\mathfrak{j}^k{}_l = \mathfrak{a}^{*k}\mathfrak{a}_l, \tag{5.35}$$

$$\mathfrak{w}_{pqr} = \mathfrak{a}_p \mathfrak{a}_q \mathfrak{a}_r, \tag{5.36}$$

$$\mathfrak{w}^{*ijk} = \mathfrak{a}^{*k} \mathfrak{a}^{*j} \mathfrak{a}^{*i}. \tag{5.37}$$

Similarly, to parametrize the bosonic part in terms of genuine invariants, one must take—according to classical invariant theory—all trace invariants, built from $\mathfrak{e}$ and $\mathfrak{u}$. This set is, however, highly redundant and it is a complicated task to find, for a fixed number K, the full set of relations.

ACKNOWLEDGMENTS

The authors are very much indebted to K. Schmüdgen and S. L. Woronowicz for a lot of helpful discussions and remarks. Moreover, they are grateful to Sz. Charzynski, P. D. Jarvis, and M. Schmidt for discussions and for reading the paper. This research was partly supported by the Polish Ministry of Scientific Research and Information Technology under Grant No. PBZ-MIN-008/P03/2003. One of the authors (J. K.) is grateful to Professor E. Zeidler for his hospitality at the Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany. The other author (G. R.) is grateful to the Foundation for Polish Science (FNP) and to the Zygmunt Zaleski Foundation for their support.

APPENDIX A: A LOCAL PARAMETRIZATION OF $(\mathrm{SU}(3)\times\mathrm{SU}(3))_{\mathrm{gen}}/\mathrm{Ad}\,\mathrm{SU}(3)$

Consider the action of the group of inner automorphisms, here denoted by Ad SU(3), on $\mathrm{SU}(3)\times\mathrm{SU}(3)$. In Sec. V D we have used an explicit local parametrization of the generic stratum of this action in terms of a bundle section. Such a section can be obtained as follows. Let $(g_1, g_2) \in \mathrm{SU}(3)\times\mathrm{SU}(3)$ be a pair of group elements lying in the generic stratum. First, we diagonolize g_1. Since g_1 is generic, the stabilizer of the Ad-action is isomorphic to $\mathrm{U}(1)\times\mathrm{U}(1)$. Next, treating SU(3) as an SU(2)-principal bundle over S^5, one can bring g_2 to a special form using the $\mathrm{U}(1)\times\mathrm{U}(1)$-action. This yields a family of local sections defined on dense subsets over the generic stratum, corresponding to a family of local trivializations of the SU(2)-principal bundle $\mathrm{SU}(3)\to S^5$. For details we refer to Ref. 21.

As a local section of the above type one can choose

$$f_1 = \begin{bmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_2 & 0 \\ 0 & 0 & \lambda_3 \end{bmatrix}, \quad f_2 = \begin{bmatrix} a & -\delta^{-1} b^\dagger \\ b & \delta\left(1 - \dfrac{bb^\dagger}{1+|a|}\right) \end{bmatrix} \times \begin{bmatrix} 1 & 0 & 0 \\ 0 & c & d \\ 0 & -\bar{d} & \bar{c} \end{bmatrix}. \tag{A1}$$

Here, λ_i are eigenvalues of g_1, fulfilling

$$|\lambda_1| = |\lambda_2| = |\lambda_3| = 1, \quad \lambda_1\lambda_2\lambda_3 = 1.$$

The entries

$$a, \delta \in \mathbb{C}, b = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}, \quad b_1, b_2 \in \mathbb{R}_+,$$

of the first factor in f_2 fulfill

$$|a|^2 + b_1^2 + b_2^2 = 1, \quad |\delta| = 1, a = |a|\delta^{-2}$$

and the lower diagonal block of the second factor is an SU(2)-matrix in the standard parametrization, with

$$|c|^2 + |d|^2 = 1.$$

APPENDIX B: PROOF OF THEOREM 5.1

Using basic results from invariant theory, see Ref. 38, we get that the only gauge invariant combinations built exclusively from generators $U^A{}_B$ are traces of their products and, whence, quantities of type (5.1).

Any other invariant is built by contracting the color indices of the fields $E^A{}_B(x,y)$, $U^A{}_B(x,y)$, $\psi^{aA}(x)$, and $\psi^*{}_{aA}(x)$. Consider such an invariant I and replace in its definition the above fields by their gauge invariant counterparts $\mathfrak{e}$, $\mathfrak{u}$, $\mathfrak{a}$, and $\mathfrak{a}^*$. In particular, the missing on-tree quantities $\mathfrak{e}$ and $\mathfrak{u}$, are defined as combinations of the off-tree ones, using the Gauss law (for $\mathfrak{e}$) and the Bianchi identities (for $\mathfrak{u}$). Formally, the new invariant obtained this way coincides with I, because the factors f and f^{-1} coming from the definition of the quantities $\mathfrak{e}$, $\mathfrak{u}$, $\mathfrak{a}$, and $\mathfrak{a}^*$ disappear under contraction. Moreover, all the fermionic quantities $\mathfrak{a}$ and $\mathfrak{a}^*$ appearing in the invariant may be grouped to give quantities $\mathfrak{j}$, $\mathfrak{w}$, and $\mathfrak{w}^*$.

As already mentioned in Sec. V D, the invariant quantities $\mathfrak{u}$ can be expressed as (nonlinear) functions of traces of U [invariants (5.1)]. We show that also $\mathfrak{e}$, $\mathfrak{j}$, $\mathfrak{w}$, and $\mathfrak{w}^*$ can be expressed in terms of invariants (5.1)–(5.4), listed in Theorem 5.1. Invariants $\mathfrak{e}^r_{is}$ can be dealt with as follows: We contract them with eight different $\mathfrak{u}$'s and use formulas (5.23) and (5.26) to obtain the following system of linear equations for the eight independent components of $\mathfrak{e}^r_{is}$:

$$\mathfrak{e}^r_{is}\mathfrak{u}^{(1)s}{}_r = E_{\gamma_1}, \ldots, \mathfrak{e}^r_{is}\mathfrak{u}^{(8)s}{}_r = E_{\gamma_8},$$

with the right-hand sides all being invariants of type (5.2). Analogously, we can write down systems of linear equations of this type for the quantities $\mathfrak{j}$, $\mathfrak{w}$, and $\mathfrak{w}^*$. Solving these systems of linear equations, we obtain $\mathfrak{e}$, $\mathfrak{u}$, $\mathfrak{j}$, $\mathfrak{w}$, and $\mathfrak{w}^*$ as functions, linear with respect to invariants (5.2)–(5.4) and nonlinear with respect to invariants (5.1) listed in Theorem 5.1.

Hence, we have formally expressed I as a combination $\tilde{I}$ of invariants listed in Theorem 5.1. In particular all Casimir operators, built from the electric fields E may be expressed in terms of these generators.

The above formulas, expressing any gauge invariant field I as a combination $\tilde{I}$ of the invariants listed in Theorem 5.1, were derived by the help of the gauge fixing section (5.20), which is not globally defined. Hence, equality $I=\tilde{I}$ holds on a dense subset of the configuration space only. But I is a differential operator (with smooth coefficients) on the whole configuration space (the rank of such an operator is equal to its algebraic order with respect to variables E). The invariant $\tilde{I}$ is a differential operator of the same rank, but *a priori* its coefficients are well defined on a dense set of the configuration space only. But, if two such operators coincide on a dense set, they coincide everywhere.

Square-integrable wave packets from the Volkov solutions

Stephan Zakowicz[a)]
Institut für Theoretische Physik, Justus-Liebig-Universität Giessen, Heinrich-Buff-Ring 16, 35392 Gießen, Germany

(Received 3 August 2004; accepted 2 November 2004; published online 11 February 2005)

Rigorous mathematical proofs of some properties of the Volkov solutions are presented, which describe the motion of a relativistic charged Dirac particle in a classical, plane electromagnetic wave. The Volkov solutions are first rewritten in a convenient form, which clearly reveals some of the symmetries of the underlying Dirac equation. Assuming continuity and boundedness of the electromagnetic vector potential, it is shown how one may construct square-integrable wave packets from momentum distributions in the space $\mathcal{C}_0^\infty(\mathbb{R}^3)^4$. If, in addition, the vector potential is $\mathcal{C}^1$ and the derivative is bounded, these wave packets decay in space faster than any polynomial and fulfill the Dirac equation. The mapping which takes momentum distributions into wave packets is shown to be isometric with respect to the $L^2(\mathbb{R}^3)^4$ norm and may therefore be continuously extended to a mapping from $L^2(\mathbb{R}^3)^4$. For a momentum function in $L^1(\mathbb{R}^3)^4 \cap L^2(\mathbb{R}^3)^4$, an integral representation of this extension is presented. © *2005 American Institute of Physics.*

I. INTRODUCTION

There exist only few exact solutions of the Dirac equation, the relativistic equation which describes the motion of a charged particle with spin $1/2$ in an external electromagnetic field. One important class was discovered by Volkov in 1935,[1] who treated the field of a classical, plane electromagnetic wave. Ever since then, the Volkov solutions have experienced a wide range of applications in the physics of interactions of electrons and positrons with a laser beam, of which we enumerate a few.

In 1952, Sengupta[2] calculated the scattering of electromagnetic waves by a free electron; to the author's knowledge, he was the first to have employed the Volkov solutions explicitly. Ten years later, Reiss[3] computed the probability for electron–positron pair production in two nonparallel classical photon fields, of which one is treated as a perturbation but the other one may be of arbitrary strength. In a more mathematical paper,[4] the same author proved that for this field configuration, the perturbation expansion converges for small parameters. Brown and Kibble[5] as well as Gol'dman[6] studied the Compton scattering of a free electron in a high-intensity laser and used the Volkov solutions to calculate the cross section for this process. Nikishov and Ritus[7] and Narozhnyĭ *et al.*[8] analyzed the $\pi \to \mu + \nu$ decay in the presence of an electromagnetic wave. The scattering of electrons by a scalar potential in the presence of an intense laser field was considered by Bergou and Varró[9]. Moreover, the production of electron–positron pairs in a laser was considered by Nikishov and Ritus[10] and by Narozhnyĭ *et al.*[8] In atomic physics, the Volkov solutions are used in the calculation of ionization rates in strong laser fields within the so-called strong-field approximation (see, for example, Refs. 11 and 12). Szymanowski and co-workers examined laser-assisted scattering of electrons in a Coulomb potential[13] and in a Yukawa potential.[14] The cross section for pair production may be enhanced in the presence of a bare atomic nucleus—a situation which was investigated by Yakovlev[15] and Müller *et al.*[16,17]

[a)]Electronic mail: zakowicz@physik.uni-giessen.de

The Volkov solutions for given "asymptotic momenta," which will be written out explicitly in the subsequent section, are not square integrable. Therefore, a direct interpretation of a physical particle that is localized in space is not easily possible. In the case of the free Dirac equation, where the same problem occurs, square-integrable solutions—so-called *wave packets*—may be constructed from complex-valued functions in momentum space by multiplying these with the free plane-wave solutions and integrating over momentum space.[18,19] The construction of such wave packets from the Volkov solutions was suggested for the Klein–Gordon equation by Neville and Rohrlich[20] and for the Dirac equation by San Román and co-workers.[21–24]

Mathematically spoken, the integration over momentum space for the free Dirac equation represents nothing but the usual Fourier transformation with a minor modification, which accounts for the spinor structure of the Dirac equation.[19] This procedure automatically guarantees the "normalization" and "completeness" of the free plane-wave solutions, i.e., corresponding functions in momentum space and in spatial space have identical L^2 norms, and any L^2 function in spatial space may be represented as such a wave packet. In the literature, only peripheral attention has been paid to a study of the "normalization" and "completeness" properties for the Volkov solutions. There exist several treatments that offer physically motivated arguments for the normalization. Bergou and Varró[9] as well as Filipowicz,[25] for example, make use of delta functions and interchange the orders of divergent integrals in order to obtain the desired result. The standard textbook by Berestetskiĭ *et al.*[26] assumes electromagentic vector potentials that decrease far away from the origin, such that—according to the authors' reasoning—the normalization integral is practically not influenced by this potential.

However, there seem to be no rigorous mathematical proofs for the claims of "normalization" and "completeness." Nevertheless, many authors use these properties in their calculations more or less explicitly. For example, San Román and collaborators[21–24] determine the time evolution of a free electron wave packet in a laser beam by first calculating the momentum distribution of the initial wave packet at time $t=0$ and then computing the resulting wave packets for positive times. The validity of this procedure relies on both "normalization" and "completeness." Furthermore, calculations of cross sections or production rates with the help of the nonsquare-integrable Volkov solutions and "delta functions"—as performed, for example, in Refs. 5–17—implicitly assume "normalization" and "completeness." To be more precise, an incorrect "normalization" would lead to wrong factors in the differential cross sections. On the other hand, the derivation of the total cross section requires an integration and summation of the differential cross section over *all* final states, i.e., these final states need to satisfy "completeness."

It is the purpose of this paper to fill part of the gap indicated above and to provide a proof for the "normalization" of the Volkov solutions. In Sec. II, we present the explicit form of the Volkov solutions. Some symmetries of the Dirac equation that will be useful in the further development are discussed in Sec. III. Section IV is devoted to the construction of *regular wave packets* from $\mathcal{C}_0^\infty$ functions in momentum space in the case where the electromagnetic vector potential is continuous and bounded. Assuming also continuous differentiability of the vector potential and boundedness of its derivative, these regular wave packets are shown to decay rapidly in spatial space and to fulfill the Dirac equation. In Sec. V, which is the central part of the paper, we state the main theorem asserting that the norms of a momentum distribution and of its corresponding wave packet are identical. The statement of the theorem is related to the physical concepts of "normalization to a delta function" and "orthogonality." The construction of wave packets from *any* L^2 functions in momentum space is exhibited in Sec. VI, which is achieved by a continuous extension from the space $\mathcal{C}_0^\infty$. Finally, in the Appendix, we give the proof of the main theorem from Sec. V.

II. THE VOLKOV SOLUTIONS

We treat a relativistic spin-1/2 particle with charge e and mass m that moves in the four-potential $A^\mu \equiv (A^0, \mathbf{A})$ of an electromagnetic field. The motion of the particle is described by the Dirac equation, which reads

$$(i\partial\!\!\!/ - eA\!\!\!/ - m)\psi = 0, \tag{1}$$

where we have used the Feynman slash notation

$$a\!\!\!/ := \gamma^\mu a_\mu$$

with the 4×4 Dirac matrices γ^μ.[18,19] These matrices fulfill

$$\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}\mathbf{1}.$$

Here as in the entire paper, we use natural units ($\hbar = c = 1$) and the signature $(+---)$ of the metric tensor $g_{\mu\nu}$. Scalar products shall be noted as

$$(ab) \equiv a^\mu b_\mu.$$

In the Lorentz gauge,

$$(\partial A) \equiv \partial_\mu A^\mu(x) = 0,$$

a plane electromagnetic wave propagating in the direction of the unit vector $\mathbf{n} \in \mathbb{R}^3$ may be represented by the four-potential

$$A^\mu(x) = \tilde{A}^\mu(\xi), \quad \xi = (nx), \tag{2}$$

with the four-vector

$$n^\mu = (1, \mathbf{n})$$

and the additional conditions

$$A^0 = \mathbf{A}\cdot\mathbf{n} \equiv 0.$$

The analytical Volkov solutions of the Dirac equation (1) with this potential are[9]

$$\psi_{\mathbf{p},r}(\mathbf{r},t) = \mathbf{M}^{(\epsilon_r)}(\mathbf{p}, t - \mathbf{n}\cdot\mathbf{r})u_r(\mathbf{p})e^{iS^{(\epsilon_r)}(\mathbf{p},\mathbf{r},t)}, \tag{3}$$

where

$$\epsilon_r = \begin{cases} 1, & r = 1,2, \\ -1, & r = 3,4, \end{cases}$$

$$\mathbf{M}^{(\pm)}(\mathbf{p},\xi) = 1 \pm \frac{e\tilde{A}\!\!\!/(\xi)}{2(E(\mathbf{p}) - \mathbf{n}\cdot\mathbf{p})} \in \mathbb{C}^{4\times 4}, \tag{4}$$

$$S^{(\pm)}(\mathbf{p},\mathbf{r},t) = \pm\left(\mathbf{p}\cdot\mathbf{r} - E(\mathbf{p})t - \int_0^{t-\mathbf{n}\cdot\mathbf{r}} J_{\mathbf{p}}^{(\pm)}(\xi)\mathrm{d}\xi\right), \tag{5}$$

$$J_{\mathbf{p}}^{(\pm)}(\xi) = \frac{1}{E(\mathbf{p}) - \mathbf{n}\cdot\mathbf{p}}\left(\mp e\mathbf{p}\cdot\tilde{\mathbf{A}}(\xi) - \frac{e^2}{2}\tilde{A}(\xi)^2\right) = \frac{1}{E(\mathbf{p}) - \mathbf{n}\cdot\mathbf{p}}\left(\mp e\mathbf{p}\cdot\tilde{\mathbf{A}}(\xi) + \frac{e^2}{2}|\tilde{\mathbf{A}}(\xi)|^2\right), \tag{6}$$

and

$$E(\mathbf{p}) = \sqrt{m^2 + |\mathbf{p}|^2} \tag{7}$$

is the energy of the particle. The spinors $u_r(\mathbf{p})$ are the free Dirac spinors, which can be written as columns of a certain matrix[19]

$$\mathbf{u}(\mathbf{p}) \equiv (u_1(\mathbf{p})u_2(\mathbf{p})u_3(\mathbf{p})u_4(\mathbf{p})) = \sqrt{\frac{E(\mathbf{p})+m}{2E(\mathbf{p})}}\left(\mathbf{1} + \frac{\boldsymbol{\alpha}\cdot\mathbf{p}}{E(\mathbf{p})+m}\right). \tag{8}$$

Here,

$$\boldsymbol{\alpha} = \gamma^0\boldsymbol{\gamma}$$

is the three-vector of the Dirac α matrices. The functions $u_r(\mathbf{p})$ are $\mathcal{C}^\infty$ in the argument $\mathbf{p}$ and satisfy

$$\not{p}u_r(\mathbf{p}) = \epsilon_r m u_r(\mathbf{p}). \tag{9}$$

In addition, they obey the orthogonality relations

$$u_r(\epsilon_r\mathbf{p})^\dagger u_s(\epsilon_s\mathbf{p}) \equiv \langle u_r(\epsilon_r\mathbf{p}), u_s(\epsilon_s\mathbf{p})\rangle_{\mathbb{C}^4} = \delta_{r,s}.$$

We remark that equation (3) is actually not the original form that was published by Volkov,[1] who considered only the superposition of at most countably many unifrequent electromagentic waves. In his formulas, infinite series over the amplitudes and phases of the external potential occur. Brown and Kibble[5] and Nikishov and Ritus[10] seem to be the first to have written down the solutions in a form that involves a more or less arbitrary form of the electromagnetic potential which involves an integral in the phase factor. A recent derivation of the Volkov solutions can be found in Ref. 21, where also the cases $r=3,4$ are treated. In addition, we mention that the authors cited above use $-\infty$ instead of 0 as the lower integration limit in the phase (5). Taking 0 (or any other finite number) does not require the vector potential to decay for large values $|\xi|$ of the argument ξ in order for the integral to converge.

For the sake of simplicity, we set $\mathbf{n}=\mathbf{e}_z$, so that

$$t - \mathbf{n}\cdot\mathbf{r} = t - z$$

and

$$E(\mathbf{p}) - \mathbf{n}\cdot\mathbf{p} = E(\mathbf{p}) - p_z.$$

The spatial part of the vector potential is then of the form

$$\mathbf{A}(\mathbf{r},t) = \tilde{A}_x(t-z)\mathbf{e}_x + \tilde{A}_y(t-z)\mathbf{e}_y \equiv \tilde{\mathbf{A}}(t-z) \in \mathbb{R}^2. \tag{10}$$

Here as in the following, we make the identification

$$\mathbb{R}^2 \cong \mathbb{R}^2 \times \{0\} \subset \mathbb{R}^3$$

in order to suppress an overduly complex notation. We also set

$$\mathbf{p}_\perp := (p_x, p_y) \in \mathbb{R}^2 \tag{11}$$

and

$$\mathbf{r}_\perp := (x,y) \in \mathbb{R}^2, \tag{12}$$

so that

$$\mathbf{p}\cdot\mathbf{A}(\mathbf{r},t) = \mathbf{p}_\perp\cdot\tilde{\mathbf{A}}(t-z).$$

In addition, we will assume throughout that the functions $\tilde{A}_x, \tilde{A}_y : \mathbb{R}\to\mathbb{R}$ are $\mathcal{C}_b$, i.e., continuous and bounded, and set

$$\|\mathbf{A}\| := \sup_{\xi\in\mathbb{R}} \sqrt{\tilde{A}_x(\xi)^2 + \tilde{A}_y(\xi)^2} < \infty. \tag{13}$$

III. SYMMETRIES OF THE VOLKOV SOLUTIONS

The construction of the Volkov solutions (3) relies heavily on certain symmetries of the Dirac equation (1): The three differential operators ∂_x, ∂_y, and $\partial_t+\partial_z$ commute formally with $(i\not{\partial}-e\not{A}-m)$, which has already been noticed by Nikishov and Ritus.[10] These translational symmetries allow the separation of variables in the equation, which is inherited by the relations

$$-i\partial_x\psi_{\mathbf{p},r} = \epsilon_r p_x \psi_{\mathbf{p},r}, \tag{14a}$$

$$-i\partial_y\psi_{\mathbf{p},r} = \epsilon_r p_y \psi_{\mathbf{p},r}, \tag{14b}$$

$$-i(\partial_t+\partial_z)\psi_{\mathbf{p},r} = \epsilon_r (p_z - E(\mathbf{p}))\psi_{\mathbf{p},r}. \tag{14c}$$

[For more symmetries of the Dirac equation (1) and a detailed group theoretical analysis, see the work of Janner and Janssen.[27]] Using the Hamiltonian form of (1), i.e.,

$$i\partial_t\psi(\mathbf{r},t) = H(t)\psi(\mathbf{r},t) \tag{15}$$

with the formally self-adjoint Hamiltonian operator

$$H(t) = \boldsymbol{\alpha}(-i\boldsymbol{\nabla} - e\mathbf{A}) + \beta m, \tag{16}$$

we easily derive from (14c) that for every t,

$$(H(t)+i\partial_z)\psi_{\mathbf{p},r} = \epsilon_r(E(\mathbf{p})-p_z)\psi_{\mathbf{p},r} \equiv \epsilon_r\kappa(\mathbf{p})\psi_{\mathbf{p},r}, \tag{17}$$

where we have introduced

$$\kappa(\mathbf{p}) := E(\mathbf{p}) - p_z = \sqrt{m^2+|\mathbf{p}|^2} - p_z > 0. \tag{18}$$

The Volkov solutions are thus simultaneous eigenfunctions of the three operators $-i\partial_x$, $-i\partial_y$, and $H(t)+i\partial_z$ with corresponding eigenvalues $\epsilon_r p_x$, $\epsilon_r p_y$, and $\epsilon_r\kappa(\mathbf{p})$, which do not depend on the chosen time t. It will be useful to define

$$\hat{\boldsymbol{\tau}}:\mathbb{R}^3 \to \mathbb{R}^2\times\mathbb{R}^+, \quad \mathbf{p}\mapsto\hat{\boldsymbol{\tau}}(\mathbf{p}) := (\mathbf{p}_\perp, \kappa(\mathbf{p})). \tag{19}$$

Note that the inverse is given by

$$\boldsymbol{\tau} := \hat{\boldsymbol{\tau}}^{-1}:\mathbb{R}^2\times\mathbb{R}^+ \to \mathbb{R}^3, \quad \boldsymbol{\tau}(\mathbf{p}_\perp,\lambda) := \left(\mathbf{p}_\perp, \frac{m^2+|\mathbf{p}_\perp|^2-\lambda^2}{2\lambda}\right). \tag{20}$$

The matrix part (4) and the phase (5) of the Volkov solutions may be rewritten in a simple form in terms of the eigenvalues

$$\mathbf{M}^{(\epsilon_r)}(\mathbf{p},\xi) = \mathbf{1} + \frac{e\not{\tilde{A}}(\xi)}{2\epsilon_r\kappa(\mathbf{p})} \in \mathbb{C}^{4\times4} \tag{21}$$

and

$$
\begin{aligned}
S^{(\epsilon_r)}(\mathbf{p},\mathbf{r},t) &= \epsilon_r \mathbf{p}_\perp \cdot \mathbf{r}_\perp - \epsilon_r \kappa(\mathbf{p}) t - \epsilon_r p_z (t-z) - \epsilon_r \int_0^{t-z} J_{\mathbf{p}}^{(\epsilon_r)}(\xi)\mathrm{d}\xi \\
&= \epsilon_r \mathbf{p}_\perp \cdot \mathbf{r}_\perp - \epsilon_r \kappa(\mathbf{p}) t - \epsilon_r \left[\left(p_z - \frac{|\mathbf{p}_\perp|^2}{2(E(\mathbf{p}) - p_z)} \right)(t-z) \right. \\
&\quad \left. + \frac{1}{2(E(\mathbf{p}) - p_z)} \int_0^{t-z} |\epsilon_r \mathbf{p}_\perp - e\tilde{\mathbf{A}}(\xi)|^2 \, \mathrm{d}\xi \right] \\
&= \epsilon_r \mathbf{p}_\perp \cdot \mathbf{r}_\perp - \epsilon_r \kappa(\mathbf{p}) t - \frac{1}{2}\left(\frac{m^2}{\epsilon_r \kappa(\mathbf{p})} - \epsilon_r \kappa(\mathbf{p}) \right)(t-z) - \frac{1}{2\epsilon_r \kappa(\mathbf{p})} \\
&\quad \times \int_0^{t-z} |\epsilon_r \mathbf{p}_\perp - e\tilde{\mathbf{A}}(\xi)|^2 \, \mathrm{d}\xi. \qquad (22)
\end{aligned}
$$

A similar form of the phase $S^{(\epsilon_r)}$ has already been found by Gol'dman.[6] Defining

$$
\pi_\perp(\xi,\mathbf{p}_\perp) := \begin{cases} \left(\frac{1}{\xi} \int_0^\xi |\mathbf{p}_\perp - e\tilde{\mathbf{A}}(\xi')|^2 \, \mathrm{d}\xi' \right)^{1/2}, & \xi \neq 0, \\ |\mathbf{p}_\perp - e\tilde{\mathbf{A}}(0)|, & \xi = 0, \end{cases} \qquad (23)
$$

$$
\boldsymbol{\nu}_\xi : \mathbb{R}^2 \times (\mathbb{R} \setminus \{0\}) \to \mathbb{R}^3, \boldsymbol{\nu}_\xi(\mathbf{p}_\perp,\lambda) := \left(\mathbf{p}_\perp, \frac{1}{2}\left[\frac{m^2 + \pi_\perp(\xi,\mathbf{p}_\perp)^2}{\lambda} - \lambda \right] \right), \qquad (24)
$$

$$
\mathbf{q}_\xi^{(\pm)}(\mathbf{p}) := \boldsymbol{\nu}_\xi(\pm\hat{\boldsymbol{\pi}}(\mathbf{p})) = \pm \left(\mathbf{p}_\perp, \frac{1}{2}\left[\frac{m^2 + \pi_\perp(\xi, \pm\mathbf{p}_\perp)^2}{\kappa(\mathbf{p})} - \kappa(\mathbf{p}) \right] \right), \qquad (25)
$$

and

$$
\mathbf{s}_t(\mathbf{r}) := (x,y,z-t), \qquad (26)
$$

we may write this as

$$
S^{(\epsilon_r)}(\mathbf{p},\mathbf{r},t) = \mathbf{q}_{t-z}^{(\epsilon_r)}(\mathbf{p}) \cdot \mathbf{s}_t(\mathbf{r}) - \epsilon_r \kappa(\mathbf{p}) t. \qquad (27)
$$

Note that

$$
0 \leqslant \pi_\perp(\xi,\mathbf{p}_\perp) \leqslant |\mathbf{p}_\perp| + |e|\|\mathbf{A}\|. \qquad (28)
$$

Moreover, for $\tilde{\mathbf{A}} \equiv 0$, $\pi_\perp(\xi,\mathbf{p}_\perp) = |\mathbf{p}_\perp|$, so that $\pi_\perp(\xi,\mathbf{p}_\perp)$ may be thought of as a modified "perpendicular momentum."

IV. REGULAR WAVE PACKETS

In this section, we shall construct square-integrable wave packets from the Volkov solutions. These wave packets will be of the form

$$
\psi(\mathbf{r},t) = \frac{1}{(2\pi)^{3/2}} \sum_{r=1}^{4} \int_{\mathbb{R}^3} \phi_r(\mathbf{p}) \psi_{\mathbf{p},r}(\mathbf{r},t) \mathrm{d}^3 p. \qquad (29)
$$

This integral representation was used, for example, by San Román *et al.*[21–24] in their calculations of the time evolution of wave packets. It will be our task to make sense of (29), i.e., we will ensure the existence of this integral for as many functions ϕ_r as possible and to show that the resulting wave packet ψ fulfills the Dirac equation (1).

In this section, we will start with momentum distributions ϕ_r that are in $\mathcal{C}_0^\infty$ and show that the wave packets defined by these decay faster than any power of $|\mathbf{r}|$ for $|\mathbf{r}|\to\infty$. In order to control the $\mathbf{p}$ dependence of the phase (27), we need to determine the inverses of the mappings $\mathbf{q}_\xi^{(\pm)}$ from (25),

$$\tilde{\mathbf{q}}_\xi^{(\pm)}(\tilde{\mathbf{p}}) := (\mathbf{q}_\xi^{(\pm)})^{-1}(\tilde{\mathbf{p}}) = \boldsymbol{\pi}(\pm\boldsymbol{\nu}_\xi^{-1}(\tilde{\mathbf{p}})) = \boldsymbol{\pi}(\pm(\mathbf{p}_\perp, \sqrt{m^2+\pi_\perp(\xi,\pm\tilde{\mathbf{p}}_\perp)^2+\tilde{p}_z^2}\mp\tilde{p}_z)), \tag{30}$$

which are $\mathcal{C}^\infty$. We claim the following.

Lemma 1: For every compact set $K\subset\mathbb{R}^3$ and every $n_x,n_y,n_z\in\mathbb{N}_0$, there is a constant $c_{n_x,n_y,n_z}(K)$ satisfying

$$\left\|\left(\frac{\partial}{\partial\tilde{p}_x}\right)^{n_x}\left(\frac{\partial}{\partial\tilde{p}_y}\right)^{n_y}\left(\frac{\partial}{\partial\tilde{p}_z}\right)^{n_z}\tilde{\mathbf{q}}_\xi^{(\pm)}(\tilde{\mathbf{p}})\right\| \leqslant c_{n_x,n_y,n_z}(K), \quad \tilde{\mathbf{p}}\in K, \quad \xi\in\mathbb{R}.$$

Proof: By the chain rule, one sees that the derivatives of $\tilde{\mathbf{q}}_\xi^{(\pm)}$ depend continuously on $\tilde{\mathbf{p}}$ as well as on $\pi_\perp(\xi,\tilde{\mathbf{p}}_\perp)^2$, $\partial_{\tilde{p}_x}[\pi_\perp(\xi,\tilde{\mathbf{p}}_\perp)]^2$, and $\partial_{\tilde{p}_y}[\pi_\perp(\xi,\tilde{\mathbf{p}}_\perp)]^2$. [Note that higher-order derivatives of $[\pi_\perp(\xi,\tilde{\mathbf{p}}_\perp)]^2$ vanish, see the definition (23).] The last three expressions are bounded for $\xi\in\mathbb{R}$ and $\tilde{\mathbf{p}}_\perp$ in a fixed compact set, which is due to the boundedness of $\tilde{\mathbf{A}}$ and (28). The derivatives of $\tilde{\mathbf{q}}_\xi^{(\pm)}$ are therefore bounded on the compact set K. ∎

We may now state the first main theorem, which allows the construction of L^2 wave packets.

Theorem 2: *Let $\phi\equiv(\phi_1,\ldots,\phi_4)\in\mathcal{C}_0^\infty(\mathbb{R}^3)^4$.*

(a) *The wave packet ψ defined by*

$$\psi(\mathbf{r},t) = \frac{1}{(2\pi)^{3/2}}\sum_{r=1}^4\int_{\mathbb{R}^3}\phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p \tag{31}$$

is continuous in $\mathbf{r}$ and t.

(b) *For any $n\in\mathbb{N}_0$, there is a constant c_n such that*

$$\|\psi(\mathbf{r},t)\|_{\mathbb{C}^4} \leqslant c_n\frac{1+|t|^n}{1+|\mathbf{s}_t(\mathbf{r})|^n} = c_n\frac{1+|t|^n}{1+[x^2+y^2+(z-t)^2]^{n/2}}. \tag{32}$$

In particular $\psi(\cdot,t)\in L^p(\mathbb{R}^3)^4$ for all $t\in\mathbb{R}$ and $p\in[1,\infty]$.

Proof: (a) It suffices to show the result for the summands r independently. Let $\mathbf{r}_n\to\mathbf{r}$ and $t_n\to t$. Then $\psi_{\mathbf{p},r}(\mathbf{r}_n,t_n)\to\psi_{\mathbf{p},r}(\mathbf{r},t)$ by continuity of the Volkov solutions (3), so the integrand in (31) converges pointwise. Furthermore, since $\psi_{\mathbf{p},r}(\mathbf{r},t)$ is bounded in $\mathbf{p}\in\operatorname{supp}\phi_r$ as well as in $\mathbf{r}$ and t, continuity of ψ is established by dominated convergence, see, e.g., Theorem I.11 in Ref. 28.

(b) We will show that for any $n_x,n_y,n_z\in\mathbb{N}_0$, there is a constant c_{n_x,n_y,n_z} such that

$$|x|^{n_x}|y|^{n_y}|z-t|^{n_z}\|\psi(\mathbf{r},t)\|_{\mathbb{C}^4} \leqslant c_{n_x,n_y,n_z}(1+|t|^{n_x+n_y+n_z}). \tag{33}$$

The estimate in (32) follows from this by using

$$[x^2+y^2+(z-t)^2]^{n/2} = (\sqrt{x^2+y^2+(z-t)^2})^n \leqslant (\sqrt{(|x|+|y|+|z-t|)^2})^n = (|x|+|y|+|z-t|)^n,$$

where the right-hand side is a polynomial of degree n in $|x|$, $|y|$, and $|z-t|$.

In order to prove the estimate (33), we shall apply the stationary-phase method (see, for example, Theorem XI.14 in Ref. 29). We only need to look at the case $\mathbf{r}\equiv(x,y,z)\in\mathbb{R}^3$ with $x,y,z-t\neq0$; for x, y, or $z-t$ equal to zero, (33) follows by continuity. Setting $\epsilon := \epsilon_r$ for abbreviation, we find

$$\begin{aligned}\int_{\mathbb{R}^3}\phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p &= \int_{\mathbb{R}^3}\phi_r(\mathbf{p})\mathbf{M}^{(\epsilon)}(\mathbf{p},t-z)u_r(\mathbf{p})\exp[i(\mathbf{q}^{(\epsilon)}_{t-z}(\mathbf{p})\cdot\mathbf{s}_t(\mathbf{r})-\epsilon\kappa(\mathbf{p})t)]\mathrm{d}^3p\\ &= \int_{\mathbb{R}^3}\phi_r(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))\mathbf{M}^{(\epsilon)}(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}),t-z)u_r(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))\\ &\quad\times\exp[i(\tilde{\mathbf{p}}\cdot\mathbf{s}_t(\mathbf{r})-\epsilon\kappa(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))t)]|\det(D\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))|\mathrm{d}^3\tilde{p}\\ &= \frac{(-i)^{n_x+n_y+n_z}}{x^{n_x}y^{n_y}(z-t)^{n_z}}\int_{\mathbb{R}^3}\phi_r(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))\mathbf{M}^{(\epsilon)}(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}),t-z)u_r(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))\\ &\quad\times\exp(-i\epsilon\kappa(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))t)|\det(D\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))|\\ &\quad\times\left[\left(\frac{\partial}{\partial\tilde{p}_x}\right)^{n_x}\left(\frac{\partial}{\partial\tilde{p}_y}\right)^{n_y}\left(\frac{\partial}{\partial\tilde{p}_z}\right)^{n_z}\exp(i\tilde{\mathbf{p}}\cdot\mathbf{s}_t(\mathbf{r}))\right]\mathrm{d}^3\tilde{p},\end{aligned}$$

where (27) has been used and the transformation formula for integrals has been applied. Since $\phi_r\in\mathcal{C}_0^\infty$ and all other $\tilde{\mathbf{p}}$ dependences are $\mathcal{C}^\infty$, we may perform integrations by parts and obtain

$$\begin{aligned}\int_{\mathbb{R}^3}\phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p &= \frac{i^{n_x+n_y+n_z}}{x^{n_x}y^{n_y}(z-t)^{n_z}}\int_{\mathbb{R}^3}\exp(i\tilde{\mathbf{p}}\cdot\mathbf{s}_t(\mathbf{r}))\left(\frac{\partial}{\partial\tilde{p}_x}\right)^{n_x}\left(\frac{\partial}{\partial\tilde{p}_y}\right)^{n_y}\left(\frac{\partial}{\partial\tilde{p}_z}\right)^{n_z}\\ &\quad\times[\phi_r(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))\mathbf{M}^{(\epsilon)}(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}),t-z)u_r(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))\\ &\quad\times\exp(-i\epsilon\kappa(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))t)|\det(D\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))|]\mathrm{d}^3\tilde{p}.\end{aligned}\tag{34}$$

Observe that by the chain rule,

$$\left|\left(\frac{\partial}{\partial\tilde{p}_x}\right)^{m_x}\left(\frac{\partial}{\partial\tilde{p}_y}\right)^{m_y}\left(\frac{\partial}{\partial\tilde{p}_z}\right)^{m_z}\exp(-i\epsilon\kappa(\tilde{\mathbf{q}}^{(\epsilon)}_{t-z}(\tilde{\mathbf{p}}))t)\right|\leqslant d_{m_x,m_y,m_z}(1+|t|^{m_x+m_y+m_z}),\quad\tilde{\mathbf{p}}\in\operatorname{supp}\phi_r,$$

for some constants d_{m_x,m_y,m_z}. Again by the chain rule and by Lemma 1, the derivatives in (34) are uniformly bounded in $\mathbf{r}$, and we may conclude that the integral is bounded in $\mathbf{r}$ and that the t dependence is governed by the above inequality. Thus,

$$|x|^{n_x}|y|^{n_y}|z-t|^{n_z}\left\|\int_{\mathbb{R}^3}\phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p\right\|_{\mathbb{C}^4}\leqslant\tilde{c}_{r,n_x,n_y,n_z}(1+|t|^{n_x+n_y+n_z})$$

for some constants $\tilde{c}_{r,n_x,n_y,n_z}$, from which (33) follows after summation over r.

■

Theorem 2 allows us to define regular wave packets.

Definition 1: For $t\in\mathbb{R}$, define

$$\mathcal{F}_t{:}\mathcal{C}_0^\infty(\mathbb{R}^3)^4\to L^2(\mathbb{R}^3)^4\cap\mathcal{C}_\infty(\mathbb{R}^3)^4,\quad\phi\mapsto\mathcal{F}_t(\phi),$$

where

$$(\mathcal{F}_t(\phi))(\mathbf{r}):=\frac{1}{(2\pi)^{3/2}}\sum_{r=1}^4\int_{\mathbb{R}^3}\phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p\tag{35}$$

and $\mathcal{C}_\infty(\mathbb{R}^3)^4\subset\mathcal{C}_b(\mathbb{R}^3)^4$ is the space of continuous functions $\mathbb{R}^3\to\mathbb{C}^4$ that vanish at infinity. The elements of the range $\mathcal{F}_t(\mathcal{C}_0^\infty(\mathbb{R}^3)^4)$ will be called regular (Volkov) wave packets.

The following theorem assures that under weak assumptions, the wave packets defined above actually fulfill the Dirac equation in the Hamiltonian form (15). We only need the additional requirement that $\tilde{\mathbf{A}} \in \mathcal{C}_b^1$, i.e., $\tilde{\mathbf{A}}$ is continuously differentiable and both $\tilde{\mathbf{A}}$ and its derivative $\tilde{\mathbf{A}}'$ are bounded.

Theorem 3: *Let* $\phi \in \mathcal{C}_0^\infty(\mathbb{R}^3)^4$, *and set*

$$\psi(\mathbf{r},t) := \mathcal{F}_t(\phi)(\mathbf{r}).$$

Assume that $\tilde{\mathbf{A}} \in \mathcal{C}_b^1$. *Then the following assertions hold:*

(a) $\psi \in \mathcal{C}^1(\mathbb{R}^4)^4$ *and*

$$i\partial_t \psi(\mathbf{r},t) = H(t)\psi(\mathbf{r},t) \equiv [\alpha(-i\boldsymbol{\nabla} - e\tilde{\mathbf{A}}(t-z)) + \beta m]\psi(\mathbf{r},t). \tag{36}$$

(b) *There are constants* c_n, $n \in \mathbb{N}_0$, *satisfying*

$$\|(H(t)\psi(\cdot,t))(\mathbf{r})\| \leqslant c_n \frac{1+|t|^n}{1+[x^2+y^2+(z-t)^2]^{n/2}}.$$

Therefore, $H(t)\psi(\cdot,t) \in L^2(\mathbb{R}^3)^4$ *for all* t.

(c) *The mapping* $\mathbb{R} \to L^2(\mathbb{R}^3)^4$, $t \mapsto \psi(\cdot,t)$, *is* $\mathcal{C}^1$, *and*

$$i\frac{d}{dt}\psi(\cdot,t) = H(t)\psi(\cdot,t), \tag{37}$$

where the derivative is taken in the space $L^2(\mathbb{R}^3)^4$.

Proof: (a) Since the Volkov solutions $\psi_{\mathbf{p},r}$ are $\mathcal{C}^1$ and satisfy the Dirac equation (15), we only have to show that the differentiations in (36) may be interchanged with the integration in (35). This is possible since the derivatives of $\psi_{\mathbf{p},r}(\mathbf{r},t)$ with respect to t, x, y, and z are continuous functions of $\mathbf{p}$, $\mathbf{r}$, and t and since the support of ϕ is compact.

(b) Upon interchange of differentiation and integration and using the boundedness of the derivative $\tilde{\mathbf{A}}'$, this statement follows as in the proof of Theorem 2.

(c) We need to show that for every t_0,

$$i\lim_{\tau\to 0}\frac{\psi(\cdot,t_0+\tau)-\psi(\cdot,t_0)}{\tau} = H(t_0)\psi(\cdot,t_0), \tag{38}$$

where the limit is to be understood in the L^2 norm. In view of part (a), pointwise convergence for every $\mathbf{r} \in \mathbb{R}^3$ is given. It remains to show that the left-hand side of (38) is bounded by a common L^2 function for $|\tau| < 1$; the statement follows then by dominated convergence. For $\tau > 0$,

$$\left\|\frac{\psi(\mathbf{r},t_0+\tau)-\psi(\mathbf{r},t_0)}{\tau}\right\| \leqslant \sup_{\sigma\in(0,\tau)}\left\|\partial_t\psi(\mathbf{r},t)\big|_{t=t_0+\sigma}\right\| = \sup_{\sigma\in(0,\tau)}\|(H(t_0+\sigma)\psi(\cdot,t_0+\sigma))(\mathbf{r})\|$$
$$\leqslant C\sup_{\sigma\in(0,\tau)}\frac{1+|t_0+\sigma|^2}{1+x^2+y^2+(z-(t_0+\sigma))^2}$$

for a certain constant C, which is clear by part (b). For $\tau < 0$, we obtain a similar result, in which $\sup_{\sigma\in(0,\tau)}$ is replaced by $\sup_{\sigma\in(\tau,0)}$. With little effort, we see that for $|\tau| \leqslant 1$,

$$\left\|\frac{\psi(\mathbf{r},t_0+\tau)-\psi(\mathbf{r},t_0)}{\tau}\right\| \leqslant C\frac{1+(|t_0|+1)^2}{1+x^2+y^2+\max\{|z-t_0|-1,0\}^2},$$

where the right-hand side is an L^2 function of x, y, and z. This confirms (38) and concludes the proof. ■

For the usual Fourier transformation, the Riemann–Lebesgue lemma holds, which states that the Fourier transformation defined on $\mathcal{C}_0^\infty$ extends uniquely to a bounded map from L^1 into $\mathcal{C}_\infty$, the continuous functions vanishing at infinity, see Theorem IX.7 in Ref. 30. In the case of the Volkov solutions, a similar result is true.

Theorem 4:

(a) *There is a constant C with*

$$\|\mathcal{F}_t(\phi)\|_\infty \leqslant C\|\phi\|_{L^1(\mathbb{R}^3)^4}$$

for all $\phi \in \mathcal{C}_0^\infty(\mathbb{R}^3)^4 \subset L^1(\mathbb{R}^3)^4$ *and all* $t \in \mathbb{R}$.

(b) *The unique bounded extension* $\mathcal{F}_t^{(1)}$ *to* $L^1(\mathbb{R}^3)^4$ *fulfills*

$$\mathcal{F}_t^{(1)}: L^1(\mathbb{R}^3)^4 \to \mathcal{C}_\infty(\mathbb{R}^3)^4,$$

i.e., $\mathcal{F}_t^{(1)}(\phi)$ *vanishes at infinity for all* $\phi \in L^1(\mathbb{R}^3)^4$.

(c) *For* $\phi \in L^1(\mathbb{R}^3)^4$,

$$(\mathcal{F}_t^{(1)}(\phi))(\mathbf{r}) = \frac{1}{(2\pi)^{3/2}} \sum_{r=1}^{4} \int_{\mathbb{R}^3} \phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p, \tag{39}$$

i.e., the same formula as in (35) *holds for all* $\phi \in L^1(\mathbb{R}^3)^4$.

Proof: (a) In order to adapt the proof for the usual Fourier transformation in Ref. 30, we have to check first that the Volkov solutions are bounded in $\mathbf{p}$. Since this is not directly clear from the defining equation (3), we shall first rewrite the Volkov solutions. To this end, observe that

$$\not{n}\tilde{\not{A}}(\xi) = -\tilde{\not{A}}(\xi)\not{n}.$$

Employing (9), we can write

$$\psi_{\mathbf{p},r}(\mathbf{r},t) = \tilde{\mathbf{M}}^{(\epsilon_r)}(\mathbf{p},t-z)u_r(\mathbf{p})e^{iS^{(\epsilon_r)}(\mathbf{p},\mathbf{r},t)} \tag{40}$$

with

$$\tilde{\mathbf{M}}^{(\pm)}(\mathbf{p},\xi) := 1 \mp e\tilde{\not{A}}(\xi)\frac{E(\mathbf{p})\not{n} \pm m - \not{p}}{2E(\mathbf{p})(E(\mathbf{p})-p_z)} = \mathbf{1} \mp e\tilde{\not{A}}(\xi)\left(\frac{\pm m + p_x\gamma^1 + p_y\gamma^2}{2E(\mathbf{p})(E(\mathbf{p})-p_z)} - \frac{1}{2E(\mathbf{p})}\gamma^3\right).$$

Using the equality

$$\frac{1}{E(\mathbf{p})(E(\mathbf{p})-p_z)} + \frac{1}{E(\mathbf{p})(E(\mathbf{p})+p_z)} = \frac{2E(\mathbf{p})}{E(\mathbf{p})(m^2+|\mathbf{p}_\perp|^2)} = \frac{2}{m^2+|\mathbf{p}_\perp|^2},$$

we find the estimate

$$\frac{m^2+|\mathbf{p}_\perp|^2}{E(\mathbf{p})(E(\mathbf{p})-p_z)} \leqslant 2$$

and conclude that $\tilde{\mathbf{M}}^{(\pm)}(\mathbf{p},\xi)$ are bounded with respect to $\mathbf{p}$ and ξ. Consequently, $\psi_{\mathbf{p},r}(\mathbf{r},t)$ is bounded in $\mathbf{p}$, $\mathbf{r}$, and t,

$$\|\psi_{\mathbf{p},r}(\mathbf{r},t)\| \leqslant c_r \tag{41}$$

for some constants $c_r \geqslant 0$. For $\phi \in \mathcal{C}_0^\infty(\mathbb{R}^3)^4$, this results in the estimate

$$\|(\mathcal{F}_t(\phi))(\mathbf{r})\| \leqslant \frac{1}{(2\pi)^{3/2}}\sum_{r=1}^{4}\int_{\mathbb{R}^3}|\phi_r(\mathbf{p})|\|\psi_{\mathbf{p},r}(\mathbf{r},t)\|\mathrm{d}^3p \leqslant \frac{1}{(2\pi)^{3/2}}\sum_{r=1}^{4} c_r\|\phi_r\|_{L^1}.$$

(b) This follows as for the Riemann–Lebesgue lemma: For a given $\phi\in L^1(\mathbb{R}^3)^4$, choose a sequence $(\phi_n)_{n\in\mathbb{N}}$ in $\mathcal{C}_0^\infty(\mathbb{R}^3)^4$ with $\phi_n\to\phi$, $n\to\infty$, in the $L^1(\mathbb{R}^3)^4$ norm. By Theorem 2, $\mathcal{F}_t^{(1)}(\phi_n)=\mathcal{F}_t(\phi_n)\in\mathcal{C}_\infty(\mathbb{R}^3)^4$ for all $n\in\mathbb{N}$. On the other hand, part (a) of the present theorem ensures that $\mathcal{F}_t^{(1)}(\phi_n)\to\mathcal{F}_t^{(1)}(\phi)$, $n\to\infty$, uniformly on $\mathbb{R}^3$. Therefore, we also have $\mathcal{F}_t(\phi)\in\mathcal{C}_\infty(\mathbb{R}^3)^4$.

(c) In view of (41), the integral on the right-hand side of (39) exists for $\phi\in L^1(\mathbb{R}^3)^4$. Taking again a sequence as in the proof of part (b), the statement follows by dominated convergence. ■

V. NORMALIZATION

The following theorem may be considered as the central point of this paper.

Theorem 5: *Let $\tilde{\mathbf{A}}\in\mathcal{C}_b^1$. Then for every $t\in\mathbb{R}$, $\mathcal{F}_t$ is an isometry with respect to the L^2 norm, i.e., for every $\phi\in L^2(\mathbb{R}^3)^4$,*

$$\|\mathcal{F}_t(\phi)\|_{L^2(\mathbb{R}^3)^4}=\|\phi\|_{L^2(\mathbb{R}^3)^4}. \tag{42}$$

As a simple conclusion, we note the following.

Corollary 6: Under the assumptions of Theorem 5,

$$\langle\mathcal{F}_t(\phi),\mathcal{F}_t(\chi)\rangle_{L^2(\mathbb{R}^3)^4}=\langle\phi,\chi\rangle_{L^2(\mathbb{R}^3)^4} \tag{43}$$

for every $\phi,\chi\in L^2(\mathbb{R}^3)^4$.

The lengthy proof of Theorem 5 will be deferred to the Appendix. Here we shall only verify Corollary 6 and then point out the connection with the "normalization to a delta function" and "orthogonality" of the Volkov solutions.

Proof of Corollary 6: This corollary is just the application of a general theorem valid for any isometry between two complex Hilbert spaces: We use the polarization identity

$$\langle x,y\rangle=\tfrac{1}{4}(\|x+y\|^2+\|x-y\|^2+i\|x-iy\|^2-i\|x+iy\|^2),$$

which follows from taking appropriate linear combinations from

$$\|x+y\|^2=\langle x+y,x+y\rangle=\|x\|^2+\|y\|^2+2\,\mathrm{Re}\langle x,y\rangle$$

and similar expressions for $\|x-y\|^2$, $\|x+iy\|^2$, and $\|x-iy\|^2$. For an isometry T (satisfying $\|Tz\|=\|z\|$ for all z), this leads to

$$\begin{aligned}\langle Tx,Ty\rangle&=\tfrac{1}{4}(\|T(x+y)\|^2+\|T(x-y)\|^2+i\|T(x-iy)\|^2-i\|T(x+iy)\|^2)\\&=\tfrac{1}{4}(\|x+y\|^2+\|x-y\|^2+i\|x-iy\|^2-i\|x+iy\|^2)=\langle x,y\rangle.\end{aligned}$$

■

In the physical literature, e.g., Refs. 10, 16, 26, and 31, the "normalization" and "orthogonality" property is laxly written as follows:

$$\int_{\mathbb{R}^3}\psi^\dagger_{\mathbf{p},r}(\mathbf{r},t)\psi_{\mathbf{p}',r'}(\mathbf{r},t)\mathrm{d}^3r=(2\pi)^3\delta_{r,r'}\delta^{(3)}(\mathbf{p}-\mathbf{p}'), \tag{44}$$

where $\delta^{(3)}$ is the three-dimensional delta function. The property (44) is used for the verification of (43),

$$\langle \mathcal{F}_t(\phi), \mathcal{F}_t(\chi)\rangle = \frac{1}{(2\pi)^3}\sum_{r,r'=1}^{4}\int_{\mathbb{R}^3}\left(\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\overline{\phi_r(\mathbf{p})}\chi_{r'}(\mathbf{p}')\langle\psi_{\mathbf{p},r}(\mathbf{r},t),\psi_{\mathbf{p}'r'}(\mathbf{r},t)\rangle_{\mathbb{C}^4}\,\mathrm{d}^3p\,\mathrm{d}^3p'\right)\mathrm{d}^3r$$

$$= \frac{1}{(2\pi)^3}\sum_{r,r'=1}^{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\overline{\phi_r(\mathbf{p})}\chi_{r'}(\mathbf{p}')\left(\int_{\mathbb{R}^3}\langle\psi_{\mathbf{p},r}(\mathbf{r},t),\psi_{\mathbf{p}'r'}(\mathbf{r},t)\rangle_{\mathbb{C}^4}\,\mathrm{d}^3r\right)\mathrm{d}^3p\,\mathrm{d}^3p'$$

$$= \sum_{r=1}^{4}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}\overline{\phi_r(\mathbf{p})}\chi_r(\mathbf{p}')\,\delta^{(3)}(\mathbf{p}-\mathbf{p}')\mathrm{d}^3p\,\mathrm{d}^3p'$$

$$= \sum_{r=1}^{4}\int_{\mathbb{R}^3}\overline{\phi_r(\mathbf{p})}\chi_r(\mathbf{p})\mathrm{d}^3p = \langle\phi,\chi\rangle_{L^2(\mathbb{R}^3)^4}.$$

This calculation certainly involves an unjustified interchange of integration orders and is therefore rather questionable from a mathematical point of view.

We mention that a different "normalization" has been employed by Neville and Rohrlich[20] and Bergou and Varró.[9] These authors use a scalar product that is calculated on those hyperplanes in Minkowski space–time where the vector potential **A** is constant, i.e., their considerations involve integrals of the form

$$\int_{\{(\mathbf{r},t)\in\mathbb{R}^4:t-z=u\}}\cdots\mathrm{d}^3r\,\mathrm{d}t$$

for fixed $u\in\mathbb{R}$. However, the L^2 norms determined from this integration cannot be regarded as a normalization for the probability to find a particle. For a probability interpretation, one would have to integrate over space for a fixed time, at least for a certain specified inertial frame. That is, one would need a spacelike hyperplane, whereas the above integration is over a lightlike hyperplane. Even though the lightlike hyperplane and the related coordinates seem more adopted to the symmetry of the problem, an integration over a spacelike hyperplane as in (43) or (44) appears much more "physical."

VI. EXTENSION TO L^2

Theorem 5 allows us to pronounce the following definition.

Definition 2: In the case $\tilde{\mathbf{A}}\in\mathcal{C}_b^1$, *let*

$$\mathcal{F}_t^{(2)}:L^2(\mathbb{R}^3)^4\to L^2(\mathbb{R}^3)^4$$

be the unique isometric extension of $\mathcal{F}_t$ *from Definition 1 to* $L^2(\mathbb{R}^3)^4$.

It will be profitable to have an integral representation of $\mathcal{F}_t^{(2)}$ for a larger subspace of L^2 than just $\mathcal{C}_0^\infty$. This is indeed possible for amplitude functions in $L^1\cap L^2$:

Theorem 7: *For* $\phi\in L^1(\mathbb{R}^3)^4\cap L^2(\mathbb{R}^3)^4$, *we have*

$$\mathcal{F}_t^{(2)}(\phi)=\mathcal{F}_t^{(1)}(\phi)\in\mathcal{C}_\infty(\mathbb{R}^3)^4, \tag{45}$$

or more explicitly,

$$(\mathcal{F}_t^{(2)}(\phi))(\mathbf{r})=\frac{1}{(2\pi)^{3/2}}\sum_{r=1}^{4}\int_{\mathbb{R}^3}\phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)\mathrm{d}^3p. \tag{46}$$

Proof: We adapt here a proof from the usual Fourier transformation, which can be found in the book of Weidmann.[32] Let $(\phi_n)_n$ be a sequence in $\mathcal{C}_0^\infty(\mathbb{R}^3)^4$ with $\phi_n\to\phi$, $n\to\infty$, in $L^1(\mathbb{R}^3)^4$ and in $L^2(\mathbb{R}^3)^4$ simultaneously. Fix $t\in\mathbb{R}$ and set $\psi_n:=\mathcal{F}_t(\phi_n)$. Theorem 2 yields $\psi_n\in L^1(\mathbb{R}^3)^4\cap\mathcal{C}_\infty(\mathbb{R}^3)^4$. We have

$$\mathcal{F}_t^{(1)}(\phi) = \lim_{n\to\infty} \psi_n \in \mathcal{C}_b(\mathbb{R}^3)^4$$

and

$$\mathcal{F}_t^{(2)}(\phi) = \lim_{n\to\infty} \psi_n \in L^2(\mathbb{R}^3)^4,$$

where the limits are understood in $\mathcal{C}_b(\mathbb{R}^3)^4$ and $L^2(\mathbb{R}^3)^4$, respectively. Choose a subsequence $(\psi_{n_k})_k$ such that

$$\psi_{n_k}(\mathbf{r}) \to \mathcal{F}_t^{(2)}(\phi)(\mathbf{r}), \quad k\to\infty, \quad \text{a.e.}$$

But since

$$\psi_{n_k}(\mathbf{r}) \to \mathcal{F}_t^{(1)}(\phi)(\mathbf{r}), \quad k\to\infty,$$

for all $\mathbf{r}$, we conclude that

$$\mathcal{F}_t^{(1)}(\phi)(\mathbf{r}) = \mathcal{F}_t^{(2)}(\phi)(\mathbf{r}), \quad \text{a.e.} \tag{47}$$

■

Corollary 8: Let $\phi \in L^2(\mathbb{R}^3)^4$ *and* $K_n := \{x \in \mathbb{R}^3 : \|x\|_2 \leqslant n\}$. *Then*

$$(\mathcal{F}_t^{(2)}\phi)(\mathbf{r}) = \lim_{n\to\infty} \frac{1}{(2\pi)^{3/2}} \sum_{r=1}^{4} \int_{K_n} \phi_r(\mathbf{p}) \psi_{\mathbf{p},r}(\mathbf{r},t) \mathrm{d}^3p. \tag{48}$$

Proof: Again adapting a proof from Weidmann,[32] let χ_n be the characteristic function of the set K_n and fix $t \in \mathbb{R}$. Then $\chi_n\phi \in L^1(\mathbb{R}^3)^4 \cap L^2(\mathbb{R}^3)^4$, and we have $\chi_n\phi \to \phi$ in $L^2(\mathbb{R}^3)^4$. According to Theorem 7,

$$(\mathcal{F}_t^{(2)}(\chi_n\phi))(\mathbf{r}) = \frac{1}{(2\pi)^{3/2}} \sum_{r=1}^{4} \int_{K_n} \phi_r(\mathbf{p}) \psi_{\mathbf{p},r}(\mathbf{r},t) \mathrm{d}^3p.$$

The claim follows from the fact that $\mathcal{F}_t^{(2)}(\chi_n\phi) \to \mathcal{F}_t^{(2)}(\phi)$ in $L^2(\mathbb{R}^3)^4$.

■

VII. SUMMARY AND OUTLOOK

In this paper, we have put some assertions concerning the relativistic Volkov solutions on solid mathematical ground. As a general assumption, we took the electromagnetic vector potential to be continuous and bounded. In Theorem 2, we have justified the construction of regular wave packets from Volkov solutions as used, for example, in Ref. 21 and have proved their rapid decay in spatial space. Theorem 3 shows that these wave packets satisfy the Dirac equation, as long as the vector potential is also $\mathcal{C}^1$ and has a bounded derivative. The "normalization" property is verified in the central Theorem 5 and allows the definition of wave packets for any L^2 function in momentum space. Finally, Theorem 7 provides a useful integral representation for the momentum-space functions contained in $L^1 \cap L^2$.

As mentioned in the introduction, it is still desirable to find a rigorous proof of the "completeness" of the Volkov solutions, i.e., for the hypothesis that for any initial wave packet $\psi_0 \in L^2(\mathbb{R}^3)^4$ at time $t=0$, there is a momentum distribution $\phi \in L^2(\mathbb{R}^3)^4$ from which ψ_0 and also the time-dependent solution $\psi(\mathbf{r},t)$ with $\psi(\cdot,0)=\psi_0$ follows. In other words, the mapping $\mathcal{F}_t^{(2)}$ from (2) should be surjective and therefore unitary for a "reasonable" vector potential $\tilde{\mathbf{A}}$. A comparison with the field-free case $\tilde{\mathbf{A}} \equiv 0$ suggests that the inverse

$$\mathcal{G}_t := (\mathcal{F}_t^{(2)})^{-1}$$

might be obtainable by the formula

$$\phi(\mathbf{p}) := (\mathcal{G}_t(\psi))(\mathbf{p}) = \left(\frac{1}{(2\pi)^{3/2}} \sum_{r=1}^{4} \int_{\mathbb{R}^3} \langle \psi_{\mathbf{p},r}(\mathbf{r},t), \psi(\mathbf{r}) \rangle \mathrm{d}^3 p \right)_{r=1,\ldots,4}, \tag{49}$$

at least when $\psi \in \mathcal{C}_0^\infty$. The "physical" version of the above inversion formula (49) is

$$\sum_{r=1}^{4} \int_{\mathbb{R}^3} \psi_{\mathbf{p},r}^\dagger(\mathbf{r},t) \psi_{\mathbf{p},r}(\mathbf{r}',t) \mathrm{d}^3 p = (2\pi)^3 \delta^{(3)}(\mathbf{r}-\mathbf{r}').$$

The validity of the inversion formula (49) would allow one to write the unitary propagator for the Dirac equation (15) as

$$U(t,t') = \mathcal{F}_t^{(2)} \circ \mathcal{G}_{t'}. \tag{50}$$

This conjecture is used by San Román and co-workers in Refs. 21–24 for the calculation of the time evolution of a Volkov wave packet. Having established (49), one might also try to understand on a more analytical level the squeezing and distortion of wave packets observed in Refs. 21 and 22.

In order to prove (49), one should (i) verify the existence of the integral on the right-hand side for $\psi \in \mathcal{C}_0^\infty$, (ii) show that $\phi \in L^1 \cap L^2$, and (iii) demonstrate with the help of Theorem 7 that

$$\psi = F_t^{(2)}(\mathcal{G}_t(\psi)).$$

There are strong indications to the author that the assertions (i) and (ii) are correct for a bounded vector potential $\tilde{\mathbf{A}} \in \mathcal{C}^2$ with bounded first and second derivates. More details and results shall be supplied in a future publication.

ACKNOWLEDGMENT

The author is grateful to Dr. Carsten Müller for valuable discussions and for his help.

APPENDIX: PROOF OF THEOREM 5

In this appendix, we provide the proof for the main Theorem 5.

Proof: Fix $t \in \mathbb{R}$ and $\phi \in \mathcal{C}_0^\infty(\mathbb{R}^3)^4$. We have to show that

$$\|\mathcal{F}_t(\phi)\|_{L^2(\mathbb{R}^3)^4}^2 \equiv \frac{1}{(2\pi)^3} \sum_{r,r'=1}^{4} \int_{\mathbb{R}^3} I_{r,r'}(\mathbf{r}) \mathrm{d}^3 r = \|\phi\|_{L^2(\mathbb{R}^3)^4}^2 \tag{A1}$$

with

$$I_{r,r'}(\mathbf{r}) := \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \overline{\phi_r(\mathbf{p})} \phi_{r'}(\mathbf{p}') \langle \psi_{\mathbf{p},r}(\mathbf{r},t), \psi_{\mathbf{p}'r'}(\mathbf{r},t) \rangle_{\mathbb{C}^4} \, \mathrm{d}^3 p \, \mathrm{d}^3 p', \tag{A2}$$

where the bar denotes complex conjugation. Note that all integrals appearing above exist since $\mathcal{F}_t(\phi) \in L^2(\mathbb{R}^3)^4$ by virtue of Theorem 2.

Inserting the Volkov solutions (3), we find

$$
\begin{aligned}
I_{r,r'}(\mathbf{r}) &= \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \overline{\phi_r(\mathbf{p})}\phi_{r'}(\mathbf{p}')\exp[i(S^{(\epsilon_{r'})}(\mathbf{p}',\mathbf{r},t) - S^{(\epsilon_r)}(\mathbf{p},\mathbf{r},t))] \\
&\quad \times \langle \mathbf{M}^{(\epsilon_r)}(\mathbf{p},t-z)u_r(\mathbf{p}), \mathbf{M}^{(\epsilon_{r'})}(\mathbf{p}',t-z)u_{r'}(\mathbf{p}')\rangle \mathrm{d}^3p\, \mathrm{d}^3p' \\
&= \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \overline{\phi_r(\mathbf{p})}\phi_{r'}(\mathbf{p}')\exp[i(\epsilon_r\kappa(\mathbf{p}) - \epsilon_{r'}\kappa(\mathbf{p}'))t] \\
&\quad \times \langle \mathbf{M}^{(\epsilon_r)}(\mathbf{p},t-z)u_r(\mathbf{p}), \mathbf{M}^{(\epsilon_{r'})}(\mathbf{p}',t-z)u_{r'}(\mathbf{p}')\rangle \\
&\quad \times \exp[i(\mathbf{q}_{t-z}^{(\epsilon_{r'})}(\mathbf{p}') - \mathbf{q}_{t-z}^{(\epsilon_r)}(\mathbf{p}))\cdot \mathbf{s}_t(\mathbf{r})]\mathrm{d}^3p\, \mathrm{d}^3p'.
\end{aligned}
$$

Note that the only x and y dependence is contained in the term $\mathbf{s}_t(\mathbf{r})$. This fact is intimately connected with the validity of the eigenvalue equations (14a) and (14b). We thus perform the integration over these two variables $\mathbf{r}_\perp \equiv (x,y)$ first and obtain

$$
\int_{\mathbb{R}^2} I_{r,r'}(\mathbf{r})\mathrm{d}^2r_\perp = \int_{\mathbb{R}^2}\left(\int_{\mathbb{R}^2}\int_{\mathbb{R}^2} \langle \tilde{\phi}_r(\mathbf{p}_\perp,z), \tilde{\phi}_{r'}(\mathbf{p}'_\perp,z)\rangle_{\mathbb{C}^4} e^{i(\epsilon_{r'}\mathbf{p}'_\perp - \epsilon_r\mathbf{p}_\perp)\cdot\mathbf{r}_\perp}\, \mathrm{d}^2p_\perp\, \mathrm{d}^2p'_\perp\right)\mathrm{d}^2r_\perp,
$$

where

$$
\begin{aligned}
\tilde{\phi}_r(\mathbf{p}_\perp,z) &:= \int_{\mathbb{R}} \phi_r(\mathbf{p})\psi_{\mathbf{p},r}(\mathbf{r},t)e^{-i\epsilon_r\mathbf{p}_\perp\cdot\mathbf{r}_\perp}\,\mathrm{d}p_z = \int_{\mathbb{R}} \phi_r(\mathbf{p})\mathbf{M}^{(\epsilon_r)}(\mathbf{p},t-z)u_r(\mathbf{p})e^{-i\epsilon_r\kappa(\mathbf{p})t} \\
&\quad \times \exp\left[i\frac{\epsilon_r}{2}\left(\frac{m^2+\pi_\perp(t-z,\epsilon_r\mathbf{p}_\perp)^2}{\kappa(\mathbf{p})} - \kappa(\mathbf{p})\right)(z-t)\right]\mathrm{d}p_z. \qquad \text{(A3)}
\end{aligned}
$$

Since $\phi_r \in \mathcal{C}_0^\infty(\mathbb{R}^3)$, we see that for every z,

$$
\tilde{\phi}_r(\cdot,z) \in \mathcal{C}_0^\infty(\mathbb{R}^2)^4 \subset L^2(\mathbb{R}^2)^4.
$$

Using Parseval's identity, we find

$$
\int_{\mathbb{R}^2} I_{r,r'}(\mathbf{r})\mathrm{d}^2r_\perp = (2\pi)^2\int_{\mathbb{R}^2} \langle \tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z), \tilde{\phi}_{r'}(\epsilon_{r'}\mathbf{p}_\perp,z)\rangle_{\mathbb{C}^4}\,\mathrm{d}^2p_\perp. \qquad \text{(A4)}
$$

Moreover, with the method applied in the proof of Theorem 2, we can even show that

$$
\tilde{\phi}_r \in L^2(\mathbb{R}^3)^4.
$$

We may therefore interchange the order of integrations by Fubini's theorem

$$
\begin{aligned}
\|\mathcal{F}_t(\phi)\|^2_{L^2(\mathbb{R}^3)^4} &= \frac{1}{2\pi}\sum_{r,r'=1}^4 \int_{\mathbb{R}}\left(\int_{\mathbb{R}^2} \langle \tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z), \tilde{\phi}_{r'}(\epsilon_{r'}\mathbf{p}_\perp,z)\rangle_{\mathbb{C}^4}\,\mathrm{d}^2p_\perp\right)\mathrm{d}z \\
&= \frac{1}{2\pi}\sum_{r,r'=1}^4 \int_{\mathbb{R}^2}\left(\int_{\mathbb{R}} \langle \tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z), \tilde{\phi}_{r'}(\epsilon_{r'}\mathbf{p}_\perp,z)\rangle_{\mathbb{C}^4}\,\mathrm{d}z\right)\mathrm{d}^2p_\perp.
\end{aligned}
$$

The identity (A1)—i.e., the statement of the theorem—is true if for every $\mathbf{p}_\perp$,

$$
\begin{aligned}
\frac{1}{2\pi}\int_{\mathbb{R}} \langle \tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z), \tilde{\phi}_{r'}(\epsilon_{r'}\mathbf{p}_\perp,z)\rangle_{\mathbb{C}^4}\,\mathrm{d}z &\equiv \frac{1}{2\pi}\langle \tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,\cdot), \tilde{\phi}_{r'}(\epsilon_{r'}\mathbf{p}_\perp,\cdot)\rangle_{L^2} \\
&= \delta_{r,r'}\int_{\mathbb{R}} |\phi_r(\epsilon_r\mathbf{p}_\perp,p_z)|^2\,\mathrm{d}p_z. \qquad \text{(A5)}
\end{aligned}
$$

For the rest of the proof, we shall fix $\mathbf{p}_\perp$ and verify (A5). In preparation for exploiting the symmetry (17) of the Volkov solutions, we set

$$\tilde{\boldsymbol{\pi}}^{(\pm)}(\lambda) := \boldsymbol{\pi}(\pm\mathbf{p}_\perp,\lambda) = \left(\pm\mathbf{p}_\perp, \frac{m^2+|\mathbf{p}_\perp|^2-\lambda^2}{2\lambda}\right) \tag{A6}$$

and find

$$\tilde{E}(\lambda) := E(\tilde{\boldsymbol{\pi}}^{(\pm)}(\lambda)) = \left(m^2+|\mathbf{p}_\perp|^2+\frac{(m^2+|\mathbf{p}_\perp|^2-\lambda^2)^2}{4\lambda^2}\right)^{1/2} = \frac{m^2+|\mathbf{p}_\perp|^2+\lambda^2}{2\lambda} \tag{A7}$$

for $\lambda>0$. In view of the equalities

$$\tilde{\boldsymbol{\pi}}^{(\pm)}(\kappa(\mathbf{p})) = (\pm\mathbf{p}_\perp, p_z) \tag{A8}$$

and

$$\kappa(\tilde{\boldsymbol{\pi}}^{(\pm)}(\lambda)) = \lambda, \quad \lambda>0, \tag{A9}$$

we may write

$$\tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z) = \int_{\mathbb{R}} \phi_r(\tilde{\boldsymbol{\pi}}^{(\epsilon_r)}(\kappa(\mathbf{p})))\tilde{\psi}_{\kappa(\mathbf{p}),r}(z)\mathrm{d}p_z. \tag{A10}$$

Here,

$$\tilde{\psi}_{\lambda,r}(z) := \psi_{\tilde{\boldsymbol{\pi}}^{(\epsilon_r)}(\lambda),r}(\mathbf{r},t)e^{-i\mathbf{p}_\perp\cdot\mathbf{r}_\perp} = \left(\mathbf{1}+\frac{e\tilde{\not{A}}(t-z)}{2\epsilon_r\lambda}\right)\tilde{u}_r(\lambda)e^{-i\epsilon_r\lambda t}\exp[i\epsilon_r(z-t)\tilde{\nu}_{t-z}(\lambda)], \tag{A11}$$

where

$$\tilde{\nu}_\xi(\lambda) := \frac{1}{2}\left(\frac{m^2+\pi_\perp(\xi,\mathbf{p}_\perp)^2}{\lambda}-\lambda\right) \tag{A12}$$

is the third component of $\boldsymbol{\nu}_\xi$ defined in (24). Furthermore,

$$\tilde{u}_r(\lambda) := u_r(\tilde{\boldsymbol{\pi}}^{(\epsilon_r)}(\lambda)), \tag{A13}$$

or, more explicitly,

$$\tilde{u}_r(\lambda) = \sqrt{\frac{\tilde{E}(\lambda)+m}{2\tilde{E}(\lambda)}}\left(\mathbf{1}+\frac{\boldsymbol{\alpha}\cdot\tilde{\boldsymbol{\pi}}^{(\epsilon_r)}(\lambda)}{\tilde{E}(\lambda)+m}\right)_r, \tag{A14}$$

where the index r on the right-hand side denotes the rth column of the enclosed matrix.

The functions $\tilde{\psi}_{\lambda,r}$ fulfill an eigenvalue equation closely related to (17),

$$\Xi\tilde{\psi}_{\lambda,r}(z) = \epsilon_r\lambda\tilde{\psi}_{\lambda,r}(z), \tag{A15}$$

where

$$\Xi := \alpha_x p_x+\alpha_y p_y - i\alpha_z\partial_z - e\boldsymbol{\alpha}\tilde{\mathbf{A}}(t-z)+\beta m + i\partial_z = i(\mathbf{1}-\alpha_z)\partial_z+\alpha_x p_x+\alpha_y p_y - e\boldsymbol{\alpha}\tilde{\mathbf{A}}(t-z)+\beta m \tag{A16}$$

is a formally self-adjoint ordinary differential operator. The validity of (A15) is shown easily. From (A11) we infer that

$$\psi_{\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda),r}(\mathbf{r},t) = e^{i\mathbf{p}_\perp\cdot\mathbf{r}_\perp}\tilde{\psi}_{\lambda,r}(z),$$

so that by (17),

$$(H(t)+i\partial_z)(e^{i\mathbf{p}_\perp\cdot\mathbf{r}_\perp}\tilde{\psi}_{\lambda,r}(z)) = \epsilon_r\kappa(\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda))\psi_{\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda),r}(\mathbf{r},t) = \epsilon_r\lambda e^{i\mathbf{p}_\perp\cdot\mathbf{r}_\perp}\tilde{\psi}_{\lambda,r}(z).$$

Since

$$(-i\alpha_x\partial_x - i\alpha_y\partial_y)(e^{i\mathbf{p}_\perp\cdot\mathbf{r}_\perp}\tilde{\psi}_{\lambda,r}(z)) = (\alpha_x p_x + \alpha_y p_y)(e^{i\mathbf{p}_\perp\cdot\mathbf{r}_\perp}\tilde{\psi}_{\lambda,r}(z)),$$

equation (A15) follows immediately.

Performing the substitution

$$\sigma: p_z \mapsto \kappa(\mathbf{p}) \equiv \lambda,$$

we are led to

$$\tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z) = \frac{1}{2}\int_0^\infty \phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda))\tilde{\psi}_{\lambda,r}(z)\left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda^2}+1\right)\mathrm{d}\lambda, \tag{A17}$$

where we have used

$$\frac{d}{\mathrm{d}\lambda}\sigma^{-1}(\lambda) = \frac{d}{\mathrm{d}\lambda}\frac{m^2+|\mathbf{p}_\perp|^2-\lambda^2}{2\lambda} = -\frac{1}{2}\left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda^2}+1\right).$$

An attempt to prove (A5) with $\tilde{\phi}_r$ from (A17) directly by interchanging the orders of integration fails because the assumptions of Fubini's theorem are not fulfilled. In order to apply the theorem, the term $\tilde{\psi}_{\lambda,r}(z)$ would have to decay for large values of $|z|$. As we shall see, we can avoid this problem by constructing an analytic continuation of (A11) to values $\lambda\in\mathbb{C}$ with $\mathrm{Re}\,\lambda>0$, and then in a limiting procedure, the desired result will follow. For this purpose we need to examine the Dirac spinor $\tilde{u}_r$ because its definition (A14) might produce a singularity and a branch cut at certain values of λ. However, for $\lambda\in\mathbb{C}\backslash\{0\}$,

$$\mathrm{Re}\,\tilde{E}(\lambda) = \left(\frac{m^2+|\mathbf{p}_\perp|^2}{2|\lambda|^2}+\frac{1}{2}\right)\mathrm{Re}\,\lambda.$$

So whenever $\mathrm{Re}\,\lambda>0$, we also have $\mathrm{Re}\,\tilde{E}(\lambda)>0$ and

$$\mathrm{Re}\,\frac{\tilde{E}(\lambda)+m}{2\tilde{E}(\lambda)} > 0.$$

Consequently, we may extend the definition (A14) also to complex arguments λ with $\mathrm{Re}\,\lambda>0$ if we choose the branch cut of the square root to lie on the negative real axis. Observing that both sides of (A15) are analytic with respect to λ and identical for real λ, we deduce the validity of this equation for *all* complex λ with $\mathrm{Re}\,\lambda>0$.

Next inspect the function $\tilde{\nu}_\xi$ for complex arguments $\mu=\lambda+i\delta$ with $\lambda>0$ and $\delta\in\mathbb{R}$,

$$\tilde{\nu}_\xi(\lambda+i\delta) = \frac{\lambda}{2}\left(\frac{m^2+\pi_\perp(\xi,\mathbf{p}_\perp)^2}{\lambda^2+\delta^2}-1\right) - \frac{i\delta}{2}\left(\frac{m^2+\pi_\perp(\xi,\mathbf{p}_\perp)^2}{\lambda^2+\delta^2}+1\right),$$

so that we obtain for the exponential in (A11),

$$|\exp[i\epsilon_r(z-t)\tilde{\nu}_{t-z}(\lambda+i\delta)]| = \exp[-\epsilon_r(z-t)\mathrm{Im}\,\tilde{\nu}_{t-z}(\lambda+i\delta)]$$
$$= \exp\left[\epsilon_r(z-t)\frac{\delta}{2}\left(\frac{m^2+\pi_\perp(t-z,\mathbf{p}_\perp)^2}{\lambda^2+\delta^2}+1\right)\right].$$

In addition,

$$\frac{\partial}{\partial\lambda}\tilde{\nu}_\xi(\lambda+i\delta) = \tilde{\nu}'_\xi(\lambda+i\delta) = -\frac{1}{2}\left(\frac{m^2+\pi_\perp(\xi,\mathbf{p}_\perp)^2}{(\lambda+i\delta)^2}+1\right),$$

for which we find

$$|\tilde{\nu}'_\xi(\lambda+i\delta)| = \frac{|m^2+\pi_\perp(\xi,\mathbf{p}_\perp)^2+(\lambda+i\delta)^2|}{2|\lambda+i\delta|^2} = \frac{\sqrt{[m^2+\pi_\perp(\xi,\mathbf{p}_\perp)^2+\lambda^2-\delta^2]^2+4\lambda^2\delta^2}}{2(\lambda^2+\delta^2)} \neq 0, \quad \lambda>0.$$

So for $\lambda>0$,

$$(z-t)\tilde{\psi}_{\lambda+i\delta,r}(z) = \left(\mathbf{1}+\frac{e\not{\tilde{A}}(t-z)}{2\epsilon_r(\lambda+i\delta)}\right)\tilde{u}_r(\lambda+i\delta)e^{-i\epsilon_r(\lambda+i\delta)t}$$
$$\times\frac{-i\epsilon_r}{\tilde{\nu}'_{t-z}(\lambda+i\delta)}\frac{\partial}{\partial\lambda}\exp[i\epsilon_r(z-t)\tilde{\nu}_{t-z}(\lambda+i\delta)]. \tag{A18}$$

Now define

$$\hat{\phi}_{r,\delta}(z) := \frac{1}{2}\int_0^\infty \phi_r(\tilde{\tau}^{(\epsilon_r)}(\lambda))\tilde{\psi}_{\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)],r}(z)\left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda^2}+1\right)\mathrm{d}\lambda \tag{A19}$$

for $\delta\geqslant 0$. This integral exists because the integrand is continuous and $\phi_r\circ\tilde{\tau}^{(\epsilon_r)}$ is compactly supported in $(0,\infty)$. Comparing with (A17), we recognize that for $\delta=0$,

$$\hat{\phi}_{r,0} = \tilde{\phi}_r(\epsilon_r\mathbf{p},\cdot).$$

The sign of the imaginary part in (A19) was chosen such that for $\delta>0$, we observe exponential decay with z,

$$\|\tilde{\psi}_{\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)],r}(z)\| \leqslant \left(\mathbf{1}+\frac{|e|}{2|\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)]|}\|\not{\tilde{A}}(t-z)\|\right)$$
$$\times\|\tilde{u}_r(\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)]\|e^{-\epsilon_r\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)]t}$$
$$\times\exp\left[-\epsilon_r|z-t|\frac{\delta}{2}\left(\frac{m^2+\pi_\perp(t-z,\mathbf{p}_\perp)^2}{\lambda^2+\delta^2}+1\right)\right], \tag{A20}$$

where (A18) was used. From this we obtain that

$$(z\mapsto\tilde{\psi}_{\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)],r}(z))\in L^2(\mathbb{R})^4, \quad \delta>0.$$

This enables us to inspect the decay properties of $\hat{\phi}_{r,\delta}$ for $|z-t|\to\infty$. We first see that

$$\|\hat{\phi}_{r,\delta}(z)\|\leqslant C_0(\phi), \quad \delta\in[0,1],$$

for a constant $C_0(\phi)$. This is clear since the integrand in (A19) is continuous with respect to δ as well as λ and again since $\phi_r\circ\tilde{\tau}^{(\epsilon_r)}$ has compact support. Furthermore, application of (A18) gives

$$(z-t)\hat{\phi}_{r,\delta}(z) = \frac{1}{2}\int_0^\infty \phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda))\left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda^2}+1\right)\left(\mathbf{1}+\frac{e\tilde{\not{A}}(t-z)}{2\epsilon_r(\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)])}\right)$$
$$\times \tilde{u}_r(\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)])\exp[-i\epsilon_r\lambda t]\exp\{-\epsilon_r\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)]t\}$$
$$\frac{\times -i\epsilon_r}{\tilde{\nu}'_{t-z}(\lambda+i\delta)}\frac{\partial}{\partial\lambda}\exp[i\epsilon_r(z-t)\tilde{\nu}_{t-z}(\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)])]\mathrm{d}\lambda.$$

Performing an integration by parts, we notice that also

$$|z-t|\|\hat{\phi}_{r,\delta}(z)\| \leqslant C_1(\phi), \quad \delta\in[0,1].$$

Concludingly,

$$\|\hat{\phi}_{r,\delta}(z)\| \leqslant \frac{C_0(\phi)+C_1(\phi)}{1+|z-t|} \equiv \frac{C(\phi)}{1+|z-t|}, \quad \delta\in[0,1], \tag{A21}$$

so that the functions $\hat{\phi}_{r,\delta}$, $\delta\in[0,1]$, are uniformly bounded in L^2. In addition, we easily see by dominated convergence that

$$\forall z\in\mathbb{R}: \hat{\phi}_{r,\delta}(z)\to\hat{\phi}_{r,0}(z)=\tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,z), \quad \delta\to 0^+.$$

Therefore,

$$\hat{\phi}_{r,\delta}\to\tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,\cdot), \quad \delta\to 0^+, \quad \text{in } L^2. \tag{A22}$$

The above considerations lead us to

$$\langle\tilde{\phi}_r(\epsilon_r\mathbf{p}_\perp,\cdot),\tilde{\phi}_{r'}(\epsilon_{r'}\mathbf{p}_\perp,\cdot)\rangle_{L^2} = \lim_{\delta\to 0^+}\langle\hat{\phi}_{r,\delta},\hat{\phi}_{r',\delta}\rangle_{L^2}, \tag{A23}$$

which necessitates the evaluation of the right-hand side for $\delta>0$. Due to the decay property (A20) that is fulfilled for positive δ, we may now invoke Fubini's theorem,

$$\langle\hat{\phi}_{r,\delta},\hat{\phi}_{r',\delta}\rangle_{L^2} = \frac{1}{4}\int_{\mathbb{R}}\int_{\mathbb{R}}\overline{\phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda))}\phi_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon_{r'})}(\lambda'))\times\left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda^2}+1\right)\left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda'^2}+1\right)$$
$$\times J_{r,r',\delta}(\lambda,\lambda')\mathrm{d}\lambda\mathrm{d}\lambda', \tag{A24}$$

where

$$J_{r,r',\delta}(\lambda,\lambda') := \int_{\mathbb{R}}\langle\tilde{\psi}_{\lambda-i\delta\cdot\mathrm{sgn}[\epsilon_r(z-t)],r}(z),\tilde{\psi}_{\lambda'-i\delta\cdot\mathrm{sgn}[\epsilon_{r'}(z-t)],r'}(z)\rangle\mathrm{d}z$$
$$= \int_{-\infty}^t\langle\tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z),\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle\mathrm{d}z + \int_t^\infty\langle\tilde{\psi}_{\lambda-i\epsilon_r\delta,r}(z),\tilde{\psi}_{\lambda'-i\epsilon_{r'}\delta,r'}(z)\rangle\mathrm{d}z$$
$$\equiv J^{(-)}_{r,r',\delta}(\lambda,\lambda')+J^{(+)}_{r,r',\delta}(\lambda,\lambda'). \tag{A25}$$

These integrals can be evaluated by employing the eigenvalue equation (A15) as follows:

$$\int_{-\infty}^t\langle\tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z),\Xi\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle\mathrm{d}z = \epsilon_{r'}(\lambda'+i\epsilon_{r'}\delta)J^{(-)}_{r,r',\delta}(\lambda,\lambda') = (\epsilon_{r'}\lambda'+i\delta)J^{(-)}_{r,r',\delta}(\lambda,\lambda')$$

and

$$\int_{-\infty}^{t} \langle \Xi \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z), \tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle = \overline{\epsilon_r(\lambda+i\epsilon_r\delta)} J^{(-)}_{r,r',\delta}(\lambda,\lambda') = (\epsilon_r\lambda - i\delta) J^{(-)}_{r,r',\delta}(\lambda,\lambda').$$

Remembering the formal self-adjointness of Ξ and performing an integration by parts, we see that

$$\begin{aligned}
&\int_{-\infty}^{t} \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z), \Xi \tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle \mathrm{d}z - \int_{-\infty}^{t} \langle \Xi \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z), \tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle \mathrm{d}z \\
&\quad = \int_{-\infty}^{t} \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z), i(\mathbf{1}-\alpha_z)\partial_z \tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle \mathrm{d}z - \int_{-\infty}^{t} \langle i(\mathbf{1}-\alpha_z)\partial_z \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(z), \tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(z)\rangle \mathrm{d}z \\
&\quad = i\langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(t), (\mathbf{1}-\alpha_z)\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(t)\rangle.
\end{aligned}$$

From the last three equations we derive that

$$J^{(-)}_{r,r',\delta}(\lambda,\lambda') = \frac{i}{\epsilon_{r'}\lambda' - \epsilon_r\lambda + 2i\delta} \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(t), (\mathbf{1}-\alpha_z)\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(t)\rangle.$$

In a similar way, one may show that

$$J^{(+)}_{r,r',\delta}(\lambda,\lambda') = -\frac{i}{\epsilon_{r'}\lambda' - \epsilon_r\lambda - 2i\delta} \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(t), (\mathbf{1}-\alpha_z)\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(t)\rangle,$$

so that

$$\begin{aligned}
J_{r,r',\delta}(\lambda,\lambda') &= \left(\frac{i}{\epsilon_{r'}\lambda' - \epsilon_r\lambda + 2i\delta} - \frac{i}{\epsilon_{r'}\lambda' - \epsilon_r\lambda - 2i\delta} \right) \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(t), (\mathbf{1}-\alpha_z)\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(t)\rangle \\
&= \frac{4\delta}{(\epsilon_r\lambda - \epsilon_{r'}\lambda')^2 + 4\delta^2} \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(t), (\mathbf{1}-\alpha_z)\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(t)\rangle. \qquad \text{(A26)}
\end{aligned}$$

This leads to

$$\begin{aligned}
\langle \hat{\phi}_{r,\delta}, \hat{\phi}_{r',\delta}\rangle_{L^2} = \frac{\pi}{2}\int_0^\infty \int_0^\infty \eta_\delta(\epsilon_r\lambda - \epsilon_{r'}\lambda') \overline{\phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon_r)}(\lambda))} \phi_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon_{r'})}(\lambda')) \left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda^2} + 1 \right) \\
\times \left(\frac{m^2+|\mathbf{p}_\perp|^2}{\lambda'^2} + 1 \right) \times \langle \tilde{\psi}_{\lambda+i\epsilon_r\delta,r}(t), (\mathbf{1}-\alpha_z)\tilde{\psi}_{\lambda'+i\epsilon_{r'}\delta,r'}(t)\rangle \mathrm{d}\lambda\, \mathrm{d}\lambda' \qquad \text{(A27)}
\end{aligned}$$

with

$$\eta_\delta(x) := \frac{2}{\pi}\frac{\delta}{x^2+4\delta^2}. \qquad \text{(A28)}$$

The integral in (A27) is of the form

$$\langle \hat{\phi}_{r,\delta}, \hat{\phi}_{r',\delta}\rangle_{L^2} = \frac{\pi}{2}\int_0^\infty \int_0^\infty \eta_\delta(\epsilon_r\lambda - \epsilon_{r'}\lambda') f(\delta,\lambda,\lambda')\mathrm{d}\lambda\, \mathrm{d}\lambda'$$

with a function f depending continuously on δ, λ, and λ'. The restriction $f|_{[0,1]\times[0,\infty)\times[0,\infty)}$ has compact support in $[0,1]\times(0,\infty)\times(0,\infty)$. The trivial extension to $[0,1]\times\mathbb{R}^2$, i.e.,

$$\tilde{f}(\delta,\lambda,\lambda') := \begin{cases} f(\delta,\lambda,\lambda'), & \lambda,\lambda' > 0, \\ 0, & \text{otherwise}, \end{cases} \qquad \text{(A29)}$$

is therefore continuous, and we may write

$$\langle \hat{\phi}_{r,\delta}, \hat{\phi}_{r',\delta} \rangle_{L^2} = \frac{\pi}{2} \int_{\mathbb{R}} \int_{\mathbb{R}} \eta_\delta(\epsilon_r \lambda - \epsilon_{r'} \lambda') \tilde{f}(\delta, \lambda, \lambda') \mathrm{d}\lambda \, \mathrm{d}\lambda'$$

$$= \frac{\pi}{2} \int_{\mathbb{R}} \int_{\mathbb{R}} \eta_\delta(\lambda - \lambda') \tilde{f}(\delta, \epsilon_r \lambda, \epsilon_{r'} \lambda') \mathrm{d}\lambda \, \mathrm{d}\lambda'. \tag{A30}$$

We are required to determine the limit of (A27) for $\delta \to 0^+$, see (A23). This can be accomplished with the help of Lemma 9 below. The result is

$$\lim_{\delta \to 0^+} \langle \hat{\phi}_{r,\delta}, \hat{\phi}_{r',\delta} \rangle_{L^2} = \frac{\pi}{2} \int_{\mathbb{R}} \tilde{f}(0, \epsilon_r \lambda, \epsilon_{r'} \lambda) \mathrm{d}\lambda. \tag{A31}$$

Owing to (A23) and (A29), we have

$$\langle \tilde{\phi}_r(\epsilon_r \mathbf{p}_\perp, \cdot), \tilde{\phi}_{r'}(\epsilon_{r'} \mathbf{p}_\perp, \cdot) \rangle_{L^2} = \lim_{\delta \to 0^+} \langle \hat{\phi}_{r,\delta}, \hat{\phi}_{r',\delta} \rangle_{L^2} = 0 \tag{A32}$$

for $\epsilon_r \neq \epsilon_{r'}$, which validates (A5) in this case.

Now assume $\epsilon_r = \epsilon_{r'} =: \epsilon$. Then again by (A23) and Lemma 9,

$$\langle \tilde{\phi}_r(\epsilon_r \mathbf{p}_\perp, \cdot), \tilde{\phi}_{r'}(\epsilon_{r'} \mathbf{p}_\perp, \cdot) \rangle_{L^2} = \frac{\pi}{2} \int_0^\infty \overline{\phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\lambda))} \phi_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\lambda)) \left(\frac{m^2 + |\mathbf{p}_\perp|^2}{\lambda^2} + 1 \right)^2$$

$$\times \langle \tilde{\psi}_{\lambda,r}(t), (\mathbf{1} - \alpha_z) \tilde{\psi}_{\lambda,r'}(t) \rangle \mathrm{d}\lambda$$

$$= \pi \int_{\mathbb{R}} \overline{\phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\kappa(\mathbf{p})))} \phi_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\kappa(\mathbf{p}))) \left(\frac{m^2 + |\mathbf{p}_\perp|^2}{\kappa(\mathbf{p})^2} + 1 \right)$$

$$\times \langle \tilde{\psi}_{\kappa(\mathbf{p}),r}(t), (\mathbf{1} - \alpha_z) \tilde{\psi}_{\kappa(\mathbf{p}),r'}(t) \rangle \mathrm{d}p_z, \tag{A33}$$

where we have substituted back from λ to p_z. By virtue of the identities

$$\mathbf{1} - \alpha_z = \gamma^0(\gamma^0 - \gamma^3) = \gamma^0 \not{n},$$

which is a Hermitian matrix, and

$$\not{n}^2 = n^2 = 0,$$

we find

$$\langle \tilde{\psi}_{\lambda,r}(t), (\mathbf{1} - \alpha_z) \tilde{\psi}_{\lambda,r'}(t) \rangle = \left\langle \left(\mathbf{1} + \frac{e \not{n} \tilde{\not{A}}(t)}{2\epsilon\lambda} \right) \tilde{u}_r(\lambda), \gamma^0 \not{n} \left(\mathbf{1} + \frac{e \not{n} \tilde{\not{A}}(t)}{2\epsilon\lambda} \right) \tilde{u}_{r'}(\lambda) \right\rangle$$

$$= \left\langle \left(\mathbf{1} + \frac{e \not{n} \tilde{\not{A}}(t)}{2\epsilon\lambda} \right) \tilde{u}_r(\lambda), \gamma^0 \not{n} \tilde{u}_{r'}(\lambda) \right\rangle$$

$$= \left\langle \gamma^0 \not{n} \left(\mathbf{1} + \frac{e \not{n} \tilde{\not{A}}(t)}{2\epsilon\lambda} \right) \tilde{u}_r(\lambda), \tilde{u}_{r'}(\lambda) \right\rangle$$

$$= \langle \gamma^0 \not{n} \tilde{u}_r(\lambda), \tilde{u}_{r'}(\lambda) \rangle = \langle \tilde{u}_r(\lambda), \gamma^0 \not{n} \tilde{u}_{r'}(\lambda) \rangle = \langle u_r(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\lambda)), \gamma^0 \not{n} u_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\lambda)) \rangle. \tag{A34}$$

In order to evaluate this scalar product, fix λ and set $\mathbf{p} := \tilde{\boldsymbol{\tau}}^{(\epsilon)}(\lambda)$. We will make use of the 4×4 matrices[18]

$$\Lambda_{\pm}(\mathbf{p}) := \frac{\pm \not{p} + m}{2m} \equiv \frac{\pm(\gamma^0 E(\mathbf{p}) - \gamma^1 p_x - \gamma^2 p_y - \gamma^3 p_z) + m}{2m}, \tag{A35}$$

which obey

$$\Lambda_{\epsilon_r}(\mathbf{p}) u_r(\mathbf{p}) = u_r(\mathbf{p}), \tag{A36}$$

and the fact that for any four-vector a,

$$\not{a}^\dagger = \gamma^0 \not{a} \gamma^0.$$

This gives

$$\begin{aligned}\langle \tilde{\psi}_{\lambda,r}(t), (\mathbf{1} - \alpha_z)\tilde{\psi}_{\lambda,r'}(t)\rangle &= \langle \Lambda_\epsilon(\mathbf{p}) u_r(\mathbf{p}), \gamma^0 \not{n} \Lambda_\epsilon(\mathbf{p}) u_{r'}(\mathbf{p})\rangle \\ &= \langle u_r(\mathbf{p}), \gamma^0 \Lambda_\epsilon(\mathbf{p}) \not{n} \Lambda_\epsilon(\mathbf{p}) u_{r'}(\mathbf{p})\rangle = \langle u_r(\mathbf{p}), \gamma^0 M u_{r'}(\mathbf{p})\rangle \end{aligned} \tag{A37}$$

with the 4×4 matrix

$$M := \Lambda_\epsilon(\mathbf{p}) \not{n} \Lambda_\epsilon(\mathbf{p}) = \frac{\epsilon \not{p} + m}{2m} \not{n} \frac{\epsilon \not{p} + m}{2m} = \frac{1}{4m^2}[\not{p} \not{n} \not{p} + \epsilon m(\not{p} \not{n} + \not{n} \not{p}) + m^2 \not{n}]. \tag{A38}$$

Using

$$\not{a} \not{b} + \not{b} \not{a} = 2(ab)\mathbf{1},$$

which is valid for any four-vectors a and b of real numbers, and

$$\not{p}^2 = p^2 = m^2,$$

we continue

$$M = \frac{1}{4m^2}[2(np)\not{p} - m^2 \not{n} + 2\epsilon m(np) + m^2 \not{n}] = \frac{\epsilon(np)}{m} \Lambda_\epsilon(\mathbf{p}) = \frac{\epsilon \kappa(\mathbf{p})}{m} \Lambda_\epsilon(\mathbf{p}).$$

Hence,

$$\langle \tilde{\psi}_{\lambda,r}(t), (\mathbf{1} - \alpha_z)\tilde{\psi}_{\lambda,r'}(t)\rangle = \frac{\epsilon \kappa(\mathbf{p})}{m} \langle u_r(\mathbf{p}), \gamma^0 \Lambda_\epsilon(\mathbf{p}) u_{r'}(\mathbf{p})\rangle = \frac{\epsilon \kappa(\mathbf{p})}{m} \langle u_r(\mathbf{p}), \gamma^0 u_{r'}(\mathbf{p})\rangle = \delta_{r,r'} \frac{\kappa(\mathbf{p})}{E(\mathbf{p})}, \tag{A39}$$

where

$$\langle u_r(\mathbf{p}), \gamma^0 u_{r'}(\mathbf{p})\rangle \equiv u_r(\mathbf{p})^\dagger \gamma^0 u_{r'}(\mathbf{p}) = \epsilon_r \delta_{r,r'} \frac{m}{E(\mathbf{p})}$$

was exploited.[18] Therefore, we obtain from (A33),

$$\begin{aligned}\langle \tilde{\phi}_r(\epsilon_r \mathbf{p}_\perp, \cdot), \tilde{\phi}_{r'}(\epsilon_{r'} \mathbf{p}_\perp, \cdot)\rangle_{L^2} &= \delta_{r,r'} \pi \int_{\mathbb{R}} \overline{\phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\kappa(\mathbf{p})))} \phi_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\kappa(\mathbf{p}))) \left(\frac{m^2 + |\mathbf{p}_\perp|^2}{\kappa(\mathbf{p})^2} + 1 \right) \frac{\kappa(\mathbf{p})}{E(\mathbf{p})} \mathrm{d}p_z \\ &= 2\pi \delta_{r,r'} \int_{\mathbb{R}} \overline{\phi_r(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\kappa(\mathbf{p})))} \phi_{r'}(\tilde{\boldsymbol{\tau}}^{(\epsilon)}(\kappa(\mathbf{p}))) \mathrm{d}p_z \\ &= 2\pi \delta_{r,r'} \int_{\mathbb{R}} |\phi_r(\epsilon_r \mathbf{p}_\perp, p_z)|^2 \, \mathrm{d}p_z, \end{aligned} \tag{A40}$$

which confirms (A5) also in the case $\epsilon_r = \epsilon_{r'}$. This completes the proof. ■

We are left with showing the following.

Lemma 9: Let $f \in \mathcal{C}_0([0,1]\times\mathbb{R}^2,\mathbb{C})$. *Then*

$$I_\delta := \int_{\mathbb{R}^2} \eta_\delta(x-x')f(\delta,x,x')\mathrm{d}x\,\mathrm{d}x' \to \int_{\mathbb{R}} f(0,x,x)\mathrm{d}x, \quad \delta\to 0^+, \tag{A41}$$

with η_δ *from* (A28).

Proof: We first collect some properties of the functions η_δ,

$$\forall\,\delta>0, \quad x\in\mathbb{R}: \eta_\delta(x)>0, \tag{A42}$$

$$\forall\,\delta>0: \int_{\mathbb{R}} \eta_\delta(x)\mathrm{d}x = 1,$$

and

$$\forall\,\gamma>0: \int_{\mathbb{R}\setminus[-\gamma,\gamma]} \eta_\delta(x)\mathrm{d}x \to 0, \quad \delta\to 0^+. \tag{A43}$$

Set

$$g(\delta,x) := \int_{\mathbb{R}} \eta_\delta(x-x')f(\delta,x,x')\mathrm{d}x' \tag{A44}$$

for $\delta>0$, so that

$$I_\delta = \int_{\mathbb{R}} g(\delta,x)\mathrm{d}x. \tag{A45}$$

The compactness of supp f implies the existence of a compact interval $[a,b]$ such that

$$g(\delta,x)=0 \text{ for } \delta>0, \quad x\notin[a,b].$$

Therefore,

$$I_\delta = \int_a^b g(\delta,x)\mathrm{d}x.$$

Note that

$$|g(\delta,x)| \leqslant \int_{\mathbb{R}} \eta_\delta(x-x')|f(\delta,x,x')|\mathrm{d}x' \leqslant \|f\|_\infty < \infty.$$

We claim that

$$\forall x\in[a,b]: \lim_{\delta\to 0^+} g(\delta,x) = f(0,x,x). \tag{A46}$$

The statement in the lemma follows then by dominated convergence.

In order to prove (A46), fix $x\in[a,b]$. For any $\gamma,\delta>0$, we estimate

$$|g(\delta,x)-f(0,x,x)| = \left| \int_{\mathbb{R}} \eta_\delta(x-x')[f(\delta,x,x')-f(0,x,x)]\mathrm{d}x' \right|$$
$$= \left| \int_{\mathbb{R}} \eta_\delta(y)[f(\delta,x,x-y)-f(0,x,x)]\mathrm{d}y \right|$$
$$\leqslant 2\|f\|_\infty \int_{\mathbb{R}\setminus[-\gamma,\gamma]} \eta_\delta(y)\mathrm{d}y + \sup_{r\in[-\gamma,\gamma]} |f(\delta,x,x+r)-f(0,x,x)|, \qquad \text{(A47)}$$

where (A42) was employed twice. Choose any $\epsilon>0$. Since f is continuous, we find $\gamma,\alpha>0$ such that

$$\sup_{r\in[-\gamma,\gamma]} |f(\delta,x,x+r)-f(0,x,x)| < \frac{\epsilon}{2} \quad \text{for } \delta\in(0,\alpha).$$

In view of (A43), we find $\beta\in(0,\alpha)$ with

$$2\|f\|_\infty \int_{\mathbb{R}\setminus[-\gamma,\gamma]} \eta_\delta(y)\mathrm{d}y < \frac{\epsilon}{2} \quad \text{for } \delta\in(0,\beta).$$

Therefore,

$$|g(\delta,x)-f(0,x,x)| < \epsilon \quad \text{for } \delta\in(0,\beta), \qquad \text{(A48)}$$

and the lemma is proved. ■

Upper limit on the critical strength of central potentials in relativistic quantum mechanics

Fabian Brau[a)]
Groupe de Physique Nucléaire Théorique, Académie Universitaire Wallonie-Bruxelles, Université de Mons-Hainaut, B-7000 Mons, Belgium

(Received 20 September 2004; accepted 8 November 2004; published online 16 February 2005)

In the context of relativistic quantum mechanics, where the Schrödinger equation is replaced by the spinless Salpeter equation, we show how to construct a large class of upper limits on the critical value, $g_c^{(\ell)}$, of the coupling constant, g, of the central potential, $V(r)=-gv(r)$. This critical value is the value of g for which a first ℓ-wave bound state appears. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.1850997]

I. INTRODUCTION

A covariant description of bound states of two particles is achieved with the Bethe–Salpeter equation.[1] This equation reduces to the spinless Salpeter equation[2] when the following approximations are performed:

(i) elimination of any dependences on timelike variables (which leads to the Salpeter equation[3]),
(ii) any references to the spin degrees of freedom of particles are neglected as well as negative energy solutions.

The spinless Salpeter equation takes the form ($\hbar=c=1$)

$$[\sqrt{\mathbf{p}^2+m^2}+V(\mathbf{r})]\Psi(\mathbf{r})=M\Psi(\mathbf{r}), \tag{1}$$

where m is the mass of the particle and M is the mass of the eigenstate ($M=m+E$, E is the binding energy). We restrict our attention to interactions which are introduced in the free equation through the substitution $M\rightarrow M-V(\mathbf{r})$, where $V(\mathbf{r})$ is the time component of a relativistic four-vector. The interaction could also, in principle, be introduced through the substitution $\mathbf{p}\rightarrow\mathbf{p}-\mathbf{A}(\mathbf{r})$, where $\mathbf{A}(\mathbf{r})$ is the spatial component of a relativistic four-vector. However we do not consider this kind of potential since the derivation of the spinless Salpeter equation from the Bethe–Salpeter equation leads to $\mathbf{A}(\mathbf{r})=0$. Equation (1) is generally used when kinetic relativistic effects cannot be neglected and when the particles under consideration are bosons or when the spin of the particles is neglected or is only taken into account via spin-dependent interactions. Despite its apparent complexity, this equation is often preferred to the Klein–Gordon equation. Equation (1) appears, for example, in mesons and baryons spectroscopy in the context of potential models (see, for example, Refs. 4–8). [For a review of several aspects of the "semirelativistic" description of bound states with the spinless Salpeter equation see W. Lucha and F. F. Schöberl, Int. J. Mod. Phys. A **14**, 2309 (1999), and references therein.]

Due to the pseudodifferential nature of the kinetic energy operator, few exact results are known about this equation. Most of these results have been obtained for a Coulomb potential (for example, upper and lower bounds on energy levels).[9–13] Recently, upper and lower limits on energy levels have also been obtained for some other particular interactions.[14–17]

[a)]Electronic mail: fabian.brau@umh.ac.be

Conversely to the Schrödinger equation, for which a fairly large number of results giving both upper and lower limits on the number of bound states can be found in the literature (see, for example, Refs. 18–27), only two results are known for the spinless Salpeter equation.[28,29] The first result, obtained in Ref. 28, is an upper bound on the total number of bound states yielding a lower limit on the critical value, $g_c^{(0)}$, of the coupling constant (strength), g, for which a first S-wave ($\ell=0$) bound state appears (ℓ being obviously the angular momentum) in the potential $V(r)=-gv(r)$. The second results, obtained in Ref. 29, is an upper limit on the number of ℓ-wave bound states which yields a lower limit on the critical value, $g_c^{(\ell)}$ for which a first ℓ-wave bound state appears.

In this paper, we obtain accurate upper limits on the critical strength $g_c^{(\ell)}$ applicable to attractive (purely negative) central potentials which are less singular than $-r^{-1}$ at the origin. This limitation has a deep reason. Indeed, it is known that for the spinless Salpeter equation, a potential which behaves like $-r^{-1}$ at the origin is characterized by a maximal value of the coupling constant above which the spectrum is no longer bounded from below. This particularity has been studied in detail for the Coulomb potential (see, for example, Ref. 9). The $-r^{-1}$ singularity is a critical singularity for the spinless Salpeter equation just as the $-r^{-2}$ singularity is a critical singularity for the Schrödinger equation. So in this paper we discard this class of potentials which should be treated separately. Moreover we suppose that the central potential $V(r)$ is piecewise continuous for $r\in]0,\infty[$. The upper limits on $g_c^{(\ell)}$ we obtain in Sec. II are compared with the exact critical value obtained numerically for some test potentials. These comparisons indicate that the new upper limits are very restrictive. Some conclusions are presented in Sec. III.

II. UPPER LIMIT ON THE CRITICAL STRENGTH

The idea used to derive the upper limit on $g_c^{(\ell)}$ is to transform the standard eigenvalue problem obtained with the time independent spinless Salpeter equation (1), and where the eigenvalues are the eigenenergies, into an eigenvalue problem where the eigenvalues are the critical coupling constants. These critical values of the strength of the potential correspond to the occurrence of an eigenstate with a vanishing binding energy. We thus consider the zero binding energy spinless Salpeter equation that we need to write as an integral equation. This has been done in Ref. 29 but since we need some modifications in the development, we recall the main line here.

We must calculate the Green function of the kinetic energy operator. Similar calculations have also already been performed previously.[30,31] In contrast to results found in Ref. 31, we need here to calculate the Green functionof the following operator:

$$T(\mathbf{p}^2)=\sqrt{\mathbf{p}^2+m^2}-m. \tag{2}$$

This is done by performing the integral

$$G(m,\Delta)=\frac{1}{(2\pi)^3}\int \mathrm{d}\mathbf{p}\frac{\exp(-i\mathbf{p}\cdot\boldsymbol{\Delta})}{\sqrt{p^2+m^2}-m}, \tag{3}$$

where $\boldsymbol{\Delta}=\mathbf{r}-\mathbf{r}'$ and $\Delta=|\boldsymbol{\Delta}|$. We find that

$$G(m,\Delta)=\frac{m}{4\pi\Delta}\left[1+\frac{2}{\pi}F(m\Delta)\right]\equiv\frac{m}{4\pi\Delta}H(m\Delta), \tag{4a}$$

with

$$F(y)=\int_y^\infty\frac{\mathrm{d}z}{z}K_1(z)+\frac{\pi}{2}=K_1(y)+\frac{\pi}{2}-\int_y^\infty \mathrm{d}z\,K_0(z), \tag{4b}$$

and where $K_\nu(y)$ is a modified Bessel function (see, for example, Ref. 32, p. 374). The zero binding energy spinless Salpeter equation takes thus the form of the following integral equation:

$$\Psi(\mathbf{r}) = -\int \mathrm{d}\mathbf{r}'\, G(m,\Delta)V(\mathbf{r}')\Psi(\mathbf{r}'), \tag{5}$$

with $G(m,\Delta)$ given by (4). We now restrict our attention to central potentials $V(\mathbf{r})=V(r)$, with $r=|\mathbf{r}|$.

Integration over angular variables reduces the integral equation (5) to the following one-dimensional integral equation

$$u_\ell(r) = -\int_0^\infty \mathrm{d}r'\, G_\ell(m,r,r')V(r')u_\ell(r'), \tag{6a}$$

with

$$G_\ell(m,r,r') = \frac{mrr'}{2}\int_0^\pi \mathrm{d}\theta'\, \sin\theta' \frac{H(m\Delta)}{\Delta} P_\ell(\cos\theta'), \tag{6b}$$

where $u_\ell(r)$ is the radial wave function, $\Psi(\mathbf{r})=(u_\ell(r)/r)Y_{\ell m}(\hat{\mathbf{r}})$ and where $H(x)$ is defined by (4a).

An important technical difficulty, to obtain a symmetrical kernel, appears if the potential possesses some change of sign [see relation (7) below]. This is overcome when one searches for necessary conditions, or upper bound on the number of bound states, by replacing the potential by its negative part $V(r)\to V^-(r)=-\max(0,-V(r))$. Indeed, the potential $V^-(r)$ is more attractive than $V(r)$ and thus a necessary condition for existence of bound states in $V^-(r)$ is certainly a valid necessary condition for $V(r)$. This procedure can no longer be used to obtain sufficient conditions. For this reason we consider potentials that are nowhere positive, $V(r)=-gv(r)$, with $v(r)\geqslant 0$.

The integral equation (6) can be written with a symmetrical kernel provided we introduce a new wave function

$$\phi_\ell(r) = |V(r)|^{1/2}u_\ell(r). \tag{7}$$

This change of function leads to the following integral equation:

$$\phi_\ell(r) = g\int_0^\infty \mathrm{d}r' K_\ell(m,r,r')\phi_\ell(r'), \tag{8a}$$

with

$$K_\ell(m,r,r') = v(r)^{1/2}G_\ell(m,r,r')v(r')^{1/2}. \tag{8b}$$

The relation (8) is thus an eigenvalue problem and, for each value of ℓ, the smallest characteristic number is just the critical value $g_c^{(\ell)}$. The other characteristic numbers correspond to the critical values of the strength of the potential for which a second, a third,…, ℓ-wave bound state appears. The kernel (8b) acting on the Hilbert space $L^2(\mathbb{R})$ is an Hilbert–Schmidt operator for potentials which decrease faster than r^{-1} at infinity. Thus this kernel satisfies the inequality

$$\int_0^\infty \int_0^\infty \mathrm{d}x\, \mathrm{d}y\, K_\ell(x,y)K_\ell(x,y) < \infty. \tag{9}$$

Consequently the eigenvalue problem (8) always possesses at least one characteristic number (Ref. 33, pp. 102–106) (in general, this problem has an infinity of characteristic numbers).

Now we use the theorem (see, for example, Ref. 33, pp. 118–119) which states that, for a symmetric Hilbert–Schmidt kernel, we have the variational principle

$$\max_{\varphi}\left|\int_0^\infty \mathrm{d}x\,\mathrm{d}y\,K_\ell(x,y)\varphi(x)\varphi(y)\right| = \frac{1}{|g_1|}, \tag{10}$$

for $\varphi(r)$ satisfying

$$\int_0^\infty \mathrm{d}r\,\varphi(r)^2 = 1. \tag{11}$$

The maximal value is reached for $\varphi(x)=\varphi_1(x)$, where $\varphi_1(x)$ is the eigenfunction associated to the smallest eigenvalue g_1. Consequently, for an arbitrary normalized function, $f(x)$, we obtain the following upper limit on g_1:

$$|g_1| \leqslant \left|\int_0^\infty \mathrm{d}x\,\mathrm{d}y\,K_\ell(x,y)f(x)f(y)\right|^{-1}. \tag{12}$$

For the clarity of the discussion we now consider in two separate sections the ultrarelativistic regime ($m=0$) and the relativistic regime ($m>0$).

A. Ultrarelativistic regime $m=0$

In this section, we derive an (among others) upper limit on the critical value, $g_c^{(\ell)}$, of the coupling constant, g, of the potential, $V(r)=-gv(r)$, for which a first ℓ-wave bound state appears in the ultrarelativistic regime ($m=0$). In this limit, the kernel takes a simple form since $mK_1(my)=1/y$ when m goes to zero. This implies that

$$\lim_{m\to 0} mH(m\Delta) = \frac{2}{\pi\Delta}. \tag{13}$$

The function $G_\ell(0,r,r')$ takes then the form

$$G_\ell(0,r,r') = \frac{rr'}{\pi}\int_0^\pi \mathrm{d}\theta' \frac{\sin\theta'}{\Delta^2}P_\ell(\cos\theta'). \tag{14}$$

A simple change of variable leads to (Ref. 32, p. 335)

$$G_\ell(0,r,r') = \frac{1}{2\pi}\int_{-1}^{1}\mathrm{d}y\frac{P_\ell(y)}{(r^2+r'^2)/(2rr')-y} = \frac{1}{\pi}Q_\ell\left(\frac{r^2+r'^2}{2rr'}\right), \tag{15}$$

where the function $Q_\ell(x)$ is a Legendre function of the second kind. The function $G_\ell(0,r,r')$ can thus be evaluated explicitly for each value of the angular momentum ℓ. We have, for example,

$$G_0(0,r,r') = \frac{1}{\pi}\ln\left|\frac{r+r'}{r-r'}\right| \tag{16}$$

and

$$G_1(0,r,r') = \frac{1}{\pi}\left[\frac{r^2+r'^2}{2rr'}\ln\left|\frac{r+r'}{r-r'}\right| - 1\right]. \tag{17}$$

Since the function $G_\ell(0,r,r')$ is given by the relation (15), it follows that the kernel $K_\ell(0,r,r')$, see (8b), is known for each value of ℓ. Now, we just need to choose a suitable normalized function $f(r)$ to apply the variational principle reported above.

For simplicity we restrict the rest of the following discussion to $\ell=0$ but extensions to nonvanishing values of the angular momentum is obvious, one just needs to compute the corresponding expression of the function $G_\ell(0,r,r')$.

TABLE I. Comparison, for some typical potentials, between the exact critical values, $g_c^{(0)}$, the upper limits $g_{\mathrm{up},1}^{m=0}$ (19), $g_{\mathrm{up},2}^{m=0}$ (21) and the lower limits obtained in Refs. 28 and 29.

$v(x)$	Reference 29	Reference 28	$g_c^{(0)}$	$g_{\mathrm{up},1}^{m=0}$	$g_{\mathrm{up},2}^{m=0}$
$\exp(-x)$	4.443	4.370	5.574	5.584	7.411
$[\cosh(x)]^{-2}$	4.126	3.886	5.008	5.018	6.769
$\exp(-x^2)$	4.513	4.169	5.426	5.442	7.399
$x\exp(-x)$	3.696	3.349	4.360	4.364	5.964

The function $f(r)$ should be as close as possible to the zero binding energy wave function but also should be general and simple enough to obtain a neat formula. We simply choose

$$f(r) = A[r^{p-1}v(r)^p]^{1/2}, \quad p > 0, \tag{18}$$

where A is the normalization factor. The relations (8b), (12), (16), and (18) lead to the following upper limit on $g_c^{(0)}$:

$$g_c^{(0)} \leqslant \frac{\alpha\pi\int_0^\infty \mathrm{d}x\, F_1(2p-1;x)}{2\int_0^\infty \mathrm{d}x\, F_1(p;x)\int_0^x \mathrm{d}y\, F_1(p;y)\ln\left(\frac{x+y}{x-y}\right)} \equiv g_{\mathrm{up},1}^{m=0}, \tag{19}$$

where $F_1(q;x)=x^{(q-1)/2}v(x)^{(q+1)/2}$ and where we have introduced the parameter α which takes the value 1, respectively, 2 for one, respectively, two (identical) particle problems. The most stringent upper limit is obviously obtained by minimizing the right-hand side of (19) with respect to all positive values of p.

A simpler, but less stringent, version of this upper limit can be obtained with the help of the following minorization:

$$\ln\left(\frac{x+y}{x-y}\right) \geqslant \frac{2y}{x}, \tag{20}$$

$$g_c^{(0)} \leqslant \frac{\alpha\pi\int_0^\infty \mathrm{d}x\, F_1(2p-1;x)}{4\int_0^\infty \mathrm{d}x\, x^{-1}F_1(p;x)\int_0^x \mathrm{d}y\, yF_1(p;y)} \equiv g_{\mathrm{up},2}^{m=0}. \tag{21}$$

The accuracy of these upper limits can be tested with some typical potentials. The comparison between the exact results (obtained by solving numerically the spinless Salpeter equation) and the upper limits (19) and (21) is reported in Table I. We have also added two lower limits on $g_c^{(0)}$ obtained with the upper limits on the number of bound states derived in Refs. 28 and 29. Note that for these tests, we choose a two identical particles problem, $\alpha=2$.

The results reported in Table I indicate clearly that the accuracy of the upper limit (19) is quite remarkable. The upper limit (21) is obviously less stringent but could prove to be useful to obtain explicit formulas. The typical value of p which optimize these upper limits varies between 2 and 3. We do not consider other choices for $f(r)$ [see (18)] here since the relation (19) is already very accurate.

As an additional indication that the upper limits obtained with the method proposed in this work are quite accurate, we report in Table II a comparison between the exact value of the critical strength $g_c^{(1)}$ ($\ell=1$) and the corresponding upper limit obtained with the relations (12), (17), and (18) and noted $g_{\mathrm{up}}^{m=0,\ell=1}$ in this table.

TABLE II. Comparison, for some typical potentials, between the exact critical values, $g_c^{(1)}$ and the upper limit $g_{\text{up}}^{m=0,l=1}$ obtained with the relations (12), (17), and (18).

$v(x)$	$g_c^{(1)}$	$g_{\text{up}}^{m=0,l=1}$
$\exp(-x)$	10.975	10.992
$[\cosh(x)]^{-2}$	8.1174	8.1268
$\exp(-x^2)$	10.200	10.231
$x\exp(-x)$	9.5442	9.5636

B. Relativistic regime $m>0$

To obtain an upper limit on $g_c^{(\ell)}$ for a nonvanishing mass m, we need to calculate the expression of the function $G_\ell(m,r,r')$. To this end we note that

$$K_1(y) \leqslant F(y) \leqslant K_1(y) + \frac{\pi}{2}. \tag{22}$$

From the relation (12), it is obvious that a minorization of the kernel $K_\ell(m,r,r')$ is enough to obtain the upper limit. However, the minorization (22) of the function $F(y)$ is too crude to obtain good results. Instead we use

$$F(y) \geqslant K_1(y) + \frac{\pi}{2} - \frac{\pi}{2}\exp(-y). \tag{23}$$

This minorization (23) is proved in the Appendix. From the definition of $G_\ell(m,r,r')$ (6b) and the inequality (23) we obtain

$$G_\ell(m,r,r') \geqslant \frac{1}{\pi}\mathcal{G}_\ell(m,r,r') + \mathcal{S}_\ell(m,r,r') - \frac{1}{2}\mathcal{T}_\ell(m,r,r'), \tag{24}$$

where

$$\mathcal{G}_\ell(m,r,r') = m\int_{|r-r'|}^{r+r'} \mathrm{d}y\, K_1(my) P_\ell\left(\frac{r^2+r'^2-y^2}{2rr'}\right), \tag{25}$$

$$\mathcal{S}_\ell(m,r,r') = m\int_{|r-r'|}^{r+r'} \mathrm{d}y\, P_\ell\left(\frac{r^2+r'^2-y^2}{2rr'}\right) = \frac{2m}{2\ell+1} r_<^{\ell+1} r_>^{-\ell}, \tag{26}$$

with $r_< = \min[r,r']$ and $r_> = \max[r,r']$ and Ref. 34,

$$\begin{aligned}\mathcal{T}_\ell(m,r,r') &= mrr'\int_{-1}^{1} \mathrm{d}y \frac{\exp(-m\sqrt{r^2+r'^2-2rr'y})}{\sqrt{r^2+r'^2-2rr'y}} P_\ell(y) \\ &= \sqrt{\frac{2}{\pi}} m^2 rr' \int_{-1}^{1} \mathrm{d}y \frac{K_{1/2}(-m\sqrt{r^2+r'^2-2rr'y})}{[m^2(r^2+r'^2-2rr'y)]^{1/4}} P_\ell(y) \\ &= 2m\sqrt{rr'} K_{\ell+1/2}(mr_>) I_{\ell+1/2}(mr_<),\end{aligned} \tag{27}$$

where $I_\nu(x)$ is a modified Bessel function (see, for example, Ref. 32, p. 374). The kernel $\mathcal{S}_\ell(m,r,r')$ is actually the Green function of the nonrelativistic kinetic energy operator and takes a simple form while the kernel $\mathcal{G}_\ell(m,r,r')$ can be calculated analytically for each value of ℓ.[30,31] We find, for example,

TABLE III. Comparison, for some typical potentials, between the exact critical values, $g_c^{(0)}$ and the upper limit $g_{\rm up}^{m>0}$ (31).

$v(x)$	$\exp(-x)$		$[\cosh(x)]^{-2}$		$\exp(-x^2)$	
β	$g_c^{(0)}$	$g_{\rm up}^{m>0}$	$g_c^{(0)}$	$g_{\rm up}^{m>0}$	$g_c^{(0)}$	$g_{\rm up}^{m>0}$
0.1	4.694	5.390	4.461	4.994	4.927	5.363
0.5	2.387	2.547	2.766	3.006	3.309	3.589
1	1.361	1.407	1.742	1.843	2.198	2.352
2	0.7133	0.7206	0.9598	0.9862	1.257	1.307
3	0.4804	0.4817	0.6549	0.6642	0.8669	0.8880
4	0.3607	0.3615	0.4956	0.4994	0.6589	0.6694
5	0.2890	0.2893	0.3981	0.3999	0.5305	0.5364

$$\mathcal{G}_0(m,r,r') = K_0(m|r-r'|) - K_0(m(r+r')), \tag{28}$$

$$\mathcal{G}_1(m,r,r') = K_0(m|r-r'|) + K_0(m(r+r')) + \frac{1}{mrr'}[(r+r')K_1(m(r+r')) - |r-r'|K_1(m|r-r'|)]. \tag{29}$$

Now, we just need to choose a suitable normalized function $f(r)$ to apply the variational principle reported above [see (12)]. We take the following expression for $f(r)$:

$$f(r) = A[r^{2p-1}v(r)^p]^{1/2}, \quad p > 0. \tag{30}$$

For simplicity we again restrict the rest of the following discussion to $\ell = 0$ but extensions to nonvanishing values of the angular momentum is obvious, one just needs to compute the corresponding expression of the function $G_\ell(m,r,r')$.

The relations (8b), (12), (18), and (28) lead to the following upper limit on $g_c^{(0)}$:

$$g_c^{(0)} \leqslant \frac{\alpha \int_0^\infty \mathrm{d}x \sqrt{x} F_2(2p-1;x)}{2\int_0^\infty \mathrm{d}x\, F_2(p;x) \int_0^x \mathrm{d}y\, F_2(p,y) T(x,y)} \equiv g_{\rm up}^{m>0}, \tag{31a}$$

with

$$T(x,y) = \frac{1}{\pi}[K_0(\beta(x-y)) - K_0(\beta(x+y))] + 2\beta y + \frac{1}{2}[\exp(-\beta(x+y)) - \exp(-\beta(x-y))], \tag{31b}$$

where $F_2(q,x) = x^{q-1/2}v(x)^{(q+1)/2}$ and where $\beta = mR$, R being the scale of length which appears in the potential $[v(r) = v(Rx)]$. Again, we have introduced in (31a) the parameter α which takes the value 1, respectively, 2 for one, respectively, two (identical) particle problems.

The accuracy of this upper limit can be tested with some typical potentials. The comparison between the exact results and the upper limit (31) is reported in Table III. Note that for these tests, we also choose a two identical particles problem, $\alpha = 2$.

The results reported in Table III indicate clearly that the accuracy of the upper limit (31) is quite good. But for a small value of β the upper limit is however less restrictive. Thus for a small value of β it is preferable to use an intermediate form for $f(r)$. We then propose in general to use

$$f(r) = A[r^{ap-1}v(r)^p]^{1/2}, \quad p > 0, \tag{32}$$

with $1 \leqslant a \leqslant 2$. This last expression for $f(r)$ improves significantly the restriction on the possible values of $g_c^{(0)}$. Indeed, for $\beta = 0.1$, $a = 1.18$ and for the exponential potential, the upper limit is then equal to 4.812 instead of 5.390. But this additional flexibility is only significant for a small value of β, indeed for $\beta = 0.5$ the best upper limit is found to be equal to 2.521 (for the exponential potential and $a = 1.69$) instead of 2.547.

However, even with the choice (32) for $f(r)$, the upper limit (31) still yields less restrictive results for small β than those obtained for larger values of β or those obtained with the upper limit (19). This is easy to understand, since this is in the sector of small β, that the error introduced by the inequality (23) is the most important. Indeed, in the limit of β going to zero, the upper limit (31) coincides with the upper limit (19) and for β going to infinity, only the nonrelativistic kernel $\mathcal{S}_\ell(m, r, r')$ contributes.

III. CONCLUSIONS

In this paper we have shown how to construct upper limits on the critical value, $g_c^{(\ell)}$, of the coupling constant, g, of a central potential, $V(r) = -gv(r)$. The method used to derive the upper limits is quite general and other (possibly more complicated) families of upper limits yielding (possibly) stronger restrictions on $g_c^{(\ell)}$ could also be obtained. Indeed, the method is based on a variational principle for which a trial zero energy wave function is needed. There is no limitation on the accuracy of such a trial function, which imply that there is, in principle, no limitation on the accuracy of the upper limit on $g_c^{(\ell)}$ derived with this procedure. However, this remark is only true for the ultrarelativistic regime, $m = 0$, where the kernel of the integral equation has been calculated exactly. For $m > 0$, a minorization of the kernel has been used yielding some errors in the restrictions on the possible values of the critical value $g_c^{(\ell)}$ which cannot be compensated by a better choice of the trial zero energy wave function. In this paper we have proposed in Sec. II a compromise between accuracy and simplicity of the final formula. The accuracy of the upper limits on $g_c^{(\ell)}$ was then tested with some typical potentials.

APPENDIX: MAJORIZATION OF THE PRIMITIVE OF $K_0(x)$

We choose the following integral representation for the modified Bessel function $K_0(x)$ (Ref. 32, p. 376):

$$K_0(x) = \int_0^\infty \mathrm{d}t \exp(-\, x \cosh t). \tag{A1}$$

We have

$$\int_y^\infty \mathrm{d}x\, K_0(x) = \int_0^\infty \mathrm{d}t \frac{\exp(-\, y \cosh t)}{\cosh t} \leqslant \exp(-\, y) \int_0^\infty \mathrm{d}t \frac{1}{\cosh t} = \frac{\pi}{2} \exp(-\, y). \tag{A2}$$

We express the equations of motion of unoriented membranes with the help of Jordan algebras. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1857032]

I. INTRODUCTION

The proposal of the matrix theory as a fundamental theory of physics[1] and its connection with the supermembrane theory[2] gave a strong impetus to the study of noncommutative space-time models. The starting point of these investigations is often the correspondence between the Poisson algebra of functions on the surface of the membrane and the associative algebra of the regularized matrix coordinates. Nevertheless, there are models where even the assumption of the associativity of the space-time coordinates is dropped. We demonstrate that the nonassociative Jordan algebras can be used to describe the motion of the bosonic membrane. In contrast to the case of Poisson algebras, our construction does not require orientable surfaces, so it can describe nonorientable surfaces, too. Let us note that Jordan algebras were used for example in string theory[3] and matrix string theory.[4]

In Sec. II we briefly review the matrix theory—membrane correspondence—while Sec. III contains the Jordan algebraic reformulation of this theory.

II. A SHORT REVIEW OF THE ORIENTED MEMBRANE

The classical equation of motion of a membrane is derived from the action

$$S = -T \int d^3\sigma \sqrt{-\det \partial_\alpha X^\mu \partial_\beta X_\mu}, \tag{2.1}$$

where the $X^\mu(\sigma_0,\sigma_1,\sigma_2)$ coordinates describe the embedding of the membrane's world volume into the ambient Minkowski space. The Hamiltonian equations of motion in the light-front coordinates are generated by the Hamiltonian

$$H = \frac{\nu T}{4} \int d^2\sigma \left(\dot{X}^i \dot{X}^i + \frac{2}{\nu^2} \{X^i, X^j\}\{X^i, X^j\} \right) \tag{2.2}$$

and the supplementary constraint

$$\{\dot{X}^i, X^i\} = 0. \tag{2.3}$$

The equation of motion is

a)Electronic mail: varga@math.klte.hu

$$\ddot{X}^i = \frac{4}{\nu^2}\{\{X^i, X^j\}, X^j\}. \tag{2.4}$$

(For references, explanation of notation, and further review of this topic we refer to Ref. 5.)

In the regularization procedure of Hoppe,[6] the X^i coordinate functions are replaced by finite size matrices, Poisson brackets by matrix commutators, and the integration over the membrane's surface by suitably normalized traces. The regularized Hamiltonian and the equations of motion are

$$H = \frac{1}{2\pi l_p^3}\,\mathrm{Tr}\left(\frac{1}{2}\dot{\mathbb{X}}^i\dot{\mathbb{X}}^i - \frac{1}{4}[\mathbb{X}^i,\mathbb{X}^j][\mathbb{X}^i,\mathbb{X}^j]\right),$$
$$\ddot{\mathbb{X}}^i + [[\dot{\mathbb{X}}^i,\dot{\mathbb{X}}^j],\dot{\mathbb{X}}^j] = 0, \quad [\dot{\mathbb{X}}^i,\mathbb{X}^i] = 0, \tag{2.5}$$

where the $\mathbb{X}^i$ coordinates are now Hermitian matrices.

This reformulation requires orientable surfaces. Nevertheless, this procedure can be extended to nonorientable surfaces, too.[7] Indeed a nonorientable surface has an orientable double cover (the orientation bundle). Inside the Poisson algebra of the functions of the double cover, one can identify the sub-Lie-algebra of those functions, which generate the area-preserving transformations of the nonorientable surface.[8,9] On $\mathbb{RP}^2$ one obtains the $USp(N)$ Lie algebra.

III. THE UNORIENTED MEMBRANE

The surface of the membrane has no intrinsic orientation. Indeed, the Hamiltonian (2.2) is invariant against the flip of the sign of the symplectic form ω of the Poisson bracket. This fact suggests that it might be possible to rewrite the expressions (2.2) and (2.3) with no reference to the sign of ω. Since the correspondence between (2.2) and (2.3) uses the replacement of the commutative algebra of the X^i functions by the noncommutative $\mathbb{X}^i$ matrices via deformation quantization, it is quite reasonable to search for a deformed algebraic structure that does not depend on the sign of ω. Let us recall that on $\mathbb{R}^2$ with $\omega = dx \wedge dy$ the deformed Moyal products look like

$$f *_h g = fg + \frac{ih}{2}(f_x g_y - f_y g_x) + \frac{h^2}{8}\left[f_{xy}g_{xy} - \frac{1}{2}(f_{xx}g_{yy} + f_{yy}g_{xx})\right] + \cdots . \tag{3.1}$$

The second-order term is symmetric with respect to the exchange of the x and y variables, so it makes no reference to the orientation of the surface. Exactly this term is the first nontrivial term in the Jordan product of f and g

$$f \circ_h g = \frac{1}{2}(f *_h g - g *_h f) = fg + \frac{h^2}{8}\left[f_{xy}g_{xy} - \frac{1}{2}(f_{xx}g_{yy} + f_{yy}g_{xx})\right] + \cdots , \tag{3.2}$$

so we try to rewrite (2.3) and (2.4) with the help of anticommutators (Jordan products) instead of commutators.

The Hamiltonian can be rewritten using the following calculation:

$$\mathrm{Tr}([\mathbb{X},\mathbb{Y}][\mathbb{X},\mathbb{Y}]) = 2\ \mathrm{Tr}(\mathbb{X}\mathbb{Y})^2 - 2\ \mathrm{Tr}(\mathbb{X}^2\mathbb{Y}^2),$$
$$\mathrm{Tr}(\mathbb{X}\circ\mathbb{X})\circ(\mathbb{Y}\circ\mathbb{Y}) = \mathrm{Tr}(\mathbb{X}^2\mathbb{Y}^2), \tag{3.3}$$
$$\mathrm{Tr}\{\mathbb{X}\circ[\mathbb{Y}\circ(\mathbb{X}\circ\mathbb{Y})]\} = \frac{1}{2}\ \mathrm{Tr}(\mathbb{X}\mathbb{Y})^2 + \frac{1}{2}\ \mathrm{Tr}(\mathbb{X}^2\mathbb{Y}^2)$$

[here $\circ$ is the usual Jordan product of matrices $\mathbb{X}\circ\mathbb{Y} = (\mathbb{X}\mathbb{Y} + \mathbb{Y}\mathbb{X})/2$].

Consequently,

$$H = \frac{1}{2\pi l_p^3}\,\mathrm{Tr}\left(\frac{1}{2}\dot{\mathbb{X}}^i \circ \dot{\mathbb{X}}^i - \mathbb{X}^i \circ (\mathbb{X}^j \circ (\mathbb{X}^i \circ \mathbb{X}^j)) + (\mathbb{X}^i \circ \mathbb{X}^i) \circ (\mathbb{X}^j \circ \mathbb{X}^j)\right). \tag{3.4}$$

The accelerations $\ddot{\mathbb{X}}^i$ of the matrix coordinates are given by double commutators (2.4), so it can be expressed by with the help of the associator of the Jordan algebra

$$(\mathbb{X},\mathbb{Y},\mathbb{Z}) = (\mathbb{X}\circ\mathbb{Y})\circ\mathbb{Z} - \mathbb{X}\circ(\mathbb{Y}\circ\mathbb{Z}) = \frac{1}{4}[\mathbb{Y},[\mathbb{X},\mathbb{Z}]], \tag{3.5}$$

whose identity gives the following equation of motion:

$$\ddot{\mathbb{X}}^i = 4(\mathbb{X}^i,\mathbb{X}^j,\mathbb{X}^j) = [\mathbb{X}^j,[\mathbb{X}^i,\mathbb{X}^j]]. \tag{3.6}$$

The substitution of double commutators by associators occurs in almost all papers on the Jordan algebraic reformulation of quantum mechanics. Our next task is to express the constraints $[\dot{\mathbb{X}}^i,\mathbb{X}^i]=0$ with the Jordan product of matrices. This is obviously impossible directly. The best we can do is to require that

$$4(\dot{\mathbb{X}}^i,\mathbb{U},\mathbb{X}^i) = [\mathbb{U},[\dot{\mathbb{X}}^i,\mathbb{X}^i]] = 0 \tag{3.7}$$

for any matrix $\mathbb{U}$. Since only the multiples of the identity matrix commute with all the other matrices, this equation implies that $[\dot{\mathbb{X}}^i,\mathbb{X}^i]=c\cdot\mathbb{1}$, but it is well known that this is impossible for finite size matrices (by taking the trace of both sides).

So we managed to rewrite the Eqs. (2.3) and (2.4) in a Jordan algebraic language. Since these equations are only finite dimensional approximations of the continuous equation (2.2), we expect that a similar procedure can be repeated for (2.2), at least up to the leading orders of a deformation parameter. For this purpose, we would like to express $\int d\sigma^2\{f,g\}^2$ with the help of the Jordan multiplication $\circ_h$. This is possible in the sense that the following identity holds on $\mathbb{R}^2$:

$$\{f,g\}^2 = (f_x g_y - f_y g_x)^2 = -\frac{4}{h^2}[f\circ_h(g\circ_h(f\circ_h g)) - (f\circ_h f)\circ_h(g\circ_h g)] + O(h^2) + \alpha_x + \beta_y, \tag{3.8}$$

where the explicit forms of α and β are

$$\begin{aligned}\alpha &= f_x(fg_y^2 - 2f_y g g_y) + g_x(2f_y^2 g - f f_y g_y),\\ \beta &= f_y(fg_x^2 - 2f_x g g_x) + g_x(2f_x^2 g - f f_x g_x).\end{aligned} \tag{3.9}$$

The verification of these formulas consists of a fairly direct but quite long calculation, which can be easily performed by a symbolic algebra package. It is amusing to compare this to the simplicity of the matrix version (3.3) and (3.4) of these identities. Since the integral of the $\alpha_x+\beta_y$ term is zero if f and g have compact support (or the integration is done over a compact closed surface), (2.2) can be expressed with the help of the deformed Jordan multiplication up to terms of order $O(h^2)$.

Next we would like to see what sort of Jordan algebra can be associated to a nonorientable surface. We treat here only the simplest case of the real projective plane $\mathbb{RP}^2$, but we believe that the same conclusion would be true for the other nonorientable surfaces, too. (It was demonstrated in Ref. 10 that the Goldstone–Hoppe regularization procedure is applicable for higher genus orientable surfaces, too.)

Let us recall that the Goldstone–Hoppe construction on the unit sphere S^2 uses the correspondence

$$x_i \leftrightarrow \frac{2}{N} J_i, \quad \{x_i, x_j\} = \epsilon_{ijk} x_k, \quad -i[J_i, J_j] = \epsilon_{ijk} J_k, \tag{3.10}$$

where the $x_{1,2,3}$ are the three-dimensional coordinates of S^2 satisfying $x_1^2+x_2^2+x_3^2=1$, while $J_{1,2,3}$ are the Hermitian generators of the N-dimensional irreducible representation of $SU(2)$. As an algebra, these matrices generate $Mat_N(\mathbb{C})$, while as a (unital) Jordan algebra they generate the self-adjoint part of $Mat_N(\mathbb{C})$, which is denoted by $H_N(\mathbb{C})$. This is probably well known for Jordan algebrists, but with the help of the standard representation of $SU(2)$

$$N = 2j + 1, \quad J_3|m\rangle = m|m\rangle,$$

$$\begin{aligned} J_+|m\rangle &= \sqrt{j(j+1) - m(m+1)}|m\rangle, \\ J_-|m\rangle &= \sqrt{j(j+1) - m(m-1)}|m\rangle, \end{aligned} \tag{3.11}$$

$$J_1 = \frac{J_+ + J_-}{2}, \quad j_2 = \frac{J_+ - J_-}{2i},$$

this can be demonstrated quite explicitly. Let us denote by e_{ij} the matrix with zero entries except at $(e_{ij})_{ij}=1$. Then e_{ii} can be written as a suitable polynomial of J_3, since J_3 is diagonal with different diagonal entries. Furthermore,

$$\begin{aligned} (e_{ii} \circ J_1) \circ e_{i+1,i+1} &= \frac{1}{4}(J_1)_{i,i+1}(e_{i+1,i} + e_{i,i+1}), \\ (e_{ii} \circ J_2) \circ e_{i+1,i+1} &= \frac{1}{4}(J_1)_{i,i+1}(-ie_{i+1,i} + ie_{i,i+1}). \end{aligned} \tag{3.12}$$

The successive Jordan products of these types of matrices generate the whole of $H_N(\mathbb{C})$. (For example,

$$(e_{i+1,i} + e_{i,i+1}) \circ (-ie_{i+1,i+2} + ie_{i+2,i+1}) = \frac{1}{2}(-ie_{i,i+2} + ie_{i+2,i}), \tag{3.13}$$

etc.)

Now let us turn our attention to the case of $\mathbb{RP}^2$. This projective plane is the quotient of S^2 by the antipodal map $(x_1,x_2,x_3) \to (-x_1,-x_2,-x_3)$, so we would like to keep those elements of the Jordan algebra generated by $J_{1,2,3}$ that are invariant with respect to the substitution $J_{1,2,3} \to -J_{1,2,3}$. This part can be generated by the matrices $\{J_i \circ J_k;\ i,k=1,2,3\}$. We restrict ourself to the very simple case when N is odd, so J_i represents $SO(3)$. In this case J_i can be chosen to be purely imaginary and antisymmetric, so $J_i \circ J_k$ is a symmetric real matrix. The Jordan algebra generated by these matrices is formally real, i.e., $\Sigma_i a_i^2=0$ implies $a_i=0$. Such unital and finite dimensional Jordan algebras are direct sums of simple ones (p. 72).[11] If this direct sum were nontrivial, or the generated algebra were realized as a diagonal embedding of, for example, $H_{N/2}(\mathbb{R})$ into $H_N(\mathbb{R})$, that would implicate the existence of a nontrivial decomposition of the vector space $\mathbb{C}^N$ into the direct sum of vector spaces, with invariant factors with respect to the action of $SO(3)$ [since the linear span of the generating set $\{J_i \circ J_k,\ i,k=1,2,3\}$ is also invariant against $SO(3)$], but this would contradict to the irreducibility of the representation. So we conclude that the Matrix theoretic description of a membrane with topology of the real projective space requires the use of the Jordan algebra of real symmetric matrices. This result is in sharp contrast compared to the construction of Ref. 7, where the Lie algebra of $USp(N)$ was used, since the closest Jordan algebraic relative of $USp(N)$ is $H_N(\mathbb{H})$, i.e., the set of self-adjoint quaternionic matrices.

(Received 30 May 2004; accepted 20 October 2004; published online 9 February 2005)

A discretization of a continuum theory with constraints or conserved quantities is called *mimetic* if it mirrors the conserved laws or constraints of the continuum theory at the discrete level. Such discretizations have been found useful in continuum mechanics and in electromagnetism. We have recently introduced a new technique for discretizing constrained theories. The technique yields discretizations that are consistent, in the sense that the constraints and evolution equations can be solved simultaneously, but it cannot be considered mimetic since it achieves consistency by determining the Lagrange multipliers. In this paper we would like to show that when applied to general relativity linearized around a Minkowski background the technique yields a discretization that is mimetic in the traditional sense of the word. We show this using the traditional metric variables and also the Ashtekar new variables, but in the latter case we restrict ourselves to the Euclidean case. We also argue that there appear to exist conceptual difficulties to the construction of a mimetic formulation of the full Einstein equations, and suggest that the new discretization scheme can provide an alternative that is nevertheless close in spirit to the traditional mimetic formulations. [DOI: 10.1063/1.1841483]

I. INTRODUCTION

Continuum theories, either mechanical systems or field theories, usually have conservation laws and sometimes constraints. When one discretizes the equations of these theories, for instance in order to solve them numerically on a computer, or for "quantization on the lattice" purposes, the resulting discrete equations will usually fail to preserve the conserved quantities of the continuum theory upon evolution. Similar comments apply to constraints. Although one may have discrete equations resulting from discretizing the constraints of the continuum theory, if one chooses initial data that solve these equations exactly, they will fail to be solved upon discrete evolution.

Mimetic discretizations are discretizations of continuum theories that preserve conserved quantities or constraints in the discrete theory that mimic those of the continuum theory. There is quite a body of literature[1] on mimetic discretizations in the context of continuum mechanics and electromagnetism. The literature on Hamiltonian lattice QCD implicitly considers a mimetic discretization of Yang–Mills theory, although this fact is not usually emphasized.

Some authors have considered the question of whether mimetic discretizations of general relativity can be constructed.[2,3] It is well known that if one discretizes the Einstein equations, the Hamiltonian and momentum constraint, which should hold for all time if satisfied initially (ignoring for the moment the issue of spatial boundaries), fail to do so in the discrete theory. Although there has been success in generating mimetic formulations of linearized relativity, it appears unlikely that something similar will be available for the full theory (or even for the linearized

theory on nontrivial backgrounds or slicings). This is due to the fact that discretized derivatives fail to satisfy Leibnitz's rule and therefore the nonlinear terms when discretized do not have properties that mirror those of the continuum.[3]

We have recently introduced a new approach to the discretization of theories, particularly of theories with constraints[4,5] called "consistent discretization." The technique guarantees that the resulting discrete equations are compatible, i.e., they admit a common set of solutions (something that is not generically true if one discretizes the equations of a constrained theory). The technique has been tried out in the context of cosmological solutions of the Einstein equations,[6] of BF theory and of Maxwell and Yang–Mills theories on the lattice.[4] Current investigations are testing it for the Gowdy models.

In this paper we would like to show that the technique we proposed, when applied to the Einstein theory linearized around a Minkowski background yields a discrete formulation that is mimetic. That is, the discretized constraints are exactly preserved under evolution without determining the Lagrange multipliers. We first consider linearized general relativity in terms of the traditional metric variables. We then consider it in terms of Ashtekar's variables, which have the advantage of being closer to the discretizations used in Yang–Mills theories (although in this case we restrict ourselves to Euclidean general relativity).

In the consistent discretization scheme, equations are discretized with variables evaluated at two (or more) different levels in time. This includes the constraints of general relativity, which in the discrete theory therefore can only be viewed as "pseudo" constraints (we will reserve the word constraint for expressions that involve all variables evaluated at the same instant of time, as in traditional canonical terminology). These equations, with variables discretized at mixed instants of time are the equations that are solved by the consistent discretization scheme. Of course, if one is in a regime in which the time-step is small, then satisfying the pseudoconstraints implies that the usual discrete constraints (with all the variables at the same time-step) are approximately satisfied as well. Therefore the resulting scheme cannot be strictly called mimetic, although it approximately is. We will show that if one uses a discretization for general relativity that is mimetic in the linearized case, one further improves the accuracy with which the consistent scheme for the full nonlinear theory satisfies the constraints. This encourages further studies of these discretization schemes in the context of numerical applications.

In the next section we will present a brief summary of the consistent discretizations scheme. In the following two sections we apply it to linearized gravity, first with the traditional variables and then with the Ashtekar variables. We end with a discussion and proposals for further research.

II. CONSISTENT DISCRETIZATION OF CONSTRAINED THEORIES

We illustrate the technique with a mechanical system for simplicity, but there is no problem working it out for field theories, since upon discretization the latter become mechanical systems. We assume we start from an action in the continuum, written in first-order form,

$$S = \int L(q,p)\mathrm{d}t \tag{1}$$

with

$$L(q,p) = p\dot{q} - H(q,p) - \lambda\phi(q,p), \tag{2}$$

where λ is a Lagrange multiplier and the theory has a single (it is immediate to incorporate several) constraint $\phi(q,p)=0$. The discretization of the action yields $S=\Sigma_0^N L(n,n+1)$, where

$$L(n,n+1) = p_n(q_{n+1} - q_n) - \epsilon H(q_n,p_n) - \lambda_n\phi(q_n,p_n), \tag{3}$$

where $\epsilon=t_{n+1}-t_n$ and we have absorbed an ϵ in the definition of the Lagrange multipliers.

We will now view the Lagrangian as the generator of a type 1 canonical transformation between the instant n and the instant $n+1$. In ordinary classical mechanics parlance, given a

canonical transformation between a canonical pair q,p and a new canonical pair Q,P, the generating function of a type 1 canonical transformation is a function of q,Q, $F(q,Q)$ and the canonically conjugate momenta are defined by $P=\partial F/\partial Q$, $p=\partial F/\partial q$. In our case we will view q_n, p_n, λ_n and q_{n+1}, p_{n+1}, λ_{n+1} as "configuration variables" and will assign to each of them a canonically conjugate momentum through the canonical transformation,

$$P^q_{n+1}=\frac{\partial L(n,n+1)}{\partial q_{n+1}}, \tag{4}$$

$$P^p_{n+1}=\frac{\partial L(n,n+1)}{\partial p_{n+1}}, \tag{5}$$

$$P^\lambda_{n+1}=\frac{\partial L(n,n+1)}{\partial \lambda_{(n+1)}}, \tag{6}$$

$$P^q_n=-\frac{\partial L(n,n+1)}{\partial q_n}, \tag{7}$$

$$P^p_n=-\frac{\partial L(n,n+1)}{\partial p_n}, \tag{8}$$

$$P^\lambda_n=-\frac{\partial L(n,n+1)}{\partial \lambda_{(n)}}. \tag{9}$$

If one explicitly computes the partial derivatives with the Lagrangian given, one can eliminate the p, P^p, and P^λ to yield a more familiar-looking set of equations,

$$P^q_{n+1}-P^q_n=-\epsilon\frac{\partial H(q_n,P^q_{n+1})}{\partial q_n}-\lambda_{nB}\frac{\partial \phi^B(q_n,P^q_{n+1})}{\partial q_n},$$

$$q_{n+1}-q_n=\epsilon\frac{\partial H(q_n,P^q_{n+1})}{\partial P^q_{n+1}}+\lambda_{nB}\frac{\partial \phi^B(q_n,P^q_{n+1})}{\partial P^q_{n+1}}, \tag{10}$$

$$\phi^B(q_n,P^q_{n+1})=0.$$

These indeed look like a discrete version of equations for a system with constraints. However, there are important differences. First of all, notice that as an evolution system the equations are implicit. Second, if one solves the first two equations one obtains P^q and q as functions of the initial data and the Lagrange multipliers. The last equation however, will generically not hold. One will have to choose specific values for the Lagrange multipliers at each time-step (and if one is dealing with a field theory at each point in space) for all the equations to be solved.

Notice that there can be particular cases in which the system does not determine the Lagrange multipliers. For instance, consider a totally constrained system like general relativity. There the Hamiltonian vanishes. Suppose now that the constraint in (10) is only a function of q_n. Then the evolution equation for q_{n+1} implies that $q_{n+1}=q_n$ and the constraint is automatically preserved. Therefore the resulting formulation is mimetic in the traditional sense of the word, a constraint that is just the discrete version of the continuum constraint is preserved under evolution by the discrete evolution equations. A similar situation develops if the constraint is only a function of P^q.

If the Hamiltonian is nonvanishing, and the constraint depends only on P^q_{n+1} then the latter is not automatically preserved upon evolution, but it cannot be satisfied by choosing the Lagrange

multipliers either since they drop out from the relevant evolution equations. On the other hand, if the constraint is only a function of q_n, its preservation could be enforced by choosing the Lagrange multipliers (the asymmetry between P^q and q in this treatment comes from the fact that we chose to write the equations as "propagating forward" in time, if one had chosen to propagate backwards, the roles of q and P^q in this discussion would be reversed).

Summarizing, the consistent discretization technique consists of discretizing the action and working out the resulting equations of motion for the discrete theory from it through the canonical transformation that implements time evolution. The resulting evolution equations (and constraints) are made of a consistent set of nonlinear algebraic equations by considering the Lagrange multipliers as dynamical variables one must solve for. In particular situations, the Lagrange multipliers are not determined by the equations. In such cases the resulting set of equations and constraints must be consistent since it has been derived from a variational principle and the resulting discrete theory is mimetic in the traditional sense of the word, the constraints are automatically preserved upon evolution. In the other case, when the Lagrange multipliers are determined the resulting discrete theory is based on a consistent set of algebraic equations, but as one can see in Eq. (10), one is enforcing the constraints with some variables evaluated at instant n and some at instant $n+1$. For small step sizes, this implies that the constraints with all the variables evaluated at the same instant of time are approximately preserved. The resulting theory therefore cannot be called mimetic in the traditional sense of the word, although it can do a good job of preserving (approximately) the discrete constraints.

In the next two sections we apply this technique to linearized general relativity. We will see that the resulting theories do not determine the Lagrange multipliers, preserve the constraints automatically, and therefore are mimetic in the traditional sense of the word. We will not discuss the case of full general relativity here, but in several examples we have considered elsewhere for the nonlinear theory (cosmologies,[6] Gowdy space–times) the Lagrange multipliers are determined. Therefore it is unlikely that this method will yield a mimetic formulation for full GR. However, as we argued above, it will yield a formulation that approximates general relativity well in certain regimes and in such regimes the discrete constraints are enforced approximately very well. We believe it is likely that this is "as close as one will get" to a mimetic formulation of full general relativity.

III. LINEARIZED GENERAL RELATIVITY IN TERMS OF METRIC VARIABLES

In this section we will apply the technique we described in the preceding section to linearized general relativity written in terms of the traditional variables. We assume the background is the Minkowski metric.

A. Continuum formulation

We start with the Arnowitt, Deser, and Misner (ADM)[7] form of the action of general relativity,

$$S = \int \mathrm{d}^4x[\pi^{ab}\dot{q}_{ab} - NC - N_aC^a], \tag{11}$$

where

$$C = \frac{1}{\sqrt{q}}\left[\pi^{ab}\pi_{ab} - \frac{1}{2}(\pi^b_b)^2\right] - \sqrt{q}^{(3)}R, \tag{12}$$

$$C^a = -2\pi^{ab}_{;b}, \tag{13}$$

and the variables (q_{ab}, N, N_a) are related to the four dimensional metric ${}^{(4)}g_{\mu\nu}$ through,

$$q_{ab} = {}^{(4)}g_{ab}, \tag{14}$$

$$N = (-{}^{(4)}g_{00})^{-1/2}, \tag{15}$$

$$N_a = {}^{(4)}g_{0a}. \tag{16}$$

The indices a,b,c run from 1 to 3. $\sqrt{q}$ is the determinant of the spatial metric q_{ab} and ${}^{(3)}R$ is its Ricci curvature scalar. The momenta π^{ab} are related to the extrinsic curvature of the spacelike surfaces $x^0=t=$constant through $\pi^{ab}=-\sqrt{q}[K^{ab}-q^{ab}K^c_c]$ and indices are raised and lowered with the spatial metric. The semicolon denotes covariant differentiation with respect to the Christoffel connection of the spatial metric. Variation with respect to π^{ab},q_{ab},N,N_a yields the Einstein equations. In particular variation of N,N_a gives rise to four constraints $C=0,C^a=0$ usually referred to as (super-) Hamiltonian and momentum (or diffeomorphism) constraints.

We have chosen the ADM action since it is one of the most traditionally used in general relativity. Modern numerical implementations favor the use of formulations in which the evolution equations are manifestly symmetric-hyperbolic. This is not the case for the ADM equations. In principle there is no obstruction in applying our technique to any action, but it just is the case that there has been little investigation about formulating the symmetric-hyperbolic formulations as deriving from an action principle. This will require further study and therefore we decided to concentrate on this paper on the ADM action for simplicity.

We now consider that the space–time metric is given by a static background metric plus small perturbations ${}^{(4)}g_{\mu\nu}={}^{(4)}g^{(0)}_{\mu\nu}+h_{\mu\nu}$. For simplicity we make the further choice that the foliation is such that the zeroth order shift $N_a=0$ and the zeroth order extrinsic curvature is therefore zero $\pi^{ab}=0$. The constraint equations to leading order in the perturbations are given by[8]

$$C^a = -2p^{ab}{}_{;b}, \tag{17}$$

$$C = -\sqrt{q}[h_{ab}{}^{;ab} - h_{;a}{}^{;a} - h_{ab}{}^{(3)}R^{ab}]. \tag{18}$$

In these expressions p^{ab} is the linear portion of the canonical momentum π^{ab} and ${}^{(3)}R^{ab}$ is the Ricci tensor of the background metric. The action for the linearized theory is

$$S = \int \mathrm{d}^4x[p^{ab}\dot{h}_{ab} - N^{(0)}H - N^{(1)}_a C^a - N^{(1)}C], \tag{19}$$

where we have kept track of the order in the perturbation expansion of the lapse and the shift (recall that we assume zero shift in the background). The constraints C, C^a are given by the expressions above, where only terms up to order linear have been kept. The quantity

$$H = \frac{1}{\sqrt{q}}\left[p^{ab}p_{ab} - \frac{1}{2}p^2\right] + \frac{1}{2}\sqrt{q}\left[\frac{1}{2}h_{ab;c}h^{ab;c} - h_{ab;c}h^{ac;b} - \frac{1}{2}h_{;a}h^{;a} + 2h_{;a}h^{ab}{}_{;b} + hh^{ab}{}_{;ab} - hh_{ab}{}^{(3)}R^{ab}\right] \tag{20}$$

is a true Hamiltonian density (not a constraint) that is responsible for the evolution of the canonical variables, and is multiplied in the action times the lapse of the background space–time.

At this point we can make an important observation. The momentum constraint (17) is only a function of the momenta p^{ab} (the covariant derivative is with respect to the background metric) and the Hamiltonian constraint (18) is only a function of the configuration variables q^{ab}. Therefore, as we discussed in Sec. II, our discretization technique will not determine the value of the Lagrange multipliers. The resulting theory therefore can only either be mimetic or inconsistent. We will proceed to show that the resulting discrete theory is indeed consistent.

B. Discretization

We start by discretizing the linearized action, $S=\Sigma_{n=1}^{N}L(n,n+1)$, where

$$L(n,n+1)=\sum_{\vec{m}}\left(\sum_{a,b=1}^{3}\{p_{ab}(n,\vec{m})(h_{ab}(n+1,m)-h_{ab}(n,m))-N(n,\vec{m})[h_{ab}(n,\vec{m}+\vec{e}_a+\vec{e}_b)\right.$$
$$-h_{ab}(n,\vec{m}-\vec{e}_a+\vec{e}_b)-h_{ab}(n,\vec{m}+\vec{e}_a-\vec{e}_b)+h_{ab}(n,\vec{m}-\vec{e}_a-\vec{e}_b)-h_{aa}(n,\vec{m}+2\vec{e}_b)$$
$$+2h_{aa}(n,\vec{m})-h_{aa}(n,\vec{m}-2\vec{e}_b)]-N_a(n,\vec{m})[2p_{ab}(n,\vec{m}+\vec{e}_b)-2p_{ab}(n,\vec{m}-\vec{e}_b)]\}$$
$$\left.-H(n,\vec{m})\right) \tag{21}$$

and

$$H(n,\vec{m})=\sum_{a,b=1}^{3}\left[p_{ab}(n,\vec{m})^2-\frac{1}{2}p_{aa}(n,\vec{m})p_{bb}(n,\vec{m})\right]+\frac{1}{2}\sum_{a,b,c=1}^{3}\left[\frac{1}{2}(h_{ab}(n,\vec{m}+\vec{e}_c)-h_{ab}(n,\vec{m}-\vec{e}_c))^2\right.$$
$$-(h_{ab}(n,\vec{m}+\vec{e}_c)-h_{ab}(n,\vec{m}-\vec{e}_c))(h_{ac}(n,\vec{m}+\vec{e}_b)-h_{ac}(n,\vec{m}-\vec{e}_b))-\frac{1}{2}(h_{aa}(n,\vec{m}+\vec{e}_c)$$
$$-h_{aa}(n,\vec{m}-\vec{e}_c))(h_{bb}(n,\vec{m}+\vec{e}_c)-h_{bb}(n,\vec{m}-\vec{e}_c))+2(h_{cc}(n,\vec{m}+\vec{e}_a)-h_{cc}(n,\vec{m}-\vec{e}_a))$$
$$\times(h_{ab}(n,\vec{m}+\vec{e}_b)-h_{ab}(n,\vec{m}-\vec{e}_b))+h_{cc}(n,\vec{m})[h_{ab}(n,\vec{m}+\vec{e}_a+\vec{e}_b)-h_{ab}(n,\vec{m}+\vec{e}_a-\vec{e}_b)$$
$$\left.+h_{ab}(n,\vec{m}-\vec{e}_a-\vec{e}_b)-h_{ab}(n,\vec{m}-\vec{e}_a+\vec{e}_b)]\right], \tag{22}$$

where we have assumed that the background metric is Minkowski and we have chosen the zeroth order lapse equal to unity and we have dropped the (1) superscript from the first order and shift. We have also chosen a centered prescription for spatial derivatives, with the following conventions, i.e., $\phi(i)_{,x}=\phi(i+1)-\phi(i-1)$ and $\phi(i)_{,xx}=\phi(i+2)+\phi(i-2)-2\phi(i)$ and similarly for higher derivatives. This choice of prescription is needed for two reasons, (i) it ensures that "summation by parts" (ignoring boundaries) is satisfied, which is important when taking variations of the action, (ii) it makes the successive application of two first derivatives the second derivative, etc. This is important when proving mimetism.

The Lagrangian is the generator of the canonical transformation that materializes evolution from instant n to instant $n+1$. Specifically, we will introduce the canonically conjugate momenta as we discussed in the preceding section,

$$P^h_{ab}(n+1,\vec{m})=p_{ab}(n,\vec{m}), \tag{23}$$

$$P^p_{ab}(n+1,\vec{m})=0, \tag{24}$$

$$P^N(n+1,m)=0, \tag{25}$$

$$P^N_a(n+1,m)=0, \tag{26}$$

$$P^h_{ab}(n,\vec{m})=p_{ab}(n,\vec{m})+N(n,\vec{m}-\vec{e}_a-\vec{e}_b)-N(n,\vec{m}-\vec{e}_a+\vec{e}_b)-N(n,\vec{m}+\vec{e}_a-\vec{e}_b)+N(n,\vec{m}+\vec{e}_a+\vec{e}_b)$$
$$-\delta_{ab}\sum_{c=1}^{3}(N(n,\vec{m}-2\vec{e}_c)-2N(n,\vec{m})+N(n,\vec{m}+2\vec{e}_c))+\frac{1}{2}\sum_{c=1}^{3}[(h_{ab}(n,\vec{m})-h_{ab}(n,\vec{m}-2\vec{e}_c))$$
$$-(h_{ab}(n,\vec{m}+2\vec{e}_c)-h_{ab}(n,\vec{m}))]-\frac{1}{2}\sum_{c=1}^{3}[(h_{ac}(n,\vec{m}+\vec{e}_b-\vec{e}_c)-h_{ac}(n,\vec{m}-\vec{e}_b-\vec{e}_c))$$

$$- (h_{ac}(n,\vec{m}+\vec{e}_b+\vec{e}_c) - h_{ac}(n,\vec{m}-\vec{e}_b+\vec{e}_c))] - \frac{1}{2}\sum_{c=1}^{3}[(h_{bc}(n,\vec{m}+\vec{e}_a-\vec{e}_c)$$

$$- h_{bc}(n,\vec{m}-\vec{e}_a-\vec{e}_c)) - (h_{bc}(n,\vec{m}+\vec{e}_a+\vec{e}_c) - h_{bc}(n,\vec{m}-\vec{e}_a+\vec{e}_c))] - \frac{1}{2}\delta_{ab}\sum_{c,d=1}^{3}[(h_{dd}(n,\vec{m})$$

$$- h_{dd}(n,\vec{m}-2\vec{e}_c)) - (h_{dd}(n,\vec{m}+2\vec{e}_c) - h_{dd}(n,\vec{m}))] + \frac{\delta_{ab}}{2}\sum_{c,d=1}^{3}[h_{cd}(n,\vec{m}+\vec{e}_d-\vec{e}_c)$$

$$- h_{cd}(n,\vec{m}-\vec{e}_d-\vec{e}_c) - h_{cd}(n,\vec{m}+\vec{e}_c+\vec{e}_d) + h_{cd}(n,\vec{m}+\vec{e}_c-\vec{e}_d)]$$

$$+ \frac{1}{2}\sum_{c=1}^{3}[(h_{cc}(n,\vec{m}+\vec{e}_a-\vec{e}_b) - h_{cc}(n,\vec{m}-\vec{e}_a-\vec{e}_b)) - (h_{cc}(n,\vec{m}+\vec{e}_a+\vec{e}_b)$$

$$- h_{cc}(n,\vec{m}-\vec{e}_a+\vec{e}_b))], \tag{27}$$

$$P^{p}_{ab}(n,\vec{m}) = - (h_{ab}(n+1,\vec{m}) - h_{ab}(n,\vec{m})) + 2p_{ab}(n,\vec{m}) - \sum_{c=1}^{3} p_{cc}(n,\vec{m})\,\delta_{ab} + N_a(n,\vec{m}-\vec{e}_b)$$

$$- N_a(n,\vec{m}+\vec{e}_b) + N_b(n,\vec{m}-\vec{e}_a) - N_b(n,\vec{m}+\vec{e}_a), \tag{28}$$

$$P^{N_a}(n,m) = \sum_{b=1}^{3}[2p_{ab}(n,\vec{m}+\vec{e}_b) - 2p_{ab}(n,\vec{m}-\vec{e}_b)], \tag{29}$$

$$P^{N}(n,m) = \sum_{a,b=1}^{3}[h_{ab}(n,\vec{m}+\vec{e}_a+\vec{e}_b) - h_{ab}(n,\vec{m}-\vec{e}_a+\vec{e}_b) - h_{ab}(n,\vec{m}+\vec{e}_a-\vec{e}_b) + h_{ab}(n,\vec{m}-\vec{e}_a-\vec{e}_b)$$

$$- h_{aa}(n,\vec{m}+2\vec{e}_b) + 2h_{aa}(n,\vec{m}) - h_{aa}(n,\vec{m}-2\vec{e}_b)]. \tag{30}$$

The system has four primary constraints (24)–(27). Preserving these constraints in time implies, via (28)–(30) that the linearized Hamiltonian and momentum constraints are satisfied,

$$C_a = 2\sum_{b=1}^{3}[P^{h}_{ab}(n,\vec{m}+\vec{e}_b) - P^{h}_{ab}(n,\vec{m}-\vec{e}_b)] = 0, \tag{31}$$

$$C = \sum_{a,b=1}^{3}[h_{ab}(n,\vec{m}+\vec{e}_a+\vec{e}_b) - h_{ab}(n,\vec{m}-\vec{e}_a+\vec{e}_b) - h_{ab}(n,\vec{m}+\vec{e}_a-\vec{e}_b) + h_{ab}(n,\vec{m}-\vec{e}_a-\vec{e}_b)$$

$$- h_{aa}(n,\vec{m}+2\vec{e}_b) + 2h_{aa}(n,\vec{m}) - h_{aa}(n,\vec{m}-2\vec{e}_b)] = 0. \tag{32}$$

Constraints (24) and (27) can be imposed strongly, the second constraint determines the variable p_{ab}. This eliminates the variable p_{ab} and its canonically conjugate momenta from the theory.

We now combine (23) and (27) to get the evolution equation for P^h,

$$P^{h}_{ab}(n+1,\vec{m}) = P^{h}_{ab}(n,\vec{m}) - N(n,\vec{m}-\vec{e}_a-\vec{e}_b) + N(n,\vec{m}-\vec{e}_a+\vec{e}_b) + N(n,\vec{m}+\vec{e}_a-\vec{e}_b)$$

$$- N(n,\vec{m}+\vec{e}_a+\vec{e}_b) + \delta_{ab}\sum_{c=1}^{3}(N(n,\vec{m}-2\vec{e}_c) - 2N(n,\vec{m}) + N(n,\vec{m}+2\vec{e}_c))$$

$$- \frac{1}{2}\sum_{c=1}^{3}[(h_{ab}(n,\vec{m}) - h_{ab}(n,\vec{m}-2\vec{e}_c)) - (h_{ab}(n,\vec{m}+2\vec{e}_c) - h_{ab}(n,\vec{m}))]$$

$$+\frac{1}{2}\sum_{c=1}^{3}[(h_{ac}(n,\vec{m}+\vec{e}_b-\vec{e}_c)-h_{ac}(n,\vec{m}-\vec{e}_b-\vec{e}_c))-(h_{ac}(n,\vec{m}+\vec{e}_b+\vec{e}_c)$$

$$-h_{ac}(n,\vec{m}-\vec{e}_b+\vec{e}_c))]+\frac{1}{2}\sum_{c=1}^{3}[(h_{bc}(n,\vec{m}+\vec{e}_a-\vec{e}_c)-h_{bc}(n,\vec{m}-\vec{e}_a-\vec{e}_c))$$

$$-(h_{bc}(n,\vec{m}+\vec{e}_a+\vec{e}_c)-h_{bc}(n,\vec{m}-\vec{e}_a+\vec{e}_c))]+\frac{1}{2}\delta_{ab}\sum_{c,d=1}^{3}[(h_{dd}(n,\vec{m})$$

$$-h_{dd}(n,\vec{m}-2\vec{e}_c))-(h_{dd}(n,\vec{m}+2\vec{e}_c)-h_{dd}(n,\vec{m}))]$$

$$-\frac{\delta_{ab}}{2}\sum_{c,d=1}^{3}[(h_{cd}(n,\vec{m}+\vec{e}_d-\vec{e}_c)-h_{cd}(n,\vec{m}-\vec{e}_d-\vec{e}_c))-(h_{cd}(n,\vec{m}+\vec{e}_c+\vec{e}_d)$$

$$-h_{cd}(n,\vec{m}+\vec{e}_c-\vec{e}_d))]-\frac{1}{2}\sum_{c=1}^{3}[(h_{cc}(n,\vec{m}+\vec{e}_a-\vec{e}_b)-h_{cc}(n,\vec{m}-\vec{e}_a-\vec{e}_b))$$

$$-(h_{cc}(n,\vec{m}+\vec{e}_a+\vec{e}_b)-h_{cc}(n,\vec{m}-\vec{e}_a+\vec{e}_b))], \tag{33}$$

and from (28) we get the evolution equation for h,

$$h_{ab}(n+1,\vec{m})=h_{ab}(n,\vec{m})+2P^h_{ab}(n,\vec{m})-\delta_{ab}\sum_{f=1}^{3}P^h_{ff}(n,\vec{m})+N_a(n,\vec{m}-\vec{e}_b)-N_a(n,\vec{m}+\vec{e}_b)$$

$$+N_b(n,\vec{m}-\vec{e}_a)-N_b(n,\vec{m}+\vec{e}_a)-2N(n,\vec{m}-\vec{e}_a-\vec{e}_b)+2N(n,\vec{m}-\vec{e}_a+\vec{e}_b)$$

$$+2N(n,\vec{m}+\vec{e}_a-\vec{e}_b)-2N(n,\vec{m}+\vec{e}_a+\vec{e}_b)-\sum_{c=1}^{3}[2h_{ab}(n,\vec{m})-h_{ab}(n,\vec{m}-2\vec{e}_c)$$

$$-h_{ab}(n,\vec{m}+2\vec{e}_c)]+\sum_{c=1}^{3}[h_{ac}(n,\vec{m}+\vec{e}_b-\vec{e}_c)-h_{ac}(n,\vec{m}-\vec{e}_b-\vec{e}_c)-h_{ac}(n,\vec{m}+\vec{e}_b+\vec{e}_c)$$

$$+h_{ac}(n,\vec{m}-\vec{e}_b+\vec{e}_c)]+\sum_{c=1}^{3}[h_{bc}(n,\vec{m}+\vec{e}_a-\vec{e}_c)-h_{bc}(n,\vec{m}-\vec{e}_a-\vec{e}_c)$$

$$-h_{bc}(n,\vec{m}+\vec{e}_a+\vec{e}_c)+h_{bc}(n,\vec{m}-\vec{e}_a+\vec{e}_c)]+\frac{1}{2}\delta_{ab}\sum_{c,d=1}^{3}[2h_{dd}(n,\vec{m})-h_{dd}(n,\vec{m}-2\vec{e}_c)$$

$$-h_{dd}(n,\vec{m}+2\vec{e}_c)]-\frac{1}{2}\delta_{ab}\sum_{c,d=1}^{3}[h_{cd}(n,\vec{m}+\vec{e}_d-\vec{e}_c)-h_{cd}(n,\vec{m}-\vec{e}_d-\vec{e}_c)$$

$$-h_{cd}(n,\vec{m}+\vec{e}_c+\vec{e}_d)+h_{cd}(n,\vec{m}+\vec{e}_c-\vec{e}_d)]-\sum_{c=1}^{3}[h_{cc}(n,\vec{m}+\vec{e}_a-\vec{e}_b)$$

$$-h_{cc}(n,\vec{m}-\vec{e}_a-\vec{e}_b)-h_{cc}(n,\vec{m}+\vec{e}_a+\vec{e}_b)+h_{cc}(n,\vec{m}-\vec{e}_a+\vec{e}_b)]. \tag{34}$$

A first point to be noted is that the evolution equations have resulted in an explicit evolution scheme. This is usually not the case, it is a particularity of the linearized theory that the evolution is explicit. It should be noted that the evolution equations obtained are just a straightforward discretization of the evolution equations one would obtain in the continuum by working out the variations of the continuum action.

We have checked, using a computer algebra code, that the evolution equations (34) and (33) exactly preserve the constraints (31) and (32), or more precisely that

$$C_a(n+1,m) = C_a(n,m), \tag{35}$$

$$C(n+1,m) = C(n,m) + \sum_{a=1}^{3} [C_a(n,m+\vec{e}_a) - C_a(n,m-\vec{e}_a)]. \tag{36}$$

This result was expected since we used differentiation operators that ensure that mixed discrete spatial derivatives commute, and that one can integrate by parts (more precisely "sum by parts"), and that is all that is needed in a linear theory on a Minkowski background to show that the constraints are preserved upon evolution. It is interesting to compare this result with that of Meier.[3] He finds a mimetic discretization of linearized general relativity around Minkowski space–time, but using staggered grids. This is a natural approach, for instance, in electromagnetism and Yang–Mills theory (and it is the one we will take in the next section where we deal with gravity with the Ashtekar variables).

It would be interesting to generalize these results to the case of linearization around a static background. In that case it is not obvious that the formulation would result automatically mimetic. In fact, the failure of the Leibnitz rule at a discrete level implies that it will be difficult to find a mimetic formulation since the equations now will have nonconstant coefficients and one will need Leibnitz' rule to show conservation. Our formalism will yield a consistent formulation, but it is possible that it will require determining the Lagrange multipliers.

C. Stability

We have discretized the time derivatives without centering them (that is, we have used a stencil that is first order accurate only). The reason for this is that the canonical theory is much cleaner with only two levels in time involved in the derivatives. It is possible to use derivatives that are second order accurate in time and use our construction by rewriting the theory in terms of new variables in such a way that the resulting theory has derivatives that are first order accurate, but we will not do this here.

The spatial derivatives, on the other hand, were centered (this was required in order to have summation by parts). The resulting scheme is therefore "forward in time centered in space," a recipe that is not stable, for instance, for the advection or the wave equation. We therefore would like to check if our scheme is stable. To simplify things, we will consider (34) and (33) and make the following assumptions: the metric and extrinsic curvatures are diagonal and only depend on the coordinates t,x, the lapse is unity and the shift is zero. The resulting equations therefore are

$$P^h_{11}(n+1,\vec{m}) = P^h_{11}(n,\vec{m}) - \frac{1}{2}\sum_{c=2}^{3} [2h_{cc}(n,\vec{m}) - h_{cc}(n,\vec{m}-2\vec{e}_1) - h_{cc}(n,\vec{m}+2\vec{e}_1)], \tag{37}$$

$$P^h_{22}(n+1,\vec{m}) = P^h_{22}(n,\vec{m}) + \tfrac{1}{2}[2h_{33}(n,\vec{m}) - h_{33}(n,\vec{m}-2\vec{e}_1) - h_{33}(n,\vec{m}+2\vec{e}_1)], \tag{38}$$

$$P^h_{33}(n+1,\vec{m}) = P^h_{33}(n,\vec{m}) + \tfrac{1}{2}[2h_{22}(n,\vec{m}) - h_{22}(n,\vec{m}-2\vec{e}_1) - h_{22}(n,\vec{m}+2\vec{e}_1)], \tag{39}$$

$$\begin{aligned} h_{11}(n+1,\vec{m}) = h_{11}(n,\vec{m}) + 2P^h_{11}(n,\vec{m}) - \sum_{f=1}^{3} P^h_{ff}(n,\vec{m}) - \frac{1}{2}\sum_{d=2}^{3} [2h_{dd}(n,\vec{m}) - h_{dd}(n,\vec{m}-2\vec{e}_1) \\ - h_{dd}(n,\vec{m}+2\vec{e}_1)], \end{aligned} \tag{40}$$

$$h_{22}(n+1,\vec{m}) = h_{22}(n,\vec{m}) + 2P^h_{22}(n,\vec{m}) - \sum_{f=1}^{3} P^h_{ff}(n,\vec{m}) - \frac{1}{2}[2h_{22}(n,\vec{m}) - h_{22}(n,\vec{m}-2\vec{e}_1)$$

$$- h_{22}(n,\vec{m}+2\vec{e}_1)] + \frac{1}{2}[2h_{33}(n,\vec{m}) - h_{33}(n,\vec{m}-2\vec{e}_1) - h_{33}(n,\vec{m}+2\vec{e}_2)], \quad (41)$$

$$h_{33}(n+1,\vec{m}) = h_{33}(n,\vec{m}) + 2P^h_{33}(n,\vec{m}) - \sum_{f=1}^{3} P^h_{ff}(n,\vec{m}) - \frac{1}{2}[2h_{33}(n,\vec{m}) - h_{33}(n,\vec{m}-2\vec{e}_1)$$

$$- h_{33}(n,\vec{m}+2\vec{e}_1)] + \frac{1}{2}[2h_{22}(n,\vec{m}) - h_{22}(n,\vec{m}-2\vec{e}_1) - h_{22}(n,\vec{m}+2\vec{e}_2)]. \quad (42)$$

As a test case, we concentrate on a subfamily of solutions of the equations, in which $h_{11}=P_{11}=0$ and $h_{22}=-h_{33}$ and $P_{22}=-P_{33}$. In that case, the equations reduce to

$$P^h_{22}(n+1,\vec{m}) = P^h_{22}(n,\vec{m}) - \tfrac{1}{2}[2h_{22}(n,\vec{m}) - h_{22}(n,\vec{m}-2\vec{e}_1) - h_{22}(n,\vec{m}+2\vec{e}_1)], \quad (43)$$

$$h_{22}(n+1,\vec{m}) = h_{22}(n,\vec{m}) + 2P^h_{22}(n,\vec{m}) - [2h_{22}(n,\vec{m}) - h_{22}(n,\vec{m}-2\vec{e}_1) - h_{22}(n,\vec{m}+2\vec{e}_1)]. \quad (44)$$

We have performed a Von Neumann analysis of this system and confirmed that the scheme is stable provided the Courant factor is less than 1. So at least for this particular subcase the scheme is stable. A more complete analysis is needed to guarantee stability in general.

IV. LINEARIZED GENERAL RELATIVITY IN TERMS OF ASHTEKAR VARIABLES

A. Continuum formulation

We will now apply the technique we outlined in the preceding section to general relativity linearized around Minkowski space using the Ashtekar formulation. The formulation of linearized gravity with the new variables was first discussed by Ashtekar and Lee.[9] The discussion presented in that paper required the use of complex variables if one was to describe general relativity with metrics with a Lorentzian signature (alternatively, one could consider real variables, but then the theory described the Euclidean signature sector). Developments that have taken place in the field since the publication of that paper that allow one to consider the Lorentzian sector using real variables,[10,11] but we will see that the discretized theory is more problematic in this case and we will not discuss it in detail in this paper.

The Ashtekar canonical variables consist of a set of triads with density weight 1, E^{ai} and a (complex) SO(3) connection A_{ai}. In this notation $a,b,\ldots$ are spatial vector indices and $i,j,\ldots$ range from 1 to 3. Following Ashtekar and Lee we omit using tildes to denote density weights since in this context they do not play an important role. To linearize the theory around Minkowski, we choose a fixed background ($E^{ai}=E^{ai}_0, A_{ai}=0$) in the phase space and consider fluctuations around it. In Cartesian coordinates, $E^{ai}_0=\delta^{ai}$. The triad is therefore given by

$$E^{ai} = \delta^{ai} + e^{ai}, \quad (45)$$

and therefore the background metric has components $q^{ab}=\delta^{ab}$ and its determinant is unity and therefore density weights are all trivial. We will denote by A_{ai} the fluctuations of the connection. The Poisson bracket of the canonical variables is $\{e^{ai}(x),A_{bj}(y)\}=i\delta^a_b\delta^i_j\delta(x-y)$.

The Ashtekar formulation has, in addition to the usual diffeomorphism and Hamiltonian constraints of the metric canonical formulation of general relativity, a set of additional constraints that make the formulation invariant under triad rotations. The additional constraints take the form of a Gauss law, which linearized will read

$$\mathcal{G}_L^i = \partial_a e^{ai} + \epsilon^{ija} A_{aj} = 0, \tag{46}$$

where from now on the subscript L means we have kept the minimum required number of terms in the perturbative expansion. In spite of the second term, one can check that if one computes the Poisson bracket of two Gauss laws, they commute, that is, they form an Abelian algebra. The internal symmetry group of the linearized theory is therefore U(1) (Ref. 3).

Ignoring boundary terms, the (super-) Hamiltonian for general relativity can be written as

$$H = \int \mathrm{d}^3x \left[N E_i^a E_j^b \left(F_{ab}^k \epsilon_{ijk} - \frac{(\beta^2 - \sigma)}{\beta^2} (\Gamma_a^i - \sigma\beta A_a^i)(\Gamma_b^j - \sigma\beta A_b^j) \right) + N^a E_i^a F_{ab}^i \right], \tag{47}$$

and in the full theory it vanishes identically. The parameter β is called the Immirzi parameter and the parameter σ is equal to +1 for the Euclidean case and −1 for the Lorentzian signature. Classically, different values of the Immirzi parameter correspond to different representations of the same theory. The quantities Γ_a^i are the spin connections compatible with the triads, defined by

$$\partial_{[a} \overline{E^i}_{b]} + \epsilon_{jk}^i \Gamma_{[a}^j \overline{E^k}_{b]} = 0, \tag{48}$$

where the $\overline{E}$'s are the triads (without density weight), related to the Ashtekar variables by $E_i^a = \det(\overline{E}) \overline{E}_i^a$, or equivalently, $E_i^a = \overline{E_b^j} \overline{E_c^k} \epsilon^{abc} \epsilon_{ijk}$. Indices are lowered and raised with the flat Euclidean metric. One can obtain an explicit expression for the spin connection in terms of the triads,

$$\Gamma_c^i = \epsilon_c^{ab} (\partial_a e_b^i - \partial_a \mathrm{Tr}(e) \delta_b^i). \tag{49}$$

To study it in the linearized theory, we need to choose a lapse and a shift. The natural choice is to use as zeroth order lapse and shift the ones that would preserve the spatial background metric explicitly time independent. This corresponds to a lapse $N=1$ and a shift $N^a=0$. So we will write $N_L = 1 + \nu$ and $N_L^a = \nu^a$, and these will become Lagrange multipliers in the linearized theory. The super-Hamiltonian then separates into two pieces, one that acts as a Hamiltonian and another piece that is given by the Lagrange multipliers times constraints of the linearized theory. These constraints are

$$C_a^L = -i f_{ab}^b = 0, \tag{50}$$

$$C^L = -i \epsilon_c^{ab} f_{ab}^c = 0, \tag{51}$$

where $f_{ab}^i = 2\partial_{[a} A^i{}_{b]}$ is the linearized field strength, and the first one is the linearized momentum constraint and the latter the linearized Hamiltonian constraint. The nonvanishing Hamiltonian for the linearized theory is given by

$$H_L = \int \mathrm{d}^3x \left(2\epsilon_k^{ib} f_{ab}^k e_i^a + (A_a^a A_b^b - A_a^b A_b^a) - \frac{\beta^2 - \sigma}{\beta^2} [(\Gamma_a^a - \sigma\beta A_a^a)(\Gamma_a^b - \sigma\beta A_a^b)) \right.$$
$$\left. - (\Gamma_a^b - \sigma\beta A_a^b)(\Gamma_b^a - \sigma\beta A_b^a) \right]. \tag{52}$$

B. Discretizing the full theory on the lattice

In this section we review some results of Refs. 4 and 5 where we discretized general relativity on the lattice. In the next section we will particularize these results to the case of linearized general relativity. We start by considering an action for general relativity written in terms of Ashtekar's variables (see for instance Ref. 12 and the book by Ashtekar,[13] p. 47),

$$L = \int E^{ai} F^{i}_{a0} - H, \tag{53}$$

where N and N^a are the lapse and shift and H the super-Hamiltonian (47). We will particularize to the Euclidean case $\sigma=1$ and choose the Immirzi parameter $\beta=1$ which correspond to the original form of Ashtekar's variables, for simplicity (see Sec. VI for more details). From now on we will not assume Einstein's summation convention and present the summations explicitly, since many expressions would otherwise be confusing. The Lagrangian can be discretized as follows:

$$L(n,n+1) = -\frac{1}{4}\sum_{v} \mathrm{Tr}\Bigg[\sum_{a} E^{a}_{n,v}(h^{a0}_{n,v} - h^{0a}_{n,v}) - \sum_{a,b} K^{ab}_{n,v}(h^{ab}_{n,v} - h^{ba}_{n,v}) + \sum_{a} \alpha_{a,n,v}(h^{a}_{n,v}(h^{a}_{n,v})^{\dagger} - 1) + \beta_{n,v}(h^{0}_{n,v}(h^{0}_{n,v})^{\dagger} - 1)\Bigg], \tag{54}$$

where h^{a}_{n+1} represents an holonomy along the a direction at instant $n+1$, h^{0}_{n} represents the "vertical" (timelike) holonomy. The holonomy associated with a plaquette in the $\alpha\beta$ $(\alpha\neq\beta)$ plane $(\alpha,\beta=0,\ldots,3)$ is

$$h^{\alpha\beta}_{n,v} \equiv h^{\alpha}_{n,v} h^{\beta}_{n,v+e_\alpha} (h^{\alpha}_{n,v+e_\beta})^{\dagger} (h^{\beta}_{n,v})^{\dagger}, \tag{55}$$

and

$$K^{ab}_{n,v} \equiv \tfrac{1}{2}[(E^{a}_{n,v}E^{b}_{n,v} - E^{b}_{n,v}E^{a}_{n,v})N_{n,v} + N^{a}_{n,v}E^{b}_{n,v} - N^{b}_{n,v}E^{a}_{n,v}]. \tag{56}$$

We will assume that the holonomies are matrices of the form $h=\Sigma_I h^I T^I$ where $T^0=I$ and $T^a=-i\sigma^a$ where σ^a are the Pauli matrices. The indices n,v represent a label for "time" n and a spatial label for the vertices of the lattice v. The elementary unit vectors along the spatial directions are labeled as e_a, so for instance $n+e_1$ labels the nearest neighbor to n along the e_1 direction. The unit vector in the timelike direction is e_0 and we chose $h^{\alpha}_{n,v+e_0} \equiv h^{\alpha}_{n+1,v}$. The quantities $E^{a}_{n,v}$ are elements of the algebra of su(2) and α and β are Lagrange multipliers, the last two terms of the Lagrangian enforcing the condition that the holonomies are elements of SU(2). We use the usual conventions of lattice gauge theories in which one has oriented links and the natural variables are the holonomies in a given orientation and based at a given vertex. If we need to traverse back, as in the case of closed loops one then considers the adjoint of the holonomy based at the vertex one is ending at.

The discretization of the field tensor is based on

$$F^{i}_{ab} \to -\tfrac{1}{4}\mathrm{Tr}[(h^{ab}_{n,v} - h^{ba}_{n,v})T^{i}]. \tag{57}$$

Instead of working out the equations of motion for this action, we will, in the next section, particularize it to the linearized case and work out the relevant equations of motion, which is equivalent to working the equations first and then linearizing if appropriate perturbative orders are kept.

C. The linearized theory on the lattice

We now proceed to linearize the action. We start with the holonomies. The explicit form of the linearized holonomy is

$$h^{\alpha}_{v} = 1 + \sum_{i} \phi^{\alpha i}_{v} T^{i}, \tag{58}$$

where we have dropped the subscript n we used in the last section to indicate the time level in order to make the notation more compact (but we will make it explicit when things are evaluated at $n+1$). In this equation $\phi^{\alpha i}_{v} T^{i}$ is an element of the algebra that can be viewed as a "phase" (it corresponds to the logarithm of the path-ordered exponential of the connection along the direction

α). The holonomy of a plaquette in the plane $\alpha\beta$ is (neglecting higher order terms)

$$h_v^{\alpha\beta} = h_v^{\alpha} h_{v+e_\alpha}^{\beta} (h_{v+e_\beta}^{\alpha})^{\dagger} (h_v^{\beta})^{\dagger} = \left(1 - \sum_i \Phi_{2v}^{\alpha\beta ii}\right) 1 + \sum_i (\Phi_{1v}^{\alpha\beta i} + \Phi_{2v}^{\alpha\beta i}) T^i. \tag{59}$$

The first order contribution is

$$\Phi_{1v}^{\alpha\beta k} \equiv + \phi_v^{\alpha k} - \phi_v^{\beta k} - \phi_{v+\hat{e}_\beta}^{\alpha k} + \phi_{v+\hat{e}_\alpha}^{\beta k}, \tag{60}$$

and the second order contribution is

$$\Phi_{2v}^{\alpha\beta ij} \equiv - \phi_v^{\alpha i} \phi_v^{\beta j} + \phi_v^{\alpha i} \phi_{v+\hat{e}_\alpha}^{\beta j} + \phi_{v+\hat{e}_\beta}^{\alpha i} \phi_v^{\beta j} - \phi_{v+\hat{e}_\beta}^{\alpha j} \phi_{v+\hat{e}_\alpha}^{\beta i} - \phi_v^{\alpha i} \phi_{v+\hat{e}_\beta}^{\alpha j} - \phi_v^{\beta j} \phi_{v+\hat{e}_\alpha}^{\beta i}, \tag{61}$$

$$\Phi_{2v}^{\alpha\beta k} \equiv \sum_{ij} \epsilon^{ijk} \Phi_{2v}^{\alpha\beta ij}. \tag{62}$$

We now linearize the expression for K defined in the preceding section, by noting that to first order,

$$e_v^a = \sum_i (\delta^{ai} + e_v^{ai}) T^i \tag{63}$$

and ignoring higher order terms we get that

$$K_v^{ab} = \sum_i (\epsilon^{abi} + K_{1,v}^{abi}) T^i \tag{64}$$

with

$$K_1^{abk} \equiv \epsilon^{abk} \nu_v + \frac{1}{2} (\nu_v^a \delta^{bk} - \nu_v^b \delta^{ak}) + \sum_i (e_v^{ai} \epsilon^{ibk} - e_v^{bi} \epsilon^{iak}). \tag{65}$$

We now consider the first term in the discretized Lagrangian (54). Substituting the expression for the holonomy around a plaquette (59) we get the following identity, valid up to second order:

$$-\frac{1}{4} \mathrm{Tr} \left[\sum_a E_{n,v}^a (h_{n,v}^{a0} - h_{n,v}^{0a}) \right] = \sum_a \Phi_{1v}^{a0a} + \sum_a \Phi_{2v}^{a0a} + \sum_{ak} e_v^{ak} \Phi_{1v}^{a0k} \tag{66}$$

and we note that when one considers the sum over all vertices, the first term on the right-hand side yields a total derivative with respect to time that can be ignored in the Lagrangian.

For the second term in (54) we use (59) and (64), getting the following identity, valid up to second order:

$$\frac{1}{4} \mathrm{Tr} \left[\sum_{ab} K_{n,v}^{ab} (h_{n,v}^{ab} - h_{n,v}^{ba}) \right] = - \sum_{abk} (\epsilon^{abk} \Phi_{1v}^{abk} + \epsilon^{abk} \Phi_{2v}^{abk} + K_{1v}^{abk} \Phi_{1v}^{abk}). \tag{67}$$

When one considers the sum over all vertices the first term on the right-hand side of this expression vanishes. The resulting Lagrangian therefore can be written as

$$\begin{aligned} L = - \sum_v \Bigg\{ & \sum_{ai} e_v^{ai} (\phi_{n+1,v}^{ai} - \phi_{n,v}^{ai}) + \sum_{ijk} \epsilon_{ijk} (\phi_v^{ij} \phi_{n+1,v}^{ik} + \Phi_{2v}^{ijk} + \nu_v \Phi_{1v}^{ijk}) + \sum_{aijk} 2 e_v^{ai} \epsilon^{ijk} \Phi_{1v}^{ajk} + \sum_{ab} \nu_v^a \Phi_{1v}^{abb} \\ & + \sum_{ij} (\phi_v^{0i} - \phi_{v+\hat{e}_j}^{0i}) e_v^{ji} + \sum_{ijk} \epsilon_{ijk} \phi_v^{0i} (\phi_{n+1,v}^{kj} + \phi_{v+\hat{e}_j}^{0k} + \phi_v^{jk}) - \sum_{ijk} \phi_{v+\hat{e}_j}^{0i} \epsilon_{ijk} (\phi_v^{jk} + \phi_{n+1,v}^{jk}) \Bigg\}. \end{aligned} \tag{68}$$

Now that we have an explicit expression for the Lagrangian we can proceed to identify the various terms. The theory has the following Lagrange multipliers: ϕ_v^{0i} the "vertical component of the phase" (which plays a role analogous to the time component of the vector potential in Maxwell

theory) and the linearized lapse and shift. These quantities multiply times the constraints of the linearized theory. Explicitly, the momentum and Hamiltonian constraint read

$$C_v^a = \sum_b \Phi_{1v}^{abb}, \tag{69}$$

$$C_v = \sum_{ijk} \epsilon_{ijk} \Phi_{1v}^{ijk}. \tag{70}$$

In order to get Gauss' law, we first take the variation of the Lagrangian with respect to the Lagrange multiplier ϕ_v^{0i} to get

$$G_v^i \equiv \sum_a (\xi_{n+1,v}^{ai} + \xi_{n+1,v}^{\bar{a}i}) = 0, \tag{71}$$

where

$$\xi_{n+1,v}^{ai} \equiv + \delta^{ai} + e_{n,v}^{ai} + \sum_k \epsilon_{aik}(- \phi_{n,v}^{ak} - \phi_{n,v+\hat{e}_a}^{0k} - \phi_{n,v}^{0k} + \phi_{n+1,v}^{ak}), \tag{72}$$

$$\xi_{n+1,v}^{\bar{a}i} \equiv - \delta^{ai} - e_{n,v-\hat{e}_a}^{ai} + \sum_k \epsilon_{aik}(\phi_{n,v-\hat{e}_a}^{ak} + \phi_{n,v}^{0k} + \phi_{n,v-\hat{e}_a}^{0k} + \phi_{n+1,v-\hat{e}_a}^{ak}). \tag{73}$$

At the moment this does not appear to be a true constraint since it involves variables at instant n and at instant $n+1$. To see that it actually is a constraint, we will call $\xi_{n+1,v}^{ai}$ the component in the direction $\hat{e}_a$ of a quantity that we will think of as an "electric field" (in the sense that it is the quantity that satisfies the usual form of Gauss law) and we will call $\xi_{n+1,v}^{\bar{a}i}$ the component in the direction $-\hat{e}_a$, both at point $(n+1,v)$. To make this more transparent, we need to see how they transform under gauge transformations. To leading order the field $e_{n,v}^a$ is $e_{0,n,v}^a = \Sigma_i \delta^{ai} T^i$. We then define

$$\check{e}_{n,v}^a = e_{n,v}^a + \frac{1}{4}[h_{n,v}^{0a} e_{0,n,v}^a (h_{n,v}^{0a})^\dagger - h_{n,v}^{a0} e_{0,n,v}^a (h_{n,v}^{a0})^\dagger] = e_{n,v}^a + \sum_{jk} \epsilon_{ajk} \Phi_{1v}^{0ak} T^j, \tag{74}$$

with the second equality valid up to second order. By inspection one sees that the field $\check{e}_{n,v}^a$ is an element of the algebra that transforms like an electric field at (n,v) under gauge transformation. One can also show the following identities, valid to first order:

$$\xi_{n+1,v}^a \equiv \sum_i \xi_{n+1,v}^{ai} T^i = (h_{n,v}^0)^\dagger \check{e}_{n,v}^a h_{n,v}^0, \tag{75}$$

$$\xi_{n+1,v}^{\bar{a}} \equiv \sum_i \xi_{n+1,v}^{\bar{a}i} T^i = - (h_{n+1,v-\hat{e}_a}^a)^\dagger \xi_{n+1,v-\hat{e}_a}^a h_{n+1,v-\hat{e}_a}^a \tag{76}$$

from which one immediately sees that the quantities we identified as components of the electric field have the appropriate transformation properties under gauge transformations.

Therefore we can identify (71) as the usual intuitive expression of Gauss' law stating that field lines cannot emanate from a point in vacuum.

We now turn our attention to the equations of motion. Given the Lagrangian (68) we work out the equations of motion from the canonical transformation. We start by computing the canonical conjugate momentum to e,

$$P_{n+1,v}^{(e)ak} \equiv \frac{\partial L(n,n+1)}{\partial e_{n+1,v}^{ak}} = 0, \tag{77}$$

$$P_v^{(e)ak} \equiv -\frac{\partial L(n,n+1)}{\partial e_v^{ak}} = -\Phi_{1v}^{a0k} + 2\sum_{ij} \epsilon^{kij}\Phi_{1v}^{aij} = 0. \tag{78}$$

Therefore the dynamics of $P^{(e)}$ is trivial. However, the last equation can be viewed as an evolution equation for ϕ through (60),

$$\phi_{n+1,v}^{ak} = \phi_v^{ak} - \phi_v^{0k} + \phi_{v+\hat{e}_a}^{0k} - 2\sum_{ij} \epsilon^{kij}\Phi_{1v}^{aij}. \tag{79}$$

Notice that by adding over indices a belonging to a given plaquette equation (79), one effectively gets an evolution equation for all the horizontal ϕ's in the plaquette. This is due to the fact that the vertical contributions in (60) will cancel out in pairs when adding through the plaquette. Explicitly,

$$\Phi_{1,n+1,v}^{abk} = \Phi_{1v}^{abk} - 2\sum_{ij} \epsilon^{kij}(\Phi_{1v}^{aij} + \Phi_{1v+\hat{e}_a}^{bij} - \Phi_{1v+\hat{e}_b}^{aij} - \Phi_{1v}^{bij}) \equiv \Phi_{1v}^{abk} - 2\sum_{ij} \epsilon^{kij} \sum_{d\in P_{ab}} \Phi_{1v_d}^{dij}, \tag{80}$$

where in the last term v_d is the vertex in which the link d originates and P_{ab} is the plaquette spanned by a and b.

We now consider the momentum canonically conjugate to ϕ. We start by computing the canonical conjugate momentum at instant $n+1$,

$$P_{n+1,v}^{(\phi)ak} \equiv \frac{\partial L(n,n+1)}{\partial \phi_{n+1,v}^{ak}} = -e_v^{ak} + \sum_i \epsilon^{aki}(\phi_v^{ai} + \phi_v^{0i} + \phi_{v+\hat{e}_a}^{0i}). \tag{81}$$

The momentum can be written in terms of the electric field in an expression that parallels the usual relation between the electric field and the canonical momentum in the lattice ξ^{ak} as

$$P_{n+1,v}^{(\phi)ak} = \delta_{ak} - \xi_{n+1,v}^{ak} + \sum_i \epsilon_{aki}\phi_{n+1,v}^{ai} \tag{82}$$

and in terms of it, Gauss' law (71) can be written as

$$G_{n+1,v}^{k} = -\sum_a \left(P_{n+1,v}^{(\phi)ak} - P_{n+1,v-\hat{e}_a}^{(\phi)ak} - \sum_i \epsilon^{aki}(\phi_{n+1,v}^{ai} + \phi_{n+1,v-\hat{e}_a}^{ai}) \right). \tag{83}$$

This final expression for Gauss' law is a genuine constraint, in the sense that all variables are expressed at the same instant of time.

We now compute the momentum conjugate to ϕ at instant n,

$$\begin{aligned} P_v^{(\phi)ab} = -\frac{\partial L(n,n+1)}{\partial \phi_v^{ab}} &= -e_v^{ab} + \nu_v^a - \nu_{v-\hat{e}_b}^a + \delta_{ab}\sum_i (-\nu_v^i + \nu_{v-\hat{e}_i}^i) + 2(-\phi_{v-\hat{e}_b}^{aa} + \phi_{v+\hat{e}_b}^{aa} + \phi_v^{ba} - \phi_{v+\hat{e}_a}^{ba} \\ &\quad - \phi_{v-\hat{e}_b}^{ba} - \phi_{v+\hat{e}_a-\hat{e}_b}^{ba}) + 2\delta_{ab}\sum_i (\phi_{v-\hat{e}_i}^{ai} - \phi_{v+\hat{e}_i}^{ai} - \phi_v^{ii} + \phi_{v+\hat{e}_a}^{ii} + \phi_{v-\hat{e}_i}^{ii} + \phi_{v+\hat{e}_a-\hat{e}_i}^{ii}) \\ &\quad + \sum_i \epsilon_{abi}(-2\nu_v + 2\nu_{v-\hat{e}_i} + \phi_v^{0i} - \phi_{v+\hat{e}_a}^{0i} - 2e_v^{aa} + 2e_{v-\hat{e}_i}^{aa} - 2e_v^{bi} + 2e_{v-\hat{e}_b}^{bi} - 2e_v^{ii} + 2e_{v-\hat{e}_i}^{ii} + \phi_{n+1,v}^{ai}) \\ &\quad + 2\delta_{ab}\sum_{i,j} \epsilon_{aij}(e_v^{ai} - e_{v-\hat{e}_j}^{ai}). \end{aligned} \tag{84}$$

One still needs to replace the expressions for the e's and for the ϕ's evaluated at instant $n+1$. The resulting substitutions lead to lengthy expressions that are not particularly illuminating, and will not be needed in what follows, so we will not display them here. We point out however, that the resulting scheme is not an explicit one for the $P^{(\phi)}$'s. Since these variables do not arise in the constraints, we do not need this evolution equation to show mimetism.

One now needs to show that the evolution is mimetic, that is, it preserves the discrete constraints (69), (70), and (83). Using the evolution equation (80) one gets that

$$C^a_{n+1,v} = C^a_v + C_v - C_{v+\hat{e}_a}, \tag{85}$$

$$C_{n+1,v} = C_v + 4\sum_a (C^a_{v+\hat{e}_a} - C^a_v). \tag{86}$$

To study the time evolution of Gauss' law one needs Eqs. (79), (81), and (84) and one gets that

$$G^k_{n+1,v} = G^k_{n,v}. \tag{87}$$

As in the preceding section, we have checked these identities using computer algebra.

V. DISCUSSION AND CONCLUSIONS

The consistent discretization scheme is such that it yields a set of discrete equations for the evolution equations and the constraints of general relativity that is compatible, that is, all can be solved simultaneously. It does so at the price of determining the Lagrange multipliers (the lapse and the shift). In the linearized case we have shown that one can discretize the theory in such a way that the Lagrange multipliers are not determined and nevertheless the theory is consistent.

When one discretizes a theory there is always an ambiguity in how to proceed. Among the ambiguities we have the dependence on how one chooses to represent the derivatives. What we have found is that in the linearized case one can choose certain derivative operators for which the Lagrange multipliers are not determined. It should be noted that the consistent discretization scheme would work even if one did not choose the derivatives this way, but the Lagrange multipliers will be determined in order to have a consistent set of equations. This is true both in the case of the traditional variables and also in the Ashtekar variables. In the latter case there is an additional element that is the presence of an extra constraint: the Gauss law. We have also chosen a specific way of discretizing the theory in such a way that Gauss' law is implemented exactly in the discrete theory (this is standard in Yang–Mills theory on the lattice, and implies that the discrete formulation is gauge invariant, and also that these discretizations are mimetic, though this is rarely emphasized in the Yang–Mills literature). In the case of the traditional variables, one can also associate mimetism with gauge invariance. The action we chose to work with is invariant under linearized coordinate transformations of the form $h'_{\mu\nu}=h_{\mu\nu}+\xi_{(\mu,\nu)}$. The discrete action, if one chooses a derivative operator such that the second derivatives coincide with the derivative of a first derivative and satisfies summation by parts, is invariant under a discrete version of the above symmetry. This symmetry is generated canonically by the discrete constraints. This explains in a geometrically nice way why mimetism was possible in the linearized case.

In the case of Lorentzian general relativity written in terms of Ashtekar's variables, the presence of the terms $(\Gamma^i_a - \sigma\beta A^i_a)$ in the Hamiltonian make it more difficult to discretize the action in such a way that the Gauss law is preserved exactly. This is because the Γ^i_a's have to be written in terms of the triads and the resulting expressions are not easy to discretize on the lattice preserving the internal symmetry (unlike the A^i_a's which are readily discretized by considering a parallel transport operator along the elementary links). It may be possible using dual lattices to discretize such terms in an invariant way, but this will require further study. There is no problem applying our discretization technique to this case directly, but what will happen is that the internal symmetry will be broken, the Lagrange multipliers associated with the Gauss law will be determined and the resulting discretization will not be mimetic in the traditional sense of the word. It is clear that further work is needed before this kind of discretizations will be useful numerically.

In the full nonlinear case either with the traditional or the new variables, the constraints involve both coordinates and momenta and therefore the application of our technique will determine the Lagrange multipliers and will therefore not furnish a mimetic discretization in the traditional sense. The resulting discrete theory is consistent, but it does so at the expense of determining the Lagrange multipliers. Based on what we learned from the linearized case, we can conclude that the only remaining possibility for a formulation that is mimetic in the traditional sense would be to implement the symmetries implied by the constraints exactly in the lattice.

Since the symmetries implied by the diffeomorphism constraint are broken by the introduction of the lattice it appears unlikely that such a formulation would ever be found.

The conclusion we can draw from this is that for the case of full nonlinear general relativity, the closest one can come to a formulation that preserves the constraints under evolution is the proposal of consistent discretizations we have introduced. Such proposal is not mimetic in the traditional sense in that it imposes the constraints by determining the Lagrange multipliers. This proposal has many new aspects that are currently in investigation. It has been successfully applied in cosmological examples and is now being studied in detail for the Gowdy space–times. If it works for this example, it is likely that it could be applied successfully in general, but this obviously requires further study.

Something to be noticed is that it is not clear that the formulations we presented are going to be useful numerically. In particular, the fact that they are not based on manifestly hyperbolic equations. We have presented a first step towards showing stability of the scheme in a particular situation, but a fuller analysis should be carried out to determine if the scheme is stable in general. Numerical relativity codes also use more sophisticated time stepping techniques than the one we use. It is clear, however, that our method can accommodate more elaborate discretizations of the time derivatives and the calculations in this paper could be repeated in that case. Another interesting point would be to attempt to apply the techniques in this paper to the several manifestly hyperbolic formulations of the Einstein equations that have been proposed in the last few years. Unfortunately, few of them have been worked out in the context of an action principle, but this difficulty could presumably be remedied. This would also allow one to study within our framework manifolds with boundaries.

Another element of interest is the impact of the choice of the derivative operators on the construction of consistent discrete theories. The consistent technique will work no matter what derivative operators are chosen. But here we have learned that one can choose them in such a way that the linearized theory is automatically mimetic. We would like to argue that the level of accuracy with which the consistent discretization enforces the constraints is improved when one chooses a formulation that is mimetic at the linear level, at least for weak fields. The argument is simple. In the consistent discretization scheme the constraints that are enforced exactly have the form $\phi(q_n, p_{n+1})=0$. The constraints one would like to see enforced are of the form $\phi(q_n, p_n)=0$. Starting from the former, and using the equations of motion one has that $\phi(q_n, p_n+O(p^2))=0$ where the terms that correct p_n are of order p^2 (or q^2 or mixed but quadratic). This is true if the theory is mimetic in the linearized level. Otherwise one would have $\phi(q_n, p_n+O(p))=0$. Therefore choosing a discretization that is mimetic at the linearized level, at least for weak fields, implies that the constraints are tracked more accurately in the full nonlinear theory when one discretizes consistently.

Summarizing, we have shown that the consistent discretization scheme we have introduced recently, when applied to general relativity discretized around Minkowski space–time yields a formulation that is mimetic. That is, a formulation in which the discrete constraints are exactly preserved upon discrete evolution. We have also argued that for the full nonlinear case, the use of consistent discretizations appears as a possibility to yield a formulation that is close to the intention of mimetic formulations, although only approximately.

(Received 5 October 2004; accepted 29 November 2004; published online 9 February 2005)

The aim of this work is to present a formulation to general relativity, which is analogous to the null surface formulation, but now instead of starting with a complete integral of the eikonal equation we start with a complete integral of the Hamilton–Jacobi equation. In the first part of this work we show that on the space of solutions of a certain class of systems of six second-order partial differential equations, $u_{ss}=\Lambda(s,s^*,\gamma,u,u_s,u_{s^*},u_\gamma), u_{s^*s^*}=\Lambda^*(s,s^*,\gamma,u,u_s,u_{s^*},u_\gamma)$, $u_{\gamma\gamma}=\Upsilon(s,s^*,\gamma,u,u_s,u_{s^*},u_\gamma), u_{ss^*}=\Phi(s,s^*,\gamma,u,u_s,u_{s^*},u_\gamma)$, $u_{s\gamma}=\Psi(s,s^*,\gamma,u,u_s,u_{s^*},u_\gamma), u_{s^*\gamma}=\Psi^*(s,s^*,\gamma,u,u_s,u_{s^*},u_\gamma)$, a four-dimensional (definite or indefinite) metric, g_{ab}, can be constructed on the four-dimensional solution space with local coordinates x^a. Furthermore the solutions, $u=Z(x^a,s,s^*,\gamma)$, satisfy the four-dimensional Hamilton–Jacobi equation, $g^{ab}u_{,a}u_{,b}=1$. We remark that this structure is invariant under a subset of contact transformations. In the next section, as an example, we apply these results to the Schwarzschild metric. Finally we use the four-dimensional metric obtained in the first part and we impose the Einstein equations. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1850366]

I. INTRODUCTION

Many years ago, Wünschmann, Cartan, and Chern,[1–6] while studying the structure and transformation properties of third-order ODE's, discovered that all three-dimensional conformal Lorentzian geometries were encoded in equivalence classes (under contact transformations) of third-order ODE's, that were characterized by the vanishing of a certain function, $W[F]$, defined from the differential equation itself, that is referred to as the Wünschmann invariant. In other words, from the solutions to equations of the form

$$\frac{d^3z}{dt^3}=F\left(z,\frac{dz}{dt},\frac{d^2z}{dt^2},t\right),$$

with $W[F]=0$, all three-dimensional conformal Lorentzian metrics could be constructed.

In a more recent series of papers Frittelli, Kozameh, Newman, Kamran, and Nurowski,[7–14] were able to generalize this result. They showed that all four-dimensional conformal Lorentzian geometries were encoded in equivalence classes (under contact transformations) of pairs of second-order partial differential equations (PDE's) that were characterized by the vanishing of an analogous (generalized) Wünschmann invariant, referred to as the *metricity conditions.*

In this work, referred to as the null surface formulation of general relativity, the metric of the space–time is a derived concept. The fundamental objects are two functions, $Z(x^a,\zeta,\zeta^*)$ and $\Omega(x^a,\zeta,\zeta^*)$, of the space–time points x^a and parametrized by points on the sphere; that is, by

functions defined on $\mathcal{M}\times\mathcal{S}^2$ (the sphere bundle over the space–time). The first of the functions, $Z(x^a,\zeta,\zeta^*)$, which encodes all the conformal information of the space–time, describes a sphere's worth of surfaces through each space–time point. It is from these surfaces that a conformal metric can be constructed. The second function, $\Omega(x^a,\zeta,\zeta^*)$, which plays the role of a conformal factor, converts it into any metric in the conformal class. The level surfaces of $Z(x^a,\zeta,\zeta^*)$ in $\mathcal{M}$, for each fixed value of ζ, are null hypersurfaces with respect to this metric. As ζ takes different values on $\mathcal{S}^2$ at a fixed point x^a in $\mathcal{M}$, the normals to the null hypersurfaces sweep out the null-cone at x^a.

To establish this new approach to general relativity, these authors began with a four-dimensional Lorentzian manifold, already containing a metric g_{ab} and a complete integral to the eikonal equation

$$g^{ab}(x^a)\nabla_a Z\cdot\nabla_b Z=0. \tag{1}$$

A complete integral, expressed as

$$u=Z(x^a,\zeta,\zeta^*), \tag{2}$$

contains the space–time coordinates, x^a, and the needed (for a complete integral) two parameters (ζ,ζ^*). By constructing the four functions,

$$\theta^i\equiv(u,\omega,\omega^*,R)\equiv(Z,\partial_\zeta Z,\partial_{\zeta^*}Z,\partial_{\zeta^*\zeta}Z) \tag{3}$$

from Eq. (2) and its derivatives, and by eliminating x^a, via the algebraic inversion

$$x^a=X^a(\zeta,\zeta^*,\theta^i), \tag{4}$$

they found that $u=Z(x^a,\zeta,\zeta^*)$ satisfies in addition to Eq. (2) the pair of second-order partial differential equations in ζ, ζ^*, of the form

$$\partial_{\zeta\zeta}Z=\Lambda(Z,\partial_\zeta Z,\partial_{\zeta^*}Z,\partial_{\zeta\zeta^*}Z,\zeta,\zeta^*),$$

$$\partial_{\zeta^*\zeta^*}Z=\Lambda^*(Z,\partial_\zeta Z,\partial_{\zeta^*}Z,\partial_{\zeta\zeta^*}Z,\zeta,\zeta^*). \tag{5}$$

The x^a, in the solution of Eq. (5), appear now as constants of integration. The roles of x^a and (ζ,ζ^*) are thereby interchanged. Note that the metric has disappeared from the equations.

The question then was, could this procedure be reversed? Could one start with a pair of equations of the form, (5), and then find the eikonal equation, (1), with a metric $g^{ab}(x^a)$.

It was shown that when the functions (Λ,Λ^*) satisfy an integrability condition, a weak inequality and a certain set of differential conditions (the metricity or generalized Wünschmann conditions), the procedure can be reversed. The solutions to the pair do determine a conformal four-dimensional Lorentzian metric and, in fact, all conformal Lorentzian metrics can be obtained from equivalence classes of equations of the form Eq. (5). When certain specific conditions,[15] in addition to the Wünschmann condition, are imposed on the (Λ,Λ^*), the metrics, determined by the solutions, are in the vacuum conformal Einstein class.

The aim of the present work is to present an approach to general relativity, which is similar to the null surface formulation, but now instead of using a complete integral to the eikonal equation, we use a complete integral to the Hamilton–Jacobi (HJ) equation.

In Sec. II we begin with a four-dimensional manifold, $\mathcal{M}$, with no further structure and then investigate arbitrary three-parameter families of surfaces on $\mathcal{M}$ given by

$$u=\text{constant}=Z(x^a,\alpha,\beta,\gamma). \tag{6}$$

(The x^a are local coordinates on $\mathcal{M}$ and α, β, and γ parametrize the families and can take values on $\mathcal{S}^3$, $\mathcal{S}^1\times\mathcal{R}^2$, $\mathcal{S}^2\times\mathcal{R}$ or on $\mathcal{R}^3$. However, in this work we combine the real α and β parameters into a pair of conjugate parameters s and s^*; γ will be real.) More specifically, we then ask when do such families of surfaces define a four-dimensional metric, $g_{ab}(x^a)$, such that

$$g^{ab}\nabla_a Z(x^a,s,s^*,\gamma)\nabla_b Z(x^a,s,s^*,\gamma)=1. \tag{7}$$

We have here either taken the mass in the HJ equation to be *one* or set it into the g^{ab} as a factor.

By taking (s,s^*,γ) derivatives of Eq. (6) and eliminating the x^a, we will show that the $u=Z(x^a,s,s^*,\gamma)$ must also satisfy a system of six second-order PDE's,

$$\begin{aligned}
\partial_{ss}Z&=\Lambda(u,w,w^*,R,s,s^*,\gamma),\\
\partial_{s^*s^*}Z&=\Lambda^*(u,w,w^*,R,s,s^*,\gamma),\\
\partial_{\gamma\gamma}Z&=\Upsilon(u,w,w^*,R,s,s^*,\gamma),\\
\partial_{ss^*}Z&=\Phi(u,w,w^*,R,s,s^*,\gamma),\\
\partial_{s\gamma}Z&=\Psi(u,w,w^*,R,s,s^*,\gamma),\\
\partial_{s^*\gamma}Z&=\Psi^*(u,w,w^*,R,s,s^*,\gamma),
\end{aligned} \tag{8}$$

with

$$w\equiv\partial_s Z,\quad w^*\equiv\partial_{s^*}Z,\quad \text{and } R\equiv\partial_\gamma Z,$$

and where Λ, Λ^*, Υ, Φ, Ψ, and Ψ^* are restricted to satisfy certain metricity or "Wünschmann-like" conditions.

Here ∂_s, ∂_{s^*}, and ∂_γ, denote the partial derivatives with respect to the parameters s, s^*, and γ, respectively. Observe that in the solutions of Eqs. (8) $u=Z(x^a,s,s^*,\gamma)$, the x^a are four constants of integration for Eqs. (8) while the s, s^*, and γ are three integration constants for Eq. (7). Observe that $u=Z(x^a,s,s^*,\gamma)$ is a complete integral to the Hamilton–Jacobi equation (7).

In this section we also remark that the four-dimensional metric $g_{ab}(x^a)$ associated with the system of partial differential equations, (8), is invariant under a subset of contact transformations of the differential equations.

In Sec. III, as an example, we apply the results derived in Sec. II to the Schwarzschild metric.

In Sec. IV, we present our formulation of general relativity. For this purpose we substitute the four-dimensional metric already obtained in Sec. II into the Einstein equations. From our results we conclude that the Einstein equations can be reformulated as equations for families of three-dimensional surfaces given by the level surfaces of $u=Z(x^a,s,s^*,\gamma)$.

This new point of view can be given in either of two versions. In the first version, the variables are the six functions, $(\Lambda,\Lambda^*,\Upsilon,\Phi,\Psi,\Psi^*)$ of the seven variables, (u,w,w^*,R,s,s^*,γ) i.e., the right-hand side of Eqs. (8). These functions must satisfy three sets of equations; the integrability conditions, the Wünschmann-like conditions and a further condition obtained from the Einstein equations. The metric, on a four-manifold, can be written down directly in terms of these six functions and their derivatives. *No use need be made of the set*, Eqs. (8). In the second version one uses the same set of $(\Lambda,\Lambda^*,\Upsilon,\Phi,\Psi,\Psi^*)$ in the right-hand side of Eqs. (8) and solves for the $Z(x^a,s,s^*,\gamma)$. The metric is then written in terms of the $Z(x^a,s,s^*,\gamma)$ and its derivatives. The advantage of the first version is that one does not need to solve Eqs. (8), but one has to extract (algebraically) the four-manifold from the (u,w,w^*,R) while in the second version the four-manifold is explicitly given by the four constants of integration, x^a.

There is no claim being made that this approach to the Einstein equations has any obvious advantage over the usual metric approach. It however does give certain mathematical insights into the differential geometry associated with general relativity.

II. 4D METRICS AND THE METRICITY OR WÜNSCHMANN-LIKE CONDITIONS

In this section we prove that in the space of solutions of a certain class of systems of six second-order PDE's, a four-dimensional definite or indefinite metric, g_{ab}, can be constructed such that the solutions satisfy the four-dimensional HJ equation. We start with a four-dimensional manifold $\mathcal{M}$ [with local coordinates $x^a=(x^0,x^1,x^2,x^3)$] and assume we are given a three-parameter set of functions $u=Z(x^a,\alpha,\beta,\gamma)$. In general the parameters α, β, and γ can take values on $\mathcal{S}^3$, $\mathcal{S}^1\times\mathcal{R}^2$, $\mathcal{S}^2\times\mathcal{R}$ or on $\mathcal{R}^3$. As we said, we combine the real α and β parameters into a pair of conjugate parameters s and s^*, and γ is real. We also assume that for fixed values of the parameters s, s^*, and γ the level surfaces

$$u = \text{constant} = Z(x^a,s,s^*,\gamma), \tag{9}$$

locally foliate the manifold $\mathcal{M}$ and that $u=Z(x^a,s,s^*,\gamma)$ satisfies the HJ equation

$$g^{ab}(x^a)\nabla_a Z(x^a,s,s^*,\gamma)\nabla_b Z(x^a,s,s^*,\gamma)=1, \tag{10}$$

for some unknown metric $g_{ab}(x^a)$.

The basic idea now is to solve Eq. (10) for the components of the metric in terms of $\nabla_a Z(x^a,s,s^*,\gamma)$. To do so, we will consider a number of parameter derivatives of the condition (10), and then by manipulation of these derivatives, obtain both the four-dimensional metric and the six partial differential equations defining the surfaces plus the conditions these PDE's must satisfy. They will be referred to as the metricity or Wünschmann-like conditions.

Remark 1: The notation is as follows: there will be two types of differentiation, one is with respect to the local coordinates, x^a, of the manifold $\mathcal{M}$, denoted by ∇_a or "comma a," the other is with respect to the parameters s, s^* and γ, denoted by ∂_s, ∂_{s^*}, and ∂_γ.

From the assumed existence of $u=Z(x^a,s,s^*,\gamma)$, we define four parameterized scalars θ^i in the following way:

$$\begin{aligned}
\theta^0 &= u \equiv Z(x^a,s,s^*,\gamma),\\
\theta^+ &= w \equiv \partial_s Z(x^a,s,s^*,\gamma),\\
\theta^- &= w^* \equiv \partial_{s^*} Z(x^a,s,s^*,\gamma),\\
\theta^1 &= R \equiv \partial_\gamma Z(x^a,s,s^*,\gamma).
\end{aligned} \tag{11}$$

Remark 2: For each value of s, s^* and γ, Eqs. (11) can be thought of as a coordinate transformation between the x^a's and (u,w,w^*,R).

We also define the following six important scalars:

$$\tilde{\Lambda} = \partial_{ss} Z(x^a,s,s^*,\gamma),$$

$$\tilde{\Lambda}^* = \partial_{s^*s^*} Z(x^a,s,s^*,\gamma),$$

$$\tilde{\Upsilon} = \partial_{\gamma\gamma} Z(x^a,s,s^*,\gamma),$$

$$\tilde{\Phi} = \partial_{ss^*} Z(x^a,s,s^*,\gamma),$$

$$\tilde{\Psi} = \partial_{s\gamma} Z(x^a,s,s^*,\gamma),$$

$$\tilde{\Psi}^* = \partial_{s^*\gamma} Z(x^a, s, s^*, \gamma). \tag{12}$$

In what follows we will assume that Eqs. (11) can be inverted, i.e., solved for the x^a's;

$$x^a = X^a(u, w, w^*, R, s, s^*, \gamma).$$

Equations (12) can then be rewritten as

$$\begin{aligned}
\partial_{ss} Z &= \Lambda(u, w, w^*, R, s, s^*, \gamma), \\
\partial_{s^*s^*} Z &= \Lambda^*(u, w, w^*, R, s, s^*, \gamma), \\
\partial_{\gamma\gamma} Z &= \Upsilon(u, w, w^*, R, s, s^*, \gamma), \\
\partial_{ss^*} Z &= \Phi(u, w, w^*, R, s, s^*, \gamma), \\
\partial_{s\gamma} Z &= \Psi(u, w, w^*, R, s, s^*, \gamma), \\
\partial_{s^*\gamma} Z &= \Psi^*(u, w, w^*, R, s, s^*, \gamma).
\end{aligned} \tag{13}$$

This means that the three-parameter family of level surfaces, Eq. (9), can be obtained as solutions to the system of six second-order PDE's (13). Note that $(\Lambda, \Lambda^*, \Upsilon, \Phi, \Psi, \Psi^*)$ satisfy the integrability conditions

$$\begin{aligned}
&D_{s^*}\Lambda = D_s\Phi, \quad D_\gamma\Lambda = D_s\Psi, \quad D_\gamma\Phi = D_{s^*}\Psi, \\
&D_s\Lambda^* = D_{s^*}\Phi, \quad D_\gamma\Lambda^* = D_{s^*}\Psi^*, \quad D_\gamma\Phi = D_s\Psi^*, \\
&D_\gamma\Psi = D_s\Upsilon, \quad D_\gamma\Psi^* = D_{s^*}\Upsilon, \quad D_{s^*}\Psi = D_s\Psi^*,
\end{aligned} \tag{14}$$

where we have the following.

Definition 1: *The total* s, s^*, *and* γ *derivatives of a function* $F = F(u, w, w^*, R, s, s^*, \gamma)$ *are defined by*

$$\begin{aligned}
D_s F &\equiv F_s + F_u w + F_w \Lambda + F_{w^*}\Phi + F_R \Psi, \\
D_{s^*} F &\equiv F_{s^*} + F_u w^* + F_w \Phi + F_{w^*}\Lambda^* + F_R \Psi^*, \\
D_\gamma F &\equiv F_\gamma + F_u R + F_w \Psi + F_{w^*}\Psi^* + F_R \Upsilon,
\end{aligned} \tag{15}$$

respectively.

The solution space of Eqs. (13) is four dimensional. This can be seen in the following way. The system of PDE's (13) is equivalent to the vanishing of the four one-forms, ω^i,

$$\begin{aligned}
\omega^0 &= \mathrm{d}u - w\,\mathrm{d}s - w^*\,\mathrm{d}s^* - R\,\mathrm{d}\gamma, \\
\omega^+ &= \mathrm{d}w - \Lambda\,\mathrm{d}s - \Phi\,\mathrm{d}s^* - \Psi\,\mathrm{d}\gamma, \\
\omega^- &= \mathrm{d}w^* - \Phi\,\mathrm{d}s - \Lambda^*\,\mathrm{d}s^* - \Psi^*\,\mathrm{d}\gamma,
\end{aligned}$$

$$\omega^1 = \mathrm{d}R - \Psi\,\mathrm{d}s - \Psi^*\,\mathrm{d}s^* - \Upsilon\,\mathrm{d}\gamma. \tag{16}$$

A simple calculation, using the integrability conditions on $(\Lambda, \Lambda^*, \Upsilon, \Phi, \Psi, \Psi^*)$, leads to $\mathrm{d}\omega^i = 0$ (modulo ω^i) from which, via the Frobenius theorem, the solution space of Eqs. (13) is four dimensional.

From the four scalars, θ^i, we have their associated gradient basis $\theta^i{}_{,a}$ given by

$$\theta^i{}_{,a} = \nabla_a \theta^i = \{Z_{,a}, \partial_s Z_{,a}, \partial_{s^*} Z_{,a}, \partial_\gamma Z_{,a}\}, \tag{17}$$

and its dual vector basis θ_i^a, so that

$$\theta_i^a \theta^j{}_{,a} = \delta_i^j, \quad \theta_i^a \theta^i{}_{,b} = \delta_b^a. \tag{18}$$

It is easier to search for the components of the four-dimensional metric in the gradient basis rather than in the original coordinate basis. Furthermore, it is preferable to use the contravariant components rather than the covariant components of the metric; i.e., we want to determine

$$g^{ij}(x^a, s, s^*, \gamma) = g^{ab}(x^a)\,\theta^i{}_{,a}\,\theta^j{}_{,b}. \tag{19}$$

The metric components and the Wünschmann-like conditions are obtained by repeatedly operating with ∂_s, ∂_{s^*}, and ∂_γ on Eq. (10), which, by definition, is

$$g^{00} = g^{ab} Z_{,a} Z_{,b} = 1. \tag{20}$$

Applying ∂_s to Eq. (20) yields $\partial_s g^{00} = 2 g^{ab} \partial_s Z_{,a} Z_{,b} = 0$, i.e.,

$$g^{+0} = 0. \tag{21}$$

In the same way we obtain that $\partial_{s^*} g^{00} = 2 g^{ab} \partial_{s^*} Z_{,a} Z_{,b} = 0$, $\partial_\gamma g^{00} = 2 g^{ab} \partial_\gamma Z_{,a} Z_{,b} = 0$ and thus,

$$\begin{aligned} g^{-0} &= 0, \\ g^{10} &= 0. \end{aligned} \tag{22}$$

A direct computation shows that

$$\partial_{ss}(g^{00}/2) = g^{ab} \partial_{ss} Z_{,a} Z_{,b} + g^{ab} \partial_s Z_{,a} \partial_s Z_{,b} = g^{ab} \Lambda_{,a} Z_{,b} + g^{++} = 0. \tag{23}$$

Since, by the assumed linear independence of $(Z_{,a}, \partial_s Z_{,a}, \partial_{s^*} Z_{,a}, \partial_\gamma Z_{,a})$,

$$\Lambda_{,a} = \Lambda_u Z_{,a} + \Lambda_w \partial_s Z_{,a} + \Lambda_{w^*} \partial_{s^*} Z_{,a} + \Lambda_\gamma \partial_\gamma Z_{,a}, \tag{24}$$

Eq. (23), using Eqs. (20)–(22) and (24), is equivalent to

$$g^{++} = -\Lambda_u. \tag{25}$$

In exactly the same way we find that

$$\partial_{s^* s^*}(g^{00}/2) = \Lambda_u^* + g^{--} = 0,$$

$$\partial_{\gamma\gamma}(g^{00}/2) = \Upsilon_u + g^{11} = 0,$$

$$\partial_{s s^*}(g^{00}/2) = \Phi_u + g^{-+} = 0,$$

$$\partial_{s\gamma}(g^{00}/2) = \Psi_u + g^{1+} = 0,$$

$$\partial_{s^*\gamma}(g^{00}/2) = \Psi_u^* + g^{-1} = 0. \tag{26}$$

Therefore, the final result is

$$(g^{ij}) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -\Lambda_u & -\Phi_u & -\Psi_u \\ 0 & -\Phi_u & -\Lambda_u^* & -\Psi_u^* \\ 0 & -\Psi_u & -\Psi_u^* & -\Upsilon_u \end{pmatrix}. \tag{27}$$

Remark 3: We require that $\det(g^{ij})=\Delta$ *be different from zero, with*

$$\Delta \equiv \Upsilon_u\Phi_u^2 - 2\Phi_u\Psi_u\Psi_u^* + \Lambda_u^*\Psi_u^2 + \Lambda_u(\Psi_u^*)^2 - \Lambda_u\Lambda_u^*\Upsilon_u. \tag{28}$$

The metricity or Wünschmann-like conditions are obtained from the third derivatives, i.e., from $\partial_{sss}g^{00}=0$, $\partial_{sss^*}g^{00}=0$, $\partial_{ss^*s^*}g^{00}=0$, $\partial_{s^*s^*s^*}g^{00}=0$, $\partial_{ss\gamma}g^{00}=0$, $\partial_{s\gamma\gamma}g^{00}=0$, $\partial_{\gamma\gamma\gamma}g^{00}=0$, $\partial_{s^*s^*\gamma}g^{00}=0$, $\partial_{s^*\gamma\gamma}g^{00}=0$. By using the integrability conditions, (14), a direct computation shows that they are equivalent to the following nine equations:

$$\begin{aligned}
&\Lambda_{us} + \Lambda_{uu}w + \Lambda_{uw}\Lambda + \Lambda_{uw^*}\Phi + \Lambda_{uR}\Psi = 2[\Lambda_w\Lambda_u + \Lambda_{w^*}\Phi_u + \Lambda_R\Psi_u],\\
&\Lambda_{us^*} + \Lambda_{uu}w^* + \Lambda_{uw}\Phi + \Lambda_{uw^*}\Lambda^* + \Lambda_{uR}\Psi^* = 2[\Phi_w\Lambda_u + \Phi_{w^*}\Phi_u + \Phi_R\Psi_u],\\
&\Lambda_{us}^* + \Lambda_{uu}^*w + \Lambda_{uw^*}^*\Phi + \Lambda_{uw}^*\Lambda + \Lambda_{uR}^*\Psi = 2[\Phi_{w^*}\Lambda_u^* + \Phi_w\Lambda_u + \Phi_R\Psi_u^*],\\
&\Lambda_{us^*}^* + \Lambda_{uu}^*w^* + \Lambda_{uw^*}^*\Lambda^* + \Lambda_{uw}^*\Phi + \Lambda_{uR}^*\Psi^* = 2[\Lambda_{w^*}^*\Lambda_u^* + \Lambda_w^*\Phi_u + \Lambda_R^*\Psi_u^*],\\
&\Lambda_{u\gamma} + \Lambda_{uu}R + \Lambda_{uw}\Psi + \Lambda_{uw^*}\Psi^* + \Lambda_{uR}\Upsilon = 2[\Psi_w\Lambda_u + \Psi_{w^*}\Phi_u + \Psi_R\Psi_u],\\
&\Upsilon_{us} + \Upsilon_{uu}w + \Upsilon_{uw}\Lambda + \Upsilon_{uw^*}\Phi + \Upsilon_{uR}\Psi = 2[\Psi_w\Psi_u + \Psi_{w^*}\Psi_u^* + \Psi_R\Upsilon_u],\\
&\Upsilon_{u\gamma} + \Upsilon_{uu}R + \Upsilon_{uw}\Psi + \Upsilon_{uw^*}\Psi^* + \Upsilon_{uR}\Upsilon = 2[\Upsilon_w\Psi_u + \Upsilon_{w^*}\Psi_u^* + \Upsilon_R\Psi_u],\\
&\Lambda_{u\gamma}^* + \Lambda_{uu}^*R + \Lambda_{uw^*}^*\Psi^* + \Lambda_{uw}^*\Psi + \Lambda_{uR}^*\Upsilon = 2[\Psi_{w^*}^*\Lambda_u^* + \Psi_w^*\Phi_u + \Psi_R^*\Psi_u^*],\\
&\Upsilon_{us^*} + \Upsilon_{uu}w^* + \Upsilon_{uw^*}\Lambda^* + \Upsilon_{uw}\Phi + \Upsilon_{uR}\Psi^* = 2[\Psi_{w^*}^*\Psi_u^* + \Psi_w^*\Psi_u + \Psi_R^*\Upsilon_u].
\end{aligned} \tag{29}$$

Summarizing we have the following.

(a) If we start from a complete integral, $u=Z(x^a,s,s^*,\gamma)$ to the HJ equation, (10), then it satisfies the system of six second-order PDE's (13), with $(\Lambda,\Lambda^*,\Upsilon,\Phi,\Psi,\Psi^*)$ satisfying Eqs. (14) and the Wünschmann-like conditions (29); in other words, in the solution space of Eqs. (13) there is the naturally defined metric,

$$\begin{aligned}
g_{ab} = u_{,a}u_{,b} + \frac{1}{\Delta}[&(\Lambda_u^*\Upsilon_u - (\Psi_u^*)^2)w_{,a}w_{,b} + (\Psi_u\Psi_u^* - \Upsilon_u\Phi_u)(w_{,a}w_{,b}^* + w_{,a}^*w_{,b}) + (\Lambda_u\Upsilon_u - \Psi_u^2)w_{,a}^*w_{,b}^*\\
&+ (\Phi_u\Psi_u^* - \Lambda_u^*\Psi_u)(w_{,a}R_{,b} + R_{,a}w_{,b}) + (\Phi_u\Psi_u - \Lambda_u\Psi_u^*)(w_{,a}^*R_{,b} + R_{,a}w_{,b}^*) + (\Lambda_u\Lambda_u^* - \Phi_u^2)R_{,a}R_{,b}],
\end{aligned} \tag{30}$$

where Δ is defined by Eq. (28).

(b) If we start with a system of six second-order PDE's (13), where $(\Lambda,\Lambda^*,\Upsilon,\Phi,\Psi,\Psi^*)$ satisfy Eqs. (29) and the integrability conditions, (14), then in its solution space there exist a

natural four-dimensional metric given by Eq. (30). Though it might appear as if the metric components depend on the parameters (s, s^*, γ), the Wünschmann-like conditions guarantees that they do not. Furthermore, the solutions $u = Z(x^a, s, s^*, \gamma)$ satisfy the HJ equation

$$g^{ab}\nabla_a Z(x^a, s, s^*, \gamma)\nabla_b Z(x^a, s, s^*, \gamma) = 1$$

with the just determined metric, Eq. (30).

Remark 4: From the results presented above we conclude that solving the four-dimensional HJ equation, in a four-dimensional background space–time, is equivalent to solving a system of six second-order PDE's.

In some of the earlier work on the eikonal equation in three- and four-dimensional Lorentzian spaces, it was proved that the conformal Lorentzian metrics associated with third-order ODE's and pairs of second-order PDE's satisfying the Wünschmann condition and generalized Wünschmann condition, is preserved when the differential equation is transformed by a contact transformation. For our present case, there is an analogous result given by the following.

Theorem 1: *Let Eqs. (13) be a system of six second-order PDE's, with* $(\Lambda, \Lambda^*, \Upsilon, \Phi, \Psi, \Psi^*)$ *satisfying the conditions (14) and (29), and let*

$$\begin{aligned}
\partial_{\overline{ss}}\overline{Z} &= \overline{\Lambda}(\overline{u}, \overline{w}, \overline{w^*}, \overline{R}, \overline{s}, \overline{s^*}, \overline{\gamma}),\\
\partial_{\overline{s^*s^*}}\overline{Z} &= \overline{\Lambda}^*(\overline{u}, \overline{w}, \overline{w^*}, \overline{R}, \overline{s}, \overline{s^*}, \overline{\gamma}),\\
\partial_{\overline{\gamma\gamma}}\overline{Z} &= \overline{\Upsilon}(\overline{u}, \overline{w}, \overline{w^*}, \overline{R}, \overline{s}, \overline{s^*}, \overline{\gamma}),\\
\partial_{\overline{ss^*}}\overline{Z} &= \overline{\Phi}(\overline{u}, \overline{w}, \overline{w^*}, \overline{R}, \overline{s}, \overline{s^*}, \overline{\gamma}),\\
\partial_{\overline{s\gamma}}\overline{Z} &= \overline{\Psi}(\overline{u}, \overline{w}, \overline{w^*}, \overline{R}, \overline{s}, \overline{s^*}, \overline{\gamma}),\\
\partial_{\overline{s^*\gamma}}\overline{Z} &= \overline{\Psi}^*(\overline{u}, \overline{w}, \overline{w^*}, \overline{R}, \overline{s}, \overline{s^*}, \overline{\gamma}),
\end{aligned} \tag{31}$$

be a second system of six second-order PDE's locally equivalent to Eqs. (13) under the subset of contact transformations generated by the generating function

$$H(s, s^*, \gamma, u, \overline{s}, \overline{s^*}, \overline{\gamma}, \overline{u}) = \overline{u} - u - G(s, s^*, \gamma, \overline{s}, \overline{s^*}, \overline{\gamma}). \tag{32}$$

Then under this subset of contact transformations the metric given by Eq. (30) is preserved.

The proof of this theorem is exactly as that presented in Ref. 12 for a system of two second-order PDE's such that on its space of solutions there is a unique four-dimensional conformal Lorentzian metric, g^{ab}, such that $g^{ab}u_{,a}u_{,b} = 0$. Here we only justify the form of the generating function (32). We first review the definition of a general contact transformation.

Theorem 2: *Every contact transformation which is not a prolonged point transformation is determined in terms of a generating function* $H(s, s^*, \gamma, u, \overline{s}, \overline{s^*}, \overline{\gamma}, \overline{u})$ *by solving the following seven implicit equations for* $\overline{s}, \overline{s^*}, \overline{\gamma}, \overline{u}, \overline{w} = \partial_{\overline{s}}\overline{u}, \overline{w^*} = \partial_{\overline{s^*}}\overline{u}, \overline{R} = \partial_{\overline{\gamma}}\overline{u}$:

$$\begin{aligned}
&H(s, s^*, \gamma, u, \overline{s}, \overline{s^*}, \overline{\gamma}, \overline{u}) = 0,\\
&H_s + wH_u = 0,\ H_{\overline{s}} + \overline{w}H_{\overline{u}} = 0,\\
&H_{s^*} + w^*H_u = 0,\ H_{\overline{s^*}} + \overline{w^*}H_{\overline{u}} = 0,
\end{aligned}$$

$$H_\gamma + RH_u = 0,\ H_{\overline{\gamma}} + \overline{R}H_{\overline{u}} = 0. \tag{33}$$

The generating function $H(s, s^*, \gamma, u, \overline{s}, \overline{s^*}, \overline{\gamma}, \overline{u})$ *is an arbitrary smooth function, subject only to the solvability of Eqs. (33) for* $\overline{s}$, $\overline{s^*}$, $\overline{\gamma}$, $\overline{u}$, $\overline{w}$, $\overline{w^*}$ *and* $\overline{R}$.

For a proof of this theorem see, for example, Olver.[16]

Without loss of generality one can take

$$H = \overline{u} - \overline{V}(u, s, s^*, \gamma, \overline{s}, \overline{s^*}, \overline{\gamma}), \tag{34}$$

so that the contact transformation has the form

$$\begin{aligned}
&\overline{u} = \overline{V}(u, s, s^*, \gamma, A(s, s^*, \gamma, u, w, w^*, R), A^*(s, s^*, \gamma, u, w, w^*, R), C(s, s^*, \gamma, u, w, w^*, R)),\\
&\overline{s} = A(s, s^*, \gamma, u, w, w^*, R),\\
&\overline{s^*} = A^*(s, s^*, \gamma, u, w, w^*, R),\\
&\overline{\gamma} = C(s, s^*, \gamma, u, w, w^*, R),\\
&\overline{w} = \overline{V}_{\overline{s}}(u, s, s^*, \gamma, A(s, s^*, \gamma, u, w, w^*, R), A^*(s, s^*, \gamma, u, w, w^*, R), C(s, s^*, \gamma, u, w, w^*, R)),\\
&\overline{w^*} = \overline{V}_{\overline{s^*}}(u, s, s^*, \gamma, A(s, s^*, \gamma, u, w, w^*, R), A^*(s, s^*, \gamma, u, w, w^*, R), C(s, s^*, \gamma, u, w, w^*, R)),\\
&\overline{R} = \overline{V}_{\overline{\gamma}}(u, s, s^*, \gamma, A(s, s^*, \gamma, u, w, w^*, R), A^*(s, s^*, \gamma, u, w, w^*, R), C(s, s^*, \gamma, u, w, w^*, R)),
\end{aligned} \tag{35}$$

where $A(s, s^*, \gamma, u, w, w^*, R)$, $A^*(s, s^*, \gamma, u, w, w^*, R)$, and $C(s, s^*, \gamma, u, w, w^*, R)$ are obtained by solving

$$\begin{aligned}
&\overline{V}_s + w\overline{V}_u = 0,\\
&\overline{V}_{s^*} + w^*\overline{V}_u = 0,\\
&\overline{V}_\gamma + R\overline{V}_u = 0,
\end{aligned} \tag{36}$$

for $\overline{s}$, $\overline{s^*}$, and $\overline{\gamma}$ in terms of s, s^*, γ, u, w, w^*, and R.

As was pointed out earlier, for each value of s, s^*, and γ, the four-parameters, x^a, family of solutions

$$u = Z(x^a, s, s^*, \gamma), \tag{37}$$

of (13) is also a three-parameters, (s, s^*, γ), family of solutions of Eq. (10), i.e., are complete integrals of Eq. (10). We now invoke the envelope construction to take one complete integral of Eq. (10) into another such solution. Consider the function $\overline{u} = \overline{Z}(x^a, \overline{s}, \overline{s^*}, \overline{\gamma})$ defined by

$$\overline{u} = \overline{V}(u, s, s^*, \gamma, \overline{s}, \overline{s}^*, \overline{\gamma}), \tag{38}$$

where u is defined by Eq. (37) and s, s^*, and γ are defined implicitly as functions of x^a, $\overline{s}$, $\overline{s^*}$, and $\overline{\gamma}$ by the envelope conditions[12,17]

$$\overline{V}_u w + \overline{V}_s = 0,$$

$$\overline{V}_u w^* + \overline{V}_{s^*} = 0, \tag{39}$$

$$\overline{V}_u R + \overline{V}_\gamma = 0.$$

Note that although Eqs. (39) have the same form as Eqs. (36), they involve the variables x^a, s, s^*, and γ. Using both Eqs. (38) and (39), we have that

$$\overline{u}_{,a} = \overline{V}_u u_{,a}. \tag{40}$$

By direct substitution of $\overline{u}_{,a}$ into the HJ equation, Eq. (10), we see that it is a new complete integral if and only if $\overline{V}_u^2 = 1$. That is, $\overline{u} = \overline{V}(u, s, s^*, \gamma, \overline{s}, \overline{s^*}, \overline{\gamma})$ has the form $\overline{u} = \pm u + G(s, s^*, \gamma, \overline{s}, \overline{s^*}, \overline{\gamma})$. For simplicity, taking the positive sign, we have that if $u(x^a, s, s^*, \gamma)$ is a complete integral of Eq. (10) then

$$\overline{u} = u + G(s, s^*, \gamma, \overline{s}, \overline{s}^*, \overline{\gamma}), \tag{41}$$

where s, s^*, and γ are defined implicitly as functions of x^a, $\overline{s}$, $\overline{s^*}$, and $\overline{\gamma}$ by the envelope conditions

$$w + G_s = 0,$$

$$w^* + G_{s^*} = 0, \tag{42}$$

$$R + G_\gamma = 0,$$

is a new complete integral of Eq. (10). Equations (41) and (42) define a particular subset of the contact transformations given by contact transformations

$$\overline{u} = u + G(s, s^*, \gamma, \overline{s}, \overline{s^*}, \overline{\gamma}), \tag{43}$$

$$w = -G_s, \tag{44}$$

$$w^* = -G_{s^*}, \tag{45}$$

$$R = -G_\gamma, \tag{46}$$

$$\overline{w} = G_{\overline{s}}, \tag{47}$$

$$\overline{w^*} = G_{\overline{s}^*}, \tag{48}$$

$$\overline{R} = G_{\overline{\gamma}}. \tag{49}$$

The generating function for this set of contact transformations is given by

$$H(s, s^*, \gamma, u, \overline{s}, \overline{s}^*, \overline{\gamma}, \overline{u}) = \overline{u} - u - G(s, s^*, \gamma, \overline{s}, \overline{s}^*, \overline{\gamma}) = 0 \tag{50}$$

thus justifying our choice of the generating function, Eq. (32).

III. EXAMPLE

As an example we apply our results to the motion of a particle in the Schwarzschild space–time. By using the coordinates $x^a = (t, r, \theta, \phi)$, the Hamilton–Jacobi equation for this case can be written as

$$\left(\frac{1}{m^2}\right)\left[\frac{u_{,t}^2}{\left(1-\frac{r_g}{r}\right)}-\left(1-\frac{r_g}{r}\right)u_{,r}^2-\frac{u_{,\theta}^2}{r^2}-\frac{u_{,\phi}^2}{r^2\sin^2\theta}\right]=1, \tag{51}$$

where m is the mass of the particle and $r_g=2M$ with M being the mass of the Schwarzschild solution. By the method of separation of variables one finds that a complete solution to Eq. (51) can be written in the following form:

$$u=Z(x^a,\alpha,\beta,\gamma)=-\gamma t+\beta\phi+\int\sqrt{\alpha^2-\frac{\beta^2}{\sin^2\theta}}\,\mathrm{d}\theta+\int\sqrt{\frac{\gamma^2r^3-(m^2r^2+\alpha^2)(r-r_g)}{r(r-r_g)^2}}\,\mathrm{d}r, \tag{52}$$

where α, β, and γ are three constants of separation. For this problem, γ, is the energy of the particle, β is the value of the angular momentum about the polar axis and α is the magnitude of the total angular momentum. To obtain the system of second-order PDE's associated with this complete integral we take $\alpha=s^*+s$ and $\beta=i(s^*-s)$. Thus the complete integral in terms of the parameters (s,s^*,γ) is given by

$$\begin{aligned}u=Z(x^a,s,s^*,\gamma)=&-\gamma t+\int\sqrt{\frac{\gamma^2r^3-[m^2r^2+(s+s^*)^2](r-r_g)}{r(r-r_g)^2}}\,\mathrm{d}r\\&+\int\sqrt{(s+s^*)^2+(s-s^*)^2\csc^2\theta}\,\mathrm{d}\theta-i(s-s^*)\phi.\end{aligned} \tag{53}$$

A direct computation shows that

$$\begin{aligned}w&=\int\frac{-(s+s^*)\mathrm{d}r}{\sqrt{r}\sqrt{\gamma^2r^3-[m^2r^2+(s+s^*)^2](r-r_g)}}+\int\frac{[(s+s^*)+(s-s^*)\csc^2\theta]\mathrm{d}\theta}{\sqrt{(s+s^*)^2+(s-s^*)^2\csc^2\theta}}-i\phi,\\w^*&=\int\frac{-(s+s^*)\mathrm{d}r}{\sqrt{r}\sqrt{\gamma^2r^3-[m^2r^2+(s+s^*)^2](r-r_g)}}+\int\frac{[(s+s^*)-(s-s^*)\csc^2\theta]\mathrm{d}\theta}{\sqrt{(s+s^*)^2+(s-s^*)^2\csc^2\theta}}+i\phi,\\R&=-t+\int\frac{\sqrt{r}r^2\gamma\,\mathrm{d}r}{(r-r_g)\sqrt{\gamma^2r^3-[m^2r^2+(s+s^*)^2](r-r_g)}}.\end{aligned} \tag{54}$$

By using Eqs. (53) and (54), one sees that the Jacobian of the coordinate transformation, $\theta^i=\theta^i(x^a,s,s^*,\gamma)$, for this case, is given by

$$J=\frac{\partial(u,w,w^*,R)}{\partial(t,r,\theta,\phi)}=\frac{2im^2r^{3/2}(s+s^*)[(s+s^*)^2+(s-s^*)^2\csc^2\theta]^{-1/2}}{[\gamma^2r^3-[m^2r^2+(s+s^*)^2](r-r_g)]^{1/2}}. \tag{55}$$

Using Eqs. (54), our system of six PDE's for a Schwarzschild space–time is obtained as follows.

First we have that

$$\partial_{ss}Z=\mathcal{A}(r,s,s^*,\gamma)+s^{*2}\mathcal{B}(\theta,s,s^*),$$

$$\partial_{s^*s^*}Z=\mathcal{A}(r,s,s^*,\gamma)+s^2\mathcal{B}(\theta,s,s^*),$$

$$\partial_{\gamma\gamma}Z=\mathcal{C}(r,s,s^*,\gamma),$$

$$\partial_{ss^*}Z=\mathcal{A}(r,s,s^*,\gamma)-ss^*\mathcal{B}(\theta,s,s^*),$$

$$\partial_{s\gamma} Z = \mathcal{D}(r,s,s^*,\gamma),$$

$$\partial_{s^*\gamma} Z = \mathcal{D}(r,s,s^*,\gamma), \tag{56}$$

where

$$\mathcal{A}(r,s,s^*,\gamma) = \int \frac{-r^{3/2}[\gamma^2 r - m^2(r-r_g)]\mathrm{d}r}{[\gamma^2 r^3 - [m^2r^2 + (s+s^*)^2](r-r_g)]^{3/2}},$$

$$\mathcal{B}(\theta,s,s^*) = \int \frac{4\csc^2\theta \mathrm{d}\theta}{[(s+s^*)^2 + (s-s^*)^2\csc^2\theta]^{3/2}},$$

$$\mathcal{C}(r,s,s^*,\gamma) = \int \frac{-\sqrt{r}r^2[m^2r^2 + (s+s^*)^2]\mathrm{d}r}{[\gamma^2 r^3 - [m^2r^2 + (s+s^*)^2](r-r_g)]^{3/2}}, \tag{57}$$

$$\mathcal{D}(r,s,s^*,\gamma) = \int \frac{\sqrt{r}r^2(s+s^*)\gamma\,\mathrm{d}r}{[\gamma^2 r^3 - [m^2r^2 + (s+s^*)^2](r-r_g)]^{3/2}}.$$

On the other hand, Eqs. (53) and (54) imply that

$$t = t(u,w,w^*R,s,s^*,\gamma),$$

$$r = r(u,w,w^*R,s,s^*,\gamma),$$

$$\theta = \theta(u,w,w^*R,s,s^*,\gamma), \tag{58}$$

$$\phi = \phi(u,w,w^*R,s,s^*,\gamma).$$

Therefore, the system of six second-order PDE's for a particle moving in the Schwarzschild space–time is given by

$$\partial_{ss} Z = \Lambda = \mathcal{A}(r(u,w,w^*R,s,s^*,\gamma),s,s^*,\gamma) + s^{*2}\mathcal{B}(\theta(u,w,w^*R,s,s^*,\gamma),s,s^*),$$

$$\partial_{s^*s^*} Z = \Lambda^* = \mathcal{A}(r(u,w,w^*R,s,s^*,\gamma),s,s^*,\gamma) + s^2\mathcal{B}(\theta(u,w,w^*R,s,s^*,\gamma),s,s^*),$$

$$\partial_{\gamma\gamma} Z = \Upsilon = \mathcal{C}(r(u,w,w^*R,s,s^*,\gamma),s,s^*,\gamma),$$

$$\partial_{ss^*} Z = \Phi = \mathcal{A}(r(u,w,w^*R,s,s^*,\gamma),s,s^*,\gamma) - ss^*\mathcal{B}(\theta(u,w,w^*R,s,s^*,\gamma),s,s^*), \tag{59}$$

$$\partial_{s\gamma} Z = \Psi = \mathcal{D}(r(u,w,w^*R,s,s^*,\gamma),s,s^*,\gamma),$$

$$\partial_{s^*\gamma} Z = \Psi^* = \mathcal{D}(r(u,w,w^*R,s,s^*,\gamma),s,s^*,\gamma).$$

Since $u(x^a,s,s^*,\gamma)$ given by Eq. (53) is a complete integral to the HJ equation (51), then Λ, Λ^*, Υ, Φ, Ψ, and Ψ^* given in Eqs. (59) satisfy Eqs. (14) and (29). Therefore a four-dimensional metric can be defined in the space of solutions of Eqs. (59). By comparison of Eqs. (10) and (51) it is clear what that metric should be. However here we show the steps to explicitly obtain this metric by the procedure developed in earlier. What is remarkable is that this metric can be

obtained without the evaluation of the integrals that arose in this problem. As we can see from Eq. (27), to obtain the four-dimensional metric in tetrad components, we need to compute Λ_u, Λ_u^*, Υ_u, Φ_u, Ψ_u, and Ψ_u^*.

Since, for example,

$$\Lambda_u = (\partial\Lambda/\partial r)(\partial r/\partial u) + (\partial\Lambda)/\partial\theta)(\partial\theta/\partial u),$$

then we need to compute $(\partial r/\partial u)$ and $(\partial\theta/\partial u)$. From Eqs. (53) and (54), via implicit derivations, we obtain that

$$\frac{\partial r}{\partial u} = -\sqrt{\frac{\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)}{m^4 r^3}},$$
$$\frac{\partial\theta}{\partial u} = -\sqrt{\frac{(s+s^*)^2 + (s-s^*)^2 \csc^2\theta}{m^4 r^4}}. \tag{60}$$

A direct computation shows that the metric in tetrad components is given by

$$g^{00} = 1, \quad g^{0+} = 0, \quad g^{0-} = 0, \quad g^{01} = 0,$$
$$g^{++} = \frac{s^{*2} f(r,\theta,s,s^*) - h(r,s,s^*,\gamma)}{m^2},$$
$$g^{+-} = -\frac{ss^* f(r,\theta,s,s^*) + h(r,s,s^*,\gamma)}{m^2},$$
$$g^{+1} = \frac{r(s+s^*)\gamma}{m^2[\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)]}, \tag{61}$$
$$g^{--} = (g^{++})^*, \quad g^{-1} = g^{+1},$$
$$g^{11} = \frac{-r[m^3 r^2 + (s+s^*)^2]}{m^2[\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)]},$$

where

$$f(r,\theta,s,s^*) = \frac{4\csc^2\theta}{r^2[(s+s^*)^2 + (s-s^*)^2\csc^2\theta]},$$
$$h(r,s,s^*,\gamma) = \frac{\gamma^2 r - m^2(r-r_g)}{\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)}. \tag{62}$$

On the other hand, from Eqs. (53) and (54), we have that

$$u_{,a} = \left(-\gamma, \sqrt{\frac{\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)}{r(r-r_g)^2}}, \sqrt{(s+s^*)^2 + (s-s^*)^2\csc^2\theta}, i(s^*-s)\right),$$
$$w_{,a} = \left(0, \frac{-(s+s^*)}{\sqrt{r}\sqrt{\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)}}, \frac{(s+s^*) + (s-s^*)\csc^2\theta}{\sqrt{(s+s^*)^2 + (s-s^*)^2\csc^2\theta}}, -i\right),$$

$$w^*_{,a} = \left(0, \frac{-(s+s^*)}{\sqrt{r}\sqrt{\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)}}, \frac{(s+s^*) - (s-s^*)\csc^2\theta}{\sqrt{(s+s^*)^2 + (s-s^*)^2\csc^2\theta}}, i\right),$$

$$R_{,a} = \left(-1, \frac{\sqrt{r}r^2\gamma}{(r-r_g)\sqrt{\gamma^2 r^3 - [m^2 r^2 + (s+s^*)^2](r-r_g)}}, 0, 0\right). \tag{63}$$

Finally, by using Eqs. (30), (61), and (63), a direct computation shows that the four-dimensional metric living in the solution space of the PDE's (59) is given by

$$ds^2 = g_{ab}\,dx^a\,dx^b = m^2\left[\left(1 - \frac{r_g}{r}\right)dt^2 - \frac{dr^2}{\left(1 - \frac{r_g}{r}\right)} - r^2(d\theta^2 + \sin^2\theta\, d\phi^2)\right], \tag{64}$$

which is the desired result.

IV. THE EINSTEIN EQUATIONS

We now adopt a new point of view towards geometry on a 4D manifold. Instead of a Lorentzian metric $g^{ab}(x^a)$ on $\mathcal{M}$, as the fundamental variable we consider as the basic variables a family of surfaces on $\mathcal{M}$ given by $u = \text{constant} = Z(x^a, s, s^*, \gamma)$ or preferable its second derivatives with respect to s, s^*, and γ. From this new point of view these surfaces are basic and the metric is a derived concept. Now we will find the conditions on $u = Z(x^a, s, s^*, \gamma)$ or more accurately on the second order system such that the 4D metric, Eq. (27), be a solution to the Einstein equations.

We start with the Einstein equations[18]

$$R_{ab} = \frac{8\pi k}{c^4}\left(T_{ab} - \frac{1}{2}g_{ab}T\right), \tag{65}$$

with the Ricci tensor given by

$$R_{ab} = \frac{1}{\sqrt{-g}}\frac{\partial}{\partial x^c}(\Gamma^c_{ab}\sqrt{-g}) - \frac{\partial^2}{\partial x^a \partial x^b}\ln\sqrt{-g} - \Gamma^c_{ad}\Gamma^d_{bc}, \tag{66}$$

$g = \det(g_{ab})$ and

$$\Gamma^c_{ab} = \frac{1}{2}g^{cd}\left(\frac{\partial g_{da}}{\partial x^b} + \frac{\partial g_{db}}{\partial x^a} - \frac{\partial g_{ab}}{\partial x^d}\right), \tag{67}$$

are the Christoffel symbols.

As in the null surface formulation of general relativity in the present case the Einstein equations are given by

$$R^{ab}Z_{,a}Z_{,b} = \frac{8\pi k}{c^4}\left(T^{ab} - \frac{1}{2}g^{ab}T\right)Z_{,a}Z_{,b}. \tag{68}$$

That is, to obtain the Einstein equation in this case, we need to compute $R^{00} \equiv R^{ab}Z_{,a}Z_{,b}$, which is *one* of the components of $R^{ij} \equiv R^{ab}\theta^i_{,a}\theta^j_{,b}$. From Eq. (27) we have that $R^{00} = R_{00}$. Using the metric given by Eq. (27) with coordinates $\theta^i = (\theta^0, \theta^+, \theta^-, \theta^1)$ in Eq. (66) to compute R_{00}, we find that Eq. (68) is equivalent to

$$-(2\Delta)^{-1}G_A R^A_{uu} - 6(2\Delta)^{-2}M_{AB}R^A_u R^B_u = \frac{8\pi k}{c^4}\left(T^{ab}Z_{,a}Z_{,b} - \frac{1}{2}T\right), \tag{69}$$

where

$$R^A = (\Lambda_u, \Lambda_u^*, \Upsilon_u, \Phi_u, \Psi_u, \Psi_u^*), \tag{70}$$

$$G_A = (a, a^*, b, 2c, 2d, 2d^*), \tag{71}$$

with

$$\begin{aligned} a &\equiv \Lambda_u^* \Upsilon_u - (\Psi_u^*)^2, \\ b &\equiv \Lambda_u \Lambda_u^* - \Phi_u^2, \\ c &\equiv \Psi_u \Psi_u^* - \Phi_u \Upsilon_u, \\ d &\equiv \Phi_u \Psi_u^* - \Lambda_u^* \Psi_u, \end{aligned} \tag{72}$$

and

$$(M_{AB}) = \begin{pmatrix} \frac{a^2}{2} & \frac{c^2}{2} & \frac{d^2}{2} & ac, & ad & cd \\ \frac{c^2}{2} & \frac{a^{*2}}{2} & \frac{d^{*2}}{2} & a^*c & cd^* & a^*d^* \\ \frac{d^2}{2} & \frac{d^{*2}}{2} & \frac{b^2}{2} & dd^* & bd & bd^* \\ ac & a^*c & dd^* & aa^* + c^2 & ad^* + cd & a^*d + cd^* \\ ad & cd^* & bd & ad^* + cd & ab + d^2 & bc + dd^* \\ cd & a^*d^* & bd^* & a^*d + cd^* & bc + dd^* & a^*b + d^{*2} \end{pmatrix}. \tag{73}$$

A direct computation shows that

$$\det(M_{AB}) = \frac{\Delta^8}{8}. \tag{74}$$

At first glance it appears that Eq. (69) cannot be equivalent to the 10 components of the Einstein equations. However, Eq. (69) is valid for any value of s, s^*, and γ. Thus if we add to Eq. (69) the metricity or Wünschmann-like conditions, we obtain a set of consistent equations equivalent to the standard Einstein equations. The final equations read

$$-(2\Delta)^{-1} G_A R^A_{uu} - 6(2\Delta)^{-2} M_{AB} R^A_u R^B_u = \frac{8\pi k}{c^4}\left(T^{ab} Z_{,a} Z_{,b} - \frac{1}{2} T\right),$$

$$\Lambda_{us} + \Lambda_{uu} w + \Lambda_{uw} \Lambda + \Lambda_{uw^*} \Phi + \Lambda_{uR} \Psi = 2[\Lambda_w \Lambda_u + \Lambda_{w^*} \Phi_u + \Lambda_R \Psi_u],$$

$$\Lambda_{us^*} + \Lambda_{uu} w^* + \Lambda_{uw} \Phi + \Lambda_{uw^*} \Lambda^* + \Lambda_{uR} \Psi^* = 2[\Phi_w \Lambda_u + \Phi_{w^*} \Phi_u + \Phi_R \Psi_u],$$

$$\Lambda^*_{us} + \Lambda^*_{uu} w + \Lambda^*_{uw^*} \Phi + \Lambda^*_{uw} \Lambda + \Lambda^*_{uR} \Psi = 2[\Phi_{w^*} \Lambda^*_u + \Phi_w \Lambda_u + \Phi_R \Psi^*_u],$$

$$\Lambda^*_{us^*} + \Lambda^*_{uu} w^* + \Lambda^*_{uw^*} \Lambda^* + \Lambda^*_{uw} \Phi + \Lambda^*_{uR} \Psi^* = 2[\Lambda^*_{w^*} \Lambda^*_u + \Lambda^*_w \Phi_u + \Lambda^*_R \Psi^*_u],$$

$$\Lambda_{u\gamma} + \Lambda_{uu} R + \Lambda_{uw} \Psi + \Lambda_{uw^*} \Psi^* + \Lambda_{uR} \Upsilon = 2[\Psi_w \Lambda_u + \Psi_{w^*} \Phi_u + \Psi_R \Psi_u],$$

$$\Upsilon_{us} + \Upsilon_{uu}w + \Upsilon_{uw}\Lambda + \Upsilon_{uw^*}\Phi + \Upsilon_{uR}\Psi = 2[\Psi_w\Psi_u + \Psi_{w^*}\Psi^*_u + \Psi_R\Upsilon_u],$$

$$\Upsilon_{u\gamma} + \Upsilon_{uu}R + \Upsilon_{uw}\Psi + \Upsilon_{uw^*}\Psi^* + \Upsilon_{uR}\Upsilon = 2[\Upsilon_w\Psi_u + \Upsilon_{w^*}\Psi^*_u + \Upsilon_R\Psi_u],$$

$$\Lambda^*_{u\gamma} + \Lambda^*_{uu}R + \Lambda^*_{uw^*}\Psi^* + \Lambda^*_{uw}\Psi + \Lambda^*_{uR}\Upsilon = 2[\Psi^*_{w^*}\Lambda^*_u + \Psi^*_w\Phi_u + \Psi^*_R\Psi^*_u],$$

$$\Upsilon_{us^*} + \Upsilon_{uu}w^* + \Upsilon_{uw^*}\Lambda^* + \Upsilon_{uw}\Phi + \Upsilon_{uR}\Psi^* = 2[\Psi^*_{w^*}\Psi^*_u + \Psi^*_w\Psi_u + \Psi^*_R\Upsilon_u], \tag{75}$$

plus the integrability conditions, Eq. (14).

As we said in the Introduction, we can now view the Einstein equations in either of the two closely related fashions:

We can consider Eqs. (75) as ten differential equations (of high order) for *the single function* $Z(s,s^*,\gamma)$. In this case the integrability conditions are not relevant. Alternatively, the Einstein equations can be considered as the 10 equations, Eqs. (75), for the six independent variables $(\Lambda,\Lambda^*,\Upsilon,\Phi,\Psi,\Psi^*)$. In this case, the integrability conditions, Eq. (14), must be added but the order of the equations is much lower.

V. CONCLUSIONS

In the first part of this work, we have shown that the ideas and procedures developed in our recent papers,[19,20] see also Ref. 21, on the two- and three-dimensional time-independent HJ equation can be generalized to the four-dimensional HJ equation on an arbitrary manifold $\mathcal{M}$. That is, we have shown that on a four-dimensional manifold $\mathcal{M}$, a definite or indefinite metric, g_{ab}, is equivalent to a family of foliations of $\mathcal{M}$, depending on three parameters s, s^*, and γ, described by $u=Z(x^a,s,s^*,\gamma)$ that satisfies the Wünschmann-like conditions, Eqs. (29). Furthermore, from Eqs. (29) we observe that one can adopt other points of view, where Λ, Λ^*, Υ, Φ, Ψ, and Ψ^* are the basic variables and $u=Z(x^a,s,s^*,\gamma)$ is an auxiliary variable. From this second point of view, Eqs. (29), are simpler but requires that we add the integrability conditions (14) so that a Z does exist.

In the second part of this work we have reformulated the Einstein equations as equations for families of surfaces. If Z is taken as the basic variable then the Einstein equations are equivalent to Eqs. (69). But if Λ, Λ^*, Υ, Φ, Ψ, and Ψ^* are the basic variables the Einstein equations are equivalent to Eqs. (69) and (14). In both cases the Wünschmann equations are needed.

To establish our main results we have used a complete integral to the HJ equation on a four-dimensional manifold. We point out that similar programs can be carried out with, rather than complete solutions, two- and one-parameter families of solutions to the HJ equation. In these cases one can prove the following statements.

Statement 1: On the space of solutions of a certain class of systems of two second-order PDE's,

$$u_{ss} = \Pi(s,s^*,u,u_s,u_{s^*},u_{ss^*}),$$
$$u_{s^*s^*} = \Pi^*(s,s^*,u,u_s,u_{s^*},u_{ss^*}), \tag{76}$$

a four-dimensional definite or indefinite metric, g_{ab}, can be constructed such that the four-dimensional Hamilton–Jacobi equation, $g^{ab}u_{,a}u_{,b}=1$ holds. Furthermore, this structure will be invariant under a subset of contact transformations.

Statement 2: On the space of solutions of a certain class of fourth-order ODE's,

$$u'''' = \Sigma(s,u,u',u'',u'''), \tag{77}$$

a four-dimensional definite or indefinite metric, g_{ab}, can be constructed such that the four-dimensional HJ equation, $g^{ab}u_{,a}u_{,b}=1$ holds. Furthermore, this structure will be invariant under contact transformations.

In a future paper we will present the proofs of these statements.

(Received 14 October 2003; accepted 3 December 2004; published online 8 February 2005)

By using an iterative algebraic method, we derive from a spectral problem a hierarchy of nonlinear evolution equations associated with dispersive long wave equation. It is shown that the hierarchy is integrable in Liouville sense and possesses bi-Hamiltonian structure. Two commutators, with zero curvature and Lax representations, for the hierarchy are constructed, respectively, by using two different systematic methods. Under a Bargmann constraint the spectral is nonlinearized to a completely integrable finite dimensional Hamiltonian system. By introducing the Abel–Jacobi coordinates, an algebro-geometric solution for the dispersive long wave equation is derived by resorting to the Riemann theta function. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1857064]

I. INTRODUCTION

The development of a integrable system representing well-known physical phenomena has shown to be meaningful and valuable. For instance, the illustration of the bi-Hamiltonian structure of a system of partial differential equations is proven to be a direct and elegant method in establishing the complete integrability of the system.[1–5] If a set of partial differential equations can be formulated as a Hamiltonian system in two distinct but compatible ways, Magri had proven in Ref. 1 that this gives rise to an infinite sequence of conserved Hamiltonians which are in involution with respect to one of those two symplectic structures. Recently, two constructive approaches that can handle both finite-dimensional and infinite-dimensional integrable Hamiltonian systems were successfuly developed. The first approach is based on the trace identity,[6,7] which is effective in constructing the infinite-dimensional Liouville integrable Hamiltonian systems. Starting from a properly defined isospectral problem, many integrable hierarchies and their Hamiltonian structures (e.g., AKNS, TC, TA, BPT, Yang) had been obtained by applying this method.[6–10] The second one used nonlinearization technique,[11,12] which has also been proven to be powerful for obtaining new finite-dimensional integrable Hamiltonian systems from various soliton hierarchies. Under the Bargmann or Neumann constraints on the potentials and the eigenvalues, which play a central role in the process of nonlinearization, the related eigenvalue problem can be nonlinearized as a finite-dimensional completely integrable system. This covers the eigenvalue problems associated with the well-known soliton hierarchies such as the KdV, AKNS, Jaulent–Miodek, Kaup–Newell, etc.[10–17] An advantage of this method is that its solution to the soliton equation associated with an eigenvalue problem can be reduced to solving a compatible system of nonlinear ordinary differ-

ential equations.[9–15] This approach has now been further developed to a general method for handling higher order constraints associated with infinitely many hierarchies of finite-dimensional integrable Hamiltonian systems.[18–20]

The algebro-geometric method is an analogue of inverse scattering transformation. It was first developed by Dubrovin, Its, Matveev, and Belokolos *et al.*[21–23] and more recently by Gesztesy and Holden.[24] The method can derive an important class of exact solutions, which is called algebro-geometric solution, to the soliton equation such as KdV equation, sine–Gordon equation, and Schrödinger equation. In the degenerated case the method gives the soliton solution and elliptic function solution. Recently, an alternate approach based on the nonlinearization technique of Lax pairs or the restricted flow technique has been proposed.[25–27] By this method or other methods,[28–33] algebro-geometric solutions for $(1+1)$- and $(2+1)$-dimensional soliton equations can now be obtained.[23–33]

The dispersive long wave (DLW) equation

$$u_t = 2uu_x + 2v_x + u_{xx},$$

$$v_t = 2(uv)_x - v_{xx} \tag{1.1}$$

was first derived by Whitham and Broer for simulating dispersive waves in shallow water.[34,35] Its symmetries, conservation laws, similarity reductions, painlevé property and soliton solutions had been fully discussed.[36–38] In recent years, the following spectral problem associated with the DLW equation (1.1),

$$\psi_x = U\psi = \begin{pmatrix} -\frac{1}{2}(\lambda - u) & -v \\ 1 & \frac{1}{2}(\lambda - u) \end{pmatrix}\psi, \tag{1.2}$$

has been proposed.[13,39] Under two different constraints between the potentials and eigenfunctions, the nonlinearization of the spectral problem gives two kinds of finite-dimensional completely integrable systems.[13] By using gauge transformation

$$\tilde{\phi}_x = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}\psi, \quad \lambda = 2i\eta, \quad u = 2\alpha r, \quad v = q + \beta r_x,$$

the spectral problem (1.1) can be shown to be in close analogy to the classical Boussinesq spectral problem,

$$\tilde{\psi}_x = \begin{pmatrix} -i\eta - \alpha r & q + \beta r_x \\ -1 & i\eta + \alpha r \end{pmatrix}\tilde{\psi}.$$

Therefore, the DLW hierarchy is intimately related to the Boussinesq hierarchy, whose algebro-geometric solutions can be found from the work of Gesztesy and Holden.[24]

In this paper, we would investigate some aspects related to the DLW equation (1.1) and its spectral problem (1.2). In Sec. II starting from a spectral problem, we first derive a hierarchy associated with the DLW equation by using an iterative algebraic method. It will be shown that the hierarchy is integrable in the Liouville sense and its bi-Hamiltonian structure can be established from trace identity. In Sec. III we present a systematic method to construct a zero curvature representation for the hierarchy. In Sec. IV, from the nonlinearization of the spectral problem (1.2), we devise a finite dimensional completely integrable Hamiltonian system under a Bargmann constraint. The Abel–Jacobi coordinates are introduced in Sec. V from which the algebro-geometric solutions for the DLW equations will be derived by resorting to the Riemann theta functions.

II. DLW HIERARCHY AND ITS BI-HAMILTONIAN STRUCTURE

We first recall briefly some notations from the theory of generalized Hamiltonian equations:[6] Let G be a finite-dimensional Lie algebra over $\mathbb{C}$ and $\tilde{G}$ be the corresponding iterated algebra,

$$\tilde{G} = G \otimes \mathbb{C}[\lambda, \lambda^{-1}],$$

where $\mathbb{C}[\lambda, \lambda^{-1}]$ is the set of Laurent polynomials in λ. Suppose that $\{e_1, \ldots, e_p\}$ is a basis of G. The set $\{e_1(n), \ldots, e_p(n)\}$ is then a basis of $\tilde{G}$, where $e_i(n) = e_i(0)\lambda^n = e_i\lambda^n$. For $e(n) \in \tilde{G}$, $i = 1, \ldots, p$, its gradation is defined by

$$\deg(e_i(n)) = \deg(e_i\lambda^n) = n.$$

Consider in the following a general spectral problem:

$$\psi_x = U(u, \lambda)\psi, \tag{2.1}$$

where $u = (u_1, \ldots, u_p)^T \in S$, S is a Schwarz space, and λ is a spectral parameter. The function $U(u, \lambda)$ can be unified to the following representation:

$$U = R + u_1 e_1 + \cdots + u_p e_p,$$

where $R, e_1, \ldots, e_p \in \tilde{G}$. We define the ranks for ∂, u, λ, and $x \in \tilde{G}$ in such a way that if ab is well defined for any two entities a and b, then

$$\operatorname{rank}(ab) = \operatorname{rank}(a) + \operatorname{rank}(b).$$

We also define the rank of R in such a way that above element U has homogeneous rank, i.e.,

$$\operatorname{rank}(R) = \operatorname{rank}(u_1 e_1) = \cdots = \operatorname{rank}(u_p e_p).$$

Finally, we define

$$\operatorname{rank}(x) = \deg(x), \quad x \in \tilde{G}, \quad \operatorname{rank}(\lambda) = \deg(x\lambda) - \deg(x),$$

$$\operatorname{rank}(u_i) = \alpha - \epsilon_i, \quad \operatorname{rank}(\partial) = \alpha,$$

$$\operatorname{rank}(\beta) = 0 \quad (\beta = \text{constant}),$$

where $\deg(R) = \alpha$ and $\deg(e_i) = \epsilon_i$.

Denote

$$g_+ = \sum_{n \geqslant \pi} g_n, \quad g_- = \sum_{n < \pi} g_n,$$

and call g_+ the positive part of g, where $\pi \in Z$ is a properly chosen integer.

The DLW hierarchy corresponding to equation (1.1) derived from the spectral problem (1.2) is now given to be a basis of iterated algebra over $\mathbb{C}$ as follows:

$$h(n) = \begin{pmatrix} \frac{1}{2}\lambda^n & 0 \\ 0 & -\frac{1}{2}\lambda^n \end{pmatrix}, \quad e(n) = \begin{pmatrix} 0 & \lambda^n \\ 0 & 0 \end{pmatrix}, \quad f(n) = \begin{pmatrix} 0 & 0 \\ \lambda^n & 0 \end{pmatrix}, \tag{2.2}$$

such that the following equalities,

$$[h(m), e(n)] = e(m+n), \quad [f(m), h(n)] = f(m+n),$$

$$[e(m), f(n)] = 2h(m+n),$$

hold. The gradation for the basis is defined by

$$\deg h(n) = \deg e(n) = \deg f(n) = n.$$

From Eqs. (2.2), the U in (1.2) can be expressed as

$$U = -h(1) + f(0) + uh(0) - ve(0),$$

and we have

$$\deg h(1) = 1, \quad \deg e(0) = \deg f(0) = 0,$$

$$\operatorname{rank}(\lambda) = \operatorname{rank}(\partial) = \operatorname{rank}(u) = \operatorname{rank}(v) = 1.$$

The adjoint equation

$$V_x = [U, V] = UV - VU$$

with

$$V = ah(0) + be(0) - cf(0)$$

can be solved and we obtain

$$a_x = 2vc - 2b, \quad b_x = -b\lambda + ub + va,$$

$$c_x = c\lambda + uc + a. \tag{2.3}$$

Substituting the Laurent expansion $a=\Sigma a_m\lambda^{-m}$, $b=\Sigma b_m\lambda^{-m}$, $c=\Sigma c_m\lambda^{-m}$ into (2.3), we obtain the following recursive formulas:

$$a_{mx} = 2vc_m - 2b_m,$$

$$b_{mx} = -b_{m+1} + ub_m + va_m,$$

$$c_{mx} = c_{m+1} + uc_m + a_m. \tag{2.4}$$

Taking $a_0=0$, $c_0=\alpha$, $b_0=\alpha v$, we further derive from (2.4) that

$$\begin{pmatrix} \frac{1}{2}a_{m+1} \\ c_{m+1} \end{pmatrix} = L \begin{pmatrix} \frac{1}{2}a_m \\ c_m \end{pmatrix},$$

where L is the matrix operator defined by

$$L = \begin{pmatrix} -\partial + \partial^{-1}u\partial & \partial^{-1}v\,\partial + v \\ 2 & \partial + u \end{pmatrix}.$$

Set

$$(\lambda^n V)_+ = \sum_{m=0}^{n} [a_m h(n-m) + b_m e(n-m) - c_m f(n-m)].$$

Then, $V_x=[U,V]$ implies that

$$-(\lambda^n V)_{+x}+[U,(\lambda^n V)_+]=-(\lambda^n V)_{-x}+[U,(\lambda^n V)_-]. \tag{2.5}$$

Notice that all the terms on the left-hand side of (2.5) have degrees $\geqslant 0$, whereas all the terms on the right-hand side of (2.5) have degrees $\leqslant 0$. Therefore, we have

$$-(\lambda^n V)_{+x}+[U,(\lambda^n V)_+]\in \mathbb{C}h(0)+\mathbb{C}e(0)+\mathbb{C}f(0). \tag{2.6}$$

In other words, we only need to calculate those terms that contain $h(0),e(0),f(0)$. Direct calculation shows that

$$-(\lambda^n V)_{+x}+[U,(\lambda^n V)_+]=b_{n+1}e(0)+c_{n+1}f(0).$$

To cancel the term $c_{n+1}f(0)$, we introduce $\Delta_n=c_{n+1}h(0)$. It is then easy to prove that, for $V^{(n)}=(\lambda^n V)_++\Delta_n$, we have

$$-(V^{(n)})_{+x}+[U,(V^{(n)})_+]=-c_{n+1x}h(0)-\tfrac{1}{2}a_{n+1x}e(0).$$

Then zero curvature equation $U_t-(V^{(n)})_{+x}+[U,(V^{(n)})_+]$ gives the following DLW hierarchy:

$$u_t=c_{n+1x},\quad v_t=\tfrac{1}{2}a_{n+1x},\quad n=1,2,\ldots. \tag{2.7}$$

We note here that the first two representative systems in the hierarchy (2.7) are

$$u_t=\alpha u_x,\quad v_t=\alpha v_x,$$

$$u_t=\alpha(u_{xx}+2v_x+2uu_x),\quad v_t=\alpha(-v_{xx}+2u_xv+2uv_x).$$

The second system is exactly the DLW equation (1.1) in the case when $\alpha=1$.

The following theorem serves to develop the Hamiltonian structure of the hierarchy (2.7).

Theorem 2.1: The hierarchy (2.7) possesses the bi-Hamiltonian structure

$$w_t=J\frac{\delta H_n}{\delta w}=K\frac{\delta H_{n-1}}{\delta w}, \tag{2.8}$$

where the vector function w, the Hamiltonian operators J,K and the Hamiltonian function are given by

$$w=\begin{pmatrix}u\\ v\end{pmatrix},\quad K=JL=\begin{pmatrix}2\partial & \partial^2+\partial u\\ -\partial^2+u\partial & v\,\partial+\partial v\end{pmatrix},$$

$$J=\begin{pmatrix}0 & \partial\\ \partial & 0\end{pmatrix},\quad H_n=\tfrac{1}{2}a_{n+2},\quad n=0,1,\ldots. \tag{2.9}$$

Proof: We introduce

$$G_{n+1}=\begin{pmatrix}\frac{1}{2}a_{n+1}\\ c_{n+1}\end{pmatrix}, \tag{2.10}$$

then hierarchy (2.7) can then be rewritten in the form of

$$w_t=JG_{n+1}=KG_n=JL^{n+1}G_0=J(J^{-1}K)^{n+1}G_0,\quad n=1,2,\ldots, \tag{2.11}$$

where $G_0=(0,1)^T$.

We take the Killing–Cartan form $\langle A,B\rangle$ to be $\mathrm{tr}(AB)$. From direct calculation we then obtain

$$\left\langle V, \frac{\partial U}{\partial \lambda} \right\rangle = -\frac{1}{2}a, \quad \left\langle V, \frac{\partial U}{\partial u} \right\rangle = \frac{1}{2}a, \quad \left\langle V, \frac{\partial U}{\partial v} \right\rangle = c.$$

By using the result of trace identity,[6] we have

$$\frac{\delta}{\delta w}\left(-\frac{1}{2}a\right) = \lambda^{-\gamma}\frac{\partial}{\partial \lambda}\left[\lambda^{\gamma}\left(\frac{1}{2}a, c\right)^{T}\right].$$

Substituting

$$a = \sum_{n=0}^{\infty} a_n \lambda^{-n}, \quad c = \sum_{n=0}^{\infty} c_n \lambda^{-n}$$

into the above equation yields

$$\frac{\delta}{\delta w}\left(-\frac{1}{2}a_{n+1}\right) = (\gamma - n)G_n, \tag{2.12}$$

which holds for all $n=0,1,2,\ldots$. The condition $n=0$ in (2.12) gives $\gamma=1$. Therefore, we obtain

$$G_{n+1} = \frac{\delta H_n}{\delta w}, \tag{2.13}$$

where H_n is given by (2.9).

Combining (2.11) with (2.13) we then obtain the desired Hamiltonian formulation (2.8) for the DLW hierarchy (2.7).

It is crucial to prove the existence of infinite involutive conserved densities. The inner product between two functions f and g is defined by

$$(f,g) = \int fg \, \mathrm{d}x,$$

and the Poisson bracket is defined by

$$\{f,g\} = \left(\frac{\delta f}{\delta w}, J\frac{\delta f}{\delta w}\right).$$

Finally, the integrability of the hierarchy (2.7) or (2.8) is given in the following Theorem 2.2.

Theorem 2.2: The Hamiltonian functions $\{H_n\}_{n=0}^{\infty}$ defined by (2.9) constitute common conserved densities for the whole hierarchy (2.8). It other words, it is an integrable Hamiltonian system in Liouville sense.

Proof: It is easy to see that $JL=L^{*}J$. We then have

$$\{H_n, H_m\} = \left(\frac{\delta H_n}{\delta w}, J\frac{\delta H_m}{\delta w}\right) = (L^{n+1}G_0, JL^{m+1}G_0) = (L^{n+1}G_0, L^{*}JL^{m}G_0) = (L^{n+2}G_0, JL^{m}G_0)$$
$$= \{H_{n+1}, H_{m-1}\}.$$

Repeating the above argument gives

$$\{H_n, H_m\} = \{H_m, H_n\} = \{H_{m+n}, H_0\}. \tag{2.14}$$

On the other hand, we have

$$\{H_m, H_n\} = (L^{m+1}G_0, JL^{n+1}G_0) = (J^{*}L^{m+1}G_0, L^{n+1}G_0) = -\{H_n, H_m\}. \tag{2.15}$$

Combining (2.14) with (2.15) gives

$$\{H_m, H_n\} = 0,$$

which implies that $\{H_n\}$ are in involution. Furthermore, we have

$$\left(\int H_n \, \mathrm{d}x\right)_t = \left(\frac{\delta H_n}{\delta u}, u_t\right) = \left(\frac{\delta H_n}{\delta u}, J\frac{\delta H_m}{\delta u}\right) = \{H_n, H_m\} = 0.$$

This implies that $\{H_n\}$ are also conserved densities.

III. ZERO CURVATURE AND LAX REPRESENTATIONS

The zero curvature and Lax representations are two different commutator representations of nonlinear evolution equations. They play an important role in the investigation of integrable systems. To obtain the two commutator representations for the DLW hierarchy (2.7), based on the general spectral problem (2.1) we first propose an approach to derive a hierarchy of nonlinear evolution equations from which their zero representation can be obtained. Recall that the Gateaux derivative of a spectral operator $U(u,\lambda)$ in direction $\xi=(\xi_1,\xi_2,\ldots,\xi_p)^T$ at point u is defined by

$$U'(\xi) = \frac{\mathrm{d}}{\mathrm{d}\varepsilon} U(u+\varepsilon\xi)|_{\varepsilon=0}.$$

Denote

$$\nabla\lambda = \left(\frac{\delta\lambda}{\delta u_1}, \cdots, \frac{\delta\lambda}{\delta u_p}\right)^T$$

to be the functional of λ. If there exist two $p\times p$ matrix integro-differential operators K and J depending on u such that

$$K\nabla\lambda = \lambda^k J\nabla\lambda,$$

where k being a constant, then K and J are called a pair of Lenard's operators.

By using the pair of Lenard's operators K and J, we can define the Lenard's recursion sequence by

$$G_0 \in \mathrm{Ker}\, J = \{G | JG\}, \quad KG_{j-1} = JG_j, \quad j = 1,2,\ldots.$$

The corresponding field $X_j = JG_j$ produces a hierarchy of nonlinear evolution equations connected with the spectral problem (2.1) as follows:

$$u_t = X_n(u) = J(J^{-1}K)^n G_0, \quad n = 1,2,\ldots. \tag{3.1}$$

The zero curvature representation of the hierarchy (3.1) can now be constructed using the following theorem.

Theorem 3.1: Suppose that

(a) $G_0 \in \mathrm{Ker}\, J = G|JG$.
(b) For arbitrary given vector function $G=(G^{(1)}, \cdots, G^{(p)})^T$, the following operator equation

$$V_x - [U,V] = U'(KG) - \lambda^\beta U'(JG) \tag{3.2}$$

has a solution $V=V(G)$.

Let

$$A_n = \sum_{j=1}^{n} V_j \lambda^{\beta(n-j)} = \sum_{j=0}^{n} V(G_j)\lambda^{\beta(n-j)},$$

where $V_j = V(G_j)$. The hierarchy (3.1) then possesses the following zero curvature representation:

$$U_t - A_{nx} + [U, A_n] = 0 \tag{3.3}$$

and also the following Lax pair:

$$\psi_x = U\psi, \quad \psi_t = A_n\psi.$$

Proof: Since $G_0 \in \operatorname{Ker} J = \{G \mid JG = 0\}$, we have

$$A_{nx} - [U, A_n] = \sum_{j=1}^{n} (V_{jx} - [U, V_j])\lambda^{\beta(n-j)} = \sum_{j=1}^{n} [U'(KG_{j-1}) - \lambda^{\beta} U'(JG_{j-1})]\lambda^{\beta(n-j)}$$
$$= \sum_{j=1}^{n} U'(JG_j)\lambda^{\beta(n-j)} - \sum_{j=0}^{n-1} U'(JG_j)\lambda^{\beta(n-j+1)} = U'(JG_n) - U'(JG_0)\lambda^{\beta(n+1)} = U'(X_n),$$

where the vector field $X_n = JG_n = KG_{n-1}$.

Since $U_t = U'(u_t)$, it follows that

$$U_t - A_{nx} + [U, A_n] = U'(u_t) - U'(X_n) = U'(u_t - X_n) = 0.$$

The construction of the zero representation for the hierarchy (2.7) is given in the following theorem. We first need the following lemmas.

Lemma 3.1: Let λ be an eigenvalue of equation (1.2). The functional gradient $\nabla\lambda$ of λ is then given by

$$\nabla\lambda = \left(\int \psi_1\psi_2 \right)^{-1} (\psi_1\psi_2, -\psi_2^2)^T,$$

where K and J are the pair of Lenard's operators

$$K\nabla\lambda = \lambda J \nabla\lambda, \tag{3.4}$$

and $\{G_j\}$ is the Lenard's sequence

$$KG_{j-1} = JG_j, \quad j = 1, 2, \ldots, \tag{3.5}$$

where K and J are defined by (2.9) and (2.10).

Proof: The result can be directly computed from (1.2).

Lemma 3.2: The differential map of $U(u, \lambda)$ in (1.2) is given by

$$U'(\xi) = \begin{pmatrix} \frac{1}{2}\xi_1 & -\xi_2 \\ 0 & -\frac{1}{2}\xi_1 \end{pmatrix}, \quad \xi = (\xi_1, \xi_2)^T,$$

so that $U'(\xi)$ is an injective homomorphism.

Lemma 3.3: If $\beta = 1$ in (3.2), then for arbitrary given vector function $G = (G^{(1)}, G^{(2)})^T$, the following operator equation

$$V_x - [U, V] = U'(KG) - \lambda U'(JG) \tag{3.6}$$

has a solution

$$V = V(G) = \begin{pmatrix} -\frac{1}{2}\lambda G^{(2)} + \frac{1}{2}(G_x^{(2)} + uG^{(2)}) & G_x^{(1)} - vG^{(2)} \\ G^{(2)} & \frac{1}{2}\lambda G^{(2)} - \frac{1}{2}(G_x^{(2)} + uG^{(2)}) \end{pmatrix}. \tag{3.7}$$

Proof: By representing the commutator $[U, V]$ as $U = U_0 + U_1\lambda$ and $V = V_0 + V_1\lambda$ such that

$$U_0 = \begin{pmatrix} \frac{1}{2}u & -v \\ 1 & -\frac{1}{2}u \end{pmatrix}, \quad U_1 = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & -\frac{1}{2} \end{pmatrix},$$

$$V_0 = \begin{pmatrix} A & B \\ C & -A \end{pmatrix}, \quad V_1 = \begin{pmatrix} D & 0 \\ 0 & -D \end{pmatrix},$$

where A, B, C, D are four undetermined functions, we have

$$\begin{aligned}[U,V] &= [U_0,V_0] + (U_0,V_1] + [U_1,V_0])\lambda + [U_1,V_1]\lambda^2 = [U_0,V_0] + (U_0,V_1] + [U_1,V_0])\lambda \\ &= \begin{pmatrix} -vC - B & 2vA + uB \\ 2A - uC & B + vC \end{pmatrix} + \begin{pmatrix} 0 & 2vD - B \\ 2D + C & 0 \end{pmatrix}\lambda, \end{aligned} \tag{3.8}$$

and

$$KG = \begin{pmatrix} 2G_x^{(1)} + G_{xx}^{(2)} + uG_x^{(2)} + u_xG^{(2)} \\ -G_{xx}^{(1)} + uG_x^{(1)} + 2vG_x^{(2)} + v_xG^{(2)} \end{pmatrix}, \quad JG = \begin{pmatrix} G_x^{(2)} \\ G_x^{(1)} \end{pmatrix}. \tag{3.9}$$

Substituting (3.8) and (3.9) into (3.6) and comparing the corresponding elements in both sides of the matrices, we can determine the values of A, B, C, and D from which the solution V as given in (3.7) can be obtained.

Finally, from Theorem 3.1 we have the following.

Theorem 3.2: Let

$$A_n = \sum_{j=1}^{n} V_j\lambda^{n-j} = \sum_{j=0}^{n} V(G_j)\lambda^{n-j},$$

where $V_j = V(G_j)$ is given by (3.7). The DLW hierarchy (2.7) possesses the following zero curvature representation:

$$U_t - A_{nx} + [U,A_n] = 0, \tag{3.10}$$

and the Lax pair

$$\psi_x = U_\psi, \quad \psi_t = A_n\psi.$$

Similarly we can obtain the Lax representation of the hierarchy (2.7) through the following lemmas and theorem.

Lemma 3.4: The spectral problem (1.2) is equivalent to

$$L\psi = \begin{pmatrix} -2\partial + u & -2v \\ -2 & 2\partial + u \end{pmatrix}\psi = \lambda\psi, \tag{3.11}$$

where the differential map of $L = L(u, v, \lambda)$ is

$$L'(\xi) = \begin{pmatrix} \xi_1 & -2\xi_2 \\ 0 & \xi_1 \end{pmatrix},$$

and $L'(\xi)$ is an injective homomorphism.

Proof: Direct calculation from (1.2).

Lemma 3.5: For arbitrary given vector function $G = (G^{(1)}, G^{(2)})^T$, the following operator equation

$$[V,L] = L'(KG) - L'(JG)L \tag{3.12}$$

has a solution

$$V = V(G) = \begin{pmatrix} \frac{1}{2}(G_x^{(2)} + uG^{(2)}) & G_x^{(1)} - vG^{(2)} \\ G^{(2)} & -\frac{1}{2}(G_x^{(2)} + uG^{(2)}) \end{pmatrix} + \begin{pmatrix} -\frac{1}{2}G^{(2)} & 0 \\ 0 & -\frac{1}{2}G^{(2)} \end{pmatrix}L. \tag{3.13}$$

Proof: Representing the commutator $[V,L]$ of $L = L_0 + L_1\partial_x$ and $V = V_0 + V_1\partial_x$ such that

$$L_0 = \begin{pmatrix} u & -2v \\ -2 & u \end{pmatrix}, \quad U_1 = \begin{pmatrix} -2 & 0 \\ 0 & 2 \end{pmatrix},$$

$$V_0 = \begin{pmatrix} A & B \\ C & D \end{pmatrix}, \quad U_1 = \begin{pmatrix} E & 0 \\ 0 & F \end{pmatrix},$$

where A,B,C,D are four undetermined functions, we have

$$\begin{aligned}
[V,L] &= [V_0,L_0] + [V_0,L_1\partial_x] + [V_1\partial_x,L_0]) + [V_1\partial_x,L_1\partial_x] \\
&= [V_0,L_0] + V_1L_{0x} - L_1V_{0x} + ([V_0,L_1] + [V_1,L_0] + V_1L_{1x} - L_1V_{1x})\partial_x \\
&= \begin{pmatrix} -2B + 2vC + u_xE + 2A_x & -2v(A-D) - 2v_xE + 2B_x \\ 2(A-D) - 2C_x & 2B - 2vC + u_xF - 2D_x \end{pmatrix} \\
&\quad + \begin{pmatrix} 2E_x & -2v(E-F) + 4B \\ 2(E-F) - 4C & -2F_x \end{pmatrix}\partial_x. \qquad (3.14)
\end{aligned}$$

We also have

$$\begin{aligned}
L'[KG] - L'(JG)L &= \begin{pmatrix} 2G_x^{(2)} & 4G_x^{(1)} \\ 0 & -2G_x^{(2)} \end{pmatrix}\partial_x \\
&\quad + \begin{pmatrix} 2G_x^{(1)} + G_{xx}^{(2)} + u_xG^{(2)} - 4G_x^{(1)} & 2G_{xx}^{(1)} - 2vG_x^{(2)} - 2v_xG^{(2)} \\ 2G_x^{(2)} & 2G_x^{(1)} + G_{xx}^{(2)} + u_xG^{(2)} \end{pmatrix}. \qquad (3.15)
\end{aligned}$$

Substituting (3.14) and (3.15) into (3.12) and comparing the corresponding elements on both sides of the matrices, we then obtain

$$A = -D = \tfrac{1}{2}G_x^{(2)}, \quad B = G_x^{(1)}, \quad C = 0, \quad E = F = G^{(2)}.$$

Since $\partial_x = L_1^{-1}(L - L_0)$, we have

$$\begin{aligned}
V = V(G) &= \begin{pmatrix} \frac{1}{2}G_x^{(2)} & G_x^{(1)} \\ 0 & -\frac{1}{2}G_x^{(2)} \end{pmatrix} + \begin{pmatrix} {}^{(2)} & 0 \\ 0 & G^{(2)} \end{pmatrix}\partial_x \\
&= \begin{pmatrix} \frac{1}{2}(G_x^{(2)} + uG^{(2)})G_x^{(1)} - vG^{(2)} & \\ G^{(2)} & -\frac{1}{2}(G_x^{(2)} + uG^{(2)}) \end{pmatrix} + \begin{pmatrix} -\frac{1}{2}G^{(2)} & 0 \\ 0 & \frac{1}{2}G^{(2)} \end{pmatrix}L.
\end{aligned}$$

Theorem 3.3: Let

$$B_n = \sum_{j=1}^{n} V_jL^{n-j} = \sum_{j=0}^{n} V(G_j)L^{n-j}, \qquad (3.16)$$

where $V_j = V(G_j)$, $G_j = (G_j^{(1)}, G_j^{(2)})^T$, and the matrix function V satisfies (3.13). The DLW hierarchy (2.7) possesses the following Lax representation:

$$L_t = [B_n, L], \qquad (3.17)$$

and the Lax pair

$$L\psi = \lambda\psi, \quad \psi_t = B_n\psi.$$

Proof: From (3.12) and (3.16), we have

$$[B_n,L]=\sum_{j=1}^{n}[V_j,L])L^{n-j}=\sum_{j=1}^{n}[L'(KG_{j-1})-L'(JG_{j-1})L]L^{n-j}$$
$$=\sum_{j=1}^{n}L'(JG_j)L^{n-j}-\sum_{j=0}^{n-1}L'(JG_j)L^{n-j}=L'(JG_n)-L'(JG_0)=L'(X_n).$$

Since $L_t=L'(u_t)$, it follows that

$$L_t-[B_m,L]=L'(u_t)-L'(X_m)=L'(u_t-X_m)=0.$$

The proof is completed.

IV. A FINITE DIMENSIONAL HAMILTONIAN SYSTEM

To construct the algebro-geometric solution of DLW hierarchy, in this section we investigate the finite dimensional Hamiltonian systems associated with the spectral problem (1.2) through a nonlinearization approach.[12,13] Let λ_j, $j=1,\ldots,N$ be N different eigenvalues of equation (1.2), and (p_j,q_j) be the associated eigenfunctions, i.e., we consider the following N eigenvalues:

$$\begin{pmatrix}p_j\\q_j\end{pmatrix}_x=\begin{pmatrix}-\frac{1}{2}(\lambda_j-u) & -v\\ 1 & \frac{1}{2}(\lambda_j-u)\end{pmatrix}\begin{pmatrix}p_j\\q_j\end{pmatrix}. \tag{4.1}$$

Denote $p=(p_1,p_2,\ldots,p_N)^T$, $q=(q_1,q_2,\ldots,q_N)^T$, and $\wedge=\mathrm{diag}(\lambda_1,\lambda_2,\ldots,\lambda_N)$. From the Bargmann constraint

$$G_1=\begin{pmatrix}v\\u\end{pmatrix}=\sum_{j=1}^{N}\nabla\lambda_j=\begin{pmatrix}\langle p,q\rangle\\-\langle q,q\rangle\end{pmatrix}, \tag{4.2}$$

we then obtain

$$w=\begin{pmatrix}u\\v\end{pmatrix}=\begin{pmatrix}-\langle q,q\rangle\\\langle p,q\rangle\end{pmatrix}\equiv h(p,q). \tag{4.3}$$

From the constraint (4.3), the equation (4.1) can further be nonlinearized into the following finite-dimensional Hamiltonian system:

$$p_x=-\frac{1}{2}\wedge p-\frac{1}{2}\langle q,q\rangle p-\langle p,q\rangle q=-\frac{\partial H}{\partial q},$$

$$q_x=p+\frac{1}{2}\wedge q+\frac{1}{2}\langle q,q\rangle q=\frac{\partial H}{\partial p}, \tag{4.4}$$

whose Hamiltonian function H is given by

$$H=\tfrac{1}{2}\langle p,p\rangle+\tfrac{1}{2}\langle\wedge p,q\rangle+\tfrac{1}{2}\langle q,q\rangle\langle p,q\rangle.$$

In the following, we proceed to show that the Hamilton system (4.4) is completely integrable in the Liouville sense. The Poisson bracket of two functions in symplectic space $(\mathbb{R}^{2N},\mathrm{d}p\wedge\mathrm{d}q)$ is defined as

$$(F,G)=\sum_{j=1}^{N}\left(\frac{\partial F}{\partial q_j}\frac{\partial G}{\partial p_j}-\frac{\partial F}{\partial p_j}\frac{\partial G}{\partial q_j}\right)=\left\langle\frac{\partial F}{\partial q},\frac{\partial G}{\partial p}\right\rangle-\left\langle\frac{\partial F}{\partial p},\frac{\partial G}{\partial q}\right\rangle,$$

which is skew-symmetric, bilinear, and satisfies the Jacobi identity. In particular, F and G are called involution if $(F,G)=0$.

Consider a bilinear function $Q_\lambda(p,q)=\langle(\lambda I-\wedge)^{-1}p,q\rangle$ such that

$$G_\lambda = G_0 + \sum_{j=1}^{N} \frac{\nabla\lambda_j}{\lambda-\lambda_j} = \begin{pmatrix} Q_\lambda(p,q) \\ 1-Q_\lambda(q,q) \end{pmatrix}. \tag{4.5}$$

From (3.4) and (4.5), we have

$$V_\lambda = V(G_\lambda) = \begin{pmatrix} -\frac{1}{2}\lambda - Q_\lambda(p,q) & -\langle p,q\rangle + Q_\lambda(p,p) \\ 1-Q_\lambda(q,q) & \frac{1}{2}\lambda + Q_\lambda(p,q) \end{pmatrix}.$$

Let $F_\lambda=\det V_\lambda$. Then, we have

$$\begin{aligned} F_\lambda &= -\tfrac{1}{4}\lambda^2 - Q_\lambda(\wedge p,q) + Q_\lambda(p,p) + \langle p,p\rangle Q_\lambda(q,q) + \begin{vmatrix} Q_\lambda(p,p) & Q_\lambda(p,q) \\ Q_\lambda(p,q) & Q_\lambda(q,q,) \end{vmatrix} \\ &= -\frac{1}{4}\lambda^2 + \sum_{m=0}^{\infty} F_m \lambda^{-m-1}, \end{aligned} \tag{4.6}$$

where

$$F_0 = 2H,$$

$$F_m = -\langle \wedge^{m+1}p,p\rangle + \langle p,q\rangle\langle \wedge^m q,q\rangle + \sum_{m=0}^{m-1} \begin{vmatrix} \langle \wedge^j p,p\rangle & \langle \wedge^{m-1-j}p,q\rangle \\ \langle \wedge^j p,q\rangle & \langle \wedge^{m-1-j}q,q\rangle \end{vmatrix}.$$

By considering that F_λ is a Hamiltonian in the symplectic space $(\mathbb{R}^{2N}, \mathrm{d}p\wedge\mathrm{d}q)$, the canonical equations of the F_λ-flow can be computed as

$$\frac{\mathrm{d}}{\mathrm{d}\tau_\lambda}\begin{pmatrix} p_k \\ q_k \end{pmatrix} = I\nabla F_\lambda = \begin{pmatrix} -\partial F_\lambda/\partial q_k \\ \partial F_\lambda/\partial p_k \end{pmatrix} = W(\lambda,\lambda_k)\begin{pmatrix} p_k \\ q_k \end{pmatrix},$$

where

$$W(\lambda,\lambda_k) = \frac{2}{\lambda-\lambda_k}V_\lambda + (1-Q_\lambda(p,q))\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Lemma 4.1: The Lax matrix V_μ satisfies the Lax equation (4.7) alone the t_λ-flow:

$$\frac{\mathrm{d}V_\mu}{\mathrm{d}\tau_\lambda} = [W(\lambda,\mu), V_\mu] \tag{4.7}$$

and

$$(F_\mu, F_\lambda) = 0, \quad \forall\, \lambda,\mu \in \mathbb{C}, \tag{4.8}$$

$$(F_j, F_k) = 0, \quad \forall\, j,k = 0,1,\ldots. \tag{4.9}$$

Proof: Notice that

$$Q_\lambda(\wedge\xi,\eta) = \lambda Q_\lambda(\wedge\xi,\eta) - \langle\xi,\eta\rangle,$$

$$\langle(\mu I - \wedge)^{-1}(\lambda I - \wedge)^{-1}\xi,\eta\rangle = \frac{1}{\mu-\lambda}(Q_\lambda(\xi,\eta) - Q_\mu(\xi,\eta)),$$

a direct calculation shows that (4.7) holds. From the Lax equation (4.7) we have

$$(F_\mu, F_\lambda) = \sum_{j=1}^{N} \left(\frac{\partial F_\mu}{\partial q_j}\frac{\partial F_\lambda}{\partial p_j} - \frac{\partial F_\mu}{\partial p_j}\frac{\partial F_\lambda}{\partial q_j} \right) = \sum_{j=1}^{N} \left(\frac{\partial F_\mu}{\partial q_j}\frac{\mathrm{d}q_j}{\mathrm{d}t_\lambda} + \frac{\partial F_\mu}{\partial p_j}\frac{\mathrm{d}p_j}{\mathrm{d}t_\lambda} \right)$$
$$= \frac{\mathrm{d}F_\mu}{\mathrm{d}\tau_\lambda} = \frac{\mathrm{d}}{\mathrm{d}\tau_\lambda}(\det V_\mu) = \frac{\mathrm{d}}{\mathrm{d}\tau_\lambda}\left(-\tfrac{1}{2}\mathrm{tr}V_\mu^2\right) = -\mathrm{tr}\left(V_\mu \frac{\mathrm{d}V_\mu}{\mathrm{d}\tau_\lambda} \right)$$
$$= -\mathrm{tr}\, V_\mu \,\mathrm{tr}[W(\lambda,\mu), V_\mu] = 0.$$

Substituting (4.6) into (4.8) and using the coefficients of λ and μ, we then obtain (4.9).

We conclude the above results in the following theorem.

Theorem 4.1: The finite dimensional Hamiltonian system defined by (4.4) is completely integrable in Liouville sense in the symplectic space $(\mathbb{R}^{2N}, \mathrm{d}p \wedge \mathrm{d}q)$.

Theorem 4.2: Let (p,q) be a solution of the Hamiltonian system (4.4). Then, u and v defined by (4.3) satisfy the following stationary DLW equation

$$X_N + c_1 X_{N-2} + \cdots + c_{N-1} X_0 = 0 \tag{4.10}$$

with suitably chosen constants $c_1, \ldots, c_{N-1}$.

Proof: Operating with $(J^{-1}K)^{k-1}$ upon the expression of (4.2), we get

$$G_k + \beta_1 G_{k-2} + \cdots + \beta_{k-1} G_0 + \beta_k G_{-1} = \sum_{j=1}^{N} \lambda_j^k \nabla \lambda_j, \tag{4.11}$$

where $\beta_1, \ldots, \beta_k$ are arbitrary constants, $G_{-1} = (0,0)^T$, and $J^{-1}KG_{-1} = G_0$.

Consider the polynomial

$$p(\lambda) = \prod_{j=1}^{N} (\lambda - \lambda_j) = \lambda^N + p_1 \lambda^{N-1} + \cdots + p_N.$$

Applying the operator $J\Sigma_{k=1}^{N} p_{N-k}$ on (4.11), we obtain (4.10), where $c_1, \ldots, c_N$ depend on $\beta_1, \ldots, \beta_k$ and $\lambda_1, \ldots, \lambda_N$.

Introduce the generating function $\{g_k\}$,

$$g_\lambda = G_0 + \sum_{k=0}^{\infty} G_k \lambda^{-k}, \tag{4.12}$$

which satisfies

$$(K - \lambda J) g_\lambda = 0,$$

we have

$$V_x(g_\lambda) - [U, V(g_\lambda)] = U'((K - \lambda J) g_\lambda) = 0.$$

This implies that

$$\frac{\partial}{\partial x}(\det V(g_\lambda)) = 0.$$

Hence, we have

$$\det V(g_\lambda) = -\tfrac{1}{4}\lambda^2. \tag{4.13}$$

Define a new set of integrals $\{H_k\}$, respectively, by

$$H_0 = \tfrac{1}{2}F_0, \quad H_1 = -\tfrac{1}{2}F_1, \quad H_2 = -\tfrac{1}{2}F_2,$$

$$H_m = -\tfrac{1}{2}F_m + 2\sum_{j=0}^{m-3} H_j H_{m-j-3}, \quad m \geqslant 3.$$

Equation (4.6) can then be transformed into the following equivalent form:

$$-\frac{4}{\lambda^2}F_\lambda = (1-4H_\lambda)^2, \tag{4.14}$$

where

$$H_\lambda = \sum_{m=1}^{\infty} H_{m-1}\lambda^{-m-1}.$$

The involutivity of $\{H_k\}$ is based on the equality

$$\{H_\mu, H_\lambda\} = \frac{1}{16\sqrt{F_\lambda F_\mu}}\{F_\mu, F_\lambda\} = 0.$$

By using (4.5) and (4.11), we have

$$\begin{aligned} G_\lambda &= G_0 + \sum_{k=0}^{\infty}\lambda^{-k-1}\sum_{j=1}^{N}\lambda_j^k \nabla\lambda_j, \\ &= G_0 + \sum_{k=0}^{\infty} c^{-k-1}(G_k + c_1 G_{k-2} + \cdots + c_{k-1}G_0 + c_k G_{-1}, \\ &= c_\lambda g_\lambda + \sum_{k=0}^{\infty}\lambda^{-k-1}c_k G_{-1}, \end{aligned}$$

where

$$c_\lambda = 1 + \sum_{k=0}^{\infty} c_{k+2}\lambda^{-k-2}. \tag{4.15}$$

Using (4.6) and (4.14) again, we have

$$V_\lambda = V\left(c_\lambda g_\lambda + \sum_{k=0}^{\infty}\lambda^{-k-1}c_k G_{-1}\right) = V(c_\lambda g_\lambda).$$

Therefore, we have

$$F_\lambda = \det V_\lambda = -\tfrac{1}{4}c_\lambda^2 g_\lambda^2. \tag{4.16}$$

From (4.14) and (4.16), we obtain

$$c_\lambda = 1 - 4H_\lambda.$$

Denote the variables of H_λ flow and H_k flow by t_λ and t_k, respectively. Applying the Leibniz rule of the Poisson bracket, we obtain

$$\frac{1}{2\lambda^2}\{\psi, F_\lambda\} = (1-4H_\lambda)\{\psi, H_\lambda\},$$

for any smooth function ψ. Thus,

$$\frac{\mathrm{d}}{\mathrm{d}t_\lambda} = \frac{1}{2\lambda^2(1-4H_\lambda)}\frac{\mathrm{d}}{\mathrm{d}\tau_\lambda} = \frac{1}{2\lambda^2 c_\lambda}\frac{\mathrm{d}}{\mathrm{d}\tau_\lambda}. \tag{4.17}$$

For $w=(u,v)^T=h(p,q)$, we have

$$\frac{\mathrm{d}w}{\mathrm{d}\tau_\lambda} = \begin{pmatrix} -2\left\langle q, \dfrac{\mathrm{d}q}{\mathrm{d}\tau_\lambda}\right\rangle \\ \left\langle p, \dfrac{\mathrm{d}q}{\mathrm{d}\tau_\lambda}\right\rangle + \left\langle \dfrac{\mathrm{d}p}{\mathrm{d}\tau_\lambda}, q\right\rangle \end{pmatrix} = 2JG_\lambda,$$

$$\frac{\mathrm{d}w}{\mathrm{d}t_\lambda} = \frac{1}{2\lambda^2 c_\lambda}\frac{\mathrm{d}w}{\mathrm{d}\tau_\lambda} = \frac{1}{\lambda^2 c_\lambda}JG_\lambda = \frac{1}{\lambda^2}Jg_\lambda$$
$$= \sum_{k=0}^{\infty} JG_K\lambda^{-k-3} = \sum_{k=0}^{\infty} JG_K\lambda^{-k-3}.$$

Finally, we state the above result in the following theorem.

Theorem 4.3: Let $(p(x,t_k),q(x,t_k))$ be a compatible solution of the h_0 and H_k flow. Then, $w(x,t_K)=h(p,q)$ solves the kth DLW equation

$$w_t = X_k(w).$$

V. ALGEBRO-GEOMETRIC SOLUTIONS

Based on results presented in Secs. III and IV, we give the construction of the algebro-geometric solutions for the hierarchy (2.7) in the following lemmas and theorem.

Lemma 5.1: The solutions u and v for the DLW hierarchy (2.7) can be expressed in the form

$$u = \sum_{k=1}^{N}(\lambda_k - \nu_k), \quad \partial_x \ln v = \sum_{k=1}^{N}(\mu_k - \nu_k), \tag{5.1}$$

where μ_k, ν_k are called the elliptic coordinates of the finite-dimensional Hamiltonian system (4.3).

Proof: We express F_λ in the form

$$F_\lambda = -V_\lambda^{11^2} - V_\lambda^{12}V_\lambda^{21} = -\frac{1}{4}\lambda^2 + \sum_{k=1}^{N}\frac{E_k}{\lambda-\lambda_k},$$

where

$$E_k = -\lambda_k p_k q_k + p_k^2 + \langle p,q\rangle q_k^2 + \sum_{j=1,j\neq k}^{N}\frac{(p_j q_k - p_k q_j)^2}{\lambda_j - \lambda_k}.$$

Let

$$F_\lambda = -\frac{b(\lambda)}{4a(\lambda)} = -\frac{R(\lambda)}{4a^2(\lambda)}, \tag{5.2}$$

$$V_\lambda^{12} = -\langle p,q\rangle + Q_\lambda(p,p) = -\langle p,q\rangle \frac{m(\lambda)}{a(\lambda)},$$

$$V_\lambda^{21} = 1 - Q_\lambda(q,q) = \frac{n(\lambda)}{a(\lambda)}, \tag{5.3}$$

where

$$a(\lambda) = \prod_{k=1}^{N} (\lambda - \lambda_k), \quad b(\lambda) = \prod_{k=1}^{N+2} (\lambda - \lambda_{N+k}),$$

$$m(\lambda) = \prod_{k=1}^{N} (\lambda - \mu_k), \quad n(\lambda) = \prod_{k=1}^{N} (\lambda - \nu_k),$$

$$R(\lambda) = a(\lambda)b(\lambda) = \prod_{k=1}^{2N+2} (\lambda - \lambda_k).$$

Comparing the coefficients of λ^{N-1} in (5.2) and (5.3) gives

$$\langle q,q\rangle = -\sum_{k=1}^{N} (\lambda_k - \nu_k), \quad \frac{\langle p,p\rangle}{\langle p,q\rangle} = \sum_{k=1}^{N} (\mu_k - \lambda_k). \tag{5.4}$$

By using (4.2) and (5.4), we then obtain (5.1).

From the Lax equation (4.7), we have

$$\frac{dV_\mu^{12}}{dt_\lambda} = 2(W^{11}V^{12} - W^{12}V^{11}),$$

$$\frac{dV_\mu^{21}}{dt_\lambda} = 2(W^{21}V^{11} - W^{11}V^{21}). \tag{5.5}$$

Taking $\lambda = \mu_k, \nu_k$ in (5.2) and (5.3), we get

$$V_{\mu_k}^{11} = \frac{\sqrt{R(\mu_k)}}{2a(\mu_k)}, \quad V_{\mu_k}^{11} = \frac{\sqrt{R(\nu_k)}}{2a(\nu_k)}.$$

Hence, we have

$$\frac{1}{2\sqrt{R(\mu_k)}} \frac{d\mu_k}{d\tau_\lambda} = \frac{m(\lambda)}{a(\lambda)(\lambda - \mu_k)m'(\mu_k)},$$

$$\frac{1}{2\sqrt{R(\nu_k)}} \frac{d\nu_k}{d\tau_\lambda} = -\frac{n(\lambda)}{a(\lambda)(\lambda - \nu_k)n'(\nu_k)}.$$

By using the polynomials interpolation formula, we have

$$\sum_{k=1}^{N} \frac{\mu_k^{N-j}}{2\sqrt{R(\mu_k)}} \frac{d\mu_k}{d\tau_\lambda} = \frac{\lambda^{N-j}}{a(\lambda)}, \quad \sum_{k=1}^{N} \frac{\mu_k^{N-j}}{2\sqrt{R(\nu_k)}} \frac{d\nu_k}{d\tau_\lambda} = -\frac{\lambda^{N-j}}{a(\lambda)}. \tag{5.6}$$

Define the hyperelliptic curve by

$$\Gamma: \xi^2 - 4R(\lambda) = 0, \tag{5.7}$$

with genus $g=N$ and the usual holomorphic differentials by

$$\tilde{\omega}_j = \frac{\lambda^{N-j}\,\mathrm{d}\lambda}{2\sqrt{R(\lambda)}}, \quad j = 1,2,\ldots,N. \tag{5.8}$$

Denote $P(\mu_k)=(\lambda, \xi=2\sqrt{R(\lambda)}) \in \Gamma$. Let $P_0 \in \Gamma$ be fixed. Define the quasi-Abel–Jacobi coordinates by

$$\tilde{\phi}_j = \sum_{k=1}^{N} \int_{P_0}^{P(\mu_k)} \tilde{\omega}_j, \quad \tilde{\psi}_j = \sum_{k=1}^{N} \int_{P_0}^{P(\nu_k)} \tilde{\omega}_j, \quad j = 1,2,\ldots,N. \tag{5.9}$$

Then, (5.6) can be represented in the form

$$\frac{\mathrm{d}\tilde{\phi}_j}{\mathrm{d}\tau_\lambda} = \frac{\lambda^{N-j}}{a(\lambda)}, \quad \frac{\mathrm{d}\tilde{\psi}_j}{\mathrm{d}\tau_\lambda} = -\frac{\lambda^{N-j}}{a(\lambda)}.$$

Let $a_1, b_1, \ldots, a_N, b_N$ be the canonical basis of cycles on the Γ and

$$C = (A_{jk})^{-1}_{N\times N}, \quad A_{jk} = \int_{a_k} \tilde{\omega}_j.$$

Define the normalized holomorphic differential by

$$\omega_s = \sum_{j=1}^{N} C_{sj}\tilde{\omega}_j, \quad \omega = (\omega_1, \ldots, \omega_N)^T = C\tilde{\omega}.$$

Then, we have

$$\int_{a_k} \omega_s = \delta_{sk}, \quad \int_{b_k} \omega_s = B_{sk},$$

where the matrix $B=(B_{sk})$ is symmetric with positive-definite imaginary part. This is used to define the Riemann theta function of Γ as

$$\theta(\zeta) = \sum_{z\in\mathbb{Z}^N} \exp(\pi i\langle Bz, z\rangle + 2\pi i\langle \zeta, z\rangle), \quad \zeta \in C^N.$$

The Abel map $A(P)$ and the Abel–Jacobi coordinate are defined as

$$A(P) = \int_{P_0}^{P} \omega, \quad A\left(\sum n_k P_k\right) = \sum n_k A(P_k),$$

$$\phi = A\left(\sum_{k=1}^{N} P(\mu_k)\right) = \sum_{k=1}^{N} \int_{P_0}^{P(\mu_k)} \omega = C\tilde{\phi},$$

$$\psi = A\left(\sum_{k=1}^{N} P(\nu_k)\right) = \sum_{k=1}^{N} \int_{P_0}^{P(\nu_k)} \omega = C\tilde{\psi}.$$

Let $S_k=\lambda_1^k+\cdots+\lambda_{2N+2}^k$, and $\tilde{R}(\lambda^{-1})=\Pi_{j=1}^{2N+2}(1=\lambda_j\lambda^{-1})$. The coefficients in

$$\frac{1}{\sqrt{\tilde{R}(\lambda^{-1})}} = \sum_{k=1}^{\infty} \Lambda_k \lambda^{-k}$$

are then given by

$$\Lambda_0 = 1, \quad \Lambda_1 = \frac{1}{2} S_1, \quad \Lambda_k = \frac{1}{2k}\left(S_k + \sum_{i+j=k, i,j \geqslant 1} S_i \Lambda_j \right).$$

From (5.2), we obtain

$$\sqrt{R(\lambda)} = \lambda a(\lambda) c_\lambda,$$

and the lemma is proved.

Lemma 5.2: Let C_k be the kth column vector of the matrix C. Under the Abel–Jacobi coordinate system, we have straightened out the flows to

$$\frac{\mathrm{d}\phi}{\mathrm{d}t_\lambda} = \sum_{k=1}^{\infty} \Omega_{k-1} \lambda^{-k-1}, \quad \frac{\mathrm{d}\psi}{\mathrm{d}t_\lambda} = -\sum_{k=1}^{\infty} \Omega_{k-1} \lambda^{-k-1}, \tag{5.10}$$

$$\frac{\mathrm{d}\phi}{\mathrm{d}t_k} = \Omega_{k-1}, \quad \frac{\mathrm{d}\psi}{\mathrm{d}t_k} = -\Omega_{k-1}, \tag{5.11}$$

where

$$\Omega_0 = \tfrac{1}{2}\Lambda_0 C_1, \quad \Omega_1 = \tfrac{1}{2}(\Lambda_1 C_1 + \Lambda_0 C_2),$$

$$\Omega_k = \tfrac{1}{2}(\Lambda_k C_1 + \cdots + \Lambda_0 C_{k+1}), \quad k \leqslant N-1,$$

$$\Omega_k = \tfrac{1}{2}(\Lambda_k C_1 + \cdots + \Lambda_{k-N+1} C_N), \quad k \geqslant N-1.$$

Proof: Notice that

$$\begin{aligned}
\frac{\mathrm{d}\phi}{\mathrm{d}t_\lambda} = \frac{1}{2\lambda^2 c_\lambda}\frac{\mathrm{d}\phi}{\mathrm{d}\tau_\lambda} &= \frac{1}{2\lambda^2 c_\lambda} C \frac{\mathrm{d}\tilde{\phi}}{\mathrm{d}\tau_\lambda} \\
&= \frac{\lambda^{N-1}}{2\sqrt{R(\lambda)}}(C_1 \lambda^{-1} + \cdots + \cdots C_N \lambda^{-N}) \\
&= \frac{1}{2\lambda^2\sqrt{\tilde{R}(\lambda^{-1})}}(C_1 \lambda^{-1} + \cdots + \cdots_N \lambda^{-N}) \\
&= \frac{1}{2}\sum_{k=0}^{\infty} \Lambda_k \lambda^{-k-2} \sum_{j=1}^{N} C_j \lambda^{-j} = \sum_{k=0}^{\infty} \Omega_k \lambda^{-k-3}.
\end{aligned}$$

Similarly, we can obtain the second formula of (5.10) and compare the coefficients of λ^{-k-1} in (5.10) to obtain (5.11).

From (5.11), we get

$$\phi = \phi_0 + \sum_{k=1}^{\infty} \Omega_{k-1} t_k, \quad \psi = \psi_0 - \sum_{k=1}^{\infty} \Omega_{k-1} t_k.$$

Hence, the evolution picture of the $1+1$ flow is given as

$$\phi = \phi_0 + \Omega_0 x + \Omega_1 t, \quad \psi = \psi_0 - \Omega_0 x - \Omega_1 t. \tag{5.12}$$

Since $\deg R = 2N+2$ on Γ, there are two infinite points ∞_1 and ∞_2 which are not branch points of Γ. From Riemann theorem, there exists two constants $M_1, M_2 \in C^N$ such that $\theta(A(P) - \phi - M_1)$, $\theta(A(P) - \psi - M_2)$ have exactly n zeroes at $\mu_1, \ldots, \mu_N$ and $\nu_1, \ldots, \nu_N$, respectively. That is,

$$\sum_{j=1}^{N} \mu_j = I(\Gamma) - \sum_{j=1}^{2} \mathrm{Res}_{\lambda=\infty_j} \lambda d \ln \theta(A(P) - \phi - M_1), \tag{5.13}$$

$$\sum_{j=1}^{N} \nu_j = I(\Gamma) - \sum_{j=1}^{2} \mathrm{Res}_{\lambda=\infty_j} \lambda d \ln \theta(A(P) - \phi - M_1), \tag{5.14}$$

with the constant

$$I(\Gamma) = \sum_{j=1}^{N} \int_{a_j} \lambda \omega_j.$$

For the same λ, there are two points on the different sheets of the Riemann surface Γ,

$$P_+(\lambda) = (\lambda, \sqrt{R(\lambda)}), \quad P_+(\lambda) = (\lambda, -\sqrt{R(\lambda)}).$$

Under the local coordinate $z = \lambda^{-1}$ at infinity, the hyperelliptic curve $\Gamma: \xi^2 - 4R(\lambda) = 0$ in the neighborhood of infinity is expressed as $\tilde{\xi}^2 - 4\tilde{R}(z) = 0$ with $\tilde{\xi} = z^{N+1}\xi$ and $(z, 2(-1)^{s-1}\sqrt{R(z)})|_{z=0} = (0, 2(-1)^{s-1})$, $s = 1, 2$. Thus, we have

$$\begin{aligned} \omega = C\tilde{\omega} &= (C_1\lambda^{-1} + \cdots + C_N\lambda^{-N}) \frac{\lambda^{N-1} d\lambda}{2\sqrt{R(\lambda)}} \\ &= (C_1\lambda^{-1} + \cdots + C_N\lambda^{-N}) \frac{d\lambda}{2\lambda^2\sqrt{\tilde{R}(\lambda^{-1})}} \\ &= \frac{1}{2}(-1)^{s-1} \sum_{j=0}^{\infty} \Omega_k z^k \, dz \end{aligned}$$

and

$$A(P(z^{-1})) = \int_{P_0}^{P} \omega = -\int_{\infty_s}^{P_0} \omega + \int_{\infty_s}^{P} \omega = -\pi_s + \frac{1}{2}(-)^{s-1} \sum_{k=0}^{\infty} \frac{1}{k+1} \Omega_k z^{k+1}.$$

Since the theta function is an even function, we have

$$\theta(A(P(z^{-1}) - \phi - M_1) = \theta(\phi + M_1 + \eta_s) + \frac{1}{2} z(-1)^{s-1} \frac{\partial}{\partial x} \theta(\phi + M_1 + \eta_s) + o(z^2). \tag{5.15}$$

From (5.13) and (5.15), we obtain

$$\begin{aligned} \sum_{j=1}^{N} \mu_j &= I(\Gamma) - \frac{1}{2}(-1)^{s-1} \frac{\partial}{\partial x} \theta(\phi + M_1 + \eta_s) \\ &= I(\Gamma) + \frac{1}{2} \partial_x \ln \frac{\theta(\phi + M_1 + \eta_2)}{\theta(\phi + M_1 + \eta_1)}. \end{aligned} \tag{5.16}$$

Simiarly, we have

$$\sum_{j=1}^{N} \mu_j = I(\Gamma) + \frac{1}{2}\partial_x \ln \frac{\theta(\psi + M_2 + \pi_1)}{\theta(\psi + M_2 + \pi_2)}. \tag{5.17}$$

Substituting (5.16) and (5.17) into (5.1), we then obtain the following algebro-geometric solution for the DLW equation

$$u = \sum_{k=1}^{N} \lambda_k - I(\Gamma) - \frac{1}{2}\partial_x \ln \frac{\theta(\Omega_0 x + \Omega_1 t + \alpha_1)}{\theta(\Omega_0 x + \Omega_1 t + \alpha_2)},$$

$$v^2 = \frac{\theta(\Omega_0 x + \Omega_1 t + \alpha_2)\theta(\Omega_0 x + \Omega_1 t + \beta_2)}{\theta(\Omega_0 x + \Omega_1 t + \alpha_1)\theta(\Omega_0 x + \Omega_1 t + \beta_1)} v^2(0,t),$$

where

$$\alpha_l = \phi_0 + M_1 + \pi_l, \quad \beta_l = -\psi_0 - M_2 - \pi_l, \quad l = 1,2.$$

VI. CONCLUSION

Spectral problem usually provides many important integrable properties related to nonlinear equations such as Lax pair, *r*-matrix, Hamiltonian structure, Darboux transformation, and algebro-geometric solution. In this paper we investigate a spectral problem associated with the DLW equation and derive a hierarchy of nonlinear evolution equations related to the DLW equation by using an iterated algebraic method. The Hamiltonian structures for the DLW hierarchy are established by using trace identity. These two methods can be extended to other kinds of hierarchies. In constructing the commutator representation, the parameter λ is found to be easier to be computed than the operator L. We thus provide a transformation to change the operator L to λ in order to obtain the Lax representation for the DLW hierarchy. Through nonlinearization technique, a finite dimensional Hamiltonian system is obtained in an explicit form. The Abel–Jacobi coordinates are introduced from which the algebro-geometric solutions for the DLW equation can be derived by resorting to the Riemann theta function. The results given in this paper can be applied to many interesting problems such as higher order constrained flow and *r*-matrix structure.

(Received 4 August 2004; accepted 16 November 2004; published online 14 February 2005)

We outline a unified approach to geometrization of Lagrange mechanics, Finsler geometry and geometric methods of constructing exact solutions with generic off-diagonal terms and nonholonomic variables in gravity theories. Such geometries with induced almost symplectic structure are modeled on nonholonomic manifolds provided with nonintegrable distributions defining nonlinear connections. We introduce the concept of Lagrange–Fedosov spaces and Fedosov nonholonomic manifolds provided with almost symplectic connection adapted to the nonlinear connection structure. We investigate the main properties of generalized Fedosov nonholonomic manifolds and analyze exact solutions defining almost symplectic Einstein spaces. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1855402]

I. INTRODUCTION

The geometry of Fedosov manifolds is a natural generalization of Kähler geometry defining a procedure of canonical deformation quantization.[1–5] By definition, a Fedosov manifold is given by a triple (M,θ,Γ) where M is a $\mathcal{C}^{\infty}$-manifold enabled with symplectic structure θ (a nondegenerated closed exterior two-form) and a symplectic connection structure Γ (i.e., a torsionless linear connection parallelizing the symplectic form). If a Lagrange fundamental function $L:(x,y)\in TM \to \mathbb{R}$ is defined on M (for simplicity, in this work we shall consider only regular Lagrangians; (x,y) denote a set of local coordinates on the tangent bundle TM with $x\in M$), there is a natural almost complex structure adapted to the canonical nonlinear connection (in brief, N-connection) induced by $L(x,y)$.[6–8] Nonlinear connections can also be naturally related to generic off-diagonal metrics and nonholonomic moving frames in (super) gravity and string theories.[9–13] So, if we want to apply the methods of symplectic geometry (and possible generalizations for Poisson manifolds[14]) to various types of Lagrange–Hamilton, and related Finsler–Cartan spaces, we have to consider spaces enabled with N-connection structure.

In this work, we study the geometry of almost symplectic connections (in general, they are not torsion-free but can be symmetrized) which are distinguished by a N-connection structure and preserve an almost symplectic form, for instance, induced by a regular Lagrangian or off-diagonal metric structure. This is related to almost symplectic manifolds (see, for instance, Refs. 15–19) but, in our case, the manifolds are nonholonomic ones.

We shall define and analyze the curvature tensor for such almost symplectic connections and related Einstein equations with nonholonomic variables. For nonholonomic manifolds, i.e., manifolds with nonintegrable distributions (in our case, with a such distribution defined by a N-connection), this is not a trivial task. The problem together with a proposal when the Riemann tensor is interpreted as a modification of the Spencer cohomology and related to solutions of partial differential equations, as well to superspaces, are analyzed in Refs. 20 and 21.

The geometry of nonholonomic manifolds has a long time historical perspective: For instance, in Ref. 22 it is stated that it is probably impossible to construct an analog of the Riemannian tensor for the general nonholonomic manifold. In two more recent reviews (Refs. 23 and 24), it is emphasized that in the past there were proposed well-defined Riemannian tensors for a number of spaces provided with nonholonomic distributions, like Finsler and Lagrange spaces and various types of their higher order generalizations, i.e., for nonholonomic manifolds possessing corresponding N-connection structures. As some examples of former such investigations, we cite Refs. 25–29.

Essentially, the Fedosov type nonholonomic geometry to be elaborated in this work is based on the notion of N-connection and considers a Whitney-like splitting of the tangent bundle to a manifold into horizontal and vertical subspaces (see the discussion and a bibliography for recent developments and applications in Refs. 30–32). Here we emphasize that the geometrical aspects of the N-connection formalism have been studied since the first papers of Cartan[33] and Kawaguchi[34–36] (who used it in component form for Finsler geometry), then one should mention the so-called Ehresmann connection[37] and the work of Barthel[38] where the global definition of N-connection was given. The monographs (Refs. 6–8) consider the N-connection formalism elaborated and applied to the geometry of generalized Finsler–Lagrange and Cartan–Hamilton spaces, see also the approaches in Refs. 39–42.

The works related to nonholonomic geometry and N-connections have appeared many times in a rather dispersive way when different schools of authors from geometry, mechanics, and physics have worked many times entirely independent of each other. We outline some recent results with explicit applications in modern mathematical physics and particle and string theories: N-connection structures were modeled on Clifford and spinor bundles,[43,44] on superbundles and in some directions of (super) string theory,[45,46] as well as in noncommutative geometry and gravity.[47] The idea to apply the N-connections formalism as a new geometric method of constructing exact solutions in gravity theories was suggested in Refs. 9 and 10 and developed in a number of works, see, for instance, Refs. 11–13).

We begin in Sec. II with an introduction into the N-connection geometry for arbitrary manifolds with tangent bundles admitting splitting into conventional horizontal and vertical subspaces. We illustrate how regular Lagrangians induce natural semispray, N-connection, metric, and almost complex structures on tangent bundles and discuss the relation between Lagrange and Finsler geometry and their generalizations. Then we prove that N-connection structures and corresponding almost complex geometries may be modeled by generic off-diagonal metrics and nonholonomic frames in gravity theories.

Section III is devoted to the theory of linear connections on N-anholonomic manifolds (i.e., on manifolds with nonholonomic structure defined by N-connections). We demonstrate how the linear connections may be adapted to the N-connection splitting of the manifolds and analyze the conditions when such distinguished connections may be naturally related to almost complex structures. This has great *philosophical* interest, because several authors have defined different notions of general connections, looking for associated parallel transport and covariant differential operator satisfying, if possible, the properties of those of a linear connection (e.g., Ehresmann connections on bundles, nonhomogeneous connections of Grifone,[48] quasi- and pseudo-connections (see Ref. 49, etc.), but it always implies losing properties or demanding more assumptions than in the case of a N-connection. [For example, nonhomogeneous connections of Grifone define a covariant derivative $D_X Y$, which in general does not define a vector field on the manifold (see p. 302 of Ref. 48) and which does not satisfy $D_X(fY)=fD_XY+(Xf)Y$ (see p. 305 of Ref. 48). In the case of nonlinear connections used in the book of Yano and Ishihara (Ref. 50, p. 209) it is assumed that horizontal distributions are invariant under dilatations (see also Ref. 51), etc.] In the present paper we shall see that one can define a canonical linear connection adapted to a given N-connection. This shall allow us to avoid extra constructions and additional restrictions.

In Sec. IV, we define the Fedosov N-anholonomic and Lagrange–Fedosov manifolds as certain

generalizations of the Fedosov spaces to nonholonomic configurations. We construct in explict form the curvature tensor of such spaces and define the Einstein equations for N-adapted linear connection and metric structures.

In Sec. V, we analyze the main conditions when vacuum gravitational configurations with N-anholonomic structures can be defined as exact solutions of the Einstein equations. We prove that for a very general five-dimensional ansatz for metric coefficients depending on two, three, and four variables the system of field equations is completely integrable. We illustrate that the method can be reduced to the case of four-dimensional spaces, which gives us the possibility to generate conformal almost complex gravitational metrics.

We shall use both physical and mathematical languages and both coordinate and intrinsic notations, when possible.

II. NONLINEAR CONNECTIONS AND FEDOSOV SPACES

In the following, we recall some results on nonlinear connections and almost symplectic structures, which in certain particular cases, are induced by regular Lagrangians, Finsler fundamental functions, or by generic off-diagonal metrics in gravity theories. From now on, all the manifolds (in general, nonholonomic ones)—in the literature, the equivalent term, anholonomic, is also used—and geometric objects are supposed to be C^∞.

A. Nonlinear connection geometry

Let $\mathbf{V}$ be an $(n+m)$-dimensional manifold. It is supposed that in any point $u\in\mathbf{V}$ there is a local splitting $\mathbf{V}_u=M_u\oplus V_u$, where M is an n-dimensional subspace and V is an m-dimensional subspace. (One has this local decomposition when $\mathbf{V}\to M$ is a surjective submersion. A particular case is that of a fiber bundle, but we can obtain the results in the general case.) We shall split the local coordinates (in general, abstract ones both for holonomic and nonholonomic variables) in the form $u=(x,y)$, or $u^\alpha=(x^i,y^a)$, where $i,j,k,\ldots=1,2,\ldots,n$ and $a,b,c,\ldots=n+1,n+2,\ldots,n+m$. We denote by $\pi^\tau:T\mathbf{V}\to TM$ the differential of a map $\pi:V^{n+m}\to V^n$ defined by fiber preserving morphisms of the tangent bundles $T\mathbf{V}$ and TM. The kernel of π^τ is just the vertical subspace $v\mathbf{V}$ with a related inclusion mapping $i:v\mathbf{V}\to T\mathbf{V}$.

Definition 1: *A nonlinear connection (N-connection)* $\mathbf{N}$ *on a manifold* $\mathbf{V}$ *is defined by the splitting on the left of an exact sequence*

$$0\to v\mathbf{V}\overset{i}{\to}T\mathbf{V}\to T\mathbf{V}/v\mathbf{V}\to 0,$$

i.e., by a morphism of submanifolds $\mathbf{N}:T\mathbf{V}\to v\mathbf{V}$ *such that* $\mathbf{N}\circ\mathbf{i}$ *is the unity in* $v\mathbf{V}$.

In an equivalent form, we can say that a N-connection is defined by a splitting to subspaces with a Whitney sum of conventional horizontal (h) subspace, $(h\mathbf{V})$, and vertical (v) subspace, $(v\mathbf{V})$,

$$T\mathbf{V}=h\mathbf{V}\oplus v\mathbf{V}, \tag{1}$$

where $h\mathbf{V}$ is isomorphic to M. Moreover, one can say that a N-connection is defined by a tensor field of type (1,1) $\mathbf{P}=\mathbf{H}-\mathbf{N}$, where $\mathbf{H}$ (respectively, $\mathbf{N}$) denotes the projection over the horizontal (respectively, vertical) subspace. Observe that $\mathbf{P}\circ\mathbf{P}=\mathbf{I}$, i.e., $\mathbf{P}$ is an almost product structure, horizontal (respectively, vertical) subspace being the eigenspace associated to the eigenvalue $+1$ (respectively, -1).

Locally, a N-connection is defined by its coefficients $N_i^a(u)$,

$$\mathbf{N}=N_i^a(u)\mathrm{d}x^i\otimes\frac{\partial}{\partial y^a}.$$

The well-known class of linear connections consists on a particular subclass with the coefficients being linear on y^a, i.e., $N_i^a(u)=\Gamma_{bj}^a(x)y^b$.

Any N-connection $\mathbf{N}=N_i^a(u)$ may be characterized by an associated frame (vielbein) structure $\mathbf{e}_\nu=(e_i,e_a)$, where

$$e_i=\frac{\partial}{\partial x^i}-N_i^a(u)\frac{\partial}{\partial y^a},\quad e_a=\frac{\partial}{\partial y^a}, \tag{2}$$

and the dual frame (coframe) structure $\vartheta^\mu=(\vartheta^i,\vartheta^a)$, where

$$\vartheta^i=\mathrm{d}x^i,\quad \vartheta^a=\mathrm{d}y^a+N_i^a(u)\mathrm{d}x^i. \tag{3}$$

These vielbeins are called N-adapted frames. In order to preserve a relation with the previous denotations,[8–11,43,44,46] we note that $\mathbf{e}_\nu=(e_i,e_a)$ and $\vartheta^\mu=(\vartheta^i,\vartheta^a)$ are, respectively, the former $\delta_\nu=\delta/\partial u^\nu=(\delta_i,\partial_a)$ and $\delta^\mu=\delta u^\mu=(d^i,\delta^a)$ which emphasize that operators (2) and (3) define, correspondingly, certain "N-elongated" partial derivatives and differentials which are more convenient for calculations on such nonholonomic manifolds.

Any N-connection also defines a N-connection curvature

$$\Omega=\tfrac{1}{2}\Omega_{ij}^a\mathrm{d}^i\wedge\mathrm{d}^j\otimes\partial_a,$$

with N-connection curvature coefficients

$$\Omega_{ij}^a=\delta_{[j}N^a_{i]}=\delta_jN_i^a-\delta_iN_j^a=\frac{\partial N_i^a}{\partial x^j}-\frac{\partial N_j^a}{\partial x^i}+N_i^b\frac{\partial N_j^a}{\partial y^b}-N_j^b\frac{\partial N_i^a}{\partial y^b}. \tag{4}$$

The vielbeins (3) satisfy the nonholonomy (equivalently, anholonomy) relations

$$[\mathbf{e}_\alpha,\mathbf{e}_\beta]=\mathbf{e}_\alpha\mathbf{e}_\beta-\mathbf{e}_\beta\mathbf{e}_\alpha=W_{\alpha\beta}^\gamma\mathbf{e}_\gamma \tag{5}$$

with (antisymmetric) nontrivial anholonomy coefficients $W_{ia}^b=\partial_aN_i^b$ and $W_{ji}^a=\Omega_{ij}^a$.

Definition 2: *A manifold* $\mathbf{V}$ *is called N-anholonomic if on the tangent space* $T\mathbf{V}$ *it is defined as a local (nonintegrable) distribution (1), i.e.,* $T\mathbf{V}$ *is enabled with a N-connection and related nonholonomic vielbein structure (5).*

We note that in this work we use boldfaced symbols for the spaces and geometric objects provided/adapted to a N-connection structure. For instance, a vector field $\mathbf{X}\in T\mathbf{V}$ is expressed as $\mathbf{X}=(X,{}^\vee X)$, or $\mathbf{X}=X^\alpha\mathbf{e}_\alpha=X^ie_i+X^ae_a$, where $X=X^ie_i$ and ${}^\vee X=X^ae_a$ state, respectively, the irreducible (adapted to the N-connection structure) horizontal (h) and vertical (v) components of the vector (which following Ref. 6 and 7 are called distinguished vectors, in brief, d-vector). In a similar fashion, the geometric objects on $\mathbf{V}$ like tensors, spinors, connections, etc., are called, respectively, d-tensors, d-spinors, d-connections if they are adapted to the N-connection splitting.

In secs. II B and II C we show how certain types of N-connection geometries can be naturally derived from Lagrange–Finsler geometry and in gravity theories.

B. N-connections and Lagrangians

We outline the main results on N-connections and almost symplectic structures induced by regular Lagrangians.[6–8] In this case the N-anholonomic manifold $\mathbf{V}$ is to be modeled on the tangent bundle (TM,π,M), where M is an n-dimensional base manifold, π is a surjective projection, and TM is the total space. One denotes by $\widetilde{TM}=TM\backslash\{0\}$ where $\{0\}$ means the null section of map π.

A differentiable Lagrangian $L(x,y)$, i.e., a fundamental Lagrange function, is defined by a map $L:(x,y)\in TM\to L(x,y)\in\mathbb{R}$ of class $\mathcal{C}^\infty$ on $\widetilde{TM}$ and continuous on the null section $0:M\to TM$ of π. A regular Lagrangian is with nondegenerated Hessian,

$${}^{(L)}g_{ij}(x,y)=\frac{1}{2}\frac{\partial^2L(x,y)}{\partial y^i\,\partial y^j} \tag{6}$$

when *rank* $|g_{ij}|=n$ on $\widetilde{TM}$.

Definition 3: *A Lagrange space is a pair* $L^n=[M,L(x,y)]$ *with* ${}^{(L)}g_{ij}(x,y)$ *being of constant signature over* $\widetilde{TM}$.

The notion of Lagrange space was introduced by Kern[52] and elaborated in detail by Miron's school on Finsler and Lagrange geometry, see Refs. 6 and 7, as a natural extension of Finsler geometry[33,53–59] (see also Refs. 45 and 46 on Lagrange–Finsler supergeometry).

By straightforward calculations, there were proved the following results:

1. The Euler–Lagrange equations,

$$\frac{\mathrm{d}}{\mathrm{d}\tau}\left(\frac{\partial L}{\partial y^i}\right)-\frac{\partial L}{\partial x^i}=0,$$

where $y^i=\mathrm{d}x^i/\mathrm{d}\tau$ for $x^i(\tau)$ depending on parameter τ, are equivalent to the "nonlinear" geodesic equations

$$\frac{\mathrm{d}^2x^i}{\mathrm{d}\tau^2}+2G^i\left(x^k,\frac{\mathrm{d}x^j}{\mathrm{d}\tau}\right)=0$$

defining paths of a canonical semispray

$$S=y^i\frac{\partial}{\partial x^i}-2G^i(x,y)\frac{\partial}{\partial y^i},$$

where

$$2G^i(x,y)=\frac{1}{2}{}^{(L)}g^{ij}\left(\frac{\partial^2 L}{\partial y^i\,\partial x^k}y^k-\frac{\partial L}{\partial x^i}\right)$$

with ${}^{(L)}g^{ij}$ being inverse to (6).

2. There exists on $\widetilde{TM}$ a canonical N-connection

$${}^{(L)}N^i_j=\frac{\partial G^i(x,y)}{\partial y^j} \tag{7}$$

defined by the fundamental Lagrange function $L(x,y)$, which prescribes nonholonomic frame structures of types (2) and (3), ${}^{(L)}\boldsymbol{e}_\nu=(e_i,{}^\vee e_k)$ and ${}^{(L)}\vartheta^\mu=(\vartheta^i,{}^\vee\vartheta^k)$. [On the tangent bundle the indices related to the base space run the same values as those related to fibers: we can use the same symbols but have to distinguish like ${}^\vee e_k$ certain irreducible v-components with respect to, (or for) N-adapted bases and cobases.]

3. The canonical N-connection (7) defining ${}^\vee e_i$, induces naturally an almost complex structure $\mathbf{F}:\chi(\widetilde{TM})\to\chi(\widetilde{TM})$, where $\chi(\widetilde{TM})$ denotes the module of vector fields on $\widetilde{TM}$,

$$\mathbf{F}(e_i)={}^\vee e_i,\quad \mathbf{F}\left({}^\vee e_i\right)=-e_i,$$

when

$$\mathbf{F}={}^\vee e_i\otimes\vartheta^i-e_i\otimes{}^\vee\vartheta^i \tag{8}$$

satisfies the condition $\mathbf{F}\rfloor\mathbf{F}=-\mathbf{I}$, i.e., $F^\alpha{}_\beta F^\beta{}_\gamma=-\delta^\alpha_\gamma$, where δ^α_γ is the Kronecker symbol and "$\rfloor$" denotes the interior product.

4. On $\widetilde{TM}$, there is a canonical metric structure

$${}^{(L)}\mathbf{g}={}^{(L)}g_{ij}(x,y)\,\vartheta^i\otimes\vartheta^j+{}^{(L)}g_{ij}(x,y)\,{}^\vee\vartheta^i\otimes{}^\vee\vartheta^j \tag{9}$$

constructed as a Sasaki type lift from M.

One holds (Refs. 6–8) the following

Theorem 1: *The space* $(\widetilde{TM},\mathbf{F},{}^{(L)}\mathbf{g})$ *with almost complex form* $\mathbf{F}$ *(8) defined by* ${}^{(L)}N^i_j$*, see (7), and canonical metric structure* ${}^{(L)}\boldsymbol{g}$ *(9) is an almost Kähler space with almost symplectic structure*

$$ {}^{(L)}\theta = {}^{(L)}\theta_{\alpha\beta}(x,y)\vartheta^\alpha \wedge \vartheta^\beta = {}^{(L)}g_{ij}(x,y)^\vee\vartheta^i \wedge \vartheta^j. \tag{10}$$

Proof: It is evident if we define

$$ {}^{(L)}\theta(\mathbf{X},\mathbf{Y}) \doteqdot {}^{(L)}\mathbf{g}(\mathbf{FX},\mathbf{Y}) $$

and put $\mathbf{X}=\mathbf{e}_\alpha$ and $\mathbf{Y}=\mathbf{e}_\beta$. ■

We conclude that any regular Lagrange mechanics can be geometrized as an almost Kähler space with N-connection distribution. In such a Lagrange–Kähler nonholonomic manifold, the fundamental geometric structures (semispray, N-connection, almost complex structure, and canonical metric on $\widetilde{TM}$) are defined by the fundamental Lagrange function $L(x,y)$.

Remark 1: *For applications in optics of nonhomogeneous media and gravity (see, for instance, Refs. 7, 9, 11, and 12) one considers metric forms of type* $g_{ij}\sim e^{\lambda(x,y)^{(L)}}g_{ij}(x,y)$ *which cannot be derived from a mechanical Lagrangian. In the so-called generalized Lagrange geometry one considers Sasaki-type metrics (9) with certain general coefficients both for the metric and* N*-connection, i.e., when* ${}^{(L)}g_{ij}\to g_{ij}(x,y)$*, and* ${}^{(L)}N^i_j\to N^i_j(x,y)$*. [In this case, we can similarly define an almost Kähler* N*-anholonomic space* $(\widetilde{TM},\mathbf{F},\theta)$ *with the geometric structures induced naturally by the* N*-connection.]*

Remark 2: *Finsler geometry with the fundamental Finsler function* $F(x,y)$*, being homogeneous of type* $F(x,\lambda y)=\lambda F(x,y)$*, for nonzero* $\lambda\in\mathbb{R}$*, may be considered as a particular case of Lagrange geometry when* $L=F^2$*. [In another turn, there is a proof*[59] *that any Lagrange fundamental function L can be modeled as a singular case in a certain class of Finsler geometries of extra dimension.] We shall apply the methods of Finsler geometry and its almost Kähler models in this work. Nevertheless, because the generalized Lagrange spaces are very general ones enabled with N-anholonomic structure inducing a corresponding almost symplectic structure we shall emphasize just such geometric configurations.*

Remark 3: *It is also proved that both generalized Lagrange and Finsler geometries can be modeled on Riemannian–Cartan N-anholonomic manifolds*[13,30–32] *if off-diagonal metrics and N-connections are introduced into consideration.*

Now we shall demonstrate how N-anholonomic configurations can be defined in gravity theories. In this case, it is convenient to work on a general manifold $\mathbf{V}$, $\dim\mathbf{V}=n+m$ with global splitting, instead of the tangent bundle $\widetilde{TM}$.

C. N-connections in gravity

Let us consider a metric structure on $\mathbf{V}$ with the coefficients defined with respect to a local coordinate basis $du^\alpha=(dx^i,dy^a)$,

$$ \mathbf{g} = \underline{g}_{\alpha\beta}(u)du^\alpha\otimes du^\beta $$

with

$$ \underline{g}_{\alpha\beta} = \begin{bmatrix} g_{ij}+N^a_iN^b_jh_{ab} & N^e_jh_{ae} \\ N^e_ih_{be} & h_{ab} \end{bmatrix}. \tag{11}$$

A metric, for instance, parametrized in the form (11) is generic off-diagonal if it cannot be diagonalized by any coordinate transforms. Performing a frame transform with the coefficients

$$ \mathbf{e}^\alpha_\alpha(u) = \begin{bmatrix} e^i_i(u) & N^b_i(u)e^a_b(u) \\ 0 & e^a_a(u) \end{bmatrix}, \tag{12}$$

$$\mathbf{e}_{\underline{\beta}}^{\beta}(u)=\begin{bmatrix} e_{\underline{i}}^{i}(u) & -N_{k}^{b}(u)e_{\underline{i}}^{k}(u) \\ 0 & e_{\underline{a}}^{a}(u) \end{bmatrix}, \tag{13}$$

we write equivalently the metric in the form

$$\mathbf{g}=\mathbf{g}_{\alpha\beta}(u)\vartheta^{\alpha}\otimes\vartheta^{\beta}=g_{ij}(u)\vartheta^{i}\otimes\vartheta^{j}+h_{ab}(u)\overset{\vee}{\vartheta}{}^{a}\otimes\overset{\vee}{\vartheta}{}^{b}, \tag{14}$$

where $g_{ij}\doteq\mathbf{g}(e_i,e_j)$ and $h_{ab}\doteq\mathbf{g}(e_a,e_b)$ and

$$\mathbf{e}_{\alpha}=\mathbf{e}_{\alpha}^{\underline{\alpha}}\partial_{\underline{\alpha}} \text{ and } \vartheta^{\beta}=\mathbf{e}_{\underline{\beta}}^{\beta}du^{\underline{\beta}}.$$

are vielbeins of types (2) and (3) defined for arbitrary $N_i^b(u)$. We can consider a special class of manifolds provided with a global splitting into conventional "horizontal" and "vertical" subspaces (1) induced by the "off-diagonal" terms $N_i^b(u)$ and prescribed type of nonholonomic frame structure.

If the manifold $\mathbf{V}$ is (pseudo) Riemannian, there is a unique linear connection (the Levi-Civita connection) ∇, which is metric, $\nabla\mathbf{g}=\mathbf{0}$, and torsionless, ${}^{\nabla}T=0$. Nevertheless, the connection ∇ is not adapted to the nonintegrable distribution induced by $N_i^b(u)$. In this case, it is more convenient to work with more general classes of linear connections which are N-adapted but contain nontrivial torsion coefficients because of nontrivial nonholonomy coefficients $W_{\alpha\beta}^{\gamma}$ (5). (For instance, in order to construct exact solutions parametrized by generic off-diagonal metrics, or for investigating nonholonomic frame structures in gravity models with nontrivial torsion.)

For a splitting of a (pseudo-) Riemannian–Cartan space of dimension $(n+m)$ [under certain constraints, we can consider (pseudo-) Riemannian configurations], the Lagrange and Finsler type geometries were modeled by N-anholonomic structures as exact solutions of gravitational field equations.[9–13,31,32] In this paper, we shall concentrate on N-anholonomic almost complex structures of vacuum gravity which can be naturally defined as $(n+n)$ configurations, in general, embedded in certain spaces of dimension $(n+m)$, $m\geqslant n$.

III. CONNECTIONS ON ALMOST SYMPLECTIC N-ANHOLONOMIC MANIFOLDS

The geometric constructions can be adapted to the N-connection structure:

Definition 4: A distinguished connection (d-connection) $\mathbf{D}$ *on a manifold* $\mathbf{V}$ *is a linear connection conserving under parallelism the Whitney sum (1) defining a general N-connection. Equivalently,* $\mathbf{DP}=0$, $\mathbf{P}$ *being the almost product structure defined by the N-connection.*

The N-adapted components $\Gamma_{\beta\gamma}^{\alpha}$ of a d-connection $\mathbf{D}_{\alpha}=(\delta_{\alpha}\rfloor\mathbf{D})$ are defined by the equations

$$\mathbf{D}_{\alpha}\delta_{\beta}=\Gamma_{\alpha\beta}^{\gamma}\delta_{\gamma},$$

or

$$\Gamma_{\alpha\beta}^{\gamma}(u)=(\mathbf{D}_{\alpha}\delta_{\beta})\delta^{\gamma}. \tag{15}$$

In its turn, this defines a N-adapted splitting into h- and v-covariant derivatives, $\mathbf{D}=D+\overset{\vee}{D}$, where $D_k=(L_{jk}^i,L_{bk}^a)$ and $\overset{\vee}{D}_c=(C_{jk}^i,C_{bc}^a)$ are introduced as corresponding h- and v-parametrizations of (15),

$$L_{jk}^{i}=(\mathbf{D}_{k}e_{j})\vartheta^{i},\quad L_{bk}^{a}=(\mathbf{D}_{k}e_{b})\vartheta^{a},\quad C_{jc}^{i}=(\mathbf{D}_{c}e_{j})\vartheta^{i},\quad C_{bc}^{a}=(\mathbf{D}_{c}e_{b})\vartheta^{a}.$$

The components $\mathbf{\Gamma}_{\alpha\beta}^{\gamma}=(L_{jk}^i,L_{bk}^a,C_{jc}^i,C_{bc}^a)$ completely define a d-connection $\mathbf{D}$ on a N-anholonomic manifold $\mathbf{V}$.

The simplest way to perform computations with d-connections is to use N-adapted differential forms like $\mathbf{\Gamma}_{\beta}^{\alpha}=\mathbf{\Gamma}_{\beta\gamma}^{\alpha}\vartheta^{\gamma}$ with the coefficients defined with respect to (3) and (2).

We shall say that a d-connection $\mathbf{D}$ preserves an almost symplectic two-form, of Lagrange type ${}^{(L)}\theta$ (10) (or any general one, θ) defined from a generalized Lagrange geometry or N-anholonomic gravity model, if

$$\mathbf{D}\theta = \mathbf{0} \tag{16}$$

or

$$\mathbf{Z}(\theta(\mathbf{X},\mathbf{Y})) = \theta(\mathbf{D}_Z\mathbf{X},\mathbf{Y}) + \theta(\mathbf{X},\mathbf{D}_\mathbf{Z}\mathbf{Y})$$

for any d-vector fields $\mathbf{X}$, $\mathbf{Y}$, $\mathbf{Z}\in T\mathbf{V}$.

Theorem 2: *The torsion* $\mathcal{T}^\alpha \doteqdot \mathbf{D}\vartheta^\alpha = d\vartheta^\alpha + \Gamma^\alpha_\beta \wedge \vartheta^\beta$ *of a d-connection has the irreducible h-, v-components (d-torsions) with N-adapted coefficients*

$$T^i_{jk} = L^i_{[jk]}, \quad T^i_{ja} = -T^i_{aj} = C^i_{ja}, \quad T^a_{ji} = \Omega^a_{ji},$$

$$T^a_{bi} = T^a_{ib} = \frac{\partial N^a_i}{\partial y^b} - L^a_{bi}, \quad T^a_{bc} = C^a_{[bc]}, \tag{17}$$

where $L^i_{[jk]} = L^i_{jk} - L^i_{kj}$ *and so on.* ■

Proof: By a straightforward calculation we can verify the formulas.

Remark 4: *The Levi-Civita linear connection* $\nabla = \{{}^\nabla\mathbf{\Gamma}^\alpha_{\beta\gamma}\}$, *with vanishing both torsion and nonmetricity, is not adapted to the global splitting (1). In fact, if* ∇ *was adapted, then* $\nabla\mathbf{P} = 0$, $\mathbf{P}$ *being the almost product structure defined by the N-connection, and then, as* ∇ *is torsionless, one obtains by means of the Lemma 2.1.6 of Ref. 60 that the Nijenhuis tensor field* $N_\mathbf{P}$ *vanishes, thus proving that both vertical and horizontal distributions are involutive in the sense of Frobenius theorem, which is not our case of anholonomic manifolds. Then, we must look for another connection to study the geometry of these manifolds.*

One holds:

Proposition 3: *There is a preferred, canonical d-connection structure,* $\hat{\mathbf{D}}$, *on N-aholonomic manifold* $\mathbf{V}$ *constructed only from the metric and N-connection coefficients* $[g_{ij}, h_{ab}, N^a_i]$ *and satisfying the conditions* $\hat{\mathbf{D}}\mathbf{g} = 0$ *and* $\hat{T}^i_{jk} = 0$ *and* $\hat{T}^a_{bc} = 0$.

Proof: By straightforward calculations with respect to the N-adapted bases (3) and (2), we can verify that the connection

$$\hat{\mathbf{\Gamma}}^\alpha_{\beta\gamma} = {}^\nabla\mathbf{\Gamma}^\alpha_{\beta\gamma} + \hat{\mathbf{P}}^\alpha_{\beta\gamma} \tag{18}$$

with the deformation d-tensor [$\hat{\mathbf{P}}^\alpha_{\beta\gamma}$ is a tensor field of type (1,2)—as is well known, the sum of a linear connection and a tensor field of type (1,2) is a new linear connection]

$$\hat{\mathbf{P}}^\alpha_{\beta\gamma} = \left(P^i_{jk} = 0, P^a_{bk} = \frac{\partial N^a_k}{\partial y^b}, P^i_{jc} = -\frac{1}{2} g^{ik}\Omega^a_{kj} h_{ca}, P^a_{bc} = 0 \right)$$

satisfies the conditions of this Proposition. It should be noted that, in general, the components $\hat{T}^i_{ja}$, $\hat{T}^a_{ji}$, and $\hat{T}^a_{bi}$ are not zero. This is an anholonomic frame (or, equivalently, off-diagonal metric) effect. ■

With respect to the N-adapted frames, the coefficients $\hat{\mathbf{\Gamma}}^\gamma_{\alpha\beta} = (\hat{L}^i_{jk}, \hat{L}^a_{bk}, \hat{C}^i_{jc}, \hat{C}^a_{bc})$ are computed:

$$\hat{L}^i_{jk} = \frac{1}{2} g^{ir}\left(\frac{\delta g_{jr}}{\partial x^k} + \frac{\delta g_{kr}}{\partial x^j} - \frac{\delta g_{jk}}{\partial x^r} \right),$$

$$\hat{L}^a_{bk} = \frac{\partial N^a_k}{\partial y^b} + \frac{1}{2} h^{ac}\left(\frac{\delta h_{bc}}{\partial x^k} - \frac{\partial N^d_k}{\partial y^b} h_{dc} - \frac{\partial N^d_k}{\partial y^c} h_{db} \right),$$

$$\hat{C}^i_{jc} = \frac{1}{2} g^{ik} \frac{\partial g_{jk}}{\partial y^c},$$

$$\hat{C}^a_{bc} = \frac{1}{2} h^{ad} \left(\frac{\partial h_{bd}}{\partial y^c} + \frac{\partial h_{cd}}{\partial y^b} - \frac{\partial h_{bc}}{\partial y^d} \right). \tag{19}$$

For the canonical d-connection there are satisfied the conditions of vanishing of torsion on the h-subspace and v-subspace, i.e., $\hat{T}^i_{jk} = \hat{T}^a_{bc} = 0$. In more general cases, such components of torsion are not zero, for instance, the metric d-connections of type $\mathbf{\Gamma}^{\gamma}_{\alpha\beta} = (\hat{L}^i_{jk} + l^i_{jk}(u), \hat{L}^a_{bk}, \hat{C}^i_{jc}, \hat{C}^a_{bc} + c^a_{bc}(u))$ are also compatible with metric (14) and has nontrivial T^i_{jk} and $\hat{T}^a_{bc}$.

Let us consider a special case with $\dim \mathbf{V} = n+n$, $h_{ab} \to g_{ij}$ and $N^a_i \to N^j_i$ in (14) when a tangent bundle structure is locally modeled on $\mathbf{V}$. We denote such a space by $\widetilde{\mathbf{V}}_{(n,n)}$. One holds:

Theorem 4: *The canonical d-connection* $\hat{\mathbf{D}}$ *(19) for a local modelling of a* $\widetilde{TM}$ *space on* $\widetilde{\mathbf{V}}_{(n,n)}$ *is defined by* $\hat{\mathbf{\Gamma}}^{\gamma}_{\alpha\beta} = (\hat{L}^i_{jk}, \hat{C}^i_{jk})$ *with*

$$\hat{L}^i_{jk} = \frac{1}{2} g^{ir} \left(\frac{\delta g_{jr}}{\partial x^k} + \frac{\delta g_{kr}}{\partial x^j} - \frac{\delta g_{jk}}{\partial x^r} \right), \quad \hat{C}^i_{jk} = \frac{1}{2} g^{ir} \left(\frac{\partial g_{jr}}{\partial x^k} + \frac{\partial g_{kr}}{\partial x^j} - \frac{\partial g_{jk}}{\partial x^r} \right). \tag{20}$$

This d-connection is almost Hermitian, i.e., it is compatible with the almost Hermitian structure $(\mathbf{g}, \mathbf{F})$, *when*

$$\hat{\mathbf{D}}\theta = 0 \text{ and } \hat{\mathbf{D}}\mathbf{F} = 0 \tag{21}$$

for a two-form [in an intrinsic way, $\theta(X,Y) = \mathbf{g}(\mathbf{F}X, Y)$]

$$\theta = \theta_{\alpha\beta}(x,y)\vartheta^{\alpha} \wedge \vartheta^{\beta} = g_{ij}(x,y)^{\vee}\vartheta^i \wedge \vartheta^j.$$

Proof: It is similar to that for the Theorem 1. ■

On almost symplectic manifolds, usually there are considered symmetric linear connections. In our case, we can always define a symmetric d-connection by taking the symmetric part **[**in coordinate-free notation, $\mathbf{S}_X Y = \frac{1}{2}(\mathbf{D}_X Y + \mathbf{D}_Y X + [X,Y])$**]** of $\mathbf{\Gamma}^{\gamma}_{\alpha\beta}$,

$$\mathbf{S}^{\gamma}_{\alpha\beta} = \tfrac{1}{2}(\mathbf{\Gamma}^{\gamma}_{\alpha\beta} + \mathbf{\Gamma}^{\gamma}_{\beta\alpha}), \tag{22}$$

where $\mathbf{\Gamma}^{\gamma}_{\alpha\beta} = (\hat{L}^i_{jk} + l^i_{jk}(u), \hat{C}^i_{jk} + c^i_{jk}(u))$. On a N-anholonomic manifold $\widetilde{\mathbf{V}}_{(n,n)}$, an almost symplectic form θ is not closed, i.e., $d\theta \neq \mathbf{0}$. But it may be closed under the action of N-adapted derivatives (2) and differentials (3) when

$$\delta\theta = \delta(\theta_{\alpha\beta}(x,y)\vartheta^{\alpha} \wedge \vartheta^{\beta}) = 0,$$

which means that

$$\mathbf{e}_{\gamma}\theta_{\alpha\beta} + \mathbf{e}_{\alpha}\theta_{\gamma\beta} + \mathbf{e}_{\beta}\theta_{\alpha\gamma} = 0. \tag{23}$$

The condition (16) written in N-adapted bases results in

$$\mathbf{e}_{\gamma}\theta_{\alpha\beta} = \mathbf{\Gamma}_{\alpha\gamma\beta} - \mathbf{\Gamma}_{\beta\gamma\alpha}$$

for $\mathbf{\Gamma}_{\alpha\gamma\beta} \doteq \theta_{\alpha\tau}\mathbf{\Gamma}^{\tau}_{\gamma\beta}$.

Definition 5: An almost symplectic two-form θ *is N-symplectic if it satisfies the conditions (23).*

There is a relation between the set of all d-connections $\mathbf{D}$ for which $\mathbf{D}\theta = \mathbf{0}$ for any given θ and $\mathbf{N}$ and the set of all symmetric connections on $\widetilde{\mathbf{V}}_{(n,n)}$. By straightforward calculations we can verify that

$$\mathbf{\Gamma}_{\alpha\gamma\beta} = \tfrac{1}{2}(\mathbf{e}_{\alpha}\theta_{\gamma\beta} - \mathbf{e}_{\gamma}\theta_{\alpha\beta} - \mathbf{e}_{\beta}\theta_{\alpha\gamma}) + (\mathbf{S}_{\alpha\gamma\beta} - \mathbf{S}_{\gamma\beta\alpha} + \mathbf{S}_{\beta\gamma\alpha}) \tag{24}$$

is inverse to (22), which for almost symplectic $\theta_{\alpha\beta}$ satisfying the conditions (23) simplifies to

$$\mathbf{\Gamma}_{\alpha\gamma\beta} = \mathbf{e}_\alpha \theta_{\gamma\beta} + (\mathbf{S}_{\alpha\gamma\beta} - \mathbf{S}_{\gamma\beta\alpha} + \mathbf{S}_{\beta\gamma\alpha}).$$

On holonomic manifolds with trivial N-connection, the formulas (23) and (24) transform into those from Ref. 3 with $\mathbf{e}_\alpha \to \partial/\partial u^\alpha$. We may conclude that N-anholonomic transforms map symplectic forms in almost symplectic ones but preserve the main symmetry properties and compatibility with the linear connection structure if the computations are performed with respect to N-adapted bases.

IV. CURVATURE OF N-SYMPLECTIC d-CONNECTIONS

Let $\mathbf{V}$ (or $\widetilde{\mathbf{V}}_{(n,n)}$) be an N-anholonomic manifold provided with a metric d-connection $\mathbf{\Gamma}^\alpha_\gamma$.

Definition 6: A Fedosov N-anholonomic manifold is defined by an almost symplectic d-connection and almost complex structure induced by the N-connection.

Definition 7: A Lagrange–Fedosov manifold is a Fedosov N-anholonomic manifold with the N-connection and almost complex structure defined by the fundamental Lagrange function, see Theorem 1.

The curvature of a symplectic d-connection $\mathbf{D}$ is defined by the usual formula

$$\mathbf{R}(\mathbf{X},\mathbf{Y})\mathbf{Z} \doteq \mathbf{D}_X\mathbf{D}_Y\mathbf{Z} - \mathbf{D}_Y\mathbf{D}_X\mathbf{Z} - \mathbf{D}_{[X,X]}\mathbf{Z}.$$

Because on N-anholonomic spaces the "simplest" adapted to the N-connection induced almost complex structures is defined by the canonical d-connection, it is convenient to use it as a symplectic d-connection.

By straightforward calculations we prove:

Theorem 5: *The curvature* $\mathcal{R}^\alpha_\beta \doteq \mathbf{D}\mathbf{\Gamma}^\alpha_\beta = d\mathbf{\Gamma}^\alpha_\beta - \mathbf{\Gamma}^\gamma_\beta \wedge \mathbf{\Gamma}^\alpha_\gamma$ *of a d-connection* $\mathbf{\Gamma}^\alpha_\gamma$ *has the irreducible h- v- components (d-curvatures) of* $\mathbf{R}^\alpha_{\beta\gamma\delta}$,

$$R^i_{hjk} = e_k L^i_{hj} - e_j L^i_{hk} + L^m_{hj} L^i_{mk} - L^m_{hk} L^i_{mj} - C^i_{ha}\Omega^a_{kj},$$

$$R^a_{bjk} = e_k L^a_{bj} - e_j L^a_{bk} + L^c_{bj} L^a_{ck} - L^c_{bk} L^a_{cj} - C^a_{bc}\Omega^c_{kj},$$

$$R^i_{jka} = e_a L^i_{jk} - D_k C^i_{ja} + C^i_{jb} T^b_{ka},$$

$$R^c_{bka} = e_a L^c_{bk} - D_k C^c_{ba} + C^c_{bd} T^c_{ka},$$

$$R^i_{jbc} = e_c C^i_{jb} - e_b C^i_{jc} + C^h_{jb} C^i_{hc} - C^h_{jc} C^i_{hb},$$

$$R^a_{bcd} = e_d C^a_{bc} - e_c C^a_{bd} + C^e_{bc} C^a_{ed} - C^e_{bd} C^a_{ec}. \tag{25}$$

Remark 5: *For an N-anholonomic manifold* $\widetilde{\mathbf{V}}_{(n,n)}$ *provided with N-sympletic canonical d-connection* $\hat{\mathbf{\Gamma}}_{\gamma\alpha\beta} = \theta_{\gamma\tau}\hat{\mathbf{\Gamma}}^\tau_{\alpha\beta}$, *see (20), the d-curvatures (25) reduces to three irreducible components*,

$$R^i_{hjk} = e_k L^i_{hj} - e_j L^i_{hk} + L^m_{hj} L^i_{mk} - L^m_{hk} L^i_{mj} - C^i_{ha}\Omega^a_{kj},$$

$$R^i_{jka} = e_a L^i_{jk} - D_k C^i_{ja} + C^i_{jb} T^b_{ka},$$

$$R^a_{bcd} = e_d C^a_{bc} - e_c C^a_{bd} + C^e_{bc} C^a_{ed} - C^e_{bd} C^a_{ec}, \tag{26}$$

where all indices $i,j,k\ldots$ *and* $a,b,\ldots$ *run the same values but label the components with respect to different h- or v-frames.*

The indices of the components of the curvature tensor are lowered as

$$\mathbf{R}_{\tau\beta\gamma\delta} = \theta_{\tau\alpha}\mathbf{R}^{\alpha}_{\beta\gamma\delta}.$$

For Lagrange–Fedosov manifolds, the two-form $\theta_{\tau\alpha}$ has the coefficients defined by the metric structure and Lagrangian, see (10). In this case we can apply the canonical d-connection and the d-metric for definition of the curvature of symplectic d-connections.

Contracting, respectively, the components of (25) and (26) we prove:

Corollary 6: *The Ricci d-tensor* $\mathbf{R}_{\alpha\beta} \doteq \mathbf{R}^{\tau}_{\alpha\beta\tau}$ *has the irreducible h- v-components*

$$R_{ij} \doteq R^{k}_{ijk}, \quad R_{ia} \doteq -R^{k}_{ika}, \quad R_{ai} \doteq R^{b}_{aib}, \quad R_{ab} \doteq R^{c}_{abc}, \tag{27}$$

for a general N-holonomic manifold $\mathbf{V}$, *and*

$$R_{ij} \doteq R^{k}_{ijk}, \quad R_{ia} \doteq -R^{k}_{ika}, \quad R_{ab} \doteq R^{c}_{abc}, \tag{28}$$

for an N-anholonomic manifold $\widetilde{\mathbf{V}}_{(n,n)}$.

Corollary 7: *The scalar curvature of a d-connection is*

$$\overleftarrow{\mathbf{R}} \doteq \mathbf{g}^{\alpha\beta}\mathbf{R}_{\alpha\beta} = g^{ij}R_{ij} + h^{ab}R_{ab,} \quad for \quad \mathbf{V};$$
$$= 2g^{ij}R_{ij} \quad for \quad \widetilde{\mathbf{V}}_{(n,n)}.$$

Corollary 8: *The Einstein d-tensor is computed* $\mathbf{G}_{\alpha\beta} = \mathbf{R}_{\alpha\beta} - \frac{1}{2}\mathbf{g}_{\alpha\beta}\overleftarrow{\mathbf{R}}$.

In modern gravity theories, one considers more general linear connections generated by deformations of type $\mathbf{\Gamma}^{\alpha}_{\beta\gamma} = \hat{\mathbf{\Gamma}}^{\alpha}_{\beta\gamma} + \mathbf{P}^{\alpha}_{\beta\gamma}$. We can split all geometric objects into canonical and postcanonical pieces which results in N-adapted geometric constructions. For instance,

$$\mathcal{R}^{\alpha}_{\beta} = \hat{\mathcal{R}}^{\alpha}_{\beta} + \mathbf{D}\mathcal{P}^{\alpha}_{\beta} + \mathcal{P}^{\alpha}_{\gamma} \wedge \mathcal{P}^{\gamma}_{\beta} \tag{29}$$

for $\mathcal{P}^{\alpha}_{\beta} = \mathbf{P}^{\alpha}_{\beta\gamma}\vartheta^{\gamma}$. This way, for almost complex geometries, the d-tensors (26) and (28) can be redefined just for symmetrized d-connections compatible with the almost complex structure.

V. EINSTEIN FLAT N-ANHOLONOMIC MANIFOLDS

In terms of differential forms, the vacuum Einstein equations are written

$$\eta_{\alpha\beta\gamma} \wedge \hat{\mathcal{R}}^{\beta\gamma} = 0, \tag{30}$$

where, for the volume four-form $\eta \doteq *1$ with the Hodge operator "*," $\eta_{\alpha} \doteq \mathbf{e}_{\alpha} \rfloor \eta$, $\eta_{\alpha\beta} \doteq \mathbf{e}_{\beta} \rfloor \eta_{\alpha}$, $\eta_{\alpha\beta\gamma} \doteq \mathbf{e}_{\gamma} \rfloor \eta_{\alpha\beta}, \ldots$ and $\hat{\mathcal{R}}^{\beta\gamma}$ is the curvature two-form. The deformation of connection (18) defines a deformation of the curvature tensor of type (29) but with respect to the curvature of the Levi-Civita connection, ${}^{\nabla}\mathcal{R}^{\beta\gamma}$. The gravitational field equations (30) transforms into

$$\eta_{\alpha\beta\gamma} \wedge {}^{\nabla}\mathcal{R}^{\beta\gamma} + \eta_{\alpha\beta\gamma} \wedge {}^{\nabla}\mathcal{Z}^{\beta\gamma} = 0, \tag{31}$$

where ${}^{\nabla}\mathcal{Z}^{\beta}_{\gamma} = \nabla\mathcal{P}^{\beta}_{\gamma} + \mathcal{P}^{\beta}_{\alpha} \wedge \mathcal{P}^{\alpha}_{\gamma}$.

A subclass of solutions of the gravitational field equations for the canonical d-connection defines also solutions of the Einstein equations for the Levi-Civita connection if and only if

$$\eta_{\alpha\beta\gamma} \wedge {}^{\nabla}\mathcal{Z}^{\beta\gamma} = 0. \tag{32}$$

This property is very important for constructing exact solutions in Einstein and string gravity, parametrized by generic off-diagonal metrics and anholonomic frames with associated N-connection structure (see reviews of results in Refs. 30–32).

A. The ansatz for metric

In this section we investigate a class of five-dimensional vacuum Einstein solutions with nontrivial associated N-connection and generic off-diagonal metric. We analyze the conditions when such solutions reduce to four dimensions and possess almost complex structure.

Let us consider a five-dimensional ansatz for the metric (14) and frame (3) when $u^{\alpha}=(x^i,y^4=v,y^5)$; $i=1, 2, 3$ and the coefficients

$$g_{ij}=\mathrm{diag}[g_1=\pm\varpi(x^k,v),\varpi(x^k,v)g_2(x^2,x^3),\varpi(x^k,v)g_3(x^2,x^3)],$$

$$h_{ab}=\mathrm{diag}[\varpi(x^k,v)h_4(x^k,v),\varpi(x^k,v)h_5(x^k,v)],$$

$$N_i^4=w_i(x^k,v),N_i^5=n_i(x^k,v) \tag{33}$$

are some functions of necessary smooth class. The partial derivative are briefly denoted $a^{\bullet}=\partial a/\partial x^2$, $a'=\partial a/\partial x^3$, $a^*=\partial a/\partial v$.

Theorem 9: *The vacuum Einstein equations (30) for the canonical d-connection (18) constructed from data (33) are equivalent to the system of equations*

$$g_3^{\bullet\bullet}-\frac{g_2^{\bullet}g_3^{\bullet}}{2g_2}-\frac{(g_3^{\bullet})^2}{2g_3}+g_2''-\frac{g_2'g_3'}{2g_3}-\frac{(g_2')^2}{2g_2}=0, \tag{34}$$

$$h_5^{**}-h_5^*\left(\ln\left|\sqrt{|h_4h_5|}\right|\right)^*=0, \tag{35}$$

$$w_i\beta+\alpha_i=0, \tag{36}$$

$$n_i^{**}+n_i^*=0, \tag{37}$$

where

$$\alpha_i=\partial_i h_5^*-h_5^*\partial_i\ln\left|\sqrt{|h_4h_5|}\right|,\quad \beta=h_5^{**}-h_5^*\left[\ln\left|\sqrt{|h_4h_5|}\right|\right]^*,$$

$$\gamma=3h_5^*/2h_5-h_4^*/h_4, \tag{38}$$

$h_4^*\neq 0$ *and* $h_5^*\neq 0$ *and the functions* h_4 *and* ϖ *must satisfy certain additional conditions*

$$\hat{\delta}_i h_4=0\quad \textit{and}\quad \hat{\delta}_i\varpi=0, \tag{39}$$

for any $\zeta_i(x^k,v)$ *defining* $\hat{\delta}_i=\partial_i-(w_i+\zeta_i)\partial_4+n_i\partial_5$.

Proof: It is a straightforward calculation, see similar ones in Refs. 31, 9, and 11. ■

We note that the conditions (39) are satisfied if

$$\varpi^{q_1/q_2}=h_4 \tag{40}$$

for some nonzero integers q_1 and q_2 and ζ_i defined from

$$\partial_i\varpi-(w_i+\zeta_i)\varpi^*=0. \tag{41}$$

Remark 6: *Under the conditions of the Theorem 9, we can also consider d-metrics with* $h_5^*=0$ *for such functions* $h_4=h^{\#}(x^i,v)$ *when*

$$\lim_{h_5^*\to 0}\left\{h_5^*[\ln\left|\sqrt{|h^{\#}h_5|}\right|]^*\right\}\to 0$$

and

$$\lim_{h_5^*\to 0}\left\{h_5^*\partial_i \ln\left|\sqrt{|h^\# h_5|}\right|\right\}\to 0.$$

In these cases, Eqs. (35) and (36) will be satisfied by any $h^\#(x^i,v)$ *and* $w_i(x^i,v)$ *and we may take* $n_i^*=n_{[1]i}(x^i)h^\#(x^i,v)$ *in order to satisfy (37).*

Theorem 10: *The system of gravitational field equations (30) for the ansatz (33) can be solved in general form if there are given certain values of functions* $g_2(x^2,x^3)$ [*or, inversely,* $g_3(x^2,x^3)$], $h_4(x^i,v)$ [*or, inversely,* $h_5(x^i,v)$].

Proof: We outline the main steps of constructing exact solutions proving this Theorem, see detailed computations presented in the Proof of Theorem 4.3 from Ref. 31.

- The general solution of Eq. (34) can be written in the form

$$\lambda = g_{[0]}\exp[a_2\tilde{x}^2(x^2,x^3)+a_3\tilde{x}^3(x^2,x^3)], \tag{42}$$

were $g_{[0]}$, a_2, and a_3 are some constants and the functions $\tilde{x}^{2,3}(x^2,x^3)$ define any coordinate transforms $x^{2,3}\to\tilde{x}^{2,3}$ for which the two-dimensional line element becomes conformally flat, i.e.,

$$g_2(x^2,x^3)(\mathrm{d}x^2)^2+g_3(x^2,x^3)(\mathrm{d}x^3)^2\to\lambda(x^2,x^3)[(\mathrm{d}\tilde{x}^2)^2+\epsilon(\mathrm{d}\tilde{x}^3)^2], \tag{43}$$

where $\epsilon=\pm 1$ for a corresponding signature. In coordinates $\tilde{x}^{2,3}$, Eq. (34) transforms into

$$\lambda(\lambda^{\bullet\bullet}+\lambda'')-\lambda^{\bullet}-\lambda'=0$$

or

$$\ddot{\psi}+\psi''=0, \tag{44}$$

for $\psi=\ln|\lambda|$. There are three alternative possibilities to generate solutions of (34). For instance, we can prescribe that $g_2=g_3$ and get Eq. (44) for $\psi=\ln|g_2|=\ln|g_3|$. If we suppose that $g_2'=0$, for a given $g_2(x^2)$, we obtain from (34)

$$g_3^{\bullet\bullet}-\frac{g_2^{\bullet}g_3^{\bullet}}{2g_2}-\frac{(g_3^{\bullet})^2}{2g_3}=0,$$

which can be integrated exactly. Similarly, we can generate solutions for a prescribed $g_3(x^3)$ in

$$g_2''-\frac{g_2'g_3'}{2g_3}-\frac{(g_2')^2}{2g_2}=0. \tag{45}$$

We note that a transform (43) is always possible for two-dimensional (2D) metrics and the explicit form of solutions depends on chosen system of 2D coordinates and on the signature $\epsilon=\pm 1$. In the simplest case, Eq. (34) is solved by arbitrary two functions $g_2(x^3)$ and $g_3(x^2)$.

- Equation (35) relates two functions $h_4(x^i,v)$ and $h_5(x^i,v)$ following two possibilities:

a) to compute

$$\sqrt{|h_5|}=h_{5[1]}(x^i)+h_{5[2]}(x^i)\int\sqrt{|h_4(x^i,v)|}\mathrm{d}v,\ h_4^*(x^i,v)\neq 0;$$
$$=h_{5[1]}(x^i)+h_{5[2]}(x^i)v,\ h_4^*(x^i,v)=0, \tag{46}$$

for some functions $h_{5[1,2]}(x^i)$ stated by boundary conditions;

b) or, inversely, to compute h_4 for a given $h_5(x^i,v)$, $h_5^*\neq 0$,

$$\sqrt{|h_4|} = h_{[0]}(x^i)(\sqrt{|h_5(x^i,v)|})^*, \tag{47}$$

with $h_{[0]}(x^i)$ given by boundary conditions.

- The exact solutions of (36) for $\beta \neq 0$ are defined from an algebraic equation, $w_i\beta + \alpha_i = 0$, where the coefficients β and α_i are computed as in formulas (38) by using the solutions for (34) and (35). The general solution is

$$w_k = \partial_k \ln[\sqrt{|h_4 h_5|}/|h_5^*|]/\partial_v \ln[\sqrt{|h_4 h_5|}/|h_5^*|], \tag{48}$$

with $\partial_v = \partial/\partial v$ and $h_5^* \neq 0$. If $h_5^* = 0$, or even $h_5^* \neq 0$ but $\beta = 0$, the coefficients w_k could be arbitrary functions on (x^i, v). For the vacuum Einstein equations this is a degenerated case imposing the compatibility conditions $\beta = \alpha_i = 0$, which are satisfied, for instance, if the h_4 and h_5 are related as in the formula (47) but with $h_{[0]}(x^i) = \text{const}$.
- Having defined h_4 and h_5 and computed γ from (38) we can solve Eq. (37) by integrating on variable "v" the equation $n_i^{**} + \gamma n_i^* = 0$. The exact solution is

$$\begin{aligned} n_k &= n_{k[1]}(x^i) + n_{k[2]}(x^i) \int [h_4/(\sqrt{|h_5|})^3] dv, \quad h_5^* \neq 0 \\ &= n_{k[1]}(x^i) + n_{k[2]}(x^i) \int h_4 \mathrm{d}v, \quad h_5^* = 0 \\ &= n_{k[1]}(x^i) + n_{k[2]}(x^i) \int [1/(\sqrt{|h_5|})^3] \mathrm{d}v, \quad h_4^* = 0, \end{aligned} \tag{49}$$

for some functions $n_{k[1,2]}(x^i)$ stated by boundary conditions.

The exact solution of (41) is given by some functions $\zeta_i = \zeta_i(x^i, v)$ if both $\partial_i \varpi = 0$ and $\varpi^* = 0$, we chose $\zeta_i = 0$ for $\varpi = \text{const}$, and

$$\zeta_i = -w_i + (\varpi^*)^{-1}\partial_i \varpi, \quad \varpi^* \neq 0, = (\varpi^*)^{-1}\partial_i \varpi, \quad \varpi^* \neq 0, \quad \text{for vacuum solutions}. \tag{50}$$

■

Theorem 10 states a general method of constructing five-dimensional exact solutions in various gravity models with generic off-diagonal metrics, nonholonomic frames and, in general, with nontrivial torsion. Such solutions are with associated N-connection structure. This method can also be applied in order to generate, for instance, certain Finsler or Lagrange configurations as v-irreducible components, or for a certain class of conformal factors $\varpi(x^i, v)$ for both h- and v-irreducible components. The five-dimensional ansatz cannot be used to generate directly standard Finsler or Lagrange geometries because the dimension of such spaces cannot be an odd number. Nevertheless, the anholonomic frame method can be applied in order to generate four-dimensional exact solutions containing Finsler–Lagrange configurations. For instance, a four-dimensional configuration can be defined just by an ansatz (14) with the data (33) where the coefficients do not depend on coordinate x^1 and the metric is stated to be four dimensional with the conformal factor $\varpi(x^2, x^3, v)$.

B. An example of induced almost Kähler gravity

Let us consider a four-dimensional ansatz which may mimic under certain constraints a generalized Lagrange geometry and induced almost Kähler structure in Riemann–Cartan space:

$$\begin{aligned} \mathbf{g} = \varpi(x^2,x^3,v)[&g_{22}(x^2,x^3)\mathrm{d}x^2 \otimes \mathrm{d}x^2 + g_{33}(x^2,x^3)\mathrm{d}x^3 \otimes \mathrm{d}x^3 + h_{44}(x^2,x^3,v)\,\delta y^4 \otimes \delta y^4 \\ &+ h_{55}(x^2,x^3,v)\,\delta y^5 \otimes \delta y^5], \end{aligned}$$

where

$$\delta y^4 = \mathrm{d}v + w_2(x^2,x^3,v)\mathrm{d}x^2 + w_3(x^2,x^3,v)\mathrm{d}x^3,$$

$$\delta y^5 = \mathrm{d}y^5 + n_2(x^2,x^3,v)\mathrm{d}x^2 + n_3(x^2,x^3,v)\mathrm{d}x^3.$$

This d-metric will define a class of vacuum solutions of the Einstein equations if the coefficients are subjected to the conditions of Theorem 10, when the dependence on coordinate x^1 is eliminated. We put $g_{22}=g(x^3)$ and $g_{33}=0$ to be a solution of (34) in the form (45), i.e.,

$$2gg'' - (g')^2 = 0$$

and choose $h_5=0$ and

$$h_4 = h^{\#}(x^3,v) = \frac{a^2}{|g(x^3)\times v|}g(x^3)$$

for $a=$const, which satisfies (35), see Remark 6. Taking any functions $w_{2,3}(x^2,x^3,v)$ and $n_{2,3}(x^2,x^3,v)$ satisfying

$$n^{*}_{2,3} = n_{2,3[0]}(x^2,x^3)h^{\#}(x^3,v)$$

we solve, respectively, Eqs. (36) and (37). We may take

$$\varpi = \varpi^{\#}(x^3,v) = [h^{\#}(x^3,v)]^{q_2/q_1}$$

like for (50). All such functions define a vacuum Einstein d-metric

$$\mathbf{g} = \varpi^{\#}(x^3,v)\left[g(x^3)\mathrm{d}x^2\otimes\mathrm{d}x^2 + \frac{a^2}{|g(x^3)\times v^2|}g(x^3)\,\delta y^4\otimes\delta y^4\right],$$

modeling an embedded generalized Lagrange geometry [it is a particular case of d-metrics considered in Ref. 8, see formula (6.3), which in our case is derived from a gravity model]. We construct a conformal almost Kähler geometry if we consider

$$\theta = \varpi^{\#}(x^3,v)g(x^3)\frac{a}{\sqrt{|g(x^3)\times v^2|}}\delta y^4\wedge\mathrm{d}x^2$$

and

$$\mathbf{F} = \frac{\sqrt{|g(x^3)\times v^2|}}{a}\left(\frac{\partial}{\partial v}\otimes\mathrm{d}x^2 + \frac{\partial}{\partial y^5}\otimes\mathrm{d}x^3\right) - \frac{a}{\sqrt{|g(x^3)\times v^2|}}\left(\frac{\delta}{\partial x^2}\otimes\mathrm{d}v + \frac{\delta}{\partial x^3}\otimes\mathrm{d}y^5\right).$$

Finally, we note that if we choose the functions $w_{2,3}(x^2,x^3,v)$ and $n_{2,3}(x^2,x^3,v)$ to parametrize a noncommutative structure, this vacuum gravitational space will possess a noncommutative symmetry like in Refs. 31 and 32. An alternative class of solutions can be generated if we put certain boundary conditions (for instance, for $v=t$ treated as a timelike coordinate, and one of the space coordinates x^2, x^3, y^5 running to infinite) when the N-connection coefficients possess a Lie algebra symmetry. In this case, we generate an explicit example of vacuum gravitational fields (in general, with nontrivial torsion) possessing Lie symmetries.[61] We can select such values of $w_{2,3}$ and $n_{2,3}$ when conditions (32) are satisfied and the solutions coincide with those for the Levi-Civita connection, but this is a very restricted case of N-connection geometry and associated almost complex structures.

Hamilton–Jacobi equations for nonholonomic dynamics

Michele Pavon[a)]
Dipartimento di Matematica Pura e Applicata, Università di Padova, via Belzoni 7, 35131 Padova, Italy

(Received 6 October 2004; accepted 17 December 2004; published online 17 February 2005)

We derive generalized Hamilton–Jacobi equations for dynamical systems subject to linear velocity constraints. As long as a solution of the generalized Hamilton–Jacobi equation exists, the action is actually minimized (not just extremized). [DOI: 10.1063/1.1858441]

I. INTRODUCTION

Consider a mechanical system with configuration space $\mathbb{R}^n$. Let L be the Lagrangian, and suppose that the system is subject to $k<n$ nonholonomic constraints of the form

$$\omega_i(x(t))^T\dot{x}(t)=0, \quad i=1,2,\ldots,k, \quad t\in[t_0,t_1], \tag{1.1}$$

where the $\omega_i:\mathbb{R}^n\to\mathbb{R}^n$ are smooth functions and T denotes transpose. Let $\Omega(x)$ be the $k\times n$ matrix whose ith row is $\omega_i(x)^T$. Then, an application of d'Alembert's principle together with the method of Lagrange multipliers, gives that the equations of motion for the system are

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{x}}-\frac{\partial L}{\partial x}=\Omega^T\lambda, \tag{1.2}$$

where λ is the k-dimensional Lagrange multiplier. Equation (1.2) together with (1.1) constitute a system of $n+k$ equations for the $n+k$ unknowns $x_1,x_2,\ldots,x_n$, $\lambda_1,\lambda_2,\ldots,\lambda_k$. The components of $\Omega^T\lambda$ can be physically interpreted as the components of the (polygenic) force that acts on the mechanical system in order to maintain the given nonholonomic conditions.[10] Notice that d'Alembert's principle is not variational. A variational approach to the dynamics of systems subject to linear velocity constraints was proposed in Ref. 15 (see also Ref. 1, Chap. 1, Sec. 4). A lucid critique of this "Vakonomic dynamics" (variational axiomatic kind dynamics) can be found in Ref. 20. It is shown there that the vakonomic equations may lead to paradoxical behavior. The relation between the vakonomic and holonomic approaches has also been discussed in Refs. 1, 4, 5, 7, 11, and 17.

We show in this paper that the second, hydrodynamic form of Hamilton's principle may be extended to nonholonomic systems. We concentrate on the *optimization aspect* that is largely ignored in the physics literature. As long as a solution of the generalized Hamilton–Jacobi equation exists, the action is *minimized* by a path satisfying the correct equations of motions (1.2). Our derivation relies on general nonlinear Lagrange functionals.[12–14] It would be quite feasible to derive the result, after a suitable transformation, using standard optimal control results such as Ref. 16, Sec. 5.2, Theorem 7, and Ref. 8, Chap. IV. We find, however, that the approach based on Lagrange functionals is more transparent.

The paper is outlined as follows. In Sec. II we recall the hydrodynamic form of the classical Hamilton principle as established in Ref. 19, Sec. II (the latter developed from Ref. 9). In Sec. III, we extend the latter result to systems subject to linear velocity constraints. In Sec. IV the paper concludes with a discussion.

II. THE CLASSICAL HAMILTON PRINCIPLE

Consider a dynamical system with configuration space $\mathbb{R}^n$. Let

$$L(x,v) := \frac{1}{2} m v \cdot v - V(x) \tag{2.1}$$

be the Lagrangian function, where $V(\cdot): \mathbb{R}^n \to R$ is of class C^1. The extension of the results of this paper to general Lagrangian functions that are strictly convex with respect to v appears straightforward. We prefer, however, to treat the simple case (2.1) in order to avoid obscuring ideas with technicalities. Let $\mathcal{X}_0$ denote the class of all C^1 paths $x: [t_0, t_1] \to R^n$ such that $x(t_0) = x_0$. Let $\mathcal{V}$ denote the family of continuous functions $v: [t_0, t_1] \to \mathbb{R}^n$. For $(x,v) \in \mathcal{X}_0 \times \mathcal{V}$, we define the functional $J(x,v)$ by

$$J(x,v) = \int_{t_0}^{t_1} L(x(t), v(t)) dt - S_1(x(t)), \tag{2.2}$$

where $S_1: R^n \to \mathbb{R}$ is continuous. Consider the following control problem:

$$\text{minimize } \{J(x,v) | (x,v) \in (\mathcal{X}_0 \times \mathcal{V})\}, \tag{2.3}$$

subject to the constraint

$$\dot{x}(t) = v(t), \quad \forall\, t \in [t_0, t_1]. \tag{2.4}$$

Remark. 1: It is apparent that this control problem is equivalent to minimizing the action functional $I(x) := J(x, \dot{x})$ *over* $\mathcal{X}_0$.

To solve problems (2.3) we rely on the following elementary, albeit fundamental, result in the spirit of Lagrange. Let Y be a nonempty set. Consider the minimization of $J: Y \to \overline{R}$, where $\overline{R}$ denotes the extended reals, over the nonempty subset M of Y.

Lemma 1: (Lagrange Lemma) *Let* $\Lambda: Y \to \overline{\mathbb{R}}$ *and let* $y_0 \in M$ *minimize* $J + \Lambda$ *over* Y. *Assume that* $\Lambda(\cdot)$ *is* finite *and* constant *over* M. *Then* y_0 *minimizes* J *over* M.

Proof: For any $y \in M$, we have $J(y_0) + \Lambda(y_0) \leqslant J(y) + \Lambda(y) = J(y) + \Lambda(y_0)$. Hence $J(y_0) \leqslant J(y)$. Q.E.D.

A functional Λ that is constant and finite on M is called the Lagrange functional. For problem (2.3), let

$$M = \{(x,v) \in \mathcal{X}_0 \times \mathcal{V} | \dot{x}(t) = v(t),\ \forall\, t \in [t_0, t_1]\}.$$

We introduce a suitable class of nonlinear Lagrange functionals for our problem. Let $F: [t_0, t_1] \times \mathbb{R}^n \to R$ be of class C^1. Corresponding to such an F, we define the nonlinear functional Λ^F on $\mathcal{X}_0 \times \mathcal{V}$

$$\Lambda^F(x,v) := F(t_1, x(t_1)) - F(t_0, x(t_0)) + \int_{t_0}^{t_1} \left[-\frac{\partial F}{\partial t}(t, x(t)) - v(t) \cdot \nabla F(t, x(t)) \right] dt.$$

When $(x,u) \in M$, by the chain rule, we have $\Lambda^F(x,u) = 0$. Thus, Λ^F is indeed a Lagrange functional for our problem. The solution procedure is now outlined as follows. Consider the unconstrained minimization

$$\min_{(x,v) \in (\mathcal{X}_0 \times \mathcal{V})} (J + \Lambda^F)(x,v). \tag{2.5}$$

We perform two-stage optimization.

Step 1: For each fixed $x \in \mathcal{X}_0$, we try to compute an optimal control v_x^* through *pointwise minimization* of the integrand of $J + \Lambda^F$. More explicitly, consider for each $x \in \mathcal{X}_0$ and each $t \in [t_0, t_1]$ the finite-dimensional problem

$$\min_{v\in\mathbb{R}^n}\left\{\frac{1}{2}mv\cdot v - V(x(t)) - \frac{\partial F}{\partial t}(t,x(t)) - v\cdot\nabla F(t,x(t))\right\}. \tag{2.6}$$

We get

$$v_x^*(t) = \frac{1}{m}\nabla F(t,x(t)). \tag{2.7}$$

We notice that v_x^* belongs to the class of admissible velocities $\mathcal{V}$.

Step 2: Consider now the minimization of the functional

$$\Gamma^F(x) = (J+\Lambda^F)(x,v_x^*)$$

on the space $\mathcal{X}_0$. We have

$$\Gamma^F(x) = -S_1(x(t_1)) + F(t_1,x(t_1)) - F(t_0,x(t_0)) + \int_{t_0}^{t_1}\left[-\frac{\partial F}{\partial t}(t,x(t)) - \frac{1}{2m}\nabla F(t,x(t))\cdot\nabla F(t,x(t)) - V(x(t))\right]dt.$$

If we can find S such that $\Gamma^S(\cdot)$ is actually constant on $\mathcal{X}_0$, then any pair $(x,v_x^*)\in\mathcal{X}_0\times\mathcal{V}$ solves problem (2.5). Then, by Lemma 1, if the pair (x,v_x^*) satisfies

$$\dot{x}(t) = v_x^*(t) = \frac{1}{m}\nabla S[t,x(t)], \quad \forall\, t\in[t_0,t_1],$$

it also solves the original constrained problem (2.3) and (2.4).

Theorem 1: (Ref. 19) *Let $S(t,x)$ be any C^1 solution on $[t_0,t_1]\times\mathbb{R}^n$ of the terminal value problem*

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\nabla S\cdot\nabla S + V(x) = 0, \tag{2.8}$$

$$S(t_1,x) = S_1(x). \tag{2.9}$$

Let $x^*\in\mathcal{X}_0$ be any solution on $[t_0,t_1]$ of

$$\dot{x}(t) = \frac{1}{m}\nabla S(x(t),t). \tag{2.10}$$

Then $\left(x^*, 1/m\,\nabla S(x^*(t),t)\right)$ solves problem (2.3) and (2.4).

Proof: If S satisfies (2.8) and (2.9), we get $\Gamma^S(x)\equiv -S(x_0,t_0)$ on $\mathcal{X}_0$. Q.E.D.

Notice that when a C^1 solution $S(x,t)$ of (2.8) and (2.9) exists, then there are also solutions x of the differential equation (2.10) satisfying $x(t_0)=x_0$, and therefore optimal pairs. In this case, the action functional is actually *minimized*, not just extremized. The difficulty lies, of course, with the terminal value problem (2.8) and (2.9) that, in general, only has a local in t solution **(**namely, on some interval $(\bar{t},t_1), t_0<\bar{t}$**)**.

Remark 2: Let us now assume that S is of class C^2. Following Ref. 9, let us introduce the *acceleration field* $a(t,x)$ through a substantial time derivative

$$a(t,x) := \left[\frac{\partial}{\partial t} + \frac{1}{m}\nabla S\cdot\nabla\right]\left(\frac{1}{m}\nabla S\right)(t,x) = \frac{1}{m}\nabla\left[\frac{\partial S}{\partial t} + \frac{1}{2m}\nabla S\cdot\nabla S\right](t,x).$$

Then, (2.8) implies the local form of Newton's law

$$a(t,x) = -\frac{1}{m}\nabla V(x). \tag{2.11}$$

III. NONHOLONOMIC DYNAMICAL SYSTEMS

Consider a system subject to linear velocity constraints of the form

$$\Omega(x(t))\dot{x}(t) = 0, \quad t \in (t_0,t_1), \tag{3.1}$$

where $\Omega:\mathbb{R}^n \to \mathbb{R}^{k\times n}$, $k<n$ is a continuous map. We assume that for eack $x\in\mathbb{R}^n$, the rows of Ω are linearly independent. These constraints are called *Pfaffian*. A simple example is provided by a disk rolling on a plane without slipping. More complex nonholonomic systems with Pfaffian constraints occur in many problems of robot motion planning and vehicular dynamics, and have therefore been the subject of intensive study, see Refs. 2, 3, and 18 and references therein. Let

$$\Omega(x(t))v(t) = 0, \quad t \in [t_0,t_1]. \tag{3.2}$$

We now study the control problem (2.3), (2.4), and (3.2), namely the same problem as in the previous section when also constraint (3.2) is present. This problem is equivalent to minimizing the action functional

$$I(x) := J(x,\dot{x}) = \int_{t_0}^{t_1} L(x(t),\dot{x}(t))dt - S_1(x(t_1)), \tag{3.3}$$

under the constraints (3.1). Reformulating the calculus of variations problem as a control problem as before, we let

$$M = \{(x,v) \in \mathcal{X}_0 \times \mathcal{V} | \dot{x}(t) = v(t), \quad \Omega(x(t))v(t) = 0, \quad \forall\, t \in [t_0,t_1]\}.$$

Let $F:[t_0,t_1]\times\mathbb{R}^n \to \mathbb{R}$ be of class C^1 and $g:[t_0,t_1]\times\mathbb{R}^n \to R^k$ be continuous. Corresponding to such a pair, we define the nonlinear functional $\Lambda^{F,g}$ on $\mathcal{X}_0\times\mathcal{V}$ by

$$\Lambda^{F,g}(x,v) := F(t_1,x(t_1)) - F(t_0,x(t_0)) + \int_{t_0}^{t_1}\left[-\frac{\partial F}{\partial t}(t,x(t)) - v(t)\cdot\nabla F(t,x(t)) + g(t,x(t))^T\Omega(x(t))v(t)\right]dt.$$

It is apparent that $\Lambda^{F,g}$ is a Lagrange functional for the problem since it is identically zero when (2.4) and (3.2) are satisfied. Following the same procedure as in the previous section, we consider the *unconstrained* minimization of $(J+\Lambda^{F,g})(x,v)$ over $\mathcal{X}_0\times\mathcal{V}$. For $x\in\mathcal{X}_0$ fixed, the pointwise minimization of the integrand of $J+\Lambda^{F,g}$ at time t gives

$$v_x^*(t) = \frac{1}{m}\left[\nabla F(t,x(t)) - \Omega^T(x(t))g(t,x(t))\right]. \tag{3.4}$$

Notice that $v_x^*\in\mathcal{V}$. We consider next the minimization of the functional

$$\Gamma^{F,g}(x) = (J+\Lambda^{F,g})(x,v_x^*)$$

on the space $\mathcal{X}_0$. We have

$$\Gamma^{F,g}(x) = -S_1(x(t_1)) + F(x(t_1),t_1) - F(x(t_0),t_0) + \int_{t_0}^{t_1} \left[-\frac{\partial F}{\partial t}(t,x(t)) - \frac{1}{2m}\| \nabla F(t,x(t)) - \Omega^T(x(t))g(t,x(t))\|^2 - V(x(t)) \right] dt,$$

where $\|\cdot\|$ denotes the Euclidean norm in R^n. Let $S(t,x)$ of class C^1 and $\mu(t,x)$ continuous solve on $R^n \times [t_0,t_1]$ of the initial value problem

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\| \nabla S - \Omega^T \mu\|^2 + V(x) = 0, \tag{3.5}$$

$$S(x,t_0) = S_0(x). \tag{3.6}$$

Then $\Gamma^{S,\mu}(x) \equiv -S(x_0,t_0)$ on $\mathcal{X}_0$. By Lemma 1, if $x \in \mathcal{X}_0$ satisfies for all $t \in [t_0,t_1]$

$$\dot{x}(t) = \frac{1}{m}\left[\nabla S - (t,x(t)) - \Omega^T(x(t))\mu(t,x(t))\right], \tag{3.7}$$

$$\Omega(x(t))\dot{x}(t) = 0, \tag{3.8}$$

then it solves the problem together with the corresponding feedback velocity (3.4).

Remark 3: As in the unconstrained case, we now show that (3.5) implies the second principle of dynamics. Assume that S is of class C^2 and that Ω, and μ are of class C^1. The acceleration field is again obtained through a substantial derivative of the velocity field

$$\begin{aligned} a(t,x) &:= \left[\frac{\partial}{\partial t} + \frac{1}{m}\left[\nabla S - \Omega^T \mu\right] \cdot \nabla \right] \left(\frac{1}{m}\left[\nabla S - \Omega^T \mu\right] \right)(t,x) \\ &= \frac{1}{m}\left\{ \nabla \left[\frac{\partial S}{\partial t} + \frac{1}{2m}\| \nabla S - \Omega^T \mu\|^2 \right] - \frac{\partial (\Omega^T \mu)}{\partial t} \right\}(t,x). \end{aligned}$$

Then, (3.5) yields

$$a(t,x) = -\frac{1}{m} \nabla V(x) - \frac{1}{m}\Omega^T \frac{\partial \mu}{\partial t}. \tag{3.9}$$

Define

$$\lambda(t,x) := -\frac{\partial \mu}{\partial t}(t,x).$$

For $x \in \mathcal{X}_0$ satisfying (3.7) and of class C^2, let $\lambda(t) := \lambda(t,x(t))$. We then get

$$m\ddot{x}(t) = -\nabla V(x(t)) + \Omega^T(x(t))\lambda(t), \tag{3.10}$$

namely Eq. (1.2). By differentiating (3.8), a simple calculation employing (3.10) shows that the Lagrange multipliers λ may be expressed as an instantaneous function of x and $\dot{x}$, see, e.g., Ref. 20, Sec. 2, and Ref. 18, pp. 269–270.

Next we show how the multiplier μ can be also eliminated in our hydrodynamic context. If x satisfies (3.7) and (3.8), then, plugging (3.7) into (3.8), we get

$$\Omega(x(t))\frac{1}{m}\left[\nabla S(t,x(t)) - \Omega^T(x(t))\mu(t,x(t))\right] = 0.$$

Since Ω has full row rank, the latter is equivalent to

$$\mu(t,x(t)) = (\Omega(x(t))\Omega^T(x(t)))^{-1}\Omega(x(t))\,\nabla S(t,x(t)). \tag{3.11}$$

Plugging this into (3.7), we get

$$\dot{x}(t) = \frac{1}{m}[(I - \pi(x(t)))\,\nabla S(t,x(t))], \tag{3.12}$$

where $\pi(t,x)$ is defined by

$$\pi(x) = \Omega^T(x)(\Omega(x)\Omega^T(x))^{-1}\Omega(x). \tag{3.13}$$

Observe that $\pi(x)^2 = \pi(x)$ and $\pi(x)^T = \pi(x)$. Thus, $\pi(x)$ is an orthogonal projection. In fact, $\pi(x)$ is the orthogonal projection onto range $(\Omega^T(x))$.

Remark 4: Notice that (3.12) implies (3.8). Indeed,

$$\Omega(x(t))\dot{x}(t) = \Omega(x(t))\frac{1}{m}[(I - \pi(x(t)))\,\nabla S(t,x(t))] = 0,$$

since $I - \pi(x)$ projects onto the kernel of $\Omega(x)$.

Remark 5: It is apparent that (3.11)–(3.13) are related to the projection technique introduced in Ref. 6. Indeed, there the constrained dynamics is obtained by suitably projecting the free dynamics.

Now we use the freedom we have in picking S and μ. Since (3.11) must be satisfied by an optimal solution, we impose that the pair (S,μ) satisfies *identically* on all of $[t_0,t_1]\times\mathbb{R}^n$

$$\mu(t,x) = (\Omega(x)\Omega^T(x))^{-1}\Omega(x)\,\nabla S(t,x). \tag{3.14}$$

Hence, we can write $\Gamma^S(x)$ instead of $\Gamma^{S,\mu}(x)$, and Eq. (3.5) becomes

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\|(I - \pi)\,\nabla S\|^2 + (x) = 0. \tag{3.15}$$

We are now ready for our main result.

Theorem 2: *For $x\in R^n$, let $\sigma(x) = I - \pi(x)$ denote the orthogonal projection onto* $\ker\,\Omega(x)$. *Let $S(t,x)$ be any C^1 solution on $[t_0,t_1]\times\mathbb{R}^n$ of*

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\,\nabla S\cdot\sigma\,\nabla S + V(x) = 0, \quad S(t_1,x) = S_1(x). \tag{3.16}$$

Then any $x\in\mathcal{X}_0$ satisfying

$$\dot{x}(t) = \frac{1}{m}\sigma(x(t))\,\nabla S(t,x(t)) \tag{3.17}$$

on $[t_0,t_1]$ solves together with

$$v(t) = \frac{1}{m}\sigma(x(t))\,\nabla S(t,x(t))$$

problems (2.3), (2.4), and (3.2). [*Equivalently, such an $x\in\mathcal{X}_0$ minimizes* (3.3) *subject to* (3.1)]. *If S is of class C^2, and $x\in\mathcal{X}_0$ satisfying* (3.17) *is also of class C^2, then x satisfies* Eq. (3.10)

$$m\ddot{x}(t) = -\,\nabla V(x(t)) + \Omega^T(x(t))\lambda(t),$$

with λ given by

$$\lambda(t) = -\,(\Omega(x(t))\Omega^T(x(t)))^{-1}\Omega(x(t))\,\nabla\frac{\partial S}{\partial t}(t,x(t)). \tag{3.18}$$

Proof: If S solves (3.16), we get $\Gamma^S(x)=-S(x_0,t_0)$ for any $x\in\mathcal{X}_0$. Thus any pair $(x,v)\in\mathcal{X}_0\times\mathcal{V}$ solves the unconstrained minimization problem. Since x satisfies (3.17), constraint (2.4) is fulfilled. Moreover, by Remark 4, (3.2) is also satisfied. By Lemma 1, the pair is optimal for the original constrained minimization. Finally, x satisfies (3.10) with λ as in (3.18) in view of Remark 3 and (3.14). Q.E.D.

IV. DISCUSSION

We conclude this paper with a few simple remarks on how the minimization of the modified action leading to the vakonomic equations relates to the problem studied in the preceding section. Assume that $L:\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n\to\mathbb{R}$ is of class C^2. Assume, moreover, that S_1 and Ω are of class C^1. Recall

$$I(x):=\int_{t_0}^{t_1} L(t,x(t),\dot{x}(t))dt - S_1(x(t_1))$$

and the constraint (3.1)

$$\Omega(x(t))\dot{x}(t)=0, \quad t\in[t_0,t_1]. \tag{4.1}$$

For $\mathcal{X}$ taking values in $\mathbb{R}^k$ of class C^1, let

$$\mathcal{L}(t,x,\dot{x}):=L(t,x,\dot{x})+\mathcal{X}^T(t)\Omega(x)\dot{x}.$$

Introduce also the modified action

$$\mathcal{I}(x):=\int_{t_0}^{t_1}\mathcal{L}(t,x(t),\dot{x}(t))dt - S_1(x(t_1)). \tag{4.2}$$

Taking as variations paths $y(t)\in C^1[t_0,t_1]$ such that $y(t)=0$, and setting the first variation of $\mathcal{I}$ equal to zero, we get the equations

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{x}}-\frac{\partial\mathcal{L}}{\partial x}=0, \tag{4.3}$$

$$\frac{\partial\mathcal{L}}{\partial\dot{x}}(t_1,x(t_1),\dot{x}(t_1))=\frac{\partial S_1}{\partial x}(x(t_1)). \tag{4.4}$$

They read

$$\frac{d}{dt}\frac{\partial L}{\partial\dot{x}}-\frac{\partial L}{\partial x}=-\Omega^T\dot{\mathcal{X}}-\mathcal{X}\cdot\Omega'\dot{x}+\frac{\partial}{\partial x}(\mathcal{X}\cdot\Omega\dot{x}), \tag{4.5}$$

$$\frac{\partial L}{\partial\dot{x}}(t_1,x(t_1),\dot{x}(t_1))+\Omega^T(x(t_1)\mathcal{X}(t_1))=\frac{\partial S_1}{\partial x}(x(t_1)), \tag{4.6}$$

where

$$(\mathcal{X}\cdot\Omega'\dot{x})_i=\sum_{\alpha=1}^{k}\mathcal{X}_a\sum_{j=1}^{n}\frac{\partial\Omega_{\alpha i}}{\partial x_j}\dot{x}_j, \quad \frac{\partial}{\partial x}(\mathcal{X}\cdot\Omega\dot{x})_i=\sum_{\alpha=1}^{k}\mathcal{X}_\alpha\sum_{j=1}^{n}\frac{\partial\Omega_{\alpha j}}{\partial x_i}\dot{x}_j.$$

Equation (4.5) together with (4.1) constitute the equations of the Vakonomic dynamics. Moreover, (4.5) and (4.6) are *necessary* conditions for the *unconstrained* minimization of the modified action (4.2) over $\mathcal{X}_0$. If x does minimize (4.2) over $\mathcal{X}_0$ *and* it satisfies (4.1), then, by Lemma 1, it also minimizes $I(x)$ over $\mathcal{X}_0$ subject to (4.1).

(Received 17 May 2004; accepted 5 August 2004; published online 7 February 2005)

In this work it is shown that, by a series of admissible functional transformations, the generalized Blasius equation in fluids can be exactly reduced to a three-term generalized Emden–Fowler equation. Furthermore, the restricted in axisymmetric flows and simplified forms of this equation can be reduced to (i) two-term generalized Emden–Fowler equations; (ii) generalized Emden–Fowler equations; (iii) Emden–Fowler equations of the normal form; and (iv) Abel equations of the second kind. By means of a recently developed mathematical solution methodology (Panayotounakos, Fifth Greek Congress on Mechanics, Xania, Crete, 22–25 June 2004, Hellas, Greece), we provide exact analytic solutions for the simplified as well as for the restricted forms of the above-mentioned Blasius equations. Thus, it is proved that important, unsolvable in exact form problems in nonlinear fluid dynamics now can be analytically solved. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1819528]

I. INTRODUCTION

There is a wide class of particularly basic second-order nonlinear ordinary differential equations (ODEs) in mathematical physics and nonlinear mechanics that does not admit exact analytic solutions in terms of known (tabulated) functions.[1–3] Among these equations, one of great interest in nonlinear fluid dynamics is that related to uniform flow past a semi-infinite plate. The first to introduce and discuss such a problem was Blasius (Ref. 4). He obtained similarity solutions of the well-known simplified Blasius equation. The generalization of the Blasius problem was introduced in Ref. 5, including nonuniform flow. Later, in Ref. 6 the generalized Blasius equation was investigated numerically, and it was proved that if one of its characteristic parameters is positive or zero, then the related convenient boundary conditions are sufficient to define a unique solution; but, when this parameter becomes negative, the property of uniqueness disappears. The more general problem with arbitrary parameters has been the object of study of many researchers.[7,8]

Several relative problems requiring the solution of the generalized Blasius equation (Falkner–Skan equation) were introduced in Ref. 9, investigating axisymmetric flow due to stretching flat surface; in Ref. 10, performing a series method for the solution of laminar boundary layers or moving surfaces; in Ref. 11, developing self-similar solutions describing thermal capillary flows in viscous layers, and in Ref. 12, using similarity solutions of the boundary equations for a stretching wall. All the above problems have to be solved numerically, or in the form of power series for fixed values of the parameters being introduced.

[a)]Electronic mail: tsakstel@central.ntua.gr

This work deals with the possibility of constructing exact analytic solutions concerning the generalized Blasius equation correlated with a wide class of nonlinear boundary value problems in mathematical physics and nonlinear mechanics. Before we address the issue of these solutions, we prove that, by a series of admissible functional transformations, the above-mentioned equation can be reduced to a three-term generalized Emden–Fowler equation, which in axisymmetric cases (restricted form) becomes two-term. In addition, the simplified Blasius equation can be reduced to a typical generalized Emden–Fowler equation, or to an Emden–Fowler equation of the normal form. Both previous types of Emden–Fowler equations, by means of admissible functional transformations, are further reduced to Abel equations of the second kind of the normal form. Thus, it is proved that the unsolvability of the Blasius problems is due to the fact that both Abel and Emden–Fowler equations do not admit exact analytic solutions in terms of known (tabulated) functions. Only very special cases of these equations can be analytically solved in parametric form, which were tabulated in Ref. 3.

Our goal is that, based on a recently developed mathematical technique leading to the construction of analytic solutions of the Abel equation of the second kind of the normal form,[13] we provide exact analytic solutions of the prescribed two types of Blasius equations: (i) the simplified equation, and (ii) the restricted form of the generalized equation (concerning axisymmetric flows), with convenient boundary conditions.

The solution methodology employed is general and can be applied to a large class of other unsolvable nonlinear ODEs in mathematical physics and nonlinear mechanics such as the Duffing nonlinear oscillator (see Ref. 14), the Van der Pol nonlinear oscillator, the Kidder equation in porous media, the Thomas–Fermi and White–Dwarf (Chandrasekhar) equations in thermodynamics and relativistic mechanics, etc.

II. SOME RESULTS OF THE CLASSES OF EMDEN–FOWLER AND ABEL EQUATIONS

There is a wide class of nonlinear ODEs which can be reduced to equations that traditionally attracted the attention of many researchers: those of the simplest appearance but involving the most difficulties for integration (Abel and Emden–Fowler equations). Both these types of equations are in general unsolvable.[3] Recently, a mathematical methodology was developed in Ref. 13 that leads to the construction of exact analytic solutions of the Abel nonlinear ODEs of the second kind.

Before we address the issue of the construction of exact analytic solutions of the Blasius equations in fluids, we will digress to some well-known classes of nonlinear ODEs, and to admissible functional transformations that reduce a class of ODEs to a different class.

A. The Emden–Fowler equation of the normal form

The Emden-Fowler nonlinear ODE of the normal form is

$$y''_{xx} = Ax^n y^m, \tag{2.1}$$

where A and n, m are arbitrary parameters. Here, the notation $y'_x = dy/dx$, $y''_{xx} = d^2y/dx^2, \ldots$ is used for the total derivatives. We note the following regarding the solution of (2.1):[3]

(i) For $m \neq 1$, Eq. (2.1) possesses the following particular solution:

$$y = \lambda x^{(n+2)/(1-m)}, \quad \text{where } \lambda = [(n+2)(n+m+1)/A(m-1)^2]^{1/(m-1)}. \tag{2.2}$$

(ii) The transformations

$$\mathcal{P}: \quad y = w(t)/t, \quad x = 1/t; \quad t \neq 0, \tag{2.3}$$

transform (2.1) into the following equation of different pair of exponents $\{n, m\}$:

$$w''_{tt} = At^{-n-m-3} w^m. \tag{2.4}$$

Equation (2.1) is, in general, unsolvable. Reference 3 discusses all solvable Emden–Fowler equations, e.g., all possible combinations of parameters A, n, and m for which exact solutions can be constructed in parametric form.

B. The generalized Emden–Fowler equation

The generalized Emden–Fowler ODE is

$$y''_{xx} = Ax^n y^m (y'_x)^\ell. \tag{2.5}$$

For $\ell = 0$ it degenerates to the normal Emden–Fowler form (2.1). To analyze Eq. (2.5) we utilize the triad notation $\{n, m, \ell\}$ to denote the specific exponents of the equation. We note the following:

(i) Considering $x = x(y)$ and introducing the $\mathcal{F}$-transformation

$$\mathcal{F}: \quad y'_x = \frac{dy}{dx} = \frac{1}{dx/dy} = \frac{1}{x'_y}, \tag{2.6}$$

we then derive the following alternative generalized Emden–Fowler equation:

$$x''_{yy} = -Ay^m x^n (x'_y)^{3-\ell}. \tag{2.7}$$

The above transformation can be represented in short-hand notation using the triad symbolism

$$\{n, m, \ell\} \overset{\mathcal{F}}{\leftrightarrow} \{m, n, 3-\ell\}.$$

(ii) If $m \neq 0$, $n \neq -1$, and $\ell \neq 1$, the coordinate transformation

$$\mathcal{J}: \quad w(t) = x^{n+1}, \quad t = (y'_x)^{1-\ell}, \tag{2.8}$$

transforms Eq. (2.5) to the following new Emden–Fowler equation:

$$w''_{tt} = Bt^{1/(1-\ell)} w^{-n/(n+1)} (w'_t)^{(2m+1)/m}, \quad \text{where} \quad B = -\frac{m}{m+1}\left[\frac{A(1-\ell)}{n+1}\right]^{1/m}. \tag{2.9}$$

We denote this transformation symbolically as

$$\{n, m, \ell\} \overset{\mathcal{J}}{\leftrightarrow} \left\{\frac{1}{1-\ell}, -\frac{n}{n+1}, \frac{2m+1}{m}\right\}.$$

Different compositions of transformation $\mathcal{F}$ and $\mathcal{J}$ generate six distinct generalized Emden–Fowler equations corresponding to different triad of exponents $\{n, m, \ell\}$ (Ref. 13, p. 301). When the solution of the transformed equation is obtained in the form $w = w(t)$, the solution of the original equation can be obtained in the parametric form

$$x = w^{1/(1+n)}, \quad y = k(w'_t)^{-1/m}; \quad k = [(n+1)/A(1-\ell)]^{1/m}. \tag{2.10}$$

(iii) In the special case when $\ell = 0$ we showed that transformation (2.3) leads to the normal Emden–Fowler equation (2.4), that is

$$\{n, m, 0\} \overset{\mathcal{P}}{\leftrightarrow} \{-n-m-1, m, 0\}.$$

Then, different compositions of transformations $\mathcal{F}$, $\mathcal{J}$, and $\mathcal{P}$ generate 12 distinct generalized Emden–Fowler equations (Ref. 3, p. 302).

(iv) Finally, with $\ell = 0$ and $n = 1$, different compositions of transformation $\mathcal{F}$, $\mathcal{J}$, and $\mathcal{P}$ generate 24 different generalized Emden–Fowler equations (Ref. 3, p. 303).

C. The Abel equation of the second kind

The Abel nonlinear ODE of the second kind is

$$[g_1(x)y + g_0(x)]y'_x = f_2(x)y^2 + f_1(x)y + f_0(x). \tag{2.11}$$

(i) The transformations

$$w = \left(y + \frac{g_0}{g_1}\right)E, \quad \text{where} \quad E = \exp\left(-\int \frac{f_2}{g_1}dx\right), \tag{2.12}$$

reduce (2.11) into the simplified form

$$w'_x = F_1(x)w + F_0(x), \tag{2.13}$$

in which

$$F_1(x) = \left[\left(\frac{g_0}{g_1}\right)'_x + \frac{f_1}{g_1} - 2\frac{g_0 f_2}{g_1^2}\right]E, \quad F_0 = \left(\frac{f_0}{g_1} - \frac{g_0 f_1}{g_1^2} + \frac{g_0^2 f_2}{g_1^3}\right)E^2. \tag{2.14}$$

(ii) With the aid of the substitution

$$\xi = \int F_1(x)dx, \tag{2.15}$$

the simplified Abel equation (2.13) reduces into the following Abel equation of the second kind of the normal form:

$$ww'_\xi - w = F(\xi), \quad \text{where} \quad F(\xi) = \frac{F_0(x)}{F_1(x)}. \tag{2.16}$$

(iii) If the variable coefficients of the original equation (2.11) satisfy the functional relation

$$g_0(2f_2 + g'_{1_x}) = g_1(f_1 + g'_{0_x}), \quad g_1 \neq 0, \tag{2.17}$$

then its general solution is given by the formula

$$\frac{g_1 y^2 + 2g_0 y}{g_1 J} = 2\int \frac{f_0}{g_1 J}dx + C, \tag{2.18}$$

where C is an integration constant and $J(x)$ the integrating factor

$$J(x) = \exp\left(\int \frac{2f_2}{g_1}dx\right). \tag{2.19}$$

The above result is attributed to Julia in 1933 (Ref. 8, p. 27).

(iv) Consider now the special form of the Abel equation (2.11)

$$yy'_x - y = \alpha x + bx^m, \quad m \text{ any number}. \tag{2.20}$$

In Ref. 3 the following result was provided: if $m \neq 1$, $\alpha > -1/4$, and assuming that

$$\alpha = -\frac{(n+2)(n+m+1)}{(2n+m+3)^2}, \quad \text{where} \quad n_{1,2} = \frac{1}{2}\left(\pm\frac{m-1}{\sqrt{1+4\alpha}} - m - 3\right), \tag{2.21}$$

the coordinate transformations

$$x=\xi^{(n+2)/(m-1)}w(\xi),\quad y=\frac{m-1}{2n+m+3}\xi^{(n+2)/(m-1)}\left(\xi w'_{\xi}+\frac{n+2}{m-1}w\right);\quad n=n_{1,2} \tag{2.22}$$

reduce (2.20) to the Emden–Fowler equation of the normal form

$$w''_{\xi\xi}=A\xi^{n}w^{m},\quad \text{where}\quad A=\left(\frac{2n+m+3}{m-1}\right)^{2}b. \tag{2.23}$$

D. Some basic transformations

(i) Consider the Emden–Fowler nonlinear ODE of the normal form

$$y''_{xx}=Ax^{n}y^{m}, \tag{2.24}$$

with $m\neq 1$ and $m\neq -2n-3$. The transformation

$$\xi=\frac{2n+m+3}{m-1}x^{(n+2)/(m-1)}y,\quad u=x^{(n+2)/(m-1)}\left(xy'_{x}+\frac{n+2}{m-1}y\right), \tag{2.25}$$

leads to the Abel equation of the second kind of the normal form

$$uu'_{\xi}-u=-\frac{(n+2)(n+m+1)}{(2n+m+3)^{2}}\xi+A\left(\frac{m-1}{2n+m+3}\right)^{2}\xi^{m}. \tag{2.26}$$

(ii) Consider the generalized Emden–Fowler equation

$$y''_{xx}=Ax^{n}y^{m}(y'_{x})^{\ell}. \tag{2.27}$$

The substitutions

$$z=\frac{x}{y}y'_{x},\quad \upsilon=Ax^{n-\ell+2}y^{m+\ell-1}, \tag{2.28}$$

reduce (2.27) into the following Abel nonlinear ODE of the second kind:

$$(z^{\ell}\upsilon-z^{2}+z)\upsilon'_{z}=[(m+\ell-1)z+n-\ell+2]\upsilon. \tag{2.29}$$

Furthermore, using the new substitution

$$\xi=\upsilon-z^{2-\ell}+z^{1-\ell}, \tag{2.30}$$

Eq. (2.29) leads to the following equation:

$$\xi\xi'_{z}=[(m+2\ell-3)z+n-2\ell+3]z^{-1}\xi+[(m+\ell-1)z^{2}+(n-m-2\ell+3)z-n+\ell-2]z^{1-2\ell}, \tag{2.31}$$

which is of the Abel form (2.13).

III. THE REDUCTION OF THE EQUATIONS OF BLASIUS

By the generalized equation of Blasius we mean the following nonlinear ODE of the third order:

$$y'''_{xxx} + \alpha y y''_{xx} = \beta(y'^2_x - 1), \tag{3.1}$$

where α and β are arbitrary constants. But, α is in general positive and can be set equal to 1 without loss of generality, as one sees from the transformation $y=\lambda z$, $x=\lambda t$, where $\lambda^2\alpha=1$. The boundary conditions of greatest interest are the following:

For $\alpha \neq 1$

$$y(0) = \alpha_1; \quad y'_x(0) = \beta_1; \quad y'_x(x) \to 0, \quad \text{as} \quad x \to \infty, \tag{3.2}$$

or

$$y(0) = \alpha_2; \quad y''_{xx}(0) = \beta_2; \quad y'_x(x) \to 0, \quad \text{as} \quad x \to \infty, \tag{3.3}$$

and for $\alpha=1$

$$y(0) = y'_x(0) = 0, \quad y'_x(x) \to k \quad \text{as} \quad x \to \infty, \tag{3.4}$$

or

$$y(0) = y''_{xx}(0) = 0, \quad y'_x(x) \to k \quad \text{as} \quad x \to \infty. \tag{3.5}$$

Here, k is a constant. When $\beta \geqslant 0$, the last conditions are sufficient to insure a unique solution of the equation (3.1), but this uniqueness fails when $\beta < 0$.[6]

The equation for the case where $\beta=0$ was originally solved by Blasius, Ref. 4, who introduced it in studying the laminar flow of a fluid. Also, the above simplified Blasius equation ($\beta=0$) was investigated in Ref. 16 for the case $\alpha=1/2$ in studying the flow of an electrically conducting fluid up a hot vertical plate in the presence of strong magnetic field normal to the plate. The generalized Blasius equation (3.1), where $\beta \neq 0$, has been the object of Refs. 5–8. Finally, the restricted form of the Blasius equation

$$y'''_{xxx} + \alpha y y''_{xx} - \beta y'^2_x = 0, \tag{3.6}$$

obeying the boundary conditions (3.2) and (3.3), or (3.4) and (3.5), has been the object of study of Refs. 10–12 and 17.

We emphasize that all the above investigations refer mainly to numerical solutions, as well as to approximate ones by series expansions, similarity variables techniques, etc. Furthermore, all previous investigations refer to concrete values of the parameters α and β.

In what follows we provide a reduction methodology concerning the generalized Blasius equation that leads to equation of the Abel or Emden–Fowler forms. This methodology is realistic and usual for deriving exact analytic solutions of the problem under consideration.

Consider the generalized Blasius equation

$$y'''_{xx} + \alpha y y''_{xx} - \beta y'^2_x + \beta = 0;$$

$$0 \leqslant x < +\infty; \quad \alpha_1 \leqslant y < +\infty; \quad y'_x(0) = \beta_1; \quad y'_x(\infty) = 0; \tag{3.7}$$

where α_1, β_1=constants, $\beta_1 > 0$; α=positive constant, β=positive or negative constant.

The substitution

$$y'_x = z(y) \Rightarrow y''_{xx} = z z'_y, \quad y'''_{xxx} = z^2 z''_{yy} + z z'^2_y, \tag{3.8}$$

reduces (3.7) into the second-order nonlinear ODE

$$z^2 z''_{yy} + z z'^2_y + \alpha y z z'_y - \beta z^2 + \beta = 0;$$

$$\alpha_1 \leqslant y < +\infty; \quad z(\alpha_1) = \beta_1; \quad z(\infty) = 0, (z \in [0, \beta_1]). \tag{3.9}$$

Introduce the transformation

$$z(y)=n(\xi),\quad \xi=\xi(y)\Rightarrow z_y'=n_\xi'\xi_y',\quad z_{yy}''=n_{\xi\xi}''\xi_y'^2+n_\xi'\xi_{yy}'', \tag{3.10}$$

and obtain the equation

$$\xi_y'^2n^2n_{\xi\xi}''+\xi_{yy}''n^2n_\xi'+\xi_y'^2nn_\xi'^2+\alpha y\xi_y'nn_\xi'-\beta n^2+\beta=0. \tag{3.11}$$

We define function $n(\xi)$ such that

$$nn_{\xi\xi}''=-n_\xi'^2\Rightarrow(nn_\xi')_\xi'=0\Rightarrow nn_\xi'=1\Rightarrow n(\xi)=\sqrt{2\xi}=z(y);\quad n\neq 0, \tag{3.12}$$

and thus Eq. (3.11) becomes of the following form, performing only the determinable function $\xi(y)$:

$$\sqrt{2\xi}\xi_{yy}''+\alpha y\xi_y'-2\beta\xi+\beta=0;$$

$$\alpha_1\leqslant y<+\infty;\quad \xi(\alpha_1)=\beta_1^2/2;\quad \xi(\infty)=0,(\xi\in[0,\beta_1^2/2]). \tag{3.13}$$

The new substitution

$$\sqrt{2\xi}=\omega\Rightarrow\xi_y'=\omega\omega_y',\quad \xi_{yy}''=\omega\omega_{yy}''+\omega_y'^2, \tag{3.14}$$

transforms (3.13) to the following second-order nonlinear ODE:

$$\omega^2\omega_{yy}''+\omega\omega_y'^2+\alpha y\omega\omega_y'-\beta\omega^2+\beta=0, \tag{3.15}$$

while the $\mathcal{F}$-transformation (2.6) reduces (3.15) to the equation

$$\omega^2y_{\omega\omega}''-\omega y_\omega'=\alpha\omega yy_\omega'^2-\beta\omega^2y_\omega'^3+\beta y_\omega'^3;$$

$$\alpha_1\leqslant y<+\infty;\quad \text{for } y=\alpha_1,\quad \omega=\beta_1;\quad \text{for}\quad y\to\infty,\quad \omega\to 0,(\omega\in[0,\beta_1]). \tag{3.16}$$

Applying again a [similar to (3.10)] transformation, that is setting

$$y(\omega)=\upsilon(s),\quad s=s(\omega),$$

with concrete form

$$s_\omega'=\omega\Rightarrow s=\omega^2/2;\quad \omega\neq 0, \tag{3.17}$$

we obtain the nonlinear ODE

$$\upsilon_s''=\frac{\alpha}{\sqrt{2}}s^{-1/2}\upsilon\upsilon_s'^2-\beta\sqrt{2}s^{1/2}\upsilon_s'^3+\frac{\beta}{\sqrt{2}}s^{-1/2}\upsilon_s'^3;$$

$$\alpha_1\leqslant\upsilon<+\infty;\quad \text{for } \upsilon=\alpha_1,\quad s=\beta_1^2/2;\quad \text{for } \upsilon\to\infty,s\to 0,(s\in[0,\beta_1^2/2]). \tag{3.18}$$

The $\mathcal{F}$-transformation (2.6) on Eq. (3.18) reduces it to the following three-term generalized Emden–Fowler equation:

$$s_{\upsilon\upsilon}''=A\upsilon s^{-1/2}s_\upsilon'+Bs^{1/2}-\frac{B}{2}s^{-1/2};\quad A=-\frac{\alpha}{\sqrt{2}},\quad B=-\beta\sqrt{2};$$

$$\alpha_1\leqslant\upsilon<+\infty;\quad \text{for}\quad s=\beta_1^2/2,\upsilon=\alpha_1;\quad \text{for}\quad s\to 0,\upsilon\to\infty,(s\in[0,\beta_1^2/2]). \tag{3.19}$$

We distinguish now the following two cases:

Case a: $\beta=0$

This case corresponds to the simplified Blasius equation

$$y'''_{xxx} + \alpha y y''_{xx} = 0;$$

$$0 \leqslant x < +\infty; \quad \alpha_1 \leqslant y < +\infty; \quad y'_x(0) = \beta_1; \quad y'_x(\infty) = 0;$$

$$\alpha = \text{positive constant}; \quad \alpha_1, \beta_1 = \text{constants}, \quad \beta_1 > 0. \tag{3.20}$$

The [equivalent to (3.13)] transformed equation becomes a generalized Emden–Fowler equation, that is

$$\xi''_{yy} = A y \xi^{-1/2} \xi'_y; \quad A = -\alpha/\sqrt{2};$$

$$\alpha_1 \leqslant y < +\infty; \quad \xi(\alpha_1) = \beta_1^2/2; \quad \xi(\infty) = 0, (\xi \in [0, \beta_1^2/2]). \tag{3.21}$$

The $\mathcal{F}$-transformation (2.6) reduces (3.21) to the generalized Emden–Fowler equation with a different pair of exponents

$$y''_{\xi\xi} = -A \xi^{-1/2} y (y'_\xi)^2; \quad A = -\alpha\sqrt{2};$$

$$\alpha_1 \leqslant y < +\infty; \quad \text{for} \quad y = \alpha_1, \xi = \beta_1^2/2; \quad \text{for} \quad y \to \infty, \xi \to 0, (\xi \in [0, \beta_1^2/2]), \tag{3.22}$$

while the $\mathcal{J}$-transformation (2.8) with concrete form

$$w(t) = \xi^{1/2}, \quad t = (y'_\xi)^{-1}, \tag{3.23}$$

transforms (3.22) into the following generalized Emden–Fowler equation:

$$w''_{tt} = B t^{-1} w (w'_t)^3; \quad B = 4\alpha\sqrt{2} = -4A;$$

$$0 \leqslant w \leqslant \beta_1/\sqrt{2}. \tag{3.24}$$

When the solution of Eq. (3.24) is obtained in the form $w = w(t)$, the solution of Eq. (3.22) can be written in the parametric form [see Eqs. (2.10)]

$$\xi = w^2, \quad y = \frac{1}{2A}(w'_t)^{-1}; \quad t = \text{parameter};$$

$$\alpha_1 \leqslant y < +\infty; \quad \text{for} \quad y = \alpha_1, \xi = w^2 = \beta_1^2/2; \quad \text{for} \quad y \to \infty, \xi = w^2 \to 0, (\xi \in [0, \beta_1^2/2]). \tag{3.25}$$

Equation (3.24) is directly reducible to the Emden–Fowler equation of the normal form

$$t''_{ww} = -B w t^{-1}; \quad B = 4\alpha\sqrt{2} = -4A;$$

$$0 \leqslant w \leqslant \beta_1/\sqrt{2}. \tag{3.26}$$

The above generalized Emden–Fowler equation (3.21) and (3.22), or the Emden–Fowler equation of the normal form (3.26), can be reduced to an Abel equation of the second kind of the normal form by means of the admissible functional transformations (2.28) and (2.25), respectively. Consider for example the reduced generalized Emden–Fowler equation (3.21). Then, by the transformation (2.28) with concrete form

$$\overset{\star}{z} = \frac{y}{\xi}\xi'_y, \quad \overset{\star}{v} = Ay^2\xi^{-1/2}, \tag{3.27}$$

(3.21) becomes the Abel equation of the second kind

$$(\overset{\star}{v} - \overset{\star}{z} + 1)\overset{\star}{v}'_z = \frac{4 - \overset{\star}{z}}{2\overset{\star}{z}}\overset{\star}{v};$$
$$\text{for} \quad y_0 = \alpha_1, \xi_0 = \beta_1^2/2, \overset{\star}{v}_0 = \sqrt{2}\alpha_1^2 A/\beta_1; \quad \text{for } y_1 \to \infty, \xi_1 \to 0. \tag{3.28}$$

Furthermore, by the transformation (2.12) with concrete form

$$r = \overset{\star}{v} - \overset{\star}{z} + 1, \tag{3.29}$$

Eq. (3.28) results in

$$rr'_{\overset{\star}{z}} = F_1(\overset{\star}{z})r + F_0(\overset{\star}{z});$$

$$F_1(\overset{\star}{z}) = \frac{4 - 3\overset{\star}{z}}{2\overset{\star}{z}}, \quad F_0(\overset{\star}{z}) = \frac{(\overset{\star}{z} - 1)(4 - \overset{\star}{z})}{2\overset{\star}{z}}. \tag{3.30}$$

Finally, the substitution (2.15) with concrete form

$$s = \int F_1(\overset{\star}{z})d\overset{\star}{z} = \int \frac{4 - 3\overset{\star}{z}}{2\overset{\star}{z}}d\overset{\star}{z} = 2\ \ln|\overset{\star}{z}| - \frac{3}{2}\overset{\star}{z}, \tag{3.31}$$

transforms (3.30) to the Abel equation of the normal form

$$rr'_s - r = \frac{F_0(\overset{\star}{z}(s))}{F_1(\overset{\star}{z}(s))};$$

$$\frac{F_0(\overset{\star}{z}(s))}{F_1(\overset{\star}{z}(s))} = \frac{(\overset{\star}{z} - 1)(4 - \overset{\star}{z})}{4 - 3\overset{\star}{z}}; \quad s = 2\ \ln|\overset{\star}{z}| - \frac{3}{2}\overset{\star}{z}. \tag{3.32}$$

When the Abel equation (3.32) is solved (including one constant of integration), then, by the transformation (3.29) one extracts the solution of the Abel equation (3.28) in the form $\overset{\star}{v} = \overset{\star}{v}(\overset{\star}{z})$, and the solution of the generalized Emden–Fowler equation (3.21) can be obtained parametrically as follows.

Using the first part of (3.27), we have

$$\overset{\star}{z}=y\frac{\xi_y'}{\xi}=\frac{y}{\xi}\frac{\xi_{\overset{\star}{z}}'}{y_{\overset{\star}{z}}'}\Leftrightarrow\frac{y_{\overset{\star}{z}}'}{y}=\frac{1}{\overset{\star}{z}}\frac{\xi_{\overset{\star}{z}}'}{\xi},\tag{3.33}$$

while by the second part we extract

$$y^2=\frac{\overset{\star}{\upsilon}\xi^{1/2}}{A}\Leftrightarrow y=\pm\frac{\overset{\star}{\upsilon}^{1/2}\xi^{1/4}}{A^{1/2}},\quad 2yy_{\overset{\star}{z}}'=\frac{1}{A}\left(\overset{\star}{\upsilon}_{\overset{\star}{z}}'\sqrt{\xi}+\overset{\star}{\upsilon}\frac{\xi_{\overset{\star}{z}}'}{2\sqrt{\xi}}\right).\tag{3.34}$$

Combination of the last two relations results in

$$y_{\overset{\star}{z}}'=\pm\frac{1}{2\sqrt{A}}\left(\frac{\overset{\star}{\upsilon}_{\overset{\star}{z}}'}{\sqrt{\overset{\star}{\upsilon}}}\xi^{1/4}+\sqrt{\overset{\star}{\upsilon}}\frac{\xi_{\overset{\star}{z}}'}{2\xi^{3/4}}\right),\tag{3.35}$$

and thus, by way of (3.28), we obtain

$$\frac{y_{\overset{\star}{z}}'}{y}=\frac{1}{2}\left(\frac{4-\overset{\star}{z}}{2\overset{\star}{z}(\overset{\star}{\upsilon}-\overset{\star}{z}+1)}+\frac{\xi_{\overset{\star}{z}}'}{2\xi}\right).\tag{3.36}$$

Both Eqs. (3.33) and (3.36) perform the following equation for $\xi_{\overset{\star}{z}}'$:

$$\frac{1}{2}\left(\frac{4-\overset{\star}{z}}{2\overset{\star}{z}(\overset{\star}{\upsilon}-\overset{\star}{z}+1)}+\frac{\xi_{\overset{\star}{z}}'}{2\xi}\right)=\frac{1}{\overset{\star}{z}}\frac{\xi_{\overset{\star}{z}}'}{\xi}\Leftrightarrow\frac{\xi_{\overset{\star}{z}}'}{\xi}=\frac{1}{\overset{\star}{\upsilon}-\overset{\star}{z}+1}.$$

Consequently, the variables ξ *and* y in transformation (3.27) are given in parametric form as follows:

$$\xi=\exp\left(C+\int\frac{d\overset{\star}{z}}{\overset{\star}{\upsilon}-\overset{\star}{z}+1}\right);$$

$$y=\pm\frac{\overset{\star}{\upsilon}^{1/2}}{A^{1/2}}\left[\exp\left(C+\int\frac{d\overset{\star}{z}}{\overset{\star}{\upsilon}-\overset{\star}{z}+1}\right)\right]^{1/4};\tag{3.37}$$

$\overset{\star}{\upsilon}=\overset{\star}{\upsilon}(\overset{\star}{z})$=the solution of the Abel equation (3.28) including one constant of integration;

$$\overset{\star}{z}=\text{parameter};C=\text{integration constant}.$$

Equations (3.37) consist the intermediate integral of the simplified Blasius equation (3.20), that is, the solution of the problem under consideration in the phase plane. The solution to the original Blasius equation (3.20) also can be obtained parametrically by means of (i) Eq. (3.12), giving $z(y)=\sqrt{2\xi}$ [y and ξ as in (3.37)] ; (ii) the transformation (3.10), giving $z(y)=n(\xi)=\sqrt{2\xi}$; and (iii) by the substitution (3.8), which permits us to write $dy/z(y)=dy/\sqrt{2\xi}=dx$.

Summarizing, the exact analytic solution of the simplified Blasius equation (3.20) in parametric form is given by the following equations:

$$y = \pm \frac{\overset{\star}{v}^{1/2}}{A^{1/2}} \left[\exp\left(C + \int \frac{d\overset{\star}{z}}{\overset{\star}{v} - \overset{\star}{z} + 1} \right) \right]^{1/4};$$

$$x = \pm \int \frac{\overset{\star}{v}^{1/2}}{\sqrt{2}A^{1/2}} \left[\exp\left(C + \int \frac{d\overset{\star}{z}}{\overset{\star}{v} - \overset{\star}{z} + 1} \right) \right]^{-1/4} \left(\overset{\star}{v}'_{\overset{\star}{z}} + \frac{1}{4(\overset{\star}{v} - \overset{\star}{z} + 1)} \right) d\overset{\star}{z} + \overset{\star}{C};$$

$$C, \overset{\star}{C} = \text{integration constants}; \tag{3.38}$$

$\overset{\star}{v}(\overset{\star}{z})$=the solution of the Abel equation (3.28) including a third constant of integration;

$$\overset{\star}{z} = \text{parameter}.$$

Case b: $\beta \neq 0$

This case corresponds to the generalized Blasius equation (3.1). We shall consider here the restricted form of this equation, that is, Eq. (3.6) governing axisymmetric flows due to stretching flat surfaces. We have already proved that this equation can be reduced to a two-term generalized Emden–Fowler equation, namely

$$s''_{vv} = A v s^{-1/2} s'_v + B s^{1/2}; \quad A = -\frac{\alpha}{\sqrt{2}}, \quad B = -\beta\sqrt{2};$$

$$\alpha_1 \leqslant v < +\infty; \quad \text{for} \quad s = \beta_1^2/2, v = \alpha_1; \quad \text{for} \quad s \to 0, v \to \infty \quad (s \in [0, \beta_1^2/2]). \tag{3.39}$$

Transformation of (2.28) with concrete form

$$\overset{\star}{z} = v\frac{s'_v}{s}, \quad \overset{\star}{t} = A v^2 s^{-1/2}, \tag{3.40}$$

furnishes the results

$$d\overset{\star}{z} = \left(\frac{s'_v}{s} + v\frac{s''_{vv}}{s} - v\frac{s'^2_v}{s^2} \right) dv; \quad d\overset{\star}{t} = A\frac{4vs - v^2 s'_v}{2s^{3/2}} dv.$$

Because of (3.40), these last relations formulate the following equation:

$$\overset{\star}{z}_{\overset{\star}{t}} = 2\frac{\overset{\star}{z} + v^2\frac{s''_{vv}}{s} - \frac{z^2}{v}}{(4 - \overset{\star}{z})\overset{\star}{t}}. \tag{3.41}$$

Solving (3.41) for s''_{vv} and introducing to the resulting new equation the expression (3.39), one obtains

$$s''_{vv} = [(4 - \overset{\star}{z})\overset{\star}{t}\overset{\star}{z}'_t - 2\overset{\star}{z} + 2\overset{\star}{z}^2]\frac{s}{2v^2} = A v s^{-1/2} s'_v + B s^{1/2},$$

which, by means of (3.39), becomes

$$[(4-\overset{\star}{z})\overset{\star}{t}\overset{\star}{z}'_{\overset{\star}{t}}-2\overset{\star}{z}+2\overset{\star}{z}^2]\frac{A}{2\overset{\star}{t}}=A\overset{\star}{z}+B. \tag{3.42}$$

This is an Abel equation of the second kind of the normal form

$$(\overset{\star}{z}-4)\overset{\star}{z}'_{\overset{\star}{t}}=\frac{2}{t}\overset{\star}{z}^2-A\left(1+\frac{1}{\overset{\star}{t}}\right)\overset{\star}{z}-\frac{2B}{A};$$

$$\text{for}\quad \upsilon_0=\alpha_1,\quad s_0=\beta_1^2/2,\quad \overset{\star}{t}_0=\sqrt{2}\alpha_1^2A/\beta_1;\quad \text{for}\quad \upsilon_1\to\infty,s_1\to 0. \tag{3.43}$$

By the transformation

$$r=(\overset{\star}{z}-4)\exp\left(-\int\frac{2}{\overset{\star}{t}}d\overset{\star}{t}\right)=\frac{(\overset{\star}{z}-4)}{\overset{\star}{t}^2}, \tag{3.44}$$

(3.43) is reduced to

$$r\overset{\star}{r}'_{\overset{\star}{t}}=F_1(\overset{\star}{t})r+F_0(\overset{\star}{t});$$

$$F_1(\overset{\star}{t})=-\frac{A(\overset{\star}{t}+1)+16}{\overset{\star}{t}},\quad F_0(\overset{\star}{t})=-\frac{2B\overset{\star}{t}-32A+4A^2(1+\overset{\star}{t})}{A\overset{\star}{t}}. \tag{3.45}$$

Finally, the substitution

$$s=-\int\frac{A(\overset{\star}{t}-1)+16}{\overset{\star}{t}}d\overset{\star}{t}=-A\overset{\star}{t}-(A+16)\ln|\overset{\star}{t}|, \tag{3.46}$$

transforms (3.45) to the following Abel equation of the second kind of the normal form:

$$rr'_s-r=\frac{F_0(\overset{\star}{t}(s))}{F_1(\overset{\star}{t}(s))}=\frac{2B\overset{\star}{t}-32A+4A^2(1+\overset{\star}{t})}{A[A(1+\overset{\star}{t})+16]};\quad s=-A\overset{\star}{t}-(A+16)\ln|\overset{\star}{t}|. \tag{3.47}$$

When the solution of the Abel equation (3.47) is obtained in the form $r=r(s)$ (including one constant of integration), the solution of Eq. (3.43) can be expressed by means of the transformation (3.44) as $\overset{\star}{z}=\overset{\star}{z}(\overset{\star}{t})$ and thus, the solution to the original Emden–Fowler equation (3.39) can be constructed parametrically as follows.

By the first part of (3.40), one obtains

$$\overset{\star}{z}=\upsilon\frac{s'_\upsilon}{s}=\frac{\upsilon}{s}\frac{\overset{\star}{s}'_{\overset{\star}{t}}}{\upsilon'_{\overset{\star}{t}}}\Leftrightarrow\frac{\upsilon'_{\overset{\star}{t}}}{\upsilon}=\frac{1}{\overset{\star}{z}}\frac{\overset{\star}{s}'_{\overset{\star}{t}}}{s}, \tag{3.48}$$

while by the second of these equations we extract

$$\upsilon^2=\frac{\overset{\star}{t}}{A}s^{1/2}\Leftrightarrow 2\upsilon\upsilon'_{\overset{\star}{t}}=\frac{1}{A}\left(s^{1/2}+\frac{\overset{\star}{t}s'_t}{2s^{1/2}}\right). \tag{3.49}$$

Combination of the last two relations results in

$$\overset{\star}{v}{}'_{\overset{\star}{t}} = \pm \frac{1}{2\sqrt{A}}\left(\frac{s^{1/4}}{\overset{\star}{t}{}^{1/2}} + \frac{\overset{\star}{t}{}^{1/2}\overset{\star}{s}{}'_{\overset{\star}{t}}}{2s^{3/4}}\right), \tag{3.50}$$

and thus

$$\frac{\overset{\star}{v}{}'_{\overset{\star}{t}}}{v} = \frac{1}{2}\left(\frac{1}{\overset{\star}{t}} + \frac{s'_t}{2s}\right). \tag{3.51}$$

Introducing expression (3.51) into (3.48), we perform the following equation for $\overset{\star}{s}{}'_{\overset{\star}{z}}$:

$$\frac{1}{2\overset{\star}{t}} + \frac{\overset{\star}{s}{}'_{\overset{\star}{t}}}{4s} = \frac{1}{\overset{\star}{z}}\frac{\overset{\star}{s}{}'_{\overset{\star}{t}}}{s} \Leftrightarrow \frac{\overset{\star}{s}{}'_{\overset{\star}{t}}}{s} = \frac{2\overset{\star}{z}}{\overset{\star}{t}(4-\overset{\star}{z})}. \tag{3.52}$$

Consequently, both s and v in transformation (3.40) are given parametrically as follows:

$$s = \exp\left(C + \int \frac{2\overset{\star}{z}}{\overset{\star}{t}(4-\overset{\star}{z})}d\overset{\star}{t}\right);$$

$$v = \pm \frac{\overset{\star}{t}{}^{1/2}}{A^{1/2}}\left[\exp\left(C + \int \frac{2\overset{\star}{z}}{\overset{\star}{t}(4-\overset{\star}{z})}d\overset{\star}{t}\right)\right]^{1/4}; \tag{3.53}$$

$\overset{\star}{z} = \overset{\star}{z}(\overset{\star}{t})$ = solution of the Abel equation (3.43) including one constant of integration;

$$C = \text{integration constant}; \quad \overset{\star}{t} = \text{parameter}.$$

The solution to the original Blasius equation (3.6) follows the same exactly steps as in case (a).

Summarizing, the simplified Blasius equation (3.20) was reduced: (i) to the generalized Emden–Fowler equations (3.21) and (3.22); (ii) to the Emden–Fowler equation of the normal form (3.26), and (iii) to the Abel equation of the second kind of the normal form (3.32). In addition, the restricted form of the generalized Blasius equation (3.6) was reduced: (i) to the two-term generalized Emden–Fowler equation (3.39), and (ii) to the Abel equation of the second kind of the normal form (3.47). In addition, the solution to the original Blasius equations can be obtained parametrically, as Eqs. (3.38) and (3.53) show. This presupposes the construction of the solution of the Abel equations (3.32) and (3.47), respectively.

In what follows, based on the mathematical construction briefly discussed in Ref. 13, we provide the exact analytic solution of the Abel equation of the second kind of the normal form $yy'_x - y = F(x)$, which consists of the fundamental ODE of the above-mentioned prescribed reduction procedure.

IV. EXACT ANALYTIC SOLUTION OF THE ABEL EQUATION, $yy'_x - y = F(x)$

Before we address the issue of the construction of exact analytic solutions to the Abel ODE of the second kind of the normal form, we will provide a mathematical result given by Julia in 1933 (see Ref. 2, p. 27) concerning the exact solution of an Abel nonlinear ODE of the second kind. According to this result, if the variable coefficients of the equation

$$[g_1(x)y + g_0(x)]y'_x = f_2(x)y^2 + f_1(x)y + f_0(x) \tag{4.1}$$

satisfy the functional relation

$$g_0(2f_2 + g'_{1_x}) = g_1(f_1 + g'_{0_x}), \quad g_1 \neq 0, \tag{4.2}$$

then there exists its general solution, given by the formula

$$\frac{g_1y^2 + 2g_0y}{g_1J} = 2\int \frac{f_0}{g_1J}dx + C, \tag{4.3}$$

where C is an integration constant and J the integrating factor $J(x)=\exp[\int(2f_2/g_1)dx]$.

Consider the Abel equation of the second kind of the normal form

$$yy'_x - y = F(x), \tag{4.4}$$

where $F(x)$ is an arbitrary smooth function of the variable x. We introduce the functional transformation

$$y(x) = f_1(x)n(\xi), \quad \xi = \xi(x), \tag{4.5}$$

which reduces (4.4) to the form

$$f_1^2\xi'_x nn'_\xi + f_1f'_{1_x}n^2 - f_1n = F. \tag{4.6}$$

Here, $f_1(x)$, $\xi(x)$, and $n(\xi)$ are to be determined. Introducing a new function $g(x)$, one rewrites (4.6) as

$$(f_1^2\xi'_x n + g)n'_\xi - 2F = (-f_1^2\xi'_x n + g)n'_\xi - 2f_1f'_{1_x}n^2 + 2f_1n. \tag{4.7}$$

The last equation splits into the following two equations:

$$(f_1^2\xi'_x n + g)n'_\xi - 2F = G(x), \tag{4.8}$$

$$(-f_1^2\xi'_x n + g)n'_\xi - 2f_1f'_{1_x}n^2 + 2f_1n = G(x). \tag{4.9}$$

Here, $g(x)$ and $G(x)$ are also arbitrary smooth functions to be determined. We develop now the following steps.

1st step: We apply Julia's construction on the Abel equation (4.8) and obtain, after integration, the following results:

$$g = f_1^2\xi'_x; \tag{4.10}$$

$$n^2 + 2n - 8\int \frac{G + 2F}{f_1^2}dx + C = 0, \tag{4.11}$$

where C is an integration constant.

2nd step: Similarly, we apply Julia's construction on the Abel equation (4.9) and obtain, after integration, the following results:

$$f_1 = (x + 2\lambda)/2; \quad n^2 - 2n + \frac{8}{(x+2\lambda)^4}\int (x+2\lambda)^2G(x)dx - \frac{\overset{\star}{C}}{(x+2\lambda)^4} = 0, \tag{4.12}$$

where λ is a parameter and $\overset{\star}{C}$ is a new constant of integration.

The problem under consideration demands that from the already introduced three constants of integration λ, C, and $\overset{\star}{C}$ only one exists. If $\lambda=0$, then $f_1(x)=x/2$, and supposing that the original Abel equation (4.4) obeys the condition for $x=0$, $y(0)=y_0\neq 0$, by (4.5) we admit the result $y_0=0\cdot n(\xi_0)=0$. This is unacceptable, and thus one concludes that $\lambda\neq 0$ and $C=\overset{\star}{C}=0$.

Summarizing, the obtained results are the following:

$$f_1(x)=\frac{x+2\lambda}{2},\quad \frac{g(x)}{\xi_x'(x)}=f_1^2, \tag{4.13}$$

$$n^2+2n-8\int\frac{G+2F}{(x+2\lambda)^2}dx=0,\quad n^2-2n+\frac{8}{(x+2\lambda)^4}\int(x+2\lambda)^2G\,dx=0, \tag{4.14}$$

where $g(x)$, $\xi(x)$, and $G(x)$ are to be determined $(x\neq -2\lambda)$.

3rd step: In what follows we are able to construct an exact analytic solution of the problem under consideration, that is of the original Abel equation (4.4). Supposing, without loss of generality, real roots of the last two equations (4.14), solving them for n, and equating the results we deduce the unique relation

$$\sqrt{1+8\int\frac{G}{\omega}dx+16\int\frac{F}{\omega}dx}=2+\sqrt{1-\frac{8}{\omega^2}\int\omega G\,dx}, \tag{4.15}$$

where

$$\omega=(x+2\lambda)^2=(2f_1)^2. \tag{4.16}$$

We rewrite (4.15) in the form

$$\sqrt{\omega^2-M(x)}=\omega\sqrt{1+N(x)}-2\omega, \tag{4.17}$$

with

$$M(x)=8\int\omega G\,dx,\quad N(x)=8\int\frac{G}{\omega}dx+16\int\frac{F}{\omega}dx, \tag{4.18}$$

and, since $M_x'=8\omega G$, $N_x'=8(G/\omega)+16(F/\omega)$, squaring and differentiating (4.17), one extracts the equation

$$6\omega\omega_x'+M_x'+2(1+N)\omega\omega_x'+\omega^2N_x'-8\sqrt{1+N}\omega\omega_x'-2\omega^2\frac{N_x'}{\sqrt{1+N}}=0. \tag{4.19}$$

Finally, introducing M_x' and N_x' by way of (4.18) into the last relation, we perform the following cubic equation for $(1+N)^{1/2}$:

$$(1+N)^{3/2}-4(1+N)+\left[3+\frac{4(G+F)}{x+2\lambda}\right](1+N)^{1/2}-4\frac{G+2F}{x+2\lambda}=0. \tag{4.20}$$

The substitution

$$(1+N)^{1/2}=\overline{N}+\tfrac{4}{3}, \tag{4.21}$$

transforms (4.20) to the Cardan form

$$\overline{N}^3+p\overline{N}+q=0, \tag{4.22}$$

where

$$p=-\frac{\boldsymbol{a}^2}{3}+b,\quad q=2\left(\frac{\boldsymbol{a}}{3}\right)^3-\frac{\boldsymbol{a}b}{3}+c,\quad \boldsymbol{a}=-4,\quad b=3+\frac{4(G+F)}{x+2\lambda},\quad c=-\frac{4(G+2F)}{x+2\lambda}. \tag{4.23}$$

It is well known that the solution of the cubic equation (4.22) can be expressed in analytic form, depending on the sign of the discriminant

$$Q=\left(\frac{p}{3}\right)^3+\left(\frac{q}{2}\right)^2. \tag{4.24}$$

When $Q<0$, (4.22) possesses three real roots, whereas when $Q>0$ there exists a single real root and a complex conjugate pair of roots. The case $Q=0$ furnishes three real roots, two of which are equal. Based on these observations and noting that only real roots are of interest, we list the specific forms of the roots of (4.22) as follows:

Case 1: $Q<0$ $(p<0)$,

$$N(x)=\left(\overline{N}(x)+\frac{4}{3}\right)^2-1;$$

$$\overline{N}_1(x)=2\sqrt{-\frac{p}{3}}\cos\frac{a}{3},\quad \overline{N}_2(x)=2\sqrt{-\frac{p}{3}}\cos\frac{a-\pi}{3},\quad \overline{N}_3(x)=-2\sqrt{-\frac{p}{3}}\cos\frac{a+\pi}{3};$$

$$\cos a=-\frac{q}{2\sqrt{-\left(\frac{p}{3}\right)^3}};\quad 0<a<\pi,\quad p,q \text{ as in (4.23)}, \tag{4.25}$$

Case 2: $Q>0$,

$$N(x)=\left(\overline{N}(x)+\frac{4}{3}\right)^2-1;\quad \overline{N}(x)=\sqrt[3]{-\frac{q}{2}+\sqrt{Q}}+\sqrt[3]{-\frac{q}{2}-\sqrt{Q}},\quad p,q \text{ as in (4.23)}. \tag{4.26}$$

Case 3: $Q=0$,

$$N(x)=\left(\overline{N}(x)+\frac{4}{3}\right)^2-1;\quad \overline{N}_1(x)=2\sqrt[3]{-\frac{q}{2}},\quad \overline{N}_2(x)=\overline{N}_3(x)=-\sqrt[3]{-\frac{q}{2}},\quad p,q \text{ as in (4.23)}. \tag{4.27}$$

By now the problem can be solved according to the following procedure.

a) Combination of the second of Eqs. (4.18) together with the substitution (4.21) results in

$$N(x)=8\int\frac{G+2F}{\omega}=\left[N(x)+\frac{4}{3}\right]^2-1. \tag{4.28}$$

Furthermore, Eq. (4.17), together with the second part of (4.14), yields the expressions

$$\sqrt{1-\frac{M}{\omega^2}}=\sqrt{1+N}-2,\quad (n-1)^2=1-\frac{M}{\omega^2}, \tag{4.29}$$

by means of which we extract the equation

$$\sqrt{1+8\int\frac{G+2F}{\omega}dx}=2+(n-1). \tag{4.30}$$

Thus, combining (4.28) and (4.30), one obtains the following solution for $n(x)$:

$$n(x)=\overline{N}(x)+\tfrac{1}{3}=[N(x)+1]^{1/2}-1, \tag{4.31}$$

where $\overline{N}(x)$ as in Eqs. (4.25)–(4.27). Since $N(x)$ has been evaluated already in (4.28), the subsidiary function $M(x)$ provided in (4.18) also can be evaluated.

Summarizing, we perform the following solutions:

$$n(x)=\overline{N}+\tfrac{1}{3}=\sqrt{1+N}-1,$$

$$N(x)=8\int\frac{G+2F}{(x+2\lambda)^2}dx=\left(\overline{N}+\frac{4}{3}\right)^2-1,$$

$$\frac{M(x)}{(x+2\lambda)^4}=\frac{8}{(x+2\lambda)^4}\int(x+2\lambda)^2Gdx=-\left(\overline{N}+\frac{1}{3}\right)\left(\overline{N}-\frac{5}{3}\right),$$

$$\overline{N}(x)\quad\text{as in Eqs. (4.25) to (4.27).} \tag{4.32}$$

Note that both $N(x)$ and $M(x)$ denote integrals, and they are expressed in terms of the unknown subsidiary function $G(x)$, which is to be determined.

b) It is easy now to show that the already constructed solution $n(x)$ in Eq. (4.31) verifies all the transformed Abel equations (4.6), (4.8), and (4.9) if and only if the derivative $\overline{N}'_x$ of the function $\overline{N}(x)$ is given by the differentiation of the second of (4.32). In other words, the set

$$n=\overline{N}+\frac{1}{3},\quad \overline{N}'_x=\frac{4(G+2F)}{(x+2\lambda)^2\left(\overline{N}+\frac{4}{3}\right)} \tag{4.33}$$

verifies all the aforementioned Abel equations.

Indeed, introducing (4.33) together with the expression for $f_1(x)$ given in (4.12) into the above Abel equations, simultaneously setting $\xi'_x=1$ ($\xi=x$), we extract the cubic equations (4.20). For example, Eq. (4.9) provides

$$(\sqrt{1+N}-2)\frac{2(G+2F)}{x+2\lambda}=-(\sqrt{1+N}-1)^2\sqrt{1+N}+2(\sqrt{1+N}-1)\sqrt{1+N}-\frac{2G}{x+2\lambda}\sqrt{1+N},$$

while Eq. (4.6) also provides

$$(\sqrt{1+N}-1)\frac{4(G+2F)}{(x+2\lambda)\sqrt{1+N}}=-(\sqrt{1+N}-1)^2+2(\sqrt{1+N}-1)+\frac{4F}{x+2\lambda},$$

which coincide with the cubic equation (4.20).

This leads to a similar result for the original Abel equation (4.4). Thus, the solution of the original Abel equation can be written

$$y(x)=\tfrac{1}{2}(x+2\lambda)[\overline{N}(x)+\tfrac{1}{3}], \tag{4.34}$$

where $\overline{N}(x)$ is given in Eqs. (4.25)–(4.27) in terms of the unknown subsidiary function $G(x)$.

c) In determining $G(x)$ we refer to the set (4.33) together with the Abel equation (4.8), or (4.9), or equivalently with the following equivalent system of equations resulting from these Abel equations:

$$(f_1 f_x' n^2 - f_1 n - F)(n+1) + n(G+2F) = 0, \tag{4.35}$$

$$n_x' = \frac{f_{1_x}'}{f_1} n^2 - \frac{1}{f_1} n + \frac{F+G}{f_1^2}. \tag{4.36}$$

The functional relation (4.35) together with first part of (4.33) leads to the cubic equation (4.20). On the other hand, the Riccati equation (4.36), by means of the set (4.33), results also in the cubic equation (4.20). This means that $n(x)=\overline{N}+1/3$ is a solution of (4.36) if and only if $\overline{N}_x'=4(G+2F)/(x+2\lambda)^2(\overline{N}+4/3)$.

By the functional transformation

$$n(x) - 1 = \overline{N}(x) - \tfrac{2}{3} = \overline{H}(\overline{\xi}), \quad \overline{\xi} = \ln|x+2\lambda|, \tag{4.37}$$

we reduce the Riccati equation (4.36) to the normal form

$$\overline{H}_{\xi}' = \overline{H}^2 - [1 - 4(G+F)e^{-\overline{\xi}}]. \tag{4.38}$$

Thus, according to the above results, a solution of the Riccati equation (4.38) is given by the following set of equations:

$$\overline{H}(\xi) = \overline{N} - \tfrac{2}{3}, \quad \overline{N}_{\xi}' = \frac{4(G+2F)}{\overline{N} + \frac{4}{3}} e^{-\overline{\xi}}. \tag{4.39}$$

It is well known (see Refs. 2 and 3), that if $\overline{N}-2/3$ is a solution of (4.38), then the general solution is given by the formula

$$\overline{H}_{\mathbb{R}}(\overline{\xi}) = \overline{N}(\overline{\xi}) - \frac{2}{3} + \frac{\phi(\overline{\xi})}{C - \int_0^{\overline{\xi}} \phi(\overline{\xi}) d\overline{\xi}}, \quad \phi(\overline{\xi}) = \exp\left(2\int_0^{\overline{\xi}} \left(\overline{N} - \frac{2}{3}\right) d\overline{\xi}\right);$$

$$\overline{N}_{\overline{\xi}}' = \frac{4(G+2F)e^{-\overline{\xi}}}{\overline{N} + \frac{4}{3}}, \quad C = \text{integration constant}. \tag{4.40}$$

For verification, inserting the quantities

$$\overline{H}_{\mathbb{R}} = \overline{N} - \tfrac{2}{3} + A, \quad A = \frac{\phi}{\left(C - \int_0^{\overline{\xi}} \phi \, d\xi\right)}, \tag{4.41}$$

into Eq. (4.38), we obtain

$$\overline{N}_{\overline{\xi}}' - (\overline{N} - \tfrac{2}{3})^2 + 1 - 4(G+F)e^{-\overline{\xi}} = -A_{\overline{\xi}}' + A^2 + 2(\overline{N} - \tfrac{2}{3})A. \tag{4.42}$$

By means of the expression for $\overline{N}_{\overline{\xi}}'$ given in (4.40), the left-hand side of the last equation results in the cubic form (4.20), which is identically equal to zero. On the other hand, the right-hand side, which is a Bernoulli equation for A, is also identically equal to zero, since the quantity A given in (4.41) is the general solution of this Bernoulli equation.

Furthermore, the same set of equations (4.41), together with the third part of (4.40), must be the solution of the Abel equation (4.6), which in the $(\overline{\xi},\overline{H})$–coordinates can be written as

$$(\overline{H}+1)\overline{H}'_{\overline{\xi}} = -\overline{H}^2 + 1 + 4Fe^{-\overline{\xi}}. \tag{4.43}$$

Introducing (4.41) into (4.43), we obtain

$$(\overline{N}-\tfrac{2}{3}+1)\overline{N}'_{\overline{\xi}} + (\overline{N}-\tfrac{2}{3})^2 - 1 - 4Fe^{-\overline{\xi}} = -(\overline{N}-\tfrac{2}{3}+1)A'_{\overline{\xi}} - A(\overline{N}'_{\overline{\xi}} + A'_{\overline{\xi}}) - A^2 - 2(\overline{N}-\tfrac{2}{3})A. \tag{4.44}$$

The left-hand side of this equation is identically equal to zero, since, by means of the third part of Eqs. (4.40), the cubic form (4.20) results. Thus, the right-hand side becomes

$$(\overline{N}-\tfrac{2}{3}+A+1)A'_{\overline{\xi}} + A\overline{N}'_{\overline{\xi}} + A^2 + 2(\overline{N}-\tfrac{2}{3})A = 0,$$

which, by way of the second part of (4.40), yields the equation

$$(\overline{N}-\tfrac{2}{3}+A+1)A'_{\overline{\xi}} + A^2 + \left[2\left(\overline{N}-\frac{2}{3}\right) + \frac{4(G+2F)e^{-\overline{\xi}}}{\overline{N}+\dfrac{4}{3}}\right]A = 0. \tag{4.45}$$

Introducing $A'_{\overline{\xi}}$ by means of (4.42), taking into account substitution (4.21), and manipulating accordingly, we extract the following cubic equation for $[1+\overline{N}(x)]$:

$$2(1+N)^{3/2} + (3A-4)(1+N) + (A^2-4A)(1+N)^{1/2} + 4(G+2F)e^{-\overline{\xi}} = 0. \tag{4.46}$$

Both cubic equations (4.20) and (4.46) are sufficient for the elimination of N and the evaluation of the subsidiary unknown function G in terms of the second member F of the original Abel equation (4.4), a fact that also ensures the general solution of this Abel equation. But, since Eq. (4.46) is a strongly nonlinear integral equation, this elimination seems to be in general impossible.

However, for the elimination of the function G and thus the construction of an exact analytic solution of the original Abel equation (4.4), one defines a functional relation by the following procedure. We seek a solution for the Riccati equation (4.38) such that

$$\lim_{\overline{\xi}\to+\infty} \overline{H}_{\mathbb{R}}(\overline{\xi}) = \lim_{\overline{\xi}\to+\infty} [\overline{N}(\overline{\xi}) - \tfrac{2}{3}]; \quad \lim_{\overline{\xi}\to-\infty} \overline{H}_{\mathbb{R}}(\overline{\xi}) = \lim_{\overline{\xi}\to-\infty} [\overline{N}(\overline{\xi}) - \tfrac{2}{3}]. \tag{4.47}$$

These assertions by way of (4.40) ensure the equations

$$\lim_{\overline{\xi}\to+\infty} \int_0^{\overline{\xi}} \varphi'_{\overline{\xi}} d\overline{\xi} = 0, \quad \lim_{\overline{\xi}\to-\infty} \int_0^{\overline{\xi}} \varphi'_{\overline{\xi}} d\overline{\xi} = 0,$$

that is, the equation

$$\int_{-\infty}^{+\infty} \varphi'_{\overline{\xi}} d\overline{\xi} = 0. \tag{4.48}$$

It is also well known [see Ref. 15, p. 406 (3.722.8)], that

$$\int_{-\infty}^{+\infty} \frac{\cos(a\overline{\xi})}{\beta - \overline{\xi}} = \pi \sin(a\beta), \quad a > 0.$$

Setting $a=1$ and $\beta=0$, the above integral becomes

$$\int_{-\infty}^{+\infty} -\frac{\cos\overline{\xi}}{\overline{\xi}}d\overline{\xi}=0. \tag{4.49}$$

Combination of (4.48) and (4.49) results in

$$\varphi'_{\overline{\xi}}=-\frac{\cos\overline{\xi}}{\overline{\xi}},$$

and thus [Ref. 15, p. 187 (2.641.2); p. 928 (8.23)], one defines

$$\varphi=\mathrm{ci}(\overline{\xi}),$$

$$\mathrm{ci}(\overline{\xi})=-\int_{\overline{\xi}}^{+\infty}\frac{\cos t}{t}dt=\mathbb{C}+\ln\overline{\xi}+\int_{0}^{\overline{\xi}}\frac{\cos t-1}{t}dt=\text{the cosine integral};$$

$$\mathrm{ci}(\overline{\xi})=\mathbb{C}+\ln\overline{\xi}+\sum_{\nu=1}^{\infty}(-1)^{\nu}\frac{\overline{\xi}^{2\nu}}{(2\nu)(2\nu)!};$$

$$\mathbb{C}=\text{Euler's constant}=0.577\ 215\ 664\ 901\ 532\ 5\ldots. \tag{4.50}$$

By Eqs. (4.50) and the second part of (4.40), one extracts the relation

$$2\int(\overline{N}-\tfrac{2}{3})d\overline{\xi}=\ln|\mathrm{ci}(\overline{\xi})|,$$

and thus defines the solution

$$\overline{N}-\frac{2}{3}=-\frac{1}{2}\frac{\cos\overline{\xi}}{\overline{\xi}\mathrm{ci}(\overline{\xi})}=\mathcal{F}(\overline{\xi}). \tag{4.51}$$

In addition, the general Riccati solution given by the first part of (4.40) becomes

$$\overline{H}_{\mathrm{R}}(\overline{\xi})=-\frac{1}{2}\frac{\cos\overline{\xi}}{\overline{\xi}\mathrm{ci}(\overline{\xi})}-\frac{\mathrm{ci}(\overline{\xi})}{C-\int\mathrm{ci}(\overline{\xi})d\overline{\xi}},$$

which, because [Ref. 15; p. 406 (3.722.7); p. 929 (8.235.2)]

$$\lim_{\overline{\xi}\to 0}\mathrm{ci}(\overline{\xi})=\mathrm{ci}(0)=-\infty,\quad \lim_{\overline{\xi}\to-\infty}\mathrm{ci}(\overline{\xi})=\pm\pi i,$$

$$\int\mathrm{ci}(\overline{\xi})d\overline{\xi}=\left[\mathbb{C}+\ln\overline{\xi}-1+\sum_{\nu=1}^{\infty}(-1)^{\nu}\frac{\overline{\xi}^{2\nu}}{(2\nu+1)(2\nu)(2\nu)!}\right]\overline{\xi},$$

satisfies the assertions (4.47).

By now, in order for the function $\overline{N}-2/3=\mathcal{F}(\overline{\xi})$ being defined in (4.51) to be a solution of the Riccati equation (4.38), and thus of the original Abel equation (4.4), the third part of Eqs. (4.40) must be also valid. Thus, we perform the equation

$$\frac{4(G+2F)e^{-\bar{\xi}}}{\bar{N}+\frac{4}{3}}=\frac{1}{2}\frac{\mathrm{ci}(\bar{\xi})(\bar{\xi}\sin\bar{\xi}+\cos\bar{\xi})+\cos^2\bar{\xi}}{[\bar{\xi}\mathrm{ci}(\bar{\xi})]^2}, \tag{4.52}$$

by means of which, introducing also the expression for $\bar{N}+4/3$, we evaluate the subsidiary function $G(\bar{\xi})$.

The above results complete the solution of the problem under consideration, that is the construction of the exact solution of the original Abel equation (4.4). Indeed, following the inverse course the above solution can be written as follows:

$$y(x)=\tfrac{1}{2}(x+2\lambda)[\bar{N}(x)+\tfrac{1}{3}],$$

$$4(G+2F)e^{-\bar{\xi}}=\frac{1}{4}\frac{[(\bar{\xi}\sin\bar{\xi}+\cos\bar{\xi})\overset{\star}{A}+\cos^2\bar{\xi}](4\bar{\xi}\overset{\star}{A}+\cos\bar{\xi})}{(\bar{\xi}\overset{\star}{A})^3};$$

$$\overset{\star}{A}(\bar{\xi})=\mathrm{ci}(\bar{\xi})=\text{the cosine integral};$$

$$\mathrm{ci}(\bar{\xi})=\mathbb{C}+\ln\,\xi+\int_0^{\bar{\xi}}\frac{\cos\,t-1}{t}dt=\mathbb{C}+\ln\bar{\xi}+\sum_{\nu=1}^{\infty}(-1)^{\nu}\frac{\bar{\xi}^{2\nu}}{(2\nu)(2\nu)!};$$

$$\bar{\xi}=\ln|x+2\lambda|\Rightarrow d\bar{\xi}=\frac{1}{x+2\lambda}dx;$$

$$\bar{N}(x)\text{ as in Eqs. (4.25) to (4.27);}$$

$$\lambda=\text{integration constant}. \tag{4.53}$$

V. EXACT ANALYTIC SOLUTIONS OF THE BLASIUS EQUATION

For simplicity and without loss of generality, we choose to extract the implicit analytic solution of the simplified Blasius equation (3.20) emphasizing that the same exactly mathematical procedure can be followed in the case of the restricted form of the generalized Blasius equation (3.6). According to the solution methodology developed in Sec. IV [formulas (4.53)], as well as in Eqs. (3.31) and (3.29), the solution of the Abel equation (3.28) can be written in exact analytic form as follows:

$$\overset{\star}{v}(\overset{\star}{z})=r(\overset{\star}{z})+\overset{\star}{z}-1=\overset{\star}{z}-1+\tfrac{1}{2}[\bar{N}(\overset{\star}{z})+\tfrac{1}{3}](2\,\ln|\overset{\star}{z}|-\tfrac{3}{2}\overset{\star}{z}+2\lambda);$$

$$4\left[G(\bar{\xi})+2\frac{F_0}{F_1}\right]e^{-\bar{\xi}}=\frac{1}{4}\frac{[(\bar{\xi}\sin\bar{\xi}+\cos\bar{\xi})\overset{\star}{A}+\cos^2\bar{\xi}](4\overset{\star}{A}\bar{\xi}+\cos\bar{\xi})}{(\bar{\xi}\overset{\star}{A})^3};$$

$$\bar{\xi}=\ln\left|2\,\ln\left|\frac{\overset{\star}{z}}{2}\right|-\frac{3}{2}\overset{\star}{z}+2\lambda\right|,\quad \overset{\star}{A}=\mathrm{ci}(\bar{\xi})=\text{the cosine integral};$$

$$\frac{F_0}{F_1}=\frac{(\overset{\star}{z}-1)(4-\overset{\star}{z})}{4-3\overset{\star}{z}},\quad \lambda=\text{integration constant}. \tag{5.1}$$

Here, $\overline{N}(\overset{\star}{z})$ is given in terms of $G(\overset{\star}{z})$ by the formulas (4.23) and (4.25)–(4.27). In order to define the type of the function $\overline{N}(\overset{\star}{z})$ which must be chosen among Eqs. (4.25)–(4.27), as well as to define the function $G(\overset{\star}{z})$ and the constant of integration λ, we must combine the above Abel equation (3.28) with the original Emden–Fowler equation (3.21) through the transformation (3.27) and the boundary data of the problem under consideration. Thus, we have the following conditions:

1st boundary condition: for $y_1\to\infty$, $\xi_1\to 0$.

By the second part of (3.27) we obtain

$$\lim_{\substack{y\to\infty\\ \xi_1\to 0}}\frac{y^2}{\sqrt{\xi}}=\lim_{\substack{y_1\to\infty\\ \xi_1\to 0}}\frac{\overset{\star}{v}_1}{A}=\infty\Rightarrow \overset{\star}{v}_1\to\infty.$$

As $\overset{\star}{v}_1\to\infty$, from substitution of (3.29) it follows that $r_1\to\infty$, and thus the Abel equation (3.30) permits us to write

$$(r'_{\overset{\star}{z}_1}-F_{1,1})r_1=F_{0,1}\Rightarrow \text{for } r_1\to\infty,\quad F_{0,1}\to\infty.$$

But, since $F_{0,1}=(\overset{\star}{z}_1-1)(4-\overset{\star}{z}_1)/2\overset{\star}{z}_1$, we have that for $F_{0,1}\to\infty$, $\overset{\star}{z}_1\to 0$.

2nd boundary condition: for $y_0=\alpha_1$, $\xi_0=\beta_1^2/2$, $\overset{\star}{v}_0=\sqrt{2}\alpha_1^2A/\beta_1$, $\overset{\star}{z}_0=$unknown.

The first boundary condition, that is to say

$$\text{for } y_1\to\infty,\quad \xi_1\to 0 \text{ and } \overset{\star}{z}_1\to 0,$$

insures the type of the function $\overline{N}(\overset{\star}{z}_1)$. In fact, by Eqs. (4.23) we estimate $b=3, c=0, p=-7/3, q=-116/3$, and thus we conclude that the discriminant $Q(\overset{\star}{z}_1)$, Eq. (4.24) , becomes positive $(Q(\overset{\star}{z}_1)=(-7/9)^3+(116/3)^2)$. This means that the form of $\overline{N}(\overset{\star}{z}_1)$ is expressed by Eq. (4.26).

Based on the above observations, one distinguishes the following two cases concerning the solution of the intermediate Emden–Fowler equation (3.21).

Case a:

This case corresponds to a unique solution of Eq. (3.21) inside the main interval $y\in(+\infty,\alpha_1]$, $\xi\in[0,\beta_1^2/2]$, that is to say to a unique solution of the Blasius equation (3.20). Thus, if the solution is unique, then the solution of the Abel equation (3.28) is expressed by Eqs. (5.1), where $\overline{N}(\overset{\star}{z})$ is given by (4.26). In addition, the solution of the Emden–Fowler equation (3.21) is expressed parametrically by Eqs. (3.37), in which $\overset{\star}{v}(\overset{\star}{z})$ is the already constructed solution given in (5.1). For the evaluation of the two constants of integration λ and C, we apply the second of the prescribed boundary conditions, that is to say the boundary condition

$$\text{for } y_0=\alpha_1,\quad \xi_0=\beta_1^2/2 \text{ and } \overset{\star}{v}_0=\sqrt{2}\alpha_1^2A/\beta_1.$$

Applying these conditions on Eqs. (5.1) and (3.37), we perform the following:

$$\frac{\sqrt{2}\alpha_1^2A}{\beta_1}=\overset{\star}{z}_0-1+\frac{1}{2}\left[\overline{N}(\overset{\star}{z}_0)+\frac{1}{3}\right]\left(2\ln|\overset{\star}{z}_0|-\frac{3}{2}\overset{\star}{z}_0+2\lambda\right),$$

$$4\left[G(\bar{\xi}_0)+2\frac{F_0}{F_1}\bigg|_{\overset{\star}{z}_0}e^{-\bar{\xi}_0}=\frac{1}{4}\frac{[(\bar{\xi}_0\sin\bar{\xi}_0+\cos\bar{\xi}_0)\overset{\star}{A}_0+\cos^2\bar{\xi}_0](4\overset{\star}{A}_0\bar{\xi}_0+\cos\bar{\xi}_0)}{(\bar{\xi}_0\overset{\star}{A}_0)^3},\right.$$

$$\frac{\beta_1^2}{2}=\exp[C+R(\overset{\star}{z}_0)],$$

$$\alpha_1=\pm\frac{\overset{\star}{\nu}{}^{1/2}(\overset{\star}{z}_0)}{A^{1/2}}\{\exp[C+R(\overset{\star}{z}_0)]\}^{1/4} \tag{5.2}$$

where

$$R(\overset{\star}{z}_0)=\int\frac{d\overset{\star}{z}}{\overset{\star}{\nu}(\overset{\star}{z})-\overset{\star}{z}+1}\Bigg|_{\overset{\star}{z}_0},\quad \bar{\xi}_0=\ln\left|2\ln\left|\frac{\overset{\star}{z}_0}{2}\right|-\frac{3}{2}\overset{\star}{z}_0+2\lambda\right|,\quad \overset{\star}{A}_0=\mathrm{ci}(\bar{\xi}_0),$$

$$\frac{F_0}{F_1}\bigg|_{\overset{\star}{z}_0}=\frac{(\overset{\star}{z}_0-1)(4-\overset{\star}{z}_0)}{4-3\overset{\star}{z}_0}. \tag{5.3}$$

In the above equations $\overset{\star}{\nu}(\overset{\star}{z})$ is given by the first of Eqs. (5.1), and $\bar{N}(\overset{\star}{z}_0)$ by Eq. (4.26).

Equations (5.2) consist of a strongly nonlinear (transcendental) system of four equations including five unknown parameters, that is, the parameters $\overset{\star}{z}_0; G(\overset{\star}{z}_0); \lambda; C$, and $R(\overset{\star}{z}_0)$. Thus, one more relation must be added for the estimation of the above five parameters. This relation is the cubic equation (4.22) at $\overset{\star}{z}=\overset{\star}{z}_0$.

The above-mentioned calculations permit us to construct the solution of the reduced Emden–Fowler equation (3.21), that is, the solution of the problem under consideration in the phase plane. The solution to the original Blasius equation (3.20) can be obtained by way of Eqs. (3.38) in combination with the third boundary condition $(y_x'(0)=\beta_1)$, indispensable for the evaluation of the third constant of integration $\overset{\star}{C}$ being introduced in (3.38).

Case b:

The solution of the intermediate Emden–Fowler equation (3.21) is not unique inside the main interval $y\in(+\infty,\alpha_1]; \xi\in[0,\beta_1^2/2]$, but it can be divided into several branches of solutions valid separately inside consecutive subintervals $y^{(n-1)}\in(y_n=+\infty,y_{n-1}), y^{(n-2)}\in[y_{n-1},y_{n-2}),\ldots,\quad y^{(0)}\in[y_1,y_0=\alpha_1];\quad \xi^{(n-1)}\in[\xi_n=0,\xi_{n-1}),\quad \xi^{(n-2)}\in[\xi_{n-1},\xi_{n-2}),\ldots,\quad \xi^{(0)}\in[\xi_1,\xi_0=\beta_1^2/2]$. Here, the superscript in parentheses denotes quantity inside the corresponding subinterval.

For simplicity, and without loss of generality, we assume two branches of solutions valid inside two consecutive subintervals $(y_2=+\infty,y_1),\quad [y_1,y_0=\alpha_1]$; and $[\xi_2=0,\xi_1),\quad [\xi_1,\xi_0=\beta_1^2/2]$. In each pair $\{+\infty,\xi_2\},\{y_1,\xi_1\}$, and $\{\alpha_1,\beta_1^2/2\}$ correspond three concrete values $\overset{\star}{z}_2$, $\overset{\star}{z}_1$, and $\overset{\star}{z}_0$ of the parameter $\overset{\star}{z}$, respectively. We note also that in each of the above subintervals two constants of integration $\lambda^{(1)}$ and $\lambda^{(0)}$, as well as two subsidiary determinable functions $G^{(1)}(\overset{\star}{z})$ and $G^{(0)}(\overset{\star}{z})$ exist, being introduced separately by the corresponding solutions of two Abel equations of the type (3.28). The same conclusion results for the parametric solutions (3.37) of two Emden–Fowler equations of the type (3.21) valid separately in the above subintervals and introducing two constants of integration $C^{(1)}$ and $C^{(0)}$, as well as two integrands $(1/(\overset{\star}{\nu}{}^{(1)}(\overset{\star}{z})-\overset{\star}{z}+1))$ and $(1/(\overset{\star}{\nu}{}^{(0)}(\overset{\star}{z})$

$-(\overset{\star}{z})+1))$. Thus, the whole problem is focused on the determination of the before-mentioned concrete values $\xi_1, y_1, \overset{\star}{z}_1$, as well as on the kind of solutions valid inside of each of the above discrete subintervals.

The first boundary condition, that is to say

$$\text{for } y_2 \to \infty, \quad \xi_2 \to 0, \quad \overset{\star}{z}_2 \to 0 \quad (\overset{\star}{v}{}^{(2)} \to \infty),$$

insures only that the discriminant $Q^{(1)}(\overset{\star}{z}{}^{(1)})$ is positive. This means that the solution $\overline{N}^{(1)}(\overset{\star}{z}{}^{(1)})$ valid inside the first subinterval $(y_2=\infty, y_1);[\xi_2=0, \xi_1)$ is given by Eq. (4.26). In other words, in the first subinterval we admit the following solution of the Abel equation (3.28):

$$\overset{\star}{v}{}^{(1)}(\overset{\star}{z}{}^{(1)}) = \overset{\star}{z}{}^{(1)} - 1 + \frac{1}{2}\left[\overline{N}^{(1)}\left(\overset{\star}{z}{}^{(1)} + \frac{1}{3}\right)\right]\left(2\ \ln|\overset{\star}{z}{}^{(1)}| - \frac{3}{2}\overset{\star}{z}{}^{(1)} + 2\lambda^{(1)}\right),$$

$$4\left[G(\overline{\xi}^{(1)}) + 2\frac{F_0}{F_1}\right]e^{-\overline{\xi}^{(1)}} = \frac{1}{4}\frac{[(\overline{\xi}^{(1)}\sin\ \overline{\xi}^{(1)} + \cos\ \overline{\xi}^{(1)})\overset{\star}{A}{}^{(1)} + \cos^2\ \overline{\xi}^{(1)}](4\overset{\star}{A}{}^{(1)}\overline{\xi}^{(1)} + \cos\ \overline{\xi}^{(1)})}{(\overline{\xi}^{(1)}\overset{\star}{A}{}^{(1)})^3},$$

$$\overline{\xi}^{(1)} = \ln\left|2\ \ln\ \left|\frac{\overset{\star}{z}{}^{(1)}}{2}\right| - \frac{3}{2}\overset{\star}{z}{}^{(1)} + 2\lambda^{(1)}\right|, \quad \overset{\star}{A}{}^{(1)} = \mathrm{ci}(\overline{\xi}^{(1)}),$$

$$\left.\frac{F_0}{F_1}\right|_{\overset{\star}{z}{}^{(1)}} = \frac{(\overset{\star}{z}{}^{(1)} - 1)(4 - \overset{\star}{z}{}^{(1)})}{4 - 3\overset{\star}{z}{}^{(1)}}, \tag{5.4}$$

where $\overline{N}^{(1)}(\overset{\star}{z}{}^{(1)})$ as in Eq. (4.26) and $\overset{\star}{z}{}^{(1)} \in (+\infty, \overset{\star}{z}_1)$.

Similarly, the solution of the corresponding Emden–Fowler equation (3.21) in the above subinterval is given parametrically as follows:

$$\xi^{(1)} = \exp(C^{(1)} + R^{(1)}(\overset{\star}{z}{}^{(1)}));$$

$$y^{(1)} = \pm\frac{\overset{\star}{v}{}^{(1)^{1/2}}(\overset{\star}{z}{}^{(1)})}{A^{1/2}}[\exp(C^{(1)} + R^{(1)}(\overset{\star}{z}{}^{(1)}))]^{1/4};$$

$$\overset{\star}{v}{}^{(1)}(\overset{\star}{z}{}^{(1)}) \text{ as in Eqs.(5.3);}$$

$$R^{(1)}(\overset{\star}{z}{}^{(1)}) = \int \frac{d\overset{\star}{z}{}^{(1)}}{\overset{\star}{v}{}^{(1)}(\overset{\star}{z}{}^{(1)}) - \overset{\star}{z}{}^{(1)} + 1}. \tag{5.5}$$

At the concrete unknown value $\overset{\star}{z}{}^{(1)} = \overset{\star}{z}_1$, where the solution changes, the continuity and the smoothness demand the validity of the following equations:

$$\overline{N}^{(1)}(\overset{\star}{z}_1) = \overline{N}^{(0)}(\overset{\star}{z}_1), \quad \overset{\star}{v}{}^{(1)}(\overset{\star}{z}_1) = \overset{\star}{v}{}^{(0)}(\overset{\star}{z}_1), \quad \overset{\star}{v}{}_{\star}^{\prime(1)}(\overset{\star}{z}_1) = \overset{\star}{v}{}_{\star}^{\prime(0)}(\overset{\star}{z}_1). \tag{5.6}$$

We emphasize that $\overline{N}^{(0)}(\overset{\star}{z}{}^{(0)})$, $\overset{\star}{v}{}^{(0)}(\overset{\star}{z}{}^{(0)})$, and $\overset{\star}{v}{}_z^{\prime(0)}(\overset{\star}{z}{}^{(0)})$ denote the corresponding quantities valid inside the second subinterval $[y_1, y_0=\alpha_1];[\xi_1, \xi_0=\beta_1^2/2]$ and including one new constant of inte-

gration $\lambda^{(0)}$, as well as a determinable function $G^{(0)}(\overset{\star}{z}{}^{(0)})$ (in terms of the unknown expression $\overline{N}^{(0)}(\overset{\star}{z}{}^{(0)})$). The expression for $\overline{N}^{(0)}(\overset{\star}{z}{}^{(0)})$ must be selected between formulas (4.25)–(4.27), while the solution for $\overset{\star}{v}{}^{(0)}(\overset{\star}{z}{}^{(0)}), G^{(0)}(\overset{\star}{z}{}^{(0)})$ is given by Eqs. (5.1) where, instead of $\lambda^{(1)}$ and $\overline{N}^{(1)}(\overset{\star}{z}{}^{(1)})$, the new expressions $\lambda^{(0)}$ and $\overline{N}^{(0)}(\overset{\star}{z}{}^{(0)})$ must be introduced.

Similarly, the continuity and the smoothness of the solution at $\overset{\star}{z}{}^{(0)}=\overset{\star}{z}_1$ demand the validity of the following two equations:

$$\xi_1^{(1)} = \xi_1^{(0)}, \quad y_1^{(1)} = y_1^{(0)}, \tag{5.7}$$

in which $\xi_1^{(1)}$ and $y_1^{(1)}$ as in Eqs. (5.5), and

$$\xi_1^{(0)} = \exp(C^{(0)} + R_1^{(0)}(\overset{\star}{z}_1));$$

$$y_1^{(0)} = \pm \frac{\overset{\star}{v}{}_1^{(0)1/2}(\overset{\star}{z}_1)}{A^{1/2}}[\exp(C^{(0)} + R_1^{(0)}(\overset{\star}{z}_1))]^{1/4};$$

$\overset{\star}{v}{}_1^{(0)}(\overset{\star}{z}_1)$ as in Eqs.(5.4) for $\overset{\star}{z}{}^{(0)} = \overset{\star}{z}_1$with $\lambda^{(0)}$ and $\overline{N}^{(0)}(\overset{\star}{z}{}^{(0)})$;

$$R_1^{(0)}(\overset{\star}{z}_1) = \left[\int \frac{d\overset{\star}{z}{}^{(0)}}{\overset{\star}{v}{}^{(0)}(\overset{\star}{z}{}^{(0)}) - \overset{\star}{z}{}^{(0)} + 1}\right]\Bigg|_{\overset{\star}{z}{}^{(0)}=\overset{\star}{z}_1}. \tag{5.8}$$

The five equations (5.6) and (5.7) introduce nine unknowns $\lambda^{(1)}, \overline{N}^{(1)}(\overset{\star}{z}_1), \lambda^{(0)}$, $\overline{N}^{(0)}(\overset{\star}{z}_1)$, $R_1^{(1)}, R_1^{(0)}, \overset{\star}{z}_1, C^{(1)}$, and $C^{(0)}$. Four additional equations of the types (5.1) and (3.37) hold true at $\overset{\star}{z}{}^{(0)}=\overset{\star}{z}_0$, that is to say at the point $y^{(0)}=y_0=\alpha_1$ and $\xi^{(0)}=\xi_0=\beta_1^2/2$, namely

$$\frac{\sqrt{2}\alpha_1^2 A}{\beta_1} = \overset{\star}{z}_0 - 1 + \frac{1}{2}\left[\overline{N}^{(0)}(\overset{\star}{z}_0) + \frac{1}{3}\right]\left(2\ \ln|\overset{\star}{z}_0| = \frac{3}{2}\overset{\star}{z}_0 + 2\lambda^{(0)}\right);$$

$$4\left[G(\overline{\xi}_0) + 2\ \frac{F_0}{F_1}\Bigg|_{\overset{\star}{z}_0}\right]e^{-\overline{\xi}_0} = \frac{1}{4}\frac{[(\overline{\xi}_0\ \sin\ \overline{\xi}_0 + \cos\ \overline{\xi}_0)\overset{\star}{A}_0 + \cos^2\ \overline{\xi}_0](4\overset{\star}{A}_0\overline{\xi}_0 - \cos\ \overline{\xi}_0)}{(\overline{\xi}_0\overset{\star}{A}_0)^3},$$

$$\frac{\beta_1^2}{2} = \left(\exp\left[C^{(0)} + \int \frac{d\overset{\star}{z}{}^{(0)}}{\overset{\star}{v}{}^{(0)}(\overset{\star}{z})^{(0)} - \overset{\star}{z}{}^{(0)} + 1}\right]\right)\Bigg|_{\overset{\star}{z}{}^{(0)}=\overset{\star}{z}_0};$$

$$a_1 = \pm \frac{\overset{\star}{v}{}^{(0)1/2}(\overset{\star}{z}_0)}{A^{1/2}} \left(\exp\left[C^{(0)} + \int \frac{d\overset{\star}{z}{}^{(0)}}{\overset{\star}{v}{}^{(0)}(\overset{\star}{z}{}^{(0)}) - \overset{\star}{z}{}^{(0)} + 1}\right]^{1/4}\right)\Bigg|_{\overset{\star}{z}{}^{(0)}=\overset{\star}{z}_0}. \tag{5.9}$$

These equations introduce the new fixed parameter $\overset{\star}{z}_0$, as well as the new integrand value

$$R_0^{(0)} \equiv \left[\int \frac{dz^{\overset{\star}{(0)}}}{\upsilon^{\overset{\star}{(0)}}(\overset{\star}{z}^{(0)}) - z^{\overset{\star}{(0)}} + 1} \right]\Bigg|_{\overset{\star}{z}^{(0)}=\overset{\star}{z}_1}.$$

Thus, a nonlinear (transcendental) system of nine equations (5.6), (5.7), and (5.9) with 11 unknowns $\lambda^{(1)}, \lambda^{(0)}, \overline{N}^{(1)}(\overset{\star}{z}_1), \overline{N}^{(0)}(\overset{\star}{z}_1), R_1^{(1)}(\overset{\star}{z}_1), \quad R_1^{(0)}(\overset{\star}{z}_1), R_0^{(0)}(\overset{\star}{z}_0), C^{(1)}, C^{(0)}, \overset{\star}{z}_1$, and $\overset{\star}{z}_0$ results, which must be enriched by two additional cubic equations of the type (4.22) valid at $\overset{\star}{z}=\overset{\star}{z}_1$ and $\overset{\star}{z}=\overset{\star}{z}_0$. The solution of the above system furnishes all the unknown parameters of the problem under consideration.

The prescribed analysis can be extended to cases of several branches of different solutions valid inside several consecutive subintervals demanding successive solutions of strongly nonlinear (transcendental) systems of the type (5.6), (5.7), and (5.9).

VI. CONCLUSIONS

Through a series of admissible functional transformations, we reduced the generalized Blasius equation in fluids to a three-term generalized Emden–Fowler equation. In addition, the restricted and the simplified forms of this equation were reduced to (i) a two-term generalized Emden–Fowler's equation; (ii) Emden–Fowler's equations of the normal form; and (iii) Abel's equations of the second kind.

By a mathematical solution methodology concerning the construction of exact analytic solutions of the Abel equation of the second kind of the normal form, we succeeded in constructing exact analytic solutions for the simplified as well as for the restricted form of the generalized Blasius equation in axisymmetric flows. Thus, important unsolvable in exact form problems in nonlinear mechanics, such as manufacturing of polymer and metal sheets, cooling of an infinite metallic plate, boundary layer along a liquid film in condensation process, thermal capillary flow in viscous layer, etc., now can be analytically solved.

The mathematical methodology introduced is general and can be applied to a wide class of unsolvable nonlinear ODEs in mathematical physics and nonlinear mechanics.

Uniform estimates on the velocity in Rayleigh–Bénard convection

Manuel Núñez[a)]
Departamento de Análisis Matemático, Universidad de Valladolid, 47005 Valladolid, Spain

(Received 17 March 2004; accepted 23 November 2004; published online 8 February 2005)

The kinetic energy of a fluid located between two plates at different temperatures is easily bounded by classical inequalities. However, experiments and numerical simulations indicate that when the convection is turbulent, the volume of the domains in which the speed is large, is rather small. This could imply that the maximum of the speed, in contrast with its quadratic mean, does not admit an *a priori* upper bound. It is proved that, provided the pressure remains bounded, a uniform estimate for the speed maximum does indeed exist, and that it depends on the maxima of certain ratios between temperature, pressure, and velocity. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1855400]

I. INTRODUCTION

The study of thermal convection of a fluid powered by the difference of temperature between two plates, known as Rayleigh–Bénard convection, has been an extensively studied subject for a long time. Computer modeling and physical experiments have produced an enormous wealth of information: for recent reviews, see Refs. 1 and 2. Perhaps unavoidably, there has not been a comparable volume of rigorous studies, if we except the study of the stability of different patterns (Ref. 3, pp. 23–95). It is well known that when the difference of temperature between the top and bottom plates exceeds a certain amount, usually measured in terms of the Rayleigh constant R, convection sets in. Near the onset, convection cells occur; with increasing R, and depending also on the ratio between viscosity and thermal diffusivity (the Prandtl number) more complex patterns appear and bifurcations to chaotic states may occur. The same may be said of the temperature: for a colorful illustration, starting with regular rolls, see e.g., Ref. 4.

The standard mathematical model of Reyleigh–Bénard convection is given by the Boussinesq approximation to the equations of motion, which we repeat here for convenience. We will consider a d-dimensional domain U of the form $\Omega\times[0,h]$, and as usual we will assume that the temperature is constant at the lower and upper lids, $T=T_0$ at $\Omega\times\{0\}$ and $T=T_h<T_0$ at $\Omega\times\{h\}$. The rest of the boundary conditions will be discussed later. Let us denote by $\mathbf{v}$ the fluid velocity, T the temperature, ν the kinematic viscosity, κ the thermal diffusivity, and π the kinetic pressure. Then the nondimensionalized Boussinesq approximation (see, e.g., Ref. 5) to the equations of motion is

$$\frac{\partial \mathbf{v}}{\partial t}=\nu\Delta\mathbf{v}-\mathbf{v}\cdot\nabla\mathbf{v}-\nabla\pi+(T-T_h)\mathbf{e}_d, \tag{1}$$

$$\frac{\partial T}{\partial t}=\kappa\Delta T-\mathbf{v}\cdot\nabla T, \tag{2}$$

[a)]Electronic mail: mnjmhd@am.uva.es

$$\nabla \cdot \mathbf{v} = 0. \tag{3}$$

$\mathbf{e}_d$ denotes the vertical unit vector. Traditionally the difference θ of the actual temperature with the linear one between the lids (associated to pure heat conduction) is used,

$$\theta = T - T_0 + \beta x_d, \qquad \beta = \frac{T_0 - T_h}{h}. \tag{4}$$

π is also changed to $\pi + \beta x_d^2/2 - (T_0 - T_h)x_d$ (which we denote again by π). The final system is

$$\frac{\partial \mathbf{v}}{\partial t} = \nu \Delta \mathbf{v} - \mathbf{v} \cdot \nabla \mathbf{v} - \nabla \pi + \theta \mathbf{e}_d, \tag{5}$$

$$\frac{\partial \theta}{\partial t} = \kappa \Delta \theta - \mathbf{v} \cdot \nabla \theta + \beta v_d, \tag{6}$$

$$\nabla \cdot \mathbf{v} = 0. \tag{7}$$

Boundary conditions are usually the following ones: the upper and lower plates are taken either rigid, where we assume a no-slip condition and $\mathbf{v}$ vanishes there, or stress free, in which case $v_d = 0$ and the vertical derivatives of the remaining components of the velocity are also zero, $\partial_d v_i = 0$. The lateral walls are assumed rigid and conducting, so that $\mathbf{v}$ and θ vanish there.

Let us state some classical results, since T satisfies (2), which is a scalar parabolic equation without terms in T, it also satisfies the maximum and minimum principles (see, e.g., Ref. 6). That means that T lies always between T_0 and T_h, which makes excellent physical sense. Therefore θ is uniformly bounded. By multiplying (5) by $\mathbf{v}$, integrating in U and making use of the boundary conditions, one gets

$$\frac{1}{2}\frac{d}{dt}\int_U v^2 \, dV + \nu \int_U |\nabla \mathbf{v}|^2 \, dV = \int_U \theta v_d \, dV \leqslant \|\theta\|_\infty \, \mathrm{Vol}(U)^2 \|v_d\|_2, \tag{8}$$

where $\mathrm{Vol}(U)$ denotes the volume (area in dimension two) of U. Since with our boundary conditions a Poincaré inequality holds, there exists a positive constant c such that

$$c \int_U |v^2| dV \leqslant \int_U |\nabla \mathbf{v}|^2 \, dV.$$

Thus, by standard inequalities,

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{v}\|_2^2 + \frac{\nu c}{2}\|\mathbf{v}\|_2^2 \leqslant \frac{1}{2\nu^2 c^2}\|\theta\|_\infty^2 \, \mathrm{Vol}(U), \tag{9}$$

which implies that $\|\mathbf{v}\|_2$ is bounded for all time.

As in many other turbulent situations, modeling of the chaotic phase of convection shows a tendency of the flow to concentrate the velocity in regions of small volume.[7] Thus the boundedness of the kinetic energy does not provide an *a priori* bound upon the maximum of the speed. It is true that physically it seems obvious that this maximum cannot grow without limit, but nevertheless it is interesting to obtain rigorous estimates in terms of the main magnitudes of the

problem. Our only hypothesis will be the boundedness of the pressure π [or, to be specific, of $\pi/(1+v)$].

II. ANALYSIS OF THE MOMENTS OF THE VELOCITY

Let us start with the momentum equation

$$\frac{\partial \mathbf{v}}{\partial t} = \nu \Delta \mathbf{v} - \mathbf{v} \cdot \nabla \mathbf{v} - \nabla \pi + \theta \mathbf{e}_d, \tag{10}$$

and for $p=1,2\ldots$, let

$$F_p = \int_U v^p \, \mathrm{d}V, \tag{11}$$

where $v=|\mathbf{v}|$ represents the modulus of $\mathbf{v}$. F_p is a function of time. Since $v^2=\mathbf{v}\cdot\mathbf{v}$,

$$\frac{\partial v^{2p}}{\partial t} = 2pv^{2p-2}\mathbf{v} \cdot \frac{\partial \mathbf{v}}{\partial t}.$$

Therefore

$$\frac{1}{2p}\dot{F}_{2p} = \int_U v^{2p-2}\mathbf{v} \cdot \frac{\partial \mathbf{v}}{\partial t} \mathrm{d}V,$$

and taking into account the momentum equation,

$$\frac{1}{2p}\dot{F}_{2p} = -\int_U v^{2p-2}(\mathbf{v} \cdot \nabla \mathbf{v}) \cdot \mathbf{v} \, \mathrm{d}V + \nu \int_U v^{2p-2}\mathbf{v} \cdot \Delta \mathbf{v} \, \mathrm{d}V + \int_U (\theta v^{2p-2} v_d - v^{2p-2}\mathbf{v} \cdot \nabla \pi) \mathrm{d}V. \tag{12}$$

In the first place,

$$\int_U v^{2p-2}(\mathbf{v} \cdot \nabla \mathbf{v}) \cdot \mathbf{v} \, \mathrm{d}V = \int_U \frac{1}{2p}\mathbf{v} \cdot \nabla v^{2p} \, \mathrm{d}V = 0. \tag{13}$$

As for the dissipative term,

$$\begin{aligned}\int_U v^{2p-2}\mathbf{v} \cdot \Delta \mathbf{v} \, \mathrm{d}V &= \int_U \sum_j (\nabla \cdot (v_j v^{2p-2} \nabla v_j) - \nabla v_j \cdot \nabla (v^{2p-2} v_j)) \mathrm{d}V \\ &= \frac{1}{2}\int_{\partial U} v^{2p-2}\frac{\partial v^2}{\partial n} \mathrm{d}\sigma - \int_U \left(v^{2p-2} |\nabla \mathbf{v}|^2 + \frac{p-1}{2} v^{2p-4} |\nabla v^2|^2 \right) \mathrm{d}V. \end{aligned} \tag{14}$$

It is understood that the last term (multiplied by $p-1$) vanishes when $p=1$; there are never negative powers of v. As for the boundary integral, it also vanishes, since $\partial v^2/\partial n$ vanishes in all the boundary, including possible stress-free surfaces.

The last term we must consider is

$$\int_U (\theta v^{2p-2} v_d - v^{2p-2}\mathbf{v}\cdot\nabla\pi)\mathrm{d}V. \tag{15}$$

Since

$$-\int_U v^{2p-2}\mathbf{v}\cdot\nabla\pi\,\mathrm{d}V = -\int_{\partial U} v^{2p-2}\pi\mathbf{v}\cdot\mathbf{n}\,\mathrm{d}\sigma + \int_U (p-1)\pi v^{2p-4}\mathbf{v}\cdot\nabla v^2\,\mathrm{d}V, \tag{16}$$

and again the boundary integral vanishes, the term in (16) is

$$\int_U (v^{2p-2}\theta v_d + (p-1)\pi v^{2p-4}\mathbf{v}\cdot\nabla v^2)\mathrm{d}V, \tag{17}$$

with the same meaning as before when $p=1$. We may bound (17) in several ways. We first choose

$$\begin{aligned}\left|\int_U v^{2p-2}\theta v_d + (p-1)\pi v^{2p-4}\mathbf{v}\cdot\nabla v^2\,\mathrm{d}V\right| &= \left|\int_U \frac{\theta}{1+v}(v_d v^{2p-2} + v_d v^{2p-1}) + (p-1)\frac{\pi}{1+v}(v^{2p-4}\right.\\ &\quad \left. + v^{2p-3})\mathbf{v}\cdot\nabla v^2\,\mathrm{d}V\right|\\ &\leqslant \left\|\frac{\theta}{1+v}\right\|_\infty \int_U (v^{2p-2}+v^{2p-1})|v_d|\mathrm{d}V + (p-1)\left\|\frac{\pi}{1+v}\right\|_\infty\\ &\quad \times\int_U (v^{2p-4}+v^{2p-3})|\mathbf{v}\cdot\nabla v^2|\mathrm{d}V\\ &\leqslant \left\|\frac{\theta}{1+v}\right\|_\infty \int_U (v^{2p-1}+v^{2p})\mathrm{d}V + (p-1)\left\|\frac{\pi}{1+v}\right\|_\infty\\ &\quad \times\int_U (v^{2p-3}+v^{2p-2})|\nabla v^2|\mathrm{d}V. \end{aligned}\tag{18}$$

From now on we will denote

$$\alpha = \left\|\frac{\theta}{1+v}\right\|_\infty,$$

$$\beta = \left\|\frac{\pi}{1+v}\right\|_\infty.$$

Notice that they are functions of t. Thus

$$\begin{aligned}\frac{1}{2p}\dot{F}_{2p} &\leqslant -\nu\int_U v^{2p-2}|\nabla\mathbf{v}|^2\,\mathrm{d}V - \frac{\nu(p-1)}{2}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V + \alpha\int_U (v^{2p-1}+v^{2p})\mathrm{d}V\\ &\quad + (p-1)\beta\int_U (v^{2p-3}+v^{2p-2})|\nabla v^2|\mathrm{d}V.\end{aligned}\tag{19}$$

For our first estimate we will not make use of the first dissipative term. We have

$$\alpha\int_U (v^{2p-2}+v^{2p-1})\mathrm{d}V \leqslant \alpha(F_{2p-1}+F_{2p}). \tag{20}$$

As for the second term, by using Cauchy–Schwarz and Young's inequalities,

$$(p-1)\beta\int_U (v^{p-1}+v^p)v^{p-2}|\nabla v^2|\mathrm{d}V \leqslant (p-1)\beta\left(\int_U (v^{p-1}+v^p)^2\,\mathrm{d}V\right)^{1/2}\left(\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V\right)^{1/2}$$
$$\leqslant (p-1)\beta^2\frac{1}{\nu}\int_U (v^{p-1}+v^p)^2\,\mathrm{d}V + \frac{(p-1)\nu}{4}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V$$
$$\leqslant (p-1)\beta^2\frac{2}{\nu}(F_{2p-2}+F_{2p}) + \frac{(p-1)\nu}{4}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V. \tag{21}$$

We have proved the recursive inequality

$$\frac{1}{2p}\dot{F}_{2p} \leqslant -\frac{\nu(p-1)}{4}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V + \alpha F_{2p-1} + \alpha F_{2p} + \frac{2(p-1)\beta^2}{\nu}F_{2p-2} + \frac{2(p-1)\beta^2}{\nu}F_{2p}. \tag{22}$$

We use now the fact that U has finite volume to bound all the F_k in terms of F_{2p},

$$F_{2p-2} \leqslant \mathrm{Vol}(U)^{1/p}F_{2p}^{1-1/p},$$
$$F_{2p-1} \leqslant \mathrm{Vol}(U)^{1/2p}F_{2p}^{1-1/2p}. \tag{23}$$

Let us begin studying a series of alternatives. It may happen

(A) $F_{2p}<1$. Otherwise,
(B) $F_{2p-2}\leqslant \mathrm{Vol}(U)^{1/p}F_{2p}$, $F_{2p-1}\leqslant \mathrm{Vol}(U)^{1/2p}F_{2p}$.

We will consider the consequences of alternative (B). We have

$$\frac{1}{2p}\dot{F}_{2p} + \frac{\nu(p-1)}{4}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V \leqslant \left(\alpha(1+m(U)^{1/2p}) + \frac{2(p-1)\beta^2}{\nu}(1+\mathrm{Vol}(U)^{1/p})\right)F_{2p}, \tag{24}$$

and if we call $k=1+\max\{\mathrm{Vol}(U),1\}$,

$$\frac{1}{2p}\dot{F}_{2p} + \frac{\nu(p-1)}{4}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V \leqslant k\left(\alpha + \frac{2(p-1)\beta^2}{\nu}\right)F_{2p}. \tag{25}$$

Let us now remember a particular case of the Gagliardo–Nirenberg inequality (Ref. 8, pp. 69 and 70). For any function $f\in H^1(U)$, there exists a constant C depending only on U such that

$$\|f\|_2^{d+2} \leqslant C(\|\nabla f\|_2 + \|f\|_1)^d\|f\|_1^2. \tag{26}$$

Since $(x+y)^d\leqslant 2^{d-1}(x^d+y^d)$, by taking $\lambda=\max\{2^{d-1}C,1\}$,

$$\|f\|_2^{d+2} \leqslant \lambda(\|\nabla f\|_2^d + \|f\|_1^d)\|f\|_1^2, \tag{27}$$

with $\lambda\geqslant 1$. Notice that for $f=v^p$,

$$\|f\|_2 = F_{2p}^{1/2}, \quad \|f\|_1 = F_p, \quad \nabla f = \frac{p}{2}v^{2p-2}\nabla v^2, \quad \|\nabla f\|_2^2 = \frac{p^2}{4}\int_U v^{2p-4}|\nabla v^2|^2\,\mathrm{d}V. \tag{28}$$

In the inequality (27), there exist two alternatives. Either

$$\text{(b1)} \quad \|f\|_2 < \lambda^{1/(d+2)}\|f\|_1, \tag{29}$$

or

$$\text{(b2)} \quad \|\nabla f\|_2^2 \geqslant \left(\frac{\|f\|_2^{d+2} - \lambda\|f\|_1^{d+2}}{\lambda\|f\|_1^2}\right)^{2/d}. \tag{30}$$

With our election of f, the first alternative means

$$F_{2p} < \lambda^{2/(d+2)}F_p^2. \tag{31}$$

Alternative (b2), when taken into (25), yields

$$\frac{1}{2p}\dot{F}_{2p} \leqslant -\frac{\nu(p-1)}{p^2}\left(\frac{F_{2p}^{(d+2)/2} - \lambda F_p^{d+2}}{\lambda F_p^2}\right)^{2/d} + k\left(\alpha + \frac{2(p-1)\beta^2}{\nu}\right)F_{2p}. \tag{32}$$

Take now, for $p \geqslant 2$,

$$\gamma_p = \lambda\left(1 + k^{d/2}\left(\frac{p^2}{\nu(p-1)}\right)^{d/2}\left(\alpha + \frac{2(p-1)\beta^2}{\nu}\right)^{d/2}\right). \tag{33}$$

Notice that $\gamma_p \geqslant \lambda \geqslant \lambda^{2/(d+2)} \geqslant 1$. A short calculation will convince us that if $F_{2p} > \gamma_p F_p^2$ and (b2) occurs, then $\dot{F}_{2p} \leqslant 0$. Since alternative (b1) is included in

$$\text{(B1)} \quad F_{2p} \leqslant \gamma_p F_p^2,$$

the remaining possibility is

$$\text{(B2)} \quad F_{2p} \leqslant 0.$$

Recall that all this assumes (B). Therefore the alternatives are (A) $F_{2p} \leqslant 1$, (B1) or (B2).

III. UNIFORM ESTIMATES IN TIME

Let us consider a time interval $[0,\tau]$, and let

$$\begin{aligned} \Phi_p(\tau) &= \max\{1, \max\{F_p(t): t \in [0,\tau]\}\} \\ \Gamma_p(\tau) &= \max\{\gamma_p(t): t \in [0,\tau]\}. \end{aligned} \tag{34}$$

For every $t \in [0,\tau]$ where (A) or (B1) occurs, certainly

$$F_{2p}(t) \leqslant \Gamma_p(\tau)\Phi_p(\tau)^2. \tag{35}$$

Now, if (35) occurs for every $t \in [0,\tau]$, obviously

$$\Phi_{2p}(\tau) \leqslant \Gamma_p(\tau)\Phi_p(\tau)^2. \tag{36}$$

The other possibility is that for a certain $t_1 \in [0,\tau]$,

$$F_{2p}(t_1) > \Gamma_p(\tau)\Phi_p(\tau)^2, \tag{37}$$

which implies that (B2) holds, i.e., $\dot{F}_{2p}(t_1) \leqslant 0$. Let $(t_0, t_1]$ be a maximal left interval where (37) occurs. We know that F_{2p} is decreasing there. If $t_0 > 0$, $F_{2p}(t_0) = \Gamma_p(\tau)\Phi_p(\tau)^2$, which, since $F_{2p}(t_1) \leqslant F_{2p}(t_0)$, contradicts our hypothesis. The only possibility is that (35) occurs nowhere, i.e., $t_0 = 0$. In that case, F_{2p} is decreasing in $[0,t_1]$ and therefore $F_{2p}(t_1) \leqslant F_{2p}(0)$. Thus, in every case

$$\Phi_{2p}(\tau) \leqslant \max\{\Gamma_p(\tau)\Phi_p(\tau)^2, F_{2p}(0)\}. \tag{38}$$

Since $\|\mathbf{v}(t)\|_p = F_p(t)^{1/p}$, if we denote

$$\phi_p(\tau) = \max\{1, \max\{\|\mathbf{v}(t)\|_p : t \in [0,\tau]\}\}, \tag{39}$$

the $2p$th root of (38) yields

$$\phi_{2p}(\tau) \leqslant \max\{\Gamma_p(\tau)^{1/2p}\phi_p(\tau), \|\mathbf{v}(0)\|_{2p}\}. \tag{40}$$

Hence

$$\begin{gathered}
\phi_4(\tau) \leqslant \max\{\Gamma_2(\tau)^{1/4}\phi_2(\tau),\ \|\mathbf{v}(0)\|_4\},\\
\phi_8(\tau) \leqslant \max\{\Gamma_4(\tau)^{1/8}\Gamma_2(\tau)^{1/4}\phi_2(\tau), \Gamma_4(\tau)^{1/8}\|\mathbf{v}(0)\|_4,\ \|\mathbf{v}(0)\|_8\}\cdots,\\
\phi_{2^n}(\tau) \leqslant \{\Gamma_{2^{n-1}}(\tau)^{1/2^n}\Gamma_{2^{n-2}}(\tau)^{1/2^{n-1}}\cdots\Gamma_2(\tau)^{1/4}\phi_2(\tau),\\
\Gamma_{2^{n-1}}(\tau)^{1/2^n}\Gamma_{2^{n-2}}(\tau)^{1/2^{n-1}}\cdots\Gamma_4(\tau)^{1/8}\|\mathbf{v}(0)\|_4\ldots,\ \|\mathbf{v}(0)\|_{2^n}.
\end{gathered} \tag{41}$$

Let us study the infinite product

$$\Gamma_2(\tau)^{1/4}\Gamma_4(\tau)^{1/8}\cdots\Gamma_{2^{n-1}}(\tau)^{1/2^n}\cdots. \tag{42}$$

Recall that

$$\alpha(t) = \left\|\frac{\theta(t)}{1+v(t)}\right\|_\infty, \quad \beta(t) = \left\|\frac{\pi(t)}{1+v(t)}\right\|_\infty. \tag{43}$$

Let us denote by $\overline{\alpha}(\tau)$, $\overline{\beta}(\tau)$ their respective maxima in $[0,\tau]$. By the expression in (33),

$$\begin{aligned}
\Gamma_{2^n}(\tau) &\leqslant \lambda\left(1 + k^{d/2}\left(\frac{2^{2n}}{\nu(2^n-1)}\right)^{d/2}\left(\overline{\alpha}(\tau) + \frac{2(2^n-1)}{\nu}\overline{\beta}(\tau)^2\right)^{d/2}\right)\\
&\leqslant \lambda\left(1 + \left(2^{2n+2}k\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2}\right)\right)^{d/2}\right) \leqslant \lambda\left(1 + \left(2^{2n+2}k\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2} + 1\right)\right)^{d/2}\right).
\end{aligned} \tag{44}$$

The addition of 1 to the parentheses is intended to ensure that

$$x = \left(2^{2n+2}k\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2} + 1\right)\right)^{d/2} \geqslant 1.$$

Since for those x, $\log(1+x) \leqslant 1 + \log x$ holds,

$$\log\Gamma_{2^n}(\tau) \leqslant \log\lambda + 1 + \frac{d}{2}\left(\log k + (2n+2)\log 2 + \log\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2} + 1\right)\right).$$

Hence the sum of the logarithms of Γ_{2^n} satisfies

$$\sum_{n=1}^{\infty}\frac{1}{2^{n+1}}\log\Gamma_{2^n}(\tau) \leqslant \frac{1}{2}\left(1 + \log\lambda + \frac{d}{2}\log k\right) + \frac{d}{2}\log 2\sum_{n=1}^{\infty}\frac{2n+2}{2^{n+1}} + \frac{d}{4}\log\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2} + 1\right). \tag{45}$$

Thus, since the sum of the series $\Sigma(2n+2)/2^{n+1}$ is 3,

$$\prod_{n=1}^{\infty}\Gamma_{2^n}(\tau)^{1/2^{n+1}} \leqslant 2^{3d/2}(\lambda e)^{1/2}k^{d/4}\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2} + 1\right)^{d/4}, \tag{46}$$

and the same may be said of any finite product

$$\prod_{n=1}^{m} \Gamma_{2^n}(\tau)^{1/2^{n+1}}. \tag{47}$$

Since, on the other hand,

$$\|\mathbf{v}(0)\|_p \leqslant \|\mathbf{v}(0)\|_\infty \operatorname{Vol}(U)^{1/p} \leqslant k\|\mathbf{v}(0)\|_\infty, \tag{48}$$

we find

$$\phi_{2^n}(\tau) \leqslant 2^{3d/2}(\lambda e)^{1/2}k^{d/4}\left(\frac{\overline{\alpha}(\tau)}{\nu} + \frac{\overline{\beta}(\tau)^2}{\nu^2} + 1\right)^{d/4} \max\{\phi_2(\tau), k\|\mathbf{v}(0)\|_\infty\}. \tag{49}$$

It is well known that $\|\mathbf{v}\|_p \to \|\mathbf{v}\|_\infty$ as $p \to \infty$, so that $\phi_{2^n}(\tau) \to \max\{1, \|\mathbf{v}(t)\|_\infty : t \in [0,\tau]\}$. Also, $\phi_2(\tau)$ represents the maximum of the kinetic energy in $[0,\tau]$, which we denote by $E(\tau)$. Calling M the universal constant written in (49), we obtain our main estimate

$$\begin{aligned}\max\{\|\mathbf{v}(t)\|_\infty : t \in [0,\tau]\} \leqslant M\left(\frac{1}{\nu}\max_{[0,\tau]}\left\|\frac{\theta(t)}{1+v(t)}\right\|_\infty + \frac{1}{\nu^2}\max_{[0,\tau]}\left\|\frac{\pi(t)}{1+v(t)}\right\|_\infty^2 + 1\right)^{d/4} \\ \times \max\{E(\tau), k\|\mathbf{v}(0)\|_\infty\}.\end{aligned} \tag{50}$$

IV. COMMENTS AND EXTENSIONS OF THE ESTIMATES

In principle it could look as if the estimates in terms of θ and π divided by $1+v$ are unnecessary, since if v is bounded so are θ and π. While there is no conceptual gain in taking these magnitudes divided by $1+v$, the estimate (50) is in fact finer than one involving only $\|\theta\|_\infty$ and $\|\pi\|_\infty$. It can be far better if the regions where θ and/or π are larger coincide with regions of high velocity. In particular, high temperature deviation propels the fluid faster, so it is likely that $\theta/(1+v)$ is considerably smaller than θ.

When the flow is chaotic, the temperature may become irregular. Therefore it is possible that some primitive of θ (e.g., a function Θ such that for some coordinate j, $\partial_j\Theta = \theta$) may have a better behavior than the temperature deviation: portions where θ is positive may compensate with others where it is negative to obtain a smooth result. We will see that $\|\mathbf{v}\|_\infty$ may also be bounded in terms of $\Theta/(1+v)$. The method follows the steps of the previous one: the term

$$\int_U \theta v^{2p-2} v_d \, \mathrm{d}V \tag{51}$$

may be written as

$$\int_U (\partial_j\Theta) v^{2p-2} v_d \, \mathrm{d}V = -\int_U \Theta \partial_j (v^{2p-2} v_d) \mathrm{d}V = -\int_U \Theta (v^{2p-2}\partial_j v_d + 2(p-1)v^{2p-4} v_d \mathbf{v}\cdot\partial_j\mathbf{v}) \mathrm{d}V. \tag{52}$$

This may be bounded by

$$(2p-1)\int_U \left|\frac{\Theta}{1+v}\right| (v^{2p-2} + v^{2p-1}) |\nabla \mathbf{v}| \mathrm{d}V \leqslant (2p-1)\left\|\frac{\Theta}{1+v}\right\|_\infty \int_U (v^{2p-2} + v^{2p-1}) |\nabla \mathbf{v}| \mathrm{d}V. \tag{53}$$

Using now the Cauchy–Schwarz inequality, the term is bounded by

$$(2p-1)^2\left\|\frac{\Theta}{1+v}\right\|_\infty \frac{1}{2\nu}\int_U (v^{2p-2}+v^{2p})\mathrm{d}V+\nu\int_U v^{2p-2}|\nabla \mathbf{v}|^2\,\mathrm{d}V. \tag{54}$$

The last term may now be cancelled with the first of the dissipative terms (which we did not use in our previous proof) and we are left with

$$(2p-1)^2\left\|\frac{\Theta}{1+v}\right\|_\infty^2 \frac{1}{2\nu}(F_{2p-2}+F_{2p}). \tag{55}$$

The rest of the proof is analogous to the previous one. We are left with a bound of the form

$$\max\{\|\mathbf{v}(t)\|_\infty : t\in[0,\tau]\} \leqslant M\left(\frac{1}{\nu^2}\max_{[0,\tau]}\left\|\frac{\Theta(t)}{1+v(t)}\right\|_\infty^2+\frac{1}{\nu^2}\max_{[0,\tau]}\left\|\frac{\pi(t)}{1+v(t)}\right\|_\infty^2+1\right)^{d/4} \times \max\{E(\tau),k\|\mathbf{v}(0)\|_\infty\}. \tag{56}$$

Notice, however, that now a factor of the form $1/\nu^2$ appears before the maximum norm of $\Theta/(1+v)$, and this is squared, while before we had only $1/\nu$ and the power of $\theta/(1+v)$ was one. This may be important when the viscosity is low.

V. CONCLUSIONS

While the kinetic energy of the flow in Rayleigh–Bénard convection may be easily bounded by classical inequalities, the maximum of the velocity is harder to handle. As soon as the flow becomes chaotic small islands or filaments of high velocity are observed, which makes compatible the boundedness of the square mean of the velocity (the kinetic energy) with the existence of large velocity peaks. It is proved here that, provided the pressure remains uniformly bounded, so does the velocity, and its maximum may be estimated by the maxima of the temperature deviation and pressure divided by one plus the velocity modulus. Other estimates may be made in terms of certain means of the temperature, which may be considerably smaller than the temperature itself if its distribution is irregular. The bounds depend on certain powers, depending on the dimension, of the previously mentioned magnitudes and the flow viscosity.

(Received 18 October 2004; accepted 9 November 2004; published online 4 February 2005)

The topological interaction method is applied to the evaluation of boundary–boundary correlation functions, which yield the square of the spontaneous magnetization m_b at the boundary in the thermodynamic limit. One of the remarkable results is that the boundary–boundary correlation function C_M is found to be nonmonotonic with respect to the system size M for $T<T_c$, because of boundary effects. On the other hand, it is monotonic above T_c, $C_M \simeq (A_+(T)/\sqrt{M})\exp(-M/\xi)$ with the correlation length ξ and with $A_+(T)\sim\sqrt{T-T_c}$ near the critical point T_c. At the critical point, $C_M \sim 1/M$, and below T_c, $C_M \simeq m_b^2+(-A_-(T)\sqrt{M}+B(T)+C(T)/\sqrt{M})\exp(-M/\xi)$, where $A_-(T)\sim m_b^3$, $B(T)\sim m_b^2$, $C(T)\sim m_b \sim \sqrt{T-T_c}$. Fisher's finite-size scaling is confirmed in this respect. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1845954]

I. INTRODUCTION

A second-order phase transition[1–8] is characterized by spontaneous symmetry breaking (SSB) accompanied by the appearance of long-range order (LRO),[5,6,9]

$$\mathrm{LRO} = \lim_{R\to\infty}\langle Q(0)Q(R)\rangle \tag{1.1}$$

for the relevant local order-parameter Q_j or $Q(R)$ of the system. The global order parameter Q is defined by the sum or integral

$$Q = \sum_j Q_j = \int Q(R)\mathrm{d}^d R \tag{1.2}$$

in d dimensions. A standard method to study SSB is to evaluate the generalized partition function of the form

$$Z(T,\Lambda) = \mathrm{Tr}\exp[-\beta(\mathcal{H}_0 - \Lambda Q)], \tag{1.3}$$

where Λ is a parameter conjugate to the order parameter Q. Then, the thermal average of Q is given by

[a]Electronic mail: msuzuki@rs.kagu.tus.ac.jp
[b]Electronic mail: j1202706@ed.kagu.tus.ac.jp
[c]Electronic mail: scchang@mail.ncku.edu.tw

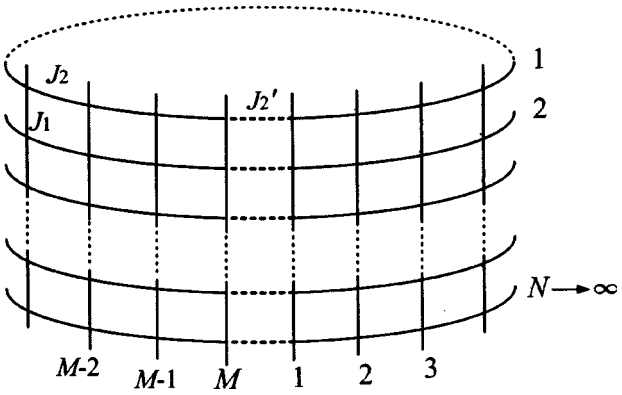

FIG. 1. Topological interaction J_2' to connect the two opposite boundary spins.

$$\langle Q\rangle_\Lambda = \frac{\partial}{\partial(\beta\Lambda)}\log Z(T,\Lambda). \tag{1.4}$$

The spontaneous order parameter is obtained by taking the following limits:

$$\langle Q\rangle_+ = \lim_{\Lambda\to+0}\lim_{N\to\infty}\langle Q\rangle_\Lambda \tag{1.5}$$

for the system size N. The order of the above two limits is crucial, as is well known. It has been proved[5,6,9] that

$$\mathrm{LRO} = \langle Q\rangle_+^2. \tag{1.6}$$

It is extremely difficult to calculate $Z(T,\Lambda)$ for a nonvanishing Λ. Yang[2] used a trick to make a magnetic field H go to zero proportionally to $N^{-1/2}=L^{-1}$ (i.e., $H\sim N^{-1/2}=L^{-1}$), in order to evaluate the spontaneous magnetization m_s of the two-dimensional Ising model. It might be impossible to obtain m_s if we set $H\sim N^{-1}$ (which means that the Zeeman energy is of the order of unity even below the critical point T_c), as was discussed by Suzuki and Suzuki.[10]

In the present paper, we study SSB in the two-dimensional Ising model by using the topological interaction method (TIM) proposed by Suzuki.[11,12] The scheme of TIM in the present model (Fig. 1) is described by the following Hamiltonian:

$$\mathcal{H} = \mathcal{H}_0 - J_2'\sum_{k=1}^{N} S_{1,k}S_{M,k}, \tag{1.7}$$

where

$$\mathcal{H}_0 = -J_1\sum_{j=1}^{M}\sum_{k=1}^{N} S_{j,k}S_{j,k+1} - J_2\sum_{j=1}^{M-1}\sum_{k=1}^{N} S_{j,k}S_{j+1,k} \tag{1.8}$$

with $S_{j,k}=\pm 1$. Clearly, J_2' changes the topology of the system, according to the conditions $J_2'\neq 0$ or $J_2'=0$. Physically, if $J_2'\neq 0$, then $\{\langle S_{1,i}S_{M,i}\rangle\}$ denote short-range correlations. However, if $J_2'=0$, then they denote the long-range correlation for $M\to\infty$, under the limit $N\to\infty$ first before setting $J_2'=0$. This condition is vital for evaluating the long-range order below T_c. This corresponds to the situation that the thermodynamic limit ($N\to\infty$) should be taken before a magnetic field H is made to vanish ($H\to+0$) in order to calculate the spontaneous magnetization in a uniform system.

Even when M is finite, this topological interaction method yields the boundary–boundary correlation function $C_M(0)=\langle S_1S_M\rangle_{J_2'=0}$ as follows:

$$C_M(0) = \lim_{J_2' \to +0} \lim_{N \to \infty} \frac{1}{\beta N} \frac{\partial \ln Z_{2D}(J_2')}{\partial J_2'}, \tag{1.9}$$

where $Z_{2D}(J_2')$ is the partition function of the system and β is the inverse temperature (i.e., $\beta = 1/k_B T$). The nearest-neighbor correlation function, denoted as $C_M(J_2)$, can be treated at the same time as

$$C_M(J_2) = \lim_{J_2' \to J_2} \lim_{N \to \infty} \frac{1}{\beta N} \frac{\partial \ln Z_{2D}(J_2')}{\partial J_2'}. \tag{1.10}$$

In the present paper, we derive boundary–boundary correlation functions in the two-dimensional Ising model and we study their asymptotic behavior for large system size.

II. PARTITION FUNCTION, CORRELATION FUNCTIONS AND BOUNDARY SPONTANEOUS MAGNETIZATION

Consider the rectangular Ising model with the spin–spin interaction $J_1(>0)$ in the vertical direction and $J_2(>0)$ in the horizontal direction. Impose the topological spin–spin interaction J_2' between column 1 and column M, as is shown in Fig. 1. The Hamiltonian of the system is the same as that given in Eqs. (1.7) and (1.8), namely

$$\mathcal{H} = -J_1 \sum_{j=1}^{M} \sum_{k=1}^{N} S_{j,k} S_{j,k+1} - J_2 \sum_{j=1}^{M-1} \sum_{k=1}^{N} S_{j,k} S_{j+1,k} - J_2' \sum_{k=1}^{N} S_{1,k} S_{M,k} \tag{2.1}$$

with periodic boundary condition in the vertical direction. The partition function of this system is expressed as

$$Z_{2D} = 2^{MN-1} (\cosh K_1)^{NM} (\cosh K_2)^{N(M-1)} (\cosh K_2')^N (-\mathrm{Pf}\, A_1 + \mathrm{Pf}\, A_2 + \mathrm{Pf}\, A_3 + \mathrm{Pf}\, A_4), \tag{2.2}$$

using the standard Pfaffian (Pf) method.[4,13–15] Here, the above four Pfaffians are evaluated in Appendix A to give the following expressions:

$$\{\mathrm{Pf}\, A_i\}^2 = \det A_i = \prod_{n=1}^{N} \{z_2(1-z_1^2)\}^M \{(f + f'\zeta^2)\alpha(\theta_n)^M + (f' + f\zeta^2)\alpha(\theta_n)^{-M} + 2(-1)^i \zeta\} \tag{2.3}$$

for $i=1$, 2, 3, and 4 with the notations $K_{1,2} = \beta J_{1,2}$, $K_2' = \beta J_2'$, $z_{1,2} = \tanh K_{1,2}$, $z_2' = \tanh K_2'$ and $\zeta = z_2'/z_2$. The arguments $\{\theta_n\}$ denote $2n\pi/N$ for $i=1$, 2 and $(2n-1)\pi/N$ for $i=3$, 4. The functions $f = f(\alpha)$ and $f' = f(1/\alpha)$ are given by

$$f = f(\alpha) = \frac{(\alpha - z_2/x_1)(\alpha - z_2 x_1)}{(1-z_2^2)(\alpha^2 - 1)} \tag{2.4}$$

and

$$f' = f(1/\alpha) = 1 - f(\alpha) = \frac{(1 - \alpha z_2/x_1)(1 - \alpha z_2 x_1)}{(1-z_2^2)(1-\alpha^2)}, \tag{2.5}$$

respectively, where $x_1 = (1-z_1)/(1+z_1) = e^{-2K_1}$ and $\alpha = \alpha(\theta)$ is the larger solution of the following equation:

$$(1+z_1^2)(1+z_2^2) - 2z_1(1-z_2^2)\cos\theta - z_2(1-z_1^2)(\alpha + \alpha^{-1}) = 0. \tag{2.6}$$

More explicitly, we have

$$\alpha = \alpha(\theta) = \frac{1}{2(1-z_1^2)z_2}[(1+z_1^2)(1+z_2^2) - 2z_1(1-z_2^2)\cos\theta + \sqrt{\{(1+z_1^2)(1+z_2^2) - 2z_1(1-z_2^2)\cos\theta\}^2 - 4(1-z_1^2)^2 z_2^2}]. \tag{2.7}$$

The correct branch of the solution differs above and below T_c. This remark is important in evaluating explicitly the root of Eq. (2.7). Namely, the function $\alpha=\alpha(\theta)$ is such a branch of the root as connects with $\alpha(0)=(1-z_1)/\{z_2(1+z_1)\}$ for $T>T_c$ and $\alpha(0)=z_2(1+z_1)/(1-z_1)$ for $T<T_c$.

Then, the correlation function $\langle S_{1,i}S_{M,i}\rangle$ for $N\to\infty$ can be evaluated as

$$C_M(J_2') \equiv \langle S_{1,i}S_{M,i}\rangle = \lim_{N\to\infty}\frac{1}{N}\frac{\partial \log Z(K_1,K_2,K_2')}{\partial K_2'} = z_2\zeta + \frac{1-z_2^2\zeta^2}{2\pi z_2}\int_0^{2\pi}\frac{(f'\alpha^M + f\alpha^{-M})\zeta + 1}{(f+f'\zeta^2)\alpha^M + (f'+f\zeta^2)\alpha^{-M} + 2\zeta}\mathrm{d}\theta, \tag{2.8}$$

where ζ denotes the topological parameter defined by $\zeta=\tanh(\beta J_2')\coth(\beta J_2)$. The above integral formula of $C_M(J_2')$ is very basic in our investigation on the boundary–boundary correlation. Note that $\alpha(\theta)\geqslant\alpha(0)>1$ except the critical point [where $\alpha(0)=1$]. Then, the limit $M\to\infty$ is easily taken in the above integral (2.8) to give the result

$$C_\infty(J_2') = z_2\zeta + \frac{1-z_2^2\zeta^2}{2\pi z_2}\int_0^{2\pi}\frac{\zeta f(1/\alpha(\theta))}{f(\alpha(\theta)) + \zeta^2 f(1/\alpha(\theta))}\mathrm{d}\theta. \tag{2.9}$$

This shows how the nearest-neighbor correlation function changes according to the change of one-line interaction ($\{J_2\}\to\{J_2'\}\neq 0$).

It is shown here from the idea of topological interaction method that the limit $J_2'\to+0$ of the function $C_\infty(J_2')$ yields the square of the boundary spontaneous magnetization m_b obtained first by McCoy and Wu[13] as follows. It should be noted first that if we set $\zeta=0$ in the integral of Eq. (2.9) then the integral (2.9) will vanish. This comes from the wrong limit for studying SSB; we must integrate Eq. (2.9) first ($N\to\infty$) before setting $J_2'=0$ (namely $\zeta=0$). No SSB occurs for finite N. This is a quite general remark in studying SSB. This situation makes our calculations very difficult or subtle in our paper, as will be seen later.

Now, we take the correct limit $J_2'\to+0$ after the integration with respect to θ in Eq. (2.9) using the delta function $\delta(x)$ as

$$\lim_{J_2'\to+0} C_\infty(J_2') = \frac{1}{2\pi z_2}\lim_{\zeta\to+0}\int_{-\pi}^{\pi}\frac{\zeta}{f(\alpha(\theta))/f(1/\alpha(\theta)) + \zeta^2}\mathrm{d}\theta = \frac{1}{2z_2}\int_{-\pi}^{\pi}\delta(\sqrt{f(\alpha(\theta))/f(1/\alpha(\theta))})\mathrm{d}\theta = \begin{cases} 0 & (T>T_c), \\ \dfrac{z_2^2(1+z_1)^2-(1-z_1)^2}{4z_1z_2^2} & (T\leqslant T_c), \end{cases} \tag{2.10}$$

because it is easily shown from Eqs. (2.4), (2.5), and (2.7) that

$$f(\alpha(\theta)) = 1 + \mathrm{O}(\theta^2) \quad \text{and } f(1/\alpha(\theta)) = \mathrm{O}(\theta^2) \quad \text{for } T>T_c \tag{2.11}$$

and

$$f(\alpha(\theta)) = \hat{f}\theta^2 + \mathrm{O}(\theta^4) \quad \text{and } f(1/\alpha(\theta)) = 1 - \hat{f}\theta^2 + \mathrm{O}(\theta^4) \quad \text{for } T<T_c \tag{2.12}$$

near $\theta=0$, where

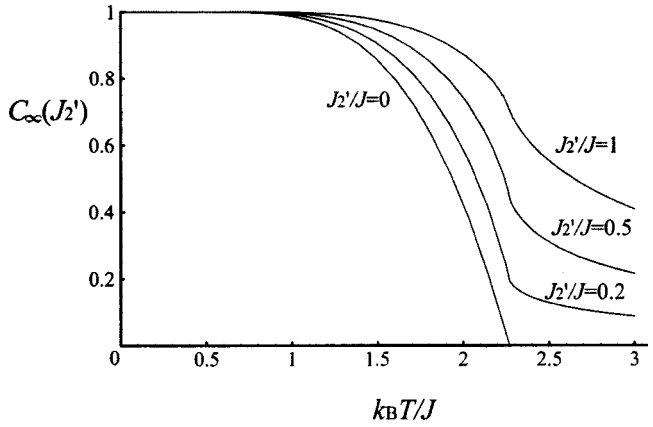

FIG. 2. Temperature dependence of the correlation functions $C_\infty(J_2')$ for various values of the ratio J_2'/J with $J_1=J_2=J$. They are all singular at T_c (where $k_BT_c/J=2.269\ldots$).

$$\hat{f}=\frac{4z_1^2z_2^2}{\{z_2^2(1+z_1)^2-(1-z_1)^2\}^2}. \tag{2.13}$$

It should be remarkable that the first integrand of Eq. (2.10) is essentially singular at $\theta=0$ and $\zeta=0$ only below the critical point T_c. Equivalently, the argument of the delta function in Eq. (2.10), $z_2\{f(\alpha(\theta))/f(1/\alpha(\theta))\}^{1/2}$, has a zero point in the integral range $(-\pi\leqslant\theta\leqslant\pi)$ only below T_c. Thus, we arrive at the following result:

$$\lim_{J_2'\to+0} C_\infty(J_2')=m_b^2, \quad m_b=\left\{\frac{\cosh 2K_2-\coth 2K_1}{\cosh 2K_2-1}\right\}^{1/2}, \tag{2.14}$$

below T_c. This is an alternative derivation of McCoy–Wu's formula on m_b.

It will be instructive to study $C_\infty(J_2')$ for various values of the ratio J_2'/J_2. In particular, $C_\infty(J_2)$ is confirmed to be equal to the uniform nearest-neighbor correlation function[16,17]

$$C_\infty(J_2)=\frac{1}{4\pi z_2}\int_{-\pi}^{\pi}\left\{1+z_2^2+\frac{(1-z_2^2)\{2z_1(1+z_2^2)\cos\theta-(1+z_1^2)(1-z_2^2\}}{\sqrt{\{(1+z_1^2)(1+z_2^2)-2z_1(1-z_2^2)\cos\theta\}^2-4z_2^2(1-z_1^2)^2}}\right\}\mathrm{d}\theta, \tag{2.15}$$

as it should be. All the functions $C_\infty(J_2')$ are singular at T_c for any values of J_2', as shown in Fig. 2.

III. BOUNDARY–BOUNDARY CORRELATION FUNCTION

The main purpose of the present paper is to evaluate the boundary–boundary correlation function both for finite M and infinite $M(\to\infty)$, using the above topological interaction method. In principle, this should be performed by taking the limit $J_2'\to+0$ (and consequently $\zeta=z_2'/z_2\to+0$) in the above basic integral formula (2.8). In fact, we obtain an integral representation of the form

$$C_M\equiv C_M(0)=\frac{1}{2\pi z_2}\int_{-\pi}^{\pi}\frac{1}{f_M(\theta)}\mathrm{d}\theta, \tag{3.1}$$

where

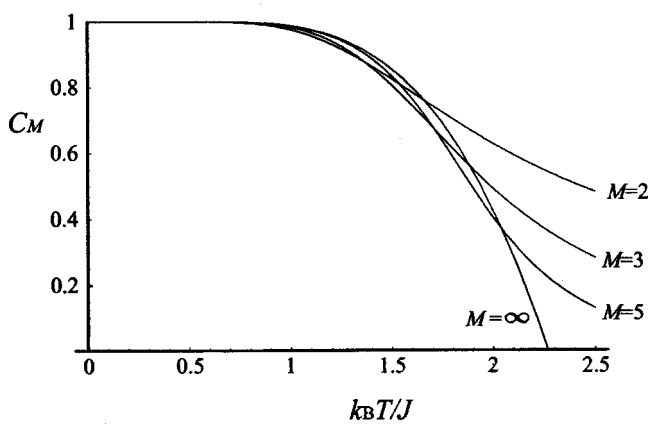

FIG. 3. Temperature dependence of C_M for various values of M with $J_1=J_2=J$. It is seen numerically that C_M is less than C_∞ at low temperatures.

$$f_M(\theta) = f(\alpha(\theta))\alpha(\theta)^M + f\left(\frac{1}{\alpha(\theta)}\right)\alpha(\theta)^{-M}. \tag{3.2}$$

It is easily found from Eqs. (2.4), (2.5), and (2.7) that $f_M(\theta)$ is an Mth order polynomial of $\cos\theta$.

For example, we have, for $M=2$,

$$f_2(\theta) = \frac{1}{z_2^2(1-z_1^2)^2}[(1+z_1^2-2z_1\cos\theta)^2 + 4z_1^2z_2^2\sin^2\theta]. \tag{3.3}$$

Then, we obtain the correlation function

$$C_2 = \frac{z_2(1+z_1^2)}{\sqrt{(1-z_1^2)^2+4z_1^2z_2^2}} = 1 - 8e^{-4K_1-2K_2} + \cdots = C_\infty - 4e^{-4K_1-2K_2} + \cdots . \tag{3.4}$$

The second expression of Eq. (3.4) is a low temperature series expansion. The third expression shows the quite remarkable fact that C_2 is less than C_∞ at low temperatures. This surprising result is found to be universal for any values of M as shown in Fig. 3, which has been calculated numerically from (3.1).

It will be interesting and useful in the theory of critical phenomena to study analytically the asymptotic behavior of the boundary–boundary correlation function C_M. First note that the integrand of Eq. (3.1) for large M is singular at $\theta=0$ below T_c. Thus, it seems to be rather complicated to evaluate Eq. (3.1) for large M below T_c. We must integrate first Eq. (3.1) before taking the limit $M\to\infty$, or at least, to perform the two procedures simultaneously. In fact, we obtain, below T_c,

$$C_\infty = C_\infty(0) = \frac{1}{2\pi z_2}\lim_{M\to\infty}\int_{-\pi}^{\pi}\frac{\alpha(0)^{-M}}{c^2\theta^2+\alpha(0)^{-2M}}\mathrm{d}\theta = \frac{1}{2\pi z_2 c}\lim_{M\to\infty}\int_{-\pi c\alpha(0)^M}^{\pi c\alpha(0)^M}\frac{\mathrm{d}x}{x^2+1}$$
$$= \frac{1}{2\pi z_2 c}\int_{-\infty}^{\infty}\frac{\mathrm{d}x}{x^2+1} = \frac{1}{2cz_2} \tag{3.5}$$

with

$$c = \sqrt{\hat{f}} = \left\{\lim_{\theta\to 0} f(\alpha(\theta))/\theta^2\right\}^{1/2} = \frac{1}{2z_2m_b^2}. \tag{3.6}$$

This relation is derived from Eqs. (2.12) and (2.13). Thus, we arrive again at the relation

$$\lim_{M\to\infty} C_M = m_b^2. \tag{3.7}$$

Clearly we have $C_\infty = 0$ for $T > T_c$. This can be also derived using the delta function as

$$\lim_{M\to\infty} C_M(0) = \frac{1}{2\pi z_2} \lim_{M\to\infty} \int_{-\pi}^{\pi} \frac{\alpha(0)^{-M}}{f + f'\alpha(0)^{-2M}} \mathrm{d}\theta$$
$$= \frac{1}{2z_2} \int_{-\pi}^{\pi} \frac{\delta(\sqrt{f/f'})}{f'} \mathrm{d}\theta = \begin{cases} 0 & (T > T_c), \\ \dfrac{z_2^2(1+z_1)^2 - (1-z_1)^2}{4z_1 z_2^2} & (T \leqslant T_c). \end{cases} \tag{3.8}$$

The above two derivations (2.14) and (3.7) of m_b^2 yield

$$\lim_{J_2'\to+0} \lim_{M\to\infty} C_M(J_2') = \lim_{M\to\infty} \lim_{J_2'\to+0} C_M(J_2') = m_b^2. \tag{3.9}$$

This exchangeability of the two limits comes from the fact that J_2' changes only the topology (not symmetry) of the system.

Next we study the asymptotic behavior of $C_M \equiv C_M(0)$.

A. Asymptotic form of C_M above T_c

Noting the property (2.11), we find, from Eq. (3.1),

$$C_M \simeq \frac{1}{2\pi z_2} \int_{-\pi}^{\pi} e^{-M \log \alpha(\theta)} \, \mathrm{d}\theta \simeq \frac{e^{-M \log \alpha(0)}}{2\pi z_2} \int_{-\infty}^{\infty} e^{-kM\theta^2} \, \mathrm{d}\theta = A_+(T) e^{-M/\xi_b} / \sqrt{M}. \tag{3.10}$$

Here, we have used the relation

$$\log \alpha(\theta) \simeq \log \alpha(0) + k\theta^2, \quad k \equiv \frac{z_1(1-z_2^2)}{(1-z_1)^2 - z_2^2(1+z_1)^2}. \tag{3.11}$$

The coefficient $A_+(T)$ is given by

$$A_+(T) = \frac{1}{2z_2} \left[\frac{(1-z_1)^2 - z_2^2(1+z_1)^2}{\pi z_1 (1-z_1^2)} \right]^{1/2} \sim \sqrt{T - T_c}. \tag{3.12}$$

The correlation length ξ_b is exactly expressed by

$$\xi_b = \frac{1}{\log \alpha(0)} = \frac{1}{\log\left(\dfrac{1-z_1}{z_2(1+z_1)} \right)}, \tag{3.13}$$

which diverges as follows:

$$\xi_b \sim \frac{1}{T - T_c} \to \infty \quad \text{as } T \to T_c, \quad \nu_b = 1. \tag{3.14}$$

It is interesting to note that the above correlation length ξ_b is exactly the same as the ordinary correlation length ξ defined by the correlation function $C(R)$ in the K_2 direction for an infinite system[18]

$$\xi^{-1} = \log \coth K_2 - 2K_1. \tag{3.15}$$

That is, from Eq. (3.13), we obtain

$$\xi_b = \xi, \quad \nu_b = \nu = 1. \tag{3.16}$$

It should be also noted that the above asymptotic form including the prefactor $(1/\sqrt{M})$ agrees with that of the ordinary correlation function[19,20]

$$C(R,T) \simeq \frac{B_+ e^{-R/\xi}}{\sqrt{R}}, \quad T > T_c, \quad R \to \infty. \tag{3.17}$$

However, the situation is different at and below T_c, as will be seen later.

B. Asymptotic form of C_M at T_c [or for $M(T-T_c)/T_c \ll 1$]

It will be interesting to evaluate the asymptotic form of C_M at T_c or for $M(T-T_c)/T_c \ll 1$. We find easily that

$$\alpha(\theta) = 1 + a\theta + \cdots = e^{a\theta} + \mathrm{O}(\theta^2), \quad a \equiv \frac{2z_{1,c}}{1-z_{1,c}^2}, \tag{3.18}$$

and

$$f(\alpha(\theta)) = \tfrac{1}{2} + \mathrm{O}(\theta) \quad \text{and } f(1/\alpha(\theta)) = \tfrac{1}{2} + \mathrm{O}(\theta), \tag{3.19}$$

using Eqs. (2.4), (2.5), and (2.7), as is shown in Appendix B. Here, $z_{1,c}$ denotes the value of z_1 at T_c. Then, we obtain

$$\begin{aligned} C_M &= \frac{1}{2\pi z_{2,c}} \int_{-\pi}^{\pi} \frac{\alpha(\theta)^{-M}}{f(\alpha(\theta)) + f(1/\alpha(\theta))\alpha(\theta)^{-2M}} \mathrm{d}\theta \simeq \frac{2}{\pi z_{2,c}} \int_0^{\infty} \frac{e^{-aM\theta}}{1+e^{-2aM\theta}} \mathrm{d}\theta \\ &= \frac{2}{\pi a M z_{2,c}} \int_0^1 \frac{\mathrm{d}t}{1+t^2} = \frac{(1+z_{1,c})^2}{4z_{1,c}} \cdot \frac{1}{M} \equiv \frac{A(T_c)}{M}, \end{aligned} \tag{3.20}$$

where $z_{2,c}=(1-z_{1,c})/(1+z_{1,c})$. [In particular, we have $A(T_c)=(\sqrt{2}+1)/2$ for $J_1=J_2$.] This asymptotic form $(C_M \sim 1/M)$ is different from the ordinary asymptotic form[1,18] $C(R,T_c) \sim R^{-1/4}$ $(\eta=1/4)$. A similar form was obtained by McCoy and Wu[13] in a different situation.

C. Asymptotic form of C_M below T_c

It is more complicated to study the asymptotic behavior of the boundary–boundary correlation function C_M below T_c, because of the existence of long-range order. We can derive, from Eq. (3.1), the following asymptotic form:

$$C_M \sim m_b^2 + \left\{ -A_-(T)\sqrt{M} + B(T) + \frac{C(T)}{\sqrt{M}} \right\} e^{-M/\xi}, \tag{3.21}$$

and

$$\xi = \frac{1}{\log \alpha(0)} = \frac{1}{\log\left(\dfrac{z_2(1+z_1)}{1-z_1} \right)} \tag{3.22}$$

for $M(T_c-T)/T_c \gg 1$, using the renormalized evaluation method of singular integrals,[21] as will be shown in Appendix C. Here, the coefficients $A_-(T)$ and $B(T)$ are given by

$$A_-(T) = 2\sqrt{\frac{1-z_2^2}{\pi}} \left[\frac{z_2^2(1+z_1)^2 - (1-z_1)^2}{4z_1 z_2^2} \right]^{3/2} = 2m_b^3 \sqrt{\frac{1-z_2^2}{\pi}} \tag{3.23}$$

and

$$B(T) = \frac{1}{2\pi z_2}\int_{-\pi}^{\pi} \frac{2(1-\cos\theta)\hat{f} - f(\alpha(\theta))}{f(\alpha(\theta))2(1-\cos\theta)\hat{f}}\mathrm{d}\theta = \mathrm{O}(1) \quad \text{in } M, \tag{3.24}$$

respectively. The function $\hat{f}$ (of T) is defined in $f(\alpha(\theta)) = \hat{f}\theta^2 + \mathrm{O}(\theta^4)$, namely by (2.13). It is easily shown that

$$A_{-}(T) \sim m_b^3, \quad B(T) \sim m_b^2, \quad \text{and } C(T) \sim m_b. \tag{3.25}$$

This yields the following finite-size scaling law:

$$C_M - \langle S_1\rangle\langle S_M\rangle \simeq P_{\mathrm{sc}}^{(\pm)}(m_b\sqrt{M})\frac{1}{M}e^{-M/\xi}, \tag{3.26}$$

where

$$P_{\mathrm{sc}}^{(\pm)}(x) = a_{\pm}x^3 + b_{\pm}x^2 + c_{\pm}x + d. \tag{3.27}$$

It is easily understood that $m_b\sqrt{M}$ is the scaling variable in Eq. (3.26), because $m_b \sim (T_c - T)^{1/2} \sim \xi^{-1/2} \sim M^{-1/2}$ to give the invariance property of $m_b\sqrt{M} \sim \sqrt{M/\xi}$. The above scaling form (3.26) is a typical example of Fisher's finite-size scaling law.[22,23]

D. Nonmonotonicity of C_M below T_c

One of the remarkable features on C_M is that it is nonmonotonic with respect to the system-size M below T_c, as is seen from Eq. (3.21). It is easily found that $A_{-}(T) > 0$ (see Appendix C). This yields the nonmonotonicity of C_M. This behavior seems to be surprising, at first. Thus, we have confirmed this result in three ways. The first one is analytic, as in Eq. (3.21) with $A_{-}(T) > 0$.

The second one is to make use of the low-temperature expansion of C_M, as was already exemplified for C_2 in Eq. (3.4). It is possible in principle to calculate the low-temperature expansion of C_M. However, it is so complicated that we are here satisfied, for the second confirmation of the nonmonotonicity of C_M, to find the following expansion up to the first order of x_2 ($=e^{-2K_2}$ with $x_1 = e^{-2K_1}$):

$$C_M = \frac{1}{2\pi z_2}\int_{-\pi}^{\pi} \frac{1}{f(\alpha(\theta))\alpha^M + f(1/\alpha(\theta))\alpha^{-M}}\mathrm{d}\theta = 1 - \frac{4\{x_1^2 + (M-1)(1-x_1^2)x_1^M - x_1^{2M}\}}{(1-x_1^2)(1+x_1^M)^2}x_2 + \mathrm{O}(x_2^2) \tag{3.28}$$

for an arbitrary value of M. On the other hand, the square of the boundary magnetization $C_\infty = m_b^2$ is generally expanded as

$$C_\infty = m_b^2 = \frac{\{1 + x_1 - (1-x_1)x_2\}\{1 - x_1 - (1+x_1)x_2\}}{(1-x_1^2)(1-x_2)^2} = 1 - \frac{4x_1^2}{1-x_1^2}\sum_{n=1}^{\infty} n x_2^n. \tag{3.29}$$

Therefore, we find

$$C_M - C_\infty = -\frac{4x_1^M\{M(1-x_1^2) - (1+x_1^2)(1+x_1^M)\}}{(1-x_1^2)(1+x_1^M)^2}x_2 + \mathrm{O}(x_2^2) \tag{3.30}$$

to confirm the inequalities $C_1 > C_M$ and $C_M < C_\infty$ at sufficiently low temperatures for $M \geqslant 2$.

The third method to confirm this behavior is to integrate Eq. (3.1) numerically. Two examples of typical monotonic behavior and nonmonotonic behavior are shown in Fig. 4. In more detail, assuming $J_1 = J_2 = J$ for simplicity, we find the inequality $C_M < C_\infty$ except for $M = 1$ below $k_BT/J = 1.6616\ldots$ as is shown in the above low-temperature expansion. For $1.6616\ldots < k_BT/J < 1.8883\ldots$, we find $C_M < C_{\ldots}$ except for $M = 1$, 2. From Fig. 4(b), it is found that C_M with M

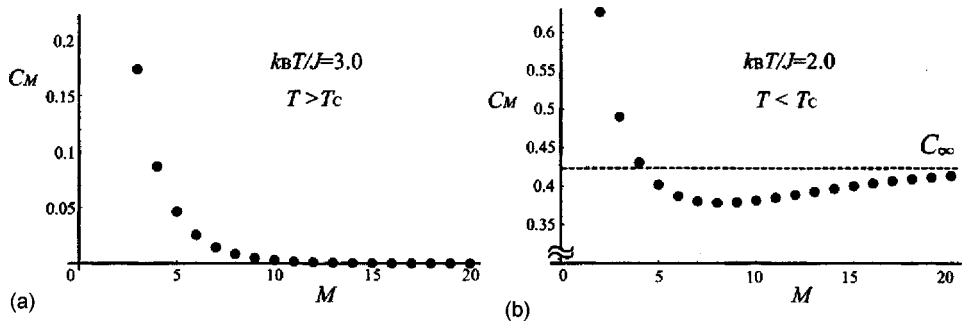

FIG. 4. Size dependence of C_M for $J_1=J_2=J$ (where $k_BT_c/J=2.269\ldots$); (a) above T_c ($k_BT/J=3.0$) and (b) below T_c ($k_BT/J=2.0$). The correlation function C_M is nonmonotonic with respect to M only below T_c.

$=1, 2, 3, 4$ are larger than C_∞ at $k_BT/J=2.0$. In addition, the minimum value of C_M is found at finite $M_{\min}\geqslant 2$. For example, C_2 takes the minimum value for $k_BT/J<1.3696\ldots$ and C_8 is minimum at $k_BT/J=2.0$ [Fig. 4(b)]. For $T\geqslant T_c$, we have $M_{\min}=\infty$.

Above T_c, the function C_M is monotonic with respect to the system size M. The reason why C_M becomes nonmonotonic only below T_c is because the finite-size effect on C_M becomes dominant only below T_c, namely because the difference between C_M and C_∞ comes from the remaining correlations longer than M. These correlations become larger at low temperatures [where the long-range order (LRO) appears]. Except at very low temperatures, the function C_M for small M denotes the short-range correlation effect coming mainly from a finite strip and consequently it decreases as M increases.

IV. SUMMARY AND DISCUSSION

We have applied a new scheme of topological interaction method to the evaluation of the boundary–boundary correlation function C_M for the system-size M. An exact integral formula of C_M has been derived to give the asymptotic scaling form,

$$C_M - m_b^2 = C_M - \langle S_0\rangle\langle S_M\rangle \simeq \tilde{P}_{\mathrm{sc}}^{(\pm)}(\sqrt{M/\xi})\frac{1}{M}e^{-M/\xi}. \tag{4.1}$$

This confirms Fisher's finite-size scaling law. More explicitly, we have

$$C_M \simeq A_+(T)e^{-M/\xi}/\sqrt{M} \quad \text{above } T_c,$$

$$C_M \simeq \frac{A(T_c)}{M},$$

$$C_M \simeq m_b^2 + \left\{-A_-(T)\sqrt{M} + B(T) + \frac{C(T)}{\sqrt{M}}\right\}e^{-M/\xi} \quad \text{below } T_c, \tag{4.2}$$

where ξ is given by Eq. (3.13) for $T>T_c$ and by Eq. (3.22) for $T<T_c$. The nonmonotonicity of C_M with respect to M has been found to appear only below T_c, owing to the competing effect of the strong short-range correlation, long-range correlation dominant at low temperatures and finite-size effect.

It will be interesting to remark that present formula $C_M\simeq(A_+(T)/\sqrt{M})\exp(-M/\xi)$ above T_c is consistent with Morita's sum rule,[24]

$$\lim_{N\to\infty}\frac{1}{N}\sum_{i,j=1}^{N}\langle S_{1,i}S_{M,j}\rangle=(e^{2K_1}\tanh K_2)^M\coth K_2=e^{-M/\xi}\coth K_2 \tag{4.3}$$

which is valid above T_c. For more details, see Appendix D.

The present topological interaction method will be applicable to many other systems to evaluate not only the boundary magnetization but also other physical quantities such as the boundary energy and boundary many-body interactions, $\langle Q_{1,i_1,i_2,\ldots,i_n}\rangle$ by introducing the topological interaction $-J_Q\Sigma Q_{1,i_1,\ldots,i_n}Q_{M,i_1,\ldots,i_n}$. The TIM will be also useful in studying quantum spin systems.[25]

APPENDIX A: EVALUATION OF PFAFFIANS $\{\mathrm{Pf}\,A_i\}$

By the standard Pfaffian method,[4,13,14] the partition function can be calculated to be

$$\begin{aligned}Z(J_2')&=(\cosh\beta J_1)^{NM}(\cosh\beta J_2)^{N(M-1)}(\cosh\beta J_2')^N\sum_{\{S\}}\left[\left\{\prod_{j=1}^{M}\prod_{k=1}^{N}(1+z_1S_{j,k}S_{j,k+1})\right\}\right.\\&\left.\times\left\{\prod_{j=1}^{M-1}\prod_{k=1}^{N}(1+z_2S_{j,k}S_{j+1,k})\right\}\left\{\prod_{j=1}^{N}(1+z_2'S_{1,k}S_{M,k})\right\}\right]\\&=2^{NM-1}(\cosh K_1)^{NM}(\cosh K_2)^{N(M-1)}(\cosh K_2')^N(-\mathrm{Pf}\,A_1+\mathrm{Pf}\,A_2+\mathrm{Pf}\,A_3+\mathrm{Pf}\,A_4),\end{aligned} \tag{A1}$$

where we use the notations $z_{1,2}=\tanh\beta J_{1,2}=\tanh K_{1,2}$ and $z_2'=\tanh\beta J_2'=\tanh K_2'$. The antisymmetrical matrices A_1 and A_3 are given by

$$A_i(j,k;j,k)=\begin{bmatrix}0&1&-1&-1\\-1&0&1&-1\\1&-1&0&1\\1&1&-1&0\end{bmatrix}\quad\text{for } i=1,3,\quad 1\leqslant j\leqslant M,\quad 1\leqslant k\leqslant N,$$

$$A_1(j,k;j,k+1)=-A_1^T(j,k+1;j,k)=\begin{bmatrix}0&z_1&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{bmatrix}\quad\text{for } 1\leqslant j\leqslant M,\quad 1\leqslant k\leqslant N,$$

$$A_3(j,k;j,k+1)=-A_3^T(j,k+1;j,k)=\begin{bmatrix}0&z_1&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{bmatrix}\quad\text{for } 1\leqslant j\leqslant M,\quad 1\leqslant k\leqslant N-1,$$

$$A_3(j,N;j,1)=-A_3^T(j,1;j,N)=\begin{bmatrix}0&-z_1&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{bmatrix}\quad\text{for } 1\leqslant j\leqslant M,$$

$$A_i(j,k;j+1,k) = -A_i^T(j+1,k;j,k) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & z_2 \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad \text{for } i=1,3, \quad 1 \leqslant j \leqslant M-1, \quad 1 \leqslant k \leqslant N,$$

$$A_i(M,k;1,k) = -A_i^T(1,k;M,k) = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & z_2' \\ 0 & 0 & 0 & 0 \end{bmatrix} \quad \text{for } i=1,3, \quad 1 \leqslant k \leqslant N. \tag{A2}$$

The matrix A_2 (A_4) is exactly the same as A_1 (A_3) except that the sign of z_2' should be reversed. The determinant of the matrix A_1 is the square of the Pfaffian of A_1, and can be calculated by the same procedure as given in Ref. 13 to be

$$\det A_1 = \prod_{\theta} [|1+z_1 e^{i\theta}|^{2M} \det D_1(\theta)], \tag{A3}$$

where $\theta = 2n\pi/N$ with $n = 1,2,\ldots,N$, and $D_1(\theta)$ is a $2M \times 2M$ matrix with the form

$$D_1(\theta) = \begin{bmatrix} -a & b & & & & & & & & & -z_2' \\ -b & a & z_2 & & & & & & & & \\ & -z_2 & -a & b & & & & & & & \\ & & -b & a & z_2 & & & & & & \\ & & & -z_2 & -a & b & & & & & \\ & & & & -b & a & \ddots & & & & \\ & & & & & \ddots & \ddots & \ddots & & & \\ & & & & & & \ddots & -a & b & & \\ & & & & & & & -b & a & z_2 & \\ & & & & & & & & -z_2 & -a & b \\ z_2' & & & & & & & & & -b & a \end{bmatrix}. \tag{A4}$$

Here all the unwritten elements in the upper-right and lower-left triangles in Eq. (A4) are zero and we use the definitions

$$a = 2iz_1 \sin\theta |1+z_1 e^{i\theta}|^{-2}, \quad b = (1-z_1^2)|1+z_1 e^{i\theta}|^{-2}. \tag{A5}$$

The determinant of the matrix $D_1(\theta)$ can be calculated to be

$$\det D_1(\theta) = (f+\zeta^2 f')\lambda^M + (f'+\zeta^2 f)\lambda'^M - 2\zeta(bz_2)^M, \tag{A6}$$

where

$$f = \frac{1}{2}\left(1 + \frac{z_2^2 + a^2 - b^2}{\lambda' - \lambda}\right), \quad f' = \frac{1}{2}\left(1 - \frac{z_2^2 + a^2 - b^2}{\lambda' - \lambda}\right),$$

$$\lambda = |1+z_1 e^{i\theta}|^{-2} z_2 (1-z_1^2)\alpha, \quad \lambda' = |1+z_1 e^{i\theta}|^{-2} z_2 (1-z_1^2)\alpha^{-1},$$

$$\zeta = z_2'/z_2 = \tanh(\beta J_2')\coth(\beta J_2) \tag{A7}$$

and α is given by Eq. (2.7). As the matrix A_2 is similar to A_1 with the sign of z_2' reversed, we have

$$\{\mathrm{Pf}\, A_i\}^2 = \det A_i = \prod_{n=1}^{N} \{z_2(1-z_1^2)\}^M \{(f+f'\zeta^2)\alpha(\theta_n)^M + (f'+f\zeta^2)\alpha(\theta_n)^{-M} + 2(-1)^i\zeta\} \quad \text{(A8)}$$

with $\theta_n = 2n\pi/N$. The expression of the determinants for A_3 and A_4 are the same except that $\theta_n = (2n-1)\pi/N$. If $z_2' = z_2$, it is easily shown that the partition function Z reduces to the regular rectangular Ising lattice with toroidal boundary conditions.

It will be instructive to separate the free energy $-k_BT \log Z_{2D}$ into the following two parts:

$$-k_BT \log Z_{2D} = NMf_0 + Nf_1, \quad \text{(A9)}$$

where f_0 is the bulk free energy defined in

$$-\beta f_0 = \log[2\cosh K_1 \cosh K_2] + \frac{1}{4\pi}\int_{-\pi}^{\pi} \log[z_2(1-z_1^2)\alpha(\theta)]\mathrm{d}\theta, \quad \text{(A10)}$$

and the remaining part f_1 contains the boundary and topological terms,

$$-\beta f_1 = \log[\cosh K_2'] - \log[\cosh K_2] + \frac{1}{4\pi}\int_{-\pi}^{\pi} \log[\{(f+f'\zeta^2) + (f'+f\zeta^2)\alpha(\theta)^{-2M} + 2\zeta\alpha(\theta)^{-M}\}]\mathrm{d}\theta. \quad \text{(A11)}$$

Note that only $\mathrm{Pf}\, A_2$ and $\mathrm{Pf}\, A_4$ contribute to the free energy and consequently that the factor $(-1)^i$ in (A8) is equal to unity. The correlation function $C_M(J_2')$ is thus given by

$$C_M(J_2') = -\frac{\partial}{\partial J_2'} f_1 = \frac{\partial}{\partial K_2'}(-\beta f_1) = \frac{1-z_2^2\zeta^2}{z_2}\frac{\partial}{\partial \zeta}(-\beta f_1). \quad \text{(A12)}$$

This gives Eq. (2.8).

APPENDIX B: PROPERTIES OF $\alpha(\theta)$, $f(\alpha(\theta))$, AND $f(1/\alpha(\theta))$ NEAR $\theta=0$

It is easy to show, from Eqs. (2.4), (2.5), and (2.7), for $T=T_c$,

$$\alpha(\theta) = \frac{(1+z_{1,c}^2)^2 - 4z_{1,c}^2\cos\theta + 4z_{1,c}\sin(\theta/2)\sqrt{1+z_{1,c}^4 - 2z_{1,c}^2\cos\theta}}{(1-z_{1,c}^2)^2} = 1 + \frac{2z_{1,c}}{1-z_{1,c}^2}\theta + \mathrm{O}(\theta^2), \quad \text{(B1)}$$

$$f(\alpha(\theta)) = \frac{1}{2}\left(1 + \frac{(1+z_{1,c}^2)\sin(\theta/2)}{\sqrt{1+z_{1,c}^4 - 2z_{1,c}^2\cos\theta}}\right) = \frac{1}{2} + \mathrm{O}(\theta) \quad \text{(B2)}$$

and

$$f(1/\alpha(\theta)) = \frac{1}{2}\left(1 - \frac{(1+z_{1,c}^2)\sin(\theta/2)}{\sqrt{1+z_{1,c}^4 - 2z_{1,c}^2\cos\theta}}\right) = \frac{1}{2} + \mathrm{O}(\theta), \quad \text{(B3)}$$

where we have substituted $z_{2,c} = (1-z_{1,c})/(1+z_{1,c})$. The above linear dependence of $\alpha(\theta)$ near $\theta = 0$ at T_c is a big contrast to the following θ^2-dependence of $\alpha(\theta)$ for $T \neq T_c$:

$$\alpha(\theta) = \begin{cases} \dfrac{1-z_1}{z_2(1+z_1)} + \dfrac{z_1(1-z_1)(1-z_2^2)}{z_2(1+z_1)\{(1-z_1)^2 - z_2^2(1+z_1)^2\}}\theta^2 + \mathrm{O}(\theta^4) \quad (T > T_c), \\ \dfrac{z_2(1+z_1)}{1-z_1} + \dfrac{z_1z_2(1+z_1)(1-z_2^2)}{(1-z_1)\{z_2^2(1+z_1)^2 - (1-z_1)^2\}}\theta^2 + \mathrm{O}(\theta^4) \quad (T < T_c). \end{cases} \quad \text{(B4)}$$

Equivalently we have

$$\log \alpha(\theta) = \begin{cases} \log\dfrac{1-z_1}{z_2(1+z_1)} + \dfrac{z_1(1-z_2^2)}{(1-z_1)^2 - z_2^2(1+z_1)^2}\theta^2 + \mathrm{O}(\theta^4) & (T > T_c) \\ \log\dfrac{z_2(1+z_1)}{1-z_1} + \dfrac{z_1(1-z_2^2)}{z_2^2(1+z_1)^2 - (1-z_1)^2}\theta^2 + \mathrm{O}(\theta^4) & (T < T_c). \end{cases} \tag{B5}$$

APPENDIX C: DERIVATION OF C_M BELOW T_c

In order to investigate the asymptotic behavior of the correlation function C_M expressed by the integral (3.1), we must study f_M near $\theta=0$, namely $f(\alpha(\theta))$ and $f(1/\alpha(\theta))$. Then we easily find

$$f(\alpha(\theta)) = \hat{f}\theta^2 + \mathrm{O}(\theta^4) \quad \text{and } f(1/\alpha(\theta)) = 1 - \hat{f}\theta^2 + \mathrm{O}(\theta^4), \tag{C1}$$

for $T<T_c$. Thus, the integral of C_M, (3.1) is essentially singular at $\theta=0$ and for $M\to\infty$. It will be useful to set

$$\varepsilon = \alpha(0)^{-M} = e^{-M/\xi}, \tag{C2}$$

which goes to zero as $M\to\infty$. Now we try to evaluate C_M given in the form

$$C_M = \frac{1}{2\pi z_2}\int_{-\pi}^{\pi} \frac{\varepsilon\tilde{\alpha}(\theta)^{-M}}{f(\alpha(\theta)) + \varepsilon^2 f(1/\alpha(\theta))\tilde{\alpha}(\theta)^{-2M}}\mathrm{d}\theta \tag{C3}$$

for large M (and consequently $\varepsilon\to 0$), where

$$\tilde{\alpha}(\theta) = \alpha(\theta)/\alpha(0). \tag{C4}$$

As was mentioned above, the integral (C3) is extremely subtle to calculate because $f(\alpha(\theta)) \simeq \hat{f}\theta^2$ and $f(1/\alpha(\theta)) \simeq 1$ near $\theta=0$ and because $\varepsilon\to 0$ and $\tilde{\alpha}(\theta)^{-M}\to 0$ $(\theta\neq 0)$ for $M\to\infty$. The main term gives m_b^2 and the remaining term becomes of the order of ε. In order to evaluate this remaining term, we make use of the renormalized evaluation method[21] of singular integrals as follows:

$$\begin{aligned} C_M &= \frac{1}{2\pi z_2}\int_{-\pi}^{\pi} \frac{\varepsilon}{f(\alpha(\theta)) + \varepsilon^2 f(1/\alpha(\theta))\tilde{\alpha}(\theta)^{-2M}}\mathrm{d}\theta - \frac{\varepsilon}{2\pi z_2}\int_{-\pi}^{\pi} \frac{1-\tilde{\alpha}(\theta)^{-M}}{f(\alpha(\theta)) + \varepsilon^2 f(1/\alpha(\theta))\tilde{\alpha}(\theta)^{-2M}}\mathrm{d}\theta \\ &\equiv C_M^{(B)} - C_M^{(A)}. \end{aligned} \tag{C5}$$

Noting that the term $C_M^{(B)}$ contains m_b^2 and using the "magic representation" of m_b^2 of the form

$$m_b^2 = \frac{1}{2\pi z_2}\int_{-\pi}^{\pi} \frac{\varepsilon}{2(1-\cos\theta)\hat{f} + \varepsilon^2}\mathrm{d}\theta + \mathrm{O}(\varepsilon^2), \tag{C6}$$

we obtain the following relation:

$$\begin{aligned} C_M^{(B)} - m_b^2 &= \frac{\varepsilon}{2\pi z_2}\int_{-\pi}^{\pi}\left\{\frac{1}{f(\alpha(\theta)) + \varepsilon^2 f(1/\alpha(\theta))\tilde{\alpha}(\theta)^{-2M}} - \frac{1}{2(1-\cos\theta)\hat{f} + \varepsilon^2}\right\}\mathrm{d}\theta + \mathrm{O}(\varepsilon^2) \\ &= \frac{\varepsilon}{2\pi z_2}\int_{-\pi}^{\pi}\left\{\frac{1}{f(\alpha(\theta)) + \varepsilon^2} - \frac{1}{2(1-\cos\theta)\hat{f} + \varepsilon^2}\right\}\mathrm{d}\theta + \mathrm{O}(\varepsilon^2) \\ &= -\varepsilon\left[\frac{1}{2\pi z_2}\int_{-\pi}^{\pi}\frac{f(\alpha(\theta)) - 2(1-\cos\theta)\hat{f}}{2f(\alpha(\theta))(1-\cos\theta)\hat{f}}\mathrm{d}\theta\right] + \mathrm{O}(\varepsilon^2) \equiv B(T)\varepsilon + \mathrm{O}(\varepsilon^2). \end{aligned} \tag{C7}$$

The function $B(T)$ defined in (C7) is easily confirmed to be finite because the integrand of it is finite in the limit $\theta\to 0$. It is also shown that $B(T)\sim m_b^2$. It should be remarked that the replacement

of the term $\varepsilon^2 f(1/\alpha(\theta))\tilde{\alpha}(\theta)^{-2M}$ by ε^2 in the above calculation gives corrections of the order of ε^2.

The term $C_M^{(A)}$ is calculated as follows:

$$C_M^{(A)} = \frac{\varepsilon}{2\pi z_2}\int_{-\pi}^{\pi} \frac{1-\tilde{\alpha}(\theta)^{-M}}{f(\alpha(\theta)) + \varepsilon^2 f(1/\alpha(\theta))\tilde{\alpha}(\theta)^{-2M}} \mathrm{d}\theta$$
$$= \frac{\varepsilon}{2\pi z_2}\int_{-\pi}^{\pi} \frac{1-\tilde{\alpha}(\theta)^{-M}}{f(\alpha(\theta))} \mathrm{d}\theta + \mathrm{O}(\varepsilon^2) = \frac{\varepsilon}{2\pi z_2}\int_{-\pi}^{\pi} \frac{1-e^{-Mb\theta^2}}{\hat{f}\theta^2} \mathrm{d}\theta + \mathrm{O}(\varepsilon^2), \tag{C8}$$

where

$$\tilde{\alpha}(\theta) \simeq e^{b\theta^2}, \quad b = \frac{z_1(1-z_2^2)}{z_2^2(1+z_1)^2 - (1-z_1)^2} = \frac{1-z_2^2}{4z_2^2 m_b^2} \sim m_b^{-2}. \tag{C9}$$

Thus, for large M (and consequently, $\varepsilon \to 0$), we obtain

$$\frac{C_M^{(A)}}{\varepsilon} = \frac{1}{2\pi z_2}\int_{-\pi}^{\pi} \frac{1-e^{-Mb\theta^2}}{\hat{f}\theta^2} \mathrm{d}\theta = \frac{\sqrt{Mb}}{2\pi z_2 \hat{f}}\int_{-\sqrt{Mb}\pi}^{\sqrt{Mb}\pi} \frac{1-e^{-t^2}}{t^2} \mathrm{d}t$$
$$\simeq \frac{\sqrt{(1-z_2^2)M}}{\pi} m_b^3 \int_{-\infty}^{\infty} \frac{1-e^{-t^2}}{t^2} \mathrm{d}t = 2m_b^3 \sqrt{\frac{(1-z_2^2)M}{\pi}} = A_-(T)\sqrt{M}, \tag{C10}$$

where we have used Eqs. (3.6) and (C9), and the following formula;

$$\int_{-\infty}^{\infty} \frac{1-e^{-t^2}}{t^2} \mathrm{d}t = 2\sqrt{\pi}. \tag{C11}$$

Thus, we arrive at the following asymptotic formula:

$$C_M^{(A)} \simeq A_-(T)\sqrt{M} e^{-M/\xi}, \quad A_-(T) = 2\sqrt{\frac{1-z_2^2}{\pi}} m_b^3. \tag{C12}$$

Note that $A_-(T) \geqslant 0$ and $A_-(T) \sim m_b^3$.

Therefore, we arrive finally at

$$C_M \sim m_b^2 + \left\{ -A_-(T)\sqrt{M} + B(T) + \frac{C(T)}{\sqrt{M}} \right\} e^{-M/\xi}. \tag{C13}$$

Here, the coefficient $C(T)$ is shown to be of the order of m_b. The details of this derivation are omitted here.

APPENDIX D: CONSISTENCY OF EQ. (3.10) ON C_M WITH MORITA'S SUM RULE

Morita's sum rule is confirmed by extending our result on C_M given in Eq. (3.10) to correlations in oblique directions, $\{\langle S_{1,i} S_{M,j}\rangle\}$ in the form

$$C(|i-j|, M) \equiv \langle S_{1,i} S_{M,j}\rangle \simeq \frac{A' e^{-R/\xi}}{\sqrt{R}}, \quad R = \sqrt{x^2 + M^2}, \quad x = a_0|i-j|, \tag{D1}$$

where a_0 is an anisotropy parameter depending on z_1 and z_2, the coefficient A' may depend on the angle of the direction of the correlation, and it is proportional to $\sqrt{\kappa} = \sqrt{1/\xi}$. Then, Morita's sum rule will be asymptotically given by

$$J(M) \equiv \int_{-\infty}^{\infty} \frac{e^{-\kappa\sqrt{x^2+M^2}}}{\sqrt{\kappa}(x^2+M^2)^{1/4}} d(kx), \quad \kappa = \frac{1}{\xi}. \tag{D2}$$

In order to study the asymptotic form of this integral, we consider the following ratio:

$$I(M) \equiv J(M)/e^{-\kappa M} = \sqrt{\kappa}\int_{-\infty}^{\infty} \frac{e^{-\kappa(\sqrt{x^2+M^2}-M)}}{(x^2+M^2)^{1/4}} \mathrm{d}x \equiv \sqrt{\kappa}\int_{-\infty}^{\infty} f(x,M)\mathrm{d}x. \tag{D3}$$

The integrand $f(x,M)$ is rewritten as

$$f(x,M) = (x^2+M^2)^{-1/4} \exp\left[- \frac{\kappa x^2}{\sqrt{x^2+M^2}+M} \right]. \tag{D4}$$

Then, we separate the integral (D3) into the two parts $I(M) = \sqrt{\kappa}(I_1(M) + I_2(M))$, where

$$I_1(M) = 2\int_0^M f(x,M)\mathrm{d}x \quad \text{and } I_2(M) = 2\int_M^{\infty} f(x,M)\mathrm{d}x. \tag{D5}$$

It is easily shown that

$$\lim_{M\to\infty} I_2(M) \leqslant \lim_{M\to\infty} 2\int_M^{\infty} \frac{e^{-\kappa x}}{\sqrt{x}}\mathrm{d}x = 0 \tag{D6}$$

for $\kappa > 0$. As the function $f(x,M)$ satisfies the inequalities

$$\frac{e^{-\kappa x^2/2M}}{2^{1/4}\sqrt{M}} \leqslant f(x,M) \leqslant \frac{e^{-\kappa x^2/\{(\sqrt{2}+1)M\}}}{\sqrt{M}} \tag{D7}$$

for $0 \leqslant x \leqslant M$, we obtain the inequalities

$$2^{1/4}\sqrt{\pi} \leqslant I(\infty) \leqslant (\sqrt{2}+1)^{1/2}\sqrt{\pi} \tag{D8}$$

for $T \geqslant T_c$. Thus, we finally arrive at

$$J(M) \simeq A'_+(T)e^{-M/\xi}, \quad A'_+(T_c) \neq 0. \tag{D9}$$

This is nothing but Morita's sum rule.

It will be instructive to present here a rough but direct estimate of the integral (D2) as follows:

$$J(M) \simeq \sqrt{\frac{\kappa}{M}}\int_{-\infty}^{\infty} \exp\left[- \kappa M\left(1 + \frac{x^2}{2M^2}\right)\right]\mathrm{d}x = \sqrt{2\pi}e^{-\kappa M}. \tag{D10}$$

The prefactor $\sqrt{2\pi}$ in Eq. (D10) satisfies the inequality (D8). This rough estimation has been already made in Ref. 26 in applications of Morita's sum rule to the coherent anomaly method.[27]

The above extended form (D1) will be derived rigorously[28] using again the topological interaction method by applying the interaction $J''\Sigma_{k=1}^{N} S_{1,i+k}S_{M,j+k}$ for fixed i and j to the two-dimensional Ising model with width M and length N.

(Received 1 October 2004; accepted 6 December 2004; published online 14 February 2005)

We apply the method of determinants to study the distribution of the largest singular values of large $m \times n$ real rectangular random matrices with independent Cauchy entries. We show that for a special one-parametric class of statistics the properties of the largest singular values (rescaled by a factor $1/m^2n^2$) agree in the limit with the statistical properties of the Poisson random point process with the intensity $(1/\pi)x^{-3/2}$ and, therefore, are different from the Tracy–Widom law. Among other corollaries of our method we show an interesting connection between the mathematical expectations of the determinants of the complex rectangular $m \times n$ standard Wishart ensemble and the real rectangular $2m \times 2n$ standard Wishart ensemble. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1855932]

I. INTRODUCTION AND FORMULATION OF RESULTS

The main goal of this paper is to study the spectral properties of a large random matrix with independent identically distributed (i.i.d.) Cauchy entries. In other words we consider a rectangular $m \times n$ matrix $A=(a_{ij}), 1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n$, where $\{a_{ij}\}$ are independent identically distributed Cauchy random variables with the probability density $f(x)=1/\pi(1+x^2)$. Our goal is to study the singular values of A as the dimensions of a matrix go to infinity, $m \to \infty$, $n \to \infty$. This is clearly equivalent to studying the eigenvalues of a positive-definite $n \times n$ matrix $M=A^tA$. Matrices of such type are quite often called sample covariance matrices in random matrix literature. Positive-definite matrices are of particular importance in statistics (we refer to Refs. 33, 50, and 20 for the classical works on statistical applications of the spectral properties of Wishart matrices, and Refs. 21, 14, 16, and 30 for a few recent developments and applications to various fields). They also are of long-standing interest in nuclear physics, starting with the classical works of Refs. 49 and 9. More recently they were used to model the "dissipative" part of the effective Hamiltonian in quantum chaotic scattering (see Ref. 19 and references therein) and appeared to be very intimately connected with the "chiral" ensembles studied in quantum chromodynamics (see Ref. 45). As other important applications of random positive-definite matrices we mention that they are used in a branch of condensed matter theory known as mesoscopics to model famous universal conductance fluctuations and other transport properties of small metallic samples and quantum dots (see Ref. 4) and also emerged in theory of information communication in random environment.[44]

It is well known that if the entries of A are i.i.d. random variables with zero mean and finite variance σ^2, the empirical distribution function of the eigenvalues of $(1/n)A^tA$ converges in the limit $m \to \infty$, $n \to \infty$, $m/n \to \gamma \in (0, +\infty)$ to the Marchenko–Pastur law (see, e.g., Refs. 29 and 2) defined by its density

$$p_\gamma(x) = (2\pi x\gamma\sigma^2)^{-1}\sqrt{(b-x)(x-a)}, \quad a \leqslant x \leqslant b, \tag{1}$$

where $a=\sigma^2(1-\gamma^{-1/2})^2$ and $b=\sigma^2(1+\gamma^{-1/2})^2$ (we assume here $\gamma \geqslant 1$). Since the spectrum of A^tA differs from the spectrum of AA^t only by the multiplicity of the eigenvalue $\lambda=0$ (for $m \geqslant n$ the matrix AA^t has $m-n$ additional zero eigenvalues) for the rest of the paper we can assume $m \geqslant n$. Under the assumption that the fourth moment of a_{ij} is finite, Yin, Bai, and Krishnaiah (Ref. 51, see also Refs. 34 and 3) showed that the largest eigenvalue of $(1/n)A^tA$ converges to b almost surely. Recently Johnstone proved that in the standard Wishart case [i.e., $\{a_{ij}\}$ are i.i.d. $N(0,1)$ random variables] the properly rescaled largest eigenvalue converges in distribution to the $\beta=1$ Tracy–Widom distribution,[42] (see also Ref. 41). Soshnikov[38] generalized the result of Johnstone to the non-Gaussian case provided $n-m=O(n^{1/3})$ and the moments of the matrix entries do not grow very fast. There are quite a few standard methods that have been successfully used for Wigner and sample covariance matrices in the case when second and higher moments of matrix entries exist, most notably the method of moments,[47,48,35–38] the method of resolvents,[29,28,2] the method of orthogonal polynomials,[13,25] the method used by Johansson[23] (and recently extended by Ben Arous and Péché to the case of sample covariance matrices) which is based on the Kazakov–Brézin–Hikami trick,[27,7,8] etc. Unfortunately, the above-mentioned approaches are not suitable for the Cauchy case. In particular, one can expect the spectral properties of A^tA in the Cauchy case to be rather different from the case of a finite variance. In our view this makes the studies of the Cauchy case especially interesting. Denote the eigenvalues of A^tA by $\lambda_1 \geqslant \lambda_2 \geqslant \lambda_3 \geqslant \cdots \geqslant \lambda_n$. It is expected that the majority of the eigenvalues are proportional to mn. We would like to specifically single out Ref. 11 where Cizeau and Bouchard studied the spectral properties of the Wigner random matrices with the heavy tails (see also Refs. 10 and 22 for physical papers on the so-called Lévy–Smirnov unitary ensembles). Among other things, Cizeau and Bouchard argued (on a physical level of rigor) that the empirical distribution function of the eigenvalues of a properly normalized Wigner matrix (with the heavy tails of the marginal distribution of matrix entries) converges to a limiting distribution that can be obtained as a solution of a quite complicated system of two integral equations [we refer to the formulas (15), (12a), (12b) in Ref. 11]. It is not difficult to guess the right order of the normalization: after the normalization, the norm of any given matrix row has to be of order of a constant (in particular in the Cauchy case one has to normalize the matrix entries by n^{-1} and in the case of a finite variance the normalization is $1/\sqrt{n}$). The support of the limiting distribution is the whole real line. One can expect (arguing at the same level of physical rigor) to derive a similar system of integral equations for the limiting distribution function of the eigenvalues of $(1/mn)A^tA$ in the case of the i.i.d. Cauchy entries of A. The support of the limiting distribution should be the positive half of the real line. Our results formulated below indicate that the asymptotics of the spectral density at infinity should be $1/\pi x^{3/2}$. This suggests that the largest eigenvalues of A^tA grow faster than mn; in fact, we will show below that the largest eigenvalues are of the order of m^2n^2. Let us rescale the eigenvalues by that factor:

$$\tilde{\lambda}_i = \frac{\lambda_i}{n^2m^2}, \quad i = 1, \ldots, n. \tag{2}$$

The goal of this paper is to study the local distribution of the largest eigenvalues by the method of determinants. Our main results are Theorems 1.1 and 1.2 formulated below.

Theorem 1.1: *Let A be a random rectangular $m \times n$ matrix $(m \geqslant n)$ with i.i.d. Cauchy entries and z a complex number with a positive real part. Then as $n \to \infty$ we have*

$$\lim_{n\to\infty} E\left(\det\left(1+\frac{z}{m^2n^2}A^tA\right)\right)^{-1/2} = E\prod_{i=1}^{n}(1+z\tilde{\lambda}_i)^{-1/2} = \exp\left(-\frac{2}{\pi}\sqrt{z}\right) \tag{3}$$

$$= \mathbf{E}\prod_{i=1}^{\infty}(1+zx_i)^{-1/2}, \tag{4}$$

where we consider the branch of $\sqrt{z}$ *on* $D=\{z:\Re z>0\}$ *such that* $\sqrt{1}=1$, *E denotes the mathematical expectation with respect to the random matrix ensemble defined above,* **E** *denotes the mathematical expectation with respect to the inhomogeneous Poisson random point process on the positive half-axis with the intensity* $1/\pi x^{3/2}$, *and the convergence is uniform inside D* (*i.e., it is uniform on the compact subsets of D*). *For a real positive* $z=t^2$, $t\in\mathbb{R}$, *one can estimate the rate of convergence, namely,*

$$\lim_{n\to\infty} E\left(\det\left(1+\frac{t^2}{m^2n^2}A^tA\right)\right)^{-1/2}=\lim_{n\to\infty} E\prod_{i=1}^{n}(1+t^2\tilde{\lambda}_i)^{-1/2}=\exp\left(-\frac{2}{\pi}|t|(1+o(n^{-1/2+\epsilon}))\right), \quad (5)$$

where ϵ *is an arbitrary small positive number and the convergence is uniform on the compact subsets of* $[0,+\infty)$.

We will discuss the properties of Poisson random point processes in the Appendix. A very useful introduction to the elementary theory and methods of random point processes is Ref. 12. It is not a coincidence that the intensity of the Poisson random process in the above theorem is equal to the leading term of the asymptotics of the density of the square of a standard Cauchy random variable.

We claim that the result can be generalized to the case of a sparse random matrix with Cauchy entries. Let, as before, $\{a_{jk}\}$, $1\leqslant j\leqslant m$, $1\leqslant k\leqslant n$, be i.i.d. Cauchy random variables, and $Q=(q_{jk})$ be a $m\times n$ nonrandom rectangular $0-1$ matrix such that the number of nonzero entries in each column is fixed and equals to b_n. For technical reasons we assume that b_n grows to infinity as some power of n, i.e., $b_n\geqslant n^{\alpha}$, for some $0<\alpha\leqslant 1$, and $\ln m$ is much smaller than any power of n. We define a $m\times n$ rectangular matrix A with the entries $\Gamma_{jk}=q_{jk}a_{jk}$, $1\leqslant j\leqslant m$, $1\leqslant k\leqslant n$. As before we denote by $\lambda_1\geqslant\lambda_2\cdots\geqslant\lambda_n$ the eigenvalues of $\Gamma^t\Gamma$. The appropriate rescaling for the largest eigenvalues in this case is going to be $\tilde{\lambda}_i=\lambda_i/m^2b_n^2$, $i=1,\ldots,n$. We claim that the result of Theorem 1.1 can be extended to the case of a sparse random matrix Γ.

Theorem 1.2: *Let* Γ *be a sparse random rectangular* $m\times n$ *matrix* ($m\geqslant n$) *defined as above and z a complex number with a positive real part. Then as* $n\to\infty$ *we have*

$$\lim_{n\to\infty} E\left(\det\left(1+\frac{z}{m^2b_n^2}\Gamma^t\Gamma\right)\right)^{-1/2}=\lim_{n\to\infty} E\prod_{i=1}^{n}(1+z\tilde{\lambda}_i)^{-1/2}=\exp\left(-\frac{2}{\pi}\sqrt{z}\right) \quad (6)$$

$$=\mathbf{E}\prod_{i=1}^{\infty}(1+zx_i)^{-1/2}, \quad (7)$$

where, as in Theorem 1.1, we consider the branch of $\sqrt{z}$ *on* $D=\{z:\Re z>0\}$ *such that* $\sqrt{1}=1$, *E denotes the mathematical expectation with respect to the random matrix ensemble defined in the paragraph above the theorem,* **E** *denotes the mathematical expectation with respect to the inhomogeneous Poisson random point process on the positive half-axis with the intensity* $1/\pi x^{3/2}$, *and the convergence is uniform inside D* (*i.e., it is unform on the compact subsets of D*). *For a real positive* $z=t^2$, $t\in R$, *one can get an estimate on the rate of convergence, namely,*

$$E\left(\det\left(1+\frac{t^2}{m^2b_n^2}\Gamma^t\Gamma\right)\right)^{-1/2}=E\prod_{i=1}^{n}(1+t^2\tilde{\lambda}_i)^{-1/2}=\exp\left(-\frac{2}{\pi}t(1+o(b_n^{-1/2+\epsilon}))\right), \quad (8)$$

where ϵ *is an arbitrary small positive number and the convergence is uniform on the compact subsets of* $[0,+\infty)$.

The result of Theorem 1.2 can be generalized even further. Let the setting be as in Theorem 1.2 but relax the condition that the number of nonzero entries in each column is exactly b_n to the condition $\Sigma_{k=1}^{n}q_{jk}=b_n(1+o(1))$, $j=1,\ldots,m$ (for example, the relaxed condition is satisfied by a typical realization of a random matrix Q with independent Bernoulli $0-1$ entries with $\Pr(q_{jk}=1)=b_n/n$]. Then we still have

$$E\left(\det\left(1+\frac{z}{m^2b_n^2}\Gamma^t\Gamma\right)\right)^{-1/2}=\exp\left(-\frac{2}{\pi}\sqrt{z}\right)(1+o(1)).$$

The proof is almost identical to the proof of Theorem 1.2 and will be left to the reader.

The case when the number of nonzero terms of Q is fixed in each row can be treated in a similar manner.

An important consequence of Theorems 1.1 and 1.2 is that the statistical properties of the largest eigenvalues $\tilde{\lambda}_1,\tilde{\lambda}_2,\ldots$ are drastically different from the statistical properties of the (rescaled) largest eigenvalues in the GOE[42] and real Wishart cases[25] that are described by the ($\beta=1$) Tracy–Widom law.

Theorems 1.1 and 1.2 follow from Proposition 1 formulated below.

Proposition 1: *Let $A=(a_{jk})$ be a random rectangular $m\times n$ matrix with independent (not necessarily identically distributed) entries with the characteristic functions of the matrix entries $g_{jk}(s)=E\exp(isa_{jk})$. Let $t_i>0$, $i=1,\ldots,r$, be some positive parameters. Then the following formula holds.*

$$E\left(\prod_{i=1}^{r}\det(1+t_i^2A^tA)\right)^{-1/2}=(2\pi)^{-r(n+m)/2}\int_{R^{r(n+m)}}\prod_{i=1}^{r}d^ns^{(i)}d^mp^{(i)}\times\exp\left(-\sum_{i=1}^{r}(|s^{(i)}|^2/2+|p^{(i)}|^2/2)\right)\prod_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}g_{jk}\left(\sum_{i=1}^{r}t_ip_j^{(i)}s_k^{(i)}\right). \tag{9}$$

Theorems 1.1 and 1.2 imply several important corollaries that are given in the next section.

The proofs of Theorems 1.1 and 1.2 and Proposition 1 are given in the next section. Section III is devoted to application of the method of determinants to random matrices with i.i.d. complex entries. We prove in Sec. III the analogue of Proposition 1 (Proposition 2) in the complex case and as a corollary establish an interesting connection between the determinants in the $2m\times 2n$ rectangular real Wishart case and the $m\times n$ rectangular complex Wishart case (see Lemma 1).

II. PROOFS OF THEOREMS 1.1 AND 1.2

We start with the proof of Proposition 1. Consider $(\det(1+t^2A^tA))^{-1/2}$, $t>0$. Let $s=(s_1,\ldots,s_n)^t$, $p=(p_1,\ldots,p_m)^t$ be real n- and m-dimensional column vectors. Let $B=B(t)=\left(\begin{smallmatrix} Id & tiA \\ tiA^t & Id\end{smallmatrix}\right)$ and $d^nsd^mp=\Pi_{i=1}^n ds_i\Pi_{j=1}^m p_i$.

Then

$$(\det(1+t^2A^tA))^{-1/2}=\left(\det\begin{pmatrix}1 & tiA\\ tiA^t & 1\end{pmatrix}\right)^{-1/2}=(\det(B))^{-1/2},$$

and, since the Hermitian part of the matrix B is positive definite, $(\det(B))^{-1/2}$ can be written as the Gaussian integral over $\mathbb{R}^{m+n}$ [according to our notations introduced above (s,p) is an $(m+n)$-dimensional vector; in the next formula $(s,p)B(s,p)^t$ stands for the value of the quadratic form associated with the matrix B on the vector (s,p)]:

$$\begin{aligned}(\det(1+t^2A^tA))^{-1/2}&=(\det(B))^{-1/2}\\&=\left(\frac{1}{\pi}\right)^{(n+m)/2}\int d^nsd^mp\exp(-(s,p)B(s,p)^t)\\&=\left(\frac{1}{\pi}\right)^{(n+m)/2}\int d^nsd^mp\exp(-(|s|^2+|p|^2))\left(\exp\left(-2i\sum_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}ta_{jk}p_js_k\right)\right).\end{aligned} \tag{10}$$

The formula (10) and the independence of matrix entries imply

$$E\left(\prod_{i=1}^{r}\det(1+t_i^2A^tA)\right)^{-1/2}=\pi^{-r(n+m)/2}\int_{R^{r(n+m)}}\prod_{i=1}^{r}d^ns^{(i)}d^mp^{(i)}\exp\left(-\sum_{i=1}^{r}(|s^{(i)}|^2+|p^{(i)}|^2)\right)$$
$$\times E\prod_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}\exp\left(2ia_{jk}\sum_{i=1}^{r}t_ip_j^{(i)}s_k^{(i)}\right)$$
$$=(2\pi)^{-r(n+m)/2}\int_{R^{r(n+m)}}\prod_{i=1}^{r}d^ns^{(i)}d^mp^{(i)}\exp\left(-\sum_{i=1}^{r}(|s^{(i)}|^2/2+|p^{(i)}|^2/2)\right)$$
$$\times\prod_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}g_{jk}\left(\sum_{i=1}^{r}t_ip_j^{(i)}s_k^{(i)}\right). \tag{11}$$

The Proposition is proven.

To prove Theorem 1.1 we observe that the functions on the lhs of (3) are analytic and uniformly bounded in $D=\{z:\Re z>0\}$. Therefore, by the Vitali's theorem it is enough to prove the convergence for real positive z. Let us denote $z=t^2$, where t is a positive real number, and apply the result of the proposition in the case $r=1$. Since the matrix entries of A are i.i.d. Cauchy we have $g_{jk}(s)=g(s)=\exp(-|s|)$ and

$$E(\det(1+t^2A^tA))^{-1/2}=(2\pi)^{-(n+m)/2}\int_{R^{n+m}}d^nsd^mp\exp(-(|s|^2+|p|^2)/2)\prod_{1\leqslant j\leqslant n,1\leqslant k\leqslant m}\exp(-t|s_kp_j|)$$
$$=2^m\int_{R^n}d^ns(2\pi)^{-n/2}\exp\left(-\frac{1}{2}|s|^2\right)\int_{R_+^m}(2\pi)^{-m/2}$$
$$\times\exp\left(-\frac{1}{2}\sum_{j=1}^{m}(p_j^2+2p_jt\sum_{k=1}^{n}|s_k|)\right)$$
$$=\int_{R^n}d^ns(2\pi)^{-n/2}\exp\left(-\frac{1}{2}|s|^2\right)\Psi^m\left(t\sum_{k=1}^{n}|s_k|\right), \tag{12}$$

where $\Psi(y)=2e^{y^2/2}\int_y^{+\infty}(1/\sqrt{2\pi})e^{-t^2/2}dt$. In particular, $\Psi(0)=1$ and $\Psi'(0)=-(2/\pi)^{1/2}$. It is easy to see that the function $\Psi(y)$ is monotonically decreasing on $[0,+\infty)$, in particular $1=\Psi(0)=\max_{[0,+\infty)}\Psi(y)$. Indeed, $\Psi'(y)=2ye^{y^2/2}\int_y^{+\infty}(1/\sqrt{2\pi})e^{-t^2/2}dt-2(1/\sqrt{2\pi})$. The assertion then follows from the inequality $y^{-1}e^{-y^2/2}>\int_y^{+\infty}e^{-t^2/2}dt$ for $y>0$.

Replacing t by t/nm we arrive at

$$E\left(\det\left(1+\frac{t^2}{n^2m^2}A^tA\right)\right)^{-1/2}=\int_{R^n}d^ns(2\pi)^{-n/2}\exp\left(-\frac{1}{2}|s|^2\right)\Psi\left(\frac{t}{nm}\sum_{k=1}^{n}|s_k|\right)^m. \tag{13}$$

The rhs of the last formula suggests to use the law of large numbers and large deviations estimates for the sum of the absolute values of n standard Gaussian random variables. Since $\int(1/2\pi)|s|e^{-s^2/2}ds=(2/\pi)^{1/2}$, we see that $(1/n)\Sigma_{j=1}^{n}|s_j|=(2/\pi)^{1/2}+o(n^{-1/2+\epsilon})$ with probability $1-O(\exp(-n^{1.99\epsilon}))$. Recalling that $\Psi(0)=1$ and $\Psi'(0)=-(2/\pi)^{1/2}$ we get

$$E\left(\det\left(1+\frac{t^2}{n^2m^2}A^tA\right)\right)^{-1/2}=\int_{R^n}d^ns(2\pi)^{-n/2}\exp\left(-\frac{1}{2}|s|^2\right)\left(1-\frac{2t(1+o(n^{-1/2+\epsilon}))}{\pi m}\right)^m$$
$$=\left(1-\frac{2t(1+o(n^{-1/2+\epsilon}))}{\pi m}\right)^m=\exp\left(-\frac{2t(1+o(n^{-1/2+\epsilon}))}{\pi}\right),\quad(14)$$

for any $\epsilon>0$ Theorem 1.1 is then followed by the Vitali theorem.

The proof of Theorem 1.2 is very similar. Again we can restrict our attention to the case when z is a real positive number, $z=t^2$. We have

$$E(\det(1+t^2\Gamma^t\Gamma))^{-1/2}=\int_{R^n}d^ns(2\pi)^{-n/2}\exp\left(-\frac{1}{2}|s|^2\right)\prod_{j=1}^m\Psi\left(t\sum_{k=1}^n q_{jk}|s_k|\right).\quad(15)$$

Let $k_1^{(j)},k_2^{(j)},\ldots,k_{b_n}^{(j)}$ be the indices k for which $q_{jk}=1$. Then $\Sigma_{k=1}^n q_{jk}|s_k|=\Sigma_{l=1}^{b_n}|s_{k_l^{(j)}}|$ and we can claim that $(1/b_n\Sigma_{l=1}^{b_n}|s_{k_l^{(j)}}|=(2/\pi)^{1/2}+o(b_n^{-1/2+\epsilon})$ with probability $1-O(\exp(-b_n^{1.99\epsilon}))$ for each $1\leqslant j\leqslant m$. Since we assumed that $\ln(m)$ is much smaller than any power of n we get similarly to (14) that

$$E\left(\det\left(1+\frac{t^2}{m^2b_n^2}\Gamma^t\Gamma\right)\right)^{-1/2}=\int_{R^n}d^ns(2\pi)^{-n/2}\exp\left(-\frac{1}{2}|s|^2\right)\left(1-\frac{2t(1+o(b_n^{-1/2+\epsilon}))}{\pi m}\right)^m$$
$$=\left(1-\frac{2t(1+o(b_n^{-1/2+\epsilon}))}{\pi m}\right)^m=\exp\left(-\frac{2t(1+o(b_n^{-1/2+\epsilon}))}{\pi}\right).\quad(16)$$

Theorem 1.2 is proven.

Below we restrict our attention to the corollaries of Theorem 1.1 (full matrix case). The corollaries of Theorem 1.2 are basically identical to those of Theorem 1.1 (with an obvious change of n to b_n where it is needed).

Remark 0: We are not aware that the results of Theorems 1.1 and 1.2 are enough to imply that ths statistics of the largest eigenvalues are Poisson in the limit of $n\to\infty$. Indeed, to prove the Poisson statistics in the limit one has to show that

$$\lim_{n\to\infty}E\prod_{i=1}^n(1+f(\tilde{\lambda}_i))=\mathbf{E}\prod_{i=1}^{+\infty}(1+f(x_i))\quad(17)$$

for a sufficiently large class of the test functions f. The results of Theorems 1.1 and 1.2 claim that (17) is valid for $f(x)=(1+zx)^{-1/2}-1$ for all z such that $\Re z>0$. Below we formulate several corollaries of our main result that are weaker than the claim about the Poisson statistics, but still give us some information about the behavior of the largest eigenvalues. The proof of the Poisson statistics for the largest eigenvalues in Wigner random matrices with heavy tails will appear in Ref. 39.

Remark 1: It follows immediately from the result of Theorem 1.1 that "only a finite number" of the eigenvalues λ_i are of the order of n^2m^2. Indeed, let $N_{n,m}$ be an integer growing to infinity arbitrarily slowly as $n\to\infty$ and let $\delta>0$ be an arbitrarily small positive number. Then $\Pr(\#(\lambda_i\geqslant\delta n^2m^2)\geqslant N_{n,m})\to 0$ as $n\to\infty$. Indeed, suppose this is not the case. Then $\Pr(\#(\lambda_i\geqslant\delta n^2m^2)\geqslant N_{n,m})\geqslant\kappa>0$ and $E(\det(1+(t^2/n^2m^2)A^tA))^{-1/2}\leqslant\kappa(1+t^2\kappa)^{-N_{n,m}}+(1-\kappa)1$. One obtains a contradiction since for $t=N_{n,m}^{-1}$ the rhs of the last inequality does not go to zero (see also the next remark). One can also rewrite the statement of this remark in the following way: for any positive δ, κ, there exist $n_0(\delta,\kappa)$ and $C(\delta,\kappa)$ such that $\Pr(\#(\lambda_i\geqslant\delta n^2m^2)\geqslant C)<\kappa$ for all $n_0\leqslant n\leqslant m$.

Remark 2: It is clear from the proof of Theorem 1.1 that the asymptotic result

$$E\left(\det\left(1+\frac{t^2}{n^2m^2}A^tA\right)\right)^{-1/2}=\exp\left(-\frac{2t(1+o(n^{-1/2+\epsilon}))}{\pi}\right)$$

holds uniformly in t on compact subsets of $[0,+\infty)$. In particular the result is valid for a sequence $t_n\to 0$.

Below we formulate and prove some additional consequences of Theorem 1.1. Our first observation is that one can repeatedly differentiate (3) with respect to parameter z.

Corollary 1: Let $\Re z>0$. *Then*

$$\lim_{n\to\infty}E\prod_{i=1}^{n}(1+z\tilde{\lambda}_i)^{-1/2}\left(\sum_{j=1}^{n}\frac{\tilde{\lambda}_i}{1+z\tilde{\lambda}_i}\right)=\frac{2}{\pi}z^{-1/2}\exp\left(-\frac{2}{\pi}\sqrt{z}\right) \tag{18}$$

$$=\mathbf{E}\prod_{i=1}^{\infty}(1+zx_i)^{-1/2}\left(\sum_{j=1}^{\infty}\frac{x_i}{1+zx_i}\right), \tag{19}$$

where, as above, **E** *stands for the mathematical expectation with respect to the inhomogeneous Poisson random point process on* $(0,+\infty)$ *with the intensity* $\rho(x)=1/\pi x^{3/2}$.

Remark 3: If we let $z\to 0$ in (18), one gets $E(\Sigma_{j=1}^{n}\tilde{\lambda}_i)=+\infty$, which trivially follows from the fact that matrix entries of A are Cauchy random variables. Essentially the result of the corollary can tell us how fast the mathematical expectation $E(\Sigma_j\tilde{\lambda}_j)$ grows if we restrict the summation only to $\tilde{\lambda}_i\leqslant L$ where L is large.

Proof of Corollary 1: The result immediately follows from the uniform convergence of the analytic functions in (3) and (4).

By differentiating (3) twice one can obtain in a similar fashion that

$$\lim_{n\to\infty}E\prod_{i=1}^{n}(1+z\tilde{\lambda}_i)^{-1/2}\left(\left(\sum_{j=1}^{n}\frac{\tilde{\lambda}_i}{1+z\tilde{\lambda}_i}\right)^2+\sum_{i=1}^{n}\frac{(\tilde{\lambda}_i)^2}{(1+z\tilde{\lambda}_i)^2}\right)=\left(\frac{4}{\pi^2}z^{-1}+\frac{2}{\pi}z^{-3/2}\right)\exp\left(-\frac{2}{\pi}\sqrt{z}\right). \tag{20}$$

Corollary 2: There is a constant C *which depends on* γ *such that for* $\Pr(\lambda_1/n^2m^2>x)<Cx^{-1/2}$ *uniformly for large* $n\leqslant m$ *and* x.

Indeed, it follows from Theorem 1.1 and Remark 1 that $E(1+t^2\tilde{\lambda}_1)^{-1/2}\geqslant\exp(-2t(1+o(n^{-1/2+\epsilon}))/\pi)$ uniformly in t on compact subsets of $[0,\infty)$. Therefore $(1-\Pr(\tilde{\lambda}_1>x))+1/\sqrt{1+t^2x}\times\Pr(\tilde{\lambda}_1>x)\geqslant\exp(-(2/\pi)t(1+o(n^{-1/2+\epsilon})))$, which implies $1-\exp(-(2/\pi)t(1+o(n^{-1/2+\epsilon})))\geqslant(1-1/\sqrt{1+t^2x})\Pr(\tilde{\lambda}_1>x)$. Choosing $t^2x=1$ we obtain that $(2/\pi)\gamma x^{-1/2}(1+\delta)\geqslant(1-2^{-1/2})\Pr(\tilde{\lambda}_1>x)$ for all sufficiently large n, m, and x.

Remark 4: It is not difficult to show that in probability $\lambda_1=O(n^2m^2)$. To see this we observe that the operator norm $\|A\|$ can be bounded from below by $\max_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}|a_{jk}|$. The maximum of $n\times m$ i.i.d. Cauchy random variables is of the order $O(nm)$ [with the limiting distribution of $1/nm\times\max_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}|a_{jk}|$ easily computable, namely $\Pr((1/nm)\max_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}|a_{jk}|\leqslant x)\to\exp(-2/\pi x)$]. We expect that the limiting distribution λ_1/n^2m^2 also exists and is given by the distribution of the rightmost particle in the Poisson process with the intensity $\rho(x)=(1/\pi)x^{-3/2}$, in other words, $\lim_{n\to\infty}\Pr(\tilde{\lambda}_1<x)=\exp(-(2/\pi)x^{-1/2})$.

It is a useful exercise to see what Proposition 1 gives in the Wishart case. Below we treat the case of one determinant:

$$
\begin{aligned}
E(\det(1+t^2A^tA))^{-1/2} &= (2\pi)^{-(n+m)/2}\int_{R^{n+m}} d^n s d^m p\, \exp(-(|s|^2+|p|^2)/2) \\
&\quad \times \prod_{1\leqslant j\leqslant n,1\leqslant k\leqslant m} \exp\left(-\frac{1}{2}(ts_kp_j)^2\right) \\
&= \int_{R^n} d^n s (2\pi)^{-n/2} \exp\left(-\frac{1}{2}|s|^2\right)\int_{R^m} d^m p (2\pi)^{-m/2} \\
&\quad \times \prod_{k=1}^{m} \exp\left(-\frac{1}{2}p_k^2\left(1+t^2\sum_{j=1}^{n} s_j^2\right)\right) \\
&= \int_{R^n} d^n s (2\pi)^{-n/2} \exp\left(-\frac{1}{2}|s|^2\right)\left(1+t^2\sum_{j=1}^{n} s_j^2\right)^{-m/2} \\
&= c_n\int_0^{+\infty} \exp\left(-\frac{1}{2}r^2\right) r^{n-1}(1+t^2r^2)^{-m/2}\, dr \\
&= c_n 2^{n/2-1}\int_0^{+\infty} e^{-r} r^{n/2-1}(1+2t^2r)^{-m/2}\, dr, \qquad (21)
\end{aligned}
$$

where c_n is the normalization constant, $c_n^{-1}=\int_0^{+\infty}\exp\left(-\frac{1}{2}r^2\right)r^{n-1}\,dr=2^{n/2-1}\Gamma(n/2)$. To study the global distribution of the eigenvalues in the Wishart ensemble one has to consider rescaling $t^2 \to t^2/n$ (since typical eigenvalues of A^tA are of the order of n). It follows that

$$
\begin{aligned}
E\left(\det\left(1+\frac{t^2}{n}A^tA\right)\right)^{-1/2} &= [\Gamma(n/2)]^{-1}\int_0^{+\infty} e^{-r} r^{n/2-1}\left(1+2t^2\frac{r}{n}\right)^{-m/2} dr \\
&= [\Gamma(2/n)]^{-1}(2/n)^{n/2}\int_0^{+\infty} e^{-n/2r} r^{n/2}(1+t^2r)^{-m/2} r^{-1}\, dr \\
&= [\Gamma(2/n)]^{-1}(2/n)^{n/2}\int_0^{+\infty} e^{-n/2\mathcal{L}(z)} z^{-1}\, dz, \qquad (22)
\end{aligned}
$$

where $\mathcal{L}(z)=z+(m/n)\ln(1+t^2z)-\ln z$. The asymptotics of the last integral can be obtained by the steepest descent method. The formulas are especially simple in the square case $m=n$. One then can find a positive solution of the equation

$$
\frac{d\mathcal{L}}{dz} = 1+\frac{t^2}{1+t^2z}-\frac{1}{z} = \frac{t^2z^2+z-1}{z(1+t^2z)} = 0 \qquad (23)
$$

to be $z(t)=(-1+\sqrt{4t^2+1})/2t^2$. Taking into account that $d^2\mathcal{L}/dz^2=\sqrt{4t^2+1}$ at $z=z(t)$ we obtain that in the square Wishart case

$$
\begin{aligned}
E\left(\det\left(1+\frac{t^2}{n}A^tA\right)\right)^{-1/2} &= \frac{2^n n^{n/2}}{\Gamma(n/2)}\exp\left(-n\frac{-1+\sqrt{4t^2+1}}{4t^2}\right)(1 \\
&\quad +\sqrt{4t^2+1})^{-n}\sqrt{\frac{2\pi\sqrt{4t^2+1}}{n}}\frac{2t^2}{-1+\sqrt{4t^2+1}}(1+o(1)). \qquad (24)
\end{aligned}
$$

The fact that the asymptotics in (24) is exponential in n is standard. Indeed, it is a straightforward exercise to verify that

$$\lim_{n\to\infty}\frac{1}{n}\ln\left(E\left(\det\left(1+\frac{t^2}{n}A^tA\right)\right)^{-1/2}\right)=-\frac{1}{2}\int_0^4(\ln(1+t^2x)p_1(x))\,dx, \tag{25}$$

where $p_1(x)$ is the probability density of the Marchenko–Pastur law defined in (1), which reflects the law of large numbers for the linear statistics $\Sigma_{i=1}^n \ln(1+t^2\lambda_i n^{-1})$ where $\{\lambda_i\}_{i=1}^n$ are the eigenvalues of the real Wishart matrix. The variance of the linear statistics is bounded and has a limit as $n\to\infty$ (for a rather general class of polynomial ensembles of random matrices it was first discovered by Johansson in (Ref. 24), thus contributing a constant term to the rhs of (24), so that

$$\begin{aligned}E\left(\det\left(1+\frac{t^2}{n}A^tA\right)\right)^{-1/2}&=E\left(\exp\left(-\frac{1}{2}\sum_{i=1}^n\ln(1+t^2\lambda_i n^{-1})\right)\right)\\&=\exp\left(-\frac{1}{2}E\left(\sum_{i=1}^n(\ln(1+t^2\lambda_i n^{-1}))\right)+\frac{1}{8}d(t)+o(1)\right),\end{aligned} \tag{26}$$

where $d(t):=\lim_{n\to\infty}\mathrm{Var}(\Sigma_{i=1}^n(\ln(1+t^2\lambda_i n^{-1})))$ and can be explicitely calculated (see Ref. 24, Theorem 2.4).

Remark 5: Another class of random matrices we are particularly interested in is the Rademacher random matrices (i.e., square random matrices with ±1 i.i.d. entries), which we are going to denote by $\mathcal{R}$. It appears that the questions of the invertibility of a Rademacher random matrix and the estimate of the norm of the inverse are of great importance in geometric functional analysis (for example, in connection with a deterministic construction of Euclidean sections of convex bodies). Similar to the previous analysis one can obtain

$$E\frac{1}{\sqrt{\det(1+t^2\mathcal{R}^t\mathcal{R})}}=\frac{1}{(2\pi)^n}\int_{R^{2n}}\prod_{i=1}^n du_i dv_i\exp\left(-\frac{1}{2}\sum_{i=1}^n(u_i^2+v_i^2)\right)\prod_{j,k=1}^n\cos(tu_jv_k). \tag{27}$$

The fact that a Rademacher matrix R is invertible with probability going to 1 as $n\to\infty$ was proved by J.Komlós (see, e.g., Ref. 6, Chap. 14). More recently, Kahn, Komlós and Szemeredi[26] proved that the probability that R is invertible is exponentially close to 1. To the best of our knowledge there is no known estimate on the norm of the inverse matrix (which, in our language, corresponds to the estimate of the smallest eigenvalue of R^tR).

III. COMPLEX MATRICES WITH i.i.d. ENTRIES

In this section we consider the ensemble of $n\times n$ complex random matrices $M=A^*A$, $A=(A_{jk})_{1\leqslant j\leqslant m,1\leqslant k\leqslant n}$, with the joint distribution of the matrix entries of A given by the formula

$$\Pr(A)dA\overline{dA}=\prod_{1\leqslant j\leqslant m,\ 1\leqslant k\leqslant n}\left\{d\Re a_{jk}d\Im a_{jk}\frac{1}{\pi}f(|a_{jk}|^2)\right\}. \tag{28}$$

In other words $\{a_{jk},1\leqslant j\leqslant m,1\leqslant k\leqslant n\}$ are independent indentically distributed random variables with a distribution depending only on the radial component, and $f(x)$ is the density of the distribution of $|a_{jk}|^2$. The ensemble (28) is a generalization of the standard Wishart (Laguerre) ensemble which corresponds to the choice $f(x)=e^{-x}$.

In the standard Wishart (Laguerre) case it is known that the smallest eigenvalues are proportional to $1/n^2$, and the (rescaled) k-point correlation functions are given in the limit $n\to\infty$ by the determinants

$$\rho_k(x_1,\ldots,x_k)=\det(K(x_i,x_j))_{i,j=1,\ldots,k},\quad k=1,2,3,\ldots, \tag{29}$$

with the Bessel kernel (with $\alpha=0$). Then

$$K^{(\alpha)}(x,y) = \frac{J_\alpha(2\sqrt{x})\sqrt{y}J'_\alpha(2\sqrt{y}) - J_\alpha(2\sqrt{y})\sqrt{x}J'_\alpha(2\sqrt{x})}{x-y}, \tag{30}$$

where J_ν is the J-Bessel function, appears as the limit of the rescaled correlation kernel at the hard edge in the Laguerre and Jacobi ensembles (see, e.g., Refs. 15 and 43).

Ban Arous and Péché,[5] following the approach suggested by Johansson[23] for Wigner matrices, have recently shown universality of the limiting distribution of the smallest eigenvalues (as well as in the bulk of the spectrum) for a special class of sample covariance matrices. Their technique requires that entries of A have a Gaussian component.

One of the possible ways to attack this problem for an ensemble (28) (assuming that all moments exist, i.e., and do not grow very fast) is to study the mathematical expectation of the ratio of determinants

$$Z(\eta_1, \eta_2, \ldots, \eta_k, \mu_1, \ldots, \mu_l) = E\frac{\prod_{i=1}^{k} \det(1 + \eta_i^2 A^* A)}{\prod_{j=1}^{l} \det(1 + t_j^2 A^* A)}$$

for appropriately scaled (large) real numbers $\eta_1, \ldots, \eta_k, t_1, \ldots, t_l$. For the standard complex Wishart (Laguerre) case these expectation values were calculated exactly for any k, l, n (see Refs. 17 and 40 and references therein), and also used to address objects interesting in mesoscopic physics,[18] and quantum chromodynamics.[1]

In particular, one can easily see that $(\partial/\partial\eta)Z(\eta,t)|_{\eta=t} = E\Sigma_{i=1}^{n} 2\eta\lambda_i/(t^2+\lambda_i)$, where $0 \leqslant \lambda_1 \leqslant \lambda_2 \leqslant \cdots \leqslant \lambda_n$ are the eigenvalues of A^*A. Such an object can be used to extract the mean eigenvalue density. In a similar fashion, by taking partial derivatives of $Z(\eta_1, \ldots, \eta_k, t_1, \ldots, t_l)$ of higher orders, one can study the correlations of the eigenvalues of A^*A. To show the universality of the distribution of the smallest eigenvalues one needs to show that local statistical quantities at the edge of the spectrum (near the origin) do not depend (in the limit $n \to \infty$) on the second and higher moments of f.

The next proposition is analogous to Proposition 1 in the real case.

Proposition 2: Let A be a random rectangular $m \times n$ matrix with the probability distribution given by (28). Let $t_l > 0$, $l = 1, \ldots, r$, be some positive parameters. Then the following formula holds:

$$E\left(\prod_{l=1}^{r} \det(1 + t_l^2 A^t A)\right)^{-1} = \pi^{-r(n+m)/} \int_{R^{2r(n+m)}} \prod_{l=1}^{r} d^n\Re s^{(l)} d^n\Im s^{(l)} d^m\Re p^{(l)} d^m\Im p^{(l)} \times \exp\left(-\sum_{l=1}^{r} (|s^{(l)}|^2 + |p^{(l)}|^2)\right) \prod_{1\leqslant j\leqslant n, 1\leqslant k\leqslant m} G\left(\left|\sum_{l=1}^{r} t_l s_k^{(l)} p_j^{(l)}\right|^2\right), \tag{31}$$

where $s^{(l)} = (s_1^{(l)}, \ldots, s_n^{(l)})$ are n-dimensional complex vectors, $p^{(l)} = (p_1^{(l)}, \ldots, p_m^{(l)})$ are m-dimensional complex vectors, $l = 1, \ldots, r$,

$$G(y) = \frac{1}{2\pi}\int_0^{2\pi} d\theta \int_0^{+\infty} f(x)\, dx \exp(2i(xy)^{1/2}\cos(\theta)) = \int_0^{+\infty} dx f(x)\phi(xy), \tag{32}$$

and

$$\phi(x) = \sum_{l=0}^{+\infty} \frac{(-1)^l}{(l!)^2} x^l = J_0(2x^{1/2}). \tag{33}$$

In the special case of single determinant $(r=1)$ the formula (31) can be simplified:

$$E(\det(1+t^2A^*A))^{-1}=\int_{(0,+\infty)^{m+n}}\prod_{i=1}^{n}e^{-u_i}\,du_i\prod_{j=1}^{m}e^{-v_i}\,dv_i\prod_{k,l}G(t^2u_kv_l). \tag{34}$$

Remark 6: As in Sec. II we can consider the case when the the matrix entries $\{|a_{jk}|\}$ are independent but not identically distributed with the densities $f_{jk}(|x|)$, $1\leqslant j\leqslant m$, $1\leqslant n\leqslant n$. The result of Proposition 2 still holds true provided we replace G in (31) and (32) by $G_{jk}(y)=(1/2\pi)\int_0^{2\pi}d\theta\int_0^{+\infty}f_{jk}(x)dx\exp(2i(xy)^{1/2}\cos(\theta))=\int_0^{+\infty}dxf_{jk}(x)\phi(xy)$.

Remark 7: In (33) $J_0(z)=(1/2\pi)\int_0^{2\pi}\exp(iz\cos\theta)d\theta$ is the standard Bessel function.[46]

Remark 8: In the special Wishart (Laguerre) case [which corresponds to $f(x)=e^{-x}$] one has $G(y)=e^{-y}$. If all moments of $f(x)$ exist and do not grow very fast, one can write $G(y)=\sum_{l=0}^{+\infty}[(-1)^l\alpha_l/(l!)^2]y^l$, where $\{\alpha_n\}_{n\geqslant 1}$ are the moments of $f(x)$.

Proof of Proposition 2: Let $\underline{s}=(s_1,\ldots,s_n)^t$, $\underline{p}=(p_1,\ldots,p_m)^t$ be complex n-and m-dimensional column vectors and $s^*=(\overline{s_1},\ldots,\overline{s_n})$, $p^*=(\overline{p_1},\ldots,\overline{p_m})$. In what follows $d^{2n}s$ and $d^{2m}p$ will stand for $d^n\Re s\,d^n\Im s$ and $d^m\Re p\,d^m\Im p$ correspondingly. Then

$$\begin{aligned}(\det(1+t^2A^*A))^{-1}&=\left(\det\begin{pmatrix}1 & tiA\\ tiA^* & 1\end{pmatrix}\right)^{-1}\\&=\left(\frac{1}{\pi}\right)^{n+m}\int d^{2n}s\,d^{2m}p\exp(-(s^*,p^*)B(t)(s,p)^t)\\&=\left(\frac{1}{\pi}\right)^{n+m}\int d^{2n}s\,d^{2m}p\exp(-(|s|^2+|p|^2))\\&\quad\times\exp\left(-i\sum_{1\leqslant j\leqslant n,1\leqslant k\leqslant m}(ta_{jk}p_k\overline{s_j}+t\overline{a_{jk}p_k}s_j)\right),\end{aligned}$$

where as before $B(t)=\left(\begin{smallmatrix}Id & itA\\ itA^* & Id\end{smallmatrix}\right)$ and $d^{2n}sd^{2m}p=\Pi_{i=1}^n d\Re s_i d\Im s_i\Pi_{j=1}^m\Re p_i d\Im p_i$.

We can then write down

$$\begin{aligned}E\left(\prod_{l=1}^{r}\det(1+t_i^2A^tA)\right)^{-1}&=\pi^{-r(n+m)}\int_{R^{2r(n+m)}}\prod_{l=1}^{r}d^{2n}s^{(l)}\,d^{2m}p^{(l)}\exp\left(-\sum_{l=1}^{r}(|s^{(l)}|^2+|p^{(l)}|^2)\right)\\&\quad\times\prod_{1\leqslant j\leqslant n,1\leqslant k\leqslant m}E\left(\exp\left(-i\left(a_{kj}\sum_{l=1}^{r}t_ls_j^{(l)}\overline{p_k^{(l)}}+\overline{a_{kj}}\sum_{l=1}^{r}t_l\overline{s_j^{(l)}}p_k^{(l)}\right)\right)\right).\end{aligned} \tag{35}$$

Let $u=\sum_{l=1}^{r}t_ls_j^{(l)}\overline{p_k^{(l)}}$. Then we can write

$$\begin{aligned}E(\exp(-i(a_{jk}u+\overline{a_{jk}u}))&=\frac{1}{\pi}\int d\Re z\,d\Im z f(|z|^2)\exp(-i(zu+\overline{zu}))\\&=\frac{1}{\pi}\int_0^{2\pi}d\theta\int_0^{+\infty}drrf(r^2)\exp(-ir(e^{i\theta}u+e^{-i\theta}\overline{u}))\\&=\frac{1}{2\pi}\int_0^{2\pi}d\theta\int_0^{+\infty}dxf(x)\exp(-i\sqrt{x}(e^{i\theta}u+e^{-i\theta}\overline{u}))\\&=\int_0^{+\infty}dxf(x)\phi(x|u|^2),\end{aligned} \tag{36}$$

where $\phi(x)$ has been defined in (33). Combining (35) and (36) we arrive at

$$E\prod_{l=1}^{r}(\det(1+t_l^2A^*A))^{-1}=\left(\frac{1}{\pi}\right)^{r(m+n)}\prod_{l=1}^{r}\int d^{2n}s^{(l)}\,d^{2m}p^{(l)}\exp\left(-\sum_{j=1}^{n}|s_j^{(l)}|^2-\sum_{k=1}^{m}|p_k^{(l)}|^2\right)$$
$$\times\prod_{1\leqslant j\leqslant n,1\leqslant k\leqslant m}G\left(\left|\sum_{l=1}^{r}t_l s_j^{(l)}p_k^{(l)}\right|^2\right). \tag{37}$$

In the special case $r=1$ the formula can be simplified further:

$$E(\det(1+t^2A^*A))^{-1}=\left(\frac{1}{\pi}\right)^{m+n}\int_{R^{2(n+m)}}d^{2n}s\,d^{2m}p\exp\left(-\sum_{j=1}^{n}|s_j|^2-\sum_{k=1}^{m}|p_k|^2\right)$$
$$\times\prod_{1\leqslant j\leqslant n,1\leqslant k\leqslant m}\int_0^\infty dx f(x)\left\{\sum_{l=0}^{\infty}\frac{1}{(l!)^2}(-x)^l t^{2l}|p_k|^{2l}|s_j|^{2l}\right\}$$
$$=2^{m+n}\int_{(0,+\infty)^{m+n}}\prod_{i=1}^{n}r_i\,dr_i\prod_{j=1}^{m}\rho_j\,d\rho_j\exp\left(-\sum_{i=1}^{n}r_i^2-\sum_{j=1}^{m}\rho_j^2\right)\prod_{k=1}^{n}\prod_{l=1}^{m}G(t^2r_k^2\rho_l^2)$$
$$=\int_{(0,+\infty)^{m+n}}\prod_{i=1}^{n}e^{-u_i}du_i\prod_{j=1}^{m}e^{-v_i}dv_i\prod_{k,l}G(t^2u_kv_l). \tag{38}$$

In the Wishart case one can simplify things even further. The calculations are very similar to the real Wishart case considered in Remark 4 (Sec. II). Since typical eigenvalues of A^*A are of the order of n, the scaling of t^2 by a factor $1/n$ allows us to study the limiting distribution of the eigenvalues. It follows from (38) that we are left with the task of evaluating the integral $E(\det(1+(t^2/n)A^*A))^{-1}\int_{(0,+\infty)^{2n}}\Pi_{i=1}^{n}e^{-u_i}\,du_i\Pi_{j=1}^{m}e^{-v_j}\,dv_j\exp(-(t^2/n)\Sigma_{k=1}^{n}u_k\Sigma_{l=1}^{m}v_l)$, which can be reduced to

$$\int_{(0,+\infty)^{m+n}}\prod_{i=1}^{n}e^{-u_i}\,du_i\prod_{j=1}^{m}e^{-v_j}\,dv_j\exp\left(-\frac{t^2}{n}\sum_{k=1}^{n}u_k\sum_{l=1}^{m}v_l\right)$$
$$=\int_{(0,+\infty)^{n}}\prod_{i=1}^{n}e^{-u_i}\,du_i\left(1+\frac{t^2}{n}\sum_{l=1}^{n}u_l\right)^{-m}$$
$$=\int_0^{+\infty}\frac{z^{n-1}}{(n-1)!}e^{-z}\left(1+\frac{t^2}{n}z\right)^{-m}dz$$
$$=\frac{n^n}{\Gamma(n)}\int_0^{+\infty}z^{n-1}e^{-nz}(1+t^2z)^{-m}\,dz=\frac{n^n}{\Gamma(n)}\int_0^{+\infty}e^{-n\mathcal{L}(z)}z^{-1}\,dz, \tag{39}$$

where $\mathcal{L}(z)=z+(m/n)\ln(1+t^2z)-\ln z$. It is remarkable that the formulas in the complex case are identical to those in the real case [(21) and (22)] modulo trivial change of parameters. We thus proved the following result.

Lemma 1: Let m and n be positive integers and $z\in\mathbb{C}\backslash(-\infty,0)$. *Then*

$$E_{2m,2n,\ real}\left(\det\left(1+\frac{z}{2}A^tA\right)\right)^{-1/2}=E_{m,n,\ complex}(\det(1+zA^*A))^{-1}, \tag{40}$$

where on the lhs we have the mathematical expectation with respect to the ensemble of rectangular $2m\times 2n$ *real matrices A with i.i.d. standard Gaussian entries (standard real Wishart ensemble), and on the rhs we have the mathematical expectation with respect to the ensemble of rectangular* $m\times n$ *complex matrices A with i.i.d. standard Gaussian entries (standard complex Wishart ensemble).*

As before, it was enough to prove the result for positive real $z=t^2$. We remind the reader that in the standard real Wishart case all entries $\{a_{j,k}\}$ are i.i.d. N(0,1) random variables, and in the standard complex Wishart case all entries $\{\Re a_{j,k}, \Im a_{j,k}\}$ are i.i.d. $N(0,1/2)$ random variables (so in both cases $E|a_{j,k}|^2=1$).

Remark 9: If all moments of $f(x)$ exist, then under some technical conditions the asymptotics of $E(\det(1+t^2A^*A))^{-1}$ in the global regime depend on the first and second moments of $f(x)dx$, (i.e., on the second and fourth moments of the matrix entries A_{kl}). This phenomena is known in random matrix theory: for example, in the case of Wigner random matrices, the limiting distribution of a global linear statistics $Tr\, h(A)-E(Tr\, h(A))$ (where h is a test function, say a polynomial, and A is a random Wigner matrix normalized so that a typical eigenvalue is of the order of a constant) depends on the second and fourth moments of the matrix entries (see e.g., Refs. 28 and 35). It is conjectured (and, in a few interesting special cases, verified) that in the local regime the dependence on the fourth moment goes away.

APPENDIX

A Poisson random point process on the positive half-axis with the locally integrable intensity function $\rho(x)$ is defined in such a way that the counting functions (e.g., numbers of particles) in the disjoint intervals $I_1, \dots, I_k$ are independent Poison random variables with the parameters $\int_{I_j}\rho(x)dx$, $j=1,\dots,k$. Equivalently, one can define the Poisson random point by requiring that the k-point correlations functions are given by the products of one-point correlation functions (intensities), i.e., $\rho_k(x_1,\dots,x_k)=\Pi_{j=1}^k\rho(x_j)$.

Let $f:(0,+\infty)\to\mathbb{C}$ be a test function with a nice behavior at the origin and infinity. Then

$$\begin{aligned}\mathbf{E}\prod_{i=1}^{\infty}(1+f(x_i)) &= 1+\sum_{k=1}^{\infty}\mathbf{E}\sum_{1\le i_1<i_2<\cdots<i_k}\prod_{j=1}^{k}f(x_{i_j})\\ &= \sum_{k=0}^{\infty}\frac{1}{k!}\int_{(0,+\infty)^k}\prod_{j=1}^{k}f(x_j)\rho_k(x_1,\dots,x_k)\,dx_1\cdots dx_k\\ &= \sum_{k=0}^{\infty}\frac{1}{k!}\left(\int_{(0,+\infty)}f(x)\rho(x)\,dx\right)^k=\exp\left(\int_{(0,+\infty)}f(x)\rho(x)\,dx\right).\end{aligned}\tag{A1}$$

If the test function $f(x)$ equals $(1+zx)^{-1/2}-1$, and $\rho(x)=1/\pi x^{3/2}$, we have

$$\int_{(0,+\infty)}f(x)\rho(x)\,dx=\int_{(0,+\infty)}((1+zx)^{-1/2}-1)\frac{1}{\pi x^{3/2}}\,dx=-\frac{2}{\pi}\sqrt{z},$$

which is exactly the exponent in (4). For random Schrödinger operators the Poisson statistics of the eigenvalues in the localization regime was first proved by Molchanov in Ref. 32 (see also Ref. 31).

(Received 14 October 2004; accepted 7 December 2004; published online 18 February 2005)

In this paper we study the statistics of combinatorial partitions of the integers, which arise when studying the occupation numbers of loops in the mean field Bose gas. We review the results of Lewis and collaborators and get some more precise estimates on the behavior at the critical point (fluctuations of the condensate component, finite volume corrections to the pressure). We then prove limit shape theorems for the loops occupation numbers. In particular we prove that in a certain range of the parameters, a finite fraction of the total mass is, in the limit, supported by infinitely long loops. We also show that this mass is equal to the mass of the condensed state where all particles have zero momentum. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1855933]

I. INTRODUCTION

Statistics of combinatorial partitions arises in many areas of science as number theory, combinatorics, probability and statistical mechanics, as illustrated by Vershik in his 1996 paper on the subject.[14]

The problem is about decomposing a positive integer $N \in \mathbb{N}_+$ into a sum of positive integers, $N=j_1+\cdots+j_k$, $k \in \mathbb{N}_+$. Let $(j_1,\dots,j_k)$ the sequence of terms in the sum and consider two such sequences equivalent if they differ by a permutation. A partition of N is then the equivalence class of a sequence whose terms sum up to N. Following Vershik we describe partitions by sequences $\underline{n}=\{n_j, j \in \mathbb{N}_+\}$, where n_j is the number of elements equal to j in a sequence representative of the partition, thus $\Sigma_j j n_j = N$. Statistics enters once we assign a statistical weight to the partitions, the choice of the weights is determined by the particular applications we have in mind and the goal is to derive limit theorems and characterize the typical partitions when N is large.

As in Ref. 14 we will consider multiplicative weights, namely we will suppose that the statistical weight of $\underline{n}$ is

$$w(\underline{n}) = \prod_{j=1}^{\infty} w(j,n_j), \quad \underline{n} = \{n_j, j \in \mathbb{N}_+\} \tag{1.1}$$

where $w(j,\cdot): \mathbb{N}_+ \to \mathbb{R}_+$.

In the language of statistical mechanics, the assumption restricts the analysis to noninteracting systems and we will relax it, to study mean field interactions as well. To make clear the connection with physics, it is convenient to generalize the above context by considering j as an element of some countable space J. For instance, a quantum gas of particles in a finite box with Bose–Einstein statistics, can be represented in terms of occupation numbers $\{n_j, j \in J\}$, with J the momentum eigenvalues of a single particle (which are countably many because particles are in a finite box). In the free case, the equilibrium distribution of such occupation numbers is determined by multiplicative weights of the form (1.1), as it will be discussed in the next section.

Bose condensation is then the phenomenon for which a positive fraction of the total number of particles occupies the state with zero momentum, the fraction converging to a deterministic value in the thermodynamic limit. The other particles are distributed over the remaining momenta and their random distribution, suitably normalized, also converges to a deterministic curve, in the thermodynamic limit. The fraction with zero momentum, thought of as a Dirac delta of positive mass added to the remaining distribution, is referred to as the mass of the condensed gas, while the remaining mass is that of the gas in its "normal state." All that happens for suitable values of temperature and density, the theory is very well known and can be found in textbooks and review papers (see, for instance, Refs. 6 and 15). The extension to the mean field case is due to Lewis and collaborators (see, for instance, Ref. 10).

Our model is the same free Bose gas discussed so far, but regarded in terms of "loops" which arise when enforcing the symmetry of the wave functions under particles permutations (Bose statistics). To make this paper self contained, in Appendix A, we derive the representation of the canonical partition function for a Bose gas in the loops language. Thus in our scheme $j \in \mathbb{N}_+$ is the "loop length," representing a cycle with j particles which describe the permutations among particles when imposing the symmetry of the wave function, see Ginibre[5] for a detailed analysis of the model also when interparticles interactions are present.

Feynman conjectured,[4] that Bose condensation is related to the appearance of long loops, namely a fraction of the total number of particles is concentrated on loops whose length diverges when Bose condensation occurs, and this fraction should be exactly the same as the condensed mass of the gas.

Results of this kind for the free gas, and also in the case when obstacles are present as well, have been proved by Kac and Luttinger,[7,8] and Suto.[13]

The purpose of this paper is to show that many properties of the free gas are easily and naturally expressed in terms of the loop representation, which in some instances could provide an alternative picture of the system with some advantages over the more usual momentum-occupation representation. We will indeed prove very detailed estimates on the statistics of the loops, both in the free and in the mean field case.

In particular our large deviation estimates can be used to extend our analysis in the case the Kac potential with $\gamma^{-1}/L \sim 1$. An extension to a more general class has been obtained in Ref. 9.

In Sec. II we present the model. In Sec. III we study the thermodynamics of the mean field Bose gas, showing that the phase diagram can be recovered by solving a variational problem in terms of a free energy functional. We also compute the finite volume corrections to the pressure. In Sec. IV we analyze the statistics of the "long loops" whose length goes to infinity faster than L^2, L being the size of the volume. In Sec. V we state large deviation theorems for the "short loops." In Sec. VI, we prove that the mass density supported by the long loops is equal to the density of the condensed state, where all particles have zero momentum.

Proofs are given in the appendixes.

II. THE FREE AND MEAN FIELD BOSE GAS

We will consider the weights $w(j,n)$ in (1.1) as dependent on the parameters $L>0$, $\beta>0$, $\lambda \in \mathbb{R}$ and given by the expression

$$w(j,n) = \frac{1}{n!}\left(\frac{L^d a(\beta j, L)}{j} e^{\beta \lambda j}\right)^n, \tag{2.1}$$

$$a(\beta j,L)=\sum_{k\in\mathbb{Z}^d}\frac{e^{-(kL)^2/(2\beta j)}}{(2\pi\beta j)^{d/2}}. \tag{2.2}$$

The quantity $L^d a(\beta j,L)$ is the partition function at temperature βj of a free quantum particle of unitary mass in a periodic cubic box of side L, namely

$$L^d a(\beta j,L)=\sum_{k\in\mathbb{Z}^d} e^{-1/2\beta j(2\pi k/L)^2}. \tag{2.3}$$

The elementary equality (2.3) is proved in Lemma A.2.

By the help of the weights (2.1), we construct three probability measures on $\mathbb{N}_+^{\mathbb{N}}$, the canonical, the grand canonical and the mean field measures. The canonical measure with $N\in\mathbb{N}_+$ particles is the probability

$$\mu_{N,L}(\mathfrak{n})=Z_{N,L}^{-1}\mathbf{1}_{\Sigma jn_j=N}w(\mathfrak{n}), \tag{2.4}$$

the partition function $Z_{N,L}$ being the normalization factor and $w(\mathfrak{n})$ is given by (1.1) with $w(j,n_j)$ as in (2.1) with $\lambda=0$. We are not making explicit the dependence on β, as it will be kept fixed throughout the sequel. As we will see in Appendix A, $Z_{N,L}$ is equal to the partition function of a Bose gas in a cubic box of length L with periodic boundary conditions and inverse temperature β.

The grand canonical probability is

$$P_{\lambda,L}(\mathfrak{n})=\Xi_{\lambda,L}^{-1}w(\mathfrak{n}), \tag{2.5}$$

where

$$\Xi_{\lambda,L}=\exp\left\{L^d\sum_j e^{\beta\lambda j}\frac{a(\beta j,L)}{j}\right\} \tag{2.6}$$

and the definition is well posed if $\lambda<0$. Indeed, the right-hand side (rhs) of (2.6) diverges for $\lambda\geqslant 0$ because $a(\beta j,L)\geqslant 1/L^d$, as follows from (2.3).

Finally, the mean field grand canonical probability is

$$P_{\lambda,L}^{mf}(\mathfrak{n})=\Xi_{\lambda,L}^{mf\,-1}e^{-\beta(\Sigma_j n_j)^2/(2L^d)}w(\mathfrak{n}) \tag{2.7}$$

(having set equal to 1 the interaction strength). Due to the presence of the interaction, which ensures convergence at infinity, the value of the chemical potential λ is now unrestricted.

To establish the connection of these measures with the Gibbs measures of the Bose gas in the momentum representation, we realize the above processes in the following way. Let $\alpha(\beta j,p,L)>0$, $j\in\mathbb{N}_+$, $p\in\Pi$, Π a countable set, be such that

$$L^d a(\beta j,L)=\sum_{p\in\Pi}\alpha(\beta j,p,L). \tag{2.8}$$

We then define new weights,

$$w(j,p,n)=\frac{1}{n!}\left(\frac{\alpha(\beta j,p,L)}{j}e^{\beta\lambda j}\right)^n, \tag{2.9}$$

and call $\mu_{N,L}^*(\mathfrak{n})$, $P_{\lambda,L}^*(\mathfrak{n})$, $P_{\lambda,L}^{mf,*}(\mathfrak{n})$, $\mathfrak{n}=\{n_{j,p},j\in\mathbb{N}_+,p\in\Pi\}$, the measures given as in (2.4)–(2.7) with the new weights $w(j,p,n)$ of (2.9) and replacing $\Sigma_j jn_j\to\Sigma_{j,p}jn_{j,p}$. Calling

$$n_j=\sum_{p\in\Pi}n_{j,p},\quad n_p=\sum_{j>0}jn_{j,p}, \tag{2.10}$$

a simple combinatorial computation, which is omitted, shows that the laws of the variables n_j under $\mu_{N,L}^*$, $P_{\lambda,L}^*$, and $P_{\lambda,L}^{mf,*}$ are the same as those under $\mu_{N,L}$, $P_{\lambda,L}$, and $P_{\lambda,L}^{mf}$.

We will see that some proofs become simpler using the representation (2.10) after a suitable choice of $\alpha(\beta j,p,L)$. To recover the momentum representation, we set $\Pi=\mathbb{Z}^d$ and

$$\alpha(\beta j,p,L)=e^{-(\beta j/2)(2\pi p/L)^2} \tag{2.11}$$

that satisfies (2.8) [cf. (2.3)]. Moreover, the law under $\mu^*_{N,L}$, $P^*_{\lambda,L}$, and $P^{mf,*}_{\lambda,L}$ of the variables n_p defined in (2.10) is the usual free Bose canonical and grand-canonical and mean field laws of the momentum occupation numbers. Examining for simplicity only the free Bose grand canonical measure, the probability to have $\nu\in\mathbb{N}$ particles of unitary mass with momentum p is

$$\frac{e^{-\beta\nu[-\lambda+1/2(2\pi p/L)^2]}}{\sum_{n\geqslant 0}e^{-\beta n[-\lambda+1/2(2\pi p/L)^2]}}. \tag{2.12}$$

This is equal to $P^*_{\lambda,L}(\{n_p=\nu\})$, because,

$$e^{-\beta\nu[-\lambda+1/2(2\pi p/L)^2]}=\sum_{\{n_{j,p},j>0\}:\Sigma_j jn_{j,p}=\nu}\prod_{j>0}\frac{1}{n_{j,p}!}\left(\frac{e^{-\beta j[-\lambda+1/2(2\pi p/L)^2]}}{j}\right)^{n_{j,p}} \tag{2.13}$$

which follows from the combinatorial identity

$$1=\sum_{\{n_j,j>0\}:\Sigma_j jn_j=\nu}\prod_{j>0}\frac{1}{n_j!}\left(\frac{1}{j}\right)^{n_j}. \tag{2.14}$$

It turns out that this identity could be proved by checking that

$$1=\frac{1}{\nu!}\left.\frac{\mathrm{d}^\nu f(x)}{\mathrm{d}x^\nu}\right|_{x=0},\quad f(x)=\sum_{\{n_j,j>0\}}\prod_{j>0}\frac{1}{n_j!}\left(\frac{x^j}{j}\right)^{n_j}. \tag{2.15}$$

III. THERMODYNAMICS OF THE MEAN FIELD BOSE GAS

By replacing the factorials in $w(\underline{n})$ with the leading terms of the Stirling formula, we obtain the following heuristics for the distribution of the loops occupation numbers at large L:

$$w(\underline{n})e^{-\beta(\Sigma_j jn_j)^2/(2L^d)}\approx e^{-\beta L^d F_\lambda(\underline{\rho})},\quad \underline{\rho}=\{jn_j/L^d, j>0\}, \tag{3.1}$$

where $F_\lambda(\underline{\rho}):[0,+\infty)^{\mathbb{N}_+}\to\mathbb{R}\sqcup\{+\infty\}$, is defined by the expression

$$F_\lambda(\underline{\rho})=\frac{1}{2}\left(\sum_j\rho_j\right)^2-\lambda\sum_j\rho_j-\frac{S(\underline{\rho})}{\beta}, \tag{3.2}$$

$$S(\underline{\rho})=-\sum_{j=1}^{\infty}\frac{\rho_j}{j}\left(\log\frac{\rho_j}{\rho^*_j}-1\right),\quad \rho^*_j=\frac{1}{(2\pi\beta)^{d/2}j^{d/2}}. \tag{3.3}$$

Besides the above heuristic derivation, the functional $F_\lambda(\underline{\rho})$ has an important role in the sequel. Indeed, as suggested by (3.1) and proved in this paper, in the thermodynamic limit $L\to\infty$, the distribution concentrates on the minimizers of F_λ, thus reducing the computation of the "macroscopic observables" to variational problems for the "limit functional" F_λ. In particular this applies to the thermodynamic potentials. Indeed, interpreting $F_\lambda(\underline{\rho})$ as the Gibbs thermodynamic potential and applying the corresponding version of the second principle of thermodynamics, we have the following expression for the equilibrium thermodynamical pressure:

$$\pi(\lambda) := -\inf_{\varrho} F_\lambda(\varrho). \tag{3.4}$$

The validity of such an interpretation is confirmed by equality with the mean field grand canonical pressure,

$$\pi(\lambda) = \lim_{L\to\infty} \frac{1}{\beta L^d} \ln \Xi^{mf}_{\lambda,L}. \tag{3.5}$$

According to thermodynamics, the free energy functional which corresponds to the Gibbs potential $F_\lambda(\varrho)$ is $F_\lambda(\varrho)+\lambda\{\Sigma\rho_j\}$; we can then use the latter to define the equilibrium thermodynamical free energy,

$$a(u) := \inf_{\varrho:\Sigma_j\rho_j=u} \{F_\lambda(\varrho) + \lambda u\}. \tag{3.6}$$

The validity of (3.6) follows from equality with the mean field canonical free energy, which can be written, if $Z^{mf}_{N_L,L}$ denotes the mean field canonical partition function,

$$a(u) = -\lim_{\substack{L\to\infty \\ N_L/L^d\to u}} \frac{1}{\beta L^d} \ln Z^{mf}_{N_L,L} \tag{3.7}$$

and thermodynamic consistency follows from checking that $a(u)$ is the Legendre transform of $\pi(\lambda)$.

Equations (3.4)–(3.7) show that the thermodynamics of the mean field Bose gas is the same thermodynamics of the free energy functional F_λ, which can be quite explicitly computed. All that, including the proofs of (3.4)–(3.7), are reported in Appendix G.

The thermodynamics of the Bose gas (in the free and in the mean field cases) is very well known and does not need to be discussed again here, but its features in terms of loops are not so familiar and, on the other hand, quite interesting and transparent. Recall first that in the free gas there is, in any dimension $d\geqslant 3$, a Bose condensation characterized by the existence of a critical density u^*, so that the free energy

$$a^0(u) := a(u) - \frac{u^2}{2} \tag{3.8}$$

[i.e., the mean field free energy $a(u)$ minus the mean field energy when the particles density is u] is constant past u^*,

$$a^0(u) = a^0(u^*). \tag{3.9}$$

Such a property is indeed verified by $a^0(u)$ as defined by (3.8) with $a(u)$ as in (3.6), which means, recalling (2.4) and (3.7), that, if $u\geqslant u^*$ and $[\cdot]$ denotes the integer part,

$$\lim_{L\to\infty} \lim_{\substack{N_L=[L^d u] \\ N^*_L=[L^d u^*]}} \frac{1}{\beta L^d} \ln\left\{\frac{Z_{N_L,L}}{Z_{N^*_L,L}}\right\} = 0. \tag{3.10}$$

Equation (3.10) shows that the ratio $Z_{N_L,L}/Z_{N^*_L,L}\to 1$ (in a very weak sense, indeed). The closeness to equality before the limit is an indication of validity of the Bose condensation phenomenon in finite volumes. We have a result (proved in Appendix B) which shows that the infinite volume description is very accurate,

Theorem 3.1: *Let* $d\geqslant 3$ *and*

$$u^* = \sum_{j>0} \rho^*_j. \tag{3.11}$$

Then, given any density $u > u^*$ and any two sequences, N_L and N_L^*, such that $N_L = [L^d u]$ and $N_L^* = [L^d u^*]$, there is a constant c_0, only dependent on d, such that

$$\lim_{L\to\infty} \frac{Z_{N_L,L}}{Z_{N_L^*,L}} = c_0. \tag{3.12}$$

Moreover, there exists another dimension dependent constant c_1, such that, if $\lambda > u^*$,

$$\lim_{L\to\infty} \frac{\Xi^{mf}_{\lambda,L} e^{-\beta\lambda^2 L^d/2}}{\Xi^{mf}_{u^*,L} e^{-\beta(u^*)^2 L^d/2}} = c_1. \tag{3.13}$$

Let us now describe the condensation phenomenon in terms of loops, starting from the analysis of the functional $F_\lambda(\underline{\rho})$. In any dimension $d \geqslant 3$, there is a critical chemical potential

$$\lambda^* = \sum_{j>0} \rho_j^* = u^* \tag{3.14}$$

and, for $\lambda > \lambda^*$, the inf in (3.4) is not a minimum, but (cf. Appendix G) it is obtained by any minimizing sequence $\underline{\rho}^{(n)} = \{\rho_j^{(n)}, j > 0\}$, such that, for any fixed j,

$$\lim_{n\to\infty} \rho_j^{(n)} = \rho_j^* \tag{3.15}$$

while

$$\rho(\lambda) := \lim_{n\to\infty} \sum_{j>0} \rho_j^{(n)} = \sum_{j>0} \rho_j^* + (\lambda - \lambda^*) = \lambda. \tag{3.16}$$

Equation (3.15) and (3.16) show that a fraction $\lambda - \lambda^*$ of the total mass $\rho(\lambda)$ concentrates on "infinite loops." The phenomenon is absent for $\lambda \leqslant \lambda^*$, where instead the rhs of (3.4) has a unique minimizer $\underline{\rho}(\lambda) = \{\rho_j(\lambda), j > 0\}$, where

$$\rho_j(\lambda) = \rho_j^* e^{\beta j \lambda_0(\lambda)} \tag{3.17}$$

and $\lambda_0(\lambda)$ is strictly positive for $\lambda < \lambda^*$, and =0 otherwise. Thus the total mass of the fluid is

$$\rho(\lambda) = \begin{cases} \sum_{j>0} \rho_j(\lambda) & \text{if } \lambda \leqslant \lambda^*, \\ \sum_{j>0} \rho_j^* + (\lambda - \lambda^*) & \text{if } \lambda \geqslant \lambda^*, \end{cases} \tag{3.18}$$

and no mass concentrates on infinite loops for $\lambda \leqslant \lambda^*$. Note that, by (3.14), $\rho(\lambda^*) = \lambda^*$.

The validity of the above interpretation follows from the following theorem, which is a corollary of the large deviation estimates proved in Appendix E.

Theorem 3.2: *For any* λ, (3.19)–(3.21) *below hold,*

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}\left(\left| \frac{j n_j}{L^d} - \rho_j(\lambda) \right| > \delta \right) = 0, \quad \forall\, \delta > 0, \tag{3.19}$$

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}\left(\left| \sum_{j \leqslant J(L)} \left\{ \frac{j n_j}{L^d} - \rho_j(\lambda) \right\} \right| > \delta \right) = 0, \quad \forall\, \delta > 0, \tag{3.20}$$

independently of the choice of $J(L)$, provided $J(L)$ is an increasing function of L and $J(L) \leqslant L^2$,

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}\left(\left| \sum_{j \geqslant 1} \left\{ \frac{j n_j}{L^d} - \rho(\lambda) \right\} \right| > \delta \right) = 0, \quad \forall\, \delta > 0. \tag{3.21}$$

While the statements relative to global quantities, like pressure, free energy, and total number of particles are known in the literature, the results on the way the mass distributes among the different loops are new for the mean field interaction; Suto[13] has analogous results in the context of the canonical free measure.

But all this is not really in the focus of our study, which is rather aimed at relaxing the assumption of mean field, for instance considering Kac potentials, with the hope that the loops language may provide some simplification. In this perspective it is important to derive sharp estimates on the deviations of the densities in (3.19)–(3.21) which have been used in Ref. 9 to prove the occurrence of Bose condensation with Kac potentials in suitable scaling limits and to get nontrivial estimates for the low momenta distribution in the condensed region for a class of long but finite range potential. Results and proofs can be found in Sec. V and Appendix B.

The rate functions of the large deviations of the above macroscopic quantities are faithfully described by the functional $F_\lambda(\varrho)$, whose suitably constrained minima give the correct large deviations rate functions. Thus, like in the case of the thermodynamical potentials, the analysis of the functional $F_\lambda(\varrho)$ gives the right answer.

The functional $F_\lambda(\varrho)$ is instead inadequate for studying how the mass of the condensed fluid (in the Bose condensation regime $\lambda > \lambda^*$) distributes among the long loops. The issue is discussed in the next section.

IV. DISTRIBUTION OF LONG LOOPS

To study the Bose condensation phenomenon, we restrict to $d \geqslant 3$ and to $\lambda > \lambda^*$. Then, see (3.18)–(3.21) and (3.14), the total mass (after the thermodynamic limit) is $\rho(\lambda) = u^* + (\lambda - \lambda^*)$, u^* is the mass of the "normal fluid" and $(\lambda - \lambda^*)$ of the condensed one. By (3.20),

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}\left(\left| \sum_{j \leqslant L^2} \frac{jn_j}{L^d} - u^* \right| > \delta \right) = 0, \quad \forall\, \delta > 0 \tag{4.1}$$

which shows that in finite volumes the mass of the normal fluid is essentially carried by loops with length $\leqslant L^2$, while the mass of the condensed concentrates on loops of length $> L^2$,

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}\left(\left| \sum_{j > L^2} \frac{jn_j}{L^d} - (\lambda - \lambda^*) \right| > \delta \right) = 0, \quad \forall\, \delta > 0. \tag{4.2}$$

Actually most of the mass is on loops whose length is a fraction of the whole volume,

$$\lim_{L\to\infty} E^{mf}_{\lambda,L}\left(\frac{1}{L^d} \sum_{j > L^2}^{\delta L^d} jn_j \right) = \delta. \tag{4.3}$$

Furthermore the number $\tilde{X}_L$ of loops larger than L^2 goes like $\ln L$ and becomes deterministic in the limit $L \to \infty$ (i.e., $\tilde{X}_L / \ln L \to a > 0$), while the cardinality of the subset of loops larger than δL^d, $\delta > 0$, is finite and has a nontrivial (i.e., nondeterministic) limit distribution.

We summarize this result in the following theorem proved in Appendix F, where we use the following notation:

$$y_{\delta,L} \equiv \frac{1}{L^d} \sum_{j \geqslant \delta L^d} jn_j, \quad X_{\delta,L} \equiv \sum_{j \geqslant \delta L^d} n_j, \quad X_L \equiv \frac{1}{\log L} \sum_{j \geqslant L^2} n_j,$$

$$j_{\max} := \max\{j : n_j > 0\}. \tag{4.4}$$

Theorem 4.1: *Suppose that* $\lambda > \lambda^*$ *and* $0 < \delta < \lambda - \lambda^*$, *then*

$$\lim_{L\to\infty} E^{mf}_{\lambda,L}(y_{\delta,L}) = \lambda - \lambda^* - \delta, \tag{4.5}$$

$$\lim_{L\to\infty}\{E^{mf}_{\lambda,L}(y^2_{\delta,L}) - E^{mf}_{\lambda,L}(y_{\delta,L})^2\} = \tfrac{1}{2}\delta^2, \tag{4.6}$$

$$\lim_{L\to\infty} E^{mf}_{\lambda,L}(X_{\delta,L}) = \log\frac{\lambda-\lambda^*}{\delta}, \quad \lim_{L\to\infty} E^{mf}_{\lambda,L}(X_L) = d-2, \tag{4.7}$$

$$\lim_{L\to\infty}\{\sqrt{\log L}[E^{mf}_{\lambda,L}(X^2_L) - E^{mf}_{\lambda,L}(X_L)^2]\} = d-2, \tag{4.8}$$

$$\lim_{L\to\infty}\{E^{mf}_{\lambda,L}(X^2_{\delta,L}) - E^{mf}_{\lambda,L}(X_{\delta,L})^2\} = D_\delta = \log\frac{\lambda-\lambda^*}{\lambda-\lambda^*-\delta}\left(1-\log\frac{\lambda-\lambda^*}{\delta}\right) + \int_\delta^{\lambda-\lambda^*-\delta}\frac{dx}{x}\left(1-\log\frac{\lambda-\lambda^*}{\lambda-\lambda^*-x}\right), \tag{4.9}$$

$$\frac{D_\delta}{\log[(\lambda-\lambda^*)/\delta]} \underset{\delta\to 0}{\longrightarrow} 1. \tag{4.10}$$

Furthermore, for any $\xi\in(1/2,1]$,

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}\left(\frac{j_{\max}}{L^d} > \xi(\lambda-\lambda^*)\right) = -\ln\xi. \tag{4.11}$$

Suto[13] has already a proof of (4.3) in the free canonical case, but he has not analyzed in detail the statistics of long loops.

V. SMALL AND LARGE DEVIATIONS

A. Small deviations

Theorem 5.1 (small fluctuations for N): *Let*

$$\sigma^2 := \lim_{L\to\infty}\frac{1}{L^d}E^{mf}_{\lambda,L}\left(\left[\sum_{j>0} j(n_j - \langle n_j\rangle)\right]^2\right), \quad \langle n_j\rangle := E^{mf}_{\lambda,L}(n_j). \tag{5.1}$$

Then, if $\lambda_0(\lambda)$ *is defined as in Appendix G,*

$$\sigma^2 = \left[\beta + \frac{\mathbf{1}_{\{\lambda<\lambda^*\}}}{\sum_j \rho^*_j j e^{\lambda_0(\lambda)\beta j}}\right]^{-1} \tag{5.2}$$

for any λ, *if* $d=3,4$, *and for* $\lambda\neq\lambda^*$, *if* $d\geqslant 5$. *Moreover, under the same conditions on* λ, *the function*

$$\mathfrak{I}(v) := \inf_{\varrho:\Sigma\rho_j=\rho(\lambda)+v} F_\lambda(\varrho) - \inf_\varrho F_\lambda(\varrho) \tag{5.3}$$

with $\rho(\lambda)$ *given by (3.18), is twice differentiable in* $v=0$ *and*

$$\sigma^2 = \left(\beta\left[\frac{d^2\mathfrak{I}(v)}{dv^2}\right]_{v=0}\right)^{-1}. \tag{5.4}$$

Proof: The value of σ^2 is calculated in Appendix C, Theorem C.2, in the case $\lambda\geqslant\lambda^*$; the case $\lambda<\lambda^*$ could be treated in a similar (simpler) way. The relation with the free energy functional, Eq. (5.4), follows from (I6) of Appendix I. ■

Remark: If $d=3$ and $\lambda\neq\lambda^*$, Eq. (5.2) was already obtained by Ref. 2, but the case $\lambda=\lambda^*$

seems new. To check that the expression given in Ref. 2 coincides with (5.2) for $\lambda \neq \lambda^*$, it is sufficient to note that, since $\rho(\lambda)=\lambda-\lambda_0(\lambda)$ and, in $d=3$, $\rho_j^*=1/(2\pi\beta j)^{3/2}$,

$$\sum_j \rho_j^* \beta j e^{\lambda_0(\lambda)\beta j} = \frac{\beta}{(2\pi\beta)^{3/2}} \sum_j \frac{1}{j^{1/2}} e^{(\lambda-\rho(\lambda))\beta j} \equiv \frac{\beta}{(2\pi\beta)^{3/2}} \mathfrak{g}_{1/2}(\lambda-\rho(\lambda)), \tag{5.5}$$

where $\mathfrak{g}_{1/2}(\mu)$ is defined in formulas 17–18 of Ref. 2.

We will also study deviations of other macroscopic quantities. In particular we will consider the following sets:

$$V_1 := \mathbb{Z}^+, \quad V_2 := \{\ell\}, \quad V_3 := \{J(L)\}, \quad V_4 := \{1,2,\ldots,J(L)\} \tag{5.6}$$

with $J(L)$ as in Theorem 3.2, namely $J(L) \in \mathbb{N}^+$ is an increasing function of L, such that $\lim_{L\to\infty} J(L)=\infty$ and $\lim_{L\to\infty} J(L)/L^2<\infty$.

For $k=1,\ldots,4$, we then define

$$\mathcal{A}_{L,\delta}^{(k)}(v) \equiv \mathcal{A}_{L,\delta}^{(k)} := \left\{ \varrho : \frac{1}{L^d} N^{(k)} \in \left(\sum_{j\in V_k} \rho_j(\lambda) + v - \delta, \sum_{j\in V_k} \rho_j(\lambda) + v + \delta \right) \right\}, \tag{5.7}$$

$$A_L^{(k)}(v) \equiv A_L^{(k)} := \left\{ \varrho : \sum_{j\in V_k} \rho_j = \sum_{j\in V_k} \rho_j(\lambda) + v \right\}, \tag{5.8}$$

with

$$N^{(k)} = \sum_{j\in V_k} j n_j \tag{5.9}$$

and $\rho_j(\lambda)$ as in (3.17).

The small deviations for $N^{(k)}$, $k\neq 1$, $N^{(k)}$ as in (5.9), are discussed in Appendix D for $\lambda>\lambda^*$. The relation of the corresponding covariances with the free energy functional goes along the same lines of Appendix I and we omit it.

B. Large deviations

In this section we will express the rate functions of large deviations for the quantities (5.7) and (5.8) in terms of variational problems for the limit functional with corresponding constraints.

Theorem 5.2: *For any* λ, *if* $k=1$, *and for any* $\lambda\neq\lambda^*$, *if* $k>1$,

$$\lim_{\delta\to 0} \lim_{L\to\infty} \left[\frac{\frac{1}{\beta L^d} \ln P_{\lambda,L}^{mf}(\mathcal{A}_{L,\delta}^{(k)})}{-\inf_{\varrho\in A_L^{(k)}} F_\lambda(\varrho) + \inf_{\varrho} F_\lambda(\varrho)} \right] = 1. \tag{5.10}$$

Proof: The proof of this theorem in the case $k=4$ and $\lambda>\lambda^*$ (the most interesting case) follows from Theorem E.3 in Appendix E and Appendix H. The other cases can be treated along the same lines. ■

Remark: The case $\lambda=\lambda^*$ is more involved, if $k>1$, so we did not study it in detail, but we think that Theorem 5.2 is still valid.

Corollary 5.3 (large deviations for $N^{(1)}\equiv N$):

$$\lim_{\delta\to 0} \lim_{L\to\infty} \frac{\ln P(\mathcal{A}_{L,\delta}^{(1)})}{\beta L^d} = -\overline{t}(\rho(\lambda)+v) + \frac{v^2}{2} + \rho(\lambda)v + \pi^0_{\lambda_0(\lambda+\overline{t})} - \pi^0_{\lambda_0(\lambda)}, \tag{5.11}$$

where $\lambda_0(\lambda)$ *is defined in* (G5), $\pi^0_{\lambda_0}$ *is the pressure of the free system with chemical potential* λ_0 [cf. Eq. (G2)] *and* $\overline{t}$ *is the solution of the equation* $\overline{t}=\lambda_0(\lambda+\overline{t})-\lambda_0(\lambda)+v$.

Remark: If $\lambda > \lambda^*$ and $\lambda + v > \lambda^*$, then $\rho(\lambda) = \lambda$, $\lambda_0 = 0$ and the expression on the rhs of (5.11) becomes $-v^2/2$.

Corollary 5.4 (large fluctuations for $N^{(2)}$ and $N^{(3)}$): *If* $\lambda \geq \lambda^*$, $-\rho_\ell^* < v < \lambda - \lambda^*$ *and we define* $\theta := v/\rho_\ell^*$, *then*

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{1}{\beta L^d}\ln P(\mathcal{A}^{(2)}_{L,\delta}) = -\frac{1}{\beta}\frac{v}{\ell}[(\theta^{-1}+1)\ln(1+\theta)-1] \tag{5.12}$$

while, if $\lambda \geq \lambda^*$ *and* $v > \lambda - \lambda^*$,

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{1}{\beta L^d}\ln P(\mathcal{A}^{(2)}_{L,\delta}) = -\frac{1}{\beta}\frac{v}{\ell}[(\theta^{-1}+1)\ln(1+\theta)-1] + \frac{\lambda_0^2}{2} - \lambda_0 + \pi^0_{\lambda_0} - \pi^0_0, \tag{5.13}$$

where $\lambda_0 = \lambda_0(\lambda - \rho_\ell^* - v)$.

If $\lambda > \lambda^*$ *and* $v > 0$,

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{J(L)}{\beta L^d \ln J(L)}\ln P(\mathcal{A}^{(3)}_{L,\delta}) = -\frac{vd}{2}. \tag{5.14}$$

For $\lambda > \lambda^*$ *and* $v < 0$ *we get*

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{1}{\beta L^d}\ln P(\mathcal{A}^{(3)}_{L,\delta}) = -\frac{c(v)d}{2}, \tag{5.15}$$

where $c(v) > 0$ *and vanishes as* $v \to 0$ (cf. *Corollary 5.5*).

Proof: By Theorem 5.2 and Appendix H,

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{1}{\beta L^d}\ln P(\mathcal{A}^{(2)}_{L,\delta}) = -\overline{t}(\rho_\ell(\lambda)+v) + \pi_{\lambda,\overline{t}} - \pi_\lambda, \tag{5.16}$$

where $\overline{t}$ is the solution of the equation $\rho_\ell(\lambda)e^{\overline{t}\beta\ell} = \rho_\ell(\lambda) + v$. The solution does exist when $v > -\rho_\ell(\lambda)$ and is given by

$$\overline{t} = \frac{1}{\beta\ell}\ln\left(\frac{\rho_\ell(\lambda)+v}{\rho_\ell(\lambda)}\right). \tag{5.17}$$

When $\lambda > \lambda_*$ and $-\rho_\ell^* < v < \lambda - \lambda^*$, we see that $\tilde{\pi}_{\lambda,\overline{t}} - \pi_\lambda = (\lambda^2/2) + (1/\beta)\Sigma_j[(\rho_j^* + v\mathbf{1}_{j=\ell})/j] - (\lambda^2/2) - (1/\beta)\Sigma_j(\rho_j^*/j) = v/\beta\ell$, so that, defining $\theta := v/\rho_\ell^*$,

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{1}{\beta L^d}\ln P(\mathcal{A}^{(2)}_{L,\delta}) = -\frac{1}{\beta}\frac{v}{\ell}[(\theta^{-1}+1)\ln(1+\theta)-1] \tag{5.18}$$

while, if $v > \lambda - \lambda^*$, we get an extra term coming from the difference $\tilde{\pi}_{\lambda,\overline{t}} - \pi_\lambda$.

Equation (5.14) is a direct consequence of (5.12), obtained in the limit $\theta \to \infty$. ■

Notice that, when $\lambda > \lambda^*$, in the limit $L \to \infty$, the fluctuation of ρ_ℓ has the law of a free Poisson distribution with parameter ρ_ℓ^*.

Corollary 5.5 (large deviations for $N^{(4)}$): *For* $\lambda > \lambda^*$; $v > 0$,

$$\lim_{\delta\to 0}\lim_{L\to\infty}\frac{J(L)}{\beta L^d \ln J(L)}\ln P(\mathcal{A}^{(4)}_{L,\delta}) = -v\left(\frac{d}{2}-1\right). \tag{5.19}$$

For $v < 0$ *and all* $\lambda \geq \lambda^*$, *we have instead,*

$$\limsup_{L\to\infty}\frac{1}{L^d}\log P^{mf}_{\lambda,L}\left(\sum_{j=1}^{j(L)} jn_j \leq [u^* - |v|]L^d\right) \leq -c(v), \tag{5.20}$$

where $c(v) > 0$ *and vanishes as* $v \to 0$ *as*

$$c(v) \sim \begin{cases} v^2, & d \geqslant 5, \\ \dfrac{v^2}{|\log|v||}, & d = 4, \\ |v|^3, & d = 3. \end{cases} \tag{5.21}$$

Proof: See Theorem E.3 and Appendix H. ■

VI. LONG LOOPS AND BOSE CONDENSATION

In this section we show that, in the mean field model, the excess density concentration $\rho - \rho^*$ on large loops implies the phenomenon of condensation (i.e., a finite fraction of the number of particles occupies the state of zero momentum).

The reduced density matrices (RDM) are the quantum analogue of correlation functions[1,12] and the Fourier transform of the one point RDM, in the case of periodic boundary conditions with translational invariant potentials, gives (Penrose[11]) the average number of particles of momentum $2\pi p/L$, $p \in \mathbb{Z}^d$,

$$\hat{\rho}_\Lambda(p) = \int_\Lambda \rho_\Lambda(0,z) e^{i(2\pi p/L)z} \mathrm{d}z. \tag{6.1}$$

Using the language of loops, in the mean field case, where the interaction does not depend on the position of the particles, the one point RDM reads[5]

$$\rho_\Lambda^{mf}(x,y) = \sum_{j_0} \Xi_{\lambda,L}^{-1} \sum_{\mathfrak{n}} w(\mathfrak{n}) e^{-\beta[(\Sigma_j j(n_j + \delta_{j,j_0}))^2/2L^d]} e^{\lambda\beta j_0} \sum_{k \in \mathbb{Z}^d} \frac{e^{-[(kL + (x-y))^2/2\beta j_0]}}{(2\pi\beta j_0)^{d/2}}. \tag{6.2}$$

Theorem 6.1: *For* $d \geqslant 3$ *and any* β, *when* λ *is larger than* λ^*,

$$\lim_{L\to\infty} \frac{\hat{\rho}_\Lambda^{mf}(0)}{L^d} = \lambda - \lambda^*. \tag{6.3}$$

Proof: From (6.1) and (6.2) we get that

$$\begin{aligned} \hat{\rho}_\Lambda^{mf}(0) &= \int_\Lambda \rho_\Lambda^{mf}(0,z)\mathrm{d}z = \sum_{j_0} \Xi_{\lambda,L}^{-1} \sum_{\mathfrak{n}} w(\mathfrak{n}) e^{-\beta[(\Sigma_j j(n_j + \delta_{j,j_0}))^2/2L^d]} e^{\lambda\beta \sum_j j(n_j + \delta_{j,j_0})} \\ &= E_{\lambda,L}^{mf}\left(\sum_j \frac{j n_j}{L^d a(\beta j, L)} \right). \end{aligned} \tag{6.4}$$

The theorem is proved using (4.5) and [cf. (D62)]

$$0 < a(\beta j, L) - \rho_j \leqslant C\rho_j e^{-L^2/(2\beta j)}.$$

■

APPENDIX A

In this appendix we recall the relation between the usual definition of the canonical partition function for a free Bose gas and its representation in the loops language given in (2.4).

The canonical partition function for a system of N identical bosons is

$$Z_N = \mathrm{Tr}\, e^{-\beta H_N},$$

where H_N is the Hamiltonian operator and the trace involves only symmetrized states.

Theorem A.1: *Let $H_N=-\Sigma_{i=1}^N\Delta_i$ be the Hamiltonian of N free Bosons in a cubic box of size L with periodic boundary conditions, then*

$$Z_{N,L}=\sum_{\boldsymbol{\nu}:|\boldsymbol{\nu}|=N} e^{-\beta\Sigma_p(2\pi p/L)^2\nu_p}=\sum_{\mathbf{n}:\Sigma jn_j=N}\prod_j\frac{1}{n_j!}\left(\frac{\sum_p e^{-\beta j(2\pi p/L)^2}}{j}\right)^{n_j}. \tag{A1}$$

Proof: The Bosons states in the momentum representation can be written as $|\boldsymbol{\nu}\rangle=|\nu_p, p\in\mathbb{Z}^d\rangle$, ν_p being the number of Bosons with momentum equal to $k=2\pi pL^{-1}$. The energy in such a state is equal to $\Sigma_p\epsilon_p\nu_p$, $\epsilon_p=(2\pi pL^{-1})^2$, hence the first equality in (A1).

To prove the second one, let $\lambda<0$ and define,

$$\mathcal{Z}(\lambda):=\sum_N e^{\beta\lambda N}\sum_{\boldsymbol{\nu}:|\boldsymbol{\nu}|=N} e^{-\beta\Sigma_p\epsilon_p\nu_p} \tag{A2}$$

that can be rewritten as

$$\mathcal{Z}(\lambda)=\exp\left\{-\sum_p \ln(1-e^{-\beta(\epsilon_p-\lambda)})\right\}=\exp\left\{\sum_j\left(\sum_p\frac{e^{-\beta(\epsilon_p-\lambda)j}}{j}\right)\right\}=\sum_M\frac{1}{M!}\left[\sum_j\left(\sum_p\frac{e^{-\beta(\epsilon_p-\lambda)j}}{j}\right)\right]^M$$

$$=\sum_{\mathbf{n}}\prod_j\left[\sum_p\frac{e^{-\beta(\epsilon_p-\lambda)j}}{j}\right]^{n_j}\frac{1}{n_j!}=\sum_N e^{\beta\lambda N}\sum_{\mathbf{n}:\Sigma_j jn_j=N}\prod_j\left[\frac{\sum_p e^{-\beta j\epsilon_p}}{j}\right]^{n_j}\frac{1}{n_j!}. \tag{A3}$$

Since $\mathcal{Z}(\lambda)$ is analytic in λ for $\mathrm{Re}\,\lambda<0$, (A1) follows. ■

An alternative proof working in the configuration representation can be obtained as follows:

$$Z_{N,L}=\frac{1}{N!}\sum_\pi\int \mathrm{d}r_1\cdots\mathrm{d}r_N\langle r_{\pi_1}\cdots r_{\pi_N}|e^{-\beta H_N}|r_1\cdots r_N\rangle,$$

where Σ_π is the sum over all permutations of $(1,2,\ldots,N)$. Since any permutation breaks up into cycles (loops), we have

$$Z_N=\frac{1}{N!}\sum_{n_1,n_2,\ldots}c(n_1,n_2,\ldots)\prod_j Z^{n_j},$$

where

(a) $c(n_1,n_2,\ldots)=N!\Pi_j(1/j^{n_j})(1/n_j!)$ is the number of ways of having n_1 loops of length 1, n_2 of length 2, etc.,
(b) the sum is over all combinations of permutations s.t. $\Sigma jn_j=N$,
(c) $Z(j)=\Sigma_p e^{-\beta j\epsilon_p}$, where $-\epsilon_p$ are the eigenvalues of the Laplace operator Δ.

In the case of a free Bose gas in a cubic box of size L with periodic boundary conditions

$$Z_{N,L}=\sum_{\mathbf{n}:\Sigma jn_j=N}\prod_j\frac{1}{n_j!}\left(\frac{\sum_p e^{-\beta j(2\pi p/L)^2}}{j}\right)^{n_j}$$

thus deriving again the last equality in (A1).

Finally, to justify Eq. (2.3), we prove the following lemma.

Lemma A.2: For any L and $\alpha>0$

$$L^d\sum_{k\in\mathbb{Z}^d}\frac{e^{-(kL)^2/(2\alpha)}}{(2\pi\alpha)^{d/2}}=\sum_{k\in\mathbb{Z}^d}e^{-1/2\alpha(2\pi k/L)^2}. \tag{A4}$$

Proof: Equation (A4) follows from the identities:

$$e^{-(kL)^2/(2\alpha)} = \frac{1}{(2\pi)^{d/2}} \int_{\mathbb{R}^d} e^{-x^2/2 + iLkx/\sqrt{\alpha}}\, dx \tag{A5}$$

and

$$\frac{1}{(2\pi)^d} \sum_{k \in \mathbb{Z}^d} e^{ivk} = \sum_{k \in \mathbb{Z}^d} \delta(v - 2\pi k). \tag{A6}$$

■

APPENDIX B

The canonical partition function (A1) of the free Bose gas can be written as

$$Z_{N,L} = \sum_{\{n_k\}} \mathbf{1}_{\Sigma n_k = N} e^{-\beta \Sigma_k n_k E_k} = \sum_{M=0}^{N} \tilde{Z}_{M,L}, \tag{B1}$$

$$\tilde{Z}_{M,L} = \sum_{\{n_k, k \neq 0\}} \mathbf{1}_{\Sigma_{k \neq 0} n_k = M} e^{-\beta \Sigma_{k \neq 0} n_k E_k}, \tag{B2}$$

where the momentum k takes values in the set $\{2\pi u/L, u \in \mathbb{Z}^d\}$, $n_k \in \mathbb{Z}$, and $E_k = k^2/2$.

In this appendix we study the tail properties of the probability distribution on $\mathbb{N}$ with density,

$$P_L(M) = \frac{\tilde{Z}_{M,L}}{Q_L}, \quad Q_L = \sum_{M=0}^{\infty} \tilde{Z}_{M,L} \tag{B3}$$

and mean value

$$\langle M \rangle_L = \sum_{k \neq 0} \frac{1}{e^{\beta E_k} - 1} \equiv L^d \lambda_L^*. \tag{B4}$$

We remark that this probability distribution is the canonical distribution of the total number of particles with $k \neq 0$ for a free Bose gas. These results will be used in the sequel to prove small and large deviation both in the free and mean field case.

We want to study the asymptotic properties of the probability measure P_L as $L \to \infty$. To begin with, note that, if $d \geqslant 3$, $\lim_{L \to \infty} \lambda_L^*$ does exist and

$$\lambda^* = \lim_{L \to \infty} \lambda_L^* = \int_{\mathbb{R}^d} \frac{dk}{(2\pi)^d} \frac{1}{e^{\beta E_k} - 1}. \tag{B5}$$

Let us define

$$c_L = L^{d-2}(\lambda^* - \lambda_L^*). \tag{B6}$$

Lemma B.1: For any $d \geqslant 3$, c_L has a limit as $L \to \infty$ and

$$c^* \equiv \lim_{L \to \infty} c_L = \int_0^\infty dt \left[1 - \sum_{u \neq 0} \frac{e^{-u^2/(2\beta t)}}{(2\pi\beta t)^{d/2}} \right]. \tag{B7}$$

Proof: (3.2) and (B4) imply that

$$L^d \lambda_L^* = \sum_{k \neq 0} \sum_{j=1}^{\infty} e^{-\beta j E_k} = \sum_{j=1}^{\infty} [L^d a(\beta j, L) - 1] \tag{B8}$$

while (B5) implies that

$$L^d\lambda^* = L^d\sum_{j=1}^{\infty}\frac{1}{(2\pi\beta j)^{d/2}} \tag{B9}$$

hence, by using the definition of $a(t,L)$ in (3.2), we get

$$c_L = \frac{1}{L^2}\sum_{j=1}^{\infty}\left[1-\sum_{n\neq 0}\frac{e^{-n^2/(2\beta t_j)}}{(2\pi\beta t_j)^{d/2}}\right], \quad t_j=\frac{j}{L^2}. \tag{B10}$$

The lemma follows from this expression, easily implying the convergence of the sum over $j\leqslant L^2$, and the identity, following from (3.2) (with $L=1$):

$$1-\sum_{n\neq 0}\frac{e^{-n^2/(2t)}}{(2\pi t)^{d/2}} = \frac{1}{(2\pi t)^{d/2}} - \sum_{n\neq 0} e^{-2\pi^2 t n^2} \tag{B11}$$

which implies immediately the convergence of the sum over $j\geqslant L^2$. ■

Let us now define

$$y_L = \frac{M-L^d\lambda_L^*}{h_L}, \quad h_L = \begin{cases} L^2, & d=3,\\ L^2\sqrt{\log L} & d=4,\\ L^{d/2}, & d\geqslant 5. \end{cases} \tag{B12}$$

An important role in this appendix has the following theorem.

Theorem B.2: *If M is a random variable with probability (B3), the distribution function of the random variable y_L converges, as $L\to\infty$, to the distribution function of a random variable y on $\mathbb{R}$ with mean 0 and smooth density $\rho(y)$ strictly positive, whose Laplace transform $F(\sigma)=\int dy\,\rho(y)\exp(-\sigma y)$, $\sigma\in\mathbb{C}$, is given, if $d=3$ and $\Re\sigma>-2\pi^2\beta$, by*

$$F(\sigma)=\exp\left(\sum_{n\neq 0} G\left(\frac{\sigma}{2\pi^2\beta n^2}\right)\right), \quad G(u)=u-\log(1+u) \tag{B13}$$

while, if $d\geqslant 4$ and $\Re\sigma\in\mathbb{R}$,

$$F(\sigma)=e^{1/2c_0\sigma^2}, \quad c_0=\begin{cases}\dfrac{1}{2\pi^2\beta^2}, & d=4\\[2ex] \dfrac{1}{(2\pi\beta)^{d/2}}\displaystyle\sum_{j=1}^{\infty} j^{1-d/2}, & d\geqslant 5.\end{cases} \tag{B14}$$

Moreover, there exists a constant C, independent of L and M, such that

$$(1+y_L^2)h_L P_L(M)\leqslant C \tag{B15}$$

and, given any $y\in\mathbb{R}$, if we choose $M=M_L^*$ so that $y_L^*=(M_L^*-L^d\lambda_L^*)/h_L\to_{L\to\infty} y$, then

$$h_L P_L(M_L^*)\xrightarrow[L\to\infty]{}\rho(y). \tag{B16}$$

Proof: To begin with, we shall prove that the Laplace transform of y_L, $F_L(\sigma)=\Sigma_{M=0}^{\infty}P_L(M)\exp[-\sigma(M-L^d\lambda_L^*)/h_L]$, is well defined and convergent as $L\to\infty$, if $\Re\sigma\in(\sigma_0,\infty)$, where $\sigma_0=-2\pi^2\beta$, if $d=3$, and $\sigma_0=-\infty$, if $d\geqslant 4$; this implies in particular that the characteristic function $f_L(t)=F_L(-it)$, $t\in\mathbb{R}$, is convergent for any t. By analyzing the decaying properties in t of $f_L(t)$, we shall also prove the bound (B15), implying that the distribution function of y_L is convergent and that its limit is the distribution function of a probability measure on $\mathbb{R}$; in fact, by a simple application of dominated convergence theorem,

$$\sum_{0\leqslant M\leqslant h_L y+L^d\lambda_L^*} P_L(M) = \frac{1}{h_L} \sum_{0\leqslant M\leqslant h_L y+L^d\lambda_L^*} h_L P_L(M) \xrightarrow[L\to\infty]{} \int_{-\infty}^{y} \rho(z)\mathrm{d}z. \tag{B17}$$

Note that this result follows from the convergence of $f_L(t)$ to $f(t)$, without using the bound (B15), since $P_L(M)$ is a probability measure.[3] We are stressing here the role of (B15) only because we shall generalize in the following the previous argument to some cases where $P_L(M)$ is not a probability measure, even if $\Sigma_{M=0}^{\infty} P_L(M)=1$.

Finally, by analyzing the properties of the limiting measure Laplace transform, we shall prove that this measure has a smooth and strictly positive density.

By a straightforward calculation, one can see that

$$\begin{aligned}\log F_L(\sigma) &= \frac{L^d\lambda_L^*}{h_L}\sigma - \sum_{k\neq 0} \log \frac{1-e^{-\beta E_k-\sigma/h_L}}{1-e^{-\beta E_k}} = \sum_{k\neq 0}\left[\frac{\sigma}{h_L}\frac{1}{e^{\beta E_k}-1} - \log\left(1+\frac{1-e^{-\sigma/h_L}}{e^{\beta E_k}-1}\right)\right] \\ &= \sum_{k\neq 0}\frac{1}{e^{\beta E_k}-1}\left[\frac{\sigma}{h_L} - (1-e^{-\sigma/h_L})\right] + \sum_{n\neq 0} G\left(\frac{1-e^{-\sigma/h_L}}{e^{2\pi^2\beta n^2/L^2}-1}\right),\end{aligned} \tag{B18}$$

where $G(u)=u-\log(1+u)$.

Let us consider first the case $d=3$. Then $h_L=L^2$, so that $F_L(\sigma)$ is well defined for $\Re\sigma>\sigma_0 \equiv -2\pi^2\beta$; hence we shall fix σ so that this condition is satisfied. Then the first term in the third line of (B18) goes to 0 as $L\to\infty$, since it is bounded by CL^{-1}, where C (here and in the following) denotes a suitable positive constant, depending on σ but independent of L. Note that

$$u_{n,L} \equiv \frac{1-e^{-\sigma/h_L}}{e^{2\pi^2\beta n^2/L^2}-1} \xrightarrow[L\to\infty]{} u_n^* \equiv \frac{\sigma}{2\pi^2\beta n^2} \tag{B19}$$

and that $|u_{n,L}|$, $|u_n^*|\leqslant Cn^{-2}$, and $|u_{n,L}-u_n^*|\leqslant C/L^2$. On the other hand, $\Re u_{n,L}$ and $\Re u_n^*$ are larger of some constant $u_0>-1$, for any n; since $G'(u)=u/(1+u)$, it immediately follows that

$$|G(u_{n,L})-G(u_n^*)| \leqslant C|u_{n,L}-u_n^*|n^{-2} \leqslant Cn^{-7/2}|u_{n,L}-u_n^*|^{1/4} \leqslant C|n|^{-7/2}L^{-1/2}. \tag{B20}$$

It follows that $\log F_L(\sigma)$ and $F_L(\sigma)$ are convergent for $L\to\infty$ and that, if $F(\sigma)=\lim_{L\to\infty} F_L(\sigma)$,

$$\Pi(\sigma) \equiv \log F(\sigma) = \sum_{n\neq 0} G\left(\frac{\sigma}{2\pi^2\beta n^2}\right). \tag{B21}$$

It is not hard to show that $\Pi(\sigma)$ is differentiable and that

$$\Pi'(\sigma) = \sum_{n\neq 0} \frac{\sigma}{2\pi^2\beta n^2(\sigma+2\pi^2\beta n^2)} \tag{B22}$$

implying that, if $x\in\mathbb{R}$,

$$\lim_{x\to+\infty} \Pi'(x) = +\infty, \quad \lim_{x\to\sigma_0^+} \Pi'(x) = -\infty. \tag{B23}$$

Let us now call $P(\mathrm{d}y)$ the probability measure such that

$$F(\sigma) = e^{\Pi(\sigma)} = \int P(\mathrm{d}y) e^{-\sigma y}. \tag{B24}$$

The property (B23) easily implies that the support of $P(\mathrm{d}x)$ is the full real line. Moreover, the characteristic function $f(t)$ of $P(\mathrm{d}x)$ is given by the equation

$$f(t) = e^{\Pi(-it)} = \prod_{n\neq 0} \frac{e^{-ita n^{-2}}}{1 - ita n^{-2}}, \quad a = (2\pi^2\beta)^{-1}. \tag{B25}$$

By using the bound $\log(1+x) \geq 2x/3$, valid for $0 \leq x \leq 1/2$, we get, if $|t| \geq 1$,

$$|f(t)| \leq \prod_{n\neq 0} (1 + t^2 a^2 |n|^{-4})^{-1/2} \leq \prod_{|n|\leq(\sqrt{2}a|t|)^{1/2}} (3/2)^{-1/2} \prod_{|n|>(\sqrt{2}a|t|)^{1/2}} e^{-t^2 a^2 |n|^{-4}/3} \leq e^{-C|t|^{3/2}}. \tag{B26}$$

This bound and the support properties of $P(\mathrm{d}y)$ imply that $P(\mathrm{d}y) = \rho(y)\mathrm{d}y$, with $\rho(y)$ a strictly positive smooth function on $\mathbb{R}$.

In order to complete the proof of the theorem in the case $d=3$, we still have to prove the strong convergence property (B16), together with the uniform bound (B15) on $h_L P_L(M)$. Note that the definition of characteristic function implies that

$$h_L P_L(M) = \frac{1}{2\pi} \int_{-\pi h_L}^{+\pi h_L} \mathrm{d}t\, e^{-ity_L} f_L(t). \tag{B27}$$

By using (B18), we see that

$$f_L(t) = F_L(-it) = \prod_{n\neq 0} \frac{e^{v_{n,L}}}{1 + u_{n,L}}, \tag{B28}$$

where $u_{n,L}$ is given by (B19) with $\sigma = -it$ and

$$v_{n,L} = \frac{-it}{L^2(e^{2\pi^2\beta n^2/L^2} - 1)}. \tag{B29}$$

It follows that $|f_L(t)| \leq \Pi_{n\neq 0} |1+u_{n,L}|^{-1}$. Moreover, by using (B19), we see that, if $|t| \leq \pi L^2/2$ and $|n|^2 \leq |t|$, $|1+u_{n,L}| \geq 1+\delta$, with a suitable $\delta > 0$. Hence, if $|t| \leq \pi L^2/2$, $|f_L(t)| \leq \Pi_{0<|n|\leq|t|^{1/2}} (1+\delta)^{-1}$ $\leq \exp(-C|t|^{-3/2})$. If $\pi L^2/2 \leq |t| \leq \pi L^2$, the same result is obtained, by observing that in this case, if $|n| \leq L$, $|1+u_{n,L}| \geq 1 + 1/(e^{2\pi^2\beta} - 1)$, so that $|f_L(t)| \leq \exp(-CL^3) \leq \exp(-C|t|^{-3/2})$. Hence, we can show that, uniformly in L,

$$|f_L(t)| \leq \exp(-C|t|^{3/2}), \quad |t| \leq \pi h_L \tag{B30}$$

which implies, together with (B27), that $h_L P_L(M) \leq C$, with C independent of L and M. Moreover, by the dominated Lebesgue convergence theorem, we get, for any $y \in \mathbb{R}$,

$$y_L \xrightarrow[L\to\infty]{} y \Rightarrow h_L P_L(M) \xrightarrow[L\to\infty]{} \frac{1}{2\pi} \int_{-\infty}^{+\infty} e^{ity} f(t) = \rho(y). \tag{B31}$$

In order to complete the proof of (B15), we use the identity

$$(-iy_L)^2 h_L P_L(M) = \frac{1}{2\pi} \int_{-\pi h_L}^{+\pi h_L} e^{-ity_L} f_L''(t). \tag{B32}$$

Since $f_L''(t) = f_L(t)[\Pi_L'(-it)^2 + \Pi_L''(-it)]$, where $\Pi_L(-it) = \log F_L(-it)$, and, as one can check easily by proceeding as in the analysis given before of $\log F_L(\sigma)$, uniformly in L,

$$|\Pi_L'(-it)| \leq C|t|, \quad |\Pi_L(-it)| \leq C \tag{B33}$$

the bound (B15) immediately follows from the bound (B30).

Let us now suppose that $d=4$. Then $h_L = L^2\sqrt{\log L}$, so that, given any $x<0$, $F_L(\sigma)$ is well defined for $\Re\sigma > x$, if $L > \exp(-x/(2\pi^2\beta))$. Moreover, as in the case $d=3$, the first term in the third line of (B18) goes to 0 as $L \to \infty$, since it is bounded by $C(\log L)^{-1/2}$.

If we define $u_{\mathfrak{a},L}$ as in (B19), $|u_{\mathfrak{a},L}| \leqslant C(\mathfrak{a}^2\sqrt{\log L})^{-1}$, with C only depending on σ if L is large enough. Hence, if $\tilde{G}(u) = u - \log(1+u) - u^2/2$,

$$\left| \sum_{\mathfrak{a}\neq 0} \tilde{G}(u_{\mathfrak{a},L}) \right| \leqslant \frac{C}{(\log L)^{3/2}} \sum_{\mathfrak{a}\neq 0} \frac{1}{|\mathfrak{a}|^6} \xrightarrow[L\to\infty]{} 0. \tag{B34}$$

Note also that $L^{-4}\Sigma_{|\mathfrak{a}|\geqslant L}[\exp(a\mathfrak{a}^2/L^2)-1]^{-2}$ is bounded for $L\to\infty$, for any $a>0$, and that

$$\frac{1}{\log L} \sum_{0<|\mathfrak{a}|\leqslant L} \left[\frac{1}{(a\mathfrak{a}^2)^2} - \frac{1}{L^4(e^{a\mathfrak{a}^2/L^2}-1)^2} \right] \leqslant \frac{C}{L^2 \log L} \sum_{0<|\mathfrak{a}|\leqslant L} \frac{1}{|\mathfrak{a}|^4} \xrightarrow[L\to\infty]{} 0 \tag{B35}$$

so that $(\log L)^{-1}L^{-4}\Sigma_{\mathfrak{a}\neq 0}[\exp(a\mathfrak{a}^2/L^2)-1]^{-2}$ is convergent for $L\to\infty$ and

$$c_0 = \lim_{L\to\infty} \frac{1}{\log L} \sum_{\mathfrak{a}\neq 0} \frac{1}{L^4(e^{a\mathfrak{a}^2/L^2}-1)^2} = \lim_{L\to\infty} \frac{1}{\log L} \sum_{0<|\mathfrak{a}|\leqslant L} \frac{1}{a^2|\mathfrak{a}|^4} = \frac{1}{a^2} \lim_{L\to\infty} \frac{1}{\log L} \int_{1\leqslant|\mathfrak{x}|\leqslant L} \frac{\mathrm{d}^4\mathfrak{x}}{|\mathfrak{x}|^4} = \frac{2\pi^2}{a^2}. \tag{B36}$$

By using (B18) and (B36) with $a = 2\pi^2\beta$, it is now easy to prove that $\log F_L(\sigma)$ is convergent for $L\to\infty$ and that

$$\Pi(\sigma) = \lim_{L\to\infty} \log F_L(\sigma) = \frac{1}{2}\sigma^2 \lim_{L\to\infty} \frac{1}{L^4 \log L} \sum_{\mathfrak{a}\neq 0} \frac{1}{(e^{2\pi^2\beta\mathfrak{a}^2/L^2}-1)^2} = \frac{1}{2}\frac{2}{(2\pi\beta)^2}\sigma^2. \tag{B37}$$

It follows immediately, if we define $P(\mathrm{d}y)$ as in the case $d=3$, that $P(\mathrm{d}y)$ is a Gaussian probability measure with density $\rho(y) = (2\pi c_0)^{-1/2}\exp[-y^2/(2c_0)]$, with $c_0 = 2/(2\pi\beta)^2$. The proof of (B15) and (B16) in the case $d=3$ can be easily extended to this case; we omit the details.

Let us finally consider the case $d\geqslant 5$. Then $h_L = L^{d/2}$ and we can proceed as in the previous case, the only relevant difference being that now $\Pi(\sigma)$ gets a contribution also from the first term in the third line of (B18). We find that $\Pi(\sigma) = \frac{1}{2}c_0\sigma^2$, with

$$\begin{aligned} c_0 &= \lim_{L\to\infty} \frac{1}{L^d} \sum_{\mathfrak{a}\neq 0} \left[\frac{1}{e^{2\pi^2\beta\mathfrak{a}^2/L^2}-1} + \frac{1}{(e^{2\pi^2\beta\mathfrak{a}^2/L^2}-1)^2} \right] = \int \frac{\mathrm{d}^d\mathfrak{k}}{(2\pi)^d} \frac{e^{-\beta E_{\mathfrak{k}}}}{(1-e^{-\beta E_{\mathfrak{k}}})^2} \\ &= \sum_{j_1,j_2\geqslant 0} \int \frac{\mathrm{d}^d\mathfrak{k}}{(2\pi)^d} e^{-\beta E_{\mathfrak{k}}(j_1+j_2+1)} = \sum_{j\geqslant 1} \frac{j}{(2\pi\beta j)^{d/2}}. \end{aligned} \tag{B38}$$

The proof of (B15) and (B16) in the case $d=3$ can be easily extended also to this case, so completing the proof of the theorem. ■

APPENDIX C: PROOF OF THEOREM 3.1

Note that the mean field grand canonical partition function can be written as

$$\Xi^{mf}_{\lambda,L} = e^{1/2\beta\lambda^2 L^d} \sum_{N=0}^{\infty} e^{-(\beta/2)L^d[(N/L^d)-\lambda]^2} Z_{N,L} \tag{C1}$$

and that

$$P_L(M\leqslant N) = P_L\left(y_L \leqslant \frac{L^d}{h_L}(\lambda-\lambda^*) + \frac{L^{d/2}}{h_L}x_N + \frac{L^2}{h_L}c_L \right),$$

$$x_N = L^{d/2}\left(\frac{N}{L^d} - \lambda\right). \tag{C2}$$

Let us now define

$$\Gamma_{\lambda,L} \equiv \frac{\Xi^{mf}_{\lambda,L}}{e^{1/2\beta\lambda^2 L^d} Q_L L^{d/2}} = \frac{1}{L^{d/2}} \sum_{N=0}^{\infty} e^{-\beta/2L^d[(N/L^d)-\lambda]^2} P_L(M \leqslant N). \tag{C3}$$

Theorem 3.1 follows from the following Lemma.

Lemma C.1: If $\lambda \geqslant \lambda^*$, *the quantity* $\Gamma_{\lambda,L}$ *has a limit as* $L \to \infty$. *If* $\lambda > \lambda^*$, *we have, for any* $d \geqslant 3$,

$$\lim_{L\to\infty} \Gamma_{\lambda,L} = \sqrt{\frac{2\pi}{\beta}} \tag{C4}$$

while, if $\lambda = \lambda_*$, *we have*

$$0 < \lim_{L\to\infty} \Gamma_{\lambda,L} = \begin{cases} \sqrt{\dfrac{2\pi}{\beta}} \displaystyle\int_{-\infty}^{c^*} dy\, \rho(y), & d = 3, \\ \sqrt{\dfrac{\pi}{2\beta}}, & d = 4, \\ \displaystyle\int_{-\infty}^{+\infty} dx\, e^{-\beta x^2/2} \int_{-\infty}^{x} dy\, \rho(y), & d \geqslant 5, \end{cases} \tag{C5}$$

where $\rho(y)$ *is the density probability defined in Theorem B.2.*

Moreover, if $N_L = [uL^d]$ ($[\cdot]$ *denotes the integer part*), $u > \lambda^*$, *and* $N_L^* = [\lambda^* L^d]$, *then*

$$\lim_{L\to\infty} \frac{Z_{N_L,L}}{Z_{N_L^*,L}} = \begin{cases} 1/P(y \leqslant c_*), & d = 3, \\ 2, & d \geqslant 4. \end{cases} \tag{C6}$$

Proof: By Theorem B.2, $P_L(y_L \leqslant \overline{y}) \to_{L\to\infty} \int_0^{\overline{y}} dy\, \rho(y)$, for any fixed $\overline{y}$, $\rho(y)$ being a strictly positive function depending on the dimension d. Hence, by using (C2) and Lemma B.1, we can easily show that, if $\lambda > \lambda^*$ and $x_N \to_{L\to\infty} x$

$$P_L(M \leqslant N) \xrightarrow[L\to\infty]{} 1, \quad \forall\, x \tag{C7}$$

while, if $\lambda = \lambda^*$ and $x_N \to_{L\to\infty} x$,

$$P_L(M \leqslant N) \xrightarrow[L\to\infty]{} \begin{cases} P(y \leqslant c_*), & d = 3, \\ P(y \leqslant 0) = 1/2, & d = 4, \\ P(y \leqslant x), & d \geqslant 5. \end{cases} \tag{C8}$$

Then (C4) and (C5) follow from (C3) and a simple application of the dominated Lebesgue convergence theorem. The proof of (C6) is a simple consequence of (C2), (C8) and the equation, valid if $N_L = [uL^d]$, $u > \lambda^*$, and $N_L^* = [\lambda^* L^d]$,

$$\lim_{L\to\infty} \frac{Z_{N_L,L}}{Z_{N_L^*,L}} = \lim_{L\to\infty} \frac{P_L(M \leqslant N_L)}{P_L(M \leqslant N_L^*)} = \lim_{L\to\infty} \frac{P_L\left(y_L \leqslant \dfrac{L^d}{h_L}(u - \lambda^*)\right)}{P_L(y_L \leqslant c_L L^2/h_L)}. \tag{C9}$$

■

By similar arguments, one can prove the following theorem (see also Ref. 2 for the case $\lambda > \lambda^*$).

Theorem C.2: *If* $\lambda > \lambda^*$, *the distribution of the random variable* x_N *converges, as* $L \to \infty$, *to a Gaussian distribution with density* $\exp(-\beta x^2/2)$; *the same result is true if* $\lambda = \lambda^*$ *and* $d = 3, 4$. *However, if* $d > 4$, *the limiting distribution is still well defined, but it is not Gaussian anymore; it is proportional to* $e^{-\beta x^2/2} \int_{-\infty}^{x} dy\, \rho(y)$, $\rho(y)$ *being the density probability defined in Theorem B.2.*

APPENDIX D: DISTRIBUTION OF "SHORT LOOPS"

In this appendix we will restrict to $d \geqslant 3$ and $\lambda \geqslant \lambda^*$ and study the distribution of the variables,

$$y_{A,L} = \frac{\sum_{j \in A} j n_j - L^d \rho_{A,L}}{h_{A,L}}, \quad \rho_{A,L} = \sum_{j \in A} \rho_{j,L}, \tag{D1}$$

where A is a finite subset of $\mathbb{N}^+$, $L^D \rho_{j,L}$ is the mean value of $j n_j$ with respect to the mean field measure and $h_{A,L}$ is a suitable scaling factor. The main results are stated in Theorems D.4 and D.5 below, the main ingredient in the proofs is the reduction to the analysis of the probability distribution $P_L(M)$ defined in Appendix B.

We start by deriving the following expression for $\rho_{j,L}$:

$$\rho_{j,L} = a(\beta j, L) \alpha_{j,L}, \tag{D2}$$

where

$$\alpha_{j,L} = \frac{1}{\Gamma_{\lambda,L}} \frac{1}{L^{d/2}} \sum_{N \geqslant 0} e^{-\beta x_N^2/2} P_L(M \leqslant N - j) \tag{D3}$$

with x_N as in (C2).

Proof of (D2): Let $w^0(j, n_j)$ be as in (2.1) with $\lambda = 0$, then

$$\rho_{j^*,L} = \frac{e^{(\beta\lambda^2/2)L^d}}{\Xi^{mf}_{\lambda,L}} \sum_N e^{-\beta(x_N^2/2)} \sum_{\underline{n}: \Sigma_j j n_j = N} \prod_j w^0(j, n_j) \frac{j^* n_{j^*}}{L^d} = \frac{e^{(\beta\lambda^2/2)L^d}}{\Xi^{mf}_{\lambda,L}} a(\beta j^*, L) \sum_N e^{-\beta(x_N^2/2)} Z_{N-j^*,L}. \tag{D4}$$

By (B1) and (B3) we get

$$\rho_{j^*,L} = \frac{e^{(\beta\lambda^2/2)L^d}}{\Xi^{mf}_{\lambda,L}} a(\beta j^*, L) Q_L \sum_N e^{-\beta(x_N^2/2)} P_L(M < N - j^*) \tag{D5}$$

hence (D2) follows by (C3). ■

Lemma D.1: For any $\lambda \geqslant \lambda^*$, *there is a constant* C, *independent of* L *and* j, *such that, if* h_L *is defined as in* (B12),

$$0 < 1 - \alpha_{j,L} \leqslant C \frac{j}{h_L}. \tag{D6}$$

Moreover, if $\lambda = \lambda^*$,

$$\lim_{L\to\infty}\frac{h_L}{j}(1-\alpha_{j,L})=\begin{cases}\dfrac{\rho(c^*)}{\displaystyle\int_{-\infty}^{c^*}\mathrm{d}y\,\rho(y)}, & d=3,\\ 2\rho(0), & d=4,\\ \dfrac{\displaystyle\int_{-\infty}^{+\infty}\mathrm{d}x\,e^{-\beta x^2/2}\rho(x)}{\displaystyle\int_{-\infty}^{+\infty}\mathrm{d}x\,e^{-\beta x^2/2}\int_{-\infty}^{x}\mathrm{d}y\,\rho(y)}, & d\geqslant 5,\end{cases}\tag{D7}$$

where $\rho(y)$ is defined as in Lemma C.1.

Proof: Note that

$$1-\alpha_{j,L}=\frac{1}{\Gamma_{\lambda,L}}\frac{1}{L^{d/2}}\sum_{N\geqslant 0}e^{-\beta x_N^2/2}P_L(N-j<M\leqslant N).\tag{D8}$$

By using the claim in Lemma C.1 that $h_L P_L(M)$ is bounded uniformly in L and M, we get

$$P_L(N-j<M\leqslant N)=\frac{1}{h_L}\sum_{M=N-j+1}^{N}h_L P_L(M)\leqslant C\frac{j}{h_L}\tag{D9}$$

which immediately implies (D6), by using Lemma C.1. On the other hand, if $\lambda=\lambda^*$ and $M=N-r$, $r\geqslant 1$, the corresponding y_L variable is equal, see (C2), to $(L^{d/2}x_N+L^2c_L-r)/h_L$, so that, by using (B16),

$$h_L P_L(M=N-r)\xrightarrow[L\to\infty]{}\begin{cases}\rho(c^*), & d=3,\\ \rho(0), & d=4,\\ \rho(x), & d\geqslant 5.\end{cases}\tag{D10}$$

Equations (D7) then follows from Lemma C.1 and dominated convergence theorem. ■

If $\lambda>\lambda^*$, $h_L P_L(M=N-r)$ goes to 0 as $L\to\infty$, so we expect the bound (D6) can be improved. This is especially true if j is taken as a diverging function of L; in particular, if $j>(\lambda-\lambda^*)L^d$, it is easy to see that $\alpha_{j,L}\to 0$ as $L\to\infty$. In order to get good bounds in all these cases, we shall use the following large deviation bound for the probability measure $P_L(M)$.

Lemma D.2: Let $0<u_1<u_2$; then there exist $\bar{L}(u_1)$, such that the probabilities,

$$S_L^+(u_1,u_2)\equiv P_L(L^d\lambda_L^*+L^d u_1\leqslant M\leqslant L^d\lambda_L^*+L^d u_2),\tag{D11}$$

$$S_L^-(u_1,u_2)\equiv P_L(L^d\lambda_L^*-L^d u_2\leqslant M\leqslant L^d\lambda_L^*-L^d u_1),\tag{D12}$$

satisfy, for $L\geqslant\bar{L}(u_1)$, the following bounds:

$$e^{-a_1u_2L^{d-2}(1+\delta_L)}\leqslant S_L^+(u_1,u_2)\leqslant e^{-a_1u_1L^{d-2}(1-\delta_L)},\quad\forall\,u_1>0,\tag{D13}$$

$$e^{-f(u_2)(L^d/h_L)^2(1+\delta_L)}\leqslant S_L^-(u_1,u_2)\leqslant e^{-f(u_1)(L^d/h_L)^2(1-\delta_L)},\quad u_2<\lambda^*,\tag{D14}$$

where δ_L is a function which goes to 0 as $L\to\infty$, a_1 is a positive constant, depending on d, and $f(u)$ is a positive function of order u^2 for $u\to 0$ (equal indeed to a_2u^2 for $d=2,3$).

Proof: By (C2), we can write

$$S_L^+(u_1,u_2)=\int_{u_1L^d/h_L}^{u_2L^d/h_L} P_L(\mathrm{d}y)=e^{\Pi_L(t)}\int_{u_1L^d/h_L}^{u_2L^d/h_L} e^{ty}P_{t,L}(\mathrm{d}y), \tag{D15}$$

where $\Pi_L(t)=\log F_L(t)$, $F_L(t)$ is the Laplace transform of $P_L(\mathrm{d}y)$ given by (B18), t is any real number such that $F_L(t)$ is well defined and $P_{t,L}(\mathrm{d}y)$ is the probability measure

$$P_{t,L}(\mathrm{d}y)=\frac{e^{-ty}P_L(\mathrm{d}y)}{F_L(t)}. \tag{D16}$$

By looking at (B18), we see that $F_L(t)$ is defined for $t>t_L^*$, where t_L^* is the value of t such that the argument $u_{n,L}$ of the function $G(u)=u-\log(1+u)$ is equal to -1 if $|\mathbf{n}|=1$, that is $t_L^*=-ah_L/L^2$. We choose t so that

$$-\Pi_L'(t)=\int \mathrm{d}y\, yP_{t,L}(\mathrm{d}y)=v\frac{L^d}{h_L},\quad v=\frac{u_1+u_2}{2}. \tag{D17}$$

By using (B18), this condition can be written

$$\frac{1}{h_L}\sum_{\mathbf{n}\neq 0}\frac{(e^{-t/h_L}-1)e^{a\mathbf{n}^2/L^2}}{(e^{a\mathbf{n}^2/L^2}-e^{-t/h_L})(e^{a\mathbf{n}^2/L^2}-1)}=v\frac{L^d}{h_L},\quad a=2\pi^2\beta. \tag{D18}$$

By proceeding as in the proof of Theorem B.2, it is easy to see that the sum in the lhs is bounded by $C|t|$, if we extract from it the terms with $|\mathbf{n}|=1$; hence we get

$$c_L-d\frac{t}{h_L^2}\frac{1}{a/L^2+t/h_L}\frac{L^2}{a}(1+\delta_{1,L})=v\frac{L^d}{h_L} \tag{D19}$$

with $\delta_{1,L}\to 0$ and $c_L\to c$ as $L\to\infty$. It follows that

$$t\frac{L^d}{h_L}=-aL^{d-2}(1+\delta_{2,L}) \tag{D20}$$

with $\delta_{2,L}\to 0$ as $L\to\infty$. It is easy to see that, for such a value of t, $\Pi_L(t)$ diverges as $C\log L$ for $d=3,4$ and as L^{d-4} for $d\geqslant 5$, so that we can write

$$S_L^+(u_1,u_2)=e^{-av L^{d-2}(1+\delta_L)}\int_{u_1L^d/h_L}^{u_2L^d/h_L} e^{t(y-vL^d/h_L)}P_{t,L}(\mathrm{d}y) \tag{D21}$$

with $\delta_L\to 0$ as $L\to\infty$. The upper bound in (D13) easily follows from this equation. In order to prove the lower bound we have also to show that

$$\int_{u_1L^d/h_L}^{u_2L^d/h_L} P_{t,L}(\mathrm{d}y)\geqslant 1-\delta_L \tag{D22}$$

with $\delta_L\to 0$. This result can be deduced as the other ones from the properties of the Laplace transform of the measure $P_{t,L}(\mathrm{d}y)$; we omit the details.

Let us now consider the upper bound of (D14). We proceed as before, by writing

$$S_L^-(u_1,u_2)=e^{\Pi_L(t)-t\Pi_L'(t)}\int_{-u_2L^d/h_L}^{-u_1L^d/h_L} e^{t(y+u_1L^d/h_L)}P_{t,L}(\mathrm{d}y)\leqslant e^{\Pi_L(t)-t\Pi_L'(t)}, \tag{D23}$$

where t is chosen so that $\Pi_L'(t)=u_1L^d/h_L$. It is easy to see that $\Pi_L'(t)$ is a monotone function and that $\lim_{t\to\infty}\Pi_L'(t)=\lambda_L^*L^d/h_L$, so that t is well defined for L large enough, if $u_1<\lambda^*$. It turns out that $\lim_{L\to\infty}t(h_L/L^d)=f_0(u)>0$, with $f_0(u)$ of order u for $u\to 0$ (and equal to c_du for $d=3,4$, for some $c_d>0$). Moreover

$$\Pi_L(t) - t\Pi'_L(t) = -\int_0^t ds \int_0^s du\, \Pi''_L(u), \quad C/2 < \Pi''_L(u) \leq C \tag{D24}$$

and one can prove that $\lim_{L\to\infty} \Pi''_l(u) = C_d > 0$, uniformly for $0 \leq u \leq t$; this allows us to get the upper bound in (D14). The lower bound is obtained in a similar way, by choosing t so that $\Pi'_L(t) = u_2 L^d/h_L$ and by proving that $\int_{-u_2 L^d/h_L}^{-u_1 L^d/h_L} P_{t,L}(dy) \to 1/2$ for $L \to \infty$. ■

We can now prove the following bounds on the factors $\alpha_{j,L}$.

Lemma D.3: Given $d \geq 3$, $\lambda > \lambda^*$ and a sequence j_L such that

$$\lim_{L\to\infty} j_L/L^d = \gamma < (\lambda - \lambda^*) \tag{D25}$$

there exists $\bar{L}$ such that, if $L \geq \bar{L}$ and $j \leq j_L$,

$$1 - \alpha_{j,L} \leq Ce^{-a_3(\lambda-\lambda^*-\gamma)L^{d-2}}, \tag{D26}$$

where C and a_3 are constants independent of L and of j.

Moreover, if $\lambda \geq \lambda^*$ and $\gamma > \lambda - \lambda^*$, there exist C, a_4 and $\bar{L}$ such that, if $L \geq \bar{L}$ and $j \geq j_L$,

$$\alpha_{j,L} \leq Ce^{-a_4[\gamma - [\lambda-\lambda^*)]\, L^{d-1}}. \tag{D27}$$

Proof. Note that

$$P_L(N - j < M \leq N) \leq P_L\left(y_L \geq \frac{(\lambda - \lambda^*)L^d + c_L L^2 + x_N L^{d/2} - j}{h_L}\right). \tag{D28}$$

Hence, if $j \leq j_L$, with $j_L/L^d \to \gamma$ as $L \to \infty$, and $|x_N| \leq L^{(d-1)/2}$, so that $|x_N| L^{d/2}/h_L \leq L^{-1/2} L^d/h_L$,

$$P_L(N - j < M \leq N) \leq P_L\left(y_L \geq \frac{(\lambda - \lambda^* - \gamma - \delta_L)L^d}{h_L}\right) \tag{D29}$$

with $\delta_L \to 0$ as $L \to \infty$. On the other hand,

$$\frac{1}{L^{d/2}} \sum_{N=0}^{\infty} e^{-(\beta/2)x_N^2} \mathbf{1}_{|x_N| \geq L^{(d-1)/2}} \leq Ce^{-(\beta/4)L^{d-1}}. \tag{D30}$$

The bound (D26) then easily follows from (D8) and Lemma D.2 since the upper bound in (D13) is independent of the u_2 value (equal to $+\infty$ in this case).

The bound (D27) is proved in a similar way, by using the upper bound in (D14) and the remark that $L^{d-1} \leq (L^d/h_L)^2$. ■

We have now all the technical ingredients to study the Laplace transform $F_{A,L}(\sigma)$ of the probability distribution of the random variables $y_{A,L}$ defined in (D1). We have

$$F_{A,L}(\sigma) = \frac{e^{\sigma(L^d \rho_{A,L}/h_{A,L})}}{\Gamma_{\lambda,L}} \frac{1}{L^{d/2}} \sum_{N \geq 0} e^{-\beta x_N^2/2} \frac{1}{Q_L} \sum_{\{n_j \geq 0, j \geq 1\}} \mathbf{1}_{\Sigma j n_j = N} \cdot \prod_{j \notin A} w(j, n_j) \prod_{j \in A} w(j, n_j) e^{-\sigma(j n_j/h_{A,L})}. \tag{D31}$$

By using (2.14) and the identity

$$w(j,n)e^{-\sigma(j n_j/h_{A,L})} = \sum_{\{n', n'' \geq 0\}} \mathbf{1}_{n'+n''=n} \frac{1}{n'!} \left[\frac{L^d a(\beta j, L) e^{-\sigma(j/h_{A,L})} - 1}{j}\right]^{n'} \frac{1}{n''!} \left(\frac{1}{j}\right)^{n''} \tag{D32}$$

we see that

$$F_{A,L}(\sigma) = G_{A,L}(\sigma)\frac{1}{\Gamma_{\lambda,L}}\frac{1}{L^{d/2}}\sum_{N\geqslant 0} e^{-\beta x_N^2/2} P_{A,L,\sigma}(M \leqslant N), \tag{D33}$$

where

$$P_{A,L,\sigma}(M) = Q_{A,L,\sigma}^{-1} \sum_{\{n_j\geqslant 0, j\geqslant 1\}} \mathbf{1}_{\Sigma j n_j = M} \prod_{j\notin A} \tilde{w}(j,n_j) \prod_{j\in A} \tilde{w}(j,n_j,\sigma), \tag{D34}$$

$$Q_{A,L,\sigma} = \sum_{\{n_j\geqslant 0, j\geqslant 1\}} \prod_{j\notin A} \tilde{w}(j,n_j) \prod_{j\in A} \tilde{w}(j,n_j,\sigma), \tag{D35}$$

$$\tilde{w}(j,n,\sigma) = \frac{1}{n!}\left[\frac{L^d a(\beta j,L) e^{-\sigma(j/h_{A,L})} - 1}{j}\right]^n, \tag{D36}$$

$$G_{A,L}(\sigma) = e^{\sigma(L^d \rho_{A,L}/h_{A,L})}\frac{Q_{A,L,\sigma}}{Q_L}. \tag{D37}$$

Note that $P_{A,L,\sigma}(M)$ in general is not a probability distribution for any value of σ (this is clear only for σ real and negative). Moreover, in all the choices of the set A we shall consider, $P_{A,L,\sigma}(M)$ is absolutely summable over M and its sum is equal to 1 (which is formally true by definition). Hence, we can consider it as a finite complex measure on $\mathbb{R}$ (with support on a lattice set) and we shall study its convergence, as $L\to\infty$, to a measure with smooth density.

A few simple calculations show that

$$\log Q_{A,L,\sigma} = \sum_{j\in A} \frac{L^d a(\beta j,L) e^{-\sigma(j/h_{A,L})} - 1}{j} + \sum_{j\notin A} \frac{L^d a(\beta j,L) - 1}{j}, \tag{D38}$$

so that

$$\begin{aligned}\log G_{A,L}(\sigma) &= \sigma\frac{L^d \rho_{A,L}}{h_{A,L}} + \sum_{j\in A} \frac{L^d a(\beta j,L)}{j}(e^{-\sigma(j/h_{A,L})} - 1) \\ &= \sigma r_{A,L}^* + \sum_{j\in A} \frac{L^d a(\beta j,L)}{j}\left(e^{-\sigma(j/h_{A,L})} - 1 + \sigma\frac{j}{h_{A,L}}\right),\end{aligned} \tag{D39}$$

where

$$r_{A,L}^* = \frac{L^d}{h_{A,L}}\sum_{j\in A} a(\beta j,L)(\alpha_{j,L} - 1). \tag{D40}$$

It will also useful to consider the random variable

$$y_{A,L,\sigma} = \frac{M - M_{A,L,\sigma}^*}{h_L}, \tag{D41}$$

where M is a random variable with measure $P_{A,L,\sigma}(M)$ and h_L is defined as in (B12).

The mean value of M is given by

$$M_{A,L,\sigma}^* \equiv \sum_{M=0}^{\infty} M P_{A,L,\sigma}(M) = \sum_{j\in A} (L^d a(\beta j,L) e^{-\sigma(j/h_{A,L})} - 1) + \sum_{j\notin A} (L^d a(\beta j,L) - 1). \tag{D42}$$

By using (B8) and (B4), we see that

$$M^*_{A,L,\sigma} = L^d \lambda^*_L + L^d \sum_{j \in A} a(\beta j, L)(e^{-\sigma(j/h_{A,L})} - 1), \tag{D43}$$

so that

$$P_{A,L,\sigma}(M \leqslant N) = P_{A,L,\sigma}\left(y_{A,L,\sigma} \leqslant \frac{L^d(\lambda - \lambda^*) + L^{d/2} x_N + L^2 c_L}{h_L} + y^*_{A,L,\sigma} \right), \tag{D44}$$

$$y^*_{A,L,\sigma} = \frac{L^d}{h_L} \sum_{j \in A} a(\beta j, L)(1 - e^{-\sigma(j/h_{A,L})}). \tag{D45}$$

As in the proof of Theorem B.2, the limiting distribution of $y_{A,L,\sigma}$ will be obtained by studying the Laplace transform $H_{A,L,\sigma}(w)$ of its measure. We have

$$\log H_{A,L,\sigma}(w) = \sum_{j=1}^{\infty} \frac{L^d a(\beta j, L) - 1}{j} \left(e^{-w(j/h_L)} - 1 + w \frac{j}{h_L} \right) + \log R_{A,L,\sigma}(w), \tag{D46}$$

$$\log R_{A,L,\sigma}(w) = \sum_{j \in A} \frac{L^d a(\beta j, L)}{j} (e^{-\sigma(j/h_{A,L})} - 1) \left(e^{-w(j/h_L)} - 1 + w \frac{j}{h_L} \right). \tag{D47}$$

If we define $f_{A,L,\sigma}(t) = H_{A,L,\sigma}(-it)$, we have also

$$h_L P_{A,L,\sigma}(M) = \frac{1}{2\pi} \int_{-\pi h_L}^{+\pi h_L} e^{-it y_{A,L,\sigma}} f_{A,L,\sigma}(t). \tag{D48}$$

Moreover, if $\sigma = 0$, the function $H_{A,L,\sigma}(w)$ has to coincide [as one could check by using the identity (A4) and some easy algebra] with the function $F_L(w)$ defined in (B18). It follows that

$$\log H_{A,L,\sigma}(w) = \log F_L(w) + \log R_{A,L,\sigma}(w),$$

$$f_{A,L,\sigma}(t) = f_L(t) R_{A,L,\sigma}(-it). \tag{D49}$$

We shall consider some special cases for the set A. First of all, we consider the simplest one, that is the case where A contains only one element; we prove the following theorem.

Theorem D.4: *If $A = \{j\}$ and $h_{A,L} = L^{d/2}$, then, if $d \geqslant 3$ and $\lambda \geqslant \lambda^*$,*

$$\rho_{\{j\},L} \xrightarrow[L \to \infty]{} \rho_j \equiv (2\pi\beta j)^{-d/2}. \tag{D50}$$

Moreover, if $d \geqslant 3$ and $\lambda > \lambda^*$ or $d = 3, 4$ and $\lambda = \lambda^*$, the probability distribution of $y_{A,L}$ converges, as $L \to \infty$, to a Gaussian distribution with variance $j\rho_j$. Finally, if $d \geqslant 5$ and $\lambda = \lambda^*$, the limiting distribution is still well defined, but its Laplace transform is given by

$$\lim_{L \to \infty} \log F_{\{j\},L}(\sigma) = -\sigma r^* j \rho_j + \frac{1}{2} \sigma^2 j \rho_j + \log \left\{ \frac{\displaystyle\int_{-\infty}^{+\infty} \mathrm{d}x\, e^{-\beta x^2/2} \int_{-\infty}^{x + \sigma j \rho_j} \mathrm{d}y\, \rho(y)}{\displaystyle\int_{-\infty}^{+\infty} \mathrm{d}x\, e^{-\beta x^2/2} \int_{-\infty}^{x} \mathrm{d}y\, \rho(y)} \right\}, \tag{D51}$$

where

$$r^* = \frac{\int_{-\infty}^{+\infty} \mathrm{d}x\, e^{-\beta x^2/2} \rho(x)}{\int_{-\infty}^{+\infty} \mathrm{d}x\, e^{-\beta x^2/2} \int_{-\infty}^{x} \mathrm{d}y\, \rho(y)}. \tag{D52}$$

Proof: By using the definition of $a(\beta j, L)$ in (2.2), we see that, for any j,

$$a(\beta j, L) \xrightarrow[L\to\infty]{} (2\pi\beta j)^{-d/2} = \rho_j. \tag{D53}$$

Moreover, by Lemma (D1) and (D2), $\forall \lambda \geqslant \lambda^*$,

$$\lim_{L\to\infty} \alpha_{j,L} = 1 \Rightarrow \lim_{L\to\infty} \rho_{j,L} = \rho_j. \tag{D54}$$

Let us now observe that, by (D47), for any fixed σ and w,

$$|\log R_{\{j\},L,\sigma}(w)| \leqslant C \frac{L^d}{L^{d/2} h_L^2} j^{2-d/2} \xrightarrow[L\to\infty]{} 0. \tag{D55}$$

Moreover, if we set $w = -it$, $t \in \mathbb{R}$, for any fixed σ, we have

$$|\log R_{\{j\},L,\sigma}(-it)| \leqslant C|t| \frac{L^d}{L^{d/2} h_L} j^{1-d/2} \leqslant C|t|. \tag{D56}$$

Hence we see, by using (D49) and the bound (B30), that $|f_{A,L,\sigma}(t)| \leqslant \exp(-C|t|^{3/2})$. It is easy to prove that this bound is valid also for $f''_{A,L,\sigma}(t)$, which implies that the measure $P_{\{j\},L,\sigma}(M)$ satisfies the analogous of (B15) and (B16) (we omit the details); and that $P_{\{j\},L,\sigma}(y \leqslant \overline{y})$ converges to $P(y \leqslant \overline{y})$ for any $\overline{y}$, if $P(\mathrm{d}y)$ is the limiting probability measure of Theorem B.2. On the other hand, we have, see (D45),

$$y^*_{\{j\},L,\sigma} \xrightarrow[L\to\infty]{} \begin{cases} 0, & d = 3,4, \\ \sigma j \rho_j, & d \geqslant 5. \end{cases} \tag{D57}$$

Note also that, by Lemmas D.1 and D.3, see (D40),

$$r^*_{\{j\},L} \xrightarrow[L\to\infty]{} \begin{cases} 0, & d = 3,4, \quad \lambda \geqslant \lambda^*, \\ 0, & d \geqslant 5, \quad \lambda > \lambda^*, \\ -r^* j \rho_j & d \geqslant 5, \quad \lambda = \lambda^*. \end{cases} \tag{D58}$$

If $d=3$ or $d=4$, it follows, by using (D33) and (D39), that, for any $\lambda \geqslant \lambda^*$,

$$\lim_{L\to\infty} \log F_{\{j\},L}(\sigma) = \lim_{L\to\infty} \log G_{\{j\},L}(\sigma) = \tfrac{1}{2}\sigma^2 j \rho_j. \tag{D59}$$

The same result is true, if $d \geqslant 5$ and $\lambda > \lambda^*$. However, if $d \geqslant 5$ and $\lambda = \lambda^*$, we get (D51).

The fact that the Laplace transform converges for any σ implies that also the characteristic function is convergent. As it is well known,[3] this is sufficient to prove the convergence of the probability distribution of $y_{A,L}$. ■

We now consider a more interesting choice of the set A.

Theorem D.5: *Let $A = \{1 \leqslant j \leqslant j_L\}$, with j_L a monotone diverging function of L such that $j_L \leqslant L^2$. Then, if $d \geqslant 3$ and $\lambda \geqslant \lambda^*$,*

$$\rho_{A,L} \xrightarrow[L\to\infty]{} \sum_{j=1}^{\infty} \rho_j = \lambda^*. \tag{D60}$$

Moreover, if $j_L/L^2 \to_{L\to\infty} 0$ *and* $\lambda > \lambda^*$, *the probability distribution of* $y_{A,L}$ *converges, as* $L \to \infty$, *to a Gaussian distribution, provided we take*

$$h_{A,L} = \begin{cases} L^2 (j_L/L^2)^{1/4}, & d = 3, \\ L^2 \sqrt{\log j_L}, & d = 4, \\ L^{d/2}, & d \geqslant 5. \end{cases} \tag{D61}$$

The same result is true, if $\lambda = \lambda^*$, *provided* $d = 3$ *or* $d = 4$ *and* $\lim_{L\to\infty} \sqrt{\log j_L / \log L} = 0$; *in the other cases the limiting distribution is still well defined but it is not Gaussian.*

Proof: By using (2.2), it is easy to prove that, if $j \leqslant L^2$, there is a constant C, independent of j and L, such that

$$a(\beta j, L) \leqslant C\rho_j, \quad 0 < a(\beta j, L) - \rho_j \leqslant C\rho_j e^{-L^2/(2\beta j)}. \tag{D62}$$

Hence, since $0 \leqslant \alpha_{j,L} \leqslant 1$,

$$0 \leqslant \sum_{j \leqslant j_L} (\rho_{j,L} - \rho_j \alpha_{j,L}) \leqslant C \sum_{j \leqslant L^2} j^{-d/2} e^{-L^2/(2\beta j)} \leqslant C L^{2-d} \xrightarrow[L\to\infty]{} 0. \tag{D63}$$

On the other hand, by (D6),

$$0 \leqslant \sum_{j \leqslant j_L} \rho_j (1 - \alpha_{j,L}) \leqslant \frac{C}{h_L} \sum_{j \leqslant L^2} j^{-d/2+1} \xrightarrow[L\to\infty]{} 0. \tag{D64}$$

Equation (D60) is an easy consequence of the last two bounds.

In order to study the limiting distribution of $y_{A,L}$, we proceed as in the proof of Theorem D.4. First of all we observe that, by (D47), if $h_{A,L}$ is chosen as in (D61), for any fixed σ and w,

$$|\log R_{A,L,\sigma}(w)| \leqslant C \frac{L^d}{h_{A,L} h_L^2} \sum_{j=1}^{j_L} j^{2-d/2} \xrightarrow[L\to\infty]{} 0. \tag{D65}$$

Moreover, if we set $w = -it$, $t \in \mathbb{R}$, for any fixed σ, we have

$$|\log R_{\{j\},L,\sigma}(-it)| \leqslant C|t| \frac{L^d}{h_{A,L} h_L} \sum_{j=1}^{j_L} j^{1-d/2} \leqslant C|t|. \tag{D66}$$

Once again, by proceeding as in the proof of Theorem D.4, one can prove that the measure $P_{A,L,\sigma}(M)$ satisfies the analogous of (B15) and (B16); we omit the details. This implies the convergence of $P_{A,L,\sigma}(y \leqslant \overline{y})$ to $P(y \leqslant \overline{y})$ for any $\overline{y}$, if $P(\mathrm{d}y)$ is the limiting probability measure of Theorem B.2. On the other hand, we have, see (D45),

$$y^*_{A,L,\sigma} \xrightarrow[L\to\infty]{} \begin{cases} 0, & d = 3, \\ \sigma (2\pi^2 \beta)^{-2} \lim_{L\to\infty} \sqrt{\log j_L / \log L}, & d = 4, \\ \sigma \sum_{j=1}^{\infty} j \rho_j, & d \geqslant 5. \end{cases} \tag{D67}$$

Let us now suppose that $\lambda > \lambda^*$. Then, by using (D26), we can easily show that, for any $d \geqslant 3$, $r^*_{A,L}$, [see (D40)] goes to 0 as $L \to \infty$. It is also very easy to show that the factor which multiplies $G_{A,L}(\sigma)$ on the rhs of (D33) goes to 1 as $L \to \infty$. Hence, by using (D39), we get

$$\lim_{L\to\infty} \log F_{A,L}(\sigma) = \lim_{L\to\infty} \log G_{A,L}(\sigma) = \lim_{L\to\infty} \sum_{j=1}^{j_L} \frac{L^d a(\beta j, L)}{j} \left(e^{-\sigma(j/h_{A,L})} - 1 + \sigma \frac{j}{h_{A,L}} \right). \tag{D68}$$

If we insert the value of $h_{A,L}$ given in (D61) on the rhs of this equation, we can see that only the terms of order σ^2 survive in the limit $L\to\infty$. Moreover, the fact that the Laplace transform converges for any σ implies that also the characteristic function is convergent. Therefore the limiting distribution of $y_{A,L}$ is well defined and is Gaussian; we can also easily calculate its variance.

If $\lambda = \lambda^*$, we get a different result for $d \geqslant 4$, because we can see, by using Lemma D.1, that

$$r^*_{A,L} \xrightarrow[L\to\infty]{} \begin{cases} 0, & d = 3, \\ -2\rho_0 (2\pi^2\beta)^{-2} \lim_{L\to\infty} \sqrt{\log j_L / \log L}, & d = 4, \\ -r^* \sum_{j=1}^{\infty} j\rho_j, & d \geqslant 5. \end{cases} \tag{D69}$$

Moreover, the factor which multiplies $G_{A,L}(\sigma)$ on the rhs of (D33) is still convergent, but it goes to 1 as $L\to\infty$ only for $d=3$ and for $d=4$, if $\lim_{L\to\infty} \sqrt{\log j_L / \log L} = 0$. It follows that the limiting distribution of $y_{A,L}$ is still well defined and its Laplace transform can be explicitly calculated; however, it is Gaussian only for $d=3$ and for $d=4$, if $\lim_{L\to\infty} \sqrt{\log j_L / \log L} = 0$. ■

APPENDIX E: LARGE DEVIATIONS FOR "SHORT LOOPS"

In this appendix we consider $d \geqslant 3$ and $\lambda > \lambda^*$; our main result is stated in Theorem E.3.

Given any finite subset A of $\mathbb{N}^+$, we define

$$S_{A,L}(v,\delta) \equiv P^{mf}_{\lambda,L} \left[L^d(\rho_{A,L} + v - \delta) \leqslant \sum_{j\in A} j n_j \leqslant L^d(\rho_{A,L} + v + \delta) \right] \tag{E1}$$

with $\rho_{A,L}$ defined as in (D1). We want to show that, if $A=\{j\}$ or $A=\{j \leqslant j_L\}$, with j_L a monotone diverging function of L, such that $j_L \leqslant L^2$, we can evaluate the behavior for $L\to\infty$ on the rhs of (E1) by substituting the measure $P^{mf}_{\lambda,L}$ with the measure, independent of λ (recall that $\lambda > \lambda^*$ in this section)

$$P_{A,L}(n_j, j \in A) = Z^{-1}_{A,L} \prod_{j\in A} w(j, n_j). \tag{E2}$$

We shall consider in detail only the case $A=\{j \leqslant j_L\}$; the other case can be treated in a similar (simpler) way.

Let us define $\Pi_{A,L}(t) = \log F_{A,L}(t h_{A,L})$ and

$$\tilde{\Pi}_{A,L}(t) = \log G_{A,L}(t h_{A,L}) - t h_{A,L} r^*_{A,L} = \sum_{j\in A} \frac{L^d a(\beta j, L)}{j} (e^{-tj} - 1 + tj), \tag{E3}$$

where $F_{A,L}(\sigma)$ and $G_{A,L}(\sigma)$ are defined as in (D33) and $r^*_{A,L}$ is defined as in (D40). Choose $t \equiv t_L(v)$ so that

$$-\tilde{\Pi}'_{A,L}(t) = v L^d. \tag{E4}$$

Lemma E.1: Let $A=\{1 \leqslant j \leqslant j_L\}$, with j_L a monotone diverging function of L such that $j_L \leqslant L^2$. Then the equation (E4) *has a solution for any $v > -\lambda^*$. Moreover, if $0 > v > -\lambda^*$, $t_L(v)$ has a finite positive limit $t(v)$ for $L\to\infty$, such that, for $v\to 0$ and suitable constants c_d,*

$$t(v) \sim \begin{cases} c_3 v^2, & d = 3, \\ c_4 v / \log(1/v), & d = 4, \\ c_d v, & d \geqslant 5, \end{cases} \tag{E5}$$

while, if $v>0$, $t_L(v)<0$ *and*

$$\lim_{L\to\infty}\frac{j_L|t_L(v)|}{\log(vj_L^{d/2-1})}=1. \tag{E6}$$

Proof: By using (D39), we see that Eq. (E4) can be written as

$$H_L(t)\equiv\sum_{j=1}^{j_L}a(\beta j,L)(e^{-tj}-1)=v. \tag{E7}$$

Note that the sign of t is the opposite of the sign of v. Let us consider first the case $v<0$. In this case $t>0$ and $H_L(t)\to-\Sigma_{j\leqslant j_L}a(\beta j,L)$, as $t\to+\infty$; since $\lim_{L\to\infty}\Sigma_{j\leqslant j_L}a(\beta j,L)=\lambda^*$, Eq. (E7) has a unique solution $t_L(v)$ only if $v>-\lambda^*$. It is an easy exercise to show that $t_L(v)$ converges, as $L\to\infty$, to a limit $t(v)$, verifying (E5).

If $v>0$, there is a unique negative solution $t_L(v)$ of (E7) for any v, since $H_L(t)\to+\infty$ as $t\to-\infty$, and it is easy to see that $\lim_{L\to\infty}t_L(v)=0$. A more careful analysis shows that Eq. (E6) is verified. ■

Lemma E.2: Let $A=\{1\leqslant j\leqslant j_L\}$, *with* j_L *a monotone diverging function of* L *such that* $j_L\leqslant L^2$. *Then, if* t *is defined as in (E4), there exists* $\eta>0$ *such that, for* L *large enough,*

$$F_{A,L}(th_{A,L})=G_{A,L}(th_{A,L})[1+\delta_L(t)],\quad |\delta_L(t)|\leqslant e^{-L^\eta}, \tag{E8}$$

$$\Pi'_{A,L}(t)=\tilde{\Pi}'_{A,L}(t)+\delta_L(t),\quad |\delta_L(t)|\leqslant e^{-L^\eta}. \tag{E9}$$

Proof: By using (D33), we see that (E8) is satisfied, if we define

$$\delta_L(t)=\delta_{L,1}+\delta_{L,2}(t), \tag{E10}$$

$$\delta_{L,1}=\frac{1}{\Gamma_{\lambda,L}}\frac{1}{L^{d/2}}\sum_{N\geqslant 0}e^{-\beta x_N^2/2}-1, \tag{E11}$$

$$\delta_{L,2}(t)=-\frac{1}{\Gamma_{\lambda,L}}\frac{1}{L^{d/2}}\sum_{N\geqslant 0}e^{-\beta x_N^2/2}P_{A,L,t}(M>N), \tag{E12}$$

where $P_{A,L,t}(M)$ is the measure defined in (D34), with $\sigma=th_{A,L}$, t being the solution of (E7). By using (C3), we see that

$$\delta_{L,1}=\frac{1}{\Gamma_{\lambda,L}}\frac{1}{L^{d/2}}\sum_{N\geqslant 0}e^{-\beta x_N^2/2}P_L(M>N), \tag{E13}$$

where $P_L(M)$ is the probability measure defined in (B3). By using (C4) and the large deviation estimates of Lemma D.2, it is easy to prove that $|\delta_{L,1}|\leqslant\exp(-L^\eta)$, with $0<\eta<d-2$.

In order to prove a similar bound for $\delta_{L,2}(t)$, we need a large deviation estimate for the measure $P_{A,L,t}(M)$. Let us consider first the case $v>0$, that is $t<0$, when $P_{A,L,t}(M)$ is a probability measure. In this case, if $\lambda-\lambda^*-v>0$ and $|x_N|\leqslant L^{d/4}$, by using (D43) and (E7), we see that, for L large enough

$$\begin{aligned}P_{A,L,t}(M>N)&=P_{A,L,t}(M-M^*_{A,L,t}>L^d(\lambda-\lambda^*-v)+L^{d/2}x_N+L^2c_L+h_{A,L}r^*_{A,L})\\&\leqslant P_{A,L,t}(M-M^*_{A,L,t}>L^d\epsilon)\end{aligned} \tag{E14}$$

if $0<\epsilon<\lambda-\lambda^*-v$, so that, for L large enough,

$$|\delta_{L,2}(t)|\leqslant 2e^{-\beta L^{d/2}/2}+2P_{A,L,t}(M-M^*_{A,L,t}>L^d\epsilon). \tag{E15}$$

Let us consider the Laplace transform $H_{L,t}(w)$ of the random variable $y=M-M^*_{A,L,t}$; it is related to the analogous function $H_{A,L,\sigma}(w)$ defined in (D46) by the relation

$$H_{L,t}(w) = H_{A,L,th_{A,L}}(wh_L). \tag{E16}$$

By proceeding as in the proof of Lemma D.2, we can write

$$P_{A,L,t}(M - M^*_{A,L,t} > L^d\epsilon) = e^{\Pi_{L,t}(w)} \int_{\epsilon L^d}^{+\infty} e^{wy} P_{L,t,w}(\mathrm{d}y), \tag{E17}$$

where $\Pi_{L,t}(w)=\log H_{L,t}(w)$ and $P_{L,t,w}(\mathrm{d}y)=e^{-wy}P_{L,t}(\mathrm{d}y)/H_{L,t}(w)$. We now fix w so that $-\Pi'_{L,t}(w) = \epsilon L^d$; it is to see that this condition can be written as

$$\epsilon L^d = L^d \sum_{j=1}^{j_L} a(\beta j, L)(e^{-tj} - 1)(1 - e^{-wj}) + \sum_{j=1}^{\infty} (L^d a(\beta j, L) - 1)(1 - e^{-wj}). \tag{E18}$$

Since $t<0$, the solution of this equation must be negative and one can show that $\Pi_{L,t}(w)+w\epsilon L^d = \Pi_{L,t}(w)-w\Pi'_{L,t}(w)$ is negative and of order L^{d-2}. It follows that

$$P_{A,L,t}(M - M^*_{A,L,t} > L^d\epsilon) \leqslant e^{\Pi_{L,t}(w)-w\Pi'_{L,t}(w)} \leqslant e^{-cL^{d-2}} \tag{E19}$$

for some $c>0$.

The case $v<0$, that is $t>0$, is a bit more involved, since in this case $P_{A,L,t}(M)$ is not necessarily a probability measure. However, it is easy to prove, by using (D34), that

$$\sum_{M=0}^{\infty} |P_{A,L,t}(M)| \leqslant e^{2\,\log j_L} \tag{E20}$$

so that, instead of the bound (E15), we have

$$|\delta_{L,2}(t)| \leqslant 2e^{-\beta L^{d/2}/2+2\,\log j_l} + 2|P_{A,L,t}(M - M^*_{A,L,t} > L^d\epsilon)|. \tag{E21}$$

Moreover, since it is still true that $\Pi_{L,t}(w)-w\Pi'_{L,t}(w)$ is negative and of order L^{d-2}, instead of bound (E19), we get

$$|P_{A,L,t}(M - M^*_{A,L,t} > L^d\epsilon)| \leqslant e^{-cL^{d-2}} \sum_{M=0}^{\infty} |P_{L,t,w}(M)| \tag{E22}$$

which is a negligible difference, since $|w|L^2 \leqslant c$, so that, as one can easily check,

$$\sum_{M=0}^{\infty} |P_{L,t,w}(M)| \leqslant e^{2e^{cj_L/L^2}\,\log j_L}. \tag{E23}$$

We still must prove (E9). By setting $\sigma=th_{A,L}$ in (D33) and by doing the derivative with respect to t, we get

$$\frac{d}{\mathrm{d}t}F_{A,L}(th_{A,L}) = L^d\rho_{A,L}F_{A,L}(th_{A,L}) - G_{A,L}(th_{A,L})\sum_{j=1}^{j_L} L^d a(\beta j, L)e^{-tj}[1 + \delta_{L,2,k}(t) + \delta_{L,1}], \tag{E24}$$

where $\delta_{L,1}$ is defined as in (E11) and

$$\delta_{L,2,k}(t) = -\frac{1}{\Gamma_{\lambda,L}}\frac{1}{L^{d/2}}\sum_{N\geqslant 0} e^{-\beta x_N^2/2} P_{A,L,t}(M > N-k). \tag{E25}$$

Since $k \leqslant j_L \leqslant L^2$, we can find as before that $|\delta_{L,2,k}(t)| \leqslant e^{-L^\eta}$. On the other hand, $\Sigma_{j\leqslant j_L} L^d a(\beta j, L) e^{-tj}$ is always of order L^d. It follows that

$$\Pi'_{A,L}(t) = \frac{\frac{d}{dt}F_{A,L}(th_{A,L})}{F_{A,L}(th_{A,L})} = L^d\rho_{A,L} - \sum_{j=1}^{j_L} L^d a(\beta j, L) e^{-tj} + O(e^{-L^\eta}) = \tilde{\Pi}'_{A,L}(t) + O(e^{-L^\eta}). \tag{E26}$$

■

Theorem E.3: *If* $\mathcal{A}^{(4)}_{L,\delta}(v)$ *is defined as in* (5.7) *and* $0 < v < \lambda - \lambda^*$, *then*

$$v - \delta \leqslant -\lim_{L\to\infty}\frac{1}{L^d}\frac{j_L}{\log(v j_L^{d/2-1})}\log P^{mf}_{\lambda,L}(\mathcal{A}^{(4)}_{L,\delta}) \leqslant u + \delta \tag{E27}$$

while, if $-\lambda^* < v < 0$, *there are positive functions* $t_d(v)$ *and* $a_d(v)$, *depending on* d, *such that*

$$a_d(v) - t_d(v)\delta \leqslant -\lim_{L\to\infty}\frac{1}{L^d}\log P^{mf}_{\lambda,L}(\mathcal{A}^{(4)}_{L,\delta}) \leqslant a_d(v) + t_d(v)\delta. \tag{E28}$$

Moreover, the two bounds above do not change if we substitute $P^{mf}_{\lambda,L}(\mathcal{A}^{(4)}_{L,\delta})$ *with* $\tilde{\Pi}_{A,L}(t_L(v)) - t\tilde{\Pi}'_{A,L}(t_L(v))$, $t_L(v)$ *being the solution of (E4).*

Proof: By (E1) $P^{mf}_{\lambda,L}(\mathcal{A}^{(4)}_{L,\delta}) = S_{A,L}(v,\delta)$. By proceeding as in the proof of Lemma D.2, we can write

$$S_{A,L}(v,\delta) = e^{\Pi_{A,L}(t) - t\Pi'_{A,L}(t)} \int_{(v-\delta)L^d}^{(v+\delta)L^d} e^{t(y - vL^d)} P_{A,L,t}(\mathrm{d}y), \tag{E29}$$

where t is chosen so that $vL^d = -\Pi'_{A,L}(t)$. By using Lemma E.2, we see that $\Pi_{A,L}(t)$ and its derivative can be substituted with $\tilde{\Pi}_{A,L}(t)$ and $\tilde{\Pi}'_{A,L}(t)$, and that t can be taken as the solution of (E4), without changing the asymptotic behavior of $S_{A,L}(v,\delta)$.

Let us consider first the case $0 < v < \lambda - \lambda^*$. It is easy to check that, in this case, $\tilde{\Pi}_{A,L}(t)$ is negligible, for $L \to \infty$, with respect to $|t| v L^d$, so that we get immediately, by using also (E6), the lower bound in (E27). In order to prove the upper bound, we need also a lower bound on $\int_{(v-\delta)L^d}^{(v+\delta)L^d} P_{A,L,t}(\mathrm{d}y)$, which can be obtained by studying the Laplace transform of $P_{A,L,t}(\mathrm{d}y)$; this analysis shows that $\int_{(v-\delta)L^d}^{(v+\delta)L^d} P_{A,L,t}(\mathrm{d}y) \to 1$ as $L \to \infty$.

If $-\lambda^* < v < 0$, as shown in Lemma E.1, the solution of (E4) converges, as $L \to \infty$, to the function $t(v)$ defined in (E5). Moreover, it is easy to check that, up to negligible corrections, for any fixed t,

$$\lim_{L\to\infty} L^{-d}[\Pi_{A,L}(t) - t\Pi'_{A,L}(t)] = -a_d(v), \tag{E30}$$

where $a_d(v)$ is a positive function equal to

$$a_d(v) = \sum_{j=1}^{\infty} \frac{1}{(2\pi\beta j)^{d/2}}\left(\frac{1-e^{-tj}}{j} - te^{-tj}\right). \tag{E31}$$

Since it is still true that $\int_{(v-\delta)L^d}^{(v+\delta)L^d} P_{A,L,t}(\mathrm{d}y) \to 1$ as $L \to \infty$, we get the bound (E28). ■

APPENDIX F: PROOF OF THEOREM 4.1

By (D2),

$$E^{mf}_{\lambda,L}(y_{\delta,L}) = \frac{1}{L^d} \sum_{j \geqslant \delta L^d} L^d a(\beta j, L) \alpha_{j,L},$$

$$E^{mf}_{\lambda,L}(X_{\delta,L}) = \sum_{j \geqslant \delta L^d} \frac{L^d a(\beta j, L)}{j} \alpha_{j,L}, \tag{F1}$$

$$E^{mf}_{\lambda,L}(X_L) = \sum_{j \geqslant L^2} \frac{L^d a(\beta j, L)}{j} \alpha_{j,L}.$$

On the other hand, by (2.3),

$$|L^d a(\beta j, L) - 1| \leqslant C \exp(-Cj/L^2), \quad \forall\, j \geqslant L^2 \tag{F2}$$

which allows us to prove very easily the limits in (4.5) and (4.7), by using Lemma D3.

The arguments given at the beginning of Appendix D can be used to prove also that

$$E^{mf}_{\lambda,L}(n_{j_1} n_{j_2}) = \frac{L^d a(\beta j_1, L)}{j_1} \frac{L^d a(\beta j_2, L)}{j_2} \alpha_{j_1+j_2,L} \quad \text{if } j_1 \neq j_2, \tag{F3}$$

$$E^{mf}_{\lambda,L}(n_j^2) = E^{mf}_{\lambda,L}(n_j(n_j-1)) + E^{mf}_{\lambda,L}(n_j) = \left(\frac{L^d a(\beta j, L)}{j} \right)^2 \alpha_{2j,L} + \frac{L^d a(\beta j, L)}{j} \alpha_{j,L}. \tag{F4}$$

It follows that

$$E^{mf}_{\lambda,L}(y^2_{\delta,L}) - E^{mf}_{\lambda,L}(y_{\delta,L})^2 = \sum_{j_1, j_2 \geqslant \delta L^d} a(\beta j_1, L) a(\beta j_2, L) (\alpha_{j_1+j_2,L} - \alpha_{j_1,L} \alpha_{j_2,L}) + \sum_{j \geqslant \delta L^d} j a(\beta j, L) \alpha_{j,L}. \tag{F5}$$

The limit (4.6) follows through some simple calculations from this identity, the bound (F2) and Lemma D.3. In a similar way, one can prove also (4.8)–(4.10).

We still must prove (4.11). The previous arguments imply that, if $\xi \in (1/2, 1]$ and $j > \xi(\lambda - \lambda^*)L^d$, then

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}(n_j = 1) = \lim_{L\to\infty} E^{mf}_{\lambda,L}(n_j) \tag{F6}$$

and

$$\lim_{L\to\infty} P^{mf}_{\lambda,L}(X_{\xi(\lambda-\lambda^*)} \geqslant 1) = \lim_{L\to\infty} \sum_{j > \xi(\lambda-\lambda^*)L^d} P^{mf}_{\lambda,L}(n_j = 1) = -\log \xi. \tag{F7}$$

APPENDIX G: THE LIMIT FUNCTIONAL

Theorem G.1: *There is a nondecreasing, negative, continuous function* $\lambda_0(\lambda)$ *on* $\mathbb{R}$, *strictly negative in* $d \leqslant 2$, *such that*

$$\pi(\lambda) := -\inf_{\varrho} F_\lambda(\varrho) = \frac{[\lambda - \lambda_0(\lambda)]^2}{2} + \pi^0_{\lambda_0(\lambda)}, \tag{G1}$$

$$\pi^0_{\lambda_0(\lambda)} = \beta^{-1} \sum_j \frac{\rho_j^*}{j} e^{\lambda_0(\lambda)\beta j}. \tag{G2}$$

Moreover, $\rho(\lambda) := \lambda - \lambda_0(\lambda)$*, is a positive, strictly increasing, continuous function of* λ *with range the whole* $(0,\infty)$ *and*

$$\inf_{\varrho} F_\lambda(\varrho) = \inf_{\varrho:\Sigma_j \rho_j = \rho(\lambda)} F_\lambda(\varrho). \tag{G3}$$

Remark 1: In Ref. 10 it is proved that the grand canonical mean field, thermodynamical pressure coincides with $\pi(\lambda)$, namely

$$\pi(\lambda) = \lim_{L\to\infty} \frac{1}{L^d} \Xi^{mf}_{\lambda,L} \tag{G4}$$

thus proving our claim in the text that the computation of the pressure using the limit functional gives the correct result.

Remark 2: The proof of Theorem G.1 identifies the function $\lambda_0(\lambda)$ as follows. There exists a dimension dependent constant λ^*, equal to $+\infty$ in $d \leqslant 2$ and $<\infty$ in $d \geqslant 3$ such that for $\lambda \leqslant \lambda^*$ (by which we will mean, here and in the sequel, *any* λ *in* $d \leqslant 2$ *and* $\lambda \leqslant \lambda^*$ *in* $d \geqslant 3$) there is a unique solution λ_0 of

$$\lambda - \lambda_0 = \sum_j \rho_j^* e^{\lambda_0 \beta j}. \tag{G5}$$

This solution, which depends on λ, coincides with the function $\lambda_0(\lambda)$ of Theorem G.1 for $\lambda \leqslant \lambda^*$, while the latter is identically 0 for $\lambda > \lambda^*$.

We will also prove that the inf in (G1) is a minimum when $\lambda \leqslant \lambda^*$, and, in such a case, the minimizer is unique and given by

$$\rho_j = \rho_j^* e^{\lambda_0 \beta j} \tag{G6}$$

in agreement with (G3), because $\Sigma_j \rho_j^* e^{\lambda_0 \beta j} = \rho(\lambda)$ by (G5).

The rhs of (G6) is the equilibrium density of j loops in the free, grand canonical ensemble with chemical potential λ_0, so that λ_0 has the meaning of an effective chemical potential.

If $d \geqslant 3$ and $\lambda > \lambda^*$, the inf in (G1) is not attained and there is a finite fraction of the density which "concentrates on infinitely long loops."

By (G3), $\rho(\lambda)$ can be interpreted as the equilibrium density when the chemical potential is λ; since the range of $\rho(\lambda)$ is the whole $(0,\infty)$, there is no "forbidden interval" for the equilibrium density, namely there is no first order phase transition in our system. This is due to the assumption that the interaction energy $u^2/2$, $u = \Sigma_j \rho_j$, is convex.

Proof of Theorem G.1: Call $m(\alpha) = \Sigma_j \rho_j^* e^{\beta \alpha j}$, $\alpha < 0$ in $d \leqslant 2$ and $\alpha \leqslant 0$ in $d \geqslant 3$. The graph of $m(\alpha)$ is as in Fig. 1, having set $\lambda^* = m(0)$ in $d \geqslant 3$. Existence and uniqueness of the solution λ_0 of (G5) for $\lambda \leqslant \lambda^*$ follow from monotonicity of $m(\cdot)$. Graphically λ_0 is the α-coordinate of the intersection point in Fig. 1.

Let us next prove (G1) and (G2) when $\lambda \leqslant \lambda^*$. With λ_0 as in (G5) we write

$$F_\lambda(\varrho) = \left[\frac{\rho^2}{2} - (\lambda - \lambda_0)\rho \right] + [-\lambda_0 \rho - \beta^{-1} S(\varrho)], \quad \rho = \sum_j \rho_j. \tag{G7}$$

Then

$$F_\lambda(\varrho) \geqslant \inf_{\varrho} \left\{ \frac{\rho^2}{2} - (\lambda - \lambda_0)\rho \right\} + \inf_{\varrho} \{-\lambda_0 \rho - \beta^{-1} S(\varrho)\}. \tag{G8}$$

We have

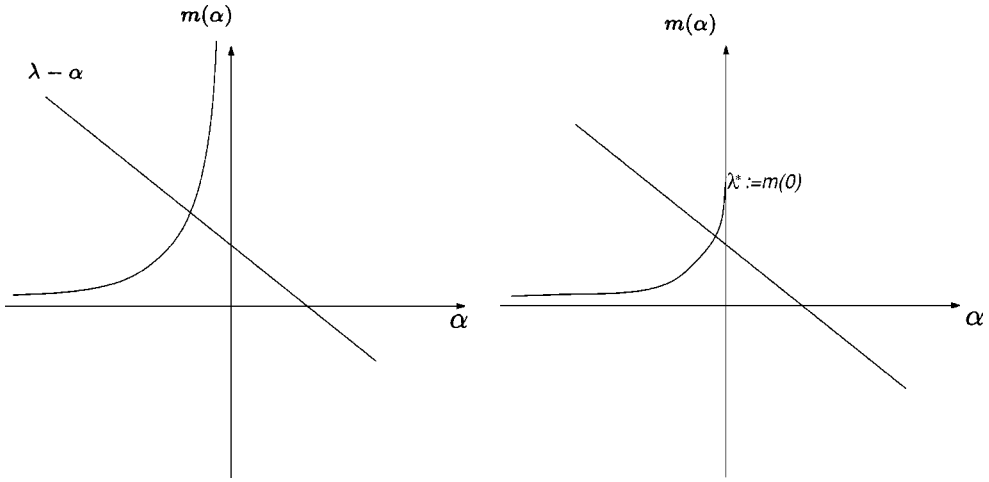

FIG. 1. The two graphs, on the left and right, refer, respectively, to $d \leqslant 2$ and $d \geqslant 3$.

$$\inf_{\varrho}\{-\lambda_0\rho - \beta^{-1}S(\varrho)\} = -\pi^0_{\lambda_0} \tag{G9}$$

with a unique minimizer given by (G6). On the other hand,

$$\inf_{\varrho}\left\{\frac{\rho^2}{2} - (\lambda - \lambda_0)\rho\right\} = -\frac{(\lambda - \lambda_0)^2}{2} \tag{G10}$$

with minimizer any ϱ such that $\Sigma_j \rho_j = \lambda - \lambda_0$. By (G5), the previous minimizer ϱ, given by (G6), satisfies such a condition, hence (G1) and (G3).

Suppose next that $d \geqslant 3$ and $\lambda > \lambda^*$. Then

$$F_\lambda(\varrho) \geqslant \inf_{\varrho}\left\{\frac{\rho^2}{2} - \lambda\rho\right\} + \inf_{\varrho}\{-\beta^{-1}S(\varrho)\} \geqslant -\frac{\lambda^2}{2} - \pi^0_0, \tag{G11}$$

where the minimizers of the first inf are those ϱ such that $\Sigma_j \rho_j = \lambda$, while the minimizer of the second inf is unique and given by $\{\rho^*_j\}$. We thus need to show that there is a sequence $\varrho^{(n)}$ such that $\Sigma_j \rho^{(n)}_j = \lambda$ and

$$\lim_{n\to\infty} S(\varrho^{(n)}) = S(\varrho^*). \tag{G12}$$

Let $a := \lambda - \rho^*$ be the excess mass, λ being the mass ρ which minimizes $\rho^2/2 - \lambda\rho$ and $\rho^* = \Sigma_j \rho^*_j$. Set

$$\varrho^{(n)}_j = \begin{cases} \rho^*_j & \text{if } j \neq n, \\ \rho^*_j + a & \text{if } j = n. \end{cases} \tag{G13}$$

Then

$$S(\varrho^{(n)}) = S(\varrho^*) + \left(\frac{\rho^*_n}{n} + \left(\frac{\rho^*_n}{n} + \frac{a}{n}\right)\left(\log\left(\frac{\rho^*_n + a}{\rho^*_n}\right) - 1\right)\right) \tag{G14}$$

with the last parentheses vanishing as $n \to \infty$.

Equations (G1)–(G3) are therefore proved. We will next show that $\rho(\lambda)$ is continuous, strictly increasing, and with range $(0, \infty)$. Let $\lambda < \lambda^*$ and λ_0' the derivative of λ_0 with respect to λ. Then

$$\frac{d\rho(\lambda)}{d\lambda} = 1 - \lambda_0' \tag{G15}$$

and, by differentiating (G5),

$$\lambda_0'\left(\beta\sum_j j\rho_j^* e^{\lambda_0\beta j} + 1\right) = 1. \tag{G16}$$

Hence $\lambda_0(\cdot)$ is a nondecreasing function, as claimed in Theorem G.1; moreover, since $\lambda_0' < 1$, $d\rho(\lambda)/d\lambda > 0$, for $\lambda < \lambda^*$. For $\lambda > \lambda^*$, $\rho(\lambda) = \lambda$ and since $\lim_{\lambda \nearrow \lambda^*} \rho(\lambda) = \lambda^*$, because $\lambda^* = m(0)$ and

$$\lim_{\alpha \nearrow 0} \sum_j \rho_j^* e^{\alpha\beta j} = \sum_j \rho_j^* = m(0), \quad d \geqslant 3 \tag{G17}$$

we conclude that $\rho(\lambda)$ is continuous and strictly increasing.

Obviously, $\lim_{\lambda\to\infty} \rho(\lambda) = \lim_{\lambda\to\infty} \lambda = \infty$. It remains to prove that $\lim_{\lambda\to-\infty} \rho(\lambda) = 0$. By monotonicity, the limit exists. Since $\rho(\cdot) > 0$, $\lambda - \lambda_0(\lambda) > 0$, so that $\lim_{\lambda\to-\infty} \lambda_0(\lambda) = -\infty$. Then

$$\lim_{\lambda\to-\infty} \sum_j \rho_j^* e^{\lambda_0(\lambda)\beta j} = \lim_{\alpha\to-\infty} \sum_j \rho_j^* e^{\alpha\beta j} = 0. \tag{G18}$$

Theorem G.1 is proved. ■

Remark: The construction of the minimizing sequence $\underline{\rho}^{(n)}$ in the case $\lambda > \lambda^*$ shows that the excess mass $\lambda - \lambda^*$ concentrates in the limit on infinitely long loops.

Let

$$a(u) := \inf_{\Sigma_j \rho_j = u} (F_\lambda(\underline{\rho}) + \lambda u) \tag{G19}$$

observing that the rhs does not depend on λ. Obviously

$$a(u) \geqslant \sup_\lambda \{\lambda u + \inf_{\underline{\rho}} F_\lambda(\underline{\rho})\}. \tag{G20}$$

We will prove that equality actually holds, namely

$$a(u) = \sup_\lambda \{\lambda u + \inf_{\underline{\rho}} F_\lambda(\underline{\rho})\} \tag{G21}$$

which then shows that

$$a(u) = \sup_\lambda \{\lambda u - \pi(\lambda)\}, \tag{G22}$$

namely that $a(u)$ is the Legendre transform of $\pi(\lambda)$. In Ref. 10 an equivalence of ensembles theorem is proved, namely that

$$-\lim_{\substack{L\to\infty \\ N_L = [L^d u]}} \frac{1}{L^d} \ln Z^{mf}_{N_L, L} = \sup_\lambda \{\lambda u - \pi(\lambda)\} \tag{G23}$$

which, together with (G22) shows that

$$\inf_{\Sigma_j \rho_j = u} (F_\lambda(\underline{\rho}) + \lambda u) = -\lim_{\substack{L\to\infty \\ N_L = [L^d u]}} \frac{1}{L^d} \ln Z^{mf}_{N_L, L} \tag{G24}$$

as claimed in the text.

Proof of (G21): By (G3) the inf of $F_\lambda(\underline{\rho})$ is achieved on the set $\{\underline{\rho} : \Sigma_j \rho_j = \lambda - \lambda_0\}$. Call α the value of λ such that

$$\rho(\alpha) = \alpha - \lambda_0(\alpha) = u \tag{G25}$$

(existence and uniqueness follow from Theorem G.1). Then

$$\sup_{\lambda}\{\lambda u + \inf_{\varrho} F_\lambda(\varrho)\} \geqslant \{\alpha u + \inf_{\varrho} F_\alpha(\varrho)\} = \{\alpha u + \inf_{\varrho:\Sigma_j \rho_j = \rho(\alpha) = u} F_\alpha(\varrho)\} = a(u) \tag{G26}$$

which, together with (G20), proves (G21). ■

By general thermodynamic relations, and making explicit now the dependence on β, the entropy $\sigma(\beta,u)$ and the internal energy, $e(\beta,u)$, are

$$\sigma(\beta,u) = \beta^2 \frac{\partial a(\beta,u)}{\partial \beta}, \quad a(\beta,u) = e(\beta,u) - \frac{\sigma(\beta,u)}{\beta}. \tag{G27}$$

In our model $e(\beta,u) = (u^2/2) + k(\beta,u)$, with $k(\beta,u)$ the kinetic part of the internal energy. By direct inspection, $\sigma(\beta,u)$ and $k(\beta,u)$ as functions of the particles density u, become constant for $u \geqslant u^*$. This is the Bose condensation phenomenon, which is interpreted by saying that the fluid added when increasing the density past u^* does not carry entropy nor momentum.

APPENDIX H

Let $\boldsymbol{\lambda} := \{\lambda_j, j > 0\}$ be the sequence defined by

$$\lambda_j := \begin{cases} \lambda + \lambda', & j \in V_k, \\ \lambda & \text{otherwise}, \end{cases} \tag{H1}$$

and

$$F_{\boldsymbol{\lambda}}(\varrho) := \frac{1}{2}\left(\sum_{j>0} \rho_j\right)^2 - \left(\sum_{j>0} \lambda_j \rho_j\right) - \frac{1}{\beta} S(\varrho), \tag{H2}$$

$$\pi_{\boldsymbol{\lambda}} := -\inf_{\varrho} F_{\boldsymbol{\lambda}}(\varrho), \quad \rho^{(k)}(\lambda) := \sum_{j \in V_K} \rho_j(\lambda). \tag{H3}$$

Then

$$\begin{aligned} \inf_{\varrho:\Sigma_{j\in V_k}\rho_j = \rho^{(k)}(\lambda)+\upsilon} F_\lambda(\varrho) &= \inf_{\varrho:\Sigma_{j\in V_k}\rho_j = \rho^{(k)}(\lambda)+\upsilon} \left[F_\lambda(\varrho) - \lambda'\left(\sum_{j\in V_k}\rho_j - (\rho^{(k)}(\lambda)+\upsilon)\right)\right] \\ &= \inf_{\varrho:\Sigma_{j\in V_k}\rho_j = \rho^{(k)}(\lambda)+\upsilon} F_{\boldsymbol{\lambda}}(\varrho) + \lambda'(\rho^{(k)}(\lambda)+\upsilon) \geqslant -\pi_{\boldsymbol{\lambda}} + \lambda'(\rho^{(k)}(\lambda)+\upsilon). \end{aligned} \tag{H4}$$

The equality in line (H4) holds if λ' is chosen in such a way that the minimizer sequence $\varrho_n(\lambda,\lambda')$ satisfies the constraint $\Sigma_{j\in V_k}\rho_j = \rho^{(k)}(\lambda)+\upsilon$.

The case $V_k = N^+$ follows directly from the arguments used in Appendix G, by changing the chemical potential from $\lambda \to \lambda + \lambda'$, where λ' is

$$\lambda' = \rho(\lambda) + \upsilon - \lambda + \tilde{\lambda}_0 \tag{H5}$$

with $\tilde{\lambda}_0 \equiv \tilde{\lambda}_0(\lambda,\upsilon) = 0$ when $\rho(\lambda)+\upsilon \geqslant \lambda^*$, while otherwise is the unique solution of the equation

$$\sum_j e^{\rho_j^* \tilde{\lambda}_0 \beta j} = \rho(\lambda) + \upsilon. \tag{H6}$$

The minimizer sequence $\{\rho_j^{(n)}\}_{j\in\mathbb{N}^+}$ is then given by

$$\rho_j^{(n)} = \rho_j^* e^{\beta j \tilde{\lambda}_0} + \mathbf{1}_{\{j=n\}}[\lambda + \lambda' - \lambda^*]_+, \tag{H7}$$

where we have indicated by $[\cdot]_+$ the positive part. In particular, if $\lambda > \lambda^*$, $v > -(\lambda - \lambda^*)$, then $\lambda' = v$.

For $k=2,3,4$, we set $\tilde{\lambda}_0(\lambda, v)$ as the solution of the equation

$$\sum_{j \notin V_k} \rho_j^* e^{\tilde{\lambda}_0 \beta j} = \lambda - \tilde{\lambda}_0 - \rho^{(k)}(\lambda) - v \tag{H8}$$

when this solution exists, otherwise we take $\tilde{\lambda}_0 = 0$. Then λ' is given by the unique solution of the equation

$$\sum_{j \in V_k} \rho_j^* e^{(\tilde{\lambda}_0 + \lambda')\beta j} = \rho^{(k)}(\lambda) + v \tag{H9}$$

whose existence and uniqueness follows (for any given value of $\tilde{\lambda}_0$) by monotonicity arguments, since V_k is bounded for $k > 1$.

Then the minimizer sequence $\{\rho_j^{(n)}\}_{j \in \mathbb{N}^+}$, $n > \max V_k$, is given by

$$\rho_j^{(n)} = \rho_j^* e^{\beta j(\tilde{\lambda}_0 + \lambda')} \mathbf{1}_{j \in V_k} + (\rho_j^* e^{\beta j \tilde{\lambda}_0} + \mathbf{1}_{\{j=n\}}[\lambda - \lambda_{\notin}^* - \rho^{(k)}(\lambda) - v]_+) \mathbf{1}_{j \notin V_k}, \tag{H10}$$

where $\lambda_{\notin}^* := \Sigma_{j \notin V_k} \rho_j^*$. Notice that, when the positive part is null, $\{\rho_j^{(n)}\}$ does not depend on n and it is actually a minimum.

In the case $k \neq 1$, $\lambda > \lambda^*$ ($\Rightarrow \rho^k(\lambda) = \lambda_{\in}^*$) and $v < \lambda - \lambda^*$,

$$\pi_\lambda = \frac{\lambda^2}{2} + \frac{1}{\beta} \sum_{j \in V_K} \frac{\rho_j^*}{j} e^{\lambda' \beta j} + \frac{1}{\beta} \sum_{j \notin V_K} \frac{\rho_j^*}{j}, \tag{H11}$$

where λ' is the unique solution of $\Sigma_{j \in V_k} \rho_j^* (e^{\lambda' \beta j} - 1) = v$.

Collecting Eqs. (G1) and (H4), we get

$$\inf_{\varrho : \Sigma_{j \in V_k} \rho_j = \rho^{(k)}(\lambda) + v} F_\lambda(\varrho) - \inf_{\varrho} F_\lambda(\varrho) = -\pi_\lambda + \lambda'(\rho^{(k)}(\lambda) + v) + \pi(\lambda). \tag{H12}$$

To prove Theorem 5.2, one must show (see proof of Theorem E.3 for notation) that

$$\lim_{L \to \infty} \frac{\log S_{A,L}(v, \delta)}{[\Pi_{A,L}(t) - t\Pi'_{A,L}(t)]} = \lim_{L \to \infty} \left[\frac{\frac{1}{\beta L^d} \ln P^{mf}_{\lambda,L}(\mathcal{A}^{(k)}_{L,\delta})}{-\inf_{\varrho \in A_L^{(k)}} F_\lambda(\varrho) + \inf_{\varrho} F_\lambda(\varrho)} \right]. \tag{H13}$$

For example, if $\lambda > \lambda^*$, $v < \lambda - \lambda^*$ and $k \neq 1$, one has

$$\inf_{\varrho : \Sigma_{j \in V_k} \rho_j = \rho^{(k)}(\lambda) + v} F_\lambda(\varrho) - \inf_{\varrho} F_\lambda(\varrho) = -\frac{1}{\beta} \sum_{j \in V_k} \frac{\rho_j^*}{j} (e^{\lambda' \beta j} - 1) + \lambda'(\rho^{(k)}(\lambda) + v). \tag{H14}$$

Hence, by using (E3), (E4), (E8), and (E9), it is easy to check that the two limits are equal in the case $k=4$. The other cases can be treated in a similar way.

APPENDIX I

If $k=1$, by the analysis in Appendix H, substituting the value of λ' as a function of λ and $\tilde{\lambda}_0$ in (H4), we get

$$\inf_{\varrho:\Sigma_j \rho_j = \rho(\lambda)+v} F_\lambda(\varrho) = \frac{1}{2}(\rho+v)^2 - (\lambda - \tilde{\lambda}_0)(\rho(\lambda)+v) - \frac{1}{\beta}\sum_j \frac{\rho_j^*}{j} e^{\beta j \tilde{\lambda}_0}. \tag{I1}$$

If $\lambda \neq \lambda^*$, this expression is twice differentiable and we get

$$\left.\frac{d^2\mathfrak{I}(v)}{dv^2}\right|_{v=0} = 1 + \mathbf{1}_{\{\lambda<\lambda^*\}}\left[2\frac{d\tilde{\lambda}_0}{dv} + \frac{d^2\tilde{\lambda}_0}{dv^2}(\rho(\lambda)+v) - \frac{d^2\tilde{\lambda}_0}{dv^2}\sum_j \rho_j^* e^{\tilde{\lambda}_0 \beta j} - \left(\frac{d\tilde{\lambda}_0}{dv}\right)^2 \sum_j \rho_j^* \beta j e^{\tilde{\lambda}_0 \beta j}\right]_{v=0}. \tag{I2}$$

On the other hand, if $\lambda < \lambda^*$ and v is small enough, $\tilde{\lambda}_0$ satisfies the equation $\rho(\lambda)+v = \Sigma_j \rho_j^* e^{\tilde{\lambda}_0 \beta j}$, so that

$$\frac{d\tilde{\lambda}_0}{dv}\sum_j \rho_j^* \beta j e^{\tilde{\lambda}_0 \beta j} = 1 \tag{I3}$$

and we get

$$\left.\frac{d^2\mathfrak{I}(v)}{dv^2}\right|_{v=0} = 1 + \mathbf{1}_{\{\lambda<\lambda^*\}}\left[2\frac{d\tilde{\lambda}_0}{dv} + \left(\frac{d\tilde{\lambda}_0}{dv}\right)^2 \sum_j \rho_j^* \beta j e^{\tilde{\lambda}_0 \beta j}\right]_{v=0} = 1 + \mathbf{1}_{\{\lambda<\lambda^*\}} \frac{1}{\sum_j \rho_j^* \beta j e^{\lambda_0 \beta j}}, \tag{I4}$$

where we used also the fact that, if $v=0$, $\tilde{\lambda}_0 = \lambda_0$, λ_0 being defined as in (G5).

If $\lambda = \lambda^*$, the right and left limit of the derivative of $\tilde{\lambda}_0$ in $v=0$ do exist and are given by

$$\lim_{v\to 0^+} \frac{d\tilde{\lambda}_0(\lambda^*, v)}{dv} = 0,$$

$$\lim_{v\to 0^-} \frac{d\tilde{\lambda}_0(\lambda^*, v)}{dv} = \lim_{v\to 0^-}\left[\frac{1}{\sum_j \rho_j^* \beta j e^{\tilde{\lambda}_0(\lambda^*, v)\beta j}}\right] = \frac{1}{\sum_j \rho_j^* \beta j}, \tag{I5}$$

so that, if $d \leqslant 4$, the second derivative of $\mathfrak{I}(v)$ in $v=0$ does exist and is given by

$$\left.\frac{d^2\mathfrak{I}(v)}{dv^2}\right|_{v=0} = \left[1 + \frac{\mathbf{1}_{\{\lambda<\lambda^*\}}}{\beta \sum_j \rho_j^* j e^{\lambda_0(\lambda)\beta j}}\right]^{-1}. \tag{I6}$$

It follows that, if $d=3,4$, $d^2\mathfrak{I}(v)/dv^2$ is given by Eq. (I6) for any λ, while, if $d>4$, the same result is true, but only for $\lambda \neq \lambda^*$.

(Received 1 April 2004; accepted 28 September 2004; published online 4 February 2005)

Generalized quantum statistics such as para-Fermi statistics is characterized by certain triple relations which, in the case of para-Fermi statistics, are related to the orthogonal Lie algebra $B_n=\mathrm{so}(2n+1)$. In this paper, we give a quite general mathematical definition of "a generalized quantum statistics associated to a classical Lie algebra G." This definition is closely related to a certain $\mathbb{Z}$-grading of G. The generalized quantum statistics is then determined by a set of root vectors (the creation and annihilation operators of the statistics) and the set of algebraic relations for these operators. Then we give a complete classification of all generalized quantum statistics associated to the classical Lie algebras A_n, B_n, C_n, and D_n. In the classification, several new classes of generalized quantum statistics are described. © *2005 American Institute of Physics.* [DOI: 10.1063/1.1827324]

I. INTRODUCTION

In classical quantum statistics one works exclusively with Bose and Fermi statistics (bosons and fermions). A historically important extension or generalization of these quantum statistics has been known for 50 years, namely the para-Bose and para-Fermi statistics as developed by Green.[1] Instead of the classical bilinear commutators or anticommutators as for bosons and fermions, parastatistics is described by means of certain trilinear or triple relations. For example, for n pairs of para-Fermi creation and annihilation operators f_i^{ξ} ($\xi=\pm$ and $i=1,\ldots,n$), the defining relations are

$$[[f_j^{\xi},f_k^{\eta}],f_l^{\epsilon}]=\tfrac{1}{2}(\epsilon-\eta)^2\delta_{kl}f_j^{\xi}-\tfrac{1}{2}(\epsilon-\xi)^2\delta_{jl}f_k^{\eta},$$

$$\xi,\eta,\epsilon=\pm\,\text{or}\,\pm 1,\quad j,k,l=1,\ldots,n. \tag{1.1}$$

About 10 years after the introduction of para-Fermi relations by Green, it was proved that these relations are associated with the orthogonal Lie algebra $\mathrm{so}(2n+1)=B_n$.[2] More precisely, the Lie algebra generated by the $2n$ elements f_i^{ξ}, with $\xi=\pm$ and $i=1,\ldots,n$, subject to the relations (1.1), is $\mathrm{so}(2n+1)$ (as a Lie algebra defined by means of generators and relations). In fact, this can be considered as an alternative definition instead of the common definition by means of Chevalley generators and their known relations expressed by means of the Cartan matrix elements (inclusive the Serre relations). Moreover, there is a certain representation of $\mathrm{so}(2n+1)$, the so-called Fermi representation $\mathcal{F}$, that yields the classical Fermi relations. In other words, the representatives $\mathcal{F}(f_i^{\xi})$ satisfy the bilinear relations of classical Fermi statistics. Thus the usual Fermi statistics corresponds to a particular realization of para-Fermi statistics. For general para-Fermi statistics, a class of finite dimensional $\mathrm{so}(2n+1)$ representations (of Fock type) needs to be investigated.

[a]Permanent address: Institute for Nuclear Research and Nuclear Energy, Boul. Tsarigradsko Chaussee 72, 1784 Sofia, Bulgaria. Electronic mail: neli.stoilova@ugent.be
[b]Electronic mail: joris.vanderjeugt@ugent.be

Twenty years after the connection between para-Fermi statistics and the Lie algebra so$(2n+1)$, a new connection, between para-Bose statistics and the orthosymplectic Lie superalgebra osp$(1|2n)=B(0,n)$ (Ref. 3) was discovered.[4] The situation here is similar, the Lie superalgebra generated by $2n$ odd elements b_i^ξ, with $\xi=\pm$ and $i=1,\ldots,n$, subject to the triple relations of para-Bose statistics, is osp$(1|2n)$ (as a Lie superalgebra defined by means of generators and relations). Also there is a particular representation of osp$(1|2n)$, the so-called Bose representation $\mathcal{B}$, that yields the classical Bose relations, i.e., where the representatives $\mathcal{B}(b_i^\xi)$ satisfy the relations of classical Bose statistics. For more general para-Bose statistics, a class of infinite dimensional osp$(1|2n)$ representations needs to be investigated, and one of these representations corresponds with ordinary Bose statistics.

From these historical examples it is clear that parastatistics, as introduced by Green[1] and further developed by many other research teams (see Ref. 5 and the references therein), can be associated with representations of the Lie (super)algebras of class B [namely B_n and $B(0,n)$]. The question that arises is whether alternative interesting types of generalized quantum statistics can be found in the framework of other classes of simple Lie algebras or superalgebras. In this paper we shall classify all the classes of generalized quantum statistics for the classical Lie algebras A_n, B_n, C_n, and D_n, by means of their algebraic relations. In a forthcoming paper we hope to perform a similar classification for the classical Lie superalgebras.

We should mention that certain generalizations related to other Lie algebras have already been considered,[6–10] although a complete classification was never made. For example, for the Lie algebra sl$(n+1)=A_n$,[7] a set of creation and annihilation operators has been described, and it was shown that n pairs of operators a_i^ξ, with $\xi=\pm$ and $i=1,\ldots,n$, subject to the defining relations

$$[[a_i^+,a_j^-],a_k^+]=\delta_{jk}a_i^+ + \delta_{ij}a_k^+,$$

$$[[a_i^+,a_j^-],a_k^-]=-\delta_{ik}a_j^- - \delta_{ij}a_k^-, \tag{1.2}$$

$$[a_i^+,a_j^+]=[a_i^-,a_j^-]=0$$

$(i,j,k=1,\ldots,n)$, generate the special linear Lie algebra sl$(n+1)$ (as a Lie algebra defined by means of generators and relations). Just as in the case of para-Fermi relations, (1.2) has two interpretations. On the one hand, (1.2) describes the algebraic relations of a new kind of generalized statistics, in this case A-statistics or statistics related to the Lie algebra A_n. On the other hand, (1.2) yields a set of defining relations for the Lie algebra A_n in terms of generators and relations. Observe that certain microscopic and macroscopic properties of A-statistics have already been studied.[11,12]

The description (1.2) was given for the first time by Jacobson[13] in the context of "Lie triple systems." Therefore, this type of generators is often referred to as the "Jacobson generators" of sl$(n+1)$. In this context, we shall mainly use the terminology "creation and annihilation operators (CAOs) for sl$(n+1)$."

In the following section we shall give a mathematical definition of "generalized quantum statistics associated with a Lie algebra G" and the corresponding creation and annihilation operators. It will be clear that this notion is closely related to gradings of G, and to regular subalgebras of G. Following the definition, we go on to describe the actual classification method. In the remaining sections of this paper, the classification results are presented. The paper ends with some closing remarks and further outlook.

II. DEFINITION AND CLASSIFICATION METHOD

Let G be a (classical) Lie algebra. A generalized quantum statistics associated with G is determined by a set of N creation operators x_i^+ and N annihilation operators x_i^-. Inspired by the para-Fermi case and the example of A-statistics, these $2N$ operators should satisfy certain condi-

tions. First of all, these $2N$ operators should generate the Lie algebra G, subject to certain triple relations like (1.1) and (1.2). Let G_{+1} and G_{-1} be the subspaces of G spanned by these elements:

$$G_{+1} = \text{span}\{x_i^+;\ i = 1, \ldots, N\}, \quad G_{-1} = \text{span}\{x_i^-;\ i = 1, \ldots, N\}. \tag{2.1}$$

Then $[G_{+1}, G_{+1}]$ can be zero [in which case the creation operators mutually commute, as in (1.2)] or nonzero [as in (1.1)]. A similar statement holds for the annihilation operators and $[G_{-1}, G_{-1}]$. The fact that the defining relations should be triple relations, implies that it is natural to make the following requirements:

$$[[x_i^+, x_j^+], x_k^+] = 0,$$

$$[[x_i^+, x_j^+], x_k^-] = \text{a linear combination of } x_l^+,$$

$$[[x_i^+, x_j^-], x_k^+] = \text{a linear combination of } x_l^+,$$

$$[[x_i^+, x_j^-], x_k^-] = \text{a linear combination of } x_l^-,$$

$$[[x_i^-, x_j^-], x_k^+] = \text{a linear combination of } x_l^-,$$

$$[[x_i^-, x_j^-], x_k^-] = 0.$$

So let $G_{\pm 2} = [G_{\pm 1}, G_{\pm 1}]$ and $G_0 = [G_{+1}, G_{-1}]$, then we may require $G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ (direct sum as vector spaces) to be a $\mathbb{Z}$-grading of a subalgebra of G. Furthermore, since we want G to be generated by the $2N$ elements subject to the triple relations, one must have $G = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$.

There are two additional assumptions, again inspired by the known examples (1.1) and (1.2). One is related to the fact that creation and annihilation operators are usually considered to be each other's conjugate. So, let ω be the standard antilinear anti-involutive mapping of the Lie algebra G [characterized by $\omega(x) = x^\dagger$ in the standard defining representation of G, where $x^\dagger$ denotes the transpose complex conjugate of the matrix x in this representation] then we should have $\omega(x_i^+) = x_i^-$. And finally, we shall assume that the generating elements $x_i^\pm$ are certain root vectors of the Lie algebra G.

Definition 1: Let G be a classical Lie algebra, with antilinear anti-involutive mapping ω. A set of 2N root vectors $x_i^\pm$ $(i = 1, \ldots, N)$ *is called a set of creation and annihilation operators for G if,*

(i) $\omega(x_i^\pm) = x_i^\mp$,

(ii) $G = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$ *is a* $\mathbb{Z}$*-grading of G, with* $G_{\pm 1} = span\{x_i^\pm,\ i = 1 \ldots, N\}$ *and* $G_{j+k} = [G_j, G_k]$.

The algebraic relations $\mathcal{R}$ *satisfied by the operators* $x_i^\pm$ *are the relations of a generalized quantum statistics (GQS) associated with G.*

Observe that this is a mathematical generalization of quantum statistics, inspired by the examples mentioned. Whether all such GQS actually lead to physically acceptable quantum statistics remains to be seen; in this sense one should interpret our GQS as "candidates for generalizations of quantum statistics." So with this terminology, a GQS is characterized by a set $\{x_i^\pm\}$ of CAOs and the set of algebraic relations $\mathcal{R}$ they satisfy. A consequence of this definition is that G is generated by G_{-1} and G_{+1}, i.e., by the set of CAOs. Furthermore, since $G_{j+k} = [G_j, G_k]$, it follows that

$$G = \text{span}\{x_i^\xi, [x_i^\xi, x_j^\eta];\ i, j = 1, \ldots, N, \xi, \eta = \pm\}. \tag{2.2}$$

This implies that it is necessary and sufficient to give all relations of the following type:

(R1) The set of all linear relations between the elements $[x_i^\xi, x_j^\eta]$ $(\xi, \eta = \pm,\ i, j = 1, \ldots, N)$.

(R2) The set of all triple relations of the form $[[x_i^{\xi},x_j^{\eta}],x_k^{\zeta}]$=linear combination of x_l^{θ}.

So in general $\mathcal{R}$ consists of a set of quadratic relations (linear combinations of elements of the type $[x_i^{\xi},x_j^{\eta}]$) and a set of triple relations. This also implies that, as a Lie algebra defined by generators and relations, G is uniquely characterized by the set of generators $x_i^{\pm}$ subject to the relations $\mathcal{R}$.

Another consequence of this definition is that G_0 itself is a subalgebra of G spanned by root vectors of G, i.e., G_0 is a regular subalgebra of G. Even more, G_0 is a regular subalgebra containing the Cartan subalgebra H of G. And by the adjoint action, the remaining G_i's are G_0-modules. Thus the following technique can be used in order to obtain a complete classification of all GQS associated with G:

(1) Determine all regular subalgebras G_0 of G. If not yet contained in G_0, replace G_0 by G_0+H.
(2) For each regular subalgebra G_0, determine the decomposition of G into simple G_0-modules g_k $(k=1,2,\ldots)$.
(3) Investigate whether there exists a $\mathbb{Z}$-grading of G of the form

$$G=G_{-2}\oplus G_{-1}\oplus G_0\oplus G_{+1}\oplus G_{+2}, \tag{2.3}$$

where each G_i is either directly a module g_k or else a sum of such modules $g_1\oplus g_2\oplus\cdots$, such that $\omega(G_{+i})=G_{-i}$.

The first stage in this technique is a known one, to find regular subalgebras one can use the method of extended Dynkin diagrams.[14] The second stage is straightforward by means of Lie algebra representation techniques. The third stage requires most of the work, one must try out all possible combinations of the G_0-modules g_k, and see whether it is possible to obtain a grading of the type (2.3). In this process, if one of the simple G_0-modules g_k is such that $\omega(g_k)=g_k$, then it follows that this module should be part of G_0. In other words, such a case reduces essentially to another case with a larger regular subalgebra.

In general, when the rank of the semisimple regular subalgebra is equal or close to the rank of G, the corresponding $\mathbb{Z}$-grading of G is "short" in the sense that $G_i=0$ for $|i|>1$ or $|i|>2$. When the rank of the regular subalgebra becomes smaller, the corresponding $\mathbb{Z}$-grading of G is "long," and $G_i\neq 0$ for $|i|>2$. Thus the analysis shows that it is usually sufficient to consider maximal regular subalgebras (same rank), or almost maximal regular subalgebras (rank of G minus 1 or 2).

Note that in Ref. 10 a definition of CAOs was already given. Our Definition 1 is inspired by the definition in Ref. 10, however it is different in the sense that the grading conditions $G_{j+k}=[G_j,G_k]$ are new. It is thanks to these new conditions that we are able to give a complete classification of CAOs and the corresponding GQS.

In the following sections we shall give a summary of the classification process for the classical Lie algebras A_n, B_n, C_n, and D_n. Note that, in order to identify a GQS associated with G, it is sufficient to give only the set of CAOs, or alternatively, to give the subspace G_{-1} [then the x_i^- are the root vectors of G_{-1}, and $x_i^+=\omega(x_i^-)$]. The set $\mathcal{R}$ then consist of all quadratic relations (i.e., the linear relations between the elements $[x_i^{\xi},x_j^{\eta}]$) and all triple relations, and all of these relations follow from the known commutation relations in G. Because, in principle, $\mathcal{R}$ can be determined from the set $\{x_i^{\pm};i=1,\ldots,N\}$, we will not always give it explicitly. In fact, when N is large, the corresponding relations can become rather numerous and long. Such examples of GQS would be too complicated for applications in physics. For this reason, we shall give $\mathcal{R}$ explicitly only when N is not too large, more precisely when N is either equal to the rank of G or at most double the rank of G.

Finally, observe that two different sets of CAOs $\{x_i^{\pm};\ i=1,\ldots,N\}$ and $\{y_i^{\pm};\ i=1,\ldots,N\}$ (same N) are said to be isomorphic if, for a certain permutation τ of $\{1,2,\ldots,N\}$, the relations between the elements $x_{\tau(i)}^{\pm}$ and $y_i^{\pm}$ are the same. In that case, the regular subalgebra G_0 spanned by $\{[x_i^+,x_j^-]\}$ is isomorphic (as a Lie algebra) to the regular subalgebra spanned by $\{[y_i^+,y_j^-]\}$.

TABLE I. Classical Lie algebras, their (extended) Dynkin diagrams with a labeling of the nodes and the corresponding simple roots.

Lie algebra	Dynkin diagram	Extended Dynkin diagram
A_n $(n>0)$		B_n $(n>1)$		C_n $(n>2)$		D_n $(n>3)$		
III. THE LIE ALGEBRA $A_n = \mathrm{sl}(n+1)$

Let G be the special linear Lie algebra $\mathrm{sl}(n+1)$, consisting of traceless $(n+1)\times(n+1)$ matrices. The Cartan subalgebra H of G is the subspace of diagonal matrices. The root vectors of G are known to be the elements e_{jk} $(j\neq k=1,\ldots,n+1)$, where e_{jk} is a matrix with zeros everywhere except a 1 on the intersection of row j and column k. The corresponding root is $\epsilon_j-\epsilon_k$, in the usual basis. The anti-involution is such that $\omega(e_{jk})=e_{kj}$. The simple roots and the Dynkin diagram of A_n are given in Table I, and so is the extended Dynkin diagram.

In order to find regular subalgebras of $G=A_n$, one should delete nodes from the Dynkin diagram of G or from its extended Dynkin diagram. We shall start with the ordinary Dynkin diagram of A_n, and subsequently consider the extended diagram.

Step 1: Delete node i from the Dynkin diagram. The corresponding diagram is the Dynkin diagram of $\mathrm{sl}(i)\oplus\mathrm{sl}(n-i+1)$, so $G_0=H+\mathrm{sl}(i)\oplus\mathrm{sl}(n-i+1)$. In this case, there are only two G_0 modules and we can set

$$G_{-1}=\mathrm{span}\{e_{kl};\ k=1,\ldots,i,\ l=i+1,\ldots,n+1\},\quad G_{+1}=\omega(G_{-1}). \tag{3.1}$$

Therefore $\mathrm{sl}(n+1)$ has the following grading:

$$\mathrm{sl}(n+1)=G_{-1}\oplus G_0\oplus G_{+1}, \tag{3.2}$$

and the number of creation and annihilation operators is $N=i(n-i+1)$. Note that the cases i and $n+1-i$ are isomorphic.

The most interesting cases are those with $i=1$ and $i=2$, for which we shall explicitly give the relations $\mathcal{R}$ between the CAOs.

For $i=1$, $N=n$, the rank of A_n. Setting

$$a_j^- = e_{1,j+1}, \quad a_j^+ = e_{j+1,1}, \quad j = 1, \ldots, n \tag{3.3}$$

(for A_n, the possible sets $\{x_i^\pm\}$ will be denoted $\{a_i^\pm\}$, for B_n, they will be denoted $\{b_i^\pm\}$, etc.) the corresponding relations $\mathcal{R}$ read $(j,k,l=1,\ldots,n)$,

$$[a_j^+, a_k^+] = [a_j^-, a_k^-] = 0,$$

$$[[a_j^+, a_k^-], a_l^+] = \delta_{jk} a_l^+ + \delta_{kl} a_j^+, \tag{3.4}$$

$$[[a_j^+, a_k^-], a_l^-] = -\delta_{jk} a_l^- - \delta_{jl} a_k^-.$$

These are the relations of A-statistics[6,7,10–12] as considered in the Introduction.

For $i=2$, $N=2(n-1)$, let

$$a_{-j}^- = e_{1,j+2}, \quad a_{+j}^- = e_{2,j+2}, \quad j = 1, \ldots, n-1,$$

$$a_{-j}^+ = e_{j+2,1}, \quad a_{+j}^+ = e_{j+2,2}, \quad j = 1, \ldots, n-1. \tag{3.5}$$

Now the corresponding relations are $(\xi, \eta, \epsilon = \pm;\ j,k,l=1,\ldots,n-1)$

$$[a_{\xi j}^+, a_{\eta k}^+] = [a_{\xi j}^-, a_{\eta k}^-] = 0,$$

$$[a_{\xi j}^+, a_{-\xi k}^-] = 0, \quad j \neq k,$$

$$[a_{-j}^+, a_{-k}^-] = [a_{+j}^+, a_{+k}^-], \quad j \neq k,$$

$$[a_{+j}^+, a_{-j}^-] = [a_{+k}^+, a_{-k}^-], \tag{3.6}$$

$$[a_{-j}^+, a_{+j}^-] = [a_{-k}^+, a_{+k}^-],$$

$$[[a_{\xi j}^+, a_{\eta k}^-], a_{\epsilon l}^+] = \delta_{\eta\epsilon}\delta_{jk} a_{\xi l}^+ + \delta_{\xi\eta}\delta_{kl} a_{\epsilon j}^+,$$

$$[[a_{\xi j}^+, a_{\eta k}^-], a_{\epsilon l}^-] = -\delta_{\xi\epsilon}\delta_{jk} a_{\eta l}^- - \delta_{\xi\eta}\delta_{jl} a_{\epsilon k}^-.$$

These relations are already more complicated than (3.4). But they are still defining relations for the Lie algebra A_n.

Step 2: Delete node i and j from the Dynkin diagram. By the symmetry of the Dynkin diagram, it is sufficient to consider $1 \leqslant i \leqslant \lfloor n/2 \rfloor$ and $i < j < n+1-i$. We have $G_0 = H + \mathrm{sl}(i) \oplus \mathrm{sl}(j-i) \oplus \mathrm{sl}(n+1-j)$. In this case, there are six simple G_0-modules. All the possible combinations of these modules give rise to gradings of the form

$$\mathrm{sl}(n+1) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}.$$

There are essentially three different ways in which these G_0-modules can be combined. To characterize these three cases, it is sufficient to give only G_{-1},

$$G_{-1} = \mathrm{span}\{e_{kl}, e_{lp};\ k = 1, \ldots, i,\ l = i+1, \ldots, j,\ p = j+1, \ldots, n+1\},$$

$$\text{with } N = (j-i)(n+1-j+i); \tag{3.7}$$

$$G_{-1} = \mathrm{span}\{e_{kl}, e_{pk};\ k = 1, \ldots, i,\ l = i+1, \ldots, j,\ p = j+1, \ldots, n+1\}, \quad \text{with } N = i(n+1-i); \tag{3.8}$$

$$G_{-1} = \mathrm{span}\{e_{kl}, e_{lp};\ k = 1, \ldots, i,\ p = i+1, \ldots, j,\ l = j+1, \ldots, n+1\}, \quad \text{with } N = j(n+1-j). \tag{3.9}$$

It turns out that the sets of CAOs corresponding to (3.8) and (3.9) are isomorphic to (3.7), so it is sufficient to consider only (3.7). Each case of (3.7) with $1 \leqslant i \leqslant \lfloor n/2 \rfloor$ and $i < j < n+1-i$ gives rise to a distinct GQS. For reasons explained earlier, we shall give the corresponding set of relations explicitly only for small N. In this case, it is interesting to give $\mathcal{R}$ for $j-i=1$, because then the number of creation or annihilation operators is $N=n$. One can label the CAOs as follows:

$$\begin{aligned} a_k^- &= e_{k,i+1}, \quad a_k^+ = e_{i+1,k}, \quad k = 1, \ldots, i, \\ a_k^- &= e_{i+1,k+1}, \quad a_k^+ = e_{k+1,i+1}, \quad k = i+1, \ldots, n. \end{aligned} \tag{3.10}$$

Using

$$\langle k \rangle = \begin{cases} 0 & \text{if } k = 1, \ldots, i, \\ 1 & \text{if } k = i+1, \ldots, n \end{cases} \tag{3.11}$$

the quadratic and triple relations read

$$[a_k^+, a_l^+] = [a_k^-, a_l^-] = 0, \quad k,l = 1, \ldots, i \text{ or } k,l = i+1, \ldots, n,$$

$$[a_k^-, a_l^+] = [a_k^+, a_l^-] = 0, \quad k = 1, \ldots, i, \quad l = i+1, \ldots, n,$$

$$\begin{aligned} [[a_k^+, a_l^-], a_m^+] &= (-1)^{\langle l \rangle + \langle m \rangle} \delta_{kl} a_m^+ + (-1)^{\langle l \rangle + \langle m \rangle} \delta_{lm} a_k^+, \quad k,l = 1, \ldots, i \text{ or } k,l = i+1, \ldots, n, \\ [[a_k^+, a_l^-], a_m^-] &= -(-1)^{\langle l \rangle + \langle m \rangle} \delta_{kl} a_m^- - (-1)^{\langle l \rangle + \langle m \rangle} \delta_{km} a_l^-, \quad k,l = 1, \ldots, i \text{ or } k,l = i+1, \ldots, n, \end{aligned} \tag{3.12}$$

$$[[a_k^\xi, a_l^\xi], a_m^{-\xi}] = -\delta_{km} a_l^\xi + \delta_{lm} a_k^\xi, \ k = 1, \ldots, i, \ l = i+1, \ldots, n,$$

$$[[a_k^\xi, a_l^\xi], a_m^\xi] = 0 \quad (\xi = \pm;\ k,l,m = 1, \ldots, n).$$

The existence of the set of CAOs (3.10) is pointed out in Ref. 6 as a possible example. The relations (3.12) with $n=2m$ and $i=m$ are the commutation relations of the so-called causal A-statistics investigated in Ref. 9.

Step 3: If we delete three or more nodes from the Dynkin diagram, the resulting $\mathbb{Z}$-gradings of $\mathrm{sl}(n+1)$ are no longer of the form $\mathrm{sl}(n+1) = G_{-2} \oplus G_{-1} \oplus G_0 \oplus G_{+1} \oplus G_{+2}$, but there would be non-zero G_i with $|i| > 2$, so these cases are not relevant for our classification.

Step 4: Next, we move on to the extended Dynkin diagram of G. If we delete node i from the extended Dynkin diagram, then remaining diagram is again of type A_n, so $G_0 = G$, and there are no CAOs.

Step 5: If we delete node i and j from the extended Dynkin diagram ($0 \leqslant i < j \leqslant n+1$), then $\mathrm{sl}(n+1) = G_{-1} \oplus G_0 \oplus G_{+1}$ with $G_0 = H + \mathrm{sl}(j-i) \oplus \mathrm{sl}(n-j+i+1)$, and

$$G_{-1} = \mathrm{span}\{e_{kl};\ k = i+1 \ldots, j,\ l \neq i+1, \ldots, j\}.$$

The number of annihilation operators is $N = (j-i)(n+1-j+i)$. It is not difficult to see that all these cases are isomorphic to those of step 1. This can also be deduced from the symmetry of the Dynkin diagram.
