Proof: By the definition of $U_\varepsilon^{\mathrm{fin}}$, $(e_i,f_i,t_i^{\pm1})$ satisfies the relations in U_ε. Therefore, there exists the following surjective $\mathbb{C}$-algebra homomorphism π,

$$\pi:U_\varepsilon\to U_\varepsilon^{\mathrm{fin}}\quad(e_i,f_i,t_i^{\pm1})\mapsto(e_i,f_i,t_i^{\pm1}).$$

By Proposition 4.7, we obtain the surjective $\mathbb{C}$-algebra homomorphism π',

$$\pi':U_\varepsilon/\mathrm{J}\to U_\varepsilon^{\mathrm{fin}}\quad(e_i,f_i,t_i^{\pm1})\mapsto(e_i,f_i,t_i^{\pm1}).$$

On the other hand, by Proposition 2.7 and Theorem 2.8, U_ε/J is spanned by

$$\{e_{\beta_1}^{m_1}\cdots e_{\beta_N}^{m_N}f_{\beta_1}^{m_{N+1}}\cdots f_{\beta_N}^{m_{2N}}t_1^{m_{2N+1}}\cdots t_n^{m_{2N+n}}|0\leqslant m_i\leqslant l-1(1\leqslant i\leqslant 2N),0\leqslant m_i\leqslant 2l-1(2N+1\leqslant i\leqslant 2N+n)\}.$$

So, by Theorem 4.6, π' is an injective homomorphism. Therefore π' is an isomorphism of algebra. □

C. $U_\varepsilon^{\mathrm{fin}}$-module structure on the $U_\varepsilon u_0$

In this section, we construct $U_\varepsilon^{\mathrm{fin}}$-module by using the Schnizer modules.

Lemma 4.9: Let $\mathfrak{g}=sp(2n,\mathbb{C}),so(2n+1,\mathbb{C})$ *or* $so(2n,\mathbb{C})$. *For any* $\lambda=(\lambda_1,\cdots,\lambda_n)\in\mathbb{Z}^n$, *we denote the* U_ε*-submodule of* $V(\lambda)$ *generated by* u_0 *by* $U_\varepsilon u_0$. *Then we have*

(i) $e_\alpha^l=0$ *on* $U_\varepsilon u_0$ *for any* $\alpha\in\Delta_+$.
(ii) $t_i^l=1$ *on* $U_\varepsilon u_0$ *for any* $i\in I$.
(iii) $f_\alpha^l=0$ *on* $U_\varepsilon u_0$ *for any* $\alpha\in\Delta_+$.

Proof: We prove the case of $\mathfrak{g}=\mathsf{sp}(2n,\mathbb{C})$. The other cases are shown similarly.

By Proposition 2.7, it is enough to prove that $e_\alpha^l u_0=f_\alpha^l u_0=(t_i^l-1)u_0=0$.

(i) By Proposition 3.4, $e_i u_0=0$ for any $i\in I$. On the other hand, by Proposition 2.6, $e_\alpha\in U_\varepsilon^+\cap(U_\varepsilon)_\alpha$ for any $\alpha\in\Delta_+$. Therefore $e_\alpha u_0=e_\alpha^l u_0=0$.

(ii) By (3.4), (3.8), and (3.9)), $t_i u_0=\varepsilon_i^{\lambda_i}u_0$ in $V(\lambda)$. Since $\lambda_i\in\mathbb{Z}, t_i^l u_0=u_0$. We shall prove (iii) in the next section. □

We call the U_ε-modules such that $e_i^l=f_i^l=0$ "nilpotent module." By Lemma 4.9, $U_\varepsilon u_0$ is a nilpotent module. In general, Schnizer modules are not necessarily nilpotent unless we specialize their parameters properly.

Theorem 4.10: *Let* $\mathfrak{g}=sp(2n,\mathbb{C}),so(2n+1,\mathbb{C})$ *or* $so(2n,\mathbb{C})$, *and* $\lambda\in\mathbb{Z}_l^n$. *Then we have*

(i) $U_\varepsilon u_0$ *is a* $U_\varepsilon^{\mathrm{fin}}$*-module*.
(ii) $U_\varepsilon u_0$ *is isomorphic to* $L_\varepsilon^{fin}(\lambda)$ *as* $U_\varepsilon^{\mathrm{fin}}$*-module. That is,* $U_\varepsilon u_0$ *is a finite dimensional irreducible* $U_\varepsilon^{\mathrm{fin}}$*-module of type* 1 *with highest weight* λ.

Proof: We prove the case of $\mathfrak{g}=sp(2n,\mathbb{C})$. The other cases are shown similarly. By Lemma 4.8, 4.9, we obtain (i).

(ii) Finite dimensionality of $U_\varepsilon u_0$ is obvious. $U_\varepsilon u_0$ is type 1 with the highest weight λ by Lemma 4.9 (ii) and its proof. So we shall prove the irreducibility of $U_\varepsilon u_0$.

We can regard $U_\varepsilon^{\mathrm{fin}}$ as a well-defined Q-graded algebra by the following way (cf. Definition 2.5).

$$(U_\varepsilon^{\mathrm{fin}})_d:=\{u+\mathrm{J}|u\in(U_\varepsilon)_d\}(d\in Q),$$

where J is the two-sided ideal as in Lemma 4.8. Hence

$$e_{i_1}\cdots e_{i_r}\in(U_\varepsilon^{\mathrm{fin}})_{\alpha_{i_1}+\cdots+\alpha_{i_r}}\quad(i_1,\ldots,i_r\in I).$$

On the other hand, by Proposition 4.7, if $(U_\varepsilon^{\mathrm{fin}})_d\neq 0$ then

$$d\leqslant(l-1)\sum_{\beta\in\Delta_+}\beta$$

for any $d\in Q$, where $d\geqslant d'\Leftrightarrow d-d'\in Q_+$. So, there exists $r_0\in\mathbb{Z}_+$ such that $e_{i_1}e_{i_2}\cdots e_{i_r}=0$ for any $r\geqslant r_0$ and $i_1,i_2\cdots,i_r\in I$. Thus, for any nonzero $U_\varepsilon^{\mathrm{fin}}$-submodule L of $U_\varepsilon u_0$, there exists a nonzero element $v\in L$ such that $e_i v=0$ for any $i\in I$. Therefore, by the uniqueness of primitive vector of Proposition (3.4), $U_\varepsilon u_0\subset L$. Then we have $L\supseteq U_\varepsilon^{\mathrm{fin}}u_0=U_\varepsilon u_0\supseteq L$. Therefore, $U_\varepsilon u_0$ is irreducible. □

Comment: We expect that we can treat infinitesimal Verma modules for orthogonal and symplectic cases in a similar way to Ref. 5.

V. PROOF OF LEMMA 4.9(III)

A. Case of λ_{l-1}

In this section we shall show Lemma 4.9 (iii) for the special case : $\lambda=\lambda_{l-1}:=(l-1,\cdots,l-1)$. For $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{Z}_l^n$, in case $\mathfrak{g}=\mathsf{sp}(2n,\mathbb{C})$, we define $m^\lambda=(m^\lambda_{i,j})^n_{i,j=1}\in M$ by

$$m^\lambda_{i,i}=\lambda_i \quad (1\leqslant i\leqslant n),$$

$$m^\lambda_{i,j}=\lambda_i+\cdots+\lambda_j \quad (1\leqslant i<j\leqslant n),$$

$$m^\lambda_{j,i}=\lambda_i+\cdots+\lambda_{j-1}+2\lambda_j+\cdots+2\lambda_n \quad (1\leqslant i<j\leqslant n).$$

Obviously, we have

$$m^\lambda_{i,j+1}-m^\lambda_{i,j}=\lambda_{j+1} \quad (1\leqslant i\leqslant j<n),$$

$$m^\lambda_{n,i}-m^\lambda_{i,n}=\lambda_n \quad (1\leqslant i<n), \tag{5.1}$$

$$m^\lambda_{j,i}-m^\lambda_{j+1,i}=\lambda_j \quad (1\leqslant i\leqslant j<n-1).$$

Similarly, in case $\mathfrak{g}=\mathsf{so}(2n+1,\mathbb{C})$, for $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{Z}_l^n$, we define $m^\lambda=(m^\lambda_{i,j})^n_{i,j=1}\in M$ by

$$m^\lambda_{i,i}:=\lambda_i \quad (1\leqslant i\leqslant n),$$

$$m^\lambda_{i,j}:=\lambda_i+\cdots+\lambda_j \quad (1\leqslant i<j\leqslant n-1),$$

$$m^\lambda_{i,n}:=2\lambda_i+\cdots+2\lambda_{n-1}+\lambda_n \quad (1\leqslant i\leqslant n-1),$$

$$m^\lambda_{j,i}:=\lambda_i+\cdots+\lambda_{j-1}+2\lambda_j+\cdots+2\lambda_{n-1}+\lambda_n \quad (1\leqslant i<j\leqslant n-1),$$

$$m^\lambda_{n,i}:=\lambda_i+\cdots+\lambda_n \quad (1\leqslant i\leqslant n-1),$$

and in case $\mathfrak{g}=\mathsf{so}(2n,\mathbb{C})$, we define $m^\lambda=(m^\lambda_{i,j})^n_{1\leqslant i\leqslant n-1,1\leqslant j\leqslant n}\in M$ by

$$m^\lambda_{i,i}:=\lambda_i \quad (1\leqslant i\leqslant n-1),$$

$$m^\lambda_{n-1,n}:=\lambda_n,$$

$$m^\lambda_{i,j}:=\lambda_i+\cdots+\lambda_j \quad (1\leqslant i<j\leqslant n-2),$$

$$m^\lambda_{i,n-1}:=\lambda_i+\cdots+\lambda_{n-2}+\lambda_n \quad (1\leqslant i\leqslant n-2),$$

$$m^\lambda_{i,n}:=\lambda_i+\cdots+\lambda_{n-2}+\lambda_{n-1} \quad (1\leqslant i\leqslant n-2),$$

$$m^\lambda_{j,i}:=\lambda_i+\cdots+\lambda_{j-1}+2\lambda_j+\cdots+2\lambda_{n-2}+\lambda_{n-1}+\lambda_n \quad (1\leqslant i<j\leqslant n-2),$$

$$m^\lambda_{n-1,i}:=\lambda_i+\cdots+\lambda_n \quad (1\leqslant i\leqslant n-2).$$

Lemma 5.1: (i) For any $\lambda\in\mathbb{Z}_l^n$ and $\alpha\in\Delta_+$, we have $f_\alpha u(m^\lambda)=0$ in $V(\lambda)$.
(ii) For any $\alpha\in\Delta_+$ and $v\in V(\lambda_{l-1})$, write

$$f_\alpha v = \sum_{m\in M} c_\alpha(m)u(m) \quad in\ V(\lambda_{l-1}) \quad (c_\alpha(m)\in\mathbb{C}).$$

Then $c_\alpha(0)=0$, *i.e., the vector* u_0 *never occurs in* $f_\alpha v$.

Proof: We only show for $\mathfrak{g}=\mathsf{sp}(2n,\mathbb{C})$. The other cases are shown similarly. By Proposition 2.6, $f_\alpha\in U_\varepsilon^-\cap(U_\varepsilon)_\alpha$. So, it is enough to prove the case of $\alpha=\alpha_j(j\in I)$.

(i) For any $1\leqslant i<j\leqslant n-2$, by (3.9) and (5.1),

$$\begin{aligned}\nu_{i,j}^{m_\lambda} &= -m_{i,j-1}^\lambda + 2m_{i,j}^\lambda - m_{i,j+1}^\lambda - m_{j+2,i}^\lambda + 2m_{j+1,i}^\lambda - m_{j,i}^\lambda\\ &= (m_{i,j}^\lambda - m_{i,j-1}^\lambda) - (m_{i,j+1}^\lambda - m_{i,j}^\lambda) + (m_{j+1,i}^\lambda - m_{j+2,i}^\lambda) - (m_{j,i}^\lambda - m_{j+1,i}^\lambda)\\ &= \lambda_j - \lambda_{j+1} + \lambda_{j+1} - \lambda_j = 0.\end{aligned}$$

Similarly, we obtain

$$\nu_{i,n-1}^{m_\lambda} = 0 \quad (1\leqslant i\leqslant n-2), \quad \nu_{i,n}^{m_\lambda} = 0 \quad (1\leqslant i\leqslant n-1).$$

Furthermore, for any $1\leqslant i\leqslant n-2$,

$$\begin{aligned}\nu_{j,j}^{m_\lambda} &= 2m_{j,j}^\lambda - m_{j,j+1}^\lambda - m_{j+1,j+1}^\lambda - m_{j+2,j}^\lambda + 2m_{j+1,j}^\lambda - m_{j+2,j+1}^\lambda\\ &= 2\lambda_j - (\lambda_j+\lambda_{j+1}) - \lambda_{j+1} - (\lambda_j+\lambda_{j+1}+2\lambda_{j+2}+\cdots 2\lambda_n) + 2(\lambda_j+2\lambda_{j+1}+2\lambda_{j+2}+\cdots 2\lambda_n)\\ &\quad - (\lambda_{j+1}+2\lambda_{j+2}+\cdots 2\lambda_n) = 2\lambda_j\end{aligned}$$

Similarly, we obtain

$$\nu_{n-1,n-1}^{m_\lambda} = 2\lambda_{n-1}, \quad \nu_{n,n}^{m_\lambda} = 2\lambda_n.$$

Thus, it follows from (3.8) that for any $1\leqslant i,j\leqslant n$,

$$\mu_{i,j}^{m^\lambda} = \sum_{k=i}^{j} \nu_{k,j}^{m^\lambda} = \nu_{j,j}^{m^\lambda} = 2\lambda_j.$$

Hence, for any $1\leqslant i<j\leqslant n-2$, by (3.10),

$$\begin{aligned}\eta_{i,j}^{m^\lambda} + \mu_{i+1,j}^{m^\lambda} - \lambda_j &= -(m_{i,j+1}^\lambda - m_{i,j}^\lambda) + (m_{j+1,i}^\lambda - m_{j+2,i}^\lambda) - (m_{j,i}^\lambda - m_{j+1,i}^\lambda) + \lambda_j\\ &= -\lambda_{j+1} + \lambda_{j+1} - \lambda_j + \lambda_j = 0,\end{aligned}$$

$$\eta_{j+1,i}^{m^\lambda} + \mu_{i+1,j}^{m^\lambda} - \lambda_j = -(m_{j,i}^\lambda - m_{j+1,i}^\lambda) + \lambda_j = -\lambda_j + \lambda_j = 0,$$

$$\begin{aligned}\eta_{j,j}^{m^\lambda} - \lambda_j &= m_{j,j}^\lambda - m_{j,j+1}^\lambda - m_{j+1,j+1}^\lambda + (m_{j+1,j}^\lambda - m_{j+2,j}^\lambda) + (m_{j+1,j}^\lambda - m_{j+2,j+1}^\lambda) - \lambda_j\\ &= \lambda_j - (\lambda_j+\lambda_{j+1}) - \lambda_{j+1} + \lambda_{j+1} + (\lambda_j+\lambda_{j+1}) - \lambda_j = 0,\end{aligned}$$

$$\eta_{j+1,j}^{m^\lambda} - \lambda_j = -m_{j+1,j+1}^\lambda + (m_{j+1,j}^\lambda - m_{j+2,j+1}^\lambda) - \lambda_j = -\lambda_{j+1} + (\lambda_j+\lambda_{j+1}) - \lambda_j = 0.$$

So, $f_j u(m^\lambda)=0$ in $V(\lambda)(1\leqslant j\leqslant n-2)$. Similarly, we obtain $f_{n-1}u(m^\lambda)=f_n u(m^\lambda)=0$.

(ii) Let $\lambda\in\mathbb{Z}_l^n$. Since for any $1\leqslant i<j\leqslant n-2, m_{i,j}$ does not appear in $\mu_{i+1,j}^m$ and $(i,j)\neq(i,j+1),(j+2,i),(j+1,i),(j,i)$, for any $c(m)\in\mathbb{C}$, we have

$$\sum_{m\in M} c(m)[\eta_{i,j}^m + \mu_{i+1,j}^m - \lambda_j] = \sum_{m\in M} c(m)[m_{i,j} - m_{i,j+1} - m_{j+2,i} + 2m_{j+1,i} - m_{j,i} + \mu_{i+1,j}^m - \lambda_j]u(m+\epsilon_{i,j})$$
$$= \sum_{m\in M} c(m-\epsilon_{i,j})[(m_{i,j}-1) - m_{i,j+1} - m_{j+2,i} + 2m_{j+1,i} - m_{j,i} + \mu_{i+1,j}^m - \lambda_j]u(m).$$

By (3.8) and (3.9), if $m\equiv 0$, we have $\mu_{i+1,j}^m=0$. Thus, we obtain that the coefficient of u_0 is equal to

$$c(-\epsilon_{i,j})[-1-\lambda_j].$$

Hence, if $\lambda=\lambda_{l-1}$, then this is 0. Similarly, we obtain that the coefficient of u_0 in $f_j v$ is equal to $c[-\lambda_j-1]$ (for some $c\in\mathbb{C}$). So, if $\lambda=\lambda_{l-1}$, then it is equal to 0. □

Lemma 5.2: We have $f_\alpha^l u_0=0$ in $V(\lambda_{l-1})$ for any $\alpha\in\Delta_+$.

Proof: By Proposition 2.7, for any $\alpha\in\Delta_+, f_\alpha^l$ is a central element of U_ε. Thus,

$$e_i(f_\alpha^l u_0) = f_\alpha^l(e_i u_0) = 0 \quad (i\in I).$$

So, $f_\alpha^l u_0$ is a primitive vector. Therefore, by the uniqueness of primitive vector (see Proposition 3.4), $f_\alpha^l u_0\in\mathbb{C}u_0$. On the other hand, by Lemma 5.1(ii), the coefficient of u_0 in $f_\alpha^l u_0$ is 0. Hence $f_\alpha^l u_0=0$. □

B. Proof of $e_\alpha^l=0$ on $V(\lambda)$

Definition 5.3: Let $\lambda=(\lambda_1,\ldots,\lambda_n)\in\mathbb{Z}_l^n, I_\lambda$ be the left ideal of U_ε generated by $\{e_i, t_i-\varepsilon_i^{\lambda_i}, f_\alpha^l | i\in I, \alpha\in\Delta_+\}$. We set $M(\lambda):=U_\varepsilon/I_\lambda$.

Proposition 5.4 (Ref. 3, Proposition 3.2, Corollary 3.2(b)):

(i) *If $\lambda=\lambda_{l-1}$, then $M(\lambda)$ is an irreducible U_ε-module.*

(ii) *For any $\lambda\in\mathbb{Z}_l^n, dimM(\lambda)=l^{n^2}$ $(=dimV(\lambda))$.*

Proposition 5.5: If $\lambda=\lambda_{l-1}$, then $M(\lambda)\cong V(\lambda)$ (as U_ε-module).

Proof: By Lemma 5.2 and the property of u_0, we have

$$e_i u_0 = 0, \quad t_i u_0 = \varepsilon_i^{\lambda_i} u_0, \quad f_\alpha^l u_0 = 0 \quad (i\in I, \alpha\in\Delta_+).$$

So, by the universality of $M(\lambda)$, there exists an U_ε-module homomorphism $\phi: M(\lambda)\to V(\lambda)$ such that $\phi(1+I_\lambda)=u_0$. By Proposition 5.4(i), $M(\lambda)$ is an irreducible U_ε-module if $\lambda=\lambda_{l-1}$, and $\phi\not\equiv 0$. Hence ϕ is injective.

On the other hand, by Proposition 5.4(ii), $\dim M(\lambda)=\dim V(\lambda)$. Thus ϕ is surjective. Therefore ϕ is an isomorphism of U_ε-module. □

Lemma 5.6: For any $\lambda\in\mathbb{Z}_l^n$ and $\alpha\in\Delta_+, e_\alpha^l=0$ on $V(\lambda)$.

Proof: By Proposition 5.5 and Proposition 5.4(i), $V(\lambda_{l-1})$ is an irreducible U_ε-module and then we have $U_\varepsilon u_0=V(\lambda_{l-1})$. Thus,

$$e_\alpha^l V(\lambda_{l-1}) = e_\alpha^l(U_\varepsilon u_0) = U_\varepsilon(e_\alpha^l u_0) = \{0\}.$$

Hence $e_\alpha^l=0$ on $V(\lambda_{l-1})$. Due to (3.2) and (3.3), we know that the action of e_i on $V(\lambda)$ does not depend on λ. Therefore, for any $\lambda\in\mathbb{Z}_l^n, e_\alpha^l=0$ on $V(\lambda)$. □

C. General case

Lemma 5.7: For any $\lambda\in\mathbb{Z}_l^n$ and $v\in V(\lambda)(v\neq 0)$, there exists $u^+\in U_\varepsilon^+$ such that $u^+v=u_0$.

Proof: By Lemma 5.6, we can regard $V(\lambda)$ as a $(U_\varepsilon^{\mathrm{fin}})^+$-module (see proof of Lemma 4.8). So, by the similar manner to the proof of Theorem 4.10(ii), we can take $u^+\in U_\varepsilon^+$ such that u^+v is a nonzero primitive vector. Therefore, by the uniqueness of the primitive vector, we have $u^+v\in\mathbb{C}^\times u_0$. □

Proof of Lemma 4.9(iii): Let us show that for any $\lambda \in \mathbb{Z}_l^n$ and $\alpha \in \Delta_+, f_\alpha^l u_0 = 0$ in $V(\lambda)$. By Lemma 5.7, there exists $u^+ \in U_\varepsilon^+$ such that $u^+ u(m^\lambda) = u_0$. Since $f_\alpha u(m^\lambda) = 0$, by Lemma 5.1(i), we obtain

$$f_\alpha^l u_0 = f_\alpha^l (u^+ u(m^\lambda)) = u^+ (f_\alpha^l u(m^\lambda)) = 0.$$

Discrete and continuous cosine transform generalized to Lie groups SU(3) and G(2)

J. Patera[a] and A. Zaratsyan[b]
Centre de Recherches Mathématiques, Université de Montréal, C.P. 6128 Succ. Centre-ville, Montréal, Québec H3C 3J7, Canada

(Received 21 March 2005; accepted 12 September 2005;
published online 11 November 2005)

In the paper we complete the development and description of the four variants of two-dimensional generalization of the cosine transform started in [Patera and Zaratsyan, J. Math Phys. **46**, 053514 (2005)]. Each variant is based on a compact semisimple Lie group G of rank 2. Here, the groups are SU(3) and G(2). The cosines are generalized as the corresponding C-functions of the Lie group. A C-function is the contribution to an irreducible character from one orbit of the appropriate Weyl group. An explicit description is provided for expansions of functions given on the fundamental region F of the two compact simple Lie groups into series of C-functions. The fundamental region F is an equilateral triangle for SU(3) and half of such a triangle for G(2). Expansion coefficients are calculated using orthogonality of C-functions on F. Discrete expansions are set up on a grid $F_M \subset F$. The grid is defined group theoretically for all positive integers M. It consists of points in F that represent conjugacy classes of elements of the finite maximal Abelian subgroup of G generated by its elements of order M. The C-functions are orthogonal on such a grid; hence, coefficients of discrete expansions are calculated independently of the continuous expansions. Processing digital data, sampled on triangular lattices, is the motivating application here. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2109707]

I. INTRODUCTION

This is the second of a series of three articles.[1,2] In this paper we complete our consideration of the four versions of generalization of cosine transform (discrete and continuous ones), each based on one semisimple compact Lie group of rank 2. The third paper of the series is devoted to two-dimensional discrete and continuous generalizations of the sine transform for the four groups.

In the first paper,[1] the cases of the group $SU(2) \times SU(2)$ and O(5) or Sp(4) were considered. Traditional cosine transform would be the discrete version of our SU(2) case. It was discovered some 30 years ago and has been extensively used ever since. Its straightforward generalization to two dimensions is, in our notation, the case of $A_1 \times A_1$ [equivalently, $SU(2) \times SU(2)$]; see Refs. [3,4]. The O(5) case is apparently not found elsewhere in the literature other than in Ref. 1. We use Lie algebraic notation for the cases, respectively, $A_1 \times A_1$ and C_2. The two cases have in common the fact that the discrete transforms are played on square lattices.

In the present paper, the cases of SU(3) and G(2) groups are considered in an analogous way. Equivalently, we call the cases A_2 and G_2. Here, the discrete transforms exploit triangular lattices.

For general comments, motivation, and additional remarks, as well as for uniform description of the four cases, we refer the reader to Ref. 1. Also, the rank 1 case of SU(2) group (equivalently A_1) is found there, as well as in Ref. 5.

[a]Electronic mail: patera@crm.umontreal.ca
[b]Electronic mail: zaratsyan@crm.umontreal.ca

The discrete general version of the method was laid down in Ref. 6. Subsequently, it was used to solve some challenging eight-dimensional decomposition problems.[7–9] Most recently, two of the discrete lowest cases were described in Ref. 10. The continuous version of the method was apparently ignored in the literature until Ref. 1.

Useful properties of the continuous extensions of the discrete method were noticed in Ref. 5 and further exploited in Refs. 11, 1, and 12, as well as here.

Lattices in physics are often taken as computationally manageable models of a continuous space. Increasing density of lattice points, one often rightfully expects to approach the continuous reality. In doing that, it hardly matters what type of lattice one chooses, the square one usually being easier to deal with. However, there are problems where such choice is not available. Indeed, recognition of the need to work on triangular lattices is not new (cf. Ref. 13). As a specific argument, one may point to the analysis of data from existing major installations of hexagonal batteries of particle counters in high-energy experimental astrophysics and/or particle physics.[11]

The method we describe here is a versatile approach to the treatment of such data, which has been mostly unexplored so far, although it originates in the general case of Ref. 6. Apparently, the first exploitation of the case A_2 [equivalently SU(3)] is quite recent.[10–12] The G(2) case is not found in the literature. One of our objectives is to make our approach as ready to use as possible also for triangular lattices.

Finally, let us point out some notations used throughout the paper. The symbols $\mathbb{R}$, $\mathbb{Z}$, and $\mathbb{N}$ denote real numbers, integers, and positive integers, respectively. The scalar product of $a,b \in \mathbb{R}^2$ in a real Euclidean space $\mathbb{R}^2$ of dimension 2 is denoted by $\langle a|b\rangle$. We denote the Hermitian product of class functions in the functional space spanned by irreducible characters (or C-functions) in a similar way. We will frequently refer to equations already given in Ref. 1, and therefore not repeated here. When we need to make such a reference, we use a notation [paper, (equation)]. For example, [1, (4.8)] is a reference to Eq. (4.8) of Ref. 1. In general, this paper should be read with Ref. 1 at hand.

In the following sections we consider the expansion of class functions on the two compact Lie groups of rank two in terms of their C-functions, and the inversion of such expansions. In both cases triangular lattices of weights and roots are involved. For more about our goal in general, as well as for more technical details, see Refs. 1, Secs. II–IV. Since similar applications of C-functions are very recent[14,15,5,11,12] for A_2 and are apparently nowhere to be found for G_2, we describe also other properties of C-functions, which do not serve our immediate goals.

Secs. II and III of this paper contain, respectively, all the details for exploitation of the method for the cases A_2 and G_2. Discretization of these cases is the subject of Sec. IV. Some motivating examples are shown in Sec. V, and concluding remarks and related problems are brought forward in Sec. VI.

II. THE CONTINUOUS CASE OF A_2

A. Root and weight lattices

All roots of A_2 are of the same length. The two simple roots with the relative angle 120° between them are given by the scalar products in $\mathbb{R}^2$:

$$\langle \alpha_1|\alpha_2\rangle = -1, \quad \langle \alpha_1|\alpha_1\rangle = \langle \alpha_2|\alpha_2\rangle = 2.$$

Consequently, the A_2 Cartan matrix and its inverse are the following:

$$C = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}, \quad C^{-1} = \frac{1}{3}\begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}.$$

The α- and ω-bases are defined through

$$\langle \alpha_j|\omega_k\rangle = \delta_{j,k}, \quad \text{where } j,k = 1,2,$$

which amounts to the explicit relations

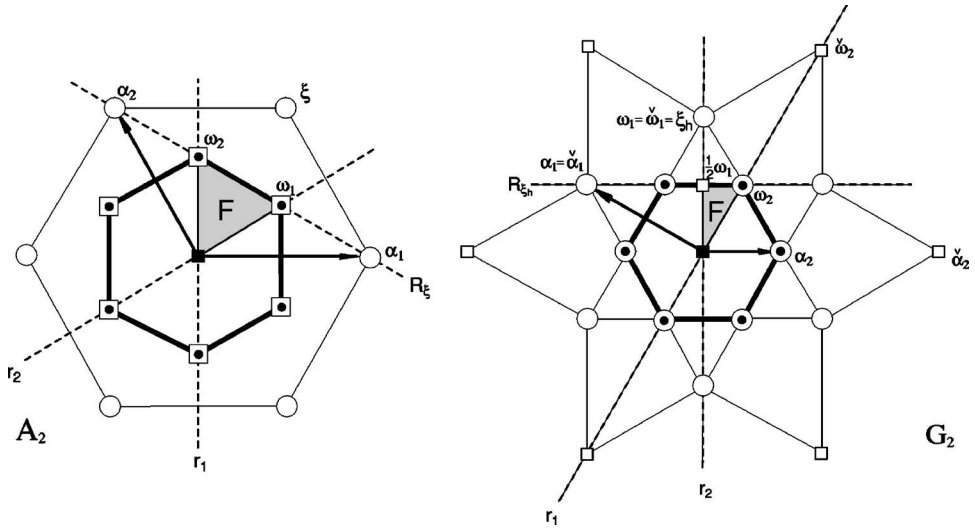

FIG. 1. The simple roots, the fundamental weights, along with their duals, and the fundamental region for the cases A_2 and G_2. The thick line hexagon encloses the proximity cell to origin of the dual root lattice in each case.

$$\alpha_1 = 2\omega_1 - \omega_2, \quad \omega_1 = \frac{1}{3}(2\alpha_1 + \alpha_2),$$

$$\alpha_2 = -\omega_2 + 2\omega_2, \quad \omega_2 = \frac{1}{3}(\alpha_1 + 2\alpha_2).$$

The root system $\Delta = \{\pm(\alpha_1+\alpha_2), \pm\alpha_1, \pm\alpha_2\}$ geometrically represents vertices of a regular hexagon. The highest root $\xi_h = \alpha_1 + \alpha_2$ (see Fig. 1).

The weight lattice P consists of three copies of the root lattice Q shifted relative to each other. Both P and Q are triangular. One has

$$P = Q \cup (Q + \omega_1) \cup (Q + \omega_2).$$

By P^+ one denotes the "positive chamber" of P, containing all the points $a\omega_1 + b\omega_2$ with $a, b \in \mathbb{Z}^{\geq 0}$.

B. Fundamental region

The fundamental region of A_2 is an equilateral triangle with vertices in 0, ω_1, and ω_2, as shown in Fig. 1. Equivalently

$$F = \{x\omega_1 + y\omega_2 \mid 0 \leqslant x, y \text{ and } x + y \leqslant 1\}.$$

Each of its sides is orthogonal either to α_1 or α_2, or to the highest root $\xi_h = \alpha_1 + \alpha_2$ (see Fig. 1).

C. Weyl group orbits of A_2

Set $\lambda = a\omega_1 + b\omega_2 = (a, b) \in P^+$. Then, A_2-Weyl group orbit $W_\lambda \equiv W_{(a,b)}$ consists of either 1, 3, or 6 points generated from λ by repeated action of the reflections r_1 and r_2, according to: [1, (4.4)]

$$W_{(a,b)} = \begin{cases} \{(0,0)\}, & \text{if } a=b=0, \\ \{(a,0),(-a,a),(0,-a)\}, & \text{if } a\neq 0 \text{ and } b=0, \\ \{(0,b),(b,-b),(-b,0)\}, & \text{if } a=0 \text{ and } b\neq 0, \\ \{(a,b),(-a,a+b),(a+b,-b),(-b,-a),(b,-a-b),(-a-b,a)\}, & \text{if } a,b\neq 0. \end{cases}$$

Each weight/point of P belongs to precisely one W-orbit.

D. C-functions of A_2

C-functions $\Omega_{(a,b)}(x,y)$, with $\lambda=a\omega_1+b\omega_2\in P^+$ and $z=x\omega_1+y\omega_2\in\mathbb{R}^2$, are defined in [1, (4.7)] In the A_2-case they are in general complex valued. Only for $a=b$ they are real

$$\begin{aligned} \Omega_{(0,0)}(x,y) &= 1, \\ \Omega_{(a,0)}(x,y) &= e^{(2\pi i/3)(2x+y)a} + e^{(2\pi i/3)(y-x)a} + e^{-(2\pi i/3)(x+2y)a}, \\ \Omega_{(0,b)}(x,y) &= e^{-(2\pi i/3)(2x+y)b} + e^{(2\pi i/3)(x-y)b} + e^{(2\pi i/3)(x+2y)b}, \\ \Omega_{(a,b)}(x,y) &= e^{(2\pi i/3)((2a+b)x+(a+2b)y)} + e^{(2\pi i/3)((b-a)x+(a+2b)y)} + e^{(2\pi i/3)((2a+b)x+(a-b)y)} \\ &\quad + e^{-(2\pi i/3)((a-b)x+(b+2a)y)} + e^{-(2\pi i/3)((a+2b)x+(b-a)y)} + e^{-(2\pi i/3)((2b+a)x+(b+2a)y)}, \\ \Omega_{(a,a)}(x,y) &= 2\cos(2\pi ax) + 2\cos(2\pi ay) + 2\cos(2\pi a(x+y)), \end{aligned} \tag{2.1}$$

assuming that $0<a,b\in\mathbb{Z}$ and $x,y\in\mathbb{R}$.

In Ref. 1 we introduced a convenient normalization of C-functions, which simplifies the calculations. The normalized C-functions, as defined in [1, (4.8)], are given for the case A_2 for all $a,b\in\mathbb{Z}^{\geq 0}$ in one expression

$$\begin{aligned} \Phi_{(a,b)}(x,y) &= e^{(2\pi i/3)((2a+b)x+(a+2b)y)} + e^{(2\pi i/3)((b-a)x+(a+2b)y)} + e^{(2\pi i/3)((2a+b)x+(a-b)y)} \\ &\quad + e^{-(2\pi i/3)((a-b)x+(b+2a)y)} + e^{-(2\pi i/3)((a+2b)x+(b-a)y)} + e^{-(2\pi i/3)((2b+a)x+(b+2a)y)}. \end{aligned} \tag{2.2}$$

E. Decomposition of products of C-functions

Products of C-functions are decomposable into finite sums of C-functions

$$\begin{aligned} \Omega_{(1,0)}\Omega_{(1,0)} &= \Omega_{(2,0)} + 2\Omega_{(0,1)}, \\ \Omega_{(1,0)}\Omega_{(0,1)} &= \Omega_{(1,1)} + 3\Omega_{(0,0)}, \\ \Omega_{(1,1)}\Omega_{(1,1)} &= \Omega_{(2,2)} + 2\Omega_{(0,3)} + 2\Omega_{(3,0)} + 2\Omega_{(1,1)} + 6\Omega_{(0,0)}, \\ &\vdots \end{aligned}$$

In general,

$$\Omega_{(a,b)}\Omega_{(c,d)} = \Omega_{(a+c,b+d)} + \cdots + \Omega_{(a-d,b-c)}.$$

The weight $(a-d,b-c)$ may not be from P^+. Nevertheless, it belongs to just one C-function. Hence, it can be used to label the C-function.

It is possible to build up recursively the C-functions of A_2, starting from the three lowest ones: $\Omega_{(1,0)}$, $\Omega_{(0,1)}$, and $\Omega_{(0,0)}=1$.

F. Weyl group symmetries of C-functions of A_2

The affine Weyl group W^{aff}, generated by the reflections $r_1 \equiv r_{\alpha_1}$, $r_2 \equiv r_{\alpha_2}$, and $R_{N\xi} \equiv R_{N(\alpha_1+\alpha_2)}$, describes the symmetries of C-functions

$$\Omega_\lambda(r_1 z) \equiv \Omega_{(a,b)}(r_1(x\omega_1 + y\omega_2)) = \Omega_{(a,b)}((-x\omega_1 + (x+y)\omega_2\ ),$$

$$\Omega_\lambda(r_2 z) \equiv \Omega_{(a,b)}(r_2(x\omega_1 + y\omega_2)) = \Omega_{(a,b)}((x+y)\omega_1 - y\omega_2), \tag{2.3}$$

$$\Omega_\lambda(R_{N\xi} z) \equiv \Omega_{(a,b)}(R_{N\xi}(x\omega_1 + y\omega_2)) = \Omega_{(a,b)}((N-y)\omega_1 + (N-x)\omega_2).$$

G. Laplace operator

Direct calculation verifies that $\Omega_\lambda(z)$ is an eigenfunction of the Laplace operator L

$$\begin{aligned} L\Omega_\lambda(z) &\overset{\text{def}}{=} (\alpha_1\partial_x + \alpha_2\partial_y)^2\Omega_\lambda(z) = 2(\partial_{xx} - \partial_{xy} + \partial_{yy})\Omega_\lambda(z) \\ &= -4\pi\langle\lambda|\lambda\rangle\Omega_\lambda(z) = -\frac{8\pi}{3}(a^2 + ab + b^2)\Omega_\lambda(z), \end{aligned} \tag{2.4}$$

where $z = x\omega_1 + y\omega_2$ and $\lambda = a\omega_1 + b\omega_2$.

As a consequence of (2.3), C-functions satisfy the Neumann condition at the boundary of F, i.e., their normal derivatives vanish.

H. Orthogonality of C-functions of A_2

The C-functions are orthogonal when integrated over the fundamental region F of A_2

$$\begin{aligned} \int_F \Omega_{(a,b)}(x,y)\overline{\Omega_{(c,d)}(x,y)}\mathrm{d}F &= \frac{1}{\sqrt{3}}\int_0^1 \mathrm{d}x \int_0^{1-x} \Omega_{(a,b)}(x,y)\Omega_{(d,c)}(x,y)\mathrm{d}y \\ &= \begin{cases} 0, & \text{if } a \neq c \text{ or } b \neq d, \\ \dfrac{1}{2\sqrt{3}}, & \text{if } a = b = c = d = 0, \\ \dfrac{\sqrt{3}}{2}, & \text{if } a = c > 0 \text{ and } b = d = 0, \\ & \text{or } a = c = 0 \text{ and } b = d > 0, \\ \sqrt{3}, & \text{if } a = c > 0 \text{ and } b = d > 0. \end{cases} \end{aligned} \tag{2.5}$$

In the case of A_2, the complex conjugation, denoted here by an overbar, is also achieved by interchange of the subscripts, $\Omega_{(d,c)}(x,y) = \overline{\Omega_{(c,d)}(x,y)}$.

Note the special case (2.5), namely $c = d = 0$ and $a + b \neq 0$

$$\int_F \Omega_{(a,b)}(x,y)\mathrm{d}F = \frac{1}{\sqrt{3}}\int_0^1 \mathrm{d}x \int_0^{1-x} \Omega_{(a,b)}(x,y)\mathrm{d}y = 0. \tag{2.6}$$

I. Decomposition of class functions

Finally, a decomposition

$$f(x,y) = \sum_{\lambda \in P^+} a_\lambda \Omega_\lambda(x,y),$$

can be inverted using (2.5), i.e., expansion coefficients a_λ can be found

$$a_\lambda = \frac{1}{\langle \Omega_\lambda | \Omega_\lambda \rangle} \int_F f(x,y) \overline{\Omega_\lambda(x,y)} \mathrm{d}x\, \mathrm{d}y,$$

with the scalar product of orbit functions, already defined in Ref. 1

$$\langle \Omega_\lambda | \Omega_\lambda \rangle = \int_F \Omega_\lambda(x,y) \overline{\Omega_\lambda(x,y)} \mathrm{d}x\, \mathrm{d}y.$$

J. Branching rules for C-functions of A_2

Reduction of C-functions with respect to a subgroup of the same rank is achieved by a corresponding change of basis and by subsequently rearranging the exponential functions according to *W*-orbits of the subgroup. In general, a C-function of the group splits into a sum of C-functions of the subgroup. The splitting is called the branching rule.

There is only one subgroup of rank 2 in A_2, namely $U_1 \times A_1$. General structure of its C-functions is particularly simple

$$\Omega_\lambda(v) = 2e^{2\pi i m_1 \theta_1} \cos \pi m_2 \theta_2, \quad m_1 \in \mathbb{Z}; \quad m_2 \in \mathbb{Z}^{\geqslant 0}; \quad \theta_1, \theta_2 \in \mathbb{R}.$$

Here, $\lambda = m_1 \nu_1 + m_2 \nu_2$ and $v = \theta_1 \nu_1 + \theta_2 \nu_2$ are given relative to an orthogonal basis $\{\nu_1, \nu_2\}$, where ν_2 is the "ω-basis" of A_1 (compare with [1, (2.2)] and [1, (3.2)]).

An A_2-weight $a\omega_1 + b\omega_2 \equiv (a\ b)$ is transformed into a weight of the subgroup in $\{\nu_1, \nu_2\}$-basis by the matrix multiplication

$$(a \quad b)\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = (a+b \quad a-b).$$

Consequently, the scalar product $\langle \lambda | z \rangle$ is

$$\begin{aligned} \langle \lambda | z \rangle &= \langle (a \quad b) | (x \quad y) \rangle \\ &= \langle (a+b \quad a-b) | (x+y \quad x-y) \rangle = (a+b)(x+y) + (a-b)(x-y) = 2ax + 2by \end{aligned}$$

III. THE CONTINUOUS CASE OF G_2

A. Root and weight lattices

Relative length and angles of the simple roots are given by

$$\langle \alpha_1 | \alpha_2 \rangle = -1, \quad \langle \alpha_1 | \alpha_1 \rangle = 2, \quad \langle \alpha_2 | \alpha_2 \rangle = \frac{2}{3}.$$

The Cartan matrix and its inverse are

$$C = \begin{pmatrix} 2 & -3 \\ -1 & 2 \end{pmatrix}, \quad C^{-1} = \begin{pmatrix} 2 & 3 \\ 1 & 2 \end{pmatrix}.$$

Consequently

$$\alpha_1 = 2\omega_1 - 3\omega_2, \quad \omega_1 = 2\alpha_1 + 3\alpha_2, \quad \check{\alpha}_1 = \alpha_1, \quad \check{\omega}_1 = \omega_1,$$

$$\alpha_2 = -\omega_1 + 2\omega_2, \quad \omega_2 = \alpha_1 + 2\alpha_2, \quad \check{\alpha}_2 = 3\alpha_2, \quad \check{\omega}_2 = 3\omega_2.$$

Note that in this case, $\alpha_1, \alpha_2 \in P$. Hence, the root and weight lattices coincide: $P=Q$.

There are 12 roots in $\Delta(\mathrm{G}_2)$, namely the following:

$$\Delta = \{\pm(2\alpha_1 + 3\alpha_2), \pm(\alpha_1 + 3\alpha_2), \pm(\alpha_1 + 2\alpha_2), \pm(\alpha_1 + \alpha_2), \pm\alpha_1, \pm\alpha_2\}.$$

Geometrically the roots are vertices of a regular hexagonal star (see Fig. 1). The long roots are $\pm\alpha_1$, $\pm(\alpha_1+3\alpha_2)$, and $\pm(2\alpha_1+3\alpha_2)$, and the short roots are $\pm\alpha_2$, $\pm(\alpha_1+\alpha_2)$, and $\pm(\alpha_1+2\alpha_2)$. The highest root of G_2 is $\xi_h=2\alpha_1+3\alpha_2$.

B. Fundamental region

The fundamental region F of G_2 is a triangle with vertices 0, $\frac{1}{2}\check{\omega}_1$, and $\frac{1}{3}\check{\omega}_2$. Geometrically F is half of an equilateral triangle. It is shown in Fig. 1. One has the fundamental region $F(\mathrm{G}_2)$

$$F(\mathrm{G}_2) = \{x\check{\omega}_1 + y\check{\omega}_2 \mid 0 \leqslant x,y; 1 \geqslant 2x + 3y\}.$$

C. Weyl group orbits of G_2

Consider the weight lattice P and its subset P^+ of weights $\mathbb{Z}^{\geqslant 0}\omega_1+\mathbb{Z}^{\geqslant 0}\omega_2$, called dominant chamber. Let

$$\lambda = a\omega_1 + b\omega_2 \equiv (a,b) \in P^+. \tag{3.1}$$

A Weyl group orbit $W_\lambda = W_{(a,b)}$ consists of 1, 6, or 12 weights that are generated by the reflections [1, (4.4)] and therefore are equidistant from the origin

$$W_{(a,b)} = \begin{cases} \{(0,0)\}, & \text{if } a=b=0, \\ \{\pm(a,0), \pm(-a,3a), \pm(2a,-3a)\}, & \text{if } a\neq 0 \text{ and } b=0, \\ \{\pm(0,b), \pm(b,-b), \pm(-b,2b)\}, & \text{if } a=0 \text{ and } b\neq 0, \\ \{\pm(a,b), \pm(-a,3a+b), \pm(a+b,-b) & \\ \pm(2a+b,-3a-b), \pm(-a-b,3a+2b), & \\ \pm(2a+b,-3a-2b)\} & \text{if } a,b\neq 0. \end{cases}$$

In particular, the root system of G_2 is a union of two W-orbits, namely the orbit of long roots with $\lambda=(1,0)$ and the orbit of short roots with $\lambda=(0,1)$

D. C-functions of G_2

In the G_2 case, any C-function with $\lambda=a\omega_1+b\omega_2$ and $z=x\check{\omega}_1+y\check{\omega}_2$ is real because for each weight $\mu \in W_\lambda$ one finds also $-\mu \in W_\lambda$, so that corresponding exponential functions in $\Omega_\lambda(z)$ combine into $2\cos 2\pi\langle\mu|z\rangle$.

$$\Omega_{(0,0)}(x,y) = 1,$$

$$\Omega_{(a,0)}(x,y) = 2\cos(2\pi a(2x+3y)) + 2\cos(2\pi ax) + 2\cos(2\pi a(x+3y)),$$

$$\Omega_{(0,b)}(x,y) = 2\cos(2\pi b(x+y)) + 2\cos(2\pi by) + 2\cos(2\pi b(x+2y)), \tag{3.2}$$

$$\begin{aligned}\Omega_{(a,b)}(x,y) = {} & 2\cos(2\pi((a+b)x+by)) + 2\cos(2\pi(ax+(3a+b)y)) + 2\cos(2\pi((2a+b)x \\ & + (3a+b)y)) + 2\cos(2\pi((2a+b)x+(3a+2b)y)) + 2\cos(2\pi(ax-by)) \\ & + 2\cos(\pi((a+b)x+(3a+2b)y)).\end{aligned}$$

The C-functions, normalized as defined in [1, (4,8)], are given for G_2 for all $a,b \in \mathbb{Z}^{\geqslant 0}$ in one expression

$$\begin{aligned}\Phi_{(a,b)}(x,y) = {} & 2\cos(2\pi((a+b)x+by)) + 2\cos(2\pi(ax+(3a+b)y)) + 2\cos(2\pi((2a+b)x \\ & + (3a+b)y)) + 2\cos(2\pi((2a+b)x+(3a+2b)y)) + 2\cos(2\pi(ax-by)) \\ & + 2\cos(\pi((a+b)x+(3a+2b)y)). \end{aligned} \tag{3.3}$$

E. Weyl group symmetries of C-functions of G_2

The affine Weyl group W^{aff}, generated by the reflections $r_1 \equiv r_{\alpha_1}$, $r_2 \equiv r_{\alpha_2}$, and $R_{N\xi_h} \equiv R_{N(2\alpha_1+3\alpha_2)}$, describes the symmetries of C-functions

$$\Omega_\lambda(r_1 z) \equiv \Omega_{(a,b)}(r_1(x\check{\omega}_1 + y\check{\omega}_2)) = \Omega_{(a,b)}((-x\check{\omega}_1 + (x+y)\check{\omega}_2)\ ,$$

$$\Omega_\lambda(r_2 z) \equiv \Omega_{(a,b)}(r_2(x\check{\omega}_1 + y\check{\omega}_2)) = \Omega_{(a,b)}((x+3y)\check{\omega}_1 - y\check{\omega}_2), \tag{3.4}$$

$$\Omega_\lambda(R_{N\xi_h} z) \equiv \Omega_{(a,b)}(R_{N\xi_h}(x\check{\omega}_1 + y\check{\omega}_2)) = \Omega_{(a,b)}((N-x-3y)\check{\omega}_1 + y\check{\omega}_2).$$

Note that variable z is given relative to a dual basis $\{\check{\omega}_1, \check{\omega}_2\}$. Its lengths are interchanged.

F. Laplace operator

Direct calculation verifies that $\Omega_\lambda(z)$ is an eigenfunction of the Laplace operator L

$$\begin{aligned} L\Omega_\lambda(z) &\overset{\text{def}}{=} (\alpha_1\partial_x + \alpha_2\partial_y)^2\Omega_\lambda(z) = 2\left(\partial_{xx} - \partial_{xy} + \frac{1}{3}\partial_{yy}\right)\Omega_\lambda(z) \\ &= -4\pi\langle\lambda|\lambda\rangle\Omega_\lambda(z) = -8\pi\left(a^2 + ab + \frac{1}{3}b^2\right)\Omega_\lambda, \end{aligned} \tag{3.5}$$

where $z = x\check{\omega}_1 + y\check{\omega}_2$ and $\lambda = a\omega_1 + b\omega_2$. The operator L is positive definite. By a change of variables it can be brought to a sum of second derivative with coefficients of the same sign. That justifies its name.

G. Orthogonality of C-functions of G_2

Orthogonality property of the C-functions in the case of G_2

$$\int_F \Omega_{(a,b)}(x,y)\Omega_{(c,d)}(x,y)\mathrm{d}F = \sqrt{3}\int_0^{1/2} dx \int_0^{1/3-2/3x} \Omega_{(a,b)}(x,y)\Omega_{(c,d)}(x,y)\mathrm{d}y$$
$$= \begin{cases} 0, & \text{if } a \neq c \text{ or } b \neq d, \\ \dfrac{1}{4\sqrt{3}}, & \text{if } a=b=c=d=0, \\ \dfrac{\sqrt{3}}{2}, & \text{if } a=c>0 \text{ and } b=d=0, \\ & \text{or } a=c=0 \text{ and } b=d>0, \\ \sqrt{3}, & \text{if } a=c>0 \text{ and } b=d>0. \end{cases} \tag{3.6}$$

H. Decomposition of products of C-functions of G_2

Since a product of W-orbits is a union of W-orbits, one has a corresponding decomposition of C-functions. Here are some G_2-examples:

$$\Omega_{(0,1)}\Omega_{(0,1)} = \Omega_{(0,2)} + 2\Omega_{(1,0)} + 2\Omega_{(0,1)} + 6\Omega_{(0,0)},$$

$$\Omega_{(1,0)}\Omega_{(0,1)} = \Omega_{(1,1)} + 2\Omega_{(0,2)} + 2\Omega_{(0,1)},$$

$$\Omega_{(1,0)}\Omega_{(1,0)} = \Omega_{(2,0)} + 2\Omega_{(0,3)} + 2\Omega_{(1,0)} + 6\Omega_{(0,0)}.$$

There is a possibility to calculate C-functions one by one by judiciously choosing the sequence of products, starting from the lowest three: $\Omega_{(0,0)}=1$, $\Omega_{(0,1)}$, and $\Omega_{(1,0)}$.

I. Branching rules for C-functions of G_2 to the subgroups $A_1\times A_1$ and A_2

A branching rule is the reduction of a C-function of G_2 to a sum of C-functions of a subgroup. In order to do that, one needs to write any $\lambda \in P(G_2)$ in a basis of P of the subgroups. The transformations are performed as follows, relative to respective ω-bases:

$$(a \quad b)_{G_2}\begin{pmatrix} 1 & 3 \\ 1 & 1 \end{pmatrix} = (a+b \quad 3a+b)_{A_1\times A_1},$$

$$(a \quad b)_{G_2}\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} = (a+b \quad a)_{A_2}.$$

Each C-function of G_2 then splits into C-functions of the subgroup. The following relations describe all the branching rules:

$$G_2 \supset A_1 \times A_1: \quad [\Omega_{(a,0)}(z)]_{G_2} = [\Omega_{(a,3a)} + \Omega_{(2a,0)}]_{A_1\times A_1},$$

$$[\Omega_{(0,b)}(z)]_{G_2} = [\Omega_{(b,b)} + \Omega_{(0,2b)}]_{A_1\times A_1},$$

$$[\Omega_{(a,b)}(z)]_{G_2} = [\Omega_{(2a+b,3a+b)} + \Omega_{(2a+b,b)} + \Omega_{(a,3a+2b)}]_{A_1\times A_1},$$

$$G_2 \supset A_2: \quad [\Omega_{(a,0)}(z)]_{G_2} = [\Omega_{(a,a)}]_{A_2},$$

$$[\Omega_{(0,b)}(z)]_{G_2} = [\Omega_{(b,0)} + \Omega_{(0,b)}]_{A_2},$$

$$[\Omega_{(a,b)}(z)]_{G_2} = [\Omega_{(a+b,a)} + \Omega_{(a,a+b)}]_{A_2}.$$

IV. DISCRETIZATION OF A_2- AND G_2-TRANSFORMS

In this section we specialize the general results of Ref. 6 to A_2 and G_2, and follow it by their continuous extensions. For more information about discretization in the case of rank $n=2$, we refer to Sec. VII of Ref. 1 Here, only a minimum is recalled to make the paper reasonably self-contained.

In general, we proceed as follows. First, we set up a triangular lattice of points of any density. The set of its points in the fundamental region F is denoted F_M. Action of the affine Weyl group W^{aff} on F allows one to tile the entire space $\mathbb{R}^2$ by copies of F. By the same action, F_M is transformed into a lattice in $\mathbb{R}^2$. Density of points in F_M is chosen by fixing a positive integer M. Subsequently, the set F_M is used in two roles: (i) it is the stage on which digital data are given; (ii) it identifies the set S_M of pairwise orthogonal C-functions on F_M.

Second, we consider any function $f(s)$ sampled digitally on the points $s \in F_M$ and its expansion in terms of normalized C-functions

$$f(s) = \sum_{\lambda \in S_M} d_\lambda \Phi_\lambda(s), \quad s \in F_M, \quad M \in \mathbb{Z}^{>0}. \tag{4.1}$$

Expansion (4.1) is inverted using the discrete orthogonality of C-functions

$$\langle \Phi_{(a,b)} | \Phi_{(a',b')} \rangle_M = \sum_{s \in F_M} c_s \Phi_{(a,b)}(s) \overline{\Phi_{(a',b')}(s)} = \delta_{a,a'} \delta_{b,b'} \langle \Phi_{(a,b)} | \Phi_{(a,b)} \rangle_M. \tag{4.2}$$

Thus, we calculate the coefficients d_λ of the expansion according to

$$d_\lambda = \frac{1}{\langle \Phi_\lambda | \Phi_\lambda \rangle_M} \sum_{s \in F_M} c_s f_\lambda(s) \cdot \overline{\Phi_\lambda(s)}. \tag{4.3}$$

Here, c_s and $\langle \Phi_\lambda | \Phi_\lambda \rangle_M$ are constants specific for each Lie group.

Our final step is the continuous extension of (4.1). It is accomplished very simply: the discrete variable $s \in F_M$ is replaced by a continuous one, $z \in F$

$$f(z) = \sum_{\lambda \in S_M} d_\lambda \Phi_\lambda(z), \quad z \in F \subset \mathbb{R}^2. \tag{4.4}$$

Coefficients d_λ and the set S_M remain as in (4.1). Through them, the continuous extension depends on the discrete expansion.

A. Discretization in the case of A_2

The density of points $s \in F_M$ is chosen by fixing a positive integer M. Individual points $s \in F_M$ are given by triplets $s=[s_0,s_1,s_2] \equiv (s_1/M, s_2/M)$ of non-negative integers, which must not be all zero simultaneously and have to satisfy the following A_2-sum rule:

$$M = s_0 + s_1 + s_2 > 0, \quad s_0, s_1, s_2 \in \mathbb{Z}^{\geq 0}. \tag{4.5}$$

All points of $F_M \subset F$ are obtained by letting the three non-negative integers run through all the values compatible with (4.5). Equivalently

$$F_M \overset{\text{def}}{=} \left\{ \frac{s_1}{M}\omega_1 + \frac{s_2}{M}\omega_2 \mid s_0, s_1, s_2 \in \mathbb{Z}^{\geq 0}, \quad s_0 + s_1 + s_2 = M > 0 \right\}. \tag{4.6}$$

For example, the vertices of F belong to F_M for all M in the case of A_2. More precisely, the three vertices are

$$[M,0,0]=(0,0),\quad [0,M,0]=(1,0),\quad [0,0,M]=(0,1),$$

for any positive integer M. Every side of the equilateral triangle F contains $M+1$ equidistant points of F_M. See Fig. 3.

Discrete orthogonality of C-functions (4.2) is valid for a finite number of C-functions. More precisely, C-functions Φ_λ and $\Phi_{\lambda'}$ are orthogonal provided $\lambda,\lambda' \in S_M \subset P^+$, where

$$S_M=\left\{ s_1\omega_1+s_2\omega_2 \,\middle|\, \frac{s_1}{M}\omega_1+\frac{s_2}{M}\omega_2 \in F_M \right\}. \tag{4.7}$$

Coefficients c_s in (4.3) and (4.2) take the following values in the case of A_2:

$$c_s \equiv c_{(s_1/M,s_2/M)}=\begin{cases} 1, & \text{if } s_1=s_2=0,\\ & \text{or } s_1=0 \text{ and } s_2=M,\\ & \text{or } s_1=M \text{ and } s_2=0,\\ 3, & \text{if } s_1=0 \text{ and } 0<s_2<M,\\ & \text{or } s_2=0 \text{ and } 0<s_1<M,\\ & \text{or } s_1,s_2>0 \text{ and } s_1+s_2=M,\\ 6, & \text{if } s_1,s_2>0 \text{ and } s_1+s_2<M. \end{cases} \tag{4.8}$$

From (4.2) we have

$$\langle \Phi_{(a,b)} | \Phi_{(a',b')} \rangle_M = 0, \quad \text{if } a\neq a' \text{ and } b\neq b';$$

otherwise, for the set of the lowest pairwise orthogonal normalized C-functions

$$\langle \Phi_{(a,b)} | \Phi_{(a,b)} \rangle_M = 18M^2 \times \begin{cases} 1, & \text{if } 0<a,b \text{ and } a+b<M,\\ 2, & \text{if } a=0 \text{ and } 0<b<M,\\ & \text{or } 0<a<M \text{ and } b=0,\\ & \text{or } 0<a,b \text{ and } a+b=M,\\ 6, & \text{if } a=b=0,\\ & \text{or } a=0 \text{ and } b=M,\\ & \text{or } a=M \text{ and } b=0, \end{cases} \tag{4.9}$$

with the higher C-functions repeating the values of the lowest ones.

Example. $F_2(A_2)$ consists of the following six points given as $[s_0,s_1,s_2]\equiv(s_1/M,s_2/M)$:

$$F_2=\left\{ [2,0,0]=(0,0),\quad [0,2,0]=(1,0),\quad [0,0,2]=(0,1),\quad [1,1,0]=\left(\tfrac{1}{2},0\right),\right.$$
$$\left. [1,0,1]=\left(0,\tfrac{1}{2}\right),\quad [0,1,1]=\left(\tfrac{1}{2},\tfrac{1}{2}\right) \right\}. \tag{4.10}$$

In Table I the values of several normalized C-functions are shown at the points of $F_2(A_2)$. The first six belong to $S_2(A_2)$. However, a closer inspection reveals the presence of another orthogonal set obtained from $S_2(A_2)$ by affine reflection $R_{(2,2)}$ applied to all its elements. See Fig. 2.

Using the entries of Table I, let us calculate several examples in the discretized A_2-case

$$\langle \Omega_{(2,0)} | \Omega_{(0,0)} \rangle_2 = \langle \Omega_{(0,0)} | \Omega_{(0,2)} \rangle_2 = 3(1+3\eta^4+3\eta^2+\eta^2+3+\eta^4)=0;$$

$$\langle \Omega_{(1,1)} | \Omega_{(1,2)} \rangle_2 = 12(3-\eta^5-\eta+3\eta^4+1+3\eta^2)=0;$$

$$\langle \Omega_{(2,1)} | \Omega_{(2,1)} \rangle_2 = 6\cdot 6+3\cdot 2\eta^5\cdot 2\eta+3\cdot 2\eta\cdot 2\eta^5+6\eta^4\cdot 6\eta^2+3\cdot(-2)\cdot(-2)+6\eta^2\cdot 6\eta^4=144.$$

TABLE I. Values of several normalized C-functions of A_2 at the points of the grid F_2. Note that only the first six C-functions are pairwise orthogonal. The higher ones repeat the values of the lowest six. The c_s are the coefficients from (4.8). Here, $\eta=e^{2\pi i/6}$.

The sesquilinear form $\langle f|g\rangle_M$ can be used to multiply any class functions f and g sampled on F_M of A_2. Moreover, dependence of (4.2) on A_2 comes only through F_M, S_M, and the sum rule for M. Otherwise, the discrete orthogonality does not change from one group to another.

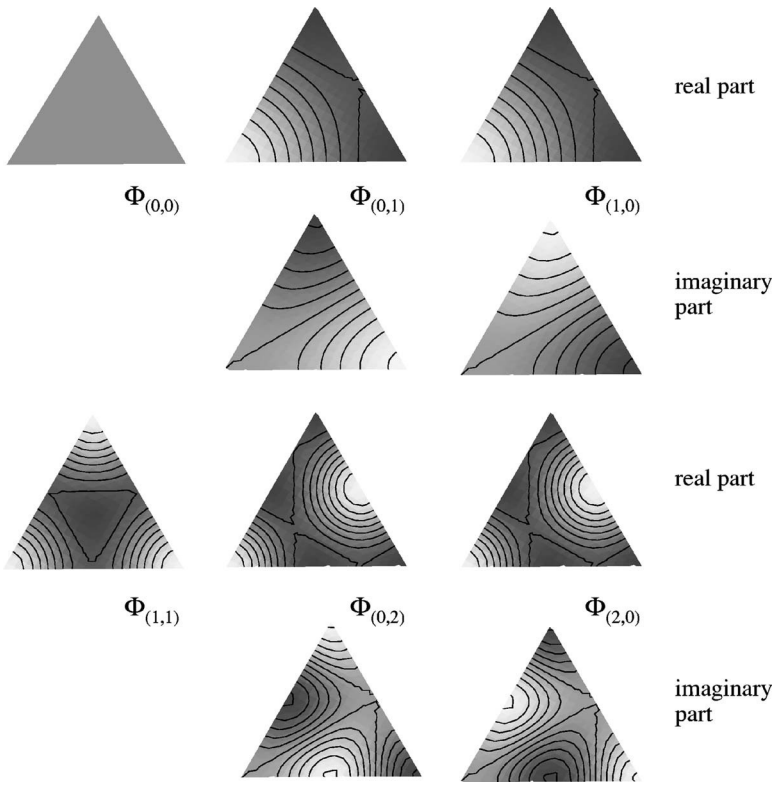

FIG. 2. The set of six lowest normalized C-functions of A_2 which are pairwise orthogonal on the grid F_2.

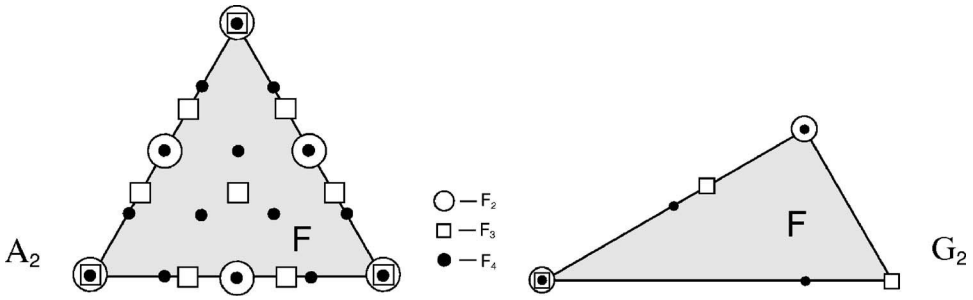

FIG. 3. The lattice points of F_2, F_3, and F_4 on the fundamental region F for A_2 and G_2.

B. Discretization in the case of G_2

Similarly as before, M is the positive integer fixing the density of the discrete points $s \in F_M \subset F$. The fundamental region F is a triangle, half of an equilateral one (see Fig. 1). The G_2 sum rule differs from that of A_2 of (4.5)

$$M = s_0 + 2s_1 + 3s_2 > 0, \quad s_0, s_1, s_2 \in \mathbb{Z}^{\geq 0}. \tag{4.11}$$

It restricts the choice of the triples $[s_0, s_1, s_2]$ to a finite set of possible values. Each triple stands for one point $s \in F_M$, where $s = [s_0, s_1, s_2] \equiv (s_1/M, s_2/M)$. In particular, origin belongs to F_M for any M, while $(1, 0)$ and $(0, 1) \in F_M$ only if M is divisible by 2 and 3, respectively. See Fig. 3.

A few more examples are the sets

$$F_8{:}[6,1,0] = \left(\tfrac{1}{8}, 0\right), \quad [5,0,1] = \left(0, \tfrac{1}{8}\right), \quad [3,1,1] = \left(\tfrac{1}{8}, \tfrac{1}{8}\right), \quad [1,2,1] = \left(\tfrac{1}{4}, \tfrac{1}{8}\right), \quad + \text{points of } F_4;$$

$$F_5{:}[5,0,0] = (0,0), \quad [2,0,1] = \left(0, \tfrac{1}{5}\right), \quad [3,1,0] = \left(\tfrac{1}{5}, 0\right), \quad [0,1,1] = \left(\tfrac{1}{5}, \tfrac{1}{5}\right), \quad [1,2,0] = \left(\tfrac{2}{5}, 0\right);$$

$$F_4{:}[1,0,1] = \left(0, \tfrac{1}{4}\right), \quad [2,1,0] = \left(\tfrac{1}{4}, 0\right), \quad + \text{points of } F_2;$$

$$F_3{:}[3,0,0] = (0,0), \quad [0,0,1] = \left(0, \tfrac{1}{3}\right), \quad [1,1,0] = \left(\tfrac{1}{3}, 0\right).$$

Discrete orthogonality (4.2) holds for the set of C-functions $\Omega_\lambda(z)$ of G_2 with λ in the set (4.7), where M is now given by the sum rule (4.11). The set of pairwise orthogonal C-functions of G_2 is again given by (4.7). Hence, we have (4.1) and (4.3), where coefficients c_s in the G_2 case are the following ones:

$$c_s \equiv c_{(s_1/M, s_2/M)} = \begin{cases} 1, & \text{if } s_1 = s_2 = 0, \\ 2, & \text{if } s_1 = 0 \text{ and } s_2 = \dfrac{M}{3}, \\ 3, & \text{if } s_1 = \dfrac{M}{2} \text{ and } s_2 = 0, \\ 6, & \text{if } s_1 = 0 \text{ and } 0 < s_2 < \dfrac{M}{3}, \\ & \text{or } s_2 = 0 \text{ and } 0 < s_1 < \dfrac{M}{2}, \\ & \text{or } s_1, s_2 > 0 \text{ and } 2s_1 + 3s_2 = M, \\ 12, & \text{if } s_1, s_2 > 0 \text{ and } 2s_1 + 3s_2 < M. \end{cases}$$

The discrete orthogonality is

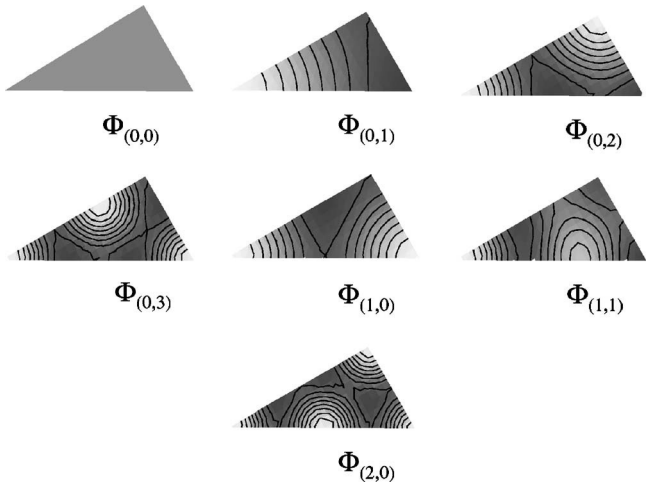

FIG. 4. The set of seven lowest normalized C-functions of G_2 which are pairwise orthogonal on the grid F_6.

$$\langle \Phi_{(a,b)} | \Phi_{(a',b')} \rangle_M = 0, \quad \text{if } a \neq a' \text{ and } b \neq b';$$

otherwise, for the set of the lowest pairwise orthogonal normalized C-functions

$$\langle \Phi_{(a,b)} | \Phi_{(a,b)} \rangle_M = 12M^2 \times \begin{cases} 1, & \text{if } 0 < a,b \text{ and } 3a + 2b < M, \\ 2, & \text{if } a = 0 \text{ and } 0 < b < \dfrac{M}{2}, \\ & \text{or } 0 < a < \dfrac{M}{3} \text{ and } b = 0, \\ & \text{or } 0 < a,b \text{ and } 3a + 2b = M, \\ 4, & \text{if } a = 0 \text{ and } b = \dfrac{M}{2}, \\ 6, & \text{if } a = \dfrac{M}{3} \text{ and } b = 0, \\ 12, & \text{if } a = b = 0, \end{cases} \tag{4.12}$$

with the higher C-functions repeating the values of the lowest ones. See Fig. 4.

V. MOTIVATING EXAMPLES

Comparison of expansions of class functions into series of C-functions of both groups considered here, as well as the two additional groups of Ref. 1, will require further study. Related results/questions are illustrated by the following examples.

There are two examples shown in this section, involving decomposition of the same function $f(x,y)$ into series of C-functions of A_2 and G_2. Goal of the examples is (i) to illustrate discrete decomposition of a given function followed by the continuous extension, and (ii) to compare the continuous extensions in both cases.

In order to make the comparison, we set up the vertices of the two fundamental regions as follows (relative to an orthonormal basis):

$$F(A_2) = \left\{ (0,0), (1,0), \left(\frac{1}{2}, \frac{\sqrt{3}}{2} \right) \right\}, \tag{5.1}$$

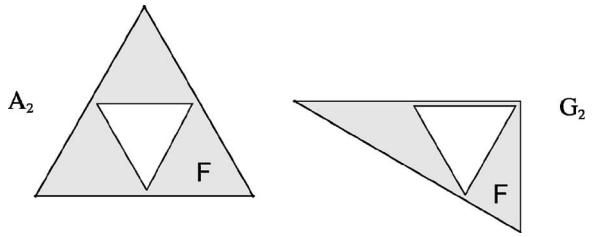

FIG. 5. The triangular step function (5.3) placed in the fundamental regions of A_2 and G_2.

$$F(G_2) = \left\{ \left(-\frac{1}{4}, \frac{\sqrt{3}}{4} \right), \left(\frac{3}{4}, \frac{\sqrt{3}}{4} \right), \left(\frac{3}{4}, \frac{\sqrt{3}-2}{4} \right) \right\}. \tag{5.2}$$

Thus, the area of $F(G_2)$ is exactly half of the area of $F(A_2)$.

We choose for $f(x,y)$ a triangular step function with sharp edges with vertices in $(1/4, \sqrt{3}/4)$, $(3/4, \sqrt{3}/4)$, and $(1/2, 0)$

$$f(x,y) = \begin{cases} 1 & \text{for } (x,y) \in \left\{ \left(\frac{1}{4}, \frac{\sqrt{3}}{4} \right), \left(\frac{3}{4}, \frac{\sqrt{3}}{4} \right), \left(\frac{1}{2}, 0 \right) \right\}, \\ 0 & \text{elsewhere in } F. \end{cases} \tag{5.3}$$

Chosen as such, $f(x,y)$ fits into the fundamental regions F of the two groups as shown in Fig. 5. Furthermore, in order to have the same density of grid points, the orders of the grids are taken with the ratio $M_{G_2} = 2M_{A_2}$. Figure 3 demonstrates the difference of densities of the grids of the same order for the two cases. It also helps to demonstrate the reason of the choice of $f(x,y)$ and its placement into the fundamental region of G_2 in order to ensure a fair comparison of the two cases.

Figures 6 and 7 contain results of our two examples. The values of the function $f(x,y)$ are sampled at the points s of the grids F_M [1, (7.2)] and taken as our digital data $f(s)$. Then, the functions are expanded [1, (7.7)] into C-functions of A_2 and of G_2 on the corresponding grid F_M, i.e., expansion coefficients are calculated [1, (7.8)]. After that, continuous extensions of the discrete expansions of $f(s)$ are made [1, (7.9)] by replacing the C-functions of the discrete argument s in the expansions by the same functions of the continuous argument, while keeping the expansion coefficients unchanged. Each figure shows the function $f_{\text{cont}}(x,y)$ resulting from the continu-

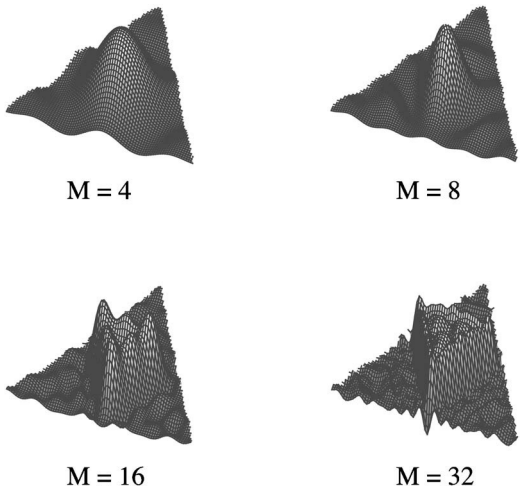

FIG. 6. Decomposition and continuous extension of a triangular step function placed in the fundamental region of A_2 on the grids of orders $M = 4$, 8, 16, and 32.

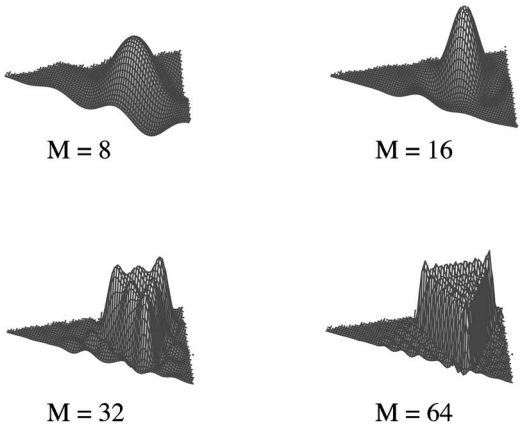

FIG. 7. Decomposition and continuous extension of a triangular step function placed in the fundamental region of G_2 on the grids of orders $M=8$, 16, 32, and 64.

ous extension of discrete expansions. More precisely, four different continuous extensions are shown in each figure. They differ by the densities of the grid F_M, namely $M_{A_2}=4$, 8, 16, 32, and $M_{G_2}=8$, 16, 32, and 64, from which the continuous extension is made. For these values the densities of grid points of A_2 and G_2 in the sample function are the same. The points of the grids are not shown in the figures.

Inspecting and comparing the two results, one readily observes the following:

(i) As in Ref. 1, increasing density of the grid, i.e., increasing the value of M, makes the continuous extension match more closely the given model function $f(x,y)$ of (5.3).

(ii) Quality of the extension, i.e., the match between the continuous extension $f_{\text{cont}}(x,y)$ and the original function $f(x,y)$, is comparable for the same density of the grid in both cases, though G_2 expansion may be slightly superior, as noticeable by comparing the two at $M_{A_2}=32$ and $M_{G_2}=64$.

(iii) The calculations of complex-valued functions in the case of A_2 took a much longer time compared to the case of G_2, which gives G_2 an obvious advantage in the discretization of real-valued functions, while A_2 is more useful for processing complex-valued information.

VI. CONCLUDING REMARKS

A number of concluding comments of Ref. 1 are equally pertinent for us here. In addition to those, we would like to point out the following:

(1) The versatile way of setting up the triangular grid F_M in the fundamental region, and, consequently, a lattice of corresponding symmetry in $\mathbb{R}^2$, should prove useful in other applications where lattices are essential. Note that the density of the lattice is chosen by a single natural number $0<M<\infty$. Also, general results of Ref. 6 allow one to set up a grid F_M and the corresponding lattice in any dimension n, using a semisimple Lie groups of rank n.

(2) Practically the most interesting question that remains is the characterization of functions $f(z)$, $z\in\mathbb{R}^2$, which are most advantageously expanded in C-functions of each of the four groups of rank 2.

(3) In general, one may expect that triangular lattices offer advantages in comparable problems due to their higher density of points. Indeed, given an equal distance between first neighbors, the ratio of densities of points (sphere packing densities) of square and triangular lattices is $1:\sqrt{2}$.

(4) There are other curious properties of C-functions we did not exploit either here or in Ref. 1. For example, the following assertion is valid for any compact semisimple Lie group.
Among the infinity of possible grid points in F, i.e., points with rational coordinates relative

to the ω-basis, there are finitely few, say $z_1, \ldots, z_k$, such that all C-functions take integer values on them

$$\Omega_\lambda(z_j) \in \mathbb{Z} \quad 1 \leqslant j \leqslant k, \quad \text{for all } \lambda \in P^+.$$

Such grid points identify the conjugacy classes of elements of the group G consisting of elements called rational.[16] For rank 2 groups, the rational conjugacy classes were found in Ref. 17.

(5) The last of the concluding remarks in Ref. 1 identifies the C-functions of that paper as two infinite families of orthogonal polynomials in two variables. Similar substitution of variables allows one to interpret the C-functions here as another two families of orthogonal polynomials in two variables. A distinguishing feature of the four families is the structure of their polynomials. Indeed, their degrees grow without limits, but the number of monomials comprising such a polynomial is equal to the order $|W|$ of the corresponding Weyl group or to one of the divisors of $|W|$. More precisely, an $\Omega_{(a,b)}(z)$ is identified as the polynomial consisting of monomials with degrees varying between $a+b$ and $-a-b$. The number of terms in such a polynomial is equal to $|W|$ precisely if $a \neq 0$ and $b \neq 0$. Recall that $|W|=4,6,8,12$, respectively, for $A_1 \times A_1$, A_2, C_2, and G_2.

(6) A systematic comparison of the quality and computational efficiency of continuous extensions, as described here and in Ref. 1 with the current methods of interpolation of digital data (for example, Refs. 18 and 19) is of considerable practical interest, but it is outside of the scope of this series of papers.

ACKNOWLEDGMENTS

Ergodic property of Markovian semigroups on standard forms of von Neumann algebras

Yong Moon Park[a)]
Department of Mathematics, Yonsei University, Seoul 120-749, Korea

(Received 29 June 2005; accepted 15 September 2005; published online 14 November 2005)

We give sufficient conditions for ergodicity of the Markovian semigroups associated to Dirichlet forms on standard forms of von Neumann algebras constructed by the method proposed by Park. We apply our result to show that the diffusion type Markovian semigroups for quantum spin systems are ergodic in the region of high temperatures where the uniqueness of the KMS state holds. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2113067]

I. INTRODUCTION

The purpose of this work is to investigate ergodic property of the Markovian semigroups associated to Dirichlet forms on the standard form of a von Neumann algebra[1,2] $\mathcal{M}$ acting on a Hilbert space $\mathcal{H}$ with a cyclic and separating vector ξ_0. Denote by $\sigma_t, t \in \mathbb{R}$, the modular automorphism on $\mathcal{M}$ associated with the pair $(\mathcal{M}, \xi_0)$ and $\mathcal{M}_{1/2}$ the dense subset of $\mathcal{M}$ consisting of every σ_t-analytic element on a domain containing the strip $\{z \in \mathbb{C}: |\mathrm{Im}\, z| \leqslant 1/2\}$.[3] Let $\{x_k : k \in I\}$ be a (finite or countable) family of elements in $\mathcal{M}_{1/2}$ which generates $\mathcal{M}$. Let $(\mathcal{E}, D(\mathcal{E}))$ be the Dirichlet form constructed with $\{x_k : k \in I\}$ and an admissible function by means of Refs. 1 and 2. For the details, see Sec. II. Denote by $T_t, t \geqslant 0$, the Markovian semigroup associated to $(\mathcal{E}, D(\mathcal{E}))$. Let $\mathcal{N}$ be the fixed point space of T_t,

$$\mathcal{N} = \{\eta \in \mathcal{H} : T_t \eta = \eta, \forall\, t \geqslant 0\}.$$

We show that $\mathcal{N} = [\mathcal{Z}(\mathcal{M})\xi_0]$, where $\mathcal{Z}(\mathcal{M})$ is the center of $\mathcal{M}$; $\mathcal{Z}(\mathcal{M}) = \mathcal{M} \cap \mathcal{M}'$, and $[\mathcal{Z}(\mathcal{M})\xi_0]$ is the closure of $\mathcal{Z}(\mathcal{M})\xi_0$. As a consequence, T_t is ergodic if and only if $\mathcal{M}$ is a factor. We apply our result to the translation invariant Markovian semigroups for quantum spin systems,[1] and show that the semigroups are ergodic in the region of high temperatures where the uniqueness of the KMS state holds.

Let us describe the background of this study briefly. The need to construct Markovian semigroups on von Neumann algebras, which are (KMS) symmetric with respect to nontracial states, is clear for various applications to open systems,[4] quantum statistical mechanics[3] and quantum probability.[5,6] Although on the abstract level we have quite well-developed theory,[7–9] the progress in concrete applications is relatively slow. For construction of Dirichlet forms and associated Markovian semigroups, we refer to Refs. 1 and 10–14 and the references there in.

During the last 10 years, systematic methods to construct Dirichlet forms and associated Markovian semigroups of jump and diffusion types have been developed. Nontrivial translation invariant symmetric semigroups of jump type for quantum spin systems have been constructed and the strong ergodicity of the semigroups has been established in Refs. 12 and 13. See also Ref. 14 and the references therein. In Ref. 1, we gave a general construction method of Dirichlet forms of diffusion type in the framework of the general theory of Dirichlet forms and Markovian semigroups on standard forms of von Neumann algebras developed by Cipriani.[7] The method has been used successfully to construct Dirichlet forms and associated Markovian semigroups for quantum

[a)]Electronic mail: ympark@yonsei.ac.kr

spin systems,[1] CCR and CAR algebras with respect to quasifree states,[10,11,15] and quantum mechanical systems.[16] Recently, in Ref. 2 we have shown that the symmetric embedding of a general Lindblad type (bounded) generator of a quantum dynamical semigroup satisfying KMS symmetry can be written in the form of a Dirichlet operator associated to a Dirichlet form given in Ref. 1.

The next step in this research area would be the investigation of detailed properties of Markovian semigroups, such as ergodicity, mixing property and convergence to the equilibrium, etc. In the case of CCR and CAR algebras with respect to quasifree states, the spectrum of the generators of the Markovian semigroups constructed in Refs. 17, 10, 11, and 15 has been analyzed. However, in general the detail properties of the Markovian semigroups associated to Dirichlet forms in Refs. 1 and 2 are hard to be established. Thus it would be nice to have a simple criteria whether the Markovian semigroup under study is ergodic or not in the sense of Cipriani.[18]

We organize the paper as follows: In Sec. II, we introduce notations and terminologies, and then list our results (Theorem 2.1 and Corollary 2.1). We also give comments (Remark 2.1) on possible applications of our results. Section III is devoted to the proof of Theorem 2.1. We first describe the basic ideas of the proof and then establish some technical lemmas (Lemma 3.1–Lemma 3.5) which are needed in the sequel. Using the lemmas we complete the proof of Theorem 2.1. In Sec. IV, we apply our main results to prove that the diffusion type translation invariant Markovian semigroups for quantum spin systems constructed in Ref. 1 are ergodic in the region of high temperature where the uniqueness of the KMS state holds.

II. NOTATION, TERMINOLOGIES AND MAIN RESULTS

We first introduce necessary terminologies in the theory of Dirichlet forms and Markovian semigroups on standard form of von Neumann algebras.[7] Next we give a brief review on the construction of Dirichlet forms developed in Ref. 1 and then list our main results.

Let $\mathcal{M}$ be a σ-finite von Neumann algebra acting on a complex Hilbert space $\mathcal{H}$ with an inner product $\langle\cdot,\cdot\rangle$ which is conjugate linear in the first and linear in the second variable. Let ξ_0 be a cyclic and separating vector for $\mathcal{M}$. We use Δ and J to denote, respectively, the modular operator and the modular conjugation associated with the pair $(\mathcal{M},\xi_0)$.[3] The associated modular automorphism is denoted by $\sigma_t{:}\sigma_t(A)=\Delta^{it}A\Delta^{-it}$, $A\in\mathcal{M}$. Finally, $j{:}\mathcal{M}\to\mathcal{M}'$ is the antilinear $*$-isomorphism defined by $j(A)=JAJ$, $A\in\mathcal{M}$, where $\mathcal{M}'$ is the commutant of $\mathcal{M}$. By the Tomita-Takesaki theorem (Theorem 2.5.14 of Ref. 3), it follows that $\sigma_t(\mathcal{M})=\mathcal{M}$ and $j(\mathcal{M})=\mathcal{M}'$.

The natural positive cone $\mathcal{P}$ associated with the pair $(\mathcal{M},\xi_0)$ is the closure of the set

$$\{Aj(A)\xi_0{:}A\in\mathcal{M}\}.$$

By a general result, the closed convex cone $\mathcal{P}$ can be obtained by the closure of the set

$$\{\Delta^{1/4}AA^*\xi_0{:}A\in\mathcal{M}\}$$

and this cone $\mathcal{P}$ is self-dual in the sense that

$$\{\xi\in\mathcal{H}{:}\langle\xi,\eta\rangle\geqslant 0,\ \forall\ \eta\in\mathcal{P}\}=\mathcal{P}.$$

For the details we refer to Ref. 19 and Sec. 2.5 of Ref. 3.

The form $(\mathcal{M},\mathcal{H},\mathcal{P},J)$ is the standard form associated with the pair $(\mathcal{M},\xi_0)$. We shall use the fact that $\mathcal{H}$ is the complexification of the real subspace $\mathcal{H}^J=\{\xi\in\mathcal{H}{:}\langle\xi,\eta\rangle\in\mathbb{R},\forall\,\eta\in\mathcal{P}\}$, whose elements are called *J-real*: $\mathcal{H}=\mathcal{H}^J\oplus i\mathcal{H}^J$. The cone $\mathcal{P}$ gives rise to a structure of ordered Hilbert space on $\mathcal{H}^J$ (denoted by $\leqslant$) and to an antilinear involution J on $\mathcal{H}$, which preserves $\mathcal{P}$ and $\mathcal{H}^J$: $J(\xi+i\eta)=\xi-i\eta$, $\forall\xi,\ \eta\in\mathcal{H}^J$. Also note that any J-real element $\xi\in\mathcal{H}^J$ can be decomposed uniquely as a difference of two mutually orthogonal, positive and negative part of ξ, respectively, $\xi=\xi_+-\xi_-$, $\xi_+,\xi_-\in\mathcal{P}$, and $\langle\xi_+,\xi_-\rangle=0$.

A bounded operator A on $\mathcal{H}$ is called *J-real* if $AJ=JA$ and *positive preserving* if $A\mathcal{P}\subset\mathcal{P}$. A semigroup $\{T_t\}_{t\geqslant 0}$ is said to be *J-real* if T_t is J-real for any $t\geqslant 0$ and it is called *positive preserving* if T_t is positive preserving for any $t\geqslant 0$. A bounded operator $A{:}\mathcal{H}\to\mathcal{H}$ is called *sub-Markovian*

(with respect to ξ_0) if $0 \leqslant \xi \leqslant \xi_0$ implies $0 \leqslant A\xi \leqslant \xi_0$. A is called *Markovian* if it is sub-Markovian and also $A\xi_0 = \xi_0$. A semigroup $\{T_t\}_{t \geqslant 0}$ is said to be *sub-Markovian* (with respect to ξ_0) if T_t is sub-Markovian for every $t \geqslant 0$. A semigroup $\{T_t\}_{t \geqslant 0}$ is called *Markovian* if T_t is Markovian for every $t \geqslant 0$.

Next, we consider a sesquilinear form on some linear manifold of $\mathcal{H}$: $\mathcal{E}(\cdot,\cdot): D(\mathcal{E}) \times D(\mathcal{E}) \to \mathbb{C}$. We also consider the associated quadratic form: $\mathcal{E}[\cdot]: D(\mathcal{E}) \to \mathbb{C}$, $\mathcal{E}[\xi] := \mathcal{E}(\xi, \xi)$. A real valued quadratic form $\mathcal{E}[\cdot]$ is said to be *semibounded* (or *bounded below*) if $\inf\{\mathcal{E}[\xi]: \xi \in D(\mathcal{E}), \|\xi\| = 1\} = -b > -\infty$. A quadratic form $(\mathcal{E}, D(\mathcal{E}))$ is said to be *J-real* if $JD(\mathcal{E}) \subset D(\mathcal{E})$ and $\mathcal{E}[J\xi] = \overline{\mathcal{E}[\xi]}$ for any $\xi \in D(\mathcal{E})$. For a semibounded quadratic form $\mathcal{E}$, one considers the inner product given by $\langle \xi, \eta \rangle_\lambda := \mathcal{E}(\xi, \eta) + \lambda \langle \xi, \eta \rangle$, for $\lambda > b$. The form $(\mathcal{E}, D(\mathcal{E}))$ is *closed* if $D(\mathcal{E})$ is a Hilbert space for some of the above inner products. The form $(\mathcal{E}, D(\mathcal{E}))$ is called *closable* if it admits a closed extension.

Associated to a semibounded closed form $(\mathcal{E}, D(\mathcal{E}))$, there are a self-adjoint operator $(H, D(H))$ and a strongly continuous, symmetric semigroup $\{T_t\}_{t \geqslant 0}$. Each of the above objects determines uniquely the others according to well-known relations (see Ref. 20 and Sec. 3.1 of Ref. 3).

Let us denoted by $\mathrm{Proj}(\xi, Q)$ the projection of the vector $\xi \in \mathcal{H}^J$ onto the closed, convex cone $Q \subset \mathcal{H}^J$. For $\xi, \eta \in \mathcal{H}^J$, define

$$\xi \vee \eta := \mathrm{Proj}(\xi, \eta + \mathcal{P}),$$

$$\xi \wedge \eta := \mathrm{Proj}(\xi, \eta - \mathcal{P}).$$

A J-real, real-valued, densely defined quadratic form $(\mathcal{E}, D(\mathcal{E}))$ is called *Markovian* with respect to $\xi_0 \in \mathcal{P}$ if

$$\xi \in D(\mathcal{E})^J \text{ implies } \xi \wedge \xi_0 \in D(\mathcal{E}) \text{ and } \mathcal{E}[\xi \wedge \xi_0] \leqslant \mathcal{E}[\xi],$$

where $D(\mathcal{E})^J := D(\mathcal{E}) \cap \mathcal{H}^J$. A closed Markovian form is called a *Dirichlet form*.

Next, we collect main results of Ref. 7. Let $(\mathcal{E}, D(\mathcal{E}))$ be a J-real, real valued, densely defined closed form. Assume that the following properties hold:

$$\text{(a)} \quad \xi_0 \in D(\mathcal{E}),$$

$$\text{(b)} \quad \mathcal{E}(\xi, \xi) \geqslant 0 \quad \text{for } \xi \in D(\mathcal{E}), \tag{2.1}$$

$$\text{(c)} \quad \xi \in D(\mathcal{E})^J \quad \text{implies } \xi_\pm \in D(\mathcal{E}) \quad \text{and } \mathcal{E}(\xi_+, \xi_-) \leqslant 0.$$

Then $(\mathcal{E}, D(\mathcal{E}))$ is a Dirichlet form if and only if $\mathcal{E}(\xi, \xi_0) \geqslant 0$ for all $\xi \in D(\mathcal{E}) \cap \mathcal{P}$. The above result follows from Proposition 4.5 (b) and Proposition 4.10 (ii) of Ref. 7. The following is one of main results (Theorem 4.11) of Ref. 7: Let $\{T_t\}_{t \geqslant 0}$ be a J-real, strongly continuous, symmetric semigroup on $\mathcal{H}$ and let $(\mathcal{E}, D(\mathcal{E}))$ be the associated densely defined J-real, real valued quadratic form. Then the following are equivalent:

$$\text{(a)} \quad \{T_t\}_{t \geqslant 0} \text{ is sub-Markovian.}$$

$$\text{(b)} \quad (\mathcal{E}, D(\mathcal{E})) \quad \text{is a Dirichlet form.}$$

We refer the reader to Ref. 7 for the details.

Next, we describe the construction of Dirichlet forms developed in Ref. 1. See also Ref. 2. For any $\lambda > 0$, denote by I_λ the closed strip given by

$$I_\lambda = \{z: z \in \mathbb{C}, |\mathrm{Im}\, z| \leqslant \lambda\}. \tag{2.2}$$

Recall that an analytic function $f: D \to \mathbb{C}$ on a domain D containing the strip $I_{1/4}$ is called *admissible* if the following properties hold:

$$\text{(a)} \quad f(t) \geqslant 0 \quad \text{for } \forall\, t \in \mathbb{R},$$

$$\text{(b)} \quad f(t+i/4) + f(t-i/4) \geqslant 0 \quad \text{for } \forall\, t \in \mathbb{R},$$

$$\text{(c)} \quad \text{there exist } M > 0 \text{ and } p > 1 \text{ such that the bound} \tag{2.3}$$

$$|f(t+is)| \leqslant M(1+|t|)^{-p}$$

holds uniformly in $s \in [-1/4, 1/4]$.

We also consider the function $f_0 : \mathbb{R} \to \mathbb{R}$ given by

$$f_0(t) = 2(e^{2\pi t} + e^{-2\pi t})^{-1}. \tag{2.4}$$

One can see that f_0 has an analytic extension, denoted by f_0 again, to the interior of $I_{1/4}$.

For any $\lambda > 0$, denote by $\mathcal{M}_\lambda$ the dense subset of $\mathcal{M}$ consisting of every σ_t-analytic element with a domain containing I_λ. By Proposition 2.5.21 of Ref. 3, any $A \in \mathcal{M}_\lambda$ is strongly analytic on I_λ. We denote by $\mathcal{M}_0$ the dense subset of $\mathcal{M}$ consisting of every σ_t-entire analytic element, i.e., $\mathcal{M} = \cap_\lambda \mathcal{M}_\lambda$.

Let I be a finite or countable (index) set. For given family $\{x_k : k \in I\} \subset \mathcal{M}_{1/2}$ of self-adjoint elements in $\mathcal{M}_{1/2}$ and an admissible function f or $f = f_0$, define a sesquilinear form by

$$D(\mathcal{E}) = \left\{ \xi \in \mathcal{H} : \sum_{k \in I} \mathcal{E}_k(\xi, \xi) < \infty \right\}, \tag{2.5}$$

$$\mathcal{E}(\eta, \xi) = \sum_{k \in I} \mathcal{E}_k(\eta, \xi), \tag{2.6}$$

where for each $k \in I$,

$$\mathcal{E}_k(\eta, \xi) = \int \langle (\sigma_{t-i/4}(x_k) - j(\sigma_{t-i/4}(x_k)))\eta, (\sigma_{t-i/4}(x_k) - j(\sigma_{t-i/4}(x_k)))\xi \rangle f(t) \mathrm{d}t. \tag{2.7}$$

For each $k \in I$, the above form is positive and bounded. In fact, the form $(\mathcal{E}_k, \mathcal{H})$ is a Dirichlet form for each $k \in I$ by Theorem 3.1 of Ref. 1. See also Theorem 2.1 of Ref. 2 for $f = f_0$. Moreover, if $D(\mathcal{E})$ is dense in $\mathcal{H}$, then the form $(\mathcal{E}, D(\mathcal{E}))$ given in (2.6) is a Dirichlet form by Theorem 5.2 of Ref. 7.

Before proceeding further, we would like to make a few remarks. The function f_0 given in (2.5) played a special role in Ref. 2. The symmetric embedding of a general Lindblad type (bounded) generator of a quantum dynamical semigroup (satisfying KMS symmetry) on $\mathcal{M}$ can be written as the Dirichlet operator associated to a Dirichlet form in (2.6) with $f = f_0$. Next, we would like to mention that it is not necessary to assume that each x_k in $\{x_k : k \in I\}$ is self-adjoint if one defines the Dirichlet form $(\mathcal{E}_k, \mathcal{H})$ in (2.7) appropriately as in (2.6) of Ref. 2. Note that, by a simple transformation, one can write $\mathcal{E}_k(\eta, \xi)$ as a sum of two Dirichlet forms corresponding with two self-adjoint elements. See Remark 2.1 (a) in Ref. 2. Thus without loss of the generality, we assume that each x_k is self-adjoint.

A family $\{x_k : k \in I\}$ is said to *generate* $\mathcal{M}$ if the $*$-algebra generated by $\{x_k : k \in I\}$ is dense in $\mathcal{M}$. For given $\{x_k : k \in I\} \subset \mathcal{M}_{1/2}$ of self-adjoint elements and either an admissible function f or else $f = f_0$, let $(\mathcal{E}, D(\mathcal{E}))$ be the Dirichlet form defined as in (2.5)–(2.7). Denote by $(H, D(H))$ and $\{T_t\}_{t \geqslant 0}$ the Dirichlet operator and Markovian semigroup associated to $(\mathcal{E}, D(\mathcal{E}))$, i.e., $T_t = e^{-tH}$. We denote by $\mathcal{N}$ the fixed point space of T_t,

$$\mathcal{N} := \{\eta \in \mathcal{H} : T_t\eta = \eta\} = \{\eta \in \mathcal{H} : H\eta = 0\}. \tag{2.8}$$

The following is the main result in this paper.

Theorem 2.1: *For a family* $\{x_k : k \in I\} \subset \mathcal{M}_{1/2}$ *of self-adjoint elements and an admissible function* f *or else* $f = f_0$, *let* $(\mathcal{E}, D(\mathcal{E}))$ *be the densely defined Dirichlet form given as in (2.5)–(2.7). Assume that* $\{x_k : k \in I\}$ *generates* $\mathcal{M}$. *Then the equality*

$$\mathcal{N} = [\mathcal{Z}(\mathcal{M})\xi_0]$$

holds, where $\mathcal{Z}(\mathcal{M})$ *is the center of* $\mathcal{M}$, *i.e.*, $\mathcal{Z}(\mathcal{M}) = \mathcal{M} \cap \mathcal{M}'$, *and* $[\mathcal{Z}(\mathcal{M})\xi_0]$ *is the closure of* $\mathcal{Z}(\mathcal{M})\xi_0$.

Recall that a symmetric, strongly continuous, positive preserving semigroup $\{T_t\}_{t\geqslant 0}$ on $\mathcal{H}$ is called *ergodic* if for each $\xi, \eta \in \mathcal{P}, \xi, \eta \neq 0$, there exists $t > 0$ such that $\langle \xi, T_t\eta \rangle > 0$.[18] Assume that $\inf \sigma(H)$ is an eigenvalue of the generator H of $\{T_t\}_{t\geqslant 0}$. Then the ergodicity of $\{T_t\}_{t\geqslant 0}$ is equivalent to that $\inf \sigma(H)$ is a simple eigenvalue of H with a strictly positive (cyclic and separating) eigenvector (Theorem 4.3 of Ref. 18). As a consequence of Theorem 2.1, we have the following.

Corollary 2.1: Let $\mathcal{M}$ *be a factor, i.e.*, $\mathcal{Z}(\mathcal{M}) = \mathbb{C}\mathbf{1}$. *Let* $(\mathcal{E}, D(\mathcal{E}))$ *be the densely defined Dirichlet form as in Theorem 2.1 and* T_t *the associated Markovian semigroup. Under the assumptions as in Theorem 2.1,* $\{T_t\}_{t\geqslant 0}$ *is ergodic in the sense that zero is a simple eigenvalue of the generator* H *of* T_t *with eigenvector* ξ_0.

Proof: Under the assumptions, $\mathcal{N} = \mathbb{C}\xi_0$ by Theorem 2.1. Since $j(\sigma_{t-i/4}(x))\xi_0 = \sigma_{t-i/4}(x)\xi_0$, it follows from (2.7) that $\mathcal{E}_k(\xi_0, \xi_0) = 0$ for each $k \in I$ and so $\mathcal{E}(\xi_0, \xi_0) = 0$, which implies that $H\xi_0 = 0$. See also Theorem 3.1 (a) of Ref. 1. Hence zero is a simple eigenvalue of H with eigenvector ξ_0.

□

We will produce the proof of Theorem 2.1 in the next section. Before closing this section, it may be worth to give comments on possible applications of Theorem 2.1.

Remark 2.1: (a) In order to apply Theorem 2.1 (and Corallary 2.1) to concrete models, one must choose a family $\{x_k : k \in I\} \subset \mathcal{M}_{1/2}$ *which generates* $\mathcal{M}$. *Recall that the condition* $x_k \in \mathcal{M}_{1/2} \subset \mathcal{M}_{1/4}$ *for each* x_k *is needed for* $(\mathcal{E}_k, \mathcal{H})$ *to be well defined. If* $\mathcal{H}$ *is a finite dimensional Hilbert space, then the modular operator* Δ *is bounded and so every element* x *of* $\mathcal{M}$ *is* σ_t*-entire analytic. In general, it would be not easy to choose a generating family* $\{x_k : k \subset I\}$ *from* $\mathcal{M}_{1/2}$ *directly*.

(b) For quantum spin systems in the region of high temperatures, every local observable belongs to $\mathcal{M}_{1/2}$. *In this case, the choice of* $\{x_k : k \in I\}$ *is easy. See Sec. IV for the details*.

(c) Let $\{f_n : n \in \mathbb{N}\}$ *be an orthonormal basis for* $L^2(\mathbb{R}^d)$ *and let* $a^*(f_n)$ *and* $a(f_n)$, $n \in \mathbb{N}$, *be the creation and annihilation operators which generate a CAR algebra* $\mathcal{A}$. *Let* ω *be a quasifree state on* $\mathcal{A}$ *and* $(\mathcal{H}_\omega, \pi_\omega(\mathcal{A}), \Omega_\omega)$ *be the cyclic representation associated to* $(\mathcal{A}, \omega)$. *Let* $\mathcal{M} = \pi_\omega(\mathcal{A})''$ *and* $\xi_0 = \Omega_\omega$. *Then for each* $n \in \mathbb{N}$, $\pi_\omega(a(f_n))$ *and* $\pi_\omega(a^*(f_n))$ *are* σ_t*-entire analytic element.*[11] *Thus one can apply Theorem 2.1 and Corollary 2.1 directly in this case*.

(d) In applications to open systems[4] *and quantum statistical mechanics,*[3] *one may need to construct a Dirichlet form for a given* $\{x_k : k \in I\}$, *where each* x_k *is unbounded (self-adjoint) operator affiliated with* $\mathcal{M}$. *By employing appropriate approximation procedures, one may be able to construct the Dirichlet form associated to* $\{x_k : k \in I\}$ *(Refs. 16 and 10) and then extend Theorem 2.1 by modifying the method used in this paper*.

III. PROOF OF THEOREM 2.1

Before producing the proof of Theorem 2.1, we first describe the basic ideas used in the proof, and then establish necessary technical lemmas which will be needed in the proof. Using the lemmas, we complete the proof at the last part of this section.

The inclusion $[\mathcal{Z}(\mathcal{M})\xi_0] \subset \mathcal{N}$ is easy to check. See the proof of Theorem 2.1. Thus we concentrate to the inclusion $\mathcal{N} \subset [\mathcal{Z}(\mathcal{M})\xi_0]$. Note that $\eta \in \mathcal{N}$ if and only if $\mathcal{E}[\eta] = \langle H^{1/2}\eta, H^{1/2}\eta \rangle$

$=0$. Since $\mathcal{E}_k[\eta]\geqslant 0$ for $\eta\in\mathcal{H}$, $k\in I$, $\eta\in\mathcal{N}$ if and only if $\mathcal{E}_k[\eta]=0$ for any $k\in I$. Since f is an admissible function or else $f=f_0$, it is easy to show that $\mathcal{E}_k[\eta]=0$ if and only if

$$\|(\sigma_{t-i/4}(x_k)-j(\sigma_{t-i/4}(x_k)))\eta\|=0$$

for any $t\in\mathbb{R}$ and $k\in I$. See Lemma 3.1. The above implies that

$$\|(\sigma_{-i/4}(x_k)-j(\sigma_{-i/4}(x_k)))\eta\|=0,\quad k\in I. \tag{3.1}$$

Suppose that η is of the form $\eta=\Delta^{1/4}Q\xi_0$, $Q\in\mathcal{M}$. Then the above equality implies that

$$[x_k,Q]\xi_0=0,\quad \forall\, k\in I$$

and so

$$[x_k,Q]A'\xi_0=0,\quad \forall\, k\in I$$

for any $A'\in\mathcal{M}'$. Since $\mathcal{M}'\xi_0$ is dense in $\mathcal{H}$, we conclude that $[x_k,Q]=0$ for $k\in I$. Since $\{x_k:k\in I\}$ generates $\mathcal{M}$, $Q\in\mathcal{M}'$. Thus $Q\in\mathcal{M}\cap\mathcal{M}'$ and $\eta=\Delta^{1/4}Q\xi_0=Q\xi_0$. However, in general $\eta\in\mathcal{N}$ cannot be written as $\eta=\Delta^{1/4}Q\xi_0$, $Q\in\mathcal{M}$.

Note that H is J-real, $JH=HJ$, and so $J\mathcal{N}=\mathcal{N}$. Any $\eta\in\mathcal{H}$ can be written as $\eta=\eta_r+i\eta_i$, where $\eta_r=(\eta+J\eta)/2$ and $\eta_i=-i(\eta-J\eta)/2$. Thus $\eta\in\mathcal{N}$ implies η_r, $\eta_i\in\mathcal{N}$. Hence we may suppose that $\eta\in\mathcal{N}\cap\mathcal{H}^J$. Because of the Dirichlet property, (2.1) (c), of $\mathcal{E}[\eta]$, it can be shown that $\eta\in\mathcal{N}\cap\mathcal{H}^J$ implies η_+, $\eta_-\in\mathcal{N}\cap\mathcal{P}$ [Lemma 3.2 (d)]. Thus the problem is reduced to the case $\eta\in\mathcal{N}\cap\mathcal{P}$.

Any $\eta\in D(\Delta^{-1/4})\cap\mathcal{P}$ can be written as $\eta=\Delta^{1/4}Q\xi_0$ where Q is positive self-adjoint operator affiliated with $\mathcal{M}$ (Lemma 3.4). For any $\eta\in D(\Delta^{-1/4})\cap(\mathcal{N}\cap\mathcal{P})$, $\eta=\Delta^{1/4}Q\xi_0$, we use (3.1) to show that

$$(x_kQ-Qx_k)\xi_0=0.$$

Using the facts that $\mathcal{M}'\xi_0$ is dense in $\mathcal{H}$ and that $\{x_k:k\in I\}$ generates $\mathcal{M}$, we will show that Q is affiliated with $\mathcal{M}'$. Since $\Delta\xi=\xi$ for any $\xi\in[\mathcal{Z}(\mathcal{M})\xi_0]$, we conclude that $\eta\in[\mathcal{Z}(\mathcal{M})\xi_0]$. Next, we use the fact that $D(\Delta^{-1/4})\cap(\mathcal{N}\cap\mathcal{P})$ is dense in $(\mathcal{N}\cap\mathcal{P})$ (Lemma 3.3) to complete the proof of Theorem 2.1.

Next, we collect technical lemmas which will be used in the sequel. In the rest of this section, we assume that the conditions in the theorem hold.

Lemma 3.1: A vector $\eta\in\mathcal{H}$ belongs to $\mathcal{N}$ if and only if the equality

$$(\sigma_{t-i/4}(x_k)-j(\sigma_{t-i/4}(x_k)))\eta=0$$

holds for any $t\in\mathbb{R}$ and $k\in I$.

Proof: Since

$$\langle\eta,H\eta\rangle=\mathcal{E}(\eta,\eta)=\sum_{k\in I}\mathcal{E}_k(\eta,\eta),$$

and $\mathcal{E}_k(\eta,\eta)\geqslant 0$ for $\eta\in\mathcal{H}$ and $k\in I$, $H\eta=0$ if and only if $\mathcal{E}_k(\eta,\eta)=0$. Recall the expression of $\mathcal{E}_k(\eta,\eta)$ in (2.7). Notice that $f_0(t)>0$ for any $t\in\mathbb{R}$ by (2.4). If f is an admissible function, $f(t)\geqslant 0$ by (2.3) (a). Since f is analytic on a domain containing $I_{1/4}$, $f(t)>0$ except on a countable set with no accumulation points. Thus the left-hand side of the expression in the lemma is zero except on a countable set of $t\in\mathbb{R}$. Since $\sigma_{t-i/4}(x_k)$ is strongly continuous with respect to $t\in\mathbb{R}$, we proved the lemma. □

Lemma 3.2: (a) $\mathcal{N}$ is a closed subspace of $\mathcal{H}$.

(b) $\Delta^{it}\mathcal{N}=\mathcal{N}$, $\forall t\in\mathbb{R}$.

(c) $J\mathcal{N}=\mathcal{N}$.

(d) $\eta\in\mathcal{N}\cap\mathcal{H}^J$ implies η_+, $\eta_-\in\mathcal{N}\cap\mathcal{P}$.

Proof: (a) Since H is self-adjoint (closed), (a) is obvious.

(b) Notice that

$$H\Delta^{-is}\eta = \Delta^{-is}(\Delta^{is}H\Delta^{-is})\eta$$

and $\Delta^{is}H\Delta^{-is}$ is the Dirichlet operator associated to the Dirichlet form constructed with $\{\sigma_s(x_k): k \in I\}$. Note that $\sigma_{t-i/4}(\sigma_s(x_k)) = \sigma_{t+s-i/4}(x_k)$. Thus, if $\eta \in \mathcal{N}$, $\Delta^{-is}\eta \in \mathcal{N}$ by Lemma 3.1. Hence $\Delta^{-is}\mathcal{N} \subset \mathcal{N}$ for any $s \in \mathbb{R}$, which also implies $\mathcal{N} \subset \Delta^{is}\mathcal{N}$ for any $s \in \mathbb{R}$.

(c) Since each $\mathcal{E}_k$ is J-real [Theorem 2.1 (b) of Ref. 2], it is easy to check that H is J-real, $JH = HJ$. Thus $HJ\eta = JH\eta = 0$ if $\eta \in \mathcal{N}$ and so $J\mathcal{N} \subset \mathcal{N}$. Since $J^2 = \mathbf{1}$, we also have that $\mathcal{N} \subset J\mathcal{N}$.

(d) Let $\eta \in \mathcal{N} \cap \mathcal{H}^J$, and $\eta = \eta_+ - \eta_-$. Notice that

$$0 = \mathcal{E}(\eta, \eta) = \mathcal{E}(\eta_+, \eta_+) - 2\mathcal{E}(\eta_+, \eta_-) + \mathcal{E}(\eta_-, \eta_-).$$

Here we have used the fact that $\eta \in D(\mathcal{E})$ implies $\eta_+, \eta_- \in D(\mathcal{E})$. Since $\mathcal{E}(\eta_+, \eta_-) \leqslant 0$ by (2.1) (c) [Theorem 2.1 (c) of Ref. 2], we have that $\mathcal{E}(\eta_+, \eta_+) = \mathcal{E}(\eta_-, \eta_-) = 0$, which imply $H\eta_+ = H\eta_- = 0$.

□

Lemma 3.3: (a) For any bounded, positive definite, continuous function $f: \mathbb{R} \to \mathbb{R}$,

$$f(\log \Delta)(\mathcal{N} \cap \mathcal{P}) \subset \mathcal{N} \cap \mathcal{P}.$$

(b) $(\cap_{\alpha \in \mathbb{R}} D(\Delta^\alpha)) \cap (\mathcal{N} \cap \mathcal{P})$ is dense in $\mathcal{N} \cap \mathcal{P}$.

Proof: (a) Let f be a bounded, positive definite, continuous function on $\mathbb{R}$. Then f can be written as

$$f(x) = \int e^{itx}\, \mathrm{d}\mu(t),$$

where μ is a positive finite Borel measure on $\mathbb{R}$. Thus

$$f(\log \Delta) = \int \Delta^{it}\, \mathrm{d}\mu(t).$$

The inclusion

$$f(\log \Delta)\mathcal{P} \subset \mathcal{P}$$

holds by the fact that $\Delta^{it}\mathcal{P} \subset \mathcal{P}$ (Proposition 2.5.26 of Ref. 3). Due to Lemma 3.2 (b), the inclusion

$$f(\log \Delta)\mathcal{N} \subset \mathcal{N}$$

also holds. This proved the part (a) of the lemma.

(b) Let

$$f_n(x) := e^{-x^2/2n^2}.$$

Then by the part (a) of the lemma,

$$f_n(\log \Delta)(\mathcal{N} \cap \mathcal{P}) \subset \mathcal{N} \cap \mathcal{P}.$$

For any $\eta \in \mathcal{N} \cap \mathcal{P}$, $f_n(\log \Delta)\eta \in D(\Delta^\alpha)$ for any $\alpha \in \mathbb{R}$, and $f_n(\log \Delta)\eta \to \eta$ as $n \to \infty$. This proved the part (b).

□

Lemma 3.4: Let $\eta \in D(\Delta^{-1/4}) \cap \mathcal{P}$. Then there is a positive self-adjoint operator Q affiliated with $\mathcal{M}$ such that $Q\xi_0 \in D(\Delta^{1/4})$ and $\eta = \Delta^{1/4}Q\xi_0$.

Proof: We use the method similar to that employed in the proof of Proposition 2.5.27 (1) of Ref. 3. Let $\eta \in D(\Delta^{-1/4}) \cap \mathcal{P}$. For any $A \in \mathcal{M}$, $\Delta^{-1/4}j(A^*)j(A)\xi_0 \in \mathcal{P}$ and so

$$\langle \Delta^{-1/4} j(A^*) j(A) \xi_0, \eta \rangle \geqslant 0, \quad \forall A \in \mathcal{M},$$

which implies

$$\langle j(A^*) j(A) \xi_0, \Delta^{-1/4} \eta \rangle \geqslant 0, \quad \forall A \in \mathcal{M}.$$

Define an operator $\tilde{Q}$, $D(\tilde{Q}) = \mathcal{M}'\xi_0$, by

$$\tilde{Q} j(B) \xi_0 = j(B) \Delta^{-1/4} \eta, \quad \forall B \in \mathcal{M}.$$

Then for any unitary $U' \in \mathcal{M}'$,

$$U' \tilde{Q} j(B) \xi_0 = U' j(B) \Delta^{-1/4} \eta = \tilde{Q} U' j(B) \xi_0,$$

and so

$$U'^* \tilde{Q} U' = \tilde{Q}.$$

For any $A \in \mathcal{M}$,

$$\langle j(A)\xi_0, \tilde{Q} j(A) \xi_0 \rangle = \langle j(A)\xi_0, j(A)\Delta^{-1/4}\eta \rangle = \langle \Delta^{-1/4} j(A^*) j(A) \xi_0, \eta \rangle \geqslant 0.$$

Thus $\tilde{Q}$ is a positive symmetric operator. Notice that for any unitary $U' \in \mathcal{M}'$, $U' D(\tilde{Q}) \subset D(\tilde{Q})$. Let Q be the Friedrichs extension of $\tilde{Q}$. By the uniqueness of Friedrichs extension

$$U'^* Q U' = Q$$

for any unitary $U' \in \mathcal{M}'$. Thus Q is affiliated with $\mathcal{M}$. Since $Q\xi_0 = \Delta^{-1/4}\eta$, $Q\xi_0 \in D(\Delta^{1/4})$, and $\eta = \Delta^{1/4} Q \xi_0$.

□

Lemma 3.5: Let $\eta \in D(\Delta^{-1/4}) \cap (\mathcal{N} \cap \mathcal{P})$ *and* $\eta = \Delta^{1/4} Q \xi_0$ *as in Lemma 3.4. Then* $x_k \xi_0 \in D(Q)$ *and* $x_k Q \xi_0 = Q x_k \xi_0$ *for any* $k \in I$.

Proof: Since $\eta \in \mathcal{N}$, it follows from Lemma 3.1 that

$$[\sigma_{-i/4}(x_k) - j(\sigma_{-i/4}(x_k))] \Delta^{1/4} Q \xi_0 = 0, \quad k \in I.$$

Recall that $\mathcal{M}_0$ is the dense subset of $\mathcal{M}$ consisting of σ_t-entire analytic elements. For any $A \in \mathcal{M}_0$,

$$\begin{aligned} 0 = \langle \sigma_{i/4}(A)\xi_0, [\sigma_{-i/4}(x_k) - j(\sigma_{-i/4}(x_k))]) \Delta^{1/4} Q \xi_0 \rangle &= \langle \sigma_{i/4}(x_k)\sigma_{i/4}(A)\xi_0, \Delta^{1/4} Q \xi_0 \rangle \\ &- \langle j(\sigma_{i/4}(x_k))\sigma_{i/4}(A)\xi_0, \Delta^{1/4} Q \xi_0 \rangle. \end{aligned} \tag{3.2}$$

For any $A \in \mathcal{M}_0$,

$$\sigma_{i/4}(x_k)\sigma_{i/4}(A)\xi_0 = \sigma_{i/4}(x_k A)\xi_0 = \Delta^{-1/4} x_k A \xi_0 \tag{3.3}$$

and

$$j(\sigma_{i/4}(x_k))\sigma_{i/4}(A)\xi_0 = j(\sigma_{i/4}(x_k)) j(\sigma_{-3i/4}(A^*))\xi_0 = \Delta^{-1/4} j(\sigma_{i/2}(x_k)) j(\sigma_{-i/2}(A))\xi_0 = \Delta^{-1/4} j(\sigma_{i/2}(x_k)) A \xi_0. \tag{3.4}$$

Substituting (3.3) and (3.4) into (3.2), we have

$$\langle A\xi_0, [x_k - j(\sigma_{-i/2}(x_k))] Q \xi_0 \rangle = 0$$

for any $A \in \mathcal{M}_0$ and $k \in I$. Since $\mathcal{M}_0 \xi_0$ is dense in $\mathcal{H}$,

$$[x_k - j(\sigma_{-i/2}(x_k))]Q\xi_0 = 0.$$

Since Q is affiliated with $\mathcal{M}$, $j(\sigma_{-i/2}(x_k))Q\xi_0 = Qj(\sigma_{-i/2}(x_k))\xi_0 = Qx_k\xi_0$, and so $x_k\xi_0 \in D(Q)$ and $x_kQ\xi_0 = Qx_k\xi_0$.

□

Next, we use Lemma 3.4 and Lemma 3.5 to prove the following result.

Proposition 3.1: Let $\eta \in D(\Delta^{-1/4}) \cap (\mathcal{N} \cap \mathcal{P})$. *Then there is a positive self-adjoint operator* Q *affiliated with* $\mathcal{Z}(\mathcal{M})$ *such that* $\eta = Q\xi_0$.

Proof: Let $\eta = \Delta^{1/4}Q\xi_0$ as in Lemma 3.4. Due to Lemma 3.5,

$$x_kQ\xi_0 = Qx_k\xi_0, \quad \forall\, k \in I.$$

Since $x_k \in \mathcal{M}_{1/2} \subset \mathcal{M}$ and Q is affiliated with $\mathcal{M}$,

$$x_kQj(A)\xi_0 = j(A)x_kQ\xi_0 = j(A)Qx_k\xi_0 = Qx_kj(A)\xi_0$$

for any $A \in \mathcal{M}$, and so

$$x_kQj(A)\xi_0 = Qx_kj(A)\xi_0, \quad \forall\, A \in \mathcal{M}.$$

Notice that for any $x_{k_1}, x_{k_2} \in \{x_k : k \in I\}$

$$x_{k_1}x_{k_2}Qj(A)\xi_0 = x_{k_1}Qx_{k_2}j(A)\xi_0 = x_{k_1}Qj(A)j(\sigma_{-i/2}(x_{k_2}))\xi_0 = Qx_{k_1}j(A)j(\sigma_{-i/2}(x_{k_2}))\xi_0 = Qx_{k_1}x_{k_2}j(A)\xi_0. \tag{3.5}$$

Let $\tilde{\mathcal{M}}$ be the $*$-algebra generated by $\{x_k : k \in I\}$. Then $\tilde{\mathcal{M}}$ is dense in $\mathcal{M}$ by the assumption in Theorem 2.1. The relation (3.5) implies that for any $x \in \tilde{\mathcal{M}}$,

$$xQj(A)\xi_0 = Qxj(A)\xi_0, \quad \forall\, A \in \mathcal{M}.$$

For given $x \in \mathcal{M}$, choose a sequence $x_n \in \tilde{\mathcal{M}}$ such that $x_n \to x$ strongly. Then

$$Qx_nj(A)\xi_0 = x_nQj(A)\xi_0 \to xQj(A)\xi_0 \quad \text{as } n \to \infty.$$

Due to the closedness of Q and the fact that $x_nj(A)\xi_0 \to xj(A)\xi_0$ as $n \to \infty$, we conclude that $xj(A)\xi_0 \in D(Q)$ and

$$xQj(A)\xi_0 = Qxj(A)\xi_0 \tag{3.6}$$

for any $x, A \in \mathcal{M}$.

Denote by

$$(\mathcal{M} \times \mathcal{M}')\xi_0 := \{AA'\xi_0 : A \in \mathcal{M}, A' \in \mathcal{M}'\}.$$

By (3.6), $(\mathcal{M} \times \mathcal{M}')\xi_0 \in D(Q)$ and for any $A_1, A_2 \in \mathcal{M}$ and $A_1', A_2' \in \mathcal{M}'$,

$$A_1QA_2A_2'\xi_0 = A_1A_2QA_2'\xi_0 = QA_1A_2A_2'\xi_0 \tag{3.7}$$

and

$$A_1'QA_2A_2'\xi_0 = QA_2A_1'A_2'\xi_0 = QA_1'A_2A_2'\xi_0. \tag{3.8}$$

Let Q_0 be the restriction of Q on $(\mathcal{M} \times \mathcal{M}')\xi_0$. Then Q_0 is a positive symmetric operator. It follows from (3.7) and (3.8) that for any unitary $U \in \mathcal{M}$, $U' \in \mathcal{M}'$,

$$U^*Q_0U = Q_0,$$

$$U'^{*}Q_0U' = Q_0. \tag{3.9}$$

Notice that U and U' leave $(\mathcal{M}\times\mathcal{M}')\xi_0$ invariant. Let $\hat{Q}$ be the Friedrichs of Q_0. By the uniqueness of Friedrichs extension,

$$U^{*}\hat{Q}U = \hat{Q},$$

$$U'^{*}\hat{Q}U' = \hat{Q},$$

for any unitary $U\in\mathcal{M}$, $U'\in\mathcal{M}'$. Thus $\hat{Q}$ is affiliated with $\mathcal{Z}(\mathcal{M})$. By the inclusions $\mathcal{M}'\xi_0\subset(\mathcal{M}\times\mathcal{M}')\xi_0\subset D(Q)$ and the uniqueness of the Friedrichs extension, $\hat{Q}=Q$. Since $\Delta\xi=\xi$ for any $\xi\in[\mathcal{Z}(\mathcal{M})\xi_0]$, $\eta=\Delta^{1/4}Q\xi=Q\xi_0$. This completes the proof of the proposition.

□

We are ready to prove Theorem 2.1.

Proof of Theorem 2.1: The inclusion

$$[\mathcal{Z}(\mathcal{M})\xi_0]\subset\mathcal{N} \tag{3.10}$$

is easy to prove as follows: Let $\xi\in\mathcal{Z}(\mathcal{M})\xi_0$. Then $\xi=A\xi_0$ for some $A\in\mathcal{Z}(\mathcal{M})$. Thus

$$[\sigma_{t-i/4}(x_k)-j(\sigma_{t-i/4}(x_k))]A\xi_0 = A[\sigma_{t-i/4}(x_k)-j(\sigma_{t-i/4}(x_k))]\xi_0 = 0.$$

By Lemma 3.1, $\xi\in\mathcal{N}$. Since $\mathcal{N}$ is closed by Lemma 3.2 (a), the closure of $\mathcal{Z}(\mathcal{M})\xi_0$ is a subspace of $\mathcal{N}$. This proved the inclusion (3.10).

Next, we prove the inclusion

$$\mathcal{N}\subset[\mathcal{Z}(\mathcal{M})\xi_0]. \tag{3.11}$$

Any $\eta\in\mathcal{N}$ can be written as $\eta=\eta_r+i\eta_i$, where $\eta_r=(\eta+J\eta)/2$ and $\eta_i=-i(\eta-J\eta)/2$. By Lemma 3.2 (c), $\eta_r,\eta_i\in\mathcal{N}$. Note that $\|\eta\|^2=\|\eta_r\|^2+\|\eta_i\|^2$. Thus we may assume that η is J-real, $\eta\in\mathcal{N}\cap\mathcal{H}^J$. η is decomposed uniquely as $\eta=\eta_+-\eta_-$, $\eta_+,\eta_-\in\mathcal{P}$ and $\eta_+\perp\eta_-$. See Proposition 2.5.28 (3) of Ref. 3. By Lemma 3.2 (d), $\eta_+,\eta_-\in\mathcal{N}\cap\mathcal{P}$. Lemma 3.3 (b) implies that $D(\Delta^{-1/4})\cap(\mathcal{N}\cap\mathcal{P})$ is dense in $\mathcal{N}\cap\mathcal{P}$. Thus Lemma 3.3 (b) and Proposition 3.1 imply that η_+, $\eta_-\in[\mathcal{Z}(\mathcal{M})\xi_0]$, and so $\eta\in[\mathcal{Z}(\mathcal{M})\xi_0]$. This completes the proof of Theorem 2.1.

□

IV. ERGODICITY OF MARKOVIAN SEMIGROUPS FOR QUANTUM SPIN SYSTEMS

In this section, we first describe the translation invariant Markovian semigroups for quantum spin systems constructed in Ref. 1, and then apply Theorem 2.1 (and Corollary 2.1) to show the ergodicity of the semigroups in the region of high temperatures where the uniqueness of the KMS state holds.

Let us describe quantum spin systems briefly. For details, we refer to Sec. 6.2 of Ref. 3. Let $\mathbb{Z}^d$ be a d-dimensional lattice space and let $\mathcal{F}$ denote the family of all finite subsets of $\mathbb{Z}^d$. Let $\mathcal{A}$ be a C^*-algebra with norm $\|\cdot\|$ defined as the inductive limit over a finite-dimensional matrix algebra $\mathbb{M}$. For any $X\in\mathcal{F}$, let $\mathcal{A}_X$ denote the subalgebra localized in X, i.e., the subalgebra in $\mathcal{A}$ isomorphic to $\mathbb{M}^X$. An element $A\in\mathcal{A}$ will be called *local* if there is some $Y\in\mathcal{F}$ such that $A\in\mathcal{A}_Y$. By $\mathcal{A}_0$ we denote the subset of all local elements, i.e., $\mathcal{A}_0=\cup_{X\in\mathcal{F}}\mathcal{A}_X$.

Let $\Phi:=\{\Phi_X\}_{X\in\mathcal{F}}$ be an interaction, i.e., a family of self-adjoint element in $\mathcal{A}$. Suppose that

$$\|\Phi\|_\lambda := \sup_{i\in\mathbb{Z}^d}\sum_{X\in\mathcal{F}:i\in X} e^{\lambda|X|}\|\Phi_X\| < \infty \tag{4.1}$$

for some $\lambda>0$, where $|X|=\mathrm{card}(X)$. Define a derivation δ by

$$D(\delta) = \mathcal{A}_0,$$
$$\delta(A) = -i \sum_{X \cap \Lambda \neq \emptyset} [\Phi_X, A], \quad A \in \mathcal{A}_\Lambda. \tag{4.2}$$

Then $\mathcal{A}_0$ is a norm-dense $*$-subalgebra of analytic element of the closure $\bar{\delta}$ of δ. Thus $\bar{\delta}$ generates one-parameter group of $*$-automorphism τ of $\mathcal{A}$. Let ω be a τ-KMS state corresponding to the interaction Φ.

Let $(\mathcal{H}_\omega, \pi_\omega, \Omega_\omega)$ be the GNS representation of $(\mathcal{A}, \omega)$. For the standard form, we choose $\mathcal{H}=\mathcal{H}_\omega$, $\mathcal{M}=\pi_\omega(\mathcal{A})''$, and $\xi_0=\Omega_\omega$. By the uniqueness of the modular automorphism (see Theorem 5.3.10 of Ref. 3), one may identify $\sigma_t=\tau_t$, $t \in \mathbb{R}$, on $\mathcal{M}$. In this section, we denote by $\mathcal{M}_0$ the algebra of local elements, i.e., $\mathcal{M}_0=\pi_\omega(\mathcal{A}_0)$. Every element $A \in \mathcal{M}_0$ is an analytic element for σ_t. For a given $\lambda > 0$, set $\gamma=\lambda/2\|\Phi\|_\lambda$. Then for any $s \in (-\gamma, \gamma)$ the series

$$\sigma_{is}(A) = \sum_{n=0}^{\infty} \frac{(-is)^n}{n!} \delta^n(A), \quad A \in \mathcal{M}_0, \tag{4.3}$$

converges absolutely, where δ is the derivation given by (4.2). See the proof of Theorem 5.2.4 of Ref. 3. From now on, we assume that Φ is chosen sufficiently small so that $\gamma > 1/2$.

We now turn to Dirichlet form for quantum spin systems.[1] Let $\{\tau_j\}_{j \in \mathbb{Z}^d}$ be the translational automorphism on $\mathcal{M}$ corresponding to the translation of the lattice by vectors $j \in \mathbb{Z}^d$. Let $x^a \in \pi_\omega(\mathbb{M})$, $a=1,2,\ldots,D$, be a basis of $\pi_\omega(\mathbb{M})$ consisting of self-adjoint elements of norm one and let $x_j^a=\tau_j(x^a)$, $j \in \mathbb{Z}^d$. For the family $\{x_j^a : j \in \mathbb{Z}^d, a=1,2,\ldots,D\}$ and an admissible function f (or else f_0), let $(\mathcal{E}, D(\mathcal{E}))$ be the quadratic form defined as in (2.5)–(2.7),

$$D(\mathcal{E}) = \left\{ \xi \in \mathcal{H} : \sum_{j \in \mathbb{Z}^d} \sum_{a=1}^{D} \mathcal{E}_{a,j}[\xi] < \infty \right\},$$
$$\mathcal{E}[\xi] = \sum_{j \in \mathbb{Z}^d} \sum_{a=1}^{D} \mathcal{E}_{a,j}[\xi], \quad \xi \in D(\mathcal{E}), \tag{4.4}$$

where

$$\mathcal{E}_{a,j}[\xi] = \int \|(\sigma_{t-i/4}(x_j^a) - j(\sigma_{t-i/4}(x_j^a)))\xi\|^2 f(t) \mathrm{d}t. \tag{4.5}$$

The following is Theorem 5.1 of Ref. 1.

Theorem 4.1 (Theorem 5.1 of Ref. 1): *Let f be an admissible function such that p in (2.3) (c) is greater than $d+1$, i.e., $p > d+1$. Let the interaction Φ be of finite range and translation invariant. Then the form $(\mathcal{E}, D(\mathcal{E}))$ defined as in (4.4) and (4.5) is a densely defined Dirichlet form which generates a translation invariant, symmetric, Markovian semigroup.*

Remark 4.1: The strongly decay property of i.e., $p > d+1$, has been used to show that $D(\mathcal{E})$ is dense in $\mathcal{H}$. See the proof of Theorem 5.1 of Ref. 1. The function f_0 given in (2.4) decays exponentially fast and so the conclusion in Theorem 4.1 holds for $f=f_0$.

In order to describe the main result, we need to replace Φ by $\beta\Phi$, where β is the inverse temperature. Then the condition $\gamma > 1/2$ is equivalent to $(\lambda/2\beta\|\Phi\|_\lambda) > \frac{1}{2}$. This is, $\beta\|\Phi\|_\lambda < \lambda$. The following is the main result in this section.

Theorem 4.2: *Let f be either an admissible function satisfying the decay property in Theorem 4.1 or else $f=f_0$. Let the interaction Φ be of finite range and translation invariant. For $\{x_j^a : j \in \mathbb{Z}^d, a=1,2,\ldots,D\}$, let $\{T_t\}_{t \geq 0}$ be the translation invariant Markovian semigroup associated to the Dirichlet form defined as in (4.4) and (4.5). Assume that $\beta\|\Phi\|_\lambda$ is sufficiently small so that (τ, β)-KMS state for Φ is unique. Then the Markovian semigroup $\{T_t\}_{t \geq 0}$ is ergodic.*

Remark 4.2: The region of high temperatures where the uniqueness of (τ,β)*-KMS state holds can be given explicitly. For an instance, see Proposition 6.2.25 of Ref. 3. For one-dimensional models with uniform bounded surface energies, the uniqueness of* (τ,β)*-KMS state is independent of temperature (Theorem 6.2.47 of Ref. 3). However, we still need the condition* $\beta\|\Phi\|_\lambda<\lambda$.

Proof of Theorem 4.2: By the condition $\beta\|\Phi\|_\lambda<\lambda$, the series (4.3) converges absolutely on a region containing $[-\beta/2,\beta/2]$. Thus it is easy to see that $\{x_j^a: j\in\mathbb{Z}^d, a=1,2,\ldots,D\}\subset\mathcal{M}_{\beta/2}$. Since the $*$-algebra generated by the family is $\mathcal{M}_0$, which is dense in $\mathcal{M}$, the condition in Theorem 2.1 hold. The uniqueness of the (τ,β)-KMS state ω implies that ω is an extremal (τ,β)-KMS state, and hence a factor state by Theorem 5.3.30 of Ref. 3. Thus $\mathcal{M}$ is a factor, and so $\{T_t\}_{t\geqslant 0}$ is ergodic by Corollary 2.1.

(Received 27 May 2005; accepted 16 September 2005; published online 14 November 2005)

We investigate the behavior of the Green functions of Schrödinger operators near the diagonal. The only nontrivial cases, where the on-diagonal singularities are nonzero and do not depend on the spectral parameter, are two and three dimensions. In the case of two dimensions we show that the singularity is independent of both the scalar and the gauge potentials. In dimension three, we obtain conditions for preserving the singularity under perturbations by nonregular potentials. Some examples illustrating dependence of the singularity on general scalar and gauge potentials are presented. © *2005 American Institute of Physics.*

I. INTRODUCTION

Singularities of the Green functions of quantum-mechanical operators play a crucial role in many branches of theoretical and mathematical physics, from which one should mention first the renormalization procedure of the quantum field theory.[1,2] From the point of view of the high-derivative quantum gravity, the corresponding problem was considered, e.g., in Ref. 3. In particular, in the case of nonminimal coupling of quantum matter to the gravitational background with conical singularities, an operator of the form $H=-\Delta+V$ arises on a Riemannian manifold X. Here Δ is the Laplace-Beltrami operator on X and V represents the nonminimal coupling term $\xi\mathcal{R}$ with the Ricci scalar $\mathcal{R}$. The scalar curvature possesses a distributional behavior at conical singularities,[4] $\mathcal{R}=\mathcal{R}_{\mathrm{reg}}+4\pi(1-\alpha)\delta_M$, where δ_M is a Dirac δ-like potential supported by a submanifold $M\subset X$ and $2\pi(1-\alpha)$ is the angle deficit. As a result, an operator

$$H_M=-\Delta+U+a\delta_M \tag{1.1}$$

arises where $U=\xi\mathcal{R}_{\mathrm{reg}}$ and the coupling constant $a=4\pi\xi(1-\alpha)$ characterizes the interaction with the background field concentrated on M. Operators of such form appear in the investigation of scalar fields with nonminimal coupling on the cosmic string background, in the Euclidean approach to the black hole thermodynamics, in the study of the particle scattering at the Planck scale (see Ref. 4 and references therein). Moreover, in the context of the scattering theory, the potential U can have singularity (e.g., of the Coulomb type) even in the case of a flat manifold X.

We are interested here in the question how to add the singular term δ_M concentrated on a zero-dimensional submanifold M of X to the operator $H_U=-\Delta+U$ (this case covers not only quantum fields with point interactions, but also the case when X is a Cartesian product of two

a)Author to whom correspondence should be addressed. Electronic mail: const@mathematik.hu-berlin.de

manifolds, $X=X_0\times Y$, and M has the form $M_0\times Z$ with M_0 being a discrete subset of X_0). If M is a uniformly discrete subset of X and $\dim X\leqslant 3$, then the Green function $G_M(x,y;\zeta)$ of H_M can be obtained through the Krein resolvent formula in terms of the Green function $G_U(x,y;\zeta)$ for H_U.[5,6] An important ingredient of this formula is the so-called "Krein $\mathcal{Q}$-matrix" (a kind of the Dirichlet-to-Neumann map) $Q_{mn}(z)$, $m,n\in M$; under the name "Wigner $\mathcal{R}$-matrix" it appears in the scattering theory[7] and is used in the charge transport theory.[8] To define the diagonal elements of Q for $\dim X>1$ a renormalization procedure is needed. For smooth U, the renormalized Green function $G_U^{\mathrm{ren}}(x,y;\zeta)$, which must be continuous in the whole $X\times X$, is defined as

$$G_U^{\mathrm{ren}}(x,y;\zeta)=G_U(x,y;\zeta)-S(x,y), \tag{1.2}$$

where the "standard singularity" S has the form $S(x,y)=-(1/2\pi)\log d(x,y)$ if $\dim X=2$, and $S(x,y)=1/4\pi d(x,y)$ if $\dim X=3$ [here $d(x,y)$ is the geodesic distance on X]. Now one can set $Q_{mm}(\zeta)=G_U^{\mathrm{ren}}(m,m;\zeta)$. The corresponding renormalization procedure in the Euclidean case is known long ago, see, e.g., Refs. 9 and 10 for the history and the quantum mechanical treatment. It is important to note that usually one obtains $G_U^{\mathrm{ren}}(x,y;\zeta)$ by a momentum cutoff (an ultraviolet regularization procedure); the result is equivalent to that obtained with the help of a dimensional regularization. In the case of brane coupling to gravity or to a gauge field it is necessary to use a dimensional regularization.[11] It is worthy to add that the strict mathematical treatment of the operators (1.1) has its origins in the paper[12] by Berezin and Faddeev. In the case $\dim X\geqslant 4$ there is no regularization procedure involving a singularity independent of the energy parameter ζ (see Example 7 below). Moreover, if U has a Coulomb-type singularity or if an interaction with a gauge field is present, then the function S in (1.2) is different from the standard one, i.e., $S(x,y)\neq 1/4\pi d(x,y)$ (see Examples 12 and 14 below); similar phenomena related to propagation of waves in strongly inhomogeneous media have been studied recently in Ref. 13.

The main goal of our paper is to investigate in detail the singularity of the Green function for the operator $H_U=H_0+U$ where H_0 is the Bochner-Laplace operator on a Riemannian manifold of dimension $\leqslant 3$ and U is a scalar potential from a wide class of measurable functions. As an important consequence we conclude that the operator of the form (1.1) is well defined in this case. It should be stressed that the operators of this form are used not only in the quantum field theory but they occur often in the single-electron theory of condensed matter physics where H_0 represents the Hamiltonian of an electron in the presence of a time-independent magnetic field, U is a confinement electric potential, and δ_M is an additional potential (e.g., the potential of impurities or of a crystal lattice). The Riemannian manifold with nontrivial curvature can appear in this situation, e.g., as a result of the reduction of a few-electron problem to the single-electron one.[14] Another example of using nontrivial three-dimensional Riemannian manifolds is the simulation of the confinement potential of a quantum dot.[15] The defects in solids were investigated previously by methods of quantum gravity in Ref. 16. New technologies of manufacturing two-dimensional nanostructures with nontrivial geometry[17,18] caused the appearance of mathematical models of such structures where, in particular, the Hamiltonian has the form (1.1) with the δ-term simulating the potential of a short range impurity[19] [if the nanostructure is placed in a magnetic field we must replace Δ in (1.1) by the Bochner Laplacian as above]. Moreover, the properties of the Green function G_U are needed for investigation of explicitly solvable models of the geometric scattering theory[20] or spectral theory of periodic hybrid manifolds.[21]

Our analysis of the singularity for the Green function G_U shows that in dimension two the singular term has the standard form even in the presence of an additional $\mathbf{U}(1)$-gauge potential (Theorem 15). On the other hand, in dimension three, S depends on U modulo a Lebesgue class of functions on X (see Theorem 16) and is defined up only to a continuous additive term (the situation here is completely similar to that for the Krein $\mathcal{Q}$-functions, they are defined up to an additive constant). The concrete value of this term is subject of analysis of a given physical problem and is out of the scope of the present work. We mention only that a possible way to fix the corresponding additive constant is to compare the integrated density of states with the trace of G_U^{ren}. At last but not at least we stress that our main results are new *even for the case of Euclidean spaces* $X=\mathbb{R}^n$.

II. DEFINITIONS AND PRELIMINARIES

Throughout the paper we denote by X a complete connected Riemannian manifold of bounded geometry, which means that the injectivity radius r_{inj} of X is positive and every covariant derivative of the Riemann curvature tensor is bounded. Examples are provided by homogeneous spaces with invariant metrics (in particular, Euclidean spaces), compact Riemannian manifolds and their covering manifolds; for discussion of various properties of such manifolds in the context of differential operators we refer to Ref. 22. The dimension of X we denote by ν; the geodesic distance between $x,y\in X$ will be denoted by $d(x,y)$. For $x\in X$ and $r\geqslant 0$ we use the notation $B(x,r)=\{y\in X: d(x,y)<r\}$; throughout the paper, we suppose $r<r_{\mathrm{inj}}$ for radiuses r of all considered sufficiently small balls. For a measurable function f on X, we denote by $\|f\|_p$ the L^p-norm of f. If K is a bounded operator from $L^p(X)$ to $L^q(X)$, $1\leqslant p,q\leqslant\infty$, then its norm will be denoted by $\|K\|_{p,q}$.

Let $A=A_j\,\mathrm{d}x^j$ be a 1-form on X, for simplicity we suppose here $A_j\in C^\infty(X)$. The functions A_j can be considered as the components of the vector potential of a magnetic field on X. On the other hand, A defines a connection ∇_A in the trivial line bundle $X\times\mathbb{C}\to X$, $\nabla_A u=\mathrm{d}u+iuA$; by $-\Delta_A=\nabla_A^*\nabla_A$ we denote the corresponding Bochner Laplacian. In addition, we consider a real-valued scalar potential U of an electric field on X. This potential will be assumed to satisfy the following conditions:

$$U_+ := \max(U,0)\in L^{p0}_{\mathrm{loc}}(X),\quad U_- := \max(-U,0)\in\sum_{i=1}^{n} L^{pi}(X),$$

$$2\leqslant p_i\leqslant\infty \quad \text{if } \nu\leqslant 3,\quad \nu/2<p_i\leqslant\infty \quad \text{if } \nu\geqslant 4,\quad 0\leqslant i\leqslant n;$$

we stress that p_i as well as n are not fixed and depend on U. The class of such potentials will be denoted by $\mathcal{P}(X)$. Below we will need an approximation of singular potentials by smooth ones; for this purpose the following lemma is useful.

Lemma 1: Let $f\in L^p_{\mathrm{loc}}(X)$, *where* $1\leqslant p<\infty$, *and* $f\geqslant 0$. *Then there is* $g\in C^\infty(X)$ *such that* $g\geqslant 0$ *and* $f-g\in L^q(X)$ *for all* $1\leqslant q\leqslant p$.

Proof: Fix $a\in X$ and for integers n, $n\geqslant 1$, denote $Y_n=B(a,n)\setminus\overline{B}(a,n-1)$. Fix a real sequence a_n, $a_n>0$ such that $\Sigma a_n\leqslant 1$ and denote by f_n the restriction of f to the set Y_n. Since the measure of Y_n is finite, for every n we can find a function g_n, $g_n\in C_0^\infty(X)$, such that $g_n\geqslant 0$, $\mathrm{supp}(g_n)\subset Y_n$, and $\max(\|f_n-g_n\|_p^p,\|f_n-g_n\|_1)\leqslant a_n$. Since the family (Y_n) is locally finite, the pointwise sum $g=\Sigma g_n$ exists and $g\in C_0^\infty(X)$. It is clear that $g\geqslant 0$ and $\max(\|f-g\|_p,\|f-g\|_1)\leqslant 1$, i.e., $f-g\in L^p(X)\cap L^1(X)$. □

We denote by $H_{A,U}$ the operator acting on functions $\phi\in C_0^\infty(X)$ by the rule $H_{A,U}\phi=-\Delta_A\phi+U\phi$. This operator is essentially self-adjoint in $L^2(X)$ and semibounded below,[23] its closure will be also denoted by $H_{A,U}$. By $\mathrm{spec}(H_{A,U})$ we denote the spectrum of $H_{A,U}$ and by $\mathrm{res}(H_{A,U})$ the set of regular points: $\mathrm{res}(H_{A,U})=\mathbb{C}\setminus\mathrm{spec}(H_{A,U})$. Let us denote the resolvent of $H_{A,U}$ by $R_{A,U}(\zeta)$, i.e., $R_{A,U}(\zeta)=(H_{A,U}-\zeta)^{-1}$.

Here we introduce two classes of integral kernels used in the paper. First class, $\mathcal{K}_{\mathrm{cont}}(p)$, $1\leqslant p\leqslant\infty$, consists of all continuous on $X\times X$ functions $K(x,y)$ satisfying for any $r>0$ the condition

$$\lfloor K\rfloor_{p,r} := \max(\sup\mathrm{ess}_{x\in X}\|\chi_{X\setminus B(x,r)}K(x,\cdot)\|_p,\sup\mathrm{ess}_{y\in X}\|\chi_{X\setminus B(y,r)}K(\cdot,y)\|_p)<\infty, \tag{2.1}$$

where χ_A stands for the characteristic function of the set $A\subset X$. The second class, $\mathcal{K}(\alpha,p)$, $0\leqslant\alpha<\nu$, $1\leqslant p\leqslant\infty$, consists of all measurable functions K on $X\times X$ obeying the condition (2.1) and

$$|K(x,y)|\leqslant c\max(1,d(x,y)^{-\alpha}) \quad \text{for a constant } c=c(K)>0. \tag{2.2}$$

We set $\mathcal{K}_{\mathrm{cont}}(\alpha,p):=\mathcal{K}(\alpha,p)\cap C(X\times X\setminus D)$, where D is the diagonal $\{(x,y)\in X\times X: x=y\}$.

The above introduced classes of integral kernels are important due to their relations to the properties of the resolvents $R_{A,U}(\zeta)$; these relationships are stated in the following theorem which is our starting point (see Ref. 23, for the proof).

Theorem 2: *For any* $\zeta \in \mathrm{res}(H_{A,U})$ *the resolvent* $R_{A,U}(\zeta)$ *has an integral kernel* $G_{A,U}(x,y;\zeta)$, *the Green function, which belongs to* $\mathcal{K}_{\mathrm{cont}}(\lambda,q)$, *where* q, $1 \leqslant q \leqslant \infty$, *is arbitrary, and* $\lambda = \nu - 2$ *for* $\nu > 2$, $\lambda \in (0,\nu)$ *is arbitrary for* $\nu = 2$, $\lambda = 0$ *for* $\nu = 1$; *moreover,* $G_{A,U}$ *is continuous in* $X \times X$ *for* $\nu = 1$.

We should point out that the Green function of a Schrödinger operator can violate the conditions (2.1) and (2.2), if the potential U is not from the class $\mathcal{P}(X)$. Even the decay of the Green function for large distances between x and y (the off-diagonal behavior) can be different from the "standard" exponential one coming from the comparison with the Laplacian; a good example is delivered by the one-dimensional inverse harmonic oscillator, whose Green function has only a polynomial decay at infinity (see Appendix A).

Our further calculations will involve a couple of operations with integral kernels introduced above; here we collect some useful estimates which will be used very intensively.

The well-known Gelfand-Dunford-Pettis theorem claims that if K is a bounded operator from $L^p(X)$ to $L^\infty(X)$ with some p, $1 \leqslant p < \infty$, then it is an integral operator and its kernel $K(x,y)$ satisfies the estimate

$$\sup \mathrm{ess}_{x \in X} \|K(x,\cdot)\|_q < \infty, \quad q = (1 - p^{-1})^{-1}. \tag{2.3}$$

Conversely, if a kernel $K(x,y)$ satisfies (2.3), then it is an integral kernel of a bounded operator from $L^p(X)$ to $L^\infty(X)$.

Lemma 3: Let $K_j : L^{q_j}(X) \to L^\infty(X)$, $1 \leqslant q_j < \infty$, *be bounded linear operators with integral kernels* $K_j(x,y)$, $j = 1,2$, *and* $W \in L^{q_1}(X)$, *then for a.e.* $(x,y) \in X \times X$ *the integral* $J(x,y) = \int_X K_1(x,z) W(z) K_2(z,y) \mathrm{d}z$ *exists and* $J(x,y)$ *is an integral kernel of the operator* $K_1 W K_2$.

Proof: The operator $K_1 W K_2$ is bounded from $L^{q_2}(X)$ to $L^\infty(X)$, therefore, it is an integral operator. Let $f \in L^{q_2}(X) \cap C(X)$ such that $f(x) > 0$ for all $x \in X$. Then there holds

$$K_1 W K_2 f(x) = \int_X K_1(x,z) W(z) \int_X K_2(z,y) f(y) \mathrm{d}y \, \mathrm{d}z. \tag{2.4}$$

From the other side, according to the estimates (2.3) for K_1 and K_2, there holds

$$\int_X |K_2(\cdot,y) f(y)| \mathrm{d}y \in L^\infty(X), \quad |W(\cdot)| \int_X |K_2(\cdot,y) f(y)| \mathrm{d}y \in L^{q_1}(X),$$

hence,

$$\int_X |K_1(x,z)| \left(|W(z)| \int_X |K_2(z,y) f(y)| \mathrm{d}y \right) \mathrm{d}z < \infty.$$

By the Fubini

$$\int_X \left(\int_X |K_1(x,z) W(z) K_2(z,y)| \mathrm{d}z \right) f(y) \mathrm{d}y < \infty,$$

and since $f(x) > 0$, the inner integral exists for a.e. $(x,y) \in X \times X$.

Let now f be an arbitrary function from $L^{q_2}(X)$. Repeating the arguments above, we get

$$K_1 W K_2 f(x) = \int_X \left(\int_X K_1(x,z) W(z) K_2(z,y) \mathrm{d}z \right) f(y) \mathrm{d}y \tag{2.5}$$

for a.e. $x \in X$. Therefore J is an integral kernel for $K_1 W K_2$. □

We will often use the estimate given by the lemma below (cf. Ref. 23).

Lemma 4: There exists $r_0>0$ *such that for any* α, r *with* $0<r<r_0$, $0\leqslant\alpha<\nu$, *and* $a,x\in X$ *there holds*

$$\int_{B(a,r)}\frac{\mathrm{d}y}{d(x,y)^{\alpha}}\leqslant cr^{\nu-\alpha} \tag{2.6}$$

with some $c>0$ *depending only on* α.

Our next auxiliary result is the following lemma.

Lemma 5: Let $K\in\mathcal{K}(\alpha,p)$, $1\leqslant p<\infty$, $p\alpha<\nu$, *and* $1/p+1/q=1$, *then* K *is an integral kernel of a bounded operator from* $L^q(X)$ *to* $L^{\infty}(X)$.

Proof: According to the Gelfand-Dunford-Pettis theorem we must prove

$$\sup\operatorname{ess}_{x\in X}\int_X|K(x,y)|^p\,\mathrm{d}y<\infty.$$

Fix r, $0<r<r_0$, and for $x\in X$ expand the integral into two parts,

$$\int_X|K(x,y)|^p\,\mathrm{d}y=\int_{B(x,r)}|K(x,y)|^p\,\mathrm{d}y+\int_{X\setminus B(x,r)}|K(x,y)|^p\,\mathrm{d}y.$$

The first term is estimated by Lemma 4, and the second one is majorated by $\lfloor K\rfloor_{p,r}^p$. □

Lemma 6: Let three measurable functions $K_1(x,y)$, $K_2(x,y)$ *and* $W(x)$ *be given, where* $x,y\in X$. *Denote* $F(x,y,z):=K_1(x,z)W(z)K_2(z,y)$, *and if the integral* $\int_X F(x,y,z)\mathrm{d}z$ *exists, denote it by* $J(x,y)$.

(A) *Let* $K_j\in\mathcal{K}_{\mathrm{cont}}(\alpha_j,p_j)$, $j=1,2$, *and* $W\in L^p(X)$, *such that* $1/p_1+1/p_2+1/p=1$ *and* $p>\nu/(\nu-\max(\alpha_1,\alpha_2))$. *Then* $F(x,y,\cdot)\in L^1(X)$ *for* $x\neq y$, *hence* J *is well defined. Moreover,* $J\in\mathcal{K}_{\mathrm{cont}}(\alpha,\infty)$, *where* $\alpha=\max(p'(\alpha_1+\alpha_2)-\nu,0)$ *with* $1/p+1/p'=1$, *if* $p'(\alpha_1+\alpha_2)\neq\nu$, *and* α *is an arbitrary number from* $(0,\nu)$ *otherwise*.

(B) *Let the conditions of the item* (A) *be satisfied. Assume additionally that* $\alpha_1+\alpha_2<\nu$ *and* $W\in L^q_{\mathrm{loc}}(X)$ *with* $q>\nu/(\nu-\alpha_1-\alpha_2)$. *Then* $F(x,y,\cdot)\in L^1(X)$ *for any* $x,y\in X$ *and* $J\in C(X\times X)$.

(C) *Let* $W\in L^p(X)$, *and* $K_1\in\mathcal{K}_{\mathrm{cont}}(p_1)$, $K_2\in\mathcal{K}_{\mathrm{cont}}(\alpha,p_2)$ *or* $K_1\in\mathcal{K}_{\mathrm{cont}}(\alpha,p_1)$, $K_2\in\mathcal{K}_{\mathrm{cont}}(p_2)$. *Assume additionally that* $1/p+1/p_1+1/p_2=1$ *and* $p>\nu/(\nu-\alpha)$. *Then* $F(x,y,\cdot)\in L^1(X)$ *for any* $x,y\in X$, *and* $J\in C(X\times X)$.

Proof: The proof of the items (A) and (B) is given in Ref. 23.

(C) We give a proof for the case $K_1\in\mathcal{K}_{\mathrm{cont}}(p_1)$ and $K_2\in\mathcal{K}_{\mathrm{cont}}(\alpha,p_2)$; the second case can be considered exactly in the same way.

Let $x,y\in X$; we show first that $F(x,y,\cdot)\in L^1(X)$. Let $r>0$, then for $z\in B(y,r)$ we have

$$|F(x,y,z)|\leqslant ck_1(x,y)W(z)d(y,z)^{-\alpha},\quad k_1(x,y):=\sup_{z\in B(y,r)}K_1(x,z)<\infty,\quad c>0, \tag{2.7}$$

therefore, $F(x,y,\cdot)\in L^1(B(y,r))$ due to the Hölder inequality and our conditions on p. For $z\notin B(y,r)$ due to the Hölder inequality we have the estimate

$$\int_{X\setminus B(y,r)}|F(x,y,z)|\mathrm{d}z\leqslant\left(\int_{X\setminus B(y,r)}|K_1(x,z)|^{p_1}\,\mathrm{d}z\right)^{1/p_1}\lfloor K_2\rfloor_{p_2,r}\|W\|_p,$$

and

$$\int_{X\setminus B(y,r)}|K_1(x,z)|^{p_1}\,\mathrm{d}z\leqslant\int_X|K_1(x,z)|^{p_1}\,\mathrm{d}z=\int_{B(x,r)}|K_1(x,z)|^{p_1}\,\mathrm{d}z+\int_{X\setminus B(x,r)}|K_1(x,z)|^{p_1}\,\mathrm{d}z,$$

where the first term on the right-hand where the first term on the right-hand side is finite due to the continuity of K_1, and the second one is estimated by (2.1). This proves the inclusion $F(x,y,\cdot)\in L^1(X)$.

Now let $x_0, y_0 \in X$, $0<r<R$, and $x \in B(x_0, r/2)$, $y \in B(y_0, r/2)$, then

$$|J(x,y)-J(x_0,y_0)| \leqslant \int_{B(y_0,r)} |F(x,y,z)|\mathrm{d}z + \int_{B(y_0,r)} |F(x_0,y_0,z)|\mathrm{d}x + \int_{X\setminus B(y_0,R)} |F(x,y,z)|\mathrm{d}z + \int_{X\setminus B(y_0,R)} |F(x_0,y_0,z)|\mathrm{d}z + \int_{B(y_0,R)\setminus B(y_0,r)} |F(x,y,z)-F(x_0,y_0,z)|\mathrm{d}z. \tag{2.8}$$

Take $\epsilon>0$ and assume $r<r_0$. For $z \in B(y_0,r)$ we estimate $F(x,y,z)$ as in (2.7), then we get using Lemma 4

$$\int_{B(y_0,r)} |F(x,y,z)|\mathrm{d}z \leqslant c \sup_{\substack{x\in B(x_0,r),\\ y\in B(y_0,r)}} K_1(x,y) \|W\|_p \left[\int_{B(y_0,r)} d(y,z)^{p\alpha/(1-p)}\,\mathrm{d}z\right]^{(p-1)/p} \leqslant Cr^{\nu-\alpha-(1/p)} = o(1)$$

as $r\to 0$. On the other hand,

$$\int_{X\setminus B(x_0,R)} |F(x,y,z)|\mathrm{d}z \leqslant \lfloor K_1\rfloor_{p_1,r} \lfloor K_2\rfloor_{p_2,r} \|\chi_{X\setminus B(x_0,R)} W\|_p = o(1) \quad \text{as } R\to\infty.$$

Finally, we conclude that r can be taken sufficiently small and R sufficiently large, such that the sum of the first four terms on the right-hand side of (2.8) is less than $\epsilon/2$. Now it is sufficient to prove that at these fixed r and R the function

$$\int_{B(y_0,R)\setminus B(y_0,r)} F(x,y,z)\mathrm{d}z$$

is continuous as $x \in B(x_0,r/2)$ and $y \in B(y_0,r/2)$. To do this, we note that with some $C'>0$ the following estimate $|F(x,y,z)| \leqslant C'|W(z)|$ takes place for all $x \in B(x_0,r/2)$, $y \in B(y_0,r/2)$, and $z \in B(y_0,R)\setminus B(y_0,r)$. Since $W \in L^1(B(y_0,R)\setminus B(y_0,r))$, the requested continuity follows from the Lebesgue majorization theorem. □

As it was mentioned in the Introduction, we are going to present the Green function in the form

$$G_{A,U}(x,y;\zeta) = S_{A,U}(x,y) + G^{\mathrm{ren}}_{A,U}(x,y;\zeta),$$

where the second term must be continuous in $X\times X$. Such a representation is trivial in the one-dimensional case, the Green function is continuous, and one can set $S_{A,U}\equiv 0$. In dimensions $\nu \geqslant 4$ the problem makes no sense, as the following example shows.

Example 7 (four-dimensional Laplace operator): Consider the simplest case of the Laplacian in $L^2(\mathbb{R}^4)$. The Green function takes the form

$$G(x,y;\zeta) = \frac{\sqrt{-\zeta}}{4\pi^2|x-y|} K_1(\sqrt{-\zeta}|x-y|),$$

where K_1 is the modified Bessel function of the first order. Near the diagonal $x=y$ one has

$$G(x,y;\zeta) = \frac{1}{4\pi^2|x-y|^2} - \frac{\zeta \log|x-y|}{8\pi^2} + k(x,y;\zeta)$$

with a continuous k. Therefore, for $\zeta_1, \zeta_2 \in \mathrm{res}(-\Delta)$, $\zeta_1 \neq \zeta_2$, the difference

$$G(x,y;\zeta_1) - G(x,y;\zeta_2) \sim \frac{\zeta_2 - \zeta_1}{8\pi^2} \log|x-y|$$

is a discontinuous function, so that the singularity cannot be chosen independent of the spectral parameter.

Therefore, the only nontrivial cases remain $\nu=2$ and $\nu=3$, which we will consider in the present paper.

Example 8 (on-diagonal singularity for the Laplace operator): Here we consider the case $A=0$ and $U=0$, i.e., the case of the Laplace-Beltrami operator $-\Delta$ on the manifold X with $\nu=2$ or $\nu=3$. Denote the Green function of $-\Delta$ by $G(x,y;\zeta)$. Take $y \in X$ and introduce polar coordinates (r_y,ω), $r_y=d(x,y)$, $\omega \in \mathbb{S}^{\nu-1}$, centered at y, then we have in a normal neighborhood W_y of y,

$$-\Delta\psi = -\frac{\partial^2\psi}{\partial r_y^2} + \left(\frac{\nu-1}{r_y} + \theta_y^{-1}\frac{\partial\theta_y}{\partial r_y}\right)\frac{\partial\psi}{\partial r_y},$$

where the function $\theta_y=\theta_y(r_y,\omega)$ is defined in such a way that in W_y, we have $\mathrm{d}x = r_y^{\nu-1}\theta_y(r_y,\omega)\mathrm{d}r_y\,\mathrm{d}\omega$. Since $r_y^{\nu-1}\theta(r_y,\omega)$ is the Jacobian for the inverse to the exponential map in W_y, there holds $\theta_y(0,\omega)\geqslant c_y>0$ and $(\partial/\partial r)\theta_y(0,\omega)=0$ for all $\omega\in\mathbb{S}^{\nu-1}$. Moreover, $\inf c_y>0$ as y runs over a compact set in X.

Denote now

$$S(x,y) = \begin{cases} \dfrac{1}{2\pi}\log\dfrac{1}{d(x,y)}, & \nu=2, \\ \dfrac{1}{4\pi d(x,y)}, & \nu=3, \end{cases}$$

and for a fixed $\zeta\in\mathrm{res}(-\Delta)$ denote $K(x,y) := G(x,y;\zeta) - S(x,y)$. Then there holds

$$(-\Delta-\zeta)K(\cdot,y) = \theta_y^{-1}\frac{\partial\theta_y}{\partial r_y}\frac{\partial}{\partial r_y}S(\cdot,y) - \zeta S(\cdot,y) =: L(x,y). \tag{2.9}$$

It is clear that $L(\cdot,y)\in L^2(W_y)$, hence due to the Sobolev embedding theorem, $x\mapsto K(x,y)$ is continuous in W_y. Let us show that really $K(x,y)$ is continuous in (x,y). To do this, we fix $y_0\in X$ and take $r_0>0$ such that $B(y_0,2r_0)\subset W_{y_0}$. We prove the following assertion:

(CM) *the map* $B(y_0,r_0)\ni y\mapsto L(\cdot,y)\in L^2(B(y_0,r_0))$ *is continuous with respect to the norm topology of the space* $L^2(B(y_0,r_0))$.

Let $\chi\in C^\infty(X)$ such that $\mathrm{supp}\,\chi\subset B(y_0,2r_0)$, $\chi(x)=1$ for $x\in B(y_0,r_0)$, and $0\leqslant\chi(x)\leqslant 1$ for all $x\in X$. Note that $B(y_0,2r_0)$ is a normal neighborhood of y for all $y\in B(y_0,2r_0)$, therefore we can assume that $L(x,y)$ is defined for all $x\in X$ and $y\in B(y_0,2r_0)$. Extend L by zero for $y\notin B(y_0,2r_0)$ and set $T(x,y)=\chi(x)\chi(y)L(x,y)$. It is clear that $T\in\mathcal{K}_{\mathrm{cont}}(\alpha,p)$ where p is arbitrary number with $1\leqslant p\leqslant\infty$, and $\alpha=1$ for $\nu=3$, α is any strictly positive number for $\nu=2$. Using items (A) and (B) of Lemma 6 we can easily show that for every $f\in L^2(X)$ the mapping $B(y_0,r_0)\ni y\to\int_{B(y_0,r_0)}L(x,y)f(y)\mathrm{d}y$ is continuous and the mapping $B(y_0,r_0)\ni y\to\int_{B(y_0,r_0)}|L(x,y)|^2\,\mathrm{d}y$ is also continuous. This proves the assertion (CM). Returning to Eq. (2.9) we see that $K(\cdot,y)$ tends to $K(\cdot,y_0)$ with respect to the topology of $W_2^2(B(y_0,r_0))$. Due to the Sobolev embedding theorem, this implies a uniform convergence in the ball $B(y_0,r)$, i.e.,

$$\lim_{y\to y_0}\sup_{x\in B(y_0,r_0)}|K(x,y)-K(x,y_0)| = 0.$$

This together with the continuity in x proves the required joint continuity in (x,y). Therefore, the functions $S(x,y)$ are suitable on-diagonal singularities of the Laplace operator.

Note that the proof of the separate continuity of the function $K(x,y)$ is considerably simpler and can be found, e.g., in Ref. 24.

III. ON-DIAGONAL BEHAVIOR FOR SINGULAR SCALAR POTENTIALS

Below we will use the notation $L^{p+}_{\mathrm{loc}}(X)=\cup_{q>p}L^q_{\mathrm{loc}}(X)$.

Lemma 9 (singularity is independent of the spectral parameter): Let $\nu=2$ *or* 3, $A\in[C^\infty(X)]^\nu$, $U\in\mathcal{P}(X)$, $\zeta_1,\zeta_2\in\mathrm{res}(H_{A,U})$, *then the difference* $G_{A,U}(x,y;\zeta_1)-G_{A,U}(x,y;\zeta_2)$ *is continuous in* $X\times X$.

Proof: The proof follows from the Hilbert resolvent identity for the kernels, $R_{A,U}(\zeta_1)-R_{A,U}(\zeta_2)=(\zeta_1-\zeta_2)R_{A,U}(\zeta_1)R_{A,U}(\zeta_2)$. The integral kernel $\int_X G_{A,U}(x,z;\zeta_1)G_{A,U}(z,y;\zeta_2)\mathrm{d}z$ of $R_{A,U}(\zeta_1)R_{A,U}(\zeta_2)$ is continuous due to Lemma 6(B). □

The preceding lemma shows that for fixed A and U, the on-diagonal singularity in question exists; for example, as a singularity one can take $G_{A,U}(x,y;\zeta_0)$ for a fixed $\zeta_0\in\mathrm{res}(H_{A,U})$. Our aim is to understand how the singularity depends on A and U.

The following lemma shows that Green functions of Schrödinger operators with smooth potentials have the same on-diagonal singularity.

Lemma 10 (singularity for operator with smooth potentials): Let $\nu=2$ *or* 3, $A\in[C^\infty(X)]^\nu$, $U,V\in\mathcal{P}(X)\cap C^\infty(\Omega)$, *where* Ω *is a domain in* X, *then the difference* $G_{A,U}(x,y;\zeta)-G_{A,V}(x,y;\zeta)$ *has a continuous extension to all points* (x,x), $x\in\Omega$. *In particular, if* $\Omega=X$, *then* $G_{A,U}(x,y;\zeta)-G_{A,V}(x,y;\zeta)\in\mathcal{K}_{\mathrm{cont}}(p)$ *with arbitrary* $p\geqslant 1$.

Proof: Fix a real E sufficiently close to $-\infty$ and take $x_0\in\Omega$. We show that in a neighborhood of (x_0,x_0) in $X\times X$, the difference $F(x,y;E)=G_{A,U}(x,y;E)-G_{A,V}(x,y;E)$ is the restriction of a continuous function in this neighborhood. Due to Lemma 9 the same will hold for all values of the spectral parameter.

Let Ω_0 be a bounded subdomain of Ω and contain x_0; denote $W=U+\chi_{\Omega_0}(V-U)$; it is clear that $W\in\mathcal{P}(X)$. Since $W-U$ is bounded with compact support, one has $R_{A,U}(\zeta)-R_{A,W}(\zeta)=R_{A,U}(\zeta)(W-U)R_{A,W}(\zeta)$, so that the difference

$$G_{A,U}(x,y;E)-G_{A,W}(x,y;E)=\int_X G_{A,U}(x,z;E)(W(z)-U(z))G_{A,W}(z,y;E)\mathrm{d}z$$

is continuous in $X\times X$ according to Lemma 6(B). It remains to show that the function $L(x,y)=G_{A,V}(x,y;E)-G_{A,W}(x,y;E)$ is continuous on $\Omega_0\times\Omega_0$. To do this, let us note that in the sense of distributions the following equality holds:

$$((H_{A,V})_x-E+\overline{(H_{A,V})_y}-E)L(x,y)=(W(x)-V(x))G_{A,W}(x,y;E)+(W(y)-V(y))G_{A,W}(x,y;E), \tag{3.1}$$

where $(H_{A,V})_x$ [respectively, $(H_{A,V})_y$] means that $H_{A,V}$ acts on the first (respectively, the second) argument in L; the bar means that we change the coefficients in $H_{A,V}$ by the complex conjugate ones. The operator in the left-hand side of (3.1) is elliptic in $\Omega_0\times\Omega_0$ with smooth coefficients, while the right-hand term vanishes in $\Omega_0\times\Omega_0$. According to the elliptic regularity theorem L is continuous in $\Omega_0\times\Omega_0$. □

The following Proposition contains our main result on the dependence of the on-diagonal singularity on singularities of the scalar potential.

Proposition 11 (preserving the on-diagonal singularity under singular perturbations): Let $\nu=2$ *or* 3, $A\in[C^\infty(X)]^\nu$, *and* $U_1,U_2\in\mathcal{P}(X)$. *If* $\nu=3$, *assume additionally that* $U_1-U_2\in L^{3+}_{\mathrm{loc}}(X)$. *Then the difference* $G_{A,U_1}(x,y;\zeta)-G_{A,U_2}(x,y;\zeta)$ *is continuous in* $X\times X$ *for any* $\zeta\in\mathrm{res}(H_{A,U_1})\cap\mathrm{res}(H_{A,U_2})$.

Proof: For the sake of brevity we fix A and remove it from the notation, i.e., instead of $G_{A,U}$ we will write G_U, etc.

First of all, using Lemma 1 we choose functions $V_1,V_2\in C^\infty(X)$ semibounded below such that $W_j:=U_j-V_j=\Sigma_{s=1}^{n_j}W_{j,s}$, where $W_{j,s}\in L^{p_{j,s}}$ with $2\leqslant p_{j,s}<\infty$, $s=1,\ldots,n_j$, $j=1,2$.

For $\zeta \in \mathrm{res}(H_{U_1}) \cap \mathrm{res}(H_{U_2})$ the sets $\mathcal{D}_j := (H_{U_j} - \zeta) C_0^\infty(X)$ are dense in $L^2(X)$, because $C_0^\infty(X)$ is an essential domain of both H_{U_1} and H_{U_2}. As $\psi \in \mathcal{D}_j$, one has

$$R_{U_j}(\zeta)\psi - R_{V_j}(\zeta)\psi = R_{V_j}(\zeta) W_j R_{U_j}(\zeta)\psi. \tag{3.2}$$

As the operators on both sides of (3.2) are bounded and coincide on a dense subset, they coincide everywhere, i.e., (3.2) holds for any $\psi \in L^2(X)$. Combining Lemma 3 and Lemma 6(B) we conclude that in the dimension two, the operator on the right-hand side of (3.2) has a continuous integral kernel, which together with Lemma 10 implies the conclusion of the proposition.

Let us consider the dimension three more carefully. To be shorter, we remove the dependence of the resolvents on ζ from the notation. We have the following chain of equalities:

$$\begin{aligned} R_{U_1} - R_{U_2} &= R_{V_1} - R_{V_2} + R_{V_1} W_1 R_{U_1} - R_{V_2} W_2 R_{U_2} = R_{V_1} - R_{V_2} + R_{V_1} W_1 R_{U_1} + R_{V_2} W_2 (R_{U_1} - R_{U_2}) \\ &\quad - R_{V_2} W_2 R_{U_1} = R_{V_1} - R_{V_2} + R_{V_2} W_2 (R_{U_1} - R_{U_2}) + R_{V_2} (W_1 - W_2) R_{U_1} + (R_{V_1} - R_{V_2}) W_1 R_{U_1}. \end{aligned}$$

Therefore, $(1 - R_{V_2} W_2)(R_{U_1} - R_{U_2}) =: L = A + B + C$, where $A := R_{V_1} - R_{V_2}$, $B := R_{V_2}(W_1 - W_2) R_{U_1}$, $C := (R_{V_1} - R_{V_2}) W_1 R_{U_1}$.

Due to Lemma 10, the operator A has an integral kernel from $\mathcal{K}_{\mathrm{cont}}(p)$ with arbitrary p, $p \geqslant 1$. Since $W_1 - W_2 \in L^{3+}_{\mathrm{loc}}(X)$, the operator B has an integral kernel from $\mathcal{K}_{\mathrm{cont}}(\infty)$ due to Theorem 2 and the items (A), (B) of Lemma 6. As $R_{V_2} - R_{V_1} \in \mathcal{K}_{\mathrm{cont}}(p)$ with arbitrary $p \geqslant 1$ (Lemma 10), the integral kernel for C is from $\mathcal{K}_{\mathrm{cont}}(\infty)$ due to Theorem 2 again and the items (A), (C) of Lemma 6. Therefore, the operator L has an integral kernel $L(x,y) = L(x,y;\zeta) \in \mathcal{K}_{\mathrm{cont}}(\infty)$. Now we note that the multiplication by $W_{2,s}$ is a continuous mapping from $L^\infty(X)$ to $L^{p_{2,s}}(X)$. At the same time, as $G_{V_2} \in \mathcal{K}_{\mathrm{cont}}(1,p)$, $p \geqslant 1$, the resolvent R_{V_2} is a bounded operator from each $L^{p_{2,s}}(X)$ to $L^\infty(X)$ due to Lemma 5. Since $L = (1 - R_{V_2} W_2)(R_{U_1} - R_{U_2})$, we can combine Theorem 2 and Lemma 5 to show that the operator L is a bounded map from $L^p(X)$ to $L^\infty(X)$ for any p with $3/2 < p < \infty$. Since $|L(x,y;\zeta)| = |L(y,x;\bar{\zeta})|$, we see from (2.3) that $L(x,y) \in \mathcal{K}_{\mathrm{cont}}(q)$ for any q with $1 < q < 3$.

One can find ζ such that $\|R_{V_2}(\zeta) W_2\|_{\infty,\infty} =: \alpha < 1$ (see Ref. 23), therefore, the operator $1 - R_{V_2} W_2$ acting in $L^\infty(X)$ is invertible and for any $n \in \mathbb{N}$ there holds

$$R_{U_1} - R_{U_2} = \sum_{k=0}^{n-1} (R_{V_2} W_2)^k L + (1 - R_{V_2} W_2)^{-1} (R_{V_2} W_2)^n L. \tag{3.3}$$

Applying iteratively Lemmas 3 and 6(A) and taking into account Theorem 2, we can show that the operators $(R_{V_2} W_2)^k R_{V_2}$ have integral kernels from $\mathcal{K}_{\mathrm{cont}}(\beta_k, \infty)$ with $\beta_k \leqslant 1$. At the same time, all these operators are bounded from $L^p(X)$ to $L^\infty(X)$ for any p with $3/2 < p < \infty$. Using the same arguments as for L above, we conclude that these kernels are in $\mathcal{K}_{\mathrm{cont}}(\beta_k, q)$ for any q with $1 < q < 3$. Applying now Lemma 6 (C) one proves that the first term on the right-hand side has a continuous integral kernel.

Denote $T_n := (1 - R_{V_2} W_2)^{-1} (R_{V_2} W_2)^{n-1} R_{V_2}$; this operator is bounded from each $L^{p_{j,s}}(X)$ to $L^\infty(X)$; due to the Gelfand-Dunford-Pettis theorem, this is an integral operator with an integral kernel $T_n(x,y)$. The second term in (3.3) takes the form $T_n W_2 L$, and by virtue of Lemma 3 this is also an integral operator with the kernel $S_n(x,y) := \int_X T_n(x,z) W_2(z) L(z,y) \mathrm{d}z$. From the other side, one can write $S_n(x,y) = T_n W_2 l_y(x)$, where $l_y(x) := L(x,y)$. Note that for each $y \in X$ there holds $l_y \in L^\infty(X)$, and the operator $T_n W_2$ is a bounded mapping from $L^\infty(X)$ to $L^\infty(X)$ with the norm $\|T_n W_2\|_{\infty,\infty} \leqslant \|(1 - R_{V_2} W_2)^{-1}\|_{\infty,\infty} \cdot \|R_{V_2} W_2\|^n_{\infty,\infty} \leqslant \alpha^n / (1 - \alpha)$.

Now let us fix $x_0 \in X$ and take a bounded open neighborhood Ω of x_0. It is clear that $\|l_y\|_\infty \leqslant c_\Omega$ for all $y \in \Omega$ with a certain $c_\Omega > 0$. Therefore $\sup_{x,y \in \Omega} |S_n(x,y;\zeta)| \leqslant c_\Omega \alpha^n / (1 - \alpha)$. Take $\epsilon > 0$ and choose n such that $c_\Omega \alpha^n / (1 - \alpha) < \epsilon$. From Eq. (3.3) we have in $\Omega \times \Omega$ the relation $G_{U_1}(x,y;\zeta) - G_{U_2}(x,y;\zeta) = K_n(x,y) + \tau_n(x,y)$, where K_n is continuous and $|S_n| < \epsilon$. As ϵ is arbitrary, this means that $G_{U_1}(x,y;\zeta) - G_{U_2}(x,y;\zeta)$ is continuous in $\Omega \times \Omega$. Since $x_0 \in X$ is arbitrary, the lemma is proven. Due to Lemma 9, this holds for all $\zeta \in \mathrm{res}(H_{V_1}) \cap \mathrm{res}(H_{V_2})$. □

The following example shows that the condition $U_1-U_2\in L^{3+}_{\mathrm{loc}}(X)$ cannot be omitted in dimension three.

Example 12 (Coulomb potential in three dimensions): Let $X=\mathbb{R}^3$, $A=0$, and $U=q/|x|$, i.e., $H\equiv H_{A,U}=-\Delta+q/|x|$. Clearly, $U\notin L^{3+}_{\mathrm{loc}}(\mathbb{R}^3)$. The Green function can be calculated explicitly,[25]

$$G(x,y;\zeta)=\frac{\Gamma(1-\kappa)}{4\pi|x-y|}[W_{\kappa,1/2}(\sqrt{-\zeta}\xi)M'_{\kappa,1/2}(\sqrt{-\zeta}\eta)-W'_{\kappa,1/2}(\sqrt{-\zeta}\xi)M_{\kappa,1/2}(\sqrt{-\zeta}\eta)], \tag{3.4}$$

where $\xi:=|x|+|y|+|x-y|$, $\eta:=|x|+|y|-|x-y|$, $\kappa=-q/\sqrt{-4\zeta}$, $M_{\kappa,1/2}$ and $W_{\kappa,1/2}$ are the Whittaker functions,

$$M_{\kappa,1/2}(x)=e^{x/2}x\Phi(a,2;x),\quad W_{\kappa,1/2}(x)=e^{x/2}x\Psi(a,2;x). \tag{3.5}$$

Here $\Phi(a,c;x)$ and $\Psi(a,c;x)$ are the Kummer function and the Tricomi function, respectively. We prove in Appendix B the asymptotics

$$G(x,0;\zeta)=\frac{1}{4\pi|x|}+\frac{q}{4\pi}\log|x|-\frac{\sqrt{-\zeta}}{4\pi}+\frac{q}{4\pi}\left(\psi\left(1+\frac{q}{2\sqrt{-\zeta}}\right)+\log\sqrt{-\zeta}+\log(2/e)+2C_E\right)$$
$$+O(|x|\log|x|). \tag{3.6}$$

Therefore, the singularity for $G(x,y;\zeta)$ contains an unavoidable logarithmic term and is different from the standard three-dimensional singularity.

IV. DEPENDENCE OF THE SINGULARITY ON THE MAGNETIC FIELD

Lemma 13 (singularity due to the magnetic field in two dimensions): Let $\nu=2$, then for any $A\in[C^\infty(X)]^\nu$ the difference $G_{A,0}(x,y;\zeta)-G_{0,0}(x,y;\zeta)$ is continuous in $X\times X$ if $\zeta\in\mathrm{res}(H_{A,0})\cap\mathrm{res}(H_{0,0})$.

Proof: Let x_0 be an arbitrary point of X. We show that the difference $G_{A,0}(x,y;\zeta)-G_{0,0}(x,y;\zeta)$ is continuous in a neighborhood of (x_0,x_0) for at least one value of the spectral parameter ζ; due to Lemma 9 this difference is continuous for all admissible spectral parameters.

Take two sufficiently small numbers r and r_0 with $0<r<r_0$. Fix a function $\phi\in C^\infty_0(X)$ such that $\mathrm{supp}\,\phi\subset B(x_0,r_0)$, $\phi(x)=1$ as $x\in B(x_0,r)$. Denote for brevity $H_0:=H_{0,0}$, $H_1:=H_{A,0}$, $H_2:=H_{\phi A,0}$; the corresponding Green functions will be denoted by G_0, G_1, and G_2, respectively.

In $B(x_0,r)\times B(x_0,r)$ for real ζ sufficiently close to $-\infty$ one has in the sense of distributions

$$(((H_1)_x-\zeta)+((\overline{H_2})_y-\zeta))(G_1(x,y;\zeta)-G_2(x,y;\zeta))=0,$$

therefore, due to the elliptic regularity, the difference $G_1(x,y;\zeta)-G_2(x,y;\zeta)$ is continuous in $B(x_0,r)\times B(x_0,r)$. Now we are going to show that $G_2(x,y;\zeta)-G_0(x,y;\zeta)$ is continuous. Since H_0 and H_2 are uniformly elliptic operators with C^∞-bounded coefficients, we are able to use estimates for the Green functions and their derivatives obtained in Ref. 22. First of all,

$$G_0(x,y;\zeta),\quad G_2(x,y;\zeta)\in\mathcal{K}_{\mathrm{cont}}(\lambda,q) \tag{4.1}$$

for arbitrary $\lambda>0$ and $q\in[1,\infty]$ (see Theorem 2). Moreover, for ζ close to $-\infty$ both these kernels are smooth outside the diagonal $x=y$, and according to (Ref. 22, Theorem A1.3.7) we have

$$|\partial_x G_0(x,y;\zeta)|\leqslant C\left(1+\frac{|\log d(x,y)|}{d(x,y)}\right)e^{-\omega d(x,y)},\quad j=1,2,$$

where ∂ is any first order derivative taken in canonical coordinates, and $C,\omega>0$. Additionally, by (Ref. 22, Theorem A1.2.3) for any $p\geqslant 1$ there exist $\epsilon,C'>0$ such that

$$\sup_x \int_{d(x,y)>r} |\partial_x G_0(x,y;\zeta)|^p e^{\epsilon d(x,y)}\, \mathrm{d}y + \sup_y \int_{d(x,y)>r} |\partial_x G_0(x,y;\zeta)|^p e^{\epsilon d(x,y)}\, \mathrm{d}x \leqslant C', \quad j=1,2.$$

This implies the inclusion

$$\partial_x G_0(x,y;\zeta) \in \mathcal{K}_{\mathrm{cont}(1+\lambda,q),} \tag{4.2}$$

with the same λ and q as in (4.1).

In canonical coordinates in $B(x_0,r_0)$ both H_0 and H_2 are given by symmetric second-order elliptic expressions with the same principal symbol, in particular, the difference $T:=H_2-H_0$ is defined by a first order differential expression, $T=b_1(x)\partial_1+b_2(x)\partial_2+c(x)$, where b_1, b_1, c are compactly supported smooth functions. For the functions of the form $\psi=(H_0-\zeta)\phi$ with $\phi \in C_0^\infty(X)$ we have $(H_2-\zeta)\phi=(H_0+T-\zeta)R_0(\zeta)\psi=(1+TR_0(\zeta))\psi$, therefore, $R_0(\zeta)\psi-R_2(\zeta)\psi = R_2(\zeta)TR_0(\zeta)\psi$. In terms of integral kernels this means

$$\begin{aligned}\int_X G_0(x,y;\zeta)\psi(y)\mathrm{d}y - \int_X G_2(x,y;\zeta)\psi(y)\mathrm{d}y &= \int_X G_2(x,z;\zeta)[b_1(z)\partial_1 + b_2(z)\partial_2 + c(z)] \\ &\quad \times \int_X G_0(z,y;\zeta)\psi(y)\mathrm{d}y\, \mathrm{d}z \\ &= \int_X G_2(x,z;\zeta) \int_X [b_1(z)K_1(z,y;\zeta) + b_2(z)K_2(z,y;\zeta) \\ &\quad + c(z)G_0(z,y;\zeta)]\psi(y)\mathrm{d}y\, \mathrm{d}z, \end{aligned} \tag{4.3}$$

where

$$K_1(z,y;\zeta) := \partial_{z_1} G_0(z,y;\zeta), \quad K_2(z,y;\zeta) := \partial_{z_2} G_0(z,y;\zeta).$$

According to the general theory of elliptic operators, the set $(H_0-\zeta)C_0^\infty(X)$ is dense in all $L^p(X)$ with any p, $1 \leqslant p < \infty$, if ζ is sufficiently close to $-\infty$ (Ref. 22, Sec. A1.2). Due to the estimates (4.1) and (4.2), and Lemma 5, the kernels K_1 and K_2 define bounded operators from $L^q(X)$ to $L^\infty(X)$ for arbitrary $q>2$; denote these operators by $K_1(\zeta)$ and $K_2(\zeta)$. In this notation, the expression on the right-hand side of (4.3) can be rewritten as

$$R_0(\zeta)\psi - R_2(\zeta)\psi = [R_2(\zeta)b_1K_1(\zeta) + R_2(\zeta)b_2K_2(\zeta) + R_2(\zeta)cR(\zeta)]\psi.$$

The operators in both sides are bounded from $L^q(X)$ to $L^\infty(X)$ with any $q>2$ and coincide on a dense subset, therefore, the corresponding kernels coincide, i.e.,

$$\begin{aligned} G_0(x,y;\zeta) - G_2(x,y;\zeta) &= \int_X G_2(x,z;\zeta)b_1(z)K_1(z,y;\zeta)\mathrm{d}z + \int_X G_2(x,z;\zeta)b_2(z)K_2(z,y;\zeta)\mathrm{d}z \\ &\quad + \int_X G_2(x,z;\zeta)c(z)G_0(z,y;\zeta)\mathrm{d}z. \end{aligned} \tag{4.4}$$

By Lemma 6 (B), the function on the right-hand side of (4.4) is continuous. □

The three-dimensional analog of Lemma 13 is not true as the following example shows.

Example 14 (three-dimensional Landau Hamiltonian): Consider in $L^2(\mathbb{R}^3)$ the vector potential of a nonzero uniform magnetic field. By a suitable choice of coordinates one can assume that the field is directed along the x_3 axis, i.e., the magnetic strength vector is $\mathbf{B}=(0,0,2\pi\xi x_3)$, where $\xi > 0$ is the density of the magnetic flux through the plane (x_1,x_2). Choose the symmetric gauge for the magnetic vector potential, $\mathbf{A}(\mathbf{x})=\frac{1}{2}\mathbf{B}\times\mathbf{x}$, then $H:=H_{\mathbf{A},0}$ takes the form

$$H=\left(i\frac{\partial}{\partial x_1}-\pi\xi x_2\right)^2+\left(i\frac{\partial}{\partial x_2}+\pi\xi x_1\right)^2-\frac{\partial^2}{\partial x_3^2},$$

and the corresponding Green function is $G(\mathbf{x},\mathbf{y};\zeta)=\Phi(\mathbf{x},\mathbf{y})F(\mathbf{x}-\mathbf{y};\zeta)$, where

$$F(\mathbf{x};\zeta)=\int_0^\infty \frac{\exp[-\pi|\xi|(\mathbf{x}_\perp^2(e^t-1)^{-1}+\mathbf{x}_\parallel^2 t^{-1}]}{(1-e^{-t})\exp\left[\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right]\sqrt{t}}\mathrm{d}t, \tag{4.5}$$

$\mathbf{x}_\perp=(x_1,x_2,0)$ and $\mathbf{x}_\parallel=(0,0,x_3)$.[26] In Appendix C we prove the asymptotics

$$G(\mathbf{x},\mathbf{y};\zeta)=\frac{e^{i\pi\xi(\mathbf{x}_\perp\wedge\mathbf{y}_\perp)}}{4\pi|\mathbf{x}-\mathbf{y}|}+\frac{1}{4}\left(\frac{|\xi|}{\pi}\right)^{1/2}Z\left(\frac{1}{2};\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)+o(|\mathbf{x}-\mathbf{y}|) \tag{4.6}$$

as $|\mathbf{x}-\mathbf{y}|\to 0$; here $Z(z;u)$ is the generalized Riemann ζ-function (also known as the Hurwitz ζ-function). Therefore, the on-diagonal asymptotics is

$$S(\mathbf{x},\mathbf{y})=\frac{e^{i\pi\xi(\mathbf{x}_\perp\wedge\mathbf{y}_\perp)}}{4\pi|\mathbf{x}-\mathbf{y}|}=\frac{1}{4\pi|\mathbf{x}-\mathbf{y}|}\exp\left(\frac{i\mathbf{B}(\mathbf{x}\times\mathbf{y})}{2}\right).$$

V. SUMMARY OF RESULTS

We summarize some corollaries from the proven assertions in the following two theorems.

Theorem 15 (on-diagonal singularities of the Green functions in dimension two): *On a two-dimensional manifold of bounded geometry X, for any vector potential $A\in[C^\infty(X)]^2$ and scalar potential $U\in\mathcal{P}(X)$, the Green function $G_{A,U}$ of the Schrödinger operator $H_{A,U}=-\Delta_A+U$ has the same on-diagonal singularity as that for the Laplace-Beltrami operator, i.e.,*

$$G_{A,U}(x,y;\zeta)=\frac{1}{2\pi}\log\frac{1}{d(x,y)}+G_{A,U}^{\mathrm{ren}}(x,y;\zeta),$$

where $G_{A,U}^{\mathrm{ren}}$ is continuous on $X\times X$.

Proof: Proposition 11 shows that the singularity does not depend on the scalar potential $U\in\mathcal{P}(X)$, and Lemma 13 shows that it is independent of the magnetic potential. Therefore, the singularity coincides with that for the Laplacian, see Example 8. □

Theorem 16 (on-diagonal singularities of the Green functions in dimension three): *Let X be a three-dimensional manifold of bounded geometry. For $U\in\mathcal{P}(X)$ and $A\in[C^\infty(X)]^3$ consider the Schrödinger operator $H_{A,U}=-\Delta_A+U$ and its Green function $G_{A,U}(x,y;\zeta)$. If $U_1,U_2\in\mathcal{P}(X)$ and $U_1-U_2\in L^{3+}_{\mathrm{loc}}(X)$, then the Green functions G_{A,U_1} and G_{A,U_2} have the same on-diagonal singularity (i.e., $G_{A,U_1}-G_{A,U_2}$ is continuous in $X\times X$). In particular, for any $U\in\mathcal{P}(X)\cap L^{3+}_{\mathrm{loc}}(X)$ there holds*

$$G_{0,U}(x,y;\zeta)=\frac{1}{4\pi d(x,y)}+G_{0,U}^{\mathrm{ren}}(x,y;\zeta), \tag{5.1}$$

where $G_{0,U}^{\mathrm{ren}}$ is continuous in $X\times X$.

Proof: The theorem is a simple corollary of Proposition 11, and the formula (5.1) follows from Example 8. □

Remark 17: Contrary to the two-dimensional case, the singular term of the Green function for the three-dimensional Schrödinger operator $H_{A,U}$ *does* depend on the scalar potential U as well as on the magnetic vector potential A. In particular, if A is the vector potential of a uniform magnetic field $\mathbf{B}$ in $X=\mathbb{R}^3$, then instead of (5.1) we have

$$G_{A,0}(\mathbf{x},\mathbf{y};\zeta)=\frac{1}{4\pi|\mathbf{x}-\mathbf{y}|}\exp\left(\frac{i\mathbf{B}(\mathbf{x}\times\mathbf{y})}{2}\right)+G^{\mathrm{ren}}_{A,0}(\mathbf{x},\mathbf{y};\zeta),$$

see Example 14. On the other hand, the dependence on scalar potentials is shown in Example 12.

APPENDIX A: OFF-DIAGONAL ASYMPTOTICS FOR THE INVERSE HARMONIC OSCILLATOR IN DIMENSION ONE

The Green function $G(x,y;\zeta)$ for the inverse harmonic oscillator $H=-d^2/\mathrm{d}x^2-\omega^2x^2/4$, has the form

$$G(x,y;\zeta)=\frac{e^{i\pi/4}\Gamma\left(\frac{1}{2}-i\zeta\right)}{\sqrt{2\pi\omega}}\times U(-i\zeta/\omega,e^{-i\pi/4}\omega^{1/2}\max(x,y))\times U(-i\zeta/\omega,e^{-i\pi/4}\omega^{1/2}\max(-x,-y)),\tag{A1}$$

where $\Im\zeta>0$ and $U(a,x)$ is the Weber function, see (Ref. 27, Chap. 19). Using (Ref. 27, No. 19.8.1), for large z one obtains $U(a,z)=e^{-z^2/4}z^{-1/2-a}u(z)$, where $\lim_{z\to\infty}u(z)=1$. Returning to the Green function we see that for fixed x and large y one has (assuming $y>x$)

$$G(x,y;\zeta)=\frac{e^{i\pi/4}\Gamma\left(\frac{1}{2}-i\zeta\right)}{\sqrt{2\pi\omega}}U(-i\zeta/\omega,-e^{-i\pi/4}\omega^{1/2}x)\frac{e^{i\omega y^2/4}}{(e^{-i\pi/4}\omega^{1/2}y)^{-i\zeta/\omega+(1/2)}}v(y),$$

where $\lim_{y\to\infty}v(y)\neq 0$. Therefore, for large $|x-y|$ the Green function has only a polynomial decay.

APPENDIX B: ON-DIAGONAL SINGULARITY FOR THE COULOMB HAMILTONIAN

Here we prove the asymptotics (3.6).

We are interested in asymptotics of the functions $x\mapsto G(x,x_0;\zeta)$ as $x\to x_0$ at fixed $\zeta\in\mathrm{res}(H)$ and $x_0\in\mathbb{R}^3$. As the potential is smooth outside the origin, the Green function has the standard on-diagonal asymptotics if $x_0\neq 0$. We consider the case $x_0=0$. We have $M_{\kappa,1/2}(0)=0$, $M'_{\kappa,1/2}(0)=1$, therefore,

$$G(x,0;\zeta)=\frac{\Gamma(1-\kappa)}{4\pi|x|}W_{\kappa,1/2}(2\sqrt{-\zeta}|x|).$$

Consider the following expansions [cf. items 6.1(1) and 6.8(13) in Ref. 28]:

$$\Phi(a,2;x)=1+\frac{a}{2}x+\frac{a(a+1)}{12}x^2+\cdots,$$

$$\begin{aligned}\Psi(a,2;x)&=\frac{1}{x\Gamma(a)}+\Phi(a,2;x)\log x+\sum_{k=0}^{\infty}\frac{\Gamma(a+k)[\psi(a+k)-\psi(1+k)-\psi(2+k)]}{\Gamma(a)(k+1)!k!}x^k\\&=A_{-1}x^{-1}+A_0+A_1x+A_2x^2+\cdots+B_0\log x+B_1x\log x+B_2x^2\log x+\cdots,\end{aligned}$$

where

$$A_{-1}=\frac{1}{\Gamma(a)},\quad A_0=\frac{\psi(a)-\psi(1)-\psi(2)}{\Gamma(a-1)},\quad A_1=\frac{a(\psi(a+1)-\psi(2)-\psi(3))}{2\Gamma(a-1)},$$

$$A_2=\frac{a(a+1)(\psi(a+2)-\psi(3)-\psi(4))}{12\Gamma(a-1)},\quad B_0=\frac{1}{\Gamma(a-1)},\quad B_0=\frac{a}{2\Gamma(a-1)},\quad B_2=\frac{a(a+1)}{12\Gamma(a-1)}.$$

Using (3.5), we get

$$\begin{aligned}W_{\kappa,1/2}(x)&=A_{-1}+\left(A_0-\frac{1}{2}A_{-1}\right)x+B_0x\log x+O(|x^2\log x|)\\&=\frac{1}{\Gamma(a)}+\left(\frac{\psi(a)-\psi(1)-\psi(2)}{\Gamma(a-1)}-\frac{1}{2\Gamma(a)}\right)x+\frac{1}{\Gamma(a-1)}x\log x+O(|x^2\log x|).\end{aligned}$$

Since $\psi(1)=-C_E$, $\psi(2)=1-C_E$, where C_E is the Euler constant, we get (3.6) after some trivial algebra.

APPENDIX C: ON-DIAGONAL SINGULARITY OF THE THREE-DIMENSIONAL LANDAU HAMILTONIAN

In this appendix, we are going to prove the asymptotics (4.6).

Set in the integral (4.5) $\mathbf{x}_\perp=0$ and denote $\mathbf{x}_\parallel=z$. Then after the change of variables $t\to t^2$ in this integral, we obtain

$$G(0,0,z;0,0,0;\zeta)=\frac{|\xi|^{1/2}}{2\pi}\int_0^\infty\frac{\exp(-az^2t^{-2}-ct^2)}{1-e^{-t^2}}\mathrm{d}t,\tag{C1}$$

where $a=\pi|\xi|$ and $c=(1/2)-(\zeta/4\pi|\xi|)$. Represent now $G(0,0,z;0,0,0;\zeta)=f_1(z;\zeta)+f_2(z;\zeta)$, where

$$f_1(z;\zeta)=\frac{|\xi|^{1/2}}{2\pi}\int_0^\infty\frac{\exp(-az^2t^{-2}-ct^2)}{t^2}\mathrm{d}t,$$

$$f_2(z;\zeta)=\frac{|\xi|^{1/2}}{2\pi}\int_0^\infty\left(\frac{1}{1-e^{-t^2}}-\frac{1}{t^2}\right)\exp(-az^2t^{-2}-ct^2)\mathrm{d}t.\tag{C2}$$

Changing the variable $t\to t^{-1}$ and using the relation

$$\int_0^\infty\exp(-bt^2-c/t^2)\mathrm{d}t=\frac{1}{2}(\pi/b)^{1/2}\exp(-2(bc)^{1/2})$$

(see Ref. 29, Sec. V. I, formula 2.3.16.3), we obtain $f_1(z;\zeta)=\exp(-(2\pi|\xi|-\zeta)^{1/2}|z|)/(4\pi|z|)$, or $G(0,0,z;0,0,0;\zeta)=(4\pi|z|)^{-1}+g(z;\zeta)$, where

$$g(z;\zeta)=-\frac{1}{4\pi}(2\pi|\xi|-\zeta)^{1/2}+f_2(z;\zeta).\tag{C3}$$

It is clear that the function g is continuous with respect to z and analytic with respect to ζ, $\zeta\in\mathrm{res}(H_{A,0})$. We can rewrite (C1) in the form

$$\frac{|\xi|^{1/2}}{2\pi}\int_0^\infty\frac{\exp(-\pi|\xi|z^2t^{-1})}{(1-e^{-t})\exp\left(\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right)\sqrt{t}}\mathrm{d}t=\frac{1}{4\pi|z|}+g(z;\zeta).\tag{C4}$$

Let $h(t)=(e^t-1)^{-1}-t^{-1}$; the function h is real analytic on the whole line, $h(t)\to0$ as $t\to+\infty$ and $h(t)\to-1$ as $t\to-\infty$. Therefore, h is bounded on $\mathbb{R}$. Let us represent $F(\mathbf{x};\zeta)$ in the form

$$F(\mathbf{x};\zeta)=\int_0^\infty \frac{\exp(-\pi|\xi|\mathbf{x}^2t^{-1})}{(1-e^{-t})\exp\left[\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right]\sqrt{t}}\mathrm{d}t+\int_0^\infty \frac{\exp(-\pi|\xi|\mathbf{x}^2t^{-1})}{(1-e^{-t})\exp\left[\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right]\sqrt{t}}$$
$$\times\{\exp[-\pi|\xi|\mathbf{x}_\perp h(t)]-1\}\mathrm{d}t\equiv I_1(\mathbf{x},\zeta)+I_2(\mathbf{x},\zeta). \tag{C5}$$

It is easy to show that I_2 is a continuous function in the domain $\mathbf{x}\in\mathbb{R}^3$, $\mathrm{Re}\,\zeta<2\pi|\xi|$. Let us show that $I_2(\mathbf{x},\zeta)\to 0$ locally uniformly with respect to ζ, $\mathrm{Re}\,\zeta<2\pi|\xi|$, as $\mathbf{x}\to 0$. It is sufficient to show that

$$A(\mathbf{x},\zeta)\equiv\int_0^\infty \frac{\exp(-\pi|\xi|\mathbf{x}^2t^{-1})}{(1-e^{-t})\exp\left[\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right]\sqrt{t}}|\exp[-\pi|\xi|\mathbf{x}_\perp^2h(t)]-1|\mathrm{d}t\to 0$$

locally uniformly with respect to $\zeta\in\mathbb{R}$, $\zeta<2\pi|\xi|$, as $\mathbf{x}\to 0$. Fix $\zeta\in\mathbb{R}$, $\zeta<2\pi|\xi|$. Since $\mathbf{x}_\perp^2\leqslant\mathbf{x}^2$, we have $|\exp[-\pi|\xi|\mathbf{x}_\perp^2h(t)]-1|\leqslant\mathrm{const}\,\mathbf{x}^2$ in a neighborhood of the point $(0,0,z)$. Therefore, using (C4), we get

$$A(\mathbf{x},\zeta)\leqslant c\mathbf{x}^2\int_0^\infty \frac{\exp(-\pi|\xi|\mathbf{x}^2t^{-1})}{(1-e^{-t})\exp\left[\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right]\sqrt{t}}\mathrm{d}t\leqslant\frac{|\mathbf{x}|}{|\xi|^{1/2}}+\frac{c\mathbf{x}^2}{|\xi|^{1/2}}f(|\mathbf{x}|,\zeta),$$

and we get the required limit. Using (C4) again, we obtain

$$I_1(|\mathbf{x}|,\zeta)=\frac{1}{|\xi|^{1/2}|\mathbf{x}|}+f(|\mathbf{x}|,\zeta). \tag{C6}$$

Using (C5) and (C6) we get

$$G(\mathbf{x},\mathbf{y};\zeta)=\frac{1}{4\pi}\frac{\exp[\pi i\xi(\mathbf{x}_\perp\wedge\mathbf{y}_\perp)]}{|\mathbf{x}-\mathbf{y}|}+\tilde{F}(\mathbf{x},\mathbf{y};\zeta),$$

where $\tilde{F}(\mathbf{x},\mathbf{y};\zeta)$ is jointly continuous with respect to $(\mathbf{x},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3$ for all $\zeta\in\mathrm{res}(H_{\mathbf{A},0})$.

Denote $Q(\zeta)=\lim_{|\mathbf{x}-\mathbf{y}|\to 0}\tilde{F}(\mathbf{x},\mathbf{y};\zeta)$; this limit is independent of $\mathbf{x}$ and $\mathbf{y}$ since $\tilde{F}(\mathbf{x},\mathbf{y};\zeta)$ is invariant with respect to magnetic translations $T_\mathbf{a}$, $\mathbf{a}\in\mathbb{R}^3$: $T_\mathbf{a}f(\mathbf{x})=\exp[\pi i\xi(\mathbf{a}_\perp\wedge\mathbf{x}_\perp)]f(\mathbf{x}-\mathbf{a})$. From (4.5) we obtain

$$\frac{\partial}{\partial\zeta}Q(\zeta)=\frac{1}{16\pi^2|\xi|^{1/2}}\int_0^\infty \exp\left[\left(\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)t\right](1-e^{-t})^{-1}\sqrt{t}\,\mathrm{d}t.$$

Using Eq. (1.10.4) from Ref. 28 we get $\int_0^\infty t^{s-1}e^{-vt}(1-e^{-t})^{-1}\,\mathrm{d}t=\Gamma(s)\mathrm{Z}(s,v)$ and the obvious relation $\partial Z(s,v)/\partial v=-sZ(s+1,v)$ implies immediately

$$Q(\zeta)=\frac{1}{4}\left(\frac{|\xi|}{\pi}\right)^{1/2}Z\left(\frac{1}{2};\frac{1}{2}-\frac{\zeta}{4\pi|\xi|}\right)+C \tag{C7}$$

with a constant $C\in\mathbb{R}$. To determine C we compare (C7) with (C3) in the limit $\Re\zeta\to-\infty$. Since $Q(\zeta)=g(0;\zeta)$, we have from (C3) and (C2),

$$Q(\zeta)-\frac{1}{4\pi}(2\pi|\xi|-\zeta)^{1/2}\to 0\quad\text{as }\Re\zeta\to-\infty.$$

On the other hand, by the Hermite relation [see (1.10.7) from Ref. 28] there holds $Z(1/2,v)+2v^{1/2}\to 0$ as $\Re v\to+\infty$. Comparing the two last relations with (C7), we get $C=0$. Thus, (4.6) is

proven. Note that the expression for $Q(\zeta)$ was obtained at the physical level of rigor in Ref. 30 and can be found also in Ref. 9.

In this paper we apply the Cartan-Kähler theory of exterior differential systems to solve the Cauchy problem for the integrable system of Lie minimal surfaces and discuss the underlying geometry. One purpose for this work is to show how methods and language from the theory of exterior differential systems may prove to be useful in the study of real analytic initial value problems, especially for gaining insight into the geometric aspects of the initial conditions and the solutions.
 [DOI: 10.1063/1.2116267]

I. INTRODUCTION

The study of surfaces in the framework of Lie sphere geometry was developed to a large extent during the 1920s, mainly by Blaschke and Thomsen. A great deal of material about it can be found in Ref. 1. Over the past years, there has been some renewed interest in the subject due to the fact that many classes of surfaces in Lie geometry have been recognized as integrable systems.[11,12,5] Examples include, among others, diagonally cyclidic surfaces and Lie minimal surfaces.

To put our discussion in context, we recall some facts about Lie geometry. Consider the set of oriented spheres in Euclidean space. If we add to this set the set of oriented planes, the set of point spheres, and the point at infinity, we obtain the space of Lie sphere geometry. This space can be identified with the standard projective quadric $\mathcal{Q}\subset\mathbb{P}^5$ of signature (3,1)—the conformal completion of Minkowski 4-space. Any smooth immersion of an oriented surface in Euclidean space has a contact lift to the unit sphere bundle of $\mathbb{R}^3$ called the Legendre lift. The unit sphere bundle embeds as an open and dense subset into the five-dimensional space Λ of lines lying on $\mathcal{Q}$. Thus the Lie transformation group, that is the projective transformations of $\mathbb{P}^5$ fixing $\mathcal{Q}$, acts on the set of Legendre surfaces. Lie geometry studies the properties of immesions which are invariant under this action. One way to do this is to think of the surface as an envelope of an appropriate congruence of invariant model surfaces. In this case, one attaches to each point p of the surface a Dupin cyclide $D(p)$ having second order contact with the immersion, a so-called Lie cyclide. The map D plays the role of a generalized Gauss map and is the analogue of the conformal Gauss map (central sphere congruence) in Möbius geometry. It defines an immersion into the space $\mathfrak{D}$ of Dupin cyclides, which is identified with the pseudo-Riemannian symmetric space given by the Grassmannian of three-dimensional subspaces of signature (2, 1) in $\mathbb{R}^{4,2}$. The geometric invariants of D are exactly the Lie invariants of the original surface. In particular, its area defines a Lie invariant functional, whose critical points are called Lie minimal surfaces. Actually, the critical points of this functional are characterized by the harmonicity of the generalized Gauss map D,[5] so

[a)]Electronic mail: musso@univaq.it
[b)]Electronic mail: lorenzo.nicolodi@unipr.it

as Willmore surfaces in Möbius geometry are characterized by the harmonicity of the central sphere congruence[3] and L-minimal surfaces in Laguerre geometry by the harmonicity of the middle sphere congruence.[15]

In this paper we discuss the Cauchy problem for Lie minimal surfaces. Application of the Cartan-Kähler theory leads to a description of the space of local real analytic Lie minimal surfaces in terms of six functions in one variable. In addition to the existence and uniqueness result for Lie minimal surfaces satisfying given initial conditions, our main contribution here is that of clarifying the geometry of the Cauchy problem, providing a neat geometric description of the real analytic initial data and of the corresponding solution surface. To do this we use the method of moving frames[9] and the theory of exterior differential systems.[4]

We turn now to a more detailed description of the main result of the paper. Consider an oriented Legendre surface $X \subset \mathbb{R}^3 \times S^2$. Under suitable nondegeneracy conditions, we can introduce on X a canonical Lie-invariant coframe α^1, α^2 (see Ref. 1 and 11). This induces two distinguished geometric structures on the surface, namely the Lorentzian metric $\Phi = \alpha^1 \cdot \alpha^2$ and the 3-web (we refer to Ref. 8 for more details on web geometry) formed by the two families of curvature lines and the family of *cyclidic curves*, defined, respectively, by the equations

$$\alpha^1 = 0, \quad \alpha^2 = 0, \quad \alpha^1 - \alpha^2 = 0.$$

Let $\Gamma \subset \mathbb{R}^3 \times S^2$ be a Legendrian curve, and $\sigma: \Gamma \to \mathcal{Q}$ a one-parameter family of osculating spheres along Γ. For each $(P, \vec{b}) \in \Gamma$, $\sigma(P, \vec{b})$ denotes the sphere in oriented contact at P with the plane through P orthogonal to $\vec{b}$. We are now in a position to state the following.

Theorem 1.1: Let $\Gamma \subset \mathbb{R}^3 \times S^2$ be a real-analytic Legendre curve, σ a generic real-analytic one-parameter family of osculating spheres along Γ, and $k, K: \Gamma \to \mathbb{R}$ real-analytic functions. Then, there exists a unique real-analytic Lie minimal surface $X \subset \mathbb{R}^3 \times S^2$ containing Γ such that

(i) Γ is anticyclidic, i.e., intersects the cyclidic curves of X orthogonally;
(ii) k is the web-curvature of Γ [the web-curvature of Γ is the function $k_\Gamma: \Gamma \to \mathbb{R}$ defined by $k_\Gamma = \Phi(D^w_{\Gamma'}(\Gamma'), \Gamma')$, where D^w denotes the covariant derivative operator associated with the connection of the 3-web and Γ' is a unit tangent vector along Γ];
(iii) $\sigma(\xi)$ is a curvature sphere of X at ξ, for each $\xi \in \Gamma$;
(iv) $K(\xi)$ is the curvature of the 3-web of X at the point ξ, for each $\xi \in \Gamma$.

According to this theorem, the appropriate Cauchy data for the problem are

(i) a curve γ of $\mathbb{R}^3$ and a field $\vec{b}: \gamma \to S^2$ of unit normals along γ;
(ii) a smooth function $r: \gamma \to \mathbb{R}$ which gives the signed radii of the osculating spheres;
(iii) other two additional functions $k, K: \gamma \to \mathbb{R}^3$.

The paper is organized as follows. In Sec. II, we briefly overview some general facts about surface theory in Lie geometry. In Sec. III, we set up an exterior differential system whose integral manifolds can be regarded as framed Lie minimal surfaces. Then, we apply the techniques of the Cartan-Kähler theory to prove the main theorem. In the Appendix we provide the details of the construction of the canonical frames used in the proof of the theorem.

II. SURFACE THEORY IN LIE SPHERE GEOMETRY

In this section, we briefly recall some background material about Lie sphere geometry and develop the method of moving frames for immersed surfaces in this context. A complete treatment of Lie sphere geometry can be found in the classical treatise of Blaschke and Thomsen[1] or in the more recent monograph of Cecil.[6]

A. Basic definitions

Let $\mathbb{R}^{4,2}$ be the vector space $\mathbb{R}^6$ endowed with the nondegenerate scalar product

$$\langle X,Y\rangle = -(x^0y^5 + x^5y^0) - (x^1y^4 + x^4y^1) + x^2y^2 + x^3y^3 = X^t gY, \tag{2.1}$$

where $x^0,\ldots,x^5$ and $y^0,\ldots,y^5$ are the coordinates of the vectors X and Y with respect to the standard basis $(\epsilon_0,\ldots,\epsilon_5)$ of $\mathbb{R}^6$. Let SO(4,2) be the identity component of the group that preserves (2.1) and let G be the quotient of SO(4,2) by its center $\mathbb{Z}_2=\{\pm\mathrm{Id}\}$. For each $A\in \mathrm{SO}(4,2)$, we denote by $A_J=A\cdot\epsilon_J, J=0,\ldots,5$, the column vectors of A. Thus $(A_0,\ldots,A_5)$ is a positive, time-oriented basis of $\mathbb{R}^{4,2}$ such that

$$\langle A_I,A_J\rangle = g_{IJ}, \quad I,J=0,\ldots,5.$$

Expressing the exterior derivatives $\mathrm{d}A_J$ in terms of the basis $(A_0,\ldots,A_5)$, we obtain

$$\mathrm{d}A_J = A_I\otimes\omega^I_J, \quad J=0,\ldots,5, \tag{2.2}$$

where $\omega=(\omega^I_J)$ is the $\mathfrak{o}(4,2)$-valued Maurer-Cartan form $A^{-1}\,\mathrm{d}A$. Taking the exterior derivative of (2.2) yields the structure equations

$$\mathrm{d}\omega + \omega\wedge\omega = 0. \tag{2.3}$$

The elements of $G=\mathrm{SO}(4,2)/\mathbb{Z}_2$ are equivalence classes $[A]$ of matrices $A\in\mathrm{SO}(4,2)$. Since the Maurer-Cartan form ω is bi-invariant under the action of $\mathbb{Z}_2$, we identify the Lie algebra $\mathfrak{g}$ of G with $\mathfrak{o}(4,2)$ and we think of ω as the Maurer-Cartan form of G.

The group G acts transitively on the following three spaces:

(i) the four-dimensional space $\mathcal{Q}\subset\mathbb{RP}^5$ of isotropic one-dimensional linear subspaces of $\mathbb{R}^{4,2}$; $\mathcal{Q}$ is known as the Lie quadric;
(ii) the five-dimensional Grassmannian $\Lambda\subset G_2(\mathbb{R}^6)$ of two-dimensional totally isotropic linear subspaces of $\mathbb{R}^{4,2}$;
(iii) the nine-dimensional Grassmannian $\mathfrak{D}=G_{2,1}(\mathbb{R}^{4,2})$ of all theree-dimensional linear subspaces of signature (2,1) in $\mathbb{R}^{4,2}$.

The geometric meaning of these spaces is the following.

(i) The Lie quadric $\mathcal{Q}$ identifies with the set of oriented spheres in $\mathbb{R}^3$, including point spheres, oriented planes and the "point at infinity." Given a point $P=(p^1,p^2,p^3)\in\mathbb{R}^3$ and a real number r, let $\sigma(P,r)$ denote the oriented sphere with center P and signed radius r. Similarly, for each $P\in\mathbb{R}^3$ and every unit vector $\vec{n}\in S^2$, let $\pi(P,\vec{n})$ denote the oriented plane through P orthogonal to $\vec{n}$. The correspondence between the points of $\mathcal{Q}$ and oriented spheres is given by

$$\sigma(P,r)\mapsto\left[\left(1,\frac{r+p^1}{\sqrt{2}},p^2,p^3,\frac{r-p^1}{\sqrt{2}},\frac{\|P\|^2-r^2}{2}\right)\right],$$

$$\pi(P,\vec{n})\mapsto\left[\left(0,\frac{1+n^1}{2},\frac{n^2}{\sqrt{2}},\frac{n^3}{\sqrt{2}},\frac{1-n^1}{2},\frac{\vec{n}\cdot P}{\sqrt{2}}\right)\right],$$

$$\infty\mapsto\epsilon_5.$$

(ii) To each contact element $\xi=(P,\vec{n})\in\mathbb{R}^3\times S^2$ we associate the null plane

$$\ell(\xi)=[F_0(P)\wedge F_1(P,\vec{n})]$$

generated by the null vectors

$$F_0(P)=\left(1,\frac{1}{\sqrt{2}}p^1,p^2,p^3,-\frac{1}{\sqrt{2}}p^1,\frac{\|P\|}{2}\right),$$

$$F_1(P,\vec{n}) = \left(0, \frac{1+n^1}{\sqrt{2}}, n^2, n^3, \frac{1-n^1}{\sqrt{2}}, \vec{n}\cdot P\right). \tag{2.4}$$

The mapping

$$\xi \in \mathbb{R}^3 \times S^2 \to \ell(\xi) \in \Lambda$$

embeds $\mathbb{R}^3 \times S^2$ as an open and dense subset of $\Lambda \cong T_1 S^3$. Thus, Λ is obtained from $\mathbb{R}^3 \times S^2$ by adding the 2-sphere of null planes through $[\epsilon_5]$ at infinity. Correspondingly, the Lie sphere group G can be viewed as a pseudogroup of contact transformations acting on $\mathbb{R}^3 \times S^2$. (See also Ref. 14)

(iii) Let $V \in \mathfrak{D}$ and consider the two-dimensional torus

$$T(V) = \{([x],[y]) \in \mathbb{P}(V) \times \mathbb{P}(V^\perp) : \|x\|^2 = \|y\|^2 = 0\} \cong S^1 \times S^1.$$

The map $([x],[y]) \in T(V) \mapsto [x \wedge y] \in \Lambda$ is a Legendre immersion and determines a *cyclide of Dupin* in $\mathbb{R}^3$. (We recall that a surface is called a cyclide of Dupin if each principal curvature is constant along its own line of curvature. A torus of revolution is a Dupin cyclide. Dupin cyclides are algebraic surfaces of the fourth order. For more details we refer to Ref. 6.) In the framework of Lie-geometry any cyclide of Dupin arises in this way. Thus, the manifold $\mathfrak{D}$ can be viewed as the space of all Dupin cyclides of $\mathbb{R}^3$. Note that $\mathfrak{D}$ is a pseudo-Riemannian symmetric space G/K of the group G, whose G-invariant pseudo-Riemannian metric $g_{\mathfrak{D}}$ is represented by the tensorial quadratic form

$$2\omega_0^1\omega_1^0 + 2\omega_0^4\omega_4^0 + 2\omega_0^2\omega_2^0 + 2\omega_3^1\omega_1^3 - \omega_2^3\omega_2^3. \tag{2.5}$$

B. Legendre surfaces

Definition 2.1: An oriented immersed surface $X \subset \mathbb{R}^3 \times S^2$ is said to be *Legendre* if $\mathrm{d}f \cdot \vec{n} = 0$, where $f: X \to \mathbb{R}^3$ and $\vec{n}: X \to S^2$ denote the restrictions to X of the natural projections.

Remark 2.2: The basic examples are the contact lifts of oriented immersed surfaces $\widetilde{X} \subset \mathbb{R}^3$. In this case $\vec{n}$ is the usual Gauss map and the embedding is given by $\widetilde{X} \ni P \mapsto (P, \vec{n}|_P) \in \mathbb{R}^3 \times S^2$.

Given a Legendre surface, we consider the quadratic forms

$$\mathrm{I} = \mathrm{d}f \cdot \mathrm{d}f, \quad \mathrm{III} = \mathrm{d}\vec{n} \cdot \mathrm{d}\vec{n}.$$

Definition 2.3: We say that X has no umbilical points if $\mathrm{I}|_\xi$ and $\mathrm{III}|_\xi$ are linearly independent, for every $\xi \in X$.

Remark 2.4: If X is the contact lift of an oriented surface $\widetilde{X} \subset \mathbb{R}^3$, then I and III are the first and the third fundamental forms, respectively. Thus, X has no umbilical points if and only if $\widetilde{X}$ is umbilic free in the usual sense.

If X is umbilic free, there exist *curvature line* coordinates, that is, positive-oriented charts $(\mathcal{U}, x^1, x^2)$ with respect to which I and III are in diagonal form. We have

$$\mathrm{d}f = \phi_1\, \mathrm{d}x^1 \vec{e}_1 + \phi_2\, \mathrm{d}x^2 \vec{e}_2,$$

$$\mathrm{d}\vec{n} = \nu_1\, \mathrm{d}x^1 \vec{e}_1 + \nu_2\, \mathrm{d}x^2 \vec{e}_2, \tag{2.6}$$

where $(\vec{e}_1, \vec{e}_2, \vec{n})$ is a positive-oriented frame field and $\phi_i, \nu_i, i = 1, 2$, are smooth functions such that $(\nu_1\phi_2 - \nu_2\phi_1)|_p \neq 0$, for every $p \in X$.

Definition 2.5: The *curvature spheres* at the point $\xi = (P, \vec{n})$ of X are the oriented spheres $\sigma_i(\xi) \in \mathcal{Q}, i = 1, 2$, represented by the null vectors

$$S_i(\xi) = \phi_i F_0(P) + \nu_i F_1(P, \vec{n}), \quad i = 1, 2.$$

Remark 2.6: If X is the contact lift of an immersed surface $\widetilde{X} \subset \mathbb{R}^3$, then $\sigma_i(P, \vec{n}|_P), i = 1, 2$, give

back the curvature spheres of $\widetilde{X}$ at P corresponding to the principal curvatures.

Definition 2.7 (nondegeneracy condition): We say that a Legendre surface X is *nondegenerate* if it is umbilic free and both the *curvature sphere mappings*

$$\sigma_i: X \ni \xi \mapsto \sigma_i(\xi) \in \mathcal{Q}, \quad i = 1,2$$

are immersions into the Lie quadric $\mathcal{Q}$.

For each $\xi \in X$ there are two *osculating Dupin cyclides* $D_i(\xi), i=1, 2$ (the Lie cyclides) represented by the three-dimensional linear subspaces,

$$D_i(\xi) = [S_i|_\xi \wedge \partial_i S_i|_\xi \wedge \partial_{ii}^2 S_i|_\xi] \in \mathfrak{D}.$$

Definition 2.8: The map $D: \xi \in X \mapsto D_1(\xi) \in \mathfrak{D}$ is called the *generalized Gauss map* of the Legendre surface (see Ref. 1 and 5).

C. Moving frames

Following the usual practice in the method of moving frames, we can construct a canonical lift to the group G for any nondegenerate Legendre surface.

Theorem 2.9: Let $X \subset \mathbb{R}^3 \times S^2 \subset \Lambda$ be a nondegenerate Legendre surface. Then there exists a unique lift $[A]: X \to G$ satisfying the Pfaffian equations

$$\alpha_0^4 = \alpha_0^2 = \alpha_1^3 = \alpha_2^3 = \alpha_0^1 - \alpha_1^2 = \alpha_1^0 - \alpha_0^3 = \alpha_2^0 = \alpha_3^1 = 0, \tag{2.7}$$

with the independence condition

$$\alpha_0^3 \wedge \alpha_1^2 > 0. \tag{2.8}$$

(The proof of this theorem is given in the Appendix. Our canonical frame is related the "Wilczynski frame" introduced by Blaschke[1] and reconsidered by Ferapontov in Ref. 11 and 12. The main difference is a final normalization, which makes our frame independent of the choice of the curvature line coordinates.)

We call $\alpha^1 := \alpha_0^3, \alpha^2 := \alpha_1^2$ canonical or Blaschke's coframe of X (Ref. 1 and 11). It is given by

$$\alpha^1 = \sqrt[3]{3\beta^2\gamma}\, \mathrm{d}x^1, \quad \alpha^2 = \sqrt[3]{3\beta^2\gamma}\, \mathrm{d}x^2, \tag{2.9}$$

where

$$\beta = \frac{\phi_1 \partial_1 \nu_1 - \partial_1 \phi_1 \nu_1}{\phi_2 \partial_2 \nu_2 - \partial_2 \phi_2 \nu_2}, \quad \gamma = \frac{\partial_2 \phi_2 \nu_2 - \phi_2 \partial_2 \nu_2}{\phi_2 \partial_2 \nu_2 - \partial_2 \phi_2 \nu_2}.$$

Remark 2.10: Geometrically, the equations $\alpha^1 = 0$ and $\alpha^2 = 0$ define the curvature lines of the surface. The curvature spheres of the surface at $\xi \in X$ are represented by the null lines $[A_0(\xi)]$ and $[A_1(\xi)]$, respectively, while the two Lie cyclides are represented by the three-dimensional subspaces $[A_0(\xi) \wedge A_3(\xi) \wedge A_5(\xi)]$ and $[A_1(\xi) \wedge A_2(\xi) \wedge A_4(\xi)]$, respectively. Note also that $\Phi := D^*(g_{\mathfrak{D}}) = \alpha^1 \cdot \alpha^2$.

The only nonzero components of the Maurer-Cartan form α of the canonical frame are $\alpha^1 = \alpha_0^3, \alpha^2 = \alpha_1^2$, and $\alpha_0^0, \alpha_1^1, \alpha_2^1, \alpha_1^1, \alpha_3^0, \alpha_4^0$. From the exterior differentiation of (2.7) and the structure equations, it follows that there exist smooth functions q_1, q_2, p_1, p_2, and r_1, r_2 such that

$$\alpha_0^0 = -2q_1\alpha^1 + q_2\alpha^2, \quad \alpha_1^1 = -q_1\alpha^1 + 2q_2\alpha^2,$$

$$\alpha_3^0 = r_1\alpha^1 + p_2\alpha^2, \quad \alpha_2^1 = p_1\alpha^1 + r_2\alpha^2,$$

$$\alpha_4^0 = -r_2\alpha^1 + r_1\alpha^2. \tag{2.10}$$

We call q_1, q_2, p_1, p_2 and r_1, r_2 the *invariant functions* of the Legendre surface. Again using the structure equations, we obtain

$$\mathrm{d}\alpha^1 = \alpha_0^0 \wedge \alpha^1, \quad \mathrm{d}\alpha^2 = \alpha_1^1 \wedge \alpha^2, \quad \mathrm{d}\alpha_2^1 = -\alpha_1^1 \wedge \alpha_2^1, \quad \mathrm{d}\alpha_3^0 = -\alpha_0^0 \wedge \alpha_3^0, \tag{2.11}$$

$$\mathrm{d}\alpha_0^0 = (\alpha^2 - \alpha_3^0) \wedge \alpha^1, \quad \mathrm{d}\alpha_1^1 = (\alpha^1 - \alpha_2^1) \wedge \alpha^2, \quad \mathrm{d}\alpha_4^0 = -(\alpha_0^0 + \alpha_1^1) \wedge \alpha_4^0, \tag{2.12}$$

which in terms of the invariant functions read

$$\mathrm{d}\alpha^1 = -q_2 \alpha^1 \wedge \alpha^2, \quad \mathrm{d}\alpha^2 = -q_1 \alpha^1 \wedge \alpha^2, \tag{2.13}$$

$$\begin{aligned} -2\,\mathrm{d}q_1 \wedge \alpha^1 + \mathrm{d}q_2 \wedge \alpha^2 &= (p_2 - q_1 q_2 - 1)\alpha^1 \wedge \alpha^2, \\ -\mathrm{d}q_1 \wedge \alpha^1 + 2\,\mathrm{d}q_2 \wedge \alpha^2 &= (-p_1 + q_1 q_2 + 1)\alpha^1 \wedge \alpha^2, \\ \mathrm{d}r_1 \wedge \alpha^1 + \mathrm{d}p_2 \wedge \alpha^2 &= (2q_2 r_1 + 3q_1 p_2)\alpha^1 \wedge \alpha^2, \\ \mathrm{d}p_1 \wedge \alpha^1 + \mathrm{d}r_2 \wedge \alpha^2 &= (2q_1 r_2 + 3q_2 p_1)\alpha^1 \wedge \alpha^2, \\ -\mathrm{d}r_2 \wedge \alpha^1 + \mathrm{d}r_1 \wedge \alpha^2 &= 4(q_1 r_1 - q_2 r_2)\alpha^1 \wedge \alpha^2. \end{aligned} \tag{2.14, 2.15}$$

We may consider (2.13)–(2.15) as the Lie sphere analogues of the *Gauss* and *Codazzi-Mainardi* equations.

Remark 2.11: If (x^1, x^2) are curvature line coordinates, then

$$q_1 = -\frac{1}{3\sqrt[3]{\beta^2 \gamma}}(\partial_1(\log \beta) + 2\partial_1(\log \gamma)),$$

$$q_2 = \frac{1}{3\sqrt[3]{\beta \gamma^2}}(2\partial_2(\log \beta) + \partial_2(\log \gamma)),$$

$$p_1 = -\frac{1}{\beta\gamma}\partial_{12}(\log \beta) + 1,$$

$$p_2 = -\frac{1}{\beta\gamma}\partial_{12}(\log \gamma) + 1.$$

From this and from (2.15), we infer that the invariant functions p_1, p_2, r_1, r_2 coincide, up to unessential normalizations, with the local differential invariants k, l, a, b defined by Ferapontov in Ref. 11.

Remark 2.12: With respect to the Blaschke coframe, the connection form of the 3-web is represented by the 1-form

$$\zeta_w = -q_1 \alpha^1 + q_2 \alpha^2,$$

while the Levi-Civita connection of the Lorentzian metric $\Phi = \alpha^1 \cdot \alpha^2$ is given by the 1-form

$$\zeta_\Phi = q_1 \alpha^1 + q_2 \alpha^2.$$

Computing the exterior derivatives of ζ_w and ζ_Φ, we obtain

$$\mathrm{d}\zeta_w = \tfrac{1}{3}(p_2 - p_1)\alpha^1 \wedge \alpha^2, \quad \mathrm{d}\zeta_\Phi = (2 - p_1 - p_2)\alpha^1 \wedge \alpha^2.$$

The respective *sectional curvatures* K_w and K_Φ are given by

$$K_w = \tfrac{1}{3}(p_2 - p_1), \quad K_\Phi = 2 - p_1 - p_2.$$

Definition 2.13: Let $\Gamma \subset X$ be a nonisotropic curve and Γ' a unit vector field tangent to Γ. The *web-curvature* of Γ is the function $k_\Gamma : \Gamma \to \mathbb{R}$ defined by

$$k_\Gamma := \Phi(D^w_{\Gamma'}(\Gamma'), \Gamma'),$$

where D^w denotes the covariant derivative operator associated to the connection of the 3-web.

Remark 2.14: If Γ is an *anticyclidic* curve, that is a solution of the Pfaffian equation $\alpha^1 + \alpha^2 = 0$, then

$$k_\Gamma = \left. \frac{1}{\sqrt{2}}(q_1 + q_2) \right|_\Gamma .$$

D. Lie minimal surfaces

Following Blaschke (see Ref. 1, Sec. 94), we say that a nondegenerate Legendre surface $X \subset \mathbb{R}^3 \times S^2$ is a *Lie minimal surface* (K-Minimalfläche) if the differential equations

$$\mathrm{d}r_1 \wedge \alpha^2 - 4q_1 r_1 \alpha^1 \wedge \alpha^2 = 0,$$

$$\mathrm{d}r_2 \wedge \alpha^1 - 4q_2 r_2 \alpha^1 \wedge \alpha^2 = 0 \tag{2.16}$$

are satisfied. Actually, due to the integrability conditions (2.15), either one of the above differential equations implies the other. Lie minimal surfaces are characterized as critical points of the area functional defined by the generalized Gauss map D (see Ref. 1, Sec. 94, and also Ref. 20).

Recently, this result has been taken up by Burstall and Hertrich-Jeromin,[5] who proved that a nondegenerate Legendre surface X is Lie minimal if and only if its generalized Gauss map D is a conformal harmonic map into the pseudo-Riemannian symmetric space $\mathfrak{D} = G/K$. In the same article, the authors apply the theory of harmonic maps of surfaces to explain the integrable structure of Lie minimal surfaces that was first recognized by Ferapontov in Ref. 11.

Remark 2.15: Note that the canonical frame field $[A] : X \to G$ is also a frame along the generalized Gauss map D. Following Ref. 5, we write $\alpha = \alpha_\mathfrak{k} + \alpha_\mathfrak{p}$ according to the symmetric decomposition $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ of the Lie algebra $\mathfrak{g}$ and set

$$\alpha_p = \alpha'_\mathfrak{p} + \alpha''_\mathfrak{p},$$

where $\alpha'_\mathfrak{p}$ and $\alpha''_\mathfrak{p}$ are the components of $\alpha_\mathfrak{p}$ along the null directions of the quadratic form Φ. The key observation (this follows from the characterization of conformal harmonic maps of Riemannian or Lorentzian surfaces into pseudo-Riemannian symmetric spaces, see for instance Refs. 17, 21, and 22) is that D is conformal and harmonic if and only if the one-parameter family of $\mathfrak{g}$-valued 1-forms

$$\alpha_\mu := \alpha_\mathfrak{k} + e^\mu \alpha'_\mathfrak{p} + e^{-\mu} \alpha''_\mathfrak{p}, \quad \mu \in \mathbb{R},$$

satisfies the Maurer-Cartan equations

$$\mathrm{d}\alpha_\mu + \alpha_\mu \wedge \alpha_\mu = 0. \tag{2.17}$$

It is now an easy matter to check that (2.17) holds true if and only if the invariant functions, in addition to the Gauss-Codazzi-Mainardi equations (2.13)–(2.15), satisfy also the equations (2.16).

Example 2.16: Examples of Lie-minimal surfaces include the analogues of Demoulin surfaces in projective differential geometry (see Refs. 13 and 11). These surfaces are defined by the equations $r_1 = r_2 = 0$. From a geometrical viewpoint, they are characterized by the property that D

has only two distinct enveloping surfaces, the original surface X and the dual surface $\hat{X}$ parametrized by the Legendre map $X \ni \ell \mapsto [A_4(\ell) \wedge A_5(\ell)] \in \Lambda$. Locally, with respect to curvature line coordinates (x_1, x_2), such surfaces satisfy

$$\partial_{12}^2(\log \beta) = \beta\gamma + \frac{1}{\beta}, \quad \partial_{12}^2(\log \gamma) = \beta\gamma + \frac{1}{\gamma}.$$

If, in addition, we require that the 3-web is exagonal (i.e., $K^w=0$), then $\beta=\gamma$ and β is a solution of *Tzitzéica equation*,

$$\partial_{12}^2(\log \beta) = \beta^2 + \frac{1}{\beta}. \tag{2.18}$$

Equation (2.18) possesses finite-gap solutions that can be written in terms of Baker-Akhiezer functions.[7,19] It is interesting to notice that (2.18) appears in various contexts such as affine spheres,[18] classical projective geometry,[2] hypercomplex four-manifolds[10] and minimal Legendre tori in S^5.[19]

Another remarkable class of Lie minimal surfaces is represented by the contact lifts of surfaces in $\mathbb{R}^3$ with plane curvature lines (see Ref. 16). These surfaces can be characterized by having curvature line coordinates (x^1, x^2) such that $\beta=\gamma$, where β is a solution of the *Liouville equation*

$$\partial_{12}^2(\log \beta) = \beta^2.$$

III. THE CAUCHY PROBLEM

A. Setting up the system

Let $P=G\times\mathbb{R}^6$ and let $(q_1, q_2, p_1, p_2, r_1, r_2)$ denote the coordinates on $\mathbb{R}^6$. On P we consider the differential ideal $\mathcal{I} \subset \Omega^*(P)$ generated by the differential 1-forms

$$\eta^1 = \omega_0^4, \quad \eta^2 = \omega_0^2, \quad \eta^3 = \omega_1^3,$$

$$\eta^4 = \omega_2^3, \quad \eta^5 = \omega_0^1 - \omega^2, \quad \eta^6 = \omega_1^0 - \omega^1,$$

$$\eta^7 = \omega_2^0, \quad \eta^8 = \omega_3^1, \tag{3.1}$$

$$\eta^9 = \omega_0^0 + 2q_1\omega^1 - q_2\omega^2,$$

$$\eta^{10} = \omega_1^1 + q_1\omega^1 - 2q_2\omega^2, \tag{3.2}$$

$$\eta^{11} = \omega_3^0 - r_1\omega^1 - p_2\omega^2,$$

$$\eta^{12} = \omega_2^1 - p_1\omega^1 - r_2\omega^2,$$

$$\eta^{13} = \omega_4^0 + r_2\omega^1 - r_1\omega^2, \tag{3.3}$$

and by the exterior differential 2-forms

$$\Theta^1 = \mathrm{d}r_1 \wedge \alpha^2 - 4q_1r_1\alpha^1 \wedge \alpha^2, \quad \Theta^2 = \mathrm{d}r_2 \wedge \alpha^1 - 4q_2r_2\alpha^1 \wedge \alpha^2, \tag{3.4}$$

with the independence condition $\Omega=\omega^1\wedge\omega^2$, where $\omega^1=\omega_0^3$ and $\omega^2=\omega_1^2$. Taking the exterior derivatives of (3.1)–(3.3) and using the structural equations of G, we obtain the *quadratic equations*

$$\mathrm{d}\eta^1 \equiv \cdots \equiv \mathrm{d}\eta^8 \equiv \cdots \equiv \mathrm{d}\eta^{13} \equiv 0 \bmod\{\mathcal{I}\}, \tag{3.5}$$

$$\begin{cases} \mathrm{d}\eta^9 \equiv 2\pi^1\wedge\omega^1 - \pi^2\wedge\omega^2 + (-1+p_2-q_1q_2)\omega^1\wedge\omega^2 \\ \mathrm{d}\eta^{10} \equiv \pi^1\wedge\omega^1 - 2\pi^2\wedge\omega^2 + (1-p_1+q_1q_2)\omega^1\wedge\omega^2 \\ \mathrm{d}\eta^{11} \equiv \zeta^1\wedge\omega^1 + \upsilon^2\wedge\omega^2 - (2r_1q_2+3q_1p_2)\omega^1\wedge\omega^2 \\ \mathrm{d}\eta^{12} \equiv \upsilon^1\wedge\omega^1 + \zeta^2\wedge\omega^2 - (3p_1q_2+2r_2q_1)\omega^1\wedge\omega^2 \end{cases} \mod\{\mathcal{I}\}, \tag{3.6}$$

where $\{\mathcal{I}\}$ denotes the algebraic ideal generated by $\eta^1,\ldots,\eta^{13},\Theta^1,\Theta^2$ and where

$$\pi^i = \mathrm{d}q_i, \quad \upsilon^i = \mathrm{d}p_i, \quad \zeta^i = \mathrm{d}r_i \quad (i=1,2).$$

If we set

$$\begin{aligned} \Omega^1 &= 2\pi^1\wedge\omega^1 - \pi^2\wedge\omega^2 + (-1+p_2-q_1q_2)\omega^1\wedge\omega^2, \\ \Omega^2 &= \pi^1\wedge\omega^1 - 2\pi^2\wedge\omega^2 + (1-p_1+q_1q_2)\omega^1\wedge\omega^2, \\ \Omega^3 &= \zeta^1\wedge\omega^1 + \upsilon^2\wedge\omega^2 - (2r_1q_2+3q_1p_2)\omega^1\wedge\omega^2, \\ \Omega^4 &= \upsilon^1\wedge\omega^1 + \zeta^2\wedge\omega^2 - (3p_1q_2+2r_2q_1)\omega^1\wedge\omega^2, \end{aligned} \tag{3.7}$$

then

$$\{\eta^1,\ldots,\eta^{13},\Theta^1,\Theta^2,\Omega^1,\Omega^2,\Omega^3,\Omega^4,\mathrm{d}\Theta^1,\mathrm{d}\Theta^2\} \tag{3.8}$$

is a set of algebraic generators of the differential ideal $\mathcal{I}$.

An integral manifold of this system is a two-dimensional submanifold $\widetilde{X}\subset P$ such that

$$\eta^a = 0, \quad \Theta^1=\Theta^2=\Omega^1=\Omega^2=\Omega^3=\Omega^4=0, \quad \Omega\neq 0.$$

Thus, if $\widetilde{X}$ is an integral manifold, the map

$$F{:}([A],q_1,q_2,p_1,p_2,r_1,r_2)\in\widetilde{X}\mapsto[A_1\wedge A_2]\in\Lambda \tag{3.9}$$

defines a Lie minimal surface. Conversely, if $X\subset\mathbb{R}^3\times S^2$ is a Lie minimal surface with normal frame field $[A]{:}X\to G$ and invariant functions $q_1,\ldots,r_2$, then

$$([A],q_1,q_2,p_1,p_2,r_1,r_2){:}X\to P, \tag{3.10}$$

is an integral manifold of the differential system $(\mathcal{I},\Omega)$. Thus we have the following.

Proposition 3.1: Lie minimal surfaces may be regarded as the integral submanifolds of the exterior differential system $(\mathcal{I},\Omega)$.

On P, consider the parallelization

$$\left(\frac{\partial}{\partial\omega^i},\frac{\partial}{\partial\eta^a},\frac{\partial}{\partial\pi^i},\frac{\partial}{\partial\upsilon^i},\frac{\partial}{\partial\zeta}\right) \quad (i=1,2;a=1,\ldots,13)$$

dual to the coframe $(\omega^i,\eta^a,\pi^i,\upsilon^i,\zeta^i)$. The one-dimensional integral elements of $(\mathcal{I},\Omega)$ are of the form

$$E_1 = \left[a^1\frac{\partial}{\partial\omega^1} + a^2\frac{\partial}{\partial\omega^2} + y^i\frac{\partial}{\partial\pi^i} + u^i\frac{\partial}{\partial\upsilon^i} + v^i\frac{\partial}{\partial\zeta^i}\right],$$

where $(a^1)^2+(a^2)^2\neq 0$. Contracting $\Theta^1,\Theta^2,\Omega^1,\ldots,\Omega^4$ with E_1, we deduce the polar equations

$$\eta^a = 0 \quad (a=1,\ldots,13),$$

$$2a^1\pi^1 - a^2\pi^2 - (2y^1 + a^2(1-p_2+q_1q_2))\omega^1 + (y^2 + a^1(1-p_2+q_1q_2))\omega^2 = 0,$$

$$a^1\pi^1 - 2a^2\pi^2 - (y^1 - a^2(1 - p_1 + q_1q_2))\omega^1 + (2y^2 - a^1(1 - p_1 + q_1q_2))\omega^2 = 0,$$

$$a^1\upsilon^1 + a^2\zeta^2 - (u^1 + a^2(3p_1q_2 + 2r_2q_1))\omega^1 - (v^2 - a^1(3p_1q_2 + 2r_2q_1))\omega^2 = 0,$$

$$a^2\upsilon^2 + a^1\zeta^1 - (v^1 + a^2(2r_1q_2 + 3q_1p_2))\omega^1 - (u^2 - a^1(2r_1q_2 + 3q_1p_2))\omega^2 = 0,$$

$$a^2\zeta^1 - 4a^2q_1r_1\omega^1 + (4a^1q_1r_1 + v^1)\omega^2 = 0,$$

$$a^1\zeta^2 - (4a^2q_2r_2 + v^2)\omega^1 + 4a^1q_2r_2\omega^2 = 0.$$

From this we see that if E_1 is noncharacteristic (i.e., $a^1a^2 \neq 0$), then the polar space $H(E_1)$ is two dimensional. Thus, from the Cartan-Kähler theorem we obtain the following.

Proposition 3.2: If $\widetilde{\Gamma}$ is a real-analytic integral curve of $(\mathcal{I}, \Omega)$ such that $\omega^1\omega^2|_{\widetilde{\Gamma}} \neq 0$, then there exists a unique real-analytic integral manifold $\widetilde{X}$ such that $\widetilde{\Gamma} \subset \widetilde{X}$.

B. Proof of Theorem 1.1

Let $\Gamma \subset \mathbb{R}^3 \times S^2 \subset \Lambda$ be a Legendre curve and $\sigma: \Gamma \to \mathcal{Q}$ a one-parameter family of osculating spheres along Γ. Then we may parametrize the curve by $\Gamma \ni \ell \mapsto [V_0(\ell) \wedge V_1(\ell)]$, where $V_0, V_1: \Gamma \to \mathbb{R}^{4,2}$ are smooth maps such that

$$\|V_0\| = \|V_1\| = \langle V_0, V_1\rangle = 0, \quad \langle V_0, \mathrm{d}V_1\rangle = 0, \quad \sigma = [V_0]. \tag{3.11}$$

If (we use the notation $\mathrm{d}V = V'\zeta$, where ζ is a nowhere vanishing 1-form on Γ)

$$V_0(\ell) \wedge V_1(\ell) \wedge V_0'(\ell) \wedge V_1'(\ell) \wedge V_0''(\ell) \wedge V_1''(\ell) \neq 0,$$

$$V_0(\ell) \wedge V_0'(\ell) \wedge \cdots \wedge V_0^{(v)}(\ell) \neq 0, \tag{3.12}$$

for every $\ell \in \Gamma$, then $[V_0(\ell) \wedge V_0'(\ell) \wedge V_0''(\ell)] \subset \mathbb{R}^{4,2}$ is a three-dimensional linear subspace of signature (2, 1), for every $\ell \in \Gamma$.

Definition 3.3: If, in addition to (3.12), the map $\delta: \ell \in \Gamma \mapsto [V_0(\ell) \wedge V_0'(\ell) \wedge V_0''(\ell)] \in \mathfrak{D}$ is nonisotropic [i.e., $\delta^*(g_{\mathfrak{D}}) \neq 0$], then σ is said to be *generic*.

Using standard moving frame techniques, we obtain (see the Appendix for a proof of this statement) the following.

Lemma 3.4: Let Γ and σ be as above, then there exists a unique map $[B]: \Gamma \to G$ such that

$$\ell = [B_0(\ell) \wedge B_1(\ell)], \quad \sigma(\ell) = [B_0(\ell)], \quad \forall\, \ell \in \Gamma \tag{3.13}$$

and that

$$B^{-1}\,\mathrm{d}B = (\mathcal{B}_{-1} + k_0\mathcal{B}_0 + k_1\mathcal{B}_1 + k_2\mathcal{B}_2 + k_3\mathcal{B}_3)\mu, \tag{3.14}$$

where μ is a nowhere vanishing 1-form, k_0, k_1, k_2, k_3 are real-valued functions and the matrices $\mathcal{B}_J \in \mathfrak{g}$ are given by $\mathcal{B}_{-1} = -E_{1,0} + E_{3,0} + E_{0,1} - E_{2,1} - E_{4,2} + E_{5,3} + E_{5,4} - E_{4,5}$, $\mathcal{B}_0 = E_{0,0} - E_{1,1} + E_{4,4} - E_{5,5}$, $\mathcal{B}_1 = E_{0,3} + E_{3,5}$, $\mathcal{B}_2 = E_{1,2} + E_{2,4}$, $\mathcal{B}_3 = E_{0,4} - E_{1,5}$, being $E_{i,j}$ $(0 \leqslant i, j \leqslant 5)$ the matrix with 1 in the (i, j) place and 0 elsewhere.

Proof of Theorem 1.1: Let Γ and σ as above and let $[B]: \Gamma \to G$ be the canonical frame constructed in Lemma 3.4. We set $h = -3\sqrt{2}k$ and we let $[C]: \Gamma \to G$ be defined by

$$C = \mathrm{Id}_{6\times 6} + \frac{h}{2}\mathcal{C}_1 + \frac{h^2}{8}\mathcal{C}_2, \tag{3.15}$$

where $\mathcal{C}_1 = E_{1,2} - E_{0,3} + E_{0,4} + E_{2,4} - E_{1,5} - E_{3,5}$ and $\mathcal{C}_2 = E_{1,4} + E_{0,5}$. We then consider the frame field $[\widetilde{B}] = [B] \cdot C$. It is now a computational matter to check that

$$\widetilde{B}^{-1}\,\mathrm{d}\widetilde{B}=\left(\mathcal{B}_{-1}+k_0\mathcal{B}_0+\hat{k}_1\mathcal{B}_1+\hat{k}_2\mathcal{B}_2+\hat{k}_3\mathcal{B}_3+\frac{h}{2}\mathcal{B}_4\right)\mu, \tag{3.16}$$

where $\mathcal{B}_4=E_{0,0}+E_{1,1}-E_{4,4}-E_{5,5}$, $\hat{k}_2=k_2+\frac{1}{2}h'-\frac{1}{2}(hk_0-\frac{1}{4}h^2)$, $\hat{k}_1=k_1-\frac{1}{2}h'-\frac{1}{2}(hk_0+\frac{1}{4}h^2)$ and $\hat{k}_3=k_3-\frac{1}{2}h'-\frac{1}{4}h^2$. We then define the function $\bar{q}_i,\bar{p}_i,\bar{r}_i:\Gamma\to\mathbb{R}$ as follows:

$$\bar{q}_1=-\hat{k}_0-\tfrac{1}{6}h,$$

$$\bar{q}_2=\hat{k}_0-\tfrac{1}{6}h,$$

$$\bar{p}_1=-\tfrac{1}{2}\left(\hat{k}_1-\hat{k}_2-\hat{k}_3-3K\right),$$

$$\bar{p}_2=-\tfrac{1}{2}\left(\hat{k}_1-\hat{k}_2+\hat{k}_3+3K\right),$$

$$\bar{r}_1=\tfrac{1}{2}\left(\hat{k}_1+\hat{k}_2-\hat{k}_3-3K\right),$$

$$\bar{r}_2=-\tfrac{1}{2}\left(\hat{k}_1+\hat{k}_2+\hat{k}_3-3K\right). \tag{3.17}$$

Consider now the embedding $\widetilde{\Gamma}=([\widetilde{B}],\bar{q},\bar{p},\bar{r}):\Gamma\to P$. From (3.16) and (3.17) it follows that $\widetilde{\Gamma}$ is a one-dimensional integral manifold of the differential system $(\mathcal{I},\Omega)$. If we set $\mathrm{d}\bar{q}_j=\bar{q}_j^*\mu$, $\mathrm{d}\bar{p}_j=\bar{p}_j^*\mu$, and $\mathrm{d}\bar{r}_j=\bar{r}_j^*\mu$, then (3.16) implies that

$$\frac{\partial}{\partial\omega^1}-\frac{\partial}{\partial\omega^2}+\bar{q}_i^*\frac{\partial}{\partial\pi^i}+\bar{p}_i^*\frac{\partial}{\partial v^i}+\bar{r}_i^*\frac{\partial}{\partial\zeta^i} \tag{3.18}$$

is a tangent vector field along $\widetilde{\Gamma}$. This yields that $\widetilde{\Gamma}$ is a noncharacteristic K-regular integral curve of $(\mathcal{I},\Omega)$. Therefore, there exists a unique two-dimensional integral manifold $\widetilde{X}\subset P$ such that $\widetilde{\Gamma}\subset\widetilde{X}$. Consider the Legendre immersion

$$F:([A],q,p,r)\in\widetilde{X}\mapsto[A_0\wedge A_1]\in\Lambda. \tag{3.19}$$

Since our reasoning is of local nature, we may suppose that F is one-to-one and that $X=F(\widetilde{X})$ is contained in $\mathbb{R}^3\times S^2\subset\Lambda$. If we identify $\widetilde{X}$ and X, $([A],q,p,r)\in X\mapsto[A]\in G$ is the canonical frame and q_1,q_2,p_1,p_2,r_1,r_2 are the invariant functions of X. From this we deduce that X is a Lie minimal surface. By construction, the curve Γ is contained in X and

$$\alpha^1|_\Gamma=-\alpha^2|_\Gamma=\mu,\quad \bar{q}_i=q_i|_\Gamma,\quad \bar{p}_i=p_i|_\Gamma,\quad \bar{r}_i=r_i|_\Gamma,\quad i=1,2. \tag{3.20}$$

In particular, the 1-form $\alpha^1+\alpha^2$ vanishes identically along Γ. This implies that Γ is an anti-cyclidic curve of X. Combining (3.17) and (3.20) we obtain

$$K=\frac{1}{3}(p_1-p_2)|_\Gamma=K_w|_\Gamma,\quad k=\frac{1}{\sqrt{2}}(q_1+q_2)|_\Gamma=k_\Gamma,\quad \sigma=[A_0]|_\Gamma=\sigma_1|_\Gamma.$$

From this we infer that X satisfies the required properties. The uniqueness of X follows from the uniqueness of the real-analytic integral manifold $\widetilde{X}$ containing $\widetilde{\Gamma}$.

APPENDIX: THE FRAME CONSTRUCTIONS

Proof of Theorem 2.9

Consider the fiber bundle

$$\mathcal{F}_0(X) = \{(\ell, A) \in X \times G : \ell = [A_0 \wedge A_1]\} \to X.$$

Local cross sections of $\mathcal{F}_0(X)$ are called *local frame fields* along X. They can be considered as smooth maps $[A]: U \to G$, where U is an open subset of X, such that $\ell = [A_0(\ell) \wedge A_1(\ell)]$, for every $\ell \in U$. For every local frame field $[A]: U \to G$ we let $\alpha = (\alpha^I_J)$ be the pull-back of the Maurer-Cartan form. Any other local frame field $[\widetilde{A}]$ on U is given by $[\widetilde{A}] = [A] \cdot [B]$, where $[B]: U \to G_0$ is a smooth map into the isotropy subgroup

$$G_0 = \{[A] \in G : [A_0 \wedge A_1] = [\epsilon_0 \wedge \epsilon_1]\}.$$

Thus, the 1-forms α and $\widetilde{\alpha}$ are related by the gauge transformation

$$\widetilde{\alpha} = B^{-1}\, \mathrm{d}B + B^{-1} \alpha B. \tag{A1}$$

A frame field $[A]: U \to G$ is of *first order* if

$$\alpha^3_0 \wedge \alpha^2_0 > 0, \quad \alpha^2_0 = \alpha^3_1 = 0. \tag{A2}$$

From (A1) it follows that first order frames exist on a neighborhood of any point of X. The totality of first order frames is a principal G_1-bundle $\mathcal{F}_1(X) \to X$ where

$$G_1 = \left\{ [X(D,S,Y,b)] \in G_0 : S = \epsilon \mathrm{Id}_{2\times 2},\ D = \begin{pmatrix} r & 0 \\ 0 & s \end{pmatrix},\ \epsilon = \pm 1,\ rs > 0 \right\}.$$

Notation: The elements of G_1 will be denoted by $[Y_\epsilon(r,s,Y,b)]$, where $\epsilon = \pm 1, Y \in \mathfrak{gl}(2,\mathbb{R}), b, r, s \in \mathbb{R}$ and $rs > 0$.

If $[A]: U \to G$ is a first order frame then, the linear differential forms $\alpha^1 = \alpha^3_0$ and $\alpha^2 = \alpha^2_1$ give a positive-oriented coframing on U so that we may write

$$\alpha = P_1 \alpha^1 + P_2 \alpha^2,$$

where $P_1, P_2 : U \to \mathfrak{g}$ are smooth maps. The components of P_a are denoted by P^I_{Ja}, where $a = 1, 2$ and where $I, J = 0, \ldots, 5$. If $[A], [\widetilde{A}] : U \to G$ are first order frames on U and if the corresponding transition function is of the form $[Y_\epsilon(r,s,Y,b)] : U \to G_1$, then

$$\widetilde{\alpha}^1 = \epsilon r \alpha^1, \quad \widetilde{\alpha}^2 = \epsilon s \alpha^2,$$

$$\widetilde{\alpha}^1_0 = r(s^{-1}\alpha^1_0 - Y^2_1 \alpha^1), \quad \widetilde{\alpha}^0_1 = s(r^{-1}\alpha^0_1 - Y^1_2 \alpha^2). \tag{A3}$$

This implies

$$\widetilde{P}^1_{01} = \epsilon(s^{-1} P^1_{01} - Y^2_1), \quad \widetilde{P}^1_{02} = \epsilon r s^{-2} P^1_{02},$$

$$\widetilde{P}^0_{12} = -\epsilon(r^{-1}P^0_{12} + Y^1_2), \quad \widetilde{P}^0_{11} = \epsilon s r^{-2} P^0_{11}. \tag{A4}$$

From (A4) we see that for every point $\ell \in X$ there exist a first order frame field $A: U \to G$ defined on an open neighborhood U of ℓ with respect to which $P^1_{01} = P^0_{12} = 0$. Such first order frame fields are said to be of *second order*. In addition, any other second order frame field on U is of the form $[\widetilde{A}] = [A] \cdot [B]$, where $[B]: U \to G_2$ is a smooth map and

$$G_2 = \left\{ [Y_\epsilon(r,s,Y,b)] \in G_1 : Y = \begin{pmatrix} p & 0 \\ 0 & q \end{pmatrix}, p,q \in \mathbb{R} \right\}.$$

Notation: The elements of G_2 will be denoted by $Y_\epsilon(r,s,p,q,b)$, where $\epsilon = \pm 1, p,q,r,s,b \in \mathbb{R}$ and $rs > 0$.

Second order frame fields are the cross sections of a reduced sub-bundle $\mathcal{F}_2(X)$ of $\mathcal{F}_1(X)$ with structural group G_2. Differentiating $\alpha^2_0 = \alpha^3_1 = 0$ and applying the structure equations and Cartan's lemma, we have that $\alpha^3_2 = 0$, for every second order frame field A. Taking the exterior derivative of $\alpha^3_2 = 0$ and using again the structure equations and the Cartan's lemma we have $\alpha^0_2 \wedge \alpha^1 - \alpha^1_3 \wedge \alpha^2 = 0$. This implies $P^0_{22} = -P^1_{31}$ and hence we may write

$$\alpha^0_2 = P^0_{21}\alpha^1 + P^0_{22}\alpha^2, \quad \alpha^1_3 = -P^0_{22}\alpha^1 + P^1_{32}\alpha^2. \tag{A5}$$

If $[A]$ and $[\widetilde{A}]$ are second order frame fields on $U \subset X$ and if $[Y_\epsilon(r,s,p,q,b)]: U \to G_2$ is the corresponding transition function, we then have

$$\widetilde{\alpha}^0_2 = \epsilon r^{-1} s p \alpha^0_1 + \epsilon r^{-1}\alpha^0_2 - sb\alpha^2, \quad \widetilde{\alpha}^1_3 = \epsilon s^{-1} r q \alpha^1_0 + \epsilon s^{-1}\alpha^1_3 + rb\alpha^1. \tag{A6}$$

From this we obtain

$$\widetilde{P}^0_{21} = r^{-2}(P^0_{21} + spP^0_{11}), \quad \widetilde{P}^0_{22} = \frac{1}{rs}P^0_{22} - \epsilon b, \quad \widetilde{P}^1_{32} = s^{-2}(P^1_{32} + rqP^1_{02}). \tag{A7}$$

Thus, for every point $\ell \in X$ there exist a second order frame field $U \to G$ defined on an open neighborhood of ℓ with respect to which

$$P^0_{22} = P^1_{31} = 0. \tag{A8}$$

Such frame fields are said to be of *third order*. Now, (A7) implies that these frame fields are the local cross sections of a reduced sub-bundle $\mathcal{F}_3(X)$ of $\mathcal{F}_2(X)$. The structure group of $\mathcal{F}_3(X)$ is

$$G_3 = \{[Y_\epsilon(r,s,p,q,b)] \in G_2 : b = 0\}.$$

Since X is nondegenerate, then the functions P^1_{02} and P^0_{11} are nowhere vanishing. Thus, from (A4) we infer that for every $\ell \in M$ there exist a third order frame field $[A]: U \to G$ defined on an open neighborhood U of ℓ such that

$$\alpha^0_1 = \alpha^1, \quad \alpha^1_0 = \alpha^2. \tag{A9}$$

A third order frame field satisfying (A9) is said to be of *fourth order*. If $[A]$ is a fourth order frame field on U, then any other is given by $[\widetilde{A}] = [A][B]$, where $[B]: U \to G_4$ and

$$G_4 = \{[Y_\epsilon(r,s,p,q,0)] \in G_3 : r = s = \epsilon\}.$$

The elements of G_4 are denoted by $[Y_\epsilon(p,q)]$, where $p,q \in \mathbb{R}$. From this we immediately see that the fourth order frame fields define a G_4 sub-bundle $\mathcal{F}_4(X)$ of $\mathcal{F}_3(X)$. Now, using (A7) we see that for every $\ell \in X$ there exist a unique fourth order frame $[A]: X \to G$ such that

$$\alpha^0_2 = \alpha^1_3 = 0.$$

Then, $[A]$ is the unique frame along X satisfying the required properties.

Proof of Lemma 3.4

Let G_0 be the fiber bundle defined by

$$\mathcal{R}_0 = \{(\ell, R) \in \Gamma \times G : \ell = [R_0 \wedge R_1], [R_0] = \sigma(\ell)\} \to \Gamma.$$

The cross sections of $\mathcal{R}_0$ are smooth maps $R : U \to G$ defined on an open subset $U \subset \Gamma$, such that

$$\ell = [R_0(\ell) \wedge R_1(\ell)], \quad [R_0(\ell)] = \sigma(\ell), \quad \forall\, \ell \in U.$$

For each frame field $R : U \to G$ we let ρ be the $\mathfrak{g}$-valued 1-form $R^{-1}\, \mathrm{d}R$. We say that $R : U \to G$ is of *first order* if

$$\rho_0^3 \neq 0, \quad \rho_0^2 = \rho_1^3 = \rho_0^3 + \rho_1^2 = \rho_0^4 = 0. \tag{A10}$$

Since Γ satisfies (3.11) and (3.12) then, first order frames do exist near any point of Γ and they define a sub-bundle $\mathcal{R}_1$ of $\mathcal{R}_0$ with fiber

$$H_1 = \{X \in G_0 : X = X(r\epsilon I, \epsilon I, Y, b), \epsilon = \pm 1, r, b \in \mathbb{R}, r \neq 0, Y \in \mathfrak{gl}(2, \mathbb{R})\}.$$

If R and $\widetilde{R}$ are first order frames related by $\widetilde{R} = RX(r\epsilon I, \epsilon I, Y, b)$ then

$$\widetilde{\rho}_1^0 = \rho_1^0 + rY_1^2\rho_0^3, \quad \widetilde{\rho}_0^1 = \rho_0^1 - rY_2^1\rho_0^3, \quad \widetilde{\rho}_2^3 = \rho_2^3 + \epsilon r(Y_2^1 + Y_1^2)\rho_0^3. \tag{A11}$$

This shows that near any point of Γ there exist first order frames such that

$$\rho_0^1 + \rho_1^0 = \rho_2^3 = 0. \tag{A12}$$

Frame fields satisfying (A12) are said to be of *second order*. From (A11) it follows that the totality of second order frames defines a fiber bundle $\mathcal{R}_2$ with fiber

$$H_2 = \{X = X(r\epsilon I, \epsilon I, Y, b) \in H_1 : Y_2^1 = Y_1^2 = 0\}.$$

Notice that the 1-form ρ_1^0 is independent of the choice of the second order frame and hence there exist $\mu \in \Omega^1(\Gamma)$ such that $\mu|_U = \rho_1^0$. Since $\delta : \Gamma \to \mathfrak{D}$ is nonisotropic and since $\delta^*(g_{\mathfrak{D}}) = -\mu^2$ we may conclude that μ is nowhere vanishing. From (A11) it follows that, locally, there exist second order frames such that

$$\rho_0^3 = -\rho_1^2 = -\rho_0^1 = \rho_1^0 = \mu. \tag{A13}$$

Frame fields satisfying (A13) are of *third order*. The totality of third order frames originates a principal fiber bundle $\mathcal{R}_3$ with structural group

$$H_3 = \{X = X(r\epsilon I, \epsilon I, Y, b) \in H_2 : r = 1\}.$$

If $\widetilde{R}$ and R are third order frame fields then

$$\widetilde{\rho}_0^0 = \rho_0^0 - \epsilon Y_2^2\rho_0^3, \quad \widetilde{\rho}_1^1 = \rho_1^1 + \epsilon Y_1^1\rho_0^3.$$

Therefore, near any point of Γ there exist a third order frame field R such that

$$\rho_1^1 + \rho_0^0 = 0. \tag{A14}$$

Frame fields satisfying (A14) define a reduced sub-bundle $\mathcal{R}_4$ with structure group

$$H_4 = \{X = X(\epsilon I, \epsilon I, Y, b) \in H_3 : Y_1^1 = Y_2^2\}.$$

Consider two local cross sections R and $\widetilde{R}$ of $\mathcal{R}_4$, we then have

$$\widetilde{\rho}_2^0 = \rho_2^0 + \epsilon\left(Y_1^1 + \frac{b}{2}\right)\mu, \quad \widetilde{\rho}_3^1 = \rho_3^1 - \epsilon\left(Y_1^1 - \frac{b}{2}\right)\mu. \tag{A15}$$

This implies that there exist fourth order frame fields with respect to which

$$\rho_2^0 = \rho_3^1 = 0. \tag{A16}$$

Fourth order frame fields satisfying (A16) are said to be of *fifth order*. The totality of fifth order frames generates a reduced sub-bundle $\mathcal{R}_5$ with fiber $\mathbb{Z}_2=\{\pm I\}$ and henceforth $\mathcal{R}_5$ is generated by a unique map $[B]:\Gamma\to G$ satisfying the required properties.

Integrable systems are usually given in terms of functions of continuous variables (on $\mathbb{R}$), in terms of functions of discrete variables (on $\mathbb{Z}$), and recently in terms of functions of q-variables (on $\mathbb{K}_q$). We formulate the Gel'fand-Dikii (GD) formalism on time scales by using the delta differentiation operator and find more general integrable nonlinear evolutionary equations. In particular they yield integrable equations over integers (difference equations) and over q-numbers (q-difference equations). We formulate the GD formalism also in terms of shift operators for all regular-discrete time scales. We give a method allowing to construct the recursion operators for integrable systems on time scales. Finally, we give a trace formula on time scales and then construct infinitely many conserved quantities (Casimirs) of the integrable systems on time scales. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2116380]

I. INTRODUCTION

Integrable systems are well studied and well understood in $1+1$ dimensions.[1–3] Here one of the dimensions denotes the time (evolution) variable and the other one denotes the space variable which is usually taken as continuous. There are also important examples where this variable takes values in $\mathbb{Z}$, i.e., integer values. In both cases the Gel'fand-Dikii (GD) approach is quite effective. One can generate hierarchies of integrable evolution equations, both on $\mathbb{R}$ and on $\mathbb{Z}$ (see Ref. 3 for GD applications and related references). In addition one can construct the conserved quantities, Hamilton operators, and recursion operators. Investigation of integrable systems on q-discrete intervals started in Refs. 4–6. They considered GD formalism on $\mathbb{K}_q$ and found q-integrable hierarchies including the q-KdV equation.

In this work we extend the Gel'fand-Dikii approach to time scales where $\mathbb{R}$, $\mathbb{Z}$, and $\mathbb{K}_q$ are special cases. In the next section we give a brief review of time scales calculus. See Refs. 7–13 for a more detailed review of the subject. In GD formalism, in obtaining integrable systems the essential tools are the differential and shift operators and their inverses. For extending the GD formulation to time scales we give the necessary means to construct in the sequel the algebra of pseudo-Δ-differential operators and the algebra of shift operators. In Sec. III we assume Δ-differential Lax operators and derive the Δ-Burgers hierarchy with its recursion operator. We present special cases of the Burgers equation for $\mathbb{T}=h\mathbb{Z}$ and $\mathbb{T}=\mathbb{K}_q$. In Sec. IV, we consider the *regular* time scales where the inverse of jump operators can be defined. Here we assume a pseudo-Δ-differential algebra and give the corresponding GD formulation. As an example we present a Δ-KdV hierarchy. We first find $n=1$ member of the hierarchy and write out it explicitly for $\mathbb{T}=\mathbb{R},\mathbb{Z},\mathbb{K}_q$ and for $\mathbb{T}=(-\infty,0)\cup\mathbb{K}_q$. Then we give the $n=3$ member and call it as the Δ-KdV system. We call it Δ-KdV equation, because the corresponding Lax operator is a second order Δ-differential operator. It involves two fields u and v, but the second field v can be expressed in

terms of the first filed u. When $\mathbb{T}=\mathbb{R}$, this system reduces to the standard KdV equation. In Sec. V, we consider the *regular-discrete* time scales and introduce the algebra of shift operators on them and give the corresponding GD formulation for all such time scales. Here several examples are presented. We first generalize the examples of discrete systems on $\mathbb{Z}$ given in Ref. 3 (one field, two fields, and four fields examples in Ref. 3) to arbitrary discrete time scales. In all these examples when $\mathbb{T}=\mathbb{Z}$ we get the discrete evolutions given in Ref. 3. We construct the recursion operators of these systems on time scales. We generalize the Frenkel's KdV system[4] introduced on $\mathbb{K}_q$ to arbitrary discrete time scales and we construct its recursion operator. In this section, we finally give an example of the KP hierarchy on discrete time scales. In Sec. VI, we extend the standard way of constructing the conserved quantities of integrable systems to time scales by introducing a *trace form* on the algebra of Δ-pseudo-differential operators. The trace form introduced in this section reduces, in particular cases, to the standard trace forms on $\mathbb{R}$ and $\mathbb{Z}$. In the Appendix we give the recursion operators of two *four-fields systems* introduced in Sec. V. We end up with a conclusion.

II. TIME SCALE CALCULUS

The time scale calculus is developed mainly to unify differential, difference, and q-calculus. A time scale ($\mathbb{T}$) is an arbitrary nonempty closed subset of the real numbers. The calculus of time scales was initiated by Aulbach and Hilger[7,8] in order to create a theory that can unify and extend discrete and continuous analysis. The real numbers ($\mathbb{R}$), the integers ($\mathbb{Z}$), the natural numbers ($\mathbb{N}$), the non-negative integers ($\mathbb{N}_0$), the h-numbers ($h\mathbb{Z}=\{hk:k\in\mathbb{Z}\}$, where $h>0$ is a fixed real number), and the q-numbers ($\mathbb{K}_q=q^{\mathbb{Z}}\cup\{0\}\equiv\{q^k:k\in\mathbb{Z}\}\cup\{0\}$, where $q>1$ is a fixed real number) are examples of time scales, as are $[0,1]\cup[2,3]$,$[0,1]\cup\mathbb{N}$, and the Cantor set, where $[0,1]$ and $[2,3]$ are real number intervals. In Refs. 7 and 8 Aulbach and Hilger introduced also dynamic equations on time scales in order to unify and extend the theory of ordinary differential equations, difference equations, and quantum equations[9] (h-difference and q-difference equations based on h-calculus and q-calculus, respectively). For a general introduction to the calculus on time scales we refer the reader to the textbooks by Bohner and Peterson.[10,11] Here we give only those notions and facts connected to time scales which we need for our purpose in this paper.

Any time scale $\mathbb{T}$ is a complete metric space with the metric (distance) $d(x,y)=|x-y|$ for $x,y\in\mathbb{T}$. Consequently, according to the well-known theory of general metric spaces, we have for $\mathbb{T}$ the fundamental concepts such as open balls (intervals), neighborhood of points, open sets, closed sets, compact sets, and so on. In particular, for a given number $r>0$, the r-neighborhood $U_r(x)$ of a given point $x\in\mathbb{T}$ is the set of all points $y\in\mathbb{T}$ such that $d(x,y)<r$. By a neighborhood of a point $x\in\mathbb{T}$ is meant an arbitrary set in $\mathbb{T}$ containing an r-neighborhood of the point x. Also we have for functions $f:\mathbb{T}\to\mathbb{R}$ the concepts of the limit, continuity, and properties of continuous functions on general complete metric spaces (note that, in particular, any function $f:\mathbb{Z}\to\mathbb{R}$ is continuous at each point of $\mathbb{Z}$). The main task is to introduce and investigate the concept of derivative for functions $f:\mathbb{T}\to\mathbb{R}$. This proves to be possible due to the special structure of the metric space $\mathbb{T}$. In the definition of derivative, the so-called forward and backward jump operators play special and important roles.

Definition 1: For $x\in\mathbb{T}$ we define the forward jump operator $\sigma:\mathbb{T}\to\mathbb{T}$ by

$$\sigma(x)=\inf\{y\in\mathbb{T}:y>x\}, \tag{1}$$

while the backward jump operator $\rho:\mathbb{T}\to\mathbb{T}$ is defined by

$$\rho(x)=\sup\{y\in\mathbb{T}:y<x\}. \tag{2}$$

In this definition we set in addition $\sigma(\max\mathbb{T})=\max\mathbb{T}$ if there exists a finite $\max\mathbb{T}$, and $\rho(\min\mathbb{T})=\min\mathbb{T}$ if there exists a finite $\min\mathbb{T}$. Obviously both $\sigma(x)$ and $\rho(x)$ are in $\mathbb{T}$ when $x\in\mathbb{T}$. This is because of our assumption that $\mathbb{T}$ is a closed subset of $\mathbb{R}$.

Let $x\in\mathbb{T}$. If $\sigma(x)>x$, we say that x is *right-scattered*, while if $\rho(x)<x$ we say that x is *left-scattered*. Also, if $x<\max\mathbb{T}$ and $\sigma(x)=x$, then x is called *right-dense*, and if $x>\min\mathbb{T}$ and

$\rho(x)=x$, then x is called *left-dense*. Points that are right-scattered and left-scattered at the same time are called *isolated*. Finally, the *graininess functions* $\mu,\nu:\mathbb{T}\to[0,\infty)$ are defined by

$$\mu(x)=\sigma(x)-x, \quad \text{and } \nu(x)=x-\rho(x) \quad \text{for all } x\in\mathbb{T}. \tag{3}$$

Example 1: If $\mathbb{T}=\mathbb{R}$, then $\sigma(x)=\rho(x)=x$ and $\mu(x)=\nu(x)=0$. If $\mathbb{T}=h\mathbb{Z}$, then $\sigma(x)=x+h$, $\rho(x)=x-h$, and $\mu(x)=\nu(x)=h$. On the other hand, if $\mathbb{T}=\mathbb{K}_q$ then we have

$$\sigma(x)=qx, \quad \rho(x)=q^{-1}x, \quad \mu(x)=(q-1)x, \quad \text{and } \nu(x)=(1-q^{-1})x. \tag{4}$$

Let $\mathbb{T}^\kappa$ denote Hilger's above truncated set consisting of $\mathbb{T}$ except for a possible left-scattered maximal point. Similarly, $\mathbb{T}_\kappa$ denotes the below truncated set obtained from $\mathbb{T}$ by deleting a possible right-scattered minimal point.

Definition 2: Let $f:\mathbb{T}\to\mathbb{R}$ be a function and $x\in\mathbb{T}^\kappa$. Then the delta derivative of f at the point x is defined to be the number $f^\Delta(x)$ (provided it exists) with the property that for each $\varepsilon>0$ there exists a neighborhood U of x in $\mathbb{T}$ such that

$$|f(\sigma(x))-f(y)-f^\Delta(x)[\sigma(x)-y]|\leqslant\varepsilon|\sigma(x)-y|, \tag{5}$$

for all $y\in U$.

Remark 1: If $x\in\mathbb{T}\backslash\mathbb{T}^\kappa$, then $f^\Delta(x)$ is not uniquely defined, since for such a point x, small neighborhoods U of x consist only of x and besides we have $\sigma(x)=x$. Therefore (5) holds for an arbitrary number $f^\Delta(x)$. This is a reason why we omit a maximal left-scattered point.

We have the following: (i) If f is delta differentiable at x, then f is continuous at x. (ii) If f is continuous at x and x is right-scattered, then f is delta differentiable at x with

$$f^\Delta(x)=\frac{f(\sigma(x))-f(x)}{\mu(x)}. \tag{6}$$

(iii) If x is right-dense, then f is delta differentiable at x iff the limit

$$\lim_{y\to x}\frac{f(x)-f(y)}{x-y} \tag{7}$$

exists as a finite number. In this case $f^\Delta(x)$ is equal to this limit. (iv) If f is delta differentiable at x, then

$$f(\sigma(x))=f(x)+\mu(x)f^\Delta(x). \tag{8}$$

Definition 3: If $x\in\mathbb{T}_\kappa$, then we define the nabla derivative of $f:\mathbb{T}\to\mathbb{R}$ at x to be the number $f^\nabla(x)$ (provided it exists) with the property that for each $\varepsilon>0$ there is a neighborhood U of x in $\mathbb{T}$ such that

$$|f(\rho(x))-f(y)-f^\nabla(x)[\rho(x)-y]|\leqslant\varepsilon|\rho(x)-y|, \tag{9}$$

for all $y\in U$.

We have the following: (i) If f is nabla differentiable at x, then f is continuous at x. (ii) If f is continuous at x and x is left-scattered, then f is nabla differentiable at x with

$$f^\nabla(x)=\frac{f(x)-f(\rho(x))}{\nu(x)}. \tag{10}$$

(iii) If x is left-dense, then f is nabla differentiable at x if and only if the limit

$$\lim_{y\to x}\frac{f(x)-f(y)}{x-y} \tag{11}$$

exists as a finite number. In this case $f^{\nabla}(x)$ is equal to this limit. (iv) If f is nabla differentiable at x, then

$$f(\rho(x))=f(x)-\nu(x)f^{\nabla}(x). \tag{12}$$

Example 2: If $\mathbb{T}=\mathbb{R}$, then $f^{\Delta}(x)=f^{\nabla}(x)=f'(x)$, the ordinary derivative of f at x. If $\mathbb{T}=h\mathbb{Z}$, then

$$f^{\Delta}(x)=\frac{f(x+h)-f(x)}{h} \quad \text{and } f^{\nabla}(x)=\frac{f(x)-f(x-h)}{h}. \tag{13}$$

If $\mathbb{T}=\mathbb{K}_q$, then

$$f^{\Delta}(x)=\frac{f(qx)-f(x)}{(q-1)x} \quad \text{and } f^{\nabla}(x)=\frac{f(x)-f(q^{-1}x)}{(1-q^{-1})x}, \tag{14}$$

for all $x\neq 0$, and

$$f^{\Delta}(0)=f^{\nabla}(0)=\lim_{y\to 0}\frac{f(y)-f(0)}{y} \tag{15}$$

provided that this limit exists.

Among the important properties of the delta differentiation on $\mathbb{T}$ we have the Leibnitz rule, if $f,g:\mathbb{T}\to\mathbb{R}$ are delta differentiable functions at $x\in\mathbb{T}^{\kappa}$, then so is their product fg and

$$(fg)^{\Delta}(x)=f^{\Delta}(x)g(x)+f(\sigma(x)g^{\Delta}(x) \tag{16}$$

$$=f(x)g^{\Delta}(x)+f^{\Delta}(x)g(\sigma(x)). \tag{17}$$

Also, if $f,g:\mathbb{T}\to\mathbb{R}$ are nabla differentiable functions at $x\in\mathbb{T}_{\kappa}$, then so is their product fg and

$$(fg)^{\nabla}(x)=f^{\nabla}(x)g(x)+f(\rho(x)g^{\nabla}(x), \tag{18}$$

$$=f(x)g^{\nabla}(x)+f^{\nabla}(x)g(\rho(x)). \tag{19}$$

In the next proposition we give a relationship between the delta and nabla derivatives (see Ref. 12).

Proposition 4: (i) Assume that $f:\mathbb{T}\to\mathbb{R}$ is delta differentiable on $\mathbb{T}^{\kappa}$. Then f is nabla differentiable at x and

$$f^{\nabla}(x)=f^{\Delta}(\rho(x)), \tag{20}$$

for $x\in\mathbb{T}_{\kappa}$ such that $\sigma(\rho(x))=x$. If, in addition, f^{Δ} is continuous on $\mathbb{T}^{\kappa}$, then f is nabla differentiable at x and (20) holds for any $x\in\mathbb{T}_{\kappa}$.

(ii) Assume that $f:\mathbb{T}\to\mathbb{R}$ is nabla differentiable on $\mathbb{T}_{\kappa}$. Then f is delta differentiable at x and

$$f^{\Delta}(x)=f^{\nabla}(\sigma(x)), \tag{21}$$

for $x\in\mathbb{T}^{\kappa}$ such that $\rho(\sigma(x))=x$. If, in addition, f^{∇} is continuous on $\mathbb{T}_{\kappa}$, then f is delta differentiable at x and (21) holds for any $x\in\mathbb{T}^{\kappa}$.

Now we introduce the concept of integral for functions $f:\mathbb{T}\to\mathbb{R}$.

Definition 5: A function $F:\mathbb{T}\to\mathbb{R}$ is called a Δ-antiderivative of $f:\mathbb{T}\to\mathbb{R}$ provided $F^{\Delta}(x)=f(x)$ holds for all x in $\mathbb{T}^{\kappa}$. Then we define the Δ-integral from a to b of f by

$$\int_a^b f(x)\Delta x = F(b) - F(a) \quad \textit{for all } a,b \in \mathbb{T}. \tag{22}$$

Definition 6: A function $\Phi:\mathbb{T}\to\mathbb{R}$ *is called a* ∇*-antiderivative of* $f:\mathbb{T}\to\mathbb{R}$ *provided* $\Phi^{\nabla}(x) = f(x)$ *holds for all* x *in* $\mathbb{T}_{\kappa}$*. Then we define the* ∇*-integral from* a *to* b *of* f *by*

$$\int_a^b f(x)\,\nabla x = \Phi(b) - \Phi(a) \quad \textit{for all } a,b \in \mathbb{T}. \tag{23}$$

If $a,b \in \mathbb{T}$ with $a \leqslant b$ we define the closed interval $[a,b]$ in $\mathbb{T}$ by

$$[a,b] = \{x \in \mathbb{T}: a \leqslant x \leqslant b\}. \tag{24}$$

Open and half-open intervals, etc., are defined accordingly. Below all our intervals will be time scale intervals

Example 3: Let $a,b \in \mathbb{T}$ with $a < b$. Then we have the following.

(i) If $f:\mathbb{T}=\mathbb{R}$ then

$$\int_a^b f(x)\Delta x = \int_a^b f(x)\,\nabla x = \int_a^b f(x)\mathrm{d}x, \tag{25}$$

where the integral on the right-hand side is the ordinary integral.

(ii) If $[a,b]$ consists of only isolated points, then

$$\int_a^b f(x)\Delta x = \sum_{x\in[a,b)} \mu(x)f(x) \quad \text{and} \quad \int_a^b f(x)\,\nabla x = \sum_{x\in(a,b]} \nu(x)f(x). \tag{26}$$

In particular, if $\mathbb{T}=\mathbb{Z}$, then

$$\int_a^b f(x)\Delta x = \sum_{k=a}^{b-1} f(k) \quad \text{and} \quad \int_a^b f(x)\,\nabla x = \sum_{k=a+1}^{b} f(k). \tag{27}$$

If $\mathbb{T}=h\mathbb{Z}$, then

$$\int_a^b f(x)\Delta x = h\sum_{x\in[a,b)} f(x) \quad \text{and} \quad \int_a^b f(x)\,\nabla x = h\sum_{x\in(a,b]}^{b} f(x) \tag{28}$$

and if $\mathbb{T}=\mathbb{K}_q$, then

$$\int_a^b f(x)\Delta x = (1-q)\sum_{x\in[a,b)} xf(x) \quad \text{and} \quad \int_a^b f(x)\,\nabla x = (1-q^{-1})\sum_{x\in(a,b]} xf(x). \tag{29}$$

The following relationship between the delta and nabla integrals follows from Definitions 5 and 6 by using Proposition 4.

Proposition 7: If the function $f:\mathbb{T}\to\mathbb{R}$ *is continuous, then for all* $a,b \in \mathbb{T}$ *with* $a<b$ *we have*

$$\int_a^b f(x)\Delta x = \int_a^b f(\rho(x))\,\nabla x \quad \textit{and} \quad \int_a^b f(x)\,\nabla x = \int_a^b f(\sigma(x))\Delta x. \tag{30}$$

Indeed, if $F:\mathbb{T}\to\mathbb{R}$ is a Δ-antiderivative for f, then $F^{\Delta}(x)=f(x)$ for all $x\in\mathbb{T}^{\kappa}$, and by Proposition 4 we have $f(\rho(x))=F^{\Delta}(\rho(x))=F^{\nabla}(x)$ for all $x\in\mathbb{T}_{\kappa}$, so that F is a ∇-antiderivative for $f(\rho(x))$. Therefore

$$\int_a^b f(\rho(x))\,\nabla x = F(b) - F(a) = \int_a^b f(x)\Delta x. \tag{31}$$

From (16)–(21) and (30) we have the following integration by parts formulas: If the functions $f, g: \mathbb{T} \to \mathbb{R}$ are delta and nabla differentiable with continuous derivatives, then

$$\int_a^b f^{\Delta}(x)g(x)\Delta x = f(x)g(x)\Big|_a^b - \int_a^b f(\sigma(x))g^{\Delta}(x)\Delta x, \tag{32}$$

$$\int_a^b f^{\nabla}(x)g(x)\,\nabla x = f(x)g(x)\Big|_a^b - \int_a^b f(\rho(x))g^{\nabla}(x)\,\nabla x, \tag{33}$$

$$\int_a^b f^{\Delta}(x)g(x)\Delta x = f(x)g(x)\Big|_a^b - \int_a^b f(x)g^{\nabla}(x)\,\nabla x, \tag{34}$$

$$\int_a^b f^{\nabla}(x)g(x)\,\nabla x = f(x)g(x)\Big|_a^b - \int_a^b f(x)g^{\Delta}(x)\Delta x. \tag{35}$$

For more general treatment of the delta integral on time scales (Riemann and Lebesgue delta integrals on time scales) see Ref. 13 and Chap. 5 of Ref. 11.

III. BURGERS EQUATION ON TIME SCALES

The Gel'fand-Dikii approach is very effective in studying the symmetries, bi-Hamiltonian formulation, and in constructing the recursion operators of integrable nonlinear partial differential equations. In this approach one takes the Lax operator L in an algebra like a differential or pseudodifferential algebra, a matrix algebra, a polynomial algebra, or the Moyal algebra. In this section we take L in the algebra of delta-differential operators.

Let $\mathbb{T}$ be a time scale. We say that a function $f: \mathbb{T} \to \mathbb{R}$ is Δ-smooth if it is infinitely Δ-differentiable (and hence infinitely ∇-differentiable). By Δ we denote the *delta-differentiation operator* which assigns to each Δ-differentiable function $f: \mathbb{T} \to \mathbb{R}$ its delta derivative $\Delta(f)$ defined by

$$[\Delta(f)](x) = f^{\Delta}(x) \quad \text{for } x \in \mathbb{T}^{\kappa}. \tag{36}$$

The *shift operator* E is defined by the formula

$$(Ef)(x) = f(\sigma(x)) \tag{37}$$

for $x \in \mathbb{T}$, where $\sigma: \mathbb{T} \to \mathbb{T}$ is the forward jump operator. It is convenient, in the operator relations to denote the delta-differentiation operator by δ rather than by Δ. For example, δf will denote the composition (product) of the delta-differentiation operator δ and the operator of multiplication by the function f. According to formula (16) we have

$$\delta f = f^{\Delta} + E(f)\delta. \tag{38}$$

Consider the Nth order δ-differential operator given by

$$L = a_N \delta^N + a_{N-1}\delta^{N-1} + \cdots + a_1\delta + a_0, \tag{39}$$

where the coefficients a_i $(i=0,1,\ldots,N)$ are some Δ-smooth functions of the variable $x \in \mathbb{T}$. These functions are assumed to depend also on a continuous variable $t \in \mathbb{R}$, however, we will not (for simplicity) indicate explicitly the dependence on t.

Proposition 8: Let L be given as in (39) and $A_n = (L^n)_{>0}$ *be the operator* L^n *missing the* δ^0

term. Then the Lax equation

$$\frac{dL}{dt_n} = [A_n, L] = A_n L - L A_n \tag{40}$$

for $n = 1, 2, \ldots$ *produces a consistent hierarchy of coupled nonlinear evolutionary equations.*

Example 4. Burgers equation on time scale: Let $L = v\delta + u$, where u and v are functions of $x \in \mathbb{T}$ and $t \in \mathbb{R}$. Then for an appropriate operator A the Lax equation

$$\frac{dL}{dt} = [A, L] \tag{41}$$

defines a system of two differential equations for the functions u and v. We find the operator A by using the Gelfand-Dikii formalism. Let us start with the second power of L and assume $A = (L^2)_{>0}$, where

$$L^2 = vE(v)\delta^2 + [vv^{\Delta} + vE(u) + uv]\delta + vu^{\Delta} + u^2. \tag{42}$$

We can assume $A = -(L^2)_0$ (the part of $-L^2$ without the δ terms). With this choice, (41) gives

$$\frac{dv}{dt} = \mu v(vu^{\Delta} + u^2)^{\Delta}, \tag{43}$$

$$\frac{du}{dt} = v(vu^{\Delta} + u^2)^{\Delta}, \tag{44}$$

where $\mu(x) = \sigma(x) - x$ for $x \in \mathbb{T}$.

Equations (43) and (44) given above are not independent of each other. It is easy to see that $v = \mu u + \lambda$, where λ is an arbitrary real function depending only on $x \in \mathbb{T}$. Then these two equations reduce to a single equation, a Burgers equation on time scales,

$$\frac{du}{dt} = (\mu u + \lambda)[u^2 + (\mu u + \lambda)u^{\Delta}]^{\Delta}. \tag{45}$$

Let us present some special cases: (i) When $\mathbb{T} = \mathbb{R}$ then $\mu = 0$ and $\delta = D$, the usual differentiation. Hence we can let $\lambda = 1$ and (45) reduces to the standard Burgers equation on $\mathbb{R}$. (ii) When $\mathbb{T} = h\mathbb{Z}$ then $\mu(m) = h$ and $f^{\Delta}(m) = (1/h)[f(m+h) - f(m)]$ for any f. Then taking $\lambda = 0$ in (45) we find

$$\frac{du(m)}{dt} = u(m)u(m+h)[u(m+2h) - u(m)], \tag{46}$$

where $m \in h\mathbb{Z}$. The evolution equation given above in (46) represents a difference version of the Burgers equation. (iii) Let $\mathbb{T} = q^{\mathbb{Z}}$, where $q \neq 1$ and $q > 0$. Then we have $\mu(x) = (q-1)x$ and $f^{\Delta}(x) = [f(qx) - f(x)]/(q-1)x$ and taking $\lambda = 0$ we get from (45)

$$\frac{du(x)}{dt} = u(x)u(qx)[u(q^2x) - u(x)]. \tag{47}$$

Taking $A_n = -(L^n)_0$ with L given as in Example 4 we get a hierarchy of evolution equations (Burgers hierarchy on time scales) from

$$\frac{dL}{dt_n} = -[(L^n)_0, v\delta + u] \tag{48}$$

for all $n = 1, 2, 3, \ldots$. Since $(L^n)_0$ is a scalar function, letting $(L^n)_0 = \rho_n$ we obtain

$$\frac{dv}{dt_n} = \mu v(\rho_n)^{\Delta}, \tag{49}$$

$$\frac{du}{dt_n} = v(\rho_n)^{\Delta}, \tag{50}$$

where the first three ρ_n are given by

$$\rho_1 = u, \tag{51}$$

$$\rho_2 = vu^{\Delta} + u^2, \tag{52}$$

$$\rho_3 = vE(v)u^{\Delta\Delta} + [vv^{\Delta} + vE(u) + uv]u^{\Delta} + (vu^{\Delta} + u^2)u. \tag{53}$$

The above hierarchy reduces to a single evolution equation with $v = \mu u + \lambda$,

$$\frac{du}{dt_n} = (\mu u + \lambda)(\tilde{\rho}_n)^{\Delta}, \quad n = 1,2, \dots , \tag{54}$$

where $\tilde{\rho}_n$ is equal to ρ_n with $v = \mu u + \lambda$. When $\mathbb{T}$ is a regular-discrete time scale, the first three $\tilde{\rho}_n$ are given for $\lambda = 0$ by

$$\tilde{\rho}_1 = u, \tag{55}$$

$$\tilde{\rho}_2 = uE(u), \tag{56}$$

$$\tilde{\rho}_3 = uE(u)E^2(u). \tag{57}$$

It is possible to construct the recursion operator $\mathcal{R}$ by using the Lax representation.[14–16] The hierarchy satisfies a recursion relation like

$$\frac{dL}{dt_{n+1}} = L\frac{dL}{dt_n} + [R_n, L], \quad n = 1,2, \dots , \tag{58}$$

where R_n is the remainder operator which has the same degree as the Lax operator L. We shall construct this operator for the Burgers equation with $\lambda = 0$ on regular-discrete time scales. Choosing $R_n = \alpha_n \delta$ we get [by choosing $v(x) = \mu(x)u(x)$]

$$\mathcal{R} = uE + [u(E(u) - u)](E - 1)^{-1}\frac{E}{E(u)}. \tag{59}$$

One can generate the hierarchy (54) by application of the recursion operator $\mathcal{R}$ to the lowest order symmetry $u_1 = u(E(u) - u)$,

$$\frac{du}{dt_n} = \mathcal{R}^{n-1}u_1, \quad n = 1,2, \dots . \tag{60}$$

IV. ALGEBRA OF PSEUDO-DELTA-DIFFERENTIAL OPERATORS ON REGULAR TIME SCALES

Let us define the notion of regular time scales.

Definition 9: We say that a time scale $\mathbb{T}$ is regular if the following two conditions are satisfied simultaneously:

$$\text{(i) } \sigma(\rho(x)) = x \quad \textit{for all } x \in \mathbb{T} \tag{61}$$

and

$$\text{(ii) } \rho(\sigma(x)) = x \quad \textit{for all } x \in \mathbb{T}, \tag{62}$$

where σ and ρ denote the forward and backward jump operators, respectively.

From (61) it follows that the operator $\sigma:\mathbb{T}\to\mathbb{T}$ is "onto" while (62) implies that σ is "one-to-one." Therefore σ is invertible and $\sigma^{-1}=\rho$. Similarly, the operator $\rho:\mathbb{T}\to\mathbb{T}$ is invertible and $\rho^{-1}=\sigma$ if $\mathbb{T}$ is regular.

Let us set $x_*=\min\mathbb{T}$ if there exists a finite $\min\mathbb{T}$, and set $x_*=-\infty$ otherwise. Also set $x^*=\max\mathbb{T}$ if there exists a finite $\max\mathbb{T}$, and $x^*=\infty$ otherwise. It is not difficult to see that the following statement holds.

Proposition 10: A time scale $\mathbb{T}$ is regular if and only if the following two conditions hold:

(i) *The point $x_*=\mathbb{T}$ is right-dense and the point $x^*=\max\mathbb{T}$ is left-dense.*
(ii) *Each point of $\mathbb{T}\backslash\{x_*,x^*\}$ is either two-sided dense or two-sided scattered.*

In particular, $\mathbb{R}$, $h\mathbb{Z}$, and $\mathbb{K}_q$ are regular time scales, as are $[0,1]$, $[-1,0]\cup\{1/k:k\in\mathbb{N}\}\cup\{k/(k+1):k\in\mathbb{N}\}\cup[1,2]$, and $(-\infty,0]\cup\{1/k:k\in\mathbb{N}\}\cup\{2k:k\in\mathbb{N}\}$, where $[-1,0]$, $[0,1]$, $[1,2]$, $(-\infty,0]$ are real line intervals.

If $f:\mathbb{T}\to\mathbb{R}$ is a function we define the functions $f^\sigma:\mathbb{T}\to\mathbb{R}$ and $f^\rho:\mathbb{T}\to\mathbb{R}$ by

$$f^\sigma(x) = f(\sigma(x)) \quad \text{and } f^\rho(x) = f(\rho(x)) \quad \text{for all } x\in\mathbb{T}. \tag{63}$$

Defining the shift operator E by the formula $Ef=f^\sigma$ we have

$$(Ef)(x) = f^\sigma(x) = f(\sigma(x)) \quad \text{for all } x\in\mathbb{T}. \tag{64}$$

The inverse E^{-1} exists only in case of regular time scales and is defined by

$$(E^{-1}f)(x) = f(\sigma^{-1}(x)) = f(\rho(x)) \quad \text{for all } x\in\mathbb{T}. \tag{65}$$

In the operator relations, for convenience, we will denote the shift operator by $\mathcal{E}$ rather than by E. For example, $\mathcal{E}f$ will denote the composition (product) of the shift operator $\mathcal{E}$ and the operator of multiplication by the function f. Obviously, for any integer $m\in\mathbb{Z}$, we have

$$\mathcal{E}^m f = (E^m f)\mathcal{E}^m. \tag{66}$$

Remember that δ denotes the delta-differentiation operator acting in the operator relations by $\delta f=f^\Delta+E(f)\delta$. The following proposition is an immediate consequence of the formulas (8) and (16).

Proposition 11: The operator formulas

$$\mathcal{E} = I + \mu\delta \tag{67}$$

and

$$\delta f = f^\Delta + E(f)\delta \tag{68}$$

hold, where the function $\mu:\mathbb{T}\to\mathbb{R}$ is defined by $\mu(x)=\sigma(x)-x$ for all $x\in\mathbb{T}$, and I denotes the identity operator.

In this section we will assume that all our considered functions from $\mathbb{T}$ to $\mathbb{R}$ are Δ-smooth and tend to zero sufficiently rapidly together with their Δ-derivatives as x goes to x_* or x^*, where $x_*=\min\mathbb{T}$ if there exists a finite $\min\mathbb{T}$ and $x_*=-\infty$ otherwise, $x^*=\max\mathbb{T}$ if there exists a finite $\max\mathbb{T}$ and $x^*=\infty$ otherwise. The inverse operator δ^{-1} exists on such functions. If $g:\mathbb{T}\to\mathbb{T}$ is such a function, then

$$[\Delta^{-1}(g)](x) = \int_{x_*}^{x} g(y)\Delta y. \tag{69}$$

Proposition 12: Let $f:\mathbb{T}\to\mathbb{R}$ be a Δ-smooth function such that f and all its Δ-derivatives vanish rapidly at x_* and x^*. Then the operator $\delta^{-1}f$ being the composition (product) of δ^{-1} and f has the form of the formal series in powers of δ^{-1},

$$\delta^{-1}f = \alpha_0\delta^{-1} + \alpha_1\delta^{-2} + \cdots, \tag{70}$$

where $\alpha_0 = E^{-1}f$, and $\alpha_k = (-1)^k(E^{-1}f)^{\nabla^k}$ for $k=1,2,\ldots$.

Proof: Multiplying (68) on the left and right by δ^{-1} we obtain

$$\delta^{-1}E(f) = f\delta^{-1} - \delta^{-1}f^{\Delta}\delta^{-1}. \tag{71}$$

Replacing here f by $E^{-1}f$ we get

$$\delta^{-1}f = (E^{-1}f)\delta^{-1} - \delta^{-1}(E^{-1}f)^{\Delta}\delta^{-1}. \tag{72}$$

Further, applying this rule to the function $(E^{-1}f)^{\Delta}$ and taking into account that by Proposition 4(i)

$$E^{-1}(E^{-1}f)^{\Delta} = (E^{-1}f)^{\nabla}, \tag{73}$$

we find

$$\delta^{-1}(E^{-1}f)^{\Delta} = (E^{-1}f)^{\nabla}\delta^{-1} - \delta^{-1}((E^{-1}f)^{\nabla})^{\Delta}\delta^{-2}. \tag{74}$$

Substituting this into the second term on the right-hand side of (72) we obtain

$$\delta^{-1}f = (E^{-1}f)\delta^{-1} - (E^{-1}f)^{\nabla}\delta^{-2} + \delta^{-1}((E^{-1}f)^{\Delta})^{\nabla}\delta^{-2}. \tag{75}$$

Continuing this procedure repeatedly we arrive at the statement of the proposition.

Definition 13: By Λ we denote the algebra of pseudo-delta-differential operators. Any operator $K\in\Lambda$ of order k has the form

$$K = \sum_{\ell=-\infty}^{k} a_\ell\delta^{\ell}, \tag{76}$$

where a_ℓ's are Δ-smooth functions of $x\in\mathbb{T}$. For K given by (76) we will use the following notations:

$$K_{\geqslant 0} = \sum_{\ell=0}^{k} a_\ell\delta^{\ell} \quad \text{and } K_{<0} = \sum_{-\infty}^{-1} a_\ell\delta^{\ell}. \tag{77}$$

As an example we let

$$L = a_N\delta^N + a_{N-1}\delta^{N-1} + \cdots + a_1\delta + a_0, \tag{78}$$

where $a_i (i=0,1,\ldots,N)$ are some Δ-smooth functions on $\mathbb{T}$. Then we have the following.

Proposition 16: Let L be given in (78). For each fixed N the Lax equation

$$\frac{\mathrm{d}L}{\mathrm{d}t_n} = [A_n, L], \quad A_n = (L^{n/N})_{\geqslant 0}, \tag{79}$$

for $n=1,2,\ldots$ not divisible by N, produces a (consistent) hierarchy of evolution equations (a KdV hierarchy on time scales).

Proof: Since $(L^{n/N})_{\geqslant 0} = L^{n/N} - (L^{n/N})_{<0}$, we get

$$\frac{dL}{dt_n} = [(L^{n/N})_{\geqslant 0}, L] = -[L^{n/N})_{<0}, L]. \tag{80}$$

Evidently the commutator $[(L^{n/N})_{\geqslant 0}, L]$ involves only non-negative powers of δ, while the commutator $[(L^{n/N})_{<0}, L]$ has the form $\Sigma_{j=-\infty}^{N-1} b_j \delta^j$. Therefore, we get by (80) that, for all n not divisible by N, (79) produces nontrivial consistent $N+1$-number of evolutionary coupled Δ-differential equations for a_i, $i=0,1,\ldots,N$. Note that a_N turns out to be a fixed (i.e., time independent) function of x.

Example 5: A KdV hierarchy on time scales. Let

$$L = \delta^2 + v\delta + u, \tag{81}$$

where u and v are Δ-smooth functions. It is straightforward to find that

$$L^{1/2} = \delta + \alpha_0 + \alpha_1 \delta^{-1} + \alpha_2 \delta^{-2} + \cdots, \tag{82}$$

where

$$E(\alpha_0) + \alpha_0 = v, \tag{83}$$

$$E(\alpha_1) + \alpha_1 + (\alpha_0)^{\Delta} + (\alpha_0)^2 = u, \tag{84}$$

$$E(\alpha_2) + \alpha_2 + \alpha_1 E^{-1}(\alpha_0) + (\alpha_1)^{\Delta} = 0. \tag{85}$$

Choosing $n=1,3,\ldots$ we get the members of the KdV hierarchy.

(1) Let $n=1$. Then Lax equation (79) becomes

$$\frac{dv}{dt}\delta + \frac{du}{dt} = [(L^{1/2})_{\geqslant 0}, L] \tag{86}$$

and gives coupled equations for u and v,

$$\frac{du}{dt} = u^{\Delta} - v(\alpha_0)^{\Delta} - (\alpha_0)^{\Delta\Delta}, \tag{87}$$

$$\frac{dv}{dt} = v^{\Delta} + E(u) - u - v[E(\alpha_0) - \alpha_0] - E(\alpha_0^{\Delta}) - E(\alpha_0)^{\Delta} = \mu(u^{\Delta} - v(\alpha_0)^{\Delta} - (\alpha_0)^{\Delta\Delta}). \tag{88}$$

Comparing the above equations we get

$$\frac{dv}{dt} - \mu\frac{du}{dt} = 0, \tag{89}$$

and therefore

$$v = \mu u + \lambda, \tag{90}$$

where λ is an arbitrary real function depending only on $x \in \mathbb{T}$. Thus, two equations (87) and (88) reduce to the following single equation:

$$\frac{du}{dt} = u^{\Delta} - (\mu u + \lambda)(\alpha_0)^{\Delta} - (\alpha_0)^{\Delta\Delta}, \tag{91}$$

where α_0 is expressed, according to (83), from

$$E(\alpha_0) + \alpha_0 = \mu u + \lambda. \tag{92}$$

If we take $\lambda = 0$, then (91) and (92) become

$$\frac{du}{dt} = u^{\Delta} - \mu u(\alpha_0)^{\Delta} - (\alpha_0)^{\Delta\Delta}, \tag{93}$$

$$E(\alpha_0) + \alpha_0 = \mu u. \tag{94}$$

We shall now give α_0, for illustration, for particular cases of $\mathbb{T}$.

(i) In the case $\mathbb{T} = \mathbb{R}$ we have $\mu = 0$ and (94) gives $\alpha_0 = 0$ and (93) becomes

$$\frac{du}{dt} = \frac{du}{dx}, \tag{95}$$

which is a linear equation explicitly solvable,

$$u(x,t) = \varphi(x+t), \tag{96}$$

where φ is an arbitrary differentiable function.

(ii) In the case $\mathbb{T} = \mathbb{Z}$ we have $\mu = 1$ and (94) is satisfied by

$$\alpha_0(n) = -\sum_{k=-\infty}^{n-1} (-1)^{n+k} u(k), \quad n \in \mathbb{Z} \tag{97}$$

and therefore the Eq. (93) becomes

$$\frac{du(n)}{dt} = -u^2(n) + 2u(n) + 2(-1)^n [2 + u(n)] \sum_{k=-\infty}^{n-1} (-1)^k u(k), \tag{98}$$

for $n \in \mathbb{Z}$.

(iii) In the case $\mathbb{T} = \mathbb{K}_q$ we have $\mu(x) = (q-1)x$ and (94) is satisfied by $\alpha_0(0) = 0$ and

$$\alpha_0(x) = -(q-1) \sum_{y \in (0, q^{-1}x]} (-1)^{\log_q(xy)} y u(y) \tag{99}$$

for $x \in \mathbb{K}_q$ and $x \neq 0$. Substituting (99) into (93) we can get an evolution equation for u.

(iv) Let $\mathbb{T} = (-\infty, 0) \cup \mathbb{K}_q = (-\infty, 0] \cup q^{\mathbb{Z}}$. In this case $\mu(x) = 0$ if $x \in (-\infty, 0]$ and $\mu(x) = (q-1)x$ if $x \in q^{\mathbb{Z}}$. The equation (94) is satisfied by the function α_0 given by

$$\alpha_0(x) = \begin{cases} 0 & x \in (-\infty, 0], \\ -(q-1)\Sigma_{y \in (0, q^{-1}x]} (-1)^{\log_q(xy)} y u(y) & x \in q^{\mathbb{Z}}. \end{cases} \tag{100}$$

Therefore (93) will yield an evolution equation coinciding on $(-\infty, 0]$ and $q^{\mathbb{Z}}$ with the evolution equations described in the examples (i) and (iii), respectively. Now an essential complementary point is that the solution u must satisfy at $x = 0$ the smoothness conditions

$$u(0^-) = u(0^+), \quad u'(0^-) = u^{\Delta}(0^+). \tag{101}$$

(2) Letting $n = 3$, first we get

$$L^{3/2} = \delta^3 + p\delta^2 + q\delta + r + (\text{terms with negative powers of } \delta), \tag{102}$$

where

$$p = \alpha_0 + E(v), \tag{103}$$

$$q = v^{\Delta} + E(u) + \alpha_0 v + \alpha_1, \tag{104}$$

$$r = u^{\Delta} + \alpha_0 u + \alpha_1 E^{-1}(v) + \alpha_2, \tag{105}$$

and the Lax equation

$$\frac{\mathrm{d}v}{\mathrm{d}t}\delta + \frac{\mathrm{d}u}{\mathrm{d}t} = [(L^{3/2})_{\geqslant 0}, L], \tag{106}$$

gives the coupled equations for u and v,

$$\frac{\mathrm{d}u}{\mathrm{d}t} = u^{\Delta\Delta\Delta} + pu^{\Delta\Delta} + qu^{\Delta} - r^{\Delta\Delta} - vr^{\Delta}, \tag{107}$$

$$\frac{\mathrm{d}v}{\mathrm{d}t} = v^{\Delta\Delta\Delta} + E(u^{\Delta\Delta}) + (E(u^{\Delta}))^{\Delta} + E(u)^{\Delta\Delta} + p[v^{\Delta\Delta} + E(u^{\Delta}) + E(u)^{\Delta}] + q(v^{\Delta} + E(u) - u) + rv - q^{\Delta\Delta}$$
$$- E(r^{\Delta}) - E(r)^{\Delta} - vq^{\Delta} - vE(r). \tag{108}$$

As in the first member of the hierarchy ($n=1$ case), the above Δ-KdV equations reduce to a single equation for the function u. Below in Corollary 23 we found that $v=\mu(x)u+\lambda(x)$. Letting $\lambda=$ constant we get

$$\frac{\mathrm{d}u}{\mathrm{d}t} = u^{\Delta\Delta\Delta} + pu^{\Delta\Delta} + qu^{\Delta} - r^{\Delta\Delta} - vr^{\Delta}. \tag{109}$$

It is possible to write the above equation more explicitly in terms of u for $\mathbb{T}=\mathbb{R}$, $\mathbb{T}=\mathbb{Z}$, and for $\mathbb{T}=\mathbb{K}_q$ but they are quite lengthy. For the discrete case we give a KdV hierarchy in Example 8, next section.

V. SHIFT LAX OPERATORS ON REGULAR-DISCRETE TIME SCALES

Let $\mathbb{T}$ be a time scale. Let us set $x_*=\min\mathbb{T}$ if there exists a finite $\min\mathbb{T}$ and $x_*=-\infty$ otherwise. Also set $x^*=\max\mathbb{T}$ if there exists a finite $\max\mathbb{T}$ and $x^*=\infty$ otherwise. We will briefly write $x_*=\min\mathbb{T}$ and $x^*=\max\mathbb{T}$.

Definition 17: We say that a time scale $\mathbb{T}$ is regular-discrete if the following two conditions are satisfied:

(i) *The point x_* is right-dense and the point x^* is left-dense.*
(ii) *Each point of $\mathbb{T}\backslash\{x_*,x^*\}$ is two-sided scattered (isolated).*

The shift operator E is defined on functions $f:\mathbb{T}\to\mathbb{R}$ by the formula

$$(Ef)(x) = f(\sigma(x)) \quad \text{for } x \in \mathbb{T}, \tag{110}$$

where $\sigma:\mathbb{T}\to\mathbb{T}$ is the forward jump operator.

In this section we deal only with regular-discrete time scales $\mathbb{T}$. For such time scales $\mathbb{T}$ we have

$$\mu(x) = \sigma(x) - x \neq 0 \quad \text{for all } x \in \mathbb{T}\setminus\{x_*,x^*\} \tag{111}$$

and, therefore, on functions given on $\mathbb{T}\backslash\{x_*,x^*\}$ we have the operator relationship

$$\delta = \frac{1}{\mu}(\mathcal{E} - 1). \tag{112}$$

All our functions will be assumed to be defined on $\mathbb{T}\backslash\{x_*,x^*\}$ and tends to zero sufficiently rapidly as x goes to x_* or x^*.

This shift operator $\mathcal{E}$, should be quite useful in the application of the Gel'fand-Dikii formalism. The reason is that for any integer m we have the simple product rule

$$\mathcal{E}^m u = (E^m u)\mathcal{E}^m. \tag{113}$$

Hence, for regular-discrete time scales, we can define an algebra of $\mathcal{E}$ operators.

Definition 18: An algebra, Λ_ϵ, of $\mathcal{E}$ operators satisfying the operator equation (113) is defined as follows: Any operator K in Λ_ϵ with degree k is of the form

$$K = \sum_{-\infty}^{k} a_\ell \mathcal{E}^\ell, \tag{114}$$

where a_ℓ are functions of $x \in \mathbb{T}$ that depend also on $t \in \mathbb{R}$.

Hence we can form Lax operators in Λ_ϵ, and produce integrable equations on regular-discrete time scales. Following[3] we obtain two classes of Lax representations.

Proposition 19: The Lax equation

$$\frac{\mathrm{d}L}{\mathrm{d}t_\ell} = [(L^\ell)_{\geqslant k}, L], \quad k = 0, 1 \tag{115}$$

produces consistent hierarchy of equations for $\ell = 1, 2, \ldots$ with the following suitable Lax operators:

$$L = \mathcal{E}^{\alpha+n} + u_{\alpha+n-1}\mathcal{E}^{\alpha+n-1} + \cdots + u_\alpha \mathcal{E}^\alpha, \tag{116}$$

$$L = v_{\alpha+n}\mathcal{E}^{\alpha+n} + v_{\alpha+n-1}\mathcal{E}^{\alpha+n-1} + \cdots + v_{\alpha+1}\mathcal{E}^{\alpha+1} + E^\alpha, \tag{117}$$

for $k=0$ and $k=1$, respectively. Here u_i and v_i are functions defined on $\mathbb{T}$ and the integer α is restricted to satisfy the inequality $-n < \alpha \leqslant -1$.

Remark: Lax operators above and the following examples are given on any regular-discrete time scale $\mathbb{T}$ (we can take in particular $\mathbb{T}=\mathbb{Z}$ or $\mathbb{K}_q$). This means that for any function u on such a time scale $E(u)=u(\sigma(x))$ where σ is the jump operator defined in the second section. Hence our examples and results should be considered as more general than those considered in Ref. 3. In the case of Ref. 3 time scale is just the integers ($\mathbb{T}=\mathbb{Z}$) where $E(u(n))=u(n+1)$.

Example 6: Two field equations. Let $k=0$, $\alpha=-1$ and

$$L = u_{-1}\mathcal{E}^{-1} + u_0 + \mathcal{E} \equiv v\mathcal{E}^{-1} + u + \mathcal{E}. \tag{118}$$

Then we find

$$\ell = 1 \quad \frac{\mathrm{d}v}{\mathrm{d}t_1} = v(u - E^{-1}(u)), \tag{119}$$

$$\frac{\mathrm{d}u}{\mathrm{d}t_1} = E(v) - v, \tag{120}$$

$$\ell = 2 \quad \frac{\mathrm{d}v}{\mathrm{d}t_2} = u^2 v + E(v)v - vE^{-1}(v) - vE^{-1}(u^2), \tag{121}$$

$$\frac{\mathrm{d}u}{\mathrm{d}t_2} = uE(v) + E(u)E(v) - vE^{-1}(u) - uv, \tag{122}$$

$$\ell = 3, \quad \frac{dv}{dt_3} = uv^2 + u^3 v - vE^{-1}(v)E^{-2}(u) - 2vE^{-1}(u)E^{-1}(v) - vE^{-1}(u^3) + 2uvE(v) - v^2E^{-1}(u) + vE(u)E(v), \tag{123}$$

$$\frac{du}{dt_3} = E(v)[u^2 + uE(u) + E(u^2) + E(v) + (E^2(v))] - v[E^{-1}(v) + E^{-1}(u^2) + uE^{-1}(u) + u^2 + v]. \tag{124}$$

This is a Toda hierarchy on discrete time scales. The recursion relation between the $n+1$th and nth elements of the hierarchy is given by

$$v_{n+1} = uv_n + vu_n + vE^{-1}(u_n) + v(E^{-1}(u) - u)(1-E)^{-1}\frac{v_n}{v}, \tag{125}$$

$$u_{n+1} = E(v_n) + uu_n + v(1-E)^{-1}\frac{v_n}{v} - E(v)(1-E)^{-1}E\frac{v_n}{v}. \tag{126}$$

From this recursion relation the recursion operator of the hierarchy follows.

Example 7: Four-field system on time scale. We give two examples which are studied in Ref. 3 for the case $\mathbb{T}=\mathbb{Z}$.

(1) Let $k=0$ and $\alpha=-2$ and

$$L = \mathcal{E}^2 + w\mathcal{E} + v + u\mathcal{E}^{-1} + p\mathcal{E}^{-2}. \tag{127}$$

Then we get the four-field equations

$$\ell = 1 \quad \frac{dp}{dt_1} = vp - pE^{-2}(v), \tag{128}$$

$$\frac{du}{dt_1} = vu + wE(p) - pE^{-2}(w) - uE^{-1}(v), \tag{129}$$

$$\frac{dv}{dt_1} = wE(u) + E^2(p) - uE^{-1}(w) - p, \tag{130}$$

$$\frac{dw}{dt_1} = E^2(u) - u. \tag{131}$$

(2) Let $k=1$ and $\alpha=-2$ and

$$L = \bar{q}\mathcal{E}^2 + \bar{w}\mathcal{E} + \bar{v} + \bar{u}\mathcal{E}^{-1} + \mathcal{E}^{-2}. \tag{132}$$

Then we get another four-field equations,

$$\ell = 1 \quad \frac{d\bar{u}}{dt_1} = \bar{w} - E^{-2}(\bar{w}), \tag{133}$$

$$\frac{d\bar{v}}{dt_1} = \bar{w}E(\bar{u}) + \bar{q} - E^{-2}(\bar{q}) - \bar{u}E^{-1}(\bar{w}), \tag{134}$$

$$\frac{\mathrm{d}\bar{w}}{\mathrm{d}t_1} = \bar{w}E(\bar{v}) + \bar{q}E^2(\bar{u}) - \bar{u}E^{-1}(\bar{q}) - \bar{v}\bar{w}, \tag{135}$$

$$\frac{\mathrm{d}\bar{q}}{\mathrm{d}t_1} = \bar{q}E^2(\bar{v}) - \bar{v}\bar{q}. \tag{136}$$

So far we considered the hierarchies coming from Proposition 19 with integer powers of the Lax operators. Now we consider the rational powers of the Lax operator.

Proposition 22: Let

$$L = w\mathcal{E}^N + u_{N-1}\mathcal{E}^{N-1} + \cdots + u_0, \tag{137}$$

where $w(x)$ *is a function of* x *which is not a dynamical variable* $\mathrm{d}w/\mathrm{d}t=0$, u_i, $i=0,1,\ldots,N-1$ *are functions of* t *and* $x \in \mathbb{T}$. *Then*

$$\frac{\mathrm{d}L}{\mathrm{d}t_n} = [(L^{n/N})_{\geqslant 0}, L], \quad n = 1,2,\ldots \tag{138}$$

produces hierarchies of integrable systems. Here n *is a positive integer not divisible by* N. *Furthermore the function* u_0 *is also not dynamical, i.e.,* $u_0=u_0(x)$, *not depending on* t.

Corollary 23: When $N=2$ *and* $w=(1/\mu)E(1/\mu)$ *then the* Δ*-KdV Lax operator (81) reduces to the above form with*

$$u_0 = -\frac{v}{\mu} + \frac{1}{\mu^2} + u, \tag{139}$$

$$u_1 = -\frac{1}{\mu}\left[E\left(\frac{1}{\mu}\right) + \frac{1}{\mu}\right] + \frac{v}{\mu}. \tag{140}$$

Hence in part (2) of Example 5 we have a single equation with $v=-\mu u_0+(1/\mu)+\mu u$.

In the following example we study the $N=2$ case in more detail.

Example 8: KdV on discrete time scales. Let

$$L = wE(w)\mathcal{E}^2 + u\mathcal{E} + v. \tag{141}$$

Then

$$L^{1/2} = w\mathcal{E} + \alpha_0 + \alpha_1\mathcal{E}^{-1} + \alpha_2\mathcal{E}^{-2} + \cdots, \tag{142}$$

where first three α_i are given as

$$w(E(\alpha_0) + \alpha_0) = u, \tag{143}$$

$$wE(\alpha_1) + E^{-1}(w)\alpha_1 = v - (\alpha_0)^2, \tag{144}$$

$$wE(\alpha_2) + E^{-2}(w)\alpha_2 = -\frac{\alpha_1 E^{-1}(u)}{E^{-1}(w)}. \tag{145}$$

Then we calculate $L^{3/2}$ by

$$L^{3/2} = wE(w)E^2(w)\mathcal{E}^3 + p_2\mathcal{E}^2 + p_1\mathcal{E} + p_0 + \text{negative powers of } \mathcal{E}, \tag{146}$$

where

$$p_2 = E(w)[wE^2(\alpha_0) + u], \tag{147}$$

$$p_1 = wE(w)E^2(\alpha_1) + uE(\alpha_0) + wv, \tag{148}$$

$$p_0 = wE(w)E^2(\alpha_2) + uE(\alpha_1) + v\alpha_0, \tag{149}$$

$$= wE^{-1}(w)[E^{-1}(w) + E(w)E]^{-1}\left(E(\alpha_1)\frac{u}{w}\right) + v(1+E)^{-1}\frac{u}{w}. \tag{150}$$

Then (138) with $N=2$ produces a hierarchy of evolution equations. It turns out that v becomes a constant in the whole hierarchy. We give the first two members of the hierarchy (for $n=1$ and $n=3$),

$$u_{t_1} = u(1-E)(1+E)^{-1}\frac{u}{w}, \tag{151}$$

$$u_{t_3} = u(1-E)p_0, \tag{152}$$

where p_0 is given above. The next members of the hierarchy can be found by taking $n=5$ in (138) or by applying the recursion operator $\mathcal{R}$ to u_{t_3}. For $\mathbb{T}=\mathbb{K}_q$ and $w=1$ the above hierarchy and its Hamilton formulation were given by Frenkel.[4] The recursion operator of this hierarchy with $w=1$ can be found by using (58) with $R_n=\alpha_n\mathcal{E}+\beta_n$. We find that

$$(E^2-1)\alpha_n = E^2(u_n), \tag{153}$$

$$(E^2-1)\beta_n = uE(u_n) + E(u)\alpha_n - uE(\alpha_n) \tag{154}$$

and the equation which determines the recursion operator is

$$u_{n+1} = vu_n - u(E-1)\beta_n, \quad n = 0,1,2,\ldots\ . \tag{155}$$

We find that

$$\mathcal{R} = v - u(E+1)^{-1}[-u + E(u)E](E^2-1)^{-1}E. \tag{156}$$

When the Lax operator is of degree one and has an infinite power series in operator $\mathcal{E}^{-1}$ the corresponding system is called the KP hierarchy.

Proposition 24: Let

$$L = \mathcal{E} + u_0 + u_1\mathcal{E}^{-1} + u_2\mathcal{E}^{-2} + \cdots\ . \tag{157}$$

Then

$$\frac{dL}{dt_n} = [(L^n)_{\geqslant 0}, L], \quad n = 1,2,\ldots\ , \tag{158}$$

produces the following hierarchy:

$$n=1 \quad \frac{du_0}{dt_1} = (E-1)u_1, \tag{159}$$

$$\frac{du_1}{dt_1} = (E-1)u_2 + u_1[u_0 - E^{-1}(u_0)], \tag{160}$$

$$\frac{du_k}{dt_1} = (E-1)u_{k+1} + u_k[u_0 - E^{-k}(u_0)], \quad k = 0,1,\ldots\ . \tag{161}$$

$$n=2 \quad \frac{du_0}{dt_2}=(E^2-1)u_2-u_1E^{-1}(E+1)u_0+E(u_1)(E(u_0)+u_0), \tag{162}$$

$$\frac{du_1}{dt_2}=(E^2-1)u_3+\alpha_1E(u_2)-u_2E^{-2}(\alpha_1)+\alpha_0u_1-u_1E^{-1}(\alpha_0), \tag{163}$$

$$\frac{du_k}{dt_2}=(E^2-1)u_{k+2}+\alpha_1E(u_{k+1})-u_{k+1}E^{-k-1}(\alpha_1)+\alpha_0u_k-u_kE^{-k}(\alpha_0), \quad k=0,1,\dots, \tag{164}$$

where $\alpha_0=(E+1)u_1+(u_0)^2$ and $\alpha_1=(E+1)u_0$. The case $\mathbb{T}=\mathbb{Z}$ of this hierarchy is discussed in Ref. 3 (see also the references therein) and the case $\mathbb{T}=\mathbb{K}_q$ is discussed in Refs. 4 and 5.

VI. TRACE FUNCTIONAL AND CONSERVATION LAWS

Let $\mathbb{T}$ be a regular time scale and Λ be the algebra of pseudo-delta-differential operators. Any operator $F\in\Lambda$ of order k has the form

$$F=a_k\delta^k+a_{k-1}\delta^{k-1}+\cdots+a_1\delta+a_0+a_{-1}\delta^{-1}+a_{-2}\delta^{-2}+\cdots, \tag{165}$$

where a_ℓ's are Δ-smooth functions of $x\in\mathbb{T}$ (they are also functions of $t\in\mathbb{R}$). The coefficients a_0 and a_{-1} we call, respectively, the *free term* (zero order term) and the *residue* of F associated with its "δ-expansion" (165) and write

$$\mathrm{Free}_\delta F=a_0(x) \quad \text{and } \mathrm{Res}_\delta F=a_{-1}(x). \tag{166}$$

In case of regular-discrete time scales $\mathbb{T}$ we have

$$\delta=\frac{1}{\mu}(\mathcal{E}-I)=\frac{1}{\mu}\mathcal{E}-\frac{1}{\mu} \tag{167}$$

and therefore the same operator F can be expanded in series with respect to the powers of $\mathcal{E}$ of the form

$$F=b_k\mathcal{E}^k+b_{k-1}\mathcal{E}^{k-1}+\cdots+b_1\mathcal{E}+b_0+b_{-1}\mathcal{E}^{-1}+b_{-2}\mathcal{E}^{-2}+\cdots. \tag{168}$$

We write

$$\mathrm{Free}_\mathcal{E} F=b_0(x) \quad \text{and } \mathrm{Res}_\mathcal{E} F=b_{-1}(x). \tag{169}$$

Substituting (167) and

$$\delta^{-1}=(\mathcal{E}-I)^{-1}\mu=(\mathcal{E}^{-1}+\mathcal{E}^{-2}+\cdots)\mu=E^{-1}(\mu)\mathcal{E}^{-1}+E^{-2}(\mu)\mathcal{E}^{-2}+\cdots, \tag{170}$$

into (165) and taking into account that

$$E^{-1}(\mu)=\mu(\rho(x))=\sigma(\rho(x))-\rho(x)=x-\rho(x)=\nu(x), \tag{171}$$

we find that

$$\mathrm{Res}_\mathcal{E} F=\nu\,\mathrm{Res}_\delta F. \tag{172}$$

Definition 25: The trace of an operator $F\in\Lambda$ is defined by

$$\mathrm{Tr}(F)=\int_\mathbb{T}\mathrm{Res}_\delta\{F(I+\mu\delta)^{-1}\}\nabla x, \tag{173}$$

where the nabla integral is defined according to Sec. II.

Proposition 26: Let F be given as in (165). In case of regular-discrete time scales we have

$$\mathrm{Res}_\delta\{F(I+\mu\delta)^{-1}\}=\frac{1}{\nu(x)}\mathrm{Free}_{\mathcal{E}}F \tag{174}$$

for $x\in\mathbb{T}\backslash\{x_*,x^*\}$, *where* $x_*=\min\mathbb{T}$ *and* $x^*=\max\mathbb{T}$. *Therefore in this case*

$$\mathrm{Tr}(F)=\int_{\mathbb{T}}(\mathrm{Free}_{\mathcal{E}}F)\frac{\nabla x}{\nu(x)}=\sum_{x\in\mathbb{T}}b_0(x). \tag{175}$$

Proof: Since $I+\mu\delta=\mathcal{E}$ we have, by using (172) and (168),

$$\begin{aligned}\nu\,\mathrm{Res}_\delta\{F(I+\mu\delta)^{-1}\}&=\mathrm{Res}_{\mathcal{E}}\{F(I+\mu\delta)^{-1}\}=\mathrm{Res}_{\mathcal{E}}(F\mathcal{E}^{-1})=\mathrm{Res}_{\mathcal{E}}(b_k\mathcal{E}^{k-1}+\cdots+b_1+b_0\mathcal{E}^{-1}+\cdots)\\&=b_0=\mathrm{Free}_{\mathcal{E}}(F).\end{aligned} \tag{176}$$

Proposition 27: For all $F_1,F_2\in\Lambda$,

$$\mathrm{Tr}([F_1,F_2])=\mathrm{Tr}(F_1F_2-F_2F_1)=0, \tag{177}$$

in other words the pairing $(F_1,F_2)=\mathrm{Tr}(F_1F_2)$ *is symmetric.*

We prove (177) only for particular cases of time scales $\mathbb{T}$. They indicate a way to the proof in the general case of regular time scales.

(i) If $\mathbb{T}=\mathbb{R}$, then $\delta=\partial=(d/\mathrm{d}x)\cdot$ and $\mu(x)=0$,

$$F=a_k\partial^k+\cdots+a_1\partial+a_0+a_{-1}\partial^{-1}+\cdots \tag{178}$$

and

$$\mathrm{Tr}(F)=\int_{\mathbb{R}}\mathrm{Res}(F)\mathrm{d}x=\int_{\mathbb{R}}a_{-1}(x)\mathrm{d}x. \tag{179}$$

It is well known that (for example, see Ref. 3) for such functional $\mathrm{Tr}(F)$ the statement (177) holds.

(ii) Let $\mathbb{T}$ be a regular-discrete time scale. Then by Proposition 26 we have

$$\mathrm{Tr}([F_1,F_2])=\int_{\mathbb{T}}\mathrm{Res}_\delta\{[F_1,F_2](I+\mu\delta)^{-1}\}\nabla x=\int_{\mathbb{T}}(\mathrm{Free}_{\mathcal{E}}[F_1,F_2])\frac{\nabla x}{\nu(x)}=0. \tag{180}$$

It is enough to check (180) for monomials $F_1=A\mathcal{E}^k$ and $F_2=B\mathcal{E}^\ell$. By the use of the property (113) of $\mathcal{E}$ we have

$$F_1F_2=A(E^kB)\mathcal{E}^{k+\ell}\quad\text{and}\quad F_2F_1=B(E^\ell A). \tag{181}$$

Therefore $\mathrm{Free}_{\mathcal{E}}[F_1,F_2]$ is either zero or

$$\mathrm{Free}_{\mathcal{E}}[F_1,F_2]=A(E^kB)-B(E^{-k}A)=(E^k-I)(E^{-k}A)B$$

$$=(I-E^{-1})(E^k+E^{k-1}+\cdots+E)(E^{-k}A)B=\nu(x)[\Phi(A,B)]^\nabla,$$

where $\Phi(A,B)=(E^k+E^{k-1}+\cdots+E)(E^{-k}A)B$. Hence

$$\int_{\mathbb{T}}\mathrm{Free}_{\mathcal{E}}[F_1,F_2]\frac{\nabla x}{\nu(x)}=\int_{\mathbb{T}}[\Phi(A,B)]^\nabla\nabla x=\Phi(A,B)\Big|_{x_*}^{x^*}=0 \tag{182}$$

so that (177) is proved for regular-discrete time scales.

(iii) Let $\mathbb{T}$ be a mixed time scale, say, of the form $\mathbb{T}=(-\infty,0)\cup\mathbb{K}_q$, where $(-\infty,0)$ denotes the real line interval. Then for any $F_1,F_2\in\Lambda$ we have, taking into account Proposition 26, that

$$\mathrm{Tr}([F_1,F_2])=\int_{\mathbb{T}}\mathrm{Res}_{\delta}\{[F_1,F_2](I+\mu\delta)^{-1}\}\nabla x=\int_{-\infty}^{0}\left(\mathrm{Res}_{\partial}([F_1,F_2])\mathrm{d}x+\int_{\mathbb{K}_q}(\mathrm{Free}_{\mathcal{E}}[F_1,F_2])\frac{\nabla x}{\nu(x)}.\right. \tag{183}$$

Take for instance $F_1=A\delta$ and $F_2=B\delta^{-1}$. Then

$$\mathrm{Res}_{\partial}[F_1,F_2]=\mathrm{Res}_{\partial}[A\partial,B\partial^{-1}]=AB'+A'B=(AB)',\mathrm{Free}_{\mathcal{E}}[F_1,F_2]=\mathrm{Free}_{\mathcal{E}}\left[\frac{A}{\mu}(\mathcal{E}-I),B(\mathcal{E}-I)^{-1}\mu\right]$$
$$=AE(B)-BE^{-1}(A). \tag{184}$$

Therefore

$$\int_{-\infty}^{0}(\mathrm{Res}_{\partial}[F_1,F_2])\mathrm{d}x=\int_{-\infty}^{0}(AB)'\,\mathrm{d}x=A(0^-)B(0^-), \tag{185}$$

$$\int_{\mathbb{K}_q}\mathrm{Free}_{\mathcal{E}}[F_1,F_2]\frac{\nabla x}{\nu(x)}=\int_{\mathbb{K}_q}[AE(B)-BE^{-1}(A)]\frac{\nabla x}{\nu(x)}$$
$$=\sum_{x\in\mathbb{K}_q}[A(x)B(qx)-A(q^{-1}x)B(x)]=-A(0^+)B(0^+). \tag{186}$$

Hence

$$\mathrm{Tr}([F_1,F_2])=A(0^-)B(0^-)-A(0^+)B(0^+)=0, \tag{187}$$

where A and B are Δ-smooth functions on $\mathbb{T}$ and hence they are continuous at $x=0$.

Proposition 28: Equation (79) implies that

$$\frac{d}{\mathrm{d}t_n}L^k=[A_n,L^k],\quad A_n=(L^{n/N})_{\geqslant 0}, \tag{188}$$

for all $k=\ell/N$, where ℓ is any positive integer.

Propositions 27 and 28 imply the next proposition.

Proposition 29: For all $\ell=0,1,\ldots$ the functionals

$$H_\ell=\mathrm{Tr}(L^{\ell/N}), \tag{189}$$

are common constants of motion for the hierarchy (79) and (115).

Note that in proof of Proposition 29 it is, in particular, used the fact that the flows (vector fields) defined by the different members of the hierarchy all commute with each other (see Refs. 2 and 17).

VII. CONCLUSION

We have developed the Gel'fand-Dikii approach to time scales. So far the integrable systems were studied on $\mathbb{R},\mathbb{Z}$ or on $\mathbb{K}_q$. Here we gave a unified and extended approach. In particular cases when $\mathbb{T}=\mathbb{R},\mathbb{Z},\mathbb{K}_q$ we find several examples of the integrable systems. We developed the algebra of Δ-pseudo differential and $\mathcal{E}$-shift operators. We established the GD formalism on these algebras and introduced several Lax representations on these algebras. All these Lax representations are straightforward generalizations of the Lax representations on pseudodifferential algebras of integrable systems on $\mathbb{R}$ and the Lax representations of the algebra of shift operators on $\mathbb{Z}$. The Burgers and KdV hierarchies on time scales that we found are the special cases of these Lax representations. We also generalized the Frenkel KdV hierarchy introduced on $\mathbb{K}_q$ to arbitrary

discrete time scales. We constructed the recursion operators of each example considered in this paper and gave a way of constructing the constants of motions by introducing an appropriate trace form on time scales.

In this work we did not consider the r-matrix construction and the Hamiltonian formulation of integrable systems on time scales. The trace form on a general time scale needs a little care. Such a work is in progress and will be communicated in a separate paper.

APPENDIX: RECURSION OPERATORS OF FOUR-FIELD SYSTEMS

We give the recursion operator of the four-field systems on time scale which are studied in example 7.

(1) For the case $k=0$, $\alpha=-2$, we obtain the recursion relation between the $n+1$th and nth elements of the hierarchy as follows:

$$\begin{aligned} w_{n+1} &= w(E+1)^{-1}E(v_n) + E(v)(E^2-1)^{-1}E^2(w_n) - v(E^2-1)^{-1}w_n \\ &\quad + w(E+1)^{-1}(1-E)w(E^2-1)^{-1}E(w_n) + E^2(u_n) + (1-E^2)\eta_n, \end{aligned} \tag{A1}$$

$$\begin{aligned} v_{n+1} &= wE(u_n) + vv_n - u(E^2-1)^{-1}E^{-1}(w_n) + E(u)(E^2-1)^{-1}E^2(w_n) \\ &\quad + (1-E^2)p(1-E^2)^{-1}\frac{p_n}{p} + E^2(p_n) + (E^{-1}(w) - wE)\eta_n, \end{aligned} \tag{A2}$$

$$\begin{aligned} u_{n+1} &= wE(p_n) + u(E+1)^{-1}(E+1+E^{-1})v_n - p(E^2-1)^{-1}E^{-2}(w_n) \\ &\quad + u(E+1)^{-1}(E-1)E^{-1}(w)(E^2-1)^{-1}w_n + E(p)(E^2-1)^{-1}E^2(w_n) \\ &\quad + (E^{-2}(w) - wE)p(1-E^2)^{-1}\frac{p_n}{p} + vu_n + (E^{-1}(v) - v)\eta_n, \end{aligned} \tag{A3}$$

$$\begin{aligned} p_{n+1} &= uE^{-1}(u_n) + p(1+E^{-2})v_n + p(E^{-1}-E^{-2})w(E^2-1)^{-1}E(w_n) \\ &\quad + (E^{-2}(v) - v)p(1-E^2)^{-1}\frac{p_n}{p} + vp_n + (E^{-1}(u) - uE^{-1})\eta_n, \end{aligned} \tag{A4}$$

where

$$\eta_n = (E^2(p) - E(p)E^2)^{-1}\left[E^2(u)E(p_n) + E^2(p)u_n + (uE^2(p) - E^2(u)E(p)E^{-1})(1-E^2)^{-1}E^2\left(\frac{p_n}{p}\right)\right].$$

(2) For the case $k=1$, $\alpha=-2$, the recursion relation between the $n+1$th and nth elements of the hierarchy is given by

$$\begin{aligned} \bar{u}_{n+1} &= E^{-2}(\bar{w}_n) + \bar{u}(1+E)^{-1}(E-1)\bar{u}(1-E^2)^{-1}E(\bar{u}_n) + \bar{v}\bar{u}_n + \bar{u}(1+E)^{-1}\bar{v}_n \\ &\quad + (E^{-1}(\bar{v}) - \bar{v})(1-E^2)^{-1}\bar{u}_n + (1-E^{-2})\bar{\zeta}_n, \end{aligned} \tag{A5}$$

$$\begin{aligned} \bar{w}_{n+1} &= \bar{u}E^{-1}(\bar{q}_n) + \bar{w}(1+E)^{-1}(E^2+E+1)\bar{v}_n + (E^{-1}(\bar{q}) - \bar{q}E^4)(1-E^2)^{-1}\bar{u}_n + \bar{w}(1+E)^{-1}(1-E)E(\bar{u}) \\ &\quad \times(1-E^2)^{-1}E^2(\bar{u}_n) + \bar{v}\bar{w}_n + (E(\bar{v}) - \bar{v})\bar{\zeta}_n + (E^2(\bar{u}) - \bar{u}E^{-1})\bar{q}(E^2-1)^{-1}E^2\left(\frac{\bar{q}_n}{\bar{q}}\right), \end{aligned} \tag{A6}$$

$$\bar{q}_{n+1} = \bar{v}\bar{q}_n + \bar{w}E(\bar{w}_n) + \bar{q}(1+E^2)\bar{v}_n + (E^2(\bar{v}) - \bar{v})\bar{q}(E^2-1)^{-1}E^2\left(\frac{\bar{q}_n}{\bar{q}}\right)$$
$$+ \bar{q}(1+E)^{-1}(1-E^2)E(\bar{u})(1-E^2)^{-1}E^2(\bar{u}_n) + (E(\bar{w}) - \bar{w}E)\bar{\zeta}_n, \tag{A7}$$

$$\bar{v}_{n+1} = E^{-2}(\bar{q}_n) + \bar{u}E^{-1}(\bar{w}_n) + (E^{-1}(\bar{w}) - \bar{w}E^3)(1-E^2)^{-1}\bar{u}_n + \bar{v}\bar{v}_n + (E(\bar{u}) - \bar{u}E^{-1})\bar{\zeta}_n$$
$$+ (1-E^{-2})\bar{q}(E^2-1)^{-1}E^2\left(\frac{\bar{q}_n}{\bar{q}}\right), \tag{A8}$$

where

$$\bar{\zeta}_n = (\bar{q}E^2 - E(\bar{q}))^{-1}\left[\bar{q}E^2(\bar{w}_n) + (E^2(\bar{w})\bar{q}E - \bar{w}E(\bar{q}))(E^2-1)^{-1}E\left(\frac{\bar{q}_n}{\bar{q}}\right)\right]. \tag{A9}$$

From the recursion relations obtained in both cases, we can construct the recursion operators of the hierarchies.

Eigenfunctions of the curl in cylindrical geometry

Edward C. Morse
University of California, Berkeley, California 94720

(Received 17 August 2005; accepted 19 September 2005;
published online 15 November 2005)

Eigenfunctions of the equation $\vec{\nabla}\times\vec{B}=\lambda\vec{B}$ are found for finite cylindrical geometry with normal boundary condition $\vec{B}\cdot\hat{n}=0$ and nonaxisymmetric modes $\sim e^{im\theta}, m\neq 0$. The vector field $\vec{B}$ can be represented by a scalar generating function of the Chandrasekhar-Kendall type with radial Bessel functions for the nondegenerate cases. A general set of solutions can also be generated by transformation of variables. A series solution in terms of radial Bessel functions is found which has excellent convergence properties ($a_n \sim 1/n^4$) and a robust method of locating eigenvalues is described. © *2005 American Institute of Physics.*

I. INTRODUCTION

The equation $\vec{\nabla}\times\vec{B}=\lambda\vec{B}$ appears in many treatments of hydrodynamics and magnetohydrodynamics. It was first noted by Beltrami[1] in 1889 and the form with $\lambda=$constant was used by Trkal[2] in 1919. In the context of magnetohydrodynamics it was identified as a special force-free magnetic field by Woltjer[3] and was associated with a variational principle by Taylor[4] and thus acquired the name "Taylor state" when describing its lowest eigenvalue in a magnetostatic equilibrium. The eigenfields $\vec{B}_n$ of the nth eigenmode λ_n of this equation form a complete Hilbert space for decomposition of divergence-free vector fields,[5] such as the magnetic field or the velocity field in an incompressible fluid. The decomposition of magnetic and velocity field components into the eigenfunctions of the curl has proven useful as a method of studying magnetohydrodynamics using a Galerkin spectral representation of these fields in dynamic simulations.[6,7]

In this paper the solution of the eigenfunction equation $\vec{\nabla}\times\vec{B}=\lambda\vec{B}$ is discussed for the case of finite cylindrical geometry with boundary conditions $\vec{B}\cdot\hat{n}=0$ for nonaxisymmetric modes. A brief treatment of the symmetric $m=0$ case is given for completeness as a special case.

II. SYMMETRIC CASE, $m=0$

The solution of the curl-eigenfunction equation in cylindrical geometry for symmetrical ($m=0$) modes is relatively straightforward. Using a scalar generating function first shown by Chandrasekhar and Kendall,[8] the vector field $\vec{B}$ can be generated by

$$\vec{B}=\vec{\nabla}\times(\hat{z}\psi(R,Z))+(1/\lambda)\vec{\nabla}\times\vec{\nabla}\times(\hat{z}\psi(R,Z))$$

and these solutions are eigenfunctions of the curl provided that $\psi(R,Z)$ is a solution of the Helmholtz equation

$$\nabla^2\psi(R,Z)+\lambda^2\psi(R,Z)=0.$$

For these axisymmetric modes, the magnetic field components are given in cylindrical coordinates (R,θ,Z) by

$$B_R = (1/\lambda)\frac{\partial^2 \psi(R,Z)}{\partial R \partial Z},$$

$$B_\theta = -\frac{\partial \psi(R,Z)}{\partial R},$$

$$B_Z = \lambda \psi(R,Z) + (1/\lambda)\frac{\partial^2 \psi(R,Z)}{\partial Z^2}.$$

Normal boundary conditions $\vec{B}\cdot\hat{n}=0$ with boundaries $R=a$ and $Z=\pm 1/2$ imply that $B_R(a,Z)=0$ and $B_Z(R,\pm 1/2)=0$. Separable solutions to the scalar Helmholtz equation in this geometry which fit the boundary condition on B_Z are

$$\psi(R,Z) = J_0(\sqrt{\lambda^2 - ((2n'-1)\pi)^2}R)\cos((2n'-1)\pi Z)$$

and

$$\psi(R,Z) = J_0(\sqrt{\lambda^2 - (2n\pi)^2}R)\sin(2n\pi Z)$$

and the radial boundary condition $B_R(a,Z)=0$ is then given by

$$J_0'(k'a) = 0,$$

where $k' = (\sqrt{\lambda^2-(2n\pi)^2}, \sqrt{\lambda^2-((2n'-1)\pi)^2})$ for the modes. (The use of both sines and cosines to describe the modes may seem artificial but will simplify the description of the $m\neq 0$ modes later on.) For these modes, the general eigenvalue equation is then written as

$$\lambda_{pq}^2 = (1/a)^2(z_p')^2 + q^2\pi^2,$$

where p and q are integers and z_p' is the pth root of the derivative of the zeroth order Bessel function, $J_0'(z_p')=0$. The integer q simply replaces the set of even integers $2n$ and odd integers $2n'-1$ given above.

III. NONSYMMETRIC CASE, $m \neq 0$

The equation $\vec{\nabla}\times\vec{B}=\lambda\vec{B}$ can be recursively applied to obtain the "squared" version $\vec{\nabla}\times\vec{\nabla}\times\vec{B}=\lambda^2\vec{B}$. The eigenfunctions of this equation are not directly applicable to the first-order equation because the eigenfunctions of $\vec{\nabla}\times\vec{\nabla}\times\vec{B}=\lambda^2\vec{B}$ contain the eigenfunctions of $\vec{\nabla}\times\vec{B}=-\lambda\vec{B}$ as well as the eigenfunctions of $\vec{\nabla}\times\vec{B}=+\lambda\vec{B}$. However examination of the system $\vec{\nabla}\times\vec{\nabla}\times\vec{B}=\lambda^2\vec{B}$ is useful because it reveals the underlying elliptic nature of the equation, with the first-order equation forming connections between the three dependent variables in the vector $\vec{B}$.

We note that the equation $\vec{\nabla}\times\vec{\nabla}\times\vec{B}=\lambda^2\vec{B}$ can be manipulated for solenoidal fields with $\vec{\nabla}\cdot\vec{B}=0$ into the form

$$LB_R = \frac{+2im}{R^2}B_\theta,$$

$$LB_\theta = \frac{-2im}{R^2}B_R,$$

$$LB_Z = -\frac{1}{R^2}B_Z,$$

where

$$L = \frac{\partial^2}{\partial R^2} + \frac{1}{R}\frac{\partial}{\partial R} + \frac{\partial^2}{\partial Z^2} - \frac{(m^2+1)}{R^2} + \lambda^2.$$

The equations are of the form $Lu=Cu$, with the matrix C being nondiagonal. Following Ref. 9, we then perform a Jordan decomposition on C by finding a unitary transformation such that $C=pC'p^{-1}$ with C' diagonal. Applying the operator matrix p^{-1} to both sides of the equation, we have

$$p^{-1}Lu = p^{-1}Cu = p^{-1}(pC'p^{-1})u,$$

$$L(p^{-1}u) - [L,p^{-1}]u = C'(p^{-1}u).$$

The transformation matrix p^{-1} is given by

$$p^{-1} = \begin{pmatrix} 0 & 0 & 1 \\ i/2 & 1/2 & 0 \\ -i/2 & 1/2 & 0 \end{pmatrix}$$

and the commutator $[L,p^{-1}]=0$ for this system. Introducing a set of variables $w=p^{-1}u$ then gives $Lw=C'w$ with the matrix C' given by

$$C' = \begin{pmatrix} -1/R^2 & 0 & 0 \\ 0 & -2m/R^2 & 0 \\ 0 & 0 & +2m/R^2 \end{pmatrix}.$$

We can relabel the variables w in a more suggestive way. We write

$$B_Z(R,\theta,Z) = w_m(R,Z)e^{im\theta},$$

$$B_\theta(R,\theta,Z) = \left(\frac{w_{m+1}(R,Z) - w_{m-1}(R,Z)}{2i}\right)e^{im\theta},$$

$$B_R(R,\theta,Z) = \left(\frac{w_{m+1}(R,Z) + w_{m-1}(R,Z)}{2}\right)e^{im\theta}.$$

The transformed equations then become

$$L_{m+1}w_{m+1} = 0,$$

$$L_m w_m = 0,$$

$$L_{m-1}w_{m-1} = 0$$

with

$$L_n = \frac{\partial^2}{\partial R^2} + \frac{1}{R}\frac{\partial}{\partial R} + \frac{\partial^2}{\partial Z^2} - \frac{n^2}{R^2} + \lambda^2.$$

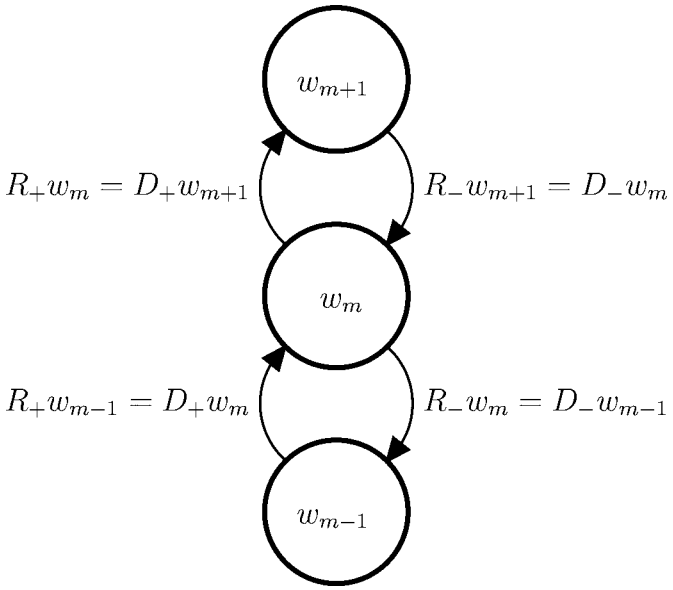

FIG. 1. Connection diagram for $m \neq 0$ transformed variables.

The first-order equations $\vec{\nabla} \times \vec{B} = \lambda \vec{B}$ and $\vec{\nabla} \cdot B = 0$ then can be manipulated into a set of first-order relations between the variables w. These relations can be written in a suggestive form of raising and lowering operators with the definitions

$$D_- = i\lambda - \partial/\partial Z,$$

$$D_+ = i\lambda + \partial/\partial Z,$$

$$R_-^n = (-1)^{n+m+1}(n/R + \partial/\partial R),$$

$$R_+^n = (-1)^{n+m+1}(n/R - \partial/\partial R).$$

The first-order equations then form a set of connection relations between the components w_n which each must satisfy the elliptic conditions given above. The connection diagram is shown in Fig. 1.

The Chandrasekhar-Kendall form may be employed to generate solutions to the $m \neq 0$ eigenequation[10], although this method does not directly translate the vector problem into a scalar problem. The Chandrasekhar-Kendall fields for $m \neq 0$ are given by

$$B_R = \left(\frac{im}{R} \psi(R,Z) + (1/\lambda) \frac{\partial^2 \psi(R,Z)}{\partial R \partial Z} \right) e^{im\theta},$$

$$B_\theta = \left(\frac{im}{\lambda R} \frac{\partial \psi(R,Z)}{\partial Z} - \frac{\partial \psi(R,Z)}{\partial R} \right) e^{im\theta},$$

$$B_Z = \left(\lambda \psi(R,Z) + (1/\lambda) \frac{\partial^2 \psi(R,Z)}{\partial Z^2} \right) e^{im\theta}.$$

For the $m \neq 0$ case, the radial boundary condition is complicated by the additional term $(im/R)\psi$, which is of course zero in the symmetric case. The radial boundary condition,

$$\left(\frac{im}{R}\psi(R,Z)+(1/\lambda)\frac{\partial^2\psi(R,Z)}{\partial R\partial Z}\right)\Bigg|_{R=a}=0,$$

is not a standard boundary condition for an elliptic equation and in fact cannot yield distinct eigenmodes without some additional restriction. The generating function $\psi=R^m\exp(-i\lambda Z)\exp(im\theta)$ solves the boundary equations independent of λ, although it does so trivially by generating zero vector field. While the Chandrasekhar-Kendall form does not compose a proper elliptic scalar problem, the Chandrasekhar-Kendall eigenfields can be used to solve the vector eigenproblem, which is well posed.[5]

Partial-term solutions to the boundary problem can be found by expansion of ψ into modes with radial Bessel functions and axial sines and cosines in the usual manner for cylindrical problems. It is important to note, however, that an alternative to the Bessel-function solution to the cylindrical Helmholtz equation exists, and this is the set of Sonine polynomials,

$$S(n,m,R,Z)=R^m e^{im\theta}e^{i\lambda Z}\frac{(-1)^n}{\Gamma(n+2)}L(n,m,i\lambda(\sqrt{R^2+Z^2}-Z))L(n,m,-i\lambda(\sqrt{R^2+Z^2}+Z)).$$

Here $L(n,m,x)$ represents the Laguerre polynomial. For integer n and m, the above expression generates solutions to the Helmholtz equation which are expressed in polynomials in R and Z times an exponential $e^{i(m\theta+\lambda Z)}$. As an example, the $n=0$ term is anharmonic in Z and satisfies $B_Z=0$ everywhere,

$$\psi=R^m\exp(i\lambda Z)\exp(im\theta).$$

The Sonine polynomials become important for calculation of degenerate solutions to the eigenequation, as shall be shown later.

IV. SERIES SOLUTION FOR $m\neq 0$ MODES

As discussed above, the transformation of the vector problem into a scalar problem using the Chandrasekhar-Kendall form generates a radial boundary condition which is perhaps unusual for elliptic equations but it has a suggestive form. The appearance of this operator $(i\cdots+(\partial/\partial Z\cdots))$ suggests that we seek a solution of form

$$\psi=\exp(im\theta)(F(R,Z)+iG(R,Z)),$$

where $F(R,Z)$ and $G(R,Z)$ are real functions and where, say, $F(R,Z)$ is an even function of Z and $G(R,Z)$ is an odd function of Z. The boundary condition can then be written as a separate pair of conditions,

$$\left(\frac{a}{m\lambda}\right)\frac{\partial^2F(R,Z)}{\partial R\partial Z}\Bigg|_{R=a}=G(a,Z),$$

$$\left(\frac{a}{m\lambda}\right)\frac{\partial^2G(R,Z)}{\partial R\partial Z}\Bigg|_{R=a}=-F(a,Z).$$

Using this form for a solution, and noting that the anharmonic term already has this form, we have a general series expression for the generating function $\psi=e^{im\theta}\psi(R,Z)$,

$$\psi(R,Z) = R^m e^{i\lambda Z} + \sum_{n'=1}^{\infty} b_{n'} \frac{J_m(R\sqrt{\lambda^2 - (2n'-1)^2\pi^2})}{J_m(a\sqrt{\lambda^2 - (2n'-1)^2\pi^2})} \cos((2n'-1)\pi Z)$$
$$+ i\sum_{n=1}^{\infty} a_n \frac{J_m(R\sqrt{\lambda^2 - 4n^2\pi^2})}{J_m(a\sqrt{\lambda^2 - 4n^2\pi^2})} \sin(2n\pi Z).$$

Here we have normalized the Bessel functions to their value at $R=a$ because at some n and n' the argument of the Bessel function becomes imaginary and thus the Bessel functions become exponentially large, since $J_m(ix)=I_m(x)\sim\exp(x)$ when $x\gg 1$. (This normalization produces spurious poles in the matrix representation at values of λ which reflect zeroes in the low-order Bessel functions. This has been found not to interfere with the calculation near an eigenvalue, which is not typically near one of these zeroes. In any case, it would be possible to leave this normalization off for the first few Bessel functions with a real argument.)

The Z derivative appearing in the boundary condition causes some complication in the Fourier decomposition. The odd-integer cosine terms when differentiated become terms in $\sin((2n'-1)\pi Z)$, and these are not independent of the functions $\sin(2n\pi Z)$. A Fourier decomposition of these terms into terms in $\sin(2n\pi Z)$ thus is done in order to generate a set of matching equations which are orthogonal to one another. The Z derivatives of the even-integer sine terms also are mapped into the basis of odd-integer cosine terms. Similarly, the anharmonic term $(\sim\cos(\lambda Z) + i\sin(\lambda Z))$ is mapped into the appropriate basis, the real part into the basis of odd-integer cosines and the imaginary part into the basis of even-integer sines.

This strategy then generates a set of $2N$ matching equations for the boundary condition, where N is the number of even-integer terms in the expansion, typically taken equal to the number of odd-integer terms. The radial differentiation operator and the Z differentiation and basis remapping operator are given here separately. (Note that in the notation that follows, the superscripts "odd" and "even" relate to the integer appearing in the trigonometric expression, not to the Z-parity of ψ. In fact the "odd" terms have even Z-parity and vice versa.) It is interesting to note that by combining the Z-differentiation and basis remapping operations a symmetrical expression for this operator is obtained, as can be demonstrated by integrating by parts.

An expression for the radial differentiation operator is

$$Q_p = \frac{\sqrt{\lambda^2 - p^2\pi^2}(J_{m-1}(a\sqrt{\lambda^2 - p^2\pi^2}) - J_{m+1}(a\sqrt{\lambda^2 - p^2\pi^2}))}{2J_m(a\sqrt{\lambda^2 - p^2\pi^2})}$$

Here p takes on even values $2n$ and odd values $2n'-1$.

The Z-differentiation and basis remapping ("sine-to-cosine") operator is given by

$$\mathbf{SC}(n,n') = \frac{8(-1)^{n'+n}(1-2n')n}{(2n'-1)^2 - 4n^2}.$$

We can now construct a set of matrix equations which form the $2N$ total boundary conditions. We write this equation in the form

$$\mathbf{M}\cdot\mathbf{x} = \mathbf{u},$$

where the forcing vector $\mathbf{u}$ is given by the Fourier decomposition of the anharmonic term as described above. The operator corresponding to the term $(a/m\lambda)\partial^2/\partial R\partial Z$ is given by

$$\mathbf{M}^{\text{even}}_{n,n'} = \frac{a\,\mathbf{SC}(n,n')Q^{\text{even}}_n}{m\lambda}$$

and

$$\mathbf{M}^{\text{odd}}_{n',n} = \frac{a\,\mathbf{SC}(n,n')Q^{\text{odd}}_{n'}}{m\lambda}.$$

The forcing vector $\mathbf{u}$ is then given by

$$\mathbf{u} = \{u^{\text{even}}_1, u^{\text{even}}_2, \ldots, u^{\text{even}}_N, u^{\text{odd}}_1, u^{\text{odd}}_2, \ldots, u^{\text{odd}}_N\},$$

where

$$u^{\text{even}}_n = \frac{8(-1)^n n\pi \sin(\lambda/2)}{(2n\pi)^2 - \lambda^2}$$

and

$$u^{\text{odd}}_{n'} = \frac{4(-1)^{n'}(1-2n')\pi\cos(\lambda/2)}{(1-2n')^2\pi^2 - \lambda^2}.$$

The vector $\mathbf{x}$ is the union of a_n and $b_{n'}$,

$$\mathbf{x} = (\mathbf{a},\mathbf{b}) = (a_1, a_2, \ldots, a_N, b_1, b_2, \ldots, b_N)$$

and the matrix $\mathbf{M}$ is given by

$$\mathbf{M} = \begin{pmatrix} \mathbf{M}^{\text{even}} & \mathbf{I} \\ \mathbf{I} & \mathbf{M}^{\text{odd}} \end{pmatrix}.$$

Some comments about the structure of the matrix equation $\mathbf{M}\cdot\mathbf{x}=\mathbf{u}$ are in order. The radial operator generates terms which are proportional to n as they become large. The terms near the diagonal of the sine-to-cosine matrix $\mathbf{SC}$ also are proportional to n, and thus the matrices $\mathbf{M}^{\text{even}}$ and $\mathbf{M}^{\text{odd}}$ have terms that increase as n^2. The alternating nature of the terms $(-1)^{n+n'}$ does result in less difficulty in inverting the matrix $\mathbf{M}$ than would be required otherwise. However, the matrix equations can become better conditioned by inverting the individual components $\mathbf{M}^{\text{even}}$ and $\mathbf{M}^{\text{odd}}$. This can be done since each can be decomposed into the product of a diagonal matrix and the basis transformation matrix $\mathbf{SC}$. The $\mathbf{SC}$ matrix has an inverse which is given by

$$\mathbf{SC}^{-1}(n',n) = \frac{-8(-1)^{n+n'}n'}{(-1+2n)((1-2n)^2 - 4n'^2)\pi^2}.$$

(This expression can be arrived at by considering that differentiating a function $f(x)$ [and obtaining function $g(x)$] in basis $|n\rangle$ and transforming into a new basis $|n'\rangle$ must have the inverse operator formed by integrating the function $g(x)$ termwise in basis $|n'\rangle$ and transforming the result into basis $|n\rangle$.) Also, upon multiplication and substitution, the matrix equations can be separated into two matrix equations each of rank N rather than $2N$. If we form auxiliary matrices $\mathbf{z}_1$ and $\mathbf{z}_2$ which are the inverses of $\mathbf{M}^{\text{even}}$ and $\mathbf{M}^{\text{odd}}$,

$$\mathbf{z}_1(n,n') = \mathbf{M}^{\text{even}^{-1}} = \frac{m\lambda}{a}\mathbf{SC}^{-1}(n,n')/Q_{\text{even}}(n),$$

$$\mathbf{z}_2(n',n) = \mathbf{M}^{\text{odd}^{-1}} = \frac{m\lambda}{a}\mathbf{SC}^{-1}(n,n')/Q_{\text{odd}}(n'),$$

$$\mathbf{Z}^{\text{even}} = \mathbf{I} - \mathbf{z}_1\cdot\mathbf{z}_2, \quad \mathbf{u}'_1 = \mathbf{z}_1\cdot\mathbf{u}_1 - \mathbf{z}_1\cdot\mathbf{z}_2\cdot\mathbf{u}_2,$$

$$\mathbf{Z}^{\text{odd}} = \mathbf{I} - \mathbf{z}_2 \cdot \mathbf{z}_1, \quad \mathbf{u}_2' = \mathbf{z}_2 \cdot \mathbf{u}_2 - \mathbf{z}_2 \cdot \mathbf{z}_1 \cdot \mathbf{u}_1,$$

then the transformed set of matrix equations is

$$\begin{aligned} \mathbf{Z}^{\text{even}} \cdot \mathbf{a} &= \mathbf{u}_1', \\ \mathbf{Z}^{\text{odd}} \cdot \mathbf{b} &= \mathbf{u}_2'. \end{aligned} \tag{4.1}$$

When these are solved for some finite N as a function of λ, a proper eigenfield is obtained only when the coefficients a_n and b_n form a convergent series representation of the field components B_R, B_θ, and B_Z. Since the operator $\mathbf{M}$ for the field components has terms proportional to n^2, it would seem that the minimum convergence criterion for the a_n and b_n is that $n^2(a_n, b_n) \to 0$ as $n \to \infty$. However, because of the additional constraints imposed by the connection relations outlined above, the a_n and $b_n \propto 1/n^4$ when λ is an eigenvalue. In fact the eigenvalue problem can be defined as solutions to (4.1) above with the limiting forms $\lim_{n\to\infty} n^3(a_n, b_n) = 0$. However, a stronger eigenvalue criterion can be formed by observing that solutions to the odd series b_n always have a $1/n^4$ characteristic independent of λ and the terms a_n have a $1/n^2$ characteristic when λ is not an eigenvalue and a $1/n^4$ characteristic as λ approaches an eigenvalue. The reason for this unequal behavior arises from the following observation regarding the trigonometric series of terms produced by the odd and even Fourier series when differentiation is included. To wit, the series of terms in $\cos((2n-1)\pi Z)$, $n = 1, 2, \ldots, \infty$ form a complete space on $(-1/2, 1/2)$ for even functions of Z, as do the terms $\sin(2n\pi Z)$, $n = 1, 2, \ldots, \infty$ for odd functions of z. These are used as the Z-basis functions for the functions ψ used as the generator. However, the derivatives of these series are also used in the method outlined above, and whereas $\sin((2n-1)\pi Z)$, $n = 1, 2, \ldots, \infty$ is complete for odd functions, the series $\cos(2n\pi Z)$, $n = 1, 2, \ldots, \infty$ is not complete for even functions on $(-1/2, 1/2)$ since the $n = 0$ term, i.e., a constant function, would be necessary to make this series complete. Since this function is not generated by the differentiation operation, a constraint for the convergence of the series solution is that the even function $F(R, Z)$ does not contain a constant part in the Fourier decomposition, i.e., $\int_{-1/2}^{1/2} F(a, Z)\mathrm{d}Z = 0$. The function F is represented by the anharmonic term $\propto \cos(\lambda Z)$ and by the Fourier terms in $b_n \cos((2n-1)\pi Z)$ and thus the eigenvalue criterion becomes

$$\epsilon(\lambda) = \sum_{n=1}^{\infty} \frac{b_n(-1)^n}{2n-1} - \pi \frac{\sin(\lambda/2)}{\lambda} = 0. \tag{4.2}$$

The summation appearing in this equation contains terms decreasing as $1/n^5$ independent of λ, so that this equation has robust convergence as a function N, the total terms used in the series expansion. The error term caused by truncation is thus proportional to $1/N^4$. It is also important to note that for eigenvalue-only studies, only one of the matrix equations need be solved, since only the b_n are needed in (4.2). In practice the matrix $\mathbf{Z}^{\text{odd}}$ is diagonally dominant (with the possible exception of the first few entries in the upper left-hand corner) and so the linear solve operation is rapidly convergent.

V. NUMERICAL STUDIES

The eigenvalues λ can be located by solving the eigenvalue equation $\epsilon(\lambda) = 0$ with a finite series of terms b_n using a linear matrix solution. Figure 2 shows a numerical solution of the eigenequation (4.2) given above for a length-to-radius ratio $1/a$ of unity with 100 terms kept in the orthonormal expansion, and Fig. 3 shows the spectrum of partial terms a_n and b_n for the lowest eigenmode at $\lambda = 1.734\,26\pi$. Note that the smooth zero crossings of $\epsilon(\lambda)$ at values of the eigenvalue parameter λ which are not integer multiples of π represent actual eigenvalues for the system. Spurious zeroes of the eigenequation occur at $\lambda = p\pi$, with p integer, because at these points the anharmonic solution used as the forcing term is identical to one of the partial eigenfields, and this redundancy forces a trivial solution which has vector fields $\vec{B} = 0$ everywhere.

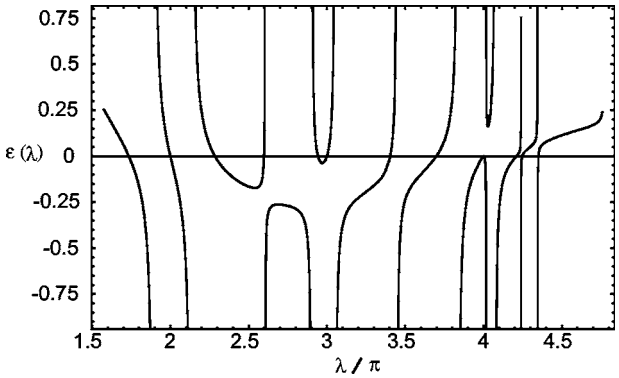

FIG. 2. Behavior of the eigenvalue parameter $\epsilon(\lambda)$ for $m=1$ mode at $1/a=1$ for a 100-term expansion of the eigenvalue solution as a function of eigenvalue parameter λ.

(Details of the construction of an eigenfield for degenerate cases where λ actually attains an integer value are discussed later.) It is a simple matter to vary the number of terms N kept in the expansion of ψ, and thus an extrapolated value λ_∞ can be calculated by applying this technique to a series of N values. The error in eigenvalue $\lambda_N-\lambda_\infty$ can then be computed. Figure 4 shows that the error in λ is of order $1/N^4$ using this approach. The robust characteristics of the matrices involved allow computation to machine accuracy on a personal computer. For example, iterative calculations with $N=2000$ can be performed on a machine with 256 MB memory that yield the eigenvalue to machine accuracy ($\approx$15 digits) in a matter of minutes. A numerical predictor for the error term remainder, $\epsilon(N)-\epsilon(\infty)$, can be added, and this has been found to speed convergence somewhat.

VI. SPECIAL CASES

It is interesting to explore the range of parameter space in the aspect ratio $1/a$ and in azimuthal mode number m in order to find simple analytical models for the behavior of the eigenproblem in extreme cases. First we examine the behavior of the eigenvalue problem when $a \rightarrow \infty$, i.e., for a "thin disk" case. Here the eigenvalues $\lambda \sim p\pi$, with integer p. For this case, a single Bessel function plus the anharmonic term can be used to approximate the solution

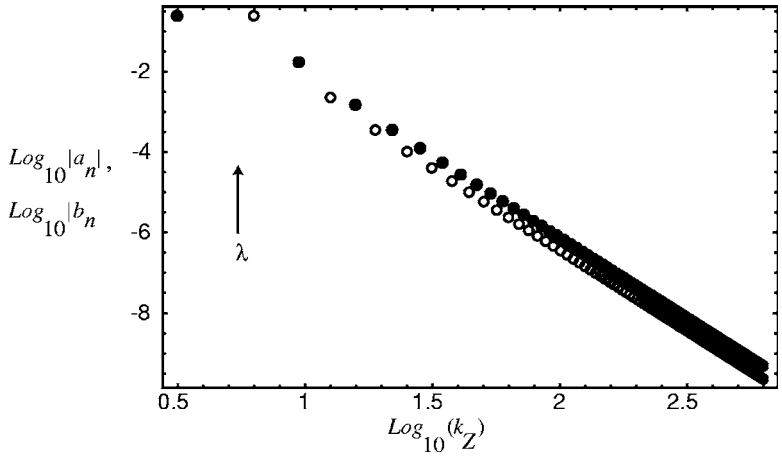

FIG. 3. Spectral plot of $|a_n|$ and $|b_n|$ vs axial wave number k_Z for the lowest $m=1$ mode with aspect ratio $1/a=1.0$. Eigenvalue λ is marked.

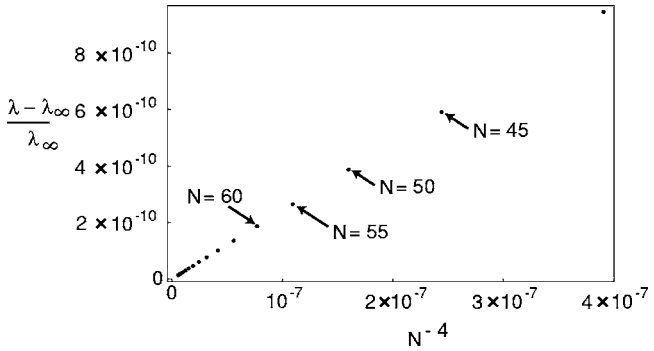

FIG. 4. Convergence study of computed eigenvalue λ as a function of number or terms N.

$$\psi(R,Z) \approx (R/a)^m e^{i\lambda Z} - J_m(\sqrt{\lambda^2 - p^2\pi^2}R)/J_m(\sqrt{\lambda^2 - p^2\pi^2}a)\begin{pmatrix}\cos\\ i\sin\end{pmatrix}(p\pi Z)$$

with the cos (sin) term used when p is odd (even). The expression automatically satisfies the boundary condition at $Z=\pm 1/2$ and the radial boundary condition is approximately satisfied when

$$\frac{m}{a}J_m(\sqrt{\lambda^2 - p^2\pi^2}a) = \sqrt{\lambda^2 - p^2\pi^2}J'_m(\sqrt{\lambda^2 - p^2\pi^2}a).$$

As an example, for the $m=1$, $p=1$ case, this is satisfied when the argument of the Bessel function is $r_1=5.135\,62$ and thus the eigenvalue equation becomes

$$\lambda^2 \approx \pi^2 + \left(\frac{5.135\,62}{a}\right)^2.$$

For the opposite extreme where $a\to 0$, the "long tube" case, we first consider the case when there is no Z-boundary, i.e., the infinitely long tube. In this case we ignore the anharmonic term and look at a complex solution of the form

$$\psi(R,Z) = e^{ik_Z Z}J_m(\sqrt{\lambda^2 - k_Z^2}R).$$

The radial boundary condition is satisfied when

$$m/aJ_m(\sqrt{\lambda^2 - k_Z^2}a) + k_Z/\lambda(\sqrt{\lambda^2 - k_Z^2}a)J'_m(\sqrt{\lambda^2 - k_Z^2}a) = 0.$$

This equation has roots in k_Z which depend on λa. There is a critical value of λa above which two distinct real roots in k_Z appear, and thus a continuum of eigenvalues are possible. For the $m=1$ case, the critical root $\lambda_c a \approx 3.112\,36$. The eigenvalue spectrum becomes discrete in the finite-length case. The asymptotic value of the lowest eigenvalue for finite $a\to 0$ is thus λ_c. A refined estimate of the lowest eigenvalue for small a becomes apparent when the spectrum of the partial terms a_n and b_n is examined numerically. Figure 5 shows the partial term spectrum for the $m=1$ case with $1/a=20$. One notes that there is a large spectral content around the eigenvalue λ which effectively cancels the contribution for the anharmonic term. There is also a large contribution from spectral terms at the two values of k_Z which satisfy the equation above when the eigenvalue is slightly above the critical value of λ_c. The significance of the separated modes can be seen by examining the Z-boundary condition. Since the radial argument $\sqrt{\lambda^2 - k_Z^2}R$ appearing in the Bessel function is nearly the same for $k_Z=k_Z^+$ and for $k_Z=k_Z^-$ when a is small, the modes corresponding to the two roots k_Z^+ and k_Z^- have nearly identical radial structure. The Z-boundary equation is satisfied approximately when the two terms cancel at $Z=\pm 1/2$. Since

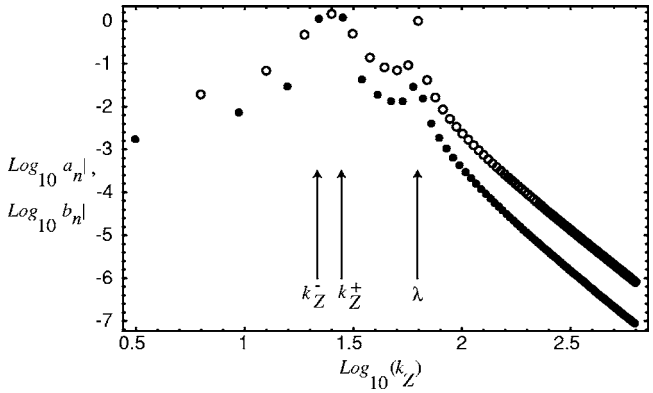

FIG. 5. Spectral plot of $|a_n|$ and $|b_n|$ vs axial wave number k_Z for the lowest $m=1$ mode with $1/a=20$. Upper and lower infinite-cylinder eigenmodes are marked. $(k_Z^+-k_Z^-)/(2\pi)=1.000\,96$ for this case.

$$e^{ik_Z^+Z}+e^{ik_Z^-Z}=2\cos((k_Z^+-k_Z^-)Z/2)e^{i[(k_Z^++k_Z^-)/2]Z},$$

we have cancellation of these terms when $\cos((k_Z^+-k_Z^-)/4)=0$. Thus the eigenvalue equation for the lowest mode becomes $k_Z^+-k_Z^-=2\pi$. Since the roots k_Z appear close to a parabolic minimum, the separation of these roots is proportional to the square root of $(\lambda-\lambda_c)$. For the $m=1$ case, one finds the approximate form

$$(k_Z^+-k_Z^-)^2\approx 9.523(\lambda-\lambda_c).$$

We wish to fit this approximate expression into a canonical form $\lambda^2=r_3^2+r_2^2/a^2$, i.e., the usual hyperbolic relationship between λ and $1/a$, and then for an approximate expression for the lowest $m=1$ eigenvalue with $a\ll 1$ we find $r_2=3.1126$, $r_3^2=2r_2(2\pi)^2/9.523$ and thus

$$\lambda^2=(3.1126/a)^2+25.8454.$$

Figure 6 shows a plot of the lowest $m=1$ eigenvalue for cylinders with aspect ratio $1/a$ ranging from 10^{-2} to 10^3 with these two asymptotic limits drawn. One sees that the eigenvalue λ is somewhat lower than either estimate near length-to-radius ratios $1/a$ near unity, as expected from physical arguments.

It is also interesting to note the special case formed by $m\to\infty$. In this case the term containing $\partial/\partial R\partial Z$ becomes small compared to the other term in the boundary equation. Thus the solutions become similar to the solution of the scalar Helmholtz equation with Dirichlet boundary condi-

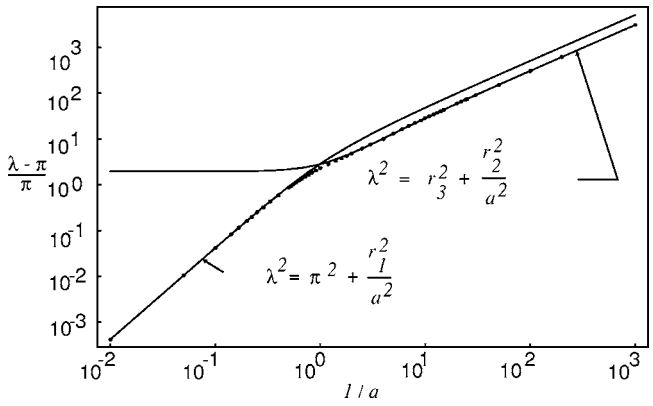

FIG. 6. Lowest $m=1$ eigenvalue as a function of aspect ratio $1/a$, with asymptotic values. Parameters $r_1=5.135\,62$, $r_2=3.112\,36$, $r_3=5.083\,83$.

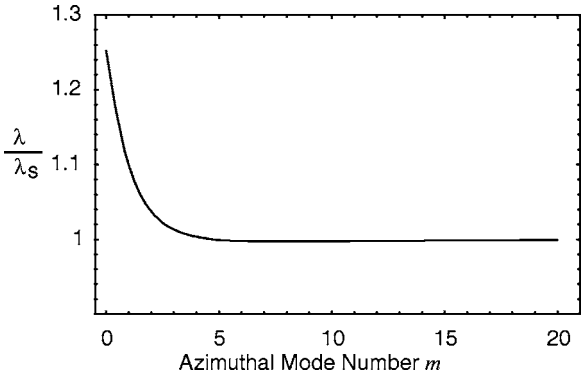

FIG. 7. Ratio of lowest eigenvalue λ to the lowest eigenvalue λ_s for the scalar Helmholtz equation with Dirichlet boundary conditions, as a function of azimuthal mode number m, for aspect ratio $1/a=1.0$.

tions as $m\rightarrow\infty$. This is illustrated by Fig. 7, where a plot of the ratio of the eigenvalue λ for the curl-eigenfunction problem to the scalar Helmholtz eigenvalue λ_s is shown for all values from $m=0$ to $m=20$. This figure shows that the ratio approaches unity rather quickly, and also illustrates that noninteger values of m can be accounted for.

Last, we treat the case where the eigenvalue $\lambda=p\pi$, $p=2,3,\ldots$. This is a degenerate case for the algorithm described above because the "anharmonic" term $\propto e^{i\lambda Z}$ is equivalent to one of the basis functions when $\lambda=n\pi$ and thus the matrix equation, while nonsingular, returns a trivial solution $\psi=0$. To avoid this situation, we observe that in this case there is a special mode which is a curl eigenfunction and has $B_Z=0$ at $Z=\pm 1/2$ that can be constructed starting with the fundamental solutions $B_Z=w_m=R^m e^{i\lambda Z}$ and $B_Z=w_m=R^m e^{-i\lambda Z}$. This solution is not obtainable from the Chandrasekhar-Kendall form with solutions of the elliptic equation with separation of variables in (R,Z) but can be derived from the connection diagram shown in Fig. 1 with the use of Sonine polynomials as solutions to the elliptic equations, or by use of the $n=2$ Sonine polynomial $S(2,m,R,Z)$ in the Chandrasekhar-Kendall form. For example, for the $m=1$ case, with $\lambda=2\pi,4\pi,\ldots$, i.e., for even p, a curl eigenfunction satisfying the Z boundary condition is

$$B_R=-4\cos(\lambda Z)-(4i\lambda Z+2\lambda^2R^2)e^{i\lambda Z}-\lambda^2R^2e^{-i\lambda Z},$$

$$B_\theta=-4i\cos(\lambda Z)+(4\lambda Z-2i\lambda^2R^2)e^{i\lambda Z}+i\lambda^2R^2e^{-i\lambda Z},$$

$$B_Z=8\lambda R\sin(\lambda Z).$$

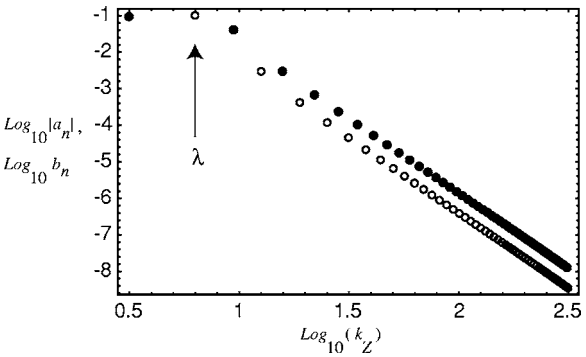

FIG. 8. Spectral plot of $|a_n|$ and $|b_n|$ vs axial wave number k_Z for the degenerate $m=1$ eigenmode with $\lambda=2\pi$. The aspect ratio $1/a=1.3272$ for this case.

Here the $e^{i\theta}$ dependence has been suppressed. The $B_R(R=a)$ component of this eigenfield is then decomposed into Fourier terms in $\sin(2n\pi Z)$ and $\cos((2n-1)\pi Z)$ as before, and this column of Fourier components is substituted into the matrix **M** at the appropriate column to replace the redundant mode. Convergence of this algorithm is obtained for the choice of radius a corresponding to the degenerate eigenvalue. Figure 8 shows the partial term spectrum for the case $m=1$, $p=2$.

(Received 17 June 2005; accepted 19 September 2005; published online 16 November 2005)

Through fractional calculus and following the method used by Dirac to obtain his well-known equation from the Klein-Gordon equation, we analyze a possible interpolation between the Dirac and the diffusion equations in one space dimension. We study the transition between the hyperbolic and parabolic behaviors by means of the generalization of the D'Alembert formula for the classical wave equation and the invariance under space and time inversions of the interpolating fractional evolution equations Dirac like. Such invariance depends on the values of the fractional index and is related to the nonlocal property of the time fractional differential operator. For this system of fractional evolution equations, we also find an associated conserved quantity analogous to the Hamiltonian for the classical Dirac case. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2121167]

I. INTRODUCTION

Following the well-known Dirac's approach,[19] the free Dirac equation can be considered as the square root of the Klein-Gordon equation. In a more general context Morinaga and Nono[11] analyzed the integer s-root of the partial differential equations of the form

$$\sum_{|I|=s} a_I \frac{\partial^{|I|}}{\partial x^I}\phi = \phi, \tag{1}$$

by defining them as the first-order system

$$\sum_{i=1}^{n} \alpha_i \frac{\partial \Phi}{\partial x_i} = \Phi, \tag{2}$$

where $\alpha_1, \ldots, \alpha_n$ are matrices. From the physical point of view the α_k describe internal degrees of freedom of the associated system.

In the above-mentioned context, Vázquez *et al.* recently considered in Refs. 21 and 22 the fractional diffusion equations with internal degrees of freedom. They can be obtained as the s-roots of the standard scalar linear diffusion equation. Thus, a possible definition of the square root of the standard diffusion equation (SDE) in one space dimension, $u_t - u_{xx} = 0$, is the following:

[a)]Electronic mail: Teresa_Pierantozzi@mat.ucm.es
[b)]Electronic mail: lvazquez@fdi.ucm.es

$$\left(A\frac{\partial^{1/2}}{\partial t^{1/2}}+B\frac{\partial}{\partial x}\right)\psi(x,t)=0, \tag{3}$$

where A and B are 2×2 matrices satisfying Pauli's algebra

$$A^2=I,\quad B^2=-I,\quad AB+BA=0, \tag{4}$$

I being the identity operator.

It is worthy of mention that Oldham and Spanier[12,13] were the first authors to derive a formulation involving the mathematical operation of semidifferentiation in replacement of Fick's laws in a work of 1970.

Here $\psi(x,t)$ is a multicomponent function with at least two scalar space-time components. Also, each scalar component satisfies the SDE. Such solutions can be interpreted as *probability distributions with internal structure associated to internal degrees of freedom of the system*. They are named *diffunors* in analogy with the spinors in Quantum Mechanics.

In this paper we deal with a further generalization of Dirac's method, considering the system of fractional evolution equations

$$(A\partial_t^{\alpha}+B\partial_x)\psi(t,x)=0,\quad \psi(t,x)=\begin{pmatrix}u_1(t,x)\\ u_2(t,x)\end{pmatrix}, \tag{5}$$

with $0<\alpha<1$, A and B satisfying (4), as the square root of the time fractional diffusion-wave equation

$$\partial_t^{2\alpha}u(t,x)-\partial_{xx}u(t,x)=0. \tag{6}$$

Equation (6), associated with anomalous diffusion, has been widely studied in the literature by many authors, including Schneider and Wyss,[18] Metzler *et al.*,[7,9,23] Mainardi *et al.*,[4–6] Sokolov *et al.*,[20] Saichev *et al.*[16] A more physical discussion of this equation was given by Metzler and Klafter in Ref. 8 and it is worthwhile mentioning that they proved that the resulting probability density is bimodal in character. In this sense, Schneider and Wyss[18] showed that, for dimensions higher than 1, the character of the solution of the fractional wave equation (when $1/2<\alpha\leqslant 1$) as a proper probability density is lost.

Each component of $\psi(t,x)$ satisfies (6) while the index property $\partial_t^{\alpha}\partial_t^{\alpha}u=\partial_t^{2\alpha}u$ holds. Thus, in the interval $1/2<\alpha<1$, the decomposition (5) of (6), expressed in terms of fractional evolution equations of Dirac-type, represents a fractional interpolation between the diffusion ($\alpha=1/2$) and wave ($\alpha=1$) equations.

The applications of the fractional calculus range in a wide spectrum of areas like material sciences (viscoelasticity, polymers, etc.), circuits, diffusion processes, Biology, Economy, Geology, traffic problems, data analysis, and others, as illustrated, for example, in the textbooks by Hilfer,[2] Ross,[15] and Samko *et al.*[17] Many of the associated models amount to replacing the time derivative in an evolution equation with a fractional derivative of real order.

The fractional derivative operator ∂_t^{α} appearing in (5) can be specified according to several definitions available in the literature (see, for example, Refs. 17 and 14); we will refer to the two commonly used definitions of Riemann-Liouville and Caputo.

The Riemann-Liouville derivative of order $\alpha>0$ is defined as

$$({}_a^{\mathrm{RL}}D_x^{\alpha}f)(x)=\frac{\mathrm{d}^n}{\mathrm{d}x^n}\frac{1}{\Gamma(n-\alpha)}\int_a^x(x-t)^{n-\alpha-1}f(t)\mathrm{d}t, \tag{7}$$

with $x>a$, $n=-[-\alpha]$, whereas the Caputo fractional derivative, usually considered as a regularized version of the Riemann-Liouville fractional differential operator, takes the form

$$({}_x^{C}D_x^{\alpha}f)(x)=\frac{1}{\Gamma(n-\alpha)}\int_a^x\frac{f^n(\tau)}{(x-\tau)^{\alpha-n+1}}\mathrm{d}\tau. \tag{8}$$

There exists the following relation between the above-noted definitions:

$$({}_a^C D_x^\alpha f)(x) = {}_a^{\mathrm{RL}} D_x^\alpha \left[f(x) - \sum_{j=0}^{n-1} f^{(j)}(a+) \frac{(x-a)^j}{j!} \right], \tag{9}$$

and, a condition under which both derivatives hold is that $f \in AC^{n-1}(a,\infty)$. Equivalence (9) allows one to use only initial conditions of the classical type when dealing with fractional equations involving Riemann-Liouville or Caputo derivatives. The integral approach pursued by Schneider and Wyss in Ref. 18 is probably the most physical way of incorporating these initial values to the corresponding equation.

Definitions (7) and (8) reproduce the classical derivative $\mathrm{d}^n/\mathrm{d}x^n$ when $\alpha=n$ ($n \in \mathbb{N}$) and the identity operator for $\alpha=0$, and they are *nonlocal* operators being given by a definite integral.

It is important to highlight that, in general (see Refs. 10 and 14, for example) the index property ${}_a D_x^\alpha {}_a D_x^\beta f = {}_a D_x^{\alpha+\beta} f$ does not hold using the definitions of fractional derivative of Riemann-Liouville (7) or Caputo (8), unless the function f verifies

$$f^{(j)}(a+) = 0, \quad j = 0,1,2,\ldots,m-1, \tag{10}$$

whenever $f(x) \in AC^{m-1}(a,\infty)$ and $f^m(x) \in L^1_{\mathrm{loc}}(a,\infty)$, $m-1 < \beta \leqslant m$.

Reference 10, Chap. 4 analyzes a restricted class of functions C for which the Riemann-Liouville fractional derivative satisfies the cited index property. Some examples of functions in C are: x^λ with $\lambda > -1$, the polynomials, the exponentials, the sine and cosine functions, and all the linear combinations of them.

The structure of the paper is as follows. In Sec. II, a physical meaning to the solutions of (5) is given, showing how they generalize the behavior of the solutions of the Dirac system, recovered when $\alpha=1$, in relation with the D'Alembert solution. Following the analogy with the classical Dirac case, the internal symmetries of the system (5) under inversions and translations in time and/or space, and Galileo transform are considered in Sec. III, whereas in Sec. IV a conserved quantity for (5), analogous to the Hamiltonian for the classical Dirac equation, is found.

II. PHYSICAL MEANING OF THE SOLUTIONS OF THE SYSTEM OF FRACTIONAL EVOLUTION EQUATIONS

It is well known that the general solution of the wave equation with zero initial velocity,

$$\begin{cases} \partial_{tt} u(t,x) - c^2 \partial_{xx} u(t,x) = 0, \\ u(0,x) = \varphi(x), \ \varphi \in \mathcal{C}^2, \\ u_t(0,x) = 0, \end{cases} \tag{11}$$

is given by the D'Alembert Formula

$$u(t,x) = \tfrac{1}{2}[\varphi(x-ct) + \varphi(x+ct)]. \tag{12}$$

From a physical point of view, we can interpret this fact as that the amplitude at time t of a perturbation created by a given starting deformation at rest, $\varphi(x)$, is the superposition of two waves, $\varphi(x+ct)$ and $\varphi(x-ct)$, whose shape is identical to the starting one's and traveling in opposite directions. The two waves are solutions of the following first-order problems:

$$\begin{cases} \partial_t u(t,x) - c \partial_x u(t,x) = 0, \\ u(0,x) = \varphi(x), \ \varphi \in \mathcal{C}^2, \end{cases} \tag{13}$$

and

$$\begin{cases} \partial_t u(t,x) + c\partial_x u(t,x) = 0, \\ u(0,x) = \varphi(x),\ \varphi \in \mathcal{C}^2, \end{cases} \tag{14}$$

and the D'Alembert solution is a linear combination of them with coefficients equal to $1/2$.

Now, if we only shrink the study to the pure real matrices leading to a system (5) of separated equations, then we have two possible choices:

$$A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \tag{15}$$

and the second pair of matrices given by the same A and $-B$.

Substituting (15) in (5), it reduces to the following system of equations:

$$\begin{cases} \partial_t^\alpha u_1(t,x) - \partial_x u_1(t,x) = 0, \\ \partial_t^\alpha u_2(t,x) + \partial_x u_2(t,x) = 0, \end{cases} \tag{16}$$

where $0<\alpha<1$, and the equations appearing in (13) and (14) are devolved for the limiting case of $\alpha=1$ and $c=1$.

We want to show that the solution $u(t,x)$ of the time fractional diffusion equation (6) is still a linear combination of the solutions $u_1(t,x)$ and $u_2(t,x)$ of (16), for each $0<\alpha<1$ and, therefore, that the relation existing between the Dirac solutions and the D'Alembert expression is extended to the fractional case.

In Ref. 3 the following initial value problem

$$\begin{gathered} ({}^C D_t^\alpha u)(t,x) = \lambda \partial_x u(t,x) \quad (t>0, x \in \mathbb{R};\ 0<\alpha<1), \\ \lim_{|x|\to\infty} u(t,x) = 0, \quad u(0+,x) = g(x), \end{gathered} \tag{17}$$

has been solved and the general solution, expressed in terms of the inverse of its Fourier transform, is given by

$$u(t,x) = u_{g,\lambda}(t,x) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} E_{\alpha,1}(-i\lambda k t^\alpha) G(k) e^{-ikx} \mathrm{d}k, \tag{18}$$

where $E_{\alpha,\beta}(z)$ is the biparametric Mittag-Leffler special function.[1] This solution is said to be *localized* due to the property $\lim_{|x|\to\infty} u(t,x)=0$.

On the other hand, the general localized solution of the Cauchy problem for the time fractional diffusion equation,

$$\begin{gathered} ({}^C D_t^{2\alpha} f)(t,x) = \lambda^2 \partial_{xx} f(t,x), \\ \lim_{|x|\to\infty} f(t,x) = 0, \quad f(0+,x) = g(x), \quad [\partial_t f(t,x)]_{t=0} = 0 \quad (t>0, x \in \mathbb{R}), \end{gathered} \tag{19}$$

where $0<\alpha<1$, can be found in Ref. 5 and it reads

$$f(t,x) = f_g(t,x) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} E_{2\alpha,1}(-(\lambda k)^2 t^{2\alpha}) G(k) e^{-ikx} \mathrm{d}k. \tag{20}$$

Now, if we apply the duplication formula[1] for the Mittag-Leffler function,

$$E_{2\alpha,1}(z) = \tfrac{1}{2}[E_{\alpha,1}(+z^{1/2}) + E_{\alpha,1}(-z^{1/2})], \tag{21}$$

then we can rewrite (20) as follows:

$$f_g(t,x) = \tfrac{1}{2}[u_{g,-\lambda}(t,x) + u_{g,\lambda}(t,x)], \tag{22}$$

where $u_{g,\lambda}$ is given in (18).

So, we can conclude that the general solution of the Cauchy problem (19) for the time fractional diffusion equation turns out to be a linear combination, with coefficients equals to 1/2, of the two general solutions of the Cauchy problems for the fractional Dirac-type equations represented by (17) and by the problem obtained when λ is replaced by $-\lambda$ in (17).

In particular, the fundamental solution of (19), when $g(x)=\delta(x)$, turns out to be

$$f(t,x) = \frac{1}{2\lambda t^{\alpha}} W\left(-\frac{|x|}{t^{\alpha}\lambda}; -\alpha, 1-\alpha\right) \quad (0<\alpha<1), \tag{23}$$

where $W(z;\alpha,\beta)$ is the Wright special function (Ref. 1, [18.1(27)].

Therefore, if we assume $\lambda=1$ in (19), we obtain

$$f(t,x) = \frac{1}{2t^{\alpha}} W\left(-\frac{|x|}{t^{\alpha}}; -\alpha, 1-\alpha\right) = \frac{1}{2}[u_1(t,x) + u_2(t,x)], \tag{24}$$

where

$$u_1(t,x) = \begin{cases} \dfrac{1}{t^{\alpha}} W\left(\dfrac{x}{t^{\alpha}}; -\alpha, 1-\alpha\right), & x \leqslant 0 \\ 0, & x > 0 \end{cases} \tag{25}$$

and

$$u_2(t,x) = \begin{cases} 0, & x < 0 \\ \dfrac{1}{t^{\alpha}} W\left(-\dfrac{x}{t^{\alpha}}; -\alpha, 1-\alpha\right), & x \geqslant 0 \end{cases} \tag{26}$$

are the functions appearing in (16), fundamental solutions of (17) when $\lambda=1$ and $\lambda=-1$, respectively (see Ref. 3).

III. INVARIANCE WITH RESPECT TO INVERSIONS AND TRANSLATIONS IN TIME AND/OR SPACE

The aim of this section is to establish whether the system (5) turns out to be invariant under inversions and translations in time and/or space, and Galileo transform, and how the nonlocal property of the time fractional differential operator affects these results.

Let us first consider the spatial inversion $P: x' = -x$ of the system (5), and set

$$\psi'(t,x') = S\psi(t,x(x')). \tag{27}$$

We look for a matrix S so that the transformed multicomponent function $\psi'(t,x')$ is still a solution of the system (5), this is:

$$A\partial_t^{\alpha}\psi'(t,x') + B\partial_{x'}\psi'(t,x') = 0, \quad \psi'(t,x') = S\begin{pmatrix} u_1(t,x(x')) \\ u_2(t,x(x')) \end{pmatrix}, \tag{28}$$

where the fractional derivative ∂_t^{α} could be specified in this context either through (7) or (8).

We calculate

$$\partial_{x'}\psi'(t,x') = S\partial_{x'}\psi(t,x(x')) = -S\partial_x\psi(t,x) \tag{29}$$

and this allows us to write:

$$A\partial_t^{\alpha}\psi'(t,x') + B\partial_{x'}\psi'(t,x') = AS\partial_t^{\alpha}\psi(t,x) - BS\partial_x\psi(t,x).$$

Therefore, in order for (28) to be verified, it has to turn out

$$S^{-1}AS\partial_t^\alpha \psi(t,x) - S^{-1}BS\partial_x \psi(t,x) = 0,$$

and, according to (4), when $S=A$, this requirement is fulfilled, being $\psi(t,x)$ solution of (5). Thus, the system of fractional evolution equations (5) is invariant under spatial inversion, as well as the time fractional diffusion equation (6) with respect to this transformation.

Let us now consider the time inversion $T: t^* = -t$ and set

$$\psi^*(t^*,x) = T\psi(t(t^*),x). \tag{30}$$

Then, as for the spatial inversion, we have to find a matrix T such that $\psi^*(t^*,x)$ is solution of the system of equations (5), where now it is necessary to specify the used definition of fractional derivative ∂_t^α.

If we assume the Caputo fractional derivative (8) in (5), then we have

$$A\,{}_a^C D_{t^*}^\alpha \psi^*(t^*,x) + B\partial_x \psi^*(t^*,x) = 0, \quad \psi^*(t^*,x) = T\begin{pmatrix} u_1(t(t^*),x) \\ u_2(t(t^*),x) \end{pmatrix}. \tag{31}$$

It results

$${}_a^C D_{t^*}^\alpha \psi^*(t^*,x) = T(-1)^\alpha\, {}_{-a}^C D_t^\alpha \psi(t,x). \tag{32}$$

and, in particular, when $a=0$:

$${}_0^C D_{t^*}^\alpha \psi^*(t^*,x) = T(-1)^\alpha\, {}_0^C D_t^\alpha \psi(t,x). \tag{33}$$

Therefore, in general, the left-hand side of the equation in (31) takes the form

$$(-1)^\alpha AT\, {}_{-a}^C D_t^\alpha \psi(t,x) + BT\partial_x \psi(t,x),$$

and we only can have invariance of (5), with respect to time inversion, if $a=0$ and the matrix T verifies

$$\begin{cases} (-1)^\alpha AT = TA, \\ BT = TB. \end{cases}$$

The matrix $T=B$ fulfills the above-noted conditions while $(-1)^\alpha = -1$, which means

$$(-1)^\alpha = e^{i(\pi+2n\pi)\alpha} = -1 = e^{i(\pi+2k\pi)},$$

with $n,k \in \{\mathbb{N} \cup \{0\}\}$, and this implies

$$\alpha = \frac{1+2k}{1+2n}, \quad k = 0,1,2,\ldots, \quad n = k+1, k+2, k+3, \ldots,$$

as the hypothesis $0 < \alpha < 1$ has to be preserved.

Some particular values of α, for which the invariance of the system (5) under time inversion holds, are the following:

$$\alpha = \tfrac{1}{3}, \tfrac{1}{5}, \tfrac{1}{7}, \ldots, \tfrac{3}{5}, \tfrac{3}{7}, \tfrac{3}{9}, \ldots, \tfrac{5}{7}, \tfrac{5}{9}, \tfrac{5}{11}, \ldots .$$

Note that the time fractional diffusion equation (6) is invariant under time inversion while $(-1)^{2\alpha} = 1$, which holds and it is well defined for

$$\alpha = \frac{k}{1+2n}, \quad n = 1,2,3,\ldots, \quad k = 1,2,\ldots,2n,$$

this is,

$$\alpha = \tfrac{1}{3}, \tfrac{2}{3}, \tfrac{1}{5}, \tfrac{2}{5}, \tfrac{3}{5}, \tfrac{4}{5}, \tfrac{1}{7}, \tfrac{2}{7}, \ldots, \tfrac{6}{7}, \tfrac{1}{9}, \ldots,$$

in agreement with known results for the classical one-dimensional time diffusion equation ($\alpha = 1/2$).

The invariance properties under time inversion of systems (5) and (6) are a partial characterization of the transition between the parabolic ($\alpha = 1/2$) and hyperbolic ($\alpha = 1$) behaviors.

If we repeat the computations when $\partial t^{\alpha} = {}_{a}^{\mathrm{RL}}D_{t^*}^{\alpha}$ in (5), we obtain the same results so that we can deal in this context with any of the two definitions of fractional derivative without losing generality.

Now, if we consider the space-time inversion $PT: t^* = -t$, $x' = -x$ and we assume

$$\bar{\psi}(t^*, x') = R\psi(t(t^*), x(x')), \tag{34}$$

over the system of equations (5), repeating exactly the same calculations as above the system turns out to be invariant under space-time inversion if we still restrict our study to the case of $a = 0$ in the lower extreme of integration of the fractional derivative and when the matrix R fulfills

$$\begin{cases} (-1)^{\alpha} AR = RA, \\ BR + RB = 0. \end{cases}$$

Therefore it must be distinguished between two cases:

(1) If $(-1)^{\alpha} = -1$ that means

$$\alpha = \frac{1+2k}{1+2n}, \quad k = 0,1,2, \ldots, \quad n = k+1, k+2, k+3, \ldots,$$

then for $R = AB = -BA$ the system (5) is invariant under space-time inversion.

(2) If $(-1)^{\alpha} = 1$, that means

$$\alpha = \frac{2k}{1+2n}, \quad k = 1,2,3, \ldots, \quad n = k, k+1, k+2, \ldots,$$

then the space-time invariance only holds when $R = A$.

The invariance property of system (5) fails, in general, with respect to space-time translation and Galileo transform. In fact, if we operate with a space-time translation on the system (5), assuming the changes of variable $t^* = t + t_0$, $x' = x + x_0$, where t_0 and x_0 are constants, and setting

$$\tilde{\psi}(t^*, x') = V\psi(t(t^*), x(x')), \tag{35}$$

the system turns out to be invariant under this space-time transformation just for the trivial case of $t_0 = 0$ and $V = I$. Actually, for the Caputo derivative, for example, it results

$${}_{a}^{C}D_{t^*}^{\alpha}\tilde{\psi}(t^*, x') = V\,{}_{a-t_0}^{C}D_{t}^{\alpha}\psi(t,x).$$

In the case of the Galileo transform: $x' = x + vt$, $t' = t$, with $v > 0$ constant, we set

$$\hat{\psi}(t, x') = W\psi(t, x(x', t)) \tag{36}$$

in (5). In general, we do not have invariance of system (5) with respect to Galileo transform, as well as it occurs with the classical Dirac equation. Indeed, it is

$${}_{a}^{C}D_{t}^{\alpha}\hat{\psi}(t,x') = W\,{}_{a}^{C}D_{t}^{\alpha}\psi(t,x) - vW\,{}_{a}I_{t}^{1-\alpha}\psi_x(t,x),$$

where I_t^{α} is the Riemann-Liouville fractional integral defined as

$$({}_aI_x^\alpha f)(x) = \frac{1}{\Gamma(\alpha)} \int_a^x (x-t)^{\alpha-1} f(t) \mathrm{d}t,$$

with $x > a$, $\alpha > 0$, $f \in L^1_{\mathrm{loc}}(a,\infty)$ and $({}_aI_t^0 f)(x) = f(x)$.

Then, the transformed multicomponent function $\hat{\psi}(t,x')$ is still a solution of (5) if the system

$$A\,{}_a^C D_t^\alpha \hat{\psi}(t,x') + B\partial_{x'}\hat{\psi}(t,x') = AW\,{}_a^C D_t^\alpha \psi(t,x) - vAW\,{}_aI_t^{1-\alpha}\psi_x(t,x) + BW\partial_x\psi(t,x) \tag{37}$$

is equal to the zero vector, which implies

$$AW\,{}_aI_t^{1-\alpha}\psi_x(t,x) = 0. \tag{38}$$

Therefore, in general, we do not have invariance of the system (5) with respect to Galileo transform because, in view of the evaluation of the beta integral,[1] valid for all $p > 0$ and $q > 0$ (or $\mathrm{Re}(p) > 0$ and $\mathrm{Re}(q) > 0$), namely

$$B(p,q) := \int_0^1 u^{p-1}(1-u)^{q-1}\mathrm{d}u = \frac{\Gamma(p)\Gamma(q)}{\Gamma(p+q)},$$

the following property for the Riemann-Liouville fractional integral can be proved

$${}_aI_t^\alpha (t-a)^\beta = \frac{\Gamma(\beta+1)}{\Gamma(\beta+\alpha+1)}(t-a)^{\beta+\alpha} \tag{39}$$

when $\beta > -1$. As a consequence, it results ${}_aI_t^{1-\alpha}\psi_x(t,x) = 0$ just in case $\psi_x(t,x) = 0$ for any $0 < \alpha < 1$, which means $\psi(t,x) = \psi(t)$, constant function in x. If this condition is not fulfilled, as occurs in general, then, being $A = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ in our case, we can obtain a restricted class of functions u_1 and u_2 for which (5) is invariant under Galileo transform.

Given $W = \left(\begin{smallmatrix} w_{11} & w_{12} \\ w_{21} & w_{22} \end{smallmatrix}\right)$, the system (38) can be reduced to

$$\begin{cases} w_{21}\,{}_aI_t^{\alpha-1}\dfrac{\partial}{\partial x}u_1(t,x) + w_{22}\,{}_aI_t^{\alpha-1}\dfrac{\partial}{\partial x}u_2(t,x) = 0, \\ w_{11}\,{}_aI_t^{\alpha-1}\dfrac{\partial}{\partial x}u_1(t,x) + w_{12}\,{}_aI_t^{\alpha-1}\dfrac{\partial}{\partial x}u_2(t,x) = 0 \end{cases}$$

and, if $\det(W) = 0$, which means $w_{12}w_{21} - w_{11}w_{22} = 0$, then it has the solution $(\partial/\partial x)u_1(t,x) = -(w_{22}/w_{21})(\partial/\partial x)u_2(t,x)$ which implies $u_1(t,x) = -(w_{22}/w_{21})u_2(t,x) + c(t)$, where $c(t)$ is a constant function in x.

The general noninvariance of the fractional evolution equations under time translation and Galileo transform is due to the nonlocal property of the time fractional derivative and it is in contrast with the invariance results holding for the Dirac equation, with respect to the time translation, as a fundamental requirement to be the relativity principle verified.[19]

IV. A CONSERVED QUANTITY: THE FRACTIONAL HAMILTONIAN

The invalidity of the invariance of the fractional Dirac-type system (5) under time translation does not prevent it from possessing a fractional conserved quantity, analogous to the Hamiltonian for the classical Dirac system.

It is well known (see, for example, Ref. 19) that the Lagrangian density for the classical Dirac equation obtained from (5) when $\alpha = 1$ is given by

$$\mathcal{L}(t,x) = \bar{\psi}A\partial_t\psi + \bar{\psi}B\partial_x\psi,$$

with $\psi = \psi(t,x) = (u_1(t,x), u_2(t,x))^T$, $\bar{\psi} = \bar{\psi}(t,x) = \psi^+ A$, and $\psi^+ = \psi^+(t,x) = (u_1^*(t,x), u_2^*(t,x))$, complex conjugate of ψ that verifies the conjugated equation of (5) with $\alpha = 1$:

$$\partial_t \psi^+ A^+ + \partial_x \psi^+ B^+ = 0.$$

Therefore, the Hamiltonian density will be

$$\mathcal{H}(t,x) = \frac{\partial \mathcal{L}(t,x)}{\partial(\partial_t \psi)} \partial_t \psi - \mathcal{L}(t,x) = \bar{\psi} A \partial_t \psi - \mathcal{L}(t,x) = -\psi^+ C \partial_x \psi, \tag{40}$$

with $C=AB=-BA$, the Hamiltonian

$$H(t,x) = \int_{-\infty}^{+\infty} \mathcal{H}(t,x)\mathrm{d}x = -\int_{-\infty}^{+\infty} \psi^+ C \partial_x \psi \mathrm{d}x, \tag{41}$$

and, its time derivative,

$$\frac{\mathrm{d}}{\mathrm{d}t} H(t,x) = \int_{-\infty}^{+\infty} \partial_x [\psi^+ \partial_x \psi] \mathrm{d}x, \tag{42}$$

provided that we restrict ourselves to the pure real matrices A and B so that the equivalence $\partial_t \psi^+ = -\partial_x \psi^+ C$ is verified. In this case, if we assume, for example, the initial condition $\psi^+ \partial_x \psi \to 0$ when $|x| \to \infty$, we can conclude that there exists a conserved quantity associated with Eq. (5) with $\alpha=1$, given by the Hamiltonian (41).

In what follows, we want to show that, as well as we did earlier, it is possible to find a conserved quantity associated with the system of fractional Dirac-type equations (5) for general $0<\alpha<1$, even if it does not present invariance with respect to time translation.

We start defining, by analogy with the classical Dirac case, a formal "fractional Lagrangian density" related to (5),

$$\mathcal{L}^\alpha(t,x) = \bar{\psi} A \partial_t^\alpha \psi + \bar{\psi} B \partial_x \psi, \tag{43}$$

and a formal "fractional Hamiltonian density,"

$$\mathcal{H}_\alpha(t,x) = \frac{\partial \mathcal{L}^\alpha(t,x)}{\partial(\partial_t^\alpha \psi)} \partial_t^\alpha \psi - \mathcal{L}^\alpha(t,x) = \bar{\psi} A \partial_t^\alpha \psi - \mathcal{L}^\alpha(t,x) = -\psi^+ C \partial_x \psi. \tag{44}$$

The final expression in (44) is equivalent to (40) and can be simplified observing that, A and B being pure real matrices, if ψ is a solution of (5), then also ψ^+ has to solve it, the reason why a pure real solution of (5) can always be found. Therefore, we will assume that ψ is a pure real solution of (5) and this allows us to write the "fractional Hamiltonian" as

$$H_\alpha(t,x) = \int_{-\infty}^{+\infty} \mathcal{H}_\alpha(t,x)\mathrm{d}x = -\int_{-\infty}^{+\infty} \psi^T C \partial_x \psi \, \mathrm{d}x \tag{45}$$

and, consequently,

$$\frac{\mathrm{d}}{\mathrm{d}t} H_\alpha(t,x) = -\int_{-\infty}^{+\infty} [\partial_t \psi^T C \partial_x \psi + \psi^T C \partial_x \partial_t \psi] \mathrm{d}x = -\int_{-\infty}^{+\infty} \partial_x [\psi^T C \partial_t \psi] \mathrm{d}x. \tag{46}$$

The equivalence $\partial_t \psi^T C \partial_x \psi = \partial_x \psi^T C \partial_t \psi$, due to the fact that the matrix $C=AB$, with pure real A and B, can only be of two types:

$$C_1 = \begin{pmatrix} c_{11} & 0 \\ 0 & -c_{11} \end{pmatrix}, \quad C_2 = \begin{pmatrix} 0 & c_{12} \\ c_{12} & 0 \end{pmatrix},$$

where c_{11} and c_{12} take the values ± 1.

At this point it is necessary to specify the definition of the fractional derivative in use.

When $0<\alpha<1$ the Riemann-Liouville fractional derivative $\partial_t^\alpha = {}^{\mathrm{RL}}D_t^\alpha$, according to (9), fulfills the following identity:

$$({}^{\mathrm{RL}}D_t^\alpha \psi)(t,x) = (I_t^{1-\alpha}\partial_t\psi)(t,x) + \frac{t^{-\alpha}}{\Gamma(1-\alpha)}\psi(0,x), \tag{47}$$

being $({}^{\mathrm{RL}}D_t^\alpha \psi(0,x))(t,x) = t^{-\alpha}/[\Gamma(1-\alpha)]\psi(0,x)$ and $({}^{C}D_t^\alpha \psi)(t,x) = (I_t^{1-\alpha}\partial_t\psi)(t,x)$ by definition (8).

Now, if we introduce the Riemann-Liouville fractional derivative in (5), using the fact that this derivative is the left inverse operator of the Riemann-Liouville fractional integral, we can write

$$(\partial_t\psi)(t,x) = -C\partial_x({}^{\mathrm{RL}}D_t^{1-\alpha}\psi)(t,x) - A\left({}^{\mathrm{RL}}D_t^{1-\alpha}\frac{t^{-\alpha}}{\Gamma(1-\alpha)}\psi(0,x)\right)(t,x) = -C\partial_x({}^{\mathrm{RL}}D_t^{1-\alpha}\psi)(t,x)$$
$$-A\partial_t\psi(0,x) = -C\partial_x({}^{\mathrm{RL}}D_t^{1-\alpha}\psi)(t,x). \tag{48}$$

In a similar straightforward way it can be proved that result (48) holds exactly the same when the Caputo derivative appears in (5).

Therefore, when $\alpha=1/2$ both derivatives verify

$$(\partial_t\psi)(t,x) = C^2(\partial_x^2\psi)(t,x) = (\partial_x^2\psi)(t,x). \tag{49}$$

In agreement with (48), the expression for the Hamiltonian time derivative (46) takes the form:

$$\frac{\mathrm{d}}{\mathrm{d}t}H_\alpha(t,x) = -\int_{-\infty}^{+\infty}\partial_x[\psi^T C\partial_t\psi]\mathrm{d}x = \int_{-\infty}^{+\infty}\partial_x[\psi^T\partial_x{}^{\mathrm{RL}}D_t^{1-\alpha}\psi], \tag{50}$$

when $0<\alpha<1$ and, in particular,

$$\frac{\mathrm{d}}{\mathrm{d}t}H_{1/2}(t,x) = \int_{-\infty}^{+\infty} -\partial_x[\psi^T C\partial_x^2\psi]\mathrm{d}x, \tag{51}$$

for $\alpha=1/2$, when the fractional derivative is either of the Riemann-Liouville or of the Caputo type.

Therefore, we can conclude that, when $0<\alpha<1$, if the condition

$$\frac{\mathrm{d}}{\mathrm{d}t}H_\alpha(t,x) = \int_{-\infty}^{+\infty}\partial_x[\psi^T\partial_x{}^{\mathrm{RL}}D_t^{1-\alpha}\psi]\mathrm{d}x = [u_1\partial_x{}^{\mathrm{RL}}D_t^{1-\alpha}u_1 + u_2\partial_x{}^{\mathrm{RL}}D_t^{1-\alpha}u_2]|_{x=-\infty}^{x=+\infty} = 0, \tag{52}$$

is fulfilled, then a conserved quantity exists associated with Eq. (5) and it is given by the fractional Hamiltonian (45).

For the particular case of $\alpha=1/2$, we deduce from (51) an alternative condition, equivalent to (52), to provide the existence of the conserved quantity $H_{1/2}(t,x)$:

$$\frac{\mathrm{d}}{\mathrm{d}t}H_{1/2} = \int_{-\infty}^{+\infty} -\partial_x[\psi^T C\partial_x^2\psi]\mathrm{d}x = -\psi^T C\partial_x^2\psi|_{x=-\infty}^{x=+\infty} = 0,$$

which means

$$(u_1\partial_x^2u_1 - u_2\partial_x^2u_2)|_{x=-\infty}^{x=+\infty} = 0, \tag{53}$$

when $C=C_1$, and

$$(u_1\partial_x^2u_2 + u_2\partial_x^2u_1)|_{x=-\infty}^{x=+\infty} = 0, \tag{54}$$

when $C=C_2$. Both conditions (53) and (54) come true when, for example, $|u_h|\to 0$ and $\partial_x^2u_h$ is bounded when $|x|\to\infty$, for $h=1,2$.

We can conclude this section recalling some results obtained in Ref. 3

If we consider the system of fractional equations of Dirac-type (5) when $\partial_t^{\alpha} = {}^{C}D_t^{\alpha}$, when A and B are given by (15) so that it turns out to be

$$C = C_1 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix},$$

and we complete (5) with the initial conditions

$$\lim_{|x|\to\infty} \psi(t,x) = 0, \quad \psi(0+,x) = \delta(x),$$

then the localized fundamental solutions are given by (25) and (26).

In Ref. 6 the asymptotic behavior of the Wright function $W(z;\alpha,\beta)$, for the case of $\alpha=-\nu$ and $\beta=1-\nu$, has been studied. In particular, if the function $M(z;\nu)=W(-z;-\nu,1-\nu)$ is introduced, when the argument $z=r>0$ is real and positive and $r\to+\infty$, it holds

$$M\left(\frac{r}{\nu};\nu\right) \sim a(\nu) r^{(\nu-1/2)/(1-\nu)} \exp[-b(\nu) r^{1/(1-\nu)}], \tag{55}$$

where $a(\nu)=1/\sqrt{2\pi(1-\nu)}$, $b(\nu)=(1-\nu)/\nu$.

This implies an asymptotic exponential decay of our solutions u_1 and u_2, and, consequently, that $|u_h|\to 0$ when $|x|\to\infty$ for $h=1,2$.

In order to ensure the existence of the conserved quantity (45) when $0<\alpha<1$, we also have to analyze the asymptotic behavior of $\partial_x {}^{\mathrm{RL}}D_t^{1-x}u_h$ for $h=1,2$.

It turns out to be

$$\begin{aligned} {}^{\mathrm{RL}}D_t^{1-\alpha}\left(\frac{1}{t^{\alpha}}W\left(-\frac{|x|}{t^{\alpha}};-\alpha,1-\alpha\right)\right) &= \partial_t I_t^{\alpha}\left[\sum_{k=0}^{+\infty}\frac{-(|x|)^k t^{-\alpha k-\alpha}}{k!\Gamma(-\alpha k+1-\alpha)}\right] = \partial_t\left[\sum_{k=0}^{+\infty}\frac{-(|x|)^k t^{-\alpha k}}{k!\Gamma(1-\alpha k)}\right] \\ &= \left[\sum_{k=0}^{+\infty}\frac{-(|x|)^k t^{-\alpha k-1}}{k!\Gamma(-\alpha k)}\right] = \frac{1}{t}W\left(-\frac{|x|}{t^{\alpha}};-\alpha,0\right) \\ &= \frac{\alpha|x|}{t^{\alpha+1}}W\left(-\frac{|x|}{t^{\alpha}};-\alpha,1-\alpha\right) \end{aligned}$$

if we use the property $W(-z;-\nu,1-\nu)=(1/\nu z)W(-z;-\nu,0)$; therefore, (55) implies that ${}^{\mathrm{RL}}D_t^{1-\alpha}u_h$, as well as $\partial_x {}^{\mathrm{RL}}D_t^{1-\alpha}u_h$, will also decay exponentially when $|x|\to\infty$ for $h=1,2$.

V. CONCLUSIONS

We have treated a generalization of the classical free Dirac equations, namely the *fractional evolution equations of Dirac-type*. For the localized solutions of these equations we have derived their relation with the corresponding solution of the *fractional diffusion equation*, showing how the latter turns out to be a linear combination of the formers, similarly to the D'Alembert solution of the classical wave equation is a linear combination of the solutions of the first-order equations derived from the decomposition of the second-order wave operator into its corresponding square-root operators.

Following the analogy existing between the fractional evolution equations and the classical Dirac equation, we have studied their internal symmetries with respect to certain transformations in space and/or time. The system of fractional Dirac-type equations is invariant under spatial inversion for each $0<\alpha<1$, whereas it possesses invariance under time inversion only for certain values of the fractional index α, so enclosing the hyperbolic behavior of the classical Dirac equation or of the time fractional diffusion equation (6) when $\frac{1}{2}<\alpha\leqslant 1$ (including the classical wave equation corresponding to $\alpha=1$), and the parabolic one of the time fractional diffusion equation (6) when $0<\alpha\leqslant\frac{1}{2}$ (including the classical diffusion equation corresponding to $\alpha=1/2$).

In keeping with the joint space-time inversion, a range of validity for the invariance is located, still depending on the index α, but wilder than the one corresponding to time inversion only.

The system proves to be never invariant under time translation and Galileo transform due to the nonlocal property of the time fractional derivative. This lack of invariance of the fractional evolution equations under time translation is in contrast to the invariance results holding for the classical Dirac equation, with respect to the same transformation, as a fundamental requirement to be the relativity principle verified, but does not prevent the fractional Dirac-type system from possessing a fractional conserved quantity, analogous to the Hamiltonian for the classical Dirac system.

(Received 12 July 2005; accepted 20 September 2005; published online 16 November 2005)

The paper is devoted to the dissipative Schrödinger-Poisson system. We indicate conditions in terms of the Schrödinger-Poisson data which guarantee that there is a unique solution. Moreover, it is shown that if the system is sufficiently small shrunken, then it always admits a unique solution. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2121187]

I. INTRODUCTION

Schrödinger-Poisson systems describe for instance the nonlinear interaction between an electric field and charged carriers (electrons and holes) in a semiconductor device, within this electric field. We investigate a model which intrinsically allows—in contrast to self-adjoint Schrödinger-Poisson systems, see Refs. 8, 19–21, 27, and 28—an interaction with the environment. In particular, in the open quantum system under consideration here (see also Refs. 10 and 29) a nontrivial current is possible. In Ref. 20 non-self-adjoint boundary conditions for the Schrödinger operators (3) were proposed which are induced by a potential flow acting on the boundary of the domain Ω which is occupied by the quantum system. The spectral theory for the associated non-self-adjoint Schrödinger-type operators has been developed in Ref. 16. For a one-dimensional device this ansatz—called dissipative Schrödinger-Poisson system—was analyzed in detail in Refs. 2, 16–18. While the existence of a solution was shown in Ref. 2 it is the aim of this paper to prove uniqueness of the solution under certain conditions. This result should be interpreted from the physical point of view as follows: it is known that uniqueness cannot be expected in general because there are physical situations where the existence of several solutions explains well observed hysteresis phenomena[14,30]. However, if the parameters of the system are chosen in accordance with our uniqueness condition of Theorem 5.4, then hysteresis phenomena cannot occur. In particular, hysteresis is absent if the device is sufficiently small, cf. Theorem 5.6. By the way, this situation is quite parallel to that of self-adjoint Schrödinger-Poisson systems with exchange correlation potentials, see Ref. 31.

In the form considered in this paper a Schrödinger-Poisson system can be regarded as a nonlinear Poisson equation

$$-\nabla\cdot(\epsilon\nabla\varphi) = C + \mathcal{N}^+(V_0^+ + \varphi) - \mathcal{N}^-(V_0^- - \varphi) \tag{1}$$

on an interval (a,b) of the real axis, combined with Dirichlet boundary conditions

$$\varphi(a) = \varphi_a, \quad \varphi(b) = \varphi_b. \tag{2}$$

By ϵ and C the dielectric permittivity and the doping profile are denoted, respectively, while $V_0^\pm$ are fixed potentials for a given device. The particle densities $\mathcal{N}^\pm(V)$ are associated to one-electron Hamiltonians in effective mass approximation (Ben-Daniel-Duke form)

[a]Electronic mail: neidhard@wias-berlin.de
[b]Electronic mail: rehberg@wias-berlin.de

$$H^{\pm}[V]\psi = -\frac{1}{2}\nabla\cdot\left(\frac{1}{m^{\pm}}\nabla\psi\right) + V\psi, \tag{3}$$

acting on $L^2(a,b)$ and supplemented by dissipative boundary conditions of the form

$$\frac{1}{2m^{\pm}(a)}\psi'(a) = -\kappa_a^{\pm}\psi(a), \quad \frac{1}{2m^{\pm}(b)}\psi'(b) = \kappa_b^{\pm}\psi(b), \tag{4}$$

$\kappa_a^{\pm}, \kappa_b^{\pm} \in \mathbb{C}_+ := \{z \in \mathbb{C} : \Im\mathrm{m}(z) > 0\}$. By $m^{\pm}$ the position dependent effective masses of holes and electrons are denoted (Planck's constant $\hbar$ and the elementary charge q are scaled to one).

The collective behavior of holes and electrons [and, hence, the particle densities $\mathcal{N}^{\pm}(V)$] is described by density operators $\varrho^{\pm}[V]$ which are given in case of closed quantum systems by equilibrium states, i.e., non-negative trace class operators of the form

$$\varrho^{\pm}[V] = f^{\pm}(H^{\pm}[V]).$$

In the case of open quantum systems, which is of interest here, the density operators are obtained as follows: one finds—by an explicit construction, see Ref. 17—a so-called (self-adjoint) dilation $K^{\pm}[V]$ of $H^{\pm}[V]$ on a larger Hilbert space $\supseteq L^2(a,b)$. As density operators now serve certain non-negative self-adjoint operators $\varrho[V]$, commuting with $K^{\pm}[V]$ and enjoying the property that their product with the orthogonal projection $P_{L^2(a,b)}$ from the dilation space onto the original Hilbert space $L^2(a,b)$ is of trace class. [In fact, these operators $\varrho[V]$ are induced by density matrices $\rho^{\pm} \in L^{\infty}(\mathbb{R}, \mathcal{B}(\mathbb{C}^2))$ with certain decaying properties.] Thus, the definition

$$\int_{\omega} \mathrm{d}x \mathcal{N}^{\pm}(V)(x) := \mathrm{tr}(P_{L^2(a,b)}^{\mathfrak{K}} \varrho^{\pm}[V]\chi_{\omega}), \quad \omega \text{ any Borel subset of } (a,b)$$

gives rise to the carrier density operators $\mathcal{N}^{\pm}$ which assigns to each electrostatic potential $V \in L^{\infty}_{\mathbb{R}}(a,b)$ carrier densities from $L^1_{\mathbb{R}}(a,b)$, see Refs. 2, 3, and 18.

The main technical tool for our uniqueness proof is to show that the carrier density operators do depend in fact locally Lipschitz continuous on the potentials—and not only continuously as proven in Ref. 3. The proof of this property relies on the theory of Kato-smooth operators, see Refs. 22 and 23. We show that the orthogonal projection $P_{L^2(a,b)}$ is Kato-smooth with respect to the minimal self-adjoint dilations $K^{\pm}[V]$ and we calculate their smoothness constants, which allows us to compute the local Lipschitz constants for the carrier density operators. For this purpose we have to strengthen the assumptions on the effective masses $m^{\pm}$. In Ref. 3 it was assumed that $m^{\pm} + (1/m^{\pm}) \in L^{\infty}_{\mathbb{R}}(\Omega)$. In addition, we demand now that $m^{\pm}$ has a finite total variation. This admits countably many discontinuities, what is sufficient for applications to heterogeneous material compositions. At the end, the solution becomes unique, if the local Lipschitz constants of the carrier density operators are small enough.

It turns out that uniqueness always takes place if we shrink the dissipative Schrödinger-Poisson system to a sufficiently small subdevice $\Omega' \subseteq \Omega$. That means, we consider the same boundary conditions (4) and (2), the same density matrices $\rho^{\pm}$ but replace the mass functions $m^{\pm}$ by $m^{\pm} \restriction \Omega'$, the potentials $V_0^{\pm}$ by $V_0^{\pm} \restriction \Omega'$, the dielectric permittivity ϵ by $\epsilon \restriction \Omega'$ and the doping profile C by $C \restriction \Omega'$. If Ω' will be sufficiently small, then the shrunken Schrödinger-Poisson systems admits a unique solution.

This has implications for dissipative hybrid models considered in Ref. 4 which use a mixed description by a drift-diffusion model and a dissipative Schrödinger-Poisson system. In more detail, one divides the device $\Delta = [a_0, b_0]$ into two regions $\Omega_c = (a_0, a) \cup (b, b_0)$ and $\Omega_q = (a,b)$, which are called "classical zone" and "quantum zone," respectively. On the "classical zone" Ω_c, which is disconnected, one uses a classical drift diffusion description, cf. Refs. 11, 25, and 32, while on the "quantum zone" Ω_q a dissipative Schrödinger-Poisson system is considered. The length $|\Omega_q|$ of the quantum zone Ω_q is crucial for the hybrid model. Indeed, if Ω_q is very large, then we have nearly a quantum description of the device which increases the costs of the numeri-

cal treatment of the model. If the quantum zone Ω_q is very small, then by the above-noted result it can happen that the hybrid model has only one solution in contradiction to a pure classical description which usually allows several solutions. This shows us that one has to very carefully choose the quantum zone in hybrid models.

The paper is organized as follows. In Sec. II we introduce constants repeatedly used in the following. If the Schrödinger-Poisson data are fixed, then the constants are fixed. The dissipative Schrödinger-type operator is introduced and in detail investigated in Sec. III. Crucial are the notions of the characteristic function, see Sec. III C, and the phase shift, see Sec. III D. The self-adjoint dilations and Lax-Phillips scattering theory are recalled in Secs. III F and III G. The carrier density operator is defined in Sec. IV. Its local Lipschitz continuity is verified in Sec. IV B. The dissipative Schrödinger-Poisson system is considered in Sec. V. The existence proof is sketched in Sec. V B, the uniqueness is proven in Sec. V C, the uniqueness for a sufficiently small shrunken Schrödinger-Poisson system is established in Sec. V D. We end with some remarks in Sec. VI.

II. NOTATION, ASSUMPTIONS, AND CONSTANTS

By $L^p(\Omega,X,m)$, $1\leqslant p<\infty$, $\Omega=(a,b)$, we denote the space of $\mathfrak{m}$-measurable and p-integrable functions over Ω with values in a Banach space X. By $L^\infty(\Omega,X,\mathfrak{m})$ the space of essentially bounded functions is denoted. If $\mathfrak{m}$ is the Lebesgue measure, then we write $L^p(\Omega)=L^p(\Omega,\mathbb{C},\mathfrak{m})$ and $L^p_{\mathbb{R}}(\Omega):=L^p(\Omega,\mathbb{R},\mathfrak{m})$, $1\leqslant p\leqslant\infty$. The Lebesgue measure of a set is denoted by $|\cdot|$.

The norm of a Banach or Hilbert space X is indicated by $\|\cdot\|_X$ or simply by $\|\cdot\|$, the scalar product of a Hilbert space X by $(\cdot,\cdot)_X$ or simply by $(\cdot,\cdot)$ where the first argument is the linear one. The dual space is indicated by X^*. By $\mathcal{B}(X,Y)$ the space of all linear bounded operators from the Banach space X to the Banach space Y is denoted with norm $\|\cdot\|_{\mathcal{B}(X,Y)}$. If $X=Y$, then $\mathcal{B}(X,X)=\mathcal{B}(X)$ and $\|\cdot\|_{\mathcal{B}(X,Y)}=\|\cdot\|_{\mathcal{B}(X)}$. If X is a Hilbert spaces, then $\mathcal{B}_1(X)$ and $\mathcal{B}_2(X)$ denote the spaces of trace class and Hilbert-Schmidt operators, respectively. For a densely defined linear operator $A:X\to Y$ we denote by A^*, $\mathrm{spec}(A)$ and $\mathrm{res}(A)$ its adjoint, spectrum, and resolvent set, respectively. We write $X[V]$ if we have in mind a parameter dependence on V and $X(V)$ if a functional dependence on V is considered. Of course, it is quite possible that a parameter dependence becomes a functional one and vice versa.

Furthermore, we denote by $W^{1,2}(\Omega)$ the usual Sobolev spaces of complex-valued functions on Ω. The subspace of elements with homogeneous Dirichlet boundary conditions at the end points of the interval $\Omega\subseteq\mathbb{R}$ is denoted by $W^{1,2}_0(\Omega)$. Its dual with respect to the L^2-pairing is denoted by $W^{-1,2}_0(\Omega)=(W^{1,2}_0(\Omega))^*$. If we have in mind only real-valued functions, then we write $W^{1,2}_{\mathbb{R}}(\Omega)$ and $W^{1,2}_{0,\mathbb{R}}(\Omega)$.

With respect to the Schrödinger-type operators we made the following assumptions.

Assumptions 2.1 (Schrödinger assumptions):

(Q_1) There are constants $\underline{m}^\pm>0$ and $\bar{m}^\pm>0$ such that $\underline{m}^\pm\leqslant m^\pm(x)\leqslant\bar{m}^\pm$ for $x\in\Omega$.

($Q2$) $\kappa^\pm_a,\kappa^\pm_b\in\mathbb{C}_+=\{z\in\mathbb{C}:\Im\mathrm{m}(z)>0\}$.

($Q3$) $V^\pm_0\in L^\infty_{\mathbb{R}}(\Omega)$.

($Q4$) The matrix valued-functions $\rho^\pm(\cdot)\in L^\infty(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$ obey $0\leqslant\rho^\pm(\lambda)=\rho^\pm(\lambda)^*$. There are real, continuous differentiable, even functions $g^\pm(\cdot):\mathbb{R}\to\mathbb{R}_+$ such that

$$0\leqslant\rho^\pm(\lambda)\leqslant g^\pm(\lambda)I_{\mathbb{C}^2},\quad \lambda\in\mathbb{R}, \tag{5}$$

$$\mathrm{sign}(\lambda)\frac{\mathrm{d}}{\mathrm{d}\lambda}g^\pm(\lambda)\leqslant 0,\quad \lambda\in\mathbb{R}, \tag{6}$$

$$\int_0^\infty \mathrm{d}\lambda\frac{g^\pm(\lambda)}{\sqrt{\lambda}}<\infty, \tag{7}$$

and

$$\left|\frac{\mathrm{d}}{\mathrm{d}\lambda}g^{\pm}(\lambda)\right| \leqslant {}^{\pm}g^{\pm}(\lambda), \quad \lambda \in \mathbb{R}, \tag{8}$$

where ${}^{\pm}$ are given real constants. In particular, the functions

$$g^{\pm}(\lambda) = {}^{\pm}_{0}(1+\lambda^2)^{-1/2}, \quad \lambda \in \mathbb{R},$$

used in Ref. 2 satisfy assumptions (6)–(8) with $\mathfrak{c}^{\pm}=\mathfrak{c}^{\pm}_{0}$.

The parameter set $:=\{m^{\pm},\kappa^{\pm}_{a},\kappa^{\pm}_{b},V^{\pm}_{0},\rho^{\pm}\}$ is called the Schrödinger data of the device Ω. The Schrödinger data are fixed in the following.

With respect to the Poisson equation we made the following assumptions.

Assumptions 2.2 (Poisson assumptions):

($P1$) The doping profile C is from $W^{-1,2}_{0}(\Omega)$.

($P2$) The dielectric permittivity ϵ is positive and satisfies $\epsilon+(1/\epsilon)\in L^{\infty}_{\mathbb{R}}(\Omega)$.

The quadruple $:=\{C,\epsilon,\varphi_a,\varphi_b\}$ is called the Poisson data of the device Ω which are also fixed through the paper. The union $:= \cup$ is called the Schrödinger-Poisson data of the device Ω.

For the convenience of the reader we collect here important constants which are composed of the Schrödinger-Poisson data and which are needed in the following. We set

$$B^{\pm}_{0} := 2g^{\pm}(0) + \frac{1}{2\pi}\sqrt{|\Omega|\bar{m}^{\pm}}\int_{0}^{\infty}\mathrm{d}\lambda\frac{g^{\pm}(\lambda)}{\sqrt{\lambda}} \tag{9}$$

and

$$B^{\pm}_{1} := \frac{1}{\pi}g(0)\sqrt{|\Omega|\bar{m}^{\pm}}. \tag{10}$$

We note that the quantities $B^{\pm}_{0}$ and $B^{\pm}_{1}$ depend only on the Schrödinger data and on the length $|\Omega|$ of the device.

The embedding operators from $W^{1,2}_{0}(\Omega)$ into $L^{\infty}(\Omega)$ and $L^{1}(\Omega)$ into $W^{-1,2}_{0}(\Omega)$ are denoted by E_{∞} and E_1, respectively. We note that $E_1=E^{*}_{\infty}\restriction L^{1}(\Omega)$. Their norms are equal and are denoted by ε_1 in the sequel. A straightforward computation shows that $\varepsilon_1\leqslant\sqrt{|\Omega|}$. Let $\hat{\varphi}$ be the function

$$\Omega \ni x \to \frac{1}{\displaystyle\int_{a}^{b}\mathrm{d}t\frac{1}{\epsilon(t)}}\left\{\varphi_a\int_{a}^{x}\mathrm{d}t\frac{1}{\epsilon(t)}+\varphi_b\int_{x}^{b}\mathrm{d}t\frac{1}{\epsilon(t)}\right\}. \tag{11}$$

Clearly, $\hat{\varphi}\in W^{1,2}(\Omega)\hookrightarrow L^{\infty}(\Omega)$. We set

$$D_0 := \varepsilon_1\|1/\epsilon\|_{L^{\infty}}\sqrt{1+|\Omega|}\{\|C\|_{W^{-1,2}_{0}}+\varepsilon_1(B^{+}_{0}+B^{-}_{0}+B^{+}_{1}\sqrt{\|V^{+}_{0}+\hat{\varphi}\|_{L^{\infty}}}+B^{-}_{1}\sqrt{\|V^{-}_{0}-\hat{\varphi}\|_{L^{\infty}}})\} \tag{12}$$

and

$$D_1 := \varepsilon^{2}_{1}\|1/\epsilon\|_{L^{\infty}}\sqrt{1+|\Omega|}(B^{+}_{1}+B^{-}_{1}). \tag{13}$$

Using D_0 and D_1 we introduce the radii

$$r_0 := \frac{1}{2}(D_1+\sqrt{D^{2}_{1}+4D_0}) \tag{14}$$

and

$$r_1^{\pm} := \|V_0^{\pm} + \hat{\varphi}\|_{L^\infty} + r_0. \tag{15}$$

If $h:[a,b]\to\mathbb{R}$ is a function of finite total variation and $x,y\in[a,b]$, then the total variation of $h|_{[x,y]}$ is denoted by $\mathsf{V}_x^y h$. If $1/m^{\pm}$ has a finite total variation, then we set

$$^{\pm} := \sqrt{\bar{m}^{\pm}} \exp\left\{ \frac{\bar{m}^{\pm}}{2} \mathsf{V}_a^b \frac{1}{m^{\pm}} \right\}. \tag{16}$$

Next we introduce the functions

$$R_j^{\pm}(y) := \quad ^{\pm}\left(1 + |\kappa_j^{\pm}| \sqrt{\frac{2}{\underline{m}^{\pm}}} \right) \exp\left\{ y|\Omega|(\quad ^{\pm})^2 \sqrt{\frac{2}{\underline{m}^{\pm}}} \right\} \tag{17}$$

for $y\geqslant 0$ and $j=a,b$. Further we set

$$L^{\pm}(y) := \sqrt{\frac{2}{\pi}} \left\{ \frac{R_a^{\pm}[2y+2+\gamma_0^{\pm}]^2}{(\alpha_a^{\pm})^2} + \frac{R_b^{\pm}[2y+2+\gamma_0^{\pm}]^2}{(\alpha_b^{\pm})^2} \right\}^{1/2} \tag{18}$$

for $y\geqslant 0$ where the representation

$$\kappa_a^{\pm} = q_a^{\pm} + i\frac{(\alpha_a^{\pm})^2}{2}, \quad \kappa_b^{\pm} = q_b^{\pm} + i\frac{(\alpha_b^{\pm})^2}{2} \tag{19}$$

is used. The constants $\gamma_0^{\pm}$ are given by

$$\gamma_0^{\pm} := 2\bar{m}^{\pm}(\quad ^{\pm})^2 \left\{ \frac{1}{2} + \frac{1}{^{\pm}|\Omega|\bar{m}^{\pm}} + \sqrt{\frac{1}{4} + \frac{1}{^{\pm}|\Omega|\bar{m}^{\pm}}} \right\}, \tag{20}$$

where

$$^{\pm} := \max\{0, q_a^{\pm}, q_b^{\pm}\}. \tag{21}$$

We define

$$^{\pm}(y) = \sqrt{B_0^{\pm} + B_1^{\pm}\sqrt{y}}, \quad y\geqslant 0. \tag{22}$$

and

$$^{\pm}(x,y) := \ ^{\pm}(\quad ^{\pm}(x) + \quad ^{\pm}(y))^2 + 4\pi|\Omega|L^{\pm}(x)L^{\pm}(y) \quad ^{\pm}(x) \quad ^{\pm}(y), \tag{23}$$

for $x,y\geqslant 0$. Finally, we introduce the constant

$$:= \quad ^{+}(r_1^{+}, r_1^{+}) + \quad ^{-}(r_1^{-}, r_1^{-}). \tag{24}$$

and we set

$$:= \varepsilon_1^2 \|1/\epsilon\|_{L^\infty} \sqrt{1+|\Omega|} \quad . \tag{25}$$

We note again that the introduced constants (9)–(25) depend only on the Schrödinger-Poisson data which means that they are fixed for fixed Schrödinger-Poisson data.

III. SCHRÖDINGER-TYPE OPERATORS

Since it is unimportant in the following whether we have to do with electrons or with holes we admit the superscript ± in this section. Further, throughout we assume that Schrödinger data $=\{m,\kappa_a,\kappa_b,V_0,\rho\}$ satisfy the Schrödinger assumptions mutatis mutandis.

A. Definitions

Following the suggestion of Refs. 20 and 21 we consider the non-self-adjoint Schrödinger-type operator $H[V]$ on the Hilbert space defined by

$$\mathrm{dom}(H[\kappa_a,\kappa_b,V]) = \left\{ \begin{array}{c} \\ f \in W^{1,2}: \\ \\ \end{array} \begin{array}{c} \dfrac{1}{m(x)} f'(x) \in W^{1,2}(\Omega), \\ \dfrac{1}{2m(a)} f'(a) = -\kappa_a f(a), \\ \dfrac{1}{2m(b)} f'(b) = \kappa_b f(b) \end{array} \right\}$$

and

$$(H[\kappa_a,\kappa_b,V]g)(x) = (l[V]g)(x), \quad g \in \mathrm{dom}(H[\kappa_a,\kappa_b,V]),$$

where

$$(l[V]g)(x) := -\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x}\frac{1}{m(x)}\frac{\mathrm{d}}{\mathrm{d}x}g(x) + V(x)g(x),$$

cf. Refs. 16 and 17, where $V \in L^\infty_{\mathbb{R}}(\Omega)$ and $\kappa_a, \kappa_b \in \overline{\mathbb{C}_+} := \{z \in \mathbb{C}: \Im\mathrm{m}(z) \geqslant 0\}$, are called the boundary coefficients. The operator $H[\kappa_a,\kappa_b,V]$ is maximal dissipative if either $\kappa_a \in \mathbb{C}_+$ or $\kappa_b \in \mathbb{C}_+$. In both cases the operator is completely non-self-adjoint, see Ref. 16. In the following we consider the case $\kappa_a, \kappa_b \in \mathbb{C}_+$. In this case we usually write $H[V]$ instead of $H[\kappa_a,\kappa_b,V]$. The spectrum of $H[V]$ consists of isolated eigenvalues in the lower half-plane with the only accumulation point at infinity, i.e., $\mathrm{spec}\,(H[V]) \subseteq \overline{\mathbb{C}_-} := \{z \in \mathbb{C}: \Im\mathrm{m}(z) \leqslant 0\}$. Since the operator $H[V]$ is completely non-self-adjoint, its eigenvalues are non-real.

Besides the operator $H[V]$ we consider the operator $H_{\mathfrak{R}}[V] := H[q_a,q_b,V]$, $V \in L^\infty_{\mathbb{R}}(\Omega)$, $q_a, q_b \in \mathbb{R}$. The operator $H_{\mathfrak{R}}[V]$ is self-adjoint and semi-bounded from below. In some sense the operator $H_{\mathfrak{R}}[V]$ can be regarded as the real part of the maximal dissipative $H[V]$. By $\gamma[V]$ we denote the bottom of the spectrum of $H_{\mathfrak{R}}[V]$, i.e., $\gamma[V] := \inf \mathrm{spec}(H_{\mathfrak{R}}[V])$.

Lemma 3.1: Let the Schrödinger assumptions Q_1 be satisfied. If $q_a, q_b \in \mathbb{R}$, then

$$\gamma[V] \geqslant -\gamma_0 - \|V_-\|_{L^\infty}, \tag{26}$$

where $V_-(x) := \frac{1}{2}\{|V(x)| - V(x)\}$, $x \in \Omega$, *and* γ_0 *is given by* (20).

Proof: We consider the quadratic form $[q_a,q_b](\cdot,\cdot)$,

$$[q_a,q_b](f,f) := -q_a|f(a)|^2 - q_b|f(b)|^2 + \int_a^b \frac{1}{2m(x)}|f'(x)|^2\mathrm{d}x,$$

$f \in \mathrm{dom}([q_a,q_b,V]) = W^{1,2}(\Omega)$, which is associated with the self-adjoint operator $H[q_a,q_b,0]$. The quadratic form $[q_a,q_b](\cdot,\cdot)$ admits the estimate

$$[q_a,q_b](f,f) \geqslant \hat{}(f,f) := -\{|f(a)|^2 + |f(b)|^2\} + \frac{1}{2\bar{m}}\int_a^b |f'(x)|^2\mathrm{d}x,$$

where $:= \max\{0,q_a,q_b\}$, cf. (21). The quadratic form $\hat{}$ corresponds to the self-adjoint operator $\hat{H}$,

$$(\hat{H}f)(x) = -\frac{1}{2\bar{m}}\frac{\mathrm{d}^2}{\mathrm{d}x^2}f(x), \quad f \in \mathrm{dom}(\hat{H}),$$

$$\mathrm{dom}(\hat{H}) = \left\{ f \in W^{2,2}(\Omega) : \frac{1}{2\bar{m}} f'(a) = -\quad f(a),\ \frac{1}{2\bar{m}} f'(b) = \quad f(b) \right\}.$$

A straightforward computation shows that $\lambda = -\mu^2$, $\mu \geqslant \mathfrak{q}\sqrt{2\bar{m}}$, is an eigenvalue of $\hat{H}$ if and only if μ satisfies

$$\mu|\Omega|\sqrt{2\bar{m}} = \ln\left(\frac{\mu + \quad \sqrt{2\bar{m}}}{\mu - \quad \sqrt{2\bar{m}}} \right).$$

Hence, if $\lambda = -\mu^2$ is an eigenvalue, then the estimate

$$\mu|\Omega|\sqrt{2\bar{m}} \leqslant \frac{2 \quad \sqrt{2\bar{m}}}{\mu - \quad \sqrt{2\bar{m}}}$$

holds. This yields

$$\lambda = -\mu^2 \geqslant -2\bar{m} \quad {}^2\left\{ \frac{1}{2} + \frac{1}{|\Omega|\bar{m}} + \sqrt{\frac{1}{4} + \frac{1}{|\Omega|\bar{m}}} \right\}.$$

Using this estimate we immediately verify (26). □

B. Elementary solutions and estimates

An important tool to investigate the dissipative operator $H[V]$ is the so-called elementary solutions defined by

$$l[V](v_a(x,z)) = z v_a(x,z), \quad v_a(a,z) = 1, \quad \frac{1}{2m(a)} v_a'(a,z) = -\kappa_a, \tag{27}$$

$$l[V](v_b(x,z)) = z v_b(x,z), \quad v_b(b,z) = 1, \quad \frac{1}{2m(b)} v_a'(b,z) = \kappa_b. \tag{28}$$

The existence of these solutions for each $z \in \mathbb{C}$ can be proved by writing (27) and (28) in integral form

$$v_a(x,z) = 1 - 2\kappa_a M_a(x) + 2\int_a^x \mathrm{d}t (M_a(x) - M_a(t))(V(t) - z) v_a(t,z) \tag{29}$$

and

$$v_b(x,z) = 1 - 2\kappa_b M_b(x) + 2\int_x^b \mathrm{d}t (M_b(x) - M_b(t))(V(t) - z) v_b(t,z) \tag{30}$$

where

$$M_a(x) := \int_a^x \mathrm{d}t\, m(t), \quad M_b(x) := \int_x^b \mathrm{d}t\, m(t).$$

Since (29) and (30) are Volterra-type equations they have always solutions for any $z \in \mathbb{C}$, in particular, for $z = \lambda \in \mathbb{R}$. Moreover, one gets that v_a and v_b as well as $(1/m)v_a'$ and $(1/m)v_b'$ are absolutely continuous.

In the following the estimates are based on Gronwall's lemma which we need in a slightly generalized form.

Lemma 3.2 (Gronwall's lemma): Let μ be a finite Borel measure on $[a,b]$. If the non-negative continuous function $g(\cdot):[a,b] \to \mathbb{R}$ obeys

$$0 \leqslant g(x) \leqslant C + \int_{[a,x]} g(t)\mathrm{d}\mu(t), \quad x \in [a,b], \quad C > 0, \tag{31}$$

then the estimate

$$g(x) \leqslant C \exp\left\{ \int_{[a,x]} \mathrm{d}\mu(t) \right\}, \quad x \in [a,b], \tag{32}$$

holds.

The proof follows immediately from Lemma 5 of Ref. 15. Using Gronwall's lemma we are going to establish bounds for the elementary solutions if $\lambda > 0$. At first we prove this for the special case $V=0$ and later on we extend the result to $V \neq 0$.

Let $V=0$. We consider the boundary value problem

$$l[0]w(x,\lambda) = \lambda w(x,\lambda), \quad w(a,\lambda) = p, \quad \frac{1}{2m(a)} w'(a,\lambda) = q,$$

where $p, q \in \mathbb{C}$.

Lemma 3.3: Let the Schrödinger assumption Q_1 be satisfied. If m has a finite total variation, then

$$|w(x,\lambda)| \leqslant \sqrt{|p|^2 + \frac{2}{\lambda m(a)}|q|^2} \quad , \tag{33}$$

for $x \in [a,b]$ and $\lambda > 0$, where is defined by (16).

Proof: We note that

$$-\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x}\frac{1}{m(x)}\frac{\mathrm{d}}{\mathrm{d}x} w(x,\lambda) = \lambda w(x,\lambda)$$

is satisfied for a.e. $x \in [a,b]$ with respect of the Lebesgue measure. Multiplying by $(1/m(x)w'(x,\lambda)$ we get

$$-\frac{1}{2}\overline{\frac{1}{m(x)} w'(x,\lambda)}\frac{\mathrm{d}}{\mathrm{d}x}\frac{1}{m(x)} w'(x,\lambda) = \lambda w(x,\lambda)\overline{\frac{1}{m(x)} w'(x,\lambda)}$$

which yields

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}x}\left| \frac{1}{m(x)} w'(x,\lambda) \right|^2 = -\frac{\lambda}{m(x)}\frac{\mathrm{d}}{\mathrm{d}x}|w(x,\lambda)|^2$$

for a.e. $x \in [a,b]$. Since $(1/m(x))w'(x,\lambda)$ is absolutely continuous we obtain

$$\frac{1}{2}\left| \frac{1}{m(x)} w'(x,\lambda) \right|^2 = \frac{1}{2}\left| \frac{1}{m(a)} w'(a,\lambda) \right|^2 - \lambda \int_a^x \frac{1}{m(t)}\frac{\mathrm{d}}{\mathrm{d}t}|w(t,\lambda)|^2 \mathrm{d}t$$

for $x \in [a,b]$. Since m has a finite total variation, the limits $m(x-0) := \lim_{y \uparrow x} m(y)$ for $x \in (a,b]$ and $m(x+0) := \lim_{y \downarrow x} m(y)$ for $x \in [a,b)$ exist. Further, we set $m(a-0) := m(a)$ and $m(b+0) := m(b)$. Notice that $m(x)$ and $m(x-0)$ are different only on a countable set. Hence we can replace $1/m(t)$ by $1/m(t-0)$ above. Using the boundary conditions we get

$$\left|\frac{1}{m(x)}w'(x,\lambda)\right|^2 = 4|q|^2 - 2\lambda\int_{[a,x]}\frac{1}{m(t-0)}\mathrm{d}|w(t,\lambda)|^2$$

for all $x\in[a,b]$ where the integral on the right-hand side is regarded as a Lebesgue-Stieltjes integral. If m has a finite total variation, then by assumption Q_1 the function $1/m$ has a finite total variation, too. By Theorem 21.67 and Remark 21.68 of Ref. 13 we get

$$\left|\frac{1}{m(x)}\frac{\mathrm{d}}{\mathrm{d}x}w(x,\lambda)\right|^2 + \frac{2\lambda}{m(x+0)}|w(x,\lambda)|^2 = 4|q|^2 + \frac{2\lambda}{m(a)}|w(a,\lambda)|^2 + 2\lambda\int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu(t), \tag{34}$$

where μ is the signed measure associated with $1/m$. Since $1/m$ is of bounded variation, the functions $\varpi(x) := \mathrm{V}_a^x(1/m)$ and $\nu(x) := \varpi(x) - 1/m(x)$, $x\in[a,b]$, are non-decreasing. Notice that $1/m(x) = \varpi(x) - \nu(x)$. Thus we find

$$\int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu(t) = \int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu_\varpi(t) - \int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu_\nu(t),$$

where μ_ϖ and μ_ν the measures associated with ϖ and ν, respectively. Hence

$$\int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu(t) \leqslant \int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu_\varpi(t), \quad x\in[a,b].$$

Inserting this estimate into (34) and using the boundary condition $w(a,\lambda)=p$ we get

$$\frac{1}{m(x+0)}|w(x,\lambda)|^2 \leqslant \frac{2}{\lambda}|q|^2 + \frac{1}{m(a)}|p|^2 + \int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu_\varpi(t), \quad x\in[a,b],$$

which yields

$$|w(x,\lambda)|^2 \leqslant m(x+0)\left(\frac{2}{\lambda}|q|^2 + \frac{1}{m(a)}|p|^2\right) + m(x+0)\int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu_\varpi(t)$$

for $x\in[a,b]$. Since $m(x)\leqslant\bar{m}$, $x\in[a,b]$, we obtain

$$|w(x,\lambda)|^2 \leqslant \bar{m}\left(\frac{2}{\lambda}|q|^2 + \frac{1}{m(a)}|p|^2\right) + \bar{m}\int_{[a,x]}|w(t,\lambda)|^2\mathrm{d}\mu_\varpi(t).$$

Applying Lemma 3.2, we immediately get

$$|w(x,\lambda)|^2 \leqslant \left(\frac{2}{\lambda}|q|^2 + \frac{1}{m(a)}|p|^2\right)\exp\left\{\bar{m}\int_{[a,x]}\mathrm{d}\mu_\varpi(t)\right\}$$

for $x\in[a,b]$. Hence

$$|w(x,\lambda)| \leqslant \sqrt{|p|^2 + \frac{2}{\lambda m(a)}|q|^2}\sqrt{\bar{m}}\exp\left\{\frac{\bar{m}}{2}\int_{[a,x]}\mathrm{d}\mu_\varpi(t)\right\}$$

for $x\in[a,b]$. Finally, taking into account

$$\int_{[a,x]}\mathrm{d}\mu_\varpi(t) \leqslant \int_{[a,b]}\mathrm{d}\mu_\varpi(t) \leqslant \mathop{\mathrm{V}}_a^b\frac{1}{m}$$

we prove (33). □

We note that a similar lemma holds if the end point a is replaced by b.

In the following we consider the solutions $w_0(x,\lambda)$ and $w_1(x,\lambda)$ of the boundary value problems

$$(l[0]w_1)(x) = \lambda w_1(x,\lambda), \quad w_1(a,\lambda) = 1, \quad \frac{1}{2m(a)} w_1'(a,\lambda) = 0,$$

$$(l[0]w_0)(x) = \lambda w_0(x,\lambda), \quad w_0(a,\lambda) = 0, \quad \frac{1}{2m(a)} w_0'(a,\lambda) = 1.$$

By Lemma 3.3 we have the estimates

$$|w_1(x,\lambda)| \leqslant \quad , \quad |w_0(x,\lambda)| \leqslant \sqrt{\frac{2}{\lambda m(a)}} \quad , \quad x \in [a,b], \quad \lambda > 0.$$

Lemma 3.4: Let the Schrödinger assumption Q_1 be satisfied and let $V \in L^\infty_{\mathbb{R}}(\Omega)$. If m has a finite total variation, then

$$|v_j(x,\lambda)| \leqslant \begin{cases} R_j(\|V\|_{L^\infty}), & \lambda \geqslant 1, \\ R_j(\|V+1-\lambda\|_{L^\infty}), & \lambda < 1, \end{cases} \quad , \quad j = a,b, \quad x \in \Omega, \tag{35}$$

where $R_j(\cdot)$ is defined by (17)

Proof: The solution $v_a(x,\lambda)$ satisfies the integral equation

$$v_a(x,\lambda) = w_1(x,\lambda) - \kappa_a w_0(x,\lambda) + \int_a^x \mathrm{d}t \, \{w_0(x,\lambda)w_1(t,\lambda) - w_0(t,\lambda)w_1(x,\lambda)\} V(t) v_a(t,\lambda),$$

$x \in \Omega$ and $\lambda \in \mathbb{R}$. Therefore, we have the estimate

$$|v_a(x,\lambda)| \leqslant \quad \left(1 + |\kappa_a| \sqrt{\frac{2}{\lambda m(a)}}\right) + \quad {}^2\sqrt{\frac{2}{\lambda m(a)}} \int_a^x \mathrm{d}t \, |V(t)||v_a(t,\lambda)|,$$

$x \in \Omega$ and $\lambda > 0$. Applying Gronwall's lemma we find

$$|v_a(x,\lambda)| \leqslant \quad \left(1 + |\kappa_a| \sqrt{\frac{2}{\lambda m(a)}}\right) \exp\left\{ \quad {}^2\sqrt{\frac{2}{\lambda m(a)}} \int_a^x \mathrm{d}t \, |V(t)| \right\}$$

for $x \in \Omega$ and $\lambda > 0$. If $\lambda \geqslant 1$, then we immediately verify the first part of (35).

If $\lambda < 1$, then $v_j(x,\lambda)$ satisfies the equation $l[V+1-\lambda]v_a(x,\lambda) = v_a(x,\lambda)$. Taking into account the first estimate of (35) we prove the second estimate. The proof for $j=b$ is similar. □

C. Characteristic function

Let us introduce the operator-valued function $T(z): \mathcal{H} \to \mathbb{C}^2$,

$$T[V](z)f := \begin{pmatrix} \alpha_b((H[V]-z)^{-1}f)(b) \\ -\alpha_a((H[V]-z)^{-1})f(a) \end{pmatrix}, \quad \alpha_a, \alpha_b > 0,$$

for $z \in \mathrm{res}(H[V])$ and $f \in L^2(\Omega)$. Using Theorem 2.1 of Ref. 17, we find

$$T[V](z)f = \frac{1}{W(z)} \begin{pmatrix} -\alpha_b \int_a^b \mathrm{d}y \, v_a(y,z) f(y) \\ \alpha_a \int_a^b \mathrm{d}y \, v_b(y,z) f(y) \end{pmatrix}$$

for $f \in L^2(\Omega)$ where $W(z)$ denotes the Wronskian of the solutions $v_a(x,z)$ and $v_b(x,z)$,

$$W(z) := v_a(x,z)\frac{1}{2m(x)}v_b'(x,z) - v_b(x,z)\frac{1}{2m(x)}v_a'(x,z),$$

which is independent from $x \in \Omega$. The adjoint operator is given by

$$(T[V](z)^*\xi)(x) = \frac{1}{W(z)}(-\alpha_b\overline{v_a(x,z)}, \alpha_a\overline{v_b(x,z)})\xi, \tag{36}$$

$x \in \Omega$, where

$$\xi = \begin{pmatrix} \xi^b \\ \xi^a \end{pmatrix} \in \mathbb{C}^2. \tag{37}$$

and the right-hand side is regarded as a matrix multiplication. Similarly, we set

$$T_*[V](z)f := \begin{pmatrix} \alpha_b((H[V]^* - z)^{-1}f)(b) \\ -\alpha_a((H[V]^* - z)^{-1}f)(a) \end{pmatrix}$$

for $z \in \mathrm{res}(H^*)$ and $f \in L^2(\Omega)$. Using again Theorem 2.1 of Ref. 17 we find

$$T_*[V](z)f = \frac{1}{W_*(z)}\begin{pmatrix} -\alpha_b\int_a^b \mathrm{d}y\, v_{*a}(y,z)f(y) \\ \alpha_b\int_a^b \mathrm{d}y\, v_{*b}(y,z)f(y) \end{pmatrix},$$

where $W_*(z)$ is the Wronskian of the solutions $v_{*a}(x,z) := \overline{v_a(x,\bar{z})}$ and $v_{*b}(x,z) := \overline{v_b(x,\bar{z})}$,

$$W_*(z) := v_{*a}(x,z)\frac{1}{2m(x)}v_{*b}'(x,z) - v_{*b}(x,z)\frac{1}{2m(x)}v_{*a}'(x,z),$$

which also independent from $x \in \Omega$. The adjoint operator has the representation

$$(T_*[V](z)^*\xi)(x) = \frac{1}{W_*(z)}(-\alpha_b\overline{v_{*a}(x,z)}, \alpha_a\overline{v_{*b}(x,z)})\xi,$$

$x \in \Omega$, $\xi \in \mathbb{C}^2$.

The operator $H[V]$ can be (up to unitary equivalence) characterized by its characteristic function $z \to \Theta[V](z)$, with $z \in \mathrm{res}(H[V]) \cap \mathrm{res}(H[V]^*)$, cf. Ref. 9. The characteristic function $\Theta[V](\cdot)$ of the maximal dissipative operator $H[V]$ is a two-by-two matrix-valued function which satisfies the relation

$$\Theta[V](z)T[V](z)f = T_*[V](z)f, \quad z \in \mathrm{res}(H[V]) \cap \mathrm{res}(H[V]^*),$$

$f \in \mathfrak{h}$. In terms of the adjoint elementary solutions the characteristic function can be expressed as follows:

$$\Theta[V](z) = I_{\mathbb{C}^2} + i\frac{1}{W_*(z)}\begin{pmatrix} \alpha_b^2 v_{*a}(b,z) & -\alpha_b\alpha_a \\ -\alpha_b\alpha_a & \alpha_a^2 v_{*b}(a,z) \end{pmatrix},$$

which can be written as

$$\Theta[V](z) = I_{\mathbb{C}^2} - i\alpha T[V](\bar{z})^*,$$

$z \in \mathrm{res}(H[V]) \cap \mathrm{res}(H[V]^*)$, where the operator $\alpha: L^2(\Omega) \to \mathbb{C}$, is defined by

$$\alpha f := \begin{pmatrix} \alpha_b f(b) \\ -\alpha_a f(a) \end{pmatrix}, \quad f \in \mathrm{dom}(\alpha) := C(\bar{\Omega}).$$

Notice that the operator α is not closed and not closable. The characteristic function $\Theta[V](\lambda)$ is a holomorphic on $\mathrm{res}(H[V]) \cap \mathrm{res}(H[V]^*)$ and contractive on $\mathbb{C}_- \cup \mathbb{R}$, i.e., it satisfies

$$\|\Theta[V](z)\| \leqslant 1 \quad \text{for} \quad z \in \mathbb{C}_- \cup \mathbb{R}.$$

In particular, it is well-defined and continuous on $\mathbb{R}$, cf. Ref. 17. We note that by Lemma 2.2 of Ref. 26 one has $\lim_{\lambda \to -\infty} \|\Theta[V](\lambda) - I_{\mathbb{C}^2}\|_{\mathcal{B}(\mathbb{C}^2)} = 0$.

D. Phase shift

The phase shift $\omega[V]$ is defined by

$$e^{2\pi i \omega[V](\lambda)} := \det(\Theta[V](\lambda)), \quad \lambda \in \mathbb{R},$$

where it is assumed that $\omega[V](\cdot) : \mathbb{R} \to \mathbb{R}$ is continuous. Notice that the phase shift is determined modulo $\mathbb{Z}$. Since $\lim_{\lambda \to -\infty} \det(\Theta[V](\lambda)) = 1$ by Lemma 2.2 of Ref. 26 we fix the phase shift by the condition

$$\lim_{\lambda \to -\infty} \omega[V](\lambda) = 0.$$

Lemma 3.5: [Ref. 26, Lemma 4.1] Let the Schrödinger assumptions Q_1 and Q_2 be satisfied. If $V \in L^\infty_{\mathbb{R}}(\Omega)$, then the phase shift is holomorphic in a neighborhood of $\mathbb{R}$ and satisfies

$$\omega'[V](\lambda) := \frac{\mathrm{d}}{\mathrm{d}\lambda} \omega[V](\lambda) = -\frac{1}{2\pi} \mathrm{tr}(T[V](\lambda) T[V](\lambda)^*) \leqslant 0 \tag{38}$$

for $\lambda \in \mathbb{R}$.

Lemma 3.5 shows that the phase shift is non-increasing. Moreover, since $\omega[V](-\infty) = 0$ the phase shift is always non-positive, i.e., $\omega[V](\lambda) \leqslant 0$ for $\lambda \in \mathbb{R}$. Let us introduce the counting function

$$\Phi[V](\lambda) := \mathrm{card}\{s \leqslant \lambda : \det(\Theta[V](s)) = 1\}, \quad \lambda \in \mathbb{R}.$$

It turns out that the $\Phi[V](\cdot)$ is comparable with the counting function $N_D[V](\cdot)$,

$$N_D[V](\lambda) := \mathrm{card}\{s \leqslant \lambda : s \in \mathrm{spec}(H_D[V])\}, \quad \lambda \in \mathbb{R}.$$

where $H_D[V]$ denotes the Schrödinger-type operator with Dirichlet boundary conditions.

Theorem 3.6: *[Ref. 26, Theorem 4.7] Let the Schrödinger assumption Q_1 and Q_2 be satisfied. If $V \in L^\infty_{\mathbb{R}}(\Omega)$, then*

$$N_D[V](\lambda) \leqslant \Phi[V](\lambda) \leqslant N_D[V](\lambda) + 1, \quad \lambda \in \mathbb{R}.$$

Corollary 3.7: Let the Schrödinger assumption Q_1 and Q_2 be satisfied. If $V \in L^\infty_{\mathbb{R}}(\Omega)$, then

$$0 \leqslant -\omega[V](\lambda) \leqslant 2 + \frac{1}{\pi} \sqrt{2\bar{m}|\Omega|} \sqrt{(\lambda + \|V_-\|_{L^\infty})_+} \tag{39}$$

for $\lambda \in \mathbb{R}$.

Proof: Since $-\omega[V](\lambda)$ is non-decreasing by Lemma 3.5 the estimate $-\omega[V](\lambda) \leqslant 1 + \Phi[V](\lambda)$, $\lambda \in \mathbb{R}$, holds. By Remark 4.8 of Ref. 26 and Theorem 3.6 one gets

$$N_D[V](\lambda) \leqslant \frac{1}{\pi}\sqrt{2\overline{m}|\Omega|}\sqrt{(\lambda + \|V_-\|_{L^\infty})_+}, \quad \lambda \in \mathbb{R},$$

which yields (39). □

E. Lipschitz continuity of the phase shift

We are going to verify the Lipschitz continuity of the phase shift by giving bounds for the derivative of $\omega[V]$.

Proposition 3.8: Let the Schrödinger assumptions Q_1 and Q_2 be satisfied and let $V \in L^\infty_{\mathbb{R}}(\Omega)$. If m has a finite total variation, then

$$|\omega[V](\lambda) - \omega[V](\lambda')| \leqslant |\Omega| L(\|V\|_{L^\infty})^2 |\lambda - \lambda'|, \tag{40}$$

$\lambda, \lambda' \in \mathbb{R}$ *where* $L(\cdot)$ *is defined by* (18).

Proof: Since the phase shift is continuously differentiable it is sufficient to show $-\omega'[V](\lambda) \leqslant |\Omega| L(\|V\|_{L^\infty})^2$, $\lambda \in \mathbb{R}$. Taking into account Lemma 3.5 we get

$$\omega'[V](\lambda) = -\frac{1}{2\pi}\sum_{j=1}^{2} \|T[V](\lambda)^* e_j\|^2_{L^2}, \quad \lambda \in \mathbb{R}, \tag{41}$$

where

$$e_1 := \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad e_2 := \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

By (36) we find

$$\|T[V](\lambda)^* e_1\|^2_{L^2} = \frac{\alpha_b^2}{|W(\lambda)|^2}\int_a^b \mathrm{d}x |v_a(x,\lambda)|^2.$$

Let

$$E := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

We note that $\|E\Theta[V](\lambda)\|_{\mathcal{B}(\mathbb{C}^2)} \leqslant 1$, $\lambda \in \mathbb{R}$, and

$$\mathrm{tr}(E\Theta[V](\lambda)) = -2i\frac{\alpha_a \alpha_b}{W(\lambda)}, \quad \lambda \in \mathbb{R},$$

which yields

$$\frac{\alpha_a \alpha_b}{|W(\lambda)|} \leqslant 1, \quad \lambda \in \mathbb{R}.$$

Hence

$$\|T[V](\lambda)^* e_1\|^2_{L^2} \leqslant \frac{1}{\alpha_a^2}\int_a^b \mathrm{d}x |v_a(x,\lambda)|^2, \quad \lambda \in \mathbb{R}.$$

Applying Lemma 3.4 we get the estimate

$$\|T[V](\lambda)^* e_1\|_{L^2}^2 \leqslant |\Omega| \frac{R_a[\|V+2-\lambda_0\|_{L^\infty}]^2}{\alpha_a^2}, \quad \lambda \in [\lambda_0 - 1, \infty). \tag{42}$$

where $\lambda_0 := -\|V\|_{L^\infty} - \gamma_0$ and γ_0 is given by (20). By Lemma 3.1 one immediately gets that $(-\infty, \lambda_0) \subseteq \mathrm{res}(H[V])$. Using the resolvent formula

$$(H[V]-\lambda)^{-1} = (H[V]-\lambda_0)^{-1}\{I + (\lambda-\lambda_0)(H[V]-\lambda)^{-1}\},$$

$\lambda \in (-\infty, \lambda_0)$, we find the representation

$$T[V](\lambda) = T[V](\lambda_0)\{I + (\lambda-\lambda_0)(H[V]-\lambda)^{-1}\}, \tag{43}$$

$\lambda \in (-\infty, \lambda_0)$. By $\Gamma[V]$ we denote the numerical range of $H[V]$. One easily verifies that $\Gamma[V] \subseteq \{z \in \mathbb{C} : \mathfrak{Re}(z) \geqslant \lambda_0\}$. Applying Theorem 3.1 of Ref. 16 we get the estimate

$$\|(H[V]-\lambda)^{-1}\|_{\mathcal{B}(L^2(\Omega))} \leqslant \frac{1}{\mathrm{dist}(\Gamma[V], \lambda)} \leqslant \frac{1}{|\lambda - \lambda_0|} \leqslant 1$$

for $\lambda \in (-\infty, \lambda_0 - 1)$. Hence we find the estimate

$$\|I + (\lambda-\lambda_0)(H[V]-\lambda)^{-1}\|_{\mathcal{B}(L^2(\Omega))} \leqslant 1 + \frac{|\lambda-\lambda_0|}{|\lambda-\lambda_0|} = 2$$

for $\lambda \in (-\infty, \lambda_0 - 1)$. Further, from (43) we get

$$T[V](\lambda)^* e_1 = \{I + (\lambda-\lambda_0)(H[V]^* - \lambda)^{-1}\} T[V](\lambda_0)^* e_1$$

for $\lambda \in (-\infty, \lambda_0 - 1)$. Using (42)

$$\|T[V](\lambda)^* e_1\|_{L^2}^2 \leqslant 4\|T[V](\lambda_0)^* e_1\|_{L^2}^2 \leqslant 4|\Omega| \frac{R_a[\|V+2-\lambda_0\|_{L^\infty}]^2}{\alpha_a^2}, \tag{44}$$

$\lambda \in (-\infty, \lambda_0 - 1)$. Taking into account (42) and (44) we finally get

$$\|T[V](\lambda)^* e_1\|_{L^2}^2 \leqslant 4|\Omega| \frac{R_a[\|V+2-\lambda_0\|_{L^\infty}]^2}{\alpha_a^2}, \quad \lambda \in \mathbb{R}. \tag{45}$$

Similarly, we prove

$$\|T[V](\lambda)^* e_2\|_{L^2}^2 \leqslant 4|\Omega| \frac{R_b[\|V+2-\lambda_0\|_{L^\infty}]^2}{\alpha_b^2}, \quad \lambda \in \mathbb{R}. \tag{46}$$

From (41), (45), and (46) we obtain

$$-\omega'[V](\lambda) \leqslant \frac{2}{\pi}|\Omega| \left\{ \frac{R_a[\|V+2-\lambda_0\|_{L^\infty}]^2}{\alpha_a^2} + \frac{R_b[\|V+2-\lambda_0\|_{L^\infty}]^2}{\alpha_b^2} \right\}$$

for $\lambda \in \mathbb{R}$. Inserting $\lambda_0 = -\|V\|_{L^\infty} - \gamma_0$ into this formula and using the definition (18) we obtain (40). □

F. Dilations

Since $H[V]$ is a maximal dissipative operator there is a larger Hilbert space $\supseteq$ and a self-adjoint operator $K[V]$ on such that

$$P\ \ (K[V]-z)^{-1}\restriction\quad =(H[V]-z)^{-1},\quad \Im\mathrm{m}(z)>0, \tag{47}$$

see Ref. 9. The operator $K[V]$ is called a self-adjoint dilation of the maximal dissipative operator $H[V]$. Obviously, from the condition (47) one gets

$$P\ \ (K[V]-z)^{-1}\restriction\quad =(H[V]^{*}-z)^{-1},\quad \Im\mathrm{m}(z)<0.$$

If the condition

$$\mathrm{clospan}\{z\in\mathbb{C}\setminus\mathbb{R}:(K[V]-z)^{-1}\quad\}=$$

is satisfied, then $K[V]$ is called a minimal self-adjoint dilation of $H[V]$. Minimal self-adjoint dilations of maximal dissipative operators are determined up to an isomorphism, in particular, all minimal self-adjoint dilations are unitarily equivalent. The self-adjoint operator $K[V]$ is absolutely continuous and its spectrum coincides with the real axis, i.e., $\mathrm{spec}(K)=\mathbb{R}$. The multiplicity of its spectrum is two. For more details the reader is referred to Ref. 17.

Definition 3.9: (cf. Ref. 22) Let K be a self-adjoint, absolutely continuous operator on a Hilbert space $\mathcal{H}$ and A be a bounded operator on $\mathcal{H}$. Then A is called K-smooth if there is a constant $C_A>0$ such that

$$\int_{-\infty}^{+\infty}\mathrm{d}t\|Ae^{-itK}\vec{f}\|_{\mathcal{H}}^{2}\leqslant 2\pi C_A^{2}\|\vec{f}\|_{\mathcal{H}}^{2} \tag{48}$$

for all $\vec{f}\in\mathcal{H}$. The smallest constant C_A is denoted by $\|A\|_K$.

Let us verify that the projection $P\quad$ is $K[V]$-smooth. To this end we need the following lemma which was proved in Ref. 26.

Lemma 3.10: [Ref. 26, Lemma 5.3] Let the Schrödinger assumptions Q_1 and Q_2 be satisfied. If $V\in L^{\infty}_{\mathbb{R}}(\Omega)$, then

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}(E_{K[V]}(\lambda)P\ \ \vec{f},P\ \ \vec{g})\ \ =(T[V](\lambda)P\ \ \vec{f},T[V](\lambda)P\ \ \vec{g})_{\mathbb{C}^2}$$

for a.e $\lambda\in\mathbb{R}$ and $\vec{f},\vec{g}\in$ where $E_{K[V]}(\cdot)$ denotes the spectral measure of the the self-adjoint dilation $K[V]$.

Proposition 3.8 and Lemma 3.10 imply the smoothness of $P\ \ $:

Theorem 3.11: *Let the Schrödinger assumptions Q_1 and Q_2 be satisfied and let $V\in L^{\infty}_{\mathbb{R}}(\Omega)$. If m has a finite total variation, then the projection $P\quad$ is $K[V]$-smooth and the estimate*

$$\|P\ \ \|_{K[V]}\leqslant\sqrt{|\Omega|}L(\|V\|_{L^{\infty}}) \tag{49}$$

holds where $L(\cdot)$ is defined by (18).

Proof: In accordance with Ref. 22 we set

$$a_2:=\sup_{\Delta\subseteq\mathbb{R},\vec{f}\in\ \ \vec{f}\neq 0}\frac{\|E_{K[V]}(\Delta)P\ \ \vec{f}\|^{2}}{|\Delta|\,\|\vec{f}\|^{2}},$$

where $\Delta=(\lambda_1,\lambda_2)\subseteq\mathbb{R}$ are bounded intervals of $\mathbb{R}$ and $|\Delta|:=\lambda_2-\lambda_1$ denotes their length. Then Theorem 5.1 of Ref. 22 states $\|P\ \ \|_{K[V])}=\sqrt{a_2}$. Thus, the $K[V]$-smoothness of the projection P including the estimate (49) is shown if we verify

$$a_2\leqslant|\Omega|L(\|V\|_{L^{\infty}})^{2}.$$

Using Lemma 3.10 we get that

$$\|E_{K[V]}(\Delta)P\ \vec{f}\|^2 = \frac{1}{2\pi}\int_\Delta d\lambda \|T[V](\lambda)f\|^2 .$$

We note that

$$\|T[V](\lambda)f\|^2 \leqslant \|f\|^2 \operatorname{tr}(T[V](\lambda)^* T[V](\lambda)) = \|f\|^2 \operatorname{tr}(T[V](\lambda)T[V](\lambda)^*),$$

$\lambda \in \mathbb{R}$. Hence

$$\|E_{K[V]}(\Delta)P\ \vec{f}\|^2 \leqslant \|\vec{f}\|^2 \frac{1}{2\pi}\int_\Delta d\lambda \operatorname{tr}(T[V](\lambda)T[V](\lambda)^*).$$

Taking into account Lemma 3.5 we obtain the estimate

$$\|E_{K[V]}(\Delta)P\ \vec{f}\|^2 \leqslant -\|\vec{f}\|^2 \int_\Delta d\lambda\ \omega'[V](\lambda).$$

Hence we obtain

$$\frac{\|E_{K[V]}(\Delta)P\ \vec{f}\|^2}{\|\vec{f}\|^2} \leqslant (\omega[V](\lambda_1) - \omega[V](\lambda_2))$$

Using (40) we find the estimate

$$\frac{\|E_{K[V]}(\Delta)P\ \vec{f}\|^2}{|\Delta|\ \|f^2} \leqslant |\Omega| L(\|V\|_{L^\infty})^2.$$

□

G. Lax-Phillips scattering theory

The dilation space admits the decomposition

$$= \mathcal{D}_- \oplus \quad \oplus \mathcal{D}_+.$$

where $\mathcal{D}_\pm = L^2(\mathbb{R}_\pm, \mathbb{C}^2)$, see Ref. 17. Since

$$e^{-itK[V]}\mathcal{D}_- \subseteq \mathcal{D}_-, \quad t \leqslant 0,$$

$$e^{-itK[V]}\mathcal{D}_+ \subseteq \mathcal{D}_+, \quad t \geqslant 0$$

as well as

$$\begin{aligned} &\bigcap_{t\in\mathbb{R}} e^{-itK[V]}\mathcal{D}_- = \bigcap_{t\in\mathbb{R}} e^{-itK[V]}\mathcal{D}_+ = \{0\}, \\ &\overline{\bigcup_{t\in\mathbb{R}} e^{-itK[V]}\mathcal{D}_-} = \overline{\bigcup_{t\in\mathbb{R}} e^{-itK[V]}\mathcal{D}_+} = \end{aligned} \tag{50}$$

the subspaces $\mathcal{D}_-$ and $\mathcal{D}_+$ are called incoming and outgoing subspaces with respect to $e^{-itK[V]}$, cf. Ref. 1, Chap. XII or Ref. 24. Further, introducing the Hilbert space $_0$,

$$_0 = L^2(\mathbb{R}, \mathbb{C}^2) = \mathcal{D}_- \oplus \mathcal{D}_+ \subseteq \quad = \mathcal{D}_- \oplus \quad \oplus \mathcal{D}_+,$$

and the self-adjoint differentiation operator K_0,

$$(K_0 f)(x) = -i\frac{\mathrm{d}}{\mathrm{d}x}f(x), \quad f \in \mathrm{dom}(K_0) = W^{1,2}(\mathbb{R},\mathbb{C}^2),$$

one easily verifies that $\mathcal{D}_-$ and $\mathcal{D}_+$ are incoming and outgoing subspaces with respect to e^{-itK_0}. The Lax-Phillips wave operators are defined by

$$W_\pm(K[V],K_0;J_\pm) := s - \lim_{t\to\pm\infty} e^{itK[V]}J_\pm e^{-itK_0},$$

where the identification operators $J_\pm$: $_0 \to$ are given by

$$\vec{f} = J_- f := P_{\mathcal{D}_-^0} f \oplus 0 \oplus 0, \quad f \in \ _0,$$

$$\vec{f} = J_+ f := 0 \oplus 0 \oplus P_{\mathcal{D}_+^0} f, \quad f \in \ _0.$$

Since

$$e^{-itK[V]}|\mathcal{D}_- = e^{-itK_0}|\mathcal{D}_-, \quad t \leqslant 0,$$

$$e^{-itK[V]}|\mathcal{D}_+ = e^{-itK_0}|\mathcal{D}_+, \quad t \geqslant 0,$$

the wave operators $W_\pm(K[V],K_0;J_\pm)$ exist. Using (50) one proves the completeness of the wave operators, i.e., $\mathrm{ran}(W_\pm(K[V],K_0;J_\pm)) =$. For details see Ref. 1, Chap. XII or Ref. 24. Defining the Fourier transform F: $_0 \to \hat{}_0 = L^2(\mathbb{R},\mathbb{C}^2)$ by

$$(Ff)(\lambda) := \frac{1}{\sqrt{2\pi}}\int_{\mathbb{R}} \mathrm{d}x\, e^{-ix\lambda} f(x), \quad f \in \ _0, \quad \lambda \in \mathbb{R},$$

one defines the generalized Fourier transform $\Phi[V]$: $\to \hat{}_0$ by

$$\Phi[V] := FW_-(K[V],K_0;J_-)^*, \tag{51}$$

cf. Remark 5.2 of Ref. 18, which is an isometry. Moreover, if M is the multiplication operator defined by

$$(M\hat{f}) = \lambda\hat{f}(\lambda), \quad \hat{f} \in \mathrm{dom}(M) = \{\hat{f} \in \hat{}_0 : \lambda\hat{f}(\lambda) \in \hat{}_0\}.$$

on the Hilbert space $_0$, then $M = \Phi[V]K[V]\Phi[V]^{-1}$.

Lemma 3.12: Let the Schrödinger assumptions Q_1 and Q_2 be satisfied and let $V, W \in L^\infty_{\mathbb{R}}(\Omega)$. If m has a finite total variation, then the estimate

$$\|(W_-(K[W],K[V]) - I\ )\|_{\mathcal{B}(\ )} \leqslant 2\pi|\Omega|L(\|V\|_{L^\infty})L(\|W\|_{L^\infty})\|V - W\|_{L^\infty} \tag{52}$$

holds where $L(\cdot)$ is given by (18).

Proof: Similar to formula (X.3.24) of Ref. 22 one has

$$((W_-(K[W],K[V]) - I\ )\vec{f},\vec{g})\ = -i\int_{-\infty}^{0} \mathrm{d}t([W - V]P\ \ e^{-itK[V]}\vec{f}, P\ \ e^{-itK[W]}\vec{g}),$$

for $\vec{f},\vec{g} \in \mathrm{dom}(K[V]) = \mathrm{dom}(K[W])$. Hence, we obtain the estimate

$$|((W_-(K[W],K[V]) - I\ )\vec{f},\vec{g})\ | \leqslant \|V - W\|_{L^\infty}\left(\int_{\mathbb{R}} \mathrm{d}t\|P\ \ e^{-itK[V]}\vec{f}\|^2\right)^{1/2}\left(\int_{\mathbb{R}} \mathrm{d}t\|P\ \ e^{-itK[W]}\vec{g}\|^2\right)^{1/2},$$

$\vec{f},\vec{g} \in$. Applying (48) and (49) we obtain

$$|((W_-(K[W],K[V])-I\ )\vec{f},\vec{g})\ | \leqslant 2\pi|\Omega|L(\|V\|_{L^\infty})L(\|W\|_{L^\infty})\|V-W\|_{L^\infty}\|\vec{f}\|\ \|\vec{g}$$

for $\vec{f},\vec{g}\in$ which proves (52). □

IV. CARRIER DENSITY OPERATOR AND CONTINUITY

A. Carrier density operator

In the following an operator $\varrho:\ \rightarrow$ is called a density operator if ϱ is a bounded, nonnegative, self-adjoint operator. The operator ϱ is called a steady state, if ϱ commutes with $K[V]$, see Ref. 18. Thus any steady state ϱ is unitarily equivalent to a multiplication operator $\hat{\rho}$ on the Hilbert space $L^2(\mathbb{R},\mathbb{C}^2)$ induced by a density matrix $\rho(\cdot)\in L^\infty(\mathbb{R},\mathcal{B}(\mathbb{C}^2))$. In the following we assume that the function $\rho(\cdot)$ is fixed. This leads to a steady state of the form

$$\varrho[V]=\Phi[V]^{-1}\hat{\rho}\Phi[V], \tag{53}$$

which depends on V. The reduced density operator $\varrho\ [V]\in\mathcal{B}(\ )$ is defined

$$\varrho\ [V]:=P\ \ \varrho[V]\restriction\ .$$

Similarly, we define the reduced density operator $g\ (K[V])\in\mathcal{B}(\ )$ by

$$g\ (K[V]):=P\ \ g(K[V])\restriction\ .$$

Notice that by the Schrödinger assumption (5) one has

$$0\leqslant\varrho\ [V]\leqslant g\ (K[V]). \tag{54}$$

Lemma 4.1; Let the Schrödinger assumptions Q_1, Q_2, and Q_4 be satisfied. If $V\in L^\infty_{\mathcal{R}}(\Omega)$, then $g\ (K[V])$ is a trace class operator such that

$$0\leqslant\mathrm{tr}(g\ (K[V]))\leqslant\ (\|V_-\|_{L^\infty})^2 \tag{55}$$

where $(\cdot)$ is defined by (22).

Proof: Let $\{\psi_k\}_{k=1}^\infty$ be an orthonormal basis in . By the spectral theorem

$$\sum_{k=1}^n(g\ (K[V])\psi_k,\psi_k)=\sum_{k=1}^n(g(K[V])\psi_k,\psi_k)=\int_{\mathbb{R}}\mathrm{d}\lambda\ g(\lambda)\sum_{k=1}^n\frac{\mathrm{d}}{\mathrm{d}\lambda}(E_{K[V]}(\lambda)\psi_k,\psi_k),$$

where we have used that the spectral measure $E_{K[V]}(\cdot)$ of $K[V]$ is absolutely continuous with respect to the Lebesgue measure. Applying Lemma 3.10 we find

$$\int_{\mathbb{R}}\mathrm{d}\lambda\ g(\lambda)\frac{\mathrm{d}}{\mathrm{d}\lambda}(E_{K[V]}(\lambda)\psi_k,\psi_k)=\frac{1}{2\pi}\int_{\mathbb{R}}\mathrm{d}\lambda\ g(\lambda)(T[V](\lambda)\psi_k,T[V](\lambda)\psi_k),\quad k\in\mathbb{N},$$

which yields

$$\sum_{k=1}^n(g(K[V])\psi_k,\psi_k)=\frac{1}{2\pi}\int_{\mathbb{R}}\mathrm{d}\lambda\ g(\lambda)\sum_{k=1}^n(T[V](\lambda)\psi_k,T[V](\lambda)\psi_k).$$

Hence we obtain

$$\sum_{k=1}^n(g(K[V])\psi_k,\psi_k)\leqslant\frac{1}{2\pi}\int_{\mathbb{R}}\mathrm{d}\lambda\ g(\lambda)\mathrm{tr}(T[V](\lambda)^*T[V](\lambda))$$

or

$$\sum_{k=1}^{n} (g(K[V])\psi_k, \psi_k) \leqslant \frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*). \tag{56}$$

By (38) we get

$$\frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*) = -\int d\lambda\, g(\lambda)\omega'[V](\lambda), \quad \lambda \in \mathbb{R},$$

which yields

$$\frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*) = -g(\lambda)\omega[V](\lambda)|_{\lambda=-\infty}^{\lambda=+\infty} + \int_{\mathbb{R}} d\lambda\, g'(\lambda)\omega[V](\lambda).$$

By Corollary 3.7 we have

$$-\omega[V](\lambda) \leqslant 2 + \frac{1}{\pi}\sqrt{\bar{m}|\Omega|}\sqrt{(\lambda + \|V_-\|_{L^\infty})_+}$$

for $\lambda \in \mathcal{R}$. We note that the conditions (6) and (7) imply

$$\lim_{\lambda\to\infty} \sqrt{\lambda} g(\lambda) = 0.$$

Taking into account this property we obtain

$$\frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*) = \int_{\mathbb{R}} d\lambda\, g'(\lambda)\omega[V](\lambda).$$

Since $g'(\lambda) \geqslant 0$ for $\lambda \leqslant 0$ and $g'(\lambda) \leqslant 0$ for $\lambda \geqslant 0$ as well as $\omega[V](\lambda) \leqslant 0$, $\lambda \in \mathbb{R}$, we get

$$\begin{aligned}\frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*) &\leqslant \int_0^{+\infty} d\lambda\, g'(\lambda)\omega[V](\lambda) \\ &\leqslant -\int_0^{\infty} d\lambda\, g'(\lambda)\left(2 + \frac{1}{\pi}\sqrt{\bar{m}|\Omega|}\sqrt{\lambda + \|V_-\|_{L^\infty}}\right).\end{aligned}$$

Integrating by parts we find

$$\begin{aligned}\frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*) &\leqslant g(0)\left(2 + \frac{1}{\pi}\sqrt{\bar{m}|\Omega|}\sqrt{\|V_-\|_{L^\infty}}\right) \\ &\quad + \frac{1}{2\pi}\sqrt{\bar{m}|\Omega|}\int_0^{\infty} d\lambda \frac{g(\lambda)}{\sqrt{\lambda + \|V_-\|_{L^\infty}}},\end{aligned}$$

which yields the estimate

$$\frac{1}{2\pi}\int_{\mathbb{R}} d\lambda\, g(\lambda)\mathrm{tr}_{\mathbb{C}^2}(T[V](\lambda)T[V](\lambda)^*) \leqslant \left(2g(0) + \frac{1}{2\pi}\sqrt{\bar{m}|\Omega|}\int_0^{\infty} d\lambda \frac{g(\lambda)}{\sqrt{\lambda}}\right) + \frac{1}{\pi}g(0)\sqrt{\bar{m}|\Omega|}\sqrt{\|V_-\|_{L^\infty}}.$$

From (56) we get the estimate

$$\sum_{k=1}^{n} (g(K[V])\psi_k, \psi_k) \leqslant \left(2g(0) + \frac{1}{2\pi}\sqrt{\bar{m}|\Omega|}\int_0^{\infty} d\lambda \frac{g(\lambda)}{\sqrt{\lambda}}\right) + \frac{1}{\pi}g(0)\sqrt{\bar{m}|\Omega|}\sqrt{\|V_-\|_{L^\infty}}$$

for $n \in \mathcal{N}$ which shows that $\Sigma_{k=1}^{\infty}(g(K[V])\psi_k, \psi_k)$ is finite for any orthonormal basis of . Hence, the restriction g $(K[V])$ is a trace class operator. Using the notation (9), (10), and (22) we obtain

(55). □

In the Hilbert space let us introduce the multiplication operator

$$(M(h)f)(x) := h(x)f(x), \quad f \in \mathrm{dom}(M(h)) = \quad ,$$

for functions $h \in L^\infty(\Omega)$. Since $\varrho\ [V]$ is a trace class operator the functional Ξ_ρ given by $h \to \mathrm{tr}(\varrho\ [V]M(h))$ is well-defined on $L^\infty(\Omega)$. Moreover, setting $\nu_\rho(\Delta) := \Xi(\chi_\Delta)$ for Borel subsets Δ of Ω one defines a Borel measure on Ω which is absolutely continuous with respect to the Lebesgue measure, cf. Ref. 18. Its Radon-Nikodym derivative $u_\rho[V] \in L^1(\Omega)$ obeys the relation

$$\mathrm{tr}(\varrho[V]M(h)) = \int_a^b \mathrm{d}x\, u_\rho[V](x)h(x), \quad h \in L^\infty(\Omega). \tag{57}$$

The function $u_\rho[V](\cdot)$ is not negative and is called the carrier density for a given potential $V \in L^\infty$. The operator $\mathcal{N}_\rho(V): L^\infty_{\mathbb{R}}(\Omega) \to L^1_{\mathbb{R}}(\Omega)$ defined by

$$\mathcal{N}_\rho(V) := u_\rho[V], \quad V \in \mathrm{dom}(\mathcal{N}_\rho) := L^\infty_{\mathbb{R}}(\Omega),$$

is called the carrier density operator.

Proposition 4.2: Let the Schrödinger assumptions Q_1, Q_2, and Q_4 be satisfied. If $V \in L^\infty_{\mathbb{R}}(\Omega)$, then

$$\|\mathcal{N}_\rho(V)\|_{L^1} \leqslant \quad (\|V_-\|_{L^\infty})^2 \tag{58}$$

where $(\cdot)$ *is defined by* (22).

Proof: From (57) one gets the estimate

$$\|u_\rho[V]\|_{L^1} \leqslant \|\varrho\ [V]\|_{\mathcal{B}_1(\ )} = \mathrm{tr}(\varrho\ [V]).$$

Using (54) we obtain the estimate

$$\|u_\rho[V]\|_{L^1} \leqslant \mathrm{tr}(g\ \ (K[V])).$$

Finally, taking into account Lemma 4.1 we verify (58). □

B. Lipschitz continuity

Further, it was shown that the carrier density operator is continuous, i.e., if $V_n \overset{L^\infty}{\to} V$, then $\mathcal{N}_\rho(V_n) \overset{L^1}{\to} \mathcal{N}_\rho(V)$. We are going to show that the continuity of the carrier density operator can be improved to bounded Lipschitz continuity, cf. Definition III.1.2 of Ref. 12.

At first let us prove the following lemma.

Lemma 4.3: Let $g(\cdot)$ be non-negative, continuously differentiable even functions obeying (6). *The condition* (8) *is satisfied if and only if*

$$|g(\lambda) - g(\mu)| \leqslant \quad \max\{g(\lambda), g(\mu)\}|\lambda - \mu| \tag{59}$$

holds for $\lambda, \mu \in \mathcal{R}$.

Proof: We assume $\lambda \leqslant \mu$. Obviously, we have

$$g(\mu) - g(\lambda) = \int_\lambda^\mu g'(t)\mathrm{d}t, \quad \lambda, \mu \in \mathbb{R},$$

which yields

$$|g(\mu)-g(\lambda)| \leqslant \int_{\lambda}^{\mu} g(t)\mathrm{d}t$$

where we have used (8). Let $\lambda \in \mathbb{R}_+$. Since $g(\lambda)$, $\lambda \in \mathbb{R}_+$, is decreasing by (6) we find

$$|g(\mu)-g(\lambda)| \leqslant g(\lambda)(\mu-\lambda), \quad 0 \leqslant \lambda \leqslant \mu,$$

which yields (59). If $\lambda \leqslant 0 \leqslant \mu$, then

$$|g(\mu)-g(\lambda)| = |g(\mu)-g(-\lambda)| \leqslant \max\{g(\mu),g(-\lambda)\}|\mu+\lambda| \leqslant \max\{g(\mu),g(\lambda)\}|\mu-\lambda|$$

which also yields (59). The case $\lambda \leqslant \mu \leqslant 0$ follows from the case $0 \leqslant \lambda \leqslant \mu$.

Conversely, if (59) is satisfied, then tending μ to λ we obtain

$$|g'(\lambda)| \leqslant \max\{g(\lambda),g(\lambda)\} = g(\lambda), \quad \lambda \in \mathbb{R},$$

which proves (8). □

Next we consider the operator $G[V] := \sqrt{g(K[V])}\restriction$ acting from into .

Lemma 4.4: Let the Schrödinger assumptions Q_1, Q_2, and Q_4 be satisfied. If $V \in L^{\infty}_{\mathbb{R}}(\Omega)$, then $G[V] \in \boldsymbol{\mathcal{B}}_2(\ ,\ )$ and

$$\|G[V]\|_{\mathcal{B}_2(\ ,\ )} \leqslant (\|V_-\|_{L^\infty}), \tag{60}$$

where $(\cdot)$ is defined by (22). If $V, W \in L^{\infty}_{\mathbb{R}}(\Omega)$, then

$$\|G[V]-G[W]\|_{\mathcal{B}_2(\ ,\ )} \leqslant (\ (\|V_-\|_{L^\infty}) + (\|W_-\|_{L^\infty}))\|V-W\|_{L^\infty}. \tag{61}$$

Proof: By

$$\|G[V]\|^2_{\mathcal{B}_2(\ ,\ )} = \mathrm{tr}(G[V]^* G[V]) = \mathrm{tr}(g\ (K[V]))$$

and Lemma 4.1 one gets (60). Further, from (8) and Lemma 4.3 we obtain that

$$|g(\lambda)-g(\mu)| \leqslant \max\{g(\lambda),g(\mu)\}|\lambda-\mu| \leqslant (g(\lambda)+g(\mu))|\lambda-\mu|, \quad \lambda,\mu \in \mathbb{R},$$

which yields

$$|\sqrt{g(\lambda)}-\sqrt{g(\mu)}|(\sqrt{g(\lambda)}+\sqrt{g(\mu)}) \leqslant (\sqrt{g(\lambda)}+\sqrt{g(\mu)})^2|\lambda-\mu|. \quad \lambda,\mu \in \mathbb{R}.$$

Therefore we get

$$|\sqrt{g(\lambda)}-\sqrt{g(\mu)}| \leqslant (\sqrt{g(\lambda)}+\sqrt{g(\mu)})|\lambda-\mu|, \quad \lambda,\mu \in \mathbb{R}.$$

Hence, if we put

$$h(\lambda,\mu) := \frac{\sqrt{g(\lambda)}-\sqrt{g(\mu)}}{(\lambda-\mu)(\sqrt{g(\lambda)}+\sqrt{g(\mu)})}, \quad \lambda,\mu \in \mathbb{R},$$

then $|h(\lambda,\mu)| \leqslant c$, $\lambda,\mu \in \mathbb{R}$. Since the operators V and W act only on the subspace we get $\sqrt{G[V]}(V-W)+(V-W)\sqrt{G[W]} \in \mathcal{B}_2(\ )$. Applying the technique of double operator spectral integrals[5–7] we find the representation

$$\sqrt{g(K[V])}-\sqrt{g(K[W])} = \int_{\mathbb{R}}\int_{\mathbb{R}} h(\lambda,\mu)\mathrm{d}E_{K[V]}(\lambda)\{G[V](V-W)+(V-W)G[W]^*\}\mathrm{d}E_{K[W]}(\mu),$$

which yields $\sqrt{g(K[V])}-\sqrt{g(K[W])} \in \mathcal{B}_2(\ )$. Moreover, we find the estimate

$$\|\sqrt{g(K[V])}-\sqrt{g(K[W])}\|_{\mathcal{B}_2(\ ,\ )} \leqslant \ \{\|G[V]\|_{\mathcal{B}_2(\ ,\ )}+\|G[W]\|_{\mathcal{B}_2(\ ,\ )}\}\|V-W\|_{\mathcal{B}(\ )}.$$

Since $G[V]:=\sqrt{g(K[V])}\restriction$ and $G[W]:=\sqrt{g(K[W])}\restriction$ we obtain

$$\|G[V]-G[W]\|_{\mathcal{B}_2(\ ,\ )} \leqslant \ \{\|G[V]\|_{\mathcal{B}_2(\ ,\ )}+\|G[W]\|_{\mathcal{B}_2(\ ,\ )}\}\|V-W\|_{\mathcal{B}(\ )}.$$

Using (60) we finally get (61). □

Proposition 4.5: Let the Schrödinger assumptions Q_1, Q_2, and Q_4 be satisfied. If m has a finite total variation and $V,W\in L^\infty_{\mathbb{R}}(\Omega)$, then

$$\|\mathcal{N}_\rho(V)-\mathcal{N}_\rho(W)\|_{L^1} \leqslant \quad (\|V\|_{L^\infty},\|W\|_{L^\infty})\|V-W\|_{L^\infty} \tag{62}$$

where $(\cdot,\cdot)$ *is given by* (23).

Proof: By (57) we get

$$\int_a^b \mathrm{d}x(u_\rho[V](x)-u_\rho[W](x))h(x)=\mathrm{tr}((\varrho\ [V]-\varrho\ [W])M(h))$$

for any $h\in L^\infty(\Omega)$ where $\varrho[V]$ and $\varrho[W]$ are defined in accordance with (53). By (51) we have

$$\varrho[V]=W_-(K[V],K_0)F^*\hat{\rho}FW_-(K[V],K_0)^*$$

and

$$\varrho[W]=W_-(K[W],K_0)F^*\hat{\rho}FW_-(K[W],K_0)^*.$$

The wave operators $W_-(K[V],K_0)$ and $W_-(K[W],K_0)$ exist and are complete; consequently, the wave operator $W_-(K[W],K[V])$ exists and is complete. Moreover, the representation

$$W_-(K[W],K_0)=W_-(K[W],K[V])W_-(K[V],K_0)$$

holds. For brevity we set $W_-[W,V]:=W_-(K[W],K[V])$ as well as $W_-[W]:=W_-(K[W],K_0)$ and $W_-[V]:=W_-(K[V],K_0)$. Let us introduce the matrix valued function

$$\rho_0(\lambda):=g(\lambda)^{-1}\rho(\lambda),\quad \lambda\in\mathbb{R}.$$

By assumption Q_4 one has

$$0\leqslant\rho_0(\lambda)\leqslant I_{\mathbb{C}^2},\quad \lambda\in\mathbb{R}.$$

Using this notation we find the representation

$$\begin{aligned}\varrho\ [V]-\varrho\ [W]&=G[V]^*\varrho_0[V]G[V]-G[W]^*\varrho_0[W]G[W]=(G[V]^*-G[W]^*)\varrho_0[V]G[V]\\&\quad+G[W]^*\varrho_0[V](G[V]-G[W])+G[W](\varrho_0[V]-\varrho_0[W])G[W].\end{aligned}$$

Hence, we get the estimate

$$\begin{aligned}\|\varrho\ [V]-\varrho\ [W]\|_{\mathcal{B}_1(\ ,\ )}&\leqslant\{\|G[V]\|_{\mathcal{B}_2(\ ,\ )}+\|G[W]\|_{\mathcal{B}_2(\ ,\ )}\}\|G[V]-G[W]\|_{\mathcal{B}_2(\ ,\ )}\\&\quad+\|G[W]\|_{\mathcal{B}_2(\ ,\ )}\|G[W]\|_{\mathcal{B}_2(\ ,\ )}\|\varrho_0[V]-\varrho_0[W]\|_{\mathcal{B}(\ )}.\end{aligned}$$

By the representation

$$\begin{aligned}\varrho_0[V]-\varrho_0[W]&=\varrho_0[V]-W_-[W,V]\varrho_0[V]W_-[W,V]^*\\&=(I\ -W_-[W,V])\varrho_0[V]W_-[W,V]^*+\varrho_0[V](I\ -W_-[W,V]^*)\end{aligned}$$

and Lemma 3.12 we obtain the estimate

$$\|\varrho_0[V]-\varrho_0[W]\|_{\mathcal{B}(\ )} \leqslant 4\pi|\Omega|L[V]L[W]\|V-W\|_{L^\infty}.$$

By Lemma 4.4 we get

$$\|\varrho\ [V]-\varrho\ [W]\|_{\mathcal{B}_1(\ ,\ )} \leqslant (\ (\quad(\|V\|_{L^\infty})+\quad(\|W\|_{L^\infty}))^2 + 4\pi|\Omega|L(\|V\|_{L^\infty})L(\|W\|_{L^\infty})\quad(\|V\|_{L^\infty})\quad(\|W\|_{L^\infty}))\|V-W\|_{L^\infty}$$

which proves (62). Taking into account the definition (23) we verify (62). □

V. DISSIPATIVE SCHRÖDINGER-POISSON SYSTEM

A. Rigorous definition

By $W_0^{1,2}(\Omega)$ we denote the subspace of $W^{1,2}(\Omega)$ given by $W_0^{1,2}(\Omega) := \{f \in W^{1,2}(\Omega) : f(a)=f(b)=0\}$. Its dual space with respect to the scalar product $\langle\cdot,\cdot\rangle$ of $L^2(\Omega)$ is denoted by $W_0^{-1,2}(\Omega)$.

At first we will give a rigorous definition of Poisson's equation and afterwards define what we will call a solution of the dissipative Schrödinger Poisson system. We define the Poisson operator $\mathcal{P}: W_{\mathbb{R}}^{1,2}(\Omega) \to W_{0,\mathbb{R}}^{-1,2}(\Omega)$ as usual by

$$\langle \mathcal{P}\upsilon, \varsigma\rangle = \int_a^b \mathrm{d}x\ \epsilon \frac{\mathrm{d}\upsilon}{\mathrm{d}x}\frac{\mathrm{d}\varsigma}{\mathrm{d}x}, \quad \upsilon \in W_{\mathbb{R}}^{1,2}(\Omega), \quad \varsigma \in W_{0,\mathbb{R}}^{1,2}(\Omega).$$

Further, we set $\mathcal{P}_0 := \mathcal{P} \restriction W_{0,\mathbb{R}}^{1,2}(\Omega)$. The operators $\mathcal{P}$ and $\mathcal{P}_0$ are linear and bounded. We have

$$|\langle \mathcal{P}\upsilon, \varsigma\rangle| \leqslant \|\epsilon\|_{L^\infty}\|\upsilon\|_{W^{1,2}}\|\varsigma\|_{W_0^{1,2}}.$$

Hence $\mathcal{P}$ is continuous. Furthermore, one has the estimate

$$\|\varphi\|_{W_0^{1,2}} \leqslant \sqrt{1+|\Omega|}\|\varphi'\|_{L^2}, \quad \varphi \in W_0^{1,2}(\Omega).$$

Thus, we get by (5.1)

$$\|\varphi\|_{W_0^{1,2}}^2 \leqslant \|1/\epsilon\|_{L^\infty}\sqrt{1+|\Omega|}\langle \mathcal{P}_0\varphi, \varphi\rangle, \quad \varphi \in W_0^{1,2}(\Omega).$$

By the Lax-Milgram lemma the inverse operator $\mathcal{P}_0^{-1}$ exists and its norm does not exceed $\|1/\epsilon\|_{L^\infty}\sqrt{1+|\Omega|}$, i.e.,

$$\|\mathcal{P}_0^{-1}\|_{\mathcal{B}(W_0^{-1,2}, W_0^{1,2})} \leqslant \|1/\epsilon\|_{L^\infty}\sqrt{1+|\Omega|}. \tag{63}$$

Definition 5.1: Let $u^\pm \in L^1$. We say that $\varphi \in W_{\mathbb{R}}^{1,2}$ satisfies Poisson's equation with boundary conditions $\varphi(a)=\varphi_a$ and $\varphi(b)=\varphi_b$ if $\zeta := \varphi - \hat{\varphi} \in W_0^{1,2}(\Omega)$ and the equation

$$\mathcal{P}_0\zeta = C + E_1 u^+ - E_1 u^-$$

is fulfilled, where $\hat{\varphi}$ is defined by (11).

Definition 5.2: We say that $\varphi \in W_{\mathbb{R}}^{1,2}(\Omega)$ is a solution of the dissipative Schrödinger-Poisson system if

1. the carrier densities $u^\pm \in L^1(\Omega)$ are given by $u^\pm = \mathcal{N}_{\rho^\pm}^{\pm}(V_0^\pm \pm \hat{\varphi} \pm E_\infty\zeta)$, $\zeta := \varphi - \hat{\varphi}$, and
2. φ satisfies the Poisson equation with boundary conditions $\varphi(a)=\varphi_a$ and $\varphi(b)=\varphi_b$.

B. Existence of solutions and estimates

Let us introduce the non-linear mappings $\mathcal{Q}: L_{\mathbb{R}}^\infty(\Omega) \to W_{0,\mathbb{R}}^{1,2}(\Omega)$,

$$\mathcal{Q}(\psi) := \mathcal{P}_0^{-1}(C + E_1\mathcal{N}_{\rho^+}^+(V_0^+ + \hat{\varphi} + \psi) - E_1\mathcal{N}_{\rho^-}^-(V_0^- - \hat{\varphi} - \psi)), \tag{64}$$

$\psi \in \mathrm{dom}(\mathcal{Q}) = L^\infty_{\mathbb{R}}(\Omega)$, and $\mathcal{Q}_\infty : L^\infty_{\mathbb{R}}(\Omega) \to L^\infty_{\mathbb{R}}(\Omega)$,

$$\mathcal{Q}_\infty(\psi) = E_\infty \mathcal{Q}(\psi),$$

$\psi \in \mathrm{dom}(\mathcal{Q}_\infty) = L^\infty_{\mathbb{R}}(\Omega)$. It was shown in Ref. 2 that the dissipative Schrödinger-Poisson system admits a solution if and only if $\mathcal{Q}_\infty$ admits a fixed point. Moreover, if $\zeta_\infty \in L^\infty_{\mathbb{R}}(\Omega)$ is a fixed point, i.e., $\mathcal{Q}_\infty(\zeta_\infty) = \zeta_\infty$, then $\varphi := \hat{\varphi} + \mathcal{Q}(\zeta_\infty)$ is a solution of the dissipative Schrödinger-Poisson system. If $\zeta_\infty \in L^\infty_{\mathbb{R}}(\Omega)$ is a fixed point, i.e., $\zeta_\infty = \mathcal{Q}_\infty(\zeta_\infty)$, then one has the estimate

$$\begin{aligned}\|\zeta_\infty\|_{L^\infty} = \|\mathcal{Q}_\infty(\zeta_\infty)\|_{L^\infty(\Omega)} \leqslant \varepsilon_1 \|\mathcal{P}_0^{-1}\|_{\mathcal{B}(W_0^{-1,2}, W_0^{1,2})} \times (\|C\|_{W_0^{-1,2}} + \varepsilon_1 \|\mathcal{N}_{\rho^+}^+(V_0^+ + \hat{\varphi} + \zeta_\infty)\|_{L^1} \\ + \varepsilon_1 \|\mathcal{N}_{\rho^-}^-(V_0^- - \hat{\varphi} - \zeta_\infty)\|_{L^1}).\end{aligned}$$

Taking into account (63) we obtain

$$\begin{aligned}\|\zeta_\infty\|_{L^\infty} = \|\mathcal{Q}_\infty(\zeta_\infty)\|_{L^\infty(\Omega)} \leqslant \varepsilon_1 \|1/\epsilon\|_{L^\infty} \sqrt{1 + |\Omega|} \times (\|C\|_{W_0^{-1,2}} + \varepsilon_1 \|\mathcal{N}_{\rho^+}^+(V_0^+ + \hat{\varphi} + \zeta_\infty)\|_{L^1} \\ + \varepsilon_1 \|\mathcal{N}_{\rho^-}^-(V_0^- - \hat{\varphi} - \zeta_\infty)\|_{L^1}).\end{aligned} \tag{65}$$

Applying Proposition 4.2 we find

$$\|\mathcal{N}_{\rho^+}^+(V_0^+ + \hat{\varphi} + \zeta_\infty)\|_{L^1} \leqslant B_0^+ + B_1^+ \sqrt{\|(V_0^+ + \hat{\varphi} + \zeta_\infty)_-\|_{L^\infty}},$$

which yields

$$\|\mathcal{N}_{\rho^+}^+(V_0^+ + \hat{\varphi} + \zeta_\infty)\|_{L^1} \leqslant B_0^+ + B_1^+ \sqrt{\|V_0^+ + \hat{\varphi}\|_{L^\infty}} + B_1^+ \sqrt{\|\zeta_\infty\|_{L^\infty}}.$$

Similarly, we obtain

$$\|\mathcal{N}_{\rho^-}^-(V_0^- - \hat{\varphi} - \zeta_\infty)\|_{L^1} \leqslant B_0^- + B_1^- \sqrt{\|V_0^- - \hat{\varphi}\|_{L^\infty}} + B_1^- \sqrt{\|\zeta_\infty\|_{L^\infty}}.$$

Inserting these estimates into (65) we find

$$\|\zeta_\infty\|_{L^\infty} \leqslant D_0 + D_1 \sqrt{\|\zeta_\infty\|_{L^\infty}}, \tag{66}$$

where D_0 and D_1 are given by (12) and (13). From (66) we obtain the estimate

$$\|\zeta_\infty\|_{L^\infty} \leqslant r_0 \tag{67}$$

for any fixed point of the map $\mathcal{Q}_\infty$ where r_0 is defined by (14). So the following theorem is proven:

Theorem 5.3: *[Ref. 3, Theorem 4.8] If the Schrödinger and Poisson assumptions are satisfied, then the dissipative Schrödinger-Poisson system always admits a solution. Moreover, for any solution* $\varphi \in W^{1,2}_{\mathbb{R}}(\Omega)$ *the estimate* $\|\varphi_\infty - \hat{\varphi}\|_{L^\infty} \leqslant r_0$ *holds.*

We note that the radius r_0 depends only on the Schrödinger and Poisson data. Therefore, if the Schrödinger and Poisson data are fixed, then the radius r_0 is fixed.

However, Theorem 5.3 does not answer the question whether this solution is unique.

C. Uniqueness

Now we are going to give conditions under which the solution of the dissipative Schrödinger-Poisson system is unique.

Theorem 5.4: *Let the Schrödinger and Poisson assumptions be satisfied. If* $m^\pm$ *have finite total variations and the condition* < 1 *is valid, where* *is given by* (25), *then the dissipative Schrödinger-Poisson system admits only one solution.*

Proof: Let ζ_∞ and ζ'_∞ be two fixed points of $\mathcal{Q}_\infty$. From (64) we get the representation

$$\zeta_\infty - \zeta'_\infty = E_\infty \mathcal{P}_0^{-1} E_1 \{(\mathcal{N}^+_{\rho^+}(V^+) - \mathcal{N}^+_{\rho^+}(W^+)) - (\mathcal{N}^-_{\rho^-}(V^-) - \mathcal{N}^-_{\rho^-}(W^-))\}$$

where

$$V^+ := V_0^+ + \hat{\varphi} + \zeta_\infty \text{ and } W^+ := V_0^+ + \hat{\varphi} + \zeta'_\infty$$

and

$$V^- := V_0^- + \hat{\varphi} + \zeta_\infty \text{ and } W^- := V_0^- + \hat{\varphi} + \zeta'_\infty.$$

Hence we find

$$\|\zeta_\infty - \zeta'_\infty\|_{L^\infty} \leqslant \varepsilon_1^2 \|\mathcal{P}_0^{-1}\|_{\mathcal{B}(W_0^{-1,2}, W_0^{1,2})} \times \{\|\mathcal{N}^+_{\rho^+}(V^+) - \mathcal{N}^+_{\rho^+}(W^+)\|_{L^1} + \|\mathcal{N}^-_{\rho^-}(V^-) - \mathcal{N}^-_{\rho^-}(W^-)\|_{L^1}\}.$$

Using (63) we obtain

$$\|\zeta_\infty - \zeta'_\infty\|_{L^\infty} \leqslant \varepsilon_1^2 \|1/\epsilon\|_{L^\infty} \sqrt{1 + |\Omega|} \times \{\|\mathcal{N}^+_{\rho^+}(V^+) - \mathcal{N}^+_{\rho^+}(W^+)\|_{L^1} + \|\mathcal{N}^-_{\rho^-}(V^-) - \mathcal{N}^-_{\rho^-}(W^-)\|_{L^1}\}.$$

Applying Proposition 4.5 we get

$$\|\zeta_\infty - \zeta'_\infty\|_{L^\infty} \leqslant \varepsilon_1^2 \|1/\epsilon\|_{L^\infty} \sqrt{1 + |\Omega|} \times \{ \quad ^+(\|V^+\|_{L^\infty}, \|W^+\|^{L^\infty}) + \quad ^-(\|V^-\|_{L^\infty}, \|W^-\|^{L^\infty})\} \|\zeta_\infty - \zeta'_\infty\|_{L^\infty}.$$

We have

$$\|V^+\|_{L^\infty} \leqslant \|V_0^+ + \hat{\varphi}\|_{L^\infty} + \|\zeta_\infty\|_{L^\infty} \leqslant r_1^+,$$

where we have used the estimate (67) and r_1^+ is defined by (15). Similarly we prove that

$$\|W^+\|_{L^\infty} \leqslant r_1^+$$

and

$$\|V^-\|_{L^\infty} \leqslant r_1^- \text{ and } \|W^-\|_{L^\infty} \leqslant r_1^-,$$

where we have used the definitions (15). Since

$$^\pm(\|V^\pm\|_{L^\infty}, \|W^\pm\|_{L^\infty}) \leqslant \quad ^\pm(r_1^\pm, r_1^\pm)$$

we obtain

$$\|\zeta_\infty - \zeta'_\infty\|_{L^\infty} \leqslant \varepsilon_1^2 \|1/\epsilon\|_{L^\infty} \sqrt{1 + |\Omega|} \quad \|\zeta_\infty - \zeta'_\infty\|_{L^\infty},$$

where given by (24). Hence, if condition (25) is satisfied, then $\|\zeta_\infty - \zeta'_\infty\|_{L^\infty}$ has to be zero which proves the uniqueness. □

D. Uniqueness and shrinking

Our next aim is to show that a dissipative Schrödinger-Poisson system admits always a solution if $|\Omega|$ is small. To this end we introduce the following

Definition 5.5: Let $\Omega' \subseteq \Omega$ and let = ∩ be Schrödinger-Poisson data of the device Ω. We say ′ := ′ ∩ ′ are shrunken Schrödinger-Poisson data of if

$$' := \{m^\pm \restriction \Omega', \kappa_a^\pm, \kappa_b^\pm, V_0^\pm \restriction \Omega', \rho^\pm\} \text{ and } ' := \{C \restriction \Omega', \epsilon \restriction \Omega', \varphi_a, \varphi_b\}.$$

The corresponding dissipative Schrödinger-Poisson system is called a shrunken dissipative Schrödinger-Poisson system.

Definition 5.5 means that we leave unchanged the boundary coefficients $\kappa_a^\pm, \kappa_b^\pm$ of the dissipative Schrödinger operators and the density matrices as well as the boundary values of the

inhomogeneous Poisson equation but we restrict the effective masses $m^{\pm}$, the external potentials $V_0^{\pm}$, the doping profile C, and dielectric permittivity ϵ to the subinterval Ω'.

We note that the quantities (9)–(25) except (19) in fact depend on the interval Ω. We express this fact by adding in notation the term $[\Omega]$, for instance, $B_0^{\pm}[\Omega]$, $B_1^{\pm}[\Omega]$, $\hat{\varphi}[\Omega](x), \ldots,$ $[\Omega]$.

Theorem 5.6: *Let the Schrödinger and Poisson assumptions be satisfied and let $m^{\pm}$ have finite total variations. A shrunken dissipative Schrödinger-Poisson system admits a unique solution if $|\Omega'|$, $\Omega' \subseteq \Omega$, is sufficiently small.*

Proof. By Theorem 4 it is sufficiently to show that $\limsup_{|\Omega'|\to 0} \quad [\Omega']=0$. Since

$$\underline{m}^{\pm} \leqslant m^{\pm}(x) \leqslant \bar{m}^{\pm}, \quad x \in \Omega',$$

we obtain from (9) and (10) that

$$\lim_{|\Omega'|\to 0} B_0^{\pm}[\Omega'] = 2g^{\pm}(0) \text{ and } \lim_{|\Omega'|\to 0} B_1^{\pm}[\Omega'] = 0.$$

Since

$$\|\hat{\varphi}[\Omega']\|_{L^{\infty}(\Omega')} \leqslant \max\{|\varphi_a|, |\varphi_b|\}$$

we find

$$\|V_0^{\pm} \restriction \Omega' + \hat{\varphi}[\Omega']\|_{L^{\infty}(\Omega')} \leqslant \|V_0^{\pm}\|_{L^{\infty}(\Omega)} + \max\{|\varphi_a|, |\varphi_b|\}.$$

Taking into account this estimate and using $\|C \restriction \Omega'\|_{W^{-1,2}} \leqslant \|C\|_{W^{-1,2}}$, $\varepsilon_1[\Omega'] \leqslant \sqrt{|\Omega'|}$ we obtain

$$\lim_{|\Omega'|\to 0} D_0^{\pm}[\Omega'] = 0 \text{ and } \lim_{|\Omega'|\to 0} D_1^{\pm}[\Omega'] = 0$$

which yields

$$\lim_{|\Omega'|\to 0} r_0^{\pm}[\Omega'] = 0$$

and

$$\limsup_{|\Omega'|\to 0} r_1^{\pm}[\Omega'] \leqslant \|V_0^{\pm}\|_{L^{\infty}(\Omega)} + \max\{|\varphi_a|, |\varphi_b|\}. \tag{68}$$

Since $\vee_{a'}^{b'}(1/m^{\pm} \restriction \Omega') \leqslant \vee_a^b 1/m^{\pm}$, $\Omega' = (a', b')$, we get

$$\limsup_{|\Omega'|\to 0} \quad {}^{\pm}[\Omega'] \leqslant \quad {}^{\pm}[\Omega].$$

Further, we have

$$\limsup_{|\Omega'|\to 0} R_j^{\pm}(r_1^{\pm}[\Omega']) \leqslant \quad {}^{\pm}[\Omega]\left(1 + |\kappa_j^{\pm}| \sqrt{\frac{2}{\underline{m}^{\pm}}}\right), \quad j = a, b.$$

Using Lemma 3.1, (20) and (68) one gets

$$\lim_{|\Omega'|\to 0} \{2r_1^{\pm}[\Omega'] + 2\gamma_0[\Omega']\}|\Omega| = 4 \ {}^{\pm}\bar{m}^{\pm}$$

which yields

$$\lim_{|\Omega'|\to 0} \sup R_j^{\pm}(2r_1^{\pm}[\Omega'] + 2\gamma_0[\Omega']) \leqslant \quad {}^{\pm}[\Omega]\left(1 + |\kappa_j^{\pm}|\sqrt{\frac{2}{\underline{m}^{\pm}}}\right) \times \exp\left\{4 \ {}^{\pm}\bar{m}^{\pm}(\quad {}^{\pm}[\Omega])^2\sqrt{\frac{2}{\underline{m}^{\pm}}}\right\}, \quad j = a,b.$$

Using that we obtain

$$\lim_{|\Omega'|\to 0} \sup L^{\pm}(r^{\pm}[\Omega']) \leqslant \quad {}^{\pm}[\Omega]\exp\left\{4 \ {}^{\pm}\bar{m}^{\pm}(\quad {}^{\pm}[\Omega])^2\sqrt{\frac{2}{\underline{m}^{\pm}}}\right\} \times \left\{\frac{1}{(\alpha_a^{\pm})^2}\left(1 + |\kappa_a^{\pm}|\sqrt{\frac{2}{\underline{m}^{\pm}}}\right) + \frac{1}{(\alpha_b^{\pm})^2}\left(1 + |\kappa_b^{\pm}|\sqrt{\frac{2}{\underline{m}^{\pm}}}\right)\right\}.$$

By

$$\lim_{|\Omega'|\to 0} \quad {}^{\pm}(r_1^{\pm}[\Omega']) = \sqrt{2g^{\pm}(0)}.$$

we have

$$\lim_{|\Omega'|\to 0} \quad {}^{\pm}(r^{\pm}[\Omega'], r^{\pm}[\Omega']) = 8 \ {}^{\pm}g^{\pm}(0).$$

Therefore, we finally obtain

$$\lim_{|\Omega'|\to 0} \quad [\Omega'] = 8(\ {}^{+}g^{+}(0) + \ {}^{-}g^{-}(0))$$

where

$$[\Omega'] := \quad {}^{+}(r_1^{+}[\Omega'], r_1^{+}[\Omega']) + \quad {}^{-}(r_1^{-}[\Omega'], r_1^{-}[\Omega']).$$

Since $\lim_{|\Omega'|\to 0}\varepsilon_1[\Omega']=0$ we find $\lim_{|\Omega'|\to 0} \ [\Omega']=0$ where

$$[\Omega'] := \varepsilon_1^2[\Omega']\sqrt{1 + |\Omega'|} \ \ [\Omega'].$$

Applying Theorem 5.4 we see that for sufficiently small domains $\Omega' \subseteq \Omega$ the solution of the dissipative Schrödinger-Poisson system is unique. □

VI. REMARKS

Let us comment on the results.

1. Comparing the existence Theorem 5.3 with Theorem 4.8 of Ref. 2 one observes that Theorem 5.3 proves the existence under weaker assumptions. In particular, the Schrödinger assumption Q_4 is weaker than Assumption 4.2 $A_4^{\pm}$ of Ref. 2. The assumption Q_4 is close to a necessary condition. However, both proofs use the Schauder fixed point theorem.
2. In contrast to Ref. 2 the proof of the crucial estimate (58) of Proposition 4.2, cf. Theorem 3.1 of Ref. 2 is now based on the phase shift and its asymptotic behavior at $-\infty$ and $+\infty$.
3. The asymptotic properties of the phase shift are established by a detailed investigation in Ref. 26.
4. The uniqueness proof is essentially based on the Lipschitz continuity of the carrier density operator, cf. Proposition 4.5 which heavily rests on the Lipschitz continuity of the Lax-Phillips wave operators, cf. Sec. III C. This continuity relies on Kato's theory of smooth operators, cf. Refs. 22 and 23.
5. The results of the paper, in particular the results of Sec. V D, suggest the possibility that the solution of the dissipative hybrid model, cf., Ref. 4, is also unique provided the quantum zone is sufficiently small.

Polyhedral realizations of crystal bases for quantum algebras of finite types

Ayumu Hoshino[a)]
Department of Mathematics, Sophia University, Tokyo 102-8554, Japan

(Received 15 July 2005; accepted 23 September 2005; published online 29 November 2005)

Polyhedral realization of crystal bases is one of the methods for describing the crystal base $B(\infty)$ of a quantized enveloping algebra explicitly. This method can be applied to symmetrizable Kac-Moody types. We can also apply this method to the crystal bases $B(\lambda)$ of integrable highest weight modules and of modified quantum algebras. But, the explicit forms of the polyhedral realizations of crystal bases $B(\infty)$ and $B(\lambda)$ are only given in the case of arbitrary rank 2, of A_n and of $A_n^{(1)}$. So, we will give the polyhedral realizations of crystal bases $B(\infty)$ and $B(\lambda)$ for all simple Lie algebras in this paper. © *2005 American Institute of Physics.*

I. INTRODUCTION

The quantum algebra $U_q(\mathfrak{g}) := \langle e_i, f_i, q^h \rangle_{i \in I} (I = \{1, 2, \ldots, n\})$ which was introduced in the study of solvable lattice models is applied to the several kinds of study of mathematical physics and plays important roles. The nilpotent part $U_q^-(\mathfrak{g}) (= \langle f_i \rangle_{i \in I})$ of $U_q(\mathfrak{g})$ has a crystal base $B(\infty)$ which was constructed by Kashiwara[1] and the irreducible integrable highest weight representaion of $U_q(\mathfrak{g})$ also has crystal base $B(\lambda)$.

The crystal base has been realized by several methods but it is not so easy to obtain the explicit form. Polyhedral realization of crystal bases is one of the methods for realizing crystal bases explicitly, which was introduced by Nakashima and Zelevinsky.[2] We can describe a vector in the crystal base $B(\infty)$ as a lattice point of certain convex polyhedron in an infinite $\mathbb{Z}$-lattice by this method. This method can be applied to symmetrizable Kac-Moody types and applied to the crystal base $B(\lambda)$ of the irreducible integrable highest weight module. In Ref. 2, polyhedral realizations of $B(\infty)$ are given when $\mathfrak{g}$ is arbitrary of rank 2, when $\mathfrak{g}$ is of type A_n and when $\mathfrak{g}$ is of type $A_{n-1}^{(1)}$ and in Ref. 3, Nakashima gave the polyhedral realizations of the crystal base $B(\lambda)$ $(\lambda \in P_+)$ of irreducible integrable highest weight module when $\mathfrak{g}$ is the same cases as the mentioned earlier. He and the author[4] applied this method to the modified quantum algebras and gave the polyhedral realizations of $B(U_q(\mathfrak{g})a_\lambda)$ and also for some specific connected component $B_0(\lambda)$ $(\lambda \in P)$ containing $u_\infty \otimes t_\lambda \otimes u_{-\infty}$ for $\mathfrak{g}$ of type A_n under certain assumptions on the weight λ and for $\mathfrak{g}$ of type $A_1^{(1)}$ on positive level λ and in Ref. 5 the author gave polyhedral realization for $B_0(\lambda)$ for arbitrary rank 2 cases on positive level λ. After Nakashima and Zelevinsky's work, Littelmann[6] described the crystal base $B(\infty)$ by some inequalities (which are called "cones") for all simple Lie algebras and $B(\lambda)$ for classical Lie algebras for a special choice of a reduced word for a longest element of Weyl group. Gleizer and Postnikov[7] described the canonical base for A_n and any reduced word. They also obtained Littlewood-Richardson coefficients $C_{\lambda,\mu}^{\nu}$. Berenstein and Zelevinsky[8] described the canonical bases for any reduced word and $C_{\lambda,\mu}^{\nu}$ for B_n, C_n, and D_n explicitly, which imply that the weight multiplicity formula of $B(\lambda)$ is given. As a result, they described the canonical bases and the crystal base $B(\lambda)$ by similar expression to our results, but it

a)Electronic mail: a-hoshin@mm.sophia.ac.jp

seems to be different from ours. In this paper, we will give the polyhedral realizations of crystal bases $B(\infty)$ and $B(\lambda)$ for all simple Lie algebras. In order to treat the cases, we improve the Theorem in Ref. 3 and obtain the polyhedral realizations.

This paper is organized as follows: in Sec. II, we review the theory of crystal base and methods of polyhedral realizations of $B(\infty)$ and $B(\lambda)$. In Sec. III, we improve the method which is given in Ref. 2 and obtain the explicit forms of the polyhedral realizations of $B(\infty)$ and $B(\lambda)$ for all simple Lie algebras. But, we do not write in this paper about the $B(\lambda)$ for E_7 and E_8 since numerous inequalities appear.

II. PRELIMINARIES

A. Crystal bases and crystals

In this section, we review the theory of crystal bases and crystals. We fix a finite index set I and let $A=(a_{ij})_{i,j\in I}$ be a generalized symmetrizable Cartan matrix, $(\mathfrak{t},\{\alpha_i\}_{i\in I},\{h_i\}_{i\in I})$ the associated Cartan data, and $\mathfrak{g}$ the associated Kac-Moody Lie algebra where α_i (respectively, h_i) is called a simple root (respectively, simple coroot). Let P be a weight lattice with a $\mathbb{Q}$-valued symmetric bilinear form $(\cdot,)$, P^* a dual lattice including $\{h_i\}_{\in I}$, and $Q:=\oplus_{i\in I}\mathbb{Q}(q)\alpha_i$ a root lattice. The quantum algebra $U_q(\mathfrak{g})$ is the associative algebra with 1 over $\mathbb{Q}(q)$ generated by e_i,f_i,q^h $(i\in I,h\in P^*)$ with the usual relations. Let $U_q^-(\mathfrak{g}):=\langle f_i\rangle_{i\in I}$ be the subalgebra of $U_q(\mathfrak{g})$ and $V(\lambda)$ be the irreducible integrable highest weight module. $U_q^-(\mathfrak{g})$ [respectively, $V(\lambda)$] have a crystal base $(L(\infty),B(\infty))$ [respectively, $(L(\lambda),B(\lambda))$] satisfying some properties. Let $\pi_\lambda: U_q^-(\mathfrak{g})\to V(\lambda)\cong U_q^-(\mathfrak{g})/\Sigma_i U_q^-(\mathfrak{g})f_i^{1+\langle h_i,\lambda\rangle}$ be the canonical projection and $\hat{\pi}_\lambda: L(\infty)/qL(\infty)\to L(\lambda)/qL(\lambda)$ be the induced map from π_λ. We note that $\hat{\pi}_\lambda(B(\infty))=B(\lambda)\sqcup\{0\}$.

The notion of crystal is obtained by abstracting the combinatorial properties of crystal bases. A crystal B has maps $wt: B\to P,\varepsilon_i,\varphi_i: B\to\mathbb{Z}\sqcup\{-\infty\}$ and $\tilde{e}_i,\tilde{f}_i: B\sqcup\{0\}\to B\sqcup\{0\}$ with some axioms. In fact, crystal bases $B(\infty)$ and $B(\lambda)$ are also crystals. The tensor product of the crystal bases is again crystal base and so we can consider the tensor product of crystals.

B. Polyhedral realization of $B(\infty)$

In this section, we review the polyhedral realization of the crystal $B(\infty)$ (see Ref. 3).

First, we recall the crystal structure of $\mathbb{Z}^\infty$. We consider the following additive groups:

$$\mathbb{Z}^\infty := \{(\cdots,x_k,\cdots,x_2,x_1)\,|\,x_k\in\mathbb{Z} \text{ and } x_k=0 \text{ for } k\gg 0\}.$$

We will denote by $\mathbb{Z}^\infty_{\geqslant 0}\subset\mathbb{Z}^\infty$ the semigroup of non-negative sequences. Take an infinite sequence of indices $\iota=(\ldots,i_k,\ldots,i_2,i_1)$ from I such that

$$i_k\neq i_{k+1} \text{ for any } k, \quad \text{and} \quad \sharp\{k>0: i_k=i\}=\infty \text{ for any } i\in I. \tag{2.1}$$

The crystal structure on $\mathbb{Z}^\infty$ associated with ι is defined as follows. Let $\vec{x}=(\ldots,x_2,x_1)\in\mathbb{Z}^\infty$. We set for $k\geqslant 1$

$$\sigma_k(\vec{x}) := x_k+\sum_{j>k}\langle h_{i_k},\alpha_{i_j}\rangle x_j. \tag{2.2}$$

Since $x_j=0$ for $j\gg 0$, σ_k is well-defined. Let $\sigma^{(i)}(\vec{x}):=\max_{k:i_k=i}\sigma_k(\vec{x})$ and

$$M^{(i)}=M^{(i)}(\vec{x}) := \{k: i_k=i,\sigma_k(\vec{x})=\sigma^{(i)}(\vec{x})\}. \tag{2.3}$$

Note that $\sigma^{(i)}(\vec{x})\geqslant 0$, and that $M^{(i)}=M^{(i)}(\vec{x})$ is finite set if and only if $\sigma^{(i)}(\vec{x})>0$. Now, we define the map $\tilde{e}_i:\mathbb{Z}^\infty\to\mathbb{Z}^\infty\sqcup\{0\}$, $\tilde{f}_i:\mathbb{Z}^\infty\to\mathbb{Z}^\infty$, by $\tilde{e}_i(0)=\tilde{f}_i(0)=0$ and

$$(\tilde{f}_i(\vec{x}))_k=x_k+\delta_{k,\min M^{(i)}}, \tag{2.4}$$

$$(\tilde{e}_i(\vec{x}))_k = x_k - \delta_{k,\max M^{(i)}} \text{ if } \sigma^{(i)}(\vec{x}) > 0 \quad \text{otherwise } \tilde{e}_i(\vec{x}) = 0, \tag{2.5}$$

where $\delta_{i,j}$ is Kronecker's delta. We also define the weight function and the function ε_i and φ_i on $\mathbb{Z}^\infty$ as follows:

$$wt(\vec{x}) := -\sum_{j=-\infty}^{\infty} x_j \alpha_{i_j}, \quad \varepsilon_i(\vec{x}) := \sigma^{(i)}(\vec{x}), \quad \varphi_i(\vec{x}) := \langle h_i, wt(\vec{x}) \rangle + \varepsilon_i(\vec{x}). \tag{2.6}$$

We denote this crystal by $\mathbb{Z}^\infty_\iota$.

Proposition 2.1 (Ref. 9): There is a unique embedding of crystals according to ι,

$$\Psi_\iota : B(\infty) \hookrightarrow \mathbb{Z}^\infty_{\geqslant 0} \subset \mathbb{Z}^\infty_\iota \ (u_\infty \mapsto (\cdots, 0, 0)). \tag{2.7}$$

This embedding is called *Kashiwara embedding*.

Next, we review the polyhedral realization of $B(\infty)$ for describing the image of *Kashiwara embedding*. We consider the following infinite dimensional vector spaces and their dual spaces:

$$\mathbb{Q}^\infty := \{\vec{x} = (\ldots, x_k, \ldots, x_2, x_1) : x_k \in \mathbb{Q} \text{ and } x_k = 0 \text{ for } k \gg 0\},$$

$$(\mathbb{Q}^\infty)^* := \mathrm{Hom}(\mathbb{Q}^\infty, \mathbb{Q}).$$

We will write a linear form $\varphi \in (\mathbb{Q}^\infty)^*$ as $\varphi(\vec{x}) = \sum_{k \geqslant 1} \varphi_k x_k$ $(\varphi_j \in \mathbb{Q})$. For the sequence $\iota = (i_k)_{k \geqslant 1}$ and $k \geqslant 1$, we set

$$k^{(+)} := \min\{l : l > k \text{ and } i_k = i_l\},$$

$$k^{(-)} := \max\{l : l < k \text{ and } i_k = i_l\} \text{ if it exists} \quad \text{otherwise } k^{(-)} = 0.$$

We define a linear form β_k $(k \geqslant 1)$ on $\mathbb{Q}^\infty$ by

$$\beta_k(\vec{x}) = \sigma_k(\vec{x}) - \sigma_{k^{(+)}}(\vec{x}) = x_k + \sum_{k < j < k^{(+)}} \langle h_{i_k}, \alpha_{i_j} \rangle x_j + x_{k^{(+)}}. \tag{2.8}$$

By using these linear forms, let us define a piecewise-linear operator $S_k = S_{k,\iota}$ on $(\mathbb{Q}^\infty)^*$ as follows:

$$S_k(\varphi) := \begin{cases} \varphi - \varphi_k \beta_k & \text{if } \varphi_k > 0, \\ \varphi - \varphi_k \beta_{k^{(-)}} & \text{if } \varphi_k \leqslant 0, \end{cases} \tag{2.9}$$

for $\varphi(\vec{x}) = \sum \varphi_k x_k \in (\mathbb{Q}^\infty)^*$. Here we set

$$\Xi_\iota := \{S_{j_l} \cdots S_{j_2} S_{j_1}(x_{j_0}) \mid l \geqslant 0, j_0, j_1, \ldots, j_l \geqslant 1\}, \tag{2.10}$$

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}^\infty \subset \mathbb{Q}^\infty \mid \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}. \tag{2.11}$$

We impose on ι the following "positivity assumption" (P):

$$\text{(P) for } \iota, \quad \text{if } k^{(-)} = 0 \text{ then } \varphi_k \geqslant 0 \text{ for any } \varphi(\vec{x}) = \sum_k \varphi_k x_k \in \Xi_\iota. \tag{2.12}$$

Theorem 2.2 (Ref. 2): *Let* ι *be the sequence of indices satisfying (2.1) and the positivity assumption* (*P*). *Let* $\Psi_\iota : B(\infty) \hookrightarrow \mathbb{Z}^\infty_\iota$ *be the Kashiwara embedding. Then, we have* $\mathrm{Im}(\Psi_\iota)(\cong B(\infty)) = \Sigma_\iota$.

We call Σ_ι the polyhedral realization of $B(\infty)$.

C. Polyhedral realization of $B(\lambda)$

In this section, we review the polyhedral realization of the crystal $B(\lambda)$ (see Ref. 3).

Let $R_\lambda := \{r_\lambda\}$ be the crystal for $\lambda \in P_+$ (P_+: set of dominant integral weights) defined in Ref. 3. For the crystal $B(\infty)\otimes R_\lambda$, we define the following map:

$$\Phi_\lambda : (B(\infty)\otimes R_\lambda) \sqcup \{0\} \to B(\lambda) \sqcup \{0\} \tag{2.13}$$

by $\Phi_\lambda(0)=0$ and $\Phi_\lambda(b\otimes r_\lambda)=\hat{\pi}_\lambda(b)$ for $b\in B(\infty)$. We set

$$\widetilde{B}(\lambda) := \{b\otimes r_\lambda \in B(\infty)\otimes R_\lambda : \Phi_\lambda(b\otimes r_\lambda)\neq 0\}.$$

Theorem 2.3 (Ref. 3): *(i) The map* Φ_λ *becomes a surjective strict morphism of crystals* $B(\lambda)\otimes R_\lambda \to B(\lambda)$.

(ii) $\widetilde{B}(\lambda)$ *is a subcrystal of* $B(\lambda)\otimes R_\lambda$, *and* Φ_λ *induces the isomorphism of crystals* $\widetilde{B}(\lambda) \simeq B(\lambda)$.

Let us denote $\mathbb{Z}_\iota \otimes R_\lambda$ by $\mathbb{Z}_\iota[\lambda]$. Here note that we can identify $\mathbb{Z}_\iota[\lambda]$ with $\mathbb{Z}_\iota^\infty$ as a set since the crystal R_λ has only one element but their crystal structures are different. By Theorem 2.3, we have the strict embedding of crystals $\Omega_\lambda : B(\lambda)(\cong \widetilde{B}(\lambda)) \hookrightarrow B(\infty)\otimes R_\lambda$. Combining Ω_λ and Kashiwara embedding Ψ_ι, we obtain the following:

Theorem 2.4 (Ref. 3): *There exists the unique strict embedding of crystals*

$$\Psi_\iota^{(\lambda)} : B(\lambda) \hookrightarrow B(\infty)\otimes R_\lambda \hookrightarrow \mathbb{Z}_\iota^\infty \otimes R_\lambda =: \mathbb{Z}_\iota^\infty[\lambda]$$

such that $\Psi_\iota^{(\lambda)}(u_\lambda)=(\ldots,0,0)\otimes r_\lambda$.

We fix an infinite sequence of indices $\iota=(\ldots,i_k,\ldots,i_2,i_1)$ satisfying (2.1) and $\lambda\in P_+$. We define a linear form $\beta_k^{(\pm)}(k\geqslant 1)$ on $\mathbb{Q}^\infty$ by

$$\beta_k^{(+)}(\vec{x}) = x_k + \sum_{k<j<k^{(+)}} \langle h_{i_k}, \alpha_{i_j}\rangle x_j + x_{k^{(+)}}, \tag{2.14}$$

$$\beta_k^{(-)}(\vec{x}) = \begin{cases} x_{k^{(-)}} + \displaystyle\sum_{k^{(-)}<j<k} \langle h_{i_k}, \alpha_{i_j}\rangle x_j + x_k & \text{if } k^{(-)}>0 \\ -\langle h_{i_k}, \lambda\rangle + \displaystyle\sum_{1<j<k} \langle h_{i_k}, \alpha_{i_j}\rangle x_j + x_k & \text{if } k^{(-)}=0. \end{cases} \tag{2.15}$$

Here note that $\beta_k^{(+)}=\beta_k$ and $\beta_k^{(-)}=\beta_{k^{(-)}}$ if $k^{(-)}>0$. By using these linear forms, let us define a piecewise-linear operator $\hat{S}_k=\hat{S}_{k,\iota}$ on $(\mathbb{Q}^\infty)^*$ as follows:

$$\hat{S}_k(\varphi) := \begin{cases} \varphi - \varphi_k \beta_k^{(+)} & \text{if } \varphi_k > 0 \\ \varphi - \varphi_k \beta_k^{(-)} & \text{if } \varphi_k \leqslant 0, \end{cases} \tag{2.16}$$

for $\varphi(\vec{x})=c+\Sigma\varphi_k x_k$ ($c,\varphi_k\in\mathbb{Q}$) on $\mathbb{Q}^\infty$. For the fixed sequence $\iota=(i_k)$, in case $k^{(-)}=0$ for $k\geqslant 1$, there exists unique $i\in I$ such that $i_k=i$. We denote such k by $\iota^{(i)}$, namely, $\iota^{(i)}$ is the first number k such that $i_k=i$. Here we set for $\lambda\in P_+$ and $i\in I$,

$$\lambda^{(i)}(\vec{x}) := -\beta_{\iota^{(i)}}^{(-)}(\vec{x}) = \langle h_i, \lambda\rangle - \sum_{1<j<\iota^{(i)}} \langle h_i, \alpha_{i_j}\rangle x_j - x_{\iota^{(i)}}. \tag{2.17}$$

For ι and $\lambda\in P_+$, let $\Xi_\iota[\lambda]$ be the set of all linear functions generated by $\hat{S}_k$ from the functions x_j ($j\geqslant 1$) and $\lambda^{(i)}$ ($i\in I$), namely,

$$\Xi_\iota[\lambda] := \{\hat{S}_{j_l}\cdots\hat{S}_{j_2}\hat{S}_{j_1}(x_{j_0}) : l\geqslant 0, j_0, j_1, \ldots, j_l \geqslant 1\}$$
$$\cup \{\hat{S}_{j_k}\cdots\hat{S}_{j_2}\hat{S}_{j_1}(\lambda^{(i)}(x)) : k\geqslant 0, i\in I, j_0, j_1, \ldots, j_k \geqslant 1\}.$$

Now we set

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}_\iota^\infty[\lambda] \subset \mathbb{Q}^\infty : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota[\lambda]\}. \tag{2.18}$$

For ι and $\lambda \in P_+$, a pair (ι,λ) is called *ample* if $\Sigma_\iota[\lambda] \ni \vec{0} = (\cdots,0,0)$.

Theorem 2.5 (Ref. 3): *Suppose that* (ι,λ) *is ample. Let* $\Psi_\iota^\lambda : B(\lambda) \hookrightarrow \mathbb{Z}_\iota^\infty[\lambda]$ *be the embedding as in Theorem 2.4. Then we have* $\mathrm{Im}(\Psi_\iota^{(\lambda)})(\cong B(\lambda)) = \Sigma_\iota[\lambda]$.

We call $\Sigma_\iota[\lambda]$ the polyhedral realization of $B(\lambda)$.

In the rest of this section, we discuss $\hat{S}_k$ and S_k. We define the linear form $\xi^{(i)}$ $(i \in I)$ on $\mathbb{Q}$ by

$$\xi^{(i)}(\vec{x}) := -\sum_{1<j<\iota^{(i)}} \langle h_i, \alpha_{i_j} \rangle x_j - x_{\iota^{(i)}} = -\langle h_i, \lambda \rangle + \lambda^{(i)}(\vec{x}) \tag{2.19}$$

and set of linear forms $\Xi_\iota^{(i)}$ by

$$\Xi_\iota^{(i)} := \{S_{j_l} \cdots S_{j_2} S_{j_1} \xi^{(i)} : l \geqslant 0, j_0, j_1, \ldots, j_l \geqslant 1\}. \tag{2.20}$$

Here we introduce the *strict positivity assumption* for ι as follows:

$$\text{if } k^{(-)} = 0 \text{ then } \varphi_k \geqslant 0 \text{ for any } \varphi(\vec{x}) = \sum_k \varphi_k x_k \in (\Xi_\iota \cup \cup_{j \in I} \Xi_\iota^{(j)}) \setminus \{\xi^{(i)} : i \in I\}, \tag{2.21}$$

where Ξ_ι is defined by (2.10). Then we have the following Lemma:

Lemma 2.6 (Ref. 3): Under the strict positivity assumption for ι, *we have*

$$\hat{S}_{j_l} \cdots \hat{S}_{j_2} \hat{S}_{j_1} x_{j_0} = S_{j_l} \cdots S_{j_2} S_{j_1} x_{j_0}, \tag{2.22}$$

for any $l \geqslant 0$, $j_0, j_1, \ldots, j_l \geqslant 1$, *and*

$$\hat{S}_{j_l} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) = \langle h_i, \lambda \rangle + S_{j_l} \cdots S_{j_2} S_{j_1} \xi^{(i)}(\vec{x}), \tag{2.23}$$

for any $l \geqslant 0$, $j_0, j_1, \ldots, j_l \geqslant 1$ *and* $i \in I$, *if the left-hand side of* (2.23) *is nonzero*.

III. EXPLICIT FORMS OF POLYHEDRAL REALIZATION OF $B(\infty)$ AND $B(\lambda)$

The polyhedral realizations of $B(\infty)$ and $B(\lambda)$ are already known in the case of all rank 2 Kac-Moody types, of A_n and of $A_{n-1}^{(1)}$.[2,3] In this section, we treat other simple types. We obtain the following Theorem by Nakashia and Zelevinsky.

Theorem 3.1: *Let* Ξ_ι' *be a set of the linear forms in* $(\mathbb{Q}^\infty)^*$ *and set*

$$\Sigma_\iota' := \{\vec{x} \in \mathbb{Z}_\iota^\infty | \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota'\}$$

satisfying the following conditions:

(i) Ξ_ι' *is closed under the action of* S_k*'s,*
(ii) ι *satisfies the positivity assumption* (P),
(iii) all entries of $\vec{x} = (\cdots, x_2, x_1) \in \Sigma_\iota'$ *are non-negative.*

Then we have

$$\mathrm{Im}(\Psi_\iota)(\cong B(\infty)) = \Sigma_\iota'.$$

Proof: We recall that the following two facts for certain $\Sigma_\iota(\subset \mathbb{Z}_\iota^\infty)$ (see Nakashia and Zelevinsky's Theorem 3.1):

A) If Σ_ι is closed under the action of $\tilde{f}_i$, then $\mathrm{Im}(\Psi_\iota) \subset \Sigma_\iota$.

B) If Σ_ι is closed under the action of $\tilde{e}_i$ and all the entries of $\vec{x} \in \Sigma_\iota$ are non-negative, then $\Sigma_\iota \subset \mathrm{Im}(\Psi_\iota)$ since every $\vec{x} \in \Sigma_\iota$ can be transformed to $\vec{0}$ by the action of $\tilde{e}_i$'s $(i \in I)$.

We assume condition (i). Condition (i) means that Σ_ι' is closed under the action of $\tilde{e}_i$'s. Using (ii), we obtain that Σ_ι' is closed under the action of $\tilde{f}_i$'s and this shows $\mathrm{Im}(\Psi_\iota) \subset \Sigma_\iota'$. Using (iii), we

obtain that $\Sigma'_\iota \subset \mathrm{Im}(\Psi_\iota)$. □

Remark 3.2: Theorem 3.1 implies that we need not consider a set of linear functions Ξ_ι which is closed under the action of the S_k's to x_j for any $j>0$. We only need to find a set of linear functions Ξ_ι which is closed under the action of the S_k's to x_j for some $j>0$ and which satisfies the two conditions (*ii*), (*iii*).

It will be convenient for us to change the indexing set for $\mathbb{Z}^\infty$ from $\mathbb{Z}_{\geqslant 1}$ to $\mathbb{Z}_{\geqslant 1}\times[1,n]$. We will do this with the help of the bijection $\mathbb{Z}_{\geqslant 1}\times[1,n]\to\mathbb{Z}_{\geqslant 1}$ given by $((j;i)\mapsto(j-1)n+i)$. Thus, we will write an element $\vec{x}\in Z^\infty$ as doubly indexed family $(x_{j;i})_{j\geqslant 1, i\in[1,n]}$ of non-negative integers. Therefore, we can write that $\vec{x}\in\mathbb{Z}^\infty$ as $(\ldots,x_{1;2},x_{1;1})$. We will adopt the convention that $x_{j;i}=0$ unless $i\in[1,n]$. Hereafter, we fix the infinite sequence ι as follows:

$$\iota := (\cdots,\underbrace{n,n-1,\cdots,2,1},\cdots,\underbrace{n,n-1,\cdots,2,1},\underbrace{n,n-1,\cdots,2,1}),$$

where n is the size of Cartan matrix. We use the same Cartan data as the one in Ref. 10 except for the cases F_4 and E_7.

A. B_n case

We consider the case of type B_n and give the explicit forms of Σ_ι and $\Sigma_\iota[\lambda]$. First, we give the polyhedral realization Σ_ι. We define for any $j\geqslant 1, 0\leqslant k\leqslant 2n-1$,

$$\varphi_{j;k} := \begin{cases} id & (k=0) \\ S_{j;k}S_{j;k-1}\cdots S_{j;2}S_{j;1} & (1\leqslant k\leqslant n-1) \\ S_{j+k-n;2n-k}S_{j+k-1-n;2n-k+1}\cdots S_{j+1;n-1}S_{j;n}\varphi_{j;n-1} & (n\leqslant k\leqslant 2n-1). \end{cases} \tag{3.1}$$

Lemma 3.3:

$$\varphi_{j;k}(x_{j;1}) = \begin{cases} x_{j;k+1}-x_{j+1;k} & (0\leqslant k\leqslant n-1) \\ x_{j+k-n+1;2n-k-1}-x_{j+k-n+1;2n-k} & (n\leqslant k\leqslant 2n-1). \end{cases} \tag{3.2}$$

Proof: By the induction on k. The case of $k=0$ is trivial.

Case I) $1\leqslant k\leqslant n-1$.

If $k=1$, we have

$$S_{j;1}(x_{j;1}) = x_{j;1}-(x_{j;1}-x_{j;2}+x_{j+1;1}) = x_{j;2}-x_{j+1;1} = \varphi_{j;1}(x_{j;1}).$$

If $1<k\leqslant n-1$, we assume that $\varphi_{j;k-1}(x_{j;1})=x_{j;k}-x_{j+1;k-1}$. Then we have

$$\begin{aligned} S_{j;k}\varphi_{j;k-1}(x_{j;1}) = S_{j;k}(x_{j;k}-x_{j+1;k-1}) &= x_{j;k}-x_{j+1;k-1}-(x_{j;k}-x_{j;k+1}-x_{j+1;k-1}+x_{j+1;k}) \\ &= x_{j;k+1}-x_{j+1;k} = \varphi_{j;k}(x_{j;1}). \end{aligned}$$

Case II) $n\leqslant k\leqslant 2n-1$.

If $k=n$, using the result of Case I), we have

$$\begin{aligned} S_{j;n}\varphi_{j;n-1}(x_{j;1}) = S_{j;n}(x_{j;n}-x_{j+1;n-1}) &= x_{j;n}-x_{j+1;n-1}-(x_{j;n}-2x_{j+1;n-1}+x_{j+1;n}) \\ &= x_{j+1;n-1}-x_{j+1;n} = \varphi_{j;n}(x_{j;1}). \end{aligned}$$

If $n<k\leqslant 2n-1$, we assume that $\varphi_{j;k-1}(x_{j;1})=x_{j+k-n;2n-k}-x_{j+k-n;2n-k+1}$. Then we have

$$\begin{aligned} S_{j+k-n;2n-k}\varphi_{j;k-1}(x_{j;1}) &= S_{j+k-n;2n-k}(x_{j+k-n;2n-k}-x_{j+k-n;2n-k+1}) \\ &= x_{j+k-n;2n-k}-x_{j+k-n;2n-k+1}-(x_{j+k-n;2n-k}-x_{j+k-n;2n-k+1}-x_{j+k-n+1;2n-k-1} \\ &\quad +x_{j+k-n+1;2n-k}) \\ &= x_{j+k-n+1;2n-k-1}-x_{j+k-n+1;2n-k} = \varphi_{j;k}(x_{j;1}). \end{aligned}$$

□

Lemma 3.4: The set $\{\varphi_{j;k}(x_{j;1}): 1 \leqslant j, 0 \leqslant k \leqslant 2n-1\}$ *is closed under the actions of all transformations* $S_{m;l}$ *for any* $m \geqslant 1, l \geqslant 1$.

Proof: Using the definition of $\varphi_{j;k}$ (3.1) and the formula (3.2) in Lemma 3.3, if $k=0$, $\varphi_{j;0} = id$ and we have

$$S_{m;l}(\varphi_{j;0}(x_{j;1})) = \begin{cases} \varphi_{j;1}(x_{j;1}) & \text{if } (m;l) = (j;1) \\ x_{j;1} & \text{otherwise.} \end{cases}$$

If $1 \leqslant k \leqslant n-1$, we have

$$S_{m;l}(\varphi_{j;k}(x_{j;1})) = \begin{cases} \varphi_{j;k-1}(x_{j;1}) & \text{if } (m;l) = (j;k) \\ \varphi_{j;k+1}(x_{j;1}) & \text{if } (m;l) = (j;k+1) \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise.} \end{cases}$$

If $n \leqslant k \leqslant 2n-1$, we have

$$S_{m;l}(\varphi_{j;k}(x_{j;1})) = \begin{cases} \varphi_{j;k-1}(x_{j;1}) & \text{if } (m;l) = (j+k-n;2n-k), \\ \varphi_{j;k+1}(x_{j;1}) & \text{if } (m;l) = (j+k-n+1;2n-k-1), \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise.} \end{cases}$$

□

Now, we define

$$\Xi_\iota := \{\varphi_{j;k}(x_{j;1}): j \geqslant 1, 0 \leqslant k \leqslant 2n-1\},$$

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}_\iota^\infty : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}.$$

Theorem 3.5: *The polyhedral realization* Σ_ι *of* $B(\infty)$ *for type* B_n *is described as follows:*

$$x_{j;i} = 0 \text{ for } j,i \notin [1,n], \tag{3.3}$$

$$x_{1;i} \geqslant x_{2;i-1} \geqslant \cdots \geqslant x_{i;1} \geqslant 0 \text{ for } 1 \leqslant i \leqslant n-1, \tag{3.4}$$

$$x_{j;n} \geqslant x_{j+1;n-1} \geqslant \cdots \geqslant x_{n;j} \geqslant 0 \text{ for } 1 \leqslant j \leqslant n, \tag{3.5}$$

$$x_{j;n-j+1} \geqslant x_{j;n-j+2} \geqslant \cdots \geqslant x_{j;n} \geqslant 0 \text{ for } 2 \leqslant j \leqslant n. \tag{3.6}$$

Proof: First, we show that Σ_ι is the polyhedral realization of $B(\infty)$, so we shall check the conditions of Theorem 3.1. Ξ_ι is closed under the action of S_k by Lemma 3.4. The coefficients of $x_{1;i}$ $(i=1,2,\ldots,n)$ are positive for $\varphi \in \Xi_\iota$ by Lemma 3.3, and this shows that ι satisfies the "positivity assumption."

We will show that all entries of $\vec{x} \in \Sigma_\iota$ are non-negative. In the case of $m \geqslant 1$, $0 \leqslant l \leqslant n-1$ for $\varphi_{m;l}(x_{m;1})$, we have

$$x_{m;l+1} \geqslant x_{m+1;l} \tag{3.7}$$

and we consider the cases that $(m;l) = (j;i-1), (j+1;i-2), \ldots, (j+i-2;1), (j+i-1;0)$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n$. We obtain

$$x_{j;i} \geqslant x_{j+1;i-1} \geqslant \cdots \geqslant x_{j+i-2;2} \geqslant x_{j+i-1;1} \geqslant 0.$$

This shows that $x_{j;i} \geqslant 0$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n$. Therefore, Σ_ι is the polyhedral realization of $B(\infty)$.

Next we show that Σ_ι has the form of Theorem 3.5. We determine when $x_{j;i} \equiv 0$ for $j \geqslant 1$, $1 \leqslant i \leqslant n$. In the case of $m \geqslant 1$, $n \leqslant l \leqslant 2n-1$ for $\varphi_{m;l}(x_{m;1})$ we have

$$x_{m+l-n+1;2n-l-1} \geqslant x_{m+l-n+1;2n-l} \tag{3.8}$$

and consider the cases that $(m;l)=(j;2n-1),(j+1;2n-2),\ldots,(j+n-1;n)$. Then we have

$$0 \geqslant x_{j+n;1} \geqslant x_{j+n;2} \geqslant \cdots \geqslant x_{j+n;n-1} \geqslant x_{j+n;n} \geqslant 0$$

and $x_{j+n;i} \equiv 0$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n$. We shall show (3.4). In (3.7), by setting $(m;l)=(1;i-1),(2;i-2),\ldots,(i;0)$ for any $1 \leqslant i \leqslant n-1$ then we obtain (3.4). Similarly, in (3.7) if $(m;l)=(j;n-1),(j+1;n-2),\ldots,(n;j-1)$ for any $1 \leqslant j \leqslant n$, then we have (3.5). Let us see (3.6). In (3.8), we consider the cases that $(m;l)=(1;n+j-2),(2;n+j-3),\ldots,(j-1;n)$ for any $2 \leqslant j \leqslant n$. Then we have (3.6). □

Next, we give the polyhedral realization $\Sigma_\iota[\lambda]$ for $\lambda := \sum_{k=1}^n \lambda_k \Lambda_k$, where $\lambda_k \in \mathbb{Z}_{\geqslant 0}$, Λ_k are the fundamental weights. Here we set

$$\Xi_\iota^{(1,n-1)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(i)}(\vec{x}) : k \geqslant 0, 1 \leqslant i \leqslant n-1, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(n)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(n)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(1,n-1)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) : k \geqslant 0, 1 \leqslant i \leqslant n-1, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(n)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(n)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota[\lambda] := \Xi_\iota \cup \Xi_\iota^{(1,n-1)}[\lambda] \cup \Xi_\iota^{(n)}[\lambda] = \{\varphi_{j;k}(x_{j;1}) : j \geqslant 1, 0 \leqslant k \leqslant 2n-1\} \cup \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) : k \geqslant 0, 1 \leqslant i \leqslant n-1, j_1, \ldots, j_k \geqslant 1\} \cup \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(n)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Sigma_\iota[\lambda] := \{\vec{x} \in \mathbb{Z}_\iota[\lambda] : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota[\lambda]\}.$$

In order to show that $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$, we give the explicit forms of $\Xi_\iota^{(1,n-1)}[\lambda]$ and $\Xi_\iota^{(n)}[\lambda]$. Since the Dynkin diagrams for A_n and B_n are the same for $1 \geqslant i \geqslant n-1$, we give the explicit form of $\Xi_\iota^{(1,n-1)}$ by the result in Ref. 2 as follows:

$$\Xi_\iota^{(1,n-1)} = \{x_{j;i-j} - x_{j;i-j+1} : 1 \leqslant i \leqslant n-1, 1 \leqslant j \leqslant i\}. \tag{3.9}$$

For giving the explicit form of $\Xi_\iota^{(n)}$, we say that an integer sequence $\mu_1, \mu_2, \ldots, \mu_n$ is an admissible pattern if:

$$\begin{cases} 1 \leqslant \mu_1 \leqslant n, \\ 0 \leqslant \mu_2 \leqslant \mu_1 - 1, \\ \qquad \cdots, \\ 0 \leqslant \mu_k \leqslant \mu_{k-1} - 1, \\ \qquad \cdots, \end{cases} \tag{3.10}$$

where if μ_k does not exist, we define $\mu_k = 0$, and

$$S^{(\mu_1)} := \begin{cases} id & (\mu_1 = 1) \\ S_{\mu_1;n-\mu_1} \cdots S_{2;n-2} S_{1;n-1} & (\mu_1 \geqslant 2), \end{cases}$$

$$S^{(\mu_k)} := \begin{cases} id & (\mu_k = 0) \\ S_{\mu_k+k-2;n-\mu_k+1} \cdots S_{k;n-1} S_{k-1;n} & (\mu_k \geqslant 1) \end{cases} \quad \text{for } k \geqslant 2,$$

$$\varphi^{(\mu)} := S^{(\mu_k)} \cdots S^{(\mu_2)} S^{(\mu_1)} \text{ for } \mu = (\mu_1, \mu_2, \ldots, \mu_k, 0, 0, \ldots).$$

We prepare the symbol X as follows:

$$X := 2x_{1;n-1} - x_{1;n} (= \xi^{(n)}(\vec{x})). \tag{3.11}$$

For convenience, we define

$$X_{j;i} := \begin{cases} 2x_{j;i} & \text{if } i \neq n \\ x_{j;n} & \text{if } i = n. \end{cases} \tag{3.12}$$

Theorem 3.6: *Let* $\mu = (\mu_1, \mu_2, \ldots, \mu_k, 0, 0, \ldots)$ *be an admissible pattern.*
(*i*) *The forms* $\varphi^{(\mu)}X$ *are given by*

$$\varphi^{(\mu)}X = \sum_{k=1}^{l} (X_{\mu_k+k-1;n-\mu_k} - X_{\mu_k+k-1;n-\mu_k+1}), \tag{3.13}$$

where

$$L := \max\{k : \mu_k \neq 0\},$$

$$l := \begin{cases} L & \text{if } \mu_L = 1, \\ L+1 & \text{if } \mu_L \geqslant 2. \end{cases}$$

(*ii*) $\Xi_{\iota}^{(n)}$ *is the set of all linear forms which are of the form* $\varphi^{(\mu)}X$, *where* μ *are the admissible patterns.*

Proof: (i) First, we give a remark. When $\mu_k - \mu_{k+1} = 1$, the terms $X_{\mu_k+k-1;n-\mu_k+1}$ and $X_{\mu_{k+1}+k;n-\mu_{k+1}}$ in the sum (3.13) are canceled as $-X_{\mu_k+k-1;n-\mu_k+1} + X_{\mu_{k+1}+k;n-\mu_{k+1}} = 0$. We show the theorem by induction on $|\mu| = \mu_1 + \mu_2 + \cdots + \mu_i$ for $\mu = (\mu_1, \mu_2, \ldots, \mu_i, 0, 0, \ldots)$.

If $|\mu| = 1$, then $l = 1$ and the sum of the right-hand side of (3.13) is $X_{1;n-1} - X_{1;n} = 2x_{1;n-1} - x_{1;n}$ and equal to $\varphi^{(\mu)}X$ by (3.11). We assume that $|\mu| = \mu_1 + \mu_2 + \cdots + \mu_i = k-1$ for $\mu = (\mu_1, \mu_2, \ldots, \mu_i, 0, 0, \ldots)$. We consider the two cases: I) $\mu_i \to \mu_i + 1$, II) "$\mu_{i+1} = 0$" $\to$ "$\mu_{i+1} = 1$".

I) $\mu_i \to \mu_i + 1$.

In this case, $l = i+1$ and we note that $1 \leqslant \mu_i \leqslant \mu_{i-1} - 2$ since μ is an admissible pattern and the term $X_{\mu_i+i-1;n-\mu_i}$ in the sum (3.13) is not canceled. We set $\mu' := (\mu_1, \mu_2, \ldots, \mu_i + 1, 0, 0, \ldots)$. We have

$$\varphi^{(\mu')}X = S_{\mu_i+i-1;n-\mu_i} \varphi^{(\mu)}X.$$

The right-hand side of (3.13) is

$$S_{\mu_i+i-1;n-\mu_i} \left(\sum_{k=1}^{l} (X_{\mu_k+k-1;n-\mu_k} - X_{\mu_k+k-1;n-\mu_k+1}) \right) = \sum_{k=1}^{l} (X_{\mu_k+k-1;n-\mu_k} - X_{\mu_k+k-1;n-\mu_k+1}) - (X_{\mu_i+i-1;n-\mu_i}$$
$$- X_{\mu_i+i-1;n-\mu_i+1} - X_{\mu_i+i;n-\mu_i-1} + X_{\mu_i+i;n-\mu_i}) = \varphi^{(\mu')}X.$$

II) "$\mu_{i+1} = 0$" $\to$ "$\mu_{i+1} = 1$".

We set $\mu' := (\mu_1, \mu_2, \ldots, \mu_i, 1, 0, \ldots)$ (i.e., $\mu_{i+1} = 1$) and then $l = i+1$. By the admissible pattern of μ, we have $0 \leqslant \mu_{i+1} \leqslant \mu_i - 1$. This shows that $\mu_i \geqslant 2$ and the term $X_{i;n}$ in the sum (3.13) is not canceled. We have

$$\varphi^{(\mu')}X = S_{i;n} \varphi^{(\mu)}X.$$

The right-hand side of (3.13) is

$$S_{i;n}\left(\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k}-X_{\mu_k+k-1;n-\mu_k+1})\right)=\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k}-X_{\mu_k+k-1;n-\mu_k+1})-(X_{i;n}-X_{i+1;n-1}+X_{i+1;n})=\varphi^{(\mu')}X.$$

(ii) It is sufficient to show that $\{\varphi^{(\mu)}X \mid \mu:\text{admissible pattern}\}$ is closed under the actions of all $S_{j;i}$. We set for $1\leqslant k\leqslant l+1$,

$$\mu=(\mu_1,\mu_2,\dots,\mu_l,0,0,\dots),\quad \mu^+=(\mu_1,\mu_2,\dots,\mu_k+1,\dots,\mu_l,0,0,\dots),$$

$$\mu^-=(\mu_1,\mu_2,\dots,\mu_k-1,\dots,\mu_l,0,0,\dots).$$

Then we have

$$S_{j;i}\varphi^{(\mu)}X=\begin{cases}\varphi^{(\mu^+)}X & \text{if } (j;i)=(\mu_k+k-1;n-\mu_k) \text{ and } \mu_{k-1}-\mu_k\neq 1\\ \varphi^{(\mu^-)}X & \text{if } (j;i)=(\mu_k+k-1;n-\mu_k+1) \text{ and } \mu_k-\mu_{k+1}\neq 1\\ \varphi^{(\mu)}X & \text{otherwise.}\end{cases}$$

□

Therefore, ι satisfies the strict positivity assumption by the explicit forms of $\Xi_\iota^{(1,n-1)}$ and $\Xi_\iota^{(n)}$. By Lemma 2.6, this shows that

$$\Xi_\iota^{(1,n-1)}[\lambda]=\{\lambda_i+x_{j;i-j}-x_{j;i-j+1}:1\leqslant i\leqslant n-1,1\leqslant j\leqslant i\},$$

$$\Xi_\iota^{(n)}[\lambda]=\left\{\lambda_n+\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k}-X_{\mu_k+k-1;n-\mu_k+1}):\mu \text{ are the admissible patterns}\right\}$$

by (3.9), (3.13) and $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$.

B. C_n case

We consider the case of type C_n. First, we give the polyhedral realization Σ_ι of $B(\infty)$. We define for $j\geqslant 1$, $0\leqslant k\leqslant 2n-1$

$$\varphi_{j;k}:=\begin{cases}id & (k=0)\\ S_{j;k}S_{j;k-1}\cdots S_{j;2}S_{j;1} & (1\leqslant k\leqslant n-1)\\ S_{j+k-n;2n-k}S_{j+k-1-n;2n-k+1}\cdots S_{j+1;n-1}S_{j;n}\varphi_{j;n-1} & (n\leqslant k\leqslant 2n-1).\end{cases}$$

Lemma 3.7:

$$\varphi_{j;k}(x_{j;1})=\begin{cases}x_{j;k+1}-x_{j+1;k} & (0\leqslant k\leqslant n-2)\\ 2x_{j;n}-x_{j+1;n-1} & (k=n-1)\\ x_{j+1;n-1}-2x_{j+1;n} & (k=n)\\ x_{j+k-n+1;2n-k-1}-x_{j+k-n+1;2n-k} & (n+1\leqslant k\leqslant 2n-1).\end{cases}$$

Proof: By the induction on k. The case of $k=0$ is trivial.
Case I) $1\leqslant k\leqslant n-2$.
If $k=1$, we have

$$S_{j;1}(x_{j;1})=x_{j;1}-(x_{j;1}-x_{j;2}+x_{j+1;1})=x_{j;2}-x_{j+1;1}=\varphi_{j;1}(x_{j;1}).$$

If $1<k\leqslant n-2$, we assume that $\varphi_{j;k-1}(x_{j;1})=x_{j;k}-x_{j+1;k-1}$. Then we have

$$S_{j;k}\varphi_{j;k-1}(x_{j;1}) = S_{j;k}(x_{j;k} - x_{j+1;k-1}) = x_{j;k} - x_{j+1;k-1} - (x_{j;k} - x_{j;k+1} - x_{j+1;k-1} + x_{j+1;k})$$
$$= x_{j;k+1} - x_{j+1;k} = \varphi_{j;k}(x_{j;1}).$$

Case II) $k=n-1,n$.

If $k=n-1$, using the result of Case I), we have

$$S_{j;n-1}\varphi_{j;n-2}(x_{j;1}) = S_{j;n-1}(x_{j;n-1} - x_{j+1;n-2})$$
$$= x_{j;n-1} - x_{j+1;n-2} - (x_{j;n-1} - 2x_{j;n} - x_{j+1;n-2} + x_{j+1;n-1})$$
$$= 2x_{j;n} - x_{j+1;n-1} = \varphi_{j;n-1}(x_{j;1}),$$

and then if $k=n$,

$$S_{j;n}\varphi_{j;n-1}(x_{j;1}) = S_{j;n}(2x_{j;n} - x_{j+1;n-1}) = 2x_{j;n} - x_{j+1;n-1} - 2(x_{j;n} - x_{j+1;n-1} + x_{j+1;n})$$
$$= x_{j+1;n-1} - 2x_{j+1;n} = \varphi_{j;n}(x_{j;1}).$$

Case III) $n+1 \leqslant k \leqslant 2n-1$.

If $k=n+1$, using the result of the case of $k=n$, we have[11,12]

$$S_{j+1;n-1}\varphi_{j;n}(x_{j;1}) = S_{j+1;n-1}(x_{j+1;n-1} - 2x_{j+1;n})$$
$$= x_{j+1;n-1} - 2x_{j+1;n} - (x_{j+1;n-1} - 2x_{j+1;n} - x_{j+2;n-2} + x_{j+2;n-1})$$
$$= x_{j+2;n-2} - x_{j+2;n-1} = \varphi_{j;n+1}(x_{j;1}).$$

If $n+1 < k \leqslant 2n-1$, we assume that $\varphi_{j;k-1}(x_{j;1}) = x_{j+k-n;2n-k} - x_{j+k-n;2n-k+1}$. Then we have

$$S_{j+k-n;2n-k}\varphi_{j;k-1}(x_{j;1}) = S_{j+k-n;2n-k}(x_{j+k-n;2n-k} - x_{j+k-n;2n-k+1})$$
$$= x_{j+k-n;2n-k} - x_{j+k-n;2n-k+1} - (x_{j+k-n;2n-k} - x_{j+k-n;2n-k+1} - x_{j+k-n+1;2n-k-1}$$
$$+ x_{j+k-n+1;2n-k})$$
$$= x_{j+k-n+1;2n-k-1} - x_{j+k-n+1;2n-k} = \varphi_{j;k}(x_{j;1}).$$

□

Lemma 3.8. *The set* $\{\varphi_{j;k}(x_{j;1}) : 1 \leqslant j, 0 \leqslant k \leqslant 2n-1\}$ *is closed under the actions of all transformations* $S_{m;l}$ *for any* $m \geqslant 1$, $l \geqslant 1$.

Proof. Using the definition of $\varphi_{j;k}$ (3.14) and the formula (3.14) in Lemma 3.7, if $k=0$, $\varphi_{j;0} = id$ and we have

$$S_{m;l}(\varphi_{j;0}(x_{j;1})) = \begin{cases} \varphi_{j;1}(x_{j;1}) & \text{if } (m;l) = (j;1) \\ x_{j;1} & \text{otherwise.} \end{cases}$$

If $1 \leqslant k \leqslant n-1$, we have

$$S_{m;l}(\varphi_{j;k}(x_{j;1})) = \begin{cases} \varphi_{j;k-1}(x_{j;1}) & \text{if } (m;l) = (j;k) \\ \varphi_{j;k+1}(x_{j;1}) & \text{if } (m;l) = (j;k+1) \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise.} \end{cases}$$

If $n \leqslant k \leqslant 2n-1$, we have

$$S_{m;l}(\varphi_{j;k}(x_{j;1})) = \begin{cases} \varphi_{j;k-1}(x_{j;1}) & \text{if } (m;l) = (j+k-n;2n-k) \\ \varphi_{j;k+1}(x_{j;1}) & \text{if } (m;l) = (j+k-n+1;2n-k-1) \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise.} \end{cases}$$

□

Now, we define

$$\Xi_\iota := \{\varphi_{j;k}(x_{j;1}) : j \geqslant 1, 0 \leqslant k \leqslant 2n-1\},$$

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}_\iota^\infty \mid \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}.$$

Theorem 3.9: *The polyhedral realization Σ_ι of $B(\infty)$ for type C_n is described as follows:*

$$x_{j;i} = 0 \text{ for } j,i \notin [1,n], \tag{3.14}$$

$$x_{1;i} \geqslant x_{2;i-1} \geqslant \cdots \geqslant x_{i;1} \geqslant 0 \text{ for } 1 \leqslant i \leqslant n-1, \tag{3.15}$$

$$2x_{j;n} \geqslant x_{j+1;n-1} \geqslant \cdots \geqslant x_{n;j} \geqslant 0 \text{ for } 1 \leqslant j \leqslant n-1, \tag{3.16}$$

$$x_{j;n-j+1} \geqslant x_{j;n-j+2} \geqslant \cdots \geqslant x_{j;n-1} \geqslant 2x_{j;n} \geqslant 0 \text{ for } 2 \leqslant j \leqslant n. \tag{3.17}$$

Proof: We shall show that Σ_ι is the polyhedral realization of $B(\infty)$ and check the conditions of Theorem 3.1. Ξ_ι is closed under the action of S_k by Lemma 3.8. The coefficients of $x_{1;i}$ $(i=1,2,\ldots,n)$ are positive for $\varphi \in \Xi_\iota$ by Lemma 3.7. This shows that ι satisfies the positivity assumption.

We shall show that all entries of $\vec{x} \in \Sigma_\iota$ are non-negative. In the case of $m \geqslant 1$, $0 \leqslant l \leqslant n-2$ for $\varphi_{m;l}(x_{m;1})$, we have

$$x_{m;l+1} \geqslant x_{m+1;l} \tag{3.18}$$

and we consider the cases that $(m;l)=(j;i-1),(j+1;i-2),\ldots,(j+i-2;1),(j+i-1;0)$. We obtain

$$x_{j;i} \geqslant x_{j+1;i-1} \geqslant \cdots \geqslant x_{j+i-2;2} \geqslant x_{j+i-1;1} \geqslant 0. \tag{3.19}$$

This shows that $x_{j;i} \geqslant 0$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n-1$. Similarly, for any $j \geqslant 1$ and $l=n-1$, we have

$$2x_{j;n} \geqslant x_{j+1;n-1} (\geqslant 0). \tag{3.20}$$

This shows $x_{j;n} \geqslant 0$ for any $j \geqslant 1$. Therefore, Σ_ι is the polyhedral realization of $B(\infty)$.

We show that Σ_ι has the form of Theorem 3.9. In the case of $(m;l)=(j+n-1;n)$ for $\varphi_{m;l}(x_{m;1})$, we obtain

$$x_{j+n;n-1} \geqslant 2x_{j+n;n} \tag{3.21}$$

and in the case of $m \geqslant 1$, $n+1 \leqslant l \leqslant 2n-1$, we have

$$x_{m+l-n+1;2n-l-1} \geqslant x_{m+l-n+1;2n-l}. \tag{3.22}$$

We consider the cases that $(m;l)=(j;2n-1),(j+1;2n-2),\ldots,(j+n-2;n+1)$, then we have

$$0 \geqslant x_{j+n;1} \geqslant x_{j+n;2} \geqslant \cdots \geqslant x_{j+n;n-2} \geqslant x_{j+n;n-1} \geqslant 2x_{j+n;n} \geqslant 0.$$

This shows that $x_{j+n;i} \equiv 0$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n$. We shall show (3.15). In (3.18), by setting $(m;l)=(1;i-1),(2;i-2),\ldots,(i;0)$ for any $1 \leqslant i \leqslant n-1$ then we have (3.15). Let us see (3.16). In (3.18), we consider the cases that $(m;l)=(j+1;n-2),(j+2;n-3),\ldots,(n;j-1)$ for any $1 \leqslant j \leqslant n$. Combining (3.20), we have (3.16). We shall show (3.17). We consider the cases that $(m;l)=(1;n+j-2),(2;n+j-3),\ldots,(j-2;n+1)$ for any $2 \leqslant j \leqslant n$ in (3.22) and the case $k=n$ for $2 \leqslant j$ in Lemma 3.14. Then we obtain (3.17). □

Next, we give the polyhedral realization $\Sigma_\iota[\lambda]$ of $B(\lambda)$. We prepare the following symbols:

$$X := x_{1;n-1} - x_{1;n} (= \xi^{(n)}(\vec{x})), \tag{3.23}$$

$$X_{j;i} := \begin{cases} x_{j;i} & \text{if } i \neq n \\ 2x_{j;n} & \text{if } i = n. \end{cases} \tag{3.24}$$

Then, we can show that the polyhedral realization $\Sigma_\iota[\lambda]$ is given by replacing $x_{j;i}$ of B_n with $X_{j;i}$.

C. D_n case

We consider the case of type D_n. First, we give the polyhedral realization Σ_ι of $B(\infty)$. We define for $j \geqslant 1$, $0 \leqslant k \leqslant 2n-2$,

$$\varphi_{j;k} := \begin{cases} id & (k=0) \\ S_{j;k}S_{j;k-1}\cdots S_{j;2}S_{j;1} & (0 \leqslant k \leqslant n) \\ S_{j+k-n;2n-k-1}S_{j+k-1-n;2n-k}\cdots S_{j+2;n-3}S_{j+1;n-2}\varphi_{j;n} & (n+1 \leqslant k \leqslant 2n-2). \end{cases}$$

$$\varphi'_{j;k} := \begin{cases} id & (k=0) \\ S_{j;k}S_{j;k-1}\cdots S_{j;2}S_{j;1} & (1 \leqslant k \leqslant n-2) \\ S_{j;n}\varphi'_{j;n-2} & (k=n-1) \\ S_{j;n-2}\varphi'_{j;n-1} & (k=n) \\ S_{j+k-n;2n-k-1}S_{j+k-1-n;2n-k}\cdots S_{j+2;n-3}S_{j+1;n-2}\varphi'_{j;n} & (n+1 \leqslant k \leqslant 2n-2). \end{cases}$$

Lemma 3.10:

$$\varphi_{j;k}(x_{j;1}) = \begin{cases} x_{j;k+1} - x_{j+1;k} & (0 \leqslant k \leqslant n-3) \\ x_{j;n-1} + x_{j;n} - x_{j+1;n-2} & (k=n-2) \\ x_{j;n} - x_{j+1;n-1} & (k=n-1) \\ x_{j+1;n-2} - x_{j+1;n-1} - x_{j+1;n} & (k=n) \\ x_{j+k-n+1;2n-k-2} - x_{j+k-n+1;2n-k-1} & (n+1 \leqslant k \leqslant 2n-2), \end{cases}$$

$$\varphi'_{j;k}(x_{j;1}) = \begin{cases} x_{j;n-1} - x_{j+1;n} & (k=n-1) \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise}. \end{cases}$$

Proof: We shall prove the case $\varphi_{j;k}$ by the induction on k since the other case can be proved by the same argument. The case of $k=0$ is trivial.

Case I) $1 \leqslant k \leqslant n-3$.

If $k=1$, we have

$$S_{j;1}(x_{j;1}) = x_{j;1} - (x_{j;1} - x_{j;2} + x_{j+1;1}) = x_{j;2} - x_{j+1;1} = \varphi_{j;1}(x_{j;1}).$$

If $1 < k \leqslant n-3$, we assume that $\varphi_{j;k-1}(x_{j;1}) = x_{j;k} - x_{j+1;k-1}$. Then we have

$$\begin{aligned} S_{j;k}\varphi_{j;k-1}(x_{j;1}) = S_{j;k}(x_{j;k} - x_{j+1;k-1}) &= x_{j;k} - x_{j+1;k-1} - (x_{j;k} - x_{j;k+1} - x_{j+1;k-1} + x_{j+1;k}) \\ &= x_{j;k+1} - x_{j+1;k} = \varphi_{j;k}(x_{j;1}). \end{aligned}$$

Case II) $k = n-2, n-1, n$.

If $k=n-2$, using the result of Case I), we have

$$\begin{aligned} S_{j;n-2}\varphi_{j;n-3}(x_{j;1}) &= S_{j;n-2}(x_{j;n-2} - x_{j+1;n-3}) \\ &= x_{j;n-2} - x_{j+1;n-3} - (x_{j;n-2} - x_{j;n-1} - x_{j;n} - x_{j+1;n-3} + x_{j+1;n-2}) \\ &= x_{j;n-1} + x_{j;n} - x_{j+1;n-2} = \varphi_{j;n-2}(x_{j;1}), \end{aligned}$$

and then if $k=n-1$,

$$S_{j;n-1}\varphi_{j;n-2}(x_{j;1}) = S_{j;n-1}(x_{j;n-1}+x_{j;n}-x_{j+1;n-2}) = x_{j;n-1}+x_{j;n}-x_{j+1;n-2}-(x_{j;n-1}-x_{j+1;n-2}+x_{j+1;n-1})$$
$$= x_{j;n}-x_{j+1;n-1} = \varphi_{j;n-1}(x_{j;1}).$$

If $k=n$, then we have

$$S_{j;n}\varphi_{j;n-1}(x_{j;1}) = S_{j;n}(x_{j;n}-x_{j+1;n-1}) = x_{j;n}-x_{j+1;n-1}-(x_{j;n}-x_{j+1;n-2}+x_{j+1;n})$$
$$= x_{j+1;n-2}-x_{j+1;n-1}-x_{j+1;n} = \varphi_{j;n}(x_{j;1}).$$

Case III) $n+1\leqslant k\leqslant 2n-2$.

If $k=n+1$, using the result of the case of $k=n$, we have

$$S_{j+1;n-2}\varphi_{j;n}(x_{j;1}) = S_{j+1;n-2}(x_{j+1;n-2}-x_{j+1;n-1}-x_{j+1;n})$$
$$= x_{j+1;n-2}-x_{j+1;n-1}-x_{j+1;n}-(x_{j+1;n-2}-x_{j+1;n-1}-x_{j+1;n}-x_{j+2;n-3}+x_{j+2;n-2})$$
$$= x_{j+2;n-3}-x_{j+2;n-2} = \varphi_{j;n+1}(x_{j;1}).$$

If $n+1<k\leqslant 2n-2$, we assume that $\varphi_{j;k-1}(x_{j;1})=x_{j+k-n;2n-k-1}-x_{j+k-n;2n-k}$. Then we have

$$S_{j+k-n;2n-k-1}\varphi_{j;k-1}(x_{j;1}) = S_{j+k-n;2n-k-1}(x_{j+k-n;2n-k-1}-x_{j+k-n;2n-k})$$
$$= x_{j+k-n;2n-k-1}-x_{j+k-n;2n-k}-(x_{j+k-n;2n-k-1}-x_{j+k-n;2n-k}-x_{j+k-n+1;2n-k-2}$$
$$+x_{j+k-n+1;2n-k-1})$$
$$= x_{j+k-n+1;2n-k-2}-x_{j+k-n+1;2n-k-1}) = \varphi_{j;k}(x_{j;1}).$$

□

Lemma 311: The set $\{\varphi_{j;k}(x_{j;1}):1\leqslant j,0\leqslant k\leqslant 2n-2\}\cup\{\varphi'_{j;k}(x_{j;1}):1\leqslant j,0\leqslant k\leqslant 2n-2\}$ *is closed under the actions of all transformations* $S_{m;l}$ *for any* $m\geqslant 1$, $l\geqslant 1$.

Proof: First, we consider the action of $S_{m;l}$ to $\varphi_{j;k}(x_{j;1})$. If $k=0$, $\varphi_{j;0}=id$ and we have

$$S_{m;l}(\varphi_{j;0}(x_{j;1})) = \begin{cases} \varphi_{j;1}(x_{j;1}) & \text{if } (m;l)=(j;1) \\ x_{j;1} & \text{otherwise.} \end{cases}$$

If $1\leqslant k\leqslant n-3$, we have

$$S_{m;l}(\varphi_{j;k}(x_{j;1})) = \begin{cases} \varphi_{j;k-1}(x_{j;1}) & \text{if } (m;l)=(j;k) \\ \varphi_{j;k+1}(x_{j;1}) & \text{if } (m;l)=(j;k+1) \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise.} \end{cases}$$

If $k=n-2$, we have

$$S_{m;l}(\varphi_{j;n-2}(x_{j;1})) = \begin{cases} \varphi_{j;n-3}(x_{j;1}) & \text{if } (m;l)=(j+1;n-2) \\ \varphi_{j;n-1}(x_{j;1}) & \text{if } (m;l)=(j;n-1) \\ \varphi'_{j;n-1}(x_{j;1}) & \text{if } (m;l)=(j;n) \\ \varphi_{j;n-2}(x_{j;1}) & \text{otherwise.} \end{cases} \tag{3.25}$$

If $k=n-1$, we have

$$S_{m;l}(\varphi_{j;n-1}(x_{j;1})) = \begin{cases} \varphi_{j;n-2}(x_{j;1}) & \text{if } (m;l)=(j+1;n-1) \\ \varphi_{j;n}(x_{j;1}) & \text{if } (m;l)=(j;n) \\ \varphi_{j;n-1}(x_{j;1}) & \text{otherwise.} \end{cases}$$

If $k=n$, we have

$$S_{m;l}(\varphi_{j;n}(x_{j;1})) = \begin{cases} \varphi_{j;n-1}(x_{j;1}) & \text{if } (m;l) = (j+1;n) \\ \varphi'_{j;n-1}(x_{j;1}) & \text{if } (m;l) = (j+1;n-1) \\ \varphi_{j;n+1}(x_{j;1}) & \text{if } (m;l) = (j+1;n-2) \\ \varphi_{j;n}(x_{j;1}) & \text{otherwise.} \end{cases} \tag{3.26}$$

If $n+1 \leqslant k \leqslant 2n-2$, we have

$$S_{m;l}(\varphi_{j;k}(x_{j;1})) = \begin{cases} \varphi_{j;k-1}(x_{j;1}) & \text{if } (m;l) = (j+k-n+1;2n-k-1) \\ \varphi_{j;k+1}(x_{j;1}) & \text{if } (m;l) = (j+k-n+1;2n-k-2) \\ \varphi_{j;k}(x_{j;1}) & \text{otherwise.} \end{cases}$$

Next, we consider the action of $S_{m;l}$ to $\varphi'_{j;k}(x_{j;1})$. Since the difference of $\varphi_{j;k}(x_{j;1})$ and $\varphi'_{j;k}(x_{j;1})$ is only the case of $k=n-1$ and by (3.25) and (3.26), we consider the case of $k=n-1$,

$$S_{m;l}(\varphi'_{j;n-1}(x_{j;1})) = \begin{cases} \varphi'_{j;n-2}(x_{j;1})(=\varphi_{j;n-2}(x_{j;1})) & \text{if } (m;l) = (j+1;n) \\ \varphi'_{j;n}(x_{j;1})(=\varphi_{j;n}(x_{j;1})) & \text{if } (m;l) = (j;n-1) \\ \varphi'_{j;n-1}(x_{j;1}) & \text{otherwise.} \end{cases}$$

□

Now, we define

$$\Xi'_\iota := \{\varphi_{j;k}(x_{j;1}) : j \geqslant 1, 0 \leqslant k \leqslant 2n-2\} \cup \{\varphi'_{j;k}(x_{j;1}) : j \geqslant 1, 0 \leqslant k \leqslant 2n-2\},$$

$$\Xi''_\iota := \{x_{j;n-1} : j \geqslant 1\} \cup \{x_{j;n} : j \geqslant 1\},$$

$$\Xi_\iota := \Xi'_\iota \cup \Xi''_\iota,$$

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}_\iota^\infty : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}.$$

Theorem 3.12: *The polyhedral realization Σ_ι of $B(\infty)$ for type D_n is described as follows:*

$$x_{j;i} = 0 \text{ for } j \notin [1,n-1] \text{ or } i \notin [1,n], \tag{3.27}$$

$$x_{1;i} \geqslant x_{2;i-1} \geqslant \cdots \geqslant x_{i;1} \geqslant 0 \text{ for } 1 \leqslant i \leqslant n-2, \tag{3.28}$$

$$x_{j;n-1} + x_{j;n} \geqslant x_{j+1;n-2} \geqslant x_{j+2;n-3} \cdots \geqslant x_{n-1;j} \geqslant 0 \text{ for } 1 \leqslant j \leqslant n-2, \tag{3.29}$$

$$x_{j;n-j} \geqslant x_{j;n-j+1} \geqslant \cdots \geqslant x_{j;n-2} \geqslant x_{j;n-1} + x_{j;n} \geqslant 0 \text{ for } 2 \leqslant j \leqslant n-1, \tag{3.30}$$

$$\begin{cases} x_{1;n-1} \geqslant x_{2;n} \geqslant x_{3;n-1} \geqslant x_{4;n} \geqslant \cdots \geqslant x_{n-1;n} \geqslant 0 \\ x_{1;n} \geqslant x_{2;n-1} \geqslant x_{3;n} \geqslant x_{4;n-1} \geqslant \cdots \geqslant x_{n-1;n-1} \geqslant 0 \end{cases} \quad (n\text{:odd}) \tag{3.31}$$

$$\left(\begin{cases} x_{1;n-1} \geqslant x_{2;n} \geqslant x_{3;n-1} \geqslant x_{4;n} \geqslant \cdots \geqslant x_{n-1;n-1} \geqslant 0 \\ x_{1;n} \geqslant x_{2;n-1} \geqslant x_{3;n} \geqslant x_{4;n-1} \geqslant \cdots \geqslant x_{n-1;n} \geqslant 0 \end{cases} \quad (\textit{respectively}, n\text{:even}) \right). \tag{3.32}$$

Proof: Since Ξ_ι is not closed under the action of S_k, we shall show that

(i) Σ_ι is closed under the action of $\tilde{f}_i$,
(ii) Σ_ι is closed under the action of $\tilde{e}_i$,

(iii) all the entries of $\vec{x} \in \Sigma_\iota$ are non-negative
(These show that Σ_ι is the polyhedral realization of $B(\infty)$),
(iv) Σ_ι has the form of Theorem 3.12.

(*i*) We show that Σ_ι is closed under the action of $\tilde{f}_i$.
Note that ι satisfies the positivity assumption by Lemma 3.11. Let $\vec{x}=(\ldots,x_2,x_1) \in \Sigma_\iota$ and $i \in I$, and suppose that $\tilde{f}_i\vec{x}=(\ldots,x_k+1,\ldots,x_2,x_1)$ for $i_k=i$. We need to show that

$$\varphi(\tilde{f}_i\vec{x}) \geqslant 0$$

for any $\varphi=\Sigma\varphi_j x_j \in \Xi_\iota$. First, we consider the case of $\varphi \in \Xi'_\iota$. Since $\varphi(\tilde{f}_i\vec{x})=\varphi(\vec{x})+\varphi_k$, it is enough to consider the case when $\varphi_k<0$. Since ι satisfies the positivity assumption, we have $k^{(-)} \geqslant 1$. By (2.4), we have $\sigma_k(\vec{x}) > \sigma_{k^{(-)}}(\vec{x})$ and by (2.9), we conclude that

$$\beta_{k^{(-)}}(\vec{x}) = \sigma_{k^{(-)}}(\vec{x}) - \sigma_k(\vec{x}) \leqslant -1.$$

It follows that

$$\varphi(\tilde{f}_i\vec{x}) = \varphi(\vec{x}) + \varphi_k \geqslant \varphi(\vec{x}) - 1 \cdot \beta_{k^{(-)}}(\vec{x}) = (S_k\varphi)(\vec{x}) \tag{3.33}$$

$$\geqslant 0 \tag{3.34}$$

since $S_k\varphi \in \Xi'_\iota$. This shows that Σ_ι is closed under the action of $\tilde{f}_i$ for $\varphi \in \Xi'_\iota$. Next, we consider the case of $\varphi=x_{j;n-1} \in \Xi''_\iota$. We have

$$\varphi(\tilde{f}_i\vec{x}) = x_{j;n-1} + 1 \geqslant 0.$$

The case of $\varphi=x_{j;n} \in \Xi''_\iota$ can be proved by the same argument.
(*ii*) We show that Σ_ι is closed under the action of $\tilde{e}_i$.
We need to show that

$$\varphi(\tilde{e}_i\vec{x}) \geqslant 0$$

for any $\varphi \in \Xi_\iota$. First, we consider the case of $\varphi \in \Xi'_\iota$. Since $\varphi(\tilde{e}_i\vec{x})=\varphi(\vec{x})-\varphi_k$, it is enough to consider the case when $\varphi_k>0$. By (2.5), $\sigma_k(\vec{x}) > \sigma_{k^{(+)}}(\vec{x})$ and by (2.9) we conclude that

$$\beta_k(\vec{x}) = \sigma_k(\vec{x}) - \sigma_{k^{(+)}}(\vec{x}) \geqslant 1.$$

It follows that

$$\varphi(\tilde{e}_i\vec{x}) = \varphi(\vec{x}) - \varphi_k \geqslant \varphi(\vec{x}) - 1 \cdot \beta_k(\vec{x}) = (S_k\varphi)(\vec{x}) \geqslant 0$$

since $S_k\varphi \in \Xi'_\iota$. This shows that Σ_ι is closed under the action of $\tilde{e}_i$ for $\varphi \in \Xi'_\iota$. Next, we consider the case of $\varphi=x_{j;n-1} \in \Xi''_\iota$. It follows that

$$\begin{aligned}\varphi(\tilde{e}_i\vec{x}) = x_{j;n-1}(\vec{x}) - 1 &\geqslant x_{j;n-1}(\vec{x}) - 1 \cdot \beta_{j;n-1}(\vec{x}) = (S_{j;n-1}x_{j;n-1})(\vec{x}) \\ &= (x_{j+1;n-2} - x_{j+1;n-1})(\vec{x}) \geqslant x_{j+1;n}(\vec{x}) \text{ (by Lemma 3.10)} \\ &\geqslant 0 \ (by\ x_{j+1;n} \in \Xi''_\iota).\end{aligned}$$

The case of $\varphi=x_{j;n} \in \Xi''_\iota$ can be proved by the same argument.
(*iii*) We show that all the entries of $\vec{x} \in \Sigma_\iota$ are non-negative.
In the case of $1 \leqslant m$, $0 \leqslant l \leqslant n-3$ for $\varphi_{m;l}(x_{m;1})$, we have

$$x_{m;l+1} \geqslant x_{m+1;l}, \tag{3.35}$$

and we consider the cases that $(m;l)=(j;i-1),(j+1;i-2),\cdots,(j+i-2;1),(j+i-1;0)$. We obtain

$$x_{j;i} \geqslant x_{j+1;i-1} \geqslant \cdots \geqslant x_{j+i-2;2} \geqslant x_{j+i-1;1} \geqslant 0.$$

This shows that $x_{j;i} \geqslant 0$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n-2$. By the definition of Ξ''_ι, we have $x_{j;n-1}$ and $x_{j;n} \geqslant 0$ for $j \geqslant 1$ and these show $x_{j;n} \geqslant 0$ for any $j \geqslant 1$.
(*iv*) We show that Σ_ι has the form of Theorem 3.12.
We determine when $x_{j;i} \equiv 0$ for $j \geqslant 1$, $1 \leqslant i \leqslant n$. In the case of $1 \leqslant m$, $n+1 \leqslant l \leqslant 2n-2$ for $\varphi_{m;l}(x_{m;1})$, we have

$$x_{m+l-n+1;2n-l-2} \geqslant x_{m+l-n+1;2n-l-1} \tag{3.36}$$

and in the case of $0 \leqslant m$, $l=n$,

$$x_{m+1;n-2} \geqslant x_{m+1;n-1} + x_{m+1;n} \geqslant 0 \text{ (since } x_{m+1;n-1} \geqslant 0 \text{ and } x_{m+1;n} \geqslant 0). \tag{3.37}$$

We consider the cases that $(m;l)=(j;2n-2),(j+1;2n-3),\ldots,(j+n-2;n)$, then we have

$$0 \geqslant x_{j+n-1;1} \geqslant x_{j+n-1;2} \geqslant \cdots \geqslant x_{j+n-1;n-3} \geqslant x_{j+n-1;n-2} \geqslant x_{j+n-1;n-1} + x_{j+n-1;n} \geqslant 0.$$

Combining $x_{j+n-1;n-1} \geqslant 0, x_{j+n-1;n} \geqslant 0$ this shows that $x_{j+n-1;i} \equiv 0$ for any $j \geqslant 1$, $1 \leqslant i \leqslant n$. We shall show (3.28). In (3.35), by setting $(m;l)=(1;i-1),(2;i-2),\ldots,(i;0)$ for $1 \leqslant i \leqslant n-2$ then we have (3.28). Let us show (3.29). We consider the cases that $(m;l)=(j+1;n-3),(j+2;n-4),\ldots,(n-1;j-1)$ for $1 \leqslant j \leqslant n-2$ in (3.35) and the case $k=n-2$ in Lemma 3.10. We have (3.29). We shall show (3.30). We consider the cases that $(m;l)=(1;n+j-2),(2;n+j-3),\ldots,(j-2;n+1)$ for $2 \leqslant j \leqslant n-1$ in (3.36) and $(m;l)=(j-1;n)$ for $2 \leqslant j \leqslant n-1$ in (3.37). This shows (3.30). Let us see (3.31). We consider the cases that $k=n-1$ for $\varphi_{j;k}$, $\varphi'_{j;k}$ in Lemma 3.10. We obtain (3.31). Here, (3.32) can be proved by the same argument as (3.31). Therefore, Σ_ι has the form of Theorem 3.12. □

Next, we give the polyhedral realization $\Sigma_\iota[\lambda]$ of $B(\lambda)$ for $\lambda := \sum_{k=1}^n \lambda_k \Lambda_k$, where $\lambda_k \in \mathbb{Z}_{\geqslant 0}$, Λ_k are the fundamental weights. Here we set

$$\Xi_\iota^{(1,n-2)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(i)}(\vec{x}) : k \geqslant 0, 1 \leqslant i \leqslant n-2, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(n-1)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(n-1)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(n)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(n)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(1,n-2)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) : k \geqslant 0, 1 \leqslant i \leqslant n-2, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(n-1)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(n-1)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(n)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(n)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\begin{aligned}
\Xi_\iota[\lambda] &:= \Xi_\iota \cup \Xi_\iota^{(1,n-2)}[\lambda] \cup \Xi_\iota^{(n-1)}[\lambda] \cup \Xi_\iota^{(n)}[\lambda] \\
&= \{\varphi_{j;k}(x_{j;1}) : j \geqslant 1, 0 \leqslant k \leqslant 2n-1\} \\
&\quad \cup \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) : k \geqslant 0, 1 \leqslant i \leqslant n-2, j_1, \ldots, j_k \geqslant 1\} \\
&\quad \cup \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(n-1)}(\vec{x}) : k \geqslant 0, j_1, \cdots, j_k \geqslant 1\} \cup \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(n)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},
\end{aligned}$$

$$\Sigma_\iota[\lambda] := \{\vec{x} \in \mathbb{Z}_\iota[\lambda] : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota[\lambda]\}.$$

In order to show that $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$, we give the explicit forms of $\Xi_\iota^{(1,n-2)}[\lambda]$, $\Xi_\iota^{(n-1)}[\lambda]$, and $\Xi_\iota^{(n)}[\lambda]$. Since the Dynkin diagrams for A_n and D_n are the same for $1 \leqslant i \leqslant n-2$, we give the explicit form of $\Xi_\iota^{(1,n-2)}$ as follows:

$$\Xi_\iota^{(1,n-2)} = \{x_{j;i-j} - x_{j;i-j+1} : 1 \leqslant i \leqslant n-2, 1 \leqslant j \leqslant i\}. \tag{3.38}$$

For giving the explicit form of $\Xi_\iota^{(n-1)}$ and $\Xi_\iota^{(n)}$, we say that an integer sequence $\mu_1, \mu_2, \ldots, \mu_n$ is an admissible pattern if:

$$\begin{cases} 1 \leqslant \mu_1 \leqslant n-1, \\ 0 \leqslant \mu_2 \leqslant \mu_1 - 1, \\ \cdots, \\ 0 \leqslant \mu_k \leqslant \mu_{k-1} - 1, \\ \cdots, \end{cases} \tag{3.39}$$

where if μ_k does not exist, we define $\mu_k = 0$, and

$$S^{(\mu_1)} := \begin{cases} id & (\mu_1 = 1) \\ S_{\mu_1 - 1;n-\mu_1} \cdots S_{2;n-3} S_{1;n-2} & (\mu_1 \geqslant 2), \end{cases}$$

$$S^{(\mu_k)} := \begin{cases} id & (\mu_k = 0) \\ S_{\mu_k+k-2;n-\mu_k} \cdots S_{k+1;n-3} S_{k;n-2} S_{k-1;n} & (\mu_k \geqslant 1 \text{ and } k\text{:even}) \\ S_{\mu_k+k-2;n-\mu_k} \cdots S_{k+1;n-3} S_{k;n-2} S_{k-1;n-1} & (\mu_k \geqslant 1 \text{ and } k\text{:odd}) \end{cases} \quad \text{for } k \geqslant 2,$$

$$S^{(\mu'_k)} := \begin{cases} id & (\mu_k = 0) \\ S_{\mu_k+k-2;n-\mu_k} \cdots S_{k+1;n-3} S_{k;n-2} S_{k-1;n} & (\mu_k \geqslant 1 \text{ and } k\text{:odd}) \\ S_{\mu_k+k-2;n-\mu_k} \cdots S_{k+1;n-3} S_{k;n-2} S_{k-1;n-1} & (\mu_k \geqslant 1 \text{ and } k\text{:even}) \end{cases} \quad \text{for } k \geqslant 2,$$

$$\varphi^{(\mu)} := S^{(\mu_k)} \cdots S^{(\mu_2)} S^{(\mu_1)} \text{ for } \mu = (\mu_1, \mu_2, \ldots, \mu_k, 0, 0, \ldots),$$

$$\varphi'^{(\mu')} := S^{(\mu'_k)} \cdots S^{(\mu'_2)} S^{(\mu_1)} \text{ for } \mu = (\mu_1, \mu'_2, \ldots, \mu'_k, 0, 0, \ldots).$$

We prepare the symbol X as follows:

$$X := x_{1;n-2} - x_{1;n-1} (= \xi^{(n-1)}(\vec{x})), \tag{3.40}$$

$$X' := x_{1;n-2} - x_{1;n} (= \xi^{(n)}(\vec{x})). \tag{3.41}$$

For convenience, we define

$$X_{j;i} := \begin{cases} x_{j;n} & \text{if } j\text{:even and } i = n-1 \\ x_{j;n-1} & \text{if } j\text{:even and } i = n \\ x_{j;i} & \text{otherwise}, \end{cases} \tag{3.42}$$

$$X'_{j;i} := \begin{cases} x_{j;n} & \text{if } j\text{:odd and } i = n-1 \\ x_{j;n-1} & \text{if } j\text{:odd and } i = n \\ x_{j;i} & \text{otherwise}. \end{cases} \tag{3.43}$$

Theorem 3.13: *Let* $\mu=(\mu_1,\mu_2,\ldots,\mu_k,0,0,\ldots)$ *be an admissible pattern.*

(i) *The forms* $\varphi^{(\mu)}X$ *are given by*

$$\varphi^{(\mu)}X=\begin{cases}\displaystyle\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k-1}-X_{\mu_k+k-1;n-\mu_k}) & \text{if } \mu_l=1\\ \displaystyle\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k-1}-X_{\mu_k+k-1;n-\mu_k})+X_{l;n} & \text{if } \mu_l\geqslant 2.\end{cases}\tag{3.44}$$

where $l:=\max\{k:\mu_k\neq 0\}$.

(ii) *The forms* $\varphi'^{(\mu')}X'$ *are given by*

$$\varphi'^{(\mu')}X'=\begin{cases}\displaystyle\sum_{k=1}^{l}(X'_{\mu_k+k-1;n-\mu_k-1}-X'_{\mu_k+k-1;n-\mu_k}) & \text{if } \mu'_l=1\\ \displaystyle\sum_{k=1}^{l}(X'_{\mu_k+k-1;n-\mu_k-1}-X'_{\mu_k+k-1;n-\mu_k})+X'_{l;n} & \text{if } \mu'_l\geqslant 2.\end{cases}\tag{3.45}$$

where $l:=\max\{k:\mu'_k\neq 0\}$.

(iii) $\Xi_\iota^{(n-1)}$ *(respectively,* $\Xi_\iota^{(n)}$*) is the set of all linear forms which are of the form* $\varphi^{(\mu)}X$ *(respectively,* $\varphi'^{(\mu')}X'$*), where* μ *(respectively,* μ'*) are the admissible patterns.*

Proof: We shall show (i), the case (ii) can be proved by the same argument. First, we give a remark. When $\mu_k-\mu_{k+1}=1$, the terms $X_{\mu_k+k-1;n-\mu_k}$ and $X_{\mu_{k+1}+k;n-\mu_{k+1}-1}$ in the sum (3.44) are canceled as $-X_{\mu_k+k-1;n-\mu_k}+X_{\mu_{k+1}+k;n-\mu_{k+1}-1}=0$. We show the theorem by induction on $|\mu|=\mu_1+\mu_2+\cdots+\mu_i$ for $\mu=(\mu_1,\mu_2,\cdots,\mu_i,0,0,\ldots)$.

If $|\mu|=1$, then $l=1$ and the sum of the right-hand side of (3.44) is $X_{1;n-2}-X_{1;n-1}=x_{1;n-2}-x_{1;n-1}$ and equal to $\varphi^{(\mu)}X$ by (3.41). We assume that $|\mu|=\mu_1+\mu_2+\cdots+\mu_i=k-1$ for $\mu=(\mu_1,\mu_2,\ldots,\mu_i,0,0,\ldots)$. We consider the two cases: I) $\mu_i\to\mu_i+1$, II) "$\mu_{i+1}=0$" $\to$ "$\mu_{i+1}=1$".

I) $\mu_i\to\mu_i+1$.

We shall prove the case $\mu_i=1$, the case $\mu_i\geqslant 2$ can be proved by the same argument. We have $l=i$ and note that $1\leqslant\mu_i\leqslant\mu_{i-1}-2$ by the fact that μ is admissible pattern and the term $X_{\mu_i+i-1;n-\mu_i-1}$ in the sum (3.13) is not canceled. We set $\mu':=(\mu_1,\mu_2,\ldots,\mu_i+1,0,0,\ldots)$. We have

$$\varphi^{(\mu')}X=S_{\mu_i+i-1;n-\mu_i-1}\varphi^{(\mu)}X.$$

The right-hand side of (3.44) is

$$\begin{aligned}S_{\mu_i+i-1;n-\mu_i-1}\left(\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k-1}-X_{\mu_k+k-1;n-\mu_k})\right)&=\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k-1}-X_{\mu_k+k-1;n-\mu_k})\\&\quad-(X_{\mu_i+i-1;n-\mu_i-1}-X_{\mu_i+i-1;n-\mu_i}-X_{\mu_i+i;n-\mu_i-2}\\&\quad+X_{\mu_i+i;n-\mu_i-1})=\varphi^{(\mu')}X.\end{aligned}$$

II) "$\mu_{i+1}=0$" $\to$ "$\mu_{i+1}=1$."

We set $\mu':=(\mu_1,\mu_2,\ldots,\mu_i,1,0,\ldots)$ (*i.e.* $\mu_{i+1}=1$) and then $l=i+1$. By the fact that μ is admissible pattern, we have $0\leqslant\mu_{i+1}\leqslant\mu_i-1$. This shows that $\mu_i\geqslant 2$ and the term $X_{i;n}$ in the sum (3.44) is not canceled. If i is odd, then we have

$$\varphi^{(\mu')}X=S_{i;n}\varphi^{(\mu)}X.$$

The right-hand side of (3.44) is

$$S_{i;n}\left(\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k-1}-X_{\mu_k+k-1;n-\mu_k})+X_{i;n}\right)=\sum_{k=1}^{l}(X_{\mu_k+k-1;n-\mu_k-1}-X_{\mu_k+k-1;n-\mu_k})$$
$$+X_{i;n}-(X_{i;n}-X_{i+1;n-2}+X_{i+1;n})=\varphi^{(\mu')}X.$$

If i is even, we can prove II) by the same argument.

(iii) It is sufficient to show that $\{\varphi^{(\mu)}X|\,\mu$:admissible pattern$\}$ is closed under the actions of all $S_{j;i}$, the other case can be proved by the same argument. We set for $1\leqslant k\leqslant l+1$, $\mu=(\mu_1,\mu_2,\ldots,\mu_k,\ldots,\mu_l,0,0,\ldots)$, $\mu^+=(\mu_1,\mu_2,\ldots,\mu_k+1,\ldots,\mu_l,0,0,\ldots)$, $\mu^-=(\mu_1,\mu_2,\ldots,\mu_k-1,\ldots,\mu_l,0,0,\ldots)$.

Then we have

$$S_{j;i}\varphi^{(\mu)}X=\begin{cases}\varphi^{(\mu^+)}X & \text{if } (j;i)=(\mu_k+k-1;n-\mu_k) \text{ and } \mu_{k-1}-\mu_k\neq 1\\ \varphi^{(\mu^-)}X & \text{if } (j;i)=(\mu_k+k-1;n-\mu_k+1) \text{ and } \mu_k-\mu_{k+1}\neq 1\\ \varphi^{(\mu)}X & \text{otherwise.}\end{cases}$$

□

Therefore, ι satisfies the strict positivity assumption by the explicit forms of $\Xi_\iota^{(1,n-2)}$, $\Xi_\iota^{(n-1)}$, and $\Xi_\iota^{(n)}$. By the Lemma 2.6, this shows that

$$\Xi_\iota^{(1,n-2)}[\lambda]=\{\lambda_i+x_{j;i-j}-x_{j;i-j+1}:1\leqslant i\leqslant n-1,1\leqslant j\leqslant i\},$$

$$\Xi_\iota^{(k)}[\lambda]=\{\lambda_k+\varphi(\vec{x}):\varphi(\vec{x})\in\Xi_\iota^{(k)}:\mu \text{ are the admissible patterns}\} \text{ for } k=n-1,n$$

by (3.38) and (3.44) and $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$.

D. F_4 case

We use the different Cartan data from the one in Ref. 10, where the Cartan matrix $(a_{ij})_{1\leqslant i,j\leqslant 4}$ is given by

$$a_{ij}:=\begin{cases}2 & \text{if } i=j\\ -1 & \text{if } |i-j|=1 \text{ and } (i,j)\neq(2,3)\\ -2 & \text{if } (i,j)=(2,3)\\ 0 & \text{otherwise.}\end{cases}$$

We fix ι as follows:

$$\iota:=(\ldots,\underbrace{4,3,2,1},\ldots,\underbrace{4,3,2,1},\underbrace{4,3,2,1}).$$

We define

$$\Xi_\iota:=\{S_{m_l}\cdots S_{m_2}S_{m_1}(x_{j;1}):l\geqslant 0,m_1,\ldots,m_l\geqslant 1,1\leqslant j\leqslant 6\},$$

$$\Sigma_\iota:=\{\vec{x}\in\mathbb{Z}_\iota^\infty|\varphi(\vec{x})\geqslant 0 \text{ for any } \varphi\in\Xi_\iota\}.$$

Using Theorem 3.3, we shall give the polyhedral realization of $B(\infty)$. We give the explicit form of Ξ_ι by direct calculation and show that the polyhedral realization of $B(\infty)$ is equal to Σ_ι using the following three steps:

(i) We check the positivity assumption,
(ii) For $\vec{x}=(\ldots,x_{1;2},x_{1;1})\in\Sigma_\iota$, we check that $x_{j;i}\geqslant 0$ for all $i,j\geqslant 1$, ((i), (ii) shows that Σ_ι is the polyhedral realization of $B(\infty)$),
(iii) We determine when $x_{j;i}\equiv 0$ for convenience.

Theorem 3.14: *We give the explicit form of* Ξ_ι *as follows*:

$$\left\{\begin{array}{ccc}
x_{j;1} & x_{j;2}-x_{j+1;1} & 2x_{j;3}-x_{j+1;2} \quad 2x_{j;4}-x_{j+3;1} \\
x_{j+1;2}-2x_{j+1;4} & x_{j+2;2}-x_{j+3;2} & x_{j+2;1}-x_{j+4;1} \quad 2x_{j+2;4}-x_{j+4;2} \\
x_{j+3;1}-x_{j+3;4} & x_{j+4;2}-2x_{j+4;3} & x_{j+5;1}-x_{j+5;2} \quad -x_{j+6;1} \\
2x_{j;4}+x_{j+1;2}-2x_{j+1;3} & 2x_{j;4}-x_{j+2;1}-x_{j+2;2} & 2x_{j+1;3}-2x_{j+1;4}-x_{j+3;1} \\
x_{j+2;1}+x_{j+2;2}-2x_{j+2;3} & 2x_{j+2;2}-2x_{j+2;3}-x_{j+3;1} & x_{j+2;1}+x_{j+3;1}-x_{j+3;2} \\
2x_{j+2;3}+x_{j+3;1}-2x_{j+3;2} & 2x_{j+2;4}+x_{j+3;1}-2x_{j+3;3} & 2x_{j+2;3}-x_{j+3;2}-x_{j+4;1} \\
x_{j+2;2}-x_{j+3;1}-x_{j+4;1} & x_{j+3;2}-2x_{j+3;4}-x_{j+4;1} & 2x_{j+3;3}-2x_{j+3;4}-x_{j+4;2} \\
2x_{j+1;3}+x_{j+2;1}-2x_{j+1;4}-x_{j+2;2} & 2x_{j+2;4}+x_{j+3;2}-2x_{j+3;3}-x_{j+4;1}
\end{array}\right\}.$$

Proof: (i) By the form of Σ_ι, coefficients of $x_{1;1}, x_{1;2}, x_{1;3}, x_{1;4}$ are positive. This shows that the "positivity assumption" is satisfied.

(ii) We assume $x_{j;1} \geqslant 0$ for any $j \geqslant 1$. We show that $x_{j;2}, x_{j;3}, x_{j;4} \geqslant 0$ for any $j \geqslant 1$. By the results of (i), we have

$$x_{j;2} \geqslant x_{j+1;1}, \quad 2x_{j;3} \geqslant x_{j+1;2}, \quad 2x_{j;4} \geqslant x_{j+3;1}.$$

Then we have $x_{j;2} \geqslant 0$ for $j \geqslant 1$ since $x_{j;2} \geqslant x_{j+1;1}$. Similarly, we obtain $x_{j;3} \geqslant 0$, $x_{j;4} \geqslant 0$ for $j \geqslant 1$ since $2x_{j;3} \geqslant x_{j+1;2}$, $2x_{j;4} \geqslant x_{j+3;1}$, respectively. (i) and (ii) show that Σ_ι is the polyhedral realization of $B(\infty)$.

(iii) We determine when $x_{j;i} \equiv 0$. By the forms of Σ_ι and (ii), we have

$$0 \geqslant x_{j+6;1} \geqslant 0.$$

This shows $x_{m;1} \equiv 0$ for $m \geqslant 7$. Similarly, we obtain

$$x_{m;2} \equiv 0, \quad x_{m;3} \equiv 0, \quad x_{m;4} \equiv 0 \quad \text{for } m \geqslant 7$$

since $x_{j+5;1} \geqslant x_{j+5;2}$, $x_{j+4;1} \geqslant x_{j+4;3}$, $x_{j+3;1} \geqslant x_{j+3;4}$, respectively. In particular, the parameter j in Ξ_ι runs over $1 \leqslant j \leqslant 6$. □

Next, we give the polyhedral realization of $B(\lambda)$ for $\lambda := \lambda_1\Lambda_1 + \ldots + \lambda_4\Lambda_4$. Here we set for $1 \leqslant i \leqslant 4$,

$$\Xi_\iota^{(i)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(i)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(i)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota[\lambda] := \Xi_\iota \cup \Xi_\iota^{(1)}[\lambda] \cup \cdots \cup \Xi_\iota^{(4)}[\lambda]$$

$$\Sigma_\iota[\lambda] := \{\vec{x} \in \mathbb{Z}_\iota[\lambda] : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota[\lambda]\}.$$

In order to show that $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$, we give the explicit forms of $\Xi_\iota^{(i)}$ for $1 \leqslant i \leqslant 4$ by direct calculation as follows:

$$\Xi_\iota^{(1)} = \{-x_{1;1}\},$$

$$\Xi_\iota^{(2)} = \{x_{1;1} - x_{1;2}, -x_{2;1}\},$$

$$\Xi_\iota^{(3)} = \left\{ \begin{array}{ccccc} x_{1;2}-x_{1;3} & x_{1;3}-x_{3;1} & x_{2;1}-x_{2;4} & x_{2;3}-x_{3;3} \\ x_{1;4}-x_{3;4} & x_{2;4}-x_{5;1} & x_{4;1}-x_{4;3} & x_{4;3}-x_{5;2} \\ & x_{4;4}-x_{5;3} & -x_{5;4} & \\ x_{1;3}+x_{2;1}-x_{2;2} & x_{1;4}+x_{2;1}-x_{2;3} & x_{1;4}+x_{2;3}-x_{3;2} & \\ x_{1;4}+x_{2;4}-x_{3;3} & x_{2;4}+x_{3;2}-2x_{3;3} & x_{2;4}+x_{4;1}-x_{4;2} & \\ x_{2;2}-x_{2;4}-x_{3;1} & 2x_{2;3}-x_{2;4}-x_{3;2} & x_{3;2}-x_{3;3}-x_{3;4} & \\ x_{2;3}-x_{2;4}-x_{3;4} & x_{3;3}-x_{3;4}-x_{5;1} & x_{4;2}-x_{4;3}-x_{5;1} & \\ x_{1;4}+x_{2;2}-x_{2;3}-x_{3;1} & x_{3;3}+x_{4;1}-x_{3;4}-x_{4;2} & & \end{array} \right\},$$

$$\Xi_\iota^{(4)} = \left\{ \begin{array}{ccccc} x_{1;3}-x_{1;4} & x_{2;2}-x_{2;3} & x_{2;3}-x_{4;1} & x_{3;1}-x_{3;4} \\ x_{3;3}-x_{4;3} & x_{2;4}-x_{4;4} & x_{3;4}-x_{6;1} & x_{5;1}-x_{5;3} \\ & x_{5;3}-x_{6;2} & x_{5;4}-x_{6;3} & -x_{6;4} \\ x_{2;3}+x_{3;1}-x_{3;2} & x_{2;4}+x_{3;1}-x_{3;3} & x_{2;4}+x_{3;3}-x_{4;2} & \\ x_{2;4}+x_{3;4}-x_{4;3} & x_{3;4}+x_{4;2}-2x_{4;3} & x_{3;4}+x_{5;1}-x_{5;2} & \\ x_{3;2}-x_{3;4}-x_{4;1} & 2x_{3;3}-x_{3;4}-x_{4;2} & x_{4;2}-x_{4;3}-x_{4;4} & \\ x_{3;3}-x_{3;4}-x_{4;4} & x_{4;3}-x_{4;4}-x_{6;1} & x_{5;2}-x_{5;3}-x_{6;1} & \\ x_{2;4}+x_{3;2}-x_{3;3}-x_{4;1} & x_{4;3}+x_{5;1}-x_{4;4}-x_{5;2} & & \end{array} \right\}.$$

Therefore, ι satisfies the strict positivity assumption by the explicit forms of $\Xi_\iota^{(i)}$ for $1 \leqslant i \leqslant 4$. This shows that

$$\Xi_\iota^{(1)}[\lambda] = \{\lambda_1 - x_{1;1}\},$$

$$\Xi_\iota^{(2)}[\lambda] = \{\lambda_2 + x_{1;1} - x_{1;2}, \lambda_2 - x_{2;1}\},$$

$$\Xi_\iota^{(k)}[\lambda] = \{\lambda_k + \varphi_k(\vec{x}) : \varphi_k(\vec{x}) \in \Xi_\iota^{(k)}\} \text{ for } k = 3,4$$

by Lemma 2.6 and $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$.

E. E_6 case

We fix ι as follows:

$$\iota := (\ldots, \underline{6,5,4,3,2,1}, \ldots, \underline{6,5,4,3,2,1}, \underline{6,5,4,3,2,1}).$$

We define

$$\Xi_\iota := \{S_{m_l} \cdots S_{m_2} S_{m_1}(x_{j;1}) : l \geqslant 0, m_1, \ldots, m_l \geqslant 1, 1 \leqslant j \leqslant 8\},$$

$$\Sigma_\iota := \{\vec{x} \in Z_\iota^\infty : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}.$$

We give the explicit form of Ξ_ι by direct calculation and show that the polyhedral realization of $B(\infty)$ is equal to Σ_ι using the following steps similar to the case of F_4:

(i) We check the positivity assumption.
(ii) For $\vec{x} = (\ldots, x_{1;2}, x_{1;1}) \in \Sigma_\iota$, we check that $x_{j;i} \geqslant 0$ for all $i, j \geqslant 1$.
(iii) We determine when $x_{j;i} \equiv 0$ for convenience.

Theorem 3.15: *We give the explicit form of* Ξ_ι *as follows*:

$$\left\{\begin{array}{c} x_{j;1} \quad x_{j;2}-x_{j+1;1} \quad x_{j;3}-x_{j+1;2} \quad x_{j;4}-x_{j+1;6} \\ x_{j;6}-x_{j+1;5} \quad x_{j+2;2}-x_{j+2;4} \quad x_{j;5}-x_{j+4;1} \quad x_{j+3;1}-x_{j+3;6} \\ x_{j+2;6}-x_{j+2;2} \quad x_{j+3;4}-x_{j+4;3} \quad x_{j+3;5}-x_{j+4;4} \quad -x_{j+4;5} \\ x_{j;4}+x_{j;6}-x_{j+1;3} \quad x_{j;5}+x_{j;6}-x_{j+1;4} \quad x_{j;5}+x_{j+2;2}-x_{j+2;3} \\ x_{j;5}+x_{j+3;1}-x_{j+3;2} \quad x_{j+2;6}+x_{j+3;1}-x_{j+3;3} \quad x_{j+1;3}-x_{j+1;5}-x_{j+1;6} \\ x_{j+1;4}-x_{j+1;5}-x_{j+4;1} \quad x_{j+2;3}-x_{j+2;4}-x_{j+4;1} \quad x_{j+3;2}-x_{j+3;6}-x_{j+4;1} \\ x_{j+3;3}-x_{j+3;6}-x_{j+4;2} \quad x_{j;5}+x_{j+1;3}-x_{j+1;4}-x_{j+1;6} \\ x_{j+1;4}+x_{j+2;2}-x_{j+1;5}-x_{j+2;3} \quad x_{j+1;4}+x_{j+3;1}-x_{j+1;5}-x_{j+3;2} \\ x_{j+2;3}+x_{j+3;1}-x_{j+2;4}-x_{j+3;2} \quad x_{j+2;6}+x_{j+3;2}-x_{j+3;3}-x_{j+4;1} \end{array}\right\}.$$

Proof: (i) By the form of Σ_ι, coefficients of $x_{1;1}$, $x_{1;2}$, $x_{1;3}$, $x_{1;4}$, $x_{1;5}$, $x_{1;6}$ are positive. This shows that the "positivity assumption" is satisfied.

(ii) We assume $x_{j;1} \geqslant 0$ for any $j \geqslant 1$. We show that $x_{j;2}, x_{j;3}, x_{j;4}, x_{j;5}, x_{j;6} \geqslant 0$ for any $j \geqslant 1$. By the form of Σ_ι, we have

$$x_{j;2} \geqslant x_{j+1;1}, \quad x_{j;3} \geqslant x_{j+1;2}, \quad x_{j;5} \geqslant x_{j+4;1}, \quad x_{j;6} \geqslant x_{j+1;5}, \quad x_{j;4} \geqslant x_{j+1;6}.$$

This shows $x_{j;2} \geqslant 0$ for $j \geqslant 1$ since $x_{j+1;1} \geqslant 0$ and similarly, we have $x_{j;3} \geqslant 0$, $x_{j;5} \geqslant 0$, $x_{j;6} \geqslant 0$, $x_{j;4} \geqslant 0$ for $j \geqslant 1$ since $x_{j;3} \geqslant x_{j+1;2}$, $x_{j;5} \geqslant x_{j+4;1}$, $x_{j;6} \geqslant x_{j+1;5}$, $x_{j;4} \geqslant x_{j+1;6}$, respectively.

(iii) We determine when $x_{j;i} \equiv 0$. We have

$$0 \geqslant x_{j+4;5} \geqslant 0.$$

This shows $x_{m;5} \equiv 0$ for $m \geqslant 5$. Similarly, we have $x_{m;4} \equiv 0$ for $m \geqslant 6$, $x_{m;3} \equiv 0$ for $m \geqslant 7$, $x_{m;6} \equiv 0$ for $m \geqslant 7$, $x_{m;2} \equiv 0$ for $m \geqslant 8$, $x_{m;1} \equiv 0$ for $m \geqslant 9$ since $x_{j+3;4} \geqslant x_{j+4;3}$, $x_{j+3;5} \geqslant x_{j+4;4}$, $x_{j;4} \geqslant x_{j+1;6}$, $x_{j;3} \geqslant x_{j+1;2}$, $x_{j;2} \geqslant x_{j+1;1}$, respectively. In particular, the parameter j in Ξ_ι runs over $1 \leqslant j \leqslant 8$. □

Next, we give the polyhedral realization of $B(\lambda)$ for $\lambda := \lambda_1\Lambda_1 + \ldots + \lambda_6\Lambda_6$. Here we set for $1 \leqslant i \leqslant 6$

$$\Xi_\iota^{(i)} := \{S_{j_k} \cdots S_{j_2} S_{j_1} \xi^{(i)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota^{(i)}[\lambda] := \{\hat{S}_{j_k} \cdots \hat{S}_{j_2} \hat{S}_{j_1} \lambda^{(i)}(\vec{x}) : k \geqslant 0, j_1, \ldots, j_k \geqslant 1\},$$

$$\Xi_\iota[\lambda] := \Xi_\iota \cup \Xi_\iota^{(1)}[\lambda] \cup \cdots \cup \Xi_\iota^{(6)}[\lambda]$$

$$\Sigma_\iota[\lambda] := \{\vec{x} \in \mathbb{Z}_\iota[\lambda] : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota[\lambda]\}.$$

In order to show that $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$, we give the explicit forms of $\Xi_\iota^{(i)}$ for $1 \leqslant i \leqslant 6$ by direct calculation as follows:

$$\Xi_\iota^{(1)} = \{-x_{1;1}\},$$

$$\Xi_\iota^{(2)} = \{x_{1;1} - x_{1;2}, -x_{2;1}\},$$

$$\Xi_\iota^{(3)} = \{x_{1;2} - x_{1;3}, x_{2;1} - x_{2;2}, -x_{3;1}\},$$

$$\Xi_\iota^{(4)} = \left\{ \begin{array}{cccccccc} x_{1;3}-x_{1;4} & x_{2;2}-x_{2;6} & x_{1;6}-x_{4;1} & x_{3;1}-x_{3;5} & x_{2;4}-x_{4;2} & x_{2;5}-x_{4;6} & x_{3;6}-x_{4;4} & \\ & & x_{5;2}-x_{5;3} & x_{6;1}-x_{6;2} & -x_{7;1} & & & \\ x_{1;6}+x_{2;2}-x_{2;3} & x_{1;6}+x_{3;1}-x_{3;2} & x_{2;4}+x_{3;1}-x_{3;3} & x_{2;5}+x_{3;1}-x_{3;4} & & & & \\ & & x_{2;5}+x_{3;6}-x_{4;3} & & & & & \\ x_{2;3}-x_{2;6}-x_{4;1} & x_{3;2}-x_{3;5}-x_{4;1} & x_{3;3}-x_{3;5}-x_{4;2} & x_{3;4}-x_{3;5}-x_{4;6} & & & & \\ & & x_{4;3}-x_{4;4}-x_{4;6} & & & & & \\ x_{2;3}+x_{3;1}-x_{2;6}-x_{3;2} & x_{2;4}+x_{3;2}-x_{3;3}-x_{4;1} & x_{2;5}+x_{3;2}-x_{3;4}-x_{4;1} & & & & & \\ x_{2;5}+x_{3;3}-x_{3;4}-x_{4;2} & x_{3;4}+x_{3;6}-x_{3;5}-x_{4;3} & & & & & & \end{array} \right\},$$

$$\Xi_\iota^{(5)} = \left\{ \begin{array}{cccccccc} x_{1;4}-x_{1;5} & x_{2;3}-x_{2;4} & x_{3;2}-x_{3;6} & x_{2;6}-x_{5;1} & x_{4;1}-x_{4;5} & x_{3;4}-x_{5;2} & x_{3;5}-x_{5;6} & \\ & & x_{4;6}-x_{5;4} & x_{6;2}-x_{6;3} & x_{7;1}-x_{7;2} & -x_{8;1} & & \\ x_{2;6}+x_{3;2}-x_{3;3} & x_{2;6}+x_{4;1}-x_{4;2} & x_{3;4}+x_{4;1}-x_{4;3} & x_{3;5}+x_{4;1}-x_{4;4} & & & & \\ x_{3;5}+x_{4;6}-x_{5;3} & x_{3;3}-x_{3;6}-x_{5;1} & x_{4;2}-x_{4;5}-x_{5;1} & x_{4;3}-x_{4;5}-x_{5;2} & & & & \\ & & x_{4;4}-x_{4;5}-x_{5;6} & x_{5;3}-x_{5;4}-x_{5;6} & & & & \\ x_{3;3}+x_{4;1}-x_{3;6}-x_{4;2} & x_{3;4}+x_{4;2}-x_{4;3}-x_{5;1} & x_{3;5}+x_{4;2}-x_{4;4}-x_{5;1} & & & & & \\ x_{3;5}+x_{4;3}-x_{4;4}-x_{5;2} & x_{4;4}+x_{4;6}-x_{4;5}-x_{5;3} & & & & & & \end{array} \right\},$$

$$\Xi_\iota^{(6)} = \left\{ \begin{array}{cccccccc} x_{1;3}-x_{1;6} & x_{2;2}-x_{2;5} & x_{1;4}-x_{4;1} & x_{3;3}-x_{4;3} & x_{3;1}-x_{6;1} & x_{2;6}-x_{4;6} & x_{1;5}-x_{4;5} & \\ & & x_{5;1}-x_{5;4} & x_{3;5}-x_{6;2} & x_{5;6}-x_{6;3} & -x_{6;1} & & \\ x_{1;4}+x_{2;2}-x_{2;3} & x_{1;5}+x_{2;2}-x_{2;4} & x_{1;4}+x_{3;1}-x_{3;2} & x_{1;5}+x_{3;1}-x_{3;6} & & & & \\ x_{2;6}+x_{3;1}-x_{2;4} & x_{1;5}+x_{2;6}-x_{4;2} & x_{2;1}+x_{4;2}-x_{4;3} & x_{1;5}+x_{3;4}-x_{4;3} & & & & \\ x_{3;1}+x_{5;1}-x_{5;2} & x_{2;6}+x_{3;6}-x_{4;3} & x_{1;5}+x_{3;5}-x_{4;4} & x_{3;5}+x_{5;1}-x_{5;3} & & & & \\ x_{2;3}-x_{2;5}-x_{4;1} & x_{3;2}-x_{4;1}-x_{6;1} & x_{3;3}-x_{3;6}-x_{4;6} & x_{2;4}-x_{2;5}-x_{4;5} & & & & \\ x_{3;3}-x_{4;2}-x_{6;1} & x_{3;3}-x_{3;4}-x_{4;5} & x_{4;2}-x_{4;5}-x_{4;6} & x_{3;4}-x_{4;6}-x_{6;1} & & & & \\ x_{3;6}-x_{4;5}-x_{6;1} & x_{5;2}-x_{5;4}-x_{6;1} & x_{4;4}-x_{4;5}-x_{6;2} & x_{5;3}-x_{5;4}-x_{6;2} & & & & \\ x_{2;3}+x_{3;1}-x_{2;5}-x_{3;2} & x_{1;5}+x_{2;3}-x_{2;4}-x_{4;1} & x_{2;4}+x_{3;1}-x_{2;5}-x_{3;6} & & & & & \\ x_{1;5}+x_{3;2}-x_{3;6}-x_{4;1} & x_{3;1}+x_{3;3}-x_{3;4}-x_{3;6} & x_{2;6}+x_{3;2}-x_{3;4}-x_{4;1} & & & & & \\ x_{2;4}+x_{2;5}-x_{2;6}-x_{4;2} & x_{1;5}+x_{3;3}-x_{3;6}-x_{4;2} & x_{2;6}+x_{3;3}-x_{3;4}-x_{4;2} & & & & & \\ x_{3;2}+x_{4;2}-x_{4;1}-x_{4;3} & x_{2;4}+x_{3;4}-x_{2;5}-x_{4;3} & x_{3;2}+x_{5;1}-x_{4;1}-x_{5;2} & & & & & \\ x_{2;4}+x_{3;5}-x_{2;5}-x_{4;4} & x_{3;4}+x_{4;2}-x_{4;3}-x_{4;6} & x_{3;3}+x_{4;2}-x_{5;1}-x_{5;2} & & & & & \\ x_{3;3}+x_{3;5}-x_{3;4}-x_{4;4} & x_{3;6}+x_{4;2}-x_{4;3}-x_{4;5} & x_{3;5}+x_{4;2}-x_{4;4}-x_{4;6} & & & & & \\ x_{3;4}+x_{5;1}-x_{4;6}-x_{5;2} & x_{3;4}+x_{3;6}-x_{4;3}-x_{6;1} & x_{3;6}+x_{5;1}-x_{4;5}-x_{5;2} & & & & & \\ x_{3;5}+x_{3;6}-x_{4;4}-x_{6;1} & x_{4;4}+x_{5;1}-x_{4;5}-x_{5;3} & x_{3;5}+x_{5;2}-x_{5;3}-x_{6;1} & & & & & \\ x_{1;5}+x_{2;6}+x_{3;1}-x_{3;3} & x_{3;4}+x_{3;6}+x_{4;2}-2x_{4;3} & 2x_{3;3}-x_{3;4}-x_{3;6}-x_{4;2} & & & & & \\ & & x_{4;3}-x_{4;5}-x_{4;6}-x_{6;1} & & & & & \\ x_{2.4}+x_{2;6}+x_{3;2}-x_{2;5}-x_{3;3}-x_{4;1} & x_{3;5}+x_{4;3}+x_{5;1}-x_{4;4}-x_{4;6}-x_{5;2} & & & & & & \\ x_{1;5}+x_{2;3}+x_{3;1}-x_{2;4}-x_{3;2} & x_{2;4}+x_{2;6}+x_{3;1}-x_{2;5}-x_{3;3} & & & & & & \\ x_{1;5}+x_{2;6}+x_{3;2}-x_{3;3}-x_{4;1} & x_{3;5}+x_{3;6}+x_{4;2}-x_{4;3}-x_{4;4} & & & & & & \\ x_{3;4}+x_{3;6}+x_{5;1}-x_{4;3}-x_{5;2} & x_{3;5}+x_{3;6}+x_{5;1}-x_{4;4}-x_{5;2} & & & & & & \\ x_{2;4}+x_{3;2}-x_{2;5}-x_{3;6}-x_{4;1} & x_{3;2}+x_{3;3}-x_{3;4}-x_{3;6}-x_{4;1} & & & & & & \\ x_{2;4}+x_{3;3}-x_{2;5}-x_{3;6}-x_{4;2} & x_{4;3}+x_{5;1}-x_{4;5}-x_{4;6}-x_{5;2} & & & & & & \\ x_{3;5}+x_{4;3}-x_{4;4}-x_{4;6}-x_{6;1} & x_{4;4}+x_{5;2}-x_{4;5}-x_{5;3}-x_{6;1} & & & & & & \end{array} \right\}.$$

Therefore, ι satisfies the strict positivity assumption by the explicit forms of $\Xi_\iota^{(i)}$ for $1 \leqslant i \leqslant 6$. This shows that

$$\Xi_\iota^{(1)}[\lambda] = \{\lambda_1 - x_{1,1}\},$$

$$\Xi_\iota^{(2)}[\lambda] = \{\lambda_2 + x_{1;1} - x_{1;2},\ \lambda_2 - x_{2;1}\},$$

$$\Xi_\iota^{(3)}[\lambda] = \{\lambda_3 + x_{1;2} - x_{1;3},\ \lambda_2 + x_{2;1} - x_{2;2},\ \lambda_3 - x_{3;1}\},$$

$$\Xi_\iota^{(k)}[\lambda] = \{\lambda_k + \varphi_k(\vec{x}) : \varphi_k(\vec{x}) \in \Xi_\iota^{(k)}\} \quad \text{for } k = 4,5,6$$

by Lemma 2.6 and $\Sigma_\iota[\lambda]$ is the polyhedral realization of $B(\lambda)$.

F. E_7 case

We use the different Cartan data from the one in Ref. 10, where the Cartan matrix $(a_{ij})_{1 \leqslant i,j \leqslant 7}$ is given by

$$a_{ij} := \begin{cases} 2 & \text{if } i = j \\ -1 & \text{if } |i-j| = 1 \text{ and } (i,j) \neq (6,7),(7,6), \text{ or } (i,j) = (4,7),(7,4) \\ 0 & \text{otherwise.} \end{cases}$$

We fix ι as follows:

$$\iota := (\cdots, \underline{7,6,5,4,3,2,1,} \cdots, \underline{7;6;5;4;3;2;1,} \underline{7;6;5;4;3;2;1).}$$

We define

$$\Xi_\iota := \{S_{m_l} \cdots S_{m_2} S_{m_1}(x_{j;1}) ; l \geqslant 0,\ m_1, \cdots, m_l \geqslant 1,\ 1 \leqslant j \leqslant 9\},$$

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}_\iota^\infty : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}.$$

Theorem 3.16: *We give the explicit form of* Ξ_ι *as follows*:

$$\left\{\begin{array}{c}
x_{j;1}\quad x_{j;2}-x_{j+1;1}\quad x_{j;3}-x_{j+1;2}\quad x_{j;4}-x_{j+1;3}\\
x_{j;5}-x_{j+1;7}\quad x_{j;7}-x_{j+1;6}\quad x_{j+2;3}-x_{j+2;5}\quad x_{j;6}-x_{j+5;1}\\
x_{j+3;2}-x_{j+3;7}\quad x_{j+2;7}-x_{j+5;2}\quad x_{j+4;1}-x_{j+4;6}\quad x_{j+3;5}-x_{j+5;3}\\
x_{j+3;6}-x_{j+5;7}\quad x_{j+4;7}-x_{j+5;5}\quad x_{j+6;3}-x_{j+6;4}\quad x_{j+7;2}-x_{j+7;3}\\
x_{j+8;1}-x_{j+8;2}\quad -x_{j+9;1}\\
x_{j;5}+x_{j;7}-x_{j+1;4}\quad x_{j;6}+x_{j;7}-x_{j+1;5}\quad x_{j;6}+x_{j+2;3}-x_{j+2;4}\\
x_{j;6}+x_{j+3;2}-x_{j+3;3}\quad x_{j;6}+x_{j+4;1}-x_{j+4;2}\quad x_{j+2;7}+x_{j+3;2}-x_{j+3;4}\\
x_{j+2;7}+x_{j+4;1}-x_{j+4;3}\quad x_{j+3;5}+x_{j+4;1}-x_{j+4;4}\quad x_{j+3;6}+x_{j+4;1}-x_{j+4;5}\\
x_{j+3;6}+x_{j+4;7}-x_{j+5;4}\quad x_{j+1;4}-x_{j+1;6}-x_{j+1;7}\quad x_{j+1;5}-x_{j+1;6}-x_{j+5;1}\\
x_{j+2;4}-x_{j+2;5}-x_{j+5;1}\quad x_{j+3;3}-x_{j+3;7}-x_{j+5;1}\quad x_{j+3;4}-x_{j+3;7}-x_{j+5;2}\\
x_{j+4;2}-x_{j+4;6}-x_{j+5;1}\quad x_{j+4;3}-x_{j+4;6}-x_{j+5;2}\quad x_{j+4;4}-x_{j+4;6}-x_{j+5;3}\\
x_{j+4;5}-x_{j+4;6}-x_{j+5;7}\quad x_{j+5;4}-x_{j+5;5}-x_{j+5;7}\\
x_{j;6}+x_{j+1;4}-x_{j+1;5}-x_{j+1;7}\quad x_{j+1;5}+x_{j+2;3}-x_{j+1;6}-x_{j+2;4}\\
x_{j+1;5}+x_{j+3;2}-x_{j+1;6}-x_{j+3;3}\quad x_{j+2;4}+x_{j+3;2}-x_{j+2;5}-x_{j+3;3}\\
x_{j+1;5}+x_{j+4;1}-x_{j+1;6}-x_{j+4;2}\quad x_{j+2;4}+x_{j+4;1}-x_{j+2;5}-x_{j+4;2}\\
x_{j+3;3}+x_{j+4;1}-x_{j+3;7}-x_{j+4;2}\quad x_{j+2;7}+x_{j+3;3}-x_{j+3;4}-x_{j+5;1}\\
x_{j+3;4}+x_{j+4;1}-x_{j+3;7}-x_{j+4;3}\quad x_{j+2;7}+x_{j+4;2}-x_{j+4;3}-x_{j+5;1}\\
x_{j+3;5}+x_{j+4;2}-x_{j+4;4}-x_{j+5;1}\quad x_{j+3;6}+x_{j+4;2}-x_{j+4;5}-x_{j+5;1}\\
x_{j+3;5}+x_{j+4;3}-x_{j+4;4}-x_{j+5;2}\quad x_{j+3;6}+x_{j+4;3}-x_{j+4;5}-x_{j+5;2}\\
x_{j+3;6}+x_{j+4;4}-x_{j+4;5}-x_{j+5;3}\quad x_{j+4;5}+x_{j+4;7}-x_{j+4;6}-x_{j+5;4}\\
x_{j+2;7}+x_{j+3;3}+x_{j+4;1}-x_{j+3;4}-x_{j+4;2}\quad x_{j+3;4}+x_{j+4;2}-x_{j+3;7}-x_{j+4;3}-x_{j+5;1}
\end{array}\right\}.$$

Proof: (*i*) By the form of Σ_ι, coefficients of $x_{1;1}$, $x_{1;2}$, $x_{1;3}$, $x_{1;4}$, $x_{1;5}$, $x_{1;6}$, $x_{1;7}$ are positive. This shows that the "positivity assumption" is satisfied.

(*ii*) We assume $x_{j;1}\geqslant 0$ for any $j\geqslant 1$. We show that $x_{j;2}$, $x_{j;3}$, $x_{j;4}$, $x_{j;5}$, $x_{j;6}$, $x_{1;7}\geqslant 0$ for any $j\geqslant 1$. By the form of Σ_ι, we have

$$x_{j;2}\geqslant x_{j+1;1},\quad x_{j;3}\geqslant x_{j+1;2},\quad x_{j;4}\geqslant x_{j+1;3},\quad x_{j;6}\geqslant x_{j+5;1},\quad x_{j;7}\geqslant x_{j+1;6},\quad x_{j;5}\geqslant x_{j+1;7}.$$

This shows $x_{j;2}\geqslant 0$ for $j\geqslant 1$ since $x_{j+1;1}\geqslant 0$ and similarly, we have $x_{j;3}\geqslant 0$, $x_{j;4}\geqslant 0$, $x_{j;6}\geqslant 0$, $x_{j;7}\geqslant 0$, $x_{j;5}\geqslant 0$ for $j\geqslant 1$ since $x_{j;3}\geqslant x_{j+1;2}$, $x_{j;4}\geqslant x_{j+1;3}$, $x_{j;6}\geqslant x_{j+5;1}$, $x_{j;7}\geqslant x_{j+1;6}$, $x_{j;5}\geqslant x_{j+1;7}$, respectively.

(*iii*) We determine when $x_{j;i}\equiv 0$. We have

$$0\geqslant x_{j+9;1}\geqslant 0.$$

This shows $x_{m;1}\equiv 0$ for $m\geqslant 10$. Similarly, we have $x_{m;2}\equiv 0$, $x_{m;3}\equiv 0$, $x_{m;4}\equiv 0$, $x_{m;5}\equiv 0$, $x_{m;6}\equiv 0$, $x_{m;7}\equiv 0$ for $m\geqslant 10$ since $x_{j+8;1}\geqslant x_{j+8;2}$, $x_{j+7;2}\geqslant x_{j+7;3}$, $x_{j+6;3}\geqslant x_{j+6;4}$, $x_{j+2;3}\geqslant x_{j+2;5}$, $x_{j+4;1}\geqslant x_{j+4;6}$, $x_{j+3;2}\geqslant x_{j+3;7}$, respectively. In particular, the parameter j in Ξ_ι runs over $1\leqslant j\leqslant 9$. □

G. E_8 case

We fix ι as follows:

$$\iota := (\ldots,\underline{8,7,6,5,4,3,2,1},\ldots,\underline{8,7,6,5,4,3,2,1},\underline{8,7,6,5,4,3,2,1}).$$

We define

$$\Xi_\iota := \{S_{m_l}\cdots S_{m_2}S_{m_1}(x_{j;1}) : l\geqslant 0, m_1,\ldots,m_l\geqslant 1, 1\leqslant j\leqslant 15\},$$

$$\Sigma_\iota := \{\vec{x} \in \mathbb{Z}_\iota^\infty : \varphi(\vec{x}) \geqslant 0 \text{ for any } \varphi \in \Xi_\iota\}.$$

Theorem 3.17: *We give the explicit form of* Ξ_ι *as follows:*

$$x_{j;1} \quad x_{j;2} - x_{j+1;1} \quad x_{j;3} - x_{j+1;2} \quad x_{j;4} - x_{j+1;3} \quad x_{j;5} - x_{j+1;4}$$

$$x_{j;6} - x_{j+1;8} \quad x_{j;7} - x_{j+6;1} \quad x_{j;8} - x_{j+1;7} \quad x_{j+2;4} - x_{j+2;6} \quad x_{j+2;8} - x_{j+6;2}$$

$$x_{j+3;3} - x_{j+3;8} \quad x_{j+3;6} - x_{j+6;3} \quad x_{j+3;7} - x_{j+6;7} \quad x_{j+4;2} - x_{j+4;7} \quad x_{j+4;8} - x_{j+6;8}$$

$$x_{j+7;5}+x_{j+9;2}-x_{j+7;6}-x_{j+9;3}-x_{j+10;1} \quad x_{j+8;4}+x_{j+9;2}-x_{j+8;8}-x_{j+9;3}-x_{j+10;1}$$

$$x_{j+8;5}+x_{j+9;2}-x_{j+8;8}-x_{j+9;4}-x_{j+10;1} \quad x_{j+8;5}+x_{j+9;3}-x_{j+8;8}-x_{j+9;4}-x_{j+10;2}$$

Proof: (*i*) By the form of Σ_ι, coefficients of $x_{1;1}$, $x_{1;2}$, $x_{1;3}$, $x_{1;4}$, $x_{1;5}$, $x_{1;6}$, $x_{1;7}$, $x_{1;8}$ are positive. This shows that the "positivity assumption" is satisfied.

(*ii*) We assume $x_{j;1} \geqslant 0$ for any $j \geqslant 1$. We show that $x_{j;2}, x_{j;3}, x_{j;4}, x_{j;5}, x_{j;6}, x_{1;7}, x_{1;8} \geqslant 0$ for any $j \geqslant 1$. By the form of Σ_ι, we have

$$x_{j,2} \geqslant x_{j+1;1}, \quad x_{j,3} \geqslant x_{j+1;2}, \quad x_{j;4} \geqslant x_{j+1;3}, \quad x_{j;5} \geqslant x_{j+1;4},$$

$$x_{j;7} \geqslant x_{j+6;1}, \quad x_{j;8} \geqslant x_{j+1;7}, \quad x_{j;6} \geqslant x_{j+1;8}.$$

This shows $x_{j;2} \geqslant 0$ for $j \geqslant 1$ since $x_{j+1;1} \geqslant 0$ and similarly, we have $x_{j;3} \geqslant 0$, $x_{j;4} \geqslant 0$, $x_{j;5} \geqslant 0$, $x_{j;7} \geqslant 0$, $x_{j;8} \geqslant 0$, $x_{j;6} \geqslant 0$ for $j \geqslant 1$ since $x_{j;3} \geqslant x_{j+1;2}$, $x_{j;4} \geqslant x_{j+1;3}$, $x_{j;5} \geqslant x_{j+1;4}$, $x_{j;7} \geqslant x_{j+1;6}$, $x_{j;8} \geqslant x_{j+1;7}$, $x_{j;6} \geqslant x_{j+1;8}$, respectively.

(iii) We determine when $x_{j;i} \equiv 0$. We have

$$0 \geqslant x_{j+15;1} \geqslant 0.$$

This shows $x_{m;1} \equiv 0$ for $m \geqslant 16$. Similarly, we have $x_{m;2} \equiv 0$, $x_{m;3} \equiv 0$, $x_{m;4} \equiv 0$, $x_{m;5} \equiv 0$, $x_{m;6} \equiv 0$, $x_{m;7} \equiv 0$, $x_{m;8} \equiv 0$ for $m \geqslant 16$ since $x_{j+14;1} \geqslant x_{j+14;2}$, $x_{j+13;2} \geqslant x_{j+13;3}$, $x_{j+12;3} \geqslant x_{j+12;4}$, $x_{j+11;4} \geqslant x_{j+11;5}$, $x_{j+7;3} \geqslant x_{j+7;6}$, $x_{j+9;1} \geqslant x_{j+9;7}$, $x_{j+8;2} \geqslant x_{j+8;8}$, respectively. In particular, the parameter j in Ξ_ι runs over $1 \leqslant j \leqslant 15$. □

Remark 3.18: For all simple Lie algebras, the number of $x_{j;i}$'s such that $x_{j;i} \neq 0$ is equal to the length of the longest element of Weyl group.

(Received 20 May 2005; accepted 12 September 2005; published online 10 November 2005)

Cariñena, Rañada, and Santander consider a classical Kepler problem in constant curvature spaces and related theory of conics in these spaces. Here we point out that earlier results exist in the literature. Some of these results date back to the nineteenth and the beginning of the twentieth century. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2107267]

In Ref. 1, Cariñena, Rañada, and Santander deal with a classical Kepler problem on constant curvature spaces. In the Introduction they cite Refs. 2–9 concerning quantum-mechanical version of this problem and related topics. After that they note: "since then, a certain number of authors have studied this question from both the classical (Kepler problem) and the quantum (hydrogen atom) point of view" (here they cite 16 papers from 1985 to 2003). It should be pointed out however that the classical Kepler problem on constant curvature spaces is naturally much older than its quantum analog.

Indeed, the analog of Newton force for the hyperbolic space $\mathbf{H}^3$ was proposed already by Lobachevski (in 1835–1838)[10] as the value $F(\rho)$ which is inverse to the area of the sphere of radius ρ in the space $\mathbf{H}^3$ with an attractive body in the center. An analytical expression for the Newtonian potential in $\mathbf{H}^3$ was written in 1870 by Schering[11] (see also his paper[12] of 1873).

In 1873 Lipschitz considered a one-body motion in a central potential on the sphere $\mathbf{S}^2$.[13] Although he knew the central potential, satisfying the Laplace equation in the space $\mathbf{S}^3$, he preferred to consider another central potential $V(\rho) \sim \sin^{-1}(\rho/R)$, where R is the curvature radius. He found a general solution to this problem in terms of elliptic functions.

In 1885 Killing found a generalization of all three Kepler laws to the case of a sphere $\mathbf{S}^3$.[14] He considered an attractive force as an inverse area of a two-dimensional sphere in $\mathbf{S}^3$, as Lobachevski did before. In 1886, similar results were published by Neumann.[15]

The extension of these results to the hyperbolic case was carried out by Liebman in Ref. 16 in 1902, and later in 1905 in his book on non-Euclidean geometry.[17] Note that he started from ellipses in $\mathbf{S}^3$ or $\mathbf{H}^3$, and derived a potential in such a way that the first Kepler law would be valid. He also derived the generalization of the oscillator potential for these spaces from the requirement that a particle motion occur along the ellipse with its center coinciding with the center of the potential.

The well-known Bertrand theorem[18] states that there are only two central potentials in Euclidean space that make all bounded trajectories of a one-particle problem closed. Its generalization for spaces $\mathbf{S}^2$ and $\mathbf{H}^2$ was proved by Liebman in 1903.[19]

One may regard classical mechanics in spaces of constant curvature as a predecessor of special and general relativity. After the rise of these theories the above-mentioned papers of Schering, Killing, and Liebmann were almost completely forgotten. Note that the description of a particle motion in central potentials in spaces $\mathbf{S}^3$ and $\mathbf{H}^3$ was shortened in the second and third

[a)]Electronic mail: quant@phys.msu.su

editions of the Liebman book[17] with respect to the first one in favor of special relativity. Similar models attracted attention later from the point of view of quantum mechanics and theory of integrable systems.

Equation (4) from Ref. 1, which is used there for an analysis of trajectories, is not a new one. Its equivalent form for different types of trajectories is presented in Ref. 16 (hyperbolic case) and later in Ref. 20 (spherical case).

Two ideas appearing in Ref. 1—the description of the spherical, hyperbolic and Euclidean cases in a uniform way with the sectional curvature κ as a parameter, and the conic nature of trajectories for the Kepler problem in constant curvature spaces—can be found in earlier literature. The first one is presented in Ref. 21, where one can also find a history of the problem prior to Schrödinger's paper.[2] The second idea was explored in Liebmann's paper,[16] and is also presented in Ref. 21.

Section V of Ref. 1 describes a theory of conics in constant curvature two-dimensional spaces, but the authors do not provide references. Note that this theory was developed as early as 1883.[22] A lot of relevant information on this theory can be found also in Refs. 16, 17, 21, and 23.

Shchepetilov starts pointing out that many references in Ref. 3 are related to Quantum Mechanics. Nevertheless this is a characteristic, not only of Ref. 3, but of many of the research papers written along the second half of the twentieth century, because it is well known that, in the study of integrable systems, classical and quantum properties are very closely related.

The first part of the comment provides historical precision on research made on the Kepler problem in the second half of the nineteenth century. This is interesting information that, unfortunately, has remained as completely forgotten for many years (we are talking of Mathematical Physics, perhaps the situation is different in the History of Science circles). This is indeed a matter of fact. Look at the paper *"Dynamical symmetries in a spherical geometry I"*[8] by Higgs that has been considered, since its publication 25 years ago, as one of the most important and cited papers on this matter: it has 20 references but no mention of any of the old papers of Lobachevski, Schering, Lipschitz, Killing, etc. Moreover, we did not find any of these references in Rosenfeld's book.[14] In any case, this question seems more related with the history of mathematics than with the actual mathematics or physics.

It seems that corresponds to Dombrowski and Zitterbarth's "rediscovery" of all these nineteenth century results in Ref. 6 that seems to be a summary of the Ph. D. thesis[16] of the second author (the comment by Shchepetilov is very closely related with the first part of this paper). These authors start with a fully detailed survey, quoting results by Bolyai, Dirichlet, Lipschitz, Beltrami, Schering, Killing, and Liebmann (spanning from 1848 to 1905), and then write "In many cases these statements are … rather incomplete, sometimes not presented in an optimal form, or their proofs are not quite sufficient resp. rather 'out of date' since several appropriate tools … were not available … . So we thought it to be worthwhile to make these (wonderful, classical) results and proofs of them accessible in a rather rigid and complete version … ." The situation they describe is thus the following: whereas some old results on the non-Euclidean Kepler problem were stated or demonstrated at different places in the literature prior to 1905, no complete, accessible and modern presentation was available when Ref. 6 was written.

Concerning the last three paragraphs, focused on three particular aspects of Ref. 3, we must first say that Ref. 3 has, roughly speaking, two parts (as mentioned in the paper's title): the first one devoted to the geodesic motion, the theory of symmetries and the general theory of central potentials with constant curvature $\kappa \neq 0$, and the second one, more specific, devoted to the Kepler problem as a particular case. We consider Secs. II and III as important, not only from the structure of the paper but also because of the results obtained (the equation of Binet is obtained for all the central potentials and for all the values of κ and not just for the Kepler problem on a particular

space). Shchepetilov restricts his comments to the second part of Ref. 3 and completely ignores the first one; we think that this can give a partial image of Ref. 3. Next we consider the last three paragraphs.

(i) All the mathematical expressions are presented using the curvature κ as a parameter. Thus, some previous results, obtained in some cases for the sphere and in others for the hyperbolic plane, arise now as particular cases of this more general κ-dependent situation. Section II of Ref. 9 contains some equations that coincide (after the appropriate changes of notation) with the $\kappa=1$ value of κ-dependent expressions in Ref. 3 (by the way, Ref. 9 has five references and none of them are related with the above-mentioned mathematicians of the second half of the nineteenth century).

(ii) The technique of introducing the curvature κ as a parameter for the joint analysis of the dynamics in the three manifolds $(S^2_\kappa, E^2, H^2_\kappa)$ has been systematically used in some of our previous papers (see, e.g., Refs. 11–13) not only for the Kepler problem but for other superintegrable systems. Moreover, in some previous papers of one of the authors, which are related to the Cayley-Klein geometries (they start with Refs. 1 and 2 and continue until recent papers such as Refs. 7 and 10), this technique is used, not just with one single parameter κ, but with *two parameters*, κ_1, κ_2, which correspond to a space M_{κ_1,κ_2} with constant curvature κ_1 and signature $(+1, \kappa_2)$. This formalism is more general and it includes the κ-dependent formalism used in Ref. 3 as the particular case $\kappa_1=\kappa$ and $\kappa_2=1$ (the "Lorentzian" version of the Kepler problem depending on the two parameters, κ_1 and κ_2, is studied in Ref. 4).

(iii) It is true that Sec. V does not have references but it is also true that the total number of references in Ref. 3 is 44 (not only the references mentioned by Shchepetilov in his introductory paragraph). The article of Story is written from a geometrical projective viewpoint and without any mechanical application, and its approach is very different from the metric approach to conics presented in Ref. 3. The situation is similar to the book by Coolidge,[5] so it seems out of place to quote them. The Liebmann books include a study of hyperbolic conics, but, aside from its role in the history of geometry, Dombrowski and Zitterbarth suggest that the list of types of Kepler orbits given by Liebmann for the hyperbolic plane was not known for sure to be complete (we recall that they consider this book as important but *"rather incomplete, sometimes not presented in an optimal form, …"* for the present time reader). Finally, we note that Dombrowski and Zitterbarth, in spite of their interest in old references, do not mention either the paper by Story[15] or the book of Klein.

Constraints on the mixing of bipartite states

Hao Chen[a)]
Department of Computing and Information Technology, Fudan University, Shanghai 200433, People's Republic of China

(Received 31 January 2005; accepted 11 October 2005; published online 13 December 2005)

A mixed state may be represented in many different ways as a mixture of pure states $\rho=\Sigma p_i|\psi_i\rangle\langle\psi_i|$. The mixing problem in quantum mechanics asks the characterization of the probability distribution (p_i) and the mixed states (ρ_i) such that $\rho=\Sigma p_i\rho_i$ for any given mixed state ρ. Some constraints based on eigenvalues of the mixed states are established in uni-party case [see Nielsen, Phys. Rev. A. **63**, 052308 (2000), **63**, 022144 (2000), Nielsern and Vidal Quantum Inf. Comput. **1** 76 (2001)]. We develop some new invariant sets for bipartite mixed states under local unitary operations, which are independent of eigenvalues, and prove some strong constraints based on these invariant sets for the mixing problem in bipartite case. This exhibits a remarkable difference from the uni-party case. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2138048]

I. INTRODUCTION

A feature of quantum mechanics is that every mixed state can be represented as an ensemble of pure states $\{p_i,|\psi_i\rangle\}$ in many different ways. An important problem in quantum mechanics is the following mixing problem: for any given mixed state ρ to characterize the probability distribution (p_i) and the mixed states (ρ_i) such that $\rho=\Sigma p_i\rho_i$. In the context of quantum information processing, the action of mixing $\{p_i,\rho_i\}\rightarrow\rho=\Sigma p_i\rho_i$ corresponds to the erasure of information concerning the identity of a member of the ensemble (see Refs. 1 and 2). Thus it is interesting to characterize this process of mixing of quantum states. In the uni-party case there is the so-called "ensemble classification theorem" of Schrödinger, which established a connection via a unitary matrix between two ensembles representing the same mixed state(Refs. 1 and 3). From the work in Refs. 4, 5, and 1, we know the constraint $(p_i)\prec\lambda(\rho)$ on the ensemble $\{p_i,|\psi_i\rangle\}$ such that $\rho=\Sigma p_i|\psi_i\rangle\langle\psi_i|$, where $\lambda(\rho)$ is the eigenvalue vector of the mixed state ρ and $\prec$ is the majorization. Here we recall the definition of the majorization (Refs. 4, 5, and 1). (p_i) and $\lambda(\rho)$ are rearranged in decreasing order as $(p_1^{\downarrow},\ldots,p_d^{\downarrow})$ and $(\lambda_1^{\downarrow},\ldots,\lambda_d^{\downarrow})$, we say $(p_i)\prec\lambda(\rho)$ if

$$\begin{aligned} p_1^{\downarrow} &\leqslant \lambda_1^{\downarrow}, \\ p_1^{\downarrow}+\cdots+p_k^{\downarrow} &\leqslant \lambda_1^{\downarrow}+\cdots+\lambda_k^{\downarrow} \\ p_1^{\downarrow}+\cdots+p_d^{\downarrow} &= \lambda_1^{\downarrow}+\cdots+\lambda_d^{\downarrow}. \end{aligned} \tag{1}$$

For the process of mixing of general quantum states $\{p_i,\rho_i\}\rightarrow\rho=\Sigma p_i\rho_i$ the constraint $\lambda(\rho)\prec\Sigma p_i\lambda(\rho_i)$ must be hold. Further analysis about the ensemble $\{p_i,|\psi_i\rangle\}$ representing ρ was presented in Ref. 6.

It is natural to consider the mixing problem in bipartite (or general multipartite) case from the theoretical view and the motivation of quantum information processing. As is well known, much of the difficulty for a complete understanding of the bipartite mixed state entanglement can be

[a)]Electronic mail: chenhao1964cn@yahoo.com.cn

traced to the basic fact that there are infinitely many ways of viewing a bipartite mixed state ρ as an ensemble of pure states $\rho=\Sigma p_i|\psi_i\rangle\langle\psi_i|$. For the purpose of understanding the entanglement of the bipartite mixed state ρ it is always useful to know the constraints on the pure states $|\psi_i\rangle$'s in the ensemble. Thus we hope to find as many constraints as possible on the mixing process of bipartite quantum states $\{p_i,\rho_i\}\rightarrow\rho=\Sigma p_i\rho_i$, where p_i is a probability distribution and $(\rho_i),\rho$ are mixed states on $H_A^m\otimes H_B^n$.

We can have some constraints of the mixing problem for bipartite states from some previous known results and invariants. First we can trace over A or B for the mixing of bipartite states $\rho=\Sigma p_i\rho_i$ and then apply the known constraints in the uni-party case to get the constraints in the bipartite case. On the other hand, it is clear that there is at least one entangled pure state $|\psi_i\rangle$ in the ensemble $\{p_i,|\psi_i\rangle\}$ representing an entangled bipartite mixed state ρ. For a bipartite mixed state ρ, it has Schmidt number k if and only if for any decomposition $\rho=\Sigma_i p_i|v_i\rangle\langle v_i|$ for positive real number p_i's and pure state $|v_i\rangle$'s, at least one the of $|v_i\rangle$'s has its Schmidt rank at least k, and there exists such a decomposition with all pure state $|v_i\rangle$'s Schmidt rank at most k (see Ref. 7). Generally speaking if the Schmidt number of ρ is k, then there is at least one pure state $|\psi_i\rangle$ with Schmidt rank at least k for the ensemble $\{p_i,|\psi_i\rangle\}$ representing ρ. This kind of constraint is a feature of the bipartite case. Of course people can have more constraints on the mixing of bipartite states based on, e.g., formation of entanglement, etc. However it is difficult to calculate invariants such as Schmidt number and formation of entanglement, thus these kinds of constraints in the bipartite case are quite restrictive in application.

For the mixing process $\{p_i,\rho_i\}\rightarrow\rho=\Sigma p_i\rho_i$, it is clear $U\rho U^\dagger=\Sigma p_i U\rho_i U^\dagger$ ($\dagger$ is the adjoint) for any unitary operation U on the system. Thus the mixing problem in the uni-party case is actually about the equivalence classes of mixed states under unitary operations, and the constraints should be based on the invariants of mixed states under unitary operations. It is clear that for bipartite mixed states $\rho=\Sigma p_i\rho_i$ is equivalent to $(U_1\otimes U_2)\rho(U_1\otimes U_2)^\dagger=\Sigma p_i(U_1\otimes U_2)\rho_i(U_1\otimes U_2)^\dagger$ for any local unitary operation $U_1\otimes U_2$ on the bipartite system. Thus when the mixing problem is considered in the bipartite case, it is actually about the equivalence classes of mixed states under local unitary operations, and the constraints should be based on the invariants of bipartite mixed states under local unitary operations. In the uni-party case it is well known that there are exactly $n-1$ invariants (i.e., n eigenvalues sum up to 1) of a mixed state on H^n under the group of unitary operations [i.e., $n-1=$dim (the space of all mixed states)-dim(the group of unitary operations) $=n(n+1)/2-1-n(n-1)/2$]. Thus it is natural that the previous known constraints in Refs. 4, 5, and 1 are based on these invariants. For bipartite mixed states on $H_A^m\otimes H_B^n$, it is known that there are $m^2n^2-m^2-n^2+1$ nonlocal invariants under local unitary operations.[8] These nonlocal invaraints have not been constructed explicitly, however we can speculate that there would be many constraints on the mixing of bipartite states based on the nonlocal invariants.

In this paper we develop some new invariant sets of bipartite mixed states under local unitary operations, which are independent of eigenvalues. These invariant sets are natural from the physical consideration of measuring mixed states by separable pure states. Some strong constraints (thus independent of eigenvalues) on the mixing of bipartite states based on these invariant sets are proved. From these constraints based on invariant sets it is easy to have constraints based on numerical quantities derived from these invariant sets (here we note that these numerical quantities are invariant under local unitary operations). Since these invariants can be computed easily it is convenient to use these constraints as illustrated in the examples to follow. Moreover the constraints are imposed on each member ρ_i appearing in $\rho=\Sigma p_i\rho_i$ and are independent of the probability distribution (p_i). Therefore they are essentially a feature of the bipartite case.

II. CONSTRAINTS BASED ON $L_A(\rho)$ AND $L_B(\rho)$

For any given bipartite mixed state ρ on $H_A^m\otimes H_B^n$, we can define $L_A(\rho)$ [respectively, $L_B(\rho)$] (the subspaces of H_A^m and H_B^n) as follows.

Definition 1:

$$L_A(\rho)=\{|a\rangle\in H_A^m:\langle a\otimes x|\rho|a\otimes x\rangle=0,\ \forall\ |x\rangle\in H_B^n\},\tag{2}$$

$$L_B(\rho) = \{|b\rangle \in H_B^n : \langle x \otimes b|\rho|x \otimes b\rangle = 0, \forall\, |x\rangle \in H_A^m\}. \tag{3}$$

It is clear $\langle a\otimes x|\rho|a\otimes x\rangle=0$ if and only if $|a\rangle\otimes|x\rangle$ is orthogonal to the range of ρ since ρ is Hermitian. Thus $L_A(\rho)$ [respectively, $L_B(\rho)$] is the linear subspace of H_A^m (respectively, H_B^m). We should note that $L_A(\rho)$ [respectively, $L_B(\rho)$] is completely determined by the range of the mixed state ρ, thus it only depends on the eigenstates of ρ and does not depend on the nonzero eigenvalues of ρ.

Since

$$\langle a \otimes b|(U_A \otimes U_B)\rho(U_A \otimes U_B)^\dagger|a \otimes b\rangle = \langle \left(U_A^\dagger a\right) \otimes \left(U_B^\dagger b\right)|\rho|\left(U_A^\dagger a\right) \otimes \left(U_B^\dagger b\right)\rangle, \tag{4}$$

we have

$$L_A((U_A \otimes U_B)\rho(U_A \otimes U_B)^\dagger) = U_A^\dagger(L_A(\rho)). \tag{5}$$

Similarly $L_B((U_A\otimes U_B)\rho(U_A\otimes U_B)^\dagger)=U_B^\dagger(L_B(\rho)))$, i.e., the dimensions of $L_A(\rho)$ and $L_B(\rho)$ are invariant under local unitary operations. It is easy to verify that $L_A(\rho)=\ker(\mathrm{Tr}_B(\rho))$ and $L_B(\rho)=\ker(\mathrm{Tr}_A(\rho))$. These subspaces have been used to give lower bound for Schmidt numbers of low-rank bipartite mixed states in Ref. 9.

For a pure state $\rho=|\psi\rangle\langle\psi|$, from the invariance under local unitary operations, we can compute $L_A(\rho)$ and $L_B(\rho)$ from the Schmidt decomposition of $|\psi\rangle=\Sigma_{i=1}^k p_i|a_i\rangle\otimes|b_i\rangle$. We have $\langle a\otimes b|\rho|a\otimes b\rangle=\Sigma_{i=1}p_i^2|\langle a|a_i\rangle\langle b|b_i\rangle|^2=0$ implies that $L_A(\rho)$ [respectively, $L_B(\rho)$] is the orthogonal complementary in H_A^m of the space span by pure states $|a_i\rangle$'s (respectively, $|b_i\rangle$'s). Thus the Schmidt rank k of the pure state ρ is just the codimensions of the linear subspaces of $L_A(\rho)$ and $L_B(\rho)$.

If $\rho=\Sigma p_i|\psi_i\rangle\langle\psi_i|$ with $p_i>0$, we have the following equation $\langle a\otimes x|\rho|a\otimes x\rangle=\Sigma p_i|\langle a\otimes x|\psi_i\rangle|^2$. Thus

$$\begin{aligned} L_A(\rho) &= \cap L_A(|\psi_i\rangle\langle\psi_i|), \\ L_B(\rho) &= \cap L_B(|\psi_i\rangle\langle\psi_i|). \end{aligned} \tag{6}$$

The following result is the main result of this section.

Theorem 1: *For any given mixed state ρ on $H_A^m\otimes H_B^n$ and an ensemble $\{p_i,|\psi_i\rangle\}$ such that $\rho=\Sigma p_i|\psi_i\rangle\langle\psi_i|$, we have:*

1) *Let $s(|v\rangle)$ be the Schmidt rank of the pure state $|v\rangle$,*

$$s(|\psi_i\rangle) \leqslant \min\{m - \dim(L_A(\rho)), n - \dim(L_B(\rho))\}. \tag{7}$$

2) *For any $r=\mathrm{rank}(\rho)$ linearly independent pure states $|\psi_{i_1}\rangle,\ldots,|\psi_{i_r}\rangle$ in the ensemble,*

$$\sum_{j=1}^r s(|\psi_{i_j}) \geqslant \max\{m - \dim(L_A(\rho)), n - \dim(L_B(\rho))\}. \tag{8}$$

Proof: We have $L_A(\rho)=\cap L(|\psi_i\rangle\langle\psi_i|)$, thus $\dim(L_A(\rho))\leqslant\dim(L_A(|\psi_i\rangle\langle\psi_i|))$ and the Schmidt rank $s(|\psi_i\rangle)=m-\dim(L_A(|\psi_i\rangle\langle\psi_i|)\leqslant m-\dim(L_A(\rho))$. Similarly we have the Schmidt rank $s(|\psi_i\rangle)\leqslant n-\dim(L_B(\rho))$. The conclusion of 1 is proved.

Because $|\psi_{i_1}\rangle,\ldots,|\psi_{i_r}\rangle$ are linearly independent, they span the range of ρ. From the fact that $\langle a\otimes x|\rho|a\otimes x\rangle=0$ is equivalent to the fact that $|a\rangle\otimes|x\rangle$ is orthogonal to the range of ρ, we have $L_A(\rho)=\cap_{j=1}^r L_A(|\psi_{i_j}\rangle\langle\psi_{i_j}|)$. Thus $\mathrm{codim}(L_A(\rho))\leqslant\Sigma_{j=1}^r\mathrm{codim}(L_A(|\psi_{i_j}\rangle\langle\psi_{i_j}|))$, then $m-\dim(L_A(\rho))\leqslant\Sigma_{j=1}^r s(|\psi_{i_j})$. Similarly we have $n-\dim(L_B(\rho))\leqslant\Sigma_{j=1}^r s(|\psi_{i_j})$. The conclusion is proved.

We can have another proof of conclusion 1 of Theorem 1 from the previous known constraint in uni-party case (see Ref. 5 and 1). First by the trace over B of $\rho=\Sigma p_i|\psi_i\rangle\langle\psi_i|$, we get $\mathrm{Tr}_B(\rho))=\Sigma p_i\mathrm{Tr}_B(|\psi_i\rangle\langle\psi_i|)$. Thus $\lambda(\mathrm{Tr}_B(\rho))\prec\Sigma p_i\lambda(\mathrm{Tr}_B(|\psi_i\rangle\langle\psi_i|))$ from the constraint in the uni-party case. If the codimension of $L_A(|\psi_i\rangle\langle\psi_i|)=\ker(Tr_B(|\psi_i\rangle\langle\psi_i|))$ is bigger than the codimension of $L_A(\rho)=\ker(Tr_B(\rho))$, there are more non zeros in the vector $\Sigma p_i\lambda(\mathrm{Tr}_B(|\psi_i\rangle\langle\psi_i|))$ than in the vector

$\lambda(\mathrm{Tr}_B(\rho))$. This is a contradiction to the fact $\lambda(\mathrm{Tr}_B(\rho)) < \Sigma p_i \lambda(\mathrm{Tr}_B(|\psi_i\rangle\langle\psi_i|))$. Thus Theorem 1.1 can be derived from the previous known constraint, however our proof here is more transparent.

Example 1: We consider the mixed state $\rho = T_1 \otimes T_2$ on $H_A^m \otimes H_B^n$, where T_1 and T_2 are the mixed states on H_A^m and H_B^n, respectively, satisfying the condition that the rank of T_1 is 1 (or the rank of T_2 is 1). It is clear that ρ is separable. However we know from Theorem 1.1 that for any ensemble $\{p_i, |\psi_i\rangle\}$ representing ρ, the pure states $|\psi_i\rangle$'s are separable. It is easy to verify that the rank of $\mathrm{Tr}_B(\rho)$ [or of $\mathrm{Tr}_A(\rho)$] is 1, thus the conclusion follows from Theorem 1.1 immediately.

Example 2: Let $\rho = \frac{1}{2}(|\psi_1\rangle\langle\psi_1| + |\psi_2\rangle\langle\psi_2|)$ be a mixed state of rank 2 on $H_A^m \otimes H_B^n$ (assume $m \leqslant n$ without loss of generality), where $|\psi_1\rangle$ is a pure state with Schmidt rank m and $|\psi_2\rangle$ is an arbitrary pure state not equal to $|\psi_1\rangle$. From the fact $L_A(|\psi_1\rangle\langle\psi_1|) = \{0\}$ we know $L_A(\rho) = \{0\}$. From Theorem 1.2), for any ensemble $\{p_i, |\phi_i\rangle\}$ representing ρ, we know that the sum of the Schmidt ranks of any two distinct pure states in the ensemble is at least m, that is, except for one pure state, all other pure states in the ensemble have their Schmidt ranks at least $m/2$. This implies that the Schmidt number of ρ is at least $m/2$.

III. CONSTRAINTS BASED ON $L_A^k(\rho)$ AND $L_B^k(\rho)$

We can see that the invariance of the dimensions of the linear subspaces $L_A(\rho)$ and $L_B(\rho)$ under the local unitary operations is derived from the symmetry of the bilinear form $\langle a \otimes x|\rho|a \otimes x\rangle$ under local unitary operations. Thus the idea about $L_A(\rho)$ [respectively, $L_B(\rho)$] can be extended as follows.

Definition 2: Let ρ be a mixed state on $H_A^m \otimes H_B^n$. For non-negative integers $k = 0, 1, \ldots, n-1$, we define $L_A^k(\rho)$ to be the set $|a\rangle \in H_A^m$, such that the Hermitian semi-positive bilinear form $\langle a \otimes x|\rho|a \otimes x\rangle$ ($|x\rangle \in H_B^n$ is considered as the variable, $|a\rangle$ is fixed) has its rank at most k. That is

$$L_A^k(\rho) = \{|a\rangle \in H_A^m : \mathrm{rank}(\langle a \otimes x|\rho|a \otimes x\rangle) \leqslant k\}. \tag{9}$$

Here $\langle a \otimes x|\rho|a \otimes x\rangle$ for a fixed $|a\rangle$ is considered as a bilinear form on H_B^n.

Similarly the set $L_B^k(\rho) \subseteq H_B^n$ can be defined for $k = 0, 1, \ldots, m-1$. It is clear that $L_A^0(\rho) = L_A(\rho)$ and $L_B^0(\rho) = L_B(\rho)$. From (4) we have $L_A^k((U_A \otimes U_B)(\rho)(U_A \otimes U_B)^\dagger) = U_A^\dagger(L_A^k(\rho))$ [respectively, $L_B^k((U_A \otimes U_B)(\rho)(U_A \otimes U_B)^\dagger) = U_B^\dagger(L_B^k(\rho))$]. $L_A^k(\rho)$ [respectively, $L_B^k(\rho)$] is the subset of H_A^m (respectively, H_B^n), which is invariant (up to unitary transformations of the ambient space) under local unitary operations.

Now we want to see how to calculate these invariant subsets by coordi nate forms. We use the standard basis $\{|11\rangle, |12\rangle, \ldots |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle\}$ of $H = H_A^m \otimes H_B^n$. Take

$$\rho = \sum_{l=1}^{t} p_l |v_l\rangle\langle v_l| \tag{10}$$

to be any given representation of ρ as a convex combination of projections with $p_1 > 0, \ldots, p_t > 0$. Suppose

$$|v_l\rangle = \sum_{i,j=1}^{m,n} a_{ijl} |ij\rangle. \tag{11}$$

Consider

$$A = (a_{ijl})_{1 \leqslant i \leqslant m, 1 \leqslant j \leqslant n, 1 \leqslant l \leqslant t} \tag{12}$$

as the $mn \times t$ matrix with mn rows corresponding to the standard basis $\{|11\rangle, \ldots, |1n\rangle, \ldots, |m1\rangle, \ldots, |mn\rangle\}$ and t columns corresponding to the expansions of $|v_1\rangle, \ldots |v_t\rangle$ with respect to this basis as in (11). It is clear that the matrix of ρ with respect to the standard basis is $APA^\dagger$, where P is the $t \times t$ diagonal matrix with diagonal entries $p_1, \ldots, p_t$.

Let A_i be the ith block $n \times t$ submatrix of A corresponding to the $A|i1\rangle, \ldots, |in\rangle$ rows. For any $|a\rangle = \Sigma_{i=1}^m r_i |i\rangle \in H_A^m$, we have

$$\langle a\otimes x|\rho|a\otimes x\rangle=\langle x|\Big(\sum_{i=1}^{m} r_iA_i\Big)P\Big(\sum_{j=1}^{m} r_jA_j\Big)^{\dagger}|x\rangle. \tag{13}$$

Thus for any fixed $|a\rangle=\Sigma_{i=1}^{m}r_i|i\rangle\in H_A^m$ the matrix of the bilinear form $\langle a\otimes x|\rho|a\otimes x\rangle$ (considered as a bilinear form on $|x\rangle\in H_B^n$, with respect to the base $\{|1\rangle,\ldots,|n\rangle\}$) is $\Sigma_{i,j=1}^{m}r_ir_j^{\dagger}A_iPA_j^{\dagger}=(\Sigma_{i=1}^{m}r_iA_i)P(\Sigma_{i=1}^{m}r_iA_i)^{\dagger}$. On the other hand, we know that $\mathrm{rank}((\Sigma_{i=1}^{m}r_iA_i)P(\Sigma_{i=1}^{m}r_iA_i)^{\dagger}))\leqslant k$ is equivalent to $\mathrm{rank}(\Sigma_{i=1}^{m}r_iA_i)\leqslant k$ because P is strictly positive definite. Therefore

$$L_A^k(\rho)=\Big\{r_1|1\rangle+\cdots+r_m|m\rangle\in H_A^m:\mathrm{rank}\Big(\sum_{i=1}^{m} r_iA_i\Big)\leqslant k\Big\}. \tag{14}$$

Thus $L_A^k(\rho)=\{\ r_1|1\rangle+\ldots+r_m|m\rangle\in H_A^m$: the determinants of all $(k+1)\times(k+1)$ submatrices of $(\Sigma_{i=1}^{m}r_iA_i)$ are zero$\}$. Similarly we have

$$L_B^k(\rho)=\Big\{r_1|1\rangle+\cdots+r_n|n\rangle\in H_B^n:\mathrm{rank}\Big(\sum_{i=1}^{n} r_iB_i\Big)\leqslant k\Big\}. \tag{15}$$

Thus $L_B^k(\rho)=\{\ r_1|1\rangle+\cdots+r_n|n\rangle\in H_B^n$: the determinants of all $(k+1)\times(k+1)$ submatrices of $(\Sigma_{i=1}^{n}r_iB_i)$ are zero $\}$, where $B_i, i=1,\ldots,n$, are defined similarly. In this way we can see that $L_A^k(\rho)$'s and $L_B^k(\rho)$'s are the zero locus of some homogeneous polynomials in H_A^m and H_B^n.

These kinds of subsets can be understood as subsets in the complex projective spaces $P(H_A^m)=CP^{m-1}$ and $P(H_B^n)=CP^{n-1}$ since their defining equations are homogeneous, and are called determinantal varieties in Algebraic Geometry (see Ref. 10). We should emphasize that these homogeneous polynomials are independent of these positive real numbers p_i's and only dependent on the pure states $|v_l\rangle$'s. In the case $k=0$ the defining homogeneous polynomials of $L_A^0(\rho)$ and $L_B^0(\rho)$ are of degree 1, thus they are subspaces. For general $k, L_A^k(\rho)$ and $L_B^k(\rho)$ are just (algebraic) subsets of H_A^m and H_B^n defined as the zero locus of some homogeneous polynomials. From the invariance under local unitary operations we know that the geometric properties of $L_A^k(\rho)$ [respectively, $L_B^k(\rho)$, considered as subset of the complex projective spaces], such as their volumes, dimensions, etc., are invariants of the mixed states under local unitary operations.

If we take the spectral decomposition of $\rho=\Sigma_i\lambda_i|\phi_i\rangle\langle\phi_j|$, where λ_i's and $|\phi_i\rangle$'s are eigenvalues and eigenstates, and then compute $L_A^k(\rho), k=0,1,\ldots n-1$ [respectively, $L_B^k(\rho), k=0,1,\ldots,m-1$] as above, it is clear that these invariant sets under local unitary operations are computed from the eigenstates and thus independent of eigenvalues of the mixed state. Therefore the following constraints on the mixing of bipartite mixed states are independent of eigenvalues.

Theorem 2: *Let ρ,ρ_i be bipartite mixed states on $H_A^m\otimes H_B^n$ and p_i's be positive real numbers. Suppose $\rho=\Sigma p_i\rho_i$. Then $L_A^k(\rho)\subseteq L_A^k(\rho_i), k=0,1,\ldots,n-1$ and $L_B^k(\rho)\subseteq L_B^k(\rho_i), k=0,1,\ldots,m-1$ for any possible index i.*

Proof: Let $\rho_i=\Sigma\lambda_j^i|\psi_j^i\rangle\langle\psi_j^i|$ be the spectral decomposition of the mixed state ρ_i. Then $\rho=\Sigma p_i\rho_i=\Sigma_{i,j}p_i\lambda_j|\psi_j^i\rangle\langle\psi_j^i|$ with $p_i\lambda_j>0$. We know that $L_A^k(\rho)$ can be computed from the matrix Σr_iA_i, where A_i's are defined from the pure states $|\psi_j^i\rangle$'s as in (13). On the other hand $L_A^k(\rho_i)$ can be computed from the matrix $\Sigma r_iA_i'$, where A_i''s are defined from the pure states $|\psi_j^i\rangle$'s for the fixed i as in (13). Thus it is clear that the matrix $\Sigma r_iA_i'$ is the submatrix of $\Sigma_i r_iA_i$ and $\mathrm{rank}(\Sigma r_iA_i)\leqslant k$ implies $\mathrm{rank}(\Sigma r_iA_i')\leqslant k$. We have $L_A^k(\rho)\subseteq L_A^k(\rho_i)$. The conclusion $L_B^k(\rho)\subseteq L_B^k(\rho_i)$ can be proved similarly.

If we consider the $L_A(\rho)$'s as algebraic subsets of the projective space, then the constraints

$$\begin{aligned}\mathrm{volume}\big(L_A^k(\rho)\big)&\leqslant\mathrm{volume}\big(L_A^k(\rho_i)\big),\\ \mathrm{dimension}\big(L_A^k(\rho)\big)&\leqslant\mathrm{dimension}\big(L_A^k(\rho_i)\big)\end{aligned} \tag{16}$$

[respectively, about $L_B^k(\rho)$] if $\rho=\Sigma p_i\rho_i$ with $p_i>0$ follows from Theorem 2 directly. Here we should note that the volume and dimension of $L_A^k(\rho)$ [respectively, $L_B^k(\rho)$] are invariants of the mixed states ρ under local unitary operations.

Example 3: Let $\rho_{BP}=\frac{1}{4}(|\psi_1\rangle\langle\psi_1|+\cdots+|\psi_4\rangle\langle\psi_4|)$ be a mixed state on $H_A^3\otimes H_B^3$ of rank 4, where

$$|\psi_1\rangle=m|11\rangle+s|31\rangle+n|22\rangle,$$

$$
\begin{aligned}
|\psi_2\rangle &= b|12\rangle + a|21\rangle + c|32\rangle,\\
|\psi_3\rangle &= n^*|11\rangle + t|13\rangle - m^*|22\rangle,\\
|\psi_4\rangle &= -a^*|12\rangle + b^*|21\rangle + d|23\rangle
\end{aligned}
\tag{17}
$$

for suitable chosen parameters. This is just the mixed states constructed in Ref. 11. It is proved there that for randomly chosen parameters ρ_{BP} is PPT entangled mixed state.

From the above noted computation we know that $L_A^2(\rho_{BP})$ is defined by the condition $\mathrm{rank}(\Sigma r_i A_i) \leqslant 2$, where $\Sigma r_i A_i$ can be computed from the above four pure states as the following:

$$
\begin{pmatrix}
mr_1 + sr_3 & ar_2 & n^* r_1 & b^* r_2\\
nr_2 & br_1 + cr_3 & -m^* r_2 & -a^* r_1\\
0 & 0 & tr_1 & dr_2
\end{pmatrix}.
\tag{18}
$$

We can check that the point $(r_1, r_2, r_3) = (0, 1, -1)$ is not in $L_A^2(\rho_{BP})$ for randomly chosen parameters.

Consider the following five pure states $|\phi_1\rangle, \ldots, |\phi_5\rangle$ in $H_A^3 \otimes H_B^3$, where

$$
\begin{aligned}
|\phi_1\rangle &= \frac{1}{\sqrt{2}}(|11\rangle - |12\rangle),\\
|\phi_2\rangle &= \frac{1}{\sqrt{2}}(|13\rangle - |23\rangle),\\
|\phi_3\rangle &= \frac{1}{\sqrt{2}}(|32\rangle - |33\rangle),\\
|\phi_4\rangle &= \frac{1}{\sqrt{2}}(|21\rangle - |31\rangle),\\
|\phi_5\rangle &= \tfrac{1}{3}(|1\rangle + |2\rangle + |3\rangle) \otimes (|1\rangle + |2\rangle + |3\rangle).
\end{aligned}
\tag{19}
$$

They form an UPB (Unextendible Product Base) as shown in Ref. 12. Let T be the orthogonal complementary space and $\rho_{\mathrm{UPB}} = (1/D)P_T$, where D is a normalizing constant and P_T is the projection to T. It is known that ρ_{UPB} is PPT entangled mixed state from the UPB context (Ref. 12).

Generally speaking we need four orthogonal pure states in T to compute $L_A^2(\rho_{\mathrm{UPB}})$. However for any four linearly independent pure states in T, it is observed that the corresponding $\Sigma r_i A_i$ and $\Sigma r_i A_i'$ defined from these two sets of pure states only differ with a non-singular 4×4 matrix on the right side, thus the conditions $\mathrm{rank}(\Sigma r_i A_i) \leqslant 2$ and $\mathrm{rank}(\Sigma r_i A_i') \leqslant 2$ are equivalent. This makes our computation simpler. Let $|v_1\rangle, \ldots, |v_4\rangle$ be the following four linearly independent pure states in T:

$$
\begin{aligned}
|v_1\rangle &= \tfrac{1}{2}(|11\rangle + |12\rangle - |21\rangle - |31\rangle),\\
|v_2\rangle &= \tfrac{1}{2}(|11\rangle + |12\rangle - |13\rangle - |23\rangle),\\
|v_3\rangle &= \tfrac{1}{2}(|11\rangle + |12\rangle - |32\rangle - |33\rangle),
\end{aligned}
\tag{20}
$$

$$|v_4\rangle = \frac{1}{\sqrt{20}}(|11\rangle + |12\rangle + |13\rangle + |23\rangle - 4|22\rangle).$$

Therefore $L_A^2(\rho_{\mathrm{UPB}})$ as defined by the rank of the following matrix is at most 2:

$$\begin{pmatrix} r_1 - r_2 - r_3 & r_1 & r_1 & r_1 \\ r_1 & r_1 & r_1 - r_3 & r_1 - 4r_2 \\ 0 & -r_1 - r_2 & -r_3 & r_1 + r_2 \end{pmatrix}. \tag{21}$$

It is easy to check that the point $(r_1, r_2, r_3) = (0, 1, -1)$ is in $L_A^2(\rho_{\mathrm{UPB}})$. Thus $L_A^2(\rho_{\mathrm{UPB}})$ is not a subset of $L_A^2(\rho_{BP})$, and from Theorem 2 we know that it is impossible to find positive real p_i's and mixed state ρ_i's with $\rho_1 = \rho_{BP}$ on $H_A^3 \otimes H_B^3$ such that $\rho_{\mathrm{UPB}} = \Sigma p_i \rho_i$.

Example 4: Let $\rho' = \frac{1}{3}(|v_1\rangle\langle v_1| + |v_2\rangle\langle v_2| + |v_4\rangle\langle v_4|)$ be a mixed state on $H_A^3 \otimes H_B^3$ where $|v_1\rangle, |v_2\rangle, |v_4\rangle$ are as above. This is a rank 3 mixed state. We want to know if there exist positive real p_i's and mixed state ρ_i's with $\rho_1 = \rho'$ such that $\rho_{BP} = \Sigma p_i \rho_i$. It is easy to check the point (0; 1; 0) is in the set $L_A^2(\rho_{BP})$ (for randomly chosen parameters). From the above-described computation the set $L_A^2(\rho')$ is defined by the condition that the following matrix has its rank at most 2:

$$\begin{pmatrix} r_1 - r_2 - r_3 & r_1 & r_1 \\ r_1 & r_1 & r_1 - 4r_2 \\ 0 & -r_1 - r_2 & r_1 + r_2 \end{pmatrix}. \tag{22}$$

Thus it is easy to check that the point (0; 1; 0) is not in the set $L_A^2(\rho')$. From Theorem 2 we know that it is impossible to find positive real p_i's and mixed state ρ_i's with $\rho_1 = \rho'$ such that $\rho_{BP} = \Sigma p_i \rho_i$.

From these examples we can see that it is not necessary to locate the set $L_A^k(\rho)$ [or $L_B^k(\rho)$] exactly when we use Theorem 2 to decide whether a mixed state is mixed by some special mixed states. Because Theorem 2 gives *strong* constraints on the mixing problem of bipartite states, it is convenient to use it to get the negative result for mixing problem in bipartite case.

In conclusion, we have developed new invariant sets of bipartite mixed states under local unitary operations and proved some strong constraints on the mixing problem of bipartite states based on these new invariant sets. The invariant sets and the constraints based on them are independent of the eigenvalues of the mixed states. This exhibits the feature that the mixing problem in bipartite case is *essentially* different from the uni-party case. These constraints can be used easily to decide if a given bipartite mixed state is mixed by some other mixed states.

(Received 18 May 2005; accepted 3 October 2005; published online 14 December 2005)

Using algebraic techniques, we realize a systematic search of different types of ladder operators for the Jaynes-Cummings model in the rotating-wave approximation. The link between our results and previous studies on the diagonalization of the associated Hamiltonian is established. Using some of the ladder operators obtained before, examples are given on the possibility of constructing a variety of interesting coherent states for this Hamiltonian. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2137718]

I. INTRODUCTION

The Jaynes-Cummings model describes the interaction between one mode of a quantized electromagnetic field and a simplified version of an atomic system with two levels.[1,2] It is a nonlinear model of great interest in atomic physics and quantum optics, where it is the fundamental theoretical tool in the study of cavity QED for analyzing ion traps.[3] Hence, it has become very valuable for researchers working in the quickly developing domain of quantum information processing.[4] The solution of the complete system (including the counter-rotating terms) is not yet known in a closed form, although there has been some conjectures never proved.[5] Using the so-called rotating-wave approximation, the Hamiltonian remains nonlinear, but it turns out to be exactly solvable; its eigenvalues and eigenvectors can be computed in a closed form.[6] In this work we are going to focus on the possibility of constructing ladder operators for this simplified model, using some of them to obtain the associated coherent states.

In Sec. II, we will recall the essential features of the Jaynes-Cummings Hamiltonian in the rotating-wave approximation using a notation which is well adapted to the purpose of this presentation. When solving this quantum mechanical problem, we will see that two "towers" of eigenstates appear. The explicit construction of ladder operators will be given in Sec. III. They are assumed to act on the eigenstates to move them up or down in one of the "towers" of eigenstates but do not mix them. We will prove that this condition is not enough to determine them completely, and some extra requirements are needed to fully accomplish our goal. Therefore, in Sec. IV, the commutator of these operators will be fixed to be either the identity operator or the Jaynes-Cummings Hamiltonian itself. In this context, some of the solutions are related with already known results on the diagonalization of the Jaynes-Cummings Hamiltonian in the rotating-wave approximation. In Sec. V we will assume the factorization of the Jaynes-Cummings Hamiltonian by these ladder operators, analyzing two of such possible factorizations. In all the cases considered in Secs. IV and V we will also study two situations of particular interest, the case in which the field and the atom are uncoupled and the case when they are in resonance. In Sec. VI,

using some of the ladder operators obtained in the preceding sections, examples are given on the possibility of constructing a wide variety of coherent states for the Jaynes-Cummings Hamiltonian. Finally, some concluding remarks will be given in Sec. VII.

II. THE JAYNES-CUMMINGS HAMILTONIAN AND ITS ENERGY SPECTRUM

We begin with the Hamiltonian of the Jaynes-Cummings model in the rotating-wave approximation[6–9]

$$\mathcal{H}_{\mathrm{JC}} = \hbar\omega\left(a^{+}a + \tfrac{1}{2}\right)\mathbb{I} + \tfrac{1}{2}\hbar\omega_0\sigma_3 + \hbar\kappa(a^{+}\sigma_{-} + a\sigma_{+}). \tag{2.1}$$

In this expression, a^{+} and a are the photon creation and annihilation operators (the usual ladder operator for the harmonic oscillator), $\mathbb{I}$ is the 2×2 identity matrix, $\{\sigma_1,\sigma_2,\sigma_3\}$ are the Pauli matrices, and $\sigma_{\pm}=\sigma_1\pm i\sigma_2$. The parameters that appear in Eq. (2.1) are the following: ω is the field mode frequency, ω_0 is the atomic frequency and κ is the coupling constant between the radiation and the atom. It must be noticed that the rotating-wave approximation is reliable only if[9]

$$|\omega_0 - \omega| \ll \omega_0, \omega. \tag{2.2}$$

In a realistic experiment we can imagine that the atomic frequency ω_0 is fixed (the atomic species do not change, and the same is true for the transition levels we are considering) and that we can modulate the field mode frequency ω. Hence, let us introduce the following "detuning" parameter ϵ, which can be positive or negative, and is such that

$$\omega = \omega_0(1+\epsilon). \tag{2.3}$$

In terms of it, the rotating-wave approximation condition (2.2) is thus

$$|\epsilon| \ll 1, 1+\epsilon, \quad \text{or } |\epsilon| \approx 0. \tag{2.4}$$

For simplicity, in the sequel we will use the following dimensionless form of the Hamiltonian (2.1), in which we use ϵ and a new parameter $\lambda=\kappa/\omega_0$,

$$\mathcal{H}_{\lambda,\epsilon} = \frac{\mathcal{H}_{\mathrm{JC}}}{\hbar\omega_0} = (1+\epsilon)\left(a^{+}a + \frac{1}{2}\right)\mathbb{I} + \frac{1}{2}\sigma_3 + \lambda(a^{+}\sigma_{-} + a\sigma_{+}). \tag{2.5}$$

As we already pointed out, this model is exactly solvable. The main results can be presented in a quite elegant form if we use the following Fock space, built as the tensor product of the Hilbert space associated to the field, times the Hilbert space associated to the spin,

$$F = F_b \otimes F_f = \left\{ |n,-\rangle = \begin{pmatrix} 0 \\ |n\rangle \end{pmatrix}, |n,+\rangle = \begin{pmatrix} |n\rangle \\ 0 \end{pmatrix}, n = 0,1,\ldots \right\}, \tag{2.6}$$

with $\{|n\rangle\}$ the eigenstates of the photon number operator

$$N = a^{+}a. \tag{2.7}$$

Working in the Fock space F given in (2.6), we can find the following matrix representation of the dimensionless Jaynes-Cummings Hamiltonian $\mathcal{H}_{\lambda,\epsilon}$:

$$\mathcal{H}_{\lambda,\epsilon}=\begin{pmatrix}(1+\epsilon)a^{+}a+1+\dfrac{\epsilon}{2} & \lambda a\\ \lambda a^{+} & (1+\epsilon)a^{+}a+\dfrac{\epsilon}{2}\end{pmatrix}=\begin{pmatrix}(1+\epsilon)N+1+\dfrac{\epsilon}{2} & \lambda a\\ \lambda a^{+} & (1+\epsilon)N+\dfrac{\epsilon}{2}\end{pmatrix}. \tag{2.8}$$

It is very easy to see that this Hamiltonian leaves invariant the following subspaces of F: the one-dimensional subspace F_0 generated by the vector $\{|0,-\rangle\}$ and the two-dimensional subspaces F^n_{n+1} generated by the vectors $\{|n,+\rangle,|n+1,-\rangle\}_{n=0}^{\infty}$. Therefore,

$$F=F_0\overset{\infty}{\underset{n=0}{\oplus}}F^n_{n+1}. \tag{2.9}$$

Taking this fact into account, it is easy to prove that the normalized energy eigenstates of $\mathcal{H}_{\lambda,\epsilon}$ are

$$|E_*\rangle=|0,-\rangle, \tag{2.10}$$

$$|E^+_n\rangle=\sin\,\vartheta(n)|n,+\rangle+\cos\,\vartheta(n)|n+1,-\rangle, \tag{2.11}$$

$$|E^-_n\rangle=\cos\,\vartheta(n)|n,+\rangle-\sin\,\vartheta(n)|n+1,-\rangle, \tag{2.12}$$

where we have set

$$\sin\,\vartheta(n)=\xi_\lambda\sqrt{\frac{q(n+1)-\dfrac{\epsilon}{2}}{2q(n+1)}},\quad \cos\,\vartheta(n)=\sqrt{\frac{q(n+1)+\dfrac{\epsilon}{2}}{2q(n+1)}}, \tag{2.13}$$

that satisfy the usual identity $\cos^2\vartheta(n)+\sin^2\vartheta(n)=1$. In the previous expressions, ξ_λ denotes the sign of the coupling constant λ and we have introduced the following auxiliary function of n:

$$q(n)=\sqrt{\left(\frac{\epsilon}{2}\right)^2+\lambda^2 n}=\frac{|\epsilon|}{2}\sqrt{1+\left(\frac{2\lambda}{\epsilon}\right)^2 n}. \tag{2.14}$$

In all these formulas and in the following, if no indication is given in another sense, it is understood that $n=0,1,\ldots$. Morevover, we will frequently make use of the following limits:

$$\lim_{\epsilon\to 0}q(n)=|\lambda|\sqrt{n},\quad \lim_{\lambda\to 0}q(n)=\frac{|\epsilon|}{2}=q(0), \tag{2.15}$$

$$\lim_{\epsilon\to 0}\sin\,\vartheta(n)=\frac{\xi_\lambda}{\sqrt{2}},\quad \lim_{\epsilon\to 0}\cos\,\vartheta(n)=\frac{1}{\sqrt{2}}, \tag{2.16}$$

and

$$\lim_{\lambda\to 0}\sin\,\vartheta(n)=\xi_\lambda H(-\epsilon)=\sin\,\vartheta(-1),\quad \lim_{\lambda\to 0}\cos\,\vartheta(n)=H(\epsilon)=\cos\,\vartheta(-1), \tag{2.17}$$

where $H(\epsilon)$ is the Heaviside function. Note that in (2.17), there is a trace of the sign of λ after taking the limit.

The "dimensionless energy" eigenvalues corresponding to the eigenstates in Eqs. (2.10)–(2.12) are

$$E_*=\frac{\epsilon}{2}, \tag{2.18}$$

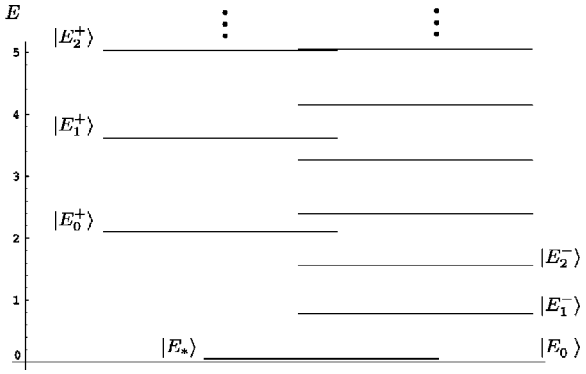

FIG. 1. The two towers of states in the Jaynes-Cummings Hamiltonian for $\epsilon=0.1$, $\lambda=1$

$$E_n^+ = (1+\epsilon)(n+1) + q(n+1), \tag{2.19}$$

$$E_n^- = (1+\epsilon)(n+1) - q(n+1). \tag{2.20}$$

We also introduce the diagonalized version of the Hamiltonian in $\mathcal{H}_{\lambda,\epsilon}$, which may be realized as

$$\mathbb{H}_{\lambda,\epsilon} = \mathcal{U}_{\lambda,\epsilon}^{+}\mathcal{H}_{\lambda,\epsilon}\mathcal{U}_{\lambda,\epsilon} = \begin{pmatrix} (1+\epsilon)(N+1)+q(N+1) & 0 \\ 0 & (1+\epsilon)(N+1)-q(N+1) \end{pmatrix}, \tag{2.21}$$

where $q(N+1)$ is the function defined in (2.14), changing the number n for the number operator N, the operator $\mathcal{U}_{\lambda,\epsilon}$ is given by

$$\mathcal{U}_{\lambda,\epsilon} = \begin{pmatrix} \sin\vartheta(N) & \cos\vartheta(N) \\ a^{+}\dfrac{\cos\vartheta(N)}{\sqrt{N+1}} & -a^{+}\dfrac{\sin\vartheta(N)}{\sqrt{N+1}} \end{pmatrix} \tag{2.22}$$

and $\mathcal{U}_{\lambda,\epsilon}^{+}$ is its adjoint. The eigenstates of (2.21) are $|n,\pm\rangle$, with $\mathbb{H}_{\lambda,\epsilon}|n,\pm\rangle = E_n^{\pm}|n,\pm\rangle$, justifying the notation used for the energy eigenstates (2.11) and (2.12). They are related to the states $|E_n^{\pm}\rangle$ by the following formulas

$$|E_n^{\pm}\rangle = \mathcal{U}_{\lambda,\epsilon}|n,\pm\rangle, \quad |n,\pm\rangle = \mathcal{U}_{\lambda,\epsilon}^{+}|E_n^{\pm}\rangle, \quad n=0,1,\ldots\ . \tag{2.23}$$

Note that the eigenstate $|E_*\rangle$ is not included in this scheme, and it satisfies

$$\mathcal{U}_{\lambda,\epsilon}^{+}|E_*\rangle = 0. \tag{2.24}$$

Due to this fact, the operator $\mathcal{U}_{\lambda,\epsilon}$ is not unitary in the whole space F, but only when it is restricted to the subspace $F-F_0$.

Let us now make some comments concerning the energy spectrum. First, the eigenstates can be arranged in two groups or "towers" denoted by $\{|E_k^+\rangle\}_{k=0}^{\infty}$ and $\{|E_k^-\rangle\}_{k=0}^{\infty}$, defined in (2.11) and (2.12), as shown in Figs. 1 and 2. Second, we see that the energies E_k^+ are strictly increasing with $k\in\mathbb{N}$ while for the energies E_k^-, there can be some values of λ and ϵ for which the spectrum is not strictly increasing and even may present some degeneracies.[10,11] Our definition of raising and lowering operators will require that both energy spectra will be strictly increasing. It is easy to show that, for example, when $\epsilon=0$, this is always true if we take $\lambda<1+\sqrt{2}$. The two examples shown in Figs. 1 and 2 correspond precisely to strictly increasing energy spectra. A more detailed analysis of the spectrum is carried out in Ref. 11.

Let us analyze now two limit cases which are significant.

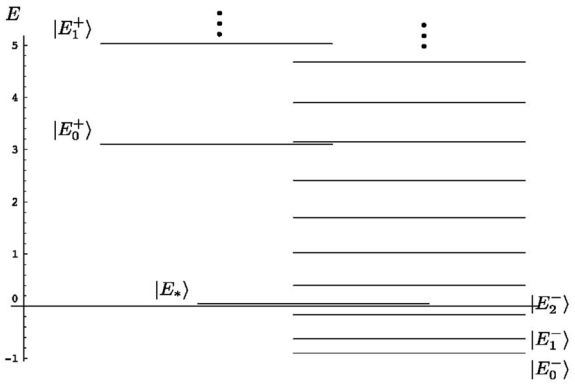

FIG. 2. The two towers of states in the Jaynes-Cummings Hamiltonian for $\epsilon=0.1$, $\lambda=2$

A. Uncoupled system

If we first take the limit for $\lambda \to 0$ of the Jaynes-Cummings Hamiltonian $\mathcal{H}_{\lambda,\epsilon}$, we get immediately, from (2.8),

$$\mathcal{H}_{0,\epsilon}=\begin{pmatrix} (1+\epsilon)N+1+\dfrac{\epsilon}{2} & 0 \\ 0 & (1+\epsilon)N+\dfrac{\epsilon}{2} \end{pmatrix}=(1+\epsilon)\left(N+\frac{1}{2}\right)\mathbb{I}+\frac{1}{2}\sigma_3, \tag{2.25}$$

which is the usual diagonal supersymmetric harmonic oscillator Hamiltonian. The limit process goes properly in the formulas (2.11) and (2.12) and (2.19) and (2.20),

$$|E_n^+\rangle = \xi_\lambda H(-\epsilon)|n,+\rangle + H(\epsilon)|n+1,-\rangle), \quad E_n^+=(1+\epsilon)(n+1)+\frac{|\epsilon|}{2}, \tag{2.26}$$

$$|E_n^-\rangle = H(\epsilon)|n,+\rangle - \xi_\lambda H(-\epsilon)|n+1,-\rangle), \quad E_n^-=(1+\epsilon)(n+1)-\frac{|\epsilon|}{2}, \tag{2.27}$$

even if the operator $\mathcal{U}_{0,\epsilon}$ is not the identity. Indeed, the Hamiltonian $\mathbb{H}_{0,\epsilon}$ is given by

$$\mathbb{H}_{0,\epsilon}=\begin{pmatrix} (1+\epsilon)(N+1)+\dfrac{|\epsilon|}{2} & 0 \\ 0 & (1+\epsilon)(N+1)-\dfrac{|\epsilon|}{2} \end{pmatrix} \tag{2.28}$$

and, using (2.17), the operator $\mathcal{U}_{0,\epsilon}$ is

$$\mathcal{U}_{0,\epsilon}=\begin{pmatrix} \xi_\lambda H(-\epsilon) & H(\epsilon) \\ a^+\dfrac{H(\epsilon)}{\sqrt{N+1}} & -\xi_\lambda a^+\dfrac{H(-\epsilon)}{\sqrt{N+1}} \end{pmatrix}. \tag{2.29}$$

B. Zero detuning

The second special case is obtained when $\epsilon \to 0$, i.e., when the detuning between the atom and the field is zero. The Hamiltonian in (2.8) thus becomes

$$\mathcal{H}_{\lambda,0}=\begin{pmatrix} N+1 & \lambda a \\ \lambda a^{+} & N \end{pmatrix}. \tag{2.30}$$

Using (2.17), we easily find, from (2.10)–(2.12), the eigenstates and eigenvalues of $\mathcal{H}_{\lambda,0}$ as

$$|E_{*}\rangle=|0,-\rangle, \quad E_{*}=0, \tag{2.31}$$

$$|E_{n}^{+}\rangle=\frac{\sqrt{2}}{2}(\xi_{\lambda}|n,+\rangle+|n+1,-\rangle), \quad E_{n}^{+}=n+1+|\lambda|\sqrt{n+1}, \tag{2.32}$$

$$|E_{n}^{-}\rangle=\frac{\sqrt{2}}{2}(|n,+\rangle-\xi_{\lambda}|n+1,-\rangle), \quad E_{n}^{-}=n+1-|\lambda|\sqrt{n+1}. \tag{2.33}$$

The diagonalized version of $\mathcal{H}_{\lambda,0}$ is now

$$\mathbb{H}_{\lambda,0}=\mathcal{U}_{\lambda,0}^{+}\mathcal{H}_{\lambda,0}\mathcal{U}_{\lambda,0}=\begin{pmatrix} N+1+|\lambda|\sqrt{N+1} & 0 \\ 0 & N+1-|\lambda|\sqrt{N+1} \end{pmatrix} \tag{2.34}$$

and the operator $\mathcal{U}_{\lambda,0}$ is given by

$$\mathcal{U}_{\lambda,0}=\frac{\sqrt{2}}{2}\begin{pmatrix} \xi_{\lambda} & 1 \\ a^{+}\dfrac{1}{\sqrt{N+1}} & -a^{+}\dfrac{1}{\sqrt{N+1}}\xi_{\lambda} \end{pmatrix}. \tag{2.35}$$

Let us mention finally that the iteration of the two limits $\lambda\to 0$ and $\epsilon\to 0$ is consistent since we have

$$\lim_{\epsilon\to 0}\mathbb{H}_{0,\epsilon}=\lim_{\lambda\to 0}\mathbb{H}_{\lambda,0}=(N+1)\mathbb{I}\equiv\mathbb{H}_{0,0} \tag{2.36}$$

and

$$\lim_{\epsilon\to 0}\mathcal{H}_{0,\epsilon}=\lim_{\lambda\to 0}\mathcal{H}_{\lambda,0}=\begin{pmatrix} N+1 & 0 \\ 0 & N \end{pmatrix}\equiv\mathcal{H}_{0,0}. \tag{2.37}$$

$\mathbb{H}_{0,0}$ and $\mathcal{H}_{0,0}$ can be related through the operator given in (2.29). Let us mention that the limit Hamiltonian $\mathcal{H}_{0,0}$ admits a degenerated energy spectrum, since in this particular case we have $E_{n}^{+}=E_{n}^{-}=n+1$.

III. RAISING AND LOWERING OPERATORS FOR THE JAYNES-CUMMINGS MODEL

A. General results

Since the energy eigenstates are organized in two towers, we want to find ladder operators which move them up or down without mixing them. This means that a lowering operator $\mathcal{M}_{\lambda,\epsilon}^{-}$ will satisfy the following relations:

$$\mathcal{M}_{\lambda,\epsilon}^{-}|E_{*}\rangle=0, \tag{3.1}$$

and

$$\mathcal{M}_{\lambda,\epsilon}^{-}|E_{n}^{\pm}\rangle=k_{\pm}(n)|E_{n-1}^{\pm}\rangle, \quad n\in\mathbb{N}. \tag{3.2}$$

We are assuming that $k_{\pm}(0)=0$ as a kind of initial condition for determining $k_{\pm}(n)$. The corresponding raising operator $\mathcal{M}^{+}_{\lambda,\epsilon}$ will be the adjoint of the lowering operator. To realize this task, it is useful to work with the diagonalized version of the model since the corresponding lowering operator $\mathbb{M}^{-}_{\lambda,\epsilon}=\mathcal{U}^{+}_{\lambda,\epsilon}\mathcal{M}^{-}_{\lambda,\epsilon}\mathcal{U}_{\lambda,\epsilon}$ satisfies

$$\mathbb{M}^{-}_{\lambda,\epsilon}|n,\pm\rangle = k_{\pm}(n)|n-1,\pm\rangle, \quad n\in\mathbb{N}. \tag{3.3}$$

Let us mention that the condition (3.1) may be written as

$$\mathcal{M}^{-}_{\lambda,\epsilon}|E_{*}\rangle = \mathcal{U}_{\lambda,\epsilon}\mathbb{M}^{-}_{\lambda,\epsilon}\mathcal{U}^{+}_{\lambda,\epsilon}|E_{*}\rangle = 0, \tag{3.4}$$

which is identically satisfied due to the relation (2.24).

Using the well-known relationships

$$a|n\rangle = \sqrt{n}|n-1\rangle, \quad a^{+}|n\rangle = \sqrt{n+1}|n+1\rangle, \tag{3.5}$$

$$g(N)a = ag(N-1), \quad g(N)a^{+} = a^{+}g(N+1), \tag{3.6}$$

it is easy to get, from (3.3),

$$\mathbb{M}^{-}_{\lambda,\epsilon} = \begin{pmatrix} \dfrac{k_{+}(N+1)}{\sqrt{N+1}}a & 0 \\ 0 & \dfrac{k_{-}(N+1)}{\sqrt{N+1}}a \end{pmatrix}. \tag{3.7}$$

The expression of $\mathcal{M}^{-}_{\lambda,\epsilon}$ in the original model will be

$$\mathcal{M}^{-}_{\lambda,\epsilon} = \mathcal{U}_{\lambda,\epsilon}\mathbb{M}^{-}_{\lambda,\epsilon}\mathcal{U}^{+}_{\lambda,\epsilon} = \begin{pmatrix} m_1(N)a & m_2(N)a^2 \\ m_3(N) & m_4(N)a \end{pmatrix}, \tag{3.8}$$

where the functions $m_i(n)$ are given by

$$m_1(n) = \frac{\sin\vartheta(n)\sin\vartheta(n+1)k_{+}(n+1) + \cos\vartheta(n)\cos\vartheta(n+1)k_{-}(n+1)}{\sqrt{n+1}}, \tag{3.9}$$

$$m_2(n) = \frac{\sin\vartheta(n)\cos\vartheta(n+1)k_{+}(n+1) - \cos\vartheta(n)\sin\vartheta(n+1)k_{-}(n+1)}{\sqrt{n+1}\sqrt{n+2}}, \tag{3.10}$$

$$m_3(n) = \cos\vartheta(n-1)\sin\vartheta(n)k_{+}(n) - \sin\vartheta(n-1)\cos\vartheta(n)k_{-}(n), \tag{3.11}$$

$$m_4(n) = \frac{\cos\vartheta(n-1)\cos\vartheta(n)k_{+}(n) + \sin\vartheta(n-1)\sin\vartheta(n)k_{-}(n)}{\sqrt{n+1}}. \tag{3.12}$$

Note that the relations on the functions $m_3(n)$ and $m_4(n)$ are, in principle, valid only for $n>0$, due to the presence of $\cos\vartheta(n-1)$ and $\sin\vartheta(n-1)$. Nevertheless, the quantities $\cos\vartheta(-1)$ and $\sin\vartheta(-1)$, make also sense, as it was shown in (2.17).

B. Particular cases

In the special case $\lambda=0$, we easily find

$$\mathcal{M}^{-}_{0,\epsilon}=\begin{pmatrix} \dfrac{H(\epsilon)k_{-}(N+1)+H(-\epsilon)k_{+}(N+1)}{\sqrt{N+1}}a & 0 \\ 0 & \dfrac{H(\epsilon)k_{+}(N)+H(-\epsilon)k_{-}(N)}{\sqrt{N+1}}a \end{pmatrix}. \tag{3.13}$$

When we take $\epsilon=0$, the annihilator $\mathcal{M}^{-}_{\lambda,0}$ is

$$\mathcal{M}^{-}_{\lambda,0}=\begin{pmatrix} \dfrac{k_{+}(N+1)+k_{-}(N+1)}{2\sqrt{N+1}}a & \xi_{\lambda}\dfrac{k_{+}(N+1)-k_{-}(N+1)}{2\sqrt{N+1}\sqrt{N+2}}a^{2} \\ \xi_{\lambda}\dfrac{k_{+}(N)-k_{-}(N)}{2} & \dfrac{k_{+}(N)+k_{-}(N)}{2\sqrt{N+1}}a \end{pmatrix}. \tag{3.14}$$

The results presented up to now are completely general, but the two functions $k_{\pm}(n)$ are not fixed at all. Therefore, in order to solve this problem, in the next section some extra requirements will be imposed to determine the functions $k_{\pm}(n)$, which are supposed to be complex in general. These will be related to conditions on the products of the ladder operators which we write as

$$\mathbb{M}^{+}_{\lambda,\epsilon}\mathbb{M}^{-}_{\lambda,\epsilon}=\begin{pmatrix} |k_{+}(N)|^{2} & 0 \\ 0 & |k_{-}(N)|^{2} \end{pmatrix}, \quad \mathbb{M}^{-}_{\lambda,\epsilon}\mathbb{M}^{+}_{\lambda,\epsilon}=\begin{pmatrix} |k_{+}(N+1)|^{2} & 0 \\ 0 & |k_{-}(N+1)|^{2} \end{pmatrix}. \tag{3.15}$$

IV. CONDITIONS ON THE COMMUTATOR OF THE LADDER OPERATORS

In this section, ladder operators are obtained by imposing two different constraints on the value of the commutator of the two ladder operators. First, the commutator is assumed to be the identity operator, and second, it is assumed to be the Hamiltonian itself.

A. The commutator is the identity operator

That situation will be the most similar to the harmonic oscillator, and taking

$$[\mathbb{M}^{-}_{\lambda,\epsilon},\mathbb{M}^{+}_{\lambda,\epsilon}]=\mathbb{I}, \tag{4.1}$$

we get the following relations:

$$|k_{\pm}(n+1)|^{2}-|k_{\pm}(n)|^{2}=1, \tag{4.2}$$

together with the initial condition $k_{\pm}(0)=0$. The general solution is thus

$$k_{\pm}(n)=e^{i\varphi_{\pm}(n)}\sqrt{n}, \tag{4.3}$$

where the phases $\varphi_{\pm}(n)$ are not yet fixed. Therefore the annihilation operator (3.7) is nothing else than

$$\mathbb{M}^{-}_{\lambda,\epsilon}=\begin{pmatrix} e^{i\varphi_{+}(N+1)}a & 0 \\ 0 & e^{i\varphi_{-}(N+1)}a \end{pmatrix}. \tag{4.4}$$

The explicit expression of the original operator $\mathcal{M}^{-}_{\lambda,\epsilon}$ is thus given by (3.8) where the functions $m_{i}(N)$ are now

$$m_1(N)=\frac{1}{2}\frac{e^{i\varphi_+(N+1)}\sqrt{q(N+1)-\frac{\epsilon}{2}}\sqrt{q(N+2)-\frac{\epsilon}{2}}+e^{i\varphi_-(N+1)}\sqrt{q(N+1)+\frac{\epsilon}{2}}\sqrt{q(N+2)+\frac{\epsilon}{2}}}{\sqrt{q(N+1)q(N+2)}},$$

$$m_2(N)=\frac{\xi_\lambda}{2}\frac{e^{i\varphi_+(N+1)}\sqrt{q(N+1)-\frac{\epsilon}{2}}\sqrt{q(N+2)+\frac{\epsilon}{2}}-e^{i\varphi_-(N+1)}\sqrt{q(N+1)+\frac{\epsilon}{2}}\sqrt{q(N+2)-\frac{\epsilon}{2}}}{\sqrt{N+2}\sqrt{q(N+1)q(N+2)}},$$

$$m_3(N)=\frac{\xi_\lambda}{2}\sqrt{N}\frac{e^{i\varphi_+(N)}\sqrt{q(N)+\frac{\epsilon}{2}}\sqrt{q(N+1)-\frac{\epsilon}{2}}-e^{i\varphi_-(N)}\sqrt{q(N)-\frac{\epsilon}{2}}\sqrt{q(N+1)+\frac{\epsilon}{2}}}{\sqrt{q(N)q(N+1)}},$$

$$m_4(N)=\frac{1}{2}\sqrt{\frac{N}{N+1}}\frac{e^{i\varphi_+(N)}\sqrt{q(N)+\frac{\epsilon}{2}}\sqrt{q(N+1)+\frac{\epsilon}{2}}+e^{i\varphi_-(N)}\sqrt{q(N)-\frac{\epsilon}{2}}\sqrt{q(N+1)-\frac{\epsilon}{2}}}{\sqrt{q(N)q(N+1)}}.$$

Let us also mention that, due to (4.4), we have $\mathbb{M}^+_{\lambda,\epsilon}\mathbb{M}^-_{\lambda,\epsilon}=N\mathbb{I}$ and $\mathbb{M}^-_{\lambda,\epsilon}\mathbb{M}^+_{\lambda,\epsilon}=(N+1)\mathbb{I}$. The original annihilation and creation operators thus satisfy

$$\mathcal{M}^+_{\lambda,\epsilon}\mathcal{M}^-_{\lambda,\epsilon}=\begin{pmatrix}N & 0\\ 0 & N-1\end{pmatrix},\quad \mathcal{M}^-_{\lambda,\epsilon}\mathcal{M}^+_{\lambda,\epsilon}=\begin{pmatrix}N+1 & 0\\ 0 & N\end{pmatrix}. \tag{4.5}$$

In the absence of coupling between the atom and the field ($\lambda=0$), using (3.13) and (4.3) we get the following diagonal annihilation operator:

$$\mathcal{M}^-_{0,\epsilon}=\begin{pmatrix}G_-(N+1)a & 0\\ 0 & \sqrt{\frac{N}{N+1}}G_+(N)a\end{pmatrix}, \tag{4.6}$$

where

$$G_+(N)=e^{i\varphi_+(N)}H(\epsilon)+e^{i\varphi_-(N)}H(-\epsilon),\quad G_-(N)=e^{i\varphi_-(N)}H(\epsilon)+e^{i\varphi_+(N)}H(-\epsilon). \tag{4.7}$$

Moreover, we have

$$\mathcal{H}_{0,\epsilon}=(1+\epsilon)\mathcal{M}^+_{0,\epsilon}\mathcal{M}^-_{0,\epsilon}+\begin{pmatrix}1+\frac{\epsilon}{2} & 0\\ 0 & 1+\frac{3\epsilon}{2}\end{pmatrix}=(1+\epsilon)\mathcal{M}^-_{0,\epsilon}\mathcal{M}^+_{0,\epsilon}+\begin{pmatrix}-\frac{\epsilon}{2} & 0\\ 0 & \frac{\epsilon}{2}\end{pmatrix}. \tag{4.8}$$

In the case of zero detuning ($\epsilon=0$), using (3.14) and (4.3), we easily get

$$\mathcal{M}^-_{\lambda,0}=\begin{pmatrix}\frac{1}{2}(e^{i\varphi_+(N+1)}+e^{i\varphi_-(N+1)})a & \frac{\xi_\lambda}{2\sqrt{N+2}}(e^{i\varphi_+(N+1)}-e^{i\varphi_-(N+1)})a^2\\ \frac{\xi_\lambda}{2}\sqrt{N}(e^{i\varphi_+(N)}-e^{i\varphi_-(N)}) & \frac{1}{2}\sqrt{\frac{N}{N+1}}(e^{i\varphi_+(N)}+e^{i\varphi_-(N)})a\end{pmatrix}. \tag{4.9}$$

B. The commutator is the Hamiltonian

An alternative choice for $k_\pm(n)$ is obtained when we take

$$[\mathcal{M}^-_{\lambda,\epsilon},\mathcal{M}^+_{\lambda,\epsilon}]=\mathcal{H}_{\lambda,\epsilon} \tag{4.10}$$

or equivalently

$$[\mathbb{M}^-_{\lambda,\epsilon},\mathbb{M}^+_{\lambda,\epsilon}]=\mathbb{H}_{\lambda,\epsilon}. \tag{4.11}$$

We thus must solve

$$|k_\pm(n+1)|^2-|k_\pm(n)|^2=E^\pm_n. \tag{4.12}$$

The general solution is

$$k_\pm(0)=0,\quad k_\pm(n)=e^{i\varphi_\pm(n)}\sqrt{\sum_{\ell=0}^{n-1}E^\pm_\ell},\quad n>0. \tag{4.13}$$

The last expresssion can also be written as follows:

$$\begin{aligned}k_\pm(n)&=e^{i\varphi_\pm(n)}\sqrt{\frac{1}{2}(1+\epsilon)n(n+1)\pm\sum_{\ell=0}^{n-1}q(\ell+1)}\\&=e^{i\varphi_\pm(n)}\sqrt{\frac{1}{2}(1+\epsilon)n(n+1)\pm|\lambda|\sum_{\ell=0}^{n-1}\sqrt{\delta+\ell+1}}\\&=e^{i\varphi_\pm(n)}\sqrt{\frac{1}{2}(1+\epsilon)n(n+1)\pm|\lambda|\left(\zeta\left(-\frac{1}{2},\delta\right)-\zeta\left(-\frac{1}{2},\delta+n\right)\right)},\end{aligned} \tag{4.14}$$

where $\delta=(\epsilon/2\lambda)^2$ and $\zeta(s,a)$ is the generalized Riemann zeta function.

In the case $\lambda=0$, the annihilation operator takes the form (3.13) with

$$(\mathcal{M}^-_{0,\epsilon})_{11}=\frac{1}{\sqrt{2}}G_-(N+1)\sqrt{(1+\epsilon)(N+1)+1}a, \tag{4.15}$$

$$(\mathcal{M}^-_{0,\epsilon})_{22}=\frac{1}{\sqrt{2}}G_+(N)\sqrt{(1+\epsilon)N+\frac{N\epsilon}{N+1}}a, \tag{4.16}$$

where $G_\pm(N)$ were defined in (4.7).

In the case where $\epsilon=0$, we get, from (4.14), the following expressions for $k_\pm(n)$:

$$k_\pm(n)=e^{i\varphi_\pm(n)}\sqrt{\tfrac{1}{2}(n+1)n+1\pm|\lambda|H_n^{(-1/2)}},\quad n>0, \tag{4.17}$$

where $H_n^{\left(-\frac{1}{2}\right)}=\Sigma_{\ell=1}^n\ell^{\frac{1}{2}}$ is a harmonic number of order $\left(-\frac{1}{2}\right)$.

V. FACTORIZATION OF THE JAYNES-CUMMINGS HAMILTONIAN

Another special set of ladder operators, which will be consider next, is the one that leads to the factorization of the Hamiltonian.

A. First type of factorization

Assuming that we have first

$$\mathbb{M}^-_{\lambda,\epsilon}\mathbb{M}^+_{\lambda,\epsilon}=\mathbb{H}_{\lambda,\epsilon}-\begin{pmatrix}\mu_+ & 0\\ 0 & \mu_-\end{pmatrix},\quad \mu_+,\mu_-\in\mathbb{R}, \tag{5.1}$$

we immediately get from (3.15),

$$k_{\pm}(n+1) = e^{i\varphi_{\pm}(n+1)}\sqrt{E_n^{\pm} - \mu_{\pm}}, \quad k_{\pm}(0) = 0. \tag{5.2}$$

If we now take the special case $\lambda = 0$, the annihilator takes the form (3.13), with

$$(\mathcal{M}^-_{0,\epsilon})_{11} = \left[H(\epsilon) e^{i\varphi_-(N+1)} \sqrt{1 + \epsilon - \frac{\epsilon + 2\mu_-}{2(N+1)}} + H(-\epsilon) e^{i\varphi_+(N+1)} \sqrt{1 + \epsilon - \frac{\epsilon + 2\mu_+}{2(N+1)}} \right] a,$$

$$(\mathcal{M}^-_{0,\epsilon})_{22} = \left[H(\epsilon) e^{i\varphi_+(N)} \sqrt{1 + \epsilon - \frac{\epsilon + 2 + 2\mu_+}{2(N+1)}} + H(-\epsilon) e^{i\varphi_-(N)} \sqrt{1 + \epsilon - \frac{\epsilon + 2 + 2\mu_-}{2(N+1)}} \right] a,$$

which leads to the following factorization of the original Hamiltonian:

$$\mathcal{H}_{0,\epsilon} = \mathcal{M}^-_{0,\epsilon}\mathcal{M}^+_{0,\epsilon} + \begin{pmatrix} H(\epsilon)\mu_- + H(-\epsilon)\mu_+ & 0 \\ 0 & H(\epsilon)\mu_+ + H(-\epsilon)\mu_- \end{pmatrix}. \tag{5.3}$$

We also have in this case

$$[\mathcal{M}^-_{0,\epsilon}, \mathcal{M}^+_{0,\epsilon}] = (1+\epsilon)\mathbb{I}. \tag{5.4}$$

Let us observe that if we choose $\mu_+ = \mu_- = -(1+\epsilon)$, then the Hamiltonian is exactly factorized as $\mathcal{H}_{0,\epsilon} = \mathcal{M}^+_{0,\epsilon}\mathcal{M}^-_{0,\epsilon}$, and we get

$$(\mathcal{M}^-_{0,\epsilon})_{11} = G_-(N+1)\sqrt{1 + \epsilon + \frac{1 + \epsilon/2}{N+1}}\, a, \tag{5.5}$$

$$(\mathcal{M}^-_{0,\epsilon})_{22} = G_+(N)\sqrt{1 + \epsilon + \frac{\epsilon/2}{N+1}}\, a, \tag{5.6}$$

with $G_{\pm}(N)$ given in (4.7)

When $\epsilon > 0$, the special choice $\mu_- = -\epsilon/2$ and $\mu_+ = -[1 + (\epsilon/2)]$ gives rise to a particularly simple form of the annihilator, i.e.,

$$\mathcal{M}^-_{0,\epsilon>0} = \sqrt{1+\epsilon}\begin{pmatrix} e^{i\varphi_-(N+1)}a & 0 \\ 0 & e^{i\varphi_+(N)}a \end{pmatrix}. \tag{5.7}$$

Something similar can be done when $\epsilon < 0$, choosing now $\mu_- = -[1 + (\epsilon/2)]$ and $\mu_+ = -\epsilon/2$. In both cases, we can thus write the Hamiltonian as

$$\mathcal{H}_{0,\epsilon} = \mathcal{M}^-_{0,\epsilon}\mathcal{M}^+_{0,\epsilon} - \begin{pmatrix} \frac{\epsilon}{2} & 0 \\ 0 & \left(1 + \frac{\epsilon}{2}\right) \end{pmatrix} = \mathcal{M}^+_{0,\epsilon}\mathcal{M}^-_{0,\epsilon} + \begin{pmatrix} \left(1 + \frac{\epsilon}{2}\right) & 0 \\ 0 & \frac{\epsilon}{2} \end{pmatrix}. \tag{5.8}$$

We get here a result similar to the one obtained in the preceding section when we ask for the commutator of the ladder operators to be the identity. It is expected due to the relation (5.4) but the ladder operators are essentially different because of the presence of the operator $\sqrt{N/(N+1)}$ in (4.6).

When we take $\epsilon = 0$, we get, from (5.2),

$$k_{\pm}(n+1) = e^{i\varphi_{\pm}(n+1)}\sqrt{n + 1 - \mu_{\pm} \pm |\lambda|\sqrt{n+1}}, \tag{5.9}$$

and the form of $\mathcal{M}^-_{\lambda,0}$ is obtained from (3.14). Since we are interested in a factorization of the original Hamiltonian which is nondiagonal in this case, further constraints must be imposed on the unknown quantities $\mu_{\pm}$. Indeed, a diagonal matrix does not remain diagonal, in general, when we

transform it by the operator $\mathcal{U}_{\lambda,0}$. The simplest choice is to take $\mu_{\pm}=0$. Thus we get an exact factorization

$$\mathcal{H}_{\lambda,0}=\mathcal{M}^{-}_{\lambda,0}\mathcal{M}^{+}_{\lambda,0}. \tag{5.10}$$

Changing the order of the factors, we get a new Hamiltonian $\mathcal{H}'_{\lambda,0}=\mathcal{M}^{+}_{\lambda,0}\mathcal{M}^{-}_{\lambda,0}$, whose explicit form in the subspace $F-F_0$ is

$$\mathcal{H}'_{\lambda,0}=\mathcal{M}^{+}_{\lambda,0}\mathcal{M}^{-}_{\lambda,0}=\begin{pmatrix} N & \lambda\sqrt{\dfrac{N}{N+1}}a \\ a^{\dagger}\lambda\sqrt{\dfrac{N}{N+1}} & N-1 \end{pmatrix}. \tag{5.11}$$

The Hamiltonian $\mathcal{H}'_{\lambda,0}$ is in fact isospectral[12] to $\mathcal{H}_{\lambda,0}$. Indeed, its eigenstates are $\mathcal{M}^{+}_{\lambda,0}|E^{\pm}_n\rangle$ with eigenvalues $E^{\pm}_n$ and also the state $E_*\rangle=|0,-\rangle$ with eigenvalue 0. Note that $\mathcal{M}^{+}_{\lambda,0}|E_*\rangle=0$ and therefore it is not an eigenstate of $\mathcal{H}'_{\lambda,0}$.

B. Second type of factorization

It is obtained when we take

$$\mathbb{M}^{+}_{\lambda,\epsilon}\mathbb{M}^{-}_{\lambda,\epsilon}=\mathbb{H}_{\lambda,\epsilon}-\begin{pmatrix}\nu_+ & 0\\ 0 & \nu_-\end{pmatrix}. \tag{5.12}$$

Indeed, the diagonal matrix is now fixed due to the initial condition on the $k_{\pm}(n)$. From (3.15), we get

$$k_{\pm}(n)=e^{i\varphi_{\pm}(n)}\sqrt{E^{\pm}_n-E^{\pm}_0},\quad \nu_{\pm}=E^{\pm}_0, \tag{5.13}$$

so that $k_{\pm}(0)=0$ as expected, although the phases $\varphi_{\pm}(n)$ are not yet fixed.

Here again, if we take $\lambda=0$, we easily get the annihilator $\mathcal{M}^{-}_{0,\epsilon}$ of (3.13) on the form

$$(\mathcal{M}^{-}_{0,\epsilon})_{11}=\sqrt{(1+\epsilon)}G_{-}(N+1)a,\quad (\mathcal{M}^{-}_{0,\epsilon})_{22}=\sqrt{(1+\epsilon)\frac{N}{N+1}}G_{+}(N)a.$$

We thus have

$$\mathcal{H}_{0,\epsilon}=\mathcal{M}^{+}_{0,\epsilon}\mathcal{M}^{-}_{0,\epsilon}+\begin{pmatrix}1+\dfrac{\epsilon}{2} & 0\\ 0 & 1+\dfrac{3\epsilon}{2}\end{pmatrix}=\mathcal{M}^{-}_{0,\epsilon}\mathcal{M}^{+}_{0,\epsilon}+\begin{pmatrix}-\dfrac{\epsilon}{2} & 0\\ 0 & \dfrac{\epsilon}{2}\end{pmatrix}. \tag{5.14}$$

When $\epsilon=0$, we have $E^{\pm}_n-E^{\pm}_0=n\pm|\lambda|(\sqrt{n+1}-1)$ and

$$\mathbb{M}^{-}_{\lambda,0}=\begin{pmatrix} e^{i\varphi_+(N+1)}\sqrt{\dfrac{N+1+|\lambda|(\sqrt{N+2}-1)}{N+1}}a & 0\\ 0 & e^{i\varphi_-(N+1)}\sqrt{\dfrac{N+1-|\lambda|(\sqrt{N+2}-1)}{N+1}}a\end{pmatrix}, \tag{5.15}$$

but the original Hamiltonian cannot be factorized in this case (except when λ is also equal to zero) since the transformation by the operator $\mathcal{U}_{\lambda,0}$ affects the constant diagonal matrix appearing in (5.12).

Note that the exact factorization for the zero detuning $\epsilon=0$ and strong coupling $\lambda=1$ encountered in the literature[13] does not contradict our result. Indeed, we can show that for $\lambda=1+\epsilon$ the Jaynes-Cummings Hamiltonian can be written as

$$\mathcal{H}_{(1+\epsilon),\epsilon}=(1+\epsilon)\mathcal{A}^{+}\mathcal{A}^{-}-\frac{\epsilon}{2}\sigma_3 \tag{5.16}$$

with

$$\mathcal{A}^{-}=\begin{pmatrix} a & 0 \\ 1 & a \end{pmatrix}. \tag{5.17}$$

The operators $\mathcal{A}^{+}$ and $\mathcal{A}^{-}$ have been introduced as some ladder operators for supersymmetric harmonic oscillator.[13,14] The operator $\mathcal{A}^{-}$ has a form similar to the general $\mathcal{M}^{-}_{\lambda,\epsilon}$ in (3.8). Nevertheless, it is not an annihilation operator for our model, as it could be easily checked from (3.2), even if $\epsilon=0$.

VI. GENERAL SETS OF COHERENT STATES

Our annihilation operators $\mathcal{M}^{-}_{\lambda,\epsilon}$ may be used to construct new sets of coherent states for the Jaynes-Cummings system. A detailed analysis of these sets and the corresponding physical properties is beyond the scope of this paper and will be presented elsewhere. Nevertheless, we will insist here on the general construction taking place into the Gazeau-Klauder scheme[15] and also its vector coherent states generalization.[16] We will also illustrate it with some specific examples which connect the new states with preceding approaches.[7,10,17]

A. General results

Let us introduce the following notation for the coherent states: $|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon}$, where $z\in\mathbb{C}$ is the usual label for a coherent state, $\boldsymbol{\alpha}=(\alpha_+,\alpha_-)$ and $\boldsymbol{\theta}=(\theta,\phi)$ are two sets of real parameters that will be specified later, $\boldsymbol{\alpha}$ related to the temporal evolution and $\boldsymbol{\theta}$ related to the normalization. As usual, these states are defined as the eigenstates of the annihilator, that is

$$\mathcal{M}^{-}_{\lambda,\epsilon}|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon}=z|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon}. \tag{6.1}$$

Once we decompose $|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon}$ in the basis of the eigenstates (2.10)–(2.12) of $\mathcal{H}_{\lambda,\epsilon}$ as

$$|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon}=C_{*}(z)|E_{*}\rangle+\sum_{n=0}^{\infty}\left(C_n^{+}(z)|E_n^{+}\rangle+C_n^{-}(z)|E_n^{-}\rangle\right) \tag{6.2}$$

and insert this expression in (6.1), using (3.1) and (3.2), we find $C_{*}(z)=0$ and

$$C_n^{\pm}(z)=\frac{z^n}{\rho_{\pm}(n)}C_0^{\pm}(z),\quad n>0, \tag{6.3}$$

with

$$\rho_{\pm}(n)=k_{\pm}(1)k_{\pm}(2)\cdots k_{\pm}(n). \tag{6.4}$$

The coherent states take the form

$$|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon}=\sum_{n=0}^{\infty}z^n\left(\frac{C_0^{+}(z)}{\rho_{+}(n)}|E_n^{+}\rangle+\frac{C_0^{-}(z)}{\rho_{-}(n)}|E_n^{-}\rangle\right), \tag{6.5}$$

if we set $\rho_{\pm}(0)=1$. Let us mention now that there are three coherent states associated to the value $z=0$, $|E_{*}\rangle$, $|E_0^{+}\rangle$, and $|E_0^{+}\rangle$.

Taking into account that from (2.5) the time-dependent Schrödinger equation for the Hamiltonian $\mathcal{H}_{\lambda,\epsilon}$ is

$$\mathcal{H}_{\lambda,\epsilon}|\psi\rangle = -i\frac{\partial}{\partial(\omega_0 t)}|\psi\rangle, \tag{6.6}$$

the temporal evolution of these coherent states is obtained as

$$\begin{aligned} U(t)|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon} &= e^{-i\omega_0 t\mathcal{H}_{\lambda,\epsilon}}|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon} \\ &= \sum_{n=0}^{\infty} z^n\left(\frac{C_0^+(z)}{\rho_+(n)}e^{-i\omega_0 tE_n^+}|E_n^+\rangle + \frac{C_0^-(z)}{\rho_-(n)}e^{-i\omega_0 tE_n^-}|E_n^-\rangle\right). \end{aligned} \tag{6.7}$$

Additional constraints can now be imposed to fix the undetermined functions appearing in such states. First, let us recall that the functions $k_\pm(n)$ in (6.4) have been determined up to a phase $\varphi_\pm(n)$, and a way to fix them is to ask for the temporal stability[15] of the coherent states (6.5), which in our case means that

$$U(t)|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon} = U(t)|z;\alpha_+,\alpha_-;\boldsymbol{\theta}\rangle_{\lambda,\epsilon} = |z;\alpha_+ + t,\alpha_- + t;\boldsymbol{\theta}\rangle_{\lambda,\epsilon}. \tag{6.8}$$

Indeed, taking into account what has been done in the two preceding sections, we first write

$$k_\pm(n) = e^{i\varphi_\pm(n)}k_\pm^0(n), \tag{6.9}$$

where $k_\pm^0(n)$ are now real functions, and then, from (6.4), we get

$$\rho_\pm(n) = e^{i\Sigma_{\ell=1}^n\varphi_\pm(\ell)}\prod_{\ell=1}^n k_\pm^0(\ell) = e^{i\Sigma_{\ell=1}^n\varphi_\pm(\ell)}\rho_\pm^0(n),\ \rho_\pm(0) = 1, \tag{6.10}$$

$\rho_\pm^0(n)$ being real functions. The states (6.5) may be written as

$$|z;\alpha_+,\alpha_-;\boldsymbol{\theta}\rangle_{\lambda,\epsilon} = C_0^+(z)|E_0^+\rangle + C_0^-(z)|E_0^-\rangle + \sum_{n=1}^{\infty} z^n\left(\frac{C_0^+(z)}{\rho_+^0(n)}e^{-i\Sigma_{\ell=1}^n\varphi_+(\ell)}|E_n^+\rangle + \frac{C_0^-(z)}{\rho_-^0(n)}e^{-i\Sigma_{\ell=1}^n\varphi_-(\ell)}|E_n^-\rangle\right), \tag{6.11}$$

where the presence of the phases is now explicit. It can be proved that the temporal stability (6.8) is assured by choosing the, up to now, arbitrary phases to be linear functions of the real parameters $\alpha_\pm$, more precisely,

$$\varphi_\pm(\ell) = \omega_0\alpha_\pm(E_\ell^\pm - E_{\ell-1}^\pm) = \omega_0(1 + \epsilon \pm [q(\ell+1) - q(\ell)])\alpha_\pm, \tag{6.12}$$

so that

$$\sum_{\ell=1}^{n}\varphi_\pm(\ell) = \omega_0\alpha_\pm(E_n^\pm - E_0^\pm). \tag{6.13}$$

If we redefine

$$K_0^\pm(z) = C_0^\pm(z)e^{i\omega_0\alpha_\pm E_0^\pm}, \tag{6.14}$$

the coherent states (6.11) will now take the form

$$|z;\alpha_+,\alpha_-;\boldsymbol{\theta}\rangle_{\lambda,\epsilon} = \sum_{n=0}^{\infty} z^n\left(\frac{K_0^+(z)}{\rho_+^0(n)}e^{-i\omega_0\alpha_+E_n^+}|E_n^+\rangle + \frac{K_0^-(z)}{\rho_-^0(n)}e^{-i\omega_0\alpha_-E_n^-}|E_n^-\rangle\right). \tag{6.15}$$

Note first that, due to the form of the eigenstates $|E_n^{\pm}\rangle$ in the Fock space F, we deal with vector coherent states.[16] More precisely, using (2.23), we can observe that the states (6.15) may be written using similar matrix decomposition as in Ref. 16, i.e.,

$$|z;\alpha_+,\alpha_-;\boldsymbol{\theta}\rangle_{\lambda,\epsilon}=\sum_{n=0}^{\infty}\mathcal{U}_{\lambda,\epsilon}\begin{pmatrix}\dfrac{1}{\rho_+^0(n)} & 0\\ 0 & \dfrac{1}{\rho_-^0(n)}\end{pmatrix}\begin{pmatrix}z & 0\\ 0 & z\end{pmatrix}^n \exp\left[-i\begin{pmatrix}\omega_0\alpha_+E_n^+ & 0\\ 0 & \omega_0\alpha_+E_n^-\end{pmatrix}\right]$$
$$\times\left\{K_0^+(z)\begin{pmatrix}|n\rangle\\ 0\end{pmatrix}+K_0^-(z)\begin{pmatrix}0\\ |n\rangle\end{pmatrix}\right\}, \tag{6.16}$$

where $\mathcal{U}_{\lambda,\epsilon}$ is the operator given in (2.22).

Second, the normalization to unity of the states (6.15) leads to the following condition on the quantities $K_0^{\pm}(z)$:

$$|K_0^+(z)|^2\left(\sum_{n=0}^{\infty}\frac{|z|^{2n}}{(\rho_+^0(n))^2}\right)+|K_0^-(z)|^2\left(\sum_{n=0}^{\infty}\frac{|z|^{2n}}{(\rho_-^0(n))^2}\right)=1. \tag{6.17}$$

Introducing now the positive real functions $K^+(z)$ and $K^-(z)$, defined as

$$K^{\pm}(z)=\left(\sum_{n=0}^{\infty}\frac{|z|^{2n}}{(\rho_{\pm}^0(n))^2}\right)^{-1/2}, \tag{6.18}$$

where

$$K_0^+(z)=K^+(z)\cos\,\theta,\quad K_0^-(z)=K^-(z)e^{i\phi}\sin\,\theta,\quad \theta\in[0,\pi],\quad \phi\in[0,2\pi). \tag{6.19}$$

We can write the final form of the general coherent states (6.15), which now contain the variables $\boldsymbol{\theta}=(\theta,\phi)\in S^2$ parametrizing the unit sphere, as

$$|z;\alpha_+,\alpha_-;\theta,\phi\rangle_{\lambda,\epsilon}=K^+(z)\cos\,\theta\left(\sum_{n=0}^{\infty}\frac{z^n}{\rho_+^0(n)}e^{-i\omega_0\alpha_+E_n^+}|E_n^+\rangle\right)+K^-(z)e^{i\phi}\sin\,\theta\left(\sum_{n=0}^{\infty}\frac{z^n}{\rho_-^0(n)}e^{-i\omega_0\alpha_-E_n^-}|E_n^-\rangle\right). \tag{6.20}$$

At this moment it is important to insist on the fact that the coherent states we have do not depend only on the complex number z, as it is usual, but also on the variables $\boldsymbol{\theta}\in S^2$. Therefore, the space parametrizing our coherent states is $\mathbb{C}\times S^2$.

Let us mention also that the mean value of the Jaynes-Cummings energy in those states is given by

$$\langle\mathcal{H}_{\lambda,\epsilon}\rangle=(K^+(z))^2\cos^2\,\theta\left(\sum_{n=0}^{\infty}E_n^+\frac{|z|^{2n}}{(\rho_+^0(n))^2}\right)+(K^-(z))^2\sin^2\,\theta\left(\sum_{n=0}^{\infty}E_n^-\frac{|z|^{2n}}{(\rho_-^0(n))^2}\right). \tag{6.21}$$

To be more precise on the results, it is necessary to fix the values of the functions $K^{\pm}(z)$; and to do that, it is necessary to consider the particular examples studied in the previous section, some of which are studied next.

B. Examples

Example 1: The commutator of the ladder operators is the identity. Let us take the ladder operators such that the commutator is the identity. In this case, from (6.3), (6.9), and (6.10), we find

$$\rho_{\pm}^{0}(n)=\sqrt{n!},\quad K^{\pm}(z)=e^{-|z|^2/2} \tag{6.22}$$

and the coherent states (6.20) may be written as

$$|z;\alpha_+,\alpha_-;\theta,\phi\rangle_{\lambda,\epsilon}=e^{-|z|^2/2}\left[\cos\,\theta\left(\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}}e^{-i\omega_0\alpha_+E_n^+}|E_n^+\rangle\right)+\sin\,\theta e^{i\phi}\left(\sum_{n=0}^{\infty}\frac{z^n}{\sqrt{n!}}e^{-i\omega_0\alpha_-E_n^-}|E_n^-\rangle\right)\right]. \tag{6.23}$$

Taking into account the explicit form (2.19) and (2.20) of the energies $E_n^{\pm}$, the mean value (6.21) is thus

$$\langle\mathcal{H}_{\lambda,\epsilon}\rangle=(1+\epsilon)(1+|z|^2)+e^{-|z|^2}\left(\sum_{n=0}^{\infty}q(n+1)\frac{|z|^{2n}}{n!}\right)\cos 2\theta. \tag{6.24}$$

For a large number of photons, i.e., $|z|\to\infty$, it has been shown[7] that we get

$$\langle\mathcal{H}_{\lambda,0}\rangle\to 1+|z|^2+|\lambda||z|\cos 2\theta. \tag{6.25}$$

Note that the coherent states given in Ref. 7 are a special case of (6.30) when $\alpha_{\pm}=0$. This means that they do not satisfy the temporal stability given in (6.8). Let us mention that other relevant mean values have been given also in Ref. 7.

For the special case when $\lambda=0$ and $\epsilon>0$ (the case $\epsilon<0$ will be similar), we get explicitly the annihilation operator (6.6),

$$\mathcal{M}_{0,\epsilon}^{-}=\begin{pmatrix} e^{i(1+\epsilon)\omega_0\alpha_-}a & 0 \\ 0 & e^{i(1+\epsilon)\omega_0\alpha_+}\sqrt{\dfrac{N}{N+1}}a \end{pmatrix}. \tag{6.26}$$

Moreover, since we have $E_n^{\pm}=(1+\epsilon)(n+1)\pm(\epsilon/2)$ and the energy eigenstates are given by $\{|E_n^+\rangle=|n+1,-\rangle,|E_n^-\rangle=|n,+\rangle\}$, we get

$$|z;\alpha_+,\alpha_-;\theta,\phi\rangle_{0,\epsilon}=e^{-|z|^2/2}\left[\cos\,\theta e^{-i\omega_0[1+(3\epsilon/2)]\alpha_+}\left(\sum_{n=0}^{\infty}\frac{(ze^{-i\omega_0(1+\epsilon)\alpha_+})^n}{\sqrt{n!}}|n+1,-\rangle\right)\right.$$
$$\left.+\sin\,\theta e^{i\phi}e^{-i\omega_0[1+(\epsilon/2)]\alpha_-}\left(\sum_{n=0}^{\infty}\frac{(ze^{-i\omega_0(1+\epsilon)\alpha_-})^n}{\sqrt{n!}}|n,+\rangle\right)\right]. \tag{6.27}$$

These are generalized coherent states of the supersymmetric harmonic oscillator $\mathcal{H}_{0,\epsilon}$ and the mean value of the energy is directly obtained through (6.24) [or through the factorization (6.8)] as

$$\langle\mathcal{H}_{0,\epsilon}\rangle=(1+\epsilon)(1+|z|^2)+\frac{\epsilon}{2}\cos 2\theta. \tag{6.28}$$

For the special case when $\epsilon=0$ the eigenstates and eigenvalues are given in (2.31)–(2.33) and using (6.12)

$$\varphi_{\pm}(n)=\omega_0(1\pm|\lambda|(\sqrt{n+1}-\sqrt{n}))\alpha_{\pm}. \tag{6.29}$$

The annihilator is given as (4.9) and the coherent states (6.23) thus take the form

$$|z;\alpha_+,\alpha_-;\theta,\phi\rangle_{\lambda,0}=\frac{\sqrt{2}}{2}e^{-|z|^2/2}\left[\cos\,\theta e^{-i\omega_0\alpha_+}\left(\sum_{n=0}^{\infty}\frac{(ze^{-i\omega_0\alpha_+})^n}{\sqrt{n!}}e^{-i\omega_0|\lambda|\sqrt{n+1}\alpha_+}(\xi_\lambda|n,+\rangle+|n+1,-\rangle)\right)\right.$$
$$\left.+\sin\,\theta e^{i(\phi-\omega_0\alpha_-)}\left(\sum_{n=0}^{\infty}\frac{(ze^{-i\omega_0\alpha_-})^n}{\sqrt{n!}}e^{i\omega_0|\lambda|\sqrt{n+1}\alpha_-}(|n,+\rangle-\xi_\lambda|n+1,-\rangle)\right)\right] \quad (6.30)$$

and the mean value of the energy is given as

$$\langle\mathcal{H}_{\lambda,0}\rangle=1+|z|^2+|\lambda|e^{-|z|^2}\cos 2\theta\left(\sum_{n=0}^{\infty}\sqrt{n+1}\frac{|z|^{2n}}{n!}\right). \quad (6.31)$$

Example 2: The Hamiltonian is factorized. Next, some annihilators dealing with the factorization of the Jaynes-Cummings Hamiltonian will be considered. Indeed, we first take the annihilator (5.7) which led to the factorization (5.8). In this case, we have $\varphi_\pm(\ell)=\omega_0(1+\epsilon)\alpha_\pm$. Thus, from (5.2) with $\mu_-=-\epsilon/2$ and $\mu_+=-[1+(\epsilon/2)]$, we get

$$k_+(n)=e^{i\omega_0(1+\epsilon)\alpha_+}\sqrt{(1+\epsilon)(n+1)},\quad k_-(n)=e^{i\omega_0(1+\epsilon)\alpha_-}\sqrt{(1+\epsilon)n} \quad (6.32)$$

and

$$\rho_+^0(n)=(1+\epsilon)^{n/2}\sqrt{(n+1)!},\quad \rho_-^0(n)=(1+\epsilon)^{n/2}\sqrt{n!}. \quad (6.33)$$

Moreover, we have

$$K^+(z)=\left(\frac{|\zeta|^2}{e^{|\zeta|^2}-1}\right)^{1/2},\quad K^-(z)=e^{-|\zeta|^2/2}, \quad (6.34)$$

introducing the new variable $\zeta=z/\sqrt{1+\epsilon}$. The coherent states are explicitly given as

$$|z;\alpha_+,\alpha_-;\theta,\phi\rangle_{0,\epsilon}=\left(\frac{\bar{\zeta}\zeta}{e^{|\zeta|^2}-1}\right)^{1/2}\cos\,\theta e^{-i\omega_0(\epsilon/2)\alpha_+}\left(\sum_{n=1}^{\infty}\frac{(\zeta e^{-i\omega_0(1+\epsilon)\alpha_+})^n}{\sqrt{n!}}|n,-\rangle\right)$$
$$+e^{-|z|^2/2}\sin\,\theta e^{i\phi}e^{-i\omega_0[1+(\epsilon/2)]\alpha_-}\left(\sum_{n=0}^{\infty}\frac{(\zeta e^{-i\omega_0(1+\epsilon)\alpha_-})^n}{\sqrt{n!}}|n,+\rangle\right), \quad (6.35)$$

which are closely related to the usual harmonic oscillator coherent states. The mean value of the energy in these coherent states is easily obtained through the factorization (5.8),

$$\langle\mathcal{H}_{0,\epsilon}\rangle=|z|^2+\frac{1+\epsilon}{2}-\frac{1}{2}\cos 2\theta. \quad (6.36)$$

Let us finally mention that when the ladder operators factorize the diagonalized Hamiltonian $\mathbb{H}_{\lambda,\epsilon}$, as in (5.12), we find the coherent states constructed in Ref. 10. In this case, we have $k_\pm^0(n)=\sqrt{E_n^\pm-E_0^\pm}$ and

$$\rho_\pm^0(n)=\sqrt{\prod_{\ell=1}^{n}(E_\ell^\pm-E_0^\pm)}. \quad (6.37)$$

C. The resolution of the identity

To end this section, we will analyze the completeness (in fact, the overcompleteness) of the systems of coherent states we have studied before. In order to accomplish this goal, we must compute the resolution of the identity,[10,12,15] which can be written here as

$$I = |E_*\rangle\langle E_*| + \int (|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon})({}_{\lambda,\epsilon}\langle z;\boldsymbol{\alpha};\boldsymbol{\theta}|)\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta}), \tag{6.38}$$

where the measure $\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta})$ could be determined through different special cases. The matrix operator appearing here can be written as follows:

$$(|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon})({}_{\lambda,\epsilon}\langle z;\boldsymbol{\alpha};\boldsymbol{\theta}|) = (K^+(z))^2\cos^2\theta\sum_{n=0}^{\infty}\frac{|z|^{2n}}{(\rho_+^0(n))^2}|E_n^+\rangle\langle E_n^+| \tag{6.39}$$

$$+ (K^-(z))^2\sin^2\theta\sum_{n=0}^{\infty}\frac{|z|^{2n}}{(\rho_-^0(n))^2}|E_n^-\rangle\langle E_n^-| \tag{6.40}$$

$$+ (K^+(z))^2\cos^2\theta\sum_{n\neq m}^{\infty}\frac{z^n\overline{z}^m}{\rho_+^0(n)\rho_+^0(m)}e^{-i\omega_0\alpha_+(E_n^+-E_m^+)}|E_n^+\rangle\langle E_m^+| \tag{6.41}$$

$$+ (K^-(z))^2\sin^2\theta\sum_{n\neq m}^{\infty}\frac{z^n\overline{z}^m}{\rho_-^0(n)\rho_-^0(m)}e^{-i\omega_0\alpha_-(E_n^--E_m^-)}|E_n^-\rangle\langle E_m^-| \tag{6.42}$$

$$+ K^+(z)K^-(z)e^{-i\phi}\cos\theta\sin\theta\sum_{n,m=0}^{\infty}\frac{z^n\overline{z}^m}{\rho_+^0(n)\rho_-^0(m)}e^{-i\omega_0(\alpha_+E_n^+-\alpha_-E_m^-)}|E_n^+\rangle\langle E_m^-| \tag{6.43}$$

$$+ K^+(z)K^-(z)e^{i\phi}\cos\theta\sin\theta\sum_{n,m=0}^{\infty}\frac{z^n\overline{z}^m}{\rho_-^0(n)\rho_+^0(m)}e^{-i\omega_0(\alpha_-E_n^--\alpha_+E_m^+)}|E_n^-\rangle\langle E_m^+|. \tag{6.44}$$

The integration of this operator with respect to the measure $\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta})$ should include an integration over the complex plane ($z\in\mathbb{C}$) and also an integration over the sphere S^2 with respect to $\theta\in[0,\pi]$ and $\phi\in[0,2\pi)$, as indicated in (6.19), with the usual measure $\mathrm{d}\Omega=\sin\theta\,\mathrm{d}\theta\,\mathrm{d}\phi$. To be precise, $\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta})=\mathcal{W}(|z|)\mathrm{d}z\,\mathrm{d}\Omega$, where $\mathcal{W}(|z|)$ is an appropriate "weight matrix" to be determined later. The integration with respect to $\mathrm{d}\Omega$ completely eliminates the terms in (6.43) and (6.44). Moreover, we can show that the terms (6.41) and (6.42) also disappear. Indeed, using polar coordinates $(r=|z|,\varphi)$ on the complex plane and assuming that $K^{\pm}(z)$ depends only on r (as it happens in the two examples considered in the preceding section), that is, $K^{\pm}(z)\equiv K^{\pm}(r)$, it is very easy to see that the integration on $\varphi\in[0,2\pi)$ eliminates all the terms in which $n\neq m$. Therefore, we get

$$\int (|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon})({}_{\lambda,\epsilon}\langle z;\boldsymbol{\alpha};\boldsymbol{\theta}|)\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta}) = \frac{8\pi^2}{3}\sum_{n=0}^{\infty}\frac{1}{(\rho_+^0(n))^2}|E_n^+\rangle\langle E_n^+|\int_0^{\infty}(K^+(r))^2\mathcal{W}(r)r^{2n+1}\,\mathrm{d}r \tag{6.45}$$

$$+ \frac{16\pi^2}{3}\sum_{n=0}^{\infty}\frac{1}{(\rho_-^0(n))^2}|E_n^-\rangle\langle E_n^-|\int_0^{\infty}(K^-(r))^2\mathcal{W}(r)r^{2n+1}\,\mathrm{d}r. \tag{6.46}$$

To go further, we remark that in the diagonal basis the operators $|E_n^+\rangle\langle E_n^+|$ and $|E_n^-\rangle\langle E_n^-|$ are proportional to the matrices

$$\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix},$$

respectively. Hence, the "weight matrix" $\mathcal{W}(r)$ should be taken diagonal, in the form

$$\mathcal{W}(r) = \begin{pmatrix} W^+(r) & 0 \\ 0 & W^-(r) \end{pmatrix}, \tag{6.47}$$

and then Eqs. (6.45) and (6.46) take the form

$$\int (|z;\boldsymbol{\alpha};\boldsymbol{\theta}\rangle_{\lambda,\epsilon})(_{\lambda,\epsilon}\langle z;\boldsymbol{\alpha};\boldsymbol{\theta}|)\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta}) = \sum_{n=0}^{\infty} \frac{\int_0^\infty h^+(u)u^n\,\mathrm{d}u}{(\rho_+^0(n))^2}|E_n^+\rangle\langle E_n^+| + \sum_{n=0}^{\infty} \frac{\int_0^\infty h^-(u)u^n\,\mathrm{d}u}{(\rho_-^0(n))^2}|E_n^-\rangle\langle E_n^-|, \tag{6.48}$$

where $u=r^2$ and

$$h^+(r^2) = \frac{4\pi^2}{3}(K^+(r))^2W^+(r), \quad h^-(r^2) = \frac{8\pi^2}{3}(K^-(r))^2W^-(r). \tag{6.49}$$

Therefore, in order to have a resolution of the identity on the subspace $F-F_0$, we must have the following conditions:

$$\int_0^\infty h^\pm(u)u^n\,\mathrm{d}u = (\rho_\pm^0(n))^2, \tag{6.50}$$

where the functions $\rho_\pm^0(n)$ are known (in particular, they can be some of the functions determined in the preceding section). What we have here is a couple of "moment problems," i.e., given $(\rho_\pm^0(n))^2$ we must find the functions $h^\pm(u)$ satisfying (6.50).

To show that this construction admits explicit solutions, let us consider now the two examples considered in the preceding section.

Example 1: The commutator of the ladder operators is the identity. In this case, the functions $\rho_\pm^0(n)$ and $K^\pm(r)$ were given in (6.22). Hence, the momentum problem is unique,

$$\int_0^\infty h^\pm(u)u^n\,\mathrm{d}u = b^n n!, \quad b=1. \tag{6.51}$$

We have introduced here the constant b in order to give a solution to the momentum problem which will be useful for the next example too. Indeed, the solution of (6.51) is well known,

$$h^\pm(u) = \left.\frac{1}{b}e^{-u/b}\right|_{b=1} = e^{-u}, \tag{6.52}$$

and therefore

$$W^+(r) = \frac{3}{4\pi^2}, \quad W^-(r) = \frac{3}{8\pi^2}. \tag{6.53}$$

Example 2: The Hamiltonian is factorized. In the present case, the functions $\rho_\pm^0(n)$ are given in (6.33) and the functions $K^\pm(r)$ in (6.34). The two momentum problems are now different,

$$\int_0^\infty h^-(u)u^n\,\mathrm{d}u = b^n n!, \quad \int_0^\infty h^+(u)u^n\,\mathrm{d}u = b^n(n+1)!, \tag{6.54}$$

where in both cases $b=1+\epsilon$. The solutions are

$$h^{-}(u) = \left.\frac{1}{b}e^{-u/b}\right|_{b=1+\epsilon} = \frac{1}{1+\epsilon}e^{-u/(1+\epsilon)}, \tag{6.55}$$

$$h^{+}(u) = \left.\frac{u}{b^2}e^{-u/b}\right|_{b=1+\epsilon} = \frac{u}{(1+\epsilon)^2}e^{-u/(1+\epsilon)}. \tag{6.56}$$

The weight matrix elements are then

$$W^{-}(r) = \frac{3}{8\pi^2}\frac{1}{1+\epsilon}, \quad W^{+}(r) = \frac{3}{4\pi^2}\frac{1-e^{-r^2/(1+\epsilon)}}{1+\epsilon}. \tag{6.57}$$

The two examples previously considered show that in every particular case, it is possible to obtain the "weight matrix" associated to the measure $\mathrm{d}\mu(z;\boldsymbol{\alpha};\boldsymbol{\theta})$ in such a way that the resolution of the identity (6.38) is satisfied by the corresponding family of coherent states.

VII. FINAL REMARKS

The main objective of this paper was to make a systematic study of the ladder operators associated to the Jaynes-Cummings model. We notice that several authors have considered some factorization of the corresponding Hamiltonian and then used the factor operators to build up coherent states, for example. Sometimes, these factors turned out to be either special cases of our ladder operators[10] or, sometimes, they had no relation with our work because they are not raising or lowering operators at all.[13,17]

Let us recall that the ladder operators $\mathcal{M}^{+}_{\lambda,\epsilon}$ and $\mathcal{M}^{-}_{\lambda,\epsilon}$ have been defined so they move up and down the energy eigenstates $\{|E^{-}_n\rangle\}$ and $\{|E^{+}_n\rangle\}$ without mixing them. We see in Figs. 1 and 2 that the energy levels are in fact intercalated into each other and the way they are mixed depends on the values of λ and ϵ. Using the fact that for the diagonalized Hamiltonian $\mathbb{H}_{\lambda,\epsilon}$ in (2.21), the energy eigenstates are given by the two sets $\{|n,-\rangle\}$ and $\{|n,+\rangle\}$, the operator which exchanges the two sets is nothing else but the matrix σ_1 and the corresponding operator for the original Hamiltonian $\mathcal{H}_{\lambda,\epsilon}$ in (2.8) is

$$\Sigma_{\lambda,\epsilon} = \mathcal{U}_{\lambda,\epsilon}\sigma_1\mathcal{U}^{+}_{\lambda,\epsilon} = \begin{pmatrix} \lambda\dfrac{\sqrt{N+1}}{q(N+1)} & \dfrac{\epsilon/2}{q(N+1)\sqrt{N+1}}a \\ a^{\dagger}\dfrac{\epsilon/2}{q(N+1)\sqrt{N+1}} & -\lambda\dfrac{\sqrt{N}}{q(N)} \end{pmatrix}. \tag{7.1}$$

The limit when $\lambda \to 0$ gives the operator

$$\Sigma_{0,\epsilon} = \begin{pmatrix} 0 & \dfrac{\epsilon/|\epsilon|}{\sqrt{N+1}}a \\ a^{\dagger}\dfrac{\epsilon/|\epsilon|}{\sqrt{N+1}} & 0 \end{pmatrix}, \tag{7.2}$$

while for $\epsilon \to 0$, we get $\Sigma_{\lambda,0} = \xi_\lambda\sigma_3$. Let us mention that it acts correctly on the eigenstates, i.e.,

$$\Sigma_{\lambda,0}|E^{\pm}_n\rangle = |E^{\mp}_n\rangle, \quad \Sigma_{\lambda,0}|E_*\rangle = 0. \tag{7.3}$$

Using the operators $\Sigma_{\lambda,\epsilon}$, $\mathcal{M}^{+}_{\lambda,\epsilon}$, and $\mathcal{M}^{-}_{\lambda,\epsilon}$, we can connect all the different eigenstates of the system, as it is shown in Fig. 3. With all of them it will be possible to make a comprehensive analysis of the Jaynes-Cummings model using in particular our new sets of coherent states. This work is in progress.

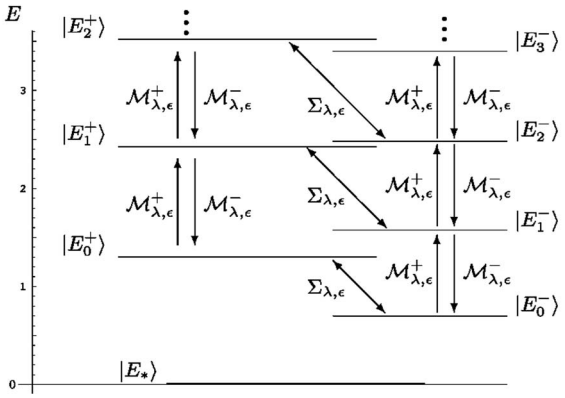

FIG. 3. The eigenstates of the Jaynes-Cummings Hamiltonian for ($\epsilon=0$, $\lambda=0.3$) are interconnected by means of the operators $\Sigma_{\lambda,\epsilon}$ $\mathcal{M}^+_{\lambda,\epsilon}$ and $\mathcal{M}^-_{\lambda,\epsilon}$

For a quantum particle interacting with a short-range potential, we estimate from below the shift of its binding threshold, which is due to the particle interaction with a quantized radiation field. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2142835]

I. INTRODUCTION

Recently, the question of enhanced binding in nonrelativistic QED has been extensively studied in several presentations.[10,9,6,4,2,3] Dressing a charged particle with photons increases the ability of a potential to confine it. For the Pauli-Fierz operator which describes a nonrelativistic particle interacting with a radiation field, this effect was proved for small values of the fine structure constant α, first under the simplifying assumption that the spin of the particle is absent,[9] and later generalized to the case of a particle with spin.[6,4] In Ref. 2, it was shown that the effect of the enhanced binding is asymptotically small in α in the sense that the binding threshold for the Pauli-Fierz operator tends to the binding threshold for the corresponding Schrödinger operator as α tends to zero. Some quantitative estimates on this effect were obtained in Ref. 3 where it was proved that the difference between the binding threshold for the Schrödinger operator and the corresponding Pauli-Fierz operator with spin zero is at least of the order α. In the work at hand, using a different method, we prove similar results for the more general case of a particle with spin zero or one-half. Notice that studying the enhanced binding effect in the case of a particle with spin requires recovering one more term of the energy's expansion in powers of α than in the spinless case.

The method of the proof is a further development of a method used in Refs. 9 and 6. We prove that the Pauli-Fierz operator has a ground state even for some value of the potential coupling constant that is smaller than the binding threshold for the corresponding Schrödinger operator. To do so, we construct a trial function for which the quadratic form of the Pauli-Fierz operator with this coupling constant takes a value strictly less than the self-energy. Then we apply (Ref. 8, Theorem 2.1) which tells us that this implies the existence of a ground state. The trial function we

[a)]Electronic mail: barbarou@univ-tln.fr
[b)]Electronic mail: Helmut.Linde@gmx.de
[c)]Electronic mail: wugalter@mathematik.uni-muenchen.de

use is similar to the one in Ref. 6 with some modifications necessary to obtain quantitative estimates in the case with spin. It is constructed using the ground state of the self-energy operator with total momentum zero.

As in all previous papers,[9,6,4,2,3] our method is asymptotic in α. Therefore, the problem of establishing the enhanced binding effect and estimating its strength for the physical value of $\alpha \approx 1/137$ still remains open.

II. DEFINITIONS AND MAIN RESULT

The Pauli-Fierz Hamiltonian H for a charged particle with or without spin in an external electrostatic potential and coupled to the quantized electromagnetic radiation field is defined by

$$H = (-i\nabla_x \otimes I_f + \sqrt{\alpha}A(x))^2 + g\sqrt{\alpha}\sigma \cdot B(x) + \lambda W(x) \otimes I_f + I_{el} \otimes H_f - c_{\text{n.o.}}\alpha. \tag{1}$$

The operator H acts on the Hilbert space $\mathfrak{H} := \mathfrak{H}^{\text{el}} \otimes \mathfrak{F}$. The Hilbert space $\mathfrak{H}^{\text{el}}$ of the nonrelativistic particle is $L^2(\mathbb{R}^3) \otimes \mathbb{C}^2$ in the case $g=1$ and $L^2(\mathbb{R}^3)$ in the case $g=0$. Here $\mathbb{R}^3$ is the configuration space of a single particle, while $\mathbb{C}^2$ accommodates its spin in the case $g=1$.

We will describe the quantized electromagnetic field by use of the Coulomb gauge condition. Accordingly, the one-photon Hilbert space is given by $L^2(\mathbb{R}^3) \otimes \mathbb{C}^2$, where $\mathbb{R}^3$ denotes either the photon momentum or configuration space, and $\mathbb{C}^2$ accounts for the two independent transversal polarizations of the photon. The photon Fock space is then defined by

$$\mathfrak{F} = \bigoplus_{n=0}^{\infty} \mathfrak{F}_s^{(n)},$$

where the n-photons space $\mathfrak{F}_s^{(n)} = \otimes_s^n (L^2(\mathbb{R}^3) \otimes \mathbb{C}^2)$ is the symmetric tensor product of n copies of $L^2(\mathbb{R}^3) \otimes \mathbb{C}^2$.

We use units such that $\hbar = c = 1$, and where the mass of the particle equals $m = 1/2$. The particle charge is then given by $e = \sqrt{\alpha}$. As usual, we will consider α as a small parameter.

The operator that couples a particle to the quantized vector potential is given by

$$A(x) = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} \frac{\zeta(|k|)}{2\pi|k|^{1/2}} \varepsilon_\lambda(k)[e^{ikx} \otimes a_\lambda(k) + e^{-ikx} \otimes a_\lambda^*(k)]\mathrm{d}k$$

$$=: D(x) + D^*(x),$$

where $\operatorname{div} A = 0$ by the Coulomb gauge condition. The operators a_λ, a_λ^* satisfy the usual commutation relations

$$[a_\nu(k), a_\lambda^*(k')] = \delta(k-k')\delta_{\lambda,\nu}, \quad [a_\nu(k), a_\lambda(k')] = 0.$$

The vectors $\varepsilon_\lambda(k) \in \mathbb{R}^3$ are the two orthonormal polarization vectors perpendicular to k,

$$\varepsilon_1(k) = \frac{(k_2, -k_1, 0)}{\sqrt{k_1^2 + k_2^2}} \quad \text{and } \varepsilon_2(k) = \frac{k}{|k|} \wedge \varepsilon_1(k). \tag{2}$$

The function $\zeta(|k|)$ describes the *ultraviolet cutoff* on the wave numbers k. We assume ζ to be of class C^1 and to have compact support.

The constant $c_{\text{n.o.}}$ is

$$c_{\text{n.o.}} = [D, D^*] = \frac{2}{\pi} \int_0^\infty r|\zeta(r)|^2 \, \mathrm{d}r,$$

and subtraction of the constant $c_{\text{n.o.}}\alpha$ amounts to normal ordering of the operator A^2.

The operator that couples a particle to the magnetic field $B = \operatorname{curl} A$ is given by

$$B(x) = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} \frac{\zeta(|k|)}{2\pi|k|^{1/2}} k \times i\varepsilon_\lambda(k)[e^{ikx} \otimes a_\lambda(k) - e^{-ikx} \otimes a_\lambda^*(k)]\mathrm{d}k$$

$$=: K(x) + K^*(x).$$

In Eq. (1), $\sigma=(\sigma_1,\sigma_2,\sigma_3)$ is the three-component vector of Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The photon field energy operator H_f is given by

$$H_f = \sum_{\lambda=1,2} \int_{\mathbb{R}^3} |k| a_\lambda^*(k) a_\lambda(k) \mathrm{d}k.$$

The multiplicative potential W is assumed to be short range and in $L^4_{\mathrm{loc}}(\mathbb{R}^3)$, and λ is a positive coupling constant. If the negative part of W is nontrivial, then there exists a critical value λ_0 such that the Schrödinger operator $-\Delta+\lambda W$ has discrete spectrum for all $\lambda>\lambda_0$, but does not have any discrete spectrum for $0\leqslant\lambda<\lambda_0$. Analogously, the Pauli-Fierz operator also has a critical coupling constant λ_1, which depends on the fine structure constant α. It is known[2] that λ_1 converges to λ_0 from below as α goes to zero.

Before stating our main result, let us introduce some notations. For v a measurable function in $\mathbb{R}^3$, we define

$$d_v = \frac{1}{2\pi}\left(\int \frac{|v(x)||v(y)|}{|x-y|^2} \mathrm{d}x\, \mathrm{d}y \right)^{1/2}, \tag{3}$$

if v is not spherically symmetric and

$$d_v = \min\left\{ \frac{1}{2\pi}\left(\int \frac{|v(x)||v(y)|}{|x-y|^2} \mathrm{d}x\, \mathrm{d}y \right)^{1/2}, \int_0^\infty t|v(t)|\mathrm{d}t \right\} \tag{4}$$

if v is spherically symmetric.

Our main result is the following.

Theorem 2.1: *Assume that $W(x)$ satisfies the following conditions: $W\in L^4_{\mathrm{loc}}(\mathbb{R}^3)$ and there exists $a>0$, $c>0$, and $\delta>0$, such that for all $|x|>a$, $|W(x)|\leqslant c(1+|x|)^{-2-\delta}$. Then*

$$\lambda_1 \leqslant \lambda_0(1 - \alpha\eta^2 + \mathcal{O}(\alpha^{5/4}))$$

with

$$\eta^2 = \frac{1}{6\pi^2} \int_{\mathbb{R}^3} \frac{\zeta(|k|)}{|k|(k^2+|k|+C_W)} \mathrm{d}k,$$

and

$$C_W = \lambda_0^2(1+\lambda_0 d_{W_+}) d_{W^2} \quad \textit{and } W_+ = (|W|+W)/2.$$

III. PROOF OF THE MAIN THEOREM

In this section, we will prove the main theorem in the case of particle with spin $g=1$. The proof for $g=0$ can easily be deduced with several simplifications.

We start with establishing some useful preliminary estimates.

A. Properties of the self-energy operator $T(0)$ with zero total momentum

This section addresses the main properties of the self-energy operator $T(0)$. Let us consider the case of a free particle coupled to the quantized electromagnetic field. The self-energy operator T is given by

$$T = (-i\nabla_x \otimes I_f + \sqrt{\alpha}A(x))^2 + g\sqrt{\alpha}\sigma \cdot B(x) + I_{\mathrm{el}} \otimes H_f - c_{\mathrm{n.o.}}\alpha.$$

We note that this system is translationally invariant, that is, T commutes with the operator of total momentum,

$$P_{\mathrm{tot}} = p_{\mathrm{el}} \otimes I_f + I_{\mathrm{el}} \otimes P_f,$$

where p_{el} and $P_f = \Sigma_{\lambda=1,2} \int k a_\lambda^*(k) a_\lambda(k) \mathrm{d}k$ denote the particle and the photon momentum operators.

Let $\mathfrak{H}_P \cong \mathbb{C}^2 \otimes \mathfrak{F}$ denote the fiber Hilbert space corresponding to conserved total momentum P. For any fixed value P of the total momentum, the restriction of T to the fiber space $\mathfrak{H}_P$ is given by (see, e.g., Ref. 5)

$$T(P) = (P - P_f + \sqrt{\alpha}A(0))^2 + g\sqrt{\alpha}\sigma \cdot B(0) + H_f - c_{\mathrm{n.o.}}\alpha. \tag{5}$$

We denote $\Sigma_0 := \inf \sigma(T(0))$.

For the reader convenience, we first collect in the following theorem different known facts regarding the ground state of the operator $T(0)$, which will be used in the proof of the main theorem.

From now on, we will denote by Π_n the projection onto the subspace of $\mathbb{C}^2 \otimes \mathfrak{F}$ corresponding to vectors which have all components zero except the n-photon components. We also define $\Pi_n^{\geqslant} = 1 - \Sigma_{i=1}^{n-1} \Pi_n$.

For vectors in $\mathbb{C}^2 \otimes \mathfrak{F}$, the norm $\|.\|$ will refer to the standard norm in $\mathbb{C}^2 \otimes \mathfrak{F}$.

Theorem 3.1: (Refs. 7, 5, 6, and 1) *For α sufficiently small we have*

Σ_0 is an eigenvalue bordering to continuous spectrum of $T(0)$ and $\Sigma_0 = \inf \sigma(T)$.

For any $\Omega_0 \in \mathrm{Ker}(T(0) - \Sigma_0)$, its projection $\Pi_0\Omega_0$ onto the zero-photon sector of $\mathbb{C}^2 \otimes \mathfrak{F}$ fulfills $\|\Pi_0\Omega_0\| \neq 0$. If Ω_0 is normalized by $\|\Pi_0\Omega_0\| = 1$, then the following inequalities are satisfied: $\|\Omega_0\| = 1 + \mathcal{O}(\alpha^{1/2})$, $\|D(0)\Omega_0\| = \mathcal{O}(\alpha^{1/2})$, and $\|H_f^{1/2}\Omega_0\| = \mathcal{O}(\alpha^{1/2})$.

For the photon number operator $N_f := \Sigma_{\lambda=1,2} \int a_\lambda^*(k) a_\lambda(k) \mathrm{d}k$, we have $\|N_f^{1/2}\Omega_0\| = \mathcal{O}(\alpha^{1/2})$.

Corollary 3.2: For any vector $\Omega_0 \in \mathrm{Ker}(T(0) - \Sigma_0)$ normalized by $\|\Pi_0\Omega_0\| = 1$, we have $\|\Omega_0\| = 1 + \mathcal{O}(\alpha)$, $\|D^*(0)\Pi_1^{\geqslant}\Omega_0\| = \mathcal{O}(\alpha^{1/2})$ and $\|\sigma \cdot K^*(0)\Pi_1^{\geqslant}\Omega_0\| = \mathcal{O}(\alpha^{1/2})$.

In the following, we consider two 4-vectors in $\mathbb{C}^2 \otimes (L^2(\mathbb{R}^3) \otimes \mathbb{C}^2)$, of the form $(\xi(\uparrow,k,\lambda_1), \xi(\uparrow,k,\lambda_2), \xi(\downarrow,k,\lambda_1), \xi(\downarrow,k,\lambda_2))$, where $\uparrow$ and $\downarrow$ refer to the spin-up and spin-down of the particle, and λ_1, λ_2 refer to the two polarizations of the transverse photons,

$$\Gamma_{a,b} := \begin{pmatrix} \Gamma(\uparrow,k,\lambda_1) \\ \Gamma(\uparrow,k,\lambda_2) \\ \Gamma(\downarrow,k,\lambda_1) \\ \Gamma(\downarrow,k,\lambda_2) \end{pmatrix} := \begin{pmatrix} \dfrac{\zeta_\Lambda(k)}{|k|^{1/2}} \left(-a\sqrt{k_1^2 + k_2^2} + b\dfrac{(k_1 - ik_2)k_3}{\sqrt{k_1^2 + k_2^2}} \right) \\ b\zeta_\Lambda(k) \dfrac{-k_2 - ik_1}{\sqrt{k_1^2 + k_2^2}} |k|^{1/2} \\ \dfrac{\zeta_\Lambda(k)}{|k|^{1/2}} \left(b\sqrt{k_1^2 + k_2^2} + a\dfrac{(k_1 + ik_2)k_3}{\sqrt{k_1^2 + k_2^2}} \right) \\ a\zeta_\Lambda(k) \dfrac{-k_2 + ik_1}{\sqrt{k_1^2 + k_2^2}} |k|^{1/2} \end{pmatrix}.$$

Let

$$\varphi_{a,b} = \sqrt{\alpha} \frac{i}{2\pi|k|(1 + |k|)} \Gamma_{a,b}. \tag{6}$$

Proposition 3.3 (approximate ground state of the Pauli-Fierz operator): *For a and b in* $\mathbb{C}$ *such that* $|a|^2+|b|^2=1$, *we consider the family of real-valued functionals* $L_{a,b}$ *defined on* $\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2$ *by*

$$L_{a,b}(\xi)=\left\langle (k^2+|k|)\xi,\xi\right\rangle+2\sqrt{\alpha}\,\mathcal{R}e\left\langle \xi,\Pi_1\sigma\cdot K^*(0)\left(\begin{pmatrix}a\\b\end{pmatrix}0,0,\cdots\right)\right\rangle,$$

where as before $B(0)=K(0)+K^*(0)$. *Then we have*

(i) *The vector* $\varphi_{a,b}$ *defined by* (6) *is the unique minimizer of* $L_{a,b}$.
(ii) $|\Sigma_0-\inf L_{a,b}(\xi)|=\mathcal{O}(\alpha^{3/2})$.
(iii) *Let* $\Omega_0\in\mathrm{Ker}(T(0)-\Sigma_0)$ *be normalized by* $\|\Pi_0\Omega_0\|=1$. *Let us denote by* $(a,b):=\Pi_0\Omega_0$. *We define the scalar product* $\langle .,.\rangle_1$ *onto the one-photon sector* $\Pi_1(\mathbb{C}^2\otimes\mathfrak{F})=\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2$ *by* $\langle f,g\rangle_1=\langle(k^2+|k|)f,g\rangle_{\Pi_1(\mathbb{C}^2\otimes\mathfrak{F})}$. *Then for* $\gamma\in\mathbb{R}$ *and* $R\in\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2$ *such that*

$$\Pi_1\Omega_0=\gamma\varphi_{a,b}+R$$

and $\langle\varphi_{a,b},R\rangle_1=0$, *we have*

$$\langle R,R\rangle_1=\mathcal{O}(\alpha^{3/2})\quad\text{and}\quad|\gamma-1|=\mathcal{O}(\alpha^{3/4}).\tag{7}$$

Remark 3.4: In the above proposition, and in the sequel, we use the same notation for $\Pi_1\Omega_0$ *as a vector in* $\mathbb{C}^2\otimes\mathfrak{F}$ *which has all components zero except its one-photon component* $(\Pi_1\Omega_0)^{(1)}$, *as well as for the vector* $(\Pi_1\Omega_0)^{(1)}$ *in* $\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2$.

Proof: In this proof, for the sake of simplicity of notations, we will drop the argument 0 in the operators $A(0)$, $B(0)$, $D(0)$, $K(0)$ and their adjoint. We first prove (i). Denoting

$$g_{a,b}:=\frac{1}{(k^2+|k|)}\Pi_1\sigma\cdot K^*\left(\begin{pmatrix}a\\b\end{pmatrix},0,0,\ldots\right),$$

we have

$$L_{a,b}(\xi)=\langle\xi,\xi\rangle_1+2\sqrt{\alpha}\,\mathcal{R}e\langle\xi,g_{a,b}\rangle_1=\left\|\xi+\sqrt{\alpha}g_{a,b}\right\|_1^2-\left\|\sqrt{\alpha}g_{a,b}\right\|_1^2,\tag{8}$$

where $\|.\|_1$ is the norm associated to the scalar product $\langle .,.\rangle_1$. Therefore, the minimizer of $L_{a,b}$ is $-\sqrt{\alpha}g_{a,b}$. A straightforward computation shows that $-\sqrt{\alpha}g_{a,b}=\varphi_{a,b}$. This implies that

$$\inf L_{a,b}=L_{a,b}(\varphi_{a,b})=-\left\|\varphi_{a,b}\right\|_1^2.\tag{9}$$

We now prove (ii). We have

$$\begin{aligned}\langle T(0)\Omega_0,\Omega_0\rangle&=\langle P_f^2\Omega_0,\Omega_0\rangle-\sqrt{\alpha}2\,\mathcal{R}e\langle P_f\Omega_0,A\Omega_0\rangle+\alpha\langle A^2\Omega_0,\Omega_0\rangle\\&\quad+\sqrt{\alpha}\langle\sigma\cdot B\Omega_0,\Omega_0\rangle+\langle H_f\Omega_0,\Omega_0\rangle-c_{\mathrm{n.o.}}\alpha.\end{aligned}\tag{10}$$

Let us estimate the terms in the above equality in order to identify those who are of order $\alpha^{3/2}$ and higher,

$$\begin{aligned}\langle P_f^2\Omega_0,\Omega_0\rangle&=\langle P_f^2\Pi_0\Omega_0,\Pi_0\Omega_0\rangle+\langle P_f^2\Pi_1\Omega_0,\Pi_1\Omega_0\rangle+\langle P_f^2\Pi_2^{\geqslant}\Omega_0,\Pi_2^{\geqslant}\Omega_0\rangle\\&=\langle P_f^2\Pi_1\Omega_0,\Pi_1\Omega_0\rangle+\langle P_f^2\Pi_2^{\geqslant}\Omega_0,\Pi_2^{\geqslant}\Omega_0\rangle,\end{aligned}\tag{11}$$

$$\begin{aligned}\langle H_f\Omega_0,\Omega_0\rangle&=\langle H_f\Pi_0\Omega_0,\Pi_0\Omega_0\rangle+\langle H_f\Pi_1\Omega_0,\Pi_1\Omega_0\rangle+\langle H_f\Pi_2^{\geqslant}\Omega_0,\Pi_2^{\geqslant}\Omega_0\rangle\\&=\langle H_f\Pi_1\Omega_0,\Pi_1\Omega_0\rangle+\langle H_f\Pi_2^{\geqslant}\Omega_0,\Pi_2^{\geqslant}\Omega_0\rangle.\end{aligned}\tag{12}$$

Now, using the fact that n-photon sectors are invariant under P_f, $P_f\Pi_0\Omega_0=0$, and $\langle P_f\Omega_0,A\Omega_0\rangle=\langle AP_f\Pi_1^{\geqslant}\Omega_0,\Omega_0\rangle=\langle A\Pi_1^{\geqslant}\Omega_0,P_f\Omega_0\rangle=\langle A\Pi_1^{\geqslant}\Omega_0,P_f\Pi_1^{\geqslant}\Omega_0\rangle$, we get

$$
\begin{aligned}
\left|\langle P_f\Omega_0, A\Omega_0\rangle\right| &= \left|\langle P_f\Pi_1^{\geqslant}\Omega_0, A\Pi_1^{\geqslant}\Omega_0\rangle\right| \\
&\leqslant \left|\langle P_f\Pi_1^{\geqslant}\Omega_0, D\Pi_2^{\geqslant}\Omega_0\rangle\right| + \left|\langle P_f\Pi_2^{\geqslant}\Omega_0, D^*\Pi_1^{\geqslant}\Omega_0\rangle\right| \\
&\leqslant \left|\langle P_f\Pi_1\Omega_0, D\Pi_2\Omega_0\rangle\right| + \left|\langle P_f\Pi_2^{\geqslant}\Omega_0, D\Pi_3^{\geqslant}\Omega_0\rangle\right| \\
&\quad + \left|\langle P_f\Pi_2^{\geqslant}\Omega_0, D^*\Pi_1^{\geqslant}\Omega_0\rangle\right| \\
&\left|\left|\left|P_f\Pi_1\Omega_0\right|\right|\right| \left\|D\Pi_2\Omega_0\right\| + \tfrac{1}{2}\left\|P_f\Pi_2^{\geqslant}\Omega_0\right\|^2 \\
&\quad + 2\left\|D\Pi_3^{\geqslant}\Omega_0\right\|^2 + 2\left\|D^*\Pi_1^{\geqslant}\Omega_0\right\|^2.
\end{aligned}
$$

Using Theorem 3.1 and Corollary 3.2 and the fact that $\|P_f\Pi_1\Omega_0\| \leqslant c(\Lambda)\|\Pi_1\Omega_0\| = \mathcal{O}(\alpha^{1/2})$, where $c(\Lambda)$ depends only on the ultraviolet cutoff, yields

$$
\left|\langle P_f\Omega_0, A\Omega_0\rangle\right| \leqslant \tfrac{1}{2}\left\|P_f\Pi_2^{\geqslant}\Omega_0\right\|^2 + \mathcal{O}(\alpha). \tag{13}
$$

We also have

$$
\begin{aligned}
&\langle A^2\Omega_0, \Omega_0\rangle \\
&= \langle (D + D^*)^2\Omega_0, \Omega_0\rangle \\
&= 2\,\mathcal{R}e\langle DD\Omega_0, \Omega_0\rangle + 2\|D\Omega_0\|^2 + \|[D, D^*]\|\|\Omega_0\|^2 \\
&= \mathcal{O}(\alpha^{1/2}) + \mathcal{O}(\alpha) + \|[D, D^*]\|(1 + \mathcal{O}(\alpha)),
\end{aligned}
$$

where we used from Theorem 3.1 that $\|\Omega_0\| = 1 + \mathcal{O}(\alpha)$ and $\|D\Omega_0\| = \mathcal{O}(\alpha^{1/2})$. Since the commutator $[D, D^*]$ equals $c_{\text{n.o.}}$ we arrive at

$$
\langle A^2\Omega_0, \Omega_0\rangle = c_{\text{n.o.}} + \mathcal{O}(\alpha^{1/2}). \tag{14}
$$

Finally we have, writing $B = K + K^*$,

$$
\begin{aligned}
\langle \sigma \cdot B\Omega_0, \Omega_0\rangle &= \langle \sigma \cdot K\Pi_1\Omega_0, \Pi_0\Omega_0\rangle + \langle \sigma \cdot K\Pi_2^{\geqslant}\Omega_0, \Pi_1^{\geqslant}\Omega_0\rangle \\
&\quad + \langle \sigma \cdot K^*\Pi_0\Omega_0, \Pi_1\Omega_0\rangle + \langle \sigma \cdot K^*\Pi_1^{\geqslant}\Omega_0, \Pi_2^{\geqslant}\Omega_0\rangle \\
&= 2\,\mathcal{R}e\langle \sigma \cdot K\Pi_1\Omega_0, \Pi_0\Omega_0\rangle + 2\,\mathcal{R}e\langle \sigma \cdot K^*\Pi_1^{\geqslant}\Omega_0, \Pi_2^{\geqslant}\Omega_0\rangle
\end{aligned}
$$

using Theorem 3.1 and Corollary 3.2 we obtain

$$
\langle \sigma \cdot B\Omega_0, \Omega_0\rangle = 2\,\mathcal{R}e\langle \sigma \cdot K\Pi_1\Omega_0, \Pi_0\Omega_0\rangle + \mathcal{O}(\alpha). \tag{15}
$$

Collecting (10)–(15) and using $\langle H_f\Pi_2^{\geqslant}\Omega_0, \Pi_2^{\geqslant}\Omega_0\rangle \geqslant 0$ we obtain

$$
\langle T(0)\Omega_0, \Omega_0\rangle \geqslant \langle P_f^2\Pi_1\Omega_0, \Pi_1\Omega_0\rangle + \langle H_f\Pi_1\Omega_0, \Pi_1\Omega_0\rangle + 2\sqrt{\alpha}\,\mathcal{R}e\langle \sigma \cdot K\Pi_1\Omega_0, \Pi_0\Omega_0\rangle + \mathcal{O}(\alpha^{3/2}). \tag{16}
$$

Since on the one-photon sector the operator P_f^2 reduces to multiplication by k^2, and the operator H_f reduces to multiplication by $|k|$, we obtain

$$\Sigma_0 = \frac{\langle T(0)\Omega_0, \Omega_0\rangle}{\|\Omega_0\|^2} \geqslant L_{a,b}(\Pi_1\Omega_0) + \mathcal{O}(\alpha^{3/2}) \geqslant \inf L_{a,b} + \mathcal{O}(\alpha^{3/2}). \tag{17}$$

On the other hand, using (i), and for $\psi_{a,b}=\binom{a}{b}, \varphi_{a,b}, 0, 0, \ldots)$ we have

$$\inf L_{a,b} = L_{a,b}(\varphi_{a,b}) = \langle T(0)\psi_{a,b}, \psi_{a,b}\rangle \geqslant \Sigma_0\|\psi_{a,b}\|^2 = \Sigma_0(1 + \mathcal{O}(\alpha)) \geqslant \Sigma_0 + \mathcal{O}(\alpha^2). \tag{18}$$

Inequalities (17) and (18) conclude the proof of (ii).

Eventually, we prove (iii). Due to the inequalities (17) and (18), we have $\inf L_{a,b}+\mathcal{O}(\alpha^{3/2}) = L_{a,b}(\Pi_1\Omega_0)$. Using (8), the fact that $-\sqrt{\alpha}g_{a,b}=\varphi_{a,b}$, and (9), we thus get

$$\inf L_{a,b} + \mathcal{O}(\alpha^{3/2}) = L_{a,b}(\Pi_1\Omega_0) = \|\gamma\varphi_{a,b} + R - \varphi_{a,b}\|_1^2 - \|\varphi_{a,b}\|_1^2 = (\gamma-1)^2\|\varphi_{a,b}\|_1^2 + \|R\|_1^2 + \inf L_{a,b}, \tag{19}$$

which proves (7). □

B. Proof of Theorem 2.1

As it was mentioned in the Introduction, we prove the theorem by constructing a trial function Ψ for which the quadratic form of H takes a value strictly smaller than $\Sigma_0\|\Psi\|^2$.

Let us start by proving an auxiliary result. For $\gamma \in (0,1)$, we define $f_\gamma \in L^2(\mathbb{R}^3)$ to be a normalized real valued eigenfunction, with associated eigenvalue e_γ, of the Schrödinger operator:

$$h_\gamma := -(1-\gamma)\Delta + \lambda_0 W(x).$$

Here λ_0 is the critical coupling constant defined in Sec. II.

Lemma 3.5: Then for $\lambda \leqslant \lambda_0$, *we have*

$$\sum_i \left\langle (-\Delta + \lambda W)\frac{\partial f_\gamma}{\partial x_i}, \frac{\partial f_\gamma}{\partial x_i}\right\rangle \leqslant C_W\|\nabla f_\gamma\|^2 + o_\gamma(1)\|\nabla f_\gamma\|^2,$$

with $C_W := \lambda_0^2(1+\lambda_0 d_{W_+})d_{W^2}$, *where* $W_+ = (W+|W|)/2$ *and* d_{W^2} *and* d_{W_+} *are defined by* (3) *and* (4).

Proof: For a potential V such that $V \in L^2_{\mathrm{loc}}$ and short range we have

$$|\langle V\psi, \psi\rangle| \leqslant d_V\|\nabla\psi\|^2.$$

Moreover, we know that f_γ is an eigenfunction of $-(1-\gamma)\Delta+\lambda_0 W$ and that the associated eigenvalue e_γ tends to zero as γ tends to zero, since λ_0 is the critical coupling constant. Therefore we obtain the following sequence of inequalities:

$$\begin{aligned}
\sum_i \left\langle (-\Delta + \lambda W)\frac{\partial f_\gamma}{\partial x_i}, \frac{\partial f_\gamma}{\partial x_i}\right\rangle &\leqslant \sum_i \left\langle (-\Delta + \lambda W_+)\frac{\partial f_\gamma}{\partial x_i}, \frac{\partial f_\gamma}{\partial x_i}\right\rangle \\
&\leqslant \sum_i \left\langle (-\Delta + \lambda_0 W_+)\frac{\partial f_\gamma}{\partial x_i}, \frac{\partial f_\gamma}{\partial x_i}\right\rangle \leqslant \sum_i \left\langle -\Delta\frac{\partial f_\gamma}{\partial x_i}, \frac{\partial f_\gamma}{\partial x_i}\right\rangle (1 + d_{\lambda_0 W_+}) \\
&= (1 + d_{\lambda_0 W_+})\langle -\Delta f_\gamma, -\Delta f_\gamma\rangle = (1 + d_{\lambda_0 W_+})\left\langle \frac{e_\gamma - \lambda_0 W}{1-\gamma} f_\gamma, -\Delta f_\gamma\right\rangle \\
&= \frac{e_\gamma(1 + d_{\lambda_0 W_+})}{1-\gamma}\langle f_\gamma, -\Delta f_\gamma\rangle - \frac{\lambda_0(1 + d_{\lambda_0 W_+})}{1-\gamma}\langle W f_\gamma, -\Delta f_\gamma\rangle.
\end{aligned} \tag{20}$$

We estimate the last term on the right-hand side by

$$-\langle Wf_\gamma, -\Delta f_\gamma\rangle = \left\langle Wf_\gamma, \frac{\lambda_0 W - e_\gamma}{1-\gamma} f_\gamma \right\rangle$$

$$\leqslant -\frac{e_\gamma d_{W_+}}{1-\gamma}\|\nabla f_\gamma\|^2 + \frac{\lambda_0}{1-\gamma} d_{W^2}\|\nabla f_\gamma\|^2. \tag{21}$$

The inequalities (20) and (21) imply for $\lambda \leqslant \lambda_0$,

$$\sum_i \left\langle (-\Delta + \lambda W)\frac{\partial f_\gamma}{\partial x_i}, \frac{\partial f_\gamma}{\partial x_i}\right\rangle \leqslant (\lambda_0^2(1+\lambda_0 d_{W_+})d_{W^2} + o_\gamma(1))\|\nabla f_\gamma\|^2. \tag{22}$$

□

In the rest of this section, we will mainly work in the space representation for both particle and photons. Following,[6] let us introduce, for given $x \in \mathbb{R}^3$, the shift operator on the photon space variables $\tau_x : \mathbb{C}^2 \otimes \mathfrak{F} \to \mathbb{C}^2 \otimes \mathfrak{F}$. For $\phi = (\phi_0, \phi_1, \ldots, \phi_n, \ldots) \in \mathbb{C}^2 \otimes \mathcal{F}$, we have writing by abuse of notation $\tau_x \phi = (\tau_x \phi_0, \tau_x \phi_1, \ldots)$,

$$\tau_x \phi_n(s; y_1, \ldots, y_n; \lambda_1, \ldots, \lambda_n) = \phi_n(s; y_1 - x, \ldots, y_n - x; \lambda_1, \ldots, \lambda_n),$$

where s is the spin of the particle and takes value in $\{\uparrow, \downarrow\}$.

We denote by Ω_0^x the ground state Ω_0 written in space representation and shifted by x, i.e.,

$$\Omega_0^x := \tau_x \mathcal{F}^{-1} \Omega_0,$$

where $\mathcal{F}$ stands for the Fourier transform.

Recall that $D^*(0)$ is an operator valued vector with three components which we denote by $D^*(0)_i$ $(i = 1, 2, 3)$. Then we consider the functions

$$\theta_i = (0, \theta_i^{(1)}, 0, \ldots) \in \mathbb{C}^2 \otimes \mathfrak{F} \tag{23}$$

with

$$\theta_i^{(1)} = \left(k^2 + |k| + C_W\right)^{-1} \Pi_1 D^*(0)_i \left(\begin{pmatrix} a \\ b \end{pmatrix}, 0, \ldots\right) \tag{24}$$

and

$$\theta_i^x = \tau_x \mathcal{F}^{-1} \theta_i. \tag{25}$$

We first state some properties of θ_i.

Lemma 3.6:

(i) *For $i \neq j$ we have*

$$\langle \theta_i, \theta_j \rangle = 0 \quad \textit{and} \ \langle \theta_i, \theta_j \rangle_1 = 0.$$

(ii) *For $i = 1, 2, 3$ holds*

$$\|\theta_i \sqrt{k^2 + |k| + C_W}\|^2 = \frac{1}{6\pi^2} \int_{\mathbb{R}^3} \frac{\zeta(|k|)}{|k|(k^2 + |k| + C_W)} \mathrm{d}k.$$

(iii) *For $i = 1, 2, 3$ $\langle k_i \varphi_{a,b}, \Pi_1 \theta_i \rangle = 0$.*

Proof: To prove this lemma we remind that θ_i has only a nonzero component $\Pi_1 \theta_i$ in the one-photon sector, and

$$\Pi_1\theta_i=\begin{pmatrix} a\dfrac{\varepsilon_{1,i}(k)\zeta(|k|)}{|k|^{1/2}(k^2+|k|+C_W)} \\ a\dfrac{\varepsilon_{2,i}(k)\zeta(|k|)}{|k|^{1/2}(k^2+|k|+C_W)} \\ b\dfrac{\varepsilon_{1,i}(k)\zeta(|k|)}{|k|^{1/2}(k^2+|k|+C_W)} \\ b\dfrac{\varepsilon_{2,i}(k)\zeta(|k|)}{|k|^{1/2}(k^2+|k|+C_W)} \end{pmatrix},$$

where the two polarization vectors $\varepsilon_1(k)$ and $\varepsilon_2(k)$ are defined in (2). The properties stated in the lemma follow straightforwardly from computations of the corresponding integrals. □

We consider the trial function $\Psi\in L^2(\mathbb{R}^3)\otimes\mathbb{C}^2\otimes\mathfrak{F}$,

$$\Psi:=\Psi_1+\Psi_2:=f_\gamma(x)\Omega_0^x+i\sqrt{\alpha}\sum_{i=1}^{3}\theta_i^x\frac{\partial f_\gamma(x)}{\partial x_i}. \tag{26}$$

Now we compute the expectation value of H in the state Ψ. We have

$$\langle H\Psi,\Psi\rangle=\langle H\Psi_1,\Psi_1\rangle+\langle H\Psi_2,\Psi_2\rangle+2\,\mathcal{R}e\langle H\Psi_1,\Psi_2\rangle.$$

As usual,[6] due to the orthogonality $\langle f,\partial f/\partial x_i\rangle=0$, we have

$$\langle H\Psi_1,\Psi_1\rangle=\Sigma_0\|\Psi_1\|^2+\langle(-\Delta+\lambda W(x))f_\gamma,f_\gamma\rangle\|\Omega_0\|^2. \tag{27}$$

Since Ψ_2 has only a nonzero component in the one photon sector, in the quadratic form $\langle H\Psi_2,\Psi_2\rangle$, all the terms involving $A(0)$ or $B(0)$ vanish. Moreover, using Lemma 3.6 and the orthogonalities $\langle\partial f_\gamma/\partial x_i,\partial f_\gamma/\partial x_j\rangle=0$ and $\langle\partial f_\gamma/\partial x_i,\partial^2 f_\gamma/\partial x_i\partial x_j\rangle=0$, for $i\neq j$, we arrive at

$$\begin{aligned}\langle H\Psi_2,\Psi_2\rangle=&\alpha\sum_l\|\theta_l^x\|^2\left\langle(-\Delta+\lambda W)\frac{\partial f_\gamma}{\partial x_l},\frac{\partial f_\gamma}{\partial x_l}\right\rangle+\mathcal{O}(\alpha^2)\|\nabla f_\gamma\|^2\\&+\alpha\sum_l\left\|\frac{\partial f_\gamma}{\partial x_l}\right\|^2\langle(|k|+k^2)\Pi_1\theta_l^x,\Pi_1\theta_l^x\rangle.\end{aligned} \tag{28}$$

To compute the last term $\langle H\Psi_1,\Psi_2\rangle$, we first note that

$$\left\langle(-\Delta+\lambda W)f_\gamma,\frac{\partial f_\gamma}{\partial x_i}\right\rangle=\left\langle(-(1-\gamma)\Delta+\lambda W)f_\gamma,\frac{\partial f_\gamma}{\partial x_i}\right\rangle-\gamma\left\langle\Delta f_\gamma,\frac{\partial f_\gamma}{\partial x_i}\right\rangle$$

$$=e_\gamma\left\langle f_\gamma,\frac{\partial f_\gamma}{\partial x_i}\right\rangle+\gamma\sum_j\left\langle\frac{\partial^2 f_\gamma}{\partial x_j^2},\frac{\partial f_\gamma}{\partial x_i}\right\rangle=0.$$

The last equality holds since f_γ is a real function vanishing at infinity. Moreover, all other terms in the quadratic form $\langle H\Psi_1,\Psi_2\rangle$ which contain $\langle f_\gamma,\partial f_\gamma/\partial x_i\rangle$ vanish also. So we arrive at

$$2\,\mathcal{R}e\langle H\Psi_1,\Psi_2\rangle=-2\,\mathcal{R}e\langle P\cdot(P_f-\sqrt{\alpha}A(0))\Psi_1,\Psi_2\rangle=2\sqrt{\alpha}\sum_i\left\|\frac{\partial f_\gamma}{\partial x_i}\right\|^2\mathcal{R}e\langle(P_f-\sqrt{\alpha}A(0))_i\Omega_0,\theta_i\rangle. \tag{29}$$

The term with P_f on the right-hand side is estimated as follows:

$$\begin{aligned}\mathcal{R}e\langle (P_f)_i\Omega_0,\theta_i\rangle_{\mathbb{C}^2\otimes\mathfrak{F}} &= \mathcal{R}e\langle \Pi_1(P_f)_i(\gamma\varphi_{a,b}+R),\Pi_1\theta_i\rangle_{\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2}\\ &= \mathcal{R}e\langle k_i(\gamma\varphi_{a,b}+R),\Pi_1\theta_i\rangle_{\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2}\\ &\leqslant \|R\|_1\||k|^{1/2}\Pi_1\theta_i\| + \gamma\,\mathcal{R}e\langle k_i\varphi_{a,b},\Pi_1\theta_i\rangle_{\mathbb{C}^2\otimes L^2(\mathbb{R}^3)\otimes\mathbb{C}^2}. \end{aligned} \tag{30}$$

Using Proposition 3.3 yields the following bound for the first term on the right-hand side of (30):

$$\|R\|_1\||k|^{1/2}\Pi_1\theta_i\| = \mathcal{O}(\alpha^{3/4}). \tag{31}$$

According to Lemma 3.6 (iii), the second term on the right-hand side of (30) equals zero. Therefore, collecting (29)–(31), we arrive at

$$2\,\mathcal{R}e\langle H\Psi_1,\Psi_2\rangle = -2\alpha\sum_i \left\|\frac{\partial f_\gamma}{\partial x_i}\right\|^2 \mathcal{R}e\langle A(0)_i\Omega_0,\theta_i\rangle + \mathcal{O}(\alpha^{5/4})\|\nabla f_\gamma\|^2. \tag{32}$$

Now we have, using Theorem 3.1 and the fact that $D(0)$ restricted to the two-photon sector is a bounded operator,

$$\begin{aligned}\mathcal{R}e\langle A(0)_i\Omega_0,\theta_i\rangle &= \mathcal{R}e\langle D(0)_i\Pi_2\Omega_0,\theta_i\rangle + \mathcal{R}e\langle D^*(0)_i\Pi_0\Omega_0,\theta_i\rangle\\ &= \mathcal{O}(\alpha^{1/2}) + \mathcal{R}e\langle D^*(0)_i\Pi_0\Omega_0,\theta_i\rangle. \end{aligned} \tag{33}$$

Due to the definition (24) of θ_i, the second term on the right-hand side of (33) is $\|\theta_i\sqrt{k^2+|k|+C_W}\|^2$. Therefore, collecting the equalities (27), (28), (32), and (33) we obtain

$$\begin{aligned}\langle H\Psi,\Psi\rangle = \Sigma_0\|\Psi_1\|^2 + \|\Omega_0\|^2\langle(-\Delta+\lambda W)f_\gamma,f_\gamma\rangle + \alpha\sum_l \|\theta_l\|^2\left\langle(-\Delta+\lambda W)\frac{\partial f_\gamma}{\partial x_l},\frac{\partial f_\gamma}{\partial x_l}\right\rangle\\ -2\alpha\sum_l\left\|\frac{\partial f_\gamma}{\partial x_l}\right\|^2\|\theta_i\sqrt{k^2+|k|+C_W}\|^2 + \mathcal{O}(\alpha^{5/4})\|\nabla f_\gamma\|^2 + \alpha\sum_l\left\|\frac{\partial f_\gamma}{\partial x_l}\right\|^2\|\theta_l\|_1^2. \end{aligned} \tag{34}$$

From Lemma 3.6, we know that $\|\theta_l\sqrt{k^2+|k|+C_W}\|^2$ is independent of l. We denote this constant by η^2. With Lemma 3.5 we thus arrive at

$$\begin{aligned}\langle H\Psi,\Psi\rangle \leqslant \Sigma_0\|\Psi\|^2 - \Sigma_0\|\Psi_2\|^2 + \|\Omega_0\|^2(\|\nabla f_\gamma\|^2 + \langle\lambda W f_\gamma,f_\gamma\rangle)\\ -\alpha\sum_l\left\|\frac{\partial f_\gamma}{\partial x_l}\right\|^2\eta^2 + \alpha o_\gamma(1)\|\nabla f_\gamma\|^2 + \mathcal{O}(\alpha^{1/2})\|\nabla f_\gamma\|^2. \end{aligned} \tag{35}$$

Note that $\Sigma_0\|\psi_2\|^2 = \mathcal{O}(\alpha^2)\|\nabla f_\gamma\|^2$. We thus obtain

$$\begin{aligned}&\langle H\Psi,\Psi\rangle - \Sigma_0\|\Psi\|^2\\ &\leqslant \|\Omega_0\|^2\left(\left(1-\frac{\alpha}{\|\Omega_0\|^2}\eta^2 + \frac{\alpha}{\|\Omega_0\|^2}(o_\gamma(1)+\mathcal{O}(\alpha^{1/4}))\right)\|\nabla f_\gamma\|^2 + \langle\lambda W f_\gamma,f_\gamma\rangle\right). \end{aligned} \tag{36}$$

Using from Corollary 3.2 that $\|\Omega_0\|^2 = 1+\mathcal{O}(\alpha)$, we obtain

$$\begin{aligned}&\langle H\Psi,\Psi\rangle - \Sigma_0\|\Psi\|^2\\ &\leqslant \|\Omega_0\|^2((1-\alpha\eta^2 + \alpha o_\gamma(1) + \mathcal{O}(\alpha^{5/4}))\|\nabla f_\gamma\|^2 + \langle\lambda W f_\gamma,f_\gamma\rangle). \end{aligned} \tag{37}$$

Therefore

$$\langle H\Psi,\Psi\rangle - \Sigma_0\|\Psi\|^2 \leqslant \|\Omega_0\|^2(1-\alpha\eta^2+\alpha o_\gamma(1)+\mathcal{O}(\alpha^{5/4}))$$

$$\times(\|\nabla f_\gamma\|^2+(1+\alpha\eta^2+\alpha o_\gamma(1)+\mathcal{O}(\alpha^{5/4}))^{-1}\langle\lambda W f_\gamma,f_\gamma\rangle). \tag{38}$$

If $\lambda>\lambda_0(1-\alpha\eta^2+\mathcal{O}(\alpha^{5/4}))$, choosing γ (depending on α) small enough, we arrive at $\langle H\Psi,\Psi\rangle - \Sigma_0\|\Psi\|^2<0$. Due to Griesemer *et al.*,[8] this implies the existence of a ground state for H.

(Received 1 June 2005; accepted 26 October 2005; published online 23 December 2005)

Using a complete basis set we have obtained an analytic expression for the matrix elements of the Coulomb interaction. These matrix elements are written in a closed form. We have used the basis set of the three-dimensional isotropic quantum harmonic oscillator in order to develop our calculations, which can be useful when treating interactions in localized systems. © *2005 American Institute of Physics.*
[DOI: 10.1063/1.2146187]

I. INTRODUCTION

Having an analytic expression for the Coulomb matrix elements is an important step for several numerical methods, like, for example, exact diagonalization method. In order to describe the Coulomb interaction in three dimensions, we have chosen the basis set of the isotropic harmonic oscillator for the single-particle wave functions, which, in one dimension, is written as

$$\psi_{n_x}(x) = (a\sqrt{\pi}2^{n_x}n_x!)^{-1/2}e^{-(1/2)x^2/a^2}H_{n_x}(x/a), \tag{1}$$

where $a=\sqrt{\hbar/m\omega}$ is taken as the characteristic unit length. One of the reasons for the election of this particular basis set is the Gaussian Product Theorem, which guarantees that the product of two Gaussian type orbitals (a linear combination of them in our case) centered on two different atoms is a finite sum of Gaussians centered on a point along the axis connecting them.

In previous works, several ways to evaluate the two-dimensional matrix elements using different approaches have been studied,[1–3] such as restricting to the lowest Landau level due to simplicity reasons.[4,5]

The purpose of this paper is to report an analytic formula for the Coulomb interaction written in closed form. It can be easily implemented by computer means and could help to improve the performance of solid state simulations in which interactions are taken into account.

II. MATRIX ELEMENTS

In order to derive an analytical expression for the Coulomb interaction matrix elements we will proceed starting with the same approach as the one used in Ref. 6, i.e., writing the single-electron wave function and the Coulomb potential as their Fourier transform integrals:

$$\psi_\lambda(\boldsymbol{r}) = \frac{1}{(2\pi)^{3/2}}\int \phi_\lambda(\boldsymbol{q})e^{-i\boldsymbol{q}\cdot\boldsymbol{r}}\mathrm{d}\boldsymbol{q}, \tag{2}$$

$$V(\boldsymbol{r}) = \frac{1}{(2\pi)^{3/2}}\int \tilde{V}(\boldsymbol{q})e^{-i\boldsymbol{q}\cdot\boldsymbol{r}}\mathrm{d}\boldsymbol{q}, \tag{3}$$

where λ stands for a set of quantum numbers $\{n_i\}$ and $V(\boldsymbol{r}_1-\boldsymbol{r}_2)=r_{12}^{-1}$ is the Coulomb potential. Now, the two-particle matrix element, which, in real space is written as

[a)]Electronic mail: jaime.zaratiegui@oulu.fi

$$\mathcal{V}^{\lambda_1\lambda_2}_{\lambda_3\lambda_4} = \int \psi^*_{\lambda_1}(\boldsymbol{r}_1)\psi^*_{\lambda_2}(\boldsymbol{r}_2)V(\boldsymbol{r}_1-\boldsymbol{r}_2) \times \psi_{\lambda_3}(\boldsymbol{r}_2)\psi_{\lambda_4}(\boldsymbol{r}_1)\mathrm{d}\boldsymbol{r}_1\boldsymbol{r}_2, \tag{4}$$

is now expressed, in momentum space, as

$$\mathcal{V}^{\lambda_1\lambda_2}_{\lambda_3\lambda_4} = \frac{1}{(2\pi)^{3/2}} \int \phi^*_{\lambda_1}(\boldsymbol{q}_1)\phi_{\lambda_4}(\boldsymbol{q}_1-\boldsymbol{q}) \times \phi^*_{\lambda_2}(\boldsymbol{q}_2)\phi_{\lambda_3}(\boldsymbol{q}_2+\boldsymbol{q})\widetilde{V}(\boldsymbol{q})\mathrm{d}\boldsymbol{q}_1\mathrm{d}\boldsymbol{q}_2\mathrm{d}\boldsymbol{q}. \tag{5}$$

Equation (5) can be rewritten in a more convenient and compact form. Let us define $C^{\lambda}_{\lambda'}(\boldsymbol{q})$ and $D^{\lambda}_{\lambda'}(\boldsymbol{q})$ as the following convolution integrals:

$$C^{\lambda}_{\lambda'}(\boldsymbol{q}) = \int \phi^*_{\lambda}(\boldsymbol{k})\phi_{\lambda'}(\boldsymbol{k}-\boldsymbol{q})\mathrm{d}\boldsymbol{k} \tag{6}$$

$$= \int \psi^*_{\lambda}(\boldsymbol{r})\psi_{\lambda'}(\boldsymbol{r})e^{-i\boldsymbol{q}\cdot\boldsymbol{r}}\mathrm{d}\boldsymbol{r}, \tag{7}$$

$$D^{\lambda}_{\lambda'}(\boldsymbol{q}) = \int \phi^*_{\lambda}(\boldsymbol{k})\phi_{\lambda'}(\boldsymbol{k}+\boldsymbol{q})\mathrm{d}\boldsymbol{k} \tag{8}$$

$$= \int \psi^*_{\lambda}(\boldsymbol{r})\psi_{\lambda'}(\boldsymbol{r})e^{i\boldsymbol{q}\cdot\boldsymbol{r}}\mathrm{d}\boldsymbol{r} \tag{9}$$

$$= C^{\lambda}_{\lambda'}(-\boldsymbol{q}). \tag{10}$$

Substituting Eqs. (6) and (8) into Eq. (5) we obtain

$$\mathcal{V}^{\lambda_1\lambda_2}_{\lambda_3\lambda_4} = \frac{1}{(2\pi)^{3/2}} \int C^{\lambda_1}_{\lambda_4}(\boldsymbol{q})D^{\lambda_2}_{\lambda_3}(\boldsymbol{q})\widetilde{V}(\boldsymbol{q})\mathrm{d}\boldsymbol{q}. \tag{11}$$

Now, it is straightforward to perform the integral appearing in Eq. (7).[7] Using Cartesian coordinates, it is possible to separate all three variables and integrate independently. For simplicity reasons, let us integrate only along the x variable, the result then reads:

$$C^{n^1_x}_{n^4_x}(q_x) = \left(\frac{2^{n^{14}_{x+}}}{n^{14}_{x+}!}\frac{n^{14}_{x-}!}{2^{n^{14}_{x-}}}\right)^{1/2} i^{n^1_x+n^4_x}(-1)^{n^{14}_{x+}} \times e^{-q_x^2a^2/4}\left(\frac{aq_x}{2}\right)^{|n^1_x-n^4_x|} L^{|n^1_x-n^4_x|}_{n^{14}_{x-}}(a^2q_x^2/2), \tag{12}$$

where n^j_i is the quantum number referring to the i axis of the particle j. We have also used the terms n^{jk}_{i+} and n^{jk}_{i-}, which are defined as $\max(n^j_i, n^k_i)$ and $\min(n^j_i, n^k_i)$ respectively. The final form for $C^{\lambda_1}_{\lambda_4}(\boldsymbol{q})$ will be

$$C^{n^1_x n^1_y n^1_z}_{n^4_x n^4_y n^4_z}(\boldsymbol{q}) = \prod_{i\in\{x,y,z\}} C^{n^1_i}_{n^4_i}(q_i). \tag{13}$$

Using the relation between D and C shown in Eq. (10), it is trivial to find out the value of the former convolution integral.

It still remains to calculate the Fourier transform $\tilde{V}(\boldsymbol{q})$ of the spherically symmetric interaction potential $V(\boldsymbol{r})$,

$$\tilde{V}(q) = \sqrt{\frac{2}{\pi}}\frac{1}{q^2}. \tag{14}$$

But it will be more convenient to substitute it by

$$\tilde{V}(q) = \sqrt{\frac{2}{\pi}}\int_0^\infty e^{-(q_x^2+q_y^2+q_z^2)u}\mathrm{d}u. \tag{15}$$

The integration over variables q_x, q_y, and q_z can be performed all in the same fashion. Using the symmetry of the problem we only need to integrate over one variable, i.e., q_x and then use the same result for q_y and q_z. Therefore, integrating over q_x yields

$$\int_{-\infty}^{\infty} e^{-(u+a^2/2)q_x^2}\left(\frac{aq_x}{2}\right)^{|n_x^1-n_x^4|+|n_x^2-n_x^3|} \times L_{n_{x-}^{14}}^{|n_x^1-n_x^4|}(a^2q_x^2/2)L_{n_{x-}^{23}}^{|n_x^2-n_x^3|}(a^2q_x^2/2)\mathrm{d}q_x. \tag{16}$$

This integral does not vanish if and only if

$$|n_x^1 - n_x^4| + |n_x^2 - n_x^3| = 2s_x, \tag{17}$$

where $s_x=0,1,2,\ldots$. Therefore, using the previous selection rule and the power series for the associated Laguerre polynomial

$$L_n^l(x) = \sum_{k=0}^{n}\frac{1}{k!}\binom{n+l}{n-k}(-x)^k, \tag{18}$$

we can write Eq. (16) as

$$\sum_{k_x=0}^{n_{x-}^{14}}\frac{(-1)^{k_x}}{k_x!}\binom{n_{x+}^{14}}{n_{x-}^{14}-k_x}\sum_{k_x=0}^{n_{x-}^{14}}\frac{(-1)^{k_x'}}{k_x'!}\binom{n_{x+}^{23}}{n_{x-}^{23}-k_x'} \times 2^{k_x+k_x'}\left(\frac{a}{2}\right)^{2s_x+2k_x+2k_x'} \times \frac{(2s_x+2k_x+2k_x'-1)!!}{(2u+a^2)^{s+k_x+k_x'+1/2}}\sqrt{2\pi}. \tag{19}$$

Taking into account only the u-dependent part in Eq. (19) and its symmetric extension for y and z variables, we end up with the last integral which will lead to the final result. This last integral is expressed as:

$$\int_0^\infty (2u+a^2)^{-\Omega-3/2}\mathrm{d}u = \frac{1}{1+2\Omega}\frac{1}{a^{1+2\Omega}}, \tag{20}$$

where $\Omega=s_x+s_y+s_z+k_x+k_y+k_z+k_x'+k_y'+k_z'$.

Finally, collecting all the terms, we end up with the analytic expression for the Coulomb interaction matrix elements:

$$\mathcal{V}^{n_x^1 n_y^1 n_z^1 n_x^2 n_y^2 n_z^2}_{n_x^3 n_y^3 n_z^3 n_x^4 n_y^4 n_z^4} = \frac{1}{a}\sqrt{\frac{2}{\pi}}(-1)^{n_x^1+n_y^1+n_z^1+n_x^4+n_y^4+n_z^4-s_x-s_y-s_z}$$
$$\times \left(\frac{2^{n_{x+}^{14}}}{n_{x+}^{14}!}\frac{n_{x-}^{14}!}{2^{n_{x-}^{14}}}\frac{2^{n_{y+}^{14}}}{n_{y+}^{14}!}\frac{n_{y-}^{14}!}{2^{n_{y-}^{14}}}\frac{2^{n_{z+}^{14}}}{n_{z+}^{14}!}\frac{n_{z-}^{14}!}{2^{n_{z-}^{14}}}\right)^{1/2}\left(\frac{2^{n_{x+}^{23}}}{n_{x+}^{23}!}\frac{n_{x-}^{23}!}{2^{n_{x-}^{23}}}\frac{2^{n_{y+}^{23}}}{n_{y+}^{23}!}\frac{n_{y-}^{23}!}{2^{n_{y-}^{23}}}\frac{2^{n_{z+}^{23}}}{n_{z+}^{23}!}\frac{n_{z-}^{23}!}{2^{n_{z-}^{23}}}\right)^{1/2}$$
$$\times \sum_{k_x=0}^{n_{x-}^{14}}\frac{(-1)^{k_x}}{k_x!}\binom{n_{x+}^{14}}{n_{x-}^{14}-k_x}\sum_{k_x'=0}^{n_{x-}^{23}}\frac{(-1)^{k_x'}}{k_x'!}\binom{n_{x+}^{23}}{n_{x-}^{23}-k_x'}\frac{(2s_x+2k_x+2k_x'-1)!!}{2^{2s_x+k_x+k_x'}}$$
$$\times \sum_{k_y=0}^{n_{y-}^{14}}\frac{(-1)^{k_y}}{k_y!}\binom{n_{y+}^{14}}{n_{y-}^{14}-k_y}\sum_{k_y'=0}^{n_{y-}^{23}}\frac{(-1)^{k_y'}}{k_y'!}\binom{n_{y+}^{23}}{n_{y-}^{23}-k_y'}\frac{(2s_y+2k_y+2k_y'-1)!!}{2^{2s_y+k_y+k_y'}}$$
$$\times \sum_{k_z=0}^{n_{z-}^{14}}\frac{(-1)^{k_z}}{k_z!}\binom{n_{z+}^{14}}{n_{z-}^{14}-k_z}\sum_{k_z'=0}^{n_{z-}^{23}}\frac{(-1)^{k_z'}}{k_z'!}\binom{n_{z+}^{23}}{n_{z-}^{23}-k_z'}\frac{(2s_z+2k_z+2k_z'-1)!!}{2^{2s_z+k_z+k_z'}}$$
$$\times \frac{1}{1+2(s_x+s_y+s_z+k_x+k_x'+k_y+k_y'+k_z+k_z')}. \tag{21}$$

III. RECURRENCE

Due to the six summatories appearing in Eq. (21), if the indices start to grow to values say, just of the order of tenths, the process for calculating a single matrix element can be quite time-consuming, and thus, a real bottleneck for any numerical simulation. Using the recurrence relations that the Hermite polynomials obey, it is possible to find a simple iterative formula for the matrix elements which will accelerate the process of calculating the matrix elements.

Let $\{n_-,n_+\}$ be any pair of quantum numbers $\{n_{i-}^{jk},n_{i+}^{jk}\}$ with $i\in\{x,y,z\}$ and $jk\in\{14,23\}$, satisfying $n_+\geqslant n_-$. Then, the Coulomb matrix elements will satisfy (remaining indices ommitted for clarity)

$$\mathcal{V}_{n_-}^{n_+} = \sqrt{\frac{n_++1}{n_-}}\mathcal{V}_{n_--1}^{n_++1} + \sqrt{\frac{n_+}{n_-}}\mathcal{V}_{n_--1}^{n_+-1} - \sqrt{\frac{n_--1}{n_-}}\mathcal{V}_{n_--2}^{n_+}, \tag{22}$$

for $n_->0$. If we consider the unnormalized matrix elements

$$\bar{\mathcal{V}}^{n_x^1 n_y^1 n_z^1 n_x^2 n_y^2 n_z^2}_{n_x^3 n_y^3 n_z^3 n_x^4 n_y^4 n_z^4} = \prod_{i\in\{1,2,3,4\}}(2^{n_x^i}n_x^i!2^{n_y^i}n_y^i!2^{n_z^i}n_z^i!)^{1/2}$$
$$\times \mathcal{V}^{n_x^1 n_y^1 n_z^1 n_x^2 n_y^2 n_z^2}_{n_x^3 n_y^3 n_z^3 n_x^4 n_y^4 n_z^4}, \tag{23}$$

Eq. (22) can be transformed to

$$\bar{\mathcal{V}}_{n_-+1}^{n_+} = \bar{\mathcal{V}}_{n_-}^{n_++1} + 2n_+\bar{\mathcal{V}}_{n_-}^{n_+-1} - 2n_-\mathcal{V}_{n_--1}^{n_+}. \tag{24}$$

Another interesting recurrence relation which, this time involves four indices $\{0,n_+\}$ and $\{m_-,m_+\}$, is the following:

$$\bar{\mathcal{V}}_{0,m_-}^{n_+,m_++1} = \bar{\mathcal{V}}_{0,m_-}^{n_++1,m_+} + \bar{\mathcal{V}}_{0,m_--1}^{n_+,m_+}. \tag{25}$$

(Received 11 January 2005; accepted 24 October 2005; published online 27 December 2005)

We develop graph theoretic methods for analyzing maximally entangled pure states distributed between a number of different parties. We introduce a technique called bicolored merging, based on the monotonicity feature of entanglement measures, for determining combinatorial conditions that must be satisfied for any two distinct multiparticle states to be comparable under local operations and classical communication. We present several results based on the possibility or impossibility of comparability of pure multipartite states. We show that there are exponentially many such entangled multipartite states among n agents. Further, we discuss a new graph theoretic metric on a class of multipartite states, and its implications. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2142840]

I. INTRODUCTION

Given the extensive use of quantum entanglement as a resource for quantum information processing,[6,19,23] the theory of entanglement, in particular, entanglement quantification, is a topic important to quantum information theory. However, apart from a limited number of cases like low dimension Hilbert spaces and for pure states, the mathematical structure of entanglement is not yet fully understood. The entanglement properties of bipartite states have been widely explored (see Refs. 8 and 12 for a comprehensive review). This has been aided by the fact that bipartite states possess the nice mathematical property in the form of the Schmidt decomposition,[19] the Schmidt coefficients encompassing all their nonlocal properties. No such simplifying structure is known in the case of larger systems. Approaches using certain generalizations of Schmidt decomposition[4,14,20] and group theoretic or algebraic methods,[15–17] have been taken in this direction. A number of methods for comparing or quantifying or qualifying entanglement have been proposed for bipartite systems and/or pure states such as entanglement of formation,[3] entanglement cost,[3,26] distillable entanglement,[3,21] relative entropy of entanglement,[11] negativity,[27]

concurrence,[28] and entanglement witnesses.[13] However, these quantifications do not always lend themselves to being computed, except in some restricted situations. As such, a general formulation is still an open problem.

It is known that state transformations under local operations and classical communication (LOCC) are very important to quantifying entanglement because LOCC can at the best increase only classical correlations. Therefore a good measure of entanglement is expected not to increase under LOCC. A necessary and sufficient condition for the possibility of such transformations in the case of bipartite states was given by Nielsen.[18] An immediate consequence of his result was the existence of *incomparable* states (the states that cannot be obtained by LOCC from one another). Bennett *et al.*,[4] formalized the notions of reducibility, equivalence and incomparability to multipartite states and gave a sufficient condition for incomparability based on *partial* entropic criteria.

In this work, our principal aim is not to quantify entanglement, but to develop graph theoretic techniques to analyze the comparability of maximally entangled multipartite states of several qubits distributed between a number of different parties. We obtain various qualitative results concerning reversibility of operations and comparability of states by observing the combinatorics of multiparitite entanglement. For our purpose, it is sufficient to consider the graph theoretic representation of various maximally entangled states (represented by specific graphs built from EPR, GHZ, and so on). Although this might at first seem overly restrictive, we will in fact be able to demonstrate a number of new results. Furthermore, being based only on the monotonicity principle, it can be adapted to any specific quantification of entanglement. Therefore, our approach is quite generic, in principle applicable to all entanglement measures. Since the entanglement of maximally entangled states is usually represented by integer values, it turns out that we can analyze entangled systems simply by studying the combinatorial properties of graphs and set systems representing the states. The basic definitions and concepts are introduced through the framework set in Sec. II. We introduce a technique called *bicolored merging* in Sec. III, which is essentially a combinatorial way of quantifying maximal entanglment between two parts of the system, and inferring transformation properties to be satisfied by the states.

In Sec. IV, we present our first result: the impossibility of obtaining two Einstein-Podolsky-Rosen (EPR) pairs among three players starting from a Greenberger-Horne-Zeilinger (GHZ) state (Theorem 2). We then show that this can be used to establish the impossibility of implementing a two-pronged teleportation (called *selective teleportation*) given preshared entanglement in the form of a GHZ state. We then demonstrate various classes of incomparable multipartite states in Sec. V. Finally, we discuss the minimum number of copies of a state required to prepare another state by LOCC and present bounds on this number in terms of the *quantum distance* between the two states in Sec. VII.

We believe that our combinatorial approach vastly simplifies the study of entanglement in very complex systems. Moreover, it opens up the road for further analysis, for example, to interpret entanglement topologically. In future works, we intend to apply and extend these insights to nonmaximal and mixed multipartite states, and to combine our approach with a suitable measure of entanglement.

II. THE COMBINATORIAL FRAMEWORK

In this section we introduce a number of basic concepts useful to describe combinatorics of entanglement. First, an *EPR graph* $G(V,E)$ is a graph whose vertices are the players ($\in V$) and edges ($\in E$) represent shared entanglement in the form of an EPR pair. Formally, we have the following.

Definition 1: EPR graph. For n agents $A_1,A_2,\ldots,A_n$ *an undirected graph* $G=(V,E)$ *is constructed as follows:* $V=\{A_i: i=1,2,\ldots,n\}$, $E=\{\{A_i,A_j\}: A_i$ *and* A_j *share an EPR pair,* $1\leqslant i,j.\leqslant n; i\neq j\}$. *The graph* $G=(V,E)$ *thus formed is called the EPR graph of the n agents.*

A spanning tree is a graph which connects all vertices without forming cycles (i.e., loops). Accordingly, we have the following.

Definition 2: Spanning EPR tree. A spanning tree *is a connected, undirected graph linking all vertices without forming cycles. An EPR graph* $G=(V,E)$ *is called a* spanning EPR tree *if the*

undirected graph $G=(V,E)$ is a spanning tree.

The above notions are generalized to more general multipartite entanglement by means of the concept of a *hypergraph.* A usual graph is built up from edges, where a normal edge links precisely two vertices. A hyperedge is a generalization that links r vertices, where $r \geqslant 2$. A graph endowed with at least one hyperedge is called a hypergraph. From the combinatorial viewpoint, a simple and interesting connection can be made between entanglement and hyperedges, an n-cat state (also sometimes called an n-GHZ state) corresponds to a hyperedge of size n. In particular, an EPR state corresponds to a simple edge connecting only two vertices. Formally, we have the following.

Definition 3: Entangled hypergraph. Let S be the set of n agents and $F=\{E_1,E_2,\ldots,E_m\}$, where $E_i \subseteq S; i=1,2,\ldots,m$ and E_i is such that its elements (agents) are in $|E_i|$-CAT state. The hypergraph (set system) $H=(S,F)$ is called an entangled hypergraph of the n agents.

A graph is connected if there is a path (having a length of one or more edges) between any two vertices. Accordingly, we have the following.

Definition 4: Connected entangled hypergraph. A sequence of j hyperedges $E_1,E_2,\ldots,E_j$ in a hypergraph $H=(S,F)$ is called a hyperpath (path) from a vertex a to a vertex b if

(1) *E_i and E_{i+1} have a common vertex for all $1 \leqslant i \leqslant j-1$,*
(2) *a and b are agents in S,*
(3) *$a \in E_1$, and*
(4) *$b \in E_j$.*

If there is a hyperpath between every pair of vertices of S in the hypergraph H, we say that H is connected.

Analogous to a spanning EPR tree we have the following.

Definition 5: Entangled hypertree. A connected entangled hypergraph $H=(S,F)$ is called an entangled hypertree if it contains no cycles, that is, there do not exist any pair of vertices from S such that there are two distinct paths between them.

Further, we have the following.

Definition 6: r-uniform entangled hypertree: An entangled hypertree is called an r-uniform entangled hypertree if all of its hyperedges are of size r for $r \geqslant 2$.

In ordinary graphs, a vertex that terminates, i.e., has precisely a single edge linked to it is called a terminal or pendent vertex. This concept is extended to the case of hypergraphs.

Definition 7: Pendant vertex. A vertex of a hypergraph $H=(S,F)$ such that it belongs to only one hyperedge of F is called a pendant vertex in H. Vertices which belong to more than one hyperedge of H are called nonpendant.

In the paper we use polygons for pictorially representing an entangled hypergraph of multipartite states. (There should be no confusion with a closed loop of EPR pairs because we consider only tree structured states.) A hyperedge representing an n-CAT amongst the parties $\{i_1,i_2,\ldots,i_n\}$ is pictorially represented by an n-gon with vertices distinctly numbered by $i_1,i_2,\ldots,i_n$. We write these vertices $i_1,i_2,\ldots,i_n$ corresponding to the n vertices of the n-gon in the pictorial representation in arbitrary order. This only means that out of n qubits of the n-CAT, one qubit is with each of the n parties.

A result we will require frequently is that there exist teleportation[2] protocols to produce n-partite entanglement starting from pairwise entanglement shared along any spanning tree connecting the n parties. That is, there exist LOCC protocols to turn a n-party spanning EPR tree into an n-regular hypergraph consisting of a single hyperedge of size n. The protocol is detailed in Refs. 24 and 23, but the basic idea is readily described. It is essentially a scheme to deterministically create a maximally entangled n-cat state from $n-1$ EPR pairs shared along a spanning tree. Briefly, the protocol consists in teleporting entanglement along a spanning tree. Players not on terminal vertices along the tree execute the following subroutine. Suppose player Alice shares an m-cat with $(m-1)$ preceding players along the tree and wishes to create an $(m+1)$-cat state including Bob, the next player down the tree. First she entangles an auxiliary particle with her

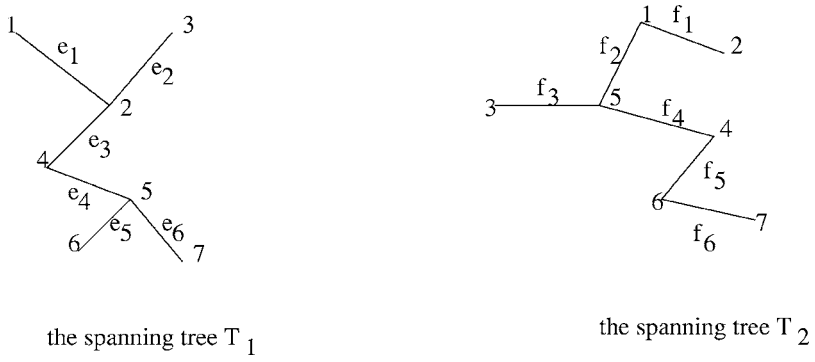

FIG. 1. Spanning EPR trees T_1 and T_2.

particle in the m-cat state by means of local operation. She then uses her EPR pair shared with Bob to teleport the state of the auxiliary particle to Bob. The $(m+1)$ players, including Alice and Bob, now share an $(m+1)$-cat state, as desired.

Another result we will require in some of our proofs, given as the theorem below, is that the spanning EPR tree mentioned above is also a necessary condition to prepare an n-CAT state starting from shared EPR pairs.

Theorem 1: *Given a communication network of n agents with only EPR pairs permitted for pairwise entanglement between agents, a necessary condition for creation of a n-CAT state is that the EPR graph of the n agents must be connected.*

Proof of the theorem is given in Appendix A using our method of bicolored merging developed in Sec. III.

III. BICOLORED MERGING

Monotonicity is easily the most natural characteristic that should be satisfied by all entanglement measures.[12] It requires that any appropriate measure of entanglement must not change under local unitary operations and more generally, the expected entanglement must not increase under LOCC. We should note here that in LOCC, LO involves unitary transformations, additions of ancillas (that is, enlarging the Hilbert space), measurements, and throwing away parts of the system, each of these actions performed by one party on his or her subsystem. CC between the parties allows local actions by one party to be conditioned on the outcomes of the earlier measurements performed by the other parties.

Apart from monotonicity, there are certain other characteristics required to be satisfied by entanglement measures. However, monotonicity itself vastly restricts the choice of entanglement measures (for example, marginal entropy as a measure of entanglement for bipartite pure states or entanglement of formation for mixed states). In the present work, we find that monotonicity, where proven for a particular entanglement measure candidate, restricts a large number of state transformations and gives rise to several classes of incomparable (multipartite) states. So, in order to study the possible state transformations of (multipartite) states under LOCC, it would be interesting to look at the kind of state transforms under LOCC which monotonicity does not allow. We can observe that monotonicity does not allow the preparation of $n+1$ or more EPR pairs between two parties starting from only n EPR pairs between them. In particular, it is not possible to prepare two or more EPR pairs between two parties starting only with a single EPR pair and only LOCC. This is an example of impossible state transformation in the bipartite case as dictated by the monotonicity postulate. We anticipate that a large class of multipartite states could also be shown to be incomparable by using impossibility results for the bipartite case through suitable reductions. For instance, consider transforming (under LOCC) the state represented by a spanning EPR tree, say T_1, to that of the state represented by another spanning EPR tree, say T_2 (see Fig. 1). This transformation can be shown to be impossible by reducing to the bipartite case as follows: We

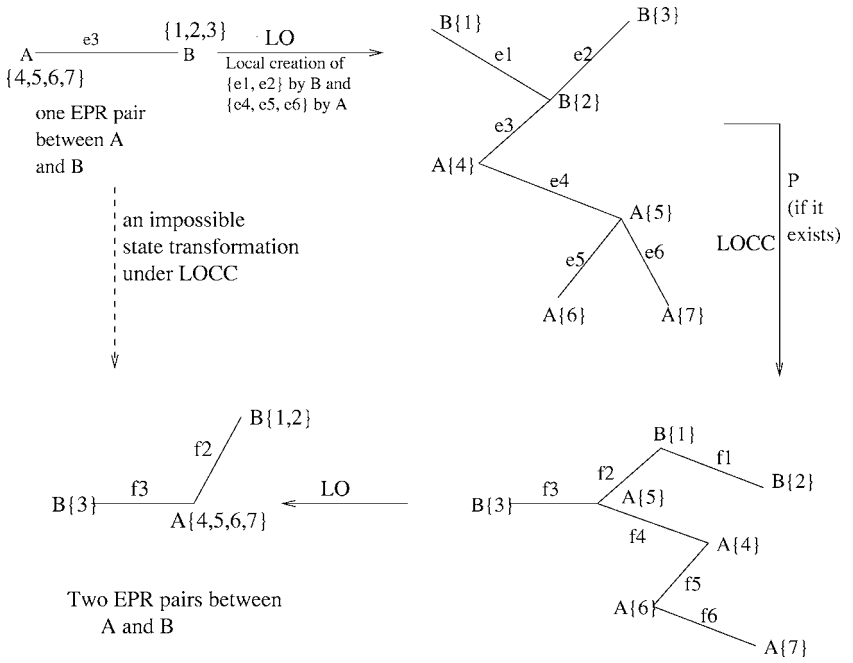

FIG. 2. Converting T_1 to T_2 under LOCC.

assume for the sake of contradiction that there exists a protocol P which can perform the required transformation. It is easy to see that the protocol P is also applicable in the case when a party A possesses all the qubits of parties 4, 5, 6, and 7 and another party B possesses all the qubits of the parties 1, 2, and 3. This means that party A is playing the role of parties 4, 5, 6, and 7 and B is playing the role of parties 1, 2, and 3. Clearly, any LOCC actions done within group {1, 2, 3} ({4, 5, 6, 7}) is a subset of LO available to B (A) and any CC done between one party from {1, 2, 3} and the other from {4, 5, 6, 7} is managed by CC between B and A.

Therefore, starting only with one edge (e_3) they eventually construct T_1 just by LO (by local creation of EPR pairs representing the edges e_1, e_2, e_4, e_5, and e_6 ($\{e_1,e_2\}$ by B and $\{e_4,e_5,e_6\}$ by A). They then apply protocol P to obtain T_2 with the edges f_1, f_2, f_3, f_4, f_5, and f_6 (refer to Fig. 2). All edges except f_2 and f_3 are local EPR pairs (that is, both qubits are with the same party, A or B). Now the parties A and B share two EPR pairs in the form of the edges f_2 and f_3, even though they started sharing only one EPR pair. But this is in contradiction with monotonicity, that expected entanglement should not increase under LOCC. Hence, we can conclude that such a protocol P cannot exist.

The approach we took in the above example could also be motivated from the marginal entropic criterion (noting that this criterion in essence is also a direct implication of monotonicity). As clear from the above example, the above scheme aims to create a bipartition among the n players in such a way that the marginal entropy of each partition is different for the two states. In many cases, this difference will simply correspond to different number of EPR pairs shared between the two partitions. Given two multipartite states, the relevant question is, "is there a bipartition such that the marginal entropy for the two states is different?" If yes, then the state (configuration of entanglement) corresponding to the higher entropy cannot be obtained from that to lower entropy by means of LOCC. It is convenient to imagine the two partitions being colored distinctly to identify the partitions which they make up.

In general, suppose we want to show that the multipartite state $|\psi\rangle$ cannot be converted to the multipartite state $|\phi\rangle$ by LOCC. This can be done by showing an assignment of the qubits (of all parties) to only two parties such that $|\psi\rangle$ can be obtained from n ($n=0,1,2,\ldots$) EPR pairs between the two parties by LOCC while $|\phi\rangle$ can be converted to more than n EPR pairs between

the two parties by LOCC. This is equivalent to saying that each party is given either of two colors (say A or B). Finally all qubits with parties colored with color A are assigned to the first party (say A) and that with parties colored with the second color to the second party (say B). This coloring is done in such a way that the state $|\psi\rangle$ can be obtained by LOCC from less number of EPR pairs between A and B than that obtained from $|\phi\rangle$ by LOCC. Local preparation (or throwing away) of EPR pairs is what we call merging in combinatorial sense. Keeping this idea in mind, we now formally introduce the idea of bicolored merging for such reductions in the case of the multipartite states represented by EPR graphs and entangled hypergraphs.

Suppose that there are two EPR graphs $G_1=(V,E_1)$ and $G_2=(V,E_2)$ on the same vertex set V (this means that these two multipartite states are shared amongst the same set of parties) and we want to show the impossibility of transforming G_1 to G_2 under LOCC, then this is reduced to a bipartite LOCC transformation which violates monotonicity, as follows:

(1) Bicoloring, assign either of the two colors A or B to every vertex, that is, each element of V.
(2) Merging, for each element $\{v_i,v_j\}$ of E_1, merge the two vertices v_i and v_j if and only if they have been assigned the same color during the bicoloring stage and assign the same color to the merged vertex. Call this graph obtained from G_1 as BCM (bicolored-merged) EPR graph of G_1 and denote it by G_1^{bcm}. Similarily, obtain the BCM EPR graph G_2^{bcm} of G_2.
(3) The bicoloring and merging is done in such a way that the graph G_2^{bcm} has more number of edges than that of G_1^{bcm}.
(4) Give all the qubits possessed by the vertices with color A to the first party (say, party A) and all the qubits possessed by the vertices with color B to the second party (say, party B). Combining this with the previous steps, it is ensured that in the bipartite reduction of the multipartite state represented by G_2, the two parties A and B share more number of EPR pairs (say, state $|\psi_2\rangle$) than that for G_1 (say, state $|\psi_1\rangle$).

We denote this reduction as $G_1 \not> G_2$. Now if there exits a protocol P which can transform G_1 to G_2 by LOCC, then P can also transform $|\psi_1\rangle$ to $|\psi_2\rangle$ just by LOCC as follows: A (B) will play the role of all vertices in V which were colored as A (B). The edges which were removed due to merging can easily be created by local operations (local preparation of EPR pairs) by the party A (B) if the color of the merged end vertices of the edge was assigned color A (B). This means that starting from $|\psi_1\rangle$ and only LO, G_1 can be created. This graph is virtually amongst $|V|$ parties even though there are only two parties. The protocol P then, can be applied to G_1 to obtain G_2 by LOCC. Subsequently $|\psi_2\rangle$ can be obtained by the necessary merging of vertices by LO, that is by throwing away the local EPR pair represented by the edges between the vertices being merged. Since the preparation of $|\psi_2\rangle$ from $|\psi_1\rangle$ by LOCC violates the monotonocity postulate, such a protocol P cannot exist. An example of bicolored merging for EPR graphs has been illustrated in Fig. 3.

The bicolored merging in the case of entangled hypergraphs is essentially the same as that for EPR graphs. For the sake of completeness, we present it here. Suppose there are two entangled hypergraphs $H_1=(S,F_1)$ and $H_2=(S,F_2)$ on the same vertex set S (that is, the two multipartite states are shared amongst the same set of parties) and we want to show the impossibility of transforming H_1 to H_2 under LOCC. Transformation of H_1 to H_2 can be reduced to a bipartite LOCC transformation which violates monotonicity thus proving the impossibility. The reduction is done as follows:

(1) Bicoloring, assign either of the two colors A or B to every vertex, that is, each element of S.
(2) Merging, for each element $E=\{v_{i1},v_{i2},\ldots,v_{ij}\}$ of $F_1(F_2)$, merge all vertices with color A to one vertex and those with color B to another vertex and give them colors A and B, respectively. This merging collapses each hyperedge to either a simple edge or a vertex and thus the hypergraph reduces to a simple graph with vertices assigned with either of the two colors A or B. Call this graph obtained from H_1 as BCM EPR graph of H_1 and denote it by H_1^{bcm}. Similarily obtain the BCM EPR graph H_2^{bcm} of H_2.
(3) The bicoloring and merging is done in such a way that the graph H_2^{bcm} has more number of edges than that of H_1^{bcm}.

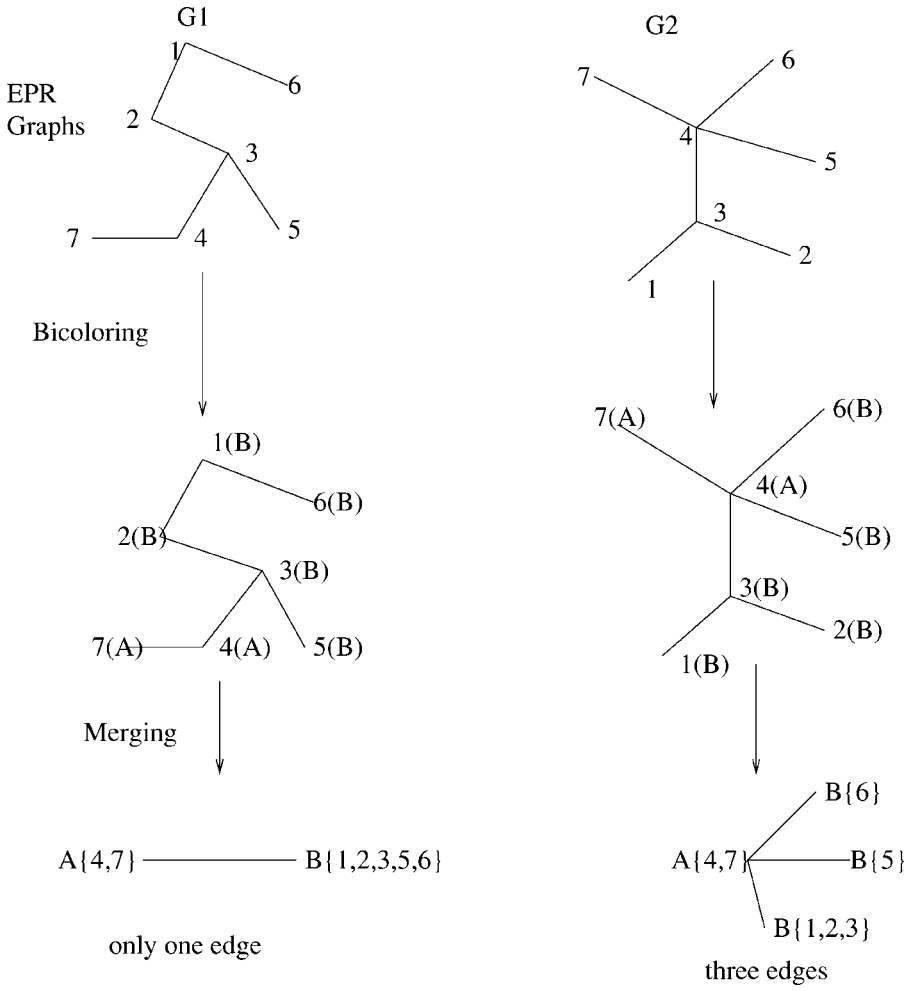

FIG. 3. Bicolored merging of EPR graphs.

(4) Give all the qubits possessed by the vertices with color A to the party one (say party A) and all the qubits possessed by the vertices with color B to the second party (say party B).

We denote the above reduction as $H_1 \succ H_2$. The rest of the discussion is similar to that for the case of EPR graphs given before. In Fig. 4, we demostrate the bicolored merging of entangled hypergraphs. Note that the two entangled hypergraphs H_1 and H_2 are LOCC comparable only if one of $H_1 \succ H_2$ and $H_2 \succ H_1$ is not true. Equivalently, if both of $H_1 \succ H_2$ and $H_2 \succ H_1$ hold, then the entangled hypergraphs H_1 and H_2 are incomparable.

It is also interesting to note at this point that LOCC incomparability shown by using the method of bicolored merging is in fact *strong incomparability* as defined in Ref. 1. We would also like to stress that any kind of reduction (in particular, various possible extensions of bicolored merging) which leads to the violation of *any* of the properties of a potential entanglement measure, is pertinent to show the impossibility of many multipartite state transformations under LOCC. Since the bipartite case has been extensively studied, such reductions can potentially provide many ideas about multipartite case by just exploiting the results from the bipartite case. In particular, the definitions of EPR graphs and entangled hypergraphs could also be suitably extended to capture more types of multipartite pure states and even mixed states and a generalization of the idea of bicolored merging as a suitable reduction for this case could also be worked out.

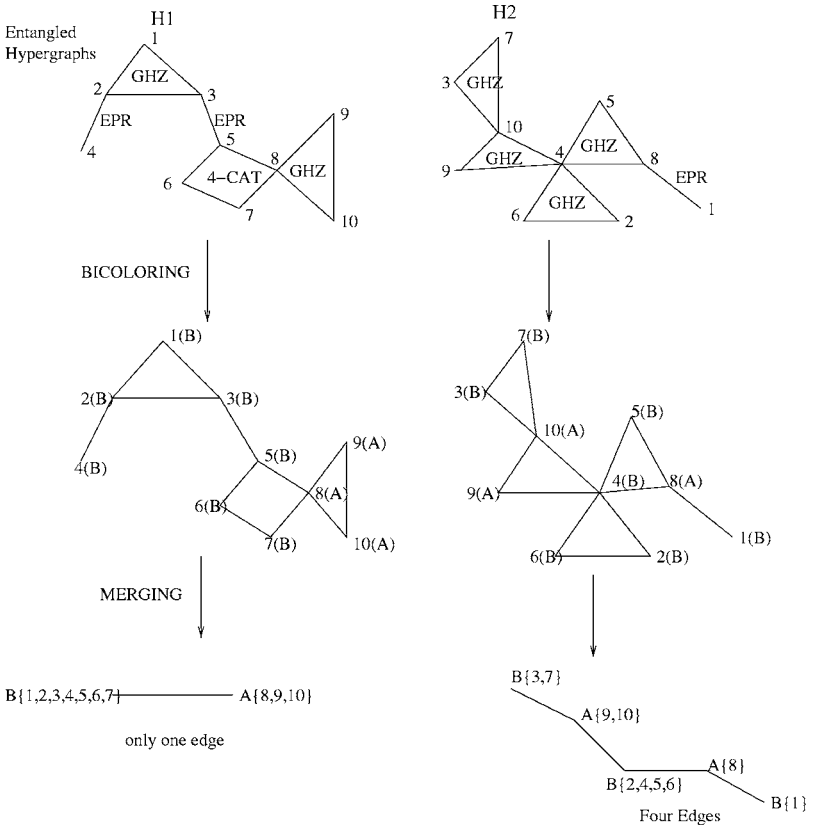

FIG. 4. Bicolored merging of entangled hypergraphs.

IV. LOCC INCOMPARABILITY AND SELECTIVE TELEPORTATION

We know that a GHZ state amongst three agents A, B, and C can be prepared from EPR pairs shared between any two pairs of the three agents using only LOCC.[24,7,29,30] We consider the problem of *reversing* this operation, that is, whether it is possible to construct two EPR pairs between any two pairs of the three agents from a GHZ state amongst the three agents, using only LOCC. By using the method of bicolored merging, we answer this question in the negative by establishing the following theorem.

Theorem 2: *Starting from a GHZ state shared amongst three parties in a communication network, two EPR pairs cannot be created between any two sets of two parties using only LOCC.*

Proof: Suppose there exists a protocol P for *reversing* a GHZ state into two EPR pairs using only LOCC. In particular, suppose protocol P starts with a GHZ state amongst the agents A, B, and C, and prepares EPR pairs between any two pairs of A, B, and C (say, $\{A,C\}$, and $\{B,C\}$, corresponding to configuration G_1 as shown in Fig. 5). Since we can prepare the GHZ state from EPR pairs between any two pairs of the three agents, we can prepare the GHZ state starting from EPR pairs between A and B, and A and C. Once the GHZ state is prepared, we can apply protocol P to construct EPR pairs between A and C and between B and C using only LOCC (i.e., configuration $G_2 \equiv \{\{A,C\},\{B,C\}\}$). So, we can use only LOCC to convert a configuration where EPR pairs exist between A and C and between A and B, to a configuration where EPR pairs are shared between A and C and between B and C. The possibility of P means that the marginal entropy of C can be increased using only LOCC, which is known to be impossible. □

The same result could also be achieved by similar bicolored merging directly applied on the GHZ state and any of G_1 or G_2 but we prefer the above proof for stressing the argument on the symmetry of G_1 and G_2 with respect to the GHZ. Moreover, this proof gives an intuition about

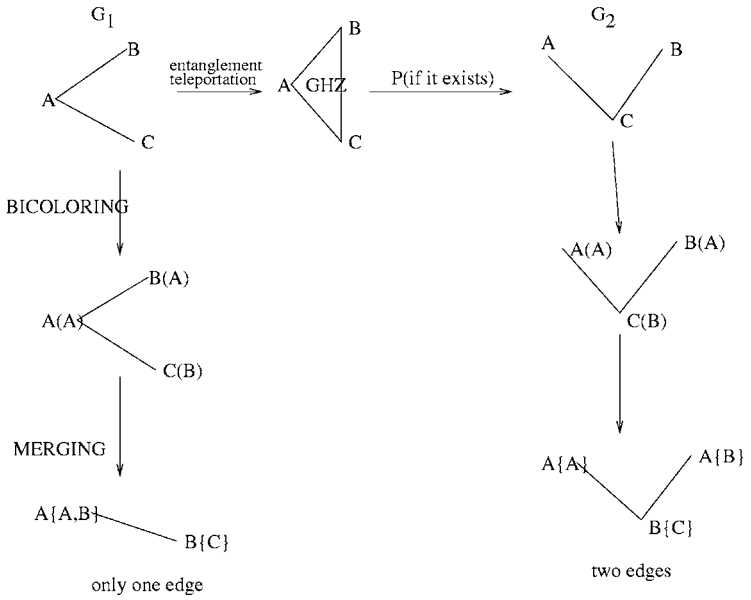

FIG. 5. LOCC irreversibility of the process [2 EPR $\rightarrow$ GHZ].

possibility of incomparability amongst spanning EPR trees as G_1 and G_2 are two distinct spanning EPR trees on three vertices. We prove this general result in the Theorem 8.

The above theorem motivates us to propose some kind of comparison between a GHZ state and two pairs of EPR pairs in terms of the nonlocal correlations they possess. In this sense, therefore, a GHZ state may be viewed as less than two EPR pairs. It is easy to see that an EPR pair between any two parties can be obtained starting only from a GHZ state shared amongst the three parties and LOCC. The third party will just do a measurement in the diagonal basis and send the result to the other two. By applying the corresponding suitable operations they get the required EPR pair. From Theorem 1, we observe that a single EPR pair, between any two of the three parties, is not sufficient for preparing a GHZ state amongst the three parties using only LOCC. These arguments can be summarized in the following theorem.

Theorem 3: *1-EPR pair* $<_{LOCC}$ *a GHZ state* $<_{LOCC}$ *2-EPR pairs.*

An interesting problem in quantum information theory is that of *selective teleportation*.[22] Given three agents A, B, and C, and two qubits of unknown quantum states $|\psi_1\rangle$ and $|\psi_2\rangle$ with A, the problem is to send $|\psi_1\rangle$ to B and $|\psi_2\rangle$ to C selectively, using only LOCC and *a priori* entanglement between the three agents. A simple solution to this problem is applying standard teleportation,[2] in the case where A shares EPR pairs with both B and C. An interesting question is whether any other form of *a priori* entanglement can help achieving selective teleportation. In particular, is it possible to perform selective teleportation where the *a priori* entanglement is in the form of a GHZ state amongst the three agents? The following theorem answers this question using the result of the Theorem 2.

Theorem 4: *With a priori entanglement given in the form of a GHZ state shared amongst three agents, two qubits cannot be selectively teleported by ane of the three parties to the other two parties.*

Proof: Suppose there exists a protocol P which can enable one of the three parties (say A) to teleport two qubits $|\psi_1\rangle$ and $|\psi_2\rangle$ selectively to the other two parties (say B and C). Now A takes four qubits; she prepares two EPR pairs one from the first and second qubits and the other from the third and fourth qubits. He then teleports the first and third qubits selectively to B and C using P (consider first qubit as $|\psi_1\rangle$ and the third qubit as $|\psi_2\rangle$). We can note here that in this way A is able to share one EPR pair each with B and C. But this is impossible because it allows A to prepare two EPR pairs starting from a GHZ state and only using LOCC. This contradicts Theorem 2. Hence follows the result. □

V. COMBINATORIAL CONDITIONS FOR LOCC INCOMPARABILITY OF EPR GRAPHS

An immediate result comparing an n-CAT state with EPR pairs follows from noting that, given a spanning EPR tree among n parties, an n-CAT state can be constructed using only LOCC using the teleportation protocol described in Sec. II. The result we present below generalizes Theorem 3.

Theorem 5: *1-EPR pair* $<_{LOCC}$ *n-CAT* $<_{LOCC}$ $(n-1)$*-spanning EPR tree.*

We can argue in a similar manner that an n-CAT state amongst n-parties cannot be converted by just using LOCC to any form of entanglement structure which possesses EPR pairs between any two or more different sets of two parties. Assume this is possible for the sake of contradiction. Then the two edges could be in either of the two forms: (1) $\{i_1,i_2\}$ and $\{j_1,j_2\}$ and (2) $\{i_1,i_2\}$ and $\{i_2,j_2\}$, where i_1,i_2,j_1,j_2 are all distinct. In bicolored-merging assign the colors as follows. In case (1), give color A to i_2 and j_2 and give the color B to the rest of the vertices. In case (2), give color A to i_2 and color B to the rest of the vertices. Since both the cases are contrary to our assumption, the assertion follows. Moreover, from Theorem 1 (see Appendix A for proof), no disconnected EPR graph would be able to yield n-CAT just by LOCC. These two observations combined together lead to the following theorem which signifies the fact that these two multipartite states cannot be compared.

Theorem 6: *A CAT state amongst n agents in a communication network is LOCC incomparable to any disconnected EPR graph associated with the n agents having more than one edge.*

The above result indicates that there are many possible forms of entanglement structures (multipartite states) which cannot be compared at all in terms of nonlocal correlations they may have. This simple result is just an implication of the necessary combinatorics required for the preparation of CAT states. One more interesting question with respect to this combinatorics is to compare a spanning EPR tree and a CAT state. A spanning EPR tree is combinatorially sufficient for preparing the CAT state and thus seems to entail more nonlocal correlations than in a CAT state. The question whether this ordering is strict needs to be further investigated. It is easy to see that an EPR pair between any two parites can be obtained starting from a CAT state shared amongst the n agents just by LOCC (Theorem 5). Therefore, given $n-1$ copies of the CAT state we can build all the $n-1$ edges of any spanning EPR tree just by LOCC. But whether this is the lower bound on the number of copies of n-CAT required to obtain a spanning EPR tree is even more interesting. The following theorem shows that this is indeed the lower bound.

Theorem 7: *Starting with only* $n-2$ *copies of n-CAT state shared amongst its n agents, no spanning EPR tree of the n agents can be obtained just by LOCC.*

Proof: Suppose it is possible to create a spanning EPR tree T from $(n-2)$ copies of n-CAT states. As we know, an n-CAT state can be prepared from any spanning EPR tree by LOCC.[24,7,29,30] Thus, if $(n-2)$ copies of n-CAT can be converted to T, then $(n-2)$ copies of any spanning EPR tree can be converted to T just by LOCC. In particular, $(n-2)$ copies of a chain EPR graph (which is clearly a spanning EPR tree, Fig. 6) can be converted to T just by LOCC. Now, we know that any tree is a bipartite connected graph with $n-1$ edges across the two parts. Let vertices $i_1,i_2,\ldots,i_m$ be the members of the first group and the rest be in the other group. Construct a chain EPR graph where the first m vertices are $i_1,i_2,\ldots,i_m$ in the sequence, and the rest of the vertices are from the other group in the sequence (Fig. 6). In bicolored merging, we give the color A to the parties $\{i_1,i_2,\ldots,i_m\}$ and the rest of the parties are given the color B. This way we are able to create $(n-1)$ EPR pairs (note that there are $n-1$ edges in T across the two groups) between A and B starting from only $(n-2)$ EPR pairs (considering the $n-2$ chainlike spanning EPR trees). So, we conclude that $(n-2)$ copies of n-CAT cannot be converted to any spanning EPR tree just by LOCC. See Fig. 6 for illustration of the required bicolored merging. The proof could also be acheived by similar kind of bicolored merging directly applied on n-CAT and T. □

In the preceding results we have compared spanning EPR trees with CAT states. We discuss the comparability/incomparability of two distinct spanning EPR trees in the next theorem and corollary.

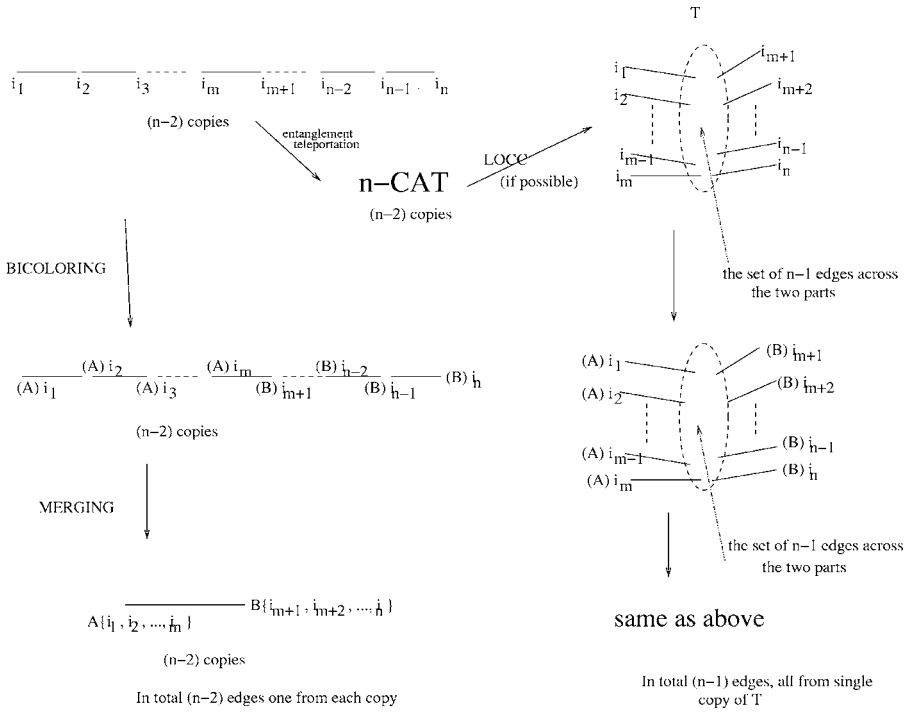

FIG. 6. $n-2$ copies of n-CAT are not sufficient to prepare a spanning EPR tree.

Theorem 8: *Any two distinct spanning EPR trees are LOCC incomparable.*

Proof: Let T_1 and T_2 be the two distinct spanning EPR trees on the same n vertices. Clearly, there exist two vertices (say i and j) which are connected by an edge in T_2 but not in T_1. Also by virtue of connectedness of spanning trees, there will be a path between i and j in T_1. Let this path be $ik_1k_2\cdots k_mj$ with $m>0$ (see Fig. 7). Since $m>0$, k_1 must exist.

Let $T_i^1 \equiv$ subtree in T_1 rooted at i except for the branch which contains the edge $\{i,k_1\}$, $T_j^1 \equiv$ subtree in T_1 rooted at j except for the branch which contains the edge $\{j,k_m\}$, $T_{k_r} \equiv$ subtree in T_1 rooted at k_r except for the branches which contain either of the edges $\{k_{r-1},k_r\}$ and $\{k_r,k_{r+1}\}$ ($k_0=i$, $k_{m+1}=j$), $T_i^2 \equiv$ subtree in T_2 rooted at i except for the branch which contains the edge $\{i,j\}$, and $T_j^2 \equiv$ subtree in T_2 rooted at j except for the branch which contains the edge $\{i,j\}$.

It is easy to see that the set $T_i^2 \cup T_j^2$ is nonempty as T_1 and T_2, being distinct, must contain more than two vertices. Also T_i^2 and T_j^2 must be disjoint; for, otherwise there will be a path between i and j in T_2 which does not contain the edge $\{i,j\}$. Thus there will be two paths between i and j in T_2 contradicting the fact that T_2 is a spanning EPR tree (Fig. 7). With these two charactistics of T_i^2 and T_j^2, it is clear that k_1 will lie either in T_i^2 or in T_j^2. Without loss of generality, let us assume that $k_1 \in T_i^2$. Now we do bicolored merging where the color A is assigned to i and all vertices in T_i^1 and the color B is assigned to the rest of the vertices (refer to Fig. 7 for illustration). Since T_1 and T_2 were chosen arbitrarily, the same arguments also imply that there cannot exist a method which converts T_2 to T_1. This leads to the conclusion that any two distinct spanning EPR trees are LOCC incomparable.

Corollary 1: There are at least exponentially many LOCC-incomparable classes of pure multipartite entangled states.

Proof: We know from results in graph theory[9] that on a labelled graph on n vertices, there are n^{n-2} posible distinct spanning trees. Hence there are n^{n-2} distinct spanning EPR trees in a network of n agents. From Theorem 8 all these spanning EPR trees are LOCC incomparable. It can be noted here that the most general local operation of n qubits is an element of the group $U(2)^n$ (local unitary rotations on each qubit alone). So, if two states are found incomparable, this means that there are actually two incomparable equivalence classes of states [where members in a class are

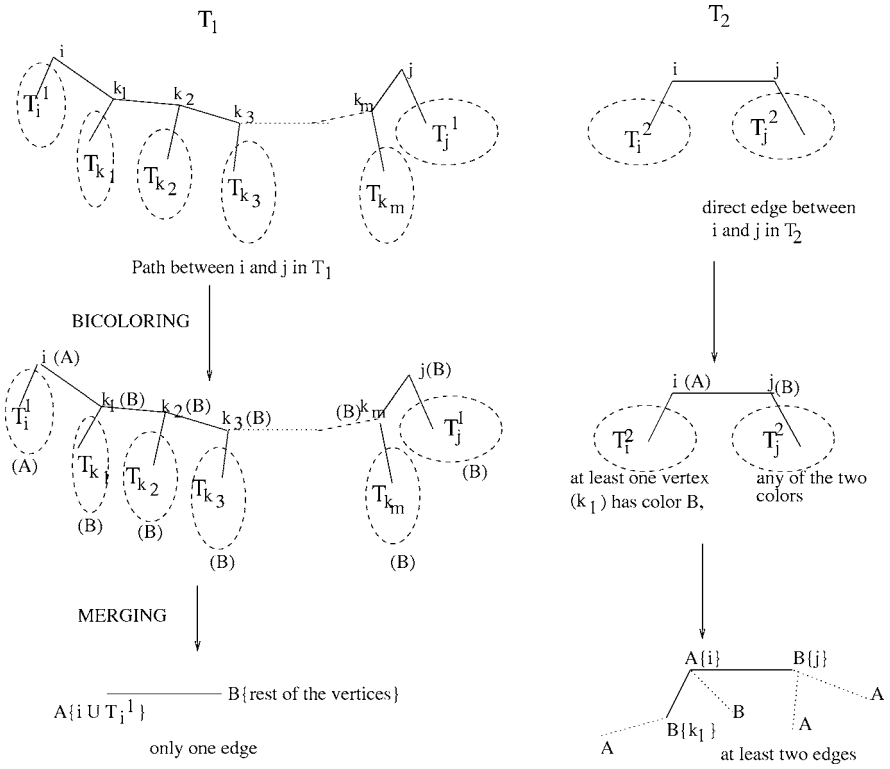

FIG. 7. Spanning EPR trees are LOCC incomparable.

related by a $U(2)^n$ transformation]. Thus we have at least exponentially many LOCC-incomparable classes of multipartite entangled states. □

VI. COMBINATORIAL CONDITIONS FOR LOCC INCOMPARABILITY OF ENTANGLED HYPERGRAPHS

Since entangled hypergraphs represent more general entanglement structures than those represented by the EPR graphs (in particular spanning EPR trees are nothing but 2-uniform entangled hypertrees), it is likely that there will be even more classes of incomparable multipartite states and this motivates us to generalize Theorem 8 for entangled hypertrees. However, remarkably this intuition does not work directly and there are entangled hypertrees which are not incomparable. But there are a large number of entangled hypertrees which do not fall under any such partial ordering and thus remain incomparable. To this end we present our first imcomparability result on entangled hypergraphs.

Theorem 9: *Let $H_1=(S,F_1)$ and $H_2=(S,F_2)$ be two entangled hypertrees. Let P_1 and P_2 be the set of pendant vertices of H_1 and H_2, respectively. If the sets $P_1\backslash P_2$ and $P_2\backslash P_1$ are both nonempty then the multipartite states represented by H_1 and H_2 are necessarily LOCC incomparable.*

Proof: Using bicolored merging we first show that H_1 cannot be converted to H_2 under LOCC. Impossibility of the reverse conversion will also be immediate. Since $P_1\backslash P_2$ is nonempty, there exists $u \in S$ such that $u \in P_1\backslash P_2$. That is, u is pendant in H_1 but nonpendant in H_2 (Fig. 8).

In the bicolored merging assign the color A to the vertex u and the color B to all other vertices. This reduces H_1 to a single EPR pair shared between the two parties A and B whereas H_2 reduces to at least two EPR pairs shared between A and B. The complete bicolored merging is shown in Fig. 8. □

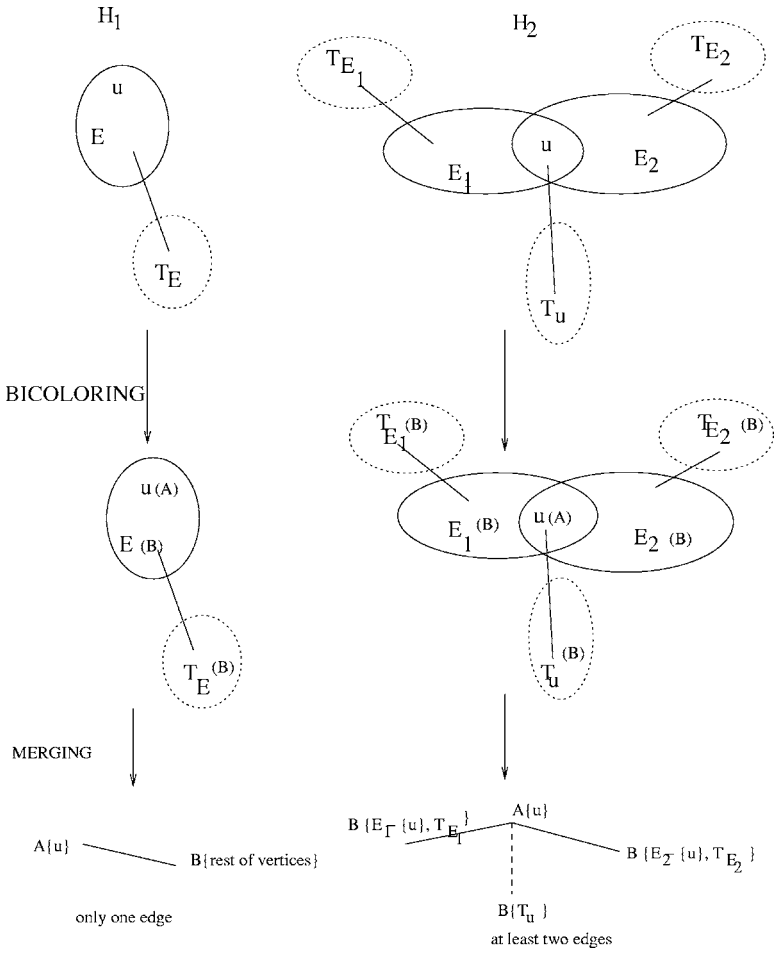

FIG. 8. Entangled hypergraphs with $P_1 \backslash P_2$ nonempty.

We note that this proof does not utilize the fact that H_1 and H_2 are entangled hypertrees, and thus the theorem is indeed true even for entangled hypergraphs satisfying the conditions specified on the set of pendant vertices.

The conditions specified on the set of pendant vertices in Theorem 9 cover a very small fraction of the entangled hypergraphs. However, these conditions are not necessary and it may be possible to find further characterizations of incomparable classes of entangled hypergraphs. We present two examples where the conditions of Theorem 9 are not satisfied.

Example 1: (Figs. 9 and 10) $P_1 \neq P_2$ but either $P_1 \subset P_2$ or $P_2 \subset P_1$.

Example 2: (Fig. 11) $P_1 = P_2$.

In the first example, the entangled hypergraphs H_1 and H_2 staisfy $P_1 \neq P_2$ and $P_1 \subset P_2$. H_1 and H_2 are comparable in Fig. 9 but incomparable in Fig. 10. In Fig. 10, the incomparability has been proved by showing that H_1 is not convertible to H_2 under LOCC because the impossibility of reverse conversion follows from the proof of Theorem 9 ($P_2 \backslash P_1 \neq \phi$). Figure 11 gives examples of comparable and incomparable entangled hypergraphs with condition $P_1 = P_2$.

Theorem 8 shows that two distinct EPR spanning trees are LOCC incomparable and the spanning EPR trees are nothing but 2-uniform entangled hypertrees. Therefore, a natural generalization of this theorem would be to r-uniform entangled hypertrees for any $r \geqslant 3$. As we show below, the generalization indeed holds. It should be noted that Theorem 9 does not necessarily capture such entanglement structures (multipartite states) (Fig. 12). However, in order to prove

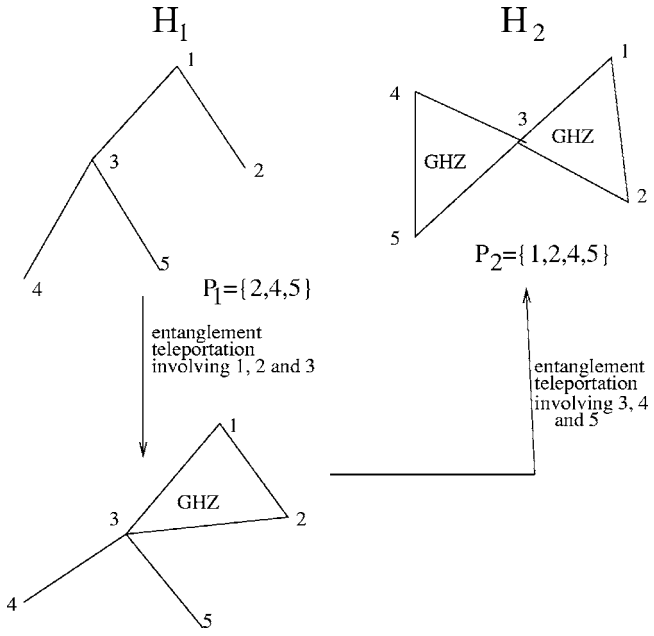

FIG. 9. Comparable with $P_1 \neq P_2$ and $P_1 \subset P_2$.

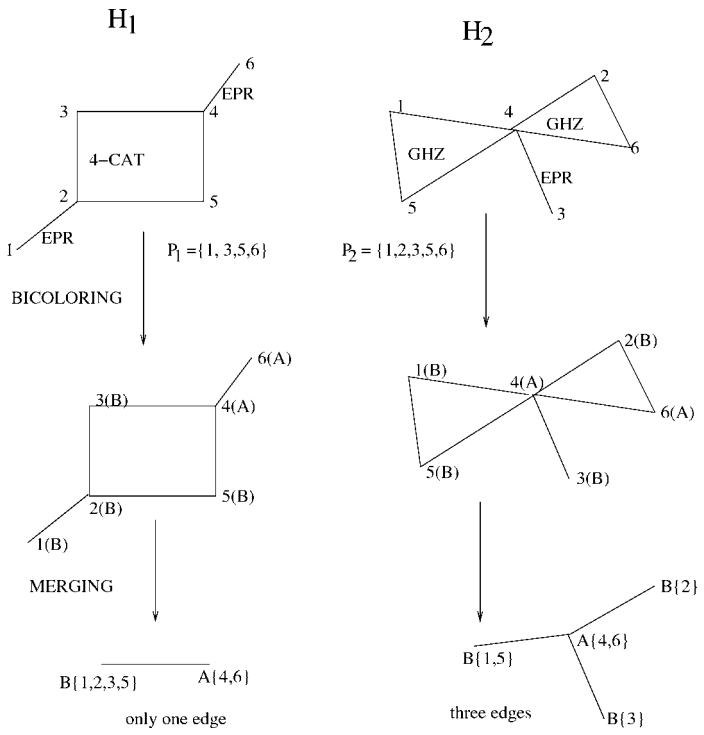

FIG. 10. Incomparable with $P_1 \neq P_2$ and $P_1 \subset P_2$.

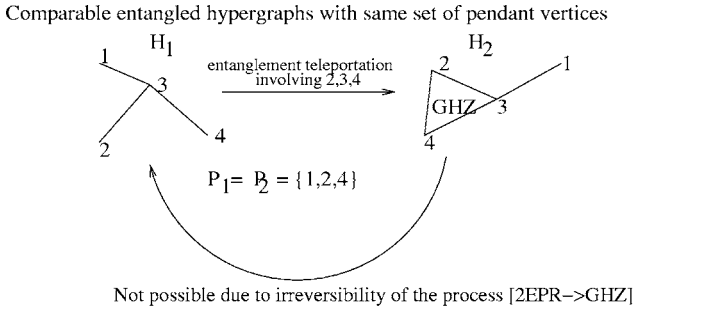

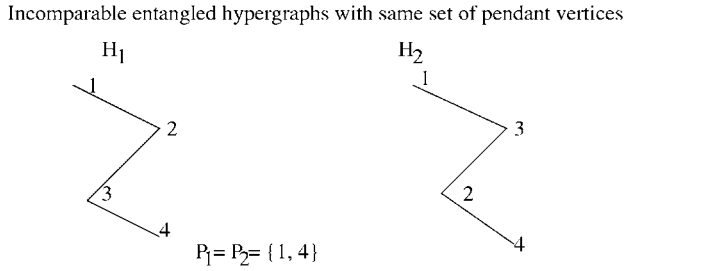

FIG. 11. $P_1 = P_2$.

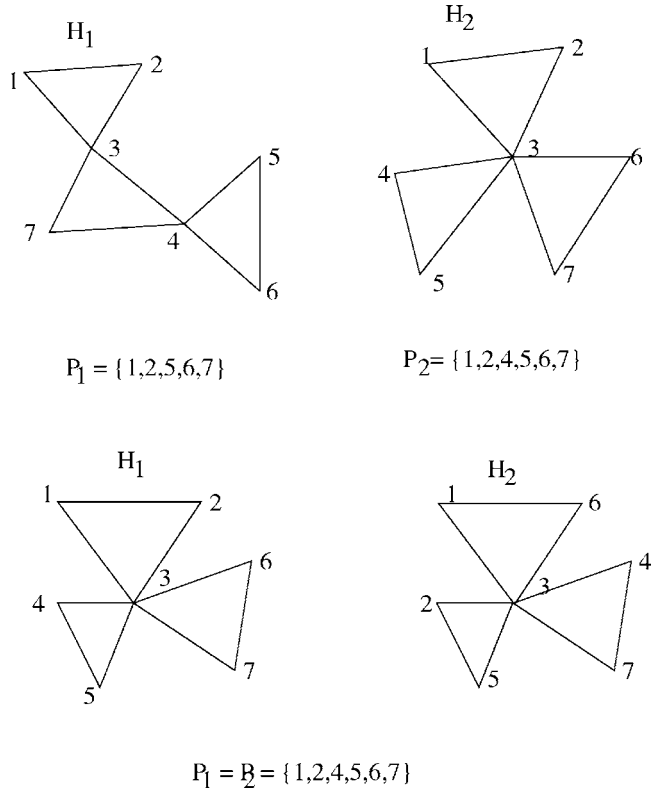

FIG. 12. r-uniform entangled hypertrees not captured in Theorem 9.

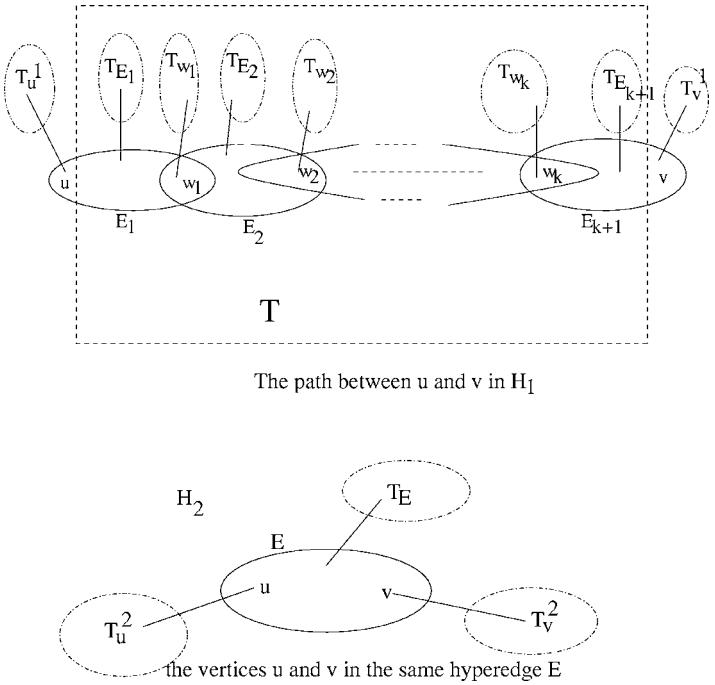

FIG. 13. Two distinct r-uniform entangled hypertrees.

that two distinct r-uniform entangled hypertrees are LOCC incomparable, we need the following important result about r-uniform hypertrees. See Appendix B for the proof.

Theorem 10: *Given two distinct r-uniform hypertrees* $H_1=(S,F_1)$ *and* $H_2=(S,F_2)$ *with* $r \geqslant 3$, *there exist vertices* $u,v \in S$ *such that u and v belong to the same hyperedge in* H_2 *but necessarily to different hyperedges in* H_1.

Now we state one of our main results on LOCC incomparability of multipartite entangled states in the following theorem.

Theorem 11: *Any two distinct r-uniform entangled hypertrees are LOCC incomparable.*

Proof: Let $H_1=(S,F_1)$ and $H_2=(S,F_2)$ be the two r-uniform entangled hypertrees. If $r=2$ then H_1 and H_2 happen to be two distinct spanning EPR trees and the proof follows from Theorem 8. Therefore, let $r \geqslant 3$.

Now from Theorem 10, there exist $u,v \in S$ such that u and v belong to the same hyperedge in H_2 but necessarily to different hyperedges in H_1. Let the same hyperedge in H_2 be $E \in F_2$. Also, since H_1, being hypertree, is *connected*, there exists a path between u and v in H_1. Let this path be $uE_1E_2 \cdots E_{k+1}v$. Clearly $k>0$ because u and v necessarily do not belong to the same hyperedge in H_1.

We introduce the following notations (Fig. 13).

T_u^1, subhypertree rooted at u in H_1 except the branch that contains E_1. T_v^1, subhypertree rooted at v in H_1 except the branch that contains E_{k+1}. T_{w_i}, subhypertree rooted at w_i in H_1 except branches containing E_i and E_{i+1}. T_{E_i}, Collection of all subhypertrees in H_1 rooted at some vertices in E_i other than w_{i-1} and w_i (where $w_0=u$ and $w_{k+1}=v$) except for the branches which contain E_i. $T=((E_1 \cup E_2 \cup \cdots \cup E_{k+1}) \cup (T_{E_1} \cup T_{E_2} \cup \cdots \cup T_{E_{k+1}}) \cup (T_{w_1} \cup T_{w_2} \cup \cdots \cup T_{w_k}))\backslash\{u,v\}$=set of all vertices from $S\backslash\{u,v\}$ which are not contained in $T_u \cup T_v$. T_u^2, subhypertree rooted at u in H_2 except the branch that contains E. T_v^2, subhypertree rooted at v in H_2 except the branch that contains E. T_E, collection of all subhypertrees in H_2 rooted at some vertices in $E\backslash\{u,v\}$ except for the branches which contain E.

In order to complete the proof we consider the following cases.

Case 1: $\exists w \in T$ such that $w \in (T_u^2 \cup T_v^2)$.

Without loss of generality let us take $w \in T_u^2$. Now since $w \in T$, $w \in$ exactly one of E_i, T_{w_i}, or T_{E_i} for some i. Accordingly there will be three subcases. *Case 1.1*, $w \in E_i$ for some i (take such minimum i).

Do bicolored merging where the vertex u along with all the vertices in

$$T_u^1, E_1, E_2, \ldots, E_{i-1}, T_{w_1}, T_{w_2}, \ldots, T_{w_{i-1}}, T_{E_1}, T_{E_2}, \ldots, T_{E_{i-1}}$$

are given the color A and the rest of the vertices are given the color B.

Case 1.2: $w \in T_{w_i}$ for some i.

Do the bicolored merging while assigning the colors as in the above case.

Case 1.3: $w \in T_{E_i}$ for some i.

Bicolored merging in this case is also the same as in Case 1.1.

Case 2: There does not exist any $w \in T$ such that $w \in T_u^2 \cup T_v^2$.

Clearly, $T_u^2 \cup T_v^2 \subset T_u^1 \cup T_v^1$ and $T \subset T_E \cup (E \setminus \{u,v\})$. Note that whenever we are talking of set relations like union, containment, etc., we are considering the trees, edges, etc., as sets of appropriate vertices from S which make them. First we establish the following claim.

Claim: $\exists t \in (E_1 \setminus \{u, w_1\}) \cup (E_2 \setminus \{w_1, w_2\})$ such that $t \in T_E$.

We have $k > 0$. Therefore, both E_1 and E_2 exist and since H_1 is r-uniform $|E_1| = |E_2| = r$. Also $(E_1 \setminus \{u, w_1\}) \cap (E_2 \setminus \{w_1, w_2\})$ is empty, for, otherwise there will be a cycle in H_1 which is not possible as H_1 is a hypertree.[5,10] Therefore,

$$|(E_1 \setminus \{u,w_1\} \cup (E_2 \setminus \{w_1,w_2\})| = |(E_1 \setminus \{u,w_1\}| + |E_2 \setminus \{w_1,w_2\}| = (r-2) + (r-2) = 2r-4.$$

Also $|E| = r$ implies that $|E \setminus \{u,v\}| = (r-2)$.

It is clear that $u, v \notin (E_1 \setminus \{u, w_1\}) \cup (E_2 \setminus \{w_1, w_2\})$. Therefore,

$$|(E_1 \setminus \{u,w_1\}) \cup (E_2 \setminus \{w_1,w_2\})| - |E \setminus \{u,v\}| = (2r-4) - (r-2) = r - 2 \geqslant 1$$

since $r \geqslant 3$.

Also $(E_1 \setminus \{u, w_1\}) \cup (E_2 \setminus \{w_1, w_2\}) \subset T \subset T_E \cup (E \setminus \{u,v\})$, and so by pigeonhole principle,[25]

$$\exists t \in (E_1 \setminus \{u,w_1\}) \cup (E_2 \setminus \{w_1,w_2\}) \text{ and } t \in T_E (\notin (E \setminus \{u,v\}))$$

Hence our claim is true.

Now we have $t \in (E_1 \setminus \{u, w_1\}) \cup (E_2 \setminus \{w_1, w_2\})$ such that $t \in T_E$. Since $t \in T_E$, by the definition of T_E it is clear that there must exist $w \in E \setminus \{u,v\}$ such that $t \in T_w$, the subhypertree in H_2 rooted at w except for the branch containing E. Depending on whether $t \in E_1 \setminus \{u, w_1\}$ or $t \in E_2 \setminus \{w_1, w_2\}$, we break this case into several subcases and futher in sub-subcases depending on the part in H_1 where w lies.

Case 2.1: $t \in E_1 \setminus \{u, w_1\}$ (Fig. 14).

Case 2.1.1: $w \in T_u^1$.

Do the bicolored merging where u and the vertices in T_u^1 are assigned the color A and the rest of the vertices from S are given the color B.

Case 2.1.2: $w \in T_v^1$.

Bicolored merging is done where v as well as all the vertices in T_v^1 are assigned the color B and rest of the vertices from S are given the color A.

Case 2.1.3: $w \in T$.

Here in this case, depending on whether w is in T_t or not, there can be two cases.

Case 2.1.3.1: $w \in T_t$.

Bicolored merging is done where all the vertices in T_t are given the color A and the rest of the vertices are assigned the color B.

Case 2.1.3.2: $w \notin T_t$.

$w \notin T_t$ implies that either $w \in E_i$ for some i, or $w \in T_q$, where $q \in E_i$ for some i and $q \neq t$. For both of these possibilities, bicolored merging is the same and is done as follows.

Assign the color A to u as well as all vertices in

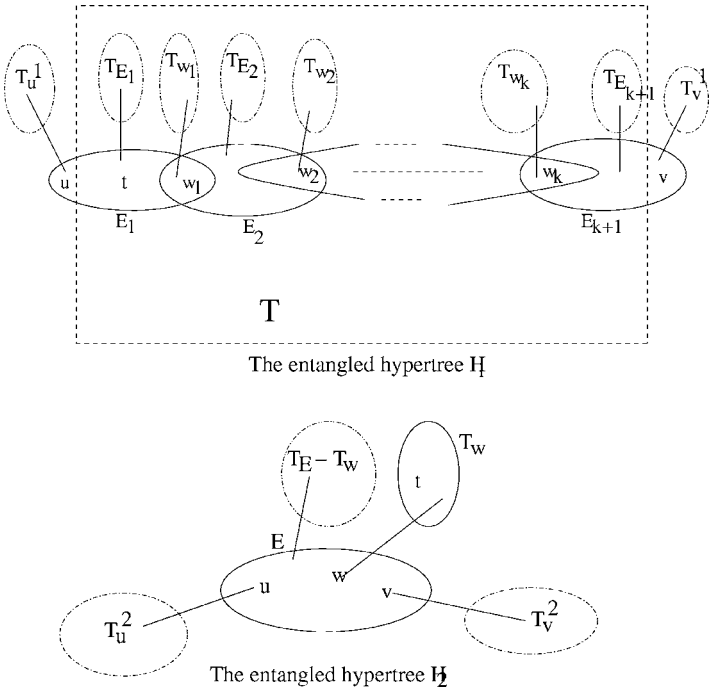

FIG. 14. Case 2.1.

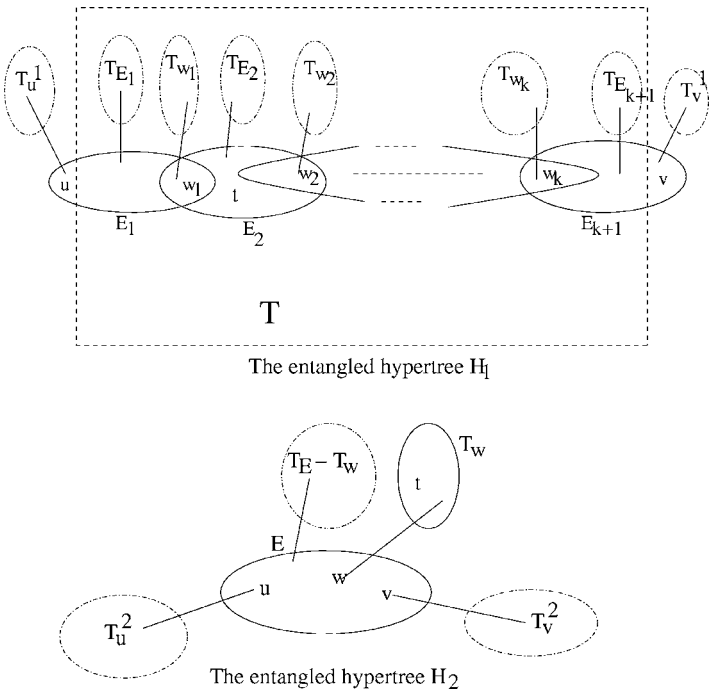

FIG. 15. Case 2.2.

$$T_u^1 \cup E_1 \cup T_{E_1} \cup T_{w_1} \cup \cdots \cup E_{i-1} \cup T_{E_{i-1}} \cup T_{w_{i-1}} \cup (E_i \setminus \{q,w,w_i\}) \cup (T_{E_i} \setminus T_q)$$

and assign the color B to rest of the vertices.

Case 2.2: $t \in E_2 \setminus \{w_1, w_2\}$ (Fig. 15).

Case 2.2.1: $w \in T_u^1 \cup E_1 \cup T_{E_1} \cup T_{w_1}$.

Do the bicolored merging where all the vertices in $T_u^1 \cup E_1 \cup T_{E_1} \cup T_{w_1}$ including u are given the color A and rest of the vertices are assigned the color B.

Case 2.2.2: $w \in T_v^1 \cup T_{E_{k+1}} \cup E_{k+1} \cup T_{w_k} \cup \cdots \cup T_{E_3} \cup E_3 \cup T_{w_2}$.

In bicolored merging give the color B to all the vertices (including v) in $T_v^1 \cup T_{E_{k+1}} \cup E_{k+1} \cup T_{w_k} \cup \cdots \cup T_{E_3} \cup E_3 \cup T_{w_2}$ and color A to the rest of the vertices.

Case 2.2.3: $w \in E_2 \cup T_{E_2}$.

In this case depending on whether $w \in T_t$, or $w \notin T_t$ the bicolored merging will be different.

Case 2.2.3.1: $w \in T_t$.

Bicolored merging is done where all the vertices in T_t are given the color A and rest of the vertices are assigned the color B.

Case 2.2.3.2: $w \notin T_t$.

$w \notin T_t$ implies that either $w \in E_2$, or $w \in T_q$ for some $q(\neq t) \in E_2$. In any case do the bicolored merging where the color A is assigned to all the vertices in

$$T_u^1 \cup E_1 \cup T_{E_1} \cup T_{w_1} \cup (E_2 \setminus \{w,q,w_2\}) \cup (T_{E_2} \setminus T_q)$$

and the rest of the vertices are assigned the color B.

Now that we have exhausted all possible cases and shown by the method of bicolored merging that the r-uniform entangled hypertree H_1 cannot be LOCC converted to the r-uniform entangled hypertree H_2. The same arguments also work for showing that H_2 can not be LOCC converted to H_1 by interchanging the roles of H_1 and H_2. Hence the theorem follows. □

Before ending our section on LOCC incomparability of multipartite states represented by EPR graphs and entangled hypergraphs, we note that partial entropic criteria of Bennett *et al.*[4] which gives a sufficient condition for LOCC incomparability of multipartite states, does not capture the LOCC incomparability of spanning EPR trees or entangled hypertrees in general. Consider two spanning EPR trees T_1 and T_2 on three vertices (say 1, 2, 3). T_1 is such that the vertex pairs 1, 2 and 1, 3 are forming the two edges where as in T_2 the vertex pairs 1, 3 and 2, 3 are forming the two edges. It is easy to see that T_1 and T_2 are not marginally isentropic.

VII. QUANTUM DISTANCE BETWEEN MULTIPARTITE ENTANGLED STATES

In the proof of Theorem 8, we have utilized the fact that there exist at least two vertices which are connected by an edge in T_2 but not in T_1. This follows as T_1 and T_2 are different and they also have equal number of edges (namely $n-1$, if there are n vertices). In fact, in general there may exist several such pairs of vertices depending on the structures of T_1 and T_2. Fortunately, the number of such pair of vertices has some nice features giving rise to a metric on the set of spanning (EPR) trees with fixed vertex set and thus giving a concept of distance.[9] The distance between any two spanning (EPR) trees T_1 and T_2 denoted by QD_{T_1,T_2} on the same vertex set is defined as the number of edges in T_1 which are not in T_2. Let us call this distance to be the *quantum distance* between T_1 and T_2. We have proved in Theorem 8 that obtaining T_2 from T_1 is not possible just through LOCC, so we need to do quantum communication. The minimum number of qubit required to be communicated for this purpose should be an interesting parameter related to state transformations amongst multipartite states represented by spanning EPR trees; let us denote this number by q_{T_1,T_2}. We note that $q_{T_1,T_2} \leqslant QD_{T_1,T_2}$. This is because each edge not present in T_2 can be created by only one qubit communication. The exact value of q_{T_1,T_2} will depend on the structures of T_1 and T_2 and, as we can note, on the number of edge disjoint paths in T_1 between the vertex pairs which form an edge in T_2 but not T_1.

We can say more about quantum distance. Recall Theorem 7 where we show that a lower bound on the number of copies of n-CAT to prepare a spanning EPR tree by LOCC, is $n-1$. Can

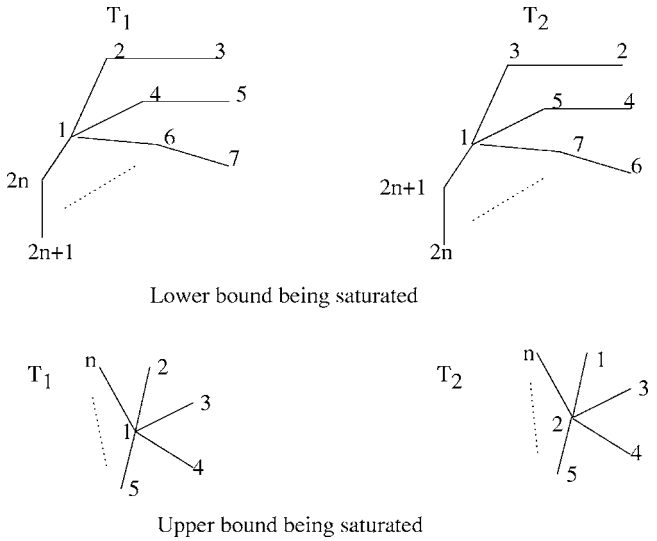

FIG. 16. Saturating bounds on copies required to go from one EPR spanning tree to another via LOCC.

we obtain a similar lower bound in the case of two spanning EPR trees and relate it to the quantum distance? The answer is indeed yes. Let C_{T_1,T_2} denote the minimum number of copies of the spanning EPR tree T_1 required to obtain T_2 just by LOCC. We claim that $2 \leqslant C_{T_1,T_2}$, $C_{T_2,T_1} \leqslant QD_{T_1,T_2}+1$. The lower bound follows from Theorem 8. The upperbound is also true because of the following reason. QD_{T_1,T_2} is the number of (EPR pairs) edges present in T_2 but not in T_1. For each such edge in T_2 (let u, v be the vertices forming the edge), while converting many copies of T_1 to T_2 by LOCC an edge between u and v must be created. Since T_1 is a spanning tree and therefore connected, there must be a path between u and v in T_1 and this path can be well converted (using entanglement swapping) to an edge between them (i.e., EPR pair between them) only using LOCC. Hence one copy each will suffice to create each such edges in T_2. Thus QD_{T_1,T_2} copies of T_1 will be sufficient to create all such QD_{T_1,T_2} edges in T_2. One more copy will supply all the edges common in T_1 and T_2. Even more interesting point is that both these bounds are saturated. This means to say that there do exist spanning EPR trees satifying these bounds (Fig. 16).

It is important to note that a similar concept of distance also holds in the case of r-uniform entangled hypertrees.

APPENDIX A

Proof of Theorem 1: We use the method of bicolored merging to prove the fact that any disconnected EPR graph G on n-vertices cannot be converted to an n-CAT state on those vertices under LOCC. We first note that the BCM EPR graph of an n-CAT state, irrespective of the bicoloring done, is always a graph which contains exactly one edge. Now as G is disconnected it will have more than one connected components. Let these components be $C_1, C_2 \vdots C_k$, where $k \geqslant 2$. The bicoloring is done as follows: assign the color A to all the vertices in the component C_1 and the color B to all other vertices, i.e., all vertices in $G \backslash C_1$. After merging, therefore, G reduces to a disconnected graph with no edges, i.e., the BCM EPR graph of G is a graph with k isolated vertices and no edges. Now if we are able to prepare an n-CAT state from G just using LOCC, we could also prepare an EPR pair between two parties who were never sharing an EPR pair just using LOCC. This violates monotonicity and hence the theorem is proved. □

APPENDIX B

Proof of Theorem 10: We first establish the following claim.

Claim: $\exists E_1 \in F_1, E_2 \in F_2$ such that $E_1 \cap E_2 \neq \phi$ and $E_2 \notin F_1 \cap F_2$.

Proof of the claim: We first show that on the same vertex set, the number of hyperedges in any r-uniform hypertree is always same. Let n and m be the number of vertices and hyperedges in a r-uniform hypertree. We show by induction on m that $n=m*(r-1)+1$.

For $m=1$, $n=1*(r-1)+1=r$ which is true because all possible vertices (since no one can be isolated) fall in the single hyperedge and it has exactly r vertices.

Let us assume that this relation between n and m for a fixed r holds for all values of the induction variable up to $m-1$. We show that it holds good for m.

Now take a r-uniform hypertree with m hyperedges. Remove any of the hyperedges to get another hypergraph (which may not be connected) having only $m-1$ edges. This removal may introduce k connected components (subhypertrees); $1 \leqslant k \leqslant r$. Let these components have, respectively, $m_1, m_2, \ldots, m_k$ number of hyperedges. Therefore, $\Sigma_{i=1}^{k} m_i = m-1$. The total number of vertices in the new hypergraph (with the k subhypertrees as components), $n^1 = \Sigma n_i$ where n_i is the number of vertices in the component i. Therefore, $n^1 = \Sigma n_i = \Sigma_{i=1}^{k} \{m_i(r-1)+1\} = (m-1)(r-1)+k$ (under induction assumption).

Now the number of vertices in the original hypertree, $n=n^1+(r-k)$ because k vertices were already covered, one each in the k components. Therefore, $n=(m-1)(r-1)+k+(r-k)=(m-1)(r-1)+r=(m-1)(r-1)+(r-1)+1=m(r-1)+1$. The result is thus true for m and hence for any number of hyperedges by induction. This result implies that any r-uniform hypertree on the same vertex set will always have the same number of hyperedges.

Let $F=F_1 \cap F_2$ and $m=|F_1|=|F_2|$. Obviously $m>|F|$ otherwise $H_1=H_2$. This implies that $\exists E \in F_2$ such that $E \notin F$.

Take any vertex say $w \in E$. Since $w \in S$ and H_1 is a hypertree therefore connected, w can not be an isolated vertex and therefore $\exists E^1 \in F_1$ such that $w \in E^1$. Take $E_1=E^1$ and $E_2=E$. This proves our claim.

Now we prove the theorem. Choose E_1 and E_2 so as to satify the above claim.

Let $E_1=\{u_1, u_2, \ldots, u_l, w_{l+1}, w_{l+2}, \ldots, w_r\}$ and $E_2=\{u_1, u_2, \ldots, u_l, v_{l+1}, v_{l+2}, \ldots, v_r\}$.

Since $E_1 \cap E_2 \neq \phi$, $l \geqslant 1$ and $E_1 \neq E_2$ implies that $l \leqslant r-1$.

Hence $1 \leqslant l \leqslant r$.

Now based on the value of l, we have the following different cases.

Case 1: $l>1$.

Case 1.1: $\exists v_i$ such that u_1 and v_i are not in the same hyperedge in H_1.

Take $u=u_1$ and $v=v_i$ in the statement of the theorem.

Case 1.2: Each v_i is in some hyperedge in H_1 in which u_1 also lies.

None of these v_i's can belong to the hyperedges in H_1 in which u_2 lies.

This is due to the fact that if, say, v_j happens to be in same hyperedge as of u_2 in H_1 then $u_1 u_2 v_j u_1$ will be a cycle in H_1, which is absurd as H_1 is a hypertree.

Note that at least one such v_i must exist as $l<r$. Take $u=u_2$ and $v=$any v_i.

Case 2: $l=1$.

Case 2.1: $\exists v_i$ such that u_1 and v_i are not in same hyperedge in H_1.

Take $u=u_1$ and $v=v_i$.

Case 2.2: Each v_i is in some hyperedge in H_1 in which u_1 also lies.

Since v_i's are $r-1$ in number and $E_2 \notin F_1 \cap F_2$, these v_i's will be distributed in at least two distinct hyperedges in H_1 in which u_1 also lies.

Therefore, $\exists v_i$, v_j such that they are in the same hyperedge in H_2 (namely in E_2) but in necessarily different edges in H_1, otherwise (that is, if they lie in the same hyperedge in H_1) $u_1 v_i v_j u_1$ will be a cycle in H_1, which is absurd as H_1 is a hypertree.

Also note that both v_i and v_j will exist as $r \geqslant 3$.

Take $u=v_i$ and $v=v_j$.

Thus we have proved Theorem 10 in all possible cases. □

We would like to point out that the result of Theorem 10 could follow from some standard results in combinatorics. We have however not found literature proving this result.

Generalized coherent states and the control of quantum systems

(Received 5 September 2005; accepted 14 October 2005;
published online 30 December 2005)

The control problem for linear and nonlinear Schrödinger equations is considered. The controls are given by applying a spatially homogeneous field or varying the frequency of a quadratic trapping potential. It is demonstrated that the existence of (exact or approximate) coherent-state-type solutions may severely limit the degree to which the system can be controlled. © *2005 American Institute of Physics.*

I. INTRODUCTION

In 1926 Erwin Schrödinger[1] discovered harmonic-oscillator quantum states with quasiclassical, particle-like properties, which have become known as coherent states. Schrödinger's original idea has since been generalized in many ways; in this paper we will focus on one of these generalizations, called "trajectory-coherent states."[2] Later, in the 1980s, questions of controlling quantum systems and engineering quantum states began to be addressed systematically.[3] The purpose of this paper is to expose a link between these developments.

Our main thesis is that the existence of coherent structures in quantum systems may limit the degree of controllability with respect to control by means of spatially homogeneous external fields (coherent control). Roughly speaking, (generalized) coherent states present "obstacles" to the control process which can be difficult to overcome.[4] The basic mechanism is that, in a first-order approximation, the application of a homogeneous field will only affect the position $\langle x \rangle$ of a wave packet, but will leave its higher moments, and hence its shape, (essentially[5]) unaffected. To illustrate this phenomenon we will consider Bose–Einstein condensates (BEC) in a quadratic trap, whose dynamics is described by a nonlinear Schrödinger equation, the *Gross–Pitaevskii equation*, and we will discuss *trajectory-coherent states*, which are Gaussian-shaped *approximate* solutions to the (linear) Schrödinger equation with a general potential.

Specifically, we will show that (a) the Gross–Pitaevskii equation supports (generalized) coherent states, which restrict the set of states that, given an initial state, can be "engineered" (by manipulating the spatially homogeneous control field) to a finite-dimensional manifold (see "Observation I" below); (b) the dominant effect of varying the frequency of a quadratic trap is a rescaling of the wave packet ("Observation II"); (c) access to the inherently *quantum* (nonclassical) degrees of freedom can only be gained indirectly by means of higher-order effects involving the external potential ("Observation III"); (d) the existence of trajectory-coherent states may render the time required to reach (or approximate) a given target state very large—essentially infinite—if the control field is not designed very carefully ("Observation IV").

These observations seem to provide a rather poor prognosis for the "dream"[6] of quantum control. However, it should be noted that the existence of "exact" coherent states is a rather exceptional occurrence,[7] very intimately linked to the harmonic oscillator potential (or, more generally, to the fact that the Hamiltonian is quadratic in its variables). For instance, the definition of coherent states for other quantum systems, such as the hydrogen atom, remains difficult,

[a)]Electronic mail: hteisman@acadiau.ca

contrary to Schrödinger's belief that quasiclassical states analogous to the ones he found for the harmonic oscillator could certainly be defined for other quantum systems as well.[1]

In this sense, this paper does not undermine the notion that coherent control of quantum systems is feasible for "the majority" of quantum systems, as they will typically not possess exact coherent states.[8] However, the existence of trajectory-coherent states for general, not necessarily quadratic, potentials shows that special care must be taken in designing the control fields if unrealistically large control times are to be avoided.

This paper is organized as follows: In Sec. II we give the basic definitions and introduce the quantum control problem. Section III presents two transformations designed to capture the dominant effects of the linear (in x) and quadratic control terms $E(t)x$ and $\frac{1}{2}\Omega(t)|x|^2$. In Sec. IV we investigate the consequences of these transformations for the control problem; this section includes Observations I–III mentioned earlier. In Sec. V we introduce trajectory-coherent states and study their effect on the control process (Observation IV). We conclude the paper with a number of remarks (Sec. VI). Many of the calculations we present here have appeared elsewhere (if often not for nonlinear equations such as the GPE); our objective here is to present them under unifying aspects, in particular concerning their significance for the quantum control problem.

II. QUANTUM CONTROL

We consider quantum systems whose dynamics can be described by (possibly nonlinear) Schrödinger equations of the form

$$i\hbar\psi_t = -\frac{\hbar^2}{2m}\Delta\psi + V(x)\psi + \frac{1}{2}\Omega(t)|x|^2\psi + (E(t)\cdot x)\psi + f(|\psi|^2)\psi \tag{1}$$

($\psi=\psi(t,x)\in\mathbb{C}$, $t\in[0,T]\subset\mathbb{R}$, $x\in\mathbb{R}^D$, $D=1, 2, 3$, $V=V(x)\in\mathbb{R}$) where the time-dependent fields $E=E(t)\in\mathbb{R}^D$ and $\Omega=\Omega(t)\in\mathbb{R}$ will play the role of *controls*. We will assume that Eq. (1) is globally well-posed in some reasonable function space $\mathcal{H}\subset L^2(\mathbb{R}^D)$, such as $\mathcal{H}:=\{\varphi(x)\in H^2(\mathbb{R}^D)\,|\,|x|^2\varphi(x)\in L^2(\mathbb{R}^D)\}$, where $L^2(\mathbb{R}^D)$ and $H^2(\mathbb{R}^D)$ denote the usual Lebesgue and Sobolev spaces.[9] The nonlinearity $f(|\psi|^2)\in\mathbb{R}$ may be local or nonlocal as we have the following examples in mind.

(a) *BEC in a quadratic trap*. Here (1) is the Gross–Pitaevskii equation with the nonlinearity $f(|\psi^2|)=\pm a^2|\psi|^2$ ($a\in\mathbb{R}$).[10] The time-independent part, V, of the external potential, will typically be zero or a periodic function or may contain an additional quadratic term.[11] Obviously, in the case $V\equiv 0$ and $f\equiv 0$ Eq. (1) reduces to the well-known quantum-mechanical *time-dependent, driven harmonic oscillator*. The functions $E(t)$ and $\Omega(t)$ model the manipulation of the system by "shaking" the trap (i.e., changing its position) and varying its frequency, respectively.

(b) *Molecular dynamics*. Here we set $\Omega\equiv 0$ as the external potential will typically be nonconfining; V may be thought of as something like the Coulomb potential. Equation (1) may be linear or nonlinear. An important example is the *Hartree equation* with the (nonlocal) nonlinearity $\kappa\Delta^{-1}|\psi|^2(\kappa\in\mathbb{R})$. Molecular systems are usually controlled by means of laser light; hence E represents an electric field. The special form of the control term $(E(t)\cdot x)$ in (1) is due to the dipole approximation.

The *control problem*[12] associated with Eq. (1) consists of the question of whether, given an *initial state* ψ_0 and a *target state* ψ_T, control fields $E(t)$ and/or $\Omega(t)$ can be found that will steer the system from ψ_0 to ψ_T, i.e., whether there exist functions $E=E(t)$ and/or $\Omega=\Omega(t)$ such that the solution $\psi=\psi(t,x)$ of (1) satisfies

$$\psi(0,x)=\psi_0(x) \quad \text{and} \quad \psi(T,x)=\psi_T(x).$$

Note that, in this formulation of the control problem, the control time—or *horizon*—, T, is finite. Note also that Eq. (1) conserves the L^2 norm, i.e.,

$$\|\psi(t)\|_{L^2}^2 = \int_{\mathbb{R}^D} |\psi(t,x)|^2 \mathrm{d}x = \int_{\mathbb{R}^D} |\psi(0,x)|^2 \mathrm{d}x = \|\psi(0)\|_{L^2}^2.$$

The appropriate state manifold is therefore given by the sphere $\mathcal{S}=\{\varphi \in \mathcal{H} \,|\, \|\varphi\|_{L^2}=1\}$, and the control problem will have to be restricted to this state manifold. The degree to which the system is controllable for a given initial state $\psi_0 \in \mathcal{S}$ is measured by the "size" of the set, $R_T(\psi_0) \subset \mathcal{S}$, of states that are reachable from ψ_0:

$$R_T(\psi_0) := \{\psi_T \in \mathcal{S} \,|\, \exists\, E(t), \Omega(t) : \psi(0) = \psi_0, \psi(T) = \psi_T\}$$

III. TWO TRANSFORMATIONS

Our point of departure is a generalized Wentzel–Kramers–Brillouin-style ansatz

$$\psi(t,x) = e^{iS(t,x)}\phi(t,x) \quad (S = S(t,x) \in \mathbb{R}, \phi = \phi(t,x) \in \mathbb{C}) \tag{2}$$

for solutions ψ of (1)—"generalized" because the function ϕ is allowed to take on complex values. For convenience we set $\hbar = m = 1$ until further notice. Then ψ is a solution to (1) iff the pair (S, ϕ) is a solution to the system

$$S_t + \tfrac{1}{2}(\nabla S)^2 = -V_1(t,x) - \tfrac{1}{2}\Omega(t)|x|^2 - E(t)\cdot x, \tag{3a}$$

$$i[\phi_t + (\nabla\phi)\cdot(\nabla S)] = -\frac{1}{2}\Delta\phi + V_2(t,x)\phi + f(|\phi|^2)\phi - \frac{i}{2}(\Delta S)\phi, \tag{3b}$$

where $V(t,x) = V_1(t,x) + V_2(t,x)$ is an arbitrary decomposition of V.

A linear (with respect to x) ansatz for the phase function S will allow us to capture the dominant effect of the linear control term $E(t)\cdot x$ by essentially removing the control field from the equation; a quadratic ansatz for S will have a similar effect for the quadratic control term $\Omega(t)|x|^2$.

A. Linear phase function

In this section we assume that

$$\Omega \equiv 0.$$

Equation (3a) is the Hamilton–Jacobi equation for the Hamiltonian function

$$H^c(t,x,p) = \tfrac{1}{2}p^2 + V_1(t,x) + E(t)\cdot x; \tag{4}$$

we denote by $(x^c, p^c) = (x^c(t), p^c(t)) \in \mathbb{R}^{2D}$ the solution of the corresponding Hamiltonian system

$$\dot{x}^c(t) = \frac{\partial H^c}{\partial p}(t, x^c(t), p^c(t)), \quad \dot{p}^c(t) = -\frac{\partial H^c}{\partial x}(t, x^c(t), p^c(t)), \quad x^c(0) = x_0, \quad p^c(0) = p_0. \tag{5}$$

Now we define the phase function $S = S^c$ by

$$S^c(t,x) = \int_0^t [\dot{x}^c(s)\cdot p^c(s) - H^c(s)]\mathrm{d}s + p^c(t)\cdot(x - x^c(t)) \tag{6}$$

(where $H^c(t) := H^c(t, x^c(t), p^c(t))$); we write $\phi(t,x) = \chi^c(t, x - x^c(t))$, and obtain *coherent-state-type* solutions $\psi = \psi^c$ of (1),

$$\psi^c(t,x) = e^{iS^c(t,x)}\chi^c(t, x - x^c(t)) \tag{7}$$

(The superscript "c" stands for "controlled;" it will be applied to quantities that depend on the control field $E(t)$.)

Then it is easy to see that ψ^c is a solution to (1) iff the function $\chi^c=\chi^c(t,x)$ is a solution to

$$i\chi_t^c = -\tfrac{1}{2}\Delta\chi^c + V_2(t,x+x^c(t))\chi^c + W^c(t,x)\chi^c + f(|\chi^c|^2)\chi^c, \tag{8}$$

where

$$W^c(t,x) := V_1(t,x+x^c(t)) - V_1(t,x^c(t)) - \nabla V_1(t,x^c(t))\cdot x.$$

There are two obvious choices for the decomposition $V(t,x)=V_1(t,x)+V_2(t,x)$.

1. $V_1\equiv 0$, $V_2\equiv V$. In this case, the equation for the classical trajectory, x^c, reads

$$\ddot{x}^c(t) = -E(t),$$

i.e., the "classical particle," x^c, only feels the control field $E(t)$ but no other external potential. Equation (8) takes the form

$$i\chi_t^c = -\tfrac{1}{2}\Delta\chi^c + V(t,x+x^c(t))\chi^c + f(|\chi^c|^2)\chi^c. \tag{9}$$

As mentioned earlier, this means that the effect of the control term $E(t)\cdot x$ is to move ("shake") the external potential V by $-x^c(t)$.

2. $V_2\equiv 0$, $V_1\equiv V$. Here the classical trajectory, x^c, satisfies

$$\ddot{x}^c(t) = -\nabla V(t,x^c(t)) - E(t), \tag{10}$$

i.e., the classical particle, x^c, feels the control field $E(t)$ *and* the external potential V. Equation (8) reads

$$i\chi_t^c = -\tfrac{1}{2}\Delta\chi^c + W^c(t,x)\chi^c + f(|\chi^c|^2)\chi^c. \tag{11}$$

Remarks:

(a) The term *(generalized) coherent states* for solutions of the form (7) is motivated by the (time-independent, undriven) harmonic-oscillator case given by

$$f\equiv 0, \quad E\equiv 0, \quad V\equiv 0, \quad \Omega\equiv 1.$$

If the solution χ of Eq. (8) are chosen to be stationary solutions $\chi(t,x)=e^{i\epsilon t}\varphi(x)$, where $\varphi(x)$ is the ground state of the harmonic oscillator Hamiltonian $\frac{1}{2}(-\Delta+|x|^2)$, then the solutions ψ in (7) coincide with the quasiclassical states discovered by Schrödinger that are now called *coherent states*.

(b) All formulas would remain the same if we were to allow the potential V to be time-dependent as well.

B. Quadratic phase function

We assume

$$E\equiv 0$$

and choose the phase function as

$$S(t,x) = \tfrac{1}{2}Q(t)x^2 \tag{12}$$

where $Q:[0,T^*)\to\mathbb{R}$ is the solution of the ODE

$$\dot{Q}(t) + Q^2(t) + \Omega(t) = 0, \quad Q(0)=0. \tag{13}$$

Then the equation for ϕ takes the form

$$i[\phi_t + Q(t)(\nabla\phi)\cdot x] = -\frac{1}{2}\Delta\phi + V(x)\phi + f(|\phi|^2)\phi - \frac{iD}{2}Q(t)\phi, \tag{14}$$

which can be transformed further by writing

$$\phi(t,x) = e^{-(D/2)R(t)}\chi(\Lambda(t), e^{-R(t)}x), \tag{15}$$

where the functions $R=R(t)$ and $\Lambda=\Lambda(t)$ satisfy the ODEs

$$\dot{R}(t) = Q(t), \quad \dot{\Lambda}(t) = e^{-2R(t)}, \quad R(0) = \Lambda(0) = 0, \tag{16}$$

and χ is a solution to

$$i\chi_t = -\tfrac{1}{2}\Delta\chi + e^{2R(\tau)}V(e^{R(\tau)}x)\chi + e^{2R(\tau)}f(e^{-DR(\tau)}|\chi|^2)\chi, \ \tau := \Lambda^{-1}(t). \tag{17}$$

To summarize, the solution ψ of (1) (with $E\equiv 0$) can be written as

$$\psi(t,x) = e^{(1/2)[iQ(t)x^2 - DR(t)]}\chi(\Lambda(t), e^{-R(t)}x), \tag{18}$$

where the functions Q, R, Λ, and χ are defined as above.

Remarks:

(a) The solution $Q(t)$ of the ODE (13) may not exist for all $t>0$ (i.e., $T^*<\infty$). For instance, for $\Omega(t)\equiv\omega>0$ the solution can be found explicitly:

$$Q(t) = -\sqrt{\omega}\tan(\sqrt{\omega}t) \Rightarrow T^* = \frac{\pi}{2\sqrt{\omega}}.$$

The above noted transformation is therefore only valid on the interval $[0, T^*)$.

(b) It is easy to see that the solution $Q(t)$ *does* exist for all $t>0$ (i.e., $T^*=\infty$) if $\Omega(t)\leqslant 0$ for all $t\geqslant 0$.

(c) Even if Q does blow up in finite time T^*, due to the dispersive properties of the function χ, the solution ψ may still be regular at $t=T^*$. As an example, consider the case $\Omega\equiv\omega$, $V\equiv 0$, $f\equiv 0$, and $\psi_0(x)=e^{-x^2/2}$.

(d) It can be shown that Eq. (13) possesses global solutions if they are allowed to be complex-valued and satisfy $\mathrm{Im}(Q(0))>0$. This fact will become important in the construction of trajectory-coherent states.

Critical power nonlinearity. If we assume that

$$f(|\psi|^2) = \kappa|\psi|^{4/D} \quad (\kappa\in\mathbb{R}),$$

Eq. (17) takes the form

$$i\chi_t = -\tfrac{1}{2}\Delta\chi + e^{2R(\tau)}V(e^{R(\tau)}x)\chi + \kappa|\chi|^{4/D}\chi. \tag{19}$$

IV. IMPLICATIONS FOR THE CONTROL PROBLEM

A. Homogeneous control field and quadratic exterior potential

In the following we consider a general quadratic potential, which we write as

$$\Omega\equiv 0, \quad V(x) = \tfrac{1}{2}x^T A x, \tag{20}$$

where A is a symmetric $D\times D$ matrix. This includes the Gross–Pitaevskii equation with a time-independent quadratic trapping potential,

$$i\psi_t = -\frac{1}{2}\Delta\psi + \frac{\omega}{2}x^2\psi + (E(t)\cdot x)\psi \pm a^2|\psi|^2\psi$$

$(\omega, a \in \mathbb{R})$. Since

$$W^c(t,x) := V(x+x^c(t)) - V(x^c(t)) - \nabla V(x^c(t))\cdot x = V(x),$$

Eq. (11) is *independent of the control field E*,

$$i\chi_t = -\tfrac{1}{2}\Delta\chi + V(x)\chi + f(|\chi|^2)\chi. \tag{21}$$

This has the following important consequence.

Observation I: *Let $\psi_0 \in \mathcal{S}$ and $x_0 = p_0 = 0$.*[13] *Then, for any control field $E = E(t)$, the solution $\psi^c = \psi^c(t,x)$ of Eq. (1) (with (20)) satisfying $\psi(0,x) = \psi_0(x)$ is given by $\psi^c(t,x) = e^{iS^c(t,x)}\chi(t, x - x^c(t))$, where χ is the unique solution of (the control-independent) Eq. (21) that satisfies the initial condition $\chi(0,x) = \psi_0(x)$. As a result, the set of reachable states, $R_T(\psi_0)$, is given by*

$$R_T(\psi_0) = \{e^{i\lambda}e^{i\pi\cdot(x-\xi)}\chi(T, x-\xi) \,|\, \lambda \in \mathbb{R}; \pi, \xi \in \mathbb{R}^D\}. \tag{22}$$

and thus finite-dimensional.

Remarks:

(a) In terms of the controllability problem, the significance of the "coherent-state transformation" (7) lies in the fact that it transforms the control problem (1) (with (20)) into the control-independent equation (21). The controlled state ψ^c can therefore essentially (i.e., up to the classical degrees of freedom—see the following) be precomputed by solving Eq. (21). Specifically, since the "shape," $|\psi^c(T,x)|$, of the terminal state is given by $|\chi(T, x - x^c(T))|$ it cannot be changed by the application of the control field E. All that can be affected by the homogeneous exterior field is a shift of the function $|\chi(T,x)|$.

(b) In physical terms, one might interpret this by saying that the centre-of-mass degrees of freedom are decoupled from the remaining degrees of freedom. This was previously observed in Refs. 14 and 15.

(c) The terminal state $\psi_T = \psi^c(T)$ is given by

$$\psi^c(T,x) = e^{iL_T^c}e^{ip^c(T)\cdot(x-x^c(T))}\chi(T, x - x^c(T)),$$

where $L_T^c := \int_0^T [\dot{x}^c(t)\cdot p^c(t) - H^c(t)]\mathrm{d}t$ denotes the classical action. The set of reachable states may therefore be parametrized by the classical degrees of freedom (cf. (22)).

(d) It is illuminating to look at the special case where the function χ is chosen to be a *stationary* solution of (21),

$$\chi(t,x) := e^{i\mu t}\varphi_\mu(x),$$

where φ_μ is a (real) solution to the nonlinear eigenvalue problem

$$\left[-\mu + \tfrac{1}{2}(\Delta - x^2) - f(\varphi^2)\right]\varphi = 0. \tag{23}$$

(here we assume $V(x) = \frac{1}{2}x^2$). For $\psi_0 = \varphi_\mu$ the set of reachable states then has the form

$$R_T(\varphi_\mu) = \{e^{i(\lambda + T\mu)}e^{i\pi\cdot(x-\xi)}\varphi_\mu(x-\xi) \,|\, \lambda \in \mathbb{R}; \pi, \xi \in \mathbb{R}^D\},$$

in particular,

$$\psi(x) \in R_T(\varphi_\mu) \Rightarrow |\psi(x)| = |\varphi_\mu(x-\xi)|, \tag{24}$$

which again highlights the fact that the shape of the state cannot be influenced by the (spatially homogeneous) control fields E.

(e) It is not difficult to show that *no transitions between nonlinear eigenstates* (corresponding to different values of μ) can be affected by the spatially homogeneous control field $E(t)$. This

is even more obvious in the linear case as the node structure of the eigenstates for the harmonic oscillator Hamiltonian $\frac{1}{2}(-\Delta+x^2)$ cannot be changed.

(f) The fact that the manifold of controllable states, $R_T(\psi_0)$, is finite-dimensional is well-known in the *linear case* (quantum-mechanical driven harmonic oscillator DHO). It is a consequence of an important result in (geometric) control theory due to Huang, Tarn, and Clark.[16,17]
This "noncontrollability property" of the DHO was also observed in Ref. 18, using essentially the transformation (7). The DHO is a classical problem in quantum mechanics. As a result, the amount of literature on the DHO is enormous. To the best of the author's knowledge, the first version of the transformation (7), applied to the DHO, appeared in Ref. 19; see also Ref 20.

(g) Let $\langle x\rangle_\psi$ denote the expectation value of the position operator with respect to the state ψ, i.e.,

$$\langle x\rangle_\psi = \int_{\mathbb{R}^D} x|\psi(x)|^2 \mathrm{d}x.$$

Then we have

$$\langle x\rangle^c(t) := \langle x\rangle_{\psi^c(t)} = x^c(t) + \langle x\rangle_{\chi(t)}.$$

Ehrenfest relations give

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\langle x\rangle_{\chi(t)} = -\langle \nabla V\rangle_{\chi(t)} = -\nabla V(\langle x\rangle_{\chi(t)}) \tag{25a}$$

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}\langle x\rangle_{\psi^c(t)} = -\langle \nabla V - E(t)\rangle_{\psi^c(t)} = -\nabla V(\langle x\rangle_{\psi^c(t)}) - E(t) \tag{25b}$$

and so

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}x^c(t) = -\nabla V(x^c(t)) - E(t)$$

(since $\nabla V(x)=Ax$), which is consistent with (10).

B. Time-dependent trap frequency and critical nonlinearity

We now consider the situation in which the control is applied by varying the trap frequency, $\Omega=\Omega(t)$. We assume that the external potential, V, has the right scaling, i.e., satisfies

$$\lambda^2 V(\lambda x) = V(x), \quad \lambda > 0,$$

which obviously includes $V\equiv 0$ as well as the inverse square potential $V(x)=\beta/|x|^2(\beta\in\mathbb{R})$. So our control problem is

$$i\psi_t = -\tfrac{1}{2}\Delta\psi + V(x)\psi + \tfrac{1}{2}\Omega(t)x^2\psi + \kappa|\psi|^{4/D}\psi \quad (\kappa\in\mathbb{R}). \tag{26}$$

As seen in Sec. III B, applying the transformation (18) results in (19), which is *independent of the control* $\Omega(t)$ due to the scaling invariance of the potential,

$$i\chi_t = -\tfrac{1}{2}\Delta\chi + V(x)\chi + \kappa|\chi|^{4/D}\chi. \tag{27}$$

We are therefore in the position to make the following observation.

Observation II: *Let $\psi_0\in\mathcal{S}$ be given. Then, for any control $\Omega(t)$, the unique solution of Eq. (26) is given by*

$$\psi(t,x) = e^{(i/2)Q(t)x^2}e^{-DR(t)/2}\chi(\Lambda(t), e^{-R(t)}x) \tag{28}$$

(for $t \in [0,T^*)$), where Q, R, and Λ are given by (13) and (16), and χ is the unique solution of (control-independent) Eq. (27) satisfying $\chi(0,x)=\psi_0(x)$. As a result, on the interval $[0,T^*)$ all the states that can be reached from ψ_0 have the form

$$\psi(t,x) = e^{(i/2)Qx^2}\frac{1}{\sigma^{D/2}}\chi\left(\Lambda, \frac{x}{\sigma}\right), \quad Q,\sigma,\Lambda \in \mathbb{R},\ \sigma > 0. \tag{29}$$

Remarks:

(a) In terms of the controllability problem, the main point here is that the solution trajectory, $\gamma := \chi(\mathbb{R}) \subset \mathcal{S}$, for Eq. (27) can be determined independently of the control Ω. Thus, the states $\psi(t) \in \mathcal{S}$ that are engineered by varying the trap frequency coincide, up to a phase factor, with *rescaled* versions of states on γ.

(b) More specifically, the geometric meaning of the function

$$\sigma(t) := e^{R(t)}$$

is readily revealed by computing the appropriate expectation values. From

$$|\psi(t,x)|^2 = \frac{1}{[\sigma(t)]^D}\left|\chi\left(\Lambda(t), \frac{x}{\sigma(t)}\right)\right|^2,$$

we get

$$\langle x\rangle_{\psi(t)} = \int_{\mathbb{R}^D} x|\psi(t,x)|^2 \mathrm{d}x = \sigma(t)\langle x\rangle_{\chi(\Lambda(t))}, \tag{30a}$$

$$\langle |x|^2\rangle_{\psi(t)} = \int_{\mathbb{R}^D} |x|^2|\psi(t,x)|^2 \mathrm{d}x = \sigma(t)^2\langle |x|^2\rangle_{\chi(\Lambda(t))}. \tag{30b}$$

Moreover, it is easy to see from (13) that $\sigma(t)$ satisfies the second-order initial value problem

$$\ddot{\sigma}(t) + \Omega(t)\sigma(t) = 0, \quad \sigma(0) = 1, \quad \dot{\sigma}(0) = 0. \tag{31}$$

(c) Our conclusion is that varying the trap frequency allows us to control the spread, $\langle |x|^2\rangle_{\psi(t)}$, of a wave packet (see (30b)); Eq. (31) can be used to determine an appropriate control function $\Omega(t)$. However, in general we do not have control over the position, $\langle x\rangle_{\psi(t)}$, of the wave packet, as, for instance, $\langle x\rangle_{\chi(\Lambda(t))}$ in (30a) may be zero so that the control of $\langle x\rangle_{\psi(t)}$ is lost completely.

(d) It should be kept in mind that the transformation is only valid *locally in time* as $Q(t)$ may blow up.

(e) It has been noticed before that time-independent quadratic potentials can be removed from the critical nonlinear Schrödinger equation by the transformation (28); see Refs. 21 and 22 and the literature therein (see also Refs. 23 and 24).

C. Homogeneous control field and general external potential (second-order approximation)

For simplicity we restrict our attention to the 1D linear case:

$$i\psi_t = -\tfrac{1}{2}\psi_{xx} + V(x)\psi + (E(t)x)\psi \quad (x \in \mathbb{R}). \tag{32}$$

Applying the coherent-state-transformation (7), $\psi(t,x) = e^{iS^c(t,x)}\chi^c(t, x-x^c(t))$, yields

$$i\chi^c_t = -\tfrac{1}{2}\chi^c_{xx} + W^c(t,x)\chi^c, \tag{33}$$

where

$$W^c(t,x) = V(x+x^c(t)) - V(x^c(t)) - V'(x^c(t))x = \frac{1}{2}V''(x^c(t))x^2 + \sum_{\alpha\geqslant 3}\frac{V^{(\alpha)}(x^c(t))}{\alpha!}x^\alpha$$

by Taylor expansion. If we truncate the Taylor series after the quadratic term and set $\Omega = \Omega^c(t) := V''(x^c(t))$, we can apply the transformation in Sec. III B to obtain the *approximate* solution

$$\chi(t,x) \approx e^{(i/2)Q^c(t)x^2}e^{-(1/2)DR^c(t)}\widetilde{\chi}(\Lambda^c(t), e^{-R^c(t)}x),$$

$$\psi^\varepsilon(t,x) \approx \widetilde{\psi}^\varepsilon(t,x) = e^{i[S^c(t,x)+(1/2)Q^c(t)(x-x^c(t))^2]}e^{-1/2DR^c(t)}\widetilde{\chi}(\Lambda^c(t), e^{-R^c(t)}[x-x^c(t)]), \tag{34}$$

where the functions $x^c(t)$, $S^c(t,x)$, $Q^c(t)$, $R^c(t)$, and $\Lambda^c(t)$ are defined by (5), (6), (13), and (16), respectively (with $\Omega(t) = \Omega^c(t) = V''(x^c(t))$), and $\widetilde{\chi}$ is a solution to the free Schrödinger equation $i\widetilde{\chi}_t = -\frac{1}{2}\widetilde{\chi}_{xx}$. From

$$|\widetilde{\psi}^\varepsilon(t,x)|^2 = \frac{1}{[\sigma^c(t)]^D}\left|\widetilde{\chi}\left(\Lambda^c(t), \frac{x-x^c(t)}{\sigma^c(t)}\right)\right|^2,$$

the expectation values are readily computed.

$$\langle x\rangle^c(t) := \langle x\rangle_{\psi^\varepsilon(t)} \approx \int_{\mathbb{R}^D} x|\widetilde{\psi}^\varepsilon(t,x)|^2 \mathrm{d}x = x^c(t) + \sigma^c(t)\langle x\rangle_{\widetilde{\chi}(\Lambda^c(t))}, \tag{35a}$$

$$(\Delta x^c)^2(t) := \langle (x-x^c(t))^2\rangle_{\psi^\varepsilon(t)} \approx \int_{\mathbb{R}^D}(x-x^c(t))^2|\widetilde{\psi}^\varepsilon(t,x)|^2\mathrm{d}x = \sigma^c(t)^2\langle x^2\rangle_{\widetilde{\chi}(\Lambda^c(t))}, \tag{35b}$$

$$\begin{aligned}[(\Delta x)^c]^2(t) &:= \langle (x-\langle x\rangle^c(t))^2\rangle_{\psi^\varepsilon(t)} \approx \langle (x-x^c(t)-\sigma^c(t)\langle x\rangle_{\widetilde{\chi}(\Lambda^c(t))})^2\rangle_{\psi^\varepsilon(t)} \\ &\approx \sigma^c(t)^2\langle x^2\rangle_{\widetilde{\chi}(\Lambda^c(t))} - \sigma^c(t)^2\langle x\rangle^2_{\widetilde{\chi}(\Lambda^c(t))} = \sigma^c(t)^2[(\Delta x)_{\widetilde{\chi}(\Lambda^c(t))}]^2.\end{aligned} \tag{35c}$$

The functions $x^c(t)$ and $\sigma^c(t)$ depend on the control $E(t)$ by way of the system

$$\ddot{x}^c(t) = -V'(x^c(t)) - E(t), \quad x^c(0) = x_0, \quad \dot{x}^c(0) = p_0, \tag{36a}$$

$$\ddot{\sigma}^c(t) = -V''(x^c(t))\sigma^c(t), \quad \sigma^c(0) = 1, \quad \dot{\sigma}^c(0) = 0. \tag{36b}$$

Remarks:

(a) If we choose the initial conditions for (36a) to be

$$x_0 = \langle x\rangle_{\psi(0)} \quad \text{and } p_0 = \langle p\rangle_{\psi(0)},$$

we get $\langle x\rangle_{\widetilde{\chi}(\Lambda^c(t))} \equiv 0$ and hence

$$\langle x\rangle^c(t) = \langle x\rangle_{\psi^\varepsilon(t)} \approx \langle x\rangle_{\widetilde{\psi}^\varepsilon(t)} = x^c(t),$$

i.e., the position of the wave packet coincides with the classical trajectory $x^c(t)$.

(b) Note that, although Eq. (36b) may have global solutions, in view of (35c) (and the definition of $\sigma^c(t)$ as an exponential), its solutions $\sigma^c(t)$ are only relevant as long as they are positive.

(c) Note also that $(\Delta x)_{\widetilde{\chi}(\Lambda^c(t))}$ is known in principle. The spread, $(\Delta x)^c(t)$, of the wave packet is therefore essentially given by the function $\sigma^c(t)$.

(d) Clearly "everything" is accurate (i.e., we may replace "≈" with "=" everywhere) if the potential V is a quadratic function.

Observation III. *Let $\psi_0 \in \mathcal{S}$. In a second-order approximation and for times $t < T^*$, the solution is given by (34) and is therefore, up to a phase factor, a translated and rescaled version of the*

state $\tilde{\chi}(t)=U(t)\tilde{\psi}_0$, *where* $\tilde{\psi}_0(x):=e^{-ip_0\cdot x}\psi_0(x+x_0)$ *and* $U(t)$ *denotes the Schrödinger evolution group. In this approximation, the effect of the control term* $E(t)x$ *is "direct" control of the position,* $\langle x\rangle^c$, *of the wave packet (cf. (36a)); the influence on the spread,* $(\Delta x)^c(t)\approx\sigma^c(t)(\Delta x)_{\tilde{\chi}(\Lambda^c(t))}$, *is indirect and depends on the properties of* V'' *(cf. (36b)). In particular, if* $V''=const$, $(\Delta x)^c$ *cannot be controlled, which is consistent with "Observation I."*

V. TRAJECTORY-COHERENT STATES

We now turn to a class of approximate solutions to the Schrödinger equation with quasiclassical and particle-like properties, introduced by Bagrov *et al.*,[2] which are closely related to the approximate solutions constructed in Sec. IV C. Trajectory-coherent states (TCS) have actually been constructed for arbitrary dimension and even for certain nonlinear equations.[25–29] However, to demonstrate the implications for the control problem, it will be sufficient to consider the simplest case: "vacuum TCS" for the 1D linear Schrödinger equation. After reintroducing the physical constants $\hbar$ and m, our control problem reads

$$\mathcal{L}\psi:=i\hbar\psi_t+\frac{\hbar^2}{2m}\psi_{xx}-V(x)\psi-(E(t)x)\psi=0\ (x\in\mathbb{R}). \tag{37}$$

A. Construction of vacuum TCS

We proceed exactly as in Sec. IV C to obtain approximate, second-order accurate, solutions, given by (34),

$$\tilde{\psi}^c(t,x)=e^{(i/\hbar)[S^c(t,x)+(1/2)Q^c(t)(x-x^c(t))^2]}e^{-R^c(t)/2}\tilde{\chi}(\Lambda^c(t),e^{-R^c(t)}[x-x^c(t)]). \tag{38}$$

As in Sec. IV C, the functions $x^c(t)$, $S^c(t,x)$, $R^c(t)$, $\Lambda^c(t)$, and $\Omega^c(t)=V''(x^c(t))$ are defined by (5), (6), and (16), respectively, and $\tilde{\chi}$ is a solution to the free Schrödinger equation $i\hbar\tilde{\chi}_t=-(\hbar^2/2m)\tilde{\chi}_{xx}$. The main shortcoming of the construction consists of the fact that the function $Q^c(t)$, given by (13), may not be defined globally. We remedy this by allowing $Q^c(t)$ to take on complex values. Specifically, the function $Q^c=Q^c(t)\in\underline{\mathbb{C}}$ is now defined as the solution of the IVP

$$\dot{Q}(t)+Q(t)^2+\Omega^c(t)=0,\quad \mathrm{Re}(Q(0))=0,\quad \mathrm{Im}(Q(0))=b>0, \tag{39}$$

where $b>0$ is a positive number which we will keep fixed. It can be shown that the solution, $Q^c=Q^c(t)\in\mathbb{C}$, of (39) exists globally and satisfies $\mathrm{Im}(Q(t))>0$ for all $t\geqslant 0$. Note that the functions $\Lambda^c(t)$, $R^c(t)$, and $\sigma^c(t)$ are now complex-valued as well; we write $Q^c=Q_1^c+iQ_2^c$, $R^c=R_1^c+iR_2^c$, etc. for the decompositions in real and imaginary parts. Moreover, the functions $\Lambda^c(t)$ and $R^c(t)$ now exist globally and the function $\sigma^c(t)$ is nonzero everywhere. The function $\tilde{\psi}^c$ satisfies

$$\mathcal{L}\tilde{\psi}^c=-[V(x)-V(x^c(t))-V'(x^c(t))(x-x^c(t))-\tfrac{1}{2}V''(x^c(t))(x-x^c(t))^2]\tilde{\psi}^c=:r. \tag{40}$$

Now "vacuum" TCS are constructed by simply choosing the function $\tilde{\chi}$ to be constant—with the constant to be chosen such that the resulting state is normalized, $\tilde{\chi}\equiv[b/\pi\hbar]^{1/4}$,

$$\begin{aligned}\tilde{\psi}^c(t,x)&=\tilde{\chi}e^{(i/\hbar)[S^c(t,x)+(1/2)Q^c(t)(x-x^c(t))^2]}e^{-R^c(t)/2}\\&=\tilde{\chi}\,[\sigma^c(t)]^{-1/2}e^{(i/\hbar)[S^c(t,x)+(1/2)Q_1^c(t)(x-x^c(t))^2]}e^{-(1/2\hbar)Q_2^c(t)(x-x^c(t))^2}.\end{aligned} \tag{41}$$

These are Gaussian-shaped states,

$$|\tilde{\psi}^c(t,x)|^2=\tilde{\chi}^2|\sigma^c(t)|^{-1}e^{-(1/\hbar)Q_2^c(t)(x-x^c(t))^2},$$

which satisfy

$$\|\tilde{\psi}^c(t)\|_{L^2}^2 = \frac{|\tilde{\chi}|^2\sqrt{\pi\hbar}}{|\sigma^c(t)|\sqrt{Q_2(t)}\sqrt{b}} = 1, \tag{42a}$$

$$\langle x\rangle_{\tilde{\psi}^c(t)} = x^c(t), \tag{42b}$$

$$\langle(\Delta x)^2\rangle_{\tilde{\psi}^c(t)} = \langle(x - \langle x\rangle_{\tilde{\psi}^c(t)})^2\rangle_{\tilde{\psi}^c(t)} = \frac{\hbar}{2Q_2(t)}. \tag{42c}$$

Lemma: *Assume that* $V'''(x)$ *is bounded,* $\sup_{x\in\mathbb{R}}|V'''(x)| \leqslant M$, *and let* $\psi_0(x) := \tilde{\psi}(0,x) = e^{-(b/2\hbar)x^2}$. *Then*

(i) (Ref. 2)

$$\|r(t)\|_{L^2}^2 \leqslant \frac{5M^2\hbar^3}{96[Q_2^c(t)]^3}.$$

(ii) *If* ψ *is the (actual) solution of (37) corresponding to the initial condition* ψ_0 *and* $\underline{Q}^c := \min_{t\in[0,t]}Q_2^c(t)$, *then*

$$\|\psi(t) - \tilde{\psi}(t)\|_{L^2} \leqslant \frac{M\hbar^{1/2}T}{2[\underline{Q}^c]^{3/2}}.$$

Proof.

(i) (Ref. 2). (The estimate may also be derived directly from (40).)

(ii) Let $\delta\psi := \psi - \tilde{\psi}$, hence

$$\mathcal{L}\,\delta\psi = -r.$$

Then, by standard calculations,

$$\|\delta\psi(t)\|_{L^2}^2 = -\frac{2}{\hbar}\,\mathrm{Im}\int_0^t \langle r(s), \delta\psi(s)\rangle_{L^2}\mathrm{d}s \leqslant \frac{2}{\hbar}\int_0^t \|r(s)\|_{L^2}\|\delta\psi(s)\|_{L^2}\mathrm{d}s$$
$$\overset{(i)}{\leqslant} 2\frac{\sqrt{5}M\hbar^{1/2}}{2\sqrt{6}[\underline{Q}^c]^{3/2}}\int_0^t \|\delta\psi(s)\|_{L^2}\mathrm{d}s$$

and so, by Gronwall's lemma,

$$\|\delta\psi(t)\|_{L^2} \leqslant t\frac{\sqrt{5}M\hbar^{1/2}}{2\sqrt{6}[\underline{Q}^c]^{3/2}} \leqslant \frac{M\hbar^{1/2}T}{2[\underline{Q}^c]^{3/2}} \qquad \square$$

B. Consequences for the control problem

We now demonstrate a mechanism by which TCS might "hamper" the control process. To this end, we choose a target state $\psi_T \in \mathcal{S}$ such that

$$|\langle\sigma^{-1/2}e^{i[\pi\cdot(x-\xi)+(1/2)Q(x-\xi)^2]}, \psi_T(x)\rangle_{L^2}| \leqslant \tfrac{1}{2} \quad \text{for all } \xi,\pi\in\mathbb{R}, \sigma, Q\in\mathbb{C}^*, \mathrm{Im}(Q) > 0, |\sigma|\sqrt{\mathrm{Im}(Q)} = 1. \tag{43}$$

Our task is to try to steer the system from the initial state $\psi_0(x) := \tilde{\psi}(0,x) = e^{-(b/2\hbar)x^2}$ to the target state ψ_T. If we are successful, i.e., if we do find a control field $E(t)$ such that $\psi(T) = \psi_T$, we obviously have

$$\langle \psi(T), \psi_T \rangle_{L^2} = 1 .$$

This suggests to estimate the overlap, $\langle \psi(T), \psi_T \rangle_{L^2}$, between the states $\psi(T)$ and ψ_T. Note that assumption (43) implies that $|\langle \tilde{\psi}(T), \psi_T \rangle_{L^2}| \leqslant \frac{1}{2}$. Thus,

$$|\langle \psi(T), \psi_T \rangle_{L^2}| \leqslant |\langle \tilde{\psi}(T), \psi_T \rangle_{L^2}| + |\langle \psi(T) - \tilde{\psi}(T), \psi_T \rangle_{L^2}| \overset{(ii)}{\leqslant} \frac{1}{2} + \frac{M\hbar^{1/2}T}{2[\underline{Q}^c]^{3/2}} .$$

Note that the right hand side of this inequality contains the factor $\hbar^{1/2}$.

$$|\langle \psi(T), \psi_T \rangle_{L^2}| < 1 \Rightarrow \psi_T \notin R_T(\psi_0),$$

we obtain an estimate for the control time, which can be unreasonably large if the control field is not designed carefully.

Observation IV: *There are states $\psi_T \in \mathcal{S}$ which cannot be attained in times T less than*

$$\frac{[\underline{Q}^c]^{3/2}}{M\hbar^{1/2}} .$$

To obtain realistic control times the control field $E(t)$ should thus be designed such that

$$\underline{Q}^c = \mathcal{O}(\hbar^{1/3}) .$$

Remarks:

(a) The dependence of $Q_2(t)$ on the control $E(t)$ is given by the system

$$\dot{Q}_1^c(t) = \frac{1}{m}[Q_2^c(t)]^2 - \frac{1}{m}[Q_1^c(t)]^2 - V''(x^c(t)), \quad Q_1^c(0) = 0, \tag{44a}$$

$$\dot{Q}_2^c(t) = -\frac{2}{m} Q_1^c(t) Q_2^c(t), \qquad Q_2^c(0) = b > 0, \tag{44b}$$

where the controlled classical trajectory $x^c(t)$ is determined by Eq. (36a). The properties of this system and strategies for accomplishing the condition $\underline{Q}^c = \mathcal{O}(\hbar^{1/3})$, such as resonance, will be discussed elsewhere.

(b) In view of (42c), the geometric interpretation of the condition $\underline{Q}^c = \mathcal{O}(\hbar^{1/3})$ is that we have to make the state spread out in order to be able to access the nonclassical degrees of freedom.

VI. CONCLUDING REMARKS

1. The discussion in Secs. III A and IV A can be extended to include homogeneous *magnetic* fields[30] and *rotating* condensates. For spherically symmetric external potentials, this will produce the "missing degrees of freedom" (angular momentum) in the parametrization (22).
2. It has been shown recently[31] that the "particle-in-the-box problem," i.e., the control problem (37) with potential

$$V(x) = \begin{cases} 0, & |x| < \frac{1}{2} \\ \infty, & |x| \geqslant \frac{1}{2} \end{cases}$$

is locally controllable in the vicinity of the ground state. On the other hand, the present paper shows that (37) is certainly *not* controllable (not even locally) if V is the harmonic oscillator potential $V = (\omega/2)x^2$. This raises the very interesting (and difficult) question of how the controllability properties of Eq. (37) depend on the external potential. There is evidence to suggest that the harmonic oscillator potential may be some sort of threshold. One might

conjecture that (local) controllability holds for potentials that are steeper than the HO potential, whereas it fails for potentials that are shallower.

3. In a first approximation, the presence of a nonlinear term of the form $f(|\psi|^2)$ does not change the controllability properties with respect to spatially homogeneous control fields. This is due to the translation invariance of $f(|\psi|^2)$.
4. While the linear potential V is the dominant factor in the *bilinear* control problem with the control $E(t)x$, the nonlinear term turns out to be the main difficulty in control problems with *additive* control. See Ref. 32 for a small-data result in this direction.
5. Solitons may be interpreted as "nonlinear coherent structures." Continuing the theme of this paper, it will be shown elsewhere that they, too, constitute obstacles to the control process.[33]

[3] Comprehensive treatments of *quantum control* are available in two recent monographs (Refs. 34 and 35).
[4] We may also reverse this observation and say that coherent states in turn may be difficult to create starting from other quantum states.
[5] This is actually exact for quadratic Hamiltonians.
[6] W. Warren, H. Rabitz, and M. Dahleh, Science **259**, 1581 (1993).
[7] As mentioned above, trajectory-coherent states are only approximate solutions to the Schrödinger equation; they become exact solutions for quadratic Hamiltonians.
[8] There is, however, strong evidence to suggest that solving the general quantum control problem is an unrealistic proposition. See Ref. 36 for some results in this direction.
[9] This is an assumption on the various parameters in Eq. (1).
[10] Depending on the character of the two-body pair interaction, the nonlinearity may also be nonlocal. The local cubic form is appropriate for short-range interactions.
[11] For instance, if the quadratic trap is time-independent altogether, we will set $\Omega \equiv 0$.
[12] In this paper "control" always means "*exact* (or *approximate*) control;" we do not consider *optimal* control.
[13] Zero initial conditions are chosen for convenience.

Decomposition of time-covariant operations on quantum systems with continuous and/or discrete energy spectrum

Dominik Janzing[a)]
IAKS, Arbeitsgruppe Quantum Computing, Universität Karlsruhe, Am Fasanengarten 5, D-76 131 Karlsruhe, Germany

(Received 8 October 2004; accepted 21 October 2005; published online 30 December 2005)

Every completely positive map G that commutes with the Hamiltonian time evolution is an integral or sum over (densely defined) CP-maps G_σ where σ is the energy that is transferred to or taken from the environment. If the spectrum is non-degenerate each G_σ is a *dephasing* channel followed by an *energy shift*. The dephasing is given by the Hadamard product of the density operator with a (formally defined) positive operator. The Kraus operator of the energy shift is a partial isometry which defines a translation on $\mathbb{R}$ with respect to a non-translation-invariant measure. As an example, this decomposition is explicitly calculated for the rotation invariant Gaussian channel on a single mode. The question of under what conditions a covariant channel destroys superpositions between mutually orthogonal states on the same orbit is addressed. For channels which allow mutually orthogonal output states on the same orbit, a lower bound on the quantum capacity is derived using the Fourier transform of the CP-map-valued measure (G_σ). © *2005 American Institute of Physics.* [DOI: 10.1063/1.2142839]

I. INTRODUCTION

It was an important insight in the early days of quantum computing and quantum cryptography research that quantum theory should not be considered as a purely physical theory, but it rather defines a new kind of information, called quantum information. The decisive feature is its fragility since quantum information is destroyed whenever one tries to copy it.[1]

The question of which physical processes and information channels preserve quantum information therefore plays a crucial role in the theory of quantum communication. A central concept for addressing this issue is the notion of a *channel*. Here we consider a channel or ("operation") to be a completely positive trace preserving map $\rho \mapsto G(\rho)$ where ρ and $G(\rho)$ are positive operators of trace one acting on Hilbert spaces $\mathcal{H}_{\text{in}}$ and $\mathcal{H}_{\text{out}}$, respectively.[2] Analyzing quantum or classical channel capacities is in general a difficult task. Here we consider a certain kind of channels or operations, namely those which are *time-covariant*. For simplicity, we will assume that the input and the output state is a state of the same physical system. Then we have $\mathcal{H}_{\text{in}} = \mathcal{H}_{\text{out}} =: \mathcal{H}$. Furthermore we have a Hamiltonian time evolution on $\mathcal{H}$ generated by a densely defined self-adjoint operator H which reads

$$\alpha_t(\rho) := e^{-iHt} \rho e^{iHt}, \tag{1}$$

where ρ is a positive operator with trace one. We call a channel G time-covariant if it satisfies

$$\alpha_t \circ G = G \circ \alpha_t. \tag{2}$$

[a)]Electronic mail: janzing@ira.uka.de

(Note that in the context of classical linear systems the corresponding property is usually referred to as time-"invariance.") It is a special case of the requirement

$$G(U_g \rho U_g^\dagger) = U_g G(\rho) U_g^\dagger, \tag{3}$$

where $g \mapsto U_g$ is an arbitrary unitary group representation.

For compact groups, each covariant CP-map G has a representation (see Ref. 3, which refers partly to Ref. 4)

$$G(\rho) = \sum_j L_j \rho L_j^\dagger,$$

where the Kraus operators L_j satisfy

$$U_g L_j U_g^\dagger = \sum_k d_{jk}(g) L_k, \tag{4}$$

and $g \mapsto [d_{jk}(g)]_{j,k \leqslant d}$ is a d-dimensional unitary representation with arbitrary d (in Ref. 3 it is mainly focused on the case that $g \mapsto U_g$ is an irreducible representation). Note that the time evolution can only be described by a compact group if it is periodic, which cannot be guaranteed even in the finite dimensional case. In Ref. 5 the case is considered that G is replaced by a whole dynamical semigroup $(G_t)_{t \in \mathbb{R}^+}$ which is covariant with respect to a group representation.

Condition (2) appears naturally, for instance, in the following situations:

1. *Theory of timing information:* Assume that the density matrix ρ is subjected to an arbitrary quantum operation G at a completely unknown time instant. Then the statistical description of this operation leads to a map G' which necessarily satisfies (2). This is the key idea in Ref. 6 where condition (2) defines a "quasiorder of clocks," which classifies systems with respect to their timing information. The time-covariant maps are exactly those which can be implemented without using external clocks. Given a nonstationary state ρ, the set of states that can be obtained from ρ using time-covariant operations are those which have at most as much timing information as ρ.
2. *Decoherence:* Dephasing of systems is described by a decay of the off-diagonal entries with respect to the energy eigenbasis. This channels satisfy clearly condition (2).
3. *Scattering processes/quantum generalization of transfer functions:* Time-covariant operations appear naturally in the description of scattering processes. Then G generalizes the scattering operator by including classical or quantum stochastic fluctuations. Here *scattering* is understood in a rather general sense. Apart from the situation that a particle is scattered by the potential of another particle, one may, for instance, also think of a light beam that passes a filter. One may consider time-covariant maps as quantum generalization of classical time-invariant linear devices which are described by their transfer functions.

The paper is organized as follows. In Sec. II we recall briefly how to describe classical time-invariant linear systems in signal processing by a transfer function.[7] Figuring out the extent to which this concept can be generalized to the quantum stochastic setting is the key motivation of this paper. In Sec. III we recall abstract scattering theory in Hilbert spaces and explain in Sec. IV why time-covariant channels are also considered as a natural generalization of scattering theory. In Sec. V we consider CP-maps which are given by the Hadamard product of the density matrix with a positive matrix. These maps will turn out as a building block of our decomposition. In Sec. VI we derive the general form of a time-covariant CP-map. The main result is that every time-covariant CP-map acting on a system with nondegenerate Hamiltonian has a (densely defined) decomposition as an integral or sum over (densely defined) CP-maps G_σ is a dephasing followed by an energy shift. In Sec. VII we address the question of whether and to what extent covariant channels can destroy superpositions between states on the same orbit (with respect to the time-evolution). We use the general decomposition to derive a lower bound on the quantum capacity of

a specific type of time-covariant channels, namely those which have as output mutually orthogonal density operators on the same orbit. In Sec. VIII we apply the decomposition to a single mode Gaussian channel.

II. CLASSICAL TIME-INVARIANT LINEAR SYSTEMS

To show the differences and the analogies to the theory of classical linear time-invariant channels we briefly rephrase the concept of transfer functions, which is among the most important tools in classical signal processing.

Consider a classical channel with an incoming and an outgoing signal. These may, for instance, be light pulses or electrical pulses, acoustical or other signals. Let $t \mapsto Y(t)$ be the incoming signal where $Y(t)$ is the value of an arbitrary physical quantity at the time instant t. Let $Y'(t)$ denote the outgoing signal. In order to avoid problems with undefined Fourier transforms we assume that Y and Y' are vectors in $L^2(\mathbb{R})$, the Hilbert space of square-integrable functions on $\mathbb{R}$. We assume that the system is described by a linear bounded operator A on $L^2(\mathbb{R})$ with

$$Y' = AY.$$

Assuming time-invariance of the channel we have $Y'(t+s)=(AY)(t+s)$. Defining the group of shifts $(S_t)_{t\in\mathbb{R}}$ by

$$(S_t Y)(s) = Y(t-s) \tag{5}$$

we have

$$S_t A = A S_t, \quad \forall\, t \in \mathbb{R}.$$

The implications of this condition can easily be derived by applying Fourier transformation to both sides of the equation: The shift operators S_t act then as the multiplication operators M_t,

$$\hat{Y} \mapsto M_t \hat{Y}$$

with

$$(M_t \hat{Y})(\omega) = e^{i\omega t}\hat{Y}(\omega).$$

A linear operator commuting with all operators M_t is necessarily a multiplication operator as well (see Ref. 8, 12.1.5). Therefore A can be characterized by a so-called transfer function a with

$$\hat{Y}'(\omega) = a(\omega)\hat{Y}(\omega). \tag{6}$$

Note that it is essential that the quantity $Y(t)$ is a scalar. If $Y(t)$ is a vector of dimension d greater than 1 the spectrum of the time-evolution group S_t is degenerate and $\hat{Y}(\omega)$ is an element of a vector space $\mathbb{C}^d$ or $\mathbb{R}^d$ and the transfer function a had to be replaced by a $d\times d$-matrix. It is straightforward to ask whether time-covariant quantum operations allow a natural generalization of the transfer function. However, one should recall that the situation with nondegenerate spectrum is possible on the Hilbert space level (this is well-known in abstract scattering theory, as will be rephrased in Sec. III) but not on the level of density matrices, where the dynamics is generated by the super-operator $-i[H,.]$. The latter always has degenerate spectrum.

III. ABSTRACT SCATTERING THEORY

A similar approach as presented earlier applies to a scattering process of a quantum mechanical particle: a particle which comes from the infinity and passes a scattering potential. After it has left the potential it disappears to infinity. Here we only recall some standard results of scattering theory[8,9] which are essential for this paper. Let $H=H_i+H_0$ be the total Hamiltonian of the system which consists of the free Hamiltonian H_0 and the interactions term H_i. One assumes that the

particle moves approximatively according to its free Hamiltonian H_0 for $t \to \pm\infty$. For potentials which decay sufficiently with the distance between particle and the scattering center, the limits

$$|\psi^{\pm}\rangle := \lim_{t\to\pm\infty} \exp(iHt)\exp(-iH_0t)|\psi\rangle \tag{7}$$

exist[9] on an appropriate subspace of wave functions $|\psi\rangle$. There is a rich literature addressing the question under which circumstances and on which subspaces one can define a unitary scattering operator

$$|\psi^-\rangle \mapsto |\psi^+\rangle =: S|\psi_-\rangle.$$

(It is usual to denote the scattering operator with S. On the other hand, it is usual to denote shifts by S_t with some index t. It is hoped that this will not lead to confusion.) However, if it exists it commutes with the free Hamiltonian evolution $\exp(-iH_0t)$. Therefore the free time evolution and the scattering operator S can simultaneously be described by multiplication operators. The analogy to Sec. II can even be closer in a scattering process with so-called Lax-Phillips evolution.[8] Assume that there exist subspaces $\mathcal{H}_- \leqslant \mathcal{H}$ and $\mathcal{H}_+ \leqslant \mathcal{H}$ ("incoming and outgoing subspaces," respectively) such that

$$e^{-iHt}\mathcal{H}_- \subset \mathcal{H}_-$$

for all negative t (the particle comes from the infinity) and

$$e^{-iHt}\mathcal{H}_+ \subset \mathcal{H}_+$$

for all positive t (the particle disappears to the infinity). Assume furthermore that the intersection

$$\cap_{t\in\mathbb{R}} \exp(-iHt)\mathcal{H}_{\pm}$$

vanishes and that the span of all spaces $\exp(-iHt)\mathcal{H}_+$ as well as the span of all $\exp(-iHt)\mathcal{H}_-$ is dense in $\mathcal{H}$. Then one can assume without loss of generality that $\mathcal{H}$ is the set of square integrable functions on $\mathbb{R}$ with respect to the Lebesgue measure, and H is the multiplication operator $(H\psi)\times(\omega) = \omega\psi(\omega)$. The scattering operator is then (like the transfer function in Sec. II) given by $(S\psi)(\omega) = s(\omega)\psi(\omega)$ with an appropriate function s.

IV. QUANTUM CHANNELS FROM SCATTERING PROCESSES

The unitary scattering operator S in Sec. III defines a channel $G(\rho) = S\rho S^{\dagger}$ which satisfies obviously the time-covariance condition (2) with respect to the *free* evolution $\alpha_t(\rho) = \exp(-iH_0t)\rho\exp(iH_0t)$ due to $SH_0 = H_0S$. It is clear that scattering with an unknown potential could lead to an operation which is a statistical mixture of maps $S\rho S^{\dagger}$. But not only classical fluctuations of the scattering potential lead to a mixture of output wave functions; due to quantum fluctuations of the potential one may also have a CP-map which is not a mixture of unitary scattering processes. To see this, consider a bipartite quantum system with Hilbert space $\mathcal{H}_A \otimes \mathcal{H}_B$ that evolves according to a joint Hamiltonian H_{AB}. Assume that the joint evolution coincides asymptotically with the separate evolution generated by $H_A + H_B$ and that the limits

$$|\psi^{\pm}\rangle := \lim_{t\to\infty} \exp(itH_{AB})\exp(-iH_At)\exp(-iH_Bt)|\psi\rangle$$

exist in an appropriate sense. Then we have formally the same situation as in Sec. III with the substitution

$$H_0 \mapsto H_A + H_B, \quad H \mapsto H_{AB}.$$

If a scattering operator U on $\mathcal{H}_A \otimes \mathcal{H}_B$ exists we have

$$[U, H_A + H_B] = 0. \tag{8}$$

Let ρ_A be an arbitrary initial density matrix of system A. Then the scattering process defines a completely positive map on the system B by

$$G(\rho_B) := \mathrm{tr}_A(U(\rho_A \otimes \rho_B)U^\dagger).$$

Due to Eq. (8) it is easy to verify that G is time-covariant if the initial state ρ_A is stationary with respect to the time evolution $\exp(-iH_A t)$. Here we do not address the difficult question in which situation the above-noted limits exist. The problem of the existence of scattering operators in the quantum stochastic setting is addressed in Ref. 10. This will not be our subject. The above-presented remarks were only to show that time-covariant channels appear naturally also in the description of (possibly inelastic) scattering processes. Another situation where time-covariance appears is when the energy spectrum is discrete and a weak interaction with the environment is switched on. Then the interaction implements clearly a unitary U on system + environment such that U satisfies (8).

V. QUANTUM CHANNELS FROM HADAMARD-PRODUCTS

Here we consider a simple type of time-covariant CP-maps which will play a crucial role in the description of general time-covariant CP-maps.

The Hadamard product $A*B$ of two $n \times n$- matrices A, B is defined as the entry-wise product $(A*B)_{ij} := A_{ij}B_{ij}$. Remarkably, the Hadamard product between a density matrix ρ with any positive matrix M of the same size n defines a completely positive map:

If $M := \Sigma_j r_j |d_j\rangle\langle d_j|$ is a spectral decomposition of M then we may define diagonal matrices D_j which have the coefficients of the vector $d_j \in \mathbb{C}^n$ as diagonal entries. Then the map

$$\rho \mapsto D_j \rho D_j^\dagger = (|d_j\rangle\langle d_j|) * \rho \tag{9}$$

is obviously completely positive. So is the positive linear combination of those maps. Channels of this type have already be considered in Ref. 11. Also Ref. 12 has already used them to describe decoherence. It is clear that they commute with the Hamiltonian time evolution if the Hadamard product is calculated with respect to the energy basis. In the finite dimensional case, we also obtain time-covariant channels by the following construction: Let $\Sigma := \{\omega_1, \ldots, \omega_n\}$ be the eigenvalues of H acting on $\mathbb{C}^n$. Let $|\omega_j\rangle$ be the corresponding eigenstates. For any $\sigma \in \mathbb{R}$ let $j_1, \ldots, j_k$ be all indices j such that $\omega_j + \sigma$ is in the spectrum Σ. Define the "partial shift" by

$$S_\sigma := \sum |\omega_{j_i} + \sigma\rangle\langle\omega_{j_i}|, \tag{10}$$

where the sum runs over all spectral values ω with $\omega + \sigma \in \Sigma$.

The map $\rho \mapsto S_\sigma \rho S_\sigma^\dagger$ is time-covariant and also every map of the form

$$\rho \mapsto \sum_\sigma S_\sigma (M_\sigma * \rho) S_\sigma^\dagger, \tag{11}$$

where the sum runs over all σ for which a nonzero partial shift exists. Each M_σ is an arbitrary positive matrix. It is easy to check that this map is trace-preserving if and only if

$$\sum_\sigma M_\sigma(\omega, \omega) = 1, \quad \forall\ \omega \in \Sigma, \tag{12}$$

where the sum runs over all values σ for which there exist an $\omega \in \Sigma$ such that $\omega + \sigma \in \Sigma$.

In the following we will show that this is the most general form of time-covariant CP-maps. As will be shown, this holds in principle even for the infinite dimensional case with continuous spectrum when the sum is replaced by an integral over a potentially uncountable number of energy shifts.

VI. THE GENERAL FORM OF TIME-COVARIANT CHANNELS

To understand our construction it is helpful to consider the finite dimensional case first. Using the Kraus representation[2]

$$G(\rho) = \sum_j A_j \rho A_j^\dagger, \tag{13}$$

one may choose A_j such that they are eigenvectors of α_t. [Since the derivation for the finite dimensional case follows actually from the general derivation later in this section we only mention briefly that this can be derived as follows. One shows that the representations $t \mapsto [d_{kj}(t)]$ of $(\mathbb{R}, +)$ in Eq. (4) corresponding to time-translations can be chosen such that they are irreducible, i.e., one-dimensional]. The eigenvalue is $\exp(-i\sigma_j t)$, where σ_j may be any possible frequency difference $\omega - \omega'$. For each possible value σ we obtain a CP-map

$$G_\sigma(\rho) := \sum_{\sigma=\sigma_j} A_j \rho A_j^\dagger.$$

Let $A_j = U_j |A_j|$ be the polar decomposition of A_j where the partial isometry U_j is computed from the pseudo-inverse $|A_j|^{-1}$ by

$$U_j := A_j |A_j|^{-1}.$$

One has $\alpha_t(U_j) = \exp(-i\sigma_j t) U_j$ and equivalently

$$[H, U_j] = \sigma_j U_j, \quad [H, |A_j|] = 0, \tag{14}$$

since $|A_j|$ is α_t-invariant according to $\alpha_t(A_j)\alpha_t(A_j^\dagger) = e^{-i\sigma_j t} e^{i\sigma_j t}$. Using Eq. (14) one checks easily that

$$U_j |\omega\rangle = V_j |\omega + \sigma\rangle, \quad \forall\, \omega \in \Sigma,$$

where V_j is an appropriate diagonal operator. Hence we can write

$$A_j = S_{\sigma_j} D_j$$

with the diagonal matrix $D_j := |A_j| V_j$. Using the remarks of Sec. V we may write

$$G_\sigma(\rho) = S_\sigma (M_\sigma * \rho) S_\sigma^\dagger,$$

where $M_\sigma = \Sigma_j |d_j\rangle\langle d_j|$ is defined as in Sec. V from the vectors $|d_j\rangle$ of diagonal entries of D_j.

We conclude:

Theorem 1 (Decomposition in finite dimensions): *Let G be a CP-map on $\mathbb{C}^n$ which commutes with the time evolution α_t corresponding to a nondegenerate diagonal Hamiltonian. Then G has the form*:

$$G(\rho) = \sum_\sigma S_\sigma (M_\sigma * \rho) S_\sigma^\dagger, \tag{15}$$

where the sum runs over all possible energy differences σ. Here S_σ denotes partial shifts and M_σ positive matrices.

The map $\rho \mapsto (M_\sigma * \rho)$ preserves the energy of every state and destroys to some extent the coherent superpositions between them. This is shown by the following two extreme cases: $M_\sigma = \mathbf{1}$ where $\mathbf{1}$ denotes the identity matrix. Then we have complete dephasing and obtain a mixture of energy eigenstates. If M_σ has only 1 as entries it is the trivial channel which does not affect the state at all. The map G consists of decohering channels followed by different energy shifts.

To see the relation of our decomposition to the transfer function note that all rank-one operators $|\omega + \sigma\rangle\langle\omega|$ span the eigenspace of $[H, .]$ with eigenvalue σ. A time-covariant operation has to

leave this subspace invariant. Therefore one could decompose G into a direct sum of linear maps B_σ acting on these eigenspaces. However, in this decomposition one would have restrictions on the family B_σ in order to yield a *completely positive map*. Therefore we have preferred a decomposition where each component is completely positive. However, the Hadamard multiplication for each frequency pair (ω,ω') reminds to the multiplication with the value of the transfer function for each frequency ω.

To generalize the decomposition to infinite dimensions we will need several vector-valued measures. Therefore we recall the precise definition:[13]

Definition 1 (Vector-valued measures and densities):

1. *Let Ω be a set and M the σ-algebra of measurable subsets of Ω. For a Banach space B a mapping $\gamma: M \to B$ is called a vector measure if*

$$\gamma(\cup_j m_j) = \sum_j \gamma(m_j)$$

for all finite collections of mutually disjoint sets m_j. It is called countably additive when the same holds for countable sums.

2. *Let ν be a measure on the measure space (Ω, M). A measurable function $f: \Omega \to B$ is the Radon-Nikodym derivative of γ with respect to ν if*

$$\int_m f \mathrm{d}\nu = \gamma(m), \quad \forall\, m \in M.$$

We also say that f is the (vector-valued) density of γ with respect to ν.

For trace-class operator-valued measures we will have countable additivity in the weak sense, i.e., that the scalar measure that is given by evaluation on observables is countably additive. For CP-map valued measures we demand countable additivity only after applying the maps to states and evaluating them on observables.

In order to construct the infinite dimensional analog of G_σ we define a function

$$f_{K,\rho}(t) := \mathrm{tr}(KG(\rho e^{-iHt})e^{iHt}) \tag{16}$$

for every observable K and state ρ. First consider the simple case that $G = A\rho A^\dagger$, where A is an operator satisfying $\alpha_t(A) = e^{-i\sigma t}A$. Then we have

$$f_{K,\rho}(t) = e^{i\sigma t} f_{K,\rho}(0).$$

If G is defined by several Kraus operators A_j which are eigenvectors with different eigenvalues σ_j the function $f_{K,\rho}$ would consist of harmonic functions with all these frequencies σ_j. Even though we do not expect in the infinite dimensional case that we have Kraus operators which are eigenvectors of α_t it will turn out that we can nevertheless construct a decomposition of G based on the Fourier transform of $f_{K,\rho}$. We show that for each positive bounded operator K and density operator ρ the function $f_{K,\rho}$ is positive semidefinite, i.e., it satisfies

$$\sum_{k,l} x_k \bar{x}_l f_{K,\rho}(t_k - t_l) \geqslant 0$$

for all vectors $x \in \mathbb{C}^m$ and m-tuples $t_1, \ldots, t_m \in \mathbb{R}$ with arbitrary m:

$$f_{K,\rho}(t_k - t_l) = \mathrm{tr}\left(K \sum_j A_j \rho e^{-iH(t_k - t_l)} A_j^\dagger e^{-iH(t_l - t_k)} \right) = \sum_j \mathrm{tr}(K e^{iHt_k} A_j e^{-iHt_k} \rho e^{iHt_l} A_j^\dagger e^{-iHt_l}),$$

where we have used

$$\sum_j A_j \rho e^{-iHt_k} A_j^\dagger e^{iHt_k} = \sum_j e^{iHt_k} A_j e^{-iHt_k} \rho A_j^\dagger,$$

which is just another version of the time-invariance condition. We have therefore

$$\sum_{k,l} x_k \bar{x}_l f(t_k - t_l) = \sum_j \mathrm{tr}\left(K\left(\sum_k x_k e^{iHt_k} A_j e^{-iHt_k} \right) \rho \left(\sum_l \bar{x}_l e^{iHt_l} A_j^\dagger e^{-iHt_l} \right) \right) = \sum_j \mathrm{tr}(K C_j \rho C_j^\dagger) \geqslant 0$$

with the abbreviation

$$C_j := \sum_k x_k e^{iHt_k} A_j e^{-iHt_k}.$$

Since $f_{K,\rho}$ is positive semidefinite it defines a unique positive scalar measure $\nu_{K,\rho}$ on $\mathbb{R}$ by Bochner's theorem.[14] For every measurable set $m \subset \mathbb{R}$ the map $K \mapsto \nu_{K,\rho}(m)$ is a positive linear functional. It is norm-continuous (with respect to the operator norm) since the norm of a positive functional is given by its value on the identity,[15] i.e., by $\nu_{\mathbf{1},\rho}(m)$. Now we restrict the functional to the set of compact operators where every norm-continuous functional is given by a trace-class operator.[16] Therefore we may define a positive trace-class operator ρ_m by

$$\mathrm{tr}(\rho_m K) = \nu_{K,\rho}(m).$$

Hence the map G_m defined by $G_m(\rho) := \rho_m$ is a positive map on the trace-class operators. One can easily check that G_m is also *completely* positive: one substitutes G and e^{-iHt} by an arbitrary tensor product extension $G \otimes id$ by and $e^{-iHt} \otimes \mathbf{1}$ and considers ρ and K as operators on the extended space. Then it is obvious that the above-noted positivity argument works similarly. We have $G_{\mathbb{R}} = G$ due to

$$\mathrm{tr}(K\rho_{\mathbb{R}}) = \nu_{K,\rho}(\mathbb{R}) = f_{K,\rho}(0) = \mathrm{tr}(K\rho).$$

Since the trace of each $G_m(\rho)$ is at most $\mathrm{tr}(G(\rho)) = \mathrm{tr}(\rho) = 1$, each map G_m is a bounded operator on T, the set of trace-class operators. Since $G_{\mathbb{R}}$ is trace-preserving the map $m \mapsto G_m$ is formally an *instrument* in the sense of Davies (see Ref. 17, Chap. 4). Think of $G_m(\rho)/\mathrm{tr}(G_m(\rho))$ as the post-measurement state given the knowledge that the measurement outcome σ is in m. Then $\rho \mapsto G(\rho)$ is formally the effect of the measurement if the measured outcome is completely ignored. Even though this interpretation refers to a virtual measurement the virtual result σ has an observable interpretation: Assume one observes the energy of the environment before and after it has interacted with the system. Due to energy conservation σ is the energy loss of the environment. Note that the initial energy of the environment can be observed without disturbing its state since we have assumed that it is in a stationary state. [The idea to observe the environment in order to have a less mixed output state (which increases information capacities) can already be found in Refs. 18 and 19]. We shall call the probability measure $\nu_{\rho,\mathbf{1}}$ the "energy shift probabilities" in the state ρ.

Each map G_m is also time-covariant: The obvious equation

$$f_{K,\rho} = f_{\alpha_t(K),\alpha_t(\rho)}$$

implies that it is irrelevant for the measure $\nu_{K,\rho}$ if α_t is applied to ρ and α_{-t} to the output state (which is equivalent to applying α_t to K).

We summarize the results:

Theorem 2: *For each time-covariant channel G there is a unique CP-map-valued-measure*

$$m \mapsto G_m$$

such that

1. *Each G_m is a time-covariant bounded operator on T.*
2. *The Fourier transform of $m \mapsto G_m$ is the function $t \mapsto \hat{G}_t$ with*

$$\hat{G}_t(\rho) := G(\rho e^{-iHt})e^{iHt}$$

in the sense that

$$t \mapsto \mathrm{tr}(K\hat{G}_t(\rho))$$

is for all $K>0$ *and all states* ρ *the Fourier transform of the (non-negative) measure*

$$m \mapsto \mathrm{tr}(KG_m(\rho)).$$

The positive-map-valued measure defines a positive operator-valued-measure (POVM)[17] $m \mapsto Q_m$ by

$$\mathrm{tr}(Q_m\rho) := \mathrm{tr}(G_m(\rho)).$$

In contrast to CP-map valued measures, POVMs describe only the probabilities for the measurement outcome without referring to the post-measurement state. The Fourier transform of this POVM will play a crucial role later.

In order to have a stronger analogy to Theorem 1 we would like to write G as an integral

$$G = \int G_\sigma \mathrm{d}\,\nu(\sigma)$$

with an appropriate measure ν. Then the function $\sigma \mapsto G_\sigma$ would be the CP-map valued Radon-Nikodym derivative of the measure $m \mapsto G_m$, i.e., G_σ would be the *density* of the measure with respect to the measure ν. The general problem of Radon-Nikodym derivatives of *instruments* (CP-map valued measures) has already been considered in Ref. 20. It is shown that it exists in the following sense:

There is a σ-finite measure ν, a dense domain $\mathcal{D} \in \mathcal{H}$, and a countable family of functions

$$\sigma \mapsto A_k^\sigma$$

defined for ν-almost all σ such that A_k^σ are linear operators $\mathcal{D} \to \mathcal{H}$ (not necessarily closable) such that

$$\int \sum_k \|A_k^\sigma|\psi\rangle\|^2 = \||\psi\rangle\|^2, \quad \forall\, |\psi\rangle \in \mathcal{D} \tag{17}$$

and

$$\mathrm{tr}(KG_m(\rho)) = \int_m \sum_k \langle A_k^\sigma\psi|KA_k^\sigma\psi\rangle \mathrm{d}\,\nu(\sigma), \quad \forall\, |\psi\rangle \in \mathcal{D}. \tag{18}$$

Note that A_k^σ could formally be considered as the Kraus operators of a CP-map G_σ with the "only" difference being that Kraus operators are not only closable but even bounded.

Equation (17) states implicitly that

$$\sum_k \langle A_k^\sigma\psi|KA_k^\sigma\psi\rangle < \infty \tag{19}$$

for ν-almost all σ. Since it even converges for $K=\mathbf{1}$, expression (19) defines a bounded positive functional on the operators K. We can find a unique positive trace-class operator ρ_σ such that

$$\mathrm{tr}(K\rho_\sigma) = \int_m \sum_k \langle A_k^\sigma \psi | K A_k^\sigma \psi \rangle$$

for all compact K. The proof in Ref. 20 states furthermore that $\mathcal{D}$ can be the finite span of any orthogonal system of $\mathcal{H}$. Summarizing these results, we have:

Theorem 3 (Radon-Nikodym derivative of the instrument): *For every orthonormal system* $(|x_j\rangle)$ *of* $\mathcal{H}$ *there is a family of CP-maps* G_σ *defined on the finite span of all rank-one operators* $|x_i\rangle\langle x_j|$ *such that*

$$G_m(\rho) = \int_m G_\sigma(\rho)\mathrm{d}\nu(\sigma) \tag{20}$$

for all ρ *in the domain of* G_σ *and an appropriate* σ*-finite measure* ν.

However, the domain of the maps G_σ can be extended:

Lemma 1 (Extended domains): Let $\rho \in T$ *be arbitrary and* ν *be an arbitrary measure. If the trace-class operators* $G_\sigma(\rho)$ *are consistently defined (in the sense that they define the density of the measure* $m \mapsto G_m(\rho)$*) then we have:*

1. *The domain of* G_σ *can consistently be extended to* ρe^{-iHt} *by*

$$G_\sigma(\rho e^{-iHt}) := G_\sigma(\rho) e^{-iHt} e^{i\sigma t}.$$

Consistency means that it is the density of the measure $m \mapsto G_m(\rho e^{-iHt})$. *Similarly, we may define* $G_\sigma(\exp(iHt)\rho) := \exp(-i\sigma t)\exp(iHt)G_\sigma(\rho)$.

2. *Let* l *be a measurable subset of* $\mathbb{R}$ *and* P_l *be the projection onto the space of functions vanishing on the complement of* l. *Then one may extend the domain of* G_σ *consistently to* ρP_l *by setting*

$$G_\sigma(\rho P_l) := G_\sigma(\rho) P_{l+\sigma},$$

and similarly $G_\sigma(P_l\rho) := P_{l+\sigma} G_\sigma(\rho)$.

Proof: The Fourier transform of the measure

$$m \mapsto \mathrm{tr}(K G_m(\rho e^{-iHt}))$$

is given by

$$f(r) := \mathrm{tr}(K\hat{G}_r(\rho e^{-iHt})) = \mathrm{tr}(K\hat{G}_{t+r}(\rho)e^{-iHt}) \tag{21}$$

$$= \int \mathrm{tr}(K G_\sigma(\rho) e^{-iHt}) e^{i(r+t)\sigma} \mathrm{d}\nu(\sigma). \tag{22}$$

The last equality holds since $\hat{G}_{r+t}$ is the Fourier transform of $m \mapsto G_m$ evaluated at $r+t$. Set $\rho_\sigma := G_\sigma(\rho)$. We write (22) as

$$\int \mathrm{tr}(K\rho_\sigma e^{-iHt} e^{it\sigma}) e^{ir\sigma} \mathrm{d}\nu(\sigma),$$

which is the Fourier transform of a measure with density

$$\sigma \mapsto tr(K\rho_\sigma e^{-iHt} e^{it\sigma}).$$

This proves statement (1).

To prove (2) we have to show that

$$\mathrm{tr}(KG_m(\rho P_l)) = \int_m G_\sigma(\rho) P_{l+\sigma} \mathrm{d}\nu(\sigma) \tag{23}$$

holds for all K and measurable m. Consider the scalar complex-valued measure

$$l \mapsto \mathrm{tr}(KG_m(\rho P_l)).$$

Its Fourier transform is

$$f(t) := \mathrm{tr}(KG_m(\rho e^{iHt})) = \int_m \mathrm{tr}(K\rho_\sigma e^{-iHt} e^{it\sigma}) \mathrm{d}\nu(\sigma),$$

where the last equality is due to statement (1). By

$$e^{-iHt} e^{it\sigma} = e^{i(H+\sigma \mathbf{1})t}$$

the last expression is the Fourier transform of the measure

$$l \mapsto \int_m G_\sigma(\rho) P_{l+\sigma} \mathrm{d}\nu(\sigma).$$

This proves that both sides of Eq. (23) coincide. □

We would like to characterize the maps G_σ more explicitly. We already have done this in Theorem 1 for the finite dimensional case when the spectrum of H is nondegenerate. Now we assume that $\mathcal{H}$ is the set of square integrable functions on $\mathbb{R}$,

$$\mathcal{H} := L^2(\mathbb{R}, \mu),$$

where μ is an arbitrary measure on $\mathbb{R}$ defined on the Lebesgue measurable sets. To formalize the assumption of nondegenerate spectrum we define H as the multiplication operator

$$(H\psi)(\omega) = \omega\psi(\omega), \quad \forall\, \omega \in \mathbb{R}. \tag{24}$$

Note that the Hadamard product can be generalized to infinite dimensions since every density operator ρ has a representation $\rho = \sum_j p_j |\phi_j\rangle\langle\phi_j|$ with eigenvectors $|\phi_j\rangle$. Then we may interpret

$$\rho(\omega, \omega') := \sum_j p_j \phi_j(\omega) \bar{\phi}_j(\omega')$$

as the entries of ρ. This is also the representation of ρ by its integral kernel, i.e.,

$$(\rho\psi)(\omega) = \int \rho(\omega, \omega')\psi(\omega') \mathrm{d}\mu(\omega').$$

Accordingly, we define:

Definition 2 (Hadamard product in infinite dimensions): For two trace-class operators ρ, ρ' and a function $M: \mathbb{R} \times \mathbb{R} \to \mathbf{C}$ we write

$$\rho' = M * \rho \tag{25}$$

if

$$\rho'(\omega, \omega') = M(\omega, \omega')\rho(\omega, \omega'). \tag{26}$$

To generalize the concept of partial shifts to $L^2(\mathbb{R}, \mu)$ is less straightforward. Since they should be partial isometries, the problem is twofold: Assume first that μ is given by a nonconstant and nonzero density with respect to the Lebesgue measure. Then it is intuitively clear that the generalized "shift" rescales the function to compensate the different densities at different points in order to be isometric. Assume, second, that H has discrete and continuous spectrum, i.e., μ

consists of singular and absolutely continuous parts with respect to the Lebesgue measure. Then one cannot expect that the discrete part of the wave function can be shifted to the continuous part and vice versa. The part of the wave function where this is the case has to be mapped to zero.

Despite these difficulties, the following lemma shows that our concept makes sense even in the general situation:

Lemma 2 (Partial shifts): For every $\sigma \in \mathbb{R}$ there is a unique partial isometry S_σ with the following properties:

1. *For all $f \in \mathcal{H}$ we have*

$$(S_\sigma f)(\omega) := s_\sigma(\omega - \sigma) f(\omega - \sigma), \tag{27}$$

   where s_σ is an appropriate measurable "scaling" function.

2. *Under all partial isometries $\widetilde{S}_\sigma$ which have a representation as in (1) with an appropriate scaling function $\widetilde{s}_\sigma$ the operator S_σ has minimal kernel, i.e., its kernel is contained in the kernel of all those $\widetilde{S}_\sigma$.*

Proof: Define the translated measure $\mu_\sigma(m) := \mu(m+\sigma)$. Then there is a unique decomposition

$$\mu = \mu_c + \mu_s, \tag{28}$$

where μ_c is absolutely continuous with respect to μ_σ and μ_s is orthogonal to μ_σ.[21] Here, orthogonality means that there is a measurable set B such that $\mu_s(B)=0$ and $\mu_\sigma(\bar{B})=0$ where $\bar{B}$ denotes the complement of B. Let p be the density of μ_c with respect to μ_σ. Set $s_\sigma := \sqrt{p}$. First we show that S_σ is an isometry of the subspace $\mathcal{H}_c$ given by all functions f with $f(\omega)=0$ for $\omega \in \bar{B}$:[22,23]

$$\int |s_\sigma(\omega-\sigma) f(\omega-\sigma)|^2 \mathrm{d}\mu(\omega) = \int |s_\sigma(\omega)|^2 |f(\omega)|^2 \mathrm{d}\mu_\sigma(\omega) = \int |f(\omega)|^2 p(\omega) \mathrm{d}\mu_\sigma(\omega) = \int |f(\omega)|^2 \mathrm{d}\mu_c. \tag{29}$$

This integral is equal to $\int |f(\omega)|^2 \mathrm{d}\mu$ if f vanishes on $\bar{B}$. On the other hand, it is zero if f vanishes on B. This shows that the space can be decomposed into the kernel of S_σ and a subspace where S_σ is an isometry. Hence we have $\|S_\sigma f\| \leq \|f\|$ on the whole space. Note that the equations showing this inequality show furthermore that S_σ is well-defined with respect to the equivalence classes in $L^2(\mathbb{R}, \mu)$.

Let $\widetilde{S}_\sigma$ be another isometry satisfying condition (1) with the scaling function $\widetilde{s}_\sigma$. Set $D := \widetilde{s}^{-1}(0)$. Clearly, condition (1) implies $[H, \widetilde{S}_\sigma] = \sigma \widetilde{S}_\sigma$ and $[H, \widetilde{S}_\sigma^\dagger] = -\sigma \widetilde{S}_\sigma^\dagger$. Hence the initial projection $\widetilde{S}_\sigma^\dagger \widetilde{S}_\sigma$ commutes with H and is therefore the multiplication operator with the characteristic function χ_D of a measurable set D. Let f vanish on $\bar{D}$. Since $\widetilde{S}_\sigma$ preserves its norm we have

$$\int |f(\omega)|^2 \mathrm{d}\mu(\omega) = \int |f(\omega)|^2 \widetilde{s}_\sigma^2(\omega) \mathrm{d}\mu_\sigma(\omega).$$

Since this holds for all functions which vanish on $\bar{D}$ μ-almost everywhere it shows that the restriction of μ to D is absolutely continuous with respect to μ_σ (with the density $\widetilde{s}_\sigma^2$). Hence the singular part of μ (with respect to μ_σ) vanishes on D and we have

$$\int |f(\omega)|^2 \mathrm{d}\mu(\omega) = \int |f(\omega)|^2 \mathrm{d}\mu_c(\omega).$$

As can be seen in Eq. (29), this shows that the norm of f is also preserved by S_σ. Hence the isometric subspace of $\widetilde{S}_\sigma$ is a subspace of the isometric subspace of S_σ and the kernel of S_σ is a subspace of the kernel of $\widetilde{S}_\sigma$. □

Fortunately, these shifts have the following property:

Lemma 3: The partial shift of Lemma 2 satisfies

$$S_\sigma^\dagger = S_{-\sigma}. \tag{30}$$

Proof: Rewriting the inner product of $\mathcal{H}$ as an integral one checks easily that $S_\sigma^\dagger$ has to be a translation by $-\sigma$ with an appropriate scaling function. It is easy to see that $S_{-\sigma}S_\sigma = S_\sigma^\dagger S_\sigma$: On the kernel of S_σ both products coincide trivially. On its orthogonal complement, i.e., the isometric subscape of S_σ the operator $S_\sigma^\dagger S_\sigma$ is the identity. But this must also be true for $S_{-\sigma}S_\sigma$ because the isometric subspace of $S_{-\sigma}$ must contain the isometric subspace of $S_\sigma^\dagger$ since $S_{-\sigma}$ has minimal kernel in the set of all partially isometric translations [see property (2) in Lemma 2]. Using general properties of partial isometries[22,23] the image of $S_\sigma^\dagger$ satisfies therefore

$$\mathrm{Im}\, S_\sigma^\dagger = \mathrm{Im}(S_\sigma^\dagger S_\sigma) = \mathrm{Im}(S_{-\sigma}S_\sigma) \leqslant \mathrm{Im}\, S_{-\sigma}.$$

Reversing this inequality by taking the orthogonal complement we obtain

$$\ker S_\sigma \geqslant \ker S_{-\sigma}^\dagger.$$

Because this holds for all $\sigma \in \mathbb{R}$ we have

$$\ker S_{-\sigma} \geqslant \ker S_\sigma^\dagger.$$

Since $S_{-\sigma}$ has minimal kernel we conclude

$$\ker S_{-\sigma} = \ker S_\sigma^\dagger.$$

Due to the uniqueness of the maximal element in the set of all partially isometric translations we have

$$S_\sigma^\dagger = S_{-\sigma}.$$

□

Note that we can only write $G_\sigma(\rho)$ in the form $S_\sigma(M_\sigma * \rho)S_\sigma^\dagger$ if the density operator $G_\sigma(\rho)$ acts only on the image of S_σ (which coincides with the image of the projection $S_\sigma S_\sigma^\dagger$). But this is indeed the case:

Lemma 4: If ρ is in the domain of G_σ its output $\rho_\sigma := G_\sigma(\rho)$ satisfies

$$S_\sigma S_\sigma^\dagger \rho_\sigma S_\sigma S_\sigma^\dagger = \rho_\sigma. \tag{31}$$

Proof: We will show $G_\sigma(\rho)S_\sigma S_\sigma^\dagger = G_\sigma(\rho)$. The statement $S_\sigma S_\sigma^\dagger G_\sigma(\rho) = G_\sigma(\rho)$ follows similarly. Due to Lemma 3 we have $S_\sigma S_\sigma^\dagger = S_{-\sigma}^\dagger S_{-\sigma}$, which is the projection onto the isometric subspace of $S_{-\sigma}$. It can explictly be given as follows (see proof of Lemma 2): Let $\mu := \mu_c \oplus \mu_s$ be the decomposition into the absolutely continuous and singular part of μ with respect to $\mu_{-\sigma}$. Let C be a set such that $\mu_{-\sigma}(\bar{C}) = 0$ and $\mu_s(C) = 0$. Then $S_{-\sigma}^\dagger S_{-\sigma} = P_C$. Due to $\mu(\bar{C} - \sigma) = \mu_{-\sigma}(\bar{C}) = 0$ we have $P_{\bar{C}-\sigma} = 0$. This implies

$$G_\sigma(\rho)P_{\bar{C}} = G_\sigma(\rho P_{\bar{C}-\sigma}) = 0.$$

□

For the construction in the sequel we choose the ONS in Theorem 3 such that its finite span contains a vector $|\psi\rangle$ with $\psi(\omega) \neq 0$ for μ-almost all ω.

Now we can define a function

$$M_\sigma : \mathbb{R} \times \mathbb{R} \to \mathbf{C}$$

by

$$M_\sigma(\omega,\omega') := \frac{k(\omega,\omega')}{\psi(\omega)\bar{\psi}(\omega')}, \tag{32}$$

where the function k represents the trace-class operator $S_\sigma^\dagger \rho_\sigma S_\sigma$. Even though this function is not well-defined, the calculations to follow show that the freedom of choosing M_σ is irrelevant.

By construction and using Lemma 4, we have

$$G_\sigma(\rho) = \rho_\sigma = S_\sigma(M_\sigma * \rho_\sigma)S_\sigma^\dagger.$$

We conclude

$$G(|\psi\rangle\langle\psi|) = \int S_\sigma(M_\sigma * (|\psi\rangle\langle\psi|))S_\sigma^\dagger \mathrm{d}\nu(\sigma)$$

with $|\psi\rangle$ as above. Using Lemma 1, part (1), we have

$$\int G_\sigma(e^{-iHt}|\psi\rangle\langle\psi|e^{iHs})\mathrm{d}\nu(\sigma) = \int S_\sigma(M_\sigma * (e^{-iHt}|\psi\rangle\langle\psi|e^{iHs}))S_\sigma^\dagger \mathrm{d}\nu(\sigma),$$

for all $s,t \in \mathbb{R}$. The finite span of these rank-one operators is dense in T since H is the multiplication with the identity and the span of all $\exp(-iHt)|\psi\rangle$ is therefore dense in $\mathcal{H}$. We conclude:

Theorem 4 (Dephasing—energy shift representation): *There is a family of functions* $(M_\sigma)_{\sigma\in\mathbb{R}}$,

$$M_\sigma : \mathbb{R}\times\mathbb{R} \to \mathbf{C}, \tag{33}$$

and a σ*-finite measure* ν *on* $\mathbb{R}$ *such that for a dense set of density operators* ρ *the decompostion*

$$G(\rho) = \int S_\sigma(M_\sigma * \rho)S_\sigma^\dagger \mathrm{d}\nu(\sigma)$$

holds.

We would like to have an analogy to the statement that M_σ is in the finite dimensional case a *positive* matrix. However, we have specified M_σ only as a function and not as an operator. It seems straightforward to consider it as an operator by

$$(M_\sigma\psi)(\omega) := \int M_\sigma(\omega,\omega')\psi(\omega')\mathrm{d}\mu(\omega').$$

But it is easy to see that this is not in general well-defined. Let, for instance, G be the identity on the density operators on $l^2(\mathbb{Z})$. Then the decomposition of G reduces to $G(\rho)=M_0*\rho$ with $M_0(\omega,\omega')=1$. The formal matrix multiplication of this "all-one" matrix with any square-integrable sequence leads to infinite coefficients. However, formally it is like a positive operator in the following sense.

$$M_\sigma * (|\psi\rangle\langle\psi|)$$

is by construction the trace-class operator ρ_σ. Translated to finite dimensions this expression to

$$DM_\sigma D^\dagger,$$

where D is a nonsingular diagonal matrix [in analogy to the statement that $\psi(\omega)$ vanishes almost nowhere]. Such a matrix can only be positive if M_σ is itself positive. In this sense we consider M_σ as positive even though it is not an operator. In analogy to the finite dimensional case, an exact measurement of the energy of the environment (before and after the interaction has taken place) would lead to a map

$$S_\sigma(M_\sigma * \rho)S_\sigma^\dagger,$$

which is only a dephasing channel up to the known energy shift.

It should be noted that (depending on ν) the integral may represent a finite, or countable infinite sum, or a continuous integral even though the Kraus representation of G is always possible with a countable sum.[2]

VII. SUPERPOSITIONS BETWEEN STATES IN THE SAME ORBIT

The "Hadamard-channel" $\rho \mapsto M * \rho$ with a positive matrix M allows perfect classical information transfer by using energy eigenstates as logical states. Its quantum capacity depends on the destruction of off-diagonal elements, i.e., whether the output states are more or less stationary states. Explicitly one has the following lower bound on the quantum capacity:

Lemma 5: In dimension n, the quantum capacity Q of the channel $\rho \mapsto M * \rho$ *with* $M(\omega, \omega) = 1$ *for all* $\omega \in \Omega$ *satisfies*

$$Q \geqslant \log_2(n) - S(M/n),$$

where S(.) denotes the von-Neumann entropy.

Proof: Let

$$M := \sum_j |m_j\rangle\langle m_j| \tag{34}$$

be a decomposition into mutually orthogonal rank-one operators with non-normalized vectors $|m_j\rangle$. Let D_j be the diagonal matrices having the coefficients of $|m_j\rangle$ as entries. Then we have

$$G(\rho) = \sum_j D_j \rho D_j^\dagger.$$

The quantum capacity is given by the supremum of the coherent information[24] over all input states for arbitrarily many copies of the channel. Let $|\phi\rangle\langle\phi|$ be a state on $\mathbb{C}^n \otimes \mathbb{C}^n$ and ρ its restriction to the right component. Then the coherent information is defined as

$$S(G(\rho)) - S((\mathrm{id} \otimes G)(|\phi\rangle\langle\phi|)),$$

where S denotes the von Neumann entropy. Consider the maximally entangled state

$$|\phi\rangle := \frac{1}{\sqrt{n}} \sum_j |j\rangle \otimes |j\rangle. \tag{35}$$

Note that ρ is the maximally mixed state and that it is preserved by the channel. Hence we have $G(S(\rho)) = \log_2(n)$ and

$$(\mathrm{id} \otimes G)(|\phi\rangle\langle\phi|) = \sum_j (1 \otimes D_j)|\phi\rangle\langle\phi|(1 \otimes D_j^\dagger). \tag{36}$$

Furthermore we have

$$\langle\phi|(1 \otimes D_j^\dagger)(1 \otimes D_i)|\phi\rangle = \mathrm{tr}(D_j^\dagger D_i) = \langle m_j|m_i\rangle = 0.$$

Therefore the sum (36) is already the spectral decomposition of $(\mathrm{id} \otimes G)(|\phi\rangle\langle\phi|)$. The eigenvalues are the square of the length of each vector $(1 \otimes D_j)|\phi\rangle$. It is given by $\langle m_j|m_j\rangle/n$. Hence the entropy of the output state is the von Neumann entropy $S(M/n)$. □

Here the destruction of quantum information coincides with the destruction of timing information in the sense that states on the same orbit of α_t become less distinguishable. It is obvious that decoherence with respect to the energy eigenbasis leads always destroys *timing* information in this sense. Here we want to address the question of what happens when one considers orthogonal

states on the same orbit of the time evolution as reference basis. Is it possible that a time-covariant channel destroys superpositions between them without affecting the basis states? Consider two vector states $|\phi_0\rangle$ and $|\phi_s\rangle := \exp(-iHs)|\phi_0\rangle$. Clearly, $G(|\phi_0\rangle\langle\phi_0|) = |\phi_0\rangle\langle\phi_0|$ implies

$$S_\sigma(M_\sigma * (|\phi_0\rangle\langle\phi_0|))S_\sigma^\dagger = 0$$

for all $\sigma \neq 0$. This follows from the observation that the output state can only be pure if all output operators are linearly dependent. Every $\sigma \neq 0$ would lead to a different output state. Furthermore we have

$$M_0 * (|\phi_0\rangle\langle\phi_s|) = M_0 * (|\phi_0\rangle\langle\phi_0|)e^{iHs} = |\phi_0\rangle\langle\phi_s|.$$

One can conclude easily that every density operator acting on the subspace spanned by $|\phi_0\rangle$ and $|\phi_s\rangle$ is preserved by G. A little bit more general, one has:

Theorem 5: *Let G be a time-covariant CP-map on a system with nondegenerate Hamiltonian. If there is any pure state* $|\phi\rangle\langle\phi|$ *with*

$$G(|\phi\rangle\langle\phi|) = |\phi\rangle\langle\phi|$$

then G leaves all density operators invariant which act on the Hilbert subspace spanned by all $\exp(-iHt)|\phi\rangle$.

The essential argument above is that there exist no states which are invariant with respect to S_σ for some $\sigma \neq 0$. An analog statement would not be true for covariance with respect to a discretized time evolution:

Consider the Hilbert space $l^2(\mathbb{Z})$ of square summable two-sided sequences and the discrete time evolution given by the translation $(U\psi)(n) := \psi(n+1)$. Let $(|e_n\rangle)_{n\in\mathbb{Z}}$ be the canaonical basis of $l^2(\mathbb{Z})$. Then the channel

$$\rho \mapsto \sum_{n\in\mathbb{Z}} |e_n\rangle\langle e_n|\rho|e_n\rangle\langle e_n|$$

leaves all basis states $|e_n\rangle$ invariant but destroys all superpositions.

The assumption that a pure state is preserved by G is rather strong. Actually we want to figure out whether *distiguishability* of different states in the same orbit may be conserved even though their *superpositions* are destroyed. We consider the following extreme case:

Definition 3 (Reliable timing): A time-covariant channel G has the "reliable timing property" (with respect to the time s) if there exists an input density operator ρ *and a real number s such that for* $\rho_s := \alpha_s(\rho)$ *the outputs* $G(\rho)$ *and* $G(\rho_s)$ *are perfectly distinguishable, i.e., the density matrices are mutually orthogonal.*

It is easy to verify that the input state ρ can be chosen to be pure. To justify the definition, we show that this property appears in the following situation: Assume a sender, say Alice, wants to send a signal to a receiver, say Bob. Assume furthermore that it should be guaranteed that Bob receives the signal in the time interval $[t_1, t_2]$. This requires that the physical state ρ of the signal (when it is sent) is perfectly distinguishable from the time evolved state ρ_s with $s := t_1 - t_2$. This is due to the fact that the following "measurement" distinguishes between them: wait the time t_1 and ask Bob whether he has already received the signal. If the medium between Alice and Bob modifies the signal, we may model this by a time-covariant operation G which has clearly to preserve the distinguishability of the states ρ and ρ_s.

It is clear that reliable transfer of classical information requires two states ρ and γ such that $G(\rho)$ and $G(\gamma)$ are mutually orthogonal. The above-noted remark shows that there are situations in classical information processing where two orthogonal output states should exist *on the same orbit* since reliable timing requires this feature. To see that nontrivial channels with this property exist one may construct a channel of the form

$$\rho \mapsto \sum_j p_j S_{\sigma_j} \rho S_{\sigma_j}^\dagger,$$

where the σ_j are chosen such that $\langle \phi | S_{\sigma_i}^\dagger S_{\sigma_j} \phi \rangle = 0$ for $i \neq j$. This condition is, for instance, satisfied if the minimal distance between the values σ_j exceeds the spectral bandwidth of the input state. Real physical channels will satisfy condition 3 at most approximately.

In order to consider the quantum capacity of reliable timing channels we choose ρ and $\rho_s = U_s \rho U_s^\dagger$ with $U_s := \exp(-iHs)$ such that ρ and ρ_s are mutually orthogonal. For simplicity we assume that the dynamical evolution of $G(\rho)$ is periodic. We obtain a set

$$G(\rho_0), G(\rho_s), G(\rho_{2s}), \ldots, G(\rho_{s(N-1)})$$

of N mutually perfectly distinguishable density matrices. Let P be the support of $G(\rho)$, i.e., the smallest projection with $PG(\rho) = G(\rho)$. Then the projections $U_{sj} P U_{sj}^\dagger$ with $j = 0, \ldots, N-1$ are mutually orthogonal.

Now we consider the channel with input

$$\mathbb{C}^N \equiv \mathrm{span}\{|\phi_{sj}\rangle\}_{j=0,\ldots,N-1}.$$

It is clear that there exist pure input states $|\psi_0\rangle, \ldots, |\psi_{s(N-1)}\rangle$ for which the orthogonality of the output states is satisfied. By sending either of these N states G can transfer $\log_2 N$ bits of classical information. We want to derive sufficient conditions under which G allows one to send superpositions between the chosen basis states. For doing so, we restrict G to a channel K on $N \times N$-density matrices as follows.

The input is restricted to the span of all $|\psi_{sj}\rangle$ with $j = 0, \ldots, N-1$. The corresponding output space is

$$\mathcal{H}_r := \oplus_{j=0}^{N-1} U_{sj} P U_{sj}^\dagger \mathcal{H}. \tag{37}$$

We may consider this space as the tensor product

$$\mathcal{H}_r = \mathbb{C}^N \otimes P\mathcal{H}$$

if we identify the spaces $U_{sj} P U_{sj}^\dagger \mathcal{H}$ for $j \neq 0$ with $P\mathcal{H}$ via arbitrary unitaries. It is straightforward and convenient to choose the isomorphisms U_{sj} with $j = 0, \ldots, N-1$. For any output density operator γ acting on $\mathcal{H}_r$ the entry corresponding to $|j\rangle\langle k|$ of its restriction to $\mathbb{C}^N$ is given by

$$\mathrm{tr}(U_{sk} P U_{sj}^\dagger \gamma).$$

To determine the channel K we have to compute all values

$$\mathrm{tr}(U_{sk} P U_{sj}^\dagger G(|\phi_{sl}\rangle\langle\phi_{sm}|)),$$

for $k, j, l, m \in \{0, \ldots, N-1\}$. Due to the reliable timing property we know that each state $|\phi_{sj}\rangle\langle\phi_{sj}|$ leads to the output state $|j\rangle\langle j|$. Furthermore the operator $|\phi_{sl}\rangle\langle\phi_{sm}|$ leads with certainty to a multiple of $|l\rangle\langle m|$. Roughly speaking, the reason is that a CP-map which maps the states $|m\rangle\langle m|$ and $|l\rangle\langle l|$ onto itself maps also $|l\rangle\langle m|$ onto multiples of itself. This could, for instance, be shown by reformulating the CP-map as the restriction of an appropriate unitary map (see Ref. 15). Hence we have only to determine which factors the off-diagonal terms obtain. Due to the symmetry of the channel with respect to time translations U_{sj} we have only to evaluate

$$v(j) := \mathrm{tr}(U_{sj} P G(|\phi_0\rangle\langle\phi_{sj}|)) = \mathrm{tr}(P G(|\phi_0\rangle\langle\phi_{sj}| U_{sj})).$$

Then K is explicitly given by

$$K\left(\sum_{jk} c_{jk}|j\rangle\langle k|\right) = \sum_{jk} c_{jk} v(j-k)|j\rangle\langle k|.$$

This shows that the channel K is a "Hadamard channel" even though we have not chosen the energy states as reference basis but the states $|\phi_{sj}\rangle$ instead. Furthermore, K is given by Hadamard multiplication with a *circulant* matrix V with entries $V_{ij} := v(i-j)$. In order to calculate v we use the explicit form of G according to Theorem 3. Using Lemma 1 this yields

$$v(j) = \int \mathrm{tr}(G_\sigma(|\phi_0\rangle\langle\phi_0|)e^{-i\sigma sj}\mathrm{d}\nu(\sigma) = f_{|\phi_0\rangle\langle\phi_0|,\mathbf{1}}(-sj),$$

i.e., the Fourier transform of the energy shift probability measure $\nu_{|\phi_0\rangle\langle\phi_0|,\mathbf{1}}$ evaluated at the points $-sj$. The eigenvalues $q_0,\ldots,q_{M-1}$ of V/n are given by the inverse Fourier transform of v:

$$q_k := \frac{1}{N}\sum_{j=0}^{N-1} v(j)e^{-ijk}.$$

Using Lemma 5 we conclude:

Theorem 6 (Q-capacity of channels with reliable timing): *Let G be a time-covariant channel with reliable timing property with respect to the time s and the initial state $|\phi_0\rangle$. Let the dynamics be periodic with period length sN. Then the quantum capacity can only be zero if the Fourier transform $\hat{p}$ of the probability measure $p(m) := \mathrm{tr}(G_m(|\phi_0\rangle\langle\phi_0|))$ has zeros at sj for $j = 1,\ldots,N-1$. Otherwise the quantum capacity is at least*

$$\log_2 N - \sum_k q_k \log_2 q_k,, \tag{38}$$

where $q=(q_0,\ldots,q_{N-1})$ is the discrete Fourier transform of the evaluation of $f_{|\phi_0\rangle\langle\phi_0|,\mathbf{1}}$ on the N points $0, -s, -2s, \ldots, -(N-1)s$.

Of course there are many possibilities to define finite dimensional channels from the original one. However, to study whether G destroys superpositions between different states in the orbit ("different pointer states of a clock") one has always to consider

$$G(|\phi_0\rangle\langle\phi_{sj}|) = \hat{G}_{-sj}(|\phi_0\rangle\langle\phi_0|)e^{iHsj}.$$

This shows that the Fourier transform of the measure (G_m) is decisive. For deriving the lower bound above we have evaluated it for the observable $\mathbf{1}$ which leads to the Fourier transform of the POVM (Q_m) defined in the last section. However, $\mathbf{1}$ is not necessarily optimal for detecting superpositions between the output states.

VIII. GAUSSIAN CHANNEL ON A SINGLE MODE

The Hilbert space of a single mode in quantum optics is $l^2(\mathbb{N}_0)$, the set of square summable sequences. It can also be interpreted as the energy levels of a harmonic oscillator. A time-covariant channel which is often considered is the following. As usual, we introduce the creation operator $a^\dagger$ and the annihilation operator a by $a|j\rangle := \sqrt{j}|j-1\rangle$ for $j \geqslant 1$ and $a|0\rangle = 0$. Using position and momentum observables X and P, respectively, we define a translation $(a_1,a_2) \in \mathbb{R}^2$ by the unitary transformation $\exp(i(a_1X+a_2P))$, where $X := a^\dagger + a$ and $P := (a^\dagger - a)/i$. It is convenient to introduce variables $r \in \mathbb{R}_0^+$ and z on the complex unit circle Γ by $a_1 + ia_2 = rz$. Rewriting the translation with operators $a^\dagger$ and a and the parameters z,r we obtain the translation operator (compare Ref. 25) by

$$D(z,r) := \exp(r(\bar{z}a^\dagger - za)) = e^{ir^2/2}e^{r\bar{z}a^\dagger}e^{-rza}.$$

Since the global phase factor is irrelevant we will, in abuse of notation, use $D(z,r)$ for the term without this factor.

Let the Gaussian channel be given by a random displacement rz according to the two-dimensional rotation invariant Gauss distribution. Note that rotation symmetry is necessary in order to obtain a time-covariant channel since the Hamiltonian $H:=diag(0,1,2,\ldots)$ corresponds to a rotation in the "phase space." Note that the possible energy shifts are in $\mathbb{Z}$, hence we expect a countable sum of G_σ which are (in contrary to the general case) not only densely defined.

The whole channel is given by (see Ref. 26)

$$G(\rho)=\int\int_{\Gamma} D(z,r)\rho D(\bar{z},r)\mathrm{d}z p(r)\mathrm{d}r$$

with $p(r):=\exp(-r^2/(2s^2))r/s^2$ and s denotes the standard deviation.

Then we write $D(z,r)$ as the power series

$$D(z,r)=e^{r\bar{z}a^\dagger}e^{-rza}=\sum_{m\geqslant 0}\frac{(r\bar{z})^n(a^\dagger)^m}{m!}\sum_{n\geqslant 0}\frac{(-rz)^n a^n}{n!}. \tag{39}$$

It decomposes canonically into terms $D_\sigma(z,r)$ with $\sigma\in\mathbb{Z}$ satisfying the commutation relation $[H,D_\sigma(z,r)]=\sigma D_\sigma(z,r)$ if we define

$$D_\sigma(z,r):=\sum_{n\geqslant -\sigma,0}\frac{(r\bar{z})^{n+\sigma}(a^\dagger)^{n+\sigma}}{(n+\sigma)!}\frac{(-rz)^n a^n}{n!}=\bar{z}^\sigma r^\sigma\sum_{n\geqslant -\sigma,0}(-1)^n\frac{(a^\dagger)^{n+\sigma}}{(n+\sigma)!}\frac{a^n}{n!}(r^2)^n.$$

Note that $D_\sigma(z,r)$ maps states with energy j onto states with energy $j+\sigma$. This suggests already that they may correspond to the maps G_σ of Sec. VI. The operator

$$D_\sigma(r):=D_\sigma(z,r)z^\sigma\sqrt{2\pi}$$

is independent of z. We conclude therefore that terms of the form $D_\sigma(\bar{z},r)\rho D_{\sigma'}(z,r)$ cancel for $\sigma\neq\sigma'$ after integration over all $z\in\Gamma$. We obtain

$$G(\rho)=\sum_{\sigma\in\mathbb{Z}}\int D_\sigma(r)\rho D_\sigma(r)p(r)\mathrm{d}r.$$

Consider the case $\sigma\geqslant 0$ first. Then we have

$$(a^\dagger)^{n+\sigma}a^n|j\rangle=\sqrt{(j+\sigma)\ldots(j+1)}j(j-1)\ldots(j-n+1)|j+\sigma\rangle=\frac{1}{\sqrt{(j+1)\ldots(j+\sigma)}}\frac{(j+\sigma)!}{(j-n)!}|j+\sigma\rangle,$$

for all $n\leqslant j$. For the case $\sigma<0$ we obtain

$$(a^\dagger)^{n+\sigma}a^n|j\rangle=\sqrt{j(j-1)\ldots(j+\sigma+1)}\frac{(j+\sigma)!}{(j-n)!}|j+\sigma\rangle.$$

For $\sigma\geqslant 0$ we conclude

$$\begin{aligned}D_\sigma(r)|j\rangle&=\frac{r^\sigma}{\sqrt{(j+1)\ldots(j+\sigma)}}\sum_{n=0}^{j}(-1)^n\frac{(j+\sigma)!}{(j-n)!\,(n+\sigma)!\,n!}(r^2)^n|j+\sigma\rangle\\&=\frac{r^\sigma}{\sqrt{(j+1)\ldots(j+\sigma)}}L_j^\sigma(r^2)|j+\sigma\rangle,\end{aligned}$$

where

$$L_j^{(\sigma)}(x):=\sum_{n=0}^{j}(-1)^n\frac{(j+\sigma)!}{(j-n)!\,(n+\sigma)!\,n!}(x)$$

is a Laguerre polynomial.[27]

Hence we have

$$M_\sigma(j,j') = \int \frac{(r^2)^\sigma}{\sqrt{(j+1)\ldots(j+\sigma)(j'+1)\ldots(j'+\sigma)}} L_j^{(\sigma)}(r^2) L_{j'}^{(\sigma)}(r^2) p(r) \mathrm{d}r.$$

For negative σ we may express M_σ similarly by Laguerre polynomials together with a different factor. Hence the decomposition of the single mode Gaussian channel can be given in a closed form even though it leads to a less familiar representation.

IX. CONCLUSIONS

We have shown that every time-covariant CP-map has a representation as an integral over a family of CP-maps. If the spectrum of the system Hamiltonian is nondegenerate, each of these components consists of a Hadamard multiplication with a positive operator followed by an energy shift. Formally, the output of the channel is an unselected post-measurement state. The measured (and ignored) quantity is the energy which has been transferred to or from the environment. Conditional to the measurement outcome a different dephasing channel is applied.

Furthermore we have addressed the question to what extent covariant channels can destroy superpositions between N mutually orthogonal states on the same orbit of the time evolution. For a specific type of channels (with "reliable timing property") we have shown that the general decomposition helps to derive lower bounds on the quantum capacity.

The decomposition presented here may be a helpful approach to describe a rather general type of decoherence and relaxation phenomena.

We have calculated the decomposition explicitly for a rotation invariant Gaussian channel acting on the state space of a single mode Fock space. The dephasing operations can then be described using Laguerre polynomials.

A de Finetti representation for finite symmetric quantum states

Robert König[a] and Renato Renner[b]
Swiss Federal Institute of Technology (ETH) Zurich, 8092 Zurich, Switzerland

(Received 4 April 2005; accepted 26 October 2005; published online 30 December 2005)

Consider a *symmetric* quantum state on an n-fold product space, that is, the state is invariant under permutations of the n subsystems. We show that, conditioned on the outcomes of an informationally complete measurement applied to a number of subsystems, the state in the remaining subsystems is close to having product form. This immediately generalizes the so-called de Finetti representation to the case of finite symmetric quantum states. © *2005 American Institute of Physics.*

I. INTRODUCTION

The analysis of physical experiments is often based on the assumption that the same experiment can be repeated many times independently. In particular, one usually assumes that the results $Z_1,\ldots,Z_n$ obtained from n repetitions of the same experiment are distributed according to some product distribution, i.e., $P_{Z_1\cdots Z_n}=(P_Z)^n$. In practical situations, however, the independence of the individual outcomes Z_i can usually not be guaranteed.

The so-called de Finetti representation theorem[6] can be seen as a solution to this problem. (See Ref. 15 for a collection of de Finetti's original papers.) Basically, it states that the assumption on the product structure of $P_{Z_1\cdots Z_n}$ can be replaced by a seemingly weaker assumption, namely that the distribution of the outcomes of infinitely many repetitions of the experiment is invariant under reordering. For instance, this is the case if the n samples $Z_1,\ldots,Z_n$ are randomly chosen from infinitely many repetitions of the experiment.

Let us briefly explain this result on a more formal level. We say that an n-partite probability distribution $P_{Z_1\cdots Z_n}$ is *symmetric* if it is invariant under any permutation of the random variables $Z_1,\ldots,Z_n$. If $P_{Z_1\cdots Z_n}$ is the marginal of a symmetric distribution $P_{Z_1\cdots Z_m}$ of $m\geqslant n$ random variables, then $P_{Z_1\cdots Z_n}$ is called *m-exchangeable.* Moreover, $P_{Z_1\cdots Z_n}$ is *infinitely exchangeable* if it is m-exchangeable for all $m\geqslant n$. The result of de Finetti now states that any infinitely exchangeable probability distribution $P_{Z_1\cdots Z_n}$ can be written as a convex combination of products $(P_Z)^n$ of n identical distributions.

This result has been generalized in different directions. Diaconis and Freedman[7] analyzed the structure of m-exchangeable probability distributions of n random variables, for $n\leqslant m<\infty$. This is of particular interest for practical applications, where the number of experiments is only finite. They found that, for appropriate values of n and m, these distributions are still close to the convex hull of the set of product distributions $(P_Z)^n$.

The result of de Finetti has also been extended to quantum states, to which the notion of symmetry and exchangeability can be adapted in an obvious way. Hudson and Moody[13] showed that any infinitely exchangeable quantum state $\rho^{\bar{n}}$ over n subsystems is a convex combination of product states, i.e., $\rho^{\bar{n}}=\Sigma_{\mathbf{z}}p_{\mathbf{z}}(\rho_{\mathbf{z}})^{\otimes n}$, for appropriate weights $p_{\mathbf{z}}$ (see also Ref. 11). An alternative proof of this claim has recently been presented by Caves, Fuchs, and Schack[4] (see also Ref. 8), relying on the original result of de Finetti.

In this paper, we analyze the structure of m-exchangeable quantum states over n subsystems, for $n \leqslant m < \infty$. In a sense, our result combines the two mentioned directions of generalizing de Finetti's result. Note that any m-exchangeable state $\rho^{\bar{n}}$ over n subsystems can be extended to an m-exchangeable state $\rho^{\overline{n+k}}$ over $n+k$ subsystems, for $n+k \leqslant m$. We show that the state $\rho_{\mathbf{z}}^{\bar{n}}$ of the first n subsystems, conditioned on the outcomes $\mathbf{z}=(z_1,\ldots,z_k)$ of an informationally complete measurement applied to each of the remaining k subsystems, is close to the n-fold product state $(\rho_{\mathbf{z}}^{\bar{1}})^{\otimes n}$, where $\rho_{\mathbf{z}}^{\bar{1}}$ is the state $\rho_{\mathbf{z}}^{\bar{n}}$ restricted to one subsystem. (The density operator $\rho_{\mathbf{z}}^{\bar{1}}$ is obtained from $\rho_{\mathbf{z}}^{\bar{n}}$ by taking the trace over $n-1$ subsystems.) In particular, since $\rho^{\bar{n}}$ can be written as a convex combination of the states $\rho_{\mathbf{z}}^{\bar{n}}$, i.e., $\rho^{\bar{n}}=\Sigma_{\mathbf{z}} p_{\mathbf{z}} \rho_{\mathbf{z}}^{\bar{n}}$, this immediately implies that $\rho^{\bar{n}}$ is close to the convex combination $\Sigma_{\mathbf{z}} p_{\mathbf{z}} (\rho_{\mathbf{z}}^{\bar{1}})^{\otimes n}$. As in the classical case, the distance between the m-exchangeable state $\rho^{\bar{n}}$ and the convex hull of the set of product states depends on the values m and n. In particular, for any fixed m, as n tends to infinity, we recover the result of Refs. 13 and 4. [A somewhat different generalization of the de Finetti theorem has been proposed in Ref. 16, where it is shown that the set of states on an infinite tensor product satisfying a weaker symmetry condition than exchangeability is identical to the convex hull of m-dependent states (which corresponds to product states if $m=0$).]

Quantum de Finetti-style theorems are crucial for a Bayesian interpretation of quantum mechanics (see Ref. 8). Moreover, they can be used in various applications such as entanglement purification[3] and the study of entanglement in general.[12] In fact, many information-theoretic tasks, e.g., entanglement purification or quantum key distillation, are well understood in the special case where the states to be considered have product form. According to the de Finetti theorem, this is equivalent to saying that the state is a part of a state on infinitely many subsystems which is invariant under reordering of the subsystems. Our result relaxes this requirement to a finite number of subsystems only. This is important for realistic situations, where such a symmetry can be obtained by applying a randomly chosen permutation. [A remarkable example illustrating the power of the quantum de Finetti theorem is in the context of quantum cryptography.[1] Many security proofs for quantum key distribution (QKD) schemes only hold against so-called *collective* attacks,[2] where one assumes that the states generated by an adversary have product form. On the other hand, the ultimate goal is to prove security against the most general, so-called *coherent,* attacks. Because any state on a product system can be turned into a symmetric state by applying a random permutation, the finite quantum de Finetti representation theorem can be used to show that coherent attacks are not stronger than collective attacks.]

Outline of the paper: In Sec. II, we introduce some basic notation and definitions, including the notion of symmetry and exchangeability. Additionally, we briefly review the properties of the variational distance between probability distributions, as well as its quantum analogue, the trace distance between density operators. Sections III–VI are devoted to the proof of our main results on the structure of symmetric quantum states. Generally speaking, our proof is based on the analysis of the statistics obtained when applying informationally complete POVMs to symmetric quantum states. We will thus be interested in good POVMs in the sense that the measurement statistics gives maximal information about the measured state. Constructing such POVMs is the main purpose of Sec. III, which is somehow independent of the remaining part of the paper. In Sec. IV, we analyze classical symmetric probability distributions and derive bounds on their distance to product distributions. In Sec. V, it is shown how to deduce structural properties of quantum states from the corresponding properties of the measurement statistics, using the POVMs constructed in Sec. III. Finally, in Sec. VI, we combine these results to obtain our main statements, including a de Finetti representation for finitely exchangeable quantum states. Additionally, in the Appendix, we present an alternative version of these statements which might be more suitable for certain applications.

II. PRELIMINARIES

A. Density operators, POVMs, and probability distributions

Throughout this paper, we will restrict our attention to finite-dimensional Hilbert spaces, denoted by $\mathcal{H}$ or $\mathcal{H}_A$, for some index A. Let $\mathrm{Herm}(\mathcal{H})$ the set of Hermitian endomorphisms on $\mathcal{H}$.

An element $\rho \in \mathrm{Herm}(\mathcal{H})$ is called a *density operator* or, equivalently, a *quantum state* on $\mathcal{H}$ if it is positive semidefinite, $\rho \geqslant 0$, and has trace one, $\mathrm{tr}(\rho)=1$. We denote by $\mathrm{S}(\mathcal{H})$ the set of density operators on $\mathcal{H}$. A *positive operator valued measure (POVM)* on $\mathcal{H}$ is a family $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ of non-negative operators $F_z \in \mathrm{Herm}(\mathcal{H})$, $F_z \geqslant 0$, such that $\Sigma_{z\in\mathcal{Z}} F_z = \mathrm{id}_{\mathcal{H}}$. The POVM $\mathfrak{Z}$ is called *informationally complete* if it is a basis of $\mathrm{Herm}(\mathcal{H})$.

To improve the readability of formulas involving density operators on product spaces, we use superscripts to indicate which subsystems an operator acts on, e.g., we write ρ^{ABC} for a density operator on $\mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}_C$. Operators with the same name but different superscripts are related to each other by the partial trace. For example, ρ^{AB} is the partial state obtained from ρ^{ABC} by tracing over $\mathcal{H}_C$, i.e., $\rho^{AB}=\mathrm{Tr}_C(\rho^{ABC})$, and, similarly, $\rho^{A}=\mathrm{Tr}_{BC}(\rho^{ABC})$. This notation is consistent since partial traces over different subsystems commute, e.g., we have $\rho^A=\mathrm{Tr}_B(\rho^{AB})=\mathrm{Tr}_C(\rho^{AC})=\mathrm{Tr}_{BC}(\rho^{ABC})$.

A similar formalism can be used to denote conditional quantum states. Let ρ^{AB} be a density operator on $\mathcal{H}_A \otimes \mathcal{H}_B$ and let $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ be a POVM on $\mathcal{H}_B$. Then $\rho^A{}_{|\mathfrak{Z}=z}$ denotes the quantum state on $\mathcal{H}_A$ conditioned on the event that the outcome of the measurement $\mathfrak{Z}$ applied to the subsystem $\mathcal{H}_B$ equals $z \in \mathcal{Z}$, i.e.,

$$\rho^A{}_{|\mathfrak{Z}=z} := \frac{1}{\mathrm{tr}((\mathrm{id}_A \otimes F_z)\rho^{AB})} \mathrm{Tr}_B((\mathrm{id}_A \otimes F_z)\rho^{AB}).$$

The notation can be extended to density operators over three and more subsystems in an obvious way. Note that, since the partial trace and the operation of conditioning on a measurement result commute, this is compatible with our notation for partial states. For instance, if ρ^{ABC} is a tripartite density operator, then the conditional states $\rho^A{}_{|\mathfrak{Z}=z}$ and $\rho^{AC}{}_{|\mathfrak{Z}=z}$ are related by the partial trace, i.e., $\rho^A{}_{|\mathfrak{Z}=z}=\mathrm{Tr}_C(\rho^{AC}{}_{|\mathfrak{Z}=z})$.

We will use a similar formalism to denote the probability distributions resulting from measurements of quantum states. Let ρ^A be a density operator and let $\mathfrak{Y}=\{E_y\}_{y\in\mathcal{Y}}$ be a POVM on $\mathcal{H}_A$. Then $\rho^A_{\mathfrak{Y}}$ denotes the distribution of the outcome of the measurement $\mathfrak{Y}$ applied to ρ^A, i.e.,

$$\rho^A_{\mathfrak{Y}}(y) = \mathrm{tr}(E_y\rho), \quad \text{for all } y \in \mathcal{Y}.$$

This can easily be generalized to product systems. For example, if $\mathfrak{Y}$ and $\mathfrak{Z}$ are POVMs on $\mathcal{H}_A$ and $\mathcal{H}_B$, respectively, then $\rho^{AB}_{\mathfrak{Y}\mathfrak{Z}}$ is the probability distribution of the outcome of the product measurement $\mathfrak{Y}\otimes\mathfrak{Z}$ applied to ρ^{AB}.

Note that the operation of taking the partial trace of a density operator has a classical analogue, namely taking the marginal distribution. Similarly, the operation of conditioning a quantum state on a measurement result corresponds to conditioning a probability distribution on the value of a random variable. Our formalism is consistent with respect to these operations in the sense that the following diagram commutes:

$$\begin{array}{ccccc}
\rho^A{}_{|\mathfrak{Z}=z} & \xleftarrow{\text{cond.}} & \rho^{AB} & \xrightarrow{\text{trace}} & \rho^A \\
\text{meas.}\downarrow & & \text{meas.}\downarrow & & \text{meas.}\downarrow \\
\rho^A_{\mathfrak{Y}|\mathfrak{Z}=z} & \xleftarrow{\text{cond.}} & \rho^{AB}_{\mathfrak{Y}\mathfrak{Z}} & \xrightarrow{\text{marginal}} & \rho^A_{\mathfrak{Y}}
\end{array}$$

Let P be a probability distribution on $\mathcal{Z}$ and let, for each $z \in \mathcal{Z}$, ρ_z be a density operator on $\mathcal{H}$. We will often write the weighted sum of ρ_z as an expectation value, i.e.,

$$\mathop{\mathbb{E}}_{z\leftarrow P}[\rho_z] := \sum_{z\in\mathcal{Z}} P(z)\rho_z.$$

If the probability distribution is clear from the context, we only write $\mathbb{E}_z[\rho_z]$. For example, using our formalism, we have

$$\mathop{\mathbb{E}}_{z\leftarrow\rho_3^B}[\rho^A_{|3=z}]=\rho^A, \tag{1}$$

for any bipartite quantum state ρ^{AB} on $\mathcal{H}_A\otimes\mathcal{H}_B$. This is a simple reformulation of the fact that the partial state ρ^A on $\mathcal{H}_A$ does not change when a measurement is applied to the subsystem $\mathcal{H}_B$.

B. Distance measures

Let $\mathrm{Distr}(\mathcal{Z})$ be the set of probability distributions on the set $\mathcal{Z}$. The *variational distance* between two probability distributions $P,Q\in\mathrm{Distr}(\mathcal{Z})$ is defined by

$$\delta(P,Q):=\frac{1}{2}\sum_{z\in\mathcal{Z}}|P(z)-Q(z)|.$$

The variational distance is a metric on $\mathrm{Distr}(\mathcal{Z})$. In particular, $\delta(P,Q)=0$ if and only if $P=Q$, δ is symmetric, $\delta(P,Q)=\delta(Q,P)$, and the triangle inequality holds, $\delta(P,R)\leqslant\delta(P,Q)+\delta(Q,R)$. For two bipartite distributions P_{XY} and$P_{X'Y'}$, the variational distance cannot increase when taking the marginals,

$$\delta(P_X,P_{X'})\leqslant\delta(P_{XY},P_{X'Y'}). \tag{2}$$

If P_{XY} and $P_{X'Y'}$ have the same marginals $P_X=P_{X'}$, their distance can be expressed as the expectation value of the distance between their conditional probability distributions,

$$\delta(P_{XY},P_{X'Y'})=\mathop{\mathbb{E}}_{x\leftarrow P_X}[\delta(P_{Y|X=x},P_{Y'|X'=x})]:=\sum_x P_X(x)\delta(P_{Y|X=x},P_{Y'|X'=x}). \tag{3}$$

In particular, if the distributions have product form

$$\delta(P_X\times P_Y,P_X\times P_{Y'})=\delta(P_Y,P_{Y'}). \tag{4}$$

A similar distance measure can be defined on the set $\mathrm{Herm}(\mathcal{H})$ of Hermitian operators on $\mathcal{H}$, using the trace norm $\|\cdot\|_1$ on $\mathrm{Herm}(\mathcal{H})$, which is defined as $\|W\|_1:=\mathrm{tr}(|W|)$ for every $W\in\mathrm{Herm}(\mathcal{H})$. [For an operator $T\in\mathrm{Herm}(\mathcal{H})$, the operator norm of T is the value $\|T\|:=\sup_{v\in\mathcal{H}:\|v\|\leqslant 1}\|Tv\|$, where $\|v\|:=\sqrt{\langle v|v\rangle}$ for every $v\in\mathcal{H}$. It is easy to see that

$$\|W\|_1=\sup_{T:\|T\|\leqslant 1}|\mathrm{tr}(WT)|, \tag{5}$$

where the supremum is over all operators $T\in\mathrm{Herm}(\mathcal{H})$ with $\|T\|\leqslant 1$. From (5), it follows that $\|\cdot\|_1$ is a norm, as the right-hand side (rhs) of (5) is the norm of the linear functional $\mathrm{tr}(W\cdot)$ in the dual space $\mathrm{Herm}(\mathcal{H})^*$ and the embedding $W\mapsto\mathrm{tr}(W\cdot)$ is an isomorphism of $\mathrm{Herm}(\mathcal{H})$ to its dual.] The *trace distance* between two operators $U,V\in\mathrm{Herm}(\mathcal{H})$ is then given by

$$\delta(U,V):=\tfrac{1}{2}\|U-V\|_1.$$

Many properties of the variational distance also hold for the trace distance. In particular, the trace distance is a metric on $\mathrm{Herm}(\mathcal{H})$. Moreover, similarly to (2), the trace distance cannot increase when taking the partial trace, i.e., for $U,V\in\mathrm{Herm}(\mathcal{H}_A\otimes\mathcal{H}_B)$,

$$\delta(\mathrm{Tr}_B(U),\mathrm{Tr}_B(V))\leqslant\delta(U,V). \tag{6}$$

[More generally, $\delta(\mathcal{E}(U),\mathcal{E}(V))\leqslant\delta(U,V)$ for any trace-preserving quantum operation $\mathcal{E}:\mathrm{Herm}(\mathcal{H})\to\mathrm{Herm}(\mathcal{H}')$, which can most generally be written as $\mathcal{E}(U):=\sum_k E_kUE_k^\dagger$ for operators $E_k:\mathcal{H}\to\mathcal{H}'$. To prove this, it suffices to show that $\|\mathcal{E}(W)\|_1\leqslant\|W\|_1$, for every $W\in\mathrm{Herm}(\mathcal{H})$. Note that the operator norm of an operator $T\in\mathrm{Herm}(\mathcal{H})$ can equivalently be written as $\|T\|=\sup_{\sigma\in\mathrm{S}(\mathcal{H})}\mathrm{tr}(T\sigma)$. Defining the operation $\mathcal{E}^\dagger:\mathrm{Herm}(\mathcal{H}')\to\mathrm{Herm}(\mathcal{H})$ by $\mathcal{E}^\dagger(T'):=\sum_k E_k^\dagger T'E_k$ for $T'\in\mathrm{Herm}(\mathcal{H}')$, we have the identity $\mathrm{tr}(\mathcal{E}^\dagger(T')W)=\mathrm{tr}(T'\mathcal{E}(W))$ for any operators W

$\in \mathrm{Herm}(\mathcal{H}), T' \in \mathrm{Herm}(\mathcal{H}')$. Hence $\|\mathcal{E}^\dagger(T')\| = \sup_{\sigma\in \mathrm{S}(\mathcal{H})} \mathrm{tr}(\mathcal{E}^\dagger(T')\sigma) = \sup_{\sigma\in \mathrm{S}(\mathcal{H})} \mathrm{tr}(T'\mathcal{E}(\sigma)) \leqslant \|T'\|$ since $\mathcal{E}(\sigma) \in \mathrm{S}(\mathcal{H}')$ for any $\sigma \in \mathrm{S}(\mathcal{H})$. Using (5), this implies that $\|\mathcal{E}(W)\|_1 = \sup_{T':\|T'\|\leqslant 1} |\mathrm{tr}(\mathcal{E}(W)T')| = \sup_{T':\|T'\|\leqslant 1} |\mathrm{tr}(W\mathcal{E}^\dagger(T'))| \leqslant \sup_{T:\|T\|\leqslant 1} \mathrm{tr}(WT) = \|W\|_1$, as required.] We will also use the strong convexity of the trace distance, which follows directly from the triangle inequality of $\|\cdot\|_1$, i.e., for any $U, U', V, V' \in \mathrm{Herm}(\mathcal{H})$ and $p, q \in [0,1]$ with $p+q=1$,

$$\delta(pU + qU', pV + qV') \leqslant p\,\delta(U,V) + q\,\delta(U',V').$$

The following lemma gives a simple expression for the trace distance between two product operators $U \otimes V$ and $U' \otimes V$ with a common factor V.

Lemma II.1: Let $U, U' \in \mathrm{Herm}(\mathcal{H}_A)$ *and* $V \in \mathrm{Herm}(\mathcal{H}_B)$. *Then*

$$\delta(U \otimes V, U' \otimes V) = \delta(U,U') \cdot \mathrm{tr}(|V|).$$

Proof: By definition,

$$\delta(U \otimes V, U' \otimes V) = \mathrm{tr}|(U - U') \otimes V|. \tag{7}$$

We use the following general fact, which can be verified easily using the appropriate definitions. Let $f: \mathbb{C} \to \mathbb{C}$ be a function satisfying

$$f(a \cdot b) = f(a) \cdot f(b) \quad \text{for all } a,b \in \mathbb{C}.$$

Then

$$f(A \otimes B) = f(A) \otimes f(B)$$

for all $A, B \in \mathrm{Herm}(\mathcal{H})$. Applying this to Eq. (7) yields

$$|(U - U') \otimes V| = |(U - U')| \otimes |V|.$$

The assertion then follows from the identity $\mathrm{tr}(A \otimes B) = \mathrm{tr}(A) \cdot \mathrm{tr}(B)$. □

As an immediate consequence of Lemma II.1, we obtain the equation

$$\delta(\rho \otimes \sigma, \rho' \otimes \sigma) = \delta(\rho, \rho'), \tag{8}$$

for states $\rho, \rho' \in \mathrm{S}(\mathcal{H}_A)$ and $\sigma \in \mathrm{S}(\mathcal{H}_B)$, which is the quantum analogue of (4). The trace distance between two density operators ρ and σ on $\mathcal{H}$ corresponds to the variational distance between the probability distributions $\rho_{\mathfrak{Z}}$ and $\sigma_{\mathfrak{Z}}$ of the outcomes of a measurement applied to ρ and σ, respectively, for an optimal POVM $\mathfrak{Z}$ on $\mathcal{H}$, i.e.,

$$\delta(\rho,\sigma) = \max_{\mathfrak{Z}} \delta(\rho_{\mathfrak{Z}}, \sigma_{\mathfrak{Z}}). \tag{9}$$

C. Symmetry and exchangeability

1. Symmetric probability distributions and symmetric functions

Let $\mathbf{z} = (z_1, \ldots, z_n) \in \mathcal{Z}^n$ and $\mathbf{z}' = (z'_1, \ldots, z'_m) \in \mathcal{Z}^m$ be tuples of elements from a set $\mathcal{Z}$. We denote by $(\mathbf{z}, \mathbf{z}')$ the $(n+m)$-tuple obtained by concatenating $\mathbf{z}$ and $\mathbf{z}'$, i.e., $(\mathbf{z}, \mathbf{z}') := (z_1, \ldots, z_n, z'_1, \ldots, z'_m)$.

The *frequency distribution* $Q_{\mathbf{z}}$ of an n-tuple $\mathbf{z} = (z_1, \ldots, z_n) \in \mathcal{Z}^n$ is the function with domain $\mathcal{Z}$ defined by (we denote by $[n]$ the set of natural numbers between 1 and n, i.e., $[n] := \{1, \ldots, n\}$)

$$Q_{\mathbf{z}}(z) := \frac{1}{n} |\{i \in [n] : z_i = z\}|, \quad \text{for every } z \in \mathcal{Z},$$

i.e., $Q_{\mathbf{z}}(z)$ is the relative number of occurrences of the symbol z in $\mathbf{z}$. Note that $Q_{\mathbf{z}}$ is a probability distribution on $\mathcal{Z}$, $Q_{\mathbf{z}} \in \mathrm{Distr}(\mathcal{Z})$.

A symmetric function f on $\mathcal{Z}^n$ is a function such that $f(\mathbf{z})$ is invariant under permutations of the entries in $\mathbf{z}$. The value $f(\mathbf{z})$ then only depends on the frequency distribution $Q_{\mathbf{z}}$ of $\mathbf{z}$. For a formal definition, let S_n be the set of permutations on $[n]$, and let, for any $\pi \in S_n$, $\pi_{\mathcal{Z}}$ be the bijection on $\mathcal{Z}^n$ defined by

$$\pi_{\mathcal{Z}}:(z_1, \ldots, z_n) \mapsto (z_{\pi(1)}, \ldots, z_{\pi(n)}), \quad \text{for all } (z_1, \ldots, z_n) \in \mathcal{Z}^n.$$

Definition II.2: A function f with domain $\mathcal{Z}^n$ is called symmetric *if*

$$f = f \circ \pi_{\mathcal{Z}}, \quad \textit{for all } \pi \in S_n.$$

In particular, a probability distribution $P_{\mathbf{Z}} \in \mathrm{Distr}(\mathcal{Z}^n)$ on $\mathcal{Z}^n$ is called *symmetric* if $P_{\mathbf{Z}}$ is a symmetric function. The following lemma is an immediate consequence of these definitions.

Lemma II.3: Let $\mathbf{Z}$ be an n-tuple of random variables over a set $\mathcal{Z}$ such that $P_{\mathbf{Z}}$ is symmetric, and let Y be a random variable over $\mathcal{Y}$ defined by a channel $P_{Y|\mathbf{Z}}$ such that for every $y \in \mathcal{Y}$, the function $\mathbf{z} \mapsto P_{Y|\mathbf{Z}=\mathbf{z}}(y)$ is symmetric. Then, for every $y \in \mathcal{Y}$, the conditional probability distribution $P_{\mathbf{Z}|Y=y}$ is symmetric.

In particular, if $f: \mathcal{Z}^n \to \mathcal{Y}$ is a symmetric function and $P_{\mathbf{Z}}$ is symmetric, then, for any $y \in \mathcal{Y}$, $P_{\mathbf{Z}|f(\mathbf{Z})=y}$ is symmetric. An example is the function mapping any n-tuple $\mathbf{z}$ to the frequency distribution $Q_{\mathbf{z}}$, i.e., $P_{\mathbf{Z}|Q_{\mathbf{Z}}=q}$ is symmetric. [$Q_{\mathbf{Z}}$ is the random variable defined by $Q_{\mathbf{z}}$, for $\mathbf{z}$ randomly chosen according to $P_{\mathbf{Z}}$, that is, $P_{Q_{\mathbf{Z}}}(q) := \mathbb{P}_{\mathbf{z} \leftarrow P_{\mathbf{Z}}}[Q_{\mathbf{z}} = q]$.] The following lemma is an immediate consequence of this fact.

Lemma II.4: Let $\mathbf{Z} = (Z_1, \ldots, Z_n)$ be an n-tuple of random variables over a set $\mathcal{Z}$ such that $P_{\mathbf{Z}}$ is symmetric. Then, for any $q \in \mathrm{Distr}(\mathcal{Z})$,

$$P_{Z_i|Q_{\mathbf{Z}}=q} = q, \quad \textit{for every } i \in [n].$$

2. Symmetric and exchangeable density operators

For any permutation $\pi \in S_n$, let $\pi_{\mathcal{H}}$ be the unique endomorphism on $\mathcal{H}^{\otimes n}$ satisfying

$$\pi_{\mathcal{H}}(|\phi_1\rangle \otimes \cdots \otimes |\phi_n\rangle) = |\phi_{\pi(1)}\rangle \otimes \cdots \otimes |\phi_{\pi(n)}\rangle, \quad \text{for all } |\phi_1\rangle, \ldots, |\phi_n\rangle \in \mathcal{H}.$$

It is easy to verify that $\pi_{\mathcal{H}}$ is unitary. Let $\rho^{B_1 \cdots B_n}$ be a density operator on $\mathcal{H}_{B_1} \otimes \cdots \otimes \mathcal{H}_{B_n}$ where, for all $i \in [n]$, $\mathcal{H}_{B_i} = \mathcal{H}$, i.e., $\rho^{B_1 \cdots B_n} \in \mathrm{S}(\mathcal{H}^{\otimes n})$. The state $\rho^{B_1 \cdots B_n}$ is called *symmetric* if $\rho^{B_1 \cdots B_n} = \pi_{\mathcal{H}} \rho^{B_1 \cdots B_n} \pi_{\mathcal{H}}^{\dagger}$ for every $\pi \in S_n$. The following definition generalizes this concept to include an additional system $\mathcal{H}_A$.

Definition II.5: A density operator $\rho^{AB_1 \cdots B_n} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n})$ is called symmetric relative to $\mathcal{H}_A$ *if*

$$\rho^{AB_1 \cdots B_n} = (\mathrm{id}_A \otimes \pi_{\mathcal{H}}) \rho^{AB_1 \cdots B_n} (\mathrm{id}_A \otimes \pi_{\mathcal{H}}^{\dagger}), \quad \textit{for all } \pi \in S_n.$$

Let $\rho^{AB_1 \cdots B_n} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n})$ be symmetric relative to $\mathcal{H}_A$. Then, for any choice of r distinct indices $i_1, \ldots, i_r \in [n]$, $r \in [n]$, the state $\rho^{AB_{i_1} \cdots B_{i_r}}$ is symmetric relative to $\mathcal{H}_A$. Since it only depends on the number r of distinct indices, we will write $\rho^{A\overline{r}}$ instead of $\rho^{AB_{i_1} \cdots B_{i_r}}$.

Similarly, for every $\mathbf{z} \in \mathcal{Z}^s$, the density operator $\rho^{AB i_1 \cdots B_{i_{n-s}}}_{|\mathfrak{Z}^{\otimes s} = \mathbf{z}}$ obtained by conditioning a symmetric state $\rho^{A\overline{n}} = \rho^{AB_1 \cdots B_n}$ on the outcomes of a POVM $\mathfrak{Z} = \{F_z\}_{z \in \mathcal{Z}}$ applied to s subsystems is independent of the indices $i_1, \ldots, i_{n-s}$. Additionally, as an immediate consequence of Lemma II.6 below, this conditional state is still symmetric relative to $\mathcal{H}_A$. We will thus use the abbreviation $\rho^{A\overline{n-s}}_{|\mathfrak{Z}^s = \mathbf{z}}$.

Lemma II.6: Let $\rho^{AB\overline{n}} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}_B \otimes \mathcal{H}^{\otimes n})$ be symmetric relative to $\mathcal{H}_A \otimes \mathcal{H}_B$. Then, for any POVM $\mathfrak{N} = \{E_y\}_{y \in \mathcal{Y}}$ on $\mathcal{H}_A$ and every $y \in \mathcal{Y}$, $\rho^{B\overline{n}}_{|\mathfrak{N}=y}$ is symmetric relative to $\mathcal{H}_B$.

Proof: It suffices to show that, for any $\pi \in S_n$ and any $y \in \mathcal{Y}$

$$(\mathrm{id}_B \otimes \pi_{\mathcal{H}})\mathrm{Tr}_A((E_y \otimes \mathrm{id}_{B\bar{n}})\rho^{AB\bar{n}})(\mathrm{id}_B \otimes \pi_{\mathcal{H}}^\dagger) = \mathrm{Tr}_A((E_y \otimes \mathrm{id}_{B\bar{n}})\rho^{AB\bar{n}}),$$

where $\mathrm{id}_{B\bar{n}} := \mathrm{id}_B \otimes \mathrm{id}_{\mathcal{H}}^{\otimes n}$. We use the general identity,

$$U\,\mathrm{Tr}_A(W)U' = \mathrm{Tr}_A((\mathrm{id}_A \otimes U)W(\mathrm{id}_A \otimes U'))$$

for endomorphisms U, U' on $\mathcal{H}_B$ and W on $\mathcal{H}_A \otimes \mathcal{H}_B$, which follows from the fact that the identity is trivial for product operators $W = S \otimes T$ and the linearity of the partial trace. Setting $U := \mathrm{id}_B \otimes \pi_{\mathcal{H}}$, $U' := \mathrm{id}_B \otimes \pi_{\mathcal{H}}^\dagger$, and $W := (E_y \otimes \mathrm{id}_{B\bar{n}})\rho^{AB\bar{n}}$ leads to

$$\begin{aligned}(\mathrm{id}_B \otimes \pi_{\mathcal{H}})\mathrm{Tr}_A((E_y \otimes \mathrm{id}_{B\bar{n}})\rho^{AB\bar{n}})(\mathrm{id}_B \otimes \pi_{\mathcal{H}}^\dagger) &= \mathrm{Tr}_A((\mathrm{id}_{AB} \otimes \pi_{\mathcal{H}})(E_y \otimes \mathrm{id}_{B\bar{n}})\rho^{AB\bar{n}}(\mathrm{id}_{AB} \otimes \pi_{\mathcal{H}}^\dagger)) \\ &= \mathrm{Tr}_A((E_y \otimes \mathrm{id}_{B\bar{n}})(\mathrm{id}_{AB} \otimes \pi_{\mathcal{H}})\rho^{AB\bar{n}}(\mathrm{id}_{AB} \otimes \pi_{\mathcal{H}}^\dagger)).\end{aligned}$$

The assertion then follows since $\rho^{AB\bar{n}}$ is symmetric relative to $\mathcal{H}_A \otimes \mathcal{H}_B$, that is,

$$(\mathrm{id}_{AB} \otimes \pi_{\mathcal{H}})\rho^{AB\bar{n}}(\mathrm{id}_{AB} \otimes \pi_{\mathcal{H}}^\dagger) = \rho^{AB\bar{n}}.$$

□

The notation for symmetric quantum states introduced above can also be used to denote symmetric probability distributions resulting from measuring a symmetric quantum state. Let, for instance, $\rho^{A\bar{n}} = \rho^{AB_1\cdots B_n} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n})$ be symmetric relative to $\mathcal{H}_A$. Then, for POVMs $\mathcal{Y}$ and $\mathcal{Z}$ on $\mathcal{H}_A$ and $\mathcal{H}$, respectively, we write $p_{\mathcal{Y}\mathcal{Z}^n}^{A\bar{n}}$ instead of $p_{\mathcal{Y}\mathcal{Z}\cdots\mathcal{Z}}^{A B_1\cdots B_n}$.

To formulate our theorems in a compact way, we will make use of the notion of exchangeability. A symmetric density operator $\rho^{\bar{n}} \in \mathrm{S}(\mathcal{H}^{\otimes n})$ is said to be *m-exchangeable,* for $m \geqslant n$, if there exists a symmetric density operator $\sigma^{\bar{m}} \in \mathrm{S}(\mathcal{H}^{\otimes m})$ such that $\rho^{\bar{n}}$ is the partial trace of $\sigma^{\bar{m}}$, i.e., $\rho^{\bar{n}} = \sigma^{\bar{n}}$. Similarly to Definition II.5, the definition of exchangeability can be generalized to include an additional system $\mathcal{H}_A$.

Definition II.7: A density operator $\rho^{A\bar{n}} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n})$ which is symmetric relative to $\mathcal{H}_A$ is called m-exchangeable relative to $\mathcal{H}_A$ *if there exists a density operator $\sigma^{A\bar{m}} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes m})$ such that $\sigma^{A\bar{n}}$ is symmetric relative to $\mathcal{H}_A$ and $\rho^{A\bar{n}} = \sigma^{A\bar{n}}$. We refer to $\sigma^{A\bar{m}}$ as an* extension of $\rho^{A\bar{n}}$.

In the following, we will often use the same label for an extension of a state. For example, we will denote an extension of $\rho^{A\bar{n}}$ to m systems (for $m \geqslant n$) by $\rho^{A\bar{m}}$.

D. Dual basis and quantum tomography

Let $\{e_i\}_{i\in\mathcal{N}}$ be a family of vectors in a Hilbert space $\mathcal{H}$. A family $\{f_i\}_{i\in\mathcal{N}}$ is called a *dual* of $\{e_i\}_{i\in\mathcal{N}}$ if $v = \sum_{i\in\mathcal{N}}\langle f_i|v\rangle e_i$ for all $v \in \mathcal{H}$, where $\langle f_i|v\rangle$ denotes the inner product of f_i and v.

Note that the set of endomorphisms on $\mathcal{H}$ forms a complex Hilbert space with inner product $(U,V) \mapsto \mathrm{tr}(UV^\dagger)$. Similarly, the set $\mathrm{Herm}(\mathcal{H})$ of Hermitian operators on $\mathcal{H}$ is a real Hilbert space with inner product $(U,V) \mapsto \mathrm{tr}(UV)$. Hence, a family $\{F_z\}_{z\in\mathcal{Z}}$ of elements from $\mathrm{Herm}(\mathcal{H})$ is a dual of a family $\{F_z^*\}_{z\in\mathcal{Z}}$ if

$$U = \sum_{z\in\mathcal{Z}} \mathrm{tr}(F_z U)F_z^*, \quad \text{for all } U \in \mathrm{Herm}(\mathcal{H}). \tag{10}$$

In particular, expression (10) states that the operator U is fully determined by the values of the traces $\mathrm{tr}(F_z U)$. The following lemma generalizes this fact to product spaces.

Lemma II.8: Let $\{F_z\}_{z\in\mathcal{Z}}$ and $\{F_z^*\}_{z\in\mathcal{Z}}$ be families of elements from $\mathrm{Herm}(\mathcal{H}_B)$ *such that $\{F_z\}_{z\in\mathcal{Z}}$ is the dual of $\{F_z^*\}_{z\in\mathcal{Z}}$. Then, for any $W \in \mathrm{Herm}(\mathcal{H}_A \otimes \mathcal{H}_B)$,*

$$W = \sum_{z\in\mathcal{Z}} W_z \otimes F_z^*,$$

where $W_z := \mathrm{Tr}_B((\mathrm{id}_A \otimes F_z)W)$, *for all* $z \in \mathcal{Z}$.

Proof: It is easy to verify that $\mathrm{Herm}(\mathcal{H}_A \otimes \mathcal{H}_B) = \mathrm{Herm}(\mathcal{H}_A) \otimes \mathrm{Herm}(\mathcal{H}_B)$. Hence there exist operators $U_i \in \mathrm{Herm}(\mathcal{H}_A)$ and $V_i \in \mathrm{Herm}(\mathcal{H}_B)$ such that $W = \sum_i U_i \otimes V_i$. By the linearity of the sum and the trace operator, it thus suffices to show that

$$U \otimes V = \sum_{z \in \mathcal{Z}} \mathrm{Tr}_B((\mathrm{id}_A \otimes F_z)(U \otimes V)) \otimes F_z^*$$

for any $U \in \mathrm{Herm}(\mathcal{H}_A)$ and $V \in \mathrm{Herm}(\mathcal{H}_B)$. Since Tr_B can be written as $\mathrm{Tr}_B = \mathrm{id}_A \otimes \mathrm{tr}_B$ (where $\mathcal{H}_A \otimes \mathbb{C}$ is identified with $\mathcal{H}_A$) we find

$$\mathrm{Tr}_B((\mathrm{id}_A \otimes F_z)(U \otimes V)) = \mathrm{Tr}_B(U \otimes (F_z V)) = \mathrm{tr}(F_z V)U,$$

and thus

$$\sum_{z \in \mathcal{Z}} \mathrm{Tr}_B((\mathrm{id}_A \otimes F_z)(U \otimes V)) \otimes F_z^* = U \otimes \left(\sum_{z \in \mathcal{Z}} \mathrm{tr}(F_z V) F_z^* \right).$$

The assertion then follows from (10). □

Let $\mathfrak{Z} = \{F_z\}_{z \in \mathcal{Z}}$ be a POVM on $\mathcal{H}_B$ and let $\{F_z^*\}_{z \in \mathcal{Z}}$ be a family of elements from $\mathrm{Herm}(\mathcal{H}_B)$ such that $\{F_z\}_{z \in \mathcal{Z}}$ is the dual of $\{F_z^*\}_{z \in \mathcal{Z}}$. Definition 10 directly implies that any density operator ρ^B on $\mathcal{H}_B$ can be written as

$$\rho^B = \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [F_z^*], \tag{11}$$

i.e., ρ^B is fully determined by the probability distribution $\rho^B_{\mathfrak{Z}}$ of the outcomes when applying the measurement $\mathfrak{Z}$ on ρ^B. On the other hand, it is an immediate consequence of Lemma II.8 that, for any density operator ρ^{AB} on $\mathcal{H}_A \otimes \mathcal{H}_B$,

$$\rho^{AB} = \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [\rho^A{}_{|\mathfrak{Z}=z} \otimes F_z^*]. \tag{12}$$

The above formulas are useful for quantum state tomography, that is, the reconstruction of an unknown quantum state ρ given only the statistics of measurement applied to identical copies of ρ. For example, it follows from (11), the strong convexity of the trace distance and Lemma II.1 that the estimate $\tilde{\rho}^B := \mathbb{E}_{z \leftarrow \tilde{P}_Z}[F_z^*]$ is close to ρ^B,

$$\delta(\rho^B, \tilde{\rho}^B) \leqslant \sum_{z \in \mathcal{Z}} |P_Z(z) - \tilde{P}_Z(z)| \cdot \mathrm{tr}|F_z^*|. \tag{13}$$

In particular, in order to obtain good estimates, one should choose a POVM $\mathfrak{Z}$ such that the traces $\mathrm{tr}|F_z^*|$ are small.

III. INFORMATIONALLY COMPLETE POVMs AND DUALS

A. Symmetric informationally complete POVMs

Intuitively, a POVM $\mathfrak{Z} = \{F_z\}_{z \in \mathcal{Z}}$ is useful for tomography if the distance between any two operators F_z and $F_{z'}$ is large. This is for instance the case for symmetric POVMs as defined below, where the operators F_z are symmetrically distributed over the space of positive operators.

Definition III.1: Let $\mathcal{H}$ *be a d-dimensional Hilbert space. A* symmetric *informationally complete POVM* $\mathfrak{Z} = \{F_z\}_{z \in [d^2]}$ *on* $\mathcal{H}$ *is an informationally complete POVM that consists of rank-one projectors*

$$F_z := \frac{1}{d} |\psi_z\rangle\langle\psi_z| \quad \textit{for all } z \in [d^2]$$

with the property that

$$\mathrm{tr}(F_z F_{z'}) = \theta_d \quad \textit{for all } z \neq z'.$$

for some $\theta_d \in \mathbb{C}$.

Analytic constructions of symmetric informationally complete POVMs are known for dimensions $d=2,3,4,6,8$ (see, e.g., Refs. 17 and 9). It can be shown that if a symmetric informationally complete POVM exists in dimension d, then θ_d is a universal constant which is independent of the particular symmetric informationally complete POVM. It equals

$$\theta_d = \frac{1}{d^2(d+1)}.$$

Lemma III.2: Let $\mathfrak{Z}=\{F_z\}_{z\in[d^2]} \in \mathrm{POVM}_{\mathcal{H}}$ *be a symmetric informationally complete POVM on a d-dimensional Hilbert space* $\mathcal{H}$. *Then there is a set of operators* $\{F_z^*\}_{z\in[d^2]} \subset \mathrm{Herm}(\mathcal{H})$ *that satisfies*

(i) $\mathfrak{Z}$ *is a dual of* $\{F_z^*\}_{z\in[d^2]}$.
(ii) *For every* $z \in [d^2]$, *the eigenvalues of* F_z^* *and their multiplicities are*

$$\lambda_0 := d, \quad n_0 := 1,$$

$$\lambda_1 := -1, \quad n_1 := d-1.$$

Proof: Let us define $\alpha := d^2+d-1$. It is straightforward to verify that the operators

$$F_z^* := \alpha F_z - \sum_{z'\neq z} F_{z'}, \quad z \in [d^2]$$

satisfy $\mathrm{tr}(F_z^* F_{z'}) = \delta_{zz'}$, where $\delta_{zz'}$ denotes the Kronecker delta, which equals one if $z=z'$ and 0 otherwise. This implies property (i). To obtain their eigenvalues, consider the matrix

$$B := F_z^* + \mathrm{id} = (\alpha+1)F_z.$$

Because $F_z = (1/d)|\psi_z\rangle\langle\psi_z|$, the eigenvalues of B are $(\alpha+1)/d$ and 0, occurring with multiplicities 1 and $d-1$, respectively. Hence statement (ii) follows. □

B. A construction for arbitrary dimensions

As mentioned in the preceding section, symmetric informationally complete POVMs are suitable for tomography. Unfortunately, their existence is only proven for certain dimensions. In this section, we will give a construction of informationally complete POVMs for any dimension. It is, however, not symmetric in the sense of Definition III.1, but still useful for tomography. Our construction is motivated by a general group-theoretic technique for finding such POVMs (see e.g., Ref. 5).

Note that a construction of an informationally complete POVM in any dimension is also given and applied in Ref. 4. Ours is more symmetric and allows us to construct a family of operators such that the informationally complete POVM is a dual of the family.

Let $\mathcal{H}$ be a d-dimensional Hilbert space and let $\omega := e^{2\pi i/d}$ be the dth primitive root of unity. Define the operators

$$D_{jk} := \omega^{j\odot k/2} \sum_{m\in\mathbb{Z}_d} \omega^{jm} |k\oplus m\rangle\langle m| \quad \text{for all } (j,k) \in \mathbb{Z}_d \times \mathbb{Z}_d,$$

where $\oplus$, $\odot$ denotes addition and multiplication modulo d, respectively. Furthermore, define

$$c((j,k),(l,m)) := jm - kl \quad \text{for all } (j,k),(l,m) \in \mathbb{Z}_d \times \mathbb{Z}_d.$$

We will use the simple identity

$$\sum_{\beta\in\mathbb{Z}_d\times\mathbb{Z}_d} \omega^{c(\alpha,\beta)} = d^2\cdot\delta_{\alpha,0} \quad \text{for all } \alpha\in\mathbb{Z}_d\times\mathbb{Z}_d, \tag{14}$$

where $\delta_{\alpha,\beta}$ denotes the Kronecker delta, which equals 1 if $\alpha=\beta$ and 0 otherwise. Note that this identity directly follows from

$$\sum_{m\in\mathbb{Z}_d} \omega^{km} = d\cdot\delta_{k,0} \quad \text{for all } k\in\mathbb{Z}_d. \tag{15}$$

Lemma III.3: The operators $\{D_\alpha\}_{\alpha\in\mathbb{Z}_d\times\mathbb{Z}_d}$ *have the following properties:*

(i) D_α *is unitary for every* $\alpha\in\mathbb{Z}_d\times\mathbb{Z}_d$.
(ii) *For every* $\rho\in\mathrm{S}(\mathcal{H})$, $\Sigma_{\alpha\in\mathbb{Z}_d\times\mathbb{Z}_d} D_\alpha\rho D_\alpha^\dagger = d\cdot\mathrm{id}$.
(iii) $D_\alpha D_\beta D_\alpha^\dagger = \omega^{c(\alpha,\beta)} D_\beta$, *for all* $\alpha,\beta\in\mathbb{Z}_d\times\mathbb{Z}_d$.
(iv) $D_\alpha^\dagger = D_{-\alpha}$, *for all* $\alpha\in\mathbb{Z}_d\times\mathbb{Z}_d$.
(v) $\mathrm{tr}(D_\alpha^\dagger D_\beta) = d\cdot\delta_{\alpha,\beta}$.

Proof: These properties are well known (see e.g., Ref. 5) and can also be verified by direct calculation. The proof is omitted here. □

Lemma III.4: Define

$$\rho := \frac{d}{d^2+1}\mathrm{id} + \frac{1}{2d(d^2+1)} \sum_{\beta\in\mathbb{Z}_d\times\mathbb{Z}_d} (D_\beta + D_\beta^\dagger).$$

Then ρ *is a state, i.e.,* $\rho\in\mathrm{S}(\mathcal{H})$.

Proof: To show that the operator ρ is non-negative, we make use of the following operators. Let

$$|\psi_{km}^\nu\rangle := \frac{1}{\sqrt{2}}(\omega^{\nu/2}|k\oplus m\rangle + \omega^{-\nu/2}|m\rangle)$$

and

$$\rho_{km}^\nu := |\psi_{km}^\nu\rangle\langle\psi_{km}^\nu| \quad \text{for } \nu\in\mathbb{R}, k,m\in\mathbb{Z}_d, \quad k\neq 0,$$

$$\rho_{0m}^\nu := \left(1+\frac{\omega^\nu+\omega^{-\nu}}{2}\right)|m\rangle\langle m|.$$

Note that ρ_{0m}^ν is not normalized, but non-negative [if $(\nu \bmod d) = d/2$ it equals 0].

With the definition

$$\nu(j,k,m) := \frac{j\odot k}{2} + jm,$$

it is easy to verify that

$$\sum_m \rho_{km}^{\nu(j,k,m)} = \mathrm{id} + \tfrac{1}{2}(D_{jk} + D_{jk}^\dagger),$$

and hence

$$\rho = \frac{1}{d(d^2+1)} \sum_{j,k}\sum_m \rho_{km}^{\nu(j,k,m)}.$$

This implies that ρ is indeed positive. Let us show that ρ given by this expression is correctly normalized. Note that

$$\sum_{j,k,m} \mathrm{tr}(\rho_{km}^{\nu(j,k,m)}) = \sum_{j,m} \sum_{k\neq 0} \mathrm{tr}(\rho_{km}^{\nu(j,k,m)}) + \sum_{j,m} \mathrm{tr}(\rho_{0m}^{\nu(j,0,m)}) = d^2(d-1) + \sum_{j,m} \left(1 + \frac{\omega^{\nu(j,0,m)} + \omega^{-\nu(j,0,m)}}{2}\right).$$

Because of

$$\sum_{j,m} \omega^{\nu(j,0,m)} = \sum_{j,m} \omega^{jm} = d,$$

where the second equation follows from (15), we obtain

$$\sum_{j,k,m} \mathrm{tr}(\rho_{km}^{\nu(j,k,m)}) = d(d^2+1).$$

This concludes the proof. □

Lemma III.5: Let

$$\Delta_\alpha := \frac{1}{d^2+1}\mathrm{id} + \frac{1}{2d^2(d^2+1)} \sum_{\beta\in\mathbb{Z}_d\times\mathbb{Z}_d} (\omega^{c(\alpha,\beta)} D_\beta + \omega^{-c(\alpha,\beta)} D_\beta^\dagger).$$

Then $\mathfrak{Z} := \{\Delta_\alpha\}_{\alpha\in\mathbb{Z}_d\times\mathbb{Z}_d}$ *is a POVM on* $\mathcal{H}$.

Proof: We show that $\Delta_\alpha := (1/d) D_\alpha \rho D_\alpha^\dagger$ where $\rho \in \mathrm{S}(\mathcal{H})$ is the state given in Lemma III.4. The statement then follows from Lemma III.3 (i) and (ii) because these imply that the operators are non-negative and resolve the identity.

We claim that

$$D_\alpha D_\beta^\dagger D_\alpha^\dagger = \omega^{-c(\alpha,\beta)} D_\beta^\dagger. \tag{16}$$

This can be verified as follows using the fact that the operators are unitary, Lemma III.3 (iii), and the identity $c(\alpha,\beta) = -c(\beta,\alpha)$,

$$D_\alpha D_\beta^\dagger D_\alpha^\dagger = D_\beta^\dagger D_\beta D_\alpha D_\beta^\dagger D_\alpha^\dagger = D_\beta^\dagger \omega^{c(\beta,\alpha)} D_\alpha D_\alpha^\dagger = \omega^{-c(\alpha,\beta)} D_\beta^\dagger.$$

By inserting the state ρ given in Lemma III.4, we obtain

$$\frac{1}{d} D_\alpha \rho D_\alpha^\dagger = \frac{1}{d^2+1}\mathrm{id} + \frac{1}{2d^2(d^2+1)} \sum_{\beta\in\mathbb{Z}_d\times\mathbb{Z}_d} (D_\alpha D_\beta D_\alpha^\dagger + D_\alpha D_\beta^\dagger D_\alpha^\dagger).$$

Using Lemma III.3 (iii) again as well as the identity (16) establishes the fact that this equals Δ_α.□

To simplify the notation, let us introduce the Hermitian operators

$$\Lambda_\alpha := \frac{1}{2d} \sum_{\beta\in\mathbb{Z}_d\times\mathbb{Z}_d} (\omega^{c(\alpha,\beta)} D_\beta + \omega^{-c(\alpha,\beta)} D_\beta^\dagger).$$

With these operators, the POVM in question has the simple form

$$\Delta_\alpha := \frac{1}{d^2+1} \cdot \left(\mathrm{id} + \frac{1}{d} \cdot \Lambda_\alpha\right) \quad \text{for all } \alpha \in \mathbb{Z}_d \times \mathbb{Z}_d. \tag{17}$$

Let us first compute two useful identities concerning the trace of these operators.

Lemma III.6: For all $\alpha, \beta \in \mathbb{Z}_d \times \mathbb{Z}_d$,

$$\mathrm{tr}(\Lambda_\alpha) = 1,$$

$$\mathrm{tr}(\Lambda_\alpha^\dagger \Lambda_\beta) = d \cdot \delta_{\alpha,\beta}.$$

Proof: As $D_0=\mathrm{id}$, we have from Lemma III.3 (v) the identity $\mathrm{tr}(D_\beta)=d\cdot\delta_{\beta,0}$. With

$$\mathrm{tr}(A^\dagger)=\overline{\mathrm{tr}(A)} \tag{18}$$

this gives

$$\mathrm{tr}(\Lambda_\alpha)=\tfrac{1}{2}(\omega^{c(\alpha,0)}+\omega^{-c(\alpha,0)})=1\,.$$

Because of

$$\Lambda_\alpha^\dagger\Lambda_\beta=\frac{1}{4d^2}\left(\sum_\gamma \omega^{-c(\alpha,\gamma)}D_\gamma^\dagger+\omega^{c(\alpha,\gamma)}D_\gamma\right)\left(\sum_\delta \omega^{c(\beta,\delta)}D_\delta+\omega^{-c(\beta,\delta)}D_\delta^\dagger\right)$$

and identity (18) we have

$$\mathrm{tr}(\Lambda_\alpha^\dagger\Lambda_\beta)=\frac{1}{4d^2}\sum_{\gamma,\delta}(\omega^{c(\beta,\delta)-c(\alpha,\gamma)}\,\mathrm{tr}(D_\gamma^\dagger D_\delta)+\omega^{c(\alpha,\gamma)+c(\beta,\delta)}\,\mathrm{tr}(D_\gamma D_\delta))+\mathrm{H.c.}\,,$$

where H.c. denotes the complex conjugate of the previous expression. Applying Lemma III.3 (iv) and (v) gives

$$\mathrm{tr}(\Lambda_\alpha^\dagger\Lambda_\beta)=\frac{1}{4d}\cdot\sum_\gamma(\omega^{c(\beta,\gamma)-c(\alpha,\gamma)}+\omega^{c(\alpha,\gamma)+c(\beta,-\gamma)})+\mathrm{H.c.}$$

But $c(\beta,-\gamma)=-c(\beta,\gamma)$ and $c(\beta,\gamma)-c(\alpha,\gamma)=c(\beta-\alpha,\gamma)$, hence we obtain

$$\mathrm{tr}(\Lambda_\alpha^\dagger\Lambda_\beta)=\frac{1}{4d}\cdot\sum_\gamma(\omega^{c(\beta-\alpha,\gamma)}+\omega^{c(\alpha-\beta,\gamma)})+\mathrm{H.c.}$$

and thus finally

$$\mathrm{tr}(\Lambda_\alpha^\dagger\Lambda_\beta)=d\cdot\delta_{\alpha,\beta},$$

as a consequence of Eq. (14). □

Lemma III.7: The POVM $\mathfrak{Z}$ *is a dual of the family of Hermitian operators*

$$\Theta_\alpha:=-d\left(\mathrm{id}-\frac{d^2+1}{d}\cdot\Lambda_\alpha\right),\quad \alpha\in\mathbb{Z}_d\times\mathbb{Z}_d.$$

Proof: The operators Θ_α are Hermitian since, by definition, the operators Λ_α are Hermitian. The fact that $\mathfrak{Z}$ is a dual of the family of operators Θ_α follows from the representation (17) of the POVM operators and Lemma III.6. □

Lemma III.8: For every $\alpha\in\mathbb{Z}_d\times\mathbb{Z}_d$, $\mathrm{tr}(|\Theta_\alpha|)\leqslant d\cdot\sqrt{d^4+d^2-1}$.

Proof: Let $\lambda_1,\ldots,\lambda_d$ be the eigenvalues of Θ_α (including multiplicities). Then using Cauchy-Schwartz,

$$\mathrm{tr}(|\Theta_\alpha|)=\sum_{i=1}^d|\lambda_i|\leqslant d^{1/2}\sqrt{\sum_{i=1}^d|\lambda_i|^2}=d^{1/2}\sqrt{\mathrm{tr}(\Theta_\alpha^\dagger\Theta_\alpha)}.$$

But $\mathrm{tr}(\Theta_\alpha^\dagger\Theta_\alpha)=d(d^4+d^2-1)$ as can be computed directly using Lemma III.6. □

IV. ANALYSIS OF SYMMETRIC PROBABILITY DISTRIBUTIONS

In this section, we derive a number of useful properties of symmetric probability distributions. These results will later be applied to probability distributions resulting from measurements of a symmetric quantum state.

It is worth noting that our proof of the finite quantum de Finetti representation does not rely on a classical de Finetti-style theorem (as opposed to Ref. 4). It is, however, straightforward to obtain a de Finetti representation for (classical) probability distributions based on the results presented in the sequel.

A. Estimating the frequency distribution of a subsequence

Let $(\mathbf{z},\bar{\mathbf{z}})$ be the concatenation of an n-tuple $\mathbf{z}$ and a k-tuple $\bar{\mathbf{z}}$ of elements from $\mathcal{Z}$. We show that, if $(\mathbf{z},\bar{\mathbf{z}})$ is randomly chosen according to a symmetric probability distribution $P_{(\mathbf{Z},\bar{\mathbf{Z}})}$, then the frequency distribution $Q_{\bar{\mathbf{z}}}$ of the subtuple $\bar{\mathbf{z}}$ is a good estimate for the frequency distribution $Q_{\mathbf{z}}$ of the remaining subsequence $\mathbf{z}$.

We need the following simple relation between the distances of frequency distributions of subsequences obtained from a sequence of elements from $\mathcal{Z}$.

Lemma IV.1: Let $\mathcal{Z}$ be a set and let $\mathbf{z}$ and $\bar{\mathbf{z}}$ be elements of $\mathcal{Z}^n$ and $\mathcal{Z}^k$, respectively. Then

$$\delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}}) \leqslant \frac{n+k}{n}\delta(Q_{\bar{\mathbf{z}}},Q_{(\mathbf{z},\bar{\mathbf{z}})}).$$

Proof: By the definition of the frequency distribution,

$$(n+k)Q_{(\mathbf{z},\bar{\mathbf{z}})} = nQ_{\mathbf{z}} + kQ_{\bar{\mathbf{z}}}.$$

Hence, using the convexity of the variational distance,

$$\delta(Q_{(\mathbf{z},\bar{\mathbf{z}})},Q_{\mathbf{z}}) = \delta\left(\frac{n}{n+k}Q_{\mathbf{z}} + \frac{k}{n+k}Q_{\bar{\mathbf{z}}},Q_{\mathbf{z}}\right) \leqslant \frac{k}{n+k}\delta(Q_{\bar{\mathbf{z}}},Q_{\mathbf{z}}).$$

The triangle inequality then leads to

$$\delta(Q_{\bar{\mathbf{z}}},Q_{\mathbf{z}}) \leqslant \delta(Q_{\bar{\mathbf{z}}},Q_{(\mathbf{z},\bar{\mathbf{z}})}) + \delta(Q_{(\mathbf{z},\bar{\mathbf{z}})},Q_{\mathbf{z}}) \leqslant \delta(Q_{\bar{\mathbf{z}}},Q_{(\mathbf{z},\bar{\mathbf{z}})}) + \frac{k}{n+k}\delta(Q_{\bar{\mathbf{z}}},Q_{\mathbf{z}}),$$

from which the assertion follows.

We now show that $Q_{\mathbf{z}}$ is close to $Q_{\bar{\mathbf{z}}}$ by showing that the expression on the rhs of the inequality in Lemma IV.1 is small in expectation.

Lemma IV.2: Let $\mathbf{Z}$ be an n-tuple and $\bar{\mathbf{Z}}$ a k-tuple of random variables over a set $\mathcal{Z}$ of size $|\mathcal{Z}|=t$ such that $P_{(\mathbf{Z},\bar{\mathbf{Z}})}$ is symmetric. Then, for $(\mathbf{z},\bar{\mathbf{z}}) \leftarrow P_{(\mathbf{Z},\bar{\mathbf{Z}})}$,

$$\mathop{\mathbb{E}}_{(\mathbf{z},\bar{\mathbf{z}})}[\delta(Q_{\bar{\mathbf{z}}},Q_{(\mathbf{z},\bar{\mathbf{z}})})] \leqslant \frac{1}{2}\sqrt{\frac{t}{k}}.$$

Proof: Let $\mathbf{Z} := (Z_1,\ldots,Z_n)$ and $\bar{\mathbf{Z}} := (\bar{Z}_1,\ldots,\bar{Z}_k)$. It suffices to show that, for all probability distributions $q \in \mathrm{Distr}(\mathcal{Z})$,

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}\leftarrow P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}}[\delta(Q_{\bar{\mathbf{z}}},q)] \leqslant \frac{1}{2}\sqrt{\frac{t}{k}}. \tag{19}$$

The assertion then follows from

$$\mathop{\mathbb{E}}_{(\mathbf{z},\bar{\mathbf{z}})\leftarrow P_{(\mathbf{Z},\bar{\mathbf{Z}})}}[\delta(Q_{\bar{\mathbf{z}}},Q_{(\mathbf{z},\bar{\mathbf{z}})})] = \mathop{\mathbb{E}}_{q\leftarrow P_{Q_{(\mathbf{Z},\bar{\mathbf{Z}})}}}\left[\mathop{\mathbb{E}}_{\bar{\mathbf{z}}\leftarrow P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}}[\delta(Q_{\bar{\mathbf{z}}},q)]\right].$$

Let thus $q \in \mathrm{Distr}(\mathcal{Z})$ be fixed. For every $z \in \mathcal{Z}$, let χ_z be the function from $\mathcal{Z}$ to $\{0,1\}$ defined by $\chi_z(z')=1$ if $z'=z$ and $\chi_z(z')=0$ otherwise. Then

$$\delta(Q_{\bar{\mathbf{z}}}, q) = \frac{1}{2} \sum_{z \in \mathcal{Z}} |d_z(\bar{\mathbf{z}})|, \tag{20}$$

where, for any $\bar{\mathbf{z}} = (\bar{z}_1, \ldots, \bar{z}_k) \in \mathcal{Z}^k$,

$$d_z(\bar{\mathbf{z}}) := \frac{1}{k} \sum_{i=1}^{k} (\chi_z(\bar{z}_i) - q(z)).$$

Using Jensen's inequality,

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}} \leftarrow P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [|d_z(\bar{\mathbf{z}})|] \leq \sqrt{\mathop{\mathbb{E}}_{\bar{\mathbf{z}} \leftarrow P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [d_z(\bar{\mathbf{z}})^2]}. \tag{21}$$

We claim that for any $i \neq j$,

$$\mathop{\mathbb{E}}_{(\bar{z}_i,\bar{z}_j) \leftarrow P_{(\bar{Z}_i,\bar{Z}_j)|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [(\chi_z(\bar{z}_i) - q(z))(\chi_z(\bar{z}_j) - q(z))] \leq 0. \tag{22}$$

To prove this identity, first note that the expectation value can be written in the form

$$\mathop{\mathbb{E}}_{\bar{z}_i \leftarrow P_{\bar{Z}_i|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [\mathop{\mathbb{E}}_{\bar{z}_j \leftarrow P_{\bar{Z}_j|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q, \bar{Z}_i=\bar{z}_i}} [(\chi_z(\bar{z}_i) - q(z))(\chi_z(\bar{z}_j) - q(z))]].$$

Since $0 \leq q(z) \leq 1$, it suffices to show that

$$\mathop{\mathbb{E}}_{\bar{z}_j \leftarrow P_{\bar{Z}_j|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q, \bar{Z}_i=\bar{z}_i}} [\chi_z(\bar{z}_j) - q(z)] \begin{cases} \leq 0 & \text{if } \bar{z}_i = z, \\ \geq 0 & \text{otherwise.} \end{cases} \tag{23}$$

Because of Lemma II.3, the probability distribution $P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q, \bar{Z}_i=\bar{z}_i}$ is symmetric. Hence by the definition of the frequency distribution, we have

$$\mathop{\mathbb{E}}_{\bar{z}_j \leftarrow P_{\bar{Z}_j|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q, \bar{Z}_i=\bar{z}_i}} [\chi_z(\bar{z}_j)] = P_{\bar{Z}_j|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q, \bar{Z}_i=\bar{z}_i}(z) = \begin{cases} \dfrac{nq(z)-1}{n-1} & \text{if } z = \bar{z}_i, \\ \dfrac{nq(z)}{n-1} & \text{otherwise.} \end{cases}$$

This proves (23) and thus (22).

Using (22) and Lemma II.4, we obtain

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}} \leftarrow P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [d_z(\bar{\mathbf{z}})^2] \leq \frac{1}{k^2} \sum_{i=1}^{k} \mathop{\mathbb{E}}_{\bar{z}_i \leftarrow P_{\bar{Z}_i|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [(\chi_z(\bar{z}_i) - q(z))^2] = \frac{1}{k^2} \sum_{i=1}^{k} (q(z) - q(z)^2) \leq \frac{q(z)}{k}. \tag{24}$$

Combining (20), (21), and (24) leads to

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}} \leftarrow P_{\bar{\mathbf{Z}}|Q_{(\mathbf{Z},\bar{\mathbf{Z}})}=q}} [\delta(Q_{\bar{\mathbf{z}}}, q)] = \frac{1}{2} \sum_{z \in \mathcal{Z}} \sqrt{\frac{q(z)}{k}}.$$

The bound (19) then follows from the Cauchy-Schwartz inequality, which concludes the proof.□

B. The product structure of symmetric probability distributions

Let $\mathbf{z}$ be an n-tuple over $\mathcal{Z}$ randomly chosen according to a probability distribution $P_{\mathbf{Z}}$ and let $q \in \mathrm{Distr}(\mathcal{Z})$ be an estimate for the frequency distribution $Q_{\mathbf{z}}$ of $\mathbf{z}$. To quantify the quality of this estimate, it is convenient to introduce the abbreviation $D_q(P_{\mathbf{Z}})$ for the expected distance between the actual frequency distribution $Q_{\mathbf{z}}$ and the estimate q, that is

$$D_q(P_{\mathbf{Z}}) := \mathop{\mathbb{E}}_{\mathbf{z} \leftarrow P_{\mathbf{Z}}} [\delta(Q_{\mathbf{z}}, q)].$$

The main result of Sec. IV A can then be rephrased as follows.

Lemma IV.3: Let $\mathbf{Z}$ *be an n-tuple and* $\overline{\mathbf{Z}}$ *a k-tuple of random variables over a set* $\mathcal{Z}$ *of size* $|\mathcal{Z}| = t$, *for* $k \leq n$, *such that* $P_{(\mathbf{Z},\overline{\mathbf{Z}})}$ *is symmetric. Then, for* $\overline{\mathbf{z}} \leftarrow P_{\overline{\mathbf{Z}}}$,

$$\mathop{\mathbb{E}}_{\overline{\mathbf{z}}} [D_{Q_{\overline{\mathbf{z}}}}(P_{\mathbf{Z}|\overline{\mathbf{Z}}=\overline{\mathbf{z}}})] \leq \sqrt{\frac{t}{k}}.$$

Proof: From Lemma IV.2 and Lemma IV.1,

$$\mathop{\mathbb{E}}_{(\mathbf{z},\overline{\mathbf{z}}) \leftarrow P_{(\mathbf{Z},\overline{\mathbf{Z}})}} [\delta(Q_{\mathbf{z}}, Q_{\overline{\mathbf{z}}})] \leq \sqrt{\frac{t}{k}}.$$

The assertion then follows from the definition of $D_{\cdot}(\cdot)$.

□

Lemma IV.4 establishes a connection between the quantity $D_q(P_{\mathbf{Z}})$ and the product structure of symmetric probability distributions.

Lemma IV.4: Let Y *be a random variable over* $\mathcal{Y}$ *and let* $\mathbf{Z} = (Z_1, \ldots, Z_r)$ *be an r-tuple of random variables over* $\mathcal{Z}$, *such that the conditional probability distribution* $P_{\mathbf{Z}|Y=y}$ *is symmetric for every* $y \in \mathcal{Y}$. *Then, for all* $q \in \mathrm{Distr}(\mathcal{Z})$,

$$\delta(P_{YZ_i}, P_Y \times q) \leq D_q(P_{\mathbf{Z}}), \quad \textit{for every } i \in [r].$$

Proof: Using the strong convexity of the variational distance, we have

$$\delta(P_{YZ_i}, P_Y \times q) \leq \mathop{\mathbb{E}}_{\tilde{q} \leftarrow P_{Q_{\mathbf{Z}}}} [\delta(P_{YZ_i|Q_{\mathbf{Z}}=\tilde{q}}, P_{Y|Q_{\mathbf{Z}}=\tilde{q}} \times q)]. \tag{25}$$

Since $P_{\mathbf{Z}|Y=y}$ is symmetric, Lemma II.4 implies $P_{Z_i|Y=y,Q_{\mathbf{Z}}=\tilde{q}} = \tilde{q}$, for every $y \in \mathcal{Y}$. In particular, conditioned on $Q_{\mathbf{z}} = \tilde{q}$, Z_i is independent of Y. Hence,

$$\delta(P_{YZ_i|Q_{\mathbf{Z}}=\tilde{q}}, P_{Y|Q_{\mathbf{Z}}=\tilde{q}} \times q) = \delta(P_{Y|Q_{\mathbf{Z}}=\tilde{q}} \times \tilde{q}, P_{Y|Q_{\mathbf{Z}}=\tilde{q}} \times q) = \delta(\tilde{q}, q), \tag{26}$$

where the last equality follows from (4). Combining (25) and (26) leads to

$$\delta(P_{YZ_i}, P_Y \times q) \leq \mathop{\mathbb{E}}_{\tilde{q} \leftarrow P_{Q_{\mathbf{Z}}}} [\delta(\tilde{q}, q)] = \mathop{\mathbb{E}}_{\mathbf{z} \leftarrow P_{\mathbf{Z}}} [\delta(Q_{\mathbf{z}}, q)] = D_q(P_{\mathbf{Z}}).$$

V. ANALYSIS OF SYMMETRIC QUANTUM STATES

The goal of this section is to derive results on symmetric quantum states, based on the corresponding results on symmetric probability distributions given in the preceding section. In Sec. V A, we first show how certain properties of the measurement statistics imply structural properties of the corresponding quantum states. Then, in Sec. V B, we combine these results with those of Sec. IV B in order to prove statements about the structure of symmetric quantum states.

A. Deducing the state structure from measurement results

Consider a state of a bipartite system conditioned on a measurement on one of the systems. We first prove an upper bound on the amount of dependence between this conditional state and the measurement outcome.

Lemma V.1: Let $\rho^{AB} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}_B)$ *and let* $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ *be a POVM on* $\mathcal{H}_B$. *Then, for all* $q \in \mathrm{Distr}(\mathcal{Z})$ *and* $z \in \mathcal{Z}$,

$$\delta(\rho^A{}_{|\mathfrak{Z}=z}, \rho^A) \leqslant \frac{2}{\rho^B_{\mathfrak{Z}}(z)} \max_{\mathfrak{Y}} \delta(\rho^{AB}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times q),$$

where the maximization is over all POVMs $\mathfrak{Y}$ *on* $\mathcal{H}_A$.

Proof: Let $\mathfrak{Y} := \{E_y\}_{y\in\mathcal{Y}}$ be a POVM on $\mathcal{H}_A$. Then, from the triangle inequality, (2) and (4),

$$\delta(\rho^{AB}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times \rho^B_{\mathfrak{Z}}) \leqslant \delta(\rho^{AB}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times q) + \delta(\rho^A_{\mathfrak{Y}} \times q, \rho^A_{\mathfrak{Y}} \times \rho^B_{\mathfrak{Z}}) = \delta(\rho^{AB}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times q) + \delta(q, \rho^B_{\mathfrak{Z}}) \leqslant 2D, \tag{27}$$

where

$$D := \max_{\mathfrak{Y}'} \delta(\rho^{A\,B}_{\mathfrak{Y}'\,\mathfrak{Z}}, \rho^A_{\mathfrak{Y}'} \times q),$$

with the maximization ranging over all POVMs $\mathfrak{Y}'$ on $\mathcal{H}_A$. Using Eq. (3), we have

$$\rho^B_{\mathfrak{Z}}(z) \cdot \delta(\rho^A_{\mathfrak{Y}|\mathfrak{Z}=z}, \rho^A_{\mathfrak{Y}}) \leqslant \mathop{\mathbb{E}}_{z\leftarrow\rho^B_{\mathfrak{Z}}} [\delta(\rho^A_{\mathfrak{Y}|\mathfrak{Z}=z}, \rho^A_{\mathfrak{Y}})] = \delta(\rho^{AB}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times \rho^B_{\mathfrak{Z}}).$$

With (27), it follows that

$$\delta(\rho^A_{\mathfrak{Y}|\mathfrak{Z}=z}, \rho^A_{\mathfrak{Y}}) \leqslant \frac{2D}{\rho^B_{\mathfrak{Z}}(z)}$$

for every $z \in \mathcal{Z}$ and every POVM $\mathfrak{Y}$ on $\mathcal{H}_A$. Therefore, using (9), we conclude that

$$\delta(\rho^A{}_{|\mathfrak{Z}=z}, \rho^A) = \max_{\mathfrak{Y}} \delta(\rho^A_{\mathfrak{Y}|\mathfrak{Z}=z}, \rho^A_{\mathfrak{Y}}) \leqslant \frac{2D}{\rho^B_{\mathfrak{Z}}(z)}.$$

□

For a POVM $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ on a Hilbert space $\mathcal{H}$, we define the constants

$$C_1(\mathfrak{Z}) := \min_{\{F^*_z\}_{z\in\mathcal{Z}}} 2 \cdot \left(\sum_{z\in\mathcal{Z}} \mathrm{tr}(|F^*_z|) \right),$$

$$C_2(\mathfrak{Z}) := \sqrt{|\mathcal{Z}|} \cdot C_1(\mathfrak{Z}),$$

where the minimum ranges over all families $\{F^*_z\}_{z\in\mathcal{Z}}$ of elements from $\mathrm{Herm}(\mathcal{H})$ such that $\mathfrak{Z}$ is the dual of $\{F^*_z\}_{z\in\mathcal{Z}}$. If no such family $\{F^*_z\}_{z\in\mathcal{Z}}$ exists, we set $C_i(\mathfrak{Z}) := \infty$, for $i=1,2$.

It is clear (from linear algebra, it is well known that whenever a family $\{f_i\}_{i\in\mathcal{N}}$ forms a basis of $\mathcal{H}$, there exists a unique family $\{e_i\}_{i\in\mathcal{N}}$ such that $\{f_i\}_{i\in\mathcal{N}}$ is a dual of $\{e_i\}_{i\in\mathcal{N}}$) that $C_i(\mathfrak{Z}) < \infty$, for $i=1,2$, if $\mathfrak{Z}$ is an informationally complete POVM. By the interpretation given to the values $\mathrm{tr}(|F^*_z|)$ in Sec. II D, the value $C_1(\mathfrak{Z})$ can be seen as a measure for the resulting accuracy when estimating an unknown state ρ given the statistics obtained by the measurement $\mathfrak{Z}$.

For a d-dimensional Hilbert space $\mathcal{H}$, let $\bar{C}_i(d)$ be the minimum of $C_i(\mathfrak{Z})$, minimized over all POVMs $\mathfrak{Z}$ on $\mathcal{H}$, that is

$$\bar{C}_i(d) := \min_{\mathfrak{Z}} C_i(\mathfrak{Z}) \quad \text{for } i = 1,2.$$

The following corollary is a direct consequence of Lemma III.2 and Lemma III.8.

Corollary V.2: Let $\mathcal{H}$ be a d-dimensional Hilbert space. Then

$$\bar{C}_1(d) \leqslant 2\sqrt{2} \cdot d^5,$$

$$\bar{C}_2(d) \leqslant 2\sqrt{2} \cdot d^6.$$

If symmetric informationally complete POVMs exist in dimension d, then

$$\bar{C}_1(d) \leqslant 2d^2(2d-1).$$

$$\bar{C}_2(d) \leqslant 2d^3(2d-1).$$

The main result of this section expresses the intuitive fact that a bipartite state has product form if every bipartite measurement yields a product distribution.

Theorem V.3: *Let $\rho^{AB} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}_B)$ and let $\mathfrak{Z}$ be a POVM on $\mathcal{H}_B$. Then, for any $q \in \mathrm{Distr}(\mathcal{Z})$,*

$$\delta(\rho^{AB}, \rho^A \otimes \rho^B) \leqslant C_1(\mathfrak{Z}) \cdot \max_{\mathfrak{Y}} \delta(\rho^{A\,B}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times q).$$

In particular, if $\mathcal{H}_B$ is d-dimensional, then

$$\delta(\rho^{AB}, \rho^A \otimes \rho^B) \leqslant \bar{C}_1(d) \cdot \max_{\mathfrak{Y},\mathfrak{Z}} \delta(\rho^{A\,B}_{\mathfrak{Y}\mathfrak{Z}}, \rho^A_{\mathfrak{Y}} \times \rho^B_{\mathfrak{Z}}).$$

(*The maxima are taken over all POVMs $\mathfrak{Y}$ on $\mathcal{H}_A$ and $\mathfrak{Z}$ on $\mathcal{H}_B$, respectively.*)

Proof: Let $\{F_z^*\}_{z \in \mathcal{Z}}$ be a family of elements from $\mathrm{Herm}(\mathcal{H}_B)$ such that $\mathfrak{Z}=\{F_z\}_{z \in \mathcal{Z}}$ is the dual of $\{F_z^*\}_{z \in \mathcal{Z}}$. Then, according to (12),

$$\rho^{AB} = \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [\rho^A{}_{|\mathfrak{Z}=z} \otimes F_z^*] \quad \text{and} \quad \rho^B = \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [F_z^*].$$

Using these identities, the strong convexity of the trace distance, and Lemma II.1, we obtain

$$\begin{aligned}\delta(\rho^{AB}, \rho^A \otimes \rho^B) &= \delta\Big(\mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [\rho^A{}_{|\mathfrak{Z}=z} \otimes F_z^*], \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [\rho^A \otimes F_z^*]\Big) \leqslant \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [\delta(\rho^A{}_{|\mathfrak{Z}=z} \otimes F_z^*, \rho^A \otimes F_z^*)] \\ &= \mathop{\mathbb{E}}_{z \leftarrow \rho^B_{\mathfrak{Z}}} [\delta(\rho^A{}_{|\mathfrak{Z}=z}, \rho^A) \cdot \mathrm{tr}(|F_z^*|)].\end{aligned}$$

The assertion then follows from Lemma V.1 and the definition of $C_1(\mathfrak{Z})$. □

B. The product structure of symmetric quantum states

We now combine the results of Sec. IV and Sec. V A. We start with a quantum analogue of Lemma IV.4.

Lemma V.4: Let $\rho^{A\bar{r}} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes r})$ be symmetric relative to $\mathcal{H}_A$ and let $\mathfrak{Z}=\{F_z\}_{z \in \mathcal{Z}}$ be a POVM on $\mathcal{H}$. Then, for any $q \in \mathrm{Distr}(\mathcal{Z})$,

$$\delta(\rho^{A\bar{1}}, \rho^A \otimes \rho^{\bar{1}}) \leqslant C_1(\mathfrak{Z}) D_q(\rho^{\bar{r}}_{\mathfrak{Z}^r})$$

and

$$\delta(\rho^{\bar{1}}_{\mathfrak{Z}}, q) \leqslant D_q(\rho^{\bar{r}}_{\mathfrak{Z}^r}).$$

Proof: Let $\mathcal{Y}$ be a POVM on $\mathcal{H}_A$. Since, by Lemma II.6, $\rho^{\bar{r}}_{|\mathcal{Y}=y}$ is symmetric, the probability distribution $\rho^{\bar{r}}_{\mathcal{Z}^r|\mathcal{Y}=y}$ is also symmetric, for all $y \in \mathcal{Y}$. Lemma IV.4 thus implies

$$\delta(\rho^{A\bar{1}}_{\mathcal{Y}\mathcal{Z}}, \rho^{A}_{\mathcal{Y}} \times q) \leq D_q(\rho^{\bar{r}}_{\mathcal{Z}^r}). \tag{28}$$

The first assertion of the lemma then follows from Theorem V.3.

The second assertion of the lemma follows directly from (28) and property (2) of the variational distance, i.e., $\delta(\rho^{\bar{1}}_{\mathcal{Z}}, q) \leq \delta(\rho^{A\bar{1}}_{\mathcal{Y}\mathcal{Z}}, \rho^{A}_{\mathcal{Y}} \times q)$. □

The next lemma shows that symmetry imposes severe constraints on the structure of quantum states. More precisely, if a symmetric quantum state has (almost) product structure with respect to one of its subsystems, this directly implies that the state has (almost) product structure with respect to all its subsystems.

Lemma V.5: Let $\rho^{A\bar{n}} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n})$ *be symmetric relative to* $\mathcal{H}_A$. *Then*

$$\delta(\rho^{A\bar{n}}, \rho^{A} \otimes (\rho^{\bar{1}})^{\otimes n}) \leq n \cdot \delta(\rho^{A\bar{n}}, \rho^{A\overline{n-1}} \otimes \rho^{\bar{1}}).$$

Proof: Using the triangle inequality for the trace distance, we get

$$\delta(\rho^{A\bar{n}}, \rho^{A} \otimes (\rho^{\bar{1}})^{\otimes n}) \leq \sum_{i=0}^{n-1} \delta(\rho^{A\overline{n-1}} \otimes (\rho^{\bar{1}})^{\otimes i}, \rho^{A\overline{n-i-1}} \otimes (\rho^{\bar{1}})^{\otimes (i+1)}). \tag{29}$$

Since, by Eq. (8), the trace distance does not change when tracing out the product state $(\rho^{\bar{1}})^{\otimes i}$, we have, for any $i \in [n]$,

$$\delta(\rho^{A\overline{n-i}} \otimes (\rho^{\bar{1}})^{\otimes i}, \rho^{A\overline{n-i-1}} \otimes (\rho^{\bar{1}})^{\otimes (i+1)}) = \delta(\rho^{A\overline{n-i}}, \rho^{A\overline{n-i-1}} \otimes \rho^{\bar{1}}). \tag{30}$$

Using the fact that the trace distance can only decrease when taking a partial trace [see (6)], we get

$$\delta(\rho^{A\overline{n-i}}, \rho^{A\overline{n-i-1}} \otimes \rho^{\bar{1}}) \leq \delta(\rho^{A\bar{n}}, \rho^{A\overline{n-1}} \otimes \rho^{\bar{1}}). \tag{31}$$

Combining (30) with (31) and inserting this into (29) concludes the proof. □

Combined with Lemma V.4, we obtain an upper bound on the distance between a symmetric state on n subsystems and an n-fold product state.

Corollary V.6: Let $\rho^{A\overline{n+m}} \in \mathrm{S}(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n+m})$ *be symmetric relative to* $\mathcal{H}_A$ *and let* $\mathcal{Z} = \{F_z\}_{z \in \mathcal{Z}}$ *be a POVM on* $\mathcal{H}$. *Then, for any* $q \in \mathrm{Distr}(\mathcal{Z})$,

$$\delta(\rho^{A\bar{n}}, \rho^{A} \otimes (\rho^{\bar{1}})^{\otimes n}) \leq n C_1(\mathcal{Z}) D_q(\rho^{\overline{m+1}}_{\mathcal{Z}^{m+1}}).$$

Proof: Obviously, the density operator $\rho^{A\overline{n+m}}$ is symmetric relative to $\mathcal{H}_{A'} := \mathcal{H}_A \otimes \mathcal{H}^{\otimes n-1}$. Thus, with $r := m+1$, we can write $\rho^{A'\bar{r}}$ instead of $\rho^{A\overline{n+m}}$, and, similarly, $\rho^{A\bar{n}} = \rho^{A'\bar{1}}$ and $\rho^{A\overline{n-1}} = \rho^{A'}$. Hence, by Lemma V.4,

$$\delta(\rho^{A\bar{n}}, \rho^{A\overline{n-1}} \otimes \rho^{\bar{1}}) = \delta(\rho^{A'\bar{1}}, \rho^{A'} \otimes \rho^{\bar{1}}) \leq C_1(\mathcal{Z}) D_q(\rho^{\bar{r}}_{\mathcal{Z}^r}).$$

Applying Lemma V.5 concludes the proof. □

Finally, we give an upper bound on the expected value of the quantity appearing on the rhs. in Corollary 6. For this, we need a quantum analogue of Lemma IV.3.

Lemma V.7: Let $\rho^{\overline{n+k}} \in S(\mathcal{H}^{\otimes n+k})$, *for* $k \leq n$, *be symmetric and let* $\mathcal{Z} = \{F_z\}_{z \in \mathcal{Z}}$ *be a POVM on* $\mathcal{H}$ *with* $|\mathcal{Z}| = t$. *Then, for* $\bar{\mathbf{z}} \leftarrow \rho^{\bar{k}}_{\mathcal{Z}^k}$,

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[D_{Q_{\mathbf{z}}}(\rho^{\bar{n}}_{\mathcal{Z}^n|\mathcal{Z}^k=\bar{\mathbf{z}}})] \leq \sqrt{\frac{t}{k}}.$$

Proof: The assertion follows directly from Lemma IV.3 and the fact that the probability

distribution $\rho^{\bar{n}}_{\mathfrak{Z}^n}{}^{\bar{k}}_{\mathfrak{Z}^k}=\rho^{\overline{n+k}}_{\mathfrak{Z}^{n+k}}$ is symmetric. □

VI. MAIN RESULTS

Our main results immediately follow from the characterizations of symmetric quantum states given in the preceding section. Basically, we consider the quantum state $\rho^{A\bar{n}}_{\bar{\mathbf{z}}}:=\rho^{A\bar{n}}{}_{|\mathfrak{Z}^k=\bar{\mathbf{z}}}$ on $\mathcal{H}_A \otimes \mathcal{H}^{\otimes n}$ obtained by conditioning an exchangeable state $\rho^{A\overline{n+k}}$ on the outcomes $\bar{\mathbf{z}}=(z_1,\ldots,z_k)$ of a POVM $\mathfrak{Z}$ applied to k subsystems. We show that $\rho^{A\bar{n}}_{\bar{\mathbf{z}}}$ is close to a product state $\rho^{A}_{\bar{\mathbf{z}}}\otimes(\rho^{\bar{1}}_{\bar{\mathbf{z}}})^{\otimes n}$ where $\rho^{\bar{1}}_{\bar{\mathbf{z}}}$ is a density operator on a single subsystem $\mathcal{H}$. Moreover, $\rho^{\bar{1}}_{\bar{\mathbf{z}}}$ is almost determined by the observed measurement statistics.

Theorem VI.1: *Let $\rho^{A\overline{n+k}}\in S(\mathcal{H}_A\otimes\mathcal{H}^{\otimes n+k})$ be $(n+2k-1)$-exchangeable relative to $\mathcal{H}_A$ and let $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ be a POVM on $\mathcal{H}$ with $|\mathcal{Z}|=t$. For every $\bar{\mathbf{z}}\in\mathcal{Z}^k$, let $\rho^{A\bar{n}}_{\bar{\mathbf{z}}}:=\rho^{A\bar{n}}{}_{|\mathfrak{Z}^k=\bar{\mathbf{z}}}$. Then for $\overline{\mathbf{z}}\leftarrow\rho^{\bar{k}}_{\mathfrak{Z}^k}$,*

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[\delta(\rho^{A\bar{n}}_{\bar{\mathbf{z}}},\rho^{A}_{\bar{\mathbf{z}}}\otimes(\rho^{\bar{1}}_{\bar{\mathbf{z}}})^{\otimes n})]\leqslant C_2(\mathfrak{Z})\frac{n}{\sqrt{k}}$$

where $\rho^{\bar{1}}_{\bar{\mathbf{z}}}=\rho^{\bar{1}}{}_{|\mathfrak{Z}^k=\bar{\mathbf{z}}}$ is determined by

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[\delta(\rho^{\bar{1}}_{\mathfrak{Z}|\mathfrak{Z}^k=\bar{\mathbf{z}}},Q_{\bar{\mathbf{z}}})]\leqslant\sqrt{\frac{t}{k}}.$$

Proof: Let $m:=k-1$. According to the definition of exchangeability, there exists an extension $\rho^{A\overline{n+k+m}}\in S(\mathcal{H}_A\otimes\mathcal{H}^{\otimes n+k+m})$ of $\rho^{A\overline{n+k}}$ which is symmetric relative to $\mathcal{H}_A$. For every $\bar{\mathbf{z}}\in\mathcal{Z}^k$, let $[\rho_{\bar{\mathbf{z}}}]^{A\overline{n+m}}:=\rho^{A\overline{n+m}}{}_{|\mathfrak{Z}^k=\bar{\mathbf{z}}}$.

By Lemma II.6, $[\rho_{\bar{\mathbf{z}}}]^{A\overline{n+m}}$ is symmetric relative to $\mathcal{H}_A$. Hence, from the second bound of Lemma V.4, with $r:=m+1$,

$$\delta([\rho_{\bar{\mathbf{z}}}]^{\bar{1}}_{\mathfrak{Z}},Q_{\bar{\mathbf{z}}})\leqslant D_{Q_{\bar{\mathbf{z}}}}([\rho_{\bar{\mathbf{z}}}]^{\overline{m+1}}_{\mathfrak{Z}^{m+1}}) \tag{32}$$

and, from Corollary V.6,

$$\delta([\rho_{\bar{\mathbf{z}}}]^{A\bar{n}},[\rho_{\bar{\mathbf{z}}}]^{A}\otimes([\rho_{\bar{\mathbf{z}}}]^{\bar{1}})^{\otimes n})\leqslant nC_1(\mathfrak{Z})D_{Q_{\bar{\mathbf{z}}}}([\rho_{\bar{\mathbf{z}}}]^{\overline{m+1}}_{\mathfrak{Z}^{m+1}}). \tag{33}$$

Since $k=m+1$, we can apply Lemma V.7 to the state $\rho^{\overline{(m+1)+k}}$, i.e.,

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[D_{Q_{\bar{\mathbf{z}}}}([\rho_{\bar{\mathbf{z}}}]^{\overline{m+1}}_{\mathfrak{Z}^{m+1}})]\leqslant\sqrt{\frac{t}{k}}.$$

The assertion follows by taking the expectation on both sides of (32) and (33), respectively. □

Using Markov's inequality, it is straightforward to turn Theorem VI.1, which expresses closeness in terms of expected distance, into a statement providing a bound on the probability that the distance is larger than a given value ε. However, by adapting the auxiliary results derived so far and using a tail inequality by Hoeffding, we obtain a tighter bound. The interested reader is referred to the Appendix for a derivation of an alternative version of Theorem VI.1.

Finally, as a simple corollary of Theorem VI.1, we obtain the following representation for finitely exchangeable quantum states.

Corollary VI.2 (finite quantum de Finetti representation): Let $\mathcal{H}$ be a d-dimensional Hilbert space and let $\rho^{\bar{n}}\in S(\mathcal{H}^{\otimes n})$ be $(n+s)$-exchangeable. Then $\rho^{\bar{n}}$ is ε-close to the convex hull of the set of n-fold product states $\{\sigma^{\otimes n}:\sigma\in S(\mathcal{H})\}$, for $\varepsilon=\sqrt{2}\bar{C}_2(d)n/\sqrt{s}$.

Proof: Let $k:=\lceil s/2\rceil$ and let $\rho^{\overline{n+k}}\in S(\mathcal{H}^{\otimes n+k})$ be an $(n+2k-1)$-exchangeable extension of $\rho^{\bar{n}}$. Let $\mathfrak{Z}$ be an informationally complete POVM on $\mathcal{H}$ and let, for any $\bar{\mathbf{z}}\in\mathcal{Z}^k$, $\rho^{\bar{n}}_{\bar{\mathbf{z}}}:=\rho^{\bar{n}}{}_{|\mathfrak{Z}^k=\bar{\mathbf{z}}}$. We show that

$$\delta(\rho^{\bar{n}}, \mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[(\rho_{\bar{\mathbf{z}}}^{\bar{1}})^{\otimes n}]) \leqslant \sqrt{2}\bar{C}_2(d)\frac{n}{\sqrt{s}}, \tag{34}$$

where $\bar{\mathbf{z}} \leftarrow \rho_{\bar{\mathfrak{Z}}^k}^{\bar{k}}$. Since, by (1),

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[\rho_{\bar{\mathbf{z}}}^{\bar{n}}] = \rho^{\bar{n}},$$

we obtain, using the strong convexity of the trace distance

$$\delta(\rho^{\bar{n}}, \mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[(\rho_{\bar{\mathbf{z}}}^{\bar{1}})^{\otimes n}]) = \delta(\mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[\rho_{\bar{\mathbf{z}}}^{\bar{n}}], \mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[(\rho_{\bar{\mathbf{z}}}^{\bar{1}})^{\otimes n}]) \leqslant \mathop{\mathbb{E}}_{\bar{\mathbf{z}}}[\delta(\rho_{\bar{\mathbf{z}}}^{\bar{n}}, (\rho_{\bar{\mathbf{z}}}^{\bar{1}})^{\otimes n})]. \tag{35}$$

Inequality (34) then follows directly from Theorem VI.1. □

While this result is of interest in its own right, we point out that taking the limit $s \to \infty$ directly gives the well-known quantum de Finetti representation for *infinitely* exchangeable quantum states,[13] thus providing yet another new (compare Ref. 4) and conceptually simple proof.

APPENDIX: MARKOV-STYLE VERSION OF THEOREM VI.1

While Theorem VI.1 provides a bound on the expected distance between the conditional state $\rho_{\bar{\mathbf{z}}}^{A\bar{n}}$ and the product state $\rho_{\bar{\mathbf{z}}}^{A} \otimes (\rho_{\bar{\mathbf{z}}}^{\bar{1}})^{\otimes n}$, Theorem A.1 below gives an expression for the minimum probability such that this distance is smaller than some given value.

Theorem A.1: *Let* $\rho^{A\overline{n+k}} \in S(\mathcal{H}_A \otimes \mathcal{H}^{\otimes n+k})$ *be* $(n+2k-1)$*-exchangeable relative to* $\mathcal{H}_A$ *and let* $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ *be a POVM on* $\mathcal{H}$ *with* $|\mathcal{Z}|=t$. *For every* $\bar{\mathbf{z}} \in \mathcal{Z}^k$, *let* $\rho_{\bar{\mathbf{z}}}^{A\bar{n}} := \rho^{A\bar{n}}_{|\mathfrak{Z}^k=\bar{\mathbf{z}}}$. Then, for all $\lambda \geqslant 0$, *and for* $\bar{\mathbf{z}} \leftarrow \rho_{\bar{\mathfrak{Z}}^k}^{\bar{k}}$, *with probability at least* $1-2ke^{-\lambda^2/8}$,

$$\delta(\rho_{\bar{\mathbf{z}}}^{A\bar{n}}, \rho_{\bar{\mathbf{z}}}^{A} \otimes (\rho_{\bar{\mathbf{z}}}^{\bar{1}})^{\otimes n}) < \frac{n\lambda}{\sqrt{k}} C_2(\mathfrak{Z})$$

and

$$\delta(\rho_{\bar{\mathfrak{Z}}|\mathfrak{Z}^k=\bar{\mathbf{z}}}^{\bar{1}}, Q_{\bar{\mathbf{z}}}) < \sqrt{\frac{t}{k}}\lambda.$$

The proof of this theorem essentially follows the lines of the proof of Theorem VI.1. The main difference is that Lemma IV.2 is replaced by a statement based on a tail inequality due to Hoeffding[10] which applies to hypergeometric distributions as defined below (for more details, see, e.g., Ref. 14).

Definition A.2: The hypergeometric distribution $\mathrm{Hyp}(n,m,k)$ *with parameters* n, m, and k *is defined as the probability distribution of the random variable* $S := |\Gamma \cap [m]|$ *where* Γ *is a randomly chosen subset of* $[n]$ *of size* $|\Gamma|=k$.

Lemma A.3. Hoeffding: Let S *be a random variable with* $P_S=\mathrm{Hyp}(n,m,k)$. *Then, for all* $\ell \geqslant 0$,

$$\mathop{\mathbb{P}}_{s}\left[s \leqslant k\frac{m}{n} - \ell \right] \leqslant e^{-\ell^2 n/2km}.$$

Lemma A.4 and Lemma A.5 are adapted versions of Lemma IV.2 and Lemma IV.3, proven in Sec. IV A and Sec. IV B, respectively.

Lemma A.4: Let $\mathbf{Z}$ *be an n-tuple and* $\overline{\mathbf{Z}}$ *a k-tuple of random variables over a set* $\mathcal{Z}$ *of size* $|\mathcal{Z}|=t$ *such that* $P_{(\mathbf{Z},\overline{\mathbf{Z}})}$ *is symmetric. Then, for any* $\varepsilon \geqslant 0$ *and for* $(\mathbf{z},\overline{\mathbf{z}}) \leftarrow P_{(\mathbf{Z},\overline{\mathbf{Z}})}$,

$$\mathop{\mathbb{P}}_{(\mathbf{z},\overline{\mathbf{z}})}[\delta(Q_{\overline{\mathbf{z}}},Q_{(\overline{\mathbf{z}},\mathbf{z})}) \geqslant \varepsilon] \leqslant te^{-k\varepsilon^2/2t}.$$

Proof: It suffices to show that, for all probability distributions $q \in \mathrm{Distr}(\mathcal{Z})$,

$$\mathop{\mathbb{P}}_{\overline{\mathbf{z}}\leftarrow P_{\overline{\mathbf{Z}}|Q_{(\mathbf{Z},\overline{\mathbf{Z}})}=q}}[\delta(Q_{\overline{\mathbf{z}}},q) \geqslant \varepsilon] \leqslant te^{-k\varepsilon^2/2t}. \tag{A1}$$

The assertion of the lemma then follows from

$$\mathop{\mathbb{P}}_{(\mathbf{z},\overline{\mathbf{z}})\leftarrow P_{(\mathbf{Z},\overline{\mathbf{Z}})}}[\delta(Q_{\overline{\mathbf{z}}},Q_{(\mathbf{z},\overline{\mathbf{z}})}) \geqslant \varepsilon] = \mathop{\mathbb{E}}_{q\leftarrow P_{Q_{(\mathbf{Z},\overline{\mathbf{Z}})}}}\Big[\mathop{\mathbb{P}}_{\overline{\mathbf{z}}\leftarrow P_{\overline{\mathbf{Z}}|Q_{(\mathbf{Z},\overline{\mathbf{Z}})}=q}}[\delta(Q_{\overline{\mathbf{z}}},q) \geqslant \varepsilon]\Big].$$

Let thus $q \in \mathrm{Distr}(\mathcal{Z})$ with $P_{Q_{(\mathbf{Z},\overline{\mathbf{Z}})}}(q)>0$ be fixed. The variational distance between $Q_{\overline{\mathbf{z}}}$ and q can be written as

$$\delta(Q_{\overline{\mathbf{z}}},q) = \sum_{z\in\mathcal{Z}'} \max(q(z) - Q_{\overline{\mathbf{z}}}(z),0), \tag{A2}$$

where $\mathcal{Z}' := \{z \in \mathcal{Z}: q(z)>0\}$. It is easy to see that, for any $z \in \mathcal{Z}$, the random variable $S_z := k \cdot Q_{\overline{\mathbf{Z}}}(z)$, conditioned on the event $Q_{(\mathbf{Z},\overline{\mathbf{Z}})}=q$, is distributed according to $\mathrm{Hyp}(n+k,(n+k)q(z),k)$. For any $z \in \mathcal{Z}'$, let $\varepsilon_z := \varepsilon\sqrt{q(z)/t}$. Lemma A.3 (with $\ell = k\varepsilon_z$) then implies

$$\mathop{\mathbb{P}}_{\overline{\mathbf{z}}\leftarrow P_{\overline{\mathbf{Z}}|Q_{(\mathbf{Z},\overline{\mathbf{Z}})}=q}}[q(z) - Q_{\overline{\mathbf{z}}}(z) \geqslant \varepsilon_z] \leqslant e^{-k\varepsilon_z^2/2q(z)} = e^{-k\varepsilon^2/2t},$$

and thus, using the union bound,

$$\mathop{\mathbb{P}}_{\overline{\mathbf{z}}\leftarrow P_{\overline{\mathbf{Z}}|Q_{(\mathbf{Z},\overline{\mathbf{Z}})}=q}}\left[\forall z \in \mathcal{Z}': q(z) - Q_{\overline{\mathbf{Z}}}(z) < \varepsilon\sqrt{\frac{q(z)}{t}}\right] \geqslant 1 - te^{k\varepsilon^2/2t}. \tag{A3}$$

Since, by the Cauchy-Schwartz inequality,

$$\sum_{z\in\mathcal{Z}'} \varepsilon\sqrt{\frac{q(z)}{t}} \leqslant \varepsilon,$$

the event in (A3) implies that the sum on the rhs of (A2) is smaller than ε, that is, $\delta(Q_{\overline{\mathbf{z}}},q)<\varepsilon$. Inequality (A1) thus follows directly from the bound (A3). □

Lemma A.5: Let $\mathbf{Z}$ *be an n-tuple and* $\overline{\mathbf{Z}}$ *a k-tuple of random variables over a set* $\mathcal{Z}$ *of size* $|\mathcal{Z}|=t$, *for* $k \leqslant n$, *such that* $P_{(\mathbf{Z},\overline{\mathbf{Z}})}$ *is symmetric. Then, for all* $\varepsilon \geqslant 0$ *and for* $\overline{\mathbf{z}} \leftarrow P_{\overline{\mathbf{Z}}}$,

$$\mathop{\mathbb{P}}_{\overline{\mathbf{z}}}[D_{Q_{\overline{\mathbf{z}}}}(P_{\mathbf{Z}|\overline{\mathbf{Z}}=\overline{\mathbf{z}}}) \geqslant \varepsilon] \leqslant 2ke^{-k\varepsilon^2/8t}.$$

Proof: Let $\tau := t/k$ and $\bar{\varepsilon} := \varepsilon - \tau$. Note that, if $\varepsilon \leqslant \tau$, the rhs of the inequality in the lemma becomes larger than 1 because $\varepsilon \leqslant 1$, i.e., the assertion is trivially true. Thus we can assume that $\bar{\varepsilon}>0$. For all $\overline{\mathbf{z}} \in \mathcal{Z}^k$, let

$$p_{\overline{\mathbf{z}}} := \mathop{\mathbb{P}}_{\mathbf{z}\leftarrow P_{\mathbf{Z}|\overline{\mathbf{Z}}=\overline{\mathbf{z}}}}[\delta(Q_{\mathbf{z}},Q_{\overline{\mathbf{z}}}) \geqslant \bar{\varepsilon}].$$

We then have, by Lemma A.4 and Lemma IV.1,

$$\mathop{\mathbb{E}}_{\bar{\mathbf{z}}\leftarrow P_{\bar{\mathbf{Z}}}}[p_{\bar{\mathbf{z}}}] = \mathop{\mathbb{P}}_{(\mathbf{z},\bar{\mathbf{z}})\leftarrow P_{(\mathbf{Z},\bar{\mathbf{Z}})}}[\delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}}) \geqslant \bar{\varepsilon}] \leqslant \mathop{\mathbb{P}}_{(\mathbf{z},\bar{\mathbf{z}})\leftarrow P_{(\mathbf{Z},\bar{\mathbf{Z}})}}\left[\delta(Q_{\bar{\mathbf{z}}},Q_{(\mathbf{z},\bar{\mathbf{z}})}) \geqslant \frac{\bar{\varepsilon}}{2}\right] \leqslant te^{-k\bar{\varepsilon}^2/8t},$$

and, by Markov's inequality,

$$\mathop{\mathbb{P}}_{\bar{\mathbf{z}}\leftarrow P_{\bar{\mathbf{Z}}}}[p_{\bar{\mathbf{z}}} \geqslant \tau] \leqslant \frac{t}{\tau}e^{-k\bar{\varepsilon}^2/8t}. \tag{A4}$$

With the definition

$$\Lambda := \{\bar{\mathbf{z}} \in \mathcal{Z}^k : p_{\bar{\mathbf{z}}} < \tau\},$$

the bound (A4) can be rewritten as

$$\mathop{\mathbb{P}}_{\bar{\mathbf{z}}\leftarrow P_{\bar{\mathbf{Z}}}}[\bar{\mathbf{z}} \notin \Lambda] \leqslant \frac{t}{\tau}e^{-k\bar{\varepsilon}^2/8t} \leqslant 2ke^{-k\varepsilon^2/8t},$$

where the second inequality follows from the observation that $\bar{\varepsilon}^2=(\varepsilon-\tau)^2 \geqslant \varepsilon^2-2\tau$ and $\tau=t/k$.

It thus remains to be shown that, for any $\bar{\mathbf{z}} \in \Lambda$,

$$D_{Q_{\bar{\mathbf{z}}}}(P_{\mathbf{Z}|\bar{\mathbf{Z}}=\bar{\mathbf{z}}}) = \mathop{\mathbb{E}}_{\mathbf{z}\leftarrow P_{\mathbf{Z}|\bar{\mathbf{Z}}=\bar{\mathbf{z}}}}[\delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}})] < \varepsilon. \tag{A5}$$

Let thus $\bar{\mathbf{z}} \in \Lambda$ be fixed. Then

$$\mathop{\mathbb{E}}_{\mathbf{z}\leftarrow P_{\mathbf{Z}|\bar{\mathbf{Z}}=\bar{\mathbf{z}}}}[\delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}})] = \sum_{\substack{\mathbf{z}\in\mathcal{Z}^n \\ \delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}})<\bar{\varepsilon}}} P_{\mathbf{Z}|\bar{\mathbf{Z}}=\bar{\mathbf{z}}}(\mathbf{z})\,\delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}}) + \sum_{\substack{\mathbf{z}\in\mathcal{Z}^n \\ \delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}})\geqslant\bar{\varepsilon}}} P_{\mathbf{Z}|\bar{\mathbf{Z}}=\bar{\mathbf{z}}}(\mathbf{z})\,\delta(Q_{\mathbf{z}},Q_{\bar{\mathbf{z}}}) < \bar{\varepsilon} + p_{\bar{\mathbf{z}}}$$

from which the bound (A5) follows by the definition of Λ and $\bar{\varepsilon}+\tau=\varepsilon$. □

Finally, using Lemma A.5, we directly obtain Lemma A.6 below which corresponds to Lemma A.7 of Sec. V B.

Lemma A.6: Let $\rho^{\overline{n+k}} \in S(\mathcal{H}^{\otimes n+k})$, *for* $k \leqslant n$, *be symmetric and let* $\mathfrak{Z}=\{F_z\}_{z\in\mathcal{Z}}$ *be a POVM on* $\mathcal{H}$ *with* $|\mathcal{Z}|=t$. *Then, for all* $\varepsilon \geqslant 0$ *and for* $\bar{\mathbf{z}} \leftarrow \rho_{\mathfrak{Z}^k}^{\bar{k}}$,

$$\mathop{\mathbb{P}}_{\bar{\mathbf{z}}}[D_{Q_{\bar{\mathbf{z}}}}(\rho_{\mathfrak{Z}^n|\mathfrak{Z}^k=\bar{\mathbf{z}}}^{\bar{n}}) \geqslant \varepsilon] \leqslant 2ke^{-k\varepsilon^2/8t}.$$

The proof of Theorem A.1 is now similar to the proof of Theorem VI.1, where, instead of Lemma V.7, Lemma A.6 is used to bound the rhs of (32) and (33).

Under SU(2) gauge transformation, the non-Abelian Chern-Simons action is invariant on a class of three dimensional manifold—3 simple knot. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2137721]

I. INTRODUCTION

The Chern-Simons gauge theory provides a topological field theoretic framework for the study of knots and links in a given three manifold.[1,2] It was Schwarz who first conjectured[3] that the now famous Jones polynomial[4] may be related to Chern-Simons theory. Witten in his pioneering paper[5] set up the general framework to study knots and links through Chern-Simons field theories. Wilson loop operators are the topological operators of this theory. Expectation value of these operators are the topological invariants for knots and links. It is well known that the Abelian Chern-Simons action

$$I = \frac{1}{4\pi}\int_M A \wedge F = \frac{1}{8\pi}\int_M \epsilon^{ijk} A_i F_{jk} d^3x \tag{1}$$

is the topological invariant on one-dimensional knots.[5,6] As for the non-Abelian Chern-Simons action

$$\Omega = \frac{1}{8\pi^2}\,\mathrm{Tr}\left(A \wedge F - \frac{2}{3} A \wedge A \wedge A\right), \tag{2}$$

although mathematical development suggests that the link invariants provide a method of obtaining topological invariants for three-manifold,[7,8] there is still no work which can give the relation between the non-Abelian Chern-Simons action and 3-knot manifold (it is three-dimensional knot, and is totally different from the knots in Jones polynomial and in the mathematical method mentioned above).

The 3-knot has a very important application in modern physics. According to the closed universe model, our universe can also be treated as a 3-sphere in modern cosmology theory, since our universe is viewed as embedding in a higher dimensional world, in which, the observed elementary particles are the light particles trapped on the $(3+1)$-dimensional defect. Since the 3-sphere S^3 is the most trivial 3-knot, it is natural to generalize the closed and oriented manifold which are homeomorphic to S^3. This may provide us with insight into modern cosmology.

In knot theory, a knotted (closed, oriented) n-manifold M, i.e., n-knot is a smoothly embedded n-sphere in S^{n+2}, $K=f(S^n)\subset S^{n+2}$. Obviously the 3-knot is a knotted three-dimensional manifold $M=f(S^3)\subset S^5$. It is well known that every classical knot bounds a compact orientable surface, known as a Seifert surface for the knot.[9] A Seifert surface for a 3-knot K is defined to be a compact orientable four-manifold W in S^5, such that

[a)]Electronic mail: sity@itp.ac.cn

$$\partial W = K. \tag{3}$$

The simple n-knots[10] are those for which $\pi_i(\overline{X})=0$ (Ref. 11) for $i<m$ with $n=2m$ or $n=2m-1$.

On the mathematical side, odd dimensional simple knots have a tendency to look like classical knots. We will show that the non-Abelian Chern-Simons action is invariant under SU(2) gauge transformation on the simple 3-knot, just like the Abelian Chern-Simons action which is invariant on one-dimensional knots under U(1) transformation.[6]

Our discussion is based on Levine's theorem,[10] which states, for any simple knot $K\subset S^{2m+1}$, with a $(m-1)$-connected Seifert surface W, as dim $W=2m$ the only nontrivial homology group of W is $H_m(W)$, where the coefficient is integer.

Applying this theorem to 3-knot, for which $m=2$, we arrive that the only nontrivial homology group of Seifert surface W of 3-knot is $H_2(W.z)$. Therefore, we have $H_4(W.z)=\emptyset$.

If we denote the non-Abelian Chern-Simons action under SU(2) gauge transformation as Ω^S, we arrive at the quantity $I=\Omega^S-\Omega$ which appeared in the many topological field theory.[12] As pointed out by many physicists, this quantity just represents the second Chern number C_2.[12] While according to the characteristic class theory, the nonzero Chern class must follow[12]

$$C_i(p) \in H^{2i}(M), \tag{4}$$

this immediately leads to $C_2(p)\in H^4(W)$. As we know, on the Seifert surface W of 3-knot, $H_4(W.z)=\emptyset$. Recall the De Rahm cohomology theory,[13] the cohomology groups $H^4(W)$ are isomorphic to homology groups $H_4(W)$, so we have $C_2(p)=0$. It means $\Omega^S-\Omega=0$, therefore the non-Abelian Chern-Simons action is an invariant under gauge transformation. It must be pointed out here that this conclusion only holds for a special class of knot—3 simple knot, which is defined by Levine.[10]

In the following we will present a more exhaustive discussion.

II. THE NON-ABELIAN CHERN-SIMONS IS AN INVARIANT ON 3 SIMPLE KNOT

Under SU(2) gauge transformation, the non-Abelian Chern-Simons action,

$$I = \int \Omega = \frac{1}{8\pi^2}\int_K \mathrm{Tr}\left(A\wedge \mathrm{d}A - \frac{2}{3}A\wedge A\wedge A\right) \tag{5}$$

can be denoted as

$$I^s = \frac{1}{8\pi^2}\int_K \mathrm{Tr}\left(A^s\wedge F^s + \frac{1}{3}A^s\wedge A^s\wedge A^s\right), \tag{6}$$

in which $A^s=SAS^{-1}+\mathrm{d}S\,S^{-1}$ and $F^s=SFS^{-1}$, S is an element of SU(2). After some algebra, one can arrive at[12]

$$I^s - I = \frac{1}{24\pi^2}\int_K \mathrm{Tr}[\mathrm{d}S\,S^{-1}\wedge \mathrm{d}S\,S^{-1}\wedge \mathrm{d}S\,S^{-1}]. \tag{7}$$

Here K is a 3 simple knot. It is well known that the right-hand side of Eq. (7) just represents the second Chern class which describes the winding number of the manifold.

Since $S\in$ SU(2) and Spin(3) is homeomorphic to SU(2), we can replace S with an element of Spin(3); n; it can be expressed in terms of Clifford algebra[14] as $n=n^a\tau_a$ $(a=0,1,2,3)$, where $\tau=(I,i\vec{\sigma})$, $\tau^\dagger=(I,-i\vec{\sigma})$ with $\vec{\sigma}$ denotes the Pauli matrices. It is easily seen that n is just the element of Spin(3) in terms of geometric algebra. Obviously $nn^\dagger=1$, from the formula $n^\dagger\,\mathrm{d}n=-\mathrm{d}n^\dagger\,n$, Eq. (7) can be written as

$$I^s - I = -\frac{1}{24\pi^2}\int_K \mathrm{Tr}[\mathrm{d}n \wedge \mathrm{d}n^\dagger \wedge \mathrm{d}n\, n^\dagger]. \tag{8}$$

Considering $\partial W = K$, following Duan's work on second Chern class,[15] it can be proved that

$$C_2 = I^s - I = \frac{1}{24\pi^2}\int_W \mathrm{Tr}[\mathrm{d}n \wedge \mathrm{d}n^\dagger \wedge \mathrm{d}n \wedge \mathrm{d}n^\dagger]. \tag{9}$$

Now we see, for the non-Abelian Chern-Simons action on a 3 simple knot, after the SU(2) gauge transformation, it becomes $I^s = I + C_2$, where C_2 is the second Chern number on the Seifert surface W of the 3 simple knot.

It will be shown in the following that, the second Chern number on the Seifert surface W of the 3 simple knot is zero. This conclusion can be deduced from Levine's theorem.[10] For any simple knot $K \subset S^{2m+1}$, a $(m-1)$-connected Seifert surface W, as $\dim W = 2m$ the only nontrivial homology group of W is $H_m(W)$, where the coefficient is integer.

For 3 knot, $m=2$. Levine's theorem suggests the only nontrivial homology group of the Seifert surface of a 3 simple knot $H_2(W.z)$. The other homology group must be empty, then $H_4(W.z) = \emptyset$.

Recall the De Rahm cohomology theory,[13] the cohomology groups are isomorphic to homology groups, i.e.,

$$b^k = \dim H^k(M) = b_k = \dim H_k(M), \tag{10}$$

where $b^k = \dim H^k(M)$ is the co-Betti number, and $b_k = \dim H_k(M)$ is the Betti number. From $H_4(W.z) = \emptyset$ and (10), one sees that

$$b^4 = \dim H^4(W) = \dim H_4(W) = 0. \tag{11}$$

According to the characteristic class theory, the possible nonzero Chern class must follow[12]

$$C_i(p) \in H^{2i}(M). \tag{12}$$

For the second Chern class C_2, we have $C_2(p) \in H^4(W)$. Considering Eq. (11), we arrive at

$$C_2(p) = 0. \tag{13}$$

So the second Chern number on the 3-knot's Seifert surface is

$$I^s - I = 0. \tag{14}$$

Therefore, the non-Abelian Chern-Simons action is invariant over 3-knot. In fact, according to Duan's ϕ-mapping topological current theory, it is easy to prove that[15] $C_2(p) = \Sigma_{\alpha=1}^{l} W_\alpha$, where W_α is the winding number around instantons in space-time; this may provide us with a deep understanding of the 3-brane world theory.[16]

Now we can conclude that the non-Abelian Chern-Simons action is invariant under SU(2) gauge transformation over a 3 simple knot.

(Received 31 August 2005; accepted 26 October 2005; published online 28 December 2005)

We study the Chern-Simons topological quantum field theory with an inhomogeneous gauge group, a non-semi-simple group obtained from a semisimple one by taking its semidirect product with its Lie algebra. We find that the standard knot observable (i.e., trace of the holonomy along the knot) essentially vanishes, and yet, the non-semi-simplicity of the gauge group allows us to consider a class of unorthodox observables which breaks gauge invariance at one point and leads to a nontrivial theory on long knots in $\mathbb{R}^3$. We have two main morals. (1) In the non-semi-simple case there is more to observe in Chern-Simons theory. There might be other interesting non-semi-simple gauge groups to study in this context beyond our example. (2) In the case of an inhomogeneous gauge group, we find that Chern-Simons theory with the unorthodox observable is actually the same as three-dimensional BF theory with the Cattaneo-Cotta-Ramusino-Martellini knot observable. This leads to a simplification of their results and enables us to generalize and solve a problem they posed regarding the relation between BF theory and the Alexander-Conway polynomial. We prove that the most general knot invariant coming from pure BF topological quantum field theory is in the algebra generated by the coefficients of the Alexander-Conway polynomial. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2146190]

I. INTRODUCTION

We would like to address the question of the most general knot invariant coming from BF topological quantum field theory (TQFT). In the mid-1990s, Cattaneo *et al.*[9–12] showed that while BF theory with cosmological constant produces the same invariants of knots as the Chern-Simons (CS) theory, the BF theory with no cosmological constant (pure BF theory) and SU(2) gauge group produces invariants that lie in the algebra generated by the coefficients of the Alexander-Conway polynomial. The BF TQFT is completely equivalent to CS theory, however, while the equivalence with nonzero cosmological constant maintains the semisimplicity property of the gauge group, the equivalence when the cosmological constant is set to zero shifts us to a CS theory with a non-semi-simple gauge group. Thus, starting with a gauge group G in the pure BF theory we end up on the CS side with a semidirect product of the group with its Lie algebra $G \ltimes \mathcal{G}$, also known as the inhomogeneous group of G (denoted IG). Eventually, the question we want to address is as follows: *What is the most general knot invariant (or knot observable) in a CS theory with an inhomogeneous gauge group*?

The natural thing to begin with is the standard gauge invariant observable, the trace of the holonomy of the gauge connection along the knot, in some chosen representation. As we shall see in Sec. II, this observable gives us no information regarding the knot (except for framing information that can be normalized to zero anyway). This fact seems to pose a contradiction since in

[a)]Electronic mail: gnaot@math.toronto.edu

the equivalent pure BF theory one can extract some nontrivial information regarding the knot [at least in the case of SU(2) gauge]. Therefore, there must be a procedure that will give us nontrivial information regarding the knot in this setting.

In this paper we will introduce the following procedure (Sec. III A): We take an observable which is not gauge invariant at one single point on the knot (holonomy along the knot without the trace). By doing that, we get a CS theory on S^3 with broken gauge symmetry at one point on the knot. Then, we declare this point to be infinity by taking the point out of our space (i.e., puncturing S^3 at that point). Since the gauge transformations are taken to vanish at infinity, we get a completely invariant CS theory on $\mathbb{R}^3$ with a long knot embedded in it. Since knot theory in S^3 and long knot theory in $\mathbb{R}^3$ are "isomorphic" theories we lose no information as far as knot theory is concerned and we get "legal" CS theory in which we can consider a new and wider class of observables.

Using perturbation theory, we will show that our observable gives nontrivial information about the knot (Sec. III B). Continuing with perturbation theory in our setting (CS with IG gauge group and the new observable) we will be able to prove that the most general knot invariant coming from such a construction is in the algebra generated by the coefficients of the Alexander-Conway polynomial (Sec. III C). Returning to BF theory (Chap. IV) we will create an observable that reproduces the Cattaneo *et al.* result for SU(2) and generalize it to every metrizable gauge group and representation thereof used in the construction of the pure BF theory.

Our construction detects, in some sense, the difference between the invariant subspace of the universal enveloping algebra of the non-semi-simple gauge group and the coinvariant quotient of the universal enveloping algebra. This enables us to extract nontrivial information regarding the knot (a difference which does not exist in the semisimple case). We discuss this issue in Chap. V.

II. PERTURBATION THEORY FOR THE STANDARD OBSERVABLE WITH AN INHOMOGENEOUS GAUGE GROUP

In this section we will show that the perturbation theory of Chern-Simons (CS) theory with an inhomogeneous gauge group and the standard knot observable is almost trivial. We start (2.1) with some reminders about perturbation theory (in CS context). Unfortunately, due to the size of the topic this reminder is not meant to teach the theory. For recent detailed pedagogic reviews see Refs. 19 and 18. This will be followed by introduction of the inhomogeneous gauge group and our notations for it (Sec. II B). We continue with giving more details about perturbation theory using this gauge group (Sec. II C). Section II C will describe the consequences of using such a gauge group on the knot invariants coming from the standard observable. Finally, in Sec. II D, we will show that the standard construction in this setting is trivial, leading to (almost) trivial knot invariants.

A. Some reminders about perturbation theory and Chern-Simons theory

We recall the setting for knot invariants in the framework of CS theory (in this section a knot is an embedding of S^1 into S^3). We take S^3 to be the three-dimensional manifold on which the CS theory is defined. We choose any gauge group G whose Lie algebra is metrizable (e.g., semisimple gauge group). Denote the metric on the Lie algebra by $\langle,\rangle$ and let A be a G-connection. We consider the following action functional:

$$\text{Chern - Simons action } \mathrm{CS}(A) = k \cdot 2\pi \int_{S^3} \left\langle A \wedge \mathrm{d}A + \frac{2}{3} A \wedge A \wedge A \right\rangle,$$

where k is a coupling constant which satisfies a quantization condition (e.g., for semisimple gauge groups it must be an integer). In what follows, however, we will work perturbatively with formal power series in k^{-1}.

Now, recall the standard knot observable, $\mathrm{Tr}_R\,\mathrm{hol}(A)$ where $\mathrm{hol}(A)$ stands for the holonomy of the connection A along the knot (the path-ordered exponent of the integral of A along the knot) and the trace is taken in some chosen representation R of the gauge group.

One obtains a knot invariant by taking the path integral over all connections with the observable plugged into the integrand,

$$Z(\text{knot}) = \int \mathcal{D}\mathcal{A} e^{i\text{CS}(A)} \operatorname{Tr}_R \operatorname{hol}(A).$$

This integral is usually referred to as the expectation value of the standard observable and it is viewed as a function from knots to the base field (the complex numbers from now on). One is usually interested in $Z(\text{knot})/Z(\emptyset)$, where $Z(\emptyset)$ is the path integral with no observable plugged in (no knot).

Calculating the integral using perturbation theory we get the following sum:

$$\sum_{D \in D_{\text{CS}}} k^{-\deg D} \cdot \zeta^{\text{CS}}(D) \cdot W_{\mathcal{G}}(D),$$

where D_{CS} is defined to be the set of all trivalent connected graphs based on S^1 (Feynman diagrams based on a Wilson loop), ζ^{CS} is the integration of the corresponding propagators over the diagram (that is, the integration over the appropriate configuration space) and $W_{\mathcal{G}}$ is the Lie-algebraic part of the expectation value which holds all the information coming from the Lie group G and its representation R (that is, the weight system, reviewed quickly below).

In the CS perturbation theory calculation, every internal edge contributes $1/k$ and every internal vertex contributes k to the total power of k of the diagram (recall that an internal edge/vertex is an edge/vertex which is not on the Wilson loop). The total power of $1/k$ is called the *degree* of the diagram. A convenient way of counting the degree is labeling each internal vertex with -1 and each edge with $+1$ and then summing all the labels to get the degree of the diagram. This number is denoted $\deg D$.

We want to factorize the perturbation theory calculation in order to get a better hold on the above knot invariant. As a first step, we can drop the weight system and replace it with the diagram D on which it is calculated. We get the following invariant:

$$\sum_{D \in D_{\text{CS}}} k^{-\deg D} \cdot \zeta^{\text{CS}}(D) \cdot D.$$

This invariant is viewed as taking values in $\mathcal{A}(S^1)$, where we define $\mathcal{A}(S^1)$ as follows.

Definition 2.1: $\mathcal{A}(S^1)$ is the algebra of all connected trivalent graphs based on a circle (i.e., D_{CS}) quotient by the IHX relation

the STU relation

and the antisymmetry relation

When we apply the weight system $W_{\mathcal{G}}$ to this invariant we get the first sum. Next we will apply the weight system by parts, in order to get a further factorization.

Weight systems are described and explored in Ref. 6. We recall the main construction of a weight system coming from a Lie algebra, which includes three parts, labeling, contracting, and the trace part. In the labeling part, after choosing a basis for the Lie algebra, one labels each internal edge of a given diagram (i.e., edges that are not contained in the base circle) with a different index on each end of the edge. In the second part, one writes the structure constants

tensor for each internal vertex and the metric tensor for each internal edge (using the indices on these vertices/edges and the chosen basis) and proceeds to contract matching indices (using the metric to raise and lower indices). At that point, one is left with an invariant tensor in the enveloping algebra of $\mathcal{G}$ whose indices are the ones on the vertices on the base loop. In the final part, the trace part, one represents this tensor using a chosen representation of $\mathcal{G}$ and takes the trace. This concludes the construction of the weight system.

Taking a diagram (more precisely a class representative but we will not make these distinctions throughout the paper) in $\mathcal{A}(S^1)$ and applying to it the labeling and contracting parts of the weight system gives us a tensor in the universal enveloping algebra. This tensor is invariant under the adjoint action (all the tensors used in building it are invariant under the action and contractions are $\mathcal{G}$-maps) and therefore it is in the invariant subspace of the universal enveloping algebra $U(\mathcal{G})^{\mathcal{G}}$. Although we did not apply the trace part of the weight system yet, we still have a trace of the trace that appears in the standard observable we started with, which comes about diagrammatically in the fact that we are looking at diagrams based on S^1. The ability to move legs around cyclically (which is the trace property) forces us to quotient the resulting tensor in $U(\mathcal{G})^{\mathcal{G}}$ into the coinvariant quotient of the algebra, thus getting an invariant in $(U(\mathcal{G})^{\mathcal{G}})_{\mathcal{G}}$. Finally, one can apply the trace part to get elements of $\mathbb{C}$.

To summarize, when we use perturbation theory for the standard observable, we get a knot invariant in the form of a series (in $1/k$) with coefficients in $\mathbb{C}$, which factorize in the following way:

$$\{\text{knots}\} \to \mathcal{A}(S^1)[[k^{-1}]] \to (U(\mathcal{G})^{\mathcal{G}})_{\mathcal{G}}[[k^{-1}]] \to \mathbb{C}[[k^{-1}]]. \tag{1}$$

Although there is much more to say about Chern-Simons theory and the use of perturbation theory in this context, we will stop at this point. We recommend Refs. 5, 4, 3, 2, 1, and 15 for various approaches (physically and/or mathematically inclined) in addition to the reviews cited above. The fact that we actually get a knot invariant in every step of the factorization above is an example of an important issue which we completely ignored here.

B. The inhomogeneous gauge group

We now present a specific type of gauge group that we wish to focus on in the context of perturbation theory of CS theory.

Start with a semisimple gauge group G and take a semidirect product of it with its Lie algebra (the semidirect action is the adjoint action). Look at the Lie algebra of this semidirect product and denote it L_0. As a vector space, L_0 is a double copy of the original algebra, $\mathcal{G} \oplus \bar{\mathcal{G}}$, where we use upper bar notation to distinguish the second copy. For any $X \in \mathcal{G}$ let $X \mapsto \bar{X}$ be the identity map between the two copies. Thus $\bar{X}$ is the element X in the second copy of $\mathcal{G}$. Let X_i be a basis for $\mathcal{G}$, $\overline{X_i}$ the corresponding basis for $\bar{\mathcal{G}}$ and $[.,.]$ the original bracket structure on $\mathcal{G}$. We have the following bracket structure on L_0:

$$[X_i, X_j]_{L_0} = [X_i, X_j], \quad [X_i, \overline{X_j}]_{L_0} = \overline{[X_i, X_j]}, \quad [\overline{X_i}, \overline{X_j}]_{L_0} = 0.$$

We see now that the second copy is the Abelianization of the original algebra.

Letting the metric on $\mathcal{G}$ be $\langle , \rangle$ (the one coming from the trace of the adjoint representation, say) we take the following (invariant) metric on L_0:

$$\langle X_i, X_j \rangle_{L_0} = 0 = \langle \overline{X_i}, \overline{X_j} \rangle_{L_0}, \quad \langle X_i, \overline{X_j} \rangle_{L_0} = \langle X_i, X_j \rangle.$$

C. The structure of the perturbation theory expansion with the inhomogeneous gauge group

Let us look at the perturbation theory expansion using the inhomogeneous gauge group L_0. As we will show, the factorization (1) factors even further as the weight system using this type of Lie algebra is more refined. We will define the space of directed "legal" diagrams and construct a factorization of the weight system W_{L_0} through a map into it.

As known from standard perturbation theory of quantum gauge theories, the algebraic contributions of vertices and edges in a Feynman diagram are determined by the structure constants and the metric on the Lie algebra. These contributions are encoded in the weight system, as described earlier.

Given a diagram, choose a basis X_i to $\mathcal{G}$, take the corresponding basis $\overline{X_i}$ to $\bar{\mathcal{G}}$ (obtaining a basis to the entire algebra) and apply the weight system using the following steps.

1(pre). Sum over all the ways of labeling the ends of the edges of the diagram with different indices i and $\bar{i}$ representing the basis for $\mathcal{G}$ and $\bar{\mathcal{G}}$, respectively. Therefore, instead of labeling with one type of indices running over the entire basis of the algebra, label with two types of indices, each running over one summand in the direct sum that forms the algebra.

2(pre). Write the structure constants tensor and the metric tensor (as before) with indices according to the labeling, and contract the matching indices [thus in each summand of step 1(pre) only a part of the algebra basis is contracted].

Since the summations are finite, one can see that this way of applying the labeling and contraction parts of the weight system (i.e., in two summation steps having two types of algebra indices instead of one) is equivalent to the usual way of applying the weight system.

Furthermore, we know that certain combinations of indices vanish in the second step. By looking at the metric we observe that the only edges which are nonzero are the ones that have a nonbar index on one end and a bar index at the other end. By looking at the bracket structure we observe that the only combination of indices on a vertex that will not be zero at step 2(pre) is a combination of two nonbar indices and one bar index. This allows us to revise step 1(pre) above into the following.

1(revised). Sum over all ways of labeling the ends of the edges of the diagram with indices i and $\bar{i}$, representing the basis for $\mathcal{G}$ and $\bar{\mathcal{G}}$, respectively, in such a way that each edge has one bar index and one nonbar index at its ends, and each vertex has two nonbar indices and one bar index at its legs.

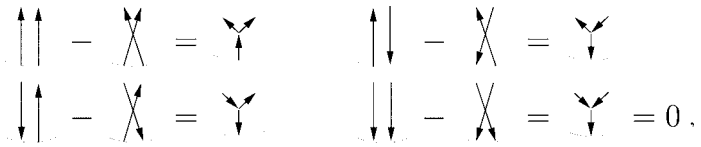
Let us introduce a notation. Wherever we have an edge after step 1(revised) we direct the edge (by setting an arrow head) from the nonbar index to the bar index and drop the bar on top of the bar index. Thus the two steps for applying the weight system of L_0 on a diagram can be finalized into the following form.

(1) Sum over all ways of directing the edges of the diagram (internal edges only) in such a way that each vertex has two outgoing legs and one ingoing leg (we call it a "legal" directing and it looks like ).

(2) Set a different index on each end of all the directed edges, write down the appropriate tensors and contract indices according to the arrow convention above (i.e., the arrow's direction indicates if the index is considered bar or nonbar, and we use the appropriate basis accordingly).

Step (1) is a map from the space of all Feynman diagrams D^{CS} to the space of all directed Feynman diagrams $\overrightarrow{D^{\mathrm{CS}}}$, defined to be all trivalent connected graphs based on a circle with arrows on the internal edges (the edges which are not a part of the base circle) such that each vertex is "legal" in the above sense. This map takes a diagram to the sum of all possible "legal" directing of it. In order to extend this map to $\mathcal{A}(S^1)$ we need to treat the STU/IHX/AS relations. For that purpose we define the directed STU, directed IHX, and directed AS relations which we will use in taking a quotient of $\overrightarrow{D^{\mathrm{CS}}}$. These relations reflect the algebraic structure of L_0 and can be read directly from the bracket structure.

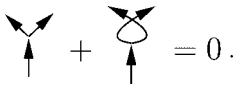
Definition 2.2: The directed STU relations in $\overrightarrow{D^{\mathrm{CS}}}$ are the following relations:



where the bottom nondirected arc is a part of the base circle.

The directed IHX relations are actually a consequence of the directed STU relations in $\overrightarrow{D^{\mathrm{CS}}}$, just as in Ref. 6. We draw one example here and the rest are just rotations thereof

The directed AS relation is defined just as the usual AS relation,



Definition 2.3: The space of all "legally" directed diagrams modulo the directed STU/IHX and AS relations, denoted $\overrightarrow{\mathcal{A}(S^1)}$, is the space of all trivalent connected graphs based on a circle (the Wilson loop) with arrows on the internal edges such that each vertex looks like

(i.e., the space $\overrightarrow{D_{\mathrm{CS}}}$ defined above), quotient by the directed STU, directed IHX and directed AS relations defined above.

Armed with these definitions we can see that step (1) of the factorization above is well defined as a map $\mathcal{A}(S^1)\to\overrightarrow{\mathcal{A}(S^1)}$. Composed with step (2) above (labeling and contracting of indices) and with taking the trace of the resulting tensor in some chosen representation, we get the following factorization of the perturbation theory expansion of CS theory with an inhomogeneous gauge group and the standard observable:

$$\{\text{knots}\}\to\mathcal{A}(S^1)[[k^{-1}]]\to\overrightarrow{\mathcal{A}(S^1)}[[k^{-1}]]\to(U(L_0)^{L_0})_{L_0}[[k^{-1}]]\to\mathbb{C}[[k^{-1}]]. \tag{2}$$

Note that the directed STU relations (which reflect the structure of L_0) tell us that two adjacent legs which touch the base circle and have arrows pointed towards it, are commutative (as the bar indices are commutative). On the other hand, if they originate from one vertex they are anticommutative according to the AS relation. Thus one gets an important relation in $\overrightarrow{\mathcal{A}(S^1)}$:

This relation will be used in the arguments presented in the next section.

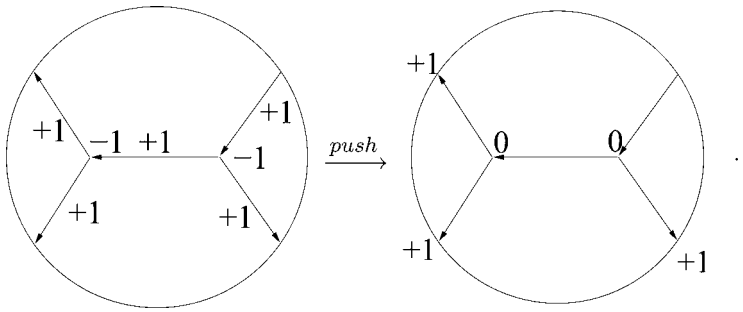
D. But $\vec{\mathcal{A}}(S^1)$ is (almost) empty

We will now prove that there are only few nonzero diagrams in $\overrightarrow{\mathcal{A}(S^1)}$ and the ones that are not zero encode a very specific type of information regarding the knot—the framing. This information can actually be normalized to zero showing that the entire weight system W_{L_0} is trivial. We will prove that the only primitive element which is nonzero in $\overrightarrow{\mathcal{A}(S^1)}$ is the directed single chord diagram $\ominus$ (drawn without the arrow here) and thus the only degree n diagram which is nonzero in $\overrightarrow{\mathcal{A}(S^1)}$ is $\ominus^n$. We will do that by first showing that the only primitive elements that are possibly

nonzero are the wheel diagrams (e.g. , ) and $\ominus$. We will then present an argument as to why the wheel diagrams are actually zero. We remind the reader that whenever we mention a diagram we mean a (representative of) diagram class.

Lemma 2.4: Every degree n diagram in $\overrightarrow{\mathcal{A}(S^1)}$ has at least n external vertices (vertices that are on the base loop).

Proof: As already mentioned, to every diagram we attach a power of $1/k$ which is called the degree. A convenient way of counting the degree is labeling each internal vertex with -1 and each edge with $+1$ and then summing up all the labels to get the degree of the diagram. Given a degree n diagram in $\overrightarrow{\mathcal{A}(S^1)}$, label it with $+1$ and -1 according to the above. "Push" the labels on the edges in the direction of the arrows. Whenever a label hits a vertex it stops and the labels at the vertex are added. An example of this procedure for a degree 3 diagram is given by



According to the "legal" directing rules, each internal vertex will have one label $+1$ hitting the vertex label -1 thus summing to a zero label. All other labels are pushed to the external vertices (on the Wilson loop). Since the total sum of labels is conserved and equal to the degree of the diagram, what we have just proven is that a degree n diagram in $\overrightarrow{\mathcal{A}(S^1)}$ has at least n vertices on the Wilson loop (in other words at least n external legs).

This lemma has immediate consequences in terms of the primitive elements that generate the algebra $\overrightarrow{\mathcal{A}(S^1)}$. The primitive elements of the nondirected algebra $\mathcal{A}(S^1)$ are these diagrams which remain connected when the Wilson loop is removed from them. Let $\mathcal{P}_n$ be the space of primitive diagrams in $\mathcal{A}(S^1)$ of degree n. Filter the primitive spaces (of different degrees) according to the number of external legs and write $\mathcal{P}_{n,d}$ for the space of primitive diagrams in $\mathcal{A}(S^1)$ of degree n and at most d external legs.

Lemma 2.5 (Refs. 14 and 13): If n is even, then $\mathcal{P}_n=\mathcal{P}_{n,n}$ and the quotient space $\mathcal{P}_{n,n}/\mathcal{P}_{n,n-1}$ is one dimensional generated by the n-degree wheel. If n is odd, then $\mathcal{P}_n=\mathcal{P}_{n,n-1}$ (with the exception of $\mathcal{P}_1$ being generated by $\ominus$).

Proof: See Refs. 14, 13, and 6 for proof and much more details on the subject. Again, we mention that a wheel diagram looks like the following: the two wheel  the four wheel  and so on.

This lemma transfers over to $\overrightarrow{\mathcal{A}(S^1)}$ where the primitives are the primitives of $\mathcal{A}(S^1)$ directed in all possible ways. Combining the previous two lemmas we obtain the following.

Corollary 2.6: The only primitive diagrams that might possibly be nonzero are the wheel diagrams and $\ominus$.

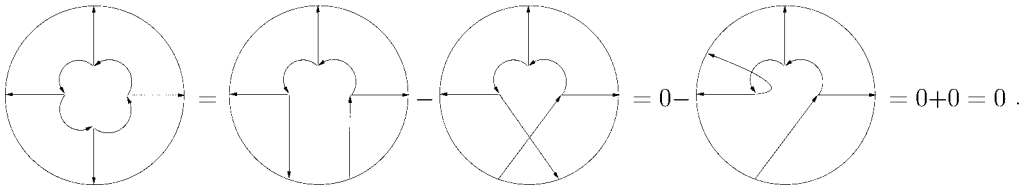
However, we have the following.

Lemma 2.7: The wheel diagrams are zero in $\overrightarrow{\mathcal{A}(S^1)}$.

Proof: We start by looking at a directed wheel diagram. There are only two directed wheel diagrams of each degree, one for each of the two ways of directing the inner loop, and it does not matter which one we choose to look at. Due to the "legal" directing rules, it is not hard to see that the external legs are always pointing towards the base loop. We apply a directed STU relation on

one of these legs  obtaining two tree diagrams (i.e., diagrams which contain no internal loops). A tree diagram will always have exactly one leg pointing from the base loop inwards. The tree diagram that corresponds to the first summand on the right-hand side of the relation has a vertex which looks like  This means the tree diagram is equal to zero (see the comment at the end of Sec. II C). The second tree diagram, corresponding to the second summand on the right-hand side of the directed STU relation, is "leg crossed." This crossing can be untangled by moving the crossed leg around the base circle using the directed AS relation when necessary and the commutativity of outward pointing legs. Moving the leg around the circle will yield a diagram which again has a vertex which looks like  (up to a sign) and thus equals to zero. Apply this argument to any n-wheel diagram and the lemma is proven.

We demonstrate the entire argument on the four wheel:



Combining all of the above lemmas we finally get the following.

Proposition 2.8: The only possible nonzero primitive element in $\widehat{\mathcal{A}(S^1)}$ *is the directed single-chord diagram* $\ominus$. *Thus, the only diagrams of degree n that are possibly nonzero in* $\widehat{\mathcal{A}(S^1)}$ *are directed* $\ominus$.

Proof: The proof is a corollary of all the above lemmas. The only primitive element which is nonzero is $\ominus$ and it generates powers of itself and sums of such powers.

In CS perturbation theory it is well known that the single-chord diagram has the framing (self-linking) of the knot as its integral $\zeta^{\mathrm{CS}}(\ominus)$ (see, for example, Ref. 15). Higher degree diagrams, which are merely power of the single-chord diagram, will hold information encoded in powers of the framing of the knot. Moreover, this framing number can be normalized as we wish, including normalization to zero, thus we can summarize this chapter with the following proposition.

Proposition 2.9: CS topological quantum field theory with an inhomogeneous gauge group and the standard knot observable (expectation value of the trace, in some representation, of the holonomy along the knot) holds no more than the framing information (which can be trivialized anyway).

CS theory with an inhomogeneous gauge group and the standard observable fail to recognize knotting in S^3. As a gauge theory, CS theory with inhomogeneous gauge group is equivalent to pure BF theory and should therefore "see" knots at least for ISU(2) gauge group, as was shown by Cattaneo *et al.*[10–12] Therefore, we need a procedure that will extract some nontrivial information regarding the knot in our setting. This is what we will be presenting in the next section.

III. EXTRACTING NONTRIVIAL INFORMATION REGARDING THE KNOT

A. Breaking gauge symmetry at one point—puncturing the space

As seen in the preceding section, the reason we got zero information when the standard observable is used is the "emptiness" of $\widehat{\mathcal{A}(S^1)}$. Working with the inhomogeneous gauge group allows us to factor through the "legally" directed diagrams space when applying perturbation theory thus there is no way of avoiding the consequences of Lemmas 2.3 and 2.4 of the preceding section which state that the only possible nonvanishing contribution in perturbation theory comes from the wheel diagrams. The best we can do is try and avoid the reasons Lemma 2.5 is true. When we look at the proof of Lemma 2.5 we can realize that the cause for the vanishing contribution of the wheel diagrams is the fact that legs can be moved around the Wilson loop (the base

circle of the diagram). Dealing with the loop translates (observablewise) to dealing with the trace (and its cyclic properties) in the standard observable. In diagrammatic terms (perturbationwise) this means trying to cut the base circle open.

Assume first that we just remove the trace from the standard observable of a knot in S^3. We get an expectation value which is formally a tensor in the universal enveloping algebra $\int \mathcal{D}\mathcal{A} e^{i\mathrm{CS}(A)}\,\mathrm{hol} \in U(L_0)$. This expression, though, is not well defined since the holonomy by itself is not well defined and transforms nontrivially by conjugation under gauge transformation $\chi(x)$. Choosing (in advance) one point on the knot, say x_0, the conjugation is done by the gauge element at that point $[\mathrm{hol} \to \chi(x_0)\mathrm{hol}\,\chi^{-1}(x_0)]$. The remedy for that would be to view this (not well defined) invariant in the coinvariant quotient $U(L_0)_{L_0}$. The way this is done (observablewise) is of course by bringing back the trace. We have done nothing then.

This leads us to try and have special considerations for x_0 (the chosen point on the knot) and the gauge symmetry at that point. Let us break the gauge symmetry at x_0. There are a few equivalent ways of looking at that process. The first is by declaring that the gauge transformation at x_0 is always the identity element. This might seem to be a bit artificial but an equivalent way of doing it is taking x_0 out of the space on which the theory is defined by puncturing S^3 on x_0. In other words, "send" x_0 to infinity where gauge transformations are taken to vanish. This shifts us to a theory on a long knot (embedding of $\mathbb{R}$) in $\mathbb{R}^3$ with an invariant $\int \mathcal{D}\mathcal{A} e^{i\mathrm{CS}(A)}\,\mathrm{hol} \in U(L_0)$ which is well defined in the framework of CS theory.

To summarize, we move from a CS theory on S^3 and a knot (embedding of S^1) in it to a CS theory on $\mathbb{R}^3$ and a long knot (embedding of $\mathbb{R}$) in it. This is done by choosing a special point on the knot, puncturing the space there and declaring the puncture as infinity. The standard observable $\mathrm{Tr}_R\,\mathrm{hol}$ *is replaced by a more general observable hol.*

As far as knots are concerned, "regular" knots and long knots are equivalent and we do not lose any information regarding the knot in the process above. Moreover, hol (and functions of it) is actually the most general observable in this framework since the connection can always be recovered (up to gauge transformations) from the holonomy information. Thus we work in the setting which allows us to extract maximum information regarding the knot when using the inhomogeneous gauge group.

We take now $\int \mathcal{D}\mathcal{A} e^{i\mathrm{CS}(A)}\,\mathrm{hol}$ and apply the same perturbation theory factorization as in Sec. II. There are several differences to note.

First, we work with a long knot. Thus, all the Feynman diagrams are not based on a loop but on an interval (representing the embedding of our long knot $\mathbb{R}$). The other properties of the diagrams do not change, though. We define the following.

Definition 3.1: $\mathcal{A}(I)$ is the algebra of all connected trivalent graphs based on an interval, modulo the STU, IHX and AS relations [i.e., $\mathcal{A}(S^1)$ with the circle replaced by an interval]. $\widehat{\mathcal{A}(I)}$ is defined the same way as $\widehat{\mathcal{A}(S^1)}$, except that the diagrams are based on an interval and not on a circle.

Second, the knot invariant factors through the invariant subspace of the universal enveloping algebra $U(L_0)^{L_0}$. This time there is no necessity in taking the coinvariant quotient of that space, a necessity that came about because of the base circle (or the trace in the observable). Note that the fact that we indeed get a tensor in the invariant subspace tells us that the construction was independent of the choice of the special point x_0.

Third, we do not have a map to $\mathbb{C}$ yet.

All together we get the following factorization for the perturbation theory of CS theory on $\mathbb{R}^3$ with a long knot in it (we denote by l the last map):

$$\{\mathrm{knots}\} \to \mathcal{A}(I)[[k^{-1}]] \to \widehat{\mathcal{A}(I)}[[k^{-1}]] \xrightarrow{l} U(L_0)^{L_0}[[k^{-1}]]. \tag{3}$$

B. Building an observable and extracting nontrivial information

We have not shown so far that the algebra $\widehat{\mathcal{A}(I)}$ is nonzero and that our construction is indeed nontrivial in the sense that it fixes the problems encountered with the standard observable. We

have also not defined a scalar observable, i.e., a map $U(L_0)^{L_0}\to\mathbb{C}$ which completes the perturbation theory factorization. We will now achieve both goals by finding an explicit functional from $\widetilde{\mathcal{A}(I)}$ to $\mathbb{C}$ that does not vanish when composed with the above factorization. We will give a formula for a scalar function $U(L_0)^{L_0}\to\mathbb{C}$ that is not zero on the part of $U(L_0)^{L_0}$ which comes from wheel diagrams in $\widetilde{\mathcal{A}(I)}$. This observable cannot possibly be any trace of hol in some representation, since that will bring us back to the case of Sec. II. Thus we need to find some other scalar function of hol.

Start with an n-dimensional representation of $\mathcal{G}$ and denote it B. Define the following representation R of L_0:

$$R(g)=\begin{pmatrix} B(g) & 0 \\ 0 & B(g) \end{pmatrix},\quad g\in\mathcal{G},\quad R(\bar{g})=\begin{pmatrix} 0 & B(g) \\ 0 & 0 \end{pmatrix},\quad \bar{g}\in\bar{\mathcal{G}}. \tag{4}$$

It is straightforward to verify that the commutation relation for R is indeed compatible with the commutation relations of the semidirect product and that R is indeed a representation of L_0. We extend R to $U(L_0)$ in the usual way.

Definition 3.2: We have the following.

(1) Let Δ denote the comultiplication of the universal enveloping algebra $U(L_0)$ and let Δ^m denote the map $U(L_0)\to U(L_0)^{\otimes m}$ we get by composing $m-1$ times the map Δ.

(2) Given the representation R above, denote by $R^{\otimes m}$ the m-tensored representation $U(L_0)^{\otimes m}\to\mathrm{End}(\mathbb{C}^{2n})^{\otimes m}$ defined by $u_1\otimes\cdots\otimes u_m\mapsto R(u_1)\otimes\cdots\otimes R(u_m)$.

(3) Define a transformation λ, $\mathrm{End}(\mathbb{C}^{2n})^{\otimes m}\to\mathrm{End}(\mathbb{C}^{2n})$ by $\tau_1\otimes\tau_2\otimes\cdots\otimes\tau_m\mapsto\tau_1\cdot C\cdot\tau_2\cdot C\cdot\cdots\cdot\tau_m\cdot C$, where C is the following $2n\times 2n$ matrix:

$$\begin{pmatrix} 0 & 0 \\ I & 0 \end{pmatrix}$$

and $\cdot$ is matrix multiplication.

(4) The "half-trace," denoted $\mathrm{Tr}_{1/2}$, is the trace over the upper-left $n\times n$ block of a $2n\times 2n$ matrix,

$$\mathrm{Tr}_{1/2}\begin{pmatrix} A & B \\ C & D \end{pmatrix}=\mathrm{Tr}(A).$$

Armed with the above definitions and notations we can finally build the following.

Definition 3.3: Let Σ_m denote the following composition of maps ($\circ$ is used for composition):

$$\mathrm{Tr}_{1/2}\circ\lambda\circ R^{\otimes m}\circ\Delta^m: U(L_0)^{L_0}\xrightarrow{\Sigma_m}\mathbb{C}.$$

Lemma 3.4: The map $\Sigma_m\circ l$ is nonzero on the m-wheel diagram for at least one choice of gauge group L_0 and representation R.

Proof: We start by looking at a directed wheel diagram [i.e., a wheel in $\widetilde{\mathcal{A}(I)}$]. All the external legs (the ones that touch the base interval) point towards the interval, as we have already seen. This means that after applying l, the tensor w that we get in $U(L_0)$ will have all its components in $\bar{\mathcal{G}}$. After applying Δ^m to w we get a tensor in $U(L_0)^{\otimes m}$ such that each of its summands actually looks like $u_1\otimes\cdots\otimes u_m\in U(\bar{\mathcal{G}})^{\otimes m}\subset U(L_0)^{\otimes m}$.

Now, the only type of tensors $u_1\otimes\cdots\otimes u_m\in U(\bar{\mathcal{G}})^{\otimes m}$ that will possibly not result in zero after applying $\lambda\circ R^{\otimes m}$ to it, is the type in which each component u_i is actually an element of $\bar{\mathcal{G}}$ [i.e., tensors of length one in $U(L_0)$ with entry from $\bar{\mathcal{G}}$]. This is immediate from the definition of R (4) on $U(\bar{\mathcal{G}})$, the definition of λ and the definition of C.

We summarize then—given a wheel diagram we apply l to it and get a tensor w in $U(L_0)$. $\Delta^m(w)$ is a tensor in $U(L_0)^{\otimes m}$ but the only nonzero contributions to $\lambda\circ R^{\otimes m}(\Delta^m(w))$ come from the summands of $\Delta^m(w)$ that look like w or any permutations of its entries,

$$w = l(\text{directed } m-\text{wheel}) = \sum_{i_1,\ldots,i_m=1}^{\dim \mathcal{G}} C^{i_1,\ldots,i_m} \bar{X}_{i_1} \otimes \cdots \otimes \bar{X}_{i_m},$$

$$\lambda \circ R^{\otimes m}(\Delta^m(w)) = \lambda \circ R^{\otimes m}\left(\sum_{i_1,\ldots,i_m=1}^{\dim \mathcal{G}} \sum_{\sigma \in S_m} C^{i_1,\ldots,i_m} \bar{X}_{i_{\sigma(1)}} \otimes \cdots \otimes \bar{X}_{i_{\sigma(m)}} \right),$$

where we made a distinction between the tensor product $\otimes$ of $U(L_0)$ and the product $\bigotimes$ of $U(L_0)^{\otimes m}$ for the sake of clarity.

The calculation of $\mathrm{Tr}_{1/2} \circ \lambda \circ R^{\otimes m} \circ \Delta^m \circ l(\text{directed } m-\text{wheel})$ is almost the same as the calculation of the weight system $W_{\mathcal{G},B}$ on the nondirected m-wheel diagram (i.e., the directed m-wheel with its arrows forgotten). The only difference is the summation over all permutations of the components of the tensor w above, but that can be done on the diagram level by permuting all external legs of the nondirected diagram. Thus we have

$$\mathrm{Tr}_{1/2} \circ \lambda \circ R^{\otimes m} \circ \Delta^m \circ l(\text{directed } m-\text{wheel}) = W_{\mathcal{G},B}(\chi(m-\text{wheel})),$$

where $\chi(D)$ is defined to be the sum over all diagrams which differ from D by permutation of the external legs.

In order to show that $\Sigma_m \circ l(\text{directed } m-\text{wheel})$ is nonzero for at least one choice of L_0 and representation R we let $L_0 = gl(n) \oplus \overline{gl(n)}$ with B taken to be the defining representation and calculate the highest order in n of $W_{gl(n),B}(\chi(m-\text{wheel}))$. Using simple counting arguments one may show that all the highest order contributions are positive and sum up to a nonzero contribution: $\Sigma_m \circ l(\text{directed } m-\text{wheel}) = mn^{m+1} + \text{lower order terms (in } n)$. We leave the exact calculation and arguments to the interested reader. These can be done using exercise 6.36 in Ref. 6.

Proposition 3.5: In $\widetilde{\mathcal{A}(I)}$, *the wheel diagrams (and possibly the directed* $\ominus$*) are nonzero.*

Proof: We already know that the only possible nonzero directed generators in $\widetilde{\mathcal{A}(I)}$ are the wheel diagrams and possibly $\ominus$ [following the exact same arguments for $\widetilde{\mathcal{A}(S^1)}$ as in Sec. II]. Applying the lemma above for all possible m implies the proposition.

The actual observable: The proposition and lemma above tell us that the perturbation theory (3) for the long knot in $\mathbb{R}^3$ factors through a nontrivial space, and that there is a way of extracting nontrivial information regarding the knot. We can now build an actual quantum observable (function of hol) to plug in the path integral such that the map $\mathrm{Tr}_{1/2} \lambda R^{\otimes m} \Delta^m$ will be the last part of the factorization $(U(L_0)^{L_0} \to \mathbb{C})$ in its perturbation theory calculation of the expectation value. This observable is $\mathrm{Tr}_{1/2}((R(\mathrm{hol}) \cdot C)^m)$, where $R(\mathrm{hol})$ stands for representing the holonomy using the representation R as defined above.

The expectation value $\int \mathcal{D}\mathcal{A} e^{i\mathrm{CS}} \mathrm{Tr}_{1/2}((R(\mathrm{hol}) \cdot C)^m)$ has a perturbation theory factorization (with Σ_m as the last map),

$$\{\text{knots}\} \to \mathcal{A}(I)[[k^{-1}]] \to \widetilde{\mathcal{A}(I)}[[k^{-1}]] \xrightarrow{l} U(L_0)^{L_0}[[k^{-1}]] \xrightarrow{\Sigma_m} \mathbb{C}[[k^{-1}]]. \tag{5}$$

C. The most general knot invariant in this setting—the Alexander-Conway polynomial

We have just seen in the preceding section that we can extract all the information contained in the wheel diagrams by using CS theory with the inhomogeneous gauge group on long knots in $\mathbb{R}^3$ (with the new class of observables). This is opposed to the fact that the standard observable in CS theory with the inhomogeneous gauge group will not see these knots in S^3. We now turn to the task of recognizing the nontrivial information we extracted.

Theorem 1: *The most general knot invariant coming from Chern-Simons topological quantum field theory with an inhomogeneous gauge group is nontrivial and is in the algebra generated by the coefficients of the Alexander-Conway polynomial (together with possible framing information).*

Proof: In Ref. 16, following motivations from Refs. 17 and 7, it is proven that any weight system which is zero on the kernel of the deframing operator and zero on all the primitive spaces which are not wheels, belongs to a knot invariant which is in the algebra generated by the coefficients of the Alexander-Conway polynomial. Since we showed that the only diagrams that contribute to our weight system are the wheel diagrams, and since we can always choose our knot to be of (standard) zero framing, the theorem follows. Other choices of framing will show up through $\ominus$.

Notice that it is possible to take the semidirect product of G with $\mathcal{G}^*$, the dual of the Lie algebra. We can follow the exact same considerations and get the same results, this time without the need of the metric on $\mathcal{G}$ (just use the natural dual pairing to get a metric on L_0). Therefore our results are true for any Lie algebra $\mathcal{G}$, not necessarily a metrizable one.

IV. PURE BF THEORY AND THE ALEXANDER-CONWAY POLYNOMIAL

Recall that the pure BF theory has the following action $S_{\mathrm{BF}}=\int_{S^3}\mathrm{Tr}(B\wedge F)$, where F is the curvature of the G-connection A and B is a one form taking values in the algebra $\mathcal{G}$. In Refs. 10–12 Cattaneo *et al.* took $\mathrm{Tr}_R(\mathrm{Exp}(\lambda\gamma_1))$ as the most general observable one can consider in pure BF theory, as long as the standard (zero) framing of the knot is chosen. Here R is any representation of G, γ_1 is $\oint_x \mathrm{Hol}(A)B(x)\mathrm{Hol}(A)$ [the first degree element in the Taylor expansion of $\mathrm{Hol}(A+\kappa B)$ around $\kappa=0$] and λ is a "coupling" constant counting orders.

Using this observable, QFT techniques and the Melvin-Morton conjecture (MMR, see Ref. 7), it was proven[10] that the set of unframed knot invariants we get from the pure BF theory, using SU(2) gauge group, is generated by the coefficients of the Alexander-Conway polynomial.

In this paper we proved the following.

Theorem 2: *The most general knot invariant coming from pure BF topological quantum field theory with any gauge group whose Lie algebra is metrizable and with any representation, is in the algebra generated by the coefficients of the Alexander-Conway polynomial.*

Proof: Using the fact that the pure BF theory with gauge group G is just CS theory with gauge group IG (Ref. 8) this theorem is just a corollary of Theorem 1.

The same generalization for nonmetrizable Lie algebras, as right after Theorem 1, applies here as well.

A closer look at our observable $\mathrm{Tr}_{1/2}((R(\mathrm{hol})\cdot C)^m)$ shows that it is actually the mth degree in the expansion of the BF observable $\mathrm{Tr}_R(\mathrm{Exp}(\lambda\gamma_1))$ (up to numerical factors coming from the exponent expansion). The fact that the BF observable also breaks the gauge symmetry of the pure BF theory at one point (it must be assumed that the special BF gauge symmetry is identity at one point on the knot) was not emphasized much before (though observed of course in Refs. 10–12). Our setting gives a natural explanation as to why this is indeed the most general observable for BF theory without any need for taking various limits or referring to MMR. We also get a somewhat clearer explanation as to why one can ignore the γ_0 part of the Taylor expansion above.

One can now say that as far as knot theory and three-dimensional BF topological quantum field theory (with or without cosmological constant) are concerned, there is nothing new beyond Chern-Simons theory, which can reproduce the same knot theoretical results.

V. DISCUSSION: NON-SEMI-SIMPLICITY

Algebraically, the main difference between our construction and the standard one is getting invariants in the invariant subspace $U(L_0)^{L_0}$ instead of the coinvariant quotient space $(U(L_0)^{L_0})_{L_0}$ of the universal enveloping algebra.

Our construction gives no new extra information if we work with a semisimple gauge group instead of L_0. This is true because for semisimple groups, $U(\mathcal{G})^{\mathcal{G}}$ is isomorphic to $(U(\mathcal{G})^{\mathcal{G}})_{\mathcal{G}} \cong U(\mathcal{G})_{\mathcal{G}}$. We get no new information from applying our procedure and working in $\mathcal{A}(I)$ instead of $\mathcal{A}(S^1)$, since these spaces are isomorphic (the diagram-space way of expressing the previous isomorphism). Our construction seems to detect the difference between the invariant subspace and

the coinvariant quotient of the non-semi-simple Lie algebra we have worked with. In other words, it uses the fact that $\overrightarrow{\mathcal{A}(I)}$ is not isomorphic to $\overrightarrow{\mathcal{A}(S^1)}$ [the map $\overrightarrow{\mathcal{A}(I)} \to \overrightarrow{\mathcal{A}(S^1)}$ that closes the base interval into the base circle has a kernel].

We saw that there is more to observe in Chern-Simons theory when dealing with a non-semi-simple gauge group. A question to be raised is whether other non-semi-simple gauge groups can hold the same property as the inhomogeneous group—meaning that the above procedure can extract more information about the knot than what was given by the standard observables.

(Received 22 April 2005; accepted 7 October 2005; published online 9 December 2005)

We present a model unifying general relativity and quantum mechanics based on a noncommutative geometry. This geometry is developed in terms of a noncommutative algebra $\mathcal{A}$ which is defined on a transformation groupoid Γ given by the action of a noncompact group G on the total space E of a principal fiber bundle over space-time M. The case is important since to obtain physical effects predicted by the model we should assume that G is a Lorentz group or some of its representations. We show that the generalized Einstein equation of the model has the form of the eigenvalue equation for the generalized Ricci operator, and all relevant operators in the quantum sector of the model are random operators; we study their dynamics. We also show that the model correctly reproduces general relativity and the usual quantum mechanics. It is interesting that the latter is recovered by performing the measurement of any observable. In the act of such a measurement the model "collapses" to the usual quantum mechanics. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2137720]

I. INTRODUCTION

Noncommutative geometry plays an increasingly important role in the present search for quantum gravity (from a host of papers let us quote at least a few[3,4,2,1,6,14–16,19]). It has also recently been recognized that it is a useful tool in superstring theory (the classical paper is Ref. 18, and a book, Ref. 13). In a series of papers,[10–12] we have proposed our own approach to the unification of general relativity and quantum mechanics based on noncommutative geometry. Our starting point is the standard method of changing a differential manifold (space-time) M into a noncommutative space (Ref. 5, p. 86). It is done by implementing the following steps: (1) we represent M as a quotient space N/R where N is a suitable space and R a suitable equivalence relation; (2) then we change from N/R to a suitably organized subset $\mathcal{R}$ of $N\times N$; we call this the "pairing process;" (3) we define a suitable algebra on $\mathcal{R}$; and finally, (4) we extract information about N/R from this algebra.

We implement this strategy as follows. Let M be a space-time manifold. The natural way to present M as a quotient space is with the help of the frame bundle over M. Let $\pi_M: E\to M$ be the frame bundle with the structure group G, then $M=E/G$. To perform the "pairing process" let us notice that the group G acts (to the right) on E (along the fibers), $E\times G\to E$. We can equip $E\times G$ with the groupoid structure. This groupoid is called a *transformation groupoid*, and will be denoted by Γ (its description is given in Sec. II). Now, we define a (noncommutative) compactly supported, smooth, complex valued algebra $\mathcal{A}$ on Γ with convolution as multiplication. Then we construct, in terms of this algebra, the (noncommutative) geometry of the groupoid Γ which is a

generalization of the usual space-time geometry (on M). The regular representation of the algebra $\mathcal{A}$ on a bundle of Hilbert spaces gives us the "quantum sector" of the model.

To smooth out some inaccuracies and avoid conceptual traps in which our previous work was involved we have tested the method on a simpler model in which the group G was finite.[8,9,17] It has turned out that this simplified model works well. Let us notice, however, that if a finite group G acts freely on a space E then G must be a cyclic group isomorphic with $\mathbb{Z}^n$ where $n=|G|$. Indeed, for $G \ni g \neq e$ the set $\{gp, g^2p, \ldots, g^np\}$ is bijective with G and, as it can be easily seen, $g^n=e$. However, we should notice that the fact that the group G is Abelian does not entail the commutativity of the groupoid algebra $\mathcal{A}$. Therefore, our model with a finite group G could serve well as an "exercise model," but to have a more physically realistic approach we must change to an infinite group G. This is exactly what we do in the present paper. Throughout this paper it is assumed that G is a noncompact group. This is an important case since to obtain physical effects predicted by our model we should assume that G is a Lorentz group or some of its representations.

In Sec. II, we briefly present the groupoid Γ and its algebra $\mathcal{A}$, and we establish notation. The geometry of the groupoid Γ is based on the module of derivations of the algebra $\mathcal{A}$. In Sec. III, we study the structure of this module and, in Secs. IV and V, we develop the differential geometry of the groupoid Γ. This enables us to formulate, in Sec. VI, generalized Einstein's equation. It turns out that it has the form of the eigenvalue equation for the generalized Ricci operator. We also show that the standard space-time geometry is obtained by suitably "averaging" elements of $\mathcal{A}$. In Sec. VII, we study the quantum sector of the model, and show that all relevant operators are random operators. We also investigate their generalized dynamics. The transition from our model to the usual quantum mechanics is presented in Sec. VIII. Interestingly, it is the act of measurement of any observable that reduces our model to the usual quantum mechanics. We thus can say that from the perspective of our model quantum mechanics is but a theory of making measurements.

The present paper focuses on mathematical aspects of the proposed model; its physical aspects will be discussed in a forthcoming paper.

II. PRELIMINARIES

Let $\Gamma=E\times G$, where E is the frame bundle over space-time M with the structural group G, such that G is a noncompact semisimple Lie group (let us notice that the Lorentz group is noncompact and semisimple) acting on E, be a transformation groupoid, and $\mathcal{A}=C_c^\infty(\Gamma,\mathbf{C})$ the noncommutative algebra of smooth, compactly supported, complex valued functions on Γ with convolution as multiplication. Let further $\gamma_1=(p_1,g_1)$, $\gamma_2=(p_2,g_2)\in\Gamma$, and $p_2=p_1g$. We assume the convention $\gamma_1\circ\gamma_2=(p_1,g_1g_2)$, and consequently

$$(f_1 * f_2)(\gamma) = \int_{\Gamma_{d(\gamma)}} f_1(\gamma_1) f_2(\gamma_1^{-1}\gamma)\mathrm{d}\gamma_1$$

for $f_1,f_2\in\mathcal{A}$, where $d(\gamma)=d(p,g)=p$.

Let us notice that the center of the algebra $\mathcal{A}$ vanishes, $\mathcal{Z}(\mathcal{A})=\{0\}$, but $\mathcal{A}$ is a module over $Z=\pi_M^*(C^\infty(\mathrm{M}))$ (here $\pi_M:E\to M$ is the bundle projection). Functions of Z, in general, are not compactly supported. However, they do act on $\mathcal{A}$ in the following way: $\alpha:Z\times\mathcal{A}\to\mathcal{A}$ by

$$\alpha(f,a)(p,q) = f(p)a(p,g),$$

$f\in Z$, $a\in\mathcal{A}$. Now, let us define the distribution

$$\tilde{f}(p,g) = f(p)\,\delta_e(g),$$

where δ is the Dirac distribution, $g\in G$, and e is the unit of G. $\tilde{f}$ convolutes well with functions of $\mathcal{A}$. Indeed, let $a\in\mathcal{A}$; we have

$$(\tilde{f} * a)(p,g) = \int_G \tilde{f}(p,g_1)a(pg_1,g_1^{-1}g)\mathrm{d}g_1 = f(p)a(p,g) \in \mathcal{A}.$$

(Here we have used the integral notation for the distribution action on test functions.)

Let $\mathcal{G}=E\times E$ be the space of the pair groupoid, where E is, as before, the total space of the frame bundle over space-time M, i.e., $\mathcal{G}=\{(x,p_1,p_2): p_1,p_2 \in E \text{ and } \pi_M(p_1)=(\pi_M(p_2))=x\}$, and the algebra $\tilde{\mathcal{A}}=C^\infty(\mathcal{G},\mathbf{C})$ with convolution as multiplication. The composition law reads $(x,p_1,p_2)\circ(x,p_2,p_3)=(x,p_1,p_3), p_1,p_2,p_3 \in E_x, x \in M$, and the convolution is defined accordingly.

Proposition 1: The mapping $J:\tilde{\mathcal{A}}\to\mathcal{A}$, given by

$$J(f)(\gamma) = f(\pi_M(p),p,pg),$$

for $f \in \tilde{\mathcal{A}}$, $\gamma=(p,g)$, is an isomorphism of algebras.

Proof: Let $\tilde{f}_1,\tilde{f}_2 \in \tilde{\mathcal{A}}$, we have

$$(\tilde{f}_1 * \tilde{f}_2)(x,p_1,p_2) = \int_{E_x} \tilde{f}_1(x,p_1,p_3)\tilde{f}_2(x,p_3,p_2)\mathrm{d}p_3.$$

We notice that the fiber E_x, for every $x \in M$, is diffeomorphic with the group G, and consequently there is a measure on E_x induced from the Haar measure on G. After making the substitution $p_3=p_1g_1$, $p_2=p_1g$, we obtain

$$(\tilde{f}_1 * \tilde{f}_2)(x,p_1,g) = \int_G \tilde{f}_1(x,p_1,p_1g_1)\tilde{f}_2(x,p_1g_1,p_1g)\mathrm{d}g_1$$

which can be rewritten as

$$(f_1 * f_2)(\gamma) = \int_{\Gamma_{d(\gamma)}} f_1(\gamma_1)f_2(\gamma_1^{-1}\circ\gamma)\mathrm{d}\gamma_1.$$

□

III. MODULE OF DERIVATIONS

Among derivations of the algebra $\mathcal{A}$ on the groupoid $\Gamma=E\times G$ we can distinguish three types, horizontal derivations, vertical derivations, and inner derivations of $\mathcal{A}$; we denote them by $\mathrm{Der}_{\mathrm{Hor}}\mathcal{A}$, $\mathrm{Der}_{\mathrm{Ver}}\mathcal{A}$, and $\mathrm{Inn}\,\mathcal{A}$, respectively. We shall study them in turn.

Lemma 1: Let $\bar{X} \in \mathcal{X}(E)$ be a right invariant vector field (on a principal bundle), i.e., $(\mathcal{R}_g)_{*p}\bar{X}(p)=\bar{X}(pg)$ for every $g \in G$. Its lifting to Γ, $\bar{\bar{X}}(p,g)=(\iota_g)_{*p}\bar{X}(p)$, where the inclusion $\iota_g: E\hookrightarrow E\times G$ is defined by $\iota_g(p)=(p,g)$, is a derivation of the algebra $(\mathcal{A},*)$.

Proof:

$$\begin{aligned}
\bar{\bar{X}}\,(p,g)(f*h)](p,g) &= [\bar{X}(p)(f*h)](\iota_g(p)) \\
&= \int_G [\bar{X}(p)f(p,g_1)]h(pg_1,g_1^{-1}g)\mathrm{d}g_1 + \int_G f(p,g_1)[(\bar{X})(p)h(pg_1,g_1^{-1}g)]\mathrm{d}g_1 \\
&= \int_G [\ (\bar{\bar{X}}))(p,g_1)f](p,g_1)h(pg_1,g_1^{-1}g)\mathrm{d}g_1 \\
&\quad + \int_G f(p,g_1)[\bar{\bar{X}}(pg_1,g_1^{-1}g)]h(pg_1,g_1^{-1}g)\mathrm{d}g_1 \\
&= (\bar{\bar{X}}f * h + f * \bar{\bar{X}}h)(p,g).
\end{aligned}$$

We have employed here the right invariance property. □

A. Horizontal derivations

The group G acts freely and transitively on the fibers of E. Consequently, the G-right-invariant vector fields on E are determined by their values at a single point of every fiber. Therefore, they can be identified with the cross sections of the bundle $\Sigma = TE/G$. Let us consider the mapping

$$(\pi_M)_*: TE \to TM.$$

Since $(\pi_M)_*$ is G-invariant, it induces the mapping

$$\pi_M: \Sigma \to TM.$$

Let us denote $\rho = (\bar{\pi}_M)_*$, and consider the exact sequence of vector bundles

$$0 \to \ker \rho \xrightarrow{j} \Sigma \underset{\sigma}{\overset{\rho}{\rightleftarrows}} TM \to 0.$$

The mappings j and ρ are homomorphisms of vector bundles, and j is an inclusion. The homomorphism of vector bundles $\sigma: TM \to \Sigma$ is a connection in the principal bundle $\pi_M: E \to M$ if it splits this sequence, i.e., if $\rho \circ \sigma = \mathrm{id}_{TM}$. In our case, such σ always exists although it is not unique. With the help of σ we lift a vector field $X \in \mathcal{X}(M)$ from M to Σ, i.e., $\bar{X}(p) = \sigma(X(\pi_M(p)), \pi_M(p) = x \in M$, and we consider $\bar{X}$ as a G-right-invariant vector field on E. Finally, we lift this field, with the help of the inclusion ι_g, to the groupoid Γ. We thus obtain

$$\bar{\bar{X}}(p,g) = (\iota_g)_{*p} \bar{X}(p) \in \mathcal{X}(E \times G)$$

for every $(p,g) \in \Gamma$. Vector fields $\bar{\bar{X}} \in \mathcal{X}(\Gamma)$, obtained in this way, inherit from σ the right invariance property. Lemma 1 evidently applies to such vector fields. Moreover, we have the following proposition.

Proposition 2: Vector fields $\bar{\bar{X}} \in \mathcal{X}(\Gamma)$ *form a Z-submodule of the Z-module* Der $\mathcal{A}$ *of derivations of the algebra* $\mathcal{A}$. *They will be called* horizontal *derivations of* $\mathcal{A}$ *and denoted by* $\mathrm{Der}_{\mathrm{Hor}}\, \mathcal{A}$.

Proof: Let $a, b \in \mathcal{A}$. One readily checks, taking into account the right invariance of $\bar{\bar{X}}$, that $f\bar{\bar{X}}(a * b)$, $f \in Z, a, b \in \mathcal{A}$, satisfies the Leibniz rule. We shall show that $f\bar{\bar{X}} \in \mathrm{Der}_{\mathrm{Hor}}\, \mathcal{A}$. Indeed, let $f_0 \in C^\infty(M)$ be such that $f = \pi_M^* f_0$, and $X' := f_0 X$, $X \in \mathcal{X}(M)$. We have

$$\bar{X}' = \pi_M^* f_0 \bar{X} = f\bar{X},$$

and by acting on both sides with ι_g we obtain $\bar{\bar{X}}' = f\bar{\bar{X}}$. □

B. Vertical derivations

Let us consider all right invariant vertical vector fields on E, i.e., all right invariant vector fields $\bar{X} \in \mathcal{X}(E)$ such that $(\pi_M)_*(\bar{X}) = 0$. Such vector fields lifted to Γ are, on the strength of Lemma 1, derivations of the algebra $(\mathcal{A}, *)$; we shall call them vertical derivations of this algebra, i.e.,

$$\bar{\bar{X}}(p,g) = (\iota_g)_{*p} \bar{X}(p) \in \mathrm{Der}_{\mathrm{Ver}}\, \mathcal{A}$$

for every $g \in G$.

Let us notice that $\bar{X} \in \mathcal{X}(E)$ can be regarded as cross sections of the vector bundle $\ker \rho$ and, as it can be easily seen, $\mathrm{Der}_{\mathrm{Ver}}\, \mathcal{A}$ is a Z-submodule of the Z-module Der $\mathcal{A}$.

C. Inner derivations

The set of inner derivations of the algebra $\mathcal{A}$ is defined as follows:

$$\mathrm{Inn}\,\mathcal{A} = \{\mathrm{ad}\,a : a \in \mathcal{A}\},$$

where $(\mathrm{ad}\,a)(b) := a*b - b*a$.

Lemma 2: The mapping $\Phi : A \to \mathrm{Inn}\,\mathcal{A}$, *given by* $\Phi(a) = \mathrm{ad}\,a$, *is an isomorphism of Lie algebras (and also of Z-moduli).*

Proof: It can be easily seen that

$$[\mathrm{ad}\,a, \mathrm{ad}\,b] = \mathrm{ad}[a,b] \in \mathcal{A},$$

i.e., $\mathrm{Inn}\,\mathcal{A}$ is a Lie algebra and Φ is a Lie algebra homomorphism. Then we have $\Phi(a) = \Phi(b) \Rightarrow [a,c] = [b,c]$, for every $c \in \mathcal{A}$. Hence $[a-b,c]=0$ since $a-b \in \mathcal{Z}(\mathcal{A}) = \{0\}$. Therefore, $a = b$. We also see that

$$\Phi(fa) = \mathrm{ad}(fa) = f\,\mathrm{ad}\,a = f\Phi(a)$$

for every $f \in Z$. □

As we have seen in the proof of this lemma, the fact that $\mathcal{Z}(\mathcal{A}) = \{0\}$ plays an important role in the entire structure.

D. Some properties of derivations

By *differential algebra* we understand a pair $(\mathcal{A}, \mathrm{Der}\,\mathcal{A})$ where $\mathcal{A}$ is a not necessarily commutative algebra and $\mathrm{Der}\,\mathcal{A}$ a (sub)module of its derivations. In the following, we will base the construction of a noncommutative geometry of the transformation groupoid Γ on the differential algebra $(\mathcal{A}, \mathrm{Der}\,\mathcal{A})$ where $\mathcal{A}$ is, as above, $C_c^\infty(\Gamma, \mathbf{C})$, and

$$\mathrm{Der}\,\mathcal{A} = \mathrm{Der}_{\mathrm{Hor}}\,\mathcal{A} \oplus \mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A} \oplus \mathrm{Inn}\,\mathcal{A}.$$

Let $\bar{\bar{X}}_1, \bar{\bar{Y}}_1 \in \mathrm{Der}_{\mathrm{Hor}}\,\mathcal{A}$, $\bar{\bar{X}}_2, \bar{\bar{Y}}_2 \in \mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}$, $\mathrm{ad}\,a$, $\mathrm{ad}\,b \in \mathrm{Inn}\,\mathcal{A}$. We have the following properties:

(1) $[\bar{\bar{X}}_1, \bar{\bar{Y}}_1] = \overline{\overline{[X_1, Y_1]}}$. This follows from the fact that $\bar{X} = \sigma(X)$ which implies that $[\bar{X}_1, \bar{Y}_1] = \overline{[X_1, Y_1]}$.
(2) $[\bar{\bar{X}}_2, \bar{\bar{Y}}_2] = \overline{\overline{[X_2, Y_2]}}$.
(3) $[\mathrm{ad}\,a, \mathrm{ad}\,b] = \mathrm{ad}[a,b] \in \mathrm{Inn}\,\mathcal{A}$, see proof of Lemma 2.
(4) $[\bar{\bar{X}}_1, \bar{\bar{X}}_2] = 0$, since cross sections of the vector bundle Σ form a Lie algebra which splits into the sum of two Lie subalgebras, and the fields $\bar{X}_1$ and $\bar{X}_2$ belong to different subalgebras.
(5) $[\bar{\bar{X}}_1, \mathrm{ad}\,a] = \mathrm{ad}\,\bar{\bar{X}}_1(a)$, by simple computations.
(6) $[\bar{\bar{X}}_2, \mathrm{ad}\,a] = \mathrm{ad}\,\bar{\bar{X}}_2(a)$, by simple computations.

IV. GEOMETRY OF $\mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}$ AND $\mathrm{Inn}\,\mathcal{A}$

Because of the decomposition of the Z-module $\mathrm{Der}\,\mathcal{A}$ into three parts, the metric on $\mathrm{Der}\,\mathcal{A}$,

$$\mathcal{G} : \mathrm{Der}\,\mathcal{A} \times \mathrm{Der}\,\mathcal{A} \to Z$$

also decomposes into three parts. If $u = u_1 + u_2 + u_3$, and $u_1 \in \mathrm{Der}_{\mathrm{Hor}}\,\mathcal{A}$, $u_2 \in \mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}$, $u_3 \in \mathrm{Inn}\,\mathcal{A}$, and analogously for $v = v_1 + v_2 + v_3$, then

$$\mathcal{G}(u,v) = \bar{g}(u_1,v_1) + \bar{k}(u_2,v_2) + h(u_3,v_3),$$

where $\bar{g}:\mathrm{Der}_{\mathrm{Hor}}\mathcal{A}\times\mathrm{Der}_{\mathrm{Hor}}\mathcal{A}\to Z$ is evidently the lifting of the metric $g:\mathcal{X}(M)\times\mathcal{X}(M)\to C^\infty(M)$ on space-time M, i.e.,

$$\bar{g}(u_1,v_1) = \pi_M^*(g(x,y)),$$

where $x,y\in\mathcal{X}(M)$. We assume that the metrics $\bar{k}:\mathrm{Der}_{\mathrm{Ver}}\mathcal{A}\times\mathrm{Der}_{\mathrm{Ver}}\mathcal{A}\to Z$ and $h:\mathrm{Inn}\,\mathcal{A}\times\mathrm{Inn}\,\mathcal{A}\to Z$ are of the Killing type. Their form will be determined below.

The preconnection is given by the Koszul formula,

$$(\nabla_u^* v)w = \tfrac{1}{2}[u(\mathcal{G}(v,w)) + v(\mathcal{G}(u,w)) - w(\mathcal{G}(u,v)) + \mathcal{G}(w,[u,v]) + \mathcal{G}(v,[w,u]) - \mathcal{G}(u,[v,w])]. \tag{1}$$

Let us now consider a more general situation which will later be specified to that in our model. Let $(\mathcal{A},*)$ be an algebra over $\mathbf{C}$, $Z=\mathcal{Z}(\mathcal{A})$ its center, and $\mathcal{V}$ a Z-module of derivations of the algebra $\mathcal{A}$. What follows is also valid if $\mathcal{Z}(\mathcal{A})=\{0\}$ and $Z=\pi_M^*(C^\infty(M))$ as in our model. We further assume that elements of Z play the role of constants for derivations of $\mathcal{V}$, i.e., $\mathcal{V}(Z)=\{v(f)=0: v\in\mathcal{V}, f\in Z\}$. Let us consider a metric $g:\mathcal{V}\times\mathcal{V}\to Z$; we assume the $Z-2$ linearity and symmetry of g, but not necessarily its nondegeneracy. Let us denote $\mathcal{V}^*=\mathrm{Hom}(\mathcal{V},Z)$, and $u^*=g(u,\cdot)=\Phi_g(u)$ is a one-form corresponding to the derivation $v\in\mathcal{V}$.

The symmetric two-form g determines the preconnection $\nabla^*:\mathcal{V}\times\mathcal{V}\to\mathcal{V}^*$ by the Koszul formula (1) (with $\mathcal{G}$ replaced by g). Since, by assumption, $\mathcal{V}(Z)=\{0\}$, one has $\nabla_u^*(fv)=f\nabla_u^* v$, and ∇^* is a $Z-2$ linear mapping, i.e., a tensor of (2,1) type. Moreover, from the Koszul formula it follows (even if g is degenerate) that

$$w(g(u,v)) = (\nabla_w^* u)(v) + (\nabla_w^* v)(u).$$

In the Koszul formula the first three terms vanish, and if we assume that

$$g(v,[w,u]) = g(u,[v,w]), \tag{2}$$

which—as we shall see below—is valid in our case, we obtain an interesting result

$$(\nabla_u^* v)(w) = g\left(\tfrac{1}{2}[u,v],w\right)$$

showing that there is a strict dependence between the (pre)connection and the metric. We should only look for a mapping $\nabla:\mathcal{V}\times\mathcal{V}\to\mathcal{V}$ that would be g-consistent with $\nabla^*:\mathcal{V}\times\mathcal{V}\to\mathcal{V}^*$, i.e., satisfying the condition

$$(\nabla_u^* v)(w) = g(\nabla_u v, w)$$

for every $u,v,w\in\mathcal{V}$. By comparison with (2), it immediately follows that

$$\nabla_u v = \tfrac{1}{2}[u,v]$$

for every $u,v\in\mathcal{V}$. Moreover, for a nondegenerate tensor g the mapping ∇, g-consistent with ∇^*, is unique. Indeed, since from

$$(\nabla_u^* v)(w) = g(\overset{1}{\nabla}_u v, w) = g(\overset{2}{\nabla}_u v, w),$$

for every $u,v\in\mathcal{V}$, it follows that

$$\overset{1}{\nabla}_u v = \overset{2}{\nabla}_u v.$$

It turns out that if g is nondegenerate, it has all properties required for connection. Let us check, for instance,

$$(\nabla^*_{u_1+u_2}v)(w) = (\nabla^*_{u_1}v)(w) + (\nabla^*_{u_2}v)(w) = g(\nabla_{u_1}v + \nabla_{u_2}v, w) = g(\nabla_{u_1+u_2} - \nabla_{u_1}v - \nabla_{u_2}v, w) = 0,$$

and, from the nondegeneracy of g, one has

$$\nabla_{u_1+u_2}v = \nabla_{u_1}v + \nabla_{u_1}v.$$

Therefore, we have proved the following proposition.

Proposition 3: Let $\mathcal{V}$ be a Z-module of derivations of an algebra $(\mathcal{A},*)$ such that $\mathcal{V}(Z)=\{0\}$. For every symmetric nondegenerate tensor $g:\mathcal{V}\times\mathcal{V}\to Z$, there exists one and only one connection g-consistent with the preconnection ∇^*. It is given by

$$\nabla_u v = \tfrac{1}{2}[u,v].$$

□

In the following, we shall assume the metric of the Killing form

$$g(u,v) = \mathrm{Tr}(u\circ v).$$

It satisfies the g-consistency condition. Indeed, from the trace definition we have

$$\mathrm{Tr}[w\circ u, v\circ u] = \mathrm{Tr}([w,u]\circ v) + \mathrm{Tr}([w,v]\circ u) = 0.$$

We now return to our model, and assume the above kind of metric for both $\mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}$ and $\mathrm{Inn}\,\mathcal{A}$, but in both these cases the trace should be defined differently.

We first define the metric for $\mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}$. We assume that G is a semisimple group. In this case, the Killing form reads

$$\mathcal{B}(V,W) = \mathrm{Tr}(\mathrm{ad}\,V\circ \mathrm{ad}\,W),$$

for $V,W\in \underline{g}$, where $\underline{g}$ is the Lie algebra of the group G, and $\mathcal{B}$ is nondegenerate. The tangent space to any fiber $E_x, x\in M$, is isomorphic to $\underline{g}$. Therefore, the metric $\bar{k}:\mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}\times\mathrm{Der}_{\mathrm{Ver}}\,\mathcal{A}\to Z$ is given by

$$\bar{k}(\bar{\bar{X}},\bar{\bar{Y}}) = \mathcal{B}(X(\pi_M(p)),\quad Y\ (\pi_M(p))).$$

To define the metric for $\mathrm{Inn}\,\mathcal{A}$, let us first define the trace for the algebra $\tilde{\mathcal{A}}$ (which, by Proposition 1, is isomorphic to the algebra $\mathcal{A}$), $\mathrm{Tr}:\mathcal{A}\to Z$, by

$$(\mathrm{Tr}\,a)(x) = \int_G a(x,g,g)\mathrm{d}g.$$

It has the following properties: (i) $\mathrm{Tr}(a+b)=\mathrm{Tr}\,a+\mathrm{Tr}\,b$, (ii) $\mathrm{Tr}(fa)=f\,\mathrm{Tr}\,a$, (iii) $\mathrm{Tr}(a*b)=\mathrm{Tr}(b*a)$, for $a,b\in\mathcal{A}$, $f\in Z$. From the last property it follows that

$$\mathrm{Tr}([a,b]) = 0,$$

and, of course, $\mathrm{Tr}\circ\mathrm{ad}\,a=0$.

Let us now turn to the submodule $\mathrm{Inn}\,\mathcal{A}$. We should notice that, on the strength of Lemma 2, we also have the connection $\tilde{\nabla}:\mathcal{A}\times\mathcal{A}\to\mathcal{A}$ on $\mathcal{A}$ given by

$$\tilde{\nabla}_a b = \tfrac{1}{2}[a,b].$$

We define the metric $h:\mathrm{Inn}\,\mathcal{A}\times\mathrm{Inn}\,\mathcal{A}\to Z$ by

$$h(\mathrm{ad}\,a,\mathrm{ad}\,b) = \mathrm{Tr}(a*b),$$

and the corresponding connection is

$$\nabla_{\mathrm{ad}\, a}\, \mathrm{ad}\, b = \tfrac{1}{2}[\mathrm{ad}\, a, \mathrm{ad}\, b].$$

We shall show that the metric h is nondegenerate. Indeed, let us assume that

$$\mathrm{Tr}(a * b) = \int_G \int_G a(x, g_{1,} g_2) b(x, g_2, g_1) \mathrm{d}g_2\, \mathrm{d}g_1 = 0.$$

If $a \neq 0$, then the support of this function is not of the measure zero, and by choosing the function $b(x, g_2, g_1) = a(x, g_1, g_2)$, we obtain

$$\int_G \int_G a^2(x, g_1, g_2) \mathrm{d}g_2\, \mathrm{d}g_1 \neq 0.$$

We conclude that if the metric is of the trace type (either $\mathcal{B}$ or Tr), the formula (2) is valid (for $g = \bar{k}$, or $g = h$).

V. CURVATURE

Let us introduce the following abbreviations:

$$V_1 = \mathrm{Der}_{\mathrm{Hor}}\, \mathcal{A}, \quad V_2 = \mathrm{Der}_{\mathrm{Ver}}\, \mathcal{A}, \quad V_3 = \mathrm{Inn}\, \mathcal{A}.$$

We continue to develop the geometry for $V_i, i = 1, 2, 3$. The curvature is

$$\overset{i}{R}: V_i \times V_i \times V_i \to V_i,$$

$$\overset{i}{R}(u, v)w = \overset{i}{\nabla}_u \overset{i}{\nabla}_v w - \overset{i}{\nabla}_v \overset{i}{\nabla}_u w - \overset{i}{\nabla}_{[u,v]} w.$$

If $j = 2, 3$, we have

$$\overset{j}{R}(u, v)w = \tfrac{1}{2}\big[u, \tfrac{1}{2}[v, w]\big] - \tfrac{1}{2}\big[v, \tfrac{1}{2}[u, w] - \tfrac{1}{2}[[u, v], w] = -\tfrac{1}{4}[[u, v], w].$$

Here we have made use of the Jacobi identity.

For every endomorphism $T: V_i \to V_i$, $i = 1, 2$, there exists $\mathrm{Tr}\, T \in Z$ satisfying the usual trace conditions. We thus can define

$$\overset{i}{R^m}_{uwm}: V_i \to V_i,$$

$$\overset{i}{R}_{uw}(v) = \overset{i}{R}(u, v)w,$$

and

$$\overset{i}{\mathbf{ric}}: V_i \times V_i \to Z$$

$$\overset{i}{\mathbf{ric}}(u, v) = \mathrm{Tr}\, \overset{i}{R}_{uw}.$$

We also define the *adjoint Ricci operator*,

$$\overset{i}{\mathbf{ric}}(u,w) = \overset{i}{\mathcal{G}}(\overset{i}{\mathcal{R}}(u),w), \tag{3}$$

where we have introduced the notation $\bar{g}=\overset{1}{\mathcal{G}}$, $\bar{k}=\overset{2}{\mathcal{G}}$. If the metric $\overset{i}{\mathcal{G}}$ is nondegenerate, there exists the unique $\overset{i}{\mathcal{R}}$ satisfying Eq. (3) for every $v \in V_i$.

The *curvature scalar* is

$$\overset{i}{r} = \operatorname{Tr} \overset{i}{\mathcal{R}} \in Z.$$

In the module V_2 there exists the usual trace operator which, in the local basis, can be written as the trace of the operator matrix. Therefore,

$$\overset{2}{R}_{uv}(w) = \tfrac{1}{4}[w,[u,v]] = \tfrac{1}{4}(\operatorname{ad} w \circ \operatorname{ad} u)(v),$$

and we have

$$\overset{2}{R}_{uw} = \tfrac{1}{4}(\operatorname{ad} w \circ \operatorname{ad} u)$$

for every $u,w \in V_2$, and

$$\operatorname{Tr} \overset{2}{R}_{uw} = \tfrac{1}{4}\operatorname{Tr}(\operatorname{ad} w \circ \operatorname{ad} u).$$

Hence,

$$\overset{2}{\mathbf{ric}}(u,w) = \tfrac{1}{4}\bar{k}(u,w) \tag{4}$$

for every $u,w \in V_2$, which can be regarded as a generalized Killing form. By analogy, we postulate

$$\overset{3}{\mathbf{ric}}(u,w) = \alpha h(u,w), \tag{5}$$

$\alpha \in Z$, for every $u,w \in V_3$.

The "Ricci scalar" can be determined from the generalized Einstein equation

$$\overset{3}{\mathbf{ric}}(u,v) - \tfrac{1}{2} r h(u,v) = 0$$

or

$$\alpha h(u,v) - \tfrac{1}{2} r h(u,v) = 0.$$

Hence we obtain

$$\left(\alpha - \tfrac{1}{2} r\right) h(u,v) = 0,$$

and

$$\alpha = \tfrac{1}{2} r.$$

We can symbolically regard $r \in Z$ as a trace of the Ricci operator $\mathcal{R}$. The Ricci 2-form is thus proportional to the metric tensor h, and the proportionality coefficient (up to factor 2) is a counterpart of the Ricci curvature scalar.

A counterpart of Eq. (3) for V_3 is

$$\overset{3}{\mathbf{ric}}(u,v) = h(\overset{3}{\mathcal{R}}(u),v). \tag{6}$$

Hence

$$\alpha h(u,v) = h(\overset{3}{\mathcal{R}}(u),v),$$

or

$$h(\alpha u,v) = h(\overset{3}{\mathcal{R}}(u),v),$$

and finally,

$$\overset{3}{\mathcal{R}}(u) = \alpha u.$$

Let us notice that for a commutative algebra we have $\alpha=0$, and the sector corresponding to V_3 vanishes. Therefore, the coefficient α could be regarded as a "measure" of noncommutativity.

This concludes the construction of the noncommutative groupoid geometry. The transition from this geometry to the usual space-time geometry can be done by the following "averaging" procedure. If $a \in \mathcal{A}$ then we have the isomorphism $a(p,g)=\tilde{a}(x,g_1,g_2)$, and we define

$$\langle\tilde{a}\rangle(x) = \int_G \tilde{a}(x,g,g)\mathrm{d}g.$$

It is clear that $\langle\tilde{a}\rangle \in C_c^\infty(M)$, and from the algebra $C_c^\infty(M)$ one can reconstruct the usual space-time geometry together with the usual Einstein equations.[7]

VI. GENERALIZED EINSTEIN'S EQUATION

We have all geometric quantities necessary to write the counterpart of Einstein's equation on the groupoid Γ. We stipulate that in the noncommutative regime at the fundamental level, there is only a "pure noncommutative geometry," and all necessary "matter terms" will somehow emerge out of it. We thus assume that there is no counterpart of the energy-momentum tensor and, consequently, the generalized Einstein's equation is of the form

$$\mathcal{R} - \tfrac{1}{2} r\,\mathrm{id}_V = 0, \tag{7}$$

where $\mathcal{R}$ is the Ricci operator defined by Eq. (3) (superscipt $i=1,2$ is omitted but presupposed), and $r=\mathrm{Tr}\,\mathcal{R}$.

It is clear that Eq. (7), for $V=V_1$, is a "lifting" of the usual Einstein equation on space-time M to the groupoid Γ, and if g solves this equation on M then $\bar{g}$ solves Eq. (7).

Let us now consider the case $V=V_2$. By comparing Eq. (3) with Eq. (4) and noticing that $\frac{1}{4}\bar{k}(u,v)=\bar{k}(\frac{1}{4}u,v)$, one obtains

$$\overset{2}{\mathcal{R}} = \tfrac{1}{4}\mathrm{id}_{V_2}.$$

Similarly, for $V=V_3$, by taking into account Eq. (5) and comparing it with Eq. (4), we obtain

$$\overset{3}{\mathcal{R}} = \alpha\,\mathrm{id}_{V_3}.$$

Let us consider the $\mathcal{G}$-orthogonal sum $V=V_1\oplus V_2\oplus V_3$. For the Ricci operator $\mathcal{R}:V\to V$ we have $\mathcal{R}(V_i)\subseteq V_i$, $i=1,2,3$, and $\mathcal{R}\,|\,V_i=\overset{i}{\mathcal{R}}$. This leads to the eigenvalue equation

$$\mathcal{R}(u) = \lambda u$$

for $u \in V$. This eigenvalue problem has the following solutions:

(1) $\lambda_1 = \frac{1}{2}r$ where r is the Ricci scalar curvature for the metric tensor $\bar{g}$. We thus have the equation

$$\mathcal{R}(u) - \tfrac{1}{2}ru = 0$$

for $u \in V_1$, and each such u satisfies this equation. It can be easily checked that this equation reduces to the equation $\mathcal{R}=0$ on space-time M.

(2) $\lambda_2 = \frac{1}{4}$ which leads to the equation

$$\mathcal{R}(u) - \tfrac{1}{4}u = 0$$

for $u \in V_2$.

(3) $\lambda_3 = \alpha$ leading to the equation

$$\mathcal{R}(u) - \alpha u = 0$$

for $u \in V_3$. In the commutative case $\alpha=0$ and we obtain $\mathcal{R}(u)=0$ (on the groupoid Γ).

VII. QUANTUM SECTOR

The quantum sector of our model is obtained by the regular representation of the groupoid algebra $\mathcal{A}$ in a Hilbert space $\mathcal{H}^p = L^2(\Gamma^p)$, $p \in E$,

$$\pi_p : \mathcal{A} \to \mathcal{B}(\mathcal{H}^p),$$

where $\mathcal{B}(\mathcal{H}^p)$ denotes the algebra of bounded operators on $\mathcal{H}^p$, given by

$$(\pi_p(a)\psi)(\gamma) = \int_{\Gamma_{d(\gamma)}} a(\gamma_1)\psi(\gamma_1^{-1} \circ \gamma)\mathrm{d}\gamma_1,$$

where $a \in \mathcal{A}$, $\psi \in \mathcal{H}^p$, γ, $\gamma_1 \in \Gamma$. Let us notice that the Haar measure on the group G, transferred to the fibers of Γ, forms a Haar system on Γ.[16]

We shall show that every element $a \in \mathcal{A}$ generates a random operator r_a on $(\mathcal{H}^p)_{p \in E}$. By a *random operator* r we mean a family of operators $(r_p)_{p \in E}$, i.e., a function

$$r : E \to \bigsqcup_{p \in E} \mathcal{B}(\mathcal{H}^p)$$

such that

(1) the function r is measurable in the following sense: if $\xi_p, \eta_p \in \mathcal{H}^p$ then the function

$$E \ni p \mapsto (r(p)\xi_p, \eta_p) \in \mathbf{C}$$

is measurable with respect to the manifold measure on E;

(2) the function r is bounded with respect to the norm,

$$\|r\| = \operatorname{ess\,sup}\|r(p)\|,$$

where ess sup means the "supremum modulo zero measure sets."

Random operator r acts, in fact, on cross sections of the Hilbert bundle $\mathcal{H} = \sqcup_{p \in E}\mathcal{H}^p$.

It can be easily seen that the family of operators $r_a = (\pi_p(a))_{p \in E}$ is a random operator. Indeed, if $\xi_p, \eta_p \in L^2(\Gamma^p)$ then we have the scalar product

$$\left(\int_{\Gamma^p} \pi_p(a)\xi_p, \eta_p\right) = \int_{\Gamma^p} \left(\int_{\Gamma_{d(\gamma)}} a(\gamma_1)\xi_p(\gamma_1^{-1}\circ\gamma)\mathrm{d}\gamma_1\right)\overline{\eta_p(\gamma)}\mathrm{d}\gamma,$$

and the Haar measure is transferred from G to Γ^p for each $p \in E$. Therefore, condition (1) is satisfied.

To check condition (2) let us introduce the isomorphisms of Hilbert spaces $I_p: L^2(G) \to \mathcal{H}^p$ given by the formula

$$(I_p\psi)(pg^{-1}, g) = \psi(g)$$

for $\psi \in L^2(G)$. Let us consider the operators $\tilde{\pi}_p(a) = I_p^{-1} \circ \pi_p(a) \circ I_p$. It is clear that $\|\pi_p(a)\| = \|\tilde{\pi}_p(a)\|$. Let us also notice that

$$\tilde{\pi}_{pg}(a) = R_{g^{-1}} \circ \tilde{\pi}_p(a) \circ R_g$$

[where R_g denotes the right translation operator in the space $L^2(G)$], which entails the (unitary) invariance of the norm

$$\|\pi_{pg}(a)\| = \|\pi_p(a)\|.$$

Hence, the norm $\|\pi_p(a)\|$ depends only on $x = \pi_M(p) \in M$; therefore, the function $x \mapsto \|\pi_p(a)\|$ is well defined, compactly supported, and continuous (in its dependence on x) on M.

Let $\mathcal{M}$ denote the set of all equivalence classes (modulo equality almost everywhere) of random operators $r_a, a \in \mathcal{A}$. It forms a von Neumann algebra; we shall call it the *algebra of random operators of the groupoid* Γ, or simply the *von Neumann algebra of the groupoid* Γ. We shall show that $\mathcal{M}$ is a semifinite algebra and, consequently, that it admits a "modular evolution," just like in the model with a finite group G.[17] To this end, let us first recall some important concepts.

A von Neumann algebra $\mathcal{M}$ is *semifinite* if there exists a faithful, normal, semifinite weight φ on $\mathcal{M}$ which is a trace.

(i) A linear functional $\varphi: \mathcal{M} \to \mathbf{C}$ is a *state* on $\mathcal{M}$ if $\varphi(r) \geqslant 0$ for every $r \in \mathcal{M}_+$, where $\mathcal{M}_+ = \{x \cdot x^* : x \in \mathcal{M}\}$ is the subset of positive elements of $\mathcal{M}$ and $\varphi(1) = 1$.

(ii) A functional $\varphi: \mathcal{M}_+ \to [0, \infty]$ is a *weight* if φ is additive, i.e., $\varphi(x+y) = \varphi(x) + \varphi(y)$, and positively homogeneous, i.e., $\varphi(\lambda x) = \lambda\varphi(x)$, for $\mathbf{R} \ni \lambda \geqslant 0, x, y \in \mathcal{M}$. We additionally assume $\lambda + \infty = \infty$, $\lambda \cdot \infty = \infty$ if $\lambda \neq 0$, and $\lambda \cdot \infty = 0$ if $\lambda = 0$. Let us notice that every state defines a weight.

(iii) A weight φ is *faithful* if for $r \in \mathcal{M}_+$ one has $\varphi(r) = 0 \Rightarrow r = 0$.

(iv) The sufficient and necessary condition for a weight φ to be *normal* is $\varphi(x) = \Sigma_i \omega_i$ for a family $\{\omega_i\}$ of normal states, i.e., $\omega(r) = \mathrm{Tr}(\rho r)$, $\mathrm{Tr}\{\rho\} = 1$.[20]

(v) Let us define $D_\varphi := \{x \in \mathcal{M}_+ : \varphi(x) < \infty\}$ and $\mathcal{M}_\varphi := \mathrm{Span}_{\mathbf{C}}(D_\varphi)$, i.e., $\mathcal{M}_\varphi$ is the space of $\mathbf{C}$-linear combinations of elements of D_φ. A weight φ is *semifinite* if $\mathcal{M}_\varphi$ is σ weakly dense in $\mathcal{M}$ (Ref. 20, p. 56).

(vi) A weight φ is a trace if $\varphi(r^* \cdot r) = \varphi(r \cdot r^*)$, for every $r \in \mathcal{M}$.

Proposition 4: The von Neumann algebra $\mathcal{M}$ *of the groupoid* Γ *is semifinite.*

Proof: We can consider the von Neumann algebra $\mathcal{M}$ as an algebra of bounded operators on the Hilbert space $H = L^2_G(E, \mathcal{H})$ of G-covariant square-integrable sections of the bundle $\mathcal{H}$. H is isomorphic to $L^2_G(E, L^2(G)) \simeq L^2(M \times G)$. The latter space is separable ($M \times G$ is a locally compact manifold). We choose the Hilbert basis $\{\psi_k\}_{k=1}^{\infty}$ in H, and define the weight $\varphi: \mathcal{M}_+ \to [0, \infty]$ by

$$\varphi(r) = \sum_{k=1}^{\infty} (r\psi_k, \psi_k).$$

This weight is clearly faithful and trace. It is also normal since $\varphi_i = \Sigma_{i=1}^{\infty} \omega_i$ where ω_i is given by $\omega_i(r) = \mathrm{Tr}(r\rho_i)$ with ρ_i being the projection onto the basis vector $\psi_i \in H$.

To show that φ is semifinite, let us notice that we have the net of finite-dimensional projections P_α such that $\varphi(P_\alpha)<\infty$ and $\lim P_\alpha=\mathbf{1}$, in strong topology, i.e., for every $h\in H$ one has $P_\alpha h=h$. And this is the necessary and sufficient condition for φ to be semifinite (Ref. 20, p. 57).□

The fact that the von Neumann algebra $\mathcal{M}$ is semifinite ensures that it admits a modular group of automorphisms (Ref. 20, Chap. 2). In our case, this group can be defined for a state (the assumption that φ is a weight was necessary only to prove that $\mathcal{M}$ is semifinite). Let us consider a functional of the form

$$\varphi(r)=\int_E \mathrm{tr}(\hat{\rho}(p)r(p))\mathrm{d}\mu_E(p),$$

where $\hat{\rho}(p)$ is a positive operator of trace class in $\mathcal{B}(\mathcal{H}^p)$, for every $p\in E$. Let $\{e_i\}$ be a basis in $\mathcal{H}^p$ such that $\hat{\rho}(p)e_i=\lambda_i(p)e_i$, $\lambda_i>0$. We also postulate

$$\sum_{i=0}^{\infty}\lambda_i(p)=\lambda(p)<\infty$$

for almost every $p\in E$, and $\lambda(\cdot)\in L^1(E)$ with

$$\int_E \lambda(p)\mathrm{d}\mu_E(p)=1.$$

With these conditions the functional φ is a state, and it satisfies all conditions of the Tomita-Takesaki theorem. We thus can write the state dependent evolution of random operators $r\in\mathcal{M}$ as

$$\sigma_s^{\varphi}(r(p))=e^{isH^{\varphi}(p)}r(p)e^{-isH^{\varphi}(p)},$$

where $H(p)=\ln\hat{\rho}(p)$ and $\ln\hat{\rho}(p)e_i=(\ln\lambda_i(p))e_i$. After differentiating the above equation it can be rewritten as

$$\left.\frac{d}{\mathrm{d}s}\right|_{s=0} r_a(p,s)=i[H^{\varphi}(p),r_a(p)]. \tag{8}$$

This is a generalization of the Heisenberg equation of the standard quantum mechanics with the only difference that now the dynamics depends on the state φ. The fact we have just proved that the von Neumann algebra $\mathcal{M}$ is semifinite, has serious consequences in this respect. The Dixmier-Takesaki theorem (Ref. 5, p. 470) states that if $\mathcal{M}$ is semifinite then every state-dependent evolution is inner equivalent to the trivial one, i.e.,

$$U_s\sigma_s^{\varphi}(r(p))U_s^*=r(p)$$

for every $s\in\mathbf{R}$, where U_s is a unitary element of $\mathcal{M}$. This means that the state-independent evolution, obtained by the Connes-Nikodym-Radon construction (Ref. 20, p. 74), is trivial. To overcome this difficulty we should assume that the group G is a locally compact nonunimodular group. We will return to this problem in a forthcoming paper.

However, a dependence of dynamics on a state need not be a drawback when we are dealing with the Planck level. The theory of von Neumann algebras can be regarded as a noncommutative counterpart of the measure theory. In the commutative case there is only one interesting measure (the Lebesgue measure), whereas in the noncommutative case there is a great variety of measures (see, for instance Ref. 21). Each pair $(\mathcal{M},\varphi)$, where $\mathcal{M}$ is a von Neumann algebra and φ a state on $\mathcal{M}$ (usually assumed to be faithful and normal), is both a dynamic object and a probabilistic object. In this context, the fact that there are as many φ-dependent dynamics as are generalized probabilistic measures φ seems quite natural.

VIII. TRANSITION TO QUANTUM MECHANICS

Let $a^*(\gamma)=\overline{a(\gamma^{-1})}$, $a\in\mathcal{A}$, $\gamma\in\Gamma$, and let us denote by $\mathcal{A}_H$ the subset of all Hermitian elements of $\mathcal{A}$, i.e., such that $a^*=a$. If $a\in\mathcal{A}_H$ then $\pi^p(a)\in(\mathcal{B}(\mathcal{H}^p))_H$ since π_p is a $*$-representation of the algebra $\mathcal{A}$. In the following we shall consider the random operators of the form $r_a(p)=\pi_p(a)$. Such operator is Hermitian if $(r_a(p)\psi,\varphi)=(\psi,r_a(p)\varphi)$. Moreover, it is a compact operator for $a\in\mathcal{A}$, since a has compact support. On the strength of the spectral theorem for Hermitian compact operators in a separable Hilbert space, there exists in $\mathcal{H}^p$ an orthonormal countable Hilbert basis of eigenvectors $\{\psi_i\}_{i\in I}$ of the Hermitian operator $r_a(p)$. We can write its eigenvalue equation as

$$r_a(p)\psi_i(p)=\lambda_i(p)\psi_i(p).$$

Let us notice that this equation is valid "for every $p\in E$" which reflects the fact that the random operator r_a is a family of functions indexed by $p\in E$. Therefore, with respect to a random operator it is meaningful to speak only about its eigenfunction $\lambda_i:E\to\mathbf{R}$ (not about its eigenvalue). However, every concrete measurement is always performed in a given local frame $p\in E$, and when such a measurement has been done the eigenfunction λ_i collapses to the eigenvalue $\lambda_i(p)$. Let us observe that from the perspective of the local measurement it looks as if the measurement result were a random effect, but in fact it is but a value of a well determined function $\lambda_i(p)$ at a given p. Its "randomness" comes from a subtler source, namely from the fact that r_a is a random operator. This is our model's version of the so often discussed "collapse of the wave function."

Let us also notice that a very act of measurement, performed at p, singles out the isomorphism $\Gamma_p^{-1}:\mathcal{H}^p\to L^2(G)$ which reproduces the usual quantum mechanics (on G). For instance, to obtain the quantum evolution for $a\in\mathcal{A}$, we apply Γ_p^{-1} to the left-hand side of Eq. (8), and I_p to its right-hand side. In this way, we obtain

$$\left.\frac{d}{dt}\right|_{t=o}\tilde{\pi}(a(t))=i[\tilde{H}^{\varphi},\tilde{\pi}(a(t))],$$

where $\tilde{\pi}(a)=\Gamma_p^{-1}\circ\pi_p\circ I_p$ and $\tilde{H}^{\varphi}=\Gamma_p^{-1}\circ H_p^{\varphi}\circ I_p$, we have also set $s=t$. This is the Heisenberg equation of the standard quantum mechanics with the only difference that it depends on the state φ. In more realistic models, to which the Connes-Nikodym-Radon construction applies, even this difference disappears (see remarks at the end of the preceding section).

The above results seem to be important as far as the interpretation of quantum mechanics is concerned. Its peculiarities are largely due to the fact that it is but a part of a larger structure, out of which it is cut off by every act of measurement. When such an act is performed the larger structure "collapses" to its substructure known as quantum mechanics. Quantum mechanics turns out to be but a theory of making measurements within our model.

Causal sites as quantum geometry

J. Daniel Christensen[a)]

(Received 20 October 2004; accepted 7 October 2005; published online 15 December 2005)

We propose a structure called a causal site to use as a setting for quantum geometry, replacing the underlying point set. The structure has an interesting categorical form, and a natural "tangent 2-bundle," analogous to the tangent bundle of a smooth manifold. Examples with reasonable finiteness conditions have an intrinsic geometry, which can approximate classical solutions to general relativity. We propose an approach to quantization of causal sites as well. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2138043]

I. INTRODUCTION AND PHYSICAL MOTIVATION

This paper is part of a program to found quantum gravity in relational topology, more precisely, to replace point set topology with a special type of category as the underlying structure on which to put geometrodynamics.

Physically, the idea is that what we actually observe are interactions between bounded regions of space-time. These could be either material systems or regions of empty space whose causal effects can be directly or indirectly distinguished by material systems. There should be a direct mathematical description of the flow of information between the regions, and points should appear only relative to an observer, as minimal distinguished regions. We will propose a specific axiomatic structure for a type of category which would contain the regions as objects and the relationships between them as different types of morphisms. The hope is that this would lead to a description of quantum physics free from ultraviolet divergences, by eliminating the underlying point set continuum.

Since categories as generalizations of topological spaces are well known in mathematics, where they are referred to as *sites* (Artin, 1962; Mac Lane and Moerdijk, 1992), we are calling our new structures *causal sites*. Strictly speaking, a site is a category together with a structure called a "Grothendieck topology," which is the analog of a topology for an ordinary space. We will explain below that our axioms also involve a structure very similar to a Grothendieck topology.

This paper will mainly discuss the "topological" side of the problem, i.e., the structure of the causal sites themselves. We discover that, unlike manifolds, causal sites with suitable finiteness conditions have an intrinsic geometry. Thus the distinction between topology and geometry is bridged over in our new picture. Examples are described which reproduce the classical solutions to general relativity above the Planck scale. We briefly consider the possibility of directly quantizing causal sites, thus directly producing a quantum theory of general relativity.

We will then briefly consider the appropriate classes of presheaves over causal sites, namely unitary and bisimplicial prestacks. We hope this can serve as a bridge between the topological aspects of causal site theory and the problem of constructing quantum physics over them. We will make some remarks as to how to construct a model for quantum gravity at the end.

[a)]Electronic mail: jdc@uwo.ca
[b)]Electronic mail: crane@math.ksu.edu

A very important feature of the topology of causal sites is that they have a tangent 2-bundle, which is analogous to the tangent bundle of a manifold. We believe this will serve as a setting for applications to quantum geometry and physics.

The structure of *causal sites* is a synthesis of two constructions, one well known from homotopy theory and algebraic geometry, the other familiar in the relativity literature. A *site* (Artin, 1962) is a category thought of as a generalization of the lattice of open sets of a topological space, with a distinguished family of covers for objects. (We warn the reader that our construction does not fully conform to the accepted definition of a site, since the covers in it do not satisfy the axioms of a Grothendieck topology, as explained below.) The morphisms of the category represent an abstract version of containment. Doing sheaf theory over such generalized spaces is an important part of modern mathematics.

On the other hand, a *causal set* (Sorkin, 2003; Hawkins *et al.*, 2003), or partially ordered set, is a discrete point set approximating the causal structure of a space-time manifold.

Now, since up to this point nobody has tried to use sites as a foundation for relativity, the natural structure that occurs when we combine the two ideas has never been considered. We will show that it is surprisingly rich and elegant.

Since causal sets are well known as models for general relativity, let us mention some of their similarities and differences with causal sites. Causal sites with a suitable finiteness condition have an intrinsic metric structure, as mentioned above. It is defined by counting the length of a maximal causal chain. This is quite similar to the intrinsic metric of a discrete causal set (Sorkin, 2003). We believe the greater flexibility of the families of regions in a causal site will mean they give much better approximations to the geometry of space-times than causal sets do. There can be infinitely many regions intermediate between two given ones in a causal site, and yet causal paths can have a finite maximal length, as we show in examples below. While random causal sets which approximate Minkowski space are believed to reproduce Lorentz invariance in the infinite volume limit, examples of causal sites which approximate Minkowski space have an invariance under germs of the Lorentz group on bounded regions as well. As models for general relativity, causal sites can be studied in many of the same ways as causal sets. Mathematically, causal sites are a "categorification" of causal sets.

The fundamental mathematical observation is that both the containment structure of a site and the causal structure of a causal set can be described as partial orders. As we will explain in Sec. V, these two partial orders give rise to a natural bisimplicial set which we call the elementary classifying space of the causal site. From this point of view, certain collections of regions can be viewed as products of simplices, and these products are glued together in a well-defined way.

We also construct another bisimplicial set, which we call the physical classifying space. This turns out to be a "special" bisimplicial set, a type of bisimplicial set which corresponds to a weak 2-category (Tamsamani, 1995). This means that causal sites fall into a class of structure which is already studied, and that the family of simplicial presheaves over it is well understood.

We will argue at the end that this suggests an approach to doing quantum general relativity over causal sites, by putting state sum models on their tangent 2-bundles.

This paper is meant to open a number of lines of research. The contents are as follows: in Sec. II we present the axioms for a causal site and some simple consequences. In Sec. III we show how a causal site with suitable finiteness conditions can have an intrinsic geometry. In Sec. IV, we briefly discuss quantization of sites, and in Sec. V we discuss the simplicial and bisimplicial structures inherent in a causal site. In Sec. VI, we translate this into a bicategorical structure. Sections VII and VIII discuss the structure of the tangent spaces and tangent bundle, while Sec. IX discusses the general analog of a bundle for a causal site, namely a prestack. In Secs. X and XI we discuss how state sum models could emerge in a causal site. Section XII contains conclusions and outlook.

Categorical background: We freely make use of terminology and ideas from category theory. In particular, we assume basic familiarity with weak 2-categories, which are also called bicategories. Good references for this topic are Leinster, 2004, Chap. 1; Leinster, 1998; and Bénabou, 1967. We also give more specific references as needed.

II. THE AXIOMATIC STRUCTURE OF CAUSAL SITES

We are now going to axiomatize the structure of regions in a causal space-time.

Example 2.1: Let M be a Lorentzian manifold with no closed timelike curves and a global time orientation. For points p and r in M, write $p \ll r$ if there is a future-directed timelike curve from p to r, and let $D(p,r)$ be the set of all points q with $p \ll q \ll r$. We call $D(p,r)$ a *diamond*, and we say that a subset A of M is *bounded* if it is contained in a finite union of diamonds. For A and B bounded regions, write $A \subseteq B$ when A is a subset of B, and write $A \prec B$ when every point in region A is in the causal past of every point in region B. That is, for each a in A and b in B, $a \ll b$.

The motivation for the above definition of "bounded" is the following. If a subset A has compact closure, then it is bounded in the above sense. And if the manifold M is globally hyperbolic, then the converse holds. So for globally hyperbolic manifolds, bounded is equivalent to compact closure. However, in general, our completion axiom below is only satisfied if one allows regions without compact closure.

Below we list some properties that this set of regions has. We then want to consider more general systems satisfying the axioms. We believe the interesting examples will actually have fewer regions than the example above coming from a Lorentzian manifold.

Definition 2.2: A *causal site* is a set of "regions" with two binary relations denoted $\subseteq$ and $\prec$ satisfying the axioms below. If $A \subseteq B$ we say that A is a *subset* of B or that B *contains* A. If $A \prec B$ we say that A *precedes* B.

(1) $\subseteq$ is a partial order on the set of regions. This means that for all regions A, B, and C,
   (a) $A \subseteq B$ and $B \subseteq C$ implies $A \subseteq C$,
   (b) $A \subseteq A$,
   (c) $A \subseteq B$ and $B \subseteq A$ implies $A = B$.

(2) The partial order $\subseteq$ has a minimum element ϕ. This means that ϕ is contained in every region A. This uniquely determines ϕ, and ϕ is called the *empty region*.

(3) The partial order $\subseteq$ has *unions*. This means that for all regions A and B, there exists a region $A \cup B$ such that
   (a) $A \subseteq A \cup B$ and $B \subseteq A \cup B$;
   (b) if $A \subseteq C$ and $B \subseteq C$ then $A \cup B \subseteq C$.

   These requirements uniquely determine $A \cup B$, and the binary operation $\cup$ is automatically associative and commutative.

(4) $\prec$ induces a strict partial order on the nonempty regions. This means that for all nonempty regions A, B, and C,
   (a) $A \prec B$ and $B \prec C$ implies $A \prec C$,
   (b) A does not precede A.

(5) For all regions A, B, and C, $A \subseteq B$ and $B \prec C$ implies $A \prec C$.

(6) For all regions A, B, and C, $A \subseteq B$ and $C \prec B$ implies $C \prec A$.

(7) For all regions A, B, and C, $A \prec C$ and $B \prec C$ implies $A \cup B \prec C$.

(8) For all regions A and B, there exists a region B_A such that
   (a) $B_A \prec A$ and $B_A \subseteq B$,
   (b) if $D \prec A$ and $D \subseteq B$ then $D \subseteq B_A$.

   These requirements uniquely determine B_A, and B_A is called the *cutting* of A by B. Note that B_A can be empty.

(9) If A and C are nonempty regions such that $A \prec C$, and there exists a D with $A \prec D \prec C$, then there exists a B complete with respect to $A \prec C$. The definition of "complete" is below (Definition 2.5).

Definition 2.3: Regions A and B in a causal site are *disjoint* if the only region which is

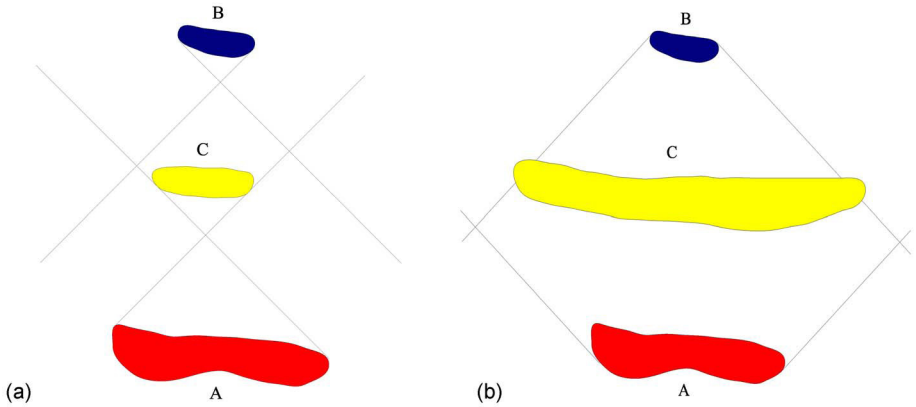

FIG. 1. (Color online) Comparing completions. (a) Completion. (b) Strong completions.

contained in both A and B is the empty region. More generally, a set of regions is *disjoint* if each pair of regions it contains is disjoint.

Note that if $A \prec B$ then A and B are disjoint.

Definition 2.4: Suppose S and T are sets of disjoint regions. If every region in S contains some region in T, we say that T is a *refinement* of S. That is, T is obtained from S by shrinking some regions and adding new regions.

A *causal path* P is a sequence $A_1 \prec A_2 \prec \cdots \prec A_m$ of nonempty regions. If $A \prec A_1$ and $A_m \prec B$, we say that P is a *causal path from A to B* and has *length* $m+1$. There is exactly one causal path of length 1.

A *refinement* of the causal path $A_1 \prec A_2 \prec \cdots \prec A_m$ is a causal path $C_1 \prec C_2 \prec \cdots \prec C_n$ such that $\{C_j\}$ is a refinement of $\{A_i\}$.

If P is a causal path from A to B, and $A' \prec A$, then P is also a causal path from A' to B. Analogous statements can be made when $A' \subseteq A$, $B \prec B'$ and $B' \subseteq B$. See Sec. VIII for more details.

Definition 2.5: If $A \prec B \prec C$, we say that B is *complete* for the causal pair $A \prec C$ if every causal path from A to C can be refined to a causal path from A to C one of whose members is contained in B. B is called a *completion of* $A \prec C$.

See Fig. 1 for an example of a completion. The final axiom of a causal site requires that completions exist. But note that they are rarely unique.

There are some elementary consequences whose proofs we leave to the reader.

Proposition 2.6: The following are true in any causal site.

(1) *For every region* A, $\phi \prec A$ *and* $A \prec \phi$.
(2) $B_A = B$ *iff* $B \prec A$.
(3) $B \subseteq C$ *implies* $B_A \subseteq C_A$.
(4) $B_A \cup C_A \subseteq (B \cup C)_A$. (*The reverse inclusion fails for some of our examples*.)
(5) *The collection of regions of a causal site which precedes a region B forms another causal site. When B is nonempty, this causal site is called the* local site *of B*.

Example 2.7: Let M be as in Example 2.1. Then the bounded regions in M, with the relations $\subseteq$ and $\prec$ defined earlier, satisfy the axioms.

We will check the nontrivial axioms. For the cutting axiom (Axiom 8), let B_A be the set of all points p such that $\{p\} \prec A$ and $p \in B$. This is bounded (contained in a finite union of diamonds) since B is.

For the completion axiom (Axiom 9 and Definition 2.5), a completion of $A \prec C$ can be taken

to be the set of all points p such that $A \prec \{p\} \prec C$. This is bounded because it is a subset of the diamond $D(a,c)$ for any points $a \in A$ and $c \in C$. (In general, this completion may not have compact closure.)

The remaining axioms are straightforward.

Example 2.8: Let $(M, \preccurlyeq)$ be any poset (partially ordered set) and let $\mathcal{P}(M)$ be the set of all subsets of M. We define $\subseteq$ to be the usual subset relation, and for A and B subsets of M, we say that $A \prec B$ iff $\forall a \in A \, \forall b \in B \; a < b$. (Note that we use the strict inequality $a < b$.) Then $\mathcal{P}(M)$, $\subseteq$, and $\prec$ form a causal site. A completion of $A \prec B$ can be taken to be $\{m \in M \,|\, \forall a \in A \, \forall b \in B \; a < m < b\}$.

Example 2.9: Let $(M, \preccurlyeq)$ be a poset such that $\{n \in M \,|\, m \preccurlyeq n \preccurlyeq m'\}$ is finite for each m and m' in M. Such a poset is called *locally finite* or a *causal set* (Sorkin, 2003). Let $\mathcal{P}'(M)$ be the set of finite subsets of M. Then $\mathcal{P}'(M)$ is a causal site using relations defined as in the previous example. The hypothesis on M ensures that completions exist.

While the axioms for a causal site were modelled on the example where regions are bounded subsets of a causally well-behaved Lorentzian manifold, and $A \prec B$ iff every element of A is in the causal past of every element of B, we can use the structure we have to define a weaker relation.

Definition 2.10: For regions A and B, write $A \preccurlyeq B$ if there exist nonempty subsets $A' \subseteq A$ and $B' \subseteq B$ with $A' \prec B'$ or $A' = B'$. We say that A *weakly precedes* B.

In the example of a Lorentzian manifold (Example 2.1), $A \preccurlyeq B$ iff some point of A is in the causal past of some point of B.

Note that $\preccurlyeq$ is not transitive. That is, $A \preccurlyeq B$ and $B \preccurlyeq C$ does not imply $A \preccurlyeq C$.

Definition 2.11: For regions A and B with $A \prec B$, we say that C is *strongly complete* for A and B if for all nonempty $A' \subseteq A$ and $B' \subseteq B$, any causal path from A' to B' can be refined to a causal path from A' to B' one of whose members is contained in C.

Note that we do not require that $A \prec C \prec B$, since a strong completion will rarely satisfy this. A strong completion is "wider" than an ordinary completion. See Fig. 1.

Definition 2.12: A region B is a *cover* of a region A if $B \prec A$ and if every causal path ending in A can be refined to a causal path ending in A one of whose elements is contained in B.

A finite set of regions $\{B_i\}$ is a *cover* of A if the union is a cover of A.

Remark 2.13: We can regard a causal site as a category whose objects are the regions by saying that there is one morphism from A to B if $A \prec B$ or $A = B$, and no morphisms otherwise. The collection of covers defined above has the feel of being a Grothendieck topology (Mac Lane and Moerdijk, 1992). But even if pullbacks exist in this category (they do, for example, in the case of Example 2.1), the pullback of a cover is not necessarily a cover.

Below we shall define a 2-category whose 1-arrows are all composable strings of arrows in this category, i.e., causal paths.

Definition 2.14: A causal site is *Noetherian* if every chain of strictly descending regions $A_1 \supset A_2 \supset A_3 \supset \cdots$ is finite. It is *locally Noetherian* if every local site is Noetherian.

Noetherian implies locally Noetherian.

The causal site $\mathcal{P}'(M)$ described in Example 2.9 is always Noetherian. If $M = \mathbb{N}$ with the usual order, then the causal site $\mathcal{P}(M)$ described in Example 2.8 is locally Noetherian but not Noetherian.

Definition 2.15: A nonempty region A in a causal site is an *absolute point* if it contains no subregions besides ϕ and A. If A and B are nonempty regions in a causal site, we say that A is a *relative point* for B if $A \prec B$ and for any C with $C \prec B$ either $A = A_C$ (i.e., $A \prec C$) or $A_C = \phi$.

If A is an absolute point and $A \prec B$, then A is a relative point for B. And if A is a relative point for B, then any nonempty subregion of A is also a relative point for B.

In Example 2.1, an absolute point is just a point in the usual sense, and every relative point is an absolute point.

In Examples 2.8 and 2.9, the absolute points are just the elements of the poset, but the relative points can be larger. For example, let Q be the poset $\{a, b, b', c\}$ with $a < b < c$, $a < b' < c$ and with b and b' unrelated. Then in the causal site $\mathcal{P}(Q)$, the subset $B = \{b, b'\}$ is a relative point for $C = \{c\}$. It is a union of the absolute points $\{b\}$ and $\{b'\}$.

We believe that because of the theorems that only a finite dimensional space of information can flow across horizons in general relativity (Flanagan *et al.*, 2000) there should be causal sites associated to Lorentzian manifolds which have interesting examples of relative points. The information contained in the relative position of a finite set of regions should exhaust what an external observer can see.

Definition 2.16: If A and B are regions in a causal site, we say that A is *amply pointed* with respect to B if $A \prec B$ and if $C, D \subseteq A$ then either C or D contains a relative point for B which the other does not, or $C=D$. A causal site is *amply pointed* if all causal pairs in it are.

Definition 2.17: A causal site which is locally Noetherian and amply pointed is a *grained world*.

In addition to the examples coming from causal sets, we believe that the family of Noetherian causal sites described in Sec. III produces grained worlds whenever there are no pairs of points connected by more than one Planck-scale geodesic. This still needs proof.

Although one can think of the regions in a causal site as like the bounded subsets of a causal space-time, we believe the interesting cases will be very different from such classical examples. The Noetherian property discussed above is an approach to imposing a Planck scale cutoff on the structure of a causal site.

III. THE INTRINSIC GEOMETRY OF CAUSAL SITES

It turns out that a causal site can contain more information than just the causal structure of a manifold. The reason is that a causal site may have a fundamental graininess which sets a length and time scale. Physically, this graininess is expected to occur at the Planck scale, and serves as a measuring rod or clock. Heuristically, a measurement at a smaller scale would result in the formation of black hole, so the maximum possible number of successive measurements along a timelike path gives its duration in Planck units.

Definition 3.1: A causal site is *causally finite* if for any two regions $A \prec B$, the length of any causal path from A to B is bounded above by a constant $M_{A,B}$.

We now want to interpret the least upper bound for the length of a causal path between two causally related regions as the discretized timelike separation between them in Planck units. This is quite similar to the notion of length in a discrete causal set in Sorkin, 2003.

We now give examples to show that the resulting geometry can be quite interesting.

Example 3.2: Consider Minkowski space. Recall from Example 2.1 that a diamond is a region $D(p,r)=\{q \mid p \ll q \ll r\}$. Define a *fundamental diamond* to be a region $D(p,r)$ where the proper time from p to r is 1. Consider the set of bounded regions which are unions of fundamental diamonds. Define $\subseteq$ and $\prec$ as in Example 2.1. This forms a causal site.

Let us check the nontrivial axioms. For the cutting axiom (Axiom 8), let B_A be the union of all fundamental diamonds D such that $D \prec A$ and $D \subseteq B$. This is bounded (contained in a finite union of diamonds) since B is. Note that it can happen that B_A is empty even though there are points of B which are in the past of A.

For the completion axiom (Axiom 9 and Definition 2.5), a completion of $A \prec C$ can be taken to be the union of all fundamental diamonds D such that $A \prec D \prec C$. This is bounded because it is a subset of the diamond $D(a,c)$ for any points $a \in A$ and $c \in C$.

The remaining axioms are straightforward.

Figure 2 gives two examples of fundamental diamonds. The timelike vectors shown have proper length 1.

The following theorem explains how this causal site captures the geometry of Minkowski space.

Theorem 3.3: *Let γ be a finite timelike geodesic segment in Minkowski space, starting at the point s and ending at t. In the causal site of Example 3.2, consider the causal paths $A_1 \prec \cdots \prec A_m$ with $s \in A_1$ and $t \in A_m$. Then the proper length of γ, rounded up to an integer, is equal to the least upper bound of the lengths of these causal paths.*

The key element of the proof is the observation that using fundamental diamonds in any other

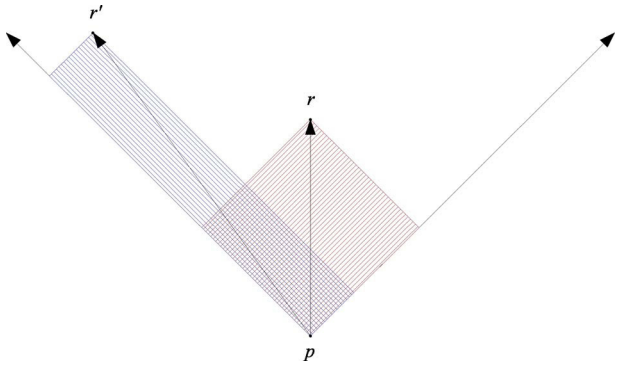

FIG. 2. (Color online) Fundamental diamonds.

rest frame than the one determined by the geodesic produces a shorter chain. This is clear from the above picture. In physical applications we would use units in which the Planck time is 1.

To handle curved space-times, we need to introduce the concept of stable causality. A Lorentzian manifold M is *stably causal* if it has no closed timelike curves, and every small perturbation of the metric g also has this property. This can be expressed by saying that there exists a metric h whose light cones are wider than those of g and such that h has no closed timelike curves. This condition is more physical than simply requiring no closed timelike curves, since measurements have only finite accuracy.

It is a nontrivial result (Hawking and Ellis, 1973, Prop. 6.4.9) that stable causality is equivalent to the existence of a global time function. In particular, a stably causal space-time is automatically time orientable.

Suppose that M is stably causal and we have chosen a time orientation. It is shown in Penrose, 1972 that since M is stably causal, the diamonds $D(p,r)$ determine the topology of M.

Example 3.4: Generalizing the previous example, let M be a stably causal Lorentzian manifold. Define a *fundamental diamond* to be a region $D(p,r)$ such that there is a future-directed timelike geodesic of length 1 from p to r. Consider the set of bounded regions which are unions of fundamental diamonds. Define $\subseteq$ and $\prec$ as in Example 2.1. This forms a causal site. The proof is the same as Example 3.2.

The following conjecture explains how these causal sites capture the large-scale geometric information of the manifold.

Conjecture 3.5: *Let M be a stably causal Lorentzian manifold whose sectional curvatures are much less than 1, and let* γ *be a timelike curve from s to t in M whose radius of curvature and length are large. In the causal site of Example 3.4, consider the causal paths* $A_1 \prec \cdots \prec A_m$ *such that each region* A_i *intersects* γ*. Then the proper length of* γ *is well approximated by the least upper bound of the lengths of these causal paths, with an error which is small compared to the length of* γ*.*

Of course, the precise statement of the error of the approximation in terms of the curvatures will require a more delicate analysis.

We believe this causal site reflects classical geometry more accurately than a causal set can. This is because we have enough relative points to adjust to any direction to get the best fit.

It is well known that the lengths of timelike curves (clock times), are enough to describe the geometry of a Lorentzian manifold completely. Thus our conjecture implies that any solution to general relativity whose sectional curvature is small compared to the Planck scale, with any type of matter whatsoever, can be approximated by the intrinsic geometry of a causally finite causal site with accuracy on the order of the Planck scale.

The causal sites discussed in this section have a fundamental graininess, but are nevertheless not Noetherian or locally Noetherian. It is not hard to invent modifications of our examples which would have stronger finiteness conditions and still recover interesting geometrodynamics. For

example, fix a discrete closed subspace L of Minkowski space and a discrete closed subspace S of the hyperboloid of unit timelike vectors. Now consider bounded regions R in Minkowski space which are unions of fundamental diamonds $D(l-s/2,l+s/2)$ centered on points l of L and pointing in directions s in S. Since R is bounded, it contains only finitely many points in L. Moreover, in any sufficiently boosted coordinate system, it would be too contracted to contain a fundamental diamond. Thus it only contains finitely many fundamental diamonds whose directions are contained in S and which are centered on points of L. Therefore this collection of regions forms a Noetherian causal site which reproduces the space-time geometry of Minkowski space at a large scale. Such a model is computationally accessible, and is a good candidate for quantization, as discussed below.

The discrete subspace L of Minkowski space could be chosen to be a random sprinkling of points, or a lattice. In a general manifold, L would have to be an irregular collection of points. If the manifold is globally hyperbolic, then one again obtains a Noetherian causal site.

Note that the use of fundamental diamonds is not crucial to any of the discussion in this section. One could use other shapes, such as "fundamental cylinders," which are regions formed by working in normal coordinates and taking the Cartesian product of a timelike interval of length 1 with a ball of radius 1 in the hyperplane orthogonal to the chosen timelike direction.

As yet, we do not know how to impose Einstein's equation on a causal site purely intrinsically.

IV. QUANTUM SITES

A causal site can be thought of as a large number of answers to questions, either telling us one region is inside another, or that one region can observe another.

The answers to these questions can be grouped together in certain good examples and reinterpreted as describing physically interesting geometries.

Therefore it is natural to reinterpret the statements that define a causal site as quantum observables and attempt to extract a quantum geometry from them. This could be a new avenue of attack on the problem of quantizing gravity.

It is not hard to see how to begin such a program. We could tensor together a finite dimensional Hilbert space for each pair of regions, and construct operators for containment and causal relatedness on each. The interesting part would be to see if suitable commutation relations could be found on the operators to reproduce Einstein's equation in the classical limit for suitable families of causal sites. We have not yet investigated this.

V. SIMPLICIAL STRUCTURES AND CAUSAL SITES

We first remind the reader of the relationship between partial orders and simplicial sets. A good reference for simplicial sets is Goerss and Jardine, 1999.

Roughly speaking, a *simplicial set* is a set of abstract simplices (points, edges, triangles, tetrahedra, etc.) with the faces of the simplices of dimension n identified with simplices of dimension $n-1$, thus gluing the simplices together into a combinatorial model of a space. The mathematically natural definition of a simplex includes an ordering of its vertices, and includes "degenerate" simplices in which some vertices are repeated. If X is a simplicial set, we write X_n for the set of n-simplices.

Associated to a given partially ordered set is a simplicial set which contains all of the information. An n-simplex of this simplicial set is a weakly ascending chain of length $n+1$. The face maps come from omitting one member of the chain, and the degeneracies from repeating one member.

Since the regions of a causal site have two partial orders on them, they have a natural description as the vertices of a bisimplicial set. Roughly speaking, a bisimplicial set is a collection of abstract cartesian products of pairs of simplices, with attachments along face maps corresponding to both simplicial factors separately. The product of a triangle with a tetrahedron, for example, has three faces which are edge $\times$ tetrahedron, and four which are triangle $\times$ triangle. If X is a bisimplicial set, we write $X_{m,n}$ for the set of (m,n)-bisimplices.

Let us give an explicit description of the bisimplicial set of a causal site. An (m,n)-bisimplex is a family $A_{i,j}$ of regions in the site, $i=0,\ldots,m$, $j=0,\ldots,n$, such that if $a<b$ then $A_{a,j}<A_{b,j}$ or $A_{a,j}=A_{b,j}$ and if $c<d$ then $A_{i,c}\subseteq A_{i,d}$. The two types of face maps come from omitting one value of i or j, and the two types of degeneracies from repeating items in the sequences.

Definition 5.1: The bisimplicial set associated to a causal site above is called its *elementary classifying space*.

Note that if X is any bisimplicial set, and we fix m, then there is a natural simplicial set $X_{m,\cdot}$ whose n-simplices are the (m,n)-bisimplices of X. We call $X_{m,\cdot}$ the *simplicial set of m-simplices*.

It is now an important observation that the elementary classifying space of a causal site satisfies the *Segal condition* (Leinster, 2002, Defn. Ta; Tamsamani, 1995). The Segal condition for a bisimplicial set has two parts. Translated into our situation, the first part states that the simplicial set of m-simplices is the subset of the product of m copies of the simplicial set of 1-simplices, where the adjacent 0-simplex objects are equal. More explicitly, it says that for each m and n, the natural map

$$X_{m,n}\to X_{m,1}\times_{X_{m,0}}\cdots\times_{X_{m,0}}X_{m,1}$$

must be a bijection. This is true for the elementary classifying space essentially because giving a chain $A_{i,0}\subseteq\cdots\subseteq A_{i,n}$ is the same as giving n chains $A_{i,0}\subseteq A_{i,1}$, $A_{i,1}\subseteq A_{i,2},\ldots,A_{i,n-1}\subseteq A_{i,n}$.

The second part of the Segal condition for bisimplicial sets is more subtle in general. The first part of the Segal condition tells us that for each m, the simplicial set $X_{m,\cdot}$ can be regarded as a category. The second part of the Segal condition then requires that for each m, the natural map

$$X_{m,\cdot}\to X_{1,\cdot}\times_{X_{0,\cdot}}\cdots\times_{X_{0,\cdot}}X_{1,\cdot}$$

must be an equivalence of categories. In our case, something stronger is true: for each m and n, the natural map

$$X_{m,n}\to X_{1,n}\times_{X_{0,n}}\cdots\times_{X_{0,n}}X_{1,n}$$

is a bijection. The reason this is true is similar to the reason that the first part of the Segal condition holds. And from this it follows that the categories above are equivalent.

Now let us describe the *Segal condition* for a simplicial set A. It simply states that there is exactly one n-simplex for each chain of n 1-simplices with the second vertex of the ith 1-simplex equal to the first vertex of the $i+1$st. That is, it states that the natural map

$$A_n\to A_1\times_{A_0}A_1\cdots\times_{A_0}A_1$$

is a bijection. This is true, for example, for the simplicial set associated to any partially ordered set. We will explain the importance of this condition below, when we study the relationship with category theory.

One point of all this is that we can completely capture the structure of a causal site as a combinatorially described space. This allows us to translate the problem of constructing physical theories on a causal site into the construction of presheaves over such a space, a problem which is well understood. Another is to join the concept of causal sites to the field of higher category theory.

Now we need to construct a modification of the elementary classifying space of a causal site. The modification will allow us to associate to a causal site a "special" bisimplicial set; see Tamsamani, 1995, where it is referred to as axiom C1, and Leinster, 2002, Defn. Ta.

Definition 5.2: A bisimplicial set X is *special* if the simplicial set $X_{0,\cdot}$ of 0-simplices is a disjoint union of points. In other words, all of the face and degeneracy maps between sets of the form $X_{0,n}$ are bijections.

This condition is important in category theory, because it is necessary for a bisimplicial set to be the nerve of a weak 2-category. As we shall see, this condition also plays a natural role when we try to construct models for quantum physical systems.

Now we want to define a new version of the classifying space of a causal site.

Definition 5.3: The *physical classifying space* of a causal site is the bisimplicial set whose (m,n)-bisimplices correspond to the following data:

(a) a sequence $A_0,\ldots,A_m$ of regions with $A_i \prec A_{i+1}$
(b) for each $i=0,\ldots,m-1$ and $j=0,\ldots,n$ a causal path C_i^j from A_i to A_{i+1}

such that for each i and j, the causal path C_i^j is a refinement of C_i^{j+1}. The two types of face maps are given by composition of rows and columns, respectively.

In this definition, refinements of causal paths play a central role. The physical motivation for this is the goal of writing discrete analogs of Feynman path integrals by summing effects of propagation along causal paths with the same beginning and end. Mathematically, we will see below that the (m,n)-bisimplices of the physical classifying space fit together to form a weak 2-category, because the initial and final paths of a refinement share a common initial and final region.

We would like to formulate the idea that all the information of a causal site is contained in its physical classifying space. We therefore make the following tentative definition.

Definition 5.4: A causal site is *tractable* if its elementary and physical classifying spaces are homotopy equivalent.

We do not know which causal sites are tractable, or whether this will prove to be a useful way to formulate the idea that the physical classifying space "suffices."

Proposition 5.5: *The physical classifying space of a causal site is a special bisimplicial set satisfying the Segal condition*.

The proof is similar to the argument given for the elementary classifying space, including the fact that a stronger form of the second part of the Segal condition holds.

Thus, as we explain below, the physically natural idea of focussing on the causal paths of a causal site supplies the missing mathematical ingredient to replace a space-time with a weak 2-category. We think this is suggestive for our program of applying higher categorical ideas of topology to quantum physics.

VI. THE WEAK 2-CATEGORY STRUCTURE OF A CAUSAL SITE

There is a very strong connection between simplicial and multisimplicial sets and higher categories. We begin with a standard theorem about (1-)categories (Leinster, 2002, p. 34; Tamsamani, 1995).

Theorem 6.1: *There is a one-to-one correspondence between categories and simplicial sets satisfying the Segal condition*.

The connection can be described by taking the nerve of the category. This is a simplicial set with one n-simplex for each string of n composable morphisms in the category, with face maps given by compositions of pairs of adjacent morphisms and degeneracies given by inserting identity maps.

This theorem has recently been extended from categories to 2-categories by Tamsamani (Leinster, 2002, Defn. Ta; Tamsamani, 1995); he proved that there is a natural one-to-one correspondence between special bisimplicial sets satisfying the Segal condition and weak 2-categories.

The connection proceeds by taking the "2-nerve" of the 2-category. This is the bisimplicial set with $(0,0)$-bisimplices the objects of the 2-category, $(1,0)$-bisimplices the 1-morphisms in the 2-category, $(1,1)$-bisimplices the 2-morphisms in the 2-category. A general (m,n)-bisimplex is a doubly indexed array of mn 2-morphisms along with some additional data.

The analogy with the structure of the physical classifying space prompts the following definition.

Definition 6.2: If the causal path $A \prec P_1 \prec P_2 \prec \cdots \prec P_p \prec B$ is a refinement of the causal path $A \prec Q_1 \prec Q_2 \prec \cdots \prec Q_q \prec B$ then we say that there is a *chain inclusion* from the causal path $\{Q_j\}$ to the causal path $\{P_i\}$.

The *inclusion 2-category* of a causal site is the 2-category whose objects are regions, 1-morphisms are causal paths, and 2-morphisms are chain inclusions.

The inclusion 2-category of a causal site connects regions, processes between regions, and inclusions of processes. These are the elements which would go into a description of an experiment. A 2-functor on this 2-category would then give us a mathematical language in which to associate calculations to an experiment, by associating concrete mathematical structures and relations to the objects and processes.

As we shall discuss below, the state sum models for quantum gravity have a natural formulation in terms of 1- or 2-categories. Any two 2-categories are connected by a 2-category of functors, natural transformations and modifications. This means the categorical structure we have described gives us a sort of calculus for constructing physical models over causal sites using the state sum models as local physical data.

To put things simply, one could easily feel that passing from point sets to regions leads to a mathematical wilderness. The structure we have discovered has geometric, categorical and algebraic aspects which make available to us a large framework of definitions and theorems which can guide us to natural constructions of physical models. The natural definition of a physical model on a causal site is a type of functor on it. The definition could in principle be found without the categorical language, but it is a foolish cave explorer who throws away a light.

VII. BISIMPLICIAL PATCHES

The geometrical and physical applications of smooth manifolds largely grow out of the fact that to every smooth manifold we can naturally associate a tangent bundle. This develops from the more elementary fact that every point of a manifold has a neighborhood which can be described as a space of a fixed and familiar kind. In this section we propose such a neighborhood structure. In the next, we show how to construct an analog of the tangent bundle, but a relational, or 2-categorical one.

Definition 7.1: If A is a region in a causal site, the bisimplicial set of regions contained in it is its *bisimplicial patch*. This bisimplicial set sits naturally inside the elementary classifying space (Definition 5.1).

With this definition in place, it is possible to treat causal sites in a manner analogous to manifolds, by working on the local bisimplicial patches thought of as coordinate patches.

Simplicial and bisimplicial sets have a homotopy theory equivalent to the homotopy theory of topological spaces. This subtle mathematical fact should allow us to use the combinatorics of the bisimplicial patch as an approximation to the local topology of a region.

Definition 7.2: Let $R \subseteq R'$ be regions. The *bisimplicial patch* of the complement is the bisimplicial set of regions A which are contained in R' and disjoint from R. The *relative homotopy type* of R in R' means the homotopy type of the pair (X, Y) where X is the bisimplicial patch of R' and Y is the bisimplicial patch of the complement of R in R'.

Definition 7.3: A region R is an *n-ball* if it is contained in a region R' such that the relative homotopy type is that of an n-sphere.

A causal site is a *grained n-manifold* if every region is contained in a union of a finite number of n-balls.

VIII. THE TANGENT 2-BUNDLE

In a physical model on a causal site, we would like to think of information being transferred along causal paths. We will now describe a construction of a version of a tangent bundle for causal sites in which the regions contain just such information as can be observed along the causal paths, while the compositions and inclusions of causal paths have a natural action.

8.1. Causal paths: For $A \prec B$ we define $\mathrm{Path}(A, B)$ to be the set of causal paths from A to B. For any $A \prec B \prec C$ there is a natural composition map $\mathrm{Path}(A, B) \times \mathrm{Path}(B, C) \to \mathrm{Path}(A, C)$ which sends $A \prec P_1 \prec \cdots P_m \prec B$ and $B \prec Q_1 \prec \cdots Q_n \prec C$ to $A \prec P_1 \prec \cdots P_m \prec B \prec Q_1 \prec \cdots Q_n \prec C$. The composition map is injective.

For a region A, define the *future cone* of A to be $A\uparrow = \{B \,|\, A \prec B\}$ and define the *future tangent space* of A to be $A\Uparrow = \{A'\uparrow \,|\, A' \subseteq A\}$, the poset of future cones of subregions of A, ordered by

inclusion. The future cone $A\uparrow$ is a minimum element of $A\Uparrow$. For a region B, define the *past cone* of B to be $B\downarrow=\{A\,|\,A\prec B\}$ and define the *past tangent space* of B to be $B\Downarrow=\{B'\downarrow\,|\,B'\subseteq B\}$, ordered by inclusion. The past cone $B\downarrow$is a minimum element of $B\Downarrow$.

The relevance of these cones is that if $A_1\uparrow=A_2\uparrow$, then $\mathrm{Path}(A_1,B)=\mathrm{Path}(A_2,B)$ for any B. (This is an equality rather than a bijection because a path from A to B doesn't include the regions A and B.) More generally, if $A_1\uparrow\subseteq A_2\uparrow$, then $\mathrm{Path}(A_1,B)\subseteq\mathrm{Path}(A_2,B)$ for any B. Similarly, $B_1\downarrow\subseteq B_2\downarrow$ implies that $\mathrm{Path}(A,B_1)\subseteq\mathrm{Path}(A,B_2)$ for any A. Writing Fut for the poset $\{A\uparrow\}$ of all future cones and Past for the poset $\{B\downarrow\}$ of all past cones, this says that $\mathrm{Path}(-,-)$ is an order preserving map from the poset Fut$\times$Past to the poset Inc of sets and inclusions. In fancier language, $\mathrm{Path}(-,-)$ is a functor.

This has various consequences. For example, if $A'\subseteq A$, then $A'\uparrow\supseteq A\uparrow$ and so $\mathrm{Path}(A',B)\supseteq\mathrm{Path}(A,B)$ for any B. And if $A'\prec A$, then $A'\uparrow\supseteq A\uparrow$ and so again $\mathrm{Path}(A',B)\supseteq\mathrm{Path}(A,B)$ for any B. Similar reasoning shows that if $B'\subseteq B$ or $B'\succ B$ (note the reversal), then $B'\uparrow\supseteq B\uparrow$ and so $\mathrm{Path}(A,B')\supseteq\mathrm{Path}(A,B)$ for any A.

8.2. Causal paths subordinate to a given path: If we are given a causal path P from A to B, we can assign to any pair of subregions $A'\subseteq A$ and $B'\subseteq B$ the set $\mathrm{Path}_P(A',B')$ of causal paths from A' to B' which are refinements of P. As above, this defines a functor, in this case from $A\Uparrow\times B\Downarrow$ to Inc.

We next describe a 2-category which is a natural target for this construction.

Definition 8.1: Define a weak 2-category $\mathcal{PP}$ in the following way. The objects are pairs (F,P) of posets with minimum elements m_F and m_P. A 1-morphism from (F_1,P_1) to (F_2,P_2) is a functor from $F_1\times P_2$ to Inc. The composite of $S:F_1\times P_2\to\mathrm{Inc}$ with $T:F_2\times P_3\to\mathrm{Inc}$ is the functor $TS:F_1\times P_3\to\mathrm{Inc}$ defined by $TS(f,p)=S(f,m_{P_2})\times T(m_{F_2},p)$. If S and T are 1-morphisms from (F_1,P_1) to (F_2,P_2), i.e., functors from $F_1\times P_2$ to Inc, a 2-morphism from S to T is a natural family of injections $S(f,p)\to T(f,p)$.

Note that the composites $(TS)R$ and $T(SR)$ of 1-morphisms are in general not equal. Instead, there is a natural bijection between them. Thus $\mathcal{PP}$ is a *weak* 2-category. This also explains why the 2-morphisms allow arbitrary injections rather than just inclusions.

The horizontal and vertical compositions of the 2-morphisms of $\mathcal{PP}$ are given by Cartesian product and composition of injections, respectively. The coherence of $\mathcal{PP}$ is natural.

The discussion above can be summarized by saying that there is a weak 2-functor from the inclusion 2-category of our causal site to the weak 2-category $\mathcal{PP}$. This can be thought of as a prestack. It sends a region A to the pair $(A\Uparrow,A\Downarrow)$ of posets. It sends a causal path P from A to B to the functor $\mathrm{Path}_P(-,-)$ from $A\Uparrow\times B\Downarrow$ to Inc. And it sends a chain inclusion from P' to P (which means that P and P' are both causal paths from A to B, and P' is a refinement of P) to the natural family of inclusions $\mathrm{Path}_{P'}(A',B')\subseteq\mathrm{Path}_P(A',B')$. If P is a causal path from A to B and Q is a causal path from B to C, there is a natural injection $\mathrm{Path}_P(A',B)\times\mathrm{Path}_Q(B,C')\to\mathrm{Path}_{Q\circ P}(A',C')$, where $Q\circ P$ denotes the composite of P and Q.

Definition 8.2: We call this weak 2-functor the *tangent 2-bundle* of the causal site.

The tangent 2-bundle contains information about how causal paths can link the observable tangent spaces together. Since we can also refine causal paths, expansions into discretized path sums will be possible by decomposing intermediate regions into unions and summing over the families of refined paths which occur.

We think the analogy between smooth manifolds and causal sites may be a good guide to applications. We use the tangent bundle as a setting in order to apply calculus to the geometry of manifolds. Similarly, the local simplicial or bisimplicial structures on a site may enable us to apply the calculus of categorical state sums to quantum geometry on them. In constructing a quantum theory over a causal site, it should be possible to use the connecting complexes as discretized analogs of a Feynman path integral, and their 2-categorical structure should help constrain such a construction, allowing us to find interesting models just from the requirement of 2-functoriality.

IX. UNITARY PRESTACKS ON A CAUSAL SITE

In the next few sections, we investigate a more conventional approach to constructing geometrical or physical models on causal sites, namely, putting suitable presheaves and prestacks over them.

We will begin with a preliminary investigation of the type of physical model which the mathematical structure of a causal site suggests. We will not attempt to construct specific physically realistic models in this paper.

The original idea of a site was motivated by the fact that a presheaf over a topological space X is equivalent to a contravariant functor from the category of open subsets of X.

Since a bundle, including the tangent bundle of a manifold, can be regarded as a type of sheaf, we have a language for describing analogs of the basic structures underlying Yang-Mills theory and general relativity available for sites, although we will probably need stronger regularity assumptions to be able to create more precise analogs.

It is interesting that including a causal structure in our model, which traditionally is expressed by changing from a Riemannian to a Lorentzian metric, is expressed here by passage from a 1-category to a 2-category, a process which has been called categorification (Crane and Frenkel, 1994; Baez-Dolan, 1998).

This has the immediate consequence that rather than looking for models over a causal site within an ordinary category, such as the category of Hilbert spaces, we must turn to a 2-category, such as the category of 2-Hilbert spaces (Baez, 1996). Instead of a presheaf of Hilbert spaces, we work with a prestack of 2-Hilbert spaces. A prestack is a weak 2-functor from our causal site to a 2-category (Breen, 1994). In a prestack, a triangle of restriction morphisms only needs to commute up to a 2-morphism.

This means that rather than thinking of an assignment of a single Hilbert space to a region (something like the space of quantum states propagating through it), we assign to it a category of Hilbert spaces. Physically, we can think of this as related to the idea that the state space of a region has dimension related to the area of its boundary, so that if the geometry is itself a quantum variable, then the Hilbert space itself cannot be unique.

Indeed, if we tried to construct a physical theory over a causal site, we would quickly discover that we couldn't find a natural linear map to associate to containment, because of the nonlocal correlations in quantum theories. We would be trapped trying to map pure states to mixed states.

It actually provides an interesting new slant on the interpretation of quantum mechanics rewriting this process in terms of the different choices of Hilbert spaces in the categories corresponding to two regions, one of which contains the other.

Let us explain in a very simple situation, using the category 2-Vect (Kapranov and Voevodsky, 1994) rather than 2-Hilb, how this would look. Objects in 2-Vect are n-vector spaces, i.e., the category of all n-tuples of vector spaces for some n. Arrows in 2-Vect are functors defined by tensoring by some column of vector spaces. Thus, a (contravariant) functor from a causal site to 2-Vect would find the vector spaces which could appear on a subregion being combined into tensor products of vector spaces associated to a larger region.

Now there is neither a natural map $A \to A \otimes B$ nor $A \otimes B \to A$, so there would be no way to represent inclusion as a map on individual Hilbert spaces. This is a mathematically elegant way to express the existence of nonlocal correlations in compound systems in quantum mechanics. The overall rule which tells us how the different Hilbert spaces associated to regions are related has an elegant functorial form, which cannot be recovered on the individual Hilbert spaces. In Hawkins *et al.*, 2003, a similar problem was studied for models on causal sets, and it was discovered that maps between causally related points must be expressed as completely positive maps on spaces of mixed states (i.e., Hermitian operators over the Hilbert spaces, rather than the Hilbert spaces themselves). The setting we are exploring, combining both causality and containment, should contain examples of this, but set in a broader algebraic context.

Now we can ask ourselves which of the models which have appeared in mathematical physics would be good candidates for extending to a causal site. An obvious choice would be 2-Yang-

Mills theory (Baez, 2002; Girelli and Pfeiffer, 2003), which is a theory which puts a nonlinear partial differential operator on a 2-form, by analogy with the Yang-Mills equation on a 1-form.

Since 2-Yang-Mills theory has the interpretation of physics on the curvature of a gerbe, which is really a special type of stack of categories, it will have a direct generalization to causal sites.

X. A BRIEF REVIEW OF CATEGORICAL STATE SUM MODELS

Categorical state sums (Crane *et al.*, 1994; Barrett and Crane, 1998; Crane and Yetter, 2003; Noui and Roche, 2003; Crane *et al.*, 2001) are models of quantum geometry on simplicial complexes. They are constructed out of unitary representations of Lie groups or quantum groups, intertwining maps of these representations, and in some cases, 2-intertwiners. The maps are composed in closed patterns related to the combinatorics of the simplicial complex, traced, and summed over. The result is a discrete version of a path integral for quantum geometry, with the unitary representations acting as Hilbert spaces on which geometric quantities are represented as operators.

For example, in the model of Barrett and Crane, 1998, we have a four-dimensional simplicial complex. The 2-simplices (triangles) are labelled with unitary representations of the Lorentz group. We think of these as quantizations of the oriented area elements a geometry would assign to the faces, because oriented area elements can be identified with elements of the Lie algebra of the Lorentz group.

In fact, in order to impose the necessary constraints on the geometry, we restrict ourselves to a class of representations called the balanced ones. We then label the tetrahedra with a sum over the balanced intertwining maps between the four representations, trace over each 4-simplex, multiply, then sum over all possible choices of representations.

There are a number of models of this type, differing by the dimension, choice of symmetry group, constraints, etc. These amount to different choices of the geometry to be quantized.

This type of model is closely related to the ideas discussed above describing simplicial sets as categories. They can be written as sums of functors from the category associated to the complex to the category of representations of the geometrical symmetry group or quantum group.

In short, the categorical state sum picture makes it natural to assign a quantum geometry to a simplicial complex.

In the context of causal sites, this can be thought of as a candidate for local quantum geometry on a tangent space, analogously to the use of inner products on tangent spaces in classical Riemannian geometry.

One of the reasons that manifold theory was so important to the development of relativity was that it gives a natural concrete expression for the equivalence principle: laws must be expressed in tensor form. The categorical underpinning of the structure of causal sites suggests a similar principle in quantum gravity: laws must be expressed in functorial form. This simple and attractive principle will cut down the possibilities greatly.

Given that we already have subcategories which express the relational world seen by an observer, it is also a natural expression of the idea behind the equivalence principle, if we take the point of view that coordinate systems are idealized observers.

XI. STATE SUM MODELS ON CAUSAL SITES

The physically interesting examples of Sec. III all possess local symmetries. (Since a bounded region which is boosted too far no longer contains fundamental diamonds, a mathematical formalization of this would need to use actions of germs of the Lorentz or Poincare groups. We will not work this out in this paper.)

It therefore seems that the Hilbert spaces in a quantum site would group together in unitary representations of the Lorentz group.

Now one of the great challenges for our proposal is to find a way to derive Einstein's equation as a classical limit for some formulation of the dynamics on a quantum site. Categorical state sum models are interesting because the laws of combination of the representations produce a classical

limit which implies Einstein's equation. In other words, Einstein's equation is actually determined by the symmetry of the model, expressed in the tensor category of unitary representations of the Lorentz group.

Now is it possible that we can introduce categorical state sum models into a suitable family of causal sites with local symmetries? Let us try to imagine how that could arise.

In order to define a class of causal sites which would be physically realistic near the Planck scale, we have defined "grained worlds" above as locally Noetherian, amply pointed causal sites. We think of this as a way to embed facts about the limited amount of information which can flow between regions in general relativity into the fabric of spacetime itself.

The combination of these two properties means that given a causally related pair of regions $A \prec B$, we can find a finite set of relational points for B in A which in some sense exhaust the information which B can see in A. This would mean that the relational tangent space would be adequately described by a simplicial set, assuming the set of points did not contain one another.

This suggests that the state sum model of Barrett and Crane, 1998, or some similar model, might appear as a good approximation to the quantum theory of the part of a quantum site contained in a region.

This is probably a better setting for state sum models than direct application to a whole universe, since the finiteness of the simplicial set becomes better motivated.

Then, when we wanted to express the flow of information from one region, described by a state sum on a simplicial set, to another, along a given causal path, we would know that the map which described it would have to behave well when we included one causal path in another.

This includes the information flow law in a 2-categorical structure, which might be rich enough to allow us to determine it.

So a program suggests itself, to make a suitable set of assumptions on a prestack over a grained world, so that if we pass to a set of relational points the relative position information ends up containing all the transferred information, and takes the form of a state sum model.

At this point, we realize that our new point of view is making us ask a series of new questions about state sums which had no motivation in the past when they were thought of as stand alone models. We need to express the relationship between two state sum models when the complex of one is embedded in the other, we need to work out expressions for causal flows of information between state sums, and we need to investigate in what sense they approximate points with quantum variables between them as they grow far apart. If nothing else, the causal sites proposal has widened our perspective on state sum models.

XII. CONCLUSIONS AND FUTURE DIRECTIONS

We now have defined a new class of mathematical objects, which are not point sets, but which can function as a topological foundation for classical general relativity. We have families of examples corresponding to classical space-times, which include descriptions of the geometrodynamics of classical spacetimes above the Planck scale, without the inclusion of a metric tensor as a mathematical datum separate from the underlying space-time structure.

The representation of geometry by a causal site is analogous to the representation by a discrete causal set, but as we have discussed, it seems to give a much closer approximation. Our relative and absolute points should not be confused with ordinary points, either in manifolds or causal sets. They are not "atomic." For example, a union of a finite family of fundamental diamonds in a Lorentzian manifold can contain an infinite number of other fundamental diamonds. Nevertheless, the causality relationship between them gives rise to a finiteness or discreteness in the structure. It therefore makes a bridge between continuous and discrete structures in a new way. The hypothesis of overlapping minimal regions seems more physically natural to us than the discrete point sets of causal sets or categorical state sum models. It also means that the continuous or discrete symmetry properties of a causal site can be more robust than a causal set. In the examples we have constructed, the symmetry with respect to the Lorentz group is not broken, because we have fundamental diamonds in all reference frames. In the theory of causal sets, by contrast, it is only possible to recover the symmetry on the average in the infinite volume of Minkowski space

(Sorkin, 2003). The fact that we are able to produce a mathematical construction which combines a fundamental graininess with symmetry in local regions gives our construction added interest.

We think it will be interesting to try to find further families of examples, for instance to try to construct quantum n-manifolds neither related to causal sets nor directly derived from manifolds. Different classes of these might give new examples of "space-time textures," which could be explored as new settings for physical models. It may well be that the physical intuition expressed in the phrase "space-time foam" can find better expression in our setting that when constrained by the necessity of considering only families of smooth manifolds.

Causality and time are integrated into the mathematical structure of a causal site in a striking fashion: space-time appears as a categorification of space. The fact that causal sites can be considered either as bisimplicial sets or as 2-categories means we have a number of well-understood tools at our disposal for constructing examples.

In addition, the structure of a causal site seems to lend itself readily to quantization. We have not yet examined this in any detail.

We have, at this point, many more questions than answers. Can the geometric picture of Example 3.4 be generalized to more intrinsic models, i.e., models which have definitions not so directly dependent on a classical space-time? Can it be quantized? Since it seems natural to approach quantization by beginning with the family of containments of a particular causal site, it will be easier to find semiclassical states in this approach than in other approaches to quantum gravity.

It would seem that the Hilbert spaces arising from quantization of a causal site with local symmetries would decompose into unitary representations of the Lorentz group. Do the state sum models arise in such a picture? We should remind ourselves that Einstein's equation is almost determined by symmetry considerations. Would a quantization of a causal site with Lorentz symmetry which was required to respect the symmetry be nearly determined as well?

We also have not yet studied the description of curvature in causal sites, nor searched for a geometric way to impose Einstein's equation.

General relativity is intimately bound up with our ideas about space-time and geometry. Changing the foundation of these creates a situation in which all the questions of classical and quantum relativity can be reexamined. The large family of accessible examples we have constructed means that a fairly broad program can be practically implemented.

Universal homogeneous causal sets

Manfred Droste[a)]
Institut für Informatik, Universität Leipzig, D-04109 Leipzig, Germany

(Received 21 April 2005; accepted 3 November 2005; published online 30 December 2005)

Causal sets are particular partially ordered sets which have been proposed as a basic model for discrete space-time in quantum gravity. We show that the class $\mathfrak{C}$ of all countable past-finite causal sets contains a unique causal set $(U, \leqslant)$ which is universal (i.e., any member of $\mathfrak{C}$ can be embedded into $(U, \leqslant)$) and homogeneous (i.e., $(U, \leqslant)$ has maximal degree of symmetry). Moreover, $(U, \leqslant)$ can be constructed both probabilistically and explicitly. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2147607]

I. INTRODUCTION

The causal set hypothesis asserts that the ultimate structure of space-time in quantum gravity is discrete, and that a fundamental relationship between points in space-time is causality, enabling us to say that x is in the past of y. Such a structure can be naturally modeled by partially ordered sets $(S, \leqslant)$ which are locally finite (i.e., any interval $[x,y]$ between two points x,y is finite) or which are even past-finite (i.e., the past of each point x is finite). Locally finite partially ordered sets are called causal sets and have been investigated in detail, cf. e.g., Refs. 3,14 and 16. Moreover, an interesting sequential growth dynamics for finite causal sets was investigated in Refs. 15, 5, and 4: a finite causal set can be extended by a single element z by adding it to the given partial order as a new maximal element (naturally, z cannot be in the past of any given element). Continuing in this way, one obtains a countable past-finite causal set. Conversely, any countable past-finite causal set can be built up this way. For further work on this dynamics, see, e.g., Refs. 1,10 and 12.

It is the goal of this paper to investigate the class of countable past-finite causal sets. We will show that there is a countable past-finite causal set $(U, \leqslant)$ which is universal and homogeneous. Here, *universal* means that $(U, \leqslant)$ contains an isomorphic copy of any countable past-finite causal set as a natural substructure. *Homogeneous* means that any isomorphism between two finite substructures (stems) of $(U, \leqslant)$ extends to an automorphism of $(U, \leqslant)$. Thus homogeneity intuitively says that $(U, \leqslant)$ has the highest possible degree of structural symmetry. Moreover, with these two properties, universality and homogeneity, $(U, \leqslant)$ is unique up to isomorphism in the class of all countable past-finite causal sets. Our proof employs the Fraïssé-Jónsson theorem well-known in model theory for constructions of homogeneous relational structures. We also give an explicit order-theoretic construction of the universal homogeneous past-finite causal set, and we show that the larger class of all countable causal sets (not requiring "past-finite"), in contrast, does not contain a universal object.

In our second result, we will describe a probabilistic construction of the universal homogeneous past-finite causal set $(U, \leqslant)$. Probabilistic procedures for constructing one-point extensions of finite causal sets were crucial for Refs. 15 and 10 and investigated in detail. Here we also propose a probabilistic construction. It is motivated by a classical construction of Erdös and Rényi[8] of the random graph (which is universal and homogeneous in the class of all countable graphs). More recently, a similar construction of the universal homogeneous countable partial

[a)]Electronic mail: droste@informatik.uni-leipzig.de

order was given in Ref. 7. If we employ the present probabilistic one-point extensions of finite causal sets successively, we obtain an infinite sequence of causal sets whose union is a countable past-finite causal set, the *random* past-finite causal set. Then we show that with probability 1, this random causal set is universal and homogeneous (hence unique up to isomorphism). Our construction of one-point extensions differs from the ones investigated in Ref. 15 in technical details, which we discuss briefly, and it would be interesting to investigate the relationship further. Finally, we describe a simple explicit number-theoretic construction of $(U,\leqslant)$. This is motivated by a classical construction of the random graph.[13] We close with a short discussion.

II. UNIVERSAL CAUSAL SETS

First we establish some terminology. For a fuller introduction to causal sets, see Ref. 16.

A partially ordered set (poset) is a pair $(S,\leqslant)$ where S is a set and $\leqslant$ is a binary relation on S which is reflexive, antisymmetric, and transitive. Let $(S,\leqslant)$ be a poset. For $x,y\in S$ we write $x<y$ to denote that $x\leqslant y$ and $x\neq y$. If $x<y$, we let $[x,y]=\{s\in S\,|\,x\leqslant s\leqslant y\}$, and for $x\in S$ let $\mathrm{past}_S(x)=\{s\in S\,|\,s\leqslant x\}$. Then $(S,\leqslant)$ is called *locally finite*, if each interval $[x,y]$ $(x,y\in S, x<y)$ is finite, and *past-finite*, if $\mathrm{past}_S(x)$ is finite for each $x\in S$. Clearly, any past-finite poset is locally finite (but not conversely as seen by the set of negative integers with their natural order). A *causal set* (or *causet*) is a locally finite poset. If $X\subseteq S$ is a subset, let $\mathrm{past}_S(X)=\cup_{x\in X}\mathrm{past}(x)$. If S is clear from the context, we also write $\mathrm{past}(x)$ and $\mathrm{past}(X)$. Then X is called a *stem of* S, denoted $(X,\leqslant)\lhd(S,\leqslant)$ or $X\lhd S$, if $\mathrm{past}(X)\subseteq X$ (note that here, in slight generalization of Ref. 16, we do not require X to be finite).

In Refs. 15 and 16, constructions of countable causal sets $(S,\leqslant)$ are given as unions of chains of finite posets $(A_1,\leqslant_1)\lhd(A_2,\leqslant_2)\lhd\ldots$. Indeed, given such a chain, let $S=\cup_{i\in\mathbb{N}}A_i$, and for $x,y\in S$ put $x\leqslant y$ if for some $i\in\mathbb{N}$ we have $x,y\in A_i$ and $x\leqslant_i y$. Then $(S,\leqslant)$ is a past-finite countable poset and $A_i\lhd S$ for each $i\in\mathbb{N}$. Such constructions will also be crucial for this paper.

Let $(S,\leqslant)$ and $(S',\leqslant)$ be two posets. A mapping $f:S\to S'$ is called an (*order-*) *embedding of* $(S,\leqslant)$ *into* $(S',\leqslant)$, if for any $x,y\in S$ we have $x\leqslant y$ iff $f(x)\leqslant f(y)$. Clearly, any embedding is one-to-one. An embedding $f:(S,\leqslant)\to(S',\leqslant)$ is called an *isomorphism*, if f is onto, and a *stem-embedding*, if $f(S)\lhd S'$. So, f is a stem-embedding iff f is an isomorphism from $(S,\leqslant)$ onto a stem of $(S',\leqslant)$. An isomorphism of $(S,\leqslant)$ onto itself is called an *automorphism* of $(S,\leqslant)$.

Let $\mathfrak{C}$ be a class (collection) of posets. A poset $(S,\leqslant)\in\mathfrak{C}$ will be called *stem-universal* in $\mathfrak{C}$, if each poset $(C,\leqslant)\in\mathfrak{C}$ is isomorphic to some stem in $(S,\leqslant)$, i.e., there exists a stem-embedding $f:(C,\leqslant)\to(S,\leqslant)$. We call $(S,\leqslant)$ *homogeneous*, if each isomorphism $f:(A,\leqslant)\to(B,\leqslant)$ between two finite stems of $(S,\leqslant)$ extends to an automorphism of $(S,\leqslant)$; equivalently, for any finite poset $(A,\leqslant)$ and any two stem-embeddings $f,f':(A,\leqslant)\to(S,\leqslant)$ there exists an automorphism g of $(S,\leqslant)$ such that $f'=g\circ f$. (We mention that in the literature there are other concepts called homogeneity. Our homogeneity, for instance, does *not* mean that $\mathrm{Aut}(S)$, the automorphism group of $(S,\leqslant)$, acts transitively on S).

We say that $(S,\leqslant)$ *realizes all one-point stem-extensions of finite stems of* S, if whenever $(A,\leqslant),(B,\leqslant)$ are finite posets such that $(A,\leqslant)\lhd(S,\leqslant),(A,\leqslant)\lhd(B,\leqslant)$ and $|B|=|A|+1$, then there exists a stem-embedding $g:(B,\leqslant)\to(S,\leqslant)$ such that $g|_A=\mathrm{id}_A$, the identity on A (this condition includes the case $A=\emptyset$).

The first main goal of this paper will be the following result.

Theorem 2.1: *Let* $\mathfrak{C}$ *be the class of all past-finite countable causal sets.*

(a) *A poset* $(U,\leqslant)\in\mathfrak{C}$ *is stem-universal and homogeneous in* $\mathfrak{C}$ *iff* $(U,\leqslant)$ *realizes all one-point stem-extensions of finite stems of* U.

(b) *There exists a stem-universal homogeneous past-finite causet* $(U,\leqslant)$ *in* $\mathfrak{C}$. *Moreover,* $(U,\leqslant)$ *is unique up to isomorphism with these properties.*

One approach to the proof of Theorem 2.1 would be to use a category-theoretic generalization of the Fraïssé-Jónsson theorem from model theory, see Ref. 6, and to argue directly for past-finite

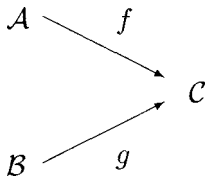
causal sets and stem embeddings. In order to avoid the category-theoretic machinery needed for this, here we will base our argument on a more classical version of the Fraïssé-Jónsson theorem, cf. Refs. 9, 2, and 11, which describes the existence of universal homogeneous objects for various classes of, e.g., relational structures. This also has the advantage of showing how to regard past-finite causal sets and stem-embeddings as relational structures and relational embeddings. For the convenience of the reader, we recall these notions. Let $\sigma=(n_i)_{i\in I}$ be a fixed I-indexed sequence of natural numbers $n_i\geqslant 1$ (a relational signature) denoting prescribed arities of relations. A tuple $\mathcal{A}=(A,(R_i)_{i\in I})$ is called a *σ-structure*, if A is a set (possibly empty) and R_i is an n_i-ary relation on A, i.e., $R_i\subseteq A^{n_i}$, for each $i\in I$. Given two σ-structures $\mathcal{A}=(A,(R_i)_{i\in I})$ and $\mathcal{B}=(B,(Q_i)_{i\in I})$, a mapping $f:A\to B$ is called an *embedding* of $\mathcal{A}$ into $\mathcal{B}$, if f is one-to-one and for each $i\in I$ and $x_1,\ldots,x_{n_i}\in A$ we have $(x_1,\ldots,x_{n_i})\in R_i$ iff $(f(x_1),\ldots,f(x_{n_i}))\in Q_i$. An embedding which is onto is called an *isomorphism*. An isomorphism of $\mathcal{A}$ onto itself is called an *automorphism of $\mathcal{A}$*. Further, $\mathcal{A}$ is said to be a *substructure* of $\mathcal{B}$, if $A\subseteq B$ and $R_i=Q_i\cap A^{n_i}$ for each $i\in I$, i.e., $A\subseteq B$ and the identity mapping $\mathrm{id}:A\to B$ is an embedding of $\mathcal{A}$ into $\mathcal{B}$; this is denoted by $\mathcal{A}\subseteq\mathcal{B}$.

Now let $\mathfrak{C}$ be a class (collection) of σ-structures. A structure $\mathcal{U}\in\mathfrak{C}$ is called *universal* in $\mathfrak{C}$, if for each $\mathcal{A}\in\mathfrak{C}$ there exists an embedding $f:\mathcal{A}\to\mathcal{U}$. Further, $\mathcal{U}$ is *homogeneous*, if each isomorphism $f:\mathcal{A}\to\mathcal{B}$ between two finite substructures $\mathcal{A},\mathcal{B}$ of $\mathcal{U}$ with $\mathcal{A},\mathcal{B}\in\mathfrak{C}$ extends to an automorphism of $\mathcal{U}$. The structure $\mathcal{U}$ *realizes all finite extensions of finite substructures*, if whenever $\mathcal{A},\mathcal{B}\in\mathfrak{C}$ are finite structures such that $\mathcal{A}\subseteq\mathcal{U}$ and $\mathcal{A}\subseteq\mathcal{B}$, then there exists an embedding $g:\mathcal{B}\to\mathcal{U}$ such that $g|_A=\mathrm{id}_A$. The class $\mathfrak{C}$ is said to be an *ω-class*, if it satisfies the following conditions:

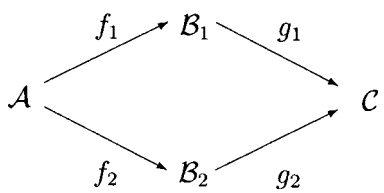
(0) Any $\mathcal{A}\in\mathfrak{C}$ is countable.
(1) Whenever $\mathcal{A}\in\mathfrak{C}$ and $\mathcal{B}$ is a structure isomorphic to $\mathcal{A}$, then $\mathcal{B}\in\mathfrak{C}$.
(2) If $\mathcal{A}_1\subseteq\mathcal{A}_2\subseteq\ldots$ are finite structures from $\mathfrak{C}$, forming a chain of substructures under inclusion, then their union $\mathcal{A}=\cup_{i\in\mathbb{N}}\mathcal{A}_i$ (whose domain and relations are defined as the union of the domain respectively corresponding relations of the structures $\mathcal{A}_i$) also belongs to $\mathfrak{C}$.
(3) If $\mathcal{A}\in\mathfrak{C}$ and F is a finite subset of the domain of $\mathcal{A}$, then there exists a finite substructure $\mathcal{S}\subseteq\mathcal{A}$ with $\mathcal{S}\in\mathfrak{C}$ whose domain contains F.

An object $\mathcal{A}\in C$ is called *weakly initial in* $\mathfrak{C}$, if for each $\mathcal{B}\in\mathfrak{C}$ there exists an embedding $f:\mathcal{A}\to\mathcal{B}$. (Often, this is the empty or a singleton structure.) The class $\mathfrak{C}$ is said to have

- the *joint embedding property*, if for any $\mathcal{A},\mathcal{B}$ there exists $\mathcal{C}\in\mathfrak{C}$ and embeddings $f:\mathcal{A}\to\mathcal{C},g:\mathcal{B}\to\mathcal{C}$



- the *amalgamation property*, if for any $\mathcal{A},\mathcal{B}_1,\mathcal{B}_2\in\mathfrak{C}$ and embeddings $f_i:\mathcal{A}\to\mathcal{B}_i$ $(i=1,2)$ there exists $\mathcal{C}\in\mathfrak{C}$ and embeddings $g_i:\mathcal{B}_i\to\mathcal{C}$ $(i=1,2)$ such that $g_1\circ f_1=g_2\circ f_2$, i.e., the subsequent diagram "commutes."



Theorem 2.2 (Refs. 2, 9, and 11): *Let σ be a relational signature and $\mathfrak{C}$ an ω-class of σ-structures.*

(a) *Let $\mathfrak{C}$ contain a weakly initial structure. Then a structure $\mathcal{U} \in \mathfrak{C}$ is universal and homogeneous in $\mathfrak{C}$ if and only if $\mathcal{U}$ realizes all finite extensions of finite substructures.*

(b) *The following are equivalent:*

(1) *$\mathfrak{C}$ contains a universal homogeneous structure $\mathcal{U}$.*

(2) *$\mathfrak{C}_{\mathrm{fin}}$, the class of all finite structures in $\mathfrak{C}$, has the joint embedding and the amalgamation property and contains up to isomorphism only countably many structures.*

Moreover, in this case $\mathcal{U}$ is unique up to isomorphism.

We just note that the proof of Theorem 2.2(a) as well as of the uniqueness of $\mathcal{U}$ in part (b) employs a standard "back-and-forth argument." The construction of the universal homogeneous structure $\mathcal{U}$ given condition (2) of part (b) uses a suitable enumeration of all possible embeddings of the finite structures in $\mathfrak{C}$.

In order to be able to apply Theorem 2.2 to causal sets, we have to enrich them to relational structures such that stem-embeddings become relational embeddings as above. Given a poset $(A, \leqslant)$, we define its *relational expansion* to be $(A, \leqslant, \mathcal{R})$ where $\mathcal{R}=(R_i)_{i\geqslant 1}$ and $R_i=\{ x \in A \,|\, |\mathrm{past}(x)|=i\}$ $(i \geqslant 1)$. Hence $\leqslant$ is a binary and each R_i a unary relation on A, so $(A, \leqslant, \mathcal{R})$ is a σ-structure for the signature $\sigma=(2,1,1,1,\ldots)$. Observe that if A is finite, then each of the relations R_i where $i>|A|$ is empty. Next we show that for past-finite causal sets, this expansion achieves our first goal:

Proposition 2.3: Let $(A, \leqslant)$ and $(B, \leqslant)$ be two past-finite causal sets and let $(A, \leqslant, \mathcal{R})$ respectively $(B, \leqslant, \mathcal{Q})$ be their relational expansions.

(a) *$(A, \leqslant)$ is a stem of $(B, \leqslant)$ iff $(A, \leqslant, \mathcal{R})$ is a substructure of $(B, \leqslant, \mathcal{Q})$.*

(b) *Let $f: A \to B$ be a mapping. Then $f: (A, \leqslant) \to (B, \leqslant)$ is a stem-embedding iff $f: (A, \leqslant, \mathcal{R}) \to (B, \leqslant, \mathcal{Q})$ is an embedding of relational structures.*

Proof: (a) We have $\mathcal{R}=(R_i)_{i\geqslant 1}$ and $\mathcal{Q}=(Q_i)_{i\geqslant 1}$ with $R_i=\{ x \in A \,|\, |\mathrm{past}_A(x)|=i\}$ and $Q_i=\{ y \in B \,|\, |\mathrm{past}_B(y)|=i\}$ $(i \geqslant 1)$.

First, let $A \lhd B$. Let $x \in A$. By $A \lhd B$ we get $\mathrm{past}_A(x)=\mathrm{past}_B(x)$, so $x \in R_i$ iff $x \in Q_i$, for each $i \geqslant 1$. Hence $(A, \leqslant, \mathcal{R}) \subseteq (B, \leqslant, \mathcal{Q})$. Conversely, assume the latter. Let $x \in A$ and $y \in B$ with $y \leqslant x$. By assumption, we have $\mathrm{past}_A(x) \subseteq \mathrm{past}_B(x)$ and $|\mathrm{past}_A(x)|=|\mathrm{past}_B(x)| \in \mathbb{N}$, so $\mathrm{past}_A(x) = \mathrm{past}_B(x) \ni y$ showing $y \in A$. Hence $A \lhd B$.

(b) Straightforward by (a), using that the image of A under f is an isomorphic copy of A and a stem respectively a substructure of B. □

This result allows us to translate all notions concerning stem-embeddings (like universality, homogeneity, etc.) into corresponding ones for the relational expansions and their embeddings.

Let $\mathfrak{C}$ be the class of all countable past-finite causal sets and let $\mathfrak{C}_{\mathrm{rel}}$ be the collection of all relational expansions $(A, \leqslant, \mathcal{R})$ where $(A, \leqslant) \in \mathfrak{C}$. Next we give an easy application of Proposition 2.3 to show how this translation of notions works:

Remark 2.4: $\mathfrak{C}_{\mathrm{rel}}$ is an ω-class of σ-structures.

Proof: Conditions (0) and (1) of the definition of ω-class are trivial. For (2), let $(A_1, \leqslant, \mathcal{R}_1) \subseteq (A_2, \leqslant, \mathcal{R}_2) \subseteq \ldots$ be a chain of finite structures from $\mathfrak{C}_{\mathrm{rel}}$, and let $(A, \leqslant, \mathcal{R}')$ be their union. Then $(A_1, \leqslant) \lhd (A_2, \leqslant) \lhd \ldots$ is a sequence of stems by Propositions 2.3 (a), and $(A, \leqslant)$ is a past-finite causal set whose expansion $(A, \leqslant, \mathcal{R})$ coincides with $(A, \leqslant, \mathcal{R}')$. Hence $(A, \leqslant, \mathcal{R}') \in \mathfrak{C}_{\mathrm{rel}}$. To check (3), let $(A, \leqslant, \mathcal{R}) \in \mathfrak{C}_{\mathrm{rel}}$ and let F be a finite subset of A. Then $\mathrm{past}(F)$ is a finite stem of $(A, \leqslant)$, so by Proposition 2.3 (a) its relational expansion is a finite substructure of $(A, \leqslant, \mathcal{R})$ belonging to $\mathfrak{C}_{\mathrm{rel}}$. □

Next we show:

Lemma 2.5: Let $(A,\leqslant),(B,\leqslant)$ *be two finite posets such that* $A\lhd B$. *Then there is a sequence of stems*

$$A=A_0\lhd A_1\lhd\ldots\lhd A_m=B$$

such that $|A_{i+1}|=|A_i|+1$ *for each* $i=0,\ldots,m-1$.

Proof: By induction on $|B\backslash A|$. Choose a minimal element x of $B\backslash A$, and put $A_1=A\cup\{x\}$. Then $A\lhd A_1\lhd B$, and by induction we obtain a sequence of stems and one-point extensions from A_1 to B. □

Now we can give the

Proof of Theorem 2.1: By Remark 2.4, $\mathfrak{C}_{\mathrm{rel}}$ is an ω-class of σ-structures.

(a) The empty structure is a weakly initial object of $\mathfrak{C}_{\mathrm{rel}}$. Lemma 2.5 shows that if $\mathcal{U}$ realizes all one-point extensions of finite stems, it also realizes all finite stem-extensions of finite stems. Now the result is a translation of Theorem 2.2 (a).

(b) Again we use Proposition 2.3. We check condition (2) of Theorem 2.2 (b). It is clear that $\mathfrak{C}_{\mathrm{rel}}$ contains up to isomorphism only countably many finite structures $(A,\leqslant,\mathcal{R})$, since if A is finite, only finitely many of the relations R_i are nonempty. It remains to show that the collection of finite posets satisfies the joint embedding and the amalgamation properties with respect to stem-embeddings. Since this collection contains the empty poset, it suffices to check the amalgamation property. For this, let $(A_i,\leqslant_i)$ $(i=0,1,2)$ be three finite posets such that $(A_0,\leqslant_0)\lhd(A_i,\leqslant_i)$ for $i=1,2$. We may assume that $A_0=A_1\cap A_2$. Put $A=A_1\cup A_2$ and $\leqslant=\leqslant_1\cup\leqslant_2$, i.e., for $x,y\in A$ let $x\leqslant y$ iff either $x,y\in A_1$ and $x\leqslant_1 y$ or $x,y\in A_2$ and $x\leqslant_2 y$. Then $\leqslant$ is transitive, since if, e.g., $x\leqslant_1 y$ and $y\leqslant_2 z$, we have $y\in A_1\cap A_2=A_0$ and $x\in A_1$. Since $A_0\lhd A_1$, we get $x\in A_0$ and $x\leqslant_0 y$, so $x\leqslant_2 y\leqslant_2 z$ which implies $x\leqslant z$. Hence $\leqslant$ is a partial order on A. Observe that if $x\in A_1\backslash A_0$ and $y\in A_2\backslash A_0$, then neither $x\leqslant y$ nor $y\leqslant x$. Also note that if $x,y\in A_1\cap A_2$ and $x\leqslant_1 y$, say, then this implies $x\leqslant_0 y$, hence also $x\leqslant_2 y$. We claim that $(A_i,\leqslant_i)\lhd(A,\leqslant)$ for $i=1,2$. By the remark just made, $\leqslant_i$ is just the restriction of $\leqslant$ to A_i. So, it only remains to show that A_i is a stem of $(A,\leqslant)$.

Indeed, let $x\in A$ and $y\in A_1$ with $x\leqslant y$. We claim that $x\in A_1$. This is trivial if $x\leqslant_1 y$. So let $x\leqslant_2 y$. Then $x,y\in A_2$ and $y\in A_0$. Now A_0 is a stem of $(A_2,\leqslant)$, so $x\in A_0\subseteq A_1$. Hence A_1 is a stem of $(A,\leqslant)$ and for A_2 we argue analogously. This proves the amalgamation property.

Now the result follows from Theorem 2.2 (b). □

Next we wish to describe the structure of the universal homogeneous past-finite causet $(U,\leqslant)$ further. A poset $(S,\leqslant)$ is called *directed*, if for any $a,b\in S$ there is $c\in S$ with $a\leqslant c$ and $b\leqslant c$. Two elements $a,b\in S$ are *incomparable*, if neither $a\leqslant b$ nor $b\leqslant a$; this is denoted by $a\|b$. A subset $A\subseteq S$ is called an *antichain*, if any two elements of A are incomparable. An element $x\in S$ is called *maximal*, if there is no $y\in S$ with $x<y$. Together with Theorem 2.1 (a), the following provides an order-theoretic characterization of the structure of the universal homogeneous past-finite causal set.

Proposition 2.6: Let $(U,\leqslant)$ *be a past-finite causal set. The following are equivalent*:

(1) $(U,\leqslant)$ *realizes all one-point stem-extensions of finite stems of* U.

(2)

- *(i)* $(U,\leqslant)$ *is directed, and*
- *(ii)* *For any finite antichain* $A\subseteq U$ *(including the case that* $A=\emptyset$*) and any* $y\in U\backslash A$ *with* $A\subseteq\mathrm{past}(y)$ *there is* $x\in U\backslash A$ *such that* $x\|y$ *and* $\mathrm{past}(x)=\mathrm{past}(A)\cup\{x\}$.

In this case, no element of $(U,\leqslant)$ *is maximal.*

Note that the condition $\mathrm{past}(x)=\mathrm{past}(A)\cup\{x\}$ means that $a\leqslant x$ for each $a\in A$, and whenever $u\in U$ with $u<x$, then $u\leqslant a$ for some $a\in A$.

Proof: (1)$\rightarrow$(2): To show (i), let $a,b\in U$. We claim that there is $c\in U$ with $a\leqslant c$ and $b\leqslant c$. Clearly, we may assume that $a\|b$. Let $A=\mathrm{past}(\{a,b\})$, choose an element $z\notin A$, and put $B=A\cup\{z\}$. We define a partial order $\leqslant^*$ on B such that it extends the order $\leqslant$ on A and $a\leqslant^* z, b\leqslant^* z$, so z is the greatest element of $(B,\leqslant^*)$. Then $(A,\leqslant)\lhd(B,\leqslant^*)$, a one-point extension of the finite stem A of U. Hence, there exists a stem-embedding $g:(B,\leqslant^*)\rightarrow(U,\leqslant)$ with $g|_A=\mathrm{id}_A$. Now put $c=g(z)$ to obtain the claim.

For (ii), choose a finite antichain $A\subseteq U$ and $u\in U\backslash A$ with $A\subseteq\mathrm{past}_U(y)$. Put $A'=\mathrm{past}_U(y)$, choose an element $z\notin A'$, and put $B=A'\cup\{z\}$. Define a partial order $\leqslant^*$ on B such that it extends the order $\leqslant$ on A, such that each $x\in\mathrm{past}_U(A)$ satisfies $x\leqslant^* z$, but each $x\in A'\backslash\mathrm{past}_U(A)$ is incomparable to z in $(B,\leqslant^*)$. Then $(A',\leqslant)\lhd(B,\leqslant^*)$, a one-point extension of the finite stem A' of U. Again, there is a stem-embedding $g:(B,\leqslant^*)\rightarrow(U,\leqslant)$ with $g|_{A'}=\mathrm{id}_{A'}$. Then $x=g(z)$ satisfies $x\notin A'$ and $x\|y$, and by $g(B)\lhd U$ we obtain

$$\begin{aligned}\mathrm{past}_U(x)&=\mathrm{past}_{g(B)}(x)=g(\mathrm{past}_B(z))=g(\mathrm{past}_B(A)\cup\{z\})\\&=\mathrm{past}_{g(B)}(A)\cup\{x\}=\mathrm{past}_U(A)\cup\{x\},\end{aligned}\tag{1}$$

as required.

(2)$\rightarrow$(1): We first show that no element of $(U,\leqslant)$ is maximal. Let $y\in U$. Applying assumption (ii) to the empty antichain, we obtain $x\in U$ with $x\|y$. Now by (i) there is $z\in U$ with $x\leqslant z$ and $y\leqslant z$. Then $y<z$.

Now let $(A',\leqslant)$ and $(B,\leqslant')$ be finite posets such that $(A',\leqslant)\lhd(U,\leqslant),(A',\leqslant)\lhd(B,\leqslant')$, and $B=A'\cup\{z\}$, say. Let A comprise all elements $a\in A'$ maximal with respect to $a<'z$ in $(B,\leqslant')$. So, A is an antichain and $\mathrm{past}_B(z)=\mathrm{past}_B(A)\cup\{z\}$. Since $(U,\leqslant)$ is directed and A' is finite, there exists $y\in U$ with $a\leqslant y$ for each $a\in A'$. Choose $y'\in U$ with $y<y'$; then $y'\notin A'$. Now by assumption (ii), there is $x\in U\backslash A$ such that in $(U,\leqslant)$ we have $x\|y'$ and $\mathrm{past}_U(x)=\mathrm{past}_U(A)\cup\{x\}$. Define $g:B\rightarrow U$ by $g|_{A'}=\mathrm{id}_{A'}$ and $g(z)=x$. By $x\|y'$, we obtain $x\notin A'$, and moreover, x is incomparable to each element of $A'\backslash\mathrm{past}_U(A)$. Hence g is an embedding, and we show that $g(B)\lhd U$. We have $A'\lhd U$, and so $\mathrm{past}_U(x)=\mathrm{past}_U(A)\cup\{x\}\subseteq A'\cup\{x\}=g(B)$. Thus g is a stem-embedding. □

Next we wish to use Theorem 2.2 (a) and Proposition 2.6 to give a direct construction (avoiding Theorem 2.2 (b)) of the universal homogeneous past-finite causal set $(U,\leqslant)$.

Construction 2.7 (of the universal homogeneous past-finite causal set $(U,\leqslant)$): We construct a sequence of finite posets $(A_1,\leqslant_1)\lhd(A_2,\leqslant_2)\lhd\ldots$ as follows. Let $(A_1,\leqslant_1)$ be any singleton set, with the trivial order. Now let $i\in\mathbb{N}$ and assume we have constructed a finite poset $(A_i,\leqslant_i)$. Let $\mathcal{A}$ comprise all antichains in $(A_i,\leqslant_i)$, and choose pairwise different elements $x_A(A\in\mathcal{A})$ not belonging to A_i. Then put $A_{i+1}=A_i\cup\{x_A|A\in\mathcal{A}\}$, and define a partial order $\leqslant_{i+1}$ on A_{i+1} such that it extends $\leqslant_i$ and for any $z\in A_{i+1}$, if $z\in\mathrm{past}_{A_i}(A)\cup\{x_A\}$ then $z\leqslant_{i+1}x_A$, but if $z\notin\mathrm{past}_{A_i}(A)\cup\{x_A\}$ then z and x_A are incomparable in $(A_{i+1},\leqslant_{i+1})$. Hence each element $x_A(A\in\mathcal{A})$ is maximal in $(A_{i+1},\leqslant_{i+1})$, and thus $(A_i,\leqslant_i)\lhd(A_{i+1},\leqslant_{i+1})$. Finally, let $(U,\leqslant)=\cup_{i\in\mathbb{N}}(A_{i+1},\leqslant_{i+1})$. Clearly, $(A_i,\leqslant_i)\lhd(U,\leqslant)$ for each $i\in\mathbb{N}$, and $(U,\leqslant)$ is a countable past-finite causal set.

Claim: $(U,\leqslant)$ is universal and homogeneous.

Proof: We show that $(U,\leqslant)$ satisfies condition (2) of Proposition 2.6; then this proposition and Theorem 2.1 (a) imply the result. For condition (2)(i), let $a,b\in U$ with $a\|b$. Then $A=\{a,b\}\subseteq A_i$ for some $i\in\mathbb{N}$, and $x_A\in A_{i+1}$ satisfies $a\leqslant x_A$ and $b\leqslant x_A$. For condition (2)(ii), let $A\subset U$ be a finite antichain and $y\in U\backslash A$ with $A\subseteq\mathrm{past}_U(y)$. Again, $A\cup\{y\}\subseteq A_i$ for some $i\in\mathbb{N}$. Then $x_A\in A_{i+1}$ and by $A_{i+1}\lhd U$ and construction of $\leqslant_{i+1}$ we obtain

$$\mathrm{past}_U(x_A) = \mathrm{past}_{A_{i+1}}(x_A) = \mathrm{past}_{A_{i+1}}(A) \cup \{x_A\} = \mathrm{past}_U(A) \cup \{x_A\}.$$

Furthermore, since $y \notin \mathrm{past}_{A_{i+1}}(A)$, we get $x_A \| y$ in $(A_{i+1}, \leqslant_{i+1})$ and in $(U, \leqslant)$, as required. Our claim follows. □

This argument is more direct and intuitive than the previous one using Theorem 2.2 (b) with its proof. However, Theorem 2.2 puts the result into a general context, and checking the amalgamation property required for condition (2) of Theorem 2.2 (b) was also uncomplicated.

Next we mention two further structural properties of the universal homogeneous past-finite causet $(U, \leqslant)$.

Corollary 2.8: Let $(U, \leqslant)$ *be the universal homogeneous countable past-finite causet.*

(a) *For any finite subset* $F \subseteq U$, $(U, \leqslant)$ *is isomorphic to the poset* $(U \backslash F, \leqslant)$. *In particular,* $(U, \leqslant) \cong (U \backslash \mathrm{past}(z), \leqslant)$ *for each* $z \in U$.

(b) *For each* $z \in U$, $(U, \leqslant)$ *is isomorphic to* $(\{u \in U | z < u\}, \leqslant)$, *the proper future of* z.

Proof: (a) We may assume that $F \neq \emptyset$. Trivially, $(U \backslash F, \leqslant)$ is a countable past-finite causet. We wish to check that $(U \backslash F, \leqslant)$ satisfies condition (2) of Proposition 2.6; then the result is immediate by Proposition 2.6 and Theorem 2.1. Since $(U, \leqslant)$ is directed and contains no maximal element, $(U \backslash F, \leqslant)$ is directed. So, let $A \subseteq U \backslash F$ be a finite antichain and $y \in (U \backslash F) \backslash A$ with $A \subseteq \mathrm{past}_{U \backslash F}(y)$. Again, since $(U, \leqslant)$ is directed and contains no maximal element, there is $y' \in U \backslash F$ with $F \cup \{y\} \subseteq \mathrm{past}_U(y')$. By Proposition 2.6, for $(U, \leqslant)$, there is $x \in U \backslash A$ such that $x \| y'$ and $\mathrm{past}_U(x) = \mathrm{past}_U(A) \cup \{z\}$. Then $x \notin F$ and neither $x \leqslant y$ nor $y \leqslant x$, and clearly $\mathrm{past}_{U \backslash F}(x) = \mathrm{past}_{U \backslash F}(A) \cup \{x\}$, as required for condition (ii). The final claim is immediate, since past(z) is finite for each $z \in U$.

(b) Let $z \in U$ and $U' = \{u \in U | z < u\}$. Again we show that $(U', \leqslant)$ satisfies condition (2) of Proposition 2.6. If the antichain A chosen is empty, replace it by $\{z\}$. Then, and also in case A is nonempty, apply condition (ii) for $(U, \leqslant)$ to obtain the element $x \in U'$ as required. □

Finally, we wish to show that the restriction to *past-finite* causets in Theorem 2.1 is essential:

Proposition 2.9: The class of all countable causets does not *contain a universal causet.*

Proof: We will exploit that this class also contains posets which are not past-finite. Suppose there was a countable causet $(U, \leqslant)$ such that each countable causet can be stem-embedded into $(U, \leqslant)$. Let $-\mathbb{N}$ denote the set of negative integers. We denote the natural partial order on $-\mathbb{N}$ by $\leqslant$, so $n-1 < n$ for each $n \in -\mathbb{N}$. For each subset $A \subseteq -\mathbb{N}$ let $(S_A, \leqslant)$ be the causet obtained from $(-\mathbb{N}, \leqslant)$ by replacing each element $n \in A$ by a 2-element antichain $\{n, n^*\}$. That is, $S_A = -\mathbb{N} \cup \{n^* | n \in A\}$, n and n^* are incomparable for each $n \in A$, and $m < n^*$ iff $m < n$ iff $m < n$ $(m \in -\mathbb{N}, n \in A)$, likewise for $m^* < n^*$, respectively, $m^* < n$. By assumption, there is a stem-embedding $f_A : (S_A, \leqslant) \to (U, \leqslant)$. Let $x_A = f_A(-1)$. Then $f_A(S_A)$ is a stem of U, and $f_A(S_A) = \mathrm{past}(x_A)$.

As is easily seen, for $A, A' \subseteq -\mathbb{N}$ we have $(S_A, \leqslant) \cong (S_{A'}, \leqslant)$ iff $A = A'$. Hence there are uncountably many nonisomorphic causets of the form $(S_A, \leqslant)$; these are isomorphic to the posets $(\mathrm{past}(x_A), \leqslant)$. But U is countable and contains only countably many posets of the form $\mathrm{past}(x)(x \in U)$, a contradiction. □

III. PROBABILISTIC CONSTRUCTIONS

In this section, we wish to provide probabilistic constructions of the universal homogeneous causal set $(U, \leqslant)$ of Sec. II. Probabilistic constructions of causal sets were already investigated in Refs. 10 and 15. This employed successive one-point extensions ("generalized percolations") of finite posets; such extensions will also be used here. Suppose we are given a finite poset $(A, \leqslant)$

and want to extend it to a poset $(B,\leqslant)$ such that $B=A\cup\{z\}$, say, and $(A,\leqslant)$ is a stem in $(B,\leqslant)$. Then we just have to define the order relations between z and the elements of A; moreover, since A should become a stem of B, z has to become a maximal element of $(B,\leqslant)$, thus for each $a\in A$ we can only put $a<z$ or $a\|z$, and this can be decided probabilistically. Let us now give the details of this construction for our case. We will discuss a technical difference to Refs. 10 and 15 afterwards. For sake of concreteness, we will take the underlying set of our causet to be $\mathbb{N}$ (as in Ref. 15, but the construction would work for any countably enumerated set). Hence we will construct a partial order $\leqslant$ on $\mathbb{N}$. Recall that we write $x<y$ if $x\leqslant y$ and $x\neq y$. We denote the natural order on $\mathbb{N}$ by $\leqslant$, i.e., $n\prec n+1$ for each $n\in\mathbb{N}$. Our basic construction will depend on a parameter $p\in[0,1]$.

Construction 3.1 (Probabilistic one-point extension of an enumerated finite poset): Let $p\in[0,1]$. Let $(A,\leqslant)$ be a finite poset with $A=\{1,\ldots,n\}$ for some $n\geqslant 1$, and let $B=A\cup\{n+1\}$. Furthermore, letting $A_j=\{1,\ldots,j\}$ for $1\leqslant j\leqslant n$, assume that $A_1\lhd\ldots\lhd A_n=A$. As noted before, we wish to extend the order $\leqslant$ to a partial order $\leqslant'$ on B such that $(A,\leqslant)$ is a stem of $(B,\leqslant')$. We proceed as follows. First choose, with equal probability, some $j\in\{1,\ldots,n\}$. If j was chosen, this means that we will restrict ourselves to having $\mathrm{past}_B(n+1)\subseteq A_j\cup\{n+1\}$. We define a binary relation R in $\{1,\ldots,n\}\times\{n+1\}$ as follows. Decide independently for each $i\in\{1,\ldots,j\}$ with probability p that $(i,n+1)\in R$, and with probability $1-p$ that $(i,n+1)\notin R$. Now let $\leqslant'$ on B be the reflexive transitive closure of the relation $\leqslant\cup R$. That is, we have $n+1\leqslant' n+1$, for $x,y\in A$ we have $x\leqslant' y$ iff $x\leqslant y$, and for any $x\in A$ we have $x\leqslant' n+1$ iff there is $i\in\{1,\ldots,j\}$ such that $x\leqslant i$ and $(i,n+1)\in R$; in this case $x\in A_j$ by $A_j\lhd A$. Clearly, $(B,\leqslant')$ is a partial order, $n+1$ is maximal in $(B,\leqslant')$, $\mathrm{past}_B(n+1)\subseteq A_j\cup\{n+1\}$, and $(A,\leqslant)\lhd(B,\leqslant')$.

Next we wish to construct our random past-finite countable causal set structure on $\mathbb{N}$.

Construction 3.2 (of a probabilistic order $\leqslant$ on $\mathbb{N}$): Let $p\in[0,1]$. Let $A_n=\{1,2,\ldots,n\}$ $(n\in\mathbb{N})$. For $n=1$, put $1\leqslant 1$. Now use Construction 3.1 to successively extend the order $\leqslant$ from A_n to A_{n+1}. We obtain a sequence of stems $A_1\lhd A_2\lhd\ldots\lhd A_n\lhd\ldots$, and we put $(\mathbb{N},\leqslant)=\cup_{n\in N}(A_n,\leqslant)$. Then each A_n is a stem of $(\mathbb{N},\leqslant)$ and $(\mathbb{N},\leqslant)$ is a past-finite causal set.

Next we will show:

Theorem 3.3: Let $p\in(0,1)$. *With probability 1, the above construction produces a partial order $\leqslant$ on $\mathbb{N}$ such that $(\mathbb{N},\leqslant)$ is a stem-universal homogeneous past-finite causal set.*

Proof: As noted before, $(\mathbb{N},\leqslant)$ is a past-finite causal set. By Theorem 2.1 (a), it suffices to show that with probability 1, $(\mathbb{N},\leqslant)$ realizes all one-point stem-extensions of finite stems of $(\mathbb{N},\leqslant)$. There are countably many such stem-extensions. Since the intersection of countably many events of probability 1 again has probability 1, it suffices to consider an arbitrary fixed one-point stem-extension $A\lhd(B,\leqslant')$ with $B=A\cup\{y\}$, A finite and $A\lhd(\mathbb{N},\leqslant)$. We claim that with probability 1 there exists $z\in\mathbb{N}$ such that the mapping $g:B\to\mathbb{N}$ with $g|_A=\mathrm{id}_A$ and $g(y)=z$ is a stem-embedding, i.e., for each $a\in A$ we have $a\leqslant' y$ in B iff $a\leqslant z$ in $\mathbb{N}$ and $A\cup\{z\}\lhd(\mathbb{N},\leqslant)$.

For each $j\in\mathbb{N}$ let $A_j=\{1,2,\ldots,j\}$. Since A is finite, there is $m\in\mathbb{N}$ such that $A\subseteq A_m$. Then $A\lhd A_m$. Now choose any integer $n\geqslant m$ and consider the extension of the order $\leqslant$ from A_n to A_{n+1} given by Construction 3.1. We wish to compute a lower bound for the probability that we can put $z=n+1$ to obtain the required stem $A\cup\{z\}\lhd(\mathbb{N},\leqslant)$. First, the probability that we choose the number m from $\{1,\ldots,n\}$ is $1/n$. Then by Construction 3.1 for each $i\in A$, if $i<' y$ in $(B,\leqslant')$ we put $(i,n+1)\in R$ with probability p, and if $i\|' y$ we put $(i,n+1)\notin R$ with probability $1-p$; further with probability $1-p$ we put $(i,n+1)\notin R$ for each $i\in A_m\backslash A$. Hence, given m, there is a (small but) fixed $r>0$, depending only on the structure of $(A_m,\leqslant)$, on $A\lhd B$ and on y (but not on n), such that at least with probability r all $i\in A_m$ satisfy the above conditions, so $A\cup\{n+1\}\lhd A_m\cup\{n+1\}\lhd A_{n+1}$ and $n+1$ realizes the one-point stem extension of A as required.

Thus the probability that in $(A_{n+1},\leqslant)$, the structure of $(A_m\cup\{n+1\},\leqslant)$ is as required is at least $r\cdot 1/n$. Hence the probability that $n+1$ and $(A_m\cup\{n+1\},\leqslant)$ do not satisfy these conditions is at most $1-r/n$. Consequently, the probability that for *no* integer $n\geqslant m,n+1$ and

$(A_m \cup \{n+1\})$ realize this one-point extension of A is $\Pi_{n=m}^{\infty}(1-r/n)$. Since the series $\Sigma_{n=m}^{\infty}(r/n)$ diverges, we obtain $\Pi_{n=m}^{\infty}(1-r/n)=0$. Hence with probability 1, this one-point extension of A is realized inside $(\mathbb{N}, \leqslant)$ as required, and the result follows. □

We just note that the above "intuitive" probabilistic statements can easily be made exact by a precise (but technical) definition of the employed probability space; this can be done analogously to the case of the random graph, cf. Refs. 8 and 11, or to the procedure in Refs. 15, 5, and 4 for constructing the probability space of completed labeled causets: The sample space of this probability space is the collection of all past-finite causets $(\mathbb{N}, \leqslant)$ (hence the underlying set, $\mathbb{N}$, is fixed, but the order $\leqslant$ can vary), and Construction 3.1 yields a corresponding probability measure. Theorem 3.3 can then be rephrased by saying that in this probability space the collection of all causets which are universal and homogeneous has measure 1.

The above construction would work also for other probability distributions on $\{1, \ldots, n\}$, in Construction 3.1, than the uniform one. However, they would have to be chosen with some care in order to ensure the final argument in the proof of Theorem 3.3.

Our construction of $(U, \leqslant)$ uses and depends on the given enumeration of $\mathbb{N}$, respectively, in Construction 3.1, of the poset $A=\{1, \ldots, n\}$, and not only on the structure of the poset $(A, \leqslant)$: After choosing $j \in \{1, \ldots, n\}$, we decided to possibly put $(i, n+1) \in R$ only for elements $i \in \{1, \ldots, j\}$. This is a bit unfortunate, since, in the notions of Ref. 15, it would correspond to some externally given time. Apart from this, our construction is very similar to the ones proposed in Refs. 10 and 15. It even shares with it a property of the "gregarious child transition," cf. Ref. 15, Lemma 2:

Remark 3.4: Let $p \in [0,1]$, let $(A, \leqslant)$ be a finite poset with $A=\{1, \ldots, n\}$, and let $B=A \cup \{n+1\}$. The probability to obtain by Construction 3.1 the poset $(B, \leqslant)$ with $(A, \leqslant) \lhd (B, \leqslant)$ and $n+1 \| a$ for each $a \in A$ depends only on the cardinality of A.

Proof: Given $j \in \{1, \ldots, n\}$, for each $i \in \{1, \ldots, j\}$ we have to put $(i, n+1) \notin R$. The probability of this equals $1/n \cdot \Sigma_{j=1}^{n}(1-p)^j$. □

Furthermore, our construction apparently satisfies a weak form of the Bell causality condition, but not the condition of discrete general covariance of Refs. 10 and 15. It would be interesting to investigate this further. Also, this raises the question whether the universal homogeneous past-finite causet $(U, \leqslant)$ can be constructed without referring as in Construction 3.1 to a given enumeration, with positive probability, say. This would require a more intricate analysis of the probabilities of the finite posets occurring.

Finally, we wish to present also a number-theoretic representation of the universal homogeneous past-finite causet $(U, \leqslant)$. As underlying set, we take again the natural numbers $\mathbb{N}$.

Construction 3.5 (of a partial order $\leqslant$ on $\mathbb{N}$): We define a binary relation R on $\mathbb{N}$ as follows. For any $j, n \in N$, put $(j, n) \in R$ iff $j \prec n$ and in the unique ternary expansion of n as a sum of distinct powers of 3, 3^j occurs with coefficient 1. That is, $(j, n) \in R$ iff

$$n = 3^j + \sum_{\substack{0 \leqslant i \leqslant n \\ i \neq j}} x_i \cdot 3^i$$

for some $x_i \in \{0, 1, 2\}$. Then let $\leqslant$ be the transitive reflexive closure of R.

Since $(j, n) \in R$ implies $j \prec n$, clearly $(N, \leqslant)$ is a past-finite causal set, for $A_n=\{1, \ldots, n\}$ we have $A_n \lhd \mathbb{N}$, and n is a maximal element of $(A_n, \leqslant)$. We show:

Theorem 3.6: *The poset $(N, \leqslant)$ constructed above is a stem-universal homogeneous past-finite causal set.*

Proof: By Theorem 2.1 (a), it suffices to show that $(N, \leqslant)$ realizes all one-point extensions.

So let $(A,\leqslant)\lhd(\mathbb{N},\leqslant)$, with A finite, $(A,\leqslant)\lhd(B,\leqslant')$ and $B=A\cup\{y\}$, say, with $y\notin A$. We claim that there exists $z\in\mathbb{N}$ such that the mapping $g:B\to\mathbb{N}$ with $g|_A=\mathrm{id}_A$ and $g(y)=z$ is a stem-embedding. Choose $m\in\mathbb{N}$ such that $A\subseteq A_m$. Put

$$z=\sum_{\substack{a\in A\\ a<'y}} 3^a+2\cdot 3^m.$$

Then $z\notin A$ and z is maximal in $(A\cup\{z\},\leqslant)$. The construction of $\leqslant$ shows that if $a\in A$ with $a<'y$, then $(a,z)\in R$, so $a<z$. Conversely, let $a\in\mathbb{N}$ and $a<z$. Since $\leqslant$ is the transitive reflexive closure of R, there is $a'\in\mathbb{N}$ such that $a\leqslant a'$ and $(a',z)\in R$. By definition of R and of z, we immediately get $a'\in A$ and $a'<'y$. Since $A\lhd\mathbb{N}$, we obtain $a\in A$ and $a<'y$. It follows that g, defined as above, is an order-embedding of $(B,\leqslant')$ into $(\mathbb{N},\leqslant)$ and that $g(B)$ is a stem of $\mathbb{N}$, as required. □

IV. DISCUSSION

We studied the class of all countable causal sets. In algebra, many classes of structures have been investigated with respect to the existence of universal or homogeneous objects. Most often, this completely depends on the given class of structures. Here, we could show that the class of all countable past-finite causets, in contrast to the class of all causets, contains a universal object. Somehow surprisingly, a random (intuitively: "chaotic") construction produces, in the end, almost surely a universal causet bearing maximal degree of symmetry.

A basic idea behind causal set theory is that a manifold M may emerge from a causal set $(S,\leqslant)$ by some sprinkling of a coarse-grained version of $(S,\leqslant)$ densely into M (cf. Ref. 16). Then it would be interesting to see how symmetry properties of $(S,\leqslant)$ are reflected in the structure of M. It is tempting to recall, in this context, Noether's close correspondence between symmetries and conservation laws. A bold question: Can conservation laws be founded on symmetry properties of causal sets and, ultimately, traced to some random constructions of causal sets?

In the jet-bundle description of time-dependent mechanics there are some elements, such as the Lagrangian energy and the construction of the Hamiltonian formalism, which require the prior choice of a connection. This situation is analyzed by Echeverría-Enríquez *et al.* [J. Phys. A **28**, 5553–5567 (1995)]. The aim of this paper is to extend the results in that paper to first order field theory, using the *k*-cosymplectic formalism described by de León and co-workers [J. Math. Phys. **39**, 876–893 (1998); **42**, 2092–2104 (2001)]. If the trivial configuration bundle of a Lagrangian system is endowed with one connection, different from the trivial one given by the product structure, we study the consequences on the geometric elements of the theory, the dynamical equations and the variational principles. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2146191]

I. INTRODUCTION

There are several ways to state first order classical field theories in a geometrical setting. All of them are a generalization of time-dependent mechanics in its different formulations, see Ref. 1 for a detailed account of these formulations. These formulations come from contact formulation, that is from symplectic or presymplectic approaches.

In the jet bundle description of time depending mechanics, one begins with the configuration bundle over $\mathbb{R}$, that is a trivial bundle $\pi:\mathbb{R}\times Q\to\mathbb{R}$, being $\mathbb{R}$ the "time." In the case of field theory, the most similar to this description is the *k*-cosymplectic formulation. Here, the base manifold of mechanics is changed by $\mathbb{R}^k$, described as "several times," and the configuration bundle is a trivial one, $\pi:\mathbb{R}^k\times Q\to\mathbb{R}^k$. See Refs. 2 and 3 for details.

The consideration of a trivial bundle hides the use of a connection in several parts of the theory: there is a natural one given by the product structure. It is natural to ask about the changes needed in the development of the theory if one takes another connection. In the case of mechanical systems, these changes are analyzed in Ref. 4.

In this paper we try to give insight into the consequences of taking another different connection in the configuration bundle to build the *k*-cosymplectic approach to classical field theory. On the one hand, the Lagrangian energy, and hence the Hamiltonian, are connection depending. But the dynamical equations are the same for different connections.

[b)]Electronic mail: modesto@zmat.usc.es
[c)]Electronic mail: svfernan@usc.es

On the other hand, it is usual to find the theory on a variational principle, both in Lagrangian and Hamiltonian settings, and we study what are the changes to be introduced in these principles in order to get the dynamical equations.

The structure of the work is as follows.

Sections II and III are devoted to the elements of the theory. In particular, in Sec. II, we review the k-cosymplectic formalism in field theory introduced in Refs. 2 and 3. The relationship between these formalisms and the multisymplectic formalism has been studied in Ref. 5 and it will be commented at the end of this section.

In Sec. III, we introduce first the basic ideas about connections in the configuration bundle $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$ and the definition and properties of the Lagrangian energy function, E_L^∇, associated with a Lagrangian L and a connection ∇. Under some assumptions, we obtain that E_L^∇ is constant along the solutions of the classical Euler-Lagrange equations. Some of the results obtained have as a particular case the results of Ref. 4.

Sections IV and V are devoted to the analysis of the deformed dynamical equations and solutions, both in Hamiltonian and Lagrangian settings. In Sec. IV, we construct the Hamiltonian formalism depending on the choice of an arbitrary connection ∇, and we show that if the curvature of the connection vanishes then the Hamilton equations of the modified Hamiltonian and classical Hamiltonian equations have the same solutions. In Sec. V we begin by constructing the vertical endomorphisms associated to a connection, which enables us to the construction of the Lagrangian formalism depending on the connection ∇. If the Lagrangian L is regular, we obtain again that if the curvature of ∇ vanishes then the Lagrangian equations of the modified Lagrangian and classical Lagrangian equations have the same solutions.

In Sec. VI, by means of other new geometrical elements in $\mathbb{R}^k\times Q$, we establish a characterization of the Lagrangian energy function based on variational principles. We conclude that the energy function E_L^∇ is the only function that performs the equivalence between the Hamiltonian principle of minimal action and the Hamilton-Jacobi principle. Section V in Ref. 4 is a particular case of this section.

Manifolds are real, paracompact, connected and C^∞. Maps are C^∞. Sum over crossed repeated indices is understood.

II. THE *k*-COSYMPLECTIC FORMALISMS IN FIELD THEORY

The concepts and results of this section are given in Refs. 2 and 3.

A. The Hamiltonian approach (Ref. 2)

1. The geometric elements

Let Q be a differentiable manifold, $\dim Q=n$, and $\tau_Q^*:T^*Q\to Q$ its cotangent bundle.

Denote by $(T^1_k)^*Q=T^*Q\overset{k}{\oplus}\dots\oplus T^*Q$, the Whitney sum of k copies of T^*Q. The manifold $(T^1_k)^*Q$ can be identified with the manifold $J^1(Q,\mathbb{R}^k)_0$ of 1-jets of mappings from Q to $\mathbb{R}^k$ with target at $0\in\mathbb{R}^k$, that is

$$J^1(Q,\mathbb{R}^k)_0\equiv T^*Q\overset{k}{\oplus}\dots\oplus T^*Q,$$

$$j^1_{q,0}\sigma\equiv(d\sigma^1(q),\dots,d\sigma^k(q)),$$

where $\sigma^A=\pi^A\circ\sigma:Q\to\mathbb{R}$ is the Ath component of σ, and $\pi^A:\mathbb{R}^k\to\mathbb{R}$ is the canonical projection onto the A component, for $1\leqslant A\leqslant k$. $(T^1_k)^*Q$ is called *the bundle of k^1-covelocities of the manifold Q*, see Ref. 6.

The manifold $J^1\pi_Q$ of 1-jets of sections of the trivial bundle $\pi_Q:\mathbb{R}^k\times Q\to Q$ is diffeomorphic to $\mathbb{R}^k\times(T^1_k)^*Q$, via the diffeomorphism given by

$$J^1\pi_Q\to\mathbb{R}^k\times(T^1_k)^*Q,$$

$$j^1_q\phi=j^1_q(\phi_Q,Id_Q)\mapsto(\phi_Q(q),\alpha^1_q,\ldots,\alpha^k_q),$$

where $\phi_Q:Q\overset{\phi}{\to}\mathbb{R}^k\times Q\overset{\pi_{\mathbb{R}^k}}{\to}\mathbb{R}^k$, $\alpha^A_q=d(\phi_Q)^A(q)$, $1\leqslant A\leqslant k$ and $(\phi_Q)^A:Q\overset{\phi_Q}{\to}\mathbb{R}^k\overset{\pi^A}{\to}\mathbb{R}$ is the Ath component of ϕ_Q.

Throughout the paper we shall use the following notation for the canonical projections:

$$\mathbb{R}^k\times(T^1_k)^*Q\xrightarrow{(\pi_Q)_{1,0}}\mathbb{R}^k\times Q\xrightarrow{(\pi_Q)}Q$$

and $(\pi_Q)_1=\pi_Q\circ(\pi_Q)_{1,0}$, where

$$\pi_Q(t,q)=q,\quad(\pi_Q)_{1,0}(t,\alpha^1_q,\ldots,\alpha^k_q)=(t,q),\quad(\pi_Q)_1(t,\alpha^1_q,\ldots,\alpha^k_q)=q,$$

with $t\in\mathbb{R}^k$, $q\in Q$ and $(\alpha^1_q,\ldots,\alpha^k_q)\in(T^1_k)^*Q$.

If (q^i) are local coordinates on $U\subseteq Q$, then the induced local coordinates (q^i,p_i), $1\leqslant i\leqslant n$, on $(\tau^*_Q)^{-1}(U)=T^*U\subset T^*Q$, are given by

$$q^i(\alpha_q)=q^i(q),\quad p_i(\alpha_q)=\alpha_q\left(\left.\frac{\partial}{\partial q^i}\right|_q\right),\tag{1}$$

and, in the same way, the induced local coordinates (t^A,q^i,p^A_i) on $[(\pi_Q)_1]^{-1}(U)=\mathbb{R}^k\times(T^1_k)^*U$ are given by

$$t^A(j^1_q\phi)=(\phi_Q(q))^A,\quad q^i(j^1_q\phi)=q^i(q),\quad p^A_i(j^1_q\phi)=d(\phi_Q)^A(q)\left(\left.\frac{\partial}{\partial q^i}\right|_q\right),$$

or equivalently

$$t^A(t,\alpha^1_q,\ldots,\alpha^k_q)=t^A,\quad q^i(t,\alpha^1_q,\ldots,\alpha^k_q)=q^i(q),\quad p^i_A(t,\alpha^1_q,\ldots,\alpha^k_q)=\alpha^A_q\left(\left.\frac{\partial}{\partial q^i}\right|_q\right),$$

where $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$.

On $\mathbb{R}^k\times(T^1_k)^*Q$, we define the differential forms

$$\eta^A_0=(\pi^A_1)^*\,\mathrm{d}t^A,\quad\theta^A_0=(\pi^A_2)^*\theta_0,\quad\omega^A_0=(\pi^A_2)^*\omega_0,\quad 1\leqslant A\leqslant k,\tag{2}$$

where $\pi^A_1:\mathbb{R}^k\times(T^1_k)^*Q\to\mathbb{R}$ and $\pi^A_2:\mathbb{R}^k\times(T^1_k)^*Q\to T^*Q$ are the projections defined by

$$\pi^A_1(t,(\alpha^1_q,\ldots,\alpha^k_q))=t^A,\quad\pi^A_2(t,(\alpha^1_q,\ldots,\alpha^k_q))=\alpha^A_q,\quad 1\leqslant A\leqslant k,$$

and $\omega_0=-\mathrm{d}\theta_0=\mathrm{d}q^i\wedge\mathrm{d}p_i$ is the canonical symplectic form on T^*Q and $\theta_0=p_i\,\mathrm{d}q^i$ is the Liouville 1-form on T^*Q. Obviously $\omega^A_0=-\mathrm{d}\theta^A_0$.

In local coordinates we have

$$\eta^A_0=\mathrm{d}t^A,\quad\theta^A_0=\sum_{i=1}^n p^A_i\mathrm{d}q^i,\quad\omega^A_0=\sum_{i=1}^n\mathrm{d}q^i\wedge\mathrm{d}p^A_i,\quad 1\leqslant A\leqslant k.\tag{3}$$

Moreover, let $V_0=\ker T(\pi_Q)_{1,0}$. Then

$$V=\left\langle \frac{\partial}{\partial p_i^1},\ldots,\frac{\partial}{\partial p_i^k}\right\rangle_{i=1,\ldots,n}.$$

A simple inspection of their expressions in local coordinates shows that the forms η_0^A and ω_0^A are closed and the following relation hold:

(1) $\eta_0^1\wedge\cdots\wedge\eta_0^k\neq 0$, $(\eta_0^A)_{|V}=0$ $(\omega_0^A)_{|V\times V}=0$,
(2) $(\cap_{A=1}^k \ker \eta_0^A)\cap(\cap_{A=1}^k \ker \omega_0^A))=\{0\}$, $\dim(\cap_{A=1}^k \ker \omega_0^A)=k$.

Remark: From the above geometrical model, the following definition is introduced in Ref. 2.

Definition 2.1: Let M be a differentiable manifold of dimension $k(n+1)+n$. A family $(\eta_A,\omega_A,V;1\leqslant A\leqslant k)$, where each η_A is a 1-form, each ω_A is a 2-form and V is an nk-dimensional distribution on M, such that

(1) $\eta_1\wedge\cdots\wedge\eta_k\neq 0$, $\eta_{A_{|V}}=0$, $\omega_{A_{|V\times V}}=0$,
(2) $(\cap_{A=1}^k \ker \eta_A)\cap(\cap_{A=1}^k \ker \omega_A)=\{0\}$, $\dim(\cap_{A=1}^k \ker \omega_A)=k$,

is called an almost k-cosymplectic structure, and the manifold M an almost k-cosymplectic manifold.

The following theorem has been proved in Ref. 2.

Theorem 2.2 (*Darboux theorem*)**:** *If the forms η_A and ω_A are closed and V is integrable then around each point of M there exist local coordinates $(t^A,q^i,p_i^A;1\leqslant A\leqslant k,1\leqslant i\leqslant n)$ such that*

$$\eta_A=\mathrm{d}t^A,\quad \omega_A=\mathrm{d}q^i\wedge\mathrm{d}p_i^A,\quad V=\left\langle \frac{\partial}{\partial p_i^1},\ldots,\frac{\partial}{\partial p_i^k}\right\rangle_{i=1,\ldots,n}.$$

In this case M will be called a k-cosymplectic manifold.

The canonical model of these geometrical structures is $(\mathbb{R}^k\times(T_k^1)^*Q,\eta_0^A,\omega_0^A,V_0)$.

For any k-cosymplectic structure (η_A,ω_A,V) on M, there exists a family of k vector fields $\{R_A,1\leqslant A\leqslant k\}$ characterized by the following conditions:

$$\iota_{R_A}\eta_B=\delta_{AB},\quad \iota_{R_A}\omega_B=0,\quad 1\leqslant A,B\leqslant k. \tag{4}$$

They are called the *Reeb vector fields* associated to the k-cosymplectic structure. In the canonical model $R_A=\partial/\partial t^A$, $1\leqslant A\leqslant k$.

2. k-vector fields and integral sections

Let M be an arbitrary manifold, T_k^1M the Whitney sum $TM\overset{k}{\oplus}\ldots\oplus TM$ of k copies of TM and $\tau:T_k^1M\to M$ its canonical projection. $\tau:T_k^1M\to M$ is usually called the tangent bundle of k^1 velocities of M, the reason for this name will be explained in Sec. II B 1.

*Definition 2.3: A section $\mathbf{X}:M\to T_k^1M$ of the projection τ will be called a k-*vector field *on M.*

Since T_k^1M is the Whitney sum $TM\overset{k}{\oplus}\ldots\oplus TM$ of k copies of TM, we deduce that to give a k-vector field $\mathbf{X}$ is equivalent to giving a family of k vector fields $X_1,\ldots,X_k$ on M by projecting $\mathbf{X}$ onto every factor. For this reason we will denote a k-vector field by $(X_1,\ldots,X_k)$.

Definition 2.4: An integral section of the k-vector field $(X_1,\ldots,X_k)$ passing through a point $x\in M$ is a map $\phi:U_0\subset\mathbb{R}^k\to M$, defined on some neighborhood U_0 of $0\in\mathbb{R}^k$, such that

$$\phi(0)=x,\quad \phi_*(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right)=X_A(\phi(t))\quad \text{for all } t\in U_0,\ 1\leqslant A\leqslant k. \tag{5}$$

We say that a k-vector field $(X_1,\ldots,X_k)$ on M is integrable if there is an integral section passing through each point of M.

In the k-cosymplectic formalism, the solutions of the field equations are described as integral sections of some k-vector fields. Observe that, in case $k=1$, this definition coincides with the definition of integral curve of a vector field.

3. Hamiltonian formalism

Let (M,η_A,ω_A,V) be a k-cosymplectic manifold, $H:M\to\mathbb{R}$ a Hamiltonian function. Let $\mathbf{X}=(X_1,\ldots,X_k)$ be a k-vector field solution to the following equations:

$$\eta_A(X_B)=\delta_{AB},\quad 1\leqslant A,B\leqslant k,$$

$$\sum_{A=1}^{k}\iota_{X_A}\omega_A=\mathrm{d}H-\sum_{A=1}^{k}R_A(H)\,\eta_A. \tag{6}$$

Using natural coordinates, given by Darboux theorem, if $\mathbf{X}=(X_1,\ldots,X_k)$ is an integrable k-vector field

$$X_A=(X_A)^B\frac{\partial}{\partial t^B}+(X_A)^i\frac{\partial}{\partial q^i}+(X_A)^B_i\frac{\partial}{\partial p^B_i}$$

then

$$(X_A)^B=\delta^B_A,\quad \frac{\partial H}{\partial p^A_i}=(X_A)^i,\quad \frac{\partial H}{\partial q^i}=-\sum_{A=1}^{k}(X_A)^A_i, \tag{7}$$

and if $\phi:\mathbb{R}^k\to M$, given by $\phi(t)=(\phi^A(t),\phi^i(t),\phi^A_i(t))$, is an integral section of $\mathbf{X}$, then

$$\frac{\partial\phi^A}{\partial t^B}=\delta^A_B,\quad \frac{\partial\phi^i}{\partial t^B}=(X_B)^i,\quad \frac{\partial\phi^A_i}{\partial t^B}=(X_B)^A_i.$$

Therefore, from (7) we obtain that $\phi(t)$ is solution to the Hamilton field equations

$$\frac{\partial H}{\partial q^i}=-\sum_{A=1}^{k}\frac{\partial\phi^A_i}{\partial t^A},\quad \frac{\partial H}{\partial p^A_i}=\frac{\partial\phi^i}{\partial t^A},$$

where $1\leqslant A\leqslant k$, $1\leqslant i\leqslant n$.

So, Eqs. (6) can be considered a *geometric version* of the Hamilton field equations.

Remark: It should be noticed that, in general, Eqs. (6) do not have a single solution. In fact, if (M,η_A,ω_A,V) is a k-cosymplectic manifold we can define the vector bundle morphism,

$$\Omega^\sharp:\quad T^1_kM\to T^*M$$

$$(X_1,\ldots,X_k)\mapsto\Omega^\sharp(X_1,\ldots,X_k)=\sum_{A=1}^{k}\iota_{X_A}\omega_A+\eta_A(X_A)\,\eta_A. \tag{8}$$

and, denoting by $\mathcal{M}_k(C^\infty(M))$ the space of matrices of order k whose entries are functions on M, the vector bundle morphism

$$\eta^\sharp:\quad T^1_kM\to\mathcal{M}_k(C^\infty(M))$$

$$(X_1,\ldots,X_k)\mapsto\eta^\sharp(X_1,\ldots,X_k)=(\eta_A(X_B)) \tag{9}$$

then the solutions of (6) are given by $(X_1,\ldots,X_k)+(\ker\Omega^\sharp\cap\ker\eta^\sharp)$, where $(X_1,\ldots,X_k)$ is a particular solution.

From the local conditions (7) we can define in a neighborhood of each point $x \in M$ a k-vector field that satisfies (6). For example, we can set

$$(X_A)^B = \delta_A^B, \quad (X_1)_i^1 = \frac{\partial H}{\partial q^i}, \quad (X_A)_i^B = 0 \quad \text{for } A \neq 1 \neq B, \quad (X_A)^i = \frac{\partial H}{\partial p_i^A}.$$

Now one can construct a global k-vector field, which is a solution of (6), by using a partition of unity in the manifold M. See Ref. 2.

B. The Lagrangian approach (Ref. 3)

1. The geometric elements

The manifold $\mathbb{R}^k \times T_k^1 Q$*:*

Let $\tau_Q : TQ \to Q$ be the tangent bundle of Q. Let us denote by $T_k^1 Q$ the Whitney sum $TQ \overset{k}{\oplus} \ldots \oplus TQ$ of k copies of TQ. Next we shall see that the manifold $\mathbb{R}^k \times T_k^1 Q$ is a cosymplectic manifold when a regular Lagrangian $L : \mathbb{R}^k \times T_k^1 Q \to \mathbb{R}$ is given.

$T_k^1 Q$ can be identified with the manifold $J_0^1(\mathbb{R}^k, Q)$ of the k^1 velocities of the manifold Q, that is, the manifold of 1-jets of maps $\sigma : \mathbb{R}^k \to Q$ with source at $0 \in \mathbb{R}^k$, say

$$J_0^1(\mathbb{R}^k, Q) \equiv TQ \overset{k}{\oplus} \ldots \oplus TQ,$$

$$j_{0,q}^1 \sigma \equiv (v_{1q}, \ldots, v_{kq}),$$

where $q = \sigma(0)$, and $v_{Aq} = \sigma_*(0)[(\partial/\partial t^A)(0)]$, $1 \leq A \leq k$. For this reason $T_k^1 Q$ is called the *tangent bundle of* k^1*-velocities of* Q, see Ref. 7.

The manifold $J^1 \pi_{\mathbb{R}^k}$ of 1-jets of sections of the trivial bundle $\pi_{\mathbb{R}^k} : \mathbb{R}^k \times Q \to \mathbb{R}^k$ is diffeomorphic to $\mathbb{R}^k \times T_k^1 Q$, via the diffeomorphism given by

$$J^1 \pi_{\mathbb{R}^k} \to \mathbb{R}^k \times T_k^1 Q,$$

$$j_t^1 \phi = j_t^1 (Id_{\mathbb{R}^k}, \phi_Q) \to (t, v_1, \ldots, v_k), \tag{10}$$

where $\phi_Q : \mathbb{R}^k \overset{\phi}{\to} \mathbb{R}^k \times Q \overset{\pi_Q}{\to} Q$, and

$$v_A = (\phi_Q)_*(t)\left(\left. \frac{\partial}{\partial t^A} \right|_t \right), \quad 1 \leq A \leq k.$$

Let us denote by $\rho : \mathbb{R}^k \times T_k^1 Q \to Q$ the canonical projection. If (q^i) are local coordinates on $U \subseteq Q$, then the induced local coordinates (q^i, v_i), $1 \leq i \leq n$, on $(\tau_Q)^{-1}(U) = TU \subset TQ$, are given by

$$q^i(v_q) = q^i(q), \quad v_i(v_q) = v_q(q^i) \tag{11}$$

and then the induced local coordinates (t^A, q^i, v_A^i) on $\rho^{-1}(U) = \mathbb{R}^k \times T_k^1 U$ are given by

$$t^A(j_t^1 \phi) = t^A, \quad q^i(j_t^1 \phi) = q^i(\phi_Q(t)), \quad v_A^i(j_t^1 \phi) = \frac{\partial (q^i \circ \phi_Q)}{\partial t^A}|_t$$

or equivalently

$$t^A(t, v_{1q}, \ldots, v_{kq}) = t^A, \quad q^i(t, v_{1q}, \ldots, v_{kq}) = q^i(q), \quad v_A^i(t, v_{1q}, \ldots, v_{kq}) = v_{Aq}(q^i),$$

where $1 \leq i \leq n$, $1 \leq A \leq k$.

Throughout the paper we shall use the following notation for the canonical projections:

$$\mathbb{R}^k \times (T_k^1)Q \xrightarrow{(\pi_{\mathbb{R}^k})_{1,0}} \mathbb{R}^k \times Q \xrightarrow{(\pi_{\mathbb{R}^k})} \mathbb{R}^k$$

and $(\pi_{\mathbb{R}^k})_1 = \pi_{\mathbb{R}^k} \circ (\pi_{\mathbb{R}^k})_{1,0}$, where

$$\pi_{\mathbb{R}^k}(t,q) = t, \quad (\pi_{\mathbb{R}^k})_{1,0}(t, v_{1q}, \ldots, v_{kq}) = (t,q), \quad (\pi_{\mathbb{R}^k})_1(t, v_{1q}, \ldots, v_{kq}) = q,$$

with $t \in \mathbb{R}^k$, $q \in Q$ and $(v_{1_q}, \ldots, v_{k_q}) \in T_k^1 Q$.

Canonical vector fields on $\mathbb{R}^k \times T_k^1 Q$*:*

Let us denote by C the *canonical vector field (Liouville vector field)* of the vector bundle $(\pi_{\mathbb{R}^k})_{1,0}: \mathbb{R}^k \times T_k^1 Q \to \mathbb{R}^k \times Q$. This vector field C is the infinitesimal generator of the following flow:

$$\mathbb{R} \times (\mathbb{R}^k \times T_k^1 Q) \to \mathbb{R}^k \times T_k^1 Q,$$

$$(s, (t, v_{1q}, \ldots, v_{kq})) \to (t, e^s v_{1q}, \ldots, e^s v_{kq}),$$

and in local coordinates it has the form

$$C = \sum_{i,A} v_A^i \frac{\partial}{\partial v_A^i}, \tag{12}$$

C is sum of the vector fields

$$C = \sum_{A=1}^{k} C_A,$$

where each C_A is the generator infinitesimal of the following flow:

$$\mathbb{R} \times (\mathbb{R}^k \times T_k^1 Q) \to \mathbb{R}^k \times T_k^1 Q,$$

$$(s, (t, v_{1q}, \ldots, v_{kq})) \to (t, v_{1q}, \ldots, v_{A-1q}, e^s v_{Aq}, v_{A+1q}, \ldots, v_{kq}).$$

Canonical tensor fields on $\mathbb{R}^k \times T_k^1 Q$*:*

The canonical k-tangent structure on $T_k^1 Q$ is the set $(S_1, \ldots, S_k)$ of tensor fields of type (1, 1) locally given by

$$S_A = \frac{\partial}{\partial v_A^i} \otimes \mathrm{d}q^i, \quad 1 \leqslant A \leqslant k. \tag{13}$$

The tensor fields S_A can be regarded as the $(0, \ldots, 0, \overset{A}{1}, 0, \ldots, 0)$-lift of the identity tensor on Q to $T_k^1 Q$ defined in Ref. 7.

In an obvious way we shall consider the extension of S_A to $\mathbb{R}^k \times T_k^1 Q$, which we also denote by S_A and it has the same local expression (13).

The k-tangent manifolds were introduced as a generalization of the tangent manifolds by de León *et al.* (Refs. 8 and 9). The canonical model of these manifolds is $T_k^1 Q$ with the structure given by $(S_1, \ldots, S_k)$.

As in the case of mechanical systems, these tensor fields S_A allow us to introduce the forms θ_L^A and ω_L^A on $\mathbb{R}^k \times T_k^1 Q$ as follows:

$$\theta_L^A = \mathrm{d}L \circ S_A, \quad \omega_L^A = -\,\mathrm{d}\theta_L^A, \quad 1 \leqslant A \leqslant k,$$

with local expressions

$$\theta_L^A = \frac{\partial L}{\partial v_A^i} \mathrm{d}q^i, \quad \omega_L^A = \mathrm{d}q^i \wedge d\left(\frac{\partial L}{\partial v_A^i}\right), \quad 1 \leqslant A \leqslant k. \tag{14}$$

These forms play an important role in the Lagrangian formulation.

Second order partial differential equations on T_k^1Q:

The aim of this section is to characterize the integrable k-vector fields on $\mathbb{R}^k \times T_k^1Q$ such that their integral sections are canonical prolongations of maps from $\mathbb{R}^k$ to Q.

In general, if $F: M \to N$ is a differentiable map, then the induced map $T_k^1(F): T_k^1M \to T_k^1N$ defined by $T_k^1(F)(j_0^1g) = j_0^1(F \circ g)$ is given by

$$T_k^1(F)(v_{1q}, \ldots, v_{kq}) = (F_*(q)v_{1q}, \ldots, F_*(q)v_{kq}),$$

where $v_{1_q}, \ldots, v_{k_q} \in T_qQ$, $q \in Q$, and $F_*(q): T_qM \to T_{F(q)}N$ is the induced map.

Definition 2.5: A k-vector field $\mathbf{X} = (X_1, \ldots, X_k)$ *on* $\mathbb{R}^k \times T_k^1Q$ *is said to be a second order partial differential equation (SOPDE for short) if*

$$\mathrm{d}t^A(X_B) = \delta_B^A, \quad (\tau_{\mathbb{R}^k} \times id_{T_k^1Q}) \circ T_k^1((\pi_{\mathbb{R}^k})_{1,0}) \circ X = id_{\mathbb{R}^k \times T_k^1Q},$$

where

$$\tau_{\mathbb{R}^k} \times id_{T_k^1Q}: \quad T_k^1(\mathbb{R}^k \times Q) \equiv T_k^1(\mathbb{R}^k) \times T_k^1Q \to \mathbb{R}^k \times T_k^1Q,$$

$$(t^A, q^i, v_A^B, v_A^i) \equiv ((t^A, v_A^B), (q^i, v_A^i)) \to (t^A, q^i, v_A^i).$$

Let (q^i) be a coordinate system on Q and (t^A, q^i, v_A^i) the induced coordinate system on $\mathbb{R}^k \times T_k^1Q$. From a direct computation in local coordinates we obtain that the local expression of a SOPDE $(X_1, \ldots, X_k)$ is

$$X_A(t, q^i, v_B^i) = \frac{\partial}{\partial t^A} + v_A^i \frac{\partial}{\partial q^i} + (X_A)_B^i \frac{\partial}{\partial v_B^i}, \quad 1 \leqslant A \leqslant k, \tag{15}$$

where $(X_A)_B^i$ are functions on $\mathbb{R}^k \times T_k^1Q$. As a direct consequence of the above local expressions, we deduce that the family of vector fields $\{X_1, \ldots, X_k\}$ are linearly independent.

Definition 2.6: Let $\phi: \mathbb{R}^k \to Q$ *be a map, we define the* first prolongation $\phi^{[1]}$ *of* ϕ *as the map*

$$\phi^{[1]}: \mathbb{R}^k \to \mathbb{R}^k \times T_k^1Q$$

$$t \to (t, j_0^1\phi_t) \equiv \left(t, \phi_*(t)\left(\frac{\partial}{\partial t^1}\right), \ldots, \phi_*(t)\left(\frac{\partial}{\partial t^k}\right)\right),$$

where $\phi_t(s) = \phi(t+s)$. *In local coordinates*

$$\phi^{[1]}(t^1, \ldots, t^k) = \left(t^1, \ldots, t^k, \phi^i(t^1, \ldots, t^k), \frac{\partial \phi^i}{\partial t^A}(t^1, \ldots, t^k)\right), \tag{16}$$

where $1 \leqslant A \leqslant k$, $1 \leqslant i \leqslant n$.

Remark: Let $(X_1, \ldots, X_k)$ be an SOPDE. From (15) we obtain: a map $\psi: \mathbb{R}^k \to \mathbb{R}^k \times T_k^1Q$, given by $\psi(t) = (\psi^B(t), \psi^i(t), \psi_A^i(t))$, is an integral section of $(X_1, \ldots, X_k)$ if and only if

$$\left.\frac{\partial \psi^B}{\partial t^A}\right|_t = \delta_A^B, \qquad \left.\frac{\partial \psi^i}{\partial t^A}\right|_t = \psi_A^i(t), \qquad \left.\frac{\partial^2 \psi^i}{\partial t^A \partial t^B}\right|_t = (X_A)_B^i(\psi(t)). \tag{17}$$

Then if $(X_1, \ldots, X_k)$ is integrable, from (17) we deduce that $(X_A)_B^i = (X_B)_A^i$.

Let us observe that the map

$$(id_{\mathbb{R}^k}, pr_2 \circ \psi): \mathbb{R}^k \to \mathbb{R}^k \times T_k^1Q$$

$$t \to (t, \psi^i(t), \psi^i_A(t))$$

coincides with the first prolongation $\phi^{[1]}$ of the map $\phi = \rho \circ \psi : \mathbb{R}^k \overset{\psi}{\to} \mathbb{R}^k \times T^1_k Q \overset{\rho}{\to} Q$, that is $\phi(t) = (\psi^i(t))$.

Conversely if $\phi : \mathbb{R}^k \to Q$ is any map such that

$$\left. \frac{\partial^2 \phi^i}{\partial t^A \partial t^B} \right|_t = (X_A)^i_B(\phi^{[1]}(t)),$$

then $\phi^{[1]}$ is an integral section of $(X_1, \ldots, X_k)$.

On $\mathbb{R}^k \times T^1_k Q$ we consider the tensor fields of type (1,1) defined by

$$\hat{S}_A = S_A - C_A \otimes \mathrm{d}t^A,$$

for each $A = 1, \ldots, k$. A characterization of the SOPDE using these tensors is the following.

Proposition 2.7: A k-vector field $(X_1, \ldots, X_k)$ *on* $\mathbb{R}^k \times T^1_k Q$ *is a* SOPDE *if*

$$\mathrm{d}t^A(X_B) = \delta^A_B, \quad \hat{S}_A(X_B) = 0$$

for all $1 \leqslant A, B \leqslant k$.

2. The Legendre transform and Lagrangian forms

Given a Lagrangian $L : \mathbb{R}^k \times T^1_k Q \to \mathbb{R}$ the Legendre map

$$FL : \mathbb{R}^k \times T^1_k Q \to \mathbb{R}^k \times (T^1_k)^* Q$$

is defined as follows:

$$FL(t, v_{1q}, \ldots, v_{kq}) = (t, \ldots, [FL(t, v_{1q}, \ldots, v_{kq})]^A, \ldots),$$

where

$$[FL(t, v_{1q}, \ldots, v_{kq})]^A(w_q) = \frac{d}{\mathrm{d}s} L\ (t, v_{1q}, \ldots, v_{Aq} + s w_q, \ldots, v_{kq}))_{|s=0},$$

for each $A = 1, \ldots, k$; and it is locally given by

$$FL : (t^A, q^i, v^i_A) \to \left(t^A, q^i, \frac{\partial L}{\partial v^i_A} \right). \tag{18}$$

From (14) and (18) one deduces the following identities:

$$\theta^A_L = FL^* \theta^A_0, \quad \omega^A_L = FL^* \omega^A_0, \quad 1 \leqslant A \leqslant k. \tag{19}$$

Definition 2.8: A Lagrangian function $L : \mathbb{R}^k \times T^1_k Q \to R$ *is said to be regular (respectively, hyperregular) if the corresponding Legendre map FL is a local (respectively global) diffeomorphism.*

From (18) we obtain that L is regular if and only if $\det(\partial^2 L / \partial v^i_A \partial v^j_B) \neq 0$, $1 \leqslant i, j \leqslant n$, $1 \leqslant A, B \leqslant k$.

The following proposition has an important role in the Lagrangian formulation. See Ref. 3.

Proposition 2.9: The following conditions are equivalent:

(1) *L is regular.*
(2) *FL is a local diffeomorphism.*
(3) $(\mathrm{d}t^A, \omega^A_L, V^0)$ *is a k-cosymplectic structure on* $\mathbb{R}^k \times T^1_k Q$ *where*

$$V^0 = \ker T(\pi_{\mathbb{R}^k})_{1,0} = \left\langle \frac{\partial}{\partial v_1^i}, \ldots, \frac{\partial}{\partial v_k^i} \right\rangle_{i=1,\ldots,n}$$

is the vertical distribution of the bundle $(\pi_{\mathbb{R}^k})_{1,0}: \mathbb{R}^k \times T_k^1 Q \to \mathbb{R}^k \times Q$.

■

3. Lagrangian formalism

Given a Lagrangian function $L = L(t^A, q^i, v_A^i)$, and by using a variational principle, the *Euler-Lagrange field equations* for L are obtained:

$$\sum_{A=1}^{k} \frac{d}{dt^A}\left(\frac{\partial L}{\partial v_A^i}\right) - \frac{\partial L}{\partial q^i} = 0, \quad v_A^i = \frac{\partial q^i}{\partial t^A}. \tag{20}$$

In this section we give a geometrical description of the above equations (20).

Let $L: \mathbb{R}^k \times T_k^1 Q \to \mathbb{R}$ be a regular Lagrangian, and let (dt^A, ω_L^A, V^0) be the k-cosymplectic structure on $\mathbb{R}^k \times T_k^1 Q$ defined by L. Let $(R_L)_A$ be the Reeb vector fields corresponding to this k-cosymplectic structure. They are characterized by

$$i_{(R_L)_A} dt^B = \delta_A^B, \quad i_{(R_L)_A}(\omega_L)_B = 0.$$

Since $(R_L)_A(E_L) = -\partial L / \partial t^A$, writing Eqs. (6) for this k-cosymplectic structure we have the following result.

Theorem 2.10: *Let L be a regular Lagrangian and let $((X_L)_1, \ldots, (X_L)_k)$ be a k-vector field such that*

$$dt^A((X_L)_B) = \delta_B^A, \quad 1 \leqslant A, B \leqslant k,$$

$$\sum_{A=1}^{k} i_{(X_L)_A} \omega_L^A = dE_L + \sum_{A=1}^{k} \frac{\partial L}{\partial t^A} dt^A, \tag{21}$$

where $E_L = C(L) - L$. Then

(1) *$((X_L)_1, \ldots, (X_L)_k)$ is an SOPDE.*

(2) *If it is integrable, and $\phi^{[1]}: \mathbb{R}^k \to \mathbb{R}^k \times T_k^1 Q$ is an integral section, then $\phi: \mathbb{R}^k \to Q$ is a solution of the Euler-Lagrange equations (20).*

The k-vector field

$$(X_L)_A = [(X_L)_A]^B \frac{\partial}{\partial t^B} + [(X_L)_A]^i \frac{\partial}{\partial q^i} + [(X_L)_A]_B^i \frac{\partial}{\partial v_B^i}, \quad 1 \leqslant A \leqslant k$$

is a solution to the equations (21) if and only if it satisfies the following identities:

$$[(X_L)_A]^B = \delta_A^B, \quad [(X_L)_A]^i = v_A^i, \quad \sum_{A=1}^{k} (X_L)_A\left(\frac{\partial L}{\partial v_A^k}\right) = \frac{\partial L}{\partial q^k}. \tag{22}$$

Remark: If we rewrite the equations (21) for the case $k = 1$, we have

$$dt(X_L) = 1, \quad i_{X_L}\omega_L = dE_L + \frac{\partial L}{\partial t} dt \tag{23}$$

which are equivalent to the dynamical equations

$$\mathrm{d}t(X_L)=1, \quad i_{X_L}\Omega_L=0,$$

where $\Omega_L=\omega_L+\mathrm{d}E_L\wedge\mathrm{d}t$ is the Poincaré-Cartan 2-form associated to the Lagrangian L, see Ref. 1. Remember that this describes the nonautonomous mechanics.

Remark: The above forms θ_L^A and ω_L^A are related with the multisymplectic Poincaré-Cartan forms θ_L and Ω_L in the Lagrangian jet formalism of field theory in a similar way as indicated in Ref. 5, Sec. V B.

The k-vector fields $((X_L)_1,\ldots,(X_L)_k)$ allow us to construct a decomposable multivector field $\mathcal{X}=(X_L)_1\wedge\ldots\wedge(X_L)_k$, which is related with the multivector field solution to the Lagrangian equation described in Ref. 10, Sec. 7, and they give the same solutions to the Lagrangian equations.

III. CONNECTIONS AND LAGRANGIAN ENERGY

A. Connections in $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$

The following Proposition can be found in Ref. 11 for an arbitrary fiber bundle $\pi:E\to M$, or in different sections in Ref. 12. The following is stated in our setting.

Proposition 3.1: Let $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$ *be the trivial bundle and* $(\pi_{\mathbb{R}^k})_{1,0}:J^1(\mathbb{R}^k\times Q)\equiv\mathbb{R}^k\times T^1_kQ\to\mathbb{R}^k\times Q$ *the corresponding first-order jet bundle. The following elements can be canonically constructed one from the other:*

(1) *A global section of* $(\pi_{\mathbb{R}^k})_{1,0}:J^1\pi_{\mathbb{R}^k}\equiv\mathbb{R}^k\times T^1_kQ\to\mathbb{R}^k\times Q$; *that is, a mapping* $\Psi:\mathbb{R}^k\times Q\to\mathbb{R}^k\times T^1_kQ$ *such that* $(\pi_{\mathbb{R}^k})_{1,0}\circ\Psi=Id_{\mathbb{R}^k\times Q}$.
(2) *A subbundle* H *of* $T(\mathbb{R}^k\times Q)$ *such that* $T(\mathbb{R}^k\times Q)=V(\pi_{\mathbb{R}^k})\oplus H$.
(3) *A* $\pi_{\mathbb{R}^k}$*-semibasic 1-form* ∇ *on* $\mathbb{R}^k\times Q$ *with values on* $T(\mathbb{R}^k\times Q)$, *such that* $\nabla^*\alpha=\alpha$, *for every* $\pi_{\mathbb{R}^k}$*-semibasic form* $\alpha\in\Lambda^1(\mathbb{R}^k\times Q)$.

Definition 3.2: A connection in the bundle $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$ *is one of the above-mentioned equivalent elements. H is called the horizontal sub-bundle of* $T(\mathbb{R}^k\times Q)$ *associated with the connection* ∇ *and its sections are the horizontal vector fields.* ∇ *is called the connection form.*

Let (q^i) be a coordinate system on $U\subset Q$ and let (t^A,q^i) be the induced coordinate system on $\mathbb{R}^k\times U$. The local expression of the connection form is

$$\nabla=\mathrm{d}t^A\otimes\left(\frac{\partial}{\partial t^A}+\Gamma^i_A\frac{\partial}{\partial q^i}\right),$$

where $\Gamma^i_A\in C^\infty(\mathbb{R}^k\times U)$.

Let $\Psi:\mathbb{R}^k\times Q\to J^1(\mathbb{R}^k\times Q)\equiv\mathbb{R}^k\times T^1_kQ$ be a section, then $\Psi(t,q)=j^1_t\phi=j^1_t(Id_{\mathbb{R}^k},\phi_Q)$ where $\phi_Q=\pi_Q\circ\phi:\mathbb{R}^k\xrightarrow{\phi}\mathbb{R}^k\times Q\xrightarrow{\pi_Q}Q$, with $\phi(t)=(t,q)$ and $\phi_Q(t)=q$.

If $\Psi(t,q)=(t,q,\Psi^i_A(t,q))$ from (10) we have

$$\Psi^i_A(t,q)=\frac{\partial(q^i\circ\phi_Q)}{\partial t^A}|_t.$$

Then we define

$$H_{(t,q)}:=\mathrm{Im}\ \phi_*(t) \quad \text{and} \quad H=\bigcup_{(t,q)\in\mathbb{R}^k\times Q}H_{(t,q)}$$

so the basis of $H_{(t,q)}$ is

$$\phi_*(t)\left(\frac{\partial}{\partial t^A}|_t\right)=\frac{\partial}{\partial t^A}|_{(t,q)}+\frac{\partial(q^i\circ\phi_Q)}{\partial t^A}|_t\frac{\partial}{\partial q^i}|_{(t,q)}, \quad 1\leqslant A\leqslant k$$

and the components of the connection Γ^i_A are given by

$$\Gamma_A^i(t,q) = \frac{\partial(q^i \circ \phi_Q)}{\partial t^A}_{|t} = \Psi_A^i(t,q),$$

where $\Psi(t,q) = j_t^1(Id_{\mathbb{R}}^k, \phi_Q)$ with $\phi_Q(t) = q$.

For a vector field

$$X = f^A \frac{\partial}{\partial t^A} + \lambda^i \frac{\partial}{\partial q^i} \in \mathfrak{X}(\mathbb{R}^k \times Q)$$

we have the splitting

$$X = (X - \nabla(X)) + \nabla(X) = \pi_\nabla^v(X) + \pi_\nabla^h(X) \tag{24}$$

and so the horizontal and vertical projections are given by

$$\pi_\nabla^h(X) = f^A\left(\frac{\partial}{\partial t^A} + \Gamma_A^i \frac{\partial}{\partial q^i}\right), \quad \pi_\nabla^v(X) = (\lambda^i - f^A\Gamma_A^i)\frac{\partial}{\partial q^i}.$$

Remark: Every connection in the bundle $\pi_{\mathbb{R}^k}: \mathbb{R}^k \times Q \to \mathbb{R}^k$ induces a horizontal lift of a vector field X on $\mathbb{R}^k$ to a horizontal vector field X^H, on $\mathbb{R}^k \times Q$, which projects on X.

Let ∇ be a connection and let us suppose that $\nabla(t,q) = j_t^1\phi$, where $\phi = (id_{\mathbb{R}^k}, \phi_Q): \mathbb{R}^k \to \mathbb{R}^k \times Q$, with $\phi(t) = (t, \phi_Q(t))$ and $\phi_Q(t) = q$. If

$$X(t) = X^A(t)\frac{\partial}{\partial t^A}_{|t}$$

then

$$X^H(t,q) = \phi_*(t)(X(t)) = X^A(t)\left(\frac{\partial}{\partial t^A}_{|(t,q)} + \frac{\partial q^i \circ \phi_Q}{\partial t^A}_{|t}\frac{\partial}{\partial q^i}_{|(t,q)}\right) = X^A(t)\left(\frac{\partial}{\partial t^A}_{|(t,q)} + \Gamma_A^i(t,q)\frac{\partial}{\partial q^i}_{|(t,q)}\right).$$

B. Vector fields in $\mathbb{R}^k \times Q$ associated to a connection ∇

Given a connection ∇ on $\mathbb{R}^k \times Q \to \mathbb{R}^k$, we consider the horizontal lifts $\widetilde{Y}_A$ of the global generators $\{\partial/\partial t^A, A = 1, \ldots, k,\}$ of $\mathfrak{X}(\mathbb{R}^k)$,

$$\widetilde{Y}_A(t,q) = \left(\frac{\partial}{\partial t^A}\right)^H_{|(t,q)} = \frac{\partial}{\partial t^A}_{|(t,q)} + \Gamma_A^i(t,q)\frac{\partial}{\partial q^i}_{|(t,q)}, \quad 1 \leqslant A \leqslant k. \tag{25}$$

Definition 3.3: The vector fields $\widetilde{Y}_A$ will be called the associated vector fields to the connection ∇.

If ∇_0 is the *standard connection* on $\pi_{\mathbb{R}^k}: \mathbb{R}^k \times Q \to \mathbb{R}^k$, then, since $\Gamma_A^i \equiv 0$, the associated vector fields to ∇_0 are given by

$$\left(\frac{\partial}{\partial t^A}\right)^H_{|(t,q)} = \left(\frac{\partial}{\partial t^A}\right)_{|(t,q)}, \quad 1 \leqslant A \leqslant k.$$

C. Lagrangian energy functions

As is well known from Saunders[12] (p. 156), in the bundle $\pi_{\mathbb{R}^k}: \mathbb{R}^k \times Q \to \mathbb{R}^k$ and associated to the form dt^A, we have a natural vector-valued 1-form S_{dt^A} with coordinate expression

$$S_{dt^A} = (dq^i - v_B^i\, dt^B) \otimes \frac{\partial}{\partial v_A^i}, \quad 1 \leqslant A \leqslant k. \tag{26}$$

Let $L:\mathbb{R}^k\times T^1_kQ\to\mathbb{R}$ be a Lagrangian. By means of the geometrical structures of $\mathbb{R}^k\times T^1_kQ$ we can construct the Lagrangians forms and the energy function associated to L.

Definition 3.4: The Poincaré-Cartan 1*-forms associated with the Lagrangian function L are the forms in* $\mathbb{R}^k\times T^1_kQ$ *defined by*

$$\Theta^A_L := \mathrm{d}L\circ S_{\mathrm{d}t^A}+\frac{1}{k}L\,\mathrm{d}t^A,\quad 1\leqslant A\leqslant k. \tag{27}$$

From (26) we deduce that Θ^A_L is locally given by

$$\Theta^A_L := \left(\frac{1}{k}\delta^A_B L-v^i_B\frac{\partial L}{\partial v^i_A}\right)\mathrm{d}t^B+\frac{\partial L}{\partial v^i_A}\mathrm{d}q^i. \tag{28}$$

These forms only depend on the Lagrangian and the natural structures in the bundle, and we can write

$$\Theta^A_L=\theta^A_L+\left(\frac{1}{k}\delta^A_B L-v^i_B\frac{\partial L}{\partial v^i_A}\right)\mathrm{d}t^B,\quad 1\leqslant A\leqslant k. \tag{29}$$

The *Lagrangian energy function* $E_L=CL-L$ is locally given by

$$E_L=v^i_A\frac{\partial L}{\partial v^i_A}-L.$$

We can intrinsically define this Lagrangian energy function in the following way: Consider the standard connection ∇_0 in the bundle $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$, and the prolongation, $j^1(\partial/\partial t^A)$, of the horizontal lifting of $\partial/\partial t^A$ given by the connection, from $\mathbb{R}^k$ to $\mathbb{R}^k\times Q$, which will be denoted as usual by $\partial/\partial t^A$, then

$$E_L=-\sum_{A=1}^{k} i_{\partial/\partial t^A}\Theta^A_L.$$

One of the most significant aspects of the above expression for the Lagrangian energy is that it is obtained by contraction of the associated vector fields to the standard connection with the Lagrangian forms.

If we consider a nonstandard connection, then in order to define the Lagrangian energy function associated to ∇ we must lift $\partial/\partial t^A$ from $\mathbb{R}^k$ to $\mathbb{R}^k\times T^1_kQ$ to be contracted with Θ^A_L in the following way.

Definition 3.5: Let ∇ *be a connection in* $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$, *and* $\widetilde{Y}_A$, $A=1,\ldots,k$, *the associated vector fields to the connection* ∇ *given by (25).*

Let $j^1\widetilde{Y}_A\in\mathfrak{X}(\mathbb{R}^k\times T^1_kQ)$ *the prolongation of the vector fields* $\widetilde{Y}_A\in\mathfrak{X}(\mathbb{R}^k\times Q)$, *defined in Ref. 12, p. 133.*

The Lagrangian energy function associated with the Lagrangian L and the connection ∇ *is*

$$E^{\nabla}_L=-\sum_{A=1}^{k} i_{j^1\widetilde{Y}_A}\Theta^A_L.$$

In a local chart, if

$$\widetilde{Y}_A=\frac{\partial}{\partial t^A}+\Gamma^i_A\frac{\partial}{\partial q^i}$$

then, see Ref. 12,

$$j^1\widetilde{Y}_A = \frac{\partial}{\partial t^A} + \Gamma_A^i \frac{\partial}{\partial q^i} + \left(\frac{\partial \Gamma_A^i}{\partial t^B} + v_B^j \frac{\partial \Gamma_A^i}{\partial q^j} \right) \frac{\partial}{\partial v_B^i} \tag{30}$$

and from (28) and (30) we obtain

$$E_L^\nabla = \sum_{A=1}^{k} \frac{\partial L}{\partial v_A^i} (v_A^i - \Gamma_A^i) - L. \tag{31}$$

It is obvious from this expression that the Lagrangian energy E_L^∇ is connection dependent.

In the following lemma, we will suppose that a Lagrangian function L and a connection ∇ are given.

Lemma 3.6: Let $(X_1, \ldots, X_k)$ be a SOPDE on $\mathbb{R}^k \times T_k^1 Q$. If

$$(1)\ X_B(\Gamma_A^i) = X_A(\Gamma_B^i), \quad (2)\ X_A\left(\frac{\partial L}{\partial v_B^i} \right) = \delta_B^A \frac{\partial L}{\partial q^i}, \quad A,B = 1, \ldots, k \tag{32}$$

then

$$X_A(E_L^\nabla) = -\, j^1\widetilde{Y}_A(L), \quad A = 1, \ldots, k.$$

Proof: From the local expressions (15), (30), and (31) we obtain

$$\begin{aligned}
X_A(E_L^\nabla) + j^1\widetilde{Y}_A(L) &= \left(\frac{\partial \Gamma_A^i}{\partial t^B} - \frac{\partial \Gamma_B^i}{\partial t^A} \right) \frac{\partial L}{\partial v_B^i} + \left(v_B^j \frac{\partial \Gamma_A^i}{\partial q^j} - v_A^j \frac{\partial \Gamma_B^i}{\partial q^j} \right) \frac{\partial L}{\partial v_B^i} + \left(\frac{\partial^2 L}{\partial t^A \partial v_C^k} + v_A^i \frac{\partial^2 L}{\partial q^i \partial v_C^k} \right. \\
&\quad \left. + (X_A)_B^j \frac{\partial^2 L}{\partial v_B^j \partial v_C^k} - \delta_C^A \frac{\partial L}{\partial q^k} \right) (v_C^k - \Gamma_C^k) \\
&= \left(\left(\frac{\partial}{\partial t^B} + v_B^j \frac{\partial}{\partial q^j} \right) (\Gamma_A^i) - \left(\frac{\partial}{\partial t^A} + v_A^j \frac{\partial}{\partial q^j} \right) (\Gamma_B^i) \right) \frac{\partial L}{\partial v_B^i} \\
&\quad + \left(\frac{\partial^2 L}{\partial t^A \partial v_C^k} + v_A^i \frac{\partial^2 L}{\partial q^i \partial v_C^k} + (X_A)_B^j \frac{\partial^2 L}{\partial v_B^j \partial v_C^k} - \delta_C^A \frac{\partial L}{\partial q^k} \right) (v_C^k - \Gamma_C^k) \\
&= (X_C(\Gamma_A^i) - X_A(\Gamma_C^i)) \frac{\partial L}{\partial v_C^i} + \left(\frac{\partial^2 L}{\partial t^A \partial v_C^k} + v_A^i \frac{\partial^2 L}{\partial q^i \partial v_C^k} \right. \\
&\quad \left. + (X_A)_B^j \frac{\partial^2 L}{\partial v_B^j \partial v_C^k} - \delta_C^A \frac{\partial L}{\partial q^i} \right) (v_C^k - \Gamma_C^k) \\
&= (X_C(\Gamma_A^i) - X_A(\Gamma_C^i)) \frac{\partial L}{\partial v_C^i} + \left(X_A\left(\frac{\partial L}{\partial v_C^k} \right) - \delta_C^A \frac{\partial L}{\partial q^k} \right) (v_C^k - \Gamma_C^k).
\end{aligned}$$

■

We know that if L is a regular Lagrangian and $((X_L)_1, \ldots, (X_L)_k)$ is an integrable solution of (21), then it is a SOPDE. Then we have the following.

Corollary 3.7: Suppose that the Lagrangian L is regular and let $((X_L)_1, \ldots, (X_L)_k)$ be an integrable solution of (21) satisfying the conditions (32).

If L is invariant by the prolongations $j^1\widetilde{Y}_A$ then the associated energy function E_L^∇ is invariant by the vector fields $(X_L)_A$, $A = 1, \ldots, k$. That is, E_L^∇ is constant along the integral sections of $((X_L)_1, \ldots, (X_L)_k)$.

■

Remark: In the case $k=1$, if X_L is the dynamical vector field on $\mathbb{R} \times TQ$, then X_L is an SODE and satisfies (1) trivially, and (2) (in Lemma 3.6) because it is a solution to the dynamical equations (23). Therefore, in this case we have

$$X_L(E_L^\nabla) = -j^1\tilde{Y}(L),$$

which is the assertion of Theorem 1 in Ref. 4.

Proposition 3.8: Let L be a Lagrangian function such that the components $[FL(t,w_q)]^A$, *of the Legendre transformation FL are different from zero at every point* $(t,w_q)=(t,v_{1_q},\dots v_{k_q})\in\mathbb{R}^k\times T_k^1Q$.

Let $f:\mathbb{R}^k\times T_k^1Q\to\mathbb{R}^k$ *be a mapping, then there exists a connection* ∇ *such that the energy function* E_L^∇ *associated to this connection is given by*

$$E_L^\nabla = \sum_{A=1}^{k} f^A,$$

where $f^A=\pi^A\circ f:\mathbb{R}^k\times T_k^1Q\overset{f}{\to}\mathbb{R}^k\overset{\pi^A}{\to}\mathbb{R}$.

If L is a regular Lagrangian and $((X_L)_1,\dots,(X_L)_k)$ *is an integrable solution of (21) that satisfies the conditions (32), and* $(X_L)_A(\Sigma_B f^B)=0$, *then* $j^1\tilde{Y}_A(L)=0$ *for* $A=1,\dots,k$.

Proof: Let ∇ be the connection such that its associated vector fields Y_A verify

$$i_{j^1\tilde{Y}_A}\Theta_L^A = -f^A, \quad 1\leqslant A\leqslant k.$$

From (28) and (30) we deduce that this connection is given by

$$-f^A = \left(\frac{1}{k}L - v_A^i\frac{\partial L}{\partial v_A^i}\right) + \frac{\partial L}{\partial v_A^i}\Gamma_A^i$$

and thus

$$E_L^\nabla = \sum_{A=1}^{k}\frac{\partial L}{\partial v_A^i}(v_A^i-\Gamma_A^i) - L = \sum_{A=1}^{k} f^A.$$

Now from Lemma 3.6 we obtain

$$0 = (X_L)_A\left(\sum_{B=1}^{k} f^B\right) = (X_L)_A(E_L^\nabla) = -j^1\tilde{Y}_A(L).$$

■

This Proposition in the case $k=1$ coincides with Proposition 4 in Ref. 4.

IV. HAMILTONIAN FORMALISM WITH NONSTANDARD FLAT CONNECTIONS

In this section, we will suppose a given connection ∇ in the bundle $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$. First, associated to this connection, we are going to construct a k-cosymplectic structure $(\mathrm{d}t^A,\omega_A^\nabla,V_0)$ on $\mathbb{R}^k\times(T_k^1)^*Q$. Second, if we have a Lagrangian, L, then a Hamiltonian function will be associated to L and ∇. With these ingredients, we study the Hamiltonian formalism and the dynamical equations.

For the k-cosymplectic structure, let us consider the canonical projections $\tau_Q^*:T^*Q\to Q$ and $\pi_2^A:\mathbb{R}^k\times(T_k^1)^*Q\to T^*Q$ given by $\pi_2^A(t,\alpha_q^1,\dots,\alpha_q^k)=\alpha_q^A$, $1\leqslant A\leqslant k$.

Since $\theta_0^A=(\pi_2^A)^*\theta_0$, using the definition of θ_0 we obtain that

$$\theta_0^A(w_{t,q}) = \alpha_q^A\circ(\tau_Q^*)_*(\alpha_q^A)\circ(\pi_2^A)_*(w_{t,q}),$$

where $w_{t,q}=(t,\alpha_q^1,\dots,\alpha_q^k)\in\mathbb{R}^k\times(T_k^1)^*Q$.

The connection ∇ enables other 1-forms on $\mathbb{R}^k\times(T_k^1)^*Q$ to be constructed in the following way.

Definition 4.1: The composition

$$T_{w_{t,q}}(\mathbb{R}^k \times (T^1_k)^*Q) \xrightarrow{((\pi_Q)_{1,0})_* w_{t,q}} T_{(t,q)}(\mathbb{R}^k \times Q) \xrightarrow{\pi^v_\nabla} V_{(t,q)}(\pi_{\mathbb{R}} k)$$

$$\subset T_{(t,q)}(\mathbb{R}^k \times Q) \xrightarrow{(\pi_Q)_*(t,q)} T_qQ \xrightarrow{\alpha^A_q} \mathbb{R},$$

define the 1*-forms* θ^A_∇ *on* $\mathbb{R}^k \times (T^1_k)^*Q$ *by*

$$\theta^A_\nabla(w_{t,q}) = \alpha^A_q \circ (\pi_Q)_*(t,q) \circ \pi^v_\nabla \circ ((\pi_Q)_{1,0})_* w_{t,q}. \tag{33}$$

From (24) we deduce that

$$\theta^A_\nabla = p^A_i \, \mathrm{d}q^i - p^A_i \Gamma^i_B \, \mathrm{d}t^B = p^A_i (\mathrm{d}q^i - \Gamma^i_B \, \mathrm{d}t^B). \tag{34}$$

The difference $\theta^A_0 - \theta^A_\nabla \equiv \eta^A_\nabla$ is a 1-form on $\mathbb{R}^k \times (T^1_k)^*Q$ whose local expression is

$$\eta^A_\nabla = p^A_i \Gamma^i_B \, \mathrm{d}t^B. \tag{35}$$

From (3), (25), and (35) we deduce the following proposition.

Proposition 4.2: If ∇ *is a connection on* $\pi_{\mathbb{R}^k}: \mathbb{R}^k \times Q \to \mathbb{R}^k$ *and* $\widetilde{Y_A}$ *are the associated vector fields then*

$$\eta^A_\nabla = \sum_{B=1}^{k} \theta^A_0(\widetilde{Y}_B) \mathrm{d}t^B.$$

■

In the sequel, in order to develop the Lagrangian and Hamiltonian formalisms, we need that the curvature of ∇ vanishes. Observe that this condition always holds in the mechanical case because the horizontal distribution is one dimensional, hence involutive. The same condition will be necessary in Sec. V, where we study the Lagrangian counterpart.

Proposition 4.3: Let V_0 *be the vertical distribution of the bundle* $(\pi_Q)_{1,0}: \mathbb{R}^k \times (T^1_k)^*Q \to \mathbb{R}^k \times Q$ *and* $\omega^A_\nabla = -d\theta^A_\nabla$. *If the curvature of* ∇ *vanishes then* $(\mathbb{R}^k \times (T^1_k)^*Q, \mathrm{d}t^A, \omega^A_\nabla, V_0)$ *is a k-cosymplectic manifold.*

Proof: Conditions (1). in Definition 2.1 are straightforward. To prove conditions (2)., let X be a vector field with local expression

$$X = X^A \frac{\partial}{\partial t^A} + X^i \frac{\partial}{\partial q^i} + X^A_i \frac{\partial}{\partial p^A_i}. \tag{36}$$

As

$$\omega^A_\nabla = -d(p^A_i(\mathrm{d}q^i - \Gamma^i_B \mathrm{d}t^B)) = \mathrm{d}q^i \wedge dp^A_i + d(p^A_i \Gamma^i_B) \wedge \mathrm{d}t^B,$$

we have that $i_X \omega^A_\nabla = 0, 1 \leqslant A \leqslant k$, if and only if X has the following local expression:

$$X = X^B \left(\frac{\partial}{\partial t^B} + \Gamma^i_B \frac{\partial}{\partial q^i} - \frac{\partial \Gamma^j_B}{\partial q^i} p^A_j \frac{\partial}{\partial p^A_i} \right),$$

and the following condition holds

$$\sum_{B=1}^{k} X^B p^A_j \left(\frac{\partial \Gamma^j_C}{\partial t^B} - \frac{\partial \Gamma^j_B}{\partial t^C} + \Gamma^i_B \frac{\partial \Gamma^j_C}{\partial q^i} - \Gamma^i_C \frac{\partial \Gamma^j_B}{\partial q^i} \right) = 0, \quad 1 \leqslant A, C \leqslant k, 1 \leqslant i \leqslant n$$

with X^B free. Observe that

$$\frac{\partial \Gamma_C^j}{\partial t^B} - \frac{\partial \Gamma_B^j}{\partial t^C} + \Gamma_B^i \frac{\partial \Gamma_C^j}{\partial q^i} - \Gamma_C^i \frac{\partial \Gamma_B^j}{\partial q^i} \tag{37}$$

are the components of the curvature of the connection ∇, see Ref. 12, p. 91.

Since the curvature vanishes, then $\cap_{A=1}^k \ker \omega_\nabla^A$ is locally spanned by the following family of k independent local vector fields:

$$\left\{ \frac{\partial}{\partial t^B} + \Gamma_B^i \frac{\partial}{\partial q^i} - \frac{\partial \Gamma_B^j}{\partial q^i} p_j^A \frac{\partial}{\partial p_i^A}; 1 \leqslant B \leqslant k \right\}$$

and second condition (2). is finished.

Moreover, if $\mathrm{d}t^A(X)=0$, for all A, then $X^A=0$, for all A, hence

$$(\cap_{A=1}^k \ker \mathrm{d}t^A) \cap (\cap_{A=1}^k \ker \omega_\nabla^A) = \{0\}$$

and the result is proved.

■

Now we shall introduce the Hamiltonian function associated with a Lagrangian L and a connection ∇ with curvature zero.

In the standard situation, assuming that the Lagrangian function is hyperregular, the Hamiltonian function is defined by the equation $E_L=(FL)^*H$. In the general case we define the following.

Definition 4.4: The Hamiltonian function associated with the Lagrangian L and the connection ∇ *is the function* $H^\nabla \in C^\infty(\mathbb{R}^k \times (T_k^1)^* Q)$ *such that*

$$E_L^\nabla = (FL)^* H^\nabla.$$

As in the standard case, the existence and uniqueness of this function is assured (at least locally) if we assume that L is a hyperregular (or regular) Lagrangian. A simple computation using (18) and (35) shows that

$$H^\nabla = H - \sum_{A=1}^k \eta_\nabla^A \left(\frac{\partial}{\partial t^A} \right). \tag{38}$$

Now we consider *the Hamiltonian formalism on* $\mathbb{R}^k \times (T_k^1)^* Q$ *considering the k-cosymplectic structure* $(\mathbb{R}^k \times (T_k^1)^* Q, \mathrm{d}t^A, \omega_\nabla^A, V_0)$ *and the Hamiltonian* H^∇, that is, we consider Eq. (6) for this particular k-cosymplectic structure and this Hamiltonian,

$$\mathrm{d}t^A(X_B) = \delta_B^A,$$

$$\sum_{A=1}^k \iota_{X_A} \omega_\nabla^A = \mathrm{d}H^\nabla - \sum_{A=1}^k R_A^\nabla(H^\nabla)\mathrm{d}t^A, \tag{39}$$

where R_A^∇ are the Reeb vector fields of the k-cosymplectic structure $(\mathbb{R}^k \times (T_k^1)^* Q, \mathrm{d}t^A, \omega_\nabla^A, V_0)$, that is

$$\iota_{R_A^\nabla} \mathrm{d}t^B = \delta_A^B, \quad \iota_{R_A^\nabla} \omega_\nabla^B = 0. \tag{40}$$

Conditions (40) are equivalent to the equations

$$(R_A^\nabla)^B = \delta_A^B, \quad (R_A^\nabla)^i = \Gamma_A^i, \quad (R_A^\nabla)_i^B = -p_j^B \frac{\partial \Gamma_A^j}{\partial q^i} \tag{41}$$

and

$$p_j^B\left(\frac{\partial\Gamma_C^j}{\partial t^A}-\frac{\partial\Gamma_A^j}{\partial t^C}+\Gamma_A^i\frac{\partial\Gamma_C^j}{\partial q^i}-\Gamma_C^i\frac{\partial\Gamma_A^j}{\partial q^i}\right)=0, \tag{42}$$

for all $1\leqslant A,B,C\leqslant k$.

Taking into account that the curvature of ∇ is zero one obtains that the Reeb vector fields are locally given by

$$R_A^\nabla=\frac{\partial}{\partial t^A}+\Gamma_A^i\frac{\partial}{\partial q^i}-p_j^B\frac{\partial\Gamma_A^j}{\partial q^i}\frac{\partial}{\partial p_i^B}. \tag{43}$$

From (34), (35), (38), and (43), we obtain that $(X_1,\ldots,X_k)$, locally given by

$$X_A=(X_A)^B\frac{\partial}{\partial t^B}+(X_A)^i\frac{\partial}{\partial q^i}+(X_A)_i^B\frac{\partial}{\partial p_i^B},$$

is a solution to (39) if and only if, $(X_A)^B,(X_A)^i,(X_A)_i^B$ verify

$$(X_A)^B=\delta_B^A,\quad (X_A)^i=\frac{\partial H}{\partial p_i^A},\quad \sum_{A=1}^{k}(X_A)_i^A=-\frac{\partial H}{\partial q^i}, \tag{44}$$

where we have used that the curvature of ∇ is zero.

Observe that Eqs. (7) coincide with Eqs. (44), thus we obtain the following proposition.

Proposition 4.5: If the curvature of ∇ *vanishes, the Hamiltonian equations (6) and (39), corresponding to* H and H^∇, *respectively, have the same solutions*.

■

V. LAGRANGIAN FORMALISM WITH NONSTANDARD FLAT CONNECTIONS

A. The vertical endomorphism S_∇^A

The aim of this section is to give the guidelines to construct the vertical endomorphism S_∇^A, which depends on the connection ∇ and coincides with the vertical endomorphism S_A when the connection is the standard one. With this endomorphism we construct the Lagrangian formalism with a nonstandard connection.

First of all we have the following natural diffeomorphisms.

(1) As $J^1\pi_{\mathbb{R}^k}=\mathbb{R}^k\times T_k^1Q$ is a vector bundle on $\mathbb{R}^k\times Q$, we have the natural diffeomorphism:

$$J^1\pi_{\mathbb{R}^k}\to\pi_{\mathbb{R}^k}^*T^*\mathbb{R}^k\otimes\pi_Q^*TQ$$

in fact, given by its inverse

$$((t,q),\lambda_B^i\alpha^B\otimes u_i)\mapsto\left((t,q),\lambda_B^i\alpha^B\left(\frac{\partial}{\partial t^1}\right)u_i,\ldots,\left(\lambda_B^i\alpha^B\left(\frac{\partial}{\partial t^k}\right)u_i\right)\right).$$

(2) $\pi_Q^*(TQ)\to V(\pi_{\mathbb{R}^k})$ because $\pi_Q:\mathbb{R}^k\times Q\to Q$ is a vector bundle.

(3) As a consequence of the above two, we have the following diffeomorphisms:

$$V((\pi_{\mathbb{R}^k})_{1,0})\simeq((\pi_{\mathbb{R}^k})_{1,0})^*(\mathbb{R}^k\times T_k^1Q)\simeq((\pi_{\mathbb{R}^k})_{1,0})^*(\pi_{\mathbb{R}^k}^*T^*\mathbb{R}^k\otimes V(\pi_{R^k})).$$

The first is because $J^1\pi_{\mathbb{R}^k}$ is a vector bundle. The second is a direct consequence of the above items.

They are diffeomorphisms of vector bundles on $\mathbb{R}^k\times T_k^1Q$.

There is a section $V\in\mathrm{Sec}(((\pi_{\mathbb{R}^k})_{1,0})^*(\pi_{\mathbb{R}^k}^*T\mathbb{R}^k\otimes V(\pi_{\mathbb{R}^k})^*\otimes V((\pi_{\mathbb{R}^k})_{1,0}))$, associated to these diffeomorphisms, in particular to the third. In local natural coordinates we have

$$V = \frac{\partial}{\partial t^A} \otimes \zeta^i \otimes \frac{\partial}{\partial v^i_A},$$

where $\{\zeta^i, i=1,\ldots,n\}$ is a local basis for Sec $V(\pi_{\mathbb{R}^k})^*$, dual to the local basis $\{\partial/\partial q^i\}$.

Observe that, although $V(\pi_{\mathbb{R}^k})$ is a subbundle of $T(\mathbb{R}^k \times Q)$, $V(\pi_{\mathbb{R}^k})^*$ is not a subbundle of $T^*(\mathbb{R}^k \times Q)$, unless we have given a connection in the bundle $\pi_{\mathbb{R}^k}: \mathbb{R}^k \times Q \to \mathbb{R}^k$.

In fact, let ∇ be one such connection. ∇ gives a decomposition $T(\mathbb{R}^k \times Q) = H(\nabla) \oplus V(\pi_{\mathbb{R}^k})$, hence we have the induced projection $\pi^v_\nabla: T(\mathbb{R}^k \times Q) \to V(\pi_{\mathbb{R}^k})$ and the injection ${}^t(\pi^v_\nabla): V(\pi_{\mathbb{R}^k})^* \to T^*(\mathbb{R}^k \times Q)$.

In natural local coordinates, if

$$\nabla = \mathrm{d}t^A \otimes \left(\frac{\partial}{\partial t^A} + \Gamma^i_A \frac{\partial}{\partial q^i} \right)$$

then

$$\pi^v_\nabla\left(\frac{\partial}{\partial t^A} \right) = -\Gamma^i_A \frac{\partial}{\partial q^i}, \quad \pi^v_\nabla\left(\frac{\partial}{\partial q^i} \right) = \frac{\partial}{\partial q^i}$$

and

$$t_{\pi^v_\nabla}(\zeta^i) = \mathrm{d}q^i - \Gamma^i_B \, \mathrm{d}t^B.$$

In this way, the connection ∇ acts on the section V giving, locally,

$$S_\nabla = \frac{\partial}{\partial t^A} \otimes (\mathrm{d}q^i - \Gamma^i_B \, \mathrm{d}t^B) \otimes \frac{\partial}{\partial v^i_A}$$

making S_∇ an element of $\mathrm{Sec}(((\pi_{\mathbb{R}^k})_{1,0})^*(\pi^*_{\mathbb{R}^k} T\mathbb{R}^k \otimes T^*(\mathbb{R}^k \times Q) \otimes V((\pi_{\mathbb{R}^k})_{1,0}))$.

Now to obtain S^A_∇, we have

$$S^A_\nabla = S_\nabla(\mathrm{d}t^A) = (\mathrm{d}q^i - \Gamma^i_B \, \mathrm{d}t^B) \otimes \frac{\partial}{\partial v^i_A} \tag{45}$$

which concludes this part.

From (45) we see that when ∇ is the standard connection then $S^A_\nabla = S_A$.

B. Lagrangian formalism with nonstandard connections

Since in the Lagrangian formalism $(\theta_L)_A = \mathrm{d}L \circ S_A$, as we have the connection ∇, we now introduce the forms

$$(\theta_L)^A_\nabla = \mathrm{d}L \circ S^A_\nabla, \quad 1 \leqslant A \leqslant k,$$

which are locally given by

$$(\theta_L)^A_\nabla = \frac{\partial L}{\partial v^i_A}(\mathrm{d}q^i - \Gamma^i_B \, \mathrm{d}t^B), \quad 1 \leqslant A \leqslant k,$$

from (18) and (34) it is obvious that $(\theta_L)^A_\nabla = (FL)^* \theta^A_\nabla$. We define $(\omega_L)^A_\nabla = -d(\theta_L)^A_\nabla$ and of course $(\omega_L)^A_\nabla = (FL)^*(\omega^A_\nabla)$.

In local coordinates we have

$$(\omega_L)^A_\nabla = \mathrm{d}q^i \wedge d\left(\frac{\partial L}{\partial v^i_A} \right) + d\left(\Gamma^i_B \frac{\partial L}{\partial v^i_A} \right) \wedge \mathrm{d}t^B. \tag{46}$$

Consider now the *Lagrangian formalism* on $\mathbb{R}^k \times T^1_k Q$ replacing E_L by E^∇_L and ω^A_L by $(\omega_L)^A_\nabla$.

From a long, but straightforward, computation, similar to the proof of Proposition 4.3, we obtain the following proposition.

Proposition 5.1: Let $L: \mathbb{R}^k \times T^1_k Q \to \mathbb{R}$ *be a regular Lagrangian, and let* V_0 *be the vertical distribution of the bundle* $(\pi_{\mathbb{R}^k})_{1,0}: \mathbb{R}^k \times T^1_k Q \to \mathbb{R}^k \times Q$. *If* ∇ *is a flat connection then* $(\mathbb{R}^k \times T^1_k Q, \mathrm{d}t^A, (\omega_L)^A_\nabla, V_0)$ *is a k-cosymplectic manifold.*

■

The equations,

$$i_{(R_L)^\nabla_A} \mathrm{d}t^B = \delta^B_A, \quad i_{(R_L)^\nabla_A} (\omega_L)^B_\nabla = 0, \quad 1 \leqslant A, B \leqslant k, \tag{47}$$

define the Reeb vector fields on $\mathbb{R}^k \times T^1_k Q$ corresponding to the k-cosymplectic structure $(\mathrm{d}t^A, (\omega_L)^A_\nabla, V_0)$.

These equations are equivalent to

$$[(R_L)^\nabla_A)]^B = \delta^B_A, \quad [(R_L)^\nabla_A)]^i = \Gamma^i_A, \tag{48}$$

$$\frac{\partial^2 L}{\partial t^A \partial v^k_C} + \Gamma^j_A \frac{\partial^2 L}{\partial q^j \partial v^k_C} + \frac{\partial \Gamma^i_A}{\partial q^k} \frac{\partial L}{\partial v^i_C} + [(R_L)^\nabla_A]^i_B \frac{\partial^2 L}{\partial v^i_B \partial v^k_C} = 0, \tag{49}$$

and

$$\frac{\partial L}{\partial v^j_B} \left(\frac{\partial \Gamma^j_C}{\partial t^A} - \frac{\partial \Gamma^j_A}{\partial t^C} + \Gamma^i_A \frac{\partial \Gamma^j_C}{\partial q^i} - \Gamma^i_C \frac{\partial \Gamma^j_A}{\partial q^i} \right) = 0, \tag{50}$$

for all $1 \leqslant A, B, C \leqslant k$.

Since the curvature vanishes then the Reeb vector fields are locally given by

$$(R_L)^\nabla_A = \frac{\partial}{\partial t^A} + \Gamma^i_A \frac{\partial}{\partial q^i} + [(R_L)^\nabla_A]^i_B \frac{\partial}{\partial v^i_B}, \tag{51}$$

where the functions $[(R_L)^\nabla_A]^i_B$ satisfy Eq. (49).

Since L is regular, from (49) we can define, in a neighborhood of each point a k-vector field that satifies (47). Next, a global k-vector field $(R_L)^\nabla = ((R_L)^\nabla_1, \ldots, (R_L)^\nabla_k)$ can be constructed, which is a solution of (47), by using a partition of unity.

As in the standard Lagrangian formalism, by writing the equations (6) for the k-cosymplectic structure $(\mathrm{d}t^A, (\omega_L)^A_\nabla, V^0)$ and by replacing H by E^∇_L, we have

$$\mathrm{d}t^A(Y_B) = \delta^A_B,$$

$$\sum_{A=1}^k i_{Y_A} (\omega_L)^A_\nabla = \mathrm{d}E^\nabla_L - \sum_{A=1}^k (R_L)^\nabla_A (E^\nabla_L) \mathrm{d}t^A, \tag{52}$$

for some k-vector field $(Y_1, \ldots, Y_k)$.

Using the regularity of L, from (46), (49), (51), and (52) we deduce that if $(Y_1, \ldots, Y_k)$ is a solution of (52) then

$$[Y_A]^B = \delta^B_A, \quad [Y_A]^i = v^i_A, \quad \sum_{A=1}^k Y_A \left(\frac{\partial L}{\partial v^k_A} \right) = \frac{\partial L}{\partial q^k} \tag{53}$$

and

$$\frac{\partial L}{\partial v^i_A} \left(\frac{\partial \Gamma^i_C}{\partial t^A} + \Gamma^j_A \frac{\partial \Gamma^i_C}{\partial q^j} - \frac{\partial \Gamma^i_A}{\partial t^C} - \Gamma^j_C \frac{\partial \Gamma^i_A}{\partial q^j} \right) = 0. \tag{54}$$

Observe that Eqs. (22) coincide with Eqs. (53), thus since (54) holds we obtain the following proposition.

Proposition 5.2: Let $L:\mathbb{R}^k\times T^1_kQ\to\mathbb{R}$ *be a regular Lagrangian. If the curvature of the connection* ∇ *vanishes then the Lagrangian equations (21) and (52) have the same solutions.*

Remark: In the case $k=1$, Propositions 4.5 and 5.2 generalize the results obtained in Ref. 1.

VI. VARIATIONAL PRINCIPLES, EQUIVALENCIES AND ANOTHER CHARACTERIZATION OF THE ENERGY

In this section we prove that the energy E_L^∇ is the unique function establishing the equivalence between the variational principles associated to the Hamiltonian and Lagrangian formalisms.

A. Some other geometrical elements in $\mathbb{R}^k\times Q$

Definition 6.1: We introduce the following k-forms on $\mathbb{R}^k\times(T^1_k)^*Q$*:*

$$\theta_0=\sum_{A=1}^k\theta_0^A\wedge d^{k-1}t^A,\quad \theta_\nabla=\sum_{A=1}^k\theta_\nabla^A\wedge d^{k-1}t^A,\quad \eta_\nabla=\sum_{A=1}^k\eta_\nabla^A\wedge d^{k-1}t^A,$$

$$\Theta_L=\sum_{A=1}^k\Theta_L^A\wedge d^{k-1}t^A, \tag{55}$$

and

$$\Theta_0=\theta_0-Hd^kt,\quad \Theta_\nabla=\theta_\nabla-H^\nabla d^kt, \tag{56}$$

where $d^kt=\mathrm{d}t^1\wedge\cdots\wedge\mathrm{d}t^k$ *and* $d^{k-1}t^A=i_{\partial/\partial t^A}d^kt$.

The relationship between these forms is given in the following proposition.

Proposition 6.2:

(1) $\Theta_L=(FL)^*\Theta_0$.
(2) $\theta_0-\theta_\nabla=\eta_\nabla=(H-H^\nabla)d^kt$.
(3) $(FL)^*\theta_\nabla=\Theta_L+E_L^\nabla d^kt$.

Proof:

(1) Since $(FL)^*\theta_0^A=\theta_L^A$ we obtain

$$(FL)^*\Theta_0=(FL)^*(\theta_0-Hd^kt)=(FL)^*\left(\sum_{A=1}^k\theta_0^A\wedge d^{k-1}t^A-Hd^kt\right)$$
$$=\sum_{A=1}^k(FL)^*\theta_0^A\wedge d^{k-1}t^A-(FL)^*Hd^kt=\sum_{A=1}^k\theta_L^A\wedge d^{k-1}t^A-E_Ld^kt.$$

On the other hand, from (29),

$$\Theta_L=\sum_{A=1}^k\Theta_L^A\wedge d^{k-1}t^A=\sum_{A=1}^k\left(\theta_L^A+\left(\frac{1}{k}\delta_B^AL-v_B^i\frac{\partial L}{\partial v_A^i}\right)\mathrm{d}t^B\right)\wedge d^{k-1}t^A$$
$$=\sum_{A=1}^k\theta_L^A\wedge d^{k-1}t^A+\sum_{A=1}^k\left(\left(\frac{1}{k}\delta_B^AL-v_B^i\frac{\partial L}{\partial v_A^i}\right)\mathrm{d}t^B\right)\wedge d^{k-1}t^A=\sum_{A=1}^k\theta_L^A\wedge d^{k-1}t^A+Ld^kt-(CL)d^kt$$
$$=\sum_{A=1}^k\theta_L^A\wedge d^{k-1}t^A-E_Ld^kt.$$

(2) The first identity is a consequence of $\theta_0^A - \theta_\nabla^A = \eta_\nabla^A$. For the second identity, from (34) and (35), we have

$$\eta_\nabla = \sum_{A=1}^{k} \eta_\nabla^A \wedge d^{k-1}t^A = p_i^A \Gamma_B^i \mathrm{d}t^B \wedge d^{k-1}t^A = \left[\sum_{A=1}^{k} \eta_\nabla^A \left(\frac{\partial}{\partial t^A} \right) \right] d^k t = (H^\nabla - H) d^k t.$$

(3) From (2),

$$\begin{aligned}(FL)^* \theta_\nabla - \Theta_L &= (FL)^* \theta_\nabla - (FL)^* \Theta_0 = (FL)^* (\theta_\nabla - \Theta_0) \\ &= (FL)^* ((H^\nabla - H) d^k t + H d^k t) = (FL)^* (H^\nabla d^k t) = E_L^\nabla d^k t.\end{aligned}$$

■

B. Characterization of the energy by sections of the bundle $\pi_{\mathbb{R}^k}: \mathbb{R}^k \times Q \to \mathbb{R}^k$

Lemma 6.3: Let β be a k-form and let f be a function on $\mathbb{R}^k \times T_k^1 Q$. For each map $\phi: U \subset \mathbb{R}^k \to Q$, where U is a compact set, the following conditions are equivalent:

(i) $(\phi^{[1]})^* (f d^k t) = (\phi^{[1]})^* \beta$,
(ii) $\int_{\phi^{[1]}(U)} f d^k t = \int_{\phi^{[1]}(U)} \beta$.

Proof: Trivially (i) $\Rightarrow$ (ii) because

$$\int_{\phi^{[1]}(U)} f d^k t = \int_U (\phi^{[1]})^* (f d^k t).$$

Conversely, if (i) is not true, then there exists a function $\phi: U \subset \mathbb{R}^k \to Q$ such that $(\phi^{[1]})^* (f d^k t - \beta) \neq 0$ and hence there exist $s \in U$ and a closed neighborhood V of s such that, taking $\psi: V \to Q$ then

$$\int_{\psi^{[1]}(U)} (f d^k t - \beta) \neq 0,$$

so (ii) is false.

■

Proposition 6.4: The Lagrangian energy function introduced in Definition 3.5 is the only function on $\mathbb{R}^k \times T_k^1 Q$ satisfying the condition

$$(\phi^{[1]})^* (E_L^\nabla d^k t) = (\phi^{[1]})^* ((FL)^* \theta_\nabla - L d^k t)$$

for every function $\phi: U \to Q$.

Proof: Uniqueness. Let f and g be two functions verifying this condition. Obviously $0 = (\phi^{[1]})^* ((f-g) d^k t) = ((f-g) \circ \phi^{[1]}) d^k t$ then $0 = (f-g) \circ \phi^{[1]}(t) = (f-g)(j_t^1 \phi)$, and this implies that $f - g = 0$, because every point in $\mathbb{R}^k \times T_k^1 Q$ is in the image of some map $\phi^{[1]}$.

Existence: From (3) in Proposition 6.2, we obtain

$$\begin{aligned}(\phi^{[1]})^* ((FL)^* \theta_\nabla - L d^k t) &= (\phi^{[1]})^* (\Theta_L + E_L^\nabla d^k t - d^k t) \\ &= (\phi^{[1]})^* \left(\sum_{A=1}^{k} \left(\mathrm{d}L \circ S_{\mathrm{d}t^A} + \frac{1}{k} L \, \mathrm{d}t^A \right) \wedge d^{k-1}t^A + E_L^\nabla d^k t - L d^k t \right) \\ &= (\phi^{[1]})^* \left(\sum_{A=1}^{k} (\mathrm{d}L \circ S_{\mathrm{d}t^A} \wedge d^{k-1}t^A) \right) + (\phi^{[1]})^* (E_L^\nabla d^k t) = (\phi^{[1]})^* (E_L^\nabla d^k t)\end{aligned}$$

because

$$(\phi^{[1]})^*\left(\sum_{A=1}^{k}(\mathrm{d}L\circ S_{\mathrm{d}t^A}\wedge d^{k-1}t^A)\right)=0.$$

In fact, from (26) we have

$$\mathrm{d}L\circ S_{\mathrm{d}t^A}=\frac{\partial L}{\partial v_A^i}(v_B^i\,\mathrm{d}t^B-\mathrm{d}q^i)$$

then

$$\sum_{A=1}^{k}(\mathrm{d}L\circ S_{\mathrm{d}t^A}\wedge d^{k-1}t^A)=\sum_{A=1}^{k}\frac{\partial L}{\partial v_A^i}(v_B^i\mathrm{d}t^B-\mathrm{d}q^i)\wedge d^{k-1}t^A$$

but

$$\begin{aligned}(\phi^{[1]})^*\left(\sum_{A=1}^{k}\frac{\partial L}{\partial v_A^i}(v_B^i\,\mathrm{d}t^B-\mathrm{d}q^i)\wedge d^{k-1}t^A\right)&=\sum_{A=1}^{k}\left(\frac{\partial L}{\partial v_A^i}\circ\phi^{[1]}\right)[(v_B^i\circ\phi^{[1]})d(t^B\circ\phi^{[1]})\\&\quad-d(q^i\circ\phi^{[1]})]\wedge d^{k-1}(t^A\circ\phi^{[1]})\\&=\sum_{A=1}^{k}\left(\frac{\partial L}{\partial v_A^i}\circ\phi^{[1]}\right)\left[\frac{\partial\phi^i}{\partial t^B}\mathrm{d}t^B-\mathrm{d}\phi^i\right]\wedge d^{k-1}t^A=0.\end{aligned}$$

■

From Proposition 6.4 we deduce that for every $\phi: U\subset\mathbb{R}^k\to Q$ with U compact, we have

$$\int_{\phi^{[1]}(U)}E_L^\nabla d^kt=\int_{\phi^{[1]}(U)}(FL)^*\theta_\nabla-Ld^kt$$

and therefore, from Proposition 6.2, we obtain

$$\begin{aligned}\int_{\phi^{[1]}(U)}Ld^kt&=\int_{\phi^{[1]}(U)}(FL)^*\theta_\nabla-E_L^\nabla d^kt\\&=\int_{\phi^{[1]}(U)}(FL)^*(\theta_\nabla-H^\nabla d^kt)=\int_{\phi^{[1]}(U)}(FL)^*(\theta_0-Hd^kt)\\&=\int_{\phi^{[1]}(U)}(FL)^*\Theta_0=\int_{FL\circ\phi^{[1]}(U)}\Theta_0.\end{aligned}$$

This equality shows the equivalence between the Hamilton principle of minimal action and the Hamilton-Jacobi principle, see later (57) and (58). Therefore, taking into account Proposition 6.4, we must conclude that the energy E_L^∇ is the only function that performs the equivalence between both variational principles which now we recall.

C. The Hamilton principle of minimal action

Each section of $\pi_{\mathbb{R}^k}:\mathbb{R}^k\times Q\to\mathbb{R}^k$ can be identified as a map $\phi:\mathbb{R}^k\to Q$. Denote its first prolongation by $\phi^{[1]}:\mathbb{R}^k\to\mathbb{R}^k\times T_k^1Q$. With this in mind, we can define the following.

Definition 6.5: Let $C_c^\infty(\mathbb{R}^k,Q)$ be the set of compact support maps from $\mathbb{R}^k$ to Q. This set can be identified with $\Gamma_c(\mathbb{R}^k,\mathbb{R}^k\times Q)$, the set of compact support sections of $\pi_{\mathbb{R}^k}$. Consider the map

$$\mathbb{L}:\ C_c^\infty(\mathbb{R}^k,Q)\equiv\Gamma_c(\mathbb{R}^k,\mathbb{R}^k\times Q)\to\mathbb{R},$$

$$\phi \equiv (Id_{\mathbb{R}^k}, \phi) \mapsto \int_{\mathbb{R}^k} (\phi^{[1]})^*(Ld^k t). \tag{57}$$

The variational problem posed by the Lagrangian function L is the problem of searching for the critical or stationary sections of the functional $\mathbb{L}$.

Remark: The sections must be stationary with respect to the variations of $(Id_{\mathbb{R}^k}, \phi)$ given by $(Id_{\mathbb{R}^k}, \phi)_s = \tau_s \circ (Id_{\mathbb{R}^k}, \phi)$ [because $\tau_s(t^A, q^i) = (t^A, \bar{\tau}^i(s,t,q))$], or equivalently $\phi_s = \pi_Q \circ \tau_s \circ (Id_{\mathbb{R}^k}, \phi)$, where $\{\tau_s\}$ is a local flow of any vector $Z \in \mathfrak{X}(\mathbb{R}^k \times Q)$ which is $\pi_{\mathbb{R}^k}$ vertical, that is

$$\frac{d}{ds}_{|_{s=0}} \int_{\mathbb{R}^k} (\phi_s^{[1]})^*(Ld^k t) = 0.$$

The proof of the following Proposition can be found in Ref. 4 for an arbitrary fiber bundle $\pi: E \to M$.

Proposition 6.6: Let L be a Lagrangian function. The following assertions on a map $\phi \in C_c^\infty(\mathbb{R}^k, \mathbb{R}^k \times Q)$ *are equivalent:*

(1) ϕ *is a critical section for* $\mathbb{L}$,
(2) $\phi^{[1]}$ *satisfy the Euler-Lagrange equations*,

$$\sum_{A=1}^{k} \frac{d}{\mathrm{d}t^A}\left(\frac{\partial L}{\partial v_A^i}_{|\phi^{[1]}(t)}\right) - \frac{\partial L}{\partial q^i}_{|\phi^{[1]}(t)} = 0, \quad v_A^i(\phi^{[1]}(t)) = \frac{\partial \phi^i}{\partial t^A}(t)$$

in any natural local coordinate system.

D. The Hamilton-Jacobi principle

Definition 6.7: Let $\Phi: \mathbb{R}^k \times Q \to \mathbb{R}^k \times Q$ *be a bundle isomorphism and* $\Phi_Q: Q \to Q$ *the induced diffeomorphism in Q. The prolongation of* Φ *to* $\mathbb{R}^k \times (T_k^1)^* Q$ *is the diffeomorphism*

$$j^{1*}\Phi\colon \mathbb{R}^k \times (T_k^1)^* Q \equiv J^1 \pi_Q \to \mathbb{R}^k \times (T_k^1)^* Q \equiv J^1 \pi_Q,$$

$$j_q^1 \gamma \to j^{1*}\Phi(j_q^1 \gamma) = j^1_{\Phi_Q(q)}(\Phi \circ \gamma \circ \Phi_Q^{-1}).$$

Definition 6.8: Let $\Gamma_c(\mathbb{R}^k, \mathbb{R}^k \times (T_k^1)^* Q)$ *be the set of compact support sections of*

$$\mathbb{R}^k \times (T_k^1)^* Q \equiv J^1 \pi_Q \xrightarrow{(\pi_Q)_{1,0}} \mathbb{R}^k \times Q \xrightarrow{\pi_{\mathbb{R}^k}} \mathbb{R}^k$$

and consider the map

$$\mathbb{H}\colon \Gamma_c(\mathbb{R}^k, \mathbb{R}^k \times (T_k^1)^* Q) \to \mathbb{R},$$

$$\psi \mapsto \int_{\mathbb{R}^k} \psi^* \Theta_0. \tag{58}$$

The associated variational problem is the search for the critical or stationary sections of the functional $\mathbb{H}$, *with respect to the variations of* ψ *given by* $\psi_s = j^{1*}\sigma_s \circ \psi$, *where* $\{\sigma_s\}$ *is a local flow of any vector field* $Z \in \mathfrak{X}(\mathbb{R}^k \times Q)$ *which is* $\pi_{\mathbb{R}^k}$ *vertical. That is*

$$\frac{d}{\mathrm{d}s}_{|_{s=0}} \int_{\mathbb{R}^k} \psi_s^* \Theta_0 = 0.$$

The proof of the following Proposition can be found in Ref. 13 for an arbitrary fiber bundle $\pi: E \to M$.

Proposition 6.9: The following assertions on a section $\phi \in \Gamma_c(\mathbb{R}^k, \mathbb{R}^k \times (T^1_k)^* Q)$ *are equivalent.*

(1) ϕ *is a critical section for* $\mathbb{H}$.
(2) ϕ *satisfy, in any natural local coordinate system, the Hamilton-De Donder-Weyl equations of the Hamiltonian formalism*,

$$\frac{\partial q^i}{\partial t^A}_{|\psi} = \frac{\partial H}{\partial p_i^A}_{|\phi(t)}, \quad \frac{\partial p_i^A}{\partial t^A}_{|\phi(t)} = -\frac{\partial H}{\partial q^i}_{|\phi(t)},$$

where H is the Hamiltonian function. (Also see Refs. 14–19.)

(Received 15 July 2005; accepted 7 October 2005; published online 15 December 2005)

The zero-entropy-density conjecture states that the entropy density defined as $s := \lim_{N\to\infty} S_N/N$ vanishes for all translation-invariant pure states on the spin chain. Or equivalently, S_N, the von Neumann entropy of such a state restricted to N consecutive spins, is sublinear. In this paper it is proved that this conjecture cannot be sharpened, i.e., translation-invariant states give rise to arbitrary fast sublinear entropy growth. The proof is constructive, and is based on a class of states derived from quasifree states on a CAR algebra. The question whether the entropy growth of pure quasifree states can be arbitrary fast sublinear was first raised by Fannes *et al.* [J. Math. Phys. **44**, 6005 (2003)]. In addition to the main theorem it is also shown that the entropy asymptotics of all pure shift-invariant nontrivial quasifree states is at least logarithmic. © *2005 American Institute of Physics.*

I. INTRODUCTION

Quantum spin chains belong to the most studied models of quantum statistical mechanics.[1] Still, only for a few types of models have the thermal and ground state structures been determined. This is mainly the consequence of the complicated correlations that can appear in quantum states. These strong correlations can even be present in pure states, while classical pure states can only have a trivial product state structure. Unlike the classical case, the restrictions of pure states on the quantum spin chain to local subsystems are typically mixed states. This type of correlation between subsystems is commonly referred to as entanglement. The von Neumann entropy, defined as $S := -\mathrm{Tr}\,\rho \log \rho$, is a natural measure of the nonpurity of the restricted density matrix ρ, thus it is a very useful quantity in the description of entanglement.

The entropy of a restricted density matrix is also a basic measure when mixed states are treated, however, in this case it cannot be interpreted as a measure of entanglement. Let S_N denote the von Neumann entropy of a translation-invariant state restricted to N consecutive spins. The entropy density $s := \lim_{N\to\infty} S_N/N$ is considered to quantify the "strong nonpurity" of the entire mixed state, and it plays a central role in the characterization of Gibbs states.[1] A natural and long-standing conjecture is that the entropy density vanishes for all translation-invariant pure states on a quantum spin chain, i.e., for such states, S_N is sublinear. In the present paper we will prove that if this zero-entropy-density conjecture is true, then it is sharp in the sense that for any sublinear function f_N ($\lim_{N\to\infty} f_N/N=0$), there exists a translation-invariant state so that $S_N \geqslant f_N$, for every sufficiently large N. This has already been conjectured by Fannes, Haegeman, and Mosonyi in Ref. 2. Moreover, they proved that any sublinear power function can be exceeded by the entropy growth of an appropriate pure translation-invariant state.

It also should be mentioned that there is a revived interest in studying entropy asymptotics for two other reasons. First, S_N seems to be a good indicator of quantum criticality. Several ground

[a)]Electronic mail: farkas@uchicago.edu
[b)]Electronic mail: cimbi@rmki.kfki.hu

states of Hamiltonians with local interactions were studied, and in these models, S_N was found to be bounded for noncritical systems, while for critical systems, it turned out to diverge logarithmically.[3–6] The prefactor of this logarithmic growth was argued to be one-third of the central charge.[7] Also higher dimensional lattice models have been investigated in this respect.[8–11] Second, entropy is supposed to play an important role in the quantification of the "essential subspace" of a restricted density matrix. The possibility of compressing the restricted density matrix from its full dimension to a much smaller subspace without loss of much information is the starting point of the DMRG calculations.[12] For ergodic translation-invariant states, with nonvanishing entropy density s, the density matrix pertaining to N consecutive spins, ρ_N, is essentially concentrated on a subspace of dimension proportional to $\exp(Ns)$.[13] In more general situations, numerical calculations suggest that the dimension of the "essential subspace" of ρ_N is proportional to $\exp(S_N)$.[14] This could lead to a very efficient compression of states with bounded or slowly diverging entropy asymptotics.

In the present paper we give a constructive proof of the sharpness of the zero-entropy-density conjecture. The states that are studied are translation-invariant pure states on the spin chain derived from quasifree states on the CAR algebra. In Sec. II we recapitulate the construction of such states in order to be self-contained. In Sec. III we prove our main theorem. The argument is based on the approach to quasifree states developed in Ref. 2. Finally, we include a proof of the statement that the entropy growth for all nontrivial gauge-invariant quasifree states are bounded from below by a logarithmic growth.

II. QUASIFREE STATES ON THE SPIN CHAIN

A. The Araki-Jordan-Wigner construction

The algebra of observables of a quantum spin chain (more precisely, spin $\frac{1}{2}$ chain) is the UHF algebra

$$\mathcal{M} := \bigotimes_{k=-\infty}^{+\infty} M_2,$$

where M_2 denotes the algebra of 2×2 matrices. Let σ_a^k $(a=1,2,3;\ k\in\mathbb{Z})$ denote the Pauli matrices embedded into the kth factor of $\mathcal{M}$. They satisfy the well-known relations:

$$\sigma_a^k\sigma_b^l = \sigma_b^l\sigma_a^k, \quad \text{when } k\neq l,$$

$$\sigma_a^l\sigma_b^l = \mathrm{i}\varepsilon_{abc}\sigma_c^l + \delta_{ab}\mathbb{1}.$$

The Pauli matrices and $\mathbb{1}$ generate $\mathcal{M}$. The translation automorphism τ on $\mathcal{M}$ is defined by $\tau(\sigma_a^k)=\sigma_a^{k+1}$.

The states we are investigating in this paper are translation-invariant pure states on $\mathcal{M}$ derived from quasifree states of a fermion chain. The C^* algebra describing a fermion chain is the CAR algebra corresponding to the one-particle Hilbert space $\ell^2(\mathbb{Z})$, i.e., it is the C^* algebra generated by $\mathbb{1}$ and the operators $\{c_k | k\in\mathbb{Z}\}$ satisfying the canonical anticommutation relations:

$$c_k c_l^* + c_l^* c_k = \delta_{k,l}\mathbb{1}, \quad c_k c_l + c_l c_k = 0.$$

Denote this C^* algebra by $\mathcal{A}$. The translation automorphism γ is defined by $\gamma(c_k)=c_{k+1}$.

The C^* algebras $\mathcal{M}$ and $\mathcal{A}$ are isomorphic. However, there exists no isomorphism $\iota:\mathcal{M}\to\mathcal{A}$ that satisfies the property $\iota\circ\tau=\gamma\circ\iota$. This is clear if we note that $(\mathcal{M},\tau)$ is asymptotically Abelian, while $(\mathcal{A},\gamma)$ is not. This intertwining property is needed to derive the translation invariance of a state $\omega\circ\iota$ on $\mathcal{M}$ from that of ω on $\mathcal{A}$. This problem can be circumvented by Araki's construction.[15] In this section we will present a modified but equivalent formulation of this construction.

First, let us introduce the parity automorphism π on $\mathcal{A}$. It is defined by $\pi(c_k)=-c_k$. The elements of $\mathcal{A}_+ := \{a \in \mathcal{A} \,|\, \pi(a)=a\}$ are called even, while those of $\mathcal{A}_- := \{a \in \mathcal{A} \,|\, \pi(a)=-a\}$ are called odd. Any element $a \in \mathcal{A}$ can uniquely be written in the form $a=a_++a_-$, where $a_+ \in \mathcal{A}_+$, and $a_- \in \mathcal{A}_-$. Thus, $\mathcal{A}=\mathcal{A}_++\mathcal{A}_-$.

Second, let $\mathcal{M}_+$ be the C^* subalgebra of $\mathcal{M}$ generated by $\mathbb{1}$, σ_3^k, and $\sigma_1^k\sigma_1^l$ $(k,l \in \mathbb{Z})$. $\mathcal{M}_+$ is isomorphic to $\mathcal{A}_+$, an explicit isomorphism α is given by the restricted Jordan-Wigner transformation:

$$\alpha(\sigma_3^k) := 2c_k^*c_k - \mathbb{1},$$

$$\alpha(\sigma_1^k\sigma_1^l) := -\prod_{m=k}^{l-1}(2c_m^*c_m - \mathbb{1})(c_k^* + c_k)(c_l^* + c_l) \quad \text{when } k < l.$$

Since $\mathcal{M}_+$ and $\mathcal{A}_+$ are invariant under the translations, τ and γ can be restricted to $\mathcal{M}_+$ and $\mathcal{A}_+$, respectively. Let us denote these restrictions by τ_+ and γ_+. Although there is no isomorphism that intertwines the translations on $\mathcal{M}$ and $\mathcal{A}$, α is an isomorphism that intertwines the translations on the subalgebras $\mathcal{M}_+$ and $\mathcal{A}_+$: $\alpha\circ\tau_+=\gamma_+\circ\alpha$.

Now, let ω_+ be the restriction of a state ω on $\mathcal{A}$ to $\mathcal{A}_+$. If ω is a translation-invariant state, i.e., $\omega\circ\gamma=\omega$, then $\omega_+\circ\alpha$, which is a state on $\mathcal{M}_+$, is invariant under τ_+. The state $\omega_+\circ\alpha$ can be extended to a state $\widetilde{\omega}$ on $\mathcal{M}$ by $\widetilde{\omega}(a)=\widetilde{\omega}(a_++a_-) := \omega_+(\alpha(a_+))$, where $a_+ \in \mathcal{A}_+$, and $a_- \in \mathcal{A}_-$. This way a translation-invariant state $\widetilde{\omega}$ on $\mathcal{M}$ is obtained. Moreover, if ω is an even state, i.e., $\omega\circ\pi=\omega$, then $\widetilde{\omega}$ is pure if and only if ω is pure.[2]

To summarize, a translation intertwining automorphism α has been given not between the algebras $\mathcal{M}$ and $\mathcal{A}$, but between their appropriate subalgebras $\mathcal{M}_+$ and $\mathcal{A}_+$. Any translation-invariant state on $\mathcal{M}_+$ can be straightforwardly extended to a translation-invariant state on $\mathcal{M}$. Thus the isomorphism α makes it possible to transport the translation-invariant states from $\mathcal{A}$ to $\mathcal{M}$.

B. Quasifree states on CAR algebras

Following Araki's construction presented in Sec. II A, a class of states will be derived from quasifree states on the CAR algebra $\mathcal{A}$. Here we will shortly recapitulate the most important definitions and facts concerning these states, more details and the proofs of the statements can be found in Refs. 1 and 16.

Let Q be an operator on the Hilbert space $\ell^2(\mathbb{Z})$, $0 \leqslant Q \leqslant \mathbb{1}$. Let $Q_{ij} := \langle \delta_i, Q\delta_j \rangle$ be the matrix elements of Q in the standard basis $\{\delta_k \,|\, k \in \mathbb{Z}\}$ of $\ell^2(\mathbb{Z})$, where δ_k is the characteristic function of the number k. The (gauge-invariant) quasifree state ω_Q on $\mathcal{A}$ is defined through the following formula:

$$\omega_Q(c_{i_1}^* \ldots c_{i_m}^* c_{j_n} \ldots c_{j_1}) = \delta_{m,n}\det([Q_{i_k,j_l}]_{k,l=1}^n).$$

The operator Q is called the symbol of the state. Quasifree states are by definition even states.

A quasifree state ω_Q is translation-invariant if and only if its symbol Q is a Toeplitz operator in the basis δ_k, i.e., there exists a sequence $(q_k)_{k\in\mathbb{Z}}$ such that $Q_{kl}=\langle \delta_k, Q\delta_l \rangle = q_{k-l}$. Let us introduce the Fourier transform:

$$\tilde{q}(\theta) := \sum_{k\in\mathbb{Z}} q_k e^{i2\pi k\theta}, \quad \text{where } \theta \in [0,1).$$

The function $\tilde{q}$ satisfies $0 \leqslant \tilde{q}(\theta) \leqslant 1$ almost everywhere. A translation-invariant quasifree state ω_Q is pure if and only if the Fourier transform $\tilde{q}$ is a characteristic function, i.e., there exists a measurable set $K \subset [0,1)$ such that $\tilde{q}(\theta)=\chi_K(\theta)$.

Now, applying the Araki-Jordan-Wigner construction to a translation-invariant quasifree state ω_Q, one obtains a translation-invariant state $\widetilde{\omega}_Q$ on the spin chain algebra $\mathcal{M}$. Since quasifree states are even, the state $\widetilde{\omega}_Q$ is pure if and only if the corresponding quasifree state ω_Q is also pure.

Let ρ_N denote the reduced density matrix obtained by restricting the state $\widetilde{\omega}_Q$ to an interval of N spins. The von Neumann entropy of the restricted state is defined as $S_N := -\mathrm{Tr}\,\rho_N \log \rho_N$. An explicit formula of this entropy is known for quasifree states:

$$S_N = -\mathrm{Tr}(Q_N \log Q_N + (\mathbb{1} - Q_N)\log(\mathbb{1} - Q_N)), \tag{1}$$

where Q_N is the restriction of Q to the N-dimensional space spanned by the set $\{\delta_k | 0 \leqslant k \leqslant N-1\}$.

On the basis of the Szegő theorem one can prove that the entropy density $s := \lim_{N\to\infty} S_N/N$ of pure translation-invariant quasifree states vanishes.[2] In Sec. III we will prove that this statement is sharp in the sense that for any f_N sublinear function there is a quasifree state for which $S_N \geqslant f_N$ for sufficiently large N.

III. QUASIFREE STATES GIVE RISE TO ARBITRARY FAST SUBLINEAR ENTROPY GROWTH

An explicit formula of the entropy function S_N for quasifree states was given in Sec. II by Eq. (1). In order to simplify further computations, we work with a quadratic lower bound of S_N introduced in Ref. 2:

$$q_N := \mathrm{Tr}\, Q_N(\mathbb{1} - Q_N).$$

That q_N is a lower bound of $S_N = -\mathrm{Tr}(Q_N \log Q_N + (\mathbb{1}-Q_N)\log(\mathbb{1}-Q_N))$ can be proved by the aid of the inequality $x(1-x) \leqslant -x \ln x - (1-x)\ln(1-x)$, which holds for $0 \leqslant x \leqslant 1$.

As derived in Ref. 2, q_N can be rewritten in the form:

$$q_N = \int_0^1 \mathrm{d}\phi \frac{\sin^2 N\pi\phi}{\sin^2 \pi\phi} \Lambda_K(\phi), \tag{2}$$

where K denotes the measurable set K that characterizes the symbol Q, and Λ_K is the function:

$$\Lambda_K(\phi) = |(K + \phi) \setminus K|.$$

$|\cdot|$ denotes the Lebesgue measure. By reducing the region of the integration in (2) to $[0, 1/(2N)]$, and substituting the trigonometric factor with its lower bound on this restricted region, we obtain a lower estimate for q_N:

$$q_N \geqslant \frac{4N^2}{\pi^2} \int_0^{1/2N} \Lambda_K(\phi)\mathrm{d}\phi. \tag{3}$$

This is the starting point in the proof of the following proposition.

Theorem: *For any sublinear function $f: \mathbb{N} \to \mathbb{R}^+$, there exists a pure translation-invariant quasifree state for which S_N is bounded from below by f_N, that is $S_N \geqslant f_N$ for every sufficiently large N.*

Proof: By (3), the problem has been reduced to showing the existence of a set $K \subset [0,1)$ for which the right-hand side of (3) grows not slower than the given f_N as N goes to infinity.

The construction of K is based on two non-negative sequences: a sequence of integers $(n_i)_{i\in\mathbb{N}}$ and another one of real numbers $(\ell_i)_{i\in\mathbb{N}}$, where $\ell_i \geqslant 2\ell_{i+1}$. Let K be the union of infinitely many disjoint intervals, the end points of which are determined by these two sequences as follows:

$$K = \bigcup_{i\in\mathbb{N}} \bigcup_{k=1}^{n_i} I_i^k, \quad I_i^k = [a_i^k, b_i^k], \quad b_i^k - a_i^k = \ell_i,$$

$$a_0^1 = 0, \quad a_i^1 = b_{i-1}^{n_{i-1}} + \ell_{i-1} \quad \text{if } i > 0, \tag{4}$$

$$a_i^k = b_i^{k-1} + \ell_i \quad \text{if } k > 1.$$

The $(\ell_i)_{i\in\mathbb{N}}$ and $(n_i)_{i\in\mathbb{N}}$ are chosen so that the above-constructed set K is bounded, and for convenience, we suppose additionally that $n_i\ell_i$ is monotonically decreasing, and

$$\sum_{i=0}^{\infty} n_i\ell_i < \frac{1}{4}.$$

Thus $K\subset[0,1/2]$. With construction (4), Λ_K takes the form

$$\Lambda_K(\phi) = \sum_{i=0}^{\infty}\sum_{k=1}^{n_i} |(I_i^k + \phi)\setminus K| \geqslant \sum_{i=i_\phi}^{\infty}\sum_{k=1}^{n_i} |(I_i^k + \phi)\setminus K|,$$

where i_ϕ is the smallest index for which $2n_i\ell_i < \phi$ for all $i \geqslant i_\phi$. Each translated interval $(I_i^k+\phi)$ with $i \geqslant i_\phi$ is situated in a region where the original intervals in the construction of K and the gaps between them are not longer than $\ell_i/2$ (or where K has no point at all). For this reason $|(I_i^k+\phi)\setminus K| \geqslant \ell_i/3$ for every term in the last summation. Therefore we obtain

$$\Lambda_K(\phi) \geqslant \frac{1}{3}\sum_{i=i_\phi}^{\infty} n_i\ell_i.$$

Now, let f_N be an arbitrary sublinear function, i.e., $\lim_{N\to\infty} f_N/N = 0$. Obviously, there exists a monotonically increasing continuously differentiable function $g:[0,1/2]\to\mathbb{R}^+$ with the properties:

$$g(0) = 0, \quad \frac{\pi^2}{2} g\left(\frac{1}{2N}\right) \geqslant \frac{f_N}{N}.$$

Let us define function h as $h(x) = (\mathrm{d}/\mathrm{d}x)(xg(x))$. h is continuous, and $h(0)=0$. We suppose that h is strictly monotonically increasing in the neighborhood of zero. If not, we choose a continuous, strictly monotonically increasing $\hat{h}$ such that $\hat{h} \geqslant h$, and $\hat{h}(0)=0$. (A possible choice is $\hat{h}(x) := \max\{h(y)\,|\,y\in[0,x]\}+x$). This $\hat{h}$ can be derived from a $\hat{g}$ for which $\hat{g}\geqslant g$, and then the argument can be continued with $\hat{h}$ instead of h.

The next step is to specify $(n_i)_{i\in\mathbb{N}}$ and $(\ell_i)_{i\in\mathbb{N}}$ so that

$$\Lambda_K(\phi) \geqslant \frac{1}{3}\sum_{i=i_\phi}^{\infty} n_i\ell_i \geqslant h(\phi) \tag{5}$$

should hold for sufficiently small ϕ.

Let s_i be the solution of the following recursive equation, starting from a given s_0 $(0 < s_0 < 1/2)$:

$$h(6(s_i - s_{i+1})) = s_{i+1}. \tag{6}$$

It is clear from the required properties of h that there is a solution that satisfies the equalities $0 \leqslant s_{i+1} \leqslant s_i$ for every i. Since $(s_i)_{i\in\mathbb{N}}$ is bounded from below and monotonically decreasing, it has a limit at infinity. Suppose that this limit differs from zero, say it is $s_\infty > 0$. Taking an arbitrary small $\epsilon > 0$, there is an i for which $\epsilon > 6(s_i - s_{i+1})$, and we find that $h(\epsilon) \geqslant h(6(s_i - s_{i+1})) = s_{i+1} \geqslant s_\infty$ for any ϵ, so $h(0) \geqslant s_\infty$ in contradiction with $h(0)=0$. Thus $\lim_{i\to\infty} s_i = 0$.

Now we are ready to specify the values of ℓ_i and n_i by

$$s_i = \frac{1}{3}\sum_{j=i}^{\infty} n_j \ell_j. \tag{7}$$

Considering that $(s_i)_{i\in\mathbb{N}}$ is a monotonically decreasing sequence tending to zero, these equalities can be satisfied by some series $(n_i)_{i\in\mathbb{N}}$ and $(\ell_i)_{i\in\mathbb{N}}$. Starting with a particular ℓ_i, we can always determine the next term by choosing some $\ell_{i+1} \leqslant \ell_i/2$. The only restriction on the choice of ℓ_i is that $s_i - s_{i+1}$ should be an integral multiple of ℓ_i. This requirement can undoubtedly be met, and then $s_i - s_{i+1} = \frac{1}{3} n_i \ell_i$ yields the value of n_i. The inclusion $K \subset [0, 1/2]$ can be assured by choosing sufficiently small s_0.

Recall that $(n_i \ell_i)_{i\in\mathbb{N}}$ has been required to be monotonic. We can easily convince ourselves that $(n_i \ell_i)_{i\in\mathbb{N}}$ constructed from $(s_i)_{i\in\mathbb{N}}$ has this property. Indeed, it follows immediately from the strict monotonicity of h: $h(2n_i\ell_i) = h(6(s_i - s_{i+1})) = s_{i+1} \leqslant s_i = h(6(s_{i-1} - s_i)) = h(2n_{i-1}\ell_{i-1})$.

Monotonicity of $(s_i)_{i\in\mathbb{N}}$ and its behavior at infinity entail that for any ϕ below a certain bound, there is an index i for which $6(s_i - s_{i+1}) \leqslant \phi \leqslant 6(s_{i-1} - s_i)$. Notice that this index is nothing but i_ϕ. Thus putting together (6) and (7), we arrive at the desired estimate (5). Consequently, for sufficiently large N, in the region of the integration in (3), $\Lambda_K(\phi) \geqslant h(\phi)$ holds. Performing the integration in (3) completes the proof:

$$S_N \geqslant q_N \geqslant \frac{4N^2}{\pi^2}\int_0^{1/2N} \Lambda_K(\phi)\mathrm{d}\phi \geqslant \frac{4N^2}{\pi^2}\int_0^{1/2N} h(\phi)\mathrm{d}\phi = \frac{4N^2}{\pi^2}\int_0^{1/2N} \frac{\mathrm{d}}{\mathrm{d}\phi}(\phi g(\phi))\mathrm{d}\phi = \frac{2N}{\pi^2} g\left(\frac{1}{2N}\right) \geqslant f_N.$$

□

We have just shown that pure translation-invariant quasifree states give rise to arbitrary fast sublinear entropy growth. In the trivial cases, $|K| = 0$ or $|K| = 1$, the entropy is identically zero. The question naturally arises whether it is possible to achieve arbitrary slow nonbounded entropy growth by such states.

Theorem: *Apart from the trivial cases*, *pure* (*gauge- and*) *translation-invariant quasifree states give at least logarithmic entropy growth.*

Proof: It has been shown in Ref. 2 that if

$$\Lambda_K(\phi) \geqslant c\phi \quad \text{for some } c > 0 \tag{8}$$

in the vicinity of zero, then S_N is bounded from below by a logarithmic growth. We will prove that (8) holds for any measurable set $K \subset [0, 1)$ (apart from the trivial cases, where $\Lambda_K(\phi) = 0$).

It is known from the Lebesgue density theorem that for any measurable set K, $|K| = |K^d|$ holds, where K^d denotes the set of the density points of K:

$$K^d = \left\{ x \in K \,\middle|\, \lim_{\delta\to 0} \frac{(x-\delta, x+\delta) \cap K}{2\delta} = 1 \right\}.$$

It can be inferred from this theorem that for any K of positive measure, there is such a point $x \in K$ that

$$\forall \epsilon > 0\text{: } \exists\, \delta > 0 \text{ so that for every interval } I \text{ that satisfies } x \in I, \text{ and } |I| < \delta,\ |K \cap I| > (1-\epsilon)|I|. \tag{9}$$

Disregarding the trivial cases, the measure of K^c (the complement of K), is also positive: $|K^c| > 0$. It means that K^c also has a point that satisfies (9). We denote this point by y. For a given ϵ, we can choose a common δ to x and y. Let I be an interval shorter than this δ: $|I| < \delta$, and $x \in I$. There is an integer n such that $y \in (I + n|I|)$. The set $(I + n|I|)$ can be assured to be disjoint from I by choosing a sufficiently small δ. The following inequalities hold for I:

$$|K \cap I| > (1-\epsilon)|I|, \quad |K^c \cap (I+n|I|)| > (1-\epsilon)|I|. \tag{10}$$

The following estimate, though seemingly weak, is the core of the proof:

$$\Lambda_K(|I|) \geqslant \left| \left(\bigcup_{k=0}^{n-1} (I+k|I|) \cap (K+|I|) \right) \setminus K \right| = \sum_{k=0}^{n-1} |((I+k|I|) \cap (K+|I|)) \setminus ((I+(k+1)|I|) \cap K)|$$

$$\geqslant \sum_{k=0}^{n-1} |((I+k|I|) \cap (K+|I|))| - |(I+(k+1)|I|) \cap K| = |I \cap K| - |(I+n|I|) \cap K|.$$

Having a look at (10), we obtain that for arbitrary positive ϵ,

$$\Lambda_K(|I|) \geqslant (1-2\epsilon)|I|,$$

if $|I|$ is sufficiently small. This inequality entails (8). □

IV. CONCLUSION AND OUTLOOK

We have shown that for any sublinear growth f_N, there exist shift-invariant pure states that have faster entropy growth than f_N. However, the question if the entropy asymptotics of any translation-invariant pure state is sublinear, that is whether they have a vanishing entropy density, is still unsolved. It is difficult to address this problem generally. One can instead take into consideration only special classes of translation-invariant states. For instance, finitely correlated states turn out to lead to bounded entropy growth.[17] A further step could be to explore the entropy growth and the entropy density of pure algebraic states, which are the generalizations of the finitely correlated states.

Another question that can be raised is whether there exists for each sublinear growth f_N a state with local von Neumann entropies S_N such that $\lim_{N\to\infty} S_N/f_N = c$, where $c>0$. As we can learn from the last proposition in Sec. III, in the case of pure translation-invariant quasifree state the answer is negative.

In the case of local Hamiltonians only ground states with bounded or logarithmic entropy growth have been found. From a mathematical point of view, our construction is not sophisticated. Any given sublinear asymptotics is exceedable by the entropy growth of a state characterized by a set of rather simple structure: a set built from countably many intervals. Nevertheless, it is still an open question whether these asymptotics can be physically realized, or entropy asymptotics stronger than logarithmic (or some other sublinear) function can never occur for ground states in the presence of only local interactions.

Extensive ground state entropy in supersymmetric lattice models

Hendrik van Eerten[a)]

(Received 22 September 2005; accepted 19 October 2005; published online 20 December 2005)

We present the result of calculations of the Witten index for a supersymmetric lattice model on lattices of various type and size. Because the model remains supersymmetric at finite lattice size, the Witten index can be calculated using row-to-row transfer matrices and the calculations are similar to calculations of the partition function at negative activity -1. The Witten index provides a lower bound on the number of ground states. We find strong numerical evidence that the Witten index grows exponentially with the number of sites of the lattice, implying that the model has extensive entropy in the ground state. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2142836]

I. INTRODUCTION

In Ref. 1 a spinless fermion lattice model was proposed that is $N=2$ supersymmetric (SUSY) regardless of lattice size or shape. The (fine-tuned) Hamiltonian of this model is written in terms of fermion creation and annihilation operators, as follows:

$$H=\sum_i \sum_{j \text{ next to } i} P_{\langle i\rangle} c_i^\dagger c_j P_{\langle j\rangle} + \sum_i P_{\langle i\rangle}, \tag{1}$$

with i numbering the lattice sites, c_i and $c_i^\dagger$ obeying $\{c_i, c_j^\dagger\}=\delta_{ij}$ and where we have introduced *projection operators* P for convenient notation. The latter have the form

$$P_{\langle i\rangle} \equiv \prod_{j \text{ next to } i} (1-c_j^\dagger c_j). \tag{2}$$

These projection operators ensure that *no two neighboring sites can be occupied simultaneously*. Therefore, we will work with a restricted Hilbert space where these states are excluded.

The SUSY model is closely related to more conventional lattice models, like the Heisenberg *XXZ* chain. This relation, which holds if we take a one-dimensional (1D) chain with special boundary conditions for the lattice, was demonstrated in Ref. 2. There it was also shown how SUSY could aid a Bethe Ansatz computation of the spectrum of the *XXZ* chain. Indeed, it is fruitful to see how SUSY can facilitate calculations on the lattice model specified by (1), especially since the symmetry holds on arbitrary graphs while exact results on higher dimensional lattices are notoriously difficult to obtain using conventional methods.

The supersymmetry can be viewed as a multiple site generalization of supersymmetric quantum mechanics. The two generators Q^+ and Q^- are given explicitly in Ref. 1,

a)Electronic mail: hveerten@science.uva.nl

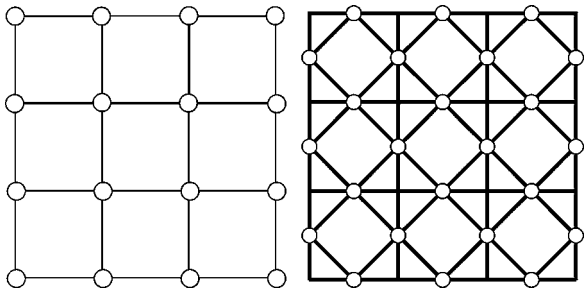

FIG. 1. The square lattice and the square dimer lattice.

$$Q^+ = \sum_{i=1}^{N} c_i^\dagger P_{\langle i \rangle}, \quad Q^- = \sum_{i=1}^{N} c_i P_{\langle i \rangle}. \tag{3}$$

We have the following algebraic structure (with F the fermionic number operator):

$$[F, Q^\pm] = \pm Q^\pm, \quad [F, H] = 0, \quad [Q^+, H] = 0, \quad [Q^-, H] = 0, \quad \{Q^+, Q^-\} = H. \tag{4}$$

In this paper we will focus on the ground states of a variety of two-dimensional (2D) lattices. We will treat the triangular and hexagonal lattice and their counterparts with dimer configurations as well as the dimer version of the square lattice. The square lattice was treated in a separate presentation.[3] All the lattices treated here have an interesting common feature, the number of ground states of the SUSY Hamiltonian on these lattices increases exponentially with increasing lattice size. This directly implies an extensive entropy of the ground state, a rare property exhibited by only a few condensed matter systems. The lattices are shown in Figs. 1–3.

All excited states in the SUSY model occur pairwise, because for every bosonic configuration we have an accompanying fermionic configuration. Here, lattice configurations with an even (odd) number of fermions are termed bosonic (fermionic) configurations. The ground states need not occur pairwise but are restricted otherwise, for their energies are all zero. All this means that we can use the Witten index operator to obtain a lower limit on the number of ground states,

$$W = \mathrm{Tr}(-1)^F e^{-\beta H}. \tag{5}$$

The pairwise cancelling of all excited states allows us to look just at the limiting case $\beta \to 0$, especially when calculating W for finite size lattices where convergence is not an issue, and we will do so for the remainder of this paper.

The operator W is completely equivalent to the well-known grand canonical partion function $Z = \mathrm{Tr}\, z^F \exp(-\beta H)$ of the classical hard particle model in the same dimension, only with a *negative* value for the activity z. It is this equivalence that puts a calculation of the Witten index for SUSY lattice models in a broader context and allows us to use well-known approaches for the

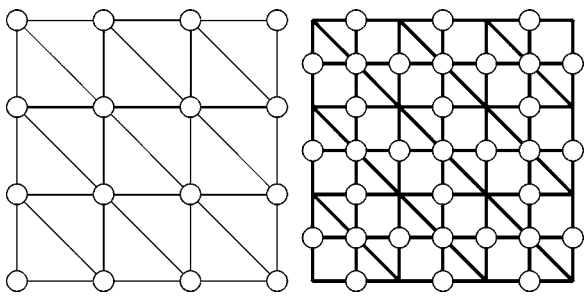

FIG. 2. The triangular lattice and the triangular dimer lattice.

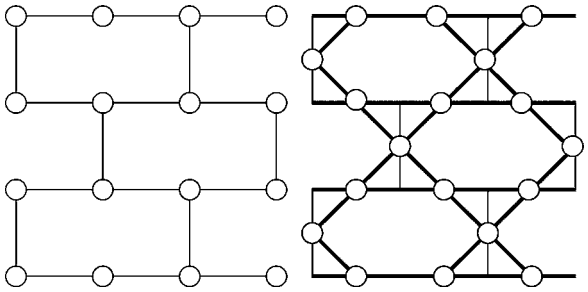

FIG. 3. The hexagonal lattice and the hexagonal dimer lattice.

calculation of Z—especially the use of *transfer matrices* that allows us to write W as the trace of a matrix product.

We have calculated the Witten index for finite sized lattices up to 15×15 (the triangular lattice) using transfer matrices. Before discussing the resulting values for the Witten indices, we will first explain how these matrices were constructed.

II. THE TRANSFER MATRICES

Transfer matrices can be constructed in various ways, as long as they provide a means of systematically summing over all possible configurations on the lattice (see Ref. 4 for an exhaustive introduction). For the N-site chain with periodic boundary conditions, the Witten index operator can be written in terms of transfer matrices as

$$W = \mathrm{Tr}\begin{pmatrix} 1 & i \\ i & 0 \end{pmatrix}^N = \mathrm{Tr}\begin{pmatrix} 1 & -1 \\ 1 & 0 \end{pmatrix}^N. \tag{6}$$

The upper left entry of the matrix corresponds to adding an empty site to the chain with an empty site at the end, the upper right entry to adding a filled site to an empty site, the lower left entry to adding an empty site to a filled site and the lower right entry to adding a filled site to a filled site. This last entry must be zero because no configurations with neighboring sites filled were allowed. To avoid an overcounting per fermion we can either use $-1,1$ or i,i for the off-diagonal entries, as long as their product is equal to -1. The resulting transfer matrices can be made symmetric, but never Hermitian.

The procedure can easily be generalized to higher dimensional lattices. The easiest strategy is to use row-to-row transfer matrices and have each matrix entry correspond to a specific row configuration. Because the size of these matrices increases fast with increasing lattice size, the actual constructions of the matrices are best left to a computer (which we did). In the following, we will briefly explain how the matrices were constructed for the various lattices.

The square lattice is the simplest. For each matrix entry (i,j) the computer program just compares the configuration denoted by i with the one denoted by j. The matrix entry will be zero if the two configurations have one or more neighboring vertices occupied when viewed next to each other. If the combination of i and j is allowed, a factor $(-1)^{f(j)}$ is written down, where $f(j)$ stands for the number of fermions in configuration j. This means we obtain a non-symmetric matrix with real numbers only. Using a mapping from the different configurations to binary numbers simplifies matters even further (e.g., ● ○ ● ○ ○→10 100, etc.). The comparison between the ith and jth configuration can now be performed using a binary AND instruction.

The program is easily modified for the triangular lattice. There are two extra edges per vertex connecting to vertices on a higher or lower row. They are similar to the vertical edge, but with all vertices of the lower row shifted one position to the right. In terms of the computer code, when comparing the ith and jth configuration, we apply a binary right shift on the jth binary representation before using AND. The program now performs two tests instead of one to ascertain if it can enter a nonzero value.

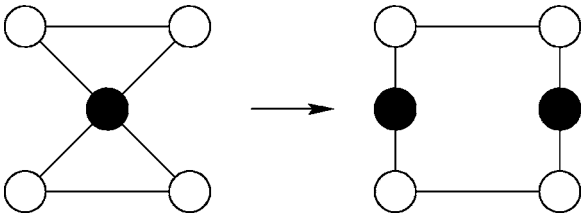

FIG. 4. Doubling sites on the even rows of the hexagonal dimer lattice.

For the hexagonal lattice we need to use two transfer matrices instead of one. Viewing the hexagonal lattice as a horizontal brick wall, we see that we have two different rows. If we work in units of 2×2 sites, we can take the transfer matrix that adds two rows at once as the matrix product of the two different matrices of the single rows.

The dimer lattices offer another complication. The square dimer lattice has both horizontal and vertical dimers. When constructing the transfer matrix we will sum over the horizontal dimer contributions. We can do this without problems because the horizontal dimers make no contact with the next row. For the triangular dimer lattice, we calculate the transfer matrices in a similar way.

For the hexagonal dimer lattice we will use yet another trick. As can be seen in Fig. 3, the even rows contain only half the number of vertices (after switching dimers and vertices in the original hexagonal lattice). As a first step we shall double this number of vertices in the even rows, as shown in Fig. 4. We must make certain that the resulting pairs consistently have the same value. Then we can formulate the transfer matrix once more as the product of two transfer matrices.

III. RESULTS

The resulting values for the Witten index on various lattice sizes are summarized in the tables in the Appendix.

The Witten index for the $M\times N$ lattice is given by Tr $(\mathbf{T}_N)^M$. Because we are taking the trace, the transfer matrices can be diagonalized without changing the resulting value for the Witten index. As a consequence, in the limiting case where the number of rows goes to infinity we can restrict ourselves to the largest roots of the characteristic polynomial of $\mathbf{T}_N$ (we would have used the term *eigenvalue* if the transfer matrix was not defective). Because the characteristic roots turn out to come in complex pairs, we must look at *two* largest roots and we get the following approximation for the Witten index:

$$W_{M,N} \approx a(t_{1,N})^M + \overline{a(t_{1,N})}^M, \tag{7}$$

where $t_{1,N}$ and $\overline{t_{1,N}}$ denote the complex pair that form the largest roots of the N-column transfer matrix.

We can define a *contribution per site* w by

$$w \equiv \lim_{N\to\infty} \frac{t_{1,N}}{t_{1,N-1}}. \tag{8}$$

If we do not take the limit to infinite N, but study finite size lattices of increasing size, we find strong numerical evidence that the contribution to the Witten index per site rapidly tends to a fixed complex number that is different for each lattice that was considered. These numbers are shown in Table I. When calculating these numbers we must select the correct phase factors manually from the two possibilities offered by the complex pairs. The quickly appearing convergence to a fixed value then justifies our choice. The square lattice is treated elsewhere,[3] but has the special property that all characteristic roots have norm equal to 1. All other lattice types have a single complex pair of largest roots.

This convergence to a complex number greater than 1 has an important consequence, for it

TABLE I. Witten index per site, various lattice types.

Lattice type	Modulus $\lvert w\rvert$ per site	Phase $\arg w$ per site
Square dimer	1.33 ± 0.01	$(0.363\times\pi)\pm0.01$
Triangular	1.14 ± 0.01	$(0.178\times\pi)\pm0.01$
Triangular dimer	1.261 ± 0.01	$(0.189\times\pi)\pm0.001$
Hexagonal	1.2 ± 0.1	Insufficient data
Hexagonal dimer	1.4 ± 0.1	$(0.310\times\pi)\pm0.001$

indicates an *extensive ground state entropy*. The Witten index can by approximated by

$$W \approx w^{MN} + \bar{w}^{MN} = 2r^{MN}\cos(MN\theta + \theta_0), \tag{9}$$

with $w=r\exp[i\theta]$. The index provides a lower bound on the number of ground states. [Indeed it is very well possible that the actual number of ground states greatly exceeds $|W|$. The reasoning presented here offers us no information on this. See Refs. 3 and 6 for an example (the square lattice).] In our understanding the oscillating (cosine) factor is due to partial cancelations in W of contributions coming from bosonic and fermionic ground states. We thus expect that the monotonically growing factor r^{MN} sets a lower bound for the actual ground state entropy $S_0 \equiv \ln[\#\text{ground states}]$ according to

$$S_0 \geqslant MN\ln r. \tag{10}$$

For example, for the triangular lattice we find

$$S_0 \geqslant MN\ln 1.14 = 0.131MN. \tag{11}$$

It is interesting to see whether the Witten index per site can be calculated analytically. The triangular lattice case, for example, is equivalent to the hard hexagon model (see Ref. 5) with activity -1 and even fits the Yang-Baxter equation at this value. Unfortunately one cannot simply modify the reasoning from Ref. 4 for the $z<0$ regime because the transfer matrices are defective, so this question remains open for the moment. It might still be possible to obtain analytical solutions using other methods. In Ref. 6, for example, an exact solution for the nonagon-triangle lattice was found by showing that it is equivalent to the number of closed packed dimer coverings on the honeycomb lattice.

The fact that we have a complex number indicates that the Witten index does not necessarily grow with increasing lattice size, like the partition sum of the corresponding hard particle model in the $z>0$ regime would. The phase factor can be used to obtain a rough first estimate on the fermion density of the ground states. The phase factor in the cosine term of W shows us how many sites we need to add to get from a majority of fermionic ground states to a majority of bosonic ground states and vice versa. [For example, the 1D chain has roots $\exp(\pm i/3\pi)$ and only two ground states both with filling factor $1/3$]. But it is only useful as such when combined with a more advanced approach to calculating the spectrum like the spectral sequence technique used in Ref. 3. After all, the phase factor is determined by *all* ground states and they do not necessarily all have the same filling factors.

ACKNOWLEDGMENTS

The author wishes to thank Paul Fendley for helpful discussions and Kareljan Schoutens for careful reading of the paper.

APPENDIX: WITTEN INDEX TABLES

The hexagonal lattice tables correspond to the vertical brick wall. It has been confirmed that the tables for the horizontal brick wall are equal to the transposed tables. (See Tables II–VIII.)

(Received 18 September 2005; accepted 20 October 2005; published online 23 December 2005)

We address this work to analyze a nonlinear diffusion equation in the presence of an absorption term taking external forces and spatial time-dependent diffusion coefficient into account. The nonlinear terms present in this equation are due to a nonlinear generalization of the Darcy law and the presence of an absorbent (source) term. We obtain new exact solutions and investigate nonlinear effects produced on the solutions by these terms. We also connect the results found here within the Tsallis formalism. © *2005 American Institute of Physics.*

I. INTRODUCTION

Recently, generalizations of the diffusion equation based on nonlinear diffusion equations have been extensively investigated due to the broadness of applications covering almost every field. One of them is the *porous medium equation*,

$$\frac{\partial}{\partial t}\rho(x,t) = \mathcal{D}\frac{\partial^2}{\partial x^2}[\rho(x,t)]^{\nu}, \tag{1}$$

that has been applied in several situations such as percolation of gases through porous media,[1] thin saturated regions in porous media,[2] a standard solid-on-solid model for surface growth, thin liquid films spreading under gravity,[3] the axisymmetric flow of a very viscous fluid,[4] turbulent diffusion,[5] an adsorption-desorption equilibrium locally maintained through a permeable solid[6] and the nonlinear diffusion in hard and soft superconductors.[7]

The formal properties of this equation have also been analyzed. For instance, in Ref. 8 is established a connection between Eq. (1) and the Tsallis formalism,[9] in Ref. 10 the presence of a spatial time-dependent diffusion coefficient is studied, in Ref. 11 a Verhuslt-type reaction term in Eq. (1) is introduced and, in Ref. 12 an anisotropic case is analyzed. Others applications of Eq. (1) can be found in Ref. 13.

Another interesting nonlinear extension of the usual diffusion equation is based on the nonlinear Darcy (or Fourier) law.[14] In particular, the diffusion equation that emerges from this consideration is given by

$$\frac{\partial}{\partial t}\rho(x,t) = \mathcal{D}\frac{\partial}{\partial x}\left\{[\rho(x,t)]^{m}\left|\frac{\partial}{\partial x}\rho(x,t)\right|^{n}\frac{\partial}{\partial x}\rho(x,t)\right\}. \tag{2}$$

Note that the above equation simplifies to Eq. (1) for a particular conditions and for $m=0$ the current density that emerges from the above equation is known as Gorter-Melling law. Equation (2) has also been employed in several situations such as nonlinear heat conduction,[14] nonlinear shear flows of non-Newtonian fluids,[15] gravity flows of non-Newtonian fluid through a porous

medium and the axial mixing generated by the buoyancy effect due to the injection of a denser fluid into a less dense one.[16] The properties of Eq. (2) have also been analyzed, for instance, a nonlinear conduction equation based on a generalized Fourier law is studied in Ref. 14 and in Refs. 17 and 18 a nonlinear diffusion in fractal structures is considered. However, Eq. (2) was not properly worked in the presence of external forces with an absorbent (source) term. In this direction, we dedicate this work to analyze Eq. (2) in the presence of external forces and taking absorbent (source) term into account in order to understand the changes produced by an external force and an absorbent (source) term. Thus, we investigate the following nonlinear diffusion equation:

$$\frac{\partial}{\partial t}\rho(x,t)=\mathcal{D}(t)\frac{\partial}{\partial x}\left\{|x|^{-\theta}\left|\frac{\partial}{\partial x}\rho(x,t)\right|^{n}\frac{\partial}{\partial x}[\rho(x,t)]^{\nu}\right\}-\frac{\partial}{\partial x}\{F(x,t)\rho(x,t)\}-\overline{\alpha}(t)[\rho(x,t)]^{\mu}, \tag{3}$$

where $\mathcal{D}(t)$ is a time diffusion coefficient, $F(x,t)$ represents an external force (drift) and $\overline{\alpha}(t)$ plays the role of an absorbent (or source) rate related to a reaction-diffusion process. It is interesting to note that the above diffusion equation can be applied to describe several scenarios such as heat conduction by electrons in a plasma, heat conduction by radiation in a fully ionized gas (Marshak waves), axisymmetric flow of a very viscous fluid,[4] turbulent diffusion,[5] an adsorption-desorption equilibrium locally maintained through a permeable solid[6] and the nonlinear diffusion in hard and soft superconductors.[7] The presence of the reaction term like the one given in the above equation has been studied in several situations. Here, for example, we may recall the so-called species coagulation, that is $A+A\rightarrow 0$ or $mA\rightarrow lA$, catalytic processes in regular, heterogeneous, or disordered systems.[19] Another example is an irreversible first-order reaction of transported substance so that the rate of removal is $\overline{\alpha}\rho$.[20] This extra term may also appear when a tracer undergoing radioactive decay is transported through a porous medium,[21] in heat flow involving heat production.[22]

For $\overline{\alpha}(t)=0$, it can be verified that $\int_{-\infty}^{\infty}dx\,\rho(x,t)$ is time independent (hence, if ρ is normalized at $t=0$, it will remain so forever). Indeed, if we write Eq. (3) as $\partial_t\rho=-\partial_x\mathcal{J}$ and assume the boundary condition $\mathcal{J}(x\rightarrow\pm\infty,t)\rightarrow 0$, it can be shown that $\int_{-\infty}^{\infty}dx\,\rho(x,t)$ is a constant of motion. Equation (3) recovers, for $(\theta,\nu,n,\mu)=(0,1,0,1)$, the standard Fokker-Planck equation[23] in the presence of a drift with an absorbent (source) term. For $(\theta,\nu)=(0,m+1)$, $F(x,t)=0$, $\mathcal{D}(t)=\mathcal{D}/(m+1)$ and $\overline{\alpha}(t)=0$ Eq. (2) is obtained from Eq. (3). The particular case $F(x,t)=0$ (no drift), $\mathcal{D}(x,t)=$const. and $n=0$ in the absence of source (absorbent) term, has been considered by Spohn.[24] Other aspects of Eq. (3) with $n=0$ have also been considered in Refs. 8 and 25. Note that as we mentioned above our present discussion involves extensions of these cases by taking a wide variety of situations into account. In particular, we obtain solutions for the above equation by considering the presence of external forces and absorbent (source) terms. We also establish a connection between the results found here and the distribution that emerges from the Tsallis thermostatics.[9]

The remainder of this paper goes as follows. In Sec. II, we consider several situations for Eq. (3) as well as the connection of the solutions with the ones obtained within the maximum entropy principle by employing the Tsallis entropy. In Sec. III, we present our conclusions.

II. NONLINEAR DIFFUSION EQUATION

Now, let us investigate time-dependent solutions for Eq. (3). We use similarity methods to reduce Eq. (3) to ordinary differential equations. The explicit form for these ordinary differential equations depends on the boundary conditions or on restrictions in the form of conservation laws. In this direction, we restrict our analysis to find a solution that can be expressed as a scaled function of the type

$$\overline{\rho}(x,t) = \frac{1}{\Phi(t)}\tilde{\rho}\left[\frac{x}{\Phi(t)}\right]. \tag{4}$$

These solutions satisfy the initial, the boundary conditions, and the normalization condition when $\overline{\alpha}(t)=0$. Before analyzing the solutions of Eq. (3), we consider $\mu=1$ and that the solution is given by $\rho(x,t)=\exp[-\int_0^t d\tilde{t}\,\overline{\alpha}(\tilde{t})]\overline{\rho}(x,t)$, where $\overline{\rho}(x,t)$ is a function to be determined and it is given by Eq. (4). The case $\mu\neq 1$ is discussed at the end of this section. By using the above statement, we obtain

$$\frac{\partial}{\partial t}\overline{\rho}(x,t) = \overline{\mathcal{D}}(t)\frac{\partial}{\partial x}\left\{|x|^{-\theta}\left|\frac{\partial}{\partial x}\overline{\rho}(x,t)\right|^{n}\frac{\partial}{\partial x}[\overline{\rho}(x,t)]^{\nu}\right\} - \frac{\partial}{\partial x}\{F(x,t)\overline{\rho}(x,t)\}, \tag{5}$$

with $\overline{\mathcal{D}}(t)=\mathcal{D}(t)\exp[-(\nu+n-1)\int_0^t d\tilde{t}\,\overline{\alpha}(\tilde{t})]$. In the following, we discuss the solutions by considering the absence of external force, the presence of a linear external force and, after we incorporate a power law external force.

We start by studying Eq. (5) in the absence of external force. For this case we have that

$$\frac{\partial}{\partial t}\overline{\rho}(x,t) = \overline{\mathcal{D}}(t)\frac{\partial}{\partial x}\left\{|x|^{-\theta}\left|\frac{\partial}{\partial x}\overline{\rho}(x,t)\right|^{n}\frac{\partial}{\partial x}[\overline{\rho}(x,t)]^{\nu}\right\}. \tag{6}$$

This equation can also be formulated in the context of heat diffusion. In the heat conduction context, to obtain the above equation, we need to consider a temperature-dependent thermal conductivity[26] and a nonlinear generalization of the Fourier law.[14]

By applying Eq. (4) in Eq. (6), thus, the last equation can be reduced to

$$\frac{d}{dz}\left\{|z|^{-\theta}\left|\frac{d}{dz}\tilde{\rho}(z)\right|^{n}\frac{d}{dz}[\tilde{\rho}(z)]^{\nu}\right\} = -\overline{k}\frac{d}{dz}[z\tilde{\rho}(z)] \tag{7}$$

and

$$[\Phi(t)]^{\xi}\frac{d}{dt}\Phi(t) = \overline{k\mathcal{D}}(t), \tag{8}$$

where $\xi=\nu+\theta+2n$, $z=x/\Phi(t)$ and $\overline{k}$ is an arbitrary constant. By solving Eq. (8), we found

$$\Phi(t) = \left[(\Phi(0))^{1+\xi} + k'\int_0^t d\tilde{t}\,\overline{\mathcal{D}}(\tilde{t})\right]^{1/(1+\xi)}, \tag{9}$$

with $k'=(1+\xi)\overline{k}$ determined by the normalization condition. Performing an integration in Eq. (7), we have that

$$|z|^{-\theta}\left|\frac{d}{dz}\tilde{\rho}(z)\right|^{n}\frac{d}{dz}[\tilde{\rho}(z)]^{\nu} = -\overline{k}z\tilde{\rho}(z) + \mathcal{C}, \tag{10}$$

where $\mathcal{C}$ is an integration constant. To find a solution for Eq. (10), we consider the following ansatz: $\tilde{\rho}(z)=(1-\alpha|z|^{\lambda})^{\beta}$ and, for simplicity, we take $\mathcal{C}=0$ to satisfy the $\rho(x\to\pm\infty,t)\to 0$. By substituting the ansatz in Eq. (10) we verify that

$$\alpha = \frac{\nu+n-1}{2+\theta+n}\left(\frac{\overline{k}}{\nu}\right)^{1/(n+1)}, \quad \beta = \frac{n+1}{\nu+n-1}, \quad \lambda = \frac{2+\theta+n}{n+1}. \tag{11}$$

Thus, the solution found to Eq. (6) can be expressed as

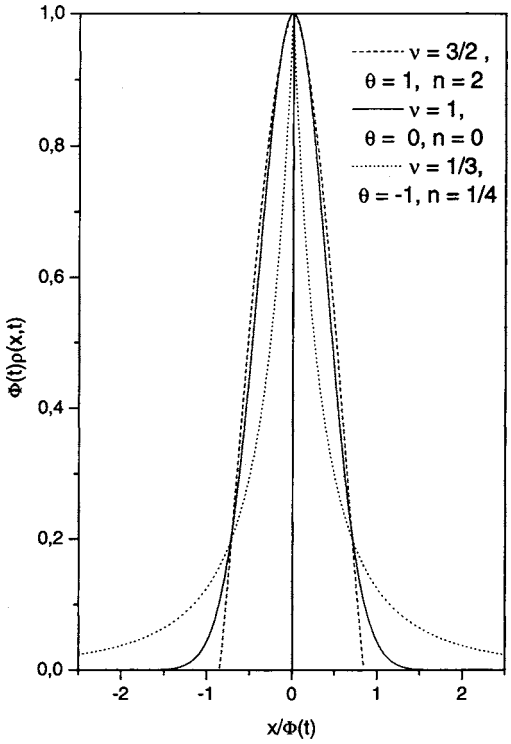

FIG. 1. Behavior of $\Phi(t)\rho(x,t)$ versus $x/\Phi(t)$ for a typical value of θ, ν, and n taking $\overline{\alpha}(t)=0$ into account. Note that, depending on the parameters θ, ν, and n, $\rho(x,t)$ can have compact or long tail.

$$\overline{\rho}(x,t)=\frac{1}{\Phi(t)}\exp_q\left[-\frac{1}{2+\theta+n}\left(\frac{\overline{k}}{\nu}\right)^{1/(n+1)}\left(\frac{|x|}{\Phi(t)}\right)^{\frac{2+\theta+n}{n+1}}\right]^{n+1}, \tag{12}$$

(see Fig. 1) with $q=2-(\nu+n)$ where $\exp_q[x]$ is defined as follows: $\exp_q[x]=(1+(1-q)x)^{1/(1-q)}$ for $1+(1-q)x\geqslant 0$ and by $\exp_q[x]=0$ for $1+(1-q)x<0$.

Notice that the $\exp_q[x]$ is the q-exponential which emerges from the Tsallis formalism[9] by maximizing the Tsallis entropy

$$S_q=\frac{1-\int \mathrm{d}x[\overline{\rho}(x)]^q}{q-1} \tag{13}$$

with appropriated constraints. For this reason, the q-exponential may be considered a signature of the Tsallis formalism and the presence of this function in the solutions indicates a connection between the solutions of Eq. (3) and Tsallis formalism. In fact, by considering suitable constraints it is possible to obtain these solutions by employing the maximum principle of entropy. Similar situation is considered in Refs. 27 and 28 for the porous medium equation. Thus, the parameter q which in the Tsallis formalism is not determined, here it is obtained in terms of the parameters of the nonlinear diffusion equation.

It is also interesting to note that the solution (12) can have a compact or a long tail behavior depending on the parameters ν, n, and θ. In addition, for the long tail behavior, we can asymptotically relate the solution with the Lévy distributions. In fact, the asymptotic limit for Eq. (12) for large x and $\nu+n<1$ is

$$\overline{\rho}(x,t) \sim \frac{1}{\Phi(t)}\left(\frac{|x|}{\Phi(t)}\right)^{-(2+\theta+n)/(1-\nu-n)}. \tag{14}$$

Now, by comparing the above result with the asymptotic limit that emerges from the Lévy distribution for large x, i.e., $\rho \sim 1/|x|^{1+\overline{\mu}}$, we obtain that $\overline{\mu}=(1+\theta+\nu+2n)/(1-\nu-n)$. Thus, for suitable parameters θ, ν, and n such that $0<\overline{\mu}<2$, Eq. (12) behaves asymptotically like a Lévy distribution. For the case $\overline{\alpha}(t)=0$ and $\mathcal{D}(t)=\mathcal{D}$, depending on the choice of the parameters (ν,θ,n), we may have an anomalous spreading of the distribution given by Eq. (12), which may characterize an anomalous diffusion or an anomalous conduction. In fact, for this case, the second moment is given by $\langle x^2\rangle \propto t^{2/(1+\xi)}$, where $2/(1+\xi)<1,=1,>1$ characterize a sub, normal or superdiffusive behavior.

Following, we analyze the implications of considering drift terms in Eq. (3). In this direction, we first study the effects produced in the solution by a linear external force. By applying Eq. (4) in Eq. (5) and taking the drift term $F(x,t)=-k_1(t)x$ into account, Eq. (5) can be written as

$$\frac{\partial}{\partial t}\overline{\rho}(x,t) = \overline{\mathcal{D}}(t)\frac{\partial}{\partial x}\left\{|x|^{-\theta}\left|\frac{\partial}{\partial x}\overline{\rho}(x,t)\right|^{n}\frac{\partial}{\partial x}[\overline{\rho}(x,t)]^{\nu}\right\} + k_1(t)\frac{\partial}{\partial x}[x\overline{\rho}(x,t)]. \tag{15}$$

By using the previous procedure, we can reduce Eq. (15) to

$$\frac{d}{dz}\left\{|z|^{-\theta}\left|\frac{d}{dz}\widetilde{\rho}(z)\right|^{n}\frac{d}{dz}[\widetilde{\rho}(z)]^{\nu}\right\} = -\overline{k}\frac{d}{dz}[z\widetilde{\rho}(z)] \tag{16}$$

and

$$[\Phi(t)]^{\overline{\xi}}\frac{d}{dt}\Phi(t) + k_1(t)[\Phi(t)]^{1+\overline{\xi}} = \overline{k\mathcal{D}}(t), \tag{17}$$

where $\overline{\xi}=\theta+\nu+2n$. The spatial solution for this case is the same that the one obtained for the free case, i.e., Eq. (12). In fact, Eq. (16) is equal to Eq. (7). The difference is present only on the time-dependent function $\Phi(t)$ which in this case is given by Eq. (17). By solving Eq. (17), we found

$$\Phi(t) = \left[(\Phi(0))^{1+\overline{\xi}} + k'\int_0^t d\widetilde{t}\,\overline{\mathcal{D}}(\widetilde{t})e^{(1+\overline{\xi})\int_0^{\widetilde{t}}dt'\,k_1(t')}\right]^{1/(1+\overline{\xi})} e^{-\int_0^t dt'\,k_1(t')}, \tag{18}$$

with $k'=(1+\overline{\xi})\overline{k}$. For $\overline{\alpha}(t)=0$ and $\mathcal{D}(t)=$const, we have a stationary solution, in contrast, to the case characterized by the absence of external force, and it is given by $\rho(x)\propto(1-\alpha'|x|^{\lambda})^{\beta}$ where α' is a constant.

Let us extend the above situation by assuming the external force $F(x,t)=-k_1(t)x-k_\alpha x|x|^{\alpha-1}$ with, for simplicity, $\mathcal{D}(t)=$const and $\overline{\alpha}(t)=0$. We do not know what happens in the general case for (α,θ,ν,n), but there is a special situation for which the scaled solution of the type indicated in Eq. (4) is still valid. This special case corresponds to $\alpha=-\theta-\nu-2n$, i.e., $\alpha+\theta+\nu+2n=0$. For this case, by using the previous procedure, we can reduce Eq. (3) to

$$-\overline{k}\frac{d}{dz}[z\widetilde{\rho}(z)] = \mathcal{D}\frac{d}{dz}\left\{|z|^{-\theta}\left|\frac{d}{dz}\widetilde{\rho}(z)\right|^{n}\frac{d}{dz}[\widetilde{\rho}(z)]^{\nu}\right\} + k_\alpha\frac{d}{dz}[z|z|^{\alpha-1}\widetilde{\rho}(z)] \tag{19}$$

and

$$[\Phi(t)]^{\overline{\xi}}\frac{d}{dt}\Phi(t) + k_1(t)[\Phi(t)]^{1+\overline{\xi}} = \overline{k}. \tag{20}$$

The solution for Eq. (20) is given by

$$\Phi(t)=\left[(\Phi(0))^{1+\overline{\xi}}+k'\int_0^t \mathrm{d}\widetilde{t}\, e^{(1+\overline{\xi})\int_0^{\widetilde{t}}\mathrm{d}t'\ k_1(t')}\right]^{1/(1+\overline{\xi})} e^{-\int_0^t \mathrm{d}t'\ k_1(t)}. \tag{21}$$

In order to obtain the solution for Eq. (19), we perform an integration leading to

$$\mathcal{D}|z|^{-\theta}\left|\frac{d}{\mathrm{d}z}\widetilde{\rho}(z)\right|^n\frac{d}{\mathrm{d}z}[\widetilde{\rho}(z)]^\nu=-(\overline{kz}+k_\alpha z|z|^{\alpha-1})\widetilde{\rho}(z)+\mathcal{C}', \tag{22}$$

where $\mathcal{C}'$ is constant. To solve this equation, we also employ the boundary condition $\rho(x\rightarrow\pm\infty,t)\rightarrow 0$ which implies in $\mathcal{C}'=0$. Thus, the solution for this equation is given by

$$\widetilde{\rho}(z)=\exp_q\left[-\frac{1}{n+1}\left(\frac{\overline{k}}{\mathcal{D}\nu}\right)^{1/(n+1)}\int^{|z|}d\overline{z}\left(\overline{z}^{1+\theta}+\frac{k_\alpha}{\overline{k}}\overline{z}^{\nu-2n}\right)^{1/(n+1)}\right]^{n+1}. \tag{23}$$

For $n=0$, we recover the solutions found in Ref. 29 after making an integration.

Now, let us study Eq. (3) by taking the general case $\mu\neq 1$ into account. For this case, Eq. (3) can be written as

$$\frac{\partial}{\partial t}\rho(x,t)=\mathcal{D}\frac{\partial}{\partial x}\left\{|x|^{-\theta}\left|\frac{\partial}{\partial x}\rho(x,t)\right|^n\frac{\partial}{\partial x}[\rho(x,t)]^\nu\right\}-\overline{\alpha}[\rho(x,t)]^\mu \tag{24}$$

when the external forces are absent for a time-independent diffusion coefficient and $\overline{\alpha}(t)=\overline{\alpha}$. Following Ref. 30, we consider that a solution for this equation may be given by $\rho(x,t)=\phi(t)\mathcal{P}(\zeta(t)x)$, where $\phi(t)$ and $\zeta(t)$ are time-dependent functions to be found. In this direction, by analyzing the simple kinetic equation that emerges from the above equation for $\mathcal{D}=0$, i.e., $\partial_t\rho(t)=-\overline{\alpha}[\rho(t)]^\mu$, whose solution is $\rho(t)\propto(1-(1-\mu)\overline{\alpha}t)^{1/(1-\mu)}$, we are suggested to employ $\phi(t)=(1-(1-\mu)kt)^{1/(1-\mu)}$. To obtain $\zeta(t)$, we substitute the proposed solution $\rho(x,t)$ in Eq. (24) with $\phi(t)$ defined above. This replacement lead us to obtain $\zeta(t)=(1-(1-\mu)kt)^{(n+\nu-\mu)/[(\mu-1)(2+n+\theta)]}$ and

$$-k\mathcal{P}(\eta)-\left(\frac{\mu-n-\nu}{2+\theta+n}\right)k\eta\frac{d}{\mathrm{d}\eta}\mathcal{P}(\eta)=\mathcal{D}\frac{d}{\mathrm{d}\eta}\left\{|\eta|^{-\theta}\left|\frac{d}{\mathrm{d}\eta}\mathcal{P}(\eta)\right|^n\frac{d}{\mathrm{d}\eta}[\mathcal{P}(\eta)]^\nu\right\}-\overline{\alpha}[\mathcal{P}(\eta)]^\mu, \tag{25}$$

with $\eta=\zeta(t)x$ and k being a constant. To find an explicit solution in the function of η for the above equation is a hard task, however, it is possible to obtain an implicit solution when $\mu=2+2n+\theta+\nu$. It is formally given by

$$\mathcal{P}(\eta)=\exp_q\left[-\frac{1}{n+1}\left(\frac{k}{\nu\mathcal{D}}\right)^{1/(n+1)}\int^{|\eta|}\mathrm{d}\overline{\eta}\,\overline{\eta}^{\theta/n+1}\left(\overline{\eta}-\frac{\overline{\alpha}}{k\mathcal{P}(\overline{\eta})}\int^{\overline{\eta}}\mathrm{d}\eta'[\mathcal{P}(\eta')]^\mu\right)^{\frac{1}{n+1}}\right]^{n+1}. \tag{26}$$

We notice that the above equation simplified to Eq. (12) for $\overline{\alpha}=0$ after performing an integration. By using the above results, we can obtain for μ, n, ν, and θ arbitraries the nth moment of this distribution. In fact, we have that

$$\langle x^{2n}\rangle=\left[\int \mathrm{d}x\, x^{2n}\rho(x,t)\right]\Big/\left[\int \mathrm{d}x\,\rho(x,t)\right]=\zeta(t)^{-2n}\left[\int \mathrm{d}\eta\,\eta^{2n}\rho(\eta)\right]\Big/\left[\int \mathrm{d}\eta\,\rho(\eta)\right]\propto\zeta(t)^{-2n} \tag{27}$$

and $\langle x^{2n+1}\rangle=0$, yielding $\langle(x-\langle x\rangle)^2\rangle\sim t^{[2(n+\nu-\mu)]/[(1-\mu)(2+n+\theta)]}$. Note that to obtain the last results we have assumed that the nth moment is defined and that the diffusive process can be subdiffusive, normal, or superdiffusive, depending on the value of $2(n+\nu-\mu)/[(1-\mu)(2+n+\theta)]$ to be less, equal or greater than 1.

III. CONCLUSIONS

In summary, we have worked on a generalized diffusion equation [Eq. (3)] for several situations by incorporating some space- and time-dependent classes of external drifts and diffusion coefficients. We have shown that it admits exact solutions where the space scales with a function of time. Another interesting point is the presence of the q-exponential function of the Tsallis formalism in the solutions found here. This fact indicates a connection between the solutions found here and the distributions that emerges from the Tsallis formalism, leading to an identification of the Tsallis entropic index with the parameters of the nonlinear diffusion equation. In particular, this explicit identification may be useful to explore the sensitivity of q to the details of the physical model. In addition, this feature could be helpful in a deeper connection between nonlinear diffusion and Tsallis entropy. We have also extended the results obtained in Refs. 8 and 25 in a unified approach. Finally, we expect that the results presented here bring new aspects and they open new possibilities of applications to the nonlinear diffusion equations and the Tsallis formalism.

(Received 30 June 2005; accepted 23 September 2005; published online 9 December 2005)

For each quantum superalgebra $U_q[\mathrm{osp}(m|n)]$ with $m>2$, an infinite family of Casimir invariants is constructed. This is achieved by using an explicit form for the Lax operator. The eigenvalue of each Casimir invariant on an arbitrary irreducible highest weight module is also calculated. © *2005 American Institute of Physics.*

I. INTRODUCTION

Representations of quantum superalgebras are known to provide solutions to the Yang-Baxter equation and represent the symmetries that underly supersymmetric exactly solvable (or integrable) models. Many such examples have arisen in the context of modelling systems of strongly correlated electrons.[1–5] More recently, the properties of solvability and supersymmetry have been applied to other areas, such as the solution of the Kondo model,[6] integrable superconformal field theory[7] and disordered systems.[8] Developing the representation theory of the quantum superalgebras is a useful step towards the complete understanding of such models. However, in many respects the representation theory of quantum superalgebras is not a straightforward generalization of the quantum algebra case, principally because not all representations of quantum superalgebras are unitary.[9] This leads, for example, to the existence of indecomposable representations not arising in the quantum algebra case, which generally make the analysis of supersymmetric models problematic (e.g., see Ref. 8).

In this paper we construct the Casimir invariants (central elements) of quantized orthosymplectic superalgebras. Our method of construction follows from the general results of Ref. 10 and the explicit form of the Lax operator obtained in Ref. 11. A fundamental problem is to determine the eigenvalues of the Casimir invariants when acting on an arbitrary finite-dimensional irreducible module. To date, the eigenvalues have only been calculated for the type I quantum superalgebras,[12,13] while the results for $U_q[\mathrm{osp}(1|n)]$ follow from an isomorphism derived in Ref. 14. In this paper we perform the calculations for the remaining nonexceptional quantum superalgebras, namely $U_q[\mathrm{osp}(m|n)]$ for $m>2$. The procedure we use for calculating the eigenvalues of the Casimir invariants when acting on any irreducible module is based on the early work by Perelomov and Popov[15,16] and Nwachuku and Rashid.[17] In doing so we follow the method used in Refs. 18 and 19 for the classical general and orthosymplectic superalgebras, respectively, which was adapted in Ref. 13 to cover $U_q[\mathrm{gl}(m|n)]$. Although the concepts are much the same as in those cases, the combination of the q-deformation and the more complex root system of $U_q[\mathrm{osp}(m|n)]$ makes the calculations in this paper more technically challenging.

In the following section we introduce our notation for $U_q[\mathrm{osp}(m|n)]$ and state the Lax operator. In Sec. III we develop the formulas for the Casimir invariants of $U_q[\mathrm{osp}(m|n)]$. The bulk of the calculations are in Sec. IV where the eigenvalues of the Casimir invariants are derived in detail.

II. THE QUANTIZED ORTHOSYMPLECTIC SUPERALGEBRA $U_q[\mathrm{osp}(m|n)]$

The quantum superalgebra $U_q[\mathrm{osp}(m|n)]$ is a q-deformation of the classical orthosymplectic superalgebra. A brief explanation of $U_q[\mathrm{osp}(m|n)]$ is given below, with a more thorough introduction to $\mathrm{osp}(m|n)$ and the q-deformation to be found in Ref. 11.

First we need to define the notation. The grading of a is denoted by $[a]$, where

$$[a]=\begin{cases}0, & a=i, \quad 1\leqslant i\leqslant m,\\ 1, & a=\mu, \quad 1\leqslant \mu\leqslant n.\end{cases} \tag{1}$$

Throughout this paper we use greek letters μ,ν, etc., to denote odd indices and italic letters i,j, etc., for even indices. If the grading is unknown, the usual a,b,c, etc., are used. Which convention applies will be clear from the context. Throughout the paper we also use the symbols $\bar{a}$ and ξ_a, which are given by

$$\bar{a}=\begin{cases}m+1-a, & [a]=0,\\ n+1-a, & [a]=1,\end{cases}$$

and

$$\xi_a=\begin{cases}1, & [a]=0,\\ (-1)^a, & [a]=1.\end{cases}$$

As a weight system for $U_q[\mathrm{osp}(m|n)]$ we take the set $\{\varepsilon_i,1\leqslant i\leqslant m\}\cup\{\delta_\mu,1\leqslant\mu\leqslant n\}$, where $\varepsilon_{\bar{i}}=-\varepsilon_i$ and $\delta_{\bar{\mu}}=-\delta_\mu$. Conveniently, when $m=2l+1$ this implies $\varepsilon_{l+1}=-\varepsilon_{l+1}=0$. Acting on these weights, we have the invariant bilinear form defined by

$$(\varepsilon_i,\varepsilon_j)=\delta^i_j, \quad (\delta_\mu,\delta_\nu)=-\delta^\mu_\nu, \quad (\varepsilon_i,\delta_\mu)=0, \quad 1\leqslant i,j\leqslant l, 1\leqslant\mu,\nu\leqslant k.$$

When describing an object with unknown grading indexed by a the weight will be described generically as ε_a. This should not be assumed to be an even weight.

The even positive roots of $U_q[\mathrm{osp}(m|n)]$ are composed entirely of the usual positive roots of $o(m)$ together with those of $\mathrm{sp}(n)$, namely,

$$\varepsilon_i\pm\varepsilon_j, \quad 1\leqslant i<j\leqslant l,$$

$$\varepsilon_i, \quad 1\leqslant i\leqslant l \quad \text{when } m=2l+1,$$

$$\delta_\mu+\delta_\nu, \quad 1\leqslant\mu,\nu\leqslant k,$$

$$\delta_\mu-\delta_\nu, \quad 1\leqslant\mu<\nu\leqslant k.$$

The root system also contains a set of odd positive roots, which are

$$\delta_\mu+\varepsilon_i, \quad 1\leqslant\mu\leqslant k, \quad 1\leqslant i\leqslant m.$$

Throughout this paper we choose to use the following set of simple roots:

$$\alpha_i=\varepsilon_i-\varepsilon_{i+1}, \quad 1\leqslant i<l,$$

$$\alpha_l=\begin{cases}\varepsilon_l+\varepsilon_{l-1}, & m=2l,\\ \varepsilon_l, & m=2l+1,\end{cases}$$

$$\alpha_\mu = \delta_\mu - \delta_{\mu+1}, \quad 1 \leqslant \mu < k,$$

$$\alpha_s = \delta_k - \varepsilon_1.$$

Note this choice is only valid for $m > 2$.

In $U_q[\mathrm{osp}(m|n)]$ the graded commutator is realized by

$$[A,B] = AB - (-1)^{[A][B]}BA$$

and tensor product multiplication is given by

$$(A \otimes B)(C \otimes D) = (-1)^{[B][C]}(AC \otimes BD).$$

Using these conventions, we have the following:

Definition 2.1: The quantum superalgebra $U_q[\mathrm{osp}(m|n)]$ *is generated by simple generators* e_a, f_a, h_a *subject to the relations*

$$[h_a, e_b] = (\alpha_a, \alpha_b)e_b,$$

$$[h_a, f_b] = -(\alpha_a, \alpha_b)f_b,$$

$$[h_a, h_b] = 0,$$

$$[e_a, f_b] = \delta_b^a \frac{(q^{h_a} - q^{-h_a})}{(q - q^{-1})},$$

$$[e_a, e_a] = [f_a, f_a] = 0 \quad \text{for } (\alpha_a, \alpha_a) = 0,$$

We remark that $U_q[\mathrm{osp}(m|n)]$ *has the structure of a quasitriangular Hopf superalgebra. In particular, there is a linear mapping known as the coproduct,* $\Delta: U_q[\mathrm{osp}(m|n)] \to U_q[\mathrm{osp}(m|n)]^{\otimes 2}$, *which is defined on the simple generators by*

$$\Delta(e_a) = q^{1/2h_a} \otimes e_a + e_a \otimes q^{-1/2h_a},$$

$$\Delta(f_a) = q^{1/2h_a} \otimes f_a + f_a \otimes q^{-1/2h_a},$$

$$\Delta(q^{\pm 1/2h_a}) = q^{\pm 1/2h_a} \otimes q^{\pm 1/2h_a},$$

and extends to arbitrary elements according to the homomorphism property, namely,

$$\Delta(AB) = \Delta(A)\Delta(B).$$

There are further defining relations such as the q-Serre relations, but they are not needed in this paper.

The quasitriangular property guarantees the existence of a universal R-matrix, which provides a solution to the Yang-Baxter equation. Before elaborating, we need to introduce the graded twist map.

The *graded twist map* $T: U_q[\mathrm{osp}(m|n)]^{\otimes 2} \to U_q[\mathrm{osp}(m|n)]^{\otimes 2}$ is given by

$$T(a \otimes b) = (-1)^{[a][b]}(b \otimes a).$$

For convenience, $T \circ \Delta$, the twist map composed with the coproduct, is denoted Δ^T. Then a *universal R-matrix*, $\mathcal{R}$, is an even, nonsingular element of $U_q[\mathrm{osp}(m|n)]^{\otimes 2}$ satisfying the following properties:

TABLE I. The action of the vector representation π on the simple generators of $U_q[\mathrm{osp}(m|n)]$.

α_a	$\pi(e_a)$	$\pi(f_a)$	$\pi(h_a)$
$\alpha_i, 1 \leqslant i < l$	$E^{i}_{i+1} - E^{\overline{i+1}}_{\bar{i}}$	$E^{i+1}_{i} - E^{\bar{i}}_{\overline{i+1}}$	$E^{i}_{i} - E^{\bar{i}}_{\bar{i}} - E^{i+1}_{i+1} + E^{\overline{i+1}}_{\overline{i+1}}$
$\alpha_l, m = 2l$	$E^{l-1}_{\bar{l}} - E^{l}_{\overline{l-1}}$	$E^{\bar{l}}_{l-1} - E^{\overline{l-1}}_{l}$	$E^{l-1}_{l-1} + E^{l}_{l} - E^{\overline{l-1}}_{\overline{l-1}} - E^{\bar{l}}_{\bar{l}}$
$\alpha_l, m = 2l+1$	$E^{l}_{l+1} - E^{l+1}_{\bar{l}}$	$E^{l+1}_{l} - E^{\bar{l}}_{l+1}$	$E^{l}_{l} - E^{\bar{l}}_{\bar{l}}$
$\alpha_\mu, 1 \leqslant \mu < k$	$E^{\mu}_{\mu+1} + E^{\overline{\mu+1}}_{\bar{\mu}}$	$E^{\mu+1}_{\mu} + E^{\bar{\mu}}_{\overline{\mu+1}}$	$E^{\mu+1}_{\mu+1} - E^{\overline{\mu+1}}_{\overline{\mu+1}} - E^{\mu}_{\mu} + E^{\bar{\mu}}_{\bar{\mu}}$
α_s	$E^{\mu=k}_{i=1} + (-1)^k E^{\overline{i=1}}_{\overline{\mu=k}}$	$-E^{i=1}_{\mu=k} + (-1)^k E^{\overline{\mu=k}}_{\overline{i=1}}$	$-E^{i=1}_{i=1} + E^{\bar{i}=1}_{\bar{i}=1} - E^{\mu=k}_{\mu=k} + E^{\bar{\mu}=\bar{k}}_{\bar{\mu}=\bar{k}}$

$$\mathcal{R}\Delta(a) = \Delta^T(a)\mathcal{R}, \quad \forall\, a \in U_q[\mathrm{osp}(m|n)],$$

$$(\mathrm{id} \otimes \Delta)\mathcal{R} = \mathcal{R}_{13}\mathcal{R}_{12},$$

$$(\Delta \otimes \mathrm{id})\mathcal{R} = \mathcal{R}_{13}\mathcal{R}_{23}. \tag{2}$$

Here $\mathcal{R}_{ab}$ represents a copy of $\mathcal{R}$ acting on the a and b components, respectively, of $U_1 \otimes U_2 \otimes U_3$, where each U is a copy of the quantum superalgebra $U_q[\mathrm{osp}(m|n)]$. When $a > b$ the usual grading term from the twist map is included, so, for example, $\mathcal{R}_{21} = [\mathcal{R}^T]_{12}$, where $\mathcal{R}^T = T(\mathcal{R})$ is the *opposite universal R-matrix*.

The *R*-matrix is significant because it is a solution to the Yang-Baxter equation, which is prominent in the study of integrable systems,[20]

$$\mathcal{R}_{12}\mathcal{R}_{13}\mathcal{R}_{23} = \mathcal{R}_{23}\mathcal{R}_{13}\mathcal{R}_{12}.$$

A superalgebra may contain many different universal *R*-matrices, but there is always a unique one belonging to $U_q[\mathrm{osp}(m|n)]^- \otimes U_q[\mathrm{osp}(m|n)]^+$, with its opposite *R*-matrix in $U_q[\mathrm{osp}(m|n)]^+ \otimes U_q[\mathrm{osp}(m|n)]^-$. Here $U_q[\mathrm{osp}(m|n)]^-$ is the Hopf subsuperalgebra generated by the lowering generators $\{f_a\}$ and Cartan elements $\{h_a\}$, while $U_q[\mathrm{osp}(m|n)]^+$ is generated by the raising generators $\{e_a\}$ and the Cartan elements. These particular *R*-matrices arise out of the $\mathbb{Z}_2$-graded version of Drinfeld's double construction.[21] In this paper we consider the universal *R*-matrix belonging to $U_q[\mathrm{osp}(m|n)]^- \otimes U_q[\mathrm{osp}(m|n)]^+$.

We also need to define the vector representation for $U_q[\mathrm{osp}(m|n)]$. Let End V be the space of endomorphisms of V, an $(m+n)$-dimensional vector space. Then the irreducible *vector representation* $\pi: U_q[\mathrm{osp}(m|n)] \to \mathrm{End}\ V$ acts on the $U_q[\mathrm{osp}(m|n)]$ generators as given in Table I, where E^a_b is the elementary matrix with a 1 in the (a,b) position and zeroes elsewhere.

One quantity that repeatedly arises in calculations for both classical and quantum Lie superalgebras is ρ, the *graded half-sum of positive roots*. In the case of $U_q[\mathrm{osp}(m|n)]$ it is given by

$$\rho = \frac{1}{2}\sum_{i=1}^{l}(m-2i)\varepsilon_i + \frac{1}{2}\sum_{\mu=1}^{k}(n-m+2-2\mu)\delta_\mu.$$

This satisfies the property $(\rho, \alpha) = \frac{1}{2}(\alpha, \alpha)$ for all simple roots α.

The Lax operator for $U_q[\mathrm{osp}(m|n)]$: Let $\mathcal{R}$ be the universal *R*-matrix of $U_q[\mathrm{osp}(m|n)]$ and π the vector representation. The Lax operator associated with $\mathcal{R}$ is given by

$$R = (\pi \otimes \mathrm{id})\mathcal{R} \in (\mathrm{End}\ V) \otimes U_q[\mathrm{osp}(m|n)].$$

It has been shown in Ref. 11 that the Lax operator is given by

$$R = \sum_a E_a^a \otimes q^{h_{\varepsilon_a}} + (q - q^{-1}) \sum_{\varepsilon_a < \varepsilon_b} (-1)^{[b]} E_b^a \otimes q^{h_{\varepsilon_a}} \hat{\sigma}_{ba},$$

where the simple operators $\hat{\sigma}_{ba}$ are given by

$$\hat{\sigma}_{ii+1} = -\hat{\sigma}_{\overline{i+1}\,\overline{i}} = q^{1/2} e_i q^{1/2h_i}, \quad 1 \leqslant i < l,$$

$$\hat{\sigma}_{l-1\bar{l}} = -\hat{\sigma}_{l\overline{l-1}} = q^{1/2} e_l q^{1/2h_l}, \quad m = 2l,$$

$$\hat{\sigma}_{l\bar{l}} = 0, \quad m = 2l,$$

$$\hat{\sigma}_{ll+1} = -q^{-1/2} \hat{\sigma}_{l+1\bar{l}} = e_l q^{1/2h_l}, \quad m = 2l+1,$$

$$\hat{\sigma}_{\mu\mu+1} = \hat{\sigma}_{\overline{\mu+1}\,\bar{\mu}} = q^{-1/2} e_\mu q^{1/2h_\mu}, \quad 1 \leqslant \mu < k,$$

$$\hat{\sigma}_{\mu=ki=1} = (-1)^k q \hat{\sigma}_{i=\bar{1}\,\bar{\mu}=\bar{k}} = q^{1/2} e_s q^{1/2h_s};$$

and the remaining operators can be calculated using the following:

(i) the q-commutation relations,

$$q^{(\alpha_c, \varepsilon_b)} \hat{\sigma}_{ba} e_c q^{1/2h_c} - (-1)^{([a]+[b])[c]} q^{-(\alpha_c, \varepsilon_a)} e_c q^{1/2h_c} \hat{\sigma}_{ba} = 0, \quad \varepsilon_b > \varepsilon_a,$$

where neither $\varepsilon_a - \alpha_c$ nor $\varepsilon_b + \alpha_c$ equals any ε_x; and

(ii) the induction relations

$$\hat{\sigma}_{ba} = q^{-(\varepsilon_b, \varepsilon_a)} \hat{\sigma}_{bc} \hat{\sigma}_{ca} - q^{-(\varepsilon_c, \varepsilon_c)} (-1)^{([b]+[c])([a]+[c])} \hat{\sigma}_{ca} \hat{\sigma}_{bc}, \quad \varepsilon_b > \varepsilon_c > \varepsilon_a,$$

where $c \neq \bar{b}$ or $\bar{a}$.

To define the opposite Lax operator $R^T = (\pi \otimes \mathrm{id})\mathcal{R}$ we require the graded conjugation action †, which is defined on the simple generators by (see Ref. 11)

$$e_a^\dagger = f_a, \quad f_a^\dagger = (-1)^{[a]} e_a, \quad h_a^\dagger = h_a.$$

It is consistent with the coproduct and extends naturally to all remaining elements of $U_q[\mathrm{osp}(m|n)]$, satisfying the following properties:

$$(\hat{\sigma}_{ab})^\dagger = (-1)^{[a]([a]+[b])} \hat{\sigma}_{ba},$$

$$(ab)^\dagger = (-1)^{[a][b]} b^\dagger a^\dagger,$$

$$(a \otimes b)^\dagger = a^\dagger \otimes b^\dagger,$$

$$\Delta(a)^\dagger = \Delta(a^\dagger).$$

Then the opposite R-matrix is given by

$$R^T = \sum_a E_a^a \otimes q^{h_{\varepsilon_a}} + (q - q^{-1}) \sum_{\varepsilon_b > \varepsilon_a} (-1)^{[a]} E_a^b \otimes \hat{\sigma}_{ab} q^{h_{\varepsilon_a}},$$

where

$$\hat{\sigma}_{ab} = (-1)^{[b]([a]+[b])} \hat{\sigma}_{ba}^\dagger, \quad \varepsilon_b > \varepsilon_a.$$

III. CASIMIR INVARIANTS OF $U_q[\mathrm{osp}(m|n)]$

We now use the Lax operator to construct a family of Casimir invariants and then to calculate their eigenvalues when acting on an irreducible highest weight module. Before constructing the Casimir invariants, however, we need to define a new object. Let h_ρ be the unique element of the Cartan subalgebra H satisfying

$$\alpha_i(h_\rho) = (\rho, \alpha_i), \quad \forall\ \alpha_i \in H^*.$$

Then from Ref. 10 we have the following theorem.

Theorem 3.1: *Let $\mathcal{V}$ be the representation space of τ, an arbitrary finite-dimensional representation of $U_q[\mathrm{osp}(m|n)]$. If $\Gamma \in (\mathrm{End}\ \mathcal{V}) \otimes U_q[\mathrm{osp}(m|n)]$ satisfies*

$$\partial(a)\Gamma = \Gamma\partial(a), \quad \forall\ a \in U_q[\mathrm{osp}(m|n)], \tag{3}$$

where $\partial \equiv (\pi \otimes \mathrm{id})\Delta$, then

$$C = (\mathrm{str} \otimes \mathrm{id})(\tau(q^{2h_\rho}) \otimes I)\Gamma,$$

belongs to the center of $U_q[\mathrm{osp}(m|n)]$. Above str denotes the supertrace.

Now choose τ to be the vector representation π. Recalling that the universal R-matrix satisfies

$$\mathcal{R}\Delta(a) = \Delta^T(a)\mathcal{R}, \quad \forall\ a \in U_q[\mathrm{osp}(m|n)],$$

it is clear that

$$\partial(a)R^TR = R^TR\partial(a), \quad \forall\ a \in U_q[\mathrm{osp}(m|n)].$$

Hence if we set $A \in (\mathrm{End}\ V) \otimes U_q[\mathrm{osp}(m|n)]$ to be

$$A = \frac{(R^TR - I \otimes I)}{(q - q^{-1})},$$

the operators A^l will satisfy condition (3) for all non-negative integers l. Thus the operators C_l defined as

$$C_l = (\mathrm{str} \otimes \mathrm{id})(\pi(q^{2h_\rho}) \otimes I)A^l, \quad l \in \mathbb{Z}^+,$$

form a family of Casimir invariants. Here A coincides with the matrix of Jarvis and Green[22] in the classical limit $q \to 1$, as do the invariants C_l.

Now write the Lax operator R and its opposite R^T in the form

$$R = I \otimes I + (q - q^{-1}) \sum_{\varepsilon_b \geqslant \varepsilon_a} E_b^a \otimes X_a^b,$$

$$R^T = I \otimes I + (q - q^{-1}) \sum_{\varepsilon_b \leqslant \varepsilon_a} E_b^a \otimes X_a^b.$$

In terms of the operators $\hat{\sigma}_{ba}$, this implies

$$X_a^b = \begin{cases} \dfrac{q^{h_{\varepsilon_a}} - I}{q - q^{-1}}, & a = b, \\ (-1)^{[b]} q^{h_{\varepsilon_a}} \hat{\sigma}_{ba}, & \varepsilon_a < \varepsilon_b, \\ (-1)^{[b]} \hat{\sigma}_{ba} q^{h_{\varepsilon_b}}, & \varepsilon_a > \varepsilon_b. \end{cases}$$

Writing A as

$$A = \sum_{a,b} E_b^a \otimes A_a^b,$$

we obtain

$$A_a^b = (1 + \delta_b^a) X_a^b + (q - q^{-1}) \sum_{\varepsilon_c \leqslant \varepsilon_a, \varepsilon_b} (-1)^{([a]+[c])([b]+[c])} X_a^c X_c^b.$$

This produces a family of Casimir invariants

$$C_l = \sum_a (-1)^{[a]} q^{(2\rho, \varepsilon_a)} A^{(l)a}_{\ \ a},$$

where the operators $A^{(l)b}_{\ \ a}$ are recursively defined as

$$A^{(l)b}_{\ \ a} = \sum_c (-1)^{([a]+[c])([b]+[c])} A^{(l-1)c}_{\ \ a} A_c^b. \tag{4}$$

Note that A corresponds to the matrix A given for the nongraded case in Ref. 23. Following a line of reasoning similar to that in Ref. 24 it can be shown that when acting on an irreducible module $V(\Lambda)$, A satisfies the following polynomial identity:

$$\prod_{a=1}^{m+n} (A - \alpha_a(\Lambda) I) = 0,$$

where

$$\alpha_a(\Lambda) = \frac{q^{(\varepsilon_a, \varepsilon_a + 2\Lambda + 2\rho) - C(\Lambda_0)} - 1}{q - q^{-1}}$$

and $C(\Lambda_0) = (\delta_1, \delta_1 + 2\rho) = m - n - 1$. In the limit $q \to 1$ this reduces to the identity given in Ref. 24.

IV. EIGENVALUES OF THE CASIMIR INVARIANTS

Now that we have found a family of Casimir invariants, we wish to calculate their eigenvalues on a general irreducible finite-dimensional module. Let $V(\Lambda)$ be an arbitrary irreducible finite-dimensional module with highest weight Λ and highest weight state $|\Lambda\rangle$. Define $t_a^{(l)}$ to be the eigenvalue of $A^{(l)a}_{\ \ a}$ on this state, so

$$A^{(l)a}_{\ \ a} |\Lambda\rangle = t_a^{(l)} |\Lambda\rangle.$$

Once we have calculated $t_a^{(l)}$ we will use this result to find the eigenvalues of the Casimir invariants C_l.

To evaluate $t_a^{(l)}$, note that if $\varepsilon_b > \varepsilon_a$ then $A^{(l)b}_{\ \ a}$ is a raising operator, implying $A^{(l)b}_{\ \ a} |\Lambda\rangle = 0$. Thus from Eq. (4) we deduce

$$\begin{aligned} t_a^{(l)} |\Lambda\rangle &= t_a^{(l-1)} t_a^{(1)} |\Lambda\rangle + \sum_{\varepsilon_a < \varepsilon_b} (-1)^{[a]+[b]} A^{(l-1)b}_{\ \ a} A_b^a |\Lambda\rangle \\ &= t_a^{(l-1)} t_a^{(1)} |\Lambda\rangle + \sum_{\varepsilon_a < \varepsilon_b} (-1)^{[a]+[b]} A^{(l-1)b}_{\ \ a} [X_b^a + (q - q^{-1}) X_b^a X_a^a] |\Lambda\rangle \\ &= t_a^{(l-1)} t_a^{(1)} |\Lambda\rangle + \sum_{\varepsilon_a < \varepsilon_b} (-1)^{[a]+[b]} q^{(\Lambda, \varepsilon_a)} A^{(l-1)b}_{\ \ a} X_b^a |\Lambda\rangle. \end{aligned}$$

Now we know that

$$A^l\partial(X_b^a) = \partial(X_b^a)A^l. \tag{5}$$

This can be used to calculate $A^{(l)b}_{\ a}X_b^a|\Lambda\rangle$ for $\varepsilon_a < \varepsilon_b$. First we need an expression for $\Delta(X_b^a)$. The R-matrix properties give

$$(\Delta \otimes I)R = R_{13}R_{23} \Rightarrow (I \otimes \Delta)R^T = R_{12}^T R_{13}^T.$$

In terms of X_b^a, this implies

$$\begin{aligned}
&I \otimes I \otimes I + (q-q^{-1}) \sum_{\varepsilon_a \leqslant \varepsilon_b} E_a^b \otimes \Delta(X_b^a) \\
&= \left(I \otimes I \otimes I + (q-q^{-1}) \sum_{\varepsilon_a \leqslant \varepsilon_b} E_a^b \otimes X_b^a \otimes I\right)\left(I \otimes I \otimes I + (q-q^{-1}) \sum_{\varepsilon_a \leqslant \varepsilon_b} E_a^b \otimes I \otimes X_b^a\right) \\
&= I \otimes I \otimes I + (q-q^{-1}) \sum_{\varepsilon_a \leqslant \varepsilon_b} E_a^b \otimes (X_b^a \otimes I + I \otimes X_b^a) \\
&+ (q-q^{-1})^2 \sum_{\varepsilon_a \leqslant \varepsilon_c \leqslant \varepsilon_b} (-1)^{([a]+[c])([b]+[c])} E_a^b \otimes X_b^c \otimes X_c^a.
\end{aligned}$$

Hence for all $\varepsilon_a < \varepsilon_b$,

$$\Delta(X_b^a) = X_b^a \otimes I + I \otimes X_b^a + (q-q^{-1}) \sum_{\varepsilon_a \leqslant \varepsilon_c \leqslant \varepsilon_b} (-1)^{([a]+[c])([b]+[c])} X_b^c \otimes X_c^a.$$

We also need an expression for $\pi(X_b^a)$ for $\varepsilon_a \leqslant \varepsilon_b$. In Ref. 11 we found the generators for R^T in the vector representation are given by

$$\hat{\sigma}_{ab}q^{h_{\varepsilon_a}} = E_b^a - (-1)^{[a]([a]+[b])}\xi_a\xi_b q^{(\rho,\varepsilon_a-\varepsilon_b)}E_{\bar{a}}^{\bar{b}}, \quad \varepsilon_a < \varepsilon_b.$$

From this we deduce that

$$\pi(X_b^a) = (-1)^{[a]}E_b^a - (-1)^{[a][b]}\xi_a\xi_b q^{(\rho,\varepsilon_a-\varepsilon_b)}E_{\bar{a}}^{\bar{b}}, \quad \varepsilon_a < \varepsilon_b.$$

Also, we know

$$\pi(X_a^a) = (q-q^{-1})^{-1}\pi(q^{h_{\varepsilon_a}} - I) = (q-q^{-1})^{-1}(q^{(\varepsilon_a,\varepsilon_a)(E_a^a - E_{\bar{a}}^{\bar{a}})} - I).$$

Applying these, we find that if $\varepsilon_a < \varepsilon_b$ then

$$\begin{aligned}
\partial(X_b^a) &= (\pi \otimes I)\Delta(X_b^a) = \pi(X_b^a) \otimes (I + (q-q^{-1})X_a^a) + (I + (q-q^{-1})\pi(X_b^b)) \otimes X_b^a \\
&+ (q-q^{-1}) \sum_{\varepsilon_a < \varepsilon_c < \varepsilon_b} (-1)^{([a]+[c])([b]+[c])} \pi(X_b^c) \otimes X_c^a \\
&= ((-1)^{[a]}E_b^a - (-1)^{[a][b]}\xi_a\xi_b q^{(\rho,\varepsilon_a-\varepsilon_b)}E_{\bar{a}}^{\bar{b}}) \otimes q^{h_{\varepsilon_a}} + q^{(\varepsilon_b,\varepsilon_b)(E_b^b - E_{\bar{b}}^{\bar{b}})} \otimes X_b^a \\
&+ (q-q^{-1}) \sum_{\varepsilon_a < \varepsilon_c < \varepsilon_b} (-1)^{([a]+[c])([b]+[c])} \\
&\times ((-1)^{[c]}E_b^c - (-1)^{[b][c]}\xi_b\xi_c q^{(\rho,\varepsilon_c-\varepsilon_b)}E_{\bar{c}}^{\bar{b}}) \otimes X_c^a.
\end{aligned}$$

Substituting this expression into Eq. (5) and equating the (a,b) entries, we find

$$
\begin{aligned}
&(-1)^{[a]}A^{(l)a}{}_{a}q^{h_{\varepsilon_a}} - \delta^{a}_{\bar{b}}(-1)^{[a][b]}\xi_a\xi_b q^{(\rho,\varepsilon_a-\varepsilon_b)}A^{(l)a}{}_{a}q^{h_{\varepsilon_a}} + q^{(\varepsilon_b,\varepsilon_b)}A^{(l)b}{}_{a}X^{a}_{b} \\
&\quad + (q-q^{-1})\sum_{\varepsilon_a<\varepsilon_c<\varepsilon_b}((-1)^{[c]}A^{(l)c}{}_{a}X^{a}_{c} - \delta^{b}_{\bar{c}}(-1)^{[b][c]}\xi_b\xi_c q^{(\rho,\varepsilon_c-\varepsilon_b)}A^{(l)\bar{b}}{}_{a}X^{a}_{c}) \\
&= (-1)^{[a]}q^{h_{\varepsilon_a}}A^{(l)b}{}_{b} - \delta^{a}_{\bar{b}}(-1)^{[a][b]}\xi_a\xi_b q^{(\rho,\varepsilon_a-\varepsilon_b)}q^{h_{\varepsilon_a}}A^{(l)b}{}_{b} + (-1)^{[a]+[b]}q^{(\varepsilon_a,\varepsilon_b)}X^{a}_{b}A^{(l)b}{}_{a} \\
&\quad - (q-q)^{-1}\delta^{a}_{\bar{b}}\sum_{\varepsilon_a<\varepsilon_c<\varepsilon_b}(-1)^{[b][c]}\xi_b\xi_c q^{(\rho,\varepsilon_c-\varepsilon_b)}X^{a}_{c}A^{(l)b}{}_{\bar{c}}.
\end{aligned}
$$

Simplifying gives

$$
\begin{aligned}
&(-1)^{[a]+[b]}q^{(\varepsilon_a,\varepsilon_b)}X^{a}_{b}A^{(l)b}{}_{a} - q^{(\varepsilon_b,\varepsilon_b)}A^{(l)b}{}_{a}X^{a}_{b} \\
&\quad = ((-1)^{[a]} - \delta^{a}_{\bar{b}}q^{(\rho,\varepsilon_a-\varepsilon_b)})q^{h_{\varepsilon_a}}(A^{(l)a}{}_{a} - A^{(l)b}{}_{b}) \\
&\qquad + (q-q^{-1})\sum_{\varepsilon_a<\varepsilon_c<\varepsilon_b}((-1)^{[c]} - \delta^{b}_{\bar{c}}q^{(\rho,\varepsilon_c-\varepsilon_b)})A^{(l)c}{}_{a}X^{a}_{c} \\
&\qquad + (q-q^{-1})\delta^{a}_{\bar{b}}\sum_{\varepsilon_a<\varepsilon_c<\varepsilon_b}(-1)^{[b][c]}\xi_b\xi_c q^{(\rho,\varepsilon_c-\varepsilon_b)}X^{a}_{c}A^{(l)\bar{a}}{}_{\bar{c}}.
\end{aligned}
$$

Remembering that $\varepsilon_a<\varepsilon_b$, we apply this to the highest weight state $|\Lambda\rangle$ to obtain

$$
\begin{aligned}
-q^{(\varepsilon_b,\varepsilon_b)}A^{(l)b}{}_{a}X^{a}_{b}|\Lambda\rangle &= q^{(\Lambda,\varepsilon_a)}((-1)^{[a]} - \delta^{a}_{\bar{b}}q^{2(\rho,\varepsilon_a)})(t^{(l)}_{a} - t^{(l)}_{b})|\Lambda\rangle \\
&\quad + (q-q^{-1})\sum_{\varepsilon_a<\varepsilon_c<\varepsilon_b}((-1)^{[c]} - \delta^{b}_{\bar{c}}q^{2(\rho,\varepsilon_c)})A^{(l)c}{}_{a}X^{a}_{c}|\Lambda\rangle. \qquad (6)
\end{aligned}
$$

The next step is to calculate $A^{(l)b}{}_{a}X^{a}_{b}|\Lambda\rangle$ for $\varepsilon_a<\varepsilon_b$. It is first convenient to order the indices according to $b>c\Leftrightarrow\varepsilon_b<\varepsilon_c$. With this ordering we say an element $a>0$ if $\varepsilon_a<0$, $a=0$ if $\varepsilon_a=0$, and $a<0$ if $\varepsilon_a>0$. Using this convention, it is apparent the solution to (6) will be of the form

$$
A^{(l)b}{}_{a}X^{a}_{b}|\Lambda\rangle = q^{(\Lambda,\varepsilon_a)}(-1)^{[a]}\sum_{a>c\geq b}\alpha^{a}_{bc}(t^{(l)}_{a} - t^{(l)}_{c})|\Lambda\rangle, \qquad (7)
$$

where α^{a}_{bc} is a function of a, b, and c. Now from Eq. (6) we have

$$
\begin{aligned}
&(q-q^{-1})\sum_{a>c>b}(-1)^{[c]}A^{(l)c}{}_{a}X^{a}_{c}|\Lambda\rangle \\
&\quad = -q^{(\varepsilon_b,\varepsilon_b)}A^{(l)b}{}_{a}X^{a}_{b}|\Lambda\rangle + (q-q^{-1})\sum_{a>c>b}\delta^{b}_{\bar{c}}q^{-2(\rho,\varepsilon_b)}A^{(l)c}{}_{a}X^{a}_{c}|\Lambda\rangle \\
&\qquad - (-1)^{[a]}q^{(\Lambda,\varepsilon_a)}(1-\delta^{a}_{\bar{b}}(-1)^{[a]}q^{2(\rho,\varepsilon_a)})(t^{(l)}_{a} - t^{(l)}_{b})|\Lambda\rangle \\
&\quad = -q^{(\varepsilon_{b+1},\varepsilon_{b+1})}A^{(l)b+1}{}_{a}X^{a}_{b+1}|\Lambda\rangle \\
&\qquad + (q-q^{-1})\sum_{a>c>b+1}\delta^{b+1}_{\bar{c}}q^{-2(\rho,\varepsilon_{b+1})}A^{(l)c}{}_{a}X^{a}_{c}|\Lambda\rangle \\
&\qquad - (-1)^{[a]}q^{(\Lambda,\varepsilon_a)}(1-\delta^{b+1}_{\bar{a}}(-1)^{[a]}q^{2(\rho,\varepsilon_a)})(t^{(l)}_{a} - t^{(l)}_{b+1})|\Lambda\rangle \\
&\qquad + (q-q^{-1})(-1)^{[b+1]}A^{(l)b+1}{}_{a}X^{a}_{b+1}|\Lambda\rangle.
\end{aligned}
$$

Substituting in the form of the solution given in Eq. (7) produces

$$
\begin{aligned}
& q^{(\varepsilon_b,\varepsilon_b)} \sum_{a>d\geqslant b} \alpha^a_{bd}(t^{(l)}_a - t^{(l)}_d)|\Lambda\rangle \\
&\quad = (q^{(\varepsilon_{b+1},\varepsilon_{b+1})} - (q-q^{-1})(-1)^{[b+1]}) \sum_{a>d\geqslant b+1} \alpha^a_{(b+1)d}(t^{(l)}_a - t^{(l)}_d)|\Lambda\rangle \\
&\qquad - (1-\delta^a_{\bar{b}}(-1)^{[a]}q^{2(\rho,\varepsilon_a)})(t^{(l)}_a - t^{(l)}_b)|\Lambda\rangle + (1-\delta^a_{\overline{b+1}}(-1)^{[a]}q^{2(\rho,\varepsilon_a)})(t^{(l)}_a - t^{(l)}_{b+1})|\Lambda\rangle \\
&\qquad + (q-q^{-1}) \sum_{a>c>b} \delta^b_{\bar{c}} q^{-2(\rho,\varepsilon_b)} \sum_{a>d\geqslant c} \alpha^a_{\bar{b}d}(t^{(l)}_a - t^{(l)}_d)|\Lambda\rangle \\
&\qquad - (q-q^{-1}) \sum_{a>c>b+1} \delta^{b+1}_{\bar{c}} q^{-2(\rho,\varepsilon_{b+1})} \sum_{a>d\geqslant c} \alpha^a_{\overline{(b+1)}d}(t^{(l)}_a - t^{(l)}_d)|\Lambda\rangle. \qquad (8)
\end{aligned}
$$

Set

$$\alpha^a_{bd} = \bar{\alpha}_{bd}(1-\delta^a_{\bar{d}}(-1)^{[a]}q^{2(\rho,\varepsilon_a)}).$$

Then from Eq. (8) we obtain

$$\bar{\alpha}_{bb} = -q^{-(\varepsilon_b,\varepsilon_b)}$$

and

$$
\begin{aligned}
\bar{\alpha}_{b(b+1)} &= q^{-(\varepsilon_b,\varepsilon_b)}[(q^{(\varepsilon_{b+1},\varepsilon_{b+1})} - (q-q^{-1})(-1)^{[b+1]})\bar{\alpha}_{(b+1)(b+1)} + 1 + (q-q^{-1})\delta^b_{\overline{b+1}}q^{-2(\rho,\varepsilon_b)}\bar{\alpha}_{\bar{b}(b+1)}] \\
&= q^{-(\varepsilon_b,\varepsilon_b)-(\varepsilon_{b+1},\varepsilon_{b+1})}(q-q^{-1})((-1)^{[b+1]} - \delta^b_{\overline{b+1}}q^{-2(\rho,\varepsilon_b)}).
\end{aligned}
$$

To simplify this expression note that $q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)} = q^{-(\varepsilon_b,\varepsilon_b)-(\varepsilon_{b+1},\varepsilon_{b+1})}$ in all cases except for $[b]=0$, $b=l$, $m=2l$, in which case $q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)} = q^2 q^{-(\varepsilon_b,\varepsilon_b)-(\varepsilon_{b+1},\varepsilon_{b+1})}$. However $[b]=0$, $b=l$, $m=2l$ if and only if $\delta^b_{\overline{b+1}}=1$, and in that case we find $\bar{\alpha}_{b(b+1)}=0$. Hence for all values of b we can write

$$\bar{\alpha}_{b(b+1)} = (q-q^{-1})q^{-2(\rho,\varepsilon_b)}((-1)^{[b+1]}q^{2(\rho,\varepsilon_{b+1})} - \delta^b_{\overline{b+1}}).$$

Now that we have found $\bar{\alpha}_{bb}$ and $\bar{\alpha}_{b(b+1)}$, they can be used to calculate the remaining $\bar{\alpha}_{bd}$. From Eq. (8) we observe that if $d>b+1$ then

$$
\begin{aligned}
\bar{\alpha}_{bd} &= q^{-(\varepsilon_b,\varepsilon_b)}(q^{(\varepsilon_{b+1},\varepsilon_{b+1})} - (q-q^{-1})(-1)^{[b+1]})\bar{\alpha}_{(b+1)d} + (q-q^{-1})q^{-(\varepsilon_b,\varepsilon_b)} \sum_{d\geqslant c>b} \delta^b_{\bar{c}} q^{-2(\rho,\varepsilon_b)}\bar{\alpha}_{\bar{b}d} \\
&\quad - (q-q^{-1})q^{-(\varepsilon_b,\varepsilon_b)} \sum_{d\geqslant c>b+1} \delta^{b+1}_{\bar{c}} q^{-2(\rho,\varepsilon_{b+1})}\bar{\alpha}_{\overline{(b+1)}d}. \qquad (9)
\end{aligned}
$$

Now define θ_{xy} by

$$\theta_{xy} = \begin{cases} 1, & x<y, \\ 0, & x\geqslant y. \end{cases}$$

Then Eq. (9) can be rewritten as

$$
\begin{aligned}
\bar{\alpha}_{bd} &= q^{-(\varepsilon_b,\varepsilon_b)}(q^{(\varepsilon_{b+1},\varepsilon_{b+1})} - (q-q^{-1})(-1)^{[b+1]})\bar{\alpha}_{(b+1)d} \\
&\quad + (q-q^{-1})q^{-(\varepsilon_b,\varepsilon_b)}q^{2(\rho,\varepsilon_c)}(\theta_{bc}\theta_{c(d+1)}\delta^b_{\bar{c}} - \theta_{(b+1)c}\theta_{c(d+1)}\delta^{b+1}_{\bar{c}})\bar{\alpha}_{cd}, \quad d>a+1. \qquad (10)
\end{aligned}
$$

Consider $\bar{\alpha}_{bd}$ for any $b>l$. Both $\theta_{b\bar{b}}$ and $\theta_{(b+1)(\overline{b+1})}$ will equal 0, so

$$\bar{\alpha}_{bd} = q^{-(\varepsilon_b,\varepsilon_b)}(q^{(\varepsilon_{b+1},\varepsilon_{b+1})} - (q-q^{-1})(-1)^{[b+1]})\bar{\alpha}^a_{(b+1)d}$$
$$= q^{-(\varepsilon_b,\varepsilon_b)}q^{-(\varepsilon_{b+1},\varepsilon_{b+1})}\bar{\alpha}_{(b+1)d} = q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)}\bar{\alpha}_{(b+1)d}.$$

Since

$$\bar{\alpha}_{(d-1)d} = (-1)^{[d]}(q-q^{-1})q^{2(\rho,\varepsilon_d-\varepsilon_{d-1})},$$

we obtain

$$\bar{\alpha}_{bd} = (-1)^{[d]}(q-q^{-1})q^{2(\rho,\varepsilon_d-\varepsilon_b)}, \quad d>b>l.$$

Substituting this together with our expression for $\bar{\alpha}_{bb}$ into Eq. (10), we find

$$\bar{\alpha}_{bd} = q^{-(\varepsilon_b,\varepsilon_b)}(q^{-(\varepsilon_{b+1},\varepsilon_{b+1})} - \delta^{b+1}_{\overline{b+1}}(q-q^{-1}))\bar{\alpha}_{(b+1)d}$$
$$+ (q-q^{-1})^2 q^{-(\varepsilon_b,\varepsilon_b)}(-1)^{[d]}q^{2(\rho,\varepsilon_d)}(\theta_{b\bar{b}}\theta_{\bar{b}d} - \theta_{(b+1)(\overline{b+1})}\theta_{(\overline{b+1})d})$$
$$- (q-q^{-1})q^{-(\varepsilon_b,\varepsilon_b)}q^{-(\varepsilon_d,\varepsilon_d)}q^{2(\rho,\varepsilon_d)}(\delta^{\bar{b}}_d - \delta^{\overline{b+1}}_d), \quad d>b+1. \tag{11}$$

But for $d>b+1$,

$$\theta_{b\bar{b}}\theta_{\bar{b}d} - \theta_{(b+1)(\overline{b+1})}\theta_{(\overline{b+1})d} = \delta^b_l\theta_{\bar{l}d} - \delta^{\bar{b}}_d\theta_{bl}$$
$$= \delta^b_l(1-\delta^d_{\bar{l}}) - \delta^{\bar{b}}_d(1-\delta^b_l) = \delta^b_l - \delta^{\bar{b}}_d.$$

Also, $-[(-1)^{[d]}(q-q^{-1})+q^{-(\varepsilon_d,\varepsilon_d)}]\delta^{\bar{b}}_d = -q^{(\varepsilon_d,\varepsilon_d)}\delta^{\bar{b}}_d$, so Eq. (11) reduces to

$$\bar{\alpha}_{bd} = (q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)}q^{-2\delta^b_{\overline{b+1}}} - \delta^{b+1}_{\overline{b+1}}q^{-1}(q-q^{-1}))\bar{\alpha}_{(b+1)d} + \delta^b_l q^{-1}(q-q^{-1})^2(-1)^{[d]}q^{2(\rho,\varepsilon_d)}$$
$$- \delta^{\bar{b}}_d(q-q^{-1})q^{2(\rho,\varepsilon_d)} + \delta^{\overline{b+1}}_d(q-q^{-1})q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)}q^{-2\delta^b_{\overline{b+1}}}q^{2(\rho,\varepsilon_d)}$$
$$= (q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)}q^{-2\delta^b_{\overline{b+1}}} - \delta^{b+1}_{\overline{b+1}}q^{-1}(q-q^{-1}))\bar{\alpha}_{(b+1)d} + \delta^b_l q^{-1}(q-q^{-1})^2(-1)^{[d]}q^{2(\rho,\varepsilon_d)}$$
$$+ (q-q^{-1})q^{-2(\rho,\varepsilon_b)}(\delta^{\overline{b+1}}_d - \delta^{\bar{b}}_d), \quad d>b+1.$$

Recall that for $b>l$ we have

$$\bar{\alpha}_{bd} = (-1)^{[d]}(q-q^{-1})q^{2(\rho,\varepsilon_d-\varepsilon_b)}, \quad d>b.$$

Then when $b=l$ we find

$$\bar{\alpha}_{bd} = (q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)}q^{-2\delta^b_{\overline{b+1}}} - \delta^{b+1}_{\overline{b+1}}q^{-1}(q-q^{-1}))(-1)^{[d]}(q-q^{-1})q^{2(\rho,\varepsilon_d-\varepsilon_{b+1})}$$
$$+ q^{-1}(q-q^{-1})^2(-1)^{[d]}q^{2(\rho,\varepsilon_d)} - (q-q^{-1})q^{-2(\rho,\varepsilon_b)}\delta^{\bar{l}}_d$$
$$= (-1)^{[d]}(q-q^{-1})q^{2(\rho,\varepsilon_d-\varepsilon_b)}[\delta^{b+1}_{\overline{b+1}}(1-(q-q^{-1})+(q-q^{-1}))$$
$$+ \delta^b_{\overline{b+1}}(q^{-2}+q^{-1}(q-q^{-1}))] - (q-q^{-1})q^{-2(\rho,\varepsilon_b)}\delta^{\bar{l}}_d$$
$$= (q-q^{-1})q^{-2(\rho,\varepsilon_b)}((-1)^{[d]}q^{2(\rho,\varepsilon_d)} - \delta^b_{\bar{d}})$$

for all $d>b+1$. Comparing this with our earlier results for $d=b+1$ and $b>l$, we have

$$\bar{\alpha}_{bd} = (q-q^{-1})q^{-2(\rho,\varepsilon_b)}((-1)^{[d]}q^{2(\rho,\varepsilon_d)} - \delta^b_{\bar{d}}), \quad \forall\, b \geqslant l, \quad d>b.$$

But for $b<l$ we know

$$\bar{\alpha}_{bd} = q^{2(\rho,\varepsilon_{b+1}-\varepsilon_b)}\bar{\alpha}_{(b+1)d} + (q-q^{-1})q^{-2(\rho,\varepsilon_b)}(\overline{\delta_d^{b+1}} - \bar{\delta}_d^b), \quad d > b+1.$$

Hence for all b we obtain

$$\bar{\alpha}_{bd} = (q-q^{-1})q^{-2(\rho,\varepsilon_b)}\left((-1)^{[d]}q^{2(\rho,\varepsilon_d)} - \sum_{c=b}^{d-1}\bar{\delta}_d^{\bar{c}} + \sum_{c=b}^{d-2}\overline{\delta_d^{c+1}}\right)$$

$$= (q-q^{-1})q^{-2(\rho,\varepsilon_b)}((-1)^{[d]}q^{2(\rho,\varepsilon_d)} - \bar{\delta}_d^b), \quad d > b.$$

Thus for all $a > b$

$$A^{(l)b}{}_a X_b^a|\Lambda\rangle = q^{(\Lambda,\varepsilon_a)}(-1)^{[a]}\sum_{a>c\geqslant b}\alpha_{bc}^a(t_a^{(l)} - t_c^{(l)})|\Lambda\rangle, \tag{12}$$

where α_{bc}^a is given by

$$\alpha_{bc}^a = \begin{cases} -q^{-(\varepsilon_b,\varepsilon_b)}(1-\delta_{\bar{b}}^a(-1)^{[a]}q^{2(\rho,\varepsilon_a)}), & c=b, \\ (q-q^{-1})q^{-2(\rho,\varepsilon_b)}((-1)^{[c]}q^{2(\rho,\varepsilon_c)} - \bar{\delta}_c^b)(1-\delta_{\bar{c}}^a(-1)^{[a]}q^{2(\rho,\varepsilon_a)}), & c>b. \end{cases}$$

A. Constructing the Perelomov-Popov matrix equation

The expression (12) can now be substituted into the equation

$$t_a^{(l)}|\Lambda\rangle = t_a^{(l-1)}t_a^{(1)}|\Lambda\rangle + \sum_{\varepsilon_a<\varepsilon_b}(-1)^{[a]+[b]}q^{(\Lambda,\varepsilon_a)}A^{(l-1)b}{}_a X_b^a|\Lambda\rangle$$

to find a matrix equation for the various $t_a^{(l)}$. The matrix factor is an analogue of the Perelomov-Popov matrix introduced in Refs. 15 and 16, which was used to calculate the eigenvalues of the Casimir invariants of various classical Lie algebras.

First recall that

$$A_a^b = (1+\delta_b^a)X_a^b + (q-q^{-1})\sum_{c\geqslant a,b}(-1)^{([a]+[c])([b]+[c])}X_a^c X_c^b,$$

where

$$X_a^b = \begin{cases} \dfrac{q^{h_{\varepsilon_a}} - I}{q-q^{-1}}, & a=b, \\ (-1)^{[b]}q^{h_{\varepsilon_a}}\hat{\sigma}_{ba}, & \varepsilon_a < \varepsilon_b, \\ (-1)^{[b]}\hat{\sigma}_{ba}q^{h_{\varepsilon_b}}, & \varepsilon_a > \varepsilon_b. \end{cases}$$

Then

$$A_a^a|\Lambda\rangle = 2X_a^a|\Lambda\rangle + (q-q^{-1})X_a^a X_a^a|\Lambda\rangle = (q-q^{-1})^{-1}(2(q^{h_{\varepsilon_a}}-1) + (q^{h_{\varepsilon_a}}-1)^2)|\Lambda\rangle$$

$$t_a^{(1)} = \frac{q^{2(\Lambda,\varepsilon_a)}-1}{q-q^{-1}}.$$

Hence we obtain

$$t_a^{(l)} = \frac{(q^{2(\Lambda,\varepsilon_a)}-1)}{(q-q^{-1})} t_a^{(l-1)} + \sum_{b<a} (-1)^{[a]+[b]} q^{(\Lambda,\varepsilon_a)} \left(q^{(\Lambda,\varepsilon_a)} (-1)^{[a]} \sum_{b\leqslant c<a} \alpha_{bc}^a (t_a^{(l-1)} - t_c^{(l-1)}) \right)$$

$$= \frac{(q^{2(\Lambda,\varepsilon_a)}-1)}{(q-q^{-1})} t_a^{(l-1)} - q^{2(\Lambda,\varepsilon_a)} \sum_{b<a} (-1)^{[b]} q^{-(\varepsilon_b,\varepsilon_b)} (1-\delta_{\bar{b}}^a (-1)^{[a]} q^{2(\rho,\varepsilon_a)}) (t_a^{(l-1)} - t_b^{(l-1)})$$

$$+ (q-q^{-1}) q^{2(\Lambda,\varepsilon_a)} \sum_{c<b<a} (-1)^{[c]} q^{-2(\rho,\varepsilon_c)} (1-\delta_{\bar{b}}^a (-1)^{[a]} q^{2(\rho,\varepsilon_a)})$$

$$\times ((-1)^{[b]} q^{2(\rho,\varepsilon_b)} - \delta_{\bar{c}}^b)(t_a^{(l-1)} - t_b^{(l-1)}).$$

Now consider the function γ_b defined by

$$\gamma_b = (-1)^{[b]} q^{-(\varepsilon_b,\varepsilon_b)} - (q-q^{-1}) \sum_{c<b} (-1)^{[c]} q^{-2(\rho,\varepsilon_c)} ((-1)^{[b]} q^{2(\rho,\varepsilon_b)} - \delta_{\bar{c}}^b)).$$

We evaluate this for all b, remembering that $C(\Lambda_0) = (\delta_1, \delta_1 + 2\rho) = m-n-1$ and

$$\rho = \frac{1}{2} \sum_{i=1}^{l} (m-2i)\varepsilon_i + \frac{1}{2} \sum_{\mu=1}^{k} (n-m+2-2\mu)\delta_\mu.$$

We find

$$\gamma_b = (-1)^{[b]} q^{2(\rho,\varepsilon_b)} q^{-C(\Lambda_0)}$$

for all values of b. We also consider the function

$$\beta_a = 1 - (q-q^{-1}) \sum_{b<a} \gamma_b (1 - \delta_{\bar{b}}^a (-1)^{[a]} q^{2(\rho,\varepsilon_a)}),$$

so that

$$t_a^{(l)} = \frac{(q^{2(\Lambda,\varepsilon_a)}\beta_a - 1)}{(q-q^{-1})} t_a^{(l-1)} + q^{2(\Lambda,\varepsilon_a)} \sum_{b<a} \gamma_b (1 - \delta_{\bar{b}}^a (-1)^{[a]} q^{2(\rho,\varepsilon_a)}) t_b^{(l-1)}. \tag{13}$$

Again, by considering the various cases individually we find

$$\beta_a = q^{(\varepsilon_a, 2\rho+\varepsilon_a) - C(\Lambda_0)}$$

for any a, regardless of whether m is even or odd. Substituting this result together with that for γ_b into Eq. (13) gives

$$t_a^{(l)} = \frac{(q^{(\varepsilon_a, 2\Lambda+2\rho+\varepsilon_a) - C(\Lambda_0)} - 1)}{(q-q^{-1})} t_a^{(l-1)} + q^{(2\Lambda,\varepsilon_a) - C(\Lambda_0)} \sum_{b<a} (-1)^{[b]} q^{(2\rho,\varepsilon_b)} (1 - \delta_{\bar{b}}^a (-1)^{[a]} q^{(2\rho,\varepsilon_a)}) t_b^{(l-1)}.$$

This can be written in the matrix form

$$\underline{t}^{(l)} = M \underline{t}^{(l-1)},$$

where M is a lower triangular matrix with entries

$$M_{ab} = \begin{cases} 0, & a < b, \\ (q-q^{-1})^{-1} (q^{(\varepsilon_a, 2\Lambda+2\rho+\varepsilon_a) - C(\Lambda_0)} - 1), & a = b, \\ q^{(2\Lambda,\varepsilon_a) - C(\Lambda_0)} ((-1)^{[b]} q^{(2\rho,\varepsilon_b)} - \delta_{\bar{b}}^a), & a > b. \end{cases}$$

Then we have

$$\underline{t}^{(l)} = M^l \underline{t}^{(0)}, \quad \text{with } t_a^{(0)} = 1 \quad \forall\, a,$$

where M is an analogue of the Perelomov-Popov matrix.

B. Solving the matrix equation

This matrix equation for $t_a^{(l)}$ can now be used to calculate the eigenvalues of C_l. Loosely speaking, the problem reduces to diagonalizing the matrix M. Recall

$$C_l = \sum_a (-1)^{[a]} q^{(2\rho,\varepsilon_a)} A^{(l)a}{}_a.$$

Denote the eigenvalue of C_l on $V(\Lambda)$ as $\chi_\Lambda(C_l)$. Then we have

$$\chi_\Lambda(C_l) = \sum_a (-1)^{[a]} q^{(2\rho,\varepsilon_a)} t_a^{(l)} = \sum_{a,b} (-1)^{[a]} q^{(2\rho,\varepsilon_a)} (M^l)_{ab}.$$

To calculate this we wish to diagonalize M. We assume the eigenvalues of M,

$$\alpha_a^\Lambda = \frac{(q^{(\varepsilon_a, 2\Lambda+2\rho+\varepsilon_a)-C(\Lambda_0)} - 1)}{(q-q^{-1})},$$

are distinct. Then we need a matrix N satisfying

$$(N^{-1}MN)_{ab} = \delta_b^a \alpha_a^\Lambda,$$

which implies

$$\chi_\Lambda(C_l) = \sum_{a,b,c} (-1)^{[a]} q^{(2\rho,\varepsilon_a)} (\alpha_b^\Lambda)^l N_{ab} (N^{-1})_{bc}. \tag{14}$$

Now

$$(MN)_{ab} = \alpha_b^\Lambda N_{ab}.$$

Substituting in the values for M_{ab} gives

$$\alpha_a^\Lambda N_{ab} + q^{(2\Lambda,\varepsilon_a)-C(\Lambda_0)} \sum_{c<a} ((-1)^{[c]} q^{(2\rho,\varepsilon_c)} - \delta_{\bar{c}}^a) N_{cb} = \alpha_b^\Lambda N_{ab}. \tag{15}$$

Since the eigenvalues α_a^Λ are distinct, this implies

$$N_{ab} = 0, \quad \forall\, a < b.$$

Set

$$P_{ab} = \sum_{c \leqslant a} (-1)^{[c]} q^{(2\rho,\varepsilon_c)} N_{cb}. \tag{16}$$

Then Eq. (15) becomes

$$\begin{aligned} 2(\alpha_b^\Lambda - \alpha_a^\Lambda) N_{ab} &= q^{(2\Lambda,\varepsilon_a)-C(\Lambda_0)} P_{(a-1)b} - \theta_{0a} q^{(2\Lambda,\varepsilon_a)-C(\Lambda_0)} N_{\bar{a}b} \\ &\Rightarrow (\alpha_b^\Lambda - \alpha_a^\Lambda)(-1)^{[a]} q^{(-2\rho,\varepsilon_a)} (P_{ab} - P_{(a-1)b}) \\ &= q^{(2\Lambda,\varepsilon_a)-C(\Lambda_0)} P_{a-1b} - \theta_{0a} q^{(2\Lambda,\varepsilon_a)-C(\Lambda_0)} N_{\bar{a}b}, \end{aligned}$$

which simplifies to

$$P_{ab} = \frac{(\alpha_b^\Lambda - \alpha_a^\Lambda + (-1)^{[a]} q^{2(\Lambda+\rho,\varepsilon_a)-C(\Lambda_0)})}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} P_{(a-1)b} - \frac{\theta_{0a}(-1)^{[a]} q^{2(\Lambda+\rho,\varepsilon_a)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} N_{\bar{a}b}.$$

Set

$$\psi_a^b = \alpha_b^\Lambda - \alpha_a^\Lambda + (-1)^{[a]} q^{2(\Lambda+\rho,\varepsilon_a)-C(\Lambda_0)},$$

so this becomes

$$P_{ab} = \frac{\psi_a^b}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} P_{(a-1)b} - \frac{\theta_{0a}(-1)^{[a]} q^{2(\Lambda+\rho,\varepsilon_a)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} N_{\bar{a}b}. \tag{17}$$

Without loss of generality we can choose $N_{aa}=1\,\forall\, a$, so $P_{bb}=(-1)^{[b]} q^{2(\rho,\varepsilon_b)}$. Then in the cases $0 \geqslant a > b$ and $a > b \geqslant 0$ the last term in Eq. (17) vanishes, giving

$$P_{ab} = (-1)^{[b]} q^{2(\rho,\varepsilon_b)} \prod_{c=b+1}^{a} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)}.$$

Similarly, for $a > \bar{b} > 0$ we obtain

$$P_{ab} = P_{\bar{b}b}^- \prod_{c=\bar{b}+1}^{a} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)}. \tag{18}$$

It remains to find P_{ab} for $\bar{b} \geqslant a > 0$. In this case, the last term in Eq. (17) contributes, giving

$$\begin{aligned} P_{ab} = {} & (-1)^{[b]} q^{2(\rho,\varepsilon_b)} \prod_{c=b+1}^{a} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)} - \frac{(-1)^{[a]} q^{2(\Lambda+\rho,\varepsilon_a)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} N_{\bar{a}b} \\ & - \sum_{d=\bar{l}}^{a-1} \frac{(-1)^{[d]} q^{2(\Lambda+\rho,\varepsilon_d)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_d^\Lambda)} N_{\bar{d}b}^- \prod_{c=d+1}^{a} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)}. \end{aligned} \tag{19}$$

Recall that if $b < a < 0$, then

$$\begin{aligned} N_{ab} &= \frac{q^{(2\Lambda,\varepsilon_a)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} P_{(a-1)b} \\ &= \frac{(-1)^{[b]} q^{2(\Lambda,\varepsilon_a)+2(\rho,\varepsilon_b)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_a^\Lambda)} \prod_{c=b+1}^{a-1} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)}. \end{aligned}$$

Substituting this into Eq. (19), we find

$$\begin{aligned} P_{\bar{b}b}^- = {} & (-1)^{[b]} q^{2(\rho,\varepsilon_b)} \prod_{c=b+1}^{\bar{b}} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)} - \frac{(-1)^{[b]} q^{-2(\Lambda+\rho,\varepsilon_b)-C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_{\bar{b}}^\Lambda)} \\ & - \sum_{d=\bar{l}}^{\bar{b}-1} \frac{(-1)^{[d]+[b]} q^{2(\rho,\varepsilon_d+\varepsilon_b)-2C(\Lambda_0)}}{(\alpha_b^\Lambda - \alpha_d^\Lambda)(\alpha_b^\Lambda - \alpha_{\bar{d}}^\Lambda)} \prod_{c=b+1}^{\bar{d}-1} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)} \prod_{c=d+1}^{\bar{b}} \frac{\psi_c^b}{(\alpha_b^\Lambda - \alpha_c^\Lambda)}, \end{aligned}$$

which can also be simplified to

$$P_{\bar{b}b}\prod_{c=b+1}^{\bar{b}}\frac{(\alpha_b^\Lambda-\alpha_c^\Lambda)}{\psi_c^b}=(-1)^{[b]}q^{2(\rho,\varepsilon_b)}\left[1-\sum_{d=\bar{l}}^{\bar{b}}\frac{(-1)^{[d]}q^{2(\rho,\varepsilon_d)-2C(\Lambda_0)}}{\psi_d^b\psi_{\bar{d}}^b}\prod_{c=\bar{d}+1}^{d-1}\frac{(\alpha_b^\Lambda-\alpha_c^\Lambda)}{\psi_c^b}\right]. \quad (20)$$

From this point we will consider the case $m=2l+1$. This is marginally more complicated than the case with even m. Define Φ_d^b to be

$$\Phi_d^b=\prod_{c=\bar{l}}^{d-1}\frac{(\alpha_b-\alpha_c)(\alpha_b-\alpha_{\bar{c}})}{\psi_c^b\psi_{\bar{c}}^b}$$

$$=\frac{(\alpha_b-\alpha_{d-1})(\alpha_b-\alpha_{\overline{d-1}})}{\psi_{d-1}^b\psi_{\overline{d-1}}^b}\Phi_{d-1}^b,\quad \Phi_{\bar{l}}^b=1.$$

Then $P_{\bar{b}b}$ can be written as

$$P_{\bar{b}b}=(-1)^{[b]}q^{2(\rho,\varepsilon_b)}\prod_{\substack{c=b+1\\c\neq 0}}^{\bar{b}}\frac{\psi_c^b}{(\alpha_b^\Lambda-\alpha_c^\Lambda)}\left[\frac{\psi_0^b}{\alpha_b-\alpha_0}-\sum_{d=\bar{l}}^{\bar{b}}\frac{(-1)^{[d]}q^{2(\rho,\varepsilon_d)-2C(\Lambda_0)}}{\psi_d^b\psi_{\bar{d}}^b}\Phi_d^b\right].$$

Note that for $c\neq 0$,

$$\psi_c^b=\frac{q^{-C(\Lambda_0)}}{(q-q^{-1})}(q^{(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)}-q^{(\varepsilon_c,2\rho+2\Lambda+\varepsilon_c)}+(q-q^{-1})(-1)^{[c]}q^{(\varepsilon_c,2\rho+2\Lambda)})$$

$$=\frac{q^{-C(\Lambda_0)}\tilde{\psi}_c^b}{(q-q^{-1})},$$

where

$$\tilde{\psi}_c^b=q^{(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)}-q^{(\varepsilon_c,2\rho+2\Lambda-\varepsilon_c)}.$$

So

$$\sum_{d=\bar{l}}^{\bar{b}}\frac{(-1)^{[d]}q^{2(\rho,\varepsilon_d)-2C(\Lambda_0)}}{\psi_d^b\psi_{\bar{d}}^b}\Phi_d^b=(q-q^{-1})\sum_{d=\bar{l}}^{\bar{b}}\frac{(-1)^{[d]}(q-q^{-1})q^{2(\rho,\varepsilon_d)}}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b}\Phi_d^b$$

$$=(q-q^{-1})\sum_{d=\bar{l}}^{\bar{b}}\frac{(q^{2(\varepsilon_d,\varepsilon_d)}-1)q^{2(\rho,\varepsilon_d)-(\varepsilon_d,\varepsilon_d)}}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b}\Phi_d^b \quad (21)$$

and

$$\Phi_{d+1}^b=\frac{(\alpha_b-\alpha_d)(\alpha_b-\alpha_{\bar{d}})}{\psi_d^b\psi_{\bar{d}}^b}\Phi_d^b$$

$$=\frac{(q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-q^{(\varepsilon_d,\varepsilon_d+2\rho+2\Lambda)})(q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-q^{(\varepsilon_d,\varepsilon_d-2\rho-2\Lambda)})}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b}\Phi_d^b$$

for $d\geqslant\bar{l}$. Now

$$(q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-q^{(\varepsilon_d,\varepsilon_d+2\rho+2\Lambda)})(q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-q^{(\varepsilon_d,\varepsilon_d-2\rho-2\Lambda)})$$

$$=q^{2(\varepsilon_d,\varepsilon_d)}(q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-q^{(\varepsilon_d,-\varepsilon_d+2\rho+2\Lambda)})(q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-q^{-(\varepsilon_d,\varepsilon_d+2\rho+2\Lambda)})$$

$$+q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}(1-q^{2(\varepsilon_d,\varepsilon_d)})+q^{2(\varepsilon_d,\varepsilon_d)}-1$$

$$= q^{2(\varepsilon_d,\varepsilon_d)}\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b - (q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)(q^{2(\varepsilon_d,\varepsilon_d)}-1).$$

Then, for $d \geqslant \bar{l}$,

$$\frac{\Phi_{d+1}^b}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)} = \left[\frac{q^{2(\varepsilon_d,\varepsilon_d)}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)} - \frac{(q^{2(\varepsilon_d,\varepsilon_d)}-1)}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b}\right]\Phi_d^b. \tag{22}$$

Now for $d=\bar{b}$,

$$\frac{(q^{2(\varepsilon_d,\varepsilon_d)}-1)q^{2(\rho,\varepsilon_d)-(\varepsilon_d,\varepsilon_d)}}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b} = \frac{(q^{2(\varepsilon_b,\varepsilon_b)}-1)q^{2(\rho,\varepsilon_{\bar{b}})-(\varepsilon_b,\varepsilon_b)}}{(q^{(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)}-q^{-(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)})q^{(\varepsilon_b,2\rho+2\Lambda)}(q^{(\varepsilon_b,\varepsilon_b)}-q^{-(\varepsilon_b,\varepsilon_b)})}$$

$$= \frac{q^{2(\rho,\varepsilon_{\bar{b}})+(\varepsilon_b,\varepsilon_b)}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)},$$

which can be written as

$$\frac{(q^{2(\varepsilon_d,\varepsilon_d)}-1)q^{2(\rho,\varepsilon_d)-(\varepsilon_d,\varepsilon_d)}}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b} = \frac{q^{2(\rho,\varepsilon_{\bar{b}-1})-(\varepsilon_{\bar{b}-1},\varepsilon_{\bar{b}-1})}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)}$$

when $b<l$. Hence Eq. (22) can be used to pairwise cancel the terms in the sum in Eq. (21). Adding the first two terms $(d=\bar{b},\bar{b}-1)$, we find

$$q^{2(\rho,\varepsilon_{\bar{b}-1})-(\varepsilon_{\bar{b}-1},\varepsilon_{\bar{b}-1})}\left[\frac{\Phi_{\bar{b}}^b}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)} + \frac{(q^{2(\varepsilon_{\bar{b}-1},\varepsilon_{\bar{b}-1})}-1)}{\tilde{\psi}_{\bar{b}-1}^b\tilde{\psi}_{b+1}^b}\Phi_{\bar{b}-1}^b\right]$$

$$= q^{2(\rho,\varepsilon_{\bar{b}-1})-(\varepsilon_{\bar{b}-1},\varepsilon_{\bar{b}-1})}\frac{q^{2(\varepsilon_{\bar{b}-1},\varepsilon_{\bar{b}-1})}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)}\Phi_{\bar{b}-1}^b$$

$$= \frac{q^{2(\rho,\varepsilon_{\bar{b}-2})-(\varepsilon_{\bar{b}-2},\varepsilon_{\bar{b}-2})}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)}\Phi_{\bar{b}-1}^b.$$

Continuing to apply Eq. (22) in this manner gives

$$\sum_{d=\bar{l}}^{\bar{b}}\frac{(q^{2(\varepsilon_d,\varepsilon_d)}-1)q^{2(\rho,\varepsilon_d)-(\varepsilon_d,\varepsilon_d)}}{\tilde{\psi}_d^b\tilde{\psi}_{\bar{d}}^b}\Phi_d^b = \frac{q^{2(\rho,\varepsilon_{\bar{l}})+(\varepsilon_l,\varepsilon_l)}}{(q^{2(\varepsilon_b,\varepsilon_b+\rho+\Lambda)}-1)}\Phi_{\bar{l}}^b$$

$$= \frac{q^{2l+1-m}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)}. \tag{23}$$

Hence in the case $m=2l+1$,

$$P_{\bar{b}\bar{b}}^- = (-1)^{[b]}q^{2(\rho,\varepsilon_b)}\left[\frac{\psi_0^b}{\alpha_b-\alpha_0} - \frac{(q-q^{-1})}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)}\right]\prod_{\substack{c=b+1\\c\neq 0}}^{\bar{b}}\frac{\psi_c^b}{(\alpha_b^\Lambda-\alpha_c^\Lambda)}.$$

By substituting in the formulas for ψ_c^b and α_b and simplifying we obtain

$$P_{\bar{b}\bar{b}}^- = (-1)^{[b]}q^{2(\rho,\varepsilon_b)}\left[1+(q-q^{-1})\frac{q^{(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}}{(q^{2(\varepsilon_b,\varepsilon_b+2\rho+2\Lambda)}-1)}\right]\prod_{c=b+1}^{\bar{b}}\frac{(q^{(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)}-q^{(\varepsilon_c,2\rho+2\Lambda-\varepsilon_c)})}{(q^{(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)}-q^{(\varepsilon_c,2\rho+2\Lambda+\varepsilon_c)})},$$

and thus for $a \geqslant \bar{b} > 0$,

$$P_{ab} = (-1)^{[b]} q^{2(\rho,\varepsilon_b)} \left[1 + (q - q^{-1}) \frac{q^{(\varepsilon_b, \varepsilon_b + 2\rho + 2\Lambda)}}{(q^{2(\varepsilon_b, \varepsilon_b + 2\rho + 2\Lambda)} - 1)} \right] \prod_{c=b+1}^{a} \frac{(q^{(\varepsilon_b, 2\rho + 2\Lambda + \varepsilon_b)} - q^{(\varepsilon_c, 2\rho + 2\Lambda - \varepsilon_c)})}{(q^{(\varepsilon_b, 2\rho + 2\Lambda + \varepsilon_b)} - q^{(\varepsilon_c, 2\rho + 2\Lambda + \varepsilon_c)})}.$$

Similarly, we find from Eqs. (18), (20), (21), and (23) that when m is even then

$$P_{ab} = (-1)^{[b]} q^{2(\rho,\varepsilon_b)} \left[1 - \frac{q(q - q^{-1})}{(q^{2(\varepsilon_b, \varepsilon_b + 2\rho + 2\Lambda)} - 1)} \right] \prod_{c=b+1}^{a} \frac{(q^{(\varepsilon_b, 2\rho + 2\Lambda + \varepsilon_b)} - q^{(\varepsilon_c, 2\rho + 2\Lambda - \varepsilon_c)})}{(q^{(\varepsilon_b, 2\rho + 2\Lambda + \varepsilon_b)} - q^{(\varepsilon_c, 2\rho + 2\Lambda + \varepsilon_c)})}$$

for $a \geqslant \bar{b} > 0$. Hence we have found expressions for P_{ab} for all a, b satisfying $a \geqslant \bar{b} > 0$. At the end of the paper these, together with the earlier results for P_{ab}, will be used to calculate $\chi_\Lambda(C_l)$.

Now we return to the diagonalization of the matrix N. We know

$$(N^{-1}M)_{ab} = \alpha_a^\Lambda (N^{-1})_{ab}.$$

Substituting in the values for M_{ab} gives

$$\alpha_b^\Lambda (N^{-1})_{ab} + (-1)^{[b]} q^{(2\rho,\varepsilon_b) - C(\Lambda_0)} \sum_{c>b} q^{(2\Lambda,\varepsilon_c)} (1 - \delta_{\bar{b}}^c (-1)^{[b]} q^{-2(\rho,\varepsilon_b)}) (N^{-1})_{ac} = \alpha_a^\Lambda (N^{-1})_{ab}. \tag{24}$$

Set

$$\hat{Q}_{ab} = \sum_{c \geqslant b} q^{2(\Lambda,\varepsilon_c)} (N^{-1})_{ac}.$$

We then solve for $\hat{Q}_{ab}$, with the calculations being very similar to those for P_{ab}. For $0 \leqslant b < a$ and $b < a \leqslant 0$ we find

$$\hat{Q}_{ab} = q^{2(\Lambda,\varepsilon_a)} \prod_{c=b}^{a-1} \frac{\psi_c^a}{(\alpha_a^\Lambda - \alpha_c^\Lambda)}.$$

For $m = 2l + 1$ we obtain

$$\hat{Q}_{ab} = q^{2(\Lambda,\varepsilon_a)} \left[1 + (q - q^{-1}) \frac{q^{(\varepsilon_a, \varepsilon_a + 2\rho + 2\Lambda)}}{(q^{2(\varepsilon_a, \varepsilon_a + 2\rho + 2\Lambda)} - 1)} \right] \prod_{c=b}^{a-1} \frac{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} - q^{(\varepsilon_c, 2\rho + 2\Lambda - \varepsilon_c)})}{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} - q^{(\varepsilon_c, 2\rho + 2\Lambda + \varepsilon_c)})}$$

for $b \leqslant \bar{a} < 0$. Similarly, for even m we find

$$\hat{Q}_{ab} = q^{2(\Lambda,\varepsilon_a)} \left[1 - \frac{q(q - q^{-1})}{(q^{2(\varepsilon_a, \varepsilon_a + 2\rho + 2\Lambda)} - 1)} \right] \prod_{c=b}^{a-1} \frac{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} - q^{(\varepsilon_c, 2\rho + 2\Lambda - \varepsilon_c)})}{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} - q^{(\varepsilon_c, 2\rho + 2\Lambda + \varepsilon_c)})}.$$

for $b \leqslant \bar{a} < 0$.

To use these results to calculate $\chi_\Lambda(C_l)$ we introduce a new function Q_{ab}, defined by

$$Q_{ab} = \sum_{c \geqslant b} (N^{-1})_{ac}.$$

Then from Eqs. (14) and (16) we deduce

$$\chi_\Lambda(C_l) = \sum_a (\alpha_a^\Lambda)^l P_{(\mu=\bar{1})a} Q_{a(\nu=1)}. \tag{25}$$

However we know

$$t_a^{(l)} = \frac{q^{2(\Lambda,\varepsilon_a)} - 1}{q - q^{-1}},$$

and

$$\sum_b (N^{-1})_{ab} t_b^{(1)} = \sum_{b,c} (N^{-1})_{ab} M_{bc} t_c^{(0)}$$

$$\Rightarrow \sum_b (N^{-1})_{ab} \frac{(q^{2(\Lambda,\varepsilon_b)} - 1)}{(q - q^{-1})} = \sum_b (N^{-1}M)_{ab}$$

$$= \sum_b \alpha_a^{\Lambda} (N^{-1})_{ab} = \sum_b (N^{-1})_{ab} \frac{(q^{(\varepsilon_a, 2\Lambda + 2\rho + \varepsilon_a) - C(\Lambda_0)} - 1)}{(q - q^{-1})}.$$

Thus

$$Q_{a(\nu=1)} = q^{C(\Lambda_0) - (\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} \hat{Q}_{a(\nu=1)}.$$

C. Explicit formulas for the eigenvalues

Substituting our formulas for $P_{(\mu=\bar{1})a}$ and $Q_{a(\nu=1)}$ into Eq. (25), noting that for $a \neq 0$ exactly one of $a < 0$ or $a > 0$ is true, we find the eigenvalues of the Casimir invariants C_l are given by

$$\chi_\Lambda(C_l) = \sum_a (-1)^{[a]} q^{C(\Lambda_0) - (\varepsilon_a, \varepsilon_a)} f(a) \left[\frac{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a) - C(\Lambda_0)} - 1)}{(q - q^{-1})} \right]^l$$

$$\times \prod_{b \neq a} \frac{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} - q^{(\varepsilon_b, 2\rho + 2\Lambda - \varepsilon_b)})}{(q^{(\varepsilon_a, 2\rho + 2\Lambda + \varepsilon_a)} - q^{(\varepsilon_b, 2\rho + 2\Lambda + \varepsilon_b)})},$$

where

$$f(a) = \begin{cases} 1 - (q - q^{-1}) \dfrac{q}{(q^{2(\varepsilon_a, \varepsilon_a + 2\rho + 2\Lambda)} - 1)}, & m = 2l, \\ 1 + (q - q^{-1}) \dfrac{q^{(\varepsilon_a, \varepsilon_a + 2\rho + 2\Lambda)}}{(q^{2(\varepsilon_a, \varepsilon_a + 2\rho + 2\Lambda)} - 1)}, & a \neq 0,\ m = 2l + 1, \\ 1, & a = 0,\ m = 2l + 1. \end{cases}$$

Throughout we assumed the eigenvalues were distinct. If they are not, the calculations are more complicated but the result is the same. Thus we have found the following.

Theorem 4.1: *The quantum superalgebra* $U_q[\mathrm{osp}(m|n)]$, *for* $m > 2$, *has an infinite family of Casimir invariants of the form*,

$$C_l = (\mathrm{str} \otimes I)(\pi(q^{2h_p}) \otimes I) A^l, \quad l \in \mathbb{Z}^+,$$

where

$$A = \frac{(R^T R - I \otimes I)}{(q - q^{-1})}.$$

The eigenvalues of the invariants when acting on an arbitrary irreducible finite-dimensional module with highest weight Λ *are given by*

$$\chi_\Lambda(C_l) = \sum_a (-1)^{[a]} q^{C(\Lambda_0)-(\varepsilon_a,\varepsilon_a)} f(a) \left[\frac{(q^{(\varepsilon_a,\varepsilon_a+2\rho+2\Lambda)-C(\Lambda_0)} - 1)}{(q-q^{-1})} \right]^l \times \prod_{b\neq a} \frac{(q^{(\varepsilon_a,2\rho+2\Lambda+\varepsilon_a)} - q^{(\varepsilon_b,2\rho+2\Lambda-\varepsilon_b)})}{(q^{(\varepsilon_a,2\rho+2\Lambda+\varepsilon_a)} - q^{(\varepsilon_b,2\rho+2\Lambda+\varepsilon_b)})},$$

where

$$f(a) = \begin{cases} 1-(q-q^{-1})\dfrac{q}{(q^{2(\varepsilon_a,\varepsilon_a+2\rho+2\Lambda)}-1)}, & m=2l, \\ 1+(q-q^{-1})\dfrac{q^{(\varepsilon_a,\varepsilon_a+2\rho+2\Lambda)}}{(q^{2(\varepsilon_a,\varepsilon_a+2\rho+2\Lambda)}-1)}, & a\neq 0,\ m=2l+1, \\ 1, & a=0,\ m=2l+1. \end{cases}$$

This completes the calculation of the eigenvalues of an infinite family of Casimir invariants of $U_q[\mathrm{osp}(m|n)]$ when acting on an arbitrary irreducible highest weight module, provided $m>2$. This had already been done for $U_q[\mathrm{osp}(2|n)]$, using a different method, in Ref. 12. Also every finite-dimensional representation of $U_q[\mathrm{osp}(1|n)]$ is isomorphic to a finite-dimensional representation of $U_{-q}[o(n+1)]$,[14] whose central elements are well understood. Hence the eigenvalues of a family of Casimir invariants, when acting on an arbitrary irreducible finite-dimensional highest weight module have now been calculated for all quantized orthosymplectic superalgebras. Together with the results for $U_q[\mathrm{gl}(m|n)]$,[13] this covers all nonexceptional quantized superalgebras.

Nehari techniques are used to prove the existence of multiple (indeed infinitely many) nodal type bound states for the quasilinear Schrödinger equation $iz_t - V_0 z + z'' + q(x)|z|^2 z + k(|z|^2)''z = 0$ with prescribed number of nodes. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2138045]

I. INTRODUCTION

Let $\mathbb{R}_+ = [0, +\infty)$ and $z := z(x,t): \mathbb{R}_+ \times \mathbb{R}_+ \to \mathbb{C}$ be a complex-valued function. In this paper we are concerned with the existence of multiple nodal type bound states for the following quasilinear Schrödinger equation:

$$\begin{gathered} iz_t - V_0 z + z'' + q(x)|z|^2 z + k(|z|^2)''z = 0, \\ i^2 = 1,\ k \in \mathbb{R},\ x \in \mathbb{R}_+,\ t \in \mathbb{R}_+,\ q: \mathbb{R}_+ \to \mathbb{R}_+, \end{gathered} \tag{1.1}$$

where $z'' = (\partial^2/\partial x^2) z(x,t)$. A bound state is a solution of (1.1) of the form $z(x,t) = e^{i\omega t} u(x)$ and real function $u(x)$ satisfies

$$\begin{gathered} u'' - Vu + k(|u|^2)''u + q(x)|u|^2 u = 0, \\ u(0) = 0, \quad \lim_{x \to +\infty} u(x) = 0,\ x \in \mathbb{R}_+, \end{gathered} \tag{1.2}$$

where we have set $V = V_0 + \omega$ and assume throughout this paper that $V(x)$ is positive and continuous on $\mathbb{R}_+$ and

$$(V) \quad \lim_{x \to 0^+} V(x) = V(0) > 0, \quad \lim_{x \to +\infty} V(x) = +\infty.$$

Equation (1.1) has been derived in the study of plasma physics, see Refs. 9, 11, and 13. When $k = 0$ and $q(x) = x^{-\theta}$, (1.2) has also been derived as a model in the nuclear physics.[5,7] Also when $k = 0$, both (1.1) and (1.2) have been studied extensively, see Refs. 6 and 10–12 and the references therein. When $k \neq 0$, the problem is much more natural and interesting from the physical point of view, but more difficulty in the mathematical treatment due to the presence of the quasilinear term. In a series of works, Ambrosetti-Liu-Wang-Wang have shown the existence results for such kind of problems, see Refs. 1, 3, and 4 and the references therein. But we do not see any results about the existence of multiple nodal (sign changing) solutions for the problem considered here. Our

[a)]Supported in part by Youth Foundation of NSFC and China Post-Doc Science Foundation.

goal here is to investigate the existence of multiple nodal solutions of (1.2) with prescribed number of nodes. More precisely, we have the following.

Theorem 1.1: *Let* $k>0$, $q(x)=x^{-\theta}$ *with* $0<\theta<1$ *and* (V) *holds. Then for any* $m\geqslant 2$, *there exists a solution* u *of* (1.2) *such that* u *has precisely* $m-1$ *zero points in* $(0,+\infty)$.

Note that in the statement of Theorem 1.1, m can be arbitrary. Hence if Theorem 1.1 is proved, then we have that (1.1) has multiple (indeed infinitely many) nodal type bound states. The proof of Theorem 1.1 is by variational methods. Let $H_0^1(\mathbb{R}_+)=\{u\in L^2(\mathbb{R}_+);u'\in L^2(\mathbb{R}_+),u(0)=0,\lim_{x\to+\infty}u(x)=0,\int_0^{+\infty}V(x)u^2<\infty\}$ be a Sobolev space under the norm $\|u\|^2=\int_0^{+\infty}(|u'|^2+V|u|^2)\mathrm{d}x$, on which we define the following functional:

$$J(u)=\int_0^{+\infty}\left(\frac{1}{2}(|u'|^2+V|u|^2)+ku^2|u'|^2-\frac{1}{4}x^{-\theta}|u|^4\right). \tag{1.3}$$

Then $J\in C^1(H_0^1(\mathbb{R}_+),\mathbb{R})$ (for the proof see, e.g., Ref. 8, Lemma 1 on p. 331). We say that $u\in H_0^1(\mathbb{R}_+)$ is a solution of (1.2) if and only if for any $\phi\in\mathcal{D}(\mathbb{R}_+)$ (the collections of all smooth functions with compact support in $\mathbb{R}_+$), there holds $\langle J'(u),\phi\rangle=0$. Hence to find multiple solutions of (1.2), it suffices to find multiple critical points of J on $H_0^1(\mathbb{R}_+)$. The idea of the proof is essentially due to Nehari,[6] which has also been used in Ref. 10, but we need to overcome the additional difficulty created by the quasilinear term.

This paper is organized as follows. The forthcoming section is some preliminaries. In Sec. III, we prove Theorem 1.1.

II. PRELIMINARIES

Let $0\leqslant\rho<\sigma\leqslant+\infty$. Denote $H_{\rho,\sigma}=H_0^1([\rho,\sigma))$ with the norm $\|u\|^2=\int_\rho^\sigma(|u'|^2+V|u|^2)\mathrm{d}x$ and we simply write $H_0^1([0,+\infty))$ as H. $L^p([\rho,\sigma))$ is the standard Lebesgue space with the standard norm $|\cdot|_p$. M, M_j denote various positive constants whose exact values are not important. For $\delta\to0$, we also use the standard notations $o(\delta)$ and $O(\delta)$ and $o(1)$ is a generic infinitesimal. Consider the Nehari manifold

$$\mathcal{N}(\rho,\sigma):=\left\{0\neq u\in H_{\rho,\sigma};\int_\rho^\sigma(|u'|^2+Vu^2+4ku^2|u'|^2-x^{-\theta}u^4)=0\right\}$$

and define

$$c(\rho,\sigma)=\inf_{u\in\mathcal{N}(\rho,\sigma)}J(u). \tag{2.1}$$

Then we have the following.

Proposition 2.1: If $0\leqslant\rho<\sigma\leqslant+\infty$, *then* $\mathcal{N}(\rho,\sigma)$ *is a manifold and* (*if* $\mathcal{N}(\rho,\sigma)\neq\emptyset$) *one has*

(i) *there exists* $M_1>0$ *such that* $\|u\|\geqslant M_1$, $\forall u\in\mathcal{N}(\rho,\sigma)$;
(ii) *if* $u^*\in\mathcal{N}(\rho,\sigma)$ *is a constrained critical point of* J *on* $\mathcal{N}(\rho,\sigma)$, *then* $J'(u^*)=0$.

Proof: We only show the case of $\rho=0$ and $\sigma=+\infty$ since other cases are similar but simpler. For any $u\in\mathcal{N}(0,+\infty)$, we have that

$$\int_0^{+\infty}(|u'|^2+Vu^2+4ku^2|u'|^2)=\int_0^{+\infty}x^{-\theta}u^4.$$

On the other hand, $0<\theta<1$ implies that

$$\int_0^{+\infty} x^{-\theta}u^4 = \int_0^1 x^{-\theta}u^4 + \int_1^{+\infty} x^{-\theta}u^4$$

$$\leqslant |u|_\infty^4 \int_0^1 x^{-\theta}\,\mathrm{d}x + \int_1^{+\infty} u^4$$

$$\leqslant M\|u\|^4.$$

It follows from $k>0$ that $\|u\|^2 \geqslant M_1 > 0$. The rest part of the proof can follow step by step as those in the proof of Ref. 1, Lemma 2.2. □

Proposition 2.2 (Ref. 1, Theorem 2.4): If $0 \leqslant \rho < \sigma \leqslant +\infty$, *then* $c(\rho,\sigma)$ *is always achieved at some positive* $u \in \mathcal{N}(\rho,\sigma)$, *which is a positive solution of* (1.2). *Clearly, the symmetric nature of the problem implies that* $-u$ *is a negative solution of* (1.2) *at this time.*

Lemma 2.3: For u obtained in Proposition 2.2, we have $u \in C^2(0,+\infty)$.

Proof: From Ref. 8, Theorem 1, we know that u is C^1 in $(0,+\infty)$. $\langle J'(u),\phi\rangle = 0$ for any $\phi \in \mathcal{D}(\mathbb{R}_+)$ and Ref. 2, p. 138, Theorem 6.5 imply that

$$u'' - Vu + k(|u|^2)''u + x^{-\theta}|u|^2u = 0 \text{ a.e. in } (0,+\infty).$$

Equivalently,

$$-(1+2ku^2)u'' + Vu = 2k(u')^2u + x^{-\theta}|u|^2u \text{ a.e. in } (0,+\infty).$$

It now follows from $k>0$ and u being C^1 in $(0,+\infty)$ that u'' is continuous in $(0,+\infty)$. The proof is complete. □

Lemma 2.4: Under the assumptions of Theorem 1.1, one has

(a) *if* $0 \leqslant \rho \leqslant \rho_1 < \sigma_1 \leqslant \sigma \leqslant +\infty$, *then* $c(\rho,\sigma) \leqslant c(\rho_1,\sigma_1)$;
(b) $c(\rho,\sigma) \to +\infty$ *as* $\sigma - \rho \to 0$;
(c) $c(\rho,+\infty) \to +\infty$ *as* $\rho \to +\infty$;
(d) $c(\rho,\sigma)$ *is a continuous function of* ρ *and* σ (*of* σ *if* $\rho=0$ *and of* ρ *if* $\sigma=+\infty$).

Proof: (a) If $0 \leqslant \rho \leqslant \rho_1 < \sigma_1 \leqslant \sigma \leqslant +\infty$, then $\mathcal{N}(\rho_1,\sigma_1) \subset \mathcal{N}(\rho,\sigma)$ and so that $c(\rho,\sigma) \leqslant c(\rho_1,\sigma_1)$.

(b) For every $u \in \mathcal{N}(\rho,\sigma)$, $\gamma(u) := \|u\|^2 + 4k|uu'|_2^2 - \int_\rho^\sigma x^{-\theta}|u|^4 = 0$. Thus

$$J(u) = \frac{1}{2}\|u\|^2 + k|uu'|_2^2 - \frac{1}{4}\int_\rho^\sigma x^{-\theta}|u|^4 = \frac{1}{4}\|u\|^2. \tag{2.2}$$

Since for $u \in \mathcal{N}(\rho,\sigma)$,

$$\|u\|^2 + 4k|uu'|_2^2 = \int_\rho^\sigma x^{-\theta}|u|^4 \leqslant |u|_\infty^4 \int_\rho^\sigma x^{-\theta}\,\mathrm{d}x$$

$$\leqslant M_2\|u\|^4(\sigma-\rho)^{1-\theta},$$

we have from $k>0$ and that

$$\|u\|^2 \geqslant M_3(\sigma-\rho)^{\theta-1}.$$

Therefore $c(\rho,\sigma) \to +\infty$ as $\sigma - \rho \to 0$ by (2.2) and $0 < \theta < 1$.

(c) Suppose to the contrary, there is $\rho_n \to +\infty$ but $c(\rho_n,+\infty) \leqslant M$ for some $M>0$. Using Proposition 2.2, we know that there are $u_n \in \mathcal{N}(\rho_n,+\infty)$ such that

$$J(u_n) = c(\rho_n, +\infty) \leqslant M.$$

On the one hand, $u_n \in \mathcal{N}(\rho_n, +\infty)$ implies that [the computations are similar to those in (2.2)]

$$M \geqslant J(u_n) = \tfrac{1}{4}\|u_n\|^2;$$

on the other hand, from $\int_{\rho_n}^{+\infty} x^{-\theta}|u|^4 = \|u\|^2 + 4k|uu'|_2^2$, $k>0$ and

$$\tfrac{1}{4}\|u_n\|^2 = J(u_n) = c(\rho_n, +\infty) \geqslant c(0, +\infty) \geqslant M_0 > 0$$

we know that there is Λ (Λ is independent of n) such that

$$\int_{\rho_n}^{+\infty} x^{-\theta}|u_n|^4 \geqslant \Lambda > 0.$$

It follows that

$$\Lambda \leqslant \int_{\rho_n}^{+\infty} x^{-\theta}|u_n|^4 \leqslant \rho_n^{-\theta}\int_{\rho_n}^{+\infty} |u_n|^4 \leqslant \rho_n^{-\theta}|u_n|_\infty^2 \int_{\rho_n}^{+\infty} |u_n|^2$$

$$\leqslant M_4\rho_n^{-\theta}(\|u_n\|^2)^2 \to 0 \quad \text{as } \rho_n \to +\infty,$$

which is impossible.

(d) We only treat the case of $\sigma = +\infty$ since the other cases are similar. We assume that $\rho_n \to \rho > 0$ and want to show $c(\rho_n, +\infty) = c(\rho, +\infty) + o(1)$. For every n, there exists $u_n \in \mathcal{N}(\rho_n, +\infty)$ such that $J(u_n) = c(\rho_n, +\infty)$. We define v_n on $[\rho, +\infty)$ by $v_n(x) := u_n(\rho_n x/\rho)$. First using $u_n \in \mathcal{N}(\rho_n, +\infty)$ and the expression of $J(u_n)$ we know that for some M_5,

$$\liminf_{n\to+\infty} \int_{\rho_n}^{+\infty} (|u_n'|^2 + V|u_n|^2) \geqslant M_5 > 0. \tag{2.3}$$

Since for any n,

$$\int_{\rho}^{+\infty} v_n^2(x)|v_n'(x)|^2\,\mathrm{d}x = \int_{\rho_n}^{+\infty} u_n^2(x)|u_n'(x)|^2\frac{\rho_n}{\rho}\,\mathrm{d}x,$$

$$\int_{\rho}^{+\infty} x^{-\theta}|v_n(x)|^4\,\mathrm{d}x = \int_{\rho_n}^{+\infty} x^{-\theta}|u_n(x)|^4\left(\frac{\rho}{\rho_n}\right)^{1-\theta}\mathrm{d}x,$$

we have from (2.3) and $\int_{\rho_n}^{+\infty}(|u_n'|^2 + Vu_n^2 + 4ku_n^2|u_n'|^2 - x^{-\theta}|u_n|^4) = 0$ that

$$\liminf_{n\to+\infty}\left|\int_{\rho}^{+\infty}(4k|v_n(x)|^2|v_n'(x)|^2 - x^{-\theta}|v_n(x)|^4)\right| \neq 0.$$

Therefore there is a unique $t_n > 0$ such that $t_n v_n \in \mathcal{N}(\rho, +\infty)$ with

$$t_n^2 = \int_{\rho}^{+\infty}(|v_n'|^2 + V|v_n|^2) \Big/ \int_{\rho}^{+\infty}(x^{-\theta}|v_n(x)|^4 - 4k|v_n(x)|^2|v_n'(x)|^2).$$

Moreover we know from the above calculations that $t_n \to 1$ as $n \to +\infty$. Now from the definition of $\mathcal{N}(\rho, +\infty)$ and $t_n v_n \in \mathcal{N}(\rho, +\infty)$ that

$$\int_{\rho}^{+\infty} (|(t_n v_n)'|^2 + V(t_n v_n)^2) = t_n^2 \int_{\rho}^{+\infty} (|v_n'|^2 + V v_n^2)$$

$$= t_n^2 \int_{\rho_n}^{+\infty} \left(\frac{\rho_n^2}{\rho^2} |u_n'|^2 + V\left(\frac{\rho}{\rho_n} x \right) u_n^2 \right) \frac{\rho}{\rho_n^2}$$

$$= \int_{\rho_n}^{+\infty} (|u_n'|^2 + V u_n^2) + o(1),$$

which implies that $J(t_n v_n) = J(u_n) + o(1)$ $(n \to +\infty)$. The conclusion follows. □

III. PROOF OF THEOREM 1.1

Proof of Theorem 1.1: (1) We fix some integer $m \geqslant 2$ and want to find a solution u of (1.2) such that u has precisely $m-1$ zero points in $(0, +\infty)$. For any $0 \leqslant \rho < \sigma \leqslant +\infty$, we obtain from Proposition 2.2 that $c(\rho, \sigma) = \inf_{u \in \mathcal{N}(\rho,\sigma)} J(u)$ is a critical value of J which has a pair of critical points which define one positive and one negative solution of (1.2).

(2) Define

$$c(\rho_0, \ldots, \rho_m) = \sum_{j=0}^{m-1} c(\rho_j, \rho_{j+1}), \quad 0 = \rho_0 < \rho_1 < \cdots < \rho_{m-1} < \rho_m = +\infty,$$

by property (d) of Lemma 2.4, $c(\rho_0, \ldots, \rho_m)$ is continuous on $\rho_1, \ldots, \rho_{m-1}$. Properties (b) and (c) of Lemma 2.4 imply that $\{\rho_j\}$ must be bounded away from each other and from infinity in any sequences of sets, for which $c(\rho_0, \ldots, \rho_m)$ tends to its greatest lower bound. It is thus sufficient to confine the values $\rho_1, \ldots, \rho_{m-1}$ to a sufficiently large finite interval $[0, T]$ and therefore the minimum of $c(\rho_0, \ldots, \rho_m)$ is actually attained for some set of $m-1$ finite distinct values ρ_j with $0 < \rho_j < \rho_{j+1}$.

(3) Define

$$w_m(x) := u_j(x), \quad \rho_j \leqslant x < \rho_{j+1}, \quad j = 0, \ldots, m-1, \tag{3.1}$$

where u_j is chosen such that

(i) u_j is a positive solution of (1.2) for $\rho_j \leqslant x < \rho_{j+1}$, $0 \leqslant j \leqslant m-1$ and j even;
(ii) u_j is a negative solution of (1.2) for $\rho_j \leqslant x < \rho_{j+1}$, $0 \leqslant j \leqslant m-1$ and j odd.

Now the conclusions of Theorem 1.1 follows from Lemma 3.1. □

Lemma 3.1: Under the assumptions of Theorem 1.1, w_m satisfies

$$u'' - Vu + k(|u|^2)'' u + x^{-\theta} |u|^2 u = 0. \tag{3.2}$$

Moreover w_m has precisely $m-1$ nodes.

Proof: Clearly, $u := w_m$ satisfies (3.2) for $x \in \{0 < x < +\infty; x \neq \rho_j, j = 1, 2, \ldots, m-1\}$. Following Nehari,[6] it suffices to prove that

$$u_+' := \lim_{x \downarrow \rho_j} u'(x) = \lim_{x \uparrow \rho_j} u'(x) := u_-', \quad j = 1, 2, \ldots, m-1. \tag{3.3}$$

We prove this by contradictions. Assuming $u_+' \neq u_-'$ and setting $\rho := \rho_{j-1}$, $\sigma := \rho_j$, $\tau := \rho_{j+1}$ for convenience, we may assume that $u \geqslant 0$ on $[\rho, \sigma]$ and $u \leqslant 0$ on $[\sigma, \tau]$. Now we fix a sufficiently small $\delta > 0$ and define $v: [\rho, \tau] \to \mathbb{R}$ by

$$v(x) := u(x) \quad \text{if } |x-\sigma| \geqslant \delta,$$
$$:= u(\sigma-\delta) + \frac{(x-\sigma+\delta)(u(\sigma+\delta)-u(\sigma-\delta))}{2\delta} \quad \text{if } |x-\sigma| \leqslant \delta.$$

Clearly, v is continuous on $[\rho,\sigma]$. Let $\sigma_0=\sigma(\delta)\in(\sigma-\delta,\sigma+\delta)$ be defined by $v(\sigma_0)=0$, indeed there holds

$$\sigma_0 = \sigma - \delta - \frac{2\delta u(\sigma-\delta)}{u(\sigma+\delta)-u(\sigma-\delta)}.$$

We now obtain from Lemma 3.2 that there is $\alpha=\alpha(\delta)>0$ such that $\alpha v\in\mathcal{N}(\rho,\sigma_0)$ with

$$\alpha^2 = \int_\rho^{\sigma_0} (|v'|^2+Vv^2) \Big/ \int_\rho^{\sigma_0} (x^{-\theta}|v|^4 - 4k|v|^2|v'|^2).$$

Similarly, we have $\beta=\beta(\delta)>0$ such that $\beta v\in\mathcal{N}(\sigma_0,\tau)$ with

$$\beta^2 = \int_{\sigma_0}^{\tau} (|v'|^2+Vv^2) \Big/ \int_{\sigma_0}^{\tau} (x^{-\theta}|v|^4 - 4k|v|^2|v'|^2).$$

Next, we define $w\colon [\rho,\tau]\to\mathbb{R}$ by setting

$$w(x) := \begin{cases} \alpha v(x) & \text{if } \rho\leqslant x\leqslant\sigma_0, \\ \beta v(x) & \text{if } \sigma_0\leqslant x\leqslant\tau. \end{cases}$$

Keeping the expression of J in mind, we obtain from the relation $\frac{1}{4}(w^4+u^4)\geqslant\frac{1}{2}w^2u^2$ and the fact that $-u''u+Vu^2-k(u^2)''u^2=x^{-\theta}u^4$ holds up to finite points that

$$\begin{aligned} J(w) &= \int_\rho^\tau \left(\frac{1}{2}(|w'|^2+V|w|^2)+kw^2|w'|^2-\frac{1}{4}x^{-\theta}|w|^4\right) \\ &\leqslant \int_\rho^\tau \left(\frac{1}{2}(|w'|^2+V|w|^2)+kw^2|w'|^2-\frac{1}{4}x^{-\theta}|u|^4-\frac{1}{2}x^{-\theta}w^2u^2+\frac{1}{2}x^{-\theta}u^4\right) \\ &= \int_\rho^\tau \left(\frac{1}{2}(|w'|^2+V|w|^2)+kw^2|w'|^2-\frac{1}{4}x^{-\theta}|u|^4-\frac{1}{2}x^{-\theta}w^2u^2\right)+\frac{1}{2}\int_\rho^\tau (-u''u+Vu^2-k(u^2)''u^2) \\ &= J(u)+k\int_\rho^\tau u^2|u'|^2+\int_\rho^\tau \left(\frac{1}{2}(|w'|^2+V|w|^2)+kw^2|w'|^2-\frac{1}{2}x^{-\theta}w^2u^2\right) \\ &= J(u)+k\int_\rho^\tau u^2|u'|^2+\int_\rho^\tau B_1. \end{aligned} \tag{3.4}$$

Note that on $[\rho,\sigma-\delta]$, $w(x)=\alpha v(x)=\alpha u(x)$, then

$$\int_\rho^{\sigma-\delta} B_1 = \int_\rho^{\sigma-\delta} \left(\frac{\alpha^2}{2}(|u'|^2+V|u|^2)+\alpha^4ku^2|u'|^2-\frac{\alpha^2}{2}x^{-\theta}u^4\right). \tag{3.5}$$

Since

$$\int_\rho^{\sigma-\delta} x^{-\theta}u^4 = \int_\rho^{\sigma-\delta} (-u''u+Vu^2-k(u^2)''u^2)$$

and

$$\int_{\rho}^{\sigma-\delta}(-u''u) = -u(\sigma-\delta)u'(\sigma-\delta) + \int_{\rho}^{\sigma-\delta}|u'|^2, \tag{3.6}$$

$$\int_{\rho}^{\sigma-\delta}(-k(u^2)''u^2) = -2ku^3(\sigma-\delta)u'(\sigma-\delta) + 4k\int_{\rho}^{\sigma-\delta}u^2|u'|^2, \tag{3.7}$$

we obtain from

$$u(\sigma+\delta) = u'_+\delta + o(\delta) \quad \text{and } u(\sigma-\delta) = -u'_-\delta + o(\delta)$$

that

$$\begin{aligned}\int_{\rho}^{\sigma-\delta}B_1 &= \int_{\rho}^{\sigma-\delta}\left(\frac{\alpha^2}{2}(|u'|^2+Vu^2)+\alpha^4ku^2|u'|^2\right) - \frac{\alpha^2}{2}\int_{\rho}^{\sigma-\delta}(-u''u+Vu^2-k(u^2)''u^2)\\ &= \int_{\rho}^{\sigma-\delta}\left(\frac{\alpha^2}{2}(|u'|^2+Vu^2)+\alpha^4ku^2|u'|^2\right) - \frac{\alpha^2}{2}\Bigg(-u(\sigma-\delta)u'(\sigma-\delta) + \int_{\rho}^{\sigma-\delta}(|u'|^2+Vu^2)\\ &\quad -2ku^3(\sigma-\delta)u'(\sigma-\delta)+4k\int_{\rho}^{\sigma-\delta}u^2|u'|^2\Bigg) = (\alpha^4-2\alpha^2)k\int_{\rho}^{\sigma-\delta}u^2|u'|^2\\ &\quad +\frac{\alpha^2}{2}u(\sigma-\delta)u'(\sigma-\delta)+ku^3(\sigma-\delta)u'(\sigma-\delta)\\ &= (\alpha^4-2\alpha^2)k\int_{\rho}^{\sigma-\delta}u^2|u'|^2 - \frac{\alpha^2}{2}\delta(u'_-)^2+o(\delta).\end{aligned} \tag{3.8}$$

On $[\sigma+\delta,\tau]$ and $w(x)=\beta v(x)=\beta u(x)$, we obtain from a similar calculation that

$$\int_{\sigma+\delta}^{\tau}B_1 = (\beta^4-2\beta^2)k\int_{\sigma+\delta}^{\tau}u^2|u'|^2 - \frac{\beta^2}{2}\delta(u'_+)^2+o(\delta). \tag{3.9}$$

We now estimate the right-hand side of equality $\int_{\sigma-\delta}^{\sigma+\delta}B_1=\int_{\sigma-\delta 2}^{\sigma+\delta 1}(|w'|^2+V|w|^2)+kw^2|w'|^2 - \frac{1}{2}x^{-\theta}w^2u^2$. Since when $|x-\sigma|\leqslant\delta$ and δ small,

$$v(x) = -u'_-\delta + o(\delta) + \tfrac{1}{2}(x-\sigma+\delta)(u'_+ + u'_- + o(\delta)), \tag{3.10}$$

we know from (3.10) and (3.17) that

$$\int_{\sigma-\delta}^{\sigma+\delta}\frac{w^2}{2}(V-x^{-\theta}u^2) = \int_{\sigma-\delta}^{\sigma_0}\frac{\alpha^2v^2}{2}(V-x^{-\theta}u^2) + \int_{\sigma_0}^{\sigma+\delta}\frac{\beta^2v^2}{2}(V-x^{-\theta}u^2) = o(\delta). \tag{3.11}$$

Similarly,

$$k\int_{\sigma-\delta}^{\sigma+\delta}w^2|w'|^2 = o(\delta). \tag{3.12}$$

For the term $\int_{\sigma-\delta}^{\sigma+\delta}\frac{1}{2}|w'|^2$, we use the fact that

$$|w'(x)|^2 = |\alpha v'(x)|^2 = \frac{\alpha^2}{4}(u'_+ + u'_- + o(\delta))^2, \quad \forall\ \sigma-\delta<x<\sigma_0$$

and

$$|w'(x)|^2 = |\beta v'(x)|^2 = \frac{\beta^2}{4}(u'_+ + u'_- + o(\delta))^2, \quad \forall\ \sigma_0 < x < \sigma + \delta$$

to get that

$$\int_{\sigma-\delta}^{\sigma+\delta} \frac{1}{2}|w'|^2 = \frac{\alpha^2}{4}(u'_+ + u'_- + o(\delta))(\delta u'_- + o(\delta)) + \frac{\beta^2}{4}(u'_+ + u'_- + o(\delta))(\delta u'_+ + o(\delta))$$

$$= \frac{\delta}{4}(u'_+ + u'_-)^2 + o(\delta), \tag{3.13}$$

where we use (3.21) and (3.22). For the term $k\int_{\sigma-\delta}^{\sigma+\delta} u^2|u'|^2$, since when $\delta \to 0$,

$$u(x) := (x-\sigma)u'_- + o(x-\sigma) \quad \text{for } \sigma - \delta < x < \sigma,$$

$$:= (x-\sigma)u'_+ + o(x-\sigma) \quad \text{for } \sigma < x < \sigma + \delta$$

and

$$u'(x) := u'_- + O(x-\sigma) \quad \text{for } \sigma - \delta < x < \sigma,$$

$$:= u'_+ + O(x-\sigma) \quad \text{for } \sigma < x < \sigma + \delta,$$

we know that

$$k\int_{\sigma-\delta}^{\sigma+\delta} u^2|u'|^2 = O(\delta^2). \tag{3.14}$$

Thus we have from (3.19) and (3.20) that

$$J(w) \leqslant J(u) + k\int_\rho^\tau u^2|u'|^2 + \int_\rho^\tau B_1 = J(u) + k\int_\rho^\tau u^2|u'|^2 + \left(\int_\rho^{\sigma-\delta} + \int_{\sigma+\delta}^\tau + \int_{\sigma-\delta}^{\sigma+\delta}\right)B_1$$

$$= J(u) + k\int_\rho^\tau u^2|u'|^2 + (\alpha^4 - 2\alpha^2)k\int_\rho^{\sigma-\delta} u^2|u'|^2 + (\beta^4 - 2\beta^2)k\int_{\sigma+\delta}^\tau u^2|u'|^2$$

$$+ \int_{\sigma-\delta}^{\sigma+\delta}\left(\frac{1}{2}|w'|^2 + kw^2|w'|^2 + \frac{w^2}{2}(V - x^{-\theta}u^2)\right)$$

$$= J(u) + (1 + \alpha^4 - 2\alpha^2)k\int_\rho^{\sigma-\delta} u^2|u'|^2 + (1 + \beta^4 - 2\beta^2)k\int_{\sigma+\delta}^\tau u^2|u'|^2$$

$$- \frac{\alpha^2}{2}\delta(u'_-)^2 - \frac{\beta^2}{2}\delta(u'_+)^2 + o(\delta) + \frac{\delta}{4}(u'_+ + u'_-)^2. \tag{3.15}$$

It follows from (3.21) and (3.22) that

$$J(w) \leqslant J(u) + o(\delta) - \frac{\delta}{4}(u'_+ - u'_-)^2.$$

$u'_+ \neq u'_-$ implies that

$$J(w) < J(u) \quad \text{for } \delta > 0 \text{ small},$$

which is a contradiction to the construction of $u := w_m$. The proof is complete. □

Lemma 3.2: For ρ, σ_0, v, *and* u *as in Lemma 3.1, there exists* $M > 0$ *such that*

$$\left| 4k\int_{\rho}^{\sigma_0} v^2|v'|^2 - \int_{\rho}^{\sigma_0} x^{-\theta}v^4 \right| \geqslant M \quad \textit{for } \delta > 0 \textit{ small enough}.$$

Proof: Suppose to the contrary, we assume that

$$4k\int_{\rho}^{\sigma_0} v^2|v'|^2 - \int_{\rho}^{\sigma_0} x^{-\theta}v^4 = o(1) \quad (\delta \to 0),$$

i.e.,

$$4k\int_{\rho}^{\sigma-\delta} u^2|u'|^2 + 4k\int_{\sigma-\delta}^{\sigma_0} v^2|v'|^2 = \int_{\rho}^{\sigma-\delta} x^{-\theta}u^4 + \int_{\sigma-\delta}^{\sigma_0} x^{-\theta}v^4 = o(1). \tag{3.16}$$

Since for $\delta \to 0$,

$$u(\sigma+\delta) = u'_+\delta + o(\delta), \quad u(\sigma-\delta) = -u'_-\delta + o(\delta),$$

we have that

$$\sigma_0 = \sigma - \delta + \frac{2u'_-\delta}{u'_+ + u'_-} + o(\delta), \tag{3.17}$$

and

$$v(x) = -u'_-\delta + o(\delta) + \tfrac{1}{2}(x-\sigma+\delta)(u'_+ + u'_- + o(\delta)). \tag{3.18}$$

Direct computations show that

$$\int_{\sigma-\delta}^{\sigma_0} v^2|v'|^2 = \frac{(u'_+ + u'_-)^2}{4}\int_{\sigma-\delta}^{\sigma_0}\left(-u'_-\delta + o(\delta) + \frac{1}{2}(x-\sigma+\delta)(u'_+ + u'_- + o(\delta))\right)$$

$$= \frac{(u'_+ + u'_-)^2}{4}(-u'_-\delta + o(\delta))^2\left(\frac{2u'_-\delta}{u'_+ + u'_-} + o(\delta)\right)$$

$$+ \frac{(u'_+ + u'_-)^2}{8}(-u'_-\delta + o(\delta))(u'_+ + u'_- + o(\delta))\left(\frac{2u'_-\delta}{u'_+ + u'_-} + o(\delta)\right)^2$$

$$+ \frac{(u'_+ + u'_-)^2}{24}(u'_+ + u'_- + o(\delta))^2\left(\frac{2u'_-\delta}{u'_+ + u'_-} + o(\delta)\right)^3$$

$$= o(\delta^2).$$

Similarly

$$\int_{\sigma-\delta}^{\sigma_0} x^{-\theta}v^4 = o(\delta^2).$$

Therefore

$$4k\int_{\rho}^{\sigma-\delta} u^2|u'|^2 = \int_{\rho}^{\sigma-\delta} x^{-\theta}u^4 + o(1).$$

Thus

$$\int_{\rho}^{\sigma-\delta} (|u'|^2 + Vu^2) = o(1),$$

which contradicts to the fact that $u \neq 0$ on (ρ, σ). The proof is complete. □

Lemma 3.3: Let ρ, σ, σ_0, α, β, v, and u be as in the proof of Lemma 3.1. Then we have that

$$1 + \alpha^4 - 2\alpha^2 = O(\delta^2) \quad (\delta \to 0), \tag{3.19}$$

$$1 + \beta^4 - 2\beta^2 = O(\delta^2) \quad (\delta \to 0). \tag{3.20}$$

Proof: Denote $E = \int_{\rho}^{\sigma}(|u'|^2 + Vu^2)$, $F = \int_{\rho}^{\sigma}(x^{-\theta}u^4 - 4ku^2|u'|^2)$ and keep the definition of v in mind, we have that

$$\int_{\rho}^{\sigma_0} (|v'|^2 + Vv^2) = \int_{\rho}^{\sigma} (|u'|^2 + Vu^2) + \int_{\sigma-\delta}^{\sigma_0} (|v'|^2 + Vv^2) - \int_{\sigma-\delta}^{\sigma} (|u'|^2 + Vu^2)$$

$$\begin{aligned} &= E + \frac{1}{4}\int_{\sigma-\delta}^{\sigma_0} (u'_+ + u'_- + o(\delta))^2 \\ &\quad + (-u'_-\delta + o(\delta) + (x - \sigma + \delta)(u'_+ + u'_- + o(\delta)))^2 \\ &\quad - \int_{\sigma-\delta}^{\sigma} (|u'|^2 + Vu^2) \end{aligned}$$

$$\begin{aligned} &= E + \frac{1}{4}\int_{\sigma-\delta}^{\sigma_0} (u'_+ + u'_- + o(\delta))^2 + o(\delta) \\ &\quad - \int_{\sigma-\delta}^{\sigma} (u'_- + o(x - \sigma))^2 + (u'_-(x - \sigma) + o(x - \sigma))^2 \end{aligned}$$

$$= E + \frac{\delta}{2}(u'_+ + u'_- + o(\delta))(u'_- + o(\delta)) - \delta(u'_-)^2 + o(\delta).$$

Similarly,

$$\int_{\rho}^{\sigma_0} (x^{-\theta}v^4 - 4kv^2|v'|^2) = F + o(\delta).$$

Combining these with the fact that $E = F$ we get that

$$\alpha^2 = \left(E + \frac{\delta}{2}(u'_+ + u'_- + o(\delta))(u'_- + o(\delta)) - \delta(u'_-)^2 + o(\delta)\right) \Big/ F + o(\delta) = 1 + \frac{\delta}{2F}(u'_+ - u'_-)u'_- + o(\delta). \tag{3.21}$$

Hence

$$1 + \alpha^4 - 2\alpha^2 = O(\delta^2) \quad (\delta \to 0).$$

Similar arguments give

$$\beta^2 = 1 + O(\delta) \tag{3.22}$$

and therefore $1 + \beta^4 - 2\beta^2 = O(\delta^2)$. The conclusions follow. □

(Received 13 July 2004; accepted 23 September 2005; published online 14 December 2005)

In this paper we classify invariant noncommutative connections in the framework of the algebra of endomorphisms of a complex vector bundle. It has been proven previously that this noncommutative algebra generalizes in a natural way the ordinary geometry of connections. We use explicitly some geometric constructions usually introduced to classify ordinary invariant connections, and we expand them using algebraic objects coming from the noncommutative setting. The main result is that the classification can be performed using a "reduced" algebra, an associated differential calculus and a module over this algebra. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2131206]

I. INTRODUCTION

Symmetries in gauge fields theories play an important role in physics. For instance, they have been used as possible procedures to introduce scalar Higgs fields using dimensional reductions. Solitons, as well as instantons and monopoles, have often been introduced and/or recognized as symmetric solutions of gauge fields equations. Extensive mathematical and physical studies of such symmetries have been proposed, using various approaches, and many examples have been given (see for instance Refs. 1 and 2 for a mathematical point of view, and Refs. 3–8 for a more physical point of view).

On the other hand, gauge fields have been generalized in the noncommutative framework, in some very natural ways. For a large class of examples developed so far, noncommutative connections incorporate at the same time, and without too much arbitrariness, not only ordinary non-Abelian gauge fields, but also some scalar fields which can be naturally interpreted as Higgs fields (see Refs. 9 and 10 for reviews, and references therein).

In the present paper, we study invariant noncommutative connections in a noncommutative framework which is very strongly connected to ordinary differential geometry. We take as our starting point a noncommutative algebra equipped with the derivation based differential calculus introduced in Ref. 11. This algebra is the algebra of endomorphisms of a SU (n)-vector bundle. Its structure and its relations to ordinary differential geometry have been extensively studied in Refs. 12 and 13, where it has been proven to play a very similar role to a SU (n)-principal fiber bundle. In this framework, noncommutative connections extend in a very natural and tractable way ordinary connections on the underlying principal fiber bundle. This permits us to generalize some of the analysis performed in previous works about invariant (ordinary) connections, in particular it is possible to use explicitly some of the geometric constructions related to their classification. Moreover, mixing those geometrical tools and the algebraic approach underlying noncommutative geometry, the classification of invariant noncommutative connections forces us to introduce mathematical objects which are more natural than in the ordinary case.

We have tried to make this paper as self-contained as possible. It is organized as follows. In Sec. II we summarize previous works about classification of invariant (ordinary) connections. These results are not new, but we have tried to make a synthesis of the main approaches to this problem. In particular, we introduce there some geometrical constructions which are extensively used later. Section III is devoted to the noncommutative framework. There, we expose the main results about the algebra we will consider, and we try to explain its relations to ordinary differential geometry. New results about the relations between this noncommutative geometry and the underlying ordinary geometry are exposed. Then comes the section which is the main part of this paper. We expose the classification of invariant noncommutative connections, emphasing what is common to the ordinary case and what is new. In particular, we show that the classification can be performed using objects inspired by noncommutative geometry: a "reduced" algebra, an associated differential calculus and a module over this algebra. At last, we study two important examples. One of our motivations for this work was to classify the degrees of freedom of spherically symmetric fields involved in noncommutative models. In the first example, we implement this spherical symmetry in a noncommutative situation which would correspond to an ordinary (trivial) SU (2)-principal fiber bundle. The results obtained lead to a natural generalization of the so-called Witten's anzatz.[14,3] The second example is a purely noncommutative situation based on a matrix algebra.

II. INVARIANT CONNECTIONS ON PRINCIPAL FIBER BUNDLES

In this section, we would like to summarize previous works on invariant connections in ordinary differential geometry. First, we introduce some notations and some general geometrical constructions which are useful to characterize invariant connections. Two approaches are then proposed, a global one, investigated in Refs. 6, 5, and 4, and a "local" one, investigated in Refs. 3 and 8. The constructions presented here will be used again in Sec. IV where we characterize noncommutative invariant connections.

A. Reduction of fiber bundles

Let us introduce the notations and the hypothesis we make. The analysis presented here is essentially based on the work of Jadczyck *et al.*[5]

We consider a principal fiber bundle $E(M,H)$, denoted by the following diagram of fibrations

$$H \to E \xrightarrow{\pi} M,$$

with structure group H. We then consider a compact Lie group G which acts on the left on E. We denote this action by $G \circlearrowright E$. We naturally assume that the two actions $G \circlearrowright E$ and $E \circlearrowright H$ do commute. In other words, G will be considered in the following as a subgroup of $\mathrm{Aut}(E)$, the group of automorphisms of E. The fiber bundle E is called a G-symmetric fiber bundle. Then the projection π induces an action $G \circlearrowright M$ which is characterized by the following diagram:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{Int}(E) & \longrightarrow & \mathrm{Aut}(E) & \longrightarrow & \mathrm{Out}(E) \simeq \mathrm{Aut}(M) & \longrightarrow & 0 \\ & & & & & \nwarrow & \uparrow & & \\ & & & & & & G & & \end{array}$$

A natural problem to consider at this stage is to try to classify all the possible lifts of an action $G \circlearrowright M$ to an action $G \circlearrowright E$. This problem is for instance investigated in Ref. 7. We will not touch upon it in the present paper.

We further require the action of G to be simple (see Refs. 4 and 5), which means that we assume M has the following fiber bundle structure:

$$G/G_0 \to M \to M/G.$$

Then, by hypothesis, the quotient space M/G is a smooth manifold and the fibers are all isomorphic to the homogeneous space G/G_0, where G_0 is a subgroup of G. All isotropy groups for the action $G \circlearrowleft M$ are isomorphic to G_0, which will denote, once for all, such a chosen reference isotropy group.

Consider now the space $P=\{x \in M, G_x=G_0\}$, where G_x is the isotropy group associated to any point $x \in M$. It can be shown that P is a principal fiber bundle with structure group $N(G_0)/G_0$, where $N(G_0)$ is the normalizer of G_0 in G. This fiber bundle is denoted by

$$N(G_0)/G_0 \to P \to M/G.$$

One can then consider the fiber bundle $M(M/G, G/G_0)$ as an associated fiber bundle to the principal fiber bundle $P(M/G, N(G_0)/G_0)$ for the natural left action $N(G_0)/G_0 \circlearrowleft G/G_0$.

A similar construction can be performed on the space E on which the group $S=G\times H$ acts on the right by

$$G \times H \times E \to E,$$

$$(g,h,p) \mapsto g^{-1}ph.$$

First note that at each point $p \in E$ there exists a canonical homomorphism,

$$\lambda_p: G_{\pi(p)} \to H,$$

defined by the relation $g_0 \cdot p = p \cdot \lambda_p(g_0)$ for all g_0 in $G_{\pi(p)}$. The isotropy group S_p of a point p in E for the action $E \circlearrowleft S$ can be completely characterized, and a straightforward computation shows that $S_p=\{(g_0, \lambda_p(g_0))/g_0 \in G_{\pi(p)}\}$. Then S_p is isomorphic to a generic group S_0 for any p in E, where S_0 is the isotropy group of a certain point p_0 in E. So E inherits the following fiber bundle structure:

$$S/S_0 \to E \to M/G.$$

This means that the action of S on E is also simple. Using the same approach as before, one can see that E contains the principal fiber sub-bundle $Q=\{p \in E, S_p=S_0\}$ given by the diagram of fibrations

$$N(S_0)/S_0 \to Q \to M/G,$$

where $N(S_0)$ is the normalizer of S_0 in S. Notice that on Q the application λ_p is independent of the point $p \in Q$, and we denote it by $\lambda: G_0 \to H$.

The restriction of the projection π to Q will be called π_Q. It is obvious that $\pi(Q) \subset P$. The kernel of π_Q is isomorphic to $Z_0=Z(\lambda(G_0), H)$, the centralizer of $\lambda(G_0)$ in H, and

$$Z_0 \to Q \xrightarrow{\pi_Q} \pi(Q)$$

is a principal fiber bundle. By the very definition one has

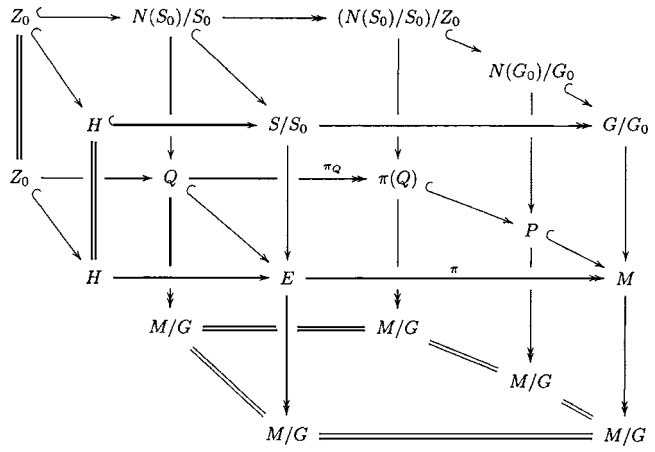
$$N(S_0) = \{(g,h) \in S/g \in N(G_0),\ h^{-1}\lambda(g_0)h = \lambda(g^{-1}g_0g),\ \forall\, g_0 \in G_0\}.$$

There is then a natural inclusion of Z_0 in $N(S_0)/S_0$ given by the following composition of maps:

$$Z_0 \simeq \{e\} \times Z_0 \hookrightarrow N(S_0) \to N(S_0)/S_0.$$

Furthermore Z_0 is a normal subgroup in $N(S_0)/S_0$, and one can finally show that $(N(S_0)/S_0)/Z_0$ is a subgroup of $N(G_0)/G_0$.

All the previous constructions can be summarized in the following commutative diagram:



(1)

In this diagram, some arrows represent true applications and other arrows are part of diagrams of fibrations, most of them explicitly given before. Some horizontal arrows correspond to the action of H (or subgroups of H) and some vertical arrows correspond to actions of groups related to G and S. One can verify that the kernel of the projection $\pi(Q)\to M/G$ is isomorphic to $(N(S_0)/S_0)/Z_0$.

B. Invariant connections

The action $G\circlearrowright E$ induces an action of G on the space $\Omega^1(E)$ of 1-forms over E. Because the actions of G and H commute, this action extends naturally to an action on the affine space of connections on E included in the space $\Omega^1(E)\otimes\mathcal{H}$, where $\mathcal{H}$ is the Lie algebra of H. For any $\omega\in\Omega^1(E)\otimes\mathcal{H}$ and any $g\in G$, we denote this action by $\omega^g=g^*\omega$. We are now interested to characterize the G-invariant connections, those which satisfy $\omega^g=\omega$ for any $g\in G$.

In order to do that, it is convenient to make some natural decompositions of the tangent spaces to the various manifolds introduced previously. These decompositions are performed along the different actions that these spaces support. Let us introduce in the following table the notations for the Lie algebras corresponding to the groups introduced so far

Group	G	H	$N(G_0)$	G_0	$N(G_0)/G_0$	Z_0	$S=G\times H$	S_0	$N(S_0)$
Lie Algebra	$\mathcal{G}$	$\mathcal{H}$	$\mathcal{N}_0$	$\mathcal{G}_0$	$\mathcal{K}$	$\mathcal{Z}_0$	$\mathcal{S}=\mathcal{G}\oplus\mathcal{H}$	$\mathcal{S}_0$	$\mathcal{N}_{S_0}$

Let,

$$\mathcal{G}=\mathcal{N}_0\oplus\mathcal{L}\quad\text{and}\ \mathcal{H}=\mathcal{Z}_0\oplus\mathcal{M},$$

be some reductive decompositions of Lie algebras (a decomposition of a Lie algebra $\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{l}$ is reductive when $\mathfrak{h}\subset\mathfrak{g}$ is a sub-Lie algebra and $\mathfrak{l}$ a reductive complementary subspace, i.e., $[\mathfrak{h},\mathfrak{l}]\subset\mathfrak{l}$) which we suppose to be also orthogonal decompositions of vector spaces for the Killing metrics. It is easy to show that there is an orthogonal decomposition of Lie algebras

$$\mathcal{N}_0=\mathcal{G}_0\oplus\mathcal{K}.$$

Then, by the very definitions, one has

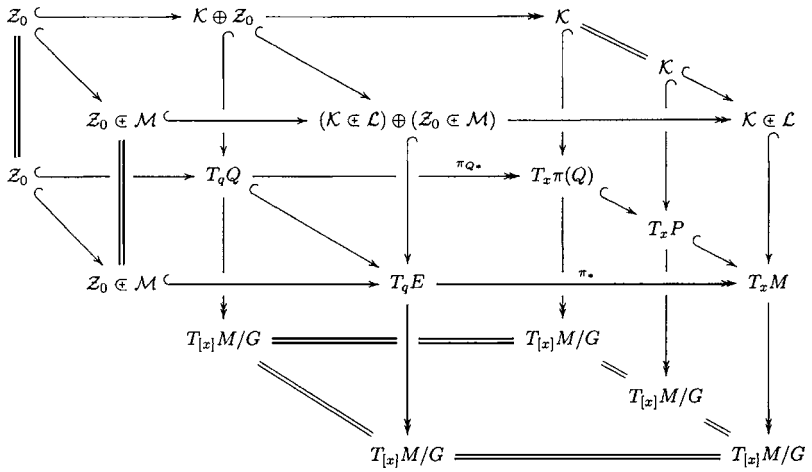
$$\mathcal{S}_0=\{(X_0,\lambda_*X_0)/X_0\in\mathcal{G}_0\},$$

where $\lambda_*:\mathcal{G}_0\to\mathcal{H}$ is the tangent application to $\lambda:G_0\to H$, which implies that $\mathcal{S}_0$ is isomorphic to $\mathcal{G}_0$. Using this identification, one can easily show that

$$\mathcal{N}_{\mathcal{S}_0} = \mathcal{S}_0 \oplus \mathcal{K} \oplus \mathcal{Z}_0$$

is an orthogonal decomposition of Lie algebras. In fact any element $(X,\xi) \in \mathcal{N}_{\mathcal{S}_0} \subset \mathcal{G}\times\mathcal{H}$ can be written in the form $(X,\xi)=(X_0+X_\mathcal{K},\lambda_* X_0+\xi_{\mathcal{Z}_0})$, where $X_0 \in \mathcal{G}_0$, $X_\mathcal{K} \in \mathcal{K}$ and $\xi_{\mathcal{Z}_0} \in \mathcal{Z}_0$.

With these decompositions and the induced maps of the group actions on manifolds at the level of Lie algebras and tangent spaces, we can decompose the different tangent spaces of the bundles introduced previously. We then get an infinitesimal version of diagram (1)



for a point $q \in Q \subset E$ with $\pi(q)=x$. Hence we have

$$T_qE = T_qQ \oplus \mathcal{L}^Q_{|q} \oplus \mathcal{M}^Q_{|q}, \tag{2}$$

where $\mathcal{L}^Q_{|q}$ (respectively, $\mathcal{M}^Q_{|q}$) is the subvector space obtained from the values X^E_q at $q \in E$ of the fundamental vector fields X^E on E associated to vectors $X \in \mathcal{L}$ (respectively, $X \in \mathcal{M}$).

Let us now consider a G-invariant connection 1-form $\omega \in \Omega^1(E)\otimes\mathcal{H}$. We are interested to characterize the degrees of freedom of ω. First, note that it is possible to study ω only at points in Q owing to the fact that by construction $G\cdot Q=E$. Then for any $q \in Q$, $\omega_{|q}$ can be evaluated on the three vector spaces T_qQ, $\mathcal{L}^Q_{|q}$, and $\mathcal{M}^Q_{|q}$.

(i) The restriction to $\mathcal{M}^Q_q \subset \mathcal{H}^Q_q$ is fixed by the relation $\omega_{|q}(X^E_q)=X$, for any $X \in \mathcal{M}$. So there is no degree of freedom in this direction.

(ii) The restriction to T_qQ gives a 1-form μ defined by $\mu(X)=\omega(X)$, for any $X \in TQ$. It satisfies the following equivariance property

$$R^*_{(q,h)}\mu = \mathrm{Ad}_{h^{-1}}\mu, \quad \forall\,(g,h) \in N(S_0),$$

where $R_{(g,h)}$ is the right action of $N(S_0)$ on Q. Considering this equivariance property for an element $(g_0,\lambda(g_0)) \in S_0$, one can show that μ is a $\mathcal{Z}_0$-valued 1-form. Together with the equivariance property restricted to Z_0, this implies in particular that μ is a connection on the principal fiber bundle $Q(\pi(Q),Z_0)$.

(iii) The restriction to $\mathcal{L}^Q_q$ induces a map

$$\psi_q : \mathcal{L} \to \mathcal{H}$$

$$X \mapsto \psi_q(X) = \omega_q(X^E_q).$$

It satisfies the following equivariance property:

$$\mathrm{Ad}_h \circ \psi_q \circ \mathrm{Ad}_{g^{-1}} = \psi_{gqh^{-1}} \quad \forall\, (g,h) \in S.$$

Then, for any $(g,h) \in S_0$, one has $\mathrm{Ad}_{\lambda(g_0)} \circ \psi_q \circ \mathrm{Ad}_{g_0^{-1}} = \psi_q$. The equivariant map $q \mapsto \psi_q$ from Q to $\mathcal{F}$, defines a section of the associated vector bundle $F^{\mathcal{L}} = Q \times_{N(S_0)/S_0} \mathcal{F}_{\mathcal{L}}$, where the fiber is defined to be the vector space of covariant maps

$$\mathcal{F}_{\mathcal{L}} = \{\ell : \mathcal{L} \to \mathcal{H}, \mathrm{Ad}_{\lambda(g_0)} \circ \ell \circ \mathrm{Ad}_{g_0^{-1}} = \ell\}.$$

So ω is completely characterized by the two objects μ and ψ described above. Notice that μ and ψ can be interpreted as genuine objects on fiber bundles related to the two principal fiber bundle structure on Q, either in the "horizontal" direction for μ or in the "vertical" direction for ψ on diagram (1). It is possible to make reference to only one of these principal fiber bundles structures. In order to do that, one needs a reference connection A on the principal fiber bundle

$$(N(S_0)/S_0)/Z_0 \to \pi(Q) \to M/G.$$

Then one can make μ in one-to-one correspondence with a couple (B,α) where

(i) B is a connection on the principal fiber bundle $Q(M/G, N(S_0)/S_0)$,
(ii) α is a section of the vector bundle $F^{\mathcal{K}}$, where $F^{\mathcal{K}} = Q \times_{N(S_0)/S_0} \mathcal{F}_{\mathcal{K}}$ is associated to $Q(M/G, N(S_0)/S_0)$. The vector space $\mathcal{F}_{\mathcal{K}}$ is defined by

$$\mathcal{F}_{\mathcal{K}} = \{k : \mathcal{K} \to \mathcal{H}, \mathrm{Ad}_{\lambda(g_0)} \circ k \circ \mathrm{Ad}_{g_0^{-1}} = k\}.$$

(Notice the similarity between $F^{\mathcal{L}}$ and $F^{\mathcal{K}}$.)

The correspondence between μ and the pair (B,α) is given explicitly by the relations

$$B = \mu + \pi^* A - \mu(\pi^* A)^Q,$$

$$\alpha_q = \mu_q\big|_{\mathcal{K}_q}.$$

In particular we have that $pr_{\mathcal{K}} B = \pi^* A$, where $pr_{\mathcal{K}}$ is the orthogonal projection from $\mathcal{K} \oplus \mathcal{Z}_0$ to $\mathcal{K}$. We refer to Ref. 5 for further details and the works by Coquereaux *et al.*[15] for the link with Kaluza-Klein theories.

C. Relation with Wang's approach

Because we have assumed that the action of the group G is simple, the space M is locally isomorphic to the product space $M/G \times G/G_0$. The study of invariant connections is greatly simplified if one considers the space M to be exactly equal to the space $M/G \times G/G_0$. This is also equivalent to restrict the study only to local objects around an orbit of G in M. So, in the following, we will assume that $M = M/G \times G/G_0$, and we will expose the main results obtained in Refs. 4, 3, and 8. This is what we call the "local" approach.

The simpler structure of the space M allows us to do a construction similar to the one performed previously, replacing the space P by the space M/G. This simplifies the bundle structure in the G's directions and also greatly simplifies the decomposition of invariant connections. Furthermore, it is possible to classify the G-symmetric fiber bundles, and the results in this special case can be compared more easily with the ones obtained by Wang.[1]

First, because of the decomposition $M = M/G \times G/G_0$, one can imbed M/G into M, identifying it with $M/G \times \{eG_0\}$. Then, G-symmetric principal H-bundles can be classified by pairs $([\lambda], \tilde{Q})$, where $[\lambda]$ is a conjugacy class of homomorphisms $\lambda : G_0 \to H$ for the action of G on G_0 by conjugation, and $\tilde{Q}$ is a principal fiber bundle over M/G with structure group $Z_0 = Z(\lambda(G_0), H)$.

Indeed, one can construct a pair $([\lambda],\tilde{Q})$ from a G-symmetric principal H-bundle E over $M=M/G\times G/G_0$ considering the restriction $E_{|M/G}$ of E over M/G. Then, define $\tilde{Q}=\{p\in E_{|M/G}/\lambda_p=\lambda\}$, for λ a chosen reference map λ_{p_0} for a $p_0\in E$.

Conversely, one can associate a G-invariant principal H-bundle to any pair $([\lambda],\tilde{Q})$. In order to do that, it is convenient to introduce the following diagram of fibrations:

$$Z_0\times G_0\to Q'=\tilde{Q}\times G\to M/G\times G/G_0$$

which defines a principal fiber bundle Q' for the action $(z,g_0,\tilde{q},g)\mapsto(\tilde{q}\cdot z_0,g\cdot g_0)$. Consider now the following left action of $Z_0\times G_0$ on H defined by (notice that the induced actions of the subgroups Z_0 and G_0 commute)

$$\rho: Z_0\times G_0\times H\to H,$$

$$(z,g_0,h)\mapsto z\cdot\lambda(g_0)\cdot h.$$

Denote by $\tilde{E}=Q'\times_{(Z_0\times G_0)}H$ the associated fiber bundle to Q' with fiber H for this action. It can be shown that $\tilde{E}$ is a G-invariant principal H-bundle characterized by the following commutative diagram (some arrows are part of diagram of fibrations)

$$\begin{array}{ccccc}
 & & Z_0\times G_0 & & Z_0\times G_0 \\
 & & \downarrow & & \downarrow \\
H & \longrightarrow & Q'\times H & \xrightarrow{pr_1} & Q'=\tilde{Q}\times G \\
 & & \downarrow\Psi & & \downarrow \\
H & \longrightarrow & \tilde{E} & \xrightarrow{\tilde{\pi}} & M=M/G\times G/G_0
\end{array} \tag{3}$$

where $Q'\times H$ is also a G-invariant principal H-bundle for the horizontal structure.

It is easy to prove that the composition of these two maps, $E\mapsto([\lambda],\tilde{Q})$ and $([\lambda],\tilde{Q})\mapsto\tilde{E}$, gives us a map $E\mapsto\tilde{E}$, for which E and $\tilde{E}$ are isomorphic G-invariant principal H-bundles. Indeed, an isomorphism between E and $\tilde{E}$ is given explicitly by the following relation: to any point $\Psi(\tilde{q},g,h)\in\tilde{E}$, associate the point $g\cdot\tilde{q}\cdot h\in E$ where $\tilde{q}\in\tilde{Q}$ is considered to be in E.

Using this isomorphism, it is possible to map a G-invariant connection on E to a G-invariant connection ω on $\tilde{E}$. Now, owing to the fact that the projection Ψ of the principal $(Z_0\times G_0)$-bundle $Q'\times H$ is also a G-equivariant map of G-symmetric principal H-bundles, one can show (see Refs. 4 and 8) that $\Psi^*\omega$ can be written in the generic form

$$\Psi^*\omega_{|(\tilde{q},g,h)}=\mathrm{Ad}_{h^{-1}}(\Lambda_{|\tilde{q}}\circ\theta^G_{|g}+\tilde{\omega}_{|\tilde{q}})+\theta^H_{|h}, \tag{4}$$

where $\tilde{\omega}$ is a connection 1-form on $\tilde{Q}(M/G,Z_0)$, θ^G and θ^H are the usual Cartan 1-form on G and H, respectively, and $\Lambda\in C^\infty(\tilde{Q})\otimes\mathcal{G}^*\otimes\mathcal{H}$ satisfies the equivariance property,

$$R^*_{z_0}\Lambda=\mathrm{Ad}_{z_0}\Lambda,\quad\forall\, z_0\in Z_0$$

and the two relations

$$\mathrm{Ad}_{\lambda(g_0)}\circ\Lambda\circ\mathrm{Ad}_{g_0^{-1}}=\Lambda,\quad\forall\, g_0\in G_0,$$

$$\Lambda_{\tilde{q}}(X_0) = \lambda_*(X_0), \quad \forall X_0 \in \mathcal{G}_0 \text{ and } \forall \tilde{q} \in \tilde{Q}.$$

Using standard techniques in differential geometry, this equivariant map $\Lambda : \tilde{Q} \to \mathcal{G}^* \otimes \mathcal{H}$ characterizes a section of a vector bundle over M/G, with fiber $\mathcal{G}^* \otimes \mathcal{H}$, associated to $\tilde{Q}$ for the adjoint action of Z_0 on $\mathcal{H}$.

We would like to conclude this section by the following remark. In the two situations presented here, the "global" one and the "local" one, it is possible to characterize the G-invariant connections on the G-symmetric principal H-bundle E using geometric objects related to the quotient space M/G, and not to the whole space M. Nevertheless, for the "global" approach, this requires an extra arbitrary connection A.

III. THE NONCOMMUTATIVE DIFFERENTIAL CALCULUS

In this section, we introduce the derivations based differential calculus defined for any associative algebra[11] and describe more precisely this calculus for the algebra of endomorphisms of a complex vector bundle introduced and studied in Refs. 12 and 13. Some new results extending these previous studies are presented here. It is in the framework of this noncommutative geometry that we will study G-invariant noncommutative connections in the next section. The notion of G-invariant noncommutative connection is introduced at the end of this section, as well as some supplemental mathematical structures that will be used later.

A. Derivation-based differential calculus

In the following, $\mathfrak{A}$ will denote an associative algebra with unit. Then the vector space $\mathrm{Der}(\mathfrak{A})$ of derivations of $\mathfrak{A}$ is a Lie algebra and a module over the center $\mathcal{Z}(\mathfrak{A})$ of $\mathfrak{A}$. The vector space of inner derivations, $\mathrm{Int}(\mathfrak{A})$, is a Lie ideal and a $\mathcal{Z}(\mathfrak{A})$-submodule. The quotient $\mathrm{Der}(\mathfrak{A})/\mathrm{Int}(\mathfrak{A})$ will be denoted by $\mathrm{Out}(\mathfrak{A})$. This is a Lie algebra and a module over $\mathcal{Z}(\mathfrak{A})$.

Define the complex $\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$ to be the set of $\mathcal{Z}(\mathfrak{A})$-multilinear antisymmetric maps from $\mathrm{Der}(\mathfrak{A})$ to $\mathfrak{A}$. It is naturally a $\mathbb{N}$-graded algebra on which one can define a differential $\hat{\mathrm{d}}$ (of degree 1) by setting, for any derivations $X_1, \ldots, X_{n+1}$ and any $\omega \in \underline{\Omega}^n_{\mathrm{Der}}(\mathfrak{A})$,

$$\hat{\mathrm{d}}\omega(X_1, \ldots, X_{n+1}) = \sum_{i=1}^{n+1} (-1)^{i+1} X_i \omega(X_1, \ldots, \overset{i}{\vee}, \ldots, X_{n+1}) + \sum_{1 \leqslant i < j \leqslant n+1} (-1)^{i+j} \omega([X_i, X_j], \ldots, \overset{i}{\vee}, \ldots, \overset{j}{\vee}, \ldots, X_{n+1}). \tag{5}$$

In the following, for all the associative algebras we will consider, this graded differential algebra $(\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A}), \mathrm{d})$ coincides with the smallest differential subalgebra of $\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$ generated by $\mathfrak{A}$, which is usually denoted by $\Omega_{\mathrm{Der}}(\mathfrak{A})$.

Let $\mathcal{G}$ be a Lie subalgebra of $\mathrm{Der}(\mathfrak{A})$. Then $\mathcal{G}$ defines a natural operation in the sense of Cartan[16] on $(\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A}), \mathrm{d})$. Indeed, for any $X \in \mathcal{G}$ and $n \geqslant 1$, let us introduce

$$i_X : \underline{\Omega}^n_{\mathrm{Der}}(\mathfrak{A}) \to \underline{\Omega}^{n-1}_{\mathrm{Der}}(\mathfrak{A})$$

by

$$(i_X \omega)(X_1, \ldots, X_{n-1}) = \omega(X, X_1, \ldots, X_{n-1})$$

for any $\omega \in \underline{\Omega}^n_{\mathrm{Der}}(\mathfrak{A})$ and $X_i \in \mathrm{Der}(\mathfrak{A})$. This interior product is defined to be 0 on $\underline{\Omega}^0_{\mathrm{Der}}(\mathfrak{A}) = \mathfrak{A}$. It is easy to show that i_X is a graded derivation of degree -1 on $\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$. The application

$$L_X = i_X\hat{\mathrm{d}} + \hat{\mathrm{d}}i_X : \underline{\Omega}^n_{\mathrm{Der}}(\mathfrak{A}) \to \underline{\Omega}^n_{\mathrm{Der}}(\mathfrak{A})$$

defined for any $n \geqslant 0$ is then a graded derivation of degree 0 on the graded algebra $\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$. This is the Lie derivative associated to the operation of $\mathcal{G}$ on $(\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A}), \hat{\mathrm{d}})$. One can compute the usual relations

$$i_X i_Y + i_Y i_X = 0, \quad L_X i_Y - i_Y L_X = i_{[X,Y]},$$

$$L_X L_Y - L_Y L_X = L_{[X,Y]}, \quad L_X \hat{\mathrm{d}} - \hat{\mathrm{d}} L_X = 0.$$

In the same way, it is possible to define a natural Cartan operation of $\mathcal{G}$ on $(\Omega_{\mathrm{Der}}(\mathfrak{A}), \hat{\mathrm{d}})$.

With such an operation of $\mathcal{G}$ on $(\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A}), \hat{\mathrm{d}})$, one can introduce the basic subspace of $\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$, which is the common kernel of all the i_X and L_X for all $X \in \mathcal{G}$. This basic subspace can be shown to be a graded differential subalgebra. The common kernel of all the L_X for all $X \in \mathcal{G}$ is called the invariant subspace of the operation. This is also a graded differential subalgebra.

In the case where $\mathfrak{A}$ is the algebra $C^\infty(M)$ of smooth complex-valued functions on a finite dimensional regular manifold M, $(\Omega_{\mathrm{Der}}(\mathfrak{A}), \hat{\mathrm{d}})$ is just the de Rham complex $(\Omega(M), \mathrm{d})$ and $\mathrm{Der}(C^\infty(M)) = \Gamma(TM)$ is the ordinary Lie algebra of vector fields on M.

Let us consider the case where $\mathfrak{A}$ is the algebra $M_n := M_n(\mathbb{C})$ of $n \times n$ complex matrices.[17] This algebra has only inner derivations, and the Lie algebra $\mathrm{Der}(M_n) = \mathrm{Int}(M_n)$ can be identified with the Lie algebra $\mathfrak{sl}_n := \mathfrak{sl}(n, \mathbb{C})$. One can show that

$$\Omega_{\mathrm{Der}}(M_n) \simeq M_n \otimes \wedge \mathfrak{sl}_n^*, \tag{6}$$

where $\mathfrak{sl}_n^*$ is the dual of $\mathfrak{sl}_n$. We denote by d' the differential on this complex.

In this situation, there exists a particular 1-form θ defined by

$$i\theta : \mathrm{Der}(M_n) \to \mathfrak{sl}_n$$

$$ad_\gamma \mapsto \gamma - \frac{1}{n}\mathrm{Tr}(\gamma)\mathbb{1}$$

for any $\gamma \in M_n$. This 1-form satisfies the relation

$$\mathrm{d}' i\theta - (i\theta)^2 = 0$$

and for any $\gamma \in M_n = \Omega^0_{\mathrm{Der}}(M_n)$, one has $\mathrm{d}'\gamma = [i\theta, \gamma]$. This 1-form θ can also be viewed as a kind of fundamental 1-form in this noncommutative space, which permits one to explicitly identify the Lie algebras $\mathrm{Der}(M_n)$ and $\mathfrak{sl}_n$.

Let us now mix the two previous examples in a trivial way, taking the matrix valued functions on a manifold $M : \mathfrak{A} = C^\infty(M) \otimes M_n$. The derivations based differential calculus for this algebra has been studied in Ref. 18. Here are the main results. The center of the algebra $\mathfrak{A}$ is exactly $C^\infty(M)$, and the Lie algebra of derivations $\mathrm{Der}(\mathfrak{A})$ splits canonically as a $C^\infty(M)$-module into

$$\mathrm{Der}(\mathfrak{A}) = [\mathrm{Der}(C^\infty(M)) \otimes \mathbb{1}] \oplus [C^\infty(M) \otimes \mathrm{Der}(M_n)]. \tag{7}$$

This implies the canonical decomposition for the complex of forms

$$\Omega_{\mathrm{Der}}(\mathfrak{A}) = \Omega(M) \otimes \Omega_{\mathrm{Der}}(M_n).$$

The differential $\hat{\mathrm{d}}$ on $\Omega_{\mathrm{Der}}(\mathfrak{A})$ is the sum $\hat{\mathrm{d}} = \mathrm{d} + \mathrm{d}'$ where d and d' has been defined in the two previous examples. The 1-form θ is well defined in $\Omega^1_{\mathrm{Der}}(\mathfrak{A})$ if we extend it on $\mathrm{Der}(\mathfrak{A})$ by zero on the $\Gamma(TM)$ terms.

B. Algebra of endomorphisms of a vector bundle

Let us now consider a nontrivial version of the previous example. Let $\mathcal{E}$ be a SU (n)-vector bundle over a regular finite dimensional smooth (i.e., paracompact, etc.) manifold M equipped with an Hermitian structure. We denote by $\mathrm{End}(\mathcal{E})$ the fiber bundle of endomorphisms of $\mathcal{E}$. The sections of this fiber bundle in matrix algebras define a unital algebra, which we denote by $\mathfrak{A}$. The Hermitian structure gives a natural involution on this algebra, denoted by $S \mapsto S^*$. The center of this algebra is exactly $C^\infty(M)$, identifying $f \in C^\infty(M)$ with $f\mathbb{1} \in \mathfrak{A}$. The trace map and the determinant, defined on each fiber of $\mathrm{End}(\mathcal{E})$, give natural maps

$$\mathrm{Tr}:\mathfrak{A} \to C^\infty(M) \quad \text{and } \det:\mathfrak{A} \to C^\infty(M).$$

By restriction to the center, there is also a natural map

$$\rho:\mathrm{Der}(\mathfrak{A}) \to \mathrm{Der}(C^\infty(M)) = \Gamma(TM). \tag{8}$$

This map is the quotient map in the short exact sequence of Lie algebras and $C^\infty(M)$-modules

$$0 \to \mathrm{Int}(\mathfrak{A}) \to \mathrm{Der}(\mathfrak{A}) \xrightarrow{\rho} \mathrm{Out}(\mathfrak{A}) \simeq \Gamma(TM) \to 0. \tag{9}$$

This short exact sequence generalizes the decomposition (7) in the trivial case. Notice that in the nontrivial case, one cannot split canonically this short exact sequence of $C^\infty(M)$-modules.

For any derivation $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$, let us denote by $X \in \Gamma(TM)$ the associated vector field on M. The 1-form $i\theta$ defined in the two previous examples is well defined here on $\mathrm{Int}(\mathfrak{A})$ only, by the relation

$$i\theta(ad_\gamma) = \gamma - \frac{1}{n}\mathrm{Tr}(\gamma)\mathbb{1}$$

for any $\gamma \in \mathfrak{A}$. In the following, for any inner derivation ad_γ, we suppose that the element γ is traceless. It can be considered as a section of the fiber bundle of traceless endomorphisms of $\mathcal{E}$. We denote by $\mathfrak{A}_0$ the space of traceless elements in $\mathfrak{A}$. The Lie subalgebra $\mathrm{Int}(\mathfrak{A})$ operates in the sense of Cartan on the differential complex $\Omega_{\mathrm{Der}}(\mathfrak{A})$.[11] The horizontal forms for this operation are exactly the differential forms on M with values in $\mathrm{End}(\mathcal{E})$, and the basic forms are ordinary differential forms on M. In the following, horizontality will refer to this operation.

It was shown in Ref. 12 that the two differential calculi $\Omega_{\mathrm{Der}}(\mathfrak{A})$ and $\underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$ coincide. We will denote by $\hat{\mathrm{d}}$ the differential on $\Omega_{\mathrm{Der}}(\mathfrak{A}) = \underline{\Omega}_{\mathrm{Der}}(\mathfrak{A})$.

Now, let $\nabla^{\mathcal{E}}$ be any connection on $\mathcal{E}$. Then it was shown in Ref. 12 that there exists a noncommutative 1-form α in $\Omega^1_{\mathrm{Der}}(\mathfrak{A})$ such that any derivation $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$ can be decomposed as

$$\mathcal{X} = \nabla_X - ad_{\alpha(\mathcal{X})}, \tag{10}$$

where ∇ is the naturally associated connection to $\nabla^{\mathcal{E}}$ on the fiber bundle $\mathrm{End}(\mathcal{E})$. Indeed, one can define α by the relation $\alpha(\mathcal{X}) = -i\theta(\mathcal{X} - \nabla_X)$. We recall that ∇ is the tensor product of the connections $\nabla^{\mathcal{E}}$ on $\mathcal{E}$ and $\nabla^{\mathcal{E}^*}$ on the dual vector bundle $\mathcal{E}^*$ of $\mathcal{E}$ where $\nabla^{\mathcal{E}^*}$ satisfies $X\langle \epsilon, e\rangle = \langle \nabla^{\mathcal{E}^*}_X \epsilon, e\rangle + \langle \epsilon, \nabla^{\mathcal{E}}_X e\rangle$ for any sections ϵ of $\mathcal{E}^*$ and e of $\mathcal{E}$.

The noncommutative 1-form α takes its values in the traceless elements of $\mathfrak{A}$ and can be considered as an extension of $-i\theta$ to all derivations. One has obviously $\alpha(ad_\gamma) = -\gamma$, with the convention that $\mathrm{Tr}(\gamma) = 0$.

This result gives us a splitting of the short exact sequence (9) as $C^\infty(M)$-modules. This splitting is not canonical and is only defined through a choice of a connection on $\mathcal{E}$, by the $C^\infty(M)$-linear map $X \mapsto \nabla_X$ from $\Gamma(TM)$ into $\mathrm{Der}(\mathfrak{A})$. This must be compared with the usual (commutative) situation where one can interpret a connection as a map from vector fields on M into vector fields on a principal bundle over M. These maps will be used and generalized in Sec. III F.

The algebra $\mathfrak{A}$ plays a similar role to a principal bundle, and the above canonical map $\nabla^{\mathcal{E}} \mapsto \alpha$ is an isomorphism of affine spaces from the affine space of SU (n)-connections on $\mathcal{E}$ onto the affine space of traceless anti-Hermitian noncommutative 1-forms on $\mathfrak{A}$ satisfying $\alpha(ad_\gamma) = -\gamma$. If $R^{\mathcal{E}}$ denotes the curvature of $\nabla^{\mathcal{E}}$, then one can show that

$$R^{\mathcal{E}}(X,Y) = \hat{\mathrm{d}}\alpha(\mathcal{X},\mathcal{Y}) + [\alpha(\mathcal{X}), \alpha(\mathcal{Y})]$$

for any $\mathcal{X}$, $\mathcal{Y} \in \mathrm{Der}(\mathfrak{A})$, X, Y being their images in $\Gamma(TM)$. In particular, the expression $\hat{\mathrm{d}}\alpha + \alpha^2$ is a horizontal element of $\Omega^2_{\mathrm{Der}}(\mathfrak{A})$.

Now, the Lie algebra of real derivations on $\mathfrak{A}$ acts naturally on the space of SU (n)-connections through the Lie derivative defined on $\Omega_{\mathrm{Der}}(\mathfrak{A})$. If one restricts this action to inner real derivations, the Lie derivative corresponds to infinitesimal gauge transformations on connections. Indeed, one has

$$\mathcal{L}_{ad_\xi}\alpha = -\hat{\mathrm{d}}\xi - [\alpha, \xi]$$

for any $\xi \in \mathcal{A}$, with $\mathrm{Tr}\,\xi = 0$ and $\xi^* + \xi = 0$ (ad_ξ is then a real inner derivation). Such ξ's are exactly the elements of the Lie algebra of the group of gauge transformations on $\mathcal{E}$.

C. Noncommutative connections

In the following, we will only consider noncommutative connections for the algebra $\mathfrak{A}$ defined above on the right module $\mathfrak{A}$ itself (this definition could be given for any associative algebra $\mathfrak{A}$). A noncommutative connection is an application

$$\hat{\nabla}_{\mathcal{X}} : \mathfrak{A} \to \mathfrak{A}$$

such that $\hat{\nabla}_{\mathcal{X}}(SS') = S\mathcal{X}(S') + \hat{\nabla}_{\mathcal{X}}(S)S'$ and $\hat{\nabla}_{f\mathcal{X}}S = f\hat{\nabla}_{\mathcal{X}}S$ for any $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$, S, $S' \in \mathfrak{A}$ and $f \in C^\infty(M)$. The curvature of a noncommutative connection is defined by $\hat{R}(\mathcal{X},\mathcal{Y})S = [\hat{\nabla}_{\mathcal{X}}, \hat{\nabla}_{\mathcal{Y}}]S - \hat{\nabla}_{[\mathcal{X},\mathcal{Y}]}S$ for any $S \in \mathfrak{A}$ and $\mathcal{X}$, $\mathcal{Y} \in \mathrm{Der}(\mathfrak{A})$, which is a right $\mathfrak{A}$-module homomorphism.

Any noncommutative connection $\hat{\nabla}$ on $\mathfrak{A}$ is completely given by $\hat{\nabla}_{\mathcal{X}}\mathbb{1} = \omega(\mathcal{X})$, where ω is a noncommutative 1-form in $\Omega^1_{\mathrm{Der}}(\mathfrak{A})$. Indeed, one then has

$$\hat{\nabla}_{\mathcal{X}}S = \mathcal{X}S + \omega(\mathcal{X})S$$

for any $S \in \mathfrak{A}$. The curvature of $\hat{\nabla}$ is then the left multiplication by the noncommutative 2-form,

$$\hat{\mathrm{d}}\omega(\mathcal{X},\mathcal{Y}) + [\omega(\mathcal{X}), \omega(\mathcal{Y})].$$

There is a natural Hermitian structure on the right module $\mathfrak{A}$ given by $\langle S, S' \rangle = S^*S' \in \mathfrak{A}$. A connection is said to be compatible with an Hermitian structure if

$$\mathcal{X}\langle S, S' \rangle = \langle \hat{\nabla}_{\mathcal{X}}S, S' \rangle + \langle S, \hat{\nabla}_{\mathcal{X}}S' \rangle$$

for any S, $S' \in \mathfrak{A}$ and real [a derivation $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$ is real if $(\mathcal{X}a)^* = \mathcal{X}a^*$ for any $a \in \mathfrak{A}$] $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$. This compatibility condition is equivalent to

$$\omega(\mathcal{X})^* + \omega(\mathcal{X}) = 0$$

for any real $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$. Such connections will be called anti-Hermitian connections. Then any unitary element $U \in \mathfrak{A}$ with $\det(U) = \mathbb{1}$ defines on $\mathfrak{A}$ a right module endomorphism $S \mapsto US$ which preserves the Hermitian structure and the det application. We denote by $\mathrm{SU}(\mathfrak{A})$ the group of such elements of $\mathfrak{A}$. In our particular case, this is exactly the gauge group of the SU (n)-vector bundle $\mathcal{E}$. We denote by $U(\mathfrak{A})$ the group of unitary elements of $\mathfrak{A}$. For any $U \in U(\mathfrak{A})$, the gauge trans-

formation of a noncommutative connection $\hat{\nabla}$ is defined by the relation $\hat{\nabla}^U_{\mathcal{X}}S = U^*\hat{\nabla}_{\mathcal{X}}(US)$. The noncommutative 1-form ω is then transformed as

$$\omega \mapsto U^*\omega U + U^*\hat{\mathrm{d}}U.$$

Any ordinary connection on $\mathcal{E}$ defines canonically a noncommutative connection on $\mathfrak{A}$. Indeed, such a connection is given by a noncommutative 1-form α. One then defines a noncommutative connection $\hat{\nabla}^\alpha$ by

$$\hat{\nabla}^\alpha_{\mathcal{X}}S := \nabla_X S + S\alpha(\mathcal{X}) = \mathcal{X}S + \alpha(\mathcal{X})S$$

for any $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$ and $S \in \mathfrak{A}$. The curvature of this connection coincides with the ordinary curvature $\hat{R}^\alpha(\mathcal{X},\mathcal{Y}) = R^{\mathcal{E}}(X,Y)$ and this noncommutative connection $\hat{\nabla}^\alpha$ is compatible with the Hermitian structure on $\mathfrak{A}$. Finally, a gauge transformation on $\nabla^{\mathcal{E}}$ induces a SU $(\mathfrak{A})$-gauge transformation on $\hat{\nabla}^\alpha$.

This means that noncommutative connections on $\mathfrak{A}$ are extensions of ordinary connections of $\mathcal{E}$. In Refs. 18–20 and 12, it was shown that the extra degrees of freedom can be interpreted as Higgs fields. We refer to these papers for details.

Because $\mathfrak{A}$ and $C^\infty(M)$ are Morita equivalent, their projective right modules are in bijection (the K-groups are the same). From the physical point of view this means that the matter contents of any associated theory does not permit one to distinguish between $C^\infty(M)$ and $\mathfrak{A}$.

D. Symmetries and noncommutative connections

In the following section, we will be interested in noncommutative connections invariant under the action of a Lie group G. Here we give a precise definition of this concept.

Let $\mathcal{G}$ be the Lie algebra of G. An action of $\mathcal{G}$ on $\mathfrak{A}$ is a Cartan operation of $\mathcal{G}$ on the graded differential algebra $\Omega_{\mathrm{Der}}(\mathfrak{A})$. In particular, any element $\mathcal{G}$ can be considered as an element in $\mathrm{Der}(\mathfrak{A})$, which means that we will always look at $\mathcal{G}$ as a Lie subalgebra of $\mathrm{Der}(\mathfrak{A})$.

A $\mathcal{G}$-invariant noncommutative connection on the right module $\mathfrak{A}$ is a noncommutative connection $\hat{\nabla}$ satisfying

$$Y(\hat{\nabla}_{\mathcal{X}}a) = \hat{\nabla}_{[Y,\mathcal{X}]}a + \hat{\nabla}_{\mathcal{X}}(Ya)$$

for any $Y \in \mathcal{G}$, $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$ and $a \in \mathfrak{A}$. If $\hat{\nabla}$ is given by the noncommutative 1-form ω, this is equivalent to

$$L_Y\omega = 0$$

for any $Y \in \mathcal{G}$.

E. $\Omega_{\mathrm{Der}}(\ )$ and $\Omega(E)$

In the next section, we will characterize the $\mathcal{G}$-invariant connections on the right module $\mathfrak{A}$, where $\mathfrak{A}$ is the algebra of endomorphisms of a SU (n)-vector bundle $\mathcal{E}$. In order to do that, it is very convenient to look at $\Omega_{\mathrm{Der}}(\mathfrak{A})$ in a different way, using a result proved in Ref. 13. There, $\Omega_{\mathrm{Der}}(\mathfrak{A})$ was shown to be some basic subalgebra of a bigger differential graded algebra. Let us describe this algebra and give new results about this very useful construction.

Let us denote by E the principal SU (n)-bundle over M for which $\mathcal{E}$ is associated, and denote by $C^\infty(E)$ the (commutative) algebra of smooth functions on E. Then one has a map $\xi \mapsto \xi^E$ which sends any $\xi \in \mathfrak{su}(n)$ into the associated vertical vector field on E. Let us introduce the algebra $\mathfrak{B} = C^\infty(E) \otimes M_n$ of matrix valued functions on E. Denote by $(\Omega_{\mathrm{Der}}(\mathfrak{B}), \hat{\mathrm{d}}) = (\Omega(E) \otimes \Omega_{\mathrm{Der}}(M_n), \mathrm{d} + \mathrm{d}')$ its differential calculus based on derivations. It is easy to see that $\{\xi^E + ad_\xi / \xi \in \mathfrak{su}(n)\}$ is a Lie

subalgebra of $\mathrm{Der}(\mathfrak{B})$ which is isomorphic to $\mathfrak{su}(n)$. This Lie subalgebra defines a Cartan operation of $\mathfrak{su}(n)$ on $\Omega_{\mathrm{Der}}(\mathfrak{B})$, whose basic subalgebra we denote by $\Omega_{\mathrm{Der,Bas}}(\mathfrak{B})$. Then it was proved in Ref. 13 that $\Omega_{\mathrm{Der}}(\mathfrak{A})=\Omega_{\mathrm{Der,Bas}}(\mathfrak{B})$.

A SU (n)-connection on E is given by a 1-form ω_E on E with values in $\mathfrak{su}(n)\subset M_n$. This connection defines a connection on $\mathcal{E}$ (denoted by ∇), which itself gives rise to a noncommutative 1-form $\alpha\in\Omega^1_{\mathrm{Der}}(\mathfrak{A})$. From the previous result, this form comes from a basic 1-form α^E in $\Omega_{\mathrm{Der,Bas}}(\mathfrak{B})$, which is nothing but $\alpha^E=\omega_E-i\theta$, where $\theta\in\Omega^1_{\mathrm{Der}}(M_n)$ is the canonical 1-form defined previously. The basicity of this 1-form is a consequence of properties of ω_E and $i\theta$, in particular the equivariance of ω_E.

At the level of derivations, the relations between the algebras $\mathfrak{A}$ and $\mathfrak{B}$ can be summarized in the following exact commutative diagram which combines derivations on $\mathfrak{A}$, derivations on $\mathfrak{B}$ and vector fields on E:

$$\begin{array}{ccccccccc}
 & & & & 0 & & 0 & & \\
 & & & & \downarrow & & \downarrow & & \\
 & & 0 & \longrightarrow & \mathcal{Z}_{\mathrm{Der}}(\mathfrak{A}) & \longrightarrow & \Gamma(TVE) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathrm{Int}(\mathfrak{A}) & \longrightarrow & \mathcal{N}_{\mathrm{Der}}(\mathfrak{A}) & \xrightarrow{\rho_E} & \Gamma_M(E) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow{\scriptstyle\tau} & & \downarrow{\scriptstyle\pi_*} & & \\
0 & \longrightarrow & \mathrm{Int}(\mathfrak{A}) & \longrightarrow & \mathrm{Der}(\mathfrak{A}) & \xrightarrow[\rho]{} & \Gamma(TM) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & 0 & & 0 & & 0 & &
\end{array} \tag{11}$$

The lower row is just the ordinary short exact sequence which relates vector fields on M, derivations on $\mathfrak{A}$ and inner derivations on $\mathfrak{A}$. In the middle column, $\mathcal{N}_{\mathrm{Der}}(\mathfrak{A})\subset\mathrm{Der}(\mathfrak{B})$ is the subset of derivations on $\mathfrak{B}$ which preserve the basic subalgebra $\mathfrak{A}\subset\mathfrak{B}$, and $\mathcal{Z}_{\mathrm{Der}}(\mathfrak{A})\subset\mathrm{Der}(\mathfrak{B})$ is the subset of derivations on $\mathfrak{B}$ which vanishes on $\mathfrak{A}$. These two Lie algebras were defined for more general algebras in Ref. 21. The short exact sequence they define is the one used to prove that $\mathfrak{A}$ is a noncommutative quotient manifold of the noncommutative algebra $\mathfrak{B}$.[13] The Lie algebra $\mathcal{Z}_{\mathrm{Der}}(\mathfrak{A})$ is generated as a $C^\infty(E)$-module by the particular elements ξ^E+ad_ξ for any $\xi\in\mathfrak{su}(n)$.

The right most column involves only geometrical objects. The space $\Gamma_M(E)$ is defined to be

$$\Gamma_M(E)=\{\hat{X}\in\Gamma(E)/\pi_*\hat{X}(p)=\pi_*\hat{X}(p')\ \forall\ p,p'\in E \text{ such that } \pi(p)=\pi(p')\}. \tag{12}$$

This is the Lie algebra of vector fields on E which can be mapped to vector fields on M using the tangent maps π_*: $T_pE\to T_{\pi(p)}M$.

In the following, for any $\eta=f\otimes\xi\in C^\infty(E)\otimes\mathfrak{su}(n)$, we will denote by $\eta^E\in\Gamma(TV\,E)$ the vector field $f\xi^E$ on E. Using this notation, any element in $\mathcal{Z}_{\mathrm{Der}}(\mathfrak{A})$ can be written as η^E+ad_η where $\eta\in C^\infty(E)\otimes\mathfrak{su}(n)$. The isomorphism between $\mathcal{Z}_{\mathrm{Der}}(\mathfrak{A})$ and $\Gamma(TV\,E)$ maps any element η^E+ad_η into η^E.

The diagram (11) bears some strange similarities with the diagram presented on page 12 in Ref. 12 which involved Lie algebroid structures. We will not make further comments about this point here.

A connection ω_E on E splits three short exact sequences in this diagram, in a compatible way. First, this connection can be used to lift vector fields X on M into horizontal vector fields X^h on E. This gives us a splitting map of

$$0 \to \Gamma(TVE) \to \Gamma_M(E) \to \Gamma(TM) \to 0 \tag{13}$$

as $C^\infty(M)$-modules. It was shown in Ref. 12, and recalled in Sec. III B, that the connection ω_E splits the short exact sequence (9) of $C^\infty(M)$-modules using the map $X \mapsto \nabla_X$. Now, using notations introduced so far, there is a splitting of the middle column by the map $\mathcal{X} \mapsto \mathcal{X}^E = \rho(\mathcal{X})^h - ad_{\alpha(\mathcal{X})^E}$ where $\alpha(\mathcal{X})^E$ is the basic element in $\mathfrak{B}$ associated to $\alpha(\mathcal{X}) \in \mathfrak{A}$ [notice that $\alpha(\mathcal{X})^E = \alpha^E(\mathcal{X}^E)$].

These splittings can be used to decompose any element in $\mathcal{N}_{\mathrm{Der}}(\mathfrak{A})$ into four parts, making explicit the kernels of the two short exact sequences in which this space is involved. Any derivation $\mathfrak{X} \in \mathcal{N}_{\mathrm{Der}}(\mathfrak{A})$ can be written, as a derivation on $\mathfrak{B}$, in the form $\mathfrak{X} = \hat{X} + ad_\gamma$, where $\hat{X} \in \Gamma(E)$ and $\gamma \in C^\infty(E) \otimes \mathfrak{sl}_n$. At this stage, it is easy to directly show that $\hat{X}$ is in $\Gamma_M(E)$ using the restriction of $\mathfrak{X}$ on the center $C^\infty(M)$ of $\mathfrak{A}$ considered as a subalgebra of $\mathfrak{B}$. A derivation $\mathfrak{X}$ belongs to $\mathcal{N}_{\mathrm{Der}}(\mathfrak{A})$ if and only if $L_\xi \mathfrak{X} \in \mathcal{Z}_{\mathrm{Der}}(\mathfrak{A})$ for any $\xi \in \mathfrak{su}(n)$. This means that there must exist $\eta \in C^\infty(E) \otimes \mathfrak{su}(n)$ such that

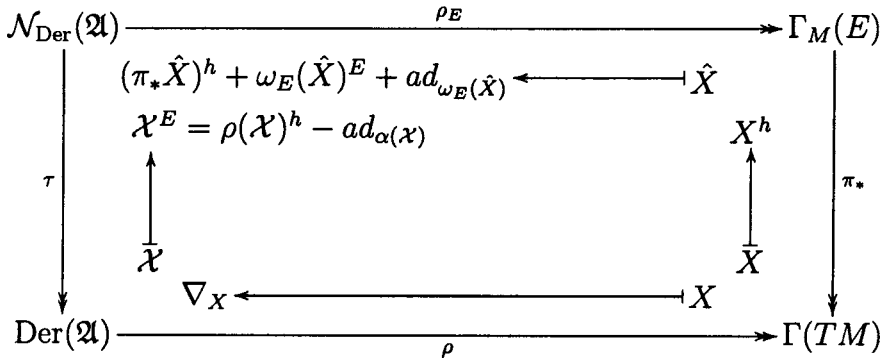
$$[\xi^E, \hat{X}] = \eta^E, \tag{14}$$

$$L_\xi \gamma = \eta. \tag{15}$$

Applying a connection ω_E on the first relation, and using the equivariance of ω_E, one gets $L_\xi(\omega_E(\hat{X})) = \eta$. Let us introduce $Z = -\alpha^E(\mathfrak{X}) = \gamma - \omega_E(\hat{X}) \in C^\infty(E) \otimes \mathfrak{sl}_n$. Then $L_\xi Z = 0$ for any $\xi \in \mathfrak{su}(n)$, which implies that $Z \in \mathfrak{A}_0$, or $ad_Z \in \mathrm{Int}(\mathfrak{A})$. Using this result, the derivation $\mathfrak{X}$ can be written as $\mathfrak{X} = \hat{X} + ad_\gamma = X^h + \hat{X}^v + ad_{\omega_E(\hat{X})+Z}$. With our notations, one has $\hat{X}^v = \omega_E(\hat{X})^E$ (vertical part of the vector field $\hat{X}$). So, one can write finally

$$\mathfrak{X} = X^h + ad_Z + \underbrace{\omega_E(\hat{X})^E + ad_{\omega_E(\hat{X})}}_{\in \mathcal{Z}_{\mathrm{Der}}(\mathfrak{A})} = X^h + \omega_E(\hat{X})^E + ad_{\omega_E(\hat{X})} + \underbrace{ad_Z}_{\in \mathrm{Int}(\mathfrak{A})}. \tag{16}$$

The situation can be summarized in the following diagram where all the splittings are explicit:



(17)

In the following $\Omega_{\mathrm{Der}}(\mathfrak{A})$ will be identified with the corresponding basic subalgebra of $\Omega_{\mathrm{Der}}(\mathfrak{B})$. Let us now look at the consequences of this construction on a noncommutative connection given by a 1-form $\omega \in \Omega^1_{\mathrm{Der}}(\mathfrak{A})$. Such a 1-form can be decomposed as

$$\omega = a - \phi \in [\Omega^1(E) \otimes M_n] \oplus [C^\infty(E) \otimes M_n \otimes \mathfrak{sl}_n^*]$$

with the basic conditions

$$(L_{\xi^E} + L_{ad_\xi})a = 0, \quad (L_{\xi^E} + L_{ad_\xi})\phi = 0,$$

$$i_{\xi^E} a - i_{ad_\xi} \phi = 0$$

for any $\xi \in \mathfrak{su}(n)$. Here we use obvious notations for geometrical and algebraic parts of the Lie derivative L and the interior product i.

At this level, some general comments about these relations are in order. First, the invariant relation on a is nothing but the covariance relation of an ordinary connection on E. But the last relation prevents a to be such a connection. Indeed, this last relation generalizes the vertical condition on ordinary connections, and connect the value of a on vertical vector fields to the values of ϕ. For ordinary connections on E, ϕ being replaced by $i\theta$, the usual vertical condition on a is recovered. The second relation, the invariance of ϕ, has a natural geometric interpretation. By its very definition, ϕ can be viewed as a map $E \to M_n \otimes \mathfrak{sl}_n^*$. Using standard results in differential geometry, the invariance relation on ϕ permits one to interpret ϕ as the section of a vector bundle over M, associated to E, whose fiber is $M_n \otimes \mathfrak{sl}_n^*$. In this identification, the Lie derivative L_{ad_ξ} on $M_n \otimes \mathfrak{sl}_n^*$ is nothing but the infinitesimal action of the Lie group H on $M_n \otimes \mathfrak{sl}_n^*$ involved in the construction of this associated vector bundle. We will use such an identification in similar cases several times in the following.

Let us now consider the following situation, which will be the starting point for the next section and which generalizes to the noncommutative connections that has been presented in Sec. II on ordinary connections. Assume we have an action of a compact connected Lie group G on the principal fiber bundle E which commutes with the natural right action of the Lie group $H = \mathrm{SU}(n)$ on E. Then for any $Y \in \mathcal{G}$, the Lie algebra of G, one can associate a vector field Y^E on E. This vector field induces a Cartan operation of $\mathcal{G}$ on $\Omega(E)$. This operation extends naturally to an operation on $\Omega_{\mathrm{Der}}(\mathfrak{B}) = \Omega(E) \otimes \Omega_{\mathrm{Der}}(M_n)$ where $\mathcal{G}$ acts only on the E part. Because the actions of G and H commute, the operation of $\mathcal{G}$ respects the basic subalgebra $\mathfrak{A}$ of $\mathfrak{B}$, and restricts to an operation on $\Omega_{\mathrm{Der}}(\mathfrak{A})$. Then the original action of G on E gives rise to a (noncommutative) action of $\mathcal{G}$ on $\mathfrak{A}$. This action is the one we will use to characterize G-invariant noncommutative connection on $\mathfrak{A}$.

F. Local point of view

In this section, we want to study more precisely the relation between the algebras $\mathfrak{A}$ and $\mathfrak{B}$ from the local point of view.

Let us first characterize local objects in $\mathfrak{A}$. Such a discussion was preformed in Refs. 12 and 13 and we recall essential points here. Over an open subset U over which the fiber bundle $\mathrm{End}(\mathcal{E})$ is trivialized, the algebra $\mathfrak{A}$ is isomorphic to $\mathfrak{A}_{\mathrm{loc}} := C^\infty(U) \otimes M_n$, and one can associate to any element $a \in \mathfrak{A}$ an element $a_{\mathrm{loc}} \in \mathfrak{A}_{\mathrm{loc}}$. Over an intersection $U \cap U' \neq \emptyset$ of two such open sets U and U', one has a transition function $g : U \cap U' \to \mathrm{SU}(n)$ which relates a'_{loc} to a_{loc} in the following way:

$$a'_{\mathrm{loc}} = \mathrm{Ad}_{g^{-1}} a_{\mathrm{loc}}.$$

One can also associate to any derivation $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$ a local derivation $\mathcal{X}_{\mathrm{loc}} \in \mathrm{Der}(C^\infty(U) \otimes M_n)$. Such a derivation can be decomposed into two parts $\mathcal{X}_{\mathrm{loc}} = X_{|U} + ad_{\gamma_{\mathrm{loc}}}$, where $X = \rho(\mathcal{X})$ [see Eq. (8)], and $X_{|U}$ is its restriction to the open subset U. It is possible to give an explicit expression for γ_{loc} if one considers a connection on $\mathrm{End}(\mathcal{E})$, to which one can associate the noncommutative 1-form α and the local 1-form $A_{\mathrm{loc}} \in \Omega^1(U) \otimes \mathcal{H}$. Then one has

$$\gamma_{\mathrm{loc}} = A_{\mathrm{loc}}(X_{|U}) - \alpha(\mathcal{X})_{\mathrm{loc}}.$$

Over an intersection $U \cap U' \neq \emptyset$, $\mathcal{X}'_{\mathrm{loc}}$ and $\mathcal{X}_{\mathrm{loc}}$ are related in the following way:

$$X'_{|U} = X_{|U},$$

$$\gamma'_{\mathrm{loc}} = \mathrm{Ad}_{g^{-1}} \gamma_{\mathrm{loc}} + g^{-1} X_{|U}(g).$$

Finally, let us consider local 1-forms, and associate to an element $\omega \in \Omega^1_{\mathrm{Der}}(\mathfrak{A})$ over U, an element $\omega_{\mathrm{loc}} \in \Omega^1_{\mathrm{Der}}(C^\infty(U) \otimes M_n)$. Such an element can be decomposed into two parts, $\omega_{\mathrm{loc}} = a + \phi \circ i\theta$ where $a \in \Omega^1(U) \otimes M_n$, and $\phi \in C^\infty(U) \otimes M_n \otimes \mathfrak{sl}_n^*$. Then over an intersection $U \cap U' \neq \emptyset$, ω_{loc} and ω'_{loc} are related in the following way:

$$a' = \mathrm{Ad}_{g^{-1}} \circ a - \mathrm{Ad}_{g^{-1}} \circ \phi \circ \mathrm{Ad}_g \circ g^* \theta^H,$$

$$\phi' = \mathrm{Ad}_{g^{-1}} \circ \phi \circ \mathrm{Ad}_g, \tag{18}$$

where θ^H is the usual Cartan form on the group H, and $g^* \theta^H = g^{-1}\, \mathrm{d}g$. One can remark that these transition relations look like the one encountered in usual commutative gauge theories, but in the present case these relations are "twisted" by the scalar field ϕ. It was shown in Ref. 13 that if one chooses a reference connection, then one can express local forms in terms of tensors which transform in a much more manageable way.

Let us now make some remarks about the relations between these local objects and the local ones associated to the algebra $\mathfrak{B} = C^\infty(E) \otimes M_n$. First, let us consider a local section $s: U \to E$. One can associate to it a trivial extension of the pullback application $s^*: \mathfrak{B} \to C^\infty(U) \otimes M_n$. Then by definition, the image of $\mathfrak{B}_{\mathcal{H}\text{-basic}|U}$ by the application s^* is the algebra $\mathfrak{A}_{\mathrm{loc}}$ obtained from the localization of $\mathfrak{A}$ over U.

For derivations, it was shown previously that with the help of an ordinary connection, one can associate to any element $\mathcal{X} \in \mathrm{Der}(\mathfrak{A})$ an element $\mathcal{X}^E \in \mathcal{N}(\mathfrak{A}) \subset \mathrm{Der}(\mathfrak{B})$, where explicitly $\mathcal{X}^E = \rho(\mathcal{X})^h - ad_{\alpha(\mathcal{X})^E}$. In a similar way, using the inclusion $\Omega_{\mathrm{Der}}(\mathfrak{A}) \hookrightarrow \Omega_{\mathrm{Der}}(\mathfrak{B})$, one can associate to any element $\omega \in \Omega_{\mathrm{Der}}(\mathfrak{A})$ an element (in opposition to the rest of this paper, we use here explicit different notations ω and ϖ) $\varpi \in \Omega_{\mathrm{Der}}(\mathfrak{B})_{\mathcal{H}\text{-basic}}$. Then one can compare the expressions $\varpi(\mathcal{X}^E)$ and $\omega(\mathcal{X})$. Over an open subset $U \subset M$ over which the principal fiber bundle E is trivialized, using the local expression of the connection, one has

$$\chi^E_{|s(x)} = s_* X_{|x} - A_{\mathrm{loc}}(X)_{|x} - ad_{\alpha(\chi)^E_{|s(x)}},$$

where $x \in U$. From the basicity of the 1-form ϖ, one can then show that $\omega_{\mathrm{loc}}(\mathcal{X}_{\mathrm{loc}}) = s^*(\varpi_{|U}(\mathcal{X}^E_{|U})) = s^* \varpi_{|U}(\mathcal{X}_{\mathrm{loc}})$, so that $s^* \varpi_{|U} = \omega_{\mathrm{loc}}$. This result generalizes the previous result about elements of the algebras, and one has $s^* \Omega_{\mathrm{Der}}(\mathfrak{B})_{\mathcal{H}\text{-basic}|U} = \Omega_{\mathrm{Der}}(\mathfrak{A}_{\mathrm{loc}})$. This relation shows that one can obtain the local expression ω_{loc} either from the 1-form $\omega \in \Omega^1_{\mathrm{Der}}(\mathfrak{A})$, or from the 1-form $\varpi \in \Omega^1_{\mathrm{Der}}(\mathfrak{B})_{\mathcal{H}\text{-basic}}$. Finally, notice that the transition relations (18) could have been obtained by considering the 1-form ϖ over the intersection $U \cap U' \neq \emptyset$ of two open sets, with the transition relation $s' = s \cdot g$ between local sections $s: U \to E$ and $s': U' \to E$.

IV. INVARIANT NONCOMMUTATIVE CONNECTIONS

Here, we characterize the degrees of freedom of invariant noncommutative connections in the setting exposed in the preceding section. The results obtained are generalizations of the results summarized in Sec. II for ordinary invariant connections. In particular, the constructions presented in Sec. II are explicitly used in the present case. Indeed, it is possible to make reference to the structure of diagram (1) thanks to the trick exposed at the end of the preceding section, which consists to look at $\mathfrak{A}$ as the basic subalgebra of $\mathfrak{B} = C^\infty(E) \otimes M_n$ for a well chosen Cartan operation of $\mathcal{H} = \mathfrak{su}(n) \subset M_n$. The starting ingredients of this section are the following. A G-invariant noncommutative connection $\omega \in (\Omega^1_{\mathrm{Der}}(\mathfrak{A}))_{\mathcal{G}\text{-inv}}$ is written as a basic element

$$\omega = a - \phi \in [\Omega^1(E) \otimes M_n] \oplus [C^\infty \otimes M_n \otimes \mathrm{Der}(M_n)^*].$$

Then the objects a and ϕ satisfy the three relations

$$L_{\xi}(a - \phi) = 0, \tag{19}$$

$$i_\xi(a-\phi)=0, \tag{20}$$

$$L_X(a-\phi)=0 \tag{21}$$

for any $\xi\in\mathcal{H}=\mathfrak{su}(n)$ and any $X\in\mathcal{G}$. Recall that the ordinary connections are those for which $\phi=i\theta$, which is a straightforward way to recover all the results of Sec. II from the results presented here.

A. Global approach

This approach is similar to the one performed in Sec. II, and it uses essentially the same technics. With the help of the G-invariance conditions (21), we can restrict the dependence of a and ϕ to $Q\subset E$. Then a is completely determined from its values on T_qE for all $q\in Q$. The application $a_q: T_qE\to M_n$ can be decomposed into several parts. Let us call $\mu\in\Omega^1(Q)\otimes M_n$ the restriction of the 1-form a to the tangent space TQ. By relation (20), one has $\mu_q(\xi_q^E)=\phi_q(\xi)$ for any $\xi\in\mathcal{Z}_0$. This 1-form satisfies the equivariance property

$$L_{(X,\xi)}\mu=(L_X+L_\xi)\mu=0, \quad \forall\,(X,\xi)\in\mathcal{N}_{\mathcal{S}_0}\subset\mathcal{G}\times\mathcal{H}$$

(there, we use notations of Sec. II B). (Recall also that L_ξ contains a geometric and an algebraic part.)

Then, using $\mathcal{S}_0$-invariance on Q, it is easy to show that μ takes its value in the vector space

$$\mathcal{W}_0 := Z(\lambda_*\mathcal{G}_0, M_n),$$

the centralizer of $\lambda_*\mathcal{G}_0$ in M_n. As a trivial consequence, $\eta_q := \phi_{q|\mathcal{Z}_0}$ has also its values in $\mathcal{W}_0$.

A simple analysis shows that $\mathcal{W}_0$ is an associative subalgebra of M_n on which the Lie algebra $\mathcal{Z}_0$ acts by the adjoint action. It is natural and useful for the following to associate to it the differential calculus $\Omega_{\mathcal{Z}_0}(\mathcal{W}_0)=\mathcal{W}_0\otimes\wedge\mathcal{Z}_0^*$ which mimics the differential calculus $\Omega_{\mathrm{Der}}(M_n)=M_n\otimes\wedge\mathfrak{sl}_n^*$. On $\Omega_{\mathcal{Z}_0}(\mathcal{W}_0)$, the differential is defined as in formula (5), where now the Lie algebra $\mathcal{Z}_0$ plays the role of the derivations on the algebra $\mathcal{W}_0$. Another important useful feature of $\mathcal{W}_0$ is that there is a natural application,

$$\mathcal{N}_{\mathcal{S}_0}\to\mathrm{Der}(C^\infty(Q)\otimes\mathcal{W}_0),$$

$$(X,\xi)\mapsto X^Q+\xi^Q+ad_\xi.$$

Notice that $\mathcal{S}_0$ is sent to zero in this application. This implies that this application factorizes through an application $\mathcal{N}_{\mathcal{S}_0}/\mathcal{S}_0\to\mathrm{Der}(C^\infty(Q)\otimes\mathcal{W}_0)$, which permits us to define a Cartan operation of $\mathcal{N}_{\mathcal{S}_0}/\mathcal{S}_0$ on $\Omega(Q)\otimes\Omega_{\mathcal{Z}_0}(\mathcal{W}_0)$, whose Lie derivation is denoted by

$$L_{(X,\xi)}=L_{X^Q+\xi^Q}+L_{ad_\xi}, \quad \forall\,(X,\xi)\in\mathcal{N}_{\mathcal{S}_0}/\mathcal{S}_0=\mathcal{K}\oplus\mathcal{Z}_0.$$

In particular, this operation induces an operation on the Lie algebra $\mathcal{Z}_0$, denoted by L_ξ, for any $\xi\in\mathcal{Z}_0$.

The difference $\mu-\eta$ is naturally an element of degree 1 in $\Omega(Q)\otimes\Omega_{\mathcal{Z}_0}(\mathcal{W}_0)$. Using relations (19)–(21), it is easy to verify that

$$i_\xi(\mu-\eta)=0, \quad \forall\,\xi\in\mathcal{Z}_0,$$

$$L_{(X,\xi)}(\mu-\eta)=0, \quad \forall\,(X,\xi)\in\mathcal{N}_{\mathcal{S}_0}.$$

This implies that $\mu-\eta\in(\Omega(Q)\otimes\Omega_{\mathcal{Z}_0}(\mathcal{W}_0))^1_{\mathcal{Z}_0\text{-basic}}$.

Now, let us introduce $\alpha\in C^\infty(Q)\otimes\mathcal{W}_0\otimes\wedge\mathcal{K}^*$, defined by

$$\alpha(X) = \mu(X^Q), \quad \forall\, X \in \mathcal{K}.$$

One can show that $\alpha \in \mathcal{W}_0 \otimes (C^\infty(Q) \otimes \wedge\mathcal{K}^*)_{\mathcal{K}\text{-inv}}$, where the $\mathcal{K}$-invariance is defined by the induced Lie derivative of the operation of $\mathcal{N}_{\mathcal{S}_0}$ on the $C^\infty(Q)$ part and by the standard Lie derivative on the $\wedge\mathcal{K}^*$ part (the differential and the Lie derivative on $\wedge\mathcal{K}^*$ are naturally induced by the Lie algebra structure of $\mathcal{K}$).

Let us now introduce the bigger differential calculus

$$\Omega_{\mathcal{Z}_0+\mathcal{K}}(M/G, \mathcal{W}_0) := (\Omega(Q) \otimes \Omega_{\mathcal{Z}_0}(\mathcal{W}_0) \otimes \wedge\mathcal{K}^*)_{(\mathcal{Z}_0+\mathcal{K})\text{-basic}}$$

equipped with the natural differential which is the sum of the differentials on each component. Later, we will make some comments about this differential algebra, in particular we will explain why M/G makes its appearance in the notation.

The main result of the previous discussion is that we can show that $\mu - \eta - \alpha \in \Omega^1_{\mathcal{Z}_0+\mathcal{K}}(M/G, \mathcal{W}_0)$. This relation permits one to characterize in a common algebraic 1-form the restrictions of a and ϕ to TQ.

Let us now look at the other parts of the space T_qE, that is $\mathcal{L}^Q_{|q}$ and $\mathcal{M}^Q_{|q}$. Using similar arguments as in Sec. II B, the restriction $\psi := a_{|\mathcal{L}^Q}$ defines a section of the vector bundle associated to $Q(M/G, N(\mathcal{S}_0)/\mathcal{S}_0)$ whose fiber is the vector space

$$\mathcal{F}_{\mathcal{L}} := (M_n \otimes \mathcal{L}^*)_{\mathcal{S}_0\text{-inv}} = \{\ell : \mathcal{L} \to M_n / L^{\mathcal{L}}_{(X,\lambda_* X)}\ell = 0\ \forall\, X \in \mathcal{G}_0\},$$

where $(L^{\mathcal{L}}_{(X,\xi)}\ell)(Y) = -\ell([X,Y]) + [\xi, \ell(Y)]$ for any $(X,\xi) \in N(\mathcal{S}_0)$. This relation is the natural action of $\mathcal{N}_{\mathcal{S}_0}$ on the space $M_n \otimes \mathcal{L}^*$. For this action, $\mathcal{F}_{\mathcal{L}} \subset M_n \otimes \mathcal{L}^*$ is invariant. The fact that $\psi \in C^\infty(Q) \otimes \mathcal{F}_{\mathcal{L}}$ is a section of a vector bundle comes from the equivariance property

$$L_{(X,\xi)}\psi = (L_{X^E + \xi^E} + L^{\mathcal{L}}_{(X,\xi)})\psi = 0 \quad \forall\, (X,\xi) \in \mathcal{N}_{\mathcal{S}_0}.$$

Therefore, one has $\psi \in (C^\infty(Q) \otimes \mathcal{F}_{\mathcal{L}})_{(\mathcal{Z}_0+\mathcal{K})\text{-inv}}$.

In the same way, the restriction $\zeta := a_{|\mathcal{M}^Q} = \phi_{|\mathcal{M}}$, considered as an element in $C^\infty(Q) \otimes M_n \otimes \mathcal{M}^*$, is a section of the vector bundle associated to $Q(M/G, N(\mathcal{S}_0)/\mathcal{S}_0)$ whose fiber is the vector space

$$\mathcal{F}_{\mathcal{M}} := (M_n \otimes \mathcal{M}^*)_{\mathcal{S}_0\text{-inv}} = \{m : \mathcal{M} \to M_n / L^{\mathcal{M}}_{(X,\lambda_* X)} m = 0\ \forall\, X \in \mathcal{G}_0\}$$

where $(L^{\mathcal{M}}_{(X,\xi)}m)(Y) = -m([X,Y]) + [\xi, m(Y)]$ for any $(X,\xi) \in N(\mathcal{S}_0)$. As before, ζ satisfies the equivariance property

$$L_{(X,\xi)}\zeta = (L_{X^E + \xi^E} + L^{\mathcal{M}}_{(X,\xi)})\zeta = 0 \quad \forall\, (X,\xi) = \mathcal{N}_{\mathcal{S}_0}$$

and so $\zeta \in (C^\infty(Q) \otimes \mathcal{F}_{\mathcal{M}})_{(\mathcal{Z}_0+\mathcal{K})\text{-inv}}$.

Now, noticing that

$$(M_n \otimes \mathcal{L}^*)_{\mathcal{S}_0\text{-inv}} \oplus (M_n \otimes \mathcal{M}^*)_{\mathcal{S}_0\text{-inv}} = (M_n \otimes (\mathcal{L}^* \oplus \mathcal{M}^*)_{\ \mathcal{S}_0\text{-inv}} =: \mathcal{F}$$

$\zeta + \psi$ can be considered as a section of the associated vector bundle to $Q(M/G, N(S_0)/S_0)$, where the fiber is the bigger vector space $\mathcal{F}$. Collecting all the previous degrees of freedom, we have proven that

$$(\Omega^1_{\mathrm{Der}}(\mathfrak{A}))_{\mathcal{G}\text{-inv}} \simeq \Omega^1_{\mathcal{Z}_0+\mathcal{K}}(M/G, \mathcal{W}_0) \oplus \mathcal{P},$$

where

$$\mathcal{P} = (C^\infty(Q) \otimes \mathcal{F})_{(\mathcal{Z}_0+\mathcal{K})-\mathrm{inv}}.$$

Denote by $\mathcal{C}$ the algebra $(C^\infty(Q)\otimes\mathcal{W}_0)_{(\mathcal{Z}_0+\mathcal{K})\text{-inv}}$. Then $\Omega_{\mathcal{Z}_0+\mathcal{K}}(M/G,\mathcal{W}_0)$ is a differential calculus associated to $\mathcal{C}$ in the sense that $\Omega^0_{\mathcal{Z}_0+\mathcal{K}}(M/G,\mathcal{W}_0)=\mathcal{C}$. This algebra can be interpreted as the sections of a fiber bundle associated to $Q(M/G,N(S_0)/S_0)$ whose fibers are modeled over the algebra $\mathcal{W}_0$. The algebra $\mathcal{C}$ can be considered as a "reduction"of the algebra $\mathfrak{A}$. As a matter of fact, it is easy to verify that the elements in SU $(\mathcal{C})$ define noncommutative gauge transformations on the space of $\mathcal{G}$-invariant connections on $\mathfrak{A}$. Equipped with the differential calculus $\Omega_{\mathcal{Z}_0+\mathcal{K}}(M/G,\mathcal{W}_0)$ and the module $\mathcal{P}$, this algebra is the natural building block, in a noncommutative viewpoint, for the $\mathcal{G}$-invariant connections on $\mathfrak{A}$.

As a last remark, notice that all the objects introduced here are naturally related to fiber bundles over the reduced space M/G, as it was also the case for ordinary $\mathcal{G}$-invariant connections. As a matter of fact, the situation is rather similar to the classical one, but here, there are new scalar fields coming from noncommutative geometry in addition to those coming from dimensional reduction. We can also notice that in the noncommutative framework, we do not need a reference connection to obtain objects which "live" over M/G.

B. Local approach

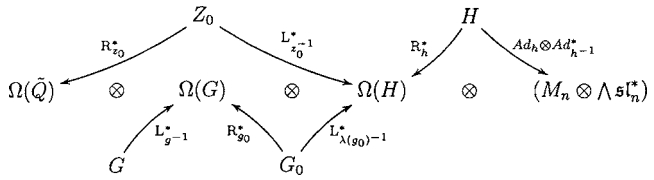
As in the classical case, we will study invariant connections in the case where $M=M/G\times G/G_0$. We will use the notations introduced in Sec. II C. The idea developed in Sec. II C is to pull back an invariant connection on $\tilde{E}$ to a bigger space $Q'\times H$. There, an invariant connection can be written in a very compact and elegant generic form using in particular the Cartan 1-forms on the groups G and H. Here we generalize this construction. In order to do that, we need to find the "good" space on which pulling back the invariant noncommutative connection. Because we work in a noncommutative framework, we must deal with algebras instead of spaces. The following diagram summarizes the relations between the spaces and algebras we consider

$$\begin{array}{ccccc} Q'\times H & & \overset{?}{\hookrightarrow} & & \Omega(Q'\times H)\otimes\Omega_{\mathrm{Der}}(M_n) \\ \downarrow{\scriptstyle\Psi} & & & & \uparrow{\scriptstyle\Psi^*} \\ \tilde{E} & \rightsquigarrow & \Omega_{\mathrm{Der}}(\mathfrak{A}) & \xhookrightarrow[\text{for }\mathcal{H}]{\text{basic}} & \Omega(\tilde{E})\otimes\Omega_{\mathrm{Der}}(M_n) \end{array}$$

The algebra we are looking at must replace the algebra $\mathfrak{A}$, in the same way the space $Q'\times H$ replaces the space $\tilde{E}$. It is natural to look at this algebra as a basic subalgebra of $C^\infty(Q'\times H)\otimes M_n$ for the Cartan operation of $\mathcal{H}$. Then the pull back $\Psi^*\omega$ of a $\mathcal{G}$-invariant connection 1-form $\omega\in\Omega_{\mathrm{Der}}(\mathfrak{A})\subset\Omega(\tilde{E})\otimes\Omega_{\mathrm{Der}}(M_n)$ belongs to $\Omega(Q'\times H)\otimes\Omega_{\mathrm{Der}}(M_n)$. Thanks to the facts that Z_0 and G_0 do not act on the M_n part of these algebras, that Ψ^* preserves the $\mathcal{G}$-invariance and the $\mathcal{H}$-basicity, one has

$$\Psi^*\omega\in\left[\Omega(\tilde{Q})\otimes\Omega(G)\otimes\Omega(H)\otimes\Omega_{\mathrm{Der}}(M_n)\right]^{G-\mathrm{inv}}_{\substack{\mathrm{H-basic}\\(Z_0\times G_0)-\mathrm{basic}}}.$$

The advantage to work at the level of the space $\Omega(\tilde{Q})\otimes\Omega(G)\otimes\Omega(H)\otimes\Omega_{\mathrm{Der}}(M_n)$, is that, there, we can decompose in an easy way the actions of the group G, G_0, Z_0, and H. These actions are shown in the following suggestive diagram:



where symbols L and R mean, respectively, left and right multiplication. Notice that the actions of Z_0 and G_0 on $\Omega(H)$ commute.

Then, using H-basicity and G-invariance, a straightforward computation shows that $\Psi^*\omega$ can be written in the generic form

$$\Psi^*\omega_{|(\tilde{q},g,h)} = \mathrm{Ad}_{h^{-1}}(\tilde{\omega}_{|\tilde{q}} + \Lambda_{\tilde{q}} \circ \theta^G_{|g} + \phi_{\tilde{q}} \circ \mathrm{Ad}_h \circ (\theta^H_{|h} - i\theta)), \tag{22}$$

where θ^G and θ^H are the Cartan 1-forms on the groups G and H and $i\theta$ is the algebraic 1-form introduced in Sec. III. It is very natural to use the 1-form $i\theta$ in this relation in order to make explicit the identification (6). Notice that θ^H and $i\theta$ are known to look very similar in their structure,[17] and that they appear together in this very compact expression. In formula (22), on has

$$\tilde{\omega} \in \Omega^1(\tilde{Q}), \quad \Lambda \in C^\infty(\tilde{Q}) \otimes M_n \otimes \mathcal{G}^*, \quad \phi \in C^\infty(\tilde{Q}) \otimes M_n \otimes \mathfrak{sl}_n^*$$

and the Z_0-invariance implies that

$$R^*_{z_0}\tilde{\omega} = \mathrm{Ad}_{z_0^{-1}} \circ \tilde{\omega}, \quad R^*_{z_0}\Lambda = \mathrm{Ad}_{z_0^{-1}} \circ \Lambda, \quad R^*_{z_0}\phi = \mathrm{Ad}_{z_0^{-1}} \circ \phi \circ \mathrm{Ad}_{z_0}$$

for any $z_0 \in Z_0$. Then Λ and ϕ can be considered as sections of some associated vector bundles to $\tilde{Q}(M/G, Z_0)$. On the other hand, the G_0-invariance implies that

$$\mathrm{Ad}_{\lambda(g_0)^{-1}}\tilde{\omega} = \tilde{\omega}, \quad \mathrm{Ad}_{\lambda(g_0)^{-1}} \circ \Lambda \circ \mathrm{Ad}_{g_0} = \Lambda, \quad \mathrm{Ad}_{\lambda(g_0)^{-1}} \circ \phi \circ \mathrm{Ad}_{\lambda(g_0)} = \phi. \tag{23}$$

for any $g_0 \in G_0$, and the $(G_0 \times Z_0)$-horizontality gives us that

$$\Lambda(X_0) = \phi(\lambda_* X_0) \quad \forall\, X_0 \in \mathcal{G}_0 \quad \text{and } \tilde{\omega}(\tilde{Z_0^Q}) = \phi(Z_0) \quad \forall\, Z_0 \in \mathcal{Z}_0. \tag{24}$$

The ordinary $\mathcal{G}$-invariant connections are recovered in formula (22) when $\phi = \mathbb{1}$. Indeed, in this case one gets

$$\Psi^*\omega_{|(\tilde{q},g,h)} = \mathrm{Ad}_{h^{-1}}(\tilde{\omega}_{|\tilde{q}} + \Lambda_{\tilde{q}} \circ \theta^G_{|g}) + \theta^H_{|h} - i\theta$$

which is to be compared to formula (4). As already explained, the extra term $i\theta$ is exactly what is needed to imbed ordinary connections into the noncommutative framework.

By means of the equivariance relation (23), Λ (respectively, ϕ) intertwines the representation of G_0 on $\mathcal{G}^{\mathbb{C}}$ (respectively, $\mathcal{H}^{\mathbb{C}}$) with the representation of G_0 on the algebra $M_n \simeq \mathrm{Vect}_{\mathbb{C}}(\mathbb{1}, \mathcal{H})$ and by virtue of the Schur lemma, it can be decomposed in a direct sum of isomorphisms between common irreducible blocks of $\mathcal{G}^{\mathbb{C}}$ (respectively, $\mathcal{H}^{\mathbb{C}}$) and $M_n \simeq \mathrm{Vect}_{\mathbb{C}}(\mathbb{1}, \mathcal{H})$. Furthermore, if one requires that the connection is anti-Hermitian, one must identify isomorphisms which correspond to complex conjugate representations, or directly look at real representations.

This "local" characterization of invariant noncommutative connections can be shown to be equivalent to the "global" approach. In order to do that, one needs to decompose the degrees of freedom and rearrange them in a different way.

From (22), it is easy to write down local expressions on M. A section $S: M \to \tilde{E}$ can be factorized through a local section $s = s_{\tilde{Q}} \times s_G$ on the fiber bundle $Q' = \tilde{Q} \times G$, and a section s_H on the trivial fiber bundle $Q' \times H$. The application $S = \Psi \circ s_H \circ s$ is represented in the following commutative diagram:

$$\begin{array}{ccc} Q' \times H & \underset{s_H}{\overset{pr_1}{\rightleftarrows}} & Q' = \tilde{Q} \times G \\ \Psi \downarrow & & \downarrow \uparrow s = s_{\tilde{Q}} \times s_G \\ \tilde{E} & \underset{S}{\overset{\tilde{\pi}}{\rightleftarrows}} & M = M/G \times G/G_0 \end{array}$$

Then, the local 1-form connection is just $S^*\omega = s^* \circ s_H^* \circ \Psi^* \tilde{\omega} \in \Omega(M) \otimes \Omega_{\mathrm{Der}}(M_n)$. It is useful to write the section S in the following way:

$$S: M \to \tilde{E},$$

$$m \mapsto \Psi(s_{\tilde{Q}}(m), s_G(m), h(m)).$$

Then, one finally obtains

$$S^*\omega = \mathrm{Ad}_{h^{-1}}(s_{\tilde{Q}}^* \tilde{\omega} + s_{\tilde{Q}}^* \Lambda \circ s_G^* \theta^G + s_{\tilde{Q}}^* \phi \circ \mathrm{Ad}_h \circ (h^* \theta^H - i\theta)). \tag{25}$$

One can look at passive gauge transformations which preserve symmetries of the local 1-form $S^*\omega$. We have three ways to perform such a passive gauge transformation. We can multiply on the right s_H by an element $h' \in H$, $s_{\tilde{Q}}$ by an element $z_0 \in Z_0$ or s_G by an element $g_0 \in G_0$. Then S is modified in the following way:

$$S \mapsto S' = \Psi \circ (s_{\tilde{Q}} \cdot z_0, s_G \cdot g_0, h \cdot h').$$

One can report the action on $\tilde{Q}$ and G to an action on H by means of the equivariance of the application Ψ, and one has

$$\Psi \circ (s_{\tilde{Q}} \cdot z_0, s_G \cdot g_0, h \cdot h') = \Psi \circ (s_{\tilde{Q}}, s_G, \lambda(g_0^{-1}) \cdot z_0^{-1} \cdot h \cdot h').$$

We will illustrate this three kind of gauge transformations in the next section.

V. EXAMPLES

In this section we apply the results found in the preceding section to two examples. The first one is a noncommutative extension of a case extensively studied and used in the literature,[3,14] that is, the spherical symmetry for SU (2)-gauge fields (see Ref. 22 and references therein for examples of applications). We will show that our framework generalizes in a straightforward way the results found in the ordinary case.

The second example is a purely noncommutative case. It consists to look at some symmetries on the matrix algebra. In this case, no geometry is involved.

A. Spherical symmetry

Consider the interesting example where $M = \mathbb{R} \times \mathbb{R}^3 \backslash \{0\}$, the first factor being parametrized by the time coordinate t and the second factor by spacial coordinates $(x,y,z) = \vec{r}$. The symmetry group is taken to be $G = \mathrm{SU}(2)$ and it acts on $\mathbb{R}^3 \backslash \{0\}$ by rotation matrices. [We consider the space $\mathbb{R}^3 \backslash \{0\}$ because we want a simple action.] Then G_0 is isomorphic to U (1), G/G_0 is isomorphic to the 2-sphere $\mathbb{S}^2$ and $M/G = \mathbb{R} \times \mathbb{R}^{+*}$. We look at a gauge theory with structure group $H = \mathrm{SU}(2)$, and so for the noncommutative part, we take $M_n = M_2(\mathbb{C})$.

We first treat this example in the approach developed in Sec. IV A. Notice that any principal SU (2)-fiber bundle over M is trivial due to the fact that $M = \mathbb{R} \times \mathbb{R}^{+*} \times \mathbb{S}^2$, where $\mathbb{R} \times \mathbb{R}^{+*}$ is contractible and $\dim(\mathbb{S}^2) = 2$. Then we will take E in the trivial form

$$E = M \times \mathrm{SU}(2) = M/G \times \mathrm{S}^2 \times \mathrm{SU}(2).$$

Now, we can lift the action of G on the base space M to an action on the fiber bundle E defining an action of G on the structure group H. One can extend this action in a trivial way by considering the action $(g,h) \mapsto h \forall_g \in G$, $\forall h \in H$. Then the reduced theory is a SU (2)-gauge theory over M/G which means that nothing very interesting is happening. A more complex case is to consider the following action:

$$G \times H \to H,$$

$$(g,h) \mapsto g \cdot h,$$

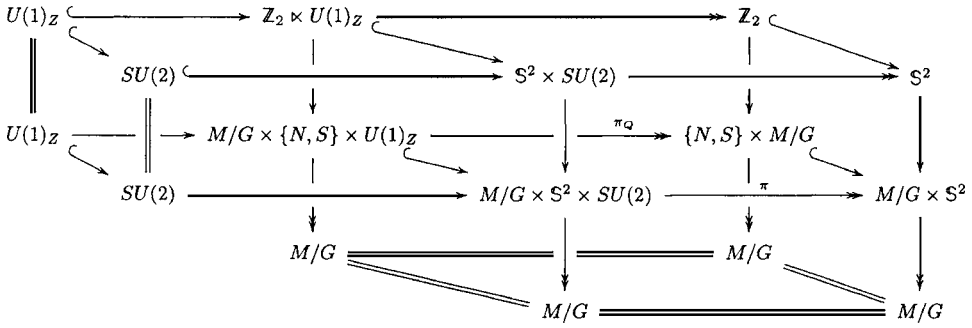
which is possible here because $G=H$. With this action, one can see that the application λ is an isomorphism and then one can take the reduced bundle Q in such a way that $\lambda=\mathbb{1}$. Then one has $Z_0=G_0=U(1)_z$, where

$$\mathrm{U}(1)_Z := \{\exp(2\epsilon T_3), \epsilon \in \mathbb{R}\}$$

and $\{T_1,T_2,T_3\}$ is a basis of anti-Hermitian generators of $\mathfrak{su}(2)$ satisfying

$$[T_1,T_2]=T_3, \quad [T_2,T_3]=T_1, \quad [T_3,T_1]=T_2.$$

The reduced fiber bundle Q is isomorphic to $M/G\times\{N,S\}\times \mathrm{U}(1)$, where N and S are the north and south poles of the 2-sphere $\mathbb{S}^2$. Without loss of generality, we can restrict the fiber Q to the point N, the symmetry relations coming from this $\mathbb{Z}_2$ structure being just conjugation relations over complex numbers. In this case, the diagram (1) becomes



Here, we have $\mathcal{L}=\mathcal{M}=\mathrm{Vect}_{\mathbb{R}}(T_1,T_2)$, $\mathcal{K}=0$ and $\mathcal{W}_0=\mathrm{Vect}_{\mathbb{C}}(\mathbb{1},T_3)$. It is then easy to see that $\mathcal{F} \simeq \mathcal{L}^{\mathbb{C}}\oplus\mathcal{M}^{\mathbb{C}}$. Finally a SU (2)-invariant connection is characterized by two sections ψ and ζ over M/G with values in $\mathrm{Vect}_{\mathbb{C}}(T_1,T_2)$ and a noncommutative 1-form $\mu-\eta\in(\Omega(M/G)\otimes\Omega(\mathcal{W}_0))^1$. Here $\Omega^1(\mathcal{W}_0)$ is simply $\mathcal{W}_0$ because $\mathcal{Z}_0$ is one dimensional. If only anti-Hermitian connections are taken into account, then one can consider vector spaces over $\mathbb{R}$, and ψ and ζ can be interpreted as complex scalar fields (because $\mathcal{L}=\mathcal{M}\simeq\mathbb{C}$). In this case, one has $\mathcal{C}=C^\infty(M/G)\otimes\mathcal{W}_0$, and $\mathrm{SU}(\mathcal{C})=\{e^{\chi T_3}=\cos(\chi/2)\mathbb{1}+\sin(\chi/2)T_3,\chi\in\mathcal{C}^\infty(M/G)\}\simeq\mathrm{U}(1)$.

In this particular example, the "local" approach of Sec. IV B is very well adapted because of the structure of the base space M. Then, we will perform the rest of its analysis using these technics. The SU (2)-principal bundle E can be constructed from a principal U (1)-fiber bundle and the conjugacy class $[\lambda]=[\mathbb{1}]$.

An invariant connection is given explicitly by formula (22), and for the simplicity of the analysis, we will consider only traceless anti-Hermitian connections in the following. [The trace term in a connection corresponds to the term $\mathbb{1}$ in the algebra $M_n=\mathrm{Vect}_{\mathbb{C}}(\mathbb{1},\mathcal{H})$, and it can be studied independently of the traceless part.] Using notations and results of Sec. IV B, we are led to study the decomposition of the adjoint representation of SU (2) in irreducible representations of $\mathrm{U}(1)_Z$. The adjoint representation of SU (2) is decomposed into the fundamental representation of U (1) on $\mathrm{Vect}_{\mathbb{R}}T_3$ and the two-dimensional representation on $\mathrm{Vect}_{\mathbb{R}}(T_1,T_2)$, corresponding to the fundamental representation of SO(2). The invariance properties (23) implies that

$$\Lambda(T_1)=\Lambda_1T_1+\Lambda_2T_2, \quad \phi(T_1)=\phi_1T_1+\phi_2T_2,$$

$$\Lambda(T_2)=-\Lambda_2T_1+\Lambda_1T_2, \quad \phi(T_2)=-\phi_2T_1+\phi_1T_2,$$

and using (23) and (24)

$$\Lambda(T_3) = \phi(T_3) = \eta T_3,$$

where η is a function over M/G. Now let us write the local expression (25) of the connection 1-form by considering two different useful gauges. First let us introduce what we call the "singular" gauge in which we take the constant section

$$s_H: Q' \to Q' \times H,$$

$$q' \mapsto (q', e).$$

We will choose the usual spherical coordinates (ϑ, φ) for the local system of coordinate on $\mathbb{S}^2$. Then we consider the natural local section,

$$s_G: \mathbb{S}^2 \to \mathrm{SU}(2),$$

$$(\vartheta, \varphi) \mapsto g = e^{\varphi T_3} e^{\vartheta T_2}$$

[we have in mind the Euler parametrization of SU (2), where ϑ and φ are two of the three Euler angles]. Then a straightforward computation gives

$$S^*\omega = aT_3 + (\Lambda_1 T_1 + \Lambda_2 T_2)\mathrm{d}\vartheta + (\Lambda_1 T_2 - \Lambda_2 T_1)\sin\vartheta\,\mathrm{d}\varphi + \eta T_3 \cos\vartheta \mathrm{d}\varphi - [(\phi_1 T_1 + \phi_2 T_2)\theta^1 + (\phi_1 T_2 - \phi_2 T_1)\theta^2 + \eta T_3 \theta^3], \tag{26}$$

where $a = a_r\,\mathrm{d}r + a_t\,\mathrm{d}t \in \Omega^1(\mathbb{R} \times \mathbb{R}^{+*})$, and $i\theta = T_a\theta^a$. This reduced 1-form connection generalizes in an obvious way the so-called Witten's anzatz[14] which is recovered by setting $\phi_1 = \eta = 1$ and $\phi_2 = 0$ (i.e., $\phi = \mathbb{1}$). One can note that the monopole term (corresponding to the local 1-form $\cos\vartheta\,\mathrm{d}\varphi$) is no more constant and is now factorized by a function η. Singularities happening in (26) are due to the fact that we try to extend the system of spherical coordinates globally on $\mathbb{S}^2$. This extension is not possible in this gauge and it is why it is called the "singular" gauge. However one can introduce another gauge in which the extension of the local 1-form to a global one is possible. This is the "regular," or "radial" gauge, defined by the following section:

$$S: M \to \widetilde{E}, \tag{27}$$

$$(r, \vartheta, \varphi) \mapsto \Psi(s_{\tilde{Q}}(r), e^{\phi T_3} e^{\vartheta T_2}, e^{-\vartheta T_2} e^{-\phi T_3}). \tag{28}$$

It can be obtained from the "singular" gauge by a (passive) gauge transformation which consist to multiply the section s_H by the element $h' = e^{-\vartheta T_2} e^{-\varphi T_3} \in H$. Then applying formula (25) leads to the following expression:

$$S^*\omega = aT_r + \Lambda_1[T_r, \mathrm{d}T_r] - \Lambda_2\,\mathrm{d}T_r - \phi_1[T_r, \hat{\mathrm{d}}Tr] + \phi_2 \hat{\mathrm{d}}Tr - \eta T_r \theta^r, \tag{29}$$

where

$$T_r = \sin\vartheta\cos\varphi T_1 + \sin\vartheta\sin\varphi T_2 + \cos\vartheta T_3,$$

$$\theta^r = \sin\vartheta\cos\varphi\theta^1 + \sin\vartheta\sin\varphi\theta^2 + \cos\vartheta\theta^3,$$

and $\hat{\mathrm{d}} = \mathrm{d} + \mathrm{d}'$ is the noncommutative differential introduced in Sec. III. The absence of singularity is clearly due to the fact that the spherical angles (ϑ, φ) do not appear explicitly, and that everything can be expressed in terms of the unique generator T_r. To illustrate the fact that we have extended the local 1-form to a global one, we will give some more explicit formulas using Euclidian coordinates. Let us introduce the notation $S^*\omega = a + A_i^a T_a \mathrm{d}x^i - \phi_b^a T_a \theta^b$. Then formula (29) gives us

$$A_i^a = \frac{\mathrm{Re}(\psi - i\phi)}{r} P_i^a + \frac{\mathrm{Im}(\psi - i\phi)}{r} g^{ab} \epsilon_{ibc} \hat{n}^c,$$

$$\phi_b^a = \mathrm{Re}(\phi) P_b^a + \mathrm{Im}(\phi) g^{ac} \epsilon_{bcd} \hat{n}^d + \eta \hat{n}^a \hat{n}_b,$$

with $\hat{n}^a = x^a/r$, $P_b^a = \delta_i^a - \hat{n}^a \hat{n}_i$, g^{ab} the Euclidian metric and ϵ_{abc} the totally antisymmetric tensor such that $\epsilon_{123} = 1$. We have introduced the useful notations $\psi = -\Lambda_2 + i\Lambda_1$ and $\phi = \phi_1 + i\phi_2$.

Finally, we would like to show how the two other passive gauge transformations (on s_G and $s_{\tilde{Q}}$ mentioned at the end of Sec. IV B) can be performed. They will correspond to a U (1) residual symmetry. In terms of the two complex scalar fields ψ and ϕ, Eq. (29) becomes

$$S^* \omega = a T_r + \mathrm{Re}(\psi - i\phi) \mathrm{d} T_r + \mathrm{Im}(\psi - i\phi)[T_r, \mathrm{d} T_r] + \mathrm{Re}(-i\phi) \mathrm{d}' T_r + \mathrm{Im}(-i\phi)[T_r, \mathrm{d}' T_r] - \eta T_r \theta^r.$$

The U (1) passive gauge transformations correspond to the transformations on s_G and $s_{\tilde{Q}}$ given by

$$s_G \rightsquigarrow s_G \cdot e^{\chi_0 T_3},$$

$$s_{\tilde{Q}} \rightsquigarrow s_{\tilde{Q}} \cdot e^{\chi_1 T_3},$$

where $\chi_0(r,t)$ and $\chi_1(r,t)$ are two arbitrary functions of r and t. This leads to transformations on the fields ψ and a,

$$\psi \rightsquigarrow e^{i(\chi_1 + \chi_0)} \psi,$$

$$a \rightsquigarrow a - \eta \mathrm{d}(\chi_1 + \chi_0). \tag{30}$$

One can remark that the scalar fields ϕ and η remain unchanged under this passive gauge transformation. One can also note the similarity with usual Abelian gauge transformations.

It is possible to consider a "true" symmetric gauge transformation (in the sense of noncommutative geometry, see Sec. III). In order to do that, one must redefine the complex scalar field ϕ to $\phi = 1 - \phi'$. Then a "true" symmetric gauge transformation parametrized by an element $e^{\chi T_3} \in \mathrm{SU}(\mathcal{C})$, where χ is a function over $M/G = \mathbb{R} \times \mathbb{R}^{+*}$, leads to the transformations

$$\phi' \rightsquigarrow e^{-i\chi} \phi',$$

$$\psi \rightsquigarrow e^{-i\chi} \psi,$$

$$a \rightsquigarrow a + \mathrm{d}\chi. \tag{31}$$

Note that these transformations are much more similar to ordinary U (1) gauge transformations.

B. A purely noncommutative example

We present in this section a purely noncommutative case in the sense that we consider a situation in which the base space is a point. Then one has $G = G_0$, and λ is an homomorphism from G to H. In this case, the noncommutative algebra is simply the algebra of matrices M_n, equipped with the noncommutative calculus exposed in Ref. 17 and summarized in Sec. III. In this situation, the problem reduces to characterize G-invariant noncommutative connections in M_n. For simplicity, as before, we will restrict in this section to traceless connections.

The general procedure to follow is to first study the representation λ of G in M_n, and then determine how the representations $\mathrm{Ad}^H \circ \lambda$ split into irreducible representations of G. These irreducible representations give rise to the degrees of freedom of the invariant noncommutative connections, one scalar field for each intertwiner of equivalent irreducible representations.

We want to illustrate this in the particular case $G=\mathrm{SU}(2)$. It is well known that representations of SU (2) on M_n are parametrized by partitions of n.[9] For instance, for $\mathfrak{A}=M_3(\mathbb{C})$, the representations are labeled by the partitions "1+1+1," "2+1," and "3" of 3. They are described in the following way:

(i) The "1+1+1" representation corresponds to the sum of three copies of the trivial representation. The representation $\mathrm{Ad}^H\circ\lambda$ is decomposed in a sum of eight copies of the trivial representation of SU (2). This gives rise to 64 scalar fields. This case is not interesting because the group SU (2) does not act on $M_3(\mathbb{C})$.

(ii) The "2+1" representation corresponds to a reducible representation of SU (2) which is the sum of the fundamental representation and the trivial one. The representation $\mathrm{Ad}^H\circ\lambda$ is decomposed into irreducible representations of SU (2) of dimensions 3, 2, 2, and 1 (six scalar fields).

(iii) The "3" representation corresponds to the irreducible representation of dimension 3 of SU (2). In this case, the representation $\mathrm{Ad}^H\circ\lambda$ can be decomposed into irreducible representations of SU (2) of dimensions 3 and 5 (two scalar fields).

We will not perform the analysis any further because our goal is just to characterize the degrees of freedom of a traceless noncommutative connection using the methods exposed in this paper.

Construction of new solutions to the fully nonlinear generalized Camassa-Holm equations by an indirect F function method

Emmanuel Yomba
Institute for Mathematics and its applications, University of Minnesota, Minneapolis, Minnesota 554556-0436 and Department of Physics, Faculty of Sciences, University of Ngaoundéré, Ngaoundéré, Cameroon

(Received 3 January 2005; accepted 7 October 2005; published online 19 December 2005)

An indirect F function method is introduced to solve the generalized Camassa-Holm equation with fully nonlinear dispersion and fully nonlinear convection $C(l,n,p)$. Taking advantage of elliptic equation, this F function is used to map the solutions of the generalized Camassa-Holm equation to those of the elliptic equation. As a result, we can successfully obtain in a unified way and for special values of the parameters of this equation, many exact solutions expressed by various single and combined nondegenerative Jacobi elliptic function solutions and their degenerative solutions (soliton, combined soliton solutions, and triangular solutions) as the modulus m is driven to 1 and 0. © *2005 American Institute of Physics*. I. INTRODUCTION

It is well known that the investigation of the travelling wave solutions of nonlinear evolution equations (NLEEs), which is an important tool in characterizing many complicated phenomena and dynamical processes in physics, mechanics, chemistry, biology, etc., plays an essential role in the study of these physical problems. Hence, seeking for solutions of the NLEEs may help enable physicists and engineers to better understand the mechanism that governs these physical problems. Especially, finding explicit solutions to nonlinear models has become one of the most exciting and extremely active areas of research investigation, since they may provide better knowledge to the physical problems and possible physical applications.

Recently, both mathematicians and physicists have made many attempts in this direction. A number of works have been done on the construction of exact solutions of NLEEs and effective and powerful methods have been developed, such as inverse scattering method,[1] Bäcklund transformation,[2] Darboux transformation,[3,4] Hirota bilinear method,[5] homogeneous balance method,[6] Jacobi elliptic function method,[7] tanh-function method,[8,9] extended tanh-function method,[10–13] improved extended tanh-function method,[14–18] the sine-cosine function method.[19]

Very recently, a unified F-expansion method[20–27] has been established to obtain Jacobi elliptic functions, solitons, and periodic functions to a large variety of NLEEs whose odd- and even-order derivative terms do not coexist. The main idea of this method is to take full advantage of the elliptic equation which has more solutions, to construct exact solutions to the NLEEs. Thus multiple exact solutions can be obtained in a unified way and much tedious and repeated calculation can be avoided.

In the present paper, a generalized Camassa-Holm equation with fully nonlinear dispersion and fully nonlinear convection term $C(l,n,p)$ (Ref. 28) is considered

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U^l)_x + \beta_3 U_x (U^n)_{xx} + \beta_4 U (U^p)_{xxx} = 0, \tag{1}$$

where k, β_1, β_2, β_3, and β_4 are arbitrary real constants.

Equation (1) is a class of physically important equations. In fact, if one takes $\beta_1=-1$, $\beta_2=3/2$, $\beta_3=-2$, $\beta_4=-1$, $l=2$, $n=p=1$, (1) becomes the shallow water equation, namely Camassa-Holm equation

$$U_t + kU_x - U_{xxt} + 3UU_x = 2U_xU_{xx} + UU_{xxx}, \tag{2}$$

which has been proposed by Camassa-Holm.[29] They used Hamiltonian methods to derive the completely integrable dispersive wave equation for water by retaining two terms that are usually neglected in small amplitude shallow water limit. They showed that for all k, Eq. (2) is integrable, and for $k=0$, (2) has travelling solutions, which are called peakons. When $\beta_1=-1$, $\beta_2=a$, $\beta_3=-2$, $\beta_4=-1$, $l=L+1$, $n=p=1$, (1) becomes another form of generalized Camassa-Holm equation,

$$U_t + kU_x - U_{xxt} + aU^LU_x = 2U_xU_{xx} + UU_{xxx}, \tag{3}$$

studied by Tian and Song.[30] They derived some exact peaked solitary wave solutions. When $k=0$, $\beta_1=-1$, $\beta_2=3/2$, $\beta_3=-2\gamma$, $\beta_4=-\gamma$, $l=2$, $n=p=1$, (1) becomes

$$U_t - U_{xxt} + 3UU_x = \gamma(2U_xU_{xx} + UU_{xxx}), \tag{4}$$

which has been derived by Dai and Huo[31] when they studied disturbances in an initially stretched or compressed rod which is composed of a compressible Mooney-Rivlin material. By using a nondimensionalization process and the reductive perturbation technique, they obtained a type of nonlinear dispersive equation (4). They also showed that Eq. (4) has a variety of travelling waves including solitary shock waves, solitary waves, periodic shock waves, etc. Liu and Chen[32] showed that Eq. (4) also generated compacton structures by using the bifurcation method of planar dynamical systems and numerical simulation of differential equations. When $k=0$, $\beta_1=-1$, $\beta_2=3/2$, $\beta_3=\beta_4=0$, $l=2$, $n=p=1$, Eq. (1) becomes the BBM equation,[33] a well-known model for surface wave in channel.

More recently, by using four direct ansatze, Tian and Yin[28] obtained abundant solutions, compactons (solutions with absence of infinite wings), solitary patterns (solutions having infinite slopes or cups), solitary waves and singular periodic wave solutions and obtained kink compacton solutions and nonsymmetry compacton solutions. In the same paper, they also studied other forms of fully nonlinear generalized Camassa-Holm equation and showed that their compacton solutions are governed by linear equations.

The present paper is motivated by the desire to extend the Tian and Yin work[28] to make further progress. More importantly, it is the objective of this work to show that abundant families of Jacobi, combined Jacobi elliptic functions, solitary wave and combined solitary wave solutions and triangular functions arise from Eq. (1). To achieve our goal, instead of taking specific functions as Tian and Yin did in Ref. 28, we will use a form of indirect F-function method [not the F-expansion method because the complexity of Eq. (1) cannot allow the use of this method]. But our indirect F method will be very close to the F-expansion method in the sense that, the indirect F-function method will also take advantage of nonlinear ordinary differential equation (ODE). Thus, one will only need to calculate the function which is a solution of the ODE, instead of calculating the Jacobi elliptic function one by one; second, the coefficients of the ODE can be selected so that the corresponding solution is a Jacobi elliptic function, exactly as in the F-expansion method.

The paper is organized as follows: In Sec. II, a derivation of the proposed method for finding exact solutions is presented. Finally, some discussions and conclusions are given in Sec. III.

II. GENERAL FORMULAS OF THE SOLUTIONS

We first make the following formal travelling wave transformation:

$$U(x,t) = U(\xi), \quad \xi = \lambda_1 x + \lambda_2 t, \tag{5}$$

where λ_i, $(i=1,2)$ are undetermined constants. Substituting (5) into Eq. (1), we have the ODE for $U(\xi)$,

$$\lambda_2 U' + k\lambda_1 U' + \beta_1\lambda_2\lambda_1^2 U''' + \beta_2\lambda_1 (U^l)' + \beta_3\lambda_1^3 U'(U^n)'' + \beta_4\lambda_1^3 U(U^p)''' = 0. \tag{6}$$

Then a suitable ansatz for the unknown $U(\xi)$ will solve Eq. (6).

Let us assume that Eq. (6) has the solution in the form

$$U(\xi) = A(F(\xi))^B, \tag{7}$$

where A and B are parameters to be determined later. We also propose that the function F should be mapped to the solutions of the following elliptic equation

$$F'^2 = r + aF^2 + \frac{b}{2}F^4, \tag{8}$$

r, a, and b are constants. Substituting the ansatz (7) along with Eq. (8) into Eq. (6), collecting coefficients of power of F with the aid of Mathematica, we can deduce the following polynomial equation:

$$\begin{aligned}
&2ABr\beta_1\lambda_2\lambda_1^2[2-3B+B^2]F^B + 2AB[k\lambda_1+\lambda_2+aB^2\beta_1\lambda_2\lambda_1^2]F^{B+2} + ABb\beta_1\lambda_2\lambda_1^2[2+3B+B^2]F^{B+4}\\
&\quad + [2lBA^l\beta_2\lambda]F^{2+Bl} + 2A^{1+n}B^2nr\beta_3\lambda_1^3[nB-1]F^{B(n+1)} + [2aA^{1+n}B^3n^2\beta_3\lambda_1^3]\times F^{2+B(n+1)}\\
&\quad + A^{1+n}B^2nb\beta_3\lambda_1^3[nB+1]F^{4+B(n+1)} + 2A^{1+p}Bpr\beta_4\lambda_1^3[2-3Bp+B^2p^2]F^{B(1+p)}\\
&\quad + [2aA^{1+p}B^3p^3\beta_4\lambda_1^3]F^{2+B(p+1)} + A^{1+p}Bpb\beta_4\lambda_1^3[2+3Bp+B^2p^2]F^{4+B(1+p)} = 0.
\end{aligned} \tag{9}$$

One may easily see that in the specific cases, where $r=1$, $a=-1$, and $b=0$ which lead to $F=\cos\xi$, when $r=1$, $a=-1$, and $b=0$ which lead to $F=\sin\xi$, when $r=-1$, $a=1$, and $b=0$ which lead to $F=\cosh\xi$ and when $r=1$, $a=1$, and $b=0$ which lead to $F=\sinh\xi$, then we are in the situation of ansatz 1, ansatz 2, ansatz 3, and ansatz 4 in Ref. 28, respectively. We are interested in the general case where $r\times a\times b\neq 0$.

In view of the study of Eq. (9), we may observe carefully the different powers of F intervening in this equation. Then, it appears that it is powers $2+Bl$, $2+B(n+1)$, and $2+B(1+p)$ whose coefficients are singles which may determine our discussion.

Thus, from Eq. (9), we get the following possible cases to be discussed.

Case 1: $2+Bl=2+B(n+1)=2+B(1+p)$, we have $l=n+1$, $p=n$,

Case 2: $2+Bl=2+B$, $2+B(n+1)=2+B(1+p)$, we have $l=1$, $p=n$,

Case 3: $2+Bl=2+B(1+p)$, $2+B(n+1)=2+B$, we have $l=1+p$, $n=0$,

Case 4: $2+Bl=2+B(1+n)$, $2+B(p+1)=2+B$, we have $l=1+n$, $p=0$.

But the cases 3 and 4 produce no solution.

From the case 1, choosing $l=1+n$ and $p=n$, substituting in Eq. (9) and collecting all terms with same power of F, we obtain the following equation:

$$\begin{aligned}
&2ABr\beta_1\lambda_2\lambda_1^2[2-3B+B^2]F^B + 2AB[k\lambda_1+\lambda_2+aB^2\beta_1\lambda_2\lambda_1^2]F^{B+2} + ABb\beta_1\lambda_2\lambda_1^2[2+3B+B^2]F^{B+4}\\
&\quad + 2A^{1+n}Bnr\lambda_1^3[\beta_3B(nB-1)+\beta_4(2-3Bn+B^2n^2)]F^{B(n+1)} + 2A^{1+n}B[(n+1)\beta_2\lambda_1 + aB^2n^2\lambda_1^3(\beta_3\\
&\quad + n\beta_4)]F^{2+B(n+1)} + A^{1+n}Bnb\lambda_1^3[B\beta_3(Bn+1)+\beta_4(2+3Bn+B^2n^2)]F^{4+B(1+n)} = 0.
\end{aligned} \tag{10}$$

From (10) it appears that when setting to zero the coefficient of F^B, i.e., $2ABr\beta_1\lambda_2\lambda_1^2[2-3B+B^2]=0$ which leads to $[2-3B+B^2]=0$ ($B=1$ or $B=2$) then the coefficient of power F^{B+4} should be different than zero, i.e., $ABb\beta_1\lambda_2\lambda_1^2[2+3B+B^2]\neq 0$. Thus the power of F^{B+4} should be shifted to another power; this may help the coefficient of this power to enter another relationship with other terms. Thus the following two subcases may be satisfied.

First subcase

$$B+4=B(n+1)\nearrow \text{ when } B=1,\ \Rightarrow n=4;\ l=5,\ p=4\searrow \text{ when } B=2,\ \Rightarrow n=2;\ l=3,\ p=2.$$

Substituting the first type of relation of the first subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_1 = \frac{\sqrt{\frac{5}{2}}}{4}\sqrt{\frac{\beta_2}{a\beta_4}}, \quad \lambda_2 = -\frac{k\lambda_1}{1+a\beta_1\lambda_1^2}, \quad A = \pm\frac{1}{2}\left(\frac{b\beta_1\lambda_2}{r\beta_4\lambda_1}\right)^{1/4}, \quad \beta_3 = -6\beta_4. \tag{11}$$

a, b, and r are arbitrary constants.

Substituting the second type of relation of the first subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_1 = \frac{\sqrt{3}}{4}\sqrt{\frac{\beta_2}{a\beta_4}}, \quad \lambda_2 = -\frac{k\lambda_1}{1+4a\beta_1\lambda_1^2}, \quad A^2 = -\left(\frac{kb\beta_1}{r(3\beta_1\beta_2+4\beta_4)}\right),$$
$$\beta_3 = -3\beta_4, \tag{12}$$

a, b, and r are arbitrary constants.

Second subcase,

$B+4 = 2+B(n+1) \nearrow$ when $B=1$, $\Rightarrow n=2$; $l=3$, $p=2 \searrow$ when $B=2$, $\Rightarrow n=1$; $l=2$, $p=1$.

Substituting the first type of relation of the second subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2 = -\frac{A^2(3\beta_2-8a\beta_4\lambda_1^2)}{3b\beta_1\lambda_1}, \quad A^2 = \lambda_1^2\left(\frac{3bk\beta_1}{3\beta_2+\lambda_1^2[a(3\beta_1\beta_2-8\beta_4)+8\beta_1\beta_4\lambda_1^2(3br-a^2)]}\right),$$
$$\beta_3 = -4\beta_4, \tag{13}$$

λ_1, a, b, and r are arbitrary constants.

Substituting the second type of relation of the second subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2 = -\frac{\lambda_1(4ar\beta_4\lambda_1^2-k)}{1+4a\beta_1\lambda_1^2}, \quad A = \frac{3bk\beta_1\lambda_1^2}{\beta_2+\lambda_1^2[2a(2\beta_1\beta_2-\beta_4)+4\beta_1\beta_2\lambda_1^2(3br-2a^2)]},$$
$$\beta_3 = -2\beta_4, \tag{14}$$

λ_1, a, b, and r are arbitrary constants.

Now, if we set the coefficient of F^{B+4} to zero, i.e., $[2+3B+B^2]=0$ ($B=-1$ or $B=-2$) then the coefficient $2ABb\beta_1\lambda_2\lambda_1^2[2-3B+B^2]$ of power F^{B+4} should be different than zero, in order to allow this coefficient to enter relationship with other coefficients of the other power of F, we have the following two subcases.

Third subcase,

$B = 2+B(n+1) \nearrow$ when $B=-1$, $\Rightarrow n=2$; $l=3$, $p=2 \searrow$ when $B=-2$, $\Rightarrow n=1$; $l=2$, $p=1$.

Substituting the first type of relation of the third subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2 = -\frac{k\lambda_1(8a\beta_4\lambda_1^2-3\beta_2)}{3\beta_2+a\lambda_1^2(3\beta_1\beta_2-8\beta_4)+8\beta_1\beta_4(3br-a^2)},$$

$$A^2 = \frac{6kr\beta_1\lambda_1^2}{3\beta_2+a\lambda_1^2(3\beta_1\beta_2-8\beta_4)+8\beta_1\beta_4(3br-a^2)}, \tag{15}$$

$$\beta_3 = -4\beta_4,$$

λ_1, a, b, and r are arbitrary constants.

Substituting the second type of relation of the third subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2 = -\frac{k\lambda_1(2a\beta_4\lambda_1^2 - \beta_2)}{12br\beta_1\beta_4\lambda_1^4 - (1+4a\beta_1\lambda_1^2)(2a\beta_4\lambda_1^2 - \beta_2)},$$

$$A = \left(\frac{6kr\beta_1\lambda_1^2}{12br\beta_1\beta_4\lambda_1^4 - (1+4a\beta_1\lambda_1^2)(2a\beta_4\lambda_1^2 - \beta_2)}\right), \tag{16}$$

$$\beta_3 = -2\beta_4,$$

λ_1, a, b, and r are arbitrary constants.

Fourth subcase,

$B = 4 + B(n+1) \nearrow$ when $B = -1$, $\Rightarrow n = 4$; $l = 5$, $p = 4 \searrow$ when $B = -2$, $\Rightarrow n = 2$; $l = 3$, $p = 2$.

Substituting the first type of relation of the fourth subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2 = -\frac{k\lambda_1}{1+a\beta_1\lambda_1^2}, \quad A = \pm\left(\frac{-rk\beta_1}{4b\beta_4(1+a\beta_1\lambda_1^2)}\right)^{1/4},$$
$$\beta_3 = -6\beta_4, \tag{17}$$

where λ_1, satisfies the following relation:

$$\beta_2 + a(5\beta_1\beta_2 - 32\beta_4)\lambda_1^2 - 32a^2\beta_1\beta_4\lambda_1^4 = 0, \tag{18}$$

a, b, and r are arbitrary constants.

Substituting the second type of relation of the fourth subcase in Eq. (10) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2 = -\frac{k\lambda_1}{1+4a\beta_1\lambda_1^2}, \quad A^2 = -\frac{rk\beta_1}{b\beta_4(1+a\beta_1\lambda_1^2)},$$
$$\beta_3 = -3\beta_4, \tag{19}$$

where λ_1, should satisfy the following relation:

$$3\beta_2 + 4a(3\beta_1\beta_2 - 4\beta_4)\lambda_1^2 - 64a^2\beta_1\beta_4\lambda_1^4 = 0, \tag{20}$$

a, b, and r are arbitrary constants.

From the case 2, taking $l=1$ and $p=n$, substituting these relations in Eq. (9) and collecting all terms with the same power of F, we obtain the following equation:

$$\begin{aligned} &2ABr\beta_1\lambda_2\lambda_1^2[2-3B+B^2]F^B + 2AB[\beta_2\lambda_1 + k\lambda_1 + \lambda_2 + aB^2\beta_1\lambda_2\lambda_1^2]F^{B+2} + ABb\beta_1\lambda_2\lambda_1^2[2+3B \\ &+ B^2]F^{B+4} + 2A^{1+n}Bnr\lambda_1^3[\beta_3 B(nB-1) + \beta_4(2-3Bn+B^2n^2)]F^{B(n+1)} + 2aA^{1+n}B^3n^2\lambda_1^3[\beta_3 \\ &+ n\beta_4]F^{2+B(n+1)} + A^{1+n}Bnb\lambda_1^3[B\beta_3(Bn+1) + \beta_4(2+3Bn+B^2n^2)]F^{4+B(1+n)} = 0. \end{aligned} \tag{21}$$

Proceeding in the same manner as above, for $[2-3B+B^2]=0$ ($B=1$ or $B=2$) then the coefficient of power F^{B+4} which should be different of zero, may enter into another relation if only we have the following relations.

First subcase,

$B + 4 = B(n+1) \nearrow$ when $B = 1$, $\Rightarrow n = 4$; $l = 1$, $p = 4 \searrow$ when $B = 2$, $\Rightarrow n = 2$; $l = 1$, $p = 2$.

Substituting the first type of relation of the first subcase in Eq. (21) and solving the set of a given system of equations we have found that there is no solution for this first subcase.

Second subcase,

$$B+4=2+B(n+1)\nearrow \text{ when } B=1,\ \Rightarrow n=2;\ l=1,\ p=2\searrow \text{ when } B=2,\ \Rightarrow n=1;\ l=1,\ p=1.$$

Substituting the first type of relation of the second subcase in Eq. (21) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2=\frac{8aA^2\beta_4\lambda_1}{3b\beta_1},\quad A^2=-\left(\frac{3b\beta_1(k+\beta_2)}{8\beta_2[a-(3br-a^2)\beta_1\lambda_1^2]}\right),$$
$$\beta_3=-4\beta_4, \tag{22}$$

λ_1, a, b, and r are arbitrary constants.

Substituting the second type of relation of the second subcase in Eq. (21) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2=\frac{2aA\beta_4\lambda_1}{3b\beta_1},\quad A=-\left(\frac{3b\beta_1(k+\beta_2)}{2\beta_2[a-2(3br-2a^2)\beta_1\lambda_1^2]}\right),$$
$$\beta_3=-2\beta_4, \tag{23}$$

λ_1, a, b, and r are arbitrary constants.

If now, it is $[2+3B+B^2]=0$ ($B=-1$ or $B=-2$) then it is the coefficient of power F^B which should be different of zero, may enter into another relation if only we have the following relations.

Third subcase,

$$B=2+B(n+1)\nearrow \text{ when } B=-1,\ \Rightarrow n=2;\ l=1,\ p=2\searrow \text{ when } B=-2,\ \Rightarrow n=1;\ l=1,\ p=1.$$

Substituting the first type of relation of the third subcase in Eq. (21) and solving the set of a given system of equations we have found the following results:

$$\lambda_2=-\frac{a\lambda_1(k+\beta_2)}{a-(3br-a^2)\beta_1\lambda_1^2},\quad A^2=\left(\frac{3r\beta_1\lambda_2}{4a\beta_4\lambda_1}\right),$$
$$\beta_3=-4\beta_4, \tag{24}$$

λ_1, a, b, and r are arbitrary constants.

Substituting the second type of relation of the third subcase in Eq. (21) and solving the set of a given system of equations we obtain the following results:

$$\lambda_2=-\left(\frac{a\lambda_1(k+\beta_2)}{a-2(3br-2a^2)\beta_1\lambda_1^2}\right),\quad A=\frac{3r\beta_4\lambda_2}{a\beta_4\lambda_1},$$
$$\beta_3=-2\beta_4, \tag{25}$$

λ_1, a, b, and r are arbitrary constants.

Fourth subcase,

$$B=4+B(n+1)\nearrow \text{ when } B=-1,\ \Rightarrow n=4;\ l=1,\ p=4\searrow \text{ when } B=-2,\ \Rightarrow n=2;\ l=1,\ p=2.$$

Substituting the first type of relation of the second subcase in Eq. (21) and solving the set of a given system of equations we have found that there is no solution for this subcase.

Since in all these cases, r, a, and b are arbitrary constants, we may choose them properly such that the corresponding solution F of the ODE (8) is one of the Jacobi elliptic, combined Jacobi elliptic functions.

If $r=1$, $a=-(1+m^2)$, $b=2m^2$, then the solution is

$$U_1 = A[\mathrm{sn}(\xi|m)]^B, \tag{26a}$$

or

$$U_2 = A[cd(\xi|m)]^B \equiv A\left[\frac{\mathrm{cn}(\xi|m)}{dn(\xi|m)}\right]^B, \tag{26b}$$

where $0 \leqslant m \leqslant 1$, is called modulus of Jacobi elliptic functions, and $\mathrm{sn}(\xi|m)$ is the Jacobi elliptic sine function, see Refs. 34 and 35.

If $r=1-m^2$, $a=2m^2-1$, $b=-2m^2$, then the solution is

$$U_3 = A[\mathrm{cn}(\xi|m)]^B, \tag{27}$$

where $\mathrm{cn}(\xi|m)$ is the Jacobi elliptic cosine function, see Refs. 34 and 35.

If $r=m^2-1$, $a=2-m^2$, $b=-2$, then the solution is

$$U_4 = A[dn(\xi|m)]^B, \tag{28}$$

where $dn(\xi|m)$ is the Jacobi elliptic function of the third kind, see Refs. 34 and 35.

If $r=m^2$, $a=-(1+m^2)$, $b=2$, then the solution is

$$U_5 = A[ns(\xi|m)]^B \equiv A\left[\frac{1}{\mathrm{sn}(\xi|m)}\right]^B, \tag{29a}$$

or

$$U_6 = A[dc(\xi|m)]^B \equiv A\left[\frac{dn(\xi|m)}{\mathrm{cn}(\xi|m)}\right]^B. \tag{29b}$$

If $r=-m^2$, $a=2m^2-1$, $b=2(1-m^2)$, then the solution is

$$U_7 = A[nc(\xi|m)]^B \equiv A\left[\frac{1}{\mathrm{cn}(\xi|m)}\right]^B. \tag{30}$$

If $r=-1$, $a=2-m^2$, $b=2(m^2-1)$, then the solution is

$$U_8 = A[nd(\xi|m)]^B \equiv A\left[\frac{1}{dn(\xi|m)}\right]^B. \tag{31}$$

If $r=1-m^2$, $a=2-m^2$, $b=2$, then the solution is

$$U_9 = A[cs(\xi|m)]^B \equiv A\left[\frac{\mathrm{cn}(\xi|m)}{\mathrm{sn}(\xi|m)}\right]^B. \tag{32}$$

If $r=1$, $a=2-m^2$, $b=2(1-m^2)$, then the solution is

$$U_{10} = A[sc(\xi|m)]^B \equiv A\left[\frac{\mathrm{sn}(\xi|m)}{\mathrm{cn}(\xi|m)}\right]^B. \tag{33}$$

If $r=1$, $a=2m^2-1$, $b=2m^2(m^2-1)$, then the solution is

$$U_{11} = A[sd(\xi|m)]^B \equiv A\left[\frac{\mathrm{sn}(\xi|m)}{dn(\xi|m)}\right]^B. \tag{34}$$

If $r=m^2(m^2-1)$, $a=2m^2-1$, $b=2$, then the solution is

$$U_{12} = A[ds(\xi|m)]^B \equiv A\left[\frac{dn(\xi|m)}{\mathrm{sn}(\xi|m)}\right]^B. \tag{35}$$

If $r=1/4$, $a=(1-2m^2)/2$, $b=1/2$, then the solution is

$$U_{13} = A[ns(\xi|m) \pm cs(\xi|m)]^B. \tag{36}$$

If $r=(1-m^2)/4$, $a=(1+m^2)/2$, $b=(1-m^2)/2$, then the solution is

$$U_{14} = A[nc(\xi|m) \pm sc(\xi|m)]^B. \tag{37}$$

If $r=m^4/4$, $a=(m^2-2)/2$, $b=1/2$, then the solution is

$$U_{15} = A[ns(\xi|m) + ds(\xi|m)]^B. \tag{38}$$

If $r=m^2/4$, $a=(m^2-2)/2$, $b=m^2/2$, $i^2=-1$ then the solution is

$$U_{16} = A[\mathrm{sn}(\xi|m) \pm i\ \mathrm{cn}(\xi|m)]^B. \tag{39}$$

In addition, we see that other solutions are obtained in case of degeneracies, when $m \to 0$, the Jacobi elliptic and combined Jacobi elliptic functions degenerate to the trigonometric functions of the given NLPDE (1), i.e., $\mathrm{sn}(\xi|m) \to \sin(\xi)$, $\mathrm{cn}(\xi|m) \to \cos(\xi)$, $dn(\xi|m) \to 1$, $ns(\xi|m) \to \csc(\xi|m)$, $cs(\xi|m) \to \cot(\xi)$, $ds(\xi|m) \to \sec(\xi)$, when $m \to 1$, the Jacobi elliptic and combined Jacobi elliptic functions degenerate to the soliton and combined soliton wave solutions of the given NLPDE (1), i.e., $\mathrm{sn}(\xi|m) \to \tanh(\xi)$, $\mathrm{cn}(\xi|m) \to \mathrm{sech}(\xi)$, $dn(\xi|m) \to \mathrm{sech}(\xi)$, $ns(\xi|m) \to \coth(\xi)$, $cs(\xi|m) \to \mathrm{csch}(\xi)$, $ds(\xi|m) \to \mathrm{csch}(\xi)$.

So we can derive solutions expressed in terms of trigonometric functions and hyperbolic functions, we omit them for simplicity.

It is worth noticing that the Jacobi transformation $dn(\xi|m)=\mathrm{cn}(\sqrt{m}\xi|m^{-1})$ (Ref. 36) implies that any solution found by the *dn* function may be transformed into an equivalent one that can be obtained by the cn function. Moreover, since other Jacobi elliptic function and combined Jacobi elliptic function solutions obtained here from a mathematics point of view as solutions of Eq. (8) have singularities, and since it is well known from a physics point of view that the singular solutions cannot have any meaning in the applications, we may focus only on nonsingular solutions among the listed mathematical solutions. When $B>0$ (i.e., $B=1$ or $B=2$) nonsingular solutions are given by (26a), (27), and (28). When $B<0$ (i.e., $B=-1$ or $B=-2$) nonsingular solutions are selected to be (29a), (30), and (31). Another interesting fact here is that by selecting $B=-1$ (or $B=-2$), the solutions (29a), (30), and (31) are reduced to the same family of solutions as (26a), (27), and (28), respectively, when $B=1$ (or $B=2$).

Taking into account the above-mentioned remarks, we have plotted for $B=1$ and $B=2$, Figs. 1–6 to illustrate our study or to raise the physics value of our study.

III. CONCLUSION

In this work, we have applied an indirect F-function method very close to the F-expansion method to solve the generalized Camassa-Holm equation with fully nonlinear dispersion and fully nonlinear convection term $C(l,n,p)$. By using this F-function method, we have been able to obtain in a unified way simultaneously many periodic wave solutions expressed by various single and combined nondegenerative Jacobi elliptic function solutions and their degenerative solutions (when the modulus m is driven to 1 and 0). This method gives elliptic solutions for specific values of the parameters n, p, l and for arbitrary values of β_1 and β_2, but β_3 and β_4 must be proportional with the proportionality constants for various cases given explicitly. In the various Camassa-Holm classes listed below, β_3 is replaced by the appropriate expression of β_4. The following Camassa-Holm family of equations has been solved by this indirect F-function method,

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U^5)_x = \beta_4 (6U_x (U^4)_{xx} - U(U^4)_{xxx}),$$

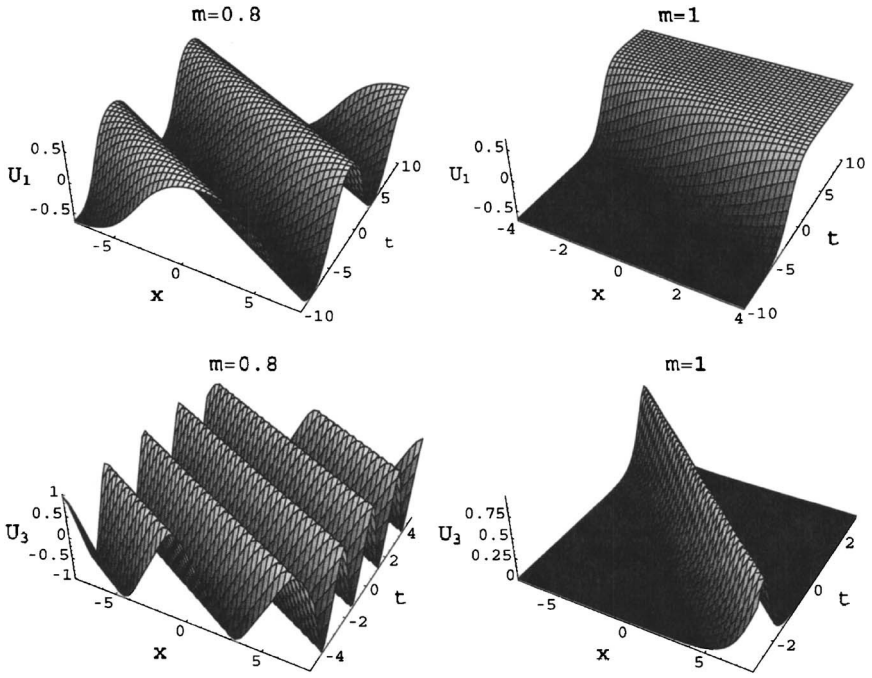

FIG. 1. The plot of sn, tanh, cn, and sech solutions, respectively. These nonsingular solutions are the structure graphs of Eq. (11), that is, $U_t+kU_x+\beta_1U_{xxt}+\beta_2(U^5)_x=\beta_4(6U_x(U^4)_{xx}-U(U^4)_{xxx})$. The first two graphs are obtained for the values $\beta_1=-1.00$, $\beta_2=1.50$, $\beta_4=-0.75$, $k=-2.00$, meanwhile the last two graphs have the same parameter values except that $\beta_4=0.75$.

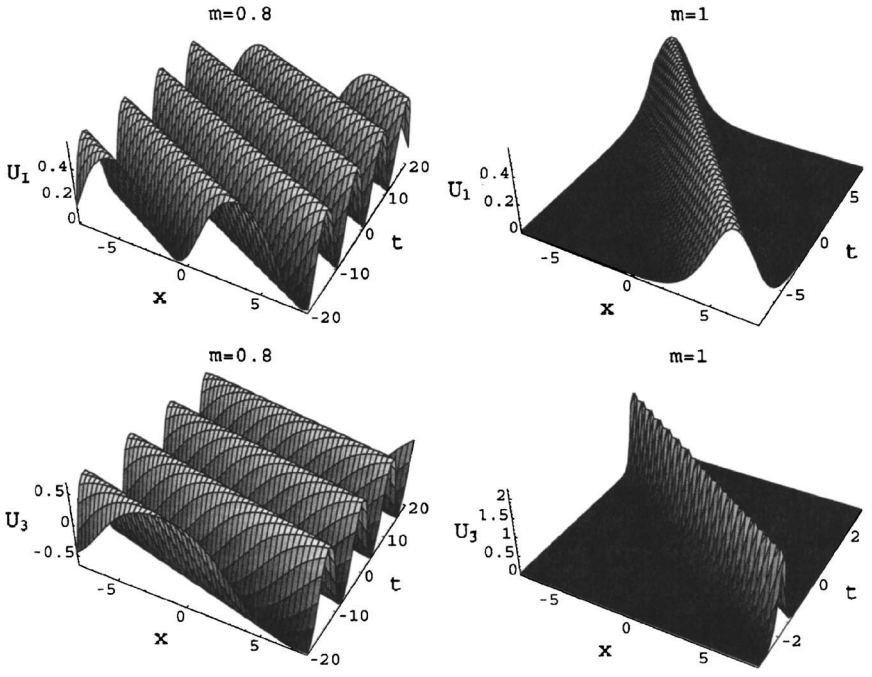

FIG. 2. The plot of sn^2, $tanh^2$, cn^2, and $sech^2$ solutions, respectively. These nonsingular solutions are the structure graphs of Eq. (12), that is, $U_t+kU_x+\beta_1U_{xxt}+\beta_2(U^3)_x=\beta_4(3U_x(U^2)_{xx}-U(U^2)_{xxx})$. The first two graphs are obtained for the values $\beta_1=-1.00$, $\beta_2=1.50$, $\beta_4=-0.75$, $k=-2.00$, meanwhile the last two graphs have the same parameter values except that $\beta_4=0.75$, $k=2.00$.

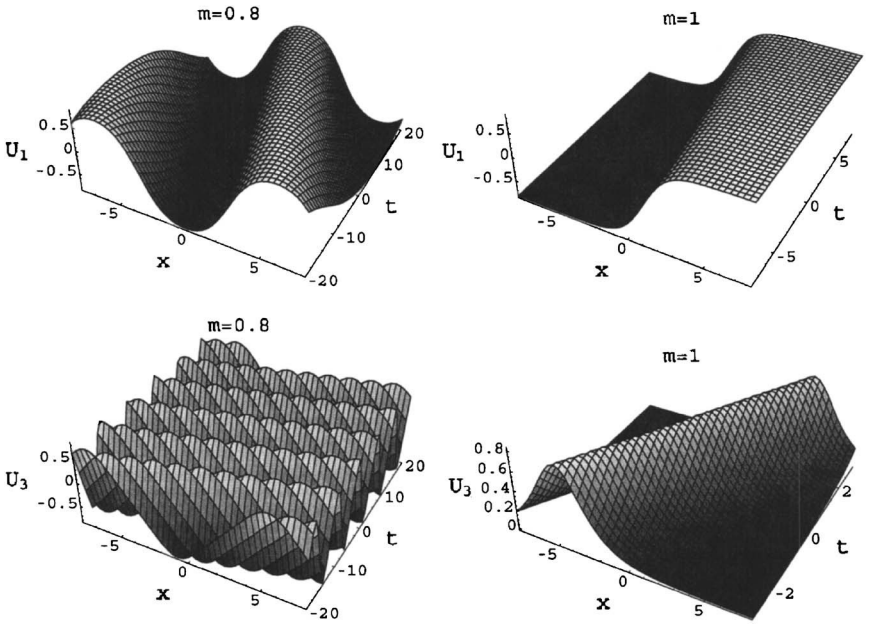

FIG. 3. The plot of sn, tanh, cn, and sech solutions, respectively. These nonsingular solutions are the structure graphs of Eq. (13), that is, $U_t+kU_x+\beta_1U_{xxt}+\beta_2(U^3)_x=\beta_4(4U_x(U^2)_{xx}-U(U^2)_{xxx})$. The first two graphs are obtained for the parameter values $\beta_1=-1.00$, $\beta_2=1.5$, $\beta_4=-0.75$, $k=-2.00$, $\lambda_1=0.65$, meanwhile the last two graphs have the same parameter values but for $\beta_4=0.75$, $k=2.00$.

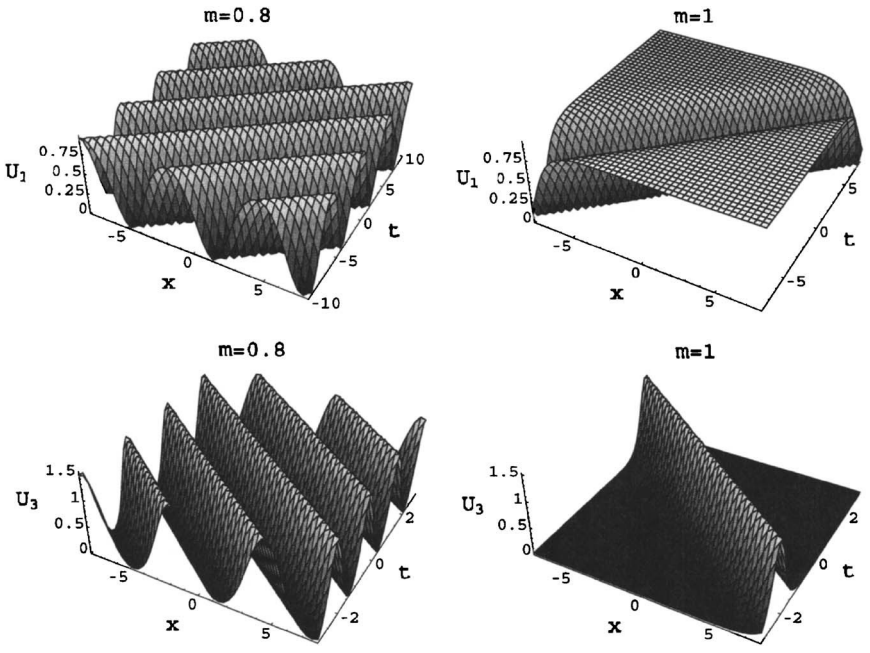

FIG. 4. The plot of sn^2, $tanh^2$, cn^2, and $sech^2$ solutions, respectively. These nonsingular solutions are the structure graphs of Eq. (14), that is, $U_t+kU_x+\beta_1U_{xxt}+\beta_2(U^2)_x=\beta_4(2U_x(U)_{xx}-U(U)_{xxx})$. The first two graphs are obtained for the values $\beta_1=-1.00$, $\beta_2=1.50$, $\beta_4=-0.75$, $k=-2.00$, $\lambda_1=0.65$, meanwhile the last two graphs have the same parameter values except that $\beta_4=0.75$, $k=2.00$.

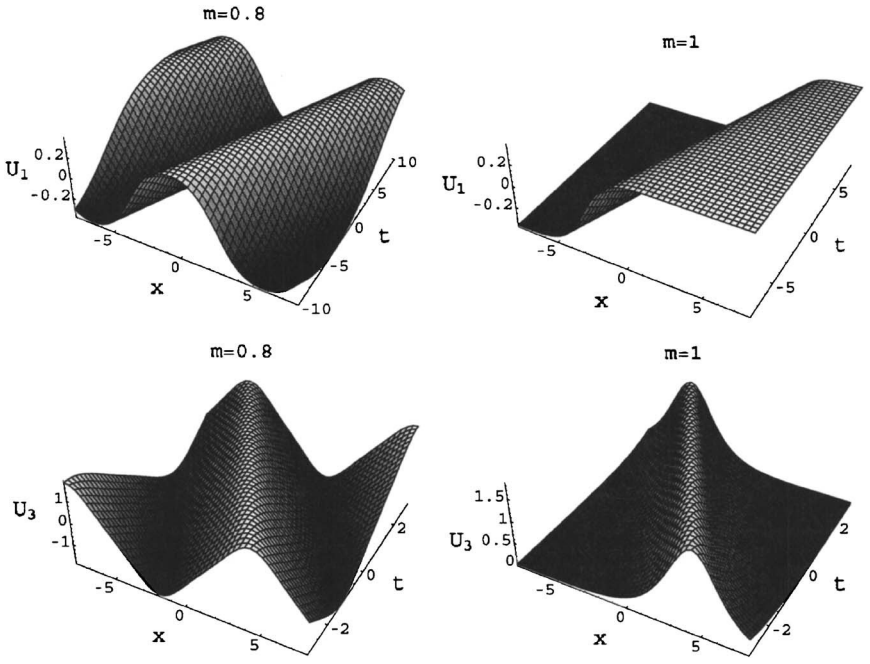

FIG. 5. The plot of sn, tanh, cn, and sech solutions, respectively. These nonsingular solutions are the structure graphs of Eq. (22), that is, $U_t+kU_x+\beta_1 U_{xxt}+\beta_2(U)_x=\beta_4(4U_x(U^2)_{xx}-U(U^2)_{xxx})$. The first two graphs are obtained for the values $\beta_1=-1.00$, $\beta_2=1.50$, $\beta_4=-0.75$, $k=-2.00$, $\lambda_1=0.65$, meanwhile the last two graphs have the same parameter values but for $\beta_4=0.75$, $k=2.00$.

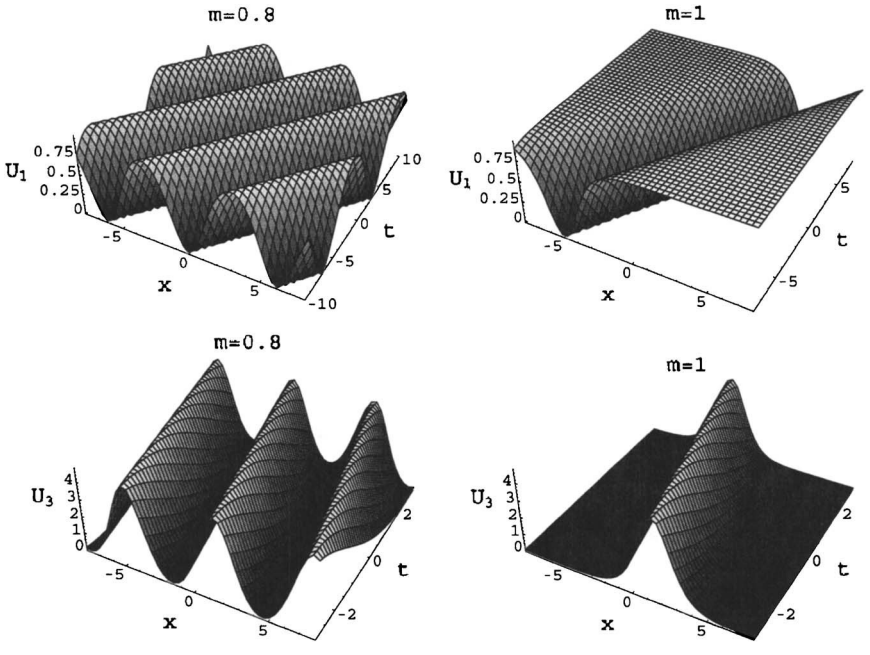

FIG. 6. The plot of sn^2, $tanh^2$, cn^2, and $sech^2$ solutions, respectively. These nonsingular solutions are the structure graphs of Eq. (23), that is, $U_t+kU_x+\beta_1 U_{xxt}+\beta_2(U)_x=\beta_4(2U_x(U)_{xx}-U(U)_{xxx})$. The first two graphs are obtained for the values $\beta_1=-1.00$, $\beta_2=1.50$, $\beta_4=-0.75$, $k=-2.00$, $\lambda_1=0.65$, meanwhile the last two graphs have the same parameter values except that $\beta_4=0.75$, $k=2.00$.

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U^3)_x = \beta_4 (3U_x (U^2)_{xx} - U(U^2)_{xxx}),$$

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U^3)_x = \beta_4 (4U_x (U^2)_{xx} - U(U^2)_{xxx}),$$

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U^2)_x = \beta_4 (2U_x (U)_{xx} - U(U)_{xxx}),$$

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U)_x = \beta_4 (4U_x (U^2)_{xx} - U(U^2)_{xxx}),$$

$$U_t + kU_x + \beta_1 U_{xxt} + \beta_2 (U)_x = \beta_4 (2U_x (U)_{xx} - U(U)_{xxx}).$$

On the spectral L_2 conjecture, 3/2-Lieb-Thirring inequality and distributional potentials

Alexei Rybkin[a)]
Department of Mathematical Sciences, University of Alaska, Fairbanks, P.O. Box 756660, Fairbanks, Alaska 99775

(Received 24 January 2005; accepted 20 October 2005; published online 20 December 2005)

Let $H=-\partial_x^2+V(x)$ be a properly defined Schrödinger operator on $L_2(\mathbb{R})$ with real potentials of the form $V(x)=q(x)+p'(x)$ (the derivative is understood in the distributional sense) with some $p,q\in L_2(\mathbb{R})$. We prove that the absolutely continuous spectrum of H fills $(0,\infty)$ which was previously proven by Deift-Killip for $V\in L_2(\mathbb{R})$. We also refine the 3/2-Lieb-Thirring inequality. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2142837]

I. INTRODUCTION

The spectral L_2-conjecture was stated first by Kiselev-Last-Simon in Ref. 7 for the one-dimensional case and later by Simon in Ref. 14 for the generic case. It says: let $H:=-\Delta+V(x)$, $x\in\mathbb{R}^d$, be the Schrödinger operator on $L_2(\mathbb{R}^d)$ and V is a real measurable function. If

$$\int |V(x)|^2|x|^{1-d}\mathrm{d}x<\infty \tag{1.1}$$

then the absolutely continuous (a.c.) spectrum[1] $\sigma_{\mathrm{a.c.}}(H)$ of H is $\mathbb{R}_+:=[0,\infty)$.

This conjecture has drawn considerable attention. To the best of our knowledge, the case $d>1$ remains an open problem. For $d=1$ it was affirmatively settled in 1999 by Deift-Killip with previous contributions by Kiselev, Christ-Kiselev, Remling, and others (see, Refs. 14 and 15 for extended literature). The Deift-Killip result is sharp in the scale of L_p spaces.[7] In 2001 this result was extended by Molchanov-Novitskii-Vainberg[10] to read ($p\in\mathbb{N}$)

$$V\in H^{p-1}(\mathbb{R})\cap L_{p+1}(\mathbb{R})\Rightarrow \sigma_{\mathrm{a.c.}}(H)=\mathbb{R}_+,$$

where H^{p-1} denotes the Sobolev space.

In all previous cases potentials are assumed to be regular (locally integrable) functions. At about the same time with the above-mentioned activity Savchuk-Shkalikov[13,12] (with contributions from Hryniv-Mykytuyk[5]) were systematically studying Sturm-Liouville operators with singular (distributional) potentials. Among others, Savchuk-Shkalikov were able to properly define one-dimensional Schrödinger operators with potentials from the Sobolev space $H^{-1}(\mathbb{R})$, i.e., the space of all generalized functions f subject to

$$\int |\hat{f}(\omega)|^2\frac{\mathrm{d}\omega}{\omega^2+1}<\infty.$$

Here $\hat{f}$ stands for the Fourier transform of f.

In the current note we combine the Savchuk-Shkalikov approach to distributional potentials and the Deift-Killip idea to use the Faddeev-Zhakharov trace formulas to prove

[a)]Electronic mail: ffavr@uaf.edu

[1]I.e. the essential support of the absolutely continuous component of the spectral measure of the operator H.

$$V \in H^{-1}(\mathbb{R}) \Rightarrow \sigma_{\text{a.c.}}(H) = \mathbb{R}_+.$$

Our main tool is a new sum rule (Theorem 1) which in a way can be interpreted as the second Faddeev-Zhakharov trace formula (2.5) at a finite energy. This formula also allows one to generalize the 3/2-Lieb-Thirring bounds to singular potentials. Note that in the distributional sense every function V from H^{-1} has a form

$$V = q + p' \quad \text{where } p,q \in L_2(\mathbb{R}). \tag{1.2}$$

The main advantage of our approach is that it allows one to unify the study of slowly decaying potentials with such potentials as oscillatory Wigner von Neumann type, Coulomb, delta, etc., which have traditionally been treated separately.

II. REGULARIZED DISPERSION FORMULA AND A TRACE INEQUALITY

Through this section we deal with pairs (H,H_0) of operators

$$H_0 = -\partial_x^2, \quad H = H_0 + V(x) \tag{2.1}$$

on $L_2(\mathbb{R})$ under a very generous assumption that $V = \bar{V} \in C_0^\infty(\mathbb{R})$, where $C_0^\infty(\mathbb{R})$ is the class of smooth compactly supported function on $\mathbb{R}$. Observe that $[\mathfrak{S}_p, p>0$, denote *Schatten-von Neumann classes* of linear operators A:

$$A \in \mathfrak{S}_p \Leftrightarrow \|A\|_{\mathfrak{S}_p}^p := \text{tr}(A^*A)^{p/2} < \infty .$$

In particular $\mathfrak{S}_1$ is the trace class and $\mathfrak{S}_2$ is the Hilbert-Schmidt class. The norms of A in $\mathfrak{S}_1, \mathfrak{S}_2$ are, respectively, $\|A\|_{\mathfrak{S}_1} = \text{tr}(A^*A)^{1/2}$, $\|A\|_{\mathfrak{S}_2} = (\text{tr}(A^*A))^{1/2}]$.

$$V \in C_0^\infty(\mathbb{R}) \Rightarrow VR_\lambda^0 \in \mathfrak{S}_1, \quad R_\lambda^0 := R_\lambda(H_0) := (H_0 - \lambda)^{-1},$$

and hence the perturbation determinant

$$\Delta(\lambda) := \det(H-\lambda)(H_0-\lambda)^{-1} = \det(I + VR_\lambda^0)$$

exists and is an analytic function on $\mathbb{C}\backslash\mathbb{R}_+$ with a finite number N of simple zeros $-\varkappa_n^2$ on $\mathbb{R}_-$. The transmission coefficient $t(k)$ can be analytically extended from $\mathbb{R}$ to $\mathbb{C}_+$ by

$$t(z) = \Delta^{-1}(z^2), \quad z \in \mathbb{C}_+, \tag{2.2}$$

and for sufficiently large z,

$$|t(z)| \leqslant C|z|^{-1}.$$

For the spectra of H, H_0 one has

$$\sigma(H_0) = \sigma_{\text{a.c.}}(H_0) = \mathbb{R}_+, \quad \sigma(H) = \{-\varkappa_n^2\}_{n=1}^N \cup \sigma(H_0),$$

all eigenvalues $-\varkappa_n^2$ being simple and $N<\infty$. What has been said actually implies the dispersion formula

$$\log t^{-1}(z) = \sum_{n=1}^N \log \frac{z - i\varkappa_n}{z + i\varkappa_n} + \frac{1}{i\pi}\int \frac{\log|t(k)|^{-1}}{k-z}\mathrm{d}k, \tag{2.3}$$

which was used by Faddeev-Zhakharov (FZ)[3] to derive their famous trace formulas (sum rules):

$$-\sum_{n=1}^N \varkappa_n + \frac{1}{2\pi}\int \log|t(k)|^{-1}\mathrm{d}k = \frac{1}{4}\int V(x)\mathrm{d}x \tag{2.4}$$

(the first FZ trace formula),

$$\frac{2}{3}\sum_{n=1}^{N}\varkappa_n^3+\frac{1}{\pi}\int k^2\,\log|t(k)|^{-1}\mathrm{d}k=\frac{1}{8}\int V^2(x)\mathrm{d}x \tag{2.5}$$

(the second FZ trace formula),

etc. Recall that (2.4) and (2.5) can merely be obtained by comparing the corresponding coefficients in the asymptotic expansions of both sides of (2.3) in z^{-n} as $|z|\to\infty$. Let V be the operator of multiplication by $V\in C_0^\infty(\mathbb{R})$. Introduce

$$Q(\lambda):=(R_\lambda^0)^{1/2}V(R_\lambda^0)^{1/2},\quad \lambda\in\mathbb{C}\setminus\mathbb{R}_+, \tag{2.6}$$

where $(R_\lambda^0)^{1/2}$ is the principle branch of R_λ^0. The operator $Q(\lambda)$ is clearly bounded and represents an analytic operator-valued function in $\mathbb{C}\setminus\mathbb{R}_+$. We will need the following technical lemma.

Lemma 1: *If* $V=\bar{V}\in C_0^\infty(\mathbb{R})$ *then for any* $a>0$,

$$\|Q_a\|_{\mathfrak{S}_2}^2=\frac{1}{a}\int|\widehat{V}(\omega)|^2\frac{\mathrm{d}\omega}{\omega^2+(2a)^2}=\|V\|_a^2, \tag{2.7}$$

where

$$Q_a:=Q(-a^2),\quad a>0.$$

Proof: By straightforward computation. □

The following assertion is a derivation of (2.3).

Theorem 1: *Let* (H,H_0) *be defined by* (2.1) *and* $V=\bar{V}\in C_0^\infty(\mathbb{R})$. *Then* $(z\in\mathbb{C}_+)$

$$\log t^{-1}(z)+\frac{1}{2iz}\int V(x)\mathrm{d}x=\sum_{n=1}^{N}\left(\log\frac{z-i\varkappa_n}{z+i\varkappa_n}+\frac{2i\varkappa_n}{z}\right)+\frac{1}{i\pi z}\int_0^\infty\frac{k^2\log|t(k)|^{-1}}{k^2-z^2}\mathrm{d}k. \tag{2.8}$$

In particular if we choose $a>0$ *so that*

$$\|Q_a\|<1 \tag{2.9}$$

then

$$\sum_{n=1}^{N}\left(\log\frac{a+\varkappa_n}{a-\varkappa_n}-\frac{2\varkappa_n}{a}\right)+\frac{1}{\pi a}\int_0^\infty\frac{k^2\log|t(k)|^{-1}}{k^2+a^2}\mathrm{d}k=\log\det(I+Q_a)e^{-Q_a}\leqslant\log(1-\|Q_a\|_{\mathfrak{S}_2}^2)^{-1}. \tag{2.10}$$

Proof: By the general properties $|t(k)|\leqslant 1$ and $t(-k)=\overline{t(k)}$, $k\in\mathbb{R}$, of the transmission coefficient $t(k)$, the function

$$f(k):=\frac{1}{\pi}\log|t(k)|^{-1}$$

is integrable, non-negative, even and hence

$$\int\frac{f(k)}{k-z}\mathrm{d}k=-\frac{1}{z}\int f(k)\mathrm{d}k+\frac{1}{z^2}\int\frac{k^2f(k)}{k-z}\mathrm{d}k=-\frac{1}{z}\int f(k)\mathrm{d}k+\frac{2}{z}\int_0^\infty\frac{k^2f(k)}{k^2-z^2}\mathrm{d}k. \tag{2.11}$$

We have used here the obvious identity

$$\frac{1}{k-z} = -\frac{k}{z^2} - \frac{1}{z} + \frac{1}{z^2}\frac{k^2}{k-z}.$$

By (2.4)

$$\int f(k)\mathrm{d}k = 2\sum_{n=1}^{N} \varkappa_n + \frac{1}{2}\int V(x)\mathrm{d}x$$

and (2.11) can be continued

$$\int \frac{f(k)}{k-z}\mathrm{d}k = -\frac{2}{z}\sum_{n=1}^{N} \varkappa_n - \frac{1}{2z}\int V(x)\mathrm{d}x + \frac{2}{z}\int_0^\infty \frac{k^2 f(k)}{k^2 - z^2}\mathrm{d}k. \tag{2.12}$$

Plugging (2.12) into (2.3) one has

$$\log t^{-1}(z) = \sum_{n=1}^{N} \log\frac{z - i\varkappa_n}{z + i\varkappa_n} + \frac{2}{iz}\sum_{n=1}^{N} \varkappa_n - \frac{1}{2iz}\int V(x)\mathrm{d}x + \frac{2}{iz}\int_0^\infty \frac{k^2 f(k)}{k^2 - z^2}\mathrm{d}k,$$

and rearranging its terms yields (2.8).

Evaluate now the left-hand side of (2.8). For $V \in C_0^\infty(\mathbb{R})$ both operators VR_λ^0 and $(R_\lambda^0)^{1/2}V(R_\lambda^0)^{1/2}$, $\lambda \in \mathbb{C}\backslash\mathbb{R}_+$, are trace class and hence

$$\mathrm{tr}(R_\lambda^0)^{1/2}V(R_\lambda^0)^{1/2} = \mathrm{tr}\, VR_\lambda^0 = \int V(x)\frac{-1}{2i\sqrt{\lambda}}\mathrm{d}x = -\frac{1}{2i\sqrt{\lambda}}\int V(x)\mathrm{d}x.$$

Introducing the regularized perturbation determinant

$$\Delta_2(\lambda) := \det\{(1 + Q(\lambda))\exp(-Q(\lambda))\},$$

we have

$$\Delta_2(\lambda) = \det(1 + Q(\lambda)) \cdot \exp(-\mathrm{tr}\, Q(\lambda))$$

$$= \det(1 + VR_\lambda^0) \cdot \exp(-\mathrm{tr}\, VR_\lambda^0) = \Delta(\lambda)\exp(-\mathrm{tr}\, VR_\lambda^0),$$

which for $\lambda = z^2$, $z \in \mathbb{C}_+$, due to (2.2) implies

$$\log t^{-1}(z) + \frac{1}{2iz}\int V(x)\mathrm{d}x = \log \Delta_2(z^2).$$

Set now $z = ia$, $a > 0$, and choose a to satisfy (2.9). One has

$$\begin{aligned}
\log \Delta_2(-a^2) &= \log\det(I + Q_a)e^{-Q_a} \\
&= \mathrm{tr}\log(I + Q_a)^{-1}e^{Q_a} = \mathrm{tr}(Q_a - \log(I + Q_a)) \\
&= \mathrm{tr}\sum_{n\geqslant 2}\frac{1}{n}(-Q_a)^n = \mathrm{tr}\sum_{n\geqslant 1}\left(\frac{1}{2n}Q_a^{2n} - \frac{1}{2n+1}Q_a^{2n+1}\right) \\
&= \mathrm{tr}\sum_{n\geqslant 1}\frac{1}{2n}Q_a^{2n}\left(1 - \frac{2n}{2n+1}Q_a\right),
\end{aligned}$$

which implies

$$\log\det(I+Q_a)e^{-Q_a} \leqslant \sum_{n\geqslant 1}\frac{1}{2n}\left\|1-\frac{2n}{2n+1}Q_a\right\|\cdot \operatorname{tr} Q_a^{2n}$$

$$\leqslant \sum_{n\geqslant 1}\frac{1}{n}\|Q_a^n\|_{\mathfrak{S}_2}^2 = \log(1-\|Q_a\|_{\mathfrak{S}_2}^2)^{-1}.$$

and (2.10) is completely proven. □

Remark 1: (2.5) *can be obtained from* (2.10) *by multiplying it by* a^3 *and then taking* $a\to\infty$. *Note in this connection that a similar to* (2.10) *relation was recently used by Denisov*[2] *in the case of Krein systems*.

Remark 2: *Identity* (2.10) *can actually be viewed as the first formula in a certain chain of trace formulas*. *In the context of Jacobi matrices*, *similar relations were recently obtained by Laptev-Naboko-Safronov*,[8] *who further developed some ideas due to Killip-Simon*.[6]

III. IMPEDANCE FORM OF SCHRÖDINGER OPERATORS WITH SINGULAR POTENTIALS

Particular cases of singular potentials (i.e., not locally integrable) like delta and Coulomb potentials were considered by many authors. However a systematical treatment of H^{-1} potentials (which include delta and Coulomb potentials) appears to have been originated by Savchuk-Shkalikov in about 1998 (see, e.g., Ref. 13, and the literature therein). We emphasize that singular perturbations of self-adjoint operators have been studied even earlier but the author was unable to find out if a general theory of singular perturbations was linked to singular potentials. Following Savchuk-Shkalikov, we rewrite

$$H = -\partial_x^2 + V(x) \quad \text{on } L_2(\mathbb{R})$$

with $V\in H^{-1}(\mathbb{R})$ in the impedance form

$$H = -\partial_x(\partial_x - p(x)) - p(x)\partial_x + q(x) \tag{3.1}$$

with some $p,q\in L_2(\mathbb{R})$ from decomposition (1.2). On the domain

$$\operatorname{Dom} H = \{u\in L_2(\mathbb{R}): u,\ u'-p(x)u\in AC_{\mathrm{loc}}(\mathbb{R}), Hu\in L_2(\mathbb{R})\}, \tag{3.2}$$

[here $AC_{\mathrm{loc}}(\mathbb{R})$ denotes the set of locally a.c. functions on $\mathbb{R}$] the operator H is self-adjoint in $L_2(\mathbb{R})$ and $\operatorname{Dom} H$ does not depend on a specific choice of $p,q\in L_2(\mathbb{R})$ in (1.2). Moreover, if $\{\widetilde{V}\}$ is a sequence of real valued functions from $C_0^\infty(\mathbb{R})$ convergent in $H^{-1}(\mathbb{R})$ to V then the sequence $\{\widetilde{H}\}$, $\widetilde{H}=-\partial_x^2+\widetilde{V}(x)$, converges in the uniform resolvent sense to H defined by (3.1). That is

$$\|V-\widetilde{V}\|_{H^{-1}(\mathbb{R})}\to 0 \Rightarrow \|R_\lambda(H)-R_\lambda(\widetilde{H})\|\to 0, \quad \operatorname{Im}\lambda\neq 0. \tag{3.3}$$

Here and in the sequel we agree to mark all objects related to $\widetilde{V}$ with a tilde. The corresponding details can be found in Ref. 13. We only note that the key ingredient here is the following representation

$$Y' = \begin{pmatrix} p(x) & 1 \\ q(x)-p^2(x)-\lambda & -p(x)\end{pmatrix}Y, \quad Y := \begin{pmatrix} u \\ u^{[1]}\end{pmatrix} \tag{3.4}$$

of the Schrödinger equation

$$-u''+V(x)u=\lambda u, \quad V(x)=p'(x)+q(x),$$

where $u^{[1]}:=u'-p(x)u$ is the so-called quasiderivative of u. Since $p,q\in L_2(\mathbb{R})$ Eq. (3.4) is solvable and $Y=(u,u'-V(x)u)\in AC_{\mathrm{loc}}(\mathbb{R})$ (although u' need not be continuous). The definition of the Wronskian $W[y_1,y_2]$ of two functions y_1,y_2 should be modified to read

$$W[y_1,y_2]=y_1y_2^{[1]}-y_1^{[1]}y_2,$$

which of course agrees with the usual Wronskian if $y_1,y_2\in AC_{\mathrm{loc}}(\mathbb{R})$. With this in hand, one can develop the Weyl theory and prove the existence of the Weyl solutions $\psi_\pm(x,\lambda)\in L_2(\mathbb{R}_\pm)$, $\mathrm{Im}\,\lambda>0$. The Titchmarsh-Weyl m-functions $M_\pm(\lambda)$ should then be defined as

$$M_\pm(\lambda)=\pm\frac{\psi_\pm^{[1]}(0,\lambda)}{\psi_\pm(0,\lambda)}.$$

Functions $M_\pm$ are Herglotz (i.e., mapping $\mathbb{C}_+$ into $\mathbb{C}_+$) which representing measures are the spectral measures of the corresponding half-line Schrödinger operators with a Dirichlet boundary condition at 0. Note that if $V\in L_{1,\mathrm{loc}}(\mathbb{R})$ then

$$M_\pm(\lambda)=m_\pm(\lambda)-p(0),$$

where $m_\pm$ are the usual Titchmarsh-Weyl m-functions, and one can immediately see that

$$M_+(\lambda)+M_-(\lambda)=m_+(\lambda)+m_-(\lambda),\quad \mathrm{Im}\,M_\pm(\lambda)=\mathrm{Im}\,m_\pm(\lambda). \tag{3.5}$$

The Weyl theory is parallel to its regular counterpart. In particular

$$\|V-\widetilde{V}\|_{H^{-1}(\mathbb{R})}\to 0\Rightarrow \widetilde{M}_\pm(z)\to M_\pm(z) \tag{3.6}$$

on compact subsets of $\mathbb{C}_+$. The arguments are similar to those of Lemma 1 in Ref. 1 with the second Hilbert resolvent identity replaced with

$$R_\lambda-R_\lambda^0=(R_\lambda^0)^{1/2}\{(I+Q(\lambda))^{-1}-I\}(R_\lambda^0)^{1/2},\quad R_\lambda:=R_\lambda(H).$$

It follows from (3.6) that the spectral measure of $\widetilde{H}$ defined on $L_2(\mathbb{R}_\pm)$ with the Dirichlet boundary condition $u(\pm 0)=0$ weakly converges to the spectral measure of H defined on $L_2(\mathbb{R}_\pm)$ with the condition $u(\pm 0)=0$, respectively.

IV. THE MAIN RESULTS

Theorem 2: *Let $V=\overline{V}\in H^{-1}(\mathbb{R})$ and H defined by* (3.1) *on domain* (3.2). *Then*

$$\sigma_{\mathrm{a.c.}}(H)=\mathbb{R}_+. \tag{4.1}$$

Theorem 3: *Assuming conditions of Theorem* 2, *let $\{-\varkappa_m^2\}_{m\geqslant 1}$ be the set of negative eigenvalues of H enumerated in the increasing order. Then for any $a>\sup\varkappa_1$ such that*

$$\|Q_a\|_{\mathfrak{S}_2}^2=\frac{1}{a}\int|\widehat{V}(\omega)|^2\frac{\mathrm{d}\omega}{\omega^2+(2a)^2}<1$$

the following inequality holds:

$$\sum_{n\geqslant 1}\frac{2}{2n+1}\sum_{m\geqslant 1}\left(\frac{\varkappa_m}{a}\right)^{2n+1}\leqslant\log\left(1-\frac{1}{a}\int|\widehat{V}(\omega)|^2\frac{\mathrm{d}\omega}{\omega^2+(2a)^2}\right)^{-1}. \tag{4.2}$$

Proof: Let $\{\widetilde{V}\}$ be sequence of C_0^∞ potentials approximating V in H^{-1} and choose a to satisfy $\|\widetilde{Q_a}\|_{\mathfrak{S}_2}<1$. Notice that if $|\alpha|<1$ then

$$\log\frac{1+\alpha}{1-\alpha}-2\alpha=2\sum_{n\geqslant 1}\frac{\alpha^{2n+1}}{2n+1}\geqslant 0 \tag{4.3}$$

and one easily sees that all terms in (2.10) are non-negative and hence

$$\frac{1}{\pi a}\int_0^\infty \frac{k^2 \log|\tilde{t}(k)|^{-1}}{k^2+a^2}\mathrm{d}k \leqslant \log(1-\|\widetilde{Q_a}\|^2_{\mathfrak{S}_2})^{-1}, \tag{4.4}$$

$$\sum_{n=1}^{\widetilde{N}} \left(\log \frac{a+\widetilde{\varkappa}_n}{a-\widetilde{\varkappa}_n} - \frac{2\widetilde{\varkappa}_n}{a} \right) \leqslant \log(1-\|\widetilde{Q_a}\|^2_{\mathfrak{S}_2})^{-1}. \tag{4.5}$$

The conclusion of Theorem 2 now follows from (4.4) by adopting the Deift-Killip arguments (Ref. 1, Theorem 1). Indeed, *a priori* estimate (4.4) replaces

$$\frac{1}{\pi}\int k^2 \log|\tilde{t}(k)|^{-1}\mathrm{d}k \leqslant \frac{1}{8}\int \widetilde{V}^2(x)\mathrm{d}x,$$

which was a crucial ingredient of Ref. 1 [which, in turn, follows from (2.5)]. Instead of (see also Ref. 4)

$$|\tilde{t}(k)| = \frac{2\sqrt{\operatorname{Im}\widetilde{m}_+(k^2+i0)}\sqrt{\operatorname{Im}\widetilde{m}_-(k^2+i0)}}{|\widetilde{m}_+(k^2+i0)+\widetilde{m}_-(k^2+i0)|},$$

we use

$$|\tilde{t}(k)| = \frac{2\sqrt{\operatorname{Im}\widetilde{M}_+(k^2+i0)}\sqrt{\operatorname{Im}\widetilde{M}_-(k^2+i0)}}{|\widetilde{M}_+(k^2+i0)+\widetilde{M}_-(k^2+i0)|},$$

which, due to (3.5), coincide for at least smooth potentials. Finally, with (3.6) in hand the Deift-Killip limiting arguments go through.

The conclusion of Theorem 3 follows from (4.5). Indeed, due to (3.3), $\widetilde{\varkappa}_n \to \varkappa_n$ and hence inequality (4.5) retains in the limit. Estimate (4.2) now follows in view of (4.3). □

Remark 3: *Inequality* (4.2) *is a generalization of the 1D Lieb-Thirring bound* (*see*, *e.g.*, *Refs.* 9 and 16)

$$\sum_{n\geqslant 1}\varkappa_n^3 \leqslant C\int V_-^2(x)\mathrm{d}x, \quad V_-(x) := \min\{0, V(x)\},$$

to the case of H^{-1} *potentials. It is just enough to consider* (4.2) *for* $V_-(x)=\min\{0,V(x)\}\in L_2(\mathbb{R})$ *and pass to the limit as* $a\to\infty$. *We especially note that in the* H^{-1} *setting we cannot in general separate* V_- *and* V_+ *since* $V\in H^{-1}(\mathbb{R})$ *need not imply* $V_-\in H^{-1}(\mathbb{R})$.

Remark 4: *One can easily see that the space* $l_2(L_1)$ *defined as*

$$l_2(L_1) := \left\{ f : \sum_n \left(\int_n^{n+1} |f(x)|\mathrm{d}x \right)^2 < \infty \right\}$$

is a proper subset of $H^{-1}(\mathbb{R})$ *and Theorem 2 quickly recovers the main result of Ref.* 11 *stating that*

$$V \in l_2(L_1) \Rightarrow \sigma_{\text{a.c.}}(H) = \mathbb{R}_+.$$

Framework for potential systems and nonlocal symmetries: Algorithmic approach

George Bluman[a] and Alexei F. Cheviakov[b]
Department of Mathematics, University of British Columbia, Vancouver, Canada V6T 1Z2

(Received 30 June 2005; accepted 17 October 2005; published online 22 December 2005)

An algorithmic framework is presented to find an extended tree of nonlocally related systems for a given system of differential equations (DEs). Each system in an extended tree is equivalent in the sense that the solution set for any system in a tree can be found from the solution set for any other system in the tree. Useful conservation laws play an essential role in the construction of an extended tree. A useful conservation law yields potential variables and equivalent nonlocally related potential systems and subsystems for any given system. Nonlocal symmetries for a given system of DEs can arise from any system in its extended tree. We construct extended trees for the systems of planar gas dynamics and nonlinear telegraph equations, and in both cases obtain new nonlocal symmetries. More importantly, due to the equivalence of solution sets, any coordinate-independent method of analysis (qualitative, numerical, perturbation, etc.) can be applied to any system within the tree, and may yield simpler computations and/or results that cannot be obtained when the method is directly applied to the given system. © *2005 American Institute of Physics.* [DOI: 10.1063/1.2142834]

I. INTRODUCTION

The potential symmetry approach[1–5] is an algorithmic procedure for seeking nonlocal symmetries of systems of differential equations (DEs). To be directly applicable, this approach requires the existence of a conservation law of a given system. Each conservation law allows the introduction of one or more auxiliary potential variables which are nonlocally defined with respect to the original dependent variables.[6–8] The resulting (extended) potential system yields nonlocal symmetries of the given system of DEs if it admits local symmetry generators that do not project onto local symmetry generators of the given system.

A symmetry of a system of DEs is any transformation of its solution manifold into itself (i.e., a symmetry transforms any solution to another solution of the same system). Hence, in general, symmetry transformations are defined topologically and are not restricted to point or contact (more generally local) transformations acting on the given system's dependent and independent variables. However, to perform calculations, a nonlocal symmetry transformation should be a local transformation acting on the space of variables of an auxiliary system equivalent to the given system. As has been shown in many examples, local symmetries obtained directly by Lie's algorithm do not include all calculable symmetries of a given system. However, the application of Lie's algorithm to related auxiliary systems systematically yields a search for nonlocal symmetries of the given system.

Further extensions arise. Starting from a potential system of DEs, one may continue to obtain a grander potential system resulting from any conservation law of the potential system. Furthermore, starting from a potential system, one may obtain nonlocally related subsystems (in addition

[a]Electronic mail: bluman@math.ubc.ca
[b]Electronic mail: alexch@math.ubc.ca

to the original given one) by "excluding" dependent variables from the potential system. For example, the $(1+1)$-dimensional system of planar gas dynamics equations $\mathbf{E}\{x,t,v,p,\rho\}=0$ in Eulerian coordinates with independent variables x=position, t=time, and dependent variables v =velocity, p=pressure, ρ=density, gives rise to potential systems $\mathbf{G}\{x,t,v,p,\rho,r\}=0$, $\mathbf{W}\{x,t,v,p,\rho,r,w\}=0$, and $\mathbf{Z}\{x,t,v,p,\rho,r,w,z\}=0$ with auxiliary potential variables r,w,z and to various subsystems with fewer dependent variables (Sec. III). This allows one to introduce the notion of a "tree of nonlocally related potential systems and subsystems" originating from a given system of DEs. It is important to note that a given system, its related potential systems and subsystems contain all solutions of each other, i.e., any solution of a related potential system or subsystem yields a solution of the given system and, mutatis mutandi, any solution of the given system yields a solution of any related potential system or subsystem. But the solution relationship is nonlocal since it is never one-to-one.

In general, the admitted point symmetries of a given system, its related potential systems and subsystems can be very different (e.g., Ref. 9). It can happen that a point symmetry of a given system is a nonlocal symmetry of a related potential system and, conversely, a point symmetry of a related potential system is a nonlocal symmetry of the given system. Moreover, it can happen that a point symmetry of the given system which is a nonlocal symmetry of a related potential system reappears as a point symmetry of a grander potential system.[9,10] Within a tree of potential systems, a "grand" system may exist that incorporates all point symmetries of the related systems with fewer potential variables as point symmetries in the grand system. Moreover, the grand system could admit point symmetries that are nonlocal symmetries of all related systems.[9,10]

The problem of finding trees of potential systems is particularly important when a given DE system contains arbitrary (constitutive) functions where one is interested in the question of symmetry classification with respect to specific forms of such functions. For different forms of the constitutive functions, the sets of conservation laws and consequent trees of related potential systems and subsystems can be different. Here, isolating useful systems and subsystems is of great importance.

If a given system of DEs has one of its equations written as a conservation law, then the conservation law equation is a natural way of leading to a related potential system and subsequent tree. In general, for any system of DEs the algorithmic direct construction method[11,12] yields its conservation laws. In particular, this method obtains factors multiplying each DE in the system so that the resulting linear combination of equations leads to a conservation law whose conserved densities are found from an integral formula. A resulting potential system (and subsequent extended tree) is found by replacing one of the DEs in such a linear combination by the conservation law. The factor multiplying the replaced DE must have the property that the solution set will not be modified when the conservation law replaces this DE. A useful conservation law for obtaining a potential system from any given system has at least one factor with this property.

The outline of this paper is as follows. In Sec. II, we present the general framework for the algorithmic construction of trees of potential systems and subsystems for a given system of DEs. In Sec. III, as a first example we consider the $(1+1)$-dimensional system of planar gas dynamics (PGD) equations[5,14] in detail within the potential system framework. Some nonlocal symmetries for the PGD system were found by Akhatov *et al.*[14] through a heuristic approach. Here, we use the systematic conservation law/potential symmetry framework to derive an extended tree of potential systems which includes the PGD systems in Euler and Lagrange coordinates. Our work clarifies and extends the work presented in Ref. 14. In particular, we obtain new nonlocal symmetries for PGD systems by a direct study of systems of the extended tree. In Sec. IV, as a second example we consider the nonlinear telegraph (NLT) equation.[9,13] Here, we show how to extend the results in Ref. 9 by introducing further potential variables. Using conservation laws for particular forms of the constitutive functions,[13] we construct extended trees for each such form. Further remarks are presented in Sec. V.

The analysis of systems of DEs through consideration of trees of potential systems and subsystems has evident practical value. First, it allows one to calculate systematically nonlocal symmetries using Lie's algorithm, which in turn are useful for obtaining new exact solutions from

known ones, for constructing invariant and nonclassical solutions, for discovering and constructing linearizations, etc. Second, and perhaps more importantly, any general method of analysis (qualitative, numerical, perturbation, conservation laws, etc.) that is being considered for a given DE system may be tried again on nonlocally related potential systems or subsystems, since all such related systems contain all solutions of the given system. In particular, since the systems are related in a nonlocal manner, new results may be obtained for any method of analysis that is not coordinate dependent.

II. ALGORITHMIC CONSTRUCTION OF TREES OF POTENTIAL SYSTEMS AND SUBSYSTEMS TO OBTAIN NONLOCAL SYMMETRIES

Consider a PDE system of m equations $\mathbf{R}\{x,t,\mathbf{u}\}=\{R_1\{x,t,\mathbf{u}\},\ldots,R_m\{x,t,\mathbf{u}\}\}=0$, with two independent variables (x,t), and n dependent variables $\mathbf{u}=(u^1,\ldots,u^n)$.

Suppose that the first equation $R_1\{x,t,\mathbf{u}\}=0$ of the system is written as a conservation law,

$$D_tT\{x,t,\mathbf{u}\}+D_xX\{x,t,\mathbf{u}\}=0. \tag{2.1}$$

Definition 2.1: The PDE system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$ given by

$$\begin{aligned} v_x &= T\{x,t,\mathbf{u}\},\\ v_t &= -X\{x,t,\mathbf{u}\},\\ R_2\{x,t,\mathbf{u}\} &= 0,\\ &\cdots,\\ R_m\{x,t,\mathbf{u}\} &= 0, \end{aligned} \tag{2.2}$$

is a *potential system* with a potential variable $v=v(x,t)$ for $\mathbf{R}\{x,t,\mathbf{u}\}=0$ related to the conservation law $R_1\{x,t,\mathbf{u}\}=0$.

The potential system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$ given by (2.2) is equivalent to the given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$. In particular, if $(\mathbf{u},v)=(\tilde{\mathbf{u}}(x,t),\tilde{v}(x,t))$ solves (2.2), then $\mathbf{u}=\tilde{\mathbf{u}}(x,t)$ solves $\mathbf{R}\{x,t,\mathbf{u}\}=0$. Conversely, for any solution $\mathbf{u}=\tilde{\mathbf{u}}(x,t)$ of $\mathbf{R}\{x,t,\mathbf{u}\}=0$, there exists a pair of functions $(\mathbf{u},v)=(\tilde{\mathbf{u}}(x,t),\tilde{v}(x,t))$ that satisfies (2.2), with $\tilde{v}(x,t)$ unique to within a constant.

Suppose the system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$ admits a Lie group of point transformations (point symmetry),

$$\begin{aligned} x^* &= x+\epsilon\xi_{\mathbf{S}}(x,t,\mathbf{u},v)+O(\epsilon^2),\\ t^* &= t+\epsilon\tau_{\mathbf{S}}(x,t,\mathbf{u},v)+O(\epsilon^2),\\ u^{*i} &= u^i+\epsilon\eta^i_{\mathbf{S}}(x,t,\mathbf{u},v)+O(\epsilon^2),\\ v^* &= v+\epsilon\zeta_{\mathbf{S}}(x,t,\mathbf{u},v)+O(\epsilon^2). \end{aligned} \tag{2.3}$$

$$\mathrm{X}=\xi_{\mathbf{S}}(x,t,\mathbf{u},v)\frac{\partial}{\partial x}+\tau_{\mathbf{S}}(x,t,\mathbf{u},v)\frac{\partial}{\partial t}+\eta^i_{\mathbf{S}}(x,t,\mathbf{u},v)\frac{\partial}{\partial u^i}+\zeta_{\mathbf{S}}(x,t,\mathbf{u},v)\frac{\partial}{\partial v} \tag{2.4}$$

is the infinitesimal generator of the point symmetry (2.3). (Throughout this paper, we assume summation over a repeated index).

Definition 2.2: A point symmetry (2.3) is called a *potential symmetry* of the given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$ related to the potential system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$ if and only if $(\partial\xi_{\mathbf{S}}/\partial v)^2+(\partial\tau_{\mathbf{S}}/\partial v)^2+\Sigma_{i=1}^n(\partial\eta^i_{\mathbf{S}}/\partial v)^2>0$, i.e., the infinitesimals $\xi_{\mathbf{S}}$, $\tau_{\mathbf{S}}$, $\eta^i_{\mathbf{S}}$ essentially depend on v. Any potential symmetry is a *nonlocal* symmetry of the given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$.[4]

Definition 2.3: An equivalent system $\underline{\mathbf{S}}\{x,t,u^{i_1},\ldots,u^{i_p},v\}=0$, $p\leqslant n-1$ that can be obtained by excluding one or more dependent variables u^k of the potential system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$, is called a *subsystem* of the potential system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$.

Definition 2.4: A *tree of potential systems and subsystems* for a given PDE system

$\mathbf{R}\{x,t,\mathbf{u}\}=0$, with some equations of $\mathbf{R}\{x,t,\mathbf{u}\}=0$ written directly as conservation laws, is a set of PDE systems composed of $\mathbf{R}\{x,t,\mathbf{u}\}=0$, all resulting potential systems, and all possible subsystems. We will refer to the number of dependent variables in a subsystem as the *level* of that subsystem.

Remark 2.1: If a potential system, as it is written, includes conservation laws with an essential dependence on potential variables, a higher potential system can be obtained, as will be illustrated by examples.

Definition 2.5: A subsystem $\underline{\mathbf{S}}\{x,t,u^{i_1},\ldots,u^{i_{P'}-1}\}=0$, obtained from a system $\mathbf{S}\{x,t,u^{j_1},\ldots,u^{j_P}\}=0$ by excluding a dependent variable u^α, is *locally related* to $\mathbf{S}\{x,t,u^{j_1},\ldots,u^{j_P}\}=0$ if u^α can be directly expressed from the equations of $\mathbf{S}\{x,t,u^{j_1},\ldots,u^{j_P}\}=0$ in terms of x,t, the remaining dependent variables and their derivatives. Otherwise the subsystem $\underline{\mathbf{S}}\{x,t,u^{i_1},\ldots,u^{i_{P'}-1}\}=0$ is *nonlocally related* to $\mathbf{S}\{x,t,u^{j_1},\ldots,u^{j_P}\}=0$.

For example, the system

$$\mathbf{S}\{x,t,u,v\}=0:\quad \begin{cases} v_x-u=0,\\ v_t-(L(u))_x=0, \end{cases} \tag{2.5}$$

has two subsystems,

$$\underline{\mathbf{S}}_1\{x,t,u\}=0:\ u_t-(L(u))_{xx}=0 \quad \text{and} \quad \underline{\mathbf{S}}_2\{x,t,v\}=0:\ v_t=(L(v_x))_x, \tag{2.6}$$

where $\underline{\mathbf{S}}_1\{x,t,u\}=0$ is nonlocally related to $\mathbf{S}\{x,t,u,v\}=0$, and $\underline{\mathbf{S}}_2\{x,t,v\}=0$ is locally related to $\mathbf{S}\{x,t,u,v\}=0$. (Throughout this paper, subindices denote corresponding partial derivatives.)

Definition 2.6: A *tree of nonlocally related potential systems and subsystems* is obtained from a tree of potential systems and subsystems by removing all locally related subsystems.

Remark 2.2: It is important to emphasize that a given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$, its related potential systems and subsystems, contain *all solutions of each other*. This directly follows from the way potentials are introduced in the potential systems and the way dependent variables are excluded in the subsystems since the integrability conditions always hold. Therefore, one may successfully apply a method of analysis (qualitative, numerical, perturbation, symmetry, conservation laws, etc.) to a potential system or a nonlocally related subsystem, even if it fails to be of use when applied to the given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$.

A. Example 1: A tree of potential systems and subsystems for the nonlinear diffusion equation

For the nonlinear diffusion equation, the given PDE system is the conservation law

$$\mathbf{R}\{x,t,u\}=0:\ u_t-(L(u))_{xx}=0, \tag{2.7}$$

where the constitutive function $L(u)$ is related to the diffusion function $K(u)=L'(u)$. Consequently, the related potential system is given by

$$\mathbf{S}\{x,t,u,v\}=0:\begin{cases} v_x-u=0,\\ v_t-(L(u))_x=0, \end{cases} \tag{2.8}$$

and the subsystem $\underline{\mathbf{S}}\{x,t,v\}=0$ is given by the equation

$$\underline{\mathbf{S}}\{x,t,v\}=0:\ v_t=(L(v_x))_x. \tag{2.9}$$

The second equation of (2.8) is a conservation law, and hence it gives rise to another potential variable w, and higher potential system $\mathbf{T}\{x,t,u,v,w\}=0$ (Remark 2.1) given by

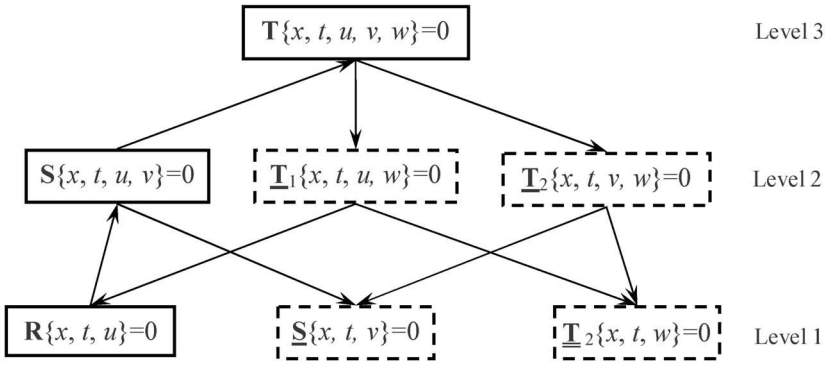

FIG. 1. The tree of potential systems and subsystems for the nonlinear diffusion equation (2.7) for an arbitrary constitutive function $L(u)$.

$$\mathbf{T}\{x,t,u,v,w\}=0\colon \begin{cases} v_x-u=0,\\ w_x-v=0,\\ w_t-L(u)=0, \end{cases} \tag{2.10}$$

and subsystems $\underline{\mathbf{T}}_1\{x,t,u,w\}=0$, $\underline{\mathbf{T}}_2\{x,t,v,w\}=0$, $\underline{\underline{\mathbf{T}}}_2\{x,t,w\}=0$ given by

$$\underline{\mathbf{T}}_1\{x,t,u,w\}=0\colon \begin{cases} w_{xx}-u=0,\\ w_t-L(u)=0, \end{cases}$$

$$\underline{\mathbf{T}}_2\{x,t,v,w\}=0\colon \begin{cases} w_x-v=0,\\ w_t-L(v_x)=0, \end{cases} \tag{2.11}$$

$$\underline{\underline{\mathbf{T}}}_2\{x,t,w\}=0\colon\ w_t-L(w_{xx})=0.$$

Since the subsystems $\underline{\mathbf{S}}\{x,t,v\}=0$, $\underline{\mathbf{T}}_1\{x,t,u,w\}=0$, $\underline{\mathbf{T}}_2\{x,t,v,w\}=0$, and $\underline{\underline{\mathbf{T}}}_2\{x,t,w\}=0$ are locally related to the potential systems (2.8) and (2.10), they are not of any interest.

This tree of potential systems and subsystems is illustrated in Fig. 1 with arrows showing the origins of elements of the tree, with dashed lines used to denote locally related subsystems. The group classification of this tree of potential systems and subsystems is given in Ref. 5 and references therein. In particular, for certain forms of the constitutive function $L(u)$ the level two system $\mathbf{S}\{x,t,u,v\}=0$ yields nonlocal symmetries of the level one system $\mathbf{R}\{x,t,u\}=0$, and vice versa. The point symmetries of the "grand" level three system $\mathbf{T}\{x,t,u,v,w\}=0$ include all point symmetries of the lower level systems. Moreover, the "grand" system $\mathbf{T}\{x,t,u,v,w\}=0$ includes a constitutive function $L(u)$ that yields symmetries that are nonlocal for the level one and level two systems.

B. Direct construction method for finding conservation laws

A direct method for finding conservation laws using factors was presented in Refs. 11 and 12. This method follows from the fact that a function $f(\mathbf{x},\mathbf{U},\partial\mathbf{U},\ldots,\partial^p\mathbf{U})$ is a divergence expression if and only if it is annihilated by the Euler differential operators,

$$E_k=\frac{\partial}{\partial U^k}-D_i\frac{\partial}{\partial U^k_i}+D_iD_j\frac{\partial}{\partial U^k_{ij}}+\cdots+(-1)^pD_{i_1}\cdots D_{i_p}\frac{\partial}{\partial U^k_{i_1\cdots i_p}}, \tag{2.12}$$

associated with each dependent variable U^k in $f(\mathbf{x},\mathbf{U},\partial\mathbf{U},\ldots,\partial^p\mathbf{U})$, $k=1,\ldots,n$. In (2.12), D_i is the total derivative operator for the independent variable x_i and $U^k_{i_1\cdots i_p}=\partial^p U^k/\partial x_{i_1}\cdots\partial x_{i_p}$.

For a given PDE system $\mathbf{R}\{x,t,\mathbf{u}\}=0$, when *additional* conservation laws are found within its tree of potential systems and subsystems, the tree can be extended. Here $x_1=t, x_2=x$.

The procedure to find additional conservation laws is as follows:

(A) Take a linear combination of the functions $R_k\{x,t,\mathbf{U}\}$ associated with the system $\mathbf{R}\{x,t,\mathbf{u}\}=0$, with unknown factors $\Lambda_k(x,t,\mathbf{U},\partial\mathbf{U},\ldots,\partial^l\mathbf{U})$ (for some fixed l),

$$M=\Lambda_k(x,t,\mathbf{U},\partial\mathbf{U},\ldots,\partial^l\mathbf{U})R_k\{x,t,\mathbf{U}\}. \tag{2.13}$$

It is essential to note that in (2.13), $\mathbf{U}$ is an *arbitrary function*. [$\mathbf{U}=\mathbf{u}(x,t)$ is a solution of $\mathbf{R}\{x,t,\mathbf{u}\}=0$.]

(B) A set of factors $\{\Lambda_k(x,t,\mathbf{U},\partial\mathbf{U},\ldots,\partial^l\mathbf{U})\}$ yields a conservation law (2.1) of $\mathbf{R}\{x,t,\mathbf{u}\}=0$ if and only if it satisfies the linear system of determining equations,

$$E_1M=0,\qquad \ldots,\qquad E_nM=0, \tag{2.14}$$

holding for arbitrary values of x,t and the components of $\mathbf{U},\partial\mathbf{U},\partial^2\mathbf{U},\ldots$.

(C) For each set of factors $\{\Lambda_k(x,t,\partial\mathbf{U},\ldots,\partial^l\mathbf{U})\}$ satisfying (2.14), there is an integral formula to find the density T and the flux X of the corresponding conservation law (2.1).[11,12]

Remark 2.3: The procedure outlined above can be applied to find conservation laws for any potential system or subsystem in a tree.

C. Construction of extended trees of nonlocally related potential systems and subsystems using additional conservation laws

Definition 2.7: If for some additional conservation law, a factor Λ_k does not vanish or vanishes only on solutions $\mathbf{U}=\mathbf{u}(x,t)$ of the given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$, then the resulting conservation law (2.1) is a *useful conservation law* and can replace the kth equation $R_k\{x,t,\mathbf{u}\}=0$ of the system $\mathbf{R}\{x,t,\mathbf{u}\}=0$.

Consequently, the resulting system

$$\tilde{\mathbf{R}}\{x,t,\mathbf{u}\}=0:\begin{cases} R_1\{x,t,\mathbf{u}\}=0,\\ \cdots,\\ R_{k-1}\{x,t,\mathbf{u}\}=0,\\ D_tT\{x,t,\mathbf{u}\}+D_xX\{x,t,\mathbf{u}\}=0,\\ R_{k+1}\{x,t,\mathbf{u}\}=0,\\ \cdots,\\ R_m\{x,t,\mathbf{u}\}=0 \end{cases} \tag{2.15}$$

has the same solution set as the original DE system $\mathbf{R}\{x,t,\mathbf{u}\}=0$. In particular, the system (2.15) explicitly contains a conservation law that leads to a related higher potential system. In determining conservation laws by the direct construction method for the related higher level potential system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$ arising from (2.15), for completeness it is essential to consider the potential system $\mathbf{S}\{x,t,\mathbf{u},v\}=0$ together with the replaced equation $R_k\{x,t,\mathbf{u}\}=0$, i.e., the system

$$\tilde{\mathbf{S}}\{x,t,\mathbf{u},v\}=0:\begin{cases} R_1\{x,t,\mathbf{u}\}=0,\\ \cdots,\\ R_{k-1}\{x,t,\mathbf{u}\}=0\\ R_k\{x,t,\mathbf{u}\}=0,\\ v_x-T\{x,t,\mathbf{u}\}=0,\\ v_t+X\{x,t,\mathbf{u}\}=0,\\ R_{k+1}\{x,t,\mathbf{u}\}=0,\\ \cdots,\\ R_m\{x,t,\mathbf{u}\}=0. \end{cases} \tag{2.16}$$

If a conservation law is not useful, then one would be too restricted in considering subsystems (with the same solution sets as $\mathbf{R}\{x,t,\mathbf{u}\}=0$) that result from elimination of one or more dependent variables.

By incorporating the direct method for finding conservation laws, we are now able to outline the algorithm for constructing the *extended* tree of nonlocally related potential systems and subsystems for a given DE system $\mathbf{R}\{x,t,\mathbf{u}\}=0$. Since $\mathbf{u}=(u^1,\ldots,u^n)$, the level (number of dependent variables) of the given system in the tree is n.

(1) *Construction of potential systems*: Suppose $\mathbf{R}\{x,t,\mathbf{u}\}=0$ includes explicit conservation laws as written. For each of these conservation laws (2.1), introduce a potential and construct a potential system of level $n+1$. For each of the potential systems of level $n+1$, repeat this step to obtain all potential systems of level $n+2$, etc., until higher potential systems include no more explicit conservation laws. Let $\mathcal{T}_1$ denote the resulting tree. (If $\mathbf{R}\{x,t,\mathbf{u}\}=0$ does not include explicit conservation laws as written, then $\mathcal{T}_1=\{\mathbf{R}\{x,t,\mathbf{u}\}=0\}$.)

(2) *Construction of subsystems*: For all systems of the tree $\mathcal{T}_1$, exclude where possible, one by one, dependent variables, to generate all subsystems of the systems in the tree $\mathcal{T}_1$. Eliminate subsystems that are locally related to it. This yields a possibly larger tree $\mathcal{T}_2$.

(3) *Additional conservation laws*: *Tree extension*: For each system in $\mathcal{T}_2$, find multipliers that yield useful conservation laws via the direct construction method. Use these additional useful conservation laws to obtain higher potential systems and corresponding subsystems. Eliminate locally related subsystems. Continue until no further useful conservation laws are found for any nonlocally related potential system or subsystem. This yields *an extended tree of nonlocally related potential systems and subsystems.*

D. Construction of nonlocal symmetries from an extended tree of potential systems and subsystems

The extended tree obtained by the above procedure can be used for different methods of analysis. In particular, it is useful in the search for nonlocal symmetries of the given DE system $\mathbf{R}\{x,t,\mathbf{u}\}=0$. Since each potential system and subsystem within the tree is nonlocally related to the given system, as well as other potential systems and subsystems in the tree, it follows that point symmetries of potential systems and subsystems may yield nonlocal (potential) symmetries of the given system, and/or other systems in the extended tree. Now we outline *the algorithm to construct nonlocal symmetries*.

(1) *Construction of extended trees of potential systems and nonlocally related subsystems*: For a given DE system $\mathbf{R}\{x,t,\mathbf{u}\}=0$, construct the extended tree of nonlocally related potential systems and subsystems. (If the given system contains constitutive functions, different extended trees may be obtained for particular forms of constitutive functions.)

(2) *Point symmetry analysis*: For each system in the extended tree, use Lie's algorithm to obtain its point symmetries.

(3) *Isolation of nonlocal symmetries*: From the set of point symmetries of each system in the

extended tree, isolate nonlocal symmetries of the given system $\mathbf{R}\{x,t,\mathbf{u}\}=0$.

An example of the use of this algorithm follows.

E. Example 2: Nonlocal symmetries and linearization of a nonlinear reaction-diffusion equation

We apply the above-described algorithm of construction of nonlocal symmetries to the reaction-diffusion equation

$$\mathbf{R}\{x,t,u\}=0:\ u_t-u^2u_{xx}-2bu^2=0. \tag{2.17}$$

First, we construct an extended tree of potential systems and subsystems. The equation (2.17) is not written as a conservation law. We look for multipliers of the form $\Lambda_1=\Lambda_1(U)$ that yield conservation laws of (2.17). Here the determining equation (2.14) becomes

$$E_1[\Lambda_1(U)(U_t-U^2U_{xx}-2bU^2)]=0,$$

and has solution $\Lambda_1(U)=-1/U^2$, with corresponding conservation law

$$\left(\frac{1}{u}\right)_t+(u+bx^2)_{xx}=0. \tag{2.18}$$

The multiplier $\Lambda_1(U)=-1/U^2$ does not vanish. Hence the conservation law (2.18) is useful and equivalent to the PDE (2.17). We let $u_1=1/u$ and denote the resulting PDE by

$$\tilde{\mathbf{R}}\{x,t,u_1\}=0:\ u_{1t}+\left(\frac{1}{u_1}+bx^2\right)_{xx}=0. \tag{2.19}$$

We introduce potential variables v and w and corresponding potential systems,

$$\begin{aligned}
&\mathbf{S}\{x,t,u_1,v\}=0:\begin{cases} v_x-u_1=0,\\ v_t+\left(\dfrac{1}{u_1}+bx^2\right)_x=0,\end{cases}\\
&\mathbf{T}\{x,t,u_1,v,w\}=0:\begin{cases} v_x-u_1=0,\\ w_x-v=0,\\ w_t+\left(\dfrac{1}{u_1}+bx^2\right)=0.\end{cases}
\end{aligned} \tag{2.20}$$

The subsystems are

$$\underline{\mathbf{S}}\{x,t,v\}=0:\ v_t+\left(\frac{1}{v_x}+bx^2\right)_x=0,$$

$$\begin{aligned}
&\underline{\mathbf{T}}_1\{x,t,u,w\}=0:\begin{cases} w_{xx}-u_1=0,\\ w_t+\left(\dfrac{1}{u_1}+bx^2\right)=0,\end{cases}\\
&\underline{\mathbf{T}}_2\{x,t,v,w\}=0:\begin{cases} w_x-v=0,\\ w_t+\left(\dfrac{1}{v_x}+bx^2\right)=0,\end{cases}
\end{aligned} \tag{2.21}$$

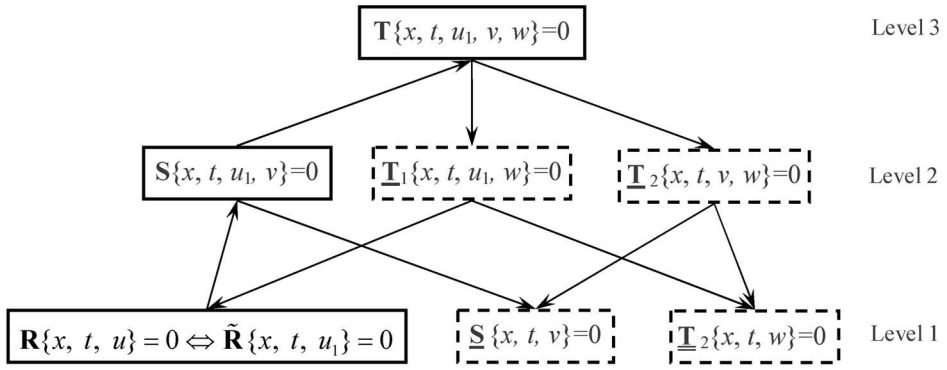

FIG. 2. The tree of potential systems and subsystems for the reaction-diffusion equation (2.17).

$$\underline{\underline{\mathbf{T}}}_2\{x,t,w\}=0\colon\ w_t+\left(\frac{1}{w_{xx}}+bx^2\right)=0.$$

The tree of potential systems and subsystems is illustrated in Fig. 2 with arrows showing the origins of elements of the tree. Locally related subsystems are outlined with dashed lines. For the analysis of nonlocal symmetries of the given system $\mathbf{R}\{x,t,u\}=0$ (2.17), only systems $\mathbf{S}\{x,t,u_1,v\}=0$ and $\mathbf{T}\{x,t,u_1,v,w\}=0$ need to be used, since all other subsystems are locally related to them.

One can show[5] that the level three potential system $\mathbf{T}\{x,t,u_1,v,w\}=0$ admits an infinitesimal generator,

$$\mathrm{X}^{\mathbf{T}}_{\infty}=e^{b(w-xv)}\Big((F^1-bxF^3)\frac{\partial}{\partial x}+(2bxu_1^2F^1-u_1^2F^2+bu_1(1-bx^2u_1)F^3)\frac{\partial}{\partial u_1}$$
$$+(vF^1-(1+bxv)F^3)\frac{\partial}{\partial w}\Big),\tag{2.22}$$

where

$$\frac{\partial F^1(v,t)}{\partial v}=F^2(v,t),\quad \frac{\partial F^3(v,t)}{\partial v}=F^1(v,t),\quad \frac{\partial F^3(v,t)}{\partial t}=F^2(v,t).\tag{2.23}$$

The point symmetry generator (2.22) is infinite dimensional; it projects to a point symmetry of $\underline{\mathbf{T}}_2\{x,t,v,w\}=0$, induces a contact symmetry of $\underline{\underline{\mathbf{T}}}_2\{x,t,w\}=0$, a Lie-Bäcklund symmetry of $\underline{\mathbf{T}}_1\{x,t,u,w\}=0$, and a nonlocal symmetry of $\mathbf{R}\{x,t,u\}=0$, $\tilde{\mathbf{R}}\{x,t,u_1\}=0$, $\mathbf{S}\{x,t,u_1,v\}=0$, and $\underline{\mathbf{S}}\{x,t,v\}=0$. Consequently, $\mathbf{T}\{x,t,u_1,v,w\}=0$, $\underline{\mathbf{T}}_2\{x,t,v,w\}=0$, and $\underline{\underline{\mathbf{T}}}_2\{x,t,w\}=0$ are linearizable by invertible mappings, and the other systems in the tree are linearizable by noninvertible mappings.[4,5]

III. TREES AND NONLOCAL SYMMETRIES FOR PLANAR GAS DYNAMICS EQUATIONS

We now use the algorithmic approach described in Sec. II to construct trees of potential systems and subsystems for the (1+1)-dimensional system of planar gas dynamics (PGD) equations. The point symmetries of some of these systems have been extensively considered in Ref. 14.

The two fundamental systems of differential equations that describe nonstationary (1+1)-dimensional gas motions are Euler and Lagrange systems. In the Eulerian description, x is a Cartesian coordinate in a fixed coordinate frame. The *Euler system* is given by

$$\mathbf{E}\{x,t,v,p,\rho\}=0:\begin{cases}\rho_t+(\rho v)_x=0,\\ \rho(v_t+vv_x)+p_x=0,\\ \rho(p_t+vp_x)+B(p,1/\rho)v_x=0.\end{cases}\tag{3.1}$$

Here v is the gas velocity, ρ is the gas density, and p is the gas pressure. In terms of the entropy density $S(p,\rho)$, the constitutive function $B(p,1/\rho)$ is given by

$$B(p,1/\rho)=-\rho^2 S_\rho/S_p.$$

In many applications, however, it is more convenient to use Lagrange mass coordinates $s=t$, $y=\int_{x_0}^{x}\rho(\xi)\mathrm{d}\xi$. In these variables, the system (3.1) takes on the equivalent form

$$\mathbf{L}\{y,s,v,p,q\}=0:\begin{cases}q_s-v_y=0,\\ v_s+p_y=0,\\ p_s+B(p,q)v_y=0,\end{cases}\tag{3.2}$$

and is called the *Lagrange system*. Here the coordinate y essentially enumerates the fluid particles; its domain does not change with time. The partial time derivative $\partial/\partial s=\partial/\partial t+v\,\partial/\partial x$ is the material derivative. The use of Lagrange mass coordinates often significantly facilitates the formulation of boundary conditions.[15–17]

We show that the potential system framework provides a direct connection between the Euler system (3.1) and the Lagrange system (3.2). Moreover, further extensions arise, and in particular, one can obtain other nonlocally related equivalent systems of equations.

We now construct a tree of nonlocally related potential systems and subsystems, with $\mathbf{E}\{x,t,v,p,\rho\}=0$ given by (3.1) serving as the given system, through the algorithm described in Sec. II.

Since the first equation of (3.1) is a conservation law, a potential variable r is naturally introduced, and the resulting level four potential system has the form

$$\mathbf{G}\{x,t,v,p,\rho,r\}=0:\begin{cases}r_x-\rho=0,\\ r_t+\rho v=0,\\ r_x(v_t+vv_x)+p_x=0,\\ r_x(p_t+vp_x)+B(p,1/r_x)v_x=0.\end{cases}\tag{3.3}$$

An obvious subsystem $\mathbf{I}\{x,t,v,p,r\}\equiv\underline{\mathbf{G}}_1\{x,t,v,p,r\}=0$ is obtained by excluding the density ρ from (3.3),

$$\mathbf{I}\{x,t,v,p,r\}=0:\begin{cases}r_t+vr_x=0,\\ r_x(v_t+vv_x)+p_x=0,\\ r_x(p_t+vp_x)+B(p,1/r_x)v_x=0.\end{cases}\tag{3.4}$$

In Ref. 14, (3.4) is referred to as the *intermediate* system. However, this system is locally related to $\mathbf{G}\{x,t,v,p,\rho,r\}=0$.

Another subsystem is $\underline{\mathbf{G}}_2\{x,t,p,\rho,r\}=0$, obtained by excluding the velocity v. This subsystem is also not of interest since it is locally related to $\mathbf{G}\{x,t,v,p,\rho,r\}=0$.

Consider a local coordinate transformation of the system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ with $r=y$, $t=s$ treated as independent variables, and x,v,p,ρ as dependent variables. Without loss of generality, $\rho\neq 0$. We let $q=1/\rho$, and obtain the system $\mathbf{G}_0\{y,s,x,v,p,\rho\}=0$ given by

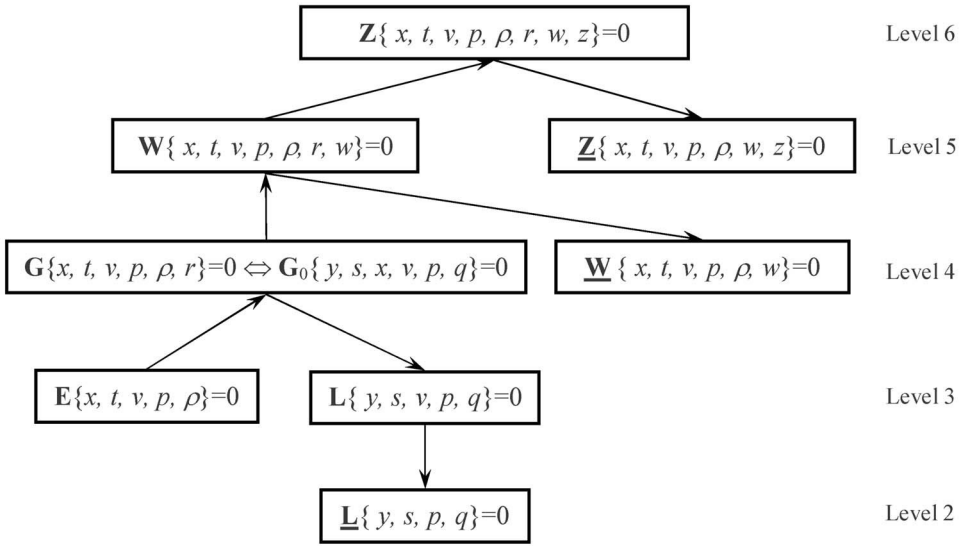

FIG. 3. The tree $\mathcal{T}_{\mathrm{PGD}}$ of nonlocally related PGD potential systems and subsystems, for an arbitrary constitutive function $B(p,1/\rho)$; $\mathbf{E}\{x,t,v,p,\rho\}=0$ is the Euler system (3.1), $\mathbf{L}\{y,s,v,p,q\}=0$ is the Lagrange system (3.2).

$$\mathbf{G}_0\{y,s,x,v,p,\rho\}=0:\begin{cases} q-x_y=0,\\ v-x_s=0,\\ v_s+p_y=0,\\ p_s+B(p,q)v_y=0, \end{cases} \tag{3.5}$$

equivalent to the potential system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ and locally related to it.

A subsystem of $\mathbf{G}_0\{y,s,x,v,p,\rho\}=0$ obtained by excluding x through $x_{sy}=x_{ys}$ is the Lagrange system (3.2), $\mathbf{L}\{y,s,v,p,q\}\equiv\underline{\mathbf{G}}_0\{y,s,v,p,q\}=0$. Thus *the Euler and Lagrange systems of PGD equations are connected through a common potential system* (see Fig. 3).

We continue the construction of the tree of potential systems and subsystems for the PGD equations for a general constitutive function $B(p,1/\rho)$. We first find possible higher potential systems arising for the potential system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ given by (3.3).

The Euler system given by (3.1) with multipliers $\Lambda_1=V$, $\Lambda_2=1$, $\Lambda_3=0$ yields a *useful* conservation law,

$$(\rho v)_t+(p+\rho v^2)_x=0, \tag{3.6}$$

which also holds for the system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$. Hence we use the conservation law (3.6) to replace the equation $r_x(v_t+vv_x)+p_x=0$, and introduce a potential variable w to obtain the level five potential system $\mathbf{W}\{x,t,v,p,\rho,r,w\}=0$ given by

$$\mathbf{W}\{x,t,v,p,\rho,r,w\}=0:\begin{cases} r_x-\rho=0,\\ r_t+\rho v=0,\\ w_x+r_t=0,\\ w_t+p+vw_x=0,\\ r_x(p_t+vp_x)+B(p,1/r_x)v_x=0. \end{cases} \tag{3.7}$$

The third equation of (3.7) is written as a conservation law, and accordingly we introduce a potential variable z to obtain a level six potential system,

$$\mathbf{Z}\{x,t,v,p,\rho,r,w,z\}=0:\begin{cases} r_x-\rho=0,\\ r_t+\rho v=0,\\ z_t-w=0,\\ z_x+r=0,\\ w_t+p+vw_x=0,\\ r_x(p_t+vp_x)+B(p,1/r_x)v_x=0. \end{cases} \tag{3.8}$$

The only nonlocally related subsystems of (3.7) and (3.8) arise from excluding r (see Fig. 3). The Lagrange system (3.2) has a nonlocally related subsystem obtained by excluding v,

$$\underline{\mathbf{L}}\{y,s,p,q\}=0:\begin{cases} q_{ss}+p_{yy}=0,\\ p_s+B(p,q)q_s=0. \end{cases} \tag{3.9}$$

The tree $\mathcal{T}_{\mathrm{PGD}}$ of useful (i.e., nonlocally related) potential systems and subsystems [for an arbitrary constitutive function $B(p,1/\rho)$] is illustrated by Fig. 3. Note that either the Euler system $\mathbf{E}\{x,t,v,p,\rho\}=0$ or the Lagrange system $\mathbf{L}\{y,s,v,p,q\}=0$ can be taken as the given system. Each of these systems gives rise to the same tree of potential systems and subsystems.

All systems in the tree $\mathcal{T}_{\mathrm{PGD}}$ are nonlocally related and equivalent (i.e., contain all solutions of each other). Therefore any general method of analysis (qualitative, numerical, perturbation, symmetry, conservation laws, etc.) may yield new results for any of these nonlocally related PGD systems. In particular, this is the case for the symmetry analysis given below.

In Ref. 14, point symmetries of three systems were studied in detail—the Euler system (3.1), the Lagrange system (3.2), and the "intermediate" system (3.4). The authors gave a classification with respect to the constitutive function $B(p,1/\rho)$ and isolated the cases in which some of the point symmetries of $\mathbf{E}\{x,t,v,p,\rho\}=0$, $\mathbf{L}\{y,s,v,p,q\}=0$ or $\mathbf{I}\{x,t,v,p,r\}=0$ were nonlocal for the other two systems. However, their approach was heuristic—the connections between their systems did not involve a general constructive framework.

Using the algorithmic approach presented in this paper, one directly arrives at the tree $\mathcal{T}_{\mathrm{PGD}}$ of nonlocally related PGD potential systems and subsystems. To find nonlocal symmetries of systems $\mathbf{E}\{x,t,v,p,\rho\}=0$ and $\mathbf{L}\{y,s,v,p,q\}=0$, one should classify the point symmetries of *all eight* systems in the tree, with respect to the constitutive function $B(p,1/\rho)$. (The system $\mathbf{I}\{x,t,v,p,r\}=0$ discussed in Ref. 14 is of no interest since it is locally related to the system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ in the tree.) For example, the subsystem $\underline{\mathbf{L}}\{y,s,p,q\}=0$ given by (3.9), in the case of a Chaplygin gas $[B(p,q)=-p/q]$, admits a point symmetry with infinitesimal generator,

$$\mathrm{X}=-y^2\frac{\partial}{\partial y}-py\frac{\partial}{\partial p}+3yq\frac{\partial}{\partial q}, \tag{3.10}$$

which yields a nonlocal symmetry for both $\mathbf{E}\{x,t,v,p,\rho\}=0$ and $\mathbf{L}\{y,s,v,p,q\}=0$. The symmetry (3.10) was not obtained in Ref. 14, since the system (3.9) did not arise.

Furthermore, for some systems in the tree $\mathcal{T}_{\mathrm{PGD}}$, particular forms of the constitutive function $B(p,1/\rho)$ may yield useful conservation laws, which in turn would yield extended trees (cf. Sec. II). We now consider two examples.

Example A: For $B(p,1/\rho)=\rho(1+e^p)$, the system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ has a family of useful conservation laws,

$$D_t\left(\frac{e^p f(r)}{1+e^p}\right)+D_x\left(\frac{ve^p f(r)}{1+e^p}\right)=0, \tag{3.11}$$

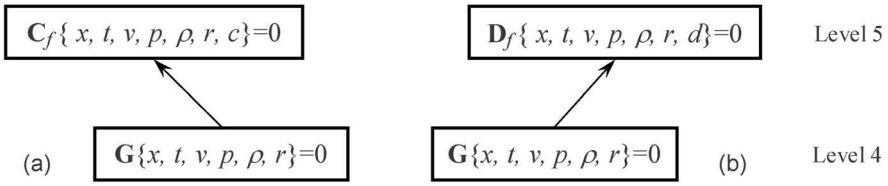

FIG. 4. PGD tree extensions for two particular forms of the constitutive function $B(p,1/\rho)$. (a) $B(p,1/\rho)=\rho(1+e^p)$. (b) Chaplygin gas $B(p,1/\rho)=-p\rho$.

for arbitrary $f(r)$. A conservation law of the form (3.11) can be used to replace the fourth equation of $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ to introduce a potential c and consequent family of potential systems $\mathbf{C}_f\{x,t,v,p,\rho,r,c\}=0$ in terms of an arbitrary function $f(r)$,

$$\mathbf{C}_f\{x,t,v,p,\rho,r,c\}=0:\begin{cases} r_x-\rho=0,\\ r_t+\rho v=0,\\ r_x(v_t+vv_x)+p_x=0,\\ c_x+e^p f(r)/(1+e^p)=0,\\ c_t-ve^p f(r)/(1+e^p)=0. \end{cases} \tag{3.12}$$

The corresponding tree extension is exhibited in Fig. 4(a).

Example B: For the Chaplygin gas $B(p,1/\rho)=-p\rho$, the family of useful conservation laws

$$D_t\left(\frac{f(r)}{p}\right)+D_x\left(\frac{vf(r)}{p}\right)=0 \tag{3.13}$$

for arbitrary $f(r)$ yields a family of potential systems

$$\mathbf{D}_f\{x,t,v,p,\rho,r,d\}=0:\begin{cases} r_x-\rho=0,\\ r_t+\rho v=0,\\ r_x(v_t+vv_x)+p_x=0,\\ d_x+f(r)/p=0,\\ d_t-vf(r)/p=0, \end{cases} \tag{3.14}$$

nonlocally related to the other systems in the tree $\mathcal{T}_{\mathrm{PGD}}$. The corresponding tree extension is exhibited in Fig. 4(b). One can show that nonlocal symmetries of the Euler system $\mathbf{E}\{x,t,v,p,\rho\}=0$ only arise in the cases where $f(r)=r$, $f(r)=\mathrm{const}$. For $f(r)=r$, the system (3.14) admits

$$\mathrm{X}_{\mathbf{D}1}=\left(-\frac{t^3}{6}+dt\right)\frac{\partial}{\partial x}+\left(d-\frac{t^2}{2}\right)\frac{\partial}{\partial v}+rt\frac{\partial}{\partial p}-\frac{rt\rho}{p}\frac{\partial}{\partial\rho}, \tag{3.15}$$

$$\mathrm{X}_{\mathbf{D}2}=\left(-\frac{t^2}{2}+d\right)\frac{\partial}{\partial x}-t\frac{\partial}{\partial v}+r\frac{\partial}{\partial p}-\frac{r\rho}{p}\frac{\partial}{\partial\rho}. \tag{3.16}$$

Symmetry (3.15) is nonlocal for both the Euler system $\mathbf{E}\{x,t,v,p,\rho\}=0$ and the Lagrange system $\mathbf{L}\{y,s,v,p,q\}=0$; symmetry (3.16) is nonlocal for the Euler system $\mathbf{E}\{x,t,v,p,\rho\}=0$ but local for the Lagrange system $\mathbf{L}\{y,s,v,p,q\}=0$. In Ref. 14, symmetry $\mathrm{X}_{\mathbf{D}1}$ was not obtained; symmetry $\mathrm{X}_{\mathbf{D}2}$ was obtained by an *ad hoc* procedure.

Through the algorithmic framework given in this paper, the symmetry results in Ref. 14 can be recovered systematically and substantially extended.

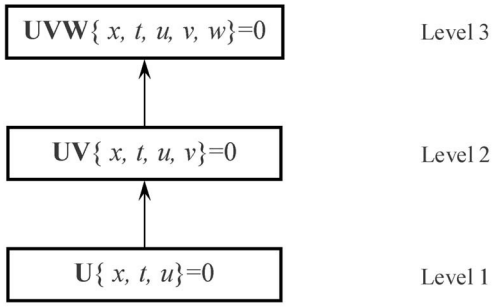

FIG. 5. NLT tree for arbitrary constitutive functions $F(u), G(u)$.

IV. EXTENDED TREES OF NONLOCALLY RELATED SYSTEMS FOR NONLINEAR TELEGRAPH EQUATIONS

We now construct trees of nonlocally related potential systems and subsystems for the nonlinear telegraph (NLT) equation, as well as further tree extensions for particular forms of constitutive functions. This allows us to extend recent results that appeared in Refs. 9, 13, and 18.

A. The tree for arbitrary constitutive functions

As a given system, we take the NLT equation,

$$\mathbf{U}\{x,t,u\}=0\text{: } u_{tt}-(F(u)u_x)_x-(G(u))_x=0. \tag{4.1}$$

Equation (4.1) is an explicit conservation law and hence is equivalent to the level two potential system,

$$\mathbf{UV}\{x,t,u,v\}=0\text{: } \begin{cases} u_t-v_x=0, \\ v_t-F(u)u_x-G(u)=0. \end{cases} \tag{4.2}$$

NLT systems of the form (4.2) represent the equations of telegraphy of a two-conductor transmission line and equations of motion of a hyperelastic homogeneous rod whose cross-sectional area varies exponentially along the rod. For further details, see Refs. 9 and 13 and references therein.

Since the first equation of (4.2) is written as a conservation law, a level three potential system is obtained,

$$\mathbf{UVW}\{x,t,u,v,w\}=0\text{: } \begin{cases} w_t-v=0, \\ w_x-u=0, \\ v_t-F(u)u_x-G(u)=0. \end{cases} \tag{4.3}$$

For *arbitrary* constitutive functions $F(u), G(u)$, there are no further potential systems.

The complete point symmetry classifications of the scalar equation (4.1) and system (4.2) appear, respectively, in Refs. 18 and 9. The point symmetries of (4.2) yield nonlocal symmetries of (4.1) for a large class of constitutive functions.

The given equation (4.1) is the only subsystem of system (4.2). The subsystems of potential system (4.3) are obtained by excluding u and/or v, $\mathbf{UW}\{x,t,u,w\}=0$, $\mathbf{VW}\{x,t,v,w\}=0$, and $\mathbf{W}\{x,t,w\}=0$. However these subsystems are not interesting since they are locally related to the potential system $\mathbf{UVW}\{x,t,u,v,w\}=0$ given by (4.3).

The tree $\mathcal{T}_{\mathrm{NLT}}$ of useful (i.e., nonlocally related) potential systems and subsystems, for arbitrary constitutive functions $F(u), G(u)$, is exhibited in Fig. 5.

TABLE I. Conservation laws of the system (4.2) using the data presented in Ref. 13.

Case	Multipliers	Conservation law
$F(u)=G'(u)$	$\Lambda_1=0,\ \Lambda_2=e^x$	(I) $D_t(ve^x)-D_x(e^xG(u))=0$
	$\Lambda_1=e^x,\ \Lambda_2=te^x$	(II) $D_t(e^x(u+tv))-D_x(e^x(tG(u)+v))=0$
$F(u)=G'(u)+1$	$\Lambda_1=\Lambda_2=e^{x+t}$	(III) $D_t(e^{x+t}(u+v))-D_x(e^{x+t}(G(u)+u+v))=0$
	$\Lambda_1=-\Lambda_2=e^{x-t}$	(IV) $D_t(e^{x-t}(u-v))+D_x(e^{x-t}(G(u)+u-v))=0$
$F(u)=G'(u)-1$	$\Lambda_1=-i\Lambda_2=e^{x+it}$	(V,VI) Real and imaginary parts of $D_t(e^{x+it}(iu+v))-D_x(e^{x+it}(G(u)-u+iv))=0$
$F(u)$ arbitrary, $G(u)=u$	$\Lambda_1=x-t^2/2,\ \Lambda_2=t$	(VII) $D_t((x-t^2/2)u+tv)+D_x((t^2/2-x)v-t\int F(u)\mathrm{d}u)=0$
	$\Lambda_1=-t,\ \Lambda_2=1$	(VIII) $D_t(v-tu)+D_x(tv-\int F(u)\mathrm{d}u)=0$

B. Tree extensions for particular constitutive functions

The complete conservation law classification of the potential system $\mathbf{UV}\{x,t,u,v\}=0$ given by (4.2) was found in Ref. 13 for multipliers of the form $\Lambda_i=\Lambda_i(x,t,U,V),\ i=1,2$. The problem of finding further potential systems from useful conservation laws of the system (4.2) was not considered in Ref. 13.

Using the data presented in Ref. 13, one sees that the following useful conservation laws (Table I) arise for (4.2).

In Table I, we exclude the cases [$G(u)=u$ with $F(u)=$const, $G(u)=0$ with $F(u)$ arbitrary] for which system (4.2) is linear or linearizable by a point transformation.

The eight conservation laws in Table I are now used to obtain additional potential systems and nonlocally related subsystems, and thus to extend the tree $\mathcal{T}_{\mathrm{NLT}}$. In particular, each conservation law in Table I [except (I)] can be used to replace either equation of system $\mathbf{UV}\{x,t,u,v\}=0$ given by (4.2), since in each of these seven cases both multipliers Λ_1,Λ_2 are nonzero and have no dependence on dependent variables.

Case 1: $F(u)=G'(u)$. For conservation law (I) in Table I, one has $\Lambda_1=0$, and hence only the second equation of the system $\mathbf{UV}\{x,t,u,v\}=0$ given by (4.2) can be replaced with this conservation law. Accordingly, we introduce a potential variable $\tilde{a}$ and let $a=e^{-x}\tilde{a}$. The corresponding potential system is given by

$$\mathbf{UVA}\{x,t,u,v,a\}=0:\begin{cases} v_x-u_t=0,\\ a+a_x-v=0,\\ a_t-G(u)=0. \end{cases} \tag{4.4}$$

Since the first equation of (4.4) is written as a conservation law, a level four potential system is obtained,

$$\mathbf{UVWA}\{x,t,u,v,w,a\}=0:\begin{cases} w_t-v=0,\\ w_x-u=0,\\ a+a_x-v=0,\\ a_t-G(u)=0. \end{cases} \tag{4.5}$$

Note that the system $\mathbf{UVW}\{x,t,u,v,w\}=0$ given by (4.3) is a subsystem of the system (4.5) through excluding the variable a. The subsystems

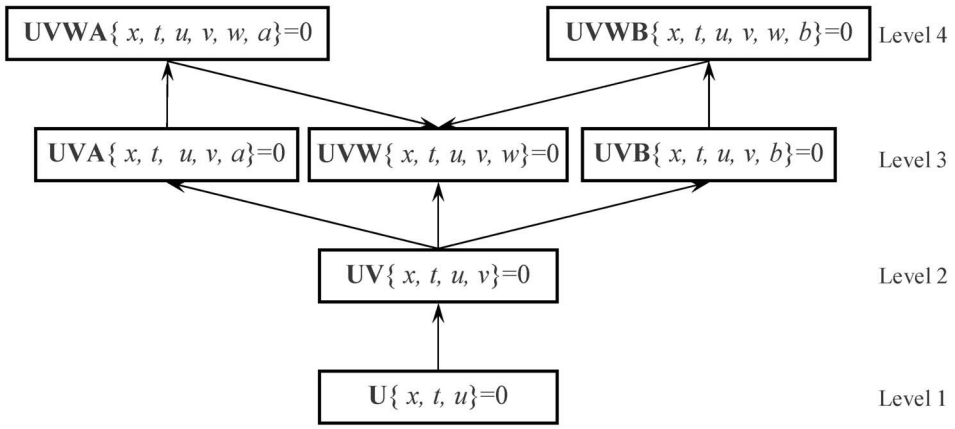

FIG. 6. The form of the extended tree of nonlocally related potential systems and subsystems of the NLT equations for Case 1 [$F(u)=G'(u)$, $G(u)$ arbitrary], Case 2 [$F(u)=G'(u)+1$, $G(u)$ arbitrary], Case 3 [$F(u)=G'(u)-1$, $G(u)$ arbitrary], and Case 4 [$F(u)$ arbitrary with $G(u)=u$].

$$\mathbf{VA}\{x,t,v,a\}=0:\begin{cases} a+a_x-v=0,\\ v_x-H'(a_t)a_{tt}=0 \quad (H=G^{-1}),\end{cases}$$
$$\mathbf{A}\{x,t,a\}=0:\ a_x+a_{xx}-H'(a_t)a_{tt}=0 \tag{4.6}$$

are locally related to (4.4) and therefore not interesting.

The useful conservation law (II) is equivalent to a pair of equations $b_t=tG(u)+v$, $b_x+b=u+tv$, and hence yields the level three potential system,

$$\mathbf{UVB}\{x,t,u,v,b\}=0:\begin{cases} v_x-u_t=0,\\ v_t-G'(u)u_x-G(u)=0,\\ b_t-tG(u)-v=0,\\ b_x+b-u-tv=0,\end{cases} \tag{4.7}$$

as well as the level four potential system,

$$\mathbf{UVWB}\{x,t,u,v,w,b\}=0:\begin{cases} w_t-v=0,\\ w_x-u=0,\\ b_t-tG(u)-v=0,\\ b_x+b-u-tv=0.\end{cases} \tag{4.8}$$

In Fig. 6 we exhibit the extended tree $\mathcal{T}^1_{\mathrm{NLT}}$ of nonlocally related potential systems and subsystems of the NLT equation (4.1) in the case $F(u)=G'(u)$.

In a similar manner, one can show that the three pairs of conservation laws for the other cases [$F(u)=G'(u)+1$, $F(u)=G'(u)-1$, $F(u)$ arbitrary with $G(u)=u$] all yield extended trees of the form exhibited in Fig. 6. For each of these three cases, the nonlocally related systems are as follows.

Case 2: $F(u)=G'(u)+1$. The set of nonlocally related potential systems and subsystems is given by

$$\mathbf{UVA}\{x,t,u,v,a\}=0:\begin{cases} v_x-u_t=0,\\ v_t-F(u)u_x-G(u)=0,\\ a_t+a-(G(u)+u+v)=0,\\ a_x+a-(u+v)=0,\end{cases}$$

$$\mathbf{UVWA}\{x,t,u,v,w,a\}=0:\begin{cases} w_t-v=0,\\ w_x-u=0,\\ a_t+a-(G(u)+u+v)=0,\\ a_x+a-(u+v)=0,\end{cases} \tag{4.9}$$

$$\mathbf{UVB}\{x,t,u,v,b\}=0:\begin{cases} v_x-u_t=0,\\ v_t-F(u)u_x-G(u)=0,\\ b_t-b-(G(u)+u-v)=0,\\ b_x+b+(u-v)=0,\end{cases}$$

$$\mathbf{UVWB}\{x,t,u,v,w,b\}=0:\begin{cases} w_t-v=0,\\ w_x-u=0,\\ b_t-b-(G(u)+u-v)=0,\\ b_x+b+(u-v)=0.\end{cases} \tag{4.10}$$

Case 3: $F(u)=G'(u)-1$. The useful complex conservation law (V,VI) in Table I is equivalent to two useful real conservation laws,

$$\text{(V)}\quad D_t[e^x(v\cos t-u\sin t)]+D_x[e^x(v\sin t-(G(u)-u)\cos t)]=0,$$

$$\text{(VI)}\quad D_t[e^x(u\cos t+v\sin t)]-D_x[e^x((G(u)-u)\sin t+v\cos t)]=0.$$

The set of nonlocally related potential systems and subsystems is given by

$$\mathbf{UVA}\{x,t,u,v,a\}=0:\begin{cases} v_x-u_t=0,\\ v_t-F(u)u_x-G(u)=0,\\ a_t+(v\sin t-(G(u)-u)\cos t)=0,\\ a_x+a-(v\cos t-u\sin t)=0,\end{cases} \tag{4.11}$$

$$\mathbf{UVWA}\{x,t,u,v,w,a\}=0:\begin{cases} w_t-v=0,\\ w_x-u=0,\\ a_t+(v\sin t-(G(u)-u)\cos t)=0,\\ a_x+a-(v\cos t-u\sin t)=0,\end{cases}$$

$$\mathbf{UVB}\{x,t,u,v,b_2\}=0:\begin{cases} v_x-u_t=0,\\ v_t-F(u)u_x-G(u)=0,\\ b_t+((G(u)-u)\sin t+v\cos t)=0,\\ b_x+b+(u\cos t+v\sin t)=0,\end{cases} \tag{4.12}$$

$$\mathbf{UVWB}\{x,t,u,v,w,b\}=0:\begin{cases} w_t - v = 0, \\ w_x - u = 0, \\ b_t + ((G(u)-u)\sin t + v\cos t) = 0, \\ b_x + b + (u\cos t + v\sin t) = 0. \end{cases}$$

Case 4: $F(u)$ arbitrary, $G(u)=u$. In this case, the set of nonlocally related potential systems and subsystems is given by

$$\mathbf{UVA}\{x,t,u,v,a\}=0:\begin{cases} v_x - u_t = 0, \\ v_t - F(u)u_x - u = 0, \\ a_x - ((x - t^2/2)u + tv) = 0, \\ a_t + \left((t^2/2 - x)v - t\int F(u)\mathrm{d}u\right) = 0, \end{cases}$$

$$\mathbf{UVWA}\{x,t,u,v,w,a\}=0:\begin{cases} w_t - v = 0, \\ w_x - u = 0, \\ a_x - ((x - t^2/2)u + tv) = 0, \\ a_t + \left((t^2/2 - x)v - t\int F(u)\mathrm{d}u\right) = 0 \end{cases} \tag{4.13}$$

and

$$\mathbf{UVB}\{x,t,u,v,b\}=0:\begin{cases} v_x - u_t = 0, \\ v_t - F(u)u_x - u = 0, \\ b_x - (v - tu) = 0, \\ b_t + \left(tv - \int F(u)\mathrm{d}u\right) = 0, \end{cases}$$

$$\mathbf{UVWB}\{x,t,u,v,w,b\}=0:\begin{cases} w_t - v = 0, \\ w_x - u = 0, \\ b_x - (v - tu) = 0, \\ b_t + \left(tv - \int F(u)\mathrm{d}u\right) = 0. \end{cases} \tag{4.14}$$

V. FURTHER REMARKS

(1) The algorithmic framework for nonlocally related potential systems and subsystems has been demonstrated to be useful for calculating new nonlocal symmetries and new nonlocal conservation laws for a given system of PDEs. It should be important to study the applicability of other methods of analysis (qualitative, numerical, perturbation, etc.) to nonlocally related systems in extended trees, especially coordinate-independent methods.

(2) In a PDE system with $n \geqslant 3$ independent variables, a conservation law is equivalent to a set of equations involving *several potential variables*.[4] The corresponding potential system is underdetermined, and requires suitable gauge constraints (in the form of additional equations on the potential variables) to be imposed in order to find nonlocal symmetries.[19]

Although a potential system without constraints is underdetermined, its potential *subsystems* may be useful for analysis without gauge constraints.

(3) In the algorithm presented in Sec. II, the nonlocally related subsystems are obtained by

exclusion of dependent variables *as written*. Alternatively any point transformation

$$U = U(x,t,u,v),$$
$$V = V(x,t,u,v),$$
$$X = X(x,t,u,v),$$
$$T = T(x,t,u,v), \tag{5.1}$$

could be used to exclude a dependent variable U or V to obtain *additional* nonlocally related subsystems. Indeed this is the situation within the tree of potential systems and subsystems of the PGD equations (Sec. III): the system $\mathbf{G}\{x,t,v,p,\rho,r\}=0$ as written has only a nonlocally related subsystem $\mathbf{E}\{x,t,v,p,\rho\}=0$. However after a local change of variables (to $\mathbf{G}_0\{y,s,x,v,p,\rho\}=0$), it admits the Lagrange system $\mathbf{L}\{y,s,v,p,q\}=0$ as a nonlocally related subsystem (Fig. 3).

(4) Using the algorithmic framework given in this paper, local and nonlocal symmetries for the PGD equations obtained in Ref. 14 can be recovered systematically and substantially extended (some examples of new nonlocal symmetries are given in Sec. III). The systematic classification of useful conservation laws and consequent nonlocal extensions of the PGD tree $\mathcal{T}_{\mathrm{PGD}}$ will appear in future works, as well as concomitant nonlocal symmetry analyses.

(5) An exhaustive study of nonlocal symmetries and nonlocal conservation laws of NLT equations resulting from extended trees of potential systems and subsystems is in progress. Preliminary results show that for a large class of constitutive functions, namely, $F(u)=G'(u)$, there exist point symmetries of the potential system $\mathbf{UVW}\{x,t,u,v,w\}=0$ given by (4.3) that are nonlocal for both the scalar NLT equation (4.1) and the system $\mathbf{UV}\{x,t,u,v\}=0$ given by (4.2). A particular example is a symmetry

$$\mathrm{X}_{\mathbf{UVW}} = v\frac{\partial}{\partial x} + \left(u + \frac{w}{3}\right)\frac{\partial}{\partial t} - \frac{uv}{3}\frac{\partial}{\partial u} - \frac{v^2}{3}\frac{\partial}{\partial v} + uv\frac{\partial}{\partial w} \tag{5.2}$$

for the case $F(u)=u^2, G(u)=u^3/3$.

(Received 13 September 2005; accepted 26 October 2005; published online 29 December 2005)

We study a new hierarchy of equations containing the short pulse equation, which describes the evolution of very short pulses in nonlinear media, and the elastic beam equation, which describes nonlinear transverse oscillations of elastic beams under tension. We show that the hierarchy of equations is integrable. We obtain the two compatible Hamiltonian structures. We construct an infinite series of both local and nonlocal conserved charges. A Lax description is presented for both systems. For the elastic beam equations we also obtain a nonstandard Lax representation.
 [DOI: 10.1063/1.2146189]

I. INTRODUCTION

The cubic nonlinear Schrödinger equation is used in the description of the propagation of pulses in nonlinear media such as optical fibers. Recently, technology progress for creating very short pulses was achieved, however, the description of the evolution of those pulses lies beyond the usual approximations leading to the nonlinear Schrödinger equation. Various approaches have been proposed to replace the nonlinear Schrödinger equation in these conditions. In Ref. 1 Schäfer and Wayne proposed an alternative model to approximate the evolution of very short pulses in nonlinear media. They derived the short pulse (SP) equation

$$u_{xt} = u + \tfrac{1}{6}(u^3)_{xx}. \tag{1}$$

Chung *et al.*[2] showed numerically that the SP equation provides a better approximation to the solution of Maxwell's equations than the nonlinear Schrödinger equation as the pulse length gets short. Also, Sakovich and Sakovich[3] have studied the integrability of (1).

In this paper we will study the integrability of the nonlocal representation of the SP equation (1),

$$u_t = (\partial^{-1}u) + \tfrac{1}{2}u^2u_x, \tag{2}$$

as well as the hierarchy of equations associated with it. The equation in this form is more feasible for a Hamiltonian description and can be obtained integrating (1) with respect to x. In what follows we will refer to the equation (2) simply as the SP equation.

The local nonlinear equation

$$u_t = \left[\frac{u_{xx}}{(1+u_x^2)^{3/2}}\right]_x, \tag{3}$$

will also appear in our hierarchy of equations. It can be embedded in the Wadati-Konno-Ichikawa (WKI) system[4] and its x derivative can be shown to describe nonlinear transverse oscillation of elastic beams under tension.[5] Therefore, we will simply call (3) the equation for elastic beams (EB).

Our paper is organized as follows. In Sec. II, we show that our system is integrable through its bi-Hamiltonian nature. We give the two Hamiltonian structures associated with the Hamiltonian description of Eqs. (2) and (3). The method of prolongation is used to prove the Jacobi identity as

well as the compatibility of the Hamiltonian structures. In Sec. III, we construct the recursion operator and its inverse to obtain the first local and nonlocal charges recursively. We also obtain the first local and nonlocal equations of the hierarchy recursively, which includes the EB and SP equations, respectively. In Sec. IV we obtain the Lax representation for the system. For the EB equation, and for other local equations in the hierarchy, we also give a nonstandard Lax representation. In Sec. V, we summarize our results and present our conclusions.

The results in this paper are much like the ones obtained for the Harry Dym and Hunter-Saxton hierarchy of equations,[6] deformed Harry Dym and Hunter-Saxton hierarchy of equations[7], and for the non-local gas hierarchy of equations.[8] [In Refs. 6 and 7 the equation obtained by Hunter and Saxton in SIAM J. Appl. Math. **51**, 1498 (1991) was erroneously named, by the present author, Hunter-Zheng. We sincerely apologize to the authors about this mistake.] In these works we have as a main characteristic of a hierarchy of integrable equations with positive and negative flows. Also, throughout this paper the calculations involving pseudodifferential operators were performed or checked by the computer algebra program PSEUDO.[9]

II. BI-HAMILTONIAN STRUCTURE

Following Ref. 7 let us introduce

$$F^2 \equiv 1 + u_x^2, \quad A \equiv \frac{u_x}{F}, \tag{4}$$

which satisfy the following useful properties:

$$F^2(1 - A^2) = 1,$$

$$\frac{F_x}{F^3} = AA_x, \tag{5}$$

$$\frac{u_{xx}}{F^3} = A_x.$$

Using (4) the SP equation (2) assumes the forms

$$\begin{aligned} F_t &= \left(\tfrac{1}{2}u^2F\right)_x, \\ A_t &= \frac{u}{F} + \frac{1}{2}u^2A_x, \end{aligned} \tag{6}$$

and, similarly, the EB equation (3) can be written in one of the forms

$$u_t = A_{xx},$$

$$F_t = AA_{xxx}, \tag{7}$$

$$A_t = \frac{A_{xxx}}{F^3}.$$

Let us stress that the basic field is u and that A and F are just place holders used to make expressions more compact. Also, it is interesting to observe that the EB equation when written in the form (7) has the same structural form of the deformed Harry Dym equation studied in Ref. 7, however, the definitions in (4) are different.

From (6) and (7) it is straightforward to note that

$$H_0 = -\int \mathrm{d}x\, F, \tag{8}$$

is conserved under both the SP and EB flows.

Introducing the Clebsch potential

$$u = \phi_x, \tag{9}$$

the equation (2) can be written as

$$\phi_t = (\partial^{-1}\phi) + \tfrac{1}{6}\phi_x^3. \tag{10}$$

This equation (10) can be obtained from a variational principle, $\delta\int \mathrm{d}t\,\mathrm{d}x\,\mathcal{L}$, with the Lagrangian density

$$\mathcal{L} = \tfrac{1}{2}\phi_t\phi_x - \tfrac{1}{24}\phi_x^4 + \tfrac{1}{2}\phi^2. \tag{11}$$

This is a first order Lagrangian density and, consequently, the Hamiltonian structure can be readily read out, or we can use, for example, Dirac's theory of constraints[10] to obtain the Hamiltonian and the Hamiltonian operator associated with (11). The Lagrangian is degenerate and the primary constraint is obtained to be

$$\Phi = \pi - \tfrac{1}{2}\phi_x, \tag{12}$$

where $\pi = \partial\mathcal{L}/\partial\phi_t$ is the canonical momentum. The total Hamiltonian can be written as

$$H_T = \int \mathrm{d}x(\pi\phi_t - \mathcal{L} + \lambda\Phi) = \int \mathrm{d}x\Big[\tfrac{1}{24}\phi_x^4 - \tfrac{1}{2}\phi^2 + \lambda\Big(\pi - \tfrac{1}{2}\phi_x\Big)\Big], \tag{13}$$

where λ is a Lagrange multiplier field. Using the canonical Poisson bracket relation

$$\{\phi(x), \pi(y)\} = \delta(x-y), \tag{14}$$

with all others vanishing, it follows that the requirement of the primary constraint to be stationary under time evolution,

$$\{\Phi(x), H_T\} = 0,$$

determines the Lagrange multiplier field λ in (13) and the system has no further constraints.

Using the canonical Poisson bracket relations (14), we can now calculate

$$K(x,y) \equiv \{\Phi(x), \Phi(y)\} = \tfrac{1}{2}\partial_y\delta(y-x) - \tfrac{1}{2}\partial_x\delta(x-y). \tag{15}$$

This shows that the constraint (12) is second class and that the Dirac bracket between the basic variables has the form

$$\{\phi(x), \phi(y)\}_D = \{\phi(x), \phi(y)\} - \int \mathrm{d}z\,\mathrm{d}z'\{\phi(x), \Phi(z)\}J(z,z')\{\Phi(z'), \phi(y)\} = J(x,y),$$

where J is the inverse of the Poisson bracket of the constraint (15),

$$\int \mathrm{d}z\, K(x,z)J(x,y) = \delta(x-y).$$

This last relation determines

$$\partial_x J(x,y) = -\delta(x-y)$$

or

$$J(x,y) = \mathcal{D}\delta(x-y),$$

where

$$\mathcal{D} = -\partial^{-1}, \tag{16}$$

and can be thought of as the alternating step function in the coordinate space. We can now set the constraint (12) strongly to zero in (13) to obtain

$$H_T = \int \mathrm{d}x\left(\tfrac{1}{24}\phi_x^4 - \tfrac{1}{2}\phi^2\right). \tag{17}$$

Using (9) and the transformation properties of Hamiltonian operators,[11] we get

$$\mathcal{D}_1 = \partial(\mathcal{D})(\partial)^* = \partial, \tag{18}$$

and the SP equation (2) can be written in the Hamiltonian form as

$$u_t = \mathcal{D}_1 \frac{\partial H_2}{\delta u},$$

with H_2 given by

$$H_2 = \int \mathrm{d}x\left[\frac{1}{24}u^4 - \frac{1}{2}(\partial^{-1}u)^2\right], \tag{19}$$

which can be easily checked to be conserved by both the SP and EB equations.

We will show that the SP and EB equations belong to the same hierarchy of equations, at this point we note that

$$u_t = \mathcal{D}_1 \frac{\delta H_0}{\delta u},$$

with H_0 given by (8), yields the EB equation (3).

It is easy to show that the charges

$$H_{-1} = \frac{1}{2}\int \mathrm{d}x\, FA_x^2, \tag{20}$$

$$H_1 = \frac{1}{2}\int \mathrm{d}x\, u^2 \tag{21}$$

are also conserved by both the SP and EB equations. Therefore, the SP equation (2) can be written in the Hamiltonian form as

$$u_t = \mathcal{D}_2 \frac{\delta H_1}{\delta u},$$

and the EB equation (3) as

$$u_t = \mathcal{D}_2 \frac{\delta H_{-1}}{\delta u},$$

where we have defined

$$\mathcal{D}_2 = \partial^{-1} + u_x \partial^{-1} u_x = (F^2 - u_x \partial^{-1} u_{xx}) \partial^{-1}. \tag{22}$$

The skew symmetry of this Hamiltonian structure is manifest. The proof of the Jacobi identity for this structure as well its compatibility with (18) can be shown through the standard method of prolongation[12] which we describe briefly.

We can construct the two bivectors associated with the two structures as

$$\Theta_{\mathcal{D}_1} = \frac{1}{2} \int \mathrm{d}x \{\theta \wedge \mathcal{D}_1 \theta\} = \frac{1}{2} \int \mathrm{d}x \theta \wedge \theta_x,$$

$$\Theta_{\mathcal{D}_2} = \frac{1}{2} \int \mathrm{d}x \{\theta \wedge \mathcal{D}_2 \theta\} = \frac{1}{2} \int \mathrm{d}x \{\theta \wedge (\partial^{-1}\theta) + u_x \theta \wedge (\partial^{-1} u_x \theta)\}.$$

Using the prolongation relations,

$$\mathbf{pr}\, \vec{v}_{\mathcal{D}_1 \theta}(u) = \theta_x,$$

$$\mathbf{pr}\, \vec{v}_{\mathcal{D}_2 \theta}(u) = (\partial^{-1}\theta) + u_x (\partial^{-1} u_x \theta), \tag{23}$$

$$\mathbf{pr}\, \vec{v}_{\mathcal{D}_2 \theta}(u_x) = (\mathbf{pr}\, \vec{v}_{\mathcal{D}_2 \theta}(u))_x,$$

it is straightforward to show that the prolongation of the bivector $\Theta_{\mathcal{D}_2}$ vanishes,

$$\mathbf{pr}\, \vec{v}_{\mathcal{D}_2 \theta}(\Theta_{\mathcal{D}_2}) = 0,$$

implying that $\mathcal{D}_2$ satisfies the Jacobi identity. Using (23), it also follows that

$$\mathbf{pr}\, \vec{v}_{\mathcal{D}_1 \theta}(\Theta_{\mathcal{D}_2}) + \mathbf{pr}\, \vec{v}_{\mathcal{D}_2 \theta}(\Theta_{\mathcal{D}_1}) = 0,$$

showing that $\mathcal{D}_1$ and $\mathcal{D}_2$ are compatible. Namely, not only are $\mathcal{D}_1, \mathcal{D}_2$ genuine Hamiltonian structures, any arbitrary linear combination of them is as well. As a result, the dynamical equations (2) and (3) are bi-Hamiltonian with the same compatible Hamiltonian structures and, consequently, are integrable.[12,13]

III. THE SHORT PULSE HIERARCHY

When a system is bi-Hamiltonian, we can naturally define a hierarchy of commuting flows through the relation

$$u_{t_n} = K_n[u] = \mathcal{D}_1 \frac{\delta H_{n+1}}{\delta u} = \mathcal{D}_2 \frac{\delta H_n}{\delta u}, \quad n = \ldots, -2, -1, 0, 1, 2, \ldots . \tag{24}$$

For $n=1$ and $n=-1$ we get the SP and EB equations, respectively. For $n=0$ we have

$$K_0 = \mathcal{D}_1 \frac{\delta H_1}{\delta u} = (\partial u) = u_x$$

and

$$\begin{aligned} K_0 &= \mathcal{D}_2 \frac{\delta H_0}{\delta u} = ((F^2 - u_x \partial^{-1} u_{xx}) \partial^{-1} A_x) \\ &= (F^2 A - u_x \partial^{-1} u_{xx} A) = F u_x - u_x F = 0, \end{aligned} \tag{25}$$

where we have used (5), i.e., $F^2 A = F u_x$ and $u_{xx} A = F_x$. Therefore, we would be lead to conclude that H_0 is a Casimir of $\mathcal{D}_2$. We can resolve this apparent contradiction being careful while per-

forming calculations with the antiderivative ∂^{-1}. We can use the following representation:

$$(\partial_x^{-1} f) \equiv (\partial^{-1} f)(x) = \int_{-\infty}^{+\infty} \mathrm{d}y\, \epsilon(x-y) f(y),$$

where

$$\epsilon(x-y) = \begin{cases} 1/2 & \text{for } x > y, \\ -1/2 & \text{for } x < y. \end{cases}$$

Then, it can be shown that

$$(\partial_x^{-1} f_x) = f - \tfrac{1}{2}(f(+\infty) + f(-\infty)). \tag{26}$$

Now, if we assume $u^{(n)} \to 0$ as $|x| \to \infty$ (which yields $A|_{\pm\infty} = 0$ and $F|_{\pm\infty} = 1$) then it follows:

$$(\partial^{-1} A_x) = A \quad \text{and} \quad (\partial^{-1} F_x) = F - 1. \tag{27}$$

Using this last result in the naive calculation (25) we obtain the desired term u_x. This sort of missing or "ghost" terms given rise to apparent contradictions in nonlocal theories were already observed in the literature (see Ref. 14 and references therein).

Let us introduce the recursion operator following from the two Hamiltonian structures as:

$$R = \mathcal{D}_2 \mathcal{D}_1^{-1}. \tag{28}$$

Then, it follows from (24) that

$$\frac{\delta H_{n+1}}{\delta u} = R^{\dagger} \frac{\delta H_n}{\delta u}, \quad n = 0, 1, 2, \ldots, \tag{29}$$

where

$$R^{\dagger} = \partial^{-2} + \partial^{-1} u_x \partial^{-1} u_x = \partial^{-2}(F^2 + u_{xx} \partial^{-1} u_x) \tag{30}$$

is the adjoint of R. The conserved charges for the hierarchy can, of course, be determined recursively from (29) and give the infinite set of (nonlocal) conserved Hamiltonians

$$\begin{aligned} H_0 &= -\int \mathrm{d}x\, F, \\ H_1 &= \frac{1}{2} \int \mathrm{d}x\, u^2, \\ H_2 &= \int \mathrm{d}x \left[\tfrac{1}{24} u^4 - \tfrac{1}{2} (\partial^{-1} u)^2 \right], \\ H_3 &= \int \mathrm{d}x \left[\tfrac{1}{720} u^6 + \tfrac{1}{2} (\partial^{-1} u)^2 + \tfrac{1}{6} (\partial^{-2} u^3) u - \tfrac{1}{4} (\partial^{-1} u)^2 u^2 \right], \\ &\ldots . \end{aligned} \tag{31}$$

The corresponding flows (the first few, since the equations become extremely nonlocal as we proceed further in the recursion) have the forms

$$u_{t_0} = u_x,$$

$$u_{t_1} = (\partial^{-1}u) + \tfrac{1}{2}u^2 u_x,$$
$$u_{t_2} = (\partial^{-3}u) + \tfrac{1}{6}(\partial^{-1}u^3) + u_x(\partial^{-1}(u_x(\partial^{-2}u))) + \tfrac{1}{24}u^4 u_x, \tag{32}$$
$$\cdots .$$

For negative values of n, the gradients of the Hamiltonians will satisfy the recursion[9]

$$\frac{\delta H_n}{\delta u} = (R^\dagger)^{-1}\frac{\delta H_{n+1}}{\delta u}, \quad n = -1, -2, \ldots . \tag{33}$$

Writing the recursion operator (28) in the form

$$R = (F^2 - u_x\partial^{-1}u_{xx})\partial^{-2}, \tag{34}$$

and using the identities (5) the inverse can be easily checked to be

$$R^{-1} = \partial^2\left(\frac{1}{F^2} + A\partial^{-1}A_x\right) = \partial^2\frac{1}{u_{xx}}\partial F\partial^{-1}\frac{u_{xx}}{F^3}. \tag{35}$$

Note that (35) can be recognized as the recursion operator obtained in Ref. 3 for the SP equation in the form (1) using cyclic basis techniques. The corresponding conserved charges can now be recursively constructed from (33) and have the forms

$$H_{-1} = \frac{1}{2}\int \mathrm{d}x\, FA_x^2,$$
$$H_{-2} = \frac{1}{8}\int \mathrm{d}x\left(FA_x^4 - 4\frac{A_{xx}^2}{F}\right),$$
$$H_{-3} = \frac{1}{16}\int \mathrm{d}x\left(FA_x^6 + 8\frac{AA_{xx}^3}{F} - 12\frac{A_x^2A_{xx}^2}{F} + 8\frac{A_{xxx}^2}{F^3}\right), \tag{36}$$
$$\cdots .$$

The corresponding flows (the first few) have the forms

$$u_{t_{-1}} = A_{xx},$$
$$u_{t_{-2}} = \left(\frac{A_{xx}}{F^2} + \frac{1}{2}A_x^2A\right)_{xx},$$
$$u_{t_3} = \left(\frac{A_{xxxx}}{F^4} + \frac{1}{2}\frac{A_x^2A_{xx}}{F^2} - 2\frac{A_{xxx}A_xA}{F^2} - \frac{3}{2}\frac{A_{xx}^2A}{F^2} - A_{xx}A_x^2A^2 + \frac{3}{8}A_x^4A\right)_{xx}, \tag{37}$$

IV. THE LAX REPRESENTATION

$\cdots$.

Conserved charges for our systems can be determined in principle recursively from (29) and (33). However, to construct the conserved charges directly we look for a Lax representation for the system of SP and EB equations.

It is well known[15,16] that for a bi-Hamiltonian system of evolution equations, $u_{t_n} = K_n[u]$, a natural Lax description

$$\frac{\partial M}{\partial t_n} = [B, M],$$

is easily obtained where, we can identify

$$M \equiv R,$$

$$B \equiv K_n'.$$

Here R is the recursion operator (34) and K_n' represents the Fréchet derivative of K_n, defined by

$$K_n'[u]v = \frac{d}{d\epsilon} K_n [u + \epsilon v]|_{\epsilon=0}.$$

For the SP and EB system of equations in (2) and (3), respectively, we have

$$B^{\mathrm{SP}} \equiv K_1' = \partial^{-1} + \tfrac{1}{2}\partial u^2,$$

$$B^{\mathrm{EB}} \equiv K_{-1}' = \partial^2 F^{-3} \partial.$$

The two systems have the same $M=R$ given in (28). It can now be checked that

$$\begin{aligned} \frac{\partial M}{\partial t} &= [B^{\mathrm{SP}}, M], \\ \frac{\partial M}{\partial t} &= [B^{\mathrm{EP}}, M], \end{aligned} \tag{38}$$

do indeed generate the SP and the EB equations and, thereby, provide a Lax pair for the system.

A Lax representation directly gives the conserved charges of the system. From the structure of (38), it follows that $\mathrm{Tr}\, M^{(2n+1)/2}$ are conserved, where "Tr" represents the Adler's trace.[17] We note that

$$\begin{aligned} \mathrm{Tr}\, M^{(2n+1)/2} &= 0, \quad n \geqslant 1, \\ \mathrm{Tr}\, M^{1/2} &= \int \mathrm{d}x\, F, \\ \mathrm{Tr}\, M^{-1/2} &= \frac{1}{2} \int \mathrm{d}x\, F A_x^2, \\ \mathrm{Tr}\, M^{-3/2} &= \frac{3}{8} \int \mathrm{d}x \left(F A_x^2 - 4 \frac{A_{xx}^2}{F} \right), \\ &\cdots . \end{aligned} \tag{39}$$

These charges correspond (up to multiplicative constants) to the ones given in (36), constructed earlier by recursion. In fact, all H_{-n} with positive $n \geqslant 0$ can be constructed from $\mathrm{Tr}\, M^{-(2n-1)/2}$ and by construction [namely, because of the nature of (38)], they are conserved under both the SP and EB flows. However, as is clear from (39), this procedure does not yield the nonlocal charges H_n with positive integer values. The construction of these nonlocal charges relies primarily on the recursion relation (29). As in our papers[6–8] it remains an interesting question to construct these charges in a more direct manner.

We can also obtain a Lax representation, in a Gelfand-Dikii form, for the EB hierarchy of equations, in a straightforward way. It is well known (see Refs. 7 and 18 and references therein) that the recursion operator defines a eigenvalue problem of the type

$$(1-\lambda R^{\dagger})\phi=0, \tag{40}$$

for the eigenfunction ϕ with eigenvalue $1/\lambda$. Since we know the inverse of the recursion operator we obtain from (40),

$$[(R^{\dagger})^{-1}-\lambda]\phi=0, \tag{41}$$

which defines a Lax eigenvalue problem. Using (35) we identify the Lax operator for our system to be

$$L\equiv(R^{\dagger})^{-1}=\frac{1}{F}\partial\frac{1}{F}\partial+A_x\partial^{-1}A_x\partial.$$

It can be readily checked that the hierarchy of EB equations (37) (up to multiplicative constants) can be obtained from the nonstandard Lax equation,

$$\frac{\partial L}{\partial t_{-n}}=[(L^{(2n+1)/2})_{\geqslant 2},L], \quad n=1,2,3,\ldots .$$

The conserved quantities (36) and H_0 in (31) for this system (up to multiplicative constants) can be obtained from $\mathrm{Tr}\,L^{(2n-1)/2}$, $n=0,1,2,\ldots$.

V. CONCLUSION

In this paper, the short pulse and elastic beam equations were shown to belong to the same hierarchy corresponding to positive and negative flows. We have shown that these systems are bi-Hamiltonian and using recursion we construct infinite series of both local and nonlocal conserved charges as well as the respective hierarchy of equations. A Lax pair for the short pulse and elastic beam equations was derived. The Lax operator yielded the local charges via Adler's trace, however, the construction of the nonlocal charges through this Lax operator is unknown by us. Also, a nonstandard Lax representation in a Gelfand-Dikii form for the elastic-beam hierarchy of equation was described.

Representations of the q-deformed algebras $U_q(so_3)$ and $U_q(so_5)$ and q-orthogonal polynomials

Alexander Rozenblyum
Mathematics Department, New York City College of Technology, City University of New York, Brooklyn, New York 11201

(Received 3 June 2005; accepted 28 October 2005; published online 29 December 2005)

Orthogonal polynomials related to irreducible representations of the classical type of the q-deformed algebras $U_q(so_3)$ and $U_q(so_5)$ are investigated. The main method consists in the diagonalization of corresponding infinitesimal operators (generators) of representations. For the algebra $U_q(so_3)$ this method leads to q-analogs of Krawtchouk polynomials. The properties of these polynomials are considered, the q-difference equation, the recurrence and explicit formulas. For the algebra $U_q(so_5)$, the diagonalization process of generators of representations leads to the connection with some class of orthogonal polynomials in two discrete variables. These variables are the so-called q-numbers $[n]$, where $[n]=(q^n-q^{-n})/(q-q^{-1})$. The introduced polynomials can be considered as two-dimensional q-analogs of Krawtchouk polynomials. The q-difference equation of the Sturm-Liouville type for these polynomials is constructed. The corresponding eigenvalues are investigated including the explicit formulas for their multiplicities. The structure of polynomial solutions is described. © *2005 American Institute of Physics.*

I. INTRODUCTION

It is well known that representation theory of the group SO(3) of the rotations in three-dimensional Euclidean space relates to different types of classical special functions including Jacobi, Krawtchouk, and Meixner polynomials (see, for example, Refs. 1–3). It is shown in Ref. 4 that representations of the group SO(n) for $n \geqslant 5$ (and other high-dimensional groups) lead to orthogonal polynomials in many discrete and continuous variables. In particular, representations of the group SO(5) are related to orthogonal polynomials in two variables that can be considered as two-dimensional analogs of the Krawtchouk and Hermite polynomials.

The aim of the present paper is to describe in a similar manner the relations between the representations of the q-deformed algebras $U_q(so_3)$ and $U_q(so_5)$ and some classes of orthogonal polynomials in one and two discrete variables. As for the classical groups SO(n) and U(n), studied in Refs. 4 and 5, the main method consists in the diagonalization of corresponding infinitesimal operators (generators) of representations. To do this, we construct the realization of representation space as the space of polynomials in q-numbers $[n]$. Orthogonal polynomials we consider here relate to eigenvectors of generators of representation and can be treated as one- and two-dimensional q-analogs of Krawtchouk polynomials. The results obtained for the group $U_q(so_3)$ allow the construction in explicit form of the matrix of the operator connecting the bases in which two generators of a representation are diagonal.

II. REPRESENTATIONS OF THE ALGEBRA $U_q(SO_3)$ AND q-KRAWTCHOUK POLYNOMIALS

Algebra $U_q(so_3)$ is the q-deformation of the universal enveloping algebra $U(so_3)$. Algebra $U_q(so_3)$ and its irreducible representations of the classical type (i.e., representations that are

q-deformations of irreducible representations of the algebra so_3) were constructed in Ref. 6. It contains (similar to the algebra so_3) three generators J^q_{12}, J^q_{23}, and J^q_{13} that satisfy the relations:

$$[J^q_{12},J^q_{23}]_q \equiv q^{1/2}\cdot J^q_{12}\cdot J^q_{23} - q^{-1/2}\cdot J^q_{23}\cdot J^q_{12} = J^q_{13},$$

$$[J^q_{23},J^q_{13}]_q = J^q_{12}, \quad [J^q_{13},J^q_{12}]_q = J^q_{23}.$$

Let T be an irreducible representation of the algebra $U_q(so_3)$. Then T is defined by a non-negative integer or a half-integer l (the highest weight of the representation). The representation space V contains the basis $\{\xi_m\}$, $m=-l,\ldots,l$, in which the operators $I^q_{jk}=T(J^q_{jk})$ act by the formulas

$$I^q_{12}\xi_m = i[m]\xi_m, \quad i=\sqrt{-1}, \quad m=-l,\ldots,l,$$

$$I^q_{13}\xi_m = iq^{1/2}(q^m A(m)\xi_{m+1} + q^{-m}A(m-1)\xi_{m-1}),$$

$$I^q_{23}\xi_m = A(m)\xi_{m+1} - A(m-1)\xi_{m-1}, \tag{1}$$

where

$$A(m) = \left(\frac{[m][m+1]}{[2m][2m+2]}[l-m][l+m+1]\right)^{1/2}. \tag{2}$$

Here the q-numbers $[n]$ are defined as

$$[n] = (q^n - q^{-n})/(q-q^{-1}) = \frac{\sinh(n\ln q)}{\sinh(\ln q)}.$$

If $k=0$, we assume that $[2k]/[k]=2$.

The basis $\{\xi_m\}$ consists of the eigenvectors of the operator I^q_{12}. Similarly, one can consider another basis in representation space V consisting of the eigenvectors of the operator I^q_{23}. We will construct the matrix connecting these two bases, i.e., we will diagonalize the operator I^q_{23}. The method used is similar to the one developed for the classical groups $SO(n)$ and $U(n)$ (Refs. 4 and 5) and is based on the realization of the representation space as a space of polynomial functions of a discrete variable. This approach leads to a class of orthogonal polynomials that can be considered as q-analogs of the Krawtchouk polynomials.[7,8] We will assume that the highest weight l of the representation T is a non-negative integer.

Let L be the space of all complex-valued functions defined on the lattice $[-l,l]$. Then $\dim L=2l+1$, and L is isomorphic to the representation space V. This isomorphism allows treating vectors from V as functions of a discrete variable m that runs through the lattice $[-l,l]$. It follows from (1) that operator I^q_{23} acts in the space L by the formula

$$(I^q_{23}f)(m) = -A(m)f(m+1) + A(m-1)f(m-1), \quad f\in L. \tag{3}$$

Let $\widetilde{P}(m)$ be an eigenfunction of the operator I^q_{23} in the space L with the eigenvalue μ,

$$(I^q_{23}\widetilde{P})(m) = \mu\cdot\widetilde{P}(m), \quad m=-l,\ldots,l. \tag{4}$$

Let us make the following substitutions in Eq. (4):

$$\widetilde{P}(m) = i^m\sqrt{\rho(m)}P(m), \tag{5}$$

where

$$\rho(m) = \frac{[2m]}{[m]}\frac{1}{[l-m]![l+m]!}, \tag{6}$$

$$[n]! = [n][n-1]\dots[2][1], \quad [0]! = 1.$$

Below we will also use the notations

$$[2n]!! = [2n][2n-2]\dots[2], \quad [2n-1]!! = [2n-1][2n-3]\dots[1].$$

The substitution (5) is equivalent to replacing the operator I_{23}^q with the operator

$$J = A^{-1} I_{23}^q A,$$

where A is the multiplication operator, $(Af)(m) = i^m \sqrt{\rho(m)} f(m)$.

Then the function $P(m)$ satisfies the equation $(JP)(m) = \mu \cdot P(m)$. Using (3) and (2), this equation can be written as

$$\frac{[m]}{[2m]}\{[l-m]P(m+1) + [l+m]P(m-1)\} = \lambda P(m), \quad \lambda = \mu i, \tag{7}$$

or

$$\frac{1}{(q^m + q^{-m})(q - q^{-1})}\{(q^{l-m} - q^{-l+m})P(m+1) + (q^{l+m} - q^{-l-m})P(m-1)\} = \lambda P(m).$$

Let us denote by A_q the operator from the left-hand part of Eq. (7),

$$(A_q f)(m) = \frac{[m]}{[2m]}\{[l-m]f(m+1) + [l+m]f(m-1)\}.$$

The following statement can be proved.

Proposition 1: For any $n = 0, 1, \dots$,

$$A_q([m]^n) = [l-n][m]^n + Q_{n-2}([m]),$$

where $Q_{n-2}(t)$ is a polynomial of t of the degree $n-2$, $n \geqslant 2$; $Q_{-1}(t) \equiv Q_{-2}(t) \equiv 0$.

It follows from Proposition 1 that the operator A_q acts in the space $\mathrm{P}\{[m]\}$ of all polynomials of $[m]$, and has in this space the eigenvalues of the form

$$\lambda = \lambda_n = [l-n] = \frac{q^{l-n} - q^{-l+n}}{q - q^{-1}}, \quad n = 0, 1, \dots .$$

Accordingly, the operator I_{23}^q is diagonalizable in the representation space V and has eigenvalues,

$$\mu = \mu_n = i[n-l] = i\frac{q^{n-l} - q^{-n+l}}{q - q^{-1}}, \quad n = 0, 1, \dots, 2l.$$

Proposition 1 allows one to realize the representation space V as the set of all polynomials in $[m]$, defined on the lattice $[-l, l]$. This realization shows that Eq. (7) has polynomial solutions. More exactly, the following statement is true:

Proposition 2: For any $n = 0, 1, \dots$, the equation

$$[l-m]P(m+1) + [l+m]P(m-1) = \frac{[2m]}{[m]}[l-n]P(m) \tag{8}$$

has a solution $P_n(m)$ which is a polynomial of $[m]$ of the degree n.

If we let $q \to 1$, then Eq. (8) is transformed into the following:

$$(l-m)P(m+1)+(l+m)P(m-1)=2(l-n)P(m).$$

This equation describes the Krawtchouk polynomials.[7] It relates to eigenvectors of the generator of representation of the group SO(3).[4] We can treat the solutions of Eq. (8) as q-analogs of the Krawtchouk polynomials.

Similar to the classical case, Eq. (8) can be written in terms of finite differences,

$$[l+m]\Delta\,\nabla\,P(m)-\frac{[2l]}{[l]}[m]\Delta P(m)=\frac{[2m]}{[m]}\{[l-n]-[l]\}P(m),$$

where $(\Delta f)(m)=f(m+1)-f(m)$, $(\nabla f)(m)=f(m)-f(m-1)$.

Equation (8) can also be written in self-adjoint form

$$\frac{[m]}{[2m]}[l-m]![l+m]!\Delta\left\{\frac{1}{[l-m]![l+m-1]!}\,\nabla\,P(m)\right\}=\{[l-n]-[l]\}P(m).$$

The following theorem can be proved.

Theorem 1: Solutions of Eq. (8) are described by the formula

$$P_n(m)=\sum_{k=0}^{n}(-1)^k\frac{[n]![l-m]![l+m]!}{[k]![n-k]![l-m-k]![l+m-n+k]!}$$
$$=a_n[m]^n+\ldots,\quad n=0,1,\ldots\ . \tag{9}$$

The leading coefficient a_n of the polynomial $P_n(m)$ is

$$a_n=\frac{[2l]}{[l]}\frac{[2l-2]}{[l-1]}\cdots\frac{[2l-2n+2]}{[l-n+1]}=\prod_{k=0}^{n-1}(q^{l-k}+q^{-l+k}).$$

Formula (9) can also be written in the following symbolic form. Denote

$$r=[m+l],\quad s=[m-l].$$

Define the symbolic powers

$$r^{(k)}=[m+l][m+l-1]\cdots[m+l-k+1],\quad r^{(0)}=1,$$

$$s^{(k)}=[m-l][m-l+1]\cdots[m-l+k-1],\quad s^{(0)}=1.$$

Then

$$P_n(m)=(r+s)^{(n)}=\sum_{k=0}^{n}\begin{bmatrix}n\\k\end{bmatrix}r^{(k)}s^{(n-k)},$$

where $\left[\begin{smallmatrix}n\\k\end{smallmatrix}\right]$ are q-binomial coefficients,

$$\begin{bmatrix}n\\k\end{bmatrix}=\frac{[n]!}{[k]![n-k]!}.$$

Here are some examples of polynomials $P_n(m)$,

$$P_0(m)\equiv 1,\quad P_1(m)=[m+l]+[m-l]=\frac{[2l]}{[l]}[m],$$

$$P_2(m) = [m+l][m+l-1] + [2][m+l][m-l] + [m-l][m-l+1]$$
$$= \frac{[2l][2l-2]}{[l][l-1]}[m]^2 - [2l],$$

$$P_3(m) = [m+l][m+l-1][m+l-2] + [3][m+l][m+l-1][m-l]$$
$$+ [3][m+l][m-l][m-l+1] + [m-l][m-l+1][m-l+2]$$
$$= \frac{[2l][2l-2][2l-4]}{[l][l-1][l-2]}[m]^3 - \frac{[2l][2l-2]}{[l][l-1]}\{[l+1] + 2[l-1]\}[m].$$

Below is a list of some properties of polynomials $P_n(m)$.

Proposition 3: Polynomials $P_n(m)$ defined in (9), satisfy the recurrence relation

$$P_{n+1}(m) = \frac{[2l-2n]}{[l-n]}[m]P_n(m) - [n][2l-n+1]P_{n-1}(m), \quad n = 0,1,\ldots; \quad P_{-1}(m) \equiv 0.$$

Proposition 4: Polynomials $P_n(m)$ are orthogonal on the lattice $[-l,l]$ with the weight (6),

$$\sum_{m=-l}^{l} P_n(m)P_k(m)\rho(m) = 0 \quad \text{if } n \neq k.$$

Proposition 5: The norm of the polynomial $P_0(m) \equiv 1$ is equal to

$$\|P_0\| = \left(\sum_{m=-l}^{l} \frac{[2m]}{[m]} \frac{1}{[l-m]![l+m]!}\right)^{1/2} = \frac{2[2l]!!}{[l]!}\sqrt{\frac{[l]}{[2l][2l]!}}. \tag{10}$$

Formula (10) can be derived from the following formula for the sum of q-binomial coefficients:

$$\sum_{k=0}^{n} \frac{[n]!}{[k]![n-k]!} = \prod_{k=1}^{n} \frac{[n+1-2k]}{[(n+1-2k)/2]} = \prod_{k=1}^{n} (1 + q^{2k-n-1}). \tag{11}$$

Formula (11) can also be represented in the form

$$\sum_{k=0}^{n} \frac{[n]!}{[k]![n-k]!} = \begin{cases} 2\left(\dfrac{[n-1]!!}{[(n-1)/2]!}\right)^2 & \text{if } n \text{ is odd,} \\ \left(\dfrac{[n-1]!!}{[1/2][3/2]\ldots[(n-1)/2]}\right)^2 & \text{if } n \text{ is even.} \end{cases}$$

Propositions 3 and 5 allow to calculate the norm of the polynomial $P_n(m)$ for arbitrary n.

Proposition 6: The norm of the polynomial $P_n(m)$ defined in (9), is equal to

$$\|P_n\| = \frac{2[2l]!!}{[l]!}\sqrt{\frac{[l-n]}{[2l-2n]}\frac{[n]!}{[2l-n]!}}, \quad n = 0,1,\ldots,2l.$$

Proposition 7: "Middle" polynomials $P_l(m)$ can also be represented by the formula

$$P_l(m) = \frac{[2l]!!}{[l]!}\prod_{k=1}^{l}[m-l-1+2k], \quad \|P_l\| = \frac{[2l]!!\sqrt{2}}{[l]!}.$$

Proposition 8: Polynomial $P_n(m)$ has the same parity as its power n,

$$P_n(-m) = (-1)^n P_n(m).$$

Proposition 9: Normalized polynomials $P_n(m)$ have the properties

$$P_{2l-n}(m) = (-1)^{l+m} P_n(m),$$

$$P_{l+m}(n-l) = (-1)^{l+m+n} \sqrt{\frac{\rho(m)}{\rho(n-l)}} P_n(m),$$

$$m = -l, \ldots, l; \quad n = 0, 1, \ldots, 2l; \quad \rho(m) \text{ is defined in (6)}.$$

Propositions 8 and 9 allow to reduce the calculation of polynomials $P_n(m)$ to the values of n and m from 0 to l such that $n \leqslant m$.

Consider the $(2l+1)\times(2l+1)$ matrix P^{norm}, consisting (in columns) of the normalized polynomials $P_n(m)$,

$$P^{\text{norm}} = \begin{pmatrix} P_0(-l) & P_1(-l) & \cdots & P_{2l}(-l) \\ P_0(-l+1) & P_1(-l+1) & \cdots & P_{2l}(-l+1) \\ & & \cdots & \\ P_0(l) & P_1(l) & \cdots & P_{2l}(l) \end{pmatrix}.$$

Then the first column of the matrix P^{norm} consists of elements

$$P_0(m) \equiv \frac{[l]!}{2[2l]!!} \sqrt{\frac{[2l][2l]!}{[l]}}, \quad m = -l, \ldots, l.$$

The middle column consists of elements

$$P_l(m) = \frac{\sqrt{2}}{2} \prod_{k=1}^{l} [m - l + 2k - 1]$$

$$= \begin{cases} (-1)^{(l-m)/2} \dfrac{\sqrt{2}}{2} [l-m-1]!![l+m-1]!! & \text{if } l-m \text{ is even}, \\ 0 & \text{if } l-m \text{ is odd}. \end{cases}$$

Here $m = -l, \ldots, l$; $[-1]!! = 1$.

The last column consists of elements

$$P_{2l}(m) = (-1)^{l+m} \frac{[l]!}{2[2l]!!} \sqrt{\frac{[2l][2l]!}{[l]}}, \quad m = -l, \ldots, l.$$

The first row consists of elements

$$P_n(-l) = (-1)^n \frac{[l]![2l-1]!!}{2} \sqrt{\frac{[2l-2n]}{[l-n]} \frac{1}{[n]![2l-n]!}}, \quad n = 0, 1, \ldots, 2l.$$

The middle row consists of elements

$$P_n(0) = \begin{cases} (-1)^{n/2} \dfrac{[n-1]!![l]!}{2[2l-n]!!} \sqrt{\dfrac{[2l-2n]}{[l-n]} \dfrac{[2l-n]!}{[n]!}} & \text{if } n \text{ is even}, \\ 0 & \text{if } n \text{ is odd}. \end{cases}$$

The last row consists of elements

$$P_n(l) = \frac{[l]![2l-1]!!}{2}\sqrt{\frac{[2l-2n]}{[l-n]}\frac{1}{[n]![2l-n]!}}, \quad n = 0,1,\ldots,2l.$$

If we multiply mth row ($m=-l,\ldots,l$) of the matrix P^{norm} by $i^m\sqrt{\rho(m)}$, where $\rho(m)$ is defined in (6), we will get unitary matrix $\tilde{P}$ consisting (in columns) of the orthonormal eigenvectors $\tilde{P}_0,\tilde{P}_1,\ldots,\tilde{P}_{2l}$ of the operator I_{23}^q. This matrix connects bases in which operators I_{12}^q and I_{23}^q are diagonal. Eigenvector $\tilde{P}_n$ corresponds to the eigenvalue $[n-l]i$ of the operator I_{23}^q ($n=0,1,\ldots,2l$).

Example: Let $l=2$. Then

$$I_{23}^q = \begin{pmatrix} 0 & -1 & 0 & 0 & 0 \\ 1 & 0 & -a & 0 & 0 \\ 0 & a & 0 & -a & 0 \\ 0 & 0 & a & 0 & -1 \\ 0 & 0 & 0 & 1 & 0 \end{pmatrix}, \quad a = \sqrt{\frac{[3]}{2}},$$

$$I_{12}^q = \text{diag}\{-[2]i,-i,0,i,[2]i\}.$$

We have $I_{12}^q=\tilde{P}^{-1}I_{23}^q\tilde{P}$, where $\tilde{P}$ is the unitary matrix,

$$\tilde{P} = \begin{pmatrix} b & c & -d & c & b \\ -ci & ci & 0 & -ci & ci \\ d & 0 & e & 0 & d \\ ci & ci & 0 & -ci & -ci \\ b & -c & -d & -c & b \end{pmatrix}, \quad \tilde{P}^{-1} = \tilde{P}^* = \overline{\tilde{P}^t},$$

$$b = -\frac{1}{2[2]}, \quad c = \frac{1}{2}, \quad d = \frac{\sqrt{2[3]}}{2[2]}, \quad e = -\frac{1}{[2]}.$$

III. REPRESENTATIONS OF THE ALGEBRA $U_q(\text{SO}_5)$ AND q-KRAWTCHOUK POLYNOMIALS IN TWO VARIABLES

A. Finite-difference equation related to eigenvectors of the infinitesimal operator

Algebra $U_q(\text{so}_n)$ for arbitrary n and its irreducible representations of the classical type were studied in Ref. 9. Let us rewrite corresponding formulas for $n=5$. Finite-dimensional irreducible representations of the algebra $U_q(\text{so}_5)$ are given by two integral or half-integral numbers n_1 and n_2 (highest weight), such that $n_1 \geqslant n_2 \geqslant 0$. We will consider the case of integers. The representation space V has the dimension

$$\dim V = \frac{(2n_1+3)(2n_2+1)(n_1-n_2+1)(n_1+n_2+2)}{6}.$$

The q-analog of Gel'fand-Tsetlin basis in the representation space corresponds to successive reduction of the representation of $U_q(\text{so}_5)$ to subalgebras $U_q(\text{so}_4)$, $U_q(\text{so}_3)$, and $U_q(\text{so}_2)$. The basis vectors ξ_α can be enumerated by the tableaux

$$\alpha = \begin{pmatrix} m_1 & & m_2 \\ & l & \\ & k & \end{pmatrix},$$

where the components of α are integers that satisfy the conditions

$$n_1 \geqslant m_1 \geqslant n_2 \geqslant m_2 \geqslant -n_2,$$

$$m_1 \geqslant l \geqslant m_2 \geqslant -l,$$

$$l \geqslant k \geqslant -l. \tag{12}$$

Vectors ξ_α are eigenvectors of the representation's generator $I_{1,2}$ which corresponds to the rotation in the plane (e_1, e_2) in the five-dimensional space. The corresponding eigenvalues are $\sigma_\alpha = \sigma_k = i[k]$, $k = -n_1, \ldots, n_1$.

Let $I_{4,5}$ be the generator in the representation space V corresponding to the rotation in the plane (e_4, e_5). Then the operator $I_{4,5}$ acts on the basic vector

$$\xi_\alpha = \xi\begin{pmatrix} m_1, m_2 \\ l \\ k \end{pmatrix}$$

by the formula

$$\begin{aligned} I_{4,5}\xi\begin{pmatrix} m_1, m_2 \\ l \\ k \end{pmatrix} &= I_{x,y}^{n_1,n_2,l}\xi\begin{pmatrix} m_1+1, m_2 \\ l \\ k \end{pmatrix} - I_{x-1,y}^{n_1,n_2,l}\xi\begin{pmatrix} m_1-1, m_2 \\ l \\ k \end{pmatrix} \\ &\quad + I_{y,x}^{n_1,n_2,l}\xi\begin{pmatrix} m_1, m_2+1 \\ l \\ k \end{pmatrix} - I_{y-1,x}^{n_1,n_2,l}\xi\begin{pmatrix} m_1, m_2-1 \\ l \\ k \end{pmatrix}. \end{aligned} \tag{13}$$

Here

$$x = m_1 + 1, \quad y = m_2,$$

$$I_{x,y}^{n_1,n_2,l} = \left(\frac{[x][x+1][n_1+x+2][n_1-x+1][x+n_2+1][x-n_2][x+l+1][x-l]}{[2x][2x+2][x+y][x-y][x+y+1][x-y+1]} \right)^{1/2}. \tag{14}$$

We consider the problem of diagonalization of the operator $I_{4,5}$. Obviously, the operator $I_{4,5}$ has the same eigenvalues $\sigma_k = i[k]$, $k = -n_1, \ldots, n_1$, as the operator $I_{1,2}$. It is not difficult to show that the multiplicity $\dim \sigma_k$ of the eigenvalue σ_k in the representation space V is described by the formula

$$\dim \sigma_k = \begin{cases} (n_1 - n_2 + 1)\left(n_2^2 - k^2 + \dfrac{(2n_2+1)(n_1-n_2+2)}{2} \right) & \text{if } |k| \leqslant n_2, \\ \dfrac{1}{2}(2n_2+1)(n_1-|k|+1)(n_1-|k|+2) & \text{if } n_2 < |k| \leqslant n_1. \end{cases}$$

$$k = -n_1, \ldots, n_1.$$

Let us fix the parameters l and k such that $|k| \leqslant l \leqslant n_1$ and consider the subspace $W_k^l \subset V$ spanned by the vectors

$$\xi_\alpha = \xi\begin{pmatrix} m_1, m_2 \\ l \\ k \end{pmatrix}.$$

As it is seen from inequalities (12), the parameters m_1 and m_2 run over the intervals

$$\max(n_2,l) \leqslant m_1 \leqslant n_1,$$
$$|m_2| \leqslant \min(n_2,l). \tag{15}$$

Therefore the subspace W_k^l has the dimension

$$\dim W_k^l = (n_1 - \max(n_2,l) + 1)(2\min(n_2,l) + 1).$$

For fixed l $(0 \leqslant l \leqslant n_1)$, all subspaces W_k^l $(k=-l,\ldots,l)$ are isomorphic and the representation space V is decomposed into the direct sum of the subspaces W_k^l,

$$V = \sum_{l=0}^{n_1} \sum_{k=-l}^{l} W_k^l.$$

It is obvious from (13) that all subspaces W_k^l are invariant with respect to the operator $I_{4,5}$. Therefore, the problem of diagonalization of the operator $I_{4,5}$ in the representation space V can be reduced to its diagonalization in each subspace W_k^l. Let us denote basic vectors ξ_α belonging to the subspace W_k^l by $\xi(x,y)$. Here the parameters x and y are defined in (14) and according to (15) run through the set of integer points of the rectangle

$$\Omega = \{(x,y) | -c \leqslant y \leqslant c < b \leqslant x \leqslant a\}, \tag{16}$$

where

$$a = n_1 + 1,$$
$$b = \max(n_2,l) + 1,$$
$$c = \min(n_2,l).$$

Operator $I_{4,5}$ acts in the space W_k^l by the formula

$$I_{4,5}\xi(x,y) = A_{x,y}^{a,b,c}\xi(x+1,y) - A_{x-1,y}^{a,b,c}\xi(x-1,y) + A_{y,x}^{a,b,c}\xi(x,y+1) - A_{y-1,x}^{a,b,c}\xi(x,y-1),$$

where

$$A_{x,y}^{a,b,c} = \left(\frac{[x][x+1][a-x][a+x+1][x-b+1][x+b][x-c][x+c+1]}{[2x][2x+2][x+y][x-y][x+y+1][x-y+1]} \right)^{1/2}.$$

Similar to the case of the group $U_q(\mathrm{so}_3)$, we can construct the following functional realization of the space W_k^l. Consider the space $L(\Omega)$ of all complex-valued functions in two discrete variables x and y, defined on the lattice (16). Obviously, the space $L(\Omega)$ is isomorphic to the space W_k^l, and the operator $I_{4,5}$ acts in $L(\Omega)$ by the formula

$$\forall f \in L(\Omega),$$
$$(I_{4,5}f)(x,y) = -A_{x,y}^{a,b,c}f(x+1,y) + A_{x-1,y}^{a,b,c}f(x-1,y) - A_{y,x}^{a,b,c}f(x,y+1) + A_{y-1,x}^{a,b,c}f(x,y-1).$$

Therefore, we can reduce the diagonalization problem of the operator $I_{4,5}$ to that in the space $L(\Omega)$. Let $Q \in L(\Omega)$ be an eigenfunction of the operator $I_{4,5}$ with the eigenvalue σ,

$$(I_{4,5}Q)(x,y) = \sigma \cdot Q(x,y), \quad (x,y) \in \Omega. \tag{17}$$

Let us make the following substitution in Eq. (17),

$$Q(x,y) = i^{x+y}\sqrt{\rho(x,y)}P(x,y),$$

where

$$\rho(x,y) = \frac{[2x][2y][x-y][x+y][x-c-1]![x+b-1]![b-y-1]![b+y-1]!}{[x][y][a-x]![a+x]![a-y]![a+y]![x+c]![y+c]![x-b]![c-y]!}. \tag{18}$$

Then the function $P(x,y)$ satisfies the equation

$$\frac{[x]}{[2x]}\{[a-x][x+b][x-c]P(x+1,y) + [x+a][x-b][x+c]P(x-1,y)\}$$

$$+ \frac{[y]}{[2y]}\{[a-y][y+b][c-y]P(x,y+1) + [y+a][b-y][y+c]P(x,y-1)\}$$
$$= \lambda([x]^2 - [y]^2)P(x,y), \quad \lambda = \sigma \cdot i. \tag{19}$$

This equation can also be written in terms of finite differences in self-adjoint form using the operators

$$(\Delta_x f)(x,y) = f(x+1,y) - f(x,y), (\nabla_x f)(x,y) = f(x,y) - f(x-1,y),$$

and similarly Δ_y and ∇_y. Equation (19) takes the form

$$\frac{[x]}{[2x]}\frac{[a+x]![a-x]![x-b]![x+c]!}{[x+b-1]![x-c-1]!}\Delta_x\left\{\frac{[x+b-1]![x-c-1]!}{[a+x-1]![a-x]![x-b-1]![x+c-1]!}\nabla_x P(x,y)\right\}$$
$$+ \frac{[y]}{[2y]}\frac{[a+y]![a-y]![c+y]![c-y]!}{[b+y-1]![b-y-1]!}\Delta_y\left\{\frac{[b+y-1]![b-y]!}{[a+y-1]![a-y]![c+y-1]![c-y]!}\nabla_y P(x,y)\right\}$$
$$= \mu([x]^2 - [y]^2)P(x,y), \quad \mu = \lambda - [a-b+c]. \tag{20}$$

If we let $q \to 1$ [case of the classical group SO(5)], Eq. (20) becomes

$$\frac{(a+x)!(a-x)!(x-b)!(x+c)!}{(x+b-1)!(x-c-1)!}\Delta_x\left\{\frac{(x+b-1)!(x-c-1)!}{(a+x-1)!(a-x)!(x-b-1)!(x+c-1)!}\nabla_x P(x,y)\right\}$$
$$+ \frac{(a+y)!(a-y)!(c+y)!(c-y)!}{(b+y-1)!(b-y-1)!}\Delta_y\left\{\frac{(b+y-1)!(b-y)!}{(a+y-1)!(a-y)!(c+y-1)!(c-y)!}\nabla_y P(x,y)\right\}$$
$$= 2\mu(x^2 - y^2)P(x,y). \tag{21}$$

This equation describes eigenvectors of infinitesimal operators of irreducible representations of the group SO(5). As is shown in Ref. 4, Eq. (21) can be considered as a two-dimensional analog of the equation for Krawtchouk polynomials. In turn, Eq. (20) can be treated as two-dimensional q-analog of the equation for Krawtchouk polynomials.

Let us make the following substitution in Eq. (21): $x = h^{-1}x_1$, $y = h^{-1}x_2$, where x_1 and x_2 are new variables, $h > 0$. If we let $h \to 0$, and $a, b, c \to \infty$ such that $ah^2 \to 1$, $bh \to \alpha$, $b - c \to s$, then the discrete equation (21) is transformed into the following differential equation:

$$\frac{1}{x_2^2 - x_1^2}e^{x_1^2}(x_1^2 - \alpha^2)^{-s}\frac{\partial}{\partial x_1}\left\{e^{-x_1^2}(x_1^2 - \alpha^2)^{s+1}\frac{\partial P(x_1,x_2)}{\partial x_1}\right\}$$
$$+ \frac{1}{x_1^2 - x_2^2}e^{x_2^2}(x_2^2 - \alpha^2)^{-s}\frac{\partial}{\partial x_2}\left\{e^{-x_2^2}(x_2^2 - \alpha^2)^{s+1}\frac{\partial P(x_1,x_2)}{\partial x_2}\right\} = 2\mu \cdot P(x_1,x_2). \tag{22}$$

Equation (22) can be considered as a two-dimensional analog of the equation for Hermite poly-

nomials. The explicit formulas for the complete set of polynomial solutions of Eq. (22) were found in Ref. 4.

B. Orthogonality of solutions of Eq. (19)

Let A be the operator

$$AP(x,y) = u_1(x,y)\Delta_x[v_1(x,y)\nabla_x P(x,y)] + u_2(x,y)\Delta_y[v_2(x,y)\nabla_y P(x,y)],$$

Ω be the lattice

$$\Omega = \{\alpha \leqslant x \leqslant \beta, \gamma \leqslant y \leqslant \delta\},$$

and $\rho(x,y)$ be a positive function on Ω. Consider the Euclidean space $L_\rho(\Omega)$ of all functions on Ω with the scalar product

$$(f,g) = \sum_{x=\alpha}^{\beta} \sum_{y=\gamma}^{\delta} f(x,y)g(x,y)\rho(x,y).$$

Proposition 10: Suppose that

(1) $\rho(x,y)u_1(x,y)$ does not depend on x.
(2) $\rho(x,y)u_2(x,y)$ does not depend on y.
(3) $v_1(\alpha,y) \equiv v_1(\beta+1,y) \equiv v_2(x,\gamma) \equiv v_2(x,\delta+1) \equiv 0$.

Then the operator A acts in the space $L_\rho(\Omega)$, and is self-adjoint in it:

$$(Af,g) = (f,Ag), \quad \forall f, \quad g \in L_\rho(\Omega).$$

This proposition can be applied to Eq. (19). Let B be the operator in the left part of (19). By representing Eq. (19) in self-adjoint form (20), it is easy to verify that the operator

$$A = ([x]^2 - [y]^2)^{-1}B \tag{23}$$

satisfies the conditions of Proposition 10, where the weight function $\rho(x,y)$ is defined in (18), and the lattice Ω is in (16). Therefore, the solutions of Eq. (19) corresponding to distinct eigenvalues are orthogonal on the lattice (16) with the weight (18).

C. Spectrum and structure of the eigenfunctions of Eq. (19)

Let A be the operator defined in (23).

Proposition 11: Let m and n be non-negative integers, having the same parity, and $m \leqslant n$. Then

$$A([x]^m[y]^n + [x]^n[y]^m) = \lambda_n([x]^m[y]^n + [x]^n[y]^m) + Q(x,y),$$

where $\lambda_n = [a-b+c-n]$, Q is a symmetric polynomial in $[x]$ and $[y]$, such that all powers of $[x]$ and $[y]$ have the same parity as n, and are less than n. In particular, if $n=0$ or $n=1$, then $Q \equiv 0$.

Consider the liner space S of all symmetric polynomials in $[x]$ and $[y]$ such that $\forall f \in S$ any monomial containing in f has powers of $[x]$ and $[y]$ of the same parity. It follows from Proposition 11 that the operator A acts in the space S.

Proposition 12: Operator A is diagonalizable in the space S and has in it the eigenvalues

$$\lambda_n = [a - b + c - n], \quad n = 0, 1, \ldots .$$

The multiplicity of λ_n is equal to the integer part of $(n+2)/2$.

Let $S(\Omega)$ be the set of all polynomials from the space S restricted onto the lattice (16).

Proposition 13: The space $S(\Omega)$ is isomorphic to the space $L(\Omega)$ of all functions on the lattice Ω.

Realization of the space $L(\Omega)$ as a space of symmetric polynomials $S(\Omega)$ allows one to prove the following main result regarding the multiplicities of eigenvalues of Eq. (19) and operator $I_{4,5}$.

Theorem 2: In the space $L(\Omega)$, Eq. (19) has $2(a-b+c)+1$ distinct eigenvalues of the form

$$\lambda = \lambda_n = [a-b+c-n], \quad n = 0,1,\ldots,2(a-b+c).$$

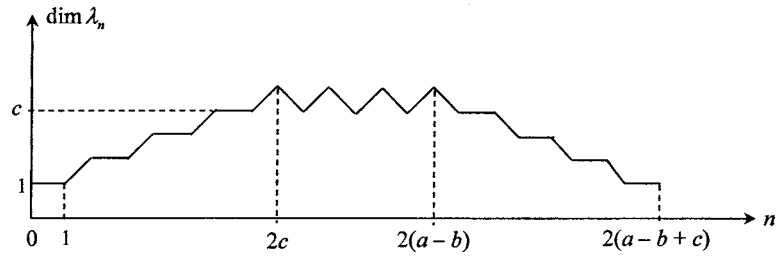
The multiplicity of the values λ_n is equal to the number of integer points (r,s) on the line $r+2s=n$ that lie in the rectangle

$$\Gamma = \{(r,s) | 0 \leqslant r \leqslant 2c,\ 0 \leqslant s \leqslant a-b\}. \tag{24}$$

The explicit formulas for the multiplicities $\dim \lambda_n$ are as follows. If $c \leqslant a-b$ then

$$\dim \lambda_n = \begin{cases} \left\langle \dfrac{n+2}{2} \right\rangle & \text{if } 0 \leqslant n \leqslant 2c, \\ c + \dfrac{(-1)^n + 1}{2} & \text{if } 2c \leqslant n \leqslant 2(a-b), \\ a-b+c - \left\langle \dfrac{n-1}{2} \right\rangle & \text{if } 2(a-b) \leqslant n \leqslant 2(a-b+c). \end{cases}$$

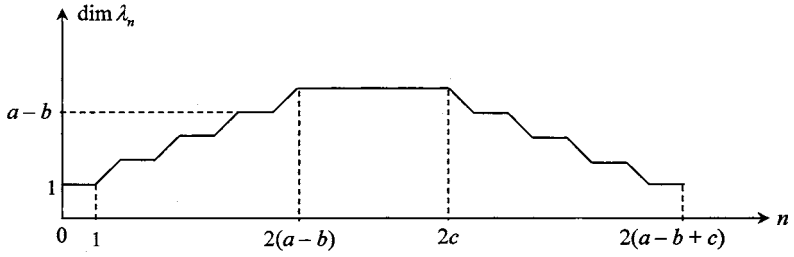
Here $\langle k \rangle$ means the integer part of the number k. The multiplicity of eigenvalues λ_n can be represented by the diagram



If $c \geqslant a-b$ then

$$\dim \lambda_n = \begin{cases} \left\langle \dfrac{n+2}{2} \right\rangle & \text{if } 0 \leqslant n \leqslant 2(a-b), \\ a-b+1 & \text{if } 2(a-b) \leqslant n \leqslant 2c, \\ a-b+c - \left\langle \dfrac{n-1}{2} \right\rangle & \text{if } 2c \leqslant n \leqslant 2(a-b+c). \end{cases}$$

The multiplicity of eigenvalues λ_n can be represented by the diagram



Proof: Consider the following two-parametric family of symmetric polynomials in $[x]$ and $[y]$:

$$f^{(r,s)}(x,y) = \varphi^{(r,s)}(x) \cdot \varphi^{(r,s)}(y),$$

where

$$\varphi^{(r,s)}(x) = [x]^{(1-(-1)^r)/2} \prod_{m=1}^{k} ([x]^2 - [c-m+1]^2) \prod_{n=1}^{s} ([x]^2 - [a-n+1]^2),$$

$(r,s) \in \Gamma$, k is an integral part of $r/2$. It is obvious that $f^{(r,s)} \in S(\Omega)$ and the highest degrees of $[x]$ and $[y]$ in $f^{(r,s)}$ are equal to $r+2s$. It is not difficult to show that all polynomials $f^{(r,s)}$ are linear independent, and, therefore, form a basis in the space $S(\Omega)$. It follows from Proposition 11 that

$$Af^{(r,s)} = \lambda_{r+2s} f^{(r,s)} + g,$$

where g is a polynomial from $S(\Omega)$ having the highest degree of $[x]$ less than $r+2s$. From here, for each polynomial $f^{(r,s)}$ we can put into correspondence the eigenfunction $P^{(r,s)}$ of the operator A with the eigenvalue λ_{r+2s} of the form

$$P^{(r,s)} = f^{(r,s)} + Q, \tag{25}$$

where $Q \in S(\Omega)$, and the highest degree of $[x]$ in Q is less than $r+2s$. All eigenfunctions $P^{(r,s)}$ are linear independent and form a basis in $S(\Omega)$ when parameters r and s run through the lattice (24). Polynomials $P^{(r,s)}$ in (25) can be described by the projection operator,

$$P^{(r,s)}(x,y) = \prod_{k=0}^{r+2s-1} \frac{A - \lambda_k E}{\lambda_{r+2s} - \lambda_k} f^{(r,s)}(x,y), \quad (r,s) \in \Gamma, \tag{26}$$

where E is an identical operator. All eigenfunctions (26) correspond to the same eigenvalue λ_n if $r+2s=n$. As follows from (24), the maximum value of n is $2(a-b+c)$. Theorem 2 is proved.

Corollary: Generator $I_{4,5}$ of the representation of the algebra $U_q(\mathrm{so}_5)$ has the following distinct eigenvalues in the subspace W_k^l:

$$\sigma = \sigma_n = [n - n_1 + |n_2 - l|] \cdot i, \quad n = 0,1,\ldots,2(n_1 - |n_2 - l|).$$

The multiplicity of σ_n is the same as multiplicity of λ_n in Theorem 2.

One possible basis of solutions of Eq. (19) is indicated in (26). The general structure of solutions and another bases are described by the following theorem.

Theorem 3: In the space $L(\Omega)$, Eq. (19) has $(a-b+1)(2c+1)$ linearly independent solutions. The solutions are symmetric polynomials in $[x]$ and $[y]$, which form a basis in the space $S(\Omega)$. Solutions belonging to different eigenvalues are orthogonal on the lattice (16) with the weight (18). A basis of solutions of Eq. (19) can be obtained by the orthogonalization of the sequence

$$\underbrace{1}_{\lambda_0}, \underbrace{[x][y]}_{\lambda_1}, \underbrace{[x]^2[y]^2, [x]^2 + [y]^2}_{\lambda_2}, \underbrace{[x]^3[y]^3, [x]^3[y] + [x][y]^3}_{\lambda_3}, \ldots .$$

Another basis can be constructed by the orthogonalization of the sequence

$$\underbrace{1}_{\lambda_0}, \underbrace{[x][y]}_{\lambda_1}, \underbrace{[x]^2 + [y]^2, [x]^2[y]^2}_{\lambda_2}, \underbrace{[x]^3[y] + [x][y]^3, [x]^3 + [y]^3}_{\lambda_3}, \ldots .$$

[DOI: 10.1063/1.2138050]

We have published two papers on low-energy scattering in two space dimensions:[1,2]

We received an email from Professor Gezstesy drawing our attention to his work with Professor Bolle and other collaborators on the same subject, which consists of the following:[3]

This paper was quoted in Ref. 1. However, we did not quote the following papers and wish to inform the readers of JMP of their existence:[4–6]

[1] K. Chadan, N. N. Khuri, A. Martin, and T. T. Wu, Phys. Rev. D **58**, 025014 (1998) for the central case.
