$$\mathrm{m}_2(M)=\frac{1-(-1)^M}{2}=M \bmod 2=\begin{cases}0 & \text{when } M \text{ is even}\\ 1 & \text{when } M \text{ is odd.}\end{cases} \tag{3.11}$$

The q-series $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ is proved to be a vector modular form with half-integral weight. The T transformation is trivial, and by use of the Poisson summation formula,

$$\sum_{n\in\mathbb{Z}} f(n)=\sum_{n\in\mathbb{Z}}\int_{-\infty}^{\infty} \mathrm{e}^{-2\pi \mathrm{i}tn}f(t)\mathrm{d}t \tag{3.12}$$

we obtain the transformation formula under the S transformation as follows.

Proposition 5: The q-series $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ *is a vector modular form with weight* $3/2$ (*respectively* $1/2$) *when* M *is even (respectively odd). Under the* S *and* T *transformations* (2.9) *we have*

$$\Phi_{\vec{p}}^{\vec{\ell}}(\tau)=\left(\frac{\mathrm{i}}{\tau}\right)^{3/2-\mathrm{m}_2(M)}\sum_{\vec{\ell}'}\mathbf{S}_{\vec{\ell}'}^{\vec{\ell}}\Phi_{\vec{p}}^{\vec{\ell}'}(-1/\tau), \tag{3.13}$$

$$\Phi_{\vec{p}}^{\vec{\ell}}(\tau+1)=\mathbf{T}^{\vec{\ell}}\Phi_{\vec{p}}^{\vec{\ell}}(\tau). \tag{3.14}$$

Here a sum of $\vec{\ell}'$ *runs over D-dimensional space* (3.7), *and matrix elements of* $D\times D$ *matrices* $\mathbf{S}$ *and* $\mathbf{T}$ *are respectively given by*

$$\mathbf{S}_{\vec{\ell}'}^{\vec{\ell}}=\frac{2^M\mathrm{i}^{M-\mathrm{m}_2(M)}}{\sqrt{2P}}(-1)^{P(1+\Sigma_{j=1}^M(\ell_j+\ell_j')/p_j)+P\Sigma_j\Sigma_{k\neq j}\ell_j\ell_k'/p_jp_k}\prod_{j=1}^M \sin\left(P\frac{\ell_j\ell_j'}{p_j^2}\pi\right), \tag{3.15}$$

$$\mathbf{T}^{\vec{\ell}}=\exp\left(\frac{P}{2}\left(1+\sum_{j=1}^M\frac{\ell_j}{p_j}\right)^2\pi\mathrm{i}\right). \tag{3.16}$$

Our vector modular form $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ may be a generalization of modular forms which appear as the character of the affine Lie algebra $\widehat{\mathrm{su}(2)}$ (a case of $M=1$, and $\Psi_P^{(a)}(\tau)$ defined below) and as the minimal Virasoro model (a case of $M=2$) up to the power of the Dedekind η function.

For our later use, we introduce other families of vector modular forms. We define the even periodic functions by

$$\theta_{2P}^{(a)}(n)=\begin{cases}1 & \text{for } n=\pm a \bmod 2P\\ 0 & \text{otherwise}\end{cases} \tag{3.17}$$

for $0\leqslant a\leqslant P$, and the odd periodic function by

$$\psi_{2P}^{(a)}(n)=\begin{cases}\pm 1 & \text{for } n\equiv \pm a \bmod 2P\\ 0 & \text{otherwise}\end{cases} \tag{3.18}$$

for $0<a<P$. We then define two families of q-series by

$$\Theta_P^{(a)}(\tau)=\frac{1}{2}\sum_{n\in\mathbb{Z}}\theta_{2P}^{(a)}(n)q^{n^2/4P}, \tag{3.19}$$

$$\Psi_P^{(a)}(\tau)=\frac{1}{2}\sum_{n\in\mathbb{Z}} n\psi_{2P}^{(a)}(n)q^{n^2/4P}. \tag{3.20}$$

These families are also vector modular forms with half-integral weight. Namely we see that $\Theta_P^{(a)}(\tau)$ is a vector modular form with weight $1/2$ satisfying

$$\Theta_P^{(a)}(\tau)=\sqrt{\frac{\mathrm{i}}{\tau}}\sum_{b=0}^{P}\mathbf{N}_b^a\Theta_P^{(b)}(-1/\tau), \tag{3.21}$$

$$\Theta_P^{(a)}(\tau+1)=\exp\left(\frac{a^2}{2P}\pi\mathrm{i}\right)\Theta_P^{(a)}(\tau), \tag{3.22}$$

where $\mathbf{N}$ is $(P+1)\times(P+1)$ matrix defined by

$$\mathbf{N}_b^a=\begin{cases}\dfrac{1}{\sqrt{2P}} & \text{for } a=0\\ \sqrt{\dfrac{2}{P}}\cos\left(\dfrac{ab}{P}\pi\right) & \text{for } a\neq 0,P\\ \dfrac{1}{\sqrt{2P}}\cos(b\pi) & \text{for } a=P.\end{cases} \tag{3.23}$$

The vector modular form $\Psi_P^{(a)}(\tau)$ with weight $3/2$ fulfills the following transformation formulae;

$$\Psi_P^{(a)}(\tau)=\left(\frac{\mathrm{i}}{\tau}\right)^{3/2}\sum_{b=1}^{P-1}\mathbf{M}_b^a\Psi_P^{(b)}(-1/\tau), \tag{3.24}$$

$$\Psi_P^{(a)}(\tau+1)=\exp\left(\frac{a^2}{2P}\pi\mathrm{i}\right)\Psi_P^{(a)}(\tau), \tag{3.25}$$

where $\mathbf{M}$ is a $(P-1)\times(P-1)$ matrix defined by

$$\mathbf{M}_b^a=\sqrt{\frac{2}{P}}\sin\left(\frac{ab}{P}\pi\right). \tag{3.26}$$

B. Eichler integrals

The Eichler integral is originally defined for modular forms with integral weight $\geqslant 2$ (see, e.g., Ref. 36). In our cases, the vector modular forms $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ have a half-integral weight, so we follow a method of Refs. 14 and 22 to define a variant of the Eichler integrals.

We define the Eichler integrals $\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)$ of the vector modular form $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ by

$$\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)=\sum_{n=0}^{\infty} n^{1-\mathrm{m}_2(M)}\chi_{2P}^{\vec{\ell}}(n)q^{n^2/4P}. \tag{3.27}$$

This can be regarded as a "half-derivative" (respectively "half-integral") of the modular form $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ with respect to τ when M is even (respectively odd). When M is odd, the q-series $\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)$ might be called the false theta function à la Rogers.[37]

Proposition 6: We assume N_1 and N_2 are coprime integers, and $N_1>0$. Limiting values of the Eichler integrals $\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)$ in $\tau\to N_2/N_1$ are given as follows;

$$\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(N_2/N_1) = -(PN_1)^{1-\mathrm{m}_2(M)} \sum_{k=0}^{2PN_1} \chi_{2P}^{\vec{\ell}}(k) \mathrm{e}^{(N_2/N_1)(k^2/2P)\pi \mathrm{i}} B_{2-\mathrm{m}_2(M)}\left(\frac{k}{2PN_1}\right), \tag{3.28}$$

where $B_k(x)$ is the kth Bernoulli polynomial.

We note that

$$\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau+1) = \mathbf{T}^{\vec{\ell}} \widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)$$

from which we have for $N \in \mathbb{Z}$

$$\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(N) = (\mathbf{T}^{\vec{\ell}})^N \widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(0) = -(\mathbf{T}^{\vec{\ell}})^N P^{1-\mathrm{m}_2(M)} \sum_{k=0}^{2P} \chi_{2P}^{\vec{\ell}}(k) B_{2-\mathrm{m}_2(M)}\left(\frac{k}{2P}\right).$$

A proof follows straightforwardly when we use the following lemma[14] (see also Ref. 38).

Lemma 7: Let $C_f(n)$ is a periodic function with modulus f and mean value zero. Then we have as $t \searrow 0$

$$\sum_{n=1}^{\infty} C_f(n) \mathrm{e}^{-n^2 t} \simeq \sum_{n=0}^{\infty} L(-2n, C_f) \frac{(-t)^n}{n!}, \tag{3.29}$$

$$\sum_{n=1}^{\infty} n C_f(n) \mathrm{e}^{-n^2 t} \simeq \sum_{n=0}^{\infty} L(-2n-1, C_f) \frac{(-t)^n}{n!}, \tag{3.30}$$

where the L function is

$$L(s, C_f) = \sum_{n=1}^{\infty} \frac{C_f(n)}{n^s} = f^{-s} \sum_{k=1}^{f} C_f(k) \zeta\left(s, \frac{k}{f}\right). \tag{3.31}$$

Note that the Hurwitz zeta function $\zeta(s,z)$, defined by

$$\zeta(s,z) = \sum_{n=0}^{\infty} \frac{1}{(n+z)^s}, \tag{3.32}$$

has an analytic continuation for $k \in \mathbb{Z}_{>0}$ as

$$\zeta(1-k, s) = -\frac{B_k(z)}{k}. \tag{3.33}$$

Proposition 8: The limiting values $\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\alpha)$ of the Eichler integrals with $\alpha \in \mathbb{Q}$ satisfy a nearly modular property. In a limit $N \to \infty$, we have the transformation formula as an asymptotic expansion as follows;

$$\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(1/N) + \left(\frac{N}{\mathrm{i}}\right)^{3/2-\mathrm{m}_2(M)} \sum_{\vec{\ell}'} \mathbf{S}_{\vec{\ell}'}^{\vec{\ell}} \widetilde{\Phi}_{\vec{p}}^{\vec{\ell}'}(-N) \simeq \sum_{k=0}^{\infty} \frac{L(-2k-1+\mathrm{m}_2(M), \chi_{2P}^{\vec{\ell}})}{k!} \left(\frac{\pi \mathrm{i}}{2PN}\right)^k. \tag{3.34}$$

Here $N \in \mathbb{Z}$, and a sum of M-tuples $\vec{\ell}'$ runs over D-dimensional space.

Proof: We introduce another variant of the Eichler integral by

$$\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(z)=\begin{cases}-\sqrt{\dfrac{P\mathrm{i}}{2\pi^2}}\displaystyle\int_{\bar{z}}^{\infty}\frac{\Phi_{\vec{p}}^{\vec{\ell}}(\tau)}{(\tau-z)^{3/2}}\mathrm{d}\tau & \text{when } M \text{ is even}\\ \dfrac{1}{\sqrt{2P\mathrm{i}}}\displaystyle\int_{\bar{z}}^{\infty}\frac{\Phi_{\vec{p}}^{\vec{\ell}}(\tau)}{\sqrt{\tau-z}}\mathrm{d}\tau & \text{when } M \text{ is odd,}\end{cases}\tag{3.35}$$

where we assume that z is in the lower half-plane, $z\in\mathbb{H}^-$, and $\bar{z}$ denotes a complex conjugate of z. By use of the S-transformation (3.13), we have

$$\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(z)+\left(\frac{1}{\mathrm{i}z}\right)^{3/2-\mathrm{m}_2(M)}\sum_{\vec{\ell}'}\mathbf{S}_{\vec{\ell}'}^{\vec{\ell}}\hat{\Phi}_{\vec{p}}^{\vec{\ell}'}(-1/z)=r_{\Phi_{\vec{p}}^{\vec{\ell}}}(z;0).\tag{3.36}$$

Here $r_{\Phi_{\vec{p}}^{\vec{\ell}}}(z;\alpha)$ is an analogue of the period function defined by

$$r_{\Phi_{\vec{p}}^{\vec{\ell}}}(z;\alpha)=\begin{cases}-\sqrt{\dfrac{P\mathrm{i}}{2\pi^2}}\displaystyle\int_{\alpha}^{\infty}\frac{\Phi_{\vec{p}}^{\vec{\ell}}(\tau)}{(\tau-z)^{3/2}}\mathrm{d}\tau & \text{when } M \text{ is even}\\ \dfrac{1}{\sqrt{2P\mathrm{i}}}\displaystyle\int_{\alpha}^{\infty}\frac{\Phi_{\vec{p}}^{\vec{\ell}}(\tau)}{\sqrt{\tau-z}}\mathrm{d}\tau & \text{when } M \text{ is odd,}\end{cases}\tag{3.37}$$

where $\alpha\in\mathbb{Q}$. We find that $\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(z)$ takes the same limiting value with that of $\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)$ in a limit z, $\tau\to\alpha\in\mathbb{Q}$;

$$\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)\big|_{\tau\to\alpha}=\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(z)\big|_{z\to\alpha}.\tag{3.38}$$

The r.h.s. of (3.34) arises from an asymptotic expansion of $r_{\Phi_{\vec{p}}^{\vec{\ell}}}(z;0)$, and we obtain (3.34). □

For our later use, we study differentials of the Eichler integral $\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)$, i.e., "fractional derivatives" of the vector modular form $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$. From the definition (3.27) of the Eichler integral, we have for $b\in\mathbb{Z}_{\geqslant 0}$

$$\left(\frac{2P}{\pi\mathrm{i}}\frac{\mathrm{d}}{\mathrm{d}\tau}\right)^b\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)=\sum_{n=0}^{\infty}n^{2b+1-\mathrm{m}_2(M)}\chi_{2P}^{\vec{\ell}}(n)q^{n^2/4P}.\tag{3.39}$$

By the same computation with (3.28), we have the following.

Proposition 9: The limiting values of fractional derivative of the vector modular forms $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ *are given by*

$$\left(\frac{2P}{\pi\mathrm{i}}\frac{\mathrm{d}}{\mathrm{d}\tau}\right)^b\widetilde{\Phi}_{\vec{p}}^{\vec{\ell}}(\tau)\bigg|_{\tau\to N_2/N_1}=-\frac{(2PN_1)^{2b+1-\mathrm{m}_2(M)}}{2b+2-\mathrm{m}_2(M)}\sum_{n=1}^{2PN_1}\chi_{2P}^{\vec{\ell}}(n)\mathrm{e}^{(N_2/N_1)(n^2/2P)\pi\mathrm{i}}B_{2b+2-\mathrm{m}_2(M)}\left(\frac{n}{2PN_1}\right),\tag{3.40}$$

where $N_1>0$ *and* N_2 *are coprime integers.*

The nearly modular property (3.34) of the Eichler integral gives the following asymptotic expansion of (3.40).

Proposition 10: In the limit $N\to\infty$, *we have the following asymptotic expansion*;

$$N^{2b+1-\mathrm{m}_2(M)}\sum_{n=1}^{2PN}\chi_{2P}^{\vec{\ell}}(n)\mathrm{e}^{(n^2/2PN)\pi\mathrm{i}}B_{2b+2-\mathrm{m}_2(M)}\left(\frac{n}{2PN}\right)$$

$$\simeq\frac{-1}{\mathrm{i}^{3/2-\mathrm{m}_2(M)}}\sum_{j=0}^{b}N^{b+j+3/2-\mathrm{m}_2(M)}\left(\frac{\mathrm{i}}{2P\pi}\right)^{b-j}K_{b,\mathrm{m}_2(M)}^{(j)}$$

$$\times\frac{2b+2-\mathrm{m}_2(M)}{2j+2-\mathrm{m}_2(M)}\sum_{\vec{\ell}'}\mathrm{S}_{\vec{\ell}'}^{\vec{\ell}}\left[\sum_{n=1}^{2P}\chi_{2P}^{\vec{\ell}'}(n)B_{2j+2-\mathrm{m}_2(M)}\left(\frac{n}{2P}\right)\right]\mathrm{e}^{-(P/2)(1+\sum_j(\ell_j'/p_j))^2\pi\mathrm{i}N}$$

$$-\frac{2b+2-\mathrm{m}_2(M)}{(2P)^{2b+1-\mathrm{m}_2(M)}}\sum_{k=0}^{\infty}\frac{L(-2k-2b-1+\mathrm{m}_2(M),\chi_{2P}^{\vec{\ell}})}{k!}\left(\frac{\pi\mathrm{i}}{2PN}\right)^k, \tag{3.41}$$

where the sum of M-tuples $\vec{\ell}'$ *runs over D-dimensional space, and we have*

$$K_{b,x}^{(j)}=\binom{b}{j}\prod_{k=0}^{b-j-1}\left(\frac{1}{2}+b-x-k\right). \tag{3.42}$$

Proof: We differentiate (3.36) with respect to z, and then take a limit $z\to 1/N$. We get

$$\frac{\mathrm{d}^b}{\mathrm{d}z^b}\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(z)\Big|_{z\to 1/N}+\frac{1}{\mathrm{i}^{1/2+\mathrm{m}_2(M)}}\sum_{\vec{\ell}'}\mathrm{S}_{\vec{\ell}'}^{\vec{\ell}}\left(w^2\frac{\mathrm{d}}{\mathrm{d}w}\right)^b w^{3/2-\mathrm{m}_2(M)}\hat{\Phi}_{\vec{p}}^{\vec{\ell}'}(w)\Big|_{w\to -N}$$

$$\simeq\left(\frac{\pi\mathrm{i}}{2P}\right)^b\sum_{k=0}^{\infty}\frac{L(-2k-2b-1+\mathrm{m}_2(M),\chi_{2P}^{\vec{\ell}})}{k!}\left(\frac{\pi\mathrm{i}}{2PN}\right)^k. \tag{3.43}$$

On the left-hand side, we use

$$\left(w^2\frac{\mathrm{d}}{\mathrm{d}w}\right)^n=\sum_{m=1}^{n}A_n^{(m)}w^{n+m}\frac{\mathrm{d}^m}{\mathrm{d}w^m},$$

where $A_n^{(m)}$ is the Lah number defined by

$$A_n^{(m)}=\frac{n!}{m!}\binom{n-1}{m-1}.$$

This denotes the number of partitions of $\{1,2,\ldots,n\}$ into m *lists* (a "list" denotes an ordered subset),[39,40] and satisfies the recursion relation

$$A_{n+1}^{(m)}=A_n^{(m-1)}+(n+m)A_n^{(m)}.$$

Thus we have

$$\left(w^2\frac{\mathrm{d}}{\mathrm{d}w}\right)^b w^{3/2-\mathrm{m}_2(M)}\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(w)=\sum_{j=0}^{b}w^{3/2-\mathrm{m}_2(M)+b+j}K_{b,\mathrm{m}_2(M)}^{(j)}\frac{\mathrm{d}^j\hat{\Phi}_{\vec{p}}^{\vec{\ell}}(w)}{\mathrm{d}w^j}.$$

Here the K number is computed as

$$K_{b,x}^{(j)}=\sum_{k=j}^{b}A_b^{(k)}\binom{k}{j}\frac{\Gamma\left(\frac{5}{2}-x\right)}{\Gamma\left(\frac{5}{2}-x-k+j\right)}$$

which reduces to (3.42) applying (A14) and (A17).

As we have (3.38), we get (3.41) with a help of (3.40).

In the same method, we have formulas of the asymptotic expansions concerning to the periodic functions with mean value zero.

Corollary 11: We assume that $C_{2P}(n)$ is an odd or even periodic function with modulus $2P$, and that it satisfies

- *a mean value zero condition*,

$$\sum_{n=0}^{2P-1} C_{2P}(n) = 0,$$

- $C_{2P}(0)=0$.

In the limit $N\to\infty$, we have the following asymptotic expansions;

- $C_{2P}(n)$ *is odd*;

$$N^{2b}\sum_{n=1}^{2PN} C_{2P}(n)\mathrm{e}^{(n^2/2PN)\pi\mathrm{i}}B_{2b+1}\left(\frac{n}{2PN}\right) \simeq \frac{-2}{\mathrm{i}^{1/2}}\sum_{j=0}^{b} N^{b+j+1/2}\left(\frac{\mathrm{i}}{2P\pi}\right)^{b-j} K_{b,1}^{(j)}\frac{2b+1}{2j+1} \times\sum_{a=1}^{P-1} C_{2P}(a)\sum_{c=1}^{P-1}\mathbf{M}_c^a B_{2j+1}\left(\frac{c}{2P}\right)\mathrm{e}^{-N(c^2/2P)\pi\mathrm{i}} - \frac{2b+1}{(2P)^{2b}}\sum_{k=0}^{\infty}\frac{L(-2k-2b,C_{2P})}{k!}\left(\frac{\pi\mathrm{i}}{2PN}\right)^k, \tag{3.44}$$

- $C_{2P}(n)$ *is even*;

$$N^{2b+1}\sum_{n=1}^{2PN} C_{2P}(n)\mathrm{e}^{(n^2/2PN)\pi\mathrm{i}}B_{2b+2}\left(\frac{n}{2PN}\right) \simeq \frac{-1}{\mathrm{i}^{3/2}}\sum_{j=0}^{b} N^{b+j+3/2}\left(\frac{\mathrm{i}}{2P\pi}\right)^{b-j} K_{b,0}^{(j)}\frac{b+1}{j+1}\sum_{a=1}^{P} C_{2P}(a) \times\sum_{c=0}^{P}\mathbf{N}_c^a(2-\delta_{c,0}-\delta_{c,P})B_{2j+2}\left(\frac{c}{2P}\right)\mathrm{e}^{-N(c^2/2P)\pi\mathrm{i}} - \frac{2b+2}{(2P)^{2b+1}}\sum_{k=0}^{\infty}\frac{L(-2k-2b-1,C_{2P})}{k!}\left(\frac{\pi\mathrm{i}}{2PN}\right)^k. \tag{3.45}$$

Proof: We use that

$$C_{2P}(n) = \begin{cases} \displaystyle\sum_{a=1}^{P-1} C_{2P}(a)\psi_{2P}^{(a)}(n) & \text{when } C_{2P}(n) \text{ is odd} \\ \displaystyle\sum_{a=1}^{P} C_{2P}(a)\theta_{2P}^{(a)}(n) & \text{when } C_{2P}(n) \text{ is even.} \end{cases}$$

In both cases, due to a condition $C_{2P}(0)=0$, we see that periodic functions which appear in the modular transformation formula such as (3.43) have a mean value zero. Applying Lemma 7, we obtain asymptotic expansions. □

IV. EXACT ASYMPTOTIC EXPANSION OF THE WRT INVARIANTS

A. Exact asymptotic expansion

As a preparation to obtain the exact asymptotic expansion of the WRT invariant $\tau_N(\mathcal{M})$ for the M-exceptional fibered Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ by use of the vector modular form $\Phi_{\vec{p}}^{\vec{\ell}}(\tau)$ defined in previous section, we give q-series identities at the root of unity related to the Bernoulli polynomials.

Lemma 12: We set ω_N as the Nth primitive root of unity;

$$\omega_N = \exp\left(\frac{2\pi \mathrm{i}}{N}\right)$$

and assume that a and k are positive integers satisfying $0 \leqslant a \leqslant N-1$. We have

$$\sum_{c=1}^{N-1} \frac{\omega_N^{(a+1)c}}{(1-\omega_N^c)^k} = \frac{(-1)^k}{(k-1)!} \sum_{j=1}^{k} \frac{S_k^{(j)}}{j} \left(B_j(1) - N^j B_j\left(\frac{a+1}{N}\right)\right), \tag{4.1}$$

where $S_k^{(j)}$ is the Stirling number of the first kind (A14).

Proof: We follow a method in Ref. 41.

We define the function $P(t;k,a)$ by

$$P(t;k,a) = \sum_{c=1}^{N-1} \frac{\omega_N^{(a+1)c}}{(1-\omega_N^c \mathrm{e}^t)^k}, \tag{4.2}$$

where a and k are positive integers. The function $P(t;k=1,a)$ is computed as follows;

$$\begin{aligned} P(t;k=1,a) &= \sum_{n=0}^{\infty} \sum_{c=1}^{N-1} \omega_N^{(a+1)c+nc} \mathrm{e}^{nt} = -\frac{1}{1-\mathrm{e}^t} + N\mathrm{e}^{-(a+1)t} \frac{\mathrm{e}^{Nt}}{1-\mathrm{e}^{Nt}} \\ &= \sum_{m=0}^{\infty} \frac{1}{(m+1)!} \left(B_{m+1}(0) - N^{m+1} B_{m+1}\left(1-\frac{a+1}{N}\right)\right) t^m. \end{aligned} \tag{4.3}$$

Here we have used

$$\sum_{c=1}^{N-1} \omega_N^{nc} = \begin{cases} N-1 & \text{if } N|n \\ -1 & \text{otherwise.} \end{cases}$$

We further introduce the function $Q(t;k,c)$ by

$$Q(t;k,c) = \frac{1}{(1-\omega_N^c \mathrm{e}^t)^k}, \tag{4.4}$$

where k and c are positive integers. By definitions we have

$$P(t;k,a) = \sum_{c=1}^{N-1} \omega_N^{(a+1)c} Q(t;k,c). \tag{4.5}$$

Definition (4.4) indicates that the function $Q(t;k,c)$ satisfies a differential-difference equation,

$$\frac{\mathrm{d}}{\mathrm{d}t} Q(t;k,c) = k(Q(t;k+1,c) - Q(t;k,c)).$$

We can check by induction that the function $Q(t;k,c)$ can be written in terms of $Q(t;k=1,c)$ as

$$Q(t;k,c)=\frac{(-1)^{k+1}}{(k-1)!}\sum_{m=0}^{k-1}(-1)^m S_k^{(m+1)}\frac{\mathrm{d}^m}{\mathrm{d}t^m}Q(t;1,c) \tag{4.6}$$

From (4.5) we find that $P(t;k,a)$ is solved as

$$P(t;k,a)=\frac{(-1)^{k+1}}{(k-1)!}\sum_{m=0}^{k-1}(-1)^m S_k^{(m+1)}\frac{\mathrm{d}^m}{\mathrm{d}t^m}P(t;1,a) \tag{4.7}$$

Substituting (4.3) for the previous solution, we complete the proof. □

Using the arithmetic identity (4.1), we can rewrite the WRT invariant (2.10) in terms of the Bernoulli polynomials.

Proposition 13: The WRT invariant for the M-exceptional fibered Seifert integral homology sphere $\mathcal{M}=\Sigma(\vec{p})$, *which was computed as in* (2.10), *is written in terms of the Bernoulli polynomials as*

$$\begin{aligned}
&\mathrm{e}^{(2\pi\mathrm{i}/N)(\phi(\vec{p})/4-1/2)}(\mathrm{e}^{(2\pi\mathrm{i}/N)}-1)\tau_N(\mathcal{M})\\
&=-\frac{1}{2}\frac{1}{(M-3)!}\sum_{j=0}^{M-3}(-N)^j\frac{S_{M-2}^{(j+1)}}{j+1}\times\sum_{n=0}^{2PN-1}\chi_{2P}^{\vec{E}}(n)\mathrm{e}^{(1/2PN)(n+P(M-3))^2\pi\mathrm{i}}B_{j+1}\left(\frac{1}{N}\left\lfloor\frac{n}{2P}\right\rfloor\right)\\
&\quad+\frac{(-1)^M}{(M-4)!}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}\sum_{\vec{\eta}(a)}{}'\sum_{n=0}^{N-1}\sum_{j=1}^{M-3}\frac{S_{M-3}^{(j)}}{j}\mathrm{e}^{\pi\mathrm{i}(2P/N)(n-b-(M-4)/2+(1/2)\sum_{i=1}^{M}\eta_i/p_i)^2}\\
&\quad\times\left(N^{j-1}B_j\left(\frac{n+1}{N}\right)-\frac{1}{N}B_j(1)\right),
\end{aligned} \tag{4.8}$$

where for our brevity we have used M-tuple

$$\vec{E}=\underbrace{(1,1,\ldots,1)}_{M} \tag{4.9}$$

and $\Sigma'_{\vec{\eta}(a)}$ *is a signed sum*

$$\sum_{\vec{\eta}(a)}{}'\cdots=\sum_{\substack{\vec{\eta}\in\{\pm1\}^M s.t.\\ 2a-1<\sum_{j=1}^{M}\eta_j/p_j<2a+1}}\left[\prod_{j=1}^{M}\eta_j\right]\cdots.$$

We remark that the second term including a sum of a in (4.8) vanishes when

$$\sum_{j=1}^{M}\frac{1}{p_j}<1$$

Even when $\Sigma_{j=1}^{M}1/p_j>1$, the second term is a finite sum. It is well known that the sum of inverse of prime numbers, $\Sigma_{p:\mathrm{prime}}1/p$ diverges, although the sum up to the 10 000th prime numbers is still 2.709 258 ….

Proof of Prop. 13: We first study a case of $\Sigma_j 1/p_j<1$. In this case, we have

$$-z^P\prod_{j=1}^{M}(z^{P/p_j}-z^{-P/p_j})=\sum_{m=0}^{2P-1}\chi_{2P}^{\vec{E}}(m)z^m, \tag{4.10}$$

where the periodic function $\chi_{2P}^{\vec{E}}(m)$ is defined in (3.2). Using this identity in (2.10), we have

$$
\begin{aligned}
&e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{2\pi i/N}-1)\tau_N(\mathcal{M})\\
&=-\frac{e^{\pi i/4}}{2\sqrt{2PN}}\sum_{m=0}^{2P-1}\sum_{k=1}^{N-1}\chi_{2P}^{\vec{E}}(m)\frac{e^{(\pi i/2PN)(m+(M-3)P)^2}}{(e^{(2\pi i/N)k}-1)^{M-2}}\sum_{j=0}^{2P-1}e^{-\pi i(N/2P)(j+(k-m-(M-3)P)/N)^2}\\
&=\frac{-1}{2N}\sum_{m=0}^{2P-1}\sum_{n=0}^{N-1}\chi_{2P}^{\vec{E}}(m)e^{(\pi i/2PN)(2Pn-m-(M-3)P)^2}\sum_{k=1}^{N-1}\frac{e^{(2\pi i/N)kn}}{(e^{2\pi ik/N}-1)^{M-2}}\\
&=\frac{-1}{2}\frac{1}{(M-3)!}\sum_{m=0}^{2P-1}\sum_{n=0}^{N-1}\chi_{2P}^{\vec{E}}(m)e^{(\pi i/2PN)(2Pn+m+(M-3)P)^2}\\
&\quad\times\sum_{j=0}^{M-3}\frac{S_{M-2}^{(j+1)}}{j+1}\left(\frac{1}{N}B_{j+1}(1)-N^jB_{j+1}\left(1-\frac{n}{N}\right)\right).
\end{aligned}
$$

Here in the first equality we have used (4.10), and decomposed a sum of n by setting $n=Nj+k$. We have then applied the Gauss sum reciprocity formula (A7) in the second equality, and then used our formula (4.1) in the last equality. As we have

$$
\sum_{n=0}^{2PN-1}\chi_{2P}^{\vec{\ell}}(n)e^{(\pi i/2PN)n^2}=0 \tag{4.11}
$$

due to (3.4), we obtain the first term of (4.8).

For other cases $\Sigma_j 1/p_j>1$, the generating function (4.10) of the periodic function $\chi_{2P}^{\vec{E}}(n)$ is replaced with

$$
\begin{aligned}
&-z^P\prod_{j=1}^{M}(z^{P/p_j}-z^{-P/p_j})+\sum_{a=1}^{\infty}{\sum_{\vec{\eta}(a)}}'z^P(z^{aP}-z^{-aP})\times(z^{P(\Sigma_j n_j/p_j-a)}+(-1)^{M+1}z^{-P(\Sigma_j\eta_j/p_j-a)})\\
&=\sum_{n=0}^{2P-1}\chi_{2P}^{\vec{E}}(n)z^n.
\end{aligned}
\tag{4.12}
$$

Thus comparing with a case of $\Sigma_j 1/p_j<1$, we need additional term τ_{add} defined by

$$
\begin{aligned}
\tau_{\mathrm{add}}=&\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}{\sum_{\vec{\eta}(a)}}'\sum_{\substack{n=0\\ N\nmid n}}^{2PN-1}\frac{e^{\pi i/4}}{2\sqrt{2PN}}\frac{e^{-(n^2/2PN)\pi i}}{(e^{(n/N)\pi i}-e^{-(n/N)\pi i})^{M-3}}\\
&\times(e^{\pi i(n/N)(\Sigma_j\eta_j/p_j-2b-1)}+(-1)^{M+1}e^{-\pi i(n/N)(\Sigma_j\eta_j/p_j-2b-1)}).
\end{aligned}
\tag{4.13}
$$

We decompose a sum of n by setting $n=Nj+k$, and apply the Gauss sum reciprocity formula (A7). After some computations, we obtain

$$
\begin{aligned}
\tau_{\mathrm{add}}=&\frac{1}{2N}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}{\sum_{\vec{\eta}(a)}}'\sum_{k=1}^{N-1}\sum_{n=0}^{N-1}\frac{e^{\pi i(2P/N)(n-(M-2)/2+(1/2))\sum_j\eta_j/p_j)^2}}{(e^{(k/N)\pi i}-e^{-(k/N)\pi i})^{M-3}}\\
&\times(e^{\pi i(k/N)(M-3-2b-2n)}+(-1)^{M+1}e^{\pi i(k/N)(2b+2n-M+3)})\\
=&\frac{1}{N}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}{\sum_{\vec{\eta}(a)}}'\sum_{n=0}^{N-1}e^{\pi i(2P/N)(n-(M-2)/2+(1/2))\sum_j\eta_j/p_j)^2}\sum_{k=1}^{N-1}\frac{e^{2\pi i(k/N)(b+n)}}{(1-e^{2\pi i(k/N)})^{M-3}},
\end{aligned}
$$

where we have used the fact that the sum (4.1) is real. Substituting (4.1) for the previous equation, we find that τ_{add} gives the second term of r.h.s. of (4.8), and thus we complete the proof. □

We now aim to relate this expression with limiting values of the Eichler integrals (3.28) and differentials (3.40) thereof. For our convention, we introduce an analog of the Bernoulli polynomial defined by

$$f_m^M(x) = \sum_{k=m}^{M} \frac{1}{k} S_M^{(k)} \binom{k}{m} \left(x + \frac{M}{2}\right)^{k-m}, \tag{4.14}$$

where $M, m \in \mathbb{Z}$ satisfying $M \geqslant m > 0$. For a case of $m=0$, we set

$$f_0^M(x) = \sum_{k=1}^{M} \frac{S_M^{(k)}}{k} \left(x + \frac{M}{2}\right)^k. \tag{4.15}$$

Some of explicit forms of the polynomials $f_m^M(x)$ are given as follows:

$$f_M^M(x) = \frac{1}{M},$$

$$f_{M-1}^M(x) = x,$$

$$f_{M-2}^M(x) = \frac{1}{M}\binom{M}{2}\left(x^2 - \frac{M}{12}\right),$$

$$f_{M-3}^M(x) = \frac{1}{M}\binom{M}{3}\left(x^3 - \frac{M}{4}x\right),$$

$$f_{M-4}^M(x) = \frac{1}{M}\binom{M}{4}\left(x^4 - \frac{M}{2}x^2 + \frac{1}{240}M(5M+2)\right).$$

Lemma 14: Let the polynomial $f_m^M(x)$ be defined by (4.14). Then the polynomial $f_{M-k\neq 0}^M(x)$ is even (respectively odd) when k is even (respectively odd).

Proof: We introduce the generating function of the polynomials $f_M^m(x)$ by

$$F_M(x,y) = \sum_{m=0}^{M} m f_m^M(x) y^{m-1}. \tag{4.16}$$

Recalling the generating function (A14) of the Stirling number of the first kind, we get

$$F_M(x,y) = \prod_{j=1}^{M-1} \left(y + x + \frac{M}{2} - j\right) \tag{4.17}$$

which shows that $F_M(x,y)$ is a polynomial of $x+y$. Further $F_M(x,y)$ becomes an odd (respectively even) polynomial of $x+y$ when M is even (respectively odd). Then we can conclude that the polynomial $f_{M-k}^M(x)$ is even (respectively odd) if k is even (respectively odd). □

By use of the generating function (4.17), we obtain the following differential equation and recursion relation of $f_m^M(x)$:

$$\frac{\mathrm{d}}{\mathrm{d}x} f_m^M(x) = (m+1) f_{m+1}^M(x), \tag{4.18}$$

$$f_j^{M+1}\left(x-\frac{1}{2}\right)=\left(x-\frac{M}{2}\right)f_j^M(x)+\frac{j-1}{j}f_{j-1}^M(x). \tag{4.19}$$

We can rewrite the WRT invariant in Proposition 13 in terms of these polynomials as follows.

Proposition 15: The WRT invariant $\tau_N(\mathcal{M})$ for the M-exceptional fibered Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ is written as

$$\begin{aligned}
e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{2\pi i/N}-1)\tau_N(\mathcal{M})=&-\frac{1}{2}\frac{1}{(M-3)!}\sum_{k=1}^{M-2}(-N)^{k-1}\sum_{n=0}^{2PN-1}\chi_{2P}^{\vec{E}}(n)f_k^{M-2}\left(\frac{n}{2P}-\left\lfloor\frac{n}{2P}\right\rfloor-\frac{1}{2}\right)\\
&\times e^{(1/2PN)(n+P(M-3))^2\pi i}B_k\left(\frac{n+P(M-3)}{2PN}\right)\\
&+\frac{(-1)^M}{(M-4)!}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}\sum_{\vec{\eta}(a)}{}'\sum_{n=0}^{N-1}e^{\pi i(2P/N)(n-b-(M-4)/2+(1/2)\sum_j \eta_j/p_j)^2}\\
&\times\sum_{k=0}^{M-3}\left(N^{k-1}f_k^{M-3}\left(b+\frac{1}{2}-\frac{1}{2}\sum_j\frac{\eta_j}{p_j}\right)\right.\\
&\left.\times B_k\left(\frac{2n-2b-M+4+\sum_j\frac{\eta_j}{p_j}}{2N}\right)-\frac{1}{N}f_k^{M-3}\left(\frac{5-M}{2}\right)B_k(0)\right).
\end{aligned} \tag{4.20}$$

Proof: To prove for a case of $\Sigma_j 1/p_j<1$, in which the second term in (4.20) vanishes, we only need to apply (A13) to $B_{j+1}((1/N)\lfloor n/2P\rfloor)$ in the first term of (4.8). As we have an identity

$$\sum_{j=1}^{M}\frac{S_M^{(j)}}{j}B_j(x+y)z^j=\sum_{k=0}^{M}f_k^M\left(yz-\frac{M}{2}\right)B_k(x)z^k \tag{4.21}$$

we obtain the required expression.

In the case of $\Sigma_j 1/p_j>1$, we need to evaluate the second term in (4.8), which we have set τ_{add} in the proof of Proposition 13. This term τ_{add} can be transformed into expression (4.20) when we apply (4.21). □

Theorem 16: The exact asymptotic expansion of the WRT invariant $\tau_N(\mathcal{M})$ for the Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ withM-singular fibers in $N\to\infty$ is given as follows;

$$\begin{aligned}
&e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{2\pi i/N}-1)\tau_N(\mathcal{M})\\
&\simeq\frac{1}{2}\frac{1}{(M-3)!}\frac{1}{i^{3/2-m_2(M)}}\sum_{j=0}^{\lfloor(M-3)/2\rfloor}N^{j+\lfloor M/2\rfloor-1/2}\left(\frac{i}{2P\pi}\right)^{\lfloor(M-3)/2\rfloor-j}K^{(j)}_{\lfloor(M-3)/2\rfloor,m_2(M)}\\
&\times\frac{1}{2j+2-m_2(M)}\sum_{\vec{\ell}'}\mathbf{S}_{\vec{\ell}'}^{\sigma_1^{M-1}(\vec{E})}\left[\sum_{n=1}^{2P}\chi_{2P}^{\vec{\ell}'}(n)B_{2j+2-m_2(M)}\left(\frac{n}{2P}\right)\right]e^{-N(P/2)(1+\sum_j\ell_j'/p_j)^2\pi i}\\
&+\frac{1}{(M-3)!}\frac{(-1)^{M\lfloor(M-3)/2\rfloor}}{i^{3/2}}\sum_{m=1}^{\lfloor(M-3)/2\rfloor}\sum_{a=0}^{P}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(a)f_{2m}^{M-2}\left(\frac{a}{2P}-\frac{m_2(M)}{2}\right)\\
&\times\sum_{j=1}^{m}N^{m+j-1/2}\left(\frac{i}{2P\pi}\right)^{m-j}K^{(j-1)}_{m-1,0}\frac{m}{j}\sum_{c=0}^{P}\mathbf{N}_c^a\frac{2-\delta_{c,0}-\delta_{c,P}}{2}B_{2j}\left(\frac{c}{2P}\right)e^{-N(c^2/2P)\pi i}
\end{aligned}$$

$$
\begin{aligned}
&+\frac{1}{(M-3)!}\frac{(-1)^{M-1}}{\mathrm{i}^{1/2}}\sum_{m=0}^{\lfloor (M-4)/2\rfloor}\sum_{a=1}^{P}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(a)f_{2m+1}^{M-2}\left(\frac{a}{2P}-\frac{\mathrm{m}_2(M)}{2}\right)\\
&\times\sum_{j=0}^{m}N^{m+j+1/2}\left(\frac{\mathrm{i}}{2P\pi}\right)^{m-j}K_{m,1}^{(j)}\frac{2m+1}{2j+1}\sum_{c=1}^{P-1}\mathbf{M}_c^a B_{2j+1}\left(\frac{c}{2P}\right)\mathrm{e}^{-N(c^2/2P)\pi\mathrm{i}}\\
&+\frac{(-1)^M}{(M-4)!}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}{\sum_{\vec{\eta}(a)}}'\left\{\sum_{m=1}^{\lfloor (M-3)/2\rfloor}f_{2m}^{M-3}\left(b+\frac{1}{2}-\frac{1}{2}\sum_i\frac{\eta_i}{p_i}\right)\frac{-1}{\mathrm{i}^{3/2}}\sum_{j=1}^{m}N^{m+j-1/2}\left(\frac{\mathrm{i}}{2P\pi}\right)^{m-j}\right.\\
&\times K_{m-1,0}^{(j-1)}\frac{m}{j}\sum_{c=0}^{P}\mathbf{N}_c^{\sigma^{M-1}(P\Sigma_i\eta_i/p_i-P(2a-1))}\frac{2-\delta_{c,0}-\delta_{c,P}}{2}B_{2j}\left(\frac{c}{2P}\right)\mathrm{e}^{-N(c^2/2P)\pi\mathrm{i}}\\
&+(-1)^{M-1}\sum_{m=0}^{\lfloor (M-4)/2\rfloor}f_{2m+1}^{M-3}\left(b+\frac{1}{2}-\frac{1}{2}\sum_i\frac{\eta_i}{p_i}\right)\frac{-1}{\mathrm{i}^{1/2}}\sum_{j=0}^{m}N^{m+j+1/2}\left(\frac{\mathrm{i}}{2P\pi}\right)^{m-j}\\
&\left.\times K_{m,1}^{(j)}\frac{2m+1}{2j+1}\sum_{c=1}^{P-1}\mathbf{M}_c^{\sigma^{M-1}(P\Sigma_i\eta_i/p_i-P(2a-1))}B_{2j+1}\left(\frac{c}{2P}\right)\mathrm{e}^{-N(c^2/2P)\pi\mathrm{i}}\right\}+\sum_{k=0}^{\infty}\frac{T_{\vec{p}}(k)}{k!}\left(\frac{\pi\mathrm{i}}{2PN}\right)^k,
\end{aligned}
\tag{4.22}
$$

where we have used an involution σ *on* $x\in\mathbb{Z}_{2P}$ *defined by*

$$
\sigma(x)=P-x \bmod 2P. \tag{4.23}
$$

The coefficients $T_{\vec{p}}(k)$ *in a tail part are defined by*

$$
\begin{aligned}
T_{\vec{p}}(k)=&\frac{(-1)^{M+1}}{2}\frac{(2P)^{2k}}{(M-3)!}\sum_{n=1}^{2P}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(n)\sum_{j=1}^{M-2}(-1)^j\frac{j}{2k+j}B_{2k+j}\left(\frac{n}{2P}\right)\\
&\times f_j^{M-2}\left(\frac{n+(M-1)P}{2P}-\left\lfloor\frac{n+(M-1)P}{2P}\right\rfloor-\frac{1}{2}\right)-\frac{(2P)^{2k}}{(M-4)!}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}{\sum_{\vec{\eta}(a)}}'\sum_{j=1}^{M-3}(-1)^{(M+1)(j+1)}\\
&\times\frac{j}{2k+j}f_j^{M-3}\left(b+\frac{1}{2}-\frac{1}{2}\sum_i\frac{\eta_i}{p_i}\right)B_{2k+j}\left(\frac{1}{2P}\sigma^{M-1}\left(P\sum_i\frac{\eta_i}{p_i}-(2a-1)P\right)\right).
\end{aligned}
\tag{4.24}
$$

Proof. We first study the case $\Sigma_j 1/p_j<1$, in which we only have the first term in (4.20). We shift the parameter n by $P(3-M)$, and we have

$$
\chi_{2P}^{\vec{E}}(n-P(M-3))=(-1)^{1-m_2(M)}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(n)
$$

As we see that

$$
\chi_{2P}^{\vec{\ell}}(n)f_k^{M-2}\left(\frac{n+(M-1)P}{2P}-\left\lfloor\frac{n+(M-1)P}{2P}\right\rfloor-\frac{1}{2}\right)
$$

is an even (respectively odd) periodic function when k is even (respectively odd), we can write by use of $f_M^M(x)=1/M$ that

$$
\begin{aligned}
&e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{2\pi i/N}-1)\tau_N(\mathcal{M})\\
&=-\frac{1}{2}\frac{N^{M-3}}{(M-2)!}\sum_{n=0}^{2PN-1}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(n)e^{(n^2/2PN)\pi i}B_{M-2}\left(\frac{n}{2PN}\right)-\frac{(-1)^M}{2}\frac{1}{(M-3)!}\sum_{c=1}^{\lfloor (M-3)/2\rfloor}N^{2c-1}\\
&\times\left[\sum_{n=0}^{2PN-1}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(n)f_{2c}^{M-2}\left(\frac{n}{2P}-\frac{m_2(M)}{2}\right)e^{(n^2/2PN)\pi i}B_{2c}\left(\frac{n}{2PN}\right)\right]\\
&+\frac{(-1)^M}{2}\frac{1}{(M-3)!}\sum_{c=0}^{\lfloor (M-4)/2\rfloor}N^{2c}\\
&\times\left[\sum_{n=0}^{2PN-1}\chi_{2P}^{\sigma_1^{M-1}(\vec{E})}(n)f_{2c+1}^{M-2}\left(\frac{n}{2P}-\frac{m_2(M)}{2}\right)e^{(n^2/2PN)\pi i}B_{2c+1}\left(\frac{n}{2PN}\right)\right].
\end{aligned}
$$

Generating function (4.10) proves

$$
\sum_{n=0}^{2P-1}\chi_{2P}^{\vec{E}}(n)g(n)=0,
$$

where $g(n)$ is an arbitrary polynomial of n of order at most $M-1$. So we find that $\chi_{2P}^{\vec{E}}(n)f_k^{M-2}(n/2P-\lfloor n/2P\rfloor-1/2)$ is a periodic function of n with mean value zero, and that the expression (4.20) can be identified with a limiting value of the Eichler integrals and their derivatives studied in the previous section. This proves that the WRT invariant is a limiting value of the holomorphic function of q in $q\to e^{2\pi i/N}$.[26] Substituting both (3.44) and (3.45) for the previous expression, we get (4.22).

For the second term τ_{add} in (4.20), recalling the periodic functions $\psi_{2P}^{(a)}(n)$ and $\theta_{2P}^{(a)}(n)$ we can rewrite it into

$$
\begin{aligned}
\tau_{\mathrm{add}}=&\frac{1}{2}\frac{(-1)^M}{(M-4)!}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}{\sum_{\vec{\eta}(a)}}'\left\{\sum_{m=0}^{\lfloor (M-3)/2\rfloor}N^{2m-1}f_{2m}^{M-3}\left(b+\frac{1}{2}-\frac{1}{2}\sum_i\frac{\eta_i}{p_i}\right)\right.\\
&\times\sum_{n=0}^{2PN-1}\theta_{2P}^{(\sigma^{M-1}(P\sum_i \eta_i/p_i-(2a-1)P))}(n)e^{\pi i(n^2/2PN)}B_{2m}\left(\frac{n}{2PN}\right)\\
&+(-1)^{M-1}\sum_{m=0}^{\lfloor (M-4)/2\rfloor}N^{2m}f_{2m+1}^{M-3}\left(b+\frac{1}{2}-\frac{1}{2}\sum_i\frac{\eta_i}{p_i}\right)\\
&\left.\times\sum_{n=0}^{2PN-1}\psi_{2P}^{(\sigma^{M-1}(P\sum_i \eta_i/p_i-(2a-1)P))}(n)e^{\pi i(n^2/2PN)}B_{2m+1}\left(\frac{n}{2PN}\right)\right\}.
\end{aligned}
$$

With this term, the mean value zero condition is satisfied even in this case, and we can apply the result of Corollary 11 to obtain the exact asymptotic expansion as required. □

We have thus obtained that the WRT invariant $Z_{N-2}(\mathcal{M})$ for the M-exceptional fibered Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ is written in a limit $N\to\infty$ as a sum of exponentially divergent terms and a *tail* part;

$$
Z_{N-2}(\mathcal{M})\simeq\sum_{k=0}^{M-3}N^{M-3-k}Z_{N-2}^{(k)}(\mathcal{M})+\text{a tail part}\tag{4.25}
$$

Here a *tail part* means an infinite power series of $1/N$, and it corresponds to a contribution from the trivial connection. Among the divergent terms in (4.25), the dominating term in the limit $N\to\infty$ is $Z_{N-2}^{(0)}(\mathcal{M})$, which is read as follows.

Corollary 17: In a limit $N\to\infty$, the asymptotics of the WRT invariant $\tau_N(\mathcal{M})$ for the

M-exceptional fibered Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ *is dominated by* N^{M-3}. $Z^{(0)}_{N-2}(\mathcal{M})$, *namely*

$$Z_{N-2}(\mathcal{M}) \sim N^{M-3}\cdot \mathrm{e}^{-[\phi(\vec{p})/2N]\pi \mathrm{i}}\frac{\mathrm{i}^{\mathrm{m}_2(M)-1}\mathrm{e}^{-(3/4)\pi \mathrm{i}}}{2\sqrt{2}(M-2)!}\times \sum_{\vec{\ell}} \mathbf{S}_{\vec{\ell}}^{\sigma_1^{M-1}(\vec{E})} C_{\vec{p}}(\vec{\ell})\mathrm{e}^{-(P/2)\left(1+\sum_{j=1}^{M}\ell_j/p_j\right)^2\pi \mathrm{i}N}, \tag{4.26}$$

i.e.,

$$Z_{N-2}(\mathcal{M}) \sim N^{M-3}\frac{2^{M-2}}{(M-2)!\sqrt{P}}\mathrm{e}^{-[\phi(\vec{p})/2N]\pi \mathrm{i}}\mathrm{e}^{-[(2M+1)/4]\pi \mathrm{i}}\sum_{\vec{\ell}} C_{\vec{p}}(\vec{\ell})\mathrm{e}^{-(P/2)\left(1+\sum_{j=1}^{M}\ell_j/p_j\right)^2\pi \mathrm{i}N}$$
$$\times (-1)^{MP\left(1+\sum_j \ell_j/p_j\right)+P\sum_j 1/p_j+P\sum_j\sum_{k\neq j}\ell_k/p_jp_k}\left[\prod_{j=1}^{M}\sin\left(P\frac{\ell_j}{p_j^2}\pi\right)\right], \tag{4.27}$$

where the sum of M-tuples $\vec{\ell}$ *runs over D-dimensional space* (3.7), *and the function* $C_{\vec{p}}(\vec{\ell})$ *is defined by*

$$C_{\vec{p}}(\vec{\ell})=\sum_{n=1}^{2P}\chi^{\vec{\ell}}_{2P}(n)B_{M-2}\left(\frac{n}{2P}\right). \tag{4.28}$$

We note that the invariance (3.6) of the periodic function $\chi^{\vec{\ell}}_{2P}(n)$ indicates that

$$C_{\vec{p}}(\sigma_i\sigma_j(\vec{\ell}))=C_{\vec{p}}(\vec{\ell}). \tag{4.29}$$

By construction, the asymptotics (4.26) should coincide with (2.19) which follows from residue part of (2.16). We do not have a direct proof, and we have checked the equivalence numerically for several $\vec{p}$'s. Recalling the path integral approach, the sum of M-tuple $\vec{\ell}$ can be regarded as a label of the gauge equivalent class of flat connections α in (1.4), and we can identify the Chern-Simons invariant with

$$\mathrm{CS}(A_{\alpha(\vec{\ell})})=-\frac{P}{4}\left(1+\sum_{j=1}^{M}\frac{\ell_j}{p_j}\right)^2 \mod 1. \tag{4.30}$$

See Refs. 42 and 43 for computations of the Chern-Simons invariant for the Seifert homology spheres. Note that this value originates from the T matrix (3.16) of the vector modular form. Correspondingly, the Reidemeister torsion is given by

$$\sqrt{T_{\alpha(\ell)}}=\left|\prod_{j=1}^{M}\sin\left(P\frac{\ell_j}{p_j^2}\pi\right)\right|\cdot C_{\vec{p}}(\vec{\ell}). \tag{4.31}$$

Here the product of sin functions originates from the S matrix of the vector modular form.

B. Ohtsuki series

A tail part in the asymptotic formula (4.22) has a simple generating function as was studied in (2.17).

Theorem 18: *Let the T series be defined by* (4.24). *Then the generating function of the T series is*

$$\frac{\prod_{j=1}^{M}\sinh\left(\frac{P}{p_j}x\right)}{[\sinh(Px)]^{M-2}}=\frac{1}{2}\sum_{k=0}^{\infty}\frac{T_{\vec{p}}(k)}{(2k)!}x^{2k}. \tag{4.32}$$

Proof: We first study a case of $\Sigma_j 1/p_j < 1$. Using (4.10), we have

$$\frac{\prod_{j=1}^{M} \sinh\left(\frac{P}{p_j}x\right)}{[\sinh(Px)]^{M-2}} = \frac{(-1)^{M-1}}{2}\sum_{k=0}^{\infty}\sum_{n=0}^{2P-1}\binom{k+M-3}{k}\vec{\chi}_{2P}^{E}(n)\mathrm{e}^{-(n+2P(k+(M-3)/2))x}.$$

We equate this expression with $\Sigma_{k=0}^{\infty}[T_k/(2k)!]x^{2k}$. Applying the Mellin transformation, we get

$$T_k = \frac{(-1)^M}{2}\frac{(2P)^{2k}}{(M-3)!}\sum_{n=0}^{2P-1}\vec{\chi}_{2P}^{E}(n)\sum_{j=0}^{M-3}\frac{1}{1+j+2k}B_{1+j+2k}\left(\frac{n+P(M-3)}{2P}\right)$$
$$\times\sum_{k=j}^{M-3}S_{M-3}^{(k)}\binom{k}{j}\left(\frac{P(M-3)-n}{2P}\right)^{k-j}.$$

Here we have used (3.33). Identities (4.14) and (4.19) give

$$\sum_{k=j}^{M-3}S_{M-3}^{(k)}\binom{k}{j}\left(\frac{P(M-3)-n}{2P}\right)^{k-j} = (-1)^{M+1+j}(j+1)f_{j+1}^{M-2}\left(\frac{n}{2P}-\frac{1}{2}\right),$$

then we have

$$T_k = \frac{1}{2}\frac{(2P)^{2k}}{(M-3)!}\sum_{n=0}^{2P-1}\vec{\chi}_{2P}^{E}(n)\times\sum_{j=1}^{M-2}(-1)^j\frac{j}{j+2k}f_j^{M-2}\left(\frac{n}{2P}-\frac{1}{2}\right)B_{2k+j}\left(\frac{n+P(M-3)}{2P}\right). \tag{4.33}$$

For this expression, we substitute an identity

$$B_{2k+j}\left(\frac{n+P(M-3)}{2P}\right) = B_{2k+j}\left(\frac{n}{2P}+\frac{\mathrm{m}_2(M)-1}{2}\right)+(2k+j)\sum_{m=0}^{\lfloor (M-4)/2\rfloor}\left(\frac{n}{2P}+m+\frac{\mathrm{m}_2(M)-1}{2}\right)^{2k+j-1}$$

which follows from (A10). As we have

$$\sum_{j=1}^{M-2}jf_j^{M-2}\left(\frac{n}{2P}-\frac{1}{2}\right)\left(-\frac{n}{2P}-m-\frac{\mathrm{m}_2(M)-1}{2}\right)^{j-1} = F_{M-2}\left(\frac{n}{2P}-\frac{1}{2},-\frac{n}{2P}-m-\frac{\mathrm{m}_2(M)-1}{2}\right)=0$$

from (4.17), we obtain (4.32).

When $\Sigma_j(1/p_j)>1$, we have another term coming from the second term in (4.12). This gives an additional term to (4.33);

$$T_k^{\mathrm{add}} = \frac{(-1)^M}{2}\frac{(2P)^{2k}}{(M-4)!}\sum_{a=1}^{\infty}\sum_{b=0}^{a-1}\sum_{\vec{\eta}(a)}{}'\sum_{j=1}^{M-3}(-1)^j\frac{j}{2k+j}f_j^{M-3}\left(\frac{1}{2}\sum_i\frac{\eta_i}{p_i}-b-\frac{1}{2}\right)$$
$$\times\left(B_{2k+j}\left(\frac{M-4}{2}+\frac{1}{2}\sum_i\frac{\eta_i}{p_i}-b\right)+(-1)^jB_{2k+j}\left(\frac{M-2}{2}-\frac{1}{2}\sum_i\frac{\eta_i}{p_i}+b\right)\right).$$

Recalling Lemma 14 and applying the same method with the previous, we recover (4.24). □

We give explicit forms of some T series as follows;

$$T_{\vec{p}}(0) = 0, \tag{4.34}$$

$$T_{\vec{p}}(1) = 4P, \tag{4.35}$$

$$T_{\vec{p}}(2) = 8P^3\left(2 - M + \sum_{j=1}^{M} \frac{1}{p_j^2}\right), \tag{4.36}$$

$$T_{\vec{p}}(3) = 4P^5\left(5\left(\sum_{j=1}^{M} \frac{1}{p_j^2} + 2 - M\right)^2 - 2\left(\sum_{j=1}^{M} \frac{1}{p_j^4} + 2 - M\right)\right), \tag{4.37}$$

Based on the exact asymptotic expansion (4.22) of the WRT invariant, we extract the *tail* part and define the formal q-series $\tau_\infty(\mathcal{M})$ as a quantum invariant of the Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ by identifying $\exp(2\pi\mathrm{i}/N)$ with q;

$$q^{\phi(\vec{p})/4-1/2}(q-1)\cdot\tau_\infty(\mathcal{M}) = \sum_{k=0}^{\infty} \frac{T_{\vec{p}}(k)}{k!}\left(\frac{\log q}{4P}\right)^k. \tag{4.38}$$

This invariant $\tau_\infty(\mathcal{M})$ of the formal q series coincides with the invariant $\tau_N^{\mathrm{int}}(\mathcal{M})$ defined in (2.16). Namely we have an integral expression for $\tau_\infty(\mathcal{M})$.

The Ohtsuki series[32] $\lambda_n(\mathcal{M})$ is defined from the formal q series $\tau_\infty(\mathcal{M})$ by

$$\tau_\infty(\mathcal{M}) = \sum_{n=0}^{\infty} \lambda_n(\mathcal{M})(q-1)^n \tag{4.39}$$

Then the Ohtsuki series $\lambda_n(\mathcal{M})$ for $\mathcal{M}=\Sigma(\vec{p})$ is computed as follows.

Theorem 19: *The Ohtsuki series* $\lambda_n(\mathcal{M})$ *for the Seifert homology sphere* $\mathcal{M}=\Sigma(\vec{p})$ *is written in terms of* $\vec{p}$ *and* $\phi(\vec{p})$ *defined in* (2.11) *as*

$$\lambda_n(\mathcal{M}) = \frac{2}{(n+1)!}\left[\prod_{j=0}^{n}\left(\frac{P}{4}\frac{\mathrm{d}^2}{\mathrm{d}x^2} + \frac{1}{2} - \frac{\phi(\vec{p})}{4} - j\right)\right]G(x)\Bigg|_{x=0}, \tag{4.40}$$

where the function $G(x)$ *is*

$$G(x) = \frac{\prod_{j=1}^{M}\sinh\left(\frac{x}{p_j}\right)}{[\sinh(x)]^{M-2}}. \tag{4.41}$$

Proof: From (4.38) and (A15), we have

$$(q-1)\tau_\infty(\mathcal{M}) = \sum_{m=0}^{\infty}\binom{\frac{1}{2} - \frac{\phi(\vec{p})}{4}}{m}(q-1)^m \sum_{j=0}^{\infty}\sum_{k=0}^{j}\frac{S_j^{(k)}}{j!}\frac{T_{\vec{p}}(k)}{(4P)^k}(q-1)^j.$$

We then have

$$\begin{aligned}\lambda_n(\mathcal{M}) &= \sum_{j=0}^{n}\frac{1}{(j+1)!}\binom{\frac{1}{2} - \frac{\phi(\vec{p})}{4}}{n-j}\sum_{k=1}^{j+1} S_{j+1}^{(k)}\frac{T_{\vec{p}}(k)}{(4P)^k} \\ &= \frac{1}{(n+1)!}\sum_{m=0}^{n}\sum_{k=1}^{n+1-m}\binom{m+k}{m}S_{n+1}^{(m+k)}\left(\frac{1}{2} - \frac{\phi(\vec{p})}{4}\right)^m\frac{T_{\vec{p}}(k)}{(4P)^k},\end{aligned}$$

where in the second equality we have expanded the binomial coefficient in terms of the Stirling number of the first kind using (A14), then we have applied (A17). Theorem 18 shows that the function $G(x)$ (4.41) gives

$$\left(P\frac{\mathrm{d}}{\mathrm{d}x}\right)^{2k} G(x)\Big|_{x=0} = \frac{1}{2}T_{\vec{p}}(k).$$

Substituting this expression and recalling (A14), we obtain the required formula. □

Explicit forms of the lowest three Ohtsuki series $\lambda_n(\mathcal{M})$ for $\mathcal{M}=\Sigma(\vec{p})$ are

$$\lambda_0(\mathcal{M}) = 1, \tag{4.42}$$

$$\lambda_1(\mathcal{M}) = 6\lambda_C(\mathcal{M}), \tag{4.43}$$

$$\lambda_2(\mathcal{M}) = \frac{3(\phi(\vec{p}))^2 + 12\phi(\vec{p}) - 4}{96} - \frac{P}{16}\left(2 - M + \sum_{j=1}^{M}\frac{1}{p_j^2}\right)(\phi(\vec{p}) + 2) + \frac{P^2}{96}\left(5\left(2 - M + \sum_{j=1}^{M}\frac{1}{p_j^2}\right)^2 - 2\left(2 - M + \sum_{j=1}^{M}\frac{1}{p_j^4}\right)\right), \tag{4.44}$$

where $\lambda_C(\mathcal{M})$ is the Casson invariant of the Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$[44,45]

$$\lambda_C(\mathcal{M}) = -\frac{1}{8} + \frac{1}{24P}\left(1 + \sum_{k=1}^{M}\left(\frac{P}{p_k}\right)^2 - (M-2)P^2\right) - \frac{1}{2}\sum_{k=1}^{M} s\left(\frac{P}{p_k}, p_k\right). \tag{4.45}$$

The relationship between the Casson invariant $\lambda_C(\mathcal{M})$ and the Ohtsuki series $\lambda_1(\mathcal{M})$ was first proved in Ref. 46. See Ref. 47 for a computation of $\lambda_2(\mathcal{M})$.

C. Lattice points

We have seen that the asymptotics of the WRT invariant is dominated by the term (4.26), which shows that the number of terms in the sum of $\vec{\ell}$ are at most D defined in (3.7). Though, as was studied in Refs. 15 and 16 for cases of $M=3$ and $M=4$, the function $C_{\vec{p}}(\vec{\ell})$ may vanish for some $\vec{\ell}$'s.

Theorem 20: *We fix M-tuple $\vec{p}$ with pairwise coprime positive integers p_j, and let the function $C_{\vec{p}}(\vec{\ell})$ be defined by (4.28) for $\vec{\ell}\in\mathbb{Z}^M$ satisfying $1\leqslant \ell_j \leqslant p_j - 1$. Due to (4.29), we have D independent functions. We set $\gamma(\vec{p})$ as the number of M-tuples $\vec{\ell}$ satisfying*

$$C_{\vec{p}}(\vec{\ell}) \neq 0,$$

and $L(\vec{p})$ as the integral lattice points $\vec{\ell}\in\mathbb{Z}^M_{>0}$ inside the M-dimensional tetrahedron,

$$0 < \sum_{j=1}^{M}\frac{\ell_j}{p_j} < 1.$$

Then we have

$$D - \gamma(\vec{p}) \geqslant L(\vec{p}). \tag{4.46}$$

Proof: As a generalization of the function $C_{\vec{p}}(\vec{\ell})$ defined in (4.28), we define $C^k_{\vec{p}}(\vec{\ell})$ for $k\geqslant 0$ by

$$C^k_{\vec{p}}(\vec{\ell}) = \sum_{n=1}^{2P}\chi^{\vec{\ell}}_{2P}(n)B_k\left(\frac{n}{2P}\right) \tag{4.47}$$

in terms of the Bernoulli polynomials. We have $C_{\vec{p}}(\vec{\ell})=C^{M-2}_{\vec{p}}(\vec{\ell})$. As a generating function $Z^{\vec{\ell}}_{\vec{p}}(t)$ of these polynomials, we define

$$Z_{\vec{p}}^{\vec{\ell}}(t) = \sum_{k=0}^{\infty} \frac{t^k}{k!} C_{\vec{p}}^{k}(\vec{\ell}). \tag{4.48}$$

Using (A8), we have

$$Z_{\vec{p}}^{\vec{\ell}}(t) = \frac{t}{e^t - 1} \sum_{n=1}^{2P} \chi_{2P}^{\vec{\ell}}(n) e^{(t/2P)n}. \tag{4.49}$$

In the case of $0 < \Sigma_j (\ell_j / p_j) < 1$, we have

$$\sum_{n=0}^{2P} \chi_{2P}^{\vec{\ell}}(n) z^n = -z^P \prod_{j=1}^{M} (z^{P\ell_j/p_j} - z^{-P\ell_j/p_j}) \tag{4.50}$$

which gives

$$Z_{\vec{p}}^{\vec{\ell}}(t) = -\frac{t}{e^{t/2} - e^{-t/2}} \prod_{j=1}^{M} (e^{(\ell_j/2p_j)t} - e^{-(\ell_j/2p_j)t}).$$

This shows that

$$Z_{\vec{p}}^{\vec{\ell}}(t) = -\left(\prod_{j=1}^{M} \frac{\ell_j}{p_j} \right) t^M + O(t^{M+2})$$

and that $C_{\vec{p}}^{k}(\vec{\ell}) = 0$ for $0 \leqslant k \leqslant M-1$. So we have $C_{\vec{p}}(\vec{\ell}) = 0$ when $0 < \Sigma_j \ell_j / p_j < 1$.

The invariance (3.6) of the periodic functions $\chi_{2P}^{\vec{\ell}}(n)$ proves the statement of the theorem. □

In the case of $\Sigma_j \ell_j / p_j > 1$, the generating function (4.50) should be replaced with a formula like (4.12), and we do not know whether the function $C_{\vec{p}}(\vec{\ell})$ vanishes. We conjecture that, when $\Sigma_j \ell_j / p_j > 1$, we have $C_{\vec{p}}(\ell) = 0$ iff $\chi_{2P}^{\vec{\ell}}(n)$ coincides with $\chi_{2P}^{\vec{\ell}'}(n)$ such that $\Sigma_j \ell_j' / p_j < 1$.

Conjecture 1: Under the conditions of Theorem 20, we have

$$D - \gamma(\vec{p}) = L(\vec{p}). \tag{4.51}$$

This conjecture was proved for $M \leqslant 4$ in Refs. 15 and 16. It states that the number of the flat connections which contribute as (4.26) coincides with the number of integral lattice points inside the M-dimensional tetrahedron.

D. Ehrhart polynomial

Explicit form of the number $L(\vec{p})$ of the lattice points inside the M-dimensional tetrahedron was first computed by Mordell[48] for cases of $M=3$ and $M=4$;

- $M=3$;

$$L(p_1,p_2,p_3) = \frac{1}{4}(p_1-1)(p_2-1)(p_3-1) + \frac{1}{12P} - \frac{1}{4} - \frac{P}{12}\left(1 - \frac{1}{p_1^2} - \frac{1}{p_2^2} - \frac{1}{p_3^2}\right) - s(p_1p_2,p_3) - s(p_2p_3,p_1) - s(p_1p_3,p_2), \tag{4.52}$$

- $M=4$,

$$L(p_1,p_2,p_3,p_4)=\frac{1}{8}\prod_{j=1}^{4}(p_j-1)+\frac{3}{8}-\frac{P}{12}+\frac{P}{24}\sum_{j=1}^{4}\frac{1+p_j}{p_j^2}+\frac{1}{24P}\left(1-\sum_{j=1}^{4}p_j\right)-\frac{P}{24}\sum_{j\neq k}^{4}\frac{1}{p_j^2p_k}$$
$$-\frac{1}{2}\sum_{j=1}^{4}s\left(\frac{P}{p_j},p_j\right)+\frac{1}{2}\sum_{j\neq k}^{4}s\left(\frac{P}{p_jp_k},p_j\right). \tag{4.53}$$

Here $s(b,a)$ is the Dedekind sum (A1). For higher dimension M, the lattice points $L(\vec{p})$ might be written in terms of Zagier's higher-dimensional Dedekind sum,[60] but there seems to exist no applicable expressions.

Although, there is a useful tool to count the lattice points (see, *e.g.*, Ref. 49). Let $\mathcal{P}$ be the M-dimensional open tetrahedron with integer vertices, $(p_1,0,\ldots,0)$, $(0,p_2,0,\ldots,0),\ldots,(0,\ldots,0,p_M)$, and (0,...,0);

$$\mathcal{P}=\left\{(\ell_1,\ldots,\ell_M)\in\mathbb{Z}^M\,\middle|\,\sum_{j=1}^{M}\frac{\ell_j}{p_j}<1,\ell_k>0\right\}. \tag{4.54}$$

Let $E_{\mathcal{P}}(t)$ denote the number of lattice points in the dilated tetrahedron $t\mathcal{P}$. So we have

$$L(\vec{p})=E_{\mathcal{P}}(t=1).$$

In the same manner, we suppose that $E_{\bar{\mathcal{P}}}(t)$ denotes the number of lattice points of the closure of $t\mathcal{P}$,

$$E_{\bar{\mathcal{P}}}(t)=\#\left\{(m_1,\ldots,m_M)\in\mathbb{Z}^M\,\middle|\,\sum_{j=1}^{M}\frac{m_j}{p_j}\leqslant t,m_k\geqslant 0\right\}.$$

These functions, $E_{\mathcal{P}}(t)$ and $E_{\bar{\mathcal{P}}}(t)$, become polynomials of t,[50] which are called the Ehrhart polynomial. Moreover we have the Ehrhart-Macdonald reciprocity formula,[50,51]

$$E_{\mathcal{P}}(-t)=(-1)^ME_{\bar{\mathcal{P}}}(t). \tag{4.55}$$

In general, the number of lattice points $E_{\bar{\mathcal{P}}}(t)$ becomes polynomial of t for arbitrary polytope $\bar{\mathcal{P}}$.[50] We set the coefficients of the Ehrhart polynomial as

$$E_{\bar{\mathcal{P}}}(t)=c_M(\mathcal{P})t^M+c_{M-1}(\mathcal{P})t^{M-1}+\cdots+c_0(\mathcal{P}). \tag{4.56}$$

It is well known that $c_M(\mathcal{P})$ is the volume of $\mathcal{P}$, $c_M(\mathcal{P})=\mathrm{Vol}(\mathcal{P})$, $c_{M-1}(\mathcal{P})$ is a half of the boundary surface area, $c_{M-1}(\mathcal{P})=\frac{1}{2}\,\mathrm{Vol}(\partial\mathcal{P})$. The coefficient $c_0(\mathcal{P})$ is the Euler characteristic $\chi(\mathcal{P})$, and $c_0(\mathcal{P})=1$ when $\mathcal{P}$ is the convex polytope.

The first nontrivial coefficient of the Ehrhart polynomial for the M-dimensional tetrahedron is thus $c_{M-2}(\mathcal{P})$. In our case of the M-dimensional tetrahedron with pairwise coprime integers p_j, we have[52,53]

$$(M-2)!\cdot c_{M-2}(\mathcal{P})=\frac{M}{4}+\frac{1}{24P}\left(2-\sum_{k=1}^{M}\left(\frac{P}{p_k}\right)^2+3\left(\sum_{k=1}^{M}\frac{P}{p_k}\right)^2\right)-\sum_{k=1}^{M}s\left(\frac{P}{p_k},p_k\right). \tag{4.57}$$

Recalling the Casson invariant $\lambda_C(\mathcal{M})$ (4.45) for the Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$, which is proportional to the first Ohtsuki series (4.43), we have the following.

Proposition 21: The Casson invariant $\lambda_C(\mathcal{M})$ for $\mathcal{M}=\Sigma(\vec{p})$ is related to the first nontrivial coefficient of the Ehrhart polynomial for the M-dimensional tetrahedron $\mathcal{P}$ (4.54);

$$\lambda_C(\mathcal{M})-\frac{(M-2)!}{2}c_{M-2}(\mathcal{P})=-\frac{M+1}{8}+\frac{M-2}{24}P-\frac{P}{8}\sum_{1\leqslant j<k\leqslant M}\frac{1}{p_jp_k}. \tag{4.58}$$

TABLE I. The WRT invariant $Z_N(\mathcal{M})$ for $\mathcal{M}=\Sigma(2,3,5,7,11)$. Asymptotic formula for $Z_N^{(0)}(\mathcal{M})$ is from (4.26).

It is remarked that the residue formula for $c_{M-2}(\mathcal{P})$ given in Ref. 52 looks like an expression (2.10) of the WRT invariant $\tau_N(\mathcal{M})$ for $\mathcal{M}=\Sigma(\vec{p})$.

V. SOME EXAMPLES OF NUMERICAL EXPERIMENTS

We give some numerical experiments on the asymptotic behavior of the WRT invariants for the Seifert homology spheres.

A. $\Sigma(2,3,5,7,11)$

For $\vec{p}=(2,3,5,7,11)$, we have $P=2310$, $D=30$, and $\phi(\vec{p})=34\,189/2310$. The bases for 30-dimensional space is given by $\vec{\ell}=(1,1,\ell_3,\ell_4,\ell_5)$ with $1\leqslant\ell_3\leqslant 2$, $1\leqslant\ell_4\leqslant 3$, $1\leqslant\ell_5\leqslant 5$. For all these 5-tuples $\vec{\ell}$, we can check that $C_{\vec{p}}(\vec{\ell})\neq 0$, which supports Conjecture 1 as we have $\Sigma_j 1/p_j = 2927/2310>1$.

In Table I we give numerical results on the Witten invariant $Z_N(\mathcal{M})$ for $\mathcal{M}=\Sigma(2,3,5,7,11)$, which is performed with a help of PARI/GP. We give both the exact value $Z_N(\mathcal{M})$ and asymptotic value $Z_N^{(0)}(\mathcal{M})$ for several N's. They vary much with N, and comparing these data we see an agreement.

B. $\Sigma(3,7,8,11,13,17)$

For $\vec{p}=(3,7,8,11,13,17)$, we have $\phi(\vec{p})=338\,099/408\,408$ and $D=5040$. This $D=5040$-dimensional vector space is spanned by $\vec{\ell}=(1,1\leqslant\ell_2\leqslant 3,1\leqslant\ell_3\leqslant 7,1\leqslant\ell_4\leqslant 5,1\leqslant\ell_5\leqslant 6,1\leqslant\ell_6\leqslant 8)$. Among these $D=5040$ bases, we check that $C_{\vec{p}}(\vec{\ell})=0$ when $\vec{\ell}=(1,1,1,1,1,1)$, (1, 1, 1, 1, 1, 2), (1, 1, 1, 1, 1, 3) (1, 1, 1, 1, 2, 1), (1, 1, 1, 1, 2, 2), (1, 1, 1, 1, 3, 1), (1, 1, 1, 2, 1, 1), (1, 1, 1, 2, 1, 2), (1, 1, 1, 2, 2, 1), (1, 1, 2, 1, 1, 1), (1, 2, 1, 1, 1, 1), which supports Conjecture 1.

Numerical results on the exact value and the asymptotics of the Witten invariant for $\Sigma(\vec{p})$ are summarized in Table II. We see an agreement.

VI. CONCLUSION AND DISCUSSION

We have studied the asymptotic expansion of the SU(2) WRT invariant $\tau_N(\mathcal{M})$ for the M-exceptional fibered Seifert homology spheres $\mathcal{M}=\Sigma(\vec{p})$ in $N\to\infty$ number theoretically. We have found that the invariant can be written in terms of a limiting value of *fractional* derivative, i.e., derivative of the Eichler integral, of the vector modular forms with weight 3/2 and 1/2. This supports a result[26] that the WRT invariant is a *limiting* value of the holomorphic function in a limit that q tends to the Nth root of unity. By use of the nearly modular property of the Eichler integral,

we have obtained an asymptotic expansion of $\tau_N(\mathcal{M})$ in the large N limit.

Although an asymptotic behavior of the WRT invariant was previously studied in, e.g., Ref. 8, the correspondence between modular forms and the quantum invariants enables us to relate topological invariants such as the Chern-Simons invariants, the Reidemeister torsion, and the Casson invariant, with geometries of modular forms. For example, we have found that the number of the gauge equivalent classes of flat connections, which dominate the WRT invariant in the large-N limit, is related to the number of integral lattice points inside the M-dimensional tetrahedron. From this view, we have established that the Casson invariant for the Seifert homology sphere has a relationship with the first non-trivial coefficient of the Ehrhart polynomial.

In our previous papers[17,25] we have shown that the WRT invariants for the Seifert manifolds with three-exceptional fibers coincides with a limiting value of the Ramanujan mock theta functions. Investigated[35] is a modular transformation formula of the newly proposed mock theta functions based on explicit form of the WRT invariants. This intriguing correspondence seems to originate from a result that the integral expression (2.16) of the WRT invariant has a connection with the Mordell integral.[34] Our results presented here will shed a new light on geometric and topological aspects of modular forms.

Though we have studied only the SU(2) invariant, the Witten partition function (1.1) can be defined for arbitrary gauge group, and an explicit form of the invariant for the Seifert manifold is given.[54] Extending the method of Lawrence and Rozansky, it is shown[55] that the partition function can be written in the integral form which can be interpreted as the matrix model, and that it becomes a sum of local contributions from the flat connections. This fact is recently reinterpreted from the viewpoint of the path integral by use of non-abelian localization.[56] As it is well known that the Chern-Simons perturbation theory of the SU(N) Witten invariant as a $1/N$ expansion can be interpreted from the string theory (see, e.g., Ref. 57), it will be interesting to investigate the quantum invariants/modular forms correspondence for the WRT invariant associated with SU(N) gauge group as a generalization of the present work.

APPENDIX: SPECIAL FUNCTIONS AND IDENTITIES

1. Dedekind sum

The Dedekind sum is defined by (see, e.g., Ref. 58)

$$s(b,a)=\sum_{k=1}^{a-1}\left(\left(\frac{k}{a}\right)\right)\left(\left(\frac{kb}{a}\right)\right), \tag{A1}$$

where $((x))$ is the sawtooth function

$$((x))=\begin{cases} x-\lfloor x\rfloor-\dfrac{1}{2} & \text{when } x\notin\mathbb{Z} \\ 0 & \text{when } x\in\mathbb{Z}. \end{cases}$$

The Dedekind sum can also be written as

$$s(b,a)=\frac{1}{4a}\sum_{k=1}^{a-1}\cot\left(\frac{k}{a}\pi\right)\cot\left(\frac{kb}{a}\pi\right). \tag{A2}$$

The Dedekind sum is known to satisfy the reciprocity formula

$$s(b,a)+s(a,b)=-\frac{1}{4}+\frac{1}{12}\left(\frac{a}{b}+\frac{b}{a}+\frac{1}{ab}\right). \tag{A3}$$

We note

$$s(-b,a)=-s(b,a), \tag{A4}$$

$$s(b,a)=s(c,a)\quad \text{for } bc=1 \bmod a. \tag{A5}$$

2. Gauss sum

As a discrete analogue of the Gaussian integral, we have a formula of the Gauss sum as

$$\sum_{n=0}^{2N-1}\mathrm{e}^{-(1/2N)n^2\pi\mathrm{i}}=\sqrt{2N}\mathrm{e}^{-(1/4)\pi\mathrm{i}}. \tag{A6}$$

The reciprocity formula of the Gauss sum follows from the Gauss integral as (see, e.g., Refs. 30 and 59)

$$\sum_{n \bmod N}\mathrm{e}^{\pi\mathrm{i}(M/N)n^2+2\pi\mathrm{i}kn}=\sqrt{\left|\frac{N}{M}\right|}\mathrm{e}^{(\pi\mathrm{i}/4)\mathrm{sign}(NM)}\sum_{n \bmod M}\mathrm{e}^{-\pi\mathrm{i}(N/M)(n+k)^2}, \tag{A7}$$

where N, $M\in\mathbb{Z}$ and $N\,k\in\mathbb{Z}$, and $N\,M$ is even.

3. Bernoulli polynomial

The nth Bernoulli polynomial $B_n(x)$ is defined from the generating function as

$$\frac{t\mathrm{e}^{xt}}{\mathrm{e}^t-1}=\sum_{k=0}^{\infty}B_k(x)\frac{t^k}{k!}. \tag{A8}$$

Some of them are written as follows;

$$B_0(x)=1,$$

$$B_1(x) = x - \frac{1}{2},$$

$$B_2(x) = x^2 - x + \frac{1}{6},$$

$$B_3(x) = x^3 - \frac{3}{2}x^2 + \frac{1}{2}x.$$

These polynomials satisfy the following relations;

$$B_k(1-x) = (-1)^k B_k(x), \tag{A9}$$

$$B_k(x+1) - B_k(x) = kx^{k-1}, \tag{A10}$$

$$\frac{\mathrm{d}}{\mathrm{d}x} B_n(x) = nB_{n-1}(x). \tag{A11}$$

Note that the Bernoulli function has the Fourier expansion as

$$B_k(x - \lfloor x \rfloor) = k! \sum_{\substack{n \in \mathbb{Z} \\ n \neq 0}} \frac{\mathrm{e}^{2\pi \mathrm{i} n x}}{(2\pi \mathrm{i} n)^k} \tag{A12}$$

and that

$$B_n(x+y) = \sum_{k=0}^{n} \binom{n}{k} B_k(x) y^{n-k}. \tag{A13}$$

4. Stirling number

The Stirling number of the first kind $S_n^{(m)}$ denotes the (signed) number of permutations of n elements which contain m permutation cycles (see, e.g., Ref. 40). The generating function of $S_n^{(m)}$ is written as

$$\prod_{j=0}^{n-1} (x-j) = \sum_{m=0}^{n} S_n^{(m)} x^m \tag{A14}$$

and $S_n^{(m)} \neq 0$ when $n \geqslant m \geqslant 0$. Another form of the generating function is given by[41]

$$\frac{(\log q)^m}{m!} = \sum_{n=m}^{\infty} S_n^{(m)} \frac{(q-1)^n}{n!} \tag{A15}$$

Based on these generating functions, we have the recursion relations of $S_n^{(m)}$ as follows;

$$S_{n+1}^{(m)} = S_n^{(m-1)} - nS_n^{(m)}, \tag{A16}$$

$$\binom{m}{r} S_n^{(m)} = \sum_{k=m-r}^{n-r} \binom{n}{k} S_{n-k}^{(r)} S_k^{(m-r)}. \tag{A17}$$

(Received 13 July 2006; accepted 1 September 2006; published online 19 October 2006)

It is shown how techniques from constructive quantum field theory may be applied to indefinite metric gauge theories in Hilbert space for the case of a Higgs-Maxwell-Chern-Simons theory on a lattice. The Hamiltonian operator is shown to be Krein essentially self-adjoint by means of unbounded but Krein unitary transformations relating the Hamiltonian to an essentially maximal accretive operator.
 [DOI: 10.1063/1.2358393]

I. INTRODUCTION

The mathematical study of Higgs gauge theories has been focused mainly on gauge-invariant quantities undertaken using Euclidean functional integrals.[1–3] However, in the theoretical physics literature, it is mostly the Higgs and gauge fields that are used directly.[4–7] In this direction we consider a $(2+1)$ dimensional space-time Maxwell-Chern-Simons field minimally coupled to a charged scalar field in the indefinite metric framework proposed by Wightman and Gårding.[8] By using a representation of the canonically quantized Chern-Simons field in a Hilbert space with a Krein indefinite metric, we show the Chern-Simons field to be a Hilbert normal and Krein self-adjoint operator. Regularizing field operators with a finite periodic lattice allows construction of the Hamiltonian operator. Initially this operator is densely defined and closable but exhibits no immediate spectral properties which would suggest direct implementation of techniques from constructive quantum field theory in obtaining a Euclidean path-space representation for a semigroup generated by this Hamiltonian. In this paper, we show the underlying structure of the Hamiltonian to be that of an accretive operator masked by unbounded Krein unitary "gauge" transformations. This leads to an unbounded semigroup which, unlike Fröhlich's theory of unbounded symmetric semigroups, is not Hilbert self-adjoint.[9] In a second paper,[10] we will obtain the corresponding Euclidean theory and examine the relation between the physical states in the Wightman-Gårding framework and Osterwalder-Schrader positivity provided by this unbounded semigroup.

In Sec. II, we describe our representation for the Maxwell-Chern-Simons field which differs from those in Refs. 11 and 12 and establish regularity of the field that we use. It is convenient to represent these fields in terms of harmonic oscillator variables in Sec. III and the Appendix since the Krein gauge transformations then become transparent as well as their properties as unbounded operators. In Sec. IV, it is shown that the real part of the transformed Hamiltonian defines an essentially self-adjoint operator which is bounded below. The gauge-transformed Hamiltonian is then shown to be an accretive operator in Sec. V. The bounds from Sec. IV allow us to prove a quadratic estimate for the transformed Hamiltonian by which it becomes a maximal accretive operator after closure, and thus Krein essentially self-adjoint.

II. MAXWELL-CHERN-SIMONS FIELDS

We work in $d=s+1$ dimensional space-time, where the number of spatial dimensions is $s=2$. The metric is given by $g_{00}=+1$ and $g_{ij}=-\delta_{ij}$, with the remaining components vanishing. As usual, Latin indices are spatial, ranging from 1 to s, while Greek indices include the time component, 0. We write the inner product of d-vectors k and x alternately as

$$kx = k_\mu x^\mu = k^\mu x_\mu = k_0 x_0 - k \cdot x = k_0 x_0 - k_i x_i,$$

where indices are raised or lowered by contraction with g and repeated indices are summed over their range. It should always be clear from context whether k and x refer to d-vectors or s-vectors. We use analogous notation for d-divergences, e.g., $\partial A \equiv \partial_\mu A^\mu$. Our units are such that $\hbar=c=1$. Finally, we make use of the notation $\omega=\omega(k)=\sqrt{k\cdot k}$ and $\mu=\mu(k)=\sqrt{k\cdot k+m^2}=\sqrt{\omega^2+m^2}$. Hopefully, our conventions are now clear.

The Maxwell-Chern-Simons (MCS) Lagrangian density is given by

$$\mathcal{L} = -\frac{1}{2}\partial_\mu A_\nu \partial^\mu A^\mu + \frac{\lambda}{2}(\partial A)^2 + \frac{m}{2}\epsilon^{\mu\nu\rho}\partial_\mu A_\nu A_\rho. \tag{1}$$

The term $(\partial A)^2$ fixes the gauge with the parameter λ

$$\lambda = \frac{2\xi}{2\xi - 1} = -\frac{\gamma}{1-\gamma} \tag{2}$$

interpolating between the various covariant gauges. Here, $\gamma=\lambda=\xi=0$ corresponds to the Feynman gauge while $\gamma=1$, $\lambda\to\infty$, $\xi=1/2$ all correspond to Landau gauge. The parameters ξ and γ are more convenient than λ for our representation below. The parameter γ is introduced for comparison with other works that start with a different Lagrangian such as Ref. 11, while ξ is introduced for comparison with works such as Refs. 12 and 13.

The Euler-Lagrange equations corresponding to Eq. (1) are

$$\Box A^\mu - \lambda \partial^\mu(\partial A) + m\epsilon^{\mu\alpha\beta}\partial_\alpha A_\beta = 0. \tag{3}$$

The homogeneous Green's function for (3) can be written

$$\begin{aligned}\langle A_\mu(x)A_\nu(y)\rangle = {} & \frac{1}{(2\pi)^2}\int d\Omega_m(k)e^{-ik(x-y)}\left[\frac{k_\mu k_\nu}{m^2} - g_{\mu\nu} - \frac{i}{m}\epsilon_{\mu\nu\rho}k^\rho\right] + \frac{1}{(2\pi)^2}\int d\Omega_0(k)e^{-ik(x-y)} \\ & \times\left[-\frac{k_\mu k_\nu}{m^2} + \frac{i}{m}\epsilon_{\mu\nu\rho}k^\rho\right] - \frac{1-2\xi}{(2\pi)^2}\int d\Omega_0(k)e^{-ik(x-y)} \\ & \times\frac{1}{2\omega}\left[\delta_{\mu 0}k_\nu + \delta_{\nu 0}k_\mu - i(x_0-y_0)k_\mu k_\nu - \frac{k_\mu k_\nu}{\omega}\right],\end{aligned} \tag{4}$$

which has support both on the light cone and the mass m hyperboloid. The canonical momenta associated with (1) are

$$\pi^0 \equiv \frac{\delta\mathcal{L}}{\delta(\partial_0 A_0)} = -\partial_0 A^0 + \lambda\,\partial A \tag{5}$$

$$\pi^j \equiv \frac{\delta\mathcal{L}}{\delta(\partial_0 A_j)} = -\partial_0 A^j + \frac{m}{2}\epsilon^{0jn}A_n. \tag{6}$$

It is convenient to express (3) in terms of differential forms. For this, we define a 1-form $A \equiv A_\mu dx^\mu$. We let $*$ denote the Hodge duality operator associated with our metric g and the orientation given by the volume form $dx^0\wedge dx^1\wedge dx^2$, so that $**=+1$. Furthermore, we define the codifferential δ in the usual way on k-forms by

$$\delta = -\det(g)(-1)^{d(k+1)} * d * = -(-1)^{3(k+1)} * d * = (-1)^k * d* \tag{7}$$

so that, for a k-form β, we have

$$\delta\beta = \delta\left(\frac{1}{k!}\beta_{\mu_1\cdots\mu_k}dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_k}\right) = -\frac{1}{(k-1)!}\partial^{\mu_1}\beta_{\mu_1\cdots\mu_k}dx^{\mu_2}\wedge\cdots\wedge dx^{\mu_k}.$$

Then, we find that $\Box \equiv \partial^\mu\partial_\mu$ is given by

$$\Box = -(\delta d + \mathrm{d}\delta), \tag{8}$$

in analogy with the Laplace-Beltrami operator in the Riemannian case. With this notation, we may write (3) as

$$\delta dA - m * dA = (\lambda - 1)d\delta A. \tag{9}$$

From this standpoint, it becomes easy to prove the following decomposition theorems, which we shall utilize in the process of canonical quantization.

Theorem II.1 (MCS Decomposition). *Let A be a 1-form satisfying (9). Then, there exist 1-forms V and S satisfying the equations*

$$dV = m * V, \quad * dS = -\frac{(\lambda-1)}{m}d\delta S \tag{10}$$

such that $A = V + S$.

Conversely, given 1-forms V and S satisfying (10), the 1-form $A = V + S$ satisfies (9).

Proof:

For the first statement, define

$$V \equiv \frac{1}{m} * dA + \frac{1}{m^2}(\lambda-1)d\delta A$$

so that

$$*dV = \frac{1}{m} * d * dA = \frac{1}{m}\delta dA = \frac{1}{m}(m * dA + (\lambda-1)d\delta A) = mV,$$

where we have used (9). Now, define the 1-form $S \equiv A - V$. This satisfies

$$*dS = *dA - *dV = *dA - mV = *dA - \left(*dA + \frac{\lambda-1}{m}d\delta A\right) = -\frac{\lambda-1}{m}d\delta A.$$

Then, the result (10) follows by noting that

$$\delta A = \delta S + \delta V = \delta S + \delta\left(\frac{*dV}{m}\right) = \delta S.$$

For the converse, we note that Eqs. (10) imply

$$\delta dV = (-1)^2 * d * dV = + * d(mV) = m^2 V,$$

$$\delta V = (-1)^1 * d * V = - * d * \left(\frac{*dV}{m}\right) = 0,$$

$$\delta dS = (-1)^2 * d * dS = + * d\left(-\frac{\lambda - 1}{m} d\delta S\right) = 0.$$

Then, we simply substitute $A = V + S$ into Eq. (9) to find

$$\text{LHS} = \delta d(V+S) - m * d(V+S) = m^2 V - m * dV - m * dS = -m\left(-\frac{\lambda - 1}{m} d\delta S\right) = (\lambda - 1) d\delta S,$$

$$\text{RHS} = (\lambda - 1) d\delta(V+S) = (\lambda - 1) d\delta S,$$

and note that RHS=LHS. Q.E.D.

Notice that the gauge dependence, as parametrized by λ, has been separated into the field S in Eqs. (10). For this reason, we often refer to V as the physical MCS field. We can say more about V and S. It has long been known that there are certain necessary conditions that a valid decomposition of a solution of (3) into the sum of a massive and a massless vector field must satisfy Refs. 14 and 15. These conditions follow easily from our theorem, so we state them as a corollary.

Corollary II.2: *The vector field* V_μ *corresponding to the* 1*-form* V *satisfies*

$$(\Box + m^2) V_\mu = 0$$

$$\partial V = 0,$$

which are the Proca field equations. The vector field S_μ *corresponding to the* 1*-form* S *satisfies*

$$\Box S_\mu = \partial_\mu (\partial S)$$

$$\Box (\partial S) = 0,$$

provided $\lambda \neq 1$.

One should note that, although V_μ satisfies the Proca field equations, it is not a true Proca field since it also satisfies the additional constraint (10). Thus, one expects the quantized version of V_μ to propagate one less physical mode than a 2+1- dimensional Proca field. We shall see that this is indeed the case. In fact, even at the classical level, we have the following result.

Proposition II.3 (*Proca Decomposition*): *Let* U *be a* 1*-form satisfying the Klein-Gordon equation*

$$(\Box + m^2) U = 0$$

for $m > 0$. *Then, it is both necessary and sufficient that* U *satisfy the decomposition*

$$U = V^+ + V^- + d\phi, \tag{11}$$

where $V^\pm$ *satisfy* $*dV^\pm = \pm m V^\pm$ *and* ϕ *is a scalar solution to the Klein-Gordon equation. If* U *is additionally a Proca field* (*i.e.*, $\delta U = 0$), *then we may choose* $\phi \equiv 0$.

Proof:

For necessity, define

$$V^\pm \equiv -\frac{1}{2}\left(\frac{1}{m^2} d\delta U \mp \frac{1}{m} * dU - U\right) \quad \text{and} \quad \phi \equiv \frac{1}{m^2}\delta U \tag{12}$$

The remainder then follows by straightforward calculations. Q.E.D.

The well-known bosonization of the MCS field exhibiting its single, massive, physical degree of freedom (see, e.g., Ref. 4) also follows easily from Theorem II.1. Thus, we state it as a corollary as well.

Corollary II.4: *A vector field satisfying*

$$\epsilon_{\mu\nu\rho}\partial^{\nu}V^{\rho} = mV_{\mu} \tag{13}$$

[*i.e.*, $*dV=mV$ *as per* (10)] *must necessarily be of the form*

$$V_0 = \frac{\sqrt{-\triangle}}{m}\phi$$

$$V_j = -\left[\frac{\partial_0\partial_j}{m\sqrt{-\triangle}} - \frac{\epsilon_{jn}\partial_n}{\sqrt{-\triangle}}\right]\phi$$

for some scalar field ϕ.

Proof:

Taking the time derivative of (13) for $\mu=j$, we find

$$m\partial_0 V_j = -\epsilon_{jn}\partial_n\partial_0 V_0 + \epsilon_{jn}\partial_0\partial_0 V_n = -\epsilon_{jn}\partial_n\partial_0 V_0 + \epsilon_{jn}(\triangle - m^2)V_n,$$

and noting that

$$m^2 V_n = m\epsilon_{nk}(\partial_0 V_k - \partial_k V_0)$$

we obtain the necessary condition

$$\triangle V_j = m\epsilon_{jn}\partial_n V_0 - \partial_0\partial_j V_0,$$

from which the result follows by defining

$$\phi \equiv \frac{m}{\sqrt{-\triangle}}V_0.$$

Q.E.D.

We proceed now to the quantization. Using the intuition gained from Theorem II.1, we seek a massive vector field $V_\mu(x)$ satisfying

$$(\Omega_R, V_\mu(x)V_\nu(y)\Omega_R)_R = \frac{1}{(2\pi)^2}\int d\Omega_m(k)\left[\frac{k_\mu k_\nu}{m^2} - g_{\mu\nu} - i\frac{\epsilon_{\mu\nu\lambda}k^\lambda}{m}\right]e^{-ik(x-y)}, \tag{14}$$

and a commuting massless vector field $S_\mu(x)$ satisfying

$$\begin{aligned}(\Omega_R, S_\mu(x)S_\nu(y)\Omega_R)_R = {} & \frac{1}{(2\pi)^2}\int d\Omega_0(k)e^{-ik(x-y)}\left[-\frac{k_\mu k_\nu}{m^2} + \frac{i}{m}\epsilon_{\mu\nu\rho}k^\rho\right] \\ & - \frac{1-2\xi}{(2\pi)^2}\int d\Omega_0(k)e^{-ik(x-y)}\frac{1}{2\omega}\left[\delta_{\mu 0}k_\nu + \delta_{\nu 0}k_\mu - i(x_0-y_0)k_\mu k_\nu - \frac{k_\mu k_\nu}{\omega}\right]\end{aligned} \tag{15}$$

so that

$$(\Omega_R, V_\mu(x)V_\nu(y)\Omega_R)_R + (\Omega_R, S_\mu(x)S_\nu(y)\Omega_R)_R = \langle A_\mu(x)A_\nu(y)\rangle \tag{16}$$

given in Eq. (4). First, we consider the massive field $V_\mu(x)$.

Guided by Proposition II.3, we define

$$V_\mu(x) = \frac{1}{\sqrt{2}}\left(-\frac{\partial_\mu\partial_\alpha}{m^2} - g_{\mu\alpha} + \frac{1}{m}\epsilon_{\mu\alpha\beta}\partial^\beta\right)U^\alpha(x) \tag{17}$$

$$= \frac{1}{2\pi\sqrt{2}} \int d\Omega_m(k) \left[b^{\alpha}(k) \left(\frac{k_\alpha k_\mu}{m^2} - g_{\mu\alpha} - \frac{i}{m} \epsilon_{\alpha\mu\beta} k^{\beta} \right) e^{-ikx} \right.$$
$$\left. + b^{\dagger\alpha}(k) \left(\frac{k_\alpha k_\mu}{m^2} - g_{\mu\alpha} + \frac{i}{m} \epsilon_{\alpha\mu\beta} k^{\beta} \right) e^{ikx} \right], \tag{18}$$

where U is a massive vector field given by

$$U_\mu(x) = \frac{1}{2\pi} \int d\Omega_m(k) [e^{-ikx} b_\mu(k) + e^{ikx} b_\mu^\dagger(k)], \tag{19}$$

with $d\Omega_m(k)$ denoting the invariant measure on the positive mass m hyperboloid and b, $b^\dagger$ satisfying the commutation relations

$$[b_\mu(k), b_\nu^\dagger(k')] = -g_{\mu\nu} 2\mu(k) \delta(k-k'). \tag{20}$$

This is clearly a covariant field that, by construction, satisfies the field equations $\epsilon_{\mu\nu\rho}\partial^\nu V^\rho(x) = mV_\mu(x)$. Furthermore, one checks that (14) is satisfied under the usual assumption $b_\mu(k)\Omega_R = 0$.

In fact, all is made rigorous by realizing the expressions as bilinear forms on the Proca Fock space $\mathcal{H}_R^P$ given by

$$\mathcal{H}_R^P \equiv \Gamma_{\text{sym}}(L^2(R^d, d\Omega_m(k)) \otimes C^d),$$

i.e., the symmetric Fock space over $\mathcal{H}_R^{P(1)} \equiv L^2(R^d, d\Omega_m(k)) \otimes C^d$. Given $\Phi \in \mathcal{H}_R^P$, we denote its projection onto the n-particle subspace $\mathcal{H}_R^{P(n)}$ by $\Phi^{(n)}$. With this notation, the inner product on $\mathcal{H}_R^P$ is given by

$$(\Phi, \Psi)_R = \sum_{n=0}^{\infty} (\Phi^{(n)}, \Psi^{(n)})_R^{(n)},$$

with

$$(f,g)_R^{(n)} = \prod_{j=1}^{n} \left[\int d\Omega_m(k_j) \right] \overline{f_{\mu_1 \cdots \mu_n}(k_1, \ldots, k_n)} g_{\mu_1 \cdots \mu_n}(k_1, \ldots, k_n) \tag{21}$$

for $f, g \in \mathcal{H}_R^{P(n)}$ with $n > 0$ and $(f,g)_R^{(0)} = \bar{f}g$ for $f, g \in \mathcal{H}_R^{P(0)}$. We denote adjoints with respect to $(\cdot,\cdot)_R$ by a superscript $*$ and refer to them as Hilbert adjoints.

We introduce the usual Fock creation and annihilation bilinear forms on $\mathcal{H}_R^P$ by

$$[c_\mu^*(k)\Phi]_{\mu_1 \cdots \mu_n}^{(n)}(k_1, \ldots, k_n) = \frac{1}{\sqrt{n}} \sum_{j=1}^{n} \delta_{\mu\mu_j} \delta(k-k_j) 2\mu(k_j) \Phi_{\mu_1 \cdots \widehat{\mu_j} \cdots \mu_n}^{(n-1)}(k_1, \ldots, \widehat{k_j}, \ldots, k_n) \tag{22}$$

$$[c_\mu(k)\Phi]_{\mu_1 \cdots \mu_n}^{(n)}(k_1, \ldots, k_n) = \sqrt{n+1}\, \Phi_{\mu\mu_1 \cdots \mu_n}^{(n+1)}(k, k_1, \ldots, k_n), \tag{23}$$

where a hat over a variable or an index means to omit it. These are well-defined (as bilinear forms) on vectors $\Phi \in D(N^{1/2}) \subset \mathcal{H}_R$, where N is the self-adjoint number operator. In fact, $c_\mu(k)$ defines an operator on this domain.[16] These formally satisfy the canonical commutation relations

$$[c_\mu(k), c_\nu^*(k')] = \delta_{\mu\nu} 2\mu(k) \delta(k-k'). \tag{24}$$

We also need to introduce the indefinite metric on $\mathcal{H}_R^P$ which is given by $\{\Phi, \Psi\}_R = (\Phi, \eta\Psi)_R$. The action of η on the n-particle subspace is given by

$$(f,\eta g)_R^{(n)} = \prod_{j=1}^{n}\left[\int d\Omega_m(k_j)(-g)_{\mu_j\nu_j}\right]\overline{f_{\mu_1\cdots\mu_n}(k_1,\ldots,k_n)}\,g_{\nu_1\cdots\nu_n}(k_1,\ldots,k_n), \tag{25}$$

which in turn determines its action on $\mathcal{H}_R^P$. In short, η is the second quantization of the operator

$$f_\mu(k) \mapsto (-g_{\mu\nu}f_\nu)(k)$$

on $\mathcal{H}_R^{P(1)}$.[16,17] With respect to the indefinite inner product $\{\cdot,\cdot\}_R$, $\mathcal{H}_R^P$ is a Krein space.[18] This follows from the observations that $\eta=\eta^*$ and $\eta^2=1$. We denote adjoints with respect to the Krein metric by a superscript †. Clearly, it is also true that $\eta=\eta^\dagger$.

Finally, we can define b, $b^\dagger$ as Krein creation and annihilation forms,

$$b_\mu^\dagger(k) = g_{\mu\nu}c_\nu^*(k), \quad b_\mu(k) = -c_\mu(k). \tag{26}$$

These, then, formally satisfy Eq. (20). Furthermore, as bilinear forms, we have the relations

$$N = \int d\Omega_m(k)c_\mu^*(k)c_\mu(k) = \int d\Omega_m(k)b_\mu^\dagger(k)(-g_{\mu\nu})b_\nu(k).$$

Calculating the commutator, we obtain

$$[V_\mu(x),V_\nu(y)] = -i\left(\partial_\mu\partial_\nu + g_{\mu\nu} - \frac{\epsilon_{\mu\nu\lambda}\partial^\lambda}{m}\right)\Delta_m(x-y). \tag{27}$$

Note that this is not a local expression, despite the facts that the Pauli-Jordan function $\Delta_m(x)$ given by

$$\Delta_m(x) = \frac{-i}{(2\pi)^s}\int d^dk\ \mathrm{sgn}(k_0)\,\delta(k^2-m^2)e^{-ikx}. \tag{28}$$

vanishes for spacelike separations and differential operators are, in general, local. This subtlety arises from the fact that a time derivative of $\Delta_m(x)$ evaluated at time zero yields a delta function (see, e.g., Appendix I of Ref. 19). Thus, we have the following nonvanishing equal-time commutators:

$$\left[V_0(t,x),V_n(t,y)\right] = \frac{i\partial_n}{m^2}\delta(x-y) \tag{29}$$

$$\left[V_j(t,x),V_n(t,y)\right] = -i\epsilon_{jn}\delta(x-y). \tag{30}$$

This is analogous to the situation that arises in canonical quantization of the Proca field without use of an indefinite metric.[19]

In order to exhibit the bosonization (and, hence, the single physical mode of Refs. 4 and 12) within this framework, we note that (18) can be written

$$V_\mu(x) = \frac{1}{2\pi\sqrt{2}}\int d\Omega_m(k)\left[(Lgb)_\mu(k)e^{-ikx} + (\bar{L}gb^\dagger)_\mu(k)e^{ikx}\right], \tag{31}$$

where

$$L_{\mu\nu} \equiv \frac{k_\mu k_\nu}{m^2} - g_{\mu\nu} - \frac{i}{m}\epsilon_{\mu\nu\lambda}k^\lambda \tag{32}$$

$$= \left(\frac{\sqrt{\mu^2+\omega^2}}{m}\hat{w}_3 - \hat{w}_2 \right) \otimes \left(\frac{\sqrt{\mu^2+\omega^2}}{m}\hat{w}_3 - \hat{w}_2 \right)^* \tag{33}$$

using the basis

$$\hat{w}_1 = \frac{1}{\sqrt{\mu^2+\omega^2}} \begin{pmatrix} \mu \\ -k_1 \\ -k_2 \end{pmatrix}$$

$$\hat{w}_2 = \frac{i}{\omega} \begin{pmatrix} 0 \\ k_2 \\ -k_1 \end{pmatrix} \tag{34}$$

$$\hat{w}_3 = \frac{1}{\omega\sqrt{\mu^2+\omega^2}} \begin{pmatrix} \omega^2 \\ \mu k_1 \\ \mu k_2 \end{pmatrix},$$

which is orthonormal in the C^3 Euclidean inner product.

Then, we can define

$$a(k) = \frac{1}{\sqrt{2}} \left(\frac{\sqrt{\mu^2+\omega^2}}{m}\hat{w}_3 - \hat{w}_2 \right)^*_\alpha g_{\alpha\beta} b_\beta(k) \tag{35}$$

$$a^\dagger(k) = \frac{1}{\sqrt{2}} \left(\frac{\sqrt{\mu^2+\omega^2}}{m}\hat{w}_3 + \hat{w}_2 \right)^*_\alpha g_{\alpha\beta} b^\dagger_\beta(k), \tag{36}$$

where we've used $\bar{\hat{w}}_2 = -\hat{w}_2$. Hence,

$$[a(k), a^\dagger(k')] = 2\mu\delta(k-k'), \tag{37}$$

and suppressing the vector index we have the representation

$$V(x) = \frac{1}{2\pi} \int d\Omega_m(k) \left[\left(\frac{\sqrt{\omega^2+\mu^2}}{m}\hat{w}_3 - \hat{w}_2 \right) a(k) e^{-ikx} + \left(\frac{\sqrt{\omega^2+\mu^2}}{m}\hat{w}_3 + \hat{w}_2 \right) a^\dagger(k) e^{ikx} \right], \tag{38}$$

for which the time evolution is implemented by

$$H_0^V = \int d\Omega_m(k) \mu(k) a^\dagger(k) a(k). \tag{39}$$

From this expression for V_μ, it is clear that the physical field is both Krein and Hilbert symmetric. It also has a dense set of analytic vectors, thereby making its closure self-adjoint.

Next, we turn to the ghost field S_μ. We wish to realize S_μ on the Maxwell Fock space $\mathcal{H}_R^M$ given as the symmetric Fock space over the single particle space

$$\mathcal{H}_R^{M(1)} \equiv L^2(R^d, d\Omega_0) \otimes C^d, \tag{40}$$

where $d\Omega_0$ is the invariant measure on the forward light cone. As before, we equip $\mathcal{H}_R^M$ with an indefinite metric $\{\cdot,\cdot\}_R \equiv (\cdot, \eta\cdot)_R$, where $\eta = -g$ on $\mathcal{H}_R^{M(1)}$. Then, we will have a realization of the Maxwell-Chern-Simons field $A_\mu \equiv V_\mu \otimes 1 + 1 \otimes S_\mu \equiv V_\mu + S_\mu$ on $\mathcal{H}_R = \mathcal{H}_R^P \otimes \mathcal{H}_R^M$. For this, we first choose the following C^3-orthonormal vectors:

$$\hat{v}_1 = \frac{1}{\omega\sqrt{2}}\begin{pmatrix} \omega \\ k_1 \\ k_2 \end{pmatrix}, \tag{41}$$

$$\hat{v}_2 = \frac{i}{\omega}\begin{pmatrix} 0 \\ k_2 \\ -k_1 \end{pmatrix}, \tag{42}$$

$$\hat{v}_3 = \frac{1}{\omega\sqrt{2}}\begin{pmatrix} \omega \\ -k_1 \\ -k_2 \end{pmatrix}. \tag{43}$$

Next, we define bilinear forms

$$a_R(k) = (\hat{v}_3)_\alpha g^{\alpha\beta} a_\beta(k), \tag{44}$$

$$a_Q(k) = (\hat{v}_1)_\alpha g^{\alpha\beta} a_\beta(k), \tag{45}$$

$$a_Q^\dagger(k) = (\hat{v}_1)_\alpha g^{\alpha\beta} a_\beta^\dagger(k), \tag{46}$$

$$a_R^\dagger(k) = (\hat{v}_3)_\alpha g^{\alpha\beta} a_\beta^\dagger(k), \tag{47}$$

in terms of the Maxwell Krein forms a, $a^\dagger$ satisfying

$$[a_\mu(k), a_\nu^\dagger(k')] = -g_{\mu\nu} 2\omega(k)\delta(k-k'). \tag{48}$$

These differ slightly from analogous forms given in Refs. 11 and 12, but are more convenient for our purposes. They satisfy the algebra

$$[a_Q(k), a_R^\dagger(k')] = -2\omega\delta(k-k') = [a_R(k), a_Q^\dagger(k')] \tag{49}$$

with the remaining commutators vanishing.

Then, we can define the field

$$S(x;\gamma) = \frac{1}{2\pi}\int d\Omega_0(k)\left\{ e^{-ikx}\left[\frac{\omega}{m}\hat{v}_1 a_R(k) + \left(\frac{\omega}{m}\hat{v}_1 - \sqrt{2}\hat{v}_2 + (1-\gamma)\left(\frac{m}{2\omega}\hat{v}_3 - ix_0 m\hat{v}_1\right)\right)a_Q(k)\right]\right.$$
$$\left. + e^{ikx}\left[\frac{\omega}{m}\hat{v}_1^* a_R^\dagger(k) + \left(\frac{\omega}{m}\hat{v}_1^* - \sqrt{2}\hat{v}_2^* + (1-\gamma)\left(\frac{m}{2\omega}\hat{v}_3^* + ix_0 m\hat{v}_1^*\right)\right)a_Q^\dagger(k)\right]\right\}, \tag{50}$$

where we have again suppressed the vector index. Clearly, this expression simplifies considerably in Landau gauge $\gamma=1$. One can check that (50) yields the correct two-point expression (15) on $\mathcal{H}_R^M$.

The time evolution of S_μ is implemented by the Hamiltonian

$$H_0^S(\gamma) = \int d\Omega_0(k)\omega\left[-a_Q^\dagger(k)a_R(k) - a_Q^\dagger(k)a_R(k) - (1-\gamma)\frac{m^2}{\omega^2}a_Q^\dagger(k)a_Q(k)\right]$$
$$= \int d\Omega_0(k)\omega a_\mu^\dagger(k)\left(-g^{\mu\nu} - (1-\gamma)\frac{m^2 k^\mu k^\nu}{2\omega^4}\right)a_\nu(k)$$
$$= \int d\Omega_0(k)\omega c_\mu^*(k)\left(\delta_\mu^\nu + (1-\gamma)\frac{m^2 k_\mu k^\nu}{2\omega^4}\right)c_\nu(k). \tag{51}$$

It is Krein symmetric, but not Hilbert symmetric unless one chooses Landau gauge $\gamma=1$. However, standard arguments show its closure to be Hilbert normal and Krein self-adjoint. By techniques similar to the Maxwell case,[13] we find

Theorem II.5:

1. $[0,\infty)\subset\sigma(H_0^S)$

2. H_0^S *is accretive*

We note that the field S_μ is also nonlocal. We have, in fact, the nonvanishing equal-time commutation relations

$$[S_0(t,x),S_n(t,y)]=\frac{-i}{m^2}\partial_n\delta(x-y) \tag{52}$$

$$[S_j(t,x),S_n(t,y)]=\frac{i}{m}\epsilon_{jn}\delta(x-y). \tag{53}$$

However, the full MCS field $A_\mu=V_\mu+S_\mu$ is local since

$$[A_0(t,x),A_n(t,y)]=[V_0(t,x),V_n(t,y)]+[S_0(t,x),S_n(t,y)]=0 \tag{54}$$

$$[A_j(t,x),A_n(t,y)]=[V_j(t,x),V_n(t,y)]+[S_j(t,x),S_n(t,y)]=0, \tag{55}$$

where we have used Eqs. (29) and (30).

We regularize the above fields by restricting them to a finite spatial volume $V\subset(\delta Z)^s$ with periodic boundary conditions (thus, V is a product of finite cyclic groups). We denote the volume of V by $|V|$. We denote the dual group of V by Γ. The measure on V is taken to be

$$\frac{1}{\sqrt{|V|}}\sum_{x\in V}\delta^s, \tag{56}$$

while that on Γ is

$$\frac{1}{\sqrt{|V|}}\sum_{k\in\Gamma}, \tag{57}$$

with Fourier transform

$$\tilde{f}(k)=\frac{1}{\sqrt{|V|}}\sum_{x\in V}\delta^s e^{-ik\cdot x}f(x). \tag{58}$$

We choose to use midpoint derivatives on the lattice so that

$$k_n=\frac{2}{\delta}\sin\left(\frac{k_n\delta}{2}\right) \tag{59}$$

and

$$\omega^2=k_nk_n=\sum_{n=1}^{s}\frac{4}{\delta^2}\sin^2\left(\frac{k_n\delta}{2}\right). \tag{60}$$

With these conventions, the regularized MCS field becomes

$$A(x) = \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma_0} \frac{1}{2\mu} \left[\left(\frac{\sqrt{\omega^2+\mu^2}}{m} \hat{w}_3 - \hat{w}_2 \right) a(k) e^{-ikx} + \left(\frac{\sqrt{\omega^2+\mu^2}}{m} \hat{w}_3 + \hat{w}_2 \right) a^\dagger(k) e^{ikx} \right]_{k_0=\mu}$$
$$+ \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma_0} \frac{1}{2\omega} \left\{ e^{-ikx} \left[\frac{\omega}{m} \hat{v}_1 a_R(k) + \left(\frac{\omega}{m} \hat{v}_1 - \sqrt{2}\hat{v}_2 + (1-\gamma) \left(\frac{m}{2\omega} \hat{v}_3 - i x_0 m \hat{v}_1 \right) \right) a_Q(k) \right] \right.$$
$$\left. + e^{ikx} \left[\frac{\omega}{m} \hat{v}_1^* a_R^\dagger(k) + \left(\frac{\omega}{m} \hat{v}_1^* - \sqrt{2}\hat{v}_2^* + (1-\gamma) \left(\frac{m}{2\omega} \hat{v}_3^* + i x_0 m \hat{v}_1^* \right) \right) a_Q^\dagger(k) \right]_{k_0=\omega} \right\}, \tag{61}$$

in which our infrared regularization is to sum over $\Gamma_0 \equiv \Gamma \backslash \{0\}$. This field is defined as a distribution-valued unbounded operator on the lattice Fock space $\mathcal{H}_R = \mathcal{H}_R^P \otimes \mathcal{H}_R^M$. Here, $\mathcal{H}_R^P$ is the symmetric Fock space over $L^2(\Gamma_0) \otimes C^d$ with measure

$$\frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma_0} \frac{1}{2\mu}, \tag{62}$$

while $\mathcal{H}_R^M$ is the symmetric Fock space over $L^2(\Gamma_0) \otimes C^d$ with measure

$$\frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma_0} \frac{1}{2\omega}. \tag{63}$$

In the following sections, we shall loosely use Γ to indicate whichever momentum sums are appropriate.

III. KREIN GAUGE TRANSFORMATIONS

The formal Lagrangian density for the MCS-Higgs model will be

$$\mathcal{L} = \mathcal{L}^{\text{cs}} + \mathcal{L}^{\text{boson}}, \tag{64}$$

where $\mathcal{L}^{\text{cs}}$ is given by Eq. (1) and the boson term is

$$\mathcal{L}^{\text{boson}} = \sum_{j=1}^{2} [D_\mu(\phi_j) D^\mu(\phi_j) - m_0^2 (\phi_j)^2] - V(\phi_1(x), \phi_2(x)) \tag{65}$$

for two neutral scalar fields $\phi_j, j=1,2$ with a potential $V(\phi_1(x), \phi_2(x)) = \lambda_4(\phi_1^2(x) + \phi_2^2(x))^2 + \lambda_2(\phi_1^2(x) + \phi_2^2(x))$ with $m_0 \geq 0, \lambda_4 > 0$ and covariant derivative $D_\mu(\phi) = (\partial_\mu + ieA_\mu)(\phi)$. The usual canonical construction produces a Hamiltonian operator on the lattice of the form

$$H(V, \delta) = H_0^{\text{cs}} + H_0^{\text{boson}} + H_{int} + V(\phi_1, \phi_2), \tag{66}$$

with the free MCS-Hamiltonian in Eqs. (39) and (51) and a free boson-Hamiltonian with mass m_0. The interaction terms contain the MCS field as

$$H_{\text{int}} = H_{\text{el}} + H_{\text{mag}},$$

$$H_{\text{el}} = \sum_{x\in V} \delta^s [e\{\pi_1(x)\phi_2(x) - \pi_2(x)\phi_1(x)\} A_0(x)],$$

$$H_{\text{mag}} = \sum_{x\in V} \delta^s \left[e\{\partial_\ell \phi_2(x)\phi_1(x) - \partial_\ell \phi_1(x)\phi_2(x)\} A_\ell(x) + \frac{e^2}{2} \{(\phi_1^2(x) + \phi_2^2(x)\} A_\ell^2(x) \right],$$

$$V(\phi_1,\phi_2)=\sum_{x\in V}\delta^s V(\phi_1(x),\phi_2(x)). \tag{67}$$

Since in our representation the MCS-field is a normal operator, the "magnetic" part of the Hamiltonian has lost the positivity which would normally arise from the spatial covariant derivatives, while the "electric" part has both real and imaginary terms in its numerical range. Usually, to maintain positivity of the Hamiltonian operator for a gauge theory of this type, quantization would be carried out in either the Coulomb or axial gauges. However, such gauges are not particularly amenable for renormalization issues arising when taking the continuum limit of the lattice theory. In order to understand the structure of $H(V,\delta)$ above and make transparent the Krein transformations that we use below, we resort to transforming the annihilation and creation operators into harmonic oscillator coordinates and momenta. Our particular conventions are standard for the boson terms and which we shall say little about them, while those for the MCS-field are given in more detail. Both are described in the Appendix.

From Eq. (A13) in the Appendix, the Fourier components of $A_0(x)$ contain both skew-symmetric and symmetric terms. The first Krein transformation removes the symmetric terms in $A_0(x)$ by means of

$$T_1=\sum_{p\in\Gamma'}(-i)\sqrt{\frac{\omega}{\mu}}q^{\mathrm{cs}}_{\ell,2}(p)p^{\mathrm{cs}}_{\ell,0}(p), \tag{68}$$

while the second Krein transformation

$$T_2=\sum_{p\in\Gamma'}(-i)q^{\mathrm{cs}}_{\ell,0}(p)p^{\mathrm{cs}}_{\ell,1}(p) \tag{69}$$

removes the skew-symmetric terms from $A'_\ell(x)$ after a Krein unitary transformation using T_1. Each of the expressions above is realized as a sum of commuting essentially self-adjoint operators for which the finite particle vectors D_F are analytic vectors. Each is also skew-symmetric with respect to the Krein metric and so will be the infinitesimal generator of a Krein unitary but unbounded operator. The number of particle estimate for each T_j on a k-particle vector increases as $O((n+k+1)^n)$ in the analytic vector calculation, which leads to geometric convergence in t as below.

Lemma III.1: The operators $\widetilde{T}_j, j=1,2$ are self-adjoint and †-skew-symmetric. Further, each $\exp[t\widetilde{T}_j]$ is self-adjoint and †-unitary for real t and satisfies

$$e^{t\widetilde{T}_2}e^{t\widetilde{T}_1}\widetilde{A_0(x)}e^{-t\widetilde{T}_1}e^{-t\widetilde{T}_2}\Phi=(A_0(x)+t[T_1,A_0(x)])=A'_0(x;t)\Phi \tag{70}$$

$$e^{t\widetilde{T}_2}e^{t\widetilde{T}_1}\widetilde{A_\ell(x)}e^{-t\widetilde{T}_1}e^{-t\widetilde{T}_2}\Phi=\big(A_\ell(x)+t[T_1,A_\ell(x)]+t[T_2,A_\ell(x)]\big)\Phi=A'_\ell(x;t)\Phi \tag{71}$$

for all $\Phi\in D_F$ and complex t with $|t|<t_0$.

To begin the proof, notice that $\eta T_j\eta=T_j$ on vectors in D_F so by closure this relation is valid for $\widetilde{T}_j$. Nelson's theorem on analytic vectors shows $\eta e^{tT_j}\eta=e^{tT_j}$, proving the first statement.

For their Krein unitary property, consider $\Phi,\Psi\in D(e^{z\widetilde{T}_j})$ for suitable complex z and sequences of vectors Φ_n,Ψ_n which have compact support with respect to the spectrum of $\widetilde{T}_j$ and converge strongly to Φ,Ψ. Then, notice $T_j^\dagger=-T_j=\eta T_j^*\eta=\eta T_j\eta$ as bounded operators on Φ_n,Ψ_n, so

$$\begin{aligned}\{e^{z\widetilde{T}_j}\Phi,e^{z'\widetilde{T}_j}\Psi\}&=\lim_{n\to\infty}\{e^{z\widetilde{T}_j}\Phi_n,e^{z'\widetilde{T}_j}\Psi_n\}=\lim_{n\to\infty}(\Phi_n,e^{z\widetilde{T}_j}\eta e^{z'\widetilde{T}_j}\Psi_n)\\&=\lim_{n\to\infty}(\Phi_n,\eta e^{(z'-z)\widetilde{T}_j}\Psi_n)=\lim_{n\to\infty}\{\Phi_n,e^{(z'-z)\widetilde{T}_j}\Psi_n\}=\{\Phi,e^{(z'-z)\widetilde{T}_j}\Psi\}.\end{aligned}$$

For the commutator identities, set $\Phi_N=\Sigma_{n=0}^N(z^nT_1^n/n!)\Phi$, which converges strongly to $e^{z\widetilde{T}_1}\Phi$ for

$\Phi \in D_F$ and $|z| < z_0$. Each Φ_N is a finite particle vector belonging to the domain of $A_\mu(x)^k$ for any positive integer k and $\mu=0,1,2$, so we may calculate the expression

$$A_0(x)\Phi_N = \sum_{n=0}^{N} \frac{z^n A_0(x) T_1^n}{n!}\Phi = \sum_{n=0}^{N} \frac{z^n T_1^n}{n!} A_0(x)\Phi + z\sum_{n=0}^{N-1} \frac{z^n T_1^n}{n!}[T_1, A_0(x)]\Phi.$$

Taking the limit in N shows the right-hand side converges for $|z| < z_0$ with $e^{\widetilde{zT_1}}\Phi$ in the domain of the closure of $A_0(x)$ and $\widetilde{A_0(x)}e^{\widetilde{zT_1}}\Phi$ in the range of $e^{\widetilde{zT_1}}$ leading to Eq. (70) since T_2 commutes with $A_0'(x)$. A similar calculation results in Eq. (71)). A short calculation produces expressions for the gauge-transformed fields which for $t=1$ are

$$A_0'(x) = \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma} \frac{\sqrt{2\omega}}{m} \{q_{1,0}^{\mathrm{cs}}(k)\cos(k\cdot x) + q_{2,0}^{\mathrm{cs}}(k)\sin(k\cdot x)\} \tag{72}$$

$$\begin{aligned} A_\ell'(x) = \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma} \Bigg\{ & \left(\frac{2\epsilon_{\ell n} k_n}{\omega\sqrt{2\omega}} q_{2,1}^{\mathrm{cs}}(k) - \frac{2\mu k_\ell}{m\omega\sqrt{2\mu}} p_{2,2}^{\mathrm{cs}}(k) \right) \cos(k\cdot x) \\ & + \left(-\frac{2\epsilon_{\ell n} k_n}{\omega\sqrt{2\omega}} q_{1,1}^{\mathrm{cs}}(k) + \frac{2\mu k_\ell}{m\omega\sqrt{2\mu}} p_{1,2}^{\mathrm{cs}}(k) \right) \sin(k\cdot x) \Bigg\}, \end{aligned} \tag{73}$$

which are, respectively, skew-symmetric and symmetric.

Turning our attention to the Hamiltonian, we find a completely analogous result in

Lemma III.2: *For all* $\Phi \in D_F$ *and complex* t *with* $|t| < t_0$

$$e^{\widetilde{tT_2}} e^{\widetilde{tT_1}} \widetilde{H} e^{-\widetilde{tT_1}} e^{-\widetilde{tT_2}} \Phi = H'(V,\delta;t)\Phi$$

$$H'(V,\delta;t) = H_0^{\mathrm{boson}} + H_0^{\mathrm{cs}\prime}(t) + H_{\mathrm{int}}'(t), \tag{74}$$

where $H_{\mathrm{int}}'(t)$ *is* $H_{\mathrm{int}}(t)$ *with* $A_\mu(x)$ *replaced by* $A_\mu'(x;t)$ *and the gauge-transformed Chern-Simons part of the free Hamiltonian given by*

$$\begin{aligned} H_0^{\mathrm{cs}\prime}(t) = \sum_{k\in\Gamma} \Bigg\{ & \frac{(\mu^2 - t^2\omega^2)}{2} q_{\ell,2}^{\mathrm{cs}}(k)^2 - \mu + \frac{\omega}{2}(q_{\ell,1}^{\mathrm{cs}}(k)^2 - 4) + \frac{\left(\sqrt{\mu} p_{\ell,2}^{\mathrm{cs}}(k) - t\sqrt{\omega} p_{\ell,1}^{\mathrm{cs}}(k)\right)_2}{2} \\ & + t\omega q_{\ell,0}^{\mathrm{cs}}(k)\left(q_{\ell,1}^{\mathrm{cs}}(k) + \sqrt{\omega/\mu} q_{\ell,2}^{\mathrm{cs}}(k)\right) - t\sqrt{\omega\mu} p_{\ell,2}^{\mathrm{cs}}(k) p_{\ell,0}^{\mathrm{cs}}(k) + \omega(1-t) p_{\ell,0}^{\mathrm{cs}}(k) p_{\ell,1}^{\mathrm{cs}}(k) \\ & + (1-t^2)\frac{\omega}{2}(p_{\ell,0}^{\mathrm{cs}}(k)^2 - q_{\ell,0}^{\mathrm{cs}}(k)^2) + \frac{\omega}{2}(1-t^2) p_{\ell,1}^{\mathrm{cs}}(k)^2 \Bigg\} \end{aligned} \tag{75}$$

The statements for the domains of the unbounded operators are the same as for Lemma III.1 while calculations use the relation $e^{tT_2}e^{tT_1} S^2 e^{-tT_1}e^{-tT_2}\Phi = \{e^{tT_2}e^{tT_1} S e^{-tT_1}e^{-tT_2}\}^2\Phi$ for $|t| < t_0$, which is valid on D_F after taking closures. In each of Lemmas III.1 and III.2 the left-hand side is analytic in a disk $|t| < t_0$ while the right-hand side is an entire function of t and provides a unique analytic continuation of the operator on the left-hand side to the entire complex plane. However, it is straightforward to find a dense domain D_0 which is a common core for all these operators and their powers on which both sides of Eqs. (70), (71), and (74) are valid as entire functions in t. Consider a k-finite particle vector Φ_k realized as a normalized Hermite function $\Phi_k(\{q_{\ell,2}^{\mathrm{cs}}\},\{q_{\ell,1}^{\mathrm{cs}}\},q')$ in the q-harmonic oscillator variables with the coordinates appearing in $\{T_j | j=1,2\}$ denoted explicitly. Let $\chi \in C_0^\infty(R_+)$ be positive, 1 for $0 \le t \le 1/2$, and 0 for $t \ge 1$ say. Form the cutoff functions $\chi_{j,N}(q) = \chi(\Sigma_{k\in\Gamma,j} q_{\ell,j}^{cs}(k)^2/N^2)$ for $N=1,2,\ldots$ which have support inside a ball of radius N. Then, by taking products and convolutions in different variables, we find

Lemma III.3: *Let* D_0 *denote the linear span of vectors formed by*

$$\Phi_{k,N}(q) = \chi_{2,N}(q)(\chi_{1,N} * \Phi_k)(q) \tag{76}$$

as k and N vary over the positive integers. For each of the operators and their powers appearing in Lemmas III.1 and III.2, D_0 forms a common dense core. Moreover, each of the relations in Eqs. (70), (71), and (74) *is valid as entire analytic functions of t. In particular, the corresponding operator relations are densely defined on D_0 for $t=1$.*

That D_0 is dense and a common core is clear as is also the analyticity. Upon re-examining convergence of the exponential series in Eqs. (70), (71), and (74), the $q^{\mathrm{cs}}_{\ell,2}(k)$ and $p^{\mathrm{cs}}_{\ell,1}(k)$ operators are bounded by N when acting on vectors in D_0 while the N-particle estimates applied to the operators $q^{\mathrm{cs}}_{\ell,0}(k)$ and $p^{\mathrm{cs}}_{\ell,0}(k)$ acting on Φ_k provide a bound $O((n+k+1)^{n/2})$. Vectors in D_0 are now entire vectors for each of the Krein gauge transformations.

The gauge transformations in Lemma III.2 are "natural" for the Hamiltonian $H(V,\delta)$, as may be seen from

$$\tilde{H}e^{itT_j}\Phi_{k,N} = e^{itT_j}\{H + it[H,T_j] + (it)^2/2[[H,T_j],T_j]\}\Phi_{k,N}, \tag{77}$$

with $\Phi_{k,N} \in D_0$ and $-\infty < t < \infty$. By using a Riemann approximation and then taking strong limits, the right-hand side converges and defines convergence of the left-hand side to the relation

$$\begin{aligned}\tilde{H}\int_{-\infty}^{\infty} F(\lambda)dE_j(\lambda)\Phi_{k,N} &= \int_{-\infty}^{\infty} \widetilde{F(t)}\tilde{H}e^{itT_j}\Phi_{k,N}dt \\ &= \int_{-\infty}^{\infty} F(\lambda)dE_j(\lambda)H\Phi_{k,N} + \int_{-\infty}^{\infty} F'(\lambda)dE_j(\lambda)[H,T_j]\Phi_{k,N} \\ &\quad + \int_{-\infty}^{\infty} F''(\lambda)/2dE_j(\lambda)[[H,T_j],T_j]\Phi_{k,N},\end{aligned} \tag{78}$$

where $\{E_j(\lambda)\}$ is the spectral measure associated with the essentially self-adjoint operator T_j. Choosing $F \in C_0^2(R)$ shows that a large class of the bounded functions of $\widetilde{T_j}$ belongs to the domain of $\tilde{H}$. As we shall show in Sec. V, the Hamiltonians $H(V,\delta)$ and $H'(V,\delta;1)$ give Krein equivalent dynamics.

IV. REAL PART OF THE HAMILTONIAN

Following the Krein gauge transformations in the previous section, all operators in the remainder of this article will take their physical values at $t=1$. The transformed Hamiltonian is thereby split into two parts. One part defines a symmetric operator while the other part defines a skew-symmetric operator. We now show that the symmetric part is bounded below and in fact is essentially self-adjoint; hence the transformed Hamiltonian is accretive. The transformed lattice Hamiltonian operator may be recast as

$$H'(V,\delta) = H_0^{\mathrm{cs}\prime} + H_0^{\mathrm{boson}} + V(\phi_1,\phi_2) + H'_{\mathrm{int}}. \tag{79}$$

To exploit positivity in the real part of the Hamiltonian, it is convenient to remove the gradient terms from H_0^{boson} and rewrite this as

$$H_0^{\mathrm{boson}} = H_0^{\mathrm{boson}\prime} + \sum_{x\in V}\frac{\delta^s}{2}[\nabla\phi_j(x)]^2, \tag{80}$$

in which

$$H_0^{\text{boson}'} = \sum_{k\in\Gamma} \frac{1}{2}[p_{j,\ell}^2(k) + m_0^2 q_{j,\ell}^2(k) - 4\mu(k)] \tag{81}$$

is again a free massive harmonic oscillator which on the lattice acts in the same way as a number operator for determining domains. By reincorporating the gradient terms into the covariant derivative, the real part of $H'(V,\delta)$ takes the form

$$\text{Re}\, H'(V,\delta) + c_1 I = X + Y, \tag{82}$$

where c_1 is a positive constant to be chosen later and

$$X = H_0^{\text{cs}\prime\prime} + H_0^{\text{boson}\prime} + c_1 I, \quad Y = Y_{\text{deg}} + Y_+, \tag{83}$$

with

$$Y_{\text{deg}} = \sum_{k\in\Gamma} [-\sqrt{\mu\omega} p_{\ell,1}^{\text{cs}}(k) p_{\ell,2}^{\text{cs}}(k)] \tag{84}$$

and

$$Y_+ = \sum_{x\in V} \frac{\delta^s}{2}[\{\partial_\ell \phi_1(x) - e\phi_2(x)A_\ell(x)\}^2 + \{\partial_\ell \phi_2(x) + e\phi_1(x)A_\ell(x)\}^2] + V(\phi_1,\phi_2). \tag{85}$$

The operator $H_0^{\text{cs}\prime\prime}$ denotes the real part of $H_0^{\text{cs}\prime}$ with the degeneracy producing term Y_{deg} removed. As a sum of squares of symmetric operators which have dense analytic vectors, Y_+ clearly defines a symmetric operator which is bounded below since the Higgs potential is taken to be bounded below. The degenerate quadratic term Y_{deg} will be treated as a perturbation which is of the same size as the Chern-Simons number operator. Following the notation used in Reed and Simon (Ref. 16, p. 174–176 and Theorem X.14, p. 164), it is a straightforward matter to use the Konrady trick for Y_+ with $Z = c_2 X^2$ to obtain the quadratic estimate

$$Z^2 \le (X + Y + Z)^2 + c_3 I \tag{86}$$

for some positive constant c_3. The degenerate quadratic piece changes none of the estimates for the commutator $[X,[X,Y]]$ and is easily bounded in the term $XY_{\text{deg}}X$ by completing the square as

$$Y_{\text{deg}} = \sum_{k\in\Gamma} \frac{1}{2}[-\mu p_{\ell,2}^{\text{cs}\,2}(k) - \omega p_{\ell,1}^{\text{cs}\,2}(k) + (\sqrt{\mu} p_{\ell,2}^{\text{cs}}(k) - \sqrt{\omega} p_{\ell,1}^{\text{cs}}(k))^2] = -Y_{\text{deg},1} + Y_{\text{deg},+}, \tag{87}$$

whereupon $XY_{\text{deg},+}X \ge 0$ and may be discarded with the other positive terms in obtaining the quadratic estimate above. The terms in $Y_{\text{deg},1}$ are canceled by terms that appear in $H_0^{\text{cs}\prime\prime}$ with the result $H_0^{\text{cs}\prime\prime} - Y_{\text{deg},1} \ge 0$. Now we find

$$2c_2X^3 + 2c_2XYX \ge 2c_2X[X + Y_+ + Y_{\text{deg},+} - Y_{\text{deg},1}]X \ge 2c_2X[H_0^{\text{boson},\prime} + c_1 I]X,$$

so

$$2c_2X^3 + 2c_2XYX + c_2[X,[X,Y]] \ge c_2(2c_1 - c_3)X^2 \ge 0 \tag{88}$$

provided we choose $c_1 \ge c_3/2$. The quadratic estimate and Wüst's theorem allow us to conclude that $\text{Re}\, H'(V,\delta) + c_1 I = X + Y$ is essentially self-adjoint and bounded below. It is important to notice that the term $2c_2XH_0^{\text{boson},\prime}X$ is a large positive operator and only its positivity is needed for the estimate (86). In fact, we have the sharper estimate

$$(X + Y + Z)^2 \ge Z^2 + c_2(2c_1 - c_3)X^2 + 2c_2XH_0^{\text{boson},\prime}X \ge Z^2 \tag{89}$$

on $D_F \times D_F$, which is used in the next section.

V. SKEW-SYMMETRIC PART OF THE HAMILTONIAN

The Krein transformations in Sec. III were chosen to obtain a Hamiltonian of the form

$$H'(V,\delta) = \mathrm{Re}\, H'(V,\delta) + S, \tag{90}$$

in which S is a densely defined skew-symmetric operator given by

$$S = S_1 + S_2,$$

where

$$S_1 = \sum_{x\in V} \delta^s e[\pi_1\phi_2 - \pi_2\phi_1](x)A_0'(x), \tag{91}$$

$$S_2 = \sum_{k\in\Gamma}\left[\omega(k)q^{\mathrm{cs}}_{\ell,0}(k)\left\{q^{\mathrm{cs}}_{\ell,1}(k) + \sqrt{\frac{\omega}{\mu}}q^{\mathrm{cs}}_{\ell,2}(k)\right\} - \sqrt{\omega\mu}p^{\mathrm{cs}}_{\ell,0}(k)p^{\mathrm{cs}}_{\ell,2}(k)\right]. \tag{92}$$

As $\mathrm{Re}\, H'(V,\delta)$ is essentially self-adjoint and bounded below, Chernoff's extension of Wüst's theorem[20] will show that $H'(V,\delta)$ is essentially maximal accretive given the estimate

$$\|Zu\| \le \|(X+Y+Z+S)u\| + c_5 I\|u\|$$

for vectors u in the core domain D_F, or equivalently

$$(Z)^2 \le (X+Y+Z)^2 + [X+Y+Z,S] + S^*S + c_5 I \tag{93}$$

as a quadratic form on $D_F \times D_F$. Using the estimate of the last section, it will then be sufficient to verify

$$c_2(2c_1 - c_3)X^2 + 2c_2 X H_0^{\mathrm{boson}\prime} X + [X+Y+Z,S] + S^*S + c_5 I \ge 0, \tag{94}$$

which follows from

Lemma V.1: *On the domain* D_F, *the commutator* $[X+Y+Z,S]$ *is Kato-tiny relative to* $XH_0^{\mathrm{boson}\prime}X$.

To prove the lemma we calculate individual terms in the commutator. From $[Z,S] = c_2[X^2,S] = c_2(X[X,S]+[X,S]X)$ since X acts as a free Hamiltonian, $[X,S]$ is bounded by $H_0^{\mathrm{boson}\prime}X^{1/2}$, while [Z,S] is bounded by $H_0^{\mathrm{boson}\prime}X^{3/2}$. Both of these are Kato-tiny relative to $2c_2XH_0^{\mathrm{boson}\prime}X$. In $X+Y$ let us recombine the gradient boson terms in Y with the boson terms in X to replace $H_0^{\mathrm{boson}\prime}$ by H_0^{boson} leading to $X+Y = H_0^{\mathrm{cs}\prime} + H_0^{\mathrm{boson}} + c_1 I + Y_{\mathrm{deg}} + Y_0$, where the "magnetic part" of the Chern-Simons interaction now appears with the boson potential in

$$\begin{aligned} Y_0 &= \sum_{x\in V}\frac{\delta^s}{2}\left[-e\{\partial_\ell\phi_1(x)\phi_2(x) - \partial_\ell\phi_2(x)\phi_1(x)\}A'_\ell(x) + \frac{e^2}{2}\{\phi_1^2(x)+\phi_2^2(x)\}A'_\ell(x)^2\right] + V(\phi_1,\phi_2) \\ &= Y_{\mathrm{mag}} + V(\phi_1,\phi_2). \end{aligned} \tag{95}$$

Clearly $[Y_{\mathrm{deg}},S_1]=0$, with the remaining terms for this part of the commutator given by

$$[Y_{\mathrm{deg}},S_2] = \sum_{k\in\Gamma}[-i\sqrt{\mu}\omega^{3/2}q^{\mathrm{cs}}_{\ell,0}(k)p^{\mathrm{cs}}_{\ell,2}(k) - i\omega^2 q^{\mathrm{cs}}_{\ell,0}(k)p^{\mathrm{cs}}_{\ell,1}(k)]. \tag{96}$$

on the core domain, $-[Y_{\mathrm{deg}},S] \le c_6 X$ for c_1 large enough as the commutator is quadratic in Chern-Simons harmonic oscillators. It is useful to look at the commutators in $[Y_{\mathrm{mag}},S]$ separately. For $[Y_{\mathrm{mag}},S_1]$ the fields A_0' and A_ℓ' commute so it is only necessary to calculate the boson field commutators. Lattice quantization preserves enough locality for the boson fields that for terms quadratic in the individual boson fields, the relation $[\phi_j^2(x),\pi_j(y)] = 2i\delta_{P,V}(x-y)\phi_j(x)$ with the periodic lattice $\delta_{P,V}$ shows their contribution to $[Y_{\mathrm{mag}},S_1]$ vanishes. As we use a symmetric $k\leftrightarrow$

$-k$ summation range, it is possible to effect an integration by parts of sorts; nevertheless, the remaining terms in this commutator are not zero and we arrive at

$$[Y_{\mathrm{mag}},S_1]=\sum_{x\in V}\delta^s ie^2[\partial_\ell\phi_1(x)\phi_1(x)+\partial_\ell\phi_2(x)\phi_2(x)]A'_\ell(x)A'_0(x)$$
$$+\sum_{x\in V}\delta^{2s}(-ie^2)[\partial_{x,\ell}\delta_{P,V}(x-y)\phi_1(x)\phi_1(y)]A'_\ell(x)A'_0(x)$$
$$+\sum_{x\in V}\delta^{2s}(-ie^2)[\partial_{x,\ell}\delta_{P,V}(x-y)\phi_2(x)\phi_2(y)]A'_\ell(x)A'_0(x). \tag{97}$$

Using $H_0^{\mathrm{boson}\prime}$ to bound $\phi_j(x)\phi_j(y)$ and X to bound $A'_\ell(x)A'_0(x)$, the commutator $-[Y_{\mathrm{mag}},S_1]\leq c_7H_0^{\mathrm{boson}\prime}X$, which is also Kato-tiny compared to $H_0^{\mathrm{boson}\prime}X^2$. Up to multiplicative terms quadratic in the boson fields, the size of the commutator $[Y_{\mathrm{mag}},S_2]$ is determined by $[A'_\ell,S_2]$. From the Landau gauge expression for $A'_\ell(x)$ in Sec. III, it is straightforward to arrive at the expression

$$[A'_\ell(x),S_2]=\frac{1}{\sqrt{|V|}}\sum_{k\in\Gamma}\left[\left\{-i\frac{\sqrt{2\omega}}{m}k_\ell q^{\mathrm{cs}}_{2,0}(k)\right\}\cos(k\cdot x)+\left\{i\frac{\sqrt{2\omega}}{m}k_\ell q^{\mathrm{cs}}_{1,0}(k)\right\}\sin(k\cdot x)\right], \tag{98}$$

which is dominated by $H_0^{\mathrm{boson}\prime}X^{1/2}$. Hence, the quadratic term $[A'^2_\ell(x),S_2]$ requires an additional factor $X^{1/2}$ to produce the estimate $-[Y_{\mathrm{mag}},S_2]\leq c_8H_0^{\mathrm{boson}\prime}X$, which is also Kato-tiny relative to $H_0^{\mathrm{boson}\prime}X^2$.

Finally $[V(\phi_1,\phi_2),S]=0$. This is immediate for $[V(\phi_1,\phi_2),S_2]=0$, while the commutator identities

$$[\phi_j(x)^4,\pi_j(y)]=4i\delta_{P,V}(x-y)\phi_j(x)^3$$

$$[\phi_1^2(x)\phi_2^2(x),\pi_1(y)]=2i\delta_{P,V}(x-y)\phi_1(x)\phi_2^2(x)$$

readily show that $[V(\phi_1,\phi_2),S_1]=0$ as well. Collecting together these estimates for the various commutators leads to the inequality

$$(X+Y+Z)^2+[X+Y+Z,S]\geq Z^2-c_5I \tag{99}$$

for some constant $c_5>0$ provided c_2 is large enough and $c_1>c_3/2$. As $(X+Y+Z)^*$ and Z^* are densely defined on the finite particle vectors, Chernoff's theorem applied to $X+Y+S=X+Y+Z+S-Z$ produces:

Theorem V.2: *After Krein gauge transformations, the transformed Hamiltonian* $H'(V,\delta)=\mathrm{Re}\,H'(V,\delta)+S$ *is maximal accretive after closure on the finite particle domain* D_F *and hence Krein essentially self-adjoint.*

Krein self-adjointness follows by a simple argument which can be found in Ref. 21, Lemma 2.2, p. 5.

ACKNOWLEDGMENT

One of us, J.L.C., would like to thank Jürg Fröhlich for the hospitality of the Institute for Theoretical Physics, ETH, Zürich, during the winter of 1998 and discussions on an indefinite metric approach to the Higgs-Maxwell-Chern-Simons model.

APPENDIX: HARMONIC OSCILLATOR COORDINATES

We choose standard harmonic oscillator coordinates for the time-zero boson field and its conjugate momentum, yielding (see, e.g., Ref. 22, Chap. II, Sec. B])

$$\phi_j(x) = \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma} \frac{1}{2\mu}[e^{ik\cdot x} a_j(k) + e^{-ik\cdot x} a_j^*(k)] = \frac{1}{\sqrt{2|V|}} \sum_{k\in\Gamma} \frac{1}{2\mu}[q_{1,j}(k)\cos(k\cdot x) + q_{2,j}(k)\sin(k\cdot x)], \tag{A1}$$

$$\pi_j(x) = \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma} \frac{-i}{2}[e^{ik\cdot x} a_j(k) - e^{-ik\cdot x} a_j^*(k)] = \frac{1}{\sqrt{2|V|}} \sum_{k\in\Gamma} \frac{1}{2\mu}[p_{1,j}(k)\cos(k\cdot x) + p_{2,j}(k)\sin(k\cdot x)], \tag{A2}$$

for $j=1,2$. The free boson Hamiltonian with Wick ordering then becomes

$$H_0^{\text{boson}} = \sum_{k\in\Gamma} \frac{1}{2} a_j^*(k) a_j(k) = \sum_{k\in\Gamma} \frac{1}{2}[p_{\ell,j}^2 + \mu^2 q_{\ell,j}^2]. \tag{A3}$$

In order to define harmonic oscillator coordinates for the MCS field $A_\mu = V_\mu + S_\mu$ in Landau gauge ($\gamma=1$), we first express the MCS field in terms of Fock operators b_μ defined by

$$b_0(k) = \frac{c_0(k)}{\sqrt{2\omega}}, \quad b_1(k) = \frac{k_n c_n(k)}{\omega\sqrt{2\omega}}, \quad b_2(k) = \frac{a(k)}{\sqrt{2\mu}}, \tag{A4}$$

so that b_0, b_1 represent the ghost degrees of freedom while b_2 corresponds to the single physical mode. In terms of these, we have for the time-zero MCS field

$$A_\mu = \frac{1}{\sqrt{|V|}} \sum_{k\in\Gamma} [M_{\mu\nu} b_\nu(k) e^{ik\cdot x} + \bar{M}_{\mu\alpha}(-g)_{\alpha\beta} b_\beta^*(k) e^{-ik\cdot x}], \tag{A5}$$

with

$$M = \begin{pmatrix} -\dfrac{\omega}{m\sqrt{2\omega}} & 0 & -\dfrac{\omega}{m\sqrt{2\mu}} \\ -\dfrac{1}{\sqrt{2\omega}}\left(\dfrac{k_1}{m} - \dfrac{ik_2}{\omega}\right) & \dfrac{-ik_2}{\omega\sqrt{2\omega}} & -\dfrac{1}{\sqrt{2\mu}}\left(\dfrac{\mu k_1}{m\omega} - \dfrac{ik_2}{\omega}\right) \\ -\dfrac{1}{\sqrt{2\omega}}\left(\dfrac{k_2}{m} + \dfrac{ik_1}{\omega}\right) & \dfrac{ik_1}{\omega\sqrt{2\omega}} & -\dfrac{1}{\sqrt{2\mu}}\left(\dfrac{\mu k_2}{m\omega} + \dfrac{ik_1}{\omega}\right) \end{pmatrix}. \tag{A6}$$

Note the appearance of the indefinite metric in the second term of (A5). We define Krein operators $a_\mu = -b_\mu$ and $a_\mu^\dagger = g_{\mu\beta} b_\beta^*$. It is in terms of these that we define our harmonic oscillator coordinates for the MCS field,

$$q_{1,\mu}^{\text{cs}}(k) = \frac{1}{2}[a_\mu(k) + a_\mu^\dagger(k) + a_\mu(-k) + a_\mu^\dagger(-k)], \tag{A7}$$

$$q_{2,\mu}^{\text{cs}}(k) = \frac{i}{2}[a_\mu(k) - a_\mu^\dagger(k) - a_\mu(-k) + a_\mu^\dagger(-k)], \tag{A8}$$

$$p_{1,\mu}^{\text{cs}}(k) = \frac{i}{2}[a_\mu(k) - a_\mu^\dagger(k) + a_\mu(-k) - a_\mu^\dagger(-k)], \tag{A9}$$

$$p_{2,\mu}^{\text{cs}}(k) = \frac{1}{2}[-a_\mu(k) - a_\mu^\dagger(k) + a_\mu(-k) + a_\mu^\dagger(-k)]. \tag{A10}$$

These satisfy the relations

$$q^{\mathrm{cs}}_{\ell,\mu}(-k) = (-1)^{\ell+1} q^{\mathrm{cs}}_{\ell,\mu}(k) \quad \text{and} \quad p^{\mathrm{cs}}_{\ell,\mu}(-k) = (-1)^{\ell+1} p^{\mathrm{cs}}_{\ell,\mu}(k). \tag{A11}$$

Thus, upon restriction to "allowed" momenta $k, k' \in \Gamma'$, we have the commutation relations

$$[q^{\mathrm{cs}}_{\ell,\mu}(k), p^{\mathrm{cs}}_{n,\nu}(k')] = i g_{\mu\nu} \delta_{\ell n} \delta_{k,k'}. \tag{A12}$$

This leads to the following expressions for the time-zero MCS field in Landau gauge:

$$A_0(x) = \frac{1}{\sqrt{|V|}} \sum_{k \in \Gamma'} \left\{ \cos(k \cdot x) \left[\frac{2\omega}{m\sqrt{2\omega}} q^{\mathrm{cs}}_{1,0}(k) + \frac{2\omega}{m\sqrt{2\mu}} q^{\mathrm{cs}}_{1,2}(k) \right] + \sin(k \cdot x) \left[\frac{2\omega}{m\sqrt{2\omega}} q^{\mathrm{cs}}_{2,0}(k) + \frac{2\omega}{m\sqrt{2\mu}} q^{\mathrm{cs}}_{2,2}(k) \right] \right\},$$

$$\begin{aligned} A_\ell(x) = \frac{1}{\sqrt{|V|}} \sum_{k \in \Gamma'} \Bigg\{ & \cos(k \cdot x) \left[-\frac{2k_\ell}{m\sqrt{2\omega}} p^{\mathrm{cs}}_{2,0}(k) - \frac{2\mu k_\ell}{m\omega\sqrt{2\mu}} p^{\mathrm{cs}}_{2,2}(k) \right. \\ & \left. - \frac{2\epsilon_{\ell n} k_n}{\omega} \left(\frac{q^{\mathrm{cs}}_{2,0}(k)}{\sqrt{2\omega}} - \frac{q^{\mathrm{cs}}_{2,1}(k)}{\sqrt{2\omega}} + \frac{q^{\mathrm{cs}}_{2,2}(k)}{\sqrt{2\mu}} \right) \right] \\ & + \sin(k \cdot x) \left[\frac{2k_\ell}{m\sqrt{2\omega}} p^{\mathrm{cs}}_{1,0}(k) + \frac{2\mu k_\ell}{m\omega\sqrt{2\mu}} p^{\mathrm{cs}}_{1,2}(k) \right. \\ & \left. + \frac{2\epsilon_{\ell n} k_n}{\omega} \left(\frac{q^{\mathrm{cs}}_{1,0}(k)}{\sqrt{2\omega}} - \frac{q^{\mathrm{cs}}_{1,1}(k)}{\sqrt{2\omega}} + \frac{q^{\mathrm{cs}}_{1,2}(k)}{\sqrt{2\mu}} \right) \right] \Bigg\}. \end{aligned} \tag{A13}$$

For the free MCS Hamiltonian in Landau gauge with Wick ordering, this leads to

$$\begin{aligned} H^{\mathrm{cs}}_0 = \sum_{k \in \Gamma'} \Bigg\{ & -\frac{\omega}{2} (p^{\mathrm{cs}}_{\ell,0}(k) p^{\mathrm{cs}}_{\ell,0}(k) + q^{\mathrm{cs}}_{\ell,0}(k) q^{\mathrm{cs}}_{\ell,0}(k)) + \frac{\omega}{2} (p^{\mathrm{cs}}_{\ell,1}(k) p^{\mathrm{cs}}_{\ell,1}(k) + q^{\mathrm{cs}}_{\ell,1}(k) q^{\mathrm{cs}}_{\ell,1}(k)) \\ & + \frac{\mu}{2} (p^{\mathrm{cs}}_{\ell,2}(k) p^{\mathrm{cs}}_{\ell,2}(k) + q^{\mathrm{cs}}_{\ell,2}(k) q^{\mathrm{cs}}_{\ell,2}(k)) \Bigg\}. \end{aligned} \tag{A14}$$

The diffeomorphism action lifted on truncated (chiral) Taylor expansion of a complex scalar field over a Riemann surface is presented in the paper under the name of large diffeomorphisms. After an heuristic approach, we show how a linear truncation in the Taylor expansion can generate an algebra of symmetry characterized by some structure functions. Such a linear truncation is explicitly realized by introducing the notion of Forsyth frame over the Riemann surface with the help of a conformally covariant algebraic differential equation. The large chiral diffeomorphism action is then implemented through a Becchi-Rouet-Stora (BRS) formulation (for a given order of truncation) leading to a more algebraic setup. In this context the ghost fields behave as holomorphically covariant jets. Subsequently, the link with the so-called $\mathcal{W}$-algebras is made explicit once the ghost parameters are turned from jets into tensorial ghost ones. We give a general solution with the help of the structure functions pertaining to all the possible truncations lower or equal to the given order. This provides another contribution to the relationship between Korteweg-de Vries (KdV) flows and $\mathcal{W}$-diffeomorphims. © *2006 American Institute of Physics.*

I. INTRODUCTION

The notion of symmetry gives a structure to spacetime (or configuration space) and/or internal spaces of the model under consideration, in the sense that the former is closely related to a geometrical setup.

At the infinitesimal level, the concept of algebra turns out to be very useful. It generally gives rise to a solution when the linearity is fulfilled. In the nonlinear situation, however, we sometimes have to explore further behind the first infinitesimal transformation step.

The development of nonlinear sciences has supported these needs,[1] and many basic physical systems were described by nonlinear extensions of algebras. This is the case for integrable systems, two-dimensional conformal models (with application to strings, gravity, or solid state physics, see e.g., Ref. 2).

Particular interest has been devoted to the so-called $\mathcal{W}$-algebras,[3] which come out from different principles,[4–6] and the question of their geometric origin still remains unclear or unsatisfactory despite various attempts given in Refs. 5 and 7–11.

In particular, the relationship between a conformally covariant sth-order differential equation

$$(\partial_{(s)} + a^{(s)}_{(2)}(z,\bar{z})\partial_{(s-2)} + \cdots + a^{(s)}_{(s)}(z,\bar{z}))f(z,\bar{z}) = 0,$$

over a generic Riemann surface and some of the so-called $\mathcal{W}$-algebra has been well established for 15 years.[6] The differential equations can be thought of as equations of motion for some matter fields. The former can also be derived as vanishing covariant derivative condition,[12] and to some extent, more general $\mathcal{W}$-algebra such as the Bershadsky one[13] can be related to a system of conformally covariant coupled differential equations.

Focusing here only on one sth-order differential equation, one may either work directly with the solutions or with uniformizing coordinates considered as ratios of linear independent solutions.[14,8] It turns out to be a matter of taste of working either with homogeneous coordinates or inhomogeneous ones on $\mathbb{C}P^{s-1}$. However, in his textbook,[14] Forsyth uses rather inhomogeneous coordinates in order to get some differential invariants. The inhomogeneous coordinates have to satisfy $s+1$th-order equations. Accordingly, our point of view proposed in Ref. 15 traced back in the literature, found an unexpected origin in the past[14] related to some algebraic type differential equations, once covariantly formulated over a generic Riemann surface. Indeed the definition of general well-defined differential operators over a (two-dimensional) Riemann surface requires some care,[16] and puts forward a deep insight into the links between covariance required by physical considerations and projective geometry. Related studies of projectively invariant differential operators as well differential invariants can be found in Ref. 17.

In Ref. 15 the notion of Laguerre-Forsyth frames was promoted. In order to avoid possible confusion with the named Laguerre-Forsyth form of a conformally covariant differential equation,[8] in the present paper, we adopt the name Forsyth frames. We simply have in mind the ideas of, first, pursuing further the method given by Forsyth in Ref. 14, and second, dealing with scalar coordinates considered as solutions of generalized Beltrami equations (see, e.g., Ref. 8 or 18 Appendix C2) just about the approach given in Refs. 8 and 10. Our motivation for using the inhomogeneous coordinates rests on the fact that they seem to be more natural for constructing projective invariants—projective action of $\mathrm{SL}(s,\mathbb{C})$ on $\mathbb{C}P^{s-1}$. In general,[19] the smooth coefficients in the above-noted sth-order covariant differential equation have been proven to be projectively invariant. Inhomogeneous coordinates are the local coordinates for projective curves in $\mathbb{C}P^{s-1}$ on which there is a symplectic structure related to the Gelfand-Dickey brackets.[20,19] Moreover, inhomogeneous coordinates offer the possibility to work with scalar fields instead of densities.

In Ref. 15, these Forsyth frames were thus made of coordinate scalar fields on some finite dimensional target space and constructed from solutions of a finite order holomorphically covariant linear differential equation over a Riemann surface of the above-mentioned type. At the quantum level, these scalar fields surprisingly have already gained at the one-loop level a noncommutative character. This phenomenon gives a quantum origin to a noncommutative structure on the target space. The noncommutativity came out by anomaly cancellation as a nonlocal effect.

The basic novelties of these Forsyth frames lie in their nontrivial properties under differentiations, which allow one to expand beyond first order the holomorphic reparametrization process still maintaining the algebra closure property. Thus investigating this type of extended algebra appears as a necessity, since this "new" structure encapsulates the (general) covariance laws.

In this paper, the construction of Forsyth frames is proposed in great detail and it strongly relies on a symmetry principle. The latter will be systematically studied in the algebraic Becchi-Rouet-Stora (BRS) language more suitable for a possible field theoretical treatment of the model.

The paper is organized as follows. Section II goes over some motivations for this extended notion of symmetry, beyond linearity. It requires the use of higher order derivatives and the closure of the algebra obliges one to introduce new fields which will play the role of structure functions for the (nonlinear) reduced symmetry algebra. Section III is devoted to the definition of the Forsyth frames and to a deep study of their properties. In Sec. IV, a convenient BRS approach is presented for the algebra of symmetry. It will be useful for improving in particular the covariance laws which come out from these properties. Section V treats the covariance under holomorphic change charts of the algebra elements. Nontensorial structures (jet) come out, in particular

under the form of jet-BRS ghosts which are harmful for physical considerations since covariant quantities are required. A rather tricky link with tensorial ghosts is presented as a change of basis of generators. Section VI gives a way (using all the differential properties of the Forsyth frames, including the ones of the subframes encapsulated into the maximal one) to decompose into tensors the jet-BRS ghosts. The process is obviously defined up to a tensorial rescaling. Some detailed examples are given and illustrate the striking property of canceling out the effects of all the subframes, in favor of a standard presentation of the $\mathcal{W}$-algebra structure. Exploiting some known results in the literature[10] allows one to clarify the algorithm. We conclude in Sec. VII.

II. MOTIVATIONS

The issue of finding the most general expression of a spacetime symmetry can find an answer in the concept of generalized frames, perhaps rather than that of prolongated frames whose local expression is obtained by successive derivations.[21] In order to consider such objects, let us first think of the Fock space of some smooth complex scalar field Z defined over a given Riemann surface Σ, endowed with a complex analytic (holomorphic) structure; this requires the use of local complex coordinates $(z,\bar{z})$. Smoothness of the complex scalar field $Z=Z(z,\bar{z})$ is understood with respect to the differential structure on Σ with which the complex structure is subordinated to. From the locality principle, recall that the Fock space for Z is generated by all the z and $\bar{z}$ derivatives of any order considered as independent monomials.

Consider now the infinitesimal action of smooth diffeomorphisms on Σ which is usually expressed by means of the Lie derivative $L_\xi Z=(\xi(z,\bar{z})\partial+\bar{\xi}(z,\bar{z})\bar{\partial})Z$.

With respect to the complex structure we shall be concerned with the so-called "chiral" diffeomorphisms acting on the complex scalar field Z which consist in separating the Lie derivative according to z-derivative, so that $Z\to Z+\xi\partial Z$; there is the complex conjugate expression as well. Denoting in the Fock space the various z-derivatives of order ℓ by $\partial_{(\ell)}Z$, $\ell=1,2,\ldots$ one wants to consider a fully chiral local variation for the complex scalar field Z (going thus beyond the first order) of the following type:

$$(\delta Z)(z,\bar{z})=\sum_{\ell\geqslant 1}\gamma^{(\ell)}(z,\bar{z})\partial_{(\ell)}Z(z,\bar{z}), \tag{2.1}$$

together with the complex conjugate expression, and into which all the z-derivatives appear.

Hence, constructing a local field theory over $\mathbb{C}$ amounts to working *a priori* on local functionals in the various z-derivatives of Z. So to speak, the physical model is built over the infinite z-frames which is locally represented by $(Z(z,\bar{z}),\partial Z(z,\bar{z}),\partial_{(2)}Z(z,\bar{z}),\ldots)$, which reproduces the "chiral" Taylor expansion of the field Z (i.e., only with respect to the z-coordinate) at the point $(z,\bar{z})$ of Σ, in other words, the infinite jet of Z.

What is called large chiral diffeomorphisms in the paper is the lifted action of usual local chiral diffeomorphisms on $\mathbb{C}$ to the infinite jet space $J^\infty(\mathbb{C},\mathbb{C})$, i.e., on the z-Taylor expansion. The former are viewed as transformations acting on the complex scalar field Z itself and they require, on the one hand, infinitely many local parameters $\gamma^{(\ell)}$ of conformal type $(-\ell,0)$ which generalize vector fields of type $(-1,0)$, and, on the other hand, any higher order derivatives of Z.

Accordingly, it is called a large chiral diffeomorphism symmetry the invariance of some observables or functional on $J^\infty(\mathbb{C},\mathbb{C})$ under the transformation (2.1). Translating this problem of symmetry on the space of local functionals in the infinite jet of the scalar field Z,

$$\delta Z(z,\bar{z})=\left(\sum_{\ell\geqslant 1}\int_{\mathbb{C}}d\bar{w}\wedge dw\,\gamma^{(\ell)}(w,\bar{w})\mathcal{W}_{(\ell)}(w,\bar{w})\right)Z(z,\bar{z}), \tag{2.2}$$

amounts to introducing local Ward operators associated to the local parameters $\gamma^{(\ell)}$,

$$\mathcal{W}_{(\ell)}(z,\bar{z}) = \partial_{(\ell)} Z(z,\bar{z}) \frac{\delta}{\delta Z(z,\bar{z})} \quad \text{for } \ell \geqslant 1, \tag{2.3}$$

which generate an infinite dimensional Lie algebra. But note that the only Lie subalgebra is for $\ell=1$ of which the bracket (as tensorial product of distributions) writes

$$\begin{aligned}\left[\mathcal{W}_{(1)}(z,\bar{z}),\mathcal{W}_{(1)}(w,\bar{w})\right] &= \mathcal{W}_{(1)}(z,\bar{z})\partial_w\delta(w-z) - \mathcal{W}_{(1)}(w,\bar{w})\partial_z\delta(z-w)\\ &= \mathcal{W}_{(1)}(w,\bar{w})\partial_w\delta(w-z) - \mathcal{W}_{(1)}(z,\bar{z})\partial_z\delta(z-w)\end{aligned} \tag{2.4}$$

and translates by duality the Lie algebra structure of vector fields to the functional level, namely, if $W_1(\xi)=\langle \mathcal{W}_1 | \xi\rangle$ then

$$\begin{aligned}[W_1(\xi),W_1(\eta)] &= \langle [\mathcal{W}_{(1)}(z,\bar{z}),\mathcal{W}_{(1)}(w,\bar{w})] | \xi(z,\bar{z})\,\eta(w,\bar{w})\rangle\\ &= \langle \mathcal{W}_1 | \eta\,\partial\,\xi - \xi\,\partial\,\eta\rangle = \langle \mathcal{W}_1 | [\eta,\xi]\rangle = W_1([\eta,\xi])\end{aligned} \tag{2.5}$$

and thus reproduces the bracket between the parameters of usual conformal transformations. (The pairing $\langle|\rangle$ stands for the functional evaluation of distributions.) In full generality, the brackets for $k,\ell \geqslant 1$ read

$$[\mathcal{W}_{(k)}(z,\bar{z}),\mathcal{W}_{(\ell)}(w,\bar{w})] = \sum_{m=1}^{\ell} \binom{\ell}{m} \partial_w^m \delta(w-z)\mathcal{W}_{(k+\ell-m)}(w,\bar{w}) - \sum_{m=1}^{k} \binom{k}{m} \partial_z^m \delta(z-w)\mathcal{W}_{(k+\ell-m)}(z,\bar{z}) \tag{2.6}$$

and close onto subspaces generated by $\{\mathcal{W}_{(u)}\}_{u=\min(k,\ell)}^{k+\ell-1}$ and leads to introducing higher order generators at each step. Note that the bracket (2.6) fulfills the Jacobi identity. Moreover for arbitrary k and $\ell=1$ one obtains by duality

$$\begin{aligned}\langle [\mathcal{W}_{(k)}(z,\bar{z}),\mathcal{W}_{(1)}(w,\bar{w})] | \xi^{(k)}(z,\bar{z})\,\eta^{(1)}(w,\bar{w})\rangle &= \langle \mathcal{W}_{(k)} | \eta^{(1)}\,\partial\,\xi^{(k)} - k\,\partial\,\eta^{(1)}\xi^{(k)}\rangle - \sum_{m=2}^{k\geqslant 2} \binom{k}{m}\\ &\quad \times \langle \mathcal{W}_{(k-m+1)} | \xi^{(k)}\partial^m\eta^{(1)}\rangle,\end{aligned} \tag{2.7}$$

where the first smearing bracket on the right-hand side shows that the conformal transformations $\mathcal{W}_{(1)}$ preserve the $\mathcal{W}_{(k)}$ transformations up to lower orders. It also defines a covariant bracket $[\eta^{(1)},\xi^{(k)}]^{(k)} = \eta^{(1)}\partial\xi^{(k)} - k\partial\eta^{(1)}\xi^{(k)}$ showing that the parameter $\xi^{(k)}$ carries a conformal weight $(-k,0)$.

The closure onto a finite dimensional Lie sub-algebra for $\ell>1$ can be obtained by a truncation in the z-derivatives of $Z(z,\bar{z})$ at the some finite order, say $s-1$, $(s\geqslant 2)$. Setting for z-derivatives of order greater than $s-1$, namely for $m\geqslant s$, the following linear combinations

$$\partial_{(m)} Z(z,\bar{z}) = \sum_{\ell=1}^{s-1} \mathcal{R}^{(\ell)}_{(m)}(z,\bar{z})\partial_{(\ell)} Z(z,\bar{z}) = \Rightarrow \mathcal{W}_{(m)}(z,\bar{z}) = \sum_{\ell=1}^{s-1} \mathcal{R}^{(\ell)}_{(m)}(z,\bar{z})\mathcal{W}_{(\ell)}(z,\bar{z}) \tag{2.8}$$

where the finite summation runs over $\ell=1,\ldots,s-1$, thus the immediate consequence is that the bracket (2.6) reduces to

$$\begin{aligned}[\mathcal{W}_{(k)}(z,\bar{z}),\mathcal{W}_{(\ell)}(w,\bar{w})] = \sum_{u=1}^{s-1} \Bigg\{ &\sum_{m=1}^{\ell} \binom{\ell}{m} \partial_w^m \delta(w-z)\mathcal{R}^{(u)}_{(k+\ell-m)}(w,\bar{w})\mathcal{W}_{(u)}(w,\bar{w})\\ &- \sum_{m=1}^{k} \binom{k}{m} \partial_z^m \delta(z-w)\mathcal{R}^{(u)}_{(k+\ell-m)}(z,\bar{z})\mathcal{W}_{(u)}(z,\bar{z})\Bigg\},\end{aligned} \tag{2.9}$$

and closes onto the generators $\{\mathcal{W}_{(u)}\}_{u=1}^{s-1}$. However, the truncation spoils the Jacobi identity due to

the restriction of the order to the range $\ell=1,\ldots,s-1$. The Jacobi identity (which guarantees the associativity of the Lie algebra) will be restored by modifying the generators $\{\mathcal{W}_{(u)}\}_{u=1}^{s-1}$ in such a way to take into account the reduction coefficients $\mathcal{R}_{(v)}^{(u)}(z,\bar{z})$ introduced in (2.8). These coefficients will play the role of "structure functions" for the finite dimensional Lie algebra generated by the modified generators $\{\tilde{\mathcal{W}}_{(u)}\}_{u=1}^{s-1}$. Owing to (2.8), this is achieved by computing, for $k\geqslant s$ and for $\ell=1,\ldots,s-1$, the difference

$$[\mathcal{W}_{(k)}(z,\bar{z}),\mathcal{W}_{(\ell)}(w,\bar{w})]-\sum_{p=1}^{s-1}\mathcal{R}_{(k)}^{(p)}(z,\bar{z})[\mathcal{W}_{(p)}(z,\bar{z}),\mathcal{W}_{(\ell)}(w,\bar{w})]$$
$$=:\sum_{u=1}^{s-1}\left[\mathcal{R}_{(k)}^{(u)}(z,\bar{z}),\mathcal{F}_{(\ell)}\left(\mathcal{R}(w,\bar{w}),\frac{\delta}{\delta\mathcal{R}(w,\bar{w})}\right)\right]\mathcal{W}_{(u)}(z,\bar{z}), \tag{2.10}$$

where $\mathcal{F}_{(\ell)}(\mathcal{R}(w,\bar{w}),\delta/\delta\mathcal{R}(w,\bar{w}))$ is a functional differential polynomial in the $\mathcal{R}$'s and ensures the modification of the generator, for each $\ell=1,\ldots,s-1$, according to

$$\mathcal{W}_{(\ell)}(w,\bar{w})\to\tilde{\mathcal{W}}_{(\ell)}(w,\bar{w})=\partial_{(\ell)}Z(w,\bar{w})\frac{\delta}{\delta Z(w,\bar{w})}+\mathcal{F}_{(\ell)}\left(\mathcal{R}(w,\bar{w}),\frac{\delta}{\delta\mathcal{R}(w,\bar{w})}\right) \tag{2.11}$$

in view to fulfill the Jacobi identity. Furthermore, of course one has for $\ell=1,\ldots,s-1$,

$$\mathcal{R}_{(k)}^{(\ell)}(z,\bar{z})=\begin{cases}\delta_k^\ell & \text{if } 1\leqslant k\leqslant s-1\\ \mathcal{R}_{(k)}^{(\ell)}(z,\bar{z}) & \text{if } k\geqslant s,\end{cases} \tag{2.12}$$

and therefore the functional operator $\mathcal{F}_{(\ell)}$ must contain functional derivatives with respect to the structure functions $\mathcal{R}_{(k)}^{(p)}$ for $k\geqslant s$ only. Thus inserting twice the brackets (2.9) into the right-hand side of (2.10), a direct comparison with the left-hand side of (2.10) amounts, on the one hand, to the vanishing of the coefficient terms of the $\mathcal{W}_{(u)}(w,\bar{w})$'s. This gives rise to some compatibility conditions that must be fulfilled by the structure functions, namely,

$$\mathcal{R}_{(k+n)}^{(u)}(w,\bar{w})=\sum_{p=1}^{s-1}\sum_{j=0}^{n}\binom{n}{j}\partial_{(j)}\mathcal{R}_{(k)}^{(p)}(w,\bar{w})\mathcal{R}_{(p+n-j)}^{(u)}(w,\bar{w})\quad\text{for } n=0,\ldots,\ell\quad\text{and } k\geqslant s. \tag{2.13}$$

If k is taken to be lower or equal to $s-1$ then (2.13) restricts to $\mathcal{R}_{(k+n)}^{(u)}=\mathcal{R}_{(k+n)}^{(u)}$, since $\mathcal{R}_{(k)}^{(p)}=\delta_k^p$.

On the other hand, the coefficient term of $\mathcal{W}_{(u)}(z,\bar{z})$ provides the functional differential operator

$$\mathcal{F}_{(\ell)}\left(\mathcal{R}(w,\bar{w}),\frac{\delta}{\delta\mathcal{R}(w,\bar{w})}\right)=\sum_{i\geqslant s}\sum_{j=1}^{s-1}\left\{\sum_{m=0}^{i}\binom{i}{m}(-1)^m\partial_{(m)}\left(\mathcal{R}_{(i+\ell-m)}^{(j)}(w,\bar{w})\frac{\delta}{\delta\mathcal{R}_{(i)}^{(j)}(w,\bar{w})}\right)-\sum_{p=1}^{s-1}\sum_{q=0}^{p}\binom{p}{q}\right.$$
$$\left.\times(-1)^q\partial_{(q)}\left(\mathcal{R}_{(i)}^{(p)}(w,\bar{w})\mathcal{R}_{(p+\ell-q)}^{(j)}(w,\bar{w})\frac{\delta}{\delta\mathcal{R}_{(i)}^{(j)}(w,\bar{w})}\right)\right\}. \tag{2.14}$$

Therefore, in addition to the scalar field Z, the structure functions $\mathcal{R}$'s come as new fields to be taken into account in the theory. Their variation is obtained to be

$$\delta\mathcal{R}^{(p)}_{(n)}(z,\bar z)=\left(\int_{\mathbb{C}}\mathrm{d}\bar w\wedge\mathrm{d}w\left[\sum_{\ell=1}^{s-1}\gamma^{(\ell)}(w,\bar w)+\sum_{u\geqslant s}\gamma^{(u)}(w,\bar w)\mathcal{R}^{(\ell)}_{(u)}(w,\bar w)\right]\tilde{\mathcal{W}}_{(\ell)}(w,\bar w)\right)\mathcal{R}^{(p)}_{(n)}(z,\bar z)$$
$$=\sum_{\ell=1}^{s-1}\left[\sum_{m=0}^{n}\binom{n}{m}\partial_{(m)}\left(\gamma^{(\ell)}+\sum_{u\geqslant s}\gamma^{(u)}\mathcal{R}^{(\ell)}_{(u)}\right)\mathcal{R}^{(p)}_{(n+\ell-m)}\right.$$
$$\left.-\sum_{j=1}^{s-1}\mathcal{R}^{(j)}_{(n)}\sum_{q=0}^{j}\binom{j}{q}\partial_{(q)}\left(\gamma^{(\ell)}+\sum_{u\geqslant s}\gamma^{(u)}\mathcal{R}^{(\ell)}_{(u)}\right)\mathcal{R}^{(p)}_{(j+\ell-q)}\right](z,\bar z),\tag{2.15}$$

while the variation (2.2) for Z rewrites

$$\delta Z(z,\bar z)=\left(\int_{\mathbb{C}}\mathrm{d}\bar w\wedge\mathrm{d}w\left[\sum_{\ell=1}^{s-1}\gamma^{(\ell)}(w,\bar w)+\sum_{u\geqslant s}\gamma^{(u)}(w,\bar w)\mathcal{R}^{(\ell)}_{(u)}(w,\bar w)\right]\tilde{\mathcal{W}}_{(\ell)}(w,\bar w)\right)Z(z,\bar z).\tag{2.16}$$

To this change $\mathcal{W}_{(\ell)}\to\tilde{\mathcal{W}}_{(\ell)}$ (for $\ell=1,\ldots,s-1$) of generators there corresponds a reduction from an infinite number to a finite number of local parameters

$$\gamma^{(m)}\to\Gamma^{(\ell)}=\sum_{m\geqslant 1}\gamma^{(m)}\mathcal{R}^{(\ell)}_{(m)},\qquad \ell=1,\ldots,s-1\tag{2.17}$$

as suggested by both the variations (2.15) and (2.16). The $s-1$ local parameters $\Gamma^{(\ell)}$ secure the fact that the $s-1$ generators $\tilde{\mathcal{W}}_{(\ell)}$ fulfill indeed the algebra (2.9). In short, this leads to a reduction of the symmetry algebra, and (2.1) reduces to the variation

$$(\delta Z)(z,\bar z)=\sum_{\ell=1}^{s-1}\Gamma^{(\ell)}(z,\bar z)\partial_{(\ell)}Z(z,\bar z).\tag{2.18}$$

By duality the following brackets $[,]^{(u)}$ corresponding to the generators $\tilde{\mathcal{W}}_{(u)}$ are found to be

$$[\eta^{(\ell)},\xi^{(k)}]^{(u)}=\sum_{m=0}^{\ell-1}\binom{\ell}{m}\mathcal{R}^{(u)}_{(k+m)}\eta^{(\ell)}\partial_{(\ell-m)}\xi^{(k)}-\sum_{m=0}^{k-1}\binom{k}{m}\mathcal{R}^{(u)}_{(\ell+m)}\xi^{(k)}\partial_{(k-m)}\eta^{(\ell)}.\tag{2.19}$$

These brackets are involved in the defining Poisson brackets for $\mathcal{W}$-algebras.[3,22,23] This leads to the

Conclusion 2.1: *The realization of large diffeomorphism algebra* (2.6) *requires the definition of frames which verify the truncation property* (2.8) *which realizes a derivative order reduction (D.O.R). So the structure functions* $\mathcal{R}^{(u)}_{(v)}(z,\bar z)$ *uniquely define the properties of the algebra.*

The problem we are after is twofold. First, due to the presence of higher order derivatives which carry a nontensorial nature (jets), one wants to perform the construction in a well-defined way, in the sense that this local symmetry has indeed a global meaning over the Riemann surface Σ. That is, constructing a field theory over the coframes $J^\infty(\Sigma,\mathbb{C})$. Second, find the appropriate generators for the symmetry algebra, (jets or tensors), which give rise to covariant quantities over the Riemann surface, these quantities being constructed from covariant differential operators, covariant in the sense to be holomorphically well defined on Σ. This would correspond to a change of generators $\{\tilde{\mathcal{W}}_{(u)}\}_{u=1}^{s-1}$ in order to get a presentation of the Poisson $\mathcal{W}$-algebras which are no longer Lie algebras. This means in particular that the lower orders in the brackets (2.7) should not be present any more.[23]

This second goal requires one in fact to work with a finite number of $s-1$ complex scalar fields Z instead of one only. Therefore, one is led to consider the jet space $J^\infty(\Sigma,\mathbb{C}^{s-1})$ on which local diffeomorphisms of $\mathbb{C}^{s-1}$ stabilizing the target point $(Z^{(1)},\ldots,Z^{(s-1)})$ are lifted by jet composition and act linearly. Presently, a truncation in the order of the jet can be implemented by means

of relations given by some PDEs. The simplest ones are given by a linear PDE which yields an algebraic relation between jet coordinates. This is what will be developed in the next section.

III. THE FORSYTH FRAMES

Over a Riemann surface Σ, let us introduce the algebraic PDE of fixed order s with smooth coefficients and defined by

$$L_s f(z,\bar{z}) = 0 \quad \text{with } L_s = \sum_{j=0}^{s} a^{(s)}_{(s-j)}(z,\bar{z})\partial_{(j)}, \quad \text{where } a^{(s)}_{(0)}(z,\bar{z}) = 1, \quad \text{and } a^{(s)}_{(1)}(z,\bar{z}) = 0. \tag{3.1}$$

When $\bar{z}$ is viewed to play the role of a parameter the PDE is considered as an ODE in the independent variable z and the function f is the unknown. It thus introduces a chiral splitting between the complex coordinates. Around any point of Σ this ODE admits s linearly independent *local* solutions $f^{(R)}$, $R=1,\ldots,s$ on a small enough neighborhood of any point. Actually, any solution turns out to be a scalar density under holomorphic changes of charts $(U,z)\to(\hat{U},w(z))$ with conformal weight $(1-s)/2$ in order to have a well-defined covariance on the Riemann surface Σ which yields

$$L_s(w,\bar{w}) = (w')^{-(1+s)/2} L_s(z,\bar{z})(w')^{(1-s)/2} \quad \text{on } U\cap\hat{U}\neq\varnothing\,. \tag{3.2}$$

Recall that $L_s f$ has conformal weight $(1+s)/2$. For an overview see, e.g., Ref. 24, and references therein. Equation (3.1) can be recast as a first-order differential operator if the jet of order $s-1$ of any solution f is considered as the variable. One has

$$(\partial + A^{(s)}(z,\bar{z}))\begin{pmatrix} f(z,\bar{z}) \\ \partial f(z,\bar{z}) \\ \vdots \\ \partial_{(r-1)} f(z,\bar{z}) \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ L_s f(z,\bar{z}) \end{pmatrix} = 0 \tag{3.3}$$

where the $s\times s$ matrix

$$A^{(s)}(z,\bar{z}) = \begin{pmatrix} 0 & -1 & 0 & \ldots & 0 \\ 0 & 0 & -1 & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ 0 & 0 & \ldots & 0 & -1 \\ a^{(s)}_{(s)}(z,\bar{z}) & a^{(s)}_{(s-1)}(z,\bar{z}) & \ldots & a^{(s)}_{(2)}(z,\bar{z}) & a^{(s)}_{(1)}(z,\bar{z}) \end{pmatrix} \tag{3.4}$$

has entries

$$[A^{(s)}(z,\bar{z})]_{lm} = \begin{cases} -1 & \text{for } m = l+1 \\ a^{(s)}_{(s-m+1)}(z,\bar{z}) & \text{for } l = s, \quad \text{with } a^{(s)}_{(1)}(z,\bar{z}) \equiv 0 \\ 0 & \text{otherwise}. \end{cases} \tag{3.5}$$

Moreover, each of them in the last row carries a z lower index content of covariant order $s-m+1$. But on account of (3.3), $A^{(s)}$ is expected to carry a covariant index z as the derivative ∂_z.

This allows one to associate to the ODE a system of s identical equations by introducing s unknowns $f^{(R)}$, $R=1,\ldots,s$. So it is a system of the same ODE over $\Sigma\times\mathbb{C}^s$. Note that any linear change in the local linearly independent solutions $\tilde{f}^{(R)}(z,\bar{z}) = A^{(R)}_{(S)} f^{(S)}(z,\bar{z})$ over $U\subset\Sigma$ preserves (3.1), $A\in GL(s,\mathbb{C})$. For the time being, the matrix A does not depend on the local complex coordinates $(z,\bar{z})$ on Σ, but this issue should be tackled as the gauging of the largest symmetry group of the ODE (3.1).

However, adapting Gunning[25] for a well-defined ODE over Σ according to (3.2) if one selects s linearly independent local solutions of (3.1), on the one hand, $f^{(R)}(z,\bar{z})$ on the coordinate neighborhood $U\subset\Sigma$, and on the other hand, $\hat{f}^{(R)}(w,\bar{w})$ on the coordinate neighborhood $\hat{U}\subset\Sigma$, then on the overlapping of these coordinate neighborhoods one has, in full generality, the following gluing rule for solutions:

$$\text{on } U\cap\hat{U}\neq\varnothing\,,\quad \hat{f}^{(R)}(w,\bar{w})=(w')^{-(1-s)/2}T^{(R)}_{(S)}f^{(S)}(z,\bar{z}), \tag{3.6}$$

where the unique constant matrix T turns out to be a one-cocycle of the chosen coordinate covering on Σ with values in $GL(s,\mathbb{C})$. To prove (3.6), for the given linearly independent s solutions $\hat{f}^{(R)}(w,\bar{w})$ in the open set $\hat{U}\subset\Sigma$, let us introduce the functions $g^{(R)}(z,\bar{z})$ on $U\cap\hat{U}\subset U$ defined by

$$g^{(R)}(z,\bar{z})=(w')^{(1-s)/2}\hat{f}^{(R)}(w,\bar{w})\quad\text{on } U\cap\hat{U}\neq\varnothing\,. \tag{3.7}$$

Upon using the covariance law (3.2) it is readily seen that the s functions $g^{(R)}(z,\bar{z})$ are linearly independent solutions of (3.1) over $U\cap\hat{U}\subset U$. Accordingly, for any other s linearly independent $f^{(R)}(z,\bar{z})$ of (3.1) in the open set U, the functions $g^{(R)}(z,\bar{z})$ are unique linear combinations of the functions $f^{(R)}(z,\bar{z})$, that is $g^{(R)}(z,\bar{z})=T^{(R)}_{(S)}f^{(S)}(z,\bar{z})$ a fact which demonstrates (3.6).

According to Ref. 14, (see also Ref. 8) one may define *locally* $s-1$ smooth scalar fields over a neighborhood of any point of Σ as quotients of $s-1$ local solutions by a preferred one which does not vanish on a neighborhood of a given point, say on U,

$$Z^{(R)}(z,\bar{z})=\frac{f^{(R+1)}(z,\bar{z})}{f^{(1)}(z,\bar{z})},\quad R=1,\ldots,s-1, \tag{3.8}$$

where the functions $f^{(R+1)}$ and $f^{(1)}$ belong to the same set of linearly independent solutions over U. By virtue of (3.6) one checks that

$$\text{on } U\cap\hat{U}\neq\varnothing\,,\quad \hat{Z}^{(R)}(w,\bar{w})=\frac{T^{(R+1)}_{(S+1)}Z^{(S)}(z,\bar{z})+T^{(R+1)}_{(1)}}{T^{(1)}_{(S+1)}Z^{(S)}(z,\bar{z})+T^{(1)}_{(1)}}, \tag{3.9}$$

a transformation law which shows that the local scalar fields Z have to be transformed in a homographic way in accordance with the Zucchini's point of view[7] on $\mathcal{W}$-algebras.

Moreover, note that any linear change in the linearly independent solutions $f^{(R)}$ on U induces a homographic transformation in the $Z^{(R)}$ on U as

$$\tilde{Z}^{(R)}(z,\bar{z})=\frac{A^{(R+1)}_{(S+1)}Z^{(S)}(z,\bar{z})+A^{(R+1)}_{(1)}}{A^{(1)}_{(S+1)}Z^{(S)}(z,\bar{z})+A^{(1)}_{(1)}}. \tag{3.10}$$

The question of gauging whether or not the matrix $A\in GL(s,\mathbb{C})$ into $A(z,\bar{z})$, in other words, render local the above-presented transformation law should also be tackled in the sequel.

This is the point where now one has to decide if $Z^{(R)}$ is a genuine scalar field on Σ or not, namely keeping T as general as possible or reduce it to the identity. If one chooses the latter what would be the meaning of $T=I$ for the space of solutions of the ODE (3.1)? A possible answer would be that there exists basis of solutions which is globally defined on Σ according to (3.6) with $T=I$. But there is a more precise statement which is the following. Consider

$$\text{on } \hat{U},\quad \hat{Z}^{(R)}(w,\bar{w})=\frac{\hat{f}^{(R+1)}(w,\bar{w})}{\hat{f}^{(1)}(w,\bar{w})},\quad R=1,\ldots,s-1 \tag{3.11}$$

and thus with (3.7) one can define on the overlapping the scalar functions

$$\text{on } U\cap\hat{U}\neq\emptyset,\quad \zeta^{(R)}(z,\bar{z})=\frac{g^{(R+1)}(z,\bar{z})}{g^{(1)}(z,\bar{z})}=\hat{Z}^{(R)}(w,\bar{w}),\quad R=1,\ldots,s-1, \tag{3.12}$$

which thus coincide with the scalar functions $\hat{Z}^{(R)}$ on the intersection $U\cap\hat{U}\neq\emptyset$. Since in the glueing rule given by (3.6) the matrix T only depends on the two coordinate neighborhoods U and $\hat{U}$, let us perform the following linear change $\tilde{f}=aTf$ of linearly independent solutions on the open set U, with given $a:U\to\mathbb{C}^*$. This yields a gauge transformation over U of the type (3.10) with $A=T$ so that

$$\text{on } U\cap\hat{U}\neq\emptyset,\quad \zeta^{(R)}(z,\bar{z})=\hat{Z}^{(R)}(w,\bar{w})=\tilde{Z}^{(R)}(z,\bar{z}),\quad R=1,\ldots,s-1. \tag{3.13}$$

Hence by these redefinitions through gauge transformations, one can construct $s-1$ scalar fields on Σ, still denoted by $Z^{(R)}$, each of those being a collection of scalar maps defined on the various coordinate neighborhoods satisfying (3.13) as matching rule.

Suppose now that a family of linear differential equations of the type (3.1) is indexed by the order $r\geqslant 2$. Accordingly, solutions must be labeled by the order r, and the above-presented construction holds for each of the orders r. One may state the

Conjecture 3.1: *Around each point of the Riemann surface* Σ *and for each integer* $r\geqslant 2$, *there is a map*, $\Sigma\to\mathbb{C}P^{r-1}$ *which defines local inhomogeneous coordinates on* $\mathbb{C}P^{r-1}$, *collectively denoted by the vector valued in* $\mathbb{C}^{r-1}$ *smooth function on* Σ,

$$\vec{Z}(z,\bar{z}|r)=(Z^{(1)}(z,\bar{z}|r),\ldots,Z^{(r-1)}(z,\bar{z}|r)), \tag{3.14}$$

where the $r-1$ *components are given by*

$$Z^{(R)}(z,\bar{z}|r)=\frac{f^{(R+1)}(z,\bar{z}|r)}{f^{(1)}(z,\bar{z}|r)},\quad R=1,\ldots,r-1. \tag{3.15}$$

$\vec{Z}(z,\bar{z}|r)$ *will be called a Forsyth frame. For a given a point on* Σ, *all the frames must be equivalent for all the physical points of view.*

Returning to the general discussion with a given equation (3.1) of order s which introduces the truncation in the jet order, the following theorem comes as a by-product.

Theorem 3.1: *For any* $m\geqslant 1$, *given an order* s *of truncation dictated by a differential equation of the type* (3.1), *one has*

$$\partial_{(m)}\vec{Z}(z,\bar{z})=\sum_{l=1}^{s-1}\mathcal{R}^{(l)}_{(m)}(z,\bar{z})\partial_{(l)}\vec{Z}(z,\bar{z})\quad\text{and}\quad\mathcal{R}^{(l)}_{(m)}(z,\bar{z})=\delta^{(l)}_{(m)}\quad\text{if } 1\leqslant m\leqslant s-1. \tag{3.16}$$

The decomposition is universal for all the inhomogeneous coordinates, $Z^{(R)}(z,\bar{z})$ *in the sense that each* $\mathcal{R}^{(l)}_{(m)}$ *does not depend on the index* (R) *of the former. The* $\mathcal{R}$*'s correspond exactly to those heuristically introduced in* (2.8) *and are specific to the order* s *of truncation imposed by* (3.1). *However the vectorial character of* $\vec{Z}$ *gives rise to some additional compatibility conditions between themselves.*

Proof 1: *The proof of Theorem 3.1 is trivial by direct computation. Indeed we can compute* $\partial_s f^{(P+1)}(z,\bar{z})$ *for all* $P=1,\ldots,s-1$ *in two different ways. The first one comes from the very definition Eq.* (3.8) *and the Leibniz rule*

$$\partial_{(s)}f^{(P+1)}=\partial_{(s)}(Z^{(P)}f^{(1)})=\partial_{(s)}Z^{(P)}f^{(1)}+Z^{(P)}\partial_{(s)}f^{(1)}+\sum_{j=1}^{s-1}\binom{s}{j}\partial_{(j)}Z^{(P)}\partial_{(s-j)}f^{(1)}. \tag{3.17}$$

The second one comes from the very definition Eq. (3.8) *and the fact that both* $f^{(P+1)}$ *and* $f^{(1)}$ *are solutions of Eq.* (3.1):

$$\partial_{(s)}f^{(P+1)} = -\sum_{j=0}^{s-1} a^{(s)}_{(s-j)}\partial_{(j)}(Z^{(P)}f^{(1)}) = -\sum_{j=0}^{s-1} a^{(s)}_{(s-j)}\sum_{m=0}^{j}\binom{j}{m}\partial_{(m)}Z^{(P)}\partial_{(j-m)}f^{(1)} = -Z^{(P)}\sum_{j=0}^{s-1} a^{(s)}_{(s-j)}\partial_{(j)}f^{(1)}(z,\bar{z})$$
$$-\sum_{j=1}^{s-1} a^{(s)}_{(s-j)}\sum_{m=1}^{j}\binom{j}{m}\partial_{(m)}Z^{(P)}\partial_{(j-m)}f^{(1)} = Z^{(P)}\partial_{(s)}f^{(1)} - \sum_{m=1}^{s-1}\partial_{(m)}Z^{(P)}\sum_{j=m}^{s-1} a^{(s)}_{(s-j)}\binom{j}{m}\partial_{(j-m)}f^{(1)}. \tag{3.18}$$

A direct comparison between Eqs. (3.17) and (3.18) *entails*

$$\partial_{(s)}Z^{(P)} = \frac{-1}{f^{(1)}}\sum_{m=1}^{s-1}\left(\binom{s}{m}\partial_{(s-m)}f^{(1)} + \sum_{j=m}^{s-1} a^{(s)}_{(s-j)}\binom{j}{m}\partial_{(j-m)}f^{(1)}\right)\partial_{(m)}Z^{(P)}. \tag{3.19}$$

The decomposition (3.16) *combined with the nonvanishing of the Wronskian determinant* (3.21) *yields*

$$\mathcal{R}^{(m)}_{(s)}(z,\bar{z}) \equiv \frac{-1}{f^{(1)}(z,\bar{z})}\left(\binom{s}{m}\partial_{(s-m)}f^{(1)}(z,\bar{z}) + \sum_{j=m}^{s-2} a^{(s)}_{(s-j)}(z,\bar{z})\binom{j}{m}\partial_{(j-m)}f^{(1)}(z,\bar{z})\right), \tag{3.20}$$

where $\mathcal{R}^{(m)}_{(s)}$ *for* $m=1,\ldots,s-1$ *depend on the coefficients* $a^{(s)}_{(s-j)}$ *and* $f^{(1)}$ *and its* z *derivatives up to order* $s-2$ *since* $a^{(s)}_{(1)}=0$. *It is readily seen that the decomposition does not depend on the index of the solution* $f^{(P+1)}$. *One can extend* (3.20) *to the case* $m=0$ *since* $f^{(1)}$ *is solution of* (3.1) *by setting* $\mathcal{R}^{(0)}_{(s)}\equiv 0$.

Let us introduce the Wronskian as a $(s-1)\times(s-1)$-matrix

$$\varpi(z,\bar{z}) = (\varpi^{(R)}_{(\ell)}(z,\bar{z})) = \begin{pmatrix} \partial Z^{(1)}(z,\bar{z}) & \cdots & \partial Z^{(s-1)}(z,\bar{z}) \\ \vdots & \ddots & \vdots \\ \partial_{(s-1)}Z^{(1)}(z,\bar{z}) & \cdots & \partial_{(s-1)}Z^{(s-1)}(z,\bar{z}) \end{pmatrix}. \tag{3.21}$$

Hence in the algebra of squared matrices of order $s-1$ the relationships (3.16) state that any z-derivative of the Wronskian ϖ can be decomposed as a product of a rectangular matrix with the functions $\mathcal{R}$ as entries by ϖ, in detail,

$$\partial_{(m)}\varpi^{(R)}_{(\ell)} = \sum_{k=1}^{s-1}\mathcal{R}^{(k)}_{(m+\ell)}\varpi^{(R)}_{(k)}. \tag{3.22}$$

In order to be the most general as possible, the Wronskian may be extended to an $m\times(s-1)$ rectangular matrix when higher derivatives $m\geqslant s$ of the $Z^{(R)}$'s are considered. In account of (3.16), the rectangular matrix of derivatives of Z up to order m can always be expressed in terms of the Wronskian matrix (3.21). We shall call this mechanism connected to the truncation heuristically introduced in (2.9) as a derivative order reduction, or in shorthand DOR. Note also that thanks to (3.16) a straightforward computation gives

$$\mathcal{R}^{(s-1)}_{(s)}(z,\bar{z}) = \partial \ln\det\varpi(z,\bar{z}). \tag{3.23}$$

The preferred solution $f^{(1)}$ which crucially takes place in the computation of the $\mathcal{R}$'s plays a distinguished role in the construction as it has already been seen. In particular it infers a linear relationship for $f^{(1)}$ with $j=s-1$ in Eq. (3.20)

$$\mathcal{R}^{(s-1)}_{(s)}(z,\bar{z}) = -s\,\partial\,\ln f^{(1)}(z,\bar{z}), \tag{3.24}$$

which yields, on the one hand, together with (3.23)

$$f^{(1)}(z,\bar{z}) = (\det \varpi(z,\bar{z}))^{-1/s}, \tag{3.25}$$

and on the other hand,

$$= \Rightarrow \partial f^{(1)} = \mathcal{Q}_{(1)} f^{(1)}, \quad \text{where } \mathcal{Q}_{(1)} = -\tfrac{1}{s}\mathcal{R}^{(s-1)}_{(s)} \tag{3.26}$$

and by successive z derivatives one gets a recursive formula

$$\partial_{(n)} f^{(1)}(z,\bar{z}) = \mathcal{Q}_{(n)}(z,\bar{z}) f^{(1)}(z,\bar{z}) \quad \text{with } \mathcal{Q}_{(n)} = \partial \mathcal{Q}_{(n-1)} + \mathcal{Q}_{(n-1)}\mathcal{Q}_{(1)} \quad \text{and } \mathcal{Q}_{(0)} = 1, \tag{3.27}$$

so that $\mathcal{Q}_{(n)}$ turns to be a differential polynomial in $\mathcal{Q}_{(1)}$ (i.e., in $\mathcal{R}^{(s-1)}_{(s)}$), namely $\mathcal{Q}_{(n)} = (\partial + \mathcal{Q}_{(1)})^{n-1}\mathcal{Q}_{(1)}$. Using (3.27) into (3.20) and eliminating $f^{(1)}$ allows one to write a linear system in a Gauss form with respect to the a's coefficients

$$\mathcal{R}^{(j)}_{(s)} + \binom{s}{j}\mathcal{Q}_{(s-j)} + \sum_{l=j}^{s-1}\binom{\ell}{j} a^{(s)}_{(s-\ell)}\mathcal{Q}_{(\ell-j)} = 0 \quad \text{for } j = 0, \ldots, s-1, \tag{3.28}$$

which expresses the relationship between the $a^{(s)}$'s and the $\mathcal{R}_{(s)}$'s. This step is independent of $f^{(1)}$ provided that the $\mathcal{R}_{(s)}$'s are given (together with some compatibility conditions) and we will consider from now on and throughout all the paper that the degrees of freedom will be the $\mathcal{R}_{(s)}$'s. Hence, solving iteratively the system (3.28) with respect to the $a^{(s)}$'s one gets

$$\begin{aligned}
&a^{(s)}_{(1)} = 0 && \text{for } j = s-1,\\
&a^{(s)}_{(2)} = -\mathcal{R}^{(s-2)}_{(s)} - \binom{s}{s-2}\mathcal{Q}_{(2)} && \text{for } j = s-2,\\
&a^{(s)}_{(3)} = -\mathcal{R}^{(s-3)}_{(s)} - \binom{s}{s-3}\mathcal{Q}_{(3)} - \binom{s-2}{s-3}a^{(s)}_{(2)}\mathcal{Q}_{(1)} && \text{for } j = s-3,\\
&\quad\vdots && \text{and so on up to } j = 0.
\end{aligned} \tag{3.29}$$

This shows that to a given a DOR (3.16) there corresponds a holomorphically covariant differential equation of the type (3.1) whose smooth coefficients are expressed as differential polynomials in the structure function $\mathcal{R}^{(s-1)}_{(s)}$ and linearly with respect to the others.

Moreover one has the following property which is exactly the compatibility condition (2.13).

Properties 1: *For* $p = 1, \ldots, s-1$ *and* $n \geqslant s$,

$$\mathcal{R}^{(p)}_{(m+n)}(z,\bar{z}) = \sum_{j=0}^{m}\binom{m}{j}\sum_{\ell=1}^{s-1}\partial_{(j)}\mathcal{R}^{(\ell)}_{(n)}(z,\bar{z})\mathcal{R}^{(p)}_{(m+\ell-j)}(z,\bar{z}), \tag{3.30}$$

where $1 \leqslant l \leqslant s-1$; *so, recursively all the* $\mathcal{R}^{(l)}_{(s+m)}(z,\bar{z})$ $m > 0$ *coefficients can be derived from the basic* $\mathcal{R}^{(l)}_{(s)}(z,\bar{z})$ *ones*.

In particular, for the case $m = 1$, one has

$$\mathcal{R}^{(p)}_{(n+1)}(z,\bar{z}) = \partial\mathcal{R}^{(p)}_{(n)}(z,\bar{z}) + \sum_{\ell=1}^{s-1}\mathcal{R}^{(\ell)}_{(n)}(z,\bar{z})\mathcal{R}^{(p)}_{(\ell+1)}(z,\bar{z}), \tag{3.31}$$

an equation which will be useful for future applications.

The basic $\mathcal{R}^{(l)}_{(s)}$'s, namely the structure functions given in the introductory section, play a central role and it would be worthwhile to have some hints about their geometric nature. In order to be closer as possible to a differential geometric setting for our approach, let us proceed as follows. For the z-jet of a fixed order, one has the following holomorphic gluing rules under the change $z \mapsto w = w(z)$:

$$\partial_z^{k+1} Z(z,\bar{z}) = \begin{cases} w'(z)\partial_w Z(w,\bar{w}) & \text{if } k=0 \\ w^{(k+1)}(z)\partial_w Z(w,\bar{w}) + \sum_{\ell=1}^{k} \partial_w^{\ell+1} Z(w,\bar{w})(z) & \\ \quad \times \sum_{r=\ell}^{k} \frac{k!}{(k-r)!} w^{(k-r+1)}(z) \left(\sum_{\substack{a_1+\cdots+ra_r=r \\ a_1+\cdots+a_r=\ell}} \left(\prod_{n=1}^{r} \frac{1}{a_n!} \left(\frac{w^{(n)}(z)}{n!} \right)^{a_n} \right) \right) & \text{if } k \geqslant 1, \end{cases} \tag{3.32}$$

where the last expression comes from the use of the Faà di Bruno formula for higher order chain rule of derivatives. For further calculations, one has more explicitly and under a more elegant form, for $k \geqslant 3$

$$\begin{aligned} (\partial_{(k+1)} Z)(z,\bar{z}) = (w')^{k+1} (\partial_{(k+1)} Z)(w,\bar{w}) &+ \binom{k+1}{2} (w')^k \partial_z \ln w' (\partial_{(k)} Z)(w,\bar{w}) \\ &+ \binom{k+1}{3} (w')^{k-1} \left(\{w,z\} + \tfrac{3}{4} k (\partial_z \ln w')^2 \right) (\partial_{(k-1)} Z)(w,\bar{w}) \\ &+ \binom{k+1}{4} (w')^{k-2} \Big(\partial_z \{w,z\} + 2(k-1)\{w,z\} \partial_z \ln w' \\ &+ \binom{k}{2} (\partial_z \ln w')^3 \Big) (\partial_{(k-2)} Z)(w,\bar{w}) + \text{lower order derivatives}, \end{aligned} \tag{3.33}$$

where $\{w,z\} = \partial_z^2 \ln w' - \frac{1}{2}(\partial_z \ln w')^2 = w'''/w' - \frac{3}{2}(w''/w')^2$ denotes the Schwarzian derivative.

Now for fixed s, one can obtain the geometric properties of the $s-1$ structure functions $\mathcal{R}$'s by solving the linear system (3.16) with respect to the $\mathcal{R}$'s by Cramer method, one gets the following Lie form associated to the PDEs (3.16) (see, e.g., Ref. 26) for $m=1,\ldots,s-1$,

$$\Phi^{(m)}(\vec{Z}_s) := (-1)^{s-1-m} \frac{\det(\partial\vec{Z}, \partial_{(2)}\vec{Z}, \ldots, \widehat{\partial_{(m)}\vec{Z}}, \ldots, \partial_{(s-1)}\vec{Z}, \partial_{(s)}\vec{Z})}{\det \varpi} = \mathcal{R}_{(s)}^{(m)}(z,\bar{z}), \tag{3.34}$$

where the caret (^) means omission. This expression can simply be rewritten as

$$\mathcal{R}_{(s)}^{(m)} = \partial_{(s)} Z^{(R)} [\varpi^{-1}]_{(R)}^{(m)}. \tag{3.35}$$

For $s=2$, one has the obvious relations $\mathcal{R}_{(m)}^{(1)} = \partial_{(m)} Z / \partial_{(1)} Z$. According to an approach advocated by Vessiot to the Picard-Vessiot theory (Ref. 26, and references therein) one can construct, regarding the present case and by a repeated use of (3.33), a natural holomorphic bundle with a $(s-1)$-dimensional fiber with fiber coordinates $(u^{(1)},\ldots,u^{(s-1)})$. It is defined by the following holomorphic transition functions induced by the holomorphic change of chart $w=\varphi(z)$ on Σ

$$w = \varphi(z),$$

$$U^{(s-1)} = \frac{1}{w'} \left(u^{(s-1)} - \binom{s}{2} \partial \ln w' \right) \text{ affine bundle } !,$$

$$U^{(s-2)} = \frac{1}{w'^2} \left(u^{(s-2)} + \binom{s-1}{2} u^{(s-1)} \partial \ln w' - \binom{s}{3} \left(\{w,z\} + \tfrac{3}{4} \binom{s-1}{1} (\partial \ln w')^2 \right) \right),$$

$$U^{(s-3)}=\frac{1}{w'^3}\left(u^{(s-3)}+\binom{s-2}{2}u^{(s-2)}\,\partial\,\ln w'+u^{(s-1)}\binom{s-1}{3}\left(\{w,z\}+\tfrac{3}{4}\binom{s-2}{1}(\partial\ln w')^2\right)-\binom{s}{4}\right.$$
$$\left.\times\left(\partial\{w,z\}+2\binom{s-2}{1}\{w,z\}\,\partial\,\ln w'+\binom{s-1}{2}(\partial\ln w')^3\right)\right),$$

$$\vdots$$

$$U^{(1)}=\text{a very intricate expression depending on all the } u^{(i)\prime}\text{s}, \tag{3.36}$$

where the transition laws become more and more involved. This bundle can be recast into a holomorphic natural bundle of geometric objects (but however with smooth sections $\mathcal{R}$ in accordance with locality) as fibered product over the Riemann surface Σ,

$$\mathcal{F}_{\text{affine}}\times_{\Sigma}\mathcal{F},$$

where $\mathcal{F}_{\text{affine}}$ is the affine bundle and $\mathcal{F}$ is the bundle with very intricate remaining but important patching rules for the sequel. Having at our disposal some of the main gluing rules of the fundamental $\mathcal{R}$'s, it is possible to obtain the geometrical nature of some of the coefficients of (3.1). Indeed, in terms of the Wronskian $\mathcal{R}^{(s-1)}_{(s)}=\partial\ln\det\varpi$, one finds for the coefficient

$$a^{(s)}_{(2)}=\tfrac{s-1}{2}\left(\partial\mathcal{R}^{(s-1)}_{(s)}-\tfrac{1}{s}(\mathcal{R}^{(s-1)}_{(s)})^2\right)-\mathcal{R}^{(s-2)}_{(s)}, \tag{3.37}$$

while both $\mathcal{R}^{(s-1)}_{(s)}$ and $\mathcal{R}^{(s-2)}_{(s)}$ glue as smooth sections of the bundle defined by (3.36). After a direct computation

$$a^{(s)}_{(2)}(z,\bar{z})=(w')^2a^{(s)}_{(2)}(w,\bar{w})+\tfrac{s(s^2-1)}{12}\left(\partial^2\ln w'-\tfrac{1}{2}(\partial\ln w')^2\right), \tag{3.38}$$

which shows that $a^{(s)}_{(2)}$ is proportional to a projective connection as is well known, since the inhomogeneous term in the gluing rule is nothing but the Schwarzian derivative $\{w,z\}=\partial^2\ln w'-\frac{1}{2}(\partial\ln w')^2$. The projective connection is constructed over the frame $\vec{Z}$ according to (3.37).

Remark 3.1: *For the case* $s=3$, *one has* $\mathcal{R}^{(2)}_{(3)}=\partial\ln\det\varpi$, *and* $\mathcal{R}^{(1)}_{(3)}=\det(\partial^3\vec{Z},\partial^2\vec{Z})/\det\varpi$. *With* $\mathcal{Q}_{(1)}=\frac{-1}{3}\mathcal{R}^{(2)}_{(3)}$, *one readily gets*

$$a^{(3)}_{(2)}=-\mathcal{R}^{(1)}_{(3)}-3\mathcal{Q}_{(2)}=-\mathcal{R}^{(1)}_{(3)}-3(\partial\mathcal{Q}_{(1)}+(\mathcal{Q}_{(1)})^2),$$
$$a^{(3)}_{(3)}=\mathcal{R}^{(1)}_{(3)}\mathcal{Q}_{(1)}+2(\mathcal{Q}_{(1)})^3-\partial^2\mathcal{Q}_{(1)}=\tfrac{1}{3}\left(\partial a^{(3)}_{(2)}+\partial\mathcal{R}^{(1)}_{(3)}+\tfrac{2}{3}\mathcal{R}^{(2)}_{(3)}a^{(3)}_{(2)}-\tfrac{1}{3}\mathcal{R}^{(1)}_{(3)}\mathcal{R}^{(2)}_{(3)}\right), \tag{3.39}$$

which are exactly those coefficients obtained for the so-called $\mathcal{W}_3$*-algebra.*[14,27] *The last expression is given in terms of the projective connection and the structure functions only.*

Remark 3.2: *The factorization property of the differential operator* L_s *of order* s *in terms of first-order differential operators with nowhere vanishing coefficients can be obtained if and only if* L_s *is a nonoscillating operator, see Ref.* 20 *for some details. For more concreteness, let us illustrate this factorization property for* $s=2,3$.

1. *The* $s=2$ *case. Take* $f^{(1)}=(\partial Z)^{-1/2}=:\lambda^{-1/2}$ *as a nowhere vanishing particular solution of* $L_2f=0$. *One can write*

$$L_2=\partial^2+a^{(2)}_{(2)}=(\partial-b)(\partial+b)\quad \textit{with } a^{(2)}_{(2)}=\partial b-b^2,\quad \textit{and } b=-\partial\ln f^{(1)}=:-\mathcal{Q}_{(1)}. \tag{3.40}$$

One finds the expected factorization

$$L_2=\left(\partial-\tfrac{1}{2}\,\partial\,\ln\,\partial\lambda\right)\left(\partial+\tfrac{1}{2}\,\partial\,\ln\,\partial\lambda\right),\quad \textit{and } a^{(2)}_{(2)}=\tfrac{1}{2}\partial^2\ln\,\partial\lambda-\tfrac{1}{4}(\partial\ln\,\partial\lambda)^2. \tag{3.41}$$

2. *The* $s=3$ *case amounts to writing*

$$L_3 = (\partial - b_1 - b_2)(\partial + b_2)(\partial + b_1) \tag{3.42}$$

with $b_1 = -\partial \ln f^{(1)} = -\mathcal{Q}_{(1)}$ *and a possible choice for* b_2 *is given by* $b_2 = b_1 - \partial \ln \partial Z^{(1)}$*—it could be possible to choose* $b_2 = b_1 - \partial \ln \partial Z^{(2)}$ *since* b_1 *never vanishes. Then substituting into*

$$a^{(3)}_{(2)} = \partial(b_1 + b_2) - (b_1 + b_2)^2 + \partial b_1 + b_1 b_2,$$

$$a^{(3)}_{(3)} = \partial^2 b_1 + \partial(b_1 b_2) - (b_1 + b_2)(\partial b_1 + b_1 b_2),$$

one exactly recovers the above-given expressions in (3.39) *for the coefficients of* L_3.

Still with a fixed given order s, it is possible to construct a connection-like object. With the Dolbeault decomposition of the de Rham differential $d = \boldsymbol{\partial} + \bar{\boldsymbol{\partial}} z$ let us define the flat connection (pure gauge)

$$\mathcal{J} = \mathrm{d}\varpi\, \varpi^{-1} = \boldsymbol{\partial}\varpi\varpi^{-1} + \bar{\boldsymbol{\partial}}\varpi\varpi^{-1} = \mathrm{d}z\mathcal{J}_z + \mathrm{d}\bar{z}\mathcal{J}_{\bar{z}}. \tag{3.43}$$

Obviously its curvature vanishes

$$\mathcal{F} = \mathrm{d}\mathcal{J} - \mathcal{J}^2 = 0 \Rightarrow \bar{\partial}_{\bar{z}}\mathcal{J}_z - \partial_z \mathcal{J}_{\bar{z}} + [\mathcal{J}_z, \mathcal{J}_{\bar{z}}] = 0. \tag{3.44}$$

The $(1,0)$-component of the $(s-1)\times(s-1)$-matrix connection of $\mathcal{J}$ is by construction

$$\mathcal{J}^{(n)}_{(z)_{(m)}}(z,\bar{z}) \equiv \sum_{R=1}^{s-1} \partial\, \varpi^{(R)}_{(m)}(z,\bar{z})[\varpi^{-1}]^{(n)}_{(R)}(z,\bar{z}) = \mathcal{R}^{(n)}_{(m+1)}(z,\bar{z}), \quad m,n = 1,\ldots,s-1 \tag{3.45}$$

or more explicitly in matrix form

$$\mathcal{J}_{(z)}(z,\bar{z}) = \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & \\ 0 & 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \\ \mathcal{R}^{(1)}_{(s)}(z,\bar{z}) & \mathcal{R}^{(2)}_{(s)}(z,\bar{z}) & \cdots & \cdots & \cdots & \mathcal{R}^{(s-1)}_{(s)}(z,\bar{z}) \end{pmatrix}. \tag{3.46}$$

This matrix turns out to be of Frobenius type (similar to the matrix (3.4)) and therefore $\mathcal{J}_z$ is not a Lie algebra-valued covariant component of an usual connection. Note that the form of the matrix is close to the Drinfeld-Sokolov one,[4] but differs by the nonvanishing term $\mathcal{R}^{(s-1)}_{(s)}$. Furthermore, it is useful to notice that

$$\mathcal{R}^{(s-1)}_{(s)}(z,\bar{z}) = \mathrm{Tr}\mathcal{J}_{(z)}(z,\bar{z}) = \mathrm{Tr}(\partial\varpi(z,\bar{z})\varpi^{-1}(z,\bar{z})), \tag{3.47}$$

in accordance with (3.23).

IV. BRS APPROACH

In this section, the heuristic presentation of the truncation procedure and its consequences on the formulation of the algebra of Ward operators given in Sec. II is translated into the BRS language. As is well known, this allows are to reformulate in more algebraic terms the presentation of a symmetry, and in particular, will give a more universal character of the possible variations on truncated Taylor expansions of the scalar fields Z.

Having still in mind that we are at a fixed given order s for the truncation (2.8) or (3.16), and by recalling Theorem 3.1, we can turn the $s-1$ local parameters $\Gamma^{(\ell)}$ to Faddeev-Popov ($\Phi\Pi$) ghosts $\mathcal{K}^{(l)}$. The variation (2.16) can be recast in a BRS algebraic language as

$$\delta_{\mathcal{W}_s} Z^{(R)}(z,\bar{z}|s) = \sum_{\ell=1}^{s-1} \mathcal{K}^{(\ell)}(z,\bar{z}|s)\partial_{(\ell)} Z^{(R)}(z,\bar{z}|s), \quad 1 \leqslant R \leqslant s-1, \tag{4.1}$$

where the variation is given by a summand over the independent derivatives up to order $s-1$ due to the DOR of order s. The ghost fields $\mathcal{K}^{(l)}$, of which number is restricted to the range $\ell = 1, \ldots, s-1$, serve to define the $\mathcal{W}_s$-algebra relative to the truncation at the level s. We emphasize that the operation $\delta_{\mathcal{W}_s}$ which is required to be nilpotent, depends on the level s of truncation. Accordingly, the ghost parameters $\mathcal{K}^{(l)}$ depend on the truncation process by their number, see (4.1), and generate a $\mathcal{W}$-algebra once the level is fixed. By an argument based on the nilpotency, for $l = 1, \ldots, s-1$,

$$\begin{aligned}\delta_{\mathcal{W}_s} \mathcal{K}^{(l)}(z,\bar{z}|s) =: \sum_{m=1}^{s-1} \mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{B}^{(l)}_{(m)}(z,\bar{z}|s) \\ = \sum_{m,n=1}^{s-1} \mathcal{K}^{(m)}(z,\bar{z}|s) \sum_{j=1}^{m} \binom{m}{j} \partial_{(j)}\mathcal{K}^{(n)}(z,\bar{z}|s)\mathcal{R}^{(l)}_{(n+m-j)}(z,\bar{z}|s),\end{aligned} \tag{4.2}$$

where on the right-hand side the dependence on the level s of truncation has been explicitly written. Note also that the products of two underived ghosts drop out by $\Phi\Pi$ charge argument. This variation defines a $(s-1)\times(s-1)$-matrix $\mathcal{B}$ carrying ghost number one, and thus depending on the level s of truncation through the structure functions $\mathcal{R}$ pertaining to that level s. In more detail,

$$\mathcal{B}^{(l)}_{(m)}(z,\bar{z}|s) := \sum_{n=1}^{s-1} \sum_{j=0}^{m} \binom{m}{j} \partial_{(m-j)}\mathcal{K}^{(n)}(z,\bar{z}|s)\mathcal{R}^{(l)}_{(n+j)}(z,\bar{z}|s), \tag{4.3}$$

a remarkable combination over the ghosts $\mathcal{K}^{(\ell)}$, $\ell = 1, \ldots, s-1$ which could have been readily read from the variation (2.15). For the Wronskian (3.21) the $\mathcal{W}_s$-algebra extended to

$$\delta_{\mathcal{W}_s} \varpi^{(R)}_{(\ell)}(z,\bar{z}|s) = \sum_{n=1}^{s-1} \mathcal{B}^{(n)}_{(\ell)}(z,\bar{z}|s)\varpi^{(R)}_{(n)}(z,\bar{z}|s), \quad \ell, R = 1, \ldots, s-1 \tag{4.4}$$

where the matrix product is understood for $(s-1)\times(s-1)$-matrices. One also has

$$\delta_{\mathcal{W}_s} \varpi^{-1} = -\varpi^{-1}\mathcal{B}, \tag{4.5}$$

and accordingly, using $\delta_{\mathcal{W}}\mathrm{d} + \mathrm{d}\delta_{\mathcal{W}} = 0$,

$$\delta_{\mathcal{W}_s} \mathcal{J} = -\mathrm{d}\mathcal{B} + [\mathcal{B}, \mathcal{J}], \tag{4.6}$$

where the bracket is graded on forms with $(s-1)\times(s-1)$-matrix values. The nilpotency property provides first,

$$\delta_{\mathcal{W}_s} \mathcal{B}(z,\bar{z}|s) = \mathcal{B}(z,\bar{z}|s)\mathcal{B}(z,\bar{z}|s) = \mathcal{B}^2(z,\bar{z}|s) \tag{4.7}$$

and second, by $\Phi\Pi$ argument

$$\delta_{\mathcal{W}_s} \mathrm{Tr}(\mathcal{B}(z,\bar{z}|s)^{(2n+1)}) = 0, \quad n = 0, 1, \ldots, \tag{4.8}$$

where Tr is the usual trace on matrices. The BRS variation of all the structure functions $\mathcal{R}^{(p)}_{(n)}(z,\bar{z}|s)$ ($p = 1, \ldots, s-1$ and even for $n \geqslant s$) can be directly found from the variation (2.15) to write

$$\delta_{\mathcal{W}_s}\mathcal{R}^{(p)}_{(n)}(z,\bar{z}|s)=\mathcal{B}^{(p)}_{(n)}(z,\bar{z}|s)-\sum_{q=1}^{s-1}\mathcal{R}^{(q)}_{(n)}(z,\bar{z}|s)\mathcal{B}^{(p)}_{(q)}(z,\bar{z}|s), \tag{4.9}$$

where $\mathcal{B}$ defined earlier, in (4.3) may be extended to a rectangular matrix for lower indices greater than $s-1$, while the upper ones are still lower than this value imposed by the level of truncation, since all the $\mathcal{R}$'s can be gathered into a rectangular matrix. One checks that it is compatible with the case $\mathcal{R}^{(k)}_{(\ell)}=\delta^k_\ell$, which is kept invariant. We stress that while the first $\mathcal{B}$ term of the right-hand side of the variation (4.9) is a rectangular matrix, the $\mathcal{B}$ under the summand is a squared one. As noted before the matrix $\varpi^R_{(m)}$ can be taken to be a rectangular as well, when $m\geqslant s$, and the variation (4.4) relative to the algebra $\mathcal{W}_s$ is accordingly modified by

$$\delta_{\mathcal{W}_s}\varpi^{(R)}_{(m)}(z,\bar{z}|s)=\sum_{\ell=1}^{s-1}\mathcal{B}^{(\ell)}_{(m)}(z,\bar{z}|s)\varpi^{(R)}_{(\ell)}(z,\bar{z}|s),\quad R=1,\ldots,s-1 \text{ and } m\geqslant 1, \tag{4.10}$$

where the matrix $(\mathcal{B}^{(\ell)}_{(m)})$ can be rectangular. Supported by the fact that the ghosts $\mathcal{K}^{(\ell)}$ are subordinated to the given level of truncation s, one may now define,[28] for $\ell=1,\ldots,s-1$, the ℓth derivatives $\partial_{(\ell)}=\{\partial/\partial\mathcal{K}^{(\ell)},\delta_{\mathcal{W}_s}\}$ as an anticommutator, thus the DOR equation (3.22) is recovered,

$$\partial_{(\ell)}\varpi^{(R)}_{(m)}(z,\bar{z}|s)=\sum_{u=1}^{s-1}\mathcal{R}^{(u)}_{(\ell+m)}(z,\bar{z}|s)\varpi^{(R)}_{(u)}(z,\bar{z}|s),\quad R,\ \ell\ =1,\ldots,s-1,\ \text{and}\ m\geqslant 1. \tag{4.11}$$

This shows that the BRS algebra encapsulates the DOR mechanism just by construction and provides a consistency of the present approach.

Furthermore, from Eq. (4.4) one has

$$\delta_{\mathcal{W}_s}\ln\det\varpi(z,\bar{z}|s)=\mathrm{Tr}\,\mathcal{B}(z,\bar{z}|s), \tag{4.12}$$

which gives for the variation of $\mathcal{R}^{(s-1)}_{(s)}$,

$$\delta_{\mathcal{W}_s}\mathcal{R}^{(s-1)}_{(s)}(z,\bar{z}|s)=\partial\,\mathrm{Tr}\,\mathcal{B}(z,\bar{z}|s)=\mathrm{Tr}\ \partial\mathcal{B}(z,\bar{z}|s).$$

V. COVARIANCE UNDER HOLOMORPHIC REPARAMETRIZATION

The covariance property under holomorphic change of local coordinates on the Riemann surface is analyzed for the so far obtained quantities. As will be shown, this analysis will amount to switching to new ghost fields of a tensorial nature in contrast to that of the $\mathcal{K}$'s.

In view of the patching rules (3.32) under finite holomorphic reparametrizations, it possibly renders more explicit some of the covariance properties of the theory relative to a fixed order s. As will be shown, the study of covariance will appear as a key step in the construction of $\mathcal{W}$-algebras.

Under finite holomorphic change of charts $z\to w(z)$ the covariance property of the $s-1$ scalar fields (emerging from the truncation at level s) writes

$$Z^{(R)}(z,\bar{z}|s)=Z^{(R)}(w,\bar{w}|s),\quad R=1,\ldots,s-1 \tag{5.1}$$

and implies that the Wronskian matrix ϖ behaves as a nontensorial covariant quantity

$$\varpi^{(R)}_{(n)}(w,\bar{w}|s)=\sum_{m=1}^{s-1}\Phi^{(m)}_{(n)}(z)\varpi^{(R)}_{(m)}(z,\bar{z}|s), \tag{5.2}$$

and while for its inverse

$$[\varpi^{-1}]^{(n)}_{(R)}(w,\bar{w}|s)=\sum_{m=1}^{s-1}[\varpi^{-1}]^{(m)}_{(R)}(z,\bar{z}|s)\Phi^{-1\,(n)}_{(m)}(z), \tag{5.3}$$

where the patching rules are governed by the $(s-1)\times(s-1)$ lower triangular holomorphic matrix $\Phi^{(\ell)}_{(k)}(z)$ for $k,\ell=1,\ldots,s-1$, depending on the Jacobian w' and its derivatives. Its inverse matrix is more easily computable and given by (see (3.32))

$$[\Phi^{-1}]^{(\ell)}_{(k)}(z)=\begin{cases} w^{(k)}(z) & \text{if } \ell=1 \\ \displaystyle\sum_{r=\ell-1}^{k-1}\frac{(k-1)!\,w^{(k-r)}(z)}{(k-r-1)!}\sum_{\substack{a_1+\cdots+ra_r=r\\ a_1+\cdots+a_r=\ell-1}}\left(\prod_{n=1}^{r}\frac{1}{a_n!}\left(\frac{w^{(n)}(z)}{n!}\right)^{a_n}\right), & k\geqslant\ell\geqslant 2 \\ 0, & k<\ell \end{cases} \tag{5.4}$$

with nonvanishing determinant, $\det\Phi^{-1}(z)=(w'(z))^{s(s-1)/2}$, since the diagonal entries are given by $[\Phi^{-1}]^{(\ell)}_{(\ell)}(z)=(w'(z))^{\ell}$. Note also that the order of the matrix $\Phi^{(\ell)}_{(k)}(z)$ (or that of its inverse as well) is subject to the order s of truncation. Accordingly, since the variation (4.1) relative to the order s has to behave as a scalar, the $s-1$ ghosts of the level s of truncation turn out to be contravariant quantities

$$\mathcal{K}^{(l)}(w,\bar{w}|s)=\mathcal{K}^{(m)}(z,\bar{z}|s)[\Phi^{-1}]^{(l)}_{(m)}(z). \tag{5.5}$$

Taking into account (5.4), the ghosts $\mathcal{K}^{(m)}(z,\bar{z})$ behave as jets, except for the top one of order $s-1$ which turns out to be a contravariant tensor of order $s-1$. For the sake of completeness, the behaviors of the rectangular matrices $\mathcal{B}^{(l)}_{(p)}(z,\bar{z}|s)$ and $\mathcal{R}^{(l)}_{(p)}(z,\bar{z}|s)$, respectively, come from (5.2), (4.4), and (3.16) or (4.9). They are respectively found to be

$$\mathcal{B}(w,\bar{w}|s)=\Phi(z)\mathcal{B}(z,\bar{z}|s)\Phi^{-1}(z), \tag{5.6}$$

and for $\ell\leqslant s-1$,

$$\mathcal{R}^{(\ell)}_{(k)}(w,\bar{w}|s)=\sum_{m=1}^{k}\sum_{p=\ell}^{s-1}\Phi^{(m)}_{(k)}(z)\mathcal{R}^{(p)}_{(m)}(z,\bar{z}|s)[\Phi^{-1}]^{(\ell)}_{(p)}(z). \tag{5.7}$$

Thanks to the their definition (2.12), one obtains the following identities for $k\leqslant s-1$:

$$[\Phi^{-1}]^{(k)}_{(k)}(z)\Phi^{(k)}_{(k)}(z)=1 \quad \text{(no summation)}, \quad \sum_{u=\ell}^{k}[\Phi^{-1}]^{(u)}_{(k)}(z)\Phi^{(\ell)}_{(u)}(z)=0 \quad \text{if } \ell<k\leqslant s-1. \tag{5.8}$$

VI. JETS VERSUS TENSORS, OR HOW TO RECOVER $\mathcal{W}$-ALGEBRAS

The algebra of transformations (4.1) and (4.2) are written in terms of ghosts which under holomorphic change of charts (see Eq. (5.5)) behave as jets, and thus do not carry any tensorial nature.

We want to show that these transformations encode a structure of $\mathcal{W}_s$-algebra if the DOR mechanism is provided by a truncation at the sth level. The latter may be implemented by means of a given differential equation (3.1) which serves to generate what it is called in the paper, the Forsyth frames. Since objects of jet nature are heavy to handle, and that (physical) fields are usually considered to be of tensorial nature in some representation space of a symmetry, it is first necessary for the BRS algebra presentation of $\mathcal{W}$-symmetry to switch from the jet-ghosts to tensor ones. This will make some contact with the results on the subject disseminated through the

literature.[1,6,5,8,10] This kind of problem is often encountered in the treatment of a local field theory, and even in the BRST quantization scheme, see, e.g., Refs. 29 and 30. The solution to this problem is obviously not unique since a tensor is defined up to a change of basis among tensors. This is why it must be solved for the moment with the tools at hand.

Let us consider the hypothesis where the $\mathcal{K}$'s are *not* universal, except the top one. Given a level s of truncation, consider the hierarchy of all lower orders of truncation $j+1 \leqslant s$ which come into the game with their own structure functions. At the level s, if $\vec{Z}$ denotes a vector in $\mathbb{C}P^{s-1}$, one has, respectively, for the DOR and the variation

$$\partial_{(s)}\vec{Z}(z,\bar{z}|s) = \sum_{\ell=1}^{s-1} \mathcal{R}^{(\ell)}_{(s)}(z,\bar{z}|s)\partial_{(\ell)}\vec{Z}(z,\bar{z}|s), \quad \delta_{\mathcal{W}_s}\vec{Z}(z,\bar{z}|s) = \sum_{\ell=1}^{s-1} \mathcal{K}^{(\ell)}(z,\bar{z}|s)\partial_{(\ell)}\vec{Z}(z,\bar{z}|s). \tag{6.1}$$

Suppose now that the DOR is rather implemented at the sublevel $s-1$ on the $s-1$ scalar fields, with

$$\partial_{(s-1)}\vec{Z}(z,\bar{z}|s) = \sum_{\ell=1}^{s-2} \mathcal{R}^{(\ell)}_{(s-1)}(z,\bar{z}|s-1)\partial_{(\ell)}\vec{Z}(z,\bar{z}|s), \tag{6.2}$$

then the above-mentioned variation can be projected onto that of the level $s-1$,

$$\begin{aligned}\delta_{\mathcal{W}_s}\vec{Z}(z,\bar{z}|s) &= \sum_{\ell=1}^{s-2} (\mathcal{K}^{(\ell)}(z,\bar{z}|s) + \mathcal{K}^{(s-1)}(z,\bar{z}|s)\mathcal{R}^{(\ell)}_{(s-1)}(z,\bar{z}|s-1))\partial_{(\ell)}\vec{Z}(z,\bar{z}|s) \stackrel{!}{=} \delta_{\mathcal{W}_{s-1}}\vec{Z}(z,\bar{z}|s) \\ &= \sum_{\ell=1}^{s-2} \mathcal{K}^{(\ell)}(z,\bar{z}|s-1)\partial_{(\ell)}\vec{Z}(z,\bar{z}|s).\end{aligned} \tag{6.3}$$

Upon requiring that $\delta_{\mathcal{W}_s}\vec{Z}(z,\bar{z}|s) = \delta_{\mathcal{W}_{s-1}}\vec{Z}(z,\bar{z}|s)$, one can identify the top tensorial ghost of the level $s-1$ in terms of those of the upper level s through the structure functions of the level $s-1$, by

$$\mathcal{K}^{(s-2)}(z,\bar{z}|s-1) = \mathcal{K}^{(s-2)}(z,\bar{z}|s) + \mathcal{K}^{(s-1)}(z,\bar{z}|s)\mathcal{R}^{(s-2)}_{(s-1)}(z,\bar{z}|s-1). \tag{6.4}$$

Repeating the DOR from the level s to an arbitrary sublevel j, with $2 \leqslant j \leqslant s-1$, the requirement that $\delta_{\mathcal{W}_s}\vec{Z}(z,\bar{z}|s) = \delta_{\mathcal{W}_j}\vec{Z}(z,\bar{z}|s)$ yields for each top tensorial ghost

$$\mathcal{K}^{(j-1)}(z,\bar{z}|j) = \mathcal{K}^{(j-1)}(z,\bar{z}|s) + \sum_{m=j}^{s-1} \mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{R}^{(j-1)}_{(m)}(z,\bar{z}|j) = \sum_{m=j-1}^{s-1} \mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{R}^{(j-1)}_{(m)}(z,\bar{z}|j). \tag{6.5}$$

Next, taking the ghost of highest conformal weight in each of the subalgebras, one generates a hierarchy of j-contravariant conformal tensors as

$$\mathcal{C}^{(j)}(z,\bar{z}) := \mathcal{K}^{(j)}(z,\bar{z}|j+1). \tag{6.6}$$

All the above-noted considerations suggest to take as an ansatz for the j-contravariant ghost conformal tensors the following pretty tricky linear combination:

$$\mathcal{C}^{(j)}(z,\bar{z}) = \sum_{m=j}^{s-1} \mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{R}^{(j)}_{(m)}(z,\bar{z}|j+1) \quad \text{for } 1 \leqslant j \leqslant s-1, \tag{6.7}$$

where the lower orders of truncation (implemented by the $\mathrm{DOR}_{s-1\to j}$) crucially enter the construction. Due to the requirement that $\delta_{\mathcal{W}}\vec{Z}(z,\bar{z}|s) = \delta_{\mathcal{W}_k}\vec{Z}(z,\bar{z}|s)$, for $k=2,\ldots,s$, it is worthwhile to emphasize that the tensorial ghosts $\mathcal{C}^{(j)}$ carry an universal nature (regarding all the hierarchy of

$\mathcal{W}_j$-algebras), in the sense that for $j=1,\ldots,k-1$, $k\geqslant j+1$ one has the identity

$$\mathcal{C}^{(j)}(z,\bar{z})=\sum_{m=j}^{s-1}\mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{R}^{(j)}_{(m)}(z,\bar{z}|j+1)=\sum_{m=j}^{k-1}\mathcal{K}^{(m)}(z,\bar{z}|k)\mathcal{R}^{(j)}_{(m)}(z,\bar{z}|j+1). \tag{6.8}$$

The latter (which generalizes (6.7)) shows that the $\mathcal{C}^{(j)}$'s do not depend on the level k of truncation for $k\geqslant j$. This strongly suggests that the tensorial ghosts $\mathcal{C}^{(j)}$'s are of universal nature. Moreover, one gets for the $\mathrm{DOR}_{s-1\to k-1}$ and with $\ell=1,\ldots,k-1$,

$$\mathcal{K}^{(\ell)}(z,\bar{z}|k)=\mathcal{K}^{(\ell)}(z,\bar{z}|s)+\sum_{m=k}^{s-1}\mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{R}^{(\ell)}_{(m)}(z,\bar{z}|k)=\sum_{m=1}^{s-1}\mathcal{K}^{(m)}(z,\bar{z}|s)\mathcal{R}^{(\ell)}_{(m)}(z,\bar{z}|k). \tag{6.9}$$

Next, by comparing in order to guarantee the transitivity property, $\mathrm{DOR}_{s-1\to j}$ with $\mathrm{DOR}_{s-1\to k-1}$ followed by $\mathrm{DOR}_{k-1\to j}$, the structure functions must verify for any $m\geqslant k$ with $j+1\leqslant k\leqslant s-1$,

$$\mathcal{R}^{(j)}_{(m)}(z,\bar{z}|j+1)=\sum_{\ell=j}^{k-1}\mathcal{R}^{(\ell)}_{(m)}(z,\bar{z}|k)\mathcal{R}^{(j)}_{(\ell)}(z,\bar{z}|j+1), \tag{6.10}$$

an identity which has to be checked with the help of (3.34) and both the choices of j and of $k-1$ coordinates among the $s-1$ coordinates given by $\vec{Z}\in\mathbb{C}P^{s-1}$ (identity between determinants). These two choices of subcoordinates define submanifolds in $\mathbb{C}P^{s-1}$. This phenomenon is the signature of the presence of flag manifolds denoted by $F_{j\cdots s-2}\mathbb{C}^{s-1}$ over $\mathbb{C}P^{s-1}$, a geometric concept already mentioned as related to $\mathcal{W}$-algebras in Ref. 5. In particular the choice $j=1$ and $k=s$ in (6.10) corresponds to the whole hierarchy (6.7) of the $\mathcal{C}$ ghosts and is associated to the flag manifold $F_{12\cdots s-2}\mathbb{C}^{s-1}$.

Owing to the above considerations, let us define now, for a fixed level s, the following nilpotent operator $\delta_{\mathcal{W}_s}=\overset{s-1}{\underset{\ell=2}{\oplus}}\delta_{\mathcal{W}_\ell}$, with $\delta^2_{\mathcal{W}_\ell}=0$ and $\{\delta_{\mathcal{W}_k},\delta_{\mathcal{W}_\ell}\}=0$, which is in some sense filtrated by the various sub-DORs relative to the flag submanifold $F_{12\cdots s-2}\mathbb{C}^{s-1}$. Then the task is to figure out the variations $\delta_{\mathcal{W}_s}\mathcal{C}^{(j)}$ for $j=1,\ldots,s-1$ in terms of the tensorial $\mathcal{C}$'s themselves.

Note that the tensorial ansatz (6.7) gives an universal character to each of the tensorial top ghosts $C^{(\ell-1)}(z,\bar{z})\coloneqq\mathcal{K}^{(\ell-1)}(z,\bar{z}|\,\ell)$ of each sublevels. By virtue of (6.9), the latter linearly depend on both the jet ghosts $\mathcal{K}(z,\bar{z}|\,\ell)$'s of the top order s of truncation and the structure functions relative to the various truncations up to order $s-1$.

In the course of checking that the $\mathcal{C}^{(j)}$'s are indeed j-contravariant conformal tensors, (5.5), (5.7) and the identities (5.8) were repeatedly used. The tensor character of $\mathcal{C}^{(j)}$ is secured by the choice of $\mathcal{R}^{(j)}_{(n)}(z,\bar{z}|j+1)$ with maximum upper index j relative to the truncation of level $j+1$. This is possible if one picks up these objects from the whole underlying DOR decompositions with a truncation mechanism at each level lower than s. So the price to pay is the introduction of all the $\mathcal{R}^{(j)}_{(n)}(z,\bar{z}|j+1)$ coefficients relative to all the (sub-)truncations from $j=1$ to $j=s-1$. The latter could have been implemented by a hierarchy of differential equations of the type (3.1). The ansatz (6.7) is a linear system in a Gauss form which is easily inverted as

$$\begin{gathered}\mathcal{K}^{(\ell)}(z,\bar{z}|s)=\sum_{m=\ell}^{s-1}\mathcal{C}^{(m)}(z,\bar{z})\mathcal{U}^{(\ell)}_{(m)}(z,\bar{z}|\,\ell+1,\ldots,s-1),\quad \ell=1,\ldots,s-2,\\ \mathcal{K}^{(s-1)}(z,\bar{z}|s)=\mathcal{C}^{(s-1)}(z,\bar{z}),\end{gathered} \tag{6.11}$$

where $\mathcal{U}^{(\ell)}_{(m)}(z,\bar{z}|\,\ell+1,\ldots,s-1)$ is the coefficient of the inverse upper triangular matrix which depends polynomially on structure functions pertaining to the sublevels from $\ell+1$ to $s-1$. More explicitly, for $k,\ell=1,\ldots,s-1$,

$$\mathcal{U}^{(\ell)}_{(k)}(z,\bar{z}|\,\ell\,+1,\ldots,s-1)=\begin{cases}1 & \text{if } k=\ell\\ 0 & \text{if } k<\ell\\ \displaystyle\sum_{j=1}^{k-\ell}(-1)^j\left[\prod_{i=1}^{j}\mathcal{R}^{(\ell_i)}_{(k_i)}(z,\bar{z}|\ell_i+1)\right]\Big|_{\substack{\ell_1=\ell,k_j=k\\ k_i>\ell_i\\ k_i=\ell_{i+1}\ \text{for}\ k-\ell\geqslant 2}} & \text{if } k>\ \ell\ .\end{cases} \tag{6.12}$$

The variation of the $\mathcal{C}^{(j)}$'s given by (6.7) is computed upon using the variation (4.2) for the level s and the variation (4.9) for all the sublevels up to $s-1$ owing to the DOR filtrations. It writes

$$\delta_{\mathcal{W}_s}\mathcal{C}^{(j)}(z,\bar{z})=\sum_{\ell=j}^{s-1}\left(\delta_{\mathcal{W}_s}\mathcal{K}^{(\ell)}(z,\bar{z}|s)\mathcal{R}^{(j)}_{(\ell)}(z,\bar{z}|j+1)-\mathcal{K}^{(\ell)}(z,\bar{z}|s)\delta_{\mathcal{W}_{j+1}}\mathcal{R}^{(j)}_{(\ell)}(z,\bar{z}|j+1)\right) \tag{6.13}$$

and after some algebra we get the following variation:

$$\begin{aligned}\delta_{\mathcal{W}_s}\mathcal{C}^{(j)}(z,\bar{z})=&\sum_{n=1}^{s-1}\sum_{a=n}^{s-1}\sum_{b=1}^{s-1}\sum_{r=0}^{n}\mathcal{C}^{(a)}(z,\bar{z})\partial_{(r)}\mathcal{C}^{(b)}(z,\bar{z})\mathcal{U}^{(n)}_{(a)}(z,\bar{z}|a+1,\ldots,s-1)\sum_{\ell=1}^{b}\sum_{k=r}^{n}\binom{k}{r}\binom{n}{k}\\
&\times\partial_{(k-r)}\mathcal{U}^{(\ell)}_{(b)}(z,\bar{z}|b+1,\ldots,s-1)\left(\sum_{p=j}^{s-1}\mathcal{R}^{(p)}_{(n+\ell-k)}(z,\bar{z}|s)\mathcal{R}^{(j)}_{(p)}(z,\bar{z}|j+1)\right)\\
&+\sum_{n=j}^{s-1}\sum_{a=n}^{s-1}\sum_{b=1}^{j}\left[\sum_{u=1}^{j}\sum_{r=0}^{u}\mathcal{C}^{(a)}(z,\bar{z})\partial_{(r)}\mathcal{C}^{(b)}(z,\bar{z})\mathcal{U}^{(n)}_{(a)}(z,\bar{z}|a+1,\ldots,s-1)\sum_{\ell=1}^{b}\sum_{k=r}^{u}\binom{k}{r}\binom{u}{k}\right.\\
&\times\partial_{(k-r)}\mathcal{U}^{(\ell)}_{(b)}(z,\bar{z}|b+1,\ldots,j)\mathcal{R}^{(u)}_{(n)}(z,\bar{z}|j+1)\mathcal{R}^{(j)}_{(u+\ell-k)}(z,\bar{z}|j+1)\\
&-\sum_{r=0}^{n}\mathcal{C}^{(a)}(z,\bar{z})\partial_{(r)}\mathcal{C}^{(b)}(z,\bar{z})\mathcal{U}^{(n)}_{(a)}(z,\bar{z}|a+1,\ldots,s-1)\sum_{\ell=1}^{b}\sum_{k=r}^{n}\binom{k}{r}\\
&\left.\times\partial_{(k-r)}\mathcal{U}^{(\ell)}_{(b)}(z,\bar{z}|b+1,\ldots,j)\mathcal{R}^{(j)}_{(n+\ell-k)}(z,\bar{z}|j+1)\right].\end{aligned} \tag{6.14}$$

Equation (6.14) can be disassembled into

$$\delta_{\mathcal{W}_s}\mathcal{C}^{(j)}(z,\bar{z})\equiv\sum_{n=1}^{j}n\mathcal{C}^{(n)}(z,\bar{z})\,\partial\,\mathcal{C}^{(j-n+1)}(z,\bar{z})+\chi^{(j)}(z,\bar{z}|j+1,\ldots,s), \tag{6.15}$$

where the first summand looks like the variation coming from a symplectic approach[11] to $\mathcal{W}$-algebra.

It is clear that the last term χ is related to the whole symmetry in the sense that it is a tensorial differential expression of ghost grading two in the various structure functions $\mathcal{R}$'s of the sublevel. Due to the nilpotency of the $\delta_{\mathcal{W}_s}$ BRS operation, the $\chi^{(j)}$'s defined in (6.15) do transform according to

$$\begin{aligned}\delta_{\mathcal{W}_s}\chi^{(j)}(z,\bar{z}|j+1,\ldots,s)=&\sum_{n=1}^{j}n(\mathcal{C}^{(n)}(z,\bar{z})\,\partial\,\chi^{(j-n+1)}(z,\bar{z}|j+1,\ldots,s)\\
&-\chi^{(n)}(z,\bar{z}|j+1,\ldots,s)\,\partial\,\mathcal{C}^{(j-n+1)}(z,\bar{z})).\end{aligned} \tag{6.16}$$

The full completion of the last equation (6.16) amounts to introducing (together with their $\mathcal{W}_s$-variations) all sets of primary fields ($\mathcal{W}$-currents) which belong to the tower of all the nested subalgebras according to the DOR filtration and the respective variations for each sublevels. This

provides a general solution for any j, and is, according to our opinion, the most general explicit expression given, up to now, for *any* $\mathcal{W}$-algebra in a BRS setting. Of course, the generic expression (6.14) contains the $\mathcal{R}$ reduction coefficients of *all* the Forsyth subframes. However, the variations given by Eq. (6.14) do not generally coincide with the ones found in the literature: this fact will be illustrated in the next two examples. In order to recover the familiar expressions[12,23] nontrivial redefinitions of the tensorial ghosts involving derivative terms must be performed. The ansatz (6.11) relating the jet ghosts to the tensorial ones is recast into the form:[15]

$$\text{for } \ell = 1, \ldots, s-2, \quad \mathcal{K}^{(\ell)}(z,\bar{z}|s) = \mathcal{C}^{(\ell)}(z,\bar{z}) + \sum_{p=\ell+1}^{s-1} \sum_{r=0}^{p-\ell} \partial_{(r)} \mathcal{C}^{(p)}(z,\bar{z}) \mathcal{T}_{(p)}^{(r,\ell)}(z,\bar{z}|s), \tag{6.17}$$

where derivatives in the tensorial ghosts explicitly enter and where $\mathcal{T}_{(p)}^{(b,m)}(z,\bar{z}|s)$ depends only on the structure functions $\mathcal{R}_{(s)}^{(\ell)}(z,\bar{z}|s)$, $\ell=1,\ldots,s-1$ with $\mathcal{T}_{(p)}^{(r,m)}(z,\bar{z}|s)=0$ for $p<m$ and $\mathcal{T}_{(p)}^{(r,m)}(z,\bar{z}|s)=\delta_{(0)}^{(r)}$ for $p=m$.

In this case, the new $\chi^{(j)}$'s will depend only on the structure functions of the level s. So, we stress, that this is a consequence of the technical difficulties coming from the jets to tensor reduction, and it is not a problem of the $\mathcal{W}$-symmetry itself.

In fact this is deduced by searching the algebraic conditions (in terms of ghosts and their derivatives, considered as independent fields), which put to zero, in all the equations (6.14) all the terms containing the structure functions of the sublevels $\mathcal{R}(z,\bar{z}|j)$, for $j<s$. For s of reasonable order, we find that the number of vanishing conditions allows one to get an unique solution, and numerically provides the $\mathcal{W}$ examples found in the literature.

The present upshot greatly improves some previous work[27,31] in the sense that it is now possible to construct explicitly the χ-term which breaks by truncation the $\mathcal{W}_\infty$-symmetry governed by an underlying symplectomorphism symmetry[11,32] to a finite $\mathcal{W}_s$-algebra.

To distinguish in a clear way a realization of such a $\mathcal{W}_s$-structure, the $\mathcal{W}_3$ and $\mathcal{W}_4$ cases will be next computed in great detail. Then, despite the lack of well-settled examples in the literature for (even if some examples exist[33,34]) $\mathcal{W}_s$ ($s\geqslant 5$), remarkable results in Ref. 10 will allow one to find out a general setting.

A. The $\mathcal{W}_3$ example

According to the general construction, one has with $s=3$ as top level, the two tensorial ghosts

$$\begin{aligned} \mathcal{C}^{(1)}(z,\bar{z}) &= \mathcal{K}^{(1)}(z,\bar{z}|2) = \mathcal{K}^{(1)}(z,\bar{z}|3) + \mathcal{K}^{(2)}(z,\bar{z}|3)\mathcal{R}_{(2)}^{(1)}(z,\bar{z}|2), \\ \mathcal{C}^{(2)}(z,\bar{z}) &= \mathcal{K}^{(2)}(z,\bar{z}|3), \end{aligned} \tag{6.18}$$

and their holomorphically covariant variations according to the DOR filtration read

$$\begin{aligned} \delta_{\mathcal{W}_3}\mathcal{C}^{(2)}(z,\bar{z}) &= \mathcal{C}^{(1)}(z,\bar{z})\,\partial\mathcal{C}^{(2)}(z,\bar{z}) + 2\mathcal{C}^{(2)}(z,\bar{z})\,\partial\mathcal{C}^{(1)}(z,\bar{z}) + \mathcal{C}^{(2)}(z,\bar{z})\partial_{(2)}\mathcal{C}^{(2)}(z,\bar{z}) \\ &\quad + \mathcal{C}^{(2)}(z,\bar{z})\,\partial\mathcal{C}^{(2)}(z,\bar{z})[2\mathcal{R}_{(3)}^{(2)}(z,\bar{z}|3) - 3\mathcal{R}_{(2)}^{(1)}(z,\bar{z}|2)], \end{aligned} \tag{6.19}$$

$$\begin{aligned} \delta_{\mathcal{W}_3}\mathcal{C}^{(1)}(z,\bar{z}) &= \mathcal{C}^{(1)}(z,\bar{z})\,\partial\mathcal{C}^{(1)}(z,\bar{z}) + 2\mathcal{C}^{(2)}(z,\bar{z})\,\partial\mathcal{C}^{(2)}(z,\bar{z})[\mathcal{R}_{(3)}^{(1)}(z,\bar{z}|3) - \partial\mathcal{R}_{(2)}^{(1)}(z,\bar{z}|2) \\ &\quad + \mathcal{R}_{(3)}^{(2)}(z,\bar{z}|3)\mathcal{R}_{(2)}^{(1)}(z,\bar{z}|2) - (\mathcal{R}_{(2)}^{(1)}(z,\bar{z}|2))^2], \end{aligned} \tag{6.20}$$

where in the course of the calculation Eq. (3.31) has been used. Performing the holomorphically covariant change of generators

$$\mathcal{C}^{(1)}(z,\bar{z}) \to \widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) := \mathcal{C}^{(1)}(z,\bar{z}) + \tfrac{1}{2}\,\partial\mathcal{C}^{(2)}(z,\bar{z}) + \mathcal{C}^{(2)}(z,\bar{z})\Big[\tfrac{2}{3}\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3) - \mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)\Big], \tag{6.21}$$

allows one to remove the $\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)$ dependence and (6.11) rewrites

$$\begin{aligned}\mathcal{K}^{(1)}(z,\bar{z}|3) &= \widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) - \tfrac{1}{2}\,\partial\mathcal{C}^{(2)}(z,\bar{z}) - \tfrac{2}{3}\mathcal{C}^{(2)}(z,\bar{z})\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3),\\ \mathcal{K}^{(2)}(z,\bar{z}|3) &= \mathcal{C}^{(2)}(z,\bar{z}),\end{aligned} \tag{6.22}$$

and depends only on the level $s=3$. Next, we get the well-known transformations[12,27] upon redefining $\widetilde{\mathcal{C}}^{(2)}=\frac{1}{2}\mathcal{C}^{(2)}$ by a numerical rescaling

$$\begin{aligned}\delta_{\mathcal{W}_3}\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) &= \widetilde{\mathcal{C}}^{(1)}(z,\bar{z})\,\partial\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) - \tfrac{4}{3}\mathcal{T}_{(2)}(z,\bar{z}|3)\mathcal{C}^{(2)}(z,\bar{z})\,\partial\mathcal{C}^{(2)}(z,\bar{z})\\ &\quad + \tfrac{1}{4}\big(\partial\mathcal{C}^{(2)}(z,\bar{z})\partial^2\mathcal{C}^{(2)}(z,\bar{z}) - \tfrac{2}{3}\mathcal{C}^{(2)}(z,\bar{z})\partial^3\mathcal{C}^{(2)}(z,\bar{z})\big)\delta_{\mathcal{W}_3}\\ \delta_{\mathcal{W}_3}\mathcal{C}^{(2)}(z,\bar{z}) &= \widetilde{\mathcal{C}}^{(1)}(z,\bar{z})\,\partial\mathcal{C}^{(2)}(z,\bar{z}) + 2\mathcal{C}^{(2)}(z,\bar{z})\,\partial\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}),\end{aligned} \tag{6.23}$$

where the expected combination (3.37) which introduces into the game a projective connection, is recovered for the case $s=3$,

$$\mathcal{T}_{(2)}(z,\bar{z}|3) = \tfrac{1}{2}\Big(\partial\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3) - \tfrac{1}{3}(\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3))^2 - \mathcal{R}^{(1)}_{(3)}(z,\bar{z}|3)\Big) = \tfrac{1}{2}a^{(3)}_{(2)}(z,\bar{z}), \tag{6.24}$$

an expression which depends on the level $s=3$ only. The remarkable fact in the course of the computation of (6.23) is that all the quantities pertaining to the suborder 2 of truncation have disappeared thanks to the change of generators (6.21) in the tensorial sector.

Comforted into this approach, one can compute also the variation of $\mathcal{T}_{(2)}(z,\bar{z}|3)$. After a straightforward but rather tedious calculation one successively obtains

$$\begin{aligned}\delta_{\mathcal{W}_3}\mathcal{T}_{(2)}(z,\bar{z}|3) &= (\partial_{(3)}\mathcal{K}^{(1)} + 2\mathcal{T}_{(2)}\,\partial\mathcal{K}^{(1)} + \mathcal{K}^{(1)}\mathcal{T}_{(2)})(z,\bar{z}|3) + \Big(\mathcal{K}^{(2)}\Big[\partial_{(3)}\mathcal{R}^{(2)}_{(3)} + \partial_{(2)}\mathcal{R}^{(1)}_{(3)} + \partial_{(2)}(\mathcal{R}^{(2)}_{(3)})^2\\ &\quad - \tfrac{2}{3}\mathcal{R}^{(2)}_{(3)}\partial_{(2)}\mathcal{R}^{(2)}_{(3)} - \tfrac{2}{3}\mathcal{R}^{(2)}_{(3)}\,\partial(\mathcal{R}^{(2)}_{(3)})^2 - 2\mathcal{R}^{(1)}_{(3)}\,\partial\mathcal{R}^{(2)}_{(3)} - \tfrac{4}{3}\mathcal{R}^{(2)}_{(3)}\,\partial\mathcal{R}^{(1)}_{(3)}\Big] + \partial\mathcal{K}^{(2)}\Big[4\partial_{(2)}\mathcal{R}^{(2)}_{(3)}\\ &\quad + \partial\mathcal{R}^{(1)}_{(3)} + \partial(\mathcal{R}^{(2)}_{(3)})^2 - \tfrac{2}{3}(\mathcal{R}^{(2)}_{(3)})^3 - \tfrac{7}{3}\mathcal{R}^{(2)}_{(3)}\mathcal{R}^{(1)}_{(3)}\Big] + \partial_{(2)}\mathcal{K}^{(2)}\Big[5\,\partial\mathcal{R}^{(2)}_{(3)} - \mathcal{R}^{(1)}_{(3)} - \tfrac{1}{3}(\mathcal{R}^{(2)}_{(3)})^2\Big]\\ &\quad + \tfrac{4}{3}\mathcal{R}^{(2)}_{(3)}\partial_{(3)}\mathcal{K}^{(2)} + \partial_{(4)}\mathcal{K}^{(2)}\Big)(z,\bar{z}|3),\end{aligned} \tag{6.25}$$

in terms of the two $\mathcal{K}$ ghosts and the structure functions relative to the level $s=3$. According to (6.22), this variation can be reexpressed in terms of the two tensorial $\widetilde{\mathcal{C}}$ ghosts as

$$\begin{aligned}\delta_{\mathcal{W}_3}\mathcal{T}_{(2)}(z,\bar{z}|3) &= \partial_{(3)}\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) + 2\mathcal{T}_{(2)}(z,\bar{z}|3)\,\partial\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) + \widetilde{\mathcal{C}}^{(1)}(z,\bar{z})\mathcal{T}_{(2)}(z,\bar{z}|3) - 2\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\,\partial\Big[\tfrac{1}{6}\partial_{(2)}\mathcal{R}^{(2)}_{(3)}\\ &\quad - \tfrac{1}{6}\,\partial(\mathcal{R}^{(2)}_{(3)})^2 + \tfrac{1}{3}\mathcal{R}^{(2)}_{(3)}\mathcal{R}^{(1)}_{(3)} + \tfrac{2}{27}(\mathcal{R}^{(2)}_{(3)})^3 - \tfrac{1}{2}\,\partial\mathcal{R}^{(1)}_{(3)}\Big](z,\bar{z}|3) - 3\,\partial\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\Big[\tfrac{1}{6}\partial_{(2)}\mathcal{R}^{(2)}_{(3)}\\ &\quad - \tfrac{1}{6}\,\partial(\mathcal{R}^{(2)}_{(3)})^2 + \tfrac{1}{3}\mathcal{R}^{(2)}_{(3)}\mathcal{R}^{(1)}_{(3)} + \tfrac{2}{27}(\mathcal{R}^{(2)}_{(3)})^3 - \tfrac{1}{2}\,\partial\mathcal{R}^{(1)}_{(3)}\Big](z,\bar{z}|3).\end{aligned} \tag{6.26}$$

The expression between the brackets corresponds to the associated W_3-current as a cubic differential relative to the level $s=3$ (up to a factor),

$$\begin{aligned}8W_{(3)}(z,\bar{z}|3) &= \Big(\tfrac{1}{6}\partial_{(2)}\mathcal{R}^{(2)}_{(3)} - \tfrac{1}{6}\,\partial(\mathcal{R}^{(2)}_{(3)})^2 + \tfrac{1}{3}\mathcal{R}^{(2)}_{(3)}\mathcal{R}^{(1)}_{(3)} + \tfrac{2}{27}(\mathcal{R}^{(2)}_{(3)})^3 - \tfrac{1}{2}\,\partial\mathcal{R}^{(1)}_{(3)}\Big)(z,\bar{z}|3)\\ &= \Big(\tfrac{1}{2}\,\partial a^{(3)}_{(2)} - a^{(3)}_{(3)}\Big)(z,\bar{z}),\end{aligned} \tag{6.27}$$

where the $a^{(3)}$'s were given in (3.39).

To sump up, the general conformally covariant differential operator (3.1) for $s=3$ can be recast in terms of the two $\mathcal{W}$-currents

$$L_3(z,\bar{z}) = \partial_{(3)} + 2\mathcal{T}_{(2)}(z,\bar{z}|3)\,\partial + \partial\mathcal{T}_{(2)}(z,\bar{z}|3) - 8W_{(3)}(z,\bar{z}|3), \tag{6.28}$$

where the last type $(3,0)$-term indicates the difference with the so-called Bol operator of order 3, see e.g., Ref. 24.

At the level of the BRS differential algebra, dropping the tilde $(\tilde{\ })$ for the tensorial ghosts, one has an explicit realization of the so-called principal $\mathcal{W}_3$-algebra, related to what it is called the pure $\mathcal{W}_3$-gravity.[35] The nilpotent BRS algebra for $\mathcal{W}_3$ writes in terms of an $\mathcal{S}$-operation acting on $\mathcal{T}$ and $W_{(3)}$ which are of spin 2 and spin 3 $\mathcal{W}$-currents, respectively, and of two conformal ghost fields $\mathcal{C}^{(1)},\mathcal{C}^{(2)}$,

$$\begin{aligned}
\mathcal{S}\mathcal{C}^{(1)} &= \mathcal{C}^{(1)}\,\partial\mathcal{C}^{(1)} + \partial\mathcal{C}^{(2)}\partial^2\mathcal{C}^{(2)} - \tfrac{2}{3}\mathcal{C}^{(2)}\partial^3\mathcal{C}^{(2)} - \tfrac{16}{3}\mathcal{T}\mathcal{C}^{(2)}\,\partial\mathcal{C}^{(2)},\\
\mathcal{S}\mathcal{C}^{(2)} &= \mathcal{C}^{(1)}\,\partial\mathcal{C}^{(2)} + 2\mathcal{C}^{(2)}\,\partial\mathcal{C}^{(1)},\\
\mathcal{S}\mathcal{T} &= \partial^3\mathcal{C}^{(1)} + 2\mathcal{T}\partial\mathcal{C}^{(1)} + \mathcal{C}^{(1)}\,\partial\mathcal{T} - 8(2\mathcal{C}^{(2)}\,\partial W_{(3)} + 3W_{(3)}\,\partial\mathcal{C}^{(2)}),
\end{aligned} \tag{6.29}$$

$$\begin{aligned}
\mathcal{S}W_{(3)} = {}& \tfrac{1}{24}(\partial^5\mathcal{C}^{(2)} + 2\mathcal{C}^{(2)}\partial^3\mathcal{T} + 10\mathcal{T}\partial^3\mathcal{C}^{(2)} + 15\,\partial\mathcal{T}\partial^2\mathcal{C}^{(2)} + 9\partial^2\mathcal{T}\partial\mathcal{C}^{(2)} + 16\mathcal{T}\partial\mathcal{T}\mathcal{C}^{(2)} + 16\mathcal{T}^2\,\partial\mathcal{C}^{(2)})\\
&+ \mathcal{C}^{(1)}\,\partial W_{(3)} + 3W_{(3)}\,\partial\mathcal{C}^{(1)}.
\end{aligned}$$

However, at the practical level, the $\mathcal{W}_3$ case stands as a particular example in the sense that the change of generators emerges by itself. But for the instance of $\mathcal{W}_4$, it is not evident at first sight, to figure out which change of generators for $C^{(1)}$ and $C^{(2)}$ must be performed. For the moment, there is no general criterion at our disposal giving any guidance on that step. Nevertheless, an explicit realization of the so-called principal $\mathcal{W}_4$-algebra can be constructed along both the ideas of respecting the covariance and the dependence of the top level $s=4$ only. These two main ideas are the crux of all the construction and must be explained in a more geometric setup.

B. The $\mathcal{W}_4$ case

According to the general construction, this time one has with $s=4$ as top level the three tensorial ghosts

$$\begin{aligned}
\mathcal{C}^{(1)}(z,\bar{z}) &= \mathcal{K}^{(1)}(z,\bar{z}|2) = \mathcal{K}^{(1)}(z,\bar{z}|4) + \mathcal{K}^{(2)}(z,\bar{z}|4)\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2) + \mathcal{K}^{(3)}(z,\bar{z}|4)\mathcal{R}^{(1)}_{(3)}(z,\bar{z}|2),\\
\mathcal{C}^{(2)}(z,\bar{z}) &= \mathcal{K}^{(2)}(z,\bar{z}|3) = \mathcal{K}^{(2)}(z,\bar{z}|4) + \mathcal{K}^{(3)}(z,\bar{z}|4)\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3),\\
\mathcal{C}^{(3)}(z,\bar{z}) &= \mathcal{K}^{(3)}(z,\bar{z}|4).
\end{aligned} \tag{6.30}$$

The holomorphically covariant variation according to the DOR filtration of the top ghost is found to be

$$\begin{aligned}
\delta_{\mathcal{W}_4}\mathcal{C}^{(3)}(z,\bar{z}) = {}& (\mathcal{C}^{(1)}\,\partial\mathcal{C}^{(3)} + 3\mathcal{C}^{(3)}\,\partial\mathcal{C}^{(1)} + 2\mathcal{C}^{(2)}\,\partial\mathcal{C}^{(2)} + \mathcal{C}^{(3)}\partial_{(3)}\mathcal{C}^{(3)} + 3\mathcal{C}^{(3)}\partial_{(2)}\mathcal{C}^{(2)} + \mathcal{C}^{(2)}\partial_{(2)}\mathcal{C}^{(3)})(z,\bar{z})\\
&+ (\mathcal{C}^{(3)}\,\partial\mathcal{C}^{(3)})(z,\bar{z})[3\,\partial\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) + 3\mathcal{R}^{(2)}_{(4)}(z,\bar{z}|4) + 3(\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4))^2 - 6\,\partial\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3)\\
&- 4\,\partial\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2) - 5\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3)\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - 4(\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2))^2 + 4\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)\mathcal{R}^{(2)}_{(3)}\\
&\times(z,\bar{z}|3) + 2(\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3))^2] + (\mathcal{C}^{(3)}\partial_{(2)}\mathcal{C}^{(3)})(z,\bar{z})[3\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - 4\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3)]\\
&+ (\mathcal{C}^{(3)}\mathcal{C}^{(2)})(z,\bar{z})[2\,\partial\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3) - 3\,\partial\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)] + (\mathcal{C}^{(2)}\,\partial\mathcal{C}^{(3)})(z,\bar{z})[2\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)
\end{aligned}$$

$$- 2\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3) - \mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)] + (\mathcal{C}^{(3)}\,\partial\,\mathcal{C}^{(2)})(z,\bar{z})[3\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - 2\mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3)$$
$$- 3\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)]. \tag{6.31}$$

The general ansatz for the conformally covariant change of ghosts which does lead to the cancellation of the structure functions of the sublevels ($s=2,3$) in the above variation (6.31) is given by

$$\begin{aligned}\mathcal{C}^{(2)}(z,\bar{z}) &= \tilde{\mathcal{C}}^{(2)}(z,\bar{z}) + H_{(0)}(z,\bar{z})\,\partial\,\mathcal{C}^{(3)}(z,\bar{z}) + H_{(1)}(z,\bar{z})\mathcal{C}^{(3)}(z,\bar{z}),\\ \mathcal{C}^{(1)}(z,\bar{z}) &= \tilde{\mathcal{C}}^{(1)}(z,\bar{z}) + F_{(0)}(z,\bar{z})\,\partial\,\tilde{\mathcal{C}}^{(2)}(z,\bar{z}) + F_{(1)}(z,\bar{z})\tilde{\mathcal{C}}^{(2)}(z,\bar{z}) + L_{(0)}(z,\bar{z})\partial_{(2)}\mathcal{C}^{(3)}(z,\bar{z})\\ &\quad + L_{(1)}(z,\bar{z})\,\partial\,\mathcal{C}^{(3)}(z,\bar{z}) + L_{(2)}(z,\bar{z})\mathcal{C}^{(3)}(z,\bar{z}).\end{aligned} \tag{6.32}$$

Cancellation of the sublevels in (6.31) gives

$$H_{(0)}(z,\bar{z}) = -\tfrac{1}{2}, \quad F_{(0)}(z,\bar{z}) = -1, \quad H_{(1)}(z,\bar{z}) = \mathcal{R}^{(2)}_{(3)}(z,\bar{z}|3) - \tfrac{3}{4}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)$$

$$F_{(1)}(z,\bar{z}) = \mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2) - \tfrac{1}{2}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4), \quad L_{(1)}(z,\bar{z}) = \tfrac{1}{4}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - \tfrac{1}{2}\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2) - \partial L_{(0)}(z,\bar{z}),$$

and the gluing rules for $\mathcal{C}^{(1)}$ infers $L_{(0)}(z,\bar{z})=\frac{1}{5}$. Plugging these results into (6.32) and inverting (6.30) the three $\mathcal{K}$ ghosts of the level $s=4$ are reexpressed as

$$\mathcal{K}^{(3)}(z,\bar{z}|4) = \mathcal{C}^{(3)}(z,\bar{z}),$$

$$\begin{aligned}\mathcal{K}^{(2)}(z,\bar{z}|4) &= \tilde{\mathcal{C}}^{(2)}(z,\bar{z}) - \tfrac{1}{2}\,\partial\,\mathcal{C}^{(3)}(z,\bar{z}) - \tfrac{3}{4}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)\mathcal{C}^{(3)}(z,\bar{z}),\\ \mathcal{K}^{(1)}(z,\bar{z}|4) &= \tilde{\mathcal{C}}^{(1)}(z,\bar{z}) - \partial\tilde{\mathcal{C}}^{(2)}(z,\bar{z}) - \tfrac{1}{2}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)\tilde{\mathcal{C}}^{(2)}(z,\bar{z}) + \tfrac{1}{5}\partial_{(2)}\mathcal{C}^{(3)}(z,\bar{z})\\ &\quad + \tfrac{1}{4}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)\,\partial\,\mathcal{C}^{(3)}(z,\bar{z}) + \mathcal{C}^{(3)}(z,\bar{z})\Big(L_{(2)}(z,\bar{z}) + \tfrac{3}{4}\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - \mathcal{R}^{(1)}_{(3)}(z,\bar{z}|2)\Big).\end{aligned} \tag{6.33}$$

Since there are various possibilities to cancel the sublevels, the remaining function coefficient $L_{(2)}(z,\bar{z})$ must be determined with the help of $\delta_{\mathcal{W}_4}\tilde{\mathcal{C}}^{(2)}$ computed from the second equation of (6.33) and the known variations at the level $s=4$ for $\mathcal{K}^{(3)}(z,\bar{z}|4)$, $\mathcal{K}^{(2)}(z,\bar{z}|4)$, and $\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)$ according to the general theory. This step will secure the nilpotency $\delta^2_{\mathcal{W}_4}=0$. After lengthy computations performed with the help of MATHEMATICA, one ends with

$$L_{(2)}(z,\bar{z}) = \tfrac{12}{25}\,\partial\,\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - \tfrac{3}{25}(\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4))^2 - \tfrac{41}{50}\mathcal{R}^{(2)}_{(4)}(z,\bar{z}|4) - \tfrac{3}{4}\mathcal{R}^{(1)}_{(2)}(z,\bar{z}|2)\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) + \mathcal{R}^{(1)}_{(3)}(z,\bar{z}|2),$$

which once substituted yields

$$\begin{aligned}\mathcal{K}^{(1)}(z,\bar{z}|4) &= \tilde{\mathcal{C}}^{(1)}(z,\bar{z}) - \partial\tilde{\mathcal{C}}^{(2)}(z,\bar{z}) - \tfrac{1}{2}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)\tilde{\mathcal{C}}^{(2)}(z,\bar{z}) + \tfrac{1}{5}\partial_{(2)}\mathcal{C}^{(3)}(z,\bar{z}) + \tfrac{1}{4}\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)\,\partial\,\mathcal{C}^{(3)}(z,\bar{z})\\ &\quad + \mathcal{C}^{(3)}(z,\bar{z})\Big(\tfrac{12}{25}\Big(\partial\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4) - \tfrac{1}{4}(\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4))^2\Big) - \tfrac{41}{50}\mathcal{R}^{(2)}_{(4)}(z,\bar{z}|4)\Big).\end{aligned} \tag{6.34}$$

This shows that the system (6.11) can be rewritten in terms of the structure functions of the level $s=4$ only thanks to the redefinition (6.32) of the tensorial ghosts coming from the sublevels. Recall that these redefinitions are required for reabsorbing the structure functions of the sublevels. The change of generators (6.33) also confirms the general ansatz (6.17) given in Ref. 15. The variation (6.31) then reduces to

$$\delta_{\mathcal{W}_4}\mathcal{C}^{(3)}(z,\bar{z}) = \widetilde{\mathcal{C}}^{(1)}(z,\bar{z})\,\partial\mathcal{C}^{(3)}(z,\bar{z}) + 3\mathcal{C}^{(3)}(z,\bar{z})\,\partial\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) + 2\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\,\partial\widetilde{\mathcal{C}}^{(2)}(z,\bar{z}) + \tfrac{1}{10}(\mathcal{C}^{(3)}(z,\bar{z})\partial_{(3)}\mathcal{C}^{(3)} \times(z,\bar{z}) - 2\,\partial\mathcal{C}^{(3)}(z,\bar{z})\partial_{(2)}\mathcal{C}^{(3)}(z,\bar{z}) + 14\mathcal{T}_{(2)}(z,\bar{z}|4)\mathcal{C}^{(3)}(z,\bar{z})\,\partial\mathcal{C}^{(3)}(z,\bar{z})) \tag{6.35}$$

from which emerges the projective connection $\mathcal{T}_{(2)}(z,\bar{z}|4)$ associated to the level $s=4$,

$$\mathcal{T}_{(2)}(z,\bar{z}|4) := \left(\tfrac{3}{10}\,\partial\mathcal{R}^{(3)}_{(4)} - \tfrac{3}{40}(\mathcal{R}^{(3)}_{(4)})^2 - \tfrac{1}{5}\mathcal{R}^{(2)}_{(4)}\right)(z,\bar{z}|4) = \tfrac{1}{5}a^{(4)}_{(2)}(z,\bar{z}), \tag{6.36}$$

where $a^{(4)}_{(2)}$ given by (3.37) carries the projective connection property as was already checked by using the general gluing rules (3.36). The variation $\delta_{\mathcal{W}_4}\widetilde{\mathcal{C}}^{(2)}$ is then computed to be

$$\begin{aligned}\delta_{\mathcal{W}_4}\widetilde{\mathcal{C}}^{(2)}(z,\bar{z}) = {}& \widetilde{\mathcal{C}}^{(1)}(z,\bar{z})\,\partial\widetilde{\mathcal{C}}^{(2)}(z,\bar{z}) + 2\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\,\partial\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) - \tfrac{3}{32}\mathcal{C}^{(3)}(z,\bar{z})\,\partial\mathcal{C}^{(3)}(z,\bar{z})W_{(3)}(z,\bar{z}|4)\\ & - \tfrac{1}{10}(\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\partial_{(3)}\mathcal{C}^{(3)}(z,\bar{z}) - 3\,\partial\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\partial_{(2)}\mathcal{C}^{(3)}(z,\bar{z}) + 5\partial_{(2)}\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\,\partial\mathcal{C}^{(3)}(z,\bar{z})\\ & - 5\partial_{(3)}\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\mathcal{C}^{(3)}(z,\bar{z}) + (18\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\,\partial\mathcal{C}^{(3)}(z,\bar{z}) - 34\,\partial\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\mathcal{C}^{(3)}(z,\bar{z}))\mathcal{T}_{(2)}(z,\bar{z}|4)\\ & - 7\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\mathcal{C}^{(3)}(z,\bar{z})\,\partial\mathcal{T}_{(2)}(z,\bar{z}|4)),\end{aligned} \tag{6.37}$$

where one also gets the conformally covariant spin three $\mathcal{W}$-current associated to the top level $s=4$,

$$W_{(3)}(z,\bar{z}|4) := (8\,\partial\mathcal{R}^{(2)}_{(4)} - 4\partial_{(2)}\mathcal{R}^{(3)}_{(4)} + 3\,\partial(\mathcal{R}^{(3)}_{(4)})^2 - 4\mathcal{R}^{(2)}_{(4)}\mathcal{R}^{(3)}_{(4)} - 8\mathcal{R}^{(1)}_{(4)})(z,\bar{z}|4). \tag{6.38}$$

Going on through the computation of the variation with the help of the third equation in (6.33) and the known variations at the level $s=4$ for $\mathcal{C}^{(3)}$, $\widetilde{\mathcal{C}}^{(2)}$, $\mathcal{R}^{(3)}_{(4)}(z,\bar{z}|4)$ and $\mathcal{R}^{(2)}_{(4)}(z,\bar{z}|4)$, and after redefining $\mathcal{C}^{(3)} := -320\widetilde{\mathcal{C}}^{(3)}$ by a numerical factor for later convenience, one gets

$$\begin{aligned}\delta_{\mathcal{W}_4}\widetilde{\mathcal{C}}^{(1)}(z,\bar{z}) = {}& (\widetilde{\mathcal{C}}^{(1)}\,\partial\widetilde{\mathcal{C}}^{(1)})(z,\bar{z}) + \tfrac{3}{5}\left(\partial\widetilde{\mathcal{C}}^{(2)}\partial_{(2)}\widetilde{\mathcal{C}}^{(2)} - \tfrac{2}{3}\widetilde{\mathcal{C}}^{(2)}\partial_{(3)}\widetilde{\mathcal{C}}^{(2)} - \tfrac{16}{3}\widetilde{\mathcal{C}}^{(2)}\,\partial\widetilde{\mathcal{C}}^{(2)}\mathcal{T}_{(2)}(z,\bar{z}|4)\right)(z,\bar{z})\\ & + \left(20\widetilde{\mathcal{C}}^{(2)}\,\partial\widetilde{\mathcal{C}}^{(3)} - \tfrac{108}{5}\,\partial\widetilde{\mathcal{C}}^{(2)}\widetilde{\mathcal{C}}^{(3)}\right)(z,\bar{z})W_{(3)}(z,\bar{z}|4) + \tfrac{28}{5}\widetilde{\mathcal{C}}^{(2)}(z,\bar{z})\widetilde{\mathcal{C}}^{(3)}(z,\bar{z})\,\partial W_{(3)}(z,\bar{z}|4)\\ & + 1024[3\widetilde{\mathcal{C}}^{(3)}\partial_{(5)}\widetilde{\mathcal{C}}^{(3)} - 5\,\partial\widetilde{\mathcal{C}}^{(3)}\partial_{(4)}\widetilde{\mathcal{C}}^{(3)} + 6\partial_{(2)}\widetilde{\mathcal{C}}^{(3)}\partial_{(3)}\widetilde{\mathcal{C}}^{(3)} + 57\widetilde{\mathcal{C}}^{(3)}\partial_{(2)}\widetilde{\mathcal{C}}^{(3)}\,\partial\mathcal{T}_{(2)}(z,\bar{z}|4)\\ & + (78\widetilde{\mathcal{C}}^{(3)}\partial_{(3)}\widetilde{\mathcal{C}}^{(3)} - 118\,\partial\widetilde{\mathcal{C}}^{(3)}\partial_{(2)}\widetilde{\mathcal{C}}^{(3)})\mathcal{T}_{(2)}(z,\bar{z}|4) + \widetilde{\mathcal{C}}^{(3)}\,\partial\widetilde{\mathcal{C}}^{(3)}(57\partial_{(2)}\mathcal{T}_{(2)}(z,\bar{z}|4)\\ & + 432(\mathcal{T}_{(2)}(z,\bar{z}|4))^2 - 14W_{(4)}(z,\bar{z}|4))](z,\bar{z}),\end{aligned} \tag{6.39}$$

from where emerges a $\mathcal{W}$-current of spin 4 (a $(4,0)$-type conformally covariant differential) associated to the level $s=4$, as can be checked by using (3.36),

$$\begin{aligned}800W_{(4)}(z,\bar{z}|4) = {}& (144(\mathcal{R}^{(2)}_{(4)})^2 + 400\mathcal{R}^{(1)}_{(4)}\mathcal{R}^{(3)}_{(4)} + 208\mathcal{R}^{(2)}_{(4)}(\mathcal{R}^{(3)}_{(4)})^2 + 39(\mathcal{R}^{(3)}_{(4)})^4 - 800\,\partial\mathcal{R}^{(1)}_{(4)}\\ & - 400\mathcal{R}^{(3)}_{(4)}\,\partial\mathcal{R}^{(2)}_{(4)} - 432\mathcal{R}^{(2)}_{(4)}\,\partial\mathcal{R}^{(3)}_{(4)} - 104\,\partial(\mathcal{R}^{(3)}_{(4)})^3 + 264(\partial\mathcal{R}^{(3)}_{(4)})^2 + 320\partial_{(2)}\mathcal{R}^{(2)}_{(4)}\\ & + 240\mathcal{R}^{(3)}_{(4)}\partial_{(2)}\mathcal{R}^{(3)}_{(4)} - 80\partial_{(3)}\mathcal{R}^{(3)}_{(4)})(z,\bar{z}|4).\end{aligned} \tag{6.40}$$

Hence, the general conformally covariant differential operator (3.1) for $s=4$ expressed in terms of the three $\mathcal{W}_4$-currents is

$$\begin{aligned}L_4(z,\bar{z}) = {}& \partial_{(4)} + 5\mathcal{T}_{(2)}(z,\bar{z}|4)\partial_{(2)} + 5\,\partial\mathcal{T}_{(2)}(z,\bar{z}|4)\,\partial + \tfrac{3}{2}\left(\partial_{(2)}\mathcal{T}_{(2)}(z,\bar{z}|4) + \tfrac{3}{2}(\mathcal{T}_{(2)}(z,\bar{z}|4))^2\right)\\ & + \tfrac{1}{8}W_{(3)}(z,\bar{z}|4)\,\partial + \tfrac{1}{16}\,\partial W_{(3)}(z,\bar{z}|4) - \tfrac{1}{2}W_{(4)}(z,\bar{z}|4),\end{aligned} \tag{6.41}$$

where the first line is the Bol operator of order 4, see, e.g., Ref. 24, depending only on the projective connection $\mathcal{T}_{(2)}$.

All this BRS algebra is an explicit realization of the so-called principal $\mathcal{W}_4$-algebra for pure $\mathcal{W}_4$-gravity.[23,36] Performing the rescaling

$$\tilde{\mathcal{C}}^{(2)} \to -8i\sqrt{5}\tilde{\mathcal{C}}^{(2)}, \quad W_{(3)}(z,\bar{z}|4) \to \tfrac{i}{8\sqrt{5}} W_{(3)}(z,\bar{z}|4),$$

and dropping out both the tilde (~) for the tensorial ghosts and the explicit reference to the level $s=4$, one gets the presentation as a full nilpotent BRS algebra for $\mathcal{W}_4$-algebra,

$$\begin{aligned}
\mathcal{S}\mathcal{C}^{(1)} &= \mathcal{C}^{(1)}\partial\mathcal{C}^{(1)} - 192\Big(\partial\mathcal{C}^{(2)}\partial_{(2)}\mathcal{C}^{(2)} - \tfrac{2}{3}\mathcal{C}^{(2)}\partial_{(3)}\mathcal{C}^{(2)} - \tfrac{16}{3}\mathcal{T}\mathcal{C}^{(2)}\partial\mathcal{C}^{(2)}\Big) + 256(27\,\partial\mathcal{C}^{(2)}\mathcal{C}^{(3)}W_{(3)} \\
&\quad - 25\mathcal{C}^{(2)}\partial\mathcal{C}^{(3)}W_{(3)} - 7\mathcal{C}^{(2)}\mathcal{C}^{(3)}\partial W_{(3)}) + 1024(3\mathcal{C}^{(3)}\partial_{(5)}\mathcal{C}^{(3)} - 5\,\partial\mathcal{C}^{(3)}\partial_{(4)}\mathcal{C}^{(3)} + 6\partial_{(2)}\mathcal{C}^{(3)}\partial_{(3)}\mathcal{C}^{(3)} \\
&\quad + 57\partial_{(2)}\mathcal{T}\mathcal{C}^{(3)}\partial\mathcal{C}^{(3)} + 57\,\partial\mathcal{T}\mathcal{C}^{(3)}\partial_{(2)}\mathcal{C}^{(3)} + (78\mathcal{C}^{(3)}\partial_{(3)}\mathcal{C}^{(3)} - 118\,\partial\mathcal{C}^{(3)}\partial_{(2)}\mathcal{C}^{(3)})\mathcal{T} \\
&\quad - 14\mathcal{C}^{(3)}\partial\mathcal{C}^{(3)}W_{(4)} + 432\mathcal{C}^{(3)}\partial\mathcal{C}^{(3)}\mathcal{T}^2),
\end{aligned}$$

$$\begin{aligned}
\mathcal{S}\mathcal{C}^{(2)} &= \mathcal{C}^{(1)}\partial\mathcal{C}^{(2)} + 2\mathcal{C}^{(2)}\partial\mathcal{C}^{(1)} + 32(\mathcal{C}^{(2)}\partial_{(3)}\mathcal{C}^{(3)} - 3\,\partial\mathcal{C}^{(2)}\partial_{(2)}\mathcal{C}^{(3)} + 5\partial_{(2)}\mathcal{C}^{(2)}\partial\mathcal{C}^{(3)} - 5\partial_{(3)}\mathcal{C}^{(2)}\mathcal{C}^{(3)} \\
&\quad + 18\mathcal{C}^{(2)}\partial\mathcal{C}^{(3)}\mathcal{T} - 34\,\partial\mathcal{C}^{(2)}\mathcal{C}^{(3)}\mathcal{T} - 7\mathcal{C}^{(2)}\mathcal{C}^{(3)}\partial\mathcal{T}) - 9600\mathcal{C}^{(3)}\partial\mathcal{C}^{(3)}W_{(3)},
\end{aligned}$$

$$\mathcal{S}\mathcal{C}^{(3)} = \mathcal{C}^{(1)}\partial\mathcal{C}^{(3)} + 3\mathcal{C}^{(3)}\partial\mathcal{C}^{(1)} + 2\mathcal{C}^{(2)}\partial\mathcal{C}^{(2)} - 32(\mathcal{C}^{(3)}\partial_{(3)}\mathcal{C}^{(3)} - 2\,\partial\mathcal{C}^{(3)}\partial_{(2)}\mathcal{C}^{(3)} + 14\mathcal{T}\mathcal{C}^{(3)}\partial\mathcal{C}^{(3)}),$$

$$\mathcal{S}\mathcal{T} = \partial_{(3)}\mathcal{C}^{(1)} + 2\mathcal{T}\partial\mathcal{C}^{(1)} + \mathcal{C}^{(1)}\partial\mathcal{T} - 8(2\mathcal{C}^{(2)}\partial W_{(3)} + 3W_{(3)}\partial\mathcal{C}^{(2)}) + 32(3\mathcal{C}^{(3)}\partial W_{(4)} + 4W_{(4)}\partial\mathcal{C}^{(3)}), \tag{6.42}$$

$$\begin{aligned}
\mathcal{S}W_{(3)} &= \mathcal{C}^{(1)}\partial W_{(3)} + 3W_{(3)}\partial\mathcal{C}^{(1)} - 8(\partial_{(5)}\mathcal{C}^{(2)} + 2\mathcal{C}^{(2)}\partial_{(3)}\mathcal{T} + 10\mathcal{T}\partial_{(3)}\mathcal{C}^{(2)} + 15\,\partial\mathcal{T}\partial_{(2)}\mathcal{C}^{(2)} + 9\partial_{(2)}\mathcal{T}\partial\mathcal{C}^{(2)} \\
&\quad + 16\mathcal{T}\partial\mathcal{T}\mathcal{C}^{(2)} + 16\mathcal{T}^2\partial\mathcal{C}^{(2)} + \mathcal{C}^{(2)}\partial W_{(4)} + 2W_{(4)}\partial\mathcal{C}^{(2)}) + 32(5\mathcal{C}^{(3)}\partial_{(3)}W_{(3)} + 10\,\partial\mathcal{C}^{(3)}\partial_{(2)}W_{(3)} \\
&\quad + 28\partial_{(2)}\mathcal{C}^{(3)}\partial W_{(3)} + 14\partial_{(3)}\mathcal{C}^{(3)}W_{(3)} + 34\mathcal{C}^{(3)}\mathcal{T}\partial W_{(3)} + 27\mathcal{C}^{(3)}W_{(3)}\partial\mathcal{T} + 52\,\partial\mathcal{C}^{(3)}\mathcal{T}W_{(3)}),
\end{aligned}$$

$$\begin{aligned}
\mathcal{S}\mathcal{W}_{(4)} &= \mathcal{C}^{(1)}\partial W_{(4)} + 4W_{(4)}\partial\mathcal{C}^{(1)} - 8(\mathcal{C}^{(2)}\partial_{(3)}W_{(3)} + 6\,\partial\mathcal{C}^{(2)}\partial_{(2)}W_{(3)} + 14\partial_{(2)}\mathcal{C}^{(2)}\partial W_{(3)} \\
&\quad + 14\partial_{(3)}\mathcal{C}^{(2)}W_{(3)} + 18\mathcal{C}^{(2)}\mathcal{T}\partial W_{(3)} + 25\mathcal{C}^{(2)}\partial\mathcal{T}W_{(3)} + 52\,\partial\mathcal{C}^{(2)}\mathcal{T}W_{(3)}) + 32(\partial_{(7)}\mathcal{C}^{(3)} \\
&\quad + 3\mathcal{C}^{(3)}\partial_{(5)}\mathcal{T} + 20\,\partial\mathcal{C}^{(3)}\partial_{(4)}\mathcal{T} + 56\partial_{(2)}\mathcal{C}^{(3)}\partial_{(3)}\mathcal{T} + 84\partial_{(3)}\mathcal{C}^{(3)}\partial_{(2)}\mathcal{T} + 70\partial_{(4)}\mathcal{C}^{(3)}\partial\mathcal{T} + 28\partial_{(5)}\mathcal{C}^{(3)}\mathcal{T} \\
&\quad + \mathcal{C}^{(3)}(177\,\partial\mathcal{T}\partial_{(2)}\mathcal{T} + 78\mathcal{T}\partial_{(3)}\mathcal{T}) + \partial\mathcal{C}^{(3)}(352\mathcal{T}\partial_{(2)}\mathcal{T} + 295(\partial\mathcal{T})^2) + 588\partial_{(2)}\mathcal{C}^{(3)}\mathcal{T}\partial\mathcal{T} \\
&\quad + 196\partial_{(3)}\mathcal{C}^{(3)}\mathcal{T}^2 + 432\mathcal{C}^{(3)}\mathcal{T}^2\partial\mathcal{T} + 288\,\partial\mathcal{C}^{(3)}\mathcal{T}^3 + 75\mathcal{C}^{(3)}W_{(3)}\partial W_{(3)} + 75\,\partial\mathcal{C}^{(3)}(W_{(3)})^2 \\
&\quad - \mathcal{C}^{(3)}\partial_{(3)}W_{(4)} - 5\,\partial\mathcal{C}^{(3)}\partial_{(2)}W_{(4)} - 9\partial_{(2)}\mathcal{C}^{(3)}\partial W_{(4)} - 6\partial_{(3)}\mathcal{C}^{(3)}W_{(4)} - 14\mathcal{C}^{(3)}\partial(\mathcal{T}W_{(4)}) \\
&\quad - 28\,\partial\mathcal{C}^{(3)}\mathcal{T}W_{(4)}).
\end{aligned}$$

Recall once more that there is a breaking term in the top ghost variation $\mathcal{S}C^{(3)}$ with respect to the symplectic variation, so that the mechanisms using the so-called θ-trick described in previous papers[11,31] for the $\mathcal{W}_3$ case do not work in the $\mathcal{W}_4$ case. Let us remark that if one sets $\mathcal{C}^{(3)}=0$ and $W_{(4)}=0$ and performs the rescalings of the generators $\mathcal{C}^{(2)} \to (i\sqrt{3}/24)\mathcal{C}^{(2)}$ and $W_{(3)} \to -8i\sqrt{3}W_{(3)}$ in (6.42) then the $\mathcal{W}_3$-algebra (6.29) is recovered. This confirms the universal definition (6.6) of the tensorial ghosts as $\mathcal{C}^{(s-1)}(z,\bar{z}) = \mathcal{K}^{(s-1)}(z,\bar{z}|s)$ as the top ghost of each level s and also the interweaving of the algebras dictated by the successive DORs.

C. Comparison with some previous work

The general ansatz (6.17) given in Ref. 15 and exemplified in (6.22), (6.33), and (6.34) for $s=3,4$, respectively, can be put into relation with some previous pioneer work.[6,5,8,10] Indeed, Ref. 10 will be of particular interest. There "Beltrami differentials" emerging from a multi-time ap-

proach for Korteweg-de Vries (KdV) flows were related to "Bilal-Fock-Kogan" generalized tensorial Beltrami coefficients[5] appearing in $\mathcal{W}$-gravity along the ideas of Ref. 6. According to their contravariant behavior these various type of Beltrami deformation parameters can be used in order to recover our ansatz (6.17).

As said in Sec. I, working with either homogeneous or inhomogeneous coordinates seems to be a matter of taste. In our construction, the latter were preferred because they strengthen the role of the symmetry algebra.

If one considers the homogeneous solutions f of the sth order conformally covariant linear equation (3.1), these solutions as $((1-s)/2)$-conformal fields are equivalently subject to a DOR since the sth order derivative can be expressed in terms of the lower order ones and the smooth coefficient of the operator L_s. Their variation under large chiral diffeomorphisms were computed in Ref. 18 to be

$$\delta_{\mathcal{W}_s} f(z,\bar{z}) = \sum_{\ell=0}^{s-1} \mathcal{M}^{(\ell)}(z,\bar{z}|s)\partial_{(\ell)} f(z,\bar{z}). \tag{6.43}$$

This variation for homogeneous coordinates must be related to the variation (4.1) for the inhomogeneous coordinates. Indeed Eqs. (3.8), (3.27) allow one to find a complete link between the ghosts $\mathcal{K}^{(m)}(z,\bar{z}|s)$ and $\mathcal{M}^{(\ell)}(z,\bar{z}|s)$,

$$\mathcal{K}^{(m)}(z,\bar{z}|s) = \sum_{\ell=m}^{s-1} \binom{\ell}{m} \mathcal{M}^{(\ell)}(z,\bar{z}|s)\mathcal{Q}_{(\ell-m)}(z,\bar{z}|s), \quad m=1,\ldots,s-1 \tag{6.44}$$

and gives a direct answer to a problem raised in Ref. 6 about the $\mathcal{W}$ deformations of the f functions via the KdV "multi-time" approach, providing a direct expression of the KdV hierarchy.

Inspired by Ref. 10, one can mimic the construction used for relating KdV flows and $\mathcal{W}$-diffeomorphisms according to the following dictionary:

$$\delta \leftrightarrow \bar{\partial}, \quad \mathcal{M}^{(\ell)} \leftrightarrow \mu_\ell, \quad \text{and} \quad \widetilde{\mathcal{C}}^{(k)} \leftrightarrow \rho_k, \tag{6.45}$$

where the $\mathcal{M}$ play the role of the ghost parameters for KdV flows and $\widetilde{\mathcal{C}}$ (for the sake of consistency with the treated examples one uses the $\widetilde{\mathcal{C}}$ ghosts) those for the infinitesimal $\mathcal{W}$-diffeomorphisms.

One can conformally covariantize the variation (6.43) by introducing tensorial ghosts $\widetilde{\mathcal{C}}$ which serve to filtrate the variation by their conformal weight according to

$$\delta_{\mathcal{W}_s} f = \sum_{k=1}^{s-1} \mathfrak{B}_{(k)}(\widetilde{\mathcal{C}}^{(k)}, a_{(2)}^{(s)}) f, \tag{6.46}$$

where the $\mathfrak{B}_{(k)}$ are the conformally covariant differential operators constructed in Ref. 10 mapping $((1-s)/2)$ conformal fields into themselves. The coefficient function $a_{(2)}^{(s)}$ has a prominent role since it is related to a projective connection (see (3.37)) and controls the Möbius transformations. For $a_{(2)}^{(s)} \equiv 0$ (owing to (3.37) this implies a nontrivial differential constraint on the structure functions and then a kind of group contraction) one recalls that[10]

$$\mathfrak{B}_{(k)}(\widetilde{\mathcal{C}}^{(k)}, a_{(2)}^{(s)} \equiv 0) = \sum_{j=k}^{s-1} \gamma_{(k)}^{(k-j)}[s](\partial_{(mkj)}\widetilde{\mathcal{C}}^{(k)})\partial_{(j)} \tag{6.47}$$

with $\gamma_{(k)}^{(0)}[s]=1$ fixing the normalization between $\mathcal{M}$ and $\widetilde{\mathcal{C}}$. Comparison between the variations (6.43) and (6.46) yields

$$\mathcal{M}^{(0)}(z,\bar{z}|s)=\sum_{k=1}^{s-1}\gamma_{(k)}^{(k)}[s]\partial_{(k)}\widetilde{\mathcal{C}}^{(k)}(z,\bar{z}),$$

$$\mathcal{M}^{(\ell)}(z,\bar{z}|s)=\sum_{k=\ell}^{s-1}\gamma_{(k)}^{(k-\ell)}[s]\partial_{(k-\ell)}\widetilde{\mathcal{C}}^{(k)}(z,\bar{z}),\qquad \ell=1,\ldots,s-1, \tag{6.48}$$

where the numerical coefficients were given in[10]

$$\gamma_{(k)}^{(j)}[s]=(-1)^j\frac{\binom{s+j-k-1}{j}\binom{k}{j}}{\binom{2k}{j}}\quad\text{with}\ \gamma_{(k)}^{(0)}[s]=1 \tag{6.49}$$

as solutions of the recursive equation

$$(j+1)(2k-j)\gamma_{(k)}^{(j+1)}[s]+(k-j)(s+j-k)\gamma_{(k)}^{(j)}[s]=0$$

coming from the study of the covariance of (6.46) under projective holomorphic transformations.

Inserting (6.48) into (6.44) one gets at $a_{(2)}^{(s)}\equiv 0$,

$$\mathcal{K}^{(m)}(z,\bar{z}|s)=\sum_{\ell=m}^{s-1}\binom{\ell}{m}\mathcal{Q}_{(\ell-m)}(z,\bar{z}|s)\sum_{k=\ell}^{s-1}\gamma_{(k)}^{(k-\ell)}[s]\partial_{(k-\ell)}\widetilde{\mathcal{C}}^{(k)}(z,\bar{z}),\qquad m=1,\ldots,s-1 \tag{6.50}$$

The dependence in $a_{(2)}^{(s)}$ can be restored by studying the conformal covariance of (6.46) under an arbitrary holomorphic transformation. The change (6.50) corresponds to

$$\delta_{\mathcal{W}_s}Z(z,\bar{z}|s)=\sum_{k=1}^{s-1}\mathfrak{D}_{(k)}(\widetilde{\mathcal{C}}^{(k)},a_{(2)}^{(s)})Z(z,\bar{z}|s). \tag{6.51}$$

an equivalent to (6.46). Thanks to filtration by the tensorial ghosts $\mathcal{C}^{(k)}$, for each k, the operator $\mathfrak{D}_{(k)}(\widetilde{\mathcal{C}}^{(k)},a_{(2)}^{(s)})$ acting on scalar fields has no constant term (by (4.1)) and must be a scalar under holomorphic transformations. They can be obtained by using the $\mathcal{B}$ operators computed in Ref. 10 without taking into account their constant terms since the inhomogeneous coordinates Z are used in the present paper. For the sake of completeness, one rewrites the first few of them

$$\mathfrak{D}_{(1)}(\widetilde{\mathcal{C}}^{(1)},a_{(2)}^{(s)})=\widetilde{\mathcal{C}}^{(1)}\,\partial\,,$$

$$\mathfrak{D}_{(2)}(\widetilde{\mathcal{C}}^{(2)},a_{(2)}^{(s)})=\widetilde{\mathcal{C}}^{(2)}\partial_{(2)}-\tfrac{s-2}{2}\,\partial\,\widetilde{\mathcal{C}}^{(2)}\,\partial\,, \tag{6.52}$$

$$\mathfrak{D}_{(3)}(\widetilde{\mathcal{C}}^{(3)},a_{(2)}^{(s)})=\widetilde{\mathcal{C}}^{(3)}\partial_{(3)}-\tfrac{s-3}{2}\,\partial\,\widetilde{\mathcal{C}}^{(2)}\partial_{(2)}+\left(\tfrac{(s-2)(s-3)}{10}\partial_{(2)}\widetilde{\mathcal{C}}^{(3)}+\tfrac{6(3s^2-7)}{5(s^3-s)}\widetilde{\mathcal{C}}^{(3)}a_{(2)}^{(s)}\right)\partial\,.$$

A direct confrontation of (6.50) (in which the $a_{(2)}^{(s)}$-dependence has been made explicit) with (6.22), (6.33), and (6.34) for, respectively, $s=3,4$ gives a perfect accord upon using the recursion (3.27) and the definition (3.37).

The general ansatz (6.17) can thus be recovered with the help of existing results in the literature. But the linear decomposition (6.11) depending on the structure functions of all the possible sublevels shows the origin of the tensorial ghosts as the highest conformal weighted parameter in each of the nested subalgebras governed by the DOR filtration. According to the treated examples $\mathcal{W}_3$ and $\mathcal{W}_4$-algebras, the appropriate ghost parameters for the linear $\mathcal{W}$-diffeomorphisms are those constructed by redefining $\mathcal{C}^{(\ell)}\to\widetilde{\mathcal{C}}^{(\ell)}$, for the intermediate DOR

decompositions in order to reabsorb all the structure functions of the sublevels. It is worthwhile to notice that the algorithm is performed in a conformally covariant manner and in the respect of the nilpotency of the $\mathcal{W}$-algebra.

VII. CONCLUSION AND PERSPECTIVE

Throughout the paper, we have considered conformal differential operators defined on a Riemann surface whose solutions are homogeneous coordinates of some complex projective space. The latter lead to the notion of Forsyth frames as projective coordinates. In this context, our main results are as follows

(i) Linear differential order reductions (DOR), see Theorem 3.1, determine the structure functions of the large chiral symmetry algebra. These structure functions are the central objects of all our construction;

(ii) Conformal differential operators can be explicitly constructed from the given structure functions entering the linear DOR.

(iii) The extension to the chiral truncated Taylor expansion of complex scalar fields of the usual infinitesimal chiral diffeomorphisms induces an algebraic framework, which, embedded into a BRS setting, leads to another presentation of $\mathcal{W}$-algebras (Eq. (4.2)) written in terms of jet-ghosts.

(iv) Physical considerations require one to transform these ghosts from jets into tensors. Obviously, this change of generators is not unique.
In doing so, we have given a general solution (for any order s of the algebra), which put into the game all the truncation mechanisms of the Forsyth frames up to order s via a differential order reduction (DOR). The price to pay in keeping the entire generality of the solution is to carry the weight of the whole hierarchy of differential equations (with orders lower than s) which rule all the linear truncations. However, if one considers, for a given level, the general solution (6.14) as (physically) uncompleted, removing the role of the intermediate levels to the benefit of the standard $\mathcal{W}$-algebra presentation comes as a satisfying surprise. It has been shown that the cancellation holds in a rather tractable way for the lowest orders and can be related with some known computation.[10] However, the existence of nontrivial redefinitions of the $\mathcal{C}\to\widetilde{\mathcal{C}}$ ghosts leading to the reabsorption of the intermediate DOR decompositions could be a very interesting problem. This gives a sharper indication on the nature of the tensorial ghosts $\widetilde{\mathcal{C}}$ associated to infinitesimal $\mathcal{W}$-diffeomorphisms. It is a close issue to the one concerning the relationship between the parameters of the KdV flows and those of infinitesimal $\mathcal{W}$-diffeomorphisms.[10] In particular, how the nested variations pertaining to the various sublevels are finally disentangled to the benefit of the top level only, deserve to be better studied. All come from both the conformal covariance (geometry and global meaning) and the nilpotency of the BRS operation (associative algebra of symmetry). This gives an algorithm similar to one obtained in Ref. 10, in which conformal covariance governs the calculation as well.

(v) $\mathcal{W}$-currents are differential polynomials in the structure functions $\mathcal{R}(z,\bar{z}|s)$ only.

Further, a window on the so-called $\mathcal{W}$-gravity is open, once the BRS algebra is given, with the use of the algebraic trick given in Refs. 28, 11, and 32 in order to incorporate the sources of the $\mathcal{W}$-currents. The relationship between the $\mathcal{W}$-diffeomorphism symmetry and the Beltrami deformation parameters for the complex geometry is given by

$$\bar{\partial}=\left\{\delta_{\mathcal{W}_s},\frac{\partial}{\partial\bar{c}}\right\},\quad \rho^{(\ell)}=\frac{\partial\widetilde{\mathcal{C}}^{(\ell)}}{\partial\bar{c}},$$

where $\bar{c}$ is the true diffeomorphism ghost along the direction $\bar{\partial}$ and the $\rho^{(\ell)}$ are expected to be the sources for the $\mathcal{W}$-currents. This justifies (6.45) and allows one to get the whole BRS algebra for $\mathcal{W}$-gravity directly from the BRS algebra for $\mathcal{W}$-algebra (e.g., (6.29) or (6.42)). In particular, this will be useful for a systematic study of $\mathcal{W}$-anomalies possibly arising at the quantum level.

As a final conclusion, we emphasize once more that, due to the nonlinearity of this type of symmetry algebra of large (chiral) diffeomorphisms, the technical intricacy is just a consequence of the reduction from jets to tensors for which nontrivial explicit solutions have been obtained. The latter can be considered as a starting point for a more pleasant treatment, and a more suitable physical formulation for general $\mathcal{W}$-algebras and their relationship not only with linear algebraic differential equations,[14,6] but also with some kind of differential systems. For instance, one ought to expect that the Bershadsky $\mathcal{W}_3^{(2)}$-algebra be rather related to a conformally covariant system of coupled differential equations (with as unknowns f and g) of the form[12]

$$(\partial_{(2)} + a_{(1)}(z,\bar{z})\,\partial + a_{(2)}(z,\bar{z}))f(z,\bar{z}) + b(z,\bar{z})g(z,\bar{z}) = 0,$$

$$\left(\partial - \tfrac{1}{2}a_{(1)}(z,\bar{z})\right)g(z,\bar{z}) + B(z,\bar{z})f(z,\bar{z}) = 0,$$

over a generic Riemann surface.

ACKNOWLEDGMENTS

We thank INFN-TS11 (Italy) and Région PACA (France) for their financial support to our collaboration. Special thanks are due to the referee for several suggestions in improving the version of the present work, in particular, in getting a more general algorithm, this brought Sec. VI C.

(Received 25 May 2006; accepted 16 August 2006; published online 9 October 2006)

It is well known that the quantum double structure plays an important role in three-dimensional quantum gravity coupled to matter field. In this paper, we show how this algebraic structure emerges in the context of three-dimensional Riemannian loop quantum gravity (LQG) coupled to a finite number of massive spinless point particles. In LQG, physical states are usually constructed from the notion of SU(2) cylindrical functions on a Riemann surfaced Σ and the Hilbert structure is defined by the Ashtekar-Lewandowski measure. In the case where Σ is the sphere S^2, we show that the physical Hilbert space is in fact isomorphic to a tensor product of simple unitary representations of the Drinfeld double DSU(2): the masses of the particles label the simple representations, the physical states are tensor products of vectors of simple representations, and the physical scalar product is given by intertwining coefficients between simple representations. This result is generalized to the case of any Riemann surface Σ. © *2006 American Institute of Physics.*

I. MOTIVATIONS

Most of the articles dealing with any aspect of three-dimensional (3D) gravity are introduced and motivated by the well-known fact that 3D gravity would provide a nice framework to answer some questions that are too cumbersome to solve in the four-dimensional (4D) context. It is true that 3D (pure) gravity is a topological theory which admits only a finite number of degrees of freedom: this makes the classical theory exactly solvable and different quantization schemes have been deeply studied in the literature.[8] The theory is nevertheless far from being trivial and exhibits very rich mathematical structures that are still extensively studied: topological invariants, knots invariants, quantum groups, moduli spaces, teichmuller spaces, and so on. The main objection is that it is not true that all these techniques will shed light on the problem of quantizing four-dimensional general relativity. The interest of 3D gravity is widely limited by the fact that there is no local degrees of freedom in the theory and therefore there are many aspects of 4D gravity that will never be clarified thanks to this toy-model. In order to make 3D gravity a richer tool, one should try to introduce local degrees of freedom in the theory.

Coupling 3D gravity to an external (nontrivial) field is a natural extension of the model that contains local degrees of freedom. Furthermore, it makes the model physically more interesting. But, the problem of defining a consistent (full) quantization of a self-gravitating field theory is very difficult and impossible to solve by making use of standard perturbative quantum field theory techniques, which are so successful for describing the physics of elementary particles. Recently, Freidel and Livine[11] proposed a solution of the problem in the context of 3D spin-foam models: they have shown that (under certain hypothesis) a quantum self-gravitating field theory is equivalent to a non-self-gravitating but noncommutative quantum field theory. The authors claim that the

[a)]Electronic mail: noui@phys.univ-tours.fr

noncommutativity encodes the quantum gravity effects on the field. Even if 3D gravity is physically irrelevant, it is rather interesting to have a model at hand where one has complete control of the quantum gravity effects. For these reasons, Ref. 11 certainly deserves attention for it is a first step in the understanding of a theory of quantum gravity with local degrees of freedom. Since, then other interesting articles dealing with different aspects of this problem have been proposed.[15,19,26]

This paper is a first step in the understanding and the analysis of Ref. 11 in the Hamiltonian context. The Hamiltonian quantization is a very interesting quantization scheme because the notions of quantum states and quantum operators are very well understood in that framework. Therefore, one can compute explicit transition amplitudes whereas spin-foam models give *a priori* only the partition function of the theory. The main problems with the Hamiltonian quantization of gravity is that it breaks the covariance of general relativity: there is an explicit choice of time slicing. Topology changings are not allowed because the topology of the spacelike surface is *a priori* fixed once and for all. On the contrary, spin-foam models propose a covariant, quantization of general relativity; this makes this approach so attractive. In this article, we reformulate the loop quantum gravity (LQG) description of 3D gravity coupled to massive point particles where we make clear the crucial role of quantum groups in the quantization. Therefore, we end up with a clear description of the n-particle states evolving in a quantum background which is an essential step toward the Hamiltonian description of a self-gravitating quantum scalar field theory. The last point is presented in a companion paper.[22]

The paper is organized as follows. After the introduction, we start by recalling the techniques used in Refs. 23 and 24 to perform the Hamiltonian quantization a la LQG of three-dimensional gravity (pure or coupled to particles). In particular, we clarified the link between the canonical quantization and the covariant spin-foam quantization. However, in previous works, we have never underlined the role of the quantum double DSU(2) in our construction whereas it is clear that it should play a central role.[13,18,19] We fill this gap within the present paper. To that aim, we first define in Sec. II the notions of partial kinematical and physical Hilbert space. These spaces are constructed from a particular observer: this observer is a given particle which defines a reference frame where the momenta of the other particles and the energy of the global system are defined. This description will appear very important above all in the construction of the Fock space.[22] In Sec. III, we show how the quantum double DSU(2) is naturally present in the (partial) physical Hilbert space: (partial) physical states are defined as vectors of a tensor product of simple representations of DSU(2) and the (partial) physical scalar product is nothing but an intertwining coefficient between simple representations of DSU(2). In this section, we also discuss some aspects concerning the observables: definition, computation of expectation values etc. We present the construction first in the case of the sphere then we generalize to the case of any Riemann surface. We conclude with same perspectives and we postpone the construction of the Fock space to the companion paper.[22]

In this paper, we will work with dimensionless quantities, in particular for the masses of the particles. But, the natural mass unit is the Planck mass m_P defined from the Newton constant G by $m_P=1/(4\pi G)$. Then, any mass value has to be understood in terms of the Plank unit.

II. SPACE OF PHYSICAL STATES

Loop quantum gravity is presented as a two step quantization of general relativity: the construction of the kinematical Hilbert space and the construction of the physical Hilbert space. The first point is completely under control, and gave rise to what is commonly called quantum geometry (for a review see Refs. 2, 28, and 30, or 32): the kinematical states (or states of quantum geometry) are described in term of spin-networks and their set is endowed with a Hilbert structure defined by the Ashtekar-Lewandowski measure. But the construction of the physical Hilbert space is one of the biggest difficulties and one of the most interesting problems of LQG. Different ways have been explored to attack the problem: construction of the extractor P by using a regularization of the Hamiltonian constraint,[16,31] the master constraint program,[33] spin-foam models,[25,27] etc.

Very recently, Thiemann[34] and Han and Ma[17] proved the existence of the physical Hilbert space in the context of the master program using spectral techniques. Nevertheless, no consistent solution has been found so far!

In a couple of papers[23,24] we have successfully studied 3D general relativity (pure gravity and gravity coupled to particles) as a toy-model for LQG. In particular, we have constructed the extractor P and have shown that the physical scalar product between states has a spin-foam representation. Thus, we made the explicit relation between LQG and spin-foam models.

This section is devoted to recalling the construction in the pure gravity case and in the case where gravity is coupled to massive spinless point particles. Then, we propose an alternative description for the physical Hilbert space from where the quantum double structure emerges naturally.

A. Pure gravity: Review and notations

Let $\mathcal{M}$ be a three-dimensional manifold. In the first-order formalism, the degrees of freedom of the gravitational field in $\mathcal{M}$ are encoded in a triad $e(x)=e^i_\mu(x)J_i\mathrm{d}x^\mu$ and in a spin-connection $\omega(x)=\omega^i_\mu(x)J_i\mathrm{d}x^\mu$ where J_1,J_2,J_3 are the generators of the Lie algebra $\mathfrak{g}=\mathfrak{su}(2)$ satisfying the Lie-algebra relation $[J_i,J_k]=\epsilon^l_{ij}J_l$. Indices are lowered and raised by the Kronecker symbols $\delta_{ij}=\delta^{ij}$. The dynamics is governed by the BF-action for the group $G=\mathrm{SU}(2)$.

When the manifold has the topology $\mathcal{M}=\Sigma\times I$, Σ being a Riemann surface of genus g and I a compact part of the real line $\mathbb{R}$, then gravity admits a Hamiltonian formulation. The nonreduced phase space is (schematically) defined by

$$\mathcal{E}\equiv\{(A,E)|A \text{ a } G \text{ connection on } \Sigma \text{ and } E \text{ an electric field on } \Sigma\}. \tag{1}$$

The variables A and E form a canonical variables pair and are, respectively, defined by the pullbacks of the spin-connection and of the triad on the surface Σ. The theory admits first class constraints that generate infinitesimal symmetries in the nonreduced phase space $\mathcal{E}$. An element $X\in\mathcal{E}$ is called $\mathcal{G}$-invariant when it Poisson-commutes with the constraints. The symmetry group is given by $\mathcal{G}=\mathcal{C}^\infty(\Sigma;\mathrm{ISU}(2))$ where ISU(2) is the (universal cover of the) group of Euclidean transformations. It is a semidirect group:

$$\mathrm{ISU}(2)=\mathrm{SU}(2)\ltimes\mathbb{R}^3 \quad \text{where } G \text{ acts on } \mathbb{R}^3 \text{ by the vectorial representation}. \tag{2}$$

Note that the symmetry group $\mathcal{G}$ contains (on-shell) the diffeomorphisms group on Σ but is not the diffeomorphism group. Important discrepencies between gravity and BF theory appears because of this fact.[20]

The physical phase space $\mathcal{P}$ is obtained by applying an infinite dimensional version of the Dirac reduction to the space $\mathcal{E}$ and schematically reads:

$$\mathcal{P}\equiv\{X\in\mathcal{E}|X \text{ is } \mathcal{G}\text{-invariant}\}/\mathcal{G}. \tag{3}$$

The space $\mathcal{P}$ is a finite dimensional symplectic manifold and it is isomorphic to the moduli space of flat ISU(2)-connections on the surface Σ. Functions on $\mathcal{P}$ are called observables and, by definition, are invariant under the (induced) action of the symmetry group $\mathcal{G}$.

Different strategies have been developed in the last 15 years to quantize the theory (see Ref. 8, and references therein). Most of them (combinatorial quantization,[1,7,6] functional quantization,[36] Nelson-Regge quantization,[21] etc.) are proper to 3D gravity and cannot be generalized to higher dimensions. What makes the loop and the spin-foam quantizations very attractive is precisely that these schemes can, in principle, be applied in 4D, even if neither LQG nor spin-foam models provide so far a complete and consistent quantization of 4D gravity.

The loop quantization program consists in first quantizing the nonphysical phase space $\mathcal{E}$, then promoting the first class constraints into quantum operators, and then finding the kernel of these quantum operators. In 4D gravity, all the constraints but one can be solved in the quantum theory.

The remaining and problematic constraint is known as the Hamiltonian constraint. In the context of 3D pure gravity, this program can be completely achieved and one can find solutions of all the constraints.[23] We proceed as follows.

1. Space of cylindrical functions on Σ: Cyl(Σ, G)

We start by choosing the connection A to be the configuration variable (choice of polarization) and we denote $\mathcal{A}$ the space of G-connections on Σ. We introduce the space of discrete connections associated to a graph γ (with E edges and V vertices), denoted $\mathcal{A}_\gamma$ by, roughly speaking, replacing local connections A with holonomies U_e of the connection along the edges e of the graph. A cylindrical function on the graph γ is an element $\psi \in \mathrm{Fun}(\mathcal{A}_\gamma) \subset \mathrm{Fun}(\mathcal{A})$ such that there exists a function $f \in \mathrm{Fun}(G^{\otimes E})$ and $\psi(A) = f(\otimes_{e=1}^{E} U_e)$. The space of cylindrical functions is denoted $\mathrm{Cyl}(\gamma; G)$ and is naturally endowed with a measure $\mathrm{d}\mu_\gamma = \otimes_{e=1}^{E} \mathrm{d}\mu_e$ where $\mathrm{d}\mu_e$ is the normalized G Haar measure associated to the edge e. Finally, we define the space of cylindrical functions on the surface Σ as the following union:

$$\mathrm{Cyl}(\Sigma; G) = \bigcup_{\gamma} \mathrm{Cyl}(\gamma; G). \tag{4}$$

This space inherits a natural measure, known as the Ashtekar-Lewandowski measure, and the completion of $\mathrm{Cyl}(\Sigma; G)$ with respect to this measure is the Hilbert space of non-physical states, denoted $\mathcal{H}(\Sigma; G)$. The action of the symmetry group $\mathcal{G}$ on the connections induces a (co-) action on $\mathrm{Cyl}(\Sigma; G)$ and on $\mathcal{H}(\Sigma; G)$ and we will use the same notation $\mathcal{G}$ to denote the symmetry group acting on $\mathrm{Cyl}(\Sigma; G)$. Physical states are those functions which are left invariant under this symmetry.

2. Invariance under the symmetry group G

The action of the symmetry subgroup $C^\infty(\Sigma; G)$ reduces to an action on the vertices of any element of $\mathcal{A}_\gamma$ for any graph γ. Invariant states under this action are called kinematical states. The set of kinematical states is a vector subspace of $\mathrm{Cyl}(\Sigma; G)$ and, due to left and right invariance of the G Haar measure, inherits the pre-Hilbert structure of $\mathrm{Cyl}(\Sigma; G)$. After completion, we obtain the kinematical Hilbert space, denoted $\mathcal{H}_{\mathrm{kin}}(\Sigma; G)$. Spin-network states provide an orthonormal basis of $\mathcal{H}_{\mathrm{kin}}(\Sigma; G)$.

3. Invariance under the translations $\mathbb{R}^3$

Physical states are *a priori* kinematical states that are invariant under the action of the residual symmetry subgroup. However, there are no physical states in the kinematical Hilbert space. This is a well-known fact that is a consequence of the noncompactness of the subgroup $\mathbb{R}^3$. Physical states are in fact "distributional," in the sense that they are elements of $\mathrm{Cyl}(\Sigma; G)^*$, the topological dual of $\mathrm{Cyl}(\Sigma; G)$. Finding physical states is equivalent to finding a physical extractor (abusively called a projector), i.e., an operator:

$$P: \mathrm{Cyl}(\Sigma; G) \to \mathrm{Cyl}(\Sigma; G)^*, \tag{5}$$

which satisfies the property $P(\psi_1)(\psi_2) = P(\psi_1)(\xi \cdot \psi_2)$ for any cylindrical functions ψ_1 and ψ_2 and any element $\xi \in \mathcal{G}$. We have denoted by $\cdot$ the action of $\mathcal{G}$ on $\mathrm{Cyl}(\Sigma; G)$. Thus the physical Hilbert space $H_{\mathrm{phys}}(\Sigma; G)$ is defined as the image of $\mathrm{Cyl}(\Sigma; G)$ by P. Given two physical states ϕ_1 and ϕ_2, there exists $\psi_1, \psi_2 \in \mathrm{Cyl}(\Sigma; G)$ such that $\phi_1 = P(\psi_1)$ and $\phi_2 = P(\psi_2)$, and the physical scalar product is defined by

$$\langle \phi_1, \phi_2 \rangle_{\mathrm{phys}} \equiv \langle \psi_1, \psi_2 \rangle_{\mathrm{phys}} \equiv P(\psi_1)(\psi_2). \tag{6}$$

The physical scalar product does not depend on the choice of the functions φ_1 and φ_2. Generally, we omit to mention the elements ϕ_1 and ϕ_2, and we write the physical scalar product between cylindrical functions. The operator P "extracts" the physical component of any cylindrical function.

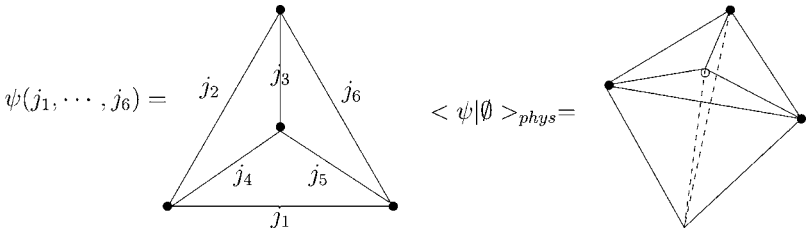

FIG. 1. The picture on the left is a spin-network state whose edges are labeled with irreps of SU(2) and vertices with normalized SU(2) intertwiners. On the right side, we have drawn the spin-foam picture illustrating the transition amplitude between the no-state and the state on the left. The amplitude associated to this spin-foam is a $(6j)$ symbol

The explicit construction of P has been done in Ref. 23. In fact, the extractor has been constructed by imposing locally the flatness condition $F(A)=0$ after a choice of regularization. The physical scalar product so obtained is well-defined (i.e., convergent), is positive, and satisfies Hermiticity condition. Moreover, the relation to the spin-foam model has been established and is briefly recalled in the following. Given two spin-network states ψ_1 and ψ_2 respectively associated to the colored graphs $\gamma_1,\gamma_2\subset\Sigma$, one associates a cellular decomposition Δ of the three-dimensional manifold $\Sigma\times I$ which interpolates the graphs γ_1 and γ_2 at the boundaries. Moreover, Δ is colored in the usual way: faces are associated with irreps of SU(2), edges with intertwiners and the colors are compatible with the boundaries' colors. At this point, one introduces the dual graph Γ whose edges are now colored with SU(2) irreps. The spin-foam amplitude associated to the graph Δ (or in an equivalent way to the dual graph Γ) gives the physical scalar product between the two spin-network states if and only ifΔ is free of bubles, i.e., Δ has a tree structure. The last condition makes the amplitude convergent and appears naturally in the Hamiltonian framework as a consequence of the regularization of the constraint $F(A)=0$. Therefore, in the case where Γ is a triangulation of $\Sigma\times I$ we have

$$\langle\psi_1,\psi_2\rangle_{\text{phys}}=\sum_{j_e}\prod_{e\in\Gamma}W_e(\{j_e\})\prod_{t\in\Gamma}W_t(\{j_e\}),\tag{7}$$

where the sum runs over SU(2) irreps coloring the edges e of Γ, the weight W_e is generically given by $d_{j_e}=2j_e+1$ and is $d_{j_e}\delta_{je,j\ell}$ if the edge e is dual to a face whose boundary contains an edge of γ_1 or γ_2 colored by $j\ell$; $W_t=(6j)$ is the normalized symmetric $(6j)$ symbols defined by the six representations coloring the edges of the tetrahedron t. This property is illustrated by the following example:

$$\langle\emptyset|\psi(j_1,\ldots,j_6)\rangle_{\text{phys}}=N(j_1,j_2,j_4)N(j_2,j_3,j_6)N(j_1,j_5,j_3)\begin{Bmatrix}j_1 & j_2 & j_6\\ j_4 & j_5 & j_3\end{Bmatrix},\tag{8}$$

where $N(j_1,j_2,j_3)$ is the norm of three-valent intertwiners (evaluation of Θ spin-network) taken to be 1. The state $\psi(j_1,\ldots,j_6)$ is the spin-network state defined on the sphere and represented in Fig. 1.

Let us finish with a remark. We consider two cylindrical functions ψ_1 and ψ_2 which differ only by the fact that their associated graphs are different but related by a diffeomorphism. Therefore, the state $P(\psi_1)-P(\psi_2)$ is a null-vector in the physical Hilbert space and we can identify the spaces $P(\text{Cyl}(\gamma;G))$ and $P(\text{Cyl}(\gamma';G))$. This is a consequence of the invariance of the theory under the diffeomorphisms group. Furthermore, the identification of the spaces still holds when the graphs γ and γ' are homotopic and not necessarily related by a diffeormorphism. Thus, we identify states that are not related by a diffeomorphism when we impose the flatness condition. We have to be aware of this fact, which is a consequence of the fact that we are working with first order gravity and then we include degenerate metrics in the model. How to avoid degenerate metrics in the quantum theory is still an open question.

B. Coupling to a finite number of particles

In order to couple particles to the gravitational field, we now consider a surface Σ with boundary: the genus of Σ is still denoted g and we assume the boundary is a disjoint union of n boundaries whose topology is a circle, i.e., $\partial\Sigma=\cup_{i=0}^{n-1}\mathcal{B}_i$. Each boundary $\mathcal{B}_i$ is associated to one particle $\mathcal{P}_i$ whose degrees of freedom are encoded in an element $X_i=(\Lambda_i,q_i)\in \mathrm{ISU}(2):q_i\in\mathbb{R}^3$ is the position of the particle and $\Lambda_i\in G$ is related to the momemtum by $\vec{p}_i=m_i\Lambda_i\vec{n}$ where $\vec{n}\in S^2$. The mass m_i of each particle$\mathcal{P}_i$ is fixed by appropriate boundary conditions of the gravitational field on $\mathcal{B}_i$.[5,9] The action of the coupled system is obtained via a minimal coupling and takes the form:

$$S=S_{BF}[e,\omega]+\sum_{i=0}^{n-1}S_{P_i}[q_i,\Lambda_i]-S_C[e,\omega;(q_i,\Lambda_i)_i]. \tag{9}$$

The explicit expression of the action is given in Ref. 24: S_{BF} is the usual SU(2) BF-action, S_P is the (first order) action of free relativistic particles and S_C represents the minimal coupling term. Note that S_C enforces the appropriate boundary conditions which fixes the masses of the particles.

The loop quantization of the action (9) is conceptually similar to the pure gravity case and has been performed in Ref. 24 Let us recall the main results.

1. Particles-cylindrical functions

Particles-cylindrical functions are a direct generalization of the usual notion of cylindrical functions. A particles-cylindrical function ψ is now a function of the connection A and of the momenta Λ_i. Such a function is defined by a graph $\gamma\subset\Sigma$ which can admit open ends at the boundaries and by a function $f\in\mathrm{Fun}(G^{\otimes(E+O)})$ where E is the number of edges and O the number of open ends such that

$$\psi(A,\Lambda_i)=f(\otimes_{e=1}^{E}U_e\otimes_{o=1}^{O}\Lambda_o). \tag{10}$$

Recall that U_e is the holonomy of the connection along the edge e and $\Lambda_o=\Lambda_i$ if the open end $o\in\mathcal{B}_i$. Therefore, the vector space of particles-cylindrical functions $\mathrm{Cyl}(\Sigma,\mathcal{P};G)$ is given by

$$\mathrm{Cyl}(\Sigma,\mathcal{P};G)\equiv\mathrm{Cyl}(\Sigma;G)\otimes\ \mathrm{Fun}(SU(2))^{\otimes n}. \tag{11}$$

$\mathcal{P}$ labels the set of the particles. This space is naturally endowed with a measure (constructed from the AL measure and the SU(2) normalized Haar measure) which makes it a pre-Hilbert space. Its completion is denoted $\mathcal{H}(\Sigma,\mathcal{P};G)$.

2. Symmetries of the system

The system admits first class constraints that generate infinitesimal symmetries. The symmetry group of the Hamiltonian theory is a Cartesian product $\mathcal{G}\times\mathcal{C}$. Any element of $\mathcal{G}$ is an element of $C^\infty(\Sigma,\mathrm{ISU}(2))$ which is constant at each boundary $\mathcal{B}_i$. As in the pure gravity case, we distinguish the "compact" subgroup $C^\infty(\Sigma,\mathrm{SU}(2))$ from the noncompact one $C^\infty(\Sigma,\mathbb{R}^3)$. The compact part generates usual gauge transformations which read on the variables A and Λ_i:

$$\forall g\in\mathcal{G}\ \text{s.t.}\ g\big|_{\mathcal{B}_i}=g(i)(A,\Lambda_i)\mapsto(g^{-1}Ag+g^{-1}\mathrm{d}g,g(i)^{-1}\Lambda_i). \tag{12}$$

The noncompact part is related to the diffeomorphisms group of the manifold $\Sigma\times I$ and acts nortrivially on the momenta canonically conjugated to the connection A.

The group $\mathcal{C}=\mathrm{Cst}(\partial\Sigma,\Gamma)$ is the set of functions on $\partial\Sigma$ which are constant on each component $\mathcal{B}_i$ and takes value in the Cartan torus Γ of ISU(2) (Note that Γ is the two-dimensional group $\mathbb{R}\times S^1$). Therefore $\mathcal{C}\simeq\Gamma^{\times n}$. It acts trivially on the connection A and by right multiplication on the momenta as shown in the following:

$$\forall(\lambda(i),\pi(i))_{i\in[0,n-1]}\in\mathcal{C}\ \text{s.t.}\ \lambda(i)\in \mathrm{SU}(2),\quad \pi(i)\in\mathbb{R}^3,\quad \Lambda_i\mapsto\Lambda_i h(i). \tag{13}$$

One can show that $\mathbb{R}\subset\Gamma$ is the subgroup of time reparatrizations of the world line of each particle whereas $S^1\subset\Gamma$ is the subgroup of internal frame rotations which preserves the momentum of each particle. It is then natural that only the SU(2) Cartan subgroup has a nontrivial action on the momenta.

The action of $\mathcal{G}$ induces a co-action on $\mathrm{Cyl}(\Sigma,\mathcal{P};G)$ and particles-physical states are the elements of $\mathrm{Cyl}(\Sigma,\mathcal{P};G)$ which are co-invariant under $\mathcal{G}$.

3. Imposing the constraints and the particles-physical Hilbert space

Invariance under reparametrization is trivial because we work in the momentum representation and invariance under internal frame rotations imposes that states are functions on the sphere $S^2=\mathrm{SU}(2)/\mathrm{U}(1)$ instead of a function on the whole group SU(2) (see Ref. 24 for more details). Therefore, the set of particles-cylindrical functions satisfying these invariances reads:

$$\mathrm{Cyl}_{\mathcal{C}}(\Sigma,\mathcal{P};G)\equiv\mathrm{Cyl}(\Sigma,\mathcal{P};G)/\mathcal{C}=\mathrm{Cyl}(\Sigma;G)\otimes\mathrm{Fun}(S^2)^{\otimes n}. \tag{14}$$

Due to the left and right invariance of the G Haar measure, the space $\mathrm{Cyl}_{\mathcal{C}}(\Sigma,\mathcal{P};G)$ inherits the measure of $\mathrm{Cyl}(\Sigma,\mathcal{P};G)$. To find particles-physical states, we have to impose the invariance under $\mathcal{G}$. As in the pure gravity case, this is a two-step procedure. First, we impose the invariance under the subgroup of gauge transformations: this is immediate to do and we obtain the particles-kinematical Hilbert space $\mathcal{H}_{\mathrm{kin}}(\Sigma,\mathcal{P};G)$. Particles-spin-network states provide an orthonormal basis of $\mathcal{H}_{\mathrm{kin}}(\Sigma,\mathcal{P};G)$ Note that particles-spin-network states are associated to graphs with (eventually) open ends at the location of the particles.

Imposing the remaining constraint (which generates the noncompact symmetry group) is done in the same way as in the pure gravity case. This means finding an extractor P:

$$P{:}\mathrm{Cyl}_{\mathcal{C}}(\Sigma,P;G)\to\mathrm{Cyl}_{\mathcal{C}}(\Sigma,P;G)^{*} \tag{15}$$

such that $P(\psi_1)(\psi_2)=P(\psi_1)(\xi\cdot\psi_2)$ for any particles-cylindrical functions ψ_1 and ψ_2 and any $\xi\in\mathcal{G}$. The image of $\mathrm{Cyl}_{\mathcal{C}}(\Sigma,\mathcal{P};G)$ by the extractor is a vector space. We endow this space with a (Ashtekar-Lewandowski) measure and after completion we end up with the particles-physical Hilbert space $\mathcal{H}_{\mathrm{phys}}(\Sigma,\mathcal{P};G)$.

The explicit construction of P has been done in Ref. 24. The relation to spin-foam models has been unraveled: the particles-physical scalar product reproduces spin-foam amplitudes of Ref. 13 as shown in the following section. It would be very interesting to ask the question of the unicity of the extractor P in the context of three-dimensional gravity because it seems that the same kinematical space is the starting point of the construction of different physical states depending on whether we are dealing with pure gravity, gravity coupled to particles or in the presence of a cosmological constant.

C. The physical states

As presented before, any physical state can be viewed as an equivalent class of a particles-cylindrical function (two states are equivalent if their difference has a nonzero physical norm) or equivalently as the image of a particles-cylindrical function by the extractor P defined above (15). A particles-physical state ψ is said to be explicitly dependent of the particles degrees of freedom if any of its representative is a particles-cylindrical function defined on a graph which has at least one open vertex (at a boundary). Otherwise, the state does not depend explicitly on the particles-degrees of freedom.

States which do not depend explicitly on the particles degrees of freedom characterize the three-dimensional space-time geometry with conical singularities but do not contain any information (apart from the masses) concerning the particles. The physical scalar product between two such (spin-network) states ψ_1 and ψ_2 has a regularized well-defined spin-foam representation of the type of Ref. 13. Indeed, one fixes a tridimensional graph $\tilde{\Gamma}\subset\Sigma\times I$ with no-buble interpolating

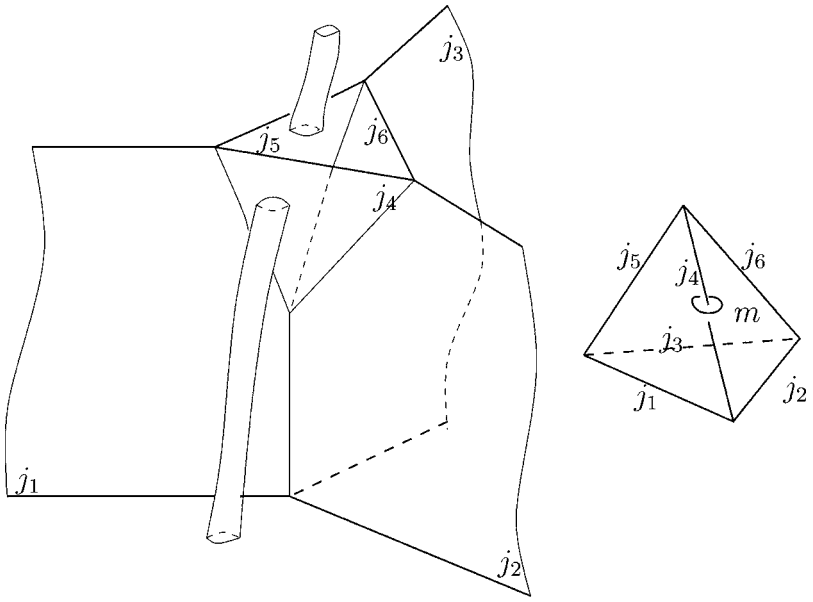

FIG. 2. Left panel: chunk of spin-foam amplitude between two spin-network states represented in thick lines: the boundary crosses the face labeled with the irrep j_4. Right panel: the dual picture the circle around the edge j_4 reminds one of the presence of the boundary.

the flat graphs γ_1 and γ_2 associated to the cylindrical functions ψ_1 and ψ_2 and the dual graph Γ, and we still have the identity (7). In that case, edges e of Γ are still colored with a representation j_e. The weight associated to each tetrahedron is still given by $W_t(\{j_e\})=(6j)_t$ but the weight W_e associated to eachedge is slightly modified: $W_e=\chi_{je}(m_i)$ where $\chi_j(m)\equiv \sin(2j+1)m/\sin m$ if the boundary associated to the particle of mass m_i crosses the dual face f of the edge e; $W_e=2j_\ell+1$ where j_ℓ is the representation coloring one edge ℓ of the graphs γ_φ or γ_ψ if the boundary of the dual face of e contains the edge ℓ; $W_e=2j_e+1$ otherwise. Note that, in the construction of Ref. 13 one has to fix a maximal tree T of Γ and to impose the condition $W_e=\delta_{j_e,0}$ to each edge $e$of T in order to make the sum (7) convergent. In our construction, we do not have such a condition because the graph $\tilde{\Gamma}$ is chosen to be free of bubbles. The two conditions are in fact equivalent.

Relation (7) is illustrated in the example of Fig. 2.

The spin-foam amplitude associated to the spin-foam on the left-hand side is given by

$$\frac{\chi_{j_4}(m)}{d_{j_4}}\begin{Bmatrix} j_1 & j_2 & j_6 \\ j_4 & j_5 & j_3 \end{Bmatrix}. \tag{16}$$

Reciprocally, the amplitude of any spin-foam of the type of Ref. 13 can be interpreted as the physical scalar product between two states which do not depend explicitly on the particles degrees of freedom.

Of particular interest is the physical scalar product between states which depend explicitly on the particles degrees of freedom. This kind of physical scalar product does not admit a spin-foam representation of the previous type.[13] In that case, the cellular decomposition of the manifold $\Sigma \times I$, defining the eventual spin-foam model, involves faces whose edges belong to, the boundaries (see Fig. 3 as an example) whereas the faces were crossed by the boundaries in the previous case.

It would be very interesting to generalize the spin-foam model developed in Ref. 13 in order to include transitions of the type of Fig. 3. We leave this issue for future investigations. In the sequel, we concentrate on the physical scalar product between particles-physical states and we do not ask for the moment the question of its spin-foam representation. Then, we want to choose a basis of physical states and we are going to compute the physical scalar product between the

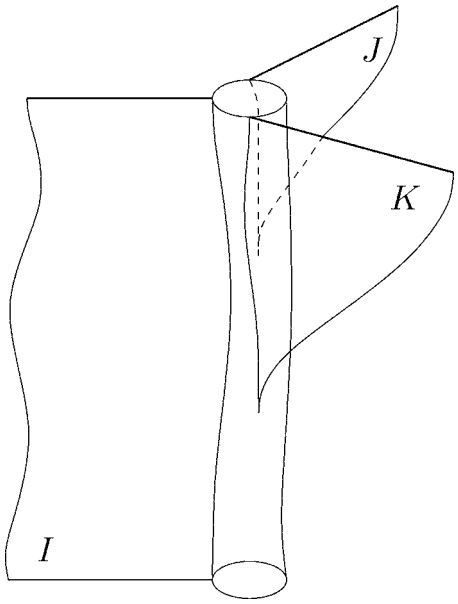

FIG. 3. Example of transition between spin-network states explicitly involving boundaries degrees of freedom. New faces can emerge from the boundaries.

elements of the basis. In other words we are going to compute explicitly the matrix elements of the extractor P whose definition and properties were briefly recalled above (15).

For that purpose, we start by choosing a minimal graph γ on the Riemann surface with boundaries $\Sigma:g$ and n denote, respectively, the genus of Σ and the number of connected components of $\partial\Sigma$. A minimal graph (Fig. 4) consists in a choice of a base point $x\in\Sigma$, a choice of n oriented edges linking x and a point on each boundary $\mathcal{B}_i$ (let E be the set of these edges), and a choice of $2g$ oriented noncontractible loops around each handle of the surface (let $H=A\cup B$ be the set of these loops that we separate as usual into two sets A and B).

The space of discrete connections on the minimal graph is denoted $\mathcal{A}_\gamma$: any discrete connection is a family $A=(U_a,U_b;U_e,\Lambda_i)_{a,b,e,i}\in G^{2(g+n)}$ where $e\in[0,n-1]$ labels the elements of E, $a,b\in[1,g]$ the elements of $H=A\cup B$, and $i\in[1,n]$ the particles. The infinite dimensional symmetry group $\mathcal{G}\times\mathcal{C}(12,13)$ acting on the space of connections reduces to a finite dimensional group when acting on $\mathcal{A}_\gamma$. The compact part of this group is trivially isomorphic to $G\times(G\times S^1)^{\times n}$. Its action on $\mathcal{A}_\gamma$ is given by

$$(G\times(G\times S^1)^{\times n})\times\mathcal{A}_\gamma\to\mathcal{A}_\gamma,$$

$$(y,(g(i),\lambda(i))_i)\times(U_a,U_b;U_e,\Lambda_i)\mapsto(y^{-1}U_a y,y^{-1}U_b y;y^1U_e g(i),g(i)^{-1}\Lambda_i\lambda(i)). \tag{17}$$

The noncompact subgroup acts trivially on the variables A and Λ_i and has a nontrivial action on the variables canonically conjugated. Imposing invariance under the noncompact subgroup is done by finding the appropriate extractor P.

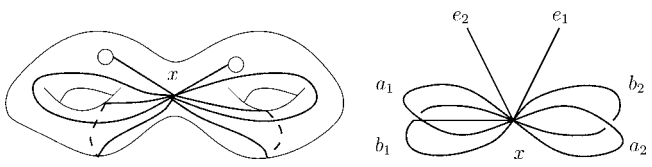

FIG. 4. A minimal graph on a genus 2 surface with two particles. On the right-hand side, the "flat projection" of the minimal graph with the labelings of each edge or loop.

The functions on discrete connections form the set $\mathrm{Cyl}(\gamma;G)$ of cylindrical functions on the minimal graph γ. Recall that $\psi\in\mathrm{Cyl}(\gamma;G)$ if there exists a function $f\in\mathrm{Fun}(G^{2(g+n)})$ such that given $\mathcal{A}\in\mathcal{A}_\gamma$ we have

$$\psi(A)=f\left(\bigotimes_{a,b=1}^{g} U_a\otimes U_b\otimes\bigotimes_{e,i=0}^{n-1} U_e\otimes\Lambda_i\right). \tag{18}$$

Due to the compactness of the gauge group $G=\mathrm{SU}(2)$, it is clear that $\mathrm{Cyl}(\gamma;G)$ is isomorphic to the space $\mathrm{Fun}(G)^{2(g+n)}$. Then, the space of cylindrical functions is naturally endowed with a pre-Hilbert structure defined by the Haar measure on the group G and its completion, denoted $\mathcal{H}(\gamma;G)$, is called the space of nonphysical states. This space is essential in the constructions of the kinematical Hilbert space and the physical Hilbert space. Obviously, these constructions do not depend on the choice of the base point x on the surface: indeed, the base point has no physical meaning and it is natural that "physical" quantities do not depend on it. Technically, it is the adjoint action of the gauge group G which makes the physical Hilbert space independent of the base point. Even the kinematical Hilbert space does not depend on that choice.

Therefore, one can choose x to be a point of a given boundary, let us say $\mathcal{B}_0$. Yet, there now exist two types of symmetries acting on the variables denned on $\mathcal{B}_0$: the action of G and the action of S^1. The former is the usual action of the gauge group SU(2) whereas S^1 is the group of internal frame symmetries (associated to the particle $\mathcal{P}_0$). To construct kinematical states, one has to consider both symmetries and find invariant functions under these two symmetries. However, it is interesting to forget the S^1 invariance. This is equivalent to choosing in particular internal frame for the particle $\mathcal{P}_0$. Thus, one can capture interesting information concerning the particles: in particular one can define the momenta of each particle in the internal frame of the particle $\mathcal{P}_0$. This is obviously impossible if we do not choose a particular frame. Thus, one can interpret the particle $\mathcal{P}_0$ as an observer sitting somewhere in the surface Σ. This observer is measuring the physical characteristics of each particle and also the properties of the spacelike geometries in its reference frame. G-invariant states defined in this reference frame are not kinematical states in the sense of LQG; in the sequel they arecalled partial kinematical states. The set of partial kinematical states is naturally endowed with a pre-Hilbert structure. Its completion is called the partial kinematical Hilbert space and is denoted $\mathcal{H}_{\mathrm{Pkin}}$. Note that one can extend the space $\mathcal{H}_{\mathrm{Pkin}}$ to distributions in the sense that one can choose the element ψ defining the spin-network to be a distribution rather than a function. In that case, one can define pure momenta states for instance as "delta" functions. As the manifold under consideration (G or S^2) is compact, we will identify the space of function with the space of distributions on this manifold. We keep this remark in mind for the following.

Proposition 1 (partial kinematical Hilbert space): *The Hilbert space of partial kinematical states* $\mathcal{H}_{\mathrm{Pkin}}$ *is isomorphic to the space* $\mathrm{Fun}(G^{2g}\otimes(S^2)^{n-1})$ *endowed with the measure* $\mathrm{d}\mu_G^{\otimes 2g}\otimes\mathrm{d}\mu_{S^2}^{\otimes(n-1)}$. *Indeed, a function* $\psi\in\mathcal{H}(\gamma;G)$ *is a partial kinematical state if and only if there exists a function* $f\in\mathrm{Fun}(G^{2g}\otimes(S^2)^{n-1})$ *such that*

$$\psi(A)=f\left(\bigotimes_{a,b}\Lambda_0^{-1}U_a\Lambda_0\otimes\Lambda_0^{-1}U_b\Lambda_0\bigotimes_{e=1}^{n-1}\Lambda_0^{-1}U_c\tilde{\Lambda}_e\right), \tag{19}$$

where $\tilde{\Lambda}_e=f\mathrm{d}h\Lambda_e h\in S^2$ *and* $\mathrm{d}h$ *is the measure on the Carton torus of G. We have used the notation* $g\tilde{\Lambda}=f\mathrm{d}hg\Lambda h$ *for the action of the group element* $g\in\mathrm{SU}(2)$ *on a point* $\tilde{\Lambda}\in\mathrm{S}^2$.

Proof: First, let us impose the invariance under the action of G on the boundary $\mathcal{B}_e$ associated to any particle $\mathcal{P}_e$ but the observer $\mathcal{P}_0$. The group G acts nontrivially on the degrees of freedom Λ_e and U_e according to the following maps (12):

$$\forall g\in G\Lambda_e\mapsto g\Lambda_e,\quad U_e\mapsto U_e g^{-1}. \tag{20}$$

This action induces a co-action on $\mathrm{Cyl}(\gamma;G)$ and it is obvious that any function $\psi\in\mathrm{Cyl}(\gamma;G)$ is co-invariant if and only if it is a function of $U_e\lambda_e$. This results holds for any particle $e\neq 0$. The action of G at the boundary $\mathcal{P}_0$ is more involved because there are many edges ending and starting

at $\mathcal{P}_0$. But the conclusion is similar because any function ψ which is G invariant at $\mathcal{P}_0$ can be written as a sum of functions of the variables $\Lambda_0^{-1}U_e$, $\Lambda_0^{-1}U_a\Lambda_0$ and $\Lambda_0^{-1}U_b\Lambda_0$. To prove this point, we decompose the function ψ into (tensor product of) irreducible unitary finite dimensional representations (irreps) of Gusing the Plancherel formula and we obtain

$$\psi(A) = \sum_{[I],[j],[k]} \overset{[I]}{f}{}^{[k]}_{[j]}(\Lambda_e) \prod_{\ell} \overset{I_\ell}{\pi}{}^{j_\ell}_{k_\ell}(U_\ell) \times \overset{I_0}{\pi}{}^{j_0}_{k_0}(\Lambda_0). \tag{21}$$

$[I] \in (\frac{1}{2}\mathbb{N})^{2g+n}$ are SU(2) irreps labeling the edges ℓ (for the links e and the noncontractible loops a,b) and the reference particle $\mathcal{P}_0$;$[j]$ and $[k]$ are families of magnetic numbers. We have denoted $\overset{I}{\pi}{}^{j}_{k} = \langle \overset{I}{e}{}^{j} | \overset{I}{\pi} | \overset{I}{e}_{k} \rangle$, the matrix elements of irreps of SU(2). $\overset{I}{V}$ is the vector space associated to the spin I representation and $\overset{I}{e}_i$, (respectively, $\overset{I}{e}{}^i$) the (respectively dual) basis of $\overset{I}{V}$ (respectively, $\overset{I}{V}{}^*$)The dependence in the variables $\Lambda_e, e \neq 0$, is contained in the definitions of the Fourier components $\overset{[I]}{f}{}^{[k]}_{[j]}(\Lambda_e)$. The decomposition (21) is nothing else but the spin-network decomposition of the state.

The G invariance at $\mathcal{P}_0$ implies that there exists a G intertwiner ι defined by

$$\iota \in \mathrm{Hom}\left(\overset{I_0}{V} \otimes \bigotimes_{\ell=1}^{2g+n-1} \overset{I_\ell}{V}; \bigotimes_{a,b=1}^{g} \overset{I_a}{V} \otimes \overset{I_b}{V} \right) \otimes \left(\overset{I_0}{V} \otimes \bigotimes_{\ell=1}^{n-1} \overset{I_e}{V} \right)^* \quad \text{such that}$$

$$\overset{[I]}{f}{}^{[k]}_{[j]} = \left\langle \bigotimes_{a,b=1}^{g} \overset{I_a}{e}{}^{k_a} \otimes \overset{I_b}{e}{}^{k_b} \middle| \iota \left(\overset{I_0}{e}{}^{k_0} \otimes \bigotimes_{e=1}^{n-1} \overset{I_e}{e}{}^{k_e} \right) \middle| \overset{I_0}{e}_{i_0} \otimes \bigotimes_{\ell=1}^{2g+n-1} \overset{I_\ell}{e}_{j_\ell} \right\rangle. \tag{22}$$

In the language of LQG, we color the vertex $\mathcal{P}_0$ with the intertwiner ι. Due to the invariance of the intertwiner ι, we have

$$\psi(A) = \sum_{[I],[j],[k]} \overset{[I]}{f}{}^{[k]}_{[j]}(\Lambda_e) \delta^{j_0}_{k_0} \prod_a \overset{I_a}{\pi}{}^{j_a}_{k_a}(\Lambda_0^{-1}U_a\Lambda_0) \prod_b \overset{I_b}{\pi}{}^{j_b}_{k_b}(\Lambda_0^{-1}U_b\Lambda_0) \prod_e \overset{I_e}{\pi}{}^{j_e}_{k_e}(\Lambda_0^{-1}U_e). \tag{23}$$

Then, we impose the G invariance at the location of each particle and we obtain in the same way that

$$\psi(A) = \sum_{[I],[j],[k]} \overset{[I]}{f}{}^{[k]}_{[j]}(1) \delta^{j_0}_{k_0} \prod_a \overset{I_a}{\pi}{}^{j_a}_{k_a}(\Lambda_0^{-1}U_a\Lambda_0) \prod_b \overset{I_b}{\pi}{}^{j_b}_{k_b}(\Lambda_0^{-1}U_b\Lambda_0) \prod_e \overset{I_e}{\pi}{}^{j_e}_{k_e}(\Lambda_0^{-1}U_e). \tag{24}$$

Finally, the invariance under the action of $\mathcal{C}$ on each (spinless) particle but the observer implies directly that $k_e=0$ for all $e=1,\ldots,n-1$. Yet $\overset{I}{\pi}{}^{j}_{0}$ are functions on the sphere $G/(U)(1)$ (spherical harmonic functions) and we can write them as follows:

$$\forall g \in \mathrm{SU}(2), \quad \overset{I}{\pi}(g)^j_0 = \int \mathrm{d}h \overset{I}{\pi}(gh)^j_0 \quad \text{where } h \in \mathrm{U}(1). \tag{25}$$

The space of such invariant functions will be denoted $\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma;G)$. It inherits the measure from $\mathrm{Cyl}(\gamma;G)$ due to left and right invariance of the Haar measure and then it possesses a natural pre-Hilbert structure. Its completion is the partial kinematical Hilbert space $H_{\mathrm{pkin}}(\gamma;G)$ and it is a sub-Hilbert space of $\mathcal{H}(\gamma;G)$.

Moreover, it is straightforward to show that any element of $\mathrm{Fun}(G^{2g} \otimes (S^2)n-1)$ is a kinematical partial Hilbert space. Finally, the proposition (1) follows immediately. □

Let us propose several remarks concerning the partial kinematical Hilbert space.

1. Note that one can precisely state the proposition in the sense that the isomorphism holds when the partial kinematical Hilbert space is defined with elements ψ which are distributional for

the observer variable and functional for the others. To clarify this claim, let us illustrate it in the case of the sphere with particles. Indeed, the fact that the observer is colored with an intertwiner means that any spin-network states can be written as

$$\psi(A) = \int \mathrm{d}g f(\Lambda_0 g, \Lambda_1 g, \ldots, \Lambda_{n-1} g). \tag{26}$$

It is then clear that to make $\psi(A)$ a function on $(S^2)^{n-1}$, it is enough to require that f is a distribution on the first argument and a function for the others. We implicitly made this asumption in the proof of the proposition.

2. We underline the fact that the proposition (1) is valid whatever the choice of observer among the different particles. Indeed, each partial kinematical Hilbert space is isomorphic one to the other. In fact, the previous proposition is still valid when the base point x is not a point of $\partial\Sigma$. To understand this point, we recall that $\mathcal{H}_{\mathrm{pkin}}(\gamma, G)$ is a sub-Hilbert space of $\mathcal{H}(\gamma; G)$ and there exists a projector $P_{\mathrm{Pkin}}: \mathcal{H}(\gamma; G) \to \mathcal{H}_{\mathrm{Pkin}}(\gamma; G)$ given by a product $P_{\mathrm{Pkin}} = P_C \cdot P_{\mathcal{C}}$ defined by

$$(P_G \psi)(A) = \int \mathrm{d}y \prod_{j=0}^{n-1} \mathrm{d}y_j f\left(\bigotimes_{a,b=1}^{g} y^{-1} U^{-1} U_a y \otimes y^{-1} U_b y \otimes \bigotimes_{i,e=0}^{n-1} y^{-1} U_e y_e \otimes y_i^{-1} \Lambda_i \right), \tag{27}$$

$$(P_{\mathcal{C}} \psi)(A) = f \prod_{j=0}^{n-1} \mathrm{d}h_j f\left(\bigotimes_{a,b-1}^{g} U_a \otimes U_b \otimes \bigotimes_{i,e=0}^{n-1} U_e \otimes \Lambda_i h_i \right), \tag{28}$$

for any $\psi \in \mathcal{H}(\gamma; G)$ associated to a function $f \in \mathrm{Fun}(G^{2(g+n)})$. Note that $\mathrm{d}y$ or $\mathrm{d}y_i$ is the Haar measure on the group G and $\mathrm{d}h_i$ the Haar measure on the group S^1. Thus, any state $\tilde{\psi} \in \mathcal{H}(\gamma; G)$ is a partial kinematical state if there exists a state $\psi \in \mathcal{H}(\gamma; G)$ associated to a function $f \in \mathrm{Fun}(G^{2(g+n)})$ such that

$$\tilde{\psi}(A) = (P\psi)(A) = (P_G \cdot P_C \psi)(A). \tag{29}$$

Therefore, after some calculations it is direct to see that there exists $j \in [0, n-1]$ such that

$$\tilde{\psi}(A) = \tilde{f}\left(\bigotimes_{a,b=1}^{g} \Lambda_j^{-1} U_j^{-1} U_a U_j \Lambda_j \otimes \Lambda_j^{-1} U_j^{-1} U_b U_j \Lambda_j \otimes \bigotimes_{e \neq j} \Lambda_j^{-1} U_j^{-1} U_e \tilde{\Lambda}_e \right) \tag{30}$$

where the function $\tilde{f} \in \mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1})$ is related to the function f by

$$\tilde{f}\left(\bigotimes_{a,b=1}^{g} U_a \otimes U_b \otimes \bigotimes_{e \neq j} U_e \right) \equiv \int \mathrm{d}y \prod_{j=0}^{n-1} \mathrm{d}y_j \mathrm{d}h_j,$$

$$f\left(\bigotimes_{a,b=1}^{g} y^{-1} (U_j \Lambda_j)^{-1} U_a U_j \Lambda_j y \otimes y^{-1} (U_j \Lambda_j)^{-1} U_b U_j \Lambda_j y \otimes \bigotimes_{e,i=0}^{n} y^{-1} (U_j \Lambda_j)^{-1} U_e \Lambda_e h_e \otimes 1 \right).$$

The choice of j corresponds to the choice of the observer. Therefore, the proposition (1) is valid for any choice of the base point. In the sequel, we will assume that the observer is the particle $\mathcal{P}_0$.

3. The final remark is that one can recover the kinematical Hilbert space from the partial kinematical Hilbert space as follows:

$$\mathcal{H}_{\mathrm{kin}}(\gamma; G) = \mathcal{H}_{\mathrm{Pkin}}(\gamma; G)/S^1, \tag{31}$$

where S^1 is the symmetry group which acts by right multiplication on the variable Λ_0 (13).

The next step is the construction of the partial physical Hilbert space $\mathcal{H}_{\mathrm{Pphys}}(\gamma; G)$. For that purpose, we start by defining the extractor $P: \mathrm{Cyl}(\gamma; G) \to \mathrm{Cyl}^*(\gamma; G)$ formally defined by

$$\forall \varphi, \psi \in \mathrm{Cyl}(\gamma; G), \quad P(\psi)(\varphi) \equiv \int \mathrm{d}\mu[A] \overline{\psi(A)} \mathcal{K}(A) \varphi(A). \tag{32}$$

The measure on the space of discrete connections $\mathcal{A}_\gamma$ is constructed from the SU(2) Haar measure $\mathrm{d}\mu$ via the relation $\mathrm{d}\mu[A] = \mathrm{d}\mu^{\otimes 2(g+n)}$ for $\mathcal{A}_\gamma$ is isomorphic to $2(g+n)$ copies of SU(2). The Kernel $\mathcal{K}$ is a distribution defined by

$$\mathcal{K}[A] \equiv \delta\left(\Lambda_0 h(m_0) \Lambda_0^{-1} \prod_{e=1}^{n-1} U_e \Lambda_e h(m_e) \Lambda_e^{-1} U_e^{-1} \prod_{(a,b)} [U_a, U_b] \right). \tag{33}$$

We have introduced the usual notation $[U_a, U_b] = U_a U_b U_a^{-1} U_b^{-1}$; (a,b) denotes the set of the pairs of noncontractible loops; and the elements $h(m_e)$ are in the Cartan (diagonal) torus of SU(2) fixed by the mass m_e by $h(me) = \mathrm{diag}(e^{+ime}, e^{-ime})$ in the SU(2) fundamental representation.

The extractor P defines a bilinear form on the space $P(\mathrm{Cyl}(\gamma; G)) \subset \mathrm{Cyl}(\gamma; G)^*$; it is denoted $\langle ; \rangle$ and is given by

$$\forall \psi, \varphi \in \mathrm{Cyl}(\gamma; G), \quad \langle P(\psi); P(\varphi) \rangle \equiv P(\psi)(\varphi). \tag{34}$$

In fact, this bilinear form defines a scalar product for it satisfies the following properties:

1. It is definite positive: the kernel $\mathcal{K}$ is a delta distribution on the group and therefore can be obtained as a limit of positive functions on G.

2. It is convergent as soon as the stability condition $2g+n-1>0$ is satisfied; we have the following bound:

$$\langle P(\varphi), P(\psi) \rangle \leq \|\varphi\| \cdot \|\psi\| \frac{1}{\prod_{e=0}^{n-1} \sin(m_e)} \sum_{k=1}^{\infty} \frac{\prod_{e=0}^{n-1} \sin(k m_e)}{k^{2g+n-2}}. \tag{35}$$

We have introduced the notation $\|\cdot\|$ for the L^2 norm on the group SU(2). The bound (35) is a direct consequence of the Plancherel theorem for SU(2) and of the expression of the SU(2) character in any $I \in \frac{1}{2}\mathbb{N}$ irrep, i.e., $X_I(H(m_e)) = \sin((2I+I)m_e)/\sin(m_e)$.

The vector space of partial physical states is defined by $P(\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma; G))$. It is clear that the kernel $\mathcal{K}$ is in fact a distribution on the space $\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma; G)$ and therefore $P(\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma; G)) \subset \mathrm{Cyl}_{\mathrm{Pinv}}(\gamma; G)^*$. In particular, the kernel $\mathcal{K}$ is co-invariant under the transformations $\Lambda_e \mapsto \Lambda_e h_e$ for any e and $h_e \in U(1) \subset (\mathrm{SU})(2)$. Thus, $\mathcal{K}$ depends only on the equivalent classes $\tilde{\Lambda}_e \equiv \int \mathrm{d}h_e \Lambda_e h_e \in S^2$ where $\mathrm{d}h_e$ is the U(1) Haar measure. For convenience, it will be useful to introduce the notation $\mathrm{d}\tilde{\Lambda}$ for the normalized measure on the two-sphere.

The bilinear form (34) defines a pre-Hilbert structure on $P(\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma; G))$ whose completion (up to null-vectors) is the partial physical Hilbert space $\mathcal{H}_{\mathrm{Pphys}}(\gamma; G)$. When restricted on $\mathcal{H}_{\mathrm{Pphys}}(\gamma; G)$, the scalar product (34) is called the partial physical scalar product and is denoted $\langle ; \rangle$Pphys.

Proposition 2 (partial physical Hilbert space): *Let* $f \in \mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1})$. *One defines a partial physical state* $P(\psi)$ *where* $\psi \in Cyl_{Pinv}(\gamma; G)$ *was introduced in Proposition* 1. *Therefore*, *there is a map*

$$\mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1}) \to \mathcal{H}_{\mathrm{Pphys}}(\gamma; G).$$

When $\mathrm{Fun}(G^{2g} \times (S^2)^{n-1})$ *is endowed with the following Hilbert structure*:

$$\forall f, g \in \mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1}),$$

$$(f, G) \equiv \int \mathrm{d}a \mathrm{d}b \mathrm{d}\tilde{z} \overline{f(a,b,\tilde{z})} \delta\left(h(m_0) \prod_{e=1}^{n-1} z_e h(m_e) z_e^{-1} \prod_{i=1}^{g} [a_i, b_i] \right) g(a,b,\tilde{z}),$$

the previous map is an isometry. Note that we have introduced the notation $a=(a_i)_i,(b_i)_i,z=(z_e)_e$, *and* $\mathrm{d}a=\Pi_a a_i, \mathrm{d}_b=\Pi_i \mathrm{d}b_i$ *for the measures.*

Proof: The proof of Proposition 1 tells us that any invariant cylindrical function ψ is completely characterized by a function $f \in \mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1})$ (to be more precise, the vector space $\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma;G)$ corresponds to the set of polynomial functions on $G^{2g} \otimes (S^2)^{n-1}$ and after completion with respect to the kinematical measure one sees $\mathrm{Cyl}_{\mathrm{Pinv}}(\gamma;G)$ as the set of functions on $G^{2g} \otimes (S^2)^{n-1}$).

Yet, by definition, the partial physical Hilbert space $\mathcal{H}_{\mathrm{pphys}}(\gamma;G)$ is the image of $\mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1})$ by the operator P and then any elemental of $\mathcal{H}_{\mathrm{Pphys}}(\gamma;G)$ can be written as $\mathcal{K}[A]\psi(A) \in \mathrm{Cyl}_{\mathrm{Pinv}}(\gamma;G)^*$. It is then natural to identify $\mathcal{H}_{\mathrm{Pphys}}(\gamma;G)$ with the space $\mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1})$.

The last point of the proposition is a direct consequence of the right/left invariances of the SU(2) Haar measure. □

Let us finish this section with some remarks.

Remark 1: The isometry given in the previous proposition holds for any choice of minimal graph γ and any choice of observer. Partial physical Hilbert spaces $\mathcal{H}_{\mathrm{Pphys}}(\gamma;G)$ where γ is any minimal graph are isomorphic one to the other and therefore are equivalent. For that reason, we will use the notation $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ to denote the partial physical Hilbert space where $[m]=(m_0,\ldots,m_{n-1})$. We have emphasized the explicit characteristics of the partial physical Hilbert space: the topological structure of Σ, the colors of the boundaries, i.e., the masses of the particles and the gauge group G of course.

Remark 2: The order of the particles matters in the definition of $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$. The space $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ is completely and uniquely characterized by a given flat graph of the type of Fig. 4 where there is an order between the links. If one modifies the order between the links, then the definition of the structure of the partial physical Hilbert space is slightly modified. However, two different orders define isomorphic partial physical Hilbert space. For instance, if we consider a sphere $\Sigma=S^2$ with three particles associated to the masses (m_0,m_1,m_2), then the following map is an isometry:

$$\mathcal{H}^{0.3}_{\mathrm{Pphys}}(m_0,m_1,m_2;G) \to \mathcal{H}^{0.3}_{\mathrm{Pphys}}(m_0,m_1,m_2;G),$$

$$f \mapsto g:(\tilde{z}_1,\tilde{z}_2) \mapsto g(\tilde{z}_1,\tilde{z}_2)=f(\tilde{z}_1,z_1 h(m_1)^{-1} z_1^{-1}\tilde{z}_2). \tag{36}$$

It is indeed easy to verify that $\|f\|_{\mathrm{Pphys}}=\|g\|_{\mathrm{Pphys}}$. One can establish a more general property that we will discuss in the next section.

Remark 3: The physical Hilbert space $\mathcal{H}^{g,n}_{\mathrm{phys}}([m];G)$ is easily obtained as the coset:

$$\mathcal{H}^{g,n}_{\mathrm{phys}}([m];G) \equiv \mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)/S^1.$$

The action of S^1 on $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ is naturally defined by

$$S^1 \times \mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G) \to \mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G), \tag{37}$$

$$(h,f) \mapsto f^h:y,\tilde{z} \mapsto f^h(a,b,\tilde{z})=f(h^{-1}ah,h^{-1}bh,h^{-1}\tilde{z}). \tag{38}$$

We have used the notations of Proposition 2 with $h^{-1}ah-(h^{-1}a_i h)_i$ and so on. Therefore, the physical Hilbert space is obviously a sub-Hilbert space $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ and can be obtained as the image of the following projector:

$$\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G) \to \mathcal{H}^{g,n}_{\mathrm{phys}}([m];G), \quad f \to \tilde{f}(a,b,\vec{z}) = \int \mathrm{d}h f(h^{-1}ah, h^{-1}bh, h^{-1}\vec{z}). \tag{39}$$

This is in fact a trivial application of refined algebra techniques in the compact S^1 case. The Hilbert structure of $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ is defined from this map as the kernel $\mathcal{K}$ is invariant by the action (37).

Remark 4: From the very definition of the partial physical Hilbert space as a subset of $\mathrm{Cyl}(\gamma;G)^*$, $\mathcal{H}^{g,n}_{\mathrm{Pphys}}(\gamma;G)$ is in fact a subset of $\mathbb{C}[G]^{2g} \otimes \mathbb{C}[S^2]^{n-1}$ where $\mathbb{C}[G]$ is the group algebra and $\mathbb{C}[S^2] = \mathbb{C}[G]/\mathrm{U}(1)$ is called the two-sphere algebra. The group algebra is defined as the algebra of formal sum of group elements. As G is compact there is a trivial isomorphism which identifies the spaces $\mathbb{C}[G]^{2g} \otimes \mathbb{C}[S^2]^{n-1}$ and $\mathrm{Fun}(G^{2g} \otimes (S^2)^{n-1})$.

Remark 5: Let us recall that any particle $e \in [0, n-1]$ is classically completely characterized by its mass m_e and the direction of its momentum given by Λ_e. The particle $\mathcal{P}_0$ plays the role of the observer and the variable Λ_0 does not appear anymore in the definition of partial physical states. One can interpret this observation by the fact that we work in the rest-frame of the observer and then Λ_0 is set to the identity: the momenta of the other particles are defined in that frame.

Besides, one can characterize the particle e by an element $k_e \in G$ such that $k_e = \Lambda_e h(m_e) \Lambda_e^{-1}$, i.e., k_e is an element of the conjugacy class of the element $h(m_e)$, denoted $C(m_e)$:

$$C(m_e) \equiv \{k \in \mathrm{SU}(2) \,|\, \exists\, y \in \mathrm{SU}(2), \text{ such that } k = y h(m_e) y^{-1}\}. \tag{40}$$

Thus, any element of $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ can be viewed as an element of $\mathrm{Fun}(G^{2g} \otimes \otimes_{e=1}^{n=1} C(m_e))$. Using the Kirillov formula for the Su(2) Haar measure,

$$\mathrm{d}k_e = \frac{1}{\pi} \sin^2(m_e) \mathrm{d}m_e \mathrm{d}\tilde{\Lambda}_e, \tag{41}$$

the partial physical scalar product between two states ψ and φ respectively associated to the functions f and g is then given by

$$\langle \psi; \varphi \rangle_{\mathrm{Pphys}} = (f,g) = \frac{\pi^{n-1}}{\prod_{e=1}^{n-1} \sin^2(m_e)} \int \mathrm{d}u \mathrm{d}k \overline{f(a,b,k)} \delta\left(h(m_0) \prod_{i=1}^{n-1} k_e \prod_{i=1}^{g} [a_i, b_i] \right) g(a,b,k). \tag{42}$$

We recall that the functions f and g are non-null if $g_e \in C(m_e)$. This reformulation of the partial physical Hilbert space will be convenient in the next section.

Remark 6: The last remark concerns the normalization of the partial physical scalar product, defined only up to a constant $\lambda(g,n,[m]) > 0$. The constant depends *a priori* on the genus g of Σ, the number of particles n, and the masses of the particles. By a direct calculation, one shows that the squared norm of the identity function $e^{g,n}[m] \in \mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ is given by the volume of the space of flat SU(2) connections on the punctured surface Σ, i.e.,

$$\| e^{g,n}[m] \|^2_{\mathrm{Pphys}} = \lambda(g,n,[m]) \sum_{k=1}^{+\infty} k^{2-2g-n} \prod_{e=0}^{n-1} \frac{\sin(k m_e)}{\sin(m_e)}. \tag{43}$$

At this point, there is no physical reason to impose the value of λ. But, we can show that the value of $\lambda(g,n,[m])$ is completely determined by the coefficients $\lambda(0,3,[m])$ and the problem to fix it reduces to the fixation of the normalization factor in the (minimal) case of the sphere with three punctures. The method is similar to the one proposed in Ref. 1 and is given in Appendix B: if we assume that $\lambda(0,3,[m]) = \lambda$ is a constant independent of the masses, then we show that $\lambda(g,n,[m]) = \lambda^{n+2g-2}$.

III. TRANSITION AMPLITUDES AND THE QUANTUM DOUBLE

In the following, we are going to show how the Drinfeld double DSU(2) structure appears in the context of three-dimensional Riemannian gravity coupled to massive point particles: the partial physical Hubert space is in fact isomorphic as a Hilbert space to a tensor product of simple representations of DSU(2). In that picture, the partial physical scalar product between two states is an intertwining coefficient between simple representations. Thus, the so-called Barrett-Crane (BC) intertwiner[4] plays a crucial role in three-dimensional quantum gravity whereas it was introduced as a model of four-dimensional gravity.

The following is organized as follows. First, we recall basic facts concerning the Drinfeld double DSU(2): definition, representation theory. We also introduce the notion of simple representation and symmetric (or BC) intertwiner. Then, we show the role of DSU(2) in the case of a sphere with n particles: DSU(2) appears as the symmetry group of the quantum theory and the nontrivial braiding is interpreted in the language of LQG. Finally, we generalize the previous results in the case of any Riemann surface Σ.

A. The quantum double DSU(2): Definition and properties

The general definition of the quantum double (or the Drinfeld double) of a Hopf algebra A is briefly recalled in Appendix A. The general definition is then illustrated in the generic case of a finite group.[10] Here, we consider the case of the compact group SU(2), i.e., the case where $A = \mathbb{C}[\mathrm{SU}(2)]$.[18]

The Drinfeld double $\mathrm{DSU}(2) = \mathbb{C}[\mathrm{SU}(2)] \otimes F(\mathrm{SU}(2))^{\mathrm{op}}$ is a Hopf algebra whose definition is precisely given in the appendix. In particular, it is quasitriangular and admits the group algebra $\mathbb{C}[\mathrm{SU}(2)]$ and the algebra of functions $F(\mathrm{SU}(2))^{\mathrm{op}}$ (with opposite co-product) as sub-Hopf algebra.

1. Hopf algebra structure

The Hopf algebra structure of $\mathbb{C}[\mathrm{SU}(2)]$ is defined by the group law and the following co-algebra relations:

$$\forall x \in \mathrm{SU}(2), \quad \Delta(x) = x \otimes x, \quad S(x) = x^{-1}, \quad \epsilon(x) = \delta(x). \tag{44}$$

Note that there exists a right and left invariant Haar measure on $\mathbb{C}[\mathrm{SU}(2)]$ given by

$$h : \mathbb{C}[\mathrm{SU}(2)] \longrightarrow \mathbb{C}, \quad h(x) = \delta(x). \tag{45}$$

The algebra of functions $F(\mathrm{SU}(2))$ is commutative and its coalgebra structure is given by

$$\Delta(f)(x,y) = f(xy), \quad S(f)(x) = f(x^{-1}), \quad \epsilon(f) = f(1), \tag{46}$$

where f is a function and $x, y \in G$. We know that $F(\mathrm{SU}(2))$ admits a Haar measure that we have denoted $\int \mathrm{d}x$ as usual.

Finally, the Drinfeld double is defined by the previous formulas and the following ones (which are a direct application of the definition given in the appendix):

$$(x \otimes f)(y \otimes g) = xy \otimes (f \circ Ad_y)g, \tag{47}$$

$$\Delta(x \otimes f)(a,b) = f(ba)x \otimes x, \tag{48}$$

where $f, g \in F(\mathrm{SU}(2))$, $x, y, a, b \in \mathrm{SU}(2)$. The action of the antipode reads

$$S(x \otimes f)(a) = x^{-1} \otimes f(x^{-1}a^{-1}x) \tag{49}$$

for any $a \in G$ and the co-unit is simply given by $\epsilon(x \otimes f) = f(1)$.

2. Representation theory

Unitary irreducible representations of DSU(2) have been studied in Ref. 18 and are classified by a couple $(m,s):m\in[0,2\pi]$ labels a conjugacy class of SU(2), denoted $C(m)$, whose representative is still chosen to be $h(m);s\in\mathbb{Z}$ is an integer which labels irreducible representations of the centralizer $Z(m)$ of the element $h(m)$. Note that $Z(m)\simeq \mathrm{U}(1)$ for $m\neq 0,2\pi$; otherwise $Z(m)$ is obviously the group $G=\mathrm{SU}(2)$ itself. In the generic case $m\neq 0,2\pi$, the vector space of a representation (m,s) consists in the subspace of functions on SU(2) defined by

$$\mathcal{V}_{m,s}\equiv\{\varphi:SU(2)\to\mathbb{C}|\ \forall\ a\in SU(2),\varphi(ah_m)=e^{\mathrm{ism}}\varphi(a)\}. \tag{50}$$

The representation of any element $(x\times f)\in\mathrm{DSU}(2)$ on the above-noted vector space is defined by

$$(\pi_{m,s}(x\otimes f)\varphi)(a)=f(ah_ma^{-1})\varphi(x^{-1}a). \tag{51}$$

The vector space $\mathcal{V}_{m,s}$ inherits a natural Hilbert space structure. The particular case $m\in\{0,2\pi\}$ has been considered in Ref. 18. In the sequel, we use the notation $\bar{m}=2\pi-m$.

3. Simple representations and symmetric intertwiners

Representations of the form $(m,0)$ are called simple representations[14] and are the building blocks of the Barrett-Crane model.[4] The vector space of a simple representation is isomorphic to the space of functions on the sphere $S^2=\mathrm{SU}(2)/\mathrm{U}(1)$. Any simple representation admits a normalized SU(2)-invariant vector denoted $\omega=1$. The vector space associated to a simple representation m will be denoted $\mathcal{V}_m$ (we omit the subscript 0 for the spin). It is obvious that $\mathcal{V}_m\simeq\mathrm{Fun}(S^2)$ and we will identify in the following the spaces $\mathcal{V}_m$ and the conjugacy class $C(m)$ which contains the information on the mass. We will use the same notation $\psi(\tilde{x})$ or $\psi(xh(m)x^{-1})$ for the state ψ when viewed as an element of $\mathrm{Fun}(S^2)$ or an element of $C(m)$.

The notion of symmetric intertwiner (or the Barrett-Crane intertwiner) was introduced a long time ago[4,14] and is defined as an intertwiner between simple representations whose decomposition into three-valent intertwiners introduces only simple representations in the intermediate channel. Up to a normalization, the simple intertwiner is unique.[29]

There exists an integral formulation of the symmetric intertwiner. To present this formulation, we need to recall the definition ofthe symmetric propagator.[14]

Given a simple representation labeled by m, the symmetric kernel K_m is an element of $F(\mathrm{SU}(2))^*\subset\mathrm{DSU}(2)^*$ defined by

$$K_m:F(\mathrm{SU}(2))\to\mathbb{C},\quad f\mapsto K_m(f)=\int \mathrm{d}x f(xh(m)x^{-1}). \tag{52}$$

It is convenient and equivalent to view (by duality) the symmetric kernel as an element of $\mathbb{C}[\mathrm{SU}(2)]$ as follows:

$$K_m=\int \mathrm{d}x\mathbb{I}_m(x)x\quad\text{with}\quad \mathbb{I}_m(x)=\int \mathrm{d}y\,\delta(xyh(\bar{m})y^{-1}). \tag{53}$$

Note that $\mathbb{I}_m$ is the characteristic function of the conjugacy class $C(m)$ and can be decomposed into Fourier modes as follows:

$$\mathbb{I}_m(x)=\sum_{I\in(1/2)\mathbb{N}}\chi_I(m)\chi_I(x)\quad\text{with}\quad \chi_I(m)\equiv\chi_I(h(m)). \tag{54}$$

If K_m had been a function on a "classical" group G, we would have defined the "classical" propagator as the function $K(x,y)\equiv K(xy^{-1})\in F(G)^{\otimes 2}$. In our case, the propagator, denoted $K_m(x,y)$, is an element of $\mathbb{C}[\mathrm{SU}(2)]^{\otimes 2}$ defined by

$$K_m(x,y) \equiv (1 \otimes S)\Delta(K_m) = \int \mathrm{d}x \mathbb{I}_m(x) x \otimes x^{-1}. \tag{55}$$

This propagator is the building block of the symmetric intertwiner whose construction is given next.[14] Let $[p]=(p_1,\ldots,p_a)$ and $[q]=(q_1,\ldots,q_b)$ be two ordered families of simple representations. One defines the symmetric intertwiner between the representations $[p]$ and $[q]$,

$$\iota_s([p];[q]): \overset{a}{\underset{i=1}{\otimes}} \mathcal{V}_{p_i} \to \overset{b}{\underset{j=1}{\otimes}} \mathcal{V}_{q_j},$$

by its matrix elements given by

$$\left\langle \overset{b}{\underset{\ell=1}{\otimes}} \varphi_i | \iota_s([p];[q]) \overset{a}{\underset{k=1}{\otimes}} \psi_k \right\rangle = h\left(\prod_{j=1}^{b} (\bar{\varphi}_j \otimes 1) K_{qj}(x_j,g) \prod_{i=a}^{1} (\psi_i \otimes 1) K_{pi}(y_i,g) \right), \tag{56}$$

where $\psi_i \in \mathcal{V}_{p_i}$ and $\varphi_j \in \mathcal{V}_{q_j}$ for any i or j. Note that h is the Haar measure on the group algebra $\mathbb{C}[\mathrm{SU}(2)]$ and the products in the formula (56) are ordered such that when one develops the expression, one obtains

$$\left\langle \overset{b}{\underset{\ell=1}{\otimes}} \varphi_\ell | \iota_s([p];[q]) \overset{a}{\underset{k=1}{\otimes}} \psi_k \right\rangle = \int \prod_{i,j} \mathrm{d}x_j \mathrm{d}y_i \mathbb{I}_{qj}(x_j) \overline{\varphi_j(x_j)} \delta\left(\prod_{\ell=1}^{b} x_\ell^{-1} \prod_{k=a}^{1} y_k \right) \mathbb{I}_{p_i}(y_i) \psi_i(y_i). \tag{57}$$

Let us propose several remarks concerning the symmetric intertwiner.

Remark 1: If one views the states ψ_i and φ_j as functions on the two-sphere, the previous formula reduce to the following one:

$$\left\langle \overset{b}{\underset{\ell=1}{\otimes}} \varphi_\ell | \iota_s([p];[q]) \overset{a}{\underset{k=1}{\otimes}} \psi_k \right\rangle = \int \prod_{j=1}^{b} \overline{\varphi_j(\tilde{x}_j)} \mathrm{d}\tilde{x}_j \prod_{i=1}^{a} \psi_i(\tilde{y}_i) \mathrm{d}\tilde{y}_i \delta\left(\prod_{l=1}^{b} x_l h(\bar{q}_l) x_l^{-1} \prod_{k=a}^{1} y_k h(p_k) y_k^{-1} \right).$$

In the particular (and singular) case where φ_ℓ and ψ_k are picked at the values $\tilde{x}_\ell$ and $\tilde{y}_k$ on the sphere, the symmetric intertwiner is a distribution given by

$$\left\langle \overset{b}{\underset{\ell=1}{\otimes}} \tilde{x}_\ell | \iota_s([p];[q]) \overset{a}{\underset{k=1}{\otimes}} \tilde{y}_k \right\rangle = \delta\left(\prod_{\ell=1}^{b} x_\ell h(\bar{q}_l) x_\ell^{-1} \prod_{k=a}^{1} y_k h(p_k) y_k^{-1} \right). \tag{58}$$

Remark 2: We easily show that the decomposition of the symmetric intertwiner introduces only simple representations in the intermediate channel. Using the previous notations, we have for instance:

$$\iota_s([p];[q]) = \frac{1}{\pi} \int \mathrm{d}r P(r) \iota_s(p_1,p_2;r) \circ \iota_s(\bar{r},p_3,\ldots,p_a;[q]), \tag{59}$$

where $\circ$ denotes the usual composition between intertwiners and $P(r)=\sin^2 r/\pi$ is the Plancherel measure.

Remark 3: Therefore, we concentrate for the moment on the three valent intertwiner $\iota_s(p;q_1,q_2): \mathcal{V}_p \to \mathcal{V}_{q_1} \otimes \mathcal{V}_{q_2}$. We start by saying that it is indeed an intertwiner, i.e., it satisfies the following identity:

$$\iota_s(p;q_1,q_2)(\pi_p(z \otimes f)) = (\pi_{q1} \otimes \pi_{q2}) \Delta(z \otimes f) \iota_s(p;q_1,q_2) \tag{60}$$

for any $z \otimes f \in \mathrm{DSU}(2)$. The symmetric intertwiner is not normalized and we define the coefficient $\Theta(p,q_1,q_2)$ such that the intertwiner $\Theta(p,q_1,q_2)^{-1/2} \iota_s(p;q_1,q_2)$ is normalized, i.e.,

$$\frac{1}{\sqrt{\Theta(p,q_1,q_2)\Theta(q_1,q_2,p')}}\iota_s(p;q_1,q_2)\circ\iota_s(q_1,q_2;p')=\frac{\delta(p-p')}{P(p)}i\mathrm{d}_{\mathcal{V}_p}. \tag{61}$$

A straightforward calculation shows that

$$\Theta(p,q_1,q_2)=\langle 1\otimes 1|\iota_s([p];[q])|1\rangle=\frac{\pi}{4}\frac{Y(p,q_1,q_2)}{4\sin p\sin q_1\sin q_2}, \tag{62}$$

where Y is the characteristic function of the set $\{(a,b,c)\,|\,a\leq b+c,b\leq c+a,c\leq a+b\}$.

Remark 4: From the previous remarks, it is easy to show that $\iota_s([p];[q])$ is an intertwiner, i.e., it satisfies

$$\iota_s([p];[q])\left(\otimes_{i=1}^{a}\pi_{p_i}\right)\Delta^{(a)}(z\otimes f)=\left(\otimes_{i=1}^{b}\pi_{q_i}\right)\Delta^{(b)}(z\otimes f)\iota_s([p];[q]). \tag{63}$$

We used the notation $\Delta^{(n)}$ defined by $\Delta^{(1)}=\Delta$ and $\Delta^{(n)}=(id\otimes\cdots\otimes id\otimes\Delta)\Delta^{(n-1)}$.

Remark 5: It is straightforward to extend the action of the symmetric intertwiner $\iota_s([p];[q])$ to the space $\mathrm{Fun}((S^2)^{\times a})$.

4. R-matrix and braiding

Another important property of the quantum double is its quasitriangularity. Indeed, the quantum double is, by construction, a quasitriangular Hopf-algebra and therefore admits an R-matrix. The universal expression of R is given by

$$R=\int \mathrm{d}g(g\otimes 1)\otimes(1\otimes\delta_g). \tag{64}$$

Then, we can evaluate the R-matrix on any pair of representations. We are particularly interested in the case of simple representations. Let (p,q) be a pair of simple representations, the evaluation of R in these representations is given by

$$R_{p,q}\equiv\pi_p\otimes\pi_q(R):\mathcal{V}_p\otimes\mathcal{V}_q-\to\mathcal{V}_q\otimes\mathcal{V}_p \tag{65}$$

such that, for any $\psi,\varphi\in\mathrm{Fun}(S^2)$, then:

$$R_{p,q}(\psi\otimes\varphi)(\tilde{x},\tilde{y})=\varphi(xh(\bar{p})x^{-1}\tilde{y})\psi(\tilde{x}), \tag{66}$$

where $g\tilde{x}$ means the action of $g\in\mathrm{SU}(2)$ on the point $\tilde{x}\in S^2$. The evaluation of the inverse R-matrix on simple representations is given by

$$R_{p,q}^{-1}(\psi\otimes\varphi)(\tilde{x},\tilde{y})=\varphi(\tilde{y})\psi(yh(q)y^{-1}\tilde{x}). \tag{67}$$

It is convenient to write the action of the R-matrix and of its inverse on the states viewed as functions on the conjugacy class. In that context, we do not need to specify the evaluation representation of the R-matrix (and its inverse R^{-1}) and we have

$$R(\psi\otimes\varphi)(x,y)=\varphi(x^{-1}yx)\psi(x),\quad R^{-1}(\psi\otimes\varphi)(x,y)=\varphi(y)\psi(yxy^{-1}). \tag{68}$$

It is then straightforward to extend the action of the R-matrix (and its inverse) to any function on $\mathrm{SU}(2)^{\otimes 2}$.

Note the important property that the symmetric intertwiner is invariant under braidings, i.e.,

$$\iota_s([p];[q])R^{\epsilon}_{p_i,p_{i+1}}=R^{\epsilon}_{q_j,q_{j+1}}\iota_s([p];[q])=\iota_s([p];[q]), \tag{69}$$

for any $i\in[1,a-1],j\in[1,b-1]$ (using the notations of the previous sections) and $\epsilon\in\{+1,-1\}$. This is known as the pivotal symmetry of the BC intertwiner.

B. Particles on the sphere S^2

We are going to show how the Drinfeld double appears in the context of 3D LQG coupled to point particles. This is in fact immediate and we have the following theorem:

Theorem 1 (the Drinfeld double in LQG): *Let* $[m]=(m_0,\dots,m_{n,\dots,1})$ *be the masses of n particles*; $[m]$ *also labels a family of simple representations of* DSU(2). *Let us define the trivial map between the partial physical Hilbert space* $\mathcal{H}^{0,n}_{\mathrm{Pphys}}([m];G)$ *and the tensor product* $\otimes_{i=0}^{n-1}\mathcal{V}_{\overline{m_i}} \simeq \mathrm{Fun}((S^2)^{\times n})$ *of simple representations as follows*:

$$\mathcal{F}:\mathcal{H}^{0,n}_{\mathrm{Pphys}}([m];G) \longrightarrow \bigotimes_{i=0}^{n-1}\mathcal{V}_{\overline{m_i}}, \quad \varphi\mapsto\mathcal{F}(\varphi):(\tilde{x}_0,\dots,\tilde{x}_{n-1})\mapsto\mathbb{I}(\tilde{x}_0)\varphi(\tilde{x}_1,\dots,\tilde{x}_{n-1}). \tag{70}$$

This map is obviously linear and is trivially extended to the algebra of functions. Moreover, the partial physical Hilbert space between two states φ *and* ψ *is given by*

$$\langle\varphi:\psi\rangle_{\mathrm{Pphys}} = \iota_s([\overline{m}];0)\big|\mathcal{F}(\overline{\varphi}\psi)\rangle. \tag{71}$$

Proof: This theorem is an immediate consequence of the results of the previous section. □

As a consequence, a (partial) physical state is a tensor product of vectors of simple representations of the quantum double DSU(2): each particle is represented by a vector of a simple representation. Therefore, the quantum double is the symmetry group of the quantum theory: given an element $x\otimes f\in\mathrm{DSU}(2)$, x is a rotation and f is a translation acting on a one-particle state. It is immediate to understand that the SU(2) part of the double generates rotations; to see that the $F(\mathrm{SU}(2))$ part generates translations, we take $\vec{a}\in\mathbb{R}^3$ and we consider the element $f_{\vec{a}}$ defined by $f_{\vec{a}}(x)=e^{i\vec{p}(x)\cdot\vec{a}}$ where $\vec{p}(x)=m\Lambda\vec{n}$ with $x=\Lambda h(m)\Lambda^{-1}$ ($\vec{n}$a unitary vector). It is clear that $f_{\vec{a}}$ acts on a state by translation.

Let us discuss some consequences of this theorem.

First of all, we note that physical processes conserve the momenta of each particle: a pure momenta state has a nontrivial physical amplitude with the same pure momenta state.

Next, we say some words concerning computation of expectation value of operators. An operator can be viewed as (a product of) the evaluation (on simple representations) of elements of DSU(2): such elements act naturally on $\mathcal{H}^{0,p}_{\mathrm{Pphys}}([m];G)$. Particular examples of operators are the multiplicative $m_i(f)$ and the derivative operator $\mathrm{d}_i(g)$, respectively, associated to a function f and a group element x acting on a given particle $i\in[1,n-1]$ as follows:

$$m_i(f)|\varphi> = f(\Lambda_i)\varphi(\Lambda_1,\dots,\Lambda_{n-1}), \quad \mathrm{d}_i(x)|\varphi> = \varphi(\Lambda_1,\dots,x\Lambda_i,\dots,\Lambda_{n-1}). \tag{72}$$

Note that the multiplicative operator can be naturally extended to the case where f is a distribution. In fact, any operator (in our sense) on the partial physical Hilbert space can be decomposed into a sum of products of these basic operators. We introduce a star (antilinear involutive) operator in the algebra of operator generated by $m_i(f)$ and $\mathrm{d}_i(x)$ as follows: $\mathrm{d}_i(x)^*=\mathrm{d}_i(x^{-1})$ and $m_i(f)^*=m_i(\overline{f})$.

An operator $\mathcal{O}$ is unitary in the partial physical Hilbert space if it satisfies the identity

$$\langle\varphi|\mathcal{O}\psi\rangle = \langle\mathcal{O}^*\varphi|\psi\rangle \tag{73}$$

for any state φ and ψ. Note that m_i is trivially an unitary operator in the partial physical Hilbert space whereas d_i is not in general. Both operators are unitary in the partial kinematical Hilbert space. To construct (nontrivial) unitary operator in the partial physical Hilbert space, one needs to consider braiding operators that are a particular combination of multiplicative and derivative operators. We will see their definition in the sequel.

There is a natural adjoint action DSU(2) on the set of operators defined by

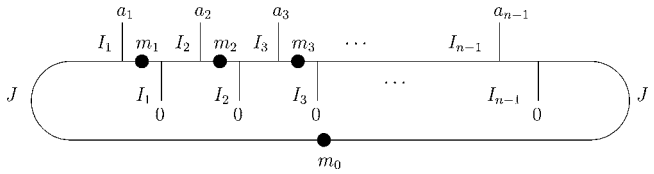

FIG. 5. Pictorial illustration of expression (78). The dot colored with the mass m denotes insertion of the element $h(m)$; any trivalent vertex denotes $(3j)$ coefficients of SU(2); each edge is colored with an irrep of SU(2) and can end up with a magnetic number like a_i or 0.

$$X \in \mathrm{DSU}(2), \quad X \triangleright \mathcal{O} = S(X_{(1)})\mathcal{O}X_{(2)}, \tag{74}$$

where we have used the Sweedler notation and $\mathcal{O}$ is an operator. This action is well-defined. Among the operators, one distinguishes particularly the so-called observables, i.e., the operators that are invariant under the action of the quantum double (74).

Given a physical process involving in and out states denoted φ_{in} and φ_{out}, the expectation value of any operator $\mathcal{O}$ during this process is given by

$$\langle \varphi_{\mathrm{out}}|\mathcal{O}|\varphi_{\mathrm{in}}\rangle_{\mathrm{Pphys}} = \iota([\bar{m}];0)|\mathcal{F}(\overline{\varphi_{\mathrm{out}}}\mathcal{O}\varphi_{\mathrm{in}})\rangle. \tag{75}$$

The mean value of any operator $\mathcal{O}$ is trivially given by

$$\langle \mathcal{O} \rangle \equiv \frac{\mathrm{Tr}(\mathcal{O})}{\mathrm{Tr}(1)} = \frac{\iota_s([\overline{m}];0)|\mathcal{F}(\mathcal{O})\rangle}{\mathrm{Tr}(1)}. \tag{76}$$

Mean values of any operator are therefore given by coefficients of simple intertwining coefficients.

Interesting operators are the monodromy around the particles and their trace are quite easy to compute. Given a finite dimensional representation K of SU(2) and a loop ℓ around p particles among the $n-1$ particles (let us denote by α_ℓ the set of particles), a monodromy $M_K(\ell)$ is defined by $M_K(\ell)=\chi_K(H_\ell)$ where the expression of the holonomy H_ℓ depends on the choice of the loop ℓ. If ℓ_i is a loop around the particle i, then $M_K(\ell_i)$ is obviously a diagonal operator whose mean value is given by the character $\langle M_K(\ell_i)\rangle=\chi_K(m_i)$. In the case where ℓ is any loop, the computation of the mean value is more involved but the result does not depend on the homotopy class of the loop $\ell$and is given by

$$\mathrm{Tr}(M_K(\ell)) = \sum_{I,J} Y(I,J,K)\mathrm{d}_I\mathrm{d}_J \prod_{i\notin\alpha_\ell} \frac{\chi_I(h(m_i))}{d_I} \prod_{j\in\alpha_\ell} \frac{\chi_J(h(m_j))}{\mathrm{d}_J} \tag{77}$$

where $Y(I,J,K)=1$ if I,J,K satisfy triangular inequalities and $Y(I,J,K)=0$ if not.

One can compute the mean value of more general operators if one knows explicitly simple intertwining coefficients. The expression of a simple intertwining coefficient in the basis of functions $\overset{I}{\pi}{}^i_j$ is explicitly given by

$$\langle \overset{n-1}{\underset{i=1}{\otimes}} \overset{I_i}{\pi}{}^{a_i}_0 \rangle_{\mathrm{Pphys}} = \sum_J \mathrm{d}_J \sum_{j_i,k_i} \prod_{i=0}^{n} C^{I_i J a_i j_i}_{k_i} \tag{78}$$

in term of the following coefficients:

$$\overset{I_i J}{C}{}^{a_i j_i}_{k_i} J \equiv \sum_k \overset{J}{\pi}{}^k_k(h(m_i)) \int \mathrm{d}\Lambda \overset{I_i}{\pi}{}^a_0(\Lambda) \overset{J}{\pi}{}^{j_i}_k(\Lambda) \overline{\overset{J}{\pi}{}^{k_i}_k(\Lambda)}, \tag{79}$$

which can easily be expressed in term of the coefficients of $(3j)$ symbols of Su(2) (see Fig. 5 for an illustration).

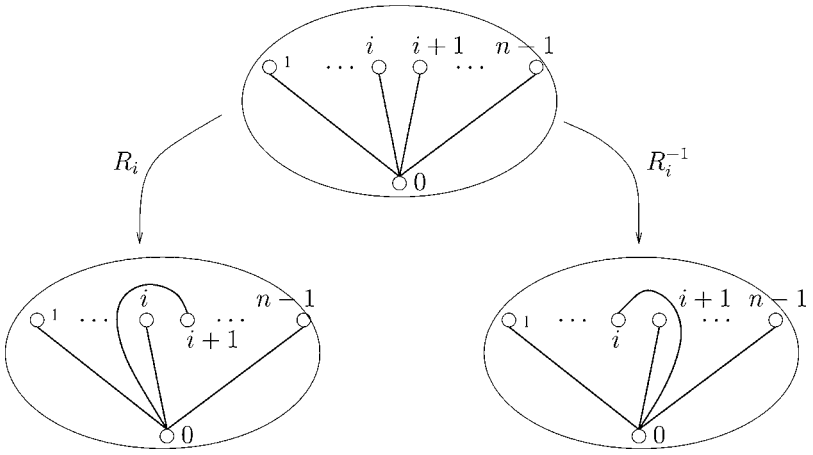

FIG. 6. Illustration of the braiding between two particles i and $i+1$. On the left, the braiding is associated to the R-matrix whereas it is associated to its inverse R^{-1} on the right.

Now, let us discuss some aspects concerning the braiding. First of all, we remark that the R matrix, as introduced in the previous section (66), defines an isomorphism of (partial physical) Hilbert spaces. Indeed, if one considers the particle labeled by $i \in [1,n-2]$, we define the following map:

$$R_{i,i+1}:\mathcal{H}^{0,n}_{\text{Pphys}}([m];G) \to \mathcal{H}^{0,n}_{\text{Pphys}}(P_i[m];G), \tag{80}$$

where $P_i[m]=(m_0,\ldots,m_{i+1},m_i,\ldots,m_{n-1})$ permutes the particles i and $i+1$. The fact that the previous map is an isometry is a consequence of the invariance of the simple intertwiner under braidings. Let us remark that the operator (80) can be written in term of multiplicative and derivative basic operators as follows:

$$R_{i,i+1} = \int \mathrm{d}x m_i(\delta_x)\mathrm{d}_{i+1}(xh(m_i)x^{-1}).$$

Then, it is easy to compute the action of the star operator on R and we show that it is an unitary operator.

Physically, the braiding operator (80) corresponds to a braiding between the two spin-network edges that link the observer with the particles i and $i+1$. In fact, there are two ways to braid the edges: one is associated to the R-matrix and the other to its inverse. This point is illustrated in Fig. 6.

This braiding property means that the partial physical Hilbert space does not depend on the order on the particles.

One can generalize the braiding operator to any pair of particles (i,j) (let us assume that $i<j$). There are many ways to do so and a simple example of such an operator is given by

$$R_{i,j} \equiv \prod_{k=i}^{j-1} R_{k,k+1} \prod_{\ell=j-2}^{i} R_{\ell,\ell+1}. \tag{81}$$

One can as well define an operator which involves not only R-matrices but also its inverse. The operator (81) defines an isometry between the Hilbert spaces $\mathcal{H}^{0,n}_{\text{Pphys}}([m],G)$ and $\mathcal{H}^{0,n}_{\text{Pphys}}(P_{ij}[m];G)$ where P_{ij} permutes the particles i and j.

C. Particles on any Riemann surface

The generalization of Theorem 1 to the case where Σ is any Riemann surface (of genus g) is quite simple. To do so, we first need the following proposition:

Proposition 3 (reduction of the genus): *Let p be a simple representation. We define the map* Υ_p *as follows*:

$$\Upsilon_p : \mathcal{H}^{g,n}_{\text{Pphys}}([m];G) \to \mathcal{H}^{g-1,n+2}_{\text{Pphys}}([m],p,\bar{p};G),$$

$$\psi \to \Upsilon_p(\psi)(A^{g-1,n},\tilde{x},\tilde{y}) = \int \mathrm{d}a_1 \mathrm{d}b_1 \delta(b_1 y h(p) y^{-1}) \delta(a y x^{-1}) \psi(A^{g,n}), \tag{82}$$

where we have used the notations of Proposition 4.

This map satisfies the following property:

$$\langle \psi, \varphi \rangle_{\text{Pphys}} = \int \mathrm{d}\mu(p) \langle \Upsilon_p(\psi), \Upsilon_p(\varphi) \rangle_{\text{Pphys}}, \tag{83}$$

where the partial physical scalar products are, respectively, those of $\mathcal{H}^{g,n}_{\text{Pphys}}([m];G)$ *and* $\mathcal{H}^{g-1,n+2}_{\text{Pphys}}([m],p,\bar{p};G)$.

Proof: Given two states ψ and φ in $\mathcal{H}^{g,n}_{\text{Pphys}}([m];G)$, we start by computing the partial physical scalar product in $\mathcal{H}^{g-1,n+2}_{\text{Pphys}}([m],p,\bar{p};G)$ and a direct calculation shows that

$$\begin{aligned}\langle \Upsilon_p(\psi), \Upsilon_p(\varphi) \rangle_{\text{Pphys}} = \int \prod_{i=1}^{n} \mathrm{d}\bar{z}_i \prod_{j=2}^{g} \mathrm{d}a_j \mathrm{d}b_j \mathrm{d}x \mathrm{d}y \overline{\psi(A^{g-1,n},x,yh(\bar{p})y^{-1})} \varphi(A^{g-1,n},x,yh(\bar{p})y^{-1}) \\ \times \delta\left(h_0 \prod_{i=1}^{n} z_i h(m_i) z_i^{-1} x y h(p) y^{-1} x^{-1} y h(\bar{p}) y^{-1} \prod_{j=2}^{g} [a_j,b_j] \right).\end{aligned} \tag{84}$$

A straightforward application of the Kirillov formula, $\int \mathrm{d}x = \int \mathrm{d}\mu(p) \mathrm{d}\tilde{\Lambda}$ where $x = \Lambda h(p) \Lambda^{-1}$, leads to (83). □

An immediate consequence of this proposition is that one can reduce the case of a Riemann surface to the case of the sphere (regarding the computation of the partial physical scalar product) and we have the following theorem:

Theorem 2 (Reduction to the case of the sphere): *Let* $[p]=(p_1,\ldots,p_g)$ *be a family of g simple representations. We define the map* $\Upsilon_{[p]} = \Upsilon_{p_g} \circ \cdots \circ \Upsilon_{p1}$ *and the partial physical scalar product between two states* $\varphi, \psi \in \mathcal{H}^{g,n}_{\text{Pphys}}([m];G)$ *is expressed in term of symmetric intertwiner as follows*:

$$\langle \varphi, \psi \rangle_{\text{Pphys}} = \int \prod_{i=1}^{g} \mathrm{d}\mu(p_i) \iota_s([m],[p,\bar{p}];0) | \mathcal{F} \circ \Upsilon_{[p]}(\bar{\varphi}\psi), \tag{85}$$

where $[p,\bar{p}]=(p_1,\bar{p}_1,\ldots,p_g,\bar{p}_g)$ *and* $\mathcal{F}$ *has been introduced in Theorem* 1.

Proof: Let $\varphi, \psi \in \mathcal{H}^{g,n}_{\text{Pphys}}([m];G)$. By a recursive use of the proposition (83), we immediately show that

$$\langle \varphi, \psi \rangle_{\text{Pphys}} = \int \prod_{i=1}^{g} \mathrm{d}\mu(p_i) \langle \Upsilon_{[p]}(\varphi), \Upsilon_{[p]}(\psi) \rangle, \tag{86}$$

where the scalar product on the right-hand side is the partial physical scalar product in the case of the sphere. Then, we conclude immediately thanks to Theorem 1. □

Let us discuss some consequences of this theorem.

1. The quantum group structure still holds when Σ is any Riemann surface. However, to make the contact between the Hilbert structure and the simple intertwiner is more involved than the case of the sphere. Anyway, the quantum double is manisfestly the symmetry group of the quantum theory.

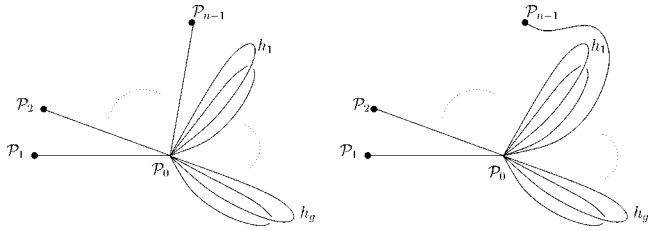

FIG. 7. Pictorial illustration of the braiding: the partial kinematical Hilbert spaces associated to the minimal graphs on the left and on the right are isometric and the isometry is defined by a "general" braiding operator. Note that $\mathcal{P}_i$ denotes the particles and h_i the handles.

2. What about the braiding? We have chosen an order to define the partial physical Hilbert space: this order is illustrated in Fig. 7 and consists in putting the particles variables first and the handledodies variables next.

We have shown previously that permuting two particles variables corresponds to acting with an R-matrix. In fact the same thing happens when one permutes particles with handles or handles with handles. Indeed, in Theorem 2, we see that one handle is decomposed into a pair of particles whose masses are m and $\bar{m}$; therefore permuting one particle with one handle corresponds to permuting this particle with the two particles associated to the handle, as a consequence this operation corresponds to acting twice with an R-matrix. To be more concrete, let us consider the example of Fig. 7. The Hilbert spaces $\mathcal{H}^{g,n}_{\text{Pphys}}([m],\gamma_1;G)$ and $\mathcal{H}^{g,n}_{\text{Pphys}}([m],\gamma_2;G)$ where γ_1 and γ_2 are the minimal graphs associated, are related by the following isometry:

$$R_{\gamma_1,\gamma_2} \equiv \int \mathrm{d}\mu(p_1) \overset{m_{n-1},\bar{p}_1}{R}{}_{n,n+1} \circ \overset{m_{n-1,n},p_1}{R}{}_{n,n-1} \circ \Upsilon_{p_1}, \tag{87}$$

where the R-matrix $R_{i,i+1}$ acts on the particles variables i and $i+1$. We have explicitly shown the representation for the evaluation of the R-matrices in order to be clear. On can easily show that this map is an isometry. It is easy to generalize this map to the case where γ_2 is any minimal graph.

3. The next remark concerns some factorization properties of the partial physical scalar product. To clarify what we mean by that we use the notation $\langle ;\rangle^{g,n}_{\text{Pphys}}[m]$ for the partial physical scalar product within this remark and we have

$$\langle ;\rangle^{g,n}_{\text{Pphysc}}([m]) = \int \mathrm{d}\mu(p) \langle ;\rangle^{g-1,n+1}_{\text{Pphys}}([m],p) \otimes \langle ;\rangle^{1,1}_{\text{Pphysc}}(\bar{p}). \tag{88}$$

Therefore, the physical scalar product can be factorized into scalar product on the torus. This property is well-known and is illustrated in the picture of Fig. 8.

The last remark concerns the evaluation of geometric observables. Indeed, in the case of a nontrivial topology, there exists nontrivial "geometric" operators which corresponds to monodromies around handles. For instance, the trace of $M_K(a_i)$ where a_i is a loop around one handle is given by

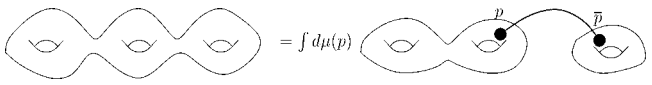

FIG. 8. Illustration of the factorization property of the partial physical scalar product: the physical scalar product on any Riemann surface can be factorized into partial physical scalar product on the torus.

$$\mathrm{Tr}(M_K(a_i)) = \sum_J (J,J,K) \frac{\Pi_{i=0}^{n-1} \chi_J(h(m_i))}{d_J^{2g+n-2}} = \sum_{j \geq [K/2]} \frac{\Pi_{i=0}^{n-1} \chi_J(h(m_i))}{d_J^{2g+n-2}}. \tag{89}$$

in the case of a genus g surface with n particles. $[x]$ denotes the entire part of x. There are at least two different ways to prove this identity: one can use the last Theorem 2 to come back to the case of the sphere or one can make a direct calculation.

As a consequence, we have now a complete description à la LQG of three-dimensional gravity coupled to massive particles.

IV. CONCLUSION AND PERSPECTIVES

In this paper, we have performed the Hamiltonian quantization of three-dimensional Riemannian gravity (with no cosmological constant) coupled with a finite number of massive spinless point particles using loop quantum gravity techniques. The work we have proposed contains: a complete description of the (partial) physical Hilbert space in the general case of any Riemann surface (i.e., states and scalar product) and a discussion concerning the question of the observables (i.e., their definition and the computation of their expectation values in some examples).

We have emphasized the crucial role of the Drinfeld double, which is clearly the symmetry group of the quantum theory, as expected. In the LQG approach, the Drinfeld double appears as a result of the dynamics in the sense that its role becomes obvious when one imposes the three-dimensional analog of the "Hamiltonian" constraint. This point of view is quite interesting because it is a nontrivial example where one sees the emergence of a noncompact quantum group (at the level of the physical Hibert space) starting from a classical compact group (at the level of the kinematical Hilbert space). Our construction is in that sense very different, at the conceptual level, from the combinatorial quantization, the group field theory quantization or the spin-foam quantization where the quantum group is put by hand as the basic starting block of these methods. From the point of view of a particles physicist, our approach might seem more satisfying for we describe particles as simple representations of the "Poincare" (in Riemannian space) group and we notice that, using LQG techniques, scattering amplitudes of these particles in a quantum background are described in terms of intertwiners of a quantum group. In fact, in three dimensions, we see that the Hamiltonian constraint (in the presence of particles) is in fact simple intertwiners!

Thus, physical states are constructed from simple representations of the Drinfeld double and the physical scalar product is in fact given by a symmetric (or Barrett-Crane—BC) intertwiner between the simple representations defining the states. The ressemblance with the usual BC model is obvious and asks the question whether the BC model is really a model of four-dimensional quantum gravity or a model of three-dimensional gravity coupled to particles.

This paper opens new insights into LQG techniques. The first one would be to see the emergence of the quantum group $\mathrm{SU}_q(2)$ when one imposes the Hamiltonian constraint with a cosmological constant (the quantum parameter q is related to Λ in the usual way). We are currently working in that direction. It also seems possible to generalize our construction to the Lorentzian case because we finally do not need to make sense of the whole space of cylindrical functions but only of the space of cylindrical functions on one graph, the minimal graph. Therefore, the obstruction raised in Refs. 12 and 35 should not be problematic in our context. Going from one minimal graph to another reduces to a nontrivial braiding which is still well defined in the Lorentzian regime. Moreover, one could introduce new types of particles: lightlike, spacelike, or timelike particles. We could also think of introducing particles that would describe a black hole in the presence of a negative cosmological constant.

Another issue to be solved is to extend this construction to the case of spinning particles. This case has been considered briefly in the spin-foam approach in Ref. 11. In the LQG point of view, the description of the kinematical Hilbert space has been performed completely in Ref. 24 but the way that the physical scalar product is related to the quantum double remains to be understood. We expect that this link works in the same way as the nonspinning case with the difference being that the physical scalar product (or spinning particles scattering amplitudes in a quantum background)

is no longer given by a simple intertwiner but a more general DSU(2) intertwiner. In our point of view, the case of spinning particles is not a conceptual issue but only a technical issue.

In fact, the original motivation for this work is the construction of a self-gravitating quantum field theory in the Hamiltonian framework. This means a precise description of the Fock space associated to its creation and annihilation operators. We are finishing a work in that direction[22] and we have shown in particular that the quantum field theory so obtained is closely related to the one constructed in Ref. 11 in the context of spin-foam models.

Finally, the last but not the least is to make use of this construction to describe a coupling of quantum gravity to matter field in four dimensions. It seems quite obvious how to generalize, at the level of the kinematical Hilbert space, the coupling of spin-networks to some matter fields. The more interesting question would be to understand what kind of matter that represents and what is the dynamics of such a coupling (see Ref. 3 for ideas in that direction).

ACKNOWLEDGMENTS

I would like to greatly thank A. Perez. I would also like to thank D. Oriti, J. Ryan, and K. Krasnov for stimulating and interesting discussions. I would also like to thank L. Freidel and P. Roche for many discussions concerning quantum groups and the quantum double.

APPENDIX A: THE DRINFELD DOUBLE

We recall the general definition of the quantum double that we illustrate in the case of a finite group.

Let A be a Hopf algebra, the quantum double of A is denoted $D(A)$ (or DA), is a quasitriangular Hopf algebra containing A as a sub-Hopf algebra and has different equivalent definitions.

If A is a Hopf algebra, we denote m the multiplication and Δ the coproduct; it will be useful to introduce a permutation operator σ. From A, we can construct different Hopf algebra: A_{op} is the Hopf algebra with multiplication $m_{\mathrm{op}}=m\circ\sigma$ and coproduct Δ; A^{op} the Hopf algebra with multiplication m and coproduct $\sigma\circ\Delta$; the dual Hopf algebra A^* construted from the duality bracket $\langle,\rangle$ between A and $A*$.

The quantum double (or Drinfeld double) $D(A)$ is the Hopf algebra defined by the following:

1. $D(A)=A\otimes A^{*\mathrm{op}}$ as a coalgebra.
2. The algebra law is given by

$$(x\otimes\xi)(y\otimes\eta)=\sum_{(y),(\xi)} xy_{(2)}\otimes\xi_{(2)}\eta\langle\xi_{(1)},S^{-1}y_{(1)}\rangle\langle\xi_{(3)},y_{(3)}\rangle, \tag{A1}$$

where $\Delta(x)=\Sigma_{(x)}x_{(1)}\otimes x_{(2)}$ and $\Delta_{A^{*\mathrm{op}}}(\xi)=\Sigma_{xi}\xi_{(1)}\otimes\xi_{(2)}$ is the usual Sweedler notation. $D(A)$ is quasitriangular and the R-matrix is given by $R=\Sigma_i e_i\otimes 1\otimes 1\otimes e^i$ where $(e_i)_i$ (respectively, $(e^i)_i$) is a basis of A (respectively, A^*).

Let us illustrate this construction in the case of a finite group to be more concrete. Let G be a finite group and we assume that A is the group algebra of G, i.e., $A=\mathbb{C}[G]$. As a result $A^*=F(G)$, the algebra of functions on G, and the quantum double $D(\mathbb{C}[G])=\mathbb{C}[G]\otimes F(G)^{\mathrm{op}}$ is usually denoted $D(G)$. A basis of $D(G)$ is $(x\otimes\delta_g)_{x,g\in G}$ and the Hopf algebra and coalgebra structures are, respectively, given by

$$(x\otimes\delta_g)\cdot(y\otimes\delta_h)=xy\otimes\delta_h(y^{-1}gy)\delta_h\Delta(x\otimes\delta_g)=\sum_{g_1,g_2|g_1g_2=H}(x\otimes g_2)\otimes(x\otimes g_1). \tag{A2}$$

The action of the antipode on the previous basis is given by $S(x\otimes\delta_g)=x^{-1}\otimes\delta_{x^{-1}g^{-1}x}$ and the co-unit is defined by $\epsilon(x\otimes\delta_g)=\delta(g)$. The R-matrix is given by $R=\Sigma_{x,g}(x\otimes 1)\otimes(1\otimes\delta_g)$. This construction can be directly generalized to the case where G is locally compact.[18]

Representation theory of $D(G)$ has been done in Ref. 10 and generalized to the compact group case ($G=\mathrm{Su}(2)$) in Ref. 18. The main results are recalled in the core of the paper.

APPENDIX B: NORMALIZATION OF THE PHYSICAL SCALAR PRODUCT

We introduce the group $\mathcal{B}^{g,n} \simeq G^{4g+1-1}$ which acts on $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$: it acts by right G-action of each variable $\tilde{z}_e$ and by right and left G-action on each variable a_i or b_i. Given a partial physical state s and an element $y \in \mathcal{B}^{g,n}$, we will use the notation $B_y(s)$ for the action of y on s. There exist many couples (g,n) such that the state s can be viewed as an element of $\mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ and we denote $(g_{\min},n_{\min})$ the minimal couple. Then, we define the invariance group transformations of $s$by $\mathcal{B}[s] \equiv \mathcal{B}^{g_{\min},n_{\min}}$. To be more concrete, $\mathcal{B}[s]$ transforms only the variables which appear explicitly in the state s. There is a natural action of $\mathcal{B}[s]$ on $\mathcal{H}^{n,g}[m]$ and we define the sub-Hilbert space $C^{g,n}[s] \subset \mathcal{H}^{n,g}[m]$ as follows:

$$C^{g,n}[s] \equiv \{f \in \mathcal{H}^{g,n}[m] |\ \forall\, y \in \mathcal{B}[s],\ B_y(f) = f\}. \tag{B1}$$

Proposition 4 (inclusions): Let $v,u \in \mathcal{H}^{g,n}_{\mathrm{Pphys}}([m];G)$ *defined by* $u=\mathrm{tr}([a_1,b_1])$ *and* $v=\mathrm{tr}(z_{n-2}h(m_{n-2})z_{n-2}^{-1}z_{n-1}h(m_{n-1})z_{n-1}^{-1})$ *where* tr *denotes the trace in the fundamental representation of* SU(2). *We have the following inclusions of Hilbert spaces*:

$$C^{g,n}[u] \hookrightarrow \int^{\oplus} \mathrm{d}\mu(p)\mathcal{H}^{g-1,n+2}_{\mathrm{Pphys}}([m],p;\bar{p};G), \tag{B2}$$

$$C^{g,n}[v] \hookrightarrow \int^{\oplus} \mathrm{d}\mu(q)\mathcal{H}^{g,n-1}_{\mathrm{Pphys}}(m_0,\ldots,m_{n-3},\bar{q};G) \otimes \mathcal{H}^{0,3}_{\mathrm{Pphys}}(q,m_{n-2},m_{n-1};G). \tag{B3}$$

The measures are given by $\mathrm{d}\mu(p)=(1/\pi)\sin^2 p\mathrm{d}p$ *where* $\mathrm{d}p$ *is the measure on the circle* S^1 *such that* $\int \mathrm{d}p = 2\pi$. *We have introduced the notation* $\bar{p}=2\pi-p$.

Proof: We concentrate on the first map (B2) and we show that an explicit map is given as follows:

$$f \mapsto \phi(A^{g-1,n},\tilde{x}_1,\tilde{y}_1) \equiv \int \mathrm{d}a_1\mathrm{d}b_1\,\delta(a_1x_1h(\bar{p})x_1^{-1})\,\delta(b_1a_1b_1^{-1}y_1h(p)y_1^{-1})f(A^{g,n}), \tag{B4}$$

where the family $A^{g,n}=(a_1,b_1;\ldots;a_g,b_g;\tilde{z}_1,\ldots,\tilde{z}_{n-1})$ contains the $n+2g$ arguments of the function f and $A^{g-1,n}=(a_2,b_2;\ldots;a_g,b_g;\tilde{z}_1,\ldots,\tilde{z}_{n-1})$ contains $n+2g-2$ arguments. The norm of the function ϕ viewed as an element of the space $\mathcal{H}^{n+2,9-1}([m],p,\bar{p};G)$ is given by

$$\|\phi\|^2_{\mathrm{Pphys}} = \int \prod_{e=1}^{n-1} \mathrm{d}\tilde{z}_e\mathrm{d}\tilde{x}_1\mathrm{d}\tilde{y}_1 \prod_{i=2}^{g} \mathrm{d}a_i\mathrm{d}b_i |\phi(A^{g-1,n},\tilde{x}_1,\tilde{y}_1)|^2 \times \delta\left(h(m_0)\prod_{e=1}^{n-1} z_e h(m_e) z_e^{-1} x_1 h(p) x_1^{-1} y_1 h(\bar{p}) y_1^{-1} \prod_{i=2}^{g} [a_i,b_i]\right).$$

It is then straightforward to verify that

$$\int \mathrm{d}\mu(p)\|\phi\|^2_{\mathrm{Pphys}} = \int \prod_{e=1}^{n-1} \mathrm{d}\tilde{z}_e \prod_{i=1}^{g} \mathrm{d}a_i\mathrm{d}b_i\,\delta\left(h(m_0)\prod_{e=1}^{n-1} z_e h(m_e) z_e^{-1} \prod_{i=1}^{g} [a_i,b_i]\right) \times \int \mathrm{d}x\,\delta([x,a_1])\overline{f(a_1,b_1;\ldots)}f(a_1,b_1x;\ldots).$$

As $f \in C^{g,n}[u]$ and $B_x(u)=u$ if $[x,a_1]=1$ then we conclude immediately that

$$\int \mathrm{d}\mu(p)\|\phi\|^2_{\mathrm{Pphys}} = \|f\|^2_{\mathrm{Pphys}}. \tag{B5}$$

Therefore, the first inclusion (B2) proven.

To prove the second one (B3), we proceed in the same way. We start by claiming that the following map trivially realizes the injection (B3):

$$f \mapsto \psi((A^{g,n-2},\tilde{x}) \otimes (\tilde{z}_{n-2},\tilde{z}_{n-1})) = f(A^{g,n})e^{g,n-2}(m_0,\ldots,m_{n-3},q) \otimes e^{0,3}(\bar{q},m_{n-2},m_{n-1}) \tag{B6}$$

Note that ψ is viewed as an element of $\mathcal{H}^{g,n-1}_{\text{Pphys}}(m_0,\ldots,m_{n-3},\bar{q};G) \otimes \mathcal{H}^{0,3}_{\text{Pphys}}(q,m_{n-2},m_{n-1};G)$ and we have introduced the notation $(A^{g,n-2,x}) = (a_1,b_1;\ldots,a_g,b_g;\tilde{z}_1,\ldots,\tilde{z}_{n-3},\tilde{x})$. The norm of ψ is trivially given by

$$\|\phi\|^2_{Pphys} = \int \prod_{i=1}^{n-1} \mathrm{d}\tilde{z}_e \mathrm{d}\tilde{x} \prod_{i=1}^{g} \mathrm{d}a_i \mathrm{d}b_i |f(A^{g,n})|^2 \delta\left(h(m_0)\prod_{e=1}^{n-3} z_e h(m_e) z_e^{-1} x h(q) x^{-1} \prod_{i=1}^{g} [a_i,b_i]\right) \times \delta(h(\bar{q}) z_{n-2} h(m_{n-2}) z_{n-2}^{-1} z_{n-1} h(m_{n-1}) z_{n-1}^{-1}).$$

Therefore, we verify easily that

$$\int \mathrm{d}\mu(q)\|\phi\|^2_{\text{Pphys}} = \int \prod_{i=1}^{n-1} \mathrm{d}\tilde{z}_e \mathrm{d}\tilde{x} \prod_{i=1}^{g} \mathrm{d}a_i \mathrm{d}b_i |f(a_1,b_1;\ldots,a_g,b_g;\tilde{z}_1,\ldots,\tilde{z}_{n-3},x\tilde{z}_{n-2},x\tilde{z}_{n-1})|^2 \times \delta\left(h(m_0)\prod_{i=1}^{n-1} z_e h(m_e) z_e^{-1} \prod_{i=1}^{g} [a_i,b_i]\right).$$

Finally, as $f \in C^{g,n}[v]$, then we conclude that

$$\int \mathrm{d}\mu(q)\|\phi\|^2_{\text{Pphys}} = \|f\|^2_{\text{Pphys}},$$

and the Hilbert spaces inclusion (B3) is proven. □

It is clear that the unit element $e^{g,n}[m] \in C^{n,g}[u]$ for any function u. Therefore, we can decompose the unit as a tensor product of unit elements of partial Hilbert spaces associated to the sphere with three particles. This is a direct consequence of the previous proposition and the explicit decomposition of $e^{g,n}[m]$ is given by

$$e^{g,n}[m] = \int \prod_{i=0}^{g-1} \mathrm{d}\mu(p_i) \prod_{j=0}^{g-1} \mathrm{d}\mu(m_{n+i}) \prod_{k=1}^{n+g-2} \mathrm{d}\mu(q_k) \bigotimes_{a=0}^{g-1} e^{0,3}(p_a,\overline{p_a},m_{n+a}) \bigotimes_{b=1}^{n+g-2} e^{0,3}(\overline{r_{b-1}},m_b,r_b) \tag{B7}$$

with the conventions $r_0 = \overline{m_0}$ and $r_{n+g-2} = m_{n+g-1}$. As a consequence, one can compute the norm of the identity in two ways and therefore one can relate the coefficients $\lambda(g,n,[m])$ to the coefficients $\lambda(0,3,[m])$. Let us assume that the coefficients $\lambda(0,3,[m]) = \lambda$ do not depend on the values of the masses, then the relation (B7) implies that

$$\|e^{g,n}[m]\|^2_{\text{Pphys}} = \lambda^{n+2g-2} \int \prod_{i=0}^{g-1} \mathrm{d}\mu(p_i) \prod_{j=0}^{g-1} \mathrm{d}\mu(m_{n+i}) \prod_{k+1}^{n+g-2} \mathrm{d}\mu(q_k) \times \prod_{a=0}^{g-1} \|e^{0,3}(p_a,\overline{p_a},m_{n+a})\|^2_{\text{Pphys}} \prod_{b=1}^{n+g-2} \|e^{0,3}(\overline{r_{b-1}},m_b,r_b)\|^2_{\text{Pphys}}. \tag{B8}$$

After some direct calculations, we show that

$$\|e^{g,n}[m]\|^2_{\text{Pphys}} = \lambda^{n+2g-2}\sum_{k=1}^{+\infty} k^{1-2g-n}\prod_{e=0}^{n-1}\frac{\sin(km_e)}{\sin(m_e)}. \tag{B9}$$

Then, by comparison with expression (43) we conclude that $\lambda(g,n.[m])$ is also independent of the values of the masses and we have

$$\lambda(g,n,[m]) \equiv \lambda(g,n) = \lambda^{n+2g-2}. \tag{B10}$$

This fixes the normalization of the partial physical scalar product.

Automorphisms and a cartography of the solution space for vacuum Bianchi cosmologies: The Type III case

T. Christodoulakis[a] and Petros A. Terzis[b]
University of Athens, Department of Physics, Nuclear & Particle Physics Section, Panepistimioupolis, Ilisia GR 157–71, Athens, Hellas, Greece

(Received 7 July 2006; accepted 11 September 2006; published online 13 October 2006)

The theory of symmetries of systems of coupled, ordinary differential equations (ODEs) is used to develop a concise algorithm for cartographing the space of solutions to vacuum Bianchi Einstein's Field Equations (EFE). The symmetries used are the well known automorphisms of the Lie algebra for the corresponding isometry group of each Bianchi Type, as well as the scaling and the time reparametrization symmetry. The application of the method to Type III results in (a) the recovery of all known solutions without a prior assumption of any extra symmetry; (b) the enclosure of the entire unknown part of the solution space into a single, second order ODE in terms of one dependent variable; and (c) a partial solution to this ODE. It is also worth mentioning that the solution space is seen to be naturally partitioned into three distinct, disconnected pieces: one consisting of the known Siklos (pp-wave) solution, another occupied by the Type III member of the known Ellis-MacCallum family and the third described by the aforementioned ODE in which a one parameter subfamily of the known Kinnersley geometries resides. Lastly, preliminary results reported show that the unknown part of the solution space for other Bianchi Types is described by a strikingly similar ODE, pointing to a natural operational unification as far as the problem of solving the cosmological EFE's is concerned. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2359141]

I. INTRODUCTION

Since the early times of cosmology, automorphisms have been identified as possible key elements for a unified treatment of spatially homogeneous Bianchi Geometries.[1] Harvey has found the automorphisms of all three-dimensional Lie Algebras,[2] while the corresponding results for the four-dimensional Lie Algebras have been reported in Ref. 3. Jantzen's tangent space approach sees the automorphic matrices as the means for achieving a convenient parametrization of a full scale-factor matrix in terms of a desired, diagonal matrix.[4] Samuel and Ashtekar were the first to look upon automorphisms from a space viewpoint.[5] The notion of *Time-Dependent Automorphism Inducing Diffeomorphisms* (A.I.D.'s), i.e., coordinate transformations mixing space and time in the new spatial coordinates and inducing automorphic motions on the scale-factor matrix, the lapse, and the shift has been developed in Ref. 6.

In this paper we revisit the problem of solving the EFE's for vacuum Bianchi Geometries. We begin with a full metric, i.e., we make no assumption for the lapse function N^2, the shift vector N^α and the spatial metric $\gamma_{\alpha\beta}$. Then we use the time-dependent A.I.D.'s to put the shift vector to zero. At this point the idea is to exploit, in a systematic way, the remaining symmetries of the field equations—sometimes called "rigid"[7]—to transform them to the most simple form possible, without loss of generality. These are the well known symmetries following from the constant auto-

[a]Electronic mail: tchris@phys.uoa.gr
[b]Electronic mail: pterzis@phys.uoa.gr

morphism group within each Bianchi Type, as well as the scaling of the metric by a constant and the time reparametrization symmetry (see, e.g., Ref. 8). Applying this analysis to Bianchi Type III Vacuum Cosmology, we produce an exhaustive cartography of the entire space of its solutions.

The paper is organized as follows: in Sec. II, we present our method. In Sec. III, after a brief description of Bianchi Type III Cosmology, we apply the method. We thus recover all known solutions, describe the unknown part of the solution space with a single, second order ODE in terms of one dependent variable, and present a new solution. A brief preview of the corresponding results obtained for other Bianchi Types is also included. Finally, some discussion and concluding remarks are given in Sec. IV.

II. THE METHOD

As is well known, for spatially homogeneous space-times with a simply transitive action of the corresponding isometry group,[10,8] the line element, assumes the form

$$ds^2 = (N^\alpha N_\alpha - N^2)dt^2 + 2N_\alpha \sigma_i^\alpha \, dx^i \, dt + \gamma_{\alpha\beta}\sigma_i^\alpha \sigma_j^\beta \, dx^i \, dx^j, \tag{2.1}$$

where the 1-forms σ_i^α are defined from

$$d\sigma^\alpha = C_{\beta\gamma}^\alpha \sigma^\beta \wedge \sigma^\gamma \Leftrightarrow \sigma_{i,j}^\alpha - \sigma_{j,i}^\alpha = 2C_{\beta\gamma}^\alpha \sigma_i^\gamma \sigma_j^\beta. \tag{2.2}$$

Then the field equations are (e.g., Ref. 6):

$$E_o \doteq K^{\alpha\beta}K_{\alpha\beta} - K^2 - \mathbf{R} = 0, \tag{2.3}$$

$$E_\alpha \doteq K_\alpha^\mu C_{\mu\epsilon}^\epsilon - K_\epsilon^\mu C_{\alpha\mu}^\epsilon = 0, \tag{2.4}$$

$$E_{\alpha\beta} \doteq \dot{K}_{\alpha\beta} + N(2K_\alpha^\tau K_{\tau\beta} - KK_{\alpha\beta}) + 2N^\rho(K_{\alpha\nu}C_{\beta\rho}^\nu + K_{\beta\nu}C_{\alpha\rho}^\nu) - N\mathbf{R}_{\alpha\beta} = 0, \tag{2.5}$$

where

$$K_{\alpha\beta} = -\frac{1}{2N}(\dot{\gamma}_{\alpha\beta} + 2\gamma_{\alpha\nu}C_{\beta\rho}^\nu N^\rho + 2\gamma_{\beta\nu}C_{\alpha\rho}^\nu N^\rho) \tag{2.6}$$

is the extrinsic curvature and

$$\mathbf{R}_{\alpha\beta} = C_{\sigma\tau}^\kappa C_{\mu\nu}^\lambda \gamma_{\alpha\kappa}\gamma_{\beta\lambda}\gamma^{\sigma\nu}\gamma^{\tau\mu} + 2C_{\beta\lambda}^\kappa C_{\alpha\kappa}^\lambda + 2C_{\alpha\kappa}^\mu C_{\beta\lambda}^\nu \gamma_{\mu\nu}\gamma^{\kappa\lambda} + 2C_{\beta\kappa}^\lambda C_{\mu\nu}^\mu \gamma_{\alpha\lambda}\gamma^{\kappa\nu} + 2C_{\alpha\kappa}^\lambda C_{\mu\nu}^\mu \gamma_{\beta\lambda}\gamma^{\kappa\nu}, \tag{2.7}$$

the Ricci tensor of the hypersurface.

In Ref. 6, particular spacetime coordinate transformations have been found, which reveal as symmetries of (2.3), (2.4), (2.5) the following transformations of the dependent variables $N, N_\alpha, \gamma_{\alpha\beta}$:

$$\tilde{N} = N, \quad \tilde{N}_\alpha = \Lambda_\alpha^\rho(N_\rho + \gamma_{\rho\sigma}P^\sigma), \quad \tilde{\gamma}_{\mu\nu} = \Lambda_\mu^\alpha \Lambda_\nu^\beta \gamma_{\alpha\beta}, \tag{2.8}$$

where the matrix Λ and the triplet P^α must satisfy

$$\Lambda_\rho^\alpha C_{\beta\gamma}^\rho = C_{\mu\nu}^\alpha \Lambda_\beta^\mu \Lambda_\gamma^\nu, \tag{2.9}$$

$$2P^\mu C_{\mu\nu}^\alpha \Lambda_\beta^\nu = \dot{\Lambda}_\beta^\alpha. \tag{2.10}$$

For all Bianchi Types, this system of equations admits solutions that contain three arbitrary functions of time plus several constants depending on the automorphism group of each type. The three functions of time are distributed among Λ and P (which also contains derivatives of these

functions). So one can use this freedom either to simplify the form of the scale factor matrix or to set the shift vector to zero. The second action can always be taken, since, for every Bianchi type, all three functions appear in P^α.

In this work we adopt the latter point of view. When the shift has been set to zero, there is still a remaining "gauge" freedom consisting of all constant Λ^α_β (automorphism group matrices). Indeed, the system (2.9), (2.10) accepts the solution Λ^α_β=const, $P^\alpha=\mathbf{0}$. The generators of the corresponding motions, induced in the space of dependent variables spanned by $\gamma'_{\alpha\beta}$s (the lapse is given in terms of $\gamma_{\alpha\beta}$, $\dot{\gamma}_{\alpha\beta}$ by algebraically solving the quadratic constraint equation) $\tilde{\gamma}_{\mu\nu}=\Lambda^\alpha_\mu\Lambda^\beta_\nu\gamma_{\alpha\beta}$ are[11]

$$X_{(I)}=\lambda^\rho_{(I)\alpha}\gamma_{\rho\beta}\frac{\partial}{\partial\gamma_{\alpha\beta}}, \tag{2.11}$$

with λ satisfying

$$\lambda^\alpha_{(I)\rho}C^\rho_{\beta\gamma}=\lambda^\rho_{(I)\beta}C^\alpha_{\rho\gamma}+\lambda^\rho_{(I)\gamma}C^\alpha_{\beta\rho}. \tag{2.12}$$

Now, these generators define a Lie algebra and each one of them induces, through its integral curves, a transformation on the configuration space spanned by the $\gamma_{\alpha\beta}$'s. If a generator is brought to its normal form (e.g., $\partial/\partial z_i$), then the Einstein equations, written in terms of the new dependent variables, will not explicitly involve z_i. They thus become a *first order* system in the function $\dot{z}_i$.[12] If the above Lie algebra happens to be Abelian, then all generators can be brought to their normal form simultaneously. If this is not the case, we can diagonalize in one step the generators corresponding to any eventual Abelian subgroup. The rest of the generators (not brought in their normal form) continue to define a symmetry of the reduced system of EFE's if the algebra of the $X_{(I)}$'s is solvable.[13] One can thus repeat the previous step by choosing one of these remaining generators. This choice will, of course, depend upon the simplifications brought to the system at the previous level. Finally, if the algebra does not contain any Abelian subgroup, one can always choose one of the generators, bring it to its normal form, reduce the system, and search for its symmetries (if there are any). Lastly, two further symmetries of (2.3), (2.4), (2.5) are also present and can be used in conjunction with the constant automorphisms: The time reparametrization $t\rightarrow f(t)+\alpha$, owing to the nonexplicit appearance of time in these equations, and the scaling by a constant $\gamma_{\alpha\beta}\rightarrow\mu\gamma_{\alpha\beta}$, as can be straightforwardly verified. Their corresponding generators are

$$Y_1=\frac{1}{\dot{f}}\frac{\partial}{\partial t}, \tag{2.13}$$

$$Y_2=\gamma_{\alpha\beta}\frac{\partial}{\partial\gamma_{\alpha\beta}}. \tag{2.14}$$

These generators commute among themselves, as well as with the $X_{(I)}$'s, as can be easily checked.

III. APPLICATION TO BIANCHI TYPE III

We are now going to apply the method, previously discussed, to the case of Bianchi Type III. For this type the structures constants are[14]

$$C^1_{13}=-C^1_{31}=1,$$
$$C^\alpha_{\beta\gamma}=0, \quad \textit{for all other values of } \alpha\beta\gamma. \tag{3.1}$$

Using these values in the defining relation (2.2) of the 1-forms σ^α_i, we obtain

$$\sigma_i^\alpha = \begin{pmatrix} 0 & e^{-x} & 0 \\ 0 & 0 & 1 \\ \frac{1}{2} & 0 & 0 \end{pmatrix}. \tag{3.2}$$

The corresponding vector fields ξ_α^i (satisfying $[\xi_\alpha, \xi_\beta] = c_{\alpha\beta}^\gamma \xi_\gamma$) with respect to which the Lie Derivative of the above 1-forms is zero are

$$\xi_1 = \partial_y, \quad \xi_2 = \partial_z, \quad \xi_3 = \partial_x + y\partial_y. \tag{3.3}$$

The Time Dependent A.I.D.'s are described by

$$\Lambda_\beta^\alpha = \begin{pmatrix} e^{-2P(t)} & 0 & x(t) \\ 0 & c_{22} & c_{23} \\ 0 & 0 & 1 \end{pmatrix}, \tag{3.4}$$

$$P^\alpha = \left(x(t)\dot{P}(t) + \frac{1}{2}\dot{x}(t), P^2(t), \dot{P}(t) \right), \tag{3.5}$$

where $P(t)$, $x(t)$, and $P^2(t)$ are arbitrary functions of time. As we have already remarked, the three arbitrary functions appear in P^α, and thus can be used to set the shift vector to zero.

The remaining symmetry of the EFEs is, consequently, described by the constant matrix:

$$M = \begin{pmatrix} e^{s_1} & 0 & s_4 \\ 0 & e^{s_2} & s_3 \\ 0 & 0 & 1 \end{pmatrix}, \tag{3.6}$$

where the parametrization has been chosen so that the matrix becomes identity for the zero value of all parameters.

Thus, the induced transformation on the scale factor matrix is $\tilde{\gamma}_{\alpha\beta} = M_\alpha^\mu M_\beta^\nu \gamma_{\mu\nu}$, which explicitly reads as

$$\begin{aligned} \tilde{\gamma}_{11} &= e^{2s_1}\gamma_{11}, \\ \tilde{\gamma}_{12} &= e^{s_1+s_2}\gamma_{12}, \\ \tilde{\gamma}_{13} &= e^{s_1}(s_3\gamma_{11} + s_4\gamma_{12} + \gamma_{13}), \\ \tilde{\gamma}_{22} &= e^{2s_2}\gamma_{22}, \\ \tilde{\gamma}_{23} &= e^{s_2}(s_3\gamma_{12} + s_4\gamma_{22} + \gamma_{23}), \\ \tilde{\gamma}_{33} &= s_3^2\gamma_{11} + 2s_3(s_4\gamma_{12} + \gamma_{13}) + s_4^2\gamma_{22} + 2s_4\gamma_{23} + \gamma_{33}. \end{aligned} \tag{3.7}$$

The previous equations define a group of transformations G_r of dimension $r = \dim(\mathrm{Aut}(III)) = 4$. The four generators of the group can be evaluated from the relation

$$X_A = \left(\frac{\partial \tilde{\gamma}_{\alpha\beta}}{\partial s_A} \right)_{s=0} \frac{\partial}{\partial \gamma_{\alpha\beta}}, \tag{3.8}$$

where $A = \{1,2,3,4\}$. Applying this definition to (3.7), we have the generators

$$X_1 = 2\gamma_{11}\frac{\partial}{\partial\gamma_{11}} + \gamma_{12}\frac{\partial}{\partial\gamma_{12}} + \gamma_{13}\frac{\partial}{\partial\gamma_{13}}, \tag{3.9}$$

$$X_2 = \gamma_{12}\frac{\partial}{\partial\gamma_{12}} + 2\gamma_{22}\frac{\partial}{\partial\gamma_{22}} + \gamma_{23}\frac{\partial}{\partial\gamma_{23}}, \tag{3.10}$$

$$X_3 = \gamma_{12}\frac{\partial}{\partial\gamma_{13}} + \gamma_{22}\frac{\partial}{\partial\gamma_{23}} + 2\gamma_{23}\frac{\partial}{\partial\gamma_{33}}, \tag{3.11}$$

$$X_4 = \gamma_{11}\frac{\partial}{\partial\gamma_{13}} + \gamma_{12}\frac{\partial}{\partial\gamma_{23}} + 2\gamma_{13}\frac{\partial}{\partial\gamma_{33}}. \tag{3.12}$$

The algebra g_r that corresponds to the group G_r has the following table of commutators:

$$\begin{aligned} &[X_1,X_2]=0, \quad [X_1,X_3]=0, \quad [X_1,X_4]=X_4, \\ &[X_2,X_3]=X_3, \quad [X_2,X_4]=0, \quad [X_3,X_4]=0. \end{aligned} \tag{3.13}$$

As is evident from the above commutators (3.13), the group is non-Abelian, so we cannot diagonalize at the same time all the generators. However, if we calculate the derived algebra of g_r, we have

$$g_{r'} = \{[X_A,X_B]:X_A,X_B \in g_r\} \Rightarrow g_{r'} = \{X_3,X_4\}, \tag{3.14}$$

and, furthermore, its second derived algebra reads as

$$g_{r''} = \{[X_A,X_B]:X_A,X_B \in g_{r'}\} \Rightarrow g_{r''} = \{0\}. \tag{3.15}$$

Thus, the group G_r is solvable since the $g_{r''}$ is zero. As is evident, X_3, X_4, Y_2 generate an Abelian subgroup, and we can, therefore, bring them to their normal form simultaneously. The appropriate transformation of the dependent variables is

$$\begin{aligned} \gamma_{11} &= e^{u_1+2u_6}, \\ \gamma_{12} &= e^{u_1+u_2+u_4+u_6}, \\ \gamma_{13} &= e^{u_1+u_6}(e^{u_6}u_3 + e^{u_2+u_4}u_5), \\ \gamma_{22} &= e^{u_1+2u_4}, \\ \gamma_{23} &= e^{u_1+u_4}(e^{u_2+u_6}u_3 + e^{u_4}u_5), \\ \gamma_{33} &= e^{u_1}(1 + e^{2u_6}u_3^2 + 2e^{u_2+u_4+u_6}u_3u_5 + e^{2u_4}u_5^2). \end{aligned} \tag{3.16}$$

In these coordinates the generators Y_2, X_A assume the form

$$Y_2 = \frac{\partial}{\partial u_1}, \quad X_3 = \frac{\partial}{\partial u_3}, \quad X_4 = \frac{\partial}{\partial u_5},$$
$$X_2 = \frac{\partial}{\partial u_4} - u_5 \frac{\partial}{\partial u_5}, \quad X_1 = \frac{\partial}{\partial u_6} - u_3 \frac{\partial}{\partial u_3}. \tag{3.17}$$

Except for the parametrization (3.16) there is also another one achieving the same result (3.17), which simply attributes a - sign to γ_{12}, and therefore any solution later described will remain valid under this change.

Evidently, a first look at (3.16) gives the feeling that it would be hopeless even to write down the Einstein equation. However, the simple form of the generators (3.17) ensures us that these equations will be of first order in the functions $\dot{u}_1$, $\dot{u}_3$, and $\dot{u}_5$.

A. Description of the solution space

Before we begin solving Einstein equations, a few comments for the possible values of the functions u_i, $i=1,\ldots,6$ will prove very useful.

The determinant of $\gamma_{\alpha\beta}$ is

$$\det[\gamma_{\alpha\beta}] = e^{3u_1+2(u_4+u_6)}(1-e^{2u_2}), \tag{3.18}$$

so we must have $u_2<0$.

The transformation from the γ' s to the u' s becomes singular when $\gamma_{12}=0$, since the function u_2 equals

$$u_2 = \ln(|\gamma_{12}|) - \frac{\ln(\gamma_{11}\gamma_{22})}{2}. \tag{3.19}$$

So two cases are naturally arising, according to whether γ_{12} is different or equal to zero. If $\gamma_{12} \neq 0$ the two linear constraint equations, written in the new variables (3.16), give

$$E_1 = 0 \Rightarrow -e^{u_6}(e^{u_6}\dot{u}_3 + e^{u_2+u_4}\dot{u}_5) = 0, \tag{3.20}$$

$$E_2 = 0 \Rightarrow -\frac{1}{2}e^{u_4}(e^{u_2+u_6}\dot{u}_3 + e^{u_4}\dot{u}_5) = 0. \tag{3.21}$$

This system admits only the trivial solution, since the determinant of the 2×2 matrix formed by the coefficients of $\dot{u}_3$, $\dot{u}_5$ becomes zero only for the forbidden value $u_2=0$. We thus have

$$u_3 = k_3, \quad u_5 = k_5. \tag{3.22}$$

Now, these values of u_3, u_5 make γ_{13}, γ_{23} functionally dependent upon γ_{11}, γ_{12}, γ_{22} [see (3.16)]. It is thus possible to set these two components to zero by means of an appropriate constant automorphism.

In the case $\gamma_{12}=0$, we can again bring simultaneously into normal form the corresponding X_3, X_4, Y_2. The appropriate change of dependent variables is given by

$$\gamma_{\alpha\beta} = \begin{pmatrix} e^{u_1+2u_6} & 0 & e^{u_1+2u_6}u_3 \\ 0 & e^{u_1+2u_5} & e^{u_1-u_4+u_5} \\ e^{u_1+2u_6}u_3 & e^{u_1-u_4+u_5} & e^{u_1}(1+e^{-2u_4}+e^{2u_6}u_3^2) \end{pmatrix}. \tag{3.23}$$

In these variables all three linear constraint equations can be integrated, yielding

$$E_1 = 0 \Rightarrow -e^{2u_6}\dot{u}_3 = 0 \Rightarrow u_3 = k_3, \tag{3.24}$$

$$E_2 = 0 \Rightarrow -\frac{1}{2}e^{-u_4+u_5}(\dot{u}_4 + \dot{u}_5) = 0 \Rightarrow u_5 = k_5 - u_4, \tag{3.25}$$

$$E_3 = 0 \Rightarrow -2e^{2u_4+2u_6}u_3\dot{u}_3 + \dot{u}_4 + \dot{u}_5 + 2e^{2u_4}\dot{u}_6 = 0 \Rightarrow u_6 = k_6. \tag{3.26}$$

Again, these values imply that a constant automorphism suffices to set the (13) and (23) components of the scale-factor matrix to zero, i.e., to put it into diagonal form. We have thus reached a first important conclusion, that is the following.

Without loss of generality, we can start our investigation of the solution space for Type III vacuum Bianchi Cosmology from a block-diagonal form of the scale-factor matrix (and, of course, zero shift),

$$\gamma_{\alpha\beta} = \begin{pmatrix} \gamma_{11} & \gamma_{12} & 0 \\ \gamma_{12} & \gamma_{22} & 0 \\ 0 & 0 & \gamma_{33} \end{pmatrix}. \tag{3.27}$$

Note that this conclusion could have not been reached off mass shell, due to the fact that the time-dependent automorphism (3.4) does not contain the necessary two arbitrary functions of time in the (13) and (23) components (besides the fact that all the freedom in arbitrary functions of time has been used to set the shift to zero). As we have earlier remarked, since the algebra (3.13) is solvable, the remaining (reduced) generators X_1, X_2 (corresponding to diagonal constant automorphisms) as well as Y_2 continue to define a Lie-Point symmetry of the reduced EFEs and can thus be used for further integration of this system of equations.

1. Case I: $\gamma_{12}=0$

The remaining (reduced) automorphism generators are

$$X_1 = 2\gamma_{11}\frac{\partial}{\partial\gamma_{11}}, \quad X_2 = 2\gamma_{22}\frac{\partial}{\partial\gamma_{22}}.$$

The appropriate change of dependent variables that brings these generators—along with Y_2 into normal form, is described by the following scale-factor matrix:

$$\gamma_{\alpha\beta} = \begin{pmatrix} e^{u_1+u_3} & 0 & 0 \\ 0 & e^{u_2+u_3} & 0 \\ 0 & 0 & e^{u_3} \end{pmatrix}. \tag{3.28}$$

In these variables the first two linear constraint equations are identically satisfied, while the third reads as $E_3=0\Rightarrow -2\dot{u}_1=0\Rightarrow u_1=k_1$. Substituting this value of u_1 into the quadratic constraint equation E_0, we obtain the lapse function

$$N^2 = \frac{1}{16}e^{u_3}\dot{u}_3(2\dot{u}_2 + 3\dot{u}_3). \tag{3.29}$$

Now, the substitution of $u_1=k_1$ and the above value for the lapse N^2 into the spatial EFE's results in the single, independent equation:

$$(\dot{u}_2 + \dot{u}_3)(2\dot{u}_3\ddot{u}_2 - 2\dot{u}_2\ddot{u}_3 + 2\dot{u}_2^2\dot{u}_3 + 3\dot{u}_3^2 + 5\dot{u}_2\dot{u}_3^2). \tag{3.30}$$

This equation is, as expected from the theory, of the first order in $\dot{u}_2$, $\dot{u}_3$. Notice that this result could have not been reached had we chosen any particular time gauge, such as $N^2=F(u_2,u_3,t)$: Not only u_2, u_3, t would appear in the Spatial EFE's, but also the number of independent such equations would have been increased to 2. This remark should not be taken as a negative view for complete gauge fixing, but rather as pointing to the fact that keeping the gauge freedom into the game helps manifesting the symmetries of the system and eventually solving the equations.

Equation (3.30) is readily integrated, leading to two different space-times according to which the parenthesis is set to zero. If the first is made to vanish, i.e., $u_2=k_2-u_3$, the ensuing line element is the known (Type III) cosmological disguise of Minkowski space-time (Ref. 15):

$$ds^2=-\frac{1}{16}e^{u_3}\dot{u}_3^2\,dt^2+\frac{1}{4}e^{u_3}\,dx^2+e^{k_1+u_3-2x}\,dy^2+e^{k_2}\,dz^2 \tag{3.31}$$

the constants being, of course, absorbable by the constant automorphisms and a shift in u_3.

If the second parenthesis of (3.30) is set to zero, i.e., $u_2=k_3-3u_3/2+\ln(1+k_2e^{u_3/2})$, we obtain an equivalent form of the Type III member of the known Ellis-MacCallum family of solutions (Refs. 8 and 15):

$$ds^2=\kappa^2\left(-\frac{e^{3u_3/2}\dot{u}_3^2}{4(e^{u_3/2}-1)}dt^2+e^{u_3}\,dx^2+e^{u_3-2x}\,dy^2+e^{-u_3/2}(e^{u_3/2}-1)dz^2\right), \tag{3.32}$$

where again we have used constant automorphisms and a shift of u_3 to take outside of the metric an overall constant. We can be assured that the constant is essential either by checking that indeed the metric inside the parenthesis does not admit a homothetic Killing vector field or, more primarily, by finding an invariant relation between curvature and higher derivative curvature scalars that explicitly involves κ. For metric (3.32), one such invariant relation is

$$\frac{18Q_1^4}{\left(Q_2-\frac{g^{AB}Q_{1;A}Q_{1;B}}{Q_1}\right)^3}=\kappa^2,\quad Q_1=R^{KLMN}R_{KLMN},\quad Q_2=\Box R^{KLMN}R_{KLMN}, \tag{3.33}$$

where capital Latin letters denote space-time indices ranging in the interval (0–3), the semicolon stands for covariant differentiation, and the $\Box$ for the covariant D'Alebertian.

This relation, being a constant scalar constructed out of the intrinsic geometry (the Riemmann tensor and its covariant derivatives), characterizes, along with many others that can be found, this metric: It will be valid for any equivalent, under general coordinate transformations, form of (3.32). It is also noteworthy to observe that in both the above line elements, the arbitrary function of time u_3 appears; This is because the number of symmetry generators matches the number of scale factors (both are 3), so that the system of spatial EFEs is reduced to first order without any choice of time. In the case of a block-diagonal scale-factor matrix, one of the four scale factors will have to play the role of time before the corresponding system can be reduced. Lastly, metric (3.32) admits, except for (3.3), a fourth Killing vector field acting on the surfaces of simultaneity, namely

$$\xi_4=-2y\partial_x+(e^{2x}-y^2)\partial_y. \tag{3.34}$$

There is thus a G_4 symmetry group acting (of course, multiply transitively) on each V_3 of this metric, with an algebra having the following table of (nonvanishing) commutators:

$$[\xi_1,\xi_3]=\xi_1,\quad [\xi_1,\xi_4]=-2\xi_3,\quad [\xi_3,\xi_4]\xi_4. \tag{3.35}$$

However, it is interesting to note that we have not imposed the extra symmetry from the beginning, but rather it emerged as a result of the investigation process.

2. Case II: $\gamma_{12}\neq 0$

The remaining (reduced) automorphism generators are

$$X_1=2\gamma_{11}\frac{\partial}{\partial\gamma_{11}}+\gamma_{12}\frac{\partial}{\partial\gamma_{12}},\quad X_2=\gamma_{12}\frac{\partial}{\partial\gamma_{12}}+2\gamma_{22}\frac{\partial}{\partial\gamma_{22}}.$$

The appropriate change of dependent variables that brings these generators—along with Y_2—into normal form, is now given by

$$\gamma_{\alpha\beta}=\begin{pmatrix} e^{u_1+2u_4} & e^{u_1+u_2+u_4} & 0 \\ e^{u_1+u_2+u_4} & e^{u_1+2u_2}u_3 & 0 \\ 0 & 0 & e^{u_1} \end{pmatrix}. \tag{3.36}$$

The generators are now reduced to

$$Y_2=\frac{\partial}{\partial u_1},\quad X_2=\frac{\partial}{\partial u_2},\quad X_1=\frac{\partial}{\partial u_4}, \tag{3.37}$$

indicating that the system will be of first order in the derivatives of these variables. The remaining variable u_3 will enter (along with $\dot{u}_3$, $\ddot{u}_3$) explicitly in the system and is therefore advisable (if not mandatory) to be used as the time parameter, i.e., to effect the change of time coordinate

$$t\to u_3(t)=s,\quad u_1(t)\to u_1(t(s)),\quad u_2(t)\to u_2(t(s)),\quad u_4(t)\to u_4(t(s)). \tag{3.38}$$

This choice of time will, of course, be valid only if u_3 is not a constant. We are thus led to consider two cases according to the constancy or nonconstancy of this variable.

a. The case $u_3=k_3$

The determinant of the scale-factor matrix becomes $\det[\gamma_{\alpha\beta}]=e^{3u_1+2(u_2+u_4)}(-1+k_3)$. We thus have $k_3>1$. The two linear constraint equations are identically satisfied, while the third yields

$$E_3=0\Rightarrow\frac{\dot{u}_2+(1-2k_3)\dot{u}_4}{2(1-k_3)}=0\Rightarrow u_4=k_4+\frac{u_2}{2k_3-1}.$$

Inserting these values of u_3, u_4 into the quadratic constraint equation we obtain the following lapse:

$$(N)^2=\frac{e^{u_1}(-1+k_3)(3(1-2k_3)^2\dot{u}_1^2+8k_3(-1+2k_3)\dot{u}_1\dot{u}_2+4k_3\dot{u}_2^2)}{4(1-2k_3)^2(-3+4k_3)}. \tag{3.39}$$

The use of these values of u_3, u_4, $(N)^2$ in the spatial EFE's results, as expected, in a system that is of the first order in the unknown variables $\dot{u}_1$, $\dot{u}_2$. The coefficient of $\ddot{u}_2$ in $E_{33}=0$ is

$$\frac{2e^{u_1}k_3\dot{u}_1((-1+2k_3)\dot{u}_1+\dot{u}_2)}{3(1-2k_3)^2\dot{u}_1^2+8k_3(-1+2k_3)\dot{u}_1\dot{u}_2+4k_3\dot{u}_2^2},$$

and can be safely regarded different from zero, since the possibilities $\dot{u}_1=0$, $\dot{u}_2=(1-2k_3)\,\dot{u}_1$ easily lead (through $E_{33}=0$ itself) to zero and negative lapse, respectively. We can thus solve $E_{33}=0$ for $\ddot{u}_2$ and substitute into $E_{12}=0$, which becomes

$$\frac{e^{k_4+u_1+2k_3u_2/(-1+2k_3)}k_3(\dot{u}_1+2\dot{u}_2)((-3+6k_3)\dot{u}_1+2(3-2k_3)\dot{u}_2)}{6-20k_3+16k_3^2}=0.$$

Again, the second parenthesis in the numerator leads to zero lapse, leaving us with the only alternative $\dot{u}_1=-2\dot{u}_2\Rightarrow u_1=2k_1-2u_2$, which indeed satisfies all spatial EFEs. Finally, inserting these values of u_3, u_4, u_1 in the lapse (3.39) and the scale-factor matrix (3.36), we obtain the following line element (after using the constant automorphisms and a shift in u_2 to purify the metric from the absorbable constants):

$$ds^2=-\lambda^2\,d\xi^2+\frac{\xi^2}{4}\,dx^2+e^{-2x}\xi^{4\lambda}\,dy^2+\frac{\lambda-1}{2\lambda-1}\,dz^2+2e^{-x}\xi^{2\lambda}\,dy\,dz, \tag{3.40}$$

where the constant λ is related to k_3 by $k_3=(\lambda-1)/(2\lambda-1)\Rightarrow 0<\lambda<\frac{1}{2}$, and we have adopted the

time gauge $e^{-u_2}=\xi$ for simplicity.

This metric is an equivalent form of a solution originally given by Siklos[16] and reproduced in.[15] An overall multiplicative constant has been omitted from (3.40) since it admits the following Homothetic Killing vector field ($\mathcal{L}_H g_{AB}=\mu g_{AB}$),

$$H^A=\xi\frac{\partial}{\partial\xi}+(1-2\lambda)y\frac{\partial}{\partial y}+z\frac{\partial}{\partial z}.$$

It also admits three more Killing vector fields [except (3.3)] acting on space-time, namely

$$\xi_4=e^{-x/2\lambda}\partial_\xi+\frac{2\lambda}{\xi}e^{-x/2\lambda}\partial_x$$

$$\xi_5=e^{-x/2\lambda}y\partial_\xi+\frac{2\lambda y}{\xi}e^{-x/2\lambda}\partial_x+\frac{\lambda(\lambda-1)}{4\lambda-1}e^{[(4\lambda-1)/2\lambda x]}\xi^{-4\lambda+1}\partial_y-\lambda e^{[(2\lambda-1)/2\lambda]x}\xi^{-2\lambda+1}\partial_z$$

$$\xi_6=e^{-x/2\lambda}z\partial_\xi+\frac{2\lambda z}{\xi}e^{-x/2\lambda}\partial_x-\lambda e^{[(2\lambda-1)/2\lambda]x}\xi^{-2\lambda+1}\partial_y-\lambda(2\lambda-1)e^{-x/2\lambda}\xi\partial_z.$$

The ξ_5 field breaks down for $\lambda=\frac{1}{4}$, in which case the valid expression is

$$\xi_5'=\left\{\frac{y}{e^{2x}},\frac{y}{2e^{2x}\xi},\frac{3(-2x+\log(\xi))}{16},\frac{-\sqrt{\xi}}{4e^x}\right\}. \tag{3.41}$$

The first of these is null $\xi_4^A\xi_4^B g_{AB}=0$ and covariantly constant $\xi^A_{4;B}=0$, signaling that the metric is a pp wave. Consequently, all scalar curvatures, constructed by forming scalar contractions of the tensor product of the Riemmann tensor and its covariant derivatives of any order [such as Q_1, Q_2 in (3.33)], vanish identically (see, e.g., Ref. 17). This raises the interesting question of how can we be certain that the constant λ is essential. An answer can be found in terms of equalities between tensors—constructed out of the Riemmann tensor and its covariant derivatives—that hold true in these space-times.[18,19] For metric (3.40) such a relation is

$$R^A{}_B{}^C{}_D R_{AECF;G;H}=\frac{4\lambda^2-2\lambda+3}{-4\lambda^2+2\lambda+2}R^A{}_B{}^C{}_{D;E}R_{AFCG;H}. \tag{3.42}$$

By the quotient law, the expression of λ on the right-hand side of this relation is a scalar function, and being a constant it cannot change value under any coordinate transformation; thus λ cannot be altered by such a transformation and is, therefore, essential.

The algebra of the six killing fields, (3.3), (3.41) has the following table of nonvanishing commutators:

$$[\xi_1,\xi_3]=\xi_1,\quad [\xi_1,\xi_5]=\xi_4,\quad [\xi_3,\xi_4]=-\frac{\xi_4}{2\lambda},\quad [\xi_3,\xi_5]=\frac{2\lambda-1}{2\lambda}\xi_5,\quad [\xi_3,\xi_6]=\frac{-1}{2\lambda}\xi_6. \tag{3.43}$$

There is an isotropy group G_2 of null rotations emanating from this algebra, which is easily seen by taking a linear combination of these fields:

$$Y_1=\xi_1-2\lambda\xi_3,\quad Y_2=\xi_4,\quad Y_3=-\xi_6,$$
$$Y_4=\xi_2,\quad Y_5=\xi_3,\quad Y_6=\xi_5, \tag{3.44}$$

e.g., $[Y_1, Y_2] = Y_2$ and $[Y_1, Y_3] = Y_3$.

The space (being a pp wave) does not obviously have curvature singularities; it thus seems to be geodesically complete and is of Petrov Type *N*.

b. The case $u_3 \neq k_3$

The function u_3 is now a valid choice of time and $\det[\gamma_{\alpha\beta}] = e^{3u_1+2(u_2+u_6)}(-1+s)$ implies the range $(1, +\infty)$ for the new time s. The only nonvanishing linear constraint equation $E_3 = 0$ yields

$$u_4 = \int \frac{\dot{u}_2}{2s-1} ds + k_4 \tag{3.45}$$

while the quadratic constraint equation $E_0 = 0$ gives the lapse

$$(N)^2 = \frac{e^{u_1}}{4(1-2s)^2(-3+4s)}\left[2(2s-1)^2\dot{u}_1 + 3(2s-1)^2(s-1)\dot{u}_1^2 + (4s-2)\dot{u}_2 + 8s(s-1)(2s-1)\dot{u}_1\dot{u}_2 + 4s(s-1)\dot{u}_2^2\right]. \tag{3.46}$$

If we insert these values $(N)^2$, u_4 into the spatial EFEs, they become the following polynomial system of first order in $\dot{u}_1$, $\dot{u}_2$,

$$\ddot{u}_1 = (1\dot{u}_1\dot{u}_1^2\dot{u}_1^3)A_1\begin{pmatrix} 1 \\ \dot{u}_2 \\ \dot{u}_2^2 \\ \dot{u}_2^3 \end{pmatrix}, \quad \ddot{u}_2 = (1\dot{u}_1\dot{u}_1^2\dot{u}_1^3)A_2\begin{pmatrix} 1 \\ \dot{u}_2 \\ \dot{u}_2^2 \\ \dot{u}_2^3 \end{pmatrix}, \tag{3.47}$$

$$A_1 = \begin{pmatrix} 0 & \frac{2}{4s^2-7s+3} & \frac{4s}{8s^2-10s+3} & 0 \\ \frac{1}{4s^2-7s+3} & 4 & \frac{8s(2s-3)(s-1)}{8s^2+10s-3} & 0 \\ \frac{2s-3}{4s-3} & -\frac{16s^2(s-1)}{8s^2-10s+3} & 0 & 0 \\ -\frac{6s(s-1)}{4s-3} & 0 & 0 & 0 \end{pmatrix}, \tag{3.48}$$

$$A_2 = \begin{pmatrix} 0 & \frac{-8s+5}{8s^3-18s^2+13s-3} & \frac{24s^2-50s+18}{8s^2-10s+3} & \frac{8s(2s-3)(s-1)}{8s^2-10s+3} \\ \frac{-4s+2}{4s^2-7s+3} & \frac{12s}{-2s+3} & -\frac{16s^2(s-1)}{8s^2+10s-3} & 0 \\ \frac{-6s+3}{4s-3} & -\frac{6s(s-1)}{4s-3} & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{3.49}$$

Due to the form of A_1, A_2 (their components are rational functions of the time s), system (3.47) can be partially integrated with the help of the following Lie-Bäklund transformation:

$$\dot{u}_1(s) = \frac{(2s-3)\tan r(s) - 2s(8s^2-10s+3)\dot{r}(s)}{4s\sqrt{s-1}(4s-3)},$$
$$\dot{u}_2(s) = \frac{2s-1}{8s(4s-3)\sqrt{(s-1)^3}}(2(-4s+3)\sqrt{s-1} + 3(s-1)\tan r(s) + 2s(s-1)(4s-3)\dot{r}(s)), \tag{3.50}$$

resulting in the single, second order ODE for the variable $r(s)$,

$$\ddot{r}=\left(\tan r-\frac{\sqrt{s-1}}{2}\right)\dot{r}^2+\frac{(-16s+6)\sqrt{s-1}+(5s-3)\tan r}{2s(4s-3)\sqrt{(s-1)}}\dot{r}$$
$$+\frac{-9(s-1)^2\tan^2 r+18(s-1)^{3/2}\tan r+4s(4s-3)}{8s^2(4s-3)^2(s-1)^{3/2}}. \tag{3.51}$$

This equation contains all the information concerning the unknown part of the solution space of the Type III vacuum Cosmology. Unfortunately, it does not posses any Lie-point symmetries that can be used to reduce its order and ultimately solve it. However, its form can be substantially simplified through the use of a new dependent and independent variable $(\rho, u(\rho))$ according to $r(s)=\pm\arcsin u(\rho)/\sqrt{\rho^2-1}$, $s=3(\rho-1)/3\rho-5$, $\rho>\frac{5}{3}$ thereby obtaining the equation

$$\ddot{u}=\pm\frac{1-\dot{u}^2}{\sqrt{(6\rho-10)(\rho^2-u^2-1)}}\Rightarrow\ddot{u}^2=\frac{(1-\dot{u}^2)^2}{(6\rho-10)(\rho^2-u^2-1)}, \tag{3.52}$$

with the corresponding lapse

$$(N)^2=\frac{\dot{u}^2-1}{8(3\rho-5)(\rho^2-u^2-1)}e^{u_1} \tag{3.53}$$

($\dot{u}=du/d\rho$) and the scale-factor matrix is given by (3.36) after insertion of (3.45), $u_3=s=3(\rho-1)/3\rho-5$ and the transformations of u_1, u_2 that led to u. Independently of the way we have reached this result, one can check (through an algebraic computing facility such as MATHEMATICA) that the line element thus described is indeed a solution of all the EFEs, provided, of course, that (3.52) is satisfied. One can also check that it does not admit any homothetic or null, covariantly constant vector field. Therefore, the two independent constants of the general solution to (3.52) along with a multiplicative constant will comprise the expected three essential constants of the general Type III vacuum Cosmology: The general algorithm for calculating this number when a space-time gauge has been chosen (usually zero shift and unit lapse), in which case the constraints must be viewed as restrictions on the initial data, reads as follows[15]: 12 (for the six components of $\gamma_{\alpha\beta}$)-1 (for the time reparametrization covariance)-number of independent constraints-dimension of Automorphism Group.

When a space-time gauge has not been fixed, i.e., when constraints are being viewed as symmetry generators, the relevant counting is given by[20]

$$D=2\times(\text{number of }\gamma_{\alpha\beta})-2\times(\text{number of linear constraints})-2\times(\text{quadratic constraint})$$
$$-(\text{number of parameters of outer}-\text{aut})-(n),$$

where $n\equiv$ dim(inner-aut)-number of independent linear constraints.

In our case the number of independent linear constraints is 3, and the dimension of the inner-aut is 2, so $n=-1$. The constants that appear at the outer-aut are 2, and obviously the number of $\gamma_{\alpha\beta}$ is 6. Thus, the expected maximal number of essential constants is indeed **3**, by both ways of counting.

Despite the relatively simple form of (3.52), its general solution is, to the best of our knowledge, not known. However, we have managed to obtain a partial solution in the parametric form,

$$u(\xi)=\frac{4(1+2e^{2\xi})^{3/2}}{3(1+e^{2\xi})^2}\quad\rho=\tfrac{1}{3}(5+\operatorname{sech}^2\xi),$$

which makes the functions u_1, u_2, u_4 read as

$$u_1(\xi) = k_1 + \xi + \ln\cosh\xi,$$

$$u_2(\xi) = k_2 + \ln\operatorname{sech}\xi - \frac{1}{2}\ln(\cosh 2\xi + 2),$$

$$u_4(\xi) = k_4 - \ln\cosh\xi + \frac{1}{2}\ln(\cosh 2\xi + 2),$$

and the lapse $(N)^2 = e^{k_1+2\xi}(e^{2\xi}+1)/4(2e^{2\xi}+1)$. The ensuing metric, after the usual purification with the constant automorphisms and a shift in ξ, is given by

$$ds^2 = \kappa^2\left(-\frac{e^{2\xi}(e^{2\xi}+1)}{4(2e^{2\xi}+1)}d\xi^2 + \frac{e^{\xi}}{4}\cosh\xi\, dx^2 + e^{-2x+\xi}(\cosh 2\xi + 2)\operatorname{sech}\xi\, dy^2 + e^{\xi}\operatorname{sech}\xi\, dz^2 + 2e^{-x+\xi}\operatorname{sech}\xi\, dy\, dz\right). \tag{3.54}$$

As we have already remarked, this metric does not admit a homothety and therefore the constant κ is essential. It does not satisfy the invariant relation (3.33), and it is not a pp wave. Therefore we conclude that it is inequivalent to (3.32) or (3.40). This mono-parametric family belongs to the Kinnersley vacuum solutions.[9] It is quite interesting that it also admits a fourth killing vector field,

$$\xi_4 = -16y\partial_x + (e^{2x} - 8y^2)\partial_y - 2e^x\partial_z, \tag{3.55}$$

which produces with (3.3) the following table of (nonvanishing) commutators:

$$[\xi_1, \xi_3] = \xi_1, \quad [\xi_1, \xi_4] = -16\xi_3, \quad [\xi_3, \xi_4] = \xi_4. \tag{3.56}$$

The isotropy group inferred from the above algebra (see the last commutator) is a G_1 spatial rotation.

Curiously enough, this algebra is equivalent to (3.35), as a simple scaling of ξ_1, ξ_4 by $2\sqrt{2}$ shows. Of course, the multiply transitive character of the action of the underlying group on the corresponding V_3's allows for these, and thus for the space-times in which they are embedded, to be inequivalent.

Again, the extra symmetry emerged in the course of the investigation of the solution space. Of course, it must have something to do with the particular nature of the solution, but it was not set as a starting point.

B. Preview for other Bianchi Types

The method described in the previous sections can be applied to other Types as well. The general pattern is s similar to that of Type III: The pp-wave solutions (for types admitting such geometries) occupy one part of the solution space, the other known solutions reside on another part, and the unknown part of the solution space is always described by an ODE strikingly similar to (3.52), namely,

$$\ddot{u}^2 = \frac{(-1+\dot{u}^2)^2}{(\kappa+\lambda\rho)(\rho^2 - u^2 - 1)}. \tag{3.57}$$

Details will be included in a forthcoming work. As indicative examples we give the form of the ODE for Types IV and VII_h:

Type IV:

$$\ddot{u}^2 = \frac{(-1+\dot{u}^2)^2}{(\kappa+\lambda\rho)(\rho^2-u^2-1)}, \quad \kappa=-6, \quad \lambda=6. \tag{3.58}$$

Type VII$_h$:

$$\ddot{u}^2 = \frac{(-1+\dot{u}^2)^2}{(\kappa+\lambda\rho)(\rho^2-u^2-1)}, \quad \kappa=-6+\frac{4}{h^2}, \quad \lambda=-6, \tag{3.59}$$

and of course the following.

Type III:

$$\ddot{u}^2 = \frac{(-1+\dot{u}^2)^2}{(\kappa+\lambda\rho)(\rho^2-u^2-1)}, \quad \kappa=-10, \quad \lambda=6. \tag{3.60}$$

IV. DISCUSSION

When one is trying to solve Einstein's Equations in cosmology, one has to deal with a nonlinear system of coupled, *ordinary differential* equations. The strategy that is frequently used is to simplify the system by choosing, a convincing form for the scale factor matrix, usually obtained by an *a priori* assumption of extra symmetry [e.g., $\gamma_{\alpha\beta}=\mathrm{diag}(a(t),b(t),c(t))$], and then try to solve it, hoping to find *some* solution. Clearly, this procedure can by no means guarantee access to the full space of solutions for the problem at hand. In this work we have presented a method for solving Einstein's Field Equations in the case of vacuum Bianchi Geometries. The main idea is to consider the Group of constant automorphisms, which emerges as the residual freedom left after the time dependent A.I.D.'s (2.8), (2.9) have been used to set the shift N^α to zero, as a Lie point symmetry of the EFEs. In a step-by-step procedure, one can bring some of the generators of this group in normal form and simplify the rest, thereby reducing the order of the system of equations. Which of the generators, and how, can be utilized in each step depends upon the characteristics of their Lie Algebra (Abelian, solvable etc.). It is also important that the information gained at a particular level must be used and, in fact, may be vital for the implementation of the next step. The method is, by construction, sweeping out all possible solutions, since no ad-hoc assumption has been made. Therefore, *if successfully applied to a given Bianchi Cosmology*, it will result in the cartography of the entire space of solutions.

The successful application of the procedure to Bianchi Type III resulted in the recovery of all known solutions without the prior assumption of any extra symmetry [(3.32), (3.40)], the enclosure of the entire unknown part of the solution space into a single, second order ODE in terms of one dependent variable (3.52), and a partial solution to this ODE. It is of interest that the solution space is naturally partitioned into three distinct disconnected pieces. Of great importance may be considered the fact that a strikingly similar ODE describes the unknown part of the solution space for other lower Bianchi Types. For Types VIII, IX there remain no rigid automorphisms after the shift has been set to zero and the constant rotations have been used to diagonalize the scale-factor matrix. However, there is the scaling symmetry Y_2 that can serve as a starting point. This issue, along with the presentation of the detailed cartography for the lower types is in our immediate scopes. Finally, the method can be extended toward either the inclusion of matter content, or in 4+1 spatially homogeneous cosmologies.

ACKNOWLEDGMENTS

The authors wish to thank Dr. G. O. Papadopoulops for enlightening discussions concerning the invariants and Dr. P. Apostolopoulos for bringing to their attention the existing solutions and discussions on them. The authors are also indebted to Professor M. A. H. MacCallum who, in a

private communication, pointed out that the solution (3.54) belongs to Kinnersley's family and is not new. The project is cofunded by the European Social Fund and National Resources—(EPEAEK II) PYTHAGORAS II.

(Received 6 June 2006; accepted 8 September 2006; published online 25 October 2006)

We investigate the existence of time-periodic solutions of the Dirac equation in the Kerr-Newman background metric. To this end, the solutions are expanded in a Fourier series with respect to the time variable t, and the Chandrasekhar separation ansatz is applied so that the question of existence of a time-periodic solution is reduced to the solvability of a certain coupled system of ordinary differential equations. First, we prove the already known result that there are no time-periodic solutions in the nonextreme case. Then, it is shown that in the extreme case for fixed black hole data there is a sequence of particle masses $(m_N)_{N\in\mathbb{N}}$ for which a time-periodic solution of the Dirac equation does exist. The period of the solution depends only on the data of the black hole described by the Kerr-Newman metric. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2358394]

I. INTRODUCTION

In this paper we consider the system consisting of a Kerr-Newman black hole and an electron. The Kerr-Newman metric describing the black hole is the most general electrovac solution of Einstein's field equations. It describes a rotating, electrically charged, massive black hole; see, e.g., Refs. 15 and 9. We are interested in the stability of a system consisting of such a black hole and an electron. To this end, we have to consider the Dirac equation for the electron in the Kerr-Newman metric; see Eqs. (1) and (2)–(6). The Dirac equation is a complicated system of partial differential equations in all four space-time variables. We call the system consisting of the black hole and the electron *stable* if there exists a nontrivial time-periodic solution of the Dirac equation which can be interpreted as the wave function of the electron.

Since the black hole is rotating, the background metric is only axisymmetric, whereas in the nonrotating cases (the Schwarzschild and the Reissner-Nordstrøm geometries) the background metric is spherically symmetric. This loss of symmetry leads to a complicated coupling of the angular and the radial coordinates in the Dirac equation. Chandrasekhar[4] showed that, in spite of this complicated coupling, the Dirac equation can be separated into a system of ordinary differential equations, the so-called angular equation (13) and the radial equation (14). These differential equations have realizations as eigenvalue equations in appropriate Hilbert spaces. For the radial equation, $\omega=\nu\omega_0$ plays the role of the eigenvalue parameter. The eigenvalue ω has the physical interpretation as the energy of the electron. It should be emphasized that, due to the lack of spherical symmetry of the space-time, the eigenvalues of the radial and the angular equation are

a)Electronic mail: winklmeier@math.uni-bremen.de
b)Electronic mail: yamadaos@se.ritsumei.ac.jp

intertwined in a highly complex way. Hence, to show the stability of the system under consideration, it does not suffice to find eigenvalues of the radial and the angular equation separately; we need to show that the eigenvalues are compatible with each other.

In Sec. II we present the separation ansatz for time-periodic solutions of the Dirac equation in the Kerr-Newman background metric due to Chandrasekhar with mathematical rigor, and we derive the radial and angular equation. In the next section we consider the radial equation. It has been shown by Belgiorno and Martellini[2] that the essential spectrum of the radial operator covers the real axis. Finster *et al.*,[7,8] show the nonexistence of time-periodic solutions of the Dirac equation in the nonextreme Kerr-Newman geometry. Schmid[12] investigates the Dirac equations in the extreme Kerr-Newman geometry with the help of special functions, and shows the existence of bounded states in the extreme Kerr case, which implies the existence theorem of time-periodic solutions. Our aim is to study the difference between the extreme and nonextreme case from the viewpoint of spectral analysis of the radial Dirac operators. We give also the existence theorem of time-periodic solutions in the extreme Kerr-Newman case. In Theorem IV. 5 we show that in the nonextreme Kerr-Newman metric the Dirac equation has no time-periodic solution that has an interpretation as a particle wave function. The case of the extreme Kerr-Newman metric is investigated in Sec. V. It turns out that in this case there may be an eigenvalue of the radial equation. Schmid[12] proved a sufficient condition for the existence of a time-periodic solution of the Dirac equation. However, it is not easy to verify that for given particle data there are black hole parameters such that this condition can be satisfied. This problem is discussed in Sec. VI. We show that for fixed data of an extreme Kerr-Newman black hole there is a sequence of particle masses such that the system consisting of the quantum particle and the black hole permits time-periodic solutions.

II. SEPARATION OF THE DIRAC EQUATION IN THE KERR-NEWMAN BACKGROUND METRIC

We consider the Dirac equation (see, e.g., Page,[11] Chandrasekhar[4])

$$(\widehat{\mathcal{R}} + \widehat{\mathcal{A}})\hat{\Psi} = 0 \tag{1}$$

for a spin-$\frac{1}{2}$ particle with the mass $m \geq 0$ and the charge e in the Kerr-Newman geometry, where

$$\widehat{\mathcal{R}} := \begin{pmatrix} imr & 0 & \sqrt{\Delta}\mathcal{D}_+ & 0 \\ 0 & -imr & 0 & \sqrt{\Delta}\mathcal{D}_- \\ \sqrt{\Delta}\mathcal{D}_- & 0 & -imr & 0 \\ 0 & \sqrt{\Delta}\mathcal{D}_+ & 0 & imr \end{pmatrix}, \tag{2}$$

$$\widehat{\mathcal{A}} := \begin{pmatrix} -am\cos\theta & 0 & 0 & \mathcal{L}_+ \\ 0 & am\cos\theta & -\mathcal{L}_- & 0 \\ 0 & \mathcal{L}_+ & -am\cos\theta & 0 \\ -\mathcal{L}_- & 0 & 0 & am\cos\theta \end{pmatrix}, \tag{3}$$

$$\mathcal{D}_\pm := \frac{\partial}{\partial r} \mp \frac{1}{\Delta}\left[(r^2 + a^2)\frac{\partial}{\partial t} + a\frac{\partial}{\partial \varphi} - ieQr\right], \tag{4}$$

$$\mathcal{L}_\pm := \frac{\partial}{\partial \theta} + \frac{\cot\theta}{2} \mp i\left[a\sin\theta\frac{\partial}{\partial t} + \frac{1}{\sin\theta}\frac{\partial}{\partial \varphi}\right], \tag{5}$$

$$\Delta(r) := r^2 - 2Mr + a^2 + Q^2 \tag{6}$$

and $\hat{\Psi}$ is the wave function of the spin-$\frac{1}{2}$ particle under consideration. If the so-called black hole condition

$$M^2 - a^2 - Q^2 \geq 0 \tag{7}$$

holds, then the Kerr-Newman geometry is interpreted as the space-time geometry generated by a black hole with the mass $M \geq 0$, the electric charge Q, and the angular moment J; if $M \neq 0$, then the so-called Kerr parameter $a = J/M$ is the angular momentum of the black hole per unit mass. The black hole condition (7) ensures that the function Δ can be written as the product

$$\Delta(r) = (r - r_+)(r - r_-), \tag{6'}$$

with

$$r_\pm = M \pm \sqrt{M^2 - a^2 - Q^2}. \tag{8}$$

The special case $M^2 - a^2 - Q^2 = 0$, that is the case where $r_+ = r_- = M$, is referred to as the extreme Kerr-Newman metric.

Let us recall that the Kerr-Newman metric is the most general electrovac solution of Einstein's field equations.[9] Special cases contained in the Kerr-Newman geometry are the Kerr geometry (if $Q=0$), the Reissner-Nordstrøm geometry (if $a=0$), and the Schwarzschild geometry (if $Q=0$ and $a=0$).

A solution $\hat{\Psi}$ of (1) for $(r,\theta,\varphi,t) \in \hat{\Omega} := (r_+,\infty) \times (0,\pi) \times (-\pi,\pi) \times (-\infty,\infty)$ such that for every fixed time t the function $\hat{\Psi}(\cdot,\cdot,\cdot,t)$ lies in a suitable L^2-space $\mathcal{H}_{r,\theta,\varphi}$ [see (9)] can be interpreted as the wave function of the electron. Hence, the existence of such a $\hat{\Psi}$ would imply that the system consisting of the black hole and the spin-$\frac{1}{2}$ particle in its exterior is stable.

Remark II.1 (Dirac equation in flat space time): In the case of flat space-time, i.e., for $a=0$, $M=0$, $Q=0$, the Dirac equation given in (1) is unitarily equivalent to the familiar Dirac equation

$$\left(-i\frac{\partial}{\partial t} - i\vec{\alpha}\cdot\vec{\nabla} + \beta m\right)\Psi = 0$$

as given, for instance, in Davydov.[5] For the proof we refer to Winklmeier.[18]

A. Time-periodic solutions

In this paper we consider time-periodic solutions $\hat{\Psi}$, that is, solutions such that

$$\hat{\Psi}(r,\theta,\varphi,t) = \hat{\Psi}\left(r,\theta,\varphi,t + \frac{2\pi}{\omega_0}\right) \quad ((r,\theta,\varphi,t) \in \hat{\Omega})$$

for some $\omega_0 > 0$. In this case, the solutions can be expanded in a Fourier series

$$\hat{\Psi}(r,\theta,\varphi,t) = \sum_{\nu\in\mathbb{Z}} \exp(-i\nu\omega_0 t)\Psi^\nu(r,\theta,\varphi).$$

For physical reasons, each wave function Ψ^ν must be an element of the Hilbert space

$$\mathcal{H}_{r,\theta,\varphi} := L^2\left((r_+,\infty) \times (0,\pi) \times (-\pi,\pi); \frac{r^2+a^2}{\Delta(r)} \sin\theta \, dr \, d\theta \, d\varphi\right)^4 \tag{9}$$

with the inner product according to Finster *et al.*[7,8]

$$(\Psi,\Phi)=\int_{r_+}^{\infty}\int_0^{\pi}\int_{-\pi}^{\pi}\langle\Psi(r,\theta,\varphi),\Phi(r,\theta,\varphi)\rangle_{\mathbb{C}^4}\frac{r^2+a^2}{\Delta(r)}\sin\theta\,\mathrm{d}r\,\mathrm{d}\theta\,\mathrm{d}\varphi. \tag{10}$$

Here $\langle\cdot,\cdot\rangle_{\mathbb{C}^4}$ is the usual scalar product on $\mathbb{C}^4$. In order to separate also the φ-dependence of the solution Ψ^ν we use the complete system $\{\exp(i\kappa\varphi):\kappa\in\mathbb{Z}+\frac{1}{2}\}$ in $L^2((-\pi,\pi);d\varphi)$ to employ the ansatz

$$\Psi^\nu(r,\theta,\varphi)=\sum_{\kappa\in\mathbb{Z}+(1/2)}\exp(-i\kappa\varphi)\Psi^{\nu,\kappa}(r,\theta).$$

Thus, if

$$\hat{\Psi}(r,\theta,\varphi,t)=\sum_{\nu\in\mathbb{Z}}\sum_{\kappa\in\mathbb{Z}+(1/2)}\exp(-i\omega_0\nu t)\exp(-i\kappa\varphi)\Psi^{\nu,\kappa}(r,\theta)$$

satisfies (1), then each $\Psi^{\nu,\kappa}$ is a solution of

$$(\mathcal{R}_{\nu,\kappa}+\mathcal{A}_{\nu,\kappa})\Psi^{\nu,\kappa}=0\quad\text{on}\quad(r_0,\infty)\times(0,\pi), \tag{11}$$

where $\mathcal{R}_{\nu,\kappa}$ and $\mathcal{A}_{\nu,\kappa}$ are obtained from (2) and (3) by replacing $\mathcal{D}_\pm$ and $\mathcal{L}_\pm$ by

$$\mathcal{D}_{\pm,\nu,\kappa}:=\frac{\partial}{\partial r}\pm\frac{i}{\Delta}[\omega_0\nu(r^2+a^2)+\kappa a+eQr],$$

$$\mathcal{L}_{\pm,\nu,\kappa}:=\frac{\partial}{\partial\theta}+\frac{\cot\theta}{2}\mp\left[a\omega_0\nu\sin\theta+\frac{\kappa}{\sin\theta}\right],$$

respectively (see the proof of Theorem IV.5).

B. Separation of the radial and the angular coordinate

To study Eq. (11) we consider the formal differential expression

$$\mathfrak{A}_{\nu,\kappa}:=\begin{pmatrix}-am\cos\theta & \mathcal{L}_{-,\nu,\kappa}\\ -\mathcal{L}_{+,\nu,\kappa} & am\cos\theta\end{pmatrix}$$

for $\theta\in(0,\pi)$. For any half integer κ the differential expression $\mathfrak{A}_{\nu,\kappa}$ has a unique self-adjoint realization $A_{\nu,\kappa}$ in the Hilbert space $L^2((0,\pi);\sin\theta\,\mathrm{d}\theta)^2$ which has purely discrete spectrum $\sigma(A_{\nu,\kappa})=\{\lambda_{\nu,\kappa,n}:n\in\mathbb{Z}\setminus\{0\}\}\subseteq\mathbb{R}$, where each eigenvalue is simple (see, e.g., Batic *et al.*,[1] Winklmeier[18]). Hence, there is a complete set of orthonormal eigenfunctions of $A_{\nu,\kappa}$

$$g^{\nu,\kappa,n}:=\begin{pmatrix}g_1^{\nu,\kappa,n}\\ g_2^{\nu,\kappa,n}\end{pmatrix}\in L^2((0,\pi);\sin\theta\,\mathrm{d}\theta)^2\quad(n\in\mathbb{Z}\setminus\{0\}) \tag{12}$$

with eigenvalues $\lambda_{\nu,\kappa,n}$. The family (12) allows us to make the ansatz

$$\Psi^{\nu,\kappa}=\sum_{n\in\mathbb{Z}\setminus\{0\}}\Psi^{\nu,\kappa,n}$$

with

$$\Psi^{\nu,\kappa,n}(r,\theta)=\begin{pmatrix} X_-^{\nu,\kappa,n}(r)g_2^{\nu,\kappa,n}(\theta) \\ X_+^{\nu,\kappa,n}(r)g_1^{\nu,\kappa,n}(\theta) \\ X_+^{\nu,\kappa,n}(r)g_2^{\nu,\kappa,n}(\theta) \\ X_-^{\nu,\kappa,n}(r)g_1^{\nu,\kappa,n}(\theta) \end{pmatrix} \quad (r\in(r_+,\infty),\theta\in(0,\pi)),$$

which leads to a separation of the angular coordinate θ and the radial coordinate r (cf. Chandrasekhar[4]): the angular function $g^{\nu,\kappa,n}$ satisfies the angular equation

$$A_{\nu,n}g^{\nu,\kappa,n}=\lambda_{\nu,\kappa,n}g^{\nu,\kappa,n}, \tag{13}$$

with the integrability condition $g^{\nu,\kappa,n}\in L^2((0,\pi);\sin\theta\,\mathrm{d}\theta)$ and the radial function $X^{\nu,\kappa,n}={}^t(X_+^{\nu,\kappa,n},X_-^{\nu,\kappa,n})$ satisfies the radial equation

$$\begin{pmatrix} -imr-\lambda_{\nu,\kappa,n} & \sqrt{\Delta}\mathcal{D}_{-,\nu,\kappa} \\ \sqrt{\Delta}\mathcal{D}_{+,\nu,\kappa} & imr-\lambda_{\nu,\kappa,n} \end{pmatrix}\begin{pmatrix} X_+^{\nu,\kappa,n}(r) \\ X_-^{\nu,\kappa,n}(r) \end{pmatrix}=0, \tag{14}$$

with the integrability condition arising from the inner product on $\mathcal{H}_{r,\theta,\varphi}$

$$\int_{r_+}^{\infty}(|X_+^{\nu,\kappa,n}(r)|^2+|X_-^{\nu,\kappa,n}(r)|^2)\frac{r^2+a^2}{\Delta(r)}\mathrm{d}r<\infty. \tag{15}$$

C. The radial equation

Let

$$W:=\frac{1}{\sqrt{2}}\begin{pmatrix} -i & i \\ -1 & -1 \end{pmatrix},\quad V:=\begin{pmatrix} 0 & -1/\sqrt{\Delta} \\ 1/\sqrt{\Delta} & 0 \end{pmatrix},$$

$$\tilde{f}^{\nu,\kappa,n}(r):=\begin{pmatrix} \tilde{f}_1^{\nu,\kappa,n}(r) \\ \tilde{f}_2^{\nu,\kappa,n}(r) \end{pmatrix}:=W\begin{pmatrix} X_+^{\nu,\kappa,n}(r) \\ X_-^{\nu,\kappa,n}(r) \end{pmatrix}. \tag{16}$$

Then, we obtain from (14)

$$\begin{aligned} 0&=VW\begin{pmatrix} -imr-\lambda_{\nu,\kappa,n} & \sqrt{\Delta}\mathcal{D}_{-,\nu,\kappa} \\ \sqrt{\Delta}\mathcal{D}_{+,\nu,\kappa} & imr-\lambda_{\nu,\kappa,n} \end{pmatrix}W^{-1}\tilde{f}^{\nu,\kappa,n}(r) \\ &=\begin{pmatrix} \dfrac{mr}{\sqrt{\Delta}}-\dfrac{a\kappa+eQr+\omega_0\nu(r^2+a^2)}{\Delta} & -\dfrac{d}{dr}+\dfrac{\lambda_{\nu,\kappa,n}}{\sqrt{\Delta}} \\ \dfrac{d}{dr}+\dfrac{\lambda_{\nu,\kappa,n}}{\sqrt{\Delta}} & -\dfrac{mr}{\sqrt{\Delta}}-\dfrac{a\kappa+eQr+\omega_0\nu(r^2+a^2)}{\Delta} \end{pmatrix}\tilde{f}^{\nu,\kappa,n}(r) \end{aligned} \tag{17}$$

for $r\in(r_+,\infty)$ (see Winklmeier[18]).

Remark II.2: If we take into account only terms of first order in $1/r$ for large r, then the radial equation becomes

$$\begin{pmatrix} m-\dfrac{eQ}{r}+\omega_0\nu & -\dfrac{d}{dr}+\dfrac{\lambda_{\nu,n,\kappa}}{r} \\ \dfrac{d}{dr}+\dfrac{\lambda_{\nu,n,\kappa}}{r} & -m-\dfrac{eQ}{r}+\omega_0\nu \end{pmatrix}\tilde{f}(r)=0,$$

which is exactly the radial equation for the relativistic hydrogen atom see; e.g., Bjorken and Drell.[3]

Remark II.3: It is important to note that in the case $a \neq 0$ the eigenvalue λ for the angular equation does depend on $\omega_0 \nu$. In the case $a=0$, the eigenvalues can be calculated explicitly; they are given by

$$\sigma(A_{\nu,\kappa}) = \left\{ \lambda_{\nu,\kappa,n} = \operatorname{sign}(n)\left(|\kappa| - \frac{1}{2} + |n| \right) : n \in \mathbb{Z} \setminus \{0\} \right\} \subseteq \mathbb{R}. \tag{18}$$

In particular, the eigenvalues $\lambda_{\nu,\kappa,n}$ of the radial equation do not depend on the eigenvalues of the radial equation. Hence, in the case $a=0$, for a solution of the complete problem (14)–(13) first the angular problem $(A_{\nu,\kappa}-\lambda_{\nu,\kappa})g=0$ is solved for the eigenvalues $\lambda_{\nu,\kappa,n}$, and then the radial equation (14) can be attacked for fixed $\lambda_{\nu,\kappa,n}$.

We introduce a new coordinate x such that

$$\frac{dx}{dr} = \frac{r^2+a^2}{\Delta(r)} \quad (r > r_+), \tag{19}$$

that is,

$$x(r) = \begin{cases} r + \dfrac{r_+^2+a^2}{r_+-r_-}\log(r-r_+) - \dfrac{r_+^2+a^2}{r_+-r_-}\log(r-r_-) + x_0 & (r_+ \neq r_-), \\ r + 2r_+\log(r-r_+) - \dfrac{r_+^2+a^2}{r-r_+} + x_0 & (r_+ = r_-), \end{cases} \tag{20}$$

where x_0 is a constant of integration that can be set $x_0=0$. The correspondence between $r>r_+$ and $x \in (-\infty, \infty)$ is a bijection. With the new coordinate x Eq. (17) becomes

$$H_{\nu,\kappa,n} f^{\nu,\kappa,n} := \begin{pmatrix} \dfrac{mr\sqrt{\Delta}}{r^2+a^2} - \dfrac{a\kappa+eQr}{r^2+a^2} & -\dfrac{d}{dx} + \dfrac{\lambda_{\nu,\kappa,n}\sqrt{\Delta}}{r^2+a^2} \\ \dfrac{d}{dx} + \dfrac{\lambda_{\nu,\kappa,n}\sqrt{\Delta}}{r^2+a^2} & -\dfrac{mr\sqrt{\Delta}}{r^2+a^2} - \dfrac{a\kappa+eQr}{r^2+a^2} \end{pmatrix} f^{\nu,\kappa,n} = \omega_0 \nu f^{\nu,\kappa,n}, \tag{21}$$

where r has to be understood as $r(x)$ and $f^{\nu,\kappa,n}(x) = \tilde{f}^{\nu,\kappa,n}(r(x))$, $f_j^{\nu,\kappa,n}(x) = \tilde{f}_j^{\nu,\kappa,n}(r(x))$ for all $x \in (-\infty, \infty)$ and $j \in \{1,2\}$. In view of (16) and (19) the integrability condition (15) becomes

$$\int_{-\infty}^{\infty} \|f^{\nu,\kappa,n}(x)\|_{\mathbb{C}^2}^2 dx = \int_{-\infty}^{\infty} [|f_1^{\nu,\kappa,n}(x)|^2 + |f_2^{\nu,\kappa,n}(x)|^2] \, dx < \infty. \tag{22}$$

The operator $H_{\nu,\kappa,n}$ is formally symmetric in the Hilbert space $\mathcal{H}_x := L^2((-\infty,\infty);dx)^2$, so it is natural to look for an operator theoretical realization of $H_{\nu,\kappa,n}$ in the Hilbert space $\mathcal{H}_x$. The purpose of this article is to investigate the spectral properties of the self-adjoint operator $H_{\nu,\kappa,n}$ in $\mathcal{H}_x = L^2((-\infty,\infty);dx)^2$ and to study the nonexistence of nontrivial solutions satisfying (11). In Sec. VI we will investigate the existence of so-called energy eigenvalues of $H_{\nu,\kappa,n}$ (cf. Schmid[12]).

Definition II. 4: We call $\omega \in \mathbb{R}$ an *energy eigenvalue* of $H_{\nu,\kappa,n}$ if there are $\lambda_{\nu,\kappa,n}$ such that ω is an eigenvalue of $H_{\nu,\kappa,n}$ and $\lambda_{\nu,\kappa,n}$ is an eigenvalue of $A_{\nu,\kappa}$, that is, if Eqs. (13) and (14) can be solved simultaneously with functions satisfying the corresponding integrability conditions.

III. THE OPERATOR *H*

In this and the following sections we consider the eigenvalue equation $(H_{\nu,\kappa,n}-\omega\nu_0)f^{\nu,\kappa,n}=0$ from (21) on the Hilbert space $\mathcal{H}_x = L^2((-\infty,\infty);dx)^2$.

If there is no ambiguity, we omit the indices ν, n, and κ in the following for the sake of clarity; for instance, we write simply H instead of $H_{\nu,\kappa,n}$, λ instead of $\lambda_{\nu,\kappa,n}$, and ω instead of $\omega_0\nu$. We decompose the operator H into the sum

$$H = H_0 + V,$$

where

$$H_0 = \begin{pmatrix} 0 & -\frac{d}{dx} \\ \frac{d}{dx} & 0 \end{pmatrix}, \quad \mathcal{D}(H_0) = \mathcal{C}_0^\infty(-\infty, \infty)^2,$$

$$V(x) = \begin{pmatrix} A(x) & B(x) \\ B(x) & C(x) \end{pmatrix},$$

$$A(x) = \frac{mr(x)\sqrt{\Delta(r(x))}}{r(x)^2 + a^2} - \frac{a\kappa + eQr(x)}{r(x)^2 + a^2},$$

$$B(x) = \lambda \frac{\sqrt{\Delta(r(x))}}{r(x)^2 + a^2},$$

$$C(x) = -\frac{mr(x)\sqrt{\Delta(r(x))}}{r(x)^2 + a^2} - \frac{a\kappa + eQr(x)}{r(x)^2 + a^2},$$

$$\Delta(x) = (r(x) - r_+)(r(x) - r_-).$$

The operator H_0 is symmetric and has a unique self-adjoint extension on the space $L^2((-\infty, \infty); dx)^2$, see, e.g., Weidmann (Ref. 17, Theorem 6.8). Since $x \to -\infty$ is equivalent to $r(x) \to r_+$ and $x \to \infty$ is equivalent to $r(x) \to \infty$, we have

$$\lim_{x \to -\infty} A(x) = -\frac{a\kappa + eQr_+}{r_+^2 + a^2} =: A_0, \quad \lim_{x \to +\infty} A(x) = m,$$

$$\lim_{x \to -\infty} C(x) = A_0, \quad \lim_{x \to +\infty} C(x) = -m,$$

$$\lim_{x \to \pm\infty} B(x) = 0$$

which implies that the functions $A(\cdot)$, $B(\cdot)$, and $C(\cdot)$ are bounded. Since we assume that the black hole condition (7) holds, the multiplication operator V is symmetric. Therefore, $H = H_0 + V$ has a unique self-adjoint extension which we again denote by H.

In what follows, a prime $'$ always denotes differentiation with respect to x.

Lemma III.1 (*Asymptotic behavior of V for* $x \to -\infty$):

(i) *For* $x \to -\infty$ *the functions*

$$A(x) - A_0, \quad B(x), \quad C(x) - A_0$$

decay exponentially in the case $r_+ \neq r_-$, *and they are of order* $O(x^{-1})$ *in the case* $r_+ = r_-$. *More precisely, in the latter case we have*

$$A(x) - A_0 = \frac{mM - \mu}{-x} + O\left(\frac{1}{x^2}\right) \quad \text{as } x \to -\infty,$$

$$A_0 - C(x) = \frac{mM+\mu}{-x} + O\left(\frac{1}{x^2}\right) \quad \text{as } x \to -\infty,$$

$$B(x) = \frac{\lambda}{x} + O\left(\frac{1}{x^2}\right) \quad \text{as } x \to -\infty,$$

where

$$\mu := -\frac{2a\kappa M}{M^2+a^2} - eQ\frac{M^2-a^2}{M^2+a^2}.$$

(ii) *The derivatives* A', B', *and* C' *are integrable with respect to* x *on* $(-\infty, 0]$.
(iii) $A'(x) = O(x^{-2})$, $B'(x) = O(x^{-2})$, *and* $C'(x) = O(x^{-2})$ *hold as* $x \to +\infty$.

Proof. We prove the assertions for the functions B and A only. The corresponding assertions for C can be obtained from those for A by substituting m by $-m$. We remark that (20) shows

$$r(x) - r_+ = O(\exp(\alpha x)) \quad \text{as } x \to -\infty \quad (r_+ \neq r_-), \tag{23}$$

$$r(x) - r_+ = O(x^{-1}) \quad \text{as } x \to -\infty \quad (r_+ = r_-) \tag{24}$$

for a positive constant α. To keep notation simple, let us write r instead of $r(x)$ in this proof.

(i) Note that

$$\frac{1}{r^2+a^2} = \frac{1}{r_+^2+a^2} - \frac{(r-r_+)(r+r_+)}{(r_+^2+a^2)(r^2+a^2)} = \frac{1}{r_+^2+a^2} + O(r-r_+). \tag{25}$$

Hence, it follows immediately that

$$B(x) = \lambda\frac{\sqrt{\Delta(r)}}{r^2+a^2} = \lambda\sqrt{\Delta(r)}\left(\frac{1}{r_+^2+a^2} + O(r-r_+)\right).$$

If we recall that $\Delta(r(x)) = (r(x)-r_+)(r(x)-r_-)$ and use the relations (23) and (24), we see that the assertion for B holds.

Now we prove the assertions for A. Simple calculations show

$$\begin{aligned} A(x) - A_0 &= \frac{mr\sqrt{\Delta(r)}}{r^2+a^2} + \frac{(r^2+a^2)(a\kappa+eQr_+) - (r_+^2+a^2)(a\kappa+eQr)}{(r^2+a^2)(r_+^2+a^2)} \\ &= \frac{mr\sqrt{\Delta(r)}}{r^2+a^2} + \frac{(r-r_+)[(r-r_+)(a\kappa+eQr_+) + 2a\kappa r_+ + eQ(r_+^2-a^2)]}{(r^2+a^2)(r_+^2+a^2)} \\ &= \frac{mr_+\sqrt{\Delta(r)}}{r^2+a^2} + \frac{r-r_+}{r^2+a^2}\left[m\sqrt{\Delta(r)} + \frac{(r-r_+)(a\kappa+eQr_+) + 2a\kappa r_+ + eQ(r_+^2-a^2)}{r_+^2+a^2}\right]. \end{aligned}$$

Using the relations (25) and (23), we see that the assertion holds for the case $r_+ \neq r_-$. In the case $r_+ = r_-$ we have $\Delta(r) = (r-r_+)^2 = (r-M)^2$; hence, we can continue the calculation above as follows:

$$A(x)-A_0=\frac{r-r_+}{r^2+a^2}\left[mr_+ +\frac{2a\kappa r_+ +eQ(r_+^2-a^2)}{r_+^2+a^2}+(r-r_+)\left(m+\frac{a\kappa+eQr_+}{r_+^2+a^2}\right)\right]$$
$$=\frac{r-r_+}{r^2+a^2}\left[mr_+ -\mu+(r-r_+)\left(m+\frac{a\kappa+eQr_+}{r_+^2+a^2}\right)\right].$$

The assertion follows now from (25) and (24).

(ii) A simple calculation gives

$$\frac{d}{dx}A(x)=\frac{dr}{dx}\frac{d}{dr}A(x(r))=\frac{\Delta(r)}{r^2+a^2}\frac{d}{dr}A(x(r))$$
$$=\frac{\sqrt{\Delta(r)}}{r^2+a^2}\left\{m\left(\frac{\Delta(r)}{r^2+a^2}+\frac{r\Delta'(r)}{2(r^2+a^2)}-\frac{2r^2\Delta(r)}{(r^2+a^2)^2}\right)\right.$$
$$\left.+\frac{2(a\kappa+eQr)r\sqrt{\Delta(r)}}{(r^2+a^2)^2}-\frac{eQ\sqrt{\Delta(r)}}{r^2+a^2}\right\}$$
$$=\begin{cases}O((r-r_+)^{1/2})=O(\exp[(1/2)\alpha x]), & (r_+\neq r_-),\\ O((r-r+)^2)=O(x^{-2}), & (r_+=r_-),\end{cases}\tag{26}$$

as $x\to-\infty$.

$$\frac{d}{dx}B(x)=\frac{dr}{dx}\frac{d}{dr}B(x(r))=\frac{\Delta(r)}{r^2+a^2}\frac{d}{dr}B(x(r))=\lambda\frac{\sqrt{\Delta(r)}}{r^2+a^2}\left\{\frac{\Delta'(r)}{2(r^2+a^2)}-\frac{2r\Delta(r)}{(r^2+a^2)^2}\right\}$$
$$=\begin{cases}O((r-r_+)^{1/2})=O(\exp[(1/2)\alpha x]), & (r_+\neq r_-),\\ O((r-r+)^2)=O(x^{-2}), & (r_+=r_-),\end{cases}\tag{27}$$

as $x\to-\infty$.

(iii) Since

$$\frac{dr}{dx}=\frac{\Delta(r)}{r^2+a^2}\sim 1,\quad x\sim r\quad \text{as } x\to+\infty,$$

and

$$2(r^2+a^2)\Delta(r)+r(r^2+a^2)\Delta'(r)-4r^2\Delta(r)=2Mr^3+2r^2(a^2-Q^2)$$
$$-6a^2Mr+2a^2(a^2+Q^2)\sim r^3\quad \text{as } r\to\infty,$$

the assertion follows from (26). The proof of the assertion concerning $B'(x)$ follows directly from (27). □

IV. ABSOLUTELY CONTINUOUS SPECTRUM

The following proposition has been shown by Belgiorno and Martellini.[2]

Proposition IV.1: $\sigma_{\mathrm{ess}}(H)=\mathbb{R}$. □

We point out that the proof of the proposition relies on the fact that

$$\lim_{x\to-\infty}[V(x)-A_0I_2]=0,\tag{28}$$

where I_2 is the 2×2 unit matrix. Lemma III.1 yields the following theorem.

Theorem IV.2:

(i) *H has purely absolutely continuous spectrum in $\mathbb{R}\backslash\{A_0\}$.*

(ii) *H has purely absolutely continuous spectrum in $(-\infty,-m)$ and $(m,+\infty)$, that is, H is absolutely continuous in the complement of $[-m,m]\cap\{A_0\}$.*

Proof.

(i) *Lemma III.1 gives (28) and any component of V' is integrable at $-\infty$. Therefore, we can prove the theorem in view of Weidmann,[16] Schmidt,[13] and also Thaller (Ref. 14, Theorem 4.18).*

(ii) The proof is the same as in (i) by using Lemma III.1 (iii). □

Remark IV.3: The above theorem has already been proven by Schmid by different means [see Schmid (Ref. 12, Corollary 3.4)]; in addition, he has shown that neither $\omega=m$ nor $\omega=-m$ is an eigenvalue of H (Ref. 12, Lemma 3.5).

Theorem IV.4: *If $r_+\neq r_-$, then A_0 is not an eigenvalue of H.*

Proof. Let us assume that $U={}^t(u_1,u_2)\in\mathcal{H}_x$ satisfies

$$\begin{pmatrix} A & B-\dfrac{d}{dx} \\ B+\dfrac{d}{dx} & C \end{pmatrix}\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}=A_0\begin{pmatrix} u_1 \\ u_2 \end{pmatrix},$$

that is,

$$U'=\begin{pmatrix} u_1' \\ u_2' \end{pmatrix}=\begin{pmatrix} -B & A_0-C \\ A-A_0 & B \end{pmatrix}\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}. \tag{29}$$

As seen in Sec. III, $A(x)-A_0$, $B(x)$ and $C(x)-A_0$ decay exponentially as $x\to-\infty$. Therefore, the Levinson theorem (e.g., Eastham[6]) gives that there are two linearly independent solutions U^1, U^2 of (29) such that

$$U^1(x)=\left\{\begin{pmatrix} 1 \\ 0 \end{pmatrix}+o(1)\right\}\quad \text{as } x\to-\infty,$$

$$U^2(x)=\left\{\begin{pmatrix} 0 \\ 1 \end{pmatrix}+o(1)\right\}\quad \text{as } x\to-\infty.$$

Hence there are constants c_1 and c_2 such that $U(x)=c_1U^1(x)+c_2U^2(x)$, which is square integrable on $(-\infty,0)$ only if $c_1=c_2=0$. □

As an important corollary we obtain the following theorem.

Theorem IV.5 (Nonexistence of time-periodic solutions for $r_+\neq r_-$): *Let $\hat{\Psi}\in C^1((r_0,\infty)\times(0,\pi)\times[-\pi,\pi]\times\mathbb{R},\mathbb{C}^4)$ be a solution of (1) satisfying the periodicity conditions*

$$\begin{aligned}&\hat{\Psi}(r,\theta,\varphi,t)=\hat{\Psi}\left(r,\theta,\varphi,t+\frac{2\pi}{\omega_0}\right), \quad (r,\theta,\varphi,t)\in\hat{\Omega}\\ &\hat{\Psi}(r,\theta,\pi,t)=\hat{\Psi}(r,\theta,-\pi,t),\end{aligned} \tag{30}$$

for some $\omega_0>0$. Furthermore, assume that for all $(\varphi,t)\in[-\pi,\pi]\times\mathbb{R}$ we have $\hat{\Psi}(\cdot,\cdot,\varphi,t)\in C^0((r_0,\infty)\times(0,\pi);\mathcal{H}_{r,\theta})$, where

$$\mathcal{H}_{r,\theta}:=L^2\left((r_+,\infty)\times(0,\pi);\ \frac{r^2+a^2}{\Delta(r)}\sin\theta\,dr\,d\theta\right)^4$$

with the norm denoted by $\|\cdot\|_{\mathcal{H}_{r,\theta}}$ and the inner product denoted by $\langle\cdot,\cdot\rangle_{\mathcal{H}_{r,\theta}}$.

If $r_- \neq r_+$, *then* $\hat{\Psi} \equiv 0$.

Proof. Let $\hat{\Psi}$ be a time-periodic solution satisfying the conditions of the theorem. Then, $\hat{\Psi}(\cdot,\cdot,\cdot,t)$ is an $\mathcal{H}_{r,\theta,\varphi}$-valued strongly continuous function with respect to t since $\hat{\Psi}(\cdot,\cdot,\varphi,t)$ is uniformly continuous in $\mathcal{H}_{r,\theta}$ with respect to $(\varphi,t) \in [-\pi,\pi]\times\mathbb{R}$. Therefore, we can expand $\hat{\Psi}(r,\theta,\varphi,t)$ as the Fourier series with respect to t

$$\hat{\Psi}(r,\theta,\varphi,t) = \sum_{\nu\in\mathbb{Z}} \exp(-i\omega_0\nu t)\Psi^{\nu}(r,\theta,\varphi)$$

strongly in $L^2([0,2\pi/\omega_0];\mathcal{H}_{r,\theta,\varphi};dt)$, where

$$\Psi^{\nu}(r,\theta,\varphi) = \frac{\omega_0}{2\pi}\int_0^{2\pi/\omega_0} \exp(i\omega_0\nu t)\hat{\Psi}(r,\theta,\varphi,t)dt, \quad \sum_{\nu} \|\Psi^{\nu}\|^2_{\mathcal{H}_{r,\theta,\varphi}} < \infty .$$

Moreover, each $\Psi^{\nu}(r,\theta,\varphi)$ can be expanded as

$$\Psi^{\nu}(r,\theta,\varphi) = \sum_{\kappa\in\mathbb{Z}+(1/2)} \exp(-i\kappa\varphi)\Psi^{\nu,\kappa}(r,\theta)$$

strongly in $L^2([-\pi,\pi];\mathcal{H}_{r,\theta};d\varphi)$ with

$$\Psi^{\nu}(\theta,\varphi) = \frac{1}{2\pi}\int_{-\pi}^{\pi} \exp(i\kappa\varphi)\Psi^{\nu}(r,\theta,\varphi)d\varphi, \quad \sum_{\kappa} \|\Psi^{\nu,\kappa}\|^2_{\mathcal{H}_{r,\theta}} < \infty .$$

For every $\Phi \in \mathcal{C}_0^{\infty}((r_0,\infty)\times(0,\pi))^4$ of the form

$$\Phi(r,\theta) = \begin{pmatrix} \rho_-(r)\,\eta_2(\theta) \\ \rho_+(r)\,\eta_1(\theta) \\ \rho_+(r)\,\eta_2(\theta) \\ \rho_-(r)\,\eta_1(\theta) \end{pmatrix}$$

with $\rho_{\pm}(r) \in \mathcal{C}_0^{\infty}((r_+,\infty))$, $\eta_1(\theta)$, $\eta_2(\theta) \in \mathcal{C}_0^{\infty}((0,\pi))$ we obtain, by using (30),

$$\begin{aligned}
0 &= \int_0^{2\pi/\omega_0} \mathrm{d}t \int_{-\pi}^{\pi} \mathrm{d}\varphi\, \langle (\hat{\mathcal{R}}+\hat{\mathcal{A}})\hat{\Psi}, \exp(-i\omega_0\nu t)\exp(-i\kappa\varphi)\Phi\rangle_{\mathcal{H}_{r,\theta}} \\
&= \int_0^{2\pi/\omega_0} \mathrm{d}t \int_{-\pi}^{\pi} \mathrm{d}\varphi\, \langle \hat{\Psi}, (\hat{\mathcal{R}}+\hat{\mathcal{A}})^* \exp(-i\omega_0\nu t)\exp(-i\kappa\varphi)\Phi\rangle_{\mathcal{H}_{r,\theta}} \\
&= \int_0^{2\pi/\omega_0} \mathrm{d}t \int_{-\pi}^{\pi} \mathrm{d}\varphi\, \langle \hat{\Psi}, \exp(-i\omega_0\nu t)\exp(-i\kappa\varphi)(\mathcal{R}_{\nu,\kappa}+\mathcal{A}_{\nu,\kappa})^*\Phi\rangle_{\mathcal{H}_{r,\theta}} \\
&= \int_0^{2\pi/\omega_0} \langle \hat{\Psi}, \exp(-i\omega_0\nu t)\exp(-i\kappa\varphi)(\mathcal{R}_{\nu,\kappa}+\mathcal{A}_{\nu,\kappa})^*\Phi\rangle_{\mathcal{H}_{r,\theta,\varphi}} \mathrm{d}t \\
&= \frac{2\pi}{\omega_0}\int_{-\pi}^{\pi} \langle \Psi^{\nu}, \exp(-i\kappa\varphi)(\mathcal{R}^*_{\nu,\kappa}+\mathcal{A}^*_{\nu,\kappa})\Phi\rangle_{\mathcal{H}_{r,\theta}} \mathrm{d}\varphi = \frac{4\pi^2}{\omega_0}\langle \Psi^{\nu,\kappa}, (\mathcal{R}^*_{\nu,\kappa}+A^*_{\nu,\kappa})\Phi\rangle_{\mathcal{H}_{r,\theta}}. \qquad (31)
\end{aligned}$$

In the above calculation, the superscript * denotes the formal adjoint operator. As in (12), for fixed ν and κ let

$$g^{\nu,\kappa,n}(\theta)=\begin{pmatrix} g_1^{\nu,\kappa,n}(\theta)\\ g_2^{\nu,\kappa,n}(\theta)\end{pmatrix}\quad (n\in\mathbb{Z}\setminus\{0\})$$

be a complete family of orthonormal eigenfunctions of $A_{\nu,\kappa}$ with eigenvalues $\lambda_{\nu,\kappa,n}$, respectively. Then, $\Psi^{\nu,\kappa}(r,\theta)$ can be expanded in terms of $g^{\nu,\kappa,n}$ $(n\in\mathbb{Z}\setminus\{0\})$ as follows:

$$\Psi^{\nu,\kappa}(r,\theta)=\sum_{n\in\mathbb{Z}\setminus\{0\}}\begin{pmatrix} X_-^{\nu,\kappa,n}(r)g_2^{\nu,\kappa,n}(\theta)\\ X_+^{\nu,\kappa,n}(r)g_1^{\nu,\kappa,n}(\theta)\\ X_+^{\nu,\kappa,n}(r)g_2^{\nu,\kappa,n}(\theta)\\ X_-^{\nu,\kappa,n}(r)g_1^{\nu,\kappa,n}(\theta)\end{pmatrix},$$

where the series converges in the strong sense in $L^2((0,\pi);\sin\theta\,\mathrm{d}\theta)^4$ and $X_\pm^{\nu,\kappa,n}(r)$ satisfies

$$\sum_{n\in\mathbb{Z}\setminus\{0\}}\int_{r_+}^{\infty}(|X_+^{\nu,\kappa,n}(r)|^2+|X_-^{\nu,\kappa,n}(r)|^2)\frac{r^2+a^2}{\Delta(r)}\mathrm{d}r<\infty.$$

Since $\mathfrak{A}_{\nu,\kappa}$ on $C_0^\infty((0,\pi))^2$ is essentially self-adjoint in $L^2((0,\pi);\sin\theta\,\mathrm{d}\theta)^2$, for any $g^{\nu,\kappa,n}(\theta)$ there exists a convergent sequence $\eta^\ell\in C_0^\infty((0,\pi))^2$ $(\ell=1,2,\dots)$ such that

$$A_{\nu,\kappa}\eta^\ell=A_{\nu,\kappa}\begin{pmatrix}\eta_1^\ell\\ \eta_2^\ell\end{pmatrix}\longrightarrow A_{\nu,\kappa}g^{\nu,\kappa,n}=\lambda_{\nu,\kappa,n}g^{\nu,\kappa,n}$$

in $L^2((0,\pi);\sin\theta\,\mathrm{d}\theta)^2$. Substituting Φ in (31) by

$$\Phi^\ell(r,\theta)=\begin{pmatrix}\rho_-(r)\eta_2^\ell(\theta)\\ \rho_+(r)\eta_1^\ell(\theta)\\ \rho_+(r)\eta_2^\ell(\theta)\\ \rho_-(r)\eta_1^\ell(\theta)\end{pmatrix}$$

and taking the limit $\ell\to\infty$, we have

$$\left\langle\sum_{m\in\mathbb{Z}\setminus\{0\}}\begin{pmatrix} X_-^{\nu,\kappa,m}(r)g_2^{\nu,\kappa,m}(\theta)\\ X_+^{\nu,\kappa,m}(r)g_1^{\nu,\kappa,m}(\theta)\\ X_+^{\nu,\kappa,m}(r)g_2^{\nu,\kappa,m}(\theta)\\ X_-^{\nu,\kappa,m}(r)g_1^{\nu,\kappa,m}(\theta)\end{pmatrix},\quad (R_{\nu,\kappa}^*-\lambda_{\nu,\kappa,n})\begin{pmatrix}\rho_-(r)g_2^{\nu,\kappa,n}(\theta)\\ \rho_+(r)g_1^{\nu,\kappa,n}(\theta)\\ \rho_+(r)g_2^{\nu,\kappa,n}(\theta)\\ \rho_-(r)g_2^{\nu,\kappa,n}(\theta)\end{pmatrix}\right\rangle_{\mathcal{H}_{r,\theta}}=0,$$

which gives

$$0=\int_{r_+}^{\infty}\mathrm{d}r\frac{r^2+a^2}{\Delta(r)}\left\langle\begin{pmatrix}X_+^{\nu,\kappa,n}\\ X_-^{\nu,\kappa,n}\end{pmatrix},\quad\begin{pmatrix} imr-\lambda_{\nu,\kappa,n} & \mathcal{D}_{+,\nu,\kappa}^*\sqrt{\Delta}\\ \mathcal{D}_{-,\nu,\kappa}^*\sqrt{\Delta} & -imr-\lambda_{\nu,\kappa,n}\end{pmatrix}\begin{pmatrix}\rho_+\\ \rho_-\end{pmatrix}\right\rangle_{\mathbb{C}^2},$$

which implies

$$\begin{pmatrix} -imr-\lambda_{\nu,\kappa,n} & \sqrt{\Delta}\mathcal{D}_{-,\nu,\kappa}\\ \sqrt{\Delta}\,\mathcal{D}_{+,\nu,\kappa} & imr-\lambda_{\nu,\kappa,n}\end{pmatrix}\begin{pmatrix}X_+^{\nu,\kappa,n}(r)\\ X_-^{\nu,\kappa,n}(r)\end{pmatrix}=0.$$

If we set [cf. (16) and (22)]

$$f^{\nu,\kappa,n}(x)=\begin{pmatrix}f_1^{\nu,\kappa,n}(r(x))\\ f_2^{\nu,\kappa,n}(r(x))\end{pmatrix}=\frac{1}{\sqrt{2}}\begin{pmatrix}-i & i\\ -1 & -1\end{pmatrix}\begin{pmatrix}X_+^{\nu,\kappa,n}(r(x))\\ X_-^{\nu,\kappa,n}(r(x))\end{pmatrix},$$

we have

$$H_{\nu,\kappa,n} f^{\nu,\kappa,n} = \omega_0 \nu f^{\nu,\kappa,n}$$

[see (21)]. Then, Theorem IV.2 and Theorem IV.4 give $f^{\nu,\kappa,n}=0$ for any $n \in \mathbb{Z}\backslash\{0\}$ and $\kappa \in \mathbb{Z}+(1/2)$, which yields $\Psi^{\nu,\kappa}(r,\theta)=0$.

The nonexistence of time-periodic solutions is shown by Finster *et al.*[7,8] by different means.

V. THE CASE $r_+=r_-$

In the previous section we have seen that there are no eigenvalues of (1) in the case $r_+ \neq r_-$. In this section we discuss whether A_0 is an eigenvalue of H in the case $r_+=r_-$. Recall that in this case the function Δ has only one zero and that $r_+=r_-=M$.

Theorem V.1: *If*

$$\lambda^2 + m^2M^2 - \mu^2 \leq \frac{1}{4},$$

then A_0 is not an eigenvalue of H.

Proof. Let us assume that $U={}^t(u_1,u_2) \in \mathcal{H}_x$ satisfies (29), that is,

$$U' = \begin{pmatrix} u_1' \\ u_2' \end{pmatrix} = \begin{pmatrix} -B & A_0 - C \\ A - A_0 & B \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}.$$

Lemma III.1 yields for $x \to -\infty$

$$U'(x) = -\frac{1}{x} \begin{pmatrix} \lambda & mM+\mu \\ mM-\mu & -\lambda \end{pmatrix} U(x) + O(x^{-2})U(x).$$

If we introduce $s=\log(-x)$, we have

$$\frac{d}{ds}U(x(s)) = \begin{pmatrix} \lambda & mM+\mu \\ mM-\mu & -\lambda \end{pmatrix} U(x(s)) + O(\exp(-s))U(x(s)) \quad \text{as } s \to +\infty. \tag{32}$$

The matrix

$$S := \begin{pmatrix} \lambda & mM+\mu \\ mM-\mu & -\lambda \end{pmatrix}$$

can be diagonalized by a nonsingular matrix T as

$$T^{-1}ST = \begin{pmatrix} \sqrt{\lambda^2 + m^2M^2 - \mu^2} & 0 \\ 0 & -\sqrt{\lambda^2 + m^2M^2 - \mu^2} \end{pmatrix}$$

if $\lambda^2+m^2M^2-\mu^2 \neq 0$. If $\lambda^2+m^2M^2-\mu^2=0$, its Jordan canonical form is

$$T^{-1}ST = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

According to Theorem 1.8.1 and Theorem 1.10.1 in Eastham,[6] we have two linearly independent solutions $U^1(s)$, $U^2(s)$ of (32) such that if $\lambda^2+m^2M^2-\mu^2 \neq 0$,

$$U^1(s) = \{v_1 + o(1)\}\exp(\sqrt{\lambda^2 + m^2M^2 - \mu^2}s) = \{v_1 + o(1)\}(-x)^{\sqrt{\lambda^2+m^2M^2-\mu^2}},$$

$$U^2(s) = \{v_2 + o(1)\}\exp(-\sqrt{\lambda^2 + m^2M^2 - \mu^2}s) = \{v_2 + o(1)\}(-x)^{-\sqrt{\lambda^2+m^2M^2-\mu^2}}$$

as $x \to -\infty$ and, if $\lambda^2+m^2M^2-\mu^2=0$,

$$U^1(s) = v_1 + o(1),$$

$$U^2(s) = sv_1 + v_2 + o(s) = v_1 \log(-x) + v_2 + o(\log(-x))$$

as $x \to -\infty$, where $T=(v_1, v_2)$.

Therefore, a necessary condition for the existence of an $\mathcal{L}^2(-\infty, 0)$-eigenfunction is

$$\sqrt{\lambda^2 + m^2M^2 - \mu^2} \in (1/2, \infty), \quad \text{i.e.}, \ \lambda^2 + m^2M^2 - \mu^2 > 1/4.$$

□

Remark V.2: The above discussions show that for ω to be an eigenvalue of H the following conditions are necessary:

$$r_+ = r_- = M \quad \text{(Theorem IV.4)}, \tag{33}$$

$$\omega = A_0 = -\frac{a\kappa + eQr_+}{r_+^2 + a^2} \quad \text{(Theorem IV.2(i))}, \tag{34}$$

$$\omega^2 < m^2 \quad \text{(Theorem IV.2(ii), Remark IV.3)}, \tag{35}$$

$$\lambda^2 + m^2M^2 - \mu^2 > \frac{1}{4} \quad \text{(Theorem V.1)}. \tag{36}$$

However, the solvability of the above system is not yet sufficient for the existence of an energy eigenvalue.

Schmid[12] showed that if in addition either

$$\beta - \sigma\lambda = 0, \quad \alpha + \eta = 0 \tag{37a}$$

or

$$N + \alpha + \eta = 0 \quad \text{for some positive integer } N, \tag{37b}$$

holds, then the solvability of the system (33)–(36) with (37a) or (37b) is sufficient for the existence of an eigenvalue ω of H.

In the above formulas, we used

$$\sigma := \operatorname{sign} \omega, \quad \eta := \sqrt{\lambda^2 + M^2m^2 - \mu^2}, \quad \mu = 2M\omega + eQ = -\frac{2a\kappa M}{M^2 + a^2} - eQ\frac{M^2 - a^2}{M^2 + a^2},$$

$$\alpha := \frac{Mm^2 - \omega\mu}{\sqrt{m^2 - \omega^2}}, \quad \beta := \frac{(M|\omega| - \sigma\mu)m}{\sqrt{m^2 - \omega^2}}.$$

Note that the variable η is denoted by κ in Ref. 12.

VI. ENERGY EIGENVALUES IN THE CASE $r_+ = r_-$

If ω is an energy eigenvalue of (1), then there must be an $N \in \mathbb{N}_0$ such that ω satisfies the complicated system of conditions (33)–(36) with (37a) or (37b). It is not clear that for given data of the black hole and the particle there are tuples $(\nu\omega_0, \kappa, \lambda_{\nu,\kappa,n})$ that solve the system (33)–(36) with (37a) or (37b). Schmid[12] has shown that in the so-called Kerr case (i.e., if $Q=0$) for fixed data of the spin-$\frac{1}{2}$ particle there exist two sequences $(a_N^{\pm})_{N\in\mathbb{N}}$ such that for $a = a_N^{\pm}$ the value $\omega_N = -\eta/2a_N^{\pm}$ is an energy eigenvalue.

Here, we fix the black hole data M, Q, and a and vary the mass of the fermion to obtain the existence of energy eigenvalues in the case $r_- = r_+$.

Theorem VI.1: *Fix $M>0$, $a, Q, e \in \mathbb{R}$, $\nu \in \mathbb{Z}$ and $\kappa \in \mathbb{Z} + \frac{1}{2}$. Let $\omega := -(\kappa a + eQM)/(a^2 + M^2)$. Take $\lambda = \lambda_{\nu,\kappa,n}$ for any sufficiently large $|n|$. If $\omega(eQ + M\omega) > 0$ then there are no energy eigenval-*

ues of $H_{\nu,\kappa,n}$. *If* $\omega(eQ+M\omega)>0$ *then there is a sequence* $(m_N)_{N\in\mathbb{N}}\subseteq(|\omega|,\infty)$ *such that if* $m\in\{m_N:N\in\mathbb{N}\}$, *then* ω *is an energy eigenvalue of* $H_{\nu,\kappa,n}$. *For* N_0 *large enough, the sequence* $(m_N)_{N\geq N_0}$ *is monotonously decreasing and converges to* $|\omega|$.

Before we prove the theorem, let us emphasize that $\lambda=\lambda_{\nu,\kappa,n}$ does depend also on m. Therefore, we denote it by $\lambda=\lambda_{\nu,\kappa,n}(m)$. In order to check the condition (36) we prepare the following lemma.

Lemma VI.2. Fix $\nu\in\mathbb{Z}$ *and* $\kappa\in\mathbb{Z}+1/2$. *If* $|n|$ *is sufficiently large, then the inequality* (36) *holds for any* $m>0$, $M>0$ *and* $\mu\in\mathbb{R}$, *that is*,

$$\lambda_{\nu,\kappa,n}^2+m^2M^2-\mu^2>\frac{1}{4}.$$

Proof. It follows from standard perturbation theory (applied to the angular operator with m as perturbation parameter, see Winklmeier,[18] Kato[10]) that

$$\left|\frac{d}{dm}\lambda_{\nu,\kappa,n}(m)\right|\leq\left\|\begin{matrix}-a\cos\theta & 0\\ 0 & a\cos\theta\end{matrix}\right\|=|a|,$$

hence, for $m>|\omega|$,

$$|\lambda_{\nu,\kappa,n}(|\omega|)|-|a|(m-|\omega|)\leq|\lambda_{\nu,\kappa,n}(m)|\leq|\lambda_{\nu,\kappa,n}(|\omega|)|+|a|(m-|\omega|). \tag{38}$$

Let $\tilde{m}=M^{-1}\sqrt{\mu^2+1/4}$. Since the sequence $(\lambda_{\nu,\kappa,n})_n$ is monotonously increasing and unbounded from below and from above, there is an integer n_0 such that

$$|\lambda_{\nu,\kappa,n}(|\omega|)|>|a|(\tilde{m}-|\omega|)+\sqrt{\mu^2+1/4}$$

for all $|n|\geq n_0$. If $m\in(|\omega|,\tilde{m}]$, we have

$$|\lambda_{\nu,\kappa,n}(m)|\geq|\lambda_{\nu,\kappa,n}(|\omega|)|-|a|(m-|\omega|)\geq|\lambda_{\nu,\kappa,n}(|\omega|)|-|a|(\tilde{m}-|\omega|)>\sqrt{\mu^2+1/4},$$

which implies

$$\sqrt{\lambda_{\nu,\kappa,n}(m)^2+M^2m^2-\mu^2}\geq\sqrt{\mu^2+1/4+m^2M^2-\mu^2}>1/2.$$

If $m>\tilde{m}=M^{-1}\sqrt{\mu^2+1/4}$, then we have

$$\sqrt{\lambda_{\nu,\kappa,n}(m)^2+M^2m^2-\mu^2}>\sqrt{M^2\tilde{m}^2-\mu^2}=1/2.$$

□

Now we shall prove Theorem VI.1.

Proof of Theorem VI.1: By definition, ω satisfies condition (34). As seen in Lemma VI.2, there is an $n_0\in\mathbb{N}$ such that condition (36) is satisfied for all $|n|\geq n_0$. From now on, let us assume that condition (36) holds. Next we consider the conditions (37a) and (37b). To this end we compute

$$\alpha+\eta=\frac{Mm^2-\omega\mu}{\sqrt{m^2-\omega^2}}+\sqrt{\lambda_{\kappa,n}^2+M^2m^2-\mu^2}=-\frac{\omega(eQ+M\omega)}{\sqrt{m^2-\omega^2}}+M\sqrt{m^2-\omega^2}+\sqrt{\lambda_{\kappa,n}^2+M^2m^2-\mu^2}.$$

If $\omega(eQ+M\omega)\leq0$, then $\alpha+\eta>\frac{1}{2}$ and condition (37a) nor (37b) cannot be satisfied for any $N\in\mathbb{N}_0$. Assume now that $\omega(eQ+M\omega)>0$. Then, the function

$$A:(|\omega|,\infty)\longrightarrow\mathbb{R},$$

$$m \mapsto -\frac{\omega(eQ+M\omega)}{\sqrt{m^2-\omega^2}} + M\sqrt{m^2-\omega^2} + \sqrt{\lambda_{\nu,\kappa,n}(m)^2 + M^2m^2 - \mu^2}$$

is continuous, satisfies $\lim_{m\searrow|\omega|}A(m)=-\infty$, $\lim_{m\to\infty}A(m)=\infty$ in view of (38). Hence, for every $N \in \mathbb{N}$ there is at least one $m_N \in (|\omega|,\infty)$ such that $A(m_N)=-N$ and therefore satisfies condition (37b). Since the function A is monotonously increasing in an interval $(|\omega|,|\omega|+\delta)$ for a sufficiently small $\delta>0$, it follows that for N large enough there is only one m_N satisfying $A(m_N)=-N$ and that the sequence $(m_N)_N$ is decreasing. □

Remark VI.3: The proof shows that for fixed m only a finite number of $\lambda_{\nu,\kappa,n}$ is allowed in order to satisfy condition (37b). The closer m is to $|\omega|$, the more (and the larger) values for $\lambda_{\nu,\kappa,n}$ are allowed.

Remark VI.4: The condition $\omega(eQ+M\omega)>0$ is satisfied if the ratio eQ/κ is sufficiently small since

$$\begin{aligned}
\omega(eQ+M\omega) &= -\frac{a}{(a^2+M^2)^2}(\kappa a + eQM)(eQa-\kappa M)\\
&= \frac{a}{(a^2+M^2)^2}[aM\kappa^2 + eQ(M^2-a^2)\kappa - aMe^2Q^2]\\
&= \frac{a^2M}{(a^2+M^2)^2}\left[\left(\kappa - \frac{eQa}{2M} + \frac{eQM}{2a}\right)^2 - \frac{e^2Q^2}{4}\left(\left(\frac{a}{M}-\frac{M}{a}\right)^2+4\right)\right]\\
&= -\frac{a^2\kappa^2M}{4(a^2+M^2)^2}\left[\left(\frac{2eQ}{\kappa} + \left(\frac{a}{M}-\frac{M}{a}\right)\right)^2 - \left(4+\left(\frac{a}{M}-\frac{M}{a}\right)^2\right)\right].
\end{aligned}$$

Remark VI.5: Let ω be an energy eigenvalue, $m \in \{m_N : N \in \mathbb{N}\}$ (see Theorem VI.1), and $f^{\nu,\kappa,n}$ the eigenfunctions of $H_{\nu,\kappa,n}$. If we set

$$\begin{pmatrix} X_+^{\nu,\kappa,n}(r) \\ X_-^{\nu,\kappa,n}(r) \end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix} i & -1 \\ -i & -1 \end{pmatrix}\begin{pmatrix} f_1^{\nu,\kappa,n}(x) \\ f_2^{\nu,\kappa,n}(x), \end{pmatrix},$$

then

$$\hat{\Psi}(r,\theta,\phi,t) = \exp(-i\omega t)\exp(-i\kappa\varphi)\begin{pmatrix} X_-^{\nu,\kappa,n}(r)g_2^{\nu,\kappa,n}(\theta) \\ X_+^{\nu,\kappa,n}(r)g_1^{\nu,\kappa,n}(\theta) \\ X_+^{\nu,\kappa,n}(r)g_2^{\nu,\kappa,n}(\theta) \\ X_-^{\nu,\kappa,n}(r)g_1^{\nu,\kappa,n}(\theta) \end{pmatrix}$$

is a time-periodic solution of (1).

Symmetries of the Robinson-Trautman equation

W. Natorf and J. Tafel
Institute of Theoretical Physics, Warsaw University, ul. Hoża 69 00-681, Warsaw, Poland

(Received 2 June 2006; accepted 8 September 2006; published online 27 October 2006)

We study point symmetries of the Robinson-Trautman equation. The cases of one- and two-dimensional algebras of infinitesimal symmetries are discussed in detail. The corresponding symmetry reductions of the equation are given. Higher dimensional symmetries are shortly discussed. It turns out that all known exact solutions of the Robinson-Trautman equation are symmetric. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2359139]

I. INTRODUCTION

In 1960, Robinson and Trautman introduced[1] a class of space-times admitting a diverging shear- and twist-free congruence of null geodesics. Such space-times, if asymptotically Minkowskian, are believed to describe gravitational radiation outgoing from spatially bounded sources. Recent numerical results suggest that the Robinson-Trautman metrics can be used to estimate the mass loss during the final phase of the collision of two black holes.[2] There are also suggestions that the subclass of the so called C-metrics[3] (and their twisting generalizations[4]) can describe space-times containing accelerating black holes.[5–8]

In terms of standard coordinates $u, r, \xi, \overline{\xi}$, where u and r are real and ξ is complex, the Robinson-Trautman metrics are given by[9]

$$g = 2\,\mathrm{d}u(H\,\mathrm{d}u + \mathrm{d}r) - 2r^2P^{-2}\,\mathrm{d}\xi\,\mathrm{d}\overline{\xi}. \tag{1}$$

The function P is independent of r. Vacuum Einstein equations imply

$$H = -r\partial_u \ln P - m(u)/r + P^2\partial_\xi\partial_{\overline{\xi}}\ln P \tag{2}$$

and a fourth order equation for P, referred to as the Robinson-Trautman equation:

$$P^2\partial_\xi\partial_{\overline{\xi}}(P^2\partial_\xi\partial_{\overline{\xi}}\ln P) + 3m\partial_u(\ln P) - \partial_u m = 0. \tag{3}$$

Using coordinate freedom m can be transformed to the value ± 1 or 0. The Gaussian curvature K of surfaces of constant u and r is given by

$$K = 2P^2\partial_\xi\partial_{\overline{\xi}}\ln P. \tag{4}$$

The existence of asymptotically flat Robinson-Trautman metrics has been recently examined.[10–12] Also, their large u asymptotic behavior is known.[13,14] These results, however, do not give any hint of how to look for explicit solutions. Only a few of them are known since 1960, none of them being asymptotically flat except for the cases of the Minkowski and the Schwarzschild metrics.

Assuming asymptotic flatness of metrics (1), the Bondi energy,[15,16] the Bondi mass aspect, and the news function were found in terms of P.[11,17–19] The asymptotic flatness of (1) with positive m follows from the assumption that in the gauge $m=1$ the function $\hat{P}=P(1+1/2\xi\overline{\xi})^{-1}$ is positive and regular on $R\times S_2$, ξ being interpreted as a complex stereographic coordinate on S_2.

The subclass of metrics with $m=0$ is characterized by the fact that K is a solution of the Laplace equation, so K must be either constant or singular. No nontrivial asymptotically flat metric exists in this subclass.

In the present paper we consider symmetries of the Robinson-Trautman equation and classify the conjugacy classes of one- and two-dimensional symmetry algebras. We find symmetry reductions of Eq. (3) for solutions preserved by these algebras. Some of these solutions might correspond to asymptotically flat metrics with a simple dependence on the time u. This research may also be of help for studying the numerical solutions of the Robinson-Trautman equation, providing natural ansatzes with smaller number of variables than in generic situations.

II. SYMMETRY TRANSFORMATIONS FOR $m \neq 0$

Suppose $m \neq 0$ and consider Eq. (3) in the gauge $m=1$,

$$P^2 \partial_\xi \partial_{\bar{\xi}} (P^2 \partial_\xi \partial_{\bar{\xi}} \ln P) + 3 \partial_u \ln P = 0. \tag{5}$$

It is easy to prove that (5) is invariant with respect to the following point transformations:

$$\begin{aligned} u &\mapsto u' = a^4 u + b, \\ \xi &\mapsto \xi' = f(\xi), \\ P &\mapsto P' = a^{-1} |f_{,\xi}| P, \end{aligned} \tag{6}$$

where $a \neq 0$ and b are real constants and f is a holomorphic function of ξ and $f_{,\xi} \neq 0$. If (6) is supplemented by

$$r' = a^2 r, \tag{7}$$

the corresponding metric transforms as $g \mapsto a^6 g$. Thus, (6) together with (7) induces a homothety of the metric. It is an isometry when $a=1$.

Infinitesimal transformations corresponding to (6) are given by the vector field

$$k = (4Au + B)\partial_u + F(\xi)\partial_\xi + \overline{F}(\bar{\xi})\partial_{\bar{\xi}} + (\operatorname{Re} F_{,\xi} - A) P \partial_P, \tag{8}$$

where A and B are real constants and F is a holomorphic function of ξ. These fields form the symmetry algebra $\mathfrak{g}$.

Solutions of (3) invariant with respect to (8) have to satisfy the following linear equation:

$$(4Au + B) P_{,u} + F P_{,\xi} + \overline{F} P_{,\bar{\xi}} + (A - \operatorname{Re} F_{,\xi}) P = 0. \tag{9}$$

We will perform the symmetry reduction of (5), assuming that its solution is preserved by vector fields (8) forming a one- or two-dimensional subalgebra of $\mathfrak{g}$ (higher-dimensional subalgebras will also be discussed shortly.) First, we will classify these subalgebras under the action of the pseudogroup of transformations (6). This way we will obtain the conjugacy classes (CC) of one- and two-dimensional subalgebras of $\mathfrak{g}$.

III. SOLUTIONS WITH ONE OR TWO SYMMETRIES

Consider a one-dimensional algebra generated by a vector field (8). Applying an appropriate transformation (6), we can simplify the coefficients A and B and the function F, obtaining one representative of each conjugacy class. For instance, if $A=0$, $B \neq 0$, and $F \neq 0$, we can scale u and ξ so that $B=1$ and $F=\xi$. This leads to

$$k = \partial_u + \xi \partial_\xi + \bar{\xi} \partial_{\bar{\xi}} + P \partial_P. \tag{10}$$

In the same way we can distinguish five conjugacy classes that are listed in Table I, together with corresponding vector k, the form of the invariant solution P, and the reduced Robinson-Trautman equation. Whenever it is needed, we explicitly write the definition of the new variable $z(u, \xi)$

TABLE I. Invariant solutions with single symmetry.

CC	k	P	RT equation
1	∂_u	$p(\xi,\overline{\xi})$	$p^2\partial_\xi\partial_{\overline{\xi}}\ln p=\mathrm{Re}\,\xi$
2	$4u\partial_u-P\partial_P$	$u^{-1/4}p(\xi,\overline{\xi})$	$p^2\partial_\xi\partial_{\overline{\xi}}(p^2\partial_\xi\partial_{\overline{\xi}}\ln p)=\frac{3}{4}$
3	$\partial_u-\xi\partial_\xi-\overline{\xi}\partial_{\overline{\xi}}-P\partial_P$	$e^u p(z,\overline{z})$	$p^2\partial_z\partial_{\overline{z}}(p^2\partial_z\partial_{\overline{z}}\ln p)-3(z\partial_z+\overline{z}\partial_{\overline{z}})\ln p+3=0,\ z=e^{-u}\xi$
4	∂_y	$p(u,x)$	$p^2\partial_x^2(p^2\partial_x^2\ln p)+3\partial_u\ln p=0$
5	$4Au\partial_u+\xi\partial_\xi+\overline{\xi}\partial_{\overline{\xi}}+P(1-A)\partial_P$	$u^{(1-A)/4A}p(z,\overline{z})$	$4Ap^2\partial_z\partial_{\overline{z}}(p^2\partial_z\partial_{\overline{z}}\ln p)+3(A-1)+3(z\partial_z+\overline{z}\partial_{\overline{z}})\ln p=0,$ $z=u^{-(4A)^{-1}}\xi$

appearing in the invariant solution. Throughout the text, we use x and y to denote, respectively, the real and imaginary parts of ξ.

Consider now the case of two-dimensional subalgebra $\mathfrak{g}_2$ of $\mathfrak{g}$. We denote the basis vectors of $\mathfrak{g}_2$ by k_1 and k_2. There are two nonisomorphic two-dimensional Lie algebras such that either

$$[k_1,k_2]=0 \tag{11}$$

or

$$[k_1,k_2]=k_2. \tag{12}$$

The Lie bracket of two fields given by (8) reads as

$$[k_1,k_2]=4(B_1A_2-B_2A_1)\partial_u+(F_1F_{2,\xi}-F_2F_{1,\xi})\partial_\xi+(\overline{F}_1\overline{F}_{2,\overline{\xi}}-\overline{F}_2\overline{F}_{1,\overline{\xi}})\partial_{\overline{\xi}}+P\,\mathrm{Re}(F_1F_{2,\xi\xi}-F_2F_{1,\xi\xi})\partial_P \tag{13}$$

where the indices 1,2 refer to vectors k_1, k_2, respectively.

In the Abelian case, Eq. (11) implies

$$A_1B_2=A_2B_1, \tag{14a}$$

$$F_1F_{2,\xi}=F_2F_{1,\xi}, \tag{14b}$$

$$\mathrm{Re}(F_1F_{2,\xi\xi}-F_2F_{1,\xi\xi})=0. \tag{14c}$$

It follows from (14b) that F_1 is proportional to F_2 and (14c) is satisfied.

Due to (14a) we can assume without loss of generality that $A_2=B_2=0$. Then $F_2\neq 0$, and using the gauge freedom in ξ we can set $F_2=i$. Then $F_1=C=\mathrm{const}\in R$ follows from (14b) and the remaining freedom in the choice of k_1. Therefore, the symmetry generators are

$$k_1=(4Au+B)\partial_u+C\partial_x-AP\partial_P,\quad k_2=\partial_y. \tag{15}$$

The invariance of a solution P of (5) with respect to k_2 implies

$$P=p(u,x). \tag{16}$$

Invariance with respect to k_1 gives

$$(4Au+B)P_{,u}+CP_{,x}=-AP. \tag{17}$$

Depending on values of A, B, and C, we can distinguish five conjugacy classes of two-dimensional Abelian subalgebras of $\mathfrak{g}$. They are listed in Table II. (Here, as well as in Tables III and IV, the symbol p' denotes a derivative of p with respect to its argument.)

In the non-Abelian case, Eq. (12) gives

TABLE II. Invariant solutions with two Abelian symmetries.

CC	k_1	k_2	P	RT equation
A.1	∂_u	∂_y	$p(x)$	$p^2(\ln p)''=x$
A.2	∂_x	∂_y	$p(u)$	$p'=0$
A.3	$\partial_u+\partial_x$	∂_y	$p(u-x)$	$p^2(p^2(\ln p)'')''+3(\ln p)'=0$
A.4	$4u\partial_u-P\partial_P$	∂_y	$u^{-1/4}p(x)$	$p^2(p^2(\ln p)'')''=\frac{3}{4}$
A.5	$4Au\partial_u+\partial_x-AP\partial_P$	∂_y	$u^{-1/4}p((4A)^{-1}\ln u-x)$	$p^2(p^2(\ln p)'')''+\frac{3}{4A}(\ln p)'=\frac{3}{4}$

$$4(A_2B_1-A_1B_2)=4A_2u+B_2, \tag{18a}$$

$$F_1F_{2,\xi}-F_2F_{1,\xi}=F_2, \tag{18b}$$

$$P\,\mathrm{Re}(F_1F_{2,\xi\xi}-F_2F_{1,\xi\bar{\xi}})=P(\mathrm{Re}\,F_{2,\xi}-A_2). \tag{18c}$$

It follows from (18a) that

$$A_2=0,\quad B_2(1+4A_1)=0. \tag{19}$$

Differentiating (18b) and its complex conjugate, we conclude that (18c) follows from (18b). Proceeding as in the Abelian case, we obtain results summarized in Table III.

IV. SOLUTIONS WITH MORE SYMMETRIES

All Lie algebras of dimension greater than three contain a three-dimensional subalgebra. Let k_i, $i=1,2,3$ be its generators. In the case of Bianchi type *VIII* or *IX*, it follows from (13) that $A_i=B_i=0$. Then the fields k_1, k_2, and k_3 are tangent to a two-dimensional surface and invariant solutions are excluded. For all other Bianchi types, the algebra contains a two-dimensional Abelian subalgebra. One can construct invariant solutions as special cases of those described in Table II. After lengthy calculations one obtains only the trivial solution $P=\mathrm{const}$ or $P=\mathrm{const}\cdot x^{3/2}$ given by Robinson and Trautman.[20] These are also solutions of the Robinson-Trautman equation for $m=0$. Thus, the assumption of three or more symmetries does not lead to any new interesting solutions.

V. SYMMETRY TRANSFORMATIONS FOR $m=0$

Suppose now that $m=0$. In this case Eq. (3) can be integrated to a second order equation,

$$P^2\partial_\xi\partial_{\bar{\xi}}\ln P=\mathrm{Re}\,\phi(u,\xi), \tag{20}$$

where ϕ is holomorphic with respect to ξ. If $\phi_{,\xi}\neq 0$, one can transform (20) to the equation[9]

TABLE III. Invariant solutions with two non-Abelian symmetries.

CC	k_1	k_2	P	RT equation
NA.1	$\epsilon\partial_u-x\partial_x-y\partial_y-P\partial_P$, $\epsilon=0$ or $\epsilon=1$	∂_y	$xp(u+\epsilon\ln x)$	$\epsilon[p^3(p'''-2p'''-p''+2p')$ $-p^2(p''^2+2p'p''+p'^2)]+3(\ln p)'=0$
NA.2	$4Au\partial_u-x\partial_x-y\partial_y-(1+A)P\partial_P$	∂_y	$u^{-\frac{1+A}{4A}}p(\underbrace{u^{\frac{1}{4A}}x}_{X})$	$p^2(p^2(\ln p)'')''+3X(\ln p)'=3(1+A)$
NA.3	$-u\partial_u+\partial_x+\frac{1}{4}P\partial_P$	∂_u	$p(x)$	$p^2(\ln p)''=x$
NA.4	$-u\partial_u+\partial_x+\frac{1}{4}P\partial_P$	$\partial_u+e^{\xi}\partial_\xi+e^{\bar{\xi}}\partial_{\bar{\xi}}$ $+P\,\mathrm{Re}\,e^{\xi}\partial_P$	$u^{-1/4}\lvert 1+u^{-1}e^{-\xi}\rvert^{3/4}p(z)$, $z=\frac{1+u^{-1}e^{-\xi}}{1+u^{-1}e^{-\bar{\xi}}}$.	$p^2(p^2(\ln p)'')''+\frac{1}{4}p^4(\ln p)''$ $-36\cos z+48(\ln p)'\sin z=0$

TABLE IV. Invariant solutions for $m=0$.

CC	k	P	RT equation
0.1	$i(\xi^2-1)\partial_\xi - i(\bar{\xi}^2-1)\partial_{\bar{\xi}}$	$p(r)$, $r=\lvert\frac{\xi+1}{\xi-1}\rvert$	$\frac{1}{4}(1-r^2)^2\frac{1}{r}(r(\ln p)')' - \frac{3}{8}+p^{-2}=0$
0.2	$\xi\partial_\xi + \bar{\xi}\partial_{\bar{\xi}}$	$p(\phi)$, $\xi=re^{i\phi}$	$\frac{1}{4}\cos^2\phi(\ln p)'' - \frac{3}{8}+p^{-2}=0$
0.3	$i(\partial_\xi - \partial_{\bar{\xi}})$	$p(x)$	$\frac{1}{4}x^2(\ln p)'' - \frac{3}{8}+p^{-2}=0$

$$P^2\partial_\xi\partial_{\bar{\xi}}\ln P = -\operatorname{Re}\xi. \tag{21}$$

Substituting

$$P = x^{3/2}p(\xi,\bar{\xi}) \tag{22}$$

into (21), we get

$$p^2(\Delta \ln p - 3/8) = -1. \tag{23}$$

Here $\Delta = x^2\partial_\xi\partial_{\bar{\xi}}$ is the Laplace operator on a pseudosphere with the metric

$$g = \frac{d\xi\, d\bar{\xi}}{x^2}, \tag{24}$$

which can be put into the standard form

$$g = \frac{4\, d\zeta\, d\bar{\zeta}}{(1-\zeta\bar{\zeta})^2}, \tag{25}$$

by means of the transformation $\zeta=(\xi+1)/(\xi-1)$. The operator Δ is preserved by the transformations

$$\xi \mapsto \xi' = \frac{a\xi+ib}{ic\xi+d}, \quad a,b,c,d \in R, \tag{26}$$

corresponding to an action of $\mathrm{SL}(2,R)$ on the pseudosphere.

It follows from (26) that infinitesimal transformations are generated by vector fields of the form

$$k = (iA\xi^2 + B\xi + iC)\partial_\xi + \text{c.c.}, \tag{27}$$

where A, B, and C are real constants. Using symmetry transformations, we can distinguish three conjugacy classes of one-dimensional subalgebras of the symmetry algebra for $m=0$ (Table IV).

Given a solution of (21), we can apply the transformation $\xi'=f(u,\xi)$ to obtain a class of solutions of (20).

Note that the only solution of (23) invariant with respect to two independent fields of the form (27) is $p=\sqrt{8/3}$, which gives the well known solution $P=\text{const}\cdot x^{3/2}$ found by Robinson and Trautman.[20]

VI. DISCUSSION

We have examined point symmetries of the Robinson-Trautman equation (3). Forms of solutions in the case of one or two symmetries were given, as well as the corresponding reduced equations. Note that all known[9] exact solutions of (3) have two or three symmetries and belong to one of the cases considered here.

The assumption of symmetry does not seem to exclude regular solutions corresponding to asymptotically flat metrics. The coordinates $\xi,\bar{\xi}$ used in Tables I–III can differ from the hypotheti-

cal Bondi-Sachs coordinates. For instance, in case 4 of Table I, the function P depends on x, which becomes $\ln|\xi'|$ under the transformation $\xi \mapsto \xi' = \exp(\xi)$. To achieve regularity of $\hat{P}$, one should demand that P is everywhere finite, positive, and

$$\lim_{|\xi'|\to\infty} |\xi'|^{-1} P = a(u), \quad \lim_{|\xi'|\to 0} |\xi'| P = b(u), \tag{28}$$

for some positive functions a and b. Rewriting (28) in terms of ξ, we get

$$\lim_{x\to-\infty} e^{x} P = a(u), \quad \lim_{x\to\infty} e^{-x} P = b(u), \tag{29}$$

which means that P behaves like $e^{|x|} f(u)$ for large $|x|$.

In the case A.3 (see Table II), the Robinson-Trautman equation can be solved analytically. This way one obtains the so-called C-metrics. A possible physical interpretation of these metrics as well as their twisting generalizations (the spinning C-metrics) was given recently.[5–8]

Goldfishing: A new solvable many-body problem

M. Bruschi[a] and F. Calogero[b]
Dipartimento di Fisica, Università di Roma "La Sapienza" and Istituto Nazionale di Fisica Nucleare, Sezione di Roma, Roma, Italy

(Received 11 April 2006; accepted 29 July 2006; published online 12 October 2006)

A recent technique allows one to identify and investigate *solvable* dynamical systems naturally interpretable as classical many-body problems, being characterized by equations of motion of Newtonian type (generally in two-dimensional space). In this paper we tersely review results previously obtained in this manner and present novel findings of this kind: mainly *solvable* variants of the *goldfish* many-body model, including models that feature *isochronous* classes of *completely periodic* solutions. Different formulations of these models are presented. The behavior of one of these *isochronous* dynamical systems in the neighborhood of its equilibrium configuration is investigated, and in this manner some remarkable *Diophantine* findings are obtained. © *2006 American Institute of Physics.*

I. INTRODUCTION

Over a quarter century ago a class of *solvable* dynamical systems was introduced, naturally interpretable as classical many-body problems characterized by Newtonian equations of motion ("accelerations proportional to forces:" with appropriate velocity-dependent one- and two-body forces).[2]

Terminology: A dynamical system is called *solvable* whenever the solution of its initial-value problem can be reduced to purely algebraic operations, typically to finding the zeros of a polynomial the coefficients of which are explicitly known in terms of the initial data and of time, or equivalently to finding the eigenvalues of a matrix the time evolution of which is explicitly known.

The simplest example of this kind is characterized by the equations of motion

$$\ddot{z}_n = i\omega\dot{z}_n + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n\dot{z}_m}{z_n - z_m}. \tag{1}$$

Notation: Here and hereafter superimposed dots denote differentiations with respect to the (*real*) independent variable t ("time"), i is the imaginary unit ($i^2=-1$), the dependent variables $z_n \equiv z_n(t)$ are generally *complex*, N is a positive integer ($N \geqslant 2$), indices such as n, m generally range from 1 to N (unless otherwise stated), and ω is a *real* constant (for definiteness, *nonnegative*) to which (whenever this constant does not vanish) is associated the basic period

$$T = \frac{2\pi}{\omega}. \tag{2}$$

The model with $\omega=0$ might be considered the simplest one; but the model with $\omega>0$ has the remarkable property to be *isochronous* and is in any case related by a simple transformation to the same model with $\omega=0$, see the following

Remark 1.1: The model characterized by the equations of motion (1) with $\omega=0$, i.e.,

[a]Electronic mail: mario.bruschi@roma1.infn.it
[b]Electronic mail: francesco.calogero@roma1.infn.it

$$\zeta_n'' = 2 \sum_{m=1, m\neq n}^{N} \frac{\zeta_n' \zeta_m'}{\zeta_n - \zeta_m} \tag{3}$$

(where we conveniently changed notation, denoting the dependent variables as $\zeta_n(\tau)$ and differentiations with respect to the independent variable τ by appended primes), is related to the model characterized by the equations of motion

$$\ddot{z}_n = (2\lambda+1) i\omega \dot{z}_n + \lambda(\lambda+1)\omega^2 z_n + 2 \sum_{m=1, m\neq n}^{N} \frac{(\dot{z}_n - i\lambda\omega z_n)(\dot{z}_m - i\lambda\omega z_m)}{z_n - z_m} \tag{4}$$

(which reduce to (1) for $\lambda = 0$) via the following change of dependent and independent variables:

$$z_n(t) = \exp(i\lambda\omega t)\zeta_n(\tau), \quad \tau = \frac{\exp(i\omega t) - 1}{i\omega}. \tag{5}$$

This transformation, introduced in Ref. 3 and often referred to as "the trick," has been subsequently largely exploited to create "ω-modified" dynamical systems that generally feature (provided λ is *real* and *rational*) the remarkable property to be *isochronous*, with the period T, see (2), or an integer multiple of it: see for instance Refs. 5, 6, 13, 7, 8, 17, 1, 15, 11, 12, 9, 10, and 21 (and additional references quoted in these papers). This can in particular be seen as the cause underlying the *isochronous* character of the *goldfish* model (1) with $\omega > 0$, as indeed shown by its solution, see the following. ■

Terminology: A dynamical system is called *isochronous* if it features in its phase space an *open* region (having therefore *full dimensionality*) where *all* its solutions are *completely periodic* (i.e., periodic in *all* degrees of freedom) with the *same* period (independent of the initial data, provided they are inside the *isochronicity* region). And let us moreover emphasize that dynamical systems obtained via the trick, see (5), from *completely integrable*, or *solvable*, systems, often feature the even more remarkable property that *all* their *nonsingular* solutions (namely, not only those in some appropriate subregion of their natural phase space) are *completely periodic* with periods that are *integer multiples* of T, see (2), besides being independent of the initial data for sufficiently small variations of these data (why this is so is explained in the literature, see for instance Ref. 6). It is therefore justified to consider them as instances of "nonlinear harmonic oscillators."[16]

Remark 1.2: The Newtonian equations of motion (1) are yielded in the standard manner by the *Hamiltonian*

$$H(\underline{p},\underline{z}) = \sum_{n=1}^{N} \left[\frac{i\omega z_n}{c} + \exp(cp_n) \prod_{m=1, m\neq n}^{N} \frac{1}{z_n - z_m} \right], \tag{6}$$

where c is an *arbitrary* (nonvanishing) constant. Some, but not all, of the Newtonian equations of motion written in the following are as well *Hamiltonian*, namely they can be obtained in the standard manner from an appropriate *Hamiltonian*. But in this paper we do not elaborate any further on this aspect of the results presented herein.[19] ■

Remark 1.3: Clearly (see (1) and (4) with $\lambda \neq -\frac{1}{2}$) if ω does *not* vanish the time evolutions of the dependent variables $z_n(t)$ *necessarily* take place in the *complex* z-plane. Only in the special case when $\omega = 0$ (or $\lambda = -\frac{1}{2}$) the motion of the N coordinates $z_n(t)$ could be limited to the *real* axis. In the following (as already mentioned earlier) we assume that the coordinates $z_n(t)$ are *complex:* motions taking place in the (*complex*) plane are in any case more interesting (see also the following *Remark 1.4*) than those limited to the *real* axis. ■

Remark 1.4: By identifying the *complex* z-plane with the *real* ("physical") horizontal plane via the correspondence $z \leftrightarrow \vec{r}$ with the assignment

$$z = x + iy, \quad \vec{r} = (x, y, 0), \tag{7}$$

the Newtonian equations of motion (4) take the following *rotation-invariant* form:

$$\ddot{\vec{r}}_n = (2\lambda+1)\omega\hat{k}\wedge\dot{\vec{r}}_n + \lambda(\lambda+1)\omega^2\vec{r}_n + 2\sum_{m=1,m\neq n}^{N} r_{nm}^{-2}\{(\dot{\vec{r}}-i\lambda\omega\vec{r}_n)[(\dot{\vec{r}}_m-i\lambda\omega\vec{r}_m)\cdot\vec{r}_{nm}] + (\dot{\vec{r}}_m-i\lambda\omega\vec{r}_m)$$

$$\times[(\dot{\vec{r}}_n-i\lambda\omega\vec{r}_n)\cdot\vec{r}_{nm}] - \vec{r}_{nm}[(\dot{\vec{r}}_n-i\lambda\omega\vec{r}_n)\cdot(\dot{\vec{r}}_m-i\lambda\omega\vec{r}_m)]\}, \tag{8}$$

where $\hat{k}=(0,0,1)$ is the unit vector orthogonal to the horizontal plane, the symbols $\wedge$ respectively $\cdot$ sandwiched between two vectors denote the standard vector, respectively, scalar products, and we use the short-hand notation $\vec{r}_{nm}\equiv\vec{r}_n-\vec{r}_m$ entailing $r_{nm}^2=r_n^2+r_m^2-2\vec{r}_n\cdot\vec{r}_m$. The models considered in the following could be similarly reformulated in terms of motions in the physical horizontal plane; we will refrain from doing so, leaving this task to the interested reader, who will find guidance to perform this transition, for instance, in Ref. 4 or in Chapter 4 ("Solvable and/or integrable many-body problems in the plane, obtained by complexification") of Ref. 6 or in Ref. 13. But we will hereafter feel free to refer to the coordinates $z_n(t)$ as describing the positions of point *particles* moving in the (*complex*) z-plane, in the context of a many-body dynamics characterized by Newtonian equations of motion. ■

The *solvable* character of the model (1) is demonstrated by the following result:[2,6] *the solution of the initial-value problem for the Newtonian equations of motion (1) is given by the N roots* $z_n(t)$ *of the following algebraic equation in the variable* z:

$$\sum_{n=1}^{N}\frac{\dot{z}_n(0)}{z-z_n(0)} = \frac{i\omega}{\exp(i\omega t)-1}. \tag{9}$$

Note that, by multiplying this algebraic equation by $\Pi_{n=1}^{N}[z-z_n(0)]$, one transforms it into a polynomial equation of degree N in the variable z, evidencing thereby that it indeed has generally N roots. Also note that, provided $\omega>0$, the time evolutions of *all* the coefficients of this polynomial are *periodic* with period T, see (2), entailing that the time evolution of each particle coordinate $z_n(t)$ is as well *periodic* with such a period (in an *open* region of phase space), or possibly (in every other region of phase space) with an *integer multiple* of this period (not exceeding N, indeed generally much smaller[21]) due to the possibility that the zeros of the polynomial get exchanged among each other through the motion.

The neat character of the Newtonian equations of motion (1), as well as their Hamiltonian character, see (6), and their physical version, see (8) with $\lambda=0$, suggested attributing (in the context of a conference devoted to the celebration of the 60th birthday of V. E. Zakharov[5]) to this many-body problem the honorary name of "goldfish" (this name was originally attributed to model (1) with $\omega=0$, but is as well used for this model with *nonvanishing real* ω, having the additional remarkable property to be *isochronous*; anyway these two models are related by the simple transformation (5) with $\lambda=0$). This terminology originated from the following description of the search for integrable systems given by V. E. Zakharov: "A mathematician, using the dressing method to find a new integrable system, could be compared with a fisherman, plunging his net into the sea. He does not know what a fish he will pull out. He hopes to catch a goldfish, of course. But too often his catch is something that could not be used for any known to him purpose. He invents more and more sophisticated nets and equipments and plunges all that deeper and deeper. As a result he pulls on the shore after a hard work more and more strange creatures. He should not despair, nevertheless. The strange creatures may be interesting enough if you are not too pragmatic. And who knows how deep in the sea do goldfishes live?"[28] Subsequently the name "goldfish" has been, more generally, used to refer to various variants (generally *isochronous*, but possibly *not* integrable) of the original model (1): see, for instance, Refs. 14, 13, 7, 8, 17, and 1. The title of the present paper reflects as well this language and refers to a current development—as detailed in the following—that calls to mind the research pattern poetically described by V. E. Zakharov, as quoted earlier.

Indeed recently a direct technique to manufacture *solvable* dynamical systems has been

used[13,7,8,17,1] to identify many-body problems, many of which can be considered variants of the basic *goldfish* model (1). This technique is tersely reviewed in Sec. II, where we also list the main *solvable* many-body problems obtained in this manner and we report the additional, novel results of this kind obtained in the present paper. As explained in the following, a natural first outcome of this technique is to yield *solvable* many-body problems characterized by Newtonian equations of motion with one- and two-body forces, the latter of which however feature generally multiplicative coefficients, playing the role of "coupling constants" but being instead time-dependent, their time evolution being characterized by a system of coupled ODEs that also contain the independent variables $z_n(t)$ identifying the particle positions in the many-body context. Only in exceptional cases—each of which seems to require a "miracle" to occur—it is possible to get rid of these time-dependent coefficients via an appropriate *ansatz* and to thereby identify a proper *solvable* many-body problem involving *only* the particle coordinates $z_n(t)$ and no additional "auxiliary variables." Hence this research strategy has so far proceeded via a sequence of contributions[13,7,8,17,1] each of which has essentially identified (and investigated) some new *solvable* many-body problem obtained in this manner; and the present paper is one more step in this sequence, its very title echoing this characteristic. And let us mention immediately—for the hasty browser—that the (in our opinion) most interesting *novel* finding reported in the following is the *isochronous N*-body model problem characterized by the Newtonian equations of motion (52) and its solution as given by **Proposition 2.7**, as well as its alternative formulation ((66a)–(66c)) the solution of which is provided by **Proposition 2.11**. Likewise, the hasty browser only interested in the *Diophantine* findings may go immediately to the end of Sec. II.

The developments that yield the main novel results reported in Sec. II are detailed in Sec. III. At the end of Sec. II we also exhibit alternative versions—obtained, and more fully presented, in Sec. IV—of the main *solvable* models identified in this paper, as well as some *Diophantine* findings obtained in Sec. V by investigating the behavior in the neighborhood of its equilibrium configuration of the (alternative version of the) main new *solvable isochronous* system identified in this paper. Hints regarding future developments are proffered in Sec. VI, and a list of useful relations is provided in the Appendix.

II. RESULTS

The starting point of this approach is a *solvable* matrix evolution equation, say

$$\ddot{U} = F(U, \dot{U}). \tag{10}$$

Here and hereafter $U = U(t)$ is a time-dependent $N \times N$ matrix, and the assumed *solvability* of this matrix ODE entails the possibility to write in *explicit* form the solution of the corresponding initial-value problem.

The function $F(U, \dot{U})$ is assumed not to depend on any other matrix besides U and $\dot{U}$ (the ordering of which in its definition is of course relevant, since these two matrices generally do not commute), so that there hold the relation

$$RF(U, \dot{U})R^{-1} = F(RUR^{-1}, R\dot{U}R^{-1}), \tag{11}$$

for any (invertible) $N \times N$ matrix R.

The main idea is then quite simple: *to investigate the time evolution of the eigenvalues* $z_n(t)$ *of the matrix* $U(t)$. And let us immediately emphasize, before proceeding to exhibit the form taken by the equations that describe this time evolution, that whenever the time evolution of the $N \times N$ matrix $U(t)$ is *periodic* with a period T, the corresponding evolution of each of its eigenvalues—unless it runs into a singularity (this may happen, but only for special, *nongeneric*, initial data)—is obviously as well *periodic* with the same period T or with a period $\widetilde{T} = pT$ with p a *positive integer* (again, due to the possibility that through the time evolution some eigenvalues get exchanged: this entails that the largest possible value of p is N, although generally it is much less, see for instance Ref. 21).

To investigate the time evolution of the eigenvalues $z_n(t)$ of $U(t)$ we set

$$U(t) = R(t)Z(t)[R(t)]^{-1}, \quad Z(t) = \mathrm{diag}[z_n(t)], \tag{12}$$

and we take note of the consequential identities

$$\dot{U} = R\{\dot{Z} + [M,Z]\}R^{-1}, \tag{13a}$$

$$\ddot{U} = R\{\ddot{Z} + [\dot{M},Z] + 2[M,\dot{Z}] + [M,[M,Z]]\}R^{-1}, \tag{13b}$$

where we set

$$M = R^{-1}\dot{R}. \tag{14}$$

Notation: Here and hereafter $[A,B]$ denotes the commutator of the two matrices A and B,

$$[A,B] \equiv AB - BA. \tag{15}$$

Remark 2.1: The diagonalizing matrix R, see (12), is clearly defined up to multiplication from the right by an *arbitrary diagonal* $N \times N$ matrix D, hence the matrix M is defined up to the "gauge transformation"

$$M \mapsto D^{-1}MD + D^{-1}\dot{D}, \tag{16}$$

which, thanks to the *arbitrariness* of the *diagonal* matrix D, entails that the *diagonal* part of the matrix M can be assigned *arbitrarily* (of course modifying correspondingly its *off-diagonal* part). ■

Via (12) and (13) the *solvable* matrix ODE (10) becomes

$$\ddot{Z} + [\dot{M},Z] + 2[M,\dot{Z}] + [M,[M,Z]] = F(Z,\dot{Z} + [M,Z]), \tag{17}$$

hence by separating the diagonal and off-diagonal parts of this matrix ODE one immediately arrives at the following systems of (altogether N^2 coupled scalar) ODEs:

$$\ddot{z}_n = -2\sum_{m=1,m\neq n}^{N}(z_n - z_m)M_{nm}M_{mn} + [F(Z,\dot{Z} + [M,Z])]_{nn}, \tag{18a}$$

$$\dot{M}_{nm} = -2\frac{\dot{z}_n - \dot{z}_m}{z_n - z_m}M_{nm} - (\mu_n - \mu_m)M_{nm} + \sum_{\ell=1,\ell\neq m,n}^{N}\frac{z_n + z_m - 2z_\ell}{z_n - z_m}M_{n\ell}M_{\ell m} - \frac{[F(Z,\dot{Z} + [M,Z])]_{nm}}{z_n - z_m}, \quad n \neq m. \tag{18b}$$

Note that we denote the *diagonal* elements of the $N \times N$ matrix M as μ_n, $M_{nn}(t) \equiv \mu_n(t)$ (we never use the convention according to which repeated indices are summed upon), and recall that, as explained earlier (see *Remark 2.1*), their values can be chosen at our convenience; the rest of the notation is, we trust, self-evident. Note that (10) (a matrix evolution equation amounting to N^2 coupled ODEs), characterizing the time evolution of the N^2 matrix elements of the $N \times N$ matrix $U(t)$, has now been replaced by the system (18), amounting again altogether to $N + N(N-1) = N^2$ coupled ODEs, and characterizing the time evolution of the N eigenvalues $z_n(t)$ and of the $N(N-1)$ off-diagonal matrix elements $M_{nm}(t)$, $n \neq m$.

Because of the way these systems of ODEs have been derived they are, as it were by definition, *solvable*. And it is clear that the first system of N coupled ODEs, (18a), has indeed the structure of a Newtonian N-body problem characterizing the motion of the N particle coordinates $z_n(t)$, while the second system of $N(N-1)$ ODEs, (18b), characterizes the evolution of the $N(N$

-1) "auxiliary variables" $M_{nm}(t)$ (with $n \neq m$). It might be possible to attribute as well to these auxiliary variables $M_{nm}(t)$ a physical meaning in terms of internal ("spin") degrees of freedom: pioneering steps in this direction were made long ago, simultaneously and independently, by Gibbons and Hermsen[20] and by Stefan Wojciechowski.[26,27] As already mentioned, in the series of papers[13,7,8,17,1] of which the present one is a natural continuation a different goal has instead been sought: to identify cases in which, via an appropriate *ansatz* (expressing the auxiliary variables in terms of the particle coordinates, and possibly also of their derivatives: see the following), thanks to some "miraculous" identities, it is possible to satisfy *identically* the second system, (18b), namely to get rid altogether of the auxiliary variables, obtaining thereby from (18a) a genuine N-body problem characterized by Newtonian equations of motion involving *only* the particle coordinates $z_n(t)$. The possibility to do so depends on the specific choice of the original *solvable* matrix ODE (see (10); actually in some cases, see the following, it might be preferable to take as starting point a first-order matrix ODE or two coupled first-order matrix ODEs rather than a second-order matrix ODE), and moreover on the identification of an appropriate *ansatz:* general rules to identify a suitable combination of these two elements are not known, so the approach followed so far has been a trial and error one, which has yielded over time a few successes, as reported in previous papers[13,7,8,17,1] and in the present one. We now review tersely these previous results, and then report the novel ones.

In Ref. 13 the starting point of the treatment is the *linear* (and obviously *solvable*) second-order matrix ODE

$$\ddot{U} + a\dot{U} + bU = 0, \tag{19}$$

where a and b are two *arbitrary* constants, and the *solvable* many-body problems manufactured are well-known classical models[6] the *solvability* of which was already known thanks to the technique invented by M. A. Olshanetsky and A. M. Perelomov, which indeed has a close relationship to that described herein: see their original papers,[22,24,25] as well as Section 2.1.3.2 ("The technique of solution of Olshanetsky and Perelomov (OP)") of Ref. 6.

In Ref. 7 the starting point of the treatment is the *solvable* second-order matrix ODE

$$\ddot{U} = a\dot{U}U^{-1}\dot{U}, \tag{20}$$

and the *solvable* many-body problems manufactured are again well-known classical models the *solvability* of which was already known thanks to the technique invented by M. A. Olshanetsky and A. M. Perelomov, but they include in addition the following *generalized goldfish* model:

$$\ddot{z}_n = i\omega\dot{z}_n + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n\dot{z}_m}{z_n - z_m} + a\sum_{n=1}^{N} \frac{\dot{z}_n\dot{z}_m}{z_m}. \tag{21}$$

Here and in (20) a is an *arbitrary* (of course scalar) constant; it is plain that for $a=0$ the Newtonian equations of motion (21) coincide with those, (1), of the basic *goldfish* model. It has moreover been shown[7] that the *solvability* of this *generalized goldfish* model, (21), could be directly inferred from the *solvability* of the *goldfish* many-body model (1). The treatment can be easily extended to a more general (and *isochronous* if λ is *rational*) model bearing to (21) the same relation that (4) bears to (1).

In Ref. 8 the starting point of the treatment is the *solvable* second-order matrix ODE

$$\ddot{U} = a(\dot{U}U + U\dot{U}), \tag{22}$$

and the *solvable* many-body problem manufactured is characterized by the Newtonian equations of motion

$$\ddot{z}_n = 2a\dot{z}_n z_n + 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n\dot{z}_m}{z_n - z_m}. \tag{23}$$

Here a is again an *arbitrary* (of course scalar) constant, and these equations of motion constitute again a generalization of those of the (*nonisochronous goldfish*) model with $\omega=0$, to which they clearly reduce for $a=0$. An *isochronous* variant of these Newtonian equations of motion obtains via the trick (see (5) with $\lambda=1$):

$$\ddot{z}_n = 3i\omega\dot{z}_n + 2\omega^2 z_n + 2a(\dot{z}_n - i\omega z_n)z_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n - i\omega z_n)(\dot{z}_m - i\omega z_m)}{z_n - z_m}. \tag{24}$$

In Ref. 17 the starting point of the treatment is the *solvable* first-order matrix ODE,

$$\dot{U} = aU^2 + C, \tag{25}$$

where a is again an *arbitrary* scalar constant and C is an *arbitrary* constant matrix. Note that time-differentiation of this first-order matrix ODE reproduces the second-order matrix ODE (22); indeed the novelty of the results of Ref. 17 relative to those of Ref. 8 is *not* due to the selection of a different solvable matrix ODE as starting point of the treatment, but rather to the identification of a *different ansatz* to get rid of the auxiliary variables, yielding the *solvable* many-body problem characterized by the Newtonian equations of motion

$$\ddot{z}_n = 2a\dot{z}_n z_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n - az_n^2)(\dot{z}_m - az_m^2)}{z_n - z_m}. \tag{26}$$

These Newtonian equations of motion differ from (23), but they provide again a generalization of those of the (*nonisochronous*) *goldfish* model with $\omega=0$, to which they clearly reduce for $a=0$. And an *isochronous* variant of these Newtonian equations of motion obtains again via the trick (see (5) with $\lambda=1$):

$$\ddot{z}_n = 3i\omega\dot{z}_n + 2\omega^2 z_n + 2a(\dot{z}_n - i\omega z_n)z_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n - i\omega z_n - az_n^2)(\dot{z}_m - i\omega z_m - az_m^2)}{z_n - z_m}. \tag{27}$$

In Ref. 1 the starting point of the treatment is the *solvable* system of two coupled first-order matrix ODEs,

$$\dot{U} = aU^2 + V, \quad \dot{V} = bV, \tag{28}$$

where a is again an *arbitrary* scalar constant and the scalar b might be an *arbitrarily* given function of time. Note that for $b=0$ this matrix ODE reduces to (25) (with $V=C$). The main contribution of Ref. 1 is to identify (and investigate) two *solvable* many-body problems. The first is characterized by the following (*autonomous*) Newtonian equations of motion:

$$\ddot{z}_n = 2a\dot{z}_n z_n + b[\dot{z}_n - az_n^2] + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{z}_n - az_n^2][\dot{z}_m - az_m^2]}{z_n - z_m}. \tag{29}$$

Here b is an *arbitrary* constant; clearly for $b=0$ this model reduces to (26). The second is characterized by the following (*autonomous*) Newtonian equations of motion (which obtains[1] via the trick from an appropriate time-dependent choice of the function $b(t)$ in (28)):

$$\ddot{z}_n = (3+k)i\omega\dot{z}_n + (2+k)\omega^2 z_n + a[2\dot{z}_n - (2+k)i\omega z_n]z_n + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{z}_n - i\omega z_n - az_n^2][\dot{z}_m - i\omega z_m - az_m^2]}{z_n - z_m}. \tag{30}$$

Here k is also an *arbitrary* constant, but the case with k a (*positive* or *negative*) *integer* is particularly interesting, since this model is then *isochronous* (with the single exception of the case

$k=-2$, when the solutions are instead *multiply periodic*). And note that this model reduces to (27) for $k=0$.

Let us now turn to the presentation of the *new* results that constitute the main contribution of the present paper.

The starting point is the following *solvable* system of two coupled first-order matrix ODEs:

$$\dot{U} = \alpha + \beta VU, \tag{31a}$$

$$\dot{V} = aV^2 + bV + c. \tag{31b}$$

Here α, β, a, b, c are five *scalar* quantities, and it is clear that this system is *solvable* (at least in the sense that its solution is achievable by quadratures) if the three parameters a, b, c, are all *constant* or if either a or c vanishes, while α, β can be two (*arbitrarily* assigned) functions of time: indeed the solution can then be obtained by first solving the second, (31b), of these two matrix ODEs, determining thereby explicitly $V(t)$, and by then solving the first, (31a), of these two matrix ODEs, which is linear in $U(t)$ and hence *solvable* (at least in the sense of being reducible to quadratures) once $V(t)$ is known. But in fact we shall need to consider this system of matrix ODEs only in some special cases, see the following.

Remark 2.2: It is clear that adding linear terms (namely, *arbitrary* constants times U or V) to the right-hand side of (31a) entails no significant generalization, since it corresponds to adding a scalar term to V in (31a) (which merely amounts to redefining the three constants a, b, c, in (31b)) or a scalar term to U in (31a) (which merely shifts all the eigenvalues of U by a constant). Likewise, as long as we restrict consideration to a constant β (as we will hereafter do), it is clear that no generality is lost by setting this constant to unity, as we will indeed hereafter do,

$$\beta = 1, \tag{31c}$$

since this merely amounts to a redefinition of V that can be compensated by appropriate modifications of the three constants a, b, c in (31b). And adding a term γVU to the right-hand side of (31a) entails no significant generalization, since it amounts to a change of the constant β and moreover to adding the term $\gamma[V,U]$, the presence of which on the right-hand side of (31a) has no effect on the eigenvalues of $U(t)$. Finally let us note that some of the constants we keep (such as α) or introduce in the following (such as ω) could be rescaled away: we prefer not to do so, because one forsakes in this manner the possibility to make quick dimensional checks of the equations one writes, and also to consider special cases in which some of these constants vanish. However at the end of this section, and in some of the following sections—when we obtain results the interest of which is presumably rather "mathematical" than "physical"—we get rid of all unessential constants and deal only with dimensionless quantities. ■

The system (31) can clearly be reformulated as a single second-order (and of course as well *solvable*) ODE for the matrix $U(t)$:

$$\ddot{U} = cU + (\dot{U} - \alpha)\{b - U^{-1}[a\alpha - (a+1)\dot{U}]\} \tag{32}$$

(to obtain this matrix ODE note first that (31a) with (31c) entails

$$V = (\dot{U} - \alpha)U^{-1}, \tag{33}$$

then time differentiate (31a), use (31b) to eliminate $\dot{V}$, and finally use (33) to eliminate V; note that to make these steps we assumed α to be time-independent, but we made no assumption on the time-dependence of a, b, c).

It can then be shown (see Sec. III) that via two (quite different) appropriate *ansatzen* two (quite different) *solvable* many-body problems can be manufactured.

The first (and less interesting) one of these two many-body systems obtains provided

$$b=0, \quad a=-\tfrac{1}{2}, \tag{34}$$

and is characterized by the following Newtonian equations of motion:

$$\ddot{z}_n = cz_n + \frac{\dot{z}_n^2-\alpha^2}{2z_n} - \frac{g^2}{2}\sum_{m=1,m\neq n}^{N}\frac{z_n(z_n+3z_m)}{(z_n-z_m)^3}, \tag{35}$$

where g is an *arbitrary* constant. Via the following redefinition of the dependent variables,

$$z_n(t) = w_n^2(t), \tag{36}$$

this system of ODEs gets reformulated as follows:

$$\ddot{w}_n = \frac{c}{2}w_n - \frac{\alpha^2}{4w_n^3} - \frac{g^2}{8}\sum_{m=1,m\neq n}^{N}\left[\frac{1}{(w_n-w_m)^3}+\frac{1}{(w_n+w_m)^3}\right], \tag{37}$$

and it is thereby recognized as a known system the *solvability* of which was established long ago.[23] Hence this case is not pursued in the following.

The second of these two *solvable* systems of ODEs obtains when c vanishes,

$$c=0, \tag{38}$$

and it reads as follows:

$$\ddot{z}_n = (\dot{z}_n-\alpha)\left[b+\frac{\alpha}{z_n}+(1+a)\sum_{m=1}^{N}\frac{\dot{z}_m-\alpha}{z_m}+2\sum_{m=1,m\neq n}^{N}\frac{\dot{z}_m-\alpha}{z_n-z_m}\right], \tag{39}$$

where b might also be time-dependent (see the following). In the *autonomous* case with constant $b=i\omega$, when this equation reads

$$\ddot{z}_n = (\dot{z}_n-\alpha)\left[i\omega+\frac{\alpha}{z_n}+(1+a)\sum_{m=1}^{N}\frac{\dot{z}_m-\alpha}{z_m}+2\sum_{m=1,m\neq n}^{N}\frac{\dot{z}_m-\alpha}{z_n-z_m}\right], \tag{40}$$

it can be clearly considered a generalized *goldfish* model: indeed for $\alpha=0$ and $a=-1$ this system reduces to (1). And more generally, whenever α vanishes, in which case this system reads

$$\ddot{z}_n = [i\omega+(1+a)S]\dot{z}_n + 2\sum_{m=1,m\neq n}^{N}\frac{\dot{z}_n\dot{z}_m}{z_n-z_m}, \tag{41a}$$

$$S = \sum_{n=1}^{N}\frac{\dot{z}_n}{z_n}, \tag{41b}$$

it can again be reduced (albeit less trivially so) to the standard *goldfish* model. Indeed it is easily seen (by dividing (41a) by z_n and summing over n from 1 to N) that the system of ODEs (41) entails

$$\dot{S}(t) = i\omega S + aS^2, \tag{42a}$$

hence

$$S(t) = S(0)\exp(i\omega t)\left[1-aS(0)\frac{\exp(i\omega t)-1}{i\omega}\right]^{-1}, \tag{42b}$$

hence (as the diligent reader will readily verify) via the change of dependent variable

$$z_n(t) = \zeta_n(\tau), \quad \tau = \frac{1}{S(0)}\left\{\left[1 - aS(0)\frac{\exp(i\omega t) - 1}{i\omega}\right]^{-1/a} - 1\right\} \tag{43}$$

the system of ODEs (41) gets transformed into the *goldfish* system (3).

But when α does *not* vanish (as we hereafter assume, $\alpha \neq 0$, unless otherwise explicitly indicated), the many-body problem of *goldfish* type characterized by the Newtonian equations of motion (40) cannot be reduced to any previously known system: it is a *solvable* model the *novelty* of which is demonstrated by the fact that its solution involves special functions not featured in the solution of any previously known *solvable* model. Indeed, as shown in the following Sec. III, the solution $z_n(t)$ of the initial-value problem for the Newtonian equations of motion (40) is given by the following **Proposition 2.3** that is now formulated for the case with ω *real* (for a more general formulation see Sec. III).

Proposition 2.3: *The particle coordinates $z_n(t)$ that provide the solution to the initial-value problem for the many-body system characterized by the Newtonian equations of motion (40) with ω real are the N eigenvalues of the $N \times N$ matrix $U(t)$ defined in terms of the initial data $z_n(0)$, $\dot{z}_n(0)$ as follows:*

$$U(t) = (1 - P)[U(0) + \alpha t] + P\{1 + a\eta[\exp(i\omega t) - 1]\}^{-1/a}[U(0) + \alpha u(t)], \tag{44a}$$

where the $N \times N$ matrix $U(0)$, the $N \times N$ projection matrix P, and the scalar constant η are defined as follows:

$$U(0) = \mathrm{diag}[z_n(0)], \tag{44b}$$

$$P_{nm} = -\frac{\{[\dot{z}_n(0) - \alpha][\dot{z}_m(0) - \alpha]\}^{1/2}}{\eta i\omega z_m(0)}, \quad P^2 = P, \tag{44c}$$

$$\eta = -\sum_{n=1}^{N} \frac{\dot{z}_n(0) - \alpha}{i\omega z_n(0)}, \tag{44d}$$

and the scalar function $u(t)$ is defined as follows: if

$$|1 - a\eta| < |a\eta|, \quad \text{i.e., } \mathrm{Re}(a\eta) > \tfrac{1}{2}, \tag{44e}$$

then

$$u(t) = \eta^{1/a}\sum_{s=0}^{\infty}\binom{1/a}{s}\left(\frac{1 - a\eta}{a\eta}\right)^s \frac{1 - \exp\left[\left(s - \frac{1}{a}\right)i\omega t\right]}{\left(s - \frac{1}{a}\right)i\omega}, \tag{44f}$$

if instead

$$|1 - a\eta| > |a\eta|, \quad \text{i.e., } \mathrm{Re}(a\eta) < \tfrac{1}{2}, \tag{44g}$$

then

$$u(t) = (1 - a\eta)^{1/a}\left[t + \sum_{s=1}^{\infty}\binom{1/a}{s}\left(\frac{a\eta}{1 - a\eta}\right)^s \frac{\exp(si\omega t) - 1}{si\omega}\right]. \tag{44h}$$

These formulas are applicable as written provided $a \neq 0$ (and note that the sums in (44f) and (44h) terminate, yielding of course the same result, if a is the inverse of a positive integer); if $a = 0$ the expression $\{1 + a\eta[\exp(i\omega t) - 1]\}^{-1/a}$ in (44a) becomes $\exp\{-\eta[\exp(i\omega t) - 1]\}$, and expression (44h) becomes

$$u(t) = \exp(-\eta)\left[t + \sum_{s=1}^{\infty} \frac{\eta^s}{s!} \frac{\exp(si\omega t) - 1}{si\omega} \right]. \tag{44i}$$

Finally, let us note that the above-written formulas assume that $\eta \neq 0$ *(see in particular (44c)). For the special case in which* η *vanishes the expression of* $U(t)$ *is somewhat simpler:*

$$U(t) = U(0) + \alpha t + V(0)\left\{ \frac{\exp(i\omega t) - 1}{i\omega} \left[U(0) - \frac{\alpha}{i\omega} \right] + \alpha t \exp(i\omega t) \right\} \tag{45a}$$

with

$$[V(0)]_{nm} = \frac{\{[\dot{z}_n(0) - \alpha][\dot{z}_m(0) - \alpha]\}^{1/2}}{z_m(0)} . \quad \blacksquare \tag{45b}$$

Notation: Here and throughout the symbol $\binom{x}{y}$ denotes the generalized binomial coefficient:

$$\binom{x}{y} = \frac{\Gamma(x+1)}{\Gamma(y+1)\Gamma(x-y+1)}. \tag{46}$$

This of course implies that $\binom{x}{y}$ vanishes whenever y or $x-y$ are *negative integers*, unless x is also a *negative integer*.

Remark 2.4: If α vanishes and the inequality (44e) holds and $a \neq 1/p$ with p an arbitrary *positive* integer, then the $N \times N$ matrix $U(t)$ is *periodic with period* T, see (2):

$$U(t+T) = U(t) . \blacksquare \tag{47}$$

Remark 2.5: As entailed by the preceding *Remark 2.4* and by **Proposition 2.3**, the many-body problem characterized by the Newtonian equations of motion of *goldfish* type (40) is *isochronous* provided $\alpha = 0$ and $a \neq 1/p$ with p an arbitrary *positive* integer: a condition on the initial data sufficient to guarantee that its solution be *completely periodic* with a period which is an *integer multiple* of T, see (2), is validity of the inequality (44e) with

$$\eta = -\frac{S(0)}{i\omega} \tag{48}$$

(see (41b) and (44d) with $\alpha = 0$). But, as noted earlier, this model with $\alpha = 0$ is not new, indeed its time evolution is rather trivial, see (44), hence the study of this case is not pursued in the following.

Remark 2.6: If $a \neq 1/p$ with p an arbitrary *positive* integer and the inequality (44e) holds, the $N \times N$ matrix $PU(t)$ is *periodic* with period T, see (2):

$$PU(t+T) = PU(t) . \blacksquare \tag{49}$$

It is moreover possible to manufacture another *isochronous* many-body problem of *goldfish* type, by starting from the following version of the system of ODEs (39),

$$\zeta_n'' = (\zeta_n' - \alpha)\left[b(\tau) + \frac{\alpha}{\zeta_n} + (1+a) \sum_{m=1}^{N} \frac{\zeta_m' - \alpha}{\zeta_m} + 2 \sum_{m=1, m \neq n}^{N} \frac{\zeta_m' - \alpha}{\zeta_n - \zeta_m} \right]. \tag{50a}$$

Note that this system coincides with (39), except for a merely notational change (the dependent variables are here denoted as $\zeta_n \equiv \zeta_n(\tau)$, appended primes indicating differentiations with respect to the independent variable τ).

It is now easy to verify that, provided

$$b(\tau) = \frac{ki\omega}{1 + i\omega\tau}, \tag{50b}$$

via the change of dependent and independent variables (as it were, just the version of the trick (5) with $\lambda = -1$)

$$\tilde{z}_n(t) = \exp(-i\omega t)\zeta_n(\tau), \tag{51a}$$

$$\tau = \frac{\exp(i\omega t) - 1}{i\omega}, \quad \exp(i\omega t) = 1 + i\omega\tau, \tag{51b}$$

the (*nonautonomous*) system of ODEs ((50a) and (50b)) yields the *solvable* many-body problem characterized by the following *autonomous* Newtonian equations of motion:

$$\ddot{\tilde{z}}_n = -i\omega\dot{\tilde{z}}_n + (\dot{\tilde{z}}_n + i\omega\tilde{z}_n - \alpha)\cdot\left[ki\omega + \frac{\alpha}{\tilde{z}_n} + (1+a)\sum_{m=1}^{N}\frac{\dot{\tilde{z}}_m + i\omega\tilde{z}_m - \alpha}{\tilde{z}_m} + 2\sum_{m=1,m\neq n}^{N}\frac{\dot{\tilde{z}}_m + i\omega\tilde{z}_m - \alpha}{\tilde{z}_n - \tilde{z}_m}\right]. \tag{52}$$

Clearly the "particle coordinates" $\tilde{z}_n(t)$ are the eigenvalues of the $N\times N$ matrix $\tilde{U}(t)$ that is related to the matrix U by the analog of (51),

$$\tilde{U}(t) = \exp(-i\omega t)U(\tau), \tag{53}$$

of course with τ related to t by (51b). It is easily seen that this implies that this matrix $\tilde{U}(t)$ evolves according to

$$\ddot{\tilde{U}} = -i\omega\dot{\tilde{U}} + (\dot{\tilde{U}} + i\omega\tilde{U} - \alpha)\{(k+1+a)i\omega - \tilde{U}^{-1}[a\alpha - (a+1)\dot{\tilde{U}}]\}, \tag{54}$$

as clearly implied (via (53)) by the basic matrix evolution equation (32) (with (38) and (50b)) satisfied by the matrix U, namely

$$U'' = (U' - \alpha)\left\{\frac{ki\omega}{1 + i\omega\tau} - U^{-1}[a\alpha - (a+1)U']\right\}, \tag{55}$$

where clearly $U \equiv U(\tau)$ and appended primes denote differentiations with respect to τ. And the solution of the Newtonian equations of motion (52) is provided, as demonstrated in Sec. III, by the following

Proposition 2.7: *The particle coordinates $\tilde{z}_n(t)$ that provide the solution to the initial-value problem for the many-body problem characterized by these Newtonian equations of motion, (52), are the N eigenvalues of the $N\times N$ matrix $\tilde{U}(t)$ defined in terms of the initial data $z_n(0)$, $\dot{z}_n(0)$ as follows:*

$$\tilde{U}(t) = \exp(-i\omega t)\{1 + [\tilde{\phi}(t) - 1]\tilde{P}\}\tilde{U}(0) + (1 - \tilde{P})\alpha\frac{1 - \exp(-i\omega t)}{i\omega} + \alpha\tilde{P}\tilde{u}(t)\tilde{\phi}(t), \tag{56a}$$

where the $N\times N$ matrix $\tilde{U}(0)$, the $N\times N$ projection matrix $\tilde{P}$, the scalar constant $\tilde{\eta}$, and the scalar function $\tilde{\phi}(t)$ are defined as follows:

$$\tilde{U}(0) = \mathrm{diag}[z_n(0)], \tag{56b}$$

$$\tilde{P}_{nm} = -\frac{\{[\dot{\tilde{z}}_n(0) + i\omega\tilde{z}_n(0) - \alpha][\dot{\tilde{z}}_m(0) + i\omega\tilde{z}_m(0) - \alpha]\}^{1/2}}{\tilde{\eta}i\omega\tilde{z}_m(0)}, \quad P^2 = P, \tag{56c}$$

$$\tilde{\eta} = -\sum_{n=1}^{N} \frac{\dot{\tilde{z}}_n(0) + i\omega\tilde{z}_n(0) - \alpha}{i\omega\tilde{z}_n(0)}, \tag{56d}$$

$$\tilde{\phi}(t) = \{1 + a\tilde{\eta}[\exp(\tilde{k}i\omega t) - 1]\}^{-1/a}, \tag{56e}$$

and the function $\tilde{u}(t)$ *is defined as follows: if*

$$|1 - a\tilde{\eta}| < |a\tilde{\eta}|, \quad \text{i.e., } \mathrm{Re}(a\tilde{\eta}) > \tfrac{1}{2}, \tag{56f}$$

then

$$\tilde{u}(t) = (a\tilde{\eta})^{1/a} \sum_{s=0}^{\infty} \binom{1/a}{s} \left(\frac{1 - a\tilde{\eta}}{a\tilde{\eta}}\right)^s \frac{\exp(-i\omega t) - \exp\left\{\left[-\tilde{k}\left(s - \frac{1}{a}\right)\right] i\omega t\right\}}{\left[\tilde{k}\left(s - \frac{1}{a}\right) - 1\right] i\omega}, \tag{56g}$$

if instead

$$|1 - a\tilde{\eta}| > |a\tilde{\eta}|, \quad \text{i.e., } \mathrm{Re}(a\tilde{\eta}) < \tfrac{1}{2}, \tag{56h}$$

then

$$\tilde{u}(t) = (1 - a\tilde{\eta})^{1/a} \left[\sum_{s=0}^{\infty} \binom{1/a}{s} \left(\frac{a\tilde{\eta}}{1 - a\tilde{\eta}}\right)^s \frac{\exp(\tilde{k}si\omega t) - \exp(-i\omega t)}{(\tilde{k}s + 1)i\omega}\right]. \tag{56i}$$

Note that we use throughout the short-hand notation

$$\tilde{k} = k + 1. \tag{56j}$$

These formulas are applicable as written provided $a \neq 0$ *(and note that the sums in (56g) and (56i) terminate, yielding of course the same result, if a is the inverse of a positive integer); if a* $= 0$ *the definition (56e) must be modified to read*

$$\tilde{\phi}(t) = \exp\{\tilde{\eta}[1 - \exp(\tilde{k}i\omega t)]\}, \tag{56k}$$

and the definition (56i) of $\tilde{u}(t)$ *must be modified to read*

$$\tilde{u}(t) = \exp(-\tilde{\eta}) \sum_{s=0}^{\infty} \frac{\tilde{\eta}^s}{s!} \frac{\exp[\tilde{k}si\omega t] - \exp(-i\omega t)}{(\tilde{k}s + 1)i\omega}. \tag{56l}$$

In the special case with $k = 0$, $\tilde{k} = 1$, *the sums in the definition of the function* $\tilde{u}(t)$ *can be performed in closed form, and one gets*

$$\tilde{u}(t) = (a\tilde{\eta})^{1/a} \frac{\exp(i\omega t/a) - \exp(-i\omega t)}{i\omega} \quad \text{for } a \neq 0, \tag{56m}$$

$$\tilde{u}(t) = \exp(-i\omega t) \frac{\exp\{\tilde{\eta}[\exp(i\omega t) - 1]\} - 1}{i\omega\tilde{\eta}} \quad \text{for } a = 0. \tag{56n}$$

Finally, let us note that the formulas written above assume that $\tilde{\eta} \neq 0$ *(see in particular (56c)). For the special case in which* $\tilde{\eta}$ *vanishes the expression of* $\tilde{U}(t)$ *is somewhat simpler:*

$$\tilde{U}(t) = \exp(-i\omega t)\tilde{U}(0) + \alpha \frac{1 - \exp(-i\omega t)}{i\omega} \tilde{V}(0) \tag{57a}$$

with

$$\widetilde{V}_{nm}(0) = \frac{[\dot{\widetilde{z}}_n(0) + i\omega\widetilde{z}_n(0) - \alpha]^{1/2}[\dot{\widetilde{z}}_m(0) + i\omega\widetilde{z}_m(0) - \alpha]^{1/2}}{i\omega\widetilde{z}_m(0)} . \quad \blacksquare \tag{57b}$$

Remark 2.8: The formulas, as written earlier, are valid for *arbitrary* values of the two constants a and $\widetilde{k}$, provided $\widetilde{k}\omega$ hence $\widetilde{k}$ itself are *real* ($\mathrm{Im}(\widetilde{k})=0$; this condition is required to guarantee the convergence for all *real* values of t of the infinite series on the right-hand sides of (56g), (56i), and (56l)). But the most interesting case is when $\widetilde{k}$ hence k (see (56j)) are *rational* numbers,

$$\widetilde{k} = \frac{\widetilde{p}}{\widetilde{q}}, \quad k = \frac{\widetilde{p} - \widetilde{q}}{\widetilde{q}}, \tag{58}$$

of course with $\widetilde{p}$ and $\widetilde{q}$ *integers* (and $\widetilde{q}>0$). Then whenever the initial data entail, via (56d), that there holds the inequality (56h), and provided moreover $\widetilde{k}s \neq -1$ for every *positive integer* s hence $\widetilde{p} \neq -1$ (see (58)), clearly (see (56a), (56e), and (56i)) the matrix $\widetilde{U}(t)$ is *periodic* with period $\widetilde{T}$, see (2),

$$\widetilde{T} = \widetilde{q}T, \quad \widetilde{U}(t + \widetilde{T}) = \widetilde{U}(t). \tag{59}$$

If the initial data entail instead that the inequality (56f) prevails (rather than (56h)) and moreover a is also *rational*, hence $\widetilde{k}/a$ is as well *rational*,

$$\frac{\widetilde{k}}{a} = \frac{k+1}{a} = \frac{\check{p}}{\check{q}}, \tag{60}$$

of course again with $\check{p}$ and $\check{q}$ *integers* (and $\check{q}>0$), then provided $\widetilde{k}(s-1/a) \neq 1$ hence $\widetilde{q}(\check{q}+\check{p}) \neq s\check{q}\widetilde{p}$ for any *nonnegative integer* s (see (58) and (60)), clearly (see (56a), (56e), and (56g)) $\widetilde{U}(t)$ is again *periodic*, but now with a period $\check{T}$ (generally) larger than $\widetilde{T}$,

$$\check{T} = \max(\widetilde{q},\check{q})T, \quad \widetilde{U}(t + \check{T}) = U(t) . \quad \blacksquare \tag{61}$$

Remark 2.9: As entailed by the preceding *Remark 2.8* and by **Proposition 2.7**, the novel many-body problem characterized by the Newtonian equations of motion of *goldfish* type (52) with k *rational* is *isochronous:* if a is *real* but otherwise *arbitrary*, a condition on the initial data sufficient to guarantee that its solution be *completely periodic* with a period which is an *integer multiple* of T, see (2), is validity of the inequality (56h) (provided moreover $\widetilde{p} \neq -1$, see (58)); if a is moreover *rational*, then *all* its solutions are *completely periodic* with a period which is an *integer multiple* of T (provided moreover $\widetilde{k}(s-1/a) \neq 1$ hence $\widetilde{q}(\check{q}+\check{p}) \neq s\check{q}\widetilde{p}$ for any *non-negative integer* s, see (58) and (60)). ■

In the rest of this section, and in Secs. IV and V (but not in Sec. III) we get rid of the unessential constants ω and α. This can be done by appropriate rescaling, or equivalently by setting (as we hereafter do, except in Sec. III)

$$\omega = 1, \quad \alpha = i. \tag{62}$$

Let us emphasize that hereafter (except in Sec. III) whenever we refer to previous formulas we understand that such assignments have been made in them.

As explained in Sec. IV, an alternative version of the system (40) is characterized by the following system of N ODEs satisfied by the N dependent variables $c_m(t)$:

$$\ddot{c}_m - [1 + (1+a)\gamma]i\dot{c}_m + (2N+1-2m)i\dot{c}_{m-1} + [(N-m)\gamma + (N-m+1)(1+a\gamma)]c_{m-1} - (N-m)(N-m+2)c_{m-2} = 0, \quad m = 1, \ldots, N, \quad c_0 = 1, \quad c_{-1} = 0, \tag{63a}$$

where

$$\gamma \equiv \gamma(t) = \frac{c_{N-1}(t) - i\dot{c}_{N-1}(t)}{c_N(t)}. \tag{63b}$$

This system of N coupled ODEs is *no less solvable* than (40), indeed, as shown by the developments reported in Sec. IV, its solution is provided by the following

Proposition 2.10: *The dependent variables $c_m(t)$ that solve the system ((63a) and (63b)) are the N coefficients of the (monic) polynomial $\psi(z,t)$ of degree N in z having the N coordinates $z_n(t)$ solutions of (40) as its zeros*,

$$\psi(z,t) = \prod_{n=1}^{N} [z - z_n(t)] = z^N + \sum_{m=1}^{N} c_m(t) z^{N-m}, \tag{64}$$

so that, as implied by ***Proposition 2.3****, this polynomial is given by the formula*

$$\psi(z,t) = \det[z - U(t)] \tag{65}$$

where $U(t)$ is the $N \times N$ matrix the time-dependence of which is given by the explicit formula (44) [with (62)]. ■

Note that this system, ((63a) and (63b)), is identically satisfied also for $m=N+1$ and for $m=N+2$, provided one sets $c_{N+1}=c_{N+2}=0$ (consistent with (64)). And also note that this new *solvable* system of N ODEs, (63a), looks superficially linear, but is in fact *nonlinear* due to the presence in it of the quantity γ, see (63b). Indeed, the highly nonlinear (and nontrivial) character of this system will be evident to the diligent reader who will take the trouble to write it out in the simpler cases with $N=2$ and with $N=1$ (in the latter case the single equation of motion ((63a) and (63b)) can be directly compared with (32), since for $N=1$ $U(t)=-c_1(t)$, see (65) and (64)).

Likewise, an alternative formulation of the system (52) is characterized by the following system of N ODEs satisfied by the N dependent variables $\tilde{c}_m(t)$:

$$\ddot{\tilde{c}}_m - (K-2m)i\dot{\tilde{c}}_m + (2N+1-2m)i\dot{\tilde{c}}_{m-1} + m(K-m)\tilde{c}_m + [(N+1-m)(K-2m) - \tilde{\gamma}]\tilde{c}_{m-1} - (N-m)(N+2-m)\tilde{c}_{m-2} = 0,$$

$$m = 1, \ldots, N, \quad \tilde{c}_0 = 1, \quad \tilde{c}_{-1} = 0, \tag{66a}$$

where

$$K \equiv K(t) = \tilde{k} + (a+1)[N + \tilde{\gamma}(t)] \tag{66b}$$

and

$$\tilde{\gamma} \equiv \tilde{\gamma}(t) = \frac{\tilde{c}_{N-1}(t) - i\dot{\tilde{c}}_N(t)}{\tilde{c}_N(t)}. \tag{66c}$$

Here of course superimposed dots denote differentiations with respect to the independent variable t.

Again, this system of N coupled ODEs is *no less solvable* than (52), indeed, as shown by the developments reported in Sec. IV, its solution is provided by the following.

Proposition 2.11:*The dependent variables $\tilde{c}_m(t)$ that solve the system ((66a)–(66c)) are the N coefficients $\tilde{c}_m(t)$ of the (monic) polynomial $\tilde{\psi}(z,t)$ of degree N in z having the N coordinates $\tilde{z}_n(t)$ solutions of (52) as its zeros*,

$$\widetilde{\psi}(z,t) = \prod_{n=1}^{N} [z - \widetilde{z}_n(t)] = z^N + \sum_{m=1}^{N} \widetilde{c}_m(t) z^{N-m}, \tag{67}$$

so that, as implied by ***Proposition 2.7****, this polynomial is given by the formula*

$$\widetilde{\psi}(z,t) = \det[z - \widetilde{U}(t)], \tag{68}$$

where $\widetilde{U}(t)$ *is the* $N \times N$ *matrix the time-dependence of which is given by (56a)–(56j) [with (62)].*■

We do not repeat the remarks proffered above (after **Proposition 2.10**), but merely note that they are as well relevant now (up to obvious modifications).

Remark 2.12: Provided $\widetilde{k}$ is a *rational number*, $\widetilde{k} = \widetilde{p}/\widetilde{q}$ (with $\widetilde{p}$ and $\widetilde{q}$ *integers* and $\widetilde{q} > 0$, see (58), and moreover $\widetilde{p} \neq -1$), the **Proposition 2.11** and the *Remark 2.9* entail that the solution of the nonlinear system of ODEs ((66a)–(66c)) is *completely periodic* with a period which is an *integer multiple* Q of 2π,

$$\widetilde{c}_m(t + 2\pi Q) = \widetilde{c}_m(t), \tag{69}$$

in the following cases. (i) If a is an arbitrary (possibly even *complex*) number and the initial data entail the inequality

$$\mathrm{Re}[-a\{N + \gamma(0)\}] < \tfrac{1}{2} \tag{70}$$

(see (66c)), then (69) holds with $Q = \widetilde{q}$. (ii) If a is an arbitrary *real* and *rational* number so that the number $\widetilde{k}/a$ is itself *rational*, $\widetilde{k}/a = \check{p}/\check{q}$ (with $\check{p}$ and $\check{q}$ *integers* and $\check{q} > 0$, see (60) and moreover $\widetilde{q}(\check{q} + \check{p}) \neq s\check{q}\widetilde{p}$ for any *non-negative integer* s), then *all* solutions of the nonlinear system of ODEs ((66a)–(66c)) are *completely periodic*, see (69) with $Q = \max(\widetilde{q}, \check{q})$.

We end this section by formulating certain conjectures (having a *Diophantine* connotation, which becomes particularly evident if one assigns *integer* values to all the numbers that are left *arbitrary*, see the following) arrived at (up to trivial notational changes) from the results of the preceding *Remark 2.12* via the treatment of Sec. V, and by reporting some examples illustrating them.

Conjecture 5.13: *Let the two* $N \times N$ *matrices* A *and* B *be defined componentwise as follows:*

$$A_{nm} = (2n - \nu)\delta_{n,m} + (2N + 1 - 2n)\delta_{n-1,m} + C_n \delta_{N,m}, \tag{71a}$$

$$\begin{aligned} B_{nm} = {} & n(n - \nu)\delta_{n,m} - [N + (N + 1 - n)(\nu - 2n)]\delta_{n-1,m} \\ & + (N - n)(N + 2 - n)\delta_{n-2,m} + C_n(\delta_{N-1,m} + N\delta_{N,m}), \end{aligned} \tag{71b}$$

where

$$C_n = -(-)^{N-n} \frac{1}{1+f} \left[\binom{N}{n-1} + f \frac{N + (N-n)\nu}{(N-\nu)} \binom{N-\nu}{n-\nu-1} + g \binom{N-\nu-1}{n-\nu} \right], \tag{71c}$$

with ν, f, *and* g arbitrary *numbers; then*

$$\det[p^2 + pA + B] = \prod_{n=1}^{N} [(p + n)(p - \nu - 1 + n)]\,. \quad \blacksquare \tag{71d}$$

Conjecture 5.14: *Let the two* $N \times N$ *matrices* A *and* B *be defined componentwise as follows:*

$$A_{nm} = (2n - \nu - 1)\delta_{n,m} + (2N + 1 - 2n)\delta_{n-1,m} + C_n \delta_{N,m}, \tag{72a}$$

$$\begin{aligned} B_{nm} = {} & n(n - \nu - 1)\delta_{n,m} + [(N - n)(2n - \nu - 3) + N]\delta_{n-1,m} + (N - m)(N + 2 - n)\delta_{n-2,m} \\ & + C_n[\delta_{N-1,m} + (N - \nu - 1)\delta_{N,m}], \end{aligned} \tag{72b}$$

where

$$C_n = (-)^{N-n}\frac{1}{1+f}\left\{\frac{g(N+1-n)-N}{N}\binom{N}{n-1}+f\left[(g-\nu-1)\binom{N-\nu-1}{n-\nu-1}-\binom{N-\nu-1}{n-\nu-2}\right]\right\}, \tag{72c}$$

with ν, f, *and* g arbitrary *numbers; then*

$$\det[p^2+pA+B] = (p+g)\left[\prod_{n=1}^{N-1}(p+n)\right]\left[\prod_{n=1}^{N}(p-\nu-1+n)\right]. \quad \blacksquare \tag{72d}$$

Examples: For $N=5$ the **Conjecture 5.13** states that

$$\begin{vmatrix} p^2+p(2-\nu)1-\nu & 0 & 0 & C_1 & (p+5)C_1 \\ 7p+11-4\nu & p^2+p(4-\nu)+2(2-\nu) & 0 & C_2 & (p+5)C_2 \\ 8 & 5p+13-3\nu & p^2+p(6-\nu)+3(3-\nu) & C_3 & (p+5)C_3 \\ 0 & 3 & 3p+11-2\nu & p^2+p(8-\nu)+4(4-\nu)+C_4 & (p+5)C_4 \\ 0 & 0 & 0 & p+5-\nu+C_5 & p^2+p(10-\nu+C_5)+5(5-\nu+C_5) \end{vmatrix}$$
$$= (p+1)(p+2)(p+3)(p+4)(p+5)\cdot(p-\nu)(p-\nu+1)(p-\nu+2)(p-\nu+3)(p-\nu+4) \tag{73a}$$

provided

$$C_1 = -\frac{1}{1+f}\left\{1+\frac{(4-\nu)(3-\nu)(2-\nu)}{6}\left[\frac{(5+4\nu)(1-\nu)f}{20}+g\right]\right\}, \tag{73b}$$

$$C_2 = \frac{1}{1+f}\left\{5+\frac{(4-\nu)(3-\nu)}{2}\left[\frac{(5+3\nu)(2-\nu)f}{12}+g\right]\right\}, \tag{73c}$$

$$C_3 = -\frac{1}{1+f}\left\{10+(4-\nu)\left[\frac{(5+2\nu)(3-\nu)f}{6}+g\right]\right\}, \tag{73d}$$

$$C_4 = \frac{1}{1+f}\left[10+\frac{(5+\nu)(4-\nu)f}{2}+g\right], \tag{73e}$$

$$C_5 = -5. \tag{73f}$$

Likewise, for $N=5$ the **Conjecture 5.14** states that

$$\begin{vmatrix} p^2p(1-\nu)-\nu & 0 & 0 & C_1 & (p+4-\nu)C_1 \\ 7p+8-3\nu & p^2+p(3-\nu)+2(1-\nu) & 0 & C_2 & (p+4-\nu)C_2 \\ 8 & 5p+11-2\nu & p^2+p(5-\nu)+3(2-\nu) & C_3 & (p+4-\nu)C_3 \\ 0 & 3 & 3p+10-\nu & p^2+p(7-\nu)+4(3-\nu)+C_4 & (p+4-\nu)C_4 \\ 0 & 0 & 0 & p+5+C_5 & p^2+p(9-\nu+C_5)+(4-\nu)(5+C_5) \end{vmatrix}$$
$$= (p+1)(p+2)(p+3)(p+4)(p+5)\cdot(p-\nu)(p-\nu+1)(p-\nu+2)(p-\nu+3)(p-\nu+4) \tag{74a}$$

provided

$$C_1 = \frac{1}{1+f}\left[g-1+\frac{(4-\nu)(3-\nu)(2-\nu)(1-\nu)f(5g-4\nu-5)}{120}\right], \tag{74b}$$

$$C_2 = -\frac{1}{1+f}\left[4g-5+\frac{(4-\nu)(3-\nu)(2-\nu)f(4g-3\nu-5)}{24}\right], \tag{74c}$$

$$C_3 = \frac{1}{1+f}\left[2(3g-5) + \frac{(4-\nu)(3-\nu)(2-\nu)f(3g-2\nu-5)}{6}\right], \tag{74d}$$

$$C_4 = -\frac{1}{1+f}\left[2(2g-5) + \frac{(4-\nu)(3-\nu)f(2g-\nu-5)}{2}\right], \tag{74e}$$

$$C_5 = g-5. \tag{74f}$$

Remark 5.15: These two examples could be verified by hand computation, although only a masochist would try to do so. They, as well as several others, have been verified by computer assisted computations, so that we are reasonably certain of the validity of the above-noted conjectures; but we have not yet managed to prove them for all values of N. ■

III. PROOFS

First, let us obtain the systems of ODEs (35) and (40) from the *solvable* matrix evolution equation (32).

Remark 3.1: Here we take the second-order matrix ODE (32) as a starting point for our treatment, but one could as well take as a starting point the system of two coupled first-order matrix ODEs (31a) and (31b). ■

Via (18) we get

$$\ddot{z}_n = cz_n + (\dot{z}_n - \alpha)\left(b + \frac{\dot{z}_n}{z_n} + a\frac{\dot{z}_n - \alpha}{z_n}\right) - \sum_{m=1, m\neq n}^{N} \frac{(z_n - z_m)[z_n + z_m + a(z_n - z_m)]}{z_m} M_{nm}M_{mn}, \tag{75a}$$

$$\frac{\dot{M}_{nm}}{M_{nm}} = -2\frac{\dot{z}_n - \dot{z}_m}{z_n - z_m} + b + (1+a)\left(\frac{\dot{z}_n}{z_n} + \frac{\dot{z}_m}{z_m}\right) - \alpha\left(\frac{1+a}{z_n} + \frac{a}{z_m}\right) - (\mu_n - \mu_m)$$
$$+ \sum_{\ell=1, \ell\neq m,n}^{N} \left\{\frac{(z_n - z_\ell) + (z_m - z_\ell)}{(z_n - z_m)} + \frac{(1+a)(z_n - z_\ell)(z_m - z_\ell)}{(z_n - z_m)z_\ell}\right\}\frac{M_{n\ell}M_{\ell m}}{M_{nm}},$$
$$n \neq m. \tag{75b}$$

As a first educated guess we now make the *ansatz*

$$M_{nm} = \frac{(\dot{z}_n\dot{z}_m)^{1/2}g}{(z_n - z_m)^2}, \quad n \neq m. \tag{76}$$

Remark 3.2: This *ansatz* (as well as analogous ones made in the following) is only applicable provided $z_n \neq z_m$ whenever $n \neq m$. Indeed the models obtained in this paper, when interpreted as N-body problems in which the N quantities z_n identify the positions of the particles (generally in the complex z-plane), feature two-body forces that are *singular* at zero separation, so that the equations of motion become *singular* whenever two particles *collide*. This constitutes no difficulty, because the initial data leading to collisions are *exceptional*, the set of such data having generally *zero* measure in the space of initial data $z_n(0)$, $\dot{z}_n(0)$ (assigned in the complex z-plane). But this entails that one cannot assign initial data in which the coordinates of two or more particles coincide, and moreover that the study of the motion in the neighborhood of such data requires caution to avoid wrong inferences (as will be illustrated in the following in the context of the investigation of motions in the neighborhood of equilibria for some of the systems discussed herein). ■

Insertion of the *ansatz* (76) in (75b) yields

$$\frac{\dot{g}}{g} = b + \left(\frac{1}{2} + a\right)\left(\frac{\dot{z}_n}{z_n} + \frac{\dot{z}_m}{z_m}\right) - \alpha\left(\frac{1+a}{z_n} + \frac{a}{z_m}\right) - (\mu_n - \mu_m) + g \sum_{\ell=1,\ell\neq m,n}^{N} \frac{(z_n - z_m)}{(z_n - z_\ell)(z_m - z_\ell)} \left\{\frac{z_\ell}{z_n - z_\ell} + \frac{z_\ell}{z_m - z_\ell} + (1+a)\right\}, \quad n \neq m. \tag{77}$$

Using the identity

$$\frac{(z_n - z_m)}{(z_n - z_\ell)(z_m - z_\ell)} = -\left(\frac{1}{z_n - z_\ell} - \frac{1}{z_m - z_\ell}\right) \tag{78}$$

we now rewrite this equation as follows:

$$\frac{\dot{g}}{g} = b + \left(\frac{1}{2} + a\right)\left[\frac{\dot{z}_n}{z_n} + \frac{\dot{z}_m}{z_m} - \alpha\left(\frac{1}{z_n} + \frac{1}{z_m}\right)\right] - (\tilde{\mu}_n - \tilde{\mu}_m) - g \sum_{\ell=1,\ell\neq m,n}^{N} \left[\frac{z_\ell}{(z_n - z_\ell)^2} - \frac{z_\ell}{(z_m - z_\ell)^2} + \frac{1+a}{z_n - z_\ell} - \frac{1+a}{z_m - z_\ell}\right], \quad n \neq m, \tag{79}$$

having conveniently set

$$\mu_n = \tilde{\mu}_n - \frac{\alpha}{2z_n}. \tag{80}$$

Recalling the freedom to assign the diagonal elements μ_n we moreover conveniently set

$$\tilde{\mu}_n = -g \sum_{\ell=1,\ell\neq n}^{N} \left\{\frac{z_\ell}{(z_n - z_\ell)^2} - \frac{1+a}{z_n - z_\ell}\right\}, \tag{81}$$

and we thereby see that (79) now reads

$$\frac{\dot{g}}{g} = b + \left(\frac{1}{2} + a\right)\left[\frac{\dot{z}_n}{z_n} + \frac{\dot{z}_m}{z_m} - \alpha\left(\frac{1}{z_n} + \frac{1}{z_m}\right) - \frac{2g}{z_n - z_m}\right], \quad n \neq m. \tag{82}$$

This equation is therefore consistent provided the two conditions $b=0$ and $a=-\frac{1}{2}$ hold (see (34)), and it implies that g is an (*arbitrary*) *constant*. It is then easy to verify that the insertion of (76) and (34) in (75a) yields (35). The first part of our first task is thus completed.

To prove the second part we use the following, different, *ansatz* for the *off-diagonal* elements of the matrix $M(t)$:

$$M_{nm} = \frac{[(\dot{z}_n - \alpha)(\dot{z}_m - \alpha)]^{1/2} g}{z_n - z_m}, \quad n \neq m. \tag{83}$$

Its insertion in (75) yields

$$\frac{\ddot{z}_n}{\dot{z}_n - \alpha} = \frac{cz_n}{\dot{z}_n - \alpha} + b + \frac{(1+a)\dot{z}_n}{z_n} - \frac{\alpha a}{z_n} + g^2 \sum_{m=1,m\neq n}^{N} (\dot{z}_m - \alpha)\left(\frac{2}{z_n - z_m} + \frac{1+a}{z_m}\right), \tag{84a}$$

$$\frac{\dot{g}}{g} + \frac{1}{2}\left(\frac{\ddot{z}_n}{\dot{z}_n - \alpha} + \frac{\ddot{z}_m}{\dot{z}_m - \alpha}\right) = -\frac{\dot{z}_n - \dot{z}_m}{z_n - z_m} + b + (1+a)\left(\frac{\dot{z}_n}{z_n} + \frac{\dot{z}_m}{z_m}\right) - \alpha\left(\frac{1+a}{z_n} + \frac{a}{z_m}\right) - (\mu_n - \mu_m) - g \sum_{\ell=1,\ell\neq m,n}^{N} (\dot{z}_\ell - \alpha)\left(\frac{1}{z_n - z_\ell} + \frac{1}{z_m - z_\ell} + \frac{1+a}{z_\ell}\right), \quad n \neq m. \tag{84b}$$

Insertion of the first of these two equations in the second yields (using again the assignment (80))

$$\frac{\dot{g}}{g}+\frac{c}{2}\left(\frac{z_n}{\dot{z}_n-\alpha}+\frac{z_m}{\dot{z}_m-\alpha}\right)+(g^2-1)\left[-\frac{\dot{z}_n-\dot{z}_m}{z_n-z_m}+\frac{1+a}{2}\left(\frac{\dot{z}_n}{z_n}+\frac{\dot{z}_m}{z_m}-\frac{\alpha}{z_n}-\frac{\alpha}{z_m}\right)\right]+\tilde{\mu}_n-\tilde{\mu}_m$$
$$=-g(1+g)\sum_{\ell=1,\ell\neq m,n}^{N}(\dot{z}_\ell-\alpha)\left(\frac{1}{z_n-z_\ell}+\frac{1}{z_m-z_\ell}+\frac{1+a}{z_\ell}\right),\quad n\neq m. \tag{84c}$$

If we now set (using our privilege to assign this quantity as we wish) $\tilde{\mu}_n=0$ (or equivalently $\tilde{\mu}_n=\tilde{\mu}$) we see that, provided there holds the condition $c=0$, see (38), the assignment

$$g=-1 \tag{85}$$

is consistent with this system of ODEs, and clearly its insertion in (84a) yields (39).

Remark 3.3: This derivation of (40) does not require that the quantity b be time-independent. ■

Having completed our first task, let us now compute the solution $U(t)$ of the system of two matrix ODEs ((31a) and (31b)) in the cases of interest to us, with *vanishing* c (see (38)), *constant* a, and b either *constant* or time-dependent as specified by (50b).

Consider first the case with a and $b=i\omega$ both *constant*. Then from (31b) with $c=0$ we get

$$V(t)=V(0)\exp(i\omega t)\left[1-aV(0)\frac{\exp(i\omega t)-1}{i\omega}\right]^{-1}. \tag{86a}$$

As we will see in the following, in the case of interest to us the $N\times N$ matrix $V(0)$ turns out to be *dyadic*, hence this formula can be simplified to read

$$V(t)=V(0)\exp(i\omega t)\{1+a\eta[\exp(i\omega t)-1]\}^{-1}, \tag{86b}$$

with

$$\eta=-\frac{\mathrm{trace}[V(0)]}{i\omega}. \tag{86c}$$

(To obtain this simplification, and analogous ones to follow, we take advantage of the following property: *if* Δ *is a dyadic matrix*,

$$\Delta_{nm}=\breve{\delta}_n\hat{\delta}_m, \tag{87a}$$

there holds the identity

$$f(\Delta)=f(0)+\frac{f(\mathrm{trace}[\Delta])-f(0)}{\mathrm{trace}[\Delta]}\Delta \tag{87b}$$

for any (scalar) function f for which the above-noted formula makes good sense.)

Then from (31a) with (31c) we get

$$U(t)=(1+[\{1+a\eta[\exp(i\omega t)-1]\}^{-1/a}-1]P)U(0)$$
$$+\alpha\int_0^t dt'\left(1+\left[\left\{\frac{1+a\eta[\exp(i\omega t)-1]}{1+a\eta[\exp(i\omega t')-1]}\right\}^{-1/a}-1\right]P\right), \tag{88a}$$

$$U(t)=(1-P)[U(0)+\alpha t]+P\{1+a\eta[\exp(i\omega t)-1]\}^{-1/a}[U(0)+\alpha u(t)], \tag{88b}$$

where η is of course defined by (86c) and P is the following "projector" $N\times N$ matrix,

$$P = \frac{V(0)}{\text{trace}[V(0)]}, \quad P^2 = P, \tag{88c}$$

where (see (33) and the following)

$$V(0) = [\dot{U}(0) - \alpha][U(0)]^{-1}, \tag{88d}$$

and

$$u(t) = \int_0^t \mathrm{d}t' \{1 + a\eta[\exp(i\omega t') - 1]\}^{1/a}. \tag{88e}$$

The integration on the right-hand side of this formula could be performed in terms of hypergeometric functions, but this is not particularly enlightening. More useful, in view of the results of interest to us is to consider the case with ω *real* and *nonvanishing* (for definiteness, $\omega > 0$), and to note that, by appropriately expanding as a (generally infinite) series the power under the integral on the right-hand side of (88e) and then integrating term by term, $u(t)$ can be rewritten as an infinite series, see the explicit expressions provided in the formulation of **Proposition 2.3.** (Of course if a is the inverse of a *positive integer*, the integration in (88e) can be performed in terms of elementary functions; in this case the infinite sums in the explicit expressions provided in **Proposition 2.3** become finite sums)

Likewise, if a is *constant* but b has the time-dependence (50b), from the version of (31b) with $c=0$ (see (38)) and the variable t formally replaced by τ,

$$V' = aV^2 + \frac{ki\omega V}{1 + i\omega\tau}, \tag{89a}$$

we get

$$V(\tau) = V(0)(1 + i\omega\tau)^k \left\{ 1 - \frac{aV(0)}{(k+1)i\omega}[(1 + i\omega\tau)^{k+1} - 1] \right\}^{-1}. \tag{89b}$$

By taking again advantage of the *dyadic* character of $V(0)$ (see the following) this formula can be simplified to read

$$V(\tau) = V(0)(1 + i\omega\tau)^k [1 - a\tilde{\eta} + a\tilde{\eta}(1 + i\omega\tau)^{k+1}]^{-1} \tag{89c}$$

with

$$\tilde{\eta} = -\frac{\text{trace}[V(0)]}{i\tilde{k}\omega}. \tag{89d}$$

In the last formula and hereafter we use whenever convenient the short-hand notation $k+1=\tilde{k}$ (see (56j)). Then from (31a) with (31c) (of course with the variable t replaced by τ)

$$U'(\tau) = \alpha + V(\tau)U(\tau), \tag{90}$$

we get

$$U(\tau) = (1 - P)[U(0) + \alpha\tau] + P\phi(\tau)\left[U(0) + \alpha \int_0^\tau \frac{\mathrm{d}\tau'}{\phi(\tau')} \right], \tag{91a}$$

$$\phi(\tau) = [1 - a\tilde{\eta} + a\tilde{\eta}(1 + i\omega\tau)^{\tilde{k}}]^{-1/a}, \tag{91b}$$

where we took again advantage of the *dyadic* character of $V(0)$ and we use again the definition (88c) of the projection matrix P.

We now use the transformation (53), of course with τ related to t by (51b), and thereby obtain (from the preceding formulas):

$$\widetilde{U}(t) = \exp(-i\omega t)\{1 + [\widetilde{\phi}(t) - 1]\widetilde{P}\}\widetilde{U}(0) + (1 - \widetilde{P})\alpha\frac{1 - \exp(-i\omega t)}{i\omega} + \alpha\widetilde{P}\widetilde{u}(t)\widetilde{\phi}(t), \tag{92a}$$

$$\widetilde{\phi}(t) = \{1 + a\widetilde{\eta}[\exp(\widetilde{k}i\omega t) - 1]\}^{-1/a}, \tag{92b}$$

$$\widetilde{u}(t) = \int_0^t \mathrm{d}t' \exp[i\omega(t' - t)][\widetilde{\phi}(t')]^{-1} \tag{92c}$$

$$= \int_0^t \mathrm{d}t' \exp[i\omega(t' - t)][1 - a\widetilde{\eta} + a\widetilde{\eta}\exp(\widetilde{k}i\omega t')]^{1/a}. \tag{92d}$$

Note that we use again the short-hand notation $k+1=\widetilde{k}$, see (56j), and we also introduced the notation $\widetilde{P}$, to avoid any confusion with the projection operator P defined previously: both P and $\widetilde{P}$ are related to $V(0)$ by the formula (88c), and in both cases $V(\tau)$ is related to $U(\tau)$ and $U'(\tau)$ by (90), but now (53) with (51b) implies

$$V(0) = [\dot{\widetilde{U}}(0) + i\omega\widetilde{U}(0) - \alpha][\widetilde{U}(0)]^{-1} = [\dot{\widetilde{U}}(0) - \alpha][\widetilde{U}(0)]^{-1} + i\omega. \tag{93}$$

The integral on the right-hand side of the formula (92d) could be expressed in terms of hypergeometric functions, but this would not be particularly enlightening. We rather perform it explicitly by series, under the assumption that the quantity $\widetilde{k}\omega$ is *real* (to guarantee the convergence of the sums), and we thereby get the results displayed in the formulation of **Proposition 2.7.** (Of course if a is the inverse of a *positive integer*, the integration in (92d) can be performed in terms of elementary functions; in this case the infinite sums in the explicit expressions provided in **Proposition 2.7** become finite sums).

The final step to prove the results (reported in the preceding section as **Propositions 2.3**) is to observe that one can set $R(0)=1$, entailing (see (12))

$$U(0) = \mathrm{diag}[z_n(0)], \tag{94}$$

and (see (13a), (83), and (85))

$$[\dot{U}(0)]_{nm} = \delta_{nm}\dot{z}_n(0) + (1 - \delta_{nm})\{[\dot{z}_n(0) - \alpha][\dot{z}_m(0) - \alpha]\}^{1/2}, \tag{95}$$

implying via (88d)

$$[V(0)]_{nm} = \frac{\{[\dot{z}_n(0) - \alpha][\dot{z}_m(0) - \alpha]\}^{1/2}}{z_m(0)}, \tag{96a}$$

which evidences the *dyadic* character of this $N\times N$ matrix and entails

$$\mathrm{trace}[V(0)] = \sum_{n=1}^{N} \frac{\dot{z}_n(0) - \alpha}{z_n(0)}, \tag{96b}$$

as well as the definitions (44c) and (44d). To complete the proof of **Proposition 2.3** one must treat the special case in which the initial data cause the quantity η, see (44d), to vanish. It is easily seen, via (96a), that this causes the square of the (dyadic) matrix $V(0)$ to vanish. This property holds as well for the matrix $V(t)$ (see (97)):

$$[V(t)]^2 = 0, \tag{97}$$

and it drastically simplifies the remaining calculations, which are analogous to those reported above and hence need not be reported.

And the analogous completion of the proof of **Proposition 2.7** is now sufficiently straightforward that we can leave it as a task for the diligent reader.

IV. ALTERNATIVE FORMULATIONS OF THE SOLVABLE MODELS

In this section we provide an alternative formulation of the *solvable* many-body models obtained in this paper, characterized by equations of motions of Newtonian type. We do not elaborate on the technique to obtain these results, since it can be considered by now rather standard (see for instance Sec. 2.3 of Ref. 6). We merely note that key to such reformulations are the relations among the *zeros* of a polynomial and its *coefficients*, hence the formulas reported in the Appendix, as applied to the *monic* polynomial $\psi(z,t)$ (respectively, $\tilde{\psi}(z,t)$), of degree N in z, having the N "particle coordinates" $z_n(t)$ (respectively, $\tilde{z}_n(t)$) as its *zeros* and the N coefficients $c_m(t)$ (respectively, $\tilde{c}_m(t)$) (see below (99), respectively, (101), and recall (62)).

Using those formulas it is indeed seen that, if the coordinates $z_n(t)$ evolve according to the equations of motion (40), that can be conveniently rewritten as follows (recall (62)),

$$\ddot{z}_n - 2\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n \dot{z}_m}{z_n - z_m} = -2i \sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n + \dot{z}_m}{z_n - z_m} - 2\sum_{m=1,m\neq n}^{N} \frac{1}{z_n - z_m} + (i\dot{z}_n + 1)\left[1 + \frac{1}{z_n} - (1+a)\sum_{m=1}^{N} \frac{i\dot{z}_m + 1}{z_m}\right], \tag{98}$$

then the polynomial $\psi(z,t)$ of degree N in z characterized by the N zeros $z_n(t)$,

$$\psi(z,t) = \prod_{n=1}^{N} [z - z_n(t)] = z^N + \sum_{m=1}^{N} c_m(t) z^{N-m} = \sum_{m=0}^{N} c_m(t) z^{N-m}, \quad c_0 = 1 \tag{99}$$

satisfies the evolution equation

$$\psi_{tt} + 2i\psi_{zt} - \psi_{zz} - i\psi_t + \psi_z - \frac{i}{z}\left[\psi_t - \frac{\dot{c}_N}{c_N}\psi\right] + \frac{1}{z}\left[\psi_z - \frac{c_{N-1}}{c_N}\psi\right] - (1+a)\left(\frac{\dot{c}_N}{c_N} + \frac{ic_{N-1}}{c_N}\right)(\psi_t + i\psi_z) = 0. \tag{100a}$$

Notation: Here and hereafter subscripted variables denote partial differentiations.

Clearly this result is a direct consequence of the (relevant) formulas ((A4)) and ((A6)), and it can be conveniently rewritten in the following two ways:

$$\psi_{tt} + 2i\psi_{zt} - i\psi_t - \psi_{zz} + \psi_z - i\left[\frac{1}{z} + (1+a)\gamma\right][\psi_t + i\psi_z] - \frac{1}{z}\gamma\psi = 0, \tag{100b}$$

$$\psi_{tt} + 2i\psi_{tz} - i\psi_t - \psi_{zz} + \psi_z - i\frac{\psi_t - \dot{c}_N}{z} + \frac{\psi_z - c_{N-1}}{z} - \frac{\psi - c_N}{z} + (1+a)(-i\psi_t + \psi_z) = 0, \tag{100c}$$

where (see (63b))

$$\gamma \equiv \gamma(t) = \frac{c_{N-1}(t) - i\dot{c}_N(t)}{c_N(t)} = \frac{\psi_z(0,t) - i\psi_t(0,t)}{\psi(0,t)}. \tag{100d}$$

And now, via the (relevant) formulas (A8), one easily obtains that the N coefficients $c_m(t)$ of the polynomial $\psi(z,t)$, see (A1), evolve according to the system of ODEs ((63a) and (63b)).

Likewise—as the diligent reader will check—analogous results can be obtained starting from the system (52) rather than (40). Then the analog of the evolution equation (100c), satisfied now by the monic polynomial $\tilde{\psi}(z,t)$ of degree N in z that has the N zeros $\tilde{z}_n(t)$,

$$\tilde{\psi}(z,t) = \prod_{n=1}^{N} [z - \tilde{z}_n(t)] = z^N + \sum_{m=1}^{N} \tilde{c}_m(t) z^{N-m} = \sum_{m=0}^{N} \tilde{c}_m(t) z^{N-m}, \quad \tilde{c}_0 = 1, \tag{101}$$

reads

$$\tilde{\psi}_{tt} + 2(1-z)i\tilde{\psi}_{tt} - \left(\frac{1}{z} - 2N + K\right) i\tilde{\psi}_t - (1-z)^2 \tilde{\psi}_{zz} + \left[\frac{1}{z} + 1 - 2N + K\right]$$
$$\times (1-z)\tilde{\psi}_z + \left[\frac{\tilde{\gamma}}{z} + N(K-N)\right]\tilde{\psi} = 0, \tag{102a}$$

where (see (66b) and (66c))

$$K \equiv K(t) = \tilde{k} + (a+1)[N + \tilde{\gamma}(t)], \tag{102b}$$

$$\tilde{\gamma} \equiv \tilde{\gamma}(t) = \frac{\tilde{c}_{N-1}(t) - i\tilde{c}_N(t)}{\tilde{c}_N(t)} = \frac{\tilde{\psi}_z(0,t) - i\tilde{\psi}_t(0,t)}{\tilde{\psi}(0,t)}. \tag{102c}$$

And the analog of the system of N ODEs ((63a) and (63b)), satisfied now by the N coefficients $\tilde{c}_m(t)$ of the polynomial $\tilde{\psi}(z,t)$, is then easily seen to be just the system ((66a)–(66c)).

Remark 4.1: The evolution equations (100c) and ((102a)–(102c)) are themselves *solvable:* note that in spite of their superficial appearance they are not (*linear*) PDEs but rather *nonlinear functional* equations, see (63b) and (102c).

V. EQUILIBRIUM CONFIGURATIONS OF THE ISOCHRONOUS SYSTEM, BEHAVIOR IN THEIR NEIGHBORHOODS, *DIOPHANTINE* FINDINGS

In this section we investigate the behavior of the system ((66a)–(66c)) in the neighborhood of its "equilibrium configurations,"

$$\tilde{c}_m(t) = \bar{c}_m, \quad \ddot{\tilde{c}}_m(t) = \dot{\tilde{c}}_m(t) = 0. \tag{103}$$

Analogous results could be investigated for the other solvable models considered in this paper, but we leave this task to the interested reader. Our motivation for focusing on the system ((66a)–(66c)) comes from its property of *isochronicity*, see *Remark 2.12:* indeed by taking advantage of it we obtain in the following the *Diophantine* findings reported at the end of Sec. II. Moreover, as we will see, there exist interesting equilibrium configurations of the system ((66a)–(66c)) that do not yield (for $N>1$)*genuine* equilibrium configurations $\bar{z}_n$ of the corresponding N-body problem (52) (namely, configurations characterized by the condition that $\bar{z}_n \neq \bar{z}_m$ whenever $n \neq m$; see the denominator in the second sum on the right-hand side of (52)), but nevertheless allow an interesting treatment.

First of all let us find these equilibrium configurations. The quantities $\bar{c}_m$ are clearly the solutions of the following system of algebraic equations (see ((66a)–(66c))):

$$m(\bar{K} - m)\bar{c}_m + \{(N+1-m)(\bar{K} - 2m) - \bar{\gamma}\}\bar{c}_{m-1} - (N-m)(N+2-m)\bar{c}_{m-2} = 0,$$

$$m = 1, \ldots, N, \quad \bar{c}_0 = 1, \quad \bar{c}_{-1} = 0, \tag{104a}$$

$$\bar{K} = \tilde{k} + (1+a)(N+\bar{\gamma}), \tag{104b}$$

$$\bar{\gamma} = \frac{\bar{c}_{N-1}}{\bar{c}_N}. \tag{104c}$$

Note that these equations are also identically satisfied for $m=N+1$ and for $m=N+2$, provided of course one sets $\bar{c}_{N+1}=\bar{c}_{N+2}=0$. While for $m=N$ via (104c) one finds that the quantity $\bar{\gamma}$ must satisfy the second-order equation

$$a\bar{\gamma}^2 + (\tilde{k}+2aN)\bar{\gamma} + N(\tilde{k}+aN) = 0 \tag{105}$$

entailing either ("*case 1*")

$$\bar{\gamma} = -N \tag{106}$$

or ("*case 2*")

$$\bar{\gamma} = -\frac{aN+\tilde{k}}{a} = -N - \frac{\tilde{k}}{a}. \tag{107}$$

To obtain the solution of the system of algebraic equations (104) we proceed as follows. Let $\bar{\psi}(z)$ be the (*monic*) polynomial of degree N in z that has the N numbers $\bar{c}_m$ as its N coefficients,

$$\bar{\psi}(z) = \sum_{m=0}^{N} \bar{c}_m z^{N-m}, \tag{108a}$$

$$\bar{c}_0 = 1. \tag{108b}$$

Then clearly (see (101)) $\bar{\psi}(z)$ is the "equilibrium" (i.e., time-independent) solution of (102a). Hence $\bar{\psi}(z)$ satisfies the ODE

$$(z-1)^2\bar{\psi}'' + \left(\frac{1}{z} + 1 - 2N + \bar{K}\right)(z-1)\bar{\psi}' + \left[\frac{\bar{\gamma}}{z} + N(N-\bar{K})\right]\bar{\psi} = 0, \tag{109}$$

with $\bar{K}$ defined by (104b) and $\bar{\gamma}$ by (104c). Here of course the appended primes indicate differentiations with respect to the independent variable z.

It is clearly convenient to set

$$\bar{\psi}(z) = \Phi(v), \quad v = z-1, \tag{110}$$

so that the ODE satisfied by $\Phi(v)$ then reads

$$(1+v)v^2\Phi'' + (1+H+Hv)v\Phi' + [\bar{\gamma} - N(H+N-1) - N(H+N-1)v]\Phi = 0, \tag{111a}$$

where we temporarily introduced the notation

$$H = 1 - 2N + \bar{K} = (1+a)\bar{\gamma} + \tilde{k} + 1 + N(a-1) \tag{111b}$$

(see also (104b)). Here of course the appended primes indicate differentiations with respect to the independent variable v.

We are seeking a solution of this ODE that is a (*monic*) polynomial of degree N in the independent variable v. Hence we set

$$\Phi(v) = \sum_{m=0}^{N} \varphi_m v^{N-m}, \tag{112a}$$

$$\varphi_0 = 1, \tag{112b}$$

which via (108a) and (112a) entails

$$\bar{c}_m = \sum_{j=0}^{m} (-)^j \binom{N+j-m}{j} \varphi_{m-j}. \tag{113}$$

It is then easily seen that the polynomial $\Phi(v)$ is a solution of (111a) provided the coefficients φ_m satisfy the recursion relation

$$(m+1)[m+1-\tilde{k}-(1+a)(N+\bar{\gamma})]\varphi_{m+1} = -[m(m-1-\tilde{k})-(m-1)(N+\bar{\gamma})]\varphi_m, \tag{114a}$$

with the "boundary conditions"

$$\varphi_{-1} = \varphi_{N+1} = 0. \tag{114b}$$

Let us consider first *case 1* (see (106)). Then the recursion (114a) takes the neat form

$$(m+1)(m+1-\tilde{k})\varphi_{m+1} = -m(m-1-\tilde{k})\varphi_m. \tag{115}$$

Remarkably, the constant a has completely dropped out of this formula.

Clearly this recursion relation, for a *generic* value of the parameter $\tilde{k}$, has the solution (clearly consistent with the boundary conditions (114b) and with (112b))

$$\varphi_m = \delta_{0,m}. \tag{116}$$

But it is moreover easily seen that, if the parameter $\tilde{k}$ is a *positive integer* less that N,

$$\tilde{k} = \nu, \tag{117a}$$

$$\nu = 1, 2, \ldots, N-1, \tag{117b}$$

then the recursion relations ((114a) and (114b)) admit the more general solution (also clearly consistent with the boundary conditions (114b) and with (112b))

$$\varphi_m = \delta_{0,m} + \left(\delta_{\nu,m} + \frac{\nu}{\nu+1}\delta_{\nu+1,m}\right)h, \tag{118}$$

with h an *arbitrary* number. Hereafter we treat this more general solution, of course on the understanding that the constant h must be set to *zero* if the parameter $\tilde{k}$ does *not* satisfy the condition (117). The corresponding equilibrium solution of the system ((66a)–(66c)) is (see (113))

$$\bar{c}_m = (-)^m \left[\binom{N}{m} + (-)^\nu \frac{N(\nu+1)-\nu(m+1)}{(\nu+1)(N-\nu)} \binom{N-\nu}{m-\nu} h\right]. \tag{119}$$

Note the consistency (via (104c)) of this expression of the coefficients $\bar{c}_m$ with the condition (106).

Hence in this *case 1* (see (108))

$$\bar{\psi}(z) = (z-1)^N + (z-1)^{N-1-\nu}\left(z - \frac{1}{\nu+1}\right)h. \tag{120}$$

Remark 5.1: Clearly the N zeros $\bar{z}_n$ of this polynomial $\bar{\psi}(z)$ can *all* be *distinct* (entailing that

the corresponding equilibrium configuration of the N-body problem (52) is *genuine*) only if $\nu = N-1$ and $h \neq 0$, so that

$$\bar{\psi}(z) = (z-1)^N + \left(z - \frac{1}{N}\right)h\,. \quad \blacksquare \tag{121}$$

Next, let us ascertain the equilibrium configuration corresponding to *case 2* (see (107)). Then the recursion (114a) takes the neat form

$$(m+1)(m-\mu)\varphi_{m+1} = -(m-1)(m-\mu-1)\varphi_m, \tag{122}$$

where we now introduce the convenient parameter μ via the assignment

$$\mu = -\frac{\tilde{k}+a}{a}, \quad \tilde{k} = -(\mu+1)a. \tag{123}$$

Now it is easily seen that, for *generic* values of this parameter μ, this recursion has the solution (clearly consistent with the boundary conditions (114b) and with (112b))

$$\varphi_m = \delta_{0,m} + \delta_{1,m}\frac{\mu+1}{\mu}, \tag{124}$$

while if μ is a *positive* integer less than N,

$$\mu = 1,2,\ldots,N-1, \tag{125}$$

then the more general solution

$$\varphi_m = \delta_{0,m} + \delta_{1,m}\frac{\mu+1}{\mu} + \delta_{\mu+1,m}h, \tag{126}$$

with h an *arbitrary* number, also solves the recursion relation (122) and is compatible with the boundary conditions (114b) and with (112b). Hereafter we treat this more general solution, of course on the understanding that the constant h must be set to *zero* if the parameters a and $\tilde{k}$ do not satisfy via (123) the condition (125). The corresponding equilibrium solution of the system ((66a)–(66c)) is (see (113))

$$\bar{c}_m = (-)^m\left[\binom{N}{m}\frac{N\mu - m(\mu+1)}{N\mu} + (-)^{\mu+1}\binom{N-\mu-1}{m-\mu-1}h\right]. \tag{127}$$

Note the consistency (via (104c) and (123)) of this expression of the coefficients $\bar{c}_m$ with the condition (107).

Hence in this *case 2* (see (108))

$$\bar{\psi}(z) = (z-1)^{N-1}\left(z + \frac{1}{\mu}\right) + (z-1)^{N-\mu-1}h. \tag{128}$$

Remark 5.2: Clearly for $N>2$ the N zeros $\bar{z}_n$ of this polynomial $\bar{\psi}(z)$ can *all* be *distinct* (entailing that the corresponding equilibrium configuration of the N-body problem (52) is *genuine*) only if $\mu = N-1$ or $\mu = N-2$ and if moreover $h \neq 0$. ■

Next, let us investigate the behavior of the system of ODEs ((66a)–(66c)) in the neighborhood of these equilibrium configurations, (119) (entailing (106)) and (127) (entailing (107)). To this end we set

$$\tilde{c}_m(t) = \tilde{c}_m + \varepsilon\rho_m(t) + \mathcal{O}(\varepsilon^2), \tag{129}$$

treating in the standard manner ε as a small parameter. We thus obtain the linearized system of ODEs

$$\ddot{\rho}_m + (2m - \bar{K})i\dot{\rho}_m + (2N + 1 - 2m)i\dot{\rho}_{m-1} + m(\bar{K} - m)\rho_m + [(N + 1 - m)(\bar{K} - 2m) - \bar{\gamma}]\rho_{m-1} - (N - m)$$
$$\times(N + 2 - m)\rho_{m-2} + \frac{m(1 + a)\bar{c}_m + [(N + 1 - m)(1 + a) - 1]\bar{c}_{m-1}}{\bar{c}_N}(\rho_{N-1} - i\dot{\rho}_N - \bar{\gamma}\rho_N) = 0,$$

$$m = 1, \ldots, N, \quad \rho_0 = 0, \quad \rho_{-1} = 0, \tag{130}$$

with $\bar{K}$ defined by (104b). To obtain this system of ODEs from ((66a)–(66c)) we used the relation

$$\tilde{\gamma}(t) = \bar{\gamma} + \varepsilon\frac{\rho_{N-1}(t) - i\dot{\rho}_N(t) - \bar{\gamma}\rho_N(t)}{\bar{c}_N} + O(\varepsilon^2) \tag{131}$$

implied by (66c) and (129)

The general solution of this linear system of ODEs, (130), reads

$$\rho_m(t) = \sum_{n=1}^{N} [a_n^{(+)} r_m^{(+)(n)} \exp(ip_n^{(+)}t) + a_n^{(-)} r_m^{(-)(n)} \exp(ip_n^{(-)}t)], \tag{132}$$

where the $2N$ numbers $a_n^{(\pm)}$ are *arbitrary* (to be fixed by the initial data) while the $2N$ numbers $p_n^{(\pm)}$, respectively, the $2N$ corresponding (t-independent) N-vectors $\underline{r}^{(\pm)(n)} \equiv (r_1^{(\pm)(n)}, \ldots, r_N^{(\pm)(n)})$, are the eigenvalues, respectively, the eigenvectors, of the (N-vector) generalized eigenvalue equation

$$(p^2 + Ap + B)\underline{r} = 0, \tag{133}$$

with the two $N \times N$ matrices A and B defined (componentwise) as follows:

$$A_{nm} = (2n - \bar{K})\delta_{n,m} + (2N + 1 - 2n)\delta_{n-1,m} + C_n\delta_{Nm}, \tag{134a}$$

$$B_{nm} = n(n - \bar{K})\delta_{n,m} + [(N + 1 - n)(2n - \bar{K}) + \bar{\gamma}]\delta_{n-1,m} + (N - n)(N + 2 - n)\delta_{n-2,m}$$
$$+ C_n(\delta_{N-1,m} - \bar{\gamma}\delta_{N,m}), \tag{134b}$$

where

$$C_n = -\frac{n(1 + a)\bar{c}_n + [(N + 1 - n)(1 + a) - 1]\bar{c}_{n-1}}{\bar{c}_N}. \tag{134c}$$

These formulas imply of course that the $2N$ numbers $p_n^{(\pm)}$ are the roots of the polynomial equation (of degree $2N$ in p)

$$\det[p^2 + Ap + B] = 0, \tag{135a}$$

namely

$$\det[p^2 + Ap + B] = \prod_{n=1}^{N} [(p - p_n^{(+)})(p - p_n^{(-)})]. \tag{135b}$$

Let us now consider the two cases, as discussed earlier.

In *case 1*, via (104b) with (106) (implying $\bar{K} = \tilde{k} = \nu$), (117) and (119), and setting for notational convenience

$$(-)^{\nu}(\nu+1)h=f, \quad (-)^{\nu}\nu(1+a)h=g \tag{136}$$

one finds for the matrices A and B the expression ((71a)–(71d)).

Likewise, in *case 2*, via (104b) with (107) (implying $\bar{K}=-\tilde{k}/a=\mu+1$, $\bar{\gamma}=-N+\mu+1$), (123), (125), and (127), and setting for notational convenience

$$(-)^{\mu}\mu h=f, \quad \mu=\nu, \quad \tilde{k}=g, \tag{137}$$

one finds for the matrices A and B the expression ((72a)–(72d)).

Remark 5.3: A shortcut to arrive at the solution (116) entailing

$$\bar{\psi}(z)=(z-1)^N \tag{138}$$

goes as follows. Let the $N\times N$ matrix $\bar{U}$ be an "equilibrium," i.e., time-independent, solution of the matrix equation (54), so that it satisfies (recall (62) and (56j))

$$(\bar{U}-1)\left(\bar{U}-\frac{a}{a+\tilde{k}}\right)=0, \tag{139}$$

and notice that

$$\bar{U}=\mathbf{1} \tag{140}$$

is clearly a solution of this equation. Then the determinantal expression (65) (recall (62)) of $\bar{\psi}(z)$, with this assignment of $\bar{U}$, yields immediately (138).

But this approach is quite misleading, because one is dealing here with the singular case in which some eigenvalues of the matrix U coincide—indeed all of them.

A hint of the misleading character of this result is provided by the following observation. The solution we just mentioned, which is clearly characterized by the "equilibrium configuration" (recall (62))

$$\bar{z}_n=1 \tag{141}$$

(for *all* values of n), might be considered to satisfy the equations of motions (52) (recall (62)), although of course only by assigning an appropriate value to an ambiguous expression ("zero divided by zero"). And of course, as entailed by the above-mentioned analysis, and implied by

$$\bar{\gamma}=-\sum_{n}^{N}\frac{1}{z_n} \tag{142}$$

(see (104c) and the first equation of Eq. (A6)), this equilibrium configuration is consistent with the value of $\bar{\gamma}$ corresponding to *case 1* (see (119)). One might then guess that the other analogous solution of (139),

$$\bar{U}=\frac{a}{a+\tilde{k}}\mathbf{1}, \tag{143}$$

yields an equilibrium configuration corresponding to *case 2*. But this does *not* happen. Indeed this solution entails (by the same argument as given earlier; again, for *all* values of n)

$$\bar{z}_n=\frac{a+\tilde{k}}{a}, \tag{144}$$

and via the same argument as given earlier this yields

$$\overline{\gamma} = -\frac{a+\widetilde{k}}{a}N = -N - N\frac{\widetilde{k}}{a}, \tag{145}$$

which does *not* agree with (107) (except for $N=1$, when indeed there is no trouble with coinciding values of z_n). And it is moreover clear that this "equilibrium configuration," (144), is inconsistent with the equations of motion (52) (recall (62)).

The singular character of the "equilibrium positions" of the N-body problems considered herein is also manifested by the following phenomenon. In order to try and study the motion of the system (52) in the neighborhood of the "equilibrium configuration" (141) (a quite legitimate enterprise), set

$$z_n(t) = 1 + \varepsilon w_n(t), \tag{146}$$

assign some arbitrary (of course, not all vanishing) values $w_n(0)$, $\dot{w}_n(0)$ and try to extract the time evolution of the coordinate $w_n(t)$ via **Proposition 2.7**, treating ε as a small parameter. One thereby discovers that such a procedure is *inconsistent:* as soon as the evolution starts (namely as soon as $t>0$), the coordinates $z_n(t)$ differ from unity by amounts of order unity rather than of order ε, in contrast to what the assignment (146) assumed to begin with.

This situation makes it impossible—or at least quite difficult—to follow such a route in order to prove the *Diophantine* findings obtained above and formulated at the end of Sec. II. ■

But as we saw earlier, no inconsistency arises when one investigates the behavior of solutions of the system of evolution equation ((66a)–(66c)) in the neighborhood of their equilibrium configurations—even when the analogous treatment of the evolution equations (52) in the neighborhood of the corresponding equilibrium configurations causes trouble, as indicated in *Remark 5.3*. Hence the periodicity properties discussed in *Remark 2.12* must hold as well for the solutions $\rho_m(t)$, and this implies that the numbers $p_m^{(\pm)}$ yielded by the generalized eigenvalue problem discussed earlier must satisfy certain *Diophantine* restrictions, in all the cases identified in *Remark 2.12*, and for the appropriate choices of the parameters $\widetilde{k}$, ν, μ, and h as discussed earlier. For the sake of brevity we leave to the interested reader the formulation of the corresponding results. Motivated by these findings we investigated numerically the solutions of the determinantal equations ((135a) and (135b)) with ((71a)–(71d)) and ((72a)–(72d)), and we were thereby led to formulate the conjectures reported at the end of Sec. II—the validity of which extends, remarkably, beyond the restricted values of the parameters ν, f, and g that are implied by the above-mentioned treatment.

VI. OUTLOOK

As mentioned in Sec. I, there is a simple procedure to manufacture *solvable* systems of equations of motion describing (according to the Newtonian paradigm: "the acceleration of each particle equals a force assigned in terms of the position, and possibly also of the velocities, of all the N particles") the evolution of N coordinates $z_n(t)$ in the (*complex*) z-plane: (i) start from a *solvable* matrix ODE describing the time evolution (within an appropriate class) of an $N\times N$ matrix $U(t)$, (ii) identify the coordinates $z_n(t)$ as the N *eigenvalues* of the matrix $U(t)$ and identify the equations of motion that then describe their evolution, (iii) find a suitable *ansatz*, compatible with the time evolution of (all the N^2 matrix elements of) $U(t)$, expressing in terms of the N eigenvalues $z_n(t)$ (and possibly of their time-derivatives) the other $N(N-1)$ variables that are generally needed, in addition to the N eigenvalues, in order to identify completely the $N\times N$ matrix $U(t)$, and whose time-evolution is therefore generally entangled with that of the N eigenvalues $z_n(t)$. Thereby the system of evolution ODEs satisfied by the coordinates $z_n(t)$ becomes self-contained, and it is likely to be interpretable as a (possibly interesting—but this is a value judgment) N-body problem characterized by Newtonian equations of motions. And this N-body model is then, by construction, *solvable:* indeed its solution consists now in the (merely algebraic) task of finding the N eigenvalues of the matrix $U(t)$, whose time evolution is supposed to be known inasmuch as we started to begin with from a *solvable* matrix evolution equation.

Of the three steps just outlined, the first one is to some extent (but not quite) amenable to systematic analysis, the second works according to a well-understood machinery, the third requires that a *miracle* occur, and some *guess-work* to identify it. So far this approach has yielded several (new) *solvable* models, but finding each one of them constituted a nontrivial challenge. In this paper we have tersely surveyed (some of) the results obtained in this manner, and we have described and analyzed some *new* N-body models obtained in this manner. Can this approach be further exploited to manufacture/discover additional *solvable* models? Presumably yes: indeed one more *integrable/solvable* model of goldfish type has just been discovered, as will be reported in a forthcoming paper.[18] Does it make sense to continue this fishing expedition? Presumably yes, as long as the catch is interesting; but this, let us repeat, entails a value judgment.

ACKNOWLEDGMENTS

F.C. would like to thank the European Union project RTN "Enigma" and the Department of Theoretical Physics at KTH in Stockholm, in particular Edwin Langmann, for the pleasant hospitality during a two-week visit to Sweden in February 2006, as well as the Japan Society for the Promotion of Science (JSPS) and the Yukawa Institute at Kyoto University, in particular Ryu Sasaki, for the pleasant hospitality during a six-week visit to Japan in March-April 2006, when the final version of this paper was drafted. We would also like to thank Ryu Sasaki for advice about references, and for substantial help in making numerical checks of the *Diophantine* relations.

APPENDIX: SOME USEFUL IDENTITIES

In this Appendix we list certain useful relations; several of them reproduce (but in a more convenient notation) results already reported in Appendix B of Ref. 1, while the derivation of the new ones is sufficiently straightforward not to required any explicit elaboration here. Note that not all the formulas reported here are used in this paper, but we thought it useful to collect a rather complete compilation here as a convenient tool for future utilizations.

Let $\psi(z,t)$ be a *monic* polynomial of degree N in z, and let us indicate as $z_n \equiv z_n(t)$ its N zeros and as $c_m \equiv c_m(t)$ its N coefficients (see (99)):

$$\psi(z,t) = \prod_{n=1}^{N} [z - z_n(t)] = z^N + \sum_{m=1}^{N} c_m(t) z^{N-m} = \sum_{m=0}^{N} c_m(t) z^{N-m}, \quad c_0 = 1. \tag{A1}$$

Then clearly

$$\psi_z(z,t) = \psi(z,t) \sum_{n=1}^{N} [z - z_n(t)]^{-1}, \tag{A2a}$$

$$\psi_t(z,t) = \psi(z,t) \sum_{n=1}^{N} [z - z_n(t)]^{-1} [-\dot{z}_n(t)]. \tag{A2b}$$

Here (and throughout) subscripted variables denote partial differentiations, $\psi_z \equiv \partial\psi/\partial z$, $\psi_t \equiv \partial\psi/\partial t$. To conveniently streamline the look of these, and of the following, formulas, we rewrite these two relations via the self-evident notation

$$\psi_z \Leftrightarrow 1, \tag{A3a}$$

$$\psi_t \Leftrightarrow -\dot{z}_n, \tag{A3b}$$

and we write accordingly the following relations:

$$z\psi_z - N\psi \Leftrightarrow z_n, \tag{A3c}$$

$$z^2\psi_z + (c_1 - Nz)\psi \Leftrightarrow z_n^2, \tag{A3d}$$

$$z^3\psi_z - (Nz^2 - c_1 z + c_1^2 - 2c_2)\psi \Leftrightarrow z_n^3, \tag{A3e}$$

$$\frac{1}{z}\left[\psi_z - \frac{c_{N-1}}{c_N}\psi\right] \Leftrightarrow \frac{1}{z_n}, \tag{A3f}$$

$$z\psi_t - \dot{c}_1\psi \Leftrightarrow -\dot{z}_n z_n, \tag{A3g}$$

$$\frac{1}{z}\left[\psi_t - \frac{\dot{c}_N}{c_N}\psi\right] \Leftrightarrow -\frac{\dot{z}_n}{z_n}, \tag{A3h}$$

$$\psi_{zz} \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2}{z_n - z_m}, \tag{A3i}$$

$$z\psi_{zz} - 2(N-1)\psi_z \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_m}{z_n - z_m}, \tag{A3j}$$

$$z\psi_{zz} \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n}{z_n - z_m}, \tag{A3k}$$

$$z\psi_{zz} - (N-1)\psi_z \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{z_n + z_m}{z_n - z_m}, \tag{A4}$$

$$z^2\psi_{zz} - N(N-1)\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n^2}{z_n - z_m}, \tag{A5a}$$

$$z^2\psi_{zz} - 2[(N-2)z - c_1]\psi_z + N(N-3)\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_m^2}{z_n - z_m}, \tag{A5b}$$

$$z^2\psi_{zz} - [(N-2)z - c_1]\psi_z - N\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{z_n^2 + z_m^2}{z_n - z_m}, \tag{A5c}$$

$$z^2\psi_{zz} - 2(N-1)z\psi_z + N(N-1)\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n z_m}{z_n - z_m}, \tag{A5d}$$

$$z^3\psi_{zz} - N(N-1)z\psi + 2(N-1)c_1\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n^3}{z_n - z_m}, \tag{A5e}$$

$$z[z^2\psi_{zz} - 2(N-1)z\psi_z + N(N-1)\psi] \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n^2 z_m}{z_n - z_m}, \tag{A5f}$$

$$z^3\psi_{zz} - 2(N-2)z^2\psi_z + 2c_1 z\psi_z + [N(N+1)z - 2(N-1)c_1]\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n z_m^2}{z_n - z_m}, \tag{A5g}$$

$$z^3\psi_{zz} - (2N-3)z^2\psi_z + c_1 z\psi_z + [N^2 z - (N-1)c_1]\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{z_n z_m^2 + z_n^2 z_m}{z_n - z_m}, \tag{A5h}$$

$$z^4\psi_{zz} - [N(N-1)z^2 - 2(N-1)c_1 z + 2(N-1){c_1}^2 - 2(2N-3)c_2]\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n^4}{z_n - z_m}, \tag{A5i}$$

$$z^4\psi_{zz} - 2z^2[(N-2)z - c_1]\psi_z + [N(N-3)z^2 - 2(N-1)c_1 z + 2c_2]\psi \Leftrightarrow \sum_{m=1,m\neq n}^{N} \frac{2z_n^2 z_m^2}{z_n - z_m}, \tag{A5j}$$

$$\psi_{zt} \Leftrightarrow -\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n + \dot{z}_m}{z_n - z_m}, \tag{A5k}$$

$$z\psi_{zt} \Leftrightarrow -\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n + \dot{z}_m)z_n}{z_n - z_m}, \tag{A5l}$$

$$z\psi_{zt} - (N-1)\psi_t \Leftrightarrow -\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n z_m + \dot{z}_m z_n}{z_n - z_m}, \tag{A5m}$$

$$z^2\psi_{zt} + [c_1 - (N-2)z]\psi_t - \dot{c}_1\psi \Leftrightarrow -\sum_{m=1,m\neq n}^{N} \frac{\dot{z}_n z_m^2 + \dot{z}_m z_n^2}{z_n - z_m}, \tag{A5n}$$

$$\psi_{tt} \Leftrightarrow = -\ddot{z}_n(t) + \sum_{m=1,m\neq n}^{N} \frac{2\dot{z}_n \dot{z}_m}{z_n - z_m}. \tag{A5o}$$

To obtain those of the formulas written above which are not just streamlined versions of equations already reported in Appendix B of Ref. 1, we used the relations

$$\frac{c_{N-1}}{c_N} = -\sum_{n=1}^{N} \frac{1}{z_n}, \quad \frac{\dot{c}_N}{c_N} = \sum_{n=1}^{N} \frac{\dot{z}_n}{z_n}, \tag{A6}$$

which are obvious consequences of the formulas

$$c_N(t) = \prod_{n=1}^{N} [-z_n(t)] = \psi(0,t), \quad c_{N-1}(t) = \sum_{n=1}^{N} \prod_{m=1,m\neq n}^{N} [-z_m(t)] = \psi_z(0,t), \tag{A7}$$

themselves direct consequences of (A1).

Likewise, we introduce the following notation whereby in the formulas written in the following (which are also straightforward consequences of (A1)) the expression on the right-hand side identifies the coefficient of z^{N-m} in the polynomial (of degree N or less) appearing on the left-hand side:

$$\psi \leftrightarrow c_m, \tag{A8a}$$

$$\frac{\psi - c_N}{z} \leftrightarrow c_{m-1}, \tag{A8b}$$

$$\psi_z \leftrightarrow (N-m+1)c_{m-1}, \tag{A8c}$$

$$z\psi_z \leftrightarrow (N-m)c_m, \tag{A8d}$$

$$\frac{\psi_z - c_{N-1}}{z} \leftrightarrow (N-m+2)c_{m-2}, \tag{A8e}$$

$$\psi_{zz} \leftrightarrow (N-m+2)(N-m+1)c_{m-2}, \tag{A8f}$$

$$z\psi_{zz} \leftrightarrow (N-m+1)(N-m)c_{m-1}, \tag{A8g}$$

$$z^2\psi_{zz} \leftrightarrow (N-m)(N-m-1)c_m, \tag{A8h}$$

$$\psi_t \leftrightarrow \dot{c}_m, \tag{A8i}$$

$$z\psi_t \leftrightarrow \dot{c}_{m+1}, \tag{A8j}$$

$$\frac{\psi_t - \dot{c}_N}{z} \leftrightarrow \dot{c}_{m-1}, \tag{A8k}$$

$$\psi_{zt} \leftrightarrow (N-m+1)\dot{c}_{m-1}, \tag{A8l}$$

$$z\psi_{zt} \leftrightarrow (N-m)\dot{c}_m, \tag{A8m}$$

$$\psi_{tt} \leftrightarrow \ddot{c}_m, \tag{A8n}$$

$$N\psi - z\psi_z \leftrightarrow mc_m, \tag{A8o}$$

$$N^2\psi - (2N-1)z\psi_z + z^2\psi_{zz} \leftrightarrow m^2c_m, \tag{A8p}$$

$$(N+1)\frac{\psi - c_N}{z} - \psi_z \leftrightarrow mc_{m-1}, \tag{A8q}$$

$$(N+1)^2\frac{\psi - c_N}{z} - (2N+1)\psi_z + z\psi_{zz} \leftrightarrow m^2c_{m-1}, \tag{A8r}$$

$$\frac{\psi - c_N - c_{N-1}z}{z^2} \leftrightarrow c_{m-2}, \tag{A8s}$$

$$\frac{(N+2)\psi - z\psi_z - (N+2)c_N - (N+1)zc_{N-1}}{z^2} \leftrightarrow mc_{m-2}, \tag{A8t}$$

$$\frac{(N+2)^2(\psi - c_N) - z[(2N+3)\psi_z + (N+1)^2 c_{N-1}] + z^2\psi_{zz}}{z^2} \leftrightarrow m^2 c_{m-2}, \tag{A8u}$$

$$(N+1)\frac{\psi_t - \dot{c}_N}{z} - \psi_{zt} \leftrightarrow m\dot{c}_{m-1}. \tag{A8v}$$

(Received 5 June 2006; accepted 30 August 2006; published online 17 October 2006)

We derive dispersionless Hirota equations of the extended dispersionless BKP(EdBKP) hierarchy proposed by Takasaki from the method of kernel formula provided by Carroll and Kodama. Moreover, we verify associativity equations (WDVV equations) in the EdBKP hierarchy from dispersionless Hirota equations and give a realization of associative algebra with structure constants expressed in terms of the residue formula. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2358002]

I. INTRODUCTION

Dispersionless integrable systems (DIS) are integrable hierarchies in dispersionless limit (or quasiclassical limit). Among them the dispersionless Kadomtsev-Petviashvili (dKP) and dispersionless Toda (dToda) hierarchies are special since they have been recognized as universal DIS in several fields of theoretical physics and mathematics (see, e.g., Refs. 1, 4, 9, 11, 13–15, 18, 19, 27, and 29 and references therein). The solutions of the dKP and dToda hierarchies can be characterized by a single function called τ functions, the logarithm of them; namely, $\mathcal{F}=\log\tau$ describe free energy of some two-dimensional topological field theories in genus zero and satisfy the Witten-Dijkgraaf-Verlinde-Verlinde (WDVV) equations.[10,11,32] In particular, the finite-dimensional reductions of dKP and dToda systems are realized as special solutions of topological Landau-Ginzburg models of A-type and topological CP^1 models, respectively.[1,10,12,18] In terms of free energy $\mathcal{F}$, the hierarchy flows of dKP and dToda can be written as a set of second derivatives of $\mathcal{F}$ called dispersionless Hirota (dHirota) equations. There are a lot of works devoted to derive dHirota equations. In Ref. 29, Takasaki and Takebe derived dHirota equations of the dKP hierarchy from dispersionless limit of differential Fay identity. Carroll and Kodama[5] studied the same dHirota equation from the method of kernel formula. On the other hand, Wiegmann, Zabrodin *et al.*[17,31] investigated dHirota equations of the dToda hierarchy in the context of conformal mapping. More recently, Teo[30] derived dHirota equations of the dKP and dToda hierarchies from complex analysis using the notions of Grunsky coefficients and Faber polynomials.

Our main purpose in this work is to demonstrate the applicability of the kernel formula to other dispersionless integrable hierarchies. In particular, we would like to derive dHirota equations of a universal integrable hierarchy underlying topological Landau-Ginzburg models of a D-type proposed by Takasaki.[24] Since this integrable hierarchy is an extension of the dispersionless BKP (dBKP) hierarchy[2,8,16,23] with two sets of time variables, we refer it to the extended dispersionless BKP (EdBKP) hierarchy.[6] The EdBKP hierarchy resembles the dToda hierarchy in many formulations such as dressing operators, Orlov functions, the Riemann-Hilbert problem, additional symmetries, w algebras, hodograph solutions, etc.[6,24] Motivated by the work for dKP,[5] we shall show that the method of a kernel formula can be applied to the EdBKP hierarchy without difficulty. As a byproduct, associativity equations (WDVV equations) in the EdBKP hierarchy can be verified

[a)]E-mail: phymhtu@ccu.edu.tw

directly from dHirota equations. Therefore our results indeed provide another point of view to understand the integrability of the dBKP hierarchy in connection with topological field theories.

Let us briefly recall the method of the kernel formula[5] for the derivation of dHirota equations of the dKP hierarchy. The dKP hierarchy is defined by the Lax equations,

$$\partial_{t_n}\lambda = \{\mathcal{B}_n, \lambda\}, \quad \mathcal{B}_n = (\lambda^n)_{\geq 0}, \quad n = 1,2, \ldots,$$

where the Lax operator λ is a Laurent series of the form

$$\lambda = p + \sum_{n=1}^{\infty} u_{n+1} p^{-n},$$

where u_j are functions of the time variables $t=(x=t_1,t_2,\ldots)$, $(A(p))_{\geq 0}$ denotes the projection on the polynomial part of $A(p)$, and $\{A,B\}$ stands for the Poisson bracket,

$$\{A,B\} = \frac{\partial A}{\partial p}\frac{\partial B}{\partial x} - \frac{\partial A}{\partial x}\frac{\partial B}{\partial p}.$$

It can be shown[27,29] that there exists a function $\mathcal{F}(t)$ called free energy such that

$$\mathcal{B}_n(\lambda) = \lambda^n - \sum_{m=1}^{\infty} \frac{\mathcal{F}_{n,m}}{m}\lambda^{-m},$$

where $\mathcal{F}_{n,m}=\partial_{t_n}\partial_{t_m}\mathcal{F}$ and thus $\mathcal{F}_{n,m}=\mathcal{F}_{m,n}$. Particularly, for $\mathcal{B}_1=p$ we have

$$p(\lambda) = \lambda - \sum_{m=1}^{\infty} \frac{\mathcal{F}_{1,m}}{m}\lambda^{-m}, \tag{1}$$

which can be viewed as the inverse map of $\lambda(p)$. Multiplying $\lambda^{n-1}\partial_p\lambda$ with $n\geq 1$ to (1) and taking the projection $()_{\geq 0}$, we obtain

$$\partial_p Q_{n+1}(\lambda) - p(\lambda)\partial_p Q_n(\lambda) - \sum_{m=1}^{n-1} \frac{\mathcal{F}_{1,m}}{m}\partial_p Q_{n-m}(\lambda), \quad n \geq 1,$$

where $Q_n=\mathcal{B}_n/n$. Multiplying μ^{-n} and summing over $n\geq 0$, we have

$$1 = \left(\mu - p(\lambda) - \sum_{m=1} \frac{\mathcal{F}_{1,m}}{m}\mu^{-m}\right)\sum_{j=1} \partial_p Q_j(\lambda)\mu^{-j},$$

$$= (p(\mu) - p(\lambda))\sum_{j=1} \partial_p Q_j(\lambda)\mu^{-j},$$

or

$$\frac{1}{p(\mu)-p(\lambda)} = \sum_{j=1}^{\infty} \partial_p Q_j(\lambda)\mu^{-j},$$

which is the kernel formula for the generating function of $\partial_p Q_j(\lambda)$. Integrating above with respect to $p(\lambda)$ and fixing the normalization at $\mu=\infty$, then

$$\frac{\mu}{p(\mu)-p(\lambda)} = e^{\sum_{j=1}^{\infty} Q_j(\lambda)\mu^{-j}},$$

which together with the expressions of the second derivatives of $\mathcal{F}$ for $\mathcal{B}_j(\lambda)$ and $p(\lambda)$ yields dHirota equations of the dKP hierarchy:[5,29]

$$D(\mu)\partial_{t_1}\mathcal{F} - D(\lambda)\partial_{t_1}\mathcal{F} = (\mu-\lambda)(1-e^{D(\mu)D(\lambda)\mathcal{F}}), \tag{2}$$

where $D(z)=\Sigma_{m=1}^{\infty} z^{-m}\partial_{t_m}/m$. A convenient way to obtain a set of relations defined by $\mathcal{F}_{m,n}$ is to consider (2) under the limit $\mu\to\lambda$. Then one gets

$$\partial_\lambda D(\lambda)\partial_{t_1}\mathcal{F} = 1 - e^{D(\lambda)D(\lambda)\mathcal{F}}.$$

By comparing the coefficients of λ^{-n} on both sides, one obtains[5]

$$\mathcal{F}_{1j} = P_{j+1}(Z_1=0, Z_2, \ldots, Z_{j+1}), \quad j\geq 1,$$

where P_j are elementary Schur polynomials and $Z_j=\Sigma_{n+m=j}(\mathcal{F}_{nm}/nm)$. A few equations from such an expansion have been given in Ref. 5. Here we just mention the simplest nontrivial equation,

$$\frac{1}{2}\mathcal{F}_{11}^2 - \frac{1}{3}\mathcal{F}_{13} + \frac{1}{4}\mathcal{F}_{22} = 0,$$

which, after noticing $u=u_2=\mathcal{F}_{11}$ and setting $t_2=y$, $t_3=t$, is just the (2+1)-dimensional dKP equation,[14]

$$u_t = 3uu_x + \frac{3}{4}\partial_x^{-1}u_{yy}.$$

Therefore, the kernel formula provides an elementary and convenient way to derive dHirota equations of dKP from the Lax formulation without referring to its dispersive counterparts, such as the (differential) Fay identity. For the dToda hierarchy,[26,28,29] its associated dHirota equations (see, e.g., Refs. 17, 30, 31, and 33) can also be derived from the method of kernel formula. We omit the derivation here and refer to our preprint[7] for details. The rest of the paper is organized as follows. In Sec. II we turn to the EdBKP hierarchy to investigate its dHirota equations. In Sec. III we verify associativity equations (or WDVV equations) in the EdBKP hierarchy from dHirota equations. The realization of associative algebra and the residue formula for structure constants of the associative algebra are also given. Section IV is devoted to the concluding remarks.

II. EXTENDED DISPERSIONLESS BKP HIERARCHY

A. Lax formalism

Having illustrated the derivation of dHirota equations of the dKP hierarchy, now we like to apply the method of kernel formula to the EdBKP hierarchy, which is the integrable hierarchy underlying topological Landau-Ginzburg models of a D type proposed by Takasaki[24] (see also Ref. 6). The EdBKP hierarchy is described by

$$\begin{gathered}\partial_{t_{2n+1}}\lambda = \{\mathcal{B}_{2n+1},\lambda\}, \quad \partial_{\bar{t}_{2n+1}}\lambda = \{\bar{\mathcal{B}}_{2n+1},\lambda\},\\ \partial_{t_{2n+1}}\bar{\lambda} = \{\mathcal{B}_{2n+1},\bar{\lambda}\}, \quad \partial_{\bar{t}_{2n+1}}\bar{\lambda} = \{\bar{\mathcal{B}}_{2n+1},\bar{\lambda}\}, \quad n=0,1,2,\ldots,\end{gathered} \tag{3}$$

with

$$\lambda = p + \sum_{n=1}^{\infty} u_{2n}p^{-2n+1}, \quad \bar{\lambda} = \sum_{n=0}^{\infty}\bar{u}_{2n}p^{2n+1}, \quad \bar{u}_0 \neq 0$$

and

$$\mathcal{B}_{2n+1} = (\lambda^{2n+1})_{\geq 0}, \quad \bar{\mathcal{B}}_{2n+1} = (\bar{\lambda}^{-2n-1})_{\leq -1},$$

where the coefficient functions u_{2n} and $\bar{u}_{2n}$ depend on the time variables $t=(t_1=x,t_3,\ldots)$ and $\bar{t}=(\bar{t}_1,\bar{t}_3,\ldots)$, the Poisson bracket $\{,\}$ here is defined as before and $(A)_{\leq -1}=A-(A)_{\geq 0}$. One can view

λ as a map defined in domain D_∞ containing $p=\infty$, while $\overline{\lambda}$ in D_0 containing $p=0$. Noting that $\lambda(-p)=-\lambda(p)$ and $\overline{\lambda}(-p)=-\overline{\lambda}(p)$ and thus $(\mathcal{B}_{2n+1})_{[0]}=(\overline{\mathcal{B}}_{2n+1})_{[0]}=0$.

The Lax equations (3) are equivalent to the zero curvature equations,

$$\partial_{t_{2n+1}}\mathcal{B}_{2m+1}-\partial_{t_{2m+1}}\mathcal{B}_{2n+1}+\{\mathcal{B}_{2m+1},\mathcal{B}_{2n+1}\}=0,$$

$$\partial_{\overline{t}_{2n+1}}\overline{\mathcal{B}}_{2m+1}-\partial_{\overline{t}_{2m+1}}\overline{\mathcal{B}}_{2n+1}+\{\overline{\mathcal{B}}_{2m+1},\overline{\mathcal{B}}_{2n+1}\}=0,$$

$$\partial_{\overline{t}_{2n+1}}\mathcal{B}_{2m+1}-\partial_{t_{2m+1}}\overline{\mathcal{B}}_{2n+1}+\{\mathcal{B}_{2m+1},\overline{\mathcal{B}}_{2n+1}\}=0,$$

which guarantees that the Lax equations (3) commute between themselves. Since the first member involving t_{2n+1} flows only is just the dBKP hierarchy and that is the reason why we call this integrable hierarchy the EdBKP hierarchy. It can be shown[24] that there exists a single function $\mathcal{F}(t,\overline{t})$ (free energy) from which one can define the functions

$$S(\lambda)=\sum_{n=0}^{\infty}t_{2n+1}\lambda^{2n+1}-\sum_{n=0}^{\infty}\frac{1}{2n+1}\partial_{t_{2n+1}}\mathcal{F}\lambda^{-2n-1},$$

$$\overline{S}(\overline{\lambda})=\sum_{n=0}^{\infty}\overline{t}_{2n+1}\overline{\lambda}^{-2n-1}-\sum_{n=0}^{\infty}\frac{1}{2n+1}\partial_{\overline{t}_{2n+1}}\mathcal{F}\overline{\lambda}^{2n+1},$$

such that

$$\mathcal{B}_{2n+1}(\lambda)=\partial_{t_{2n+1}}S\Big|_{\lambda\ \text{fixed}}=\lambda^{2n+1}-\sum_{m=0}^{\infty}\frac{1}{2m+1}\mathcal{F}_{2n+1,2m+1}\lambda^{-2m-1},\tag{4}$$

$$\mathcal{B}_{2n+1}(\overline{\lambda})=\partial_{t_{2n+1}}\overline{S}\Big|_{\overline{\lambda}\ \text{fixed}}=-\sum_{m=0}^{\infty}\frac{1}{2m+1}\mathcal{F}_{2n+1,\overline{2m+1}}\overline{\lambda}^{2m+1},\tag{5}$$

$$\overline{\mathcal{B}}_{2n+1}(\lambda)=\partial_{\overline{t}_{2n+1}}S\Big|_{\lambda\ \text{fixed}}=-\sum_{m=0}^{\infty}\frac{1}{2m+1}\mathcal{F}_{\overline{2n+1},2m+1}\lambda^{-2m-1},\tag{6}$$

$$\overline{\mathcal{B}}_{2n+1}(\overline{\lambda})=\partial_{\overline{t}_{2n+1}}\overline{S}\Big|_{\overline{\lambda}\ \text{fixed}}=\overline{\lambda}^{-2n-1}-\sum_{m=0}^{\infty}\frac{1}{2m+1}\mathcal{F}_{\overline{2n+1},\overline{2m+1}}\overline{\lambda}^{2m+1},\tag{7}$$

where $\mathcal{F}_{n,\overline{m}}=\partial_{t_n}\partial_{\overline{t}_m}\mathcal{F}$ and $\mathcal{F}_{\overline{n},\overline{m}}=\partial_{\overline{t}_n}\partial_{\overline{t}_m}\mathcal{F}$. Noticing that (4) and (6) are defined in D_∞, while (5) and (7) are in D_0. From (4)–(7), we have, for $n=0$,

$$p(\lambda)=\partial_{t_1}S(\lambda)=\lambda-\sum_{m=1}^{\infty}f_{2m}\lambda^{-2m+1},\quad f_{2m}=\frac{1}{2m-1}\mathcal{F}_{1,2m-1},\tag{8}$$

$$p(\overline{\lambda})=\partial_{t_1}\overline{S}(\overline{\lambda})=\sum_{m=0}^{\infty}\overline{f}_{2m}\overline{\lambda}^{2m+1},\quad \overline{f}_{2m}=-\frac{1}{2m+1}\mathcal{F}_{1,\overline{2m+1}},\tag{9}$$

$$\overline{u}_0^{-1}p^{-1}(\lambda)=\partial_{\overline{t}_1}S(\lambda)=\sum_{m=0}^{\infty}g_{2m}\lambda^{-2m-1},\quad g_{2m}=-\frac{1}{2m+1}\mathcal{F}_{\overline{1},2m+1},\tag{10}$$

$$\overline{u_0}^{-1}p^{-1}(\overline{\lambda}) = \partial_{\overline{t}_1}\overline{S}(\overline{\lambda}) = \overline{\lambda}^{-1} - \sum_{m=1}^{\infty} \overline{g}_{2m}\overline{\lambda}^{2m-1}, \quad \overline{g}_{2m} = \frac{1}{2m-1}\mathcal{F}_{\overline{1},\overline{2m-1}}, \tag{11}$$

where we use the notations $\partial_{t_1}S(\lambda) \equiv \partial_{t_1}S|_{\lambda \text{ fixed}}$, etc. for brevity. Therefore the dynamical variables u_{2j} and $\overline{u}_{2j}$ of the system are characterized by the second derivatives of the free energy $\mathcal{F}$. In particular, from (8) and (9), we have $u_2 = \mathcal{F}_{11}$ and $\overline{u}_0^{-1} = -\mathcal{F}_{1,\overline{1}}$, respectively. Note that $p(\overline{\lambda})$ is the inverse map of $\overline{\lambda}(p)$ and cannot be viewed as the same function as $p(\lambda)$ with λ replaced by $\overline{\lambda}$.

B. Kernel formulas

In contrast to the dKP hierarchy, where only one Lax operator is defined in D_∞, the EdBKP hierarchy contains two Lax operators, λ and $\overline{\lambda}$, that are defined in domains D_∞ and D_0, respectively. To derive dHirota equations for the EdBKP hierarchy, we shall generalize the method of kernel formula to the domains D_∞, D_0, and $D_\infty \cap D_0$.

In D_∞ multiplying (8) by $\lambda^{2n-1}\,\partial_p\lambda$ for $n \geq 1$, we have

$$\lambda^{2n}\,\partial_p\lambda = p\lambda^{2n-1}\,\partial_p\lambda + \sum_{j=1}^{\infty} f_{2j}\lambda^{2n-2j}\,\partial_p\lambda,$$

which, after taking the polynomial part, leads to the recurrence relation

$$\partial_p Q_{2n+1}(\lambda) = p(\lambda)\partial_p Q_{2n}(\lambda) + \sum_{j=1}^{n} f_{2j}\,\partial_p Q_{2n-2j+1}(\lambda), \tag{12}$$

where $Q_{2n+1} \equiv \mathcal{B}_{2n+1}/(2n+1)$ and $Q_{2n} \equiv (\lambda^{2n})_{\geq 0}/(2n)$. Multiplying (12) by μ^{-2n} $(n \geq 0)$ and summing over n we obtain

$$p(\mu)\sum_{n=0}^{\infty} \partial_p Q_{2n+1}(\lambda)\mu^{-2n-1} - p(\lambda)\sum_{n=0}^{\infty} \partial_p Q_{2n+2}(\lambda)\mu^{-2n-2} = 1. \tag{13}$$

On the other hand, multiplying both sides on (8) by $\lambda^{2n}\,\partial_p\lambda$ for $n \geq 1$, it follows that

$$\lambda^{2n+1}\,\partial_p\lambda = p\lambda^{2n}\,\partial_p\lambda + \sum_{j=1}^{\infty} f_{2j}\lambda^{2n-2j+1}\,\partial_p\lambda.$$

After taking the polynomial part we get another recurrence relation

$$\partial_p Q_{2n+2}(\lambda) = p(\lambda)\partial_p Q_{2n+1}(\lambda) + \sum_{j=1}^{n} f_{2j}\,\partial_p Q_{2n-2j+2}(\lambda). \tag{14}$$

Multiplying (14) by μ^{-2n-1} $(n \geq 0)$ and summing over n, we obtain

$$p(\mu)\sum_{n=0}^{\infty} \partial_p Q_{2n+2}(\lambda)\mu^{-2n-2} = p(\lambda)\sum_{n=0}^{\infty} \partial_p Q_{2n+1}(\lambda)\mu^{-2n-1}. \tag{15}$$

Plugging (15) into (13) to eliminate $\Sigma_{n=0}^{\infty}\partial_p Q_{2n+2}(\lambda)\mu^{-2n-2}$, we obtain the generating function of $\partial_p Q_{2n+1}(\lambda)$ as

$$\frac{p(\mu)}{p^2(\mu) - p^2(\lambda)} = \sum_{n=0}^{\infty} \partial_p Q_{2n+1}(\lambda)\mu^{-2n-1}. \tag{16}$$

Now we integrate the kernel (16) with respect to $p(\lambda)$, and normalize at $\mu = \infty$ to obtain

$$\frac{p(\mu)-p(\lambda)}{p(\mu)+p(\lambda)}=\exp\left(-2\sum_{n=0}^{\infty}Q_{2n+1}(\lambda)\mu^{-2n-1}\right). \tag{17}$$

If we denote $D(z)$ the differential operator,

$$D(z)=\sum_{n=0}^{\infty}\frac{z^{-2n-1}}{2n+1}\partial_{t_{2n+1}},$$

then (17) can be rewritten as

$$\frac{p(\mu)-p(\lambda)}{p(\mu)+p(\lambda)}=\exp(-2D(\mu)S(\lambda))=\frac{\mu-\lambda}{\mu+\lambda}e^{2D(\lambda)D(\mu)\mathcal{F}}, \tag{18}$$

which is the same result derived by Bogdanov and Konopelchenko,[2] where they obtained dHirota equations of the dBKP hierarchy from that of the dKP hierarchy by taking into account the symmetry condition $S(-\lambda)=-S(\lambda)$.

In D_0 to obtain the generating function of $\partial_p\overline{Q}_{2n+1}(\overline{\lambda})$ we multiplying (11) by $\overline{\lambda}^{-2n-1}\,\partial_p\overline{\lambda}$ for $n\geq 1$; then

$$\overline{\lambda}^{-2n-2}\,\partial_p\overline{\lambda}=\overline{u}_0^{-1}p^{-1}(\overline{\lambda})\overline{\lambda}^{-2n-1}\,\partial_p\overline{\lambda}+\sum_{j=1}^{\infty}\overline{g}_{2j}\overline{\lambda}^{-2n+2j-2}\,\partial_p\overline{\lambda}.$$

Taking the negative part leads to the recurrence relation

$$\partial_p\overline{Q}_{2n+1}(\overline{\lambda})=\overline{u}_0^{-1}p^{-1}(\overline{\lambda})\partial_p\overline{Q}_{2n}(\overline{\lambda})+\sum_{j=1}^{n}\overline{g}_{2j}\partial_p\overline{Q}_{2n-2j+1}(\overline{\lambda}), \tag{19}$$

where $\overline{Q}_{2n+1}\equiv\overline{\mathcal{B}}_{2n+1}/(2n+1)$ and $\overline{Q}_{2n}\equiv(\overline{\lambda}^{-2n})_{\leq -1}/(2n)$. Multiplying (19) by $\overline{\mu}^{2n}$ $(n\geq 0)$ and summing over n, we obtain

$$p^{-1}(\overline{\mu})\sum_{n=0}^{\infty}\partial_p\overline{Q}_{2n+1}(\overline{\lambda})\overline{\mu}^{2n+1}-p^{-1}(\overline{\lambda})\sum_{n=1}^{\infty}\partial_p\overline{Q}_{2n}(\overline{\lambda})\overline{\mu}^{2n}=-p^{-2}(\overline{\lambda}). \tag{20}$$

On the other hand, multiplying (11) by $\overline{\lambda}^{-2n}\partial_p\overline{\lambda}$ for $n\geq 1$, it follows that

$$\overline{\lambda}^{-2n-1}\,\partial_p\overline{\lambda}=\overline{u}_0^{-1}p^{-1}(\overline{\lambda})\overline{\lambda}^{-2n}\,\partial_p\overline{\lambda}+\sum_{j=1}^{\infty}\overline{g}_{2j}\overline{\lambda}^{-2n+2j-1}\,\partial_p\overline{\lambda}.$$

After taking the negative part, we get another recurrence relation,

$$\partial_p\overline{Q}_{2n}(\overline{\lambda})=\overline{u}_0^{-1}p^{-1}(\overline{\lambda})\partial_p\overline{Q}_{2n-1}(\overline{\lambda})+\sum_{j=1}^{n-1}\overline{g}_{2j}\,\partial_p\overline{Q}_{2n-2j}(\overline{\lambda}). \tag{21}$$

Multiplying (21) by $\overline{\mu}^{2n-1}$ $(n\geq 1)$ and summing over n, we obtain

$$p^{-1}(\overline{\mu})\sum_{n=1}^{\infty}\partial_p\overline{Q}_{2n}(\overline{\lambda})\overline{\mu}^{2n}=p^{-1}(\overline{\lambda})\sum_{n=0}^{\infty}\partial_p\overline{Q}_{2n+1}(\overline{\lambda})\overline{\mu}^{2n+1}. \tag{22}$$

Plugging (22) into (20) to eliminate $\Sigma_{n=1}\,\partial_p\overline{Q}_{2n}(\overline{\lambda})\overline{\mu}^{2n}$, which yields the generating function of $\partial_p\overline{Q}_{2n+1}(\overline{\lambda})$ as

$$\frac{p(\bar{\mu})}{p^2(\bar{\mu})-p^2(\bar{\lambda})}=\sum_{n=0}^{\infty}\partial_p\bar{Q}_{2n+1}(\bar{\lambda})\bar{\mu}^{2n+1}. \tag{23}$$

Now we integrate the kernel (23) with respect to $p(\bar{\lambda})$, and normalize at $\bar{\mu}=0$ to obtain

$$\frac{p(\bar{\lambda})-p(\bar{\mu})}{p(\bar{\lambda})+p(\bar{\mu})}=\exp\left(-2\sum_{n=0}^{\infty}\bar{Q}_{2n+1}(\bar{\lambda})\bar{\mu}^{2n+1}\right), \tag{24}$$

which can be expressed as

$$\frac{p(\bar{\lambda})-p(\bar{\mu})}{p(\bar{\lambda})+p(\bar{\mu})}=\frac{\bar{\lambda}-\bar{\mu}}{\bar{\lambda}+\bar{\mu}}e^{2\bar{D}(\bar{\lambda}^{-1})\bar{D}(\bar{\mu}^{-1})\mathcal{F}}, \tag{25}$$

where

$$\bar{D}(z)=\sum_{n=0}^{\infty}\frac{z^{-2n-1}}{2n+1}\partial_{\bar{t}_{2n+1}}.$$

In $D_\infty\cap D_0$ in view of (4) and (5), the functional $Q_{2n+1}(\lambda)$ and $p(\lambda)$ can be replaced by $\partial_{t_{2n+1}}\bar{S}(\bar{\lambda})/(2n+1)$ and $\partial_{t_1}\bar{S}(\bar{\lambda})$, respectively. Then (17) becomes

$$\frac{p(\mu)-\partial_{t_1}\bar{S}(\bar{\lambda})}{p(\mu)+\partial_{t_1}\bar{S}(\bar{\lambda})}=e^{2D(\mu)\bar{D}(\bar{\lambda}^{-1})\mathcal{F}}. \tag{26}$$

Similarly, in view of (6) and (7), the functional $\bar{Q}_{2n+1}(\bar{\lambda})$ and $\bar{u}_0^{-1}p^{-1}(\bar{\lambda})$ can be replaced by $\partial_{\bar{t}_{2n+1}}S(\lambda)/(2n+1)$ and $\partial_{\bar{t}_1}S(\lambda)$, respectively. Then (24) becomes

$$\frac{\bar{u}_0^{-1}p^{-1}(\bar{\mu})-\partial_{\bar{t}_1}S(\lambda)}{\bar{u}_0^{-1}p^{-1}(\bar{\mu})+\partial_{\bar{t}_1}S(\lambda)}=e^{2D(\lambda)\bar{D}(\bar{\mu}^{-1})\mathcal{F}}. \tag{27}$$

Note that, after making the replacements $\lambda\to\mu$ and $\bar{\mu}\to\bar{\lambda}$, the right-hand side of (27) coincides with that of (26). Hence,

$$p(\mu)\partial_{\bar{t}_1}S(\mu)=\bar{u}_0^{-1}p^{-1}(\bar{\lambda})\partial_{t_1}\bar{S}(\bar{\lambda})=\bar{u}_0^{-1}, \tag{28}$$

where the last equality is determined by setting $\mu\to\infty$ and $\bar{\lambda}\to 0$:

$$\lim_{\mu\to\infty}p(\mu)\partial_{\bar{t}_1}S(\mu)=\lim_{\bar{\lambda}\to 0}\bar{u}_0^{-1}p^{-1}(\bar{\lambda})\partial_{t_1}\bar{S}(\bar{\lambda})=-\bar{\mathcal{F}}_{11}=\bar{u}_0^{-1}.$$

Equation (28) contains the definitions (9) and (10) and can be regarded as an extra condition, besides the dHirota equations (18), (25), and (26).

In summary, the EdBKP hierarchy can be characterized by a single function $\mathcal{F}$ satisfying (18) and (25)–(27) [or (18), (25), (26), and (28)].

C. Dispersionless Hirota equations

Let us rewrite (18) and (25)–(27) as a set of equations satisfied by the second derivatives of $\mathcal{F}$.

(1) We first rewrite the equation (18) in the form

$$\log\left(\frac{p(\lambda)-p(\mu)}{\lambda-\mu}\frac{\lambda+\mu}{p(\lambda)+p(\mu)}\right)=2D(\lambda)D(\mu)\mathcal{F},$$

where $p(\lambda)$ is defined by (8), and for $\lambda\to\mu$ we have

$$\log(\mu\partial_\mu \log p(\mu))=2D^2(\mu)\mathcal{F},$$

$$=\sum_{j=1}^{\infty}\left(\sum_{\substack{m+n=j-1\\ m,n\geq 0}}\frac{2\mathcal{F}_{2m+1,2n+1}}{(2m+1)(2n+1)}\right)\mu^{-2j}.$$

Then, using the elementary Schur polynomials and (8), we obtain

$$\frac{1+\Sigma_{m=0}^{\infty}\mathcal{F}_{1,2m+1}\mu^{-2m-2}}{1-\Sigma_{m=0}^{\infty}\frac{1}{2m+1}\mathcal{F}_{1,2m+1}\mu^{-2m-2}}=\sum_{k=0}^{\infty}P_k(\theta_1,\theta_2,\ldots,\theta_k)\mu^{-2k},$$

where θ_i, $i\geq 1$ are defined by

$$\theta_i=\sum_{\substack{m+n=i-1\\ m,n\geq 0}}\frac{2\mathcal{F}_{2m+1,2n+1}}{(2m+1)(2n+1)}.$$

By comparing the coefficients of μ^{-2k} on both sides, we obtain a set of relations satisfied by $\mathcal{F}_{2i+1,2j+1}$:

$$\frac{2m+2}{2m+1}\mathcal{F}_{1,2m+1}-P_{m+1}(\theta)+\sum_{\substack{j+k=m-1\\ j,k\geq 0}}\frac{1}{2j+1}\mathcal{F}_{1,2j+1}P_{k+1}(\theta)=0. \tag{29}$$

(2) Similarly, we consider (25) by taking the limit $\bar{\lambda}\to\bar{\mu}$. Then

$$\log(\bar{\mu}\partial_{\bar{\mu}}\log p(\bar{\mu}))=2D^2(\bar{\mu})\mathcal{F},$$

$$=\sum_{j=1}^{\infty}\left(\sum_{\substack{m+n=j-1\\ m,n\geq 0}}\frac{2\mathcal{F}_{\overline{2m+1},\overline{2n+1}}}{(2m+1)(2n+1)}\right)\bar{\mu}^{2j}.$$

Also, using the elementary Schur polynomials and (11), we obtain

$$\frac{1+\Sigma_{m=0}^{\infty}\mathcal{F}_{\overline{1,2m+1}}\bar{\mu}^{2m+2}}{1-\Sigma_{m=0}^{\infty}\frac{1}{2m+1}\mathcal{F}_{\overline{1,2m+1}}\bar{\mu}^{2m+2}}=\sum_{k=0}^{\infty}P_k(\bar{\theta}_1,\bar{\theta}_2,\ldots,\bar{\theta}_k)\bar{\mu}^{2k},$$

where $\bar{\theta}_i$, $i\geq 1$ are defined by

$$\bar{\theta}_i=\sum_{\substack{m+n=i-1\\ m,n\geq 0}}\frac{2\mathcal{F}_{\overline{2m+1},\overline{2n+1}}}{(2m+1)(2n+1)}.$$

By comparing the coefficients of $\bar{\mu}^{2k}$ on both sides, we obtain a set of relations satisfied by $\mathcal{F}_{\overline{2i+1},\overline{2j+1}}$:

$$\frac{2m+2}{2m+1}\mathcal{F}_{\overline{1,2m+1}}-P_{m+1}(\bar{\theta})+\sum_{\substack{j+k=m-1\\ j,k\geq 0}}\frac{1}{2j+1}\mathcal{F}_{\overline{1,2j+1}}P_{k+1}(\bar{\theta})=0. \tag{30}$$

(3) From (26), by taking $\overline{\lambda}\to 1/\mu$ and using (8) and (9), it is straightforward to obtain

$$\frac{1-\Sigma_{m=0}^{\infty}\frac{1}{2m+1}(\mathcal{F}_{1,2m+1}-\mathcal{F}_{1,\overline{2m+1}})\mu^{-2m-2}}{1-\Sigma_{m=0}^{\infty}\frac{1}{2m+1}(\mathcal{F}_{1,2m+1}+\mathcal{F}_{1,\overline{2m+1}})\mu^{-2m-2}}=\sum_{k=0}^{\infty}P_k(\tilde{\theta}_1,\tilde{\theta}_2,\ldots,\tilde{\theta}_k)\mu^{-2k},$$

where $P_k(\tilde{\theta})$ are elementary Schur polynomials and $\tilde{\theta}_i$, $i\geq 1$ are defined by

$$\tilde{\theta}_i=\sum_{\substack{m+n=i-1\\ m,n\geq 0}}\frac{2\mathcal{F}_{2n+1,\overline{2m+1}}}{(2m+1)(2n+1)}.$$

By comparing the coefficients of μ^{-2k} on both sides, we obtain a set of relations satisfied by $\mathcal{F}_{2i+1,\overline{2j+1}}$:

$$\frac{2}{2m+1}\mathcal{F}_{1,\overline{2m+1}}-P_{m+1}(\tilde{\theta})+\sum_{\substack{j+k=m-1\\ j,k\geq 0}}\frac{1}{2j+1}(\mathcal{F}_{1,2j+1}+\mathcal{F}_{1,\overline{2j+1}})P_{k+1}(\tilde{\theta})=0. \tag{31}$$

(4) From (27), it is straightforward to taking $\overline{\mu}\to 1/\lambda$ and by (11) and (10) we have

$$\frac{1-\Sigma_{m=0}^{\infty}\frac{1}{2m+1}(\mathcal{F}_{\overline{1,2m+1}}-\mathcal{F}_{\overline{1,2m+1}})\lambda^{-2m-2}}{1-\Sigma_{m=0}^{\infty}\frac{1}{2m+1}(\mathcal{F}_{\overline{1,2m+1}}+\mathcal{F}_{\overline{1,2m+1}})\lambda^{-2m-2}}=\sum_{k=0}^{\infty}P_k(\tilde{\theta}_1,\tilde{\theta}_2,\ldots,\tilde{\theta}_k)\lambda^{-2k},$$

where $P_k(\tilde{\theta})$ is defined as before and the above equation can be simplified as

$$\frac{2}{2m+1}\mathcal{F}_{\overline{1,2m+1}}-P_{m+1}(\tilde{\theta})+\sum_{\substack{j+k=m-1\\ j,k\geq 0}}\frac{1}{2j+1}(\mathcal{F}_{\overline{1,2j+1}}+\mathcal{F}_{\overline{1,2j+1}})P_{k+1}(\tilde{\theta})=0. \tag{32}$$

Note that for $u_2=\mathcal{F}_{11}$, the first equation in (29) is nothing but the 2+1-dimensional dBKP equation,[8]

$$3u_t+15u^2u_x-5uu_y-5u_x\partial_x^{-1}u_y-\frac{5}{3}\partial_x^{-1}u_{yy}=0,$$

where $t_1=x$, $t_3=y$, $t_5=t$ and $u\equiv u_2$, while the first equation in (31) is the simplest nontrivial 2+1-dimensional equation of EdBKP hierarchy involving $t_1=x$, $t_3=y$, and $\overline{t_1}$:

$$uu_{\overline{t_1}}+u_x\partial_x^{-1}u_{\overline{t_1}}-\frac{1}{3}\partial_x^{-1}u_{y\overline{t_1}}=0.$$

For convenience, we list other higher flows of (29)–(32) in Appendix .

III. ASSOCIATIVITY EQUATIONS IN EdBKP HIERARCHY

A. WDVV equations and generating functions

Following Ref. 3, let us briefly recall the basic notions of associativity equations. Let $\mathcal{F}$ be a differentiable functions of a set of time variables $t=(t_1,t_2,\ldots)$; namely, $\mathcal{F}=\mathcal{F}(t_1,t_2,t_3,\ldots)$ and define $\mathcal{F}_{ij}=\partial_{t_i}\partial_{t_j}\mathcal{F}$, $\mathcal{F}_{ijk}=\partial_{t_i}\partial_{t_j}\partial_{t_k}\mathcal{F}$. One can choose one of the time variables, say t_1, and assume the nondegenerate metric $\eta_{ij}=\mathcal{F}_{ij1}$, which can be regarded as a transform from $\{t_i\}$ to $\{\mathcal{F}_{j1}\}$. Define the matrix $C_{ij}^{l}=\partial\mathcal{F}_{ij}/\partial\mathcal{F}_{l1}$; then

$$\mathcal{F}_{ijk} = \sum_l C_{ij}^l \eta_{lk} = \sum_l C_{ij}^l \mathcal{F}_{lk1} \tag{33}$$

connects $\mathcal{F}_{ijk}$ and η_{ij}. It can also be treated as a definition of C_{ij}^l.

If C_{ij}^l is the structure constant of an associativity algebra generated by $\{\phi_i\}$; namely, $\phi_i \cdot \phi_j = \Sigma_l C_{ij}^l \phi_l$, then we have the constraints $\Sigma_l C_{ij}^l C_{lk}^n = \Sigma_l C_{jk}^l C_{il}^n$, or, equivalently,

$$\sum_l C_{ij}^l \mathcal{F}_{lkm} = \sum_l C_{jk}^l \mathcal{F}_{ilm},$$

which is the so-called WDVV equations arising from topological field theories.[10,32] Thus

$$X_{ijkn} \equiv \sum_l C_{ij}^l \mathcal{F}_{lkn} \tag{34}$$

is symmetric with respect to permutations of any indices. In general, one may choose any t_a to define the metric $\eta(a)_{ij} = \mathcal{F}_{ija}$, and the structure constants $C_{ij}^l(a) = \partial \mathcal{F}_{ij} / \partial \mathcal{F}_{la}$; then they obey the same associativity relations,

$$\sum_l C_{ij}^l(a) \mathcal{F}_{lkm} = \sum_l C_{jk}^l(a) \mathcal{F}_{ilm}. \tag{35}$$

Introducing matrices $\mathbf{F}_a$ with matrix elements $(\mathbf{F}_a)_{ij} = \mathcal{F}_{ija}$, one can rewrite the WDVV equations as

$$\mathbf{F}_j \mathbf{F}_a^{-1} \mathbf{F}_m = \mathbf{F}_m \mathbf{F}_a^{-1} \mathbf{F}_j.$$

In the case of infinitely many variables, it is convenient to define generating functions for $\mathcal{F}_{ij}$, $\mathcal{F}_{ijk}$, C_{ij}^l, and X_{ijkl} as follows:[3]

$$D_1 D_2 \mathcal{F} = \sum_{i,j=1}^{\infty} \frac{z_1^{-i}}{i} \frac{z_2^{-j}}{j} \mathcal{F}_{ij},$$

$$D_1 D_2 D_3 \mathcal{F} = \sum_{i,j,k=1}^{\infty} \frac{z_1^{-i}}{i} \frac{z_2^{-j}}{j} \frac{z_3^{-k}}{k} \mathcal{F}_{ijk},$$

$$C^l(z_1, z_2) = \sum_{i,j=1}^{\infty} \frac{z_1^{-i}}{i} \frac{z_2^{-j}}{j} C_{ij}^l,$$

$$X(z_1, z_2, z_3, z_4) = \sum_{i,j,k,n=1}^{\infty} \frac{z_1^{-i}}{i} \frac{z_2^{-j}}{j} \frac{z_3^{-k}}{k} \frac{z_4^{-n}}{n} X_{ijkn},$$

where $D_i \equiv D(z_i) = \Sigma_{j=1}^{\infty} z_i^{-j} \partial_{t_j} / j$. From the definition (34), it is easy to see that X_{ijkn} is symmetric in (ij) and (kn), while the associativity equations (35) implies that $X_{ijkn} = X_{ikjn}$ or, in terms of the generating function,

$$X(z_1, z_2, z_3, z_4) = X(z_1, z_3, z_2, z_4). \tag{36}$$

In Ref. 3, the associativity equations in the dKP and dToda hierarchies were verified from the corresponding dHirota equations by investigating the symmetric property (36).

B. From dHirota to WDVV

To derive WDVV equations from dHirota equations for EdBKP we set $\bar{t}_{-2k-1}=t_{2k+1}$ $(k\leq -1)$ for convenience and rewrite the operator $\bar{D}(z)$ as

$$\bar{D}(z)=\sum_{k\leq -1}\frac{-z^{2k+1}}{2k+1}\partial_{t_{2k+1}}.$$

We will use the notation $D(z_i)=D_i$ and $\bar{D}(z_i)=\bar{D}_i$ for brevity. The functions

$$D_1D_2\mathcal{F}=\sum_{k,m\geq 0}\frac{z_1^{-2k-1}z_2^{-2m-1}}{(2k+1)(2m+1)}\mathcal{F}_{2k+1,2m+1},$$

and $D_1D_2D_3\mathcal{F}$ generate separately the sets of $\mathcal{F}_{2k+1,2m+1}$ and $\mathcal{F}_{2k+1,2m+1,2n+1}$ for all $k,m,n\geq 0$. On the other hand, the functions

$$D_1\bar{D}_2\mathcal{F}=\sum_{k\geq 0,m\leq -1}\frac{-z_1^{-2k-1}z_2^{2m+1}}{(2k+1)(2m+1)}\mathcal{F}_{2k+1,2m+1}$$

generate the set of $\mathcal{F}_{2k+1,2m+1}$ for all $k\geq 0$, and $m\leq -1$, etc. We also introduce generating functions for the structure constants $C^{2l+1}_{2i+1,2j+1}$:

$$C^l(z_1^+,z_2^+)=\sum_{i,j\geq 0}C^{2l+1}_{2i+1,2j+1}\frac{z_1^{-2i-1}z_2^{-2j-1}}{(2i+1)(2j+1)},$$

$$C^l(z_1^-,z_2^-)=\sum_{i,j\leq -1}C^{2l+1}_{2i+1,2j+1}\frac{z_1^{2i+1}z_2^{2j+1}}{(2i+1)(2j+1)}, \tag{37}$$

$$C^l(z_1^+,z_2^-)=\sum_{i\geq 0,j\leq -1}C^{2l+1}_{2i+1,2j+1}\frac{-z_1^{-2i-1}z_2^{2j+1}}{(2i+1)(2j+1)},$$

and the X_{ijkn}:

$$X(z_1,z_2,z_3,z_4)\equiv\sum_{i,j,k,n=-\infty}^{\infty}\frac{z_1^{-|i|}}{|i|}\frac{z_2^{-|j|}}{|j|}\frac{z_3^{-|k|}}{|k|}\frac{z_4^{-|n|}}{|n|}X_{ijkn},\quad i,j,k,n\in\mathbf{Z_{odd}}. \tag{38}$$

Notice that from (37) the property holds: $C^l(z_1^+,z_2^-)=C^l(z_2^-,z_1^+)$. The infinite WDVV equations are thus equivalent to the symmetry of the $X(z_1,z_2,z_3,z_4)$ under permutations of z_1, z_2, z_3, and z_4. In the following, we shall show that the associativity equations in the EdBKP hierarchy can be verified in a similar way as the dToda case.[3]

Let us rewrite the dHirota equations (18), (25), and (26) as

$$\frac{p_1-p_2}{p_1+p_2}=\frac{z_1-z_2}{z_1+z_2}e^{2D_1D_2\mathcal{F}}, \tag{39}$$

$$\frac{\bar{p}_1-\bar{p}_2}{\bar{p}_1+\bar{p}_2}=\frac{z_1-z_2}{z_1+z_2}e^{2\bar{D}_1\bar{D}_2\mathcal{F}}, \tag{40}$$

$$\frac{p_1+\overline{D}_2\partial_{t_1}\mathcal{F}}{p_1-\overline{D}_2\partial_{t_1}\mathcal{F}}=e^{2D_1\overline{D}_2\mathcal{F}}, \tag{41}$$

where $p_i\equiv p(z_i)=z_i-D_i\,\partial_{t_1}\mathcal{F}$ and $\overline{p_i}\equiv\overline{u_0}^{-1}p^{-1}(z_i^{-1})=z_i-\overline{D_i}\,\partial_{t_{-1}}\mathcal{F}$. The symmetric form of Eqs. (39) and (40) are[2]

$$f_{12}f_{23}f_{31}+f_{12}+f_{23}+f_{31}=0, \tag{42}$$

$$\overline{f}_{12}\overline{f}_{23}\overline{f}_{31}+\overline{f}_{12}+\overline{f}_{23}+\overline{f}_{31}=0, \tag{43}$$

where

$$f_{ij}=\frac{p_i-p_j}{p_i+p_j}=\frac{z_i-z_j}{z_i+z_j}e^{2D_iD_j\mathcal{F}},\quad 1\le i,j\le 3,$$

$$\overline{f}_{ij}=\frac{\overline{p_i}-\overline{p_j}}{\overline{p_i}+\overline{p_j}}=\frac{z_i-z_j}{z_i+z_j}e^{2\overline{D}_i\overline{D}_j\mathcal{F}},\quad 1\le i,j\le 3.$$

By taking the D_4 and $\overline{D}_4$ derivatives of (42), we get the following useful identities:

$$p_1^2(p_3D_2-p_2D_3)D_1D_4\mathcal{F}+p_2^2(p_1D_3-p_3D_1)D_2D_4\mathcal{F}+p_3^2(p_2D_1-p_1D_2)D_3D_4\mathcal{F}=0, \tag{44}$$

$$p_1^2(p_3D_2-p_2D_3)D_1\overline{D}_4\mathcal{F}+p_2^2(p_1D_3-p_3D_1)D_2\overline{D}_4\mathcal{F}+p_3^2(p_2D_1-p_1D_2)D_3\overline{D}_4\mathcal{F}=0. \tag{45}$$

Similarly, we have another two identities if we apply D_4 and $\overline{D}_4$ to (43). We define a nondegenerate metric to be $\eta_{2i+1,2j+1}=\mathcal{F}_{2i+1,2j+1,1}$, and the structure constants as

$$\mathcal{F}_{2i+1,2j+1,2k+1}=\sum_{l=-\infty}^{\infty}C_{2i+1,2j+1}^{2l+1}\mathcal{F}_{2l+1,2k+1,1},$$

where the indices take integer values. From the definition of the metric, we have $C_{1,2j+1}^{2l+1}=\delta_j^l$ for all l,j. To find other structure constants, apply $\partial_{t_{2k+1}}$ to the dHirota equations (39)–(41):

$$D_1D_2\,\partial_{2k+1}\mathcal{F}=\frac{p_1D_2-p_2D_1}{p_1^2-p_2^2}\mathcal{F}_{2k+1,1}, \tag{46}$$

$$\overline{D}_1\overline{D}_2\,\partial_{2k+1}\mathcal{F}=\frac{\overline{p}_1\overline{D}_2-\overline{p}_2\overline{D}_1}{\overline{p}_1^2-\overline{p}_2^2}\mathcal{F}_{2k+1,-1}, \tag{47}$$

$$D_1\overline{D}_2\,\partial_{2k+1}\mathcal{F}=\frac{p_1\overline{D}_2+(\overline{D}_2\partial_{t_1}\mathcal{F})D_1}{p_1^2-(\overline{D}_2\partial_{t_1}\mathcal{F})^2}\mathcal{F}_{2k+1,1}. \tag{48}$$

Comparing with (33), the generating functions of structure constants (37) can be read out from the right-hand side of these equations, except that the rhs of Eq. (47) is related to the partial derivative of $\mathcal{F}$ with respect to t_{-1} (not t_1), which forbids us to extract structure constants from (47) directly. Fortunately, this problem can be removed by considering (28) in the form

$$D_1\partial_{t_{-1}}\mathcal{F}=\frac{\overline{p_2}}{p_1}\overline{D_2}\,\partial_{t_1}\mathcal{F}. \tag{49}$$

Differentiating above with respect to t_{2k+1} yields

$$D_1\mathcal{F}_{2k+1,-1}=\frac{\partial_{2k+1}\overline{p_2}}{p_1}\overline{D_2}\,\partial_{t_1}\mathcal{F}+\frac{\overline{p_2}}{p_1}\overline{D_2}\mathcal{F}_{2k+1,1}-\frac{\overline{p_2}\partial_{2k+1}p_1}{p_1^2}\overline{D_2}\,\partial_{t_1}\mathcal{F},$$

which, together with $\partial_{2k+1}p_1=-D_1\mathcal{F}_{2k+1,1}$ and $\partial_{2k+1}\overline{p_2}=-\overline{D_2}\mathcal{F}_{2k+1,-1}$, implies that

$$D_1\mathcal{F}_{2k+1,-1}=-\frac{\overline{D_2}\,\partial_{t_1}\mathcal{F}}{p_1}\overline{D_2}\mathcal{F}_{2k+1,-1}+\frac{\overline{p_2}}{p_1}\overline{D_2}\mathcal{F}_{2k+1,1}+\frac{\overline{p_2}}{p_1^2}(\overline{D_2}\,\partial_{t_1}\mathcal{F})D_1\mathcal{F}_{2k+1,1}. \tag{50}$$

Taking the limit $z_1\to\infty$ in (50), we obtain

$$\overline{D_2}\mathcal{F}_{2k+1,-1}=\frac{\overline{p_2}}{\overline{D_2}\mathcal{F}_1}\overline{D_2}\mathcal{F}_{2k+1,1}, \tag{51}$$

which, after substituting back into (50), yields

$$D_1\mathcal{F}_{2k+1,-1}=\frac{\overline{p_2}}{p_1^2}(\overline{D_2}\,\partial_{t_1}\mathcal{F})D_1\mathcal{F}_{2k+1,1}.$$

On the other hand, exchanging the variables $z_1\leftrightarrow z_2$, we have

$$\overline{D_1}\mathcal{F}_{2k+1,-1}=\frac{\overline{p_1}}{\overline{D_1}\mathcal{F}_1}\overline{D_1}\mathcal{F}_{2k+1,1}, \tag{52}$$

$$D_2\mathcal{F}_{2k+1,-1}=\frac{\overline{p_1}}{p_2^2}(\overline{D_1}\mathcal{F}_1)D_2\mathcal{F}_{2k+1,1}.$$

Substituting (51) and (52) into the numerator of (47) and taking into account (49), then (47) becomes

$$\overline{D_1}\overline{D_2}\partial_{2k+1}\mathcal{F}=\frac{(\overline{D_2}\partial_{t_1}\mathcal{F})\overline{D_1}-(\overline{D_1}\partial_{t_1}\mathcal{F})\overline{D_2}}{(\overline{D_1}\partial_{t_1}\mathcal{F})^2-(\overline{D_2}\partial_{t_1}\mathcal{F})^2}\mathcal{F}_{2k+1,1}. \tag{53}$$

Now we can find all structure constants by using Eqs. (46), (48), and (53). First, we conclude from (46) and (53) that $C^{2l+1}_{2i+1,2j+1}=0$ for $i,j\geq 0$ and $l\leq -1$, or $i,j\leq -1$ and $l\geq 0$. Next, if all the indices are positive, we have

$$C^l(z_1^+,z_2^+)=\frac{p_1z_2^{-2l-1}-p_2z_1^{-2l-1}}{(2l+1)(p_1^2-p_2^2)},\quad l\geq 0, \tag{54}$$

while all the indices are negative, it gives

$$C^l(z_1^-,z_2^-)=\frac{(\overline{D_1}\partial_{t_1}\mathcal{F})z_2^{2l+1}-(\overline{D_2}\partial_{t_1}\mathcal{F})z_1^{2l+1}}{(2l+1)((\overline{D_1}\,\partial_{t_1}\mathcal{F})^2-(\overline{D_2}\,\partial_{t_1}\mathcal{F})^2)},\quad l\leq -1. \tag{55}$$

When i and j have different signs, we use (48) to obtain

$$C^l(z_1^+,z_2^-)=\begin{cases}\dfrac{(\overline{D}_2\,\partial_{t_1}\mathcal{F})z_1^{-2l-1}}{(2l+1)(p_1^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2)}, & l\geq 0,\\ \dfrac{-p_1 z_2^{2l+1}}{(2l+1)(p_1^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2)}, & l\leq -1.\end{cases} \tag{56}$$

Making use of the structure constants, we show that any solution $\mathcal{F}$ of the EdBKP hierarchy obeys the WDVV equations:

$$\sum_{l=-\infty}^{\infty} C_{2i+1,2j+1}^{2l+1}\mathcal{F}_{2l+1,2k+1,2n+1}=\sum_{l=-\infty}^{\infty} C_{2i+1,2k+1}^{2l+1}\mathcal{F}_{2l+1,2j+1,2n+1},\quad i,j,k,n\in\mathbf{Z}. \tag{57}$$

To show that the generating functions (38) is totally symmetric w.r.t. permutations of $z_1,\ldots,z_4$, however, it is enough to prove the symmetry w.r.t. the permutations of z_2 and z_3 in (38), i.e., $X(z_1,z_2,z_3,z_4)=X(z_1,z_3,z_2,z_4)$.

For all positive indices in (57), we use (54) to obtain the generating function

$$X(z_1,z_2,z_3,z_4)=\frac{1}{p_1^2-p_2^2}(p_1D_2-p_2D_1)D_3D_4\mathcal{F}.$$

Hence we have to prove

$$(p_1^2-p_3^2)(p_1D_2-p_2D_1)D_3D_4\mathcal{F}=(p_1^2-p_2^2)(p_1D_3-p_3D_1)D_2D_4\mathcal{F}. \tag{58}$$

It is straightforward to bring (58) into the identity (44) by eliminating $p_1^3D_2D_3D_4\mathcal{F}$ to both sides of (58), which concludes the proof for this case. If the index n in (57) is negative, then with the help of (45) the same arguments go through.

Let all the indices in (57) be negative; then by (55) we have the following equation to be verified:

$$\begin{aligned}0=&(\overline{D}_1\,\partial_{t_1}\mathcal{F})^2((\overline{D}_3\,\partial_{t_1}\mathcal{F})\overline{D}_2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})\overline{D}_3)\overline{D}_1\overline{D}_4\mathcal{F}+(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2((\overline{D}_1\,\partial_{t_1}\mathcal{F})\overline{D}_3\\&-(\overline{D}_3\,\partial_{t_1}\mathcal{F})\overline{D}_1)\overline{D}_2\overline{D}_4\mathcal{F}+(\overline{D}_3\,\partial_{t_1}\mathcal{F})^2((\overline{D}_2\,\partial_{t_1}\mathcal{F})\overline{D}_1-(\overline{D}_1\,\partial_{t_1}\mathcal{F})\overline{D}_2)\overline{D}_3\overline{D}_4\mathcal{F},\end{aligned}$$

which, after consulting (53), is indeed an identity. This completes the proof for this case.

Let j in (57) be negative; and all others be positive. In terms of the generating functions the WDVV equations now reads as

$$\frac{(p_1\overline{D}_2+(\overline{D}_2\,\partial_{t_1}\mathcal{F})D_1)D_3D_4\mathcal{F}}{p_1^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2}=\frac{(p_1D_3-p_3D_1)\overline{D}_2D_4\mathcal{F}}{p_1^2-p_3^2}. \tag{59}$$

We express $D_3\overline{D}_2D_4$ and $D_1\overline{D}_2D_4$ from (48) [multiplying it by $z_4^{-2k-1}/(2k+1)$, and summing over k] and substitute them back into (59). It follows that

$$D_1D_3D_4\mathcal{F}=\frac{(p_1D_3-p_3D_1)D_4\,\partial_{t_1}\mathcal{F}}{p_1^2-p_3^2},$$

which is provided by (46). We conclude the proof of this case.

Finally, let j,k be negative and i,n be positive. In this case we have the following WDVV equations to prove:

$$\frac{(p_1\overline{D}_2+(\overline{D}_2\,\partial_{t_1}\mathcal{F})D_1)\overline{D}_3D_4\mathcal{F}}{p_1^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2}=\frac{(p_1\overline{D}_3+(\overline{D}_3\,\partial_{t_1}\mathcal{F})D_1)\overline{D}_2D_4\mathcal{F}}{p_1^2-(\overline{D}_3\,\partial_{t_1}\mathcal{F})^2}, \tag{60}$$

where we have used $C^l(z_2^-,z_1^+)$ and $C^l(z_3^-,z_1^+)$ defined in (56) to the lhs and rhs of (60), respectively. Expressing $D_1\overline{D}_3D_4$ and $D_1\overline{D}_2D_4$ from (48) and substituting them back into (60), then

$$\overline{D}_2\overline{D}_3D_4\mathcal{F}=\frac{((\overline{D}_3\,\partial_{t_1}\mathcal{F})\overline{D}_2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})\overline{D}_3)D_4\,\partial_{t_1}\mathcal{F}}{(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2-(\overline{D}_3\,\partial_{t_1}\mathcal{F})^2},$$

which is provided by (53). This completes the proof of WDVV equations for the EdBKP hierarchy.

C. Associative algebra and residue formula

The realization of the associative algebra with the structure constants (54)–(56) is obtained with the help of the kernel formulas (16) and (23) by introducing the generators

$$\phi_{2k+1}(p)=\frac{d\mathcal{B}_{2k+1}(p)}{dp},\quad k\in\mathbf{Z},$$

where $\mathcal{B}_{2k+1}\equiv\overline{\mathcal{B}}_{-2k-1}$ for $k\leq -1$. Then the kernel formulas (16) and (23) give us the following relations:

$$\frac{p(z)}{p^2-p^2(z)}=-\sum_{k\geq 0}\frac{z^{-2k-1}}{2k+1}\phi_{2k+1}(p), \tag{61}$$

$$\frac{\overline{D}(z)\partial_{t_1}\mathcal{F}}{p^2-(\overline{D}(z)\partial_{t_1}\mathcal{F})^2}=-\sum_{k\leq -1}\frac{z^{2k+1}}{2k+1}\phi_{2k+1}(p). \tag{62}$$

For example, we start by writing the identity

$$\frac{p_1p_2}{(p^2-p_1^2)(p^2-p_2^2)}=\frac{p_1p_2}{p_1^2-p_2^2}\left(\frac{1}{p^2-p_1^2}-\frac{1}{p^2-p_2^2}\right), \tag{63}$$

and expanding both sides in z_1^{-1},z_2^{-1}. Then, using (61) and (63), and comparing with (54), we obtain the algebra

$$\phi_{2i+1}(p)\phi_{2j+1}(p)=\sum_{l\geq 0}C_{2i+1,2j+1}^{2l+1}\phi_{2l+1}(p),\quad i,j\geq 0.$$

Next, we can expand both sides of the identity,

$$\frac{p_1\overline{D}_2\,\partial_{t_1}\mathcal{F}}{(p^2-p_1^2)(p^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2)}=\frac{p_1\overline{D}_2\,\partial_{t_1}\mathcal{F}}{p_1^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2}\left(\frac{1}{p^2-p_1^2}-\frac{1}{p^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2}\right), \tag{64}$$

in z_1^{-1},z_2. Using (61), (62), and (64), and comparing with (56), we have the algebra

$$\phi_{2i+1}(p)\phi_{2j+1}(p)=\sum_{l=-\infty}^{\infty}C_{2i+1,2j+1}^{2l+1}\phi_{2l+1}(p),\quad i\geq 0,\ j\leq -1.$$

The other algebra for $i,j,l\leq -1$ can be verified in a similar way and the structure constants are given by (55).

Now let us derive the residue formulas for third order derivatives of $\mathcal{F}$ (i.e., $\mathcal{F}_{2j+1,2k+1,2m+1}$) directly from dHirota equations. For the case of all positive indices, using (46) for $k=0$,

$$D_1D_2\,\partial_{t_1}\mathcal{F}=\frac{p_1D_2-p_2D_1}{p_1^2-p_2^2}\partial_{t_1}^2\mathcal{F},$$

we can express $D_1D_2D_3\mathcal{F}$ in terms of $D_i\partial_{t_1}^2\mathcal{F}$ only:

$$D_1D_2D_3\mathcal{F}=2\sum_{i=1}^{3}\operatorname{res}_{p_i}\left(\frac{p_1p_2p_3D(z(p))\partial_{t_1}^2\mathcal{F}}{(p^2-p_1^2)(p^2-p_2^2)(p^2-p_3^2)}dp\right). \tag{65}$$

Expanding both sides of (65) in the series in z_1,z_2,z_3 and using (61), we obtain

$$\mathcal{F}_{2j+1,2k+1,2m+1}=\frac{-1}{\pi i}\oint_{C_\infty}\frac{\partial_{t_1}z(p)}{z'(p)}\phi_{2j+1}(p)\phi_{2k+1}(p)\phi_{2m+1}(p)dp,\quad j,k,m\geq 0,$$

where, due to the fact that $0=\partial_{t_1}p(p)=\partial_{t_1}p(z)+\partial_zp(z)\partial_{t_1}z$, we have rewritten $D(z(p))\partial_{t_1}^2\mathcal{F}=-\partial_{t_1}p(z)=\partial_{t_1}z/z'(p)$ in the numerator of (65).

Similarly, for those cases containing nonpositive indices, we have

$$D_1D_2\overline{D}_3\mathcal{F}=2\sum_{i=1}^{3}\operatorname{res}_{p_i}\left(\frac{p_1p_2(\overline{D}_3\,\partial_{t_1}\mathcal{F})\partial_{t_1}p}{(p^2-p_1^2)(p^2-p_2^2)(p^2-(\overline{D}_3\,\partial_{t_1}\mathcal{F})^2)}dp\right),$$

$$D_1\overline{D}_2\overline{D}_3\mathcal{F}=2\sum_{i=1}^{3}\operatorname{res}_{p_i}\left(\frac{-p_1(\overline{D}_2\,\partial_{t_1}\mathcal{F})(\overline{D}_3\,\partial_{t_1}\mathcal{F})\partial_{t_1}p}{(p^2-p_1^2)(p^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2)(p^2-(\overline{D}_3\,\partial_{t_1}\mathcal{F})^2)}dp\right),$$

$$\overline{D}_1\overline{D}_2\overline{D}_3\mathcal{F}=2\sum_{i=1}^{3}\operatorname{res}_{p_i}\left(\frac{(\overline{D}_1\partial_{t_1}\mathcal{F})(\overline{D}_2\,\partial_{t_1}\mathcal{F})(\overline{D}_3\,\partial_{t_1}\mathcal{F})\partial_{t_1}p}{(p^2-(\overline{D}_1\,\partial_{t_1}\mathcal{F})^2)(p^2-(\overline{D}_2\,\partial_{t_1}\mathcal{F})^2)(p^2-(\overline{D}_3\,\partial_{t_1}\mathcal{F})^2)}dp\right),$$

where $\partial_{t_1}p_i=-D_i\,\partial_{t_1}^2\mathcal{F}$ when we evaluate the residue at $p=p_i$, while $\partial_{t_1}p_i=\overline{D}_i\,\partial_{t_1}^2\mathcal{F}$ at $p=\overline{D}_i\,\partial_{t_1}\mathcal{F}$. Using (61) and (62), similar residue formulas can be written down.

IV. CONCLUDING REMARKS

We have demonstrated the method of kernel formula to derive dHirota equations for dispersionless integrable hierarchies. After recalling the original approach to the dKP hierarchy, we apply the method to the EdBKP hierarchy. The results enables us to investigate the associativity equations in the EdBKP hierarchy.

Three remarks are in order. First, we like to mention that Takasaki[25] recently obtained dHirota equations of two-component BKP hierarchy by taking the quasi-classical limit of the corresponding(differential) Fay identities. Both approaches (that in Ref. 25 and ours) basically reach the same dHirota equations, except that the free energy differs by a factor 2. However in Ref. 25 the dispersionless Lax equations for a two-component BKP hierarchy can be formulated in two different ways, which reveals that the system has two spatial dimensions (t_1 and $\overline{t_1}$). It would be interesting to investigate this peculiar property from the viewpoint of WDVV equations. Second, the associativity equations discussed in Sec. III is an infinite-dimensional version of WDVV equations in which the number of variables t_k is infinite. However, in Ref. 6, some finite-dimensional reductions of the EdBKP hierarchy have been obtained via Riemann-Hilbert construction. Therefore, it is quite natural to ask whether these solutions satisfy the finite-dimensional version of WDVV equations. Third, in Refs. 20–22 Pavlov discussed dHirota equations of dBKP

system from the point of view of Egorov hydrodynamic chains and constructed associated solutions of WDVV equations. His approach in some sense gave a Hamiltonian approach to the dBKP system. Therefore it is also interesting to investigate the Hamiltonian formulation to the EdBKP hierarchy, which has the advantage of studying solutions of WDVV equations. Works in these directions are now in progress.

ACKNOWLEDGMENTS

We would like to thank Maxim Pavlov for his useful comments on the manuscript. We also thank the anonymous referee for helpful comments and suggestions. This work is supported by the National Science Council of Taiwan under Grant No. NSC94-2112-M-194-009 (MHT).

(Received 26 July 2006; accepted 11 September 2006; published online 20 October 2006)

An explicit solution for the longitudinal and transverse polarizability of the symmetric dielectric intersecting double sphere is obtained as a rapidly converging series of integral operators, which is fast enough for real time calculation in Java Applet. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2359140]

I. INTRODUCTION

The problem of polarizability of an intersecting metallic double sphere was solved in 1949 by Schiffer and Szego. Fifty years later it was reinvented by Felderhof and Palaniappan in their article.[1] Their solution is given in terms of a one-dimensional integral and applies also to the asymmetric double spheres. The problem of a symmetric intersecting dielectric double sphere has not yet been solved in explicit form. In the year 1994, Radchik, Paley, and Smith gave a nice try in their article,[2] but they did not show enough respect to the normal boundary conditions, and eventually their results were proven to be false by Felderhof and Palaniappan.

Polarizability is a property of an object that measures its ability to interact with an electromagnetic force field. It depends on the electric properties of the matter and the shape of the object. When studying heterogeneous mixtures of dielectric objects, the polarizability of a single object provides crucial information.[3]

II. TOROIDAL COORDINATE SYSTEM

We define a coordinate transformation Λ from toroidal coordinates (u,v,φ) to Cartesian coordinates (x,y,z) by formulas

$$x=\frac{\sinh u\cos\varphi}{R^2},\quad y=\frac{\sinh u\sin\varphi}{R^2},\quad z=\frac{\sin v}{R^2},$$

where $R=\sqrt{\cosh u-\cos v}$. Coordinates (u,v,ϕ) have ranges $0\leq u<\infty$, $-\pi\leq v<\pi$, and $-\pi\leq\varphi<\pi$. The parametric surface $(v,\varphi)\mapsto\Lambda(u_1,v,\varphi)$ defines a family of toroidal surfaces parametrized by the coordinate u_1 and $(u,\varphi)\mapsto\Lambda(u,v_1,\varphi)$ defines a family of surfaces of intersecting double spheres parametrized by the coordinate v_1. In other words, the set

$$\mathcal{B}(v_1)=\{\Lambda(u,v,\varphi)\in\mathbb{R}^3|0\leq u<\infty,|v|=v_1,-\pi<\varphi<\pi\}$$

defines the surface of a symmetric intersecting double sphere. We can see that the surface $\mathcal{B}(\pi/2)$ is a sphere with unit radius, the surface $\mathcal{B}(\pi)$ is a disk with unit radius, and the surface $\mathcal{B}(0)$ is touching spheres having an infinite radius. All the other surfaces are between these extreme cases.

In the following, we shall be considering a domain:

$$\mathcal{D}(v_1)=\{\Lambda(u,v,\varphi)\in\mathbb{R}^3|0\leq u<\infty,v_1\leq|v|\leq\pi,-\pi<\varphi<\pi\},$$

which describes a symmetric double sphere with permittivity ε with a separation parameter v_1 that is connected to the relative distance d between the centers of the spheres by $d=2\cos v_1$. In

[a)]Electronic address: mpitkone@cc.tkk.fi

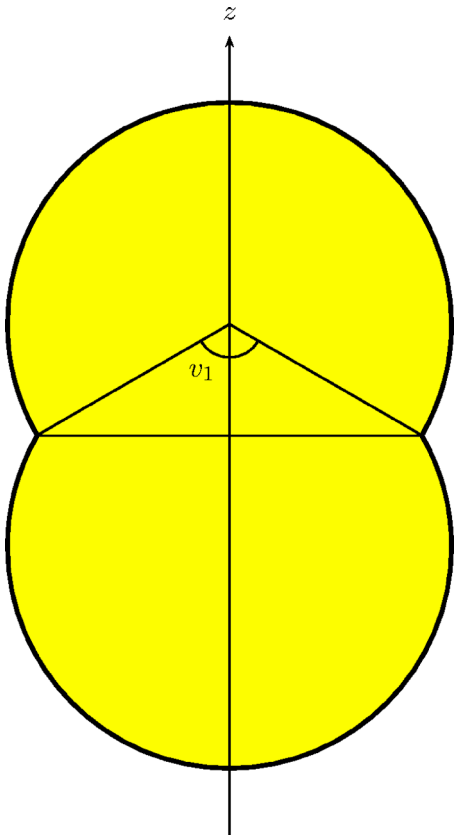

FIG. 1. A symmetric intersecting double sphere when separation parameter $v_1=\pi/3$.

particular, when $0\leq d<2$, we have an intersecting double sphere, and when $-2\leq d<0$ we have a lens. (See Fig. 1)

III. LONGITUDINAL POLARIZABILITY

Let ϕ be the scattered potential when the incident field $\mathbf{E}(\mathbf{r})=\mathbf{u}_z$, having potential $\phi_0=-z$, is applied. We can see that the Laplacian of the incident potential ϕ_0 vanishes meaning that for the scattered potential ϕ, we have $(\nabla^2\phi)(\mathbf{r})=0$ when $\mathbf{r}\notin\mathcal{B}(v_1)$. Therefore, it is a good idea to split the solution ϕ into two pieces:

$$\phi(u,v)=\begin{cases}\phi_1(u,v), & v<v_1,\\ \phi_2(u,v), & v\geq v_1,\end{cases}$$

because they both satisfy the Laplace's equation separately and are connected through the continuity and normal boundary conditions,

$$\phi_1(u,v_1)=\phi_2(u,v_1), \tag{1}$$

$$\partial\phi_1(u,v_1)-\varepsilon\ \partial\phi_2(u,v_1)=(1-\varepsilon)\,\partial\phi_0(u,v_1), \tag{2}$$

where we have used the notation $\partial\Phi(u,v)=(\partial/\partial v)\Phi(u,v)$. In addition, the symmetry of the scatterer and incident potential require that the potential ϕ is independent of the coordinate φ. The scattered potential must also vanish when $z=0$; thus we need to demand that $\phi_1(u,0)=0$ and $\phi_2(u,\pi)=0$ for all $0\leq u<\infty$.

Having now all the necessary integredients to solve the Laplace's equations, we shall proceed by introducing our main mathematical tool: the Mehler-Fock transform.

The Mehler-Fock Transform $\mathcal{F}$ is a mapping $f \mapsto F$, where f and F are mappings $\mathbb{R}^+ \to \mathbb{R}$ such that

$$F(\lambda) = \lambda \tanh(\pi\lambda) \int_0^\infty P_{-1/2+i\lambda}(\cosh u) \sinh u f(u) \mathrm{d}u.$$

According to Ref. 4, the inverse transform $\mathcal{F}^{-1}$ is the mapping $F \mapsto f$, where

$$f(u) = \int_0^\infty P_{-1/2+i\lambda}(\cosh u) F(\lambda) \mathrm{d}\lambda.$$

We shall use a more convenient notation $\overline{\Phi} = \mathcal{F}(\Phi)$ in the following. The Legendre function of the first kind P_ν in the core of the Mehler-Fock transform satisfies the well-known Legendre's differential equation,

$$(1 - x^2) P_\nu''(x) - 2x P_\nu'(x) + \nu(\nu + 1) P_\nu(x) = 0, \tag{3}$$

where the degree $\nu = -1/2 + i\lambda$ is a complex number, making it crucially different from the familiar Legendre's polynomials P_n.

It can be shown that Laplace's equation in the toroidal coordinate system is separable when we define a new function Φ_i by $\phi_i = R\Phi_i$, where the index $i \in \{1, 2\}$. Now, we may try to find solutions of the form

$$\Phi_i(u, v) = U(u) V_i(v),$$

and it turns out that we get two ordinary differential equations: the equation for the function U is the Legendre's equation (3) and for the functions V_i we have the equations

$$V_i'' = \lambda^2 V_i,$$

where λ is an arbitrary non-negative number, meaning that we have a continuous spectrum of solutions. Solutions satisfying the conditions $V_1(0) = 0$ and $V_2(\pi) = 0$ and the antisymmetry of the potential ϕ are given by

$$V_1(v) = c_1(\lambda) \sinh(v\lambda),$$

$$V_2(v) = c_2(\lambda) \begin{cases} \sinh((\pi - v)\lambda), & 0 \le v < \pi, \\ -\sinh((\pi + v)\lambda), & -\pi \le v < 0. \end{cases}$$

In the following, we may assume that $0 \le v < \pi$ because the boundary conditions (1) and (2) remain unchanged if we change the sign of the separation parameter v_1.

Now, the superposition principle suggests that the solutions could be of the form

$$\Phi_1(u, v) = \int_0^\infty c_1(\lambda) P_{-1/2+i\lambda}(\cosh u) \sinh(v\lambda) \mathrm{d}\lambda,$$

$$\Phi_2(u, v) = \int_0^\infty c_2(\lambda) P_{-1/2+i\lambda}(\cosh u) \sinh((\pi - v)\lambda) \mathrm{d}\lambda,$$

which indeed look like an inverse Mehler-Fock transform when the corresponding transforms are

$$\bar{\Phi}_1(\lambda,v) = c_1(\lambda)\sinh(v\lambda),$$

$$\bar{\Phi}_2(\lambda,v) = c_2(\lambda)\sinh((\pi - v)\lambda).$$

We shall begin our hunt for the unknown amplitude functions c_1 and c_2 by transforming the continuity equation (1) to obtain an equation,

$$c_1(\lambda)\sinh(v_1\lambda) = c_2(\lambda)\sinh((\pi - v_1)\lambda),$$

that we use to choose a new coefficient function c, which gives us the transforms

$$\bar{\Phi}_1(\lambda,v) = c(\lambda)\frac{\sinh(v\lambda)}{\sinh(v_1\lambda)},$$

$$\bar{\Phi}_2(\lambda,v) = c(\lambda)\frac{\sinh((\pi - v)\lambda)}{\sinh((\pi - v_1)\lambda)}.$$

Now, the solutions read as

$$\phi_i(u,v) = R(u,v)\int_0^\infty P_{-1/2+i\lambda}(\cosh u)\bar{\Phi}_i(\lambda,v)\mathrm{d}\lambda,$$

when $0 < v < \pi$.

There seems to be only one condition left to be fulfilled and one degree of freedom, namely the function c, to play with. We immediately see that the boundary condition (2) is an integral equation for the function c. It could be solved by means of the method of moments, however, due to the oscillatory kernel, it is not a good idea. Instead, we shall use the Mehler-Fock transform to obtain a much more nicely behaving integral equation.

A. Conducting double sphere

Next, we analyze briefly the case $\varepsilon \to \infty$. The boundary condition for a symmetric metallic double sphere is

$$\phi(u,v_1) = \phi_0(u,v_1) = \frac{\sin v}{R(u,v_1)^2},$$

which can be written in the form

$$\Phi(u,v_1) = \frac{\sin v_1}{R(u,v_1)^3}.$$

The Mehler-Fock transform of this equation yields

$$c_\infty = \bar{\Phi}(\lambda,v_1) = \sin v_1 \mathcal{F}\left(\frac{1}{R^3}\right). \tag{4}$$

Fortunately, the transform $\mathcal{F}(1/R^3)$ has a simple analytical expression, which we shall soon derive from the solution obtained by Felderhof and Palaniappan.

B. Dielectric double sphere

Using the definition $\phi_i = R\Phi_i$, the normal boundary condition (2) at $v = v_1$ can be written in the form

$$\frac{1}{2}\sin v_1 \frac{\Phi_{12}}{R^2} + \partial\Phi_{12} = (\varepsilon - 1)\left(\frac{\cos v_1}{R^3} - \frac{\sin^2 v_1}{R^5}\right),$$

where $\partial\Phi(u,v) = (\partial/\partial v)\Phi(u,v)$ and $\Phi_{12} = \Phi_1 - \varepsilon\Phi_2$. Now, we apply the Mehler-Fock transform with respect to coordinate u and obtain the equation

$$\partial\overline{\Phi}_{12} + \frac{1}{2}\sin v_1 \mathcal{F}\left(\frac{\Phi_{12}}{R^2}\right) = (\varepsilon - 1)\left(\cos v_1 \mathcal{F}\left(\frac{1}{R^3}\right) - \sin^2 v_1 \mathcal{F}\left(\frac{1}{R^5}\right)\right),$$

which, as it turns out, can be transformed to a Fredholm integral equation of the second kind.

In the article of Ref. 1, the case $\varepsilon \to \infty$ has been solved analytically. From that solution, we can extract the unknown function,

$$c_\infty = 2\sqrt{2}\lambda\left(\frac{\sinh((\pi - v_1)\lambda)}{\cosh(\pi\lambda)}\right).$$

Now, comparing this equation to Eq. (4), we conclude that

$$\mathcal{F}\left(\frac{1}{R^3}\right) = \frac{c_\infty}{\sin v_1},$$

and differentiating this with respect to parameter v_1 yields the transform

$$\mathcal{F}\left(\frac{1}{R^5}\right) = -\frac{2}{3\sin v_1}\partial\mathcal{F}\left(\frac{1}{R^3}\right) = \frac{4}{3}\sqrt{2}\lambda\left(\frac{\lambda\cosh((\pi - v_1)\lambda) + \cot v_1 \sinh((\pi - v_1)\lambda)}{\sin^2 v_1 \cosh(\pi\lambda)}\right).$$

A simple differentiation gives us the derivative

$$\partial\overline{\Phi}_{12} = (\coth(v_1\lambda) + \varepsilon\coth((\pi - v_1)\lambda))\lambda c(\lambda),$$

evaluated at $v = v_1$. Finally, we make a substitution $p = \cosh u$ and change the order of integration, giving us the term

$$\mathcal{F}\left(\frac{\Phi_{12}}{R^2}\right) = (1 - \varepsilon)\lambda\tanh(\pi\lambda)\int_1^\infty \frac{P_{-1/2+i\lambda}(p)}{p - \cos v_1}\int_0^\infty P_{-1/2+i\tau}(p)c(\tau)\mathrm{d}\tau\mathrm{d}p$$

$$= (1 - \varepsilon)\lambda\tanh(\pi\lambda)\int_0^\infty c(\tau)\underbrace{\int_1^\infty \frac{P_{-1/2+i\lambda}(p)P_{-1/2+i\tau}(p)}{p - \cos v_1}\mathrm{d}p}_{\mathcal{K}(\lambda,\tau)}\mathrm{d}\tau$$

So, our normal boundary condition has taken the form of a Fredholm's integral equation of the second kind:

$$c(\lambda) - \int_0^\infty k(\lambda,\tau)c(\tau)\mathrm{d}\tau = f(\lambda), \tag{5}$$

where the kernel k and the function f are given by expressions

$$k(\lambda,\tau) = \frac{(1 - \varepsilon)\sin v_1 \tanh(\pi\lambda)\mathcal{K}(\lambda,\tau)}{2(\coth(v_1\lambda) + \varepsilon\coth((\pi - v_1)\lambda))},$$

$$f(\lambda) = \frac{(\varepsilon - 1)\left(\cos v_1 \mathcal{F}\left(\frac{1}{R^3}\right) - \sin^2 v_1 \mathcal{F}\left(\frac{1}{R^5}\right)\right)}{\lambda(\coth(v_1\lambda) + \varepsilon\coth((\pi - v_1)\lambda))}.$$

It turns out that the integral operator K, defined by

$$(Kg)(\lambda) = \int_0^\infty k(\lambda,\tau)g(\tau)\mathrm{d}\tau,$$

is small (meaning that $\|K\| < 1$), so that the solution function c can be written in terms of the Neumann series,

$$c = \sum_{n=0}^{\infty} K^n f,$$

which converges for all $\varepsilon \geq 0$ and $0 < v_1 < \pi$. The convergence is quite fast: For instance, when $\varepsilon = 2$ and $v_1 = \pi/2$ only 5 terms was needed to get 4 digit precision. However, it seems that $\|K\| \to 1$ when $\varepsilon \to \infty$ and $v_1 \to 0$.

A highly recommended way to evaluate the Neumann series is to use a so-called nested form, which means that $c_n \to c$, where $c_{n+1} = Kc_n + f$ and $c_0 = f$.

C. Polarizability

The polarizability of the double sphere is obtained by looking the behavior of the potential ϕ on the z axis, where the coordinate $u = 0$. Using the Taylor expansions $\sin v \approx v$ and $\cos v \approx 1 - v^2/2$ we have $v \approx 2/z$ and $R \approx \sqrt{2}/z$ when z is large. We also need the expansion $\sinh(v\lambda) \approx v\lambda \approx 2\lambda/z$. Now we have the farfield expression for the potential on the z axis,

$$\phi(z) = \frac{2\sqrt{2}}{z^2}\int_0^\infty \frac{\lambda c(\lambda)}{\sinh(v_1\lambda)}\mathrm{d}\lambda,$$

where we have used the property $P_{-1/2+i\lambda}(1) = 1$ for all $\lambda \geq 0$. Now, we can compare this and the potential of the $\mathbf{u}_z$ directed dipole to get the normalized longitudinal polarizability,

$$\alpha_z = \frac{8\sqrt{2}\pi}{\mathcal{V}}\int_0^\infty \frac{\lambda c(\lambda)}{\sinh(v_1\lambda)}\mathrm{d}\lambda,$$

where $\mathcal{V}$ is the volume of the double sphere.

To calculate the volume of the double sphere, we need the Jacobian determinant

$$J = \frac{\sinh u}{R^3}$$

in the toroidal coordinate system. Now, the volume can be integrated analytically:

$$\mathcal{V} = 2\int_{-\pi}^{\pi}\int_0^\infty\int_{\pi}^{v_1} J\,\mathrm{d}v\,\mathrm{d}u\,\mathrm{d}\phi$$

$$= \frac{\pi}{6}\left(\frac{\cos\left(\frac{3v_1}{2}\right) - 3\cos\left(\frac{v_1}{2}\right)}{\sin^3\left(\frac{v_1}{2}\right)}\right).$$

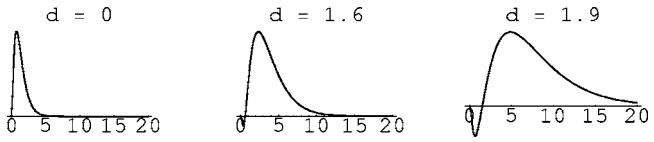

FIG. 2. Function f when $\varepsilon=2$ with different separation values.

IV. IMPLEMENTATION

To solve the integral equation (5), we approximate the functions c_n by vectors $c_n(\lambda_i)$, where the numbers λ_i are the integration points determined by the numerical integration method. The integrand of the integral operator K is a very smooth function, hence, the Gaussian quadrature is the best choice for the numerical integration. The iteration proceeds as

$$c_{n+1}(\lambda_i) = \sum_{j=1}^{j} w_j k(\lambda_i, \lambda_j)\, c_n(\lambda_j) + f(\lambda_i).$$

In each iteration, the kernel k has to be evaluated j^2 times. Therefore, we need a fast implementation for the subkernel $\mathcal{K}(\lambda, \tau)$, which we shall consider briefly, but first, we need to determine a proper choice for the integration points λ_i.

As we can see from Fig. 2, the initial guess function $f(\lambda)$ spreads when the separation parameter v_1 gets smaller. In addition, the integrand of the subkernel $\mathcal{K}$ becomes very oscillatory for large values of λ. Therefore, we need to exclude those values of v_1 that are close to 0, which correspond the touching case. When we choose 192 Gaussian points on the interval $[0,100]$, it is possible to analyze the cases $d \in [-1.99, 1.99]$.

A. Calculation of the subkernel

First, it is a good idea to do the integration with respect to variable u (meaning that $p = \cosh u$), which leads to integrand that decays as e^{-u} as $u \to \infty$ and oscillates with constant frequency.

The easiest way to calculate the subkernel $\mathcal{K}$ is to use the software package MATHEMATICA 5.2, which provides an implementation for the Legendre function P_ν and sophisticated numerical integration methods. When the Gaussian points λ_i are chosen, one can pick some separation parameter v_1 of interest and calculate the table $\mathcal{K}(\lambda_i, \lambda_j)$, which will be used in the iteration process.

In order to do real-time calculations, for example, in Java Applet, we need to choose another set of integration points u_i. Once again, the Gaussian quadrature outperforms the other methods, but now, due to the oscillatory behavior of the integrand of the subkernel, we need a lot of integration points. Using 1024 Gaussian points on the interval $[0, 20]$ provides a precision such that the polarizability can be calculated to precision that is 5 significant digits at worse. (See Fig. 3)

B. Speeding things up

We have to do about 20 000 evaluations of the subkernel $\mathcal{K}$ to calculate the table $\mathcal{K}(\lambda_i, \lambda_j)$. Every evaluation of the subkernel requires 2048 Legendre function evaluations. How to calculate a Legendre function 40 million times in one second?

Evaluating it by definition, as a hypergeometric series, is far too slow. A better idea is to save the values of the Legendre function $P_{-1/2+i\lambda_n}(\cosh u_m)$ in a table to 16-digit precision using MATHEMATICA. Such a high precision is a good idea because there occurs loss of precision in the integration. Constructing 1024 Gaussian points is not easy, but can be done with MATHEMATICA's command `Findroot` with initial guesses given by the formula $\cos(\pi(j-1/4)/(n+1/2))$. These Gaussian points (abscissas) should be calculated with 600-digit precision to get the desired

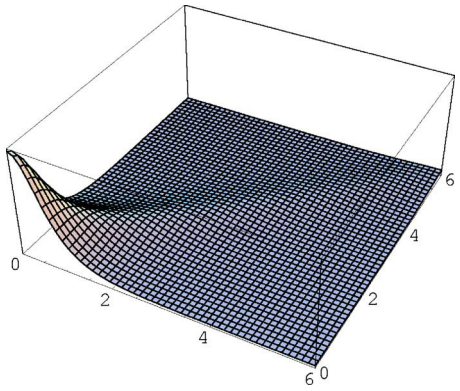

FIG. 3. The subkernel $\mathcal{K}(\lambda,\tau)$ when $v_1=\pi/2$.

16-digit precision for the weights. More details can be found, for example, in the paper of Ref. 5.

Evaluating the Legendre function $P^{\mu}_{-1/2+i\lambda}(\cosh u)$ as MATHEMATICA's function `LegendreP` is very time consuming for large values of λ. A faster way is to use a Formula 8.11.1 of the book[6] for small values of u and Formula 8.11.1 with the hypergeometric part replaced by the formula 15.3.6 for large values of u. The condition for which one to use is the number $u=0.1371+0.202e^{-0.0312\lambda}$, which we found in Appendix C of the article in Ref. 7.

V. TRANSVERSE POLARIZABILITY

To obtain the transverse polarizability, we need to apply the incident field $\mathbf{E}_0=\mathbf{u}_x$ corresponding to the potential $\phi_0=\cos\varphi$, which now depends on the coordinate φ. Fortunately, the solution is quite similar to the solution of the longitudinal case, in fact, the solutions are

$$\Phi_1(u,v,\varphi)=\cos\varphi\int_0^{\infty}c(\lambda)P^1_{-1/2+i\lambda}(\cosh u)\left(\frac{\cosh(v\lambda)}{\cosh(v_1\lambda)}\right)\mathrm{d}\lambda,$$

$$\Phi_2(u,v,\varphi)=\cos\varphi\int_0^{\infty}c(\lambda)P^1_{-1/2+i\lambda}(\cosh u)\left(\frac{\cosh((\pi-v)\lambda)}{\cosh((\pi-v_1)\lambda)}\right)\mathrm{d}\lambda.$$

The dependence of the coordinate φ causes no additional difficulties because it cancels out in the boundary conditions.

The function c should satisfy the integral equation

$$c(\lambda)-\int_0^{\infty}k(\lambda,\tau)c(\tau)\mathrm{d}\tau=f(\lambda), \tag{6}$$

where the kernel k and the function f are in this case given by expressions

$$k(\lambda,\tau)=-\frac{(1-\varepsilon)\sin v_1\tanh(\pi\lambda)\mathcal{K}(\lambda,\tau)}{2(\tanh(v_1\lambda)+\varepsilon\tanh((\pi-v_1)\lambda))},$$

$$f(\lambda)=\frac{(\varepsilon-1)\left(\sin v_1\mathcal{F}_{-1}\left(\frac{\cosh u}{R^5}\right)\right)}{\lambda(\tanh(v_1\lambda)+\varepsilon\tanh((\pi-v_1)\lambda))},$$

and the subkernel $\mathcal{K}$ is defined by the integral

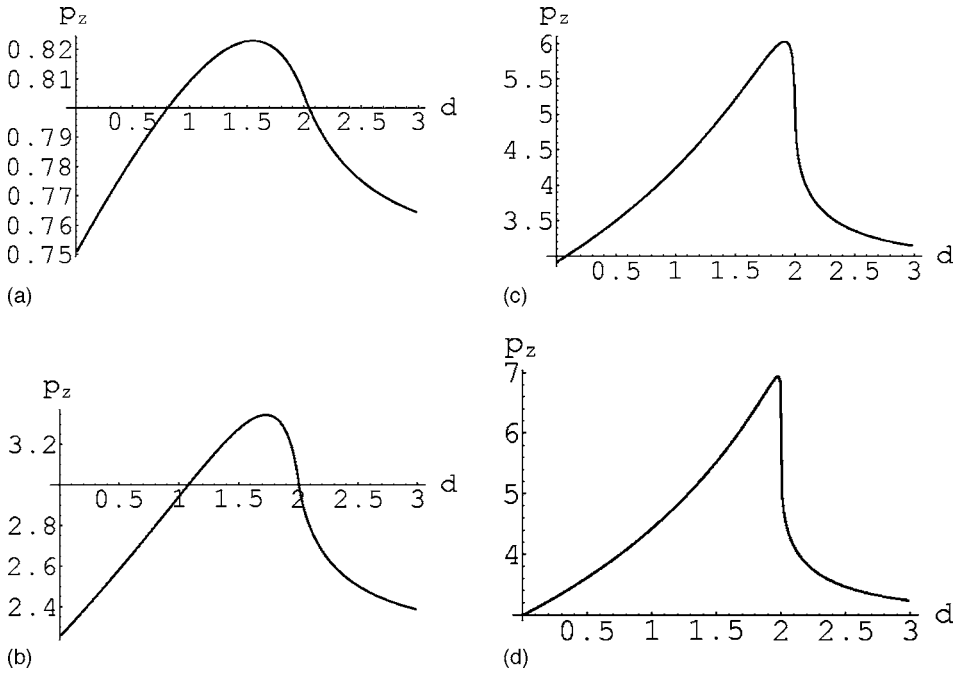

FIG. 4. Longitudinal polarizability as a function of d with different permittivities.

$$\mathcal{K}(\lambda,\tau)=\int_1^\infty \frac{P^{-1}_{-1/2+i\lambda}(p)P^{1}_{-1/2+i\tau}(p)}{p-\cos v_1}\mathrm{d}p.$$

The required Mehler-Fock transforms of order -1 can be derived from order 0 by differentiating the expressions with respect to coordinate u. Felderhof and Palaniappan[1] provide us with the metal limit

$$c_\infty=\frac{1}{2\sqrt{2}}\left(\frac{\cosh((\pi-v_1)\lambda)}{\cosh(\pi\lambda)}\right),$$

which, by taking the Mehler-Fock transform of order -1 of the incident potential, can be stated such that

$$c_\infty=-\mathcal{F}_{-1}\left(\frac{\cosh u}{R^3}\right).$$

Now, the differentiate this respect to the coordinate v_1 to obtain the missing term for the function f.

The transverse polarizability of the double sphere is obtained by looking the behavior of the potential ϕ on the neighborhood of the z axis, where the coordinate $u\approx 0$ and potential decays as x/z^3 for large z. Using the Taylor expansions $\sin v\approx v$ and $\cos v\approx 1-v^2/2$, we have $v\approx 2/z$ and $R\approx\sqrt{2}/z$ when z is large. This time we need also the expansion $\cosh(v\lambda)\approx 1$, which, together with the identity $P^1_{-1/2+i\lambda}(\cosh u)=\sinh u P'_{-1/2+i\lambda}(\cosh u)$, gives a farfield expression for the potential

$$\phi(z)=-2\sqrt{2}\frac{x}{z^3}\int_0^\infty \frac{(1+4\lambda^2)c(\lambda)}{\cosh(v_1\lambda)}\mathrm{d}\lambda,$$

where we have used the property $P'_{-1/2+i\lambda}(1)=-(1+4\lambda^2)/8$. Next, we can compare this and the potential of the $\mathbf{u}_z$ directed dipole to get the normalized longitudinal polarizability,

$$\alpha_x = -\frac{8\sqrt{2}\pi}{\mathcal{V}} \int_0^\infty \frac{(1+4\lambda^2)c(\lambda)}{\cosh(v_1\lambda)} d\lambda,$$

where $\mathcal{V}$ is the volume of the double sphere.

VI. CONCLUSION

The old electrostatic problem of a symmetric intersecting dielectric double sphere is solved explicitly for the first time. The solution is given in terms of an integral of a function c, which is given by a Neumann series. Using the high precision capabilities of the MATHEMATICA software package and efficient numerical integration techniques, the polarizabilities are implemented to real time calculations in the Java Applet:

`users.tkk.fi/~mpitkone/Kaksoispallo/Kaksoispallo.html`

where five-digit precision is achieved for the longitudinal polarizability and six-digit precision for the transversal polarizability. The results were verified at the metal limit $\varepsilon \to \infty$ using the solutions provided by Felderhof and Palaniappan.

Figure 4 represents the behavior of the longitudinal polarizability as a function of the separation d with different permittivity values. For values $d > 2$, the polarizability is calculated from the difference equation (3.9) of Ymeri's article[8] simply by solving that difference equation as an ordinary linear system. The same difference equation approach analysis was presented also in the article in Ref. 9 in 1976. It should be mentioned that Ymeri's article has a misprint in the formula (4.8), which should read as $\alpha_n = (n-1)(e^{-\eta_0} + \Delta_1 e^{-2n\eta_0})$. These results were verified at the metal limit using very accurate results from article in Ref. 10.

For the system driven by a stationary Markov process $\{\xi_t: t \in \mathbb{R}^+\}$, if it is in nonequilibrium steady state (i.e., irreversible), then there exists a function φ such that the fluctuation spectrum (or say: power spectrum density) of $\{\varphi(\xi_t)\}$ is nonmonotonic in $[0, +\infty)$ under mild conditions, which means that there exist nonzero spectrum peaks of the fluctuation spectrum. For the system driven by a Markov chain with discrete time $\{\xi_t: t \in \mathbb{Z}^+\}$, even if it is in equilibrium state (i.e., reversible), one cannot distinguish the equilibrium and nonequilibrium steady state in terms of the monotonicity of the fluctuation spectrum any more. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2338763]

I. INTRODUCTION

We explain the main terminology used, hoping that this paper can be interested by both the probability kingdom and the statistical physics kingdom readers. In the present paper, unlike the classical probability theory, equilibrium means not just a stationary distribution but a stationary distribution of the reversible Markov process, and the term "nonequilibrium steady state" means a stationary distribution of the irreversible Markov process.

It is significant to consider the fluctuation spectrums (or say: power spectrum, power spectrum density, spectrum density of fluctuation) in the study of nonequilibrium steady states and especially of stochastic resonance since they have immediate intuitive meaning and are readily measurable.[1,2] In Refs. 3–5, the authors proved that when a stationary Markov process $\{\xi_t: t \in \mathbb{R}^+\}$ is in an equilibrium state, the fluctuation spectrum of any stationary process $\{\varphi(\xi_t)\}$ (where φ is a complex-valued function) decreases monotonically on $[0, +\infty)$ as a function of the frequency.

The question naturally arises if there is some nonmonotonic fluctuation spectrum for a stationary Markov process $\{\xi_t: t \in \mathbb{R}^+\}$ in nonequilibrium steady state; in other words, whether monotonicity of all fluctuation spectrums characterizes equilibrium.

Reference 6 gives a positive answer to the above-presented question in the situation of continuous-time finite states Markov chains. It proves that if the process $\{\xi_t\}$ is in nonequilibrium steady state, then one can always find a complex function φ such that the fluctuation spectrum of $\{\varphi(\xi_t)\}$ is nonmonotonic on $[0, +\infty)$.

[a)]Electronic mail: chenyong77@gmail.com
[b)]Electronic mail: qianmp@math.pku.edu.cn
[c)]Electronic mail: js_xie@yahoo.com.cn

In the present paper, we extend the above-presented result to more general stationary Markov processes, including n-dimensional diffusions and denumerable Markov chains with continuous time. Under several mild technical conditions, we prove that the conclusion for the fluctuation spectrum in Ref. 6 remains true (see Theorem 2.1).

That is to say, for continuous-time Markov processes, equilibrium can be characterized by the monotonicity of all fluctuation spectrum under some technical conditions. For the nonequilibrium steady state Markov processes, the nonmonotonic fluctuation spectrums on $[0,\infty)$ mean that there exist off-zero peaks in the fluctuation spectrums. Reference 7 gave some criteria to show the stochastic resonance maximum in terms of the center frequency of the spectrum peak, spectrum peak height, and quality factor or signal-to-noise ratio. All the criteria are relevant to the off-zero peak in the fluctuation spectrums. The difference between Ref. 7 and this paper is that various values of the noise strength are not considered here.

But for a discrete-time irreducible aperiodic Markov chain $\{\xi_t: t\in\mathbb{Z}^+\}$ in equilibrium, if there exist two real eigenvalues λ_i and λ_j of the transient matrix P with $\lambda_i\cdot\lambda_j<0$ and $|\lambda_i|<1, |\lambda_j|<1$, then there exists a real function φ such that the fluctuation spectrum of $\{\varphi(\xi_t)\}$ is nonmonotonic on $[0,\pi]$, so one cannot distinguish the equilibrium and nonequilibrium steady state in terms of the monotonicity of the fluctuation spectrum any more. (see Sec. III). This gives an useful insight about continuous time Markov processes and explains why we treat only continuous time Markov processes on characterization of Markov processes in equilibrium by monotonicity of the fluctuation spectral density.

II. NONMONOTONIC FLUCTUATION SPECTRUM OF GENERAL STATIONARY MARKOV PROCESSES

In this section $\xi=\{\xi_t: t\geqslant 0\}$ always denotes a stationary Markov process, with its steady distribution written μ and infinitesimal generator written $\mathcal{A}$. The state space of the process is denoted by E, which is an abstract Polish space. The transition semigroup of the process is written $\{\mathsf{P}_t: t\geqslant 0\}$.

We shall need the following notations. Denote the real Hilbert space as $L^2(E,\mu)$. Denote the complex Hilbert space $\{h_1+\mathrm{i}h_2: h_1,h_2\in L^2(\mathrm{E},\mu)\}$ by $L^2_{\mathbb{C}}(E,\mu)$, where $\mathrm{i}=\sqrt{-1}$. The inner product on this complex Hilbert space is naturally defined by

$$\langle f,g\rangle=\int_E f(x)g^*(x)\mu(\mathrm{d}x),\quad \forall\, f,g\in L^2_{\mathbb{C}}(E,\mu),$$

where $g^*(x)$ stands for the conjugate complex number of $g(x)$, and the norm on $L^2_{\mathbb{C}}(E,\mu)$ as $\|\cdot\|$. For any $h\in L^2_{\mathbb{C}}(E,\mu)$, we write

$$\mu(h)=\int_E h(x)\mu(\mathrm{d}x),$$

$$\mathsf{P}_t h(x)=\int_E h(y)\mathsf{P}(t,x,\mathrm{d}y),$$

$$(\mathsf{P}_t-\mu)h(x)=\mathsf{P}_t h(x)-\mu(h).$$

Assume that $\{\mathsf{P}_t: t\geqslant 0\}$ is strongly continuous, i.e.,

$$\lim_{t\downarrow 0}\|\mathsf{P}_t f-f\|=0,\quad \forall\, f\in L^2_{\mathbb{C}}(E,\mu). \tag{1}$$

It is $L^2_{\mathbb{C}}(E,\mu)$ on which we consider the semigroup and the generator in the present paper. So if we suppose that $f\in\mathcal{D}(\mathcal{A})$ where $\mathcal{D}(\mathcal{A})$ is the domain of the operator $\mathcal{A}$, we mean that $f,\mathcal{A}f$

$\in L^2_{\mathbb{C}}(E,\mu)$ at the same time. Similarly, if we suppose $f \in \mathcal{D}(\mathcal{A}^2)$, we mean that $f, \mathcal{A}f, \mathcal{A}^2 f \in L^2_{\mathbb{C}}(E,\mu)$ at the same time.

A. Statement of the main results

Theorem 2.1: *For a continuous-time Markov process* $\{\xi_t\}$ *in nonequilibrium steady state, if there exist real functions* $f, g \in \mathcal{D}(\mathcal{A}^2) \cap L^2(E,\mu)$ *such that*

$$\langle \mathcal{A}^2 f, g\rangle - \langle f, \mathcal{A}^2 g\rangle \neq 0, \tag{2}$$

$$\begin{aligned} &\lim_{t\to+\infty} \langle \mathsf{P}_t f, \mathcal{A}^2 g\rangle = 0, \quad \lim_{t\to+\infty} \langle \mathsf{P}_t g, \mathcal{A}^2 f\rangle = 0, \\ &\lim_{t\to+\infty} t\langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle = 0, \quad \lim_{t\to+\infty} t\langle \mathsf{P}_t \mathcal{A} g, \mathcal{A}^2 f\rangle = 0, \end{aligned} \tag{3}$$

and

$$\begin{aligned} &t\langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 f\rangle, \quad t\langle \mathsf{P}_t \mathcal{A}^2 g, \mathcal{A}^2 g\rangle \in L^1([0,\infty)), \\ &t\langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 g\rangle, \quad t\langle \mathsf{P}_t \mathcal{A}^2 g, \mathcal{A}^2 f\rangle \in L^1([0,\infty)), \end{aligned} \tag{4}$$

then the fluctuation spectrum of either $\{\mathcal{A}^2 f(\xi_t) + \mathrm{i}\mathcal{A}^2 g(\xi_t)\}$ *or* $\{\mathcal{A}^2 f(\xi_t) - \mathrm{i}\mathcal{A}^2 g(\xi_t)\}$ *is nonmonotonic on* $[0,+\infty)$.

When we have some information on the point spectrum and the eigenfunctions of the generator $\mathcal{A}$ of the irreversible stationary Markov process, we can yield the following

Corollary 2.2: For a continuous-time Markov process $\{\xi_t\}$ *in nonequilibrium steady state, if any one of the following conditions is satisfied:*

1) *There exists a complex eigenvalue* $-a+\mathrm{i}\omega$ *of* $\mathcal{A}$ *corresponding to an eigenfunction* $f(x) + \mathrm{i}g(x)$ *such that* $a>0, \omega \neq 0$.
2) *There exist two distinct real eigenvalues* $\lambda_1<0, \lambda_2<0$ *of* $\mathcal{A}$ *corresponding to eigenfunctions* $f(x), g(x)$, *respectively, such that* $\langle f, g\rangle \neq 0$.
3) *There exists a real eigenvalue* $\lambda<0$ *of* $\mathcal{A}$ *and there exist general eigenfunctions* $f(x), g(x)$ *with the following property*

$$\mathcal{A}f(x) = \lambda f(x), \quad \mathcal{A}g(x) = f(x) + \lambda g(x),$$

then one can find a complex function φ *such that the fluctuation spectrum of* $\{\varphi(\xi_t)\}$ *is nonmonotonic on* $[0,+\infty)$.

B. Proof of the main results

In order to prove the main theorem, we need some propositions and lemmas.

Let $f_1, f_2 \in L^2(E,\mu)$ and $\varphi = f_1 + \mathrm{i}f_2$. Denote the autocorrelation function and the fluctuation spectrum of $\{\varphi(\xi_t)\}$ as $B_\varphi(t), S_\varphi(\omega)$, respectively, which are defined as

$$B_\varphi(t) = \mathbb{E}[(\varphi(\xi_t) - \mu(\varphi))((\varphi^*(\xi_0) - \mu(\varphi)^*))] \quad \text{if } t \geqslant 0,$$

$$B_\varphi(t) = \mathbb{E}[(\varphi(\xi_0) - \mu(\varphi))((\varphi^*(\xi_{-t}) - \mu(\varphi)^*))] \quad \text{if } t < 0,$$

$$S_\varphi(\omega) = \frac{1}{2\pi}\int e^{-\mathrm{i}\omega t} B_\varphi(t)\mathrm{d}t,$$

where $\mathbb{E}$ is the expectation operator with respect to the process ξ.

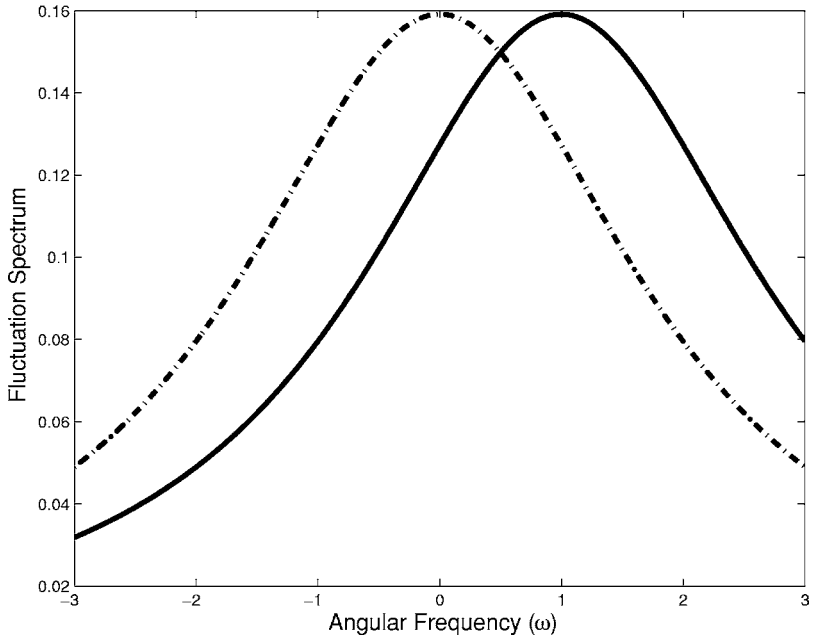

FIG. 1. Two fluctuation spectrums with the frequency limited on $[-3,3]$.

Lemma 2.3: If $B_\varphi(t) \in L^1(\mathbb{R})$, $S'_\varphi(\omega)$ *exists and* $[\mathrm{d}S_\varphi(\omega)]/\mathrm{d}\omega|_{\omega=0} > 0$, *then* $S_\varphi(\omega)$ *is nonmonotonic on* $[0,+\infty)$.

Proof: Since $B_\varphi(t) \in L^1(\mathbb{R})$, $\lim_{\omega\to+\infty} S_\varphi(\omega)=0$ by Riemann-Lebesgue's lemma. It is well known that $S_\varphi(\omega) \geqslant 0$, and since $S'_\varphi(0) > 0$, there exists some $\delta > 0$ such that $S_\varphi(\delta) > 0$.

Now suppose on the contrary that $S_\varphi(\omega)$ is monotonic in $[0,+\infty)$, then it must increase monotonically since $S'_\varphi(0) > 0$. Then $S_\varphi(\omega) \geqslant S_\varphi(\delta) > 0$ for all $\omega > \delta$. Therefore $\underline{\lim}_{\omega\to+\infty} S_\varphi(\omega) > 0$, a contradiction. □

Remark 1: Lemma 2.3 is the start point of the proof of the main theorem. The following sketch map gives two fluctuation spectrums with the frequency limited on $[-3,3]$. One is nonmonotonic on $[0,\infty)$ with $S'_\varphi(0) > 0$, the other is monotonic on $[0,\infty)$ with $S'_\varphi(0)=0$ (Fig. 1).

It is clear that

$$B_\varphi(t) = \langle \mathsf{P}_t\varphi,\varphi\rangle - |\mu(\varphi)|^2 = \langle (\mathsf{P}_t - \mu)\varphi,\varphi\rangle \quad \text{if } t \geqslant 0,$$

$$B_\varphi(t) = \langle \varphi,\mathsf{P}_{-t}\varphi\rangle - |\mu(\varphi)|^2 = \langle \varphi,(\mathsf{P}_{-t} - \mu)\varphi\rangle \quad \text{if } t < 0.$$

For $t \geqslant 0$, let us write

$$F(t) = \langle \mathsf{P}_t f_1, f_1\rangle - |\mu(f_1)|^2 + \langle \mathsf{P}_t f_2, f_2\rangle - |\mu(f_2)|^2,$$

$$G(t) = \langle f_1, \mathsf{P}_t f_2\rangle - \langle \mathsf{P}_t f_1, f_2\rangle.$$

Since the transition semigroup $\{\mathsf{P}_t : t \geqslant 0\}$ is strongly continuous, then one can get that $F(t)$ is a continuous function of t on $[0,\infty)$ by Proposition 4.3.1 of Ref. 5 (p. 112). And similarly that $G(t)$ is a continuous function of t on $[0,\infty)$.

Lemma 2.4: For the above complex-valued function φ, *we have*

$$B_\varphi(t) = F(|t|) + \mathrm{i}\cdot \mathrm{sgn}(t) G(|t|), \tag{5}$$

where $\mathrm{sgn}(t) := 1$ *for* $t \geqslant 0$ *and* $\mathrm{sgn}(t) := -1$ *for* $t < 0$. *And if* $F(t), G(t) \in L^1([0,\infty))$, *then* $S_\varphi(\omega)$ *exists and*

$$S_\varphi(\omega)=\frac{1}{\pi}\int_0^{+\infty}[F(t)\cos(\omega t)+G(t)\sin(\omega t)]\mathrm{d}t. \tag{6}$$

Proof: When $t\geqslant 0$, the correlation function of $\{\varphi(\xi_t)\}$ is

$$B_\varphi(t)=\langle \mathsf{P}_t\varphi,\varphi\rangle-|\mu(\varphi)|^2$$

$$=\langle \mathsf{P}_t f_1+\mathrm{i}\mathsf{P}_t f_2, f_1+\mathrm{i}f_2\rangle-|\mu(f_1)+\mathrm{i}\mu(f_2)|^2$$

$$=\langle \mathsf{P}_t f_1,f_1\rangle-|\mu(f_1)|^2+\langle \mathsf{P}_t f_2,f_2\rangle-|\mu(f_2)|^2$$

$$+\mathrm{i}(\langle f_1,\mathsf{P}_t f_2\rangle-\langle \mathsf{P}_t f_1,f_2\rangle)$$

$$=F(t)+\mathrm{i}G(t).$$

And when $t<0$,

$$B_\varphi(t)=B_\varphi^*(-t)=F(-t)-\mathrm{i}G(-t).$$

This means

$$B_\varphi(t)=F(|t|)+\mathrm{i}\cdot\mathrm{sgn}(t)G(|t|),\quad t\in\mathbb{R},$$

where $\mathrm{sgn}(\cdot)$ is the sign function. If $F(t),G(t)\in L^1([0,\infty))$, then it is clear that $B_\varphi(t)\in L^1(\mathbb{R})$. So the fluctuation spectrum exists and

$$S_\varphi(\omega)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}B_\varphi(t)\exp(-\mathrm{i}\omega t)\mathrm{d}t=\frac{1}{\pi}\int_0^{+\infty}F(t)\cos(\omega t)\mathrm{d}t+\frac{1}{\pi}\int_0^{+\infty}G(t)\sin(\omega t)\mathrm{d}t.$$

□

Lemma 2.5: If $tF(t),tG(t)\in L^1([0,\infty))$, *then* $S'_\varphi(\omega)$ *exists, and*

$$\frac{\mathrm{d}S_\varphi(\omega)}{\mathrm{d}\omega}=-\frac{1}{\pi}\int_0^{+\infty}t[F(t)\sin(\omega t)-G(t)\cos(\omega t)]\mathrm{d}t. \tag{7}$$

Especially,

$$S'_\varphi(0)=\frac{1}{\pi}\int_0^{+\infty}tG(t)\mathrm{d}t. \tag{8}$$

And if

$$\int_0^{+\infty}tG(t)\mathrm{d}t>0, \tag{9}$$

then the fluctuation spectrum of $\{\varphi(\xi_t)\}$ *is nonmonotonic on* $[0,+\infty)$.

Proof: Since $tF(t),tG(t)\in L^1([0,\infty))$, it is clear that $tB_\varphi(t)\in L^1(\mathbb{R})$. So $S'_\varphi(\omega)$ exists and by Lemma 2.4, we have

$$\frac{\mathrm{d}S_\varphi(\omega)}{\mathrm{d}\omega}=-\frac{1}{\pi}\int_0^{+\infty}t[F(t)\sin(\omega t)-G(t)\cos(\omega t)]\mathrm{d}t,$$

$$S'_{\varphi}(0) = \frac{1}{\pi}\int_0^{+\infty} tG(t)\mathrm{d}t.$$

If condition (9) is satisfied, then $S'_{\varphi}(0) > 0$. This ends the proof by Lemma 2.3. □

By Lemma 2.5, now the last key point is to find two real functions $f_1, f_2 \in L^2(\mathrm{E}, \mu)$ such that Eq. (9) is satisfied. The following lemma is needed.

Lemma 2.6: *For any Markov process* $\{\xi_t\}$ *in steady state, if* $f, g \in \mathcal{D}(\mathcal{A}^2) \cap L^2(E, \mu)$ *and*

$$\lim_{t\to+\infty} \langle \mathsf{P}_t f, \mathcal{A}^2 g\rangle = 0, \tag{10}$$

$$\lim_{t\to+\infty} t\langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle = 0, \tag{11}$$

then

$$\langle f, \mathcal{A}^2 g\rangle = \int_0^{+\infty} t\langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 g\rangle \mathrm{d}t. \tag{12}$$

Proof: When $t \geqslant 0$, by Kolmogorov equations,

$$\mathrm{d}\mathsf{P}_t f = \mathsf{P}_t \mathcal{A} f \mathrm{d}t,$$

$$\text{and} \quad \mathrm{d}\langle \mathsf{P}_t f, g\rangle = \langle \mathsf{P}_t \mathcal{A} f, g\rangle \mathrm{d}t.$$

Hence we have

$$\int_0^{+\infty} t\langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 g\rangle \mathrm{d}t = \int_0^{+\infty} t\mathrm{d}\langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle$$

$$= t\langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle|_{t=0}^{+\infty} - \int_0^{+\infty} \langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle \mathrm{d}t$$

$$= \lim_{t\to+\infty} t\langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle - \int_0^{+\infty} \langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle \mathrm{d}t$$

$$= -\int_0^{+\infty} \langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle \mathrm{d}t.$$

And by Kolmogorov equations again,

$$\int_0^{+\infty} \langle \mathsf{P}_t \mathcal{A} f, \mathcal{A}^2 g\rangle \mathrm{d}t = \int_0^{+\infty} \mathrm{d}\langle \mathsf{P}_t f, \mathcal{A}^2 g\rangle = \lim_{t\to+\infty} \langle \mathsf{P}_t f, \mathcal{A}^2 g\rangle - \langle f, \mathcal{A}^2 g\rangle = -\langle f, \mathcal{A}^2 g\rangle.$$

□

Now we start the proof of the main theorem and Corollary.

Proof of Theorem 2.1: Without loss of generality, let us assume $\langle \mathcal{A}^2 f, g\rangle - \langle f, \mathcal{A}^2 g\rangle > 0$. Let $f_1 = \mathcal{A}^2 f, f_2 = \mathcal{A}^2 g$. Since $\mu(\mathcal{A}^2 f) = \mu(\mathcal{A}^2 g) = 0$,

$$F(t) = \langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 f\rangle + \langle \mathsf{P}_t \mathcal{A}^2 g, \mathcal{A}^2 g\rangle,$$

$$G(t) = \langle \mathcal{A}^2 f, \mathsf{P}_t \mathcal{A}^2 g\rangle - \langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 g\rangle.$$

By condition (4), $tF(t), tG(t) \in L^1([0,\infty))$. Then $S'_\varphi(\omega)$ exists by Lemma 2.5.

By condition (3), the following equations

$$\int_0^{+\infty} t\langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 g\rangle \mathrm{d}t = \langle f, \mathcal{A}^2 g\rangle,$$

$$\int_0^{+\infty} t\langle \mathcal{A}^2 f, \mathsf{P}_t \mathcal{A}^2 g\rangle \mathrm{d}t = \langle \mathcal{A}^2 f, g\rangle$$

hold by Lemma 2.6.

By Eq. (8) of Lemma 2.5

$$S'_\varphi(0) = \frac{1}{\pi}\int_0^{+\infty} tG(t)\mathrm{d}t = \frac{1}{\pi}\int_0^{+\infty} t[\langle \mathcal{A}^2 f, \mathsf{P}_t \mathcal{A}^2 g\rangle - \langle \mathsf{P}_t \mathcal{A}^2 f, \mathcal{A}^2 g\rangle]\mathrm{d}t = \langle \mathcal{A}^2 f, g\rangle - \langle f, \mathcal{A}^2 g\rangle > 0.$$

Thus the fluctuation spectrum of $\{\varphi(\xi_t)\}$ is nonmonotonic by Lemma 2.5. □

Proof of Corollary 2.2: Conditions (2)–(4) of Theorem 2.1 are satisfied when applied with the functions $f(x)$ and $g(x)$ appearing in conditions 1), 2) or 3) of Corollary 2.2. This ends the proof.□

C. Applications

Example 1: If $\{\xi_t : t \in \mathbb{R}\}$ is a stationary continuous-time finite states Markov chain, if it is in nonequilibrium steady state, then by the Lemma 2.4 of Ref. 6, one of the conditions in Corollary 2.2 is satisfied at least. Thus one can always find a nonmonotonic fluctuation spectrum by Corollary 2.2.

Example 2: For Ornstein-Uhlenbeck equation (or Langevin equation)

$$\begin{bmatrix} \mathrm{d}X_1(t) \\ \mathrm{d}X_2(t) \end{bmatrix} = \begin{bmatrix} -r & \Omega \\ -\Omega & -r \end{bmatrix} \begin{bmatrix} X_1(t) \\ X_2(t) \end{bmatrix} \mathrm{d}t + \sigma \begin{bmatrix} \mathrm{d}B_1(t) \\ \mathrm{d}B_2(t) \end{bmatrix}, \tag{13}$$

where $r > 0, \Omega > 0$ (Ref. 8, pp. 181–186), the generator is

$$\mathcal{A} = (-rx + \Omega y)\frac{\partial}{\partial x} + (-\Omega x - ry)\frac{\partial}{\partial y} + \frac{1}{2}\sigma^2 \cdot \triangle, \tag{14}$$

with the stationary distribution

$$\mu(\mathrm{d}x, \mathrm{d}y) = \frac{r}{\pi\sigma^2} \exp\left\{-\frac{r(x^2+y^2)}{\sigma^2}\right\} \mathrm{d}x\mathrm{d}y. \tag{15}$$

Since $-r+\mathrm{i}\Omega$ is the complex eigenvalue of the generator $\mathcal{A}$ corresponding to the eigenfunction $x-\mathrm{i}y$, the generator $\mathcal{A}$ is a nonsymmetric operator with respect to μ. So the existence of a nonmonotonic fluctuation spectrum is solved by Corollary 2.2.

Example 3: Let $\{\xi_t : t \in \mathbb{R}^1\}$ be a continuous-time Markov chain, with the state space $E = \{-2,-1,0,1,2,\ldots\}$ and the transition rate matrix

$$\mathsf{Q} = \begin{bmatrix} -1 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 0 & -1 & 1 & 0 & 0 & 0 & \cdots \\ 1 & 0 & -2 & 1 & 0 & 0 & \cdots \\ 0 & 0 & 2 & -4 & 2 & 0 & \cdots \\ 0 & 0 & 0 & 4 & -7 & 3 & \cdots \\ 0 & 0 & 0 & 0 & 6 & -10 & \cdots \\ \vdots & \ddots & \ddots & & & & \end{bmatrix}.$$

That is $q_{-2,-1}=q_{-1,0}=q_{0,-2}=1$, and when $n\geqslant 0$, $q_{n,n+1}=n+1$ and $q_{n,n-1}=2n$. Clearly the steady distribution μ is defined by $\mu(-2)=\mu(-1)=1/4$, and $\mu(n)=1/4(1/2)^n$ for $n\geqslant 0$. Let $f(x)=\delta_{-2,x}$ and $g(x)=\delta_{-1,x}$, where the Kronecker delta $\delta_{-2,x}$ is 1 when x is equal to -2, and is 0 otherwise. One can check that condition (2) is satisfied. By Ref. 9, Theorem 3, Ref. 10, Theorem 6.5 and Example 4.57 in Ref. 11, pp. 162, it is clear that this Markov chain is exponentially ergodic. And since $\mathcal{A}f(x), \mathcal{A}g(x), \mathcal{A}^2 f(x), \mathcal{A}^2 g(x)$ are all compact supported, conditions (3) and (4) are valid. Therefore a nonmonotonic fluctuation spectrum is found by Theorem 2.1.

III. FLUCTUATION SPECTRUM FOR DISCRETE-TIME MARKOV CHAINS IN EQUILIBRIUM

Let $\{\xi_t : t\in\mathbb{Z}^+\}$ be a discrete-time finite states Markov chain, and let P be its $k\times k$ irreducible probability transition matrix, where k is the number of states. If $\{\xi_t\}$ is in equilibrium state, then all the eigenfunctions of P can be chosen to be orthonormal with respect to the steady distribution μ, and denote them by $\{f_1, f_2, \ldots, f_k\}$, and let λ_i be the eigenvalue of the matrix P corresponding to the eigenfunction f_i. We might as well let $\lambda_1=1$ with the eigenvector $f_1=(1,1,\ldots,1)$. For any complex function $\varphi\in\mathbb{C}^k$, let $\varphi=\Sigma_{j=1}^k a_j f_j$. Denote the autocorrelation function and the fluctuation spectrum of $\{\varphi(\xi_t)\}$ as $B_\varphi(t), S_\varphi(\omega)$, respectively, which are defined as

$$B_\varphi(t) = \mathbb{E}[(\varphi(\xi_t)-\mu(\varphi))((\varphi^*(\xi_0)-\mu(\varphi)^*))] \quad \text{if } t\in\mathbb{Z}^+,$$

$$B_\varphi(t) = \mathbb{E}[(\varphi(\xi_0)-\mu(\varphi))((\varphi^*(\xi_{-t})-\mu(\varphi)^*))] \quad \text{if } t\in\mathbb{Z}^-,$$

$$S_\varphi(\omega) = \frac{1}{2\pi}\sum_{t=-\infty}^{\infty} B_\varphi(t)e^{-\mathrm{i}t\omega}, \quad -\pi\leqslant\omega\leqslant\pi,$$

where $\mathbb{E}$ is the expectation operator with respect to the process ξ.

And similar to Refs. 6 and 12, based on elementary facts of self-adjoint operators in finite dimensional spaces and obvious elementary calculus, one can obtain that

Proposition 3.1: If $\{\xi_t : t\in\mathbb{Z}^+\}$ *is in equilibrium state, and its probability transition matrix* P *is irreducible, then*

$$B_\varphi(t) = \sum_{i=2}^{k} |a_i|^2 \lambda_i^{|t|}, \quad t\in\mathbb{Z}. \tag{16}$$

If P *is aperiodic in addition, then the fluctuation spectrum of* $\{\varphi(\xi_t)\}$ *exists and*

$$S_\varphi(\omega) = \frac{1}{2\pi}\sum_{i=2}^{k} |a_i|^2 \frac{1-\lambda_i^2}{1+\lambda_i^2-2\lambda_i\cos\omega}. \tag{17}$$

In particular, the fluctuation spectrum is monotonic if and only if all eigenvalues of the irreducible, aperiodic transient matrix P *which are not equal to 1 have same signs.*

Example 4:

$$P = \begin{bmatrix} 0 & \frac{1}{4} & \frac{3}{4} \\ \frac{1}{4} & \frac{1}{2} & \frac{1}{4} \\ \frac{3}{4} & \frac{1}{4} & 0 \end{bmatrix}.$$

The above transition matrix is obviously symmetrical with an equilibrium state $\mu = (1/3, 1/3, 1/3)$. Clearly $-3/4, 1/4$ are two eigenvalues with different signs. This example shows the existence of the nonmonotonic fluctuation spectrum for the discrete-time Markov chains in equilibrium.

IV. CONCLUSION

For continuous-time Markov processes, equilibriums can be characterized by the monotonicity of all fluctuation spectrum under some good conditions. For discrete-time irreducible aperiodic Markov chains, one cannot distinguish the equilibrium and nonequilibrium steady state in terms of the monotonicity of the fluctuation spectrum any more.

(Received 16 June 2006; accepted 16 August 2006; published online 11 October 2006)

The solutions of the nonlinear diffusion equation $\partial_t\rho=r^{1-\mathcal{N}}\mathcal{D}\partial_r\{r^{\mathcal{N}-1-\theta}\rho^\gamma\partial_r[r^{-\eta}\rho^\nu]\}-r^{1-\mathcal{N}}\partial_r[r^{\mathcal{N}-1}\mathcal{F}\rho]$ are investigated by considering the presence of an external force $\mathcal{F}$ which exhibits an explicit dependence on the distribution. First, the stationary case is considered; after that the dynamical case, i.e., the case dependent on time. The stationary solution is obtained by considering the external force $\mathcal{F}(r;\rho)=\mathcal{F}_1(r)+\mathcal{F}_2(r)[\rho(r)]^{\nu+\gamma-1}$ and the result found is related to the distributions which emerge from the Tsallis statistics or the Boltzmann-Gibbs statistics. The dynamical solution is investigated by considering the external force $\mathcal{F}(r,t;\rho)=-k(t)r+\mathcal{K}/r^{1+\theta+\eta}[\rho(r,t)]^{\gamma+\nu-1}$ and related to the Levy distributions in the asymptotic limit. In both cases, the solutions are expressed in terms of the q-exponentials and the q-logarithmics functions which emerge from the Tsallis formalism. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2354334]

I. INTRODUCTION

The broadness of the anomalous diffusion processes covering many physical contexts has motivated the study of several approaches.[1–8] One of them is based on the nonlinear diffusion equations[4] which has been used to investigate many situations such as percolation of gases through porous media,[9] thin saturated regions in porous media,[10] a standard solid-on-solid model for surface growth, thin liquid films spreading under gravity,[11] the axisymmetric flow of a very viscous fluid,[12] turbulent diffusion,[13] and the nonlinear diffusion in hard and soft superconductors.[14] A representative nonlinear diffusion equation is the *porous medium equation* ($\partial_t\rho=\mathcal{D}\nabla^2\rho^\nu$) which has been intensively investigated. In fact, it has been analyzed by considering several situations such as the presence of external forces,[15] a spatial time dependent diffusion coefficient,[16–18] and reaction diffusion terms.[19] In this direction, in Refs. 20 and 21 was obtained a Langevin equation related to the porous medium equation and in Refs. 22 and 23 the connection between the solutions and distribution of probability that emerges from the Tsallis formalism was investigated. The escape time, or mean first passage time, has also been studied leading eventually to a generalization of the Arrhenius law.[24] However, the presence of nonlinear drift in the porous medium equation and its connection with the Tsallis formalism[25] or the usual thermostatistics (Boltzmann-Gibbs statistics)[26] have not been properly investigated. Thus, we dedicate the present work to establish some classes of solutions of a general nonlinear diffusion equation and investi-

[a)]Electronic mail: eklenzi@dfi.uem.br

gate the connections with the Tsallis formalism and the usual thermostatistics. We focus our attention on the following generalized equation:

$$\frac{\partial}{\partial t}\rho(r,t)=\frac{\mathcal{D}}{r^{\mathcal{N}-1}}\frac{\partial}{\partial r}\left\{r^{\mathcal{N}-1-\theta}[\rho(r,t)]^{\gamma}\frac{\partial}{\partial r}[r^{-\eta}(\rho(r,t))^{\nu}]\right\}-\frac{1}{r^{\mathcal{N}-1}}\frac{\partial}{\partial r}\{r^{\mathcal{N}-1}\mathcal{F}(r,t;\rho)\rho(r,t)\},\tag{1}$$

where $\mathcal{D}$ is a (dimensionless) diffusion coefficient, r is non-negative, $\mathcal{N}$ represents the dimension of the system, $\mathcal{F}(r,t;\rho)$ is a (dimensionless) nonlinear convection or transport term (external force). For $\alpha(t)=0$, it can be verified that $\int_0^\infty dr r^{\mathcal{N}-1}\rho(r,t)$ is time independent (hence, if ρ is normalized at $t=0$, it will remain so forever). Indeed, if we write the equation in the $\partial_t\rho=r^{1-\mathcal{N}}\partial_r\mathcal{J}$ form and assume the boundary condition $\mathcal{J}(\infty,t)\to 0$, it can be shown that $\int_0^\infty dr r^{\mathcal{N}-1}\rho(r,t)$ is a constant of motion. Note that Eq. (1) has as particular case several situations such as mentioned above and also recovers, for $(\eta,\gamma,\theta,\nu)=(0,0,0,1)$ and $\mathcal{F}(r,t;\rho)=0$ the standard Fokker-Planck equation[27] in the absence of drift and to $(\eta,\gamma,\theta,\nu,\mathcal{N})=(0,0,0,1,1)$ with $\mathcal{F}(r,t;\rho)=\mathcal{K}[\rho(r,t)]^2/2$ the Burgers equation[28] in the one-dimensional case. Thus, our present discussion involves extensions of these cases taking a wide variety of situations into account by employing a nonlinear diffusion equation with a nonlinear convection or transport term. In particular, in Sec. II, we consider several situations for Eq. (1) by starting to the stationary case and after we analyze the dynamical, i.e., the time dependent solutions. For the stationary case, we consider the external force $\mathcal{F}(r;\rho)=\mathcal{F}_1(r)+\mathcal{F}_2(r)[\rho(r)]^{\nu+\gamma-1}$ ($\mathcal{F}_1(r)$ and $\mathcal{F}_2(r)$ are arbitrary functions) and for the time dependent case we employ $\mathcal{F}(r,t;\rho)=-k(t)r+\mathcal{K}/r^{1+\theta+\eta}[\rho(r,t)]^{\nu+\gamma-1}$ ($k(t)$ is a time dependent function and $\mathcal{K}$ is a constant). In Sec. III, we present our conclusions.

II. NONLINEAR DIFFUSION EQUATION

Let us start our study by investigating the stationary solutions for Eq. (1). For this case, by taking into account the external force $\mathcal{F}(r;\rho)=\mathcal{F}_1(r)+\mathcal{F}_2(r)[\rho(r)]^{\nu+\gamma-1}$ and employing the stationary condition,[27,29] we can reduce Eq. (1) to

$$\mathcal{D}r^{-\theta}[\rho(r)]^{\gamma}\frac{d}{dr}[r^{-\eta}(\rho(r))^{\nu}]-\mathcal{F}_1(r)\rho(r)-\mathcal{F}_2(r)[\rho(r)]^{\nu+\gamma}=0\tag{2}$$

for an arbitrary $\mathcal{N}$. Note that this equation has a nonlinear diffusive term and also a nonlinear convection or transport term. This nonlinear term incorporated in the external force may produce in the solution a new behavior to the stationary solution which was not present in the results found in Refs. 15–17. In fact, the solution which emerges from this equation may present two behaviors, one of them is a power-law (Tsallis formalism) and the other is an exponential (Boltzmann-Gibbs statistics). In order to show this feature and obtain the solution of this equation, we may use the procedure employed by Plastino and Plastino in Ref. 22 which is based on the Tsallis formalism.[25] Following Ref. 22, we consider the solution given by

$$\rho(r)=r^{\eta/\nu}\exp_q[-\mathcal{G}(r)]/\mathcal{Z},\tag{3}$$

where $\mathcal{G}(r)$ is determined by the equation which emerges by substituting Eq. (3) in Eq. (2), $\mathcal{Z}$ is obtained from the normalization condition, and $\exp_q$ is the q-exponential present in the Tsallis formalism. The $\exp_q$ is given by $\exp_q[x]=(1+(1-q)x)^{1/(1-q)}$ if $1+(1-q)x\geqslant 0$ and $\exp_q[x]=0$ if $1+(1-q)x<0$ and it emerges from the Tsallis formalism by maximizing the Tsallis entropy $S_q=(1-\int dx(\rho(x))^q)/(q-1)$ with suitable constraints. Substituting Eq. (3) in Eq. (2) and taking $q=2-\nu-\gamma$ into account, the equation satisfied by $\mathcal{G}(r)$ is

$$\frac{d}{dr}\mathcal{G}(r)-(1-q)r^{\eta+\theta}\frac{\mathcal{F}_2(r)}{\mathcal{D}\nu}\mathcal{G}(r)=-\frac{r^{\theta+\eta}}{\mathcal{D}\nu}\left[\mathcal{F}_2(r)+\left(\frac{\mathcal{Z}}{r^{\frac{\eta}{\nu}}}\right)^{\gamma+\nu-1}\mathcal{F}_1(r)\right].\tag{4}$$

The solution for this equation is given by

$$\mathcal{G}(r) = -\frac{\mathcal{Z}^{\nu+\gamma-1}}{\mathcal{D}\nu}\int_0^r d\bar{r}\bar{r}^{(\eta/\nu)(1-\gamma)+\theta}\mathcal{F}_1(\bar{r})\exp\left(-\frac{1-q}{\mathcal{D}\nu}\left[\int_0^{\bar{r}} d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\eta+\theta} - \int_0^r d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\eta+\theta}\right]\right) - \ln_q\left[\exp\left(\frac{1}{\mathcal{D}\nu}\int_0^r d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\theta+\eta}\right)\right], \tag{5}$$

where $\ln_q[x]=(x^{1-q}-1)/(1-q)$ is the q-logarithmic function which is the inverse function of the above-defined q-exponential. By applying Eq. (5) in Eq. (3) we found the stationary solution

$$\rho(r) = r^{\eta/\nu}\exp_q\left[\frac{\mathcal{Z}^{\nu+\gamma-1}}{\mathcal{D}\nu}\int_0^r d\bar{r}\bar{r}^{(\eta/\nu)(1-\gamma)+\theta}\mathcal{F}_1(\bar{r})\exp\left(-\frac{1-q}{\mathcal{D}\nu}\left(\int_0^{\bar{r}} d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\eta+\theta} - \int_0^r d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\eta+\theta}\right)\right) + \ln_q\left[\exp\left(\frac{1}{\mathcal{D}\nu}\int_0^r d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\theta+\eta}\right)\right]\right] \Big/ \mathcal{Z}. \tag{6}$$

From Eq. (6), we note that the stationary solution may behave, as we mentioned before, as a Boltzmann-Gibbs distribution or as a Tsallis distribution depending on the choice of $\mathcal{F}_1(r)$ and $\mathcal{F}_2(r)$. In fact, by taking $\mathcal{F}_1(r)=0$ in Eq. (6) we obtain $\rho(r)=r^{\eta/\nu}\exp((1/\mathcal{D}\nu)\int_0^r d\tilde{r}\mathcal{F}_2(\tilde{r})\tilde{r}^{\theta+\eta})/\mathcal{Z}$ which essentially behaves like a Boltzmann-Gibbs distribution and for $\mathcal{F}_2(r)=0$ we obtain the Tsallis distribution $\rho(r)=r^{\eta/\nu}\exp_q[\mathcal{Z}^{\nu+\gamma-1}\int_0^r d\bar{r}\bar{r}^{(\eta/\nu)(1-\gamma)+\theta}\mathcal{F}_1(\bar{r})/\mathcal{D}\nu]/\mathcal{Z}$. The presence of a stationary solution with an exponential behavior like the Boltzmann-Gibbs distribution indicates that the solution may have an anomalous relaxation to a usual stationary solution. A similar effect is verified in the fractional diffusion equations which employ a time fractional derivative.[3] In Fig. 1, we illustrate by using numerical calculation based on the method of finite difference[30] how a solution of Eq. (1) for a typical choice of $\mathcal{F}_1(r)$ and $\mathcal{F}_2(r)$, for simplicity, in the one-dimensional case, evolves in time and has Eq. (6) as stationary solution.

Now, we consider the dynamical case by taking into account the external force $\mathcal{F}(r,t;\rho)=-k(t)r+\mathcal{K}/r^{1+\theta+\eta}[\rho(r,t)]^{\gamma+\nu-1}$ which depends on the distribution of the system. For this case, after substituting this external force in Eq. (1) we obtain

$$\frac{\partial}{\partial t}\rho(r,t) = \frac{\mathcal{D}}{r^{\mathcal{N}-1}}\frac{\partial}{\partial r}\left\{r^{\mathcal{N}-1-\theta}[\rho(r,t)]^{\gamma}\frac{\partial}{\partial r}[r^{-\eta}(\rho(r,t))^{\nu}]\right\} + \frac{1}{r^{\mathcal{N}-1}}\frac{\partial}{\partial r}\left\{r^{\mathcal{N}-1}\left[k(t)r - \frac{\mathcal{K}}{r^{1+\theta+\eta}}[\rho(r,t)]^{\gamma+\nu-1}\right]\rho(r,t)\right\}. \tag{7}$$

In order to obtain the solution for this case, we use, for simplicity, the similarity method to reduce this partial differential equation to ordinary differential equations. The explicit form for these ordinary differential equations depends on the boundary conditions or on restrictions in the form of conservation laws. Thus, we restrict our analysis to the solutions of the type

$$\rho(r,t) = \left[\frac{1}{\Phi(t)}\right]^{\mathcal{N}}\mathcal{P}\left(\frac{r}{\Phi(t)}\right), \tag{8}$$

which need to satisfy the initial, the boundary conditions, and the normalization condition. By substituting Eq. (8) in Eq. (7) we obtain

$$-\frac{\dot{\Phi}(t)}{(\Phi(t))^2}\frac{d}{dz}[z^{\mathcal{N}}\mathcal{P}(z)] = \frac{\mathcal{D}}{(\Phi(t))^{\xi}}\frac{d}{dz}\left\{z^{\mathcal{N}-1-\theta}[\mathcal{P}(z)]^{\gamma}\frac{d}{dz}[z^{-\eta}(\mathcal{P}(z))^{\nu}]\right\} + \frac{k(t)}{\Phi(t)}\frac{d}{dz}[z^{\mathcal{N}}\mathcal{P}(z)] - \frac{1}{(\Phi(t))^{\xi}}\frac{d}{dz}\left\{z^{\mathcal{N}-1}\left[\frac{\mathcal{K}}{z^{1+\theta+\eta}}(\mathcal{P}(z))^{\gamma+\nu}\right]\right\}, \tag{9}$$

where $\xi=3+\theta+\eta+\mathcal{N}(\gamma+\nu-1)$ and $z=r/\Phi(t)$. From Eq. (9) we can obtain

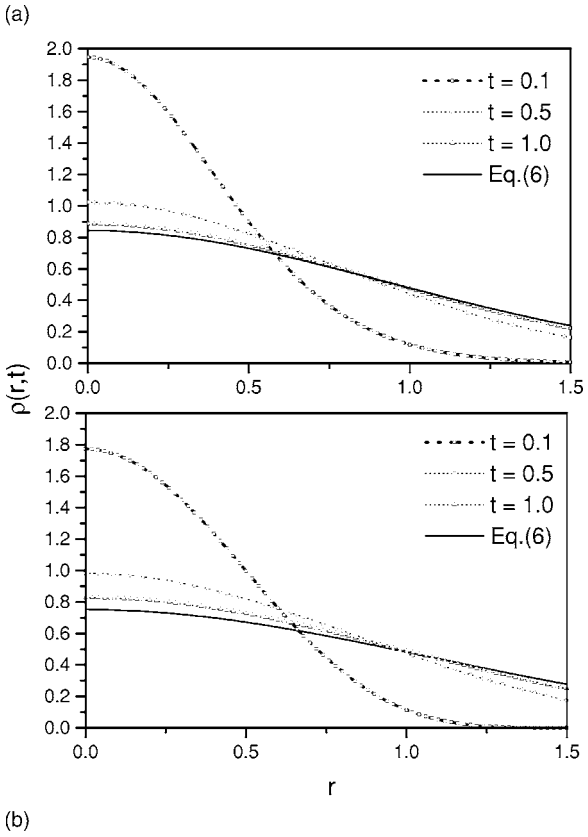

FIG. 1. Behavior of $\rho(r,t)$ vs r, which illustrates Eq. (1) for typical values of ν and t by considering, for simplicity, $\mathcal{D}=1$, $\gamma=0$, $\theta=0$, $\eta=0$, $\mathcal{N}=1$, $\mathcal{F}_1(r)=0$, and $\mathcal{F}_2(r)=-kr$ with $k=1$. In (a), we illustrated the case characterized by $\nu=0.9$ and in (b) the case $\nu=1.2$. Note that in both cases the solutions for long time have the stationary case given by Eq. (6).

$$\frac{\dot{\Phi}(t)}{(\Phi(t))^2}+\frac{k(t)}{\Phi(t)}=\frac{k'}{(\Phi(t))^{\xi}} \tag{10}$$

and

$$-k'\frac{\mathrm{d}}{\mathrm{d}z}[z^{\mathcal{N}}\mathcal{P}(z)]=\mathcal{D}\frac{\mathrm{d}}{\mathrm{d}z}\left\{z^{\mathcal{N}-1-\theta}[\mathcal{P}(z)]^{\gamma}\frac{\mathrm{d}}{\mathrm{d}z}[z^{-\eta}(\mathcal{P}(z))^{\nu}]\right\}-\frac{\mathrm{d}}{\mathrm{d}z}\left\{z^{\mathcal{N}-1}\left[\frac{\mathcal{K}}{z^{1+\theta+\eta}}(\mathcal{P}(z))^{\gamma+\nu}\right]\right\} \tag{11}$$

by introducing the constant of separation k' which can be determined by the normalization condition. After some calculations, we obtain that the solution to Eq. (10) is given by

$$\Phi(t)=\left[(\Phi(0))^{\xi-1}+(\xi-1)k'\int_0^t \mathrm{d}\tilde{t}e^{(\xi-1)\int_0^{\tilde{t}}\mathrm{d}t'k(t')}\right]^{1/(\xi-1)}e^{-\int_0^t \mathrm{d}t'k(t')}. \tag{12}$$

Note that similar solutions for the time dependent function have been found for different nonlinear fractional diffusion equations.[31–35] This fact indicates that different diffusion equations have a similar anomalous spreading for the probability distribution and the difference is on the parameters present in the diffusion equation. From this solution it is also possible to obtain the behavior of spreading of Eq. (7) by using $\rho(0,t)$, since for this case $\langle r^2\rangle \propto 1/[\rho(0,t)]^2 \propto [\Phi(t)]^2$. Thus, depending on the parameters ν,γ,θ, and η, we may have an anomalous or usual behavior for the spreading and consequently to the second moment. In particular, for the case characterized by the

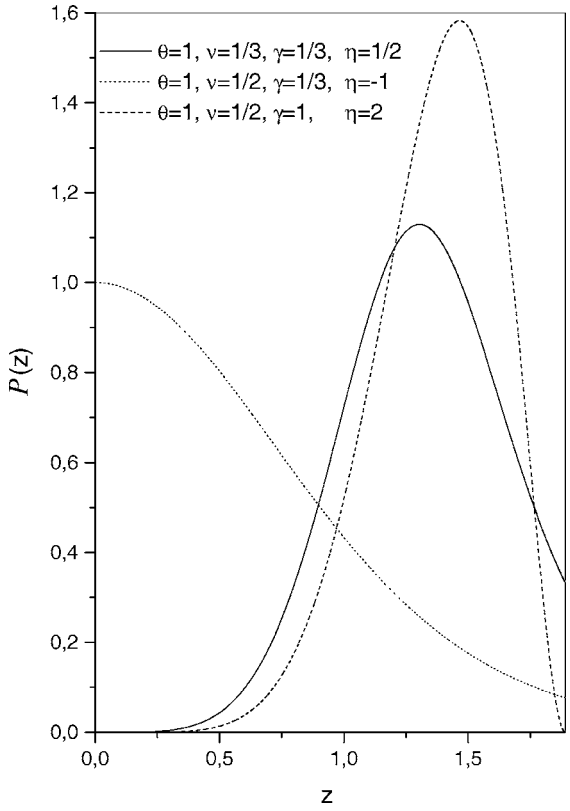

FIG. 2. Behavior of $\mathcal{P}(z)$ vs z, which illustrates Eq. (14) for typical values for θ, ν, η, and γ, for simplicity, by taking into account $\mathcal{K}=1$, $\mathcal{N}=1$, and $\mathcal{D}=1$. Notice that depending on the choice of these parameters the distribution may have a compact or a long tail behavior.

absence of external forces the second moment is $\langle r^2\rangle \sim t^{2/(\xi-1)}$, where $\xi>3, \xi=3$ or $\xi<3$ lead us to a subdiffusive, normal or superdiffusive behavior, respectively. Now let us address our discussion to the solution of Eq. (11). Performing an integration in Eq. (11) results in

$$-k' z^{\mathcal{N}}\mathcal{P}(z) = \mathcal{D} z^{\mathcal{N}-1-\theta}[\mathcal{P}(z)]^{\gamma}\frac{\mathrm{d}}{\mathrm{d}z}[z^{-\eta}(\mathcal{P}(z))^{\nu}] - \mathcal{K} z^{\mathcal{N}-(2+\theta+\eta)}[\mathcal{P}(z)]^{\gamma+\nu} + \mathcal{C}. \tag{13}$$

We take $\mathcal{C}=0$ in order to simplify our analysis about the solutions which satisfy the boundary condition $\mathcal{P}(z\to\infty)\to 0$. By applying the last consideration in Eq. (13), after some calculation we obtain that

$$\mathcal{P}(z) = z^{\eta/\nu+\mathcal{K}/\mathcal{D}\nu}\exp_q\left[-\frac{k' z^{\bar{\xi}}}{\mathcal{D}\nu\bar{\xi}}\right], \tag{14}$$

where $q=2-\nu-\gamma$ and $\bar{\xi}=2+\theta+\eta(1-\gamma)/\nu-\mathcal{K}(\nu+\gamma-1)/(\mathcal{D}\nu)$ (see Fig. 2). Note that the behavior of Eq. (14) can be compact or characterized by long tail depending on the parameters η, ν, γ, and θ. For the last case, we may relate the solution obtained to the Levy distributions in the asymptotic limit. In fact, by taking the asymptotic limit of the above equation for large z ($\mathcal{P}(z) \sim 1/z^{(2+\theta+\eta)/(q-1)}$) and comparing to the asymptotic limit of the Levy distributions ($\mathcal{P}(z) \sim 1/z^{1+\mu}$)[8] we obtain $q=(3+\theta+\eta+\mu)/(1+\mu)$. Now, in order to show the explicit form of the time dependent solution for this case, we substitute Eq. (14) in Eq. (8) to obtain

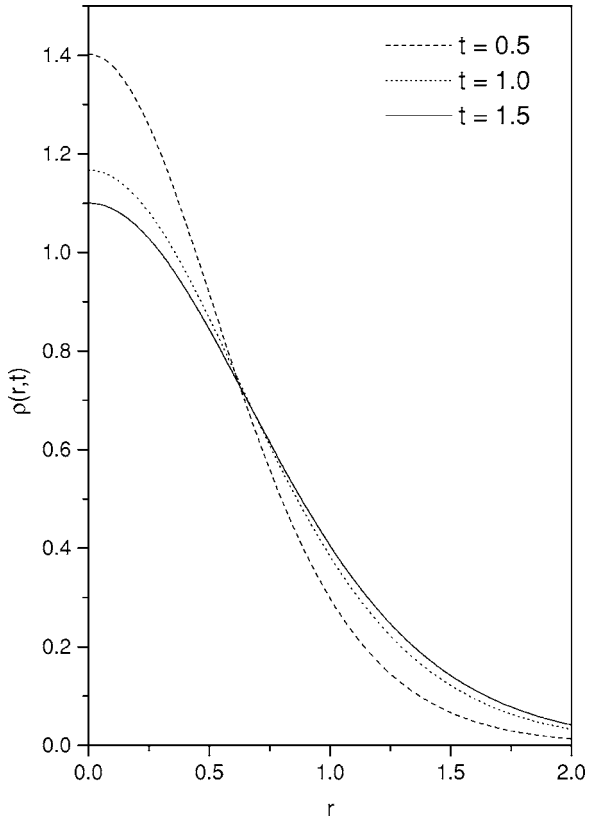

FIG. 3. Behavior of $\rho(r,t)$ vs r, which illustrates how Eq. (15) evolves on the time for $\theta=1$, $\nu=1/2$, $\eta=-1$, and $\gamma=1/3$, for simplicity, by taking into account $\mathcal{K}=1$, $\mathcal{N}=1$, $\Phi(0)=0$, $k(t)=1$, and $\mathcal{D}=1$.

$$\rho(r,t)=\left(\frac{1}{\Phi(t)}\right)^{\mathcal{N}}\left(\frac{r}{\Phi(t)}\right)^{\eta/\nu+\mathcal{K}/\mathcal{D}\nu}\exp_q\left[-\frac{k'}{\mathcal{D}\nu\bar{\xi}}\left(\frac{r}{\Phi(t)}\right)^{\bar{\xi}}\right] \tag{15}$$

with $\Phi(t)$ defined by Eq. (12) (see Fig. 3).

III. SUMMARY AND CONCLUSION

In summary, we have worked out an $\mathcal{N}$-dimensional nonlinear diffusion equation by considering a nonlinear convective or transport term. We have analyzed a stationary solution and a time dependent case which emerge from this equation. For the stationary case it was verified that the solution obtained may present a power-law or an exponential behavior. Thus for the first case, it was possible to relate the solution found here with the Tsallis formalism and in the second case may be established a connection to the Boltzmann-Gibbs formalism. The last behavior is very interesting since it indicates that the solution may have an anomalous relaxation to the usual stationary solution. Similar behavior is found in the fractional diffusion equations which employ a time fractional time derivative. For the time dependent case, we have shown that it admits exact solutions where space scales with a function of time and lead us to a power-law distribution with a compact or a long tailed behavior depending on the parameters values $\nu,\theta,\eta,\gamma,\mathcal{K}$, and $\mathcal{D}$. In particular, for the case characterized by a long tailed behavior, the distribution was connected to the Levy distribution in the asymptotic limit. However, it is interesting to note that the time dependent solution has a power-law behavior due to the choice of the convective term. Other choices to this term may lead us to obtain different solutions. Finally, we hope that the results obtained here may be useful to study physical systems exhibiting anomalous diffusion.

(Received 31 May 2006; accepted 28 August 2006; published online 26 October 2006)

We study the variance and the Laplace transform of the probability law of linear eigenvalue statistics of unitary invariant Matrix Models of $n \times n$ Hermitian matrices as $n \to \infty$. Assuming that the test function of statistics is smooth enough and using the asymptotic formulas by Deift *et al.* [Commun. Pure Appl. Math. **52**, 1325–1425 (1999)] for orthogonal polynomials with varying weights, we show first that if the support of the Density of States of the model consists of $q \geq 2$ intervals, then in the global regime the variance of statistics is a quasiperiodic function of n as $n \to \infty$ generically in the potential, determining the model. We show next that the exponent of the Laplace transform of the probability law is not, in general, $1/2 \times$ variance, as it should be if the Central Limit Theorem would be valid, and we find the asymptotic form of the Laplace transform of the probability law in certain cases. © *2006 American Institute of Physics.*

I. INTRODUCTION

Random matrix theory deals mostly with eigenvalue distributions of various ensembles of $n \times n$ random matrices as $n \to \infty$. Many questions of this branch of the theory can be formulated in terms of the Eigenvalue Counting Measure $\mathcal{N}_n$, $\mathcal{N}_n(\Delta_n)$ is the number of eigenvalues in a given part Δ_n of the spectrum of a matrix M_n. In a particular case of $n \times n$ Hermitian matrices, eigenvalues are real, and we can write for $\Delta_n \subset \mathbb{R}$,

$$\mathcal{N}_n(\Delta_n) := \#\{\lambda_l^{(n)} \in \Delta_n, l = 1, \ldots, n\} = \sum_{l=1}^{n} \chi_{\Delta_n}(\lambda_l^{(n)}), \tag{1.1}$$

where χ_Δ is the indicator of Δ. A more general object is a linear eigenvalue statistic, defined as

$$\mathcal{N}_n[\varphi_n] := \sum_{l=1}^{n} \varphi_n(\lambda_l^{(n)}) = \mathrm{Tr}\, \varphi_n(M_n) = \int_{\mathbb{R}} \varphi_n(\lambda) \mathcal{N}_n(d\lambda), \tag{1.2}$$

for a certain test function,

$$\varphi_n : \mathbb{R} \to \mathbb{C}. \tag{1.3}$$

It is known that in many cases there exists a scaling of matrix entries (i.e., a choice of the scale of the spectral axis), such that for a sufficiently big class of n-independent intervals in (1.1) [test functions in (1.2)] the Normalized Counting Measure of eigenvalues,

[a)]Permanent address: Institute for Low Temperatures, 47 Lenin's Ave, 61103 Kharkiv, Ukraine; electronic mail: lpastur@ilt.kharkov.ua

$$N_n = \mathcal{N}_n/n, \tag{1.4}$$

converges weakly to a non-random measure N, known as the Integrated Density of States measure (IDS) of the ensemble,

$$N_n \to N. \tag{1.5}$$

The corresponding scale (asymptotic regime) is called the *global* (or *macroscopic*). The convergence is either in probability or even with probability 1. We refer the reader to the works in Refs. 19, 9, and 30, where this fact is proved and discussed for two most widely studied classes of random matrix ensembles: the Wigner Ensembles (independent or weakly dependent entries) and the Matrix Models (invariant matrix probability laws). Analogous facts are also known for many other ensembles.

Besides, in many cases the measure N possesses a bounded and continuous density:[16,29]

$$N(d\lambda) = \rho(\lambda)d\lambda. \tag{1.6}$$

We call ρ the Density of States (DOS) of the ensemble.

These results can be viewed as analogs of the Law of Large Numbers of probability theory. Hence, a natural next question, important also for applications, concerns the limiting probability law of fluctuation of the Normalized Counting Measures of eigenvalues or their linear statistics, i.e., an analog of the Central Limit Theorem of probability theory. The question is not going to be completely trivial, because eigenvalues of random matrices are strongly dependent, and, as a result, the variance of the linear statistics (1.2) with a C^1 test function does not grow with n [see, e.g., formulas (2.36) and (2.37) later]. Nevertheless, it was found that in a variety of cases, the fluctuations of various spectral characteristics of eigenvalues of random matrix ensembles are asymptotically Gaussian (see, e.g., Refs. 5, 6, 13, 15, 18, 19, 21, 23–25, and 35–39). In particular, for the global scale and a C^1 test function in (1.2), this requires, roughly speaking, the same order of magnitude of the entries for the Wigner Ensembles (see Refs. 19 and 25 for exact conditions, similar to the Lindeberg condition of the probability theory), and for the Matrix Models one needs to assume that the support of the IDS (1.5) is a connected interval of the spectral axis:[23] $\operatorname{supp} N = [a,b]$. The last result was obtained by using variational techniques, introduced in the random matrix theory in the paper in Ref. 9 in order to prove (1.5).

Being applicable to Matrix Models of all three symmetry classes of the random matrix theory (real symmetric, Hermitian, and quaternion real matrices), the variational techniques were efficient so far in the study of fluctuations of eigenvalue statistics only in the case where $\operatorname{supp} N = [a,b]$. In this paper we consider only the Matrix Models of Hermitian matrices, but for a general case of a multi-interval support of N:

$$\sigma := \operatorname{supp} N = \bigcup_{l=1}^{q} [a_l, b_l], \quad q \geq 1. \tag{1.7}$$

In this case we can use the recent powerful results by Deift *et al.*[17] on the asymptotics of a special class of orthogonal polynomials. We find that if φ is smooth enough, then the traditional Central Limit Theorem is not always valid for the case $q \geq 2$. In particular, the variance and the probability law oscillate in n as $n \to \infty$, hence their limiting form depends on a sequence $n_j \to \infty$. Moreover, the limiting probability laws are not always Gaussian.

The paper is organized as follows. In Sec. II we study the variance of linear eigenvalue statistics in the global regime, i.e., for n-independent φ in (1.2), confining ourselves mostly to the case of C^1 test functions φ. We find that the variance is quasiperiodic in n, in general, and its frequency module is determined by the charges

$$\beta_l = N([a_{l+1}, \infty)), \quad l = 1, \ldots, q-1, \tag{1.8}$$

determined by the IDS of (1.5) and its support (1.7). Hence, the variance has no limit as $n \to \infty$ for $q \geq 2$ and its asymptotic forms are indexed by points of the subset $\mathbb{H}^{q-1} \subset \mathbb{T}^{q-1}$, which is the closure of limit points of the vectors,

$$(\{\beta_1 n\}, \ldots, \{\beta_{q-1} n\}) \in \mathbb{T}^{q-1}, \tag{1.9}$$

where $\{\beta_l n\}, l = 1, \ldots, q-1$ are the fractional parts of $\beta_l n, l = 1, \ldots, q-1$. This phenomenon has been already found in certain cases,[3,8] but we give its general description.

In Sec. III we study the Laplace transform of the probability law of linear eigenvalue statistics (1.2) in the global regime, passing to the limit along a subsequence,

$$(\{\beta_1 n_j(x)\}, \ldots, \{\beta_{q-1} n_j(x)\}) \to x \in \mathbb{H}^{q-1}, \tag{1.10}$$

and confining ourselves to real analytic test functions. We give first a general formula for the corresponding limit. Since the formula is rather complex, we consider several particular cases, where we show that the exponent of the limiting [in the sense (1.10)] Laplace transform is not quadratic in φ, hence the limiting law is not Gaussian [see formulas (3.1), (3.13), (3.19), and (3.20)]. This has to be compared with results of the paper in Ref. 14, according to which the limits of variance and the probability law are the same for all sequences $n_j \to \infty$ (i.e., exist), and the limiting probability law is Gaussian.

The random matrix theory deals also with two more asymptotic regimes in addition to the global one. Namely, if, having fixed the global spectral scale allowing us to prove (1.5), we set in (1.2),

$$\varphi_n(\lambda) = \varphi((\lambda - \lambda_0) n^{\alpha}), \quad 0 < \alpha < 1, \quad \lambda_0 \in \operatorname{supp} N, \tag{1.11}$$

where φ is n independent, we obtain the *intermediate* regime, and if

$$\varphi_n(\lambda) = \varphi((\lambda - \lambda_0) n), \quad \lambda_0 \in \operatorname{supp} N, \tag{1.12}$$

then we have the *local* (or *microscopic*) regime. In Sec. IV we discuss the form of variance and the validity of the CLT in these regimes.

In the Appendix we compute the variational derivative of β_1 in the case $q=2$, which is used in Sec. III, and discuss related topics.

We note that a completely rigorous derivation of the results of this paper, especially those of Sec. III, requires rather technical and tedious arguments. They will not be presented in this paper. Rather, we confine ourselves to the presentation of results, their discussion, and outline of corresponding proofs.

II. VARIANCE OF LINEAR EIGENVALUE STATISTICS

A. Generalities

Recall that unitary invariant Matrix Models are $n \times n$ Hermitian random matrices, defined by the probability law

$$\mathbf{P}_n(dM_n) = Z_n^{-1} \exp\{-n \operatorname{Tr} V(M_n)\} dM_n, \tag{2.1}$$

where $M_n = \{M_{jk}\}_{j,k=1}^n, M_{jk} = \overline{M_{kj}}$,

$$dM_n = \prod_{j=1}^n dM_{jj} \prod_{1 \leq j < k \leq n} d\Re M_{jk}\, d\Im, M_{jk},$$

and $V: \mathbb{R} \to \mathbb{R}_+$ is a continuous function, called the potential, and such that

$$V:\mathbb{R}\to\mathbb{R}_+,\quad V(\lambda)\geq(2+\delta)\log|\lambda|,\quad |\lambda|>L, \tag{2.2}$$

for some positive δ and L.

The limit (1.5) can be described as follows.[9,23] Consider the functional:

$$\mathcal{E}_V[m]=-\int_{\mathbb{R}}\int_{\mathbb{R}}\log|\lambda-\mu|m(d\lambda)m(d\mu)+\int_{\mathbb{R}}V(\lambda)m(d\lambda), \tag{2.3}$$

where m is a non-negative unit measure.

The variational problem, defined by (2.3), goes back to Gauss and is called the minimum energy problem in the external field V. The unit measure N minimizing (2.3) is called the equilibrium measure in the external field V because of its evident electrostatic interpretation as the equilibrium distribution of linear charges on the ideal conductor occupying the axis $\mathbb{R}$ and confined by the external electric field of potential V. We stress that the respective minimizing procedure determines both the support σ of the measure and the form of the measure. This should be compared with the variational problem of the theory of logarithmic potential, where the external field is absent but the support σ is given [see (2.50)]. The minimum energy problem in the external field (2.3) arises in various domains of analysis and its applications (see a recent book[34] for a rather complete account of results and references concerning the problem).

The measure N and its support σ are uniquely determined by the Euler-Lagrange equation of the variational problem:[9,34]

$$V_{\mathrm{eff}}(\lambda)=F,\quad \lambda\in\sigma, \tag{2.4}$$

$$V_{\mathrm{eff}}(\lambda)\geq F,\quad \lambda\notin\sigma, \tag{2.5}$$

where

$$V_{\mathrm{eff}}(\lambda)=V(\lambda)-2\int_\sigma\log|\lambda-\mu|N(d\mu), \tag{2.6}$$

and F is a constant [the Lagrange multiplier of the normalization condition $N(\mathbb{R})=1$].

According to Ref. 9 (see also Ref. 23), if the potential V in (2.1) and (2.2) satisfies the local Lipshitz condition,

$$|V(\lambda_1)-V(\lambda_2)|\leq C|\lambda_1-\lambda_2|^\gamma,\quad |\lambda_1|,|\lambda_2|\leq L, \tag{2.7}$$

valid for any $L>0$ and some positive C and γ; then (1.5) holds with probability 1, and N is the minimizer of (2.3). Moreover, if V' is continuously differentiable, and the support (1.7) is a finite union of disjoint finite intervals, then (1.6) is valid[16,29] and the Density of States can be written as

$$\rho(\lambda)=P(\lambda)\sqrt{R_q(\lambda)},\quad \lambda\in\sigma, \tag{2.8}$$

where $P(\lambda)$ is a continuous function,

$$\sqrt{R_q(\lambda)}=\sqrt{R_q(z)}\big|_{z=\lambda+i0},\quad R_q(z)=\prod_{l=1}^{q}(z-a_l)(z-b_l), \tag{2.9}$$

and $\sqrt{R_q(z)}$ is the branch, determined by the condition $\sqrt{R_q(z)}=z^q+O(z^{q-1}), z\to\infty$. To obtain these formulas, provided that the support (1.7) is given, we differentiate (2.4) and (2.6) and obtain the singular integral equation,

$$\text{v.p.}\int_\sigma\frac{\rho(\mu)d\mu}{\mu-\lambda}=-\frac{V'(\lambda)}{2},\quad \lambda\in\sigma. \tag{2.10}$$

Then the bounded solution of the equation has the form (2.8) (see, e.g., Ref. 28) in which

$$P(\lambda) = \frac{1}{2\pi^2} \int_\sigma \frac{V'(\mu) - V'(\lambda)}{\mu - \lambda} \frac{d\mu}{\sqrt{R_q(\mu)}}. \tag{2.11}$$

The endpoints of the support are rather complex functionals of the potential, in general. Thus, it is of interest to mention a simple case.[11]

Let $v : \mathbb{R} \to \mathbb{R}$ be a monic polynomial of degree q with real coefficients. Assume that for some $g > 0$ all zeros of $v^2 - 4g$ are real and simple and set

$$V(\lambda) = \frac{v^2(\lambda)}{2gq}. \tag{2.12}$$

Then the DOS of the matrix model (2.1) with this potential is

$$\rho(\lambda) = \frac{|v'(\lambda)|}{2\pi g q} |v^2(\lambda) - 4g|^{1/2}, \quad \lambda \in \sigma, \tag{2.13}$$

where

$$\sigma = \{\lambda \in \mathbb{R} : v^2(\lambda) \leq 4g\}. \tag{2.14}$$

Besides, in this case we have for the charges (1.8),

$$\beta_l = \frac{q-l}{q}, \quad l = 1, \ldots, q-1, \tag{2.15}$$

hence the set $\mathbb{H}^{q-1}$ is $\{0, 1/q, \ldots, (q-1)/q\}$.

The case $q = 1$ corresponds to the Gaussian Unitary Ensemble and (2.13) yields the semicircle law by Wigner:

$$V = \frac{\lambda^2}{2g}, \quad \sigma = [-2g, 2g], \quad \rho(\lambda) = \frac{1}{2\pi g} \begin{cases} \sqrt{4g - \lambda^2}, & \lambda \in \sigma, \\ 0, & \lambda \notin \sigma. \end{cases} \tag{2.16}$$

In the case $q = 2$ and

$$v(\lambda) = \lambda^2 - m^2, \quad m^2 > 2\sqrt{g}, \tag{2.17}$$

we have

$$\sigma = [-b, -a] \cup [a, b], \quad a = \sqrt{m^2 - 2\sqrt{g}}, \quad b = \sqrt{m^2 + 2\sqrt{g}}, \tag{2.18}$$

and

$$\rho(\lambda) = \frac{|\lambda|}{2\pi g} \begin{cases} \sqrt{(b^2 - \lambda^2)(\lambda^2 - a^2)}, & \lambda \in \sigma, \\ 0, & \lambda \notin \sigma. \end{cases} \tag{2.19}$$

We will use in this paper the expressions for the variance of linear statistics (1.2) and for the Laplace transform of their probability law via special orthogonal polynomials. The technique dates back to works by Dyson, Gaudin, Mehta, and Wigner of the 1960s (see, e.g., Ref. 27). Namely, we have for the joint probability density of eigenvalues of ensemble (2.1):

$$p_n(\lambda_1, \ldots, \lambda_n) = (\det\{\psi_{j-1}^{(n)}(\lambda_k)\}_{j,k=1}^n)^2 / n!, \tag{2.20}$$

where

$$\psi_l^{(n)} = e^{-nV/2} P_l^{(n)}, \tag{2.21}$$

and

$$\{P_l^{(n)}\}_{l\geq 0} \tag{2.22}$$

is the system of orthonormal polynomials with respect to the weight

$$w_n = e^{-nV}, \tag{2.23}$$

so that

$$\int_{\mathbb{R}} e^{-nV(\lambda)} P_l^{(n)}(\lambda) P_m^{(n)}(\lambda) d\lambda = \delta_{l,m}, \quad l,m = 0,1,\ldots . \tag{2.24}$$

The polynomials satisfy the three-term recurrence relation for $l=0,1,\ldots$:

$$r_l^{(n)}\psi_{l+1}^{(n)}(\lambda) + s_l^{(n)}\psi_l^{(n)}(\lambda) + r_{l-1}^{(n)}\psi_{l-1}^{(n)}(\lambda) = \lambda\psi_l^{(n)}(\lambda), \quad r_{-1}^{(n)} = 0, \tag{2.25}$$

thereby determining a semi-infinite Jacobi matrix:

$$J_{j,k}^{(n)} = r_j^{(n)}\delta_{j+1,k} + s_k^{(n)}\delta_{j,k} + r_{j-1}^{(n)}\delta_{j-1,k}, \quad j,k = 0,1,\ldots . \tag{2.26}$$

By using (2.20) it can be shown that[28]

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\} = \frac{1}{2}\int_{\mathbb{R}}\int_{\mathbb{R}} |\varphi(\lambda_1) - \varphi(\lambda_2)|^2 K_n^2(\lambda_1,\lambda_2)\, d\lambda_1 d\lambda_2, \tag{2.27}$$

$$= \int_{\mathbb{R}}\int_{\mathbb{R}} \left|\frac{\Delta\varphi}{\Delta\lambda}\right|^2 \mathcal{V}_n(\lambda_1,\lambda_2) d\lambda_1\, d\lambda_2, \tag{2.28}$$

where

$$K_n(\lambda_1,\lambda_2) = \sum_{l=0}^{n-1} \psi_l^{(n)}(\lambda_1)\psi_l^{(n)}(\lambda_2) \tag{2.29}$$

is known as the reproducing kernel of the system (2.21),

$$\frac{\Delta\varphi}{\Delta\lambda} = \frac{\varphi(\lambda_1) - \varphi(\lambda_2)}{\lambda_1 - \lambda_2}, \tag{2.30}$$

and

$$\mathcal{V}_n(\lambda_1,\lambda_2) = \{r_{n-1}^{(n)}[\psi_n^{(n)}(\lambda_1)\psi_{n-1}^{(n)}(\lambda_2) - \psi_{n-1}^{(n)}(\lambda_1)\psi_n^{(n)}(\lambda_2)]\}^2/2. \tag{2.31}$$

Note that in passing from (2.27) and (2.28), we used the Christoffel-Darboux formula,[40]

$$K_n(\lambda_1,\lambda_2) = r_{n-1}^{(n)}\frac{\psi_n^{(n)}(\lambda_1)\psi_{n-1}^{(n)}(\lambda_2) - \psi_{n-1}^{(n)}(\lambda_1)\psi_n^{(n)}(\lambda_2)}{\lambda_1 - \lambda_2}. \tag{2.32}$$

It is of interest to have a spectral-theoretic interpretation of the above formulas. Notice that the $J^{(n)}$ of (2.26) determines a self-adjoint operator, that we denote again as $J^{(n)}$. It acts in $l^2(\mathbb{Z}_+)$, and the matrix

$$\mathcal{E}^{(n)}(d\lambda) = e^{(n)}(\lambda)d\lambda, \quad e^{(n)}(\lambda) = \{e_{lm}^{(n)}(\lambda)\}_{l,m=0}^{\infty}, \quad e_{lm}^{(n)}(\lambda) = \psi_l^{(n)}(\lambda)\psi_m^{(n)}(\lambda) \tag{2.33}$$

is its resolution of identity.[1] This allows us to write (2.31) in the form

$$\mathcal{V}_n(\lambda_1,\lambda_2) = (r_{n-1}^{(n)})^2(e_{n,n}^{(n)}(\lambda_1)e_{n-1,n-1}^{(n)}(\lambda_2) + e_{n,n}^{(n)}(\lambda_2)e_{n-1,n-1}^{(n)}(\lambda_1) - 2e_{n-1,n}^{(n)}(\lambda_1)e_{n,n-1}^{(n)}(\lambda_2))/2. \tag{2.34}$$

Assume now that φ satisfies the Hölder condition:

$$|\varphi(\lambda_1) - \varphi(\lambda_2)| \le C|\lambda_1 - \lambda_2|, \tag{2.35}$$

for some positive C. It follows then from (2.24) and (2.28)–(2.31) that

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\} \le C^2(r_{n-1}^{(n)})^2. \tag{2.36}$$

It can be shown[33] that if the potential satisfies the local Lipshitz condition (2.7), then the coefficients $r_{n-1}^{(n)}$ are bounded in n. We conclude that the variance of a linear statistic (1.2) is bounded in n if the test function satisfies (2.35):

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\} \le \mathrm{Const}. \tag{2.37}$$

This has to be compared with the well known fact of probability theory, according to which the variance of a linear statistics of i.i.d. random variables is $O(n)$ for any test function.

B. Asymptotic behavior of $\psi_l^{(n)}(\lambda)$

We present now powerful asymptotic formulas for orthonormal functions $\psi_l^{(n)}$ of (2.21)–(2.24) of Deift *et al.*,[17] valid in the case of a real analytic potential V in (2.1). We give a bit different form that will be more convenient later. Our form is reminiscent of standard semiclassical formulas and is similar to that, given in Refs. 7 and 8. Notice that Ref. 8 contains another, although heuristic, derivation of the asymptotic formulas as well as an interesting heuristic explanation of the quasiperiodicity of formulas for $q \ge 2$, based on ideas of statistical mechanics and quantum field theory.

Assume that V is real analytic. Then the support (1.7) of N is a union of $q < \infty$ finite disjoint intervals.[17] The function P in (2.8), (2.11) is also real analytic. Following Ref. 17, we say that V is regular if the inequality (2.5) is strict and P is strictly positive on σ. Hence, the DOS ρ of (1.6) is strictly positive inside σ and vanishes precisely like a square root at the endpoints. Denote

$$N(\lambda) = N([\lambda, \infty)). \tag{2.38}$$

According to Ref. 17, in the regular case there exist functions $d_n(\lambda)$, and $\gamma_n(\lambda)$ such that if λ belongs to the interior of the support (1.7), then

$$\psi_n^{(n)}(\lambda) = (2d_n(\lambda))^{1/2}\cos(\pi n N(\lambda) + \gamma_n(\lambda)) + O(n^{-1}), \quad n \to \infty. \tag{2.39}$$

Moreover, $d_n(\lambda)$ and $\gamma_n(\lambda)$ depend on n via the vector $n\beta$, where $\beta = (\beta_1, \ldots, \beta_{q-1})$ is given by (1.8). This means that there exist n-independent continuous functions $\mathcal{D}: \sigma \times \mathbb{T}^{q-1} \to \mathbb{R}_+$, and $\mathcal{G}: \sigma \times \mathbb{T}^{q-1} \to \mathbb{R}$, such that

$$d_n(\lambda) = \mathcal{D}(\lambda, n\beta), \quad \gamma(\lambda) = \mathcal{G}(\lambda, n\beta). \tag{2.40}$$

If λ belongs to the exterior of σ, then $\psi_n^{(n)}(\lambda)$ decays exponentially in n as $n \to \infty$.

Similar asymptotic formulas are valid for coefficients of the Jacobi matrix $J^{(n)}$ of (2.26), i.e., there exist n-independent continuous functions $\mathcal{R}: \mathbb{T}^{q-1} \to \mathbb{R}_+$ and $\mathcal{S}: \mathbb{T}^{q-1} \to \mathbb{R}$ such that

$$r_{n-1}^{(n)} = \mathcal{R}(n\beta) + O(n^{-1}), \quad s_n^{(n)} = \mathcal{S}(n\beta) + O(n^{-1}), \quad n \to \infty. \tag{2.41}$$

The functions $\mathcal{D}, \mathcal{G}, \mathcal{R}$, and $\mathcal{S}$ can be expressed via the Riemann theta function, associated in the standard way with a two-sheeted Riemann surface obtained by gluing together two copies of the complex plane slit along the gaps $(b_1, a_2), \ldots, (b_{q-1}, a_q), (b_q, a_1)$ of the support of the measure N, the last gap goes through infinity.

The components of the vector $\beta = \{\beta_l\}_{l=1}^{q-1}$ are rationally independent generically in V; thus the functions $\mathcal{D}(\lambda, n\beta), \mathcal{G}(\lambda, n\beta), \mathcal{R}(n\beta)$, and $\mathcal{S}(n\beta)$ are quasiperiodic in n, in general.

We will also need asymptotic formulas for $\psi_{n+k}^{(n)}$ as $n\to\infty$ and $k=O(1)$ [in particular, we need the case $k=-1$ in (2.31)]. They can be extracted from Ref. 17 (see also Ref. 8), but it will be convenient to present a different derivation, because the corresponding argument will be used in our analysis of limiting laws for linear eigenvalue statistics. To this end we replace a regular potential V in (2.20) by $V/g, g>0$, introducing explicitly the amplitude of the potential. Then the quantities of asymptotic formulas (2.38)–(2.41) will depend on g, and it follows from the results of Ref. 17 and 26 that these quantities will be differentiable functions of g in a certain neighborhood of $g=1$, provided that the support (1.7) for $g=1$ consists of q disjoint intervals. Consider now $r_{n+k-1}^{(n)}(g)$. Taking into account that the origin of the super-index n in the above formulas is the factor n in front of V in (2.23), we can write

$$n\frac{V}{g}=(n+k)\frac{V}{g(1+k/n)}. \tag{2.42}$$

In other words, to obtain $r_{n+k-1}^{(n)}(g)$ and $\psi_{n+k}^{(n)}(\lambda,g)$, we have to make the change

$$g\to g+\frac{k}{n}g \tag{2.43}$$

in the inverse amplitude of the potential. We obtain, in view of (2.41), for $k=o(n)$:

$$r_{n+k-1}^{(n)}(g)=r_{n+k-1}^{(n+k)}((1+k/n)g)\simeq\mathcal{R}((1+k/n)g,(n+k)\beta((1+k/n)g))\simeq\mathcal{R}(g,n\beta(g)+k\alpha(g)), \tag{2.44}$$

where

$$\alpha(g)=(g\beta(g))', \tag{2.45}$$

and the symbol "$\simeq$" denotes here and below the leading term(s) of the corresponding lhs as $n\to\infty$.

We have an analogous formula for (2.38):

$$(n+k)N(\lambda,(1+k/n)g)\simeq nN(\lambda,g)+k\nu(\lambda,g),$$

where

$$\nu(\lambda,g)=\frac{\partial}{\partial g}(gN(\lambda,g)). \tag{2.46}$$

By using these formulas, we can write for any fixed k [in fact $k=o(n)$]:

$$\psi_{n+k}^{(n)}(\lambda,g)\simeq(2\mathcal{D}(\lambda,g,n\beta+k\alpha))^{1/2}\cos(\pi nN(\lambda,g)+\pi k\nu(\lambda,g)+\mathcal{G}(\lambda,g,n\beta+k\alpha)). \tag{2.47}$$

Applying to (2.44) and its analog for $s_{n+k}^{(n)}$ the limiting procedure (1.10), we obtain the coefficients

$$r_{k-1}(x)=\mathcal{R}(x+k\alpha),\quad s_k(x)=\mathcal{S}(x+k\alpha),\quad x\in\mathbb{T}^{q-1},\ k\in\mathbb{Z}. \tag{2.48}$$

They determine a family of the double infinite Jacobi matrices $J(x), x\in\mathbb{T}^{q-1}$:

$$(J(x)\psi)_k=r_k(x)\psi_{k+1}+s_k(x)\psi_k+r_{k-1}(x)\psi_{k-1},\quad k\in\mathbb{Z}, \tag{2.49}$$

that can be viewed as a quasiperiodic operator, acting in $l^2(\mathbb{Z})$.

Consider now the functional

$$\mathcal{E}[m] = -\int_{\sigma} \log|\lambda - \mu| m(d\lambda) m(d\mu), \tag{2.50}$$

defined on unit non-negative measures, whose support is contained in σ. This is the standard variational problem of the potential theory.[34] Denote ν the unique minimizer of (2.50). Then, according to Ref. 12 (see also Refs. 11 and 29), the nonincreasing function $\nu(\lambda) = \nu([\lambda, \infty))$ [cf. (2.38)] coincides with the function, defined in (2.46). Moreover, according to Ref. 31 the measure ν is the Integrated Density of States (IDS) measure of $J(x)$ (see Ref. 32 for a definition of the IDS measure in a general setting of ergodic operators), the support (1.7) is a spectrum of $J(x)$, and [cf. (1.8)]

$$\alpha_l = \nu([a_l, \infty)), \quad l = 1, \ldots, q-1 \tag{2.51}$$

are the frequencies of quasiperiodic coefficients (2.48) of $J(x)$. In other words, $J(x)$ is a "finite band" Jacobi matrix, well known in spectral theory and integrable systems.[41]

By using these facts and also taking into account that $\psi_n^{(n)}(\lambda)$ decays exponentially in n outside the support,[17] we can prove that for any continuous $\Phi: \mathbb{R} \to \mathbb{C}$ of a compact support we have, in the limit (1.10) of (2.33),

$$\lim_{n_j(x)\to\infty} \int_{\mathbb{R}} \Phi(\lambda) e^{(n)}_{n_j(x)+l, n_j(x)+m}(\lambda) d\lambda = \int_{\sigma} \Phi(\lambda) e_{lm}(\lambda, x) d\lambda, \tag{2.52}$$

where we have for $\lambda \in \sigma$:

$$e_{lm}(\lambda, x) = \psi_l^+(\lambda, x)\overline{\psi_m^+(\lambda, x)} + \psi_l^-(\lambda, x)\overline{\psi_m^-(\lambda, x)}, \tag{2.53}$$

$$\psi_l^+(\lambda, x) = e^{i\pi l \nu(\lambda)} \mathcal{U}(\lambda, x + l\alpha), \quad \mathcal{U}(\lambda, x) = (\mathcal{D}(\lambda, x)/2)^{1/2} e^{i\mathcal{G}(\lambda, x)}, \tag{2.54}$$

and $\psi_l^- = \overline{\psi_l^+}$. The above formula can also be written as

$$\psi_l^{\pm}(\lambda, x) = \psi_0^{\pm}(\lambda, x + T^l \alpha), \tag{2.55}$$

where $T: \mathbb{T}^{q-1} \to \mathbb{T}^{q-1}$ is defined as $Tx = x + \alpha$. This shows that $\Psi^{\pm}(\lambda, x) = \{\psi_l^{\pm}(\lambda, x)\}_{l \in \mathbb{Z}}$ is a generalized (quasi-Bloch) eigenfunction of $J(x)$:

$$J(x)\Psi^{\pm}(\lambda, x) = \lambda \Psi^{\pm}(\lambda, x).$$

In fact, $\{\Psi^{\pm}(\lambda, x)\}_{\lambda \in \sigma}$ form a complete system in $l^2(\mathbb{Z})$.

We refer the reader to Ref. 31 for more details of this aspect of asymptotic formulas of Ref. 17.

C. Asymptotic behavior of variance

We assume in this section that the test function φ in (1.2) is of the class C^1 and does not depend on n. Hence, function (2.30) is continuous in (λ_1, λ_2). As a result, fast oscillating in n functions, entering (2.47), do not contribute to the limit, as was already in obtaining (2.52)–(2.54). We have then, from (2.28), (2.34), and (2.52)–(2.54),

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\} \simeq \mathcal{V}(n\beta), \tag{2.56}$$

where

$$\mathcal{V}(x) = \int_{\sigma}\int_{\sigma} \left|\frac{\Delta\varphi}{\Delta\lambda}\right|^2 \mathcal{V}(\lambda_1, \lambda_2, x) d\lambda_1\, d\lambda_2, \tag{2.57}$$

$$\mathcal{V}(\lambda_1,\lambda_2,x)=\mathcal{R}^2(x)(e_{0,0}(\lambda_1,x)e_{-1,-1}(\lambda_2,x)-e_{-1,0}(\lambda_1,x)e_{-1,0}(\lambda_2,x)), \tag{2.58}$$

and $e_{lm}(\lambda,x)$ are given by (2.53) and (2.54), in particular,

$$\int_\sigma e_{lm}(\lambda,x)d\lambda=\delta_{lm}. \tag{2.59}$$

Since the charges $\beta_l, l=1,\dots,q-1$ of (1.8) are continuous and nonconstant functionals of the potential (see Refs. 17 and 26), the leading term of variance is a quasiperiodic function generically in the potential. In particular, it has no limit as $n\to\infty$. Its limiting points are indexed by the subset $\mathbb{H}^{q-1}\subset\mathbb{T}^{q-1}$, the closure of limiting points of the $q-1$ dimensional vectors (1.9). $\mathbb{H}^{q-1}$ is $\mathbb{T}^{q-1}$ generically in V, but it can also be a proper subset of $\mathbb{T}^{q-1}$ [see, e.g. (2.15)].

The simplest case is $q=1$ of a single interval support. Here $\mathbb{H}^0$ is a point, there exist the limits[2,16]

$$\lim_{n\to\infty} r_{n+k-1}^{(n)}=r,\quad \lim_{n\to\infty} s_{n+k}^{(n)}=s,\quad \forall\, k\in\mathbb{Z}, \tag{2.60}$$

and the "limiting" Jacobi matrix $J(x)$ of (2.49) has constant coefficients:

$$J_{jk}=r\delta_{j+1,k}+s\delta_{j,k}+r\delta_{j-1,k}.$$

Placing the origin of the spectral axis at s, we obtain that $\lambda=2r\cos\pi\nu$, $\psi^\pm$ are just the plane waves,

$$\sigma=[-2r,2r],$$

and

$$\mathcal{D}(\lambda)=-\nu'(\lambda)=\frac{1}{\pi\sqrt{4r^2-\lambda^2}},\quad \lambda\in\sigma. \tag{2.61}$$

This and general formula (2.58) yield a version of (2.56) and (2.57), in which the role of $\mathcal{V}(x,\lambda_1,\lambda_2)$ plays

$$\mathcal{V}^{(1)}(\lambda_1,\lambda_2)=\frac{1}{4\pi^2}\frac{4r^2-\lambda_1\lambda_2}{\sqrt{4r^2-\lambda_1^2}\sqrt{4r^2-\lambda_2^2}},\quad \lambda_1,\lambda_2\in\sigma. \tag{2.62}$$

This form of the variance was first found in physical papers[4,10] and proved rigorously in Ref. 23. We see that in the single interval case the variance is universal, i.e., its functional form does not depend explicitly on the potential, the information on the potential being encoded in the unique parameter r of (2.60). In particular, we have (2.62) for the Gaussian Unitary Ensemble (2.16).[13]

In the case (2.12)–(2.15), $\mathbb{H}^{q-1}$ consists of q points [see (2.15)], and the variance is a q-periodic function of n. Example (2.17)–(2.19) corresponds to the simplest nontrivial case $q=2$, where $\beta_1=1/2, \mathbb{H}^1=\{0,1/2\}$, the matrix $J(x)$ is 2-periodic, its coefficients are

$$r_k=\frac{b-(-1)^k a}{2},\quad s_k=0, \tag{2.63}$$

and the variance is asymptotically a 2-periodic function in n:[8,3]

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\}\simeq\mathcal{V}^{(2)}(n/2),$$

where $\mathcal{V}^{(2)}(x)$ is given by (2.57), in which $\mathcal{V}(\lambda_1,\lambda_2,x), x\in\mathbb{H}^1=\{0,1/2\}$ is

$$\mathcal{V}^{(2)}(\lambda_1,\lambda_2,x)=\frac{1}{2\pi^2}\frac{\varepsilon_{\lambda_1}\varepsilon_{\lambda_2}}{\sqrt{|R_2(\lambda_1)|}\sqrt{|R_2(\lambda_2)|}}((a^2-\lambda_1\lambda_2)(b^2-\lambda_1\lambda_2)-(-1)^{2x}ab(\lambda_1-\lambda_2)^2),$$

$$\lambda_1,\lambda_2\in\sigma, \tag{2.64}$$

with

$$R_2(\lambda)=(\lambda^2-a^2)(\lambda^2-b^2), \tag{2.65}$$

and $\varepsilon_\lambda=1$ if $\lambda\in(-b,-a)$ and $\varepsilon_\lambda=-1$ if $\lambda\in(a,b)$. In fact, these formulas are valid for any real analytic and even potential, producing a symmetric two-interval support,

$$\sigma=[-b,-a]\cup[a,b],\quad 0<a<b<\infty, \tag{2.66}$$

(see Refs. 3 and 8). The general case of a two-interval and not necessarily symmetric support was analyzed in Ref. 8, where it was found that the variance can be expressed via the classical elliptic functions of Jacobi and Weierstrass.

We conclude that a minimum modification of the limiting law of linear eigenvalue statistics in the case of a multi-interval support of the IDS, comparing with the case of i.i.d. random variables, could be a family of normal laws, indexed by the points of $\mathbb{H}^{q-1}$. We shall see below that this modification is not sufficient in certain cases.

We remark in the conclusion of this section that formulas (2.56)–(2.58) allow us to characterize the universality classes of ensembles (2.1) with respect to the variance in the global regime, i.e., the sets of ensembles (potentials), leading to the same asymptotic form of the variance of linear statistics in the regime. Namely, since the potential is present in (2.56)–(2.58) only via the endpoints $(a_1,\ldots,b_q)$ of support and via the charges $(\beta_1,\ldots,\beta_{q-1})$ of all but one intervals of the support, these parameters determine a universality class. Notice that the parameters are not necessarily independent.

III. LIMITING LAWS

A. Laplace transform of the probability law of linear eigenvalue statistics

In this section we obtain an expression for the Laplace transform of the probability law of linear eigenvalue statistics (1.2) via orthogonal polynomials. We consider here real-valued test functions $\varphi:\mathbb{R}\to\mathbb{R}$. The Laplace transform is evidently

$$Z_n[\varphi]=\mathbf{E}_V\{e^{\overset{\circ}{\mathcal{N}}_n[\varphi]}\}, \tag{3.1}$$

where $\mathbf{E}_V\{\cdots\}$ denotes the expectation with respect to (2.1) [or (2.20)], determined by a given potential V, and

$$\overset{\circ}{\mathcal{N}}_n[\varphi]=\mathcal{N}_n[\varphi]-\mathbf{E}_V\{\mathcal{N}_n[\varphi]\}.$$

It is convenient to introduce the parameter $s\in[0,1]$ and to consider the function

$$F_n(s)=\log Z_n[s\varphi],\quad s\in[0,1].$$

It is easy to see that

$$F_n(0)=0,F_n'(0)=-\mathbf{E}_V\{\overset{\circ}{\mathcal{N}}_n[\varphi]\}=0,$$

and

$$F_n''(s)=\mathbf{E}_{V+s\varphi/n}\{\mathcal{N}_n^2[\varphi]\}-\mathbf{E}_{V+s\varphi/n}^2\{\mathcal{N}_n[\varphi]\}:=\mathbf{Var}_{V+s\varphi/n}\{\mathcal{N}_n[\varphi]\}.$$

This yields the following expression for the logarithm of (3.1):

$$\log Z_n[\varphi] = F_n(1) := F_n[\varphi] = \int_0^1 (1-s)\mathbf{Var}_{V+s\varphi/n}\{\mathcal{N}_n[\varphi]\}ds. \tag{3.2}$$

We mention that there exists another expression for the Laplace transform (3.1). It dates back to the Heine formulas in the theory of orthogonal polynomials (see, e.g., Ref. 40, Theorem 2.1.1) and can be easily obtained from the Gram theorem:

$$Z_n[\varphi] = \det\left\{\int_{\mathbb{R}} e^{-\overset{\circ}{\varphi}(\lambda)}\psi_j^{(n)}(\lambda)\psi_k^{(n)}(\lambda)d\lambda\right\}_{j,k=1}^n = e^{\mathbf{E}\{\mathcal{N}_n[\varphi]\}}\det(1-K_{n,\varphi}),$$

where

$$\overset{\circ}{\varphi}(\lambda) = \varphi(\lambda) - \mathbf{E}_V\{\mathcal{N}_n[\varphi]\}, \quad \mathbf{E}_V\{\mathcal{N}_n[\varphi]\} = n\int_{\mathbb{R}} \varphi(\lambda)\mathbf{E}_V\{N_n(d\lambda)\},$$

and $K_{n,\varphi}$ is the integral operator, defined as

$$(K_{n,\varphi}f)(\lambda) = \int_{\mathbb{R}} K_n(\lambda,\mu)(1-e^{-\varphi(\mu)})f(\mu)d\mu, \quad \lambda\in\mathbb{R}.$$

These formulas and their analogs for unitary matrices were used to prove various versions of the Central Limit Theorem (see, e.g., Refs. 6, 23, 24, 37–39, and 42).

B. Asymptotic behavior of the Laplace transform

We will assume in this section that φ is real analytic. According to (3.2), (2.28), and (2.31), we have to find the asymptotic form of $\psi_n^{(n)}$ and $\psi_{n-1}^{(n)}$ for the potential $V+s\varphi/n$. We have already seen in the previous section that adding terms of the order $O(n^{-1})$ to the potential, we obtain nontrivial contributions to the asymptotic formulas because of fast oscillating in n functions on the rhs of (2.39)–(2.41), etc. The $O(n^{-1})$ terms appeared there because of the passage $n\to n+k$, leading to (2.45)–(2.48). In this case the terms are proportional to the potential, since we just change its amplitude: $V\to V(1-k/n)$ [see (2.42) and (2.43)]. This required derivatives (2.45) and (2.46) of "frequencies" β_l, $l=1,\ldots,q-1$, and $N(\lambda)$ of fast oscillating functions in (2.39)–(2.41) with respect to the inverse amplitude g of the potential.

On the other hand, to find the asymptotic behavior of the Laplace transform, we have to add to the potential the term $s\varphi/n$ [see (3.2)]. Since $\varphi\neq V$, in general, this requires variational derivatives of frequencies with respect to potential, i.e., we have to add the term $\varepsilon\varphi$ to the potential, and find the derivative of $\beta_l, l=1,\ldots,q-1$, and $N(\lambda)$ with respect to ε at $\varepsilon=0$.

Consider first the case $q=1$, where the support of the IDS is a single interval. Here the dependence on x of functions $\mathcal{D},\mathcal{G},\mathcal{R}$, and $\mathcal{S}$ of (2.39)–(2.41) is absent [see (2.60)–(2.62)]. Hence the term $s\varphi/n$ is negligible in the limit $n\to\infty$, because there are no fast oscillating in n functions in the asymptotics of $\psi_{n+k}^{(n)}$, $k=0,-1$, $r_{n-1}^{(n)}$, and $s_n^{(n)}$, and we obtain from (3.2) and (2.62),

$$\lim_{n\to\infty} F_n[\varphi] = \lim_{n\to\infty} \mathbf{Var}\{\mathcal{N}_n[\varphi]\}/2. \tag{3.3}$$

Notice also that we have here the "genuine" limit as $n\to\infty$, but not a sublimit (1.10) along a subsequence. We conclude that the Central Limit Theorem is valid in this case. This was proved in Ref. 23 by the variational method and for a rather broad class of potentials and test functions (not necessarily real analytic).

As it was shown in the previous section, the variance of a linear statistics with a C^1 test function has no limit as $n\to\infty$ if $q\geq 2$. Its sublimits are indexed by points of the "hull" $\mathbb{H}^{q-1}\subset\mathbb{T}^{q-1}$. Hence we cannot expect the traditional CLT (3.3), as in the case of $q=1$. Rather this should be a collection of the CLT, indexed by $\mathbb{H}^{q-1}$:

$$\lim_{n_j(x)\to\infty} F_{n_j(x)}[\varphi] = \lim_{n_j(x)\to\infty} \mathbf{Var}\{\mathcal{N}_{n_j(x)}[\varphi]\}/2 = \mathcal{V}(x)/2,\ x \in \mathbb{H}^{q-1}, \tag{3.4}$$

where $\{n_j(x)\}$ and $\mathcal{V}(x)$ are defined in (1.10), (2.57), and (2.58). We will call this the generalized CLT.

We will show now that the generalized CLT is not always the case for $q \geq 2$. Recall that $N(\lambda)$ and β_l are functionals of V and denote

$$\dot{\beta}_l[\varphi] = \frac{\partial}{\partial\varepsilon}\beta_l\bigg|_{\varepsilon=0}, \quad l = 1, \ldots, q-1, \quad \dot{N}[\varphi] = \frac{\partial}{\partial\varepsilon}N(\lambda)\bigg|_{\varepsilon=0} \tag{3.5}$$

the variational derivatives of β_l and $N(\lambda)$ with respect to V. $\dot{\beta}_l[\varphi]$ and $\dot{N}[\varphi]$ are linear functionals of φ and nonlinear functionals of V. It follows from Ref. 26 that they are well defined if V is real analytic and regular and φ is real analytic and such that $\max_{\lambda\in\mathbb{R}}|V(\lambda)/\varphi(\lambda)| < \infty$.

Arguing as in Sec. II B, we obtain that in this case $\psi_{n+k}^{(n)}$ is given by (2.47) and (2.48) with the replacement

$$k\alpha_l \to k\alpha_l + s\dot{\beta}_l[\varphi], \quad \pi k\nu \to \pi k\nu + \pi s\dot{N}[\varphi].$$

Now, assuming (1.10) and taking into account (3.2), (2.28), and (2.34), we obtain from (3.2),

$$F[\varphi] := \lim_{n_j(x)\to\infty} \log Z_{n_j(x)}[\varphi] = \int_0^1 (1-s)\mathcal{V}(x + s\dot{\beta}[\varphi])ds, \tag{3.6}$$

where $\mathcal{V}$ is given by (2.57). According to (2.57), $\mathcal{V}$ is a quadratic functional of φ. Hence, the functional $F[\varphi]$ is not quadratic in general, because of the presence of the term $s\dot{\beta}[\varphi]$ in the argument of the integrand in (3.6). In other words, we have here a limiting law in the sense of (1.10), but the law is not necessarily Gaussian.

It seems that a general classification of possible cases is rather complex. We thus will give several examples showing different cases of asymptotic behavior of the Laplace transform of the probability law of linear eigenvalue statistics.

Consider first the case where the test function is a multiple of the potential:

$$\varphi(\lambda) = tV(\lambda), \quad t \in \mathbb{R}. \tag{3.7}$$

Then (2.45) and the relation $\dot{\beta}_l[V] = -\beta'(g)|_{g=1}$ yield

$$\dot{\beta}_l[\varphi] = \dot{\beta}_l[tV] = -t(\beta_l(1) - \alpha_l(1)), \quad l = 1, \ldots, q-1,$$

where $\alpha_l, l = 1, \ldots, q-1$ are defined in (2.51). Hence, if

$$\beta_l(1) = \alpha_l(1), \quad l = 1, \ldots, q-1, \tag{3.8}$$

then the integrand in (3.6) does not depend on s, and we obtain in view of (2.56) and (2.57) the generalized Central Limit Theorem (3.4).

The equality (3.8) is valid for any potential of the form (2.12) with $g=1$ and v^2-4 having only simple and real zeros, because, according to Ref. 26,

$$\beta_l(1) = \alpha_l(1) = \frac{q-l}{q}, \quad l = 1, \ldots, q-1.$$

It is also valid for any even potential, having two equal local minima and one local maximum, which is high enough to produce a two-interval support (2.66). In this case (3.8) results from the symmetry, implying

$$\beta_1 = \alpha_1 = 1/2 \tag{3.9}$$

[recall that in this case the vectors β of (1.8) and α of (2.45) are one-dimensional: $\beta_1 = N(a), \alpha_1 = \nu(a)$].

In all these cases the limiting Jacobi matrix J of (2.49) is q periodic [$q=2$ in the case of (2.66); see (2.63)].

It can also be shown that we have the generalized Central Limit Theorem for potentials (2.12) and $\varphi = tv$ (here the limiting matrix J is also q periodic).

To demonstrate a possibility to have a non-Gaussian limiting law, we consider a simplest nontrivial case of even potential with the two-interval support (2.66) and of the test function

$$\varphi(\lambda) = t\lambda, \quad t \in \mathbb{R}, \tag{3.10}$$

i.e., the case of "linear" linear statistic

$$t\sum_{l=1}^{n} \lambda_l^{(n)} = t \operatorname{Tr} M_n. \tag{3.11}$$

Since in this case $\Delta\varphi/\Delta\lambda$ of (2.30) is equal to t, it follows from (2.58) and (2.59) that

$$\mathcal{V}(x) = t^2\mathcal{R}^2(x), \tag{3.12}$$

and then (3.6) implies that in the case (3.10) (and for any support) we have for the exponent of the limiting Laplace transform:

$$F[\varphi]\big|_{\varphi(\lambda)=t\lambda} = \lim_{n_j(x)\to\infty} \log Z_{n_j(x)}[\varphi]\big|_{\varphi(\lambda)=t\lambda} = t^2\int_0^1 (1-s)\mathcal{R}^2\Big(x + s\dot{\beta}[\varphi]\Big|_{\varphi(\lambda)=t\lambda}\Big)ds. \tag{3.13}$$

According to Ref. 8, it is possible to express the coefficient $\mathcal{R}(x)$, corresponding to the two-interval support, via the Jacobi elliptic function:

$$\mathcal{R}^2(x) = \frac{(b-a)^2}{4} + \frac{ab}{2}\operatorname{cn}^2(x+1/2), \tag{3.14}$$

where $\operatorname{cn}(x) = \operatorname{cn}(2K(k)x|k), k^2 = 4ab/(a+b)^2, K(k)$ is the elliptic integral of the first kind. In view of (3.9), the coefficient r_k of (2.48) is given by (2.63):

$$r_{k-1} = \mathcal{R}\left(\frac{k}{2}\right) = \frac{b-(-1)^k a}{2},$$

and is 2-periodic (see also Ref. 2). In view of (3.12) this implies that the variance of (3.11) is asymptotically 2-periodic in n:

$$\mathcal{R}^2\left(\frac{n}{2}\right) = \frac{b^2+a^2}{4} - (-1)^n\frac{ab}{2}. \tag{3.15}$$

Furthermore, it is shown in the Appendix that

$$\dot{\beta}_1[\varphi]\big|_{\varphi(\lambda)=t\lambda} = t\omega, \quad \omega = \frac{a}{4K(a/b)}, \tag{3.16}$$

Hence we obtain from (3.14),

$$F[\varphi]|_{\varphi(\lambda)=t\lambda} = \int_0^t (t-s)\mathcal{R}^2(x+s\omega)ds. \tag{3.17}$$

It follows from (3.16) that ω is irrational generically in a, and b; hence $\mathcal{R}^2(x+s\omega)$ is quasiperiodic in s in these cases. Since $\mathcal{R}^2$ is 1-periodic and real analytic, we can write its Fourier series,

$$\mathcal{R}^2(x) = \sum_{m\in\mathbb{Z}} c_m e^{2\pi imx}, \tag{3.18}$$

with fast decaying coefficients. Plugging (3.16) and (3.18) in (3.13), we obtain

$$F[\varphi]|_{\varphi(\lambda)=t\lambda} = \frac{c_0 t^2}{2} - tA'(x) - A(x) + A(x+\omega t), \tag{3.19}$$

where

$$A(x) = \sum_{m\in\mathbb{Z}\setminus\{0\}} \frac{c_m}{(2\pi im\omega)^2} e^{2\pi imx}. \tag{3.20}$$

We see that the logarithm of the limiting Laplace transform of the probability law of statistics (3.11) contains not only a multiple of $t^2/2$, that would correspond to the CLT, but also a linear in t term, a constant in t term, and either quasiperiodic (generically in a,b, when ω is irrational) or periodic (in special cases, where ω is rational) function of t. Besides, while the variance of statistics (3.11) is (3.15) in the limit (1.10), the coefficient in front of $t^2/2$ is

$$c_0 = \int_{\mathbb{T}} \mathcal{R}^2(x)dx = \frac{b^2+a^2}{4},$$

hence is not the variance (3.15).

Notice also that in the case $q\geq 3$ we would have in (3.20) the sum over $\mathbb{Z}^{q-1}\setminus\{0\}$, and the expression

$$\dot\beta\cdot m := \dot\beta_1 m_1 + \ldots \dot\beta_{q-1} m_{q-1},$$

in the denominator, that can be arbitrary small for certain collections of $(m_1,\ldots,m_{q-1})\in\mathbb{Z}^{q-1}$ and $\dot\beta := (\dot\beta_1,\ldots,\dot\beta_{q-1})\in\mathbb{R}^{q-1}$ in the case, where the components of $\dot\beta$ are irrational. Hence, to make the series in (3.20) convergent, we have to assume that the components of $\dot\beta$ are sufficiently bad approximated by rationals (e.g., a Diophantine condition).

According to the Appendix , in a general case of a real analytic φ and a two-interval support,

$$\sigma = [a_1,b_1]\cup[a_2,b_2], \quad -\infty < a_1 < b_1 < a_2 < b_2 < \infty, \tag{3.21}$$

we have

$$\dot\beta_1[\varphi] = -\frac{1}{2\pi i I}\int_\sigma \frac{\varphi(\mu)}{\sqrt{R_2(\mu)}}d\mu, \tag{3.22}$$

where $\sqrt{R_2(\mu)}$ is defined in (2.9),

$$I = \int_{b_1}^{a_2} \frac{d\mu}{\sqrt{(b_2-\mu)(a_2-\mu)(\mu-b_1)(\mu-a_1)}} = \frac{2}{((b_2-b_1)(a_2-a_1))^{1/2}}K(\kappa), \tag{3.23}$$

and

$$\kappa^2 = \frac{(a_2 - b_1)(b_2 - a_1)}{(b_2 - b_1)(a_2 - a_1)}$$

[see Ref. 20, formula (3.149.4)]. In the symmetric case (2.66), we have

$$I = \frac{2}{b+a} K\left(\frac{2\sqrt{ab}}{b+a}\right) = \frac{2}{a} K\left(\frac{b}{a}\right),$$

where the second equality results from the formula $(1+k)^{-1}K[2\sqrt{k}/(1+k)]=K(k)$,[41] formula (8.126.3). It follows then that in this case and for $\varphi=t\lambda$, (3.22) coincides with (3.16).

Formula (3.22) allows us to characterize the class of potentials and test functions for which the (generalized) Central Limit Theorem (3.4) is valid in the case of a general two-interval support (3.21). Indeed, for any pair (V,φ) for which the rhs of (3.22) is zero, the integrand of (3.6) does not depend on s and we have the generalized CLT (3.4). In particular, in the symmetric case (2.66) it follows from (3.22) that $\dot{\beta}_1[\varphi]$ is zero if and only if

$$\int_a^b \frac{\varphi(\mu) - \varphi(-\mu)}{\sqrt{(b^2 - \mu^2)(\mu^2 - a^2)}} d\mu = 0.$$

In particular, for an even potential of support (2.66) and an even test function φ, the generalized CLT is valid.

One can view φ as an analog of external field in statistical mechanics. Hence, we can say that in this case an even external field "does not break the symmetry." On the other hand, a "generic" φ or an odd φ, such that

$$\int_a^b \frac{\varphi(\mu) d\mu}{\sqrt{(b^2 - \mu^2)(\mu^2 - a^2)}} \neq 0,$$

is a "breaking symmetry field" and leads to a non-Gaussian limiting law. Its simplest case $\varphi(\lambda)=t\lambda$ (3.10) is given by (3.19).

IV. INTERMEDIATE AND LOCAL REGIMES

In this section we consider limiting laws of linear eigenvalue statistics for the test functions, given by (1.11) and (1.12) with a C^1 function φ and λ_0 belonging to the interior of σ.

We begin again by calculating the asymptotic form of the variance in these cases. Changing variables to

$$\lambda_{1,2} = \lambda_0 + t_{1,2}/n^\alpha, \quad 0 < \alpha \leq 1, \tag{4.1}$$

we obtain from (2.28),

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\} = \int_{\mathbb{R}} \int_{\mathbb{R}} \left(\frac{\Delta\varphi}{\Delta t}\right)^2 \mathcal{V}_n(\lambda_0 + t_1/n^\alpha, \lambda_0 + t_2/n^\alpha) dt_1\, dt_2. \tag{4.2}$$

To find the asymptotic form of the rhs we will use again (2.34) and (2.33) in which $\psi_{n+k}^{(n)}(\lambda)$, $k=0.-1$ is given by (2.47) with $\lambda=\lambda_0+t/n^\alpha$. Taking into account that $\mathcal{D}, N$, and $\mathcal{G}$ are smooth functions of λ in a sufficiently small neighborhood of λ_0, we can write

$$\psi_{n+k}^{(n)}(\lambda) \simeq (2\mathcal{D}(\lambda_0, n\beta + k\alpha))^{1/2} \cos(\pi n N(\lambda_0) + \pi k \nu(\lambda_0) - \pi\rho(\lambda_0) n^{1-\alpha} + \mathcal{G}(\lambda_0, n\beta + k\nu)),$$

where $\rho(\lambda)=-N'(\lambda)$, and we do not indicate the dependence on g (in fact, it suffices to consider the case $g=1$). Plugging this into (2.33) and (2.34), and omitting in the resulting integrand of the rhs of (4.2) the fast oscillating terms, we obtain

$$\mathbf{Var}\{\mathcal{N}_n[\varphi]\} \simeq B(\lambda_0, n\beta)\int_{\mathbb{R}}\int_{\mathbb{R}}(\varphi(t_1)-\varphi(t_2))^2\frac{\sin^2(\pi\rho(\lambda_0)(t_1-t_2)n^{1-\alpha})}{2\pi^2(t_1-t_2)^2}dt_1\,dt_2, \tag{4.3}$$

where

$$B(\lambda,x) = 2\pi^2\mathcal{R}^2(x)\mathcal{D}(\lambda,x)\mathcal{D}(\lambda,x-\alpha)\sin^2(\pi\nu(\lambda)+\mathcal{G}(\lambda,x)-\mathcal{G}(\lambda,x-\alpha)). \tag{4.4}$$

This leads to the following result in the local regime $\alpha=1$, and for the limit (1.10),

$$\lim_{n_j(x)\to\infty}\mathbf{Var}\{\mathcal{N}_{n_j(x)}[\varphi_{n_j(x)}]\} = B(\lambda_0,x)\int_{\mathbb{R}}\int_{\mathbb{R}}(\varphi(t_1)-\varphi(t_2))^2\frac{\sin^2(\pi\rho(\lambda_0)(t_1-t_2))}{2\pi^2(t_1-t_2)^2}dt_1\,dt_2. \tag{4.5}$$

It is known that in the local regime the variance of linear eigenvalue statistics has a universal limiting form[17,33]

$$\lim_{n\to\infty}\mathbf{Var}\{N_n[\varphi_n]\} = \int_{\mathbb{R}}\int_{\mathbb{R}}(\varphi(t_1)-\varphi(t_2))^2\frac{\sin^2(\pi\rho(\lambda_0)(t_1-t_2))}{2\pi^2(t_1-t_2)^2}dt_1\,dt_2, \tag{4.6}$$

in which all the information on the potential is encoded in $\rho(\lambda_0)$. This and (4.5) imply the identity

$$B(\lambda,x) = 1, \tag{4.7}$$

valid for all $x\in\mathbb{T}^{q-1}$ and λ, belonging to the interior of the σ (a direct proof of the identity can be extracted from the proof of Lemma 6.1 of Ref. 20).

In the intermediate regime $0<\alpha<1$, we still have a fast oscillating factor,

$$\sin^2(n^{1-\alpha}\pi\rho(\lambda_0)(t_1-t_2))$$

in the integrand of (4.3). Replacing the factor by its average 1/2, and using (4.7), we obtain in this regime

$$\lim_{n\to\infty}\mathbf{Var}\{N_n[\varphi_n]\} = \int_{\mathbb{R}}\int_{\mathbb{R}}\frac{(\varphi(t_1)-\varphi(t_2))^2}{4\pi^2(t_1-t_2)^2}dt_1\,dt_2. \tag{4.8}$$

As in the case of the local regime, the limit here is the same for any subsequence (1.10); hence we do not need to assume (1.10). We conclude that the variance of linear statistics has a well defined limit in the intermediate regime as well. Moreover, (4.8) is the "smoothed" version of variance (4.6) in the local regime, since (4.8) is (4.6), in which the "oscillating" factor $\sin^2(\pi\rho(\lambda_0)(t_1-t_2))$ is replaced by its average 1/2.

Passing to the Fourier transform,

$$\widehat{\varphi}(k) = \frac{1}{2\pi}\int_{\mathbb{R}}e^{ikt}\varphi(t)dt,$$

we can rewrite the rhs of (4.8) in the form

$$\int_{\mathbb{R}}|k|\widehat{\varphi}(k)\widehat{\varphi}(-k)dk,$$

appearing in the continuous analog of the strong Szegö theorem (see Refs. 6, 18, and 37 and references therein).

The universality property of unitary invariant Matrix Models[17,33] implies that the Laplace transform of the probability law of linear eigenvalue statistics has the following limiting form in the local regime:

$$\lim_{n\to\infty} Z_n[\varphi_n]\Big|_{\varphi_n(\lambda)=\varphi((\lambda-\lambda_0)n)} = e^{2\pi\rho(\lambda_0)\widehat{\varphi}(0)} \det(1-S_\varphi), \tag{4.9}$$

where S_φ is the integral operator, defined as

$$(S_\varphi f)(t) = \int_{\mathbb{R}} \frac{\sin \pi\rho(\lambda_0)(t-u)}{\pi\rho(\lambda_0)(t-u)}(1-e^{-\varphi(u)})f(u)du, \tag{4.10}$$

and we assume that φ in (1.12) is continuous and integrable on $\mathbb{R}$. It is obvious that the logarithm of the rhs of (4.9) is not quadratic in φ; hence the CLT is not valid in the local regime (see, e.g., Ref. 22 for related results).

If, however, we take in the above formulas,

$$\varphi(t) = \Phi((t-t_0)\delta),$$

where Φ does not depend on $\delta\to 0$, and $t_0 \in \mathbb{R}$, i.e., we assume that the test function in (4.9) and (4.10) is "slow varying," then it can be shown (see, e.g., Refs. 6, 15, and 39) that the limit of the rhs of (4.9) as $\delta\to 0$ is the rhs of (4.8), divided by 2.

On the other hand, take as a test function in (3.6),

$$\varphi(\lambda) = \Phi((\lambda-\lambda_0)/\delta), \tag{4.11}$$

where Φ does not depend on $\delta\to 0$, and λ_0 belongs to the interior of the support of N, i.e., assume that φ is "fast varying." Since the variational derivatives (linear functionals of φ) $\dot{\beta}_l[\varphi]$, $l=1,\ldots,q-1$ of (3.5) can be written as

$$\dot{\beta}_l[\varphi] = \int_{\mathbb{R}} b_l(\lambda)\varphi(\lambda)d\lambda,$$

we have

$$\dot{\beta}_l[\varphi] = \delta\int_{\mathbb{R}} b_l(\lambda_0+\delta t)\Phi(t)dt \to 0, \quad \delta\to 0.$$

Hence, the term $s\dot{\beta}$ in the argument of the integrand of (3.6) vanishes in the limit $\delta\to 0$ and we obtain from (2.57), changing variables to $\lambda_{1,2}=\lambda_0+\delta t_{1,2}$:

$$\lim_{\delta\to\infty} F[\varphi]\Big|_{\varphi(\lambda)=\Phi(\lambda-\lambda_0)/\delta} = \frac{1}{2}\mathcal{V}(x), \tag{4.12}$$

where

$$\mathcal{V}(x) = \mathcal{V}(\lambda_0,\lambda_0,x)\int_{\mathbb{R}}\int_{\mathbb{R}} \frac{(\Phi(t_1)-\Phi(t_2))^2}{2\pi^2(t_1-t_2)^2}dt_1\,dt_2.$$

Now it can be shown, by using (2.58), (2.54), (2.55), and (4.4), that the rhs of the last formula coincides with (4.8). Hence, the limit (4.12) coincides again with the rhs of (4.8), divided by 2.

The above suggests that the CLT is valid in the intermediate regime. This was indeed proved in several cases (see Ref. 37 and references therein).

APPENDIX: VARIATIONAL DERIVATIVE OF FREQUENCY IN THE TWO-INTERVAL CASE

Here we derive formula (3.16). We will use the variational approach, based on the functional (2.3).

Write the minimum condition (2.4) and (2.6) for $V+\varepsilon\varphi$, and compute its derivative at $\varepsilon=0$. This yields

$$\varphi(\lambda) - 2\int_\sigma \log|\lambda-\mu|\dot\rho(\mu)d\mu = \text{const}, \quad \lambda\in\sigma, \tag{A1}$$

where

$$\dot\rho = \left.\frac{\partial}{\partial\varepsilon}\rho\right|_{\varepsilon=0},$$

and ρ is the density of the measure N of (1.5). Notice that the differentiation of the limits of integration in (2.6) does not contribute to (A1), because ρ vanishes at each endpoint of the support according to (2.8).

The derivative of (A1) in λ is the singular integral equation [cf. (2.10)],

$$\text{v.p.}\int_\sigma \frac{\rho(\mu)d\mu}{\mu-\lambda} = -\frac{\varphi'(\lambda)}{2}, \quad \lambda\in\sigma.$$

The general solution of the equation in the case (2.66) is[25]

$$\frac{C_1\lambda + C}{X_2(\lambda)} + \frac{1}{2\pi^2 X_2(\lambda)}\text{v.p.}\int_\sigma \frac{\varphi'(\mu)X_2(\mu)d\mu}{\mu-\lambda},$$

where

$$X_2(\lambda) = -i\sqrt{R_2(\lambda)}, \quad \sqrt{R_2(\lambda)} = \sqrt{R_2(z)}|_{z=\lambda+i0},$$

$R_2(z)=(z^2-a^2)(z^2-b^2)$ [see (2.9) for $q=2$] and $\sqrt{R_2(z)}$ is the branch of the square root, fixed by the condition $\sqrt{R(z)}=z^2+O(z), z\to\infty$. The branch assumes pure imaginary values of opposite sides on the edges of σ, seen as a cut of $\mathbb{C}$.

Taking into account the equalities

$$\int_\sigma \dot\rho(\mu)d\mu = 0,$$

and

$$\int_\sigma \frac{d\mu}{\sqrt{R_2(\mu)}} = 0, \int_\sigma \frac{\mu d\mu}{\sqrt{R_2(\mu)}} = -\pi i,$$

we find that

$$\dot\rho(\lambda) = \frac{iC}{\sqrt{R_2(\lambda)}} + \frac{1}{2\pi^2\sqrt{R_2(\lambda)}}\text{v.p.}\int_\sigma \frac{\varphi'(\mu)\sqrt{R_2(\mu)}d\mu}{\mu-\lambda}. \tag{A2}$$

The constant C can be found as follows. Denote $f(z)$ the Stieltjes transform of ρ:

$$f(z) = \int_\sigma \frac{\rho(\mu)d\mu}{\mu-z}, \quad z\notin\sigma. \tag{A3}$$

Recalling that V is real analytic, using (2.8), (2.11), and arguing as above, we find that

$$f(z) = -\frac{V'(z)}{2} - \frac{\sqrt{R_2(z)}}{2\pi i}\int_\sigma \frac{V'(\mu)-V'(z)}{\mu-z}\frac{d\mu}{\sqrt{R_2(\mu)}} \tag{A4}$$

[the analog of the formula with R_q instead of R_2 is valid for any finite number q of intervals in (1.7)].

Write now the minimum condition (2.4) as

$$V_{\text{eff}}(b) - V_{\text{eff}}(a) = 0,$$

or, in view of (2.6) and (A3), as

$$\int_{-a}^{a} \left(f(\lambda) + \frac{V'(\lambda)}{2} \right) d\lambda = 0. \tag{A5}$$

The condition is valid for any potential, in particular, for $V+\varepsilon\varphi$. According to (A4) for any sufficiently small ε, the integrand here is proportional to $\sqrt{R_2(\lambda)}$, in which a and b are now functions of ε. Hence, the integrand vanishes at the edges of the support and the derivative of (A5) with V replaced by $V+\varepsilon\varphi$ with respect to ε at $\varepsilon=0$ is

$$\int_{-a}^{a} \left(\dot{f}(\lambda) + \frac{\varphi'(\lambda)}{2} \right) d\lambda = 0. \tag{A6}$$

This and the formula

$$\dot{f}(z) = \int_{\sigma} \frac{\dot{\rho}(\mu) d\mu}{\mu - z} = -\frac{\pi C}{\sqrt{R_2(z)}} - \frac{1}{2\pi i \sqrt{R_2(z)}} \int_{\sigma} \frac{\varphi'(\mu)\sqrt{R_2(\mu)}}{\mu - z} d\mu, \tag{A7}$$

following from (A2), yield in the case $\varphi(\lambda)=t\lambda$:

$$\dot{\rho}(\lambda) = \frac{C}{\sqrt{(b^2-\lambda^2)(\lambda^2-a^2)}} + \frac{P_2(\lambda)}{2\pi\sqrt{(b^2-\lambda^2)(\lambda^2-a^2)}}, \quad \lambda \in \sigma,$$

where $P_2(\lambda)=\lambda^2-(a^2+b^2)/2$,

$$C = \frac{tI_2}{2\pi I_1}, \tag{A8}$$

and

$$I_1 = \int_{-a}^{a} \frac{d\lambda}{\sqrt{(b^2-\lambda^2)(a^2-\lambda^2)}}, \quad I_2 = 2\int_{-a}^{a} \frac{P_2(\lambda) d\lambda}{\sqrt{(b^2-\lambda^2)(a^2-\lambda^2)}}. \tag{A9}$$

Now we can find $\dot{\beta}_1[\varphi]$ for $\varphi(\lambda)=t\lambda$. We have by (A8) and (A9),

$$\dot{\beta}_1 := \int_{a}^{b} \dot{\rho}(\lambda) d\lambda = \frac{t}{2\pi I_1}(I_2 J_1 - I_1 J_2), \tag{A10}$$

where

$$J_1 = \int_{a}^{b} \frac{d\lambda}{\sqrt{(b^2-\lambda^2)(\lambda^2-a^2)}}, \quad J_2 = \int_{a}^{b} \frac{P_2(\lambda) d\lambda}{\sqrt{(b^2-\lambda^2)(\lambda^2-a^2)}}.$$

By using standard formulas (see, e.g., Ref. 20, formulas (3.159)], we find

$$I_1 = 2K(k)/a, \quad I_2 = 2a\left(\frac{1-k^2}{2} K(k) - E(k) \right), \tag{A11}$$

$$J_1 = K(k')/a, \quad J_2 = a\left(E(k') - \frac{1+k^2}{2}K(k')\right), \tag{A12}$$

where $K(k)$ and $E(k)$ are the complete elliptic integrals of the first and second kind, $k=b/a, k'=\sqrt{1-k^2}$. These formulas and the identity $EK'+E'K-KK'=\pi/2$, where $K'=K(k'), E'=E(k')$ [Ref. 20, formula (8.122)] imply (3.16).

A more involved version of the above argument leads to (3.22). We note first that to prove the formula for a real analytic φ, it suffices to consider

$$\varphi_{z_0}(\lambda) = \frac{1}{\lambda - z_0}, \quad z_0 \notin \sigma.$$

We have in this case (see below)

$$\dot{\beta}_1[\varphi_{z_0}] = -\frac{1}{2I\sqrt{R_2(z_0)}}, \tag{A13}$$

where I is defined in (3.23).

Assuming that this formula is valid and using the Cauchy theorem to write

$$\varphi(\lambda) = \frac{1}{2\pi i}\int_{C_\sigma} \frac{\varphi(z_0)dz_0}{\lambda - z_0}, \quad \lambda \in \sigma,$$

where C_σ is the contour encircling σ in the clockwise direction; we obtain in view of the linearity of $\dot{\beta}_1[\varphi]$ in φ,

$$\dot{\beta}_1[\varphi] = \frac{1}{2\pi i}\int_{C_\sigma} \dot{\beta}_1[\varphi_{z_0}]\varphi(z_0)dz_0 = -\frac{1}{2I}\frac{1}{2\pi i}\int_{C_\sigma} \frac{\varphi(z_0)}{\sqrt{R_2(z_0)}}dz_0.$$

Now the relation $\sqrt{R_2(\lambda - i0)} = -\sqrt{R_2(\lambda + i0)}$ yields (3.22).

To prove (A13) we use the general formulas (A2), (A7), and (A6) with

$$\varphi'_{z_0}(\lambda) = -\frac{1}{(\lambda - z_0)^2} = -\frac{\partial}{\partial z_0}\frac{1}{\lambda - z_0}.$$

Arguing as in the case $\varphi(\lambda)=t\lambda$ above, we obtain an analog of (A10) whose denominator contains I of (3.23) instead of I_1 of (A9), and whose numerator is a bilinear combination of integrals of $|R_2(\mu)|^{-1/2}$ over $[a_2,b_2]$ and of derivatives with respect to z_0 of the integrals over $[b_1,a_2]$ and $[a_2,b_2]$ of $[(\mu - z_0)|R_2(\mu)|^{1/2}]^{-1}$ and $P_2(\mu)[(\mu - z_0)|R_2(\mu)|^{1/2}]^{-1}$, where P_2 is defined now by the relation $\sqrt{R_2(z)} = P_2(z) + O(1/z), z \to \infty$. These integrals can be expressed via the complete elliptic integrals of the first, second, and third kinds. Furthermore, the complete elliptic integrals of the third kind can be expressed via the incomplete elliptic integrals of the first and the second kinds, whose arguments depend on z_0. This allows us to obtain a formula for $\dot{\beta}_1[\varphi_{z_0}]$, whose numerator is expressed via the complete elliptic integrals of the first and the second kind and derivatives with respect to z_0 of the incomplete elliptic integrals of the first and the second kind. The derivatives are proportional to $(R_2(z_0))^{-1/2}$ [see Ref. 41, formulas (8.123)] This and a bit tedious algebra lead eventually to (A13).

Another derivation of (A13) is given in Ref. 8 (see formula (3.14) of the paper). The derivation is based on a two step procedure of the minimization of (2.3): the first step is the minimization over all unit measures with a given charge $\beta_1 \in (0,1)$ of the "band" $[a_2,b_2]$ of the support, and the second is the minimization of this minimum over β_1.

Linearizing the Heisenberg equations of motion around the ground state of an interacting quantum many-body system, one gets a time-evolution generator in the positive cone of a real symplectic Lie algebra. The presence of disorder in the physical system determines a probability measure with support on this cone. The present paper analyzes a discrete family of such measures of exponential type, and does so in an attempt to capture, by a simple random matrix model, some generic statistical features of the characteristic frequencies of disordered bosonic quasiparticle systems. The level correlation functions of the said measures are shown to be those of a determinantal process, and the kernel of the process is expressed as a sum of biorthogonal polynomials. While the correlations in the bulk scaling limit are in accord with sine-kernel or Gaussian Unitary Ensemble universality, at the low-frequency end of the spectrum an unusual type of scaling behavior is found. [DOI: 10.1063/1.2356798]

I. INTRODUCTION

Perturbing the ground state of an interacting quantum many-body system and linearizing the Heisenberg equations of motion for the boson Fock operators, one faces the standard problem of small oscillations. Concrete examples are furnished by the vibrational modes of a solid, the spin waves in a magnet, the electromagnetic modes in an optical medium, and the oscillations of the superfluid density of a Bose–Einstein condensate. Common to these excitations is that they second-quantize as bosons or bosonic quasiparticles.

Adding some amount of disorder to the system, one may ask: what are the statistical features of the excitation spectrum and, in particular, which of these features (if any) reflect the bosonic nature of the quasiparticle excitations? Is there some kind of universality akin to the Wigner–Dyson universality known from other disordered systems? If so, what are the universal laws, and what is the role of symmetry in determining these laws?

In the parallel case of fermionic quasiparticles the situation is now fairly well understood. If the system is of metallic type and in the ergodic limit, the statistical behavior at high energies is in accord with the universal laws of Wigner–Dyson statistics. For low excitation energies, however, the canonical anticommutation relations obeyed by the fermion operators make themselves felt: they constrain the form of the Hamiltonian matrix and thus give rise to several new universality classes beyond Dyson's threefold way.[1] Some of these are realized by chiral Dirac fermions in a random gauge field,[2] others by quasiparticles in disordered gapless superconductors.[3,4] A

[a)]Electronic mail: zirn@thp.uni-koeln.de

complete symmetry classification of quadratic fermion Hamiltonians has been carried out,[5] and the role of Riemannian symmetric spaces and superspaces in providing an effective description has been emphasized.[6,7]

Progress has been slower for bosonic systems, and so for good reason, as these are set apart by several distinctive features from other random problems studied and solved in the past. For one thing, in the case of bosons it makes little sense to choose—as one often does for fermions—the matrix elements of the quasiparticle Hamiltonian as independent and identically distributed random variables. In fact, most of the boson Hamiltonians produced in such a manner would generate runaway dynamics rather than oscillatory motion around a stable ground state. In the case of bosons one therefore has to pay attention to the fact that the matrix elements depend in a complicated way on the ground state of the many-boson system and, hence, on the disorder of the microscopic parent problem.[8,9] As a technical consequence, a direct analog of the so-called Gaussian Ensembles, which were pivotal in initiating the Wigner–Dyson theory and establishing its universal statistics, is unavailable in the context of bosons.

For another complication, low-frequency bosons are usually insensitive to weak disorder. Many of the excitations listed above are Goldstone bosons associated with a spontaneously broken symmetry, and for such excitations low frequency is tantamount to low wave number, or large wavelength, which causes the scattering by disorder to be suppressed, as the disorder is effectively seen only on average over regions of size given by the large wavelength. Thus the disorder averages out and becomes less effective, and hence, the behavior of weakly disordered Goldstone bosons tends to be system specific. (Of course this still leaves it possible for weakly disordered bosons of *non*-Goldstone type to exhibit universal statistics.[8,9]) In order for any universality to set in, the disorder strength often has to be so large that standard calculational tools such as the impurity diagram technique fail to apply.

In the present paper we are going to introduce and completely solve a simple random matrix model of disordered bosonic quasiparticles, which we believe to be most closely analogous to the Wigner–Dyson Gaussian Ensembles while retaining the crucial features of bosonic statistics and stability of the motion. In a follow-up paper we will investigate the question whether this simple model might be representative of a whole universality class of related problems.

To formulate the model, let q_j, p_j $(j=1,\ldots,N)$ be a canonical set of position and momentum operators, and consider their linearized Heisenberg equations of motion in the most general form

$$\dot{q}_j = \sum_{i=1}^{N} (q_i A_{ij} + p_i C_{ij}), \qquad -\dot{p}_j = \sum_{i=1}^{N} (q_i B_{ij} + p_i A_{ji}),$$

where $B_{ij}=B_{ji}$, $C_{ij}=C_{ji}$, and A_{ij} are real numbers. If the system was invariant under time reversal $(q_j \mapsto q_j, p_j \mapsto -p_j)$, the coefficients A_{ij} would have to be zero, but we here consider the generic case without symmetries. The criterion for stability of the dynamics is that the stability matrix be positive

$$h := \begin{pmatrix} B & A \\ A^t & C \end{pmatrix} > 0.$$

Assuming $h^t=h>0$, the generator of the Heisenberg time evolution

$$X := \begin{pmatrix} A & -B \\ C & -A^t \end{pmatrix},$$

has eigenvalues that come as imaginary pairs $\pm i\omega_j$ where $\omega_j>0$ $(j=1,\ldots,N)$ are the characteristic frequencies (or single-boson energies) of the small-amplitude motion. In a classical setting one would introduce the generator X as the symplectic gradient of the Hamiltonian function linearized at a stable equilibrium point of the classical flow.

The natural transformation group of the problem at hand is the real symplectic group in $2N$ dimensions, $\mathrm{Sp}_{2N}(\mathbb{R})$, acting by linear canonical transformations on the operators q_j, p_j and by

conjugation on the generator X. We can now explain one of the distinctive features of the present problem: when formulating the Gaussian Ensembles of the Wigner–Dyson theory one makes the postulate that the transformation group of the problem (O_N, U_N, or USp_{2N}, as the case may be) also be the symmetry group of the chosen probability measure, whereas in our case no such simplification is possible. Indeed, $Sp_{2N}(\mathbb{R})$ is noncompact, and a probability measure $d\mu$ cannot be invariant under a noncompact group action and at the same time have total mass $\int d\mu = 1$.

One is therefore looking for some construction principle other than symmetry. Our key here is the positivity of the real symmetric stability matrix h: a natural way of building positive real symmetric matrices h is by adding a sufficient number of rank-one projectors with positive weights. Equivalently, we may put

$$h_{ij} = \sum_{\alpha=1}^{M} v_{i\alpha} v_{j\alpha} \quad (i,j = 1, \ldots, 2N) \tag{1.1}$$

for some set of real numbers $v_{i\alpha}$. We now consider the $v_{i\alpha}$ as the fundamental variables, and choose them to be independent and normal (or Gaussian) distributed random variables with zero mean and variance τ^{-1}. Then we use Eq. (1.1) to push forward the normal distribution for the $v_{i\alpha}$ to a probability distribution $d\mu(h)$ for h (and, hence, for X). If $M \geqslant 2N$, the result is

$$d\mu(h) \propto e^{-(1/2)\tau \mathrm{Tr} h} \mathrm{Det}(h)^{(1/2)(l-1)} \prod_{i \leqslant j} dh_{ij}, \quad l = M - 2N \geqslant 0, \tag{1.2}$$

with the domain for h still defined by $h > 0$. The probability distribution (1.2) is the object of study of this paper.

We now give a summary of the contents and the results of the paper. After collecting some basic facts from symplectic linear algebra in Sec. II, we reduce $d\mu(h)$ in Sec. III to a probability distribution on the space of characteristic frequencies $\omega_1, \ldots, \omega_N$ (the positive eigenvalues of $-iX$), and find this to be

$$d\mu_{N,l}(\omega_1, \ldots, \omega_N) = c_{N,l}(\tau) \prod_{i<j} (\omega_i - \omega_j)(\omega_i^2 - \omega_j^2) \prod_{k=1}^{N} \omega_k^l e^{-r\omega_k} d\omega_k. \tag{1.3}$$

Using the method of biorthogonal polynomials we show in Sec. V C that the n-level correlation functions of this probability distribution are of determinant type and are completely determined in the usual way—see Eq. (5.19)—by a certain kernel $K_N(\omega, \tilde{\omega})$ given as a sum over biorthogonal polynomials. We compute the large-N asymptotics of this kernel in the bulk of the spectrum (in Sec. V D) and at the "hard" edge $\omega = 0$ (Sec. V E), using a contour integral representation of the biorthogonal polynomials (Sec. V C). In the former case we establish the scaling limit

$$\tau \lim_{N\to\infty} K_N(Nx/\tau + \omega, Nx/\tau + \tilde{\omega}) = \frac{\sin[\pi\rho_\infty(x)(\omega - \tilde{\omega})]}{\pi(\omega - \tilde{\omega})} e^{-r(x)(\omega - \tilde{\omega})}, \tag{1.4}$$

which is independent of l. The function $\rho_\infty(x)$ of the scaling variable $x = \omega\tau/N$ is the large-N limit of the level density. Viewing $\pi\rho_\infty(x)$ as the imaginary part of a Green's function $\lim_{\epsilon\to 0+} g(x + i\epsilon)$, the function $r(x)$ is the real part. We compute $\rho_\infty(x)$ by two independent methods (from a variational calculation in Sec. IV, and from biorthogonal polynomials in Sec. V D), with the result being

$$\rho_\infty(x) = \frac{\tau}{2\pi} (x/b)^{-1/3} [(1 + \sqrt{1 - x^2/b^2})^{1/3} - (1 - \sqrt{1 - x^2/b^2})^{1/3}] \quad (0 < x \leqslant b = 3\sqrt{3}). \tag{1.5}$$

Apart from the last factor, which is irrelevant since it cancels on passing to the level correlation functions, the right-hand side of Eq. (1.4) is the famous sine kernel known from systems with unitary symmetry. Thus we recover Wigner–Dyson universality of the class of the Gaussian Unitary Ensemble (GUE) at bulk frequencies.

At low frequencies $\omega \sim N^{-1/2}$ we find convergence to an unusual kind of scaling limit

$$\lim_{N\to\infty} N^{-1/2} K_N(N^{-1/2}y_1/\tau, N^{-1/2}y_2/\tau) = \frac{\tau^2}{2\pi^2}\int_{i\mathbb{R}+\epsilon} du \oint_{\mathrm{U}_1} \frac{dv}{v} e^{-y_1/u+y_2/v}(v/u)^l \frac{e^{u^2-v^2}-1}{u^2-v^2}, \tag{1.6}$$

where U_1 denotes the unit circle in $\mathbb{C}$, and $i\mathbb{R}+\epsilon$ is any axis in the right half plane parallel to the imaginary axis. The result (1.6) is reminiscent of formulas obtained by Efetov's supersymmetry method, with u and v playing the role of radial polar coordinates of a Riemannian symmetric superspace. We intend to elucidate this connection in a future publication.

II. THE HAMILTONIANS OF STABLE MOTIONS

Let there be some position variables $q_1, \ldots, q_N$ and canonical momenta $p_1, \ldots, p_N$, and consider Hamiltonians H of the quadratic form

$$H = \frac{1}{2}\sum_{i,j=1}^{N} [C_{ij}p_ip_j + B_{ij}q_iq_j + A_{ij}(q_ip_j + p_jq_i)], \tag{2.1}$$

where A, B, and C are real matrices satisfying $B=B^t$ and $C=C^t$. Rewriting H as

$$H = \frac{1}{2}(q\ p)\begin{pmatrix} A & -B \\ C & -A^t \end{pmatrix}\begin{pmatrix} p \\ -q \end{pmatrix},$$

we see that the matrix, X, of H satisfies the linear condition

$$X^tJ + JX = 0, \quad J = \begin{pmatrix} 0 & -1_N \\ 1_N & 0 \end{pmatrix}, \quad X = \begin{pmatrix} A & -B \\ C & -A^t \end{pmatrix}. \tag{2.2}$$

This is saying that X lies in $\mathfrak{sp}_{2N}(\mathbb{R})$, the Lie algebra of the real symplectic group defined by

$$\mathrm{Sp}_{2N}(\mathbb{R}) = \{g \in \mathrm{GL}_{2N}(\mathbb{R}) | g^tJg = J\}.$$

A matrix $X \in \mathfrak{sp}_{2N}(\mathbb{R})$ need not be diagonalizable (e.g., the generator of free motion, $A=B=0$ and $C=1_N$, is not); and even if it is, the eigenvalues will in general be complex.

We now impose the condition

$$h := \begin{pmatrix} B & A \\ A^t & C \end{pmatrix} > 0, \tag{2.3}$$

i.e., we require all eigenvalues of the real symmetric matrix h to be positive. The corresponding domain in $\mathfrak{sp}_{2N}(\mathbb{R})$ will be denoted by $\mathfrak{E}^0$:

$$\mathfrak{E}^0 := \{X \in \mathfrak{sp}_{2N}(\mathbb{R}) | X = hJ, h = h^t > 0\}. \tag{2.4}$$

Although the eigenvalues of h have no direct relation to the dynamics of the system, positivity of h ensures that the motion generated by the Hamiltonian H is stable, or "elliptic." As a consequence of ellipticity, there exists some linear canonical transformation $(\mathbf{q},\mathbf{p}) \to (\mathbf{Q},\mathbf{P})$ which takes the Hamiltonian to a sum of harmonic oscillators

$$H = \frac{1}{2}\sum_{i=1}^{N} (P_i^2 + \omega_i^2 Q_i^2),$$

with $\omega_i^2 > 0$. Put differently, for $X \in \mathfrak{E}^0$ one can always find a symplectic transformation $g \in \mathrm{Sp}_{2N}(\mathbb{R})$ that conjugates X to quasidiagonal form

$$X = g\Omega g^{-1}, \quad \Omega = \begin{pmatrix} 0 & -\omega \\ \omega & 0 \end{pmatrix}, \quad \omega = \mathrm{diag}(\omega_1, \omega_2, \ldots, \omega_N), \tag{2.5}$$

with real and positive ω_i $(i=1,\ldots,N)$.

All of the discussion below will be based on the elliptic domain $\mathfrak{E}^0$. Let us therefore collect some of its mathematical properties. First of all, if X is in $\mathfrak{E}^0$, then so is its conjugate gXg^{-1} by any element $g \in \mathrm{Sp}_{2N}(\mathbb{R})$. Thus $\mathfrak{E}^0$ is invariant under the action of $\mathrm{Sp}_{2N}(\mathbb{R})$ on $\mathfrak{E}^0$ by conjugation. Second, let $\mathfrak{t}$ denote the Abelian algebra of block-diagonal matrices of the form of Ω in Eq. (2.5) but with diagonal elements ω_i that are any real numbers (not necessarily positive). Let $\mathfrak{t}_+ \subset \mathfrak{t}$ be the subset of block-diagonal Ω with positive ω_i. Then, as we said earlier, every $X \in \mathfrak{E}^0$ is conjugate to a unique $\Omega \in \mathfrak{t}_+$ by some $g \in \mathrm{Sp}_{2N}(\mathbb{R})$. Third, introducing $T := \exp(\mathfrak{t})$, which is an N-dimensional compact torus, $T \cong (S^1)^N$, let G/T be the quotient of $G \equiv \mathrm{Sp}_{2N}(\mathbb{R})$ by the right action of T. Then the mapping

$$(G/T) \times \mathfrak{t}_+ \to \mathfrak{E}^0, \quad (gT, \Omega) \mapsto g\Omega g^{-1} \tag{2.6}$$

(the reverse of the process of quasidiagonalization), is a smooth bijection.

We are stating these facts without proof, as they are standard facts of symplectic linear algebra.

III. PROBABILITY MEASURE

By placing a probability distribution on the elliptic domain $\mathfrak{E}^0$, one gets a random matrix model for disordered bosonic quasiparticles. We are then interested in the statistics of the characteristic frequencies or levels ω_i.

It is well known that in the Wigner–Dyson situation of random Hermitian or random real symmetric matrices, where the symmetry group is compact, the level correlation functions exhibit universal behavior in a suitable scaling limit. One may therefore ask whether a similar scenario—leading to universal laws, possibly of a new kind—might be at work in the case being considered.

To answer this question we need to investigate a class of probability distributions on $\mathfrak{E}^0$ as wide as possible. As a first step, the present paper deals with a family of well motivated distributions which are easy to analyze.

A. Choice of measure

Coming from the standard Wigner–Dyson situation with a compact symmetry group, one might be inclined to try and consider a Gaussian distribution

$$P(X)dX \overset{?}{\propto} e^{-\mathrm{Tr}X^2} dX,$$

where dX is a Lebesgue measure for $\mathfrak{E}^0$:

$$dX := \prod_{i,j} dA_{ij} \prod_{i \leqslant j} dB_{ij} dC_{ij}. \tag{3.1}$$

However, such a distribution has infinite mass, since it is invariant under the action $X \mapsto gXg^{-1}$ by the *noncompact* group $\mathrm{Sp}_{2N}(\mathbb{R})$, and it therefore cannot be normalized to be a probability measure.

Staying within the class of Gaussian distributions, a better choice of distribution function is

$$P(X = Jh) \propto e^{-\tau \mathrm{Tr}h/2 - \sigma \mathrm{Tr}h^2} = e^{-\tau \mathrm{Tr}(J^{-1}X)/2 - \sigma \mathrm{Tr}(J^{-1}X)^2} \tag{3.2}$$

for some positive parameters σ, τ. Because of the presence of J^{-1} under the trace, this distribution function is invariant under conjugation $X \mapsto gXg^{-1}$ only if $g \in \mathrm{Sp}_{2N}(\mathbb{R})$ satisfies the additional condition $g^{-1}Jg = J$. Combining the two conditions, $g^t Jg = J = g^{-1}Jg$, one sees that the invariance group of the function $P(X)$ in Eq. (3.2) is the intersection of the real symplectic and orthogonal groups in $2N$ dimensions

$$K = \mathrm{Sp}_{2N}(\mathbb{R}) \cap \mathrm{SO}_{2N}(\mathbb{R}). \tag{3.3}$$

This group K is isomorphic to U_N, the group of unitary transformations in N complex dimensions. Indeed, changing from the symplectic basis $\{q_1, \ldots, q_N, p_1, \ldots, p_N\}$ to the oscillator basis

$$\{a_1, \ldots, a_N, a_1^\dagger, \ldots, a_N^\dagger\}, \quad a_j = \frac{1}{\sqrt{2}}(q_j + ip_j), \quad a_j^\dagger = \frac{1}{\sqrt{2}}(q_j - ip_j),$$

one finds that K is the subgroup of canonical transformations that do not mix the lowering operators $\{a_j\}$ with the raising operators $\{a_j^\dagger\}$. Moreover, $\mathrm{U}_N \cong K \subset \mathrm{Sp}_{2N}(\mathbb{R})$ is known to be a maximal compact subgroup. It therefore is the biggest symmetry group possible in our problem.

In the sequel we will consider Eq. (3.2) with $\sigma = 0$. Thus we take our probability distribution to be

$$P(X)dX := c_N(\tau) e^{-\tau \mathrm{Tr}(J^{-1}X)/2} dX, \tag{3.4}$$

with the normalization constant $c_N(\tau)$ chosen in such a way that $\int_{\mathfrak{E}^0} P(X)dX = 1$. Further motivation for this choice of distribution was put forth in the introduction (Sec. I).

B. Polar decomposition and reduction

Let now $F(X) = F(gXg^{-1})$ be some function on $\mathfrak{E}^0$ which is *radial*, i.e., invariant under conjugation by every element $g \in \mathrm{Sp}_{2N}(\mathbb{R})$. Given such a function F, which depends only on the eigenfrequencies $\omega_1, \ldots, \omega_N$ of X, we wish to take the expectation of F with respect to the probability measure $P(X)dX$:

$$\langle F \rangle := \int_{\mathfrak{E}^0} F(X)P(X)dX. \tag{3.5}$$

The problem of computing such expectations is best tackled by using the polar decomposition $\mathfrak{E}^0 \cong \mathfrak{t}_+ \times (G/T)$ which is given by quasidiagonalization of X; see Eq. (2.6). Inserting that decomposition into Eq. (3.5) one has

$$\langle F \rangle = \int_{\mathfrak{t}_+} \left[\int_{G/T} P(g\Omega g^{-1}) dg_T \right] F(\Omega) j(\Omega) d\Omega, \quad d\Omega = d\omega_1 d\omega_2 \cdots d\omega_N, \tag{3.6}$$

where g_T is a G-invariant measure for G/T, and $j(\Omega)$ is the Jacobian of the change of variables $X = g\Omega g^{-1}$.

Let us calculate this Jacobian. Differentiating the polar coordinate mapping Eq. (2.6) we get

$$\delta(g\Omega g^{-1}) = g(\delta\Omega + [g^{-1}\delta g, \Omega])g^{-1}.$$

The Jacobian we are seeking is the product of all nonzero eigenvalues of the linear operator $X \mapsto [X, \Omega]$. These eigenvalues are called the roots of the pair $[\mathfrak{sp}_{2N}(\mathbb{R}), \mathfrak{t}]$. They are

$$\pm(\omega_i + \omega_j) \quad (i \leqslant j), \qquad \pm(\omega_i - \omega_j) \quad (i < j),$$

each with multiplicity one. Thus, by taking the product of all nonvanishing roots

$$j(\Omega)d\Omega = \prod_{i<j} (\omega_i^2 - \omega_j^2)^2 \prod_{k=1}^{N} (2\omega_k)^2 d\omega_k. \tag{3.7}$$

To complete the polar integration formula (3.6) we need $\int_{G/T} P(g\Omega g^{-1}) dg_T$. In the next subsection we are going to show that this integral can be calculated in closed form and depends on $\omega_1, \ldots, \omega_N$ as

$$\int_{G/T} P(g\Omega g^{-1})dg_T \propto \prod_{i<j}(\omega_i+\omega_j)^{-1}\prod_{k=1}^{N}\omega_k^{-1}e^{-\tau\omega_k}. \tag{3.8}$$

Thus, in total, the expectation of a radial observable $F(X)=F(\Omega)\equiv F(\omega_1,\ldots,\omega_N)$ becomes

$$\langle F\rangle = \tilde{c}_N(\tau)\int_{\mathbb{R}_+^N} F(\omega_1,\ldots,\omega_N)\prod_{i<j}(\omega_i-\omega_j)(\omega_i^2-\omega_j^2)\prod_{k=1}^{N}e^{-\tau\omega_k}\omega_k d\omega_k, \tag{3.9}$$

where $\tilde{c}_N(\tau)$ is another normalization constant. This expectation, for the special choices of F that give the level correlation functions, will be calculated in Sec. V of the paper.

C. Computation of the integral (3.8)

We now establish Eq. (3.8). Omitting a normalization constant, we denote the integral on the left-hand side of Eq. (3.8) by

$$I(\Omega) := \int_{G/T} e^{-\tau \mathrm{Tr}(J^{-1}g\Omega g^{-1})/2}dg_T. \tag{3.10}$$

What makes this integral computable in closed form is that J lies in $\mathfrak{sp}_{2N}(\mathbb{R})$ and $\Omega\mapsto g\Omega g^{-1}$ is the adjoint action of $G=\mathrm{Sp}_{2N}(\mathbb{R})$ on its Lie algebra. These circumstances place the integral in the class of integrals of Harish–Chandra–Itzykson–Zuber type, which are covered by the Duistermaat–Heckman theorem and its generalizations. In the present case, the integral can be computed in a particularly simple manner, as follows.

Let dg and dt be Haar measures for G and T, respectively, with $dg=dg_T dt$ and $\int_T dt=\mathrm{vol}(T)$. Our first step is to switch from G/T to integrating over the full symplectic group G:

$$I(\Omega)=\frac{1}{\mathrm{vol}(T)}\int_G e^{-\tau \mathrm{Tr}(J^{-1}g\Omega g^{-1})/2}dg.$$

Next we use that dg is invariant under inversion, $g\mapsto g^{-1}$. After this transformation the integrand is expressed in terms of the combination $gJ^{-1}g^{-1}=-gJg^{-1}$. Since $kJk^{-1}=J$ for $k\in K\cong \mathrm{U}_N$, we can push down the resulting integral over G to an integral over the quotient space G/K. Let dg_K and dk be invariant resp. Haar measures for G/K and K so that $dg=dg_K dk$. Then

$$I(\Omega)=\frac{\mathrm{vol}(K)}{\mathrm{vol}(T)}\int_{G/K} e^{\tau \mathrm{Tr}(\Omega gJg^{-1})/2}dg_K, \quad \mathrm{vol}(K)=\int_K dk. \tag{3.11}$$

The homogeneous space $G/K\cong \mathrm{Sp}_{2N}(\mathbb{R})/\mathrm{U}_N$ has the salient feature of being a noncompact symmetric space of Hermitian type. Such spaces carry the structure of a Kähler manifold, which means that G/K comes with a non-degenerate, closed, and G-invariant two-form (the Kähler form of G/K). Writing $gJg^{-1}=:Q$ this is the form

$$\beta=\mathrm{Tr}(Q\mathrm{d}Q\wedge \mathrm{d}Q). \tag{3.12}$$

Notice that $\dim_{\mathbb{R}} G/K=N(2N+1)-N^2=N(N+1)$. Raising β to its $(1/2)N(N+1)$th exterior power one obtains a top-dimensional form, $\beta^{(1/2)N(N+1)}$, which is still G-invariant and nonzero. Since G/K is homogeneous, there can be at most one such form up to multiplication by scalars. Therefore, there exists some (nonzero) constant such that

$$dg_K=\mathrm{const}\,\beta^{(1/2)N(N+1)}. \tag{3.13}$$

By Darboux's theorem one can find local symplectic coordinates for G/K that bring β into canonical form. While this fact by itself would not be of much practical help, in the present case such coordinates exist *globally* and, moreover, they can be chosen in such a way that $\mathrm{Tr}(\Omega gJg^{-1})$

depends on them *quadratically*.

To describe these perfect coordinates, consider the space of complex symmetric $N\times N$ matrices, $\mathrm{Sym}(\mathbb{C}^N)$, which has dimension $(1/2)N(N+1)$ over $\mathbb{C}$ and thus shares with G/K the dimension $N(N+1)$ over $\mathbb{R}$. With every $Z\in\mathrm{Sym}(\mathbb{C}^N)$ associate a positive Hermitian $2N\times 2N$ matrix $\tilde{g}$ by

$$\tilde{g}=\tilde{g}(Z,Z^\dagger)=\begin{pmatrix}(1+ZZ^\dagger)^{1/2} & Z\\ Z^\dagger & (1+Z^\dagger Z)^{1/2}\end{pmatrix}. \tag{3.14}$$

Now if S is the matrix of the unitary transformation from the real symplectic basis $\{p_j,q_j\}$ of $\mathbb{R}^{2N}$ to the oscillator basis $\{a_j,a_j^\dagger\}$:

$$S:=\frac{1}{\sqrt{2}}\begin{pmatrix}1_N & i1_N\\ -1_N & i1_N\end{pmatrix},$$

then $g:=S^{-1}\tilde{g}S$ is immediately seen to be a real matrix and, using the relation

$$SJS^{-1}=i\Sigma_3,\quad \Sigma_3=\begin{pmatrix}1_N & 0\\ 0 & -1_N\end{pmatrix},$$

one finds that $g=S^{-1}\tilde{g}S$ satisfies $g^\dagger Jg=g^tJg=J$ and hence lies in $\mathrm{Sp}_{2N}(\mathbb{R})$. Moreover, the reverse correspondence $k\mapsto\tilde{k}=SkS^{-1}$ is the isomorphism between K and U_N discussed in the paragraph after Eq. (3.3); it takes $k\in K$ to the block-diagonal form

$$\tilde{k}=\begin{pmatrix}U & 0\\ 0 & \bar{U}\end{pmatrix},\quad U\in\mathrm{U}_N.$$

It is now clear that the mapping $\mathrm{Sym}(\mathbb{C}^N)\to G/K$ by $Z\mapsto S^{-1}\tilde{g}(Z,Z^\dagger)SK\equiv gK$ is a bijection. Using it to express the Kähler form β in terms of the complex symmetric matrix Z, one obtains

$$\beta=\mathrm{Tr}(Q\mathrm{d}Q\wedge\mathrm{d}Q)=-4i\mathrm{Tr}(\Sigma_3\mathrm{d}\tilde{g}^{-1}\wedge\mathrm{d}\tilde{g})=8i\mathrm{Tr}(\mathrm{d}Z\wedge\mathrm{d}Z^\dagger). \tag{3.15}$$

Thus, the top-dimensional form $\beta^{(1/2)N(N+1)}$ is constant in Z:

$$\frac{\beta^{(1/2)N(N+1)}}{\left[\frac{1}{2}N(N+1)\right]!}=(8i)^{(1/2)N(N+1)}2^{(1/2)N(N-1)}\prod_{i\leqslant j}dZ_{ij}\wedge d\bar{Z}_{ij}, \tag{3.16}$$

and from Eq. (3.13) the invariant measure dg_K is a constant multiple of the Lebesgue measure for $\mathrm{Sym}(\mathbb{C}^N)$.

Finally, from $g=S^{-1}\tilde{g}S$, $SJS^{-1}=\mathrm{i}\Sigma_3$, and Eq. (3.14) one has

$$-\mathrm{Tr}(\Omega gJg^{-1})=\mathrm{Tr}\omega(1+2ZZ^\dagger)+\mathrm{Tr}\omega(1+2Z^\dagger Z),\quad \omega=\mathrm{diag}(\omega_1,\ldots,\omega_N).$$

Our integral (3.11) now becomes a Gaussian integral

$$I(\Omega)=\mathrm{const}\,e^{-\tau\Sigma_k\omega_k}\int e^{-2\tau\mathrm{Tr}Z^\dagger(Z\omega+\omega Z)}\prod_{i\leqslant j}dZ_{ij}d\bar{Z}_{ij}.$$

Doing this integral one immediately obtains the result for $I(\Omega)$ stated in Eq. (3.8).

D. Generalization

A slight generalization of Eq. (3.4) is afforded by the observation that the determinant of X in Eq. (2.2) is always positive:

$$\mathrm{Det}(X) = \mathrm{Det}(\Omega) = \prod_{k=1}^{N} \omega_k^2.$$

Thus, by multiplying the probability measure $P(X)dX$ by some power $l-1>-1$ of the positive square root $\mathrm{Det}(X)^{1/2}$ and adjusting the normalization constant, we get another probability measure

$$P_l(X)dX = \text{const}\ \mathrm{Det}(X)^{(1/2)(l-1)} e^{-(1/2)\tau \mathrm{Tr}(J^{-1}X)} dX. \tag{3.17}$$

This measure is still U_N invariant. By the process of quasidiagonalization and drawing on our results above, we push it forward to a measure for the eigenfrequencies. The result is

$$d\mu_{N,l}(\omega_1, \ldots, \omega_N) = c_{N,l}(\tau) \prod_{i<j} (\omega_i - \omega_j)^2 (\omega_i + \omega_j) \prod_{k=1}^{N} \omega_k^l e^{-\tau\omega_k} d\omega_k. \tag{3.18}$$

This, for any non-negative power $l \in \mathbb{Z}$, is the family of probability distributions to be studied in the present paper.

IV. LARGE-*N* LIMIT OF THE ONE-POINT DENSITY IN THE BULK

The one-point density $\rho(\omega)d\omega$ is defined as the probability density for any one of the eigenfrequencies ω_i to have the value of ω, irrespective of what the values of the other eigenfrequencies are; thus $\rho(\omega)$ is the function

$$\rho(\omega) := \int \sum_{i=1}^{N} \delta(\omega - \omega_i) d\mu_{N,l}(\omega_1, \ldots, \omega_N), \tag{4.1}$$

which has the properties $\rho(\omega) \geqslant 0$ and

$$\int_0^\infty \rho(\omega) d\omega = N. \tag{4.2}$$

We are now interested in the behavior of the density function $\rho(\omega)$ in the limit of $N \to \infty$. From the expression (3.18) and experience with similar problems (see, e.g., Ref. 11), we expect that this limit can be obtained by maximizing the functional

$$F = \frac{1}{2} \int_0^\infty \int_0^\infty \ln[(\omega - \omega')^2(\omega + \omega')] \rho(\omega)\rho(\omega') d\omega' d\omega + \int_0^\infty \ln(\omega^l e^{-\omega\tau}) \rho(\omega) d\omega \tag{4.3}$$

subject to the constraint (4.2) and the condition $\rho(\omega) \geqslant 0$. More precisely, the limit is expected to exist in the scaled variable $x := \omega\tau/N$; i.e., there should exist a certain non-negative function $\rho_\infty(x)$ with $\int \rho_\infty(x)dx = 1$ such that $\rho(\omega)$ is asymptotic to $\tau\rho_\infty(\omega\tau/N)$.

Varying F with respect to $\rho(\omega)$ we get

$$\frac{\delta F}{\delta \rho(\omega)} = \int_0^\infty [2 \ln|\omega - \omega'| + \ln(\omega + \omega')] \rho(\omega') d\omega' + l \ln \omega - \omega\tau.$$

We now insert the asymptotic equality $\rho(Nx/\tau) \approx \tau\rho_\infty(x)$ and pass to the limit $N \to \infty$ in the scaling variable x. Let $\mathrm{supp}(\rho_\infty) = [0, b]$ be the region of support of ρ_∞. Then the condition $\delta F / \delta \rho(\omega) = N\lambda$, where λ is a Lagrange multiplier for the constraint (4.2), yields the equation

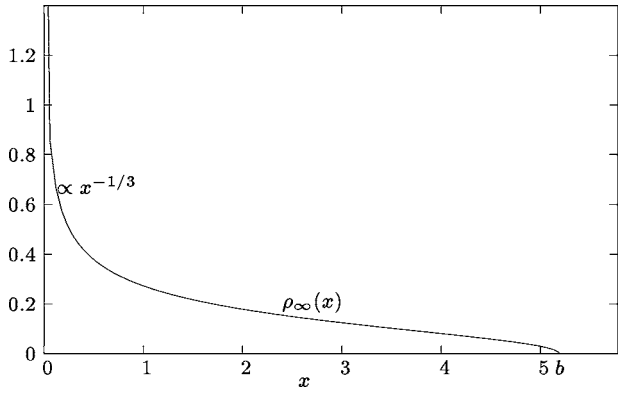

FIG. 1. The graph of the function ρ_∞.

$$\int_0^b [2\ln|x-x'|+\ln(x+x')]\rho_\infty(x')dx' - x = \lambda \quad (0<x<b), \tag{4.4}$$

which no longer depends on the parameter l. It can be shown that our functional F is convex; as a result, the solution ρ_∞ of Eq. (4.4) exists and is unique when supplemented by the normalization condition

$$\int_0^b \rho_\infty(x)dx = 1. \tag{4.5}$$

In the following subsections, we are going to construct the solution to the mathematical problem posed by Eqs. (4.4) and (4.5). It will turn out to be

$$\rho_\infty(x) = \frac{1}{2\pi}(x/b)^{-1/3}[(1+\sqrt{1-x^2/b^2})^{1/3} - (1-\sqrt{1-x^2/b^2})^{1/3}] \quad (0<x\leqslant b=3\sqrt{3}). \tag{4.6}$$

The graph of this function is plotted in Fig. 1. From the expression (4.6) the behavior near the lower edge $x=0$ is

$$\rho_\infty(x) \simeq \frac{1}{2\pi}(2b/x)^{1/3} \quad (0<x\ll b),$$

while close to the upper edge $x=b$ one gets

$$\rho_\infty(x) \simeq \frac{1}{3\pi}(1-x^2/b^2)^{1/2} \quad (x<b,\ x\to b).$$

In the vicinity of the upper and lower edges there exists crossover to a fine-scale behavior that cannot be found by the present method of maximization of the functional F. The crossover at the upper edge involves Airy functions on a scale $N^{1/3}$, which is small compared to the bulk scale N. At the lower edge, the crossover occurs on a very fine scale, $N^{-1/2}$, which is small even in comparison with the bulk mean level spacing (which is of order N^0).

A. Method of solution (idea)

We do not know how to solve Eq. (4.4) for the unknown function $\rho_\infty(x)$ directly. Therefore, to simplify the problem we differentiate once with respect to x to obtain the equation

$$2\mathcal{P}\int_0^b \frac{\rho_\infty(x')dx'}{x-x'} + \int_0^b \frac{\rho_\infty(x')dx'}{x+x'} = 1, \tag{4.7}$$

where $\mathcal{P}$ means the principal value of the integral. At this stage, the value of b is unknown but assumed to be finite.

Introducing the Green's function (or Stieltjes transform)

$$g(z) := \int_0^b \frac{\rho(x)dx}{x-z}, \quad z \in \mathbb{C}\backslash[0,b], \tag{4.8}$$

and the related functions

$$g_\pm(x) := \lim_{\varepsilon\to 0+} g(x \pm i\varepsilon), \quad g_0(x) := -g(-x), \tag{4.9}$$

we bring Eq. (4.7) into the form

$$g_+(x) + g_-(x) + g_0(x) = -1 \quad (0 < x < b). \tag{4.10}$$

To solve this equation, we are led to do an exercise in complex analysis which is motivated as follows.

Let $w \mapsto f(w)$ be some meromorphic function of a complex variable w, and let the equation $z=f(w)$ have r simple roots $w_1(z), w_2(z), \ldots, w_r(z)$, i.e., $z=f[w_1(z)]=\ldots=f[w_r(z)]$. If the function f is analytic in $1/w$ at $w=\infty$, these roots add up to a constant

$$\sum_{i=1}^{r} w_i(z) = \text{const} =: c \quad (\text{independent of } z). \tag{4.11}$$

Indeed, if γ is a closed contour encircling all of the roots in the counterclockwise sense, then

$$\sum w_i'(z) = \sum \frac{1}{f'[w_i(z)]} = \frac{1}{2\pi i}\oint_\gamma \frac{dw}{f(w)-z} = 0,$$

where the second equality is by the residue theorem, and the last equality follows by contracting γ to the point at infinity. Thus $\Sigma w_i'(z)=0$ and, hence, $\Sigma w_i(z)=$const.

Equation (4.11) for $r=3$ looks similar to Eq. (4.10) and can, in fact, be made to look identical to it by the following observation. Notice that the function $z \mapsto g(z)$ defined by Eq. (4.8) is holomorphic in the interior of the left half of the complex plane. Suppose, therefore, that we have found a root $g(z)$ of $z=f[g(z)]$ which is holomorphic in the left half plane, and that $g_\pm(x) = \lim_{\varepsilon\to 0+} g(x\pm i\varepsilon)$ are its two analytic continuations to positive real $x \in (0,b)$. Moreover, suppose that the function f has a reflection symmetry

$$f(w) = -f(2a-w) \quad (a \in \mathbb{C}). \tag{4.12}$$

Then $z \mapsto 2a-g(-z)$ is a root of $z=f(w)$ holomorphic in the right half plane, and from Eq. (4.11) we infer that

$$g_+(x) + g_-(x) + [2a - g(-x)] = c.$$

Setting $g_0(x) \equiv -g(-x)$ this becomes the same as Eq. (4.10) if

$$c - 2a = -1. \tag{4.13}$$

Thus we are inspired to interpret g_+, g_-, and $2a+g_0$ as the three roots of an equation $z=f(w)$. Given this interpretation, solving Eq. (4.10) amounts to finding the function f.

B. The good function *f* to consider

We are looking for a certain meromorphic function f on $\mathbb{C}$. By adding a point at infinity we can view such a function f as a mapping of the Riemann sphere $S^2=\mathbb{C}\cup\{\infty\}$ to itself. We want this mapping to have degree $r=3$; i.e., every regular point z of f is to have three distinct preimages

$$f^{-1}(z)=\{w_1(z),w_2(z),w_3(z)\}.$$

Such a mapping can be presented in the general form

$$f(\omega)=f_\infty+\sum_{i=1}^{3}\frac{b_i}{w-a_i} \tag{4.14}$$

with some complex numbers a_i, b_i, and f_∞.

Let us narrow down the choice of parameters. From the normalization condition (4.5) and the definition of $g(z)$ in Eq. (4.8), we have the limit $zg(z)\to -1$ for $z\to\infty$. Therefore, since $f[g(z)]=z$ by construction, we need $f(w)$ to have a pole at $w=g(\infty)=0$ with residue -1. So we choose $a_1=0$ and $b_1=-1$. The reflection symmetry (4.12) is then implemented by setting $f_\infty=0$, $b_3=b_1$, and $a_i=(i-1)\ a$ for $i=1,2,3$ and some $a\in\mathbb{C}$. Thus

$$f(w)=-\frac{1}{w}+\frac{b_2}{w-a}-\frac{1}{w-2a},$$

where the parameters a and b_2 are still unknown.

Next observe that for a degree-r holomorphic mapping f: $S^2\to S^2$, the number of singular points, where $f'(w)=0$, is $2r-2$. Indeed, writing f as $f(w)=p(w)/q(w)$ where p and q are polynomials of degree r, one has

$$f'(w)=\frac{p'(w)q(w)-p(w)q'(w)}{q(w)^2},$$

the numerator of which is a polynomial of degree $2r-2$ and so has $2r-2$ zeros.

Thus we should expect our function (4.14) to have $2\times 3-2=4$ singular points. The reflection symmetry (4.12) makes for their images $\{f(w)\in\mathbb{C}\,|\,f'(w)=0\}$ to be arranged symmetrically around $z=0$. Now notice that our Green's function $g(z)$, being the Stieltjes transform of $\rho_\infty(x)$ with support $[0,b]$, must have singularities at $z=0$ and $z=b$. The image of the singular set had better contain these values, and thus is determined to be $\{-b,0,+b\}$ by reflection symmetry. Actually, since our situation calls for f to have four singular points, the singularity at $z=0$ (corresponding to $w=\infty$) must have multiplicity two. This is achieved by choosing $b_2=-b_1-b_3=+2$, so that

$$f(w)=-\frac{1}{w}+\frac{2}{w-a}-\frac{1}{w-2a}=\frac{-2a^2}{w(w-a)(w-2a)},$$

resulting in the behavior $f(w)\sim w^{-3}$ for $w\to\infty$. The singular points of f now are $w=a\pm a/\sqrt{3}$, and ∞. These correspond to $z=f(w)=\pm 3\sqrt{3}/a$, and 0, respectively, so we infer

$$b=3\sqrt{3}/|a|. \tag{4.15}$$

It remains to pin down the last unknown parameter a. For that purpose, recall that the sum of the roots $f^{-1}(z)=\{w_1(z),w_2(z),w_3(z)\}$ is a constant, c, independent of z. To determine this constant, look at $\Sigma w_i(\infty)$ and use that the poles of f are at $w=0$, a, $2a$ to obtain

$$c=\Sigma w_i(z)=\Sigma w_i(\infty)=3a. \tag{4.16}$$

We then conclude $a=-1$ from Eq. (4.13), and $b=3\sqrt{3}$ from Eq. (4.15). In summary, the good meromorphic function f for us to consider is

$$w \mapsto f(w) = \frac{-2}{w(w+1)(w+2)}. \tag{4.17}$$

Let us mention in passing that the idea to consider the equation $z=f(w)$ or, equivalently

$$w(w+1)(w+2) + 2/z = 0,$$

first came to one of us (H.-J.S.) from previous work[10] on the Green's function of the Bures measure, whose large-N limit leads to a similar equation.

C. Solution of the problem

The situation can now be succinctly described like this: thinking of

$$W := \mathbb{C}\setminus\{-1+1/\sqrt{3}, -1-1/\sqrt{3}\}, \quad Z := (\mathbb{C}\setminus\{b,0,-b\}) \cup \{\infty\} \quad (b = 3\sqrt{3}),$$

as two Riemann surfaces W and Z, the function f of Eq. (4.17) gives us a holomorphic cover

$$f: W \to Z, \quad f^{-1}(z) = \{w_1(z), w_2(z), w_3(z)\}.$$

What is the monodromy of this cover, i.e., what happens when the locally defined functions $z \mapsto w_i(z)$ are analytically continued around one of the singular points $z=b,0,-b$? At the point $z=0$ (or $w=\infty$) we have a cubic singularity $z \sim w^{-3}$. Consequently, the monodromy at $z=0$ cyclically permutes the roots $w_i(z)$. Turning to $z=\pm b$, we see that linearization $z=\pm b+\delta z$ and $w=f^{-1}(\pm b)+\delta w$ gives

$$\delta z \sim (\delta w)^2.$$

In the latter two cases the monodromy must exchange two of the $w_i(z)$ while leaving the third one invariant.

Now focus on the situation near the singular point $z=-b$ and denote by $w(z) \equiv g(z)$ the root which, there, is trivial under monodromy and, hence, exists as a holomorphic function in some neighborhood of $z=-b$. With the remaining two singularities being at $z=0$ and $z=b$, the function $g(z)$ actually extends to a holomorphic function on the Riemann sphere $\mathbb{C}\cup\{\infty\}$ cut along, say, $[0,b] \subset \mathbb{R}$. Let us verify that this holomorphic function $g: (\mathbb{C}\setminus[0,b]) \cup \{\infty\} \to W$ coincides with the Green's function (4.8) solving our problem (4.10).

By the holomorphic nature of g and Cauchy's theorem, we have that

$$g(z) = \frac{1}{2\pi i} \oint_{\gamma} \frac{g(z')dz'}{z'-z},$$

where γ is a small loop running around z in the counterclockwise sense. Since g is holomorphic at infinity, the loop γ can be deformed (through infinity) to a loop encircling the cut $[0,b]$, but now with the orientation reversed. Collapse the deformed loop to the two line segments connecting 0 with b. Then, setting $g_{\pm}(x) = \lim_{\varepsilon \to 0+} g(x \pm i\varepsilon)$ and

$$\rho_{\infty}(x) := \frac{g_+(x) - g_-(x)}{2\pi i} \quad (0 < x < b), \tag{4.18}$$

$g(z)$ is obviously given by the integral in Eq. (4.8).

Because $g_+(x)$ and $g_-(x)$ arise by analytic continuation from $g(z) \in f^{-1}(z)$, these are two of the three elements in the set $f^{-1}(x)$. How is the third element of $f^{-1}(x)$ related to $g(z)$? To see that, recall $a=-1$ and from Eq. (4.12) the invariance of the equation $z=f(w)$ under $(z,w) \mapsto (-z, 2a-w)$. Thus, if $g(-z)$ is a root over $-z$, then $-2-g(-z)$ is a root over z, and it follows that $g_0(x)-2$ with $g_0(x) := -g(-x)$ (for $0<x<b$) is a root over x. The roots $g_+(x)$, $g_-(x)$, and $g_0(x)-2$ all are different as functions. In fact, $\Im\mathrm{m}\, g_+(x) > 0 = \Im\mathrm{m}\, g_0(x) > \Im\mathrm{m}\, g_-(x)$ for $0<x<b$. So,

$$f^{-1}(x) = \{g_+(x), g_-(x), g_0(x) - 2\},$$

and from Eq. (4.16) we deduce that

$$g_+(x) + g_-(x) + g_0(x) - 2 = \sum_{w \in f^{-1}(x)} w = c = 3a = -3 \quad (0 < x < b),$$

which agrees with Eq. (4.10). Recall that in order for our analysis to work out we must choose

$$b = 3\sqrt{3}. \tag{4.19}$$

With a full understanding of the situation in hand, it is now an easy exercise to obtain $\rho_\infty(x)$ in explicit form. Solving the equation $z=f(w)$ one finds the holomorphic function $g(z)$ in the interval $-b<x<0$ to be

$$g(x) = (-x)^{-1/3}(1 + \sqrt{1 - x^2/b^2})^{1/3} + (-x)^{-1/3}(1 - \sqrt{1 - x^2/b^2})^{1/3} - 1,$$

where all square roots and cubic roots are understood to be positive. This function indeed extends holomorphically to a neighborhood of $x=-b$, as the Taylor expansion at $x=-b$ contains only even powers of $\sqrt{1-x^2/b^2}$. Analytic continuation around the singularity at $z=0$ gives

$$g_\pm(x) = x^{-1/3}e^{\pm \pi i/3}(1 + \sqrt{1 - x^2/b^2})^{1/3} + x^{-1/3}e^{\mp \pi i/3}(1 - \sqrt{1 - x^2/b^2})^{1/3} - 1 \quad (0 < x \leqslant b).$$

Computing the difference (4.18) we then get the result for $\rho_\infty(x)$ claimed in Eq. (4.6), with the value for b given by Eq. (4.19).

As a final remark, let us note that the good form of $g(z)$ to use near infinity is

$$g(z) = -1 + e^{i\pi/6}\left(\sqrt{\frac{1}{b^2} - \frac{1}{z^2}} + \frac{i}{z}\right)^{1/3} + e^{-i\pi/6}\left(\sqrt{\frac{1}{b^2} - \frac{1}{z^2}} - \frac{i}{z}\right)^{1/3}. \tag{4.20}$$

From this, all moments of $\rho_\infty(x)dx$ can be found by expanding $g(z)$ in powers of $1/z$.

V. EXACT SOLUTION USING BIORTHOGONAL POLYNOMIALS

We now express the probability measure (3.18) as

$$d\mu_{N,l}(\omega_1, \ldots, \omega_N) = c_{N,l}(\tau)\prod_{i<j}(\omega_i - \omega_j)(\omega_i^2 - \omega_j^2)\prod_{k=1}^{N} e^{-\tau\omega_k}\omega_k^l d\omega_k, \tag{5.1}$$

and embark on another approach to handling it.

To get started, recall the formula for the Vandermonde determinant

$$\prod_{i>j}(\omega_i - \omega_j) = \mathrm{Det}(\omega_j^{i-1})_{i,j=1,\ldots,N} = \begin{vmatrix} 1 & 1 & \cdots & 1 \\ \omega_1 & \omega_2 & \cdots & \omega_N \\ \vdots & \vdots & \ddots & \vdots \\ \omega_1^{N-1} & \omega_2^{N-1} & \cdots & \omega_N^{N-1} \end{vmatrix}.$$

Using it we reorganize the probability measure (5.1) as

$$d\mu_{N,l}(\omega_1, \ldots, \omega_N) = c_{N,l}(\tau)\mathrm{Det}(\omega_j^{i-1})\mathrm{Det}(\omega_j^{2i-2})\prod_{k=1}^{N} e^{-\tau\omega_k}\omega_k^l d\omega_k. \tag{5.2}$$

We also simplify our notation by setting $\tau=1$.

By standard properties of the determinant, $\mathrm{Det}(\omega_j^{i-1})$ changes only by a multiplicative constant when the monomials ω_j^{i-1} are replaced by any polynomials in ω_j of degree $i-1$. We have two

Vandermonde determinants, $\Pi_{i<j}(\omega_i-\omega_j)$ and $\Pi_{i<j}(\omega_i^2-\omega_j^2)$, so we introduce two sets of polynomials, denoting those of the first set by $P_{i-1}(\omega_j)$ and those of the second one by $Q_{i-1}(\omega_j^2)$. Our measure then becomes

$$d\mu_{N,l}(\omega_1,\ldots,\omega_N)=\tilde{c}_{N,l}\mathrm{Det}[P_{i-1}(\omega_j)]\mathrm{Det}[Q_{i-1}(\omega_j^2)]\prod_{k=1}^{N}e^{-\omega_k}\omega_k^l d\omega_k. \tag{5.3}$$

In order for the introduction of the polynomials $P_n(\omega)$ and $Q_n(\omega^2)$ to be useful we require them to be orthogonal with respect to the integration measure $e^{-\omega}\omega^l d\omega$:

$$I_{m,n}\equiv\int_0^\infty P_m(\omega)Q_n(\omega^2)e^{-\omega}\omega^l d\omega=h_n\delta_{m,n}, \tag{5.4}$$

where the numbers $h_n=I_{n,n}$ depend on the choice of normalization for $P_n(\omega)$ and $Q_n(\omega^2)$. Such polynomials are constructed by a variant of the Gram–Schmidt algorithm, as follows.

A. Biorthogonal polynomials

We review the construction in the general setting of two real vector spaces V, W with a pairing (or nondegenerate bilinear form)

$$\gamma: V\times W\to\mathbb{R}.$$

Given some basis $v_0,v_1,v_2,\ldots$ of V, and a basis $w_0,w_1,w_2,\ldots$ of W, let the entries of the corresponding pairing matrix be denoted by

$$\gamma_{m,n}:=\gamma(v_m,w_n)\quad(m,n=0,1,2,\ldots).$$

The goal now is to construct a new basis $e_0,e_1,e_2,\ldots$ of V, and a new basis $f_0,f_1,f_2,\ldots$ of W such that

$$e_n=v_n+\sum_{n'=0}^{n-1}A_{nn'}v_{n'},\quad f_n=w_n+\sum_{n'=0}^{n-1}B_{nn'}w_{n'},$$

(with real coefficients $A_{nn'}$ and $B_{nn'}$), and the transformed basis vectors form a biorthogonal system

$$\gamma(e_m,f_n)=0\quad m\neq n.$$

This problem has a unique solution by the process of Gram–Schmidt orthogonalization. A nice way of presenting the solution is by means of the following determinants (where, by a slight abuse of notation, the matrix entries in the last column resp. last row are vectors, whereas all of the other matrix entries are numbers)

$$e_n=D_{n-1}^{-1}\begin{vmatrix}\gamma_{0,0}&\cdots&\gamma_{0,n-1}&v_0\\ \gamma_{1,0}&\cdots&\gamma_{1,n-1}&v_1\\ \vdots&\ddots&\vdots&\vdots\\ \gamma_{n,0}&\cdots&\gamma_{n,n-1}&v_n\end{vmatrix},\quad f_n=D_{n-1}^{-1}\begin{vmatrix}\gamma_{0,0}&\gamma_{0,1}&\cdots&\gamma_{0,n}\\ \vdots&\vdots&\ddots&\vdots\\ \gamma_{n-1,0}&\gamma_{n-1,1}&\cdots&\gamma_{n-1,n}\\ w_0&w_1&\cdots&w_n\end{vmatrix}\quad(n=1,2,\ldots), \tag{5.5}$$

with normalization factor

$$D_n=\begin{vmatrix}\gamma_{0,0}&\cdots&\gamma_{0,n}\\ \vdots&\ddots&\vdots\\ \gamma_{n,0}&\cdots&\gamma_{n,n}\end{vmatrix}.$$

These formulas are easily verified. Indeed, pairing e_m with w_n for $m>n$ one gets

$$\gamma(e_m,w_n)=D_{m-1}^{-1}\begin{vmatrix}\gamma_{0,0} & \cdots & \gamma_{0,m-1} & \gamma_{0,n}\\ \gamma_{1,0} & \cdots & \gamma_{1,m-1} & \gamma_{1,n}\\ \vdots & \ddots & \vdots & \vdots\\ \gamma_{m,0} & \cdots & \gamma_{m,m-1} & \gamma_{m,n}\end{vmatrix}=0,$$

which vanishes because the last column coincides with one of the other columns. Since f_n is a linear combination of the vectors $w_{n'}$ with $n'\leqslant n$, it follows that $\gamma(e_m,f_n)=0$ for $m>n$. The same conclusion for $m<n$ follows by reversing the roles of V and W. Notice that $e_n=1v_n+\ldots$ and $f_n=1w_n+\ldots$ by insertion of the factor D_{n-1}^{-1}. The nonvanishing pairing matrix elements for $n\geqslant 1$ are $\gamma_{n,n}=\gamma(e_n,f_n)=\gamma(e_n,w_n)=D_n/D_{n-1}$.

To apply these general formulas to the case under consideration, we choose the vectors v_m and w_n to be the functions $\omega\mapsto\omega^m$ resp. $\omega\mapsto\omega^{2n}$, and take the pairing to be given by integration with our measure $e^{-\omega}\omega^l d\omega$:

$$\gamma_{m,n}=\int_0^\infty \omega^{m+2n}e^{-\omega}\omega^l d\omega=\Gamma(m+2n+l+1). \tag{5.6}$$

Making the identification $e_n\equiv P_n(\omega)$, the general formula for e_n in Eq. (5.5) then gives $P_0(\omega)=1$ and

$$P_n(\omega)=D_{n-1}^{-1}\begin{vmatrix}\Gamma(l+1) & \cdots & \Gamma(l+2n-1) & \omega^0\\ \Gamma(l+2) & \cdots & \Gamma(l+2n) & \omega^1\\ \vdots & \ddots & \vdots & \vdots\\ \Gamma(l+n+1) & \cdots & \Gamma(l+3n-1) & \omega^n\end{vmatrix}\quad (n\geqslant 1). \tag{5.7}$$

Similarly, identifying $f_n\equiv Q_n(\omega^2)$ we obtain $Q_0(\omega^2)=1$ and

$$Q_n(\omega^2)=D_{n-1}^{-1}\begin{vmatrix}\Gamma(l+1) & \Gamma(l+3) & \cdots & \Gamma(l+2n+1)\\ \vdots & \vdots & \ddots & \vdots\\ \Gamma(l+n) & \Gamma(l+n+2) & \cdots & \Gamma(l+3n)\\ \omega^0 & \omega^2 & \cdots & \omega^{2n}\end{vmatrix}\quad (n\geqslant 1). \tag{5.8}$$

Using the relation $\Gamma(z+1)=z\Gamma(z)$ an easy Gauss elimination process gives the normalization constant as

$$D_n=\begin{vmatrix}\Gamma(l+1) & \cdots & \Gamma(l+2n+1)\\ \vdots & \ddots & \vdots\\ \Gamma(l+n+1) & \cdots & \Gamma(l+3n+1)\end{vmatrix}=\prod_{k=0}^{n}2^k k!(2k+1)!. \tag{5.9}$$

From this, note the diagonal pairing matrix elements $h_0=l!$ and

$$\int_0^\infty P_n(\omega)Q_n(\omega^2)e^{-\omega}\omega^l d\omega=h_n=D_n/D_{n-1}=2^n n!(2n+l)!\quad (n\geqslant 1). \tag{5.10}$$

B. *n*-level correlation functions

The n-level correlation function $R_n(\omega_1, \ldots, \omega_n)$ in the present context is defined as

$$R_n(\omega_1, \omega_2, \ldots, \omega_n) = n! \int_{\mathbb{R}_+^N} \sum_{i_1<i_2<\cdots<i_n} \delta(\omega_1 - \tilde{\omega}_{i_1}) \delta(\omega_2 - \tilde{\omega}_{i_2}) \cdots \delta(\omega_n - \tilde{\omega}_{i_n}) d\mu_{N,l}(\tilde{\omega}_1, \ldots, \tilde{\omega}_N). \tag{5.11}$$

A closed-form expression for it can be given from the biorthogonal polynomials $P_{n'}(\omega)$ and $Q_{n'}(\omega^2)$ for $0 \leqslant n' \leqslant N$. The result will take its most succinct form when expressed in terms of the modified functions

$$\tilde{P}_n(\omega) := (-2)^{-n} n!^{-1} e^{-\omega} P_n(\omega), \tag{5.12}$$

$$\tilde{Q}_n(\omega) := (-1)^n (2n+l)!^{-1} \omega^l Q_n(\omega^2), \tag{5.13}$$

[the motivation for the sign $(-1)^n$ will become clear later], which from Eqs. (5.4) and (5.10) obey the orthogonality relations

$$\int_0^\infty \tilde{P}_m(\omega) \tilde{Q}_n(\omega) d\omega = \delta_{m,n}. \tag{5.14}$$

The probability measure (5.3) expressed by these functions takes the form

$$d\mu_{N,l}(\omega_1, \ldots, \omega_N) = \frac{1}{N!} \mathrm{Det}[\tilde{P}_{i-1}(\omega_j)] \mathrm{Det}[\tilde{Q}_{i-1}(\omega_j)] \prod_k d\omega_k.$$

Now, by using the multiplicative property of the determinant, we can also write

$$d\mu_{N,l}(\omega_1, \ldots, \omega_N) = \frac{1}{N!} \mathrm{Det}[K_N(\omega_i, \omega_j)]_{i,j=1,\ldots,N} \prod_k d\omega_k, \tag{5.15}$$

where the kernel $K(\omega_i, \omega_j)$ is defined by

$$K_N(\omega_i, \omega_j) = \sum_{n=0}^{N-1} \tilde{P}_n(\omega_i) \tilde{Q}_n(\omega_j). \tag{5.16}$$

From the orthogonality relations (5.14) this kernel has the reproducing property

$$\int_0^\infty K_N(\omega_i, \omega) K_N(\omega, \omega_j) d\omega = K_N(\omega_i, \omega_j), \tag{5.17}$$

and the trace

$$\int_0^\infty K_N(\omega, \omega) d\omega = N. \tag{5.18}$$

To proceed further, take notice of the relation

$$\int_0^\infty \begin{vmatrix} K_N(\omega_1, \omega_1) & \cdots & K_N(\omega_1, \omega_n) \\ \vdots & \ddots & \vdots \\ K_N(\omega_n, \omega_1) & \cdots & K_N(\omega_n, \omega_n) \end{vmatrix} d\omega_n = (N-n+1) \begin{vmatrix} K_N(\omega_1, \omega_1) & \cdots & K_N(\omega_1, \omega_{n-1}) \\ \vdots & \ddots & \vdots \\ K_N(\omega_{n-1}, \omega_1) & \cdots & K_N(\omega_{n-1}, \omega_{n-1}) \end{vmatrix},$$

which is proved by expanding the determinant with respect to the last row or column and exploiting the properties (5.17) and (5.18). Using it, an inductive procedure starting from

$R_N(\omega_1, \ldots, \omega_N) = \mathrm{Det}[K_N(\omega_i, \omega_j)]_{i,j=1,\ldots,N}$ gives the n-level correlation functions as

$$R_n(\omega_1, \ldots, \omega_n) = \mathrm{Det}[K_N(\omega_i, \omega_j)]_{i,j=1,\ldots,n}. \tag{5.19}$$

Thus the correlations are those of a determinantal process and are completely determined by the kernel $K_N(\omega_i, \omega_j)$. The remaining discussion therefore focuses on this kernel, but first we make another preparatory step.

C. Contour integral representation

We are now going to show that the functions $\widetilde{P}_n(\omega)$ and $\widetilde{Q}_n(\omega)$ have expressions as complex contour integrals

$$\widetilde{P}_n(\omega) = \oint_{S_\epsilon(1)} e^{-\omega u}(1-u^{-2})^{-n-1}u^{l-2}du/\pi i, \tag{5.20}$$

$$\widetilde{Q}_n(\omega) = \oint_{S_\epsilon(0)} e^{\omega v}(1-v^{-2})^{n}u^{-l-1}dv/2\pi i. \tag{5.21}$$

Both integrals are over circles in the complex plane with radius ϵ and counterclockwise orientation; the first circle is centered at $u=1$ and has radius $\epsilon<2$ (to avoid the singularity at $u=-1$), the second one is centered at $v=0$.

Our proof of these expressions for $\widetilde{P}_n(\omega)$ and $\widetilde{Q}_n(\omega)$ will be indirect and in two steps. First, we establish some information on power series. In the case of $\widetilde{Q}_n(\omega)$ we insert the power series of the exponential function $e^{\omega v}$, use the binomial expansion of $(1-v^{-2})^n$, and compute a residue to obtain

$$\widetilde{Q}_n(\omega) = \sum_{k=0}^{n} \binom{n}{k} \frac{(-1)^k \omega^{2k+l}}{(2k+l)!}. \tag{5.22}$$

In the case of $\widetilde{P}_n(\omega)$, calculating the residue at $u=1$ we have that

$$\widetilde{P}_n(\omega) = \frac{2}{n!}\frac{d^n}{du^n}\left[\frac{e^{-\omega u}u^{n+l-1}}{(1+u^{-1})^{n+1}}\right]\Bigg|_{u=1}. \tag{5.23}$$

In both cases, defining $P_n(\omega)$ and $Q_n(\omega^2)$ by the reverse of the relations (5.12) and (5.13), we see from Eqs. (5.22) and (5.23) that these are polynomials of degree n in ω resp. ω^2 and that the highest-degree term (ω^n resp. ω^{2n}) has coefficient one.

Recall now from Sec. V A that, given these properties, the polynomials $P_n(\omega)$ and $Q_n(\omega^2)$ are completely determined by the orthogonality relations (5.4) for $m \neq n$. Via Eqs. (5.12) and (5.13) the latter are in one-to-one correspondence with the orthogonality relations (5.14) (still for $m \neq n$). Therefore, defining

$$\widetilde{I}_{m,n} = \int_0^\infty \widetilde{P}_m(\omega)\widetilde{Q}_n(\omega)d\omega, \tag{5.24}$$

the second and final step of our proof is to show that $\widetilde{I}_{m,n}=0$ for $m \neq n$.

To that end, we insert the expressions (5.20) and (5.21) into Eq. (5.24). The ω dependence then is $e^{-\omega(u-v)}$ with $u \in S_\epsilon(1)$ and $v \in S_\epsilon(0)$. Taking the radius ϵ to be very small ($\epsilon \ll 1$), we have that $e^{-\omega(u-v)}$ decreases rapidly as ω goes to $+\infty$. Therefore, the integral over ω exists, and we may interchange the order of integrations. Doing first the ω integral

$$\int_0^\infty e^{-\omega(u-v)}d\omega = \frac{1}{u-v},$$

the remaining contour integrals for $\tilde{I}_{m,n}$ defined by Eq. (5.24) are

$$\tilde{I}_{m,n} = \oint_{S_\epsilon(1)} \frac{u^{l-2}}{(1-u^{-2})^{m+1}} \left[\oint_{S_\epsilon(0)} \frac{(1-v^{-2})^n dv}{v^{l+1}(v-u)} \right] \frac{du}{2\pi^2}.$$

To simplify the inner integral over v we use the identity

$$\left(\frac{1-v^{-2}}{1-u^{-2}}\right)^n = 1 - \frac{v^2-u^2}{v^2(1-u^2)} \sum_{k=0}^{n-1} \left(\frac{1-v^{-2}}{1-u^{-2}}\right)^k.$$

Inserting this into the expression for $\tilde{I}_{m,n}$ we see that the terms in the k sum do not contribute as the residue at $v=0$ vanishes for all of those terms. Doing the v integral for the first term on the right-hand side, we get

$$\oint_{S_\epsilon(0)} v^{-l-1}(v-u)^{-1}dv = -2\pi i u^{-l-1},$$

so the remaining u integral is

$$\tilde{I}_{m,n} = (\pi i)^{-1} \oint_{S_\epsilon(1)} (1-u^{-2})^{n-m-1} u^{-3} du.$$

This integrand is holomorphic near $u=1$ for $m<n$, and the integral therefore vanishes in that case. For $m>n$ we use the invariance of the integration form under $u \to -u$ to write $I_{m,n}$ as an integral over a sum of two circles

$$\tilde{I}_{m,n} = \frac{1}{2\pi i} \oint_\gamma \frac{u^{2m-2n-1}du}{(u^2-1)^{m-n+1}}, \quad \gamma = S_\epsilon(1) + S_\epsilon(-1).$$

The integrand in this case is holomorphic near $u=0$. In the punctured plane $\mathbb{C}\backslash\{1,-1\}$ the chain $S_\epsilon(1)+S_\epsilon(-1)$ is homologous to the circle at infinity, where the integrand vanishes. Therefore the integral again is zero. This proves that $\tilde{I}_{m,n}=0$ for $m \neq n$, which in turn completes our proof that the contour integrals (5.20) and (5.21) are the same as the functions $\tilde{P}_n(\omega)$, $\tilde{Q}_n(\omega)$ defined from Eqs. (5.7) and (5.8) by Eqs. (5.12) and (5.13). As a final check, note that

$$\tilde{I}_{n,n} = (\pi i)^{-1} \oint_{S_\epsilon(1)} \frac{du}{u(u^2-1)} = 1,$$

which is what it ought to be in view of Eq. (5.14).

Now we harvest a major benefit from the contour integral representations (5.20) and (5.21): using these, we can carry out the sum in the definition (5.16) of the kernel K_N as a geometric sum. The result is a double contour integral

$$K_N(\omega_1,\omega_2) = \oint_{S_\epsilon(1)} du \oint_{S_\epsilon(0)} dv F_N(u,v;\omega_1,\omega_2), \tag{5.25}$$

$$F_N(u,v;\omega_1,\omega_2)=\frac{1}{2\pi^2}e^{-\omega_1 u+\omega_2 v}\frac{u^l v^{-l+1}}{u^2-v^2}\left[\left(\frac{1-v^{-2}}{1-u^{-2}}\right)^N-1\right]. \tag{5.26}$$

This exact expression represents the complete solution of our problem. We will now use it to determine the large-N asymptotics in the bulk and at the hard edge $\omega=0$.

D. Asymptotics in the bulk

The kernel on the diagonal $\omega_1=\omega_2$ is the same as the one-level function, $R_1(\omega)=K_N(\omega,\omega)$; see Eq. (5.19). We already know from Sec. IV the asymptotics of $R_1(\omega)\equiv\rho(\omega)$ in the bulk: introducing the scaling variable $x=\omega/N$ (formerly $x=\omega\tau/N$), this is

$$\lim_{N\to\infty} K_N(Nx,Nx)=\rho_\infty(x),$$

with $\rho_\infty(x)$ given by Eq. (4.6). In the present subsection we are going to demonstrate that the scaling limit of the kernel $K_N(\omega_1,\omega_2)$ off the diagonal leads to sine-kernel universality for all level correlation functions:

$$\lim_{N\to\infty} R_n(Nx+\omega_1,\ldots,Nx+\omega_n)=\mathrm{Det}\left\{\frac{\sin[\pi\rho_\infty(x)(\omega_i-\omega_j)]}{\pi(\omega_i-\omega_j)}\right\}_{i,j=1,\ldots,n}, \tag{5.27}$$

as is expected for systems in the universality class of the Gaussian Unitary Ensemble. As a corollary, we will obtain an independent confirmation of the result (4.6).

Looking at the integral representation (5.25) one might think that the large-N limit could be taken by applying the saddle-point method to that integral. However, as we shall see, the dominant saddle points lie on the line $u=v$ where the integrand has a singularity of type 0/0 which, albeit removable, complicates the saddle-point evaluation.

Therefore, rather than calculating $K_N(\omega_1,\omega_2)$ directly, we look at the product $(\omega_1-\omega_2)K_N(\omega_1,\omega_2)$. Using the relation $(\omega_2-\omega_1)\mathrm{e}^{\omega_2 v-\omega_1 u}=(\partial_v+\partial_u)\mathrm{e}^{\omega_2 v-\omega_1 u}$ and partially integrating, we rewrite Eq. (5.25) as

$$(\omega_1-\omega_2)K_N(\omega_1,\omega_2)=\oint_{S_\epsilon(1)}du\oint_{S_\epsilon(0)}dv\,\widetilde{F}_N(u,v;\omega_1,\omega_2), \tag{5.28}$$

$$\widetilde{F}_N(u,v;\omega_1,\omega_2)=\frac{1}{2\pi^2}e^{-\omega_1 u+\omega_2 v}\left(\frac{\partial}{\partial u}+\frac{\partial}{\partial u}\right)\frac{u^l v^{-l+1}}{u^2-v^2}\left[\left(\frac{1-v^{-2}}{1-u^{-2}}\right)^N-1\right], \tag{5.29}$$

which constitutes the starting point for the following analysis.

In preparation for taking the limit $N\to\infty$, we set $\omega_1=Nx+\omega$ and $\omega_2=Nx+\tilde{\omega}$. The deciding factor in the integrand of $(\omega_1-\omega_2)K_N(\omega_1,\omega_2)$ in the large-N limit will then be

$$\exp[-Nx(u-v)+N\log(1-v^{-2})-N\log(1-u^{-2})],$$

leading to the saddle-point equation

$$\varphi(u)=x=\varphi(v),\quad \varphi(w)=-\partial_w\log(1-w^{-2})=\frac{-2}{w(w^2-1)}. \tag{5.30}$$

Notice that φ is related to our function (4.17) by $f(w-1)=\varphi(w)$. A comprehensive study of the equation $f(w)=z$ and its solutions for w was made in Sec. IV. From there we know that the saddle-point equation $\varphi(w)=x$ has three solutions in general, and for $0<x\leqslant b=3\sqrt{3}$ these are

$$w_\alpha(x) = -x^{-1/3}e^{-2\pi i\alpha/3}(1+\sqrt{1-x^2/b^2})^{1/3} - x^{-1/3}e^{2\pi i\alpha/3}(1-\sqrt{1-x^2/b^2})^{1/3} \quad (\alpha = 1,-1,0). \tag{5.31}$$

In the range of interest $(0<x<b)$ the first two solutions, $w_{\pm 1}(x)$, are complex conjugates of each other while the third one, $w_0(x)$, is negative. Expanding the logarithm of $(1-v^{-2})^N/(1-u^{-2})^N$ to second order around a pair of saddle points w_α, w_β we encounter the Gaussian

$$\exp\left\{\frac{1}{2}N\varphi'[w_\alpha(x)](\delta u)^2 - \frac{1}{2}N\varphi'[w_\beta(x)](\delta v)^2\right\}, \quad \varphi'(x) = \frac{6w^2-2}{w^2(w^2-1)^2}.$$

For the negative saddle point one has $\varphi'[w_0(x)]>0$, so its path of steepest descent would be perpendicular to the real axis in the case of u and along the real axis in the case of v. The latter is inconsistent with the original integration contour for v being $S_\epsilon(0)$. In the former case, $w_0(x)<-1$ is inaccessible because of the singularity of $(1-u^{-2})^{-N}$ intervening at $u=-1$. Thus this saddle point is irrelevant for present purposes and may be discarded.

We now make another preparation of the saddle-point evaluation of the integral, by investigating the behavior of the integrand near the two remaining saddle points. We set

$$u = w_\alpha(x) + N^{-1/2}\delta u, \quad v = w_\beta(x) + N^{-1/2}\delta v \quad (\alpha,\beta = \pm 1),$$

and first look at the diagonal case, $\alpha=\beta$. Using the identity

$$\frac{1}{u-v}\left(\frac{\partial}{\partial u}+\frac{\partial}{\partial v}\right)\left(\frac{1-u^{-2}}{1-u^{-2}}\right)^N = 2N\frac{u^2+uv+v^2-1}{u(u^2-1)v(v^2-1)}\left(\frac{1-v^{-2}}{1-u^{-2}}\right)^N, \tag{5.32}$$

we find the scaling limit of the integrand $\tilde{F}_N$ to be

$$\lim_{N\to\infty} N^{-1}\tilde{F}_N[w_\alpha(x)+N^{-1/2}\delta u, w_\alpha(x)+N^{-1/2}\delta v; Nx+\omega, Nx+\tilde{\omega}]$$
$$= (2\pi)^{-2}e^{-w_\alpha(x)(\omega-\tilde{\omega})}\varphi'[w_\alpha(x)]e^{(1/2)\varphi'[w_\alpha(x)](\delta u^2-\delta v^2)}.$$

The same limit in the off-diagonal case $(\alpha\neq\beta)$ vanishes. Indeed,

$$w_\alpha^2 + w_\alpha w_\beta + w_\beta^2 - 1 = \frac{w_\alpha(w_\alpha^2-1) - w_\beta(w_\beta^2-1)}{w_\alpha - w_\beta} = \frac{-2}{w_\alpha - w_\beta}(x^{-1}-x^{-1}) = 0 \quad (\alpha\neq\beta),$$

and therefore the factor in the numerator on the right-hand side of Eq. (5.32) gives zero.

We now deform the contours of integration as indicated in Fig. 2. The deformed contours pass through the saddle points $w_{\pm 1}$ but miss the saddle point w_0. At $w_{\pm 1}$ the paths of steepest descent for u and v cross at right angles, valleys in one case being mountains in the other case and vice versa.

Next we do the Gaussian integrals. Given the counterclockwise orientations of the original contours $S_\epsilon(1)$ resp. $S_\epsilon(0)$, and taking into account the directions of the paths of steepest descent, we get

$$\int e^{(1/2)\varphi'(w_{+1})\delta u^2}d(\delta u) = \sqrt{2\pi}|\varphi'(w_{+1})|^{-1/2}e^{(1/2)[-\pi i - i\arg\varphi'(w_{+1})]},$$

$$\int e^{-(1/2)\varphi'(w_{+1})\delta v^2}d(\delta v) = \sqrt{2\pi}|\varphi'(w_{+1})|^{-1/2}e^{(1/2)[2\pi i - i\arg\varphi'(w_{+1})]}.$$

The product of these two integrals is $2\pi i/\varphi'(w_{+1})$. The same calculation for the other saddle w_{-1} gives $-2\pi i/\varphi'(w_{-1})$. Thus, putting the factors together and summing over the contributions from diagonal pairs of saddle points $(\alpha=\beta)$ we obtain

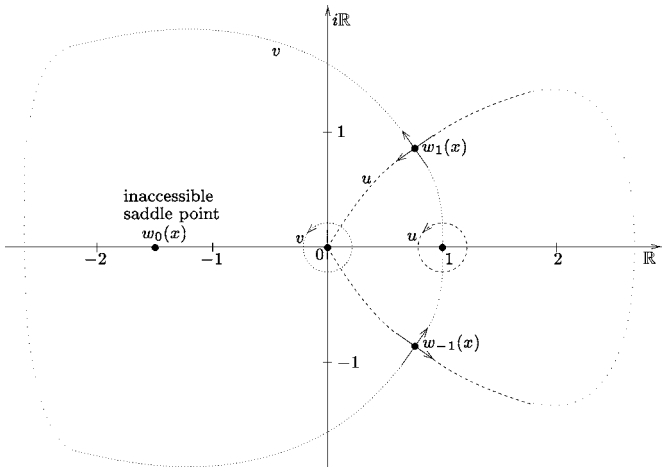

FIG. 2. Sketch of the saddle points for the case of $x=1$. By deforming the original contours, which are small circles around the singular points $u=1$ and $v=0$, one arranges for the contours of integration to pass through the saddle points $w_{\pm 1}(x)$ in the direction of steepest descent. Away from the saddle points the deformed contours are drawn as paths of constant phase, which interpolate between different zeroes of the integrand: they run between 0 and $+\infty$ for u, and between 1 and $-\infty$ for v.

$$(\omega-\tilde{\omega})\lim_{N\to\infty} K_N(Nx+\omega,Nx+\tilde{\omega})=\frac{1}{2\pi i}(e^{-w_{-1}(x)(\omega-\tilde{\omega})}-e^{-w_{+1}(x)(\omega-\tilde{\omega})}).$$

Since $\Re e w_{+1}=\Re e w_{-1}$ and $\Im m w_{+1}=-\Im m w_{-1}$ this means that, with $\Im m w_{+1}(x)=:\pi\rho_\infty(x)$, we have

$$\lim_{N\to\infty} K_N(Nx+\omega,Nx+\tilde{\omega})=e^{-\Re e w_{\pm 1}(x)(\omega-\tilde{\omega})}\frac{\sin[\pi\rho_\infty(x)(\omega-\tilde{\omega})]}{\pi(\omega-\tilde{\omega})}.$$

The exponential factor $e^{-\Re e w_{\pm 1}(x)(\omega-\tilde{\omega})}$ drops out when forming the determinant on the right-hand side of Eq. (5.19). Thus we arrive at the universal sine-kernel (or GUE) correlation functions (5.27).

Setting $\omega=\tilde{\omega}$ notice the special result $\lim_{N\to\infty}K_N(Nx,Nx)=\rho_\infty(x)$. Since the kernel on the diagonal is none other than the one-level function, $K_N(\omega,\omega)=\rho(\omega)$, this gives another determination of the large-N level density ρ_∞. From Eq. (5.31) one sees that $\rho_\infty(x)=\pi^{-1}\Im m w_{+1}(x)$ agrees with our earlier result Eq. (4.6).

E. Asymptotics near $\omega=0$

At the lower edge ($\omega=0$) of the spectrum, a new type of behavior is expected to emerge. This behavior, as we shall see presently, occurs on a scale $\omega\sim N^{-1/2}$.

To exhibit the scaling limit near $\omega=0$, it is best to send the integration variables u, v to their reciprocals, $u\to u^{-1}$ and $v\to v^{-1}$. Then $du\to -u^{-2}du$, $dv\to -v^{-2}dv$, and the integration contour for v has its radius inverted and orientation reversed, $S_\epsilon(0)\to -S_{1/\epsilon}(0)$. However, since the integrand is holomorphic in v on $\mathbb{C}\backslash\{0\}$ we may return to the original radius ϵ (or any other radius, for that matter). In the case of u we take the radius ϵ of $S_\epsilon(1)$ to be very small. Then inversion $u\to u^{-1}$ sends $S_\epsilon(1)$ to itself (or, in any case, to the same homology class on $\mathbb{C}\backslash\{1\}$), with no change of orientation. Altogether, then, carrying out the transformation $(u,v)\to(u^{-1},v^{-1})$ the integral representation (5.25) continues to hold true if we make the replacement

$$F_N(u,v;\omega_1,\omega_2)\to -u^{-2}v^{-2}F_N(u^{-1},v^{-1};\omega_1,\omega_2)=\frac{1}{2\pi^2}e^{-\omega_1/u+\omega_2/v}\frac{u^{-l}v^{l-1}}{u^2-v^2}\left[\left(\frac{1-v^2}{1-u^2}\right)^N-1\right].$$

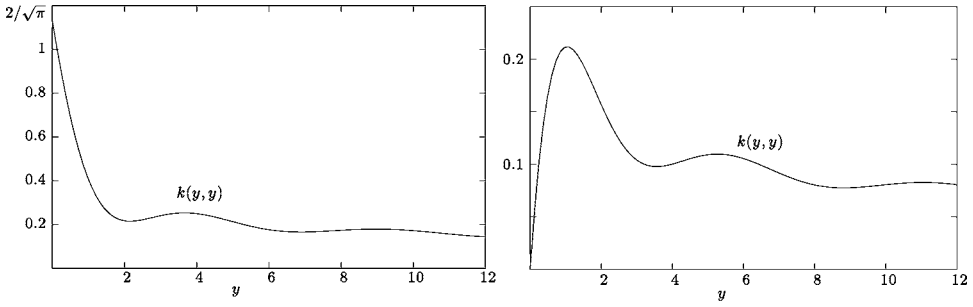

FIG. 3. The graph of the scaling function $k(y,y)$ for the case of $l=0$ (left) and $l=1$ (right).

Next, as another preparation for taking the limit $N\to\infty$, we deform the u-contour $S_\epsilon(1)$ to some axis parallel to the imaginary axis. The deformed contour crosses the real axis between $u=0$ and $u=1$ and is directed from $u=+i\infty$ to $u=-i\infty$. We also reverse the direction of integration for u and change the overall sign of the integral.

Then we set $\omega_j=N^{-1/2}y_j$ and rescale $u\to N^{-1/2}u$ and $v\to N^{-1/2}v$ accordingly. Again, in view of the analytic properties of the integrand we can keep the integration contours fixed while rescaling. Because the u integral converges at infinity we have a good limit

$$\lim_{N\to\infty}(1-u^2/N)^{-N}=\exp(u^2).$$

In total, we thus obtain the following scaling limit for our kernel K_N:

$$k(y_1,y_2):=\lim_{N\to\infty}N^{-1/2}K_N(N^{-1/2}y_1,N^{-1/2}y_2)=\frac{1}{2\pi^2}\int_{i\mathbb{R}+\epsilon}du\int_{\mathrm{U}_1}\frac{dv}{v}e^{-y_1/u+y_2/v}(v/u)^l\frac{e^{u^2-v^2}-1}{u^2-v^2},\tag{5.33}$$

where $\mathrm{U}_1\equiv S_1(0)$ means the unitary numbers, and $i\mathbb{R}+\epsilon$ is the imaginary axis translated by $\epsilon>0$ into the right half of the complex plane. Plots of the scaling function $k(y,y)$ for $l=0,1$ are shown in Fig. 3. Using the method of saddle-point evaluation as in Sec. V C one can show that this function behaves as $k(y,y)\sim y^{-1/3}$ for large y.

Taking the same scaling limit for the functions $\tilde{P}_N(\omega)$ and $\tilde{Q}_N(\omega)$ in Eqs. (5.20) and (5.21) one gets

$$p(y)=\lim_{N\to\infty}N^{-(l-1)/2}\tilde{P}_N(N^{-1/2}y)=\frac{1}{\pi i}\int_{i\mathbb{R}+\epsilon}e^{u^2-y/u}u^{-l}du,\tag{5.34}$$

$$q(y)=\lim_{N\to\infty}N^{l/2}\tilde{Q}_N(N^{-1/2}y)=\frac{1}{2\pi i}\int_{\mathrm{U}_1}e^{-v^2+y/v}v^{l-1}dv.\tag{5.35}$$

Both functions have convergent series expansions

$$p(y)=\sum_{n=0}^{\infty}\frac{(-y)^n}{n!\Gamma[(l+n+1)/2]},\quad q(y)=y^l\sum_{n=0}^{\infty}\frac{(-y^2)^n}{n!(2n+l)!}.\tag{5.36}$$

The expansion for $q(y)$ can be obtained either directly from Eq. (5.35), or by taking the limit $N\to\infty$ in Eq. (5.22). In the case of $p(y)$, the earlier formula (5.23) is not suitable; rather, in order to verify Eq.(5.36) for $p(y)$ one expands the integrand of Eq. (5.34) in powers of y, makes use of $\mathfrak{Re}u=\epsilon>0$ to write

$$u^{-n-l} = (n+l-1)!^{-1} \int_0^\infty e^{-tu} t^{n+l-1} dt \quad (n+l>0),$$

does the Gaussian u integral by completing the square, and uses the duplication formula for the Gamma function.

Note added in proof. After submission of this manuscript, P. Forrester pointed out to us that the joint eigenvalue distribution derived and analyzed here falls in a broad class of models solved by Borodin.[12] Borodin's expression for the kernel $K_N(x,y)$ is equivalent to ours by old work of Konhauser.[13] The mathematical results of Konhauser were first introduced into random matrix physics by Muttalib,[14] who suggested to use them for an approximate treatment of the statistics of transmission eigenvalues of disordered conductors.

We investigate overlap fluctuations of the Sherrington-Kirkpatrick mean field spin glass model in the framework of the Random Overlap Structure (ROSt). The concept of ROSt has been introduced recently by Aizenman and co-workers, who developed a variational approach to the Sherrington-Kirkpatrick model. Here we propose an iterative procedure to show that, in the so-called Boltzmann ROSt, Aizenman-Contucci polynomials naturally arise for almost all values of the inverse temperature (not in average over some interval only). These polynomials impose restrictions on the overlap fluctuations in agreement with Parisi theory. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2357995]

I. INTRODUCTION

The study of mean field spin glasses has been very challenging from both a physical and a mathematical point of view. It took several years after the main model (the Sherrington-Kirkpatrick, or simply SK) was introduced before Giorgio Parisi was able to compute the free energy so ingeniously (Ref. 12 and references therein), and it took much longer still until a fully rigorous proof of Parisi's formula was found.[11,14] Parisi went beyond the solution for the free energy and gave an Ansatz about the pure states of the model as well, prescribing the so-called ultrametric or hierarchical organization of the phases (Ref. 12 and references therein). From a rigorous point of view, the closest the community could get so far to ultrametricity are identities constraining the probability distribution of the *overlaps*, namely, the Aizenman-Contucci (AC) and the Ghirlanda-Guerra identities (see Refs. 1 and 9, respectively). For further reading, we refer to Refs. 6, 7, and 13, but also to the general references.[5,15] Most of the few important rigorous results about mean field spin glasses can be elegantly summarized within a powerful and physically profound approach introduced recently by Aizenman *et al.* in Ref. 2. We want to show here that in this framework the AC identities can be deduced too. This is achieved by studying a stochastic stability of some kind, similarly to what is discussed in Ref. 6, inside the environment (the *Random Overlap Structure*) suggested in Ref. 2, and taking into account also the intensive nature of the internal energy density. A central point of the treatment is a power series expansion similar to the one performed in Ref. 3.

The paper is organized as follows. In Sec. II we introduce the concept of Random Overlap Structure (henceforth ROSt), and use it to state the related Extended Variational Principle. In Sec. III we present the main results regarding the ac identities and similar families of relations. Section IV is left for a few concluding remarks.

II. MODEL, NOTATIONS, PREVIOUS BASIC RESULTS

The Hamiltonian of the SK model is defined on Ising spin configurations $\sigma: i \to \sigma_i = \pm 1$ of N spins, labeled by $i = 1, \ldots, N$, as

$$H_N(\sigma; J) = -\frac{1}{\sqrt{N}} \sum_{i<j}^{1,N} J_{ij} \sigma_i \sigma_j$$

where J_{ij} are i.i.d. centered unit Gaussian random variables. We will assume there is no external field. Being a centered Gaussian variable, the Hamiltonian is determined by its covariance,

$$\mathbb{E}[H_N(\sigma) H_N(\sigma')] = \frac{1}{2} N q_{\sigma\sigma'}^2$$

where

$$q_{\sigma\sigma'} = \frac{1}{N} \sum_{i=1}^{N} \sigma_i \sigma_i'$$

is the overlap, and here $\mathbb{E}$ denotes the expectation with respect to all the (quenched) Gaussian variables.

The partition function $Z_N(\beta)$, the quenched free energy density $f_N(\beta)$, and pressure $\alpha_N(\beta)$ are defined as

$$Z_N(\beta) = \sum_{\sigma} \exp(-\beta H_N(\sigma)),$$

$$-\beta f_N(\beta) = \frac{1}{N} \mathbb{E} \ln Z_N(\beta) = \alpha_N(\beta).$$

The Boltzmann-Gibbs average of an observable $\mathcal{O}(\sigma)$ is denoted by ω and defined as

$$\omega(\mathcal{O}) = Z_N(\beta)^{-1} \sum_{\sigma} \mathcal{O}(\sigma) \exp(-\beta H_N(\sigma)),$$

but we will use the same ω to indicate, in general (weighted) sums over spins or nonquenched variables, to be specified when needed, and with Ω we will mean the product (*replica*) measure of the needed number of copies of ω.

Let us now introduce an auxiliary system.

Definition 1: A Random Overlap Structure $\mathcal{R}$ *is a triple* $(\Sigma, \tilde{q}, \xi)$, *where*

- $\Sigma \ni \gamma$ *is a discrete space* (*set of abstract spin configurations*);
- $\tilde{q}: \Sigma^2 \to [0,1]$ *is a positive definite kernel* (*overlap kernel*), *with* $|\tilde{q}| \leq 1$ (*and* $\tilde{q} = 1$ *on the diagonal of* Σ^2);
- $\xi: \Sigma \to \mathbb{R}_+$ *is a normalized discrete positive random measure, i.e., a system of random weights such that there is a probability measure* μ *on* $[0,1]^{\Sigma}$ *so that* $\Sigma_{\gamma \in \Sigma} \xi_\gamma < \infty$ *almost surely in the* μ *sense*.

The randomness in the weights ξ is independent of the randomness of the quenched variables from the original system with spins σ. We equip a ROSt with two families of independent and centered Gaussians $\tilde{h}_i$ and $\hat{H}$ with covariances

$$\mathbb{E}[\tilde{h}_i(\gamma) \tilde{h}_j(\gamma')] = \delta_{ij} \tilde{q}_{\gamma\gamma'}, \tag{1}$$

$$\mathbb{E}[\hat{H}(\gamma)\hat{H}(\gamma')] = \tilde{q}^2_{\gamma\gamma'}. \tag{2}$$

Given a ROSt $\mathcal{R}$, we define the trial pressure as

$$G_N(\mathcal{R}) = \frac{1}{N}\mathbb{E}\ln\frac{\sum_{\sigma,\gamma}\xi_\gamma \exp\left(-\beta\sum_{i=1}^N \tilde{h}_i(\gamma)\sigma_i\right)}{\sum_\gamma \xi_\gamma \exp(-\beta\sqrt{N/2}\hat{H}(\gamma))}, \tag{3}$$

where $\mathbb{E}$ denotes hereafter the expectation with respect to all the (quenched) random variables (including the randomness in the random weights ξ) but spins σ and the abstract spins γ, the sum over which is, in fact, written explicitly.

The following theorem (Ref. 2) can be easily proven by interpolation.

Theorem 1 (Extended Variational Principle): *Infimizing for each N separately the trial function* $G_N(\mathcal{R})$ *defined in* (3) *over the whole ROSt space, the resulting sequence tends to the limiting pressure* $-\beta f(\beta)$ *of the SK model as N tends to infinity*,

$$\alpha(\beta) \equiv \lim_{N\to\infty} \alpha_N(\beta) = \lim_{N\to\infty} \inf_{\mathcal{R}} G_N(\mathcal{R}).$$

For a given ROSt and a given inverse temperature β, the trial pressures $\{G_N\}$ are a well defined sequence of real numbers indexed by N; a ROSt $\mathcal{R}$ is said to be optimal if $\alpha \equiv \lim_{N\to\infty}\alpha_N(\beta) = \lim_{N\to\infty} G_N(\mathcal{R})$ for all β.

An optimal ROSt is the Parisi one (Refs. 12 and 14), another optimal one is the so-called Boltzmann ROSt $\mathcal{R}_B$, defined as follows. Take $\Sigma = \{-1,1\}^M$, and denote by τ the points of Σ. We clearly have in mind an auxiliary spin system (and that is why we use τ as opposed to the previous γ to denote its points). In fact, we also choose

$$\tilde{h}_i = -\frac{1}{\sqrt{M}}\sum_{k=1}^M \tilde{J}_{ik}\tau_k, \quad \hat{H} = -\frac{1}{M}\sum_{k,l}^{1,M} \hat{J}_{kl}\tau_k\tau_l,$$

which satisfy (1) and (2) with $\tilde{q}_{\tau\tau'} = (1/M)\Sigma_k \tau_k\tau'_k$, and $\tilde{J}$ and $\hat{J}$ are families of i.i.d. random variables independent of the original couplings J, with whom they share the same distribution (i.e., all the $\tilde{J}$ and $\hat{J}$ are centered unit Gaussian random variables). The variables $\tilde{h}_\cdot$ are called *cavity fields*. Let us also choose

$$\xi_\tau = \exp(-\beta H_M(\tau;\hat{J})) = \exp\left(\beta\frac{1}{\sqrt{M}}\sum_{k,l}^{1,M}\hat{J}_{kl}\tau_k\tau_l\right).$$

If we call $\mathcal{R}_{\mathrm{B}}(M)$ the structure defined above, we will formally write $\mathcal{R}_{\mathrm{B}}(M)\to\mathcal{R}_{\mathrm{B}}$ as $M\to\infty$, and we call $\mathcal{R}_{\mathrm{B}}$ the Boltzmann ROSt. The reason why such a ROSt is optimal is purely thermodynamic, and equivalent to the existence of the thermodynamic limit of the free energy per spin. A detailed proof of this fact can be found in Ref. 2; here we just mention the main point:

$$\alpha(\beta) = \mathbf{C}\lim_M \frac{1}{N}\mathbb{E}\ln\frac{Z_{N+M}}{Z_M} = \lim_{N\to\infty}\mathbf{C}\lim_M G_N(\mathcal{R}_{\mathrm{B}}(M)) = G_N(\mathcal{R}_{\mathrm{B}}) = G(\mathcal{R}_{\mathrm{B}}),$$

where **C** lim is the limit in the Cesàro sense. Notice that the Boltzmann ROSt does not depend on N, after the M limit.

III. ANALYSIS OF THE BOLTZMANN ROSt

In this section we show that in the optimal Boltzmann ROSt's the overlap fluctuations obey some restrictions, namely, those found by Aizenman and Contucci in Ref. 1. In other words, we exhibit a recipe to generate the ac polynomials within the ROSt approach.

A. The internal energy term

Let us focus on the denominator of the trial pressure $G(\mathcal{R}_B)$, defined in (3), computed at the Boltzmann ROSt $\mathcal{R}_B$, defined in the previous section. Let us normalize this quantity by dividing by Z_N and weight $\hat{H}$ with an independent variable β' as opposed to β, which appears in the *Boltzmannfaktor* ξ_τ. As in the Boltzmann structure we have actual spins (τ) and we do not use the spins σ here; we will still use ω (or Ω) to denote the Boltzmann-Gibbs (replica) measure (at inverse temperature β) in the space $\Sigma=\{-1,1\}^M$. Moreover, we will use the notation $\langle\cdot\rangle=\mathbb{E}\Omega(\cdot)$ and, if present, a subscript β recalls that the *Boltzmannfaktor* in Ω has inverse temperature β. More precisely, we are computing the left hand side of the next equality to get this.

Lemma 1:

$$\frac{1}{N}\mathbb{E}\ln\Omega\exp\left(-\beta'\sqrt{\frac{N}{2}}\hat{H}(\tau)\right)=\frac{\beta'^2}{4}(1-\langle\tilde{q}^2\rangle_\beta). \tag{4}$$

Similar calculations have been performed already, but in this specific context the result has been only stated without proof in Ref. 10, while a detailed proof is given only in the dilute case in Ref. 8. So let us prove the lemma. Let us take M finite. Thanks to the property of the addition of independent Gaussian variables, the left hand side of (4) is the same as

$$\frac{1}{N}\mathbb{E}\ln\frac{Z_M(\beta^*)}{Z_M(\beta)}=\frac{M}{N}(\alpha_M(\beta^*)-\alpha_M(\beta)),\quad \beta^*=\sqrt{\beta^2+\frac{\beta'^2N}{M}},$$

which, in turn, thanks to the convexity of α, can be estimated as follows:

$$\frac{M}{N}(\beta^*-\beta)\alpha'_M(\beta)\le\frac{M}{N}(\alpha_M(\beta^*)-\alpha_M(\beta))\le\frac{M}{N}(\beta^*-\beta)\alpha'_M(\beta^*).$$

Now

$$\frac{M}{N}(\beta^*-\beta)=\frac{\beta'^2}{2\beta}+o\left(\frac{1}{M}\right),\quad \alpha'(\beta)=\frac{\beta}{2}(1-\langle\tilde{q}^2\rangle_\beta).$$

Therefore, when $M\to\infty$, we get (4) for almost all β, i.e., whenever $\alpha'(\beta^*)\to\alpha'(\beta)$, or, equivalently, whenever $\langle\cdot\rangle_{\beta^*}\to\langle\cdot\rangle_\beta$. Notice that the quantity in (4) does not depend on N.[8,10]

Theorem 2: *The following statements hold:*

- *The left hand side of (4) is intensive (does not depend on N);*
- *The left hand side of (4) is a monomial of order two in β';*
- *The Aizenman-Contucci identities hold.*

Proof: Recall that $\hat{H}$ is a centered Gaussian, and so is therefore $-\hat{H}$, and the Gibbs measure is such that the substitution $\hat{H}\to\hat{H}-\hat{H}'$ implies

$$\frac{1}{N}\mathbb{E}\ln\Omega\exp\left(-\beta'\sqrt{\frac{N}{2}}\hat{H}\right)=\frac{1}{2N}\mathbb{E}\ln\Omega\exp\left(-\beta'\sqrt{\frac{N}{2}}(\hat{H}-\hat{H}')\right).$$

Expand now in powers of β' the exponential first and then the logarithm:

$$\frac{1}{N}\mathbb{E}\ln\Omega\exp\left(-\beta'\sqrt{\frac{N}{2}}\hat{H}\right)=\frac{\beta'^2}{4}(1-\langle\tilde{q}^2\rangle)$$

$$=\frac{1}{2N}\mathbb{E}\ln\Omega\left(1+\frac{\beta'^2}{2}\frac{N}{2}(\hat{H}-\hat{H}')^2+\frac{\beta'^4}{4!}\frac{N^2}{4}(\hat{H}-\hat{H}')^4+\cdots\right)$$

$$=\frac{1}{2N}\mathbb{E}\left[\left(\frac{N\beta'^2}{4}(2\Omega(\hat{H}^2)-2\Omega^2(\hat{H}))\right)\right.$$

$$+\frac{N^2}{4}\frac{\beta'^4}{4!}[2\Omega(\hat{H}^4)-8\Omega(\hat{H})\Omega(\hat{H}^3)+6\Omega^2(\hat{H}^2)]$$

$$\left.-\frac{N^2}{2}\frac{\beta'^4}{4}[\Omega^2(\hat{H}^2)+\Omega^4(\hat{H})-2\Omega(\hat{H}^2)\Omega^2(\hat{H})]+\cdots\right].$$

A straightforward calculation yields

$$\mathbb{E}\Omega(\hat{H}^4)=3,\quad \mathbb{E}[\Omega(\hat{H}^3)\Omega(\hat{H})]=3\langle\tilde{q}_{12}^2\rangle,\quad \mathbb{E}\Omega^2(\hat{H}^2)=1+2\langle\tilde{q}_{12}^4\rangle,$$

$$\mathbb{E}[\Omega(\hat{H}^2)\Omega^2(\hat{H})]=\langle\tilde{q}_{12}^2\rangle+2\langle\tilde{q}_{12}^2\tilde{q}_{13}^2\rangle,\quad \mathbb{E}\Omega^4(\hat{H})=3\langle\tilde{q}_{12}^2\tilde{q}_{34}^2\rangle,$$

and so on. All quantities of this sort can be computed in the same way. As an example, let us calculate $\mathbb{E}[\Omega(\hat{H}^2)\Omega^2(\hat{H})]=\mathbb{E}[\omega(\hat{H}_1^2)\omega(\hat{H}_2)\omega(\hat{H}_3)]$. Like, for overlaps, subscripts denote replicas. In order to evaluate the expectation of products of Gaussian variables, we can use Wick's theorem: we just count all the possible ways to contract the four Gaussian terms $\hat{H}_1$, $\hat{H}_1$, $\hat{H}_2$, $\hat{H}_3$ and sum over every nonvanishing contribution,

$$\langle\overbrace{\hat{H}_1\hat{H}_2}\overbrace{\hat{H}_1\hat{H}_3}\rangle = \langle\tilde{q}_{12}^2\tilde{q}_{23}^2\rangle\ ,$$

$$\langle\overbrace{\hat{H}_1\hat{H}_1}\overbrace{\hat{H}_2\hat{H}_3}\rangle = \langle 1\cdot\tilde{q}_{12}^2\rangle\ ,$$

$$\langle\overbrace{\hat{H}_1\hat{H}_3}\overbrace{\hat{H}_1\hat{H}_2}\rangle = \langle\tilde{q}_{12}^2\tilde{q}_{23}^2\rangle\ .$$

The sum of all the terms gives the exactly $\langle\tilde{q}_{12}^2\rangle+2\langle\tilde{q}_{12}^2\tilde{q}_{23}^2\rangle$. Now Eq. (4) is therefore expressed in terms of an identity for all β' of two polynomials in β': one is of order two; the other is a whole power series. We can then equate the coefficient of the same order, or equivalently put to zero all the terms of order higher than two in β'. The consequent equalities are exactly the Aizenman-Contucci ones (Ref. 1); an example of these is

$$\langle\tilde{q}_{12}^4\rangle-4\langle\tilde{q}_{12}^2\tilde{q}_{13}^2\rangle+3\langle\tilde{q}_{12}^2\tilde{q}_{34}^2\rangle=0,$$

which arises from the lowest order in the expansion above. □

B. The entropy term

In the same spirit as in the previous section, let us move on to the normalized numerator of the trial pressure $G(\mathcal{R}_B)$, defined in (3), computed at the Boltzmann ROSt $\mathcal{R}_B$, defined in the previous section. If we define

$$c_i=2\cosh(-\beta\tilde{h}_i)=\sum_{\sigma_i}\exp(-\beta\tilde{h}_i\sigma_i);$$

then

$$\frac{1}{N}\mathbb{E}\ln\Omega\sum_{\sigma}\exp\left(-\beta\sum_{i=1}^{N}\tilde{h}_i\sigma_i\right)=\frac{1}{N}\mathbb{E}\ln\Omega(c_1\cdots c_N) \tag{5}$$

does not depend on N,[8,10] if we consider the infinite Boltzmann ROSt, where $M\to\infty$.

Again, assume we replace the β in front of the cavity fields $\tilde{h}$ (but not in the state Ω) with a parameter $\sqrt{t}$, and define, upon rescaling,

$$\Psi(t)=\mathbb{E}\ln\Omega\sum_{\sigma}\exp\frac{\sqrt{t}}{\sqrt{N}}\sum_{i=1}^{N}\tilde{h}_i\sigma_i. \tag{6}$$

We want to study the flux (in t) of Eq. (6) to obtain an integrable expansion. The t flux of the cavity function Ψ is given by

$$\partial_t\Psi(t)=\frac{1}{2}(1-\langle q_{12}\tilde{q}_{12}\rangle_t), \tag{7}$$

which is easily seen by means of a standard use of Gaussian integration by parts. The subscript in $\langle\cdot\rangle_t=\mathbb{E}\Omega_t$ means that such an average includes the t-dependent exponential appearing in (6), beyond the sum over σ.

Theorem 3: *Let F_s be measurable with respect to the σ algebra generated by the overlaps of s replicas of $\{\sigma\}$ and $\{\tau\}$. Then the cavity streaming equation is*

$$\partial_t\langle F_s\rangle_t=\left\langle F_s\left(\sum_{\gamma,\delta}^{1,s}q_{\gamma,\delta}\tilde{q}_{\gamma,\delta}-s\sum_{\gamma=1}^{s}q_{\gamma,s+1}\tilde{q}_{\gamma,s+1}+\frac{s(s+1)}{2}q_{s+1,s+2}\tilde{q}_{s+1,s+2}\right)\right\rangle_t. \tag{8}$$

Proof: We consider the Boltzmann ROSt $\mathcal{R}_{\mathrm{B}}(M)$ with any value of M. The proof relies on the repeated application of the usual integration by parts formula for Gaussian variables:

$$\partial_t\langle F_s\rangle_t=\partial_t\mathbb{E}\frac{\sum_{\sigma\tau}F_s\exp(-\beta H_M(\tau))\exp\left(\sqrt{\frac{t}{MN}}\sum_{ij}\sum_{\gamma}\tilde{J}_{ij}\tau_i^{\gamma}\sigma_j^{\gamma}\right)}{\sum_{\sigma\tau}\exp(-\beta H_M(\tau))\exp\left(\sqrt{\frac{t}{MN}}\sum_{ij}\sum_{\gamma}\tilde{J}_{ij}\tau_i^{\gamma}\sigma_j^{\gamma}\right)}$$

$$=\frac{1}{2\sqrt{tMN}}\mathbb{E}\sum_{ij}J_{ij}\sum_{\gamma}^{s}(\Omega_t[F_s\tau_i^{\gamma}\sigma_j^{\gamma}]-\Omega_t[F_s]\Omega_t[\tau_i^{\gamma}\sigma_j^{\gamma}])$$

$$=\frac{1}{2\sqrt{tMN}}\sum_{ij}\mathbb{E}J_{ij}\left(\sum_{\gamma}\Omega_t[F_s\tau_i^{\gamma}\sigma_j^{\gamma}]-s\Omega_t[F_s]\omega[\tau_i\sigma_j]\right)$$

$$=\frac{1}{2MN}\sum_{ij}\mathbb{E}\left(\sum_{\gamma,\delta}\Omega_t[F_s\sigma_j^{\gamma}\tau_i^{\gamma}\sigma_j^{\delta}\tau_i^{\delta}]-\sum_{\gamma,\delta}\Omega_t[F_s\tau_i^{\gamma}\sigma_j^{\gamma}]\Omega_t[\tau_i^{\delta}\sigma_j^{\delta}]-s\omega_t[\tau_i\sigma_j]\sum_{\delta}(\Omega_t[F_s\tau_i^{\delta}\sigma_j^{\delta}]\right.$$

$$\left.-\Omega_t[F_s]\Omega_t[\tau_i^{\delta}\sigma_j^{\delta}]-s\Omega_t[F_s](1-\omega_t^2[\tau_i\sigma_j]))\right)$$

$$=\frac{1}{2}\mathbb{E}\left(\sum_{\gamma,\delta}\Omega_t[F_sq_{\gamma,\delta}\tilde{q}_{\gamma,\delta}]-s\sum_{\gamma}\Omega_t[F_sq_{\gamma,s+1}\tilde{q}_{\gamma,s+1}]\right.$$

$$\left.+ss\Omega_t[F_sq_{s+1,s+2}\tilde{q}_{s+1,s+2}]-s\Omega_t[F_s]\Omega_t[F_sq_{s+1,s+2}\tilde{q}_{s+1,s+2}]\right),$$

where in Ω_t we have included the sum over σ and τ, the *Boltzmannfaktor* in τ, and the t-dependent exponential. At this point, remembering that $\tilde{q}_{\gamma\gamma}=1$, we can write

$$\sum_{\gamma,\delta} \Omega_t[F_s q_{\gamma\delta} \tilde{q}_{\gamma\delta}] = 2 \sum_{\gamma,\delta} \Omega_t[F_s q_{\gamma\delta} \tilde{q}_{\gamma\delta}] + s\Omega_t[F_s]$$

which completes the proof. □

Now the way to proceed is simple: we have to expand the t derivative of $\Psi(t)$ [the right hand side of (7)] using the cavity streaming equation (8), and we will stop the iteration at the first nontrivial order (that is expected to be at least four, being the first ac relation of that order). Once a closed-form expression is in our hands, we can write down an order by order expansion of the (modified) denominator of the Boltzmann ROSt (that is, the function $N^{-1}\psi(t)$ evaluated for $t = N\beta^2$).

We have

$$\partial_t \langle q_{12}\tilde{q}_{12}\rangle_t = \langle q_{12}^2\tilde{q}_{12}^2 - 4q_{12}\tilde{q}_{12}q_{23}\tilde{q}_{23} + 3q_{12}\tilde{q}_{12}q_{34}\tilde{q}_{34}\rangle_t.$$

After the first iteration:

$$\partial_t \langle q_{12}^2\tilde{q}_{12}^2\rangle_t = \langle q_{12}^3\tilde{q}_{12}^3 - 4q_{12}^2\tilde{q}_{12}^2\tilde{q}_{23}p_{23} + 3q_{12}^2\tilde{q}_{12}^2\tilde{q}_{34}\rangle_t,$$

$$\partial_t \langle \tilde{q}_{12}q_{12}\tilde{q}_{23}q_{23}\rangle_t = \langle \tilde{q}_{12}q_{12}\tilde{q}_{23}q_{23}\tilde{q}_{13}q_{13} + 2\tilde{q}_{12}^2q_{12}^2\tilde{q}_{23}q_{23} - 6\tilde{q}_{12}q_{12}\tilde{q}_{23}q_{23}\tilde{q}_{34}q_{34} - 3\tilde{q}_{12}q_{12}\tilde{q}_{13}q_{13}\tilde{q}_{14}q_{14} + 6\tilde{q}_{12}q_{12}\tilde{q}_{34}q_{34}\tilde{q}_{45}q_{45}\rangle_t,$$

$$\partial_t \langle \tilde{q}_{12}q_{12}\tilde{q}_{34}q_{34}\rangle_t = \langle 4\tilde{q}_{12}q_{12}\tilde{q}_{23}q_{23}\tilde{q}_{34}q_{34} + 2\tilde{q}_{12}^2q_{12}^2\tilde{q}_{34}q_{34} - 16\tilde{q}_{12}q_{12}\tilde{q}_{34}q_{34}\tilde{q}_{45}q_{45} + 10\tilde{q}_{12}q_{12}\tilde{q}_{34}q_{34}\tilde{q}_{56}q_{56}\rangle_t.$$

The higher orders can be obtained exactly in the same way, so we can write down right away the expression for $\langle q_{12}\tilde{q}_{12}\rangle$, referring to Refs. 1 and 3 for a detailed explanation of this iterative method:

$$\langle q_{12}\tilde{q}_{12}\rangle_t = \langle q_{12}^2\tilde{q}_{12}^2\rangle t - 2\langle q_{12}\tilde{q}_{12}q_{23}\tilde{q}_{23}q_{13}\tilde{q}_{13}\rangle t^2 - \frac{1}{6}\langle q_{12}^4\tilde{q}_{12}^4\rangle t^3 - 2\langle q_{12}^2\tilde{q}_{12}^2q_{23}^2\tilde{q}_{23}^2\rangle t^3 + \frac{3}{2}\langle q_{12}^2\tilde{q}_{12}^2q_{34}^2\tilde{q}_{34}^2\rangle t^3 + 6\langle q_{12}\tilde{q}_{12}q_{23}\tilde{q}_{23}q_{34}\tilde{q}_{34}q_{14}\tilde{q}_{14}\rangle t^3. \tag{9}$$

Notice that the averages no longer depend on t. In this expansion we considered both q overlaps and $\tilde{q}$ overlaps, but as the sum over the spins σ can be performed explicitly, we can obtain an explicit expression at least for the q overlaps, and get

$$\langle q_{12}^2\rangle = \frac{1}{N^2}\mathbb{E}\sum_{ij} \omega^2(\sigma_i\sigma_j) = \frac{1}{N},$$

$$\langle q_{12}q_{23}q_{31}\rangle = \frac{1}{N^3}\mathbb{E}\sum_{ijk} \omega(\sigma_i\sigma_j)\omega(\sigma_j\sigma_k)\omega(\sigma_k\sigma_i) = \frac{1}{N^2},$$

$$\langle q_{12}^2q_{34}^2\rangle = \frac{1}{N^4}\mathbb{E}\sum_{ijkl} \omega^2(\sigma_i\sigma_j)\omega^2(\sigma_k\sigma_l) = \frac{1}{N^2},$$

$$\langle q_{12}q_{23}q_{34}q_{14}\rangle = \frac{1}{N^4}\mathbb{E}\sum_{ijkl} \omega(\sigma_i\sigma_j)\omega(\sigma_j\sigma_k)\omega(\sigma_k\sigma_l)\omega(\sigma_l\sigma_i) = \frac{1}{N^3},$$

$$\langle q_{12}^4\rangle = \frac{1}{N^4}\mathbb{E}\sum_{ijkl} \omega(\sigma_i\sigma_j\sigma_k\sigma_l)\omega(\sigma_i\sigma_j\sigma_k\sigma_l) = \frac{3(N-1)}{N^3} + \frac{1}{N^3},$$

$$\langle q_{12}^2 q_{23}^2 \rangle = \frac{1}{N^4} \mathbb{E} \sum_{ijkl} \omega(\sigma_i \sigma_j) \omega(\sigma_i \sigma_j \sigma_k \sigma_l) \omega(\sigma_i \sigma_j) = \frac{1}{N^2}.$$

Moreover, as the q overlaps have been calculated explicitly, we can use a graphical formalism.[1,3] In such a formalism we use points to identify replicas and lines for the overlaps between them. So, for example,

$$\langle \bullet\!\!-\!\!\bullet \rangle = \langle \tilde{q}_{12} \rangle, \qquad \langle \text{O} \rangle = \langle \tilde{q}_{12}^2 \rangle, \qquad \langle \triangle \rangle = \langle \tilde{q}_{12} \tilde{q}_{23} \tilde{q}_{13} \rangle$$

and so on. Now we can integrate (7) thanks to the polynomial expansion based on (9) and to the expressions for the q fluctuations. We obtain

$$\Psi(t) = \frac{1}{2} \int_0^t [1 - \langle q_{12} \tilde{q}_{12} \rangle_{t'}] dt',$$

$$\frac{1}{N} \Psi(t = N\beta^2) = \frac{\beta^2}{2} - \langle \text{O} \rangle \frac{\beta^4}{4} + \langle \triangle \rangle \frac{\beta^6}{3} - \langle \text{θ} \rangle \frac{\beta^8}{24} - \langle \square \rangle \frac{3\beta^8}{4} + N\beta^8 \left[\frac{1}{16} \langle \text{θ} \rangle - \frac{1}{4} \langle \infty \rangle + \frac{3}{16} \langle \text{8} \rangle \right]. \tag{10}$$

This expression, though truncated at this low order, already looks pretty much alike the expansion found using the internal energy part of the Boltzmann pressure.

We stress, however, two important features of expression (10). The first is that within this approach we do not have problems concerning the Replica Symmetry Anzatz (RS),[12] and this can be seen by the proliferating of the overalaps fluctuations, via which we expand the entropy (a RS theory does not allow such fluctuations). Second, we note that not all the terms inside the equations (10) are intensive: the last three graphs are all multiplied by a factor N. Recalling that this expansion does not depend on N, and physically a density is intensive by definition, we put to zero all the terms in the squared bracket, so to have

$$\langle \text{θ} - 4 \infty + 3 \text{8} \rangle = 0.$$

Again we can find the AC identities.

IV. CONCLUSIONS AND OUTLOOK

We have shown how some constraints on the distribution of the overlap naturally arise within the Random Overlap Structure approach. As our analysis of the Boltzmann ROSt is similar to the study of stochastic stability, it is not surprising that the constraints coincide with the Aizenman-Contucci identities. In the ROSt context, such identities are easily connected with the existence of the thermodynamic limit of the free energy density (which is equivalent to the optimality of the Boltzmann ROSt) and with the physical fact that the internal energy is intensive. We also showed that, as expected, the entropy part of the free energy yields the same constraints as the other part (i.e., the internal energy).

The hope for the near future is that the ROSt approach will lead eventually to a good understanding of the pure states and the phase transitions of the model. A first step has been taken in Ref. 10, and our present results can be considered as a second step in this direction. (Other more interesting results regarding the phase transition at $\beta=1$ can also be obtained with the same techniques employed here, including the graphical representation.[4]) A further step should bring the Ghirlanda-Guerra identities, and then hopefully a proof of ultrametricity.

ACKNOWLEDGMENTS

The authors warmly thank Francesco Guerra and Pierluigi Contucci for precious scientific and personal support, and sincerely thank Peter Sollich for useful discussions and much advice.

Geometric prequantization of the moduli space of the vortex equations on a Riemann surface

Rukmini Dey
Harish-Chandra Research Institute, Chhatnag Road, Jhusi, Allahabad, U.P. 211019 India

(Received 11 April 2006; accepted 16 August 2006; published online 3 October 2006)

The moduli space of solutions to the vortex equations on a Riemann surface are well known to have a symplectic (in fact, Kähler) structure. We show this symplectic structure explictly and proceed to show a family of symplectic (in fact, Kähler) structures Ω_{Ψ_0} on the moduli space, parametrized by Ψ_0, a section of a line bundle on the Riemann surface. Next, we show that corresponding to these, there is a family of prequantum line bundles $\mathcal{P}_{\Psi_0}$ on the moduli space whose curvature is proportional to the symplectic forms Ω_{Ψ_0}. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2352858]

I. INTRODUCTION

Geometric prequantization is a construction, if possible, of a prequantum line bundle $\mathcal{L}$ on a symplectic manifold, $(\mathcal{M},\Omega)$ whose curvature is proportional to the symplectic form. The Hilbert space of the quantization is the space of the square integrable sections of $\mathcal{L}$. To every $f \in C^\infty(\mathcal{M})$, we associate an operator acting on the Hilbert space, namely, $\hat{f}=-i\hbar[X_f - (i/\hbar)\theta(X_f)]+f$, where X_f is the vector field defined by $\Omega(X_f,\cdot)=-df$ and θ is a symplectic potential corresponding to Ω. Then if $f_1, f_2 \in C^\infty(\mathcal{M})$ and $f_3=\{f_1,f_2\}$, the Poisson bracket of the two induced by the symplectic form, then $[\hat{f}_1,\hat{f}_2]=-i\hbar\hat{f}_3$.[1]

The motivating example in our context would be the geometric quantization of the moduli space of flat connections on a principal G bundle P on a compact Riemann surface Σ.[2,3] Let $\mathcal{A}$ be the space of Lie-algebra valued connections on the principal bundle P. Let $\mathcal{N}$ be the moduli space of flat connections (i.e., the space of flat connections modulo the gauge group). One can construct the determinant line bundle of the Cauchy-Riemann operator, namely, $\mathcal{L}=\wedge^{\text{top}}(\text{Ker}\ \bar{\partial}_A)^* \otimes \wedge^{\text{top}}(\text{Coker}\ \bar{\partial}_A)$ on $\mathcal{A}$.[4] The curvature induced by the Quillen metric on this bundle coincides with the natural Kähler form $\mathcal{A}$, namely, $-\text{Tr}\int_\Sigma \alpha\wedge\beta$, where $\alpha,\beta \in T_A\mathcal{A}=\Omega^1(M,\text{ad}\ P)$. It can be shown, using a moment map construction, that this symplectic form descends to the moduli space of flat connections $\mathcal{N}$. The determinant line bundle is also well defined on $\mathcal{N}$ and is the candidate for the prequantum line bundle of the geometric quantization.

Inspired by this construction, we constructed three prequantum line bundles on the moduli space of solutions to the self-duality equations over a Riemann surface[5,6] corresponding to the three symplectic forms that give rise to the hyper-Kähler structure of the moduli space.

In this paper we geometrically quantize the moduli space of vortex equations. Geometric quantization of the vortex moduli space has been done before in Refs. 7 and 8. In the first paper the authors use algebraic geometry and in the second paper the author uses the special form of the moduli space when the Riemann surface is a sphere. It would be interesting to see what the relation is of the present quantization to the ones in Refs. 7 and 8. The relation may not be straightforward, since in the present quantization we find a whole family of (topologically equivalent, but perhaps holomorphically nonequivalent) prequantum line bundles $\mathcal{P}_{\Psi_0}$ whose curvatures correspond to a family of symplectic forms Ω_{Ψ_0} parametrized by Ψ_0 a section of a line bundle on the Riemann surface, as explained later. This symplectic form Ω_{Ψ_0} is a variant of the standard symplectic form Ω on the vortex moduli space.

The vortex equations are as follows. Let M be a compact Riemann surface and let $\omega = h^2\, dz\wedge d\bar{z}$ be the purely imaginary volume form on it (i.e., h is real.) Let A be a unitary connection on a principal $U(1)$ bundle P, i.e., A is a purely imaginary valued one form, i.e., $A=A^{(1,0)}+A^{(0,1)}$ such that $A^{(1,0)}=-\overline{A^{(0,1)}}$. Let L be a complex line bundle associated to P by the defining representation. Let Ψ be a section of L, i.e., $\Psi\in\Gamma(M,L)$ and $\bar{\Psi}$ be a section of its dual, $\bar{L}$. There is a Hermitian metric H on L, i.e., the inner product $\langle\Psi_1,\Psi_2\rangle_H=\Psi_1 H\bar{\Psi}_2$ is a smooth function on M. (Here H is real).

The pair (A,Ψ) will be said to satisfy the vortex equations if

$$F(A)=(1-|\Psi|_H^2)\omega, \tag{1}$$

$$\bar{\partial}_A\Psi=0, \tag{2}$$

where $F(A)$ is the curvature of the connection A and $d_A=\partial_A+\bar{\partial}_A$ is the decomposition of the covariant derivative operator into (1,0) and (0,1) pieces. Let $\mathcal{S}$ be the space of solutions to (1) and (2). There is a gauge group G acting on the space of (A,Ψ) that leaves the equations invariant. We take the group G to be Abelian and locally it looks like Maps $(M,U(1))$. If g is an $U(1)$ gauge transformation, then (A_1,Ψ_1) and (A_2,Ψ_2) are gauge equivalent if $A_2=g^{-1}\,dg+A_1$ and $\Psi_2=g^{-1}\Psi_1$. Taking the quotient by the gauge group of $\mathcal{S}$ gives the moduli space of solutions to these equations and is denoted by $\mathcal{M}$. It is well known that there is a natural metric on the moduli space $\mathcal{M}$ and, in fact, the metric is Kähler; see Refs. 9–11, 8, and 12–14, and the references there.

In this paper, we show the metric explicitly and write down the symplectic (in fact, the Kähler form) Ω arising from this metric and the complex structure. This is because some modification of this symplectic form gives us a whole family of symplectic forms Ω_{Ψ_0} parametrized by a fixed section Ψ_0 of the line bundle L that vanishes on a set of measure zero. Ω_{Ψ_0} coincides with Ω when L is a trivial bundle with $|\Psi_0|_H=1$. In fact, Ω_{Ψ_0} is a Kähler form on the moduli space. We show that there exists a holomorphic prequantum line bundle, namely, a determinant line bundle, whose Quillen curvature is proportional to the symplectic form Ω_{Ψ_0}. Thus, as Ψ_0 varies, we get a whole family of prequantum line bundles that are topologically equivalent, but perhaps not holomorphically equivalent.

II. METRIC AND SYMPLECTC FORMS

Let $\mathcal{A}$ be the space of all unitary connections on P and $\Gamma(M,L)$ be sections of L. Let $\mathcal{C}=\mathcal{A}\times\Gamma(M,L)$ be the configuration space on which Eqs. (1) and (2) are imposed. Let $p=(A,\Psi)\in\mathcal{C}$, $X=(\alpha_1,\beta)$, $Y=(\alpha_2,\eta)\in T_p\mathcal{C}\equiv\Omega^1(M,i\mathbb{R})\times\Gamma(M,L)$, i.e., $\alpha_i=\alpha_i^{(0,1)}+\alpha_i^{(1,0)}$, such that $\alpha_i^{(0,1)}=-\alpha_i^{(1,0)}, i=1,2$. On $\mathcal{C}$ one can define a metric,

$$\mathcal{G}(X,Y)=\int_M *_1\alpha_1\wedge\alpha_2+2i\int_M \mathrm{Re}\langle\beta,\eta\rangle_H\omega$$

and an almost complex structure

$$\mathcal{I}=\begin{bmatrix} *_1 & 0\\ 0 & i\end{bmatrix}:T_p\mathcal{C}\to T_p\mathcal{C},$$

where $*_1:\Omega^1\to\Omega^1$ is the Hodge star operator on M such that $*_1(\eta\,dz)=-i\eta\,dz$ and $*_1(\bar{\eta}\,d\bar{z})=i\bar{\eta}\,d\bar{z}$.

It is easy to check that $\mathcal{G}$ is positive definite. In fact, if $\alpha_1=\alpha^{(1,0)}+\alpha^{(0,1)}=a\,dz-\bar{a}\,d\bar{z}$ is an imaginary valued 1-form, $*_1\alpha_1=-i(a\,dz+\bar{a}\,d\bar{z})$ and $\mathcal{G}(X,X)=4\int_M|a|^2\,dx\wedge dy+4\int_M|\beta|_H^2h^2\,dx\wedge dy$, where $\omega=h^2\,dz\wedge d\bar{z}=-2ih^2\,dx\wedge dy$.

The symplectic form Ω: We define

$$\Omega(X,Y) = -\int_M \alpha_1 \wedge \alpha_2 + 2i\int_M \mathrm{Re}\langle i\beta, \eta\rangle_H \omega = -\int_M \alpha_1 \wedge \alpha_2 - \int_M (\beta H\bar{\eta} - \bar{\beta}H\eta)\omega,$$

such that $\mathcal{G}(\mathcal{I}X,Y)=\Omega(X,Y)$. Moreover, we have the following.

Proposition 2.1: The metrics $\mathcal{G}$, the symplectic form Ω, and the almost complex structure $\mathcal{I}$ are invariant under the gauge group action on $\mathcal{C}$.

Proof: Let $p=(A,\Psi)\in\mathcal{C}$ and $g\in G$, the gauge group, where $g\cdot p=(A+g^{-1}\,dg, g^{-1}\Psi)$.

Then $g_*: T_p\mathcal{C}\to T_{g\cdot p}\mathcal{C}$ is given by the mapping (Id, g^{-1}) and it is now easy to check that g and Ω are invariant and $\mathcal{I}$ commutes with g_*. □

Proposition 2.2: The equation (1) *can be realized as a moment map $\mu=0$ with respect to the action of the gauge group and the symplectic form Ω.*

Proof: Let $\zeta\in\Omega(M,i\mathbb{R})$ be the Lie algebra of the gauge group (the gauge group element being $g=e^{\zeta}$); note that ζ is purely imaginary. It generates a vector field X_ζ on $\mathcal{C}$ as follows:

$$X_\zeta(A,\Psi) = (d\zeta, -\zeta\Psi) \in T_p\mathcal{C},$$

where $p=(A,\Psi)\in\mathcal{C}$.

We show next that X_ζ is Hamiltonian. Namely, define $H_\zeta:\mathcal{C}\to\mathbb{C}$ as follows:

$$H_\zeta(p) = \int_M \zeta\cdot(F_A - (1-|\Psi|_H^2)\omega).$$

Then, for $X=(\alpha,\beta)\in T_p\mathcal{C}$,

$$dH_\zeta(X) = \int_M \zeta\, d\alpha + \int_M \zeta(\Psi H\bar{\beta} + \bar{\Psi}H\beta)\omega = -\int_M (d\zeta)\wedge\alpha + 2i\int_M \mathrm{Re}\big(i(-\zeta\Psi)H\bar{\beta}\big)\omega = \Omega(X_\zeta, X),$$

where we use that $\bar{\zeta}=-\zeta$.

Thus we can define the moment map $\mu:\mathcal{C}\to\Omega^2(M,i\mathbb{R})=\mathcal{G}^*$ (the dual of the Lie algebra of the gauge group) to be

$$\mu(A,\Psi) = \big(F(A) - (1-|\Psi|_H^2)\omega\big).$$

Thus, Eq. (1) is $\mu=0$. □

Lemma 2.3: *Let $\mathcal{S}$ be the solution spaces to Eqs. (1) and (2), $X\in T_p\mathcal{S}$. Then $\mathcal{I}X\in T_p\mathcal{S}$ if and only if X is $\mathcal{G}$ orthogonal to the gauge orbit $O_p=G\cdot p$.*

Proof: Let $X_\zeta\in T_pO_p$, where $\zeta\in\Omega^0(M,i\mathbb{R})$, $\mathcal{G}(X,X_\zeta)=-\Omega(\mathcal{I}X,X_\zeta)=-\int_M\zeta\cdot d\mu(\mathcal{I}X)$, and therefore $\mathcal{I}X$ satisfies the linearization of Eq. (1) iff $d\mu(\mathcal{I}X)=0$, i.e., iff $\mathcal{G}(X,X_\zeta)=0$ for all ζ. Second, it is easy to check that $\mathcal{I}X$ satisfies the linearization of Eq. (2) whenever X does. □

Theorem 2.4: *$\mathcal{M}$ has a natural symplectic structure and an almost complex structure compatible with the symplectic form Ω and the metric $\mathcal{G}$.*

Proof: First we show that the almost complex structure descends to $\mathcal{M}$. Then using this and the symplectic quotient construction, we will show that Ω gives a symplectic structure on $\mathcal{M}$.

(a) To show that $\mathcal{I}$ descends as an almost complex structure, we let $\mathrm{pr}:\mathcal{S}\to\mathcal{S}/G=\mathcal{M}$ be the projection map and set $[p]=pr(p)$. Then we can naturally identify $T_{[p]}\mathcal{M}$ with the quotient space $T_p\mathcal{S}/T_pO_p$, where $O_p=G\cdot p$ is the gauge orbit. Using the metric $\mathcal{G}$ on $\mathcal{S}$ we can realize $T_{[p]}\mathcal{M}$ as a subspace in $T_p\mathcal{S}$, $\mathcal{G}$ orthogonal to T_pO_p. Then by Lemma 2.3, this subspace is invariant under $\mathcal{I}$. Thus $I_{[p]}=\mathcal{I}|_{T_p(O_p)^\perp}$, gives the desired almost complex structure. This construction does not depend on the choice of p since $\mathcal{I}$ is G invariant.

(b) The symplectic structure Ω descends to $\mu^{-1}(0)/G$, (by Proposition 2.2 and by the Marsden-Weinstein symplectic quotient construction,[15,16] since the leaves of the characteristic foliation are the gauge orbits). Now, as a 2-form Ω descends to $\mathcal{M}$, due to Proposition 2.1 so does the metric $\mathcal{G}$. The closure of Ω is easy. We check that Eq. (2) does not give rise to new degeneracy

of Ω [i.e., the only degeneracy of Ω is due to (1) but along gauge orbits]. Thus, Ω is symplectic on $\mathcal{M}$. Since $\mathcal{G}$ and $\mathcal{I}$ descend to $\mathcal{M}$, the latter is symplectic and almost complex. □

The family of symplectic forms Ω_{Ψ_0}. Choose a fixed $\Psi_0 \in \Gamma(M,L)$ such that $|\Psi_0|_H=0$ only on a set of measure zero on M. (This Ψ_0 has nothing to do with Ψ.)

Define a symplectic form on $\mathcal{C}$ as

$$\Omega_{\Psi_0}(X,Y) = -\int_M \alpha_1 \wedge \alpha_2 + 2i\int_M \mathrm{Re}\langle i\beta,\eta\rangle_H |\Psi_0|_H^2 \omega = -\int_M \alpha_1 \wedge \alpha_2 - \int_M (\beta H\bar{\eta} - \bar{\beta} H\eta)|\Psi_0|_H^2\omega.$$

$|\Psi_0|_H^2$ plays the role of a conformal rescaling of the volume form ω on M that appears in Ω, where we allow the conformal factor to have zeros on sets of measure zero.

Theorem 2.5: *Ω_{Ψ_0} descends to $\mathcal{M}$ as a symplectic form.*

Proof: Let $p=(A,\Psi)$.

It is easy to show that Ω_{Ψ_0} is closed [this follows from the fact that on $\mathcal{C}$ it is a constant form—does not depend on (A,Ψ)]. We have to show it is nondegenerate.

Suppose there exists $(\alpha_1,\beta) \in T_{[p]}(\mathcal{M})$, s.t.,

$$\Omega_{\Psi_0}((\alpha_2,\eta),(\alpha_1,\beta)) = 0,$$

$\forall (\alpha_2,\eta) \in T_{[p]}(\mathcal{M})$. Using the metric $\mathcal{G}$, we identify $T_{[p]}\mathcal{M}$ with the subspace in $T_p\mathcal{S},\mathcal{G}$ orthogonal to T_pO_p (i.e., the tangent space to the moduli space is identified to the tangent space to solutions that are orthogonal to the gauge orbits, the orthogonality is with respect to the metric $\mathcal{G}$). Thus $(\alpha_1,\beta),(\alpha_2,\eta)$ satisfy the linearization of Eqs. (1) and (2) and $\mathcal{G}((\alpha_1,\beta),X_\zeta)=0$ and $\mathcal{G}((\alpha_2,\eta),X_\zeta)=0$ for all ζ.

Now, by 2.3, $\mathcal{I}(\alpha_2,\eta) \in T_pS$. Also,

$$\mathcal{G}(\mathcal{I}(\alpha_1,\beta),X_\zeta) = \Omega((\alpha_1,\beta),X_\zeta) = -\int_M \zeta\, d\mu((\alpha_1,\beta)) = 0,$$

since $d\mu((\alpha_1,\beta))=0$ is precisely one of the equations saying that $(\alpha_1,\beta) \in T_pS$. Thus $\mathcal{I}(\alpha_1,\beta) \in T_{[p]}\mathcal{M}$, (since it is in T_pS and $\mathcal{G}$ orthogonal to gauge orbits).

Take $(\alpha_2,\eta)=\mathcal{I}(\alpha_1,\beta)=(*_1\alpha_1, i\beta)$. Then

$$\begin{aligned} 0 = \Omega_{\Psi_0}(\mathcal{I}(\alpha_1,\beta),(\alpha_1,\beta)) &= -\int_M (*_1\alpha_1 \wedge \alpha_1) + 2i\int_M \mathrm{Re}\langle i(i\beta),\beta\rangle_H |\Psi_0|_H^2\omega \\ &= -4\int_M |\alpha|^2\, dx\wedge dy - 4\int_M |\beta|_H^2 |\Psi_0|_H^2 h^2\, dx\wedge dy, \end{aligned}$$

where $\omega=-2ih^2\, dx\wedge dy$ and $\alpha_1=a\, dz-\bar{a}\, d\bar{z} \in \Omega^1(M,i\mathbb{R})$ and $*_1\alpha_1=-i(a\, dz+\bar{a}\, d\bar{z})$. By negativity of both the terms and the fact that Ψ_0 has zero on a set of measure zero on M, $(\alpha_1,\beta)=0$, a.e. Thus Ω_{Ψ_0} is symplectic. □

III. PREQUANTUM LINE BUNDLE

In this section we briefly review the Quillen construction of the determinant line bundle of the Cauchy Riemann operator $\bar{\partial}_A=\bar{\partial}+A^{(0,1)}$,[4] which enables us to construct a prequantum line bundle on the vortex moduli space.

First let us note that a connection A on a $U(1)$-principal bundle induces a connection on any associated line bundle L. We will denote this connection also by A since the same "Lie-algebra valued 1-form" A (modulo representations) gives a covariant derivative operator enabling you to take derivatives of sections of L,[17] p. 348. A very clear description of the determinant line bundle can be found in Refs. 4 and 18. Here we mention the formula for the Quillen curvature of the determinant line bundle $\wedge^{\mathrm{top}}(\mathrm{Ker}\,\bar{\partial}_A)^* \otimes \wedge^{\mathrm{top}}(\mathrm{Coker}\,\bar{\partial}_A)=\det(\bar{\partial}_A)$, given the canonical unitary con-

nection ∇_Q, induced by the Quillen metric.[4] Recall that the affine space $\mathcal{A}$ (the notation as in Ref. 4) is an infinite-dimensional Kähler manifold. Here each connection is identified with its (0,1) part that is the holomorphic part. Since the connection A is unitary (i.e., $A=A^{(1,0)}+A^{(0,1)}$, s.t., $\overline{A^{(1,0)}}=-A^{(0,1)}$) this identification is easy. In fact, for every $A\in\mathcal{A}$, $T'_A(\mathcal{A})=\Omega^{0,1}(M,i\mathbb{R})$ and the corresponding Kähler form is given by

$$F(\alpha_1^{(0,1)},\alpha_2^{(0,1)})=\mathrm{Re}\int_M(\alpha_1^{(0,1)}\wedge *_2\alpha_2^{(0,1)}),=-\frac{1}{2}\int_M\alpha_1\wedge\alpha_2,$$

where $\alpha^{(0-1)}$, $\beta^{(0,1)}\in\Omega^{0,1}(M,i\mathbb{R})$ and $*_2$ is the Hodge-star operator such that $*_2(\eta\,dz)=-\bar{\eta}\,d\bar{z}$ and $*_2(\bar{\eta}\,d\bar{z})=\eta\,dz$, and we have used $\overline{\alpha_i^{(0,1)}}=-\alpha_i^{(1,0)}$, $i=1,2$. Let ∇_Q be the connection induced from the Quillen metric. Then the Quillen curvature of $\det(\bar{\partial}_A)$ is

$$\mathcal{F}(\nabla_Q)=\frac{i}{\pi}F.$$

IV. PREQUANTUM BUNDLE ON $\mathcal{M}$

First we note that to the connection A we can add any one form and still obtain a derivative operator.

Let $\omega=h^2\,dz\wedge d\bar{z}$ where recall h is real. Let $\theta=h\,dz$, $\bar{\theta}=h\,d\bar{z}$ be 1-forms (Ref. 19, p. 28), such that $\omega=\theta\wedge\bar{\theta}=h^2\,dz\wedge d\bar{z}$. Let Ψ_0 be the same *fixed* section used to define Ω_{Ψ_0}. Recall that Ψ_0 has zero on a set of measure zero on M. Note, that $\Psi H\bar{\Psi}_0$ is a smooth function on M. Thus $B^{(0,1)}=\Psi H\bar{\Psi}_0\bar{\theta}$ is a (0,1) form we would like to add to the connection $A^{(0,1)}$ to make another connection form. Note that $B^{(0,1)}$ is gauge invariant, since Ψ and Ψ_0 gauge transform in the same way. Note that $A^{(0,1)}\pm B^{(0,1)}$ are the (0,1) parts of a connection defined by $A\pm B=A^{(0,1)}\pm B^{(0,1)}+A^{(1,0)}+\pm B^{(1,0)}$, where $B^{(1,0)}$ is defined to be $\overline{B^{(1,0)}}=-B^{(0,1)}$.

Definitions: Let us denote by $\mathcal{L}_\pm=\det(\bar{\partial}+A^{(0,1)}\pm B^{(0,1)})$ a determinant bundle on $\mathcal{T}_\pm=\{A^{(0,1)}\pm\Psi H\bar{\Psi}_0\bar{\theta}|A\in A,\Psi\in\Gamma(M,L)\}$ that is isomorphic to $\mathcal{C}=\mathcal{A}\times\Gamma(M,L)$.

Thus $\mathcal{P}_{\Psi_0}=\mathcal{L}_+\otimes\mathcal{L}_-$ well-defined line bundle on $\mathcal{C}$.

Lemma 4.1: *$\mathcal{P}_{\Psi_0}$ is a well-defined line bundle over $\mathcal{M}\subset\mathcal{C}/G$, where G is the gauge group.*

Proof: First consider the Cauchy-Riemann operator $D=\bar{\partial}+A^{(0,1)}+B^{(0,1)}$. Under the gauge transformation, $D=\bar{\partial}+A^{(0,1)}+B^{(0,1)}\to D_g=g(\bar{\partial}+A^{(0,1)}+B^{(0,1)})g^{-1}$. We can show that the operators D and D_g have an isomorphic kernel and cokernel and their corresponding Laplacians have the same spectrum and the eigenspaces are of the same dimension. Let Δ denote the Laplacian corresponding to D and Δ_g that correspond to D_g. The Laplacian is $\Delta=\tilde{D}D$, where $\tilde{D}=\partial+A^{(1,0)}+B^{(1,0)}$, where we recall that $\overline{A^{(1,0)}}=-A^{(0,1)}$ and $\overline{B^{(1,0)}}=-B^{(0,1)}$. Note that $\tilde{D}\to\tilde{D}_g=g\tilde{D}g^{-1}$ under a gauge transformation. Then $\Delta_g=g\,\Delta g^{-1}$. Thus, the isomorphism of eigenspaces is $s\to gs$. We describe here how to define the line bundle on the moduli space. Let $K^a(\Delta)$ be the direct sum of eigenspaces of the operator Δ of eigenvalues $<a$, over the open subset $U^a=\{A^{(0,1)}+B^{(0,1)}|a\notin\mathrm{Spec}\,\Delta\}$ of the affine space $\mathcal{T}_+$. The determinant line bundle is defined using the exact sequence,

$$0\to\mathrm{Ker}\,D\to K^a(\Delta)\to D(K^a(\Delta))\to\mathrm{Coker}\,D\to 0.$$

Thus one identifies the following.

$\wedge^{\mathrm{top}}(\mathrm{Ker}\,D)^*\otimes\wedge^{\mathrm{top}}(\mathrm{Coker}\,D)$ with $\wedge^{\mathrm{top}}(K^a(\Delta))^*\otimes\wedge^{\mathrm{top}}(D(K^a(\Delta)))$ (see Ref. 18, for more details) and there is an isomorphism of the fibers as $D\to D_g$. Thus one can identify

$$\wedge^{\mathrm{top}}(K^a(\Delta))^*\otimes\wedge^{\mathrm{top}}(D(K^a(\Delta)))\equiv\wedge^{\mathrm{top}}(K^a(\Delta_g))^*\otimes\wedge^{\mathrm{top}}(D(K^a(\Delta_g))).$$

By extending this definition from U^a to $V^a=\{(A,\Psi)|a\notin\mathrm{Spec}\,\Delta\}$, an open subset of $\mathcal{C}$, we can define the fiber over the quotient space V^a/G to be the equivalence class of this fiber. Covering $\mathcal{C}$ with open sets of the type V^a, we can define it on $\mathcal{C}/G$. Then we can restrict it to $\mathcal{M}\subset\mathcal{C}/G$.

Similarly, one can deal with the other case of $\bar{\partial}+A^{(0,1)}-B^{(0,1)}$. Let $([A],[\Psi]) \in \mathcal{C}/G$ where $[A],[\Psi]$ are gauge equivalence classes of A, Ψ, respectively. Then associated to the equivalence class $([A],[\Psi])$ in the base space, there is an equivalence class of fibers coming from the identifications of $\det(\bar{\partial}+A^{(0,1)}-B^{(0,1)})$ with $\det\mathbf{(}g(\bar{\partial}+A^{(0,1)}-B^{(0,1)})g^{-1}\mathbf{)}$, as mentioned in the previous case.

This way one can prove that P_{Ψ_0} is well defined on $\mathcal{C}/G$. Then we restrict it to $\mathcal{M} \subset \mathcal{C}/G$.

A. Curvature and symplectic form

Let $p=(A,\Psi) \in \mathcal{S}$. Let X, $Y \in T_{[p]}\mathcal{M}$. Since $T_{[p]}\mathcal{M}$ can be identified with a subspace in T_pS orthogonal to T_pO_p, if we write $X=(\alpha_1,\beta)$ and $Y=(\alpha_2,\eta)$, $\alpha_1,\alpha_2 \in T_A\mathcal{A}=\Omega^1(M,i\mathbb{R})$, and β, $\eta \in T_\Psi\Gamma(M,L)=\Gamma(M,L)$, then X, Y can be said to satisfy (a) X, $Y \in T_pS$ and (b) X,Y are $\mathcal{G}$ orthogonal to T_pO_p, the tangent space to the gauge orbit.

Let $\mathcal{F}_{\mathcal{L}_\pm}$ denote the Quillen curvatures of the determinant line bundles $\mathcal{L}_\pm$, respectively. $\mathcal{L}_\pm$ are determinants of Cauchy-Riemann operators of the connections $A^{(0,1)} \pm \Psi H \bar{\Psi}_0 \bar{\theta}$. Thus, in the curvature, we will have $\alpha_1^{(0,1)} \pm \beta H \bar{\Psi}_0 \bar{\theta}$ and $\alpha_2^{(0,1)} \pm \eta H \bar{\Psi}_0 \bar{\theta}$ (see Quillen's formula in the section above),

$$\mathcal{F}_{\mathcal{L}_\pm}(X,Y) = \frac{i}{\pi}\mathrm{Re}\int_M (\alpha_1^{(0,1)} \pm \beta H \bar{\Psi}_0 \bar{\theta}) \wedge *_2(\alpha_2^{(0,1)} \pm \eta H \bar{\Psi}_0 \bar{\theta})$$

$$= \frac{i}{\pi}\mathrm{Re}\int_M (\alpha_1^{(0,1)} \pm \beta H \bar{\Psi}_0 \bar{\theta}) \wedge (-\alpha_2^{(1,0)} \pm \bar{\eta} H \Psi_0 \theta).$$

Note that $\mathrm{Re}\int_M \alpha_1^{(0,1)} \wedge \alpha_2^{(1,0)} = (1/2)\int_M \alpha_1 \wedge \alpha_2$, where we have used the fact that $\alpha_i = \alpha^{(0,1)} + \alpha_i^{(1,0)}$, s.t., $\overline{\alpha_i^{(0,1)}} = -\alpha_i^{(1,0)}$, $i=1,2$. We have also used that $\bar{\theta} \wedge \theta = -\omega = 2ih^2\, dx \wedge dy$, is purely imaginary. One can easily compute that

$$(\mathcal{F}_{\mathcal{L}+} + \mathcal{F}_{\mathcal{L}-})(X,Y) = \frac{i}{\pi}\left[-\int_M \alpha_1 \wedge \alpha_2 - \int_M (\beta H \bar{\eta} - \bar{\beta} H \eta)|\Psi_0|_H^2 \omega \right] = \frac{i}{\pi}\Omega_{\Psi_0}(X,Y).$$

Now $A^{(0,1)}$ is holomorphic w.r.t. the complex structure $*_1$ and Ψ is holomorphic w.r.t. multiplying by i, $A^{(0,1)} \pm B^{(0,1)}$ is holomorphic w.r.t. the complex structure $\mathcal{I}$. Thus $\mathcal{L}_+$, $\mathcal{L}_-$, and $\mathcal{P}_{\Psi_0}$ are holomorphic (the same argument as in Ref. 4).

Thus, we have proven the following theorem.

Theorem 4.2: *$\mathcal{P}_{\Psi_0} = \mathcal{L}_+ \otimes \mathcal{L}_-$ is a well-defined holomorphic line bundle on $\mathcal{M}$ whose Quillen curvature is $\mathcal{F}_{\mathcal{L}+} + \mathcal{F}_{\mathcal{L}-}$, which is $(i/\pi)\Omega_{\Psi_0}$. Thus $\mathcal{P}_{\Psi_0}$ is a prequantum bundle on $\mathcal{M}$.*

B. Polarization

In passing from prequantization to quantization, one needs a polarization. It can be shown that the almost complex structure $\mathcal{I}$ is integrable on $\mathcal{M}$ (see, for example, Ruback's argument mentioned in Ref. 9 or matscinet review of Refs. 11 and 10). In fact, Ω_{Ψ_0} is a Kähler form and $\mathcal{G}_{\Psi_0}(X,Y) = \Omega_{\Psi_0}(X,\mathcal{I}Y)$ is a Kähler metric on the moduli space (since it is positive definite). $\mathcal{P}_{\Psi_0}$ is a holomorphic line bundle on $\mathcal{M}$. Thus we can take holomorphic square integrable sections of $\mathcal{P}_{\Psi_0}$ as our Hilbert space. The dimension of the Hilbert space is not easy to compute. [For instance, the holomorphic sections of the determinant line bundle on the moduli space of flat connections for $SU(2)$ gauge group is the Verlinde dimension of the space of conformal blocks in a certain conformal field theory.] This would be a topic for future work.

C. Remark

As Ψ_0 varies, the corresponding line bundles are all topologically equivalent since the curvature forms have to be of integral cohomology, and that would be constant. Thus, they have the same Chern class. However, they may not be holomorphically equivalent.

ACKNOWLEDGMENT

I would like to thank Professor Jonathan Weitsman for pointing out the equivalence of these line bundles.

Removable singularities for solutions of coupled Yang-Mills-Dirac equations

Wei Li[a)]
Department of Mathematical Sciences, Tsinghua University, Beijing 100084, People's Republic of China

(Received 6 November 2005; accepted 21 August 2006; published online 4 October 2006)

We prove a removable singularity theorem for solutions of coupled Yang-Mills-Dirac equations on compact four-dimensional manifolds. We show that a field satisfying the coupled equations with a point singularity is gauge equivalent to a smooth field if the energy functional is finite. The hypotheses are very natural. Only conformally invariant conditions are placed on force field and particle field interacting with the force field. It is noticeable that there is no assumption on the derivative of the particle field. © *2006 American Institute of Physics.*

I. INTRODUCTION

We consider the problem of removable isolated singularities of coupled Yang-Mills-Dirac fields in four dimensions.

In the case of non-coupled fields, i.e., pure Yang-Mills fields, Uhlenbeck's theorem[1] states that apparent point singularities in finite action solutions may be removed by a continuous gauge transformation.

Parker[2] generalized the result to coupled systems in four dimensions: solutions of coupled Yang-Mills-Dirac equations cannot have point singularities if the total energy of the coupled field is finite.

As noted by Uhlenbeck, the coupled equations (2.1) becomes elliptic in A (connection 1-form) only when $d^*A=0$. This constraint is always satisfied in a specific local trivialization, which is called the broken Hodge gauge.[1] By making a gauge transformation to Hodge gauge, one can obtain a co-closed connection satisfying a system of equations whose principal part is the Laplacian. However, because of the borderline assumptions made on curvature, i.e. the Yang-Mills field F is required to be an element of the space L^2, the gauge transformation which gives the elliptic system need not be continuous[3] and, hence, the topology in the original bundle with which we began may be altered. Therefore, the heart of the proof is to show that $F \in L^p$ for some $p>2$. Then the gauge transformation to Hodge gauge can be continuous. At this point, standard elliptic theory applies.[3]

Distinguishing from Parker's method of estimating the total field, we estimate the curvature F and the particle field ϕ, respectively. This results in a meticulous analytic proof. First, small energy regularity is proved, then a broken Hodge gauge could be applied to prove that finite energy solutions of coupled field equations cannot have isolated singularities. It is noticeable that we place no condition on the derivative of ϕ.

For convenience, we concentrate on bundles over flat manifolds. For the regularity theory, the curvature of the base manifold itself is not particularly important. The restriction to a flat base manifold does not crucially affect our results.

In Sec. I we give a brief description of the problem. The basic geometric framework is well documented in the literatures.[2,1] In Sec. III we prove the small energy regularity, which allows us

[a)]Electronic mail: weili973@yahoo.com.cn

to apply the broken Hodge gauge. In Sec. IV, we make use of the broken Hodge gauge to prove that the finite energy solutions of the coupled field equations cannot have isolated singularities.

II. YANG-MILLS-DIRAC FIELDS

We assume (M,g) is a compact oriented four-dimensional Riemannian manifold with usual Riemannian connection ∇ and Riemannian curvature R.

Fix a principal bundle $\pi: P \to M$ with compact structure group G whose Lie algebra is denoted by $\mathfrak{g}$. If $\rho: G \to \mathrm{Aut}(\tilde{E})$ is a unitary representation of G, define vector bundle $E = P \times_\rho \tilde{E}$. We define a connection ∇^E on E, which is required to be compatible with the Riemannian structure. Locally, we represent ∇^E as a Lie-algebra valued 1-form $A \in \Gamma(\Lambda \otimes \mathrm{ad}\, E)$ and its curvature $F \in \Gamma(\Lambda^2 \otimes \mathrm{End}\, E)$ as the Lie-algebra valued 2-form $dA + \frac{1}{2}[A,A]$, where $[,]$ is the Lie bracket on $\mathfrak{g}$.

We also need to assume M admits spin structures. Let V be the spin bundle over M. Then we can form a product $V \otimes E$ of two complex vector bundles that are both four-dimensional, such that End $V = C(E)$, where $C(E)$ is the Clifford algebra associated with E. If $\{e_i\}$ is an orthonormal basis for E, $C(E)$ is the graded algebra generated by the relation $e_i e_j + e_j e_i = -2\delta_{ij}$.

Sections $\phi \in \Gamma(V \otimes E)$ are called *E-valued spinors*.

Define $\tilde{\nabla} = \nabla \otimes 1 + 1 \otimes \nabla^E$ to be the total covariant derivative on $V \otimes E$. Let $\{e^i\}$ be an orthonormal local frame around a point $x \in M$. Then the *Dirac operator*

$$\not{D}: \Gamma(V \otimes E) \to \Gamma(V \otimes E)$$

is defined for E-valued spinors by

$$\not{D} = e^i \tilde{\nabla}_i.$$

As we noted, the essential geometry occurs in the bundle, thus in the sequel we expediently ignore the curvature of the base manifold.

The following *Weitzenböck formula* gives an important algebraic decomposition for the square of Dirac operator into Laplacian and curvature terms,[2]

$$\not{D}^2 = \tilde{\nabla}^* \tilde{\nabla} + \frac{1}{2} e^i e^j F_{ij}.$$

The coupled Yang-Mills-Dirac equations are the following nonlinear system of partial differential equations:[2]

$$\begin{aligned} D^* F = J(\phi) :&= -\frac{1}{2} \langle \phi, e^i \varrho(\sigma^\alpha) \phi \rangle e_i \otimes \sigma_\alpha, \\ \not{D}\phi &= m\phi, \end{aligned} \tag{2.1}$$

where D is the exterior covariant derivative, $*: \Lambda^p \to \Lambda^{4-p}$ is the Hodge star operator, $\{\sigma_\alpha\}$ is a local orthogonal basis in $\Gamma(\mathrm{Ad}\, \mathfrak{g})$, $\varrho: \mathfrak{g} \to \mathrm{End}(\tilde{E})$ is the Lie algebra representation induced by the Lie group representation $\rho: G \to \mathrm{Aut}(\tilde{E})$, and $\langle , \rangle$ is the inner product on $V \otimes E$. The eigenvalue m of $\not{D}$ is a real constant since $\not{D}$ is self-adjoint.

Conformal invariance is crucial for our results. Let ω be a positive number, if u takes values in a vector bundle E, by setting $u_r(x) = r^\omega u(y)$ under the local scale transformation $y = rx (r > 0)$ the L^p norm of u will satisfy

$$\|u(y)\|_{L^p(\Omega(y))} = r^{4/p - \omega} \|u_r(x)\|_{L^p(\Omega(x))}.$$

If $\omega p = 4$, we say u has *conformal weight* ω under the L^p norm, i.e.,

$$\|u(y)\|_{L^p(\Omega(y))} = \|u_r(x)\|_{L^p(\Omega(x))}.$$

The curvature form F, the particle mass m, and the spinor ϕ have conformal weight $2,1$, and $3/2$, respectively.[2]

III. SMALL ENERGY REGULARITY

Now we consider the local behavior of the coupled equations (2.1). Since the removable singularity theorem is a fact about arbitrarily small domains, in the sequel we may assume M to be a domain on $\mathbb{R}^4$ with trivial spin structure. The ball of radius r on M will be denoted by B_r.

Definition 3.1: Let U be a domain on M, the energy of (F,ϕ) on U is defined by

$$E(F,\phi,U):=\int_U |F|^2\,dV_g+\left(\int_U |\phi|^{8/3}\,dV_g\right)^{3/4}=\|F\|^2_{L^2(U)}+\|\phi\|^2_{L^{8/3}(U)}.$$

Note that the energy is conformally invariant. It is crucial for our results.

The main result of this section is small energy regularity as the following, which will be proved at the end of this section.

Theorem 3.2: *There exists a constant $\varepsilon>0$ such that if (F,ϕ) is a smooth solution of the coupled Yang-Mills-Dirac equations* (2.1) on B_2, *satisfying $E(F,\phi,B_2)<\varepsilon$, then there holds*

$$\|F\|_{C^0(B_1)}+\|\phi\|_{C^0(B_1)}\le C(\|F\|_{L^2(B_2)}+\|\phi\|_{L^{8/3}(B_2)}),$$

where C is a positive constant depending only on ε.

A. Three subelliptic inequalities

Our starting point is the following three subelliptic inequalities, where $\{k_i\}$ are non-negative constants. Let Δ be the ordinary Laplacian on functions.

Proposition 3.3: There holds the following subelliptic inequalities for the solutions (F,ϕ) of the coupled Yang-Mills-Dirac equations (2.1):

$$\Delta|\phi|+k_1|F||\phi|\ge 0, \tag{3.1}$$

$$\Delta|\tilde{\nabla}\phi|+k_2(|F||\tilde{\nabla}\phi|+|\phi|^2)\ge 0, \tag{3.2}$$

$$\Delta|F|+k_3(|F|^2+|\phi||\tilde{\nabla}\phi|)\ge 0. \tag{3.3}$$

Proof: (i) Using Kato's inequality $|d|\phi||\le|\tilde{\nabla}\phi|$, we have

$$|\phi|\Delta|\phi|=\langle\phi,\tilde{\nabla}^*\tilde{\nabla}\phi\rangle+\langle\tilde{\nabla}\phi,\tilde{\nabla}\phi\rangle-|d|\phi||^2\ge\langle\phi,\tilde{\nabla}^*\tilde{\nabla}\phi\rangle.$$

Applying the Weitzenböck formula and noting $\not{D}^2\phi=m^2\phi$ gives

$$|\phi|\Delta|\phi|\ge\langle\phi,m^2\phi\rangle-\frac{1}{2}\langle\phi,e^ie^jF_{ij}(\phi)\rangle\ge-\frac{1}{2}\langle\phi,e^ie^jF_{ij}(\phi)\rangle\ge-|\phi||e^ie^jF_{ij}(\phi)|.$$

Dividing by $|\phi|$ then gives (3.1).

(ii) Set $\psi=\tilde{\nabla}\phi$. The Weitzenböck formula gives

$$\tilde{\nabla}^*\tilde{\nabla}\psi=\not{D}^2\psi-\frac{1}{2}e^ie^jF_{ij}\psi=\not{D}^2(\tilde{\nabla}\phi)-\frac{1}{2}e^ie^jF_{ij}\psi.$$

Combining the identity $\not{D}^2\tilde{\nabla}=\tilde{\nabla}\not{D}^2+J+2e^ie^jF_{ij}\tilde{\nabla}$ (Ref. 3) and $\not{D}^2\phi=m^2\phi$, we get

$$\tilde{\nabla}^*\tilde{\nabla}\psi = \tilde{\nabla}(\not{D}^2\phi) + J(\phi) + 2e^i e^j F_{ij}(\tilde{\nabla}\phi) - \tfrac{1}{2}e^i e^j F_{ij}\psi = \tilde{\nabla}(m^2\phi) + J(\phi) + \tfrac{3}{2}e^i e^j F_{ij}\psi$$
$$= m^2\psi + J(\phi) + \tfrac{3}{2}e^i e^j F_{ij}\psi.$$

Using Kato's inequality, we have

$$|\psi|\Delta|\psi| \geq \langle\psi, \tilde{\nabla}^*\tilde{\nabla}\psi\rangle = m^2|\psi|^2 + \langle\psi, J(\phi)\rangle + \left\langle\psi, \tfrac{3}{2}e^i e^j F_{ij}\psi\right\rangle \geq \langle\psi, J(\phi)\rangle + \left\langle\psi, \tfrac{3}{2}e^i e^j F_{ij}\psi\right\rangle$$
$$\geq -k_2|\psi|(|\phi|^2 + |F||\psi|).$$

Dividing by $|\psi|$ gives (3.2).

(iii) Differentiating the field equation $D^*F = J(\phi)$ and using Bianchi identity $DF = 0$, we have

$$(D^*D + DD^*)F = DJ.$$

The Laplacians $D^*D + DD^*$ and $\tilde{\nabla}^*\tilde{\nabla}$ differ by a curvature term:[1]

$$\tilde{\nabla}^*\tilde{\nabla}F - (D^*D + DD^*)F = [F, F].$$

Hence

$$\tilde{\nabla}^*\tilde{\nabla}F = [F, F] + DJ.$$

By Kato's inequality again,

$$|F|\Delta|F| \geq \langle F, \tilde{\nabla}^*\tilde{\nabla}F\rangle = \langle F, [F, F]\rangle + \langle F, DJ\rangle \geq -k_3|F|(|F|^2 + |DJ|).$$

Hence

$$\Delta|F| + k_3(|F|^2 + |DJ|) \geq 0.$$

By the definition of $J(\phi)$, a direct computation shows that

$$|DJ| \leq k_3'|\phi||\tilde{\nabla}\phi|,$$

which gives (3.3). ■

B. Some *a priori* estimates in PDE

Before proving Theorem 3.2, we state some standard *a priori* estimates in PDE that will be used repeatedly.

Theorem 3.4:[4] *Assume $n \geq 3$; B_1 is the unit ball in $\mathbb{R}^n$. Suppose $a^{ij} \in L^\infty(B_1)$ satisfies*

$$\lambda|\xi|^2 \leq a^{ij}(x)\xi_i\xi_j \leq \Lambda|\xi|^2, \quad \text{for any } x \in B_1,\ \xi \in R^n,$$

for some positive constants λ and Λ.

Assume $c \in L^{n/2}(B_1)$ and $f \in L^q(B_1)$ for some $q \in [2n/(n+2), n/2)$. Suppose that $u \in H^1(B_1)$ is a subsolution in the following sense:

$$\int_{B_1} a^{ij} D_i u\, D_j\varphi + cu\varphi \leq \int_{B_1} f\varphi,$$

for any $\varphi \in H_0^1(B_1)$ and $\varphi \geq 0$ in B_1, then $u^+ \in L^{q^*}_{\mathrm{loc}}(B_1)$ for $1/q^* = 1/q - 2/n$.

Moreover, there exists a small constant $\varepsilon > 0$ such that if $\|c\|_{L^{n/2}(B_1)} < \varepsilon$ there holds

$$\|u^+\|_{L^{q^*}(B_{1/2})} \leq C\{\|u^+\|_{L^2(B_1)} + \|f\|_{L^q(B_1)}\},$$

where $C = C(n, \lambda, \Lambda, q, \varepsilon)$ is a positive constant. ■

Theorem 3.5:[5] *Assume* $b \in L^q(U)$, $q > n/2$, $u^\lambda \in W^{1,2}_{\mathrm{loc}}(U)$ *with* $1/2 < \lambda \leq 1$, $u \geq 0$ *satisfy the following subelliptic inequality in a weak sense:*

$$\Delta u + bu \geq 0,$$

then u is bounded on compact subdomains of U. Moreover, if $B(x,a) \subset B(x_0,a_0) \subset U$, *there holds that*

$$|u^\lambda(x)|^2 \leq Ca^{-n} \int_{B(x_0,a_0)} |u^\lambda|^2,$$

where constant C depends on n, q, λ *and* $a_0^{2/n-1/q}\|b\|_{L^q(B(x_0,a_0))}$. ■

C. Small energy regularity

Now we start to prove Theorem 3.2 by the approach of applying the above *a priori* estimates to the coupled equations (2.1) in the case of four dimensions. In the proof, C is a constant varying from line to line and $B_1 \subset B_{R_1} \subset B_{R_2} \subset B_2$ are fixed balls with the same center.

Lemma 3.6: For any given $p \geq 4$, *there exists a positive constant* ε_p *such that if* $\|F\|^2_{L^2(B_2)} < \varepsilon_p$, *there holds that*

$$\|\phi\|_{L^p(B_{R_2})} \leq C_p \|\phi\|_{L^{8/3}(B_2)},$$

where C_p *is a positive constant depending on p and* ε_p.

Proof: By (3.1), ϕ *satisfies*

$$\Delta|\phi| + k_1|F||\phi| \geq 0.$$

Let $u = |\phi|$, $c = -k_1|F|$, $f = 0$ and $n = 4$. Note that $f \in L^q$ for any arbitrarily fixed $q \in [2n/(n+2), n/2) = [\frac{4}{3}, 2)$. Applying Theorem 3.4, there exists constant $\delta > 0$ such that if $\|c\|_{L^2(B_2)} < \delta$, i.e., $\|F\|_{L^2(B_2)} < \delta/k_1$, there holds that

$$\|\phi\|_{L^{q^*}(B_{R_2})} \leq C_q \|\phi\|_{L^2(B_2)},$$

where $q^* \in [4, +\infty)$. Noting that $\|\phi\|_{L^2(B_2)} \leq C\|\phi\|_{L^{8/3}(B_2)}$ and q^* runs over $[4, +\infty)$ while q runs over $[\frac{4}{3}, 2)$, we prove the lemma by choosing $\varepsilon = (\delta/k_1)^2$. ■

Next, we estimate the derivative of ϕ. Since F is smooth, Uhlenbeck's theorem[3] ensures that, by rescaling to get $\|F\|_{L^2}$ sufficiently small, there exists a continuous gauge transformation such that

$$\|A\|_{W^{1,2}(B_2)} \leq C(n)\|F\|_{L^2(B_2)},$$

where n is the dimension of the base manifold.

Then the Sobolev embedding theorem for four dimensions implies

$$\|A\|_{L^4(B_2)} \leq C\|F\|_{L^2(B_2)}.$$

Lemma 3.7: For any given $p < 4$ *there holds that*

$$\|\tilde{\nabla}\phi\|_{L^p(B_{R_2})} \leq C_p(1 + \|F\|_{L^2(B_2)})\|\phi\|_{L^{4p/(4-p)}(B_2)},$$

where constant C_p *depends on p.*

Proof: We write the Dirac operator in the form $\not{D} = e^i(\nabla_i + A_i)$; then the eigenvalue equation $\not{D}\phi = m\phi$ can be rewritten as

$$e^i \nabla_i \phi = m\phi - e^i A_i \phi.$$

Applying the interior estimate for first-order elliptic operator and noting m is locally constant, we get

$$\begin{aligned}\|\phi\|_{W^{1,p}(B_{R_2})} &\le C\|\phi\|_{L^p(B_2)} + C\|m\phi\|_{L^p(B_2)} + C\|A\phi\|_{L^p(B_2)}\\ &\le C\|\phi\|_{L^p(B_2)} + C\|m\|_{L^4(B_2)}\|\phi\|_{L^{4p/(4-p)}(B_2)} + C\|A\|_{L^4(B_2)}\|\phi\|_{L^{4p/(4-p)}(B_2)}\\ &\le C\|\phi\|_{L^{4p/(4-p)}(B_2)} + C\|\phi\|_{L^{4p/(4-p)}(B_2)} + C\|F\|_{L^2(B_2)}\|\phi\|_{L^{4p/(4-p)}(B_2)}\\ &\le C(1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{4p/(4-p)}(B_2)}.\end{aligned}$$

Hence,

$$\begin{aligned}\|\tilde{\nabla}\phi\|_{L^p(B_{R_2})} &\le \|\nabla\phi\|_{L^p(B_{R_2})} + \|A\phi\|_{L^p(B_{R_2})} \le \|\phi\|_{W^{1,p}(B_{R_2})} + \|A\phi\|_{L^p(B_{R_2})}\\ &\le C(1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{4p/(4-p)}(B_2)} + C\|F\|_{L^2(B_2)}\|\phi\|_{L^{4p/(4-p)}(B_2)}\\ &\le C(1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{4p/(4-p)}(B_2)}.\end{aligned}$$

■

Since $4p/(4-p) \ge 4 \Leftrightarrow 2 \le p < 4$, the arguments of Lemma 3.6 and Lemma 3.7 can be used to obtain the following corollary.

Corollary 3.8: Assume $2 \le p < 4$. *There exists a positive constant* ε_p *such that if* $\|F\|^2_{L^2(B_2)} < \varepsilon_p$ *there holds that*

$$\|\tilde{\nabla}\phi\|_{L^p(B_{R_2})} \le C_p(1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{8/3}(B_2)},$$

where C_p *is a positive constant depending on* p *and* ε_p.

Proof: By an argument similar to the one used in Lemma 3.7, we have

$$\|\tilde{\nabla}\phi\|_{L^p(B_{R_2})} \le C_p(1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{4p/(4-p)}(B_{R_3})}$$

with some ball B_{R_3} satisfying $B_{R_2} \subset B_{R_3} \subset B_2$.

Then by an argument similar to the one used in Lemma 3.6, there exists a positive constant ε_p such that if $\|F\|^2_{L^2(B_2)} < \varepsilon_p$ there holds that

$$\|\phi\|_{L^{4p/(4-p)}(B_{R_3})} \le C_p\|\phi\|_{L^{8/3}(B_2)}.$$

This proves the corollary. ■

Corollary 3.9: There exists a small constant $\varepsilon_1 > 0$ *such that if* $\|F\|^2_{L^2(B_2)} < \varepsilon_1$ *there holds that*

$$\||\phi||\tilde{\nabla}\phi|\|_{L^{4/3}(B_{R_2})} \le C(1+\|F\|_{L^2(B_2)})\|\phi\|^2_{L^{8/3}(B_2)},$$

where C_p *is a positive constant depending on* p *and* ε_1.

Proof: Hölder's inequality gives

$$\||\phi||\tilde{\nabla}\phi|\|_{L^{4/3}(B_{R_2})} \le \|\phi\|_{L^4(B_{R_2})}\|\tilde{\nabla}\phi\|_{L^2(B_{R_2})},$$

where $\|\phi\|_{L^4(B_{R_2})}$ and $\|\tilde{\nabla}\phi\|_{L^2(B_{R_2})}$ can be estimated by Lemma 3.6 and Corollary 3.8, respectively. ■

Now we can get the L^4 norm estimates for $\tilde{\nabla}\phi$ and F as the following Lemma 3.10 Lemma 3.11, respectively, which are combinations of Theorem 3.4 with Corollary 3.8 and Corollary 3.9, respectively.

Lemma 3.10: There exists a small constant $\varepsilon_2 > 0$ *such that if* $\|F\|^2_{L^2(B_2)} < \varepsilon_2$ *there holds that*

$$\left\|\tilde{\nabla}\phi\right\|_{L^4(B_{R_1})} \le C(\|\phi\|_{L^{8/3}(B_2)} + \|\phi\|^2_{L^{8/3}(B_2)} + \|F\|_{L^2(B_2)}\|\phi\|_{L^{8/3}(B_2)}),$$

where constant C depends on ε_2.

Proof: Recall in Proposition 3.3 that $\tilde{\nabla}\phi$ satisfies the subelliptic inequality

$$\Delta|\tilde{\nabla}\phi| + k_2(|F||\tilde{\nabla}\phi| + |\phi|^2) \ge 0.$$

Applying Theorem 3.4 with $u=|\tilde{\nabla}\phi|$, $c=-k_2|F|$, $f=k_2|\phi|^2$, $n=4$, and $q=2n/(n+2)=\frac{4}{3}$ (consequently $q^*=4$), there exists small constant $\delta>0$ such that if $\|c\|_{L^2(B_{R_2})}<\delta$, i.e., $\|F\|^2_{L^2(B_{R_2})} < (\delta/k_2)^2$, there holds that

$$\|\tilde{\nabla}\phi\|_{L^4(B_{R_1})} \le C_\delta(\|\tilde{\nabla}\phi\|_{L^2(B_{R_2})} + \||\phi|^2\|_{L^{4/3}(B_{R_2})}) \le C_\delta(\|\tilde{\nabla}\phi\|_{L^2(B_{R_2})} + \|\phi\|^2_{L^{8/3}(B_2)}).$$

Applying Corollary 3.8 with $p=2$, there exists small constant $\delta'>0$ such that if $\|F\|^2_{L^2(B_2)} < \delta'$ there holds that

$$\|\tilde{\nabla}\phi\|_{L^2(B_{R_2})} \le C_{\delta'}(1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{8/3}(B_2)}.$$

Choose $\varepsilon_2 \le \min\{(\delta/k_2)^2, \delta'\}$, then if $\|F\|^2_{L^2(B_2)} < \varepsilon_2$ there holds that

$$\begin{aligned}\|\tilde{\nabla}\phi\|_{L^4(B_{R_1})} &\le C_{\varepsilon_2}((1+\|F\|_{L^2(B_2)})\|\phi\|_{L^{8/3}(B_2)} + \|\phi\|^2_{L^{8/3}(B_2)}) \\ &\le C_{\varepsilon_2}(\|\phi\|_{L^{8/3}(B_2)} + \|\phi\|^2_{L^{8/3}(B_2)} + \|F\|_{L^2(B_2)}\|\phi\|_{L^{8/3}(B_2)}).\end{aligned}$$

■

Lemma 3.11: There exists small constant $\varepsilon_3>0$ *such that if* $\|F\|^2_{L^2(B_2)}<\varepsilon_3$ *there holds that*

$$\|F\|_{L^4(B_{R_1})} \le C(\|F\|_{L^2(B_2)} + \|\phi\|^2_{L^{8/3}(B_2)} + \|F\|_{L^2(B_2)}\|\phi\|^2_{L^{8/3}(B_2)}),$$

where constant C depends on ε_3.

Proof: Recall in Proposition 3.3 F satisfies the subelliptic inequality:

$$\Delta|F| + k_3|F||F| + k_3|\phi||\tilde{\nabla}\phi| \ge 0.$$

Applying Theorem 3.4 with $u=|F|$, $c=-k_3|F|$, $f=k_3|\phi||\tilde{\nabla}\phi|$, $n=4$, and $q=2n/(n+2)=\frac{4}{3}$ (consequently $q^*=4$), there exists small constant $\delta>0$ such that if $\|c\|_{L^2(B_{R_2})}<\delta$, i.e., $\|F\|^2_{L^2(B_{R_2})} < (\delta/k_3)^2$, there holds that

$$\|F\|_{L^4(B_{R_1})} \le C_\delta(\|F\|_{L^2(B_{R_2})} + \||\phi||\tilde{\nabla}\phi|\|_{L^{4/3}(B_{R_2})}) \le C_\delta(\|F\|_{L^2(B_2)} + \||\phi||\tilde{\nabla}\phi|\|_{L^{4/3}(B_{R_2})}).$$

Choose $\varepsilon_3 \le \min\{\varepsilon_1, (\delta/k_3)^2\}$; then if $\|F\|^2_{L^2(B_2)}<\varepsilon_3$ we can substitute the estimate for $\||\phi||\tilde{\nabla}\phi|\|_{L^{4/3}(B_{R_2})}$ in Corollary 3.9 onto the right-hand side of the inequality above, so we get

$$\begin{aligned}\|F\|_{L^4(B_{R_1})} &\le C_{\varepsilon_3}(\|F\|_{L^2(B_2)} + C_{\varepsilon_3}(1+\|F\|_{L^2(B_2)})\|\phi\|^2_{L^{8/3}(B_2)}) \\ &\le C_{\varepsilon_3}(\|F\|_{L^2(B_2)} + \|\phi\|^2_{L^{8/3}(B_2)} + \|F\|_{L^2(B_2)}\|\phi\|^2_{L^{8/3}(B_2)}).\end{aligned}$$

■

Now we can prove the main result of this section.

Proof of Theorem 3.2: Set $u=|F|+|\phi|$ and $b=k_4(|F|+|\tilde{\nabla}\phi|)$. Adding (3.1) and (3.3) gives

$$\Delta u + bu \ge 0.$$

Choose $\varepsilon=\min\{\varepsilon_2,\varepsilon_3\}$. If $\|F\|^2_{L^2(B_2)}<\varepsilon$ we can apply Lemma 3.10 and Lemma 3.11 to get a bound on $\|b\|_{L^4(B_{R_1})}$ as the following:

$$\begin{aligned}\|b\|_{L^4(B_{R_1})} &\le k_4\|F\|_{L^4(B_{R_1})}+k_4\|\tilde{\nabla}\phi\|_{L^4(B_{R_1})}\\ &\le C(\|F\|_{L^2(B_2)}+\|\phi\|_{L^{8/3}(B_2)}+\|\phi\|^2_{L^{8/3}(B_2)}+\|F\|_{L^2(B_2)}\|\phi\|_{L^{8/3}(B_2)}+\|F\|_{L^2(B_2)}\|\phi\|^2_{L^{8/3}(B_2)}),\end{aligned}$$

where constant C depends on ε.

Now Theorem 3.5 applies with $u=|F|+|\phi|$, $b=k_4(|F|+|\tilde{\nabla}\phi|)$, $\lambda=1$, and $q=4$. For any $x\in B_1$ there holds that

$$(|F(x)|+|\phi(x)|)^2\le C\int_{B_{R_1}}(|F|+|\phi|)^2\le C\int_{B_2}(|F|+|\phi|)^2.$$

Hence

$$\|F\|_{C^0(B_1)}+\|\phi\|_{C^0(B_1)}\le C(\|F\|_{L^2(B_2)}+\|\phi\|_{L^2(B_2)})\le C(\|F\|_{L^2(B_2)}+\|\phi\|_{L^{8/3}(B_2)}).$$

Since $\|F\|_{L^2(B_2)}$ and $\|\phi\|_{L^{8/3}(B_2)}$ are both invariant under dilation, the size of the ball does not affect the constant C of Theorem 3.5. ■

Theorem 3.2 is immediately applicable to the problem of the behavior of fields around a singularity.

Corollary 3.12: There exists a constant $\varepsilon>0$ such that if (F,ϕ) is a smooth solution of the coupled Yang-Mills-Dirac equations (2.1) *on $B_2\backslash\{0\}$ satisfying $E(F,\phi,B_2)<\varepsilon$; then for any $x\in B_1\backslash\{0\}$ there holds that*

$$|F(x)||x|^2+|\phi(x)||x|^{3/2}\le C(\|F\|_{L^2(B_2)}+\|\phi\|_{L^{8/3}(B_2)}),$$

where constant C depends on ε.

Proof: Choose ε as in Theorem 3.2. For any fixed $x_0\in B_1\backslash\{0\}$ we define

$$\tilde{F}(x):=\left(\frac{|x_0|}{2}\right)^2F\left(x_0+\frac{|x_0|}{2}x\right),\quad \tilde{\phi}(x):=\left(\frac{|x_0|}{2}\right)^{3/2}\phi\left(x_0+\frac{|x_0|}{2}x\right).$$

It is clear that $(\tilde{F},\tilde{\phi})$ is a smooth solution of the coupled Yang-Mills-Dirac equations on B_2 and $E(\tilde{F},\tilde{\phi},B_2)<\varepsilon$ by conformal invariance. Applying Theorem 3.2, we have

$$\|\tilde{F}\|_{C^0(B_1)}+\|\tilde{\phi}\|_{C^0(B_1)}\le C(\|\tilde{F}\|_{L^2(B_2)}+\|\tilde{\phi}\|_{L^{8/3}(B_2)}).$$

Scaling back, we prove the corollary. ■

IV. REMOVABLE SINGULARITY THEOREM

Now we state the main result of this paper, which will be proved at the end.

Theorem 4.1 (removable singularity): *Let (F,ϕ) be a smooth solution of the coupled Yang-Mills-Dirac equations with finite energy on $B_2\backslash\{0\}$. Then (F,ϕ) is gauge equivalent by a continuous gauge transformation to a smooth solution on B_2.*

By rescaling, we can assume that the energy $E(F,\phi,B_2)$ is sufficiently small, i.e., $E(F,\phi,B_2)<\varepsilon$ with ε is chosen as in Corollary 3.12. Then for any $x\in B_1\backslash\{0\}$ there holds that

$$|F(x)||x|^2\le CE(F,\phi,B_2)\le C\varepsilon.$$

The above inequality guarantees the existence of a specific choice of gauge that is the so called *broken Hodge gauge*. The existence of this gauge is crucial for removing singularities, since in such a gauge the powerful regularity argument of elliptic theory can be applied to the coupled

equations (2.1). An important theorem of Uhlenbeck[1] provides such a gauge around the singularity and includes rather specific information about the connection and curvature forms in this gauge.

Theorem 4.2:[2,1] *Let A be a smooth connection form on $B_2\backslash\{0\}$ with curvature F. Then there is a constant $\kappa>0$ such that if $|F(x)||x|^2\leq\varepsilon<\kappa$ on $B_1\backslash\{0\}$ then there exists a broken Hodge gauge on $B_1\backslash\{0\}$ whose properties we now describe. Set*

$$U_i=\{x:2^{-i}\leq|x|\leq 2^{-i+1}\},\quad i=1,2,3,\ldots,$$

$$S_i=\{x:|x|=2^{-i}\},\quad i=1,2,3,\ldots\ .$$

The broken Hodge gauge is smooth on each U_i and the gauges from U_i and U_{i+1} agree on S_i. Write

$$A^i=A\big|_{U_i},\quad F^i=F\big|_{U_i}.$$

Then $\{A^i\}$ and $\{F^i\}$ satisfy

(a) $d^*A^i=0$,

(b) $A^i_\theta\big|_{S_i}=A^{i+1}_\theta\big|_{S_i}$, $\quad A_\theta=$ *tangential components of* A,

(c) $d^*A^i_\theta\big|_{S_i}=0=d^*A^i_\theta\big|_{S_{i-1}}$,

(d) $\displaystyle\int_{S_i}A^i_r=0=\int_{S_{i-1}}A^i_r$, $\quad A_r=$ *radial component of* A,

$$(e)\quad \int_{S_0}|A^1|^2\leq b\int_{S_0}|F^1|^2, \tag{4.1}$$

$$(f)\quad \int_{U_i}|A^i|^4\leq c_0\varepsilon^2\int_{U_i}|F^i|^2,\quad \int_{B_1}|A|^4\leq c_0\varepsilon^2\int_{B_1}|F|^2\leq c_0\varepsilon^4, \tag{4.2}$$

for some positive constants b and c_0 whenever ε is sufficiently small. ■

Since we are assuming that the energy of the fields is small enough, we can apply Corollary 3.12 to obtain a field on $B_2\backslash\{0\}$ satisfying the hypotheses of Theorem 4.2. Hence ***there exists a broken Hodge gauge***. In the sequel the broken Hodge gauge is used as a "reference frame" in which to observe the particle field and to obtain our gauge dependent estimates.

Proof of Theorem 4.1: The proof consists of three parts. We will give the estimates with boundary data for F, ϕ, and $\nabla\phi$, respectively. In the sequel $\{c_k\}$ are nonnegative constants.

(i) **Part 1: estimate for F with boundary data.** Integrating by parts on U_i gives

$$\int_{U_i}|F^i|^2=\int_{U_i}\langle D^*F^i,A^i\rangle-\frac{1}{2}\int_{U_i}\langle F^i,[A^i,A^i]\rangle+\left(\int_{S_{i-1}}-\int_{S_i}\right)A^i_\theta\wedge(*F^i)_\theta:=I_1+I_2+\text{boundary term}.$$

Using the field equation $D^*F=J(\phi)$ and the properties of broken Hodge gauge, we get

$$\begin{aligned}I_1&=\int_{U_i}\langle J(\phi),A^i\rangle\leq c_1\int_{U_i}|\phi|^2|A^i|=c_1\int_{U_i}(\varepsilon^{1/4}|\phi|^2)(\varepsilon^{-1/4}|A^i|)\\&\leq c_2\left(\varepsilon^{1/3}\int_{U_i}|\phi|^{8/3}+\varepsilon^{-1}\int_{U_i}|A^i|^4\right)\leq c_2\left(\varepsilon^{1/3}\int_{U_i}|\phi|^{8/3}+c_0\varepsilon\int_{U_i}|F^i|^2\right),\end{aligned}$$

$$I_2 \le \frac{1}{2}\int_{U_i} |F^i||A^i|^2$$
$$\le \frac{1}{2}\left(\int_{U_i}|F^i|^2\right)^{1/2}\left(\int_{U_i}|A^i|^4\right)^{1/2} \le \frac{1}{2}\left(\int_{U_i}|F^i|^2\right)^{1/2}\left(c_0\varepsilon^2\int_{U_i}|F^i|^2\right)^{1/2} \le c_3\varepsilon\int_{U_i}|F^i|^2.$$

Since the energy bound ε appearing in I_1 and I_2 could be sufficiently small, we have

$$(1-\varepsilon')\int_{U_i}|F^i|^2 \le c_4\varepsilon^{1/3}\int_{U_i}|\phi|^{8/3} + \left(\int_{S_{i-1}} - \int_{S_i}\right)A^i_\theta \wedge (*F^i)_\theta.$$

Summing on i, noting that $|A^1_\theta \wedge (*F^1)_\theta| \le |A^1||F^1|$, and using Hölder's inequality gives

$$(1-\varepsilon')\int_{B_1}|F|^2 \le c_4\varepsilon^{1/3}\int_{B_1}|\phi|^{8/3} + \left(\int_{\partial B_1}|A^1|^2\right)^{1/2}\left(\int_{\partial B_1}|F^1|^2\right)^{1/2}.$$

Noting the property (4.1) of the broken Hodge gauge, we get

$$\int_{B_1}|F|^2 \le C\varepsilon^{1/3}\int_{B_1}|\phi|^{8/3} + C\int_{\partial B_1}|F|^2.$$

By a scaling argument, we have, for $0 \le r \le 1$;

$$\int_{B_r}|F|^2 \le C\varepsilon^{1/3}\int_{B_r}|\phi|^{8/3} + Cr\int_{\partial B_r}|F|^2. \tag{4.3}$$

(ii) **Part 2: estimate for ϕ with boundary data.** In the sequel, we denote $\|\ \|_{W^{k,p}(B)}$ by $\|\ \|_{B,k,p}$, where B is the unit ball B_1.

Write the eigenvalue equation $\not{D}\phi = m\phi$ in the form $e^i\,\boldsymbol{\nabla}_i\phi = m\phi - e^iA_i\phi$. Choose a cutoff function $\eta_\rho \in C_0^\infty(B_{2\rho})$ with $2\rho < 1$ such that $\eta_\rho|_{B_\rho} \equiv 1$ and $|\boldsymbol{\nabla}\eta_\rho| \le C/\rho$. Then we have

$$e^i\nabla_i((1-\eta_\rho)\phi) = (1-\eta_\rho)e^i\,\boldsymbol{\nabla}_i\phi + e^i\boldsymbol{\nabla}_i(1-\eta_\rho)\phi = (1-\eta_\rho)(m\phi - e^iA_i\phi) + e^i\boldsymbol{\nabla}_i(1-\eta_\rho)\phi.$$

The estimate with boundary data for a first-order elliptic operator gives

$$\|(1-\eta_\rho)\phi\|_{B,1,8/5} \le C\|m\phi - e^iA_i\phi\|_{B,0,8/5} + C\|\boldsymbol{\nabla}\eta_\rho\,\phi\|_{B,0,8/5} + C\|\phi\|_{\partial B,1,8/5}.$$

Letting $\rho \to 0$, using

$$\lim_{\rho\to 0}\|\boldsymbol{\nabla}\eta_\rho\phi\|_{B,0,8/5} \le \lim_{\rho\to 0}\frac{C}{\rho}\|\phi\|_{B_{2\rho},0,8/5} = 0,$$

the Sobolev embedding theorem and (4.2), we get

$$\|\phi\|_{B,0,8/3} \le C\|m\phi - e^iA_i\phi\|_{B,0,8/5} + C\|\phi\|_{\partial B,1,8/5} \le C(\|m\|_{B,0,4} + \|A\|_{B,0,4})\|\phi\|_{B,0,8/3} + C\|\phi\|_{\partial B,1,8/5}$$
$$\le C(\|m\|_{B,0,4} + \sqrt[4]{c_0}\varepsilon)\|\phi\|_{B,0,8/3} + C\|\phi\|_{\partial B,1,8/5}.$$

We can assume $\|m\|_{B,0,4}$ is sufficiently small by a scaling argument. Noting ε is also sufficiently small, we transfer the term that contains $\|\phi\|_{B,0,8/3}$ on the right-hand side of the above inequality to the left-hand side. This gives

$$\|\phi\|_{B,0,8/3} \le C\|\phi\|_{\partial B,1,8/5} \le C\|\phi\|_{\partial B,0,8/3} + C\|\nabla\phi\|_{\partial B,0,8/5}.$$

By rescaling, we have for any $0 \le r \le 1$,

$$\left(\int_{B_r}|\phi|^{8/3}\right)^{3/8} \le C\left(r\int_{\partial B_r}|\phi|^{8/3}\right)^{3/8} + C\left(r\int_{\partial B_r}|\nabla\phi|^{8/5}\right)^{5/8}$$
$$\le C\left(r\int_{\partial B_r}|\phi|^{8/3}\right)^{3/8} + C\left(r\int_{\partial B_r}|\nabla\phi|^{8/5}\right)^{3/8}.$$

Thus

$$\int_{B_r}|\phi|^{8/3} \le Cr\int_{\partial B_r}|\phi|^{8/3} + Cr\int_{\partial B_r}|\nabla\phi|^{8/5}. \tag{4.4}$$

(iii) **Part 3: estimate for $\nabla\phi$ with boundary data.** Set $\bar{\phi}=(1/|\partial B|)\int_{\partial B}\phi$, $\psi=\phi-\bar{\phi}$. Choosing the same cut-off function η_ρ as in Part 2, we have

$$e^i\nabla_i((1-\eta_\rho)\psi) = (1-\eta_\rho)e^i\,\nabla_i\psi + e^i\nabla_i(1-\eta_\rho)\psi.$$

Again, the estimate with boundary data for the first-order elliptic operator gives

$$\|(1-\eta_\rho)\psi\|_{B,1,8/5} \le C\|e^i\,\nabla_i\psi\|_{B,0,8/5} + C\|\nabla\eta_\rho\psi\|_{B,0,8/5} + C\|\psi\|_{\partial B,1,8/5}.$$

Letting $\rho\to 0$, using

$$\lim_{\rho\to 0}\|\nabla\eta_\rho\psi\|_{B,0,8/5} = 0,$$

we get

$$\|\psi\|_{B,1,8/5} \le C\|e^i\nabla_i\psi\|_{B,0,8/5} + C\|\psi\|_{\partial B,1,8/5} := CI_3 + CI_4.$$

Since

$$e^i\,\nabla_i\psi = e^i\,\nabla_i\phi = m\phi - e^iA_i\phi = (m\psi - e^iA_i\psi) + (m\bar{\phi} - e^iA_i\bar{\phi}),$$

there holds that

$$I_3 \le \|m\psi - e^iA_i\psi\|_{B,0,8/5} + \|m\bar{\phi} - e^iA_i\bar{\phi}\|_{B,0,8/5}$$
$$\le (\|m\|_{B,0,4} + \|A\|_{B,0,4})\|\psi\|_{B,0,8/3} + (\|m\|_{B,0,8/5} + \|A\|_{B,0,8/5})|\bar{\phi}|$$
$$\le (\|m\|_{B,0,4} + \sqrt[4]{c_0}\varepsilon)\|\psi\|_{B,1,8/5} + (\|m\|_{B,0,8/5} + \|A\|_{B,0,8/5})|\bar{\phi}|.$$

Applying Poincaré's inequality gives an estimate for I_4:

$$I_4 = \|\psi\|_{\partial B,1,8/5} \le C\|\nabla\phi\|_{\partial B,0,8/5}.$$

Hence

$$\|\psi\|_{B,1,8/5} \le C(\|m\|_{B,0,4} + \sqrt[4]{c_0}\varepsilon)\|\psi\|_{B,1,8/5} + C(\|m\|_{B,0,8/5} + \|A\|_{B,0,8/5})|\bar{\phi}| + C\|\nabla\phi\|_{\partial B,0,8/5}.$$

Again, by the smallness of $\|m\|_{B,0,4}$ and ε, we get

$$\|\nabla\phi\|_{B,0,8/5} \le C(\|m\|_{B,0,8/5} + \|A\|_{B,0,8/5})|\bar{\phi}| + C\|\nabla\phi\|_{\partial B,0,8/5}$$
$$\le C(\|m\|_{B,0,4} + \|A\|_{B,0,4})\|\phi\|_{\partial B,0,8/3} + C\|\nabla\phi\|_{\partial B,0,8/5}.$$

Hence,

$$\int_B |\nabla\phi|^{8/5} \le C\left(\int_B |m|^4\right)^{2/5}\left(\int_{\partial B} |\phi|^{8/3}\right)^{3/5} + C\left(\int_B |A|^4\right)^{2/5}\left(\int_{\partial B} |\phi|^{8/3}\right)^{3/5} + C\int_{\partial B} |\nabla\phi|^{8/5}.$$

Applying Young's inequality to the first two terms on the right-hand side of the above inequality with conjugate indices $\frac{5}{2}$ and $\frac{5}{3}$, we have

$$\begin{aligned}\int_B |\nabla\phi|^{8/5} &\le C\delta\int_B |m|^4 + C\delta\int_B |A|^4 + \frac{C}{\sqrt[3]{\delta^2}}\int_{\partial B} |\phi|^{8/3} + C\int_{\partial B} |\nabla\phi|^{8/5} \\ &\le C\delta\int_B |m|^4 + C\ \delta c_0\varepsilon^2\int_B |F|^2 + \frac{C}{\sqrt[3]{\delta^2}}\int_{\partial B} |\phi|^{8/3} + C\int_{\partial B} |\nabla\phi|^{8/5},\end{aligned}$$

where $\delta>0$ is a sufficiently small constant. Hence, for $0\le r\le 1$,

$$\int_{B_r} |\nabla\phi|^{8/5} \le C\delta\int_{B_r} |m|^4 + Cc_0\ \delta\varepsilon^2\int_{B_r} |F|^2 + \frac{C}{\sqrt[3]{\delta^2}}r\int_{\partial B_r} |\phi|^{8/3} + Cr\int_{\partial B_r} |\nabla\phi|^{8/5}. \tag{4.5}$$

Finally, putting (4.3)–(4.5) together, we have for any $0\le r\le 1$ and some constant $C>0$, that

$$\int_{B_r} (|F|^2 + |\phi|^{8/3} + |\nabla\phi|^{8/5}) \le Cr\int_{\partial B_r} (|F|^2 + |\phi|^{8/3} + |\nabla\phi|^{8/5}) + Cr^4, \tag{4.6}$$

where the last term r^4 comes from the term $\int_{B_r}|m|^4$ in (4.5) by noting m is a constant locally.

Denote $f(r) := \int_{B_r}(|F|^2+|\phi|^{8/3}+|\nabla\phi|^{8/5})$; then (4.6) implies that

$$f(r) \le Crf'(r) + Cr^4. \tag{4.7}$$

Since $f'(r)\ge 0$, we can choose $C>\frac{1}{3}$. Then we write (4.7) in the form

$$\frac{d}{dr}\left(\frac{f(r)}{r^\alpha}\right) + r^{3-\alpha} \ge 0,$$

where $\alpha := 1/C$. Integrating this inequality between r and 1 gives

$$f(r) \le \widetilde{C}r^\alpha.$$

From this it is easy to conclude that there exist some $2>\beta>1$ and $2>p>\frac{8}{5}$ such that

$$F \in L^{2\beta}(B), \quad \phi \in W^{1,p}(B).$$

Furthermore, since $d^*A=0$ in the broken Hodge gauge,

$$|\nabla A| = |dA| = \left|F - \frac{1}{2}[A,A]\right| \le |F| + |A|^2,$$

and hence $A \in W^{1,2\beta}(B)$ [using (4.2)].

Then Sobolev embedding theorem implies

$$A \in L^{4\beta/(2-\beta)}(B), \quad \phi \in L^{p^*}(B),$$

where $p^*=4p/(4-p)$.

Choose positive constants p_1, p', and q' as follows:

$$p_1 = \frac{2\beta p}{2\beta-(\beta-1)p}, \quad p' = \frac{4\beta}{(2-\beta)p_1}, \quad q' = \frac{p^*}{p_1}.$$

One can check that $1/p'+1/q'=1$ and $p<p_1<p^*$ (since $1<\beta<2$).

Using the eigenvalue equation $\not{D}\phi = m\phi$, we have

$$\begin{aligned}\int_B |\nabla\phi|^{p_1} &\le C\int_B (|m||\phi| + |A||\phi|)^{p_1} \\ &\le C\left(\int_B |m|^{p_1 p'}\right)^{1/p'}\left(\int_B |\phi|^{p_1 q'}\right)^{1/q'} + C\left(\int_B |A|^{p_1 p'}\right)^{1/p'}\left(\int_B |\phi|^{p_1 q'}\right)^{1/q'} \\ &= C\left(\int_B |m|^{p_1 p'}\right)^{1/p'}\left(\int_B |\phi|^{p^*}\right)^{1/q'} + C\left(\int_B |A|^{4\beta/(2-\beta)}\right)^{1/p'}\left(\int_B |\phi|^{p^*}\right)^{1/q'} < \infty .\end{aligned}$$

Hence, $\nabla\phi \in L^{p_1}(B)$. Noting $\phi \in L^{p_1}(B)$ since $p_1 < p^*$, we have

$$\phi \in W^{1,p_1}(B), \quad \text{with } p_1 = \frac{2\beta p}{2\beta - (\beta - 1)p} > p.$$

From above, we see that $F \in L^{2\beta}(B)$ and $\phi \in W^{1,p}(B)$ imply $F \in L^{2\beta}(B)$ and $\phi \in W^{1,p_1}(B)$. By iteration, $F \in L^{2\beta}(B)$ and $\phi \in W^{1,p_k}(B)$ imply $F \in L^{2\beta}(B)$ and $\phi \in W^{1,p_{k+1}}(B)$ with

$$p_0 = p, \quad p_{k+1} = \frac{2\beta p_k}{2\beta - (\beta - 1)p_k}, \quad k = 0, 1, \ldots .$$

Since

$$\frac{p_{k+1}}{p_k} = \frac{2\beta}{2\beta - (\beta - 1)p_k} > 1,$$

there exists some k such that $p_k > 2$. Therefore, we have that $F \in L^{\beta_0}(B)$ and $\phi \in W^{1,p}(B)$ for some $\beta_0 > 2$ and $p > 2$. We can then conclude that (F, ϕ) is smooth on B_1 through the standard bootstrap method. This completes the proof of Theorem 4.1. ■

The fractional Hamiltonian analysis of $1+1$ dimensional field theory is investigated and the fractional Ostrogradski's formulation is obtained. The fractional path integral of both simple harmonic oscillator with an acceleration-squares part and a damped oscillator are analyzed. The classical results are obtained when fractional derivatives are replaced with the integer order derivatives. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2356797]

I. INTRODUCTION

Fractional calculus deals with the generalization of differentiation and integration to noninteger orders. Fractional calculus has gained importance, especially during the last three decades.[1–5] A large body of mathematical knowledge on fractional integrals and derivatives has been constructed. Fractional calculus, as a natural generalization of classical calculus, has played a significant role in engineering, science, and pure and applied mathematics in recent years. The fractional derivatives are the infinitesimal generators of a class of translation invariant convolution semigroups that appear universally as attractors.

Various applications of fractional calculus are based on replacing the time derivative in an evolution equation with a derivative of fractional order. The results of several recent researchers confirm that fractional derivatives seem to arise for important mathematical reasons.[5–21]

The fractional variational principles represents an important part of fractional calculus and it is deeply related to the fractional quantization procedure. There are several proposed methods to obtain the fractional Euler-Lagrange equations and the corresponding fractional Hamiltonians. However, this issue is not yet complectly clarified and it requires a more further detailed analysis.

The quantization of systems with fractional derivatives is a novel area in the theory of application of fractional differential and integral calculus. *Schrödinger* equation was considered with the first order time derivative modified to Caputo fractional ones in Ref. 22. In this case the obtained Hamiltonian was found to be non-Hermitian and nonlocal in time. In addition, the obtained wave functions are not invariant under the time reversal. The quantization of fractional Klein-Gordon field and fractional electromagnetic potential in the Coulomb gauge and the temporal gauge were investigated very recently in Ref. 23.

Recently, the fractional variational principles and the fractional Euler-Lagrange were obtained.[24,25]

Even more recently, the fractional constrained Lagrangian and Hamiltonian were analyzed.[26,27] The notion of the fractional Hessian[27] was introduced and the Euler-Lagrange equations were obtained for a Lagrangian linear in velocities.[26] Besides, the Hamiltonian equations

have been obtained for systems with linear velocities.[28] The classical fields with fractional derivatives were investigated by using the fractional Lagrangian formulation and the fractional Euler-Lagrange equations were obtained in Ref. 29.

Nonlocal theories have been investigated in several physical problems.[30] During the last decade, the nonlocal theories were subjected to an intense debate.[31–35] A Hamilton formalism for nonlocal Lagrangians was developed in Refs. 34 and 35, an equivalent singular first order Lagrangian was obtained and the corresponding Hamiltonian was pulled back on the phase space by using the corresponding constraints.[34] It was shown the space-time noncommutative field theories are acausal and the unitarity is lost.[36,37] The fractional Lagrangians and Hamiltonians are typical examples of nonlocal theories.

For these reasons the fractional quantization of field theory is an interesting issue to be investigated.

In this paper we analyze the fractional Hamiltonian quantization of nonsingular systems possessing higher order derivatives.

The plan of the paper is as follows.

In Sec. II the $1+1$ classical dimensional field theory analysis of nonlocal theories is briefly reviewed and the fractional generalization of Ostrogradski's formulation is presented. In Sec. III the path integral quantization of the simple harmonic oscillator with an acceleration-squares part is analyzed. Section IV is dedicated to the fractional path integral formulation of the damped oscillator. Finally, Sec. V is dedicated to our conclusions.

II. FRACTIONAL FIELD THEORY

A. Classical nonlocal theory

Let us start with an ordinary local Lagrangian depending on a finite number of derivatives at a given time, namely,

$$L(q(t),\dot{q}(t),\ldots,q^{(n)}(t)). \tag{1}$$

The next step is to consider a Lagrangian depending on a piece of the trajectory $q(t,\lambda)$ for $\forall\lambda$ belonging to an interval $[a,b]$,

$$L^{\mathrm{non}}(t)=L(q(t+\lambda)), \tag{2}$$

where a,b are real numbers. Therefore a nonlocal Lagrangian was introduced. In this case the action function corresponding to (2) is given by

$$S(q)=\int dt\, L^{\mathrm{non}}(t) \tag{3}$$

and the Euler-Lagrange equation corresponding to (3) are given by

$$\int dt\frac{\delta L^{\mathrm{non}}(t)}{\delta(q(t))}=0. \tag{4}$$

Equations (4) should be understood as a functional relation to be satisfied by physical trajectories, i.e., a Lagrangian constraint. These functional relations define a subspace J_R of physical trajectories $J_R\subset J$, in the space of all possible trajectories.[32,34] The crucial point is that there is no dynamics except the displacement inside the trajectory, namely,

$$q(t)\rightarrow q(t+\lambda). \tag{5}$$

Let us introduce now the dynamical variable $Q(t,\lambda)$ as follows:

$$Q(t,\lambda)=q(t+\lambda). \tag{6}$$

If we consider a field $Q(t,\lambda)$ instead of a trajectory $q(t)$, such that

$$\dot{Q}(t,\lambda) = Q'(t,\lambda), \tag{7}$$

where $\dot{Q} = \partial Q(t,\lambda)/\partial t$ and $Q'(t,\lambda) = \partial Q(t,\lambda)/\partial \lambda$ we obtain a field theory in one spatial and one time dimension, namely a $1+1$ dimensional formulation of nonlocal Lagrangians.[32,34]

The coordinates and momenta are suppose to have the following forms:

$$Q(t,\lambda) = \sum_{m=0}^{\infty} e_m(\lambda) q^{(m)}(t), \quad P(t,\lambda) = \sum_{m=0}^{\infty} e^m(\lambda) p_{(m)}(t), \tag{8}$$

where

$$\{q^{(n)}(t), p_{(m)}(t)\} = \delta_m^n \tag{9}$$

and

$$e_m(\lambda) = \frac{\lambda^m}{m!}, \quad e^m(\lambda) = (-\partial_\lambda)^m \delta(\lambda). \tag{10}$$

Therefore, the Hamiltonian for the $1+1$ dimensional field becomes

$$H(t,[Q,P]) = \int d\lambda\, P(t,\lambda) Q'(t,\lambda) - \tilde{L}(t,[Q]), \tag{11}$$

where P denotes the canonical momentum of Q. The phase space is T^*J together with the fundamental Poisson brackets,

$$\{Q(t,\lambda), P(t,\lambda')\} = \delta(\lambda - \lambda'). \tag{12}$$

The functional $\tilde{L}(t,[Q])$ is defined as follows:

$$\tilde{L}(t,[Q]) = \int d\lambda\, \delta(\lambda) \mathcal{L}(t,\lambda). \tag{13}$$

By using (13), the primary constraint arises as given below:

$$\phi(t,\lambda,[q,P]) = P(t,\lambda) - \int d\sigma\, \chi(\lambda,-\sigma) \varepsilon(t;\sigma,\lambda) \approx 0. \tag{14}$$

Here $\varepsilon(t;\sigma,\lambda)$ and $\chi(\lambda,-\sigma)$ have the following definition:

$$\varepsilon(t;\sigma,\lambda) = \frac{\partial \mathcal{L}(t,\sigma)}{\partial Q(t,\lambda)}, \quad \chi(\lambda,-\sigma) = \frac{\varepsilon(\lambda) - \varepsilon(\sigma)}{2}, \tag{15}$$

where $\varepsilon(\lambda)$ is the sigma distribution. The Euler-Lagrange equation is guaranteed by itself,

$$\dot{\phi} \sim \psi = \int d\sigma\, \xi(t;\sigma,\lambda). \tag{16}$$

B. Fractional Ostrogradski's construction

Higher-derivatives theories[38,39] appear naturally as corrections to general relativity and cosmic strings.[40] Unconstrained higher order derivatives possess specific features, namely they have more degrees of freedom than lower-derivative theories and they lack a lower-energy bound. A method how to remove all these problems was presented in Ref. 41. It was observed that the nonlocal formulation translates into infinite order Ostrogradski's formulation.[34,35]

In this section, we would like to derive both the Lagrangian and the Hamiltonian formalisms for nonsingular Lagrangians with fractional order derivatives starting from the Hamiltonian formalism of nonlocal theories.[32] Let us consider the following Lagrangian to start with:

$$L(q,t) = L(t, q^{\alpha_m}), \tag{17}$$

where the generalized coordinates are defined as

$$q^{\alpha_m} = {}_a\mathbf{D}_t^{\alpha_m} x(t), \tag{18}$$

where m is a natural number.

To obtain the reduced phase space quantization, we start with the infinite dimensional phase space $T^*J(t)=\{Q(t,\lambda), P(t,\lambda)\}$.

The key issue is to find an appropriate generalization of (10) for the fractional case. As it was pointed out in Refs. 32 and 34, the coordinates and the momenta are considered as a Taylor series. Therefore, the first step is to generalize the classical series to the fractional case. A natural extension is to use instead of the factorial the Gamma function. In this way we introduce naturally the generalized functions[42] instead of $e_m(\lambda)$ and $e^m(\lambda)$ given by (10).

As it is already known, several fractional Taylor's series expansions were developed,[3,43] therefore we have to decide which one is appropriate for our generalization. Since we are dealing with fractional Riemann-Liouville derivatives we choose the generalization proposed in Ref. 44, namely,

$$Q(t,\lambda) = \sum_{m=-\infty}^{\infty} e_{\alpha_m}(\lambda) q^{(\alpha_m)}(t),$$

$$P(t,\lambda) = \sum_{m=-\infty}^{\infty} e^{\alpha_m}(\lambda) p_{(\alpha_m)}(t), \tag{19}$$

where

$$e_{\alpha_m}(\lambda) = \frac{(\lambda-\lambda_0)^{\alpha_m}}{\Gamma(\alpha_m+1)}, \quad e^{\alpha_m}(\lambda) = \mathbf{D}_\lambda^{\alpha_m}\delta(\lambda-\lambda_0), \tag{20}$$

and $\alpha_m = m+\alpha$, with $0 \le \alpha < 1$. Here λ_0 is a constant. The coefficients in (19) are new canonical variables,

$$\{q^{(\alpha_m)}, p_{(\alpha_{m'})}\} = \delta_{\alpha_m}^{\alpha_{m'}}. \tag{21}$$

By using (21), we obtain that

$$\sum_{m=-\infty}^{\infty} e^{\alpha_m}(\lambda) e_{\alpha_m}(\lambda') = \delta(\lambda-\lambda'), \tag{22}$$

and

$$\int_{-\infty}^{+\infty} d\lambda\, e^{\alpha_m}(\lambda) e_{\alpha_{m'}}(\lambda) = \delta_{\alpha'_m}^{\alpha_m}. \tag{23}$$

Therefore, $e^{\alpha_m}(\lambda)$ and $e_{\alpha_m}(\lambda)$ form an orthonormal basis.

We stress the fact that (22) and (23) involve the generalized functions and the relations have the meaning in the sense of generalized functions approach.[42,44]

The fractional Hamiltonian is now given by

$$H = \sum_{m=-\infty}^{\infty} p^{\alpha_m} q^{\alpha_{m+1}} - L(q^0, q^{\alpha_m}). \tag{24}$$

The momenta constraints become an infinite set of constraints,

$$\phi_n = p_{\alpha_n}(t) - \sum_{m=n}^{\infty} {}_t\mathbf{D}_b^{\alpha_{m-n}} \frac{\partial L}{\partial q^{(\alpha_{m+1})}(t)} = 0. \tag{25}$$

The fractional Euler-Lagrange equations are as follows;

$$\sum_{l=-\infty}^{\infty} {}_t\mathbf{D}_b^{\alpha_l} \frac{\partial L(t)}{\partial q^{\alpha_l}(t)} = 0. \tag{26}$$

An interesting property of the fractional series proposed by Riemann and discussed by Hardy in Ref. 44 is that when α_m become integers, the usual form of Taylor series is obtained. Therefore one should notice that for integer values of α_m, we have

$$p_{\alpha_m}(t) - \sum_{l=0}^{n-m-1} \left(-\frac{d}{dt}\right)^l \frac{\partial L(t)}{\partial(\partial_t^{l+m+1} q(t))} = 0, \tag{27}$$

which is the definition of Ostrogradski's momenta.[38]

In this case the Euler-Lagrange equation for the original fractional derivative Lagrangian[26–30] is given below,

$$\sum_{l=0}^{n} {}_t\mathbf{D}_b^{\alpha_l} \frac{\partial L(t)}{\partial q^{\alpha_l}(t)} = 0. \tag{28}$$

Now, from this equation, for integer values of α_m we obtain the Euler-Lagrange equation for a higher derivative Lagrangian,[32,34,38] namely

$$\sum_{l=0}^{n} \left(-\frac{d}{dt}\right)^l \frac{\partial L(t)}{\partial(\partial_t^l q(t))} = 0. \tag{29}$$

The constraints (27) and (29) lead us to eliminate canonical pairs $\{q^{\alpha_l}, p_{\alpha_l}\}(l \geq n)$.

In this case the infinite dimensional phase space is reduced to a finite dimensional one. The reduced space is coordinated by $T^*J^n = \{q^{\alpha_l}, p_{\alpha_l}\}$ with $l = 0, 1, \ldots, n-1$. The Hamiltonian in the reduced space is given by

$$H = \sum_{m=0}^{n-1} p^{\alpha_m} q^{\alpha_{m+1}} - L(q^0, q^{\alpha_m}). \tag{30}$$

One should notice that the canonical reduced phase space Hamiltonian (30) is obtained in terms of the reduce canonical phase space coordinates $\{q^{\alpha_l}, p_{\alpha_l}\}$ with $l = 0, 1, \ldots, n-1$. In this case the path integral quantization of a field system is given by

$$K = \int \prod_{m=0}^{n-1} dq^{\alpha_m}\, dp^{\alpha_m}\, e^{i\{\int dt(\Sigma_{m=0}^{n-1} p^{\alpha_m} q^{\alpha_{m+1}} - H)\}}. \tag{31}$$

We observe that when α are integers, we obtain the path integral for systems with higher order Lagrangians.[32,45,46]

III. FRACTIONAL PATH INTEGRAL QUANTIZATION OF A SIMPLE HARMONIC OSCILLATOR POSSESSING AN ACCELERATION-SQUARES PART

The classical Lagrangian to start with is given by[41]

$$L_c = \frac{1}{2}(1+\epsilon^2\omega^2)\dot{x}^2 - \frac{1}{2}\omega^2 x^2 - \frac{1}{2}\epsilon^2\ddot{x}^2. \tag{32}$$

The fractional generalization of (32) has the following form:

$$L = \frac{1}{2}(1+\epsilon^2\omega^2)({}_t\mathbf{D}_a^{\alpha}x(t))^2 - \frac{1}{2}\omega^2 x^2 - \frac{1}{2}\epsilon^2[{}_t\mathbf{D}_a^{\alpha}({}_t\mathbf{D}_a^{\alpha}x(t))]^2. \tag{33}$$

The independent coordinates are $x(t)$ and ${}_t\mathbf{D}_a^{\alpha}x(t)$, respectively. Let us denote their corresponding momenta as $p_1^{\alpha}=p_x$ and $p_2^{\alpha}=p_{({}_t\mathbf{D}_a^{\alpha}x(t))}$. The fractional canonical momenta are[38]

$$p_1^{\alpha} = \frac{\partial L}{\partial {}_t\mathbf{D}_a^{\alpha}x(t)} - {}_t\mathbf{D}_a^{\alpha}\left(\frac{\partial L}{\partial {}_t\mathbf{D}_a^{2\alpha}x(t)}\right), \quad p_2^{\alpha} = \frac{\partial L}{\partial {}_t\mathbf{D}_a^{2\alpha}x(t)}. \tag{34}$$

By making use of (33), we obtain the forms of the fractional canonical momenta, as given below:

$$p_1^{\alpha} = (1+\epsilon^2\omega^2){}_t\mathbf{D}_a^{\alpha}x(t) + \epsilon^2{}_t\mathbf{D}_a^{3\alpha}x(t), \tag{35}$$

$$p_2^{\alpha} = -\epsilon^2{}_t\mathbf{D}_a^{2\alpha}x(t). \tag{36}$$

The fractional canonical Hamiltonian becomes

$$H = p_1^{\alpha}{}_t\mathbf{D}_a^{\alpha}x(t) + p_2^{\alpha}{}_t\mathbf{D}_a^{2\alpha}x(t) - L. \tag{37}$$

Taking into account (33), (35), and (36) the form of (37) is given by

$$H = \frac{1}{2}\left[2p_1^{\alpha}{}_t\mathbf{D}_a^{\alpha}x(t) - \frac{(p_2^{\alpha})^2}{\epsilon^2} + \omega^2x^2(t) - (1+\epsilon^2\omega^2)({}_t\mathbf{D}_a^{\alpha}x(t))^2\right]. \tag{38}$$

By making use of (38), the fractional path integral is written as

$$K = \int dx\, d({}_t\mathbf{D}_a^{\alpha}x(t))dp_1^{\alpha}\, dp_2^{\alpha}\, e^{i\{\int dt(p_1^{\alpha}x(t)+p_2^{\alpha}{}_t\mathbf{D}_a^{\alpha}x(t)-H)\}}. \tag{39}$$

IV. FRACTIONAL PATH INTEGRAL QUANTIZATION OF DAMPED HARMONIC OSCILLATOR

The Lagrangian for this system in Ostrogradski's notations[38] takes the form[9]

$$L = \frac{1}{2}mq_1^2 + i\frac{\gamma}{2}q_{1/2}^2 - V(q_0), \tag{40}$$

where

$$q^{\alpha_n} = {}_t\mathbf{D}_b^{\alpha_n}x, \quad n=0,1,2. \tag{41}$$

Here $\alpha_0=0, \alpha_1=1/2$, $\alpha_2=1$, and $q_0=x$, $q_1=\dot{x}$, $q_{1/2}={}_t\mathbf{D}_b^{1/2}x$, $q_2=\ddot{x}$.

The expressions for canonical momenta are

$$p_0 = i\gamma x_{(1/2)} + imx_{(3/2)}, \tag{42}$$

$$p_{1/2} = m\dot{x}. \tag{43}$$

By using (40) the classical Euler-Lagrange equation of motion read as[9]

$$m\ddot{x} + \gamma\dot{x} + \frac{\partial V}{\partial x} = 0. \tag{44}$$

The canonical reduced Hamiltonian has the following expression:

$$H = \frac{p_{1/2}^2}{2m} + q_{1/2}p_0 - i\frac{\gamma}{2}q_{1/2}^2 + V(q_0). \tag{45}$$

As a result the corresponding fractional path integral representation is given by

$$K = \int d\mu \exp i\left[\int \left(q_1 p_{1/2} - \frac{p_{1/2}^2}{2m} + i\frac{\gamma}{2}q_{1/2}^2 - V(q_0)\right)dt\right], \tag{46}$$

where $d\mu = dq_0\, dp_0\, dq_{1/2}\, dp_{1/2}$.

The path integral representation for (46) is an integration over the canonical phase space coordinates (q_0, p_0) and $(q_{1/2}, p_{1/2})$. Integrating over $p_{1/2}$ and p_0, we obtain

$$K = \int dq_0\, dq_{1/2} \exp i \int \left(\frac{1}{2}mq_1^2 - V(q_0) + i\frac{\gamma}{2}q_{1/2}^2\right)dt. \tag{47}$$

Equation (47) can be put in a compact form as follows:

$$K = \int dq_0\, e^{i\int((1/2)mq_1^2 - V(q_0))dt}\, dq_{1/2}\, e^{i\int(i(\gamma/2)q_{1/2}^2)dt}. \tag{48}$$

After performing an integration over $q_{1/2}$, (48) becomes

$$K = C\int dq_0\, e^{i\int((1/2)mq_1^2 - V(q_0))dt}\, dt,$$

where C represents a constant.

V. CONCLUSIONS

The interest in fractional quantization appears because it describes both conservative systems and nonconservative systems as well. The fractional quantization of field theory is not an easy task, especially when the fractional Hamiltonian is involved. The fractional derivatives represent the generalization of the classical ones, and therefore some of the classical properties are lost, e.g., the fractional Leibniz rule or the chain rule that becomes more complicated than the classical counterparts. The fractional path integral formulation deserves further investigations, mainly because the fractional generalization of the classical case is not yet complectly understood. Namely, for a system possessing second class constraints in Dirac's classification it is difficult to find the corresponding fractional generalization. In addition, there are no fractional formulations of the classical secondary or tertiary constraints due to the fact that the fractional Hamiltonian is not a constant of motion.

In this paper we generalize to the fractional case the nonlocal theories in one space and one time dimension via the infinite Ostrogradski's formalism. The classical Taylor series involved in this problem are convergent because of the properties of the Dirac's delta function. Namely, the coordinates and the corresponding momenta are defined as Taylor series and the Ostrogradski's canonical pairs fulfill the classical Poisson's brackets commutation relations. The generalization to the fractional case of all the above mentioned results is not straightforward because there exist many formulations for the fractional Taylor series. However, a powerful tool in fractional field theory is to work to the Riemann-Liouville derivatives because of their important property of integration by parts. Therefore, in this paper we focus on the fractional Taylor series involving the Riemann-Liouville derivatives. We assumed that the fractional Lagrangian density has a compact

support in the x directions. In this work we have obtained the path integral quantization for fractional generalization of a $1+1$ dimensional nonlocal field theory. The path integral formulation for the simple harmonic oscillator with an acceleration-squares part as well as for the damped oscillator are obtained. It is worthwhile to mention that the general expression for the path integral leads to the path integral representation for systems with higher order Lagrangians.

(Received 17 May 2006; accepted 29 August 2006; published online 16 October 2006)

An uncertainty Fisher information relation in quantum mechanics is derived for multidimensional single-particle systems with central potentials. It is based on the concept of Fisher information in the two complementary position and momentum spaces, which is a gradient functional of the corresponding probability distributions. The lower bound of the product of position and momentum Fisher informations is shown to depend on the orbital and magnetic quantum numbers of the physical state and the space dimensionality. Applications to various elementary systems is discussed. © *2006 American Institute of Physics.*

I. INTRODUCTION

Quantum-mechanical uncertainty relations state that probability distributions of canonically conjugate variables of a physical system cannot be simultaneously sharply localized. The standard uncertainty relation is the variance-based Heisenberg principle[1,2] given by the expression

$$V_\rho V_\gamma \geqslant \frac{1}{4}, \tag{1}$$

where $V_\rho(V_\gamma)$ denotes the variance of the probability density in the position $\rho(\boldsymbol{r})$ [momentum $\gamma(\boldsymbol{p})$] space, assumed to be normalized to unity. This inequality is so relevant in quantum mechanics, not because of its accuracy (generally, very small), but because it indicates that refined single-particle position measurements require large indeterminations for the single-particle momenta. This principle and its moment-based generalizations[3] reflect the essential inadequacy of the classical concepts of one-particle position and momentum to describe real systems.

The use of information-theoretic quantities as uncertainty measures has led to derive uncertainty relations that provide a strict improvement upon the standard uncertainty relation. This is the case of the celebrated entropic uncertainty relation,[4–6]

$$S_\rho + S_\gamma \geqslant D(1 + \ln \pi),$$

where $S_\rho = -\langle \ln \rho \rangle = -\int_{\mathbb{R}^D} \rho(\boldsymbol{r}) \ln \rho(\boldsymbol{r}) d^D r$ describes the Shannon information entropy of the position probability density in the D-dimensional space $\mathbb{R}^D$,[7,8] and S_γ denotes the corresponding momentum Shannon entropy of the system. This relation was conjectured by Hirschman[4] in 1957 and proved by Beckner[5] and Bialynicki-Birula and Mycielski.[6] For probabilistic and dimensional reasons, it is more convenient to reformulate it as

[a]Electronic mail: eromera@ugr.es
[b]Electronic mail: pablos@ugr.es
[c]Electronic mail: dehesa@ugr.es

$$N_\rho N_\gamma \geqslant \frac{1}{4}, \tag{2}$$

where $N_\rho(N_\gamma)$ denotes the Shannon entropy power[9] of the position (momentum) density, defined by $N_\rho=(2\pi e)^{-1}\exp(2S_\rho/D)$.

A most important information-theoretic alternative to the Shannon entropy as uncertainty measure is the Fisher information,[10,11] given by

$$I_\rho = \int_{\mathbb{R}^D} \frac{|\nabla_D \rho(\mathbf{r})|^2}{\rho(\mathbf{r})} d^D r = 4\int_{\mathbb{R}^D} |\nabla_D \sqrt{\rho(\mathbf{r})}|^2 d^D r. \tag{3}$$

Contrary to the Shannon entropy, which is a global measure of the spreading of the density because it is a logarithmic functional, the Fisher information has a property of locality as it is a gradient functional of the density. The higher is this quantity, the more localized is the density, the smaller is the uncertainty, and the higher is the accuracy in predicting the localization of the particle.[12,13]

On the other hand, the Fisher information is the basic variable of the principle of extreme physical information[12] in the same manner as the Shannon entropy is the cornerstone of the maximum entropy method.[14–16] The former principle has allowed us to derive various fundamental equations of quantum physics.[12,17] Moreover, it has been used (a) to describe some macroscopic quantities such as the kinetic[18] and the Weiszäcker[19,20] energies, (b) to characterize correlation properties in atomic systems[21] and (c) to identify the most distinctive nonlinear phenomena (the avoided crossings) of the energy spectra of atomic and molecular systems in strong external fields.[22] For other quantum-mechanical uses of the Fisher information, see Refs. 12, 23, and 24.

Moreover, the Fisher information is involved in the so-called Stam uncertainty relations,[13,24–26]

$$\langle r^2\rangle I_\gamma^{-1} \geqslant \frac{1}{4}; \quad \langle p^2\rangle I_\rho^{-1} \geqslant \frac{1}{4}.$$

However, we do not know yet an uncertainty relation based on the position and momentum Fisher information, of the same type as the variance-based Heisenberg principle (1) and the entropic uncertainty relation (2). To find such a relation for multidimensional central potentials is the main purpose of this paper; that is, to derive a lower bound for the product of the Fisher informations in position and momentum spaces of arbitrary dimensions. This is done in Sec. II. We have used a two-step methodology. First, we express the position (momentum) Fisher information in terms of the radial expectation values $\langle p^2\rangle$ and $\langle r^{-2}\rangle$ ($\langle r^2\rangle$ and $\langle p^{-2}\rangle$); this is proved in Sec. II A. Second, we obtain some radial uncertainty-like inequalities that involve these expectation values, which is proved in Sec. II B. Then, the Fisher informations of some elementary D-dimensional systems (hydrogen atom, isotropic harmonic oscillator) are calculated in a closed form in Sec. III, and some concluding remarks and open problems are given.

II. THE FISHER UNCERTAINTY RELATION FOR CENTRAL POTENTIALS

Here we prove that the Fisher information of single-particle systems with a central potential $V_D(r)$ in D-dimensional ($D\geqslant 3$) position and momentum spaces satisfy the uncertainty relation

$$I_\rho I_\gamma \geqslant 4D^2\left(1-\frac{(2l+D-2)|m|}{2l(l+D-2)}\right)^2 \quad (l>0), \tag{4}$$

where the hyperangular quantum numbers l and m have the values given below. When $l=0$ the inequality reduces to $I_\rho I_\gamma \geqslant 4D^2$, and when $D=2$ it gives the trivial inequality $I_\rho I_\gamma \geqslant 0$.

The position probability density $\rho(\mathbf{r})=|\Psi(\mathbf{r})|^2$, where the wave function $\Psi(\mathbf{r})$ is the physical solution of the Schrödinger equation,

$$\left(-\frac{1}{2}\nabla_D^2 + V_D(r)\right)\Psi(\boldsymbol{r}) = E\Psi(\boldsymbol{r}), \tag{5}$$

where atomic units are used.

Due to the spherical symmetry of the problem, it is most convenient to work it out by use of the polar hyperspherical coordinates $(r,\theta_1,\theta_2,\ldots,\theta_{D-1}\equiv\phi)=(r,\Omega_{D-1})$ $(0\leqslant\theta_k\leqslant\pi,\ k=1,\ldots,D-2$, and $0\leqslant\theta_{D-1}\leqslant 2\pi)$, instead of Cartesian coordinates $(x_1,\ldots,x_D)$, defined by

$$x_1 = r\cos\theta_1,$$

$$x_2 = r\sin\theta_1\cos\theta_2,$$

$$\vdots$$

$$x_k = r\sin\theta_1\ldots\sin\theta_{k-1}\cos\theta_k,$$

$$\vdots$$

$$x_{D-1} = r\sin\theta_1\ldots\sin\theta_{D-2}\cos\theta_{D-1},$$

$$x_D = r\sin\theta_1\ldots\sin\theta_{D-2}\sin\theta_{D-1},$$

$$\sum_{i=1}^{D} x_i^2 = r^2,$$

in which case the D-dimensional gradient is

$$\begin{aligned}\nabla_D &= \left(\frac{\partial}{\partial r},\frac{1}{r}\frac{\partial}{\partial\theta_1},\frac{1}{r\sin\theta_1}\frac{\partial}{\partial\theta_2},\ldots,\frac{1}{r\prod_{j=1}^{k-1}\sin\theta_j}\frac{\partial}{\partial\theta_k},\ldots,\frac{1}{r\prod_{j=1}^{D-2}\sin\theta_j}\frac{\partial}{\partial\theta_{D-1}}\right)\\ &= \hat{r}\frac{\partial}{\partial r} + \sum_{k=1}^{D-1}\hat{\theta}_k\frac{1}{r\prod_{j=1}^{k-1}\sin\theta_j}\frac{\partial}{\partial\theta_k},\end{aligned} \tag{6}$$

so that the Laplacian operator ∇_D^2 has the expression

$$\nabla_D^2 = \frac{1}{r^{D-1}}\frac{\partial}{\partial r}r^{D-1}\frac{\partial}{\partial r} - \frac{\Lambda^2}{r^2}. \tag{7}$$

The operator Λ is the D-dimensional generalization of the square of the angular momentum operator,[27–29] which only depends on the $D-1$ angular coordinates Ω_{D-1} of the D-dimensional sphere in the form

$$\Lambda^2 = -\sum_{i=1}^{D-1}\frac{(\sin\theta_i)^{i+1-D}}{(\prod_{j=1}^{i-1}\sin\theta_j)^2}\frac{\partial}{\partial\theta_i}\left((\sin\theta_i)^{D-i-1}\frac{\partial}{\partial\theta_i}\right). \tag{8}$$

This operator is known to fulfill

$$\Lambda^2\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1}) = l(l+D-2)\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1}), \tag{9}$$

where the $\mathcal{Y}$ symbol denotes the hyperspherical harmonics described by the $D-1$ hyperangular quantum numbers $(l\equiv\mu_1,\mu_2,\ldots,\mu_{D-1}\equiv m)\equiv(l,\{\mu\})$, which are natural numbers with values l

$=0,1,2,\ldots$, and $l\equiv\mu_1\geqslant\mu_2\geqslant\cdots\geqslant\mu_{D-2}\geqslant|\mu_{D-1}|\equiv|m|$. These hyperfunctions are known to have the form[27–31]

$$\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1})=\mathcal{N}_{l,\{\mu\}}e^{im\theta_{D-1}}\prod_{j=1}^{D-2}C_{\mu_j-\mu_{j+1}}^{\alpha_j+\mu_{j+1}}(\cos\theta_j)(\sin\theta_j)^{\mu_{j+1}}=\frac{e^{im\theta_{D-1}}}{\sqrt{2\pi}}\prod_{j=1}^{D-2}Y_{\mu_j,\mu_{j+1}}^{(j)}(\theta_j), \tag{10}$$

where the normalization constant is given by

$$|\mathcal{N}_{l,\{\mu\}}|^2=\frac{1}{2\pi}\prod_{j=1}^{D-2}\frac{(\alpha_j+\mu_j)(\mu_j-\mu_{j+1})!\,\Gamma^2(\alpha_j+\mu_{j+1})}{\pi 2^{1-2\alpha_j-2\mu_{j+1}}\Gamma(2\alpha_j+\mu_j+\mu_{j+1})}=\frac{1}{2\pi}\prod_{j=1}^{D-2}N_{\mu_j,\mu_{j+1}}^{(j)}, \tag{11}$$

$\alpha_j=(D-j-1)/2$, and $C_k^{\lambda}(t)$ denotes the Gegenbauer polynomial of degree k and parameter λ. In addition we have used the notation

$$Y_{\mu_j,\mu_{j+1}}^{(j)}(\theta_j)=N_{\mu_j,\mu_{j+1}}^{(j)}C_{\mu_j-\mu_{j+1}}^{\alpha_j+\mu_{j+1}}(\cos\theta_j)(\sin\theta_j)^{\mu_{j+1}}. \tag{12}$$

[Remark that for $D=2$ there are no products in Eqs. (10) and (11) so that the corresponding spherical harmonics for this case is just $e^{im\phi}/\sqrt{2\pi}$.]

The hyperspherical harmonics $\mathcal{Y}(\Omega_{D-1})$ satisfy the orthonormalization conditions

$$\int_{S_{D-1}}d\Omega_{D-1}\,\mathcal{Y}_{l',\{\mu'\}}(\Omega_{D-1})\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1})=\delta_{ll'}\delta_{\{\mu\},\{\mu'\}}, \tag{13}$$

and the harmonics $Y_{\mu_j,\mu_{j+1}}^{(j)}(\theta_i)$ have the two following integral properties:[23,28]

$$\int_0^{\pi}[Y_{\mu_j,\mu_{j+1}}^{j}(\theta_j)]^2(\sin\theta_j)^{D-j-1}\,d\theta_j=1 \tag{14}$$

and

$$\int_0^{\pi}[Y_{\mu_j,\mu_{j+1}}^{j}(\theta_j)]^2(\sin\theta_j)^{D-j-3}\,d\theta_j=\frac{2\mu_j+D-j-1}{2\mu_{j+1}+D-j-2}. \tag{15}$$

Notice that, when $j=D-2$, $\int_0^{\pi}[Y_{\mu_{D-2},\mu_{D-1}}^{j}(\theta_{D-2})]^2(\sin\theta_{D-2})^{-1}\,d\theta_{D-2}=(2\mu_{D-2}+1)/2|\mu_{D-1}|$.

Then, the wave functions $\Psi(\boldsymbol{r})$ of the problem (5)–(7) can be separated out as

$$\Psi_{E,l,\{\mu\}}(\boldsymbol{r})=R_{E,l}(r)\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1}).$$

To prove the inequality (4), we first find that the position and momentum Fisher information are related to the radial expectation values $\langle r^k\rangle$ and $\langle p^k\rangle$, $k=-2$ and 2, by means of the expressions

$$I_\rho=4\langle p^2\rangle-2|m|(2l+D-2)\langle r^{-2}\rangle, \tag{16}$$

$$I_\gamma=4\langle r^2\rangle-2|m|(2l+D-2)\langle p^{-2}\rangle, \tag{17}$$

respectively. This is done in Sec. II A. Then, we use the radial uncertainty-like relations,

$$\langle p^2\rangle\geqslant l(l+D-2)\langle r^{-2}\rangle, \tag{18}$$

$$\langle r^2\rangle\geqslant l(l+D-2)\langle p^{-2}\rangle, \tag{19}$$

which are proved in Sec. II B.

Combining the expressions (16)–(19), one has that

$$I_\rho I_\gamma \geqslant 16\left(1-\frac{(2l+D-2)|m|}{2l(l+D-2)}\right)^2\langle r^2\rangle\langle p^2\rangle, \tag{20}$$

which emphasizes the uncertainty character of the inequality. Now, it remains to use the modified Heisenberg uncertainty inequality,

$$\langle r^2\rangle\langle p^2\rangle \geqslant \frac{D^2}{4}, \tag{21}$$

to finally obtain the new uncertainty relation (4). In the case that $l=0$, expressions (16)–(19) lead to $I_\rho I_\gamma \geqslant 4D^2$.

The use of the grand orbital quantum number $L=l+(D-3)/2$ leads to write $2l+D-2=2L+1$ and $l(l+D-2)=\frac{1}{4}(2L-D+3)(2L+D-1)=L(L+1)-\frac{1}{4}(D-1)(D-3)$, so that the new uncertainty relation can be expressed as

$$I_\rho I_\gamma \geqslant 4D^2\left(1-\frac{(2L+1)|m|}{2L(L+1)-\frac{1}{2}(D-1)(D-3)}\right)^2,$$

which reduces to

$$I_\rho I_\gamma \geqslant 36\left(1-\frac{(2l+1)|m|}{2l(l+1)}\right)^2,$$

for tridimensional systems, as recently found by the authors[32] in a semiheuristic way. Moreover, let us highlight that for states with $m=0$ the new uncertainty relation gets simplified as

$$I_\rho I_\gamma \geqslant 4D^2, \tag{22}$$

which saturates for the isotropic harmonic oscillator case (see Sec. III B). Finally, it is also known[33] that for arbitrary monodimensional systems with even wave functions the uncertainty inequality $I_\rho I_\gamma \geqslant 4$ is fulfilled.

Let us finally point out that when D goes to infinity and $m=0$, expression (4) reaches the equality for the particular cases of the D-dimensional hydrogen atom and isotropic harmonic potential [see Eqs. (37), (38), (42), and (43) in Sec. III].

A. Position and momentum Fisher's informations for central potentials

Here we derive the expressions (16) and (17), which gives the position (momentum) Fisher information of a single-particle system with a D-dimensional central potential in terms of the radial expectation values $\langle p^2\rangle$ and $\langle r^{-2}\rangle$ ($\langle r^2\rangle$ and $\langle p^{-2}\rangle$). To begin with, we realize that the position density $\rho(\boldsymbol{r})$ is equal to

$$\rho(\boldsymbol{r}) = |\Psi_{El\{\mu\}}(\boldsymbol{r})|^2 = |\Psi_{El\{\mu\}}(r,\theta_1,\theta_2,\ldots,\theta_{D-2},0)|^2.$$

Then, the position Fisher information $I_\rho(D)\equiv I_\rho$ defined by Eq. (3) gets reduced as

$$I_\rho(D) = 4\int_{\mathbb{R}^D} |\boldsymbol{\nabla}_D \Psi_{El\{\mu\}}(r,\theta_1,\theta_2,\ldots,\theta_{D-2},0)|^2\, d^D r, \tag{23}$$

where the D-dimensional volume element $d^D r$ is

$$d^D r = r^{D-1}\, dr\, d\Omega_{D-1};$$
$$d\Omega_{D-1} = \left(\prod_{j=1}^{D-2} (\sin\theta_j)^{2\alpha_j}\, d\theta_j \right) d\theta_{D-1}. \tag{24}$$

On the other hand, we know that the momentum expectation value $\langle p^2 \rangle$ given by

$$\langle p^2 \rangle = \int_{\mathbb{R}^D} |\nabla_D \Psi_{El\{\mu\}}(r, \theta_1, \theta_2, \ldots, \theta_{D-1})|^2\, d^D r, \tag{25}$$

can be decomposed, according to polar coordinate form (6) of the gradient, as

$$\langle p^2 \rangle = \int_{\mathbb{R}^D} |\nabla_D \Psi_{El\{\mu\}}(r, \theta_1, \theta_2, \ldots, \theta_{D-2}, 0)|^2\, d^D r + K_{lm}(D). \tag{26}$$

The K symbol denotes the integral

$$\begin{aligned} K_{lm}(D) &= \int_{\mathbb{R}^D} \left| \frac{1}{r} \prod_{i=1}^{D-2} (\sin\theta_i)^{-1} \frac{\partial}{\partial \theta_{D-1}} \Psi_{El\{\mu\}}(\mathbf{r}) \right|^2 d^D r \\ &= \langle r^{-2} \rangle \prod_{i=1}^{D-2} \int_0^{\pi} |Y^{(i)}_{\mu_i,\mu_{i+1}}(\theta_i)|^2 (\sin\theta_i)^{D-i-3}\, d\theta_i \frac{1}{2\pi} \int_0^{2\pi} \left| \frac{\partial}{\partial \theta_{D-1}} (e^{im\theta_{D-1}}) \right|^2 d\theta_{D-1} \\ &= \langle r^{-2} \rangle m^2 \prod_{i=1}^{D-2} \frac{2\mu_i + D - i - 1}{2\mu_{i+1} + D - i - 2} \\ &= \frac{1}{2} \langle r^{-2} \rangle |m| (2l + D - 2), \end{aligned} \tag{27}$$

where we have taken into account the integral properties (14) and (15) for the harmonics $Y(\theta_i)$, $i = 1, 2, \ldots, D-2$, in the second equality, and the expression

$$\prod_{i=1}^{D-2} \frac{2\mu_i + D - i - 1}{2\mu_{i+1} + D - i - 2} = \frac{2l + D - 2}{2|m|}$$

in the third equality. Moreover, the radial expectation value,

$$\langle r^{-2} \rangle = \int_{\mathbb{R}^D} r^{-2} \rho(\mathbf{r}) d^D r = \int_0^{\infty} r^{-2} R^2_{El}(r) r^{D-1}\, dr,$$

has been used. The combination of Eqs. (23), (26), and (27) leads to the following relation between the position Fisher information $I_\rho(D)$ and the radial expectation values $\langle p^2 \rangle$ and $\langle r^{-2} \rangle$:

$$\langle p^2 \rangle = \frac{1}{4} I_\rho(D) + \frac{1}{2} |m| (2l + D - 2) \langle r^{-2} \rangle,$$

which gives the searched expression (16) for the position Fisher information.

The application of the same procedure in momentum space has allowed us to obtain that

$$\langle r^2\rangle = \frac{1}{4}I_\gamma(D) + \frac{1}{2}|m|(2l+D-2)\langle p^{-2}\rangle,$$

which provides the searched expression (17) for the momentum Fisher information in terms of the radial expectation values $\langle r^2\rangle$ and $\langle p^{-2}\rangle$. These expressions have been previously found for the tridimensional case.[32]

Let us mention that when $D=2$, having only one angular quantum number l, these expressions reduce to $\langle p^2\rangle = I_\rho/4 - l^2\langle r^{-2}\rangle$ and $\langle r^2\rangle = I_\gamma/4 - l^2\langle p^{-2}\rangle$.

B. Radial uncertainty-like relations

Let us here derive the dual uncertainty-like relations (18) and (19) between the radial expectation values $\langle p^2\rangle$ and $\langle r^{-2}\rangle$, and $\langle r^2\rangle$ and $\langle p^{-2}\rangle$, respectively. To find Eq. (18), we start from the expressions (6) and (25), which provide

$$\langle p^2\rangle = J_R(D) + \langle r^{-2}\rangle J_A(D), \tag{28}$$

where the radial integral

$$J_R(D) = \int_{\mathbb{R}^D} \left|\frac{\partial}{\partial r}\Psi(\boldsymbol{r})\right|^2 d^D r = \int_0^\infty \left(\frac{dR_{El}}{dr}\right)^2 r^{D-1}\, dr,$$

and the angular integral

$$\begin{aligned} J_A(D) &= \int_{S_{D-1}} \sum_{i=1}^{D-1} \left| \frac{1}{\prod_{j=1}^{i-1}\sin\theta_j}\frac{\partial}{\partial\theta_i}\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1})\right|^2 d\Omega_{D-1} \\ &= \sum_{i=1}^{D-1}\int_{S_{D-1}} \frac{1}{\left(\prod_{j=1}^{i-1}\sin\theta_j\right)^2}\frac{\partial}{\partial\theta_i}\mathcal{Y}^*_{l,\{\mu\}}(\Omega_{D-1})\frac{\partial}{\partial\theta_i}\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1})\prod_{j=1}^{D-2}[(\sin\theta_j)^{D-j-1}\, d\theta_j]d\theta_{D-1}, \end{aligned} \tag{29}$$

where we have used the expression (24) of the volume element $d\Omega_{D-1}$. Remark that, for convention, the products $\Pi_{j=1}^{i-1}$ and $\Pi_{j=1}^{D-2}$ are empty when $i=1$ and $D=2$, respectively. Then, taken into account the non-negativity of the radial integral $J_R(D)$, one has that

$$\langle p^2\rangle \geqslant \langle r^{-2}\rangle J_A(D). \tag{30}$$

In momentum space, a similar procedure has allowed us to obtain that

$$\langle r^2\rangle \geqslant \langle p^{-2}\rangle J_A(D). \tag{31}$$

To calculate $J_A(D)$, we perform an integration by parts in the integral of Eq. (29). Then, one obtains that

$$\begin{aligned} J_A(D) = &-\sum_{i=1}^{D-1}\int_{S_{D-1}} \mathcal{Y}^*_{l,\{\mu\}}(\Omega_{D-1})\frac{1}{(\prod_{j=1}^{i-1}\sin\theta_j)^2}\frac{\partial}{\partial\theta_i}\left((\sin\theta_i)^{D-i-1}\frac{\partial}{\partial\theta_i}\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1})\right) \\ &\times \prod_{j=1,j\neq i}^{D-2}[(\sin\theta_j)^{D-j-1}\, d\theta_j]d\theta_{D-1} \\ = &-\sum_{i=1}^{D-1}\int_{S_{D-1}} \mathcal{Y}^*_{l,\{\mu\}}(\Omega_{D-1})\frac{(\sin\theta_i)^{1+i-D}}{(\prod_{j=1}^{i-1}\sin\theta_j)^2}\frac{\partial}{\partial\theta_i}\left((\sin\theta_i)^{D-i-1}\frac{\partial}{\partial\theta_i}\mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1})\right) \end{aligned}$$

$$\times \prod_{j=1}^{D-2} [(\sin\theta_j)^{D-j-1}\, d\theta_j] d\theta_{D-1}$$

$$= \int_{S_{D-1}} \mathcal{Y}^*_{l,\{\mu\}}(\Omega_{D-1}) \Lambda^2 \mathcal{Y}_{l,\{\mu\}}(\Omega_{D-1}) d\Omega_{D-1} = l(l+D-2), \tag{32}$$

where we have used the expression (8) in the third equality and the expressions (9) and (13) in the last equality.

Finally, the substitution of the value (32) for the angular integral $J_A(D)$ into the inequalities (30) and (31) produces the radial uncertainty-like inequalities (18) and (19),

$$\langle p^2 \rangle \geqslant l(l+D-2)\langle r^{-2}\rangle,$$

$$\langle r^2 \rangle \geqslant l(l+D-2)\langle p^{-2}\rangle,$$

respectively, which we were looking for.

For the case $D=3$ the former inequality has been recently and rigorously found by completely different means, while the latter one was only suggested.[32]

Finally, let us point out that up until now the only existing inequality of this type, to the best of our information, has been shown by one of us[26] to be

$$\langle p^2 \rangle \geqslant \left(\frac{D-2}{2}\right)^2 \langle r^{-2}\rangle, \tag{33}$$

for general systems. The comparison of Eqs. (18) and (33) shows that (i) the former one is stronger than the latter one when $l > (\sqrt{2}-1)(D-2)/2$, indicating its greater accuracy when $D \leqslant 6$ for states with $l>0$; and (ii) the latter one is stronger for $l=0$ regardless of the value of the space dimensionality.

III. THE FISHER INFORMATIONS FOR SOME *D*-DIMENSIONAL ELEMENTARY SYSTEMS

Here we find the position and momentum Fisher informations for the most prominent prototypes of D-dimensional systems: the hydrogen atom and the isotropic harmonic oscillator.

A. Hydrogen atom

In this case, $V(r)=1/r$. The energies of the bound states are given by

$$E = -\frac{1}{2\eta^2}, \tag{34}$$

where η denotes the grand principal quantum number,

$$\eta = n + \frac{D-3}{2}; \quad n = 1,2,3,\ldots .$$

The radial expectation values $\langle r^{-2}\rangle$ and $\langle r^2\rangle$ are known[34] to have the expressions

$$\langle r^{-2}\rangle = \frac{2}{\eta^3}\frac{1}{2L+1}; \quad \langle r^2\rangle = \frac{1}{2}\eta^2[5\eta^2 - 3L(L+1)+1], \tag{35}$$

and the momentum expectation values $\langle p^{-2}\rangle$ and $\langle p^2\rangle$ are given[35] by

$$\langle p^{-2}\rangle = \frac{8\eta - 3(2L+1)}{2L+1}\eta^2; \quad \langle p^2\rangle = \frac{1}{\eta^2}. \tag{36}$$

Then, according to Eqs. (16), (35), and (36), the Fisher information of the D-dimensional hydrogen atom in position space has the value

$$I_\rho = 4\langle p^2\rangle - 2|m|(2L+1)\langle r^{-2}\rangle = \frac{4}{\eta^3}(\eta - |m|), \tag{37}$$

which has been recently found by different means.[23] Moreover, let us notice that for the real ($D=3$) hydrogen atom one has I_ρ (hydrogen)$=4(n-|m|)/n^3$, as recently derived.[32,36]

On the other hand, according to Eqs. (17), (35), and (36), the Fisher information of the D-dimensional hydrogen atom in momentum space has the value

$$I_\gamma = 4\langle r^2\rangle - 2|m|(2L+1)\langle p^{-2}\rangle = 2\eta^2\{5\eta^2 - 3L(L+1) - [8\eta - 3(2L+1)]|m| + 1\}, \tag{38}$$

which has also been recently shown.[23] It is worthy to point out that for the tridimensional hydrogen atom one straightforwardly has the known value[32]

$$I_\gamma(\text{hydrogen}) = 2n^2\{5n^2 - 3l(l+1) - [8n - 3(2l+1)]|m| + 1\},$$

since the grand quantum numbers η, L, and m for $D=3$ reduces to the familiar tridimensional quantum numbers (n,l,m).

Finally, it is worthy to point out that for $l=n-1$ the accuracy of inequalities (18) and (19) for this system improves when n is increasing; moreover, they get saturated when $n\to\infty$.

B. Isotropic harmonic oscillator

Here, $V(r)=\frac{1}{2}\omega^2 r^2$ (mass$=1$). The energies of the physical states are given by

$$E = \left(\eta + \frac{3}{2}\right)\omega, \tag{39}$$

with

$$\eta = n + \frac{D-3}{2} = 2n_r + l + \frac{D-3}{2} \equiv 2n_r + L; \quad n_r = 0,1,2,\ldots, \quad l = 0,1,2,\ldots .$$

For this system the radial expectation values $\langle r^{-2}\rangle$ and $\langle r^2\rangle$ have the form[34,37,38]

$$\langle r^{-2}\rangle = \frac{2\omega}{2L+1}; \quad \langle r^2\rangle = \left(\eta + \frac{3}{2}\right)\omega^{-1}, \tag{40}$$

and the momentum expectation values $\langle p^\alpha\rangle = \omega^\alpha\langle r^\alpha\rangle$, so that

$$\langle p^{-2}\rangle = \frac{2}{2L+1}\omega^{-1}; \quad \langle p^2\rangle = \left(\eta + \frac{3}{2}\right)\omega. \tag{41}$$

Then the Fisher information of the D-dimensional isotropic harmonic oscillator in position space has, according to Eqs. (16), (40), and (41), the value

$$I_\rho = 4\left(\eta - |m| + \frac{3}{2}\right)\omega = 4\left(2n_r + l - |m| + \frac{D}{2}\right)\omega. \tag{42}$$

Similarly, according to Eqs. (17), (40), and (41), we have found the following value for the Fisher information of the D-dimensional isotropic harmonic oscillator in momentum space,

$$I_\gamma = 4\left(\eta - |m| + \frac{3}{2}\right)\omega^{-1} = 4\left(2n_r + l - |m| + \frac{D}{2}\right)\omega^{-1}. \tag{43}$$

Let us point out that these expressions for the position and momentum D-dimensional Fisher informations reduces to the corresponding known three-dimensional quantities for $D=3$.[32]

It is most interesting to realize that for the ground state ($n_r=l=m=0$), one has that $I_\rho = 2D\omega$ and $I_\gamma = 2D\omega^{-1}$, so that the Fisher uncertainty product $I_\rho I_\gamma = 4D^2$. Therefore, the D-dimensional Fisher uncertainty relation (22) for $m=0$ states of arbitrary central potential gets saturated at the harmonic oscillator ground state.

Furthermore, it is nice to remark from Eqs. (34) and (37), and Eqs. (39) and (42), that the position Fisher information for the two multidimensional central potentials of the r^α type considered in this section, has the following behavior:

$$I_\rho = aE_{\eta L} + b|m|\eta^{\alpha-2},$$

where real parameters a and b are controlled by the strength of the potential, being aware that $E_{\eta L}$ goes as $\eta^{\alpha-1}$.

For completeness, let us also point out that the equality in inequalities (18) and (19) is obtained for this system when l goes to infinity.

IV. CONCLUSIONS

The spreading of the quantum-mechanical wave functions of physical systems in a D-dimensional space can be measured by moments of different orders of the corresponding probability density (particularly, the second moment or variance) and, more recently, by some information-theoretic measures, the Shannon entropy and the Fisher information. These spreading measures grasp differently the distribution of the quantum-mechanical probability cloud of the system. The development of uncertainty relations associated to the probability distributions of canonically conjugate spreading measures is at the heart of the quantum physics from its early days. The variance-based Heisenberg-Kennard relation[1,2] and its generalizations[3] based on moments with orders bigger than 2, have played a fundamental role in understanding the quantum behavior of the physical systems in a deeper way. The advent of the entropic uncertainty relation based on the Shannon information entropy[4–6] has strictly improved the standard relation, mainly because of the true information-theoretic character of the involved spreading measure.

The uncertainty relation based on the Fisher information is not yet known. This is a serious lack because this quantity has a local character, contrary to both the moments and the Shannon entropy that are global spreading measures. Here we have derived this Fisher uncertainty relation, not for general systems but "only" for D-dimensional single-particle systems with central potentials. The lower bound of the Fisher informations in the two complementary spaces has been found to depend on the orbital and magnetic quantum numbers and the space dimensionality. To do that, we have first calculated the explicit expressions for the position and momentum Fisher informations [see Eqs. (16) and (17)] in terms of the radial expectation values $(\langle p^2\rangle, \langle r^{-2}\rangle)$ and $(\langle r^2\rangle, \langle p^{-2}\rangle)$, respectively. Second, we have derived uncertainty relations for these two pairs of radial expectation values as given by Eqs. (18) and (19). Then, the Fisher product $I_\rho I_\gamma$ is bounded from below in terms of the Heisenberg uncertainty product $\langle p^2\rangle\langle r^2\rangle$ [see Eq. (20)]. Finally, the $D^2/4$ lower bound for the latter product has allowed us to find the new Fisher uncertainty inequality (4). The application to some quantum prototypes of physical systems is also shown not only for checking reasons but also because of their intrinsic and fundamental interests.

Two open problems come naturally. First, to improve the new uncertainty relation given by Eq. (4) mainly by means of increasing the accuracy of the Heisenberg principle (21); and second, to find the Fisher uncertainty relation for general systems; that is, systems with quantum potentials of any character.

(Received 9 May 2006; accepted 31 July 2006; published online 17 October 2006)

The Lyapunov stability is established for the *N*-soliton solutions in the Lax hierarchy of the Benjamin-Ono (BO) equation. We characterize the *N*-soliton profiles as critical points of certain Lyapunov functional. By using several results derived by the inverse scattering transform of the BO equation, we demonstrate the convexity of the Lyapunov functional when evaluated at the *N*-soliton profiles. From this fact, we deduce that the *N*-soliton solutions are energetically stable. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2344854]

I. INTRODUCTION

The Benjamin-Ono (BO) equation describes the unidirectional propagation of long internal waves in stratified fluids of great depth. It may be written in an appropriate dimensionless form as

$$u_t + 2uu_x + Hu_{xx} = 0. \tag{1.1a}$$

Here, $u=u(x,t)$ represents the amplitude of wave, H is the Hilbert transform given by

$$Hu(x,t) = \frac{1}{\pi} P \int_{-\infty}^{\infty} \frac{u(y,t)}{y-x} \mathrm{d}y, \tag{1.1b}$$

and the subscripts t and x appended to u denote partial differentiation. The BO equation can be written as an infinite-dimensional completely integrable Hamiltonian dynamical system.[1,2] A common feature of integrable evolution equations is the existence of an infinite sequence of conservation laws. The Lax hierarchy of the BO equation is generated by the conservation laws, which we shall denote by $I_n (n=2,3,4,\ldots)$. The first three of I_n read

$$I_2 = \frac{1}{2} \int_{-\infty}^{\infty} u^2 \mathrm{d}x, \tag{1.2a}$$

$$I_3 = -\int_{-\infty}^{\infty} \left(\frac{1}{3} u^3 + \frac{1}{2} uHu_x \right) \mathrm{d}x, \tag{1.2b}$$

$$I_4 = \int_{-\infty}^{\infty} \left(\frac{1}{4} u^4 + \frac{3}{4} u^2 Hu_x + \frac{1}{2} u_x^2 \right) \mathrm{d}x. \tag{1.2c}$$

In (1.2), the mass conservation has been excluded since it is irrelevant in the present analysis. The BO hierarchy is defined by the following nonlinear evolution equations:

a)Electronic mail: matsuno@yamaguchi-u.ac.jp

$$\frac{\partial u}{\partial t_n} = \frac{\partial}{\partial x}\frac{\delta I_{n+2}}{\delta u}, \quad (n = 0,1,2,\ldots), \tag{1.3}$$

where $\delta/\delta u$ is the variational derivative defined by

$$\frac{\partial}{\partial \epsilon} I_{n+2}(u+\epsilon v)\bigg|_{\epsilon=0} = \int_{-\infty}^{\infty} \frac{\delta I_{n+2}}{\delta u(x)} v(x)\mathrm{d}x. \tag{1.4}$$

When $n=1$, (1.3) becomes the BO equation (1.1) with the identification $t_1=t$ while when $n=2$, it yields the first higher-order BO equation[3]

$$u_{t_2} = \left(u^3 + \tfrac{3}{2}uHu_x + \tfrac{3}{2}H(uu_x) - u_{xx}\right)_x. \tag{1.5}$$

Note that the first member of (1.3) reduces simply to a linear equation $u_{t_o}=u_x$. As will be shown in the following, all the members of the BO hierarchy exhibit the N-soliton solution characterized by the $2N$ parameters a_j and $x_{j0}(j=1,2,\ldots,N)$ where N is an arbitrary positive integer:

$$u = u_N(x-x_1, x-x_2, \ldots, x-X_N). \tag{1.6a}$$

Here

$$x_j = \sum_{s=0}^{\infty} (-1)^{s+1}\frac{s+1}{2^s}a_j^s t_s + x_{j0}, \quad (j=1,2,\ldots,N), \tag{1.6b}$$

a_j are amplitude parameters satisfying the conditions $a_j>0, a_j\neq a_k$ for $j\neq k(j,k=1,2,\ldots,N)$ and x_{j0} are arbitrary phase parameters. Explicitly, u_N has a simple expression in terms of a tau function f,

$$u_N = i\frac{\partial}{\partial x}\ln\frac{f}{f^*}, \quad f = \det F, \tag{1.7a}$$

where $F=(f_{jk})_{i\leq j,k\leq N}$ is an $N\times N$ matrix with elements

$$f_{jk} = \left(x - x_j + \frac{i}{a_j}\right)\delta_{jk} - \frac{2i}{a_j - a_k}(1-\delta_{jk}). \tag{1.7b}$$

Here, f^* is a complex conjugate of f and δ_{jk} is Kronecker's delta. In particular, for $N=1$, (1.7) represents the one-soliton solution with a Lorenzian profile

$$u_1 = \frac{2a_1}{a_1^2(x-x_1)^2+1}. \tag{1.8}$$

A direct proof of (1.7) using an elementary theory of determinants will be presented in Appendix A.

The definition of the stability of solitons may be classified according to the following three categories: i) linear (or spectral) stability, ii) energetic stability, iii) nonlinear stability. The energetic stability implies that the second variation of certain Lyapunov functional becomes strictly positive when evaluated at the soliton solutions. It would also lead to the linear stability since the second variation is preserved for the linearized equation. In order to extend the energetic stability to the nonlinear stability which deals with small but finite amplitude perturbations, one must take into account higher-order nonlinear terms neglected in evaluating the Lyapunov functional and this makes the analysis more difficult. In accordance with the above classification of the stability, we shall briefly review some known results associated with the stability characteristics of the BO solitons. The linear stability of the BO one-soliton solution has been proved by solving the eigenvalue problem associated with the linearized BO equation.[4] A subsequent nonlinear analysis shows that the soliton is also stable against small but finite perturbations.[5] As for the general

N-soliton solution, its linear stability characteristic has been established by solving explicitly the initial value problem of the linearlized BO equation and investigating the large-time asymptotic of the solution.[6,7] In the process, the completeness relation for the eigenfunctions of the BO equation linearized around the N-soliton solution has played a central role. The recent study demonstrates the orbital stability of the two-soliton solution in which the stability problem has been settled based on the Lyapunov method combined with the spectral analysis of the operators associated with the linearized BO equation.[8] The approach used in this paper originates from the stability analysis of the multisoliton solutions of the Korteweg-de Vries (KdV) equation by means of the constrained variational principle.[9] See also an analogous work dealing with the spectral stability of the multisoliton solutions in the KdV hierarchy.[10] All the above-mentioned works are concerned with the stability of solitons for the BO equation. The stability characteristics of solitons in the BO hierarchy have not been considered as yet.

The purpose of this paper is to establish the Lyapunov stability of the general N-soliton solution (1.6). To be more specific, let us consider the following higher-order BO equation which consists of the commuting flows of the BO hierarchy

$$u_t = \frac{\partial}{\partial x}\frac{\delta H_N}{\delta u}, \tag{1.9a}$$

where the Lyapunov functional H_N is given by

$$H_N(u) = I_{N+2} + \sum_{n=1}^{N} \mu_n I_{n+1}, \tag{1.9b}$$

and μ_n are Lagrange multipliers which will be expressed in terms of the elementary symmetric functions of $a_1, a_2, \ldots, a_N$. See Sec. III for details. We define the profile (or shape) of the N-soliton solution by $U_N = U_N(x) \equiv u_N|_{t_0=t_1=\cdots=0}$. We observe from (1.7) that the N-soliton profile has the same functional form for all the members of the hierarchy, the only difference being the velocities of the solitons. We show that U_N is a stationary solution of (1.9) decaying at infinity. Namely, U_N is realized as a critical point of the functional H_N. Using (1.9b), this condition can be written as the Euler-Lagrange equation

$$\frac{\delta I_{N+2}}{\delta u} + \sum_{n=1}^{N} \mu_n \frac{\delta I_{n+1}}{\delta u} = 0 \quad \text{at } u = U_N. \tag{1.10}$$

The Lyapunov stability of U_N may characterize U_N as a minimal point of the functional I_{N+2} subjected to N constraints

$$I_{n+1}(u) = d_n, \quad (n = 1,2, \ldots, N), \tag{1.11}$$

where d_n are real constants and consequently the second variation of H_N is strictly positive at U_N. This means that H_N is convex at U_N, so that the following inequality holds:

$$H_N(U_N + \epsilon v) - H_N(U_N) > 0, \tag{1.12}$$

where ϵv is a perturbation imposed on U_N which belongs to certain function space specified by the $2N$ integral conditions. We assume that the L^2 norm of v is finite. The small parameter ϵ has been introduced to measure the magnitude of the perturbation. The inequality (1.12) shows that the N-soliton solutions are energetically stable. We give a direct proof of (1.12) with the aid of the results obtained by the inverse scattering transform (IST) for the BO equation.[1,2,11,12] In Sec. II, we summarize the background results arising from the perturbation theory and the Hamiltonian formulation of the BO equation which provide the necessary machinery in carrying out the stability analysis. In Sec. III, we prove the inequality and hence establish the Lyapunov stability of the N-soliton solutions in the Lax hierarchy of the BO equation. In Appendix A, we present a direct

proof of the N-soliton solution (1.7). In Appendix B, we evaluate the number of positive eigenvalues of the Hessian matrix associated with H_N.

II. BACKGROUND RESULTS OF IST

The IST has been applied successfully to solve the initial value problem of the BO equation.[11,12] Furthermore, for real generic potentials it has been used to prove the complete integrability of the BO equation.[1,2] Here, we summarize some background results of the IST necessary for the stability analysis.

A. Eigenvalue problem

The eigenvalue problem associated with the IST of the BO equation may take the form

$$i\phi_x^+ + \lambda(\phi^+ - \phi^-) = -u\phi^+, \tag{2.1}$$

where $\phi^+(\phi^-)$ is the boundary value of the analytic function in the upper(lower)-half complex x plane, u is a real potential rapidly decreasing at infinity, and λ is the eigenvalue (or the spectral parameter). We define the two Jost solutions of (2.1) specified by the boundary condition as $x \to +\infty$,

$$N(x,\lambda) \to e^{i\lambda x}, \quad \overline{N}(x,\lambda) \to 1, \tag{2.2}$$

and the analogous ones as $x \to -\infty$,

$$\overline{M}(x,\lambda) \to 1, \quad M(x,\lambda) \to e^{i\lambda x}. \tag{2.3}$$

These solutions satisfy the linear integral equations

$$N_x - i\lambda N = iP_+(uN), \tag{2.4a}$$

$$\overline{N}_x - i\lambda \overline{N} = iP_+(u\overline{N}) - i\lambda, \tag{2.4b}$$

$$M_x - i\lambda M = iP_+(uM) - i\lambda, \tag{2.4c}$$

$$\overline{M}_x - i\lambda \overline{M} = iP_+(u\overline{M}), \tag{2.4d}$$

where P_+ is the projection operator defined by $P_+ = \frac{1}{2}(1 - iH)$. The solutions of (2.4) subjected to the boundary conditions (2.2) and (2.3) exist for $\lambda > 0$. The Jost functions M, N, and $\overline{N}$ are then related by

$$M = \overline{N} + \beta N, \tag{2.5}$$

where β is a reflection coefficient. For pure soliton potentials, this reflection coefficient vanishes identically.

There exists a set of solutions $\Phi_j(x)$ for negative $\lambda = \lambda_j (j = 1, 2, \ldots, N)$ which satisfy

$$\Phi_{j,x} - i\lambda_j \Phi_j = iP_+(u\Phi_j), \quad (j = 1,2, \ldots, N), \tag{2.6a}$$

with the boundary conditions

$$\Phi_j \to \frac{1}{x}, \quad x \to +\infty, \quad (j = 1,2, \ldots, N). \tag{2.6b}$$

B. Conservation laws

It follows from (1.1), (2.4b), and the time evolution equation for $\overline{N}$,

$$\overline{N}_t - 2\lambda\overline{N}_x - i\overline{N}_{xx} - 2(P_+u_x)\overline{N} = 0, \tag{2.7}$$

that the quantity $\int_{-\infty}^{\infty} u(x,t)\overline{N}(x,t)\mathrm{d}x$ is conserved in time. Expanding $\overline{N}$ in inverse powers of λ,

$$\overline{N} = \sum_{n=0}^{\infty} \frac{(-1)^n \overline{N}_{n+1}}{\lambda^n}, \quad \overline{N}_1 = 1, \tag{2.8a}$$

and substituting (2.8a) into (2.4b), we obtain the following recursion relation that determines $\overline{N}_n$:

$$\overline{N}_{n+1} = i\overline{N}_{n,x} + P_+(u\overline{N}_n), \quad n \geq 1. \tag{2.8b}$$

The nth conservation law may be taken as

$$I_n = (-1)^n \int_{-\infty}^{\infty} u\overline{N}_n \,\mathrm{d}x, \tag{2.9}$$

where a factor $(-1)^n$ is multiplied for convenience. The first three of I_n except I_1 are already given by (1.2). In terms of the scattering data β and λ_j, I_n can be evaluated as

$$I_n = (-1)^n \left\{ 2\pi \sum_{j=1}^{N} (-\lambda_j)^{n-1} + \frac{(-1)^n}{2\pi} \int_0^{\infty} \lambda^{n-2} \beta^*(\lambda)\beta(\lambda)\,\mathrm{d}\lambda \right\}, \quad (n = 1,2,\ldots). \tag{2.10}$$

The first term on the right-hand side of (2.10) is the contribution from solitons and the second term comes from radiations. It is important that both contributions are additive. A remarkable feature of the conservation laws is that they are in involution, namely $I_n (n=1,2,\ldots)$ commute each other in an appropriate Poisson bracket. In particular,

$$\int_{-\infty}^{\infty} \left(\frac{\delta I_n}{\delta u(x)} \right)_{u=U_N} \frac{\partial}{\partial x} \left(\frac{\delta I_m}{\delta u(x)} \right)_{u=U_N} \mathrm{d}x = 0, \quad (n,m = 1,2,\ldots). \tag{2.11}$$

C. Variational derivatives

The variational derivatives of the scattering date with respect to the potential are calculated explicitly. In developing the Lyapunov stability, we need the formulas of the variational derivatives evaluated for the N-soliton potential $u=U_N$. In particular, the following formula plays an important role in our analysis:

$$\left(\frac{\delta \lambda_j}{\delta u(x)} \right)_{u=U_N} = \frac{1}{2\pi\lambda_j} \Phi_j^*(x)\Phi_j(x), \quad (j = 1,2,\ldots,N). \tag{2.12}$$

Here, the eigenfunction Φ_j corresponding to the discrete spectrum λ_j satisfies the system of linear algebraic equations

$$(x - \gamma_j)\Phi_j + i \sum_{\substack{k=1 \\ (k\neq j)}}^{N} \frac{1}{\lambda_j - \lambda_k} \Phi_k = 1, \quad (j = 1,2,\ldots,N), \tag{2.13}$$

where $\gamma_j = x_{j0} + i/(2\lambda_j)$ and x_{j0} are real constants. Recall that λ_j are related to the amplitude parameters a_j introduced in (1.7) by the relations $\lambda_j = -a_j/2 (j=1,2,\ldots,N)$. Taking account of the fact that the reflection coefficient β becomes zero for $u=U_N$, we can derive from (2.10) and (2.12) the formula

$$\left(\frac{\delta I_n}{\delta u(x)}\right)_{u=U_N} = (-1)^n(n-1)\sum_{j=1}^{N}(-\lambda_j)^{n-3}\Phi_j^*(x)\Phi_j(x), \quad (n=2,3,\ldots,N). \tag{2.14}$$

In terms of Φ_j, U_N has the following two alternative expressions:

$$U_N = i\sum_{j=1}^{N}(\Phi_j - \Phi_j^*), \tag{2.15}$$

$$U_N = -\sum_{j=1}^{N}\frac{1}{\lambda_j}\Phi_j^*\Phi_j. \tag{2.16}$$

The positive definiteness of U_N is obvious from (2.16) since all λ_j are negative quantities. One can derive (2.16) by using (2.13) and (2.15). The formula (2.16) also follows from (1.2a), (2.10) and (2.14). In Appendix A, we show that U_N can be rewritten in a compact form in terms of a determinant.

The following relation concerning the variational derivative of β with respect to u is useful in evaluating the contribution of the continuous part to the functional H_N:

$$\frac{\delta\beta(\lambda)}{\delta u(x)} = iM(x,\lambda)N^*(x,\lambda). \tag{2.17}$$

For the N-soliton potential $u=U_N$, M reduces to $\overline{N}$ by (2.5) and $\beta\equiv 0$. The function MN^* satisfies the orthogonality conditions

$$\int_{-\infty}^{\infty} M(x,\lambda)N^*(x,\lambda)\frac{\partial}{\partial x}(\Phi_j^*(x)\Phi_j(x))\,dx = 0, \quad (j=1,2,\ldots,N). \tag{2.18}$$

Finally, we emphasize that all the results presented here are obtained through the analysis of the spatial part (2.1) of the Lax pair for the BO equation.

III. LYAPUNOV STABILITY

A. Variational characterization of the *N*-soliton profile

We first show that the stationary solution U_N of the higher-order BO equation (1.9) satisfies (1.10) if one prescribes the Lagrange multipliers μ_n appropriately. This provides a variational characterization of U_N. Let $\Psi_j=\Phi_j^*\Phi_j$ and $b_j=-\lambda_j=a_j/2$. With this notation, (1.10) and (2.14) give a linear relation among Ψ_j,

$$(N+1)\sum_{j=1}^{N} b_j^{N-1}\Psi_j + \sum_{n=1}^{N}(-1)^{N-n+1}n\mu_n\sum_{j=1}^{N} b_j^{n-2}\Psi_j = 0. \tag{3.1}$$

In view of the fact that Ψ_j are functionally independent squared eigenfunctions,[1,2] μ_n must satisfy the following system of linear algebraic equations:

$$\sum_{n=1}^{N}(-1)^{N-n}nb_j^{n-1}\mu_n = (N+1)b_j^N, \quad (j=1,2,\ldots,N). \tag{3.2}$$

To solve (3.2), we introduce an $N\times N$ matrix V

$$V=(v_{jk})_{1\le j,k\le N}, \quad v_{jk}=b_j^{k-1}, \tag{3.3}$$

and the cofactor of v_{jk} by

$$V_{jk} = \frac{\partial |V|}{\partial v_{jk}}, \quad |V| = \det V, \tag{3.4}$$

where $|V|$ is the Vandermonde determinant. Notably, since $|V| = \Pi_{1 \le j < k \le N}(b_k - b_j)$ and $b_j \neq b_k$ for $j \neq k$, $|V|$ never vanishes. This fact will be used essentially in the following calculation. It is also convenient to define the polynomials $g(x)$ and $g_k(x)$ by

$$g(x) = \prod_{j=1}^{N} (x - b_j) = \sum_{s=1}^{N} (-1)^s \sigma_s x^{N-s}, \tag{3.5}$$

$$g_k(x) = \prod_{\substack{j=1 \\ (j \neq k)}}^{N} (x - b_j) = \sum_{s=1}^{N-1} (-1)^s \sigma_{k,s} x^{N-s}, \tag{3.6}$$

where $\sigma_0 = 1$ and $\sigma_s (1 \le s \le N)$ are elementary symmetric functions of $b_1, b_2, \ldots, b_N$,

$$\sigma_1 = \sum_{j=1}^{N} b_j, \quad \sigma_2 = \sum_{\substack{j,k=1 \\ (j<k)}}^{N} b_j b_k, \ldots, \sigma_N = \prod_{j=1}^{N} b_j, \tag{3.7a}$$

and $\sigma_{k,s}$ are given by the relation

$$\sigma_{k,s} = \sum_{j=0}^{s} \sigma_j (-b_k)^{s-j}. \tag{3.7b}$$

Obviously, all σ_j are positive quantities since $b_j > 0 (j = 1, 2, \ldots, N)$. Now, applying Cramer's rule to (3.2) with use of the fact $|V| \neq 0$, we find that μ_n are determined uniquely as

$$\mu_n = (-1)^{N-n} \frac{N+1}{n} \frac{\Sigma_{k=1}^{N} V_{kn} b_k^N}{|V|}, \quad (n = 1, 2, \ldots, N). \tag{3.8}$$

Substituting the formulas[13]

$$V_{kn} = \frac{(-1)^{N-n} \sigma_{k,N-n|V|}}{g_k(b_k)}, \quad (k, n = 1, 2, \ldots, N), \tag{3.9}$$

$$\sum_{k=1}^{N} \frac{\sigma_{k,N-n} b_k^N}{g_k(b_k)} = \sigma_{N-n+1}, \quad (n = 1, 2, \ldots, N), \tag{3.10}$$

into (3.8), we arrive at a simple expression of μ_n

$$\mu_n = \frac{N+1}{n} \sigma_{N-n+1}, \quad (n = 1, 2, \ldots, N). \tag{3.11}$$

If we use the relations $b_j = a_j/2 (j = 1, 2, \ldots, N)$, we can see that μ_n are expressed in terms of elementary symmetric functions of $a_1, a_2, \ldots, a_N$.

B. Stability

Let us now prove the inequality (1.12) which assures that the functional H_N is convex at the N-soliton profile U_N. The method used here is based on the ideas developed in a recent work[10] on the spectral stability of the N-soliton solution of the KdV hierarchy as well as an earlier work[14] on the algebraic structure of the BO N-soliton solution. We first rewrite (2.10) as

$$I_{n+1}(u) = (-1)^{n+1}\left\{ 2\pi \sum_{j=1}^{N} b_j^n + (-1)^{n+1} r_n \right\}, \tag{3.12a}$$

where we have put $b_j = -\lambda_j$ and

$$r_n = \frac{1}{2\pi}\int_{\infty}^{0} \lambda^{n-1}\beta^*(\lambda)\beta(\lambda)\, d\lambda. \tag{3.12b}$$

Let ΔQ be the increment of any functional $Q(u)$ around $u=U_N$, i.e.,

$$\Delta Q = Q(U_N + \epsilon v) - Q(U_N). \tag{3.13}$$

It then follows from the constraints (1.11) that

$$\Delta I_{n+1} = 0, \quad (n = 1,2,\ldots,N). \tag{3.14}$$

We then use (3.12) to rewrite (3.14) in the form

$$2\pi n \sum_{j=1}^{N} b_j^{n-1}\Delta b_j + (-1)^{n+1}\Delta r_n = 0, \quad (n = 1,2,\ldots,N), \tag{3.15}$$

where we have neglected the higher-order terms $(\Delta b_j)^s (s=2,3,\ldots,N)$. These relations indicate that the increments of soliton amplitudes are balanced with the increments of radiations. We recall that $\beta \equiv 0$ for $u=U_N$ and consequently $\Delta(\beta^*\beta) = \Delta\beta^*\Delta\beta$. This leads to the estimates $\Delta r_n \sim O(\epsilon^2)$ and $\Delta r_n > 0$ for all n. The case $\Delta r_n = 0$ calls a special attention and it will be considered in detail later. Hence, (3.15) can be solved consistently in Δb_j only if $\Delta b_j \sim O(\epsilon^2)$. Since by the definition (1.4)

$$\Delta b_j = \epsilon \int_{-\infty}^{\infty} \left(\frac{\delta b_j}{\delta u} \right)_{u=U_N} v(x)dx + O(\epsilon^2), \tag{3.16}$$

one must impose the integral conditions on the perturbation $v(x)$,

$$\int_{-\infty}^{\infty} \left(\frac{\delta b_j}{\delta u} \right)_{u=U_N} v(x)dx = 0, \quad (j = 1,2,\ldots,N), \tag{3.17}$$

in accordance with the above-presented estimate for Δb_j. We can see from (2.12), (2.14) together with the relations $b_j = -\lambda_j (j=1,2,\ldots,N)$ and $|V| \neq 0$ that (3.17) are equivalent to

$$\int_{-\infty}^{\infty} \left(\frac{\delta I_{n+1}}{\delta u} \right)_{u=U_N} v(x)dx = 0, \quad (n = 1,2,\ldots,N). \tag{3.18}$$

Owing to (3.14), however, these conditions are satisfied automatically. The above-noted observations allow us to solve (3.15). Indeed, the solutions are written, with use of Cramer's rule, as

$$\Delta b_j = \frac{1}{2\pi} \frac{\Sigma_{n=1}^{N} \dfrac{(-1)^n}{n} V_{jn}\Delta r_n}{|V|}, \quad (j = 1,2,\ldots,N). \tag{3.19}$$

It now follows from (1.9b), (3.12), and (3.14) that

$$\Delta H_N = (-1)^N \left\{ 2\pi(N+1) \sum_{j=1}^{N} b_j^N \Delta b_j + (-1)^{N+2}\Delta r_{N+1} \right\}. \tag{3.20}$$

If we substitute (3.19) into (3.20) and use the formulas (3.9) and (3.10), ΔH_N simplifies to

$$\Delta H_N = (N+1)\sum_{n=1}^{N} \frac{\sigma_{N-n+1}}{n}\Delta r_n + \Delta r_{N+1}. \tag{3.21}$$

Since $\sigma_{N-n+1} > 0$ for $n=1,2,\ldots,N$ by the definition (3.7), we find that if at least one of Δr_n is not zero, then $\Delta H_N > 0$. On the other hand, if all Δr_n become zero, then $\Delta H_N = 0$. In the latter case, we see from (3.15) that $\Delta b_j = 0$ for all j. This situation will happen when the perturbation ϵv represents the small variation of U_N with respect to the phase parameters x_{j0}. Specifically

$$\epsilon v(x) = \sum_{j=1}^{N} \frac{\partial U_N}{\partial x_{j0}}\delta x_{j0}, \tag{3.22}$$

where δx_{j0} are small perturbations of order ϵ. If we impose the following N integral conditions on $v(x)$ in addition to (3.28)

$$\int_{-\infty}^{\infty} \frac{\partial}{\partial x}\left(\frac{\delta I_{n+1}}{\delta u}\right)_{u=U_N} v(x)\mathrm{d}x = 0, \quad (n=1,2,\ldots,N), \tag{3.23}$$

then the perturbation of the form (3.22) ceases to be admissible, as we shall now demonstrate. We first notice that the right-hand side of (3.22) can be expressed in terms of the x derivative of $(\delta I_{n+1}/\delta u)_{u=U_N}$. Indeed, we take $u=u_N$ in (1.3) and then put $t_0=t_1=\cdots=0$ to obtain

$$(-1)^n n\sum_{j=1}^{N} b_j^{n-1}\frac{\partial U_N}{\partial x_{j0}} = \frac{\partial}{\partial x}\left(\frac{\delta I_{n+1}}{\delta u}\right)_{u=U_N}, \quad (n=1,2,\ldots,N), \tag{3.24}$$

where we have used (1.6), the definition of U_N and $b_j = a_j/2$. Thanks to the fact $|V| \neq 0$, the relations (3.24) can be inverted to give

$$\frac{\partial U_N}{\partial x_{j0}} = \sum_{n=1}^{N} \frac{(-1)^n}{n}\frac{V_{jn}}{|V|}\frac{\partial}{\partial x}\left(\frac{\delta I_{n+1}}{\delta u}\right)_{u=U_N}, \quad (j=1,2,\ldots,N). \tag{3.25}$$

An alternative expression of (3.22) follows immediately upon introducing (3.25) into (3.22), which reads

$$\epsilon v(x) = \sum_{j=1}^{N}\sum_{n=1}^{N} \frac{(-1)^n}{n}\frac{V_{jn}}{|V|}\frac{\partial}{\partial x}\left(\frac{\delta I_{n+1}}{\delta u}\right)_{u=U_N}\delta x_{j0}. \tag{3.26}$$

We observe that this perturbation satisfies the conditions (3.18) by virtue of (2.11). It is important that the $N\times N$ matrix $C=(c_{jk})_{1\le j,k\le N}$ with elements

$$c_{jk} = \int_{-\infty}^{\infty} \frac{\partial}{\partial x}\left(\frac{\delta I_{j+1}}{\delta u}\right)_{u=U_N}\frac{\partial}{\partial x}\left(\frac{\delta I_{k+1}}{\delta u}\right)_{u=U_N}\mathrm{d}x \tag{3.27}$$

is positive definite and hence $|C| \neq 0$. In view of this fact, we deduce from (3.23) and (3.26) that $\delta x_{j0} = 0 (j=1,2,\ldots,N)$ and consequently $v=0$, which implies the above-mentioned assertion. An additional relation which deserves remark is

$$\int_{-\infty}^{\infty} \left(\frac{\delta\beta}{\delta u}\right)_{u=U_N} v(x)\mathrm{d}x = 0, \tag{3.28}$$

which follows from (2.14), (2.17), (2.18), and (3.26). This leads to the estimates $\Delta\beta \sim O(\epsilon^2)$ and $\Delta r_n \sim O(\epsilon^4)$. As a result, the pertubation (3.26) gives rise to higher-order contributions to (3.21) which also means that the second variation of H_N turns out to be zero. In conclusion, the inequality $\Delta H_N > 0$ holds under the simultaneous conditions (3.18) and (3.25) imposed on $v(x)$, which completes the proof of (1.12). The convexity of H_N implies that the second variation of H_N is

strictly positive and consequently the N-soliton solutions are energetically stable.

C. Remark

In this paper, the convexity of H_N has been proved by invoking some results obtained by the IST of the BO equation. There exists, however, another method to establish the same convex property without recourse to the IST. To illustrate this, we put $u(x,t)=U_N(x)+\epsilon v(x)e^{\lambda t}$ and linearize (1.9) around U_N. The resulting eigenvalue equation can be written as

$$\frac{\partial}{\partial x}\mathcal{L}_N v = \lambda v, \tag{3.29}$$

where $\mathcal{L}_N$ is a self-adjoint operator. This operator may be defined through the relation

$$\delta^2 H_N = \frac{\epsilon^2}{2}\int_{-\infty}^{\infty} v(x)\mathcal{L}_N v(x)\mathrm{d}x, \tag{3.30}$$

where $\delta^2 H_N$ denotes the second variation of H_N. Let $n(\mathcal{L}_N)$ be the number of negative eigenvalues of $\mathcal{L}_N$ and $p(\mathcal{H}_N)$ be the number of positive eigenvalues of the Hessian matrix defined by

$$\mathcal{H}_N = (h_{jk})_{1\le j,k\le N}, \quad h_{jk} = \frac{\partial^2 H_N}{\partial \mu_j\, \partial \mu_k}. \tag{3.31}$$

Then, under the conditions (3.18) and (3.23) the positivity of $\delta^2 H_N$ is satisfied if and only if $n(\mathcal{L}_N)=p(\mathcal{H}_N)$. The above-noted criterion of the positivity property has been proved in Ref. 15 and has been applied to the Lyapunov stability of the N-soliton solution of the KdV equation.[9] In particular, the spectral property of the $2N$th-order differential operator associated with the linearized KdV equation has been investigated by extending the classical Sturmian theory. See also a related work dealing with the stability of the N-soliton solutions in the KdV hierarchy.[10] In the case of the BO equation, however, the eigenvalue equation (3.29) is not purely differential equation but actually integrodifferential equation since it includes the Hilbert transform. This makes the spectral analysis more difficult. Quite recently, a new method was developed to characterize the spectral property of $\mathcal{L}_N$ for $N=2$.[8] The extension to the general N-soliton solutions of the BO equation and its hierarchy is still to be resolved. It is noteworthy that $P(\mathcal{H}_N)$ can be evaluated explicitly for the N-soliton profile U_N. This calculation is presented in Appendix B. The stability analysis developed in this paper would suggest that $n(\mathcal{L}_N)$ is equal to $P(\mathcal{H}_N)$. This interesting issue will be pursued in a future study.

APPENDIX A: PROOF OF THE *N*-SOLITON SOLUTION

In this Appendix, we provide a direct proof of the N-soliton solution (1.7) of the nth higher-order BO equation (1.3) by means of an elementary theory of determinants. For convenience, we write down some basic formulas for determinants upon which our proof relies. Let F be an $N\times N$ matrix with elements f_{jk} given by (1.7b) and F_{jk} be the cofactor of f_{jk}. The expansion of $|F|$ by elements and their cofactors is given in two ways:

$$\sum_{k=1}^{N} f_{jk}F_{lk} = \delta_{jl}|F|, \tag{A1a}$$

$$\sum_{j=1}^{N} f_{jk}F_{jl} = \delta_{kl}|F|. \tag{A1b}$$

The following formula is a consequence of (A1):

$$\sum_{j,k=1}^{N}(f_j+g_k)f_{jk}F_{jk}=\sum_{j=1}^{N}(f_j+g_j)|F|. \tag{A2}$$

The differential rule applied to the determinant $|F|$ gives

$$|F|_x=\sum_{j=1}^{N}F_{jj}, \tag{A3a}$$

$$|F|_{t_n}=(-1)^n\sum_{j=1}^{N}c_jF_{jj}, \tag{A3b}$$

where $c_j=(n+1)a_j^n/2^n$. To carry out the proof, it is necessary to assign the time dependence of the eigenfunction Φ_j for the discrete spectrum λ_j. This can be accomplished simply by replacing the phase factor γ_j introduced in (2.13) by x_j which is defined in (1.6). We first show that (2.15) can be rewritten in an alternative determinantal form (1.7). The solution to (2.13) is found by using Cramer's rule as

$$\Phi_j=i\sum_{k=1}^{N}\frac{F_{kj}}{|F|}. \tag{A4}$$

We put $f_j=a_j$ and $g_j=-a_j$ in (A2) to derive the relation

$$\sum_{j,k=1}^{N}F_{jk}=\sum_{j=1}^{N}F_{jj}. \tag{A5}$$

It follows from (A3) to (A5) that

$$\sum_{j=1}^{N}\Phi_j=i(\ln|F|)_x. \tag{A6}$$

Substituting (A6) and its complex conjugate expression into (2.15), we find that (2.15) coincides with (1.7).

Let us now proceed to the proof of the N-soliton solution. We substitute (1.7) and (2.14) into (1.3) and integrate it once with respect to x to recast (1.3) into the form

$$i(|F|^*|F|_{t_n}-|F||F|^*_{t_n})/|F|^*|F|=(-1)^n(n+1)\sum_{j=1}^{N}\left(\frac{a_j}{2}\right)^{n-1}\Phi_j^*\Phi_j, \tag{A7}$$

where we have used the relation $\lambda_j=-a_j/2$. The following identity has been established by using Jacobi's formula for determinants:

$$i\left(\frac{|F|^*F_{jk}}{a_k}-\frac{|F|F^*_{kj}}{a_j}\right)=2\frac{(|F|\Phi_j)^*(|F|\Phi_k)}{a_ja_k},\quad (j,k=1,2,\ldots,n). \tag{A8}$$

Indeed, (A8) coincides with (A20) in Ref. 7 with the identification $f=|F|^*, \Delta_{jk}=F^*_{jk}, \psi_j=\Phi_j^*$. If we multiply (A8) with $j=k$ by c_j and sum up with respect to j, we obtain

$$\frac{i}{2}\sum_{j=1}^{N}c_j(|F|^*F_{jj}-|F|F^*_{jj})=\frac{n+1}{2^n}\sum_{j=1}^{N}a_j^{n-1}\Phi_j^*\Phi_j|F|^*|F|. \tag{A9}$$

The left-hand side of (A9) is modified further by introducing the formula (A3b) and its complex conjugate expression. It leads, after dividing the resultant expression by $|F|^*|F|$, to (A7) and thus completing the proof.

APPENDIX B: POSITIVE EIGENVALUES OF THE HESSIAN MATRIX $\mathcal{H}_N$

The Hessian matrix $\mathcal{H}_N$ is defined by (3.31). It is a real symmetric matrix whose elements are calculated explicitly for the N-soliton solution. Indeed, by taking $\beta=0$ in (2.10), the nth conservation law corresponding to $u=u_N$ reduces to

$$I_n = 2\pi(-1)^n \sum_{l=1}^{N} b_l^{n-1}, \quad (b_l = -\lambda_l). \tag{B1}$$

If we regard H_N as a function of $\mu_j (j=1,2,\ldots,N)$, we obtain from (1.9b) and (1.10)

$$\frac{\partial H_N}{\partial \mu_j} = I_{j+1}, \quad (j = 1,2,\ldots,N). \tag{B2}$$

Hence

$$h_{jk} = \frac{\partial I_{j+1}}{\partial \mu_k} = 2\pi(-1)^{j+1} j \sum_{l=1}^{N} b_l^{j-1} \frac{\partial b_l}{\partial \mu_k}. \tag{B3}$$

Let $P=(p_{jk})_{1\le j,k\le N}$ and $Q=(q_{jk})_{i\le j,k\le N}$ be $N\times N$ matrices with elements

$$p_{jk} = 2\pi(-1)^{j+1} j b_k^{j-1}, \tag{B4a}$$

$$q_{jk} = \frac{\partial \mu_j}{\partial b_k} = \frac{N+1}{j} \frac{\partial \sigma_{N-j+1}}{\partial b_k}, \tag{B4b}$$

respectively. Note that the right-hand side of (B4b) follows from (3.11). Using the above-presented definition, we can rewrite (B3) in the form

$$\mathcal{H}_N = PQ^{-1}, \tag{B5}$$

if Q^{-1} exists. To show the nonsingular nature of Q, we use the definition (3.7a) of σ_{N-j+1} and (B4b) to evaluate the determinant of Q. A simple calculation immediately leads to

$$|Q| = \frac{(N+1)^N}{N!} \prod_{1\le j<k\le N} (b_k - b_j). \tag{B6}$$

Since $b_j \neq b_k$ for $j \neq k$, we confirm that $|Q| \neq 0$, implying that Q is invertible.

It now follows from (B5) that

$$Q^T \mathcal{H}_N Q = Q^T P. \tag{B7}$$

In accordance with Sylvester's law of inertia, one can see from (B7) that the number of positive eigenvalues of $\mathcal{H}_N$ coincides.with that of Q^TP. The latter can be counted easily, as we shall now demonstrate. Using (B4), the (j,k) element of Q^TP becomes

$$(Q^T P)_{jk} = 2\pi(N+1) \sum_{l=1}^{N} (-1)^{l+1} \frac{\partial \sigma_{N-l+1}}{\partial b_j} b_k^{l-1}. \tag{B8}$$

We differentiate (3.5) by b_j and then put $x=b_k$ to derive the relation

$$\sum_{l=1}^{N}(-1)^{l+1}\frac{\partial\sigma_{N-l+1}}{\partial b_j}b_k^{l-1}=\delta_{jk}\prod_{\substack{l=1\\(l\neq j)}}(b_l-b_k). \tag{B9}$$

Introducing (B9) into (B8), we find that Q^TP is a diagonal matrix. We can order the magnitude of b_j as $b_1>b_2>\cdots>b_N>0$ without loss of generality. Then, (B8) and (B9) indicate that the number of positive eigenvalues of Q^TP is equal to $[(N+1)/2]$ where $[x]$ denotes the integer part of x. If we take account of (B7) and Sylvester's law of inertia, we conclude that $p[\mathcal{H}_N]=[(N+1)/2]$.

(Received 18 May 2006; accepted 29 July 2006; published online 18 October 2006; publisher error corrected 20 October 2006)

In this paper variational principles for eigenvalues of an abstract model of the Klein–Gordon equation with electromagnetic potential are established. They are used to characterize and estimate eigenvalues in cases where the essential spectrum has a gap around 0, even in the presence of complex eigenvalues. As a consequence, a comparison between eigenvalues of the Klein–Gordon equation in $\mathbb{R}^d$ and eigenvalues of certain Schrödinger operators is obtained. The results are illustrated on examples including the Klein–Gordon equation with Coulomb and square-well potential. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2345108]

I. INTRODUCTION

The motion of a relativistic spinless particle of mass m and charge e in an electromagnetic field with scalar potential φ and vector potential $\vec{A}$ is described by the Klein–Gordon equation

$$\left(-\left(-\mathrm{i}\hbar\frac{\partial}{\partial t}-e\varphi\right)^2+c^2\left(-\mathrm{i}\hbar\,\nabla-\frac{e}{c}\vec{A}\right)^2+m^2c^4\right)U=0; \tag{1.1}$$

here c is the speed of light and $\hbar$ is the Planck constant. If we set

$$U(x,t)=:e^{(i\lambda/\hbar)t}u(x),\quad x\in\mathbb{R}^d,\quad t\in\mathbb{R},$$

denote the multiplication operator by $e\varphi$ in $L^2(\mathbb{R}^d)$ by V, the positive symmetric operator $c^2(-\mathrm{i}\hbar\nabla-(e/c)\vec{A})^2$ in $L^2(\mathbb{R}^d)$ by A_0 and set $\gamma:=mc^2$, then (1.1) becomes a quadratic eigenvalue problem of the form

$$(-(\lambda-V)^2+A_0+\gamma^2)u=0,\quad \lambda\in\mathbb{C}. \tag{1.2}$$

As a consequence, the spectral properties of (1.2) determine the solvability of the time-dependent Klein–Gordon equation (1.1) subject to certain initial conditions. The abstract spectral problem (1.2) has been studied by a number of authors under various conditions on V and on A_0, using different techniques (see Ref. 6 for a list of references).

In recent papers[6,7] the abstract Klein–Gordon equation (1.2) was investigated by means of associated block operator matrices and suitable indefinite inner products, imposing rather general conditions on the unbounded operator V. These conditions, which will also be used in the present paper, ensure that the essential spectrum of problem (1.2) has a gap around 0, but they do not exclude the occurrence of complex eigenvalues.

It is the aim of this paper to establish variational principles for eigenvalues of the spectral problem (1.2) in the spectral gap around 0 and to derive eigenvalue estimates and comparisons with eigenvalues of certain Schrödinger operators. As in the case of Dirac operators, standard variational principles do not apply to eigenvalues in gaps of the essential spectrum; to overcome this difficulty, other functionals than the classical Rayleigh functional have been used, see, e.g., Refs. 2 and 4, and references therein.

In general the assumptions on V do not guarantee that the sum of operators on the left-hand side of (1.2) is densely defined, and hence the corresponding operator $T(\lambda)$ has to be introduced by means of quadratic forms. The variational principles are proved for abstract quadratic eigenvalue problems of the form (1.2) in a Hilbert space $\mathcal{H}$ with an arbitrary self-adjoint operator $A_0 \geqslant 0$ in $\mathcal{H}$ and a symmetric operator V in $\mathcal{H}$; the proof uses variational principles for eigenvalues of operator functions defined on an arbitrary interval, recently proved in Ref. 2. As a result of the possible presence of complex eigenvalues, an index shift occurs, which is characterized by means of a linearization of the operator polynomial T.

The paper is organized as follows. In Sec. II we associate an operator polynomial T formally given by

$$T(\lambda) = A_0 + \gamma^2 - (\lambda - V)^2, \quad \lambda \in \mathbb{C},$$

with (1.2). Assuming that $\mathcal{D}(A_0^{1/2}) \subset \mathcal{D}(V)$ and $S := V(A_0 + \gamma^2)^{-1/2} = S_0 + S_1$ with $\|S_0\| < 1$ and S_1 compact (cf. Ref. 6), we obtain the operators $T(\lambda)$ via the forms

$$\mathbf{t}(\lambda)[x,y] = (A_0^{1/2}x, A_0^{1/2}y) + \gamma^2(x,y) - ((V-\lambda)x, (V-\bar{\lambda})y),$$

which are defined for all $x, y \in \mathcal{D}(A_0^{1/2})$. The spectrum, eigenvalues, etc., of the abstract Klein–Gordon equation (1.2) are given by the spectrum, eigenvalues, etc., of the operator polynomial T.

In order to investigate the spectral properties of T, we use two different auxiliary objects. First we employ the operator polynomial L given by

$$L(\lambda) = I - (S^* - \lambda H_0^{-1/2})(S - \lambda H_0^{-1/2}), \quad \lambda \in \mathbb{C},$$

whose values are bounded operators in $\mathcal{H}$. We show that $T(\lambda) = H_0^{1/2} L(\lambda) H_0^{1/2}$ and that the essential spectrum of T on the real axis has a gap around 0 and for every point λ in this gap the number of negative eigenvalues of T is finite. Second, we introduce a family

$$\mathcal{A}_{\lambda_0} = \begin{pmatrix} \lambda_0 & I \\ T(\lambda_0) & 2V - \lambda_0 \end{pmatrix}, \quad \lambda_0 \in \mathbb{C},$$

of operators in the space $\mathcal{H}_{1/2} \oplus \mathcal{H}$, where $\mathcal{H}_{1/2} = (\mathcal{D}(H_0^{1/2}), (H_0^{1/2}\cdot, H_0^{1/2}\cdot))$. For every fixed $\lambda_0 \in \rho(T)$, $\mathcal{A}_{\lambda_0}$ can be considered as a linearization of T. We prove that the spectra, eigenvalues, and essential spectra of T and $\mathcal{A}_{\lambda_0}$, respectively, coincide. Note that the particular operator $\mathcal{A}_0$ coincides with the block operator matrix used in Ref. 6 to study the spectral problem (1.2). We use the more flexible choice of λ_0, e.g., to maximize the range of applicability of our variational principle in the spectral gap. Using an indefinite product on $\mathcal{H}_{1/2} \oplus \mathcal{H}$ induced by the form $\mathbf{t}(\lambda_0)$ in the first component, we show that the essential spectrum of $\mathcal{A}_{\lambda_0}$, and hence of T, is real and has a gap around 0, and that the nonreal spectrum consists of at most finitely many pairs of complex conjugate eigenvalues of finite algebraic multiplicity.

In Sec. III we establish variational principles for real eigenvalues of T in the spectral gap around 0; for the result of Ref. 2 that is applied here it is convenient that the domain of the form $\mathbf{t}(\lambda)$ is independent of λ. The functionals $p_\pm$ used in this characterization, which replace the Rayleigh functionals used for linear spectral problems, are defined as the roots $p_\pm(x)$ of the quadratic equation $\mathbf{t}(\lambda)[x] = 0$ (if the latter are real). In certain circumstances including the presence of complex eigenvalues an index shift may occur in the variational principle.

In Sec. IV we use the variational principles derived in Sec. III to establish various bounds for the eigenvalues of the abstract Klein–Gordon equation (1.2). These bounds are obtained by esti-

mating the functionals $p_\pm$ in the particular cases that V is semibounded, bounded, or has a definite sign. Further refined estimates for eigenvalues of the Klein–Gordon equation in the spectral gap are obtained by comparing them with eigenvalues of Schrödinger operators of the form

$$H_\pm = \pm \frac{1}{2\gamma} A_0 + V = \pm \frac{1}{2m} \left(-i\hbar \nabla - \frac{e}{c} \vec{A} \right)^2 + e\varphi.$$

It turns out that for the Klein–Gordon equation in $\mathbb{R}^d$ these estimates are sharp in the sense that for $c \to \infty$ the eigenvalues of the Klein–Gordon equation converge to the respective eigenvalues of the Schrödinger operators above.

Finally, in Sec. V we illustrate our results by applying them to the Klein–Gordon equation in $\mathbb{R}^d$ with Coulomb and square-well potential. In the Coulomb case we compare our results with the explicitly known eigenvalues. In the square-well case we choose the depth of the potential so that complex eigenvalues occur (cf. Ref. 11) and illustrate how our results apply in this situation.

In the following we introduce some notation, which is used throughout the paper.

For a closed linear operator A in a Hilbert space we denote by $\mathcal{D}(A)$ the domain of A and, if applicable, by $\mathcal{Q}(A)$ its form domain. We also use $\mathcal{D}(\cdot)$ for domains of quadratic forms.

Let T be an operator function on $\mathbb{C}$ such that $T(\lambda)$ is a closed linear operator in a Hilbert space for every $\lambda \in \mathbb{C}$. The *spectrum*, the *resolvent set*, the *point spectrum*, and the *essential spectrum* of T are defined by

$$\sigma(T) := \{\lambda \in \mathbb{C}: 0 \in \sigma(T(\lambda))\}, \quad \rho(T) := \mathbb{C} \setminus \sigma(T),$$

$$\sigma_p(T) := \{\lambda \in \mathbb{C}: 0 \in \sigma_p(T(\lambda))\},$$

$$\sigma_{\mathrm{ess}}(T) := \{\lambda \in \mathbb{C}: T(\lambda) \text{ is not Fredholm}\},$$

respectively; here a closed operator is called *Fredholm* if its kernel is finite dimensional and its range has finite (algebraic) co-dimension (which implies that the range is closed). Note that $\lambda \in \sigma_{\mathrm{ess}}(T) \Leftrightarrow 0 \in \sigma_{\mathrm{ess}}(T(\lambda))$; thus the above-presented definition of the essential spectrum corresponds to the essential spectrum $\sigma_{e3}(\cdot)$ of linear operators defined in Ref. 1, Chap IX.

For a self-adjoint operator A in a Hilbert space and an interval $I \subset \mathbb{R}$ let $\mathcal{L}_I(A)$ denote the spectral subspace of A corresponding to I. Further, we define

$$\kappa_-(A) := \dim \mathcal{L}_{(-\infty,0)}(A).$$

If $\kappa_-(A)$ is finite, then the negative spectrum of A consists only of finitely many eigenvalues of finite multiplicity and $\kappa_-(A)$ is equal to the number of these eigenvalues counted with multiplicities.

II. THE QUADRATIC OPERATOR POLYNOMIAL *T*

Let $(\mathcal{H}, (\cdot,\cdot))$ be a Hilbert space with corresponding norm $\|\cdot\|$, $A_0 \geqslant 0$ a self-adjoint operator in $\mathcal{H}$, $\gamma > 0$ a real constant, and V a symmetric operator in $\mathcal{H}$ and set

$$H_0 := A_0 + \gamma^2.$$

Note that $H_0 \geqslant \gamma^2$ and $\mathcal{D}(H_0^{1/2}) = \mathcal{D}(A_0^{1/2})$.

The following assumptions play a crucial role throughout the paper:

(A1) $\mathcal{D}(A_0^{1/2}) \subset \mathcal{D}(V)$,

(A2) $S := VH_0^{-1/2} = S_0 + S_1$ such that $\|S_0\| < 1$ and S_1 is compact.

Note that in order to satisfy assumption (A2) an arbitrary constant may be added to the operator V, which induces a shift in the spectral parameter in (1.2).

Assumption (A1) implies that V is both $A_0^{1/2}$-bounded and $H_0^{1/2}$-bounded, i.e., there exist a_1, b_1, a_2, $b_2 \geqslant 0$ such that

$$\|Vx\| \leqslant a_1\|x\| + b_1\|A_0^{1/2}x\|, \tag{2.1}$$

$$\|Vx\| \leqslant a_2\|x\| + b_2\|H_0^{1/2}x\| \tag{2.2}$$

for $x \in \mathcal{D}(A_0^{1/2}) = \mathcal{D}(H_0^{1/2})$. This shows that the operator S in assumption (A2) is bounded in $\mathcal{H}$; assumption (A2) then implies that (2.1) and (2.2) hold with $b_1 < 1$ and $b_2 < 1$, respectively.

Remark 2.1: Note that (2.1) is equivalent to

$$\|Vx\|^2 \leqslant a_3\|x\|^2 + b_3\|A_0^{1/2}x\|^2, \quad x \in \mathcal{D}(A_0^{1/2}), \tag{2.3}$$

with constants a_3, $b_3 \geqslant 0$; moreover, (2.1) holds with $b_1 < 1$ if and only if (2.3) holds with $b_3 < 1$ (cf. Ref. 3, Sec. V.4.1).

Under the above-noted assumptions we introduce the family $\mathfrak{t}(\lambda)$, $\lambda \in \mathbb{C}$, of sesquilinear forms by

$$\mathfrak{t}(\lambda)[x,y] := (A_0^{1/2}x, A_0^{1/2}y) + \gamma^2(x,y) - ((V-\lambda)x, (V-\bar\lambda)y) = (H_0^{1/2}x, H_0^{1/2}y) - ((V-\lambda)x, (V-\bar\lambda)y) \tag{2.4}$$

for all $x, y \in \mathcal{D}(\mathfrak{t}(\lambda)) := \mathcal{D}(A_0^{1/2})$. As usual, the corresponding quadratic form is defined by the relation $\mathfrak{t}(\lambda)[x] := \mathfrak{t}(\lambda)[x,x]$ for $x \in \mathcal{D}(\mathfrak{t}(\lambda))$.

Proposition 2.2: The form $\mathfrak{t}(\lambda)$ *is closed and sectorial for all* $\lambda \in \mathbb{C}$. *Moreover*, $\mathfrak{t}(\cdot)[x]$ *is holomorphic on* $\mathbb{C}$ *for* $x \in \mathcal{D}(A_0^{1/2})$.

Proof: The holomorphy of the function $t(\cdot)[x]$ is clear. From (2.1) and Remark 2.1 it follows that there exist a_4, $b_4 \geqslant 0$, $b_4 < 1$, such that for all $x \in \mathcal{D}(A_0^{1/2})$,

$$\|(V-\lambda)x\|^2 \leqslant a_4\|x\|^2 + b_4\|A_0^{1/2}x\|^2.$$

This together with

$$|((V-\lambda)x, (V-\bar\lambda)x)| \leqslant \|(V-\lambda)x\| \cdot \|(V-\bar\lambda)x\| = \|(V-\lambda)x\|^2$$

implies that the quadratic form $((V-\lambda)\cdot, (V-\bar\lambda)\cdot)$ is relatively bounded with respect to the form $(A_0^{1/2}\cdot, A_0^{1/2}\cdot)$ with relative bound less than 1. Hence, by Ref. 3, Theorem VI.1.33, the quadratic form $\mathfrak{t}(\lambda)$ is closed and sectorial for $\lambda \in \mathbb{C}$. □

Proposition 2.2 and the first representation theorem (see Ref. 3, Theorem VI.2.1 or Ref. 10, Theorem VIII.16) show that there exist m-sectorial operators $T(\lambda)$, $\lambda \in \mathbb{C}$, in $\mathcal{H}$ such that

$$\mathfrak{t}(\lambda)[x,y] = (T(\lambda)x, y), \quad x \in \mathcal{D}(T(\lambda)), \quad y \in \mathcal{D}(\mathfrak{t}(\lambda)). \tag{2.5}$$

Since the domain of $\mathfrak{t}(\lambda)$ is independent of λ, the family T is a holomorphic family of operators of type (B) (cf. Ref. 3, Sec. VII.4). Formally, $T(\lambda)$ is given by

$$T(\lambda) = A_0 + \gamma^2 - (V-\lambda)^2;$$

this is a correct identity, e.g., if V is bounded, but in general the right-hand side of the latter equality may have a very small domain.

In the following we show that there exists a real point λ_0 in the resolvent set of T such that the negative spectral subspace of $T(\lambda_0)$ is finite dimensional. For this purpose we consider the operator polynomial

$$L(\lambda) := I - (S^* - \lambda H_0^{-1/2})(S - \lambda H_0^{-1/2}), \quad \lambda \in \mathbb{C},$$

which was introduced in Ref. 6. Assumption (A1) guarantees that the coefficients of L are bounded operators.

Proposition 2.3: Suppose that assumption (A1) *holds*.

(i) *For every* $\lambda \in \mathbb{C}$ *the operator identity*

$$T(\lambda) = H_0^{1/2} L(\lambda) H_0^{1/2} \tag{2.6}$$

holds; hence,

$$\begin{aligned}\mathcal{D}(T(\lambda)) &= \{x \in \mathcal{D}(H_0^{1/2}) : L(\lambda) H_0^{1/2} x \in \mathcal{D}(H_0^{1/2})\} \\ &= \{x \in \mathcal{D}(H_0^{1/2}) : (I - S^* S) H_0^{1/2} x \in \mathcal{D}(H_0^{1/2})\} = \mathcal{D}(T(0)),\end{aligned} \tag{2.7}$$

which is independent of λ.

(ii) $\sigma(T) \cap \mathbb{R} = \sigma(L) \cap \mathbb{R}$, $\sigma_p(T) = \sigma_p(L)$, $\sigma_{\mathrm{ess}}(T) \cap \mathbb{R} = \sigma_{\mathrm{ess}}(L) \cap \mathbb{R}$.

(iii) *For* $\lambda, \lambda_0 \in \mathbb{C}$ *the following relation holds:*

$$T(\lambda) = T(\lambda_0) + (\lambda - \lambda_0)(2V - \lambda - \lambda_0). \tag{2.8}$$

Proof: (i) For $x, y \in \mathcal{D}(\mathfrak{t}(\lambda))$ we have

$$\begin{aligned}(L(\lambda) H_0^{1/2} x, H_0^{1/2} y) &= ((I - (S^* - \lambda H_0^{-1/2})(S - \lambda H_0^{-1/2})) H_0^{1/2} x, H_0^{1/2} y) \\ &= (H_0^{1/2} x, H_0^{1/2} y) - ((S - \lambda H_0^{1/2}) H_0^{1/2} x, (S - \bar{\lambda} H_0^{-1/2}) H_0^{1/2} y) \\ &= (H_0^{1/2} x, H_0^{1/2} y) - ((V - \lambda) x, (V - \bar{\lambda}) y) = \mathfrak{t}(\lambda)[x, y].\end{aligned} \tag{2.9}$$

For the inclusion $H_0^{1/2} L(\lambda) H_0^{1/2} \subset T(\lambda)$, let $x \in \mathcal{D}(H_0^{1/2} L(\lambda) H_0^{1/2}) \subset \mathcal{D}(H_0^{1/2}) = \mathcal{D}(\mathfrak{t}(\lambda))$. Then for all $y \in \mathcal{D}(H_0^{1/2})$ we have

$$(H_0^{1/2} L(\lambda) H_0^{1/2} x, y) = (L(\lambda) H_0^{1/2} x, H_0^{1/2} y) = \mathfrak{t}(\lambda)[x, y].$$

Now Ref. 3 (Theorem VI.2.1.iii) implies that $x \in \mathcal{D}(T(\lambda))$ and $H_0^{1/2} L(\lambda) H_0^{1/2} x = T(\lambda) x$.

For the converse inclusion we observe that (2.9) together with (2.5) implies that

$$(T(\lambda) x, y) = (L(\lambda) H_0^{1/2} x, H_0^{1/2} y), \quad x \in \mathcal{D}(T(\lambda)), \quad y \in (\mathfrak{t}(\lambda)) = \mathcal{D}(H_0^{1/2}).$$

Since the left-hand side is continuous in y, this shows that for $x \in \mathcal{D}(T(\lambda))$ we have $L(\lambda) H_0^{1/2} x \in \mathcal{D}((H_0^{1/2})^*) = \mathcal{D}(H_0^{1/2})$.

The first equality in (2.7) is obvious. For the second equality we note that $H_0^{-1/2} V \subset \overline{H_0^{-1/2} V} = S^*$ and hence for $y \in \mathcal{D}(H_0^{1/2}) \subset \mathcal{D}(V)$ we have $S^* y = H_0^{-1/2} V y \in \mathcal{D}(H_0^{1/2})$. Thus

$$\begin{aligned}\mathcal{D}(T(\lambda)) &= \{x \in \mathcal{D}(H_0^{1/2}) : (I - (S^* - \lambda H_0^{-1/2})(S - \lambda H_0^{-1/2})) H_0^{1/2} x \in \mathcal{D}(H_0^{1/2})\} \\ &= \{x \in \mathcal{D}(H_0^{1/2}) : (I - S^* S) H_0^{1/2} x + \lambda (H_0^{-1/2} S H_0^{1/2} + S^*) x - \lambda^2 H_0^{-1/2} x \in \mathcal{D}(H_0^{1/2})\} \\ &= \{x \in \mathcal{D}(H_0^{1/2}) : (I - S^* S) H_0^{1/2} x \in \mathcal{D}(H_0^{1/2})\} = \mathcal{D}(T(0)).\end{aligned}$$

(ii) Since $H_0^{1/2}$ is bijective, it is clear from (1) that $\sigma_p(T) = \sigma_p(L)$. If $L(\lambda)$ is boundedly invertible, then obviously $T(\lambda)^{-1} = H_0^{-1/2} L(\lambda)^{-1} H_0^{-1/2}$ is bounded, which shows that $\sigma(T) \subset \sigma(L)$. Conversely, let $\lambda \in \mathbb{R}$ be such that $T(\lambda)$ is boundedly invertible. Then $T(\lambda)$ is self-adjoint and we can write

$$H_0^{1/2} T(\lambda)^{-1} H_0^{1/2} = H_0^{1/2} |T(\lambda)|^{-1/2} \operatorname{sgn}(T(\lambda)) |T(\lambda)|^{-1/2} H_0^{1/2}.$$

The operator $H_0^{1/2} |T(\lambda)|^{-1/2}$ is closed and everywhere defined since $\mathcal{D}(H_0^{1/2}) = \mathcal{D}(\mathfrak{t}(\lambda)) = \mathcal{D}(|T(\lambda)|^{1/2})$. Thus $H_0^{1/2} |T(\lambda)|^{-1/2}$ is bounded and so is the operator $|T(\lambda)|^{-1/2} H_0^{1/2} \subset (H_0^{1/2} |T(\lambda)|^{-1/2})^*$. Altogether this shows that $L(\lambda)^{-1} = \overline{H_0^{1/2} T(\lambda)^{-1} H_0^{1/2}}$ is bounded and hence $\sigma(L) \cap \mathbb{R} \subset \sigma(T) \cap \mathbb{R}$.

Next we prove that $\sigma_{\mathrm{ess}}(L) \cap \mathbb{R} \subset \sigma_{\mathrm{ess}}(T) \cap \mathbb{R}$. Let $\lambda \in \mathbb{R}$ be such that $T(\lambda)$ is a Fredholm operator. Then $T(\lambda)$ is self-adjoint, and we can write

$$L(\lambda) = (|T(\lambda)|^{1/2}H_0^{-1/2})^* \operatorname{sgn}(T(\lambda))|T(\lambda)|^{1/2}H_0^{-1/2}.$$

Since $T(\lambda)$ is Fredholm, so are $|T(\lambda)|^{1/2}$ and $\operatorname{sgn}(T(\lambda))$ by the spectral theorem. As $H_0^{-1/2}$ is a bijection from $\mathcal{H}$ onto $\mathcal{D}(H_0^{1/2}) = \mathcal{D}(\mathfrak{t}(\lambda)) = \mathcal{D}(|T(\lambda)|^{1/2})$, the operator $|T(\lambda)|^{1/2}H_0^{-1/2}$ is a bounded Fredholm operator. Hence also $(|T(\lambda)|^{1/2}H_0^{-1/2})^*$ is a bounded Fredholm operator (cf. Ref. 1, Theorem IX.1.1). Altogether this implies that $L(\lambda)$ is Fredholm.

Conversely, assume that $\lambda \in \sigma_{\mathrm{ess}}(T) \cap \mathbb{R}$; then (cf. Ref. 1, Theorem IX.1.3 and Theorem IX.1.6) there exists a singular sequence (x_n) for $T(\lambda)$, i.e., $x_n \in \mathcal{D}(T(\lambda))$ such that $\|x_n\| = 1$, $\lim_{n\to\infty} T(\lambda)x_n = 0$ and (x_n) has no convergent subsequence. Set $y_n := H_0^{1/2}x_n / \|H_0^{1/2}x_n\|$. We prove that (y_n) is a singular sequence for $L(\lambda)$. First it is clear that $\|y_n\| = 1$. Then

$$L(\lambda)y_n = \frac{1}{\|H_0^{1/2}x_n\|} L(\lambda)H_0^{1/2}x_n = \frac{1}{\|H_0^{1/2}x_n\|} H_0^{-1/2}T(\lambda)x_n \to 0$$

for $n \to \infty$ since $H_0^{-1/2}$ is bounded and $\|H_0^{1/2}x_n\| \geqslant \gamma$. Assume now that (y_n) has a convergent subsequence (y_{n_k}) with limit y. Then $y \neq 0$ as $\|y_n\| = 1$ and

$$x_{n_k} = \frac{1}{\|H_0^{-1/2}y_{n_k}\|} H_0^{-1/2}y_{n_k} \to \frac{1}{\|H_0^{-1/2}y\|} H_0^{-1/2}y,$$

a contradiction. So (y_n) is a singular sequence for $L(\lambda)$ and $\lambda \in \sigma_{\mathrm{ess}}(L)$.

(iii) Note that by (i), $\mathcal{D}(T(\lambda)) = \mathcal{D}(T(0)) = \mathcal{D}(T(\lambda_0)) \subset \mathcal{D}(H_0^{1/2}) \subset \mathcal{D}(V)$. Hence, the left- and right-hand sides of (2.8) have the same domain. So it suffices to prove this equality for the corresponding forms. For $x, y \in \mathcal{D}(H_0^{1/2})$ we have

$$\begin{aligned}\mathfrak{t}(\lambda)[x,y] - \mathfrak{t}(\lambda_0)[x,y] &= -((V-\lambda)x,(V-\overline{\lambda})y) + ((V-\lambda_0)x,(V-\overline{\lambda_0})y)\\ &= 2\lambda(Vx,y) - 2\lambda_0(Vx,y) - (\lambda^2 - \lambda_0^2)(x,y) = (\lambda-\lambda_0)((2V-(\lambda+\lambda_0))x,y),\end{aligned}$$

which proves the assertion. □

Lemma 2.4: Suppose that assumptions (A1) *and* (A2) *hold. Let* $\alpha := \gamma(1 - \|S_0\|)$ *and set* $\lambda_e^- := \sup \sigma_{\mathrm{ess}}(T) \cap (-\infty, 0)$, $\lambda_e^+ := \inf \sigma_{\mathrm{ess}}(T) \cap (0, +\infty)$. *Then*

$$\sigma_{\mathrm{ess}}(T) \cap (-\alpha, \alpha) = \emptyset,$$

that is, $\lambda_e^- \leqslant -\alpha < 0 < \alpha \leqslant \lambda_e^+$, *and for all* $\lambda \in (\lambda_e^-, \lambda_e^+)$,

$$\kappa_-(T(\lambda)) < \infty.$$

Proof: According to assumption (A2) we have the decomposition

$$L(\lambda) = L_0(\lambda) + K(\lambda), \quad \lambda \in \mathbb{C},$$

where $K(\lambda)$ is compact and

$$L_0(\lambda) := I - (S_0^* - \lambda H_0^{-1/2})(S_0 - \lambda H_0^{-1/2}).$$

Now let $\lambda \in (-\alpha, \alpha)$. Then

$$c_\lambda := \|S_0\| + |\lambda|\|H_0^{-1/2}\| < \|S_0\| + \gamma(1 - \|S_0\|)\frac{1}{\gamma} = 1$$

and hence

$$L_0(\lambda) \geqslant I - \|S_0 - \lambda H_0^{-1/2}\|^2 \geqslant 1 - c_\lambda^2 > 0.$$

In particular, $\sigma(L_0) \cap (-\alpha, \alpha) = \emptyset$ and $\kappa_-(L_0(\lambda)) = 0$ for $\lambda \in (-\alpha, \alpha)$. Since $K(\lambda)$ is compact, we have

$$\sigma_{\mathrm{ess}}(L) = \sigma_{\mathrm{ess}}(L_0). \tag{2.10}$$

Now Proposition 2.3 (ii) shows that

$$\sigma_{\mathrm{ess}}(T) \cap \mathbb{R} = \sigma_{\mathrm{ess}}(L) \cap \mathbb{R} = \sigma_{\mathrm{ess}}(L_0) \cap \mathbb{R}, \tag{2.11}$$

which implies the first assertion.

For the second assertion we first observe that $\lambda_e^- = \max \sigma_{\mathrm{ess}}(L_0) \cap (-\infty, 0)$, and $\lambda_e^+ = \min \sigma_{\mathrm{ess}}(L_0) \cap (0, +\infty)$ by (2.11). Using the fact that the operator $L_0(0) = I - S_0^* S_0$ is strictly positive and, e.g., Ref. 2, Theorem 2.1 and Lemma 2.9, we obtain that $\kappa_-(L_0(\lambda)) < \infty$ for $\lambda \in (\lambda_e^-, \lambda_e^+)$. Since $K(\lambda)$ is compact, it follows that $\kappa_-(L(\lambda)) < \infty$ for $\lambda \in (\lambda_e^-, \lambda_e^+)$. Finally, (2.6) implies that $\kappa_-(T(\lambda)) = \kappa_-(L(\lambda)) < \infty$ for $\lambda \in (\lambda_e^-, \lambda_e^+)$. □

Remark 2.5: If $S_1 = 0$, then the proof of the previous lemma and Proposition 2.3(ii) show that $\sigma(T) \cap (-\alpha, \alpha) = \emptyset$.

Next we construct a family of linearizations of T in order to investigate the spectral properties of T.

To this end we introduce the Hilbert spaces $\mathcal{H}_{1/2} := (\mathcal{D}(H_0^{1/2}), (H_0^{1/2} \cdot, H_0^{1/2} \cdot))$ and $\mathcal{G} := \mathcal{H}_{1/2} \oplus \mathcal{H}$. Then according to assumption (A1), for $\lambda_0 \in \mathbb{C}$, the operator $\mathcal{A}_{\lambda_0}$ in $\mathcal{G}$ given by

$$\mathcal{A}_{\lambda_0} := \begin{pmatrix} \lambda_0 & I \\ T(\lambda_0) & 2V - \lambda_0 \end{pmatrix}, \quad \mathcal{D}(\mathcal{A}_{\lambda_0}) = \mathcal{D}(T(\lambda_0)) \oplus \mathcal{H}_{1/2}, \tag{2.12}$$

is well defined. The operator $\mathcal{A}_0$ was investigated in Ref. 6. In certain cases, however, e.g., if $0 \in \sigma(T)$, the operator $\mathcal{A}_0$ is not suitable for our purpose.

Lemma 2.6: Suppose that assumption (A1) *holds. If* $\lambda_0 \in \rho(T)$, *then* $\mathcal{A}_{\lambda_0} - \lambda_0$ *is boundedly invertible in* $\mathcal{G}$ *and hence closed.*

Proof: The equation $(\mathcal{A}_{\lambda_0} - \lambda_0)(x\ y)^{\mathsf{T}} = (f\ g)^{\mathsf{T}}$ is equivalent to the relations $y = f$ and $T(\lambda_0)x + 2(V - \lambda_0)y = g$. The latter equation can be solved for x, namely $x = T(\lambda_0)^{-1}(-2(V - \lambda_0)f + g)$. Hence the inverse of $\mathcal{A}_{\lambda_0} - \lambda_0$ is given by

$$(\mathcal{A}_{\lambda_0} - \lambda_0)^{-1} = \begin{pmatrix} -2T(\lambda_0)^{-1}(V - \lambda_0) & T(\lambda_0)^{-1} \\ I & 0 \end{pmatrix}. \tag{2.13}$$

We have to show that this operator is bounded in $\mathcal{G}$. The operator $T(\lambda_0)^{-1}$ is closed in $\mathcal{H}$ with $\mathcal{D}(T(\lambda_0)) \subset \mathcal{H}_{1/2}$ and hence also closed from $\mathcal{H}$ to $\mathcal{H}_{1/2}$; therefore it is bounded from $\mathcal{H}$ to $\mathcal{H}_{1/2}$. As V is bounded from $\mathcal{H}_{1/2}$ to $\mathcal{H}$ by assumption (A1), the left upper entry in (2.13) is bounded in $\mathcal{H}_{1/2}$. Since the embedding from $\mathcal{H}_{1/2}$ into $\mathcal{H}$ is bounded, also the left lower entry is bounded. □

For fixed $\lambda_0 \in \mathbb{R}$ an inner product

$$\left[\begin{pmatrix} x \\ y \end{pmatrix}, \begin{pmatrix} x' \\ y' \end{pmatrix} \right]_{\lambda_0} := \mathfrak{t}(\lambda_0)[x, x'] + (y, y'), \quad \begin{pmatrix} x \\ y \end{pmatrix}, \begin{pmatrix} x' \\ y' \end{pmatrix} \in \mathcal{G},$$

is defined on $\mathcal{G}$, which may be indefinite. If $\lambda_0 \in \rho(T) \cap \mathbb{R}$ and $\kappa_-(T(\lambda_0)) < \infty$, then $(\mathcal{G}, [\cdot, \cdot]_{\lambda_0})$ becomes a Pontryagin space with negative index $\kappa_-(T(\lambda_0))$, i.e., $\mathcal{G}$ is the direct sum of a Hilbert space and a $\kappa_-(T(\lambda_0))$-dimensional anti-Hilbert space.

Due to Lemma 2.4 the assumptions (A1) and (A2) ensure the existence of a point λ_0 with the above-mentioned properties.

Proposition 2.7: Suppose that assumptions (A1) *and* (A2) *hold and let* $\lambda_0 \in \rho(T) \cap \mathbb{R}$ *be such that* $\kappa_-(T(\lambda_0)) < \infty$. *Then the following assertions are true.*

(i) *The operator* $\mathcal{A}_{\lambda_0}$ *is self-adjoint in the Pontryagin space* $(\mathcal{G}, [\cdot, \cdot]_{\lambda_0})$.
(ii) *The various parts of the spectra of* T *and* $\mathcal{A}_{\lambda_0}$ *coincide:*

$$\sigma(T) = \sigma(\mathcal{A}_{\lambda_0}), \quad \sigma_p(T) = \sigma_p(\mathcal{A}_{\lambda_0}), \quad \sigma_{\mathrm{ess}}(T) = \sigma_{\mathrm{ess}}(\mathcal{A}_{\lambda_0}).$$

Proof: (i) For $(x\ y)^{\mathsf{T}} \in \mathcal{D}(\mathcal{A}_{\lambda_0})$ we have

$$\left[\mathcal{A}_{\lambda_0}\begin{pmatrix}x\\y\end{pmatrix},\begin{pmatrix}x\\y\end{pmatrix}\right]_{\lambda_0} = \mathfrak{t}(\lambda_0)[\lambda_0 x + y, x] + (T(\lambda_0)x + (2V - \lambda_0)y, y)$$
$$= \lambda_0 \mathfrak{t}(\lambda_0)[x,x] + \mathfrak{t}(\lambda_0)[y,x] + \mathfrak{t}(\lambda_0)[x,y] + ((2V - \lambda_0)y, y),$$

which is real; hence $\mathcal{A}_{\lambda_0}$ is symmetric in $(\mathcal{G}, [\cdot,\cdot]_{\lambda_0})$. Since $\mathcal{A}_{\lambda_0} - \lambda_0$ is boundedly invertible by Lemma 2.6, $\mathcal{A}_{\lambda_0}$ is self-adjoint.

(ii) Using relation (2.8) in Proposition 2.3(iii) one can easily show that the following equality holds:

$$\begin{pmatrix}T(\lambda) & 0\\ 0 & I\end{pmatrix} = \begin{pmatrix}-2V + \lambda + \lambda_0 & I\\ I & 0\end{pmatrix}(\mathcal{A}_{\lambda_0} - \lambda)\begin{pmatrix}I & 0\\ \lambda - \lambda_0 & I\end{pmatrix}, \quad \lambda \in \mathbb{C}. \tag{2.14}$$

Since the operators $T(\lambda)$ and $\mathcal{A}_{\lambda_0} - \lambda$ are closed in $\mathcal{H}$ and $\mathcal{G}$, respectively, it is sufficient to show that the dimensions of the kernels and the algebraic co-dimensions of the ranges of $T(\lambda)$ and $\mathcal{A}_{\lambda_0} - \lambda$ coincide.

To see this we consider the operator on the left-hand side as an operator from the space $\mathcal{D}(T(\lambda)) \oplus \mathcal{H}_{1/2}$ into $\mathcal{H} \oplus \mathcal{H}_{1/2}$ and $\mathcal{A}_{\lambda_0} - \lambda$ as an operator from $\mathcal{D}(T(\lambda_0)) \oplus \mathcal{H}_{1/2}$ into $\mathcal{H}_{1/2} \oplus \mathcal{H}$; note that according to Eq. (2.7), $\mathcal{D}(T(\lambda_0)) = \mathcal{D}(T(\lambda))$. Next we observe that the last operator on the right-hand side of (2.14) is bijective from $\mathcal{D}(T(\lambda_0)) \oplus \mathcal{H}_{1/2}$ onto $\mathcal{D}(T(\lambda_0)) \oplus \mathcal{H}_{1/2}$ since $\mathcal{D}(T(\lambda_0)) \subset \mathcal{H}_{1/2}$, and that the first operator is bijective from $\mathcal{H}_{1/2} \oplus \mathcal{H}$ onto $\mathcal{H} \oplus \mathcal{H}_{1/2}$ since $\mathcal{H}_{1/2} \subset \mathcal{D}(V)$.

Therefore the factorization (2.14) implies that

$$\dim \ker T(\lambda) = \dim \ker(\mathcal{A}_{\lambda_0} - \lambda), \tag{2.15}$$

$$\dim(\mathcal{H}/\operatorname{ran} T(\lambda)) = \dim((\mathcal{H}_{1/2} \oplus \mathcal{H})/\operatorname{ran}(\mathcal{A}_{\lambda_0} - \lambda)), \tag{2.16}$$

where in the latter equation the factor spaces are purely algebraic. Now the claim follows from the facts that $\lambda \notin \sigma(T)$ if and only if both numbers on the left-hand sides of (2.15) and (2.16) are 0, $\lambda \in \sigma_p(T)$ if and only if $\dim \ker(T(\lambda)) \neq 0$, and $\lambda \notin \sigma_{\mathrm{ess}}(T)$ if and only if both numbers on the left-hand sides of (2.15) and (2.16) are finite, and analogously for $\mathcal{A}_{\lambda_0} - \lambda$. □

Theorem 2.8: *Suppose that assumptions* (A1) *and* (A2) *hold.*

(i) *The essential spectrum* $\sigma_{\mathrm{ess}}(T)$ *is real and has a gap around* 0; *more exactly*,

$$\sigma_{\mathrm{ess}}(T) \cap (-\alpha, \alpha) = \emptyset,$$

where $\alpha := (1 - \|S_0\|)\gamma$.

(ii) *The nonreal spectrum of T is symmetric with respect to the real axis and consists of at most finitely many complex conjugate pairs of eigenvalues of finite algebraic multiplicity.*

(iii) *If* $S_1 = 0$, *then the spectrum of T is real and*

$$\sigma(T) \cap (-\alpha, \alpha) = \emptyset.$$

If $S_0 = 0$, *then*

$$\sigma_{\mathrm{ess}}(T) = \{\lambda \in \mathbb{R} : \lambda^2 \in \sigma_{\mathrm{ess}}(H_0)\}.$$

Proof: Claim (ii) and the first assertion in (i) follow from Proposition 2.7 and general properties of self-adjoint operators in Pontryagin spaces (cf. Ref. 5 and also Ref. 6, Sec. II). The remaining assertions in (i) are immediate from Lemma 2.4. The first claim in (iii) follows from Remark 2.5. Since by (i) $\sigma_{\mathrm{ess}}(T) \subset \mathbb{R}$, Proposition 2.3 (ii) shows that $\sigma_{\mathrm{ess}}(T) = \sigma_{\mathrm{ess}}(L)$. According to (2.10) we have $\sigma_{\mathrm{ess}}(L) = \sigma_{\mathrm{ess}}(L_0)$, where $L_0(\lambda) = I - \lambda^2 H_0^{-1}$ since $S_0 = 0$. Now the claim follows from the spectral mapping theorem. □

III. VARIATIONAL PRINCIPLE

In this section we characterize the eigenvalues of T in certain parts of the gap of the essential spectrum around 0. To this end we introduce functionals p_+ and p_- on the set $\mathcal{D}(H_0^{1/2})\backslash\{0\}$ as follows. For $x\in\mathcal{D}(H_0^{1/2})$, $x\neq 0$, we define $p_+(x)$ and $p_-(x)$, with $p_-(x)\leqslant p_+(x)$, to be the roots of the quadratic equation

$$\mathbf{t}(\lambda)[x]=-\lambda^2\|x\|^2+2(Vx,x)\lambda-(Vx,Vx)+(H_0^{1/2}x,H_0^{1/2}x)=0$$

if the latter are real; otherwise we set $p_+(x):=-\infty$ and $p_-(x):=+\infty$. If $p_\pm(x)$ are finite and $\|x\|=1$, then $p_\pm(x)$ are given by the formula

$$p_\pm(x)=(Vx,x)\pm\sqrt{(Vx,x)^2-(Vx,Vx)+(H_0^{1/2}x,H_0^{1/2}x)}; \tag{3.1}$$

for $\|x\|\neq 1$ we observe that $p_\pm(cx)=p_\pm(x)$ for $c\in\mathbb{C}\backslash\{0\}$. Moreover, set

$$\nu_-:=\sup\{p_-(x):\ x\in\mathcal{D}(H_0^{1/2}),p_-(x)\neq\ +\infty\},$$

$$\nu_+:=\inf\{p_+(x):\ x\in\mathcal{D}(H_0^{1/2}),p_+(x)\neq -\infty\}.$$

The functionals $p_\pm$ are related to the numerical range of the form polynomial $\mathbf{t}$,

$$W(\mathbf{t})=\{\lambda\in\mathbb{C}:\ \mathbf{t}(\lambda)[x]=0 \text{ for some } x\in\mathcal{D}(H_0^{1/2}),x\neq 0\}.$$

In fact, $W(\mathbf{t})\cap\mathbb{R}$ is equal to the union of all finite values of $p_+(x)$ and $p_-(x)$ with $x\in\mathcal{D}(H_0^{1/2})$, $x\neq 0$. Obviously, $\sigma_p(T)\subset W(\mathbf{t})$, and for every $\lambda\in\sigma_p(T)\cap\mathbb{R}$ with eigenvector x, we have $\lambda=p_+(x)$ or $\lambda=p_-(x)$.

The following theorem contains a variational characterization of the eigenvalues of T in the spectral gap around 0 to the right of ν_- in terms of the functionals p_+.

Theorem 3.1: *Suppose that assumptions* (A1) *and* (A2) *are satisfied and assume that* $\nu_-<\lambda_e^+:=\min(\sigma_{\mathrm{ess}}(T)\cap(0,\infty))$.

(i) $(\nu_-,\lambda_e^+)\cap\sigma_{\mathrm{ess}}(T)=\emptyset$ *and there exists an* $\varepsilon>0$ *with* $(\nu_-,\nu_-+\varepsilon)\subset\rho(T)$.

(ii) *Let* $\lambda_0\in(\nu_-,\lambda_e^+)\cap\rho(T)$ *and denote by* $\lambda_1^+\leqslant\lambda_2^+\leqslant\cdots\leqslant\lambda_{N_+}^+$, $N_+\in\mathbb{N}_0\cup\{\infty\}$, *the finite or infinite sequence of the eigenvalues of* T *in the interval* (λ_0,λ_e^+), *counted with multiplicities. Then* $\kappa_+:=\kappa_-(T(\lambda_0))<\infty$ *and*

$$\lambda_n^+=\min_{\substack{\mathcal{L}\subset\mathcal{D}(H_0^{1/2})\\ \dim\mathcal{L}=n+\kappa_+}}\ \max_{\substack{x\in\mathcal{L}\\ x\neq 0}} p_+(x),\quad n=1,2,\ldots,N_+. \tag{3.2}$$

If $N_+=\infty$, *then* $\lim_{n\to\infty}\lambda_n^+=\lambda_e^+$; *otherwise*,

$$\inf_{\substack{\mathcal{L}\subset\mathcal{D}(H_0^{1/2})\\ \dim\mathcal{L}=n+\kappa_+}}\ \max_{\substack{x\in\mathcal{L}\\ x\neq 0}} p_+(x)=\lambda_e^+,\quad n>N_+.$$

Remark 3.2: The condition $x\neq 0$ in the second variations above can be replaced by $\|x\|=1$.

Proof: We want to apply Ref. 2, Theorem 2.1 to $\mathbf{t}$ defined on the intervals (ν_-,λ_e^+) and $[\lambda_0,\lambda_e^+)$, respectively. Assumptions (i) and (ii) of this theorem are satisfied because T is a holomorphic family of operators of type (B). For assumption (iii) of this theorem we have to show that if $\mathbf{t}(\mu_0)[x]=0$ for $\mu_0>\nu_-$ and $x\in\mathcal{D}(H_0^{1/2})$, $x\neq 0$, then

$$\mathbf{t}(\lambda)[x]>0\quad\text{for } \lambda\in(\nu_-,\mu_0),$$

$$\mathbf{t}(\lambda)[x] < 0 \quad \text{for } \lambda > \mu_0. \tag{3.3}$$

In fact, if $\mathbf{t}(\mu_0)[x]=0$ and $\mu_0 > \nu_-$, then $\mathbf{t}(\cdot)[x]$ has two zeros, μ_0 is the larger one of these and the smaller one is $\leqslant \nu_-$. Since $\mathbf{t}(\cdot)[x]$ is concave, (3.3) follows.

Lemma 2.4 shows that there exists a $\nu_0 \in (\nu_-, \lambda_e^+)$ such that $\kappa_-(T(\nu_0)) < \infty$, which is exactly assumption (iv) of Ref. 2, Theorem 2.1.

Finally, assumption (v) of Ref. 2, Theorem 2.1 requires that for every $\mu_0 > \nu_-$ and $\varepsilon > 0$ there exists a positive number $\delta(\mu_0, \varepsilon)$ such that $0 < \mathbf{t}(\mu_0)[x] < \delta(\mu_0, \varepsilon)$ for $x \in \mathcal{D}(H_0^{1/2})$, $\|x\|=1$, implies $\mathbf{t}(\mu_0+\varepsilon)[x] \leqslant 0$. We show that we can choose $\delta(\mu_0, \varepsilon) = \varepsilon(\mu_0 - \nu_-)$. In fact, it follows from $\mathbf{t}(\mu_0)[x] > 0$ that $p_\pm(x) \neq \mp\infty$, and hence we can write $\mathbf{t}(\mu_0)[x] = (\mu_0 - p_-(x))(p_+(x) - \mu_0)$. Therefore if $0 < \mathbf{t}(\mu_0)[x] < \delta(\mu_0, \varepsilon)$, then

$$p_+(x) = \frac{\mathbf{t}(\mu_0)[x]}{\mu_0 - p_-(x)} + \mu_0 < \frac{\delta(\mu_0, \varepsilon)}{\mu_0 - \nu_-} + \mu_0 = \varepsilon + \mu_0,$$

which implies that $\mathbf{t}(\mu_0+\varepsilon)[x] < 0$.

Now all assumptions of Ref. 2, Theorem 2.1 are satisfied on the interval (ν_-, λ_e^+) and hence also for every subinterval. The second claim in (i) follows directly from Ref. 2, Theorem 2.1 applied on the interval (ν_-, λ_e^+). The first part of (i) is obvious if $\nu_- \geqslant 0$; if $\nu_- < 0$, then $(\nu_-, 0) \cap \sigma_{\text{ess}}(T) = \emptyset$ follows from Ref. 2, Lemma 2.9 and the fact that $\kappa_-(T(0)) < \infty$ by Lemma 2.4.

All assertions in (ii) follow from Ref. 2, Theorem 2.1 applied on the interval $[\lambda_0, \lambda_e^+)$. Note that the functional p_+ defined here differs slightly from the definition in Ref. 2, where $p_+(x) = -\infty$ if both zeros of $\mathbf{t}(\cdot)[x]$ are $\leqslant \nu_-$; however, this modification does not affect the maximum in (3.2) since in every subspace of dimension greater than κ_+ there exists an x such that $p_+(x) > \nu_-$. □

The following theorem is the analogue of Theorem 3.1 for the eigenvalues in the spectral gap of T around 0 to the left of ν_+. In this case the functionals p_- are used for the variational principle.

Theorem 3.3: *Suppose that assumptions* (A1) *and* (A2) *are satisfied and assume that* $\nu_+ > \lambda_e^- := \max(\sigma_{\text{ess}}(T) \cap (-\infty, 0))$.

(i) $(\lambda_e^-, \nu_+) \cap \sigma_{\text{ess}}(T) = \emptyset$ *and there exists an* $\varepsilon > 0$ *with* $(\nu_+ - \varepsilon, \nu_+) \subset \rho(T)$.

(ii) *Let* $\lambda_0 \in (\lambda_e^-, \nu_+) \cap \rho(T)$ *and denote by* $\lambda_1^- \geqslant \lambda_2^- \geqslant \cdots \geqslant \lambda_{N_-}^-$, $N_- \in \mathbb{N}_0 \cup \{\infty\}$, *the finite or infinite sequence of the eigenvalues of* T *in the interval* (λ_e^-, λ_0), *counted with multiplicities. Then* $\kappa_- := \kappa_-(T(\lambda_0)) < \infty$ *and*

$$\lambda_n^- = \max_{\substack{\mathcal{L} \subset \mathcal{D}(H_0^{1/2}) \\ \dim \mathcal{L} = n + \kappa_-}} \min_{\substack{x \in \mathcal{L} \\ x \neq 0}} p_-(x), \quad n = 1, 2, \ldots, N_-.$$

If $N_- = \infty$, *then* $\lim_{n\to\infty} \lambda_n^- = \lambda_e^-$; *otherwise*,

$$\sup_{\substack{\mathcal{L} \subset \mathcal{D}(H_0^{1/2}) \\ \dim \mathcal{L} = n + \kappa_-}} \min_{\substack{x \in \mathcal{L} \\ x \neq 0}} p_-(x) = \lambda_e^-, \quad n > N_-.$$

In the following we characterize the index shift in the variational principles above by means of the types of eigenvalues of T with respect to the indefinite inner product $[\cdot, \cdot]_{\lambda_0}$. As a consequence we obtain an estimate of the number of nonreal eigenvalues of T in terms of the index shift.

Proposition 3.4: Suppose that assumptions (A1) *and* (A2) *hold. Let* $\lambda_0 \in \rho(T) \cap \mathbb{R}$ *be such that* $\kappa_-(T(\lambda_0)) < \infty$. *Further, let* $\lambda \in \mathbb{R}$ *be an eigenvalue of* T *and* $x \in \mathcal{D}(T(\lambda_0))$, $x \neq 0$, *a corresponding eigenvector, i.e.,* $T(\lambda_0)x = 0$. *Then* $\mathbf{x} = \begin{pmatrix} x \\ (\lambda - \lambda_0)x \end{pmatrix}$ *is an eigenvector of* $\mathcal{A}_{\lambda_0}$ *corresponding to* λ. *Moreover, the following equivalences are true:*

$$[\mathbf{x},\mathbf{x}]_{\lambda_0} > 0 \Leftrightarrow \begin{cases} \lambda > \lambda_0 \text{ and } \lambda \neq p_-(x) \\ \text{or} \\ \lambda < \lambda_0 \text{ and } \lambda \neq p_+(x) \end{cases}$$

$$[\mathbf{x},\mathbf{x}]_{\lambda_0} < 0 \Leftrightarrow \begin{cases} \lambda > \lambda_0 \text{ and } \lambda \neq p_+(x) \\ \text{or} \\ \lambda < \lambda_0 \text{ and } \lambda \neq p_-(x) \end{cases}$$

$$[\mathbf{x},\mathbf{x}]_{\lambda_0} = 0 \Leftrightarrow \lambda = p_+(x) = p_-(x).$$

Proof: From the definition of $\mathcal{A}_{\lambda_0}$ in (2.12) and Proposition 2.3(iii) it follows that

$$(\mathcal{A}_{\lambda_0} - \lambda)\begin{pmatrix} x \\ (\lambda - \lambda_0)x \end{pmatrix} = \begin{pmatrix} 0 \\ T(\lambda_0)x + (\lambda - \lambda_0)(2V - \lambda_0 - \lambda)x \end{pmatrix} = \begin{pmatrix} 0 \\ T(\lambda)x \end{pmatrix} = 0.$$

Without loss of generality we can assume that $\|x\|=1$. Using (2.8) we obtain

$$\begin{aligned} \left[\begin{pmatrix} x \\ (\lambda - \lambda_0)x \end{pmatrix}, \begin{pmatrix} x \\ (\lambda - \lambda_0)x \end{pmatrix}\right]_{\lambda_0} &= \mathfrak{t}(\lambda_0)[x,x] + ((\lambda - \lambda_0)x, (\lambda - \lambda_0)x) = (T(\lambda_0)x,x) + (\lambda - \lambda_0)^2 \\ &= (T(\lambda)x,x) - (\lambda - \lambda_0)((2V - \lambda - \lambda_0)x,x) + (\lambda - \lambda_0)^2 \\ &= (\lambda - \lambda_0)(-(2Vx,x) + \lambda + \lambda_0 + \lambda - \lambda_0) = 2(\lambda - \lambda_0)(\lambda - (Vx,x)). \end{aligned} \tag{3.4}$$

Formula (3.1) shows that $(Vx,x)=\frac{1}{2}(p_+(x)+p_-(x))$. Since $\lambda=p_+(x)$ or $\lambda=p_-(x)$, this implies that

$$\lambda > (Vx,x) \Leftrightarrow \lambda \neq p_-(x),$$

$$\lambda < (Vx,x) \Leftrightarrow \lambda \neq p_+(x),$$

$$\lambda = (Vx,x) \Leftrightarrow \lambda = p_+(x) = p_-(x).$$

Now the claim is immediate from (3.4) □

Proposition 3.5: Suppose that the assumptions of Theorem 3.1 hold and choose λ_0 as in Theorem 3.1. Then every eigenvalue $\lambda > \lambda_0$ of T is of positive type with respect to the inner product $[\cdot,\cdot]_{\lambda_0}$, i.e., $[\mathbf{x},\mathbf{x}]_{\lambda_0} > 0$ for every eigenvector x and $\mathbf{x}=\binom{x}{(\lambda-\lambda_0)x}$. Moreover, the index shift κ_+ in Theorem 3.1 satisfies

$$\kappa_+ = \sum_{\lambda \in \sigma(T) \cap \mathbb{C}^+} \dim \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0}) + \sum_{\lambda \in \sigma(T) \cap (-\infty, \lambda_0)} \dim_- \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0}), \tag{3.5}$$

where $\mathcal{L}_\lambda(\mathcal{A}_{\lambda_0})$ denotes the algebraic eigenspace of $\mathcal{A}_{\lambda_0}$ at λ and $\dim_- \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0})$ denotes the maximal dimension of a nonpositive subspace of $\mathcal{L}_\lambda(\mathcal{A}_{\lambda_0})$.

Proof: Since $\lambda_0 > \nu_-$, it is clear that for every eigenvalue $\lambda > \lambda_0$ with eigenvector x we have $\lambda \neq p_-(x)$. Hence by the previous theorem it follows that $[\mathbf{x},\mathbf{x}]_{\lambda_0} > 0$. According to Theorem 3.1, the index shift κ_+ is the negative index of the Pontryagin space $(\mathcal{G}, [\cdot,\cdot]_{\lambda_0})$. By Ref. 5 it is hence equal to

$$\sum_{\lambda \in \sigma(T) \cap \mathbb{C}^+} \dim \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0}) + \sum_{\lambda \in \sigma(T) \cap \mathbb{R}} \dim_- \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0}).$$

By the first claim we have $\dim_- \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0}) = 0$ for $\lambda > \lambda_0$. □

Since $\dim \mathcal{L}_\lambda(\mathcal{A}_{\lambda_0}) = \dim \mathcal{L}_{\bar\lambda}(\mathcal{A}_{\lambda_0})$, the following corollary is an immediate consequence of (3.5).

Corollary 3.6: The number of nonreal eigenvalues of T, counted with multiplicities, is at most $2\kappa_+$.

IV. EIGENVALUE ESTIMATES

If additional information on the operator V is available, we can estimate the functionals $p_\pm$ and hence the eigenvalues of T as well as the numbers $\nu_\pm$. Further we compare the eigenvalues of T with eigenvalues of a certain abstract Schrödinger operator.

Proposition 4.1: Suppose that assumption (A1) *holds. Let $x \in \mathcal{D}(H_0^{1/2})$, $x \neq 0$, be such that $p_\pm(x) \neq \mp\infty$ and let a_3, $b_3 \geqslant 0$, $b_3 < 1$, be real constants such that (2.3) is satisfied.*

(i) *If V is bounded from above, $V \leqslant v_{\max}$, then*

$$p_-(x) \leqslant v_{\max} - \sqrt{\max\{0, \gamma^2 - a_3\}} \leqslant v_{\max}.$$

If, in addition, $v_{\max} \leqslant 0$, then

$$p_-(x) \leqslant v_{\max} - \sqrt{\max\{0, v_{\max}^2 + \gamma^2 - a_3\}} \leqslant v_{\max} \leqslant 0.$$

(ii) *If V is bounded from below, $V \geqslant v_{\min}$, then*

$$p_+(x) \geqslant v_{\min} + \sqrt{\max\{0, \gamma^2 - a_3\}} \geqslant v_{\min}.$$

(iii) *If V is bounded, $v_{\min} \leqslant V \leqslant v_{\max}$, then*

$$p_-(x) \leqslant v_{\max} - \sqrt{\max\{0, \gamma^2 - \|V\|^2\}} \leqslant v_{\max},$$

$$p_+(x) \geqslant v_{\min} + \sqrt{\max\{0, \gamma^2 - \|V\|^2\}} \geqslant v_{\min}.$$

If, in addition, $v_{\max} \leqslant 0$, then

$$p_-(x) \leqslant v_{\max} - \sqrt{\max\{0, v_{\max}^2 + \gamma^2 - \|V\|^2\}} \leqslant v_{\max} \leqslant 0,$$

$$p_+(x) \geqslant v_{\min} + \sqrt{\max\{0, v_{\max}^2 + \gamma^2 - \|V\|^2\}} \geqslant v_{\min}.$$

Proof: Let $x \in \mathcal{D}(H_0^{1/2}) = \mathcal{D}(A_0^{1/2})$, $\|x\| = 1$, be such that $p_-(x) \neq +\infty$. From (3.1) and (2.3) it follows that

$$\begin{aligned} p_-(x) &= (Vx,x) - \sqrt{(Vx,x)^2 - (Vx,Vx) + (A_0^{1/2}x, A_0^{1/2}x) + \gamma^2} \\ &\leqslant (Vx,x) - \sqrt{\max\{0, -\|Vx\|^2 + \|A_0^{1/2}x\|^2 + \gamma^2\}} \\ &\leqslant (Vx,x) - \sqrt{\max\{0, -a_3 + (1-b_3)\|A_0^{1/2}x\|^2 + \gamma^2\}} \\ &\leqslant (Vx,x) - \sqrt{\max\{0, -a_3 + \gamma^2\}}, \end{aligned}$$

where we have used that $b_3 < 1$ in (2.3). This proves the first inequality in (i); for the second inequality one additionally has to use the estimate $(Vx,x)^2 \geqslant v_{\max}^2$. The proof of (ii) is completely analogous. The claim in (iii) is an immediate consequence of (i) and (ii) since in this case we can choose $a_3 = \|V\|^2$ in (2.3). □

The above proposition together with the variational principle in Theorem 3.1 yields the following estimate for eigenvalues of T. We restrict ourselves to the case that V is bounded; the other cases are similar.

Corollary 4.2: Suppose that V is bounded, $v_{\min} \leqslant V \leqslant v_{\max}$ and that assumption (A2) *is satisfied. Then, using the notation of Theorem 3.1, we have*

$$\nu_- \leqslant v_{\max} - \sqrt{\max\{0, \gamma^2 - \|V\|^2\}} \leqslant v_{\max}$$

and

$$\lambda_k^+ \geqslant v_{\min} + \sqrt{\max\{0, \gamma^2 - \|V\|^2\}} \geqslant v_{\min}, \quad k = 1,2, \ldots, N_+.$$

If the operator V is bounded and has a definite sign, then assumption (A2) in Theorem 3.1 can be replaced by assuming that $\|V\| < 2\gamma$ (or even $v_{\max} - v_{\min} < 2\gamma$, cf. Ref. 9). In this case, the spectrum of T is real, the essential spectrum has a gap to the right of $-\gamma$ and there is no index shift in the variational principle.

Theorem 4.3: *Assume that* $-2\gamma \leqslant v_{\min} \leqslant V \leqslant 0$. *Then for* $x \in \mathcal{D}(H_0^{1/2})$, $x \neq 0$,

$$p_-(x) \leqslant -\gamma, \quad p_+(x) \geqslant \gamma + v_{\min} \geqslant -\gamma.$$

If, in addition, $v_{\min} > -2\gamma$, *then* $\sigma(T) \subset \mathbb{R}$, $(-\gamma, \gamma + v_{\min}) \subset \rho(T)$ *and the eigenvalues* $\lambda_1^+ \leqslant \lambda_2^+ \leqslant \cdots \leqslant \lambda_{N_+}^+$, $N_+ \in \mathbb{N}_0 \cup \{\infty\}$, *of* T *in* $(\gamma + v_{\min}, \lambda_e^+)$, $\lambda_e^+ = \min(\sigma_{\mathrm{ess}}(T) \cap (-\gamma, +\infty))$, *can be characterized by*

$$\lambda_n^+ = \min_{\substack{\mathcal{L} \subset \mathcal{D}(H_0^{1/2}) \\ \dim \mathcal{L} = n}} \max_{\substack{x \in \mathcal{L} \\ x \neq 0}} p_+(x), \quad n = 1,2, \ldots, N_+. \tag{4.1}$$

Proof: Let E_t be the spectral family of the self-adjoint operator V. Then

$$\|Vx\|^2 = \int_{v_{\min}}^0 t^2 \mathrm{d}(E_t x, x) \leqslant v_{\min} \int_{v_{\min}}^0 t \mathrm{d}(E_t x, x) = v_{\min}(Vx, x).$$

Using this estimate and the fact that the function $f(t) = t + \sqrt{(t+a)^2 + b}$, $t \in \mathbb{R}$, is increasing if $a \in \mathbb{R}$ and $b \geqslant 0$ we obtain

$$p_+(x) = (Vx,x) + \sqrt{(Vx,x)^2 - \|Vx\|^2 + \|A_0^{1/2}x\|^2 + \gamma^2} \geqslant (Vx,x) + \sqrt{(Vx,x)^2 - v_{\min}(Vx,x) + \gamma^2} \tag{4.2}$$

$$= (Vx,x) + \sqrt{\left((Vx,x) - \frac{v_{\min}}{2}\right)^2 - \frac{v_{\min}^2}{4} + \gamma^2} \geqslant v_{\min} + \sqrt{\left(v_{\min} - \frac{v_{\min}}{2}\right)^2 - \frac{v_{\min}^2}{4} + \gamma^2} = v_{\min} + \gamma. \tag{4.3}$$

Note that $b = -v_{\min}^2/4 + \gamma^2 \geqslant 0$ since $0 \geqslant v_{\min} \geqslant -2\gamma$. This also shows that the roots in (4.3) and hence in (4.2) are real. The proof for the estimate of $p_-(x)$ is similar.

Now assume that $v_{\min} > -2\gamma$. Then for $\lambda \in (-\gamma, \gamma + v_{\min})$ we have $\|V - \lambda\| < \gamma$ and hence the self-adjoint operator $T(\lambda) = H_0 - (V - \lambda)^2$ is strictly positive and $\kappa_-(T(\lambda)) = 0$. This implies that $(-\gamma, \gamma + v_{\min}) \subset \rho(T)$.

Further, we observe that for every $x \in \mathcal{D}(H_0^{1/2})$, $x \neq 0$, the equation $t(\lambda)[x] = 0$ has two real solutions $p_\pm(x)$ and hence

$$W(\mathfrak{t}) = \{p_\pm(x) : x \in \mathcal{D}(H_0^{1/2}), x \neq 0\} \subset (-\infty, -\gamma] \cup [\gamma + v_{\min}, +\infty).$$

Since $\rho(T) \neq \emptyset$, we have $\sigma(T) \subset \overline{W(T)} = \overline{W(\mathfrak{t})} \subset \mathbb{R}$ (cf. Ref. 8, Theorem 26.6).

Finally, it is not difficult to see that the proof of Theorem 3.1 carries over with $\lambda_0 \in (-\gamma, \gamma + v_{\min})$ and $\kappa_+ = \kappa_-(T(\lambda_0)) = 0$. □

The following theorem provides a comparison between the eigenvalues of the Klein–Gordon equation and a corresponding Schrödinger operator.

Theorem 4.4: *Suppose that assumptions* (A1) *and* (A2) *as well as the assumptions of Theorem 3.1 hold. Then the operator*

$$H_+ := \frac{1}{2\gamma}A_0 + V$$

is self-adjoint and bounded from below. If $\mu_1^+ \leqslant \mu_2^+ \leqslant \cdots \leqslant \mu_{M_+}^+$, $M_+ \in \mathbb{N}_0 \cup \{\infty\}$, *are the eigenvalues of* H_+ *below* $\sigma_{\mathrm{ess}}(H_+)$ *and* $\mu_n^+ := \min\sigma_{\mathrm{ess}}(H_+)$ *for* $n > M_+$, *then the eigenvalues* λ_n^+ *of* T *satisfy the estimate*

$$\lambda_n^+ \leqslant \mu_{n+\kappa_+}^+ + \gamma, \quad n = 1, \ldots, N_+.$$

Proof: It follows from (2.1) and the fact that $A_0^{1/2}$ is A_0-bounded with relative bound 0 that V is A_0-bounded with relative bound 0; hence H_+ is self-adjoint and bounded from below. Let $\mathfrak{h}_+$ be the quadratic form associated with H_+, i.e.,

$$\mathfrak{h}_+[x] := \frac{1}{2\gamma}(A_0^{1/2}x, A_0^{1/2}x) + (Vx, x), \quad x \in \mathcal{D}(A_0^{1/2}).$$

An elementary calculation shows that

$$\mathfrak{t}(\lambda)[x] = 2\gamma(\mathfrak{h}_+ + \gamma - \lambda)[x] - \|(V - \lambda + \gamma)x\|^2, \quad x \in \mathcal{D}(A_0^{1/2}). \tag{4.4}$$

Let $x \in \mathcal{D}(A_0^{1/2})$, $\|x\| = 1$. Then (4.4) implies that $\mathfrak{t}(\lambda)[x] \leqslant 0$ for all $\lambda \geqslant \mathfrak{h}_+[x] + \gamma$. Hence $p_+(x) \leqslant \mathfrak{h}_+[x] + \gamma$ since $\mathfrak{t}(\cdot)[x]$ is concave. Using Theorem 3.1 and the standard variational principle for semi-bounded self-adjoint operators, we obtain

$$\lambda_n^+ = \min_{\substack{\mathcal{L} \subset \mathcal{D}(H_0^{1/2}) \\ \dim \mathcal{L} = n + \kappa_+}} \max_{\substack{x \in \mathcal{L} \\ \|x\| = 1}} p_+(x) \leqslant \min_{\substack{\mathcal{L} \subset \mathcal{D}(H_0^{1/2}) \\ \dim \mathcal{L} = n + \kappa_+}} \max_{\substack{x \in \mathcal{L} \\ \|x\| = 1}} \mathfrak{h}_+[x] + \gamma = \mu_{n+\kappa_+}^+ + \gamma,$$

which completes the proof. □

Theorem 4.5: *Suppose that assumptions* (A1) *and* (A2) *as well as the assumptions of Theorem 3.3 hold. Then the operator*

$$H_- := -\frac{1}{2\gamma}A_0 + V$$

is self-adjoint and bounded from above. If $\mu_1^- \geqslant \mu_2^- \geqslant \cdots \geqslant \mu_{M_-}^-$, $M_- \in \mathbb{N}_0 \cup \{\infty\}$, *are the eigenvalues of* H_- *above* $\sigma_{\mathrm{ess}}(H_-)$ *and* $\mu_n^- := \max\sigma_{\mathrm{ess}}(H_-)$ *for* $n > M_-$, *then the eigenvalues* λ_n^- *of* T *satisfy the estimate*

$$\lambda_n^- \geqslant \mu_{n+\kappa_-}^- - \gamma, \quad n = 1, \ldots, N_-.$$

Proof: The proof is completely analogous to that of Theorem 4.4 if relation (4.4) is replaced by

$$\mathfrak{t}(\lambda)[x] = -2\gamma(\mathfrak{h}_- - \gamma - \lambda)[x] - \|(V - \lambda - \gamma)x\|^2, \quad x \in \mathcal{D}(A_0^{1/2}),$$

where $\mathfrak{h}_-$ is the quadratic form associated with H_-. □

Remark 4.6:

(i) For the Klein–Gordon equation in $\mathbb{R}^d$ we have $A_0 = c^2(-i\hbar\nabla - e/c\vec{A})^2$ and $\gamma = mc^2$, and the operator

$$H_+ = \frac{1}{2m}\left(-i\hbar\nabla - \frac{e}{c}\vec{A}\right)^2 + V$$

is the classical Schrödinger operator in $\mathbb{R}^d$.

(ii) In the particular case that $\vec{A} = 0$ the estimate

$$\lambda^+_{k-\kappa_+} - mc^2 \leqslant \mu^+_k \tag{4.5}$$

in Theorem 4.4 is sharp in the following sense. The Schrödinger operator $H_+ = -(\hbar^2/2m)\Delta + V$ and hence its eigenvalues on the right-hand side of (4.5) do not depend on c; one can show that $\kappa_+ = 0$ if c is large enough and that $\lim_{c\to\infty}(p_+(x) - mc^2) = (H_+x, x)/\|x\|^2$ uniformly on finite-dimensional spaces and hence

$$\lim_{c\to\infty}(\lambda^+_{k-\kappa_+} - mc^2) = \mu^+_k.$$

It was already proved in Ref. 12 that $\lambda^+_n - mc^2$ converges to some eigenvalue of H_+.

V. THE KLEIN–GORDON EQUATION IN $\mathbb{R}^d$

In this section we consider the Klein–Gordon equation in $\mathbb{R}^d$. Here $\mathcal{H} = L^2(\mathbb{R}^d)$,

$$A_0 = c^2\left(-i\hbar\nabla - \frac{e}{c}\vec{A}\right)^2,$$

$$H_0 = c^2\left(-i\hbar\nabla - \frac{e}{c}\vec{A}\right)^2 + m^2c^4,$$

and V is the multiplication operator by a function $V: \mathbb{R}^d \to \mathbb{R}$. Note that here and in the sequel $(-i\hbar\nabla - (e/c)\vec{A})^2$ denotes the self-adjoint operator $(-i\hbar\nabla - (e/c)\vec{A})^*(-i\hbar\nabla - (e/c)\vec{A})$.

Lemma 5.1: Assume that $(e/c)\vec{A}$ is $-i\hbar\nabla$-bounded with relative bound less than 1 and let $\hat{H}_0 := c^2(-i\hbar\nabla)^2 + m^2c^4$. Then $\hat{H}_0^{1/2}H_0^{-1/2}$ is bounded and $\mathcal{D}(H_0^{1/2}) = W^{1,2}(\mathbb{R}^d)$.

Proof: Obviously, $\hat{H}_0^{1/2}H_0^{-1/2}$ is closed. By the assumption on $\vec{A}$ it follows that $-i\hbar\nabla - (e/c)\vec{A}$ is closed and $\mathcal{D}(-i\hbar\nabla - (e/c)\vec{A}) = \mathcal{D}(-i\hbar\nabla)$. Hence we have the following chain of equalities of domains:

$$\begin{aligned}\mathcal{D}(H_0^{1/2}) = \mathcal{Q}(H_0) &= \mathcal{Q}\left(c^2\left(-i\hbar\nabla - \frac{e}{c}\vec{A}\right)^2 + m^2c^4\right) = \mathcal{Q}\left(\left(-i\hbar\nabla - \frac{e}{c}\vec{A}\right)^2\right)\\ &= \mathcal{D}\left(-i\hbar\nabla - \frac{e}{c}\vec{A}\right) = \mathcal{D}(-i\hbar\nabla) = \mathcal{Q}((-i\hbar\nabla)^2) = \mathcal{Q}(c^2(-i\hbar\nabla)^2 + m^2c^4) = \mathcal{Q}(\hat{H}_0)\\ &= \mathcal{D}(\hat{H}_0^{1/2}) = W^{1,2}(\mathbb{R}^d).\end{aligned}$$

Thus $\hat{H}_0^{1/2}H_0^{-1/2}$ is everywhere defined and hence bounded. □

Note that in general $\mathcal{D}(H_0) \neq \mathcal{D}(\hat{H}_0)$.

Corollary 5.2: If $V\hat{H}_0^{-1/2}$ is bounded or compact, then so is $VH_0^{-1/2}$.

Now the following sufficient conditions for assumptions (A1) and (A2), proved in Ref. 6, Theorem 6.1 for the case $\vec{A} = 0$ carry over to the case $\vec{A} \neq 0$.

Proposition 5.3: Assume that $d \geqslant 3$ and that $(e/c)\vec{A}$ is $-i\hbar\nabla$-bounded with relative bound less than 1. Then the following assertions are true.

(i) *If $V \in L^p(\mathbb{R}^d)$ with $d \leqslant p < \infty$, then $VH_0^{-1/2}$ is compact.*

(ii) *There exists a constant $\eta_0 > 0$ (depending on $\vec{A}$) such that if $|V(x)| \leqslant \eta/|x|$, $\eta < \eta_0$, then assumptions* (A1) *and* (A2) *are satisfied with $S_0 = VH_0^{-1/2}$, $S_1 = 0$. If $\vec{A} = 0$, then we can choose $\eta_0 = c\hbar(d-2)/2$, and we have $\|S_0\| \leqslant 2\eta/c\hbar(d-2)$.*

As an illustration of Theorem 4.4 we consider two examples: the Klein–Gordon equation with Coulomb potential in $\mathbb{R}^3$ and with square-well potential in $\mathbb{R}$. In both cases we assume that there is no vector potential, i.e., $\vec{A}=0$.

Example 1: The Coulomb potential. The eigenvalues $\lambda_{n,l}$ of the Klein–Gordon equation in $\mathbb{R}^3$ with Coulomb potential are known explicitly, see, e.g., Ref. 12. In this case

$$V(x) = -\frac{Ze^2}{|x|},$$

where Z is the atomic number. If $Z \leqslant 1/2\alpha \approx 68.5$, where $\alpha = e^2/\hbar c \approx 1/137$ is the fine structure constant, then V satisfies assumptions (A1) and (A2) according to Proposition 5.3. Since V is $-\Delta$-compact (cf. Ref. 3, Lemma V.5.8), the difference of the resolvents of $T(\lambda)$ and $H_0-\lambda^2$ is compact for every $\lambda \in \mathbb{R}$ and hence $\sigma_{\mathrm{ess}}(T) = (-\infty, -mc^2] \cup [mc^2, +\infty)$ (cf. also Ref. 13). The eigenvalues $\lambda_{n,l}$ all lie in the interval $(0, mc^2)$; they are given by the formula

$$\lambda_{n,l} = mc^2 \left[1 + \frac{(Z\alpha)^2}{\left(n-l-\frac{1}{2} + \sqrt{\left(l+\frac{1}{2}\right)^2 - (Z\alpha)^2} \right)^2} \right]^{-1/2}, \quad \begin{array}{l} n = 1,2,\ldots, \\ l = 0,1,\ldots,n-1, \end{array}$$

and have multiplicity $2l+1$. The eigenvalues $\lambda_{n,l}$ can be expanded as

$$\lambda_{n,l} = mc^2 - \frac{me^4Z^2}{2\hbar^2}\frac{1}{n^2} - \frac{me^8Z^4}{2\hbar^4}\frac{1}{n^4}\left(\frac{n}{l+\frac{1}{2}} - \frac{3}{4} \right)\frac{1}{c^2} + O\left(\frac{1}{c^4}\right), \quad c \to \infty;$$

here the second term is exactly an eigenvalue of the Schrödinger operator,

$$\mu_n = -\frac{me^4Z^2}{2\hbar^2}\frac{1}{n^2},$$

which has multiplicity n^2. In this case the estimate of the Klein–Gordon eigenvalues by the Schrödinger eigenvalues proved in Theorem 4.4 reads

$$\lambda_{n,l} - mc^2 \leqslant \mu_n, \quad l = 0,1,\ldots,n-1, \tag{5.1}$$

for $n=1,2,\ldots$. The values for $n=3$ and $Z=1$,

$$\lambda_{3,0} - mc^2 = -1.511\,79 \text{ eV},$$

$$\lambda_{3,1} - mc^2 = -1.511\,75 \text{ eV}, \quad \mu_3 = -1.511\,74 \text{ eV}$$

$$\lambda_{3,2} - mc^2 = -1.511\,75 \text{ eV},$$

show that the estimate (5.1) is rather tight.

Example 2: The square-well. It was noted already in Ref. 11 that the Klein–Gordon equation in $\mathbb{R}^3$ with square-well potential has complex eigenvalues if the potential is sufficiently deep. Here we consider a square-well potential in $\mathbb{R}$,

$$V(x) = \begin{cases} -v_1, & |x| \leqslant a \\ 0, & |x| > a, \end{cases} \tag{5.2}$$

where $a>0$ and $v_1>0$ are constants. The operator of multiplication by V in $L^2(\mathbb{R})$ satisfies assumption (A1) since it is bounded; it also satisfies assumption (A2). In fact, V is relatively compact with respect to A_0 and H_0 since V has compact support. By Theorem 2.8, this shows that the essential spectrum of the operator polynomial T is given by

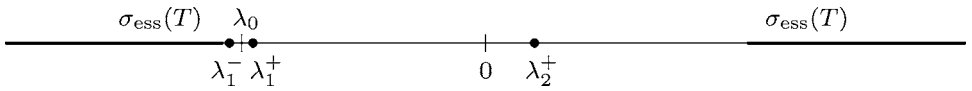

FIG. 1. Spectrum for $2mc^2<v_1=2.07<v_{\mathrm{crit}}$, $m=c=\hbar=a=1$.

$$\sigma_{\mathrm{ess}}(T)=(-\infty,-mc^2]\cup[mc^2,\infty).$$

Theorem 4.3 implies that if $v_1<2mc^2$, then the spectrum is real, $\nu_-\leqslant -mc^2$, the eigenvalues are confined to the interval (mc^2-v_1,mc^2) and all these eigenvalues, $\lambda_1^+\leqslant\lambda_2^+\leqslant\cdots\leqslant\lambda_{N_+}^+$, can be characterized by the variational principle (4.1).

If v_1 is increased such that $v_1>2mc^2$, then eigenvalues $\lambda_1^-\geqslant\lambda_2^-\geqslant\cdots$ start to emerge at $-mc^2$, the bottom of the gap in the essential spectrum. If we choose λ_0 in Theorem 3.1 between λ_1^- and λ_1^+, then we can characterize all eigenvalues λ_n^+ and λ_n^- to the right and left of λ_0, respectively, by the variational principles in Theorems 3.1 and 3.3 with $\kappa_\pm=0$.

If v_1 reaches some critical value v_{crit}, then the two eigenvalues λ_1^+ and λ_1^- meet; if $v_1>v_{\mathrm{crit}}$, they become a pair of nonreal complex conjugate eigenvalues. We can still characterize the real eigenvalues to the right of ν_- and the eigenvalues to the left of ν_+; in both cases the index shifts $\kappa_\pm$ are greater than or equal to the number of pairs of nonreal eigenvalues. Note that the enumeration of the real eigenvalues changes whenever a new pair of complex eigenvalues appears.

The index shift, say κ_+, can be determined exactly: it is equal to the number of negative eigenvalues of $T(\lambda_0)$. For example, if $m=c=\hbar=a=1$ and $v_1=2.11$, then there are no eigenvalues in the interval $(-mc^2,0]$, so we can choose $\lambda_0=0$, and the second sum in (3.5) is 0. Since the Schrödinger operator $T(0)$ has exactly one negative eigenvalue, it follows that $\kappa_+=1$. Now formula (3.5) implies that there is exactly one pair of nonreal complex conjugate eigenvalues, which are algebraically simple.

Finally, we illustrate the estimate of the Klein–Gordon eigenvalues λ_n^+ by the eigenvalues μ_k^+ of the Schrödinger operator $H_+=-\frac{1}{2}(\mathrm{d}^2/\mathrm{d}x^2)+V$ proved in Theorem 4.4, assuming that $m=c=\hbar=a=1$. We consider the two special values $v_1=2.07$ and $v_1=2.11$. In the first case, for which the spectrum is displayed in Fig. 1, there are two eigenvalues $\lambda_1^+<\lambda_2^+$ in the spectral gap $(-1,1)$ (and one eigenvalue λ_1^-), the index shift κ_+ is 0 and hence we obtain the estimates

$$\lambda_1^+\leqslant\mu_1^+ + mc^2,\quad \lambda_2^+\leqslant\mu_2^+ + mc^2;$$

in fact, the corresponding numerical values are

$$\lambda_1^+ = -0.887\,840,\quad \mu_1^+ + 1 = -0.532\,969, \tag{5.3}$$

$$\lambda_2^+ = 0.186\,578,\quad \mu_2^+ + 1 = 0.764\,013. \tag{5.4}$$

In the second case, for which the spectrum is displayed in Fig. 2, there is one eigenvalue λ_1^+ in the spectral gap $(-1,1)$, the index shift κ_+ is 1 and hence

$$\lambda_1^+\leqslant\mu_2^+ + mc^2;$$

here the numerical values are

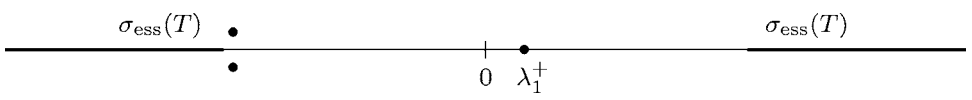

FIG. 2. Spectrum for $v_1=2.11>v_{\mathrm{crit}}$, $m=c=\hbar=a=1$.

$$\lambda_1^+ = 0.148\,517, \quad \mu_2^+ + 1 = 0.744\,769.$$

If c is increased to its physical value, then the Klein–Gordon eigenvalues λ_n^+ come much closer to the respective shifted Schrödinger eigenvalues.

(Received 5 July 2006; accepted 21 August 2006; published online 19 October 2006)

We characterize a class of integrable Hamiltonian hydrodynamic chains, based on the necessary condition for the integrability provided by the vanishing of the Haantjes tensor. We prove that the vanishing of the first few components of the Haantjes tensor is already sufficiently restrictive, and allows a complete description of the corresponding Hamiltonian densities. In each of the cases we were able to explicitly construct a generating function for conservation laws, thus establishing the integrability. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2354590]

I. INTRODUCTION

We consider Hamiltonian systems of the form

$$\mathbf{u}_t = \left(B\frac{\mathrm{d}}{\mathrm{d}x} + \frac{\mathrm{d}}{\mathrm{d}x}B^t \right)\frac{\partial h}{\partial \mathbf{u}}, \tag{1}$$

where $\mathbf{u}=(u^1,u^2,u^3,\ldots)^t$ is an infinite-component column vector of the dependent variables, and the matrix B of the Hamiltonian operator $B(\mathrm{d}/\mathrm{d}x)+(\mathrm{d}/\mathrm{d}x)B^t$ is defined as $B^{ij}=(\alpha(i-1)+\beta)u^{i+j-1}$. Explicitly, one has

$$B = \begin{pmatrix} \beta u^1 & \beta u^2 & \beta u^3 & \ldots. \\ (\alpha+\beta)u^2 & (\alpha+\beta)u^3 & (\alpha+\beta)u^4 & \ldots. \\ (2\alpha+\beta)u^3 & (2\alpha+\beta)u^4 & (2\alpha+\beta)u^5 & \ldots. \\ \ldots. & \ldots. & \ldots. & \ldots. \end{pmatrix};$$

here α and β are arbitrary constants. Hamiltonian operators of this type first appeared in Ref. 8, and belong to the general class introduced in Ref. 2. The Hamiltonian density h is assumed to be a function of the first two independent variables u^1,u^2 only: $h=h(u^1,u^2)$. In this paper we address the problem of the classification of all densities $h(u^1,u^2)$ such that the corresponding Hamiltonian system is *integrable* (partial results were reported earlier in Ref. 8). The integrability of Hamiltonian chains of the type (1) can be defined by either of two properties:

(1) The existence of infinitely many additional conservation laws which Poisson commute with the Hamiltonian $\int h(u^1,u^2)\mathrm{d}x$, see Ref. 8.
(2) The existence of infinitely many hydrodynamic reductions, see Refs. 5, 6, and 3.

To derive the integrability conditions we utilize the second approach, based on the calculation of the so-called Haantjes tensor.[7] Let us first represent the system (1) in a hydrodynamic form,

$$\mathbf{u}_t = V(\mathbf{u})\mathbf{u}_x,$$

where $V=v^i_j$ is an $\infty\times\infty$ matrix. This matrix has the following properties:

(a) each row of V contains *finitely many* nonzero elements;
(b) each matrix element of V depends on *finitely many* variables u^i.

Infinite systems of this type are known as "hydrodynamic chains." The properties (a) and (b) ensure that both the Nijenhuis tensor,

$$N^i_{jk} = v^p_j \partial_{u^p} v^i_k - v^p_k \partial_{u^p} v^i_j - v^i_p(\partial_{u^j} v^p_k - \partial_{u^k} v^p_j) \tag{2}$$

(the standard summation convention over repeated indices is adopted), and the Haantjes tensor,

$$H^i_{jk} = N^i_{pr} v^p_j v^r_k - N^p_{jr} v^i_p v^r_k - N^p_{rk} v^i_p v^r_j + N^p_{jk} v^i_r v^r_p, \tag{3}$$

are well-defined objects, so that the calculation of each particular component H^i_{jk} requires finitely many summations only. Moreover, for a fixed upper index i, one has *finitely many* nonzero components H^i_{jk}, see Ref. 3. According to the results of Tsarev,[15] the vanishing of the Haantjes tensor is necessary and sufficient for the integrability of finite-component Hamiltonian systems of hydrodynamic type by the generalized hodograph method. Thus, we formulate our main

Conjecture: The vanishing of the Haantjes tensor is a necessary and sufficient condition for the integrability of Hamiltonian hydrodynamic chains. In particular, it implies the existence of infinitely many Poisson commuting conservation laws, and infinitely many hydrodynamic reductions.

The necessity part of this conjecture follows from the general result of Ref. 3, according to which the vanishing of the Haantjes tensor is a necessary condition for the integrability of hydrodynamic chains (not necessarily Hamiltonian). The sufficiency is a far more delicate property and requires, as a subproblem, the classification of infinite-component Hamiltonian structures. The conjecture is supported by all examples of integrable Hamiltonian chains known to us. Since components of the Haantjes tensor can be calculated using computer algebra, this approach provides an effective classification criterion. The main goal of this paper is to demonstrate that the conjecture is indeed true for Hamiltonian chains of the type (1).

Upon setting the first components H^1_{jk} equal to zero we obtain the expressions for all third-order partial derivatives of the Hamiltonian density $h(u^1,u^2)$ in terms of lower order derivatives, see Eq. (4) in Sec. II. A complete list of integrable Hamiltonian densities is obtained in Sec. III by solving these equations for $h(u^1,u^2)$. In the general case ($\beta\neq 0$, $\alpha+2\beta\neq 0$) we have three essentially different examples,

$$h(u^1,u^2) = (u^2 + f(u^1))^{\beta/(\alpha+2\beta)},$$

where $f(u^1)=a(u^1+c)^{(\alpha+2\beta)/\beta}+b(u^1-c)^{(\alpha+2\beta)/\beta}$, as well as

$$h(u^1,u^2) = (u^1+c)^{-(\alpha+\beta)/\beta}u^2 + a(u^1-c)^{2+\alpha/\beta}(u^1+c)^{-1-\alpha/\beta}$$

and

$$h(u^1,u^2) = u^2 + c(u^1)^2;$$

here a,b,c are arbitrary constants. In the case $\beta=0$ we have two extra examples,

$$h(u^1,u^2) = \ln(u^2 + f(u^1)), \quad f'' = cf,$$

and

$$h(u^1,u^2)=e^{cu^1}u^2+e^{2cu^1}.$$

Finally, the case $\alpha+2\beta=0$ gives three extra examples,

$$h(u^1,u^2)=e^{au^2+f(u^1)},$$

here

$$f(u^1)=\frac{b}{2\sqrt{b^2+1}}\ln\frac{\sqrt{b^2+1}+cu^1}{\sqrt{b^2+1}-cu^1}+\frac{1}{2}\ln(b^2+1-c^2(u^1)^2),$$

as well as

$$h(u^1,u^2)=(u^1+c)u^2+b(u^1+c)\ln\frac{u^1+c}{u^1-c}$$

and

$$h(u^1,u^2)=u^1u^2+\frac{c}{u^1}.$$

These examples correct the list presented in Ref. 8.

We prove in Sec. IV that all remaining components of the Haantjes tensor of the corresponding Hamiltonian chains vanish identically by virtue of (4).

In Sec. V we demonstrate that the requirement of the existence of an additional conservation law of the form $p(u^1,u^2,u^3)_t=q(u^1,u^2,u^3,u^4)_x$ leads to the same relations (4).

As shown in Sec. VI, Eq. (4) implies the existence of a generating function of conservation laws and, hence, the infinity of conservation laws. This establishes the integrability of all examples constructed in Sec. III. In the general case the generating function is expressed in terms of a hypergeometric function of Gauss.

II. DERIVATION OF THE INTEGRABILITY CONDITIONS

There are two "trivial" cases which are to be excluded from the further analysis:

(i) $\alpha+\beta=0$. In this case the Haantjes tensor vanishes identically for any Hamiltonian density $h(u^1,u^2)$, indeed, the first two equations for u^1, u^2 form an independent subsystem, while the remaining equations become strictly lower-triangular.

(ii) $\Delta=(\alpha+\beta)h_2+(\alpha+2\beta)u^2h_{22}+2\beta u^1h_{12}=0$. In this case the first equation of the chain decouples from the rest, taking the form $u^1_t=\lambda(u^1)u^1_x$ where $\lambda(u^1)$ is a function of u^1. The Haantjes tensor is also identically zero.

Assuming in what follows that neither of the expressions in (i) and (ii) vanishes (they appear as denominators in the formulas to follow), calculating the components H^1_{jk} of the Haantjes tensor (one can use computer algebra to perform calculations of this type), and setting them equal to zero, we obtain the following expressions for third-order partial derivatives of the Hamiltonian density $h(u^1,u^2)$:

$$h_{222}=\frac{(2\alpha+3\beta)h_{22}^2}{(\alpha+\beta)h_2},$$

$$h_{122}=\frac{(2\alpha+3\beta)h_{22}h_{12}}{(\alpha+\beta)h_2},$$

$$h_{112}=\frac{(\alpha+2\beta)h_{12}^2+(\alpha+\beta)h_{22}h_{11}}{(\alpha+\beta)h_2},$$

$$h_{111}=\frac{-\alpha(\alpha+2\beta)u^2h_{12}^3+(\alpha+\beta)((2\alpha+3\beta)h_2+3(\alpha+2\beta)u^2h_{22})h_{11}h_{12}}{(\alpha+\beta)h_2\Delta}$$
$$+\frac{2\beta(\alpha+3\beta)u^1h_{12}^2h_{11}+2\alpha\beta u^1h_{22}h_{11}^2}{(\alpha+\beta)h_2\Delta}; \tag{4}$$

here $\Delta=(\alpha+\beta)h_2+(\alpha+2\beta)u^2h_{22}+2\beta u^1h_{12}$, and lower indices indicate differentiation with respect to u^1 and u^2. We have verified the involutivity of this system.

Remark 1: Since u^1 is the density of the momentum of the Hamiltonian structure (1), the addition of terms linear in u^1 to the Hamiltonian density h effects neither the integrability of the chain, nor the vanishing of the Haantjes tensor. Thus, the classification to follow is carried out up to transformations of the form

$$h\to ah+bu^1+c, \tag{5}$$

where a, b, c are arbitrary constants.

III. INTEGRABLE HAMILTONIAN DENSITIES

We begin with the general case when both β and $\alpha+2\beta$ are nonzero. The cases when either of them vanishes will be considered separately.

A. General case

If $h_{22}\neq 0$ then, using the first two equations (4), we obtain

$$h_{22}=ch_2^{(2\alpha+3\beta)/(\alpha+\beta)},\quad c=\text{const}.$$

This can be integrated twice to give $h=(u^2+f(u^1))^{\beta/(\alpha+2\beta)}+g(u^1)$. The substitution into the third equation implies $g''=0$. Thus, up to transformations (5), we have

$$h(u^1,u^2)=(u^2+f(u^1))^{\beta/(\alpha+2\beta)}. \tag{6}$$

Substituting this into the remaining expression for h_{111} we obtain an ODE for $f(u^1)$,

$$f'''=\alpha f''\frac{(\alpha+\beta)f'-2\beta u^1f''}{(\alpha+\beta)((\alpha+2\beta)f-2\beta u^1f')},$$

with the general solution

$$f=a(u^1+c)^{(\alpha+2\beta)/\beta}+b(u^1-c)^{(\alpha+2\beta)/\beta};$$

here a,b,c are arbitrary constants (we thank Sasha Veselov for this observation).

If $h_{22}=0$ then the first two equations (4) are satisfied identically, while the last two equations imply either

$$h(u^1,u^2)=(u^1+c)^{-(\alpha+\beta)/\beta}u^2+\tau(u^1), \tag{7}$$

where $\tau(u^1)$ satisfies an ODE

$$\tau'''=\frac{\tau''}{\beta}\left(\frac{\alpha}{u^1-c}-\frac{\alpha+3\beta}{u^1+c}\right)$$

with the general solution

$$\tau = a(u^1 - c)^{2+\alpha/\beta}(u^1 + c)^{-1-\alpha/\beta},$$

or

$$h(u^1,u^2) = u^2 + c(u^1)^2. \tag{8}$$

We point out that the integrability of the Hamiltonian chain with the density (8) was established in Ref. 8.

B. Case $\beta=0$

The equations for h take the form

$$h_{222} = \frac{2h_{22}^2}{h_2},$$

$$h_{122} = \frac{2h_{22}h_{12}}{h_2},$$

$$h_{112} = \frac{h_{11}h_{22} + h_{12}^2}{h_2},$$

$$h_{111} = \frac{-u^2h_{12}^3 + 2h_2h_{11}h_{12} + 3u^2h_{22}h_{12}h_{11}}{h_2(h_2 + u^2h_{22})}.$$

If $h_{22} \neq 0$ then, up to transformations (5), the first three equations imply

$$h(u^1,u^2) = \ln(u^2 + f(u^1)), \tag{9}$$

and the substitution of this ansatz into the fourth equation gives $f'''f - f'f'' = 0$, which integrates to $f'' = cf$, c=const. If $h_{22}=0$ then the first two equations (4) are satisfied identically, while the other two imply either

$$h(u^1,u^2) = e^{cu^1}u^2 + e^{2cu^1}, \tag{10}$$

or

$$h(u^1,u^2) = u^2 + c(u^1)^2, \tag{11}$$

c=const, the latter case coinciding with (8).

C. Case $\alpha+2\beta=0$

The equations for h take the form

$$h_{222} = \frac{h_{22}^2}{h_2},$$

$$h_{122} = \frac{h_{22}h_{12}}{h_2},$$

$$h_{112} = \frac{h_{11}h_{22}}{h_2},$$

$$h_{111} = \frac{h_2 h_{11} h_{12} + 2u^1 h_{12}^2 h_{11} - 4u^1 h_{22} h_{11}^2}{h_2(h_2 - 2u^1 h_{12})}.$$

If $h_{22} \neq 0$ then, up to transformations (5), the first three equations imply

$$h(u^1,u^2) = e^{au^2 + f(u^1)}. \tag{12}$$

The substitution of this ansatz into the fourth equation gives an ODE for f,

$$f''' + 2f'f'' = 2u^1(f'f''' - 2(f'')^2),$$

which can be solved as follows. Setting $f' = 1/w$ we obtain $w''(w - 2u^1) = 2w'(w' - 1)$. Introducing $w = v + 2u^1$ we arrive at an autonomous ODE $v''v = 2(v' + 2)(v' + 1)$ which integrates twice leading to the general solution

$$f = \frac{b}{2\sqrt{b^2+1}} \ln \frac{\sqrt{b^2+1} + cu^1}{\sqrt{b^2+1} - cu^1} + \frac{1}{2} \ln(b^2 + 1 - c^2(u^1)^2), \quad c, b = \text{const},$$

or its linear degeneration $f = cu^1$. Setting $b = \sinh a$ we can rewrite the above expression in the form

$$f = \frac{1}{2\cosh a}(e^a \ln(\cosh a + cu^1) + e^{-a} \ln(\cosh a - cu^1)).$$

The case $h_{22} = 0$ leads to either

$$h(u^1,u^2) = (u^1 + c)u^2 + b(u^1 + c) \ln \frac{u^1 + c}{u^1 - c}, \tag{13}$$

where c, b are arbitrary constants, or its degeneration,

$$h(u^1,u^2) = u^1 u^2 + \frac{c}{u^1}. \tag{14}$$

Further degeneration $h_{22} = h_{12} = 0$ results in

$$h(u^1,u^2) = u^2 + c(u^1)^2. \tag{15}$$

IV. THE VANISHING OF THE HAANTJES TENSOR

In this section we demonstrate that the relations (4), which were obtained from the requirement of the vanishing of the first few components H^1_{jk} of the Haantjes tensor, are already sufficiently restrictive and imply the vanishing of all other components. The proof utilizes an important property of Hamiltonian chains (1), namely, the existence of finite-component reductions for *any* (not necessarily integrable) Hamiltonian density h.[12] Let us parametrize u^i in terms of finitely many "moments" v^a, $a = 1, \ldots, n$, as follows:

$$u^k = \frac{1}{2 + \dfrac{\alpha}{\beta}(k-1)} \sum_1^n (v^a)^{2 + \alpha/\beta(k-1)},$$

$k = 1, 2, 3, \ldots$. (we consider the generic case when all expressions in the denominators are nonvanishing, see Ref. 12 for a discussion of the exceptional cases). Thus,

$$u^1 = \frac{1}{2}\sum_1^n (v^a)^2, \quad u^2 = \frac{1}{2+\frac{\alpha}{\beta}}\sum_1^n (v^a)^{2+\alpha/\beta}, \tag{16}$$

etc. One can verify that under this substitution the infinite chain (1),

$$u_t^k = (\alpha(k-1)+\beta)u^k(h_1)_x + (\alpha(k-1)+\beta)u^{k+1}(h_2)_x + \beta(u^k h_1)_x + (\alpha+\beta)(u^{k+1}h_2)_x,$$

reduces to an n-component "symmetric" conservative system for v^a,

$$v_t^a = \beta(v^a h_1 + (v^a)^{1+\alpha/\beta}h_2)_x, \tag{17}$$

$a=1,\ldots,n$, see Ref. 13. Here $h(u^1,u^2)$ is an *arbitrary* Hamiltonian density, not necessarily satisfying the integrability conditions (4), and u^1,u^2 are given by (16). Notice that the system (17) is manifestly Hamiltonian: $v_t^a = \beta(\partial h/\partial v^a)_x$. Similar formulas can be obtained if the density h depends on more than two u's. We have the following

Theorem 1: *For a Hamiltonian density $h(u^1,u^2)$ satisfying the integrability conditions (4), the Haantjes tensor of any finite-component reduction (17) is identically zero.*

The proof follows from the explicit formulas for the Nijenhuis tensor,

$$\begin{aligned}
N_{23}^1 = {} & \beta v^1v^2v^3((v^2)^{\alpha/\beta}-(v^3)^{\alpha/\beta})\Big[2\beta^2u^1(h_{11}h_{12}^2-h_{11}^2h_{22}) + \beta\Big(2+\frac{\alpha}{\beta}\Big)(\alpha u^2 - 2\beta(v^1)^{\alpha/\beta}u^1)(h_{11}h_{22}h_{12} \\
& - h_{12}^3) + (\alpha+\beta)\Big(2\Big(1+\frac{\alpha}{\beta}\Big)u^3 - \beta\Big(2+\frac{\alpha}{\beta}\Big)^2(v^1)^{\alpha/\beta}u^2\Big)(h_{11}h_{22}^2-h_{12}^2h_{22}) + (\alpha+\beta)h_2[(\alpha+2\beta) \\
& \times (h_{11}h_{12}+(v^1v^2v^3)^{\alpha/\beta}h_{22}^2) + ((v^1v^2)^{\alpha/\beta}+(v^1v^3)^{\alpha/\beta}+(v^2v^3)^{\alpha/\beta})h_{12}h_{22} + ((\alpha+\beta)((v^1)^{\alpha/\beta} \\
& + (v^2)^{\alpha/\beta}+(v^3)^{\alpha/\beta}) - (2\alpha+\beta)((v^1)^{\alpha/\beta})h_{11}h_{22} + (\beta((v^1)^{\alpha/\beta}+(v^2)^{\alpha/\beta}+(v^3)^{\alpha/\beta}) + (2\alpha+\beta) \\
& \times (v^1)^{\alpha/\beta})h_{12}^2)]\Big]
\end{aligned}$$

and

$$\begin{aligned}
N_{12}^1 = {} & \beta^2(v^1)^2v^2((v^1)^{\alpha/\beta}-(v^2)^{\alpha/\beta})\Big[\Big(2+\frac{\alpha}{\beta}\Big)(\alpha u^2 - 2\beta(v^1)^{\alpha/\beta}u^1)(h_{11}h_{22}h_{12}-h_{12}^3) + 2\beta^2u^1(h_{11}h_{12}^2 \\
& - h_{11}^2h_{22}) + \Big(\Big(2+\frac{\alpha}{\beta}\Big)(\alpha-2\beta)(v^1)^{\alpha/\beta}u^2 - 2(\alpha+\beta)\Big(1+\frac{\alpha}{\beta}\Big)u^3\Big)(h_{12}^2h_{22}-h_{22}^2h_{11})\Big] \\
& - \beta(\alpha+\beta)h_2v^2\Big[(v^1v^2)^{\alpha/\beta}\Big(2(\alpha+\beta)\Big(1+\frac{\alpha}{\beta}\Big)u^3 + (\alpha+2\beta)((v^2)^{\alpha/\beta}-(v^1)^{\alpha/\beta})(v^1)^{2+\alpha/\beta}\Big)h_{22}^2 \\
& + \Big(-\alpha(v^1)^{\alpha/\beta}\Big(-\Big(2+\frac{\alpha}{\beta}\Big)u^2 - 2(v^2)^{\alpha/\beta}u^1 + 2((v^1)^{\alpha/\beta}-(v^2)^{\alpha/\beta})(v^1)^2\Big) + \beta\Big(\Big(2+\frac{\alpha}{\beta}\Big) \\
& \times ((v^1)^{\alpha/\beta}+(v^2)^{\alpha/\beta})u^2 + 2(v^1v^2)^{\alpha/\beta}u^1 + 2\Big(1+\frac{\alpha}{\beta}\Big)u^3 + (v^1)^{2+\alpha/\beta}(2(v^2)^{\alpha/\beta}-3(v^1)^{\alpha/\beta}) \\
& + (v^2)^{\alpha/\beta}(v^1)^2\Big)\Big)h_{12}^2 + 2\beta u^1h_{11}^2 + \Big(2((\alpha+\beta)(v^1)^{\alpha/\beta}+\beta(v^2)^{\alpha/\beta})u^1 + \beta\Big(2+\frac{\alpha}{\beta}\Big)(((v^2)^{\alpha/\beta} \\
& - (v^1)^{\alpha/\beta}(v^1)^2+u^2)\Big)h_{11}h_{12} + \Big(2\Big(1+\frac{\alpha}{\beta}\Big)((\alpha+\beta)(v^1)^{\alpha/\beta}+\beta(v^2)^{\alpha/\beta})u^3 + \Big(2+\frac{\alpha}{\beta}\Big) \\
& \times (v^1)^{\alpha/\beta}(2(v^2)^{\alpha/\beta}(\alpha+\beta)u^3 + \beta(2(v^2)^{2\alpha/\beta}-(v^1)^{2\alpha/\beta}-(v^1v^2)^{\alpha/\beta})(v^1)^2)\Big)h_{12}h_{22}\Big] - (\alpha
\end{aligned}$$

$$+\beta)^2 h_2 v^2[((\alpha-\beta)(v^1)^{\alpha/\beta}+\beta(v^2)^{\alpha/\beta})h_{11}+((\alpha+\beta)(v^2)^{\alpha/\beta}-\beta(v^1)^{\alpha/\beta})(v^1v^2)^{\alpha/\beta}h_{22}$$
$$+(2\alpha(v^1v^2)^{\alpha/\beta}+\beta((v^2)^{2\alpha/\beta}-(v^1)^{2\alpha/\beta}))h_{12}],$$

which were obtained using the integrability conditions (4). Notice that, since (17) is invariant under permutations of v's, it is sufficient to specify N^1_{23} and N^1_{12} only. We emphasize that these expressions do not explicitly depend on the size n of the reduction (17): this dependence is hidden in the variables u^1,u^2,u^3. The vanishing of the Haantjes tensor (3) is now a straightforward algebraic calculation.

Thus, for the Hamiltonian densities $h(u^1,u^2)$ which satisfy the integrability conditions (4), the corresponding hydrodynamic chains possess diagonalizable n-component reductions (17) for any value of n. According to the results of Ref. 3, this implies that the full Haantjes tensor of the Hamiltonian chain vanishes identically.

V. CONSERVATION LAWS

For any Hamiltonian density $h(u^1,u^2)$ the system (1) necessarily possesses two conservation laws, namely,

$$u^1_t=(2\beta u^1h_1+(\alpha+2\beta)u^2h_2-\beta h)_x$$

and

$$h_t=((\alpha+\beta)u^3h_2^2+(\alpha+2\beta)u^2h_1h_2+\beta u^1h_1^2)_x,$$

which correspond to the conservation of the momentum and the Hamiltonian, respectively. Let us require that there exists an "extra" conservation law of the form

$$p(u^1,u^2,u^3)_t=q(u^1,u^2,u^3,u^4)_x. \tag{18}$$

Theorem 2: *The integrability conditions* (4) *are necessary and sufficient for the existence of an additional conservation law of the form* (18).

The proof is computational: substituting in for u^1_t,u^2_t,u^3_t,u^4_t into the left-hand side of (18), we collect coefficients at $u^1_x,\ldots,u^4_x$ and equate them to zero. This results in a system of first-order partial differential equations for the flux q,

$$q_1=(3\alpha+2\beta)u^4p_3h_{12}+(\alpha+2\beta)u^2(p_1h_{12}+p_2h_{11})+2(\alpha+\beta)u^3(p_3h_{11}+p_2h_{12})$$
$$+\beta h_1p_1+2\beta u^1p_1h_{11},$$

$$q_2=(3\alpha+2\beta)u^4h_{22}p_3+(\alpha+\beta)(2u^3(h_{12}p_3+h_{22}p_2)+h_2p_1)+(\alpha u^2p_2+2\beta(u^1p_1+u^2p_2))h_{12}$$
$$+u^2(\alpha+2\beta)p_1h_{22}+\beta h_1p_2,$$

$$q_3=\beta h_1p_3+(\alpha+\beta)h_2p_2,$$

$$q_4=(\alpha+\beta)h_2p_3.$$

Calculating the consistency conditions for the flux, $q_{ij}=q_{ji}$, we obtain all second-order partial derivatives of the density p,

$$p_{11}=\frac{2(2\alpha+\beta)((\alpha+\beta)u^3h_{12}^2+\beta u^1h_{11}^2)p_3+(2(2\alpha^2+5\alpha\beta+2\beta^2)u^2h_{12}p_3+(\alpha+\beta)^2p_2h_2)h_{11}}{(\alpha+\beta)^2h_2^2},$$

$$p_{12}=\frac{(\alpha+\beta)^2h_2h_{12}p_2+(2\alpha+\beta)(2\beta u^1h_{12}h_{11}+(\alpha+\beta)(2u^3h_{22}h_{12}+h_2h_{11}))p_3}{(\alpha+\beta)^2h_2^2}$$
$$+\frac{(2\alpha^2+5\alpha\beta+2\beta^2)u^2(h_{12}^2+h_{22}h_{11})p_3}{(\alpha+\beta)^2h_2^2},$$

$$p_{22}=\frac{(2\alpha+\beta)((\alpha+\beta)(2u^3p_3h_{22}^2+2h_{12}h_2p_3)+2((\alpha+2\beta)u^2h_{22}+\beta u^1h_{12})p_3h_{12})+(\alpha+\beta)^2h_{22}h_2p_2}{(\alpha+\beta)^2h_2},$$

$$p_{13}=\frac{(2\alpha+\beta)h_{12}p_3}{(\alpha+\beta)h_2},$$

$$p_{23}=\frac{(2\alpha+\beta)h_{22}p_3}{(\alpha+\beta)h_2},$$

$$p_{33}=0.$$

These equations imply, in particular, that p is linear in u^3, and q is linear in u^4. Upon imposing the consistency condition $(p_{ij})_k=(p_{ik})_j$ we get a system of third-order partial differential equations for the density $h(u^1,u^2)$, which is identical to (4). This finishes the proof.

We will demonstrate in Sec. VI that Eq. (4) imply the existence of a generating function for conservation laws. Thus, we can claim that the existence of one additional conservation law is already very restrictive and implies the existence of an infinity of conservation laws, thus manifesting the integrability.

Remark: Taking $p(u^1,u^2,u^3)$ defined by the above equations as a Hamiltonian density, one obtains a system (1) which commutes with the Hamiltonian system defined by the density $h(u^1,u^2)$, and also has the identically vanishing Haantjes tensor. We emphasize that the densities $p(u^1,u^2,u^3)$ arising in this way are necessarily linear in u^3. One can formulate a natural question: describe all Hamiltonian densities of the form $p(u^1,u^2,u^3)$ such that the associated chain (1) has the vanishing Haantjes tensor. A detailed analysis of this problem leads to the two possibilities: (i) the density p is linear in u^3. In this case one can show the existence of a lower order commuting flow with the Hamiltonian density $h(u^1,u^2)$, which brings us back to the situation discussed earlier.

(ii) The density p is such that the quantity $2\beta u^1p_1+(\alpha+2\beta)u^2p_2+2(\alpha+\beta)u^3p_3-\beta p$ is a function of the first coordinate u^1 only. In this case the first equation of the chain,

$$u_t^1=(2\beta u^1p_1+(\alpha+2\beta)u^2p_2+2(\alpha+\beta)u^3p_3-\beta p)_x,$$

decouples from the rest. The general form of all such densities is

$$p=\sqrt{u^1}F(u^2(u^1)^{-(\alpha+2\beta)/2\beta},u^3(u^1)^{-(\alpha+\beta)/\beta})+f(u^1),$$

where F and f are arbitrary functions. This result shows that, essentially, there exist no nontrivial "genuine" integrable densities of the form $p(u^1,u^2,u^3)$.

VI. GENERATING FUNCTIONS FOR CONSERVATION LAWS

The structure of reductions (17) suggests that one should seek a generating function for conservation laws in the form

$$\lambda=\lambda(p,u^1,u^2,u^3,\dots) \tag{19}$$

so that the following Gibbons-type relation holds:

$$\lambda_t - \beta(h_1 + (1+\alpha/\beta)p^{\alpha/\beta}h_2)\lambda_x = \lambda_p(p_t - \beta(ph_1 + p^{1+\alpha/\beta}h_2)_x); \tag{20}$$

this relation is required to be satisfied identically modulo (1). We will demonstrate the existence of a generating function of this form for any Hamiltonian density satisfying the integrability conditions (4). Suppose the relation (20) is already established. Then, setting $\lambda=\text{const}$, one has $\lambda_t=\lambda_x=0$, so that the relation (20) takes the form

$$p_t - \beta(ph_1 + p^{1+\alpha/\beta}h_2)_x = 0.$$

This provides an infinite sequence of conserved densities after one expands p as a series in λ by virtue of (19). The method of generating functions is standard, and can be traced back to, Refs. 1, 4, 9, and 10 see also Ref. 12 for recent developments. A detailed analysis of the relation (20) reveals that the dependence of λ on u^2,u^3,u^4, etc., is fixed uniquely,

$$\lambda = \sum_{k=2}^{\infty} q^{1-2\beta/\alpha-k}u^k + s(u^1,q), \quad q = p^{\alpha/\beta}, \tag{21}$$

while the function $s(u^1,q)$, which specifies the dependence of λ on u^1, satisfies

$$s_1 = q^{-1-2\beta/\alpha}F, \quad s_q = \frac{1}{\alpha}q^{-1-2\beta/\alpha}G. \tag{22}$$

Here F and G are the following rational expressions in q depending on the Hamiltonian density h:

$$F = \frac{(h_{11}+qh_{12})((\alpha+\beta)qh_2 - (\alpha+2\beta)u^2h_{12}) + (\alpha+2\beta)u^2h_{11}(h_{12}+qh_{22})}{(\alpha+\beta)h_2[q^2h_{22}+2qh_{12}+h_{11}] + (2\beta u^1q - (\alpha+2\beta)u^2)[h_{12}^2 - h_{11}h_{22}]},$$

$$G = \frac{(\alpha+\beta)^2qh_2 + 2\beta(\alpha+2\beta)u^1u^2(h_{12}^2 - h_{11}h_{22}) + (\alpha+\beta)h_2[(\alpha+2\beta)qu^2h_{22} - 2\beta u^1h_{11}]}{(\alpha+\beta)h_2[q^2h_{22}+2qh_{12}+h_{11}] + (2\beta u^1q - (\alpha+2\beta)u^2)[h_{12}^2 - h_{11}h_{22}]}.$$

With the ansatz (21), all terms in (20) containing $p_t,p_x,u_x^3,u_x^4,\ldots$, cancel identically, while the requirement of cancellation of coefficients at u_x^1 and u_x^2 results in (22). The functions F and G satisfy the relations

$$F_2 = 0, \quad G_2 = 0, \quad G_1 = \alpha F_q - (\alpha+2\beta)F/q, \tag{23}$$

which are the consistency conditions of Eq. (22). These relations are satisfied identically modulo the integrability conditions (4). Conversely, relations (23) imply the integrability conditions (4). Notice that, although the variable u^2 is seemingly present in the expressions for F and G, the right-hand sides of (22) do not depend on u^2. For each of the cases arising in the classification in Sec. III, Eq. (22) for $s(u^1,q)$ can be solved explicitly. Thus, the generating function λ can be reconstructed in closed form. This is mainly due to a simple dependence of the derivative s_q on q: integrating it with respect to q we obtain a closed form expression which, in most of the cases, automatically solves the equation for s_1. We consider the canonical forms (6)–(15) case by case in the following.

A. Generating functions in the general case: Densities (6)–(8)

For the Hamiltonian density (6) the function $s(u^1,q)$ is given by

$$s(u^1,q)=\frac{\beta^2 q^{1-2\beta/\alpha}((u^1)^2-c^2)^{-\alpha/\beta}}{4abc^2(\alpha^2-4\beta^2)}\left[a(u^1-c)^2(u^1+c)^{\alpha/\beta}F\left(\frac{\beta q(u^1-c)^{-\alpha/\beta}}{2bc(\alpha+2\beta)}\right)\right.$$
$$\left.+b(u^1-c)^{\alpha/\beta}(u^1+c)^2F\left(-\frac{\beta q(u^1+c)^{-\alpha/\beta}}{2ac(\alpha+2\beta)}\right)\right]+q^{-2\beta/\alpha}u^1;$$

here $F(t)={}_2F_1(1-2\beta/\alpha,1,2-2\beta/\alpha,t)$ is the hypergeometric function of Gauss. In the case (7) one has

$$s(u^1,q)=\frac{\beta^2 q^{1-2\beta/\alpha}(u^1-c)^{2-\alpha/\beta}}{4ac^2(\alpha^2-4\beta^2)}F\left(\frac{\beta q(u^1-c)^{-\alpha/\beta}}{2ac(\alpha+2\beta)}\right)+q^{-2\beta/\alpha}u^1;$$

here F is the same hypergeometric function as above. Finally, the case of (8) leads to

$$s(u^1,q)=\left(u^1+\frac{\alpha+\beta}{2c(\alpha-2\beta)}q\right)q^{-2\beta/\alpha}. \tag{24}$$

B. Generating functions in the case $\beta=0$: Densities (9)–(11)

Here the relation (20) takes the form

$$\lambda_t-e^p h_2\lambda_x=\lambda_p(p_t-(h_1+e^p h_2)_x)$$

where

$$\lambda=\sum_{k=2}^{\infty}q^{1-k}u^k+s(u^1,q),\quad q=e^p.$$

The function $s(u^1,q)$ satisfies

$$s_1=\frac{h_2(h_{11}+qh_{12})+u^2(h_{11}h_{22}-h_{12}^2)}{h_2h_{11}+u^2(h_{11}h_{22}-h_{12}^2)+2qh_2h_{12}+q^2h_2h_{22}},$$

$$s_q=\frac{h_2(u^2h_{22}+h_2)}{h_2h_{11}+u^2(h_{11}h_{22}-h_{12}^2)+2qh_2h_{12}+q^2h_2h_{22}},$$

which are consistent and define $s(u^1,q)$ explicitly: for the Hamiltonian density (9) one has

$$s(u^1,q)=\frac{1}{\sqrt{c}}\operatorname{arctanh}\left(\frac{q+f'}{\sqrt{c}f}\right);$$

recall that $f''=cf$. The density (10) leads to

$$s(u^1,q)=\frac{1}{2}u^1+\frac{1}{2c}\log(2ce^{cu^1}+q).$$

The density (11) gives

$$s(u^1,q)=u^1+q/2c;$$

notice that this expression can be obtained from (24) by setting $\beta=0$.

C. Generating functions in the case $\alpha+2\beta=0$: Densities (12)–(15)

Here the relation (20) takes the form (set $\beta=1,\alpha=-2$):

$$\lambda_t - (h_1 - p^{-2}h_2)\lambda_x = \lambda_p(p_t - (h_1 p + p^{-1}h_2)_x),$$

where

$$\lambda = \sum_{k=2}^{\infty} q^{2-k}u^k + s(u^1,q), \quad q = p^{-2}.$$

The function $s(u^1,q)$ satisfies

$$s_1 = -qh_2 \frac{h_{11} + qh_{12}}{(h_{11} + qh_{12})(2u^1 h_{12} - h_2) - (h_{12} + qh_{22})(2u^1 h_{11} + qh_2)},$$

$$s_q = -\frac{h_2}{2} \frac{2u^1 h_{11} + qh_2}{(h_{11} + qh_{12})(2u^1 h_{12} - h_2) - (h_{12} + qh_{22})(2u^1 h_{11} + qh_2)},$$

which are consistent and define $s(u^1,q)$ explicitly: for the Hamiltonian density (12) one has

$$s(u^1,q) = -\frac{b \operatorname{arctanh}\left(\frac{cu^1}{\sqrt{1+b^2}}\right)}{2\sqrt{1+b^2}} + \frac{b \operatorname{arctanh}\left(\frac{2q(1+b^2-c^2(u^1)^2)^2 - cb(b-cu^1)^2 - cb + 2c^2u^1}{c\sqrt{1+b^2}(1+(b-cu^1)^2)}\right)}{4\sqrt{1+b^2}}$$
$$+ \frac{1}{8}\log[-4cbq(1+b^2) + 4q^2(1+b^2)^2 - 4c^3bq(u^1)^2 + 4c^4q^2(u^1)^4 - c^2 + 8c^2qu^1(1+b^2)(1 - qu^1)].$$

The density (13) leads to

$$s(u^1,q) = \frac{1}{4c}q(u^1+c)^2 + \frac{b}{2}[1 - \log(q(u^1-c)^2 + 2cb)].$$

In the case of (14) one has

$$s(u^1,q) = qu^1 + \frac{1}{8c}q^2(u^1)^4.$$

Finally, the case of (15) gives

$$s(u^1,q) = qu^1 + \frac{1}{8c}q^2;$$

this follows from (24) when $\beta=1, \alpha=-2$.

We point out that the case $\alpha=0$ requires a special treatment: it corresponds to the chains which possess linearly degenerate hydrodynamic reductions. The approach of generating functions does not apply to this class, see, e.g., Ref. 11 for a discussion of a particular example of this type.

VII. CONCLUDING REMARKS

There exists a whole variety of approaches to the classification of integrable Hamiltonian hydrodynamic chains, based on seemingly different requirements, namely:

(1) the vanishing of the Haantjes tensor;
(2) the existence of infinitely many n-component hydrodynamic reductions for any n;
(3) the existence of one "extra" conservation law.
(4) the existence of a generating function for conservation laws.

All examples known to us support the evidence that these approaches are essentially equivalent, leading to the same integrability conditions and classification results. Among others, the approach based on the Haantjes tensor seems to be the most universal, leading to the required integrability conditions in a straightforward way. We emphasize that components of the Haantjes tensor can be calculated using computer algebra. Moreover, the vanishing of the first few components H^1_{jk} is already sufficiently restrictive and implies the identical vanishing of the Haantjes tensor.

It should be pointed out that, at present, there is no hope to *prove* the equivalence of the above listed approaches in the full generality: one first needs a classification of infinite-dimensional Poisson brackets of hydrodynamic type, which is an interesting and nontrivial problem on its own.[14] Some approaches in this direction were outlined recently in Ref. 12.

The inverse problem in the calculus of variations for a given set of second-order ordinary differential equations consists of deciding whether their solutions are those of Euler–Lagrange equations and whether the Lagrangian, if it exists, is unique. This paper discusses the exterior differential systems approach to this problem. In particular, it proposes an algorithmic procedure towards the construction of a certain differential ideal. The emphasis is not so much on obtaining a complete set of integrability conditions for the problem, but rather on producing a minimal set to expedite the differential ideal process. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2358000]

I. INTRODUCTION: THE INVERSE PROBLEM IN THE CALCULUS OF VARIATIONS

The inverse problem in the calculus of variations involves deciding whether for a given system of second-order ordinary differential equations,

$$\ddot{x}^a = F^a(t,x^b\dot{x}^b), \quad a,b = 1,\ldots,n,$$

a so-called multiplier matrix $g_{ab}(t,x^c,\dot{x}^c)$ can be found, such that

$$g_{ab}(\ddot{x}^b - F^b) \equiv \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{x}^a}\right) - \frac{\partial L}{\partial x^a},$$

for some Lagrangian function $L(t,x^b,\dot{x}^b)$, and to what extent such a multiplier, if it exists, is unique. Necessary and sufficient conditions for the existence of a Lagrangian are generally referred to as the *Helmholtz conditions*, but have been formulated in the literature in a variety of different ways. When regarded as conditions that a nonsingular multiplier must satisfy, a concise description of the Helmholtz conditions was derived by Douglas[6] and later recast in the following form by Sarlet:[14]

$$g_{ab} = g_{ba}, \quad \Gamma(g_{ab}) = g_{ac}\Gamma^c_b + g_{bc}\Gamma^c_a, \quad g_{ac}\Phi^c_b = g_{bc}\Phi^c_a, \quad \frac{\partial g_{ab}}{\partial \dot{x}^c} = \frac{\partial g_{ac}}{\partial \dot{x}^b}, \tag{1}$$

where

[a)]Electronic mail: J.Aldridge@latrobe.edu.au, G.Prince@latrobe.edu.au
[b)]Electronic mail: Willy.Sarlet@Ugent.be
[c)]Electronic mail: Thompson@math.utoledo.edu

$$\Gamma^a_b := -\frac{1}{2}\frac{\partial F^a}{\partial \dot{x}^b}, \quad \Phi^a_b := -\frac{\partial F^a}{\partial x^b} - \Gamma^c_b\Gamma^a_c - \Gamma(\Gamma^a_b),$$

and where

$$\Gamma := \frac{\partial}{\partial t} + \dot{x}^a\frac{\partial}{\partial x^a} + F^a\frac{\partial}{\partial \dot{x}^a}.$$

Douglas solved this problem for $n=2$ in the sense that he exhaustively classified all second-order ODEs according to the existence and multiplicity of solutions of the Helmholtz conditions. He did this essentially via the Jordan normal forms of the matrix Φ^a_b. The corresponding solution for $n=3$ remains unavailable although various subcases for arbitrary n have been elaborated.[5,15] Our principal purpose in this paper is to explore one of the key aspects in the analysis of the inverse problem using Exterior Differential Systems theory (EDS). The general structure of the EDS approach was set out in Anderson and Thompson,[2] although these authors only examined the case of arbitrary n when Φ is a multiple of the identity. As we will demonstrate, progress using EDS almost certainly relies on explicit use of the Jordan normal forms of Φ. This is the approach taken in the thesis.[1] The aspect that we will examine in detail is the so-called differential ideal step, in which there is an algorithmic search for the largest submodule of a certain module of 2-forms generating a differential ideal. We will explore the relation of this step to the hierarchies of integrability conditions for the Helmholtz conditions known in the literature. Importantly, we will expose the details of this step in the case where Φ is diagonalizable with distinct eigenfunctions. We give a nontrivial, three-dimensional example of the step and the way in which it leads directly to a solution of the Helmholtz conditions. A subsequent paper will deal with the remaining steps in the EDS process, and we will give a complete solution of a whole class of equations in the sense of Douglas.

We now outline the geometrical framework upon which progress over the last two or three decades has depended. In geometric terms, Γ is a second-order vector field (SODE) on the first-jet extension J^1E of a bundle $E\to\mathbb{R}$. For all practical purposes, E can be identified (choosing a "trivialization") with a product manifold $\mathbb{R}\times M$, and then $J^1E\equiv\mathbb{R}\times TM$. We shall denote adapted coordinates on $\mathbb{R}\times TM$ by (t,x^a,u^a) from now on, and use π for the projection $\mathbb{R}\times TM\to\mathbb{R}\times M$.

Every SODE equips $\mathbb{R}\times TM$ with a (nonlinear) connection, the connection coefficients being the functions Γ^a_b just introduced. As a result, an adapted local frame for decomposing arbitrary vector fields on $\mathbb{R}\times TM$ into their "horizontal" and "vertical" parts is given by $\{\Gamma,H_a,V_a\}$, where

$$H_a := \frac{\partial}{\partial x^a} - \Gamma^b_a\frac{\partial}{\partial u^b}, \quad V_a := \frac{\partial}{\partial u^a}.$$

The dual basis of 1-forms is given by $\{dt,\theta^a,\psi^a\}$, with

$$\theta^a := dx^a - u^a\,dt, \quad \psi^a := du^a - F^a\,dt + \Gamma^a_b\theta^b.$$

For a given regular Lagrangian function $L\in C^\infty(J^1E)$, we define the Poincaré-Cartan 1-form θ_L by

$$\theta_{\mathrm{L}} := L\,dt + dL\circ S = L\,dt + \frac{\partial L}{\partial u^a}\theta^a,$$

where $S=V_a\otimes dx^a$ is the vertical endomorphism, and the Euler-Lagrange equations come from the unique SODE, determined by (see, e.g., Goldschmidt and Sternberg[8])

$$i_\Gamma d\theta_{\mathrm{L}} = 0 \quad \text{and} \quad dt(\Gamma) = 1.$$

Inspired by the properties of the Poincaré-Cartan 2-form $d\theta_{\mathrm{L}}$, the following theorem from Ref. 4 gives a geometric version of the Helmholtz conditions.

Theorem 1.1: *Given a* SODE Γ, *the necessary and sufficient conditions for there to be a*

Lagrangian for which Γ *is the Euler-Lagrange field is that there should exist a 2-form* Ω, *of maximal rank, which further has the following properties:* Ω *vanishes on any two vertical vector fields,* $\Gamma \lrcorner \Omega = 0$ *and* $d\Omega = 0$.

Observe that the third and fourth conditions imply that $\mathcal{L}_\Gamma \Omega = 0$, and the first condition means that Ω has a one-dimensional kernel, which, as shown by the third condition, is spanned by Γ. Another important observation is that Ω, which if it exists, will become the Poincaré-Cartan 2-form $d\theta_{\mathrm{L}}$ of the corresponding Lagrangian, then has the following particularly simple representation in the adapted frame $\{dt, \theta^a, \psi^a\}$,

$$d\theta_{\mathrm{L}} = g_{ab}\psi^a \wedge \theta^b, \quad \text{with } g_{ab} = \frac{\partial^2 L}{\partial u^a \, \partial u^b}.$$

There are a number of geometrical ways of expressing this feature, one of which requires a brief discussion of the calculus of vector fields and forms along the projection π (see Ref. 17, or 11 for a slightly different approach).

Vector fields along π are sections of the pullback bundle $\pi^* TE$ over J^1E, and we let $\mathfrak{X}(\pi)$ denote the $C^\infty(J^1E)$ module of such vector fields. Similarly, $\wedge(\pi)$ denotes the graded algebra of forms along π. There is a canonical vector field along π, given by

$$\mathbf{T} := \frac{\partial}{\partial t} + u^a \frac{\partial}{\partial x^a}.$$

The natural bases for $\mathfrak{X}(\pi)$ and $\mathfrak{X}^*(\pi)$ are then $\{\mathbf{T}, \partial/\partial x^a\}$ and $\{dt, \theta^a\}$. We further write $\bar{\mathfrak{X}}(\pi)$ for the elements of $\mathfrak{X}(\pi)$ that have no time component, i.e., $\bar{\mathfrak{X}}(\pi) = \mathrm{Sp}\{\partial/\partial x^a\}$. Then, if

$$X := X^0 \mathbf{T} + X^a \frac{\partial}{\partial x^a}$$

is an arbitrary vector field along π, its horizontal and vertical lift give vector fields on J^1E, respectively, given by

$$X^H := X^0 \Gamma + X^a H_a, \quad X^V := X^a V_a.$$

In what follows, we will almost exclusively have to deal with horizontal and vertical lifts of vector fields along π that belong to the submodule $\bar{\mathfrak{X}}(\pi)$. So, in referring to vector fields on J^1E of the form $X^V, Y^H, \ldots$, it will be understood that $X, Y, \ldots$, belong to $\bar{\mathfrak{X}}(\pi)$. This is important, because it means that all the essential formulas are formally those of the time-independent calculus developed in Refs. 12 and 13, rather than the corresponding ones in Ref. 17. In particular, we will frequently use the commutator relations:

$$[X^V, Y^V] = (\mathrm{D}_X^V Y - \mathrm{D}_Y^V X)^V,$$

$$[X^H, Y^V] = (\mathrm{D}_X^H Y)^V - (\mathrm{D}_Y^V X)^H,$$

$$[X^H, Y^H] = (\mathrm{D}_X^H Y - \mathrm{D}_Y^H X)^H + R(X, Y)^V.$$

Here, D_X^V and D_X^H, the vertical and horizontal covariant derivative operators, are degree zero derivations on scalar and vector-valued forms along π, determined by $\mathrm{D}_X^H F = X^H(F)$, $\mathrm{D}_X^V F = X^V(F)$ for their action on functions $F \in C^\infty(J^1E)$:

$$\mathrm{D}_X^H \frac{\partial}{\partial x^a} = X^b \Gamma^c_{ba} \frac{\partial}{\partial x^c}, \quad \mathrm{D}_X^V \frac{\partial}{\partial x^a} = 0$$

(with $\Gamma^c_{ba} = \partial \Gamma^c_a / \partial u^b$), gives the action on $\bar{\mathfrak{X}}(\pi)$ and the standard duality rules give the action on 1-forms along π. The vector-valued 2-form R along π represents the curvature of the SODE connection with coordinate form,

$$R = \tfrac{1}{2} R^a_{bc} \theta^b \wedge \theta^c \otimes \frac{\partial}{\partial x^a}, \quad R^a_{bc} := H_c(\Gamma^a_b) - H_b(\Gamma^a_c).$$

We do not distinguish notationally the contact forms θ^a, as forms on J^1E from their counterparts along π. In fact, there is a dual process of lifting 1-forms along π giving (with an obvious slight abuse of notation),

$$\theta^{aH} = \theta^a, \quad \theta^{aV} = \psi^a.$$

The dynamical covariant derivative $\boldsymbol{\nabla}$ and the Jacobi endomorphism Φ that appear in (1) arise naturally through the following formulas:

$$[\Gamma, X^V] = -X^H + (\boldsymbol{\nabla} X)^V, \quad [\Gamma, X^H] = (\boldsymbol{\nabla} X)^H + \Phi(X)^V.$$

In coordinates,

$$\Phi = \Phi^a_b \frac{\partial}{\partial x^a} \otimes \theta^b,$$

with Φ^a_b as defined before, whereas $\boldsymbol{\nabla}$, defined to vanish on $\mathbf{T}$ and dually on dt, acts on $\bar{\mathfrak{X}}(\pi)$ (with dual action on contact forms) by

$$\boldsymbol{\nabla} F = \Gamma(F) \text{ on functions}, \quad \boldsymbol{\nabla} \frac{\partial}{\partial x^a} = \Gamma^b_a \frac{\partial}{\partial x^b}, \quad \boldsymbol{\nabla} \theta^a = -\Gamma^a_b \theta^b.$$

Now we can give the link we wanted between the geometric Helmholtz conditions of Theorem 1.1 with their coordinate form in (1). The observation we made about the simple structure of $d\theta_L$ in the adapted coframe means that the 2-form Ω on J^1E of Theorem 1.1 that we seek is completely determined by a symmetric type (0,2) tensor along π, of the form $g = g_{ab} \theta^a \otimes \theta^b$ (i.e., g vanishes on $\mathbf{T}$). To be precise, Ω is the so-called Kähler lift of g, $\Omega = g^K$, which vanishes on Γ and further is defined by

$$g^K(X^V, Y^V) = g^K(X^H, Y^H) = 0, \quad g^K(X^V, Y^H) = g(X, Y).$$

The intrinsic formulation of the conditions (1) (see Ref. 17, or 13 for the autonomous case) then reads as

$$\boldsymbol{\nabla} g = 0, \quad g(\Phi X, Y) = g(X, \Phi Y), \quad \mathrm{D}^V_X g(Y, Z) = \mathrm{D}^V_Y g(X, Z). \tag{2}$$

In the next section we briefly sketch the ideas of the exterior differential systems approach, specifically in the context of the inverse problem, and we identify our objectives concerning the construction of a differential ideal containing all possible two forms Ω.

II. EDS AND THE INVERSE PROBLEM

The inverse problem involves the search for a closed 2-form and so lends itself to analysis by EDS. For a general reference to EDS, we refer to Ref. 3. A thorough analysis of the inverse problem by means of such techniques (at least for autonomous differential equations) can be found in the work of Grifone and Muzsnay,[9,10] where the approach, however, starts from the partial differential equations that the Lagrangian itself has to satisfy, rather than equations such as (1) for the multiplier.

Anderson and Thompson in Ref. 2 describe the three components of the EDS process: finding a differential ideal, setting up a Pfaffian system for finding the closed 2-forms within that ideal, and finally analyzing this system, following the Cartan-Kähler theory to determine the generality of the solution (if any). We limit ourselves to a brief synopsis of the reasoning that underlies the first two steps here, with particular emphasis on the new elements involving the eigenspectrum of Φ that we want to bring to the differential ideal construction.

Given a SODE Γ, we know that the 2-form Ω we are looking for is going to be the Kähler lift of a symmetric $(0,2)$-tensor field g along the projection, i.e., $g=g_{ab}\theta^a\otimes\theta^b$, $g_{ab}=g_{ba}$. So we start by considering on J^1E the module Σ^0 of such Kähler lifts: intrinsically, ω belongs to Σ^0, if and only if

$$i_\Gamma\omega=0, \tag{3}$$

$$\omega(X^V,Y^V)=\omega(X^H,Y^H)=0, \tag{4}$$

$$\omega(X^V,Y^H)=\omega(Y^V,X^H). \tag{5}$$

(During the EDS process we will use lower case ω as the generic name for our 2-forms, reserving Ω for the 2-form of Theorem 1.1.) In coordinates, Σ^0 is spanned by the 2-forms

$$\omega^{ab}:=\frac{1}{2}(\psi^a\wedge\theta^b+\psi^b\wedge\theta^a). \tag{6}$$

Note however, that $\{dt,\theta^a,\psi^a\}$ may as well be any basis comprising of dt, n horizontal forms, and n vertical forms. In fact later we will use such a basis made up of the eigenforms of Φ.

The first step in the EDS approach produces from Σ^0 a sequence of submodules $\Sigma^0\supset\Sigma^1\supset\Sigma^2\supset\cdots$, arriving finally (or not at all) at a nontrivial submodule $\Sigma^l=\mathrm{Sp}\{\omega^k\}$ generating a differential ideal. Obtaining Σ^l consists of computing at each stage the exterior derivative of forms belonging to the submodule under consideration, and verifying whether they belong to the ideal generated by that submodule. In principle, whenever an obstruction is found, it is translated into a further restriction on the admissible 2-forms and the process is restarted from there. We shall be more specific about this in a moment. But, for the time being, assume that we have found $\Sigma^l=\mathrm{Sp}\{\omega^1,\ldots,\omega^d\}$, so that

$$d\omega^k=\xi^k_h\wedge\omega^h,\quad k=1,\ldots,d,$$

for some 1-forms ξ^k_h. In order to construct a closed 2-form in Σ^l we first identify a basis of d-tuples of 1-forms ρ^A_h such that $\rho^A_h\wedge\omega^h=0$. Then, if $r_k\omega^k\in\Sigma^l$ is required to be closed, the functions r_k must solve the Pfaffian system of equations (the notations are taken to conform with those in Ref. 2),

$$dr_k+r_h\xi^h_k+p_A\rho^A_k=0, \tag{7}$$

for some as yet arbitrary functions p_A. The freedom in the choice of p_A must then be exploited in the final part of the EDS procedure. This last part is by no means a straightforward matter; in fact, it is fair to say that it consists of several steps still and may even, if the involutivity test fails, lead to prolonging the system and starting again (see, e.g., Ref. 2 for a brief survey). We will argue in the final section that it may be better, therefore, to address the partial differential equations of the inverse problem in a more direct way, once the differential ideal procedure is complete. Our approach to specific examples should be contrasted with that of Anderson and Thompson,[2] who follow the formal EDS process.

Here are the details of the differential ideal process. At each step Σ^i, say, we will first identify the requirements for a 3-form ρ to be in $\langle\Sigma^i\rangle$, the ideal generated by Σ^i, because a large part of such an analysis does not depend on whether or not $\rho=d\omega\in\langle\Sigma^i\rangle$. Once we apply these requirements to such $d\omega$, the general formula,

$$d\omega(U,V,W) = \sum_{U,V,W} [U(\omega(V,W)) - \omega([U,V],W)], \tag{8}$$

(where a notation like $\Sigma_{\xi,\eta,\zeta}$ will always refer to a cyclic sum over the indicated arguments), produces algebraic restrictions on admissible 2-forms. If these are different from those already implemented, they are used to define the next submodule Σ^{i+1} in the sequence. But a couple of important remarks are in order here. First of all, the issue of algebraic conditions in the inverse problem is quite delicate. There are several infinite hierarchies of such conditions (see, e.g., Refs. 9 and 10), but it is impossible to tell in all generality which of these are more important, from which others possibly might follow, or simply which are more efficient in determining the existence or nonexistence of a multiplier. We therefore propose to integrate the decision about the usefulness of algebraic restrictions as much as possible into this differential ideal algorithm. That is to say, we shall attempt to obtain at each step in restricting to a submodule Σ^i, conditions for a 3-form ρ to belong to $\langle\Sigma^i\rangle$ which are both necessary and sufficient. It is, to some extent, the degree to which fresh conditions tend to be sufficient, which will guide the decision about the selection of further restrictions for defining the next submodule. It is precisely in this way that we will be able to push the EDS procedure beyond the level of results obtained in Ref. 2. However, as has always been the case in the study of the multiplier problem, there is no possibility of a general solution for an arbitrary dimension. At some point further progress relies on a classification of cases and subcases. Most notorious in this respect is the paper by Douglas[6] (see Ref. 16 for a geometrical account of Douglas' analysis). We should expect this to occur also in our current attempt.

III. THE FIRST STEP IN THE EDS ALGORITHM

Consider the module Σ^0, defined above, and let ρ be a 3-form in $\langle\Sigma^0\rangle$, so that $\rho=\beta_k\wedge\omega^k$ for some 1-forms β_k and $\omega^k\in\Sigma^0$. Then $i_\Gamma\rho=\beta_k(\Gamma)\omega^k$, so that $i_\Gamma\rho$ belongs to Σ^0 *if and only if*

$$\rho(\Gamma,X^V,Y^V) = 0, \tag{9}$$

$$\rho(\Gamma,X^H,Y^H) = 0, \tag{10}$$

$$\rho(\Gamma,X^V,Y^H) = \rho(\Gamma,Y^V,X^H). \tag{11}$$

Next, starting from the contraction of ρ with a vertical vector field,

$$i_{X^V}\rho = \beta_k(X^V)\omega^k - \beta_k\wedge i_{X^V}\omega^k,$$

we must have

$$\rho(X^V,Y^V,Z^V) = 0, \tag{12}$$

but how can we take other restrictions on Σ^0 into account, when further combinations of horizontal and vertical vector fields are inserted? For example, we can manipulate the right-hand side by using the properties of $\omega^k\in\Sigma^0$, until every appearance of the β_k has been eliminated and a condition about ρ emerges. We have

$$\begin{aligned}\rho(X^V,Y^V,Z^H) &= \beta_k(X^V)\omega^k(Y^V,Z^H) - \beta_k(Y^V)\omega^k(X^V,Z^H) = \beta_k(X^V)\omega^k(Z^V,Y^H) - \beta_k(Y^V)\omega^k(Z^V,X^H)\\ &= \rho(X^V,Z^V,Y^H) + \beta_k(Z^V)\omega^k(X^V,Y^H) - \beta_k(Y^V)\omega^k(Z^V,X^H) = \rho(X^V,Z^V,Y^H)\\ &\quad + \beta_k(Z^V)\omega^k(Y^V,X^H) - \beta_k(Y^V)\omega^k(Z^V,X^H) = \rho(X^V,Z^V,Y^H) + \rho(Z^V,Y^V,X^H).\end{aligned}$$

So it follows that ρ should satisfy

$$\sum_{X,Y,Z} \rho(X^V,Y^V,Z^H) = 0, \tag{13}$$

and in exactly the same way also

$$\sum_{X,Y,Z} \rho(X^V, Y^H, Z^H) = 0. \tag{14}$$

There remains the condition

$$\rho(X^H, Y^H, Z^H) = 0. \tag{15}$$

Details such as the way the cyclic sum condition (13) is obtained will not be repeated further on.

In total, we have obtained seven necessary conditions and, following the strategy deployed in the previous section, we now explore their sufficiency. But before we proceed, we remark that a number of the conditions to be encountered here, and in the subsequent sections, only have an effect when the number n of degrees of freedom of the system is at least 3. This is the case, for example, with the conditions (12) to (15), which are clearly void when $n=2$. As a result, each time a question of the sufficiency of conditions arises, we will say a few words about the case $n=2$. Besides, the case $n=2$ has been extensively studied already (see Refs. 6, 10, and 16) and therefore is not of prime interest for this paper.

Proposition 3.1: For an arbitrary 3-form ρ to belong to the ideal $\langle \Sigma^0 \rangle$, it is necessary and sufficient that ρ satisfies the conditions (9)–(15), where X, Y, Z are arbitrary vector fields along π.

Proof: It is easy to see that conditions (9)–(11) imply that ρ is of the form

$$\rho = dt \wedge \sigma + \bar{\rho}, \quad \text{with } \sigma \in \Sigma^0 \quad \text{and} \quad i_\Gamma \bar{\rho} = 0.$$

For $n \geq 3$, the remaining conditions then indicate that $\bar{\rho}$ is of the form

$$\bar{\rho} = \tfrac{1}{2} \mathcal{A}_{abc} \theta^a \wedge \psi^b \wedge \psi^c + \tfrac{1}{2} \mathcal{B}_{abc} \psi^a \wedge \theta^b \wedge \theta^c,$$

where $\mathcal{A}_{abc}$ and $\mathcal{B}_{abc}$ are skew-symmetric in their last two indices and satisfy [in view of (13) and (14)]

$$\sum_{abc} \mathcal{A}_{abc} = \sum_{abc} \mathcal{B}_{abc} = 0.$$

For $n=2$, $i_\Gamma \bar{\rho}=0$ is already enough to ensure that $\bar{\rho}$ is of the above form, but with two of the three indices the same. The skew symmetry of the coefficients in their last two indices then implies that they formally can be regarded as having this cyclic sum property as well.

The skew symmetry $\mathcal{A}_{abc}=-\mathcal{A}_{acb}$ and the cyclic sum property $\Sigma_{abc}\mathcal{A}_{abc}=0$ imply that

$$\begin{aligned}
\mathcal{A}_{abc} \theta^a \wedge \psi^b \wedge \psi^c &= \tfrac{1}{3} (\mathcal{A}_{abc} \theta^a \wedge \psi^b \wedge \psi^c + \mathcal{A}_{bca} \theta^b \wedge \psi^c \wedge \psi^a + \mathcal{A}_{cab} \theta^c \wedge \psi^a \wedge \psi^b) \\
&= \tfrac{1}{3} \mathcal{A}_{abc} (\psi^c \wedge \theta^a + \psi^a \wedge \theta^c) \wedge \psi^b - \tfrac{1}{3} \mathcal{A}_{bca} (\psi^c \wedge \theta^b + \psi^b \wedge \theta^c) \wedge \psi^a \\
&= -\tfrac{4}{3} \mathcal{A}_{abc} \omega^{ab} \wedge \psi^c,
\end{aligned}$$

where we have used the skew symmetry in the first and the cyclic sum property in the last term for the transition from the first to the second line. The same is also true for the other term in $\bar{\rho}$, so

$$\rho = dt \wedge \sigma - \tfrac{2}{3} \mathcal{A}_{abc} \omega^{ab} \wedge \psi^c + \tfrac{2}{3} \mathcal{B}_{abc} \omega^{ab} \wedge \theta^c, \tag{16}$$

or putting

$$A_{abc} = \mathcal{A}_{abc} + \mathcal{A}_{bac}, \quad B_{abc} = \mathcal{B}_{abc} + \mathcal{B}_{bac},$$

$$\rho = dt \wedge \sigma - \tfrac{1}{3} A_{abc} \omega^{ab} \wedge \psi^c + \tfrac{1}{3} B_{abc} \omega^{ab} \wedge \theta^c, \tag{17}$$

where the new coefficients now are symmetric in their first two indices and still have the cyclic sum property $\Sigma_{abc}A_{abc}=\Sigma_{abc}B_{abc}=0$. This manifestly exhibits that ρ belongs to $\langle \Sigma^0 \rangle$. □

Remark: An expression like $A_{abc}\omega^{ab} \wedge \psi^c$ with $A_{abc}=A_{bac}$ clearly belongs to $\langle \Sigma^0 \rangle$ without any further requirements. That the above necessary and sufficient conditions are not contradictory,

however, follows from the fact that one can assume that the coefficients further have the cyclic sum property without loss of generality. Verifying this is left to the reader.

From now on we will use the representation (17) of ρ.

To terminate the first step now, we apply the *necessary and sufficient conditions* (9)–(15) to an exact 3-form $d\omega$, for any $\omega \in \Sigma^0$ and use thereby the familiar identity (8). In doing that, only the second part that involves the Lie brackets can contribute; the list of bracket relations that are frequently used in these calculations has been given in Sec. I. It easily follows then that the conditions (9) and (11)–(14) are identically satisfied, whereas the remaining conditions (10) and (15) give rise to the following extra restrictions on admissible 2-forms (which are, in one form or another, well known in the literature):

$$\omega((\Phi X)^V, Y^H) = \omega((\Phi Y)^V, X^H), \tag{18}$$

$$\sum_{X,Y,Z} \omega(R(X,Y)^V, Z^H) = 0. \tag{19}$$

We could implement both of these new requirements to define the next submodule Σ^1, but it will be more convenient to continue in stages and start by implementing the Φ condition (18) only.

The first step has identified the structure of 3-forms in $\langle\Sigma^0\rangle$. When we apply the differential ideal algorithm to Σ^0 now, conditions on ρ that have Γ as one of the arguments will be easy to handle and merely impose that the 2-form σ in (17) belongs to the submodule under consideration. Other conditions must clearly come in pairs: for each condition that has two vertical and one horizontal argument and thus has an effect on the A part in ρ only, there will be a corresponding condition that has the "mirror" effect on the B part. The underlying reason for that is the basic symmetry property (5) of 2-forms in Σ^0, which makes that a condition like (18), for example, can equivalently be written in the form

$$\omega((\Phi X)^H, Y^V) = \omega((\Phi Y)^H, X^V). \tag{20}$$

Bearing this in mind avoids unnecessary duplications of conditions later on.

Finally, we examine the necessary and sufficient conditions that $\langle\Sigma^0\rangle$ is itself a differential ideal.

Theorem 3.2: *The module* Σ^0 *generates a differential ideal if and only* Φ *is a multiple of the identity*.

Proof: From the immediately preceding discussion, it follows that $\langle\Sigma^0\rangle$ is a differential ideal if and only if (18) and (19) are satisfied by all $\omega \in \Sigma^0$. If Φ is a multiple of the identity, the first of these is satisfied because of (5), and the second is true by virtue of the identity $V_a(\Phi^c_b) - V_b(\Phi^c_a) = 3R^c_{ab}$. Conversely, if (18) is true for all $\omega \in \Sigma^0$, then it is true for all ω^{ab} given by (6): using $X = \partial/\partial x^c$, $Y = \partial/\partial x^d$ yields

$$\Phi^a_c \delta^b_d + \Phi^b_c \delta^a_d = \Phi^a_d \delta^b_c + \Phi^b_d \delta^a_c.$$

Hence, $\Phi = \mu I$ and (19) follows automatically, again because of the stated identity. □

This is a stronger result than that obtained by Anderson and Thompson in Ref. 2, where it was shown that if Φ is a multiple of the identity then $\langle\Sigma^0\rangle$ is a differential ideal. Anderson and Thompson demonstrated that in this case the system is variational. However, in general there remain obstructions to variationality after a differential ideal has been obtained.

IV. A SECOND STEP IN THE PROCESS

We define Σ^1 to be the submodule of Σ^0 whose elements satisfy condition (18).

Let $\rho = \beta_k \wedge \omega^k$ be a 3-form in $\langle\Sigma^1\rangle$. Then, a contraction with Γ leads to the further restriction

$$\rho(\Gamma,(\Phi X)^V,Y^H)=\rho(\Gamma,(\Phi Y)^V,X^H), \tag{21}$$

which, as indicated before, says that σ in (17) must be in Σ^1 and plays further no role. When we take X^V as the first argument and follow the procedure that led to (13), but this time with $(\Phi Y)^V,Z^H$ as a further argument, we obtain

$$\sum_{X,Y,Z}(\rho(X^V,(\Phi Y)^V,Z^H)-\rho(X^V,(\Phi Z)^V,Y^H))=0.$$

But the left-hand side is $\Sigma_{X,Y,Z}(\rho(X^V,(\Phi Y)^V,Z^H)+\rho((\Phi Y)^V,Z^V,X^H))$ and then (13) gives the more transparent version

$$\sum_{X,Y,Z}\rho(X^V,Y^V,(\Phi Z)^H)=0. \tag{22}$$

Immediately we conclude that the "mirror" condition, which can, of course, independently be derived, will read as

$$\sum_{X,Y,Z}\rho(X^H,Y^H,(\Phi Z)^V)=0. \tag{23}$$

Unfortunately, this is not the end of the line, as there are other possible combinations of terms. For example, with $(\Phi X)^V$ as a first argument, rather than X^V,

$$i_{(\Phi X)^V}\rho=\beta_k((\Phi X)^V)\omega^k-\beta_k\wedge i_{(\Phi X)^V}\omega^k,$$

we can choose $(\Phi Y)^V,Z^H$ as second and third arguments. The by now familiar procedure of eliminating all terms involving the 1-forms β_k then leads to the new requirement

$$\sum_{X,Y,Z}\rho((\Phi X)^V,(\Phi Y)^V,Z^H)=0, \tag{24}$$

and its counterpart

$$\sum_{X,Y,Z}\rho((\Phi X)^H,(\Phi Y)^H,Z^V)=0. \tag{25}$$

We already reach a point here where it is difficult to say whether all such necessary conditions will generically be independent or whether perhaps there are still other ways of producing more conditions; hence our strategy to approximate, as best as possible, conditions that are also sufficient and demonstrate their utility in this way. So let us address the sufficiency question here.

Let ρ be of the form (17), where the A and B coefficients are symmetric in their first two indices and can, as argued before, without loss of generality be assumed to have the cyclic sum property $\Sigma_{abc}A_{abc}=\Sigma_{abc}B_{abc}=0$. The two conditions (22) and (24) affect only the A-term (23) and (25) will have the same sort of effect on the B term. Using a basis of horizontal and vertical vector fields, (H_i,V_j) say, we can compute the A-term of ρ acting on the triple $(V_r,V_t,\Phi_s^uH_u)$ and then take a cyclic sum over the indices (r,s,t). What remains (leaving out a numerical factor) is the following condition:

$$\sum_{rst}(A_{rut}-A_{tur})\Phi_s^u=0, \tag{26}$$

which, by recombining terms, can equivalently be written in the perhaps more appealing form

$$\sum_{rst}(A_{rut}\Phi_s^u-A_{sut}\Phi_r^u)=0. \tag{27}$$

Similarly, evaluating $\rho((\Phi X)^V,(\Phi Y)^V,Z^H)$ on $(\Phi_s^uV_u,\Phi_t^vV_v,H_r)$ and then taking the cyclic sum, the condition (24) is found to mean:

$$\sum_{rst} (A_{ruv} - A_{rvu})\Phi^u_s \Phi^v_t = 0. \tag{28}$$

Now, the 2-forms in Σ^1 we are talking about are of the form

$$\omega = h_{ab}\omega^{ab}, \quad \text{with} \quad h_{su}\Phi^u_r - h_{ru}\Phi^u_s = 0 \tag{29}$$

[we purposely avoid using g_{ab}, which we reserve for candidate multipliers satisfying (1)]. So the idea would be to prove that the requirements (26) [or (27)] and (28) force the functions A_{abc} to be of the form

$$A_{abc} = h_{ab}{}^k\, b_{kc}, \tag{30}$$

where, for each k, the $h_{ab}{}^k$ have the property (29) and the b_{kc} are arbitrary functions, representing the components of the 1-forms β_k in an expression like $\rho = \beta_k \wedge \omega^k$. Unfortunately, we were unable to prove that this is true in all generality, but we shall show now that it is a valid statement in an interesting (reasonably generic) special case.

As we know already from Douglas,[6] a classification into different cases where a multiplier g_{ab} for a given dynamics Γ does or does not exist, will largely be governed by properties of the Jacobi endomorphism Φ associated with Γ. A specific assumption about Φ that comes up in several situations (see, e.g., Ref. 5) is that of (algebraic) diagonalizability. So let us assume this, and that the (real) eigenvalues $\lambda_{(a)}$ are distinct, and let $\{\phi^a\}$ denote a complete set of eigenforms of Φ, so that

$$\Phi(\phi^a) = \lambda_{(a)}\phi^a \quad \text{(no sum)}.$$

These ϕ^a can be taken to be combinations of contact forms and are of course still semi-basic forms. We now have a new basis for $\mathfrak{X}(J^1E)$, namely $\{dt, \phi^{aH}, \phi^{aV}\}$ and new spanning 2-forms for Σ^0, namely,

$$\phi^{ab} := \tfrac{1}{2}(\phi^{aV} \wedge \phi^{bH} + \phi^{bV} \wedge \phi^{aH}).$$

It is important to realize that with this change of basis, nothing changes in our considerations of the first differential ideal step. For example, the 2-forms in Σ^0 are now of the form $\bar{h}_{ab}\phi^{ab}$ and 3-forms in the ideal $\langle\Sigma^0\rangle$ are of the form (17), with the ϕ^{aH} replacing the θ^a, and so on. Explicitly,

$$\rho = dt \wedge \sigma - \tfrac{1}{3}\bar{A}_{abc}\phi^{ab} \wedge \phi^{cV} + \tfrac{1}{3}\bar{B}_{abc}\phi^{ab} \wedge \phi^{cH}.$$

We will freely use the original basis formulas in the eigenform basis (and refer to their equation numbers) just by adding overbars and switching θ^a for ϕ^{aH} etc.

The additional restriction (18) that defines Σ^1, or equivalently (29), reduces to

$$(\lambda_{(b)} - \lambda_{(a)})\bar{h}_{ab} = 0, \tag{31}$$

and hence implies that the elements of Σ^1 must be diagonal in the eigenform basis, i.e., $\bar{h}_{ab}=0$ for $a \neq b$.

Proportion 4.1: Suppose that Φ *is diagonalizable with distinct (real) eigenvalues. Then, the necessary and sufficient conditions for a 3-form* ρ *to be in the ideal* $\langle\Sigma^1\rangle$ *are the conditions to be in* $\langle\Sigma^0\rangle$, *supplemented by* (21), (22), and (24), together with their counterparts (23) and (25).

Proof: What has to be proved is the sufficiency of the conditions. Using the eigenform basis of Φ, we already know that $\rho \in \langle\Sigma^0\rangle$ implies that it is of the form (17). The first extra condition (21) requires σ to belong to the smaller module Σ^1 now. As explained before, it suffices to study the effect of (22) and (24), or explicitly (26) and (28), on the A term in ρ. Under the present circumstances, this leads to the conditions

$$\sum_{abc} \bar{A}_{abc}(\lambda_{(a)} - \lambda_{(b)}) = 0, \tag{32}$$

$$\sum_{abc} \bar{A}_{abc}\lambda_{(c)}(\lambda_{(a)} - \lambda_{(b)}) = 0. \tag{33}$$

These conditions are identically satisfied whenever two of the indices are the same, so we begin by considering $n \geq 3$. For each set of three distinct indices, they produce, together with the given cyclic sum property, a homogeneous system of algebraic equations with coefficient matrix

$$\begin{pmatrix} 1 & 1 & 1 \\ \lambda_{(a)} - \lambda_{(b)} & \lambda_{(b)} - \lambda_{(c)} & \lambda_{(c)} - \lambda_{(a)} \\ \lambda_{(c)}(\lambda_{(a)} - \lambda_{(b)}) & \lambda_{(a)}(\lambda_{(b)} - \lambda_{(c)}) & \lambda_{(b)}(\lambda_{(c)} - \lambda_{(a)}) \end{pmatrix}.$$

The determinant of this matrix is proportional to $(\lambda_{(a)}-\lambda_{(b)})(\lambda_{(b)}-\lambda_{(c)})(\lambda_{(c)}-\lambda_{(a)})$ and hence is nonzero. Therefore, all $\bar{A}_{abc}$ with distinct indices must be zero. It further follows from the cyclic sum property that $\bar{A}_{aab}=-2\bar{A}_{baa}$. With these data, the A term of ρ becomes

$$\begin{aligned} -\tfrac{1}{3}\bar{A}_{abc}\phi^{ab} \wedge \phi^{cV} &= -\tfrac{1}{3}\left(\sum_{a\neq b} \bar{A}_{aab}\phi^{aa} \wedge \phi^{bV} + 2\sum_{a\neq b} \bar{A}_{baa}\phi^{ab} \wedge \phi^{aV} \right) \\ &= -\tfrac{1}{3}\left(\sum_{a\neq b} \bar{A}_{aab}\phi^{aa} \wedge \phi^{bV} - \sum_{a\neq b} \bar{A}_{aab}\phi^{ab} \wedge \phi^{aV} \right) = -\tfrac{1}{2}\sum_{a\neq b} \bar{A}_{aab}\phi^{aa} \wedge \phi^{bV}, \end{aligned}$$

where we have used the fact that $\phi^{ab}\wedge\phi^{aV}=-\frac{1}{2}\phi^{aa}\wedge\phi^{bV}$. But we know from (31) that the 2-forms in Σ^1 are diagonal in the basis of eigenforms, i.e., of the form $\bar{h}_{aa}\phi^{aa}$, and the above computation then shows that the A term of ρ is manifestly in $\langle\Sigma^1\rangle$. The effect of (23) and (25) on the B term is similar.

When $n=2$, only the condition (21) survives and implies as before that σ must belong to Σ^1. Moreover, it is easy to verify explicitly that for $n=2$, the $\bar{\rho}$ part of our 3-form in $\langle\Sigma^0\rangle$ automatically belongs to $\langle\Sigma^1\rangle$ as well, so the general claim is still valid. □

We now return once more to the general case with no assumptions about Φ. The final stage in our step 2 procedure is to apply the conditions on 3-forms again to the special case of exact 3-forms. This will determine possibly new restrictions on admissible 2-forms, which can then be used to identify further submodules. The computation related to condition (21) is straightforward and produces the new requirement,

$$\omega((\nabla\Phi(X))^V, Y^H) = \omega((\nabla\Phi(Y))^V, X^H), \tag{34}$$

When (22) is imposed on a 3-form $d\omega$, it merely reproduces the condition (19) we already have, in view of the general identity [see Ref. 13, remembering always that we are restricting to vector fields in $\bar{\mathfrak{X}}(\pi)$]

$$3R(X,Y) = D^V_X\Phi(Y) - D^V_Y\Phi(X). \tag{35}$$

But its counterpart (23) gives rise to the new condition,

$$\sum_{X,Y,Z} \omega(\nabla R(X,Y)^V, Z^H) = 0, \tag{36}$$

because we also have the identity

$$\nabla R(X,Y) = D^H_X\Phi(Y) - D^H_Y\Phi(X). \tag{37}$$

The computations for (24) and (25) run parallel and produce the following new requirements

$$\sum_{X,Y,Z} \omega((D^V_{\Phi X}\Phi(Y) - D^V_{\Phi Y}\Phi(X))^V, Z^H) = 0, \tag{38}$$

$$\sum_{X,Y,Z} \omega((D^H_{\Phi X}\Phi(Y) - D^H_{\Phi Y}\Phi(X))H, Z^V) = 0. \tag{39}$$

Conditions such as (34) and (36) are well known in the literature. It was pointed out in Ref. 14 that such conditions must hold for arbitrary ∇ derivatives of Φ and R and it is not difficult to see how this double hierarchy will emerge in the EDS process also, simply from the restrictions on ρ which have Γ in their arguments and will be produced step by step.

The conditions (38) and (39), however, have only been reported in the thesis[1] (though they must be related in some sense to requirements involving the Nijenhuis tensor of Φ in the approach adopted in Ref. 10). It is impossible to say in all generality which of the many algebraic restrictions are somehow the "more independent ones," but the message from our current algorithmic analysis is that it is likely to be more efficient in applications to impose the last mentioned requirements on admissible 2-forms first, before extracting all information, for example, from the double infinite hierarchy of $\nabla^k\Phi$ and $\nabla^k R$ conditions, which were the only conditions taken into consideration in Ref. 15.

But we must not yet embark on using any of these conditions to define a further submodule, as we have only dealt with half of the information that came out of the first step so far. We shall study the curvature condition (19) in the next section, but for the sake of applications it is worthwhile summing up what we now know about the termination of the differential ideal process at this level.

Proportion 4.2: Assume that Φ *is diagonalizable with distinct (real) eigenvalues. Then the necessary and sufficient conditions for* Σ^1 *to generate a differential ideal are that all 2-forms of the form* (29) *satisfy the algebraic conditions* (19), (34), (36), (38), and (39).

Proof: 2-forms in Σ^1 are characterized by (29). If Φ is diagonalizable, the necessary and sufficient conditions for their exterior derivative to belong to $\langle\Sigma^1\rangle$ (as identified by Proposition 4.1 and the subsequent analysis) are that they satisfy the supplementary restrictions (19), (34), (36), (38), and (39). But saying that Σ^1 generates a differential ideal already is the same as saying *that no further restrictions beyond those defining* Σ^1 *should be found* and thus that the five conditions just mentioned must hold for all 2-forms in Σ^1. □

Remark: as we observed in the proof of Proposition 4.1, only one of the five extra conditions survives when $n=2$ and this condition translates to the $\nabla\Phi$ condition (34) when applied to the exterior derivative of a 2-form in Σ^1. This is, therefore, the only condition to take into account when applying the above proposition to the case $n=2$.

V. A FURTHER STEP FOR DIAGONALIZABLE Φ

We return again to the general situation without assuming that Φ is diagonalizable. Define Σ^2 to be the module of 2-forms in Σ^1, which further satisfy the condition (19).

As before, if $\rho=\beta_k\wedge\omega^k$ is a 3-form in $\langle\Sigma^2\rangle$, a contraction with Γ, in view of (19), leads to the further restriction

$$\sum_{X,Y,Z} \rho(\Gamma, R(X,Y)^V, Z^H) = 0. \tag{40}$$

Likewise, when we contract first with an arbitrary vertical element and then proceed to eliminate all terms involving the β_k, a procedure that is more involved here (but we leave the details to the reader), the condition we obtain reads as

$$\sum_{X,Y,Z,U}^{e} \rho(X^V, R(Y,Z)^V, U^H) = 0, \tag{41}$$

where the upper index in the summation sign is meant to indicate that the sum extends over all even permutations of the indicated vector fields. Needless to say, there will be a mirror condition that can independently be derived, and reads as

$$\sum_{X,Y,Z,U}^{e} \rho(X^H, R(Y,Z)^H, U^V) = 0. \tag{42}$$

Obviously there are more possibilities as in the preceding section. For example, repeating the above computation, but with $(\Phi X)^V$ as first argument, rather than X^V, gives

$$\sum_{X,Y,Z,U}^{e} \rho((\Phi X)^V, R(Y,Z)^V, U^H) = 0, \tag{43}$$

and its analog with two horizontal and one vertical elements.

Once again, we have to try and find necessary conditions that are also sufficient for 3-forms to belong to $\langle \Sigma^2 \rangle$. Should we, for example, search for a condition also with two R-arguments in it? To begin with, here is a further infinite number of necessary conditions for ρ to be in $\langle \Sigma^2 \rangle$.

Lemma 5.1: Necessary conditions for a 3-form ρ to belong to $\langle \Sigma^2 \rangle$ are that

$$\sum_{X,Y,Z,U}^{e} \rho((\Phi^m X)^V, R(Y,Z)^V, U^H) = 0, \tag{44}$$

for all m.

Proof: Observe first that 2-forms that have the symmetry property (5) and satisfy (18), automatically also satisfy

$$\omega((\Phi^m X)^V, Y^H) = \omega((\Phi^m Y)^V, X^H), \tag{45}$$

for all m. Indeed, using successively the properties (18), (20), and (5), we have

$$\omega((\Phi^2 X)^V, Y^H) = \omega((\Phi Y)^V, (\Phi X)^H) = \omega(X^V, (\Phi^2 Y)^H) = \omega((\Phi^2 Y)^V, X^H).$$

The statement for general m follows by induction.

Replacing now ΦX by $\Phi^m X$ in the considerations that lead to (43), it is fairly straightforward to verify that we will arrive at (44) in view of (45). □

When a 2-form ω is in Σ^1 and so has the symmetry property (18) with respect to Φ, it makes no sense to impose symmetry with respect to powers Φ^m as further restrictions, because ω will automatically have these properties. Likewise, if we already knew that a 3-form ρ satisfying (41) and (43) belongs to the ideal $\langle \Sigma^2 \rangle$, there would be no sense in looking further at (44). But it is just because we do not have yet sufficiency, that extra requirements like (44) can have practical value.

Let us now first look at the impact of the curvature conditions we obtained so far, on the A part of ρ. Referring to the coordinate expression of R that was given in Sec. I, the condition (19) that further defines the module Σ^2, reads as

$$\sum_{abc} h_{ra} R^r_{bc} = 0. \tag{46}$$

One easily verifies that (41) and (43) imply that the A part of ρ must have the properties

$$\sum_{abcd}^{e} R^s_{bc}(A_{das} - A_{dsa}) = 0, \tag{47}$$

$$\sum_{abcd}^{e} \Phi_a^r R_{bc}^s (A_{drs} - A_{dsr}) = 0. \tag{48}$$

And (44), for $m=2$ for example, will require that

$$\sum_{abcd}^{e} \Phi_a^r \Phi_r^t R_{bc}^s (A_{dts} - A_{dst}) = 0. \tag{49}$$

It is of some interest to write out explicitly what such conditions mean. The first one, for example, making use of the skew-symmetry of the R_{bc}^a and the symmetry of the A_{abc} to recombine terms, can be written in the form

$$R_{bc}^s (A_{asd} - A_{dsa}) + R_{cd}^s (A_{asb} - A_{bsa}) + R_{db}^s (A_{asc} - A_{csa}) + R_{ad}^s (A_{bsc} - A_{csb}) + R_{ca}^s (A_{bsd} - A_{dsb}) + R_{ab}^s (A_{csd} - A_{dsc}) = 0. \tag{50}$$

Notice that the left-hand side of this expression is skew-symmetric in any pair of indices [the same can be verified for (48) and (49)]. Hence, these conditions are identically satisfied when the free indices are not distinct. In other words, for them to have any effect, the dimension must be at least 4.

We now return to the interesting case of diagonalizable Φ with distinct eigenvalues, as introduced in the previous section. Any further such assumption on Φ has an effect on curvature-type conditions, since Φ determines R according to (35). Let X_a denote a basis of eigenvectors of Φ, dual to the basis of eigenforms considered before; so we have $\Phi(X_a)=\lambda_{(a)}X_a$. With $\bar{R}_{bc}^a$ now denoting the components of R with respect to this adapted frame, we find from (35) and introducing the structure functions τ_{ab}^c, defined by

$$\mathrm{D}_{X_a}^V X_b = \tau_{ab}^c X_c, \tag{51}$$

that

$$3\bar{R}_{ab}^a = -(\mathrm{D}_{X_b}^V \lambda_{(a)} + (\lambda_{(a)} - \lambda_{(b)})\tau_{ab}^a), \tag{52}$$

$$3\bar{R}_{ab}^b = \mathrm{D}_{X_a}^V \lambda_{(b)} + (\lambda_{(b)} - \lambda_{(a)})\tau_{ba}^b, \tag{53}$$

$$3\bar{R}_{ab}^s = (\lambda_{(b)} - \lambda_{(s)})\tau_{ab}^s - (\lambda_{(a)} - \lambda_{(s)})\tau_{ba}^s, \quad s \neq a,b. \tag{54}$$

Now, when Φ is diagonalizable with distinct eigenvalues, we already know from the Σ^1-analysis that $\bar{A}_{abc}=0$ when all indices are distinct. Taking the condition (50) with a, b, c, d different, the summation in each of the terms gives rise to only two terms. Further simplifications arise from taking into account that $\Sigma_{abc}\bar{A}_{abc}=0$ implies $\bar{A}_{bba}=-2\bar{A}_{abb}$. Finally, using the R information, we find that only components of the type (54) enter. The condition is then

$$\sum_{abcd}^{e} (\lambda_{(b)} - \lambda_{(c)})(\bar{A}_{abb}\tau_{dc}^b + \bar{A}_{acc}\tau_{db}^c) = 0. \tag{55}$$

The corresponding condition (46) for the 2-forms defining Σ^2 (knowing that $\bar{h}_{ab}$ is diagonal) likewise reduces to

$$\sum_{abc} (\lambda_{(a)} - \lambda_{(b)})(\bar{h}_{aa}\tau^a_{cb} + \bar{h}_{bb}\tau^b_{ca}) = 0. \tag{56}$$

The similarity in structure between (55) and (56) becomes even clearer if we proceed as follows: for dealing with an expression such as (41), we write, for arbitrary $X_1, \ldots, X_4$,

$$\sum_{ijkl}^{e} \rho(X_i{}^V, R(X_j, X_k)^V, X_l{}^H) = \sum_{i=1}^{4} (-1)^i \sum_{jkl} \rho(X_i{}^V, R(X_j, X_k)^V, X_l{}^H). \tag{57}$$

The notation that is being used here on the right-hand side should be read as follows: for each $i = 1, \ldots, 4$, (i,j,k,l) is a cyclic permutation of (1), (2), (3), (4) and then with i being kept fixed, we perform a cyclic sum over the three other indices. Applying this idea to the explicit form of the condition (41) we are considering, (55) can be recast in the form:

$$\begin{aligned}\sum_{abcd}^{e} (\lambda_{(b)} - \lambda_{(c)})(\bar{A}_{abb}\tau^b_{dc} + \bar{A}_{acc}\tau^c_{db}) \equiv & \sum_{bcd} (\lambda_{(b)} - \lambda_{(c)})(\bar{A}_{abb}\tau^b_{dc} + \bar{A}_{acc}\tau^c_{db}) \\ & - \sum_{cda} (\lambda_{(c)} - \lambda_{(d)})(\bar{A}_{bcc}\tau^c_{ad} + \bar{A}_{bdd}\tau^d_{ac}) \\ & + \sum_{dab} (\lambda_{(d)} - \lambda_{(a)})(\bar{A}_{cdd}\tau^d_{ba} + \bar{A}_{caa}\tau^a_{bd}) \\ & - \sum_{abc} (\lambda_{(a)} - \lambda_{(b)})(\bar{A}_{daa}\tau^a_{cb} + \bar{A}_{dbb}\tau^b_{ca}) = 0. \end{aligned} \tag{58}$$

We can now be precise about what it is we should be able to prove to reach sufficiency of conditions for ρ to be in $\langle \Sigma^2 \rangle$. From the Σ^1 analysis we already know that the A part of ρ will be of the form:

$$\rho_A = \sum_{a \neq d} \bar{A}_{daa} \phi^{aa} \wedge \phi^{dV}. \tag{59}$$

To conclude that such a term "manifestly belongs" to the ideal generated by Σ^2 (or, in fact, to any further submodule of Σ^1) we must be able to show that for each fixed d, there exists a function α_d such that $\Sigma_{a \neq d} \bar{A}_{daa} \phi^{aa} + \alpha_d \phi^{dd}$ belongs to Σ^2 (or to the submodule under consideration). For the case at hand, assuming the dimension is at least 4, this 2-form should, in particular, have the property [see (56)] that for each set of three distinct indices a,b,c that are different from d: $\Sigma_{abc}(\lambda_{(a)} - \lambda_{(b)})(\bar{A}_{daa}\tau^a_{cb} + \bar{A}_{dbb}\tau^b_{ca}) = 0$. But the available data on ρ so far only tell us that a sum of four such terms is zero. So again, maybe, by throwing in more conditions, we might be able to ensure that all four parts in the expression (58) vanish separately.

Now consider the hierarchy (44) of further necessary conditions we have obtained. Following the different steps of the calculation that led from (47) to (55), one can show that (48) and (49) for diagonalizable Φ become

$$\sum_{abcd}^{e} \lambda_{(a)}(\lambda_{(b)} - \lambda_{(c)})(\bar{A}_{abb}\tau^b_{dc} + \bar{A}_{acc}\tau^c_{db}) = 0, \tag{60}$$

$$\sum_{abcd}^{e} \lambda^2_{(a)}(\lambda_{(b)} - \lambda_{(c)})(\bar{A}_{abb}\tau^b_{dc} + \bar{A}_{acc}\tau^c_{db}) = 0. \tag{61}$$

Lemma 5.2: If Φ is diagonalizable with distinct eigenvalues, then for ρ to satisfy the hierarchy of conditions (44), it is sufficient that these properties hold for $m = 0,1,2,3$.

Proof: The assumption is that we have for each set of four distinct indices a,b,c,d:

$$\sum_{abcd}^{e} \lambda_{(a)}^{n}(\lambda_{(b)}-\lambda_{(c)})(\bar{A}_{abb}\tau_{dc}^{b}+\bar{A}_{acc}\tau_{db}^{c})=0,$$

and this for $m=0,1,2,3$. Splitting the sum of 12 even permutations into four cyclic sum parts, as was done in (58), we get a homogeneous linear system of four equations for these sums, with the coefficient matrix

$$\begin{pmatrix} 1 & -1 & 1 & -1 \\ \lambda_{(a)} & -\lambda_{(b)} & \lambda_{(c)} & -\lambda_{(d)} \\ \lambda_{(a)}^{2} & -\lambda_{(b)}^{2} & \lambda_{(c)}^{2} & -\lambda_{(d)}^{2} \\ \lambda_{(a)}^{3} & -\lambda_{(b)}^{3} & \lambda_{(c)}^{3} & -\lambda_{(d)}^{3} \end{pmatrix}.$$

Its determinant, a Vandermonde-type determinant, is equal to the product

$$(\lambda_{(a)}-\lambda_{(b)})(\lambda_{(a)}-\lambda_{(c)})(\lambda_{(a)}-\lambda_{(d)})(\lambda_{(b)}-\lambda_{(c)})(\lambda_{(b)}-\lambda_{(d)})(\lambda_{(c)}-\lambda_{(d)}),$$

and hence is nonzero. It follows that for each set of four distinct indices a,b,c,d, we have

$$\sum_{abc}(\lambda_{(a)}-\lambda_{(b)})(\bar{A}_{daa}\tau_{cb}^{a}+\bar{A}_{dbb}\tau_{ca}^{b})=0. \tag{62}$$

This in turn implies that all further conditions in the hierarchy (44) are automatically satisfied.□

With this result, we are getting as close as we possibly can to concluding that we have sufficiency in this step of the differential ideal process. Indeed, we have now obtained with (62) all the properties that the 2-forms $\Sigma_{a\neq d}\bar{A}_{daa}\phi^{aa}+\alpha_d\phi^{dd}$ must have for belonging to Σ^2, except for those conditions of type (56) for which the cyclic sum over three indices will involve the undetermined function α_d (and this for each fixed d). These missing conditions may cause true obstructions to the existence of a solution for the inverse problem, as for each fixed d, there may, in principle, be three requirements to be satisfied, for only one unknown α_d. But there is no chance of getting more information about such possible obstructions at this level of generality, i.e., without breaking the discussion up into more subcases, because the 2-forms that interest us in an expression like (59) always appear in a wedge product with some ϕ^{dV}, so the functions we called α_d remain completely undetermined.

Let us summarize the situation now. For a 3-form ρ to be in the ideal $\langle\Sigma^2\rangle$, it must satisfy the requirement (40) and the curvature condition (41), but, in fact, also the infinite set of conditions (44) (plus corresponding analogs) that contain the one just mentioned for $m=0$. The special case of diagonalizable Φ has shown that imposing these conditions for $m=0,1,2,3$ is probably the closest we can get to having conditions that are also sufficient. So it is worthwhile exploring what comes out of such conditions when we apply them to exact forms, in terms of possibly new algebraic restrictions on admissible 2-forms.

Applying (40) to $d\omega$ is an easy computation: as already indicated, it reproduces the requirement (36) we obtained before. The other computations are a lot more involved, so we give a brief indication about the way to proceed. Starting with (44) for $m=0$, the bracket terms of the expansion of $\Sigma_{X,Y,Z,U}^{e}\, d\omega(X^V,R(Y,Z)^V,U^H)$ include, as terms in which X is fixed,

$$-\sum_{Y,Z,U}\{\omega([X^V,R(Z,U)^V],Y^H)+\omega([R(Z,U)^V,Y^H],X^V)+\omega([Y^H,X^V],R(Z,U)^V)\}$$

$$=-\sum_{Y,Z,U}\{\omega(\mathrm{D}_X^V(R(Z,U))^V-(\mathrm{D}_{R(Z,U)}^V X)^V,Y^H)+\omega((\mathrm{D}_{R(Z,U)}^V Y)^H,X^V)-\omega((\mathrm{D}_X^V Y)^H,R(Z,U)^V)\},$$

and there are similar terms in which one of the other vector fields is kept fixed each time. If, in the last term on the right, we make use of the property (19), it is easy to see that all terms that arise this way will directly cancel out the terms coming from the expansion of the first term on the right,

except those in which the tensor R itself is being derived. The second and third terms on the right will all disappear if the totality of all even sum permutations is taken into account. The only terms that remain then are those involving vertical derivatives of R. But they can be seen to cancel out as well in view of the Bianchi identity,

$$\sum_{X,Y,Z} \mathrm{D}^V R(X,Y,Z) = 0. \tag{63}$$

For the horizontal counterpart (42), something entirely similar happens in view of

$$\sum_{X,Y,Z} \mathrm{D}^H R(X,Y,Z) = 0. \tag{64}$$

We can now more or less see what will happen for the conditions (44) with $m \neq 0$. When, in the terms that have been made explicit above, X is replaced by ΦX, for example, most of the cancellations remain the same, but there will be extra terms in which derivatives of Φ appear; moreover, derivatives of R will now be taken with respect to arguments such as ΦX instead of X and that makes that the Bianchi identity does not directly help. In conclusion, we get the following new requirements:

$$\sum_{X,Y,Z,U}^{e} \omega(\mathrm{D}^V_{\Phi^m X} R(Z,U)^V - (\mathrm{D}^V_{R(Z,U)} \Phi^m)(X)^V, Y^H) = 0, \tag{65}$$

which in the context of the last lemma would be imposed only for $m=1,2,3$, plus analogous conditions with horizontal and vertical lifts or derivatives interchanged.

We have now obtained extra requirements more closely defining the module Σ^2, namely not only the ones just mentioned, but also those that came out of the analysis of the preceding section: (34), (36), and (38), (39). However, continuing further at this level of generality is not profitable.

VI. BEYOND THE DIFFERENTIAL IDEAL: EXAMPLES

In all practical situations, the algebraic conditions discussed so far will establish either that no nondegenerate multiplier exists, or that we have reached the stage of a differential ideal. In the latter case we then construct a Kähler lift g^{K} in the ideal that is closed. In principle, this means addressing the Pfaffian system of Eqs. (7), which is, of course, a particular way of representing a system of partial differential equations for the unknown functions r_k. While it is certainly true that the Cartan-Kähler theory is a powerful vehicle to decide about the integrability of such equations and the generality of their solutions, a drawback of (7) is that it is setup in such a general way as to lose contact with the specific geometrical structure of the inverse problem. For example, the symmetry relating to horizontal and vertical parts suggest splitting (7) into its horizontal and vertical components. But that inevitably must be equivalent to considering the partial differential equations of the inverse problem the way they were encoded geometrically in their most compact form in (2).

In other words, what we are advocating here is that, once we have reached a differential ideal, we go back to the partial differential equations in the original Helmholtz conditions, for example, in the representation

$$D^V_X g(Y,Z) = \mathrm{D}^V_Y g(X,Z), \quad \boldsymbol{\nabla} g = 0, \tag{66}$$

and specifically in that order. Indeed, by splitting the equations for the r_k in that way, we expect that they will become quite tractable: the first set of equations will determine the allowed velocity dependence of the unknown r_k, and $\boldsymbol{\nabla} g = 0$ will subsequently further restrict the arbitrary functions that may turn up in solving the first part. It may look rather disappointing that, after all the efforts of the differential ideal process, we now still have to address two of the three Helmholtz conditions (2). But we knew from the beginning that the differential ideal process was not going to solve these equations. The point is that, specifically by the way we have pursued obtaining

"efficient" algebraic conditions in that process, the algebraic freedom in the module of admissible 2-forms will likely be restricted in such a way that addressing the equations (66) directly will now become possible.

We will finish with two illustrations: one in which the differential ideal process leads to a negative result and one where we reach the final stage and subsequently solve the partial differential equations for the r_k. For these examples, we consider cases where Φ is diagonalizable with distinct eigenvalues and go back to the situation described at the end of Sec. IV. So, if the hope is that we will reach a decisive state at that point, it means that we are in the situation described by Proposition 4.2, so that Σ^1 generates a differential ideal, or that the conditions in that statement lead to the conclusion that no nondegenerate multiplier can exist.

The following is an important preliminary observation. Conditions that involve $\nabla\Phi$, ∇R, or other covariant derivatives of these tensors are likely to produce restrictions that contain the functions $\nabla\lambda_{(a)}$ and even $\nabla\tau^a_{bc}$ (or other derivatives of structure functions) and will prompt for further assumptions about $\nabla\Phi$, for example. The curvature condition (19) is more interesting to look at first, therefore, because it is purely algebraic in the structure functions τ^a_{bc}, as we have seen with (56). It turns out that also (38) is of such a nature in the case of diagonalizable Φ we are considering. Indeed, we have

$$(D^V_{\Phi X_a}\Phi)(X_b) = \lambda_{(a)}X_a{}^V(\lambda_{(b)})X_b + \lambda_{(a)}(\lambda_{(b)} - \lambda_{(c)})\tau^c_{ab}X_c,$$

from which it follows that for a 2-form of type $\omega = \bar{h}_{aa}\phi^{aa}$,

$$\omega((D^V_{\Phi X_a}\Phi(X_b) - D^V_{\Phi X_b}\Phi(X_a))^V, X_c{}^H) = \bar{h}_{bb}\lambda_{(a)}X_a{}^V(\lambda_{(b)})\delta_{bc} - \bar{h}_{aa}\lambda_{(b)}X_b{}^V(\lambda_{(a)})\delta_{ac} + \bar{h}_{cc}(\lambda_{(a)}(\lambda_{(b)} - \lambda_{(c)})\tau^c_{ab} - \lambda_{(b)}(\lambda_{(a)} - \lambda_{(c)})\tau^c_{ba}).$$

But for taking the cyclic sum (38), we need to take a,b,c distinct, so that derivatives of the eigenvalues will disappear. The condition in the end reduces to

$$\sum_{abc}\lambda_{(c)}(\lambda_{(a)} - \lambda_{(b)})(\bar{h}_{aa}\tau^a_{cb} + \bar{h}_{bb}\tau^b_{ca}) = 0, \tag{67}$$

which has a remarkable resemblance to (56). In fact, it is interesting to work out some conclusions from the combination of the conditions (56) and (67). To fix the idea, take $\{a,b,c\}=\{1,2,3\}$ and put, for example, $H_{12}=(\lambda_{(1)}-\lambda_{(2)})G_{12}$, with $G_{12}=(\bar{h}_{11}\tau^1_{32}+\bar{h}_{22}\tau^2_{31})$. Then, it is easy to see that the combination of both conditions is equivalent to requiring that $G_{12}=G_{23}=G_{31}$. So, for example, in dimension 3, we get the following two conditions of curvature type:

$$\bar{h}_{11}\tau^1_{32} + \bar{h}_{22}(\tau^2_{31} - \tau^2_{13}) - \bar{h}_{33}\tau^3_{12} = 0, \tag{68}$$

$$\bar{h}_{11}\tau^1_{23} - \bar{h}_{22}\tau^2_{13} + \bar{h}_{33}(\tau^3_{21} - \tau^3_{12}) = 0, \tag{69}$$

which actually only involve τ^a_{bc} with a,b,c distinct. In dimension 4, there will already be eight of such conditions, coming from the four combinations of three distinct indices: if these are not identically satisfied, chances are small that there will still be a nondegenerate ω.

Our first example is taken from Ref. 7 and is shown there to have no Lagrangian. We wish to confirm that we come to the same conclusion. Consider the four-dimensional system (b constant),

$$\ddot{x} = b\dot{x}\dot{w},$$

$$\ddot{y} = \dot{y}\dot{w},$$

$$\ddot{z} = (1-b)\dot{x}\dot{y} + by\dot{x}\dot{w} - bx\dot{y}\dot{w} + (b+1)\dot{z}\dot{w},$$

$$\ddot{w} = 0.$$

With u, v, s, t as the notation for the derivatives, we have

$$4\Phi = \begin{pmatrix} -b^2t^2 & 0 & 0 & b^2ut \\ 0 & -t^2 & 0 & vt \\ a_1 & a_2 & a_3 & a_4 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

where

$$a_1 = (2b+1)(b+1)tv - (2b+1)byt^2,$$

$$a_2 = -(b+1)(b+2)ut + b(b+2)xt^2,$$

$$a_3 = -(b+1)^2t^2,$$

$$a_4 = b(2b+1)yut + (1-b^2)uv - b(b+2)xvt + (b+1)^2st.$$

The eigenvalues and corresponding eigenvectors are

$$-b^2t^2 \quad \text{and} \quad (t,0,(b+1)v - byt,0),$$

$$t^2 \quad \text{and} \quad (0,bt,bxt - (b+1)u,0),$$

$$-(b+1)^2t^2 \quad \text{and} \quad (0,0,1,0),$$

$$0 \quad \text{and} \quad (u,v,s,t).$$

It is easy to compute structure functions, as defined by (51); of the ones with distinct indices, only the following two appear to be nonzero:

$$\tau^3_{21} = (b+1)bt, \quad \tau^3_{12} = -(b+1)t.$$

For having distinct eigenvalues, we have to require that $b \neq 0$ and $b \neq -1$. The eight conditions coming from (56) and (67), applied to the multiplier g_{ab} we are now constructing, then reduce to 2, and they both require that $g_{33}=0$, so that there is indeed no nonsingular multiplier. Of course, it is a fact that, as shown in Ref. 7, the curvature condition by itself already leads to this conclusion, so that there is no real contribution from the extra condition (67).

To get beyond the differential ideal step we choose, as our second example, a three-dimensional system inspired by one of the favorable two-dimensional cases in Ref. 6. Consider the system

$$\ddot{x} = -x,$$

$$\ddot{y} = y^{-1}(1 + \dot{y}^2 + \dot{z}^2),$$

$$\ddot{z} = 0,$$

on an appropriate domain. Denoting the derivatives by u, v, w, Φ this time is given by

$$\Phi = \frac{1}{y^2}\begin{pmatrix} y^2 & 0 & 0 \\ 0 & 2(1+w^2) & -2vw \\ 0 & 0 & 0 \end{pmatrix}.$$

Eigenvalues and corresponding eigenvectors are

$$0 \quad \text{and} \quad (0, vw, 1+w^2),$$

$$1 \quad \text{and} \quad (1,0,0),$$

$$2y^{-2}(1+w^2) \quad \text{and} \quad (0,y,0).$$

The eigenvectors X_a are chosen in such a way that $\nabla X_a = 0$, which is possible because $\nabla\Phi$ commutes with Φ in this case. The corresponding dual basis of eigenforms is given by

$$\phi^1 = \frac{1}{1+w^2}\theta^3, \quad \phi^2 = \theta^1, \quad \phi^3 = \frac{1}{y}\theta^2 - \frac{vw}{y(1+w^2)}\theta^3.$$

Again, the structure functions τ^a_{bc} are easy to compute and they are zero, except the following:

$$\tau^3_{11} = \frac{v}{y}, \quad \tau^1_{11} = 2w, \quad \tau^3_{31} = w.$$

It is immediately clear that this implies that the conditions (68) and (69) are identically satisfied because all the τ's involved are zero. Going back to the result expressed in Proposition 4.2, we have just dealt with (19) and (38). Let us introduce also horizontal structure functions by $D^H_{X_a} X_b = \nu^c_{ab} X_c$, and observe now that in view of the similarity in structure between (35) and (37), and also between (38) and (39), the explicit form of the conditions (36) and (39), for example for $n=3$, will be the same as (68) and (69), with ν^c_{ab} replacing τ^c_{ab}. But in view of the commutator identity $[\nabla, D^V_X] = D^V_{\nabla X} - D^H_X$, and the fact that we chose the X_a to be ∇ invariant, we simply have $\nu^a_{bc} = -\Gamma(\tau^a_{bc})$ here and thus these two other conditions will be identically satisfied as well. It remains to look at (34), but this will hold trivially because $\nabla\Phi$ commutes with Φ. We conclude from Proposition 4.2 that Σ^1 generates a differential ideal.

The admissible g's are of the form $g = \Sigma_k r_k \phi^k \otimes \phi^k$ and following the scheme explained at the beginning of this section, we now start looking at the equations to be satisfied by the r_k. For the vertical closure conditions in (66), it is convenient to re-express g in the standard basis of θ^i, from which we learn that

$$g_{11} = r_2, \quad g_{22} = \frac{r_3}{y^2}, \quad g_{33} = \frac{1}{(1+w^2)^2}\left(r_1 + r_3\frac{v^2w^2}{y^2}\right),$$

$$g_{12} = g_{13} = 0, \quad g_{23} = -r_3\frac{vw}{y^2(1+w^2)}.$$

The vertical closure conditions then are

$$\frac{\partial g_{11}}{\partial v} = \frac{\partial g_{11}}{\partial w} = 0, \quad \frac{\partial g_{22}}{\partial u} = \frac{\partial g_{33}}{\partial u} = 0,$$

$$\frac{\partial g_{22}}{\partial w} = \frac{\partial g_{23}}{\partial v}, \quad \frac{\partial g_{33}}{\partial v} = \frac{\partial g_{23}}{\partial w},$$

or translated into equations for the r_k,

$$\frac{\partial r_2}{\partial v} = \frac{\partial r_2}{\partial w} = 0, \quad \frac{\partial r_3}{\partial u} = \frac{\partial r_1}{\partial u} = 0,$$

$$(1+w^2)\frac{\partial r_3}{\partial w} + vw\frac{\partial r_3}{\partial v} = -r_3 w,$$

and

$$y^2\frac{\partial r_1}{\partial v} = -v^2w^2\frac{\partial r_3}{\partial v} - vw(1+w^2)\frac{\partial r_3}{\partial w} - r_3 v(1+w^2).$$

The solution of these equations is quite straightforward. We have that r_2 can depend on u only and, of course, also arbitrarily on x,y,z,t for the moment. r_3, on the other hand, cannot depend on u and using the method of characteristics on the other equation that involves r_3 only gives

$$r_3 = \frac{1}{v}\chi(\xi), \quad \text{with } \xi = \frac{v}{\sqrt{1+w^2}},$$

where χ is an arbitrary function of the indicated argument, which again can further depend on x,y,z,t. The last equation and the fact that r_1 cannot depend on u either, then produces

$$r_1 = -\frac{\sqrt{1+w^2}}{y^2}\psi(\xi) + \zeta(w),$$

where $\psi' = \chi$ and, like ψ, the arbitrary ζ can further depend on x,y,z,t.

It remains to impose that ∇g must be zero. Since $\nabla\phi^a = 0$ by construction, this simply means that the r_k must be first integrals. The conclusion for r_2 is immediately that it cannot depend on y and z and simply must be a first integral of the equation $\ddot{x} = -x$. Equating $\Gamma(r_3) = 0$, we see that χ can no longer depend on x and further must satisfy

$$\left(\xi + \frac{1}{\xi}\right)\frac{\partial\chi}{\partial\xi} + y\frac{\partial\chi}{\partial y} + \frac{y}{v}\left(w\frac{\partial\chi}{\partial z} + \frac{\partial\chi}{\partial t}\right) - \left(1 + \frac{1}{\xi^2}\right)\chi = 0.$$

Now every function that depends on v and w through the variable ξ only, gives zero when acted upon by the vector field $(1+w^2)\,\partial/\partial w + vw\,\partial/\partial v$. Applying this operator to the left-hand side of the above equation, it follows that we must have

$$\frac{\partial\chi}{\partial z} - w\frac{\partial\chi}{\partial t} = 0,$$

and repeating the same process subsequently implies that χ cannot depend on z and t at all. The reduced equation for χ then can easily be solved by the method of characteristics again and yields

$$\chi(\xi, y) = \xi\chi_0\left(\frac{\sqrt{1+\xi^2}}{y}\right),$$

where χ_0 is an arbitrary function of the indicated single argument. With this further restriction, one can verify that the first term in the expression for r_1 is a first integral, and if the same must hold for ζ, this function cannot depend on x and y and simply has to be a first integral of the equation $\ddot{z} = 0$. In summary, the general solution for the r_k is given by

$$r_1 = -\frac{\sqrt{1+w^2}}{y^2}\psi(\xi, y) + \zeta(w, z, t),$$

$$r_2 = \sigma(u, x, t),$$

$$r_3 = \frac{1}{v}\chi(\xi, y) = \frac{\xi}{v}\chi_0\left(\frac{\sqrt{1+\xi^2}}{y}\right), \quad \xi = \frac{v}{\sqrt{1+w^2}},$$

where χ_0 is further arbitrary, $\partial\psi/\partial\xi = \chi$, ζ is a first integral of the equation $\ddot{z}=0$, and σ a first integral of the equation $\ddot{x}=-x$.

In a forthcoming paper, we plan to apply these techniques more systematically to the identification of a number of classes of three dimensional (and possibly higher dimensional) systems for which a multiplier exists. The last example here, for example, belongs to a class that is characterized by the fact that two of the eigenform codistributions of a diagonalizable Φ are integrable, and the third one is not, and this is one of the cases we shall be able to treat in all generality, even in any dimension.

Integrable and superintegrable systems with spin

(Received 21 April 2006; accepted 14 September 2006; published online 23 October 2006)

A system of two particles with spin $s=0$ and $s=\frac{1}{2}$, respectively, moving in a plane is considered. It is shown that such a system with a nontrivial spin-orbit interaction can allow an eight dimensional Lie algebra of first-order integrals of motion. The Pauli equation is solved in this superintegrable case and reduced to a system of ordinary differential equations when only one first-order integral exists. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2360042]

I. INTRODUCTION

A Hamiltonian system with n degrees of freedom in classical mechanics is called integrable if it allows n functionally independent integrals of motion $\{X_1,\ldots,X_n\}$. These integrals must be well-defined functions on phase space and be in involution. The Hamiltonian H belongs to this set of n integrals. A "superintegrable system" is one that allows some additional integrals of motion, $\{Y_1,\ldots,Y_k\}$ such that the set $\{X_1,\ldots,X_n,Y_1,\ldots,Y_k\}$ is functionally independent. The integrals $\{Y_1,\ldots,Y_k\}$ are not necessarily in involution among each other, nor with the X_i. A system is maximally superintegrable if we have $k=n-1$, minimally superintegrable for $k=1$.

The concepts of integrability and superintegrability are also introduced in quantum mechanics. The only difference is that the integrals of motion are now well-defined linear quantum mechanical operators, assumed to be algebraically independent.[1,6–9,12,13,15,16,18,19,21]

The best known superintegrable systems are the Kepler, or Coulomb, system[1,8] and the harmonic oscillator.[12,16] They are characterized by the fact that all finite classical trajectories in these systems are periodic. In quantum mechanics these systems are exactly solvable, i.e., their bound state energy levels can be calculated algebraically and their wave function expressed in terms of polynomials.

The above properties are shared by all other known maximally superintegrable systems (see, for example, Ref. 19).

A systematic search for superintegrable systems and their properties was started quite some time ago.[6,7,9,15,21] Originally the approach concentrated on Hamiltonians of the type

$$H=-\frac{1}{2}\Delta+V(\vec{r}), \tag{1}$$

in two- and three- dimensional Euclidean spaces with the restriction that all integrals of motion should be first- or second-order polynomials in the momenta. More recently, the study of superintegrable systems with second-order integrals of motion was extended to curved spaces and also higher-dimensional ones (see Ref. 13 for some recent results and an extensive list of references).

For Hamiltonians of the type (1) with second-order integrals of motion there is a close relation between integrability and the separation of variables in the Schrödinger and Hamilton-Jacobi equations. Typically, superintegrable systems of this type are multiseparable: they allow the separation of variables in more than one system of coordinates.

[a]Electronic mail: wintern@crm.umontreal.ca
[b]Electronic mail: yurdusen@crm.umontreal.ca

This relationship between integrability and separability breaks down in other cases. Thus for natural Hamiltonians of the type (1), the existence of third-order integrals of motion does not lead to the separation of variables.[4,5,10,11] Furthermore, if we consider velocity dependent potentials (e.g., related to a magnetic field),

$$H = -\frac{1}{2}\Delta + V(\vec{r}) + (\vec{A},\vec{p}), \tag{2}$$

then quadratic integrability no longer implies the separation of variables.[2,3,17,20]

In this paper we initiate the study of integrability and superintegrability in a different type of system, namely, one involving particles with spin. More specifically, we consider two nonrelativistic quantum particles, moving in a plane: one with spin $1/2$, the other with spin 0. In this case the Hamiltonian will be a matrix operator, acting on two component spinors, and we can decompose it in terms of the identity matrix I and the Pauli matrices σ_i $(i=1,2,3)$.

From the physical point of view, the most interesting Hamiltonian to consider would be

$$H = -\frac{\hbar^2}{2m}\Delta + V_0(\vec{r}) + \frac{1}{2}\{V_1(\vec{r}),(\vec{\sigma},\vec{L})\}, \tag{3}$$

in the three-dimensional Euclidean space E_3 (we drop the matrix I whenever this does not cause confusion). The curly bracket represents an anticommutator and $V_a(\vec{r})$, $a=0,1$ are real functions. The Hamiltonian is Hermitian and satisfies the requirements of parity and time reversal invariance. The spin-orbital interaction term $V_1(\vec{r})(\vec{\sigma},\vec{L})$ is the standard one in quantum mechanics.[14]

In this paper, the first one on integrability and superintegrability for particles with nonzero spin, we restrict to the two-dimensional space E_2. The orbital angular momentum $\vec{L}$ then only has one component, L_3, perpendicular to the xy plane E_2. The scalar product $(\vec{\sigma},\vec{L})$ reduces to $\sigma_3 L_3$ (since L_1 and L_2 are zero). We shall set the reduced mass m of the two particle system equal to $m=1$ and use units in which the Planck constant is $\hbar=1$ (we do not need to consider a classical limit here). Finally, the Hamiltonian to be considered in this paper is

$$H = \frac{1}{2}(p_1^2 + p_2^2) + V_0(x,y) + V_1(x,y)\sigma_3 L_3 + \frac{1}{2}\sigma_3(L_3 V_1(x,y)), \tag{4}$$

with

$$p_1 = -i\partial_x, \quad p_2 = -i\partial_y, \quad L_3 = i(y\partial_x - x\partial_y), \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{5}$$

A priori, the functions $V_0(x,y)$ and $V_1(x,y)$ are arbitrary. In specific physical applications they may be related or they may both be specified. Our aim is to determine the conditions on these two functions under which one or more integrals of motion exist.

We request that at least one first-order integral of motion should exist, namely,

$$X = (A_0 p_1 + B_0 p_2 + \phi_0)I + (A_1 p_1 + B_1 p_2 + \phi_1)\sigma_3, \tag{6}$$

where A_μ, B_μ, and ϕ_μ $(\mu=0,1)$ are real functions of x and y. These functions as well as the potentials V_0 and V_1 are to be determined from the commutativity condition

$$[H,X] = 0. \tag{7}$$

The general formulation is set up in Sec. II, where we determine A_μ and B_μ and obtain the partial differential equations (PDE) that ϕ_0, ϕ_1, V_0, and V_1 must satisfy. In Sec. III we consider a special case when the Hamiltonian (4) allows six independent nontrivial integrals of the type (6). They generate an eight-dimensional symmetry group of the system. Section IV is devoted to more general integrable Hamiltonians, allowing just one first-order integral. The system of equations,

$$H\Psi = E\Psi, \quad X\Psi = \lambda\Psi, \tag{8}$$

is studied in Sec. V. We shall call the system (8) the Pauli system. Some conclusions and future directions are outlined in Sec. VI.

II. FORMULATION OF THE PROBLEM

In order to obtain determining equations for the coefficients A_μ, B_μ, and ϕ_μ ($\mu=0,1$) in the integral (6), we impose the commutation relation (7). The commutator will involve terms of the type p_1^2, $p_1^2\sigma_3$, p_2^2, $p_2^2\sigma_3$, p_1p_2, $p_1p_2\sigma_3$, p_1, $p_1\sigma_3$, p_2, $p_2\sigma_3$, I, and σ_3.We have $\sigma_3^2=I$, so no higher powers of σ_3 appear. We set the coefficients of each of the above terms equal to zero. This gives us 12 linear partial differential equations for A_μ, B_μ, and ϕ_μ. Those coming from the coefficients of second-order terms in the momentum imply that A_μ and B_μ are linear functions and we obtain, for any potentials V_0 and V_1,

$$A_\mu = \omega_\mu y + a_\mu, \quad B_\mu = -\omega_\mu x + b_\mu, \tag{9}$$

where ω_μ, a_μ, and b_μ are real constants. The coefficients of $\vec{p}$, $\vec{p}\sigma_3$, I, and σ_3 in the commutator provide an overdetermined system of six first-order PDEs for the four functions V_0, V_1, ϕ_0, and ϕ_1. They are

$$\phi_{\mu,x} = \delta_{\mu,1-\nu}[-b_\nu V_1 - (\omega_\nu y + a_\nu)yV_{1,x} + (\omega_\nu x - b_\nu)yV_{1,y}],$$

$$\phi_{\mu,y} = \delta_{\mu,1-\nu}[a_\nu V_1 + (\omega_\nu y + a_\nu)xV_{1,x} - (\omega_\nu x - b_\nu)xV_{1,y}], \tag{10}$$

$$(\omega_\mu y + a_\mu)V_{0,x} + (-\omega_\mu x + b_\mu)V_{0,y} = \delta_{\mu,1-\nu}(x\phi_{\nu,y} - y\phi_{\nu,x})V_1 \quad (\mu,\nu=0,1). \tag{11}$$

The coefficients of I and σ_3 *a priori* involve second-order derivatives of $V_1(x,y)$. These second-order terms cancel, once Eqs. (9) and (10) are taken into account. This leads to the two first-order equations (11).

Before solving this system, let us introduce "allowed transformations" that leave the Hamiltonian (4) form invariant, i.e., change only the functions $V_0(x,y)$ and $V_1(x,y)$. Such transformations will be used to simplify Hamiltonians, integrals of motion, and also the equations to be solved.

Allowed transformations for any potentials V_0 and V_1 are as follows.

(1) Rotations in the xy plane.
(2) Gauge transformations of the form

$$\tilde{H} = U^{-1}HU, \quad U = \begin{pmatrix} e^{i\alpha} & 0 \\ 0 & e^{-i\alpha} \end{pmatrix}, \quad \alpha = \alpha(\xi), \quad \xi = \frac{y}{x}. \tag{12}$$

The transformation of the potentials is

$$\tilde{V}_1 = V_1 + \frac{\dot{\alpha}}{x^2}, \quad \tilde{V}_0 = V_0 + \left(1 + \frac{y^2}{x^2}\right)\left(\frac{1}{2}\frac{\dot{\alpha}^2}{x^2} + \dot{\alpha}V_1\right). \tag{13}$$

For certain specific potentials V_1, further allowed transformations exist (for any V_0), namely, simultaneous translations and gauge transformations.

(1) $V_1=\gamma=$ const. The allowed transformations are given by

$$\tilde{x} = x + x_0, \quad \tilde{y} = y + y_0, \quad \alpha = \gamma(y_0x - x_0y), \tag{14}$$

and the transformation of the potentials is

$$\tilde{V}_1 = V_1 = \gamma, \quad \tilde{V}_0(x,y) = V_0(x+x_0, y+y_0) - \frac{1}{2}\gamma^2(x_0^2 + y_0^2 + 2(xx_0 + yy_0)). \tag{15}$$

(2) $V_1 = V_1(x)$. The allowed transformation is

$$\tilde{x} = x, \quad \tilde{y} = y + y_0, \quad \alpha(x) = y_0 \int V_1(x)dx, \quad \tilde{V}_1 = V_1, \quad \tilde{V}_0(x,y) = V_0(x, y+y_0) - \frac{1}{2}V_1^2 y_0(y_0 + 2y). \tag{16}$$

Let us now return to Eq. (10). The compatibility conditions $\phi_{\mu,xy} = \phi_{\mu,yx}$ imply

$$(\omega_\mu y + a_\mu)(xV_{1,xx} + yV_{1,xy} + 3V_{1,x}) + (-\omega_\mu x + b_\mu)(yV_{1,yy} + xV_{1,xy} + 3V_{1,y}) = 0 \quad (\mu = 0,1). \tag{17}$$

In general, (17) represents an overdetermined system of two different equations for the potentials $V_1(x,y)$ and this system can be written as

$$xV_{1,xx} + yV_{1,xy} + 3V_{1,x} = 0,$$

$$yV_{1,yy} + xV_{1,xy} + 3V_{1,y} = 0. \tag{18}$$

An exception occurs if the two equations (17) coincide. This occurs if the constants figuring in Eq. (17) satisfy the three following equations:

$$\omega_0 a_1 - \omega_1 a_0 = 0, \quad \omega_0 b_1 - \omega_1 b_0 = 0, \quad a_1 b_0 - a_0 b_1 = 0. \tag{19}$$

We shall treat the case (18) in Sec. III. The case when (19) is satisfied and $V_1(x,y)$ satisfies only one equation (17) will be considered in Sec. IV.

III. SPIN ORBITAL INTERACTION WITH KINEMATICAL INVARIANCE GROUP

Let us now solve Eqs. (18). We transform the first equation to characteristic variables, solve and substitute into the second equation. The result is

$$V_1(x,y) = \gamma + \frac{G(\xi)}{x^2}, \quad \xi = \frac{y}{x}, \quad \gamma = \text{const}. \tag{20}$$

Comparing with Eq. (13) we see that we can annul the function $G(\xi)$ by a gauge transformation. Thus we have

$$V_1 = \gamma. \tag{21}$$

Substituting (21) into Eqs. (10) and (11), we obtain

$$V_0 = \frac{1}{2}\gamma^2(x^2 + y^2), \quad \phi_0 = -\gamma(b_1 x - a_1 y), \quad \phi_1 = -\gamma(b_0 x - a_0 y). \tag{22}$$

The Hamiltonian thus has the form

$$H = -\frac{1}{2}\Delta + \frac{1}{2}\gamma^2(x^2 + y^2) + \gamma\sigma_3 L_3, \quad \gamma \in R. \tag{23}$$

Since H does not depend on the constants ω_μ, a_μ, and b_μ we obtain six independent integrals of motion, generating the symmetry group of this Hamiltonian.

A basis for the symmetry algebra is given by the eight operators:

$$L_\pm = i(y\partial_x - x\partial_y)(I \pm \sigma_3),$$

$$X_\pm = (i\partial_x \mp \gamma y)(I \pm \sigma_3),$$

$$Y_\pm = (i\partial_y \pm \gamma x)(I \pm \sigma_3),$$

$$I_\pm = I \pm \sigma_3. \tag{24}$$

The nonzero commutation relations are

$$[L_\pm, X_\pm] = 2iY_\pm, \quad [L_\pm, Y_\pm] = -2iX_\pm, \quad [X_\pm, Y_\pm] = \pm 4i\gamma I_\pm. \tag{25}$$

The symmetry algebra is thus isomorphic to the direct sum of two central extensions of the Euclidean Lie algebra,

$$L \sim \tilde{e}_+(2) \oplus \tilde{e}_-(2) = \{L_+, X_+, Y_+, I_+\} \oplus \{L_-, X_-, Y_-, I_-\}. \tag{26}$$

The Casimir operators of L are

$$C_\pm = X_\pm^2 + Y_\pm^2 \pm 4\gamma L_\pm I_\pm, \quad I_\pm = I \pm \sigma_3, \tag{27}$$

and we have

$$H = \frac{1}{8}(C_+ + C_-). \tag{28}$$

The integral of motion X is a linear combination of the eight operators (24) with arbitrary real constant coefficients. Such operators X can be classified into conjugacy classes under the action of the group generated by the algebra (24). The conjugacy classes that lead to different types of solutions of the Pauli system (8) can be represented by

$$X_1 = L_+ + \alpha L_-, \quad X_2 = L_+ + \alpha X_-, \quad X_3 = X_+ + \alpha X_-, \quad \alpha \in R. \tag{29}$$

The Hamiltonian (23) is not only integrable, but actually "first-order superintegrable." For particles of spin 0 first-order superintegrability occurs only for free motion. Notice that if we set the spin-orbit interaction equal to zero in Eq. (23) (i.e., $\gamma=0$), we obtain free motion.

IV. HAMILTONIANS ALLOWING ONE FIRST-ORDER INTEGRAL

Let us now consider the case when Eqs. (19) are satisfied. The two equations (17) then coincide and the potential $V_1(x,y)$ satisfies just one second-order PDE. The equation (17) is of hyperbolic type. Its characteristic variables are

$$\xi = \frac{y}{x}, \quad \eta = \frac{1}{2}\omega_1(x^2 + y^2) - b_1 x + a_1 y. \tag{30}$$

Here we shall just consider two interesting special cases.

(a) $\omega_1 \neq 0$, $a_0 = b_0 = 0$, $a_1 = b_1 = 0$

We transform Eq. (17) to polar coordinates and obtain

$$\rho V_{1,\rho\theta} + 2V_{1,\theta} = 0, \quad x = \rho\cos\theta, \quad y = \rho\sin\theta. \tag{31}$$

The potential V_1 hence is

$$V_1 = f(\rho) + \frac{1}{\rho^2} g(\theta), \tag{32}$$

where $f(\rho)$ and $g(\theta)$ are arbitrary. Comparing with Eq. (13), we see that the function $g(\theta)$ can be set equal to $g=0$ by a gauge transformation. Solving (10) and (11), we obtain

$$V_0 = V_0(\rho), \quad V_1 = V_1(\rho), \quad \phi_0 = \phi_1 = 0, \tag{33}$$

$$X = (\omega_0 + \omega_1 \sigma_3) L_3. \tag{34}$$

(b) $\omega_0 = \omega_1 = 0$, $a_1^2 + b_1^2 \neq 0$
Equation (17) in characteristic variables (30) is

$$V_{1,\xi\eta} + \frac{2}{\eta} V_{1,\xi} = 0, \tag{35}$$

and we obtain

$$V_1 = F_1(a_1 y - b_1 x) + \frac{F_2\left(\frac{y}{x}\right)}{(a_1 y - b_1 x)^2}. \tag{36}$$

By a gauge transformation we set $F_2 = 0$ and rotate in the xy plane to obtain

$$V_1 = V_1(x). \tag{37}$$

From Eqs. (10) and (11) we obtain

$$V_0 = \frac{y^2}{2} V_1^2(x) + F(x), \tag{38}$$

$$\phi_0 = -b_1 \int V_1(x) dx, \quad \phi_1 = -b_0 \int V_1(x) dx. \tag{39}$$

Let us put $b_1 = 1$, $b_0 \neq 0$. We then have

$$\phi_1 = b_0 \phi_0, \quad V_1(x) = -\phi_0'(x),$$

$$V_0(x,y) = \frac{1}{2} y^2 [\phi_0'(x)]^2 + F(x), \tag{40}$$

and

$$X = -i b_0 \partial_y + \phi_0(x) + (-i \partial_y + b_0 \phi_0(x)) \sigma_3. \tag{41}$$

We shall call the case (33) the "polar" case, (37) and (38) the "Cartesian" one, because of the form of the operator X in (34) and (41), respectively.

V. SOLUTIONS OF THE PAULI EQUATION

In this section we shall analyze and solve the pair of equations (8) for the different superintegrable, or first-order integrable cases, found above.

A. The superintegrable Hamiltonian

Let us consider the Hamiltonian (23) with $\gamma \neq 0$, i.e., a constant spin-orbital potential and a harmonic oscillator spin-independent one. The Hamiltonian commutes with the entire kinematical algebra (24). We shall choose the operator X of Eq. (8) in the form of one of the different one-dimensional subalgebras shown in Eq. (29) and consider each of the three cases separately. The potentials $V_0(x,y)$ and $V_1(x,y)$ in this case have the form (33) and (40) simultaneously.

Hence, we can separate variables in polar coordinates, as well as in Cartesian ones. Moreover, we can consider a mixed case: separation in different coordinate systems for the upper and lower components of Ψ.

1. Polar case

We introduce polar coordinates (ρ,θ) and choose the operator X in the form

$$X=-i\begin{pmatrix}a_1 & 0\\ 0 & a_2\end{pmatrix}\partial_\theta,\quad a_i\neq 0. \tag{42}$$

The condition $X\Psi=\lambda\Psi$ provides a wave function in the form

$$\Psi(\rho,\theta)=\begin{pmatrix}F_1(\rho)e^{i(\lambda/a_1)\theta}\\ F_2(\rho)e^{i(\lambda/a_2)\theta}\end{pmatrix}. \tag{43}$$

Substituting into the Pauli equation with Hamiltonian (23) we find that the function $F_i(\rho)$ satisfies

$$\left\{-\frac{1}{2}\left(\frac{\partial^2}{\partial\rho^2}+\frac{1}{\rho}\frac{\partial}{\partial\rho}-\frac{1}{\rho^2}\frac{\lambda^2}{a_i^2}\right)+\frac{1}{2}\gamma^2\rho^2\right\}F_i=\left(E\mp\gamma\frac{\lambda}{a_i}\right)F_i, \tag{44}$$

so both components satisfy radial harmonic oscillator type equations.

The solution of Eq. (44) is

$$F_i(\rho)=N_{n_i m_i}e^{-(\gamma/2)\rho^2}\rho^{|m_i|}L_{n_i}^{|m_i|}(\gamma\rho^2), \tag{45}$$

where $L_{n_i}^{|m_i|}(z)$ are Laguerre polynomials. The quantum number λ satisfies

$$\frac{\lambda}{a_1}=m_1,\quad \frac{\lambda}{a_2}=m_2; \tag{46}$$

hence we must choose

$$\frac{a_2}{a_1}=\frac{m_1}{m_2} \tag{47}$$

rational. The energy satisfies

$$E-\gamma m_1=\gamma(2n_1+|m_1|+1),$$

$$E+\gamma m_2=\gamma(2n_2+|m_2|+1), \tag{48}$$

so the two radial quantum numbers are constrained by

$$2(n_2-n_1)=m_1\left(\frac{a_1}{a_2}+1\right)-|m_1|\left(\left|\frac{a_1}{a_2}\right|-1\right). \tag{49}$$

If we normalize to have

$$\int_0^\infty\int_0^{2\pi}(|\Psi_1|^2+|\Psi_2|^2)\rho\,d\rho\,d\theta=1, \tag{50}$$

we must put the normalization constants in (45) equal to

$$N_{n_i m_i}=\sqrt{\frac{\gamma^{|m_i|+1}}{2\pi}}\sqrt{\frac{n_i!}{(n_i+|m_i|)!}}. \tag{51}$$

2. Cartesian case

We choose the operator to be diagonalized in the form

$$X=\begin{pmatrix} a_1(i\partial_y+\gamma x) & 0 \\ 0 & a_2(i\partial_y-\gamma x)\end{pmatrix}, \quad a_i\neq 0. \tag{52}$$

The equation $X\Psi=\lambda\Psi$ implies

$$\Psi=\begin{pmatrix} F_1(x)e^{-(i/a_1)(\lambda-a_1\gamma x)y} \\ F_2(x)e^{-(i/a_2)(\lambda+a_2\gamma x)y}\end{pmatrix}. \tag{53}$$

Substituting into the Pauli equation $H\Psi=E\Psi$ with H as in Eq. (23), we obtain

$$\ddot{F}_i-4\gamma^2\left(x\mp\frac{\lambda}{2a_i\gamma}\right)^2F_i+2EF_i=0, \quad i=1,2, \tag{54}$$

and hence

$$F_i=N_{n_i}e^{-\gamma\tilde{x}_i^2}H_{n_i}(\sqrt{2\gamma}\tilde{x}_i),$$

$$E=2\gamma\left(n_1+\frac{1}{2}\right)=2\gamma\left(n_2+\frac{1}{2}\right), \quad n_1=n_2=n,$$

$$N_{n_i}=\sqrt{\frac{\sqrt{2\gamma}}{\sqrt{\pi}n!\,2^n}}, \quad \tilde{x}_{1,2}=x\mp\frac{\lambda}{2a_i\gamma}, \tag{55}$$

where $H_n(z)$ is a Hermite polynomial.

3. Mixed case

Let us take the operator X in the form

$$X=\begin{pmatrix} -ia_1\partial_\theta & 0 \\ 0 & a_2(i\partial_y-\gamma x)\end{pmatrix}, \quad a_i\neq 0. \tag{56}$$

The wave function will then be

$$\Psi=\begin{pmatrix} F_1(\rho)e^{i(\lambda/a_1)\theta} \\ F_2(x)e^{-(i/a_2)(\lambda+a_2\gamma x)y}\end{pmatrix}, \tag{57}$$

where (ρ,θ) are polar coordinates; (x,y) Cartesian ones. The function $F_1(\rho)$ will satisfy Eq. (44) with $i=1$; $F_2(x)$ Eq. (54) with $i=2$. We hence obtain

$$F_1(\rho)=N_{n_1m_1}\,e^{-(\gamma/2)\rho^2}\rho^{|m_1|}L_{n_1}^{|m_1|}(\gamma\rho^2),$$

$$F_2(x)=N_{n_2}e^{-\gamma\tilde{x}_2^2}H_{n_2}(\sqrt{2\gamma}\tilde{x}_2), \tag{58}$$

with

$$E=\gamma(m_1+2n_1+|m_1|+1)=2\gamma\left(n_2+\frac{1}{2}\right). \tag{59}$$

B. Hamiltonians with one first order integral

1. Polar case

We consider the potential $V_0=V_0(\rho)$, $V_1=V_1(\rho)$ as in Eq. (33). We write the integral (34) in the form

$$X=-i\begin{pmatrix}a_1 & 0\\ 0 & a_2\end{pmatrix}\partial_\theta, \quad a_i\neq 0, \tag{60}$$

and the equation $X\Psi=\lambda\Psi$ implies

$$\Psi(\rho,\theta)=\begin{pmatrix}F_1(\rho)e^{i(\lambda/a_1)\theta}\\ F_2(\rho)e^{i(\lambda/a_2)\theta}\end{pmatrix}. \tag{61}$$

Substituting into the Pauli equation, we find that the radial functions F_1, F_2 satisfy

$$\left\{-\frac{1}{2}\left(\frac{\partial^2}{\partial\rho^2}+\frac{1}{\rho}\frac{\partial}{\partial\rho}-\frac{1}{\rho^2}\frac{\lambda^2}{a_i^2}\right)+V_0\pm V_1\frac{\lambda}{a_i}\right\}F_i=EF_i, \quad i=1,2. \tag{62}$$

For instance, choosing

$$V_0=\frac{\alpha}{\rho}, \quad V_1=\frac{\beta}{\rho^2}, \tag{63}$$

we can solve Eq. (62) in terms of Coulomb wave functions.

2. Cartesian case

Let us now consider V_0, V_1 and the integral X as in (40) and (41). The equation $X\Psi=\lambda\Psi$ with X as in (41) implies

$$\Psi=\begin{pmatrix}\chi_1(x)e^{i\{[\lambda-(1+b_0)\phi_0(x)]/(1+b_0)\}y}\\ \chi_2(x)e^{i\{[\lambda-(1-b_0)\phi_0(x)]/(b_0-1)\}y}\end{pmatrix}. \tag{64}$$

The Pauli equation then reduces to the following two ODEs:

$$\ddot{\chi}_i-\left\{\frac{(\lambda\mp(b_0\pm1)\phi_0)^2}{(b_0\pm1)^2}\mp2x\phi_0'\frac{\lambda\mp(b_0\pm1)\phi_0}{(b_0\pm1)}+2F(x)-2E\right\}\chi_i=0, \quad i=1,2. \tag{65}$$

To solve these equations, or analyze further, we would have to specify the two functions $F(x)$, $\phi_0(x)$.

VI. CONCLUSIONS

Let us first of all compare the problem of integrability and superintegrability for particles with spin $s=0$ and spin $s\neq0$; in this case $s=\frac{1}{2}$. The spin zero case with a scalar potential in the two-dimensional Euclidean space E_2 corresponds to the Hamiltonian (1). First-order superintegrability is trivial: it requires $V(x)=$ const and corresponds to free motion. Superintegrability with one first-order and one second-order integral occurs for the potentials $V=\alpha r^2$, αr^{-1}, αx, and αx^{-2}.[18] Quadratic superintegrability leads to four families of potentials,[9,21] each depending on three significant constants and allowing the separation of variables in at least two coordinate systems.

By contrast, for $s=\frac{1}{2}$ first-order superintegrability leads to a nontrivial system, namely the Hamiltonian (23) with the symmetry algebra (24). The Hamiltonian allows the separation of variables in polar coordinates [see (43)] and "R separation" in Cartesian ones [see (53)]. Indeed, in Eq. (53) there is a term involving the product xy that does not depend on the separation constant λ. The same is true for Hamiltonians, allowing just one first-order integral. In the polar case we have separation [see (61)], in the Cartesian one R separation (64).

The next step in this research program will be to look for integrable and superintegrable systems with spin in Euclidean 3-space. This would provide a realistic and solvable model for pion-nucleon and possibly nucleon-nucleon interactions.

When is negativity not a problem for the ultradiscrete limit?

Alex Kasman[a] and Stéphane Lafortune[b]
Department of Mathematics, College of Charleston, Charleston, South Carolina 29424

(Received 25 July 2006; accepted 14 September 2006; published online 24 October 2006)

The "ultradiscrete limit" has provided a link between integrable difference equations and cellular automata displaying soliton-like solutions. In particular, this procedure generally turns *strictly positive* solutions of algebraic difference equations with *positive* coefficients into corresponding solutions to equations involving the "Max" operator. Although it certainly is the case that dropping these positivity conditions creates potential difficulties, it is still possible for solutions to persist under the ultradiscrete limit, even in their absence. To recognize when this will occur, one must consider whether a certain expression, involving a measure of the rates of convergence of different terms in the difference equation and their coefficients, is equal to zero. Applications discussed include the solution of elementary ordinary difference equations, a discretization of the Hirota Bilinear Difference Equation and the identification of integrals of motion for ultradiscrete equations.

I. INTRODUCTION

Integrable nonlinear partial differential equations are of special interest in part because of their "soliton solutions" that exhibit particle-like behavior.[1,3,7,23] The link between these equations and the cellular automata that exhibit superficially similar solutions[2,11,13,18] was the observation in Ref. 20 that solutions to the discretizations of the soliton equations become solutions to these cellular automata under the "ultradiscrete limit." Loosely speaking, this works because of the fact that, for $a,b \in \mathbb{R}$

$$\lim_{\epsilon \to 0^+} \epsilon \ln(e^{a/\epsilon} + e^{b/\epsilon}) = \mathrm{Max}(a,b). \tag{1}$$

This formula can be understood intuitively by noting that the term corresponding to the smaller of the two exponents will be relatively insignificant when ϵ is very small and that with it eliminated the entire expression is simply equal to the numerator of the other exponent. It can also be easily verified using L'Hôpital's rule.

In applying (1) to difference equations, previous authors have been very cautious, allowing negative coefficients in front of the exponentials, and have not been concerned at all about the question of how allowing a and b in the formula above to depend on ϵ might affect the outcome. In fact, they are correct that letting those coefficients be negative may invalidate the prediction that the resulting limit will merely be given by the "Max." In this paper, we will be especially interested in the case in which the linear combination of exponential functions *does* involve negative coefficients. Our viewpoint is that it is worthwhile to investigate this situation to understand what can go wrong.

Theorem 2.1 demonstrates two surprising facts: (a) Even if negative coefficients are involved, a formula analogous to (1) continues to work "most of the time." (b) In determining when it might

[a]Electronic mail: kasmana@cofc.edu
[b]Electronic mail: lafortunes@cofc.edu

fail, it is necessary to explicitly consider the rate of convergence of the exponents under the limit in ϵ. This theorem is illustrated by an application to two simple, ordinary difference equations in Sec. III. In a more sophisticated application, the theorem is used to guarantee the production of a solution to an ultradiscrete limit of the Hirota Bilinear Difference Equation in Sec. IV. Finally, these results are applied to the question of when integrals of motion for difference equations survive the ultradiscrete limit in Sec. V.

Both to refer readers to other work that may be of interest and to emphasize the differences with this paper, we would like to conclude this Introduction with a discussion of three other papers. Equation (1) has been previously generalized in Ref. 21 to the case in which a and b are complex constants. This is of great interest, but clearly quite different from what we do below by allowing the argument of the logarithm to be an arbitrary linear combination of exponentials and letting the exponents be real functions of ϵ. Also, Ref. 8 presents work related to the goals of the present paper by addressing the question of how one can take an ultradiscrete limit of a solution to a difference equation that takes on negative values. Their approach involves an alternative method of introducing dependence on ϵ into the solution so that the new variable can be real, even in the case that the original variable was negative. However, in doing so, they are careful to be certain that they always apply (1) only in the case that the coefficients of the exponentials are equal to one and make no explicit mention of the possibility that the results may be affected by the dependence of the exponents on ϵ. So, that paper takes what might be viewed as an "orthogonal" approach to the question to the one that will be pursued later. It might be of interest to attempt to combine the two, by applying Theorem 2.1 to the *s-ultradiscrete limit* as defined in that paper. Finally, perhaps most closely related to this paper in spirit, Ref. 12 generalizes the procedure of ultradiscretization by formally extending the Max-Plus algebra through the introduction of an extra $\mathbb{Z}_2$ component. This extension of the Max-Plus semiring to a full ring, as is normally done in the Max-Plus community by moving to the symmetrized ring $\mathbb{S}_{\max}$,[4] means that the resulting equations are not ordinary ultradiscrete equations (the Max operator and even equality have slightly different meanings). In contrast, in this paper we address the question of when negativity fails to create any problems under the original definition of the ultradiscrete limit and integrable ultra-discrete equations.

A. Notation

In the following, a superscript of ϵ will indicate that the parameter depends *differentiably* on the real variable ϵ in some open interval $(0,\beta)$. Thus u_n^ϵ would be an ϵ dependent bi-infinite sequence and could be a solution to a difference equation in which the coefficients also depend on ϵ, and we would only call it a solution if the equation were true, not only for all n but also for all $\epsilon \in (0,\beta)$. [For example, $u_n^\epsilon = \epsilon n$ satisfies $u_{n+1}^\epsilon u_{n-1}^\epsilon = (u_n^\epsilon)^2 - \epsilon^2$].

B. An enlightening example

As we will see in Theorem 2.1, it is possible to generalize (1) to the case in which the argument of the logarithm is a more general linear combination of exponentials whose exponents depend on ϵ. As one might guess, the value of the limit turns out to be equal to the maximum of the limits of the numerators of the exponents. However, the theorem can only be applied subject to the condition that a certain expression involving the coefficients and the rates of convergence is not equal to zero. Following is a cautionary example whose purpose is to illustrate the fact that failing to consider this condition is liable to produce incorrect results.

If we consider the expression

$$\tau = e^{u_1^\epsilon/\epsilon} + \gamma e^{u_2^\epsilon/\epsilon}$$

then using the previously stated argument that the term with the lower power can simply be ignored, we may naively think that

$$\lim_{\epsilon\to 0^+} \epsilon \ln \tau = \mathrm{Max}(u_1,u_2), \quad \text{where } u_i = \lim_{\epsilon\to 0^+} u_i^\epsilon. \tag{2}$$

However, (2) may be false for some choices of u_i^ϵ and γ.

For instance, if we let

$$u_1^\epsilon = a + 2\epsilon \ln(e^{-k/\epsilon} + \sqrt{8 + e^{-2k/\epsilon}}), \quad u_2^\epsilon = a + \epsilon \ln 2 \quad \text{and } \gamma = -4$$

where $k>0$ and a is arbitrary, then

$$u_1 = u_2 = a.$$

However, despite the predictions of Eq. (2), one can check that, in fact,

$$\lim_{\epsilon\to 0^+} \epsilon \ln \tau = a - k.$$

The total avoidance of negativity in the literature on "ultradiscrete limits" might suggest that it is the fact that $\gamma<0$ that is causing a problem here, but that would be a drastic oversimplification. The fact is that for *any* choice of $\gamma\neq -4$ the prediction of (2) would have been correct and the limit would have the value a, as expected. So, an explanation of this phenomenon would have to shed light on the question of why this occurs only at $\gamma=-4$. (Such an explanation is provided in the following section.)

This example is not as artificial as it may at first seem since it will arise in a more general form as part of an investigation of a simple ordinary difference equation in Sec. III. It demonstrates that the coefficients in the linear combination of exponentials can have unexpected effects on the "ultradiscrete limit." It also demonstrates that the natural generalization of (1) provided by (2) is correct *generically* in the sense that it is only for rather specific choices of coefficient that it fails.

II. A MORE GENERAL LIMIT

In this section we state and prove a generalization of (1) that will later be applied to questions involving difference equations. We wish to consider instead the case in which the argument of the logarithm, τ, may be an arbitrary linear combination of exponentials and in which the numerator of the exponents can also depend upon ϵ. The following theorem gives conditions that are sufficient (but not necessary, as we will see in Sec. III A) to conclude that the limit of $\epsilon \ln \tau$ is still equal to the largest limit of the numerators of the exponents.

Theorem 2.1: *Let*

$$\tau = \sum_{i=1}^{n} \gamma_i e^{w_i^\epsilon/\epsilon}, \tag{3}$$

where $\gamma_i \in \mathbb{C}$ *are arbitrary, nonzero constants and* w_i^ϵ *are real valued functions such that the limits*

$$M_i = \lim_{\epsilon\to 0^+} w_i^\epsilon, \quad i = 1, \ldots, n,$$

are finite. Let

$$\mathfrak{M} = \mathrm{Max}(M_1, \ldots, M_n) \quad \text{and} \quad \mathfrak{I} = \{i | M_i = \mathfrak{M}\}$$

denote the largest value of these limits and the set of indices for which this maximum is achieved, respectively.

Then

$$\lim_{\epsilon\to 0^+} \epsilon \ln \tau = \mathfrak{M},$$

if either

(i) $|\mathfrak{I}|=1$ (*the maximum is achieved only once*) or
(ii) *the limits*

$$\mu_i = \lim_{\epsilon\to 0^+} (w_i^\epsilon - \mathfrak{M})/\epsilon, \quad for \quad i \in \mathfrak{I}$$

are finite and $D\neq 0$, *where*

$$D = \sum_{i\in\mathfrak{I}} \gamma_i e^{\mu_i}.$$

Proof: In the case $|\mathfrak{I}|=1$ let $\mathfrak{I}=\{i_0\}$ so that $M_{i_0}=\mathfrak{M}>M_i$ for $i\neq i_0$. Then

$$\begin{aligned}\lim_{\epsilon\to 0^+} \epsilon \ln \tau &= \lim_{\epsilon\to 0^+} \epsilon \ln(e^{\mathfrak{M}/\epsilon}\sum \gamma_i e^{(w_i^\epsilon-\mathfrak{M})/\epsilon})\\ &= \epsilon \ln e^{\mathfrak{M}/\epsilon} + \epsilon \ln \sum \gamma_i e^{(w_i^\epsilon-\mathfrak{M})/\epsilon}\\ &\quad \text{(then since } w_i^\epsilon - \mathfrak{M} < 0 \text{ for } i\neq i_0 \text{ and } \epsilon \text{ sufficiently small)}\\ &= \mathfrak{M} + \lim_{\epsilon\to 0^+} \epsilon \ln \gamma_{i_0} = \mathfrak{M}.\end{aligned}$$

The situation is more complicated in the case that $|\mathfrak{I}|>1$. We now assume that $D\neq 0$ and show that again the limit is simply equal to the maximum of the exponents.

First, we wish to show that $D\neq 0$ implies that τ is nonzero on a small open interval $(0,\beta)$ and so it makes sense to consider the function $\epsilon \ln \tau$. (There is no need to require $\tau>0$, however, since the proof to follow continues to be valid in the case that this function takes on complex values or even if it becomes multivalued as a consequence of analytic continuation.)

$$\begin{aligned}D = \sum_{i\in\mathfrak{I}} \gamma_i e^{\mu_i} &= \lim_{\epsilon\to 0^+} \sum_{i\in\mathfrak{I}} \gamma_i e^{(w_i^\epsilon-\mathfrak{M})/\epsilon}\\ &\quad \text{(then since } w_i^\epsilon - \mathfrak{M} < 0 \text{ for } i\notin\mathfrak{I} \text{ and } \epsilon \text{ sufficiently small)}\\ &= \lim_{\epsilon\to 0^+} \sum_{i=1}^{n} \gamma_i e^{(w_i^\epsilon-\mathfrak{M})/\epsilon} = \lim_{\epsilon\to 0^+} e^{-\mathfrak{M}/\epsilon}\tau.\end{aligned}$$

Suppose $\epsilon_i>0$ is a sequence that converges to 0 and with the property that $\tau=0$ for $\epsilon=\epsilon_i$. Then, since the limit above converges to D, it must be the case that $D=0$. Since $D\neq 0$, no such sequence of $\{\epsilon_i\}$ can exist.

Now, we simply compute that

$$\begin{aligned}\lim_{\epsilon\to 0^+} \epsilon \ln \tau &= \lim_{\epsilon\to 0^+} \epsilon \ln(e^{\mathfrak{M}/\epsilon}\sum \gamma_i e^{(w_i^\epsilon-\mathfrak{M})/\epsilon})\\ &= \lim_{\epsilon\to 0^+} \epsilon \ln e^{\mathfrak{M}/\epsilon} + \lim_{\epsilon\to 0^+} \epsilon \ln \sum_{i=1}^{n} e^{(w_i^\epsilon-\mathfrak{M})/\epsilon}\\ &= \mathfrak{M} + \lim_{\epsilon\to 0^+} \epsilon \ln\left(\sum_{i\in\mathfrak{I}} e^{(w_i^\epsilon-\mathfrak{M})/\epsilon} + \sum_{i\notin\mathfrak{I}} e^{(w_i^\epsilon-\mathfrak{M})/\epsilon}\right)\\ &= \mathfrak{M} + \lim_{\epsilon\to 0^+} \epsilon \ln(D+0) = \mathfrak{M}.\end{aligned}$$

□

Note that, apart from the restriction that $D\neq 0$, the value of the limit is independent of the choice of coefficients γ_i. We will take advantage of this feature in Secs. III–V to effectively apply

the procedure of ultradiscrete limits to integrable difference equations, even in the absence of any positivity restrictions. Furthermore, note that as a consequence of this lack of dependence on the value of the coefficients, the limit will be unaffected by an extra common factor of -1. In particular, we have the following corollary.

Corollary 2.2: If the conditions of Theorem 2.1 are met, then

$$\lim_{\epsilon\to 0^+} \epsilon \ln|\tau| = \lim_{\epsilon\to 0^+} \epsilon \ln \tau.$$

Again, this ability for us to take the absolute value prior to taking the ultra-discrete limit will be useful in our attempt to apply this result in the case of difference equations.

A. Continuation of earlier example

It is important to note that if neither conditions (i) or (ii) are met, then the value of the limit cannot necessarily be determined through knowledge of the limits M_i of the functions in the exponents. This is demonstrated by the example from Sec. I B in which the value of the limit of the entire expression, $a-k$, depends on the parameter k not appearing in the limits of the functions in the exponents when $\gamma=-4$.

We can now apply Theorem 2.1 to explain the significance of $\gamma=-4$ in that example. Again let

$$\tau = e^{u_1^\epsilon/\epsilon} + \gamma e^{u_2^\epsilon/\epsilon}, \quad u_1^\epsilon = a + 2\epsilon \ln(e^{-k/\epsilon} + \sqrt{8 + e^{-2k/\epsilon}}) \quad \text{and} \quad u_2^\epsilon = a + \epsilon \ln 2,$$

but consider γ arbitrary. The paramters μ_i measuring convergence are then

$$\mu_1 = \lim_{\epsilon\to 0^+} (u_1^\epsilon - a)/\epsilon = \ln 8 \quad \text{and} \quad \mu_2 = \lim_{\epsilon\to 0^+} (u_2^\epsilon - a)/\epsilon = \ln 2.$$

Hence, we find that

$$D = e^{\ln 8} + \gamma e^{\ln 2} = 2(4+\gamma).$$

Since this is only equal to zero at $\gamma=-4$, the "mystery" is resolved.

B. An example where *D* does not exist

To illustrate the role of condition (i) in Theorem 2.1, we briefly point out that for

$$\tau = e^{u_1^\epsilon/\epsilon} - e^{u_2^\epsilon/\epsilon} \quad u_1^\epsilon = \epsilon \sin(1/\epsilon) \quad u_2^\epsilon = -2 + 3\epsilon,$$

one has $\mathfrak{M}=\lim_{\epsilon\to 0^+} u_1^\epsilon = 0 > \lim_{\epsilon\to 0^+} u_2^\epsilon = -2$. Since $|\mathfrak{I}|=1$, we know that $\lim_{\epsilon\to 0^+}\epsilon \ln \tau = 0$, even though the limit defining μ_1 has no value.

III. APPLICATION: ORDINARY DIFFERENCE EQUATIONS

Consider the difference equation

$$\sum_{i=1}^{N} \left(\alpha_i^\epsilon \prod_{j=-d}^{d} (x_{n+j}^\epsilon)^{m_{ij}} \right) = \sum_{i=1}^{\hat{N}} \left(\hat{\alpha}_i^\epsilon \prod_{j=-d}^{d} (x_{n+j}^\epsilon)^{\hat{m}_{ij}} \right). \tag{4}$$

We will generally be interested in the case $m_{ij}, \hat{m}_{ij} \in \mathbb{Z}$ for the sake of preserving the integrality of solutions under the ultradiscrete limit.

Definition 3.1: *We say that a solution x_n^ϵ to (4) is a candidate for the ultradiscrete limit if the following conditions are met:*

- *$x_{n-d}^\epsilon, \ldots, x_{n+d}^\epsilon$, α_i^ϵ, and $\hat{\alpha}_i^\epsilon$ take non-zero real values for $\epsilon \in (0, \beta)$ for some small, positive number β.*

- The limits $u_n=\lim_{\epsilon\to 0^+}\epsilon\ln|x_n^\epsilon|$, $A_i=\lim_{\epsilon\to 0^+}\epsilon\ln|\alpha_i^\epsilon|$, *and* $\hat{A}_i=\lim_{\epsilon\to 0^+}\epsilon\ln|\hat{\alpha}_i^\epsilon|$ *exist and are finite*.
- The limits

$$\mu_i=\lim_{\epsilon\to 0^+}\frac{(\epsilon\ln|\alpha_i^\epsilon|+\epsilon\sum_{j=-d}^{d}m_{ij}\ln|x_{n+j}^\epsilon|)-\mathfrak{M}}{\epsilon},\quad \text{for } i\in\mathfrak{I}$$

and

$$\hat{\mu}_i=\lim_{\epsilon\to 0^+}\frac{(\epsilon\ln|\hat{\alpha}_i^\epsilon|+\epsilon\sum_{j=-d}^{d}\hat{m}_{ij}\ln|x_{n+j}^\epsilon|)-\hat{\mathfrak{M}}}{\epsilon},\quad \text{for } i\in\hat{\mathfrak{I}}$$

exist and are finite where

$$\mathfrak{M}=\operatorname*{Max}_{i=1}^{N}\left(A_i+\sum_{j=-d}^{d}m_{ij}u_{n+j}\right)$$

and

$$\mathfrak{I}=\left\{i\middle|A_i+\sum_{j=-d}^{d}m_{ij}u_{n+j}=\mathfrak{M}\right\}$$

is the set of indices for which this maximum is attained, and, similarly,

$$\hat{\mathfrak{M}}=\operatorname*{Max}_{i=1}^{\hat{N}}\left(\hat{A}_i+\sum_{j=-d}^{d}\hat{m}_{ij}u_{n+j}\right)\quad \textit{and}\ \hat{\mathfrak{I}}=\left\{i\middle|\hat{A}_i+\sum_{j=-d}^{d}\hat{m}_{ij}u_{n+j}=\hat{\mathfrak{M}}\right\}.$$

Theorem 3.2: *Suppose x_n^ϵ is a solution to the algebraic difference equation (4), which is a candidate for the ultradiscrete limit (see Definition 3.1 for terminology and notation). The ultradiscrete limit of x_n^ϵ,*

$$u_n=\lim_{\epsilon\to 0^+}\epsilon\ln|x_n^\epsilon|$$

is a solution to the equation

$$\operatorname*{Max}_{i=1}^{N}\left(A_i+\sum_{j=-d}^{d}m_{ij}u_{n+j}\right)=\operatorname*{Max}_{i=1}^{\hat{N}}\left(\hat{A}_i+\sum_{j=-d}^{d}\hat{m}_{ij}u_{n+j}\right)\tag{5}$$

if the maximum value on each side is never attained simultaneously for more than one value of the index, or as long as both

$$\sum_{i\in\mathfrak{I}}\sigma_i e^{\mu_i}\neq 0\quad\text{and}\ \sum_{i\in\hat{\mathfrak{I}}}\hat{\sigma}_i e^{\hat{\mu}_i}\neq 0,\tag{6}$$

where

$$\sigma_i=\frac{|\alpha_i^\epsilon\prod_{j=-d}^{d}(x_{n+j}^\epsilon)^{m_{ij}}|}{\alpha_i^\epsilon\prod_{j=-d}^{d}(x_{n+j}^\epsilon)^{m_{ij}}},\qquad \hat{\sigma}_i=\frac{|\hat{\alpha}_i^\epsilon\prod_{j=-d}^{d}(x_{n+j}^\epsilon)^{\hat{m}_{ij}}|}{\hat{\alpha}_i^\epsilon\prod_{j=-d}^{d}(x_{n+j}^\epsilon)^{\hat{m}_{ij}}},$$

are the signs of the corresponding term in the equation.

Proof: Letting

$$w_i^\epsilon = \epsilon \ln \left| \alpha_i^\epsilon \prod_{j=-d}^{d} (x_{n+j}^\epsilon)^{m_{ij}} \right|,$$

we can write the left side of (4) in the form

$$\tau = \sum_{i=1}^{N} \sigma_i e^{w_i^\epsilon/\epsilon}.$$

If $|\mathfrak{I}|=1$ or $D\neq 0$, then Theorem 2.1 tells us that the limit of $\epsilon \ln \tau$ will be

$$\max_{i=1}^{N}(\lim_{\epsilon\to 0^+} w_i^\epsilon).$$

But that D is nonzero is exactly the first of the two requirements in (6) and so

$$\lim_{\epsilon\to 0^+} w_i^\epsilon = \lim_{\epsilon\to 0^+}\left(\epsilon \ln \alpha_i^\epsilon + \epsilon \sum_{j=-d^d} m_{ij} \ln x_{n+j}^\epsilon\right) = A_i + \sum_{j=-d}^{d} m_{ij} u_{n+j},$$

and that $|\mathfrak{I}|=1$ is equivalent requiring that the maximum on the left hand side of (5) is achieved for a unique value of the index.

Similarly, we conclude that the limit of ϵ times the log of the right hand side of the equation is $\mathrm{Max}_i(\hat{A}_i+\Sigma_{j=-d}^{d}\hat{m}_{ij}u_{n+j})$. If x_n^ϵ is a solution, then these two sides are always equal and hence their limits are equal as well. □

A. Basic example

Consider the difference equation

$$x_{n+1}^\epsilon + e^{2b/\epsilon} x_{n-1}^\epsilon - e^{2c/\epsilon} x_{n-1}^\epsilon = 2e^{b/\epsilon} x_n^\epsilon. \tag{7}$$

Let $N=3$ because there are three terms on the left, $\hat{N}=1$ because there is one monomial on the right, and $d=1$ because we only see n shifted up and down by this much. The monomials on the left are given by letting

$$\alpha_1^\epsilon = \sigma_1 = 1, \quad m_{1,-1} = m_{1,0} = 0, \quad m_{1,1} = 1,$$

$$\alpha_2^\epsilon = e^{2b/\epsilon}, \quad \sigma_2 = 1, \quad m_{2,-1} = 1, \quad m_{2,0} = m_{2,1} = 0,$$

and

$$\alpha_3^\epsilon = e^{2c/\epsilon}, \quad \sigma_3 = -1, \quad m_{3,-1} = 1, \quad m_{3,0} = m_{3,1} = 0.$$

The monomial on the right is given by letting

$$\hat{\sigma}_1 = 1, \quad \hat{\alpha^\epsilon} = 2e^{b/\epsilon}, \quad \hat{m}_{1,-1} = \hat{m}_{1,1} = 0 \quad \text{and} \quad \hat{m}_{1,0} = 1.$$

A solution to this equation is given by

$$x_n^\epsilon = (e^{b/\epsilon} + e^{c/\epsilon})^n,$$

since expanding the left hand side of (7) with this definition for x_n^ϵ gives an expression equal to the right hand side for any n or ϵ.

Trivially, this same solution x_n^ϵ *also* solves the difference equation

$$e^{2b/\epsilon}x_{n-1}^{\epsilon} - e^{2c/\epsilon}x_{n-1}^{\epsilon} = 2e^{b/\epsilon}x_n^{\epsilon} - x_{n+1}^{\epsilon}. \tag{8}$$

In fact, in most circumstances one would want to consider this equation to be completely equivalent to (7) since one can simply add x_{n+1}^{ϵ} to both sides of one to make it into the other. *However*, for the purposes of this paper they are quite different.

Regardless of whether we are working with the difference equation in the form (7) or (8), the solution $x_n^{\epsilon}=(e^{b/\epsilon}+e^{c/\epsilon})^n$ is the same. Then our solution u_n to the ultradiscrete equation should take the form

$$u_n = \lim_{\epsilon\to 0^+} \epsilon \ln(e^{b/\epsilon}+e^{c/\epsilon})^n = n \lim_{\epsilon\to 0^+} \epsilon \ln(e^{b/\epsilon}+e^{c/\epsilon}) = n\,\mathrm{Max}(b,c).$$

Ignoring condition (6) of Theorem 3.2, we get from (7) that u_n should satisfy

$$\mathrm{Max}(u_{n+1}, 2b+u_{n-1}, 2c+u_{n-1}) = b+u_n, \tag{9}$$

and from (8) we get that it should satisfy

$$\mathrm{Max}(2b+u_{n-1}, 2c+u_{n-1}) = \mathrm{Max}(b+u_n, u_{n+1}). \tag{10}$$

However, it is *not* the case that u_n satisfies each of these equations, regardless of the choice of b and c. In particular, condition (6) may not be met and, as we will see, this causes u_n not to solve (9) when $b<c$.

Look at the arguments of Max on the left hand side of (9) and consider the question of which of them are *equal* to the maximum value. If $b>c$ then the terms have the values $(n+1)b$, $(n+1)b$ and $(n-1)b+2c$, respectively, so that the first two terms are equal to the maximum value. [Using the notation of the theorem, $\mathfrak{M}=(n+1)b$ and $\mathfrak{I}=1,2$.] All of the μ_i are zero (which means that these solutions converge quickly to their limits), and so all of the exponential terms are just equal to one. Now, we must look at the sum of σ_1 and σ_2 to make certain that it is not equal to zero. Since $\sigma_1+\sigma_2=2\neq 0$, the condition is met. And, in fact, one can easily verify that if $b>c$, then $u_n=nb$ *is* indeed a solution to (9). However, when $b<c$, then things are quite different. In that case, $\mathfrak{M}=(n+1)c$ and$\mathfrak{I}=\{1,3\}$, but $\sigma_1+\sigma_3=0$, and so Theorem 3.2 does *not* predict that u_n will solve the equation. In fact, it does not, because then the left hand side has the value $(n+1)c$ while the right side has the value $nc+b$.

In contrast, the theorem predicts that u_n will solve (10) when $b>c$ *and* when $b<c$. In particular, if $b>c$, then $\mathfrak{M}=\mathrm{Max}(2b+u_{n-1},2c+u_{n-1})=(n+1)b$ and $\mathfrak{I}=\{1\}$, while if $c>b$ then $\mathfrak{M}=(n+1)c$ and $\mathfrak{I}=\{2\}$. Thus, we conclude from the theorem that u_n should satisfy (10) as long as $b\neq c$. In fact, it can be checked explicitly that u_n is a solution to (10) in the case $b=c$ as well. This is true even though the conditions of the theorem fail to be satisfied in that case. This shows that the conditions of the theorem, while sufficient, are not necessary.

B. Another example: Demonstrating the role of rate of convergence

Consider the difference equation

$$x_{n+1}^{\epsilon} - 2x_{n-1}^{\epsilon} = e^{\lambda/\epsilon}x_n^{\epsilon}.$$

Considering the survival of solutions of this equation under the ultradiscrete limit illustrates the importance of the parameters μ_i, which measure the rate of convergence of the terms.

This has a solution of the form

$$x_n^{\epsilon} = \left(\frac{\sqrt{8+e^{2\lambda/\epsilon}}+e^{\lambda/\epsilon}}{2}\right)^n.$$

Consequently, we would expect

$$u_n = \lim_{\epsilon \to 0^+} \epsilon \ln x_n^\epsilon = \begin{cases} n\lambda, & \lambda > 0, \\ 0, & \lambda \le 0, \end{cases}$$

to solve

$$\mathrm{Max}(u_{n+1}, u_{n-1}) = \lambda + u_n.$$

And, indeed, if $\lambda > 0$ this is true. However, it fails when $\lambda < 0$. This could be predicted by the Theorem. Condition (6) is trivially met when $\lambda > 0$ because the exponents on the left do not have the same limit. However, when $\lambda < 0$ then both exponents go to 0 and $\mu_1 = \ln 2$, and hence the sum is $D = e^{\ln 2} - e^{\ln 2} = 0$.

IV. APPLICATION: HIROTA BILINEAR DIFFERENCE EQUATION

The Hirota Bilinear Difference Equation (HBDE)[10,17,22] for a function $x^\epsilon(a,b,c,d)$ of four variables is

$$\begin{aligned}(\lambda_4^\epsilon - \lambda_3^\epsilon)(\lambda_2^\epsilon - \lambda_1^\epsilon) x^\epsilon(a,b,c+1,d+1) x^\epsilon(a+1,b+1,c,d) \\ + (\lambda_4^\epsilon - \lambda_1^\epsilon)(\lambda_3^\epsilon - \lambda_2^\epsilon) x^\epsilon(a+1,b,c,d+1) x^\epsilon(a,b+1,c+1,d) \\ = (\lambda_4^\epsilon - \lambda_2^\epsilon)(\lambda_3^\epsilon - \lambda_1^\epsilon) x^\epsilon(a+1,b,c+1,d) x^\epsilon(a,b+1,c,d+1).\end{aligned}$$

As a consequence of the main result in Ref. 5, a solution to this equation can be constructed as

$$x^\epsilon(a,b,c,d) = \det(P \cdot (I - \lambda_1^\epsilon S)^a \cdot (I - \lambda_2^\epsilon S)^b \cdot (I - \lambda_3^\epsilon S)^c \cdot (I - \lambda_4^\epsilon S)^d \cdot \Omega),$$

where Ω is any $n \times k$ matrix ($k < n$), S is any $n \times n$ matrix such that the lower-left $k \times (n-k)$ block has rank one, I is the $n \times n$ identity matrix, and $P = (0 I_k)$ is the $k \times n$ matrix that has the $k \times k$ identity matrix as a block and all zeroes to the left of it.

It is interesting to note that even though $x^\epsilon(a,b,c,d)$ has dependence upon ϵ inherited from the presence of λ_i^ϵ in the formula, one is also free to choose S and Ω to depend upon ϵ and $x^\epsilon(a,b,c,d)$ would still solve the difference equation.

For example, let us consider

$$\lambda_1^\epsilon = e^{-2/\epsilon} - e^{2/\epsilon} + e^{3/\epsilon}, \quad \lambda_2^\epsilon = e^{3/\epsilon} - e^{2/\epsilon}, \quad \lambda_3^\epsilon = e^{3/\epsilon} + e^{-2/\epsilon}, \quad \lambda_4^\epsilon = e^{3/\epsilon},$$

so that

$$(\lambda_4^\epsilon - \lambda_3^\epsilon)(\lambda_2^\epsilon - \lambda_1^\epsilon) = e^{-4/\epsilon}, \quad (\lambda_4^\epsilon - \lambda_2^\epsilon)(\lambda_3^\epsilon - \lambda_1^\epsilon) = e^{4/\epsilon}.$$

[It is necessarily the case that $(\lambda_4^\epsilon - \lambda_1^\epsilon)(\lambda_3^\epsilon - \lambda_2^\epsilon)$ is the difference of the other two.]

Now, just for the sake of example, let us consider the solution that comes from using $k=2$, $n=4$,

$$S = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & e^{1/\epsilon} & 0 & 0 \\ 0 & 0 & e^{5/\epsilon} & 0 \\ 0 & e^{5/\epsilon} & 0 & e^{12/\epsilon} \end{pmatrix} \quad \text{and} \quad \Omega = \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{pmatrix}.$$

This solution has the form (up to a common multiple independent of a, b, c, and d that does not matter due to the bilinear nature of the equation)

$$x^\epsilon(a,b,c,d) = x_1^\epsilon(a,b,c,d) - x_2^\epsilon(a,b,c,d) + x_3^\epsilon(a,b,c,d)$$

where

$$x_1^\epsilon(a,b,c,d) = e^{4/\epsilon}(1 - e^{4/\epsilon})^d (1 - e^{-1/\epsilon} - e^{4/\epsilon})^c (1 + e^{3/\epsilon} - e^{4/\epsilon})^b (1 - e^{-1/\epsilon} + e^{3/\epsilon} - e^{4/\epsilon})^a$$

$$(1-e^{8/\epsilon})^d(1-e^{3/\epsilon}-e^{8/\epsilon})^c(1+e^{7/\epsilon}-e^{8/\epsilon})^b(1-e^{3/\epsilon}+e^{7/\epsilon}-e^{8/\epsilon})^a,$$

$$x_2^\epsilon(a,b,c,d)=(1-e^{8/\epsilon})^d(1-e^{3/\epsilon}-e^{8/\epsilon})^c(1+e^{7/\epsilon}-e^{8/\epsilon})^b(1-e^{3/\epsilon}+e^{7/\epsilon}-e^{8/\epsilon})^a$$

$$(1-e^{15/\epsilon})^d(1-e^{10/\epsilon}-e^{15/\epsilon})^c(1+e^{14/\epsilon}-e^{15/\epsilon})^b(1-e^{10/\epsilon}+e^{14/\epsilon}-e^{15/\epsilon})^a,$$

and

$$x_3^\epsilon(a,b,c,d)=e^{11/\epsilon}(1-e^{8/\epsilon})^d(1-e^{3/\epsilon}-e^{8/\epsilon})^c(1+e^{7/\epsilon}-e^{8/\epsilon})^b(1-e^{3/\epsilon}+e^{7/\epsilon}-e^{8/\epsilon})^a$$

$$(1-e^{15/\epsilon})^d(1-e^{10/\epsilon}-e^{15/\epsilon})^c(1+e^{14/\epsilon}-e^{15/\epsilon})^b(1-e^{10/\epsilon}+e^{14/\epsilon}-e^{15/\epsilon})^a.$$

Before even worrying about the structure of the equation, one must worry that this solution itself will not have a well defined or simple ultradiscrete limit. In particular, if we define

$$u(a,b,c,d)=\lim_{\epsilon\to 0^+}\epsilon\ln x^\epsilon(a,b,c,d),$$

and we do not worry about the requirement that $D\neq 0$ in Theorem 2.1, then we would conclude that

$$u(a,b,c,d)=\mathrm{Max}(4+12a+12b+12c+12d,23a+23b+23c+23d,11+23a+23b+23c+23d). \tag{11}$$

(This is found by adding up for each factor in the expression of x_i^ϵ with $i=1,2,3$ the highest numerator of the exponent when viewed as a fraction having ϵ as the denominator. For instance, the first expression is found from x_1^ϵ as $4+4d+4c+4+4a+8d+8c+8b+8a$.) Yet, as the examples of the previous section demonstrate, we ought to be worried that this formula is not accurate in the case that $D=0$ when Theorem 2.1 is applied to this example.

In fact, it turns out that there is no need to worry about this since it is always the case here that $|\mathfrak{I}|=1$. Note first that the third is always 11 more than the second, and so there is no possibility that these would be equal. By the same argument, there would be no problem if the first two were equal since they could not be the maximum (with the third being 11 more all the time). Finally, we need only worry about the possibility that the first and third are equal. Certainly, it *is* possible for these two expressions to have the same value, but *never for integer values of* a,b,c, *and* d. In particular, they are only equal when

$$a=-\left(b+c+d+\frac{7}{11}\right).$$

A similar argument applies when we wish to compute the limit of the Hirota Bilinear Difference Equation to find the equation that this $u(a,b,c,d)$ satisfies. Rewriting the HBDE as

$$\sigma_1 e^{(u^\epsilon(a+1,b+1,c,d)+u^\epsilon(a,b,c+1,d+1)-4)/\epsilon}+\sigma_2 e^{(u^\epsilon(a+1,b,c,d+1)+u^\epsilon(a,b+1,c+1,d)+\epsilon\ln(e^{4/\epsilon}-e^{-4/\epsilon}))/\epsilon}$$

$$=\sigma_3 e^{(u^\epsilon(a+1,b,c+1,d)+u^\epsilon(a,b+1,c,d+1)+4)/\epsilon},$$

where $u^\epsilon(a,b,c,d)=\epsilon\ln|u(a,b,c,d)|$ and $\sigma_1=\pm 1$ as needed when u is negative, leads to its ultradiscretization as

$$\begin{aligned}&\mathrm{Max}(u(a+1,b+1,c,d)+u(a,b,c+1,d+1)-4,\ u(a+1,b,c,d+1)+u(a,b+1,c+1,d)+4),\\&=u(a+1,b,c+1,d)+u(a,b+1,c,d+1)+4.\end{aligned} \tag{12}$$

Then to show that (11) gives a solution, we apply Theorem 3.2 and note that since

$$u(a+1,b+1,c,d) = u(a,b,c+1,d+1) = u(a+1,b,c,d+1) = u(a,b+1,c+1,d),$$

the first argument of the Max operator is always 8 less than the second argument.

V. APPLICATION: FIRST INTEGRALS

In this section, we consider difference equations that admit first integrals and ask the following question: When does the ultradiscretization of the equation leave the ultradiscretization of the first integral invariant? The study performed in this section will be more algebraic than analytic: the results about first integrals will apply to the complete set of solutions as opposed to a particular solution, as considered before.

A. Preliminary examples

A well-known class of second order difference equations is given by the *QRT* mappings discovered by Quispel, Roberts, and Thompson.[14] The ultradiscrete limit of members of that class of mappings together with their first integrals was first performed in Ref. 19, but, each time this is done, one has to check explicitly that the resulting ultradiscretization of the first integral is indeed invariant.

Let us start with the following simple example of a difference equation,

$$x_{n+1} = \frac{\alpha^{\epsilon} x_n + 1}{x_n x_{n-1}}, \tag{13}$$

where α^{ϵ} is constant in n. Equation (13) is a member of the class of QRT mappings. As such, (13) admits the following first integral,

$$\iota^{\epsilon}(x_{n-1},x_n) = x_n + x_{n-1} + \frac{\alpha^{\epsilon}}{x_n} + \frac{\alpha^{\epsilon}}{x_{n-1}} + \frac{1}{x_n x_{n-1}}. \tag{14}$$

We say that ι^{ϵ} is a first integral for (13) because $\iota^{\epsilon}(x_{n-1},x_n) = \iota^{\epsilon}(x_n,x_{n+1})$ if x_n is a solution to (13). To obtain the ultradiscrete version of these two expressions, one writes $\alpha^{\epsilon} = e^{A/\epsilon}$ and $x_n = e^{u_n/\epsilon}$. Then we take the limit as $\epsilon \to 0^+$ of the equation using the identity (1) (note that in this particular example, we do not need the more general relation given by Theorem 2.1). We obtain

$$u_{n+1} = \mathrm{Max}(u_n + A, 0) - u_n - u_{n-1} \tag{15}$$

and

$$I = \mathrm{Max}(u_n, u_{n-1}, A - u_{n-1}, A - u_n, -u_n - u_{n-1}). \tag{16}$$

The quantity I defined in (16) is conserved by the equation (15). Following Ref. 9, this can be shown directly by substituting the expression for u_{n-1} in terms of u_n and u_{n+1} coming from (15) into the definition of I as follows:

$$\begin{aligned} I_n &= \mathrm{Max}(u_n, -u_{n+1} - u_n + (u_n + A)_+, A - u_n, A + u_{n+1} + u_n - (u_n + A)_+, u_{n+1} - (u_n + A)_+) \\ &= \mathrm{Max}(u_n, A - u_{n+1}, -u_n - u_{n+1}, A - u_n, \mathrm{Max}(A + u_{n+1} + u_n - (u_n + A)_+, u_{n+1} - (u_n + A)_+)) \\ &= \mathrm{Max}(u_n, A - u_{n+1}, -u_n - u_{n+1}, A - u_n, , u_{n+1}) = I_{n+1}, \end{aligned}$$

where we have introduced the notation $(k)_+ \equiv \mathrm{Max}(k,0)$.

Another more complex example is given by a difference equation that is related (through the process of deautonomization) to a discrete version of the third Painlevé equation,[6,15,16]

$$x_{n+1} = \frac{(\alpha_1^{\epsilon}\alpha_2^{\epsilon} + x_n)(\alpha_1^{\epsilon}/\alpha_2^{\epsilon} + x_n)}{x_{n-1}(\alpha_1^{\epsilon}\alpha_3^{\epsilon} x_n + 1)(\alpha_1^{\epsilon}/\alpha_3^{\epsilon} x_n + 1)}. \tag{17}$$

Again, as a member of the QRT family of mapping, (17) has a first integral given by

$$\iota^{\epsilon} = \alpha_1^{\epsilon}\alpha_3^{\epsilon}(1+\alpha_2^{\epsilon 2})\left(\frac{1}{x_{n-1}}+\frac{1}{x_n}\right) + \alpha_1^{\epsilon}\alpha_2^{\epsilon}(1+\alpha_3^{\epsilon 2})(x_n+x_{n-1}) + \alpha_1^{\epsilon 2}\alpha_2^{\epsilon}\alpha_3^{\epsilon}\left(x_n x_{n-1}+\frac{1}{x_n x_{n-1}}\right)$$
$$+ \alpha_2^{\epsilon}\alpha_3^{\epsilon}\left(\frac{x_n}{x_{n-1}}+\frac{x_{n-1}}{x_n}\right). \tag{18}$$

The ultradiscretization of these two expressions is performed the same way as before by setting $\alpha_i^{\epsilon}=e^{A_i/\epsilon}$ and $x_n=e^{u_n/\epsilon}$. In the limit as $\epsilon\to 0^+$, one gets

$$u_{n+1} = 2u_n + (A_1+A_2-u_n)_+ + (A_1-A_2-u_n)_+ - (A_1+A_3+u_n)_+ - (A_1-A_3+u_n)_+ - u_{n-1}, \tag{19}$$

with first integral

$$I = \mathrm{Max}(A_1+A_3-u_{n-1}, A_1+A_3-u_n, A_1+A_3+2A_2-u_{n-1}, A_1+A_3+2A_2-u_n, A_1+A_2+u_n, A_1+A_2$$
$$+u_{n-1}, A_1+A_2+2A_3+u_n, A_1+A_2+2A_3+u_{n-1}, 2A_1+A_2+A_3+u_n+u_{n-1}, 2A_1+A_2+A_3-u_n$$
$$-u_{n-1}, A_2+A_3+u_n-u_{n-1}, A_2+A_3+u_{n-1}-u_n). \tag{20}$$

Checking that I defined above is a first integral is quite a cumbersome task. Instead, we will rely on a general theorem that we prove later.

B. Main result about first integrals

Consider the difference equation

$$x_{n+d}^{\epsilon} = f(x_n^{\epsilon}, x_{n+1}^{\epsilon}, \ldots, x_{n+d-1}^{\epsilon}) \tag{21}$$

where f is a rational function on $\mathbb{R}^d$ of the form

$$f(a_0,a_1,\ldots,a_{d-1}) \equiv \frac{\sum_{i=1}^{N}\left(\alpha_i^{\epsilon}\prod_{j=0}^{d-1}(a_j)^{m_{ij}}\right)}{\sum_{i=1}^{\hat{N}}\left(\hat{\alpha}_i^{\epsilon}\prod_{j=0}^{d-1}(a_j)^{\hat{m}_{ij}}\right)}.$$

A first integral for (21) is defined to be a rational function ι^{ϵ} on $\mathbb{R}^d$ of the form

$$\iota^{\epsilon}(a_0,a_1,\ldots,a_{d-1}) = \frac{\sum_{i=1}^{M}\left(\beta_i^{\epsilon}\prod_{j=0}^{d-1}(a_j)^{l_{ij}}\right)}{\sum_{i=1}^{\hat{M}}\left(\hat{\beta}_i^{\epsilon}\prod_{j=0}^{d-1}(a_j)^{\hat{l}_{ij}}\right)}, \tag{22}$$

where $l_{ij},\hat{l}_{ij}\in\mathbb{N}$, which remains invariant when restricted to any solution to (21), that is, $\iota^{\epsilon}(a_1,a_2,\ldots,a_{d-1},f(a_0,a_1,\ldots,a_{d-1}))=\iota^{\epsilon}(a_0,a_1,\ldots,a_{d-1})$. Here, we assume the coefficients β_i^{ϵ} and $\hat{\beta}_i^{\epsilon}$ to be nonzero for ϵ in a certain interval $(0,\beta)$. In all our examples, these coefficients will be exponentials and thus never zero.

The following question arises: is the ultradiscretization of (22) a first integral for the ultradiscretization of (21)? Precisely, does the function

$$I(b_0,b_1,\ldots,b_{d-1}) = \operatorname*{Max}_{i=1}^{M}\left(B_i+\sum_{j=0}^{d-1}l_{ij}b_j\right) - \operatorname*{Max}_{i=1}^{\hat{M}}\left(\hat{B}_i+\sum_{j=0}^{d-1}\hat{l}_{ij}b_j\right),$$

where $B_i,\hat{B}_i$ are defined as $B_i=\lim_{\epsilon\to 0^+}\epsilon\ln|\beta_i^{\epsilon}|$ and $\hat{B}_i=\lim_{\epsilon\to 0^+}\epsilon\ln|\hat{\beta}_i^{\epsilon}|$, define a first integral for the equation

$$u_{n+d} = g(u_n,u_{n+1},\ldots,u_{n+d-1}) \tag{23}$$

where g a function on $\mathbb{R}^d$ defined by

$$g(b_0,b_1,\ldots,b_{d-1}) \equiv \underset{i=1}{\overset{N}{\mathrm{Max}}}\left(A_i + \sum_{j=0}^{d-1} m_{ij}b_j\right) - \underset{i=1}{\overset{\hat{N}}{\mathrm{Max}}}\left(\hat{A}_i + \textstyle\sum_{j=0}^{d-1} \hat{m}_{ij}b_j\right),$$

where A_i are defined in Definition (3.1).

Before stating the theorem, let us define the function D on $\mathbb{R}^d$ by

$$D(b_0,b_1,\ldots,b_{d-1}) \equiv \sum_{i\in\mathfrak{I}} \sigma_i e^{\mu_i},$$

where

$$\sigma_i = \frac{|\beta_i^{\epsilon}(f(e^{b_0/\epsilon},e^{b_1/\epsilon},\ldots,e^{b_{d-1}/\epsilon}))^{l_{id-1}}|}{\beta_i^{\epsilon}(f(e^{b_0/\epsilon},e^{b_1/\epsilon},\ldots,e^{b_{d-1}/\epsilon}))^{l_{id-1}}}$$

[σ_i is the sign of $\beta_i^{\epsilon}(f(e^{b_0/\epsilon},e^{b_1/\epsilon},\ldots,e^{b_{d-1}/\epsilon}))^{l_{id-1}}$ for ϵ close to zero] and

$$\mathfrak{M} = \underset{i=1}{\overset{M}{\mathrm{Max}}}\left(B_i + \sum_{j=0}^{d-2} l_{ij}b_{j+1} + l_{id-1}g(b_0,b_1,\ldots,b_{d-1})\right)$$

and

$$\mathfrak{I} = \left\{ i \middle| B_i + \sum_{j=0}^{d-2} l_{ij}b_{j+1} + l_{id-1}g(b_0,b_1,\ldots,b_{d-1}) = \mathfrak{M} \right\},$$

and

$$\mu_i = \lim_{\epsilon\to 0^+} \frac{\epsilon \ln|\beta_i^{\epsilon}| + \sum_{j=0}^{d-2} l_{ij}b_{j+1} + l_{id-1}h^{\epsilon}(b_0,b_1,\ldots,b_{d-1}) - \mathfrak{M}}{\epsilon}, \text{ for } i \in \mathfrak{I},$$

where

$$h^{\epsilon}(b_0,b_1,\ldots,b_{d-1}) = \epsilon \ln(|f(e^{b_0/\epsilon},e^{b_1/\epsilon},\ldots,e^{b_{d-1}/\epsilon})|).$$

Note that

$$\lim_{\epsilon\to 0^+} h^{\epsilon}(b_0,b_1,\ldots,b_{d-1}) = g(b_0,b_1,\ldots,b_{d-1}).$$

Furthermore, the function $\hat{D}$ is defined the same way by replacing $\sigma_i,\mu_i,\alpha_i^{\epsilon},B_i,l_{ij},M$ above by $\hat{\sigma}_i,\hat{\mu}_i,\hat{\alpha}_i^{\epsilon},\hat{B}_i,\hat{l}_{ij},\hat{M}$.

Theorem 5.1: *If D and $\hat{D}$ are nonzero almost everywhere in $\mathbb{R}^d$, then I is a first integral for (23).*

Proof: By definition of I, we have the equality

$$\lim_{\epsilon\to 0^+} \epsilon \ln(\iota^{\epsilon}(e^{b_0/\epsilon},e^{b_1/\epsilon},\ldots,e^{b_{d-1}/\epsilon})) = I(b_0,b_1,\ldots,b_{d-1}).$$

Furthermore, as a direct consequence of Theorem 2.1, since both D and $\hat{D}$ are nonzero almost everywhere in $\mathbb{R}^d$, the following equality must hold everywhere, except in a subset of measure zero,

$$\lim_{\epsilon\to 0^+} \epsilon \ln(\iota^{\epsilon}(e^{b_1/\epsilon},e^{b_2/\epsilon},\ldots,e^{b_{d-1}/\epsilon},e^{h^{\epsilon}(b_0,b_1,\ldots,b_{d-1})})) = I(b_1,b_2,\ldots,b_{d-1},g(b_0,b_1,\ldots,b_{d-1})).$$

Because both the argument of the limit and the right hand side of the equation are continuous in $\mathbb{R}^d$, the equality holds in all $\mathbb{R}^d$.

Since ι^ϵ is a first integral for (21), the arguments of the two limits above are equal. Hence, since both limits exist, the right sides are equal, which shows that I is a first integral for (23). □

C. Examples

Consider the difference equation

$$x_{n+2} = -x_n - x_{n+1} + \frac{\alpha^\epsilon}{x_{n+1}}, \tag{24}$$

which admits the first integral given by

$$\iota^\epsilon = x_{n+1}^2 x_n + x_{n+1} x_n^2 - \alpha^\epsilon (x_{n+1} + x_n) \tag{25}$$

[note that (24) was intentionally written so that x_{n+2} is a function of x_n and x_{n+1} in order to apply Theorem 5.1 directly with $d=2$]. Equation (24) is related to a discrete version of the first Painlevé equation.[6,15,16] For the ultradiscrete limit, we choose $\alpha^\epsilon = e^{A/\epsilon}$ and find

$$u_{n+2} = \mathrm{Max}(u_n, u_{n+1}, A - u_{n+1}) \equiv g(u_n, u_{n+1}), \tag{26}$$

$$I(u_n, u_{n+1}) = \mathrm{Max}(2u_{n+1} + u_n, u_{n+1} + 2u_n, A + u_{n+1}, A + u_n). \tag{27}$$

The quantity defined in (27) is not a first integral for (26). To see this, we consider the specific example with $A < 8$, in which we have that $I(3,5) = 13$ and $I(5, g(5,3)) = I(5,5) = 15 \neq I(3,5)$.

We now show that the conditions of Theorem 5.1 are not met. Specifically, it is not true that the function D is nonzero almost everywhere in $\mathbb{R}^2$. We first set

$$\beta_1^\epsilon = 1, \quad l_{1,0} = 2, \quad l_{1,1} = 1,$$

$$\beta_2^\epsilon = 1, \quad l_{2,0} = 1, \quad l_{2,1} = 2,$$

$$\beta_3^\epsilon = -e^{A/\epsilon}, \quad l_{3,0} = 1, \quad l_{3,1} = 0,$$

$$\beta_4^\epsilon = -e^{A/\epsilon}, \quad l_{4,0} = 0, \quad l_{4,1} = 1.$$

and

$$\mathfrak{M} = \mathrm{Max}(2g(b_1,b_2) + b_2, g(b_1,b_2) + 2b_2, A + g(b_1,b_2), A + b_2).$$

Furthermore, to apply Theorem 5.1, it is useful to write the following quantity explicitly:

$$f(e^{b_1/\epsilon}, e^{b_2/\epsilon}) = -e^{b_1/\epsilon} - e^{b_2/\epsilon} + e^{(A-b_2)/\epsilon}.$$

Consider the case where b_2 is greater than both b_1 and $A - b_1$. We obtain $g(b_1,b_2) = b_2$ and $\mathfrak{I} = \{1,2\}$. The sign of $f(e^{b_1/\epsilon}, e^{b_2/\epsilon})$ for small positive ϵ is negative, which means that $\sigma_1 = -\sigma_2 = 1$. Since $\mu_1 = \mu_2 = 0$, we finally get that $D = e^{\mu_1} - e^{\mu_2} = 0$. Thus, the function D is zero in the semi-infinite triangular region of the plane $b_2 > b_1$ and $b_2 > A - b_1$. The conditions of the Theorem 5.1 are thus not met.

Let us now consider the two examples of Sec. V A. In both cases, all the σ_i's are equal to one. Thus, this automatically implies that both D and $\hat{D}$ are nonzero. In particular, this shows that (20) is indeed a first integral for (19).

We now consider a last example,

$$x_{n+2} = \frac{x_{n+1}}{1 - x_{n+1}^2} - x_n \equiv f(x_n, x_{n+1}), \tag{28}$$

with first integral

$$\iota = x_{n+1}^2 + x_n^2 - x_{n+1}^2 x_n^2 - x_{n+1} x_n. \tag{29}$$

The ultradiscretization reads as

$$u_{n+2} = \mathrm{Max}(u_n + 2u_{n+1}, u_{n+1}, u_n) - \mathrm{Max}(2u_{n+1}, 0) \equiv g(u_n, u_{n+1}), \tag{30}$$

$$I = \mathrm{Max}(2u_{n+1}, 2u_n, 2u_{n+1} + 2u_n, u_{n+1} + u_n). \tag{31}$$

To apply Theorem 5.1, we set

$$\beta_1^\epsilon = 1, \quad l_{1,0} = 0, \quad l_{1,1} = 2,$$

$$\beta_2^\epsilon = 1, \quad l_{2,0} = 2, \quad l_{2,1} = 0,$$

$$\beta_3^\epsilon = -1, \quad l_{3,0} = l_{3,1} = 2,$$

$$\beta_4^\epsilon = -1, \quad l_{4,0} = l_{4,1} = 1,$$

and

$$\mathfrak{M} = \mathrm{Max}(2g(b_1, b_2), 2b_2, 2g(b_1, b_2) + 2b_2, g(b_1, b_2) + b_2).$$

Furthermore, it is useful to write the following explicitly:

$$f(e^{b_1/\epsilon}, e^{b_2/\epsilon}) = \frac{e^{b_2/\epsilon}}{1 - e^{2b_2/\epsilon}} - e^{b_1/\epsilon}.$$

To prove that the function D is nonzero almost everywhere in $\mathbb{R}^2$, we consider four cases. First, in the case $b_1, b_2 > 0$, we have that $g(b_1, b_2) = b_1$ and $\mathfrak{I} = \{3\}$ and, thus, because there is only one term in D, it cannot be zero. In the case $b_2 > 0, b_1 < 0$, $g(b_1, b_2) = \mathrm{Max}(b_1, -b_2)$ and $\mathfrak{I} = \{2\}$. Again, D cannot be zero. In the case $b_2 < 0, b_1 > b_2$, we have that $g(b_1, b_2) = b_1$ and $\mathfrak{I} = \{1\}$. Finally, in the case $b_1 < b_2 < 0$, $g(b_1, b_2) = b_2$ and $\mathfrak{I} = \{1, 2, 4\}$. Here, D is not trivially nonzero and a little more work is required. The sign of $f(e^{b_1/\epsilon}, e^{b_2/\epsilon})$ for small ϵ is positive, $\mu_i = 0$, $i = 1, 2, 4$ and $\sigma_1 = \sigma_2 = -\sigma_4 = 1$. Thus, $D = 1 + 1 - 1 = 1 \neq 0$. We thus have proven that D is nonzero almost everywhere in $\mathbb{R}^2$, which means, by Theorem 5.1, that (31) is a first integral for (30). Note, however, that D is not nonzero everywhere in $\mathbb{R}^2$. For example, in the case $b_1 = 0$ and $b_2 > 0$, we have that $g(b_1, b_2) = 0$, $\mathfrak{I} = \{2, 3\}$, the sign of $f(e^{b_1/\epsilon}, e^{b_2/\epsilon})$ is negative, $\sigma_2 = -\sigma_3 = 1$, and thus $D = 0$.

VI. CONCLUSIONS

Although it is the case that problems can arise in computing a limit of the form

$$\lim_{\epsilon \to 0^+} \epsilon \ln \tau$$

with τ of the form (3) when some terms are negative, it is not true that these problems arise "most of the time." Consequently, it is often still possible to use the procedure of ultradiscrete limits developed in Ref. 20 to produce integer solutions to equations involving the "Max" operator, even in the absence of positivity, as illustrated in Secs. III and IV. Furthermore, it is especially useful to apply the results of Theorem 2.1 to the question of which integrals of motion are preserved by an ultradiscrete limit since in that case one does not need to consider individual solutions (cf. Sec. V).

It should be noted that there are various different possibilities for the value of the limit in the case that $D=0$ and $|\mathfrak{I}|>1$, which we do not presently have the ability to differentiate, in general. For instance, in the example presented in Sec. III A the value of the limit is not the maximum of the exponents as usual, but rather the next largest of the exponents. (This happens here because the sum that forms D does not only vanish in the limit but actually is equal to zero for all ϵ, as briefly mentioned in Ref. 8.) On the other hand, in the case of the limit

$$\lim_{\epsilon\to 0^+} \epsilon \ln(e^{u_1^\epsilon/\epsilon} - e^{u_2^\epsilon/\epsilon} + e^{u_3^\epsilon/\epsilon}),$$

with $u_1^\epsilon=\sin(2\epsilon)/\epsilon$, $u_2^\epsilon=2\sin(\epsilon)/\epsilon$, and $u_3^\epsilon=1$, the limit yields the maximum value of 2, despite the fact that $D=0$. Most interestingly, in the example shown in Sec. I B it is evident that the value of the limit is not determined by the values of the limits of the functions in the exponents, since the ultradiscrete limit, $a-k$, could be varied arbitrarily by selecting k without affecting the limits of the individual exponents, all equal to a. It would be interesting to extend Theorem 2.1 to be able to predict the value of the limit in the case that neither conditions (i) nor (ii) are met.

(Received 14 December 2005; accepted 12 September 2006; published online 30 October 2006)

Quantum doubles of finite group algebras form a class of quasitriangular Hopf algebras that algebraically solve the Yang–Baxter equation. Each representation of the quantum double then gives a matrix solution of the Yang–Baxter equation. Such solutions do not depend on a spectral parameter, and to date there has been little investigation into extending these solutions such that they do depend on a spectral parameter. Here we first explicitly construct the matrix elements of the generators for all irreducible representations of quantum doubles of the dihedral groups D_n. These results may be used to determine constant solutions of the Yang–Baxter equation. We then discuss Baxterization ansätze to obtain solutions of the Yang–Baxter equation with a spectral parameter and give several examples, including a new 21-vertex model. We also describe this approach in terms of minimal-dimensional representations of the quantum doubles of the alternating group A_4 and the symmetric group S_4. © *2006 American Institute of Physics.*

I. INTRODUCTION

Solutions of the Yang–Baxter equation [see (1)] provide a systematic way to construct exactly solvable models of two-dimensional statistical mechanics,[1] integrable quantum systems,[2–5] as well as having applications in other areas such as knot theory.[6] A great impetus to this field was given by Drinfeld,[7] who proposed the *quantum double construction*. This allows for any Hopf algebra A to be embedded in a larger Hopf algebra $D(A)$ in such a way that $D(A)$ is quasitriangular. A consequence of the quasitriangular property is that there exists a canonical element $R \in D(A) \otimes D(A)$, called the *universal R-matrix*, which solves the Yang–Baxter equation algebraically. Thus, for any representation of $D(A)$ a matrix solution of the Yang–Baxter equation is obtained. (Below we will abuse the notation and use R to denote both the universal R-matrix and its matrix representatives.) The seminal examples of quasitriangular Hopf algebras were given by both Drinfeld[7] and Jimbo,[8,9] who independently introduced the notion of quantum algebras, which are deformations of universal enveloping algebras of Lie algebras.

For applications to the areas mentioned above one is generally interested in solutions of the Yang–Baxter equation with a spectral parameter; i.e., for a vector space V one looks for $R(u,v) \in \mathrm{End}(V \otimes V)$ where u,v are complex variables such that

[a]Electronic mail: dancer@maths.uq.edu.au
[b]Electronic mail: psi@maths.uq.edu.au
[c]Electronic mail: jrl@maths.uq.edu.au

$$R_{12}(u,v)R_{13}(u,w)R_{23}(v,w) = R_{23}(v,w)R_{13}(u,w)R_{12}(u,v), \tag{1}$$

holds on the threefold tensor product space $V \otimes V \otimes V$. The subscripts above refer to the way in which the action of $R(u,v)$ is embedded into the space of endomorphisms on $V \otimes V \otimes V$.

In the context of quantum algebras, the spectral parameter arises naturally when one considers the loop representations of affine algebras.[8,9] In such instances the solutions always satisfy the *difference property* $R(u,v)=R(u-v)$. However, it is worth mentioning that there are solutions that do not have the difference property, including the well-known cases of the solutions giving rise to the Hubbard model,[10] the Bariev model,[11] and the chiral Potts model.[12] Moreover, the spectral parameter need not necessarily be a scalar, but can be a complex vector variable.[13–17] Later we will only concern ourselves with cases of scalar spectral parameters where the difference property does hold.

For later use, we introduce the permutation operator P such that $P(x \otimes y)=y \otimes x$ and set $\check{R}(u)=PR(u)$. Then (1) can equivalently be expressed as

$$\check{R}_{12}(u)\check{R}_{23}(u+v)\check{R}_{12}(v) = \check{R}_{23}(v)\check{R}_{12}(u+v)\check{R}_{23}(u), \tag{2}$$

which we will refer to as the *braiding* Yang–Baxter equation. It is in this form that the Yang–Baxter equation is relevant to knot theory.[6] Indeed, setting

$$\check{\mathcal{R}} = \lim_{u \to -\infty} \check{R}(u)$$

gives us

$$\check{\mathcal{R}}_{12}\check{\mathcal{R}}_{23}\check{\mathcal{R}}_{12} = \check{\mathcal{R}}_{23}\check{\mathcal{R}}_{12}\check{\mathcal{R}}_{23}, \tag{3}$$

which can be recognized as a defining relation in the braid group.[6] In terms of

$$\mathcal{R} = \lim_{u \to -\infty} R(u),$$

we have

$$\mathcal{R}_{12}\mathcal{R}_{13}\mathcal{R}_{23} = \mathcal{R}_{23}\mathcal{R}_{13}\mathcal{R}_{12}, \tag{4}$$

which we will refer to as the *constant* Yang–Baxter equation. Finally, we mention that if

$$\check{R}(u)\check{R}(-u) \propto I \otimes I,$$

then the R-matrix is said to satisfy the *unitarity* condition, while if

$$\check{R}(0) \propto I \otimes I, \tag{5}$$

then it is said to satisfy the *regularity* condition. When the regularity condition holds, there is a standard procedure[1–4] for constructing an integrable quantum system on a one-dimensional lattice with periodic boundary conditions. The Hamiltonian is given by

$$H = \sum_{j=1}^{L-1} h_{j,j+1} + h_{L,1}, \tag{6}$$

where the two-site Hamiltonians are given by

$$h = \left. \frac{d}{du}\check{R}(u) \right|_{u=0}.$$

Models constructed in this manner, and other approaches, can be solved exactly using Bethe ansatz methods.[1–6]

One class of quasitriangular Hopf algebras is the set of quantum doubles of the group algebras of finite groups.[18,19] (Throughout we will refer to these as *finite group doubles*). Applications of finite group double representations to knot theory have been addressed in Ref. 20. These algebraic structures also underlie systems of *anyons* in two spatial dimensions. In cases where the global symmetry of the system is spontaneously broken to a discrete gauge group, the finite group double is the appropriate structure to describe the fusion properties and statistics. The fusion properties are essentially determined by the Clebsch-Gordan decomposition of tensor products into irreducible representations. The statistics associated with the interchange of two anyons is described by braiding. The consistency condition for the two ways in which three anyons may be interchanged by a sequence of three two-anyon exchanges is precisely (3), where $\check{R}_{jk}$ is the operation that interchanges the jth and kth anyons. For a comprehensive review of the salient features we refer to Refs. 21 and 22.

Such systems may exhibit topological order,[23] where quantum numbers are conserved for topological reasons, as opposed to the manifest symmetry. Due to the topological nature, excitations are resistant to decoherence. This property forms the basis of topological quantum computation that was first put forth by Kitaev[24] (see also, e.g., Refs. 25–28). When the symmetry is described by a finite group double, the braiding $\check{R}_{jk}$ is a unitary operator that can be employed as a quantum gate.

In view of the previous literature, it is surprising that there has been very little study on the role of finite group doubles in obtaining solutions for the spectral parameter dependent Yang–Baxter equation (1). Integrable systems constructed from such solutions via (6) realize models for interacting anyons with internal symmetries described by the finite group double. Even though the models are one-dimensional, there is a precedent, the Hubbard model, which leads us to believe that such models may have applications for understanding two-dimensional systems. One property that is evident from the analysis of the Bethe ansatz solution of the one-dimensional Hubbard model is spin-charge separation. The Hubbard model has an $so(4) \cong so(3) \oplus so(3)$ symmetry, where the two quantum numbers associated with the two copies of $so(3)$ can be assigned to spin and charge degrees of freedom. From this symmetry and the Bethe ansatz solution, it can be concluded that in one-dimension there exist excitations that carry spin but not charge, and *vice versa*, so spin-charge separation occurs.[29] It has been proposed that spin-charge separation is the mechanism responsible for high temperature superconductivity in two-dimensions.[30] Likewise, there may be insights gained into the properties of interacting anyons by studying one-dimensional models that can be solved exactly.

Our aim is to investigate the extent to which solutions of the spectral parameter dependent Yang–Baxter equation can be obtained using the Hopf algebra structure of finite group doubles. This is not straightforward, as there appears to be no obvious manner in which to consider the affine extension of a finite group double that affords loop representations. Using a different approach, some preliminary results in this regard have been obtained by Yang *et al.*[31] We believe these represent the tip of an iceberg, and there is ample scope for further work. Our aim here is to continue the advances in this direction.

Our starting point is to consider the quantum doubles of the dihedral groups D_n. Of all non-Abelian finite groups, the series of dihedral groups has the simplest representation theory. We will show that the representation theory for the quantum doubles is also readily tractable. Using the general results on the representation theory of finite group doubles given in Refs. 18 and 19, we begin by explicitly constructing *all* irreducible representations for the doubles $D(D_n)$[1] From these results it is straightforward to explicitly construct solutions R for the constant Yang–Baxter equation (4) that do not depend on the spectral parameter.

Our next goal is to determine if these constant solutions of the Yang–Baxter equation can be extended to spectral parameter dependent solutions. This is a procedure colloquially known as

[1]After completing this work, we learned that for odd n these representations have been constructed in the thesis by de Wild Propitius.[22] Results for even n have independently been obtained by Slingerland.[32]

Baxterization, as coined by Jones,[33] and there is sizable literature on this topic.[34–41] We begin by studying the case of the two-dimensional irreducible representations of $D(D_n)$ and find that Baxterization can be performed successfully. Our approach is based on an ansatz taken from Ref. 35, which is chosen by symmetry considerations. In all these cases we find that the resulting solution of the Yang–Baxter equation is a particular case of the well-known trigonometric six-vertex model in the symmetric gauge at a specific root of unity. We mention that this result is not obvious in the sense that the Baxterization is not underpinned by a Hecke algebra representation.

We then turn our attention to the three-dimensional irreducible representations of $D(D_n)$. We find that the only cases for which an irreducible three-dimensional representation exists are $D(D_3)$ and $D(D_6)$. All instances give unitarily equivalent constant solutions of the Yang–Baxter equation. Our Baxterization ansatz leads to a 21-vertex solution of the spectral parameter dependent Yang–Baxter equation, which as far as we can ascertain is new.

Rather than continuing on to investigate higher dimensional representations of the $D(D_n)$ series, we finish by considering minimal-dimensional representations of the double of the alternating group A_4 and the symmetric group S_4. Neither of these cases admit irreducible two-dimensional representations, but they both admit three-dimensional ones. Our ansatz for Baxterizing the constant solutions does lead us to spectral parameter dependent solutions. Remarkably though, we find in these latter examples that the infinite spectral parameter limit of the Baxterized solutions do not necessarily reproduce the original solutions of the constant Yang–Baxter equation.

II. THE DIHEDRAL GROUP D_n

Consider the dihedral group D_n. This has two generators σ, τ satisfying

$$\sigma^n = e, \quad \tau^2 = e, \quad \tau\sigma = \sigma^{n-1}\tau.$$

The properties of D_n vary according to whether n is odd or even, with the odd case being slightly simpler.

A. D_n where n is odd

When n is odd, there are $(n+3)/2$ conjugacy classes divided into three families, given by

$$\{e\},$$

$$\{\sigma^k, \sigma^{-k}\}, \quad \text{for } 1 \le k \le \frac{n-1}{2},$$

$$\{\sigma^i\tau, 0 \le i \le n-1\}.$$

There are $(n+3)/2$ irreducible representations (irreps), two of which are one-dimensional and the remaining $(n-1)/2$ which are two-dimensional. They are given by

$$\pi_\pm(\sigma) = 1, \quad \pi_\pm(\tau) = \pm 1$$

and

$$\pi_k(\sigma) = \begin{bmatrix} \omega^k & 0 \\ 0 & \omega^{-k} \end{bmatrix}, \quad \pi_k(\tau) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad \omega = \exp\left(\frac{2\pi i}{n}\right), \quad 1 \le k \le \frac{n-1}{2}.$$

As required, the sum of the squares of the dimensions of the irreps is $2\times 1^2 + (n-1)/2 \times 2^2 = 2n = |D_n|$.[42]

B. D_n where n is even

When n is even, there are $(n+6)/2$ conjugacy classes divided into five families, given by

$$\{e\},$$

$$\{\sigma^{n/2}\},$$

$$\{\sigma^k,\sigma^{-k}\}, \quad \text{for } 1 \le k \le (n-2)/2,$$

$$\{\sigma^{2j}\tau, 0 \le j \le (n-2)/2\},$$

$$\{\sigma^{(2j+1)}\tau, 0 \le j \le (n-2)/2\}.$$

The $(n+6)/2$ irreps consist of 4 one-dimensional irreps and $(n-2)/2$ two-dimensional irreps. They are given by

$$\pi(\sigma) = (-1)^a, \quad \pi(\tau) = (-1)^b, \quad \text{for } a,b \in \{0,1\}$$

and

$$\pi_k(\sigma) = \begin{bmatrix} \omega^k & 0 \\ 0 & \omega^{-k} \end{bmatrix}, \quad \pi_k(\tau) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad \omega = \exp\left(\frac{2\pi i}{n}\right), \quad 1 \le k \le \frac{n-2}{2}.$$

Again, the sum of the squares of the dimensions of the irreps is $2n$.

III. THE QUANTUM DOUBLE ALGEBRA $D(G)$

Here we give a brief survey of finite group doubles $D(G)$. Throughout, our approach follows that of Ref. 19. Let A be the group algebra of a finite group G over the complex field $\mathbb{C}$. Then A becomes a co-commutative Hopf algebra with coproduct, antipode, and counit, respectively, defined by

$$\Delta(g) = g \otimes g, \quad S(g) = g^{-1}, \quad \varepsilon(g) = e, \quad \forall\, g \in G.$$

Let A^* be the dual space of A, so $A^* = \{f | f: A \to \mathbb{C}\}$. Then A^* becomes an algebra on the dual elements g^* defined by

$$g^*(h) = \delta(g,h), \quad \forall\, g,h \in G,$$

which have the property

$$g^*h^* = \delta(g,h)h^*.$$

The resultant dual algebra is commutative and does not have an interesting representation theory. Now we follow the quantum double construction to obtain $D(G)$, which is a $|G|^2$-dimensional algebra spanned by the free products,

$$gh^*, \quad g,h \in G.$$

The elements h^*g are calculated using

$$h^*g = g(g^{-1}hg)^*.$$

Then $D(G)$ becomes a quasitriangular Hopf algebra with coproduct $\bar{\Delta}$, antipode $\bar{S}$, and counit $\bar{\varepsilon}$ given by

$$\bar{\Delta}(gh^*) = \sum_{k\in G} g(k^{-1}h)^* \otimes gk^* = \sum_{k\in G} gk^* \otimes g(kh^{-1})^*,$$

$$\bar{S}(gh^*) = g^{-1}(gh^{-1}g^{-1})^*,$$

$$\bar{\varepsilon}(gh^*) = \delta(h,e).$$

Note that we identify $g\varepsilon$ with g and eg^* with g^* for all $g \in G$. The universal R-matrix is given by

$$R = \sum_{g\in G} g \otimes g^*,$$

which can easily be shown to satisfy the defining relations for a quasitriangular Hopf algebra:

$$R\bar{\Delta}(a) = \bar{\Delta}^T(a)R, \quad \forall\, a \in D(G), \tag{7}$$

$$(\bar{\Delta} \otimes \mathrm{id})R = R_{13}R_{23}, \tag{8}$$

$$(\mathrm{id} \otimes \bar{\Delta})R = R_{13}R_{12}, \tag{9}$$

where $\bar{\Delta}^T$ is the opposite coproduct,

$$\bar{\Delta}^T(gh^*) = \sum_{k\in G} gk^* \otimes g(k^{-1}h)^* = \sum_{k\in G} g(kh^{-1})^* \otimes gk^*.$$

It follows from the relations (7)–(9) that R is a solution of the constant Yang–Baxter equation. We note that in any tensor product representation $\pi\otimes\pi$ we have that $\check{R}=PR$ commutes with the action of the finite group double; i.e.,

$$[\check{R}, (\pi \otimes \pi)\bar{\Delta}(a)] = 0, \quad \forall\, a \in D(G).$$

IV. REPRESENTATION THEORY OF *D*(*G*)

Several properties of group algebras extend to the quantum double. For example, the set

$$Q = \{gh^* | g,h \in G \text{ with } gh = hg\},$$

is stable under the adjoint action of G, i.e., $gQg^{-1}=Q$. Hence, Q can be partitioned into G-conjugacy classes, which implies[19] the following.

Theorem 4.1: *The number of nonisomorphic $D(G)$-modules equals the number of G-equivalence classes of Q.*

Moreover, a construction for these modules is known.[19] The general form is included in this section, with the explicit results for the odd and even dihedral groups given in the following two sections, respectively.

First, partition G into conjugacy classes,

$$G = \bigcup_k C_k.$$

Recall that the centralizer subgroup of an element h is defined by

$$Z(h) = \{g \in G | gh = hg\}.$$

Then, for each conjugacy class C_k choose a representative $g_k \in C_k$ and set $Z_k = Z(g_k)$ to be the centralizer subgroup of g_k, noting that $|Z_k||C_k| = |G|$. Denote the group algebra of Z_k by A_k. Also, for each $s \in C_k$ choose a fixed element $\alpha_s \in G$ satisfying

$$s = \alpha_s g_k \alpha_s^{-1}.$$

For simplicity, choose $\alpha_{g_k} = e, \forall g_k$.

Lemma 4.1: *We have the following properties of* α_s:

1. $G = \cup_{s \in C_k} \alpha_s Z_k$
2. *Given* $g \in G, s \in C_k, \exists t \in C_k$ *unique with the property* $\alpha_t^{-1} g \alpha_s \in Z_k$; *explicitly* $t = gsg^{-1}$.

Again, a proof can be found in Ref. 19.

The irreducible modules of $D(G)$ can be constructed from modules of the group algebras A_k. Let V_β^k denote an irreducible A_k-module. Then there is a corresponding induced A-module,[42]

$$V_{k,\beta} \subseteq A \otimes_{A_k} V_\beta^k,$$

spanned by vectors

$$v(s) = \alpha_s \otimes v, \quad v \in V_\beta^k, \quad s \in C_k,$$

where the action of G is given by

$$g(\alpha_s \otimes v) = \alpha_{gsg^{-1}} \otimes (\alpha_{gsg^{-1}}^{-1} g \alpha_s) v,$$

or, equivalently,

$$gv(s) = (\alpha_{gsg^{-1}}^{-1} g \alpha_s v)(gsg^{-1}).$$

Note $\dim V_{k,\beta} = |C_k| \dim V_\beta^k$. It follows from Lemma 4.1 that $V_{k,\beta}$ is an A-module under this definition.

The module $V_{k,\beta}$ can be decomposed according to

$$V_{k,\beta} = \underset{s \in C_k}{\oplus} V_{k,\beta}(s),$$

where

$$V_{k,\beta}(s) = \{v(s) | v \in V_\beta^k\}.$$

The latter becomes an irreducible module over the group algebra of $Z(s) = \alpha_s Z_k \alpha_s^{-1}$. When $s = g_k$, the module is isomorphic to V_α^k. Then $V_{k,\beta}$ becomes an irreducible $D(G)$-module with the action

$$h^* v(s) = \delta(h,s) v(s), \quad \forall h \in G.$$

Moreover, two $D(G)$-modules of this form, $V_{k,\beta}, V_{l,\gamma}$, are isomorphic iff $k = l$ and V_β^k, V_γ^k are isomorphic. Then using counting arguments the following can be shown.

Theorem 4.2: *Every irreducible* $D(G)$*-module is isomorphic to one of the* $V_{k,\beta}$.

V. REPRESENTATIONS OF $D(G)$, WHERE $G = D_n$, n EVEN

The conjugacy classes C_k of $G = D_n$, chosen representatives g_k, corresponding centralizer subgroups and the elements $\alpha_s, \forall s \in C_k$, are given in Table I.

Throughout the remainder of this paper, E_j^i denotes an elementary matrix with a 1 in the (i,j) position and zeros elsewhere. We also abuse notation by using g to denote both an element of the algebra $D(G)$ and its matrix representative in a given irrep, which should be clear from the context.

TABLE I. C_k, g_k, Z_k, and α_s for $G=D_n$, n even.

C_k	g_k	$Z_k=Z(g_k)$	$\alpha_s, \forall s \in C_k$
$\{e\}$	e	D_n	$\alpha_e=e$
$\{\sigma^{n/2}\}$	$\sigma^{n/2}$	D_n	$\alpha_{\sigma^{n/2}}=e$
$\{\sigma^k,\sigma^{-k}\}, 1\le k<n/2$	σ^k	$\{\sigma^i \mid 0\le i<n\}$	$\alpha_{\sigma^k}=e, \alpha_{\sigma^{-k}}=\tau$
$\{\sigma^{2i}\tau \mid 0\le i<n/2\}$	τ	$\{e,\tau,\sigma^{n/2},\sigma^{n/2}\tau\}$	$\alpha_{(\sigma^{2i}\tau)}=\sigma^i$
$\{\sigma^{2i+1}\tau \mid 0\le i<n/2\}$	$\sigma\tau$	$\{e,\sigma\tau,\sigma^{n/2},\sigma^{n/2+1}\tau\}$	$\alpha_{(\sigma^{2i+1}\tau)}=\sigma^i$

Representations induced by $C_k=\{e\}$. The module elements are of the form $e\otimes v$ where $v \in V$, V a D_n-module. In representation terms, there are 4 one-dimensional irreps and $(n/2-1)$ two-dimensional irreps. They are

$$\sigma=(-1)^a, \quad \tau=(-1)^b, \quad g^*=\delta(g,e)$$

where $a,b\in\{0,1\}$, and

$$\sigma=\begin{bmatrix}\omega^k & 0\\ 0 & \omega^{-k}\end{bmatrix}, \quad \tau=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}, \quad g^*=\delta(g,e)I_2,$$

where $1\le k<n/2$.

Representations induced by $C_k=\{\sigma^{n/2}\}$. The module elements are of the form $e\otimes v$, where $v \in V$, V a D_n-module. Again, there are 4 one-dimensional irreps and $(n-2)/2$ two-dimensional irreps. They are

$$\sigma=(-1)^a, \quad \tau=(-1)^b, \quad g^*=\delta(g,\sigma^{n/2}),$$

where $a,b\in\{0,1\}$, and

$$\sigma=\begin{bmatrix}\omega^k & 0\\ 0 & \omega^{-k}\end{bmatrix}, \quad \tau=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}, \quad g^*=\delta(g,\sigma^{n/2})I_2,$$

where $1\le k<n/2$.

Representations induced by $C_k=\{\sigma^k,\sigma^{-k}\}$, $1\le k<n/2$. The module elements are of the form $e\otimes v, \tau\otimes v$, where $v\in V$, V a module of the group algebra of $Z_k=\{\sigma^j \mid 0\le j<n\}$. There are n such A_k-modules, with the corresponding representations given by $\pi(\sigma)=\omega^j$, $0\le j<n$, where $\omega=\exp(2\pi i/n)$. Thus, we have $n(n-2)/2$ different irreducible representations of $D(D_n)$ induced by these conjugacy classes, given by

$$\sigma=\begin{bmatrix}\omega^j & 0\\ 0 & \omega^{-j}\end{bmatrix}, \quad \tau=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}, \quad (\sigma^k)^*=\begin{bmatrix}1 & 0\\ 0 & 0\end{bmatrix}, \quad (\sigma^{-k})^*=\begin{bmatrix}0 & 0\\ 0 & 1\end{bmatrix}, \quad g^*=0, \quad \text{otherwise},$$

where $0\le j<n$, $1\le k<n/2$.

Representations induced by $C_k=\{\sigma^{2j}\tau \mid 0\le j<n/2\}$. The module elements are of the form $\sigma^j\otimes v$, $0\le j<n/2$, where $v\in V$, V a module of the group algebra of $Z_k=\{e,\tau,\sigma^{n/2},\sigma^{n/2}\tau\}$. Hence, there are 4 $(n/2)$-dimensional irreps of this form. They are

$$\sigma=A\in M_{n/2\times n/2}, \quad \text{where } [A]_{ij}=(-1)^{a\delta(i,1)}\delta(i,j+1), \quad \text{addition mod } n/2,$$

$$\tau=(-1)^{a+b}B\in M_{n/2\times n/2}, \quad \text{where } [B]_{ij}=(-1)^{a\delta(i,1)}\delta(i+j,2), \quad \text{addition mod } n/2,$$

$$(\sigma^j)^*=0, \quad (\sigma^{2j}\tau)^*=E_{j+1}^{j+1}, \quad (\sigma^{(2j+1)}\tau)^*=0, \quad 0\le i<n, \quad 0\le j<n/2,$$

where $a,b\in\{0,1\}$.

Example 5.1: *In* $D(D_6)$, σ *and* τ *are as follows:*

$$\sigma = \begin{bmatrix} 0 & 0 & (-1)^a \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad \tau = (-1)^b \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & (-1)^a \\ 0 & (-1)^a & 0 \end{bmatrix},$$

where $a,b \in \{0,1\}$, *giving 4 three-dimensional irreps.*

Representations induced by $C_k = \{\sigma^{2j+1}\tau | 0 \le j < n/2\}$. The module elements are of the form $\sigma^j \otimes v$, $0 \le j < n/2$, where $v \in V$, V a module of the group algebra of $Z_k = \{e, \sigma\tau, \sigma^{n/2}, \sigma^{(n+2)/2}\tau\}$. Hence, there are 4 $(n/2)$-dimensional irreps of this form. They are as follows:

$$\sigma = A \in M_{n/2\times n/2} \quad \text{where } [A]_{ij} = (-1)^{a\delta(i,1)}\delta(i,j+1), \quad \text{addition mod } n/2,$$

$$\tau = (-1)^{a+b}B \in M_{n/2\times n/2} \quad \text{where } [B]_{ij} = \delta(i+j,n/2+1), \quad \text{addition mod } n/2,$$

$$(\sigma^j)^* = 0, \quad (\sigma^{2j}\tau)^* = 0, \quad (\sigma^{(2j+1)}\tau)^* = E^{j+1}_{j+1}, \quad 0 \le i < n, \quad 0 \le j < n/2,$$

where $a,b \in \{0,1\}$.

Example 5.2: *In* $D(D_6)$, σ *and* τ *are as follows:*

$$\sigma = \begin{bmatrix} 0 & 0 & (-1)^a \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad \tau = (-1)^{a+b} \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix},$$

where $a,b \in \{0,1\}$, *giving 4 three-dimensional irreps.*

Thus when n is even $D(D_n)$ has 8 one-dimensional irreps, 8 $(n/2)$-dimensional irreps, and $(n+2)(n/2-1)$ two-dimensional irreps. The sum of the squares of the dimension of the irreps is $|D_n|^2 = |D(D_n)|$, as required.[19]

Analogous results for odd n are given in the Appendix .

VI. SOLUTIONS OF THE YANG–BAXTER EQUATION ASSOCIATED WITH THE TWO-DIMENSIONAL IRREPS OF $D(D_n)$

As stated earlier, a solution to the constant Yang–Baxter equation in $D(G)$ is given by

$$R = \sum_{g \in G} g \otimes g^*.$$

In this section we will only consider the two-dimensional irreps of $D(G)$. Then, by inspection, the R-matrix will always be of the form

$$R = \mathrm{diag}(\omega^j, \omega^{-j}, \omega^{-j}, \omega^j),$$

where $\omega = \exp(2\pi i/n)$ and $0 \le j < n$, with the cases $j=0$ and $j=n/2$ being trivial. Thus $\check{R} = PR$ is given by

$$\check{R} = \begin{bmatrix} \omega^j & 0 & 0 & 0 \\ 0 & 0 & \omega^{-j} & 0 \\ 0 & \omega^{-j} & 0 & 0 \\ 0 & 0 & 0 & \omega^j \end{bmatrix}. \tag{10}$$

As remarked earlier, $\check{R}$ commutes with the action of $D(D_n)$. We seek a solution $\check{R}(x)$ of the braiding Yang–Baxter equation that has this symmetry. Now the matrix (10) has 3 different eigenvalues, namely $w^j, \pm w^{-j}$. Hence, for any k, $\check{R}^k$ can be written as a linear combination of $I \otimes I, \check{R}$ and $\check{R}^{-1}$. Making a change of variables $x = \exp(u)$, $z = \exp(v)$ in Eq. (2), we look for $\check{R}(x)$ in the following form:

$$\check{R}(x) = f(x)I \otimes I + g(x)\check{R} + h(x)\check{R}^{-1}.$$

Then

$$\check{R}(x) = \begin{bmatrix} A(x) & 0 & 0 & 0 \\ 0 & f(x) & B(x) & 0 \\ 0 & B(x) & f(x) & 0 \\ 0 & 0 & 0 & A(x) \end{bmatrix},$$

where

$$A(x) = f(x) + \omega^j g(x) + \omega^{-j} h(x),$$

$$B(x) = \omega^{-j} g(x) + \omega^j h(x).$$

We directly apply the braiding Yang–Baxter equation in the form

$$\check{R}_{12}(x)\check{R}_{23}(xz)\check{R}_{12}(z) = \check{R}_{23}(z)\check{R}_{12}(xz)\check{R}_{23}(x). \tag{11}$$

Although there are 20 nonzero entries on each side of the equation, there are only two independent nontrivial relations that must be satisfied. These are

$$A(z)f(xz)A(x) = f(x)A(xz)f(z) + B(x)f(xz)B(z), \tag{12}$$

$$A(z)B(xz)f(x) = f(x)A(xz)B(z) + B(x)f(xz)f(z). \tag{13}$$

Note that $f(x)=0$, $\forall x$ trivially satisfies the Yang–Baxter equation.

A proposal for constructing $\check{R}(x)$ when $\check{R}$ has three distinct eigenvalues λ_1, λ_2, and λ_3 has been discussed in Refs. 31 and 35, but it has not been proven to always be true. The conjecture is

$$\check{R}(x) = (\lambda_1 + \lambda_2 + \lambda_3 + \lambda_1\lambda_3\lambda_2^{-1})xI \otimes I - (x-1)\check{R} + \lambda_1\lambda_3 x(x-1)\check{R}^{-1}.$$

Three distinct solutions are obtained by changing the ordering of the eigenvalues. We note that when the ansatz holds we have

$$\check{\mathcal{R}} = \lim_{x\to 0} R(x) = R.$$

Applying this ansatz to (10), we find that if $\lambda_2 = \pm\omega^{-j}$, then $f(x)=0$, which we have already shown gives a trivial result. Hence we consider the case when $\lambda_2 = \omega^j$. This gives

$$f(x) = (\omega^j - \omega^{-3j})x, \quad g(x) = -(x-1), \quad h(x) = -w^{-2j}x(x-1),$$

$$\Rightarrow A(x) = \omega^j - \omega^{-3j}x^2, \quad B(x) = -\omega^{-j}(x^2-1).$$

It can be easily shown that $f(x)$, $A(x)$, and $B(x)$ satisfy relations (12) and (13). Hence, we have solutions to the braiding Yang–Baxter equation, which are

$$\check{R}(x) = \begin{bmatrix} \omega^j - \omega^{-3j}x^2 & 0 & 0 & 0 \\ 0 & (\omega^j - \omega^{-3j})x & -\omega^{-j}(x^2-1) & 0 \\ 0 & -\omega^{-j}(x^2-1) & (\omega^j - \omega^{-3j})x & 0 \\ 0 & 0 & 0 & \omega^j - \omega^{-3j}x^2 \end{bmatrix},$$

where $\omega = \exp(2\pi i/n)$ and $0 \le j < n$. Rescaling by a factor of $\omega^j x^{-1}$, we can write

TABLE II. Possible solutions for $f(x)$, $g(x)$, and $h(x)$.

$f(x)$	$g(x)$	$h(x)$
x	$1-x$	$x(x-1)$
ωx	$1-x$	$\omega^2 x(x-1)$
$\omega^2 x$	$1-x$	$\omega x(x-1)$

$$\check{R}(x)=\begin{bmatrix} \omega^{2j}x^{-1}-\omega^{-2j}x & 0 & 0 & 0 \\ 0 & \omega^{2j}-\omega^{-2j} & x^{-1}-x & 0 \\ 0 & x^{-1}-x & \omega^{2j}-\omega^{-2j} & 0 \\ 0 & 0 & 0 & \omega^{2j}x^{-1}-\omega^{-2j}x \end{bmatrix}. \tag{14}$$

Note that the unitarity condition $\check{R}(x)\check{R}(x^{-1})=[\omega^{4j}+\omega^{-4j}-(x^2+x^{-2})]I\otimes I$ is satisfied. We can recognize (14) as specific cases of the six-vertex solution in the symmetric gauge, where the parameter q in the general solution is constrained to be a root of unity. We remark that the choice of gauge is related to the gradation chosen for the affine algebra (e.g., see Ref. 43). It is interesting to note that in the nonsymmetric gauge the constant solution $\check{\mathcal{R}}=\lim_{x\to 0} R(x)$ can be used to give rise to a representation of the Temperley-Lieb algebra. In this case there is a well known procedure for Baxterizing $\check{\mathcal{R}}$ to recover $\check{R}(x)$.[33,34] This is not the case for the symmetric gauge case described previously.

VII. SOLUTIONS OF THE YANG–BAXTER EQUATION ASSOCIATED WITH THE THREE-DIMENSIONAL IRREPS OF $D(D_3)$ AND $D(D_6)$

From the construction of the irreps of $D(D_n)$ given explicitly in Sec. V and the Appendix, we find that three-dimensional irreps only occur for $D(D_3)$ and $D(D_6)$. Moreover, the 2 three-dimensional irreps of $D(D_3)$ are also representations for the $D(D_3)$ subalgebra of $D(D_6)$, so these cases give identical R matrices. For any three-dimensional irrep of $D(D_6)$, we find $\check{R}=PR=P\Sigma_g g\otimes g^*$ is of the following form:

$$\check{R}=(-1)^b\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & (-1)^a & 0 \\ 0 & 0 & (-1)^a & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & (-1)^a & 0 & 0 \\ 0 & (-1)^a & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

where $a,b\in\{0,1\}$. Without loss of generality we take $b=0$, and find the eigenvalues of $\check{R}$ are 1, ω, and ω^2 with multiplicities 5, 2, and 2, respectively, where $\omega=\exp(2\pi i/3)$. As the two values of a give unitarily equivalent R matrices, we choose to take $a=0$. We can then write

$$\check{R}(x)=f(x)I\otimes I+g(x)\check{R}+h(x)\check{R}^{-1}.$$

Again we follow the procedure outlined in Refs. 31 and 35 to find possible solutions, which gives the following:

Using MATHEMATICA, we find only the first of these possible solutions satisfies the braiding Yang–Baxter equation (11) (see Table II):

$$\check{R}(x)=\begin{bmatrix} x^2-x+1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & x & 0 & 0 & 0 & 1-x & x(x-1) & 0 & 0 \\ 0 & 0 & x & x(x-1) & 0 & 0 & 0 & 1-x & 0 \\ 0 & 0 & 1-x & x & 0 & 0 & 0 & x(x-1) & 0 \\ 0 & 0 & 0 & 0 & x^2-x+1 & 0 & 0 & 0 & 0 \\ 0 & x(x-1) & 0 & 0 & 0 & x & 1-x & 0 & 0 \\ 0 & 1-x & 0 & 0 & 0 & x(x-1) & x & 0 & 0 \\ 0 & 0 & x(x-1) & 1-x & 0 & 0 & 0 & x & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & x^2-x+1 \end{bmatrix}.$$

The corresponding R-matrix $R(x)=P\check{R}(x)$ is given by

$$R(x)=\begin{bmatrix} x^2-x+1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1-x & x & 0 & 0 & 0 & x(x-1) & 0 \\ 0 & 1-x & 0 & 0 & 0 & x(x-1) & x & 0 & 0 \\ 0 & x & 0 & 0 & 0 & 1-x & x(x-1) & 0 & 0 \\ 0 & 0 & 0 & 0 & x^2-x+1 & 0 & 0 & 0 & 0 \\ 0 & 0 & x(x-1) & 1-x & 0 & 0 & 0 & x & 0 \\ 0 & 0 & x & x(x-1) & 0 & 0 & 0 & 1-x & 0 \\ 0 & x(x-1) & 0 & 0 & 0 & x & 1-x & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & x^2-x+1 \end{bmatrix}. \quad (15)$$

Note $\check{R}(x)\check{R}(x^{-1})=(x-1+1/x)^2 I\otimes I$, so the unitarity property holds.

The previous solution gives rise to a 21-vertex model, which appears to be new. It does not belong to the class of 21-vertex models discussed in Ref. 44. Viewed as a two-dimensional lattice statistical mechanics model though, it does not have real, non-negative Boltzmann weights. Since the regularity property (5) holds, we can, however, construct an integrable one-dimensional model. Even though $\check{R}(x)$ is not Hermitian, we obtain a Hermitian Hamiltonian in the following manner. We rescale $\check{R}(x)$ by a factor of i/x and define the two-site Hamiltonian h as

$$h=\frac{d}{dx}\left.\frac{i\check{R}(x)}{x}\right|_{x=1}=i\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

which can also be written as

$$h=\sum_{\gamma\in D_3} i(E^{\gamma(1)}_{\gamma(2)}\otimes E^{\gamma(2)}_{\gamma(3)}-E^{\gamma(2)}_{\gamma(3)}\otimes E^{\gamma(1)}_{\gamma(2)}), \quad (16)$$

where the elements γ of D_3 are written as permutations of $\{1,2,3\}$. The above integrable system describes a one-dimensional lattice of anyons with $D(D_3)$ or $D(D_6)$ symmetry and local interactions given by (16). The two-site Hamiltonian may also be expressed in terms of spin-1 operators:

$$-ih=-S_+^2\otimes(S_zS_-+S_-S_z)+(S_zS_-+S_-S_z)\otimes S_+^2$$

$$+S_-^2\otimes(S_zS_++S_+S_z)-(S_zS_++S_+S_z)\otimes S_-^2$$

$$+ S_+S_z \otimes S_zS_+ - S_zS_+ \otimes S_+S_z$$

$$+ S_-S_z \otimes S_zS_- - S_zS_- \otimes S_-S_z,$$

where $S_\pm = 1/2(S_x \pm iS_y)$. This Hamiltonian is not the same as other known integrable spin-1 Hamiltonians.[45–49]

In principle, the integrability of the previous model implies that algebraic Bethe ansatz methods may be used to obtain the exact solution. In the present case, however, there is no simple choice of reference state needed for the Bethe ansatz calculation, and a generalized algebraic Bethe ansatz similar to that employed for the XYZ model[50] is required. Because of the technical nature of such a calculation we defer it to a future publication.

VIII. SOLUTIONS OF THE YANG–BAXTER EQUATION ASSOCIATED WITH $D(A_4)$

The same procedure can be applied to the symmetric and alternating groups. The *symmetic group* S_n is the group of permutations of $\{1,2,\ldots,n\}$ where the operation is composition. The subgroup of S_n consisting of permutations that can be written as the product of an even number of transpositions is known as the *alternating group* and denoted A_n. Now $S_3 \cong D_3$ and $A_3 \cong Z_3$, so we only consider $n \geq 4$. In A_n the only conjugacy class with only one element is $\{e\}$, which always gives rise to the trivial R-matrix $R = I \otimes I$. Moreover, there are no conjugacy classes with two elements and only A_4 has a conjugacy class with three elements. Therefore only A_4 can give rise to a three-dimensional irrep, and we can never obtain a two-dimensional irrep.

Consider A_4, using the convention $(12)\circ(13) = (132)$. The relevent conjugacy class C_k and the details required to construct the representations are

$$C_k = \{(12)(34),(13)(24),(14)(23)\}, \quad g_k = (12)(34),$$

$$Z_k = \{e,(12)(34),(13)(24),(14)(23)\},$$

$$\alpha_{(12)(34)} = e, \quad \alpha_{(13)(24)} = (132), \quad \alpha_{(14)(23)} = (123).$$

This time $Z_k \cong \mathbb{Z}_2 \times \mathbb{Z}_2$, with the 4 one-dimensional irreps given by $(12)(34) = (-1)^a$, $(13)(24) = (-1)^b$, $a,b \in \{0,1\}$. We obtain

$$R = \mathrm{diag}((-1)^a,(-1)^{a+b},(-1)^b,(-1)^b,(-1)^a,(-1)^{a+b},(-1)^{a+b},(-1)^b,(-1)^a).$$

Applying the permutation operator, we find

$$\check{R} = \begin{bmatrix} (-1)^a & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & (-1)^b & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & (-1)^{a+b} & 0 & 0 \\ 0 & (-1)^{a+b} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & (-1)^a & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & (-1)^b & 0 \\ 0 & 0 & (-1)^b & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & (-1)^{a+b} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & (-1)^a \end{bmatrix},$$

which has eigenvalues $1,-1$ with multiplicities $6,3$, respectively, when $a=0$, and eigenvalues $-1,i,-i$, each with multiplicity 3 when $a=1$. When $a=b=0$ this is the permutation matrix and gives rise to a representation of the Hecke algebra. Baxterization then leads to the known $su(3)$ invariant solution. In the case $a=0,b=1$, $\check{R}$ is again a Hecke algebra representation, which can be Baxterized as $\check{R}(u) = I \otimes I + u\check{R}$. This solution corresponds to the rational 15-vertex solution with a

Reshetikhin twist.[51] The last case is when $b=1$, in which case we can write without loss of generality:

$$\check{R}=\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

We recognize this solution as belonging to the class of *nonstandard* solutions of the Yang–Baxter equation. However, it is curious that the origin of the nonstandard structure cannot be explained in terms of an underlying Lie superalgebra or colour Lie algebra structure,[52,53] nor is it due to a Reshetikhin twist.[51]

As $\check{R}$ has three eigenvalues, we try the ansatz $\check{R}(x)=f(x)I\otimes I+g(x)\check{R}+h(x)\check{R}^{-1}$. Applying the conjecture given in Refs. 31 and 35, we obtain three possible solutions. Two of these, however, have $f(x)=0$, which is undesirable if we want the regularity property to hold. The third possible case can be shown to not satisfy the braiding Yang–Baxter equation (11). Hence, we attempt to find another way to introduce a spectral parameter.

First we return to the original variables u,v instead of x,z. Writing $a(u)=f(u)+g(u)+h(u)$ and $b(u)=g(u)-h(u)$, we note $\check{R}(u)$ is

$$\check{R}(u)=\begin{bmatrix} a(u) & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & f(u) & 0 & b(u) & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & f(u) & 0 & 0 & 0 & -b(u) & 0 & 0 \\ 0 & -b(u) & 0 & f(u) & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & a(u) & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & f(u) & 0 & b(u) & 0 \\ 0 & 0 & b(u) & 0 & 0 & 0 & f(u) & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -b(u) & 0 & f(u) & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a(u) \end{bmatrix}.$$

Substituting $\check{R}(u)$ into the braiding Yang–Baxter equation (2), we find $\check{R}(u)$ satisfies the Yang–Baxter equation if and only if the following conditions are met:

$$b(u+v)f(u)f(v)=f(u+v)[b(u)f(v)+b(v)f(u)], \tag{17}$$

$$a(u)b(u+v)f(v)=b(v)f(u)f(u+v)+a(u+v)b(u)f(v), \tag{18}$$

$$a(u+v)f(u)f(v)=f(u+v)[a(u)a(v)+b(u)b(v)]. \tag{19}$$

First, consider the case when $b(u)=0$. Then equations (17), (18) are automatically satisfied, and we need only consider Eq. (19). The solution $\check{R}(u)\propto I\otimes I$ is uninteresting, so we instead choose $f(u)=1$ and $a(u)=e^{u}$, giving

$$\check{R}(u) = \mathrm{diag}(e^u, 1, 1, 1, e^u, 1, 1, 1, e^u).$$

Observe that this solution has the following peculiar property:

$$\check{R} \neq \lim_{u \to -\infty} \check{R}(u). \tag{20}$$

Next consider $b(u) \neq 0$. We begin by choosing $f(u)=1$. Then we see that $b(u)=b_0 u$ is the only solution to (17). We substitute these into Eq. (18) to obtain

$$(u+v)a(u) = v + ua(u+v),$$

$$(u+v)a(v) = u + va(u+v).$$

Eliminating $a(u+v)$, we find

$$(u+v)\left(\frac{a(u)}{u} - \frac{a(v)}{v}\right) = \frac{v}{u} - \frac{u}{v} = \frac{v^2 - u^2}{uv}$$

$$\Rightarrow \left(\frac{a(u)}{u} - \frac{a(v)}{v}\right) = \frac{v-u}{uv} = \frac{1}{u} - \frac{1}{v}$$

$$\Rightarrow \frac{a(u)-1}{u} = \frac{a(v)-1}{v} = c$$

$$\Rightarrow a(u) = 1 + cu.$$

We find that this satisfies (19), provided $c = \pm i b_0$, so we have found a solution to the braiding Yang–Baxter equation (2). Note that b_0 is just a scaling factor on u, so we can choose any nonzero complex number. Choosing $b_0 = i$ and $c=1$, we have

$$\check{R}(u) = \begin{bmatrix} 1+u & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & iu & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & -iu & 0 & 0 \\ 0 & -iu & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1+u & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & iu & 0 \\ 0 & 0 & iu & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -iu & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1+u \end{bmatrix}.$$

The previous solution again corresponds to the rational 15-vertex solution with a Reshetikhin twist.[51] We also note that the property (20) also holds for this solution.

IX. SOLUTIONS OF THE YANG–BAXTER EQUATION ASSOCIATED WITH $D(S_4)$

As with $D(A_n)$, the algebra $D(S_n)$ has no nontrivial two-dimensional irreps, and the only nontrivial three-dimensional irrep occurs when $n=4$. Then C_k, g_k, Z_k, and α_s, $s \in C_k$ are given by

$$C_k = \{(12)(34), (13)(24), (14)(23)\}, \quad g_k = (12)(34),$$

$$Z_k = \{e, (12), (34), (12)(34), (13)(24), (14)(23), (1324), (1423)\},$$

$$\alpha_{(12)(34)} = e, \quad \alpha_{(13)(24)} = (14), \quad \alpha_{(14)(23)} = (13).$$

Note that $Z_k \cong D_4$ with generators $\{(12),(1324)\}$, so we know it has exactly 4 one-dimensional reps given by $(12)=(-1)^a$, $(1324)=(-1)^b$, $a,b \in \{0,1\}$. Following the same procedure as earlier, we obtain

$$R = \sum_{g \in S_4} g \otimes g^* = \mathrm{diag}(1,(-1)^{a+b},(-1)^{a+b},(-1)^{a+b},1,(-1)^{a+b},(-1)^{a+b},(-1)^{a+b},1).$$

Both these solutions arose in $D(A_4)$ and were discussed in the previous section.

X. CONCLUSION

Our results show that for certain constant solutions of the Yang–Baxter equation obtained by using representations of finite group doubles, it is possible to Baxterize them to yield solutions of the spectral parameter Yang–Baxter equation. We have considered several examples where this is true and, in particular, we have found a new 21-vertex solution (15) from which we obtained an integrable model for a system of anyons with $D(D_3)$ or $D(D_6)$ symmetry. It is clearly of interest to determine if all constant solutions may be Baxterized. In contrast to the case of affine quantum algebras, where the spectral parameter has its origins in the loop representation, the origin of the spectral parameter for the above instances is unknown.

In all our examples we have only looked for cases where the spectral parameter has the difference property. For the case of the generalized chiral Potts model in Ref. 15, which does not have the difference property, an underlying finite group structure appears. This suggests that a Baxterization ansatz without the assumption of the difference property may also be fruitful. Certainly more work is needed to fully realize the potential of finite group doubles in solving the Yang–Baxter equation with spectral parameter.

ACKNOWLEDGMENTS

This work was supported by the Australian Research Council. We thank Mark Gould, Jabin Kirk, and Liam Wagner for numerous helpful discussions on finite group doubles. We also thank Carlos Mochon and Andrew Doherty for clarifying several aspects about properties of anyons, and Joost Slingerland for bringing relevant references to our attention.

APPENDIX: REPRESENTATIONS OF $D(G)$, WHERE $G=D_n$, n ODD

The conjugacy classes C_k of $G=D_n$, chosen representatives g_k, corresponding centralizer subgroups Z_k and the elements α_s, $\forall s \in C_k$, are given in Table III.

1. Representations induced by $C_k=\{e\}$

The module elements are of the form $e \otimes v$, where $v \in V$, V a D_n-module. In representation terms, there are 2 one-dimensional irreps and $(n-1)/2$ two-dimensional irreps. They are as follows:

$$\sigma = 1, \quad \tau = \pm 1, \quad g^* = \delta(g,e)$$

and

TABLE III. C_k, g_k, Z_k and α_s for $G=D_n$, n odd.

C_k	g_k	$Z_k=Z(g_k)$	$\alpha_s, \forall s \in C_k$
$\{e\}$	e	D_n	$\alpha_e=e$
$\{\sigma^k,\sigma^{-k}\}, 1 \le k \le n-1/2$	σ^k	$\{\sigma^i\vert, 0 \le i < n\}$	$\alpha_{\sigma^k}=e, \alpha_{\sigma^{-k}}=\tau$
$\{\sigma^i\tau \vert 0 \le i < n\}$	τ	$\{e,\tau\}$	$\alpha_{\sigma^i\tau}=\sigma^{(n+1/2)i}$

$$\sigma = \begin{bmatrix} \omega^k & 0 \\ 0 & \omega^{-k} \end{bmatrix}, \quad \tau = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad g^* = \delta(g,e)I_2,$$

where $1 \leq k \leq (n-1)/2$.

2. Representations induced by $C_k = \{\sigma^k, \sigma^{-k}\}$, $1 \leq k \leq (n-1)/2$

The module elements are of the form $e \otimes v, \tau \otimes v$, where $v \in V$, V a module of the group algebra of $Z_k = \{\sigma^j | 0 \leq i < n\}$. There are n such A_k-modules, with the corresponding representations π_j given by $\pi_j(\sigma) = \omega^j$, $0 \leq j < n$, where $\omega = \exp(2\pi i/n)$. Thus, there are $n(n-1)/2$ different irreps of $D(D_n)$ induced by these conjugacy classes, given by

$$\sigma = \begin{bmatrix} \omega^j & 0 \\ 0 & \omega^{-j} \end{bmatrix}, \quad \tau = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad (\sigma^k)^* = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad (\sigma^{-k})^* = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}, \quad g^* = 0 \text{ otherwise},$$

where $0 \leq j < n$, $1 \leq k \leq (n-1/2)$.

3. Representations induced by $C_k = \{\sigma^j \tau | 0 \leq i < n\}$

The module elements are of the form $\sigma^{j(n+1)/2} \otimes v$, $0 \leq j < n$, where $v \in V$, V a module of the group algebra of $Z_k = \{e, \tau\}$. Hence, there are two n-dimensional irreps of this form. They are as follows:

$$\sigma = A \in M_{n\times n}, \quad \text{where } [A]_{ij} = \delta(i, j+2), \quad \text{addition mod } n,$$

$$\tau = \pm B \in M_{n\times n}, \quad \text{where } [B]_{ij} = \delta(i+j, 2), \quad \text{addition mod } n,$$

$$(\sigma^i)^* = 0, \quad (\sigma^i \tau)^* = E^{i+1}_{i+1}, \quad 0 \leq i < n.$$

Example 10.1: *In $D(D_3)$, σ and τ are as follows:*

$$\sigma = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}, \quad \tau = \pm \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}.$$

Hence, when n is odd $D(D_n)$ has 2 one-dimensional irreps, 2 n-dimensional irreps and $(n^2-1)/2$ two-dimensional irreps, all of which are given above. Note that the sum of the squares of the dimensions is $4n^2 = |D_n|^2 = |D(D_n)|$, as we expect.[19]

Isomorphisms between C^*-ternary algebras

Choonkil Park[a)]
Department of Mathematics, Hanyang University, Seoul, 133-791 Republic of Korea

(Received 9 March 2006; accepted 12 September 2006; published online 31 October 2006)

In this paper, we prove the Hyers-Ulam-Rassias stability of homomorphisms in C^*-ternary algebras and of derivations on C^*-ternary algebras for the following generalized Cauchy–Jensen additive mapping:

$$2f\left(\frac{\sum_{j=1}^{p} x_j}{2}+\sum_{j=1}^{d} y_j\right)=\sum_{j=1}^{p} f(x_j)+2\sum_{j=1}^{d} f(y_j).$$

This is applied to investigate isomorphisms between C^*-ternary algebras. The concept of Hyers-Ulam-Rassias stability originated from the Rassias stability theorem that appeared in his paper: On the stability of the linear mapping in Banach spaces, see Proc. Amr. Math. Soc. **72**, 297–300 (1978). © *2006 American Institute of Physics.* [DOI: 10.1063/1.2359576]

I. INTRODUCTION AND PRELIMINARIES

Ternary algebraic operations were considered in the 19th century by several mathematicians and physicists such as Cayley,[5] who introduced the notion of a *cubic matrix*, which in turn was generalized by Kapranov *et al.*[15] The simplest example of such nontrivial ternary operation is given by the following composition rule:

$$\{a,b,c\}_{ijk}=\sum_{l,m,n} a_{nil}b_{ljm}c_{mkn} \quad (i,j,k,\ldots=1,2,\ldots,N).$$

Ternary structures and their generalization, the so-called n-ary structures, raise certain hopes in view of their applications in physics. Some significant physical applications are as follows (see Refs. 16 and 17):

(1) The algebra of "*nonions*" generated by two matrices,

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & \omega \\ \omega^2 & 0 & 0 \end{pmatrix} \quad (\omega=e^{2\pi i/3}),$$

was introduced by Sylvester as a ternary analog of Hamilton's quaternions (cf. Ref. 1).

(2) A natural ternary composition of four-vectors in the four-dimensional Minkowskian space-time M_4 can be defined as an example of a ternary operation:

$$(X,Y,Z)\to U(X,Y,Z)\in M_4,$$

with the resulting four-vector U^μ defined via its components in a given coordinate system as follows:

[a)]Electronic address: baak@hanyang.ac.kr

$$U^{\mu}(X,Y,Z) = g^{\mu\sigma}\eta_{\sigma\nu\lambda\rho}X^{\nu}Y^{\lambda}Z^{\rho}, \quad \mu,\nu,\ldots = 0,1,2,3,$$

where $g^{\mu\sigma}$ is the metric tensor and $\eta_{\sigma\nu\lambda\rho}$ is the canonical volume element of M_4 (see Ref. 17).

(3) The quark model inspired a particular brand of ternary algebraic systems. The so-called "*Nambu mechnics*" is based on such structures (see Ref. 7).

There are also some applications, although still hypothetical, in the fractional quantum Hall effect, the nonstandard statistics, supersymmetric theory, and Yang-Baxter equation (cf. Refs. 1, 17, and 35).

Following the terminology of Ref. 2 a non-empty set G with a ternary operation $[\cdot,\cdot,\cdot]:G\times G\times G\to G$ is called a *ternary groupoid* and is denoted by $(G,[\cdot,\cdot,\cdot])$. The ternary groupoid $(G,[\cdot,\cdot,\cdot])$ is called *commutative* if $[x_1,x_2,x_3]=[x_{\sigma(1)},x_{\sigma(2)},x_{\sigma(3)}]$ for all $x_1,x_2,x_3\in G$ and all permutations σ of $\{1,2,3\}$.

If a binary operation $\circ$ is defined on G such that $[x,y,z]=(x\circ y)\circ z$ for all $x,y,z\in G$, then we say that $[\cdot,\cdot,\cdot]$ is derived from $\circ$. We say that $(G,[\cdot,\cdot,\cdot])$ is a *ternary semigroup* if the operation $[\cdot,\cdot,\cdot]$ is *associative*, i.e., if $[[x,y,z],u,v]=[x,[y,z,u],v]=[x,y,[z,u,v]]$ holds for all $x,y,z,u,v\in G$ (see Ref. 4).

A C^*-ternary algebra is a complex Banach space A, equipped with a ternary product $(x,y,z)\mapsto[x,y,z]$ of A^3 into A, which is $\mathbb{C}$ linear in the outer variables, conjugate $\mathbb{C}$-linear in the middle variable, and associative in the sense that $[x,y,[z,w,v]]=[x,[w,z,y],v]=[[x,y,z],w,v]$, and satisfies $\|[x,y,z]\|\le\|x\|\cdot\|y\|\cdot\|z\|$ and $\|[x,x,x]\|=\|x\|^3$ (see Refs. 2 and 36). Every left Hilbert C^* module is a C^*-ternary algebra via the ternary product $[x,y,z]:=\langle x,y\rangle z$.

If a C^*-ternary algebra $(A,[\cdot,\cdot,\cdot])$ has an identity, i.e., an element $e\in A$ such that $x=[x,e,e]=[e,e,x]$ for all $x\in A$, then it is routine to verify that A, endowed with $x\circ y:=[x,e,y]$ and $x^*:=[e,x,e]$, is a unital C^* algebra. Conversely, if $(A,\circ)$ is a unital C^* algebra, then $[x,y,z]:=x\circ y^*\circ z$ makes A into a C^*-ternary algebra.

A $\mathbb{C}$-linear mapping $H:A\to B$ is called a *C^*-ternary algebra homomorphism* if

$$H([x,y,z]) = [H(x),H(y),H(z)],$$

for all $x,y,z\in A$. If, in addition, the mapping H is bijective, then the mapping $H:A\to B$ is called a *C^*-ternary algebra isomorphism*. A $\mathbb{C}$-linear mapping $\delta:A\to A$ is called a *C^*-ternary derivation* if

$$\delta([x,y,z]) = [\delta(x),y,z]+[x,\delta(y),z]+[x,y,\delta(z)],$$

for all $x,y,z\in A$ (see Refs. 2 and 18).

In 1940, Ulam[34] gave a talk before the Mathematics Club of the University of Wisconsin in which he discussed a number of unsolved problems. Among these was the following question concerning the stability of homomorphisms.

We are given a group G and a metric group G' with metric $\rho(\cdot,\cdot)$. Given $\epsilon>0$, does there exist a $\delta>0$ such that if $f:G\to G'$ satisfies $\rho(f(xy),f(x)f(y))<\delta$ for all $x,y\in G$, then a homomorphism $h:G\to G'$ exists with $\rho(f(x),h(x))<\epsilon$ for all $x\in G$?

In 1941, Hyers[10] considered the case of approximately additive mappings $f:E\to E'$, where E and E' are Banach spaces and f satisfies *Hyers inequality*,

$$\|f(x+y)-f(x)-f(y)\|\le\epsilon,$$

for all $x,y\in E$. It was shown that the limit

$$L(x) = \lim_{n\to\infty}\frac{f(2^n x)}{2^n}$$

exists for all $x\in E$ and that $L:E\to E'$ is the unique additive mapping satisfying

$$\|f(x)-L(x)\|\le\epsilon.$$

In 1978, Rassias[26] provided a generalization of Hyers' Theorem that allows the *Cauchy difference to be unbounded*.

Theorem 1.1: (Rassias[26]) *Let $f:E\to E'$ be a mapping from a normed vector space E into a Banach space E', subject to the inequality*

$$\|f(x+y)-f(x)-f(y)\| \le \epsilon(\|x\|^p+\|y\|^p), \tag{1.1}$$

for all $x,y\in E$, where ϵ and p are constants with $\epsilon>0$ and $p<1$. Then the limit

$$L(x)=\lim_{n\to\infty}\frac{f(2^n x)}{2^n},$$

exists for all $x\in E$ and $L:E\to E'$ is the unique additive mapping that satisfies

$$\|f(x)-L(x)\| \le \frac{2\epsilon}{2-2^p}\|x\|^p, \tag{1.2}$$

for all $x\in E$. If $p<0$, then inequality (1.1) holds for $x,y\neq 0$ and (1.2) for $x\neq 0$.

In 1990, Rassias,[27] during the 27th International Symposium on Functional Equations, asked the question of whether such a theorem can also be proved for $p\ge 1$. In 1991, Gajda[8] following the same approach as in Rassias,[26] gave an affirmative solution to this question for $p>1$. It was shown by Gajda,[8] as well as by Rassias and Šemrl[32] that one cannot prove a Rassias' type theorem when $p=1$. The counterexamples of Gajda,[8] as well as of Rassias and Šemrl,[32] have stimulated several mathematicians to invent new definitions of *approximately additive* or *approximately linear* mappings; cf. Găvruta,[9] Jung,[14] who, among others, studied the Hyers-Ulam-Rassias stability of functional equations. The inequality (1.1) that was introduced for the first time by Rassias[26] provided a lot of influence in the development of a generalization of the Hyers-Ulam stability concept. This new concept is known as the *Hyers-Ulam-Rassias stability* of functional equations (cf. the books of Czerwik,[6] Hyers, Isac, and Rassias.[11])

Rassias,[24] following the spirit of the innovative approach of Rassias[26] for the unbounded Cauchy difference, proved a similar stability theorem in which he replaced the factor $\|x\|^p+\|y\|^p$ by $\|x\|^p\cdot\|y\|^q$ for $p,q\in\mathbb{R}$ with $p+q\neq 1$ (see also Ref. 25 for a number of other new results).

Găvruta[9] provided a further generalization of Rassias' Theorem. In 1996, Isac and Rassias[13] applied the Hyers-Ulam-Rassias stability theory to prove fixed point theorems and study some new applications in Nonlinear Analysis. In Ref. 12, Hyers, Isac, and Rassias studied the asymptoticity aspect of Hyers-Ulam stability of mappings. During the past few years several mathematicians have published on various generalizations and applications of Hyers-Ulam stability and Hyers-Ulam-Rassias stability to a number of functional equations and mappings, for example, quadratic functional equation, invariant means, multiplicative mappings—superstability, bounded nth differences, convex functions, generalized orthogonality functional equation, Euler-Lagrange functional equation, and Navier-Stokes equations. Several mathematicians have contributed works on these subjects; we mention a few: Baak and Moslehian,[3] Park,[19–23] Rassias,[28–31] and Skof.[33]

Throughout this paper, assume that p, d are non-negative integers with $p+d\ge 3$.

In Sec. II, we prove the Hyers-Ulam-Rassias stability of homomorphisms in C^*-ternary algebras for the generalized Cauchy-Jensen additive mapping.

In Sec. III, we investigate isomorphisms between unital C^*-ternary algebras associated with the generalized Cauchy-Jensen additive mapping.

In Sec. IV, we prove the Hyers-Ulam-Rassias stability of derivations on C^*-ternary algebras for the generalized Cauchy-Jensen additive mapping.

II. STABILITY OF HOMOMORPHISMS IN C^*-TERNARY ALGEBRAS

Throughout this section, assume that A is a C^*-ternary algebra with norm $\|\cdot\|_A$ and that B is a C^*-ternary algebra with norm $\|\cdot\|_B$.

For a given mapping $f:A\to B$, we define

$$C_\mu f(x_1,\ldots,x_p,y_1,\ldots,y_d) := 2f\left(\frac{\sum_{j=1}^{p}\mu x_j}{2}+\sum_{j=1}^{d}\mu y_j\right)-\sum_{j=1}^{p}\mu f(x_j)-2\sum_{j=1}^{d}\mu f(y_j),$$

for all $\mu\in\mathbb{T}^1:=\{\lambda\in\mathbb{C}\,|\,|\lambda|=1\}$ and all $x_1,\ldots,x_p,y_1,\ldots,y_d\in A$.

One can easily show that a mapping $f:A\to B$ satisfies $C_1f(x_1,\ldots,x_p,y_1,\ldots,y_d)=0$ if and only if f is Cauchy additive, and that if a mapping $f:A\to B$ satisfies $C_1f(x_1,\ldots,x_p,y_1,\ldots,y_d)=0$ then $f(0)=0$.

We prove the Hyers-Ulam-Rassias stability of homomorphisms in C^*-ternary algebras for the functional equation $C_\mu f(x_1,\ldots,x_p,y_1,\ldots,y_d)=0$.

Theorem 2.1: *Let $r>3$ and θ be non-negative real numbers, and let $f:A\to B$ be a mapping such that*

$$\|C_\mu f(x_1,\ldots,x_p,y_1,\ldots,y_d)\|_B\le\theta\left(\sum_{j=1}^{p}\|x_j\|_A^r+\sum_{j=1}^{d}\|y_j\|_A^r\right),\tag{2.1}$$

$$\|f([x,y,z])-[f(x),f(y),f(z)]\|_B\le\theta(\|x\|_A^r+\|y\|_A^r+\|z\|_A^r),\tag{2.2}$$

for all $\mu\in\mathbb{T}^1$ and all $x,y,z,x_1,\ldots,x_p,y_1,\ldots,y_d\in A$. Then there exists a unique C^*-ternary algebra homomorphism $H:A\to B$, such that

$$\|f(x)-H(x)\|_B\le\frac{p+d}{2(p+2d)^r-(p+2d)2^r}\theta\|x\|_A^r,\tag{2.3}$$

for all $x\in A$.

Proof: Let us assume $\mu=1$ and $x_1=\cdots=x_p=y_1=\cdots=y_d=x$ in (2.1). Then we get

$$\left\|2f\left(\frac{p+2d}{2}x\right)-(p+2d)f(x)\right\|_B\le(p+d)\theta\|x\|_A^r,\tag{2.4}$$

for all $x\in A$. So

$$\left\|f(x)-\frac{p+2d}{2}f\left(\frac{2}{p+2d}x\right)\right\|_B\le\frac{p+d}{2(p+2d)^r}\theta\|x\|_A^r,$$

for all $x\in A$. Hence

$$\begin{aligned}&\left\|\frac{(p+2d)^l}{2^l}f\left(\frac{2^l}{(p+2d)^l}x\right)-\frac{(p+2d)^m}{2^m}f\left(\frac{2^m}{(p+2d)^m}x\right)\right\|_B\\&\le\sum_{j=l}^{m-1}\left\|\frac{(p+2d)^j}{2^j}f\left(\frac{2^j}{(p+2d)^j}x\right)-\frac{(p+2d)^{j+1}}{2^{j+1}}f\left(\frac{2^{j+1}}{(p+2d)^{j+1}}x\right)\right\|_B\\&\le\frac{(p+d)}{2(p+2d)^r}\sum_{j=l}^{m-1}\frac{2^{rj}(p+2d)^j}{2^j(p+2d)^{rj}}\theta\|x\|_A^r,\end{aligned}\tag{2.5}$$

for all non-negative integers m and l with $m>l$ and all $x\in A$. From this it follows that the sequence $\{[(p+2d)^n/2^n]f([2^n/(p+2d)^n]x)\}$ is a Cauchy sequence for all $x\in A$. Since B is complete, the sequence $\{[(p+2d)^n/2^n]f([2^n/(p+2d)^n]x)\}$ converges. Thus one can define the mapping $H:A\to B$ by

$$H(x) := \lim_{n\to\infty} \frac{(p+2d)^n}{2^n} f\left(\frac{2^n}{(p+2d)^n}x\right),$$

for all $x \in A$. Moreover, letting $l=0$ and passing the limit $m\to\infty$ in (2.5), we get (2.3).

It follows from (2.1) that

$$\begin{aligned}
&\left\| 2H\left(\frac{\sum_{j=1}^{p} x_j}{2} + \sum_{j=1}^{d} y_j\right) - \sum_{j=1}^{p} H(x_j) - 2\sum_{j=1}^{d} H(y_j)\right\|_B \\
&= \lim_{n\to\infty} \frac{(p+2d)^n}{2^n} \left\| 2f\left(\frac{2^n}{(p+2d)^n}\frac{\sum_{j=1}^{p} x_j}{2} + \frac{2^n}{(p+2d)^n}\sum_{j=1}^{d} y_j\right)\right. \\
&\quad \left. - \sum_{j=1}^{p} f\left(\frac{2^n}{(p+2d)^n}x_j\right) - 2\sum_{j=1}^{d} f\left(\frac{2^n}{(p+2d)^n}y_j\right)\right\|_B \\
&\le \lim_{n\to\infty} \frac{2^{nr}(p+2d)^n}{2^n(p+2d)^{nr}}\theta\left(\sum_{j=1}^{p}\|x_j\|_A^r + \sum_{j=1}^{d}\|y_j\|_A^r\right) = 0,
\end{aligned}$$

for all $x_1,\ldots,x_p,y_1,\ldots,y_d \in A$. Hence

$$2H\left(\frac{\sum_{j=1}^{p} x_j}{2} + \sum_{j=1}^{d} y_j\right) = \sum_{j=1}^{p} H(x_j) + 2\sum_{j=1}^{d} H(y_j),$$

for all $x_1,\ldots,x_p,y_1,\ldots,y_d \in A$. So the mapping $H:A\to B$ is Cauchy additive.

By the same reasoning as in the proof of Theorem 2.1 of Ref. 21, the mapping $H:A\to B$ is $\mathbb{C}$-linear.

It follows from (2.2) that

$$\begin{aligned}
\|H([x,y,z]) - [H(x),H(y),H(z)]\|_B &= \lim_{n\to\infty} \frac{(p+2d)^{3n}}{8^n}\left\| f\left(\frac{8^n[x,y,z]}{(p+2d)^{3n}}\right)\right. \\
&\quad \left. - \left[f\left(\frac{2^n x}{(p+2d)^n}\right), f\left(\frac{2^n y}{(p+2d)^n}\right), f\left(\frac{2^n z}{(p+2d)^n}\right)\right]\right\|_B \\
&\le \lim_{n\to\infty} \frac{2^{nr}(p+2d)^{3n}}{8^n(p+2d)^{nr}}\theta(\|x\|_A^r + \|y\|_A^r + \|z\|_A^r) = 0,
\end{aligned}$$

for all $x,y,z \in A$. Thus

$$H([x,y,z]) = [H(x),H(y),H(z)],$$

for all $x,y,z \in A$.

Now, let $T:A\to B$ be another generalized Cauchy-Jensen additive mapping satisfying (2.3). Then we have

$$\begin{aligned}\|H(x)-T(x)\|_B &= \frac{(p+2d)^n}{2^n}\left\|H\left(\frac{2^n x}{(p+2d)^n}\right)-T\left(\frac{2^n x}{(p+2d)^n}\right)\right\|_B \\ &\le \frac{(p+2d)^n}{2^n}\left(\left\|H\left(\frac{2^n x}{(p+2d)^n}\right)-f\left(\frac{2^n x}{(p+2d)^n}\right)\right\|_B\right. \\ &\quad \left.+\left\|T\left(\frac{2^n x}{(p+2d)^n}\right)-f\left(\frac{2^n x}{(p+2d)^n}\right)\right\|_B\right) \\ &\le \frac{p+d}{2(p+2d)^r-(p+2d)2^r}\cdot\frac{2^{nr+1}(p+2d)^n}{2^n(p+2d)^{nr}}\theta\|x\|_A^r,\end{aligned}$$

which tends to zero as $n\to\infty$ for all $x\in A$. So we can conclude that $H(x)=T(x)$ for all $x\in A$. This proves the uniqueness of H. Thus, the mapping $H:A\to B$ is a unique C^*-ternary algebra homomorphism satisfying (2.3).

Theorem 2.2: *Let $r<1$ and θ be non-negative real numbers, and let $f:A\to B$ be a mapping satisfying* (2.1) and (2.2). *Then there exists a unique C^*-ternary algebra homomorphism $H:A\to B$ such that*

$$\|f(x)-H(x)\|_B \le \frac{2^r(p+d)}{2^r(p+2d)-2(p+2d)^r}\theta\|x\|_A^r, \tag{2.6}$$

for all $x\in A$.

Proof: It follows from (2.4) that

$$\left\|f(x)-\frac{2}{p+2d}f\left(\frac{p+2d}{2}x\right)\right\|_B \le \frac{p+d}{p+2d}\theta\|x\|_A^r,$$

for all $x\in A$. So

$$\begin{aligned}&\left\|\frac{2^l}{(p+2d)^l}f\left(\frac{(p+2d)^l}{2^l}x\right)-\frac{2^m}{(p+2d)^m}f\left(\frac{(p+2d)^m}{2^m}x\right)\right\|_B \\ &\le \sum_{j=l}^{m-1}\left\|\frac{2^j}{(p+2d)^j}f\left(\frac{(p+2d)^j}{2^j}x\right)-\frac{2^{j+1}}{(p+2d)^{j+1}}f\left(\frac{(p+2d)^{j+1}}{2^{j+1}}x\right)\right\|_B \\ &\le \frac{p+d}{p+2d}\sum_{j=l}^{m-1}\frac{2^j(p+2d)^{jr}}{2^{jr}(p+2d)^j}\theta\|x\|_A^r,\end{aligned} \tag{2.7}$$

for all non-negative integers m and l with $m>l$ and all $x\in A$. From this it follows that the sequence $\{[2^n/(p+2d)^n]f([(p+2d)^n/2^n]x)\}$ is a Cauchy sequence for all $x\in A$. Since B is complete, the sequence $\{[2^n/(p+2d)^n]f([(p+2d)^n/2^n]x)\}$ converges. So one can define the mapping $H:A\to B$ by

$$H(x) := \lim_{n\to\infty}\frac{2^n}{(p+2d)^n}f\left(\frac{(p+2d)^n}{2^n}x\right),$$

for all $x\in A$. Moreover, letting $l=0$ and passing the limit $m\to\infty$ in (2.7), we get (2.6).

The rest of the proof is similar to the proof of Theorem 2.1. □

Theorem 2.3: *Let $r>1$ and θ be non-negative real numbers, and let $f:A\to B$ be a mapping such that*

$$\|C_\mu f(x_1,\ldots,x_p,y_1,\ldots,y_d)\|_B \le \theta\prod_{j=1}^{p}\|x_j\|_A^r\cdot\prod_{j=1}^{d}\|y_j\|_A^r, \tag{2.8}$$

$$\|f([x,y,z])-[f(x),f(y),f(z)]\|_B \le \theta\cdot(\|x\|_A^r\cdot\|y\|_A^r\cdot\|z\|_A^r), \tag{2.9}$$

for all $\mu\in\mathbb{T}^1$ *and all* $x,y,z,x_1,\ldots,x_p,y_1,\ldots,y_d\in A$. *Then there exists a unique* C^**-ternary algebra homomorphism* $H:A\to B$ *such that*

$$\|f(x)-H(x)\|_B \le \frac{2^{(p+d)r}}{2(p+2d)^{(p+d)r}-2^{(p+d)r}(p+2d)}\theta\|x\|_A^{(p+d)r}, \tag{2.10}$$

for all $x\in A$.

Proof: Let us assume $\mu=1$ and $x_1=\cdots=x_p=y_1=\cdots=y_d=x$ in (2.8). Then we get

$$\left\|2f\left(\frac{p+2d}{2}x\right)-(p+2d)f(x)\right\|_B \le \theta\|x\|_A^{(p+d)r}, \tag{2.11}$$

for all $x\in A$.So

$$\left\|f(x)-\frac{p+2d}{2}f\left(\frac{2}{p+2d}x\right)\right\|_B \le \frac{2^{(p+d)r}}{2(p+2d)^{(p+d)r}}\theta\|x\|_A^{(p+d)r},$$

for all $x\in A$. Hence

$$\begin{aligned}&\left\|\frac{(p+2d)^l}{2^l}f\left(\frac{2^l}{(p+2d)^l}x\right)-\frac{(p+2d)^m}{2^m}f\left(\frac{2^m}{(p+2d)^m}x\right)\right\|_B\\&\le\sum_{j=l}^{m-1}\left\|\frac{(p+2d)^j}{2^j}f\left(\frac{2^j}{(p+2d)^j}x\right)-\frac{(p+2d)^{j+1}}{2^{j+1}}f\left(\frac{2^{j+1}}{(p+2d)^{j+1}}x\right)\right\|_B\\&\le\frac{2^{(p+d)r}}{2(p+2d)^{(p+d)r}}\sum_{j=l}^{m-1}\frac{2^{(p+d)rj}(p+2d)^j}{2^j(p+2d)^{(p+d)rj}}\theta\|x\|_A^{(p+d)r},\end{aligned} \tag{2.12}$$

for all non-negative integers m and l with $m>l$ and all $x\in A$. From this it follows that the sequence $\{[(p+2d)^n/2^n]f([2^n/(p+2d)^n]x)\}$ is a Cauchy sequence for all $x\in A$. Since B is complete, the sequence $\{[(p+2d)^n/2^n]f([2^n/(p+2d)^n]x)\}$ converges. Thus one can define the mapping $H:A\to B$ by

$$H(x):=\lim_{n\to\infty}\frac{(p+2d)^n}{2^n}f\left(\frac{2^n}{(p+2d)^n}x\right),$$

for all $x\in A$. Moreover, letting $l=0$ and passing the limit $m\to\infty$ in (2.12), we get (2.10).

The rest of the proof is similar to the proof of Theorem 2.1. □

Theorem 2.4: *Let* $r<1/(p+d)$ *and* θ *be non-negative real numbers, and let* $f:A\to B$ *be a mapping satisfying* (2.8) and (2.9). *Then there exists a unique* C^**-ternary algebra homomorphism* $H:A\to B$ *such that*

$$\|f(x)-H(x)\|_B \le \frac{2^{(p+d)r}}{2^{(p+d)r}(p+2d)-2(p+2d)^{(p+d)r}}\theta\|x\|_A^{(p+d)r}, \tag{2.13}$$

for all $x\in A$.

Proof: It follows from (2.11) that

$$\left\|f(x)-\frac{2}{p+2d}f\left(\frac{p+2d}{2}x\right)\right\|_B \le \frac{\theta}{p+2d}\|x\|_A^{(p+d)r},$$

for all $x\in A$. So

$$\begin{aligned}
&\left\|\frac{2^l}{(p+2d)^l}f\left(\frac{(p+2d)^l}{2^l}x\right)-\frac{2^m}{(p+2d)^m}f\left(\frac{(p+2d)^m}{2^m}x\right)\right\|_B\\
&\le\sum_{j=l}^{m-1}\left\|\frac{2^j}{(p+2d)^j}f\left(\frac{(p+2d)^j}{2^j}x\right)-\frac{2^{j+1}}{(p+2d)^{j+1}}f\left(\frac{(p+2d)^{j+1}}{2^{j+1}}x\right)\right\|_B\\
&\le\frac{\theta}{p+2d}\sum_{j=l}^{m-1}\frac{2^j(p+2d)^{j(p+d)r}}{2^{j(p+d)r}(p+2d)^j}\|x\|_A^{(p+d)r},
\end{aligned}\tag{2.14}$$

for all non-negative integers m and l with $m>l$ and all $x\in A$. From this it follows that the sequence $\{[2^n/(p+2d)^n]f([(p+2d)^n/2^n]x)\}$ is a Cauchy sequence for all $x\in A$. Since B is complete, the sequence $\{[2^n/(p+2d)^n]f([(p+2d)^n/2^n]x)\}$ converges. So one can define the mapping $H:A\to B$ by

$$H(x):=\lim_{n\to\infty}\frac{2^n}{(p+2d)^n}f\left(\frac{(p+2d)^n}{2^n}x\right),$$

for all $x\in A$. Moreover, letting $l=0$ and passing the limit $m\to\infty$ in (2.14), we get (2.13).

The rest of the proof is similar to the proof of Theorem 2.1. □

III. ISOMORPHISMS BETWEEN C^*-TERNARY ALGEBRAS

Throughout this section, assume that A is a unital C^*-ternary algebra with norm $\|\cdot\|_A$ and unit e, and that B is a unital C^*-ternary algebra with norm $\|\cdot\|_B$ and unit e'.

We investigate isomorphisms between C^*-ternary algebras associated with the functional equation $C_\mu f(x_1,\ldots,x_p,y_1,\ldots,y_d)=0$.

Theorem 3.1: *Let $r>1$ and θ be non-negative real numbers, and let $f:A\to B$ be a bijective mapping satisfying* (2.1), *such that*

$$f([x,y,z])=[f(x),f(y),f(z)],\tag{3.1}$$

for all $x,y,z\in A$. If $\lim_{n\to\infty}[(p+2d)^n/2^n]f(2^ne/(p+2d)^n)=e'$, then the mapping $f:A\to B$ is a C^*-ternary algebra isomorphism.

Proof: By the same reasoning as in the proof of Theorem 2.1, there exists a unique $\mathbb{C}$-linear mapping $H:A\to B$ such that

$$\|f(x)-H(x)\|_B\le\frac{p+d}{2(p+2d)^r-(p+2d)2^r}\theta\|x\|_A^r,$$

for all $x\in A$. The mapping $H:A\to B$ is defined by

$$H(x):=\lim_{n\to\infty}\frac{(p+2d)^n}{2^n}f\left(\frac{2^n}{(p+2d)^n}x\right),$$

for all $x\in A$.

Since $f([x,y,z])=[f(x),f(y),f(z)]$ for all $x,y,z\in A$,

$$\begin{aligned}
H([x,y,z])&=\lim_{n\to\infty}\frac{(p+2d)^{3n}}{8^n}f\left(\left[\frac{2^nx}{(p+2d)^n},\frac{2^ny}{(p+2d)^n},\frac{2^nz}{(p+2d)^n}\right]\right)\\
&=\lim_{n\to\infty}\left[\frac{(p+2d)^n}{2^n}f\left(\frac{2^nx}{(p+2d)^n}\right),\frac{(p+2d)^n}{2^n}f\left(\frac{2^ny}{(p+2d)^n}\right),\frac{(p+2d)^n}{2^n}f\left(\frac{2^nz}{(p+2d)^n}\right)\right]\\
&=[H(x),H(y),H(z)],
\end{aligned}$$

for all $x,y,z\in A$. So the mapping $H:A\to B$ is a C^*-ternary algebra homomorphism.

It follows from (3.1) that

$$H(x) = H([e,e,x]) = \lim_{n\to\infty} \frac{(p+2d)^{2n}}{4^n} f\left(\frac{4^n}{(p+2d)^{2n}}[e,e,x]\right)$$
$$= \lim_{n\to\infty} \frac{(p+2d)^{2n}}{4^n} f\left(\left[\frac{2^n e}{(p+2d)^n}, \frac{2^n e}{(p+2d)^n}, x\right]\right)$$
$$= \lim_{n\to\infty} \left[\frac{(p+2d)^n}{2^n} f\left(\frac{2^n e}{(p+2d)^n}\right), \frac{(p+2d)^n}{2^n} f\left(\frac{2^n e}{(p+2d)^n}\right), f(x)\right] = [e',e',f(x)] = f(x),$$

for all $x \in A$. Hence the bijective mapping $f:A\to B$ is a C^*-ternary algebra isomorphism. □

Theorem 3.2: *Let $r<1$ and θ be non-negative real numbers, and let $f:A\to B$ be a bijective mapping satisfying* (2.1) and (3.1). *If* $\lim_{n\to\infty}[2^n/(p+2d)^n]f([(p+2d)^n/2^n]e)=e'$, *then the mapping $f:A\to B$ is a C^*-ternary algebra isomorphism.*

Proof: By the same reasoning as in the proofs of Theorems 2.1 and 2.2, there exists a unique $\mathbb{C}$-linear mapping $H:A\to B$ such that

$$\|f(x)-H(x)\|_B \le \frac{2^r(p+d)}{2^r(p+2d)-2(p+2d)^r}\theta\|x\|_A^r,$$

for all $x \in A$. The mapping $H:A\to B$ is defined by

$$H(x) := \lim_{n\to\infty} \frac{2^n}{(p+2d)^n} f\left(\frac{(p+2d)^n}{2^n}x\right),$$

for all $x \in A$.

The rest of the proof is similar to the proof of Theorem 3.1. □

Theorem 3.3: *Let $r>1/(p+d)$ and θ be non-negative real numbers, and let $f:A\to B$ be a bijective mapping satisfying* (2.8) and (3.1). *If* $\lim_{n\to\infty}[(p+2d)^n/2^n]f(2^n e/(p+2d)^n)=e'$, *then the mapping $f:A\to B$ is a C^*-ternary algebra isomorphism.*

Proof: By the same reasoning as in the proofs of Theorems 2.1 and 2.3, there exists a unique $\mathbb{C}$-linear mapping $H:A\to B$ such that

$$\|f(x)-H(x)\|_B \le \frac{2^{(p+d)r}}{2(p+2d)^{(p+d)r}-2^{(p+d)r}(p+2d)}\theta\|x\|_A^{(p+d)r},$$

for all $x \in A$. The mapping $H:A\to B$ is defined by

$$H(x) := \lim_{n\to\infty} \frac{(p+2d)^n}{2^n} f\left(\frac{2^n}{(p+2d)^n}x\right),$$

for all $x \in A$.

The rest of the proof is similar to the proofs of Theorems 2.3 and 3.1. □

Theorem 3.4: *Let $r<1/(p+d)$ and θ be non-negative real numbers, and let $f:A\to B$ be a bijective mapping satisfying* (2.8) and (3.1). *If* $\lim_{n\to\infty}[2^n/(p+2d)^n]f([(p+2d)^n/2^n]e)=e'$, *then the mapping $f:A\to B$ is a C^*-ternary algebra isomorphism.*

Proof: By the same reasoning as in the proofs of Theorems 2.1 and 2.4, there exists a unique $\mathbb{C}$-linear mapping $H:A\to B$ such that

$$\|f(x)-H(x)\|_B \le \frac{2^{(p+d)r}}{2^{(p+d)r}(p+2d)-2(p+2d)^{(p+d)r}}\theta\|x\|_A^{(p+d)r},$$

for all $x \in A$. The mapping $H:A\to B$ is defined by

$$H(x) := \lim_{n\to\infty} \frac{2^n}{(p+2d)^n} f\left(\frac{(p+2d)^n}{2^n}x\right),$$

for all $x \in A$.

The rest of the proof is similar to the proofs of Theorems 2.4 and 3.1. □

IV. STABILITY OF DERIVATIONS ON C^*-TERNARY ALGEBRAS

Throughout this section, assume that A is a C^*-ternary algebra with norm $\|\cdot\|_A$.

We prove the Hyers-Ulam-Rassias stability of derivations on C^*-ternary algebras for the functional equation $C_\mu f(x_1,\ldots,x_p,y_1,\ldots,y_d)=0$.

Theorem 4.1: *Let $r>3$ and θ be non-negative real numbers, and let $f:A\to A$ be a mapping satisfying (2.1) such that*

$$\|f([x,y,z]) - [f(x),y,z] - [x,f(y),z] - [x,y,f(z)]\|_A \le \theta(\|x\|_A^r + \|y\|_A^r + \|z\|_A^r), \tag{4.1}$$

for all $x,y,z \in A$. Then there exists a unique C^*-ternary derivation $\delta:A\to A$ such that

$$\|f(x) - \delta(x)\|_A \le \frac{p+d}{2(p+2d)^r - (p+2d)2^r}\theta\|x\|_A^r, \tag{4.2}$$

for all $x \in A$.

Proof: By the same reasoning as in the proof of Theorem 2.1, there exists a unique $\mathbb{C}$-linear mapping $\delta:A\to A$ satisfying (4.2). The mapping $\delta:A\to A$ is defined by

$$\delta(x) := \lim_{n\to\infty} \frac{(p+2d)^n}{2^n} f\left(\frac{2^n}{(p+2d)^n}x\right),$$

for all $x \in A$.

It follows from (4.1) that

$$\begin{aligned}
&\|\delta([x,y,z]) - [\delta(x),y,z] - [x,\delta(y),z] - [x,y,\delta(z)]\|_A \\
&= \lim_{n\to\infty} \frac{(p+2d)^{3n}}{8^n} \left\| f\left(\frac{8^n}{(p+2d)^{3n}}[x,y,z]\right) - \left[f\left(\frac{2^n x}{(p+2d)^n}\right), \frac{2^n y}{(p+2d)^n}, \frac{2^n z}{(p+2d)^n}\right] \right. \\
&\quad \left. - \left[\frac{2^n x}{(p+2d)^n}, f\left(\frac{2^n y}{(p+2d)^n}\right), \frac{2^n z}{(p+2d)^n}\right] - \left[\frac{2^n x}{(p+2d)^n}, \frac{2^n y}{(p+2d)^n}, f\left(\frac{2^n z}{(p+2d)^n}\right)\right] \right\|_A \\
&\le \lim_{n\to\infty} \frac{2^{nr}(p+2d)^{3n}}{8^n(p+2d)^{nr}} \theta(\|x\|_A^r + \|y\|_A^r + \|z\|_A^r) = 0,
\end{aligned}$$

for all $x,y,z \in A$. Hence

$$\delta([x,y,z]) = [\delta(x),y,z] + [x,\delta(y),z] + [x,y,\delta(z)],$$

for all $x,y,z \in A$. Thus the mapping $\delta:A\to A$ is a unique C^*-ternary derivation satisfying (4.2).□

Theorem 4.2: *Let $r<1$ and θ be nonnegative real numbers, and let $f:A\to A$ be a mapping satisfying (2.1) and (4.1). Then there exists a unique C^*-ternary derivation $\delta:A\to A$ such that*

$$\|f(x) - \delta(x)\|_A \le \frac{2^r(p+d)}{2^r(p+2d) - 2(p+2d)^r}\theta\|x\|_A^r, \tag{4.3}$$

for all $x \in A$.

Proof: By the same reasoning as in the proofs of Theorems 2.1 and 2.2, there exists a unique $\mathbb{C}$-linear mapping $\delta:A\to A$ satisfying (4.3). The mapping $\delta:A\to A$ is defined by

$$\delta(x) := \lim_{n\to\infty} \frac{2^n}{(p+2d)^n} f\left(\frac{(p+2d)^n}{2^n}x\right),$$

for all $x \in A$.

The rest of the proof is similar to the proof of Theorem 4.1. □

Theorem 4.3: *Let $r>1$ and θ be non-negative real numbers, and let $f:A\to A$ be a mapping satisfying (2.8) such that*

$$\|f([x,y,z]) - [f(x),y,z] - [x,f(y),z] - [x,y,f(z)]\|_A \le \theta \cdot \|x\|_A^r \cdot \|y\|_A^r \cdot \|z\|_A^r, \tag{4.4}$$

for all $x,y,z \in A$. Then there exists a unique C^*-ternary derivation $\delta:A\to A$ such that

$$\|f(x) - \delta(x)\|_A \le \frac{2^{(p+d)r}}{2(p+2d)^{(p+d)r} - 2^{(p+d)r}(p+2d)} \theta \|x\|_A^{(p+d)r}, \tag{4.5}$$

for all $x \in A$.

Proof: By the same reasoning as in the proofs of Theorems 2.1 and 2.3, there exists a unique $\mathbb{C}$-linear mapping $\delta:A\to A$ satisfying (4.5). The mapping $\delta:A\to A$ is defined by

$$\delta(x) := \lim_{n\to\infty} \frac{(p+2d)^n}{2^n} f\left(\frac{2^n}{(p+2d)^n}x\right),$$

for all $x \in A$.

The rest of the proof is similar to the proof of Theorem 4.1. □

Theorem 4.4: *Let $r<1/(p+d)$ and θ be non-negative real numbers, and let $f:A\to A$ be a mapping satisfying (2.8) and (4.4). Then there exists a unique C^*-ternary derivation $\delta:A\to A$ such that*

$$\|f(x) - \delta(x)\|_A \le \frac{2^{(p+d)r}}{2^{(p+d)r}(p+2d) - 2(p+2d)^{(p+d)r}} \theta \|x\|_A^{(p+d)r}, \tag{4.6}$$

for all $x \in A$.

Proof: By the same reasoning as in the proofs of Theorems 2.1 and 2.4, there exists a unique $\mathbb{C}$-linear mapping $\delta:A\to A$ satisfying (4.6). The mapping $\delta:A\to A$ is defined by

$$\delta(x) := \lim_{n\to\infty} \frac{2^n}{(p+2d)^n} f\left(\frac{(p+2d)^n}{2^n}x\right),$$

for all $x \in A$.

The rest of the proof is similar to the proof of Theorem 4.1. □

Bell-type inequalities for nonlocal resources

Nicolas Brunner, Valerio Scarani, and Nicolas Gisin
Group of Applied Physics, University of Geneva, 20 rue de l'Ecole-de-Médecine, CH-1211 Geneva 4, Switzerland

(Received 6 April 2006; accepted 16 August 2006; published online 1 November 2006)

We present bipartite Bell-type inequalities which allow the two partners to use some nonlocal resource. Such inequalities can only be violated if the parties use a resource which is more nonlocal than the one permitted by the inequality. We introduce a family of N-input nonlocal machines, which are generalizations of the well-known PR (Popescu-Rohrlich) box. Then we construct Bell-type inequalities that cannot be violated by strategies that use one of these new machines. Finally we discuss implications for the simulation of quantum states. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2352857]

I. INTRODUCTION

One of the most striking properties of quantum mechanics is nonlocality. It is well known that two separated observers, each holding half of an entangled quantum state and performing appropriate measurements, share correlations which are nonlocal, in the sense that they violate a Bell inequality.[1] Indeed, this has been demonstrated in many laboratory experiments.[2] A key feature of entanglement is that it does not allow the two distant observers to send information to each other faster than light, i.e., correlation from measurements on quantum states is no-signaling.

It is an interesting problem to quantify how powerful the nonlocal correlations of quantum mechanics are. In order to do that, one has to use some nonlocal resource. A quite natural choice is indeed classical communication. In 2003, Toner and Bacon showed that a single bit of communication is enough to reproduce the correlations of the singlet state.[3] In the last years another nonlocal resource, the PR (Popescu-Rohrlich) box, has also been proposed to study this problem. Introduced in 1994 by Popescu and Rohrlich,[4,5] the PR box was then proven to be a powerful resource for information theoretic tasks, such as communication complexity[6,7] and cryptography.[8] It was also recently suggested that the PR box is a unit of nonlocality.[9] The PR box has the appealing feature that it is intrinsically nonsignaling, which is of course not the case of classical communication.[10] Note that a PR box is a strictly weaker resource than a bit of communication.[11] Recently, Cerf *et al.* presented a model using a single PR box which simulates correlations from any projective measurement on the singlet.[12] It appears very natural to extend this study to other quantum states, but this turns out to be quite difficult, even for nonmaximally entangled pure states of two qubits. In a recent paper we showed a family of nonmaximally entangled states, whose correlations cannot be reproduced by a single PR box.[11] In other words, some nonmaximally entangled states require a strictly larger amount of nonlocal resources than the maximally entangled state to be simulated. This suggests that entanglement and nonlocality are different resources. To demonstrate this result we found a Bell-type inequality allowing some nonlocal resource; in this case a single use of a PR box. Then, it was proven that this inequality is violated by some nonmaximally entangled state.

In the present paper, we introduce N-input bipartite nonlocal machines (NLM), which appear as a natural extension of the two-input PR box. These machines, denoted PR_N, have a nice connection to a family of N-setting Bell inequalities known as I_{NN22},[13] similar to the one that relates the PR box to the Clauser-Horne-Shimony-Holt (CHSH) inequality,[14]

$$\text{CHSH} \Rightarrow \text{PR box}, \tag{1}$$

$$I_{NN22} \Rightarrow PR_N.$$

In fact, the structure of the N-input NLM can be directly deduced from the corresponding I_{NN22} inequality. Then, we present a family of N-setting inequalities, M_{NN22}, which allows one use of the PR_{N-1} machine. Again, the structure of these new inequalities is easily deduced from the structure of the I_{NN22} inequalities, i.e.,

$$I_{NN22} \Rightarrow M_{NN22}. \tag{2}$$

Thus, a nice construction appears: for any number of settings N, we have a Bell inequality I_{NN22} and the related NLM, PR_N, which reaches the upper (no-signaling) bound of the inequality. Adding one setting we find another inequality, $M_{(N+1)(N+1)22}$, which cannot be violated by strategies which require a single use of PR_N.

The organization of the paper is as follows. In Sec. II we present the mathematical tools and introduce the notations by reviewing the simplest case of two settings on each side. The link between the PR box and the CHSH inequality is pointed out. Section III is devoted to the case of three settings: we introduce a three-setting NLM and study an inequality for a single use of a PR box. In Sec. IV, the construction of Sec. III is extended to the case N settings. Section V concludes the paper by reviewing the main results about Bell inequalities with and without resources. Our present work is then clearly situated in this context.

II. TOOLS

Let us consider a typical Bell test scenario. Two distant observers, Alice and Bob, share some quantum state. Each of them chooses between a set of measurements (settings) $\{A_i\}_{i=1\ldots N_A}$, $\{B_j\}_{j=1\ldots N_B}$. The result of the measurement is noted r_A, r_B. Here we will focus on dichotomic observables and we will restrict Alice and Bob to use the same number of settings, i.e., $r_{A,B} \in \{0,1\}$ and $N_A = N_B \equiv N$. An "experiment" is fully characterized by the family of $4N^2$ probabilities $P(r_A, r_B | A_i, B_j) \equiv P_{ij}(r_A, r_B)$ and can be seen as a point in a $4N^2$-dimensional probability space. As probabilities must satisfy

(i) Positivity: $P_{ij}(r_A, r_B) \geq 0 \quad \forall\, i,j,r_A,r_B$

(ii) Normalization: $\sum_{r_A,r_B=0,1} P_{ij}(r_A, r_B) = 1 \quad \forall\, i,j,$

all relevant experiments are contained in a bounded region of this probability space. Since we want to restrict ourselves to no-signaling probability distributions, we impose also the no-signaling conditions

$$\begin{aligned} \sum_{r_A=0,1} P_{ij}(r_A, r_B) &= P_j(r_B) \quad \forall\, i, \\ \sum_{r_B=0,1} P_{ij}(r_A, r_B) &= P_i(r_A) \quad \forall\, j. \end{aligned} \tag{3}$$

Conditions (3) mean that Alice's output cannot depend on Bob's setting, and vice versa. This shrinks further the region of possible experiments, and the dimension of the probability space is now reduced to $d = N(N+2)$. So, each no-signaling experiment is represented by a point in a d-dimensional probability space. In fact, the region containing all relevant probability distributions (strategies), i.e., satisfying positivity, normalization, and no-signaling, forms a polytope, i.e., a convex set with a finite number of vertices. It is the no-signaling polytope.

One can restrict the probability distributions even further by requiring that these are built only by local means, such as shared randomness. We then obtain a smaller polytope: the local polytope. The facets of this polytope are Bell inequalities, in the sense that a probability distribution lying inside (outside) the local polytope satisfies (violates) a Bell inequality. The vertices (extremal

points) of this polytope are deterministic strategies obtained by setting the outputs r_A and r_B always to 0 or always to 1. Finding the facets of a polytope knowing its vertices is a computationally difficult task. In fact, Pitowsky has shown this problem to be NP-complete.[15] That is why all Bell inequalities have been listed for the case of two or three settings, whereas not much is known for a larger number of settings.

Let us start with a brief review of the simplest situation: two settings on each side.

This case has been largely studied, and both the local and the no-signaling polytope have been completely characterized.[16] The probability space has eight dimensions. We choose the eight probabilities $P_i(r_A=0)$, $P_j(r_B=0)$, and $P_{ij}(r_A=r_B=0)$ to characterize the space.

The local polytope. The local polytope has 16 vertices. Fine[17] showed that all nontrivial facets are equivalent to the CHSH inequality

$$\mathrm{CHSH} \equiv \begin{array}{c|cc} & -1 & 0 \\ \hline -1 & 1 & 1 \\ 0 & 1 & -1 \end{array} \leq 0. \tag{4}$$

Here, the notation represents the coefficients that are put in front of the probabilities, according to

$$\begin{array}{c|c} & P_i(r_A=0) \\ \hline P_j(r_B=0) & P_{ij}(r_A=r_B=0). \end{array} \tag{5}$$

The extremal points (vertices) of the local polytope are deterministic strategies, i.e., for each setting Alice and Bob always output 0 or always output 1. Let us do an example: Alice outputs bit 0 for the first setting A_0 and outputs 1 for the second setting A_1; Bob always outputs 0, for both settings. This strategy corresponds to the point in probability space

$$[\underbrace{0_d,1_d}_{\text{Alice}} ; \underbrace{0_d,0_d}_{\text{Bob}}] = \begin{array}{c|cc} & 1 & 0 \\ \hline 1 & 1 & 0 \\ 1 & 1 & 0 \end{array}. \tag{6}$$

All probability distributions lying outside this polytope are nonlocal.

The *quantum set* is the set of correlations that can be obtained by local measurements on quantum states. Inequality (4) can indeed be violated by quantum mechanics, and the maximal violation is $1/\sqrt{2}-1/2\approx 0.2071$, obtained by suitable measurements on the singlet state. Of course the quantum set is included in the no-signaling polytope, but the converse is not true. There are no-signaling correlations that are more nonlocal than those of quantum mechanics. The PR box is indeed among these correlations.

The no-signaling polytope. The no-signaling polytope has 24 vertices: 16 of them are the local vertices seen before and the eight others are the nonlocal vertices. Each one of these points corresponds to a PR box. Let us make this clear. The PR box is a two-input, two-output NLM. Alice inputs x into the machine and gets outcome a, while Bob inputs y and gets output b. The outcomes are correlated such that $a\oplus b=xy$. The local marginals are however completely random, i.e., $P(a=0)=P(b=0)=1/2$, which ensures no-signaling. In probability space, the PR box corresponds to the point

$$\mathrm{PR} = \frac{1}{2} \times \begin{array}{c|cc} & 1 & 1 \\ \hline 1 & 1 & 1 \\ 1 & 1 & 0 \end{array}. \tag{7}$$

According to the symmetries $x\to x+1$, $y\to y+1$, $a\to a+1$, there are eight "equivalent" PR boxes. As pointed out in Ref. 16 there is a strong correspondence between the eight CHSH facets of the local polytope and the eight PR boxes. Above each CHSH inequality lies one of the PR boxes. Each PR box violates its corresponding inequality up to 0.5, which is the maximal value for

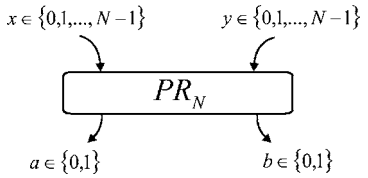

FIG. 1. An N-input NLM: generalization of the two-input PR box.

a no-signaling strategy. Formally, this correspondence is also pretty obvious by looking at Eqs. (4) and (7). To get the PR box from the CHSH inequality, proceed as follows:

Recipe. When the coefficient of a joint probability is +1 or 0 in the inequality, replace it with 0.5; when a coefficient is equal to −1, replace it with 0 in the machine.

In other words, when a joint probability appears with a coefficient +1 or 0, the outputs of the machine are correlated, and when the coefficient is −1, the outputs are anticorrelated. This simple recipe can be straightforwardly extended to Bell inequalities with more settings. For a Bell inequality with N settings, we then get a new NLM, denoted PR_N. This machine has N inputs and binary outcomes (see Fig. 1).

III. MAIN RESULT—THREE SETTINGS

In this paper we present Bell-type inequalities allowing the use of some nonlocal resource. This means that all strategies satisfying such inequalities can be simulated by local means (i.e., shared randomness, etc.) together with some nonlocal resource—for example, one NLM. In other words, any strategy violating such inequalities would require a strictly larger amount of nonlocal resource than is allowed by the inequality. In the case of two settings, described in the previous section, such inequalities cannot exist. This is because the most elementary nonlocal resource, the PR box, suffices already to generate all the nonlocal vertices of the no-signaling polytope.

Therefore we switch to the next case, i.e., three settings (with two outputs) on each side. Here, the situation becomes much more complicated but remains tractable. All facets of the local polytope have been listed.[13] No-signaling strategies are now living in a 15-dimensional space.

The local polytope. The local polytope has 64 vertices. Surprisingly, it turns out that each of the 648 nontrivial facets is equivalent to one of the two following Bell inequalities:

$$\mathrm{CHSH} \equiv \begin{array}{c|ccc} & -1 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ -1 & 1 & 1 & 0 \\ 0 & 1 & -1 & 0 \end{array} \leq 0, \tag{8}$$

$$I_{3322} \equiv \begin{array}{c|ccc} & -1 & 0 & 0 \\ \hline -2 & 1 & 1 & 1 \\ -1 & 1 & 1 & -1 \\ 0 & 1 & -1 & 0 \end{array} \leq 0. \tag{9}$$

The CHSH inequality is still a facet of the local polytope. This is a general property of Bell inequalities, known as "lifting"[18]: a facet Bell inequality, defined in a given configuration, remains a facet when the number of settings, outcomes, or parties is augmented.

Quantum mechanics indeed violates the three-setting CHSH inequality. The second inequality, I_{3322}, is also violated by quantum mechanics. Furthermore, this inequality is relevant, since it is violated by some quantum states which do not violate the CHSH inequality.[13]

The no-signaling polytope. The local polytope has 72 CHSH-type facets. Above each of these facets lies a PR box. This is clear since the CHSH inequality, while still being a facet of any local polytope with more settings, is a true two-input Bell inequality. Now, it is interesting to see that

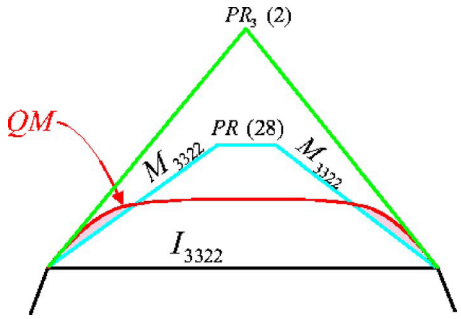

FIG. 2. A facet I_{3322} viewed in a simplified representation of the probability space. Above the facet, on the hyperplane $I_{3322}=0.5$, lie 28 strategies with a single PR. Above this hyperplane ($I_{3322}=1$) lie two strategies with a single PR_3. The local polytope is in black and the no-signaling in green. In blue is the polytope of all strategies using at most one PR; M_{3322} is a facet of this polytope. The quantum set is in red. Note that some quantum states violate M_{3322} (shaded area).

above each I_{3322} inequality (which is a true three-input Bell inequality) we find a no-signaling strategy which is more nonlocal than a PR box. This strategy is represented by a three-input NLM, defined by the relation $[xy/2]=a+b(\mathrm{mod}2)$, where $x,y\in\{0,1,2\}$ and $a,b\in\{0,1\}$. This machine will be referred to as PR_3. In probability space this new machine corresponds to the point

$$PR_3=\frac{1}{2}\times\begin{array}{c|ccc} & 1 & 1 & 1 \\ \hline 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \end{array}. \tag{10}$$

Note that $\langle I_{3322}|PR_3\rangle=1$, while $\langle I_{3322}|PR\rangle=0.5$ (see Fig. 2). Here, we have used a *scalar product-type* notation $\langle I|S\rangle=z$, which means that testing inequality I with strategy S gives a value z. The machine PR_3 can be simply obtained from the inequality I_{3322} using the Recipe mentioned at the end of Sec. II. One needs two PR boxes to simulate PR_3, as shown in Appendix A. PR_3 can also be rewritten in the elegant manner $x=y\Leftrightarrow a=b$, which corresponds to the probability point

$$\frac{1}{2}\times\begin{array}{c|ccc} & 1 & 1 & 1 \\ \hline 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{array}. \tag{11}$$

The distribution (11) is indeed equivalent to (10) up to local symmetries: here, both Alice and Bob flip their outputs for their first setting.

In a recent paper Jones and Masanes[19] gave a complete characterization of all the vertices of the no-signaling polytope for any number of settings and two outcomes—note that Barrett *et al.*studied the reversed case: two settings and any number of outcomes.[16] From their result it is clear that all vertices of the no-signaling polytope for three settings and two outputs can be constructed with a PR_3.

Numerically we find all the vertices of the no-signaling polytope. We proceed as follows. First we generate all strategies that use at most one PR_3. These are all the strategies where Alice and Bob can choose each of their three inputs in the set $\{0d,1d,0m,1m,2m,0mf,1mf,2mf\}$. Here $0d,1d$ means that they deterministically output the value 0 or 1; $0m,1m,2m$ means that they input $0,1,2$ in the machine PR_3; $0mf,1mf,2mf$ means that they input $0,1,2$ in PR_3 and flip the output of the machine. Second, we remove those strategies which are inside the local polytope by testing all the 648 Bell inequalities. Finally there are 1344 strategies left which are the nonlocal vertices

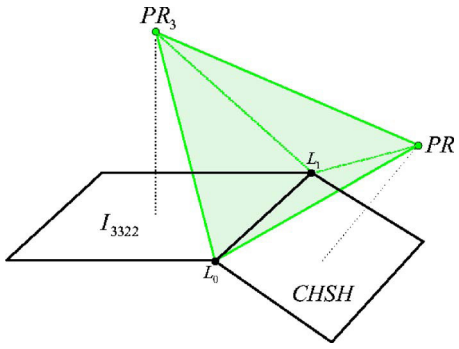

FIG. 3. Simplified three-dimensional view of a facet of the no-signaling polytope (green shaded surface). Among the extremal points of this facet are a PR-box strategy (38), a PR_3 (28) strategy, and a deterministic strategy, $L_0=[0_d,0_d,0_d;0_d,0_d,0_d]$. Behind this facet is another no-signaling facet which has a vertex $L_1=[1_d,1_d,1_d;1_d,1_d,1_d]$. Indeed, L_0,L_1 are extremal points of the local polytope. Note that PR and PR_3 are both above the CHSH and the I_{3322} facets.

of the (three-input, two-outcome) no-signaling polytope. We find four different classes of those vertices—given in Appendix B. A curious feature of those points is that each of them violates several inequalities of the local polytope. For example, the strategy

$$PR=\frac{1}{2}\times\begin{array}{c|ccc} & 1 & 1 & 0 \\ \hline 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 0 & 0 \end{array} \tag{12}$$

violates the CHSH inequality (8). But, it clearly also violates eight I_{3322}-type inequalities, among which

$$\begin{array}{c|ccc} & -1 & 0 & 0 \\ \hline -2 & 1 & 1 & 1 \\ -1 & 1 & 1 & -1 \\ 0 & 1 & -1 & 0 \end{array}\leq 0, \qquad \begin{array}{c|ccc} & -1 & 0 & -1 \\ \hline 0 & -1 & -1 & 1 \\ -1 & 1 & 1 & 0 \\ 0 & 1 & -1 & 0 \end{array}\leq 0. \tag{13}$$

Formally this is clear, since each of these eight I_{3322} inequalities [for example, (13)] reduces to the CHSH inequality (8) once Alice's third setting and Bob's first setting are discarded. Figure 3 gives some geometrical intuition of the situation.

Inequality with a PR box. We have just seen that, in the case of three settings on each side, there are two types of NLM, the PR box and the PR_3, generating different types of nonlocal vertices of the no-signaling polytope. As mentioned, the PR_3 is a stronger nonlocal resource than the PR box—it needs two PR boxes to be simulated. Thus there is a new polytope, sandwiched between the local and the no-signaling polytopes. It is formed by all strategies that can be simulated using at most one PR box (see Fig. 2). A facet of this polytope was recently found.[11] It corresponds to the inequality

$$M_{3322}\equiv\begin{array}{c|ccc} & -2 & 0 & 0 \\ \hline -2 & 1 & 1 & 1 \\ -1 & 1 & 1 & -1 \\ 0 & 1 & -1 & 0 \end{array}\leq 0. \tag{14}$$

Although M_{3322} is not violated by the maximally entangled state, it is violated by a family of nonmaximally entangled states of two qubits.[11] Indeed, the maximally entangled state does not

violate this inequality, since its correlations can be simulated using a single PR box.[12] Note that the structure of M_{3322} is similar to I_{3322}, the only difference being the coefficient of Alice's first marginal.

We prove now that M_{3322} is a facet of the polytope of all strategies using at most one PR box. This result will be extended to the case of N settings in the next section.

The proof consists of two parts: first we show that no strategy with a single use of a PR box violates M_{3322}; then we show that there are (at least) $N(N+2)=15$ linearly independent strategies using at most one PR box which saturate M_{3322}. Here, we just sketch the idea of the proof; see Appendix C for details.

To prove the first part, we state a Lemma. Any no-signaling strategy S violating M_{3322}, also violates the two following inequalities:

$$C_1 \equiv \begin{array}{c|ccc} & -1 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ -1 & 1 & 1 & 0 \\ 0 & 1 & -1 & 0 \end{array} \leq 0, \quad C_2 \equiv \begin{array}{c|ccc} & -1 & 0 & 0 \\ \hline -1 & 1 & 0 & 1 \\ 0 & 1 & 0 & -1 \\ 0 & 0 & 0 & 0 \end{array} \leq 0.$$

The proof is straightforward. One needs only to note that, for no-signaling strategies, joint probabilities are smaller (or equal) than their respective marginals. Then by inverting the Lemma, we get the following proposition: if S does not violate both inequalities C_1 and C_2, then S does not violate M_{3322}. Finally, it is obvious that with a single PR box one can violate either C_1 or C_2, but not both at the same time.

For the second part of the proof, we find numerically eight local deterministic distributions which saturate M_{3322}. Then we find 57 other strategies with one PR box saturating M_{3322}. Altogether these strategies form a hyperplane of dimension 14. This completes the proof that M_{3322} is a facet of the polytope.

IV. *N* SETTINGS

In this section, the results of Sec. III are extended to the case of an arbitrary number of settings N. We use a family of Bell inequalities, known as I_{NN22}, which were proven to be facets of the local polytope.[13] These inequalities are generalization of the I_{3322} seen before. For N settings, the inequality reads

$$I_{NN22} \equiv \begin{array}{c|cccccc} & -1 & 0 & 0 & \cdots & 0 & 0 \\ \hline -(N-1) & 1 & 1 & 1 & \cdots & 1 & 1 \\ -(N-2) & 1 & 1 & 1 & \cdots & 1 & -1 \\ -(N-3) & 1 & 1 & 1 & \cdots & -1 & 0 \\ \vdots & \vdots & & & & & \vdots \\ -1 & 1 & 1 & -1 & \cdots & 0 & 0 \\ 0 & 1 & -1 & 0 & \cdots & 0 & 0 \end{array} \leq 0.$$

Using the Recipe of Sec. II, we construct a family of N-settings NLM

$$PR_N \equiv \frac{1}{2}\begin{array}{c|cccccc} & 1 & 1 & 1 & \cdots & 1 & 1 \\ \hline 1 & 1 & 1 & 1 & \cdots & 1 & 1 \\ 1 & 1 & 1 & 1 & \cdots & 1 & 0 \\ 1 & 1 & 1 & 1 & \cdots & 0 & 1 \\ \vdots & \vdots & & & & & \vdots \\ 1 & 1 & 1 & 0 & \cdots & 1 & 1 \\ 1 & 1 & 0 & 1 & \cdots & 1 & 1 \end{array}. \tag{15}$$

TABLE I. Main results about Bell inequalities with and without nonlocal resources. We consider only the case of binary outcomes. N is the number of settings. The last line represents the vertices of the no-signaling polytope. The first column is almost empty since, for two settings, any no-signaling correlation can be generated with a PR box. The question marks mean that it is not known if there are more of these inequalities. For $N=3$, we are quite confident that M_{3322} is the only inequality for one use of a PR box, though we could not prove it rigorously.

Resource	$N=2$	$N=3$	$N\geq 4$
lhv	CHSH (Ref. 17)	CHSH+I_{3322} (Ref. 13)	CHSH+$\{I_{NN22}\}_{N\geq 3}$+ ?? (Ref. 13)
PR-box	…	M_{3322} (Ref. 11)	M_{3322}+ ??
1 bit	…	(Ref. 3)	??
PR_{N-1}	…	(Ref. 11)	M_{NN22} (this paper) + ??
No-signaling	PR (Ref. 16)	$PR+PR_3$ (Ref. 19)	$PR+\{PR_N\}_{N\geq 4}$ (Ref. 19)

One can simulate PR_N with $N-1$ PR-boxes. This is easily shown using a straightforward generalization of Appendix A. We think that PR_N cannot be simulated with fewer than $(N-1)$ PR-boxes, but we do not have a proof. The inequality

$$M_{(N+1)22} \equiv \begin{array}{c|ccccc} & -N & 0 & \cdots & 0 & 0 \\ \hline -N & 1 & 1 & \cdots & 1 & 1 \\ -(N-1) & 1 & 1 & \cdots & 1 & -1 \\ -(N-2) & 1 & 1 & \cdots & -1 & 0 \\ \vdots & \vdots & \vdots & & & \vdots \\ -1 & 1 & 1 & \cdots & 0 & 0 \\ 0 & 1 & -1 & \cdots & 0 & 0 \end{array} \leq 0 \tag{16}$$

is an $(N+1)$-setting Bell inequality that cannot be violated by strategies which require a single use of PR_N, as proven in Appendix C. In (16) we have omitted a factor $(N+1)$ in the name of the inequality for practical reasons. Again the structure of M_{NN22} is similar to I_{NN22}, up to Alice's first marginal: in order to get M_{NN22} from I_{NN22}, one simply changes Alice's first marginal to $-(N-1)$.

So, finally we get the following nice construction. For any number of settings N we have a Bell inequality I_{NN22} and an N-input NLM (PR_N) which reaches the upper no-signaling bound of I_{NN22}. From there, we construct an $(N+1)$-setting inequality $(M_{(N+1)(N+1)22})$, which cannot be violated with one use of PR_N, i.e.,

$$(I_{NN22}, PR_N) \rightarrow (M_{(N+1)(N+1)22}, PR_{N+1}). \tag{17}$$

V. CONCLUSION

To conclude, we review briefly the main results concerning polytopes and Bell inequalities with and without nonlocal resources. We focus on two-outcome settings. Table I summarizes the situation. The oldest result is due to Fine, who showed that all (nontrivial) facets of the two-input, two-outcome local polytope are equivalent to the CHSH inequality.[17] Then Collins and Gisin completely characterized the case of three settings.[13] In particular, they showed that there is a single new inequality (I_{3322}) which is inequivalent to CHSH. They also found a family of facet inequalities I_{NN22} of the N setting local polytope, but for $N>3$ it is not known if there are other inequalities. The vertices of the no-signaling polytope for two settings and any number of outcomes have been characterized by Barrett *et al.*,[16] while Jones and Masanes studied the reversed case: an arbitrary number of settings with two outcomes.[19]

Not much is known about inequalities allowing nonlocal resources. In 2003 Toner and Bacon found inequalities allowing one bit of communication for the case of two and three settings.[20] They showed that the correlations from measurements on any quantum state satisfy those inequali-

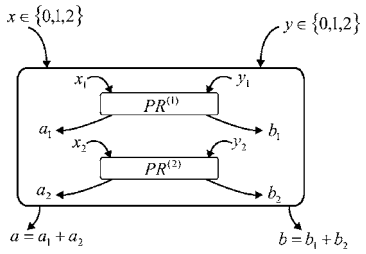

FIG. 4. A PR_3 with two PR's. The inputs of each PR, $x_{1,2}$ and $y_{1,2}$, are bits. For each ternary input $x(y)$, there is a combination of $x_{1,2}(y_{1,2})$. Finally, the output on each side is the sum (modulo 2) of the two binary outputs of the PR boxes.

ties. In the present paper we introduced a family of N-input NLMs ($\{PR_N\}_{N\geq 3}$), which are a generalization of the well-known PR box. These NLMs can be derived from Bell inequalities in the same way than the PR box is derived from the CHSH inequality. Then, we presented a new family of inequalities ($\{M_{NN22}\}_{N\geq 3}$) allowing one use of PR_N.

For $N=3$, we get an inequality which cannot be violated with a single PR box. This inequality, presented in a previous work,[11] is however violated by some nonmaximally entangled state of two qubits. Here, we checked numerically that no states of two qubits violates M_{4422} and M_{5522}, which suggests that these states could be simulated with two PR boxes, or even a PR_3 box. However such model has still not been found.

ACKNOWLEDGMENT

We acknowledge support from the project QAP (IST-FET FP6–015848).

APPENDIX A

Since $\langle M_{3322}|PR_3\rangle = 0.5$, PR_3 cannot be simulated with a single PR box. In this Appendix, we show how to construct a PR_3 with 2 PR boxes.

Alice and Bob each receive a trit. For each value of the trit they input one bit in each PR box. The strategy is the following:

x	x_1	x_2	y	y_1	y_2
0	0	0	0	0	0
1	0	1	1	1	0
2	1	0	2	0	1

, (A1)

where x,y denote the settings, and x_i,y_i are the binary inputs into PR-box number i. Finally, Alice and Bob output the sum (modulo 2) of both outputs of the PR boxes. See Fig. 4. Intuitively the strategy works as follows. The first machine introduces an anticorrelation of the outputs for the pair of settings $x=1,y=2$. The second PR box does the same for $x=2,y=1$. A nice way to show that this strategy works is by computing the parity of the outputs for each pair of settings. So, we compute a parity matrix P by multiplying Alice strategy by the transpose of Bob's strategy

$$P = S_A S_B^{\dagger} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}. \tag{A2}$$

Note that matrix P has the same structure as the correlation terms of I_{3322}. So, Alice and Bob's outputs are identical when a 1 appears in the inequality and different when -1 is in the inequality.

This construction is easily generalized to N settings. Since I_{NN22} has $N-1$ correlation terms equal to -1, one simply uses a PR box to anticorrelate the outcomes for each of those terms. Thus it can be shown that a PR_N NLM is constructed with $N-1$ PR-boxes.

APPENDIX B

We find four classes of nonlocal vertices of the three-setting, two-outcome no-signaling polytope

$$S_1 = \begin{array}{c|ccc} & x & x & x \\ \hline x & x & x & x \\ x & x & x & 0 \\ x & x & 0 & x \end{array}, \quad S_2 = \begin{array}{c|ccc} & x & x & 0 \\ \hline 0 & 0 & 0 & 0 \\ x & x & x & 0 \\ x & x & 0 & 0 \end{array}, \tag{B1}$$

$$S_3 = \begin{array}{c|ccc} & x & x & 0 \\ \hline x & x & x & 0 \\ x & x & x & 0 \\ x & x & 0 & 0 \end{array}, \quad S_4 = \begin{array}{c|ccc} & x & x & x \\ \hline x & x & x & x \\ x & x & x & x \\ x & x & 0 & x \end{array}, \tag{B2}$$

where $x = 1/2$. Class S_1 corresponds to strategies with a PR_3. They violate maximally I_{3322}, i.e., up to 1. Classes S_2-S_4 are strategies which can be obtained with a PR box. In S_2, Alice and Bob have a deterministic output for one of their setting; in S_3, only Alice (or Bob) has a deterministic setting; in S_4, no one outputs deterministic values.

There are 192 vertices in class 1, 288 in class 2, 576 in class 3, and 288 in class 4. All strategies in the same class violate the same number of CHSH inequalities and the same number of I_{3322} inequalities. These numbers are summarized in the table below. For each class of vertices, the number of CHSH and I_{3322} inequalities violated is given:

Class	CHSH	I_{3322}
S_1	6	18
S_2	1	8
S_3	2	12
S_4	4	24

APPENDIX C

This Appendix is divided in two parts. In the first part, it is shown that inequality

$$M_{NN22} \equiv \begin{array}{c|cccccc} & -(N-1) & 0 & 0 & \cdots & 0 & 0 \\ \hline -(N-1) & 1 & 1 & 1 & \cdots & 1 & 1 \\ -(N-2) & 1 & 1 & 1 & \cdots & 1 & -1 \\ -(N-3) & 1 & 1 & 1 & \cdots & -1 & 0 \\ \vdots & \vdots & & & & & \vdots \\ -1 & 1 & 1 & -1 & \cdots & 0 & 0 \\ 0 & 1 & -1 & 0 & \cdots & 0 & 0 \end{array} \leq 0$$

cannot be violated by strategies using (at most) one PR_{N-1}. In the second part, we show that, for $N \leq 5$, inequality M_{NN22} is tight, i.e., it is a facet of the polytope containing all strategies that use (at most) one PR_{N-1}. We conjecture that this is also true for any number of settings N. To motivate our conjecture we show that there are 2^N deterministic strategies lying on the

$(d-1)$-dimensional hyperplane, where $d=N(N+2)$ is the dimension of the probability space.

Part 1. We start with a Lemma.

Lemma 1. Let us define the two inequalities

$$C_1^N \equiv \begin{array}{c|cccccc} & -(N-2) & 0 & 0 & \cdots & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\ -(N-2) & 1 & 1 & 1 & \cdots & 1 & 0 \\ -(N-3) & 1 & 1 & 1 & \cdots & -1 & 0 \\ \vdots & \vdots & & & & & \vdots \\ -1 & 1 & 1 & -1 & \cdots & 0 & 0 \\ 0 & 1 & -1 & 0 & \cdots & 0 & 0 \end{array} \leq 0,$$

$$C_2^N \equiv \begin{array}{c|cccccc} & -(N-2) & 0 & 0 & \cdots & 0 & 0 \\ \hline -(N-2) & 1 & 0 & 1 & \cdots & 1 & 1 \\ -(N-3) & 1 & 0 & 1 & \cdots & 1 & -1 \\ -(N-4) & 1 & 0 & 1 & \cdots & -1 & 0 \\ \vdots & \vdots & & & & & \vdots \\ 0 & 1 & 0 & -1 & \cdots & 0 & 0 \\ 0 & 0 & 0 & 0 & \cdots & 0 & 0 \end{array} \leq 0.$$

Let S be a strategy with N settings for each of the two partners. S is in a probability space of dimension $N(N+2)$. If S violates inequality M_{NN22}, then S also violates both inequalities C_1^N and C_2^N.

Proof. S violates M_{NN22}, i.e.,

$$-(N-1)P(A_0)-\sum_{k=0}^{N-2}(N-k-1)P(B_k)+\sum_{k=0}^{N-1}P(A_kB_0)+\sum_{m=1}^{N-1}\left[\left(\sum_{k=0}^{N-m-1}P(A_kB_m)\right)-P(A_{N-m}B_m)\right] > 0. \tag{C1}$$

According to the no-signaling condition, we have

$$P(A_0) \geq P(A_0B_0), \tag{C2}$$

$$(N-1)P(B_0) \geq \sum_{k=1}^{N-1}P(A_kB_0), \tag{C3}$$

$$P(A_{N-1}B_1) \geq 0. \tag{C4}$$

Inserting these relations into (C1) we get

$$-(N-2)P(A_0)-\sum_{k=1}^{N-2}(N-k-1)P(B_k)+\sum_{k=0}^{N-2}P(A_kB_1)+\sum_{m=2}^{N-1}\left[\left(\sum_{k=0}^{N-m-1}P(A_kB_m)\right)-P(A_{N-m}B_m)\right] > 0,$$

which means S violates inequality C_1^N.

Again from to the no-signaling condition, we have

$$P(A_0) \geq P(A_0B_{N-1}), \tag{C5}$$

$$P(B_j) \geq P(A_1 B_j) \quad \forall\, j \in \{0, N-1\}, \tag{C6}$$

$$P(A_1 B_{N-1}) \geq 0, \tag{C7}$$

which inserted into (C1) gives

$$-(N-2)P(A_0) - \sum_{k=0}^{N-3} (N-k-2)P(B_k) + \sum_{k=0}^{N-2} P(A_0 B_k) + \sum_{k=2}^{N-1} P(A_k B_0) + \sum_{m=1}^{N-3} \left[\left(\sum_{k=2}^{N-m-1} P(A_k B_m) \right) - P(A_{N-m} B_m) \right] - P(A_2 B_{N-2}) > 0,$$

which means S violates inequality C_2^N.

This completes the proof.

Part 2. For $N \leq 5$, we checked numerically that all strategies using at most one PR_{N-1} form a subspace of dimension $d-1$, where $d=N(N+2)$ is the dimension of the probability space. This shows that inequality M_{NN22} is tight. We conjecture that this is also the case for any number of settings N. Below we show that there are 2^N deterministic strategies on the hyperplane $M_{NN22}=0$, which strongly supports our conjecture.

First we note that there are eight local strategies on the M_{3322} facet.

	0	1	1
1	0	1	1
0	0	0	0
0	0	0	0

	0	1	1
0	0	0	0
0	0	0	0

	0	0	0
0	0	0	0
0	0	0	0
0	0	0	0

(C8)

Obviously the marginals fix entirely a deterministic strategy. Then it is clear that if a three-setting strategy

	A_0	A_1	A_2
B_0			
B_1		⋯	
B_2			

(C9)

is on the facet M_{3322}, then both (four settings) strategies

	A_0	A_1	A_2	0
0	0	0	0	0
B_0				0
B_1		⋯		0
B_2				0

(C10)

$$S'' = \begin{array}{c|cccc} & A_0 & A_1 & A_2 & 1 \\ \hline B_0 & & & & \beta_0 \\ B_1 & & \cdots & & \beta_1 \\ B_2 & & & & \beta_2 \\ 0 & 0 & 0 & 0 & 0 \end{array}, \tag{C11}$$

are on the facet M_{4422}. The notation β_j for some correlation coefficients means that their value depends on Bob's marginal. Indeed, all these strategies are extremal since they are deterministic.

Then the argument is extended to the next case: for each of the 16 strategies (constructed above) which lie on M_{4422}, there are two strategies on M_{5522}. Thus there are 2^N deterministic strategies on M_{NN22}. Note that $2^N > N(N+2)$ for $N \geq 6$. In this case the number of local strategies on the hyperplane $M_{NN22}=0$ is larger than the dimension of the probability space. This suggests that M_{NN22} is a facet of the polytope of all strategies using at most one PR_{N-1}.

On the Weyl algebras for systems with semibounded and bounded configuration space

L. Bracci[a] and L. E. Picasso[b]

(Received 7 February 2006; accepted 20 September 2006; published online 3 November 2006)

We define the Weyl algebra suitable to represent the quantization postulate for one-dimensional systems whose configuration space is semibounded. It consists of a group $\{V(\beta)=\exp(-i\beta q), \beta \in \mathbb{R}\}$ of unitary operators and a semigroup $\{U(\alpha), \alpha \geqslant 0\}$ of nonunitary isometries. We show that the spectrum $\sigma(q)$ is a half-line $[x_0, \infty)$, with an arbitrary $x_0 > -\infty$, and that the irreducible representations of the Weyl algebra with the same x_0 are equivalent. We also consider the case when the semigroup of translations is substituted with a semigroup of partial isometries of index 1 (particle confined to a segment of unit length). The uniqueness of the irreducible representations of the related Weyl algebra is proved also for this case by exploiting the result for the half-line. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2363256]

I. INTRODUCTION

In quantum mechanics the momentum (p) and position (q) operators obey the Heisenberg commutation relation

$$[p,q] = -i \tag{1}$$

which holds for a dense domain $\mathcal{D}$ of vectors where both pq and qp are defined. Since the spectrum of q is the range of positions accessible to the system, for unconstrained systems p and q can be represented in $L^2(-\infty, \infty)$ as the operators

$$qf = xf \quad \mathcal{D}_q = \{f: xf \in L^2\}, \tag{2}$$

$$pf = -if' \quad \mathcal{D}_p = \{f: f \text{ absolutely continuous}, f' \in L^2\}. \tag{3}$$

This representation is not unique: for example also $\tilde{p}=p+h(q)$ and $\tilde{q}=q$ obey Eq. (1).

The self-adjoint operators p, q in Eqs. (2) and (3) generate two strongly continuous groups of unitary operators $U(\alpha)=\exp(-i\alpha p)$ and $V(\beta)=\exp(-i\beta q)(\alpha_i, \beta_j \in \mathbb{R})$,

$$U(\alpha_1)U(\alpha_2) = U(\alpha_1+\alpha_2) \quad U(0)=I, \quad \lim_{\alpha\to 0}\|(U(\alpha)-I)f\| = 0, \tag{4}$$

$$V(\beta_1)V(\beta_2) = V(\beta_1+\beta_2) \quad V(0)=I, \quad \lim_{\beta\to 0}\|(V(\beta)-I)f\| = 0, \tag{5}$$

such that

[a]Author to whom correspondence should be addressed; electronic-mail: bracci@df.unipi.it
[b]Electronic-mail: luigi.picasso@df.unipi.it

$$U(\alpha)f = f(x-\alpha), \quad V(\beta)f = \exp(-i\beta x)f(x), \tag{6}$$

which obey the following multiplication law:

$$U(\alpha)V(\beta) = \exp(i\alpha\beta)V(\beta)U(\alpha). \tag{7}$$

Equation (7) is referred to as the Weyl form of the commutation relations. A set of operators $U(\alpha)$, $V(\beta)$ which form two strongly continuous groups and obey Eq. (7) generate the Weyl algebra $\mathcal{W}_\infty$. von Neumann proved[1] that the irreducible representations of $\mathcal{W}_\infty$ are unitarily equivalent. Hence, they are equivalent to the representation given in Eqs. (2) and (3) (Schrödinger representation) which is easily seen to be irreducible.

In this paper we prove a similar result when the spectrum $\sigma(q)$ of q is bounded from below: $\sigma(q) \subset \{x : x \geqslant x_0\}$. This occurs, for example, when the Hilbert space $\mathcal{H}$ of the system is $L^2(0,\infty)$. While the self-adjoint operator q generates a group $V(\beta)$ of unitary operators, the momentum operator $p = -i\partial/\partial x$ does not possess self-adjoint extensions.[2,3] Only the right translations $U(\alpha)$ are isometric operators and constitute a continuous semigroup: Eq. (4) only holds for $\alpha_1, \alpha_2 \geqslant 0$, while Eqs. (5) and (7) still hold. Left translations are represented by the operators $U^\dagger(\alpha), \alpha \geqslant 0$, which do not conserve the norm of vectors. The $\{U^\dagger(\alpha)\}$ operators are properly a semigroup of contractions ($\|U^\dagger(\alpha)x\| \leqslant \|x\|$).

The relation of $U(\alpha)$ with its adjoint $U^\dagger(\alpha)$ is

$$U^\dagger(\alpha)U(\alpha) = I, \quad U(\alpha)U^\dagger(\alpha) = E_\alpha, \tag{8}$$

where E_α is the projection onto $\mathcal{H}_\alpha = U(\alpha)\mathcal{H}$. The algebra $\mathcal{W}_\infty$ is replaced by the algebra $\mathcal{W}_+$ generated by the positive translations, their adjoints and the unitary operators $V(\beta)$. The multiplication law between $U^\dagger(\alpha)$ and $V(\beta)$ is found by taking the adjoint of Eq. (7),

$$U^\dagger(\alpha)V(\beta) = \exp(-i\alpha\beta)V(\beta)U^\dagger(\alpha). \tag{9}$$

We will prove that, given an irreducible representation of the algebra $\mathcal{W}_+$, either all the operators $U(\alpha)$ are unitary, $\mathcal{H}_\alpha = \mathcal{H}$ and $E_\alpha = I$ for any α and $\mathcal{W}_+$ can be extended to the Weyl algebra $\mathcal{W}_\infty$ by defining $U(\alpha) = U^\dagger(-\alpha)$ for $\alpha \leqslant 0$, or the spectrum of the generator q of the group $\{V(\beta)\}$ is a half line $\{x : x \geqslant x_0\}$. In this latter case the irreducible representations of $\mathcal{W}_+$ with the same lower bound for the spectrum $\sigma(q)$ are proved to be unitarily equivalent. As a consequence the Schrödinger representation of $\mathcal{W}_+$ in $L^2(x_0,\infty)$,

$$U(\alpha)f = f(x-\alpha)\theta(x-\alpha), \quad V(\beta)f = \exp(-i\beta x)f(x), \tag{10}$$

which is irreducible (see below) is essentially unique.

Our approach is based on the construction, in Sec. IV, of a Hilbert space $\mathcal{K}$ where a Weyl algebra $\mathcal{W}_\infty = \{U_\mathcal{K}(\alpha), V_\mathcal{K}(\beta), \alpha, \beta \in \mathbb{R}\}$ is defined starting from the algebra $\mathcal{W}_+$ defined in $\mathcal{H}$. $\mathcal{K}$ can be seen as a direct sum $\mathcal{H} \oplus \mathcal{H}$, and the algebra $\mathcal{W}_+$ is recovered from $\mathcal{W}_\infty$ by projecting onto $\mathcal{H}$. For example, if $\mathcal{H} = L^2(0,\infty)$, then $\mathcal{K} = L^2(-\infty,\infty)$.

The representation of $\mathcal{W}_\infty$ in $\mathcal{K}$ is proved to be irreducible if the representation of $\mathcal{W}_+$ in $\mathcal{H}$ is irreducible, and equivalent representations of $\mathcal{W}_\infty$ give rise to equivalent representations of $\mathcal{W}_+$. We will rely on the property of irreducible representations of *algebras that the only bounded operators commuting with the operators of the *algebra are multiples of the identity operator.[3]

In this framework, whereas the definition of the group $V_\mathcal{K}(\beta)$ is immediate by a simple doubling of the group $V(\beta)$, the passage from a semigroup $U(\alpha)$ to a unitary group $U_\mathcal{K}(\alpha)$, such that the Weyl condition, Eq. (7), is satisfied depends on the existence of a family $\{R(\alpha), \alpha \geqslant 0\}$ of operators which fulfill conditions, given in detail in Sec. V, implying that the $U_\mathcal{K}(\alpha)$'s are a group and that with the $V_\mathcal{K}(\beta)$'s they obey Eq. (7).

The passage from a semigroup of isometries to a group of unitary operators in a larger space is not new. Cooper[4] first showed that a Hilbert space $\mathcal{H}$ where a semigroup of isometries is defined can be imbedded in a space $\mathcal{K}$ where a group of unitary operators exists whose components in the original space are the semigroup of isometries. His work relies on the use of the generator of the

semigroup and the definition of a homeomorphic and isometric mapping from $L^2(0,\infty)$ to $\mathcal{H}$. Instead, our approach is global in that we use the operators $U(\alpha)$, $V(\beta)$ directly, and show that the construction of $\mathcal{W}_\infty$ is reduced to the proof that a single operator $R(\alpha_0)$ exists, subject to appropriate conditions. This operator is shown to exist in Sec. VI, where we also give an explicit expression for it.

Later, building on an inspiring work by Sz.-Nagy,[5,6] who proved that any continuous one-parameter semigroup of contractions $\{T(\sigma),\sigma\geqslant 0\}$ in $\mathcal{H}$ can be dilated into a continuous unitary group in a space $\mathcal{K}\supset\mathcal{H}$, Foiaş and Gehér[7] showed that two continuous semigroups of contractions $\{U(\alpha),V(\beta),\alpha,\beta\geqslant 0\}$ obeying Eq. (7) can be simultaneously dilated into two continuous groups of unitary operators satisfying the Weyl condition for any $\alpha,\beta\in\mathbb{R}$ (see also Ref. 8, where the proof is somewhat simplified). The construction of Sz.-Nagy relies on a theorem on positive definite operator valued functions on a group, and Foiaş and Gehér show that the procedure of Sz.-Nagy can be iterated for any two semigroups of contractions $\{U(\alpha),V(\beta),\alpha,\beta\geqslant 0\}$ satisfying the Weyl form of the commutation relations in such a way that Eq. (7) still holds. Though Sz.-Nagy's technique is very elegant, we believe our construction of $\mathcal{K}$ and of the unitary group $\{U_{\mathcal{K}}(\alpha)\}$ is more intuitive and nearer to the physicists' approach to the problem.

Concerning the irreducible representations of $\mathcal{W}_+$, Cooper does not address the problem of the representation of this algebra, while Foiaş and Gehér do not consider the problem of the irreducible representations of $\mathcal{W}_+$. Although a lot of work has been made about the Heisenberg commutation relations (see Ref. 9, for example, and Ref. 10, where representations of the commutation relations intermediate between Heisenberg's and Weyl's are explored), as far as we know the proof presented in the paper is the first proof that all the irreducible representations of the algebra $\mathcal{W}_+$ with the same lower bound for the spectrum of q are unitarily equivalent. This is the ultimate reason why the use of the Schrödinger representation for systems with semibounded configuration space is not arbitrary.[14]

As a by-product of the aforementioned result, in Secs. VIII and IX we will also consider the representations of the algebra $\mathcal{W}_1$ generated by a semigroup of partial isometries $\{U(\alpha)\}$, $U(1)=0$, their adjoints and the operators $V(\beta)$, which obey the composition law Eq. (7). We will associate to a representation of $\mathcal{W}_1$ in a Hilbert space $\mathcal{H}_1$ a representation of $\mathcal{W}_+$ in a Hilbert space $\mathcal{H}\equiv\oplus_{n=1}^{\infty}\mathcal{H}_n,\mathcal{H}_n=\mathcal{H}_1$, and will derive the uniqueness of the irreducible representations of $\mathcal{W}_1$ from that of the irreducible representations of $\mathcal{W}_+$.

We aimed at writing a self-contained paper. This is why we did not refrain from giving space to some preliminary details and from writing expanded versions of the proofs of our statements in Secs. V and VI.

II. GENERAL PROPERTIES

Let $\mathcal{H}$ be a Hilbert space, $\{V(\beta),\beta\in\mathbb{R}\}$ a strongly continuous group of unitary operators, $\{U(\alpha),\alpha\geqslant 0\}$ a strongly continuous semigroup of isometries which obey the Weyl condition Eq. (7). We assume there is no Hilbert subspace invariant under all of them and the adjoints $U^\dagger(\alpha)$.

The $U(\alpha)$ operators obey $U^\dagger(\alpha)U(\alpha)=I$. The operators $E_\alpha=U(\alpha)U^\dagger(\alpha)$ are orthogonal projections: $E_\alpha^\dagger=E_\alpha=E_\alpha^2$. Hence, the operators $U^\dagger(\alpha)$ are contractions: $\|U^\dagger(\alpha)x\|^2\leqslant\|x\|^2$. The $U^\dagger(\alpha)$'s too are a continuous semigroup. Indeed, the composition law is seen to hold by taking the adjoint of Eq. (4). Moreover, we have

$$0\leqslant\|U^\dagger(\alpha)x-x\|^2\leqslant 2\|x\|^2-(x,U(\alpha)x)-(U(\alpha)x,x),$$

which shows that

$$\lim_{\alpha\to 0}\|U^\dagger(\alpha)x-x\|^2=0.$$

The semigroup condition implies strong continuity of $U^\dagger(\alpha)$ for any α.

The semigroup property fixes the composition law for $U^\dagger(\alpha)$ and $U(\beta)$. We have

$$U^\dagger(\alpha)U(\beta)=U^\dagger(\alpha-\beta),\quad U^\dagger(\beta)U(\alpha)=U(\alpha-\beta)\quad\alpha\geqslant\beta,\tag{11}$$

$$U(\beta)U^{\dagger}(\alpha) = U(\beta-\alpha)E_{\alpha} = E_{\beta}U(\beta-\alpha) \quad \alpha \leqslant \beta, \tag{12}$$

$$U(\alpha)U^{\dagger}(\beta) = E_{\alpha}U^{\dagger}(\beta-\alpha) = U^{\dagger}(\beta-\alpha)E_{\beta} \quad \alpha \leqslant \beta. \tag{13}$$

From the above equations we get

$$E_{\beta}U(\alpha) = U(\alpha) \quad \alpha \geqslant \beta, \tag{14}$$

$$E_{\beta}U(\alpha) = U(\alpha)E_{\beta-\alpha} \quad \alpha < \beta, \tag{15}$$

$$E_{\beta}U^{\dagger}(\alpha) = U^{\dagger}(\alpha)E_{\alpha+\beta}. \tag{16}$$

The projections $\{E_{\alpha}\}$ are strongly continuous:

$$\|E_{\alpha}x - E_{\beta}x\| = \|U(\alpha)[U^{\dagger}(\alpha) - U^{\dagger}(\beta)]x + [U(\alpha) - U(\beta)]U^{\dagger}(\beta)x\| \leqslant \|[U^{\dagger}(\alpha) - U^{\dagger}(\beta)]x\| + \|[U(\alpha) - U(\beta)]U^{\dagger}(\beta)x\| \overset{\alpha\to\beta}{\to} 0.$$

For the projections $\{E_{\alpha}\}$ we have

$$E_{\alpha}E_{\alpha+\beta} = E_{\alpha+\beta} = E_{\alpha+\beta}E_{\alpha} \quad \beta \geqslant 0, \tag{17}$$

since $E_{\alpha}E_{\alpha+\beta}=U(\alpha)[U^{\dagger}(\alpha)U(\alpha)]U(\beta)U^{\dagger}(\alpha+\beta)=E_{\alpha+\beta}$. Taking the adjoint one gets the latter of Eqs. (17). Hence, $E_{\alpha}-E_{\beta}, \beta \geqslant \alpha$, is a projection. Also, since $U(\alpha)E_{\beta}=E_{\alpha+\beta}U(\alpha)$, from Eqs. (16) and (17) we get

$$U(\alpha)E_{\beta}U^{\dagger}(\alpha) = E_{\alpha+\beta}, \tag{18}$$

$$U^{\dagger}(\alpha)E_{\beta}U(\alpha) = E_{\beta-\alpha} \quad \beta \geqslant \alpha. \tag{19}$$

The projections E_{α} either are constant, $E_{\alpha}=I \ \forall \alpha \geqslant 0$, or are a strictly decreasing family of operators. Indeed, if $E_{\alpha}=E_{\alpha+\gamma}$ and $0<\beta\leqslant\gamma$ we have

$$E_{\alpha} - E_{\alpha+\beta} = -[E_{\alpha+\beta} - E_{\alpha+\gamma}].$$

Since both $E_{\alpha}-E_{\alpha+\beta}$ and $E_{\alpha+\beta}-E_{\alpha+\gamma}$ are positive operators, we find $E_{\alpha+\beta}=E_{\alpha}, \beta\leqslant\gamma$. Equations (18) and (19) then imply that E_{α} is periodic with any period $\beta\leqslant\gamma$, so $E_{\alpha}=I\forall\alpha$. In this case the operators $U(\alpha)$ are unitary, the semigroup can be extended to a group by the obvious definition $U(\alpha)=U^{\dagger}(-\alpha)$ for $\alpha<0$ and we retrieve the Weyl algebra $\mathcal{W}_{\infty}$ which is the object of von Neumann's theorem. The case of interest to us is when the E_{α}'s are strictly decreasing and the operators $U^{\dagger}(\alpha)$ are genuine contractions.

In this latter case, the decreasing sequence of positive operators E_{α} has a strong limit E_{∞}, which is the projection onto the closed subspace $\mathcal{H}_{\infty}=\cap_{\alpha}\mathcal{H}_{\alpha}$. Indeed

$$E_{\alpha}E_{\infty}x = \lim_{\beta\to+\infty} E_{\alpha}E_{\beta}x = \lim_{\beta\to+\infty} E_{\beta}x = E_{\infty}x.$$

Because of Eq. (15), E_{∞} commutes with $U(\alpha)$, and, being self-adjoint, with $U^{\dagger}(\alpha)$. In addition, Eqs. (7) and (9) imply that $V(\beta)$ and E_{α} commute

$$[V(\beta), E_{\alpha}] = 0 \tag{20}$$

and consequently E_{∞} commutes with $V(\beta)$. In conclusion, since $\mathcal{H}_{\infty}$ is invariant under the operators $U(\alpha), U^{\dagger}(\alpha), V(\beta)$, in an irreducible representation of $\mathcal{W}_{+}$ for which $E_{\alpha}\neq I$ for $\alpha\neq 0$ we must have $\mathcal{H}_{\infty}=\{0\}$. In this case $\lim_{\alpha\to+\infty}E_{\alpha}x=0$ and the projections $\{P_{\alpha}\}=\{I-E_{\alpha}\}$ are a resolution of the identity, as can be verified taking into account the properties of the E_{α}'s. In the following we will only consider the case $\mathcal{H}_{\infty}=\{0\}$.

III. THE SPECTRAL RESOLUTION OF q

In this section we prove that, if $\mathcal{H}$ hosts an irreducible representation of the algebra $\mathcal{W}_+$, then the spectrum $\sigma(q)$ of the generator q of the group $\{V(\beta), \beta \in \mathbb{R}\}$ is $[x_0, \infty)$. To this purpose, we compare the operators $V(\beta)$ with the operators $V'(\beta)=\int_0^\infty \exp(-i\beta\gamma)dP_\gamma$. According to Stone's theorem[3] these latter operators constitute a group of unitary operators, due to the properties of the spectral family $\{P_\alpha\}$. $V(-\beta)V'(\beta)$ commutes with the operators $V(\alpha)$ (see Eq. (20)) as well as with the operators $U(\alpha)$ and $U^\dagger(\alpha)$. Indeed, we have

$$U(\alpha)V(-\beta)V'(\beta) = \exp(-i\alpha\beta)V(-\beta)U(\alpha)V'(\beta) = V(-\beta)\exp(-i\alpha\beta)\int_0^\infty \exp(-i\beta\gamma)dP_{\alpha+\gamma}U(\alpha)$$

$$= V(-\beta)\int_\alpha^\infty \exp(-i\beta\gamma)dP_\gamma U(\alpha) = V(-\beta)V'(\beta)U(\alpha),$$

where we used Eqs. (14) and (15). Similarly, $V(-\beta)V'(\beta)$ commutes with $U^\dagger(\alpha)$. Since the representation of $\mathcal{W}_+$ is irreducible, we have $V'(\beta)=V(\beta)f(\beta)$. Since both $V(\beta)$ and $V'(\beta)$ are groups of unitary operators we must have $f(\beta)=\exp(ix_0\beta)$. Hence,

$$V(\beta) = \exp(-ix_0\beta)\int_0^\infty \exp(-i\beta\gamma)dP_\gamma = \int_{x_0}^\infty \exp(-i\beta\gamma)dP_{\gamma-x_0}, \tag{21}$$

which shows that the generator q has the spectral representation

$$q = \int_0^\infty (x_0+\gamma)dP_\gamma = x_0 I + \int_0^\infty \gamma dP_\gamma = \int_{x_0}^\infty \gamma dF_\gamma \tag{22}$$

with $F_\gamma = P_{\gamma-x_0}$.

The above equation shows that for an irreducible representation of $\mathcal{W}_+$ (with $E_\alpha \neq I$ for any positive α) the situation is completely different from the case of the algebra $\mathcal{W}_\infty$. For $\mathcal{W}_+$ the generator of the group $\{V(\beta)\}$ is expressed in terms of the projections E_α, and the irreducibility of the representation depends only on the irreducibility with respect to the translations $U(\alpha)$ and $U^\dagger(\alpha)$. For an irreducible representation no proper subspace $\mathcal{H}'$ may be invariant with respect to the translations, since this would entail invariance also under the group $\{V(\beta)\}$. Conversely, if $\mathcal{H}$ is irreducible under translations, the group $\{\exp(-i\beta q)\}$, with q given by Eq. (22), together with the translations $U(\alpha)$ and $U^\dagger(\alpha)$, yields an irreducible representation in $\mathcal{H}$ of the algebra $\mathcal{W}_+$. The comparison between the representation of $\mathcal{W}_\infty$ in $\mathcal{H}_1=L^2(-\infty,\infty)$, Eq. (6), and that of $\mathcal{W}_+$ in $\mathcal{H}_2=L^2(x_0,\infty)$ (Eq. (10)) clarifies the situation. In $\mathcal{H}_1$ any subspace

$$\mathcal{H}'_A = \{f\text{: the Fourier transform of } f \text{ has support in a measurable set } A\}$$

is invariant under translations[11] (but not under the operators $V(\beta)$). Conversely, $\mathcal{H}_2$ has no subspace invariant with respect to (right and left) translations. Indeed, should such a subspace $\mathcal{H}'$ exist, given $f \in \mathcal{H}'$, for any γ, δ, and

$$g = [E_\gamma - E_{\gamma+\delta}]f = \chi_{[\gamma,\gamma+\delta]}f,$$

also $g \in \mathcal{H}'$. For any function $h \in \mathcal{H}_2 \ominus \mathcal{H}'$ (also invariant), any interval Δ and any positive α we have $(h, U(\alpha)\chi_\Delta f)=0$. This implies $h=0$ a.e., which means $\mathcal{H}'=\mathcal{H}_2$.

The most useful consequence of Eq. (22) is that we can limit our attention to the case that the generator q of $V(\beta)$ has spectrum $[0,\infty)$. In fact, when $\sigma(q)=[x_0,\infty)$ we can write $q=x_0 I + q_0, q_0=\int_0^\infty dP_\gamma$, with $\sigma(q_0)=[0,\infty)$. The (inequivalent) representations of the algebra $\mathcal{W}_+$ with $V(\beta)=\exp(-i\beta q)$ or $V'(\beta)=\exp(-iq_0\beta)$ are either both reducible or both irreducible, since they are related by the equation $V(\beta)=\exp(-ix_0\beta)V'(\beta)$.

IV. CONSTRUCTION OF $\mathcal{K}$

In this section we start with an irreducible representation of the algebra $\mathcal{W}_+$ in a Hilbert space $\mathcal{H}$, with $V(\beta)=\exp(-i\beta q), q=\int_0^\infty \gamma dP_\gamma$. We show how a Hilbert space $\mathcal{K}$ containing $\mathcal{H}$ can be introduced in such a way that the representation of $\mathcal{W}_+$ in $\mathcal{H}$ induces a representation of $\mathcal{W}_\infty$ in $\mathcal{K}$.

Let $\mathcal{K}$ be the vector space of pairs $\{x,y\}$, $x,y\in\mathcal{H}$, with scalar product $(\{x,y\},\{u,v\})=(x,u)+(y,v)$. $\mathcal{K}$ is a Hilbert space, and $\mathcal{H}$ can be identified with either of the subspaces

$$\mathcal{K}_1=\{\{x,0\}:\ x\in\mathcal{H}\},\quad \mathcal{K}_2=\{\{0,y\}:\ y\in\mathcal{H}\},$$

so that $\mathcal{K}_1=\mathcal{K}\oplus\mathcal{K}_2$ can be seen as the direct sum $\mathcal{H}\oplus\mathcal{H}$.

As hinted in Sec. I, we mimic the obvious procedure by which a representation of $\mathcal{W}_+$ in $\mathcal{H}=L^2(0,\infty)$ yields a representation of the Weyl algebra in $\mathcal{K}=L^2(-\infty,\infty)=\mathcal{H}\oplus\mathcal{H}$ according to the following equations:

$$U_\mathcal{K}(\alpha)\{f,g\}=\{U(\alpha)f+R(\alpha)g,U^\dagger(\alpha)g\}\quad \alpha\geqslant 0, \tag{23a}$$

$$U_\mathcal{K}(\alpha)\{f,g\}=\{U^\dagger(-\alpha)f,U(-\alpha)g+R^\dagger(-\alpha)f\}\quad \alpha\leqslant 0, \tag{23b}$$

$$V_\mathcal{K}(\beta)\{f,g\}=\{V(\beta)f,V(-\beta)g\}, \tag{23c}$$

where the operators $U(\alpha)$, $V(\beta)$ are defined in Eq. (10) and the "cut plus reflection" operator $R(\alpha)$ is defined as

$$R(\alpha)f=\theta(\alpha-x)f(\alpha-x).$$

It is obvious that the above defined operators $U_\mathcal{K}$ and $V_\mathcal{K}$ realize the Schrödinger representation of the Weyl algebra in $L^2(-\infty,\infty)$.

We want to translate Eqs. (23) into similar equations which yield a representation of the Weyl algebra in $\mathcal{K}=\mathcal{H}\oplus\mathcal{H}$ starting from a representation of $\mathcal{W}_+$ in $\mathcal{H}$. In matrix form the operators $U_\mathcal{K}(\alpha)$ and $V_\mathcal{K}(\beta)$ (as in Eqs. (23)) can be written as

$$U_\mathcal{K}(\alpha)=\begin{pmatrix} U(\alpha) & R(\alpha)\\ 0 & U^\dagger(\alpha)\end{pmatrix}\quad \alpha\geqslant 0,\quad U_\mathcal{K}(\alpha)=U^\dagger(-\alpha)\quad \alpha\leqslant 0, \tag{24}$$

$$V_\mathcal{K}(\beta)=\begin{pmatrix} V(\beta) & 0\\ 0 & V(-\beta)\end{pmatrix}. \tag{25}$$

The operators $V_\mathcal{K}(\beta)$ are obviously a continuous group of unitary operators in $\mathcal{K}$. They can be represented in terms of the generator $q_\mathcal{K}=\int_{-\infty}^\infty \alpha dG_\alpha$ as $V_\mathcal{K}(\beta)=\exp(-iq_\mathcal{K}\beta)$, with

$$G_\alpha=\theta(\alpha)(P_\alpha K_1+K_2)+\theta(-\alpha)E_{-\alpha}K_2,\quad G_0=K_2, \tag{26}$$

K_1 and K_2 being the projections onto $\mathcal{K}_1$ and $\mathcal{K}_2$, respectively. On the other hand, in order to ensure the group composition law (Eq. (4)) for the $U_\mathcal{K}(\alpha)$ operators as well as the Weyl composition law (Eq. (7)) we need to define an appropriate operator $R(\alpha)$. Note that we allow for a nonself-adjoint $R(\alpha)$, although the operator $R(\alpha)$ presented above for $L^2(0,\infty)$ is self-adjoint. Actually, $\tilde{R}(\alpha)=\exp(i\theta)R(\alpha)$ would work as well. As a matter of fact, it can be shown that the operator $R(\alpha)$ such that the $U_\mathcal{K}(\alpha)$'s obey the defining Eqs. (4) and (7) is unique up to a constant phase factor.

V. TOWARD THE CONSTRUCTION OF THE OPERATORS $R(\alpha)$

We report the conditions which the operators $R(\alpha)$ have to obey in order that Eq. (4) be satisfied, together with the composition law which forces them. The arguments α,α_i will be meant to be non-negative, with $\alpha_1\leqslant\alpha_2$,

$$U_{\mathcal{K}}(\alpha)U_{\mathcal{K}}(-\alpha)=I\Rightarrow\begin{cases}R(\alpha)R^{\dagger}(\alpha)=P_{\alpha} & (27a)\\ R(\alpha)U(\alpha)=0, & (27b)\end{cases}$$

$$U_{\mathcal{K}}(-\alpha)U_{\mathcal{K}}(\alpha)=I\Rightarrow\begin{cases}R^{\dagger}(\alpha)R(\alpha)=P_{\alpha} & (28a)\\ U^{\dagger}(\alpha)R(\alpha)=0, & (28b)\end{cases}$$

$$U_{\mathcal{K}}(\alpha_1)U_{\mathcal{K}}(\alpha_2)=U_{\mathcal{K}}(\alpha_1+\alpha_2)\Rightarrow U(\alpha_1)R(\alpha_2)+R(\alpha_1)U^{\dagger}(\alpha_2)=R(\alpha_1+\alpha_2), \quad (29)$$

$$U_{\mathcal{K}}(\alpha_2)U_{\mathcal{K}}(\alpha_1)=U_{\mathcal{K}}(\alpha_1+\alpha_2)\Rightarrow U(\alpha_2)R(\alpha_1)+R(\alpha_2)U^{\dagger}(\alpha_1)=R(\alpha_1+\alpha_2), \quad (30)$$

$$U_{\mathcal{K}}(\alpha_2)U_{\mathcal{K}}(-\alpha_1)=U_{\mathcal{K}}(\alpha_2-\alpha_1)\Rightarrow\begin{cases}R(\alpha_2)R^{\dagger}(\alpha_1)=U(\alpha_2-\alpha_1)P_{\alpha_1} & (31a)\\ R(\alpha_2)U(\alpha_1)=R(\alpha_2-\alpha_1) & (31b)\\ U^{\dagger}(\alpha_2)R^{\dagger}(\alpha_1)=0, & (31c)\end{cases}$$

$$U_{\mathcal{K}}(-\alpha_2)U_{\mathcal{K}}(\alpha_1)=U_{\mathcal{K}}(\alpha_1-\alpha_2)\Rightarrow\begin{cases}R^{\dagger}(\alpha_2)R(\alpha_1)=U(\alpha_2-\alpha_1)P_{\alpha_1} & (32a)\\ U^{\dagger}(\alpha_2)R(\alpha_1)=0 & (32b)\\ R^{\dagger}(\alpha_2)U(\alpha_1)=R^{\dagger}(\alpha_2-\alpha_1). & (32c)\end{cases}$$

The relations imposed by the remaining composition laws follow from the above equations.

The equations reported above are not independent. In fact, we have:

Theorem 1: *Eqs. (27a) and (28a) and either of Eqs. (29), (30) imply all the other equations reported above.*

Proof: Assume Eq. (29); nothing changes if Eq. (30) is assumed instead. By multiplying Eq. (27a) by $U^{\dagger}(\alpha)$ and $U(\alpha)$ at left and right, respectively, we find $R^{\dagger}(\alpha)U(\alpha)=0$, which implies Eq. (28b). Similarly, Eq. (27b) is obtained by multiplying Eq. (28a) by $U^{\dagger}(\alpha)$ (left) and $U(\alpha)$ (right). Equations (31c) and (32b) are a consequence. By right multiplying Eq. (29) by $U(\alpha_2)$ we find $R(\alpha_1)=R(\alpha_1+\alpha_2)U(\alpha_2)$, which is equivalent to Eq. (31b). By left multiplying Eq. (29) by $U^{\dagger}(\alpha_1)$ we get $R(\alpha_2)=U^{\dagger}(\alpha_1)R(\alpha_1+\alpha_2)$, which is equivalent to Eq. (32c). Using this equation in the form $R^{\dagger}(\alpha_1)=R^{\dagger}(\alpha_2)U(\alpha_2-\alpha_1)$ we find Eq. (31a). Using Eq. (31b) in the form $R(\alpha_1)=R(\alpha_2)U(\alpha_2-\alpha_1)$ we find Eq. (32a).

To prove Eq. (30) first note that $R(\alpha)=R(\alpha)P_{\alpha}=P_{\alpha}R(\alpha)$ as a consequence of Eqs. (27b) and (28b), respectively. This implies, by Eq. (31a), $R(\alpha_1+\alpha_2)P_{\alpha_1}=U(\alpha_2)R(\alpha_1)$. Hence, by Eq. (31b),

$$\begin{aligned}U(\alpha_2)R(\alpha_1)+R(\alpha_2)U^{\dagger}(\alpha_1)&=U(\alpha_2)R(\alpha_1)+R(\alpha_1+\alpha_2)U(\alpha_1)U^{\dagger}(\alpha_1)\\&=U(\alpha_2)R(\alpha_1)-R(\alpha_1+\alpha_2)P_{\alpha_1}+R(\alpha_1+\alpha_2)=R(\alpha_1+\alpha_2).\end{aligned}$$ □

For later use we prove the following Lemma.

Lemma 1: *If an operator $R(\alpha_0)$ is such that, if $\alpha\leqslant\alpha_0$,*

$$R(\alpha_0)R^{\dagger}(\alpha_0)=P_{\alpha_0}, \quad (33a)$$

$$R^{\dagger}(\alpha_0)R(\alpha_0)=P_{\alpha_0}, \quad (33b)$$

$$R(\alpha_0)U(\alpha)=U^{\dagger}(\alpha)R(\alpha_0), \quad (33c)$$

then

$$R(\alpha_0)U(\alpha_0)=0, \quad (34a)$$

$$R(\alpha_0)P_{\alpha_0} = R(\alpha_0), \tag{34b}$$

$$P_{\alpha_0}R(\alpha_0) = R(\alpha_0), \tag{34c}$$

$$P_{\alpha_0-\alpha}R(\alpha_0) = R(\alpha_0)E_\alpha, \tag{34d}$$

$$R(\alpha_0)P_\alpha = U(\alpha_0-\alpha)R(\alpha_0)U(\alpha_0-\alpha). \tag{34e}$$

Proof: Eq. (34a) follows from:

$$U^\dagger(\alpha_0)R^\dagger(\alpha_0)R(\alpha_0)U(\alpha_0) = U^\dagger(\alpha_0)P_{\alpha_0}U(\alpha_0) = 0.$$

Equations (34b) and (34c) are a consequence. Equation (34d) follows from:

$$\begin{aligned} R(\alpha_0)E_\alpha &= R(\alpha_0)P_{\alpha_0}E_\alpha = [R(\alpha_0)U(\alpha)][U^\dagger(\alpha)R^\dagger(\alpha_0)]R(\alpha_0) = U^\dagger(\alpha)R(\alpha_0)R^\dagger(\alpha_0)U(\alpha)R(\alpha_0) \\ &= U^\dagger(\alpha)P_{\alpha_0}U(\alpha)R(\alpha_0) = P_{\alpha_0-\alpha}R(\alpha_0). \end{aligned}$$

Equation (34e) follows by writing:

$$R(\alpha_0)P_\alpha = E_{\alpha_0-\alpha}R(\alpha_0) = U(\alpha_0-\alpha)[U^\dagger(\alpha_0-\alpha)R(\alpha_0)] = U(\alpha_0-\alpha)R(\alpha_0)U(\alpha_0-\alpha). \quad \square$$

We are now in the position to show that a family of operators $R(\alpha), \alpha \geqslant 0$, exists which satisfy Eqs. (27a), (28a), and (29) (and consequently the rest of the equations required by the group composition laws) provided an operator $R(\alpha_0)$ exists which satisfies the hypotheses of Lemma 1. First we prove this statement, and later we exhibit a suitable (nonunique) operator $R(\alpha_0)$.

The proof is achieved through the following steps.

Theorem 2: *Let $R(\beta)$ satisfy the hypotheses of Lemma 1. For $\alpha \leqslant \beta$ the operators $R(\alpha) \equiv R(\beta)U(\beta-\alpha)$ obey Eqs. (27a) and (28a). Given $\alpha_2 \geqslant \alpha_1 \geqslant 0, \alpha_1+\alpha_2 \leqslant \beta$, Eq. (29) is satisfied.*

Theorem 3: *If $R(\alpha_0)$ satisfies the hypotheses of Lemma 1 and $R(n\alpha_0)$ is defined recursively as follows*:

$$R(n\alpha_0) \equiv U((n-1)\alpha_0)R(\alpha_0) + R((n-1)\alpha_0)U^\dagger(\alpha_0),$$

then also $R(n\alpha_0)$ obeys the hypotheses of Lemma 1. Moreover,

$$R(n\alpha_0) = U(k\alpha_0)R((n-k)\alpha_0) + R(k\alpha_0)U^\dagger((n-k)\alpha_0) \quad k \leqslant (n-1). \tag{35}$$

Theorem 4: *For any $\alpha \geqslant 0$, choose n such that $n\alpha_0 \geqslant \alpha$. The operators $R(\alpha) \equiv R(n\alpha_0)U(n\alpha_0-\alpha)$ are independent of n and satisfy Eqs. (27a), (28a), and (29).*

Proof of Theorem 2:

$$R^\dagger(\alpha)R(\alpha) = U^\dagger(\beta-\alpha)R^\dagger(\beta)R(\beta)U(\beta-\alpha) = U^\dagger(\beta-\alpha)P_\beta U(\beta-\alpha) = P_\alpha.$$

Equation (27a) is proved in a similar way. Equation (29) is verified using Eq. (34d),

$$\begin{aligned} U(\alpha_1)R(\alpha_2) + R(\alpha_1)U^\dagger(\alpha_2) &= U(\alpha_1)U^\dagger(\beta-\alpha_2)R(\beta) + R(\beta)U(\beta-\alpha_1)U^\dagger(\alpha_2) \\ &= E_{\alpha_1}U^\dagger(\beta-\alpha_1-\alpha_2)R(\beta) + R(\beta)E_{\beta-\alpha_1}U(\beta-\alpha_1-\alpha_2) \\ &= [E_{\alpha_1}+P_{\alpha_1}]R(\alpha_1+\alpha_2) = R(\alpha_1+\alpha_2). \quad \square \end{aligned}$$

Proof of Theorem 3: The proof is by induction. If Eqs. (33) hold true up to $k=n$, then by Eq. (34a) we find

$$[U(n\alpha_0)R(\alpha_0)+R(n\alpha_0)U^\dagger(\alpha_0)]^\dagger[U(n\alpha_0)R(\alpha_0)+R(n\alpha_0)U^\dagger(\alpha_0)]=R^\dagger(\alpha_0)R(\alpha_0)$$
$$+U(\alpha_0)R^\dagger(n\alpha_0)R(n\alpha_0)U^\dagger(\alpha_0)=P_{\alpha_0}+P_{(n+1)\alpha_0}E_{\alpha_0}=P_{(n+1)\alpha_0}.$$

In a similar way Eq. (33a) is proved. In order to prove Eq. (35), suppose it is true for $k\leqslant n$. Then

$$R((n+1)\alpha_0)\equiv U(n\alpha_0)R(\alpha_0)+R(n\alpha_0)U^\dagger(\alpha_0)=U(k\alpha_0)U((n-k)\alpha_0)R(\alpha_0)+[U(k\alpha_0)R((n-k)\alpha_0)$$
$$+R(k\alpha_0)U^\dagger((n-k)\alpha_0)]U^\dagger(\alpha_0)=U(k\alpha_0)[U((n-k)\alpha_0)R(\alpha_0)+R((n-k)\alpha_0)U^\dagger(\alpha_0)]$$
$$+R(k\alpha_0)U^\dagger((n-k+1)\alpha_0)=U(k\alpha_0)R((n-k+1)\alpha_0)+R(k\alpha_0)U^\dagger((n-k+1)\alpha_0),$$

which shows that also $R((n+1)\alpha_0)$ can be seen as the result of the composition law Eq. (35) if this is true for $k\leqslant n$.

We now prove Eq. (33c) for $R(n\alpha_0)$. For a $\alpha\geqslant\alpha_0$ we have

$$R(n\alpha_0)U(\alpha)=[U((n-1)\alpha_0)R(\alpha_0)+R((n-1)\alpha_0)U^\dagger(\alpha_0)]U(\alpha)=R((n-1)\alpha_0)U(\alpha-\alpha_0)$$
$$=U^\dagger(\alpha-\alpha_0)R((n-1)\alpha_0)=U^\dagger(\alpha)[U(\alpha_0)R((n-1)\alpha_0)+R(\alpha_0)U^\dagger((n-1)\alpha_0)]$$
$$=U^\dagger(\alpha)R(n\alpha_0),$$

where we used the just proved independence of $R(n\alpha_0)$ on the way it is composed, and the inductive hypothesis that Eqs. (33) are satisfied up to $k=n-1$. For $\alpha<\alpha_0$, writing $R(n\alpha_0)=U((n-1)\alpha_0)R(\alpha_0)+R((n-1)\alpha_0)U^\dagger(\alpha_0)$ we find

$$D\equiv U^\dagger(\alpha)R(n\alpha_0)-R(n\alpha_0)U(\alpha)=U((n-1)\alpha_0-\alpha)R(\alpha_0)+R((n-1)\alpha_0)U(\alpha)U^\dagger(\alpha_0)$$
$$-U((n-1)\alpha_0)U^\dagger(\alpha)R(\alpha_0)-R((n-1)\alpha_0)U^\dagger(\alpha_0-\alpha)=U((n-1)\alpha_0-\alpha)P_\alpha R(\alpha_0)$$
$$-R((n-1)\alpha_0)P_\alpha U^\dagger(\alpha_0-\alpha).$$

Using Eq. (34e) for $R((n-1)\alpha_0)P_\alpha$, D can be written as

$$D=U((n-1)\alpha_0-\alpha)[P_\alpha R(\alpha_0)-R(\alpha_0)E_{\alpha_0-\alpha}]=0$$

since the term in bracket vanishes by Eq. (34d). □

Proof of Theorem 4: Taking into account Eq. (34a) we have

$$R((n+1)\alpha_0)U((n+1)\alpha_0-\alpha)=[U(n\alpha_0)R(\alpha_0)+R(n\alpha_0)U^\dagger(\alpha_0)]U((n+1)\alpha_0-\alpha)$$
$$=R(n\alpha_0)U(n\alpha_0-\alpha).$$

Thus the operators $R(\alpha)$ are uniquely defined, due to Theorem 3. Due to Lemma 1 and Theorem 2 they obey Eqs. (27a), (28a), and (29). □

We stress the gist of our argument to prove the existence of a family $\{R(\alpha),\alpha\geqslant 0\}$ such that all the Eqs. from (27) to (32) are satisfied: it suffices to exhibit an operator which satisfies the hypotheses of Lemma 1 for a definite value, say 2π, to conclude that the operators $R(\alpha)$ constructed according to Theorem 4 are uniquely defined and, by Theorem 2, satisfy Eqs. (27a), (28a), and (29). By Theorem 1, all the Eqs. from (27) to (32) are then satisfied, and consequently the group composition laws for the operators $U_{\mathcal{K}}(\alpha)$ are satisfied.

We note that in the language of Ref. 6 the operators $U_{\mathcal{K}}(\alpha)$ are a minimal dilation of $U(\alpha)$. Indeed, $\forall x\in\mathcal{H}=K_1\mathcal{K}$, $U(\alpha)x=K_1U_{\mathcal{K}}(\alpha)x$, and the vectors $U_{\mathcal{K}}(\alpha)x$, $\alpha\in\mathbb{R}$, $x\in K_1\mathcal{K}$, span the whole space $\mathcal{K}$. In fact, for any $\alpha=-\beta\leqslant 0$, $K_2U_{\mathcal{K}}(\alpha)x=R^\dagger(\beta)x$. Since $P_\beta=R^\dagger(\beta)R(\beta)$ we see that the vectors $R^\dagger(\beta)x$ are dense in $\mathcal{H}$, hence, $\{K_2U_{\mathcal{K}}(\alpha)x\}$ is dense in $K_2\mathcal{K}$. Our construction, however, is completely different from that of Ref. 6, and much more direct.

Now we consider the conditions imposed to the operators $R(\alpha)$ by the requirement that Eq. (7) holds for $U_{\mathcal{K}}(\alpha),V_{\mathcal{K}}(\beta)$. These conditions are

$$R(\alpha)V(-\beta)U(\alpha)=0, \tag{36a}$$

$$R(\alpha)V(-\beta)R^{\dagger}(\alpha) = \exp(i\alpha\beta)V(\beta)P_{\alpha}. \tag{36b}$$

They are equivalent to the single equation

$$V(-\beta)R(\alpha)V(-\beta) = \exp(i\alpha\beta)R(\alpha). \tag{37}$$

Indeed, by multiplying Eq. (36b) by $V(-\beta)$ (left) and by $R(\alpha)$ (right) we have Eq. (37), which can be transformed back into Eq. (36b) by multiplication by $V(\beta)$ (left) and $R^{\dagger}(\alpha)$ (right). Equation (36a) is obtained from Eq. (37) by multiplying by $V(\beta)$ (left) and by $U(\alpha)$ (right). It is useful to note that Eq. (37) holds for any α provided it holds for $R(\alpha_0)$. Indeed, we have:

Theorem 5: *If an operator $R(\alpha_0)$ obeys Eq. (37), then $\forall \alpha \geqslant 0$ the operators $R(\alpha)$ constructed according to Theorem 4 obey Eq. (37).*

Proof: By induction, using Eqs. (7) and (9), we check that $R(n\alpha_0)$ defined in Theorem 3 obeys Eq. (37). Likewise, the operators $R(\alpha) \equiv R(n\alpha_0)U(n\alpha_0 - \alpha)$ verify Eq. (37). □

VI. CONSTRUCTION OF THE OPERATOR $R(2\pi)$

Here again we mimic the situation which occurs in $\mathcal{H}=L^2(0,\infty)$. There in the basis $e_n = \exp(inx)/\sqrt{2\pi}$ of $L^2(0,2\pi)=P_{2\pi}\mathcal{H}=\oplus\mathcal{H}_n$, with $\mathcal{H}_n$ the subspaces generated by the vectors e_n, we have $R(2\pi)e_n=e_{-n}$. The subspaces $\mathcal{H}$ are connected to $\mathcal{H}_0$ by the equation

$$V(n)Q_0 = Q_n V(n), \tag{38}$$

where the Q_n's are the projections onto the subspaces $\mathcal{H}_n$.

In order to introduce a similar definition for $R(2\pi)$, first note that $R(2\pi)=R(2\pi)P_{2\pi}$ needs to be defined only in $\mathcal{H}_{2\pi}=P_{2\pi}\mathcal{H}$. Next, we resort to a well known lemma to Stone's theorem[12] which states that, given a strongly continuous one-parameter periodic group of unitary operators $\widetilde{U}(\alpha)$, $\widetilde{U}(\alpha)=\widetilde{U}(\alpha+2\pi)$, $\widetilde{U}(0)=I$, then the operators

$$Q_n = \int_0^{2\pi} \exp(-in\alpha)\widetilde{U}(\alpha)\frac{d\alpha}{2\pi} \tag{39}$$

are orthogonal projections such that $\Sigma_{-\infty}^{\infty} Q_n = I$. The inverse of Eq. (39) is

$$\widetilde{U}(\alpha) = \sum_{-\infty}^{\infty} Q_n \exp(in\alpha). \tag{40}$$

The operators

$$\widetilde{U}(\alpha) = U(\alpha)P_{2\pi-\alpha} + P_{\alpha}U^{\dagger}(2\pi-\alpha) \quad 0 \leqslant \alpha \leqslant 2\pi \quad \widetilde{U}(\alpha+2n\pi) = \widetilde{U}(\alpha) \tag{41}$$

verify the hypotheses of the lemma. By Eq. (7) they satisfy

$$V(n)\widetilde{U}(\alpha) = \exp(-in\alpha)\widetilde{U}(\alpha)V(n) \tag{42}$$

and by Eq. (15),

$$E(\alpha)\widetilde{U}(\alpha) = P_{2\pi}U(\alpha) \quad \alpha \leqslant 2\pi. \tag{43}$$

By integrating Eq. (42) over $[0,2\pi]$ we get Eq. (38), which implies that $V(n)$ is an invertible isometry from $\mathcal{H}_0=Q_0\mathcal{H}_{2\pi}=Q_0\mathcal{H}$ to $\mathcal{H}_n=Q_n\mathcal{H}_{2\pi}=Q_n\mathcal{H}$.

We define an operator $R(2\pi)$ in each $\mathcal{H}_n$ in the following way: if $x_n=V(n)x_0, x_0 \in \mathcal{H}_0$,

$$R(2\pi)x_n = R(2\pi)V(n)x_0 = V(-n)x_0. \tag{44}$$

$R(2\pi)$ satisfies the hypotheses of Lemma 1 and Eq. (37).

Equations (33a) and (33b) are obvious, since $R(2\pi)$ is self-adjoint and $R^2(2\pi)=P_{2\pi}$. To verify Eq. (33c) note that Eq. (44) is equivalent to

$$R(2\pi)V(n) = V(-n)R(2\pi), \tag{45a}$$

$$R(2\pi)Q_0 = Q_0 = Q_0R(2\pi). \tag{45b}$$

As a consequence, by Eq. (38) we get

$$R(2\pi)Q_n = Q_{-n}R(2\pi) \tag{46}$$

and by Eqs. (40) and (46),

$$R(2\pi)\widetilde{U}(\alpha) = \widetilde{U}^\dagger(\alpha)R(2\pi). \tag{47}$$

Hence, using Eq. (43), for $\alpha \leqslant 2\pi$ we have

$$\begin{aligned} R(2\pi)U(\alpha) &= R(2\pi)P_{2\pi}U(\alpha) = R(2\pi)E_\alpha\widetilde{U}(\alpha) = P_{2\pi-\alpha}R(2\pi)\widetilde{U}(\alpha) = P_{2\pi-\alpha}\widetilde{U}^\dagger(\alpha)R(2\pi) \\ &= U^\dagger(\alpha)P_{2\pi}R(2\pi) = U^\dagger(\alpha)R(2\pi), \end{aligned}$$

which proves Eq. (33c). The hypotheses of Lemma 1 are satisfied.

Finally, we prove that $R(2\pi)$ obeys Eq. (37). By Eqs. (34b), (34d) we have

$$\begin{aligned} R(2\pi)V(-\beta) &= R(2\pi)\int_0^\infty \exp(i\beta\lambda)dP_\lambda = \int_0^{2\pi} \exp(i\beta\lambda)d(R(2\pi)P_\lambda) = \int_0^{2\pi} \exp(i\beta\lambda)dE_{2\pi-\lambda}R(2\pi) \\ &= \int_0^{2\pi} \exp(i\beta(2\pi-\lambda))dP_\lambda R(2\pi) = \exp(2\pi i\beta)\int_0^\infty \exp(-i\beta\lambda)dP_\lambda R(2\pi) \\ &= \exp(2\pi i\beta)V(\beta)R(2\pi), \end{aligned}$$

which is equivalent to Eq. (37).

In conclusion, the operators $R(\alpha)$ constructed according to the procedure outlined in the previous section, starting from the operator $R(2\pi)$ defined in Eq. (44), obey equations from Eqs. (27) to (32) and (37). In this way we construct a representation of the Weyl algebra in the space $\mathcal{K}$ starting from a representation of $\mathcal{W}_+$ in the space $\mathcal{H}$.

We wish to stress that an explicit expression of the operators $R(\alpha)$ can be given in terms of P_λ, $U(\alpha)$, $U^\dagger(\alpha)$. Let

$$\widetilde{R}(\alpha) = \int_0^{\alpha/2} U(\alpha-2\lambda)dP_\lambda + \int_{\alpha/2}^{\alpha} U^\dagger(2\lambda-\alpha)dP_\lambda. \tag{48}$$

The (strong) convergence of the above integrals can be proved along the lines of Ref. 4. The $\widetilde{R}(\alpha)$'s are self-adjoint and their role as cut plus reflection operators is apparent when viewed in $L^2(0,\infty)$. We show that they satisfy Eqs. (27a), (28a), (29), and (37).

To this purpose, note the following identity:

$$P_\mu dP_\lambda = \theta(\mu-\lambda)dP_\lambda, \tag{49}$$

which implies

$$\widetilde{R}(\alpha)\widetilde{R}^{\dagger}(\alpha)=\widetilde{R}^{\dagger}(\alpha)\widetilde{R}(\alpha)$$
$$=\int_0^{\alpha/2}U(\alpha-2\lambda)dP_\lambda\int_0^{\alpha/2}dP_\mu U^{\dagger}(\alpha-2\mu)+\int_{\alpha/2}^{\alpha}U^{\dagger}(2\lambda-\alpha)dP_\lambda\int_{\alpha/2}^{\alpha}dP_\mu U(2\mu-\alpha)$$
$$=\int_0^{\alpha/2}U(\alpha-2\lambda)dP_\lambda U^{\dagger}(\alpha-2\lambda)+\int_{\alpha/2}^{\alpha}U^{\dagger}(2\lambda-\alpha)dP_\lambda U(2\lambda-\alpha).$$

By Eqs. (15) and (16), noting that $P_{\alpha-2\lambda}\,dP_{\alpha-\lambda}=0$ due to Eq. (49), we find

$$\widetilde{R}(\alpha)\widetilde{R}^{\dagger}(\alpha)=\int_0^{\alpha/2}E_{\alpha-2\lambda}dP_{\alpha-\lambda}+\int_{\alpha/2}^{\alpha}dP_{\alpha-\lambda}=P_\alpha.$$

As for Eq. (29), by recalling Eqs. (11)–(13) and (16) we have ($\alpha\leqslant\beta$):

$$U(\alpha)\widetilde{R}(\beta)+\widetilde{R}(\alpha)U^{\dagger}(\beta)=\int_0^{\beta/2}U(\alpha+\beta-2\lambda)dP_\lambda+\int_{\beta/2}^{(\alpha+\beta)/2}U(\alpha+\beta-2\lambda)E_{2\lambda-\beta}dP_\lambda$$
$$+\int_{(\alpha+\beta)/2}^{\beta}U^{\dagger}(2\lambda-\alpha-\beta)E_{2\lambda-\beta}dP_\lambda+\int_0^{\alpha}U^{\dagger}(2\lambda+\beta-\alpha)dP_{\lambda+\beta}.$$

Using Eq. (49) again and passing to a new variable $\sigma=\lambda+\beta$ in the last integral we conclude

$$U(\alpha)\widetilde{R}(\beta)+\widetilde{R}(\alpha)U^{\dagger}(\beta)=\int_0^{(\alpha+\beta)/2}U(\alpha+\beta-2\lambda)dP_\lambda+\int_{(\alpha+\beta)/2}^{\beta}U^{\dagger}(2\lambda-\alpha-\beta)dP_\lambda=\widetilde{R}(\alpha+\beta).$$

We prove Eq. (37) in the form $V(\beta)\widetilde{R}(\alpha)=\exp(-i\alpha\beta)\widetilde{R}(\alpha)V(-\beta)$. We note that, as a consequence of Eq. (49),

$$V(\beta)dP_\lambda=\int_0^{\infty}\exp(-i\beta\mu)dP_\mu dP_\lambda=\exp(-i\beta\lambda)dP_\lambda. \tag{50}$$

By Eqs. (7) and (9)

$$V(\beta)\widetilde{R}(\alpha)=\exp(-i\alpha\beta)\left\{\int_0^{\alpha/2}U(\alpha-2\lambda)\exp(2i\beta\lambda)dP_\lambda+\int_{\alpha/2}^{\alpha}U^{\dagger}(2\lambda-\alpha)\exp(2i\beta\lambda)dP_\lambda\right\}V(\beta).$$

Equation (50) implies

$$\exp(2i\beta\lambda)V(\beta)dP_\lambda=\exp(i\beta\lambda)dP_\lambda=V(-\beta)dP_\lambda,$$

which proves that Eq. (37) is satisfied.

VII. RELATION BETWEEN THE REPRESENTATIONS IN $\mathcal{H}$ AND IN $\mathcal{K}$

In this section we prove that:

(a) if the representation of the algebra $\mathcal{W}_+$ in $\mathcal{H}$ is irreducible, then the representation $U_{\mathcal{K}},V_{\mathcal{K}}$ in $\mathcal{K}$ is irreducible too; and
(b) if two representations of $\mathcal{W}_+$ in $\mathcal{H}$ generate equivalent representations of $\mathcal{W}_\infty$ in $\mathcal{K}$, then the representations of $\mathcal{W}_+$ are equivalent.

As a consequence, given two irreducible representations of $\mathcal{W}_+$, by (a) von Neumann's Theorem ensures that the representations of the Weyl algebra are equivalent. Hence, by (b) the representations of $\mathcal{W}_+$ are equivalent. In conclusion, the irreducible representations of $\mathcal{W}_+$ are unique, up to equivalence.

In order to prove (a), let T be a bounded operator in $\mathcal{K}=\mathcal{H}\oplus\mathcal{H}$,

$$T = \begin{pmatrix} A & B \\ C & D \end{pmatrix}, \tag{51}$$

which commutes with the operators $U_{\mathcal{K}}(\alpha), V_{\mathcal{K}}(\beta)$ generated by an irreducible representation of $\mathcal{W}_+$ in $\mathcal{H}$. Since these operators are unitary in $\mathcal{K}$, also the adjoint $T^\dagger$ commutes with them, so we may assume T to be self-adjoint

$$A = A^\dagger, \quad D = D^\dagger, \quad B = C^\dagger. \tag{52}$$

We will prove $T = \lambda I$, which implies that the representation in $\mathcal{K}$ is irreducible.

Commutation of T with $V_{\mathcal{K}}(\beta)$ implies commutation with the projections G_α given in Eq. (26), in particular with G_0. This implies $B = C = 0$ and

$$AV(\beta) = V(\beta)A, \quad DV(\beta) = V(\beta)D. \tag{53}$$

Moreover, for $\alpha \geqslant 0$ we find

$$TU_{\mathcal{K}}(\alpha) = U_{\mathcal{K}}(\alpha)T \Rightarrow \begin{cases} AU(\alpha) = U(\alpha)A & \text{(54a)} \\ DU^\dagger(\alpha) = U^\dagger(\alpha)D & \text{(54b)} \\ AR(\alpha) = R(\alpha)D. & \text{(54c)} \end{cases}$$

Equations (53), (54a), and (54b), together with the irreducibility of the representation of $\mathcal{W}_+$, imply $A = \lambda I, D = \mu I$. Finally, Eq. (54c) implies $\lambda = \mu$, and consequently $T = \lambda I$. The representation in $\mathcal{K}$ is irreducible.

To prove (b), assume we have two equivalent representations of the Weyl algebra in $\mathcal{K}$, $\{V_{\mathcal{K}}^{(1)}, U_{\mathcal{K}}^{(1)}\}$ and $\{V_{\mathcal{K}}^{(2)}, U_{\mathcal{K}}^{(2)}\}$, induced by two representations $\{U_1, V_1\}, \{U_2, V_2\}$ in $\mathcal{H}$. Let S be the unitary operator such that

$$SU_{\mathcal{K}}^{(1)} = U_{\mathcal{K}}^{(2)}S, \quad SV_{\mathcal{K}}^{(1)} = V_{\mathcal{K}}^{(2)}S. \tag{55}$$

We represent S as

$$S = \begin{pmatrix} A & B \\ C & D \end{pmatrix}. \tag{56}$$

The latter of Eqs. (55) implies $SG_\alpha^{(1)} = G_\alpha^{(2)}S$ for any α. In particular, for $\alpha = 0$ we find

$$B = C = 0, \tag{57}$$

which implies

$$AV_1 = V_2A, \quad DV_1^\dagger = V_2^\dagger D \tag{58}$$

and, by the unitarity of S,

$$AA^\dagger = A^\dagger A = DD^\dagger = D^\dagger D = I_{\mathcal{H}}. \tag{59}$$

The former of Eqs. (55) for $\alpha \geqslant 0$ implies $AU_1 = U_2A$, $DU_1^\dagger = U_2^\dagger D$, $AR_1 = R_2D$. Recalling Eqs. (58) and (59) we can conclude

$$U_2 = AU_1A^\dagger, \quad V_2 = AV_1A^\dagger. \tag{60}$$

The representations $\{U_1, V_1\}$ and $\{U_2, V_2\}$ are equivalent.

VIII. THE PARTICLE ON A SEGMENT: THE WEYL ALGEBRA

In this section we define the Weyl algebra appropriate to describe a particle on a segment and in the next section we shall prove also in this case the analogous of the von Neumann Theorem.

The algebra we are looking for differs from the algebra for the half-line $\mathcal{W}_+$ since right translations do not vanish only in an interval, say $0 \leqslant \alpha < 1$, and therefore they are no longer isometries: the isometric condition $U^\dagger(\alpha)U(\alpha)=I$ for the algebra $\mathcal{W}_+$ is now replaced by the assumption that $U^\dagger(\alpha)U(\alpha)$ is a projection. The defining equations of the algebra, that we shall denote by $\mathcal{W}_1$, are

$$U(0)=I; \quad U(\alpha)\neq 0 \quad \text{for} \quad 0 \leqslant \alpha < 1; \quad U(1)=0, \tag{61}$$

$$U(\alpha_1)U(\alpha_2)=U(\alpha_1+\alpha_2), \tag{62}$$

$$P_{1-\alpha} \equiv U^\dagger(\alpha)U(\alpha)=P_{1-\alpha}^2, \tag{63}$$

$$V(\beta_1)V(\beta_2)=V(\beta_1+\beta_2), \quad \beta_1,\beta_2 \in \mathbb{R}, \quad V(0)=I, \tag{64}$$

$$U(\alpha)V(\beta)=\exp(i\alpha\beta)V(\beta)U(\alpha), \tag{65}$$

where the $U(\alpha)$'s and the unitary operators $V(\beta)$ are assumed strongly continuous.

Equations (61)–(63) define what is called a semigroup of partial isometries of index 1; in particular Eq. (63) implies

$$U(\alpha)U^\dagger(\alpha)U(\alpha)=U(\alpha). \tag{66}$$

In fact, $U^\dagger U$ being a projection, for any $v \in \mathcal{H}$, $v=v_1+v_2$ with $U^\dagger U v_1=v_1, U^\dagger U v_2=0$, we have $Uv_2=0$, hence, $UU^\dagger Uv=Uv_1=Uv_1+Uv_2=Uv$. As a consequence $(UU^\dagger)^2=UU^\dagger$, i.e., also $UU^\dagger$ is a projection

$$E_\alpha \equiv U(\alpha)U^\dagger(\alpha)=E_\alpha^2. \tag{67}$$

The projections E_α commute among themselves. If $\alpha_1 \leqslant \alpha_2$, thanks to Eqs. (62) and (66),

$$E_{\alpha_1}E_{\alpha_2}=U(\alpha_1)U^\dagger(\alpha_1)U(\alpha_1)U(\alpha_2-\alpha_1)U^\dagger(\alpha_2)=E_{\alpha_2}=E_{\alpha_2}^\dagger=E_{\alpha_2}E_{\alpha_1}$$

and similarly

$$P_{\alpha_1}P_{\alpha_2}=P_{\alpha_2}P_{\alpha_1}=P_{\alpha_1} \quad (\alpha_1 \leqslant \alpha_2).$$

Moreover, the E_α's commute with the P_β's: since $(E_\alpha P_\beta)^2=E_\alpha P_\beta$ and $\|E_\alpha P_\beta\| \leqslant 1$, $E_\alpha P_\beta$ is a projection, hence, $E_\alpha P_\beta=(E_\alpha P_\beta)^\dagger=P_\beta E_\alpha$.

The algebra $\mathcal{W}_1$ could have been realized as the restriction of the algebra $\mathcal{W}_+$ to the interval $0 \leqslant \alpha \leqslant 1$ by the substitutions $U(\alpha) \to P_1 U(\alpha), V(\beta) \to P_1 V(\beta), P_1$ being the projection defined at the end of Sec. II. In this case, in addition to Eqs. (61)–(66), we have also $E_\alpha+P_\alpha \equiv U(\alpha)U^\dagger(\alpha)+U^\dagger(1-\alpha)U(1-\alpha)=I$. This equation obviously holds for the algebra of truncated shifts in $L^2(0,1)$. It can be proved[13] that, conversely, if the representation of the algebra $\mathcal{U}_1$ generated by $U(\alpha), U^\dagger(\alpha)$ is faithful and irreducible, the equation $E_\alpha+P_\alpha=I$ follows from the defining Eqs. (61)–(63). Thus, with these hypotheses, the algebra $\mathcal{U}_1$ is equivalent to the algebra of truncated shifts in $L^2(0,1)$. For the sake of completeness we outline the proof.

The operator $X(\alpha) \equiv E_\alpha+P_\alpha$ is a projection which obeys the following equations:

$$U(\alpha)X(\beta)=\begin{cases} X(\alpha+\beta)U(\alpha) & \alpha+\beta \leqslant 1 \\ U(\alpha) & \alpha+\beta \geqslant 1, \end{cases} \tag{68}$$

$$X(\alpha)U(\beta)=U(\beta) \quad \text{for} \quad \beta \geqslant \alpha. \tag{69}$$

As a consequence, the operator $Z \equiv \int_0^1 X(\alpha)d\alpha=Z^\dagger$ commutes with the operators $U(\alpha)$, $U^\dagger(\alpha)$ and in an irreducible representation is a multiple of the identity. Actually, $Z=I$ since, if $Z(\lambda)$

$\equiv \int_0^\lambda X(\alpha)d\alpha$, from Eqs. (68) and (69) we have $Z(\lambda)U(\lambda)=\lambda U(\lambda)$. Since $\|U(\lambda)\|\neq 0$ for $\lambda<1$ we find $\|Z(\lambda)\|\geqslant\lambda$. On the other hand, $\|Z(\lambda)\|\leqslant\int_0^\lambda\|X(\alpha)\|d\alpha=\lambda$, hence, $\|Z(\lambda)\|=\lambda$ for $\lambda<1$. Since $\lim_{\lambda\to 1}\|Z(\lambda)-Z(1)\|=0$, we conclude $\|Z(1)\|=1$. Thus $Z=I$, i.e., $\int_0^1(I-X(\alpha))d\alpha=0$. Since $I-X(\alpha)\geqslant 0$ we conclude $X(\alpha)=I$.

In the next section we show that the algebra $\mathcal{W}_1$ can always be considered as the restriction of the algebra $\mathcal{W}_+$ to the interval $0\leqslant\alpha\leqslant 1$.

IX. THE PARTICLE ON A SEGMENT: THE VON NEUMANN THEOREM

By the same arguments of Sec. III it can be shown that in an irreducible representation of $\mathcal{W}_1$ the spectrum $\sigma(q)$ of the generator q of the group $\{V(\beta),\beta\in\mathbb{R}\}$ is a segment $[x_0,x_0+1]$ and that, although representations with different values of x_0 are inequivalent, we can always limit our attention to the case $\sigma(q)=[0,1]$. Moreover, as for the algebra $\mathcal{W}_+$, the irreducibility of $\mathcal{W}_1$ entails the irreducibility of $\mathcal{U}_1$.

Suppose now that $\mathcal{H}_1$ hosts a representation of $\mathcal{W}_1$ and consider the space

$$\mathcal{H}\equiv\bigoplus_{n=1}^{\infty}\mathcal{H}_n,\quad \mathcal{H}_n=\mathcal{H}_1\quad x\in\mathcal{H}=(x_1,x_2,\cdots,x_n,\cdots):\ \sum_n\|x_n\|^2<\infty \tag{70}$$

and in $\mathcal{H}$ define $(0\leqslant\lambda\leqslant 1,\alpha\geqslant 0,\beta\in\mathbb{R})$,

$$U_{\mathcal{H}}(\lambda)x\equiv(U(\lambda)x_1,U^\dagger(1-\lambda)x_1+U(\lambda)x_2,\cdots,U^\dagger(1-\lambda)x_{n-1}+U(\lambda)x_n,\cdots), \tag{71a}$$

$$U_{\mathcal{H}}(n)\equiv[U_{\mathcal{H}}(1)]^n,\ U_{\mathcal{H}}(\alpha=n+\lambda)\equiv U_{\mathcal{H}}(n)U_{\mathcal{H}}(\lambda)=U_{\mathcal{H}}(\lambda)U_{\mathcal{H}}(n), \tag{71b}$$

$$V_{\mathcal{H}}(\beta)x\equiv(V(\beta)x_1,e^{-i\beta}V(\beta)x_2\cdots,e^{-i(n-1)\beta}V(\beta)x_n,\cdots). \tag{71c}$$

Using the properties of the $U(\lambda)$'s, and in particular $X(\lambda)=I$ (which ensures that the $U_{\mathcal{H}}(\alpha)$'s are isometries), it is easy to verify that $\{U_{\mathcal{H}}(\alpha),V_{\mathcal{H}}(\beta)\}$ generate the algebra $\mathcal{W}_+$.

As for the case of the half-line we show that if the representation of the algebra $\mathcal{W}_1$ in $\mathcal{H}_1$ is irreducible, then the representation of $\{U_{\mathcal{H}}(\alpha),V_{\mathcal{H}}\beta\}$ in $\mathcal{H}$ is irreducible too. Let T be a bounded operator in $\mathcal{H}$ commuting with the operators $U_{\mathcal{H}}(\alpha),U_{\mathcal{H}}^\dagger(\alpha)$ (hence with $V_{\mathcal{H}}(\beta)$) and let $T_{n,m}\equiv P_nTP_m$, where P_n is the projection on $\mathcal{H}_n$ $(P_n=U_{\mathcal{H}}(n-1)U_{\mathcal{H}}^\dagger(n-1)-U_{\mathcal{H}}(n)U_{\mathcal{H}}^\dagger(n))$. Since T commutes with the projections P_n, only the "diagonal" elements $T_{n,n}$ are different from zero. Moreover commutation with $U_{\mathcal{H}}(1)$ implies that $T_{n,n}$ is independent of n,

$$U_{\mathcal{H}}(1)Tx=(0,T_{1,1}x_1,T_{2,2}x_2,\cdots)=TU_{\mathcal{H}}(1)x=(0,T_{2,2}x_1,T_{3,3}x_2,\cdots).$$

Now, by imposing commutation with $U_{\mathcal{H}}(\lambda),U_{\mathcal{H}}^\dagger(\lambda)$ $(0\leqslant\lambda\leqslant 1)$, we conclude that $T=\mu I$.

Finally, we prove that all the irreducible representations of $\mathcal{W}_1$ are equivalent. Let $\{U_1(\lambda),V_1(\beta)\},\{U_2(\lambda),V_2(\beta)\}$ be two irreducible representations of $\mathcal{W}_1$ in $\mathcal{H}_1$ and $\{U_{\mathcal{H}}^{(1)}(\alpha),V_{\mathcal{H}}^{(1)}\times(\beta)\},\{U_{\mathcal{H}}^{(2)}(\alpha),V_{\mathcal{H}}^{(2)}(\beta)\}$ the induced irreducible representations of $\mathcal{W}_+$ in $\mathcal{H}$, according to Eqs. (71). Since we have proved that all the irreducible representations of $\mathcal{W}_+$ are equivalent, there exists a unitary operator S such that

$$SU_{\mathcal{H}}^{(1)}(\alpha)=U_{\mathcal{H}}^{(2)}(\alpha)S,\quad SV_{\mathcal{H}}^{(1)}(\beta)=V_{\mathcal{H}}^{(2)}(\beta)S. \tag{72}$$

Since $U_1(0)=U_2(0)=I$, $U_1(1)=U_2(1)=0$, S commutes with the projections P_n and, as before, only the diagonal element $S_n\equiv P_nSP_n$ are different from zero and independent of n. It is straightforward to conclude that $S_1U_1(\lambda)=U_2(\lambda)S_1$, with S_1 unitary in $\mathcal{H}_1$.

published online 7 November 2006)

We calculate the Green's functions for the particle-vortex system, for two anyons on a plane with and without a harmonic regulator and in a uniform magnetic field. These Green's functions which describe scattering or bound states (depending on the specific potential in each case) are obtained exactly using an algebraic method related to the SO(2,1) Lie group. From these Green's functions we obtain the corresponding wave functions and for the bound states we also find the energy spectra. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2363259]

I. INTRODUCTION

In this paper we study exactly solvable problems for one or two particles on a plane bound or not by external potentials by constructing algebraically their Green's functions. These Green's functions describe scattering or bound states, depending on the kind of interaction in each situation. The algebraic method used here is based on the Schwinger representation[1] for the inverse of an operator which is an integral representation involving the exponential of the operator. The operator is identified with the Hamiltonian of the problem which can be written as a linear combination of the generators of a Lie algebra. In particular, we are interested in the so(2,1) Lie algebra which describe some well known problems as the harmonic oscillator, the hydrogen atom, and the Morse potential.[2–16] Some other problems with more involved potentials can also be described by this algebra (see, for instance Refs. 17–32). Once the Hamiltonian is written in terms of the SO(2,1) generators one can use Baker–Campbell–Hausdorff (BCH) formulas[33–35] to split the exponential of the Hamiltonian into a convenient product of the so(2,1) generators. BCH formulas are also used to change the order of the product of the exponentials of generators to simplify the computation of the Green's functions. This method was used to describe the Dirac electron in a Coulomb potential[9] and the discussion presented here is a nonrelativistic version modified to include other potentials.[16,27] As we will see, for the simplest cases the Hamiltonian is identified simply with just one so(2,1) generator. In these particular cases just one BCH formula is used.

The two-dimensional problems we are going to discuss here have been studied before in Refs. 36–48 with other approaches, although for instance, in Ref. 43 the so(2,1) symmetry was invoked to construct the wave function for the particle-vortex system. The problem of particles moving on a plane is relevant to the studies of condensed matter systems as the fractional quantum Hall effect

and anyonic superconductivity,[49–57] supersymmetry,[58,59] and fault-tolerant quantum computing.[60] Free anyon Green's functions have been recently used to study correlation functions of anyon interferometry.[61]

This paper is organized as follows: In Sec. II we discuss the particle-vortex system and its so(2,1) dynamical algebra and in Sec. III we use it to obtain its Green's function algebraically. From this Green's function we obtain the wave functions and find a continuous energy spectrum. In Sec. IV, we discuss the two anyon problem on a plane within a harmonic well and obtain its Green's function using the above mentioned algebraic method related to the SO(2,1) Lie group. From this Green's function we obtain the corresponding wave functions and the discrete energy spectrum. Then, in Sec. V, we obtain the Green's function for the problem of two anyons without any regulator from the results of the previous section. We also show that this problem is equivalent to the particle-vortex system, if one identifies the quantized flux of the particle-vortex with the anyon statistical parameter. Finally, in Sec. VI we obtain exactly the Green's function for two anyons in a uniform magnetic field and the corresponding wave functions and the discrete energy spectrum. In Sec. VII we present our conclusions.

II. THE PARTICLE-VORTEX SYSTEM

Let us start the discussion with the particle-magnetic vortex which is defined to be a two-dimensional system characterized by the Schrödinger equation

$$i\hbar\frac{\partial\Psi}{\partial t}=H\Psi. \tag{1}$$

The Hamiltonian of interest is given by

$$H=\frac{1}{2M}\left(\vec{p}-\frac{e}{c}\vec{A}\right)^2 \tag{2}$$

with an externally prescribed vector potential

$$\vec{A}=\frac{\Phi}{2\pi r^2}\mathbf{e}_3\wedge\vec{r}, \tag{3}$$

where $\mathbf{e}_3$ is a constant unit vector perpendicular to the plane in which $\vec{r}$ lies.

The vector potential gives rise to a magnetic field

$$B=\nabla\wedge\vec{A}=\Phi\delta^2(\vec{r}) \tag{4}$$

with flux $\Phi=\int B(\vec{r})d^2r$.

A simple example is given by the motion of a charged particle around a magnetic flux line when the force motion parallel to the flux line is ignored. If one solves the two-dimensional problem one may apply a boost along the direction of the flux line and get the description of the three-dimensional system. The experimental setup was considered in the Bohm–Aharonov effect.[36]

Clearly, the system is invariant under two-dimensional rotations whose generator is given by the conserved angular momentum

$$J=\vec{r}\wedge\vec{p}, \tag{5}$$

where $\vec{p}$ is the canonical momentum and J generates the O(2) group of rotations in a plane. Also, since H does not have an explicit time dependence it is a constant of motion. In principle we expect to have two more constants of motion. In an interesting paper Jackiw[43] constructed them in explicit form as

$$D = tH - \frac{1}{4}(\vec{r}\cdot\vec{p} + \vec{p}\cdot\vec{r}), \tag{6}$$

$$K = -t^2H + 2tD + \frac{Mr^2}{2}, \tag{7}$$

where the fact that $\vec{r}\cdot\vec{A}=0$ in Eq. (6) was used.

It may be noted that D and K are generators of scale and conformal transformations which change the Lagrangian by a total time derivative. One can verify that

$$[H,D] = -i\hbar H, \tag{8}$$

$$[D,K] = -i\hbar K, \tag{9}$$

$$[K,H] = +2i\hbar D, \tag{10}$$

which are the commutation relations of the generators of the algebra associated with the group SO(2,1).

Since J commutes with H, D, and K the symmetry group of the system is the direct product $\mathrm{SO}(2)\times\mathrm{SO}(2,1)$. In the following we consider the construction of the Green's function for the particle vortex system by making use of the BCH formulas for the exponentials of the generators of the algebra of SO(2,1) group. Since we separate the time variable we only need the form of the generators at $t=0$.

The Green's function associated with the particle-vortex system satisfies the equation

$$\left(i\hbar\frac{\partial}{\partial t} - H\right)G(\vec{r},t;\vec{r}',t') = -\delta(\vec{r}-\vec{r}')\delta(t-t'). \tag{11}$$

Since H is time independent one may write

$$G(\vec{r},t;\vec{r}',t') = \frac{1}{2\pi}\int dE G_E(\vec{r},\vec{r}')e^{-iE(t-t')/\hbar} \tag{12}$$

and get

$$(-H+E)G_E(\vec{r},\vec{r}') = \delta(\vec{r}-\vec{r}'). \tag{13}$$

Then, using the Schwinger[1] representation for the inverse of an operator one can write the Green's function as

$$G_E(\vec{r},\vec{r}') = \frac{i}{\hbar}\int_0^\infty ds e^{i(E-H+i\epsilon)s/\hbar}\delta(\vec{r}-\vec{r}'), \tag{14}$$

where s is usually known as the Schwinger's proper time and $\epsilon>0$ is included to assure the convergence of the above integral. Let us now calculate explicitly this Green's function algebraically.

III. GREEN'S FUNCTION FOR THE PARTICLE-VORTEX SYSTEM

Since H is invariant under rotations we may use the result

$$\delta(\vec{r}-\vec{r}') = \frac{1}{r}\delta(r-r')\delta(\phi-\phi'), \tag{15}$$

where

$$\delta(\phi-\phi')=\frac{1}{2\pi}\sum_m e^{im(\phi-\phi')}, \tag{16}$$

with integer m. Thus if we write

$$G_E(\vec{r},\vec{r}')=\frac{1}{2\pi}\sum_m e^{im(\phi-\phi')}G_{Em}(r,r') \tag{17}$$

then the one-dimensional Green's function is

$$G_{Em}(r,r')=\frac{i}{\hbar r'}\int_0^\infty e^{i(E-H_m)s/\hbar}\delta(r-r')ds, \tag{18}$$

where

$$H_m=-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}-\frac{(m-\nu)^2}{r^2}\right) \tag{19}$$

is the radial Hamiltonian dependent on the integer angular momentum quantum number m and ν is the quantized flux

$$\nu=\frac{e\Phi}{2\pi\hbar c}. \tag{20}$$

In the following we use the set of differential operators given by:

$$T_1=\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}-\frac{(m-\nu)^2}{r^2}, \tag{21}$$

$$T_2=-\frac{i}{2}\left(r\frac{\partial}{\partial r}+1\right), \tag{22}$$

$$T_3=-\frac{1}{8}r^2, \tag{23}$$

which can be easily related to the ones defined in the previous section. These operators satisfy the so(2,1) Lie algebra

$$[T_1,T_2]=-iT_1, \tag{24}$$

$$[T_2,T_3]=-iT_3, \tag{25}$$

$$[T_3,T_1]=+iT_2, \tag{26}$$

as well as the operators H, K, and D. Next we note the following representation for the delta function:

$$\delta(r-r')=\frac{M}{4\pi i r'^{\delta-1}}\int_{-i\infty}^{i\infty} e^{(1/4)qM(r^2-r'^2)}r^\delta dq, \tag{27}$$

where $r, r'\geqslant 0$, and the arbitrary parameter δ will be fixed later. Thus the one-dimensional Green's function can be written as

$$G_{Em}(r,r') = \frac{M}{4\pi\hbar\, r'^{\delta}} \int_0^{\infty} e^{iEs/\hbar} ds \int_{-i\infty}^{i\infty} e^{-(qM/4)r'^2} e^{(is\hbar/2M)T_1} e^{-2MqT_3} r^{\delta} dq. \tag{28}$$

Further, one can show that the following identity holds:

$$e^{(is\hbar/2M)T_1} e^{-2MqT_3} = e^{-i\zeta_3 T_3} e^{-i\zeta_2 T_2} e^{-i\zeta_1 T_1}, \tag{29}$$

where

$$e^{\zeta_2/2} = \frac{s\hbar}{2i}\left(q + \frac{2i}{s\hbar}\right) \tag{30}$$

$$-i\zeta_3 = -2M\left(\frac{2i}{s\hbar} + \frac{4}{(s\hbar)^2\left(q + \frac{2i}{s\hbar}\right)}\right). \tag{31}$$

The proof of the above relations is given, e.g., in Refs. 16 and 27 where ζ_1 is also calculated. Note however that the value of ζ_1 is not needed here since we will choose δ such that

$$T_1 r^{\delta} = 0, \tag{32}$$

which implies

$$\delta = |m - \nu|. \tag{33}$$

In fact the condition (32) also allows $\delta = -|m-\nu|$, but these negative values lead to unphysical solutions as will be seen in the following. Next, it is easy to verify that

$$e^{-ibT_2} f(r) = e^{-b/2} f(re^{-b/2}) \tag{34}$$

so that

$$G_{Em}(r,r') = \frac{Mr^{\delta}}{4\pi\hbar\, r'^{\delta}} \int_0^{\infty} ds \exp\left\{\frac{iEs}{\hbar}\right\} \exp\left\{\frac{iM}{2s\hbar} r^2\right\} \int_{-i\infty}^{i\infty} dq \exp\left\{-\frac{qM}{4} r'^2\right\} \times \exp\left\{\frac{Mr^2}{(s\hbar)^2\left(q + \frac{2i}{s\hbar}\right)}\right\} \left[\frac{s\hbar}{2i}\left(q + \frac{2i}{s\hbar}\right)\right]^{-(1+\delta)}. \tag{35}$$

Expanding the exponential as a power series and doing the integrations by repeatedly using the result

$$\frac{1}{2\pi i} \int_{-i\infty}^{i\infty} dq \frac{\exp\left\{-\frac{qM}{4} r'^2\right\}}{\left(q + \frac{2i}{s\hbar}\right)^{\xi+1}} = \frac{\exp\left\{\frac{iM}{2s\hbar} r'^2\right\} \left(-\frac{M}{4} r'^2\right)^{\xi}}{\Gamma(\xi+1)}, \tag{36}$$

we find that the one-dimensional Green's function can be written as

$$G_{Em}(r,r') = -\frac{M}{\hbar} \int_0^{\infty} \frac{ds}{s} e^{iEs/\hbar} \exp\left\{\frac{iM}{2s\hbar}(r^2 + r'^2)\right\} e^{-(i\pi/2)\delta} J_{\delta}\left(\frac{Mrr'}{s\hbar}\right), \tag{37}$$

where we have used the definition of Bessel functions

$$J_{\delta}(z) = \left(\frac{z}{2}\right)^{\delta} \sum_n \frac{(-z^2/4)^n}{n!\,\Gamma(n+\delta+1)}. \tag{38}$$

Next using the result[62]

$$\int_0^\infty dz e^{-\xi z} J_\delta(2\beta\sqrt{z}) J_\delta(2\gamma\sqrt{z}) = \frac{1}{\xi} e^{-(1/\xi)(\beta^2+\gamma^2)} I_\delta\left(\frac{2\beta\gamma}{\xi}\right) \tag{39}$$

valid for $\Re(\delta) > -1$ and identifying $I_\delta(z) = i^{-\delta} J_\delta(iz)$ we get

$$G_{Em}(r,r') = \int_0^\infty dE' \frac{\mathcal{U}^m_{E'}(r)\mathcal{U}^m_{E'}(r')}{E - E' + i\epsilon}, \tag{40}$$

where

$$\mathcal{U}^m_{E'}(r) = \frac{\sqrt{M}}{\hbar} J_\delta\left(\sqrt{2ME'}\frac{r}{\hbar}\right). \tag{41}$$

Substituting this result into Eq. (17) we get

$$G_E(\vec{r},\vec{r}') = \int_0^\infty dE' \frac{1}{E - E' + i\epsilon} \sum_m \frac{e^{im(\phi-\phi')}}{2\pi} \mathcal{U}^m_{E'}(r)\mathcal{U}^m_{E'}(r'). \tag{42}$$

Note that Eq. (40) is the spectral representation of the one-dimensional Green's function (18), $\mathcal{U}^m_{E'}(r)$ are the corresponding one dimensional wave functions and the energy spectrum is continuous for energy $E > 0$ and angular momentum m, in agreement with Ref. 43. Note that this should be the case since the Hamiltonian (19) corresponds to a particle in a nonconfining potential of a centrifugal barrier $1/r^2$.

It is interesting to note that the above calculation leading to the wave functions (41) is rather different from Jackiw's[43] group theoretical discussion. To trace the main differences first we mention that he considered the operators

$$R = \frac{1}{2}\left(\frac{1}{a}K + aH\right), \tag{43}$$

$$S = \frac{1}{2}\left(\frac{1}{a}K - aH\right), \tag{44}$$

where a is a fixed parameter with time dimensionality. The operators R, S, and D also close the so(2,1) Lie algebra, analogous to Eqs. (8)–(10). Then, he calculated the eigenstates of R. Note that for any fixed time, as for instance $t=0$, the operator

$$R = \frac{1}{2}\left(\frac{1}{a}\frac{Mr^2}{2} + aH\right) \tag{45}$$

has a discrete spectrum because of the presence of the bounding potential r^2. Next, using further group theoretical methods he expressed the continuous eigenstates of H in terms of the eigenstates of R. This procedure can be understood as an infrared cutoff regularization of the continuous eigenstates of H. Our results are in agreement with those present by Jackiw.[43] In the next section we are going to discuss the problem of anyons in a harmonic well which, as we will discuss, can be interpreted as the particle-vortex problem with a harmonic regulator.

Before we move to the next section, let us comment that the Green's function (42) can also be written in terms of associated Laguerre's polynomials $L^\xi_n(x)$. Using the relation

$$J_\xi(2\sqrt{xz}) = e^{-z}(xz)^{\xi/2}\sum_{n=0}^{\infty}\frac{z^n L_n^\xi(x)}{\Gamma(n+\xi+1)} \tag{46}$$

valid for $\xi > -1$. Identifying $x = Mr^2/\hbar$, $z = E/2\hbar$ we get

$$\mathcal{U}_{E'}^m(r) = \frac{\sqrt{M}}{\hbar}e^{-E'/2\hbar}\left(\frac{E'Mr^2}{2\hbar^2}\right)^{\delta/2}\sum_{n=0}^{\infty}\left(\frac{E'}{2\hbar}\right)^n\frac{L_n^\delta\left(\frac{Mr^2}{\hbar}\right)}{\Gamma(n+\delta+1)}, \tag{47}$$

so that

$$G_E(\vec{r},\vec{r}') = \frac{M}{2\pi\hbar}\int_0^\infty \frac{dE'e^{-E'/\hbar}}{E-E'+i\epsilon}\sum_m e^{im(\phi-\phi')}\left(\frac{E'Mrr'}{2\hbar^2}\right)^\delta \times \sum_{n=0}^{\infty}\left(\frac{E'}{2\hbar}\right)^n\frac{L_n^\delta\left(\frac{Mr^2}{\hbar}\right)}{\Gamma(n+\delta+1)}\sum_{\ell=0}^{\infty}\left(\frac{E'}{2\hbar}\right)^\ell\frac{L_\ell^\delta\left(\frac{Mr'^2}{\hbar}\right)}{\Gamma(\ell+\delta+1)}. \tag{48}$$

Further, one can also perform the integration in E' so that this Green's function can be rewritten as

$$G_E(\vec{r},\vec{r}') = -\frac{M}{2\pi\hbar}e^{-E/\hbar}\sum_m e^{im(\phi-\phi')}\left(\frac{Mrr'}{\hbar}\right)^\delta\sum_{n=0}^{\infty}\sum_{\ell=0}^{\infty}L_n^\delta\left(\frac{Mr^2}{\hbar}\right)L_\ell^\delta\left(\frac{Mr'^2}{\hbar}\right) \times (-E)^{n+\ell+\delta}\frac{\Gamma(n+\ell+\delta+1)}{\Gamma(n+\delta+1)\Gamma(\ell+\delta+1)}\Gamma\left(-n-\ell-\delta,-\frac{E}{\hbar}\right), \tag{49}$$

where $\Gamma(a,x)$ is the incomplete gamma function.

IV. TWO ANYONS IN A HARMONIC WELL

Anyons are quasiparticles that obey fractional statistics, i.e., an intermediate statistics between the Bose–Einstein and Fermi–Dirac cases.[37–41] The boson and fermion wave functions differ by the interchange of two or more identical particles. The bosonic wave function is completely symmetric while the fermionic is completely antisymmetric. Then, the two-particle wave functions before and after the interchange of two particles are related by

$$\psi(\vec{r}_2,\vec{r}_1) = e^{i\theta}\psi(\vec{r}_1,\vec{r}_2), \tag{50}$$

where θ determines the statistics of the system. If $\theta = 0$ (modulo 2π) the system obeys Bose–Einstein (BE) statistics and if $\theta = \pi$ (modulo 2π) the system obeys Fermi–Dirac (FD) statistics. In three spatial dimensions these are the only allowed possibilities. However, if the particles are restricted to live in two spatial dimensions θ can assume any real value interpolating the BE and FD statistics.

Considering the path integral formulation of quantum mechanics, the transition amplitude between two states is proportional to $\exp\{iS/\hbar\}$, where S is the classical action. Then, to reproduce the above behavior we consider that a two anyon system (any θ) can be represented by a conventional Lagrangean L plus a topological term[57]

$$L \to L_\theta = L + \frac{\theta}{\pi}\dot{\phi}, \tag{51}$$

where ϕ is the relative angle between $\vec{r}_1$ and $\vec{r}_2$. This way, turning around one particle in respect to the other by an angle $\phi = \pi$ we obtain a phase

$$\exp\left\{\frac{i\theta}{\pi}\int_0^{\pi} d\phi\right\} = \exp\{i\alpha\pi\}, \tag{52}$$

where

$$\alpha = \frac{\theta}{\pi}, \tag{53}$$

is the statistical parameter of the two anyon system.

Here, in this section we consider a two anyon system characterized by the coordinates $\vec{r}_1$ and $\vec{r}_2$ moving on a plane subjected to a harmonic regulator $V(\vec{r}_1,\vec{r}_2)=\frac{1}{2}m_0\omega^2(r_1^2+r_2^2)$, where m_0 is the mass of each anyon. The use of a potential as a regulator is not mandatory but it is usual in the literature[41] since it simplifies the discussion once the spectrum becomes discrete. An alternative regulator procedure is to use boundary conditions as considered in Arovas *et al.*[40] to calculate the second virial coefficient of the two anyon system. Nonetheless, it is also possible to avoid the use of any regulator and consider the case of "free" anyons, as will be discussed in the next section. This situation is in fact related to the case of the magnetic vortex discussed in the previous section. The connection of these cases will be discussed in the next section.

Introducing the center of mass and relative coordinates $\vec{R}=\vec{r}_1+\vec{r}_2$, and $\vec{r}=\vec{r}_1-\vec{r}_2=(r,\phi)$, respectively, the Lagrangean for the two anyon system with a harmonic regulator can be written as

$$L_\alpha = \frac{1}{2}M\dot{R}^2 + \frac{1}{2}M\omega^2R^2 + \frac{1}{2}\mu(\dot{r}^2 + r^2\dot{\phi}^2 + \omega^2r^2) + \alpha\hbar\,\dot{\phi}, \tag{54}$$

where $M=2m_0$, $\mu=m_0/2$. The motion of the center of mass is described by the first part of the Lagrangean corresponding to a two-dimensional harmonic motion that does not contribute to the statistical behavior. From now on we will only consider the relative motion of the two anyon system. The canonical momenta are then given by

$$p_\phi = \frac{\partial L}{\partial\dot{\phi}} = \mu r^2\dot{\phi} + \alpha\hbar\,; \quad p_r = \mu\dot{r}, \tag{55}$$

and the Hamiltonian of the relative motion of the two particles is

$$H = -\frac{\hbar^2}{2\mu}\left[\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r} + \frac{1}{r^2}\left(\frac{\partial}{\partial\phi} - i\alpha\right)^2\right] + \frac{1}{2}\mu\omega^2r^2. \tag{56}$$

Here we are going to construct the Green's function for this problem using an algebraic method associated with the dynamical SO(2,1) Lie group.[16,27] The technique used here is a generalization of the one presented in the previous section, and we will recover that results in the following sections. The Green's functions for this problem satisfies the equation

$$(H-E)G_E(r,r',\phi,\phi') = \frac{\delta(r-r')}{r}\delta(\phi-\phi'), \tag{57}$$

where $G_E(\vec{r},\vec{r}')\equiv G_E(r,r',\phi,\phi')$. Decomposing this Green's function as we did in the previous section, Eq. (17), one can obtain the radial Hamiltonian H_r for this problem and we write the resolvent operator as

$$\Lambda_r = (H_r - E) = g_0 + g_1T_1(r) + g_3T_3(r), \tag{58}$$

where the operators T_i are given by Eqs. (21)–(23) which satisfy the so(2,1) Lie algebra Eqs. (24)–(26) and the parameters g_i are given by

$$g_0 = -E, \quad g_1 = -\frac{\hbar^2}{2\mu}, \quad g_3 = -4\mu\omega^2. \tag{59}$$

Note that $H_r = H_m + \frac{1}{2}\mu\omega^2 r^2$, with H_m given by Eq. (19), if we further identify α with ν. Using the Schwinger[1] representation as before we find

$$G_E(r,r') = i\int_0^\infty ds\, \exp[-is(g_0 + g_1 T_1(r) + g_3 T_3(r) - i\epsilon)]\frac{\delta(r-r')}{r}. \tag{60}$$

In addition to Eq. (29), here we need another BCH formula

$$\exp\left\{-i\frac{s}{\hbar}(g_1 T_1 + g_3 T_3)\right\} = \exp\{-iaT_3\}\exp\{-ibT_2\}\exp\{-icT_1\}, \tag{61}$$

where the parameters a, b, c, and k are given by

$$a = 2\frac{k}{g_1}\tan k\frac{s}{\hbar}, \quad b = 2\ln\left(\cos k\,\frac{s}{\hbar}\right), \quad c = \frac{g_1}{k}\tan k\,\frac{s}{\hbar}, \quad k = \sqrt{\frac{g_1 g_3}{2}}. \tag{62}$$

Following Ref. 16 we find

$$\exp\left\{-i\frac{s}{\hbar}(g_1 T_1 + g_3 T_3)\right\}\frac{\delta(r-r')}{r} = -\frac{ik\exp\{2i\pi\delta\}}{2g_1\sin(ks/\hbar)}r'\exp\left\{-\frac{ik}{4g_1}(r'^2 + r^2)\cot k\,\frac{s}{\hbar}\right\} \times I_\delta\left(-\frac{kr'r}{2ig_1\sin(ks/\hbar)}\right) \tag{63}$$

with δ given by

$$\delta = |m-\alpha|. \tag{64}$$

As before, $\delta = -|m-\alpha|$ would imply non-normalizable solutions and we will not consider this case.

Then we obtain the Green's function as

$$G_E(r,r') = -\frac{i}{\hbar}\int_0^\infty ds\,\exp\left\{-i\frac{s}{\hbar}(g_0 - i\epsilon)\right\}\frac{ik\exp(2i\pi\delta)}{2g_1\sin(ks/\hbar)}(rr')^{(1/2)} \times \exp\left\{-\frac{ik}{4g_1}(r^2 + r'^2)\cot(ks/\hbar)\right\}I_\delta\left[\frac{-krr'}{2ig_1\sin(ks/\hbar)}\right], \tag{65}$$

where I_δ is the modified Bessel function of order δ. This Bessel function is related to the associated Laguerre's polynomials L_n^δ by

$$I_\delta\left(2\frac{\sqrt{y'yz}}{1-z}\right)\exp\left\{-z\frac{y'+y}{1-z}\right\} = (y'yz)^{\delta/2}(1-z)\sum_{n=0}^{+\infty}\frac{n!}{\Gamma(n+\delta+1)}L_n^\delta(y)L_n^\delta(y')z^n. \tag{66}$$

Then integrating over the proper time s one finds for the Green's function of two anyons on a plane with a harmonic regulator

$$G_E(r,r',\phi,\phi') = -\frac{1}{\pi}\sum_{m=-\infty}^{+\infty}e^{2\pi i|m-\alpha|}\left(\frac{\mu\omega}{\hbar}\right)^{1+|m-\alpha|}(rr')^{|m-\alpha|} \times e^{im(\phi-\phi')}\sum_{n=0}^{\infty}\frac{n!\,L_n^{|m-\alpha|}\left(\frac{\mu\omega}{\hbar}r^2\right)L_n^{|m-\alpha|}\left(\frac{\mu\omega}{\hbar}(r')^2\right)}{\Gamma(n+|m-\alpha|+1)} \times \exp\left\{-\frac{\mu\omega}{2\hbar}(r^2+r'^2)\right\}\frac{1}{E-\hbar\,\omega(2n+|m-\alpha|+1)}. \tag{67}$$

If one writes the spectral representation for the Green's function as (Note that the obtained Green's function is real up to a complex phase $i\pi|m-\alpha|$. Then we are using a nonstandard definition for the spectral decomposition to preserve this nontrivial phase which is related to the statistics of the system.)

$$G(r,r',\phi,\phi') = \sum_{n=0}^{\infty} \sum_{m=-\infty}^{\infty} \frac{\psi_{n,m}(r,\phi)\psi_{n,m}(r',\phi')}{E-E_{n,m}}, \tag{68}$$

so that the wave functions are given by its residues

$$\psi^{\alpha}_{n,m}(r,\phi) = \frac{i}{\sqrt{\pi}} e^{\pi i|m-\alpha|} e^{im\phi} \left(\frac{\mu\omega}{\hbar}\right)^{(1/2)(1+|m-\alpha|)} r^{|m-\alpha|} \frac{\sqrt{n!} L_n^{|m-\alpha|}\left(\frac{\mu\omega}{\hbar} r^2\right)}{\sqrt{\Gamma(n+|m-\alpha|+1)}} \exp\left\{-\frac{\mu\omega}{2\hbar} r^2\right\} \tag{69}$$

and the poles correspond to the energy spectrum

$$E^{\alpha}_{nm} = \hbar\,\omega(2n+|m-\alpha|+1), \tag{70}$$

where $n=0,1,2,3,\ldots$ is the radial quantum number. This spectrum corresponds to that of a two-dimensional harmonic oscillator with angular momentum $|m-\alpha|$.

If we had started with particles identified with bosons then the allowed angular momentum values would be $m=0,\pm 2,\pm 4,\ldots$. Had we started with fermions then the values of the angular momentum should be $m=\pm 1,\pm 3,\pm 5,\ldots$. The quantized energy levels are periodic functions of the statistical parameter α with period 2, although the energy of a single state with quantum numbers (n,m) is not periodic. These conclusions are in agreement with Refs. 40 and 41 where the second virial coefficient for anyons has been calculated without a harmonic regulator, but considering boundary conditions on the wave functions.

V. TWO "FREE" ANYONS

In this section we are going to obtain the Green's function for two anyons as discussed above but without any regulator. Here, the relative motion Hamiltonian after separating the angular variable ϕ is

$$H = -\frac{\hbar^2}{2M}\left(\frac{d^2}{dr^2} + \frac{1}{r}\frac{d}{r} - \frac{1}{r^2}(m-\alpha)^2\right), \tag{71}$$

where $m=0,1,2,\ldots$ are again the eigenvalues of the angular momentum and $\alpha=\theta/\pi$. The so(2,1) Lie algebra here is analogous to the one discussed in the previous section with generators defined by Eqs. (21)–(23). Here the resolvent operator is simply

$$(H-E) = g_0 + g_1 T_1(r), \tag{72}$$

with g_0 and g_1 given by Eq. (59) (here $g_3=0$), so that the radial Green's function can be written as

$$G(r,r') = \frac{i}{\hbar}\int_0^{\infty} ds \exp\left\{-i\frac{s}{\hbar}(g_0 - i\epsilon)\right\} \exp\left\{-i\frac{s}{\hbar} g_1 T_1\right\} \frac{1}{r}\delta(r-r'). \tag{73}$$

It has been shown in Ref. 16 that

$$\exp\{icT_1\}\frac{\delta(r-r')}{r} = i(-i)^{|m-\alpha|}\frac{M}{s\hbar}\exp\left\{\frac{iM}{2s\hbar}(r^2-r'^2)\right\} J_{|m-\alpha|}\left(\frac{M}{s\hbar} rr'\right) \tag{74}$$

so that the radial Green's function is given by

$$G(r,r') = -\frac{M}{\hbar}(-i)^{|m-\alpha|}\int_0^\infty \frac{ds}{s}\exp\left\{i\frac{s}{\hbar}(E+i\epsilon)\right\}\exp\left\{\frac{iM}{2s\hbar}(r^2-r'^2)\right\}J_{|m-\alpha|}\left(\frac{M}{s\hbar}rr'\right). \quad (75)$$

Another way to approach the two anyon system without a regulator potential is to consider the two anyon system in the harmonic well, Eq. (56), and take the limit where the regulator vanishes $\omega \to 0$. This limit corresponds to take $k \to 0$ in Eq. (65), so that the above Green's function is reobtained.

This Green's function can be compared with the one obtained for the particle-vortex system, Eq. (37). One can note that they are identical if one identifies the quantized flux ν, Eq. (20), with the anyon statistical parameter α, Eq. (53).

VI. TWO ANYONS IN A UNIFORM MAGNETIC FIELD

The Hamiltonian of the relative motion of two anyons in a uniform and constant magnetic field B is given by[42–48]

$$H = \frac{1}{2\mu}\left(\vec{p} + \frac{1}{2}\mu\omega_c r\hat{\phi} + \frac{\alpha\hbar}{r}\hat{\phi}\right)^2, \quad (76)$$

where $\omega_c = eB/mc$ is the cyclotron frequency, the second term on brackets corresponds to the physical (external) magnetic vector potential $\vec{A} = Br\hat{\phi}/2$ and the third term is the statistical vector potential. This statistical term can be absorbed in the angular part of the kinetical term that contributes to the angular momentum of the particles. The radial part of this Hamiltonian can be written as before as

$$H = -\frac{\hbar^2}{2\mu}\left[\frac{1}{r}\frac{\partial}{\partial r}r\frac{\partial}{\partial r} - \frac{1}{r^2}(m-\alpha)^2\right] - \frac{m\hbar\,\omega_c}{4} + \frac{1}{8}\mu\omega_c^2 r^2. \quad (77)$$

The presence of the magnetic field B implies an r-independent term that contributes to the energy but the form of this Hamiltonian is similar to that of the problem of two anyons in a harmonic well, discussed in Sec. IV. This fact allows the use of the algebraic method as before to calculate the Green's functions. Then the so(2,1) generators that describe the two anyons in a magnetic field are the ones given by Eqs. (21)–(23). The resolvent operator is again given by Eq. (58) with the parameters

$$g_0 = -\left(E + \frac{1}{4}m\hbar\,\omega_c\right), \quad g_1 = -\frac{\hbar^2}{2\mu}, \quad g_3 = -\mu\omega_c^2. \quad (78)$$

Following the algebraic method as in Sec. IV with these parameters we find the Green's function:

$$\begin{aligned} G_E(r,r',\phi,\phi') = -\frac{1}{\pi}\sum_{m=-\infty}^{+\infty} & e^{2\pi i|m-\alpha|}\left(\frac{\mu\omega_c}{2\hbar}\right)^{1+|m-\alpha|}(rr')^{|m-\alpha|}e^{-im(\phi-\phi')} \\ & \times \sum_{n=0}^{\infty}\frac{n!\,L_n^{|m-\alpha|}\left(\frac{\mu\omega_c}{2\hbar}r^2\right)L_n^{|m-\alpha|}\left(\frac{\mu\omega_c}{2\hbar}(r')^2\right)}{\Gamma(n+|m-\alpha|+1)} \\ & \times \exp\left\{-\frac{\mu\omega_c}{4\hbar}(r^2+r'^2)\right\}\frac{1}{E-\frac{\hbar\omega_c}{2}\left(2n+|m-\alpha|+1+\frac{m}{2}\right)}. \end{aligned} \quad (79)$$

From this Green's function we obtain the normalized wave functions

$$\psi_{n,m}^{\alpha}(r,\phi)=\frac{i}{\sqrt{\pi}}e^{i\pi|m-\alpha|}e^{-im\phi}\left(\frac{\mu\omega_c}{2\hbar}\right)^{(1/2)(1+|m-\alpha|)}r^{|m-\alpha|}\frac{\sqrt{n!}L_n^{|m-\alpha|}\left(\frac{\mu\omega_c}{2\hbar}r^2\right)}{\sqrt{\Gamma(n+|m-\alpha|+1)}}\exp\left\{-\frac{\mu\omega_c}{4\hbar}r^2\right\} \tag{80}$$

and the corresponding energy levels

$$E_{nm}^{\alpha}=\frac{\hbar\omega_c}{2}\left(2n+|m-\alpha|+1+\frac{m}{2}\right). \tag{81}$$

These energy levels coincide with the Landau levels if the anyon statistical contribution vanishes ($m=\alpha=0$). In particular, the ground state wave function is obtained when one takes $m=n=0$,

$$\psi_{0,0}^{\alpha}(r)=\frac{i}{\sqrt{\pi}}e^{i\pi\alpha}\left(\frac{\mu\omega_c}{2\hbar}\right)^{(1/2)(1+\alpha)}\frac{r^{\alpha}}{\sqrt{\Gamma(1+\alpha)}}\exp\left\{-\frac{\mu\omega_c}{4\hbar}r^2\right\}. \tag{82}$$

VII. CONCLUSIONS

In this paper we have calculated algebraically the Green's functions for one and two particles confined on a plane, namely the particle-vortex system and a pair of anyons with and without external potentials. The external potentials considered were a harmonic well and a uniform magnetic field. In these problems we have identified the Hamiltonian operator in each case with the generators of the SO(2,1) Lie group satisfying the so(2,1) Lie algebra. From these algebraic properties we obtained all relevant dynamical quantities of each system. This means that these systems are described by the so(2,1) dynamical algebra.

In particular, we calculated the Green's function for particle-vortex system and the Green's function for a pair of free anyons and found that these Green's functions are equivalent, once one identifies the quantized flux ν of the particle-vortex system with the anyon statistical parameter α. These two Green's functions exhibit respectively the phase factors $(-i)^{|m-\nu|}$ and $(-i)^{|m-\alpha|}$ as a commom signature of fractional statistics for both systems.

We obtained also the Green's function for the two anyon system in a harmonic well as an integral representation of Bessel functions, and as a sum of product of Laguerre's generalized polynomials. This sum is recognized as the spectral representation of the Green's function from which we identify the normalized wave functions and energy spectrum.

It is interesting to note that in the particle-vortex discussion presented by Jackiw,[43] he obtained a discrete spectrum of the generator R (our Eq. (45)) of conformal transformations, and them, by a rotation in operators space he obtain the continuous spectrum calculated by standard methods to the particle-vortex system. This discrete spectrum is identical to one obtained for anyons in presence of an harmonic regulator. The eigenfunctions (up to a phase factor) and eigenvalues of this operator, (48) in Ref. 43 are equivalent to those ones we have obtained for the two anyon system in a harmonic well.

Regarding the Green's functions for the two anyon system in a harmonic well and two anyons in a uniform magnetic field both lead to bound states and we see that they are very similar to each other, although they differ in the energy spectrum. Charged anyons orbiting in a uniform magnetic field are equivalent to anyon bound states in the presence of a harmonic well. Note that wave functions (69) and (80), obtained from those Green's functions, are identical if we identify ω with $\omega_c/2$.

In particular the ground state wave function obtained for two charged particles in a magnetic field, Eq. (82), is similar to the two particle wave function used by Laughlin[54] to construct his ansatz for N-particles to describe the quantum Hall effect. In the problem discussed by Laughlin, there is also a Coulombic interaction which in general could not be disregarded. Then, he supposed that this interaction is infinitely short ranged and that the Landau levels energy is dominant

so $\hbar\omega_c \gg e^2/l$, where l is the magnetic length. Since the particles are separated by some finite length, this allows one to build an ansatz for the many particle ground state wave function as a superposition of single particle wave functions

$$\psi_{00}^{\alpha}(r_{p,q}) = e^{i\pi\alpha}\frac{i}{\sqrt{\pi\Gamma(1+\alpha)}}\left(\frac{\mu\omega_c}{2\hbar}\right)^{(1/2)(1+\alpha)}\prod_{p<q} r_{p,q}^{\alpha}\exp\left(-\frac{\mu\omega_c}{4\hbar}\sum_{p<q} r_{p,q}^2\right). \tag{83}$$

This is essentially the Laughlin's ansatz for N-particles.[54] Note that the interchange of particle positions adds a phase to the wave function in agreement with Ref. 57.

Let us now consider the excited states for the two anyon system in a uniform magnetic field. The wave functions (80), or equivalently (69), represent the excited states of this system. If we follow a similar reasoning as the ones that support (83), as discussed in Refs. 49, 50, and 54, we can superpose Eq. (80) to obtain an ansatz for the many particle excited state wave function

$$\psi_{n,m}^{\alpha}(r,\phi) = ie^{i\pi|m-\alpha|}\frac{\sqrt{n!}}{\sqrt{\pi}\sqrt{\Gamma(n+|m-\alpha|+1}}\left(\frac{\mu\omega_c}{2\hbar}\right)^{(1/2)(1+|m-\alpha|)} e^{-im\phi}\prod_{i<j} r_{ij}^{|m-\alpha|}L_n^{|m-\alpha|}\left(\frac{\mu\omega_c}{2\hbar}r_{ij}^2\right)$$
$$\times\exp\left\{-\frac{\mu\omega_c}{4\hbar}\sum_{i<j} r_{ij}^2\right\}. \tag{84}$$

This wave function is formally in agreement with the result for many anyons obtained by Dunne *et al.*[46]

The Selberg trace formula for Dirac operators

Jens Bolte[a] and Hans-Michael Stiepan[b]
Institut für Theoretische Physik, Universität Ulm, Albert-Einstein-Allee 11, D-89069 Ulm, Germany

(Received 24 July 2006; accepted 12 September 2006; published online 8 November 2006)

We examine spectra of Dirac operators on compact hyperbolic surfaces. Particular attention is devoted to symmetry considerations, leading to nontrivial multiplicities of eigenvalues. The relation to spectra of Maaß-Laplace operators is also exploited. Our main result is a Selberg trace formula for Dirac operators on hyperbolic surfaces. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2359578]

I. INTRODUCTION

Trace formulae play a prominent role in spectral geometry and in quantum chaos (see, e.g., Ref. 2). In spectral geometry, they relate spectra of certain (pseudo-) differential operators on manifolds to the geometry of that manifold. The prime example of such a trace formula, the classical Selberg trace formula,[33,19,20] is concerned with the Laplace-Beltrami operator on a hyperbolic manifold, i.e., a Riemannian manifold with constant negative sectional curvatures. This trace formula establishes a connection between the spectrum of the Laplacian and the length spectrum of closed geodesics on the manifold.

In a semiclassical context spectra of semiclassical operators are related to the periodic orbits of an associated Hamiltonian flow. In extensions of this procedure to operators acting on sections in vector bundles over the relevant phase space, it turned out that the Hamiltonian flow does not provide the entire input on the classical side of the trace formula (see, e.g., Ref. 8). In particular, for the Dirac operator on $\mathbb{R}^3$, the corresponding classical dynamics are given in terms of skew-product flows over Hamiltonian flows, with spin precessions as their cocycles. A similar result is found in the case of a trace formula for the Dirac operator on a graph.[7] A microlocal version of a trace formula for Dirac-type operators on compact manifolds was established in Ref. 31. Very recently, in the context of quantum ergodicity, Jakobson and Strohmaier[23] observed that (the square of) a Dirac operator on a compact Riemannian manifold is related to the associated frame flow, which is a geometric analog of the skew-product flows in the semiclassical setting. A previous approach to quantum ergodicity that uses representation-theoretic lifts for vector bundles can be found in Ref. 12.

In this paper, our goal is to investigate spectra of Dirac operators on compact hyperbolic surfaces in a geometric setting. On the way we exploit the well-known relation of the squared Dirac operator to a Laplacian that contains a coupling to a magnetic field (see, e.g., Ref. 28). In particular, we show that spectra of these Maaß-Laplacians, when they correspond to odd weights, possess multiplicities of at least two. This is a consequence of Kramers' degeneracy in the spectrum of the Dirac operator, which follows from quantum mechanical time reversal invariance. We further investigate the relation of the Dirac spectrum to a dynamical system that is associated with the surface in a geometric way. To this end we develop a Selberg trace formula in a classical approach, i.e., via Green's functions and point-pair invariants. This complements previous studies of related questions, which often focus on computations of eta invariants (see, e.g., Ref. 27) and employ a representation theoretic approach to trace formulae as, e.g., summarized in Ref. 11. The geometric side of the trace formula for the Dirac operator is primarily determined by the closed

[a]Electronic mail address: jens.bolte@uni-ulm.de
[b]Electronic mail address: hans-michael.stiepan@uni-ulm.de

geodesics on the surface. In addition, we identify traces of the frame flow of the surface and its lift into the spin structure, which provides suitable phase factors associated with the closed geodesics. These factors are finally responsible for the differences in the eigenvalue distributions of Dirac and Laplace-Beltrami operators, respectively.

The paper is organized as follows: In Sec. II we review the definition of a Dirac operator on a Riemannian manifold and explicitly carry out the constructions in the case of the hyperbolic plane. Section III then is devoted to an identification of spinor bundles over compact hyperbolic surfaces via factors of automorphy. We then investigate symmetries of the Dirac operator on a compact surface and study their influence on the spectrum in Sec. IV. After having introduced point-pair invariants in Sec. V, we calculate traces of Hilbert-Schmidt operators to arrive at the desired trace formula in Sec. VI. Finally, in Sec. VII, we discuss some applications.

II. THE DIRAC OPERATOR

A Dirac operator is a first order, elliptic differential operator acting on sections in a spinor bundle over a Riemannian manifold. For its construction one first needs to supply an orientable, n-dimensional Riemannian manifold $(M,\mathbf{g})$ with a spin structure. To this end, let FM be the $\mathrm{SO}(n)$-principal bundle of oriented orthonormal frames of TM. A $\mathrm{Spin}(n)$-principal bundle Q is called spin structure on M if there exists a principal-bundle morphism $\phi: Q \to FM$ that is equivariant with respect to the two-fold covering $\Lambda: \mathrm{Spin}(n) \to \mathrm{SO}(n)$ (see, e.g., Refs. 15 and 4). Moreover, in even dimensions n the complexified Clifford algebra $\mathfrak{C}_n^c$ is isomorphic to $\mathrm{M}(2^{n/2},\mathbb{C})$, i.e., the algebra of complex $2^{n/2}\times 2^{n/2}$ matrices. The action of $\mathrm{M}(2^{n/2},\mathbb{C})$ on $\mathbb{C}^{2^{n/2}}$ defines the Clifford module Δ_n. As $\mathrm{Spin}(n)$ is contained in $\mathfrak{C}_n^c$, Δ_n is also a module for the spin group. This yields the spin representation $\rho: \mathrm{Spin}(n) \to \mathrm{Aut}(\Delta_n)$, which can be used to associate the spinor bundle $S := Q\times_\rho \Delta_n$ to a given spin structure.

The definition of the Dirac operator D rests on the canonical connection on Q that is given by the lift of the Levi-Civita connection on FM. Denoting the space of smooth sections of S by $C^\infty(S)$, this connection induces a covariant derivative $\boldsymbol{\nabla}^S: C^\infty(S) \to C^\infty(S\otimes T^*M)$. One then defines $D=\mu\circ\iota\circ\nabla^S$, where ι denotes the canonical isomorphism between T^*M and TM induced by the metric $\mathbf{g}$, and μ is the Clifford multiplication of a vector field and a smooth section in S.

The space $C_0^\infty(S)$ of smooth, compactly supported sections in S can be turned into a pre-Hilbert space by introducing the inner product,

$$\langle \Psi,\Phi\rangle_{L^2} := \int_M \langle \Psi(m),\Phi(m)\rangle_{\mathbb{C}^{2^{n/2}}}\, \mathrm{d}\mu(m),$$

where $\mathrm{d}\mu(m)$ denotes the volume form on M. The resulting Hilbert space will be denoted by $L^2(S)$. The Dirac operator D is elliptic and essentially self-adjoint on $C_0^\infty(S)$, thus its spectrum is real. Moreover, on a compact manifold M the spectrum is discrete.

In the sequel we will focus on compact surfaces of constant negative curvature. Their universal covering space is the upper half-plane $\mathbb{H}^2 := \{(x,y)\in\mathbb{R}^2 \,|\, y>0\}$ endowed with the Poincaré metric $\mathbf{g}=y^{-2}(\mathrm{d}x\otimes\mathrm{d}x+\mathrm{d}y\otimes\mathrm{d}y)$ of constant negative Gaussian curvature $K=-1$. The group of orientation-preserving isometries $\mathrm{PSL}(2,\mathbb{R})=\mathrm{SL}(2,\mathbb{R})/\{\pm\mathrm{Id}\}$ acts on $\mathbb{H}^2$ via fractional linear transformations,

$$z \mapsto \gamma z = \frac{az+b}{cz+d},$$

where $\gamma=\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}(2,\mathbb{R})$ is a representative for an element in $\mathrm{PSL}(2,\mathbb{R})$ and $z=x+\mathrm{i}y$ is viewed as a point in $\mathbb{H}^2$. Any compact hyperbolic surface can now be represented as $\Gamma\backslash\mathbb{H}^2$, where $\Gamma\subset\mathrm{PSL}(2,\mathbb{R})$ is a discrete, strictly hyperbolic subgroup (a cocompact Fuchsian group of the first kind).

On the simply connected upper half-plane the relevant bundles are trivial, i.e., $F\mathbb{H}^2 \simeq \mathbb{H}^2 \times \mathrm{SO}(n)$ and $Q \simeq \mathbb{H}^2 \times \mathrm{Spin}(n)$. This allows an immediate construction of the Dirac operator, which is explicitly given as the matrix-valued operator,

$$D = \mathrm{i}\begin{pmatrix} 0 & \mathrm{i}y\frac{\partial}{\partial x} + y\frac{\partial}{\partial y} - \frac{1}{2} \\ -\mathrm{i}y\frac{\partial}{\partial x} + y\frac{\partial}{\partial y} - \frac{1}{2} & 0 \end{pmatrix};$$

see, e.g., also Ref. 28. The operators appearing in the off-diagonals have been introduced by Maaß and have been further investigated by Roelcke (Refs. 25, 29, and 30). In fact, they considered the operators

$$K_k := \mathrm{i}y\frac{\partial}{\partial x} + y\frac{\partial}{\partial y} + \frac{k}{2},$$

$$\Lambda_k := \mathrm{i}y\frac{\partial}{\partial x} - y\frac{\partial}{\partial y} + \frac{k}{2}.$$

It is therefore natural to introduce the weighted Dirac operators,

$$D_k := \mathrm{i}\begin{pmatrix} 0 & K_{k-2} \\ -\Lambda_k & 0 \end{pmatrix}, \tag{2.1}$$

which reduce to the Dirac operator for $k=1$. In physical terms the additional parameter k, which from now on will be called a weight, corresponds to a constant magnetic field on the surface. In normalized units the field strength is given by

$$B = \frac{k-1}{2e}. \tag{2.2}$$

On a compact surface the Dirac quantization condition for the magnetic flux implies that k must be an integer. Therefore, from now on we will only consider $k \in \mathbb{Z}$.

The weighted Dirac operator D_k is closely related to the weighted Maaß-Laplacian,

$$\Delta_k = -K_{k-2}\Lambda_k - \frac{k}{2}\left(1 - \frac{k}{2}\right) = y^2\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right) - \mathrm{i}ky\frac{\partial}{\partial x},$$

since

$$D_k^2 = \begin{pmatrix} -\Delta_k - \frac{k}{2}\left(1 - \frac{k}{2}\right) & 0 \\ 0 & -\Delta_{k-2} - \frac{k}{2}\left(1 - \frac{k}{2}\right) \end{pmatrix}. \tag{2.3}$$

We remark that both the weighted Laplacians and the weighted Dirac operators are elliptic operators, as their principal symbols do not depend on k.

As yet, we have neither specified spaces of sections in spinor bundles S, nor have we introduced Dirac operators on compact surfaces. It turns out that both purposes can be conveniently achieved by identifying suitable automorphic forms. We devote the following section to this task.

III. AUTOMORPHIC FORMS

All relevant bundles over a compact surface $\Gamma\backslash\mathbb{H}^2$ correspond to trivial bundles over $\mathbb{H}^2$ (see Refs. 17 and 18). More specifically, given the canonical projection $p:\mathbb{H}^2 \to \Gamma\backslash\mathbb{H}^2$ and the vector

bundle $\zeta=(E,\Gamma\backslash\mathbb{H}^2,\pi,V)$ over the compact surface, its pullback $p^*(\zeta)$ is trivial, i.e., the total space is isomorphic to $\mathbb{H}^2\times V$. Now any covering translation $\gamma\in\Gamma$ extends to a bundle homomorphism $\tilde{\gamma}$ on $p^*(\zeta)$, and this can be written as

$$\tilde{\gamma}(z,v)=(\gamma z,\sigma(z,\gamma)v), \tag{3.1}$$

where $\sigma:\mathbb{H}^2\times\Gamma\to\mathrm{GL}(V)$.

For our purposes it will be useful to consider the subgroup $\bar{\Gamma}\subset\mathrm{SL}(2,\mathbb{R})$ that corresponds to the Fuchsian group $\Gamma\subset\mathrm{PSL}(2,\mathbb{R})$ via $\Gamma=\bar{\Gamma}/\{\pm\mathrm{Id}\}$. Instead of σ one hence considers a function $j:\mathbb{H}^2\times\bar{\Gamma}\to\mathrm{GL}(V)$, called factor of automorphy. To define the action of $\gamma\in\Gamma$ unambiguously, one therefore requires a suitable character χ of $\bar{\Gamma}$ (multiplier system) depending on the value of $j(z,-\mathrm{Id})$. Based on these observations, sections in ζ can be obtained from global sections in $p^*(\zeta)$: any vector-valued function $\psi:\mathbb{H}^2\to V$ with $\psi(\gamma z)=\chi(\gamma)j(z,\gamma)\psi(z)$, called automorphic form, yields a section in ζ, and vice versa.

Definition 1: Let $\Gamma\subset\mathrm{PSL}(2,\mathbb{R})$ be a strictly hyperbolic Fuchsian group, then a multiplier system of weight k is a unitary character χ of $\bar{\Gamma}$ with $\chi(-\mathrm{Id})=(-1)^k$. A factor of automorphy for the Maaß-Laplacian of weight k is defined by $j_\gamma(z,k):=(cz+d)^{k/2}/(c\bar{z}+d)^{k/2}$ when $\gamma=\begin{pmatrix}a & b\\ c & d\end{pmatrix}$. Then $\psi:\mathbb{H}^2\to\mathbb{C}$ is an automorphic form for the Maaß-Laplacian of weight k, if

$$\psi(\gamma z)=\chi(\gamma)j_\gamma(z,k)\psi(z),\quad \forall\ \gamma\in\bar{\Gamma}.$$

The space of all such automorphic forms is denoted by ${}^L\mathfrak{F}(\Gamma,k,\chi)$. Similarly, ${}^L\mathfrak{C}^l(\Gamma,k,\chi)$ and ${}^L\mathfrak{L}^2(\Gamma,k,\chi)$ are the spaces of differentiable and square-integrable automorphic forms, respectively. In the latter case, integrability is meant with respect to the measure $\mathrm{d}\mu(z)=\mathrm{d}x\,\mathrm{d}y/y^2$ over a fundamental domain $F\subset\mathbb{H}^2$ of Γ.

It is well known that Δ_k acting on a (twice differentiable) automorphic form of weight k yields again an automorphic form of weight k (see Refs. 29, 30, and 19). We denote the space of all eigenforms of $-\Delta_k$ with eigenvalue λ by ${}^L\mathfrak{F}_\lambda(\Gamma,k,\chi)$. In case $k\geq 2$ there exist certain special eigenvalues that are known explicitly,

$$\lambda_j^{(k)}=\frac{k-2j}{2}\left(1-\frac{k-2j}{2}\right),\quad j=0,1,2,\ldots,\left[\frac{k-1}{2}\right], \tag{3.2}$$

where $[x]$ is the integer part of $x\in\mathbb{R}$. For multiplier systems $\chi\neq 1$ the eigenvalue (3.2) has a multiplicity $(g-1)(k-2j-1)$; see Ref. 19; here $g\geq 2$ is the genus of the closed surface $\Gamma\backslash\mathbb{H}^2$.

The relations (2.1) and (2.3) now suggest the following definition of automorphic forms for the weighted Dirac operator.

Definition 2: Let

$$J_\gamma(z,k):=\begin{pmatrix} j_\gamma(z,k) & 0\\ 0 & j_\gamma(z,k-2)\end{pmatrix}.$$

Then we define the space $\mathfrak{F}(\Gamma,k,\chi)$ of automorphic forms for the Dirac operator with weight k to consist of the functions $\Psi:\mathbb{H}^2\to\Delta_2=\mathbb{C}^2$ that transform as

$$\Psi(\gamma z)=\chi(\gamma)J_\gamma(z,k)\Psi(z),\quad \forall\ \gamma\in\bar{\Gamma}. \tag{3.3}$$

The spaces $\mathfrak{C}^l(\Gamma,k,\chi)$, $\mathfrak{L}^2(\Gamma,k,\chi)$ are defined analogously, and $\mathfrak{F}_\rho(\Gamma,k,\chi)$ denotes the eigenspace of $-D_k$ corresponding to the eigenvalue ρ.

In order to demonstrate that the weighted Dirac operator D_k maps a differentiable automorphic form of the type (3.3) to a form of the same type, one has to show that under a covering translation γ the operator D_k behaves as

$$D_k \mapsto J_\gamma(z,k) D_k J_\gamma^{-1}(z,k). \tag{3.4}$$

This can be done in a straightforward calculation. Hence, the automorphic forms (3.3) represent sections in spinor bundles over the surface $\Gamma\backslash\mathbb{H}^2$.

We also note that D_k is essentially self-adjoint on $\mathfrak{C}^1(\Gamma,k,\chi)$. The proof is practically identical to the case of the Dirac operator ($k=1$), which is well-known (see, e.g., Ref. 15 where also Spin^C connections are considered). Thus, we conclude that the spectrum of D_k is real and discrete.

We are now able to establish a connection between the eigenforms of the Laplacian and of the Dirac operator. For this we recall that the spectrum of $-\Delta_k$ is bounded from below by $(k/2)(1-k/2)$.[29]

Proposition 1: Let $\Psi=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}$ *be an eigenform of* $-D_k$ *with eigenvalue* ρ, *and let* $\lambda=\rho^2+(k/2)(1-k/2)$. *Then* $\psi_1 \in {}^L\mathfrak{F}_\lambda(\Gamma,k,\chi)$. *On the other hand, if* $\psi \in {}^L\mathfrak{F}_\lambda(\Gamma,k,\chi)$, *then* $\Psi=\begin{pmatrix}\rho\psi\\ i\Lambda_k\psi\end{pmatrix} \in \mathfrak{F}_\rho(\Gamma,k,\chi)$. *Moreover, if eigenforms of the Dirac operator* ($\rho\neq 0$) *are linearly independent, the same holds for the corresponding eigenforms of the Maaß-Laplacian, and vice versa.*

Proof: As both operators are elliptic, all eigenforms are smooth. The relation between ρ and λ can be obtained by using Eq. (2.3). To establish the desired transformation properties one has to write down the conditions on the components. The rest then follows from Ref. 29. The linear independence can be obtained from some straightforward manipulations using

$$-i\Lambda_k\psi_1 + \rho\psi_2 = 0,$$

which can be solved for ψ_2 if $\rho\neq 0$. □

IV. SYMMETRIES

Apart from the fact that spectra of weighted Dirac operators on compact surfaces are real and discrete, further spectral properties can be concluded from symmetry considerations.

Lemma 1: The weighted Dirac operator possesses a chiral symmetry, i.e., if $\Psi=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix} \in \mathfrak{F}_\rho(\Gamma,k,\chi)$, *then* $\begin{pmatrix}\psi_1\\ -\psi_2\end{pmatrix} \in \mathfrak{F}_{-\rho}(\Gamma,k,\chi)$. *Hence the spectrum of* D_k *is symmetric about zero.*

Proof: The proof amounts to a simple calculation that can be performed conveniently by using the relations in Ref. 29 once again. □

The symmetry statement extends to zero modes in that the Atiyah-Singer index theorem (see Refs. 21 and 1) implies that their number is even. From now on we will denote this number by $2N$.

A further symmetry is concerned with quantum mechanical time reversal. For the Dirac operators considered here, this is implemented through the antilinear operator $T:=i\sigma_2 C$ acting on automorphic forms of arbitrary weight, where C denotes complex conjugation and $\sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}$ is one of the Pauli matrices. Hence $T^2=-\mathrm{Id}$. Moreover, on the Hilbert space $\mathfrak{L}^2(\Gamma,k,\chi)$ this operator is anti-unitary.

Lemma 2: Let $\Psi \in \mathfrak{F}_\rho(\Gamma,k,\chi)$; *then* $T\Psi \in \mathfrak{F}_\rho(\Gamma,2-k,\bar{\chi})$. *In particular, if* $k=1$ *and the multiplier system* χ *is real valued, every eigenvalue of D has a multiplicity of (at least) two.*

Proof: The first part of this lemma can be checked by straightforward calculations that we omit here. For the second part one merely has to use the fact that T is anti-unitary with $T^2=-\mathrm{Id}$. This immediately yields that the eigenforms Ψ and $T\Psi$ with eigenvalue ρ are linearly independent. □

At this point we add a few remarks.

(i) Above we have always assumed that Γ contains, apart from unity, only hyperbolic elements; hence there are no elements of finite order. Thus one can construct a real-valued multiplier system by simply assigning ± 1 to the generators of Γ and extending this to $\bar{\Gamma}$. If one also allows for elliptic elements this clearly will not work.

(ii) Lemma 2 says that D_k and D_{2-k} possess identical nonvanishing eigenvalues (including multiplicities). According to (2.2), the weights k and $2-k$, up to sign correspond to the same magnetic field strengths. We will therefore restrict subsequent discussions to the case $k \geq 1$.

(iii) In general, quantum systems with half-integer spin share the same behavior under time reversal as in the present case. For the respective quantum Hamiltonians, the multiplicity two of their eigenvalues due to time-reversal symmetry is known as Kramers' degeneracy.[24] Moreover, magnetic fields usually break time-reversal invariance. This is the reason for the special role played by the weight $k=1$.

(iv) In his tenfold-way scheme Zirnbauer classified quantum systems according to their behavior under basic symmetry operations like time-reversal, rotations, and chiral transformations.[36] The resulting symmetry classes are unambiguously linked with Cartan's ten classes of symmetric spaces. In this context the present case, with time-reversal symmetry, $T^2=-\mathrm{Id}$, and chiral symmetry is identified as the type *C*II and is related to the symmetric space $\mathrm{Sp}(p+q)/\mathrm{Sp}(p)\times\mathrm{Sp}(q)$ (of compact type).

(v) Following the conjecture of Bohigas, Giannoni, and Schmit,[6] one expects that, generically, correlations among the eigenvalues of geometric operators on manifolds of negative curvature can be described by random matrix theory. (See, however, exceptions when the Fuchsian group is arithmetic.[5,9]) The relevant random matrix ensemble for the present case is the chiral Gaussian symplectic ensemble (chGSE).

From supersymmetry considerations (see, e.g., Ref. 35) it is known that eigenvalues of the square of a Dirac operator have even multiplicities. We stress that this observation is unrelated to Lemma 2. Rather, this degeneracy stems from chiral symmetry (Lemma 1) combined with the squaring.

However, the degeneracy due to time reversal somewhat unexpectedly extends to the spectrum of D_k for odd weight. To this end we recall that the Maaß operator K_k raises the weight by two, without changing the eigenvalue of an eigenform of the appropriate Maaß-Laplacian.[29,30] It hence maps ${}^L\mathfrak{F}_\lambda(\Gamma,k,\chi)$ to ${}^L\mathfrak{F}_\lambda(\Gamma,k+2,\chi)$. The operator Λ_{k+2} is its formal adjoint from ${}^L\mathfrak{L}^2(\Gamma,k+2,\chi)$ to ${}^L\mathfrak{L}^2(\Gamma,k,\chi)$. As a consequence, up to the special eigenvalues (3.2) the spectrum of $-\Delta_k$ depends only on k mod 2.

Lemma 3: Let Γ *be a strictly hyperbolic group and* χ *a real-valued multiplier system. If the weight k is odd the eigenvalues of the Maaß-Laplacian* Δ_k *have a multiplicity of (at least) two.*

Proof: For odd $k=2m+1$, the multiplicities of the special eigenvalues (3.2) are known to be $(g-1)2(m-j)$; see Ref. 19 and after Eq. (3.2). In all other cases the statement follows immediately from Proposition 1 and Lemma 2. □

Apart from the special eigenvalues, a twofold degeneracy of the eigenvalues can also be obtained in a constructive way. To this end, one first lowers the weight from $k=2m+1$, $m \in \mathbb{N}_0$, to one by successive applications of operators Λ_l, then applies complex conjugation (i.e., time reversal for spin zero), and finally raises the weight back to $k=2m+1$. Altogether, one thus applies the antilinear operator

$$ {}^L S_{2m+1} := C\Lambda_{-2m+1}\Lambda_{-2m+3}\ldots\Lambda_{2m+1}. \tag{4.1}$$

Now some straightforward calculations show that this way an eigenform ψ is mapped to a linearly independent eigenform $\phi={}^L S_{2m+1}\psi$ of the same weight and with the same eigenvalue. In particular, ϕ may only vanish when its eigenvalue is of the special type (3.2).

We stress that this argument fails if k is even. In the case $k=0$ it is easy to see that if $\psi \in {}^L\mathfrak{F}_\rho(\Gamma,0,\chi)$, then $C\psi \in {}^L\mathfrak{F}_\rho(\Gamma,0,\chi)$, as long as χ is real. But it is well known that for $k=0$ the eigenforms can be chosen to be real valued, so ψ and $C\psi$ are not linearly independent.

Of course, according to Proposition 1, the degeneracy in the spectra of Maaß-Laplacians implies a corresponding degeneracy in the spectra of the Dirac operators D_k. Except for the eigenvalues that derive from the special eigenvalues (3.2) of the associated Maaß-Laplacian, one can again devise a constructive approach that reveals more clearly that the degeneracy is a consequence of a "generalized time reversal symmetry." To this end we introduce the operator

$$A_k^\dagger := \begin{pmatrix} \rho' K_k & 0 \\ \mathrm{i}k & \rho K_{k-2} \end{pmatrix}.$$

This maps $\mathfrak{F}_\rho(\Gamma,k,\chi)$ into $\mathfrak{F}_{\rho'}(\Gamma,k+2,\chi)$, where ρ' is determined by $\rho^2+k=\rho'^2$ and $\mathrm{sgn}(\rho')=\mathrm{sgn}(\rho)$. From Ref. 29, Satz 5.3 one can deduce that $A_k^\dagger$ indeed is an isomorphism between $\mathfrak{F}_\rho(\Gamma,k,\chi)$ and $\mathfrak{F}_{\rho'}(\Gamma,k+2,\chi)$ if $\rho\neq 0$. Its formal adjoint reads as

$$A_{k+2} := -\begin{pmatrix} \rho' \Lambda_{k+2} & \mathrm{i}k \\ 0 & \rho \Lambda_k \end{pmatrix}.$$

The analog to the operator (4.1) now is

$$S_{2m+1} := B_{2m-1}^\dagger \ldots B_1^\dagger T C_3 \ldots C_{2m+1},$$

where $B_k^\dagger := (1/\rho)A_k^\dagger$ and $C_k=(1/\rho')\mathrm{A}_k$. A direct calculation shows that S_{2m+1} does not depend on ρ.

Proposition 2: Let $k=2m+1$ and assume that the multiplier system χ is real valued. Then the eigenvalues of the weighted Dirac operator D_{2m+1} occur with multiplicities of at least two. Moreover,

$$S_{2m+1} = T\begin{pmatrix} \Lambda_{-2m+3}\Lambda_{-2m+5}\cdots\Lambda_{2m+1} & 0 \\ 0 & \Lambda_{-2m+1}\Lambda_{-2m+3}\cdots\Lambda_{2m-1} \end{pmatrix}$$

is identical on all spaces $\mathfrak{F}_\rho(\Gamma,2m+1,\chi)$ of eigenforms, and can therefore be extended to all of $\mathfrak{C}^\infty(\Gamma,2m+1,\chi)$. Then $\Psi\in\mathfrak{F}_\rho(\Gamma,2m+1,\chi)$ implies $\Phi := S_{2m+1}\Psi \in \mathfrak{F}_\rho(\Gamma,2m+1,\chi)$ and $\langle\Phi,\Psi\rangle_{L^2}=0$. For $m>0$ the form Φ vanishes identically iff ρ is related to one of the special eigenvalues (3.2) via $\lambda_j^{(k)}=\rho^2+(k/2)(1-k/2)$.

Proof: The statement about the multiplicities of eigenvalues is implied by Proposition 1 and Lemma 3. The conclusions $\Phi\in\mathfrak{F}_\rho(\Gamma,k,\chi)$ and $\langle\Phi,\Psi\rangle_{L^2}=0$ follow directly from the preceding considerations. One must only take care of the possibility that Φ may vanish. But evaluating $\|\Phi\|_{L^2}$ shows that this norm is zero, iff $\lambda=\rho^2+(k/2)(1-k/2)$ is of the form (3.2). □

V. POINT-PAIR INVARIANTS

From the case of the Laplacian it is well known that setting up a Selberg trace formula amounts to calculating traces of Hilbert-Schmidt operators L that commute with the Laplacian.[33,19,20] The kernels of such operators can be obtained from suitable Poincaré series over so-called point-pair invariants, whose construction will be briefly outlined in this section.

We first introduce two matrix-valued functions on the upper half-plane, which help to study transformation properties under fractional linear transformations,

$$A(z',z) := \begin{pmatrix} \dfrac{(z-\bar{z}')^{1/2}}{(z'-z)^{1/2}} & 0 \\ 0 & \dfrac{(z'-\bar{z})^{1/2}}{(\bar{z}-\bar{z}')^{1/2}} \end{pmatrix},$$

$$B(z',z) := \begin{pmatrix} \dfrac{(z'-z)^{1/2}}{(z'-\bar{z})^{1/2}} & 0 \\ 0 & \dfrac{(\bar{z}-\bar{z}')^{1/2}}{(z-\bar{z}')^{1/2}} \end{pmatrix}.$$

Definition 3: Let $\Phi=\begin{pmatrix}\Phi_1 & \Phi_2 \\ \Phi_3 & \Phi_4\end{pmatrix}:[1,\infty)\to\mathbb{R}^{2\times 2}$ be continuous. Assume, moreover, that $\Phi_2=\Phi_3$ and that there exists a constant C_ϵ such that each component satisfies

$$|\Phi_i(\sigma)| \leq C_\epsilon \sigma^{-1-\epsilon}, \tag{5.1}$$

for some $\epsilon > 0$. Then we call

$$K(z',z) = -\mathrm{i}A(z',z)\Phi\left(\frac{1}{2}(\cosh(d(z',z)+1))\right)B(z',z),$$

where $d(z',z)$ denotes the hyperbolic distance of two points $z,z' \in \mathbb{H}^2$, a point-pair invariant.

Applying any transformation $\gamma \in \mathrm{SL}(2,\mathbb{R})$ yields

$$K(\gamma z', \gamma z) = J_\gamma(z',1)K(z',z)J_\gamma^{-1}(z,1).$$

The restrictions on the components of Φ assure that K is Hermitian, i.e., $K(z',z)=K^\dagger(z,z')$. In order to proceed we need a technical lemma, which can be found in Ref. 19.

Lemma 4: Let $f:[1,\infty)\to\mathbb{C}$ *and* $\epsilon>0$. *Moreover, assume that*

$$f(\sigma) \leq C_\epsilon \sigma^{-1-\epsilon}$$

holds for all σ *and a constant* C_ϵ. *Then the sum*

$$\sum_{\gamma\in\bar{\Gamma}} f\left(\tfrac{1}{2}(\cosh(d(z',\gamma z))+1)\right)$$

converges absolutely and uniformly for all $z',z \in \mathbb{H}^2$.

Starting from the point-pair invariant, we can now construct automorphic kernels via Poincaré series. Due to our restrictions on Φ,

$$K_\Gamma(z',z) = \frac{1}{2}\sum_{\gamma\in\bar{\Gamma}} K(z',\gamma z)\chi(\gamma)J_\gamma(z,1) \tag{5.2}$$

is well defined. Some standard manipulations show that the behavior of K_Γ under transformations is given by

$$K_\Gamma(\gamma_1 z', \gamma_2 z) = \chi(\gamma_1)J_{\gamma_1}(z',1)K_\Gamma(z',z)J_{\gamma_2}^{-1}(z,1)\chi^{-1}(\gamma_2). \tag{5.3}$$

This allows us to define automorphic kernels.

Definition 4: Let F be a fundamental domain for the Fuchsian group Γ. We say that $K_\Gamma:\mathbb{H}^2\times\mathbb{H}^2\to\mathbb{C}^{2\times 2}$ is an element of $\mathfrak{L}^2(\Gamma\backslash\mathbb{H}^2,\Gamma\backslash\mathbb{H}^2,\chi)$, if (5.3) holds for all $\gamma\in\bar{\Gamma}$ and

$$\|K_\Gamma\|_{\mathrm{L}^2}^2 := \int_F\int_F \mathrm{tr}(K_\Gamma^\dagger(z',z)K_\Gamma(z',z))\mathrm{d}\mu(z)\mathrm{d}\mu(z') < \infty .$$

It is well known that such an automorphic kernel defines a Hilbert-Schmidt operator $L:\mathfrak{L}^2(\Gamma,1,\chi)\to\mathfrak{L}^2(\Gamma,1,\chi)$ via

$$[L\Psi](z') := \int_F K_\Gamma(z',z)\Psi(z)\mathrm{d}\mu(z).$$

If K_Γ is Hermitian there exists a basis $\{\Psi_n\}$ of orthonormal eigenforms of L in $\mathfrak{L}^2(\Gamma,1,\chi)$ such that $K_\Gamma(z',z)=\Sigma_n a_n\Psi_n(z')\Psi_n^\dagger(z)$. Furthermore, if K_Γ was constructed from a point-pair invariant via (5.2), then one can easily check that the operator L has a finite trace that is given by $\Sigma_n a_n$. In the following section we will construct point-pair invariants from a Green's function and then calculate such traces.

VI. THE TRACE FORMULA

Before we can proceed to introduce point-pair invariants, we have to identify Green's functions for Dirac operators on surfaces $\Gamma\backslash\mathbb{H}^2$. For this, and the following, we restrict our attention to the Dirac operator itself, i.e., to the weight $k=1$. The starting point will be a Green's function for D on the hyperbolic plane, from which the corresponding Green's function on the compact surface can be obtained in terms of a Poincaré series.

Since the resolvent of D is a bounded operator when $\mathrm{Im}(\rho)<0$, we can make the ansatz

$$(D+\rho)^{-1}\Psi(z') = \int_{\mathbb{H}^2} G(z',z;\rho)\Psi(z)\mathrm{d}\mu(z),$$

with $G(\cdot,\cdot;\rho):\mathbb{H}^2\times\mathbb{H}^2\to\mathbb{C}^{2\times 2}$. For the matrix entries of G, we use the notation $G=\begin{pmatrix} G_1 & G_2 \\ G_3 & G_4 \end{pmatrix}$. Then G can be uniquely characterized as a solution of the matrix-differential equation

$$(D+\rho)G(z',z;\rho) = 0, \quad \text{for } z\neq z', \tag{6.1}$$

with a specified behavior in a neighborhood of $z=z'$. That is, for the diagonal matrix entries

$$\lim_{d(z',z)\to 0}\left(G_i(z',z;\rho) - \frac{\rho}{4\pi}\log(d(z',z))\right) < \infty, \quad i=1,4,$$

is required, whereas the nondiagonal entries are regular in $z=z'$. In addition, $G_i(z',z;\rho)$ must approach zero as $d(z',z)\to\infty$.

Furthermore, the transformation property (3.4) implies the corresponding behavior,

$$G(z',z;\rho) = J_\gamma^{-1}(z',1)G(\gamma z',\gamma z;\rho)J_\gamma(z,1),$$

of the Green's function under an isometry $\gamma\in\mathrm{PSL}(2,\mathbb{R})$.

In order to solve for this Green's function we closely follow Refs. 29 and 30, where the corresponding problem for the Maaß-Laplacians is treated. We begin with introducing

$$\check{G}(z',z;\rho) := A^{-1}(z',z)G(z',z;\rho)B^{-1}(z',z),$$

which is invariant under $\mathrm{PSL}(2,\mathbb{R})$, and note that $\check{D}:=A^{-1}(z,\mathrm{i})DA(z,\mathrm{i})$ is invariant under the stability group $\mathrm{PSO}(2,\mathbb{R})$ of $z=\mathrm{i}$. Therefore, the differential equation for $\check{G}$ corresponding to (6.1) is transformed into polar coordinates (σ,ϕ) for $z\in\mathbb{H}^2$, where $\sigma=\frac{1}{2}(\cosh(d(z,z'))+1)$. With $H(\sigma;\rho)=\check{G}(z',z;\rho)$, this leads to a system of ordinary linear differential equations for $H=\begin{pmatrix} H_1 & H_2 \\ H_3 & H_4 \end{pmatrix}$,

$$\begin{pmatrix} \rho & \mathrm{i}\left[(\sigma(\sigma-1))^{1/2}\dfrac{\partial}{\partial\sigma}+\dfrac{1}{2}\left(\dfrac{\sigma-1}{\sigma}\right)^{1/2}\right] \\ \mathrm{i}\left[(\sigma(\sigma-1))^{1/2}\dfrac{\partial}{\partial\sigma}+\dfrac{1}{2}\left(\dfrac{\sigma-1}{\sigma}\right)^{1/2}\right] & \rho \end{pmatrix} H(\sigma;\rho)$$

$$= -\mathrm{i}\begin{pmatrix} \dfrac{1}{2}(\sigma(\sigma-1))^{-1/2}H_3(\sigma;\rho) & 0 \\ 0 & \dfrac{1}{2}(\sigma(\sigma-1))^{-1/2}H_2(\sigma;\rho) \end{pmatrix}. \tag{6.2}$$

The solution of (6.2) for $\sigma\to\infty$ is given by

$$H_1(\sigma;\rho) = -\frac{\rho}{4\pi}\sigma^{-\frac{1}{2}-i\rho}\frac{\Gamma(i\rho)\Gamma(i\rho+1)}{\Gamma(2i\rho+1)}F\left(i\rho,1+i\rho;1+2i\rho;\frac{1}{\sigma}\right)$$
$$= -\frac{\rho}{4\pi}\sigma^{-\frac{1}{2}}\int_0^1 t^{i\rho}(1-t)^{i\rho-1}(\sigma-t)^{-i\rho}\,dt, \tag{6.3}$$

and

$$H_2(\sigma;\rho) = -\frac{i}{4\pi}\sigma^{-1-i\rho}(\sigma-1)^{1/2}\frac{\Gamma^2(i\rho+1)}{\Gamma(2i\rho+1)}F\left(1+i\rho,1+i\rho;1+2i\rho;\frac{1}{\sigma}\right)$$
$$= \frac{\rho}{4\pi}(\sigma-1)^{1/2}\int_0^1 t^{i\rho}(1-t)^{i\rho-1}(\sigma-t)^{-i\rho-1}\,dt, \tag{6.4}$$

where $F(a,b;c;z)$ is a hypergeometric function (see, e.g., Ref. 14). Moreover, $H_3(\sigma;\rho) = H_2(\sigma;\rho)$ and $H_4(\sigma;\rho) = H_1(\sigma;\rho)$. From this representation we infer an upper bound for the components of the Green's function,

$$|G_i(z',z;\rho)| \le \text{const}|\rho|e^{-(1/2-\text{Im}(\rho))d(z',z)}, \quad \text{if } d(z',z) \ge d_0 > 0. \tag{6.5}$$

As the singularity of G for $d(z',z)\to 0$ is integrable, we obtain the following lemma.

Lemma 5: Let $f:\mathbb{H}^2\to\mathbb{C}^2$ *be bounded and continuous, then*

$$\int_{\mathbb{H}^2} G(z',z;\rho)f(z)d\mu(z)$$

converges absolutely and uniformly in $\text{Re}(\rho)$ *as long as* $\text{Im}(\rho) < -\frac{1}{2}$.

With Lemma 4 and the estimate (6.5), the Green's function for the Dirac operator on a compact surface can now be obtained in terms of a Poincaré series (5.2).

Lemma 6: Let $\text{Im}(\rho) < -\frac{1}{2}$; *then*

$$G_\Gamma(z',z;\rho) := \frac{1}{2}\sum_{\gamma\in\bar{\Gamma}} G(z',\gamma z;\rho)\chi(\gamma)J_\gamma(z,1)$$

converges for $z \ne z' \bmod \Gamma$, *and is the Green's function for D on* $\Gamma\backslash\mathbb{H}^2$.

We are now in a position to construct point-pair invariants as in Definition 3 through

$$\Phi(\sigma) := \frac{1}{\pi}\int_{-\infty}^{\infty} H(\sigma;\rho)h(\rho)d\rho,$$

where h is a function, as specified below.

Definition 5: A function $h:\mathbb{C}\to\mathbb{C}$ that satisfies the following:

- h is even, i.e. $h(\rho)=h(-\rho)$,
- h is complex analytic in the strip $|\text{Im}(\rho)| \le \beta$ for some fixed $\beta \ge \frac{1}{2}+\epsilon$,
- there exists $\delta > 0$, such that the bound

$$|h(\rho)| \le \text{const}(1+\text{Re}(\rho))^{-2-\delta}$$

holds uniformly for all ρ in the above mentioned strip, is called an admissible test function.

We denote the Fourier transform of an admissible test function by

$$g(u) := \frac{1}{2\pi}\int_{-\infty}^{\infty} h(\rho)\mathrm{e}^{-\mathrm{i}\rho u}\,\mathrm{d}\rho.$$

All that we have to check that this indeed leads to a point-pair invariant is the condition (5.1).

Lemma 7: Let $\sigma-1\geq\kappa>0$; *then the components* K_i *of* K *are bounded from above by*

$$|K_i(z',z)| \leq C_\kappa \mathrm{e}^{-(1/2+\beta)d(z',z)}, \quad i=1,\ldots,4, \tag{6.6}$$

with some $C_\kappa>0$. *Furthermore, the limit* $\lim_{d(z',z)\to 0}K(z',z)$ *is well defined. More precisely, we have*

$$\operatorname{tr} K(z,z) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \rho h(\rho)\coth(\pi\rho)\mathrm{d}\rho.$$

Proof: To prove the first part one shifts the integral by $-i\beta$. Using the estimate (6.5) on G_i and shifting back, the bound (6.6) follows immediately. For the second part we note that

$$\lim_{\sigma\to 1^+}\frac{1}{4\pi}\int_{-\infty}^{\infty}\rho h(\rho)\log(\sigma-1)\mathrm{d}\rho = 0;$$

thus we can add this term to Φ. Then again shifting the integral by $-\mathrm{i}\epsilon$ and using Ref. 26, p. 44, one obtains

$$\lim_{d(z',z)\to 0} K_i(z',z) = \frac{1}{4\mathrm{i}\pi^2}\int_{-\infty-\mathrm{i}\epsilon}^{\infty-\mathrm{i}\epsilon}\rho h(\rho)[\psi(\mathrm{i}\rho)+\psi(\mathrm{i}\rho+1)]\mathrm{d}\rho, \quad i=1,4,$$

where $\psi(z)=(\mathrm{d}/\mathrm{d}z)\log\Gamma(z)$. After substituting ρ by $-\rho$ and using the fact that h is even, the statement follows immediately. □

Having shown that K is indeed a point-pair invariant, we can introduce the automorphic kernel,

$$K_\Gamma(z',z) := \frac{1}{2}\sum_{\gamma\in\bar{\Gamma}} K(z',\gamma z)\chi(\gamma)J_\gamma(z,1), \tag{6.7}$$

which by construction is in $\mathfrak{L}^2(\Gamma\backslash\mathbb{H}^2,\Gamma\backslash\mathbb{H}^2,\chi)$. The corresponding Hilbert-Schmidt operator on $\mathfrak{L}^2(\Gamma,1,\chi)$ is called L.

Lemma 8: Any $\Psi\in\mathfrak{F}_\rho(\Gamma,1,\chi)$ *is simultaneously an eigenform of the Hilbert-Schmidt operator* L,

$$[L\Psi](z') = \Lambda(\rho)\Psi(z'),$$

where the eigenvalue Λ *satisfies the equation*

$$\Lambda(\rho)+\Lambda(-\rho) = 2h(\rho). \tag{6.8}$$

Proof: With

$$[L\psi](z') = \frac{1}{2\pi\mathrm{i}}\int_F\left(\sum_{\gamma\in\bar{\Gamma}}\int_{-\infty}^{\infty} h(\rho)G(z',\gamma z;\rho)\chi(\gamma)J_\gamma(z,1)\mathrm{d}\rho\right)\Psi(z)\mathrm{d}\mu(z),$$

a standard calculation yields

$$[L\psi](z') = \frac{1}{\pi\mathrm{i}}\int_{-\infty-\mathrm{i}\beta}^{\infty-\mathrm{i}\beta} h(\rho')\left(\int_F G_\Gamma(z',z;\rho')\Psi(z)\mathrm{d}\mu(z)\right)\mathrm{d}\rho'.$$

From this we read off the eigenvalue of L as

$$\Lambda(\rho) = \frac{1}{2\pi \mathrm{i}} \int_{-\infty-\mathrm{i}\beta}^{\infty-\mathrm{i}\beta} \frac{h(\rho')}{\rho' - \rho} \mathrm{d}\rho',$$

and this implies (6.8). □

As already noted in Sec. IV, the spectrum of the Dirac operator on a compact surface is real and discrete. Moreover, according to Lemma 1, the spectrum is symmetric with respect to zero. We hence denote the non-negative eigenvalues (listed with their respective multiplicities) by $0 \leq \rho_0 \leq \rho_1 \leq \cdots$, which include N of the $2N$ zero modes. The Hilbert space $\mathfrak{L}^2(\Gamma, 1, \chi)$ therefore has a basis of orthonormal eigenforms $\Psi_{n,\pm}$,

$$(D \pm \rho_n)\Psi_{n,\pm} = 0.$$

Thus the automorphic kernel possesses a spectral expansion of the form

$$K_\Gamma(z', z) = \sum_{n=0}^{\infty} \left(\Lambda(\rho_n)\Psi_{n,+}(z')\Psi_{n,+}^\dagger(z) + \Lambda(-\rho_n)\Psi_{n,-}(z')\Psi_{n,-}^\dagger(z)\right),$$

which immediately yields the spectral side of the desired trace formula.

Lemma 9: The Hilbert-Schmidt operator L has a finite trace, given by

$$\mathrm{tr}(L) = 2\sum_{n=0}^{\infty} h(\rho_n).$$

Next, we need to compute the geometric side of the trace formula, i.e.,

$$\mathrm{tr}(L) = \int_F K_\Gamma(z, z)\mathrm{d}\mu(z),$$

with the representation (6.7) of the automorphic kernel. Following a standard procedure, this yields

$$\mathrm{tr}(L) = \frac{1}{2}\sum_{\{\gamma\}} \chi(\gamma) \sum_{[g] \in \bar{Z}_\gamma \backslash \bar{\Gamma}} \mathrm{tr}\left(\int_{gF} K(z, \gamma z) J_\gamma(z, 1)\mathrm{d}\mu(z)\right), \tag{6.9}$$

where $\{\gamma\}$ denotes the $\bar{\Gamma}$-conjugacy classes of $\gamma \in \bar{\Gamma}$ and $\bar{Z}_\gamma$ is the centralizer of γ in $\bar{\Gamma}$. Next, we use the natural pairing of the disjoint conjugacy classes $\{\gamma\}$ and $\{-\gamma\}$, which cancels the factor $\frac{1}{2}$. Within these pairs we choose the conjugacy classes with $\mathrm{tr}(\gamma) > 0$. Moreover, it is well known that

$$D_\gamma := \bigcup_{[g] \in Z_\gamma \backslash \Gamma} g(F)$$

is a fundamental set for the centralizer $Z_\gamma \subset \Gamma$. Introducing primitive hyperbolic elements γ_p and their conjugacy classes, one can rewrite (6.9) as

$$\mathrm{tr}(L) = \mathrm{tr}\left(\int_F K(z, z)\mathrm{d}\mu(z)\right) + \sum_{\{\gamma_p\}} \sum_{n=1}^{\infty} \chi(\gamma_p^n)\mathrm{tr}\left(\int_{D_{\gamma_p}} K(z, \gamma_p^n z) J_{\gamma_p^n}(z, 1)\mathrm{d}\mu(z)\right).$$

Upon a conjugation with a matrix in $\mathrm{SL}(2, \mathbb{R})$, any hyperbolic element can be brought into the Jordan normal form

$$\gamma = \begin{pmatrix} e^{\frac{l_\gamma}{2}} & 0 \\ 0 & e^{-\frac{l_\gamma}{2}} \end{pmatrix}.$$

A fundamental domain for the group generated by γ is given by $\{z \in \mathbb{H}^2 | 1 < y < e^{l_\gamma}\}$. Note that $J_\gamma(z,1)=1$, so all that remains to be done is evaluating integrals of the form

$$I(\gamma^n) = \mathrm{tr}\left(\int_1^{e^l} \int_{-\infty}^{\infty} K(z, \gamma^n z) \mathrm{d}x \frac{\mathrm{d}y}{y^2} \right). \tag{6.10}$$

In order to calculate this integral, we introduce

$$\tau = \cosh^2 \frac{nl}{2} + \left(\frac{x}{y} \sinh \frac{nl}{2} \right)^2,$$

which allows us to perform the integration with respect to y. Inserting the explicit expressions (6.3) and (6.4) for the function H, the integral (6.10) reduces to

$$I(\gamma^n) = \frac{\mathrm{i} l_\gamma}{2\pi^2} \coth \frac{n l_\gamma}{2} \int_{-\infty}^{\infty} \rho h(\rho)$$
$$\times \int_{\cosh^2 \frac{n l_\gamma}{2}}^{\infty} \tau^{-1-\mathrm{i}\rho} \left(\tau - \cosh^2 \frac{n l_\gamma}{2} \right)^{-1/2} \sum_{m=0}^{\infty} \frac{\Gamma(\mathrm{i}\rho + m)\Gamma(\mathrm{i}\rho + m + 1)}{\Gamma(2\mathrm{i}\rho + m + 1) m!} \tau^{-m} \, \mathrm{d}\tau \, \mathrm{d}\rho.$$

Interchanging the order of integration and summation and employing the relation

$$\left(\frac{1}{2\cosh\left(\frac{a}{2}\right)} \right)^{-2q} \sum_{m=0}^{\infty} \frac{2q\Gamma(2q+2m)}{\Gamma(2q+m+1)m!} \left(\frac{1}{2\cosh\left(\frac{a}{2}\right)} \right)^{-2m} = e^{-qa},$$

which follows from Ref. 16, 1.114 for $a>0$ and $\mathrm{Re}(q)>0$, finally yields

$$I(\gamma^n) = \frac{l_\gamma}{\sinh \frac{n l_\gamma}{2}} \frac{1}{2\pi} \int_{-\infty}^{\infty} h(\rho) e^{-\mathrm{i}\rho n l_\gamma} \, \mathrm{d}\rho = \frac{l_\gamma g(n l_\gamma)}{\sinh\left(\frac{n l_\gamma}{2}\right)}. \tag{6.11}$$

Putting together Lemma 7, Lemma 9, and Eq. (6.11) then leads to the desired trace formula.

Theorem 1 (Selberg trace formula for the Dirac operator): *Let $\Gamma \subset \mathrm{PSL}(2,\mathbb{R})$ be a strictly hyperbolic Fuchsian group with fundamental domain F of area $A(F)$ and fix a multiplier system χ of weight one. Moreover, let $\{\rho_n\}_{n=0}^{\infty}$ be the non-negative eigenvalues of the Dirac operator D on $\mathfrak{L}^2(\Gamma,1,\chi)$, including half of the zero modes. Then, for any admissible test function h, see Definition 5, the following trace formula holds*:

$$\sum_{m=0}^{\infty} h(\rho_m) = \frac{A(F)}{4\pi} \int_{-\infty}^{\infty} \rho h(\rho) \coth(\pi\rho) \mathrm{d}\rho + \sum_{\{\gamma_p\}} \sum_{n=1}^{\infty} \chi(\gamma_p^n) \frac{l_{\gamma_p} g(n l_{\gamma_p})}{2 \sinh\left(\frac{n l_{\gamma_p}}{2}\right)}. \tag{6.12}$$

In accordance with Proposition 1, this trace formula is identical to the one for the Maaß-Laplacian $-\Delta_1$ on the same surface and with the same multiplier system. We stress, however, a difference in the interpretation of the geometric side. Both expressions can be viewed as sums over the closed geodesics on $\Gamma\backslash\mathbb{H}^2$, weighted with the factors $\chi(\gamma_p^n)$. For the Maaß-Laplacian, these factors stem from the nonvanishing magnetic fluxes that are necessarily present (see, e.g., Ref. 13), whereas for the Dirac operator with weight $k=1$ there is no magnetic field involved. Here the

factors $\chi(\gamma_p^n)$ reflect the fact that the classical dynamical system associated with the quantum dynamics generated by the Dirac operator is not the geodesic flow, but its associated frame flow; see also Ref. 23. This is analogous to Dirac operators on $\mathbb{R}^3$.[8]

The frame flow (see, e.g., Ref. 10) is a flow in the frame bundle FM over a Riemannian manifold M consisting of a parallel transport of oriented orthonormal frames along geodesics. To be precise, let $\{e_1(p),\ldots,e_n(p)\}$ be an orthonormal basis of T_pM. Then this frame is transported along the geodesic determined by e_1 with the Levi-Civita connection. This flow can be lifted into the spin structure by assigning an element $g(p)\in \mathrm{Spin}(n)$ to every point along the geodesic. This may also be done in the spin representation yielding $\rho(g(p))$. In the present case, where $M=\Gamma\backslash\mathbb{H}^2$, $\rho(g(z))$ must equal $\rho(g(\gamma z))$ for every $\gamma\in\bar{\Gamma}$. However, in the induced (trivial) bundle over the hyperbolic plane, the transformation property,

$$\rho(g(\gamma z))=\chi(\gamma)J_\gamma(z,1)\rho(g(z)),$$

applies; see (3.1) and (3.3). The factors $\chi(\gamma_p^n)$ in Eq. (6.12) therefore reflect the spin structure. Hence, although on two-dimensional manifolds the frame flow is not much different from the geodesic flow, only the latter is a natural dynamics that can be lifted into the spin structure. For $n\geq 3$ the situation will be different since in such a case a frame flow yields interesting classical dynamics beyond the geodesic flow.

VII. SOME APPLICATIONS

A first immediate application of the trace formula, which can be proved in the standard way (see, e.g., Ref. 19), concerns the asymptotic distribution of the eigenvalues.

Proposition 3 (Weyl's law): *Let $N(\rho)$ be the number of non-negative eigenvalues of D that are smaller than ρ. Then*

$$N(\rho)\sim\frac{A(F)}{4\pi}\rho^2,\quad \rho\to\infty.$$

This result also follows from Ref. 22.

Another application consists of determining properties of the related Selberg zeta function. If $\mathrm{Re}(s)$, $\mathrm{Re}(\sigma)>1$, the function

$$h(\rho):=\frac{1}{\rho^2+\left(s-\frac{1}{2}\right)^2}-\frac{1}{\rho^2+\left(\sigma-\frac{1}{2}\right)^2}$$

satisfies the criteria of Definition 5 to serve as an admissible test function. In the trace formula (6.12), it leads to a relation for the trace of a regularized resolvent,

$$\sum_{m=0}^{\infty}\left(\frac{1}{\rho_m^2+\left(s-\frac{1}{2}\right)^2}-\frac{1}{\rho_m^2+\left(\sigma-\frac{1}{2}\right)^2}\right)=-\frac{A(F)}{2\pi}\left(\psi\left(s-\tfrac{1}{2}\right)-\psi\left(\sigma-\tfrac{1}{2}\right)\right)+\frac{A(F)}{4\pi}\left(\frac{1}{\sigma-\frac{1}{2}}-\frac{1}{s-\frac{1}{2}}\right)$$
$$+\frac{1}{2s-1}\frac{Z'(s)}{Z(s)}-\frac{1}{2\sigma-1}\frac{Z'(\sigma)}{Z(\sigma)}.$$

Here $Z(s)$ is Selberg's zeta function, which is defined by

$$Z(s):=\prod_{\{\gamma_p\}}\prod_{k=0}^{\infty}(1-\chi(\gamma_p)\mathrm{e}^{-l_{\gamma_p}(k+s)}),\quad \mathrm{Re}(s)>1.$$

Now proceeding along the lines of Refs. 34 and 32, we find an analytic continuation of $Z(s)$ into the entire complex plane.

Proposition 4: The Selberg zeta function for the Dirac operator is an entire analytic function. Moreover, it can be represented as

$$Z(s)=\frac{Z^{(2N)}\left(\frac{1}{2}\right)}{(2N)!}\left(s-\frac{1}{2}\right)^{2N}\mathrm{e}^{(s-1/2)^2\gamma_D}\mathrm{e}^{(s-1/2)\frac{A(F)}{2\pi}}$$
$$\times\left[(2\pi)^{-(s-1/2)}\mathrm{e}^{(s^2-1/4)}G^2\left(s+\frac{1}{2}\right)\right]^{A(F)/2\pi}\prod_{m=N}^{\infty}\left[\left(1+\frac{\left(s-\frac{1}{2}\right)^2}{\rho_m^2}\right)\mathrm{e}^{-(s-1/2)^2/\rho_m^2}\right], \quad (7.1)$$

where G is Barnes' double Γ function (see Ref. 3) and $2N$ denotes the number of zero modes of D. The trivial zeros of $Z(s)$ are given by $s=-\frac{1}{2}-n$ with multiplicities $(2n)^{A(F)/2\pi}$, $n\in\mathbb{N}$. The nontrivial zeros are $s=\frac{1}{2}\pm\mathrm{i}\rho_m$, with the same multiplicities as the eigenvalues ρ_m of D.

In (7.1) the constant γ_D is a generalized Euler constant as introduced in Ref. 34 and $Z^{(2N)}$ denotes a derivative of the zeta function of order $2N$. Moreover, due to the Gauß-Bonnet theorem, $A(F)/2\pi=2(g-1)$ is a positive integer, where g is the genus of the surface $\Gamma\backslash\mathbb{H}^2$.

published online 16 November 2006)

A general technique for the study of magnetic Rashba Hamiltonians in quantum graphs is presented. We use this technique to show how manipulating the magnetic and spin parameters can be used to create localized states in a certain periodic graph (T_3 lattice). © *2006 American Institute of Physics.*

I. INTRODUCTION

In this work, we discuss the creation of eigenvalues in periodic quantum graphs by certain external interactions, namely, by magnetic field and spin-orbit coupling.

The analysis of quantum graphs, i.e., of differential operators on singular one-dimensional manifolds, becomes one of the central topics in the mathematical physics during the last decades; see Refs. 28–33 and 35. This has many reasons; in particular, quantum graph Hamiltonians appear in the de Gennes-Alexander theory of superconductivity.[4,15,25] Some other fields of applications are described, e.g., in Ref. 31.

The spectral theory of compact quantum graphs has many common features, with the usual theory of differential operators; cf. Refs. 6, 42, and 48. Nevertheless, such an analogy is rather limited when considering noncompact structures. Some particular features of quantum graph models become obvious if one studies periodic configurations. For example, for a large class of periodic Schrödinger operators in Euclidian spaces, the spectrum is known to be absolutely continuous,[9,50] while even the simplest periodic quantum graphs can have eigenvalues.[12,33] Some other examples may include the sensibility of periodic quantum graphs to some arithmetic characteristics.[24]

Recently, in the physics literature one discussed the so-called extreme localization in the T_3 lattice (dice lattice).[1,54] From the mathematical point of view, it was shown that under certain magnetic fields the Hamiltonian of a quantum graph with the corresponding shape has no bands of a continuous spectrum, and the spectrum consists of infinitely degenerate eigenvalues. This effect was observed also experimentally by transport measuring in superconducting and metallic wire networks.[39–41] (It is worth emphasizing that bound states in the T_3 lattice appear without any external interactions;[51] the coexistence of the continuous and the point spectra is implied by the rich internal symmetry of the lattice and of its dual, Kagomé.[2]) Various aspects of this localization mechanism and its stability under disorder and external interactions are studied in a number of works.[8,38,52–54] In particular, it is shown that additional interactions, like the interparticle interaction, destroy the extreme localization mechanism, and a continuous spectrum appears.[53]

In Ref. 7 it was shown that in some periodic quantum graphs similar localization phenomena can be induced not only by magnetic fields, but also by the spin-orbit interaction at certain values of the Rashba constant.[14,47] Nevertheless, the numerical analysis of Ref. 8 shows that the Rashba localization does not appear in the T_3 lattice. In the present paper we consider the above situation

with both the spin-orbit and magnetic interactions. We note that the quantum graph models with spin were studied previously, e.g., in Refs. 10, 11, 13, and 27, but the attention was mostly concentrated on Dirac- and Pauli-type operators. The theory of Rashba Hamiltonians is not developed, even in the Euclidian spaces, and the spin-orbit interaction promises to show effects that are absent in the scalar case, like embedded eigenvalues in short-range potentials or localization in crystals, hence giving possibilities for constructing new nanodevices.[17,34]

The aim in this paper is two-fold. First, we are going to describe the Schrödinger operators in two-dimensional networks with magnetic field and spin-orbit interaction. An essential part here is the reduction of the quantum graph Hamiltonian to a certain discrete equation. In the scalar case, an analogous procedure was done in Ref. 23 for the solutions of the stationary Schrödinger equation and recently in Ref. 44 for the spectra. Note that there is another approach to the relationship between the quantum graphs and tight-binding Hamiltonians coming from some asymptotic considerations.[36,37] Second, by considering the localization effects in the T_3 lattice we would like to attract the attention of researchers working on quantum graphs to potential applications in the study of superconducting networks. In Sec. II we give a mathematical formalism of quantum graphs with external interactions; essentially we describe rigorously the constructions of Refs.7 and 8. In Sec. III we use this machinery to study the spectrum of the T_3 lattice with a magnetic field and the Rashba interaction. We show that the spectral problem is of a supersymmetric type and that the study of some energy levels is equivalent to the study of zero modes in a certain discrete model. As a result, we give a rigorous justification of the extreme localization for the case of nontrivial scalar potentials on the edges and nonideal couplings at the nodes. We show that at zero spin-orbit interaction this effect is independent of the edge potential. At the same time, it appears that the generic Rashba interaction destroys the localization. We also show that at a certain combination of the magnetic and spin parameters a new localization effect appears, where one can localize one of the spin projections using the magnetic field.

II. QUANTUM GRAPHS WITH EXTERNAL INTERACTIONS

A. Schrödinger operator on a quantum graph embedded in Euclidian space

In this section we describe the construction of the Hamiltonian in a two-dimensional network with a magnetic field and Rashba interaction. Recall that the Rashba Hamiltonian of a two-dimensional system acts on two-component vector functions and takes the form[14,47]

$$H = (\mathbf{p} - \mathbf{A})^2 + 2k_{\mathrm{R}}\langle \boldsymbol{\sigma}, (\mathbf{p} - \mathbf{A}) \times \mathbf{n}\rangle + U, \tag{1}$$

where $\mathbf{A}$ is the magnetic vector potential, k_{R} is the Rashba constant expressing the strength of the spin-orbit interaction, U is a scalar potential, $\boldsymbol{\sigma}$ is the vector of Pauli matrices, and $\mathbf{n}$ is the unit vector orthogonal to the plane of the system. The second term, which is the formal mixed product on the right-hand side of (1), takes into account the spin-orbit coupling. For $k_{\mathrm{R}}=0$ the problem splits into two identical scalar problems. The corresponding Hamiltonian for a network is obtained by projecting all the interactions onto each edge and by introducing suitable boundary conditions at the nodes, which will be described later. (We remark that some effects of the Rashba interaction and the magnetic field in a wire can be studied in other types of models.[19])

Let $\mathcal{V}$ be a uniformly discrete subset of the xy plane in $\mathbb{R}^3$, the set of nodes (vertices). The uniform discreteness means the existence of a constant $d>0$ such that $|\boldsymbol{\alpha}-\boldsymbol{\beta}| \geqslant d$ for all $\boldsymbol{\alpha}, \boldsymbol{\beta} \in \mathcal{V}$ with a $\boldsymbol{\alpha} \neq \boldsymbol{\beta}$. Denote

$$l_{\boldsymbol{\alpha}\boldsymbol{\beta}} := |\boldsymbol{\alpha} - \boldsymbol{\beta}|, \quad \mathbf{e}_{\boldsymbol{\alpha}\boldsymbol{\beta}} := \frac{1}{l_{\boldsymbol{\alpha}\boldsymbol{\beta}}}(\boldsymbol{\beta} - \boldsymbol{\alpha}).$$

Some nodes are connected by a directed edge. The set of all edges will be denoted by $\mathcal{E}$, $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$. The edge with initial vertex $\boldsymbol{\alpha} \in \mathcal{V}$ and terminal vertex $\boldsymbol{\beta} \in \mathcal{V}$ will be denoted by $\boldsymbol{\alpha}\boldsymbol{\beta}$. For $\boldsymbol{\alpha} \in \mathcal{V}$ denote $\operatorname{indeg} \boldsymbol{\alpha} := \#\{\boldsymbol{\beta}\boldsymbol{\alpha} \in \mathcal{E}\}$, $\operatorname{outdeg} \boldsymbol{\alpha} = \#\{\boldsymbol{\alpha}\boldsymbol{\beta} \in \mathcal{E}\}$, $\deg \boldsymbol{\alpha} := \operatorname{indeg} \boldsymbol{\alpha} + \operatorname{outdeg} \boldsymbol{\alpha}$. We assume that the degrees satisfy the following conditions: that

$$\text{there exists } N \in \mathbb{Z} \text{ with} 1 \leqslant \deg \boldsymbol{\alpha} \leqslant N \text{ for all } \boldsymbol{\alpha} \in \mathcal{V}; \tag{2}$$

in particular, we assume that there are no isolated vertices. The configuration consisting of all segments $[\boldsymbol{\alpha}, \boldsymbol{\beta}]$, $\boldsymbol{\alpha\beta} \in \mathcal{E}$ will be referred to as a metric graph or as a (wire) network. We assume that the system has no self-intersections and that

$$0 < \inf\{l_{\boldsymbol{\alpha\beta}}\} \leqslant \sup\{l_{\boldsymbol{\alpha\beta}}\} < \infty . \tag{3}$$

The quantum state space corresponding to the metric graph is introduced as follows. Each edge $\boldsymbol{\alpha\beta}$ will be identified with the segment $[0, l_{\boldsymbol{\alpha\beta}}]$ such that $\boldsymbol{\alpha}$ is identified with 0 and $\boldsymbol{\beta}$ is identified with $l_{\boldsymbol{\alpha\beta}}$. The state space of each edge $\boldsymbol{\alpha\beta}$ is $\mathcal{H}_{\boldsymbol{\alpha\beta}} := L^2([0, l_{\boldsymbol{\alpha\beta}}], \mathbb{C}^2)$. The state space of the whole structure is $\mathcal{H} = \oplus_{\boldsymbol{\alpha\beta} \in \mathcal{E}} \mathcal{H}_{\boldsymbol{\alpha\beta}}$.

On each edge consider a real-valued scalar potential $U_{\boldsymbol{\alpha\beta}} \in L^2[0, l_{\boldsymbol{\alpha\beta}}]$. To avoid unnecessary technical difficulties we will assume that the scalar potentials are uniformly L^2 bounded,

$$\sup \|U_{\boldsymbol{\alpha\beta}}\|_{L^2} < \infty . \tag{4}$$

Assume that the system is subjected to an external magnetic field given by a vector potential $\mathbf{A} \in C^1(\mathbb{R}^3, \mathbb{R}^3)$. This induces magnetic potentials on each edge, $a_{\boldsymbol{\alpha\beta}}(t) := \langle \mathbf{A}(\boldsymbol{\alpha} + t\mathbf{e}_{\boldsymbol{\alpha\beta}}), \mathbf{e}_{\boldsymbol{\alpha\beta}} \rangle$.

Denote by k_{R} the Rashba constant. The spin-orbit interaction can be taken into account by adding the term $2k_R(-\mathrm{i}(\mathrm{d}/\mathrm{d}t) - a_{\boldsymbol{\alpha\beta}}(t))\langle \boldsymbol{\sigma} \times \mathbf{n}, \mathbf{e}_{\boldsymbol{\alpha\beta}} \rangle$ with $\mathbf{n} = (0, 0, 1)$. Therefore, the dynamics along each edge $\boldsymbol{\alpha\beta}$ is described by the differential expression

$$\begin{aligned} L_{\boldsymbol{\alpha\beta}} &= \left(-\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}t} - a_{\boldsymbol{\alpha\beta}}(t) \right)^2 + 2k_{\mathrm{R}} \left(-\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}t} - a_{\boldsymbol{\alpha\beta}}(t) \right) \langle \boldsymbol{\sigma} \times \mathbf{n}, \mathbf{e}_{\boldsymbol{\alpha\beta}} \rangle + U_{\boldsymbol{\alpha\beta}} \\ &\equiv \left(\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}t} + a_{\boldsymbol{\alpha\beta}}(t) + k_R \sigma_{\boldsymbol{\alpha\beta}} \right)^2 + U_{\boldsymbol{\alpha\beta}} - k_{\mathrm{R}}^2, \end{aligned}$$

where

$$\sigma_{\boldsymbol{\alpha\beta}} = \begin{pmatrix} 0 & e_{\boldsymbol{\alpha\beta}2+\mathrm{i}e_{\boldsymbol{\alpha\beta}1}} \\ e_{\boldsymbol{\alpha\beta}2-\mathrm{i}e_{\boldsymbol{\alpha\beta}1}} & 0 \end{pmatrix}.$$

For a uniform magnetic field with the strength $\mathbf{B} \in \mathbb{R}^3$ it is useful to use the symmetric gauge, $\mathbf{A}(\mathbf{r}) = \frac{1}{2}\mathbf{B} \times \mathbf{r}$. In this case the magnetic potentials $a_{\boldsymbol{\alpha\beta}}$ are constant, $a_{\boldsymbol{\alpha\beta}} = \frac{1}{2}\langle \mathbf{B} \times \boldsymbol{\alpha}, \mathbf{e}_{\boldsymbol{\alpha\beta}} \rangle$.

Denote by L an operator in $\mathcal{H}$, acting as

$$(\mathbf{f}_{\boldsymbol{\alpha\beta}}) \mapsto (\mathbf{L}_{\alpha\beta}\mathbf{f}_{\boldsymbol{\alpha\beta}}) \tag{5}$$

on functions $\mathbf{f}_{\boldsymbol{\alpha\beta}} \in H^2([0, l_{\boldsymbol{\alpha\beta}}], \mathbb{C}^2)$ satisfying, at each $\alpha \in \mathcal{V}$,

$$\mathbf{f}_{\boldsymbol{\alpha\beta}}(0) = \mathbf{f}_{\boldsymbol{\gamma\alpha}}(l_{\boldsymbol{\gamma}}\boldsymbol{\alpha}) =: \mathbf{f}(\boldsymbol{\alpha}), \quad \boldsymbol{\alpha\beta}, \boldsymbol{\gamma\alpha} \in \mathcal{E}, \tag{6a}$$

$$\begin{aligned} &\sum_{\boldsymbol{\alpha\beta} \in \mathcal{E}} \left(\frac{\mathrm{d}}{\mathrm{d}t} - \mathrm{i}(a_{\boldsymbol{\alpha\beta}} + k_R \sigma_{\boldsymbol{\alpha\beta}}) \right) \mathbf{f}_{\boldsymbol{\alpha\beta}}(0) \\ &\quad - \sum_{\boldsymbol{\beta\alpha} \in \mathcal{E}} \left(\frac{\mathrm{d}}{\mathrm{d}t} - \mathrm{i}(a_{\boldsymbol{\beta\alpha}} + k_R \sigma_{\boldsymbol{\beta\alpha}}) \right) \mathbf{f}_{\boldsymbol{\beta\alpha}}(l_{\boldsymbol{\beta\alpha}}) = \varepsilon(\boldsymbol{\alpha}) \mathbf{f}(\alpha), \end{aligned} \tag{6b}$$

where $\varepsilon(\boldsymbol{\alpha})$ are real-valued parameters. The case $\varepsilon(\boldsymbol{\alpha}) = 0$ may be considered as an ideal coupling, which is the analog of the Kirchhoff coupling in the scalar case. We are going to consider L as the Hamiltonian of the system, and our next aim is to show its self-adjointness.

B. Self-adjointness and spectral analysis

Denote by $\mathcal{D}$ the set of all functions $\mathbf{f}=(\mathbf{f}_{\boldsymbol{\alpha\beta}})$, with components $(\mathbf{f}_{\boldsymbol{\alpha\beta}}) \in \oplus H^2([0,l_{\boldsymbol{\alpha\beta}}]\mathbb{C}^2)$, $\boldsymbol{\alpha\beta} \in \mathcal{E}$, which are continuous at all nodes, i.e., such that the condition (6a) is satisfied. Clearly, for $\mathbf{f} \in \mathcal{D}$ the values $\mathbf{f}(\boldsymbol{\alpha})$, $\boldsymbol{\alpha} \in \mathcal{V}$, have the direct sense. Furthermore, for $\mathbf{f} \in \mathcal{D}$ and $\boldsymbol{\alpha} \in \mathcal{V}$ denote

$$\mathbf{f}'(\boldsymbol{\alpha}) := \sum_{\boldsymbol{\alpha\beta}\in\mathcal{E}} \left(\frac{\mathrm{d}}{\mathrm{d}t} - \mathrm{i}(a_{\boldsymbol{\alpha\beta}} + k_{\mathrm{R}}\sigma_{\boldsymbol{\alpha\beta}})\right)\mathbf{f}_{\boldsymbol{\alpha\beta}}(0) - \sum_{\boldsymbol{\beta\alpha}\in\mathcal{E}} \left(\frac{\mathrm{d}}{\mathrm{d}t} - \mathrm{i}(a_{\boldsymbol{\beta\alpha}} + k_R\sigma_{\boldsymbol{\beta\alpha}})\right)\mathbf{f}_{\boldsymbol{\beta\alpha}}(l_{\boldsymbol{\beta\alpha}}).$$

Consider in $\mathcal{H}$ a linear operator Π with domain $\mathcal{D}$ acting by the rule (5).

Proposition 1: The operator Π *is closed. For any* $\mathbf{f} \in \operatorname{dom}\Pi \equiv \mathcal{D}$ *the vectors* $\Gamma\mathbf{f} := (\mathbf{f}(\boldsymbol{\alpha}))$ *and* $\Gamma'\mathbf{f} := (\mathbf{f}'(\boldsymbol{\alpha}))$ *belong to* $\ell^2(\mathcal{V},\mathbb{C}^2)$ *and the map* $(\Gamma,\Gamma'):\operatorname{dom} L \to \ell^2(\mathcal{V},\mathbb{C}^2)\oplus\ell^2(\mathcal{V},\mathbb{C}^2)$, *is surjective. For any* $\mathbf{f},\mathbf{g} \in \operatorname{dom}\Pi$ *there holds*

$$\langle \mathbf{f}, \Pi\mathbf{g}\rangle - \langle \Pi\mathbf{f}, \mathbf{g}\rangle = \langle \Gamma\mathbf{f}, \Gamma'\mathbf{g}\rangle - \langle \Gamma'\mathbf{f}, \Gamma\mathbf{g}\rangle. \tag{7}$$

Proof: Denote by $\Theta_{\boldsymbol{\alpha\beta}}$ the unitary transformation of $\mathcal{H}_{\boldsymbol{\alpha\beta}}$, given by

$$\Theta_{\boldsymbol{\alpha\beta}}\mathbf{f}(t) = \exp\left(\mathrm{i}\int_0^t (a_{\boldsymbol{\alpha\beta}}(s) + k_R\sigma_{\boldsymbol{\alpha\beta}})\mathrm{d}s\right)\mathbf{f}(t). \tag{8}$$

Denoting $\partial := \mathrm{d}/\mathrm{d}t$, we see $(\partial - \mathrm{i}a_{\boldsymbol{\alpha\beta}} - \mathrm{i}k_R\sigma_{\boldsymbol{\alpha\beta}})\Theta_{\boldsymbol{\alpha\beta}} \equiv \Theta_{\boldsymbol{\alpha\beta}}\partial$.

By the Sobolev inequality, for any $c_1 > 0$ there exists $c_2 > 0$ such that for any $l > 0$ and $\varphi \in H^2[0,l]$ there holds that

$$\|\varphi\|_\infty \leqslant c_1 l^{3/2}\|\varphi''\|_{L^2[0,l]} + \frac{c_2}{l^{1/2}}\|\varphi\|_{L^2[0,l]},$$

$$\|\varphi'\|_\infty \leqslant c_1 l^{1/2}\|\varphi''\|_{L^2[0,l]} + \frac{c_2}{l^{1/2}}\|\varphi\|_{L^2[0,l]}.$$

Note that for any $t \in [0,l_{\boldsymbol{\alpha\beta}}]$ one has $\|\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\|_{\mathbb{C}^2} = \|\Theta_{\boldsymbol{\alpha\beta}}\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\|_{\mathbb{C}^2}$. Therefore, using the above estimate, for any $\mathbf{f}_{\boldsymbol{\alpha\beta}} \in H^2([0,l_{\boldsymbol{\alpha\beta}}],\mathbb{C}^2)$, one has

$$\begin{aligned}\|\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\|_{\mathbb{C}^2} &= \|\Theta^*_{\boldsymbol{\alpha\beta}}\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\|_{\mathbb{C}^2} \leqslant c_1 l_{\boldsymbol{\alpha\beta}}^{3/2}\|\partial^2\Theta^*_{\boldsymbol{\alpha\beta}}\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}} + \frac{c_2}{l_{\boldsymbol{\alpha\beta}}^{1/2}}\|\Theta^*_{\boldsymbol{\alpha\beta}}\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}}\\ &= c_1 l_{\boldsymbol{\alpha\beta}}^{3/2}\|\Theta^*_{\boldsymbol{\alpha\beta}}(\partial - \mathrm{i}a_{\boldsymbol{\alpha\beta}} - ik_{\mathrm{R}}\sigma_{\boldsymbol{\alpha\beta}})^2\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}} + \frac{c_2}{l_{\boldsymbol{\alpha\beta}}^{1/2}}\|\Theta^*_{\boldsymbol{\alpha\beta}}\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}}\\ &= c_1 l_{\boldsymbol{\alpha\beta}}^{3/2}\|(\partial - \mathrm{i}a_{\boldsymbol{\alpha\beta}} - ik_{\mathrm{R}}\sigma_{\boldsymbol{\alpha\beta}})^2\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}} + \frac{c_2}{l_{\boldsymbol{\alpha\beta}}^{1/2}}\|\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}},\end{aligned}$$

and, in the same way,

$$\|(\partial - \mathrm{i}a_{\boldsymbol{\alpha\beta}} - \mathrm{i}k_{\mathrm{R}}\sigma_{\boldsymbol{\alpha\beta}})\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\|_{\mathbb{C}^2} \leqslant c_1 l_{\boldsymbol{\alpha\beta}}^{1/2}\|(\partial - \mathrm{i}a_{\boldsymbol{\alpha\beta}} - \mathrm{i}k_{\mathrm{R}}\sigma_{\boldsymbol{\alpha\beta}})^2\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}} + \frac{c_2}{l_{\boldsymbol{\alpha\beta}}^{1/2}}\|\mathbf{f}_{\boldsymbol{\alpha\beta}}\|_{\mathcal{H}_{\boldsymbol{\alpha\beta}}}.$$

Using the assumptions (3) and (4), we conclude that there exist positive constants C_1 and C_2 such that for any $\boldsymbol{\alpha\beta} \in \mathcal{E}$, $\mathbf{f}_{\boldsymbol{\alpha\beta}} \in H^2([0,l_{\boldsymbol{\alpha\beta}}],\mathbb{C}^2), t \in [0,l_{\boldsymbol{\alpha\beta}}]$ one has

$$\|\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\| \leqslant C_1\|L_{\boldsymbol{\alpha\beta}}f_{\boldsymbol{\alpha\beta}}\| + C_2\|f_{\boldsymbol{\alpha\beta}}\|, \tag{9a}$$

$$\|(\partial - \mathrm{i}a_{\boldsymbol{\alpha\beta}} - \mathrm{i}k_{\mathrm{R}}\sigma_{\boldsymbol{\alpha\beta}})\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)\| \leqslant C_1\|L_{\boldsymbol{\alpha\beta}}f_{\boldsymbol{\alpha\beta}}\| + C_2\|f_{\boldsymbol{\alpha\beta}}\|. \tag{9b}$$

Here the norms are taken in $\mathbb{C}^2$ on the left-hand side and in $\mathcal{H}_{\boldsymbol{\alpha\beta}}$ on the right-hand side.

Denote by $\widetilde{\Pi}$ the operator acting in $\mathcal{H}$ by the rule (5) on the domain $\mathrm{dom}\,\Pi = \oplus_{\boldsymbol{\alpha\beta}\in\mathcal{E}} H^2([0,l_{\boldsymbol{\alpha\beta}}],\mathbb{C}^2)$. Clearly, $\widetilde{\Pi}$ is closed. By (9a), the linear maps

$$T_{\boldsymbol{\alpha\beta\gamma}}:\mathrm{dom}\,\widetilde{\Pi} \ni \mathbf{f} \mapsto \mathbf{f}_{\boldsymbol{\alpha\beta}}(0) - \mathbf{f}_{\boldsymbol{\gamma\alpha}}(l_{\boldsymbol{\gamma\alpha}}) \in \mathbb{C}^2, \quad \boldsymbol{\alpha\beta},\boldsymbol{\gamma\alpha} \in \mathcal{E},$$

are bounded with respect to the graph norm of $\widetilde{\Pi}$. Therefore, the restriction of $\widetilde{\Pi}$ to the subspace where all these functionals vanish is a closed operator. As this restriction is exactly Π, the operator Π is closed.

For $\mathbf{f}\in\mathcal{D}$ the inclusions $\Gamma\mathbf{f},\Gamma'\mathbf{f}\in\ell^2(\mathcal{V},\mathbb{C}^2)$ follow immediately from the estimates (9) and the assumption (2); and the identity (7) can be verified directly using the partial integration.

To prove the surjectivity condition, we fix first four functions $f_{jk}\in H^2[0,1]$ with $f_{jk}^{(i)}(l) = \delta_{ij}\delta_{kl}, i,j,k,l\in\{0,1\}$. Take arbitrary $\boldsymbol{\xi},\boldsymbol{\xi}'\in\ell^2(\mathcal{V},\mathbb{C}^2)$. Denote

$$\tau_{\boldsymbol{\alpha\beta}} := \exp\left(\mathrm{i}\int_0^{l_{\boldsymbol{\alpha\beta}}} (a_{\boldsymbol{\alpha\beta}}(s) + k_R\sigma_{\boldsymbol{\alpha\beta}})\mathrm{d}s\right) \equiv \exp\left(\mathrm{i}\int_0^{l_{\boldsymbol{\alpha\beta}}} a_{\boldsymbol{\alpha\beta}}(s)\mathrm{d}s\right)(\cos k_R l_{\boldsymbol{\alpha\beta}} + \mathrm{i}\,\sigma_{\boldsymbol{\alpha\beta}}\sin k_R l_{\boldsymbol{\alpha\beta}})$$
$$\in \mathbf{U}(2). \tag{10}$$

By direct calculation, the function $\mathbf{f}\in\mathcal{H}$ whose components are of the form $\mathbf{f}_{\boldsymbol{\alpha\beta}} = \Theta_{\boldsymbol{\alpha\beta}}\mathbf{g}_{\boldsymbol{\alpha\beta}}$, where

$$\mathbf{g}_{\boldsymbol{\alpha\beta}}(t) = f_{00}\left(\frac{t}{l_{\boldsymbol{\alpha\beta}}}\right)\boldsymbol{\xi}(\boldsymbol{\alpha}) + f_{01}\left(\frac{t}{l_{\boldsymbol{\alpha\beta}}}\right)\tau^*_{\boldsymbol{\alpha\beta}}\boldsymbol{\xi}(\boldsymbol{\beta}) + \frac{l_{\boldsymbol{\alpha\beta}}}{\deg\boldsymbol{\alpha}} f_{10}\left(\frac{t}{l_{\boldsymbol{\alpha\beta}}}\right)\boldsymbol{\xi}'(\boldsymbol{\alpha}) - \frac{l_{\boldsymbol{\alpha\beta}}}{\deg\boldsymbol{\beta}} f_{11}\left(\frac{t}{l_{\alpha\beta}}\right)\tau^*_{\boldsymbol{\alpha\beta}}\boldsymbol{\xi}'(\boldsymbol{\beta}),$$

lies in $\mathcal{D}$ and satisfies $(\Gamma\mathbf{f},\Gamma'\mathbf{f}) = (\boldsymbol{\xi},\boldsymbol{\xi}')$. □

Proposition 1 shows that the space $\mathcal{G} := \ell^2(\mathcal{V},\mathbb{C}^2)$ and the maps $\Gamma,\Gamma':\mathrm{dom}\,\Pi\to\mathcal{G}$ form a *boundary triple* for Π see e.g., [Refs. 21 and 46, for a detailed discussion. The self-adjointness of Π would follow from the following assertion:[21] if Π has at least one self-adjoint restriction (i.e., if Π^* is symmetric) and A is a self-adjoint operator in $\mathcal{G}$, then the restriction of Π to the vectors $\varphi\in\mathrm{dom}\,\Pi$ satisfying $\Gamma'\varphi = A\Gamma\varphi$ is self-adjoint in $\mathcal{H}$.

Consider the restriction D of Π to the functions $\mathbf{f}$ satisfying $\Gamma\mathbf{f} = \mathbf{0}$. Clearly, this restriction is nothing but the direct sum $\oplus_{\boldsymbol{\alpha\beta}\in\mathcal{E}} D_{\boldsymbol{\alpha\beta}}$, where $D_{\boldsymbol{\alpha\beta}}$ is an operator in $\mathcal{H}_{\boldsymbol{\alpha\beta}}$ acting as $\mathbf{f}_{\boldsymbol{\alpha\beta}}\mapsto L_{\boldsymbol{\alpha\beta}}\mathbf{f}_{\boldsymbol{\alpha\beta}}$ on functions satisfying $\mathbf{f}_{\boldsymbol{\alpha\beta}}(0) = \mathbf{f}_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}}) = \mathbf{0}$. As each $D_{\boldsymbol{\alpha\beta}}$ is self-adjoint, so is D. Note that L itself is the restriction of Π to the functions $\mathbf{f}$ satisfying $\Gamma'\mathbf{f} = T\Gamma\mathbf{f}, T = \mathrm{diag}(\varepsilon(\boldsymbol{\alpha}))$. This implies

Proposition 2: The spin-orbit Hamiltonian L is self-adjoint.

To carry out the spectral analysis of L, it is useful to relate the resolvents of L and D by Krein's resolvent formula,[21]

$$(D-E)^{-1} - (L-E)^{-1} = \gamma(E)[M(E)-T]^{-1}\gamma^*(\bar{E}), \tag{11}$$

where $E\notin\mathrm{spec}\,L\cup\mathrm{spec}\,D$ and the maps $\gamma(E)$ and $M(E)$ are defined as follows. For a given $E\notin\mathrm{spec}\,D$ and $\boldsymbol{\xi}\in\ell^2(\mathcal{V},\mathbb{C}^2)$, the function $\gamma(E)\boldsymbol{\xi} = (\mathbf{f}_{\boldsymbol{\alpha\beta}})$ is the solution to $(\Pi - E)\mathbf{f} = \mathbf{0}$ satisfying $\Gamma\mathbf{f} = \boldsymbol{\xi}$. The map $M(E):\ell^2(\mathcal{V},\mathbb{C}^2)\to\ell^2(\mathcal{V},\mathbb{C}^2)$ is given by $M(E) = \Gamma'\gamma(E)$. A direct consequence of Eq. (11) is the relationship

$$\mathrm{spec}\,L\setminus\mathrm{spec}\,D = \{E\notin\mathrm{spec}\,D : 0\in\mathrm{spec}(M(E)-T)\}. \tag{12}$$

Moreover, $E\notin\mathrm{spec}\,D$ is an eigenvalue of L iff 0 is an eigenvalue of $M(E)-T$, and $\gamma(E)\ker(M(E)-T)$ is the corresponding eigensubspace.[26]

Denote by $\widetilde{D}_{\boldsymbol{\alpha\beta}}$ the self-adjoint operator in $L^2[0,l_{\boldsymbol{\alpha\beta}}]$ acting as $g_{\boldsymbol{\alpha\beta}}\mapsto -g''_{\boldsymbol{\alpha\beta}} + (U_{\boldsymbol{\alpha\beta}} - k_R^2)g_{\boldsymbol{\alpha\beta}}$ on functions $g_{\boldsymbol{\alpha\beta}}\in H^2[0,l_{\boldsymbol{\alpha\beta}}]$ satisfying the Dirichlet boundary condition, $g_{\boldsymbol{\alpha\beta}}(0) = g_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}}) = 0$. Note that the operators $\Theta^*_{\boldsymbol{\alpha\beta}}D_{\boldsymbol{\alpha\beta}}\Theta_{\boldsymbol{\alpha\beta}}$ are of the form $\widetilde{D}_{\boldsymbol{\alpha\beta}}\oplus\widetilde{D}_{\boldsymbol{\alpha\beta}}$. In particular, the spectra of $D_{\boldsymbol{\alpha\beta}}$ coincide with those of $\widetilde{D}_{\boldsymbol{\alpha\beta}}$ and are discrete sets, and $\mathrm{spec}\,D = \overline{\cup_{\boldsymbol{\alpha\beta}\in\mathcal{E}}\mathrm{spec}\,D_{\boldsymbol{\alpha\beta}}}$.

Equation (12) shows that the spectrum of L outside spec D is completely described in terms of $M(E)$. The question whether spec D or some parts of it enter to the spectrum of L must be analyzed individually, taking into account the magnetic and spin parameters and the topological properties of the graph.

Therefore, to carry out the spectral analysis for L, it is useful to calculate the map $M(E)$. This can be done in terms of special (scalar) solutions to the equation

$$-y''+U_{\alpha\beta}y=zy,\quad z\in\mathbb{C}. \tag{13}$$

Namely, denote by $s_{\alpha\beta}$ and $c_{\alpha\beta}$ the uniquely determined solutions of (13) satisfying the boundary conditions

$$s_{\alpha\beta}(0;z)=c'_{\alpha\beta}(0;z)=0,\quad s'_{\alpha\beta}(0;z)=c_{\alpha\beta}(0;z)=1.$$

Now let $\boldsymbol{\xi}\in\ell^2(\mathcal{V},\mathbb{C}^2)$. To find $\gamma(E)\boldsymbol{\xi}=:(\mathbf{f}_{\alpha\beta})$, we need to solve the boundary value problems,

$$\left[\left(\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}t}+a_{\alpha\beta}+k_{\mathrm{R}}\sigma_{\alpha\beta}\right)^2+U_{\alpha\beta}-k_R^2\right]\mathbf{f}_{\alpha\beta}=E\mathbf{f}_{\alpha\beta},$$

$$\mathbf{f}_{\alpha\beta}(0)=\boldsymbol{\xi}(\alpha),\quad \mathbf{f}_{\alpha\beta}(l_{\alpha\beta})=\boldsymbol{\xi}(\beta). \tag{14}$$

Writing $\mathbf{f}_{\alpha\beta}:=\Theta_{\alpha\beta}\mathbf{g}_{\alpha\beta}$, where $\Theta_{\alpha\beta}$ is the unitary transformation from (8), we rewrite (14) as a boundary value problem for $\mathbf{g}_{\alpha\beta}$,

$$-\mathbf{g}''_{\alpha\beta}+U_{\alpha\beta}\mathbf{g}_{\alpha\beta}=(E+k_{\mathrm{R}}^2)\mathbf{g}_{\alpha\beta},$$

$$\mathbf{g}_{\alpha\beta}(0)=\boldsymbol{\xi}(\alpha),\quad \mathbf{g}_{\alpha\beta}(l_{\alpha\beta})=\tau^*_{\alpha\beta}\boldsymbol{\xi}(\beta). \tag{15}$$

The solution to (15) takes the form

$$\mathbf{g}_{\alpha\beta}(t)=\frac{s_{\alpha\beta}(t;E+k_{\mathrm{R}}^2)}{s_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)}\cdot[\tau^*_{\alpha\beta}\boldsymbol{\xi}(\beta)-c_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)\boldsymbol{\xi}(\alpha)]+c_{\alpha\beta}(t;E+k_{\mathrm{R}}^2)\boldsymbol{\xi}(\alpha).$$

Now we have

$$\mathbf{g}'_{\alpha\beta}(0)=\frac{1}{s_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}^2})}[\tau^*_{\alpha\beta}\boldsymbol{\xi}(\beta)-c_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)\boldsymbol{\xi}(\alpha)], \tag{16}$$

$$\mathbf{g}'_{\alpha\beta}(l_{\alpha\beta})=\frac{1}{s_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)}[s'_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)\tau^*_{\alpha\beta}\boldsymbol{\xi}(\beta)-\boldsymbol{\xi}(\alpha)]. \tag{17}$$

Nothing that

$$\mathbf{f}'(\alpha)=\sum_{\alpha\beta\in\mathcal{E}}\mathbf{g}'_{\alpha\beta}-\sum_{\beta\alpha\in\mathcal{E}}\tau_{\beta\alpha}\mathbf{g}'_{\alpha\beta}(l_{\alpha\beta})$$

we arrive at

$$\begin{aligned}M(E)\boldsymbol{\xi}(\alpha)=&\sum_{\alpha\beta\in\mathcal{E}}\frac{1}{s_{\alpha\beta}(l_{\alpha\beta};E+k_R^2)}\tau^*_{\alpha\beta}\boldsymbol{\xi}(\beta)+\sum_{\beta\alpha\in\mathcal{E}}\frac{1}{s_{\beta\alpha}(l_{\beta\alpha};E+k_R^2)}\tau^*_{\beta\alpha}\boldsymbol{\xi}(\beta)\\&-\left(\sum_{\alpha\beta\in\mathcal{E}}\frac{c_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)}{s_{\alpha\beta}(l_{\alpha\beta};E+k_{\mathrm{R}}^2)}+\sum_{\beta\alpha\in\mathcal{E}}\frac{s'_{\beta\alpha}(l_{\beta\alpha};E+k_{\mathrm{R}}^2)}{s_{\beta\alpha}(l_{\beta\alpha};E+k_{\mathrm{R}}^2)}\right)\boldsymbol{\xi}(\alpha).\end{aligned} \tag{18}$$

Using Krein's resolvent formula (11) we come to the following theorem.

Theorem 3: *The set* spec $L\backslash$spec D *consists exactly of the real numbers* E *such that* 0

$\in \operatorname{spec}[M(E)-T]$, *where* $M(E)$ *and* T *are operators in* $\ell^2(\mathcal{V},\mathbb{C}^2)$, $M(E)$ *is given by* (18) *and* $T=\operatorname{diag}(\varepsilon(\boldsymbol{\alpha}))$. *Moreover, such* E *is an eigenvalue of* L *iff* 0 *is an eigenvalue of* $M(E)-T$, *and* $\gamma(E)\ker(M(E)-T)$ *is the corresponding eigenspace.*

We remark that in the above calculations it does not matter whether $\boldsymbol{\xi}$ is in ℓ^2 or not. Actually, all the construction hold for any set of vectors $\boldsymbol{\xi}(\boldsymbol{\alpha})\in\mathbb{C}^2, \boldsymbol{\alpha}\in\mathcal{V}$. This observation can be formulated as follows:

Theorem 4: *For* $E\notin \operatorname{spec} D$, *any continuous solution* $\mathbf{f}$ *to* $(L-E)\mathbf{f}=0$ *has the form*

$$\mathbf{f}_{\boldsymbol{\alpha\beta}}(t)=\frac{s_{\boldsymbol{\alpha\beta}}(t;E+k_R^2)}{s_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}};E+k_R^2)}\cdot\boldsymbol{\Theta}_{\boldsymbol{\alpha\beta}}[\tau^*_{\boldsymbol{\alpha\beta}}\mathbf{f}(\boldsymbol{\beta})-c_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}};E+k_{\mathrm{R}}^2)\mathbf{f}(\boldsymbol{\alpha})]+\boldsymbol{\Theta}_{\boldsymbol{\alpha\beta}}c_{\boldsymbol{\alpha\beta}}(t;E+k_{\mathrm{R}}^2)\mathbf{f}(\boldsymbol{\alpha}).$$

Such a function satisfies the boundary conditions (6b) *iff*

$$\sum_{\boldsymbol{\alpha\beta}\in\mathcal{E}}\frac{1}{s_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}};E+k_{\mathrm{R}}^2)}\tau^*_{\boldsymbol{\alpha\beta}}\mathbf{f}(\boldsymbol{\beta})+\sum_{\boldsymbol{\beta\alpha}\in\mathcal{E}}\frac{1}{s_{\boldsymbol{\beta\alpha}}(l_{\boldsymbol{\beta\alpha}};E+k_{\mathrm{R}}^2)}\tau_{\boldsymbol{\beta\alpha}}\mathbf{f}(\boldsymbol{\beta})$$
$$=\left(\sum_{\boldsymbol{\alpha\beta}\in\mathcal{E}}\frac{c_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}};E+k_{\mathrm{R}}^2)}{s_{\boldsymbol{\alpha\beta}}(l_{\boldsymbol{\alpha\beta}};E+k_{\mathrm{R}}^2)}+\sum_{\boldsymbol{\beta\alpha}\in\mathcal{E}}\frac{s'_{\boldsymbol{\beta\alpha}}(l_{\boldsymbol{\beta\alpha}};E+k_{\mathrm{R}}^2)}{s_{\boldsymbol{\beta\alpha}}(l_{\boldsymbol{\beta\alpha}};E+k_{\mathrm{R}}^2)}+\boldsymbol{\varepsilon}(\boldsymbol{\alpha})\right)\mathbf{f}(\boldsymbol{\alpha}).$$

Such an $\mathbf{f}$ *is an eigenfunction of* L (*i.e., belongs to* L^2) *iff* $(\mathbf{f}(\boldsymbol{\alpha}))_{\alpha\in\mathcal{V}}\in\ell^2(\mathcal{V},\mathbb{C}^2)$.

Note that similar formulas for more simple situations were obtained earlier, e.g., in Refs. 3, 5, 8, 22, 23, and 32.

The expression (18) can be simplified significantly if all the edges are the same, i.e., if $l_{\boldsymbol{\alpha\beta}}\equiv l$ and $U_{\boldsymbol{\alpha\beta}}\equiv U$, $s_{\boldsymbol{\alpha\beta}}=s, c_{\boldsymbol{\alpha\beta}}=c$ for all $\boldsymbol{\alpha\beta}\in\mathcal{E}$. Note that in this case the spectrum of D coincides with the Dirichlet spectrum of the operator $\widetilde{D}:=-\mathrm{d}^2/\mathrm{d}t^2+U-k_{\mathrm{R}}^2$ on the segment $[0,l]$ and hence is a discrete set. We have

$$M(E)\boldsymbol{\xi}(\boldsymbol{\alpha})=\frac{1}{s(l;E+k_{\mathrm{R}}^2)}\left\{\left[\sum_{\boldsymbol{\alpha\beta}\in\mathcal{E}}\tau^*_{\boldsymbol{\alpha\beta}}\boldsymbol{\xi}(\boldsymbol{\beta})+\sum_{\boldsymbol{\beta\alpha}\in\mathcal{E}}\tau_{\boldsymbol{\beta\alpha}}\boldsymbol{\xi}(\boldsymbol{\beta})\right]-[\operatorname{outdeg}\boldsymbol{\alpha}c(l;E+k_{\mathrm{R}}^2)\right.$$
$$\left.+\operatorname{indeg}\boldsymbol{\alpha}s'(l;E+k_{\mathrm{R}}^2)]\boldsymbol{\xi}(\boldsymbol{\alpha})\right.. \tag{19}$$

Even this expression admits further simplifications.

Proposition 5: Assume that all edges are identical, $l_{\boldsymbol{\alpha\beta}}\equiv l$, $U_{\boldsymbol{\alpha\beta}}\equiv U, U$ *is even,* $U(x)\equiv U(l-x)$, *and the coupling constants* $\varepsilon(\boldsymbol{\alpha})$ *are of the form* $\varepsilon(\boldsymbol{\alpha})=\deg\boldsymbol{\alpha}\varepsilon$, *then* $\operatorname{spec}L\setminus\operatorname{spec}\widetilde{D}=t_\varepsilon^{-1}(\operatorname{spec}\Delta)$, *where* $t_\varepsilon(E)=c(l;E+k_{\mathrm{R}}^2)+\varepsilon s(l;E+k_{\mathrm{R}}^2)$ *and* Δ *is the discrete Hamiltonian,*

$$\Delta\boldsymbol{\xi}(\boldsymbol{\alpha})=\frac{1}{\deg\boldsymbol{\alpha}}\left(\sum_{\boldsymbol{\alpha\beta}\in\mathcal{E}}\tau^*_{\boldsymbol{\alpha\beta}}\boldsymbol{\xi}(\boldsymbol{\beta})+\sum_{\boldsymbol{\beta\alpha}\in\mathcal{E}}\tau_{\boldsymbol{\beta\alpha}}\boldsymbol{\xi}(\boldsymbol{\beta})\right),$$

acting on the space $\ell^2(\mathcal{V},\mathbb{C}^2;\deg)$ *with the scalar product*

$$\langle\boldsymbol{\xi},\boldsymbol{\eta}\rangle_{\deg}=\sum_{\boldsymbol{\alpha}\in\mathcal{V}}\deg\boldsymbol{\alpha}\cdot\overline{\boldsymbol{\xi}(\boldsymbol{\alpha})}\,\boldsymbol{\eta}(\boldsymbol{\alpha}).$$

Proof: If the potential U is even, one has $c(l;E+k_{\mathrm{R}}^2)\equiv s'(l;E+k_{\mathrm{R}}^2):=t(E)$, see e.g., Ref. 44; hence

$$M(E)-T=\frac{1}{s(l;E+k_{\mathrm{R}}^2)}[\widetilde{\Delta}-t_\varepsilon(E)\deg],\quad \deg=\operatorname{diag}(\deg\boldsymbol{\alpha}),$$

where $\widetilde{\Delta}$ is the discrete Hamiltonian in $\ell^2(\mathcal{V},\mathbb{C}^2)$,

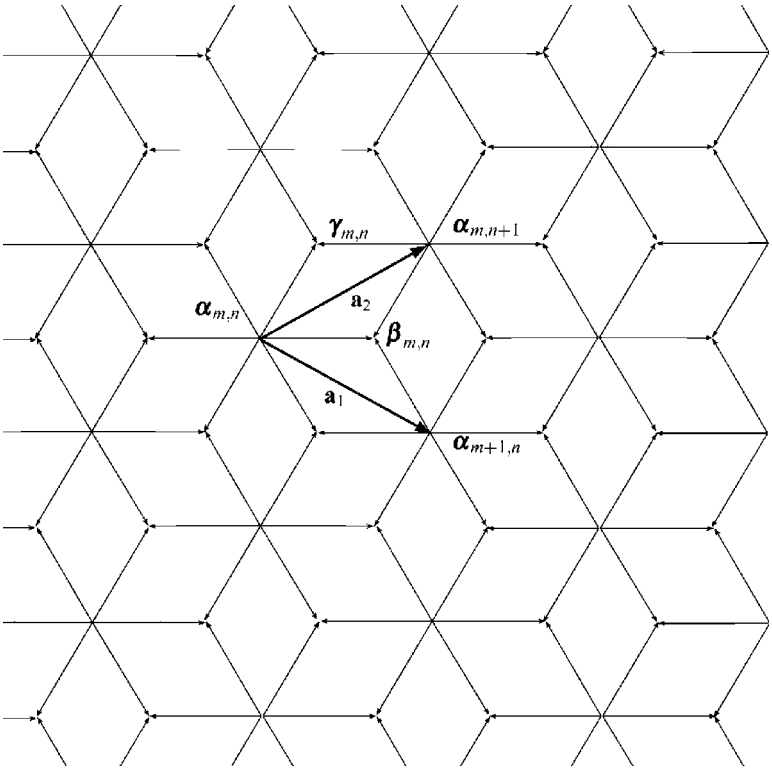

FIG. 1. A finite piece of a T_3 lattice.

$$\widetilde{\Delta}\boldsymbol{\xi}(\alpha) = \sum_{\boldsymbol{\alpha\beta}\in\mathcal{E}} \tau^*_{\alpha\beta}\boldsymbol{\xi}(\boldsymbol{\beta}) + \sum_{\boldsymbol{\beta\alpha}\in\mathcal{E}} \tau_{\beta\alpha}\boldsymbol{\xi}(\boldsymbol{\beta}).$$

The condition $0\in$ spec $[M(E)-T]$ takes the form $0\in\text{spec}[\widetilde{\Delta}-t_\varepsilon(E)\text{deg}]$ in $\ell^2(\mathcal{V},\mathbb{C}^2)$, which is equivalent to $0\in$ spec $[\Delta-t_\varepsilon(E)]$ in $\ell^2(\mathcal{V},\mathbb{C}^2;\text{deg})$. □

Proposition 5 shows that the spectral problem for a class of quantum graphs reduces to the study of the tight-binding Hamiltonian Δ. In the case $U\equiv 0$ and $\varepsilon(\boldsymbol{\alpha})\equiv 0$ one has $t_\varepsilon(E)=\cos\sqrt{E+k_\mathrm{R}^2}$, and we arrive at spec $L=\text{Arccos}^2$ spec $\Delta-k_\mathrm{R}^2$ (up to the discrete set spec $\widetilde{D}$), which is exactly the formula connecting the network and the tight-binding spectra in the de Gennes-Alexander model of superconductivity.[4] For the scalar situation, an analog of this correspondence was given, e.g., in Ref. 5 for the Laplacian on compact graphs, and in Ref. 16 for the Laplacian on noncompact graphs, and in Ref. 44 for more general Schrödinger operators. At the same time, Proposition 5 does not exhaust all possibilities of such a reduction, i.e., the reduction to a discrete Hamiltonian is possible also for some noneven U. (Such questions will be discussed in greater detail in Ref. 45.) One of such situations will be discussed in the next section.

III. SPECTRUM OF T_3 LATTICE

A. Description of the lattice

In this section, we consider the spectral problem for a quantum graph whose underlying structure is the so-called T_3 lattice (see Fig. 1). The nodes are the points $\boldsymbol{\alpha}_{m,n},\boldsymbol{\beta}_{m,n},\boldsymbol{\gamma}_{m,n}$, with $\boldsymbol{\alpha}_{m,n}=m\mathbf{a}_1+n\mathbf{a}_2,\mathbf{a}_1=\left(\frac{3}{2},-\sqrt{3}/2,0\right)$, $\mathbf{a}_2=\left(\frac{3}{2},\sqrt{3}/2,0\right),\boldsymbol{\beta}_{m,n}=\boldsymbol{\alpha}_{m,n}+(1,0,0),\boldsymbol{\gamma}_{m,n}=\boldsymbol{\alpha}_{m,n}+\left(\frac{1}{2},\frac{\sqrt{3}}{2},0\right),m,n\in\mathbb{Z}$, i.e.,

$$\boldsymbol{\alpha}_{m,n}=\left(\frac{3(m+n)}{2},\frac{\sqrt{3}(n-m)}{2},0\right),\quad \boldsymbol{\beta}_{m,n}=\left(\frac{3(m+n)+2}{2},\frac{\sqrt{3}(n-m)}{2},0\right),$$

$$\boldsymbol{\gamma}_{m,n} = \left(\frac{3(m+n)+1}{2}, \frac{\sqrt{3}(n-m+1)}{2}, 0 \right).$$

The edges are

$$e_{m,n,1} = \boldsymbol{\alpha}_{m,n}\boldsymbol{\gamma}_{m,n}, \quad e_{m,n,2} = \boldsymbol{\alpha}_{m,n}\boldsymbol{\beta}_{m-1,n}, \quad e_{m,n,3} = \boldsymbol{\alpha}_{m,n}\boldsymbol{\gamma}_{m,n-1},$$

$$e_{m,n,4} = \boldsymbol{\alpha}_{m,n}\boldsymbol{\beta}_{m,n-1}, \quad e_{m,n,5} = \boldsymbol{\alpha}_{m,n}\boldsymbol{\gamma}_{m+1,n-1}, \quad e_{m,n,6} = \boldsymbol{\alpha}_{m,n}\boldsymbol{\beta}_{m,n}.$$

All the edges have the length 1. The direction vectors of $e_{m,n,j}$ are $\mathbf{e}_j = [\cos(\pi j/3), \sin(\pi j/3), 0], j = 1, \ldots, 6$.

B. Reduction to tight-binding Hamiltonian

We will assume that the system is subjected to the following external interactions. On each edge there is the same potential $U \in L^2[0,1]$. The lattice is subjected to the uniform magnetic field $\mathbf{B} = (0,0,2\pi\xi)$ orthogonal to the plane, and the magnetic vector potential in the symmetric gauge is $\mathbf{A}(\mathbf{x}) = (-\pi\xi x_2, \pi\xi x_1, 0)$. In what follows we use the magnetic parameter $\omega = \pi\xi\sqrt{3}/2$ expressing the magnetic flux through the elementary rhombus (for example, $\boldsymbol{\alpha}_{m,n}\boldsymbol{\beta}_{m,n}\boldsymbol{\alpha}_{m,n+1}\boldsymbol{\gamma}_{mn}$).

The external magnetic field implies nontrivial magnetic potentials on $e_{m,n,j}, a_{m,n,j} = 1/2\langle \mathbf{B} \times \boldsymbol{\alpha}_{m,n}, \mathbf{e}_j \rangle$,

$$a_{m,n,1} = \omega(2m+n), \quad a_{m,n,2} = \omega(m+2n), \quad a_{m,n,3} = \omega(n-m),$$

$$a_{m,n,4} = -\omega(2m+n), \quad a_{m,n,5} = -\omega(m+2n), \quad a_{m,n,3} = \omega(m-n).$$

The dynamics along $e_{m,n,j}$ is described by the differential expression

$$L_{m,n,j} = \left(\mathrm{i}\frac{\mathrm{d}}{\mathrm{d}t} + a_{m,n,j} + k_{\mathrm{R}}\sigma_{m,n,j} \right)^2 + U - k_{\mathrm{R}}^2,$$

$$\sigma_{m,n,j} = \begin{pmatrix} 0 & e_{j2} + ie_{j1} \\ e_{j2} - ie_{j1} & 0 \end{pmatrix} \equiv \begin{pmatrix} 0 & \exp\left[\mathrm{i}\left(\frac{\pi}{2} - \frac{\pi j}{3} \right) \right] \\ \exp\left[\mathrm{i}\left(\frac{\pi j}{3} - \frac{\pi}{2} \right) \right] & 0 \end{pmatrix},$$

$$m,n \in \mathbb{Z} \quad j \in \{1, \ldots, 6\}.$$

Here e_{jk} are the components of the vectors $\mathbf{e}_j$ and k_{R} is the Rashba constant. We consider boundary conditions of the form (6) at all the nodes, assuming that there are only two types of coupling constants: $\lambda := \varepsilon(\boldsymbol{\alpha}_{m,n})$ and $\mu := \varepsilon(\boldsymbol{\beta}_{m,n}) = \varepsilon(\boldsymbol{\gamma}_{m,n})$.

The corresponding matrices $\tau_{m,n,j}$ from Eq. (10), $\tau_{m,n,j} = \exp[\mathrm{i}(a_{m,n,j} + k_R\sigma_{m,n,j})]$, are as follows:

$$\tau_{m,n,1} = \tau^*_{m,n,4} = \mathrm{e}^{\mathrm{i}\omega(2m+n)} \left\{ \cos k_{\mathrm{R}} + \mathrm{i} \sin k_{\mathrm{R}} \begin{pmatrix} 0 & \mathrm{e}^{\mathrm{i}\pi/6} \\ \mathrm{e}^{-\mathrm{i}\pi/6} & 0 \end{pmatrix} \right\}, \tag{20a}$$

$$\tau_{m,n,2} = \tau^*_{m,n,5} = \mathrm{e}^{\mathrm{i}\omega(m+2n)} \left\{ \cos k_{\mathrm{R}} + \mathrm{i} \sin k_{\mathrm{R}} \begin{pmatrix} 0 & \mathrm{e}^{-\mathrm{i}\pi/6} \\ \mathrm{e}^{\mathrm{i}\pi/6} & 0 \end{pmatrix} \right\}, \tag{20b}$$

$$\tau_{m,n,3} = \tau^*_{m,n,6} = \mathrm{e}^{\mathrm{i}\omega(n-m)} \left\{ \cos k_{\mathrm{R}} + \mathrm{i} \sin k_{\mathrm{R}} \begin{pmatrix} 0 & \mathrm{e}^{-\mathrm{i}\pi/2} \\ \mathrm{e}^{\mathrm{i}\pi/2} & 0 \end{pmatrix} \right\}. \tag{20c}$$

Clearly, for any $m,n \in \mathbb{Z}$, one has

$$\text{outdeg}\,\boldsymbol{\alpha}_{m,n}=6,\quad \text{indeg}\,\boldsymbol{\beta}_{m,n}=\text{indeg}\,\boldsymbol{\gamma}_{m,n}=3,$$

$$\text{indeg}\,\boldsymbol{\alpha}_{m,n}=\text{outdeg}\,\boldsymbol{\beta}_{m,n}=\text{outdeg}\,\boldsymbol{\gamma}_{m,n}=0.$$

For the subsequent analysis, we use the fact that the lattice is bipartite. Represent the set of nodes as the disjoint union $\mathcal{V}=\mathcal{V}_0\cup\mathcal{V}_1, \mathcal{V}_0=\{\boldsymbol{\alpha}_{m,n}\}, \mathcal{V}_1=\{\boldsymbol{\beta}_{m,n}\}\cup\{\boldsymbol{\gamma}_{m,n}\}$. Clearly, for the set of edges one has $\mathcal{E}\subset\mathcal{V}_0\times\mathcal{V}_1$. With respect to the decomposition $\ell^2(\mathcal{V},\mathbb{C}^2)=\ell^2(\mathcal{V}_0,\mathbb{C}^2)\oplus\ell^2(\mathcal{V}_1,\mathbb{C}^2)$, the operator T in Theorem 3 takes the block-diagonal form

$$T=\begin{pmatrix}\lambda & 0\\ 0 & \mu\end{pmatrix}.$$

Using the above decomposition and Eq. (19), we rewrite $M(E)-T$ as

$$M(E)-T=\frac{1}{s(1;E+k_{\mathrm{R}}^2)}\begin{pmatrix}-a(E) & A^*\\ A & -b(E)\end{pmatrix},$$

$$a(E)=6c(1;E+k_{\mathrm{R}}^2)+\lambda s(1;E+k_{\mathrm{R}}^2),$$

$$b(E)=3s'(1;E+k_{\mathrm{R}}^2)+\mu s(1;E+k_{\mathrm{R}}^2),$$

where

$$A\mathbf{f}(\boldsymbol{\beta}_{m,n})=\tau_{m+1,n,2}\mathbf{f}(\boldsymbol{\alpha}_{m+1,n})+\tau_{m,n+1,4}\mathbf{f}(\boldsymbol{\alpha}_{m,n+1})+\tau_{m,n,6}\mathbf{f}(\boldsymbol{\alpha}_{m,n}),$$

$$A\mathbf{f}(\boldsymbol{\gamma}_{m,n})=\tau_{m,n,1}\mathbf{f}(\boldsymbol{\alpha}_{m,n})+\tau_{m,n+1,3}\mathbf{f}(\boldsymbol{\alpha}_{m,n+1})+\tau_{m-1,n+1,5}\mathbf{f}(\boldsymbol{\alpha}_{m-1,n+1}),$$

$$\begin{aligned}A^*\mathbf{f}(\boldsymbol{\alpha}_{m,n})=&\tau_{m,n,1}^*\mathbf{f}(\boldsymbol{\gamma}_{m,n})+\tau_{m,n,2}^*\mathbf{f}(\boldsymbol{\beta}_{m-1,n})+\tau_{m,n,3}^*\mathbf{f}(\boldsymbol{\gamma}_{m,n-1})\\&+\tau_{m,n,4}^*\mathbf{f}(\boldsymbol{\beta}_{m,n-1})+\tau_{m,n,5}^*\mathbf{f}(\boldsymbol{\gamma}_{m+1,n-1})+\tau_{m,n,6}^*\mathbf{f}(\boldsymbol{\beta}_{m,n}).\end{aligned}\tag{21}$$

The operator $A^*, A^*:\ell^2(\mathcal{V}_1,\mathbb{C}^2)\to\ell^2(\mathcal{V}_0,\mathbb{C}^2)$ is adjoint to $A, A:\ell^2(\mathcal{V}_0,\mathbb{C}^2)\to\ell^2(\mathcal{V}_1,\mathbb{C}^2)$. Using Theorem 3, we write the condition $E\in\operatorname{spec}L$ or, equivalently, $0\in\operatorname{spec}(M(E)-T)$, as

$$\frac{a(E)+b(E)}{2}\in\operatorname{spec}\left[\frac{b(E)-a(E)}{2}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}+\begin{pmatrix}0 & A^*\\ A & 0\end{pmatrix}\right].\tag{22}$$

Note that $E\notin\operatorname{spec}\widetilde{D}$ in all the above constructions, where $\widetilde{D}$ is the Dirichlet realization of $-\mathrm{d}^2/\mathrm{d}t^2+U-k_{\mathrm{R}}^2$ on $[0,1]$. The question of whether spec $\widetilde{D}$ is a part of spec L or admits a simple answer in our case.

Lemma 6: For all ω and k_R one has $\operatorname{spec}\widetilde{D}\subset\operatorname{spec}L$.

Proof: Using the Schnol-type arguments, cf. Refs. 12 and 13, it is sufficient to show that for each $E\in\operatorname{spec}\widetilde{D}$ the equation $L\mathbf{f}=E\mathbf{f}$ has a bounded solution $\mathbf{f}$ satisfying the boundary conditions (6). Let $E\in\widetilde{D}$ and g be the corresponding eigenfunction of $\widetilde{D}$. Choose any infinite path $\mathcal{P}$ without intersection on the graph and any nonzero vector $\mathbf{z}\in\mathbb{C}^2$. For a fixed $e\in\mathcal{P}$ set $\mathbf{f}_e:=\Theta_e g\mathbf{z}$, where Θ_e is given by (8). Now extend $\mathbf{f}$ to the whole graph in such a way that (a) $\mathbf{f}_e=\mathbf{0}$ for $e\notin\mathcal{P}$ and (b) on each $b\in\mathcal{P}$ one has $\mathbf{f}_b=\Theta_b g\mathbf{z}_b$, where the vectors $\mathbf{z}_b$ are chosen in such a way that the boundary conditions (6) are satisfied. By construction, there holds $L\mathbf{f}=E\mathbf{f}$. At the same time, due to the unitarity of the matrices $\tau_{m,n,j}$ the obtained function $\mathbf{f}$ is bounded. This finishes the proof. □

C. Supersymmetric analysis

Equation (22) is a typical supersymmetric spectral problem. Using Proposition 11 and Corollary 12 in the Appendix , one easily sees that the set Σ of E for which the condition (22) is satisfied is the union $\Sigma=\Sigma_1\cup\Sigma_2\cap\Sigma_3$,

$$\Sigma_1=\{E\notin \operatorname{spec}\widetilde{D}: a(E)b(E)\neq 0 \text{ and } a(E)b(E)\in \operatorname{spec}A^*A\},$$

$$\Sigma_2=\begin{cases}\{E\notin \operatorname{spec}\widetilde{D}: a(E)=0\}, & \text{if } 0\in\operatorname{spec}A^*A,\\ \varnothing, & \text{otherwise;}\end{cases}$$

$$\Sigma_3=\begin{cases}\{E\notin \operatorname{spec}\widetilde{D}: b(E)=0\}, & \text{if } 0\in\operatorname{spec}AA^*,\\ \varnothing, & \text{otherwise.}\end{cases}$$

To summarize, we have the following.

Proposition 7: $\operatorname{spec}L=\Sigma_1\cup\Sigma_2\cup\Sigma_3\cup\operatorname{spec}\widetilde{D}$.

Note that the sets Σ_2,Σ_3, and $\operatorname{spec}\widetilde{D}$ are discrete. Therefore, only the set Σ_1 is responsible for the continuous spectrum. Writing $\mathbf{f}(\boldsymbol{\alpha}_{m,n})=:\mathbf{f}(m,n)$, we note that A^*A is an operator on $\ell^2(\mathbb{Z}^2,\mathbb{C}^2)$ of the form

$$\begin{aligned}A^*A\mathbf{f}(m,n)=&\,6\mathbf{f}(m,n)+(\tau^*_{m,n,1}\tau_{m,n+1,3}+\tau^*_{m,n,6}\tau_{m,n+1,4})\mathbf{f}(m,n+1)+(\tau^*_{m,n,3}\tau_{m,n-1,1}\\&+\tau^*_{m,n,4}\tau_{m,n-1,6})\mathbf{f}(m,n-1)+(\tau^*_{m,n,5}\tau_{m+1,n,3}+\tau^*_{m,n,6}\tau_{m+1,n,2})\mathbf{f}(m+1,n)+(\tau^*_{m,n,2}\tau_{m-1,n,6}\\&+\tau^*_{m,n,3}\tau_{m-1,n,5})\mathbf{f}(m-1,n)+(\tau^*_{m,n,1}\tau_{m-1,n+1,5}+\tau^*_{m,n,2}\tau_{m-1,n+1,4})\mathbf{f}(m-1,n+1)\\&+(\tau^*_{m,n,4}\tau_{m+1,n-1,2}+\tau^*_{m,n,5}\tau_{m+1,n-1,1})\mathbf{f}(m+1,n-1),\end{aligned}$$

i.e.,

$$\begin{aligned}A^*A=&\,6+\cos\omega\cdot\sin^2k_{\mathrm{R}}\cdot\widetilde{\Delta}+2\left[\cos\omega\cdot\cos^2k_{\mathrm{R}}-\sin^2k_{\mathrm{R}}\begin{pmatrix}\cos\left(\omega-\frac{\pi}{3}\right)&0\\0&\cos\left(\omega+\frac{\pi}{3}\right)\end{pmatrix}\right]\\&\times\begin{pmatrix}\Delta&0\\0&\Delta\end{pmatrix},\end{aligned}\tag{23}$$

where Δ is a spinless operator in $\ell^2(\mathbb{Z}^2)$,

$$\begin{aligned}\Delta f(m,n)=&\,\mathrm{e}^{-3\mathrm{i}\omega m}f(m,n+1)+\mathrm{e}^{3\mathrm{i}\omega m}f(m,n-1)+\mathrm{e}^{3\mathrm{i}\omega n}f(m+1,n)+\mathrm{e}^{-3\mathrm{i}\omega n}f(m-1,n)+\mathrm{e}^{-3\mathrm{i}\omega(m+n)}f(m\\&-1,n+1)+\mathrm{e}^{3\mathrm{i}\omega(m+n)}f(m+1,n-1),\end{aligned}$$

and

$$\begin{aligned}\widetilde{\Delta}\mathbf{f}(m,n)=&\,R_1\mathrm{e}^{-3\mathrm{i}\omega m}\mathbf{f}(m,n+1)+R_1^*\mathrm{e}^{3\mathrm{i}\omega m}\mathbf{f}(m,n-1)+R_2\mathrm{e}^{3\mathrm{i}\omega n}\mathbf{f}(m+1,n)+R_2^*\mathrm{e}^{-3\mathrm{i}\omega n}\mathbf{f}(m-1,n)\\&+R_3\mathrm{e}^{-3\mathrm{i}\omega(m+n)}\mathbf{f}(m-1,n+1)+R_3^*\mathrm{e}^{3\mathrm{i}\omega(m+n)}\mathbf{f}(m+1,n-1),\end{aligned}$$

with

$$R_1=\begin{pmatrix}0&\frac{3}{2}-\frac{\sqrt{3}}{2}\mathrm{i}\\-\frac{3}{2}-\frac{\sqrt{3}}{2}\mathrm{i}&0\end{pmatrix},\quad R_2=\begin{pmatrix}0&\frac{3}{2}+\frac{\sqrt{3}}{2}\mathrm{i}\\-\frac{3}{2}+\frac{\sqrt{3}}{2}\mathrm{i}&0\end{pmatrix},$$

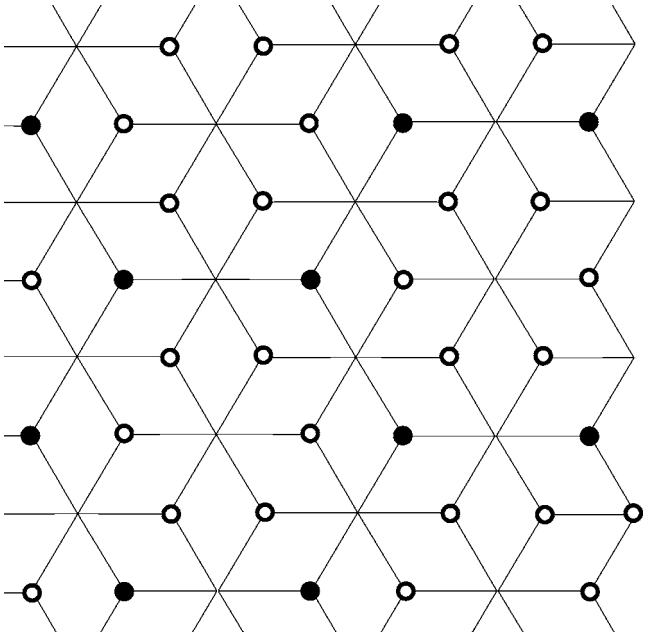

FIG. 2. Classification of the nodes $\boldsymbol{\beta}_{m,n}$ and $\boldsymbol{\gamma}_{m,n}$.

$$R_3 = \begin{pmatrix} 0 & -\sqrt{3}\mathrm{i} \\ -\sqrt{3}\mathrm{i} & 0 \end{pmatrix}.$$

The expression for A^*A shows explicitly the contribution of the magnetic and spin-orbit parameters to the spectrum. Let us discuss the situations where the spectrum shows certain localization phenomena.

D. Magnetic field induced extreme localization

If the spin-orbit interaction is not taken into account, $k_{\mathrm{R}}=0$, then one has $A^*A=6+2\cos\omega(\Delta\oplus\Delta)$. In particular, at $\omega-\pi/2\in\pi\mathbb{Z}$, one has $A^*A=6$, i.e., the spectrum of A^*A degenerates to a point. If $\omega-\pi/2\in\pi\mathbb{Z}$, but the spin-orbit interaction is nontrivial, similar phenomena occur only at certain values of the Rashba constant, i.e., $k_{\mathrm{R}}\in\pi\mathbb{Z}$. For generic values of k_{R}, obviously, there are some bands of continuous spectrum.

Let us analyze the sets Σ_2 and Σ_3 for this case, i.e., for $\omega-\pi/2\in\pi\mathbb{Z}$ and $k_{\mathrm{R}}\in\pi\mathbb{Z}$. Clearly, the set Σ_2 is empty, as $0\notin\operatorname{spec}A^*A$. Let us look at the operator AA^*.

Lemma 8: For $\omega-\pi/2\in\pi\mathbb{Z}$ and $k_R\in\mathbb{Z}$, one has $0\in\operatorname{spec}AA^*$.

Proof: In view of periodicity, it is sufficient to show that the equation $AA^*\psi=0$ has nontrivial bounded solutions, $\psi\in\ell^\infty(\mathcal{V}_1;\mathbb{C}^2)$.

Let us classify the nodes $\boldsymbol{\beta}_{m,n}$ and $\boldsymbol{\gamma}_{m,n}$ as shown in Fig. 2. Consider all vector-valued functions on $\mathcal{V}_1$ vanishing at the white marked nodes. For such a function ψ, the condition $A^*\psi=0$ is of very simple form, because in the expression (21) only two of the six terms on the right-hand side are nonzero. Therefore, fixing the value of ψ at a single black marked node, one uniquely extends ψ to a bounded solution of $A^*\psi=0$. The conditions $\omega\in\pi/2+\pi\mathbb{Z}$ and $k_{\mathrm{R}}\in\pi\mathbb{Z}$ guarantee that this solution is well defined, i.e., that the phase factor along each cycle on the hexagonal lattice of black nodes is 1. □

To summarize the previous considerations, we note that the set $\operatorname{spec}\widetilde{D}$ consists of the real E satisfying $s(1;E+k_{\mathrm{R}}^2)=0$. Proposition 7 reads as follows.

Theorem 9: *Let $\omega\in\pi/2+\pi\mathbb{Z}$ and $k_R\in\pi\mathbb{Z}$, then the spectrum of L consists of the real numbers E satisfying at least one of the following conditions:*

$$\left(c(1;E+k_{\mathrm{R}}^2)+\frac{\lambda}{6}(1;E+k_{\mathrm{R}}^2)\right)\cdot\left(s'(1;E+k_{\mathrm{R}}^2)+\frac{\mu}{3}s(1;E+k_{\mathrm{R}}^2)\right)=\frac{1}{3}, \tag{24a}$$

$$s'(1;E+k_{\mathrm{R}}^2)+\frac{\mu}{3}s(1;E+k_{\mathrm{R}}^2)=0, \tag{24b}$$

$$s(1;E+k_{\mathrm{R}}^2)=0. \tag{24c}$$

Each point of the spectrum is an infinitely degenerate eigenvalue.

Note that the eigenvalues (24a) are the most interesting ones, as they arise as the limit of the continuous spectrum. The Dirichlet eigenvalues (24c) are usually neglected in the physical works.

In the simplest case, when the scalar potential is zero and the couplings are trivial, i.e., $U=0,\lambda=\mu=0$, one has $s(x;E)=(1/\sqrt{E})\sin\sqrt{E}x, c(x;E)=\cos\sqrt{E}x$, and Eq. (24a) takes the form

$$\cos^2\sqrt{E+k_{\mathrm{R}}^2}\in\left\{0,\tfrac{1}{3},1\right\},$$

which was previously obtained in Ref. 54 for the case $k_{\mathrm{R}}=0$.

We remark that the presence of the extreme localization is periodic with respect to the shifts $k_{\mathrm{R}}\to k_{\mathrm{R}}+\pi$, but not the energy levels themselves, as the functions $s(\cdot;E+k_R^2)$, etc., are not periodic with respect to the Rashba constant. It is worthwhile to note that the above results hold for any potential U and any coupling constants λ and μ.

E. Magneto-spin induced localization

Another interesting situation appears at $\cos k_{\mathrm{R}}=0$, i.e., at $k_{\mathrm{R}}\in\pi/2+\pi\mathbb{Z}$. In this case one has

$$A^*A=6-2\begin{pmatrix}\cos\left(\omega-\frac{\pi}{3}\right)\Delta & 0\\ 0 & \cos\left(\omega+\frac{\pi}{3}\right)\Delta\end{pmatrix}.$$

For the values $\omega\in-\pi/6+\pi\mathbb{Z}$ the first component of A^*A degenerates. In particular, any function of the form $(f,0), f\in\ell^2(\mathbb{Z}^2)$ becomes an eigenfunction of A^*A. For $\omega\in\pi/6+\pi\mathbb{Z}$ the same holds for the functions $(0,f)$.

For a further analysis we calculate the spectrum of Δ.

Lemma 10: For $\omega\in\pm\pi/6+\pi\mathbb{Z}$ the spectrum of Δ is absolutely continuous and covers the segments $[-2\sqrt{3},-\sqrt{3}]$ and $[\sqrt{3},2\sqrt{3}]$.

Proof: Consider the unitary transformation

$$U:\ell^2(\mathbb{Z}^2)\ni(f(m,n))\mapsto(\mathrm{e}^{3\mathrm{i}\omega mn}f(m,n))\in\ell^2(\mathbb{Z}^2).$$

Clearly, U is unitary, and the operator $\hat{\Delta}:=U^*\Delta U$ has the form

$$\hat{\Delta}f(m,n)=\mathrm{e}^{-6\mathrm{i}\omega m}f(m,n+1)+\mathrm{e}^{6\mathrm{i}\omega m}f(m,n-1)+f(m+1,n)+f(m-1,n)+\mathrm{e}^{-3\mathrm{i}\omega(2m-1)}\times f(m-1,n+1)+\mathrm{e}^{3\mathrm{i}\omega(2m+1)}f(m+1,n-1).$$

The operator obtained has the same spectrum as Δ, but is periodic with respect to the shifts $n\mapsto n+1$ and can be studied using the Bloch analysis. Making the Bloch substitution $f(m,n)=\mathrm{e}^{\mathrm{i}nq}\xi_m$, where $q\in[0,2\pi)$ is the quasimomentum, we observe that the spectrum of $\hat{\Delta}$ is the union of the spectra of operators $H(q)$ acting in $\ell^2(\mathbb{Z})$ and defined by

$$(H(q)\xi)_m = 2\exp\left[-3\mathrm{i}\omega\left(m-\frac{1}{2}\right)+\mathrm{i}\frac{q}{2}\right]\cos\left[3\omega\left(m-\frac{1}{2}\right)-\frac{q}{2}\right]\xi_{m-1}+2\cos[6\omega m-q]\xi_m$$
$$+2\exp\left[3\mathrm{i}\omega\left(m+\frac{1}{2}\right)-\mathrm{i}\frac{q}{2}\right]\cos\left[3\omega\left(m+\frac{1}{2}\right)-\frac{q}{2}\right]\xi_{m+1}.$$

The operators $H(q)$ are nothing but the Harper operators for the triangular lattice.[18] Note that for $\omega\in\pm\pi/6+\pi\mathbb{Z}$, all these operators are invariant under the shift $m\mapsto m+2$. Therefore, substituting into the equation $H(q)\xi=E\xi$ a vector ξ satisfying $\xi_m=\mathrm{e}^{\mathrm{i}\theta}\xi_{m-2}$ for all m, where $\theta\in[0,2\pi)$ is another quasimomentum, one arrives at a 2×2 linear system for the components ξ_0 and ξ_1,

$$\mathrm{e}^{\mathrm{i}(3\omega/2+q/2)}\cos\left(\frac{3\omega}{2}+\frac{q}{2}\right)\mathrm{e}^{-\mathrm{i}\theta}\xi_1+\cos q\xi_0+\mathrm{e}^{-\mathrm{i}(3\omega/2-q/2)}\cos\left(\frac{3\omega}{2}-\frac{q}{2}\right)\xi_1=\frac{E}{2}\xi_0,$$

$$\mathrm{e}^{-\mathrm{i}(3\omega/2-q/2)}\cos\left(\frac{3\omega}{2}-\frac{q}{2}\right)\xi_0-\cos q\xi_1+\mathrm{e}^{-\mathrm{i}(3\omega/2+q/2)}\cos\left(\frac{3\omega}{2}+\frac{q}{2}\right)\mathrm{e}^{\mathrm{i}\theta}\xi_0=\frac{E}{2}\xi_1.$$

The condition for the determinants to vanish takes the form

$$\frac{E^2}{4}=1+\cos^2 q+\cos(q-\theta)\cos q=\frac{3}{4}+\left(\cos q+\frac{1}{2}\cos(q-\theta)\right)^2+\sin^2(q-\theta).$$

Here, taking all possible values of q and θ, we arrive at the conclusion. □

Lemma 10 means that for the values ω in question, the spectrum of A^*A has a continuous part, which is the union of the segments [0,3] and [9,12], and an infinitely degenerate eigenvalue 6.

Therefore, we arrive, as in Sec. III D, to a series of infinitely degenerate eigenvalues E satisfying the same Eq. (24a) (i.e., the *same* eigenvalues as in the extreme localization case), which are isolated in the spectrum, but we have additionally bands of continuous spectrum given by

$$\left(c(1;E+k_{\mathrm{R}}^2)+\frac{\lambda}{6}s(1;E+k_{\mathrm{R}}^2)\right)\cdot\left(s'(1;E+k_{\mathrm{R}}^2)+\frac{\mu}{3}s(1;E+k_{\mathrm{R}}^2)\right)\in\left[0,\frac{1}{6}\right]\cup\left[\frac{1}{2},\frac{2}{3}\right].$$

In particular, for the free case with zero coupling constants, one has the following characterization for E to be in the spectrum of L:

$$\cos^2\sqrt{E+k_R^2}\in\left[0,\frac{1}{6}\right]\cup\left\{\frac{1}{3}\right\}\cup\left[\frac{1}{2},\frac{2}{3}\right]\cup\{1\}.$$

The localization effect described in this section seems to be not covered by the existing works, and it would be interesting to know whether it can be really observed. As for different values of the magnetic paramteres we have completely different eigensubspaces of A^*A, we conjecture that this localization mechanism can be used to control the spin polarization by the magnetic field, but this needs a further analysis.

ACKNOWLEDGMENTS

Numerous discussions with Vladimir Geyler and Denis Bulaev are gratefully acknowledged.

The research was supported by the Deutsche Forschungsgemeinschaft (fellowship PA 1555/1-1) and the German–New Zealand cooperation of BMBF (Project No. NZL 05/001 of the International Bureau at the German Aerospace Center) and ISAT (Grant No. 9144/360402 of the Royal Society of New Zealand). A large part of the work was done during the stay at the Department of Mathematics of the University of Auckland in March 2006. The author thanks Boris Pavlov for valuable interaction and the warm hospitality during the visit.

Appendix: Supersymmetric spectral analysis

Here we prove the following proposition.

Proposition 11: Let $\mathcal{H}_1,\mathcal{H}_2$ are some Hilbert spaces, A be a bounded linear operator from $\mathcal{H}_1$ to $\mathcal{H}_2$, and $m\in\mathbb{R}$. On $\mathcal{H}_1\oplus\mathcal{H}_2$ consider the operator

$$L=\begin{pmatrix} m & A^* \\ A & -m \end{pmatrix}.$$

Then

$$\operatorname{spec} L=-\sqrt{\operatorname{spec}(AA^*+m^2)}\cup\sqrt{\operatorname{spec}(A^*A+m^2)}. \tag{A1}$$

This proposition is formulated (without proof) in Ref. 43 and is nothing but an abstract version of Proposition 2.5 in Ref. 49; we give here a complete proof just for the sake of completeness.

Proof: First, note that $\operatorname{spec} AA^*\setminus\{0\}=\operatorname{spec} A^*A\setminus\{0\}$.[20] Clearly,

$$L^2=\begin{pmatrix} A^*A+m^2 & 0 \\ 0 & AA^*+m^2 \end{pmatrix}. \tag{A2}$$

Therefore, $\operatorname{spec} L^2\setminus\{m^2\}=\operatorname{spec}(AA^*+m^2)\setminus\{m^2\}$, and for any $\lambda\in\operatorname{spec} AA^*\setminus\{0\}\equiv\operatorname{spec}AA^*\setminus\{0\}$, at least one of the numbers $-\sqrt{\lambda+m^2},\sqrt{\lambda+m^2}$ lies in spec L. Let us show that actually they both are in the spectrum of L.

Let $\lambda>0,\lambda\in\operatorname{spec} A^*A$; then there exists a sequence $(\phi_n),\phi_n\in\mathcal{H}_1$, such that $\|\phi_n\|\geqslant 1$ and $\lim(A^*A-\lambda)\phi_n=0$. Denote

$$\psi_n:=\left[\lambda+(\sqrt{\lambda+m^2}-m)\begin{pmatrix} 0 & A^* \\ A & 0 \end{pmatrix}\right]\begin{pmatrix} \phi_n \\ 0 \end{pmatrix}. \tag{A3}$$

Clearly,

$$\begin{pmatrix} \phi_n \\ 0 \end{pmatrix}\perp\begin{pmatrix} 0 & A^* \\ A & 0 \end{pmatrix}\begin{pmatrix} \phi_n \\ 0 \end{pmatrix},$$

which implies that

$$\|\psi_n\|\geqslant\lambda\|\phi_n\|\geqslant\lambda. \tag{A4}$$

By direct calculation,

$$(L-\sqrt{\lambda+m^2})\psi_n=(\sqrt{\lambda+m^2}-m)\begin{pmatrix} (A^*A-\lambda)\phi_n \\ 0 \end{pmatrix}.$$

Therefore, $\lim(L-\sqrt{\lambda+m^2})\psi_n=0$. Together with (A4), this implies that $\sqrt{\lambda+m^2}\in\operatorname{spec} L$.

To show $-\sqrt{\lambda+m^2}\in\operatorname{spec} L$ one has to consider the functions

$$\psi_n:=\left[\lambda-(\sqrt{\lambda+m^2}-m)\begin{pmatrix} 0 & A^* \\ A & 0 \end{pmatrix}\right]\begin{pmatrix} 0 \\ \phi_n \end{pmatrix},$$

where $\|\phi_n\|\geqslant 1$ and $\lim(AA^*-\lambda)\phi_n=0$, and to repeat the above steps. To finish the proof of Eq. (A1) it is necessary to study the points $\pm m$.

For $m=0$, Eq. (A2) reads as $\operatorname{spec} L^2=\operatorname{spec} AA^*\cup\operatorname{spec} A^*A$, and the conditions $0\in\operatorname{spec} L$ and $0\in\operatorname{spec} AA^*\cup\operatorname{spec} A^*A$ are equivalent.

Assume $m\neq 0$ and $m\in\operatorname{spec} L$, then there exist sequences $(\phi_n)\in\mathcal{H}_1,(\varphi_n)\in\mathcal{H}_2$ with

$$\|\phi_n\| + \|\varphi_n\| \geqslant 1 \tag{A5}$$

and

$$\lim(L-m)\begin{pmatrix}\phi_n\\ \varphi_n\end{pmatrix} \equiv \lim\begin{pmatrix}A^*\varphi_n\\ A\phi_n - 2m\varphi_n\end{pmatrix} = 0. \tag{A6}$$

Clearly, this implies $\lim A^*A\phi_n = 0$. Assume that $\lim \phi_n = 0$; then (A6) shows $\lim \varphi_n = 0$, which contradicts (A5). Therefore, there exists a subsequence (ϕ_n') of (ϕ_n) such that $\|\phi_n'\| \geqslant \varepsilon$ for some $\varepsilon > 0$. Together with $\lim A^*A\phi_n' = 0$, this implies $0 \in \operatorname{spec} A^*A$.

Assume now $0 \in \operatorname{spec} A^*A$, then there is a sequence $(\phi_n) \in \mathcal{H}_1$ with $\|\phi_n\| \geqslant 1$ and $\lim\langle A^*A\phi_n, \phi_n\rangle \equiv \lim\|A\phi_n\| = 0$. Then

$$\lim(L-m)\begin{pmatrix}\phi_n\\ 0\end{pmatrix} = \lim\begin{pmatrix}0\\ A\phi_n\end{pmatrix} = 0,$$

from which $m \in \operatorname{spec} L$.

The relationship between the conditions $-m \in L$ and $0 \in \operatorname{spec} AA^*$ can be proved in a completely similar way. □

It may be useful to have an alternative formulation of Proposition 11.

Corollary 12: There holds

$$\begin{aligned}\operatorname{spec} L \setminus \{-m, m\} &= -\sqrt{\operatorname{spec}(AA^* + m^2)} \cup \sqrt{\operatorname{spec}(AA^* + m^2)} \setminus \{-m, m\}\\ &\equiv -\sqrt{\operatorname{spec}(A^*A + m^2)} \cup \sqrt{\operatorname{spec}(A^*A + m^2)} \setminus \{-m, m\}.\end{aligned}$$

Furthermore, for $m \neq 0$, *one has* $m \in \operatorname{spec} L$ *iff* $0 \in \operatorname{spec} A^*A, -m \in \operatorname{spec} L$ *iff* $0 \in \operatorname{spec} AA^*$, *and for* $m = 0$ *there holds* $0 \in \operatorname{spec} L$ *iff* $0 \in \operatorname{spec} A^*A \cup \operatorname{spec} AA^*$.

(Received 2 June 2006; accepted 5 October 2006; published online 30 November 2006)

The current-current correlation measure plays a crucial role in the theory of conductivity for disordered systems. We prove a Pastur-Shubin-type formula for the current-current correlation measure expressing it as a thermodynamic limit for random Schrödinger operators on the lattice and the continuum. We prove that the limit is independent of the self-adjoint boundary conditions and independent of a large family of expanding regions. We relate this finite-volume definition to the definition obtained by using the infinite-volume operators and the trace-per-unit volume. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2378618]

I. INTRODUCTION AND BASIC DEFINITIONS

The study of the transport properties of disordered systems requires an analysis of higher-order correlation measures of the spectral density operator $\rho_{H_\omega}(E) \equiv \pi^{-1} \lim_{\epsilon \to 0} \mathrm{Im}(H_\omega - E - i\epsilon)^{-1} \equiv \delta(H_\omega - E)$ of the one-particle random Schrödinger operator H_ω. The one-point correlation measure

$$\rho(E) = \mathbb{E}\{\langle x|\rho_{H_\omega}(E)|x\rangle\}, \tag{1}$$

which is independent of x by translational covariance [cf. Eq. (34)], is the density of states (DOS) measure. This measure has been extensively studied for random Schrödinger operators in recent years, and we refer the reader to the monographs.[1,2] The two-point correlation measure

$$K_2(x_1,y_1,x_2,y_2;E_1,E_2) = \mathbb{E}\{\langle x_1|\rho_{H_\omega}(E_1)|y_1\rangle\langle x_2|\rho_{H_\omega}(E_2)|y_2\rangle\}, \tag{2}$$

is related to, the current-current correlation measure that plays an important role in describing the conductivity of the system. In this note, we prove some fundamental properties of the current-current correlation measure such as the Pastur-Shubin formula. This formula expresses the function as the thermodynamic limit of quantities involving the system restricted to regions of finite volume.

Although this current-current correlation measure has been described in the literature, we could not find a complete proof of the Pastur-Shubin formula. Pastur[3] mentions the feasibility of a proof based on a perturbative expansion but this requires stronger conditions on the random potential than used here. The crucial point for continuum models is an estimate on the derivatives of the heat kernel. The necessary estimates on heat kernels associated with elliptic operators are proved by Eidelman and Ivasisen.[4] Shubin[5,6] considered the density of states and the current-current correlation measure for Schrödinger operators with uniformly almost periodic potentials, and more general elliptic operators with almost periodic coefficients. His results are similar to those we present here for random ergodic Schrödinger operators.

Our results apply to both lattice models with Hilbert space $\ell^2(\mathbb{Z}^d)$, and continuum models with Hilbert space $L^2(\mathbb{R}^d)$. For both of these settings, the random Hamiltonian H_ω, acting on $\ell^2(\mathbb{Z}^d)$ or $L^2(\mathbb{R}^d)$, is the self-adjoint operator given by

$$H_\omega = H_0 + V_\omega. \tag{3}$$

The Schrödinger operator $H_0 = L + V_0$ is the unperturbed, background operator, and V_ω is an ergodic, random, real-valued potential describing the disorder. Precise hypotheses on the deterministic potential V_0, and the random, ergodic potential V_ω, are given in Sec. II. We use the symbol L to denote either the finite-difference Laplacian on $\ell^2(\mathbb{Z}^d)$, or the non-negative Laplacian on $L^2(\mathbb{R}^d)$. The finite-difference Laplacian is defined by

$$(Lf)(n) = \sum_{m:|n-m|=1} f(m), \tag{4}$$

so that the spectrum is $[-2d, 2d]$. The non-negative Laplacian on $L^2(\mathbb{R}^d)$ is given by $L = -\Delta = -\Sigma_{\alpha=1}^d \partial^2/\partial x_\alpha^2 \geqslant 0$ and has spectrum $[0, \infty)$.

For one-particle quantum systems, the current operator J_α, describing the flow of charge in the x^α-direction, is proportional to the velocity operator ∇H_α. In order to define this observable, we let X_α denote the self-adjoint operator describing multiplication by the coordinate x_α, i.e., $X_\alpha f(x) = x_\alpha f(x)$, for $f \in C_0(\mathbb{R}^d)$. The *velocity operator* ∇H_α for direction x_α is the deterministic operator defined by

$$\nabla H_\alpha = i[H_\omega, X_\alpha] = i[L, X_\alpha], \tag{5}$$

so that $\nabla H_\alpha = -2i\,\partial/\partial x_\alpha$ on $L^2(\mathbb{R}^d)$. We describe ∇H_α on $\ell^2(\mathbb{Z}^d)$ in Sec. IV. Note that the velocity operator is independent of ω.

The *current-current correlation measure* can be described through either the trace-per-unit-volume formalism, in which one works directly with the infinite-volume operators, that is, with operators acting on $\ell^2(\mathbb{Z}^d)$ or on $L^2(\mathbb{R}^d)$, or through a limiting procedure of measures described by finite-volume observables acting on $\ell^2(\Lambda)$ or on $L^2(\Lambda)$, for bounded regions Λ. One of our results is that these two definitions define the same measure. In order to describe the finite-volume approach, we denote by H_Λ the restriction of H_ω to a finite volume $\Lambda \subset \mathbb{Z}^d$ or $\Lambda \subset \mathbb{R}^d$, with self-adjoint boundary conditions on the boundary $\partial\Lambda$. As H_Λ has discrete spectrum, we let $\psi_i^\Lambda(x) \in L^2(\Lambda)$ be the normalized eigenfunctions of the local Hamiltonian H_Λ with corresponding eigenvalues ϵ_i^Λ. We let $\nabla H_{i,j}^{(\alpha)}$ denote the matrix element of the velocity operator ∇H_α in the eigenstates ψ_j^Λ given by

$$\nabla H_{i,j}^{(\alpha)} = \langle \psi_i^\Lambda, \nabla H_\alpha \psi_j^\Lambda \rangle. \tag{6}$$

Note that these matrix-elements are well-defined although ∇H_α is not a self-adjoint operator when restricted to a finite volume region.

Definition 1.1: The *finite-volume current-current correlation measures* $m_\Lambda^{(\alpha)}$, *for current direction* α, *with* $\alpha = 1, \ldots, d$, *and for any bounded open region* $\Lambda \subset \mathbb{Z}^d$, *or* $\mathbb{R}^d$, *is the point measure on* $\mathbb{R}^2$ *defined, up to a constant prefactor, by*

$$m_\Lambda^\alpha(dE, dE') = \frac{1}{|\Lambda|} \sum_{i,j} \delta(E - \epsilon_i^\Lambda)\delta(E' - \epsilon_j^\Lambda)|\nabla H_{i,j}^{(\alpha)}|^2 dE dE', \tag{7}$$

with $\nabla H_{i,j}^{(\alpha)}$ *is the matrix element of the velocity operator in the direction* α *given in Eq.* (6), *and* $\{\epsilon_i^\Lambda\}_i$ *are the eigenvalues of the local Hamiltonian* H_Λ *corresponding to the eigenfunctions* ψ_i^Λ. *We write* $m_\Lambda(dE, dE') = \Sigma_{\alpha=1}^d m_\Lambda^\alpha(dE, dE')$ *for the total finite-volume current-current correlation measure*.

Of course, the point measures m_Λ^α depend on the configuration ω, the region Λ, and the boundary conditions on $\partial\Lambda$. One of our results is to prove that for a reasonable family of increasing regions $\Lambda_n \uparrow \mathbb{Z}^d$ or $\mathbb{R}^d$, and self-adjoint boundary conditions, the limit is independent of these, and almost surely independent of the configuration ω.

The physical significance of the limit measures $m_\alpha(dE, dE')$ is discussed thoroughly in Refs. 7–10, for example. These measures are directly related to the diagonal components of the finite-volume conductivity measures that we define as

$$\sigma_{\alpha\beta}(dE,dE') = \frac{\pi e^2}{|\Lambda|}\sum_{i\neq j}\delta(E-\epsilon_i^\Lambda)\,\delta(E'-\epsilon_j^\Lambda)\,\nabla H_{i,j}^{(\alpha)}\,\nabla H_{j,i}^{(\beta)}dEdE', \tag{8}$$

for $\alpha,\beta=1,\ldots,d$. The properties of these measures are basically unknown. In general, it is not known if the measures are absolutely continuous with respect to Lebesgue measure on $\mathbb{R}^2$ so that there exists a density $m(E,E')$. There has been some progress in understanding $m_\alpha(dE,dE')$ in the strong localization regime. Bellissard and Hislop[7] proved the existence of a smooth density in the strong disorder regime outside of the diagonal $E=E'$ for random Schrödinger operators with probability densities analytic in a strip. In Ref. 10, a density expansion for the correlation functions is developed based on the idea of Lifshitz emphasizing the role tunneling between deep and sparsely distributed potential wells that effectively trap the quantum particle in the strong localization regime. The authors apply this method to study the zero-temperature ac-conductivity tensor that is formally given by

$$\sigma_{\alpha\beta}(\nu,E_F) = \lim_{|\Lambda|\to\infty}\frac{\pi e^2}{|\Lambda|}\sum_{i\neq j}\delta(E_F+\nu-\epsilon_i^\Lambda)\,\delta(E_F-\epsilon_i^\Lambda)\,\nabla H_{i,j}^{(\alpha)}\,\nabla H_{j,i}^{(\beta)}, \tag{9}$$

where $\nu>0$ is the frequency of the external ac-field and E_F is the Fermi energy of the system. The goal is to study the low frequency behavior of the total ac-conductivity $\sigma(\nu,E_F)=\Sigma_\alpha\sigma_{\alpha\alpha}(\nu,E_F)$ in the strong localization regime. Mott[11] argued that the behavior is given by

$$\sigma(\nu,E_F) = C_0\rho^2(E_F)\,\nu^2(\log(1/\nu))^{d+1}, \tag{10}$$

now known as Mott's formula. The main result of[10] is an application of the density expansion method to give a heuristic derivation of Eq. (10). An upper bound on $\sigma(\nu,E_F)$, of the form given on the right in Eq. (10) but with an exponent $d+2$, has recently been proved in the strong localization regime by Klein, Lenoble, and Müller.[9]

II. PRELIMINARIES AND THE MAIN RESULTS

In this section, we first state the necessary hypotheses for the proof of the existence of the thermodynamic limit. As the techniques used in the continuum and lattice cases are different, the hypotheses on the potentials are different. For continuum models, we distinguish models that are $\mathbb{Z}^d$-ergodic or $\mathbb{R}^d$-ergodic, while for lattice models, the Hamiltonians are $\mathbb{Z}^d$-ergodic. We begin with the assumptions on the potentials for the continuum models. Let C_0 be the unit cube centered at the origin.

(H1C). For models that are $\mathbb{Z}^d$-ergodic, the background potential V_0 is a bounded, real-valued potential that is $\mathbb{Z}^d$-periodic and we assume $V_0\in C^{1,\beta}(C_0)$, for some $0<\beta$, where β is the Hölder continuity exponent. For models that are $\mathbb{R}^d$-ergodic, we take $V_0=0$.

(H2C). The potential V_ω is ergodic with respect to the group of translations $\mathbb{R}^d$ or the lattice translations $\mathbb{Z}^d$. It is lower semibounded and we assume that $V_\omega\in C^{1,\beta}(C_0)$, for some $0<\beta$, where β is the Hölder continuity exponent, and for almost every $\omega\in\Omega$.

For the lattice models, we make the following assumptions.

(H1L). The background potential V_0 is a bounded, real-valued potential that is $\Gamma_N\equiv N\mathbb{Z}^d$-periodic, for some $N\geqslant 1$.

(H2L). The potential V_ω is ergodic with respect to the group of lattice translations $\mathbb{Z}^d$. It is lower semibounded and has finite local expectation $\mathbb{E}\{|V_\omega(0)|\}<\infty$.

Note that if V_0 is $\Gamma_1=\mathbb{Z}^d$-periodic, it is simply a constant. We will denote by $C_0(N)$ a fundamental domain for the translation group Γ_N.

By shifting the energy, we may assume that the potentials V_0 and V_ω are non-negative. Under these assumptions, the Hamiltonians H_ω is self-adjoint for the lattice and continuum models, cf. Ref. 1, Chap. V. For a bounded region $\Lambda\subset\mathbb{R}^d$ or $\mathbb{Z}^d$, the local Hamiltonian H_Λ is obtained by taking the restriction of H_ω to Λ with some self-adjoint boundary conditions on $\partial\Lambda$, the boundary of Λ. *For continuum models, we may take either Dirichlet, Robin, or Neumann boundary conditions on the boundary $\partial\Lambda$ of the region Λ. For lattice models, we take Dirichlet boundary condi-*

tions. When not explicitly stated to the contrary, any result holds for any of the boundary conditions.

We also need some properties of the families of expanding regions Λ_n that we take to $\mathbb{Z}^d$ or $\mathbb{R}^d$. These conditions guarantee that the surface area of the boundary is vanishing small compared to the volume. We also need a mild regularity condition in the continuum case.

(vH). A sequence of bounded regions Λ_n converges to $\mathbb{Z}^d$ in the *sense of van Hove* if the following holds for any $a \in \mathbb{N}$. Consider a covering of $\mathbb{Z}^d$ by cubes Λ_a of side a centered at lattice points. For a bounded subset $\Lambda \subset \mathbb{Z}^d$, let $N_a^-(\Lambda) = \#\{\Lambda_a \cap \Lambda \neq \emptyset\}$ and let $N_a^+(\Lambda) = \#\{\Lambda_a \subset \Lambda\}$. Then, we require that

$$\lim_{n\to\infty} \frac{N_a^-(\Lambda_n)}{N_a^+(\Lambda_n)} = 1. \tag{11}$$

(F). A sequence of bounded regions Λ_n converges to $\mathbb{R}^d$ in the *sense of Fisher* if

$$\lim_{n\to\infty} \frac{|\partial\Lambda_n|}{|\Lambda_n|} = 0. \tag{12}$$

We assume that the boundary $\partial\Lambda_n \in C^{2,\beta}$, for $0 < \beta$ the Hölder exponent as in (H1C).

Let $E_{H_\omega}(\cdot)$ be the spectral family of the Hamiltonian H_ω (3), and for $x, y \in \mathbb{R}^d$, let $(\nabla H_\alpha E_H(dE) \nabla H_\alpha E_H(dE'))(x,y)$ represent the kernel of the operator defined, for any $f, g \in C_0(\mathbb{R})$ by

$$\nabla H_\alpha f(H_\omega) \nabla H_\alpha g(H) = \int_{\mathbb{R}} \int_{\mathbb{R}} f(E) g(E') m_\alpha(dE, dE'), \tag{13}$$

and described in Sec. V. The main results are the following theorems and representations of the current-current correlation measure. It proves the validity of a Pastur-Shubin formula for the current-current correlation measure. We begin with the continuum case.

Theorem 2.1: *We consider the continuum model (3) and the family of finite-volume current-current correlation measures* $m_\Lambda^\alpha(dE, dE')$, *defined in Eq.* (7), *for an increasing family of regions* Λ *satisfying condition* (*F*), *with Dirichlet*, *Robin*, *or Neumann boundary conditions*. *We assume hypotheses* (*H*1*C*) *and* (*H*2*C*). *Then*, *the sequence of finite-volume current-current correlation measures* $m_\Lambda^\alpha(dE, dE')$ *converges vaguely as* $|\Lambda| \to \infty$ *almost surely to a nonnegative measure* m_α. *The limit measure m is independent of the sequence of regions and the boundary conditions*. *Furthermore*, *the measure* m_α *admits the following representation*:

(1) *For the case with an* $\mathbb{R}^d$*-ergodic action*, *the limit measure* m_α *is given by*

$$\begin{aligned} m_\alpha(dE, dE') &= \lim_{|\Lambda|\uparrow\infty} m_\Lambda^\alpha(dE, dE') \\ &= \mathbb{E}\{(\nabla H_\alpha E_H(dE) \nabla H_\alpha E_H(dE'))(0,0)\}. \end{aligned} \tag{14}$$

(2) *For the case with a* $\mathbb{Z}^d$*-ergodic action*, *the limit measure* m_α *is given by*

$$\begin{aligned} m_\alpha(dE, dE') &= \lim_{|\Lambda|\uparrow\infty} m_\Lambda^\alpha(dE, dE') \\ &= \mathbb{E}\{Tr(\chi_{C_0} \nabla H_\alpha E_H(dE) \nabla H_\alpha E_H(dE') \chi_{C_0})\}. \end{aligned} \tag{15}$$

Consequently, the total current-current correlation measure $m = \sum_{\alpha=1}^d m_\alpha$ *exists and admits a representation as in Eqs.* (14) *or* (15).

The lattice case is different as we can use the Feynman-Kac formula directly. Because of this, we do not require any regularity on the potential.

Theorem 2.2: *We consider the* $\mathbb{Z}^d$*-ergodic lattice model given by Eqs.* (3) and (4), *and a family of finite-volume current-current correlation measures* $m_\Lambda^\alpha(dE, dE')$, *defined in Eq.* (7), *for*

an increasing family of regions Λ *satisfying condition* (vH), *with Dirichlet boundary conditions. We assume hypotheses* $(H1L)$ and $(H2L)$. *Then, the sequence of finite-volume current-current correlation measures* $m_\Lambda^\alpha(dE,dE')$ *converges vaguely as* $|\Lambda|\to\infty$ *almost surely to a nonnegative measure* m_α. *The limit measure* m *is independent of the sequence of regions. For a background potential* V_0 *that is* Γ_N*-periodic, for* $N\geqslant 1$, *the measure* m_α *admits the following representation*:

$$m_\alpha(dE,dE') = \lim_{|\Lambda|\uparrow\infty} m_\Lambda^\alpha(dE,dE')$$

$$= \frac{1}{N^d}\sum_{m\in C_0(N)} \mathbb{E}\{(\nabla H_\alpha E_H(dE)\,\nabla\, H_\alpha E_H(dE'))(m,m)\}. \tag{16}$$

The total current-current correlation measure $m=\sum_{\alpha=1}^d m_\alpha$ *exists and admits a representation as in Eq.* (16).

III. THE CURRENT-CURRENT CORRELATION MEASURE AS A THERMODYNAMIC LIMIT: CONTINUUM CASE

Introductory material in this section applies to both the lattice and continuum models. Details specific to the lattice models are given in Sec. IV. We will prove Theorem 2.1 using the two-variable Laplace transform, in analog with a standard proof of the Pastur-Shubin formula for the density of states (DOS) measure, cf. Ref. 12, and estimates on the convergence of finite-volume heat kernels[4]. We recall that in the study of the DOS measure, the convergence of the Laplace transform of the finite-volume DOS measure implies the vague convergence of the measures (cf. Ref. 12). We state and prove a similar result in Appendix A for a class of probability measures supported on the positive cone $(\mathbb{R}^+)^d$. The double Laplace transform of the finite-volume measure (7)), with $t>0$ and $p>0$, is given by

$$M_\Lambda^\alpha(t,p) = \int_{[0,\,\infty[^2} e^{-tE}e^{-pE'}\,m_\Lambda^\alpha(dE,dE') \tag{17}$$

$$= \frac{1}{|\Lambda|}\sum_{i,j} e^{-t\epsilon_i^\Lambda}e^{-p\epsilon_j^\Lambda}|\nabla H_{i,j}^{(\alpha)}|^2. \tag{18}$$

As above, we denote by ψ_i^Λ the normalized eigenvector of H_Λ associated with the energy ϵ_i^Λ. When Λ is fixed, we will occasionally omit the superscript Λ. We note that the integrals in Eq. (17) converge since

$$|\nabla H_{i,j}^{(\alpha)}|^2 \leqslant C_0|\mathrm{diam}\,\Lambda|^2|\epsilon_i^\Lambda-\epsilon_j^\Lambda|^2, \tag{19}$$

as follows from Eq. (5). Expanding these matrix elements in terms of the eigenfunctions for H_Λ, we find that

$$M_\Lambda^{(\alpha)}(t,p) = \frac{-4}{|\Lambda|}\int_{\Lambda^2} dxdy\sum_{i,j} e^{-t\epsilon_i}\partial_{x_\alpha}\psi_i(x)\bar{\psi}_i(y)e^{-p\epsilon_j}\partial_{y\alpha}\psi_j(y)\bar{\psi}_j(x). \tag{20}$$

The sums (20) can be expressed in terms of the local heat kernel and its derivatives. By Mercer's theorem, the local heat kernel can be expanded in the eigenfunctions of H_Λ and we write

$$K_\Lambda(t;x,y) = e^{-tH\Lambda}(x,y) = \sum_{i\geqslant 1} e^{-t\epsilon_i^\Lambda}\psi_i(x)\bar{\psi}_i(y), \tag{21}$$

for $t>0$, and $x,y\in\Lambda$. We then write $M_\Lambda^\alpha(t,p)$ in Eq. (20) as

$$M_\Lambda^{(\alpha)}(t,p) = \frac{-4}{|\Lambda|}\int_{\Lambda^2} dxdy\,\partial_{x_\alpha}K_\Lambda(t;x,y)\partial_{y_\alpha}K_\Lambda(t;y,x). \tag{22}$$

A. Heat kernels

Estimates on the heat kernels play an important role in evaluating the thermodynamic limit of Eq. (22). We will use the local heat kernels associated with H_Λ, and the nonrandom, unperturbed operator H_0^Λ on Λ, with the same self-adjoint boundary conditions. We denote these kernels by $K_\Lambda(t;x,y)$, and $K_\Lambda^{(0)}(t;x,y)$, respectively. We denote the heat kernel for the random operator $H_\omega(3)$, and the unperturbed operator H_0, both on $L^2(\mathbb{R}^d)$, by $K(t;x,y)$ and $K^{(0)}(t;x-y)$, respectively. Recall that $H_0=L$, the free operator, in the $\mathbb{R}^d$-ergodic case, and $H_0=L+V_0$, the unperturbed operator, in the $\mathbb{Z}^d$-ergodic case. In either case, we denote the free, translation-invariant, heat kernel associated with the Laplacian L by $K^{(\mathrm{free})}(t;x)$. These heat kernels are all real, nonnegative functions, and satisfy the following relationships:

$$0 \leqslant K_\Lambda(t;x,y) \leqslant K_\Lambda^{(0)}(t;x,y) \leqslant K^{(0)}(t;x,y) \leqslant K^{(free)}(t;x-y), \quad x,y \in \Lambda, \tag{23}$$

where the first inequality follows from the positivity assumptions (H1C) and (H2C), and the second follows from the Feynman-Kac representation (31). The free heat kernel associated with $H_0=L$ on $\mathbb{R}^d$ or $\mathbb{Z}^d$ is translation invariant and so a function of $(x-y)$ only. It is given by

$$K^{(\mathrm{free})}(t;x) = \frac{1}{(4\pi t)^{d/2}} e^{\frac{-\|x\|^2}{4t}}, \quad x \in \mathbb{R}^d, \tag{24}$$

with derivatives

$$\partial_{x_\alpha} K^{(\mathrm{free})}(t;x) = -\frac{2\pi x_\alpha}{(4\pi t)^{d/2+1}} e^{\frac{-\|x\|^2}{4t}}. \tag{25}$$

In the case when $H_0=L+V_0$, with a $\mathbb{Z}^d$-periodic operator, the heat kernel $K^{(0)}(t;x,y)$ is $\mathbb{Z}^d$-periodic. Finally, we note that the self-adjointness of the Hamiltonians implies that the corresponding heat kernels are symmetric $K^{(*)}(t;x,y)=K^{(*)}(t;y,x)$.

We now state a version of a general theorem for higher-order operators on smooth domains in $\mathbb{R}^d$ due to Eidelman and Ivasisen.[4] The version cited here also appears in the articles of Shubin[5,6] on the DOS measure for almost periodic operators.

Theorem 3.1: *Let $\Lambda \subset \mathbb{R}^d$ be a domain satisfying the regularity conditions stated in (F). We assume the local Hamiltonian H_Λ satisfies conditions (H1C) and (H2C) with Dirichlet, Robin, or Neumann boundary conditions on $\partial\Omega$. Let $K_\Lambda(t;x,y)$ denote the kernel of the local heat semigroup e^{-tH_Λ} on $L^2(\Lambda)$, and let $K(t;x,y)$ denote the kernel of the heat semigroup e^{-tH_ω} on $L^2(\mathbb{R}^d)$. We then have*

$$K_\Lambda(t;x,y) = K(t;x,y) + E_\Lambda(t;x,y), \quad \text{for } x,y \in \Lambda, \tag{26}$$

where, the difference E_Λ satisfies

$$|E_\Lambda(t;x,y)| \leqslant \frac{C_d}{t^{d/2}} e^{-(c_d/t)[\|x-y\| + d(w,\partial\Lambda)]^2}, \tag{27}$$

where w can be taken to be x or y, the constants C_d, $c_d>0$ are finite positive constants independent of Λ,t,x,y. The difference of the first partial derivatives of the heat kernels

$$\partial_{x_\alpha} K_\Lambda(t;x,y) = \partial_{x_\alpha} K(t;x,y) + F_\Lambda(t;x,y), \quad \text{for } x,y \in \Lambda, \tag{28}$$

satisfies

$$|F_\Lambda(t;x,y)| \leqslant \frac{\widetilde{C}_d}{t^{(d+1)/2}} e^{-(\tilde{c}_d/t)[\|x-y\| + d(w,\partial\Lambda)]^2}, \tag{29}$$

where w can be taken to be x or y, and the constants $\widetilde{C}_d, \tilde{c}_d>0$ are finite positive constants

independent of Λ, t, x, y. *The infinite-volume heat kernel and its first partial derivatives satisfy the following bound:*

$$|\partial_{x_\alpha}^j K(t;x,y)| \leqslant \frac{\widetilde{C}_{d,j}}{t^{(d+j)/2}} e^{-(\tilde{c}_{d,j}/t)\|x-y\|^2}, \tag{30}$$

for $j=0,1$.

Remark: Estimates on the difference of the Dirichlet heat kernels and the infinite volume heat kernel, as in Eqs. (26) and (27), *can be obtained from the Feynman-Kac formula. Using this representation, we have*

$$K_\Lambda(t;x,y) = K(t;x,y) + \mathbb{E}_{0,x}^{t,y}(e^{-\int_0^t (V_\omega(r(u))+V_0(r(u)))du}(1-\chi_\Lambda(r(\cdot)))), \tag{31}$$

where $\chi_\Lambda(r(u))=1$, *if* $r(u)\in\Lambda$ *for all* $u\in[0,t]$, *and zero otherwise. The difference term in Eq.* (31) *can be estimated as in Ref.* 12, *for example, and one obtains an upper bound like Eq.* (27). *This suffices for the DOS measure, but the higher-order correlation measures require estimates on the derivatives of the heat kernels that do not seem to be readily obtained from the Feynman-Kac formula.*

B. The Birkhoff Ergodic theorem for the continuum models

We now turn to the convergence of the sequence of the two-dimensional Laplace transforms $M_\Lambda^{(\alpha)}(t,p)$ defined in Eq. (22). We will use the estimates of Theorem 3.1 and the standard Birkhoff ergodic theorem in order to control the infinite volume limit. The form of the Birkhoff ergodic theorem depends upon whether the symmetry group is $\mathbb{Z}^d$ or $\mathbb{R}^d$. For models on $\mathbb{R}^d$, the random potential can either be $\mathbb{R}^d$ ergodic, such as a Gaussian random potential, or $\mathbb{Z}^d$-ergodic, such as the standard Anderson-type random potential. Suppose that the family $X_\omega(x)\in L^1(\Omega,\mathbb{P})$ is $\mathbb{R}^d$-ergodic. That is, there is an action τ_a for $\mathbb{R}^d$ on $(\Omega,\mathbb{P})$ so that the covariance property holds: $X_\omega(x+a) = X_{\tau_a\omega}(x)$. Then, the form of the Birkhoff ergodic theorem is

$$\mathbb{E}(X_\omega(0)) = \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|}\int_\Lambda X_\omega(x)dx. \tag{32}$$

Let $C_0\subset\mathbb{R}^d$ denote the unit cube centered at the origin. In the $\mathbb{Z}^d$-ergodic case, we consider families of random variables $X_\omega(x)\in L^1(\Omega,\mathbb{P})$, satisfying the covariance property as above, but for $a\in\mathbb{Z}^d$, the Birkhoff ergodic theorem has the form

$$\int_{C_0} \mathbb{E}(X_\omega(x))dx = \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|}\int_\Lambda X_\omega(x)dx. \tag{33}$$

We note that under our assumptions (H1C) and (H2C), the random potential V_ω is either $\mathbb{Z}^d$ or $\mathbb{R}^d$ ergodic, and that the Hamiltonian (3) satisfies

$$U_a H_\omega U_a^{-1} = H_{\tau_a\omega}, \tag{34}$$

for $a\mathbb{Z}^d$ or $a\in\mathbb{R}^d$, appropriately. As a consequence, the infinite-volume heat kernel $K_\omega(t;x,y)$ satisfies

$$K_\omega(t;x+a,y+a) = K_{\tau_a\omega}(t;x,y). \tag{35}$$

Furthermore, since the translations commute with differentiation, we have the following covariance property of the derivatives of the heat kernel:

$$U_a \partial_{x_\alpha} K_\omega(t;x,y) U_a^{-1} = \partial_{x_\alpha} K_\omega(t;x+a,y+a) = \partial_{x_\alpha} K_{\tau_a\omega}(t;x,y). \tag{36}$$

C. Convergence of the Laplace transform of the finite-volume measure

The main technical result is the convergence of the Laplace transforms of the finite-volume current-current correlation measure (7) in the continuous case.

Proposition 3.1: Let $K_\omega(t;x,y)$ denote the heat kernel for the Hamiltonian H_ω (3) on $L^2(\mathbb{R}^d)$. For every $t>0$ and $p>0$, the limit as $|\Lambda|\to\infty$ of $M_\Lambda^{(\alpha)}(t,p)$, with either Dirichlet, Robin, or Neumann boundary conditions, exists almost surely, for any $\alpha=1,\ldots,d$, and for any increasing sequence of domains satisfying condition (F). For $\mathbb{R}^d$ ergodic models on $\mathbb{R}^d$, the limit is equal to

$$M_\alpha(t,p) = \lim_{|\Lambda|\to\infty} M_\Lambda^{(\alpha)}(t,p) \tag{37}$$

$$= \mathbb{E}\left(-4 \int_{\mathbb{R}^d} dx \partial_{x_\alpha} K_\omega(t;x,0) \partial_{x_\alpha} K_\omega(p;0,x) \right). \tag{38}$$

For $\mathbb{Z}^d$-ergodic models on $\mathbb{R}^d$, the limit is equal to

$$M_\alpha(t,p) = \lim_{|\Lambda|\to\infty} M_\Lambda^{(\alpha)}(t,p) \tag{39}$$

$$= \mathbb{E}\left(-4 \int_{\mathbb{R}^d} dx \int_{C_0} dy \partial_{x_\alpha} K_\omega(t;x,y) \partial_{y_\alpha} K_\omega(p;y,x) \right). \tag{40}$$

Proof: We fix either Dirichlet, Robin, or Neumann boundary conditions and omit them from the notation. We always assume the regions satisfy (F). Recall that $M_\alpha(t,p)$ is given by

$$M_\alpha(t,p) = \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_{\Lambda^2} dxdy \partial_{x_\alpha} K_\Lambda(t;x,y) \partial_{y_\alpha} K_\Lambda(p;y,x). \tag{41}$$

We first replace the derivatives of the finite-volume heat kernel K_Λ by the corresponding derivatives of the infinite-volume heat kernel K_ω in Eq. (41). We obtain

$$M_\alpha(t,p) = \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_{\Lambda^2} dxdy \partial_{x_\alpha} K_\omega(t;x,y) \partial_{y_\alpha} K_\omega(p;y,x)$$

$$+ \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_{\Lambda^2} dxdy Q_\Lambda(t,p;x,y). \tag{42}$$

We estimate the remainder term involving Q_Λ using Theorem 3.1 and prove that this term converges to zero as $|\Lambda|\to\infty$. The details are given in Appendix B 1.

In order to apply the Birkhoff ergodic theorem, Eqs. (32) or (33), we replace the domain of $x\in\Lambda$ by $\mathbb{R}^d$ and obtain

$$M_\alpha(t,p) = \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_{\mathbb{R}^d} dx \int_\Lambda dy \partial_{x_\alpha} K_\omega(t;x,y) \partial_{y_\alpha} K_\omega(p;y,x)$$

$$- \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_{\mathbb{R}^d\setminus\Lambda} dx \int_\Lambda dy \partial_{x_\alpha} K_\omega(t;x,y) \partial_{y_\alpha} K_\omega(p;y,x). \tag{43}$$

For the second term on the right of Eq. (43), we use estimate (30) and we prove that this term converges to zero in Appendix B 2. Let $X_\omega(t,p;y)$ be the family of random variables defined by

$$X_\omega(t,p;y) \equiv \int_{\mathbb{R}^d} dx \partial_{x_\alpha} K_\omega(t;x,y) \partial_{y_\alpha} K_\omega(p;y,x). \tag{44}$$

This family of random variable is $\mathbb{R}^d$ or $\mathbb{Z}^d$-covariant, as follows from Eq. (36), since

$$X_{\tau_a\omega}(t,p;y) = \int_{\mathbb{R}^d} dx \partial_{x_\alpha} K_\omega(t;x+a,y+a) \partial_{y_\alpha} K_\omega(p;y+a,x+a) = X_\omega(t,p;y+a). \tag{45}$$

Furthermore, we observe that $X_\omega(t,p;y) \in L^\infty(\Omega,\mathbb{P})$, uniformly in $y \in \mathbb{R}^d$. It follows from the translational invariance of the upper bound in Eq. (30) that

$$|X_\omega(t,p;y)| \leqslant \frac{(C_{d,1})^2}{t^{(d+1)/2} p^{(d+1)/2}} \int_{\mathbb{R}^d} dx e^{-2\tilde{c}_{d,1}(t+p)/tp\|x\|^2} \leqslant \frac{C_d}{(tp)^{1/2}(t+p)^{d/2}}. \tag{46}$$

Consequently, we apply Eq. (32) in the $\mathbb{R}^d$-ergodic case and obtain

$$\begin{aligned} M_\alpha(t,p) &= \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_\Lambda dy X_\omega(t,p;y) \\ &= \mathbb{E}\left\{ \int_{\mathbb{R}^d} dx \partial_{x_\alpha} K_\omega(t;x,0) \partial_{y_\alpha} K_\omega(p;0,x) \right\}. \end{aligned} \tag{47}$$

In the $\mathbb{Z}^d$-ergodic case, we apply Eq. (33) and obtain

$$\begin{aligned} M_\alpha(t,p) &= \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_\Lambda dy X_\omega(t,p;y) \\ &= \mathbb{E}\left\{ \int_{\mathbb{R}^d} dx \int_{C_0} dy \partial_{x_\alpha} K_\omega(t;x,y) \partial_{y_\alpha} K_\omega(p;y,x) \right\}. \end{aligned} \tag{48}$$

This proves the proposition. □

Corollary 3.1: From the definition of the velocity operator (5), we have

$$\partial_{x_\alpha} K_\omega(t;x,y) = \frac{-i}{2} (\nabla H_\alpha e^{-tH})(x,y), \tag{49}$$

so we can rewrite $M_\alpha(t,p)$ as given in Eq. (38) as

$$M_\alpha(t,p) = \mathbb{E}\{(\nabla H_\alpha e^{-tH} \nabla H_\alpha e^{-pH})(0,0)\}, \tag{50}$$

and as given in Eq. (40) as

$$M_\alpha(t,p) = \mathbb{E}\{Tr(\chi_{C_0} \nabla H_\alpha e^{-tH} \nabla H_\alpha e^{-pH} \chi_{C_0})\}. \tag{51}$$

D. Proof of Theorem 2.1

1. Proposition 3.1 shows that the limit of the double Laplace transform of the finite-volume current-current correlation measure exists almost surely. The limit is clearly independent of the family of expanding regions provided they satisfy condition (F). *A priori*, this limit depends on the boundary conditions, Dirichlet, Robin, or Neumann, used to define the finite-volume Hamiltonians. The independence of the boundary conditions follows from an estimate on the difference between pairs of heat kernels defined with the various boundary conditions. For example, the independence of Dirichlet or Neumann boundary conditions follow from estimating:

$$\partial_{x_\alpha}[K_\Lambda^D(t;x,y) - K_\Lambda^N(t;x,y)] = \partial_{x_\alpha}[K_\Lambda^D(t;x,y) - K(t;x,y)] + \partial_{x_\alpha}[K(t;x,y) - K_\Lambda^N(t;x,y)], \quad (52)$$

restricted to Λ. As each of the terms on the right in Eq. (52) are bounded above as in Eq. (27), we can show that

$$M_{\alpha,\Lambda}^D(t,p) - M_{\alpha,\Lambda}^N(t,p) \to 0, \quad (53)$$

as $\Lambda \to \mathbb{R}^d$ and for each $\alpha = 1, \ldots, d$. A similar estimate holds for any other pair of boundary conditions. Hence, the limit function $M_\alpha(t,p)$ is independent of the boundary conditions.

2. Given the convergence of the Laplace transforms, we prove in Appendix A, that there exists a unique measure $m_\alpha(dE, dE')$ such that

$$m_\alpha(dE, dE') = \lim_{|\Lambda| \uparrow \infty} m_\Lambda^\alpha(dE, dE'), \quad (54)$$

vaguely, and that

$$M_\alpha(t,p) = \int_{[0,\infty[^2} e^{-tE} e^{-pE'} m_\alpha(dE, dE'). \quad (55)$$

This expression of $M_\alpha(t,p)$ is given in Eq. (50) for the $\mathbb{R}^d$-ergodic case

$$M_\alpha(t,p) = \mathbb{E}_\omega((\nabla H_\alpha e^{-tH} \nabla H_\alpha e^{-pH})(0,0)), \quad (56)$$

and in Eq. (51) for the $\mathbb{Z}^d$-ergodic case

$$M_\alpha(t,p) = \mathbb{E}\{T_r(\chi C_0 \nabla H_\alpha e^{-tH} \nabla H_\alpha e^{-pH} \chi_{C_0})\}. \quad (57)$$

The spectral theorem allows us to write the semigroup e^{-mH} as $\int_\Sigma e^{-mE} E_H(dE)$, where Σ is the almost sure spectrum of the random family H_ω. In the case of a positive potential and $H_0 = -\Delta$, we have $\Sigma = [0, \infty[$. Using this representation in Eq. (56), we have

$$M_\alpha(t,p) = \int_{[0,\infty[^2} e^{-tE} e^{-pE'} \mathbb{E}\{(\nabla H_\alpha E_H(dE) \nabla H_\alpha E_H(dE'))(0,0)\}, \quad (58)$$

and the corresponding relation for Eq. (57). Comparing Eqs. (58) and (55), we obtain the result.□

IV. THE CURRENT-CURRENT CORRELATION MEASURE AS A THERMODYNAMIC LIMIT: LATTICE CASE

In this section, we prove Theorem 2.2 for the lattice case. The computation of the Pastur-Shubin formula for lattice models is different from the continuous case in two respects. First, the free heat kernel has sub-Gaussian, rather than Gaussian, decay. Second, the spatial derivative is a lattice translation so that estimates on the heat kernels only suffice for proving the existence of the thermodynamic limit.

A. Heat kernels

The lattice Laplacian defined in Eq. (4) has a Fourier transform given by $\mathcal{F}(L)(k) = \Sigma_{j=1}^d 2\cos(2\pi k_j)$, with $k \in T^d = [0,1]^d$. Using this to compute the $\mathbb{Z}^d$ -translation-invariant free heat kernel, one obtains

$$K^{(0)}(t;n) = e^{tL}(n) = \prod_{j=1}^d k^{(0)}(t;n_j), \quad n = (n_1, \ldots, n_d) \in \mathbb{Z}^d, \quad (59)$$

with $k^{(0)}(t;n_j)$, for $n_j \in \mathbb{Z}$, is the one-dimensional heat kernel given by

$$k^{(0)}(t;n_j) = i^{n_j} J_{n_j}(-2ti), \tag{60}$$

where $J_k(z)$ is the Bessel function of the first kind of order k given by

$$J_k(z) = \frac{1}{2\pi}\int_0^{2\pi} e^{iz\sin\theta} e^{-ik\theta} d\theta. \tag{61}$$

A simple calculation using the power series representation of $J_k(z)$ shows that $J_k(-2it) = i^{-k} P_k(t)$, where $P_k(t)$ is a positive function for $t \geqslant 0$. Consequently, the heat kernel $K^{(0)}(t;n)$ is a positive function for $t \geqslant 0$. The large $|n|$ behavior of this kernel is

$$K^{(0)}(t;n) \leqslant \frac{t^{C_d\|n\|}}{|n_1|!\ \ldots |n_d|!} e^{dt^2} \leqslant e^{dt^2} \prod_{j=1}^{d} (et)^{|n_j|} e^{-\alpha_d |n_j| \log(|n_j|+1)}. \tag{62}$$

This should be be compared with Eq. (24). In the case that $H_0 = L + V_0$, where V_0 satisfies (H1L), the free heat kernel is $\mathbb{Z}^d$-periodic. Inequalities (23) hold for the lattice model under hypotheses (H1L) and (H2L).

For the derivative in the x_α-direction, let e_α be the unit vector in that direction. There are actually two unitarily equivalent definitions of the derivative, one being

$$(\partial^+_{x_\alpha} f)(n) = f(n + e_\alpha), \tag{63}$$

and the other being

$$(\partial^-_{x_\alpha} f)(n) = f(n - e_\alpha). \tag{64}$$

We will work with the first definition $\partial^+_{x_\alpha}$, and drop the $+$ from the notation. With these definitions, the Laplacian defined in Eq. (4) is equal to $\Sigma_\alpha \partial^\pm_{x_\alpha}$, for either derivative. We compute, via Eq. (5), the αth-component of the velocity operator ∇H_α as i-times the partial derivative given in Eq. (63). The boundary $\partial\Lambda$ of the set $\Lambda \subset \mathbb{Z}^d$ is defined to be

$$\partial\Lambda = \left\{ n \in \Lambda^c; \quad \inf_{m\in\Lambda} |m-n| = 1 \right\}, \quad \partial\Lambda \subset \Lambda^c. \tag{65}$$

We present a version of Proposition 3.1 that holds for the lattice models with Dirichlet boundary conditions (DBC). The method of proof uses the Feynman-Kac formula (31). We refer the reader to Refs. 12 and 13 for a discussion of the Feynman-Kac formula and notation. Brownian motion on the lattice $\mathbb{Z}^d$ is discussed in the book of Carmona and Lacroix.[1] The proof given here in the lattice case is also applicable to the continuous models on $\mathbb{R}^d$ as remarked in Sec. III A. One has to use the Gaussian kernel (24) for $K^{(0)}$ and the Gaussian probability density in the calculation of the integral in Eq. (72) below. This will give the upper bound (27) for the difference of the heat kernels (26) in Theorem 3.1.

Proposition 4.1: *Let $K(t;m,n)$ and $K_\Lambda(t;m,n)$ be the infinite-volume and finite-volume heat kernels, respectively, for the Hamiltonian $H_\omega = L + V_0 + V_\omega$, on $\ell^2(\mathbb{Z}^d)$, respectively, on $\ell^2(\Lambda)$, with DBC and satisfying (H1L) and (H2L). We have*

$$K_\Lambda(t;m,n) = K(t;m,n) + E_\Lambda(t;m,n), \quad \text{for } m,n \in \Lambda, \tag{66}$$

where the difference E_Λ satisfies

$$|E_\Lambda(t;m,n)| \leqslant C_d e^{-c_d t} e^{-(\|m-n\|\log\|m-n\| + d(p,\partial\Lambda)\log d(p,\partial\Lambda))}, \tag{67}$$

where p can be taken to be either m or n, $d(\cdot,\cdot)$ denotes the distance function, and the constants $C_d, c_d > 0$ are finite positive constants independent of Λ, t, m, n.

Proof: The difference between the infinite volume heat kernel of the Hamiltonian $H = H_0 + V_\omega$ and the finite volume heat kernel (with Dirichlet boundary conditions) is given by the Feynman-Kac formula. Let $B(s)$ be d-dimensional Brownian motion on the lattice $\mathbb{Z}^d$ so that

$B(0)=0$. For $m,n \in \Lambda \subset \mathbb{Z}^d$ and $t>0$, let $b(s)$ be the Brownian bridge connecting m at $s=0$ to n at $s=t$. We then have

$$K(t;m,n) - K_\Lambda(t;m,n) = \mathbb{E}^{t,n}_{0,m}(e^{-\int_0^t (V_0+V_\omega)(b(u))du}) - \mathbb{E}^{t,n}_{0,m}(e^{-\int_0^t (V_0+V_\omega)(b(u))du}\chi_\Lambda(b(\cdot)))$$
$$= \mathbb{E}^{t,n}_{0,m}(e^{-\int_0^t (V_0+V_\omega)(b(u))du}(1-\chi_\Lambda(b(\cdot)))) \leqslant \mathbb{E}^{t,n}_{0,m}(1-\chi_\Lambda(b(\cdot))), \quad (68)$$

since the potential V_0+V_ω is nonnegative (actually, only lower semibounded is necessary). We recall that the measure corresponding to the expectation $\mathbb{E}^{t,n}_{0,m}$ in Eq. (68) satisfies

$$\mathbb{P}^{t,n}_{0,m}(\cdot) = K^{(0)}(t;n-m)\widetilde{\mathbb{P}}^{t,n}_{0,m}(\cdot), \quad (69)$$

where $\widetilde{\mathbb{P}}^{t,n}_{0,m}(\cdot)$ is the normalized probability measure on paths connecting m at $s=0$ to n at $s=t$. Because of the translation invariance and the nature of the integrand in the last term in Eq. (68), we have

$$\mathbb{E}^{t,n}_{0,m}(1-\chi_\Lambda(b(\cdot))) = \mathbb{E}^{t,n-m}_{0,0}(1-\chi_\Lambda(B(\cdot)+m)) = \mathbb{E}^{t,n-m}_{0,0}(B(s)+m \notin \Lambda, \quad \text{for some } 0 \leqslant s \leqslant t). \quad (70)$$

With reference to Eqs. (69) and (70), we note that the measure $\widetilde{\mathbb{P}}^{t,n-m}_{0,0}$ is the conditional probability measure for Brownian motion satisfying $B(0)=0$ and conditioned by $B(t)=n-m$. Bounding this above by the unconditioned probability measure $\bar{P}_{0,0}$, we obtain from Eq. (70)

$$\mathbb{E}^{t,n}_{0,m}(1-\chi_\Lambda(b(\cdot))) \leqslant K^{(0)}(t;m-n)\widetilde{\mathbb{P}}_{0,0}(B(s)+m \notin \Lambda, \quad \text{for some } 0 \leqslant s \leqslant t)$$
$$\leqslant K^{(0)}(t;m-n)\widetilde{\mathbb{P}}_{0,0}(|B(s)| \geqslant \operatorname{dist}(m,\partial\Lambda), \quad \text{for some } 0 \leqslant s \leqslant t). \quad (71)$$

The probability on the last line in Eq. (71) is calculated in Ref. 12 for the Gaussian case. The first line in Eq. (72) below, proven, for example, in Ref. 13, is called Lévy's inequality. We repeat this calculation here

$$\widetilde{\mathbb{P}}_{0,0}(|B(s)| \geqslant \operatorname{dist}(m,\partial\Lambda), \quad \text{for some } 0 \leqslant s \leqslant t)$$
$$\leqslant 2\widetilde{\mathbb{P}}_{0,0}(|B(t)| \geqslant \operatorname{dist}(m,\partial\Lambda))$$
$$\leqslant 2C(d,t) \sum_{\{n\in\mathbb{Z}^d : \|n\| > \operatorname{dist}(m,\partial\Lambda)\}} K^0(t;n), \quad (72)$$

where K^0 is defined in Eq. (59) and $C(d,t)>0$ is the normalization constant so that

$$C(d,t)\sum_{n\in\mathbb{Z}^d} K^0(t;n) = 1. \quad (73)$$

Using Eq. (62), we find that

$$\sum_{\{n\in\mathbb{Z}^d : \|n\| > \operatorname{dist}(m,\partial\Lambda)\}} K^{(0)}(t;n) \leqslant C_0 e^{-2t} e^{-C_1 d(m,\partial\Lambda)(\log d(m,\partial\Lambda) - |\log t|)}, \quad (74)$$

for some finite constants $C_0, C_1 > 0$. This estimate, along with the estimate (62) for the heat kernel prove bound (67). □

B. The Birkhoff Ergodic theorem for lattice models

For lattice models on $\ell^2(\mathbb{Z}^d)$, the translation group is $\mathbb{Z}^d$, or a subgroup $\Gamma_N = N\mathbb{Z}^d$, for $N \geqslant 1$. When $N=1$, we have $\Gamma_1 = \mathbb{Z}^d$. The operator $L+V_\omega$ is $\mathbb{Z}^d$-covariant, but the background potential V_0 may be only Γ_N-periodic. Consequently, the entire operator H_ω is Γ_N-covariant. In this case, the Birkhoff ergodic theorem that we will use is as follows. Let $X_\omega(m) \in L^1(\Omega,\mathbb{P})$ be a Γ_N-ergodic,

uniformly bounded, random variable such that $X_\omega(m+a)=X_{\tau_a\omega}(m)$, for any $a\in\Gamma_N$ and $m\in\mathbb{Z}^d$. Recall that τ_k is an ergodic action of Γ_N on the probability space $(\Omega,\mathbb{P})$. Let $C_0(N)$ denote a fundamental cell for Γ_N centered at the origin with volume $|C_0(N)|=N^d$. We then have

$$\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}(X_\omega(k))=\lim_{|\Lambda|\to\infty}\frac{1}{|\Lambda|}\sum_{m\in\Lambda}X_\omega(m), \tag{75}$$

where the sequence of Γ_N-compatible regions Λ increases to $\mathbb{Z}^d$. When $N=1$, we obtain the usual expression

$$\mathbb{E}(X_\omega(0))=\lim_{|\Lambda|\uparrow\infty}\frac{1}{|\Lambda|}\sum_{j\in\Lambda}X_\omega(j). \tag{76}$$

C. Convergence of the Laplace transform of the finite-volume measure

We next present the analog of Proposition 3.1 for the lattice case.

Proposition 4.2: Let $K_\omega(t;x,y)$ denote the heat kernel for the Hamiltonian $H_\omega=L+V_0+V_\omega$ (3) on $\ell^2(\mathbb{Z}^d)$, with V_0 a Γ_N-periodic background potential. For every $t>0$ and $p>0$, the limit as $|\Lambda|\to\infty$ of $M_\Lambda^{(\alpha)}(t,p)$, with Dirichlet boundary conditions, exists almost surely, for any $\alpha=1,\ldots,d$, and for any increasing sequence of domains satisfying, condition (νH). The limit is equal to

$$M_\alpha(t,p)=\lim_{|\Lambda|\to\infty}M_\Lambda^{(\alpha)}(t,p) \tag{77}$$

$$=\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\left(\sum_{m\in\mathbb{Z}^d}\partial_{m_\alpha}K_\omega(t;m,k)\partial_{m_\alpha}K_\omega(p;k,m)\right). \tag{78}$$

Proof: 1. In the lattice case, formula (22) reads

$$M_\Lambda(t,p)=\frac{1}{|\Lambda|}\sum_{m,n\in\Lambda}\partial_{m_\alpha}K_\Lambda(t;m,n)\partial_{n_\alpha}K_\Lambda(p;n,m). \tag{79}$$

From the definition (63), there are four terms involving the heat kernels K_Λ. We write $M_\Lambda=I+II+III+IV$, where

$$I=\frac{1}{|\Lambda|}\sum_{m,n\in\Lambda}K_\Lambda(t;m+e_\alpha,n)K_\Lambda(p;n+e_\alpha,m), \tag{80}$$

$$II=-\frac{1}{|\Lambda|}\sum_{m,n\in\Lambda}K_\Lambda(t;m,n)K_\Lambda(p;n+e_\alpha,m), \tag{81}$$

$$III=-\frac{1}{|\Lambda|}\sum_{m,n\in\Lambda}K_\Lambda(t;m+e_\alpha,n)K_\Lambda(p;n,m), \tag{82}$$

$$IV=\frac{1}{|\Lambda|}\sum_{m,n\in\Lambda}K_\Lambda(t;m,n)K_\Lambda(p;n,m). \tag{83}$$

2. We next replace each finite-volume heat kernel K_Λ by the infinite-volume heat kernel K_ω, restricted to Λ. As in the continuous case, the estimate of the difference E_Λ given in Proposition 4.1 is sufficient to repeat the arguments of Appendix B in the lattice case proving that the substitution can be performed.

3. We now use the Birkhoff ergodic theorem to control the resulting terms I,II,III,IV. For example, term I has the form

$$\frac{1}{|\Lambda|}\sum_{n,m\in\Lambda} K_\omega(t;m+e_\alpha,n)K_\omega(p;n+e_\alpha,m). \tag{84}$$

As in Sec. III, we replace the sum over $n\in\Lambda$ by the sum over $n\in\mathbb{Z}^d$. We now define

$$F_\omega(m)=\sum_{n\in Z^d} K_\omega(t;m+e_{\alpha,n})K_\omega(p;n+e_\alpha,m). \tag{85}$$

The covariance rule (35) and the translational invariance on the sum over n allow us to verify that

$$F_\omega(m+a)=F_{\tau_a\omega}(m), \tag{86}$$

for $a\in\Gamma_N$. As a consequence, the Birkhoff ergodic theorem (76) implies that

$$\lim_{\Lambda\to Z^d}\frac{1}{|\Lambda|}\sum_{m\in\Lambda} F_\omega(m)=\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\{F_\omega(k)\}, \tag{87}$$

so that term I has a limit

$$\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\left\{\sum_{n\in Z^d} K_\omega(t;n+e_\alpha,k)K_\omega(p;e_\alpha,n)\right\}. \tag{88}$$

4. In the same way, we see that the limit of terms II–IV can be evaluated using the Birkhoff ergodic theorem and the invariance of the sum over Γ_N. We then find for these terms

$$-\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\left\{\sum_{n\in Z^d} K_\omega(t;e_\alpha,n)K_\omega(p;n,k)\right\}, \tag{89}$$

$$-\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\left\{\sum_{n\in Z^d} K_\omega(t;k,n)K_\omega(p;n+e_\alpha,k)\right\} \tag{90}$$

and

$$\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\left\{\sum_{n\in Z^d} K_\omega(t;k,n)K_\omega(p;n,k)\right\}. \tag{91}$$

Combining the limits (88)–(91), we see that

$$\lim_{\Lambda\to Z^d} M_\Lambda^{(\alpha)}(t,p)=\frac{1}{N^d}\sum_{k\in C_0(N)}\mathbb{E}\left\{\sum_{n\in Z^d}\partial_{k_\alpha}K_\omega(t;k,n)\partial_{n_\alpha}K_\omega(p;n,k)\right\}. \tag{92}$$

The remaining parts of the proof proceed as in the continuum case. □

V. THE TRACE-PER-UNIT VOLUME APPROACH

There is another common, and equivalent, definition of the density of states measure using the infinite-volume Hamiltonian. We refer to this as the trace-per-unit volume definition. We refer the reader to Refs. 8 and 14 for further discussion. We extend this definition to the current-current

correlation measure. A covariant operator A_ω, for $\omega \in \Omega$, is a family of bounded, measurable operators satisfying $A_{\tau_j \omega} = U_j A_\omega U_j^{-1}$, for j in a translation group $\mathbb{R}^d$ or $\mathbb{Z}^d$.

Definition 5.1: *Let χ_Λ be the characteristic function on region $\Lambda \subset \mathbb{Z}^d$ or $\mathbb{R}^d$. The trace-per-unit volume of a covariant operator A_ω is defined as*

$$\mathcal{T}_{\mathbb{P}}(A) \equiv \lim_{\Lambda \to X} \frac{1}{|\Lambda|} Tr \chi_\Lambda A_\omega \chi_\Lambda, \tag{93}$$

where $X = \mathbb{Z}^d$ or $X = \mathbb{R}^d$.

Provided the limit in Eq. (93) exists, the ergodicity of the group action and the covariance property of A_ω imply that the limit is almost surely independent of ω. In order to obtain the integrated density of states $N(E)$, let $P_\omega(E)$ be the spectral projector for H_ω on the half-line $(-\infty, E]$. Then, we have $N(E) = \mathcal{T}_{\mathbb{P}}(P_\omega(E))$, and the DOS measure ν is defined through the relation

$$\int f(E) d\nu(E) = \mathcal{T}_{\mathbb{P}}(f(H_\omega)). \tag{94}$$

For the current-current correlation measures, we use standard notation for the velocity observable

$$\nabla H_\alpha \equiv i[H_\omega, X_\alpha] = i[H_0, X_\alpha], \tag{95}$$

as in the other sections. The infinite-volume *current-current correlation measures* $\tilde{m}_\alpha$, for $\alpha = 1, \ldots, d$, are defined directly using the infinite-volume operators H_ω. For two functions $f, g \in C_0(\mathbb{R})$, we define the bilinear mapping $\tilde{m}_\alpha$ by

$$f, g \in C_0(\mathbb{R}) \to \tilde{m}_\alpha(f, g) \equiv \mathcal{T}_{\mathbb{P}}\{\nabla H_\alpha f(H_\omega) \nabla H_\alpha g(H_\omega)\}. \tag{96}$$

This is the trace-per-unit volume of the covariant operator $\nabla H_\alpha f(H_\omega) \nabla H_\alpha g(H_\omega)$ and corresponds to the operator defined in Eq. (13).

Proposition 5.1: The map $\tilde{m}_\alpha$ defined on pairs of function as in Eq. (96) extends to a unique nonnegative linear functional on $C_0(\mathbb{R}^2)$ and hence determines a measure $\tilde{m}_\alpha$ on $\mathbb{R}^2$.

As a consequence, we note that for two intervals $\Delta_j \subset \mathbb{R}$, for $j = 1, 2$, the current-current correlation measure $\tilde{m}_\alpha$ is

$$\tilde{m}_\alpha(\Delta_1, \Delta_2) \equiv \mathcal{T}_{\mathbb{P}}\{\nabla H_\alpha E_H(\Delta_1) \nabla H_\alpha E_H(\Delta_2)\}. \tag{97}$$

The next theorem is the analog of a well-known result for the DOS. The DOS can be described through the thermodynamic limit as in Sec. II, or it can be described through the trace-per-unit volume approach as in Eq. (94). In most cases, these yield the same measure.

Theorem 5.1: *We assume the hypotheses of Theorems 2.1 or 2.2 and use the same increasing families of regions to construct $\tilde{m}_\alpha$. Then, the nonnegative measure $\tilde{m}_\alpha$, described in Proposition 5.1, is equal to the current-current correlation measure $\tilde{m}_\alpha$ constructed in Theorem 2.1, for continuum models, or in Theorem 2.2, for lattice models.*

Proof: We use the converse of Lemma 6.1 stating that if a uniformly bounded sequence of measures μ_n on $\mathbb{R}^d$ is such that the Laplace transforms converge pointwise, then the measures converge vaguely. We compare the Laplace transform of the local measure defined using H_Λ given by

$$\begin{aligned} L(\mu_\Lambda)(t,p) &= \frac{1}{|\Lambda|} Tr_\Lambda \nabla H_\alpha e^{-tH_\Lambda} \nabla H_\alpha e^{-pH_\Lambda} \\ &= \frac{1}{|\Lambda|} Tr_{\mathbb{R}^d} \chi_\Lambda \nabla H_\alpha e^{-tH_\Lambda} \nabla H_\alpha e^{-pH_\Lambda} \chi_\Lambda, \end{aligned} \tag{98}$$

with the expression involving the infinite-volume Hamiltonian H_ω restricted to Λ

$$L(\nu_\Lambda)(t,p) = \frac{1}{|\Lambda|} Tr_{\mathbb{R}^d} \chi_\Lambda \nabla H_\alpha e^{-tH_\omega} \nabla H_\alpha e^{-tH_\omega} \chi_\Lambda. \tag{99}$$

Note that the semigroups are smoothing operators. The convergence of the Laplace transforms requires that we prove the vanishing of the following two terms:

$$I = \frac{1}{|\Lambda|} Tr \chi_\Lambda (\nabla H_\alpha e^{-tH_\Lambda} - \nabla H_\alpha e^{-tH_\omega}) \nabla H_\alpha e^{-pH_\Lambda} \chi_\Lambda, \tag{100}$$

$$II = \frac{1}{|\Lambda|} Tr \chi_\Lambda \nabla H_\alpha e^{-tH_\omega} (\nabla H_\alpha e^{-pH_\Lambda} - \nabla H_\alpha e^{-pH_\omega}) \chi_\Lambda. \tag{101}$$

This follows directly from the estimates on the differences of the finite-volume and infinite-volume heat kernels and their derivatives as used in Secs. III and IV, and the arguments in Appendix B on the replacement of the finite-volume heat kernel by the infinite-volume one. □

It is, of course, an immediate consequence of the equality of m_α, constructed with some self-adjoint boundary condition, and $\tilde{m}_\alpha$, independent of any boundary conditions, that the current-current correlation measure is independent of the self-adjoint boundary conditions used to construct it.

APPENDIX A: THE *d*-DIMENSIONAL LAPLACE TRANSFORM

We state the main results on the d-dimensional Laplace transform of positive measures supported on the positive cone $C_d^+ \equiv \{x \in \mathbb{R}^d | x_j > 0, \text{ for } j=1,\ldots,d\} \subset \mathbb{R}^d$ that we use in this paper. Let $\lambda=(\lambda_1,\ldots,\lambda_d)$ and $x=(x_1,\ldots,X_d)$ denote vectors in $\mathbb{R}^d$. Let μ be a d-dimensional positive measure defined on C_d^+ so that $\mu(C_d^+) \leqslant 1$. The d-dimensional Laplace transform of μ, denoted by $L(\mu)(\lambda)$, is given by

$$L(\mu)(\lambda) = \int_{C_d^+} e^{-\lambda \cdot x} d\mu(x), \tag{A1}$$

and we have $|L(\mu)(\lambda)| \leqslant 1$, for $\lambda \in C_d^+$. Of course, the Laplace transform exists for a much more general class of measures, but we do not deal with them here. We also need the following analyticity hypothesis on the Laplace transform.

Analyticity Hypothesis: The Laplace transform $L(\mu)(\lambda)$ *is analytic for* λ *in the product of half-planes* $\Pi^+ \equiv \{\lambda \in \mathbb{C}^d | \Re\lambda_j > 0, j=1,\ldots,d\}$.

It is clear from the representations (38) and (40), and the analyticity of the heat kernels in a half-plane, that this analyticity hypothesis is satisfied for the cases considered here.

We first recall the definition of vague convergence of measures, cf. Ref. 15. A sequence of measures μ_n on a measurable space Y *converges vaguely* to a measure μ if for any $f \in C_0(Y)$, we have $\mu_n(f) \to \mu(f)$, where $\mu(f) \equiv \int_Y f d\mu$. The main results that we use in this paper is the following theorem.

Theorem 6.1: *Let* $\{\mu_n\}$ *be a sequence of positive measures on* C_d^+ *such that* $\mu_n(C_d^+) \leqslant 1$ *and each measure* μ_n *satisfies the analyticity hypothesis. If the sequence of d-dimensional Laplace transforms* $L(\mu_n)$ *on* C_d^+ *converges pointwise to a finite function* ϕ, *also analytic on the product of half-planes* Π^+, *then there exists a unique positive measure* μ *on* C_d^+ *satisfying* $\mu(C_d^+) \leqslant 1$ *so that* $\phi(\lambda)=L(\mu)(\lambda)$, *and the measures* $\mu_n \to \mu$ *vaguely.*

We need two auxiliary lemmas.

Lemma 6.1: Suppose a sequence of nonnegative, normalized measures μ_n *on* C_d^+ *converges*

vaguely to a non-negative, normalized measure μ, *and the Laplace transforms* $L(\mu_n)(t)$ *converge pointwise for* $t \in C_d^+$ *to a function* $\phi(t)$. *Then, the Laplace transforms* $L(\mu_n)$ *converge pointwise to* $L(\mu)$, *that is,* $\phi(t)=L(\mu)(t)$.

Proof: Let f_n be a nonnegative function that is one for $t \in B_n(0) \cap C_d^+$, and zero otherwise. Because of the hypotheses on the measures, we note that for any n

$$\lim_{m\to\infty} L((1-f_m)\mu_n)(t) = 0, \quad t \in C_d^+. \tag{A2}$$

We also have uniformity in the sense that if $m>k$

$$0 \leqslant L(f_m\mu_n)(t) - L(f_k\mu_m)(t) \leqslant e^{-kt}, \quad t \in C_d^+. \tag{A3}$$

Using Eq. (A2), we have the following limits:

$$\lim_{n\to\infty}\lim_{m\to\infty} L(f_m\mu_n)(t) = \phi(t) \tag{A4}$$

and

$$\lim_{m\to\infty}\lim_{n\to\infty} L(f_m\mu_n)(t) = L(\mu)(t), \tag{A5}$$

for $t \in C_d^+$. Also, it is easy to show that

$$\lim_{m\to\infty} L(f_m\mu_m)(t) = \phi(t), \quad t \in C_d^+. \tag{A6}$$

If $m<n$, we have $0 \leqslant L(f_m\mu_n)(t) \leqslant L(f_n\mu_n)(t)$. Taking $n\to\infty$, we obtain from Eq. (A6) and vague convergence that $0 \leqslant L(f_m\mu)(t) \leqslant \phi(t)$, from which it follows that $0 \leqslant L(\mu)(t) \leqslant \phi(t)$. On the other hand, if $m>k$, we have

$$0 \leqslant L(f_m\mu_m)(t) = L((f_m - f_k)\mu_m)(t) + L(f_k\mu_m)(t) \leqslant e^{-kt} + L(f_k\mu_m)(t). \tag{A7}$$

Taking $m\to\infty$, it follows from Eq. (A3), Eq. (A6) and this inequality that $0 \leqslant \phi(t) \leqslant e^{-kt} + L(f_k\mu)(t)$. Now, taking $k\to\infty$, we obtain $0 \leqslant \phi(t) \leqslant L(\mu)(t)$. Hence, we have $\phi(t)=L(\mu)(t)$, for all $t \in C_d^+$. □

Lemma 6.2: (*Uniqueness*) *Distinct d-dimensional probability measures, satisfying the analyticity hypothesis, have distinct d-dimensional Laplace transforms.*

Proof: We use a multiple contour integral representation of the inverse Laplace transform (ILT) for contours $\gamma_j=\sigma_j+it_j$, with $t_j \in \mathbb{R}$ and $\sigma_j>0$. We first consider rectangles $R = \Pi_{j=1}^d [a_j,b_j] \subset C_d^+$, and compute the following limit:

$$\lim_{(t_j)\to\infty} \left(\frac{1}{2\pi i}\right)^d \int_{\sigma_1-it_1}^{\sigma_1+it_1} ds_1 \cdots \int_{\sigma_d-it_d}^{\sigma_d+it_d} ds_d \Pi_{k=1}^d \left(\frac{e^{s_k b_k} - e^{s_k a_k}}{s_k}\right) \mathcal{L}(\mu)(s_1, \ldots, s_d). \tag{A8}$$

We use the following identity:

$$\lim_{t_j\to\infty} \frac{1}{2\pi i} \int_{\sigma_j-it_j}^{\sigma_j+it_j} \frac{e^{s_j(b_j-x_j)} - e^{s_j(a_j-x_j)}}{s_j} ds_j = -[\Theta(x_j-b_j) - \Theta(x_j-a_j)], \tag{A9}$$

and the representation of the Laplace transform (A1). As a consequence, we see that the limit in Eq. (A8) is $\mu(R)$, for any rectangle $R \subset C_d^+$. Setting $a_j=0$, we recover a distribution function of the measure supported on C_d^+ and defined by $F_\mu(x_1,\ldots,x_d) \equiv \mu([0,x_1]\times[0,x_2]\times\cdots\times[0,x_d])$, Since the distribution function uniquely determines the measure, we see that if two measures μ_j, satisfying the above hypotheses, are such that $L(\mu_1)=L(\mu_2)$, their distribution functions, and hence the measures themselves, are equal. □

Proof of Theorem 6.1: 1. A normalized measure on C_d^+ is a positive measure with $\mu(C_d^+) \leqslant 1$.

Let μ_n be a sequence of normalized measures on $X=C_0(C_d^+)$ with the norm $\|f\|=\sup|f(x)|$. Each normalized measure defines a bounded linear functional on X since

$$|\mu(f)| \equiv \left| \int_{C_d^+} f d\mu \right| \leqslant \|f\|, \tag{A10}$$

for all $f \in X$. If $S^* \subset X^*$ denotes the unit ball of the dual X^*, then $\mu_n \in S^*$. Since S^* is compact in the weak* topology on X^*, there exists a weak* convergent subsequence μ_{n_j} in S^*. Let $\mu \in S^*$ be its limit point. By definition of weak* convergence, this means that $\mu_{n_j} \to \mu$ vaguely.

2. To prove that the sequence μ_n converges vaguely to μ, we use the Laplace transform $\phi_n \equiv L(\mu_n)$ defined in Eq. (A1). By hypothesis, the sequence $L(\mu_n)$ converges pointwise to a function ϕ on C_d^+. By Lemma 6.1, the vague convergence of measures implies the convergence of the Laplace transforms. Consequently, the subsequence $L(\phi_{n_j})$ converges to $L(\mu)$. But since the limit is unique, we have $L(\mu)=\phi=\lim_j L(\mu_j)$. By the uniqueness result Lemma 6.2, the function ϕ is the Laplace transform of μ.

3. Finally, we need to show that μ_n converges vaguely to μ. It follows that any vaguely convergent subsequence μ_{n_j} converges to μ. Since for any $f \in C_0(C_d^+)$, the sequence $\mu_n(f)$ is uniformly bounded, this implies $\mu_n(f) \to \mu(f)$. □

In order to apply Theorem 6.1 to the measures m_Λ^α, we need a renormalization since these positive measures are not probability measures. Since these measures grow at most polynomially in (E,E'), the Laplace transform exists and is pointwise bounded. Let $(t_0,p_0) \in C_2^+$ be a point at which the Laplace transform $L(m_{\Lambda_n}^\alpha)$ exists and is nonzero (such a point exists for all n). We define a sequence of renormalized measures by

$$\tilde{m}_{\Lambda_n}^\alpha(dE,dE') \equiv e^{-t_0 E - p_0 E'} \frac{m_{\Lambda_n}^\alpha(dE,dE')}{L(m_{\Lambda_n}^\alpha)(t_0,p_0)}. \tag{A11}$$

These positive measures satisfy

$$\tilde{m}_{\Lambda_n}^\alpha(C_2^+) = 1, \tag{A12}$$

and are hence probability measures. We can apply Theorem 6.1 to this sequence since, by Theorem 3.1, the Laplace transforms of m_Λ^α, and consequently of $\tilde{m}_\Lambda^\alpha$ converge pointwise. The Laplace transform of $\tilde{m}_\Lambda^\alpha$, dropping the subscript n, is then

$$L(\tilde{m}_\Lambda^\alpha)(t,p) = \int_{[0,\infty[^2} e^{-itE-pE'} \tilde{m}_\Lambda^\alpha(dE,dE') = \frac{L(m_\Lambda^\alpha)(t+t_0,p+p_0)}{L(m_\Lambda^\alpha)(t_0,p_0)}. \tag{A13}$$

As the Laplace transform is strictly positive, we know that $L(m_{\Lambda_n}^\alpha)(t_0,p_0) \to L(m_\alpha)(t_0,p_0) > 0$, so that the Laplace transforms $L(\tilde{m}_\Lambda^\alpha)(t,p)$ converge pointwise to

$$L(\tilde{m}_\Lambda^\alpha)(t,p) = \frac{L(m_\alpha)(t+t_0,p+p_0)}{L(m_\alpha)(t_0,p_0)}. \tag{A14}$$

So there exists a unique probability measure $\tilde{m}_\alpha(dE,dE')$ whose Laplace transform is $L(\tilde{m}_\alpha)$ and $\tilde{m}_\Lambda^\alpha \to \tilde{m}_\alpha$ vaguely. In order to remove the renormalization, we define a measure m_α by

$$m_\alpha(dE,dE') \equiv e^{t_0 E + p_0 E'} L(\tilde{m}_\alpha)(t_0,p_0) \tilde{m}_\alpha(dE,dE'). \tag{A15}$$

We have then the vague convergence

$$m_\alpha(dE,dE') = \lim_{\Lambda \to \mathbb{R}^d} m_\Lambda^\alpha(dE,dE'), \tag{A16}$$

completing the proof of Theorems 2.1 and 2.2.

APPENDIX B: SUBSTITUTION OF INFINITE-VOLUME HEAT KERNELS IN THE PROOF OF PROPOSITION 3.1

We present the technical details needed in the proof of Proposition 3.1. We work in the continuous case. Similar arguments work in the lattice case for the proof of Proposition 4.2, and we omit the details.

1. Replacement of finite-volume heat kernels by infinite-volume heat kernels

We provide the details of the replacement of the finite-volume heat kernels $\partial_{x_\alpha} K_\Lambda$ in Eq. (41) by the infinite-volume heat kernels $\partial_{x_\alpha} K$ restricted to the region Λ. Since these kernels should differ only on the boundary of the region, the difference should be of order of $|\partial\Lambda|$. We let $d(x,\partial\Lambda)$ denote the distance from $x \in \Lambda$ to the boundary of Λ, denoted by $\partial\Lambda$. In light of Eq. (29), the following integral plays a crucial role:

$$B(\Lambda) \equiv \int_\Lambda e^{-C_0(t)d(x,\partial\Lambda)^2} dx. \tag{B1}$$

We analyze this integral for families of increasing regions satisfying conditions (vH) or (F) in Appendix C and prove that

$$\lim_{n\to\infty} \frac{B(\Lambda_n)}{|\Lambda_n|_d} = 0, \tag{B2}$$

for a wide family of increasing regions Λ_n. We will always assume that we are working with a sequence Λ_n satisfying these conditions in this Appendix, and we will omit the index n from the notation. We consider the term in Eq. (41)

$$I_1 \equiv \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_\Lambda dy \int_\Lambda dx \partial_{x_\alpha} K_\Lambda(t;x,y) \partial_{y_\alpha} K_\Lambda((t;y,x)) \tag{B3}$$

$$\begin{aligned} &= \lim_{|\Lambda|\uparrow\infty} \left(\frac{1}{|\Lambda|} \int_\Lambda dy \int_\Lambda dx \partial_{x_\alpha} K(t;x,y) \partial_{y_\alpha} K(t;y,x) \right. \\ &\quad \left. + \frac{1}{|\Lambda|} \int_\Lambda dy \int_\Lambda dx Q_\Lambda(t,p;x,y) \right), \end{aligned} \tag{B4}$$

where we must control three terms

$$\begin{aligned} Q_\Lambda(t,p;x,y) &\equiv \partial_{x_\alpha} K_\Lambda(t;x,y) \partial_{y_\alpha} K_\Lambda(p;y,x) - \partial_{x_\alpha} K(t;x,y) \partial_{y_\alpha} K(p;y,x) \\ &= \partial_{x_\alpha} K(t;x,y) (\partial_{y_\alpha} K_\Lambda(p;y,x) - \partial_{y_\alpha} K(p;y,x)) \\ &\quad + (\partial_{x_\alpha} K_\Lambda(t;x,y) - \partial_{x_\alpha} K(t;x,y)) \partial_{y_\alpha} K(p;y,x) \\ &\quad + (\partial_{x_\alpha} K_\Lambda(t;x,y) - \partial_{x_\alpha} K(t;x,y)) (\partial_{y_\alpha} K_\Lambda(p;y,x) - \partial_{y_\alpha} K(p;y,x)) \\ &= J_1 + J_2 + J_3. \end{aligned} \tag{B5}$$

By Theorem 3.1, the differences can be written in terms of F_Λ described in Eqs. (28) and (29). To prove that the integral with $Q_\Lambda(t,p;x,y)$ in Eq. (B5) converges to zero, we first foucus on J_1, and note that J_2 is similar

$$J_1 = \lim_{|\Lambda|\uparrow\infty} \frac{1}{|\Lambda|} \int_\Lambda dy \int_\Lambda dx \partial_{x_\alpha} K(t;x-y) F_\Lambda(p;y,x). \tag{B6}$$

By using estimates (29) and (30), Eq. (B1), we easily obtain the upper bound

$$|J_1| \leq C(t,d)\frac{1}{|\Lambda|}\int_{\mathbb{R}^d} dy \int_\Lambda dx e^{-(\beta_d/t)\|x-y\|^2} e^{-(\bar{c}_d/t)d(x,\partial\Lambda)^2}$$

$$\leq \frac{C(t,d)}{|\Lambda|}\left(\int_{\mathbb{R}^d} du\ e^{-(\beta_d/t)\|u\|^2}\right)\left(\int_\Lambda dx e^{-(\bar{c}_d/t)d(x,\partial\Lambda)^2}\right) \leq C(t,d)\frac{B(\Lambda)}{|\Lambda|_d}. \tag{B7}$$

Because, of condition (F), this term vanishes as Λ increases to $\mathbb{R}^d$. The term J_3 in Eq. (B5) is treated in the same manner since

$$J_3 = \frac{1}{|\Lambda|}\int_\Lambda dy \int_\Lambda dx F_\Lambda(t;x,y)F_\Lambda(p;y,x) \leq \frac{C(t,d)}{|\Lambda|}\int_{\mathbb{R}^d} dy \int_\Lambda dx e^{-(\beta_d/t)\|x-y\|^2} e^{-(\bar{c}_d/t)d(x,\partial\Lambda)^2}$$

$$\leq C(t,d)\frac{B(\Lambda)}{|\Lambda|_d}. \tag{B8}$$

This proves the convergence to zero of the remainder integral in Eq. (42).

2. Convergence of the remainder integral in Eq. (43)

In this Appendix, we prove that the integral in the proof of the Proposition 3.1, obtained by replacing Λ by $\mathbb{R}^d\backslash\Lambda$, converges to zero as $\Lambda\to\mathbb{R}^d$. The term appearing in Eq. (43) is

$$\frac{1}{|\Lambda|}\int_{\mathbb{R}^d\backslash\Lambda} dx \int_\Lambda dy \partial_{x_\alpha} K_\omega(t;x,y)\partial_{y_\alpha} K_\omega(p;y,x). \tag{B9}$$

Since $x\in\mathbb{R}^d\backslash\Lambda$ and $y\in\Lambda$, we have $\|x-y\|\geq d(y,\Lambda)$. In view of estimate (30), we have the upper bound

$$\frac{C_{t,p}}{|\Lambda|}\int_{\mathbb{R}^d\backslash\Lambda} dx \int_\Lambda dy e^{-(\tilde{c}_d/t)\|x-y\|^2} e^{-(\tilde{c}_d/t)d(y,\partial\Lambda)^2}. \tag{B10}$$

Integrating first over x, the remaining integral over $y\in\Lambda$ is expressed in terms, of Eq. (B1). It then follows that the infinite-volume limit vanishes due to Eq. (B2).

APPENDIX C: INTEGRALS OVER BOUNDARY-DISTANCE FUNCTIONS

Let $\Lambda\subset\mathbb{R}^d$ or $\mathbb{Z}^d$ be a bounded set. As in Appendix B, for $x\in\Lambda$, we let $d(x,\partial\Lambda)\equiv\text{dist}(x,\partial\Lambda)$ be the distance function to the boundary of Λ. In the continuous case, we see from Proposition 3.1 that there are integrals of the type

$$B(\Lambda) \equiv \int_\Lambda e^{-c_0 d(x,\partial\Lambda)^2/t} d^d x, \tag{C1}$$

that we must evaluate. In particular, we must prove that

$$\lim_{|\Lambda|\to\infty} \frac{B(\Lambda)}{|\Lambda|_d} = 0, \tag{C2}$$

for a suitable sequence of increasing regions Λ_n, where $|A|_k$ denotes the k-dimensional Lebesgue measure of A. In order to verify this limit (C2), we assume that the sequence Λ_n satisfies either condition (vH) (11) in the lattice $\mathbb{Z}^d$ case, or condition (F) (12) in the continuous case. Furthermore, we assume the following property of the boundary-distance function:

Regularity: Given $\epsilon>0$, *there exists a constant* $0<R<\infty$ *so that*

$$|\{x\in\Lambda | d(x,\partial\Lambda)\leq\epsilon\}|_d \leq C\epsilon|\partial\Lambda|_{d-1}, \quad \text{for } 0<\epsilon<R \tag{C3}$$

and

$$|\{x \in \Lambda | d(x, \partial\Lambda) \leqslant \epsilon\}|_d \leqslant |\Lambda|_d, \quad for\ \epsilon > R. \tag{C4}$$

Proposition 8.1: Suppose Λ_n is an increasing sequence of bounded regions satisfying (vH) or (F), Eqs. (11) or (12), respectively, and conditions (C3) and (C4) with constants (C_n, R_n) and the constant C_n in Eq. (C3) is uniformly bounded $0 \leqslant C_n \leqslant C_0 < \infty$, and $R_n \to \infty$ as $|\Lambda_n| \to \infty$. Then, we have

$$\lim_{|\Lambda_n| \to \infty} \frac{B(\Lambda_n)}{|\Lambda_n|_d} = 0, \tag{C5}$$

where $B(\Lambda_n)$ is defined in (C1).

Proof: If Eq. (C5) holds true, the value of the parameter t is not important so we set $t=1$ for convenience. We estimate the integral (C1) for large n as follows:

$$\begin{aligned} B(\Lambda_n) &\leqslant \left\{ \int_{\{x \in \Lambda_n | d(x, \partial\Lambda_n) \leqslant 1\}} + \int_{\{x \in \Lambda_n | 1 < d(x, \partial_n) \leqslant R_n\}} \right\} e^{-c_0 d(x, \partial\Lambda_n)^2} d^d x \\ &\quad + \int_{\{x \in \Lambda_n | d(x, \partial\Lambda_n) \geqslant R_n\}} e^{-c_0 d(x, \partial\Lambda_n)^2} d^d x \\ &\leqslant C_n |\partial\Lambda_n|_{d-1} + \sum_{k=1}^{[\log R_n]+1} e^{-c_0 (1 + K_n (k-1))^2} |\{x \in \Lambda_n | C_k \\ &\quad \leqslant d(x, \partial\Lambda_n) \leqslant C_{k+1}\}|_d + e^{-c_0 R_n^2} |\Lambda_n|_d, \end{aligned} \tag{C6}$$

where $K_n = ((R_n - 1)/[\log R_n])$, with $[x]$ the greatest integer less than x, and $C_k = 1 + -K_n(k-1)$. The sum in Eq. (C6) is bounded above by

$$\begin{aligned} &\sum_{k=1}^{[\log R_n]+1} e^{-c_0 (1 + K_n (k-1))^2} |\{x \in \Lambda_n | C_k \leqslant d(x, \partial\Lambda_n) \leqslant C_{k+1}\}|_d \\ &\quad \leqslant D_0 \left(1 + \frac{1}{K_n}\right) (1 - e^{-c_0 K_n^2 ([\log R_n] - 1)^2}) |\partial\Lambda_n|_{d-1}, \end{aligned} \tag{C7}$$

for some finite constant $D_0 > 0$ independent of n. Consequently, we have

$$\frac{B(\Lambda_n)}{|\Lambda_n|_d} \leqslant D_1 \frac{|\partial\Lambda_n|_{d-1}}{|\Lambda_n|_d}, \tag{C8}$$

for some other finite constant $D_1 > 0$, independent of n, and the result follows. □

For what regions are conditions (C3) and (C4) satisfied? We state the following simple result. The proof follows from the existence of a boundary collar neighborhood.

Lemma 8.1: Let $\Lambda \subset \mathbb{R}^d$ be a bounded region with a piecewise C^1-boundary. Then conditions (C3) and (C4) are satisfied.

We can consider the family Λ_n obtained by dilations of a given region satisfying the hypothesis of Lemma 8.1 and easily check the hypotheses of Proposition 8.1.

Equilibrium and eigenfunctions estimates in the semiclassical regime

Brice Camus[a)]
Ruhr-Universität Bochum, Fakultät für Mathematik, Universitätsstr. 150, D-44780 Bochum, Germany

(Received 19 June 2006; accepted 5 October 2006; published online 30 November 2006)

We establish eigenfunctions estimates, in the semiclassical regime, for critical energy levels associated to an isolated singularity. For Schrödinger operators, the asymptotic repartition of eigenvectors is the same as in the regular case, excepted in dimension one where a concentration at the critical point occurs. This principle extends to pseudo-differential operators and the limit measure is the Liouville measure as long as the singularity remains integrable. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2378619]

I. INTRODUCTION

The problem we consider here concerns the asymptotic behavior of eigenvectors of a self-adjoint operator and follows the works of Colin de Verdière[1] and Zelditch,[2] on the basis of a result stated first by Shnirel'man. We are more precisely interested in a proof of a microlocal concentration phenomena, in the semiclassical regime, as established in Refs. 3 and 4. The adaptation to semiclassical analysis was done in Ref. 5 following a technique proposed by Voros.[6] We also mention Ref. 7 for a more general approach in the scattering setting.

Consider a quantum operator P_h, realized as a self-adjoint operator acting on a dense subset of $L^2(\mathbb{R}^n)$. A typical example, studied in Sec. II, is the Schrödinger operator $P_h=-h^2\Delta+V$ where the potential V is smooth and bounded from below. If the spectrum of P_h is discrete in $[E-\varepsilon,E+\varepsilon]$, a sufficient condition for this is given below, we can enumerate the eigenvalues in this interval as a sequence $\lambda_j(h)$ with finite multiplicities. We note ψ_j^h the corresponding normalized eigenvectors, i.e.,

$$P_h\psi_j^h=\lambda_j(h)\psi_j^h, \quad \|\psi_j^h\|_{L^2}=1.$$

Our objective is to establish eigenfunctions estimates

$$\begin{cases} \nu_j(a)=\langle \mathrm{Op}_h^w(a)\psi_j^h,\psi_j^h\rangle, \\ \lambda_j(h)\to E,\ h\to 0^+, \end{cases}$$

where $a\in S^0(\mathbb{R}^{2n})$, so that by the Calderon-Vaillancourt theorem

$$f\mapsto \mathrm{Op}_h^w(a)f(x)=\frac{1}{(2\pi h)^n}\int_{\mathbb{R}^{2n}} a\left(\frac{x+y}{2},\xi\right)e^{(i/h)\langle x-y,\xi\rangle}f(y)dyd\xi,$$

is bounded on $L^2(\mathbb{R}^n)$. Note that the statement of the problem is local w.r.t. E and we are interested here in the case of $E=E_c$ critical. Let $\Phi_t=\exp(tH_p)$ be the Hamiltonian flow of the principal symbol p of P_h. Each $\nu_j(a)$ measures the observable $\mathrm{Op}_h^w(a)$ in the state ψ_j^h. Interpreted as distributions, these measures are Φ_t-invariant which easily follows from:

[a)]Electronic mail: brice.camus@univ-reims.fr

$$\langle e^{-(it/h)P_h}\mathrm{Op}_h^w(a)e^{(it/h)P_h}\psi_j^h,\psi_j^h\rangle = \langle \mathrm{Op}_h^w(a)e^{(it/h)\lambda_j(h)}\psi_j^h, e^{(it/h)\lambda_j(h)}\psi_j^h\rangle = \nu_j(a).$$

By Egorov's theorem $e^{-(it/h)P_h}\mathrm{Op}_h^w(a)e^{(it/h)P_h}$ is an operator of principal symbol $(a\circ\Phi_t)$ and ν_j is invariant under Φ_t, up to $\mathcal{O}(h)$.

We recall that E is regular if $\nabla p \neq 0$ on the energy surface

$$\Sigma_E = \{(x,\xi) \in T^*\mathbb{R}^n / p(x,\xi) = E\},$$

and critical otherwise. When E_c is critical, Σ_{E_c} is not a smooth manifold. For E regular, Σ_E inherits a measure, invariant by Φ_t, given by

$$\mathrm{dLvol}(z) = \frac{dz}{\|\nabla p(z)\|}|_{\Sigma_E}, \quad z \in \Sigma_E,$$

where dz is the Riemannian surface element. We note $\mathcal{V}(E)$ the associated volume of Σ_E and we obtain a probability measure via

$$d\mu^E(z) = \frac{1}{\mathcal{V}(E)}\mathrm{dLvol}(z).$$

Note that if E_c is critical, $d\mu^{E_c}$ has a sense if and only if $1 \in L^1(\Sigma_{E_c}, \mathrm{dLvol})$. Via a wave equation approach, substituting here the heat equation strategy of Ref. 1 on a compact manifold, the problem is related at the first order to the geometry of the energy surfaces. Accordingly, the integrability of dLvol has a strong effect on the asymptotic behavior of the sequence ν_j.

First, we explain what is known in the presence of singularities. The micro-local concentration near a singularity was proven in Ref. 4 for one-dimensional Schrödinger operators with a nondegenerate instable equilibrium attached to a maximum of the potential. At the same time, in Ref. 3 several contributions of nondegenerate critical points are established in a more general setting. The case of critical energy level is specifically considered in Ref. 8 for several commuting elliptic operators and, more recently, in Refs. 9 and 10 these results have been generalized to the case of completely integrable Laplacians on compact Riemannian manifolds. In particular, precise estimates on the unboundedness of L^∞ and L^p norms of eigenfunctions attached to singular leaves are given. As concerns Schrödinger operators on $\mathbb{R}^n$, we mention Ref. 11 where the tunnel effect between degenerate minima of the potential is studied.

Next, we explain the contents of this article. Several results concerning the asymptotics of semiclassical spectral distributions, see Eq. (4), have been obtained in Refs. 12–15 following the approach of Ref. 3. For degenerate critical energy levels the existence of particular asymptotics are established and have been applied to the study of singularities of the distributional trace. The objective of this contribution is to complete these results by the study of the quantum probability $|\psi_j^h|^2$, attached to such critical energy levels, and the associated measures ν_j. As a corollary one obtains precise estimates for the microlocal counting function of eigenvalues. We are first interested in the case of Schrödinger operators, but a generalization to pseudo-differential operators is easy and provides more examples.

Finally, we recall that in Riemannian geometry, e.g., for Laplace operators on compact surfaces of negative curvature, the question to ask is if the full sequence ν_j converges to the invariant measure (quantum unique ergodicity) is still open and has attracted a lot of attention during the last years.

Definitions: We define now the objects used in Secs. II and III. If E_c is a critical energy level, we pick an h-dependant interval

$$I(h) = [E_c - dh, E_c + dh], \quad d > 0. \tag{1}$$

The associated counting function of eigenvalues is

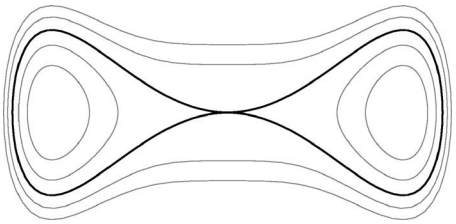

FIG. 1. Energy surfaces of $V(x)=-x^4+x^6$.

$$\Upsilon(h)=\sum_{\lambda_j(h)\in I(h)}\langle\psi_j^h,\psi_j^h\rangle=\#\{j/\lambda_j(h)\in I(h)\}. \tag{2}$$

For $A=\mathrm{Op}_h^w(a)$ a pseudo-differential operator of order zero, whose principal symbol is $a\in S^0(\mathbb{R}^{2n})$ we put

$$\Upsilon_a(h)=\sum_{\lambda_j(h)\in I(h)}\langle A\psi_j^h,\psi_j^h\rangle=\sum_{\lambda_j(h)\in I(h)}\nu_j(a). \tag{3}$$

Observe that $\Upsilon(h)=\Upsilon_1(h)$ since for every quantization used in this contribution the symbol of the identity is 1.

II. SCHRÖDINGER OPERATORS

Let $p(x,\xi)=\xi^2+V(x)$, where the potential $V\in C^\infty(\mathbb{R}^n)$ is a real value. To obtain a well defined spectral problem, we use

($\mathcal{H}_1$) There exists $C\in\mathbb{R}$ such that: $\liminf_\infty V>C$.

By a classical result, $P_h=-h^2\Delta+V(x)$ is essentially self-adjoint. Note that ($\mathcal{H}_1$) is always satisfied if V goes to infinity at infinity. Let $J=[E_1,E_2]$, with $E_2<\liminf_\infty V$. Since $p^{-1}(J)$ is compact, the spectrum $\sigma(P_h)\cap J$ is discrete and consists in a sequence $\lambda_1(h)\leqslant\lambda_2(h)\leqslant\cdots\leqslant\lambda_j(h)$ of eigenvalues of finite multiplicities, if h is small enough. Next, we impose the singularity:

($\mathcal{H}_2$) On Σ_{E_c} the symbol p has an isolated critical point $z_0=(x_0,0)$. This critical point can be degenerate but is associated to a local extremum of V

$$V(x)=E_c+V_{2k}(x)+\mathcal{O}(\|x-x_0^j\|^{2k+1}),\quad k\in\mathbb{N}^*,$$

where V_{2k}, homogeneous of degree $2k$, is definite positive or negative.

The case $k=1$, i.e., a nondegenerate singularity in dimension n, is treated in Ref. 3 without any extremum condition. In Fig. 1 the line in bold is the critical energy level attached to the top of a one-dimensional symmetric degenerate double well. Observe the instability near the recurrent critical point.

To simplify notations we write $z=(x,\xi)\in T^*\mathbb{R}^n$ and z_0 for a critical point. The first result concerns the statistical behavior of the sequence $\nu_j(a)$.

Theorem 1: *Assume ($\mathcal{H}_1$) and ($\mathcal{H}_2$) satisfied. If $n>1$ we have*

$$\lim_{h\to0^+}\frac{\Upsilon_a(h)}{\Upsilon(h)}=\int a d\mu^{E_c},$$

but in dimension 1 we obtain

$$\lim_{h\to 0^+}\frac{\Upsilon_a(h)}{\Upsilon(h)}=\langle\delta_{z_0},a\rangle=a(x_0,0).$$

These relations are statistical since when $h\to 0$ the number of eigenvalues in $I(h)$ tends to infinity, see Proposition 4. We define

$$K(h)=\{j\in\mathbb{N}/\lambda_j(h)\in I(h)\}.$$

Following the results of Refs. 1–3 and 5, for $n>1$ Theorem 1 implies that if Φ_t is ergodic on Σ_{E_c} there exists a density one subset $L(h)\subset K(h)$ such that for all integer valued function $h\to j(h)\in L(h)$ we have

$$\lim_{h\to 0}\langle\psi^h_{j(h)},\mathrm{Op}^w_h(a)\psi^h_{j(h)}\rangle=\int_{\Sigma_{E_c}}a d\mu^{E_c}.$$

Here, density one simply means that

$$\lim_{h\to 0}\frac{\#L(h)}{\#K(h)}=1.$$

Since there is nothing new to prove, we refer to Refs. 3 and 5 for a precise study. More interesting, is the generalization of the result of Ref. 4.

Corollary 2: In dimension one, assume that Σ_{E_c} is connected. Then, for the weak * topology, we have $\nu_{j(h)}\to\delta(z_0)$, $j(h)\in K(h)$, uniformly as $h\to 0$.

Hence, we obtain a concentration at z_0. Observe that $\delta(z_0)$ is Φ_t-invariant. If a is simply a function, the quantum probability satisfies

$$\lim_{h\to 0}\lambda_j(h)=E_c\Rightarrow\lim_{h\to 0}|\psi^h_{j(h)}|^2(x)=\delta_{x_0}.$$

The interpretation is as follows. In dimension one, the invariant measure on Σ_{E_c} has a singularity

$$d\mathrm{Lvol}(z)\sim c\frac{dz}{\|z-z_0\|},\quad \text{near } z_0=(x_0,0).$$

The measure is not integrable and the result has to be different. For $n>1$, the singularity is integrable and an isolated critical point has no effect. This reinforces the universality of the Liouville measure in quantum ergodicity. However, the case $n=1$ is important since many problems, with symmetries, can be reduced to the study of such a singular Schrödinger equation. See, e.g., Ref. 4 for an application in Riemannian-geometry.

Preliminary remarks: The case of a local minimum of V is not really deep. Since $\xi^2\geqslant 0$, z_0 is a local extremum of p and is an isolated point of Σ_{E_c}. According to the results of Ref. 13, the contribution of a minimum is significant only if $n=1$. We consider now the nontrivial case of a local maximum of V, corresponding to an unstable equilibrium of the flow. Finally, since we use the functional calculous below, p has to be a symbol. But with $(\mathcal{H}_1)$ we can eventually modify the potential V outside of a compact subset of $\mathbb{R}^n$, without modifying the main results. Hence no extra assumption is required. Similar comments apply for Sec. III.

Proof of Theorem 1: We use the semiclassical trace formula technique. This approach, analogous to the trace of the heat operator of Ref. 1, uses the propagator $e^{(it/h)P_h}$ and a generalization of the Poisson summation formula for this operator. Let $\varphi\in\mathcal{S}(\mathbb{R})$, a Schwartz function. To approximate Υ we define

$$\gamma(E_c,h,\varphi)=\sum_{|\lambda_j(h)-E_c|\leqslant\varepsilon}\varphi\left(\frac{\lambda_j(h)-E_c}{h}\right). \tag{4}$$

This object can be treated by mean of Fourier integral operators (FIO), see e.g., Ref. 16, and we refer to Refs. 3, 12, and 13 for a detailed study of the trace. We recall that the Tauberian approximation concerns expressions

$$\Upsilon^{\alpha}_{E,h}(\varphi)=\sum_j \alpha_j(h)\varphi\left(\frac{\lambda_j(h)-E}{h}\right).$$

Under our assumptions, the behavior of $\Upsilon^{\alpha}_{E,h}$ determines the behavior of the weighted counting functions

$$N^{\alpha}_{E,d}(h)=\sum_{|\lambda_j(h)-E|\leqslant dh}\alpha_j(h).$$

Precisely, we will apply the results of Sec. 6 of Ref. 3 for $\alpha_j(h)=1$ or $\nu_j(a)$. Strictly speaking, $\alpha_j(h)\geqslant 0$ is required but, by a standard result of pseudodifferential calculus, we can modify the quantization to have $\nu_j(a)\geqslant 0$. This does not change the main results, see Eq. (14) below.

To attain our objective, we can suppose that $\mathrm{supp}(\hat{\varphi})\subset[-M,M]$, $M>0$. Let $\Theta\in C_0^{\infty}(]E_c-\varepsilon,E_c+\varepsilon[)$, such that $\Theta=1$ in a neighborhood of E_c and $0\leqslant\Theta\leqslant 1$ on $\mathbb{R}$. We localize the problem near E_c by writing

$$\gamma(E_c,h,\varphi)=\gamma_1(E_c,h,\varphi)+\gamma_2(E_c,h,\varphi),$$

with

$$\gamma_2(E_c,h,\varphi)=\sum_{|\lambda_j(h)-E_c|\leqslant\varepsilon}\Theta(\lambda_j(h))\varphi\left(\frac{\lambda_j(h)-E_c}{h}\right)=\mathrm{Tr}\,\Theta(P_h)\varphi\left(\frac{P_h-E_c}{h}\right).$$

Where the last equality holds by support considerations. By a classical result, see, e.g., Ref. 12 Lemma 1, the term $\gamma_1=\gamma-\gamma_2$ satisfies

$$\gamma_1(E_c,h,\varphi)=\mathcal{O}(h^{\infty}),\quad \text{as } h\to 0. \tag{5}$$

The Fourier inversion formula for γ_2 and the previous estimate provide

$$\gamma(E_c,h,\varphi)=\frac{1}{2\pi}\mathrm{Tr}\int_{\mathbb{R}}e^{i(tE_c/h)}\hat{\varphi}(t)\exp\left(-\frac{i}{h}tP_h\right)\Theta(P_h)dt+\mathcal{O}(h^{\infty}). \tag{6}$$

Next, with a function $\Psi\in C_0^{\infty}(T^*\mathbb{R}^n)$, with $\Psi=1$ near z_0, we write

$$\gamma_2(E_c,h,\varphi)=\gamma_{z_0}(E_c,h,\varphi)+\gamma_{\mathrm{reg}}(E_c,h,\varphi),$$

where

$$\gamma_{z_0}(E_c,h,\varphi)=\frac{1}{2\pi}\mathrm{Tr}\int_{\mathbb{R}}e^{i(tE_c/h)}\hat{\varphi}(t)\Psi^w(x,hD_x)\exp\left(-\frac{i}{h}tP_h\right)\Theta(P_h)dt, \tag{7}$$

and γ_{reg} is simply the difference. The micro-local term γ_{z_0} contains the contribution of the singularity and the discussion below determines if this term is dominant. For finitely many critical point on Σ_{E_c}, we could repeat the procedure. For the convenience of the reader, we recall the contributions of an equilibrium to the trace formula.

Proposition 3: Assume $(\mathcal{H}_1)$, $(\mathcal{H}_2)$ *and that* $\hat{\varphi}\in C_0^{\infty}([-M,M])$, $M\leqslant M_0$. *If* x_0 *is a local maximum of V we have*

$$\gamma_{z_0}(E_c,h,\varphi) \sim h^{-n+n/2+n/2k} \sum_{m=0,1} \sum_{j,l\in\mathbb{N}^2} h^{j/2+l/2k} \log(h)^m \Lambda_{j,l,m}(\varphi).$$

If $n(k+1)/2k \in \mathbb{N}$ *and* n *is odd then the top-order term is*

$$C_{n,k} \log(h) h^{-n+n/2+n/2k} \int_{\mathbb{S}^{n-1}} |V_{2k}(\eta)|^{-n/2k} d\eta \int_{\mathbb{R}} |t|^{n[(k+1)/2k]-1} \varphi(t) dt.$$

Otherwise the first nonzero coefficient are given by

$$h^{-n+n/2+n/2k} \langle T_{n,k}, \varphi \rangle \int_{\mathbb{S}^{n-1}} |V_{2k}(\eta)|^{-n/2k} d\eta.$$

This result is the contribution of an equilibrium since the distributional coefficients have a non-discrete support, contrary to the Weyl-term supported in $t=0$ and the contributions of closed orbits supported by the length spectrum. The distributions $T_{n,k}$ and the universal constants $C_{n,k} \neq 0$ depend only on (n,k) and are explicitly determined in Ref. 14. Mainly, we need the order w.r.t. h of these contributions determined by the functions

$$w_c(h) = h^{-n+n/2+n/2k} \log(h)^j, \quad j = 0 \text{ or } 1.$$

First, we give a natural application of Proposition 3.

Proposition 4: The microlocal counting function satisfies

$$\Upsilon(h) = \begin{cases} 2d\mathcal{V}(E_c)(2\pi h)^{1-n} + o(h^{1-n}), & \text{if } n > 1, \\ \Lambda(\chi_{[-d,d]}) w_c(h) + o(w_c(h)), & \text{if } n = 1. \end{cases}$$

Here Λ *is the first nonzero distribution of Prop. 3 and* $\chi_{[-d,d]}$ *the characteristic function of* $[-d,d,]$.

Proof: By construction we have

$$\gamma_{\text{reg}}(E_c,h,\varphi) = \frac{1}{2\pi} \operatorname{Tr} \int_{\mathbb{R}} e^{i(tE_c/h)} \hat{\varphi}(t)(1 - \Psi^w(x,hD_x)) \exp\left(-\frac{i}{h} t P_h\right) \Theta(P_h) dt.$$

By the standard calculus on FIO and an easy application of the stationary phase method, as h tends to 0 we obtain

$$\gamma_{\text{reg}}(E_c,h,\varphi) \sim \frac{\hat{\varphi}(0)}{(2\pi h)^{n-1}} \operatorname{Lvol}(\Sigma_{E_c} \cap \operatorname{supp}(1-\Psi)) + \mathcal{O}(h^{2-n}).$$

Hence γ_{reg} always contributes at the order h^{1-n}.

Case of $n>1$*:* We have $w_c(h)=o(h^{1-n})$ and

$$\operatorname{Lvol}(\Sigma_{E_c} \cap \operatorname{supp}(1-\Psi)) \leqslant \mathcal{V}(E_c) < \infty, \quad \forall\, \Psi.$$

It follows easily by shrinking the support of the cut-off Ψ that

$$\gamma(E_c,\varphi,h) = (2\pi h)^{1-n} \hat{\varphi}(0) \mathcal{V}(E_c) + o(h^{1-n}). \tag{8}$$

Since the distributional factor is

$$\hat{\varphi}(0) = \int \varphi(t) dt = \langle 1, \varphi \rangle,$$

replacing φ by $\chi_{[-d,d]}$, via Theorem 6.3 of Ref. 3, provides

$$\Upsilon(h) = 2d\mathcal{V}(E_c)(2\pi h)^{1-n} + o(h^{1-n}).$$

Case of $n=1$: Here the contribution of the critical point has a bigger order than the regular one. We obtain

$$\gamma(E_c,\varphi,h) = w_c(h)\Lambda(\varphi) + o(w_c(h)). \tag{9}$$

To apply the Tauberian argument of Ref. 3, we observe that our distribution $\Lambda \in \mathcal{S}'(\mathbb{R})$ can be represented by an element of $L^1_{\mathrm{loc}}(\mathbb{R})$ and hence can be extended as a linear form on $C_0(\mathbb{R}) \cap L^\infty(\mathbb{R})$. We obtain

$$\Upsilon(h) \sim \Lambda(\chi_{[-d,d]})w_c(h). \tag{10}$$

Which provides the desired result for $n=1$. ■

As a matter of illustration, for $n=k=1$, we have

$$\log(h)|V_{2k}(x_0)|^{-1/2}\int_{-d}^{d} dt = \frac{2d\log(h)}{|V''(x_0)|^{\frac{1}{2}}}. \tag{11}$$

Which is the result established for $\Upsilon(h)$ in Refs. 3 and 4. Observe that for $n=1$, $k=1$ is the only case where a logarithm occurs and $\Upsilon(h)$ is slowly increasing w.r.t. k since for all $k>1$

$$\Upsilon(h) \sim Ch^{1/2k-1/2}|V^{(2k)}(x_0)|^{-1/2k}. \tag{12}$$

A. Eigenfunctions estimates

We recall how to derive eigenfunction estimates from the trace formula. First, to insert an observable A changes almost nothing. If Π is the spectral projector on $[E_c-\varepsilon, E+\varepsilon]$, computing the trace in the basis ψ_j^h and by cyclicity

$$\mathrm{Tr}\left(\Pi A\varphi\left(\frac{P_h - E_c}{h}\right)\right) = \sum_{|\lambda_j(h)-E_c|\leqslant\varepsilon} \langle A\psi_j^h, \psi_j^h\rangle \varphi\left(\frac{\lambda_j(h)-E_c}{h}\right).$$

Since A is a bounded operator, if $\varphi \in \mathcal{S}(\mathbb{R})$ we can again smooth the problem via an energy cut-off $\Theta(P_h)$, with an error of order $\mathcal{O}(h^\infty)$. Hence we can insert $A=\mathrm{Op}_h^w(a)$ in Eq. (7) and the results of Prop. 3 are the same after multiplication by $a(z_0)$. Similarly, the regular contribution changes via

$$\frac{\hat{\varphi}(0)}{(2\pi h)^{1-n}}\int_{\Sigma_{E_c}} a(z)(1-\Psi(z))\mathrm{dLvol}(z).$$

By evaluation of the trace, we have

$$\sum_{|\lambda_j(h)-E_c|\leqslant\varepsilon} \langle A\psi_j^h, \psi_j^h\rangle \varphi\left(\frac{\lambda_j(h)-E_c}{h}\right) \sim c_0(\varphi)w(h)m(a) + o(w(h)),$$

where $w(h)$ changes only if $n=1$. By Theorem 6.3 of Ref. 3 we obtain

$$\sum_{\lambda_j(h)\in I(h)} \langle A\psi_j^h, \psi_j^h\rangle = m(a)w(h) + o(w(h)).$$

In particular this implies that

$$\lim_{h\to 0^+}\frac{1}{\Upsilon(h)}\sum_{\lambda_j(h)\in I(h)} \langle A\psi_j^h, \psi_j^h\rangle = \lim_{h\to 0^+}\frac{\Upsilon_a(h)}{\Upsilon(h)} = \frac{m(a)}{m(1)}. \tag{13}$$

Substituting the correct expressions for these measures we obtain

(i) for $n>1$: m is a constant multiple of the Liouville measure;

(ii) for $n=1$: m is a multiple of the delta-Dirac distribution in z_0.

B. Extraction of a subsequence

We chose $a \geqslant 0$ and modify the quantization. Different choices are possible: Friedrichs quantization Op^F as in Ref. 3 or the anti-Wick quantization Op^{AW} as in Ref. 5. These quantization are positive, i.e.,

$$a \geqslant 0 \Rightarrow \langle f, \mathrm{Op}^{AW}(a) f \rangle \geqslant 0, \quad \forall f \in C_0^\infty(\mathbb{R}^n).$$

Since $\mathrm{Op}_h^w(a) - \mathrm{Op}_h^{AW}(a)$ is of order -1, we obtain

$$\langle \psi_j^h, (\mathrm{Op}_h^w(a) - \mathrm{Op}_h^{AW}(a)) \psi_j^h \rangle = \mathcal{O}(h), \tag{14}$$

and we can work with this positive operator. For $n>1$, under the condition that Φ_t is ergodic on Σ_{E_c}, the extraction of a convergent subsequence of density one is the same as in Refs. 1, 3, and 5 to which we refer for a detailed proof. For $n=1$, if Σ_{E_c} is connected, there is only one probability measure invariant by Φ_t and the full sequence converges to δ_{z_0}. Once the result is established for a positive symbol it can be extended by linearity to any $a \in S^0(\mathbb{R}^{2n})$.

III. PSEUDO-DIFFERENTIAL OPERATORS

The case of pseudo-differential operators provides more explicit examples. Let $P_h = \mathrm{Op}_h^w(p(x,\xi))$, obtained by Weyl quantization, where the symbol p is a real-valued smooth function on $T^*\mathbb{R}^n$. In a general position, one can also consider h-dependent symbols $\Sigma h^j p_j(x,\xi)$, see Ref. 5. However, to simplify, we consider only the homogeneous case. As above we impose

($\mathcal{A}_1$) There exists $\varepsilon_0 > 0$ such that $p^{-1}([E_c-\varepsilon_0, E_c+\varepsilon_0])$ is compact.

As in Sec. II, $\sigma(P_h) \cap [E_c-\varepsilon, E_c+\varepsilon]$ is discrete. *A fortiori*, ($\mathcal{A}_1$) ensures that Σ_{E_c} is compact. Next, we chose a homogeneous singularity

($\mathcal{A}_2$) On Σ_{E_c}, p has a unique critical point $z_0=(x_0,\xi_0)$ and near z_0:

$$p(z) = E_c + \mathfrak{p}_k(z) + \mathcal{O}(\|(z-z_0)\|^{k+1}), \quad k>2,$$

where $\mathfrak{p}_k$ is homogeneous of degree k w.r.t. $z-z_0$.

Strictly speaking, one could consider $k=2$. But this case is precisely treated in Ref. 3. The case of a critical point which is not an extremum is technical because the singularity is transferred on the blow up of z_0. To obtain a problem that can be explicitly solved, we consider the following hypothesis inspired by Hörmander's real principal condition:

($\mathcal{A}_3$) We have $\nabla \mathfrak{p}_k \neq 0$ on the set $C(\mathfrak{p}_k) = \{\theta \in \mathbb{S}^{2n-1} / \mathfrak{p}_k(\theta) = 0\}$.

For example, $\mathfrak{p}_3(x,\xi) = x^3 - \xi^3$ is admissible and $p(x,\xi) = x^3 - \xi^3 + x^4 + \xi^4$ satisfies all our hypothesis for $E_c = 0$.

Remark 5: With ($\mathcal{A}_3$), contrary to the case of a local extremum, z_0 is not an isolated point of Σ_{E_c} which imposes to study the classical dynamics in a neighborhood of z_0. The study of singularities as in ($\mathcal{A}_3$) is detailed in Ref. 17, Chap. 4 to which we refer concerning the integrability of dLvol.

As in Sec. II, it is sufficient to study the local problem γ_{z_0} defined in Eq. (7). The contributions to the trace formula are

Proposition 6: Under ($\mathcal{A}_1$) to ($\mathcal{A}_3$), we have an asymptotic expansion

$$\gamma_{z_0}(E_c,\varphi,h) \sim h^{\frac{2n}{k}-n} \sum_{m=0,1} \sum_{j=0}^{\infty} h^{j/k} \log(h)^m \Lambda_{j,m}(\varphi),$$

where the logarithms only occur when $(2n+j)/k \in \mathbb{N}^*$ *and* $\Lambda_{j,m} \in \mathcal{S}'(\mathbb{R})$. *For the leading term, we obtain, respectively:*

(1) If $k>2n$ *(nonintegrable singularity on* Σ_{E_c}*) we have*

$$\gamma_{z_0}(E_c,\varphi,h) \sim h^{2n/k-n}\Lambda_{0,0}(\varphi) + \mathcal{O}(h^{(2n+1)/k-n} \log(h)), \quad as\ h \to 0,$$

where $\Lambda_{0,0}$ *is a universal distribution.*

(2) If the ratio $2n/k \in \mathbb{N}$ *we obtain logarithmic contributions*

$$\gamma_{z_0}(E_c,\varphi,h) \sim h^{2n/k-n} \log(h)\Lambda_{0,1}(\varphi) + \mathcal{O}(h^{2n/k-n}), \quad as\ h \to 0,$$

(3) For $2n>k$, $2n/k \notin \mathbb{N}$ *the result is as in Eq.* (1) *with a different distribution.*

These results precisely describe the singularity at z_0. But this is not our purpose here and we refer to Ref. 15 for a detailed formulation of these contributions. For $n=1$, $k=2$, the case *(2)* agrees with Sec. II and allows us to recover some results established in Refs. 3 and 4.

A. Application to microlocal measures

The proof is exactly the same as in Sec. II. The main difference is that the singularity on Σ_{E_c} can be of arbitrary order. In our setting, according to Prop. 6 the top order coefficient changes if and only if we have

$$\frac{2n}{k} - n < 1 - n \Leftrightarrow \frac{2n}{k} < 1. \tag{15}$$

If $k<2n$ the singularity is integrable and contributes at a lower order compared to $h^{1-n}\mathcal{V}(E_c)$. But if $k \geqslant 2n$, which corresponds to a nonintegrable singularity for $d\mu^{E_c}$, the main term changes. To summarize, we obtain

$$\lim_{h\to 0} \frac{\Upsilon_a(h)}{\Upsilon(h)} = \begin{cases} \int a d\mu^{E_c}, & \text{for } k < 2n, \\ a(z_0), & \text{for } k \geqslant 2n. \end{cases}$$

Contrary to Sec. II, observe that for $k \geqslant 2n$ and if $n>1$ we do not obtain the convergence of the full sequence $\nu_{j(h)}$, $j(h) \in K(h)$, to the dirac-mass at the equilibrium. The obstruction is that an invariant probability measure can be supported by the closed orbits of Σ_{E_c}.

B. Comments

From these two examples the conclusion is that the limiting measure changes only if Σ_{E_c} carries a measure such that $1 \notin L^1_{\text{loc}}(\Sigma_{E_c}, \text{dLvol})$. Interpreted as a quantum measurement, one can obtain a very precise localization: If $a=0$ around z_0 the limit is the Liouville-measure but if $a(z_0) \neq 0$ the limit strongly differs.

An interesting problem would be to study the repartition in the presence of two equilibria z_1, z_2 on Σ_{E_c} of the same nature and with a nonintegrable singularity. In this case any convex combination

$$\nu = a\delta(z_1) + (1-a)\delta(z_2), \quad a \in [0,1], \tag{16}$$

provides an invariant probability measure. A natural question is to determine if the limiting measures are equally distributed between z_1 and z_2: This problem could be related with the approach proposed in Ref. 11.

On Chern–Simons (super) gravity, E_8 Yang–Mills and polyvector-valued gauge theories in Clifford spaces

Carlos Castro[a)]
Center for Theoretical Studies of Physical Systems, Clark Atlanta University, Atlanta, Georgia 30314

(Received 11 June 2006; accepted 18 September 2006; published online 6 November 2006)

It is shown how the E_8 Yang–Mills theory is a small sector of a Cl(16) algebra gauge theory and why the 11D Chern–Simons (super) gravity theory can be embedded into a Cl(11) algebra gauge theory. These results may shed some light into the origins behind the hidden E_8 symmetry of 11D supergravity. To finalize, we explain how the Clifford algebra gauge theory (that contains the Chern–Simons gravity action in $D=11$, for example) can itself be embedded into a more fundamental polyvector-valued gauge theory in Clifford spaces involving *tensorial* coordinates $x^{\mu_1\mu_2}, x^{\mu_1\mu_2\mu_3}, \ldots, x^{\mu_1\mu_2\cdots\mu_D}$ in addition to antisymmetric tensor gauge fields $A_{\mu_1\mu_2}, A_{\mu_1\mu_2\mu_3}, \ldots, A_{\mu_1\mu_2\cdots\mu_D}$. The polyvector-valued supersymmetric extension of this polyvector valued bosonic gauge theory in Clifford spaces may reveal more important features of a Clifford-algebraic structure underlying M, F theory. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2363257]

I. INTRODUCTION: WHY CLIFFORD ALGEBRAS

Ever since the discovery[1] that 11-dimensional (D) supergravity, when dimensionally reduced to an n-dim torus led to maximal supergravity theories with hidden exceptional symmetries E_n for $n \leqslant 8$, it has prompted intensive research to explain the higher dimensional origins of these hidden exceptional E_n symmetries.[2,3] More recently, there has been a lot of interest in the infinite-dim hyperbolic Kac–Moody E_{10} and non-linearly realized E_{11} algebras arising in the asymptotic chaotic oscillatory solutions of Supergravity fields close to cosmological singularities.[1,2]

The classification of symmetric spaces associated with the scalars of N extended supergravity theories (emerging from compactifications of 11D supergravity to lower dimensions), and the construction of the U-duality groups as spectrum-generating symmetries for four-dimensional BPS black-holes[6] also involved exceptional symmetries associated with the Jordan algebras $J_3[R,C,H,O]$. The discovery of the anomaly free 10-dim heterotic string for the algebra $E_8 \times E_8$ was another hallmark of the importance of exceptional Lie groups in physics.

Exceptional, Jordan, Division, and Clifford algebras are deeply related and essential tools in many aspects in Physics.[4–14] In this work we will focus mainly on the Clifford algebraic structures and show how the E_8 Yang–Mills theory can naturally be embedded into a Cl(16) algebra gauge theory and why the 11D Chern–Simons (super) gravity[15] is a very small sector of a more fundamental theory based on the Cl(11) algebra gauge theory. Polyvector-valued supersymmetries[16] in Clifford spaces[4] turned out to be more fundamental than the supersymmetries associated with M, F theory superalgebras.[17,18] For this reason we believe that Clifford structures may shed some light into the origins behind the hidden E_8 symmetry of 11D supergravity and reveal more important features underlying M, F theory.

In the remaining part of this introduction a very brief overview of the basic features of the extended relativity in Clifford spaces is presented along with the basic formulas involving the *polyvector* valued generalized supersymmety algebra in Clifford spaces. In Sec. II we show how

[a)]Electronic mail: castro@ctsps.cau.edu

the E_8 Yang–Mills theory can be obtained from a gauge theory based on the Clifford (16) algebra. In Sec. III the Chern–Simons gravity in 11-dim is embedded into a Clifford algebra gauge theory. This in itself is not much different than constructing a Chern–Simons gravity-theory based on a $gl(N,R)$ algebra, for example. However, the fundamental difference is shown in Sec. IV where we explain how the Clifford algebra gauge theory (that contains the Chern–Simons gravity action in $D=11$) is itself embedded into a more fundamental polyvector-valued gauge theory in Clifford spaces involving *tensorial* coordinates $x^{\mu_1\mu_2}$, $x^{\mu_1\mu_2\mu_3},\ldots$ in addition to antisymmetric tensor gauge fields. $A_{\mu_1\mu_2}, A_{\mu_1\mu_2\mu_3,\ldots}$. We leave for future work the explicit construction of the polyvector-valued generalized supersymmetric extension of our polyvector valued bosonic gauge theory in Clifford spaces and its implications for the further developments of M, F theory.

A. The extended relativity in Clifford spaces

The extended relativity theory in Clifford paces (C-spaces) is a natural extension of the ordinary relativity theory. A natural generalization of the notion of a space-time interval in Minkwoski space to C-space is

$$dX^2 = d\sigma^2 + dx_\mu dx^\mu + dx_{\mu\nu} dx^{\mu\nu} + \cdots . \tag{1.1}$$

The Clifford valued polyvector

$$X = X^M E_M = \sigma \mathbf{1} + x^\mu \gamma_\mu + x^{\mu\nu}\gamma_\mu \wedge \gamma_\nu + \ldots x^{\mu_1\mu_2\cdots\mu_D}\gamma_{\mu_1} \wedge \gamma_{\mu_2} \ldots \wedge \gamma\mu_D \tag{1.2a}$$

denotes the position of a polyparticle in a manifold, called Clifford space ro C-space. The series of terms in Eq. (1.2a) terminates at a *finite* value depending on the dimension D. A Clifford algebra $\mathrm{Cl}(r,q)$ with $r+q=D$ has 2^D basis elements. For simplicity, the gamma γ^μ correspond to a Clifford algebra associated with a flat spacetime

$$\frac{1}{2}\{\gamma^\mu, \gamma^\nu\} = \eta^{\mu\nu}\mathbf{1}, \tag{1.2b}$$

but in general one could extend this formulation to curved spacetimes with metric $g^{\mu\nu}$. The multigraded basis elements E_M of the Clifford-valued polyvectors are

$$E_M \equiv \mathbf{1}, \quad \gamma^\mu, \quad \gamma^{\mu_1} \wedge \gamma^{\mu_2}, \quad \gamma^{\mu_1} \wedge \gamma^{\mu_2} \wedge \gamma^{\mu_3}, \quad \gamma^{\mu_1} \wedge \gamma^{\mu_2} \wedge \gamma^{\mu_3} \wedge \cdots \wedge \gamma^{\mu D}. \tag{1.2c}$$

It is convenient to order the collective M indices as $\mu_1 < \mu_2 < \mu_3 < \cdots < \mu_D$.

The connection to strings and p-branes can be seen as follows. In the case of a closed string (a 1-loop) embedded in a target flat spacetime background of D-dimensions, one represents the projections of the closed string (1-loop) onto the embedding spacetime coordinate planes by the variables $x_{\mu\nu}$. These variables represent the respective *areas* enclosed by the projections of the closed string (1-loop) onto the corresponding embedding spacetime planes. Similary, one can embed a closed membrane (a 2-loop) onto a D-dim flat spacetime, where the projections given by the antisymmetric variables $x_{\mu\nu\rho}$ represent the corresponding *volumes* enclosed by the projections of the 2-loop along the hyperplanes of the flat target spacetime background.

This procedure can be carried to all closed p-branes (p-loops) where the values of p are $p=0,1,2,3,\ldots,D-2$. The $p=0$ value represents the center of mass and the coordinates $x^{\mu\nu}, x^{\mu\nu\rho}\ldots$ have been *coined* in the string-brane literature[19] as the *holographic* areas, volumes, … projections of the nested family of p-loops (closed p-branes) onto the embedding spacetime coordinate planes/hyperplanes. The classification of Clifford algebras $\mathrm{Cl}(r,q)$ in $D=r+q$ dimensions (modulo 8) for different values of the spacetime signature r,q is discussed, for example, in the book of Porteous.[20]

All Clifford algebras can be understood in terms of CL(8) and the CL(k) for k less than 8 due to the modulo 8 periodicity theorem $\mathrm{CL}(n)=\mathrm{CL}(8)\times\mathrm{Cl}(n-8)$, where $\mathrm{Cl}(r,q)$ is a matrix algebra for even $n=r+q$ or the sum of two matrix algebras for odd $n=r+q$. Depending on the signature, the matrix algebras may be real, complex, or quaternionic. For further details we refer to Ref. 20.

If we take the differential dX and compute the scalar product among two polyvectors $\langle dX^T dX\rangle_{\text{scalar}}$ we obtain the C-space extension of the particles proper time in Minkwoski space. The symbol X^T denotes the *reversion* operation and involves reversing the order of all the basis γ^μ elements in the expansion of X. The C-space proper time associated with a polyparticle motion is then

$$\langle dX^T dX\rangle_{\text{scalar}} = d\Sigma^2 = (d\sigma)^2 + \Lambda^{2D-2} dx_\mu dx^\mu + \Lambda^{2D-4} dx_{\mu\nu} dx^{\mu\nu} + \dots . \tag{1.3}$$

Here we have explicitly introduced the Planck scale Λ since a length parameter is needed in order to tie objects of different dimensionality together: 0-loops, 1-loops,…, p-loops. Einstein introduced the speed of light as a universal absolute invariant in order to "unite" space with time (to match units) in the Minkwoski space interval

$$ds^2 = c^2 dt^2 - dx_i dx^i . \tag{1.4}$$

A similar unification is needed here to unite objects of different dimensions, such as x^μ, $x^{\mu\nu}$, etc…. The Planck scale then emerges as another universal invariant in constructing an extended scale relativity theory in C-spaces.[4]

To continue along the same path, we consider the analog of Lorentz transformations in C-spaces which transform a polyvector X into another polyvector X' given by $X' = RXR^{-1}$ with

$$R = e^{\omega^A E_A} = \exp[(\omega \mathbf{1} + \omega^\mu \gamma_\mu + \omega^{\mu_1\mu_2} \gamma_{\mu_1} \wedge \gamma_{\mu_2} \dots)] \tag{1.5}$$

and

$$R^{-1} = e^{-\omega^A E_A} = \exp[-(\omega \mathbf{1} + \omega^\nu \gamma_\nu + \omega^{\nu_1\nu_2} \gamma_{\nu_1} \wedge \gamma_{\nu_2} \dots)], \tag{1.6}$$

where the ω parameters also belong to a Clifford-valued quantity

$$\omega; \omega^\mu; \omega^{\mu\nu}; \dots , \tag{1.7}$$

they are the C-space version of the Lorentz rotations/boosts parameters.

Since a Clifford algebra admits a matrix representation, one can write the norm of a polyvectors in terms of the trace operation as: $\|X\|^2 = \text{Trace} X^2$. Hence, under C-space Lorentz transformation the norms of polyvectors behave as follows:

$$\text{Trace} X'^2 = \text{Trace}[RX^2R^{-1}] = \text{Trace}[RR^{-1}X^2] = \text{Trace} X^2 . \tag{1.8}$$

These norms are invariant under C-space Lorentz transformations due to the cyclic property of the trace operation and $RR^{-1} = 1$. Another way of rewriting the inner product of polyvectors is by means of the reversal operation that reverses the order of the Clifford basis generators: $(\gamma^\mu \wedge \gamma^\nu)^T = \gamma^\nu \wedge \gamma^\mu$, etc…. Hence, the inner product can be rewritten as the scalar part of the geometric product $\langle X^T X\rangle_s$. The analog of an orthogonal matrix in Clifford spaces is $R^T = R^{-1}$ such that

$$\langle X'^T X'\rangle_s = \langle (R^{-1})^T X^T R^T R X R^{-1}\rangle_s = \langle R X^T X R^{-1}\rangle_s = \langle X^T X\rangle_s = \text{invariant}. \tag{1.9a}$$

This condition $R^T = R^{-1}$ of course, will *restrict* (constrain) the type of terms allowed inside the exponential defining the rotor R in Eq. (1.6) because the *reversal* of a p-vector obeys

$$(\gamma_{\mu_1} \wedge \gamma_{\mu_2} \dots \wedge \gamma_{\mu_p})^T = \gamma_{\mu_p} \wedge \gamma_{\mu_{p-1}} \dots \wedge \gamma_{\mu_2} \wedge \gamma_{\mu_1} = (-1)^{p(p-1)/2} \gamma_{\mu_1} \wedge \gamma_{\mu_2} \dots \wedge \gamma_{\mu_p} . \tag{1.9b}$$

Hence, only those terms that change sign (under the reversal operation) are permitted in the exponential defining $R = \exp[\omega^A E_A]$.

Another possibility is to *complexify* the C-space polyvector valued coordinates $= Z = Z^A E_A = X^A E_A + i Y^A E_A$ (which is *not* the same as *complexifying* the Clifford algebra) as well as the

boost/rotation parameters ω^A in order to allow the unitarity condition $U^\dagger \equiv U^{-1}$ to hold. The generalized Clifford unitary transformations $Z' = UZU^\dagger = UZU^{-1}$ associated with the complexified polyvector $Z = Z^A E_A$ must be such so the interval

$$\langle dZ^\dagger dZ \rangle_s = d\bar{\sigma} d\sigma + d\bar{z}^\mu dz_\mu + d\bar{z}^{\mu\nu} dz_{\mu\nu} + d\bar{z}^{\mu\nu\rho} dz_{\mu\nu\rho} + \ldots \tag{1.9c}$$

remains invariant under these unitary transformations above (upon setting the Planck scale $\Lambda = 1$).

The unitary condition $U^\dagger = U^{-1}$, under the *combined* reversal and complex-conjugate operation, will constrain the form of the complexified boosts/rotation parameters ω^A appearing in: $U = \exp[\omega^A E_A]$. The parameters ω^A must be either purely real, or purely imaginary, depending if the reversal $E_A^T = \pm E_A$, to ensure that an overall change of sign occurs in the terms $\omega^A E_A$ inside the exponential defining U so that $U^\dagger = U^{-1}$ actually holds, and the norm $\langle Z^\dagger Z \rangle_s$ remains invariant under the analog of unitary transformations in *complexified* C-spaces. These techniques are not very different from Penrose Twistor spaces. As far as we know a Clifford–Twistor space construction of C-spaces has not been performed so far.

Another alternative is to define the unitary transformations by $U = \exp(\Omega^{AB}[E_A, E_B])$ where the commutator $[E_A, E_B] = F_{AB}^C E_C$ is the C-space analog of the $i[\gamma_\mu, \gamma_\nu]$ commutator which is the generator of the Lorentz algebra, and the parameters Ω^{AB} are the C-space analogs of the rotation/boots parameters. The diverse parameters Ω^{AB} are purely real or purely imaginary depending whether the reversal $[E_A, E_B]^T = \pm [E_A, E_B]$ to ensure that $U^\dagger = U^{-1}$ such that the scalar part $\langle Z^\dagger Z \rangle_s$ remains invariant under the transformations $Z' = UZU^{-1}$. This last alternative seems to be more physical because a polyrotation should map the E_A direction into the E_B direction in C-spaces, hence, the meaning of the generator $[E_A, E_B]$ which is the extension of the $i[\gamma_\mu, \gamma_\nu]$ Lorentz generator. We refer to the review[4] for further details about the extended relativity theory in Clifford spaces. In particular, why relativity in *curved* Clifford spaces is equivalent to a higher derivative gravity with torsion associated with the underlying spacetime.[4]

B. Polyvector-valued super Poincare algebras and Clifford-space supersymmetry

Polyvector super-Poincare algebras as extensions of ordinary super-Poincare algebras have been studied by Ref. 18. The former Lie superalgebras (involving commutators and anticommutators) should not be confused with the Z_2-graded extensions of ordinary Lie algebras, in particular with Z_2-graded extensions of Clifford algebras involving only commutators. The polyvector super Poincare algebras have the form of $\mathbf{g} = \mathbf{g}_0 + \mathbf{g}_1$, where the even sector is $\mathbf{g}_0 = so(V) + W_0$ and the odd sector $\mathbf{g}_1 = W_1$ consists of a spinorial representation of $so(V) = so(p,q)$; i.e., W_1 is an $so(p,g)$-spinorial module, where V is a vector space of signature p,q.

The algebra of generalized translations $W = W_0 + W_1$ is the maximal solvable ideal of $\mathbf{g}$. W_0 is generated by W_1: $[W_1, W_1] \subseteq W_0$ and $[W_0, W_1] = 0$; $[W_0, W_0] = 0$. For example, in the ordinary super-Poincare algebra, the translations are generated by the supersymmetry generators: $\{Q, \bar{Q}\} \sim P$ and $[Q, P] = [P, P] = 0$. Choosing W_1 to be a spinorial $so(V)$-module consisting of a sum of spinors and semispinors (chiral spinors) the authors[18] proved that W_0 consists of *polyvectors*. They provided the classification of all polyvector Lie superalgebras, for all dimensions and signatures, after analyzing all the $so(V)$-invariant polyvector-valued bilinear forms that can be defined on the spinor modules. N-extended polyvector super Poincare algebras were also classified in Ref. 18.

The anticommutator is

$$\{S_\alpha, S_\beta\} = \sum_k (\mathcal{C}\Gamma^{\mu_1 \mu_2 \ldots \mu_k})_{\alpha\beta} W_{0 \mu_2 \mu_2 \ldots \mu_k}^{(k)}, \tag{1.10}$$

where α, β denote spinor indices and the summation over k must obey certain crucial restrictions to match degrees of freedom with the terms on the left-hand side (lhs). The matrix $\mathcal{C}$ is the charge conjugation matrix. Depending on the given spacetime and its signature there are at most two charge conjugation matrices $\mathcal{C}_S$, $\mathcal{C}_A$ given by the product of all symmetric and all antisymmetric gamma matrices, respectively. In special spacetime signatures they collapse into a single matrix.

These charge conjugation matrix $\mathcal{C}$ are essential in order to satisfy the nontrivial graded super Jacobi identities.

A Chern–Simons supergravity (CS-SUGRA) in $D=11$ involves the symplectic supergroup $OSp(32|1)$ and the connection[15]

$$\mathbf{A}_\mu = e_\mu^a \Gamma_a + \omega_\mu^{ab} \Gamma_{ab} + A_\mu^{a_1 a_2 \ldots a_5} \Gamma_{a_1 a_2 \ldots a_5} + \bar{\Psi}_\mu^\alpha Q_\alpha, \tag{1.11}$$

whereas the M theory superalgebra involve 32-component spinorial supercharges Q_α whose anticommutators are[17,18]

$$\{Q_\alpha, Q_\beta\} = (\mathcal{A}\Gamma_\mu)_{\alpha\beta} P^\mu + (\mathcal{A}\Gamma_{\mu_1\mu_2})_{\alpha\beta} Z^{\mu_1\mu_2} + (\mathcal{A}\Gamma_{\mu_1\mu_2\ldots\mu_5})_{\alpha\beta} Z^{\mu_1\mu_2\ldots\mu_5}. \tag{1.12}$$

There are 32×32 symmetric real matrices with at most $\frac{1}{2}(32\times 33)=528$ independent components that match the number of degrees of freedom associated with the translations P^μ and the antisymmetric rank 2, 5 abelian tensorial central charges $Z^{\mu_1\mu_2}$, $Z^{\mu_1\mu_2\ldots\mu_5}$ on the right-hand side (rhs) since $11+55+462=528$. The matrix $\mathcal{A}$ plays the role of the timelike γ^0 matrix in Minkowski spacetime and is used to introduce barred-spinors.[17,18]

The F theory $12D$ superalgebra involves the Majorana–Weyl spinors with 32 components whose anticommutators are[17]

$$\{Q_\alpha, Q_\beta\} = (\mathcal{A}\Gamma_{\mu\nu})_{\alpha\beta} Z^{\mu\nu} + (\mathcal{A}\Gamma_{\mu_1\mu_2\ldots\mu_6})_{\alpha\beta} Z^{\mu_1\mu_2\ldots\mu_6} \tag{1.13}$$

and the counting of components in $D=12$ yields also $32\times 33/2=528=66+462$. In $13D$ it requires the superalgebra $OSp(64|1)$ which is connected to a membrane, a 3-brane and a 6-brane, respectively, since antisymmetric tensors of ranks 2, 3, 6 in $13D$ have a total of $64\times 65/2=78+286+1716=2080$ components.

Therefore, by studying the polyvector super Poincare algebras, the M and F theory superalgebras ((1.10), (1.11), (1.12)) one concludes that these cannot be incorporated into Clifford superspaces because one cannot have a restricted summation in the k rank of the terms appearing in the $\{Q_\alpha, Q_\beta\}$ (anti)commutators. Unless one adds further spinorial degrees of freedom by introducing multispinor valued quantities $\theta^{\alpha_1\alpha_2}, \theta^{\alpha_1\alpha_2\alpha_3}, \ldots$, which are the fermionic partners of $x^{\mu_1\mu_2}, x^{\mu_1\mu_2\mu_3}, \ldots$, or by recurring to N extended supersymmetries, one will not be able to match the number of degrees of freedom in a satisfactory manner. N extended polyvector Super Lie Algebras which were also studied by Ref. 18. This means that the odd sector W_1 consists of N copies of the irreducible spinor module S. There are cases where there are two inequivalent copies (complex-even dimensional, or real with spatial signatures $s=0,4$) involving N_+ chiral generators and N_- antichiral ones. For further details we refer to Ref. 18.

Hence, by introducing a judicious number of extra spinorial degrees of freedom $\theta^{\alpha_1\alpha_2}, \theta^{\alpha_1\alpha_2\alpha_3}, \ldots$ in "Clifford superspace," depending on the dimensions and spacetime signatures, one can accommodate for the larger number of polyvector coordinates associated with C-spaces. For this reason we believe that polyvector-valued supersymmetries in Clifford superspaces[16] deserve to be investigated further since they are more fundamental than the supersymmetries associated with M, F theory superalgebras.

Nevertheless, there are instances, in particular when $D=4=3+1$, that the $\{Q_\alpha, Q_\beta\}$ is a symmetric matrix in α, β with ten independent components and which matches exactly the degrees of freedom of the momentum vector and bi-vector P^μ, $P^{\mu\nu}$ given by $4+6=10$. Therefore, in $D=4$, one may have the anticommutator written in terms of the charge conjugation matrix C as

$$\{Q_\alpha, Q_\beta\} = \frac{1}{2} C\gamma^\mu P_\mu + \frac{1}{2} C\gamma^{\mu\nu} P_{\mu\nu} \tag{1.14}$$

and the Jacobi indentities

$$\{[\mathcal{M}_{\mu_1\mu_2}, Q_\alpha], Q_\beta\} + \{[\mathcal{M}_{\mu_1\mu_2}, Q_\beta], Q_\alpha\} = [\mathcal{M}_{\mu_1\mu_2}, \{Q_\alpha, Q_\beta\}]. \tag{1.15a}$$

$$\{[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},Q_\alpha],Q_\beta\}+\{[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},Q_\beta],Q_\alpha\}=[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_2},\{Q_\alpha,Q_\beta\}] \tag{1.15b}$$

with the commutators

$$[M_{\mu_1\mu_2},P_{\rho_1\rho_2}]=-\eta_{\mu_1\rho_1}P_{\mu_2\rho_2}+\eta_{\mu_2\rho_1}P_{\mu_1\rho_2}\pm\ldots;\quad [\mathcal{M}_{\mu_1\mu_2},Q_\alpha]=-\frac{1}{2}(\gamma_{\mu_1\mu_2})_\alpha^\delta Q_\delta, \tag{1.15c}$$

where

$$\{Q_\alpha,Q_\beta\}=\frac{1}{2}C\gamma^\mu P_\mu+\frac{1}{2}C\gamma^{\mu\nu}P_{\mu\nu}, \tag{1.15d}$$

the spinorial charges Q_α behave under polyrotations as follows:

$$[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},Q_\alpha]=-\frac{1}{2}(\gamma_{\mu_1\mu_2\mu_3\mu_4})_\alpha^\delta Q_\delta, \tag{1.15e}$$

and the remaining commutators are

$$[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},P_{\nu_1\nu_2}]=\eta_{\mu_1\mu_2\nu_1\nu_2}P_{\mu_3\mu_4}+\eta_{\mu_3\mu_4\nu_1\nu_2}P_{\mu_1\mu_2}\pm\ldots;\quad [\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},P_{\nu_1}]=0, \tag{1.15f}$$

$$[M_{\mu_1\mu_2},M_{\nu_1\nu_2}]=-\eta_{\mu_1\nu_1}M_{\mu_2\nu_2}+\eta_{\mu_2\nu_1}M_{\mu_1\nu_2}\pm\ldots, \tag{1.15g}$$

$$[M_{\mu_1\mu_2\mu_3\mu_4},M_{\nu_1\nu_2\nu_3\mu_4}]=\eta_{\mu_1\mu_2\nu_1\nu_2}M_{\mu_3\mu_4\nu_3\nu_4}\pm\ldots, \tag{1.15h}$$

$$[M_{\mu_1\mu_2},M_{\nu_1\nu_2\nu_3\mu_4}]=-\eta_{\mu_1\nu_1}M_{\mu_2\nu_2\nu_3\nu_4}\pm\ldots \tag{1.15i}$$

In the Appendix we will prove that this algebra Eqs. (1.15) closes and satisfies the Jacobi identities. G_{MN} is the *flat* C-space generalized metric $\eta_{\mu_1\nu_1\mu_2\nu_2\ldots\mu_n\nu_n}$ given by the determinant of the $N\times N$ matrix $\mathbf{\Upsilon}_{mm}$ whose entries are $\eta_{\mu_m\nu_n}$. For instance

$$\eta_{\mu_1\nu_1\mu_2\nu_2\ldots\mu_n\nu_n}=\det\mathbf{\Upsilon}_{mm}=\frac{1}{N!}\boldsymbol{\epsilon}^{j_1i_2\ldots i_n}\boldsymbol{\epsilon}^{j_1j_2\ldots j_n}\eta_{\mu_{i_1}\nu_{j_1}}\eta_{\mu_{i_2}\nu_{j_2}}\cdots\eta_{\mu_{i_n}\nu_{j_n}}, \tag{1.16}$$

so that

$$\eta_{\mu_1\nu_1\mu_2\nu_2}=\eta_{\mu_1\nu_1}\eta_{\mu_2\nu_2}-\eta_{\mu_1\nu_2}\eta_{\mu_2\nu_1},\ \text{etc.} \tag{1.17}$$

Similar results apply to the definition of $\eta_{i_1j_1\ldots i_nj_n}$.

The graded super Jacobi identities (nontrivial matter) in C-space due to the nontrivial algebraic relations obtained from the (geometric) product of two polyvector basis elements $\Gamma^M\Gamma^N$ that involves a sum of terms with polyvectors of mixed grade

$$\langle\Gamma^M\Gamma^N\rangle_{m+n},\ \langle\Gamma^M\Gamma^N\rangle_{m+n-2},\ \langle\Gamma^M\Gamma^N\rangle_{m+n-4},\ \cdots\ \langle\Gamma^M\Gamma^N\rangle_{|m-n|}. \tag{1.18}$$

Using the standard notation

$$\gamma^{\nu_1\nu_2\ldots\nu_p}\equiv\gamma^{\mu_1}\wedge\gamma^{\mu_2}\wedge\cdots\wedge\gamma^{\mu_p}, \tag{1.19}$$

where the antisymmetrization of indices is performed with unit weight, one has for example

$$\gamma^\mu\gamma^\nu=\frac{1}{2}\{\gamma^\mu,\gamma^\nu\}+\frac{1}{2}[\gamma^\mu,\gamma^\nu]=\eta^{\mu\nu}\mathbf{1}+\frac{1}{2}\gamma^{\mu\nu}, \tag{1.20}$$

$$\gamma^{\mu_1\mu_2\cdots\mu_p}\gamma^{\mu_{p+1}} = \gamma^{\mu_1\mu_2\cdots\mu_p\mu_{p+1}} + p\,\gamma^{[\mu_1\mu_2\cdots\mu_{p-1}}\eta^{\mu_p]\mu_{p+1}}, \tag{1.21}$$

$$\gamma^{\mu}\gamma^{\nu_1\nu_2\cdots\nu_p} - (-1)^p\gamma^{\nu_1\nu_2\cdots\nu_p}\gamma^{\mu} = 2p\,\eta^{\mu[\nu_1}\gamma^{\nu_2\nu_3\cdots\nu_p]}. \tag{1.22}$$

Having outlined the basic features of the extended relativity theory in Clifford spaces and polyvector-valued supersymmetries we proceed with the main bulk of this work.

II. THE E_8 YANG–MILLS FROM A Cl(16) ALGEBRA GAUGE THEORY

It is well known among the experts that the E_8 algebra admits the SO(16) decomposition $\mathbf{248}\rightarrow\mathbf{120}\oplus\mathbf{128}$. The E_8 admits also a SL$(8,R)$ decomposition.[3] Due to the triality property, the SO(8) admits the vector $\mathbf{8}_v$ and spinor representations $\mathbf{8}_s,\mathbf{8}_c$. After a triality rotation, the SO(16) vector and spinor representations decompose as[3]

$$\mathbf{16}\rightarrow\mathbf{8}_s\oplus\mathbf{8}_c, \tag{2.1a}$$

$$\mathbf{128}_s\rightarrow\mathbf{8}_v\oplus\mathbf{56}_v\oplus\mathbf{1}\oplus\mathbf{28}\oplus\mathbf{35}_v, \tag{2.1b}$$

$$\mathbf{128}_c\rightarrow\mathbf{8}_s\oplus\mathbf{56}_s\oplus\mathbf{8}_c\oplus\mathbf{56}_c. \tag{2.1c}$$

To connect with (real) Clifford algebras,[6] i.e., how to fit E_8 into a Clifford structure, start with the 248-dim fundamental representation E_8 that admits a SO(16) decomposition given by the 120-dim bivector representation plus the 128-dim chiral-spinor representations of SO(16). From the modulo 8 periodicity of Clifford algebras one has $\mathrm{Cl}(16)=\mathrm{Cl}(2\times 8)=\mathrm{Cl}(8)\otimes\mathrm{Cl}(8)$, meaning, roughly, that the $2^{16}=256\times 256$ Cl(16)-algebra matrices can be obtained effectively by replacing each single one of the *entries* of the $2^8=256=16\times 16$ Cl(8)-algebra matrices by the 16×16 matrices of the second copy of the Cl(8) algebra. In particular, $120=1\times 28+8\times 8+28\times 1$ and $128=8+56+8+56$, hence, the 248-dim E_8 algebra decomposes into a $120+128$ dim structure such that E_8 can be represented indeed within a tensor product of Cl(8) algebras.

At the E_8 Lie algebra level, the E_8 gauge connection decomposes into the SO(16) vector $I,J=1,2,\ldots,16$ and (chiral) spinor $A=1,2,\ldots,128$ indices as follows:

$$\mathcal{A}_\mu = \mathcal{A}^{IJ}_\mu X_{IJ} + \mathcal{A}^{A}_\mu Y_A, \quad X_{IJ}=-X_{JI}, \quad I,J=1,2,3,\ldots,16. \quad A=1,2,\ldots,128, \tag{2.2}$$

where X_{IJ}, Y_A are the E_8 generators. The Clifford algebra $(\mathrm{Cl}(8)\otimes\mathrm{Cl}(8))$ structure behind the SO(16) decomposition of the E_8 gauge field $\mathcal{A}^{IJ}_\mu X_{IJ}+\mathcal{A}^{A}_\mu Y_A$ can be deduced from the expansion of the generators X_{IJ}, Y_A in terms of the Cl(16) algebra generators. The Cl(16) bivector basis admits the decomposition

$$X^{IJ} = \alpha^{IJ}_{ij}(\gamma_{ij}\otimes\mathbf{1}) + b^{IJ}_{ij}(\mathbf{1}\otimes\gamma_{ij}) + c^{IJ}_{ij}(\gamma_i\otimes\gamma_j), \tag{2.3}$$

where γ_i, are the Clifford algebra generators of the Cl(8) algebra present in $\mathrm{Cl}(16)=\mathrm{Cl}(8)\otimes\mathrm{Cl}(8)$; $\mathbf{1}$ is the unit Cl(8) algebra element that can be represented by a unit 16×16 diagonal matrix. The tensor products $\otimes$ of the 16×16Cl(8)-algebra matrices, like $\gamma_i\otimes\mathbf{1}$, $\gamma_i\otimes\gamma_j,\ldots$ furnish a 256×256 Cl(16)-algebra matrix, as expected. The Cl(8) algebra basis elements are

$$\gamma_M=\mathbf{1},\ \gamma_i, \quad \gamma_{i_1i_2}=\gamma_{i_1}\wedge\gamma_{i_2}, \quad \gamma_{i_1i_2i_3}=\gamma_{i_1}\wedge\gamma_{i_2}\wedge\gamma_{i_3},\ldots,\gamma_{i_1i_2\ldots i_8}=\gamma_{i_1}\wedge\gamma_{i_2}\wedge\cdots\wedge\gamma_{i_8}. \tag{2.4}$$

Therefore, the decomposition in Eq. (2.3) yields the $28+28+8\times 8=56+64=120$-dim bivector representation of SO(16); i.e., for each *fixed* values of IJ there are 120 terms on the rhs of Eq. (2.5), that match the number of *independent* components of the E_8 generators $X^{IJ}=-X^{JI}$, given by $\frac{1}{2}(16\times 15)=120$. The decomposition of Y_A is more subtle. A spinor Ψ in $16D$ has $2^8=256$ components and can be decomposed into a 128 component left-handed spinor Ψ^A and a 128 compo-

nent right-handed spinor $\Psi^{\dot{A}}$; The 256 spinor indices are $\alpha=A,\ \dot{A};\ \beta=B,\dot{B},\ldots$ with $A,B=1,2,\ldots,128$ and $\dot{A},\dot{B}=1,2,\ldots,128$, respectively.

Spinors are elements of right (left) ideals of the Cl(16) algebra and admit the expansion $\Psi=\Psi_\alpha\xi^\alpha$ in a 256-dim spinor basis ξ^α which in turn can be expanded as sums of Clifford polyvectors of *mixed* grade; i.e., into a sum of scalars, vectors, bivectors, trivectors, …. The chiral (left-handed, right-handed) 128-component spinors $\Psi^\pm$ are obtained via the projection operators

$$\Psi^\pm=\frac{1}{2}(1+\Gamma_{17})\Psi,\quad \Gamma^{17}=\Gamma^1\wedge\Gamma^2\wedge\cdots\wedge\Gamma^{16}, \tag{2.5}$$

such that $\xi^\alpha_+\equiv\xi^A$; $\xi^\alpha_-\equiv\xi^{\dot{A}}$, so the left-handed (right-handed) spinor basis $\xi_\pm$ can be represented by a column matrix (an element of the left ideal) with 128 nonvanishing upper (lower) components in the Weyl representation as

$$\xi^\alpha_\pm=\left(\frac{1\pm\Gamma_{17}}{2}\right)^{\alpha\beta}[(\mathbf{1}\otimes\mathbf{1})^{\beta\delta}\mathcal{A}^\delta+(\gamma_i\otimes 1)^{\beta\delta}\mathcal{A}^\delta_i+(\gamma_{i_1i_2}\otimes\mathbf{1})^{\beta\delta}\mathcal{A}_{i_1i_2}+\ldots\quad(\gamma_{i_1i_2\ldots i_7}\otimes\mathbf{1})^{\beta\delta}\mathcal{A}^\delta_{i_1i_2\ldots i_7}$$
$$+(\gamma_{i_1i_2-_2\ldots i_8}\otimes\mathbf{1})^{\beta\delta}\mathcal{A}_{i_1i_2\ldots i_8}], \tag{2.6}$$

where the numerical tensor-spinorial coefficients on the rhs of Eq. (2.6) are constrained to satisfy all the conditions imposed by the definition of an ideal element of the Cl(16) algebra; namely that *any* element of the ideal upon a multiplication from the left by any Clifford algebra element yields another element of the left ideal. Similar definitions apply to the right ideal elements upon multiplication from the right by any Clifford algebra element. The row matrix (an element of the right ideal) with 128 nonvanishing components is just given by $(\xi^\pm)^\dagger$.

The rigorous procedure to construct spinors as elements of right/left ideals of Clifford algebras using primitive idempotents can be found in Ref. 5, and references therein. The final outcome is the same as performing the expansion Eq. (2.6) and solving for the coefficients. In this fashion one can construct the 128-dim left-handed (right-handed) chiral spinor representations of SO(16) that match the number of 128 generators Y_A. Hence, the total number of E_8 generators is then $120+128=248$. What remains to be done is to enforce the E_8 commutation relations that in conjunction with the defining relations of a primitive ideal element of the Cl(16) algebra will fix the values of the coefficients appearing in (2.4) and (2.6). Based on the fact that the Clifford algebra commutators of even and odd grade satisfy the relations

$$[\text{Even},\text{Even}]=\text{Even},\ [\text{Odd},\text{Odd}]=\text{Even},\ [\text{Even},\text{Odd}]=[\text{Odd},\text{Even}]=\text{Odd}, \tag{2.7}$$

which are similar to the E_8 commutation relations described below, one can immediately choose to expand the spinor basis elements in Eq. (2.6) as sums of polyvectors of *odd* grade only, meaning that for each fixed value of δ, there are only 128 terms on the rhs of Eq. (2.6) given by the number of odd-grade elements of the Cl(8) algebra $8+56+56+8=128$. This is consistent with the fact that a chiral spinor in $16D$ has 128 nonvanishing components in a Weyl representation. Therefore, the generators $Y^A\equiv Y^\alpha_+$; $Y^{\dot{A}}=Y^\alpha_-$ must involve odd grade elements of the form

$$Y^\alpha_\pm=\left(\frac{1\pm\Gamma_{17}}{2}\right)^{\alpha\beta}[(\gamma_i\otimes\mathbf{1})^{\beta\delta}\mathcal{A}^\delta_i+(\gamma_{i_1i_2i_3}\otimes\mathbf{1})\beta\delta\mathcal{A}^\delta_{i_1i_2i_3}+(\gamma_{i_1i_2\ldots i_5}\otimes\mathbf{1})^{\beta\delta}\mathcal{A}^\delta_{i_1i_2\ldots i_5}$$
$$+(\gamma_{i_1i_2\ldots i_7}\otimes\mathbf{1})^{\beta\delta}\mathcal{A}^\delta_{i_1i_2\ldots i_7}]. \tag{2.8}$$

The commutation relations of E_8 are[3]

$$[X^{IJ},X^{KL}]=4(\delta^{IK}X^{LJ}-\delta^{IL}X^{KJ}+\delta^{JK}X^{IL}-\delta^{JL}X^{IK}),\quad [X^{IJ},Y^{A}]=-\frac{1}{2}\Gamma^{IJ}_{AB}Y^{B};\quad [Y^{A},Y^{B}]=\frac{1}{4}\Gamma^{IJ}_{AB}X^{IJ}. \tag{2.9}$$

The combined E_8 indices are denoted by $\mathcal{A}\equiv[IJ],A$ $(120+128=248$ indices in total) that yield the Killing metric and the structure constants

$$\eta^{\mathcal{AB}}=\frac{1}{60}\,\mathrm{Tr}\,T^{\mathcal{A}}T^{\mathcal{B}}=-\frac{1}{60}f^{\mathcal{A}}_{\mathcal{CD}}f^{\mathcal{BCD}}, \tag{2.10a}$$

$$f^{IJ,KL,MN}=-8\,\delta^{JK}\delta^{LJ}_{MN}+\text{permutations};\quad f^{IJ,A,B}=-\frac{1}{2}\Gamma^{IJ}_{AB};\quad \eta^{IJKL}=-\frac{1}{60}f^{IJ}_{\mathcal{CD}}f^{KL,\mathcal{CD}}. \tag{2.10b}$$

Therefore, the odd grade expansion in Eq. (2.8) and the bivector grade expansion in Eq. (2.3) is consistent with the commutation relations of E_8. We shall proceed with the construction of a novel Cl(16) gauge theory that encodes the exceptional Lie algebra E_8 symmetry from the start. The E_8 gauge theory in $D=4$ is based on the E_8-valued field strengths

$$F^{IJ}_{\mu\nu}X_{IJ}=(\partial_\mu\mathcal{A}^{IJ}_\nu-\partial_\nu\mathcal{A}^{IJ}_\nu)X_{IJ}+\mathcal{A}^{KL}_\mu\mathcal{A}^{MN}_\nu[X_{KL},X_{MN}]+\mathcal{A}^{A}_\mu\mathcal{A}^{B}_\nu[Y_A,Y_B], \tag{2.11}$$

$$F^{A}_{\mu\nu}Y_A=(\partial_\mu\mathcal{A}^{A}_\nu-\partial_\nu\mathcal{A}^{A}_\mu)Y_A+\mathcal{A}^{A}_\mu\mathcal{A}^{IJ}_\nu[Y_A,X_{IJ}]. \tag{2.12}$$

The E_8 actions are

$$\begin{aligned}S_{\text{Topological}}[E_8]&=\int d^4x\frac{1}{60}\,\mathrm{Tr}[F^{\mathcal{A}}_{\mu\nu}F^{\mathcal{B}}_{\rho\tau}T_{\mathcal{A}}T_{\mathcal{B}}]\epsilon^{\mu\nu\rho\tau}=\int d^4xF^{\mathcal{A}}_{\mu\nu}F^{\mathcal{B}}_{\rho\tau}\eta_{\mathcal{AB}}\epsilon^{\mu\nu\rho\tau}\\&=\int d^4x[F^{IJ}_{\mu\nu}F^{KL}_{\rho\tau}\eta_{IJKL}+F^{A}_{\mu\nu}F^{B}_{\rho\tau}\eta_{AB}+2F^{IJ}_{\mu\nu}F^{B}_{\rho\tau}\eta_{IJB}]\epsilon^{\mu\nu\rho\tau},\end{aligned} \tag{2.13}$$

where $\epsilon^{\mu\nu\rho\tau}$ is the covariantized permutation symbol and

$$\begin{aligned}S_{YM}[E_8]&=\int d^4x\sqrt{g}\frac{1}{60}\,\mathrm{Tr}[F^{\mathcal{A}}_{\mu\nu}F^{\mathcal{B}}_{\rho\tau}T_{\mathcal{A}}T_{\mathcal{B}}]g^{\mu\rho}g^{\nu\tau}=\int d^4x\sqrt{g}F^{\mathcal{A}}_{\mu\nu}F^{\mathcal{B}}_{\rho\tau}\eta_{\mathcal{AB}}g^{\mu\rho}g^{\nu\tau}\\&=\int d^4x\sqrt{g}[F^{IJ}_{\mu\nu}F^{KL}_{\rho\tau}\eta_{IJKL}+F^{A}_{\mu\nu}F^{B}_{\rho\tau}\eta_{AB}+2F^{IJ}_{\mu\nu}F^{B}_{\rho\tau}\eta_{IJB}]g^{\mu\rho}g^{\nu\tau}.\end{aligned} \tag{2.14}$$

The above E_8 actions (are part of) can be embedded onto more general Cl(16) actions with a much larger number of terms given by

$$S_{\text{Topological}}[\mathrm{Cl}(16)]=\int d^4x\langle F^{\mathcal{M}}_{\mu\nu}F^{\mathcal{N}}_{\rho\tau}\Gamma_{\mathcal{M}}\Gamma_{\mathcal{N}}\rangle\epsilon^{\mu\nu\rho\tau}=\int d^4xF^{\mathcal{M}}_{\mu\nu}F^{\mathcal{N}}_{\rho\tau}G_{\mathcal{MN}}\epsilon^{\mu\nu\rho\tau} \tag{2.15}$$

and

$$S_{YM}[\mathrm{Cl}(16)]=\int d^4x\sqrt{g}\langle F^{\mathcal{M}}_{\mu\nu}F^{\mathcal{N}}_{\rho\tau}\Gamma_{\mathcal{M}}\Gamma_{\mathcal{N}}\rangle g^{\mu\rho}g^{\nu\tau}=\int d^4x\sqrt{g}F^{\mathcal{M}}_{\mu\nu}F^{\mathcal{N}}_{\rho\tau}G_{\mathcal{MN}}g^{\mu\rho}g^{\nu\tau}, \tag{2.16}$$

where $\langle\Gamma_{\mathcal{M}}\Gamma_{\mathcal{N}}\rangle=G_{\mathcal{MN}}\mathbf{1}$ denotes the *scalar* part of the Clifford geometric product, of the gammas. Notice that there are a total of 65 536 terms in

$$F^{\mathcal{M}}_{\mu\nu}F^{\mathcal{N}}_{\rho\tau}G_{\mathcal{MN}}=F_{\mu\nu}F_{\rho\tau}+F^{I}_{\mu\nu}F^{I}_{\rho\tau}+F^{I_1I_2}_{\mu\nu}F^{I_1I_2}_{\rho\tau}+\cdots+F^{I_1I_2\cdots I_{16}}_{\mu\nu}F^{I_1I_2\cdots I_{16}}_{\rho\tau}, \tag{2.17}$$

where the indices run as $I=1,2,\ldots,16$. The Clifford algebra Cl(16) has the graded structure (scalars, bivectors, trivectors,..., pseudoscalar) given by

$$1\ 16\ 120\ 560\ 1820\ 4368\ 8008\ 11\,440\ 12\,870$$

$$11\,440\ 8008\ 4368\ 1820\ 560\ 120\ 16\ 1, \tag{2.18}$$

consistent with the dimension of the Cl(16) algebra $2^{16}=256\times256=65\,536$. The possibility that one can accommodate another copy of the E_8 algebra within the Cl(16) algebraic structure warrants further investigation by working with the duals of the bivectors X_{IJ} and recurring to the remaining Y_A generators. The motivation is to understand the full symmetry of the $E_8\times E_8$ heterotic string from this Clifford algebraic perspective. A clear embedding is, of course, the following:

$$E_8\times E_8\subset \mathrm{Cl}(8)\otimes\mathrm{Cl}(8)\otimes\mathrm{Cl}(8)\otimes\mathrm{Cl}(8)\subset\mathrm{Cl}(16)\otimes\mathrm{Cl}(16)=\mathrm{Cl}(32), \tag{2.19}$$

where $\mathrm{SO}(32)\subset\mathrm{Cl}(32)$ and SO(32) is also an anomaly free group of the heterotic string that has the same dimension and rank as $E_8\times E_8$.

III. CHERN–SIMONS GRAVITY IN 11*D* FROM A CLIFFORD ALGEBRA GAUGE THEORY

The 11*D* Chern–Simons supergravity action is based on the smallest Anti de Sitter $\mathrm{OSp}(32|1)$ superalgebra. The Anti de Sitter group $\mathrm{SO}(10,2)$ must be embedded into a larger group $\mathrm{Sp}(32,R)$ to accomodate the fermionic degrees of freedom associated with the superalgebra $\mathrm{OSp}(32|1)$. The bosonic sector involves the connection[5]

$$\mathbf{A}_\mu=A^a_\mu\Gamma_a+A^{ab}_\mu\Gamma_{ab}+A^{a_1a_2\ldots a_5}_\mu\Gamma_{a_1a_2\ldots a_5}=e^a_\mu\Gamma_a+\omega^{ab}_\mu\Gamma_{ab}+A^{a_1a_2\ldots a_5}_\mu\Gamma_{a_1a_2\ldots a_5} \tag{3.1}$$

with $11+55+462=528$ generators. A Hermitian complex 32×32 matrix has a total of $32+2((32\times31)/2)=992+32=1024=32^2=2^{10}$ independent real components (parameters), the same number as the real parameters of the antisymmetric and symmetric real 32×32 matrices $496+528=1024$. The dimension of $\mathrm{Sp}(32)=(1/2)(32\times33)=528$. Notice that $2^{10}=1024$ is also the number of independent generators of the Cl(11) algebra since out of the 2^{11} generators, only half of them 2^{10}, are truly independent due to the duality conditions valid in odd dimensions only

$$\epsilon^{a_1a_2\ldots a_{2n+1}}\Gamma_{a_1}\wedge\Gamma_{a_2}\wedge\cdots\wedge\Gamma_{a_p}\sim\Gamma^{a_{p+1}}\wedge\Gamma^{a_{p+2}}\wedge\cdots\wedge\Gamma^{a_{2n+1}}. \tag{3.2}$$

This counting of components is the underlying reason why the Cl(11) algebra appears in this section. The generators of the Cl(11) algebra $\{\Gamma^a,\Gamma^b\}=2\eta^{ab}\mathbf{1}$ and the unit element $\mathbf{1}$ generate the Clifford polyvectors (including a scalar, pseudoscalar) of different grading

$$\Gamma^A=\mathbf{1},\Gamma^a,\Gamma^{a_1}\wedge\Gamma^{a_2},\Gamma^{a_1}\wedge\Gamma^{a_2}\wedge\Gamma^{a_3},\ldots,\Gamma^{a_1}\wedge\Gamma^{a_2}\wedge\cdots\wedge\Gamma^{a_{11}}, \tag{3.3}$$

obeying the conditions (3.2). The commutation relations (see Eqs. (3.4) below) involving the generators $\Gamma_a,\Gamma_{ab},\Gamma_{a_1a_2}\ldots a_5$ do in fact *close* due to the duality conditions (3.2). The Cl(11) algebra commutators, up to numerical factors, are

$$[\Gamma^a,\Gamma^b]=\Gamma^{ab},\quad [\Gamma^a,\Gamma^{bc}]=2\eta^{ab}\Gamma^c-2\eta^{ac}\Gamma^b, \tag{3.4a}$$

$$[\Gamma^{a_1a_2},\Gamma^{b_1b_2}]=-\eta^{a_1b_1}\Gamma^{a_2b_2}+\eta^{a_1b_2}\Gamma^{a_2b_1}-\cdots, \tag{3.4b}$$

$$[\Gamma^{a_1a_2a_3},\Gamma^{b_1b_2b_3}]=\Gamma^{a_1a_2a_3b_1b_2b_3}-(\eta^{a_1b_1a_2b_2}\Gamma^{a_3b_3}+\cdots), \tag{3.4c}$$

$$[\Gamma^{a_1a_2a_3a_4},\Gamma^{b_1b_2b_3b_4}]=-(\eta^{a_1b_1}\Gamma^{a_1a_2a_3a_4b_2b_3b_4}+\cdots)-(\eta^{a_1b_1a_2b_2a_3b_3}\Gamma^{a_4b_4}+\cdots), \tag{3.4d}$$

$$[\Gamma^{a_1a_2},\Gamma^{b_1b_2b_3b_4}] = -\eta^{a_1b_1}\Gamma^{a_2b_2b_3b_4} + \cdots, \tag{3.4e}$$

$$[\Gamma^{a_1},\Gamma^{b_1b_2b_3}] = \Gamma^{a_1b_1b_2b_3}[\Gamma^{a_1a_2},\Gamma^{b_1b_2b_3}] = -2\eta^{a_1b_1}\Gamma^{a_2b_2b_3} + \cdots, \tag{3.4f}$$

$$[\Gamma^{a_1},\Gamma^{b_1b_2b_3b_4}] = -\eta^{a_1b_1}\Gamma^{b_2b_3b_4} + \cdots, \tag{3.4g}$$

$$\begin{aligned}[\Gamma^{a_1a_2\ldots a_5},\Gamma^{b_1b_2\ldots b_5}] &= \Gamma^{a_1a_2\ldots a_5b_1b_2\ldots b_5} + (\eta^{a_1b_1a_2b_2}\Gamma^{a_3a_4a_5b_3b_4b_5} + \cdots) + (\eta^{a_1b_1a_2b_2a_3b_3a_4b_4}\Gamma^{a_5b_5} + \cdots)\\ &= \epsilon^{a_1a_2\ldots a_5b_1b_2\ldots b_5c}\Gamma_c + (\eta^{a_1b_1a_2b_2}\epsilon^{a_3a_4a_5b_3b_4b_5c_1c_2\ldots c_5}\Gamma_{c_1c_2\ldots c_5} + \cdots)\\ &\quad + (\eta^{a_1b_1a_2b_2a_3b_3a_4b_4}\Gamma^{a_5b_5} + \cdots),\end{aligned} \tag{3.4h}$$

etc, with

$$\eta_{a_1b_1a_2b_2} = \eta_{a_1b_1}\eta_{a_2b_2} - \eta_{a_2b_1}\eta_{a_1b_2}, \tag{3.5a}$$

$$\eta_{a_1b_1a_2b_2a_3b_3} = \eta_{a_1b_1}\eta_{a_2b_2}\eta_{a_3b_3} - \eta_{a_1b_2}\eta_{a_2b_1}\eta_{a_3b_3} + \cdots, \tag{3.5b}$$

$$\eta_{a_1b_1a_2b_2\ldots a_nb_n} = \frac{1}{n!}\epsilon_{i_1i_2\ldots i_n}\epsilon_{j_1j_2\ldots j_n}\eta_{a_{i_1}b_{j_1}}\eta_{a_{i_2}b_{j_2}}\cdots\eta_{a_{i_n}b_{j_n}}. \tag{3.5c}$$

The Cl(11) algebra gauge field is

$$\mathbf{A}_\mu = \mathcal{A}^A_\mu = \mathcal{A}_\mu\mathbf{1} + \mathcal{A}^a_\mu\Gamma_a + \mathcal{A}^{a_1a_2}_\mu\Gamma_{a_1a_2} + \mathcal{A}^{a_1a_2a_3}_\mu\Gamma_{a_1a_2a_3} + \cdots + \mathcal{A}^{a_1a_2\ldots a_{11}}_\mu\Gamma_{a_1a_2\ldots a_{11}}, \tag{3.6}$$

and the Cl(11)-algebra-valued field strength

$$\begin{aligned}\mathcal{F}^A_{\mu\nu}\Gamma_A &= \partial_{[\mu}A_{\nu]}\mathbf{1} + [\partial_{[\mu}A^a_{\nu]} + A^{b_2}_{[\mu}A^{b_1a}_{\nu]}\eta_{b_1b_2} + \cdots]\Gamma_a + [\partial_{[\mu}A^{ab}_{\nu]} + A^a_{[\mu}A^b_{\nu]} - A^{a_1a}_{[\mu}A^{b_1b}_{\nu]}\eta_{a_1b_1}\\ &\quad - A^{a_1a_2a}_{[\mu}A^{b_1b_2b}_{\nu]}\eta_{a_1b_1a_2b_2} - A^{a_1a_2a_3a}_{[\mu}A^{a_1b_2b_3b}_{\nu]}\eta_{a_1b_1a_2b_2a_3b_3} + \cdots]\Gamma_{ab} + [\partial_{[\mu}A^{abc}_{\nu]}\\ &\quad + A^{a_1a}_{[\mu}A^{b_1bc}_{\nu]}\eta_{a_1b_1} + \cdots]\Gamma_{abc} + [\partial_{[\mu}A^{abcd}_{\nu]} - A^{a_1a}_{[\mu}A^{b_1bcd}_{\nu]}\eta_{a_1b_1} + \cdots]\Gamma_{abcd}\\ &\quad + \cdots[\partial_{[\mu}A^{a_1a_2\ldots a_5b_1b_2\ldots b_5}_{\nu]} + A^{a_1a_2\ldots a_5}_{[\mu}A^{b_1b_2\ldots b_5}_{\nu]} + \cdots]\Gamma_{a_1a_2\ldots a_5b_1b_2\ldots b_5} + \cdots.\end{aligned} \tag{3.7}$$

The Chern–Simons actions rely on Stokes theorem

$$\int_{M^{12}}\epsilon^{\mu_1\mu_2\ldots\mu_{11}\mu_{12}}\partial_{\mu_{12}}(A_{\mu_1\mu_2\ldots\mu_{11}}) = \int_{\partial M^{12}=\Sigma^{11}}\epsilon^{\mu_1\mu_2\ldots\mu_{11}\mu_{12}}A_{\mu_1\mu_2\ldots\mu_{11}}d\Sigma^{11}_{\mu_{12}}, \tag{3.8}$$

which in our case reads

$$d(\mathcal{L}_{\text{Clifford}}) = \langle\mathcal{F}\wedge\mathcal{F}\wedge\cdots\wedge\mathcal{F}\rangle = \langle\mathcal{F}^{A_1}\wedge\mathcal{F}^{A_2}\wedge\cdots\wedge\mathcal{F}^{A_6}\Gamma_{A_1}\Gamma_{A_2}\ldots\Gamma_{A_6}\rangle, \tag{3.9}$$

where the bracket $\langle\cdots\rangle$ means taking the scalar part of the Clifford geometric product among the gammas. It involves products of the d_{ABC}, f_{ABC} structure constants corresponding to the (anti) commutators $\{\Gamma A,\Gamma_B\}=d_{ABC}\Gamma^C$ and $[\Gamma_A,\Gamma_B]=f_{ABC}\Gamma^C$.

One of the main results of this work is that the Cl(11) algebra based action (3.9) contains a *vast number* of *terms* among which is the Chern–Simons action of Ref. 15 $\mathcal{L}^{11}_{\text{CS}}(e,\omega,A_5)$,

$$\mathcal{L}_{\text{Clifford}}(\mathcal{A}^A_\mu\Gamma_A) = \mathcal{L}^{11}_{\text{CS}}(\omega,e,A_5) + \text{EXTRA TERMS}, \tag{3.10}$$

$$S_{\text{CS}}(\omega,e,A_5) = \int_{\partial M^{12}}\mathcal{L}^{11}_{\text{CS}} = \int_{\Sigma^{11}}\mathcal{L}^{11}_{\text{CS}}, \tag{3.11}$$

$$\mathcal{L}^{11}_{\rm CS}(\omega,e,A_5)=\mathcal{L}^{11}_{\rm Lovelock}(\omega,e)+\mathcal{L}^{11}_{\rm Pontryagin}(\omega,e)+\mathcal{L}^{11}(A_5,\omega,e). \tag{3.12}$$

In odd dimensions $D=2n-1$, the Lanczos–Lovelock Lagrangian is

$$\mathcal{L}^{D}_{\rm Lovelock}=\sum_{p=0}^{n-1}a_pL_p(D),\quad a_p=\kappa\frac{(\pm 1)^{p+1}l^{2p-D}}{(D-2p)}C_p^{n-1}\quad p=1,2,\ldots,n-1. \tag{3.13}$$

C_p^{n-1} is the binomial coefficient. The constants κ, l are related to the Newton's constant G and to the cosmological constant Λ through $\kappa^{-1}=2(D-2)\Omega_{D-2}G$ where Ω_{D-2} is the area of the $D-2$ -dim unit sphere and $\Lambda=\pm(D-1)(D-2)/2l^2$ for de Sitter (Anti de Sitter) spaces.[15] A derivation of the vacuum energy density of Anti de Sitter space (de Sitter) as the geometric mean between an upper and lower scale was obtained in Ref. 11 based on a BF–Chern–Simons–Higgs theory. Upon setting the lower scale to the Planck scale L_P and the upper scale to the Hubble radius (today) R_H, it yields the observed value of the cosmological constant $\rho=L_P^{-2}R_H^{-2}=L_P^{-4}(L_P/R_H)^2\sim 10^{-120}M_P^4$.

The terms inside the summand of Eq. (3.13) are

$$L_p(D)=\epsilon_{a_1a_2\ldots a_D}R^{a_1a_2}R^{a_3a_4}\ldots R^{a_{2p-1}a_{2p}}e^{a_{2p+1}}\ldots e^{a_D}, \tag{3.14}$$

where we have omitted the space-time indices $\mu_1,\mu_2,\ldots$. Despite the higher powers of the curvature (after eliminating the spin connection ω_μ^{ab} in terms of the e_μ^a field) the $\mathcal{L}^D_{\rm Lovelock}$ furnishes equations of motion for the e_μ^a field containing at most derivatives of *second* order, and not higher, due to the topological property of the Lovelock terms

$$d(\mathcal{L}^{11}_{\rm Lovelock})=\epsilon_{a_1a_2\ldots a_{11}}\left(R^{a_1a_2}+\frac{e^{a_1}e^{a_2}}{l^2}\right)\ldots\left(R^{a_9a_{10}}+\frac{e^{a_9}e^{a_{10}}}{l^2}\right)T^{a_{11}}=\text{Euler density in } 12D. \tag{3.15}$$

The exterior derivative of the Lovelock terms can be rewritten compactly as

$$d(\mathcal{L}^{11}_{\rm Lovelock})=\epsilon_{A_1A_2\ldots A_{12}}F^{A_1A_2}\ldots F^{A_{11}A_{12}}, \tag{3.16}$$

where $F^{A_1A_2}$ is the curvature field strength associated with the SO(10,2) connection $\Omega_\mu^{A_1A_2}$ in $12D$ and which can be decomposed in terms of the fields e_μ^a, ω_μ^{ab}, $a,b=1,2,\ldots,11$ by identifying $\Omega_\mu^{aD}=(1/l)e_\mu^a$ and $\Omega_\mu^{ab}=\omega_\mu^{ab}$ so that the Torsion and Lorenz curvature 2-forms are

$$T^a(\omega,e)=F^{aD}=d\Omega^{aD}+\Omega^a_b\wedge\Omega^{bD}=\frac{1}{l}(de^a-\omega^a_b\wedge e^b),$$
$$F^{ab}=(d\Omega^{ab}+\Omega^a_c\wedge\Omega^{cd})+(\Omega^a_D\wedge\Omega^{Db})=R^{ab}(\omega)+\frac{1}{l^2}e^a\wedge e^b,\quad R^{ab}(\omega)=d\omega^{ab}+\omega^a_c\wedge\omega^{cb}, \tag{3.17}$$

where a length parameter l must be introduced to match dimensions since the connection has units of $1/l$. This l parameter is related to the cosmological constant.

$\mathcal{L}^{11}_{\rm Pontryagin}(\omega,e)$ is the Chern–Simons 11-form whose exterior derivative

$$d(\mathcal{L}_{\rm Pontryagin})=F^{A_1}_{A_2}F^{A_2}_{A_3}\ldots F^{A_5}_{A_6}F^{A_6}_{A_1} \tag{3.18}$$

is the (one of the many) Pontryagin 12-form (up to numerical factors) for the SO(10,2) connection in $12D$. As mentioned above, the SO(10,2) connection Ω_μ^{AB} can be broken into the e_μ^a field and the SO(10,1) spin connection ω_μ^{ab} such that the number of components is $11+\frac{1}{2}(11\times 10)=66=\frac{1}{2}(12\times 11)$. Finally, the exterior derivative $d\mathcal{L}(A_5,\omega,e)$ is the 12-form (we are omitting space-time indices $\mu_1,\mu_2,\ldots,\mu_{12}$) that is comprised of terms of the form

$$(R^{a_1a_2\cdots a_5}R_{a_1a_2\cdots a_5})(R^{b_1b_2}R_{b_1b_2})(T^cT_c),(R^{a_1a_2\cdots a_5}R_{a_1a_2\cdots a_5})^2(R^{b_1b_2}R_{b_1b_2}),(R^{a_1a_2\cdots a_5}R_{a_1a_2\cdots a_5})^3, \tag{3.19}$$

the curvature 2-from associated with the field $A_\mu^{c_1c_2\cdots c_5}$ is given by

$$R_{\mu\nu}^{c_1c_2\cdots c_5} = \partial_{[\mu}A_{\nu]}^{c_1c_2\cdots c_5} + A_{[\mu}^{a_1a_2\cdots a_5}A_{\nu]}^{b_1b_2\cdots b_5}f_{a_1a_2\cdots a_5b_1b_2\cdots b_5}^{c_1c_2\cdots c_5}, \tag{3.20}$$

where the structure constants f_{ABC} in Eq. (3.18) are obtained from the Cl(11) algebra commutation relations in Eq. (3.4h).

IV. CONCLUSIONS: GENERALIZED CHERN–SIMONS GRAVITY IN CLIFFORD SPACES

The Cl(11) algebra based action [(3.9), (3.10)] can in turn be embedded into a more general expression in C-space (Clifford space) which is a generalized tensorial spacetime of coordinates $\mathbf{X}=\sigma,x^\mu,x^{\mu\nu},x^{\mu\nu\rho}\ldots$[4] involving a scalar $\Phi(\mathbf{X})$ and antisymmetric tensor gauge fields $A_\mu(\mathbf{X})$, $A_{\mu\nu}(\mathbf{X})$, $A_{\mu\nu\rho}(\mathbf{X})\ldots$ of higher rank (higher spin theories).[21] The most general action onto which the action (3.9), (3.10) itself can be embedded requires a tensorial gauge field theory[21] (generalized Yang–Mills theories) and an integration with respect to all the Clifford-valued coordinates $\mathbf{X}=X^M\Gamma_M$ corresponding to the 2^D-dim C-space associated with the underlying $Cl(2n)$-algebra in $D=2n$ dimensions

$$S = \int [d^{2^n}X]\langle(\mathcal{F}\wedge\mathcal{F}\wedge\cdots\wedge\mathcal{F})\rangle, \quad [d^{2^n}X] = (d\sigma)(dx^\mu)(dx^{\mu\nu})(dx^{\mu\nu\rho})\ldots. \tag{4.1}$$

A different sort of generalized Yang–Mills theories have been studied by Ref. 22 without the Clifford algebraic structure.

Given a Lie algebra $\mathbf{G}$ with generators T_a for $a=1,2,3,\ldots,dim\ \mathbf{G}$, it has for commutators $[T_a,T_b]=f_{ab}^cT_c$ and whose structure constants f_{abc} are fully antisymmetric in their indices. The Lie-algebra valued one-form is $\mathbf{A}=(A_M^a(\mathbf{X})T_a)dX^M$ and its generalized Lie-algebra valued field strength

$$\mathbf{F} = [F_{MN}^c(X)T_c]dX^M\wedge dX^N = [\partial_{[M}A_{N]}^c(X)T_c + gA_M^a(X)A_N^b(X)f_{ab}^cT_c]dX^M\wedge dX^N, \tag{4.2}$$

has for components

$$F_{[[\mu_1\mu_2\ldots\mu_m][\nu_1\nu_2\ldots\nu_n]]}^c = \partial_{[\mu_1\mu_2\ldots\mu_m]}A_{[\nu_1\nu_2\ldots\nu_n]}^c - \partial_{[\nu_1\nu_2\ldots\nu_n]}A_{[\mu_1\mu_2\ldots\mu_m]}^c + gA_{[\mu_1\mu_2\ldots\mu_m]}^aA_{[\nu_1\nu_2\ldots\nu_n]}^bf_{ab}^c. \tag{4.3}$$

The remaining components are of the form

$$F_{[0,N]}^c = F_{[0[\nu_1\nu_2\ldots\nu_n]]}^c = \partial_\sigma A_{[\nu_1\nu_2\ldots\nu_n]}^c - \partial_{x[\nu_1\nu_2\ldots\nu_n]}A_0^c + gA_0^aA_{[\nu_1\nu_2\ldots\nu_n]}^bf_{ab}^c, \tag{4.4}$$

where A_0^c is the Clifford-scalar part $\Phi(\mathbf{X})$ of the Lie-algebra valued Clifford polyvector and in general we must consider the $m=n$ and $m\neq n$ cases resulting from the mixing of different grades (ranks). The antisymmetry with respect the collective indices MN is explicit.

In order to raise, lower and contract polyvector indices in C-space it requires a generalized metric G^{MN}. In flat C-space it is defined by the components

$$G^{\mu\nu} = \eta^{\mu\nu}, \quad G^{\mu_1\mu_2\nu_1\nu_2} = \eta^{\mu_1\nu_1}\eta^{\mu_2\nu_2} - \eta^{\mu_1\nu_2}\eta^{\mu_2\nu_1}, \text{ etc}\,., \tag{4.5}$$

in addition to the scalar-scalar component $G^{\sigma\sigma}=1$. It can be recast as

$$G^{\mu_1\mu_2\cdots\mu_m\nu_1\nu_2\cdots\nu_m} = \det\mathbf{G}^{\mu_I\nu_J} = \frac{1}{m!}\epsilon_{i_1i_2\ldots i_m}\epsilon_{j_1j_2\ldots j_m}\eta^{\mu_{i_1}\nu_{j_1}}\eta^{\mu_{i_2}\nu_{j_2}}\ldots\eta^{\mu_{i_m}\nu_{j_m}}, \tag{4.6}$$

where $\mathbf{G}^{\mu_I\nu_J}$ is an $m\times m$ matrix whose entries are $\eta^{\mu_i\nu_j}$ for $i,j=1,2,3,\ldots,m\leq D$ and $\mu,\nu=1,2,3,\ldots,D$.

As a result of the expression for the flat C-space metric, given by sums of antisymmetrized products of $\eta^{\mu\nu}$, the Clifford-space generalized Yang–Mills action is of the form

$$S_{YM} = -\frac{1}{2}\int [\mathcal{D}X] \sum \text{trace}[F^{a}_{[[\mu_1\mu_2\ldots\mu_m][\nu_1\nu_2\ldots\nu_m]]} F^{[[\mu_1\mu_2\ldots\mu_m][\nu_1\nu_2\ldots\nu_m]]b} T_a T_b] +$$
$$-\frac{1}{2}\int [\mathcal{D}X] \sum \text{trace}[F^{a}_{[0[\nu_1\nu_2\ldots\nu_m]]} F^{[[0\nu_1\nu_2\ldots\nu_m]]b} T_a T_b], \tag{4.7}$$

where the C-space 2^D-dim measure associated with a Clifford algebra in D-dim is

$$[\mathcal{D}X] = [d\sigma][\mathbf{\Pi} dx^{\mu}][\mathbf{\Pi} dx^{\mu_1\mu_2}][\mathbf{\Pi} dx^{\mu_1\mu_2\mu_3}]\ldots[dx^{\mu_1\mu_2\cdots\mu_d}] \tag{4.8}$$

and the indices are ordered as $\mu_1 < \mu_2 < \mu_3 \ldots < \mu_m$, etc.

The action (4.7) is invariant under the infinitesimal gauge transformations

$$\delta_\xi A^c_M = \partial_M \xi^c + g f^c_{ab} A^a_M \xi^b, \quad \delta_\xi A^c_{\mu_1\mu_2\ldots\mu_n} = \partial_{x_{\mu_1\mu_2\ldots\mu_n}} \xi^c + g f^c_{ab} A^a_{\mu_1\mu_2\ldots\mu_n} \xi^b \tag{4.9}$$

associated with a Lie-algebra valued Clifford-scalar parameter $\xi(\mathbf{X}) = \xi^a(\mathbf{X}) T_a$.

In Sec. I A it was explained why another alternative to define the transformations in C-space was by writing the generators of polyrotations as $R = \exp(\Omega^{AB}[E_A, E_B])$ where the commutator $[E_A, E_B] = F^C_{AB} E_C$ is the C-space analog of the $i[\gamma_\mu, \gamma_\nu]$ commutator which is the generator of the Lorentz algebra, and the parameters Ω^{AB} are the C-space analogs of the rotation/boots parameters. This last alternative seems to be more physical because a polyrotation should map the E_A direction into the E_B direction in C-spaces, hence the meaning of the generator $[E_A, E_B]$ which is the generalization of the ordinary $i[\gamma_\mu, \gamma_\nu]$ Lorentz generator.

Therefore, when we recast the generators of polyrotations as $\mathcal{J}_{AB} = [\Gamma_A, \Gamma_B]$, an action of the form

$$S(C_{\text{space}}) = \int [\mathcal{D}X] F^{A_1B_1}_{M_1N_1} F^{A_2B_2}_{M_2N_2} \ldots F^{A_{2^{d-1}}B^2_{d-1}}_{M_{2^{d-1}}N_{2^{d-1}}} \epsilon_{A_1B_1A_2B_2\ldots A_{2^{d-1}}B_{2^{d-1}}} \epsilon^{M_1N_1M_2N_2\ldots M_{2^{d-1}}N_{2^{d-1}}} \tag{4.10}$$

is the natural generalization of the Euler density types of the D-dim ($D = 2n$) actions given by Eq. (3.16) in C-space.

This action $S(C_{\text{space}})$ (4.10) is more general than the action $S_{\text{Clifford}}(\mathcal{A}^A_\mu \Gamma_A)$ of Eq. (3.10), and which in turn, is more general than the Chern–Simons gravitational action $S_{\text{CS}}(\omega, e, A_5)$ given by Eq. (3.12). Therefore, we have the inclusions

$$S_{\text{CS}}(\omega, e, A_5) \subset S_{\text{Clifford}}[\mathcal{A}^A_\mu(x^\mu)\Gamma_A] \subset S(C_{\text{space}})[\mathcal{A}^{AB}_M(\sigma, x^\mu, x^{\mu_1\mu_2}, x^{\mu_1\mu_2\mu_3}, \ldots)\mathcal{J}_{AB}], \tag{4.11}$$

which should be very relevant in future developments of M, F theory upon the introduction of polyvector-valued supersymmetries in C-spaces.[16] These generalized supersymmetries deserve to be investigated further since they are more fundamental than the supersymmetries associated with M, F theory superalgebras and also span well beyond the N-extended supersymmetric field theories involving superalgebras like $\text{OS}_\text{p}(32|N)$ for example, which are related to a $\text{SO}(N)$ gauge theory coupled to matter fermions (besides the gravitinos). It is these polyvector-valued supersymmetries in C-spaces[16] that will permit the supersymmetrization of the most general action in C-spaces $S(C_{\text{space}})$ given by Eq. (4.10).

Finally, the results of this work may shed some light into the origins behind the hidden E_8 symmetry of $11D$ supergravity, the hyperbolic Kac–Moody algebra E_{10} and the nonlinearly realized E_{11} algebra related to chaos in M theory and oscillatory solutions close to cosmological singularities.[1–3]

APPENDIX: CLOSURE OF THE CLIFFORD SPACE SUPERSYMMERTRY

The classification of the family of symmetric matrices $(C\gamma^{\mu_1\mu_1\cdots\mu_n})_{\alpha\beta}$ is what restricts the type of terms that appear in the $\{Q_\alpha, Q_\beta\}$ anticommutator and depends on the number of space time dimensions D, the signatures (s,t) and the rank n. A table of the allowed values of D,s,t,n can be found in Ref. 18. In particular, when $D=4=3+1$, the $\{Q_\alpha, Q_\beta\}$ is a symmetric matrix in α,β with ten independent components and which matches the degrees of freedom in P^μ, $P^{\mu\nu}$ given by $4+6=10$. Let us study the closure of

$$\{[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4}, O_\alpha], Q_\beta\} + \{[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4}, Q_\beta], Q_\alpha\} = [\mathcal{M}_{\mu_1\mu_2\mu_3\mu_2}, \{Q_\alpha Q_\beta\}], \tag{A1}$$

where

$$\{Q_\alpha, Q_\beta\} = \frac{1}{2} C\gamma^\mu P_\mu + \frac{1}{2} C\gamma^{\mu\nu} P_{\mu\nu}. \tag{A2}$$

In $D=4$, with signatures $-,+,+,+$ one can find a charge conjugation matrix C and its transpose C^T obeying the properties

$$(C\gamma^\mu)^T = (C\gamma^\mu), \quad (C\gamma^{\mu\nu})^T = (C\gamma^{\mu\nu}), \tag{A3}$$

$$C^T = -C, C\gamma_\mu C^{-1} = -\gamma_\mu^T, \quad C^\dagger C = CC^\dagger = 1, \quad C^{-1}\gamma_{\mu\nu} C = -\gamma_{\mu\nu}^T. \tag{A4}$$

It is convenient to use a Majorana representation where the charge conjugation matrix is given by $C=\gamma_0$ and $\gamma_5^T = -\gamma_5$ is a hermitian matrix that has zero entries along the diagonal and $-i\sigma_1$, $i\sigma_1$ off the diagonal.

We must verify that Eq. (A1) is obeyed. This requires that the spinorial charges Q_α behave under polyrotations as follows:

$$[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4}, Q_\alpha] = -\frac{1}{2}(\gamma_{\mu_1\mu_2\mu_3\mu_4})_\alpha^\delta Q_\delta \tag{A5}$$

and

$$[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4}, P_{\nu_1\nu_2}] = \eta_{\mu_1\mu_2\nu_1\nu_2} P_{\mu_3\mu_4} + \eta_{\mu_3\mu_4\nu_1\nu_2} P_{\mu_1\mu_2} \pm \cdots, \tag{A6}$$

the $\pm$ signs on the rhs of Eq. (A6) depend on the permutation of indices with respect to the initial combination $\mu_1\mu_2\mu_3\mu_4$, $\nu_1\nu_2$. There are six terms in Eq. (A6). The lhs of Eq. (A1) is

$$\begin{aligned} &-\frac{1}{4}\gamma_5(C\gamma^\mu P_\mu + C\gamma^{\mu\nu} P_{\mu\nu}) - \frac{1}{4}[\gamma_5(C\gamma^\mu P_\mu + C\gamma^{\mu\nu} P_{\mu\nu})]^T \\ &= -\frac{1}{4}\gamma_5(C\gamma^\mu P_\mu + C\gamma^{\mu\nu} P_{\mu\nu}) - \frac{1}{4}[(C\gamma^\mu)^T \gamma_5^T P_\mu + (C\gamma^{\mu\nu})\gamma_5^T P_{\mu\nu}] \\ &= -\frac{1}{4}\gamma_5(C\gamma^\mu P_\mu + C\gamma^{\mu\nu} P_{\mu\nu}) + \frac{1}{4}(C\gamma^\mu P_\mu + C\gamma^{\mu\nu} P_{\mu\nu})\gamma_5, \end{aligned} \tag{A7}$$

where we have used the conditions (A3) and $\gamma_5^T = -\gamma_5$.

Multiplying Eq. (A7) from the left by C^{-1} and using $C^{-1}\gamma_5 C = -\gamma_5$ yields

$$\frac{1}{4}(\gamma_5\gamma^{\mu}+\gamma^{\mu}\gamma_5)P_{\mu}+\frac{1}{4}(\gamma_5\gamma^{\mu\nu}+\gamma^{\mu\nu}\gamma_5)P_{\mu\nu}$$

$$=\frac{1}{4}(\gamma_5\gamma^{\mu\nu}+\gamma^{\mu\nu}\gamma_5)P_{\mu\nu}+\frac{1}{2}\gamma_5\gamma^{\mu\nu}P_{\mu\nu}=\frac{1}{2}\gamma_{[\mu_1}\gamma_{\mu_2}\gamma_{\mu_3}\gamma_{\mu_4}\gamma^{\nu_1\nu_2}P_{\nu_1\nu_2}$$

$$=\frac{1}{2}[\gamma_{[\mu_1\mu_2]}\eta^{\nu_1\nu_2}_{\mu_3\mu_4}+\cdots]P_{\nu_1\nu_2}$$

$$=\frac{1}{2}[\gamma_{[\mu_1\mu_2]}P_{\mu_3\mu_4}+\gamma_{[\mu_3\mu_4]}P_{\mu_1\mu_2}\pm\cdots]. \tag{A8}$$

One may notice that due to the condition $\{\gamma_5,\gamma_\mu\}=0$ there are no P_μ terms in Eq. (A8). The rhs of Eq. (A1) is

$$\frac{1}{2}[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},(C\gamma^{\nu_1}P_{\nu_1})+(C\gamma^{\nu_1\nu_2})P_{\nu_1\nu_2}]$$

$$=\frac{1}{2}(C\gamma^{\nu_1\nu_2})[\eta_{\nu_1\mu_2\nu_1\nu_2}P_{\mu_3\mu_4}+\eta_{\nu_2\mu_4\nu_1\nu_2}P_{\mu_1\mu_2}+\cdots], \tag{A9}$$

where

$$[\mathcal{M}_{\mu_1\mu_2\mu_3\mu_4},(C\gamma^{\nu_1}P_{\nu_1})]=C\gamma^{\nu_1}[\mathcal{M}\mu_1\mu_2\mu_3\mu_4,P_{\nu_1}]=0. \tag{A10}$$

Multiplying, Eq. (A9) on the left by C^{-1} yields

$$\frac{1}{2}\gamma^{\nu_1\nu_2}[\eta_{\mu_1\mu_2\nu_1\nu_2}P_{\mu_3\mu_4}+\eta_{\mu_3\mu_4\nu_1\nu_2}P_{\mu_1\mu_2}+\cdots]=\frac{1}{2}[\gamma_{[\nu_1\nu_2]}P_{\mu_3\mu_4}+\gamma_{[\mu_3\mu_4]}P_{\mu_1\mu_2}\pm\cdots]. \tag{A11}$$

We have seen that a left-multiplication of the rhs and lhs of Eq. (A1) by C^{-1}, leads to the equality of Eq. (A8) with Eq. (A11), which implies that Eq. (A1) is indeed satisfied.

The Jacobi identity

$$\{[\mathcal{M}_{\mu_1\mu_2},Q_\alpha],Q_\beta\}+\{[\mathcal{M}_{\mu_1\mu_2},Q_\beta],Q_\alpha\}=[\mathcal{M}_{\mu_1\mu_2},\{Q_\alpha,Q_\beta\}], \tag{A12}$$

when

$$[M_{\mu_1\mu_2},P_{\rho_1\rho_2}]=-\eta_{\mu_1\rho_1}P_{\mu_2\rho_2}\pm\cdots,[\mathcal{M}_{\mu_1\mu_1},Q_\alpha]$$

$$=-\frac{1}{2}(\gamma_{\mu_1\mu_2})^{\delta}_{\alpha}Q_\delta,\{Q_\alpha,Q_\beta\}=\frac{1}{2}C\gamma^{\nu}P^{\nu}+\frac{1}{2}C\gamma\nu_1\nu_2P_{\nu_1\nu_2} \tag{A13}$$

involves terms containing P_μ and $P_{\mu\nu}$. We know that the Jacobi identity is satisfied for the P_μ terms since this is what the ordinary supersymmetry algebra entails.

The $P_{\mu\nu}$ terms involve the commutator

$$-[\gamma_{\nu_1\nu_2},\gamma_{\nu_1\nu_2}]P^{\nu_1\nu_2}=(\eta_{\mu_1\nu_1}\gamma_{\mu_2\nu_2}\pm\cdots)P^{\nu_1\nu_2}. \tag{A14}$$

Each one of the four terms in Eq. (A14), for example, like the term $\eta_{\mu_1\nu_1}\gamma_{\mu_2\nu_2}P^{\nu_1\nu_2}$ can be rewritten as

$$\eta_{\mu_1\nu_1}\gamma_{\mu_2\nu_2}P^{\nu_1\nu_2} = \eta_{\mu_1\nu_1}\gamma^{\rho_1\rho_2}\eta_{\rho_1\rho_2\mu_2\nu_2}\eta^{\nu_1\nu_2\mu_2\rho_2}P_{\mu_2\rho_2} = -\eta_{\mu_1\nu_1}\delta^{\nu_1}_{\rho_1}\gamma^{\rho_1\rho_2}P_{\mu_2\rho_2} = -\eta_{\mu_1\rho_1}\gamma^{\rho_1\rho_2}P_{\mu_2\rho_2} \tag{A15}$$

and similarly one can rewrite the other three terms of Eq. (A14), so that the Jacobi identity (A12) is satisfied due to the equality in (A15)

$$\gamma^{\rho_1\rho_2}[M_{\mu_1\mu_2}, P_{\rho_1\rho_2}] = \gamma^{\rho_1\rho_2}(-\eta^{\mu_1\rho_1}P_{\mu_2\rho_2} \pm \cdots) = -[\gamma_{\mu_1\mu_2}, \gamma_{\nu_1\nu_2}]P^{\nu_1\nu_2} = P^{\nu_1\nu_2}(\eta_{\mu_1\nu_1}\gamma_{\mu_2\nu_2} \pm \cdots), \tag{A16}$$

i.e, the equality among the terms of Eq. (A16) can be seen effectively as exchanging $\gamma \leftrightarrow P$ and $(\nu_1, \nu_2) \leftrightarrow (\rho_1, \rho_2)$.

One must have as well

$$[Q_\alpha, P_\mu] = [Q_\alpha, P_{\mu\nu}] = 0, \quad [P_\mu, P_\nu] = [P_{\mu_1\mu_2}, P_{\nu_1\nu_2}] = 0 \ldots \tag{A17}$$

This example in $D=4$ should be valid in other dimensions and signatures provided we have the appropriate list of symmetric $(C\gamma^{\mu_1\mu_2\cdots\mu_n})_{\alpha\beta}$ matrices.

One has the remaining commutators

$$[M_{\mu_1\mu_2}, M_{\nu_1\nu_2}] = -\eta_{\mu_1\nu_1}M_{\mu_2\nu_2} + \eta_{\mu_2\nu_1}M_{\nu_1\nu_2} \pm \cdots, \tag{A18}$$

$$[M_{\mu_1\mu_2\mu_3\mu_4}, M_{\nu_1\nu_2\mu_3\mu_4}] = \eta_{\mu_1\nu_2\nu_1\mu_2}M_{\mu_3\nu_4\mu_3\mu_4} \pm \cdots, \tag{A19}$$

$$[M_{\mu_1\mu_2}, M_{\nu_1\nu_2\mu_3\mu_4}] = -\eta_{\mu_1\nu_1}M_{\mu_2\nu_2\nu_3\nu_4} \pm \cdots, \tag{A20}$$

which obey the Jacobi identities.

Foundations of a spacetime path formalism for relativistic quantum mechanics

Ed Seidewitz[a)]
14000 Gulliver's Trail, Bowie, Maryland 20720

(Received 3 July 2006; accepted 5 October 2006; published online 14 November 2006)

Quantum field theory is the traditional solution to the problems inherent in melding quantum mechanics with special relativity. However, it has also long been known that an alternative first-quantized formulation can be given for relativistic quantum mechanics, based on the parametrized paths of particles in spacetime. Because time is treated similarly to the three space coordinates, rather than as an evolution parameter, such a spacetime approach has proved particularly useful in the study of quantum gravity and cosmology. This paper shows how a spacetime path formalism can be considered to arise naturally from the fundamental principles of the Born probability rule, superposition, and Poincaré invariance. The resulting formalism can be seen as a foundation for a number of previous parametrized approaches in the literature, relating, in particular, "off-shell" theories to traditional on-shell quantum field theory. It reproduces the results of perturbative quantum field theory for free and interacting particles, but provides intriguing possibilities for a natural program for regularization and renormalization. Further, an important consequence of the formalism is that a clear probabilistic interpretation can be maintained throughout, with a natural reduction to nonrelativistic quantum mechanics. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2375033]

I. INTRODUCTION

The idea of constructing quantum states as a "sum over histories" is well known in the form of the Feynman path integral formulation. However, this approach is best known in its application to nonrelativistic quantum mechanics,[1,2] in which particle paths are parametrized by coordinate time. A natural relativistic generalization is to consider parametrized paths in four-dimensional spacetime rather than time-parametrized paths in three-dimensional space. Feynman himself developed such an approach, and this conception seems to have informed much of Feynman's early view of relativistic quantum mechanics.[3–5]

At an even earlier date, Stueckelberg presented a detailed formulation of relativistic quantum mechanics in terms of parametrized spacetime paths.[6,7] A number of other authors (notably Refs. 8–18) have also developed related approaches involving an invariant "fifth parameter" governing the evolution of a quantum system, though not necessarily identifying this explicitly as a path parameter.

A key feature of these approaches is that time is treated comparably to the three space coordinates, rather than as an evolution parameter. This is particularly applicable to the study of quantum gravity and cosmology, in which the fundamental equations (such as the Wheeler–DeWitt equation) make no explicit distinction for the time coordinate (see, e.g., Refs. 19–25).

Also, in the infinite-tension limit, string theory reduces to a worldline formalism for relativistic quantum theory.[26–32] One would therefore expect a path formulation of relativistic quantum mechanics to provide a natural bridge to the typically first-quantized formulation of string theory.

[a)]Electronic mail: seidewitz@mailaps.org

Despite the promise of the approach, spacetime path formalisms have often been presented in the literature as simply alternative formulations of results obtained from the more traditional quantum field theory formalism. The motivation of the present paper, however, is to construct a first-quantized spacetime path formalism that can be considered foundational in its own right. This means that many typical tools of field theory, such as Hamiltonian dynamics and the Lagrangian stationary action principle for fields, cannot be assumed to apply *a priori*.

Instead, we will begin with the fundamental principles of special-relativistic quantum theory—the Born probability rule, superposition, and Poincaré invariance—and introduce six additional, physically motivated postulates related to spacetime paths. (The perhaps even more fundamental question of why quantum probabilities are given via superpositions of probability amplitudes will not be addressed here.) Results deduced from these postulates then provide the basis for further physical interpretation.

Since this formalism is first quantized, particular care is given to properly handling particles and antiparticles and to developing a consistent probabilistic interpretation. The result is an approach that fully deals with the usual issues of negative energies and negative probabilities, but without necessitating the introduction of fields as fundamental entities. Rather, fields can be considered to be simply a convenient formalism for handling multiparticle states. The present work only discusses massive scalar particles, but the approach can be extended to handle nonscalar particles (e.g., Ref. 34).

Section II first introduces the formalism for free scalar particles, culminating in free multiparticle fields. Section III then extends the formalism to consider interacting states and scattering. In order to reduce clutter in the text, certain propositions resulting from purely mathematical, but somewhat involved, derivation are cited without proof in the main body of the text, with proofs given in appendices.

Natural units with $\hbar=1=c$ are used throughout the following and the metric has a signature of $(-+++)$.

II. FREE PARTICLES

For any path based approach, it is obviously critical to be clear on what is meant by the term *path*. In the present case, a path for a particle is an arbitrary curve through spacetime, that is, a continuous (though not necessarily differentiable), one-dimensional subspace of spacetime. Note that there is no *a priori* requirement that such a curve is timelike or lightlike. Indeed, the path may cross arbitrarily forwards and backwards in time. Since such a path is continuous, there is a one-to-one mapping between it and some interval of the real numbers. That is, a path may be given by functions $q^\mu(\lambda)$, for $\mu=0,1,2,3$, of a *path parameter* λ.

In this formulation, the path parameter λ serves a purpose similar to that of time in the traditional non-relativistic path integral approach.[2] For the restricted case of an everywhere-timelike path, this parameter is analogous to proper time. For the general case of an unrestricted path, there has been some debate as to the physical nature of the path parameter (see, for example, Refs. 35 and 36). In order not to presuppose any specific interpretation, we will consider, for each path, all possible parametrizations of the path.

To do this, choose a fiducial parametrization s, say over the interval $[0,1]$, and define any other parametrization as a monotonically increasing function $\lambda(s)$. Geometrically, the so called *lapse multiplier*

$$w(s) \equiv \frac{\mathrm{d}\lambda}{\mathrm{d}s} > 0$$

then gives an effective length metric $\mathrm{d}\lambda = w(s)\mathrm{d}s$ for the path, and the corresponding parametrization λ is an *intrinsic length* measure along the path.

Given this basic conception of a particle path, this section will review the fundamental postulates required for a path integral approach, derive the scalar free particle propagator, and carefully consider the corresponding probability interpretation.

A. The free particle propagator

The fundamental postulate of any spacetime path integral approach is that a particle's transition amplitude between two points in spacetime is a superposition of the transition amplitudes for all possible paths between those points. Let the functional $\Delta[q]$ give the transition amplitude for a path $q^\mu(\lambda)$. Then the total transition amplitude $\Delta(x,x_0)$ must be given by a path integral over $\Delta[q]$, for all paths q from x_0 to x.

Postulate 1: *For a free scalar particle, the transition amplitude* $\Delta(x,x_0)$ *is given by the superposition of path transition amplitudes* $\Delta[q]$, *for all possible four-dimensional path functions* $q^\mu(\lambda)$ *beginning at* x_0 *and ending at* x, *parametrized by all possible monotonically increasing functions* $\lambda(s)$. *That is*,

$$\Delta(x,x_0) = \int \mathrm{D}\lambda\, \theta\left[\frac{\mathrm{d}\lambda}{\mathrm{d}s}\right] F[\lambda]\Delta(x,x_0;[\lambda]), \tag{1}$$

where the real-valued functional $F[\lambda]$ *allows for the possibility of allowing different weights for different parametrizations, and*

$$\Delta(x,x_0;[\lambda]) \equiv \eta[\lambda] \int \mathrm{D}^4 q\, \delta^4(q(\lambda(1)) - x)\, \delta^4(q(\lambda(0)) - x_0)\Delta[q], \tag{2}$$

where $\eta[\lambda]$ *is a parametrization-dependent normalization factor as required to keep the path integral finite*.

Note that, in Eqs. (1) and (2), the notation $\mathrm{D}\lambda$ indicates a path integral over the parametrization function $\lambda(s)$ while $\mathrm{D}^4 q$ indicates a path integral over the four path functions $q^\mu(\lambda)$.

In the traditional Feynman sum-over-paths approach, the form of $\Delta[q]$ is simply assumed to be an exponential of the classical action.[2] This is justified because the resulting transition amplitudes agree with the results of the usual formulation of quantum mechanics. However, if the path-based formulation is to be considered foundational, one would prefer a more fundamental justification.

As a transition amplitude, $\Delta[q]$ strictly only applies to a particle on a specific path q from the starting position $q(\lambda_0)$ to the ending position $q(\lambda_1)$ (where the parameter range of q is $[\lambda_0,\lambda_1]$). However, by translational invariance in Minkowski spacetime, the particle propagation embodied in $\Delta[q]$ cannot depend on the absolute positions $q(\lambda)$, but only on the relative positions

$$\Delta q(\lambda) \equiv q(\lambda) - q(\lambda_0).$$

That is, we can take $\Delta[q]=\Delta[\Delta q]$.

Now, consider a *family* of parallel paths q_{x_0}, indexed by the starting position x_0, such that

$$q_{x_0}(\lambda) = x_0 + \Delta q(\lambda),$$

for a fixed relative position function Δq. Since all members of such a family have the same relative position function Δq, the amplitude $\Delta[q_{x_0}]=\Delta[\Delta q]$ must be the same for all members of the family.

Suppose that a probability amplitude $\psi(x_0)$ is given for a particle to be at an initial position x_0 and that the transition amplitude is known to be $\Delta[\Delta q]$ for a specific relative position function Δq. Then, the probability amplitude for the particle to traverse a specific path q_{x_0} from the family for relative position Δq is just $\Delta[q_{x_0}]\psi(x_0)=\Delta[\Delta q]\psi(x_0)$.

However, the very meaning of being on the specific path q_{x_0} is that the particle must propagate from the starting position at x_0 to the ending position at $q_{x_0}(\lambda_1)$. Therefore, the probability for reaching the end position $q_{x_0}(\lambda_1)$ must be the same as the probability for having started out at the position x_0. That is,

$$|\Delta[\Delta q]\psi(x_0)|^2 = |\psi(x_0)|^2.$$

But, since $\Delta[\Delta q]$ is independent of x_0, we must have $|\Delta[q]|^2 = 1$ in general.

Of course, this argument is really just a suggestive motivation rather than a proof, so we take the conclusion as a postulate, rather than a proposition.

Postulate 2: *For any path $q^\mu(\lambda)$, the transition amplitude $\Delta[q]$ preserves the position probability density for the particle along the path. That is, it satisfies*

$$|\Delta[q]|^2 = 1. \tag{3}$$

If the configuration space for a path is expanded to be a representation of the full Poincaré group—that is, to include a matrix representation of the (homogeneous) Lorentz group as well as the four spacetime coordinates—then members of a family of "parallel" paths are related by Poincaré transformations, not just translations. This can be used as the basis for extending the spacetime path formalism to cover nonscalar particles. If, further, the assumption of flat spacetime is dropped, then it is not generally possible to construct a family of parallel paths covering all spacetime. However, one can still consider infinitesimal variations along a path corresponding to arbitrary coordinate transformations. Such further generalizations of the spacetime path approach will be explored in future papers.

The requirements of Eq. (3) and translation invariance mean that $\Delta[q]$ must have the form

$$\Delta[q] = e^{iS[\Delta q]}, \tag{4}$$

for some phase functional S. Substituting Eq. (4) into Eq. (2) gives

$$\Delta(x,x_0;[\lambda]) = \eta[\lambda] \int D^4q\, \delta^4(q(\lambda(1)) - x)\, \delta^4(q(\lambda(0)) - x_0) e^{iS[\Delta q]}. \tag{5}$$

So far, we have made no assumption that the particle path functions $q^\mu(\lambda)$ are differentiable. Indeed, paths under a path integral will generally not be differentiable. Nevertheless, it is common practice to use (with some care) path derivatives in the integrand of a path integral. This is because a path integral is defined as the limit of discretized approximations in which path derivatives are approximated as the mean value $\Delta q/\Delta\lambda$, for finite differences Δq and $\Delta\lambda$. The limit $\Delta\lambda \to 0$ is then taken over the path integral as a whole, not each derivative individually. Thus, even though $\lim_{\Delta\lambda\to 0}\Delta q/\Delta\lambda$ may not be defined, the path integral has a well-defined value so long as the overall path integral limit is defined. (For a discussion of some of the issues involved here, see, for example, Sec. 7.3 of Ref. 2. See also the explicit example of the derivation in Appendix B.)

We are therefore justified in replacing the difference functions $\Delta q^\mu(\lambda)$ used in the phase functional under the path integral in Eq. (5) with the path derivatives $\dot{q}^\mu(\lambda) \equiv dq^\mu/d\lambda$, such that

$$\Delta q^\mu(\lambda) = \int_{\lambda_0}^{\lambda} d\lambda' \dot{q}^\mu(\lambda'),$$

letting the $q^\mu(\lambda)$ be considered as differentiable. This gives

$$\Delta(x,x_0;[\lambda]) = \eta[\lambda] \int D^4q\, \delta^4(q(\lambda(1)) - x)\, \delta^4(q(\lambda(0)) - x_0) e^{iS[\dot{q}]}, \tag{6}$$

which reflects the typical form of a Feynman sum over paths,[2] where each path is weighted by a phase determined by the action S. Unlike the usual nonrelativistic formulation, however, the path parameter here is λ, rather than time.[5,21]

Now, by dividing a path q into two paths at some arbitrary parameter value λ and propagating over each segment, we can see that

$$S[\dot{q};\lambda_1,\lambda_0] = S[\dot{q};\lambda_1,\lambda] + S[\dot{q};\lambda,\lambda_0], \tag{7}$$

where $S[\dot{q};\lambda',\lambda]$ denotes the value of $S[\dot{q}]$ for the parameter range of $\dot{q}$ restricted to $[\lambda,\lambda']$. Using this property to build the total value of $S[\dot{q}]$ from infinitesimal increments leads to the following result (proved in Appendix A).

Proposition A (Form of the Phase Functional): *The phase functional S must have the form*

$$S[\dot{q}] = \int_{\lambda_0}^{\lambda_1} d\lambda' L[\dot{q};\lambda'], \tag{8}$$

where the parametrization domain for $\dot{q}$ *is* $[\lambda_0,\lambda_1]$ *and* $L[\dot{q};\lambda]$ *depends only on* $\dot{q}$ *and its higher derivatives evaluated at* λ.

The question remains as to what form the function L should take. Traditionally, it is taken to be just the classical Langrangian, but, from a foundational viewpoint, one would like a better justification.

Of course, the simplest form for L would be a constant, independent of $\dot{q}$. However, this would result in a superficially divergent path integral in Eq. (6) which, when normalized, would leave to just a trivial phase. This would not give any appropriate particle dynamics. The next simplest form for L would be for it to depend only on $\dot{q}$ and no higher derivatives. Further, since L is a scalar quantity, it must then depend only on the Lorentz-invariant scalar function

$$\dot{q}^2(\lambda) \equiv \dot{q}^\mu(\lambda)\dot{q}_\mu(\lambda).$$

Taking L to further have the tractable form of a linear function of $\dot{q}^2$ gives

$$L[\dot{q};\lambda] = L(\dot{q}^2(\lambda)) = a\dot{q}^2(\lambda) + b,$$

for some a and b. Now, the factor a can be fixed arbitrarily, since any variation is effectively equivalent to a reparametrization of the path parameter λ. For a free particle, it is convenient to take $a=1/4$. If we further assume that b is always negative, we can set $b=-m^2$ and identifying m with the mass of the particle does, indeed, give a classical relativistic Lagrangian function.

As we will see in the following, evaluating the path integral in Eq. (6) with this Lagrangian function leads to the usual free-particle Feynman propagator. If, on the other hand, we take b to be positive, then the result is a similar propagator, but with an effective imaginary particle mass. Such particles are tachyons, which we will not consider further in this paper.

Postulate 3: *For a free scalar particle of mass m, the Lagrangian function is given by*

$$L(\dot{q}^2) = \tfrac{1}{4}\dot{q}^2 - m^2. \tag{9}$$

Substituting Eq. (8) into Eq. (6) gives

$$\Delta(x,x_0;[\lambda]) = \eta[\lambda]\int \mathrm{D}^4 q\,\delta^4(q(\lambda(1)) - x)\,\delta^4(q(\lambda(0)) - x_0)\exp\left(i\int_{\lambda(0)}^{\lambda(1)} d\lambda' L(\dot{q}^2(\lambda'))\right). \tag{10}$$

With the Lagrangian given by Eq. (9), it is well known that this path integral may be evaluated (see, for example, Ref. 21). However, in the present context, some care must be taken to mathematically evaluate the integral without making any further assumptions based on field equations or underlying traditional quantum mechanics. In any case, the result (proved in Appendix B) is as follows.

Proposition B (Evaluation of the Path Integral): *The path integral in Eq.* (10), *with the Lagrangian given by Eq.* (9), *may be evaluated to get*

$$\Delta(x,x_0;[\lambda]) = \Delta(x-x_0;\lambda(1)-\lambda(0)) \equiv (2\pi)^{-4}\int d^4p\, e^{ip(x-x_0)} e^{-i[\lambda(1)-\lambda(0)](p^2+m^2)}. \tag{11}$$

Note that the only dependency left of $\Delta(x-x_0;\lambda(1)-\lambda(0))$ on the parametrization $\lambda(s)$ is on

the total *intrinsic path length*

$$T = \lambda(1) - \lambda(0) = \int_0^1 \mathrm{d}s w(s) > 0.$$

If we were to take $F[\lambda]=1$ in Eq. (1) for all $\lambda(s)$, there would then be a parametrization gauge symmetry: all parametrizations that give the same intrinsic path lengths would be equivalent. Therefore, equivalent reparametrizations would be overcounted in the λ path integral of Eq. (1), so the integral would diverge.

If, on the other hand, the path integral over λ had not been included at all in Eq. (1), the result would have been to overspecify a specific path parametrization. The possible particle paths would then have been *undercounted*, missing the need to include paths of different intrinsic lengths. It is thus necessary to reduce the λ path integration in Eq. (1) to eliminate the overcounting due to the path gauge symmetry, without overspecifying the path parametrization.

In the usual fashion for a gauge symmetry, we retain the integration, but fix a specific gauge. This can be easily done by including a gauge fixing delta functional in $F[\lambda]$. The gauge typically chosen is to require that $w(s)=\mathrm{d}\lambda/\mathrm{d}s$ be constant,[21] which corresponds to setting

$$F[\lambda] = f(\lambda(1) - \lambda(0))\delta\left[\frac{\mathrm{d}\lambda}{\mathrm{d}s} - [\lambda(1) - \lambda(0)]\right],$$

for some real function $f(T)$. Using this in Eq. (1) gives

$$\Delta(x,x_0) = \int_0^\infty \mathrm{d}T f(T)\Delta(x - x_0;T).$$

In the following, we will generally assume equal weighting of all parametrizations, that is $f(T)=1$. However, in Sec. III D, we will see that an alternate choice provides a fruitful path for regularizing the infinite integrals that appear in the formalism for interacting particles. Nevertheless, assuming, for now, that $f(T)=1$, gives

$$\Delta(x,x_0) = \int_0^\infty \mathrm{d}T\Delta(x - x_0;T) = (2\pi)^{-4}\int \mathrm{d}^4 p \mathrm{e}^{ip\cdot(x-x_0)}\int_0^\infty \mathrm{d}T\mathrm{e}^{-iT(p^2+m^2)}. \tag{12}$$

This can be evaluated by introducing a convergence factor $\exp(-T\varepsilon)$, for infinitesimal ε, resulting in just the Feynman propagator

$$\Delta(x,x_0) = \Delta(x - x_0) \equiv -i(2\pi)^{-4}\int \mathrm{d}^4 p \frac{\mathrm{e}^{ip(x-x_0)}}{p^2 + m^2 - i\varepsilon}.$$

The integration of T from 0 to ∞ in Eq. (12) is similar to the integration carried out by Nambu,[9] based on previous work of Fock,[8] in order to obtain the Feynman propagator. Note, though, that this integration arises naturally here as the gauge-fixed reduction of the path parametrization integral in Eq. (1).

The relationship between the propagator $\Delta(x-x_0)$ and $\Delta(x-x_0;T)$ can be viewed in another way, which will also prove useful in Sec. III D. For $T>0$,

$$\Delta(x-x_0;T) = e^{-iTm^2}\int d^4p e^{ip(x-x_0)}\int_0^\infty dT' e^{-iT'p^2}\delta(T'-T)$$
$$= (2\pi)^{-1}e^{-iTm^2}\int d^4p e^{ip(x-x_0)}\int_0^\infty dT' e^{-iT'p^2}\int dm'^2 e^{-i(T'-T)m'^2}$$
$$= (2\pi)^{-1}e^{-iTm^2}\int dm'^2 e^{iTm'^2}\Delta(x-x_0;m'^2), \tag{13}$$

where

$$\Delta(x-x_0;m'^2) \equiv \int_0^\infty dT'\int d^4p e^{ip(x-x_0)}e^{-iT'(p^2+m'^2)} = -i(2\pi)^{-4}\int d^4p \frac{e^{ip(x-x_0)}}{p^2+m'^2-i\varepsilon}. \tag{14}$$

This form for $\Delta(x-x_0;T)$ is essentially that of the parametrized Green's function derived by Horwitz *et al.* for parametrized quantum field theory[37,38] as a superposition of propagators for different mass states (see also Refs. 39 and 40). Equation (13) differs from those references in the factor $\exp(-iTm^2)$. As a result of this factor, integrating Eq. (13) over T as in Eq. (12) effectively acts as a Fourier transform, resulting in a propagator with mass sharply defined at m.

B. Free particle position states

The path integral form for $\Delta(x-x_0;\lambda-\lambda_0)$ given in Eq. (2) is essentially the same as that of the path integral for the nonrelativistic *kernel*,[2] except that λ is used as the evolution parameter instead of t. Therefore, $\Delta(x-x_0;\lambda-\lambda_0)$ has similar properties as a propagation kernel in λ:

$$\int d^4x_1 \Delta(x-x_1;\lambda-\lambda_1)\Delta(x_1-x_0;\lambda_1-\lambda_0) = \Delta(x-x_0;\lambda-\lambda_0)$$

and

$$\Delta(x-x_0;\lambda-\lambda_0)^* = \Delta(x_0-x;\lambda_0-\lambda).$$

Given these properties, define a family of probability amplitude functions $\psi(x;\lambda)$, for which

$$\psi(x;\lambda) = \int d^4x_0 \Delta(x-x_0;\lambda-\lambda_0)\psi(x_0;\lambda_0), \tag{15}$$

for any λ and λ_0, normalized such that

$$\int d^4x |\psi(x;\lambda)|^2 = 1, \tag{16}$$

for each λ. Formally, these functions are probability amplitudes for the position x, with λ serving as an index identifying individual functions in the family. However, they can be interpreted as just the parametrized probability amplitude functions defined by Stueckelberg.[6] In this sense, the $\psi(x;\lambda)$ represent the probability amplitude for a particle to reach position x at the point along its path with parameter value λ.

Note that

$$i\frac{\partial}{\partial\lambda}\Delta(x-x_0;\lambda-\lambda_0) = (2\pi)^{-4}\int d^4p e^{ip(x-x_0)}(p^2+m^2)e^{-i(\lambda-\lambda_0)(p^2+m^2)}.$$

This means that $\psi(x;\lambda)$, as given by Eq. (15), satisfies

$$-i\frac{\partial}{\partial\lambda}\psi(x;\lambda)=\left(\frac{\partial^2}{\partial x^2}-m^2\right)\psi(x;\lambda). \tag{17}$$

Equation (17) is a generalized Schrödinger equation, such as proposed by Stueckelberg.[7] However, Stueckelberg and subsequent authors[4,12,15] used a Hamiltonian of the form $(2m)^{-1}\partial^2/\partial x^2$, by analogy with nonrelativistic mechanics, rather than the form of Eq. (17) (though Ref. 41 uses a Hamiltonian form similar to Eq. (17)). This difference is the origin of the extra factor $\exp(-iTm^2)$ in Eq. (13) relative to Refs. 37 and 38.

The properties of the kernel $\Delta(x-x_0;\lambda-\lambda_0)$ also allow for the definition of a consistent family of *position state* bases $|x;\lambda\rangle$, such that

$$\psi(x;\lambda)=\langle x;\lambda|\psi\rangle, \tag{18}$$

given a single Hilbert space state vector $|\psi\rangle$. These position states are normalized such that

$$\langle x';\lambda|x;\lambda\rangle=\delta^4(x'-x)$$

for each value of λ. Further, it follows from Eqs. (15) and (18) that

$$\Delta(x-x_0;\lambda-\lambda_0)=\langle x;\lambda|x_0;\lambda_0\rangle. \tag{19}$$

Thus, $\Delta(x-x_0;\lambda-\lambda_0)$ effectively defines a unitary transformation between the various Hilbert space bases $|x;\lambda\rangle$, indexed by the parameter λ.

Finally, the overall state for propagation from x_0 to x is given by the superposition of the states for paths of all intrinsic lengths. If we fix $q^\mu(\lambda_0)=x_0^\mu$, then $|x;\lambda\rangle$ already includes all paths of length $\lambda-\lambda_0$. Therefore, the overall state $|x\rangle$ for the particle to arrive at x should be given by the superposition of the states $|x;\lambda\rangle$ for all $\lambda>\lambda_0$:

$$|x\rangle\equiv\int_{\lambda_0}^{\infty}d\lambda|x;\lambda\rangle. \tag{20}$$

Then, using Eq. (19),

$$\langle x|x_0;\lambda_0\rangle=\int_{\lambda_0}^{\infty}d\lambda\Delta(x-x_0;\lambda-\lambda_0)=\int_0^{\infty}d\lambda\Delta(x-x_0;\lambda)=\Delta(x-x_0). \tag{21}$$

Now, the $|x\rangle$ are not actually proper Hilbert space states, since $\langle x|x_0\rangle$ is infinite (as can be seen by integrating Eq. (21) over λ_0). Nevertheless, via Eq. (12), the corresponding bras $\langle x|$ can be considered to be well-defined functions on proper, normalizable states $|\psi\rangle$ such that

$$\langle x|\psi\rangle=\int d^4x_0\Delta(x-x_0)\psi(x_0;\lambda_0)$$

is the transition amplitude for a particle with known probability amplitude $\psi(x_0;\lambda_0)$ at λ_0 to eventually reach position x at some $\lambda>\lambda_0$. We will thus continue to use $|x\rangle$ as a formal quantity, with the understanding that it is really just a shorthand for constructing propagators and transition amplitudes.

C. On-shell particle and antiparticle states

The states constructed so far have naturally been off-shell states. That is, they represent what are normally considered to be "virtual" particles. However, rather than simply imposing the on-shell mass condition to obtain "physical" states, on-shell states will be constructed in this subsection as the infinite time limit of off-shell states. That is, particles with paths that, in the limit, are unbounded in time will turn out to be naturally on-shell.

In order to take a time limit, it is necessary to make some distinction between past and future that can be used as the basis for taking the limit. For this purpose, divide the set of all possible paths q^μ that end at some specific $q^\mu(\lambda)=x^\mu$ into two subsets: those that begin (at $q^\mu(\lambda_0)=x_0^\mu$) in the *past* of x and those that begin in the *future* of x.

Outside of the light cone of x, the division into future and past is, of course, not Lorentz covariant and depends on the choice of a specific coordinate system. However, when we take the time limit, the light cone expands to cover all space, and, in this limit, the division into particle and antiparticle becomes fully coordinate system independent. The possibility of the particle/antiparticle distinction being coordinate system dependent in anything other than the infinite time limit is a subject for future exploration.

Now, particles are normally considered to propagate from the past to the future. On the other hand, antiparticles may be considered to propagate from the future into the past.[3,6,7]

Postulate 4: *Normal particle states* $|x_+\rangle$ *are such that*

$$\langle x_+|x_0;\lambda_0\rangle = \theta(x^0-x_0^0)\Delta(x-x_0).$$

Antiparticle states $|x_-\rangle$ *are such that*

$$\langle x_-|x_0;\lambda_0\rangle = \theta(x_0^0-x^0)\Delta(x-x_0).$$

Using the usual decomposition of the Feynman propagator (see, for example, Sec. 6.2 of Ref. 42)

$$\Delta(x-x_0) = \theta(x^0-x_0^0)\Delta_+(x-x_0) + \theta(x_0^0-x^0)\Delta_-(x-x_0), \tag{22}$$

where

$$\Delta_\pm(x-x_0) \equiv (2\pi)^{-3}\int \mathrm{d}^3p \frac{\mathrm{e}^{i[\mp\omega_{\boldsymbol{p}}(x^0-x_0^0)+\boldsymbol{p}\cdot(\boldsymbol{x}-\boldsymbol{x}_0)]}}{2\omega_{\boldsymbol{p}}}, \tag{23}$$

with $\omega_{\boldsymbol{p}}\equiv\sqrt{\boldsymbol{p}^2+m^2}$, it is clear that

$$\langle x_\pm|x_0;\lambda_0\rangle = \theta(\pm(x^0-x_0^0))\Delta(x-x_0) = \theta(\pm(x^0-x_0^0))\Delta_\pm(x-x_0). \tag{24}$$

We would now like to take the time limits for future and past directed particle and antiparticle states. In doing this, one cannot expect to hold the three-position of the path end point constant. However, for a free particle, it is reasonable to take the particle *three-momentum* as being fixed. Therefore, consider the state of a particle or antiparticle with a three-momentum $\boldsymbol{p}$ at a certain time t. (The importance of the specific factor $\exp(\mp i\omega_{\boldsymbol{p}}t)$ in the definition below will become clear in a moment.)

Postulate 5: *The state of a particle* (+) *or antiparticle* (−) *with three-momentum* $\boldsymbol{p}$ *is given by*

$$|t,\boldsymbol{p}_\pm\rangle \equiv (2\pi)^{-3/2}\int \mathrm{d}^3x \mathrm{e}^{i(\mp\omega_{\boldsymbol{p}}t+\boldsymbol{p}\cdot\boldsymbol{x})}|t,\boldsymbol{x}_\pm\rangle = (2\pi)^{-1/2}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}}t}\int \mathrm{d}p^0\mathrm{e}^{ip^0t}|p_\pm\rangle, \tag{25}$$

where

$$|p_\pm\rangle \equiv (2\pi)^{-2}\int \mathrm{d}^4x \mathrm{e}^{ip\cdot x}|x_\pm\rangle \tag{26}$$

is the corresponding four-momentum state.

Let

$$|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle \equiv (2\pi)^{-3/2}\int \mathrm{d}^3x \mathrm{e}^{i(\mp\omega_{\boldsymbol{p}}t_0+\boldsymbol{p}\cdot\boldsymbol{x})}|t_0,\boldsymbol{x};\lambda_0\rangle = (2\pi)^{-1/2}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}}t_0}\int \mathrm{d}p^0\mathrm{e}^{ip^0t_0}|p;\lambda_0\rangle, \tag{27}$$

where

$$|p;\lambda_0\rangle \equiv (2\pi)^{-2}\int \mathrm{d}^4x \mathrm{e}^{ip\cdot x}|x;\lambda_0\rangle. \tag{28}$$

Substituting from Eqs. (26), (28), and (24),

$$\langle p_\pm|p_0;\lambda_0\rangle = (2\pi)^{-4}\int \mathrm{d}^4x\mathrm{d}^4x_0\mathrm{e}^{-ip\cdot x}\mathrm{e}^{ip_0\cdot x_0}\theta(\pm(x^0-x_0^0))\Delta_\pm(x-x_0) = \delta^4(p-p_0)\Delta_\pm(p), \tag{29}$$

where

$$\Delta_\pm(p) \equiv \int \mathrm{d}^4x\mathrm{e}^{-ip\cdot x}\theta(\pm x^0)\Delta_\pm(x). \tag{30}$$

Substituting Eq. (23) into Eq. (30) gives

$$\begin{aligned}\Delta_\pm(p) &= \int \mathrm{d}^4x\mathrm{e}^{-ip\cdot x}\theta(\pm x^0)(2\pi)^{-3}\int \mathrm{d}^3p'(2\omega_{\boldsymbol{p}'})^{-1}\mathrm{e}^{i(\mp\omega_{\boldsymbol{p}'}x^0+\boldsymbol{p}'\cdot\boldsymbol{x})}\\ &= \int \mathrm{d}t\mathrm{e}^{ip^0t}\theta(\pm t)\int \mathrm{d}^3p'(2\omega_{\boldsymbol{p}'})^{-1}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}'}t}(2\pi)^{-3}\int \mathrm{d}^3x\mathrm{e}^{i(\boldsymbol{p}'-\boldsymbol{p})\cdot\boldsymbol{x}}\\ &= \int \mathrm{d}t\mathrm{e}^{ip^0t}\theta(\pm t)\int \mathrm{d}^3p'(2\omega_{\boldsymbol{p}'})^{-1}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}'}t}\delta^3(\boldsymbol{p}'-\boldsymbol{p}) = (2\omega_{\boldsymbol{p}})^{-1}\int \mathrm{d}t\theta(\pm t)\mathrm{e}^{i(p^0\mp\omega_{\boldsymbol{p}})t}.\end{aligned} \tag{31}$$

Using Eq. (29) (and the completeness of the $|p;\lambda_0\rangle$ states) in Eq. (25), and substituting from Eq. (31) for $\Delta_\pm(p)$, then gives

$$\begin{aligned}|t,\boldsymbol{p}_\pm\rangle &= (2\pi)^{-1/2}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}}t}\int \mathrm{d}p^0\mathrm{e}^{ip^0t}\Delta_\pm(p)^*|p;\lambda_0\rangle\\ &= (2\pi)^{-1/2}(2\omega_{\boldsymbol{p}})^{-1}\int \mathrm{d}t'\,\theta(\pm t')\mathrm{e}^{\mp i\omega_{\boldsymbol{p}}(t-t')}\int \mathrm{d}p^0\mathrm{e}^{ip^0(t-t')}|p;\lambda_0\rangle.\end{aligned}$$

Change variables $t' \to t-t_0$ to get

$$|t,\boldsymbol{p}_\pm\rangle = (2\pi)^{-1/2}(2\omega_{\boldsymbol{p}})^{-1}\int dt_0\theta(\pm(t-t_0))\int \mathrm{d}p^0\mathrm{e}^{i(p^0\mp\omega_{\boldsymbol{p}})t_0}|p;\lambda_0\rangle = \begin{cases}(2\omega_{\boldsymbol{p}})^{-1}\displaystyle\int_{-\infty}^{t}\mathrm{d}t_0|t_0,\boldsymbol{p}_+;\lambda_0\rangle,\\ (2\omega_{\boldsymbol{p}})^{-1}\displaystyle\int_{t}^{+\infty}\mathrm{d}t_0|t_0,\boldsymbol{p}_-;\lambda_0\rangle.\end{cases} \tag{32}$$

It is then straightforward to take the time limit $t\to\pm\infty$. Note that

$$\begin{aligned}\int_{-\infty}^{+\infty}\mathrm{d}t_0|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle &= (2\pi)^{-1/2}\int \mathrm{d}p^0\int dt_0\mathrm{e}^{i(p^0\mp\omega_{\boldsymbol{p}})t_0}|p;\lambda_0\rangle = (2\pi)^{-1/2}\int \mathrm{d}p^0(2\pi)\,\delta(p^0\mp\omega_{\boldsymbol{p}})|p;\lambda_0\rangle\\ &= (2\pi)^{1/2}|\pm\omega_{\boldsymbol{p}},\boldsymbol{p};\lambda_0\rangle.\end{aligned}$$

Therefore

$$|\boldsymbol{p}_\pm\rangle \equiv \lim_{t\to\pm\infty}|t,\boldsymbol{p}_\pm\rangle = (2\pi)^{1/2}(2\omega_{\boldsymbol{p}})^{-1}|\pm\omega_{\boldsymbol{p}},\boldsymbol{p};\lambda_0\rangle. \tag{33}$$

Thus, a normal particle (+) or antiparticle (−) that has three-momentum $\boldsymbol{p}$ as $t\to\pm\infty$ is *on-shell*, with energy $\pm\omega_{\boldsymbol{p}}$. Such on-shell particles are unambiguously normal particles or antiparticles, independent of choice of coordinate system. (Note that these states are similar to the "mass representation" states of Ref. 12.)

Note also that the factor of $\exp(\mp i\omega_{\boldsymbol{p}}t)$ in the definition of $|t,\boldsymbol{p}_\pm\rangle$ (Eq. (25)) is not arbitrary. Without this, a factor of $\exp(\pm i\omega_{\boldsymbol{p}}t)$ would remain in Eq. (32), making it impossible to take the limit $t\to\pm\infty$.

D. On-shell probability interpretation

Unfortunately, the states defined in Eq. (33) are not normalizable using the usual inner product, since

$$\langle \boldsymbol{p}'_\pm|\boldsymbol{p}_\pm\rangle = 2\pi(2\omega_{\boldsymbol{p}})^{-2}\delta(0)\,\delta^3(\boldsymbol{p}'-\boldsymbol{p})$$

is infinite. In Ref. 12, this is handled by allowing the mass m to vary, even though the energy is fixed at $\sqrt{\boldsymbol{p}^2+m^2}$. Here we will take a different approach, noting that, from Eq. (28),

$$\langle p';\lambda|p;\lambda\rangle = \delta^4(p'-p).$$

Using this and Eq. (33), we clearly have

$$\langle \boldsymbol{p}_\pm|p_0;\lambda_0\rangle = (2\pi)^{1/2}(2\omega_{\boldsymbol{p}})^{-1}\,\delta(\pm\omega_{\boldsymbol{p}}-p_0^0)\,\delta^3(\boldsymbol{p}-\boldsymbol{p}_0). \tag{34}$$

Moreover, from this equation and Eq. (27),

$$\begin{aligned}\langle \boldsymbol{p}_\pm|t_0,\boldsymbol{p}_{0\pm};\lambda_0\rangle &= (2\pi)^{-1/2}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}}t_0}\int \mathrm{d}p_0^0\mathrm{e}^{ip_0^0t_0}(2\pi)^{1/2}(2\omega_{\boldsymbol{p}})^{-1}\,\delta(\pm\omega_{\boldsymbol{p}}-p_0^0)\,\delta^3(\boldsymbol{p}-\boldsymbol{p}_0)\\ &= (2\omega_{\boldsymbol{p}})^{-1}\delta^3(\boldsymbol{p}-\boldsymbol{p}_0),\end{aligned} \tag{35}$$

for any value of t_0. This is essentially the basis for an "induced" inner product, in the sense of Refs. 23 and 43.

Let $\mathcal{H}$ be the Hilbert space of the $|x;\lambda_0\rangle$ and let $\mathcal{H}_t$ be the subspaces spanned by the $|t,\boldsymbol{x};\lambda_0\rangle$, for each t, forming a foliation of $\mathcal{H}$. Now, from Eq. (27), it is clear that the particle and antiparticle 3-momentum states $|t,\boldsymbol{p}_\pm;\lambda_0\rangle$ also each span $\mathcal{H}_t$. In these representations, states in $\mathcal{H}_t$ have the form

$$|t,\psi_\pm;\lambda_0\rangle = \int \mathrm{d}^3p\,\psi(\boldsymbol{p})|t,\boldsymbol{p}_\pm;\lambda_0\rangle, \tag{36}$$

for square-integrable functions $\psi(\boldsymbol{p})$. Conversely, it follows from Eq. (35) that a probability amplitude $\psi(\boldsymbol{p})$ is given by

$$\psi(\boldsymbol{p}) = (2\omega_{\boldsymbol{p}})\langle \boldsymbol{p}_\pm|t,\psi_\pm;\lambda_0\rangle. \tag{37}$$

Let $\mathcal{H}'_t$ be the space of linear functions dual to $\mathcal{H}_t$. Via Eq. (37), the bra states $\langle \boldsymbol{p}_\pm|$ can be considered to be members of $\mathcal{H}'_t$, for all t. Indeed, they span two common subspaces $\mathcal{H}'_\pm$ of the $\mathcal{H}'_t$, the states of which have the form

$$\langle\psi_\pm| = \int \mathrm{d}^3p\,\psi(\boldsymbol{p})^*\langle \boldsymbol{p}_\pm|.$$

Now, define an inner product on the functions $\psi(\boldsymbol{p})$ such that

$$(\psi_1,\psi_2) \equiv \langle\psi_{1\pm}|t,\psi_{2\pm};\lambda_0\rangle = \int \frac{\mathrm{d}^3p}{2\omega_{\boldsymbol{p}}}\psi_1(\boldsymbol{p})^*\psi_2(\boldsymbol{p}), \tag{38}$$

where the second equality follows from Eq. (35). Equipped with this inner product, each $\mathcal{H}_t$ is itself a Hilbert space of the wave functions $\psi(\boldsymbol{p})$. Note that it is the states of the *dual* spaces $\mathcal{H}'_\pm$ that naturally satisfy the on-shell constraint $\langle\psi_\pm|\hat{H}=0$ (as suggested by, for example, Ref. 44).

The operators $(2\omega_{\boldsymbol{p}})|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\langle\boldsymbol{p}_\pm|$ are self-adjoint under the inner product given in Eq. (38), in the sense that the conjugate of

$$(2\omega_{\boldsymbol{p}})\langle\psi_\pm|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\langle\boldsymbol{p}_\pm| = \psi(\boldsymbol{p})^*\langle\boldsymbol{p}_\pm|$$

is

$$(2\omega_{\boldsymbol{p}})|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\langle\boldsymbol{p}_\pm|t,\psi_\pm;\lambda_0\rangle = |t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\psi(\boldsymbol{p})$$

for that inner product. Further,

$$\int \mathrm{d}^3p(2\omega_{\boldsymbol{p}})\langle\psi_{1\pm}|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\langle\boldsymbol{p}_\pm|t,\psi_{2\pm};\lambda_0\rangle = \int \frac{\mathrm{d}^3p}{2\omega_{\boldsymbol{p}}}\psi_1(\boldsymbol{p})^*\psi_2(\boldsymbol{p}) = \langle\psi_{1\pm}|t,\psi_{2\pm};\lambda_0\rangle,$$

which gives the effective resolution of the identity

$$\int \mathrm{d}^3p(2\omega_{\boldsymbol{p}})|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\langle\boldsymbol{p}_\pm| = 1. \tag{39}$$

In fact, such a resolution of the identity generally holds for families of conjugate bra and ket states with a *biorthonormality relationship* such as Eq. (35) (see Ref. 45 and Appendix A.8.1 of Ref. 46). We can, therefore, take the operator $(2\omega_{\boldsymbol{p}})|t_0,\boldsymbol{p}_\pm;\lambda_0\rangle\langle\boldsymbol{p}_\pm|$ to represent the quantum proposition that an on-shell particle or antiparticle has the three-momentum $\boldsymbol{p}$. Then, with the normalization

$$(\psi,\psi) = \int \frac{\mathrm{d}^3p}{2\omega_{\boldsymbol{p}}}|\psi(\boldsymbol{p})|^2 = 1,$$

$|\psi(\boldsymbol{p})|^2$ is the corresponding probability density in three-momentum space.

Finally, consider that $|t,\boldsymbol{x};\lambda_0\rangle$ is an eigenstate of the three-position operator $\hat{\boldsymbol{X}}$, representing a particle localized at the three-position $\boldsymbol{x}$ at time t. From Eq. (37), and using the inverse Fourier transform of Eq. (28) with Eq. (33), its three-momentum wave function in $\mathcal{H}_t$ is

$$(2\omega_{\boldsymbol{p}})\langle\boldsymbol{p}_\pm|t,\boldsymbol{x};\lambda_0\rangle = (2\pi)^{-3/2}\mathrm{e}^{i(\pm\omega_{\boldsymbol{p}}t-\boldsymbol{p}\cdot\boldsymbol{x})}. \tag{40}$$

This is just a plane wave, and it is an eigenfunction of the operator

$$\mathrm{e}^{\pm i\omega_{\boldsymbol{p}}t}i\frac{\partial}{\partial\boldsymbol{p}}\mathrm{e}^{\mp i\omega_{\boldsymbol{p}}t},$$

which is the traditional momentum representation $i\partial/\partial\boldsymbol{p}$ of the three-position operator $\hat{\boldsymbol{X}}$, translated to time t.

This result contrasts with the well-known result of Newton and Wigner,[47] who conclude that a localized particle wave function satisfying the Klein–Gordon equation is an eigenfunction of

$$i\left(\frac{\partial}{\partial\boldsymbol{p}} - \frac{\boldsymbol{p}}{2\omega_{\boldsymbol{p}}^2}\right),$$

which has an extra term over the expected $i\partial/\partial\boldsymbol{p}$. The key reason for this difference is our use of the three-momentum basis $|t,\boldsymbol{p}_\pm;\lambda_0\rangle$. With the dual basis $(2\omega_{\boldsymbol{p}})\langle\boldsymbol{p}_\pm|$ from Eq. (35), this leads to the relation given in Eq. (37) and used in Eq. (40).

In contrast, the traditional formalism assumes that both bra and ket states are on-shell. Instead of the time-dependent spaces $\mathcal{H}_t$, the spaces $\mathcal{H}_\pm$ are used, with on-shell ket basis states $|\boldsymbol{p}_\pm\rangle$ that are dual to the bra states $\langle\boldsymbol{p}_\pm|$ under an inner product such that, instead of Eq. (35), one has

$$(2\omega_{\boldsymbol{p}'})^{1/2}\langle \boldsymbol{p}'_{\pm}|\boldsymbol{p}_{\pm}\rangle(2\omega_{\boldsymbol{p}})^{1/2} = \delta^3(\boldsymbol{p}'-\boldsymbol{p}),$$

where the factor of $(2\omega_{\boldsymbol{p}})^{1/2}$ is introduced symmetrically on dual bra and ket states in order provide an orthonormal basis. If we were to use the traditional dual basis $(2\omega_{\boldsymbol{p}})^{1/2}\langle \boldsymbol{p}_{\pm}|$, instead of $(2\omega_{\boldsymbol{p}}) \times\langle \boldsymbol{p}_{\pm}|$, the wave function of $|t,\boldsymbol{x};\lambda_0\rangle$ would be

$$(2\omega_{\boldsymbol{p}})^{1/2}\langle \boldsymbol{p}_{\pm}|t,\boldsymbol{x};\lambda_0\rangle = (2\pi)^{-3/2}(2\omega_{\boldsymbol{p}})^{-1/2}e^{i(\pm\omega_{\boldsymbol{p}}t-\boldsymbol{p}\cdot\boldsymbol{x})}. \tag{41}$$

At $t=0$ this is exactly the Newton–Wigner wave function for a localized particle.[47]

Note that Eq. (40) is effectively related to Eq. (41) by a scalar Foldy–Wouthuysen transformation.[48,49] This makes sense, since the Foldy–Wouthuysen transformation produces a representation that separates positive and negative energy states (particles and antiparticles) and gives a reasonable non-relativistic limit.

Indeed, from Eq. (27) we can easily see that the time evolution of the three-momentum states $|t,\boldsymbol{p}_{\pm};\lambda_0\rangle$ is given by

$$e^{i\hat{P}^0\Delta t}|t,\boldsymbol{p}_{\pm};\lambda_0\rangle = e^{\pm i\omega_{\boldsymbol{p}}\Delta t}|t+\Delta t,\boldsymbol{p}_{\pm};\lambda_0\rangle = e^{\pm i\hat{H}_{\mathrm{FW}}\Delta t}|t+\Delta t,\boldsymbol{p}_{\pm};\lambda_0\rangle,$$

where

$$\hat{H}_{\mathrm{FW}} = (\hat{\boldsymbol{P}}\cdot\hat{\boldsymbol{P}}+m^2)^{1/2}$$

is the scalar Foldy–Wouthuysen Hamiltonian and the $\hat{P}^\mu$ are the generators of spacetime translations. Define the operation of time translation on the time-dependent states $|t,\psi;\lambda_0\rangle$ so that

$$|t+\Delta t,\psi_{\pm};\lambda_0\rangle = e^{i\hat{P}^0\Delta t}|t,\psi_{\pm};\lambda_0.$$

Substituting Eq. (36) then gives

$$\begin{aligned}|t+\Delta t,\psi_{\pm};\lambda_0\rangle &= \int d^3p\,\psi(t,\boldsymbol{p})e^{i\hat{P}^0\Delta t}|t,\boldsymbol{p}_{\pm};\lambda_0\rangle = \int d^3p\,\psi(t,\boldsymbol{p})e^{\pm i\omega_{\boldsymbol{p}}\Delta t}|t+\Delta t,\boldsymbol{p}_{\pm};\lambda_0\rangle \\ &= \int d^3p\,\psi(t+\Delta t,\boldsymbol{p})|t+\Delta t,\boldsymbol{p}_{\pm};\lambda_0\rangle,\end{aligned}$$

where the time dependence of the three-momentum wave function has been made explicit, with time evolution given by

$$\psi(t+\Delta t,\boldsymbol{p}) = e^{\pm i\omega_{\boldsymbol{p}}\Delta t}\psi(t,\boldsymbol{p}).$$

In the nonrelativistic limit, for positive-energy particles, $\omega_{\boldsymbol{p}}\approx m+\boldsymbol{p}^2/2m$, and this time evolution reduces to time evolution according to the usual nonrelativistic Hamiltonian (up to the momentum-independent phase factor $\exp(im\Delta t)$).

E. Free multiparticle states

The formalism introduced in the previous sections can be extended in a straightforward way to a Fock space of noninteracting multiparticle states. In order to allow for multiparticle states with different types of particles, extend the position state of each individual particle with a *particle type index n*, such that

$$\langle x',n';\lambda|x,n;\lambda\rangle = \delta_n^{n'}\delta^4(x'-x).$$

Then, construct a basis for the Fock space of multiparticle states as symmetrized products of N single particle states:

$$|x_1,n_1,\lambda_1;\ldots;x_N,n_N,\lambda_N\rangle \equiv (N!)^{-1/2}\sum_{\text{perms }\mathcal{P}}|x_{\mathcal{P}1},n_{\mathcal{P}1};\lambda_{\mathcal{P}1}\rangle\cdots|x_{\mathcal{P}N},n_{\mathcal{P}N};\lambda_{\mathcal{P}N}\rangle, \tag{42}$$

where the sum is over all permutations $\mathcal{P}$ of $1,2,\ldots,N$. (Since only scalar particles are being considered in the present work, only Bose–Einstein statistics need be accounted for.)

Define multiparticle states $|x_1,n_1;\ldots;x_N,n_N\rangle$ as similarly symmetrized products of $|x\rangle$ states. Then,

$$\langle x_1',n_1';\ldots;x_N',n_N'|x_1,n_1,\lambda_0;\ldots;x_N,n_N,\lambda_0\rangle = \sum_{\text{perms }\mathcal{P}}\prod_{i=1}^{N}\delta_{n_i}^{n_{\mathcal{P}i}'}\Delta(x_{\mathcal{P}i}'-x_i;m_i^2), \tag{43}$$

where m_i is the mass of particles of type n_i. Note that the use of the same parameter value λ_0 for the starting point of each particle path is simply a matter of convenience, using the path parametrization gauge freedom to choose this value arbitrarily. The intrinsic lengths of each particle path are still integrated over *separately* in $|x_1,n_1;\ldots;x_N,n_N\rangle$, which is important for obtaining the proper particle propagator factors in Eq. (43). Nevertheless, by using λ_0 as a common starting parameter value, we can make the small notational simplification of not repeating it multiple times in $|x_1,n_1,\lambda_0;\ldots;x_N,n_N,\lambda_0\rangle$, defining, instead,

$$|x_1,n_1;\ldots;x_N,n_N;\lambda_0\rangle \equiv |x_1,n_1,\lambda_0;\ldots;x_N,n_N,\lambda_0\rangle.$$

Following the same procedures as in Sec. II C for each particle in a multiparticle state, it is straightforward to construct the multiparticle three momentum states $|t_1,\boldsymbol{p}_{1\pm},n_1;\ldots;t_N,\boldsymbol{p}_{N\pm},n_N\rangle$ and $|t_1,\boldsymbol{p}_{1\pm},n_1;\ldots;t_N,\boldsymbol{p}_{N\pm},n_N;\lambda_0\rangle$. Note that each particle may be *either* a normal particle (+) or an antiparticle (−). Then, to obtain on-shell states we need to take $t_i\to+\infty$ in $|t_1,\boldsymbol{p}_{1\pm},n_1;\ldots;t_N,\boldsymbol{p}_{N\pm},n_N\rangle$ for particles, but $t_i\to-\infty$ for antiparticles. This results in the multiparticle on-shell states $|\boldsymbol{p}_{1\pm},n_1;\ldots;\boldsymbol{p}_{N\pm},n_N\rangle$.

Now, it can be seen that the $|\boldsymbol{p}_{1\pm},n_1;\ldots;\boldsymbol{p}_{N\pm},n_N\rangle$ states may not always be particularly convenient, since they describe normal particles at $t=+\infty$ and antiparticles at $t=-\infty$. For describing the asymptotic state of outgoing particles from a scattering process, for instance, we would like to take the limit for all particles and antiparticles together as $t\to+\infty$.

To do this, we can take the viewpoint of considering antiparticles to be positive energy particles traveling forwards in time, rather than negative energy particles traveling backwards in time. Since both particles and their antiparticles will then have positive energy, it becomes necessary to explicitly label antiparticles with separate (though related) types from their corresponding particles. Let n_+ denote the type label for a normal particle type and n_- denote the corresponding antiparticle type.

For normal particles of type n_+, position states are defined as in Eq. (24),

$$\langle x,n_+|x_0,n_+;\lambda_0\rangle = \theta(x^0-x_0^0)\Delta_+(x-x_0).$$

For antiparticles of type n_-, however, position states are now defined such that

$$\langle x,n_-|x_0,n_-;\lambda_0\rangle = \theta(x^0-x_0^0)\Delta_-(x_0-x). \tag{44}$$

Note the reversal with respect to Eq. (24) of x_0 and x on the righthand side of this equation.

Using Eq. (23), the Fourier transform of Eq. (44) is

$$\int \mathrm{d}^4x\mathrm{e}^{-ip\cdot x}\theta(x^0)\Delta_-(-x) = \int \mathrm{d}^4x\mathrm{e}^{-ip\cdot x}\theta(x^0)\Delta_+(x^0,-\boldsymbol{x}) = \int \mathrm{d}^4x\mathrm{e}^{\mathrm{i}(p^0x^0+\boldsymbol{p}\cdot\boldsymbol{x})}\theta(x^0)\Delta_+(x) = \Delta_+(p^0,-\boldsymbol{p}),$$

where $\Delta_+(p)$ is as given in Eq. (30). From this we can see that carrying through the derivation for antiparticle three-momentum states will, indeed, give positive energy states, but with reversed three momentum

$$|t,\boldsymbol{p},n_-\rangle = (2\omega_{\boldsymbol{p}})^{-1}\int_{-\infty}^{t} \mathrm{d}t_0 |t_0,\boldsymbol{p},n_-;\lambda_0\rangle,$$

where

$$|t_0,\boldsymbol{p},n_-;\lambda_0\rangle = |t_0,-\boldsymbol{p}_+,n;\lambda_0\rangle.$$

Further, taking the limit $t\to+\infty$ gives the on-shell states

$$|\boldsymbol{p},n_-\rangle \equiv \lim_{t\to+\infty}|t,\boldsymbol{p},n_-\rangle = (2\pi)^{1/2}(2\omega_{\boldsymbol{p}})^{-1}|+\omega_{\boldsymbol{p}},-\boldsymbol{p};\lambda_0\rangle.$$

We can now reasonably construct Fock spaces $\mathcal{F}_t$ with single time, multiparticle basis states

$$|t;\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle \equiv |t,\boldsymbol{p}_1,n_{1\pm};\ldots;t,\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle,$$

over all combinations of particle and antiparticle types. Similarly defining

$$|t;\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm}\rangle \equiv |t,\boldsymbol{p}_1,n_{1\pm};\ldots;t,\boldsymbol{p}_N,n_{N\pm}\rangle,$$

we can now take $t\to+\infty$ for particles and antiparticles alike to get the multiparticle on-shell states $|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm}\rangle$. The corresponding bra states $\langle\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm}|$ then span a subspace of the dual space $\mathcal{F}_t'$, for any t. Analogously to the case for single particle states, this can be used to define a Hilbert space of multiparticle probability amplitudes for each time t.

Finally, since $|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm}\rangle$ now uniformly represents particles and antiparticles in the $t\to+\infty$ limit, it can be used as the asymptotically free state of outgoing particles from a scattering process. The corresponding state for incoming particles is $|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle \equiv \lim_{t\to-\infty}|t;\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle$.

F. Fields

Even though the theory presented here is essentially first quantized, it is still often convenient to introduce the formalism of creation and annihilation fields on the Fock space of multiparticle states. Specifically, define the creation field $\hat{\psi}^\dagger(x,n;\lambda)$ by

$$\hat{\psi}^\dagger(x,n;\lambda)|x_1,n_1,\lambda_1;\ldots;x_N,n_N,\lambda_N\rangle = |x,n,\lambda;x_1,n_1,\lambda_1;\ldots;x_N,n_N,\lambda_N\rangle,$$

with the corresponding annihilation field $\hat{\psi}(x,n;\lambda)$ having the commutation relation

$$[\hat{\psi}(x',n';\lambda),\hat{\psi}^\dagger(x,n;\lambda_0)] = \delta_n^{n'}\Delta(x'-x;\lambda-\lambda_0).$$

Further define

$$\hat{\psi}(x,n) \equiv \int_{\lambda_0}^{\infty}\mathrm{d}\lambda\,\hat{\psi}(x,n;\lambda), \tag{45}$$

so that

$$[\hat{\psi}(x',n'),\hat{\psi}^\dagger(x,n;\lambda_0)] = \delta_n^{n'}\Delta(x'-x), \tag{46}$$

which is consistent with the multiparticle inner product as given in Eq. (43).

Note the asymmetry in Eq. (46): $\hat{\psi}^\dagger(x,n;\lambda_0)$ is at the reference value λ_0 of the path parameter (at the start of the path), while in $\hat{\psi}(x',n')$ the path parameter (at the end of the path) is integrated over. This results from the fact that it is the integrated position bra state $\langle x',n'|$, created by $\hat{\psi}(x',n')$, that generates complete particle transition amplitudes (as discussed at the end of Sec.

II A). It is thus convenient to consider $\langle x,n|$ to be "dual" to $|x,n;\lambda_0\rangle$, in a similar fashion to the states $\langle \boldsymbol{p}_\pm|$ and $|t,\boldsymbol{p}_\pm;\lambda_0\rangle$ in Sec. II C, even though, by Eq. (21), the position states are not orthogonal.

In the field operator notation, this duality can be captured by introducing a *special adjoint* $\hat{\psi}^\ddagger$ defined by

$$\hat{\psi}^\ddagger(x,n) = \hat{\psi}^\dagger(x,n;\lambda_0) \quad \text{and} \quad \hat{\psi}^\ddagger(x,n;\lambda_0) = \hat{\psi}^\dagger(x,n). \tag{47}$$

The commutation relation in Eq. (46) then takes on the more symmetric form

$$[\hat{\psi}(x',n'),\hat{\psi}^\ddagger(x,n)] = \delta_n^{n'}\Delta(x'-x).$$

We can also define field operators for explicit particle and antiparticle types, as considered in Sec. II E. Define the *normal particle field* $\hat{\psi}(x,n_+)$ by

$$\hat{\psi}(x,n_+) \equiv \int \mathrm{d}^4x_0 \Delta_+(x-x_0)\hat{\psi}(x_0,n_+;\lambda_0), \tag{48}$$

giving the commutation rule

$$[\hat{\psi}(x',n_+),\hat{\psi}^\dagger(x,n_+;\lambda_0)] = [\hat{\psi}(x',n_+),\hat{\psi}^\ddagger(x,n_+)] = \Delta_+(x'-x). \tag{49}$$

Substituting Eq. (23) into Eq. (48) gives the familiar expression

$$\hat{\psi}(x,n_+) = (2\pi)^{-3/2}\int \mathrm{d}^3p \mathrm{e}^{i(-\omega_{\boldsymbol{p}}x^0+\boldsymbol{p}\cdot\boldsymbol{x})}\hat{a}(\boldsymbol{p},n_+),$$

where

$$\hat{a}(\boldsymbol{p},n_+) \equiv (2\pi)^{-3/2}(2\omega_{\boldsymbol{p}})^{-1}\int \mathrm{d}^4x_0 \mathrm{e}^{i(\omega_{\boldsymbol{p}}x_0^0-\boldsymbol{p}\cdot\boldsymbol{x}_0)}\hat{\psi}(x_0,n_+;\lambda_0)$$

is the *on-shell particle three-momentum field*.

For antiparticles, reverse the roles of the antiparticle creation and annihilation operators relative to increasing-λ propagation as defined for the normal particle type. Define the antiparticle *creation* field analogously to Eq. (48) for the corresponding normal particle *annihilation* field

$$\hat{\psi}^\dagger(x,n_-) \equiv \int \mathrm{d}^4x_0 \Delta_-(x-x_0)\hat{\psi}^\dagger(x_0,n_-;\lambda_0).$$

Now, $\Delta_-(x-x_0)^* = \Delta_-(x_0-x)$ (see Eq. (23)). Therefore,

$$\hat{\psi}(x,n_-) = \int \mathrm{d}^4x_0 \Delta_-(x_0-x)\hat{\psi}(x_0,n_-;\lambda_0), \tag{50}$$

giving the commutation rule (note the switching of x' and x on the right, relative to Eq. (49))

$$[\hat{\psi}(x',n_-),\hat{\psi}^\dagger(x,n_-;\lambda_0)] = [\hat{\psi}(x',n_-),\hat{\psi}^\ddagger(x,n_-)] = \Delta_-(x-x').$$

Substituting Eq. (23) into Eq. (50) and changing variables $\boldsymbol{p}\to-\boldsymbol{p}$ then gives

$$\hat{\psi}(x,n_-) = (2\pi)^{-3/2}\int \mathrm{d}^3p \mathrm{e}^{i(-\omega_{\boldsymbol{p}}x^0+\boldsymbol{p}\cdot\boldsymbol{x})}\hat{a}(\boldsymbol{p},n_-),$$

where

$$\hat{a}(\boldsymbol{p},n_-) \equiv (2\pi)^{-3/2}(2\omega_{\boldsymbol{p}})^{-1}\int \mathrm{d}^4x_0 \mathrm{e}^{i(\omega_{\boldsymbol{p}}x_0^0-\boldsymbol{p}\cdot\boldsymbol{x}_0)}\hat{\psi}(x_0,n_-;\lambda_0)$$

is the *on-shell antiparticle three-momentum field*.

III. INTERACTING PARTICLES

In conventional second-quantized quantum field theory, interactions are introduced via the Lagrangian density into the Hamiltonian used to propagate the fields. The very conception of interacting particles and their paths then only arises at all as a result of the perturbative expansion of the Hamiltonian. Such an approach is thus not very natural for a foundational formalism based on spacetime paths.

Now, the actual traditional motivation for introducing fields in the first place is largely a heuristic response to the well known difficulties with negative energies and probabilities in relativistic quantum mechanics. However, as we have seen in Sec. II, these difficulties can also be handled in the context of the spacetime path formalism. Further, the spacetime path approach can very directly accommodate the creation and destruction of particles, as required in a relativistic theory. One simply considers particle paths with a finite length: a particle is created at the start of its path and destroyed at the end.

Taking this path viewpoint, an *interaction vertex* can then simply be considered as an event at which a set of particle paths all end together and another set of particle paths all begin. An *interaction graph* is a set of interaction vertices connected by particle paths. For a collection of interacting particles, it is essentially such graphs that act as the fundamental building blocks of the system state, rather than the individual particle paths themselves.

The natural spacetime path approach for interactions is therefore first quantized rather than second quantized. As we will see in this section, the first-quantized spacetime path formalism can duplicate the basic results of perturbative quantum field theory for Feynman diagrams and scattering. It is also consistent with the typically first-quantized geometric approach used in string theory.[50]

Of course, taking a first-quantized formalism as foundational requires that issues of consistency and convergence that appear in traditional perturbation theory be addressed directly, without recourse to a posited nonperturbative solution. We will return to this point at the end of Sec. III D, though a full discussion is beyond the scope of the present paper.

A. Interactions

Since incoming particles are destroyed at an interaction vertex, and outgoing particles are created, the vertex can be represented by an operator constructed as an appropriate product of the creation and annihilation operator fields introduced in Sec. II F. Note that "incoming" and "outgoing" are used here in the sense of the path evolution parameter λ, not time. That is, we are not separately considering particles and antiparticles at this point.

Postulate 6: *An interaction vertex, possibly occurring at any position in spacetime, with some number a of incoming particles and some number b of outgoing particles, is represented by the operator*

$$-\mathrm{i}\hat{V} \equiv h\int \mathrm{d}^4x \prod_{i=1}^{a}\hat{\psi}^{\ddagger}(x,n_i')\prod_{j=1}^{b}\hat{\psi}(x,n_j), \tag{51}$$

where the coefficient h represents the relative probability amplitude of the interaction and $\hat{\psi}^{\ddagger}$ *is the special adjoint defined in Eq.* (47).

The probability amplitude for a transition from an initial state $|x_1,n_1;\ldots;x_N,n_N;\lambda_0\rangle$ to a final state $|x_1',n_1';\ldots;x_{N'}',n_{N'}'\rangle$, with a single intermediate interaction, is then

$$G_1(x_1',n_1';\ldots;x_{N'}',n_{N'}'|x_1,n_1;\ldots;x_N,n_N) = \langle x_1',n_1';\ldots;x_{N'}',n_{N'}'|(-\mathrm{i})\hat{V}|x_1,n_1;\ldots;x_N,n_N;\lambda_0\rangle.$$

This is essentially the amplitude for a first-order *Wick diagram*.[51] That is, it is equivalent to the first-order terms in the Wick expansion of the Dyson series in conventional quantum field theory (including all permutations that may result from crossing symmetries if any of the incoming or outgoing particles in the interaction are of the same type).

The probability amplitude corresponding to multiple intermediate interactions can then be obtained by repeated applications of $\hat{V}$. Thus, the amplitude for m interactions is

$$G_m(x'_1,n'_1;\ldots;x'_{N'},n'_{N'}|x_1,n_1;\ldots;x_N,n_N) = \langle x'_1,n'_1;\ldots;x'_{N'},n'_{N'}|\frac{(-i)^m}{m!}\hat{V}^m|x_1,n_1;\ldots;x_N,n_N;\lambda_0\rangle,$$

where the $(m!)^{-1}$ factor accounts for all possible permutations of the m identical factors of $\hat{V}$. The *complete* interacting transition amplitude, with any number of intermediate interactions, is then

$$\begin{aligned} G(x'_1,n'_1;\ldots;x'_{N'},n'_{N'}|x_1,n_1;\ldots;x_N,n_N) &= \sum_{m=0}^{\infty} G_m(x'_1,n'_1;\ldots;x'_N,n'_N|x_1,n_1;\ldots;x_N,n_N) \\ &= \langle x'_1,n'_1;\ldots;x'_N,n'_N|\hat{G}|x_1,n_1;\ldots;x_N,n_N;\lambda_0\rangle, \end{aligned} \tag{52}$$

where

$$\hat{G} \equiv \sum_{m=0}^{\infty} \frac{(-i)^m}{m!}\hat{V}^m = e^{-i\hat{V}}. \tag{53}$$

Extend the operation of the special adjoint in the natural way to sums and products. Then it is clear, at least formally, that $\hat{G}$ is unitary relative to this adjoint (that is, $\hat{G}^{\ddagger}\hat{G}=\hat{G}\hat{G}^{\ddagger}=1$), so long as $\hat{V}$ is self-adjoint relative to it (that is, $\hat{V}^{\ddagger}=\hat{V}$).

From Eq. (51), there are two consequences to $\hat{V}$ being self-adjoint. First $ih=g$ must be real. Second, the interaction must involve the same number of incoming and outgoing particles, of the same types. This second consequence is a result of assuming so far that there is only one possible type of interaction. The formalism can be easily extended to allow for multiple types of interactions by adding additional terms to the definition of $\hat{V}$. In this case, only the overall operator $\hat{V}$ needs to be self-adjoint, not the individual interaction terms.

For example, consider the case of a three-particle interaction of the form $\hat{\psi}^{\ddagger}(x,n_A)\hat{\psi}(x,n_B)\hat{\psi}(x,n_A)$. Then, for the overall interaction operator $\hat{V}$ to be self-adjoint, there must also be a conjugate interaction term $\hat{\psi}^{\ddagger}(x,n_A)\hat{\psi}^{\ddagger}(x,n_B)\hat{\psi}(x,n_A)$. That is,

$$\hat{V} = g\int d^4x[\hat{\psi}^{\ddagger}(x,n_A)\hat{\psi}(x,n_B)\hat{\psi}(x,n_A) + \hat{\psi}^{\ddagger}(x,n_A)\hat{\psi}^{\ddagger}(x,n_B)\hat{\psi}(x,n_A)].$$

This corresponds to the case of the particle of type B being indistinguishable from its antiparticle. Defining the self-adjoint effective field

$$\hat{\psi}'(x,n_B) \equiv \hat{\psi}(x,n_B) + \hat{\psi}^{\ddagger}(x,n_B)$$

then allows $\hat{V}$ to be put back into the form of a single type of interaction:

$$\hat{V} = g\int d^4x\hat{\psi}^{\ddagger}(x,n_A)\hat{\psi}'(x,n_B)\hat{\psi}(x,n_A). \tag{54}$$

An alternate interpretation of a self-adjoint interaction vertex is to pair up incoming and outgoing particles of the same type and consider them to be the *same* particle before and after the interaction. For example, an interaction of the form given in Eq. (54) would be considered to represent a *single* particle of type A interacting with a self-adjoint particle of type B.

This viewpoint can be seen more explicitly by considering a first-order interaction matrix element and using Eq. (12) to expand the A-particle propagators

$$\begin{aligned}
&\langle x_A,n_A;x_B,n_B|\hat{V}|x_0,n_A;\lambda_0\rangle \\
&\quad = g\int \mathrm{d}^4x\Delta_A(x_A-x)\Delta_B(x_B-x)\Delta_A(x-x_0) \\
&\quad = g\int \mathrm{d}^4x\Delta_B(x_B-x)\int_{\lambda_0}^{\infty}\mathrm{d}\lambda\int_{\lambda_0}^{\infty}\mathrm{d}\lambda'\Delta_A(x_A-x;\lambda'-\lambda_0)\Delta_A(x-x_0;\lambda-\lambda_0) \\
&\quad = g\int \mathrm{d}^4x\Delta_B(x_B-x)\int_{\lambda_0}^{\infty}\mathrm{d}\lambda\int_{\lambda}^{\infty}\mathrm{d}\lambda'\Delta_A(x_A-x;\lambda'-\lambda)\Delta_A(x-x_0;\lambda-\lambda_0).
\end{aligned}$$

Substituting for the A-particle kernels from Eq. (6), the path integral for the first kernel ends at the same point x as the path integral for the second kernel begins. Therefore, the two path integrals can be combined into a single path integral, with the constraint that the paths always pass through the intermediate point x:

$$\begin{aligned}
&\langle x_A,n_A;x_B,n_B|\hat{V}|x_0,n_A;\lambda_0\rangle \\
&\quad = g\int \mathrm{d}^4x\Delta_B(x_B-x)\int_{\lambda_0}^{\infty}\mathrm{d}\lambda\int_{\lambda}^{\infty}\mathrm{d}\lambda'\,\eta\int \mathrm{D}^4q\,\delta^4(q(\lambda')-x_A)\,\delta^4(q(\lambda)-x)\,\delta^4(q(\lambda_0)-x_0)\mathrm{e}^{iS_A[q]} \\
&\quad = g\int_{\lambda_0}^{\infty}\mathrm{d}\lambda'\int_{\lambda_0}^{\lambda'}\mathrm{d}\lambda\,\eta\int \mathrm{D}^4q\,\delta^4(q(\lambda')-x_A)\,\delta^4(q(\lambda_0)-x_0)\mathrm{e}^{iS_A[q]}\Delta_B(x_B-q(\lambda)).
\end{aligned}$$

This form clearly reflects the viewpoint of a single A particle interacting with a B particle at the point $q(\lambda)$ in its path.

Now consider a second-order interaction in which the incoming and outgoing particles are all A particles

$$\begin{aligned}
&\langle x_1',n_A;x_2',n_A|\frac{1}{2}\hat{V}^2|x_1,n_A;x_2,n_A;\lambda_0\rangle \\
&\quad = \frac{g^2}{2}\int \mathrm{d}^4y_1\int \mathrm{d}^4y_2[\Delta_A(x_1'-y_2)\Delta_A(y_2-y_1)\Delta_A(y_1-x_1)\Delta_B(y_2-y_1)\Delta_A(x_2'-x_2) \\
&\qquad + \Delta_A(x_1'-y_1)\Delta_A(y_1-x_1)\Delta_B(y_2-y_1)\Delta_A(x_2'-y_2)\Delta_A(y_2-x_2)+\cdots],
\end{aligned} \tag{55}$$

where the additional terms not shown are the result of position interchanges from the terms given. The first term shown in Eq. (55) reflects a self-interaction of one A particle via the B particle, with the second A particle propagating freely. The self-interaction factor can be given the path integral representation

$$\begin{aligned}
&\int \mathrm{d}^4y_1\int \mathrm{d}^4y_2\Delta_A(x_1'-y_2)\Delta_A(y_2-y_1)\Delta_A(y_1-x_1)\Delta_B(y_2-y_1) \\
&\quad = \int_{\lambda_0}^{\infty}\mathrm{d}\lambda'\int_{\lambda_0}^{\lambda'}\mathrm{d}\lambda_2\int_{\lambda_0}^{\lambda_2}\mathrm{d}\lambda_1\,\eta\int \mathrm{D}^4q\,\delta^4(q(\lambda')-x_1')\,\delta^4(q(\lambda_0)-x_1)\mathrm{e}^{\mathrm{i}S_A[q]}\Delta_B(q(\lambda_2)-q(\lambda_1)),
\end{aligned} \tag{56}$$

reflecting an A particle interacting with the B particle at points λ_1 and λ_2. The second term shown in Eq. (55) reflects an interaction of two A particles via a B particle. It can be given the path integral representation

$$\int \mathrm{d}^4 y_1 \int \mathrm{d}^4 y_2 \Delta_A(x_1' - y_1)\Delta_A(y_1 - x_1)\Delta_A(x_2' - y_2)\Delta_A(y_2 - x_2)\Delta_B(y_2 - y_1)$$
$$= \int_{\lambda_0}^{\infty} \mathrm{d}\lambda_2' \int_{\lambda_0}^{\infty} \mathrm{d}\lambda_1' \int_{\lambda_0}^{\lambda_2'} \mathrm{d}\lambda_2 \int_{\lambda_0}^{\lambda_1'} \mathrm{d}\lambda_1 \eta^2 \int \mathrm{D}^4 q_2 \delta^4(q_2(\lambda_2') - x_2') \delta^4(q_2(\lambda_0) - x_2) \mathrm{e}^{iS_A[\dot{q}_2]}$$
$$\times \int \mathrm{D}^4 q_1 \delta^4(q_1(\lambda_1') - x_1') \delta^4(q_1(\lambda_0) - x_1) \mathrm{e}^{iS_A[\dot{q}_1]} \Delta_B(q_2(\lambda_2) - q_1(\lambda_1)),$$

showing the B particle propagating from the point at λ_1 on the path of the first A particle to the point at λ_2 on the path of the second A particle. If the B particle is taken to be a photon, then Barut and Duru have shown that expansions of just the form given above can be obtained from a general path integral formulation of quantum electrodynamics[52] (see also the similar result obtained in Ref. 33 using a parametrized perturbation series approach).

B. Feynman diagrams

Computing a scattering amplitude requires moving from the Wick diagram formulation of Eq. (52) to a Feynman diagram formulation. To do this, replace the initial and final states in Eq. (52) with on-shell multiparticle momentum states $|t_1, \boldsymbol{p}_{1\pm}, n_1; \ldots; t_N, \boldsymbol{p}_{N\pm}, n_N; \lambda_0\rangle$ and $|\boldsymbol{p}'_{1\pm}, n'_1; \ldots; \boldsymbol{p}'_{N'\pm}, n'_{N'}; \lambda_0\rangle$ (note that these are the on-shell multiparticle states defined early in Sec. II E, with antiparticles propagating *backwards* in time, not the single-time states defined at the end of that section):

$$G(\boldsymbol{p}'_{1\pm}, n'_1; \ldots; \boldsymbol{p}'_{N'\pm}, n'_{N'} | \boldsymbol{p}_{1\pm}, n_1; \ldots; \boldsymbol{p}_{N\pm}, n_N)$$
$$\equiv \left[\prod_{i=1}^{N'} 2\omega_{\boldsymbol{p}'_i} \prod_{i=1}^{N} 2\omega_{\boldsymbol{p}_i} \right]^{1/2} \langle \boldsymbol{p}'_{1\pm}, n'_1; \ldots; \boldsymbol{p}'_{N'\pm}, n'_{N'} | \hat{G} | t_1, \boldsymbol{p}_{1\pm}, n_1; \ldots; t_N, \boldsymbol{p}_{N\pm}, n_N; \lambda_0 \rangle. \quad (57)$$

The $2\omega_{\boldsymbol{p}}$ factors are required by the resolution of the identity for these multiparticle states, generalizing the single particle case of Eq. (39),

$$\sum_{N=0}^{\infty} \sum_{n_i \pm} \int \mathrm{d}^3 p_1 \cdots \mathrm{d}^3 p_N \left[\prod_{i=1}^{N} 2\omega_{\boldsymbol{p}_i} \right] |t_1, \boldsymbol{p}_{1\pm}, n_1; \ldots; t_N, \boldsymbol{p}_{N\pm}, n_N; \lambda_0 \rangle \langle \boldsymbol{p}_{1\pm}, n_1; \ldots; \boldsymbol{p}_{N\pm}, n_N | = 1, \quad (58)$$

where the summation over the $n_i\pm$ is over all particle types and particle/antiparticle states.

Note that use of the on-shell states in Eq. (57) requires specifically identifying external lines as particles and antiparticles. For each initial and final particle, + is chosen if it is a normal particle and − if it is an antiparticle. The result is a sum of Feynman diagrams, including all possible permutations of interaction vertices and crossing symmetries. The inner products of the on-shell states for individual initial and final particles with the off-shell states for interaction vertices give the proper factors for the external lines of a Feynman diagram.

For a final particle, the on-shell state $\langle \boldsymbol{p}'_+|$ is obtained in the limit $t' \to +\infty$. Such a particle is thus an *outgoing* particle from the scattering process. If the external line for this particle starts at an interaction vertex x, then the line contributes an appropriate factor

$$(2\omega_{\boldsymbol{p}'})^{1/2} \langle \boldsymbol{p}'_+ | x; \lambda_0 \rangle = (2\pi)^{-3/2} (2\omega_{\boldsymbol{p}'})^{-1/2} \mathrm{e}^{i(+\omega_{\boldsymbol{p}'} x^0 - \boldsymbol{p}' \cdot \boldsymbol{x})}.$$

For a final antiparticle, however, the on-shell state $\langle \boldsymbol{p}'_-|$ is obtained in the limit $t' \to -\infty$. This means that the antiparticle is *incoming* to the scattering process, even though it derives from a final vertex, reflecting the time-reversal of antiparticle paths. If the external line for this antiparticle starts at an interaction vertex x, then the line contributes the factor

$$(2\omega_{\boldsymbol{p}'})^{1/2}\langle \boldsymbol{p}'_-|x;\lambda_0\rangle = (2\pi)^{-3/2}(2\omega_{\boldsymbol{p}'})^{-1/2}e^{i(-\omega_{\boldsymbol{p}'}x^0+\boldsymbol{p}'\cdot\boldsymbol{x})}.$$

Next, consider an initial particle on an external line ending at an interaction vertex x'. The factor for this line is (assuming $x'^0 > t$),

$$(2\omega_{\boldsymbol{p}})^{1/2}\langle x'|t,\boldsymbol{p}_+;\lambda_0\rangle = (2\pi)^{-3/2}(2\omega_{\boldsymbol{p}})^{-1/2}e^{i(-\omega_{\boldsymbol{p}}x'^0+\boldsymbol{p}\cdot\boldsymbol{x}')}.$$

Note that this expression is independent of t, so we can take $t\to-\infty$ and treat the particle as incoming. For an initial antiparticle, the corresponding factor is (assuming $x'^0 < t$),

$$(2\omega_{\boldsymbol{p}})^{1/2}\langle x'|t,\boldsymbol{p}_-;\lambda_0\rangle = (2\pi)^{-3/2}(2\omega_{\boldsymbol{p}})^{-1/2}e^{i(+\omega_{\boldsymbol{p}}x'^0-\boldsymbol{p}\cdot\boldsymbol{x}')}.$$

Taking $t\to+\infty$, this represents the factor for an antiparticle that is outgoing.

If a particle or antiparticle both starts at an initial vertex x and ends at a final vertex x', then, by Eq. (35),

$$(2\omega_{\boldsymbol{p}'}2\omega_{\boldsymbol{p}})^{1/2}\langle \boldsymbol{p}'_\pm|t,\boldsymbol{p}_\pm;\lambda_0\rangle = \delta^3(\boldsymbol{p}'-\boldsymbol{p}).$$

Finally, particles that start and end on interaction vertices (i.e., internal edges) are "virtual" particles propagating between interactions, retaining the full Feynman propagator factor $\Delta(x'-x)$.

Thus, the effect of Eq. (57) is to remove the propagator factors from the external lines of the summed Feynman diagrams, retaining them on internal edges. Since, in the position representation, G is essentially a sum of Green's functions G_m, this procedure is effectively equivalent to the usual LSZ reduction of the Green's functions.[42,51,53]

C. Scattering

The formulation of Eq. (57) is still not that of the usual scattering matrix, since the initial state involves incoming particles but outgoing antiparticles, and vice versa for the final state. To construct the usual scattering matrix, it is necessary to have multiparticle states that involve either all incoming particles and antiparticles (that is, they are composed of individual asymptotic particle states that are all consistently for $t\to-\infty$) or all outgoing particles and antiparticles (with individual asymptotic states all for $t\to+\infty$). These are the states $|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle$ and $|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm}\rangle$ defined at the end of Sec. II E.

Reorganizing the scattering amplitude of Eq. (57) in terms of these asymptotic states gives the more usual form using the scattering operator $\hat{S}$. Showing explicitly the asymptotic time limit used for each particle

$$\begin{aligned}&\langle +\infty,\boldsymbol{p}'_+,n';\ldots;-\infty,\bar{\boldsymbol{p}}'_-,\bar{n}';\ldots|\hat{G}|-\infty,\boldsymbol{p}_+,n;\ldots;+\infty,\bar{\boldsymbol{p}}_-,\bar{n};\ldots;\lambda_0\rangle\\ &\quad=\langle \boldsymbol{p}',n'_+;\ldots;\bar{\boldsymbol{p}},\bar{n}_-;\ldots|\hat{S}|\boldsymbol{p},n_+;\ldots;\bar{\boldsymbol{p}}',\bar{n}'_-;\ldots;\lambda_0\rangle.\end{aligned}\tag{59}$$

Using the resolution of the identity

$$\sum_{N=0}^{\infty}\sum_{n_{i\pm}}\int d^3p_1\cdots d^3p_N\left[\prod_{i=1}^{N}2\omega_{\boldsymbol{p}_i}\right]|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle\langle \boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm}| = 1,\tag{60}$$

expand the state $\hat{S}|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle$ as

$$\begin{aligned}\hat{S}|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle = \sum_{N'=0}^{\infty}\sum_{n_{i\pm}}\int d^3p'_1\cdots d^3p'_{N'}\left[\prod_{i=1}^{N'}2\omega_{\boldsymbol{p}'_i}\right]|\boldsymbol{p}'_1,n'_{1\pm};\ldots;\boldsymbol{p}'_{N'},n'_{N'\pm};\lambda_0\rangle\\ \times\langle \boldsymbol{p}'_1,n'_{1\pm};\ldots;\boldsymbol{p}'_{N'},n'_{N'\pm}|\hat{S}|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle.\end{aligned}$$

This shows how $\hat{S}|\boldsymbol{p}_1,n_{1\pm};\ldots;\boldsymbol{p}_N,n_{N\pm};\lambda_0\rangle$ is a superposition of possible out states, with the square

of the scattering amplitude, Eq. (59), giving the probability of a particular out state for a particular in state.

Next, use Eqs. (49) and (50) in Eq. (22) to write the propagator as

$$\Delta(x-x_0)=\theta(x^0-x_0^0)[\hat{\psi}(x,n_+),\hat{\psi}^\ddagger(x_0,n_+)]+\theta(x_0^0-x^0)[\hat{\psi}(x_0,n_-),\hat{\psi}^\ddagger(x,n_-)]. \tag{61}$$

Then, reversing the usual derivation for Feynman diagrams (see, for example, Ref. 42) gives the Dyson series expansion

$$\hat{S}=1+\sum_{n=1}^{\infty}\frac{(-i)^n}{n!}\int_{-\infty}^{\infty}\mathrm{d}t_1\int_{-\infty}^{t_1}\mathrm{d}t_2\cdots\int_{-\infty}^{t_{n-1}}\mathrm{d}t_n\hat{V}(t_1)\hat{V}(t_2)\cdots\hat{V}(t_n) \tag{62}$$

in terms of the *time-dependent interaction operator*

$$\hat{V}(t)\equiv g\int\mathrm{d}^3x\prod_{i=1}^{a}\hat{\Psi}^\ddagger(t,\mathbf{x},n_i')\prod_{j=1}^{b}\hat{\Psi}(t,\mathbf{x},n_j),$$

where

$$\hat{\Psi}(x,n)\equiv\hat{\psi}(x,n_+)+\hat{\psi}^\ddagger(x,n_-). \tag{63}$$

Since $\hat{V}(t)$ represents an interaction with the same number of incoming and outgoing particles, of the same types, as $\hat{V}$, the self-adjointness of $\hat{V}$ implies the self-adjointness of $\hat{V}(t)$, from which it can be shown that $\hat{S}$ is unitary. The case of a self-adjoint effective field $\hat{\psi}'(x,n)$ in $\hat{V}$ (as discussed at the end of Sec. III A) corresponds to the requirement of self-adjointness for $\hat{\Psi}(x,n)$. As can be seen from Eq. (63), this requirement implies that particles of type n are indistinguishable from their (path-reversed) antiparticles (indeed, a working definition of "indistinguishable" in this sense might very well be "cannot be distinguished by any interaction").

D. Regularization and renormalization

Of course, the development given in the previous subsections is actually only formal, because of the usual problems with divergence of the series in Eq. (52). As in conventional field theory, it is necessary to regularize infinite integrals and renormalize the resulting amplitudes. For a first-quantized approach, though, these problems seem particularly severe, since Eq. (52) is taken as the fundamental definition for the interacting amplitude, rather than as a perturbation expansion.

Fortunately, there is a relatively straightforward way to approach regularization within the context of a spacetime path approach, inspired by the work of Frastai and Horwitz[37] (see also Refs. 54 and 55 for a similar approach in the context of off-shell electrodynamics). This is to make the interaction coupling dependent on the intrinsic path length. This can be naturally introduced into the spacetime path formalism by making a choice for the weight function $f(T)$ introduced in Sec. II A different than $f(T)=1$.

To see this, consider that replacing the field operator $\hat{\psi}(x,n)$ defined in Eq. (45) with

$$\hat{\psi}_f(x,n)\equiv\int_{\lambda_0}^{\infty}\mathrm{d}\lambda f(\lambda-\lambda_0)\hat{\psi}(x,n;\lambda)$$

gives the commutation relation

$$[\hat{\psi}_f(x',n),\hat{\psi}^\dagger(x,n;\lambda_0)]=\int_0^\infty \mathrm{d}T f(T)\Delta(x'-x;T),$$

resulting in a propagator including the weight factor $f(T)$. Using this new field operator for, say, particles of type n_A in the interaction vertex operator given in Eq. (54) produces the desired path-length-dependent coupling

$$\hat{V}=g\int \mathrm{d}^4x\int_{\lambda_0}^\infty \mathrm{d}\lambda f(\lambda-\lambda_0)\hat{\psi}^\dagger(x,n_A;\lambda_0)\hat{\psi}(x,n_A;\lambda)\hat{\psi}'(x,n_B). \tag{64}$$

For the purposes of the present section, an appropriate choice for $f(\lambda-\lambda_0)$ is the Gaussian

$$f(\lambda-\lambda_0)=\mathrm{e}^{-(\lambda-\lambda_0)^2/2\Delta\lambda^2},$$

where $\Delta\lambda$ is a *correlation length*. For $\Delta\lambda\to\infty$, $f(\lambda-\lambda_0)\to 1$, and Eq. (64) reduces to Eq. (54).

Now, consider again the self-interaction term from Eq. (55). Using the interaction vertex operator from Eq. (64), this becomes

$$\Delta_A(p)\int \mathrm{d}^4p'\int_{\lambda_0}^\infty \mathrm{d}\lambda_1\int_{\lambda_0}^\infty \mathrm{d}\lambda_2 f(\lambda_2-\lambda_0)\Delta_A(p';\lambda_2-\lambda_0)f(\lambda_1-\lambda_0)\Delta_B(p-p')\Delta_A(p;\lambda_1-\lambda_0).$$

For simplicity, the momentum representation has been used here, in which

$$\Delta_A(p;\lambda-\lambda_0)\equiv \mathrm{e}^{-i(\lambda-\lambda_0)(p^2+m_A^2)}$$

and

$$\Delta_A(p)\equiv\int_0^\infty \mathrm{d}T\Delta_A(p;T)=-i(p^2+m_A^2-i\varepsilon)$$

(and similarly for Δ_B). The propagator from λ_0 to λ_1 is not divergent, so we can let $f(\lambda_1-\lambda_0)\to 1$, giving $\Delta_A(p)T'(p)\Delta_A(p)$, where

$$T'(p)\equiv\int \mathrm{d}^4p'\int_{\lambda_0}^\infty \mathrm{d}\lambda f(\lambda-\lambda_0)\Delta_A(p';\lambda-\lambda_0)\Delta_B(p-p'). \tag{65}$$

Inserting Eq. (13) into Eq. (65) gives

$$T'(p)=\int \mathrm{d}m^2T(p;m^2)F(m^2), \tag{66}$$

where

$$T(p;m^2)\equiv\int \mathrm{d}^4p'\Delta(p';m^2)\Delta_B(p-p')$$

is the unregulated self-interaction amplitude (without the external legs), with

$$\Delta(p;m^2)\equiv\int_0^\infty \mathrm{d}\lambda'\mathrm{e}^{-i\lambda'(p^2+m^2)}=-i(p^2+m^2-i\varepsilon), \tag{67}$$

and

$$F(m^2) \equiv (2\pi)^{-1} \int_0^\infty d\lambda e^{i\lambda(m^2 - m_A^2)} f(\lambda).$$

The unregulated quantity $T(p;m_A^2)$ is divergent. However, Eq. (66) is exactly the Pauli-Villars regularization prescription in continuous form.[56] Adjust the Fourier transform of the coefficients $F(m^2)$ so that

$$\tilde{F}(\lambda) = \begin{cases} f(\lambda) e^{-i\lambda m_A^2}, & \text{if } \lambda > \delta; \\ 0, & \text{if } \lambda \leqslant \delta. \end{cases}$$

This then meets the Pauli–Villars conditions in Fourier space for cancellation of singularities:[10] $\tilde{F}(0)=0$ and $\tilde{F}'(0)=0$. For $\Delta\lambda \to \infty$ and $\delta \to 0$, $T'(p)$ reduces to the unregulated quantity $T(p;m_A^2)$. (For further discussion, see Ref. 37. In Refs. 54 and 55, a similar result is obtained for a photon mass spectrum cutoff for the renormalization of off-shell quantum electrodynamics.)

Once the divergent integrals have been regulated, one can apply the usual techniques of multiplicative renormalization in the context of the Feynman diagram formalism obtained in Sec. III B. However, further discussion of renormalization is beyond the scope of the present paper. An intriguing direction for future exploration is the development of a complete regularization and renormalization program based on a physically motivated formulation of spacetime interactions. This would be consistent with the first-quantized approach of considering the series expansion to be the primary representation of the physical situation of the scattering amplitude, rather than a perturbative approximation to a nonperturbative Lagrangian formulation.

A potentially more serious issue is whether, even after renormalization, series such as that in Eq. (52) converge at all. However, Dyson's classic argument against convergence[57] is based on the conception of traditional quantum electrodynamics, where such series result from perturbation expansion. In the present first-quantized formalism, Dyson's argument might simply imply that the traditional formalism, and arguments from it, are not always applicable.

Actually, it is not the convergence of series for probability amplitudes, such as Eq. (52), that is really important. Rather, the real issue is whether there is a well-defined limit as $N \to \infty$ for physically testable probabilities such as given by

$$\frac{|\langle \alpha_{\text{out}} | \hat{S}^{(N)} | \psi_{\text{in}} \rangle|^2}{\langle \psi_{\text{in}} | \hat{S}^{(N)\ddagger} \hat{S}^{(N)} | \psi_{\text{in}} \rangle},$$

where $\hat{S}^{(N)}$ is the result of summing Eq. (62) to Nth order, $|\psi_{\text{in}}\rangle$ is a properly normalized multiparticle in state and $|\alpha_{\text{out}}\rangle$ is a member of a complete basis for multiparticle out states. Quantities such as this for, say, QED produce values that agree with experiment for large N. If it turns out that they do diverge for very large N, this just means that there is some mechanism in the real universe that suppresses the interference effect of interaction graphs with very large N, producing a finite cutoff of the series in Eq. (62).

Indeed, from this perspective, the Lagrangian and Hamiltonian formulations could be viewed as the approximations, obtained by assuming the summing of series for $N \to \infty$. In the end, the problem of divergences might even be seen as an artifact of the conventional second-quantized Lagrangian formulation itself, rather than of its perturbation expansion. Clearly this is an area that bears continued exploration.

IV. CONCLUSION

Spacetime approaches to relativistic quantum mechanics have been developed along a number of different threads in the literature, from the early work on proper time formalisms by Schwinger and others,[8–10] to the equally early work of Stueckelberg[6,7] and the parametrized relativistic quantum theory it inspired,[12–16,18,36] to the path integral approach introduced by Feynman[4,11,17,52] and its application to quantum gravity,[19,21,25] to the worldline formalism obtained as the infinite-

tension limit of string theory[26–32] and its relation to the typically first-quantized approach to interaction taken in string theory.[50] The formalism presented in the previous sections can be seen as a foundation underlying all these approaches.

A particularly significant additional result is the derivation of on-shell particles and antiparticle states as the infinite time limit of free particle states. This provides a connection between off-shell parametrized spacetime quantum theories[33,37,41,58,59] and traditional on-shell quantum field theory. It also suggests the intriguing possibility that, while real particles are likely on-shell to a very high degree of approximation, there may be testable consequences to this approximation not being exact.

The foundation presented here provides a number of interesting avenues for exploration in future publications.

The approach can be readily extended to incorporate path integral representations for nonscalar particles.[60–64] It can also handle massless particles, though it is not so straightforward to deal properly with the resulting gauge symmetries[58] and non-Abelian interactions.

Further, an important payoff of the spacetime path formalism is the intuitive grounding it gives to the theory, as opposed to the somewhat arbitrary mathematical justifications for introducing fields in traditional quantum field theory. Moreover, the formalism for interacting spacetime paths provides interesting possibilities for addressing the issues of regularization and renormalization (which is all the more important because of the first-quantized nature of the formalism).

Finally, a natural interpretational framework for the formalism is the consistent histories approach to quantum theory.[65–69] Particle paths can be treated as fine-grained histories in the sense of this approach, with coarse-grained histories corresponding to the superposition of fine-grained states, including cosmological histories of the universe as a whole.[19,70–72]

For example, scattering probabilities can be considered to represent the probabilities of decohering alternative coarse-grained spacetime histories for the scattering process. Probabilities can even be given to decohering cosmological histories of the universe.[73] Such an interpretation also provides for a natural way to see how the macroscopic classical view of the universe emerges from the more detailed quantum description, rather than viewing quantum physics as a "quantization" of a classical description (see, for example, Ref. 74), just as one would wish from a foundational quantum theory.

ACKNOWLEDGMENTS

The author would like to thank George Baker for his encouragement on an early version of this work and express his great appreciation to Philip Johnson and Lawrence Horwitz for extensive comments and discussion on subsequent versions.

APPENDIX A: FORM OF THE PHASE FUNCTIONAL

Proposition: *The phase functional S must have the form*

$$S[\dot{q}] = \int_{\lambda_0}^{\lambda_1} d\lambda' L[\dot{q};\lambda'], \tag{A1}$$

where the parametrization domain for $\dot{q}$ *is* $[\lambda_0,\lambda_1]$ *and* $L[\dot{q};\lambda]$ *depends only on* $\dot{q}$ *and its higher derivatives evaluated at* λ.

Proof: In

$$S[\dot{q};\lambda',\lambda_0] = S[\dot{q};\lambda',\lambda] + S[\dot{q};\lambda,\lambda_0],$$

consider $\lambda' = \lambda + \delta\lambda$, for infinitesimal $\delta\lambda$:

$$S[\dot{q};\lambda+\delta\lambda,\lambda_0]=S[\dot{q};\lambda+\delta\lambda,\lambda]+S[\dot{q};\lambda,\lambda_0]\approx\delta\lambda\left.\frac{\partial S[\dot{q};\lambda',\lambda]}{\partial\lambda'}\right|_{\lambda'=\lambda}+S[\dot{q};\lambda,\lambda_0],$$

or

$$\frac{S[\dot{q};\lambda+\delta\lambda,\lambda_0]-S[\dot{q};\lambda,\lambda_0]}{\delta\lambda}\approx\left.\frac{\partial S[\dot{q};\lambda',\lambda]}{\partial\lambda'}\right|_{\lambda'=\lambda}.$$

Taking the limit $\delta\lambda\to 0$ then gives

$$\frac{\partial S[\dot{q};\lambda,\lambda_0]}{\partial\lambda}=L[\dot{q};\lambda], \tag{A2}$$

where

$$L[\dot{q};\lambda]\equiv\left.\frac{\partial S[\dot{q};\lambda',\lambda]}{\partial\lambda'}\right|_{\lambda'=\lambda}.$$

Now, the functional L depends only on $\dot{q}$ and λ, not λ_0. Therefore, integrate Eq. (A2) over λ, with the initial condition $S[\dot{q};\lambda_0,\lambda_0]=0$, to get

$$S[\dot{q};\lambda,\lambda_0]=\int_{\lambda_0}^{\lambda}d\lambda' L[\dot{q};\lambda'], \tag{A3}$$

which is just Eq. (A1).

Further, by definition $S[\dot{q};\lambda,\lambda_0]$ only depends on values of $\dot{q}^\mu$ between λ_0 and λ. Therefore, $S[\dot{q};\lambda+\delta\lambda,\lambda]\approx L[\dot{q};\lambda]\delta\lambda$ should only depend on $\dot{q}$ infinitesimally close to λ. As $\delta\lambda\to 0$, this effectively limits $L[\dot{q};\lambda]$ to depend only on $\dot{q}$ and its derivatives evaluated at λ.

APPENDIX B: EVALUATION OF THE PATH INTEGRAL

Proposition: *The path integral*

$$\Delta(x,x_0;[\lambda])=\eta[\lambda]\int \mathrm{D}^4q\,\delta^4(q(\lambda(1))-x)\,\delta^4(q(\lambda(0))-x_0)\exp\left(i\int_{\lambda_0}^{\lambda}d\lambda'\left[\tfrac{1}{4}\dot{q}^2(\lambda')-m^2\right]\right) \tag{B1}$$

may be evaluated to get

$$\Delta(x,x_0;[\lambda])=\Delta(x-x_0;\lambda-\lambda_0)\equiv(2\pi)^{-4}\int \mathrm{d}^4p\,\mathrm{e}^{ip(x-x_0)}\mathrm{e}^{-i(\lambda-\lambda_0)(p^2+m^2)}. \tag{B2}$$

Proof: The path integral in Eq. (B1) may be defined as

$$\Delta(x,x_0;[\lambda])=\lim_{N\to\infty}\bar{\Delta}^{(N)}(x,x_0;[\lambda]),$$

where

$$\bar{\Delta}^{(N)}(x,x_0;[\lambda])\equiv\bar{\eta}(\bar{\lambda}_0,\ldots,\bar{\lambda}_N)\int \mathrm{d}^4\bar{q}_0\cdots\mathrm{d}^4\bar{q}_N\,\delta^4(\bar{q}_N-x)\,\delta^4(\bar{q}_0-x_0)\exp\left(i\sum_{j=1}^{N}\Delta\bar{\lambda}_j\left(\tfrac{1}{4}\bar{q}_j^2-m^2\right)\right), \tag{B3}$$

$\bar{\eta}(\bar{\lambda}_0,\ldots,\bar{\lambda}_N)\to\eta[\lambda]$ as $N\to\infty$ and the N-point discrete approximations to the functions $\lambda(s)$ and $q(\lambda(s))$ are given by

$$\bar{\lambda}_j = \lambda(j/N)$$

and

$$\bar{q}_j = q(\bar{\lambda}_j), \tag{B4}$$

for $j=0,\ldots,N$. The λ integral is approximated by a summation with

$$\Delta\bar{\lambda}_j \equiv \bar{\lambda}_j - \bar{\lambda}_{j-1}$$

and

$$\dot{\bar{q}}_j \equiv (\bar{q}_j - \bar{q}_{j-1})/\Delta\bar{\lambda}_j, \tag{B5}$$

for $j=1,\ldots,N$.

To compute the path integral, insert the product of Gaussian integrals

$$\prod_{j=1}^{N} i\left(\frac{\Delta\bar{\lambda}_j}{\pi}\right)^2 \int \mathrm{d}^4\bar{p}_j \mathrm{e}^{-i\Delta\bar{\lambda}_j\bar{p}_j^2} = 1$$

into the N-point approximation of Eq. (B3) to get

$$\bar{\Delta}^{(N)}(x,x_0;[\lambda]) = \bar{\xi}(\bar{\lambda}_0,\ldots,\bar{\lambda}_N)\int \mathrm{d}^4\bar{q}_0\cdots\mathrm{d}^4\bar{q}_N \int \mathrm{d}^4\bar{p}_1\cdots\mathrm{d}^4\bar{p}_N \delta^4(\bar{q}_N - x)\,\delta^4(\bar{q}_0 - x_0)$$
$$\times \exp\left(i\sum_{j=1}^{N}\Delta\bar{\lambda}_j\left(-\bar{p}_j^2 + \tfrac{1}{4}\dot{\bar{q}}_j^2 - m^2\right)\right),$$

where

$$\bar{\xi}(\bar{\lambda}_0,\ldots,\bar{\lambda}_N) \equiv \left[\prod_{j=1}^{N} i\left(\frac{\Delta\bar{\lambda}_j}{\pi}\right)^2\right]\bar{\eta}(\bar{\lambda}_0,\ldots,\bar{\lambda}_N).$$

Inside the $\bar{p}_j$ integrals, make the change of variables $\bar{p}_j \to \bar{p}_j - (1/2)\dot{\bar{q}}_j$, so that

$$\sum_{j=1}^{N}\Delta\bar{\lambda}_j\left(-\bar{p}_j^2 + \tfrac{1}{4}\dot{\bar{q}}_j^2 - m^2\right) \to \sum_{j=1}^{N}\Delta\bar{\lambda}_j\left(-\bar{p}_j^2 + \bar{p}_j\cdot\dot{\bar{q}}_j - \tfrac{1}{4}\dot{\bar{q}}_j^2 + \tfrac{1}{4}\dot{\bar{q}}_j^2 - m^2\right) = \sum_{j=1}^{N}\Delta\bar{\lambda}_j[\bar{p}_j\cdot\dot{\bar{q}}_j - (\bar{p}_j^2 + m^2)]. \tag{B6}$$

Now, using Eq. (B5),

$$\sum_{j=1}^{N}\Delta\bar{\lambda}_j\bar{p}_j\dot{\bar{q}}_j = \sum_{j=1}^{N}\bar{p}_j\cdot(\bar{q}_j - \bar{q}_{j-1}) = \bar{p}_N\cdot\bar{q}_N - \bar{p}_1\cdot\bar{q}_0 - \sum_{j=1}^{N-1}(\bar{p}_{j+1} - \bar{p}_j)\cdot\bar{q}_j$$

(this is essentially just integration by parts within the approximation to the path integral). But, for each $\bar{q}_j$, $j=1,\ldots,N-1$,

$$\int \mathrm{d}^4\bar{q}_j \mathrm{e}^{-i(\bar{p}_{j+1}-\bar{p}_j)\bar{q}_j} = (2\pi)^4\delta^4(\bar{p}_{j+1} - \bar{p}_j),$$

so, integrating over the $\bar{p}_j$ for $j=2,3,\ldots,N$ gives $\bar{p}_{j+1}=\bar{p}_j$. Therefore,

$$\bar{\Delta}^{(N)}(x,x_0;[\lambda]) = \bar{\xi}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N) \int \mathrm{d}^4\bar{q}_0 \mathrm{d}^4\bar{q}_N \delta^4(\bar{q}_N - x)\,\delta^4(\bar{q}_0 - x_0) \int \mathrm{d}^4\bar{p}_1 (2\pi)^{4(N-1)} \mathrm{e}^{i\bar{p}_1(\bar{q}_N - \bar{q}_0)}$$
$$\times \exp\left(-i \sum_{j=1}^{N} \Delta\bar{\lambda}_j (\bar{p}_1^2 + m^2) \right) = (2\pi)^{-4} \bar{\zeta}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N) \int \mathrm{d}^4 p \mathrm{e}^{ip(x-x_0)} \mathrm{e}^{-i(\bar{\lambda}_N - \bar{\lambda}_0)(p^2+m^2)}, \tag{B7}$$

where

$$\bar{\zeta}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N) \equiv (2\pi)^{4N} \bar{\xi}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N) = \left[\prod_{j=1}^{N} i(4\pi\Delta\bar{\lambda}_j)^2 \right] \bar{\eta}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N).$$

Now set the normalization factor

$$\bar{\eta}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N) = \prod_{j=1}^{N} (-i)(4\pi\Delta\bar{\lambda}_j)^{-2}.$$

Then $\bar{\zeta}(\bar{\lambda}_0, \ldots, \bar{\lambda}_N) = 1$, so we can take the limit $N \to \infty$ of Eq. (B7) to get Eq. (B2).

(Received 13 June 2006; accepted 16 August 2006; published online 28 November 2006)

Choquet-Bruhat was the first to give a proper physical definition of covariant spinors, taking into account the reference system and treating them as equivalence classes defined from the transformation laws of the representatives when the reference system is changed. Recently, Rodriguez *et al.*[Int. J. Theor. Phys. **35**, 1849 (1996)] have adapted this procedure from covariant spinors to the case of algebraic and operator spinors. These approaches are restrained in the sense that the type of spinor is chosen from the beginning, and it does not admit a general formulation. In this paper, we present a unified definition that is valid for any type of the space of representation, being independent of its particular properties. In our formulation the three types of spinors appear as particular cases of the general definition. Moreover, we stick out the importance of the bilinear covariants in the definition of spinors. From this, we recognize a completely different kind of spinor, characterized by the different nature of their bilinears. The unnoticed difference between this last one, which we have called right-operator spinors, and the previous (left-)operator spinors has been motive of a long time discussion. © *2006 American Institute of Physics.*

I. INTRODUCTION

Usually, for the same physical concept or for the same (in some sense) mathematical object, there exist different mathematical formalizations or constructions. Naturally, these different formalizations lead to or are based on different interpretations for the meaning of the object involved. This typically occurs for the concept of *vector*. Indeed, the word "vector" is especially polysemous. It is used in many different frameworks, where the unique common property is that vectors are, or can be, represented by ordered sets of numbers. It is not our intention to be so general. We restrict ourselves to some geometric frameworks, where the notion of vector is referred to a directional physical magnitude. In this context, the concept of observer or reference system plays a fundamental role. Most definitions of vectors include the *transformation* properties of their representatives when there is a change of reference system. There exist also alternative definitions where the transformation properties do not form part of the definition, but are a consequence of the defining properties.[1]

In order to be more concrete, we can think on some typical vectorial spaces in classical physics or in relativity. For instance, the space of translations or velocities in a flat Euclidean space, or the tangent space of a differential manifold at a point. We can mention here three different definitions of the tangent space of a manifold: the equivalence class of curves that are tangent at the point, the derivatives of scalar fields and, elements of $\mathbb{R}^n$ subject to a *contravariant*

transformation under a change of coordinates.[2–5] Of these three definitions, only the third includes the transformation properties. But all three are equivalent in the sense that, after having established some identifications, each one can be deduced from each other. However, each formalization suggests a different idea of the object, facilitating or obstructing the intuition or the obtainment of some properties.

Standard identifications are the assimilation of reference systems with a basis in the vector space, with coordinates in a manifold, or with fields of tetrads. The description of vectors in a reference system is fundamental for its numerical manipulation and for its relationship with experimental measures. Nevertheless, vectors themselves can be thought as independent of the observer and manipulated conceptually by giving one symbol to it. In the case of a definition based on the transformation properties, a proper formalization is the following. Each vector is defined as an equivalence class given by the set of pairs formed by each of its representatives and its corresponding reference system. The transformation properties define, in fact, the equivalence relation.

The most usual manner of representing vectors in a reference system is by the collection of its n components. This means that the representative of the vector is an element of the Cartesian product of n copies of $\mathbb{R}$, denoted by $\mathbb{R}^n$. However, this is not the unique type of representatives that can be used. One example of this is the use of complex numbers or quaternions to represent vectors in a bidimensional or a tridimensional space.[6] Typically, the reason for using these other representations is the possibility of using computational properties of the space of representation, which has some meaning for the vectors considered. For instance, the multiplication by a phase in the complex plane generates the rotation of the bidimensional vectors represented. This is especially the case when the vector representation is aimed to be related with some spinorial representation, usually linked to a Clifford algebra.

There are at least two different ways of defining vectors through equivalence classes. One of them is unavoidably attached to the representation of vectors in a reference system by its components, $(v^1,\ldots,v^n)\in\mathbb{R}^n$, and seems to be the most extended formalization and conceptualization for representing vectors. The other way, although less common, has the merit that it can be generalized to other types of representations of vectors. Moreover, in our opinion, this alternative formalization involves a more physical idea of vectors, since it makes explicit the *representation map* between the space of vectors represented and the space in which the vectors are represented. The identification and comparison of these two different, but generally unnoticed, approaches is one of the goals of this paper.

The concept of spinor is intimately related with the representations of groups of isometries. From a group theoretical point of view, they are the space of representation of the double covering group, $\mathrm{Spin}_{p,q}$, of the orthogonal group $\mathrm{SO}(p,q)$. In this approach, the idea of a reference system has no place. But, from a physical point of view, spinors are always representatives in a given reference system. Thus, an important defining property of spinors is their transformation properties when changing the reference system. In this sense, a *physical* formalization of spinors has to follow a construction analogous to the one described for vectors: each spinor will be an equivalence class of pairs formed by each of its representatives and the corresponding *spinorial* reference system. Again, different spaces of representation can be considered to represent spinors. From this point of view, in the literature,[7–11,6,12,13] there are essentially three types of spinors: classical spinors, algebraic spinors, and operator spinors. The most known of them, and the first ones that were introduced, are what we have called *classical* spinors. (Classical spinors have been previously called *covariant spinors*.[10,14,11] But this name is not appropriate since the three of them have the same properties of covariance.) They are characterized by being represented with a *column matrix*, which is an ordered collection of real or complex numbers arranged to be used with the matrix product. Algebraic spinors are defined by representatives on a minimal left ideal of the corresponding Clifford algebra, $\mathcal{C}\ell_{p,q}$. Thus, instead of the matrix product, it is the Clifford product that is used to act on spinors. Operator spinors use as a space of representation the even Clifford subalgebra, $\mathcal{C}\ell^+_{p,q}$; thus it also uses the Clifford product. The even subalgebra corresponds to the linear extension of the spin group inside the Clifford algebra, $\mathrm{Spin}_{p,q}\subset\mathcal{C}\ell_{p,q}$. There always exists

a clear correspondence between classical and algebraic spinors in any dimension and signature. However, operator spinors are clearly defined only for three and four dimensions. For higher dimensions, their definition is controversial since they are nonequivalent to classical and algebraic spinors. The use of different spaces of representation allows us to use different algebraic operations to perform physically meaningful operations, like the obtainment of the bilinear observables. This also suggests different images of the meaning of spinors. In addition, it leads to different formulation of the physical equation of motion, as, for instance, the Dirac equation.[15,16,12,17,18] This implies the possibility of using different techniques to solve the equation.[19–22,3]

Choquet-Bruhat introduced,[23,24] to the best of our knowledge, the first clear formalization of spinors as equivalence classes of pairs containing the reference system. In this treatment only the classical spinors are considered and the definitions are strongly dependent on the space of representation used. The same mechanism has been recently adapted by Rodrigues *et al.*[10,11] to the definition of the other types of spinors: algebraic and operator spinors. However, in this formalization, the definition of the two types of spinors is also dependent on the space of representation, forcing us to state an independent definition for each one. One of our main goals in this paper is to present a unique definition valid for the three types of spinors, since the particular properties of the space of representation are not involved in the definition itself. (A seed work, developed by the authors, was presented by D. M. in Ref. 25.) Thus, the different types appear simply by particularizing to the desired space of representation.

The definition of spinors requires the introduction of a spinorial frame. This structure includes the vectorial reference system, but is more complex than this one. This complicates particularly the definition of spinors. In previous formalizations of spinors the definition of the spinorial frames is mixed with the definition of spinors themselves, making the structure more obscure. Besides, this definition of the spinorial frame is also representation dependent. In our presentation, the definition of the spinorial frames is independent of the definition of the spinors, and is also completely independent of any representation. This considerably clarifies the structure.

The physical content of spinors is, if not completely included, a least strongly linked to the bilinear observables that they define. In fact, except the phase of the spin, the value of the spinor can be recovered from the value of the bilinears.[26–28] The bilinears are scalars, vectors, and tensors, in general. Thus, the formalism used to define vectors affects the way in which spinors are treated. In particular, if vectors and spinors are defined as equivalence classes of objects containing a representative for each reference system, then the two equivalence relations must be compatible. The formula for a vectorial bilinear of the representative of a spinor, has as output the representative of a vector. Then, it is required that the operation is well defined when translated to the quotient spaces. This is usually expressed by demanding the *covariance* of the bilinear observables of a spinor. This fact implies that the equivalence relation defining spinors is not independent of the equivalence relation defining vectors.

In contrast, we must remark that this is not the unique framework in which the relationship between spinors and vectors can be understood. We have observed that in the literature[12,17,13,3] there exist two essentially different kinds of operator spinors, which we will call *left operator* and *right operator spinors*. The left operator spinors are the type mentioned above as simply *operator spinors*. Thus, their relationship with vectors follows the scheme described in the previous paragraph. On the contrary, right operator spinors follow a completely different scheme. Their bilinears are not the representatives of the vectors in the corresponding reference system, but the vectors themselves. For this reason they are not, and cannot be, embraced by the definition unifying the other three types. This new type of spinor involves a different conceptualization of the role of the spinors, and has been used before especially by Parra.[12] However, it has never been formalized, especially confronted with the other types of spinors. In our opinion, this unnoticed different conceptualization has been the origin of many endless discussions. A comparison from another point of view can be found in Ref. 29. In the last section we introduce and formalize right operator spinors and discuss the nature of their bilinears.

II. VECTOR PASSIVE TRANSFORMATIONS

Consider a vector $X \in \mathcal{A}$ and a basis $\Sigma \equiv \{e_I\}$ in a vector space $\mathcal{A}$. We can write the vector in the basis Σ as $X = X^I e_I$. Another basis $\Sigma' \equiv \{e'_I\}$ is related to Σ by means of a linear transformation:

$$e'_I = M(e_I) = M^J{}_I e_J, \quad \text{where } M \in \mathrm{GL}(\mathcal{A}) \quad \text{and} \quad M^J{}_I \in \mathbb{R}(n). \tag{1}$$

This expression can be understood in two different ways:

- If the transformation is $M \in \mathrm{GL}(\mathcal{A})$, then two different changes of basis,

  $$e'_I = M(e_I) \quad \text{and} \quad e'''_I = N(e''_I),$$

  will be defined by the same transformation if $M = N \in \mathrm{GL}(\mathcal{A})$. This can be expressed in components

  $$e'_I = M^J{}_I e_J \quad \text{and} \quad e'''_I = N^{J''}{}_{I''} e''_J.$$

  The two transformations will be equal if $M^J{}_I = N^J{}_I$, but not if $M^J{}_I = N^{J''}{}_{I''}$, where $N^J{}_I$ is the transformation N written in the basis $\{e_I\}$ and $N^{J''}{}_{I''}$ is the same transformation N written in the basis $\{e''_I\}$.
- On the contrary, if we define the transformation by the matrix $M^J{}_I \in \mathbb{R}(n)$, then two different changes of basis,

  $$e'_I = M^J{}_{I'} e_J \quad \text{and} \quad e'''_I = N^{J''}{}_{I'''} e''_J,$$

  will be related by the same transformation if $M^J{}_{I'} = N^{J''}{}_{I'''}$.

These two clearly different ways of conceiving the basis transformation is the origin for correspondingly different ways of understanding vectors. As we will see, this difference also has implications in the manner of conceiving spinors. Observe that the different conceptualization affects also the meaning of the indices and, accordingly, the use of primes.

The two alternatives are explained in detail in Appendix. Our understanding of vectors corresponds to the first option, $M \in \mathrm{GL}(\mathcal{A})$, and will be the one followed in this paper. A more objective reason for this preference is that it is this unique one that can be generalized for any kind of space of representation. The second option is directly valid exclusively for the type of representation of vectors and spinors, which we call in this paper *Cartesian representation*, based on $\mathbb{R}^n$ (or $\mathbb{C}^n$) as a space of representation.

Now, we can relate the expression of X in Σ with its expression in Σ':

$$X = X^{I'} e'_I = X^{I'} M^J{}_I e_J = X^I e_I. \tag{2}$$

The last equality will be fulfilled iff $X^I = M^I{}_J X^{J'}$. It is important to make clear that the equal sign refers to the resulting expressions and not to them in a particular form. Thus, writing, for instance, $X^I e_I = X^{I'} e'_I$ does not mean that the components X^I and $X^{I'}$ are equal. Neither, writing $X = X^I e_I$ means that the vector X is attached to the reference frame $\{e_I\}$, or is necessarily expressed in it.

A. Cartesian representation

Let us denote by $\mathcal{B} \subset \mathcal{A}^n$ the set of basis of $\mathcal{A}$. The components of a vector in a particular basis, $\{X^I\}$, can be collected together as an element of $\mathbb{R}^n$. In order to make explicit the components and basis information in vectors, they can be displayed in an ordered pair,

$$X^I e_I \mapsto (\Sigma, \{X^I\}), \quad \text{where } \Sigma \equiv \{e_I\} \in \mathcal{B} \quad \text{and} \quad \{X^I\} \in \mathbb{R}^n. \tag{3}$$

In the set collecting all these pairs, $\mathcal{B} \times \mathbb{R}^n$, we can define the following equivalence relation:

$$\mathcal{R}_c:(\Sigma,\{X^I\}) \sim (\Sigma',\{Y^I\}) \Leftrightarrow \exists\, M \in \mathrm{GL}(\mathcal{A}) | \Sigma' = M\Sigma, \quad X^I = M^I{}_J Y^J, \tag{4}$$

where M^IJ are the components of the transformation M in the basis Σ. (They coincide with the components in Σ': $M^I{}_J = M^{I'}{}_{J'}$.) This implies that two pairs, $(\Sigma,\{X^I\})$ and $(\Sigma',\{Y^I\})$, are equivalent when they *generate* the same vector, i.e., $X^I e_I = Y^I e'_I$. Let us denote the equivalence class associated to the vector X by the symbol $[X]$. Then, the elements of $[X]$ are the *Cartesian representatives* of X. If the first element of a Cartesian representative pair is the basis Σ it is said the *representative in the basis* Σ. A *passive transformation* of a vector X is indeed a transformation from a representative to another, for the same vector X, i.e., a mapping between elements of the equivalence class $[X]$. On the contrary an *active transformation* is a correspondence between vectors (or between equivalence classes), where the concept of representative is not involved.

Let us observe that the equivalence relation (4) is based on considering the basis transformation $M \in \mathrm{GL}(\mathcal{A})$, and it involves the obtainment of the components of M in the basis Σ. Probably this is not the most popular formalization, which would be based on considering the transformation given by $M \in \mathbb{R}(n)$. The corresponding equivalence relation is

$$\mathcal{R}'_c:(\Sigma,\{X^I\}) \sim (\Sigma',\{Y^I\}) \Leftrightarrow \exists\, M \in \mathbb{R}(n) | e'_I = M^J{}_I e_J, \quad X^I = M^I{}_J Y^J. \tag{5}$$

Here $M^I{}_J$ are the components of the matrix $M \in \mathbb{R}(n)$ in the canonical basis of $\mathbb{R}(n)$, which is well defined and completely independent of the vector space $\mathcal{A}$ and the basis Σ and Σ'.

As commented above, this latter formalization (5) is fully attached to the representation of vectors in the space $\mathbb{R}^n$. Therefore, it can hardly be generalized for other representation spaces. However, the former formalization (4) is generalizable for using any vectorial space $\hat{\mathcal{A}}$ as the representation space. This generalization will be called the *vectorial representation* of vectors.

B. Vectorial representation

Let us consider a generic vector space $\hat{\mathcal{A}}$, with the same required properties as $\mathcal{A}$ (of the same dimension over the same field of scalars) but completely independent of it and devoided of any physical or geometrical meaning. It will play the same role as $\mathbb{R}^n$ in the Cartesian representation. Until now, only linear properties of $\mathcal{A}$ have been considered. But later the inclusion of a suitable geometric algebra for the linear space $\mathcal{A}$ will be essential.

Let $\mathcal{B}$ be the set of basis of $\mathcal{A}$. We establish the *representation function* as

$$f:\mathcal{B} \times \mathcal{A} \to \hat{\mathcal{A}}; \quad (\Sigma,X) \mapsto f(\Sigma,X) \equiv f_\Sigma(X),$$

where $f_\Sigma : \mathcal{A} \to \hat{\mathcal{A}}$ is a 1–1 mapping. We will interpret $f_\Sigma(X) \in \hat{\mathcal{A}}$ as a linear representation of $X \in \mathcal{A}$, as seen from the reference frame $\Sigma \in \mathcal{B}$. Then, considering the vectors X, Y and the linear frames Σ, Σ' related by the same linear active transformation $Y = M(X)$ and $\Sigma' = M(\Sigma)$, it seems natural to require that $f_\Sigma(X) = f_{\Sigma'}(Y)$. By linearity, this is equivalent to the condition

$$f_\Sigma(\Sigma) = f_{\Sigma'}(\Sigma'), \text{ or using composition } f_\Sigma = f_{\Sigma'} \circ M. \tag{6}$$

Note that this appoints a privileged basis in the generic space $\hat{\mathcal{A}}$,

$$\{\hat{e}_I\} \equiv \hat{\Sigma}_0 \equiv f_\Sigma(\Sigma). \tag{7}$$

Following the same structure as for the Cartesian representation, we define for the pairs $(\Sigma, \hat{X}) \in \mathcal{B} \times \hat{\mathcal{A}}$ the equivalence relation

$$\mathcal{R}_v:(\Sigma,\hat{X}) \sim (\Sigma',\hat{Y}) \Leftrightarrow f_\Sigma^{-1}(\hat{X}) = f_{\Sigma'}^{-1}(\hat{Y})$$

$$\text{or equivalently, } \Leftrightarrow \hat{Y} = f_{\Sigma'} \circ f_\Sigma^{-1}(\hat{X}) \equiv \hat{M}^{-1}(\hat{X}), \tag{8}$$

where $\hat{M}:\hat{\mathcal{A}} \to \hat{\mathcal{A}}$ is the endomorphism in $\hat{\mathcal{A}}$ corresponding to $M:\mathcal{A} \to \mathcal{A}$, as seen by the basis Σ or Σ':

$$\hat{M} = f_\Sigma \circ M \circ f_\Sigma^{-1} = f_{\Sigma'} \circ M \circ f_{\Sigma'}^{-1}.$$

This equivalence relation guarantees that two pairs $\mathbf{(\Sigma, f_\Sigma(X))}$ and $\mathbf{(\Sigma', f_{\Sigma'}(Y))}$ are equivalent iff $X=Y \in \mathcal{A}$.

It is interesting to note that taking $\hat{\mathcal{A}}=\mathbb{R}^n$ as the generic vector space, we recover the Cartesian representation. In this case, since $\mathbb{R}^n$ has a privileged *canonical basis*,

$$\hat{e}_1 = (1,0,\ldots,0), \quad \hat{e}_2 = (0,1,0,\ldots,0), \quad \ldots, \quad \hat{e}_n = (0,\ldots,0,1),$$

there exists a *canonical* representation function such that $f_\Sigma(\Sigma)=\{\hat{e}_I\}$, which implies that the representative of a vector $X \in \mathcal{A}$ in a basis $\Sigma=\{e_I\}$ is the collection of its components in this basis:

$$f_\Sigma(X) = f_\Sigma(X^I e_I) = X^I \hat{e}_I = (X^1, X^2, \ldots, X^n).$$

The introduction of the representation function f_Σ has two objectives. First, the generalization of the type of representatives considered for vectors and especially, as we will see, for spinors. Second, to make explicit that, even in the Cartesian representation, a concrete representation function is present, although it is concealed in the standard formalizations. This gives a more clear understanding of the representation of vectors.

III. CLIFFORD ALGEBRA AND SPIN GROUP

In the previous section we have treated the representation of vectors without considering any metric. Let us now consider the vectorial space $\mathcal{A}$ endowed with a nondegenerate metric g of signature (p,q) and the generic vectorial space also endowed with a metric $\hat{g}$ of the same signature. We will restrict ourselves to representation functions $f_\Sigma:\mathcal{A} \to \hat{\mathcal{A}}$ that are isometries,

$$g(a,b) = \hat{g}(f_\Sigma(a), f_\Sigma(b)).$$

The vector space $\mathcal{A}$ generates via the exterior product the exterior or Grassmann algebra $\wedge(\mathcal{A})$. When endowed with the metric g, it also generates the Clifford algebra $\mathcal{C}\ell_{p,q}$.[30] The two algebras share the same base linear space in such a way that the exterior product and the graduation of the exterior algebra is many times considered as an ingredient of the Clifford algebra. Analogously the generic $(\hat{\mathcal{A}},\hat{g})$ results in the *generic Clifford algebra* $\widehat{\mathcal{C}\ell}_{p,q}$. The function f_Σ can be then extended to the full Clifford algebra space[17] via the outermorphism, defined by the property of being a morphism of exterior algebras:

$$f_\Sigma:\mathcal{C}\ell_{p,q} \to \widehat{\mathcal{C}\ell}_{p,q}; \quad f_\Sigma(A \wedge B) = f_\Sigma(A) \wedge f_\Sigma(B). \tag{9}$$

The fact that $f_\Sigma:\mathcal{A} \to \hat{\mathcal{A}}$ is an isometry implies that its extension (9) is also an isomorphism of Clifford algebras: $f_\Sigma(AB)=f_\Sigma(A)f_\Sigma(B)$. (For the sake of simplicity we will use the same symbol f_Σ.)

The *spin group* $\mathrm{Spin}_{p,q}$ is a subset of the even Clifford subalgebra $\mathcal{C}\ell^+_{p,q}$,

$$\mathrm{Spin}_{p,q} = \{R \in \mathcal{C}\ell^+_{p,q} | RvR^{-1} \in \mathcal{A}, \ \forall v \in \mathcal{A}, \ R\tilde{R} = \pm 1\}. \tag{10}$$

$\mathrm{Spin}_{p,q}$ is the double covering group of the group of isometries $\mathrm{SO}(\mathcal{A})$. Let us denote $\mathcal{H}$ the mapping that relates both groups,

$$\mathcal{H}:\mathrm{Spin}_{p,q} \to \mathrm{SO}(\mathcal{A}); \quad R \mapsto \mathcal{H}(R), \tag{11}$$

where $\mathcal{H}(R) \in \mathrm{SO}(\mathcal{A})$ is the endomorphism,

$$\mathcal{H}(R):\mathcal{A} \to \mathcal{A}; \quad v \mapsto \mathcal{H}(R)(v) \equiv RvR^{-1}. \tag{12}$$

Analogously to (10), the *generic spin group* $\widehat{\mathrm{Spin}}_{p,q}$ is defined as the corresponding subset of the generic even Clifford subalgebra $\widehat{\mathcal{C}\ell}^{+}_{p,q}$. The restriction of $f_\Sigma:\mathcal{C}\ell_{p,q} \to \widehat{\mathcal{C}\ell}_{p,q}$ to the subset $\mathrm{Spin}_{p,q} \subset \mathcal{C}\ell_{p,q}$ is a group isomorphism that maps it to the generic $\widehat{\mathrm{Spin}}_{p,q}$,

$$f_\Sigma:\mathrm{Spin}_{p,q} \to \widehat{\mathrm{Spin}}_{p,q}; \quad f_\Sigma(R_1R_2) = f_\Sigma(R_1)f_\Sigma(R_2), \quad \forall\, R_1, R_2 \in \mathrm{Spin}_{p,q}.$$

We can also define the function $\hat{\mathcal{H}}:\widehat{\mathrm{Spin}}_{p,q} \to \mathrm{SO}(\hat{\mathcal{A}})$, where $\mathrm{SO}(\hat{\mathcal{A}}) \equiv \widehat{\mathrm{SO}}$, as the generic copy of (11) and (12).

IV. SPINORS AND SPINORIAL FRAMES

Using equivalence classes as presented above for vectors, we will introduce spinors following the well exposed presentation by Choquet-Bruhat found in Ref. 24. However, there, it has only been considered a type of linear space representation for spinors, which here we call *classical*. Recently, in Ref. 10 the Choquet-Bruhat presentation has been extended to other linear spaces of representation in order to connect with *algebraic and operator spinors*. Our presentation intends to be general in the sense that we do not fix a concrete linear space in the definition. Our discussion will allow us to contrast the three different cases mentioned above and give their relationships in this geometrical frame.

Let us consider a linear space S over which we have defined a left operation of the group $\widehat{\mathrm{Spin}}_{p,q}$:

$$\alpha:\widehat{\mathrm{Spin}}_{p,q} \times S \to S; \quad (\hat{R}, \psi) \mapsto \alpha(\hat{R}, \psi) \equiv \alpha_{\hat{R}}(\psi),$$

satisfying the property

$$\alpha(\hat{R}_1, \alpha(\hat{R}_2, \psi)) = \alpha(\hat{R}_1\hat{R}_2, \psi).$$

This product constitutes a representation of the group $\widehat{\mathrm{Spin}}_{p,q}$:

$$\tilde{\alpha}:\widehat{\mathrm{Spin}}_{p,q} \to \mathrm{End}(S); \quad \tilde{\alpha}(\hat{R}) \equiv \alpha_{\hat{R}}.$$

The space S is called *the space of representation*. The elements of this space, $\psi \in S$, are usually named *spinors*. However, this naming hides the fact that ψ is only the *representative* of the spinor in some *spinorial frame* Σ_S. A rigorous definition needs to specify how the representative ψ transforms when the spinorial frame is transformed.

Following the presentation of Ref. 24, a first attempt to define spinors is introducing them as equivalence classes of dyads where orthonormal vectorial frames are used as spinorial frames. If $\mathcal{B}_0 \subset \mathcal{B}$ is the set of proper[1] orthonormal basis of $\mathcal{A}$ then the dyads would be of the form

$$(\Sigma, \psi), \quad \text{where} \quad \Sigma = \{e_I\} \in \mathcal{B}_0 \quad \text{and} \quad \psi \in S.$$

The equivalence class would be defined by

$$(\Sigma, \psi) \sim (\Sigma', \psi') \Leftrightarrow \exists\, R \in \mathrm{Spin}(\mathcal{A}), \text{ so that } \Sigma' = \mathcal{H}(R)\Sigma \text{ and } \psi = \alpha(f_\Sigma(R), \psi').$$

This definition has as consequence that any two dyads of the form (Σ, ψ) and $(\Sigma, -\psi)$ are equivalent. This says that for the same observer Σ there are two possible representatives, ψ and $-\psi$, of

[1]Future and right-hand oriented.

the same spinor. This possibility is not usually considered. Instead, to avoid this problem the spinorial frame is introduced.

The spinorial frame will contain a vectorial frame Σ and a sign to distinguish the two representatives ψ and $-\psi$. The equivalence relation should allow us to relate different representatives continuously, while signs form a discrete set $\{+,-\}$. For this reason, the standard definition of the spinorial frame introduces a more sophisticated structure.

Definition 4.1: Any element (Σ,R) *of the set* $\mathcal{B}_0\times \mathrm{Spin}_{p,q}$ *will be called a* potential spinorial frame.

They have been called "potential" because this set contains much more elements than needed. The proper set of spinorial frames will be a restriction of this one.

Definition 4.2: Two potential spinorial frames are said to be compatibles *if they satisfy the equivalence relation*:

$$\mathcal{C}:(\Sigma,R)\bowtie(\Sigma',R')\Leftrightarrow \mathcal{H}(R'^{-1})\Sigma'=\mathcal{H}(R^{-1})\Sigma\equiv\Sigma_0,$$

where each compatibility class is characterized by a fiducial vectorial frame Σ_0, *since in every class there is a unique element of the form* $(\Sigma_0,1)$.

Each *compatibility* class is an element of the quotient set $(\mathcal{B}_0\times \mathrm{Spin}_{p,q})/\mathcal{C}$, which defines a foliation. The proper set of spinorial frames is the restriction of $\mathcal{B}_0\times \mathrm{Spin}_{p,q}$ to a chosen compatibility class. Observe that in each compatibility class $\mathcal{F}\in(\mathcal{B}_0\times \mathrm{Spin}_{p,q})/\mathcal{C}$, for every vectorial frame $\Sigma\in\mathcal{B}_0$, there are two and only two elements and they are different only by a change of sign: $(\Sigma,R)\bowtie(\Sigma,-R)$, that is,

$$\forall\Sigma\in\mathcal{B}_0\quad \exists\,!\,R\in \mathrm{Spin}_{p,q}\quad \text{(up to a sign), such that}\quad (\Sigma,R),(\Sigma,-R)\in\mathcal{F}.$$

Definition 4.3: The set of spinorial frames $\mathcal{F}$ *is a chosen element* $\mathcal{F}\in(\mathcal{B}_0\times \mathrm{Spin}_{p,q})/\mathcal{C}$.

Let us emphasize that the set of spinorial frames is NOT the quotient space, $\mathcal{F}\neq(\mathcal{B}_0\times \mathrm{Spin}_{p,q})/\mathcal{C}$, but only one equivalence class, $\mathcal{F}\in(\mathcal{B}_0\times \mathrm{Spin}_{p,q})/\mathcal{C}$. Thus, a spinorial frame is a single element of $\mathcal{B}_0\times \mathrm{Spin}_{p,q}$, and not an equivalence class. (Obviously, a construction based on the quotient space as the set of spinorial frames would be a more elegant mathematical construction. Unfortunately, such a construction cannot be consistently defined for spinorial frames.)

The set $\mathcal{F}$ is usually defined equivalently[24] through the fiducial vectorial frame Σ_0. The election of the compatibility class $\mathcal{F}$ is completely arbitrary. The definition of spinors that results will be equivalent whatever set $\mathcal{F}$ is chosen, but they will be well defined only if one $\mathcal{F}$ is fixed from the beginning. This is usually worded by "the fiducial frame is arbitrary but fixed."

Finally, we can enunciate the general definition for spinors, independently of the space of representation used.

Definition 4.4: An α spinor *is a class of equivalence of the set* $\mathcal{F}\times S$ *defined by the equivalence relation*

$$\mathcal{R}_s:(\Sigma_S,\psi)\sim(\Sigma'_S,\psi')\Leftrightarrow \alpha(f_\Sigma(R),\psi)=\alpha(f_{\Sigma'}(R'),\psi'),\tag{13}$$

where $\Sigma_S=(\Sigma,R)$ *and* $\Sigma'_S=(\Sigma',R')$.

The original content of our presentation is triple.

- First, we have tried to clarify the structure. Observe that by definition $\Sigma_S,\Sigma'_S\in\mathcal{F}$, which implies that they are compatible (see Definition 4.2):

$$\Sigma'=\mathcal{H}(R'R^{-1})\Sigma.\tag{14}$$

  This condition has generally appeared[24,10] as part of the definition of spinors, without defining previously the set of spinorial frames $\mathcal{F}$. Then, the problem of the redundancy of spinorial frames in $\mathcal{B}_0\times \mathrm{Spin}_{p,q}$, is blended into the definition of spinors. In contrast, segregating the discussion of spinorial frames from the definition of spinors helps to clarify the two concepts.
- Second, from properties (14) and (6), we have

$$f_{\Sigma'} = f_{\Sigma} \circ \mathcal{H}(RR'^{-1}),$$

which applied to Definition 4.4 gives us the expression of the "spinorial transformation:"

$$\psi' = \alpha(f_{\Sigma}(RR'^{-1}), \psi). \tag{15}$$

In the original definition presented in Ref. 24 and adapted in Ref. 10, the representation function f_{Σ} is not present. In the original form[24] the transformation of orthonormal basis (or spinorial frames) is considered as a matrix $M \in \mathbb{R}(n)$ (in the sense discussed at the beginning of Sec. II), so that the representation function is not necessary for the mathematical construction. However, let us comment that the abstract formalization in Ref. 24 led us to forget some element, which makes the relation defining the equivalence classes to be not really an equivalence relation, as is proved and discussed in Appendix. This error can be considered almost a misprint, but it has caused some confusion, since then the formulation seems to be applicable trivially to other representation spaces. In Ref. 10, the authors follow this construction for defining algebraic and operator spinors, translating the (likely) misprint in a more serious error, since there the representation function cannot be avoided. This defect in the definition of spinors has deep implications, because it hides a real conceptual and mathematical necessity of the representation function.

- Third, in contrast with other treatments, we have not fixed any concrete representation α and f_{Σ}. This means that, by specializing Definition 4.4 for different representation spaces S, it includes every type of spinor discussed in the literature: classical, algebraic, and operator.

It must be said that recently Rodrigues in Ref. 11 improved correctly the presentation of Ref. 10 that had motivated our interest about spinorial reference frames. We observe, however, that his definition of algebraic spinors in Ref. 11 does not correspond to the definition of algebraic spinor given in the present paper. In fact, they are a kind of *right* algebraic spinors since the nature of their bilinear covariants must coincide with the ones of the right operator spinors presented in Sec. VI. Also, it is worth mentioning here that in Ref. 31 a rigorous presentation of left and right algebraic spinor fields and also Dirac-Hestenes spinor fields and a thoughtful discussion of the Dirac-Hestenes equation using the theory of fiber bundles is given for the first time.

A. Classical spinors

The most extended treatment of spinors is based on representations of the group $\mathrm{Spin}_{p,q}$ over the space of representation $S=\mathbb{C}^n$ or $\mathbb{R}^n$. This representation is realized by considering a set of $p+q$ matrices, $\{\gamma_\mu\} \subset \mathbb{C}(n)$ or $\mathbb{R}(n)$, generators of a matricial Clifford algebra:

$$\widehat{\mathcal{C}\ell}_{p,q} \equiv \mathrm{gen}\{\gamma_\mu\}, \quad \gamma_\mu\gamma_\nu + \gamma_\nu\gamma_\mu = 2\eta_{\mu\nu}\mathbf{1},$$

where $\eta_{\mu\nu}=\mathrm{diag}(\overset{p}{1,\ldots,1},\overset{q}{-1,\ldots,-1})$. These kinds of spinors will be called *classical spinors*. (The term *classical* has been employed because this is the first kind that was defined.[32,7] In addition, it is the only one that is considered by most groups in mathematics and theoretical physics.) The generic space is the vector space spanned by linear combinations of the generating matrices:

$$\hat{\mathcal{A}} \equiv \mathrm{span}\{\gamma_\mu\}.$$

Observe that for classical spinors, the generic spin group is a matricial group generated by the basis of matrices $\{\gamma_\mu\}$, $\widehat{\mathrm{Spin}}_{p,q}=\mathrm{Spin}\{\gamma_\mu\} \subset \mathbb{R}(n)$ or $\mathbb{C}(n)$.

A typical example is the case of Dirac matrices[7] $\{\gamma_0^D, \gamma_1^D, \gamma_2^D, \gamma_3^D\}$ with the representation function defined by this basis $\{\gamma_\mu^D\}=\hat{\Sigma}_0=f_{\Sigma}(\Sigma)$, that is,

$$\gamma_\nu^D = f_{\{e_\mu\}}(e_\nu), \quad \forall \{e_\mu\} \in \mathcal{B}_0.$$

Example 4.1: A classical Pauli spinor *is a* $\mathcal{P}$ *spinor, where*

$$\mathcal{P}:\mathrm{Spin}\{\sigma_i\}\times\mathbb{C}^2\to\mathbb{C}^2,\quad \mathcal{P}(\hat{R},\psi)=\hat{R}\psi,$$

where $\hat{R}\psi$ *denotes the standard matrix product and* σ_i *are the usual Pauli matrices*[7] *for the algebra* $\mathcal{C}\ell_{3,0}$. *Note that* $\mathrm{Spin}\{\sigma_i\}=\mathrm{SU}(2)$.

Example 4.2: A classical Dirac spinor *is a* $\mathcal{D}$ *spinor*, *where*

$$\mathcal{D}:\mathrm{Spin}\{\gamma_\mu^D\}\times\mathbb{C}^4\to\mathbb{C}^4,\quad \mathcal{D}(\hat{R},\psi)=\hat{R}\psi,$$

where γ_μ^D *are the usual Dirac matrices*[7] *for the algebra* $\mathcal{C}\ell_{1,3}$.

B. Algebraic spinors

Let us consider the generic Clifford algebra $\widehat{\mathcal{C}\ell}_{p,q}$ over the field $\mathbb{K}=\mathbb{R}$ or $\mathbb{C}$, denoted by $\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{K})$. In general, the vector space $\hat{\mathcal{A}}$ is real, thus the natural Clifford algebra would be $\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{R})$. However, we will consider in some cases its complexification $\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{C})\equiv\mathbb{C}\otimes\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{R})$, although the vector space $\hat{\mathcal{A}}$ is still considered real. Let us also consider a minimal left-ideal $\hat{\mathcal{I}}$ of $\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{K})$. Then, the restriction of the regular representation into the minimal left-ideal $\hat{\mathcal{I}}$ is an irreducible representation of $\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{K})$:

$$\mathcal{L}_{p,q}^{\hat{\mathcal{I}}(\mathbb{K})}:\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{K})\times\hat{\mathcal{I}}\to\hat{\mathcal{I}},\quad (\hat{C},\hat{\psi})\mapsto\mathcal{L}_{p,q}^{\hat{\mathcal{I}}(\mathbb{K})}(\hat{C},\hat{\psi})=\hat{C}\hat{\psi},$$

where $\hat{C}\hat{\psi}$ denotes the Clifford product between $\hat{C}$ and $\hat{\psi}$.

The concept of algebraic spinors is based on considering a minimal left-ideal $\hat{\mathcal{I}}\subset\widehat{\mathcal{C}\ell}_{p,q}$, as the representation space S of spinors. Notice that using this representation for spinors is possible because any representation of the algebra $\widehat{\mathcal{C}\ell}_{p,q}$ is also a representation of the group $\widehat{\mathrm{Spin}}_{p,q}$, since this group is a subset of $\widehat{\mathcal{C}\ell}_{p,q}$.[33] (For Weyl spinors, a representation of only the even subalgebra is used instead. It sufices since $\widehat{\mathrm{Spin}}_{p,q}\subset\widehat{\mathcal{C}\ell}^+_{p,q}$. However, this restriction is the reason for which the parity operator cannot be included in the representation.)

If a matrix representation is used as the generic Clifford algebra $\widehat{\mathcal{C}\ell}_{p,q}(\mathbb{K})$, then the most typical example of representation space is provided by the left ideal $\hat{\mathcal{I}}$ consisting in the matrices with all the elements vanishing except the first column,

$$\hat{\mathcal{I}}=\left\{\left.\begin{pmatrix} m_{11} & 0 & \cdots & 0\\ m_{21} & 0 & \cdots & 0\\ \vdots & \vdots & & \vdots\\ m_{n1} & 0 & \cdots & 0\end{pmatrix}\right| m_{A1}\in\mathbb{K}\right\},$$

which is clearly isomorphic to the space of classical spinors, $S=\mathbb{K}^n$.

Example 4.3: An algebraic Pauli spinor is a $\mathcal{L}_{3,0}^{\hat{\mathcal{I}}(\mathbb{R})}$ *spinor. The typical case is obtained by considering the left ideal* $\hat{\mathcal{I}}=\widehat{\mathcal{C}\ell}_{3,0}P$ *generated by the idempotent* $P=\frac{1}{2}(1+\hat{e}_3)$. *Note that this privileges one vector in the generic space*, *which*, *in turn*, *privileges one direction*, $e_3=f_\Sigma^{-1}(\hat{e}_3)$, *for each reference frame* Σ.

Example 4.4: An algebraic Dirac spinor *is a* $\mathcal{L}_{1,3}^{\hat{\mathcal{I}}(\mathbb{C})}$ *spinor. The left ideal usually considered is generated by the idempotent* $\frac{1}{2}(1+\hat{e}_0)\frac{1}{2}(1+i\hat{e}_{12})$.

A very clear exposition treating deeply these kind of spinors can be found in Ref. 6.

C. Left operator spinors

As we commented on in the Introduction, we have found that, depending on the author the name of operator spinor is used for two objects of a different nature. And this difference is not remarked by the authors.

One of these two kinds of objects is embraced by Definition 4.4 and we will call them *left operator spinors*. In fact, this reflects that, beyond the representation space on which they are based, left operator spinors share with classical and algebraic spinors the same notion for the covariance of the bilinears, as we will see in the next section.

The other kind of operator spinors, which we will call *right operator spinor*, cannot be included in Definition 4.4 since their bilinears are of a totally different nature. These spinors will be studied in Sec. VI.

The representation space of left operator spinors is the real even subalgebra $S=\widehat{\mathcal{C}\ell}^{+}_{p,q}(\mathbb{R})$, on which the regular representation of itself, as an algebra on its own, is considered:[2]

$$\mathcal{L}^{+}_{p,q}:\widehat{\mathcal{C}\ell}^{+}_{p,q}\times\widehat{\mathcal{C}\ell}^{+}_{p,q}\to\widehat{\mathcal{C}\ell}^{+}_{p,q};\quad(\hat{C},\hat{\psi})\mapsto\mathcal{L}^{+}_{p,q}(\hat{C},\hat{\psi})\equiv\hat{C}\hat{\psi}$$

where $\hat{C}\hat{\psi}$ implies the Clifford product between them.

Example 4.5: A left operator Pauli *spinor is a* $\mathcal{L}^{+}_{3,0}$ *spinor.*

Example 4.6: A left operator Dirac spinor *is a* $\mathcal{L}^{+}_{1,3}$ *spinor. This operator spinor is usually known as Dirac-Hestenes spinor.*[13]

V. BILINEAR COVARIANTS

Physically, the bilinear covariants (scalars, vectors or tensors) are the observables of a spinor or spinor field. This fact implies, in particular, that the meaning that we attach to spinors is intimately tied to their bilinear covariants. In this section we will describe how the bilinear covariants of the three classes—classical, algebraic, and left-operator spinors—are obtained.

Given their physical relevance, we will concentrate in the case of the Dirac spinors. This case is sufficiently representative to illustrate the mechanisms involved in, and the differences between the three classes of spinors. Even more concretely, we will only consider the density current, i.e., the bilinear vector J. The consideration of the other bilinears does not involve any qualitative difference.

Recall that a spinor (Definition 4.4) is an equivalence class of pairs (Σ_S,ψ), where

$$\mathcal{R}_s:(\Sigma_S,\psi)\sim(\Sigma'_S,\psi')\Leftrightarrow\alpha(f_\Sigma(R),\psi)=\alpha(f_{\Sigma'}(R'),\psi').$$

In the definition of the equivalence relation $\mathcal{R}_s$, it is involved in the representation function f_Σ corresponding to a previously defined representation of vectors, given by the equivalence relation (see Sec. II B):

$$\mathcal{R}_v:(\Sigma,\hat{X})\sim(\Sigma',\hat{X}')\Leftrightarrow f^{-1}_{\Sigma}(\hat{X})=f^{-1}_{\Sigma'}(\hat{X}').$$

The key idea for the treatment of the bilinear covariants is that to each representative (Σ_S,ψ) of a spinor it corresponds to a representative of the observable, $(\Sigma,\hat{J})$, where $\hat{J}$ is constructed bilinearly from ψ. Then, the equivalence relation $\mathcal{R}_s$ for spinors induces an equivalence relation $\mathcal{R}_b$ between the representatives $(\Sigma,\hat{J})$ of observables. The covariant property of the bilinear $\hat{J}$ corresponds to the fact that the induced relation $\mathcal{R}_b$ coincides with the vectorial equivalent relation $\mathcal{R}_v$. Obviously, as we will see immediately, this requirement implies some condition on the bilinear function $\hat{J}(\psi)$.

Consider a representative of a spinor $((\Sigma,R),\psi)$. Its bilinear covariant $\hat{J}$ is defined as a quadratic function of ψ,

---

[2]For Weyl and Majorana spinors the *complete* regular representation is not used but it is used as a regular representation restricted to a particular left ideal:

$$\mathcal{L}^{+}_{p,q}|_{\hat{\mathcal{I}}}:\widehat{\mathcal{C}\ell}^{+}_{p,q}\times\hat{\mathcal{I}}\to\hat{\mathcal{I}},\quad\text{where}\quad\mathcal{L}^{+}_{p,q}|_{\hat{\mathcal{I}}}(\hat{C},\hat{\psi})\equiv\mathcal{L}^{+}_{p,q}(\hat{C},\hat{\psi})\ \ \forall\ \hat{\psi}\in\hat{\mathcal{I}}\subset\widehat{\mathcal{C}\ell}^{+}_{p,q}.$$

$$\hat{J} \equiv \hat{\beta}(\psi), \tag{16}$$

where $\hat{\beta}$ is independent of Σ and R. From the definition of an α spinor, two representatives are equivalent if and only if

$$\mathcal{R}_s:((\Sigma,R),\psi) \sim ((\Sigma',R'),\psi') \Leftrightarrow \Sigma' = \mathcal{H}(R'R^{-1})\Sigma \quad \text{and} \quad \psi' = \alpha_{\hat{R}}(\psi),$$

where $\hat{R} \equiv f_\Sigma(RR'^{-1})$. This induces the equivalence relation

$$\mathcal{R}_b:(\Sigma,\hat{J}) \sim (\Sigma',\hat{J}') \Leftrightarrow \hat{J} = \hat{\beta}(\psi), \quad \hat{J}' = \hat{\beta}(\psi') = \hat{\beta} \circ \alpha_{\hat{R}}(\psi). \tag{17}$$

The equivalence relation used to represent vectors is

$$\mathcal{R}_v:(\Sigma,\hat{J}) \sim (\Sigma',\hat{J}') \Leftrightarrow \hat{J}' = f_{\Sigma'} \circ f_\Sigma^{-1}(\hat{J}).$$

Since, here, the two vectorial frames are related by

$$\Sigma' = \mathcal{H}(R'R^{-1})\Sigma,$$

it follows that

$$f_{\Sigma'} = f_\Sigma \circ \mathcal{H}(RR'^{-1}) = \hat{\mathcal{H}}[f_\Sigma(RR'^{-1})] \circ f_\Sigma = \hat{\mathcal{H}}(\hat{R}) \circ f_\Sigma.$$

Hence

$$\mathcal{R}_v:(\Sigma,\hat{J}) \sim (\Sigma',\hat{J}'), \quad \Leftrightarrow \quad \hat{J}' = \hat{\mathcal{H}}(\hat{R})\hat{J}. \tag{18}$$

From expressions (17) and (18), we see that $\mathcal{R}_b$ and $\mathcal{R}_v$ are the same equivalence relation iff

$$\hat{\beta} \circ \alpha_{\hat{R}}(\psi) = \hat{\mathcal{H}}(\hat{R}) \circ \hat{\beta}(\psi), \quad \forall\, \psi \in S, \quad \forall\, R' \in \mathrm{Spin}_{1,3}.$$

That is, iff

$$\hat{\beta} \circ \alpha_{\hat{R}} = \hat{\mathcal{H}}(\hat{R}) \circ \hat{\beta}, \quad \forall\, \hat{R} \in \widehat{\mathrm{Spin}}_{1,3}. \tag{19}$$

We have found here the simplest expression for the condition of covariance for the bilinear $\hat{J} = \hat{\beta}(\psi)$. Let us check now that the three classes of Dirac spinors satisfy this condition.

Classical spinors: The bilinear covariant $\hat{J}$ is usually computed as[7]

$$\hat{J}_\mu = \bar{\psi}\gamma_\mu^D\psi = \psi^\dagger\gamma_0^D\gamma_\mu^D\psi,$$

where $\hat{J} \in \mathbb{R}^4$ and $\{\hat{J}_\mu\}$ are its four components. Here we must make a remark. For the definition of classical Dirac spinors we considered as generic space the linear space spanned by the four Dirac generating matrices $\hat{\mathcal{A}} = \mathrm{span}\{\gamma_\mu^D\}$, instead of the space $\mathbb{R}^4$. Then, as usually, for classical spinors we must consider $\hat{J}$ as *gammarized*,

$$\hat{\beta}(\psi) = \hat{J} = \hat{J}_\mu\gamma^{D\mu} = [\bar{\psi}\gamma_\mu^D\psi]\gamma^{D\mu} \in \hat{\mathcal{A}}.$$

Now we can check that (19) is satisfied,

$$\hat{\beta}[\mathcal{D}_{\hat{R}}(\psi)] = [\bar{\psi}\gamma_0^D\hat{R}^\dagger\gamma_0^D\gamma_\mu^D\hat{R}\psi]\gamma^{D\mu} = [\bar{\psi}\hat{R}^{-1}\gamma_\mu^D\hat{R}\psi]\gamma^{D\mu},$$

where we have used the property $\gamma_0^D\hat{R}^\dagger\gamma_0^D = \tilde{\hat{R}} = \hat{R}^{-1}$, where $\tilde{\ }$ denotes the reversion.[6] Using also that $\hat{R}^{-1}\gamma_\mu^D\hat{R} = \Lambda^\nu{}_\mu\gamma_\nu^D$ is an isometry and hence , we obtain that

$$\hat{\beta}[\mathcal{D}_{\hat{R}}(\psi)] = [\bar{\psi}\gamma_{\mu}^{D}\psi]\hat{R}\gamma^{D\mu}\hat{R}^{-1} = \hat{R}\hat{\beta}(\psi)\hat{R}^{-1}.$$

Algebraic spinors: The bilinear covariant $\hat{J} \in \hat{\mathcal{A}}$ is computed as[6]

$$\hat{\beta}(\hat{\psi}) = \hat{J} = \langle \hat{\psi}\hat{e}_0\widetilde{\hat{\psi}^*}\rangle_1,$$

where * denotes the complex conjugate. The condition (19) can be easily checked,

$$\hat{\beta}[\mathcal{L}_{1,3}^{\hat{I}(\mathbb{C})}(\hat{R},\hat{\psi})] = \langle \hat{R}\hat{\psi}\hat{e}_0\widetilde{\hat{\psi}^*}\hat{R}^{-1}\rangle_1 = \hat{R}\langle \hat{\psi}\hat{e}_0\widetilde{\hat{\psi}^*}\rangle_1\hat{R}^{-1} = \hat{R}\hat{\beta}(\hat{\psi})\hat{R}^{-1}.$$

Left operator spinors: In this case the bilinear covariant $\hat{J} \in \hat{\mathcal{A}}$ is[17]

$$\hat{\beta}(\hat{\psi}) = \hat{J} = \hat{\psi}\hat{e}_0\widetilde{\hat{\psi}}. \tag{20}$$

To check condition (19) is immediate,

$$\hat{\beta}[\mathcal{L}_{1,3}^{+}(\hat{R},\hat{\psi})] = \hat{R}\hat{\psi}\hat{e}_0\widetilde{\hat{\psi}}\hat{R}^{-1} = \hat{R}\hat{\beta}(\hat{\psi})\hat{R}^{-1}.$$

VI. RIGHT OPERATOR SPINORS

Right operator spinors are radically different from the spinors defined in Sec. IV. It is crucial that this new type does not fit Definition 4.4, and that this fact is intimately related to the different nature of the bilinear obtained from right operator spinors.

Definition 6.1: A right operator spinor is an equivalence class of the set $\mathcal{F}\times\mathcal{C}\ell_{p,q}^{+}$ *defined by the equivalence relation*,

$$\mathcal{R}_r{:}(\Sigma_S,\Psi) \sim (\Sigma_S',\Psi') \Leftrightarrow \Psi R = \Psi' R', \tag{21}$$

where $\Sigma_S=(\Sigma,R)$ and $\Sigma_S'=(\Sigma',R')$.

This definition has two differences with Definition 4.4. The first is merely technical. In (21) the action of the spin group,

$$\alpha_r{:}\mathrm{Spin}_{p,q}\times\mathcal{C}\ell_{p,q}^{+}\to\mathcal{C}\ell_{p,q}^{+};\quad \alpha_r(R,\Psi) = \Psi R$$

is not a representation but an *antirepresentation*:

$$\alpha_r(R_1,\alpha_r(R_2,\Psi)) = \alpha_r(R_2R_1,\Psi).$$

The second is more subtle and fundamental. Subtle since it is not usually noticed[24,10] that the equivalence relation defining α spinors is basis dependent. This dependence is carried by $f_{\Sigma}(R)$ in (13). In contrast, observe that α_r is independent of the basis Σ. Fundamental because α_r is a representation of the group $\mathrm{Spin}_{p,q}$, which is constructed directly from the vectorial space of interest $\mathcal{A}$, while α is a representation of $\widehat{\mathrm{Spin}}_{p,q}$ defined from the generic space $\hat{\mathcal{A}}$. This is the fact that takes relevance in the nature of the bilinear observables obtained.

We can particularize this type of spinors for the cases of Pauli or Dirac spinors simply by considering, respectively, the algebra of the tridimensional space, $\mathcal{C}\ell_{3,0}$, or the algebra of the four-dimensional space-time, $\mathcal{C}\ell_{3,1}$ or $\mathcal{C}\ell_{1,3}$.[12]

Example 6.1: A right operator Pauli spinor *is a right operator spinor for a tridimensional space*.

Example 6.2: A right operator Dirac spinor *is a right operator spinor for a four-dimensional space-time*.

The bilinear observables of right operator spinors have an expression similar to the one considered for left operator spinors. Taking, for instance, the density current vector J for Dirac spinor, the expressions for the left operator (20) and for the right operator are, respectively,

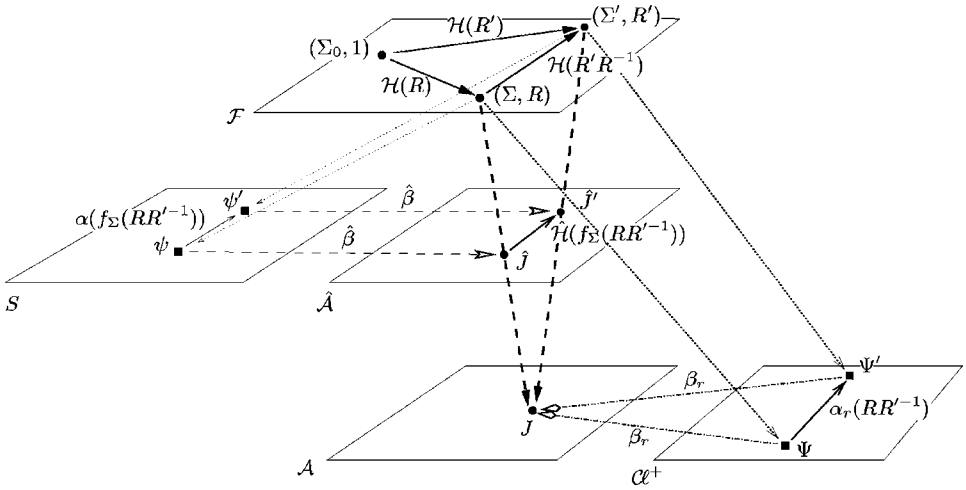

FIG. 1. Diagram representing the relationships between spinorial frames $\mathcal{F}$, vectors $\mathcal{A}$, vector representatives $\hat{\mathcal{A}}$ and spinor representatives S and $\mathcal{C}\ell^+$. Vector representatives are the bilinears of (left) α spinors, $\hat{J}=\hat{\beta}(\psi)$, while vectors are bilinears of right operator spinors, $J=\beta_r(\Psi,\Sigma)$. Observe that the bilinear function $\hat{\beta}$ does not depend on the reference frame Σ, but the transformation of spinorial representatives $\alpha(f_\Sigma(RR'^{-1})$ does. In contrast, the bilinear function β_r does depend on Σ, but the transformation of spinorial representatives $\alpha_r(RR'^{-1})$ does not.

$$\hat{J} = \hat{\psi}\hat{e}_0\tilde{\hat{\psi}} \tag{22a}$$

and

$$J = \Psi e_0 \tilde{\Psi}. \tag{22b}$$

Behind the similarity of these two formulas there is an essential difference. $\hat{J}$ belongs to the generic space $\hat{\mathcal{A}}$ and, together with the frame Σ, it forms a representative $(\hat{J},\Sigma)$ of the current vector. However, J belongs to the space $\mathcal{A}$ and is itself the current vector. Coherently, J does not transform when we change the frame Σ_S of the spinor with representative (Σ_S,Ψ). (See Fig. 1.)

In Eq. (22b), the vector e_0 is the time-like vector of the frame Σ. Hence, it changes when Σ changes:

$$e_0' = M(e_0) = \mathcal{H}(R'R^{-1})e_0,$$

where (Σ,R), $(\Sigma',R') \in \mathcal{F}$.

Accordingly to Definition 6.1, $\Psi \in \mathcal{C}\ell^+_{1,3}$ changes as

$$\Psi' = \Psi RR'^{-1}.$$

Therefore, a simple computation makes clear that the bilinear observable J is the same for both representants (Σ_S,Ψ) and (Σ_S',Ψ'):

$$J' = \Psi' e_0' \widetilde{\Psi'} = \Psi RR'^{-1}R'R^{-1}e_0 RR'^{-1}R'R^{-1}\tilde{\Psi} = \Psi e_0 \tilde{\Psi} = J. \tag{23}$$

As we announced in the Introduction, the interpretation of spinors that guides the whole of this paper is based on considering that a spinor does not describe objectively a physical particle but it describes how a physical particle is linked to the observer. It is for right operator spinors when this interpretation takes its most transparent expression[12]. This is clear from Eq. (23) since the spinor representative Ψ links the observer vector e_0 to the particle current field J. Equation (23) can be then paraphrased as *a transformation in the observer induces a transformation in the link so that the observable does not change*.

VII. CONCLUSIONS

Benn and Tucker in Ref. 34 manifested the *confusion of tongues* that it exists in the theory of spinors.

The theory of spinors was developed independently by physicist and mathematicians, and this historical apartheid has continued. […] Thus there is now a language, with many dialects, for discussing spinors in physics which makes little contact with the expositions of the theory to be found in mathematics literature.

Our aim in this paper has been to unify the definitions of spinors independently of their representations. Moreover, this goal has allowed us to identify and distinguish between two essential kinds of definitions as we showed in Secs. IV and VI. These definitions are intimately related with the bilinears and therefore with vectors. In fact, to demand covariance of the bilinear observables of spinors means that the equivalent relation defining spinors depends on the equivalence relation defining vectors, as we have seen in Sec. V.

Nowadays, we are working with a new kind of spinors.[35] They share with right operator spinors the property of generating directly the observables, instead of their representatives. However, their definition will not be necessarily constructed by means of an equivalent class, but they can be defined by a unique representative with no mention of observer tetrads or spinorial frames. This characteristic places those spinors close to being intrinsic spinors, in the sense of being defined independently of basis.

APPENDIX: ABOUT THE NECESSITY OF THE REPRESENTATION FUNCTION ON THE DEFINITION OF VECTORS AND SPINORS

In the literature, there are few formal treatments for defining vectors and spinors as equivalent relation attending to their transformation properties in changing the reference frame.

A broadly accepted definition is the one found in Ref. 25. In this appendix we will discuss the correctness of this definition and two possible interpretations of it.

The definition of vectors in Ref. 25, p. 134 is the following.

A vector is a class of equivalence defined by

$$(u_{(i)},\rho_{(i)}) \sim (u_{(j)},\rho_{(j)}) \Leftrightarrow u_{(i)} = Lu_{(j)} \quad \text{and} \quad \rho_{(j)} = L\rho_{(i)}, \tag{A1}$$

where $u_{(i)} \in \mathbb{R}^n$, $\rho_{(i)}$ is a reference frame in V, and $L \in \mathrm{GL}(n)$.

This definition cannot be correct, at least without some explanatory complement. The reason is that the linear application L is applied to two different spaces: the representative space, $u_{(i)} \in \mathbb{R}^n$, and the space of reference frames $\rho_{(i)} \in \mathcal{B}$. Moreover, the guessing of an implicit canonical relation between the two different applications L affecting each of the two spaces, is misleading. Indeed, we present below two possible amendments of this definition.

A crucial point is that, even if the two spaces could be considered identified in some sense, so that the same application L could be applied to both, this definition would be incorrect because the relation $\sim$ introduced is not an equivalent relation. In concrete this relation does not satisfy transitivity. For three representatives we have

$$(u_{(1)},\rho_{(1)}) \sim (u_{(2)}\rho_{(2)}) \;\Leftrightarrow\; u_{(1)} = L_{12}u_{(2)} \quad \rho_{(2)} = L_{12}\rho_{(1)},$$

$$(u_{(2)},\rho_{(2)}) \sim (u_{(3)}\rho_{(3)}) \;\Leftrightarrow\; u_{(2)} = L_{23}u_{(3)} \quad \rho_{(3)} = L_{23}\rho_{(2)}, \tag{A2}$$

$$(u_{(1)},\rho_{(1)}) \sim (u_{(3)}\rho_{(3)}) \;\Leftrightarrow\; u_{(1)} = L_{13}u_{(3)} \quad \rho_{(3)} = L_{13}\rho_{(1)}.$$

But the two first relations imply that

$$u_{(1)} = L_{12}L_{23}u_{(3)} \quad \text{and} \quad \rho_{(3)} = L_{23}L_{12}\rho_{(1)}.$$

This is compatible with the third relation only if the two applications commute:

$$L_{12}L_{23} = L_{23}L_{12} = L_{13},$$

which is not true, in general.

Obviously, the theory of vectorial and spinorial transformations is not badly grounded. Thus, since the relation is not transitive, we are led to consider that the formal definition above does not recover properly or completely the actually utilized transformations. In order to reflect the actual transformations, we need to add an extra operation. Indeed, there are, at least, two different possibilities. They appear when we study more carefully the space of reference frames $\mathcal{B}$.

A reference frame ρ is a collection of n linearly independent vectors in V:

$$\rho = (\rho_1, \ldots, \rho_n), \quad \rho_I \in V.$$

Thus, we can write

$$\mathcal{B} = V \times \cdots \times V = V^n = \mathbb{R}^n \otimes V.$$

The last expression suggests two types of transformations for reference frames: acting on $\mathbb{R}^n$ or acting on V. The first possibility seems to be the one implied in definition (A1). However, in this case, the definition is misleading since the correct definition involves the operation of transposition. The second possibility is, in fact, the one considered in this work and it involves the representation function f_Σ.

(1) Consider that $L \in \mathrm{GL}(n)$ is a linear application on $\mathbb{R}^n$. Then, it seems natural to make it act on the $\mathbb{R}^n$ structure of $\mathcal{B}=\mathbb{R}^n \otimes V$. But then we will not have an equivalence relation. Let us write the usual operation of applying a linear transformation on components and basis in index notation:

$$\rho_{(2)}I = L^J{}_I\rho_{(1)J} \quad \text{and} \quad u^I_{(1)} = L^I{}_J u^J_{(2)}.$$

Observe that, in fact, the $\mathbb{R}^n$ in $\mathcal{B}=\mathbb{R}^n \otimes V$ is not the same as the $\mathbb{R}^n$ space of components, but the dual space of it, $\mathbb{R}^{n^*}$. Therefore, while $\mathbb{R}^n$ is transformed with the application $L:\mathbb{R}^n \to \mathbb{R}^n$, the space $\mathbb{R}^{n^*} \otimes V$ is transformed with the transposed application $L^{\mathsf{T}}:\mathbb{R}^{n^*} \to \mathbb{R}^{n^*}$,

$$(u_{(i)},\rho_{(i)}) \sim (u_{(j)},\rho_{(j)}) \quad \Leftrightarrow \quad u_{(i)} = Lu_{(j)} \quad \text{and} \quad \rho_{(j)} = L^{\mathsf{T}}\rho_{(i)}.$$

It is easy to see that with this transposition the relation is transitive. Taking three representatives as in (A2), we would obtain the conditions $L_{12}L_{23}=L_{13}$ and $L^{\mathsf{T}}_{23}L^{\mathsf{T}}_{12}=L^{\mathsf{T}}_{13}$, which are compatible. Hence, we have an equivalent relation.

This interpretation of the vectorial transformations is possibly the most extended one. Nevertheless, it is not the unique and, certainly, it was not the one primarily thought by the authors of this work. But, what is important to note is that it cannot be generalized for other types of representatives different from the Cartesian one.

(2) Let us consider L as an application on V, instead of one on $\mathbb{R}^n$. Then, it can be applied to reference frames $\rho_{(i)} \in \mathcal{B}=\mathbb{R}^{n^*} \otimes V$ by operating on the V structure. However, $L \in \mathrm{GL}(V)$ cannot be

applied to $u_{(i)} \in \mathbb{R}^n$. Thus, we need a way of relating the application $L \in \mathrm{GL}(V)$ with some application $\hat{L} \in \mathrm{GL}(\mathbb{R}^n)$. Let us express the application L by its components in the basis $\rho_{(i)}=\{e^{(i)}{}_I\}$:

$$e^{(2)}{}_I = L(e^{(1)}{}_I) = L^J{}_I\, e^{(1)}{}_J.$$

Now, these components can be used to define the application $\hat{L}$, which should relate the two representatives $u_{(i)}=\{u^I_{(i)}\} \in \mathbb{R}^n$:

$$u_{(1)}{}^I = [\hat{L}(u_{(2)})]^I \equiv L^I{}_J\, u_{(2)}{}^J.$$

This is formalized by considering the representation function $f_{\rho_{(i)}}: V \to \mathbb{R}^n$, which maps each vector $u \in V$ into its components in the corresponding reference frame $f_{\rho_{(i)}}(u)=u_{(i)}$, so that it satisfies

$$f_{\rho_{(i)}}(\rho_{(i)}) = f_{\rho_{(j)}}(\rho_{(j)}), \quad \forall\, i,j.$$

Then, the application $\hat{L}$ is defined by

$$\hat{L} \equiv f_{\rho_{(i)}} \circ L \circ f^{-1}_{\rho_{(i)}}. \tag{A3}$$

Let us remark that the relationship between L and $\hat{L}$ is frame dependent.

Now, we have the relation

$$(u_{(i)},\rho_{(i)}) \sim (u_{(j)},\rho_{(j)}) \quad \Leftrightarrow \quad u_{(i)} = \hat{L}_{ij} u_{(j)} \quad \text{and} \quad \rho_{(j)} = L_{ij}\rho_{(i)}.$$

Since $\hat{L}$ is frame dependent, we must check that the relation is symmetric, i.e., $\hat{L}_{ji}=\hat{L}^{-1}_{ij}$, provided that $L_{ji}=L^{-1}_{ij}$. The symmetry is obtained by taking into account Eq. (A3):

$$\rho_{(j)} = f^{-1}_{\rho_{(j)}} \circ f_{\rho_{(i)}}(\rho_{(i)}) \Rightarrow L_{ij} = f^{-1}_{\rho_{(j)}} \circ f_{\rho_{(i)}}$$

which implies the identity

$$\hat{L}_{ji} = f_{\rho_{(j)}} L_{ji} f_{\rho_{(j)}}{}^{-1} = f_{\rho_{(j)}} f_{\rho_{(i)}}{}^{-1} f_{\rho_{(j)}} f_{\rho_{(j)}}{}^{-1} = f_{\rho_{(i)}} f_{\rho_{(i)}}{}^{-1} f_{\rho_{(j)}} f_{\rho_{(i)}}{}^{-1}$$

$$= f_{\rho_{(i)}} L_{ji} f_{\rho_{(i)}}{}^{-1} = (\hat{L}_{ij})^{-1}.$$

This result is usually paraphrased as: "The transformation matrix is the same written in both reference frames, the original and the transformed one." The transitivity property is satisfied if $\hat{L}_{12}\hat{L}_{23}=\widehat{(L_{23}L_{12})}$. This is obtained by

$$\hat{L}_{12}\hat{L}_{23} = f_{\rho(1)} L_{12} f_{\rho(1)}{}^{-1} f_{\rho(2)} L_{23} f_{\rho(2)}{}^{-1} = f_{\rho(1)} L_{12} L_{12}{}^{-1} L_{23} f_{\rho(2)}{}^{-1}$$

$$= f_{\rho(1)} L_{23} f_{\rho(2)}{}^{-1} f_{\rho(1)} f_{\rho(1)}{}^{-1} = f_{\rho(1)} L_{23} L_{12} f_{\rho(1)}{}^{-1}$$

$$= \widehat{(L_{23}L_{12})}.$$

(Received 23 February 2006; accepted 27 September 2006; published online 30 November 2006)

We investigate the Seiberg-Witten monopole equations on noncommutative (N.C.) $\mathbb{R}^4$ at the large N.C. parameter limit, in terms of the equivariant cohomology. In other words, $\mathcal{N}=2$ supersymmetric U(1) gauge theories with a hypermultiplet on N.C.$\mathbb{R}^4$ are studied. It is known that after topological twisting partition functions of $\mathcal{N}>1$ supersymmetric theories on N.C. $\mathbb{R}^{2D}$ are invariant under the N.C. parameter shift; then the partition functions can be calculated by its dimensional reduction. At the large N.C. parameter limit, the Seiberg-Witten monopole equations are reduced to ADHM equations with the Dirac equation reduced to the 0 dimension. The equations are equivalent to the dimensional reduction of non-Abelian $U(N)$ Seiberg-Witten monopole equations in $N\to\infty$. The solutions of the equations are also interpreted as a configuration of a brane antibrane system. The theory has global symmetries under torus actions originated in space rotations and gauge symmetries. We investigate the Seiberg-Witten monopole equations reduced to the 0 dimension and the fixed point equations of the torus actions. We show that the Dirac equation reduced to the 0 dimension is automatically satisfied when the fixed point equations and the ADHM equations are satisfied. Then, we find that the Seiberg-Witten equations reduced to the 0 dimension and fixed point equations of the torus action are equivalent to just the ADHM equations with the fixed point equations. For finite N, it is known that the fixed points of the ADHM data are isolated and are classified by the Young diagrams. We also give a new proof of this statement by solving the ADHM equations and the fixed point equations concretely and by giving graphical interpretations of the field components and these equations. © *2006 American Institute of Physics.*

I. INTRODUCTION

The Seiberg-Witten theory causes a revolution of nonperturbative analysis for $\mathcal{N}=2$ supersymmetric Yang-Mills theories.[1,2] In the Seiberg-Witten theory, the instanton effects of $\mathcal{N}=2$ supersymmetric Yang-Mills theories are encoded in the prepotential, which is defined by using the Seiberg-Witten curve. (See, for example, Ref. 3 and references therein.) The Seiberg-Witten theory

[a)]Electronic mail: sako@math.keio.ac.jp
[b)]Electronic mail: tsuzuki@phys.ocha.ac.jp

also provides a powerful tool, the monopole equation, to investigate the topology of four dimensional manifolds.[4,5] The monopole equations are more tractable than the instanton equation, and yield many results in mathematics as well as physics.

Meanwhile, instanton calculus has developed by using ADHM data or *D*-instanton. (See, for example, Ref. 6.) Particularly, an important calculation technology for $\mathcal{N}=2$ supersymmetric Yang-Mills theories is brought by Nekrasov.[7] After Ref. 7, many related works have been made.[8–38] In Ref. 7 and so on, the localization theorem plays an essential role.[39–42] (See also Refs. 43 and 44.) The localization theorem is valid when the theory has symmetries that correspond to some group action and the group action has isolated fixed points. It is expected that many kinds of calculations of $\mathcal{N}>1$ supersymmetric gauge theory are carried out by using this theorem.

It is shown that partition functions of $\mathcal{N}>1$ supersymmetric gauge theories on noncommutative (N.C.) $\mathbb{R}^{2D}$ are invariant under the N.C. parameter change.[45] Therefore we can perform the calculation at the large N.C. parameter limit. As discussed in Refs. 45–48, taking this limit causes dimensional reduction, and we can calculate the partition functions by using the theory after dimensional reduction. For this reason, it is important to investigate the dimensional reduction.

In this paper, we will study a 0 dimensional model given by a dimensional reduction of Seiberg-Witten monopole equations derived from $\mathcal{N}=2$ supersymmetric $U(1)$ theory on N.C. $\mathbb{R}^4$. The equations are equivalent to the ADHM equations and the Dirac equation reduced to the 0 dimension. The equations are also equivalent to the dimensional reduction of non-Abelian $U(N)$ Seiberg-Witten monopole equations on commutative $\mathbb{R}^4$ at the large N limit. In this paper, we investigate both cases of finite N and infinite N. The finite N case is not only the toy model, but also the model that is possible to be implanted into the $N=\infty$ theory and the results are valid for some special cases of the $N=\infty$ model. We will find that the solutions of the equations are also interpreted as a configuration of the brane antibrane system. The theory has global symmetries under torus actions originated in space rotations and gauge symmetries. The torus actions define their fixed point equations. We will investigate the fixed point equations and the dimensional reduction of the Seiberg-Witten monopole equations. We will show that the Dirac equation is trivial when the fixed point equations and the ADHM equations are satisfied. For the finite N case, it is known that solutions satisfying the fixed point equations and the ADHM equations are isolated and classified by the Young diagrams.[49] We will give a new proof of this statement by solving the ADHM equations and the fixed point equations concretely and by giving a graphical interpretation of the field components and these equations.

Here is the organization of this paper. In Sec. II, we review the $\mathcal{N}=2$ supersymmetric gauge theory on $\mathbb{R}^4$ and N.C. $\mathbb{R}^4$ with a hypermultiplet. In Sec. III, a *D*-brane interpretation is discussed. In Sec. IV, we deform a BRS transformation defined as a topological twist of supersymmetric transformation by using the global symmetries of the theory. In Sec. V, we solve the Seiberg-Witten monopole equations reduced to a 0 dimension and the fixed point equations, and show our main claims. That is to say we show that the dimensional reduced Seiberg-Witten equations and fixed point equations of the torus action are equivalent to just the ADHM equations with the fixed point equations. We also give a new proof of the statement that solutions of the equations are localized and they are classified by Young diagrams. In Sec. VI, we briefly comment on the localization theorem. Section VII is a summary of this paper.

II. $\mathcal{N}=2$ SUPERSYMMETRIC $U(1)$ THEORY ON N.C. $\mathbb{R}^4$

In this section we review $\mathcal{N}=2$ supersymmetric theory and its topological twist on $\mathbb{R}^4$ and N.C. $\mathbb{R}^4$. We consider the case with a hypermultiplet.[50–54] For conventions in this paper, see Appendix A.

At first, we set up the model of the $\mathcal{N}=2$ supersymmetric theory on $\mathbb{R}^4$. $SO(4)$ spacetime rotation of four dimensional Euclidean space is locally equivalent to $SU(2)_L \otimes SU(2)_R$. $\mathcal{N}=2$ supersymmetric theories have $SU(2)_I$ R symmetry. The supersymmetry generators $Q_{\alpha i}$, $\bar{Q}_{\dot{\alpha} i}$ have indices $i=1,2$ for the R symmetry. $\mathcal{N}=2$ supersymmetric theories on $\mathbb{R}^4$ have the following symmetry:

$$H = SU(2)_L \otimes SU(2)_R \otimes SU(2)_I. \tag{1}$$

The supersymmetric gauge multiplet is given by

$$\begin{matrix} & A_\mu & \\ \psi^1 & & \psi^2. \\ & \phi & \end{matrix} \tag{2}$$

Here ψ_1 and ψ_2 are Weyl spinors. We denote $\bar{\psi}_1$ and $\bar{\psi}_2$ as their CPT conjugate. ϕ is a scalar field. We denote $\bar{\phi}$ as its complex conjugate. Their quantum number of H are assigned as

$$\psi^1 = (1/2,0,1/2), \quad \psi^2 = (1/2,0,1/2), \quad \phi = (0,0,0),$$

$$\bar{\psi}^1 = (0,1/2,1/2), \quad \bar{\psi}^2 = (0,1/2,1/2), \quad \bar{\phi} = (0,0,0). \tag{3}$$

The action functional is given by

$$L = -\frac{1}{4}F^a_{\mu\nu}F_a^{\mu\nu} - i\bar{\psi}^a_{\dot{\alpha}i}\,\bar{\sigma}^{\mu\dot{\alpha}\alpha}\,D_\mu\psi_{\alpha a}{}^i - D_\mu\bar{\phi}^a\,D^\mu\phi_a \tag{4}$$

$$-\frac{i}{\sqrt{2}}\psi^{\alpha ia}[\bar{\phi},\psi_{\alpha i}]_a - \frac{i}{\sqrt{2}}\bar{\psi}_{\dot{\alpha}}{}^{ia}[\phi,\bar{\psi}^{\dot{\alpha}}{}_i]_a - \frac{1}{2}[\bar{\phi},\phi]^2. \tag{5}$$

The supersymmetric transformation with parameter ξ and $\bar{\xi}$ are written as

$$\delta A_\mu = i\xi^{\alpha i}\sigma_{\mu\alpha\dot{\alpha}}\bar{\psi}^{\dot{\alpha}}{}_i - i\psi^{\alpha i}\sigma_{\mu\alpha\dot{\alpha}}\bar{\xi}^{\dot{\alpha}}{}_i,$$

$$\delta\psi_\alpha{}^i = \sigma_\alpha^{\mu\nu\beta}\xi_\beta{}^i F_{\mu\nu} + \sqrt{2}i\sigma^\mu_{\alpha\dot{\alpha}}\,D_\mu\phi\bar{\xi}^{\dot{\alpha}i} + [\phi,\bar{\phi}]\xi_\alpha{}^i,$$

$$\delta\bar{\psi}_{\dot{\alpha}i} = -\bar{\xi}_{\dot{\beta}i}\bar{\sigma}^{\mu\nu\dot{\beta}}_{\dot{\alpha}}F_{\mu\nu} + \sqrt{2}i\xi^{\alpha i}\sigma^\mu_{\alpha\dot{\alpha}}\,D_\mu\bar{\phi} - [\phi,\bar{\phi}]\bar{\xi}_{\dot{\alpha}i},$$

$$\delta\phi = \sqrt{2}\xi^{\alpha i}\psi_{\alpha i},$$

$$\delta\bar{\phi} = \sqrt{2}\bar{\xi}^{\dot{\alpha}}_i\bar{\psi}_{\dot{\alpha}}{}^i. \tag{6}$$

To classify the solutions of BPS equations by equivariant cohomology, let us introduce a topological twist here.[55,56] We use a diagonal subgroup $SU(2)_{R'}$ in $SU(2)_R \otimes SU(2)_I$ of H. We redefine the space time rotation group by

$$K' := SU(2)_L \otimes SU(2)_{R'}. \tag{7}$$

Then combinations of spinors whose quantum number of H are $(1/2,0,1/2)\oplus(0,1/2,1/2)$ have quantum number $(1/2,1/2)\oplus(0,1)\oplus(0,0)$ of K'. Particularly $(0,0)$ is scalar and $Q=\epsilon^{\dot{\alpha}i}\bar{Q}_{\dot{\alpha}i}$ is a BRS operator. Fermionic fields are similarly topological twisted as $\psi^i(\frac{1}{2},0,\frac{1}{2}) \to \psi_\mu(\frac{1}{2},\frac{1}{2})$ and $\bar{\psi}^i(0,\frac{1}{2},\frac{1}{2}) \to \chi_{\mu\nu}(0,1)\oplus\eta(0,0)$. BRS transformations are given as

$$\hat{\delta}A_\mu = i\psi_\mu, \quad \hat{\delta}\psi_\mu = -D_\mu\phi, \quad \hat{\delta}\phi = 0,$$

$$\hat{\delta}\chi_{\mu\nu} = H_{\mu\nu}, \quad \hat{\delta}\bar{\phi} = i\eta,$$

$$\hat{\delta}H_{\mu\nu} = i[\phi, \chi_{\mu\nu}], \quad \hat{\delta}\eta = [\phi, \bar{\phi}]. \tag{8}$$

Here we introduce auxiliary field $H_{\mu\nu}$.

As a next step, let us introduce hypermultiplets. The $\mathcal{N}=2$ hypermultiplet consists of two Weyl fermions λ_q and $\lambda_{\tilde{q}}^{\dagger}$ and two complex scalar bosons, q and $\tilde{q}^{\dagger}$,

$$\begin{matrix} & \lambda_q & \\ q & & \tilde{q}^{\dagger}. \\ & \lambda_{\tilde{q}}^{\dagger} & \end{matrix}$$

The definition of the symbol † is seen in Appendix A. Their supersymmetric transformations are given by

$$\begin{aligned} \delta q^i &= -\sqrt{2}\xi^{\alpha i}\lambda_{q\alpha} + \sqrt{2}\bar{\xi}_{\dot{\alpha}}{}^{i}\bar{\lambda}_{\tilde{q}}^{\dot{\alpha}}, \\ \delta\lambda_{q\alpha} &= -\sqrt{2}i\sigma^{\mu}_{\alpha\dot{\alpha}} D_{\mu} q^i \bar{\xi}^{\dot{\alpha}}{}_{i} - 2T_a q^i \bar{\phi}^a \xi_{\alpha i}, \\ \delta\bar{\lambda}_{\tilde{q}}^{\dot{\alpha}} &= -\sqrt{2}i\bar{\sigma}^{\mu\dot{\alpha}\alpha} D_{\mu} q^i \xi_{\alpha i} + 2T_a q^i \phi^a \bar{\xi}^{\dot{\alpha}}{}_{i}, \end{aligned} \tag{9}$$

where T_a is a generator of the gauge group. In the following, we consider the case that representation of the gauge group of the hypermultiplet is fundamental representation. After topological twisting, BRS transformations are given by

$$\begin{aligned} &\hat{\delta}q^{\dot{\alpha}} = \psi_q^{\dot{\alpha}}, \quad \hat{\delta}q_{\dot{\alpha}}^{\dagger} = \psi_{q\dot{\alpha}}^{\dagger}, \\ &\hat{\delta}\psi_q^{\dot{\alpha}} = -i\phi^a T_a q^{\dot{\alpha}}, \quad \hat{\delta}\psi_{q\dot{\alpha}}^{\dagger} = iq_{\dot{\alpha}}^{\dagger}\phi^a T_a, \\ &\hat{\delta}\chi_{q\alpha} = H_{q\alpha}, \quad \hat{\delta}\chi_q^{\dagger\alpha} = H_q^{\dagger\alpha} \\ &\hat{\delta}H_{q\alpha} = -i\phi^a T_a \chi_{q\alpha}, \quad \hat{\delta}H_q^{\dagger\alpha} = i\chi_q^{\dagger\alpha}\phi^a T_a, \end{aligned} \tag{10}$$

where fields are rescaled, $\phi \to (i/2\sqrt{2})\phi$, $\sqrt{2}\bar{\lambda}_q^{\dot{\alpha}} \to \bar{\lambda}_q^{\dot{\alpha}}$, $\sqrt{2}\bar{\lambda}_{q\dot{\alpha}} \to \bar{\lambda}_{q\dot{\alpha}}$, and also auxiliary field $H_{q\alpha}$ is introduced. After topological twisting, we rename the fermions as $\lambda_q \to \chi_q$ and $\bar{\lambda}_q \to \psi_q$.

Using these field contents, let us construct the action of Seiberg-Witten theory. The action with fundamental hypermultiplet terms are defined by

$$S = k - \hat{\delta}\Psi \tag{11}$$

where k is an instanton number,

$$k = \frac{1}{8\pi^2}\int \mathrm{Tr}(F_A \wedge F_A), \tag{12}$$

and Ψ is a gauge fermion;

$$\begin{aligned} \Psi = &-\chi_+^{\mu\nu a}\{H_{+\mu\nu}^a - s_{+\mu\nu}^a\} - \chi_q^{\dagger\alpha}\{H_{q\alpha} - s_{\alpha}\} - \{H_q^{\dagger\alpha} - s^{\dagger\alpha}\}\chi_{q\alpha} \\ &+ i[\phi, \bar{\phi}]^a \eta^a + D_{\mu}\bar{\phi}^a \psi^{\mu a} - (-iq_{\dot{\alpha}}^{\dagger}\bar{\phi})\psi_q^{\dot{\alpha}} - \psi_{q\dot{\alpha}}^{\dagger}(i\bar{\phi}q^{\dot{\alpha}}). \end{aligned} \tag{13}$$

Here

$$s^{\mu\nu}(A, q, q^{\dagger}) = F_a^{+\mu\nu} + q^{\dagger}\bar{\sigma}^{\mu\nu}T_a q,$$

$$s^{\alpha}(A,q) = \sigma^{\mu} D_{\mu} q = \not{D} q. \tag{14}$$

After integration of the auxiliary fields $H_{+\mu\nu}$ and H_q, the bosonic action are given as

$$S_B = \int d^4x \sqrt{g} \left[\frac{1}{4} |s^{\mu\nu}|^2 + \frac{1}{2} |s^{\alpha}|^2 \right] + \cdots . \tag{15}$$

Notice that when the gauge group is $U(1)$ and the theory is defined on simple type commutative manifolds, we get the Seiberg-Witten invariants as the partition function of this model.[4,5,50,51] From (15) we get the BPS equations,

$$s^{\mu\nu}(A,q,q^{\dagger}) = 0, \quad s^{\alpha}(A,q) = 0, \tag{16}$$

which is known as the non-Abelian Seiberg-Witten monopole equations.

In the following, we investigate some properties of $\mathcal{N}=2$ supersymmetric gauge theory on N.C. $\mathbb{R}^4$ whose noncommutativity is defined as

$$[x^{\mu}, x^{\nu}] = i\theta^{\mu\nu}, \tag{17}$$

where the $\theta^{\mu\nu}$ is an element of an antisymmetric matrix and called the N.C. parameter. For simplicity, we take

$$(\theta^{\mu\nu}) = \begin{pmatrix} 0 & \theta^1 & 0 & 0 \\ -\theta^1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \theta^2 \\ 0 & 0 & -\theta^2 & 0 \end{pmatrix}. \tag{18}$$

In the following, we only use operator formalisms to describe the N.C. field theory; therefore the fields are operators acting on the Hilbert space $\mathcal{H}$. Then differential operators ∂_{μ} are expressed by using commutation brackets $-i\theta^{-1}_{\mu\nu}[x^{\nu}, *] \equiv [\hat{\partial}_{\mu}, *]$ and $\int d^{2D}x$ is replaced with $\det(\theta)^{1/2}\mathrm{Tr}_{\mathcal{H}}$.

When we consider only the case of N.C. $\mathbb{R}^4$, field theories are expressed by the Fock space formalism. (See the appendix in Ref. 45.) In the Fock space representation, fields are expressed as $A_{\mu} = \Sigma A^{n_1 n_2}_{\mu_{m_1 m_2}} |n_1, n_2\rangle\langle m_1, m_2|$, $\psi_{\mu} = \Sigma \psi^{n_1 n_2}_{\mu_{m_1 m_2}} |n_1, n_2\rangle\langle m_1, m_2|$, etc. Therefore, the above BRS transformations are expressed as

$$\hat{\delta} A^{n_1 n_2}_{\mu_{m_1 m_2}} = \psi^{n_1 n_2}_{\mu_{m_1 m_2}}, \quad \hat{\delta} \psi^{n_1 n_2}_{\mu_{m_1 m_2}} = (D_{\mu}\phi)^{n_1 n_2}_{m_1 m_2}, \ldots , \tag{19}$$

where the covariant derivative is defined by $D_{\mu} * := [\hat{\partial}_{\mu} + iA_{\mu}, *]$ with $\hat{\partial}_{\mu} := -i\theta^{-1}_{\mu\nu} x^{\nu}$. The action functional is given by

$$S = \mathrm{Tr}_{\mathcal{H}} L(A_{\mu}, \ldots ; \hat{\partial}_{z_i}, \hat{\partial}_{\bar{z}_i}) = \mathrm{Tr}_{\mathcal{H}}\ \mathrm{tr}\ \hat{\delta}\Psi . \tag{20}$$

Let us change the dynamical variables as

$$A_\mu \to \frac{1}{\sqrt{\theta}}\tilde{A}_\mu, \quad \psi_\mu \to \frac{1}{\sqrt{\theta}}\tilde{\psi}_\mu, \quad \bar{\phi} \to \frac{1}{\theta}\tilde{\bar{\phi}}, \quad \eta \to \frac{1}{\theta}\tilde{\eta}, \quad q \to \frac{1}{\sqrt{\theta}}\tilde{q}, \quad q^\dagger \to \frac{1}{\sqrt{\theta}}\tilde{q}^\dagger$$

$$\chi^+_{\mu\nu} \to \frac{1}{\theta}\tilde{\chi}^+_{\mu\nu}, \quad H^+_{\mu\nu} \to \frac{1}{\theta}\tilde{H}^+_{\mu\nu}, \quad \phi \to \tilde{\phi} \quad \psi_q \to \frac{1}{\sqrt{\theta}}\tilde{\psi}_q, \quad \psi^\dagger_q \to \frac{1}{\sqrt{\theta}}\tilde{\psi}^\dagger_q, \tag{21}$$

$$\chi_q \to \frac{1}{\theta}\tilde{\chi}_q, \quad \chi^\dagger_q \to \frac{1}{\theta}\tilde{\chi}^\dagger_q, \quad H_q \to \frac{1}{\theta}\tilde{H}_q, \quad H^\dagger_q \to \frac{1}{\theta}\tilde{H}^\dagger_q.$$

Note that this changing does not cause nontrivial Jacobian from the path integral measure because of the BRS symmetry. Then, the action is rewritten as

$$S \to \frac{1}{\theta^2}\tilde{S}, \quad L(A_\mu, \ldots; \hat{\partial}_{z_i}, \hat{\partial}_{\bar{z}_i}) \to \frac{1}{\theta^2}L(\tilde{A}_\mu, \ldots; -a^\dagger_i, a_i). \tag{22}$$

Here the action on the left hand side (lhs) depends on θ because the derivative is given by $\partial_{z_i} = -\sqrt{\theta^{-1}}[a^\dagger_i,]$, and so on. In contrast, the action $\tilde{S}$ on the rhs does not depend on θ because all θ parameters are factorized out. Using the BRS symmetry, it is proved that the partition function is invariant under the deformation of θ, because $\delta_\theta Z = -2(\delta\theta)\theta^{-3}\langle\tilde{S}\rangle = 0$. As discussed in Ref. 45, the partition function of this theory is possible to be determined by using a lower dimension theory that is given by dimensional reduction. Therefore, the investigation of the dimensional reduction of the theories is important.

The dimensional reduction of Seiberg-Witten monopole equations (14) are expressed as

$$P^{\mu\nu\rho\tau}_+[A_\rho, A_\tau] + q\bar{\sigma}^{\mu\nu}q^\dagger = 0, \tag{23}$$

$$\sigma^\mu A_\mu q = 0, \tag{24}$$

where $P^{\mu\nu\rho\tau}_+$ is a self-dual projection operator. These expressions are valid for the dimensional reduction of the non-Abelian theory on commutative $\mathbb{R}^4$. Using $q_+ := (q_1 + q_2)/\sqrt{2}$ and $q_- := (q_1 - q_2)/\sqrt{2}$, if we start from the $U(1)$ theory on N.C.$\mathbb{R}^4$, the equation (23) is rewritten as ADHM equations:

$$[A_{z_1}, A^\dagger_{z_1}] + [A_{z_2}, A^\dagger_{z_2}] + q_- q_-^{*T} - q_+ q_+^{*T} = 0,$$

$$[A_{z_1}, A_{z_2}] + q_- q_+^{*T} = 0. \tag{25}$$

Note that these operators in (25) are expressed by infinite dimensional matrices and the ADHM equations correspond to the instanton of the $U(N)$ gauge group with instanton number N at the large N limit. We consider the finite N situation in the next section.

III. *D*-BRANE INTERPRETATION

In this paper, we study the details of the solution of (23) and (24). On the N.C. $\mathbb{R}^4$ the fields appearing in (23) and (24) are infinite dimensional matrices acting on Hilbert space. But the equations are important even if the dimension of the matrix is finite, because there is a corresponding physical model. In this section, we consider the correspondence between Seiberg-Witten monopole equations, the D-brane picture, and (23), (24).[57]

At first, we construct the physical model by using the similar manner of the article.[57] (See also Refs. 58–65.)

The generalized second order effective action of an N $D3$-brane N $\bar{D}3$-brane system without topological terms are given by

$$\int \mathrm{tr}\left\{\frac{1}{4}F^{(N)}_{\mu\nu}F^{(N)\mu\nu}+\frac{1}{4}F^{(\bar{N})}_{\mu\nu}F^{(\bar{N})\mu\nu}+|D^{\mu}\phi|^2+\frac{1}{2}(\tau^2-\phi\bar{\phi})^2\right\}. \tag{26}$$

Here the $F^{(N)}_{\mu\nu}$ and $F^{(\bar{N})}_{\mu\nu}$ are the curvature of the $A^{(N)}$ and $A^{(\bar{N})}$, respectively, where $A^{(N)}$ and $A^{(\bar{N})}$ correspond to open strings attached on the $D3$ brane and the $\bar{D}3$ brane. Up to topological terms, we can rewrite this action as

$$\int \mathrm{tr}\left\{\frac{1}{4}F^{(\bar{N})}_{\mu\nu}F^{(\bar{N})\mu\nu}+\frac{1}{2}|F^{(N)}_{z^1\bar{z}^1}+F^{(N)}_{z^2\bar{z}^2}+(\phi\bar{\phi}-\tau^2)|^2+8|F_{z^1z^2}|^2+2|D_{\bar{z}_1}\phi|^2+2|D_{\bar{z}_2}\phi|^2\right\}. \tag{27}$$

From this action, considering the case of $A^{(\bar{N})}_{\mu}=0$, stationary points are given by

$$F^{(N)}_{z^1\bar{z}^1}+F^{(N)}_{z^2\bar{z}^2}+q_-q_-^{*T}=\zeta, \tag{28}$$

$$F^{(N)}_{z^1z^2}=0, \tag{29}$$

$$D_{\bar{z}^1}q_-=0, \tag{30}$$

$$D_{\bar{z}^2}q_-=0, \tag{31}$$

where we replace ϕ by q_- and τ^2 by ζ. Then, this is the Seiberg-Witten monopole equations with $q_+=0$ condition and background constant field ζ. (See also the next section.) This case corresponds to the $\zeta>0$, as we will see in Sec. V. Note that q_- can be regarded as a complex scalar field when we consider the $\mathbb{R}^4$ case.

The solution of (23) and (24) of the finite matrix model is realized as some $D3$-$\bar{D}3$ configuration.

IV. DEFORMED BRS TRANSFORMATION

In this section, we will investigate the symmetry of the dimension reduction of (20) to 0 dimension, and deform the BRS symmetry as $\mathcal{G}\otimes T^{N+2}$ equivariant derivative, where $\mathcal{G}$ is the gauge transformation group of $U(N)$ and T^{N+2} is the torus action, in order to derive the fixed point equations. Note that the $U(N)$ symmetry is caused from the $U(1)$ symmetry if we consider the N.C. theory. As explained in Sec. II, the action functional is defined by infinite dimensional matrices when we start from N.C. theories; then N.C.$U(1)$ gauge symmetry is expressed by $U(\infty)$ symmetry. For simplicity, in some discussions of this paper, we restrict our analysis to the finite dimensional, $N\times N$, matrix case. (Only the proof of Theorem 3 in Sec. V and the calculations of the partition function of a toy model in Sec. VI are based on discussions of finite N.) All of the fields contents, A_μ, q, etc., are given by $N\times N$ matrices. Then the $U(\infty)$ symmetry is also truncated to $U(N)$. From the viewpoint of N.C. field theory, there might be another type of solutions that is not studied in this paper, and the following analysis might not be completed. On the other hand, as discussed in the previous section, the finite $N\times N$ theory has a $D3$-$\bar{D}3$ brane interpretation; then it has physical applications.

The path integral for cohomological field theories reduced to the integral over the moduli space of vacuum. In our case, the moduli space is defined by solutions of (23) and (24). As demonstrated in Ref. 7, the localization theorem is a powerful tool for path integrals of cohomological field theories. The localization theorem is valid when a theory under consideration has symmetries under some group actions, and the group actions have isolated fixed points. (For the localization theorem, also see Sec. VI.) Therefore, to investigate solutions of the fixed point equation is important. This is our main subject in this paper.

Adding to the $U(N)$ gauge symmetry and the Lorentz symmetry $SO(4)=SU(2)_L\otimes SU(2)_R$, the action reduced to 0 dimension has the next extra unitary symmetry, denoted by $\tilde{U}(N)$,

$$\delta^{\tilde{U}(N)} q_{\dot{\alpha}} = i q_{\dot{\alpha}} b, \tag{32}$$

where b is a generator of $\tilde{U}(N)$. When we consider the case that $q_{\dot{\alpha}}$ is a $N \times k$ matrix in the next section, then the symmetry becomes $\tilde{U}(k)$;

$$\delta^{\tilde{U}(k)} q_{\dot{\alpha}} = i q_{\dot{\alpha}} b, \quad b \in \tilde{u}(k). \tag{33}$$

Recall that q and $q^\dagger$ are fundamental representations of the gauge group. The gauge transformation of q is defined by left action of the $U(N)$. Notice that if we define the gauge transformation by using right action, we can define another gauge symmetry with the corresponding gauge field. We do not introduce this gauge field; then the symmetry appears only after the dimensional reduction. This is the origin of $\tilde{U}(N)$.

Now we use the Abelian subgroup $U(1)^2 \otimes U(1)^N$ of $SO(4) \otimes \tilde{U}(N)$. That is, we consider the following symmetry of the action:

$$\delta^{U(1)^2 \otimes U(1)^N} A_{z_i} = -i \epsilon_i A_{z_i}, \tag{34}$$

$$\delta^{U(1)^2 \otimes U(1)^N} q_{\dot{\alpha}} = +i M_{R\dot{\alpha}}{}^{\dot{\beta}} q_{\dot{\beta}} + i q_{\dot{\alpha}} b, \tag{35}$$

where $b = \mathrm{diag}.(b_1, \cdots, b_N)$ is a generator of an Abelian subgroup $U(1)^N$ of $\tilde{U}(N)$, and $\epsilon_i (i = 1, 2)$ is a generator of an Abelian subgroup $U(1)^2$ of $SO(4)$, defined by

$$\delta A_\mu = M_\mu{}^\nu A_\nu, \quad M_\mu{}^\nu = \begin{pmatrix} 0 & -\epsilon_1 & & \\ +\epsilon_1 & 0 & & \\ & & 0 & -\epsilon_2 \\ & & -\epsilon_2 & 0 \end{pmatrix}. \tag{36}$$

Also, $M_{R\dot{\alpha}}{}^{\dot{\beta}}$ is the generator of $U(1) \subset SU(2)_R$,

$$M_{R\dot{\alpha}}{}^{\dot{\beta}} = \begin{pmatrix} 0 & \epsilon_+ \\ \epsilon_+ & 0 \end{pmatrix}, \quad \epsilon_+ = \frac{\epsilon_1 + \epsilon_2}{2}. \tag{37}$$

By using $U(1)^2 \otimes U(1)^N$, let us deform the BRS symmetry from $\hat{\delta}$ to $\tilde{\delta}$. We define the deformation by replacing $\hat{\delta}^2 = \delta^{U(N)\text{gauge}}_{(-\phi)}$ to

$$\tilde{\delta}^2 = \delta^{U(N)\text{gauge}}_{(-\phi)} + \delta^{U(1)^N}_{(b)} + \delta^{U(1)^2}_{(\epsilon_1, \epsilon_2)}. \tag{38}$$

Here $\delta^G_{(\Delta)}$ is a gauge transformation operator with the group G and the transformation parameter Δ. Then, for ψ_{z_i} and $\psi_{q\dot{\alpha}}$, the BRS transformation rules are given by

$$\tilde{\delta}^2 A_{z_i} = \tilde{\delta} \psi_{z_i} = i[A_{z_i}, \phi] - i \epsilon_i A_{z_i}, \tag{39}$$

$$\tilde{\delta}^2 q_{\dot{\alpha}} = \tilde{\delta} \psi_{q\dot{\alpha}} = -i \phi q_{\dot{\alpha}} + M_{R\dot{\alpha}}{}^{\dot{\beta}} q_{\dot{\beta}} + i q_{\dot{\alpha}} b, \tag{40}$$

$$\tilde{\delta}^2 q^{\dagger \dot{\alpha}} = \tilde{\delta} \psi_q{}^{\dagger \dot{\alpha}} = q^{\dagger \dot{\alpha}} i \phi - M_{R\dot{\beta}}{}^{\dot{\alpha}} q^{\dagger \dot{\beta}} - i b q^{\dagger \dot{\alpha}}. \tag{41}$$

Now we list the equations, the solutions of which we will investigate. Some of them are the equations of motion, often called BPS equations. They are the same as (23) or (25), (24). However, we take some deformation of them, to remove singular solutions. We introduce a nonzero number ζ, and take

$$i([A_{z_1},A_{\bar{z}_1}]+[A_{z_2},A_{\bar{z}_2}])+q(\bar{\sigma}_{z_1\bar{z}_1}+\bar{\sigma}_{z_2\bar{z}_2})q^\dagger=i\zeta, \tag{42}$$

$$i[A_{z_1},A_{z_2}]+q\bar{\sigma}_{z_1z_2}q^\dagger=0, \tag{43}$$

$$(A_{z_1}\sigma^{z_1}+A_{\bar{z}_1}\sigma^{\bar{z}_1}+A_{z_2}\sigma^{z_2}+A_{\bar{z}_2}\sigma^{\bar{z}_2})q=0. \tag{44}$$

Here, (42), (43) are realized by the redefinition of $s^{\mu\nu}(A,q,q^\dagger)$,

$$s^{\mu\nu}(A,q,q^\dagger)\to F^{+\mu\nu}+q\bar{\sigma}^{\mu\nu}q^\dagger-\zeta^+_{\mu\nu},$$

$$\zeta_{z_1\bar{z}_1}+\zeta_{z_2\bar{z}_2}=i\zeta,\quad \zeta_{z_1z_2}=0. \tag{45}$$

This constant ζ is considered as a background field and we define its BRS transformation by $\tilde{\delta}\zeta=0$. Then, we find that all of the above discussions in previous sections are valid, although we add this background field. For later use, we rewrite them into

$$[A_{z_1},A_{\bar{z}_1}]+[A_{z_2},A_{\bar{z}_2}]-(q_{\dot{2}}q_{\dot{1}}^{*T}+q_{\dot{1}}q_{\dot{2}}^{*T})=\zeta, \tag{46}$$

$$[A_{z_1},A_{z_2}]+\frac{1}{2}(q_{\dot{1}}q_{\dot{1}}^{*T}-q_{\dot{2}}q_{\dot{2}}^{*T})+\frac{1}{2}(q_{\dot{1}}q_{\dot{2}}^{*T}-q_{\dot{2}}q_{\dot{1}}^{*T})=0, \tag{47}$$

$$(A_{\bar{z}_1}-A_{z_2})q_{\dot{2}}-(A_{\bar{z}_1}+A_{z_2})q_{\dot{1}}=0, \tag{48}$$

$$(A_{\bar{z}_2}+A_{z_1})q_{\dot{2}}-(A_{\bar{z}_2}-A_{z_1})q_{\dot{1}}=0. \tag{49}$$

The rest of the equations to be investigated are the fixed point equations of the deformed BRS transformation (39)–(41). They are given by

$$i[A_{z_i},\phi]-i\epsilon_iA_{z_i}=0, \tag{50}$$

$$-i\phi q_{\dot{\alpha}}+M^{\dot{\beta}}_{R\dot{\alpha}}q_{\dot{\beta}}+iq_{\dot{\alpha}}b=0. \tag{51}$$

In the next section, we will investigate solutions of (42), (43), (44), (50), (51), and will show that they have isolated solutions. This fact guarantees that the localization theorem is valid to our case.

V. SOLUTIONS OF (42), (43), (44), (50), (51)

In this section, we solve (42), (43), (44), (50), (51), and show that these equations have only isolated solutions, and the solutions are expressed by the Young diagrams. Notice that our analysis is also valid to a case where q_α's are $N\times k,(k\neq N)$ matrices, though we will treat q_α as $N\times N$ matrices in this section. If we take $q_{\dot{\alpha}}$ to be $N\times k$, $q^{*T}_{\dot{\alpha}}$ to be $k\times N$ and $b\in u(k)$, our proof in this section includes a new proof for Proposition 5.6. in Ref. 49.

First of all, we diagonalize ϕ by using the $U(N)$ gauge symmetry,

$$\phi=\mathrm{diag}(\phi_1,\phi_2,\ldots,\phi_N). \tag{52}$$

Next we tackle (50) and (51). From (50) we see immediately that if and only if

$$\phi_J-\phi_I=\epsilon_i, \tag{53}$$

A_{z_iIJ} could be nonzero,

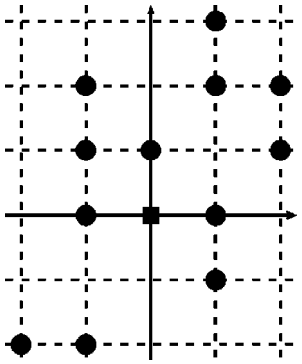

FIG. 1. $P_{[\hat{x_I}]}$.

$$A_{z_i IJ} \neq 0. \tag{54}$$

In this section, we use "$\neq 0$" as not "nonzero" but "not always zero." Also, from (51) we see that if and only if

$$\phi_I = b_J \pm \epsilon_+, \tag{55}$$

$q_{\dot{1}IJ}$ and $q_{\dot{2}IJ}$ could be nonzero,

$$q_{\dot{1}IJ} = \pm q_{\dot{2}IJ} \neq 0. \tag{56}$$

Notice $q_{\dot{1}IJ}$ and $q_{\dot{2}IJ}$ are not independent from one another.

These observations lead us to the following proposition.

Lemma 1: If (42), (50), (51) *have a solution, then* ϕ_I *takes any of* $\varphi^{(n_1,n_2)}_{[x_I^\wedge]}$, *given by*

$$\varphi^{(n_1,n_2)}_{[x_I^\wedge]} = x_I^\wedge + n_1\epsilon_1 + n_2\epsilon_2, \quad n_1, n_2 \in \mathbb{Z} \tag{57}$$

where

$$x_I^\wedge \in \{b_I^{(-)} \in \mathbb{R}, I = 1, \ldots, N | b_I^{(-)} := b_I - \epsilon_+\}, \tag{58}$$

or

$$x_I^\wedge \in \{y_{\bar{I}}^- \in \mathbb{R}, \bar{I} = 1, \ldots, \bar{N} | \forall I, n_1, n_2, y_{\bar{I}}^- \neq b_I^{(-)} + n_1\epsilon_1 + n_2\epsilon_2\}. \tag{59}$$

(proof)

Suppose that ϕ_I does not take any of $\varphi^{(n_1,n_2)}_{[x_I^\wedge]}$ given above. This implies that $\exists I, \forall J, q_{\dot{\alpha}IJ} = 0, A_{z_i IJ} = A_{z_i JI} = 0$. Consider (42). It is easy to see that the (I,I) component of the lhs of (42) is 0, whereas the (I,I) component of the rhs of (42) is $i\zeta \neq 0$. Therefore no solution to (42), (50), (51) is allowed. ■

For a set of all $\{\varphi^{(n_1,n_2)}_{[x_I^\wedge]} | x_I^\wedge$ is given $\}$, assign a graph $P_{[x_I^\wedge]}$. See Fig. 1. In Fig. 1, the origin, denoted by the black square, corresponds to the eigenvalue $\varphi^{(0,0)}_{[x_I^\wedge]} = x_I^\wedge$, and other lattice points (n_1, n_2), denoted by black dots, correspond to eigenvalues $\varphi^{(n_1,n_2)}_{[x_I^\wedge]}$. For given a set of $P_{[x_I^\wedge]}$, ϕ is written as

$$\phi = \bigoplus_I \begin{pmatrix} \varphi^{(n_1,n_2)}_{[b_I^{(-)}]}\mathbf{1}_{N^{(n_1,n_2)}_{[b_I^{(-)}]}} & & & \\ & \varphi^{(n_1',n_2')}_{[b_I^{(-)}]}\mathbf{1}_{N^{(n_1',n_2')}_{[b_I^{(-)}]}} & & \\ & & \varphi^{(n_1'',n_2'')}_{[b_I^{(-)}]}\mathbf{1}_{N^{(n_1'',n_2'')}_{[b_I^{(-)}]}} & \\ & & & \ddots \end{pmatrix}, \tag{60}$$

$$\bigoplus_{\bar{I}} \begin{pmatrix} \varphi^{(n_1,n_2)}_{[y_{\bar{I}}]}\mathbf{1}_{N^{(n_1,n_2)}_{[y_{\bar{I}}]}} & & & \\ & \varphi^{(n_1',n_2')}_{[y_{\bar{I}}]}\mathbf{1}_{N^{(n_1',n_2')}_{[y_{\bar{I}}]}} & & \\ & & \varphi^{(n_1'',n_2'')}_{[y_{\bar{I}}]}\mathbf{1}_{N^{(n_1'',n_2'')}_{[y_{\bar{I}}]}} & \\ & & & \ddots \end{pmatrix}. \tag{61}$$

In each Ith or $\bar{I}$th block, we suppose that eigenvalues $\varphi^{(n_1,n_2)}_{[b_I^{(-)}]}$ or $\varphi^{(n_1,n_2)}_{[y_{\bar{I}}]}$ are arranged by order,

$$\varphi^{(n_1,n_2)}_{[b_I^{(-)}]} < \varphi^{(n_1',n_2')}_{[b_I^{(-)}]} < \varphi^{(n_1'',n_2'')}_{[b_I^{(-)}]} < \cdots,$$

$$\varphi^{(n_1,n_2)}_{[y_{\bar{I}}]} < \varphi^{(n_1',n_2')}_{[y_{\bar{I}}]} < \varphi^{(n_1'',n_2'')}_{[y_{\bar{I}}]} < \cdots. \tag{62}$$

The index I is mapped to the triad of indices $(\hat{I},(n_1,n_2))$,

$$I \mapsto (\hat{I},(n_1,n_2)). \tag{63}$$

We denote the degeneracy of $\varphi^{(n_1,n_2)}_{[x_{\hat{I}}]}$ as $N^{(n_1,n_2)}_{[x_{\hat{I}}]}$,

$$^{\#}\{\phi_I | \phi_I = \varphi^{(n_1,n_2)}_{[x_{\hat{I}}]}\} = N^{(n_1,n_2)}_{[x_{\hat{I}}]} \geq 0, \tag{64}$$

$$\sum_{\hat{I}} \sum_{(n_1,n_2)} N^{(n_1,n_2)}_{[x_{\hat{I}}]} = N. \tag{65}$$

A_{z_i} takes a similar block structure,

$$A_{z_i} = \bigoplus_I \begin{pmatrix} & \vdots & \\ \cdots & A_{z_i(I,(n_1,n_2)),(I,(m_1,m_2))} & \cdots \\ & \vdots & \end{pmatrix} \bigoplus_{\bar{I}} \begin{pmatrix} & \vdots & \\ \cdots & E_{z_i(\bar{I},(n_1,n_2)),(\bar{I},(m_1,m_2))} & \cdots \\ & \vdots & \end{pmatrix}, \tag{66}$$

where

$$A_{z_i(I,(n_1,n_2)),(I,(m_1,m_2))} \quad \text{is a } N^{(n_1,n_2)}_{[b_I^{(-)}]} \times N^{(m_1,m_2)}_{[b_I^{(-)}]} \text{ complex matrix},$$

and

$$E_{z_i(\bar{I},(n_1,n_2)),(\bar{I},(m_1,m_2))} \text{ is a } N^{(n_1,n_2)}_{[y_{\bar{I}}]} \times N^{(m_1,m_2)}_{[y_{\bar{I}}]} \text{ complex matrix}.$$

A nontrivial component of A_{z_1} appears in $\{(\hat{I},(n_1,n_2)),(\hat{I},(n_1-1,n_2))\}$th block and, that of A_{z_2} appears in $\{(\hat{I},(n_1,n_2)),(\hat{I},(n_1,n_2-1))\}$th block,

$$A_{z_1(I,(n_1,n_2)),(I,(n_1-1,n_2))} \neq 0, \quad E_{z_1(\bar{I},(n_1,n_2)),(\bar{I},(n_1-1,n_2))} \neq 0, \tag{67}$$

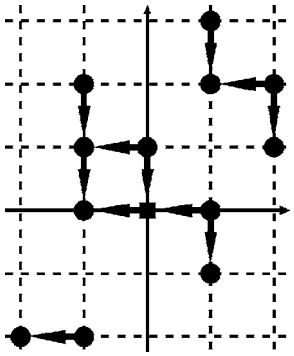

FIG. 2. $G_{[\hat{x}_{\hat{I}}]}$.

$$A_{z_2(I,(n_1,n_2)),(I,(n_1,n_2-1))} \neq 0, \quad E_{z_2(\bar{I},(n_1,n_2)),(\bar{I},(n_1,n_2-1))} \neq 0. \tag{68}$$

By adding left arrows connecting (n_1,n_2) and (n_1-1,n_2) and down arrows connecting (n_1,n_2) and (n_1,n_2-1) to the graph $P_{[x_{\hat{I}}]}$, we obtain a graph $G_{[x_{\hat{I}}]}$. For example, see Fig. 2. The left arrow corresponds to A_{z_1}'s nontrivial component, and the down arrow corresponds to A_{z_2}'s nontrivial component. Also, the nontrivial components of $q_{\dot{\alpha}}$ are

$$q_{\dot{1}(I,(0,0)),J} = -q_{\dot{2}(I,(0,0)),J} \neq 0, \quad \text{for } I,J, \text{ s.t. } \phi_I = b_J + \epsilon_+, \tag{69}$$

$$q_{\dot{1}(I,(1,1)),J} = +q_{\dot{2}(I,(1,1)),J} \neq 0, \quad \text{for } I,J, \text{ s.t. } \phi_I = b_J - \epsilon_+. \tag{70}$$

From (66), (69), (70), we obtain the next proposition.

Lemma 2: If ϕ_I takes any of $\varphi^{(n_1,n_2)}_{[y_{\bar{I}}]} = y_{\bar{I}} + n_1\epsilon_1 + n_2\epsilon_2$, then (42), (50), (51) have no solution.

(proof)

Suppose that some ϕ_I are given by

$$\phi_I = \varphi^{(n_1,n_2)}_{[y_{\bar{I}}]}. \tag{71}$$

Then, the lhs of (46), equivalent to (42), is given by the following:

$$\begin{aligned} \text{lhs of (46)} &= \sum_{i=1,2} [A_{z_i}, A_{\bar{z}_i}] - (q_{\dot{2}} q_{\dot{1}}^{*T} + q_{\dot{1}} q_{\dot{2}}^{*T}) \\ &= \begin{pmatrix} \oplus_I \sum_{i=1,2} [A^I_{z_i}, A^I_{\bar{z}_i}] - (q_{\dot{2}} q_{\dot{1}}^{*T} + q_{\dot{1}} q_{\dot{2}}^{*T}) & 0 \\ 0 & \oplus_{\bar{I}} \sum_{i=1,2} [E^{\bar{I}}_{z_i}, E^{\bar{I}}_{\bar{z}_i}] \end{pmatrix}, \end{aligned} \tag{72}$$

because the nontrivial components of $q_{\dot{\alpha}}$ are given by (69), (70). On the other hand, the rhs of (46) is proportional to a unit matrix,

$$\text{rhs of (46)} = \zeta \begin{pmatrix} \oplus_I \mathbf{1}^{I,I} & 0 \\ 0 & \oplus_{\bar{I}} \mathbf{1}^{\bar{I},\bar{I}} \end{pmatrix}. \tag{73}$$

The $(\bar{I},\bar{I})$ block of (72) is a traceless matrix, whereas the $(\bar{I},\bar{I})$ block of (73) has a nonzero trace. These are mutually exclusive. ■

When we consider the case of $N=\infty$, we cannot use the nature that the commutator is traceless; then this proof is not correct. But we can prove this statement even if $N=\infty$. Because, if $[E^{\bar{I}}_{z_i}, E^{\bar{I}}_{\bar{z}_i}]$ is not traceless, we can show that the curvature F does not converge to zero at infinity.

This means that if the set of the gauge fields is $\{A\,|\lim_{x\to\infty}|F(x)|=0\}$, then this theorem still holds. By the same reason, Theorem 1 in this section is valid for the $N=\infty$ case. That is why, all theorems in this section without Theorem 3 holds for the $N=\infty$ case.

Corollary 1: (42), (50), (51) *can have a solution, if and only if* ϕ *is given by*

$$\phi = \bigoplus_I \bigoplus_{(n_1,n_2)\in G_{[b_I^{(-)}]}} \varphi_{[b_I^{(-)}]}^{(n_1,n_2)} \mathbf{1}_{N_{[b_I^{(-)}]}^{(n_1,n_2)}}, \tag{74}$$

$$\varphi_{[b_I^{(-)}]}^{(n_1,n_2)} = b_I^{(-)} + n_1\epsilon_1 + n_2\epsilon_2, \tag{75}$$

and A_{z_i} *is given by*

$$A_{z_i} = \bigoplus_I A_{z_i}^I. \tag{76}$$

From now on, we suppose that the parameter ζ is a positive number,

$$\zeta > 0. \tag{77}$$

(If we assume $\zeta<0$, we have to change some statements in the following theorems, but essentially same theorems hold.) Then we obtain the next theorem.

Theorem 1: *Let* $G_{[b_I^{(-)}]}$ *be a graph defined from the eigenvalues* $\varphi_{[b_I^{(-)}]}^{(n_1,n_2)}$ *given by* (74). *Also let* ζ *be positive. The following three conditions are necessary for a solution of* (42), (50), and (51) *to exist.*

(1) $G_{[b_I^{(-)}]}$ *consists of one connected part.*
(2) $G_{[b_I^{(-)}]}$ *includes the origin* $(0,0)$.
(3) *All points* (n_1,n_2) *in* $G_{[b_I^{(-)}]}$ *must be in* $n_1\le 0, n_2\le 0$.

(proof)

First of all, notice that $A_{z_i}^I$ is a direct sum of upper triangle (block) matrices and $A_{\bar{z}_i}^I$ is of lower triangle (block) matrices [remember (62)],

$$A_{z_i}^I = \bigoplus_a A_{z_i}^{I(a)} = \bigoplus_a \begin{pmatrix} 0 & * & \cdots & * & * \\ 0 & 0 & \cdots & * & * \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & * \\ 0 & 0 & \cdots & 0 & 0 \end{pmatrix}, \tag{78}$$

$$A_{\bar{z}_i}^I = \bigoplus_a A_{\bar{z}_i}^{I(a)} = \bigoplus_a \begin{pmatrix} 0 & 0 & \cdots & 0 & 0 \\ * & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ * & * & \cdots & 0 & 0 \\ * & * & \cdots & * & 0 \end{pmatrix}, \tag{79}$$

where the index a labels connected diagrams $G_{[b_I^{(-)}]}^{(a)}$ in $G_{[b_I^{(-)}]}$. See Fig. 3. From (78) and (79), we obtain

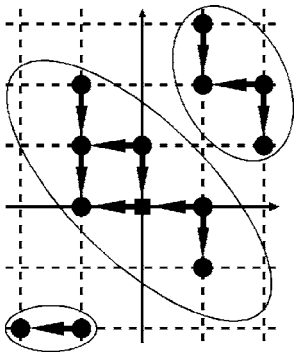

FIG. 3. $G_{[b_I^{(-)}]}$ consists of connected graphs $G^{(a)}_{[b_I^{(-)}]}$.

$$[A^{I(a)}_{z_i}, A^{I(a)}_{\bar{z}_i}] = \begin{pmatrix} M_{\min} & * & 0 \\ * & M_{\text{int}} & * \\ 0 & * & M_{\max} \end{pmatrix}, \tag{80}$$

where

$$M_{\min} = + \sum_{(m_1,m_2)} A^{I(a)}_{z_i(n_1^{\min},n_2^{\min}),(m_1,m_2)} A^{I(a)}_{\bar{z}_i(m_1,m_2),(n_1^{min},n_2^{\min})}, \tag{81}$$

$$M_{\max} = - \sum_{(m_1,m_2)} A^{I(a)}_{\bar{z}_i(n_1^{\max},n_2^{\max}),(m_1,m_2)} A^{I(a)}_{z_i(m_1,m_2),(n_1^{max},n_2^{\max})}, \tag{82}$$

and

$$M_{\text{int}} = \begin{pmatrix} M_{\text{int}}^{(n_1,n_2)} & * & * & \\ * & M_{\text{int}}^{(n_1',n_2')} & * & \\ * & * & M_{\text{int}}^{(n_1'',n_2'')} & \\ & & & \ddots \end{pmatrix}, \tag{83}$$

$$M_{\text{int}}^{(n_1,n_2)} = + \sum_{(m_1,m_2)} A^{I(a)}_{z_i(n_1,n_2),(m_1,m_2)} A^{I(a)}_{\bar{z}_i(m_1,m_2),(n_1,n_2)} - \sum_{(m_1,m_2)} A^{I(a)}_{\bar{z}_i(n_1,n_2),(m_1,m_2)} A^{I(a)}_{z_i(m_1,m_2),(n_1,n_2)}, \cdots . \tag{84}$$

$(n_1^{\min},n_2^{\min})$ in (81) denotes the point corresponding to the lowest eigenvalue in $G^{(a)}_{[b_I^{(-)}]}$, and $(n_1^{\max},n_2^{\max})$ in (82) denotes the point corresponding to the highest eigenvalue in $G^{(a)}_{[b_I^{(-)}]}$. Also $(n_1,n_2),\cdots$ in (83) denote other points corresponding to intermediate eigenvalues in $G^{(a)}_{[b_I^{(-)}]}$. Let us consider a $\{(I(a))(I(a))\}$ block of (46),

$$\sum_{i=1,2} [A^{I(a)}_{z_i}, A^{I(a)}_{\bar{z}_i}] - (q_2 q_1^{*T} + q_1 q_2^{*T})_{\{(I(a))(I(a))\}} = \zeta \mathbf{1}_{\{(I(a))(I(a))\}}. \tag{85}$$

If a connected part $G^{(a)}_{[b_I^{(-)}]}$ does not include $(0,0)$ or $(1,1)$, the second term on the lhs of (85) vanishes, since the nontrivial components of $q_{\dot{\alpha}}$ are given by (69), (70). We have supposed $\zeta > 0$, so (80)–(84) tell us that such $G^{(a)}_{[b_I^{(-)}]}$ does not exist.

Next, consider the $\{(I,(n_1^{\max},n_2^{\max}))(I,(n_1^{\max},n_2^{\max}))\}$ block of (46),

$$-\sum_{(m_1,m_2)} A^I_{\bar{z}_i(n_1^{\max},n_2^{\max}),(m_1,m_2)} A^I_{z_i(m_1,m_2),(n_1^{\max},n_2^{\max})} - (q_2 \dot{q}_1^{*T} + q_1 \dot{q}_2^{*T})_{\{(I,(n_1^{\max},n_2^{\max}))(I,(n_1^{\max},n_2^{\max}))\}}$$
$$= \zeta \mathbf{1}_{N^{(n_1^{\max},n_2^{\max})}_{[b_I^{(-)}]}}. \tag{86}$$

If

$$n_1^{\max} > 1 \quad \text{or} \quad n_2^{\max} > 1, \tag{87}$$

the second term on the lhs of (86) vanishes, since the nontrivial components of $q_{\dot{\alpha}}$ are given by (69), (70); then

$$\text{lhs of (86)} = -\sum_{(m_1,m_2)} A^I_{\bar{z}_i(n_1^{\max},n_2^{\max}),(m_1,m_2)} A^I_{z_i(m_1,m_2),(n_1^{\max},n_2^{\max})} \leq 0. \tag{88}$$

On the other hand,

$$\text{rhs of (86)} = \zeta > 0. \tag{89}$$

These are inconsistent from each other. Then, we conclude

$$n_1^{\max} \leq 1 \quad \text{and} \quad n_2^{\max} \leq 1. \tag{90}$$

Consider the maximal case, the $\{(I,(1,1))(I,(1,1))\}$ component of (46). The first term on the lhs is

$$-\sum_{(m_1,m_2)} A^I_{\bar{z}_i(1,1),(m_1,m_2)} A^I_{z_i(m_1,m_2),(1,1)} \leq 0, \tag{91}$$

and the second term is

$$-(q_2 \dot{q}_1^{*T} + q_1 \dot{q}_2^{*T}) = -2 q_1 \dot{q}_1^{*T} \leq 0. \tag{92}$$

Again, the rhs is $\zeta > 0$. Then we see that the $\{I(1,1)\}$ component does not exist. Repeating similar arguments, we conclude that

$$(n_1^{\max},n_2^{\max}) = (0,0). \tag{93}$$

We have finished the proof of Theorem 1. ■

Let us introduce such a map $\mathcal{I}$, that

$$\mathcal{I}:\{l|l=1,\cdots,M\} \to \{I|I=1,\cdots,N\}, \quad M \leq N, \tag{94}$$

$$N^{(0,0)}_{[b_{\mathcal{I}(l)}]} \neq 0. \tag{95}$$

For each l, assign a connected graph $C_{\mathcal{I}(l)}$. For example, see Fig. 4. For given $C_{\mathcal{I}(l)}$, nontrivial components of A_{z_i} are

$$A_{z_1\{l,(n_1-1,n_2)\}\{l,(n_1,n_2)\}} \neq 0, \quad (n_1-1,n_2),(n_1,n_2) \in C_{\mathcal{I}(l)}, \tag{96}$$

and

$$A_{z_2\{l,(n_1,n_2-1)\}\{l,(n_1,n_2)\}} \neq 0, \quad (n_1,n_2-1),(n_1,n_2) \in C_{\mathcal{I}(l)}. \tag{97}$$

Also nontrivial components of $q_{\dot{\alpha}}$ are

$$\dot{q}_{1I=\{l,(0,0)\},J=\mathcal{I}(l)} = -\dot{q}_{2I=\{l,(0,0)\},J=\mathcal{I}(l)} \neq 0. \tag{98}$$

For the nontrivial components (96)–(98), (42) and (43) are reduced to

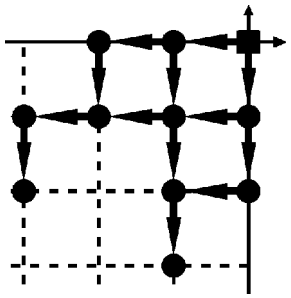

FIG. 4. $C_{\mathcal{I}(l)}$.

$$A_{z_1\{l,(n_1,n_2)\},\{l,(n_1+1,n_2)\}}A_{\bar{z}_1\{l,(n_1+1,n_2)\},\{l,(n_1,n_2)\}} - A_{\bar{z}_1\{l,(n_1,n_2)\},\{l,(n_1-1,n_2)\}}A_{z_1\{l,(n_1-1,n_2)\},\{l,(n_1,n_2)\}}$$
$$+ A_{z_2\{l,(n_1,n_2)\},\{l,(n_1,n_2+1)\}}A_{\bar{z}_2\{l,(n_1,n_2+1)\},\{l,(n_1,n_2)\}} - A_{\bar{z}_2\{l,(n_1,n_2)\},\{l,(n_1,n_2-1)\}}A_{z_2\{l,(n_1,n_2-1)\},\{l,(n_1,n_2)\}}$$
$$+ 2q_{\dot{1}_{\{l,(n_1,n_2)\},J}}q^{*T}_{\dot{1}J,\{l,(n_1,n_2)\}} = \zeta, \tag{99}$$

and

$$A_{z_1\{l,(n_1,n_2)\},\{l,(n_1+1,n_2)\}}A_{z_2\{l,(n_1+1,n_2)\},\{l,(n_1+1,n_2+1)\}} - A_{z_2\{l,(n_1,n_2)\},\{l,(n_1,n_2+1)\}}A_{z_1\{l,(n_1,n_2+1)\},\{l,(n_1+1,n_2+1)\}} = 0. \tag{100}$$

On the other hand, the Dirac equation reduced to 0 dimension (44) gives no constraint, which follows from the next theorem.

Theorem 2: *If A_{z_i} and $q_{\dot{\alpha}}$ satisfy Eqs.* (42), (43) *and Eqs.* (50), (51), *they satisfy the Dirac equation reduced to* 0 *dimension* (44) *automatically*.

(proof)

From (98), (44) is reduced to

$$A_{\bar{z}_1}q_{\dot{1}} = 0, \quad A_{\bar{z}_2}q_{\dot{1}} = 0. \tag{101}$$

Since we have taken the ordering (62), $A_{\bar{z}_i(l,(n_1,n_2)),(l,(m_1,m_2))}$ and $q_{\dot{1}\,(l,(n_1,n_2)),J=\mathcal{I}(l)}$ have the next structures,

$$A_{\bar{z}_i(l,(n_1,n_2)),(l,(m_1,m_2))} = \begin{pmatrix} 0 & 0 & \cdots & 0 & 0 \\ * & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ * & * & \cdots & 0 & 0 \\ * & * & \cdots & * & 0 \end{pmatrix}, \quad q_{\dot{1}(l,(n_1,n_2)),J=\mathcal{I}(l)} = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ * \end{pmatrix}. \tag{102}$$

So, (101) always holds. ■

The above theorem means that the solutions of the dimensional reduction of the Seiberg-Witten monopole equations with the constant background under the fixed point conditions of the torus actions are equivalent to the solutions of the N.C. ADHM equations with the same fixed point conditions.

The above discussions and theorems are valid for infinite N as well as finite N. In the following, we consider only a finite N case to study more details. As we saw in Sec. III, the finite N case itself has a physical picture. Furthermore, solutions and their natures of finite N models are important, even if we consider the N.C. field theory, because such solutions are possible to be embedded in infinite N solutions.

From now on, we suppose that ϕ_I does not degenerate,

FIG. 5. A_{z_1}.

$$N_{[b_I^{(-)}]}^{(n_1,n_2)} \leq 1. \tag{103}$$

The reason is as follows. (We tried to prove the nondegeneracy of ϕ_I's by using a graphical consideration similar to one in the proof of Theorem 3. Although for several simple cases we succeeded in proving that the nondegeneracy is necessary for (42)–(44), (50), (51) to have a solution, we do not have a complete proof for general cases yet.)

(i) The solution of (42), (43) (44), (50), (51) is clearly included in solutions of (42), (43), (50), (51). The nondegeneracy of the solutions of (42), (43), (50), (51) is the very same one considered in Ref. 49. See the argument at the end of Sec. II and the above discussions. In this case, the nondegeneracy is certified.

(ii) It is clear that the degenerate solutions do not contribute to the path integral for the partition function, because the factor $\Pi_{I\neq J}(\phi_I-\phi_J)$ in (113) becomes zero if there are degenerate solutions of ϕ_I.[7]

Let us give graphical interpretations of (96), (97), (98).

• $A_{z_1\ \{l,(n_1,n_2)\}\{l,(n_1+1,n_2)\}}$ corresponds to a left arrow connecting (n_1,n_2) and (n_1+1,n_2) in $C_{\mathcal{I}(l)}$. See Fig. 5. The number of nontrivial real components, $^{\#}\{A_{z_1}\}$, is given by two times of the number of left arrows.

• $A_{z_2\ \{l,(n_1,n_2)\}\{l,(n_1,n_2+1)\}}$ corresponds to a down arrow connecting (n_1,n_2) and (n_1,n_2+1) in $C_{\mathcal{I}(l)}$. See Fig. 6. The number of nontrivial components, $^{\#}\{A_{z_2}\}$, is given by two times the number of the down arrows.

• $q_{I=\{l,(0,0)\}J=\mathcal{I}(l)}$ corresponds to the origin $(0,0)$ in $C_{\mathcal{I}(l)}$. See Fig. 7. The number of nontrivial components, $^{\#}\{q\}$, is given by 2.

The total number of undetermined real variables is $^{\#}\{A_{z_1}\}+^{\#}\{A_{z_2}\}+^{\#}\{q\}$.

Also graphical meanings of Eqs. (99), (100), and the residual gauge symmetry $U(1)^N$ are given as follows.

• Each equation of (99) corresponds to ending points of the left arrow or down arrow or the origin in $C_{\mathcal{I}(l)}$. In other words, each point $C_{\mathcal{I}(l)}$ corresponds to each equation of (99). See Fig. 8. The number of nontrivial constraints, $^{\#}\{\mathrm{Eq.}(49)\}$ is given by the number of points.

• Each equation of (100) corresponds to a hook connecting (n_1,n_2) and (n_1+1,n_2+1), which includes an intermediating point (n_1+1,n_2) or (n_1,n_2+1), in $C_{\mathcal{I}(l)}$. See Fig. 9. The number of nontrivial constraints, $^{\#}\{\mathrm{Eq.}(100)\}$, is given by two times the number of hooks.

• Each $U(1)$ factor of the residual gauge symmetry $U(1)^N$ corresponds to each point (n_1,n_2) in $C_{\mathcal{I}(l)}$. See Fig. 10. The number of degrees of the residual gauge symmetry $U(1)^N$, denoted by $^{\#}\{U(1)\}$, is given by the number of points.

The total number of real constraints is $^{\#}\{\mathrm{Eq.}(99)\}+^{\#}\{\mathrm{Eq.}(100)\}+^{\#}\{U(1)\}$.

Now let us prove the next theorem.

Theorem 3: *Let N be a finite natural number. If and only if* $C_{\mathcal{I}(l)}$ *is a Young diagram*, (42), (43), (44), (50), (51) *has a solution, and the solution is an isolated one.*

(proof)

From Theorem 1-2, it is enough to show that if and only if $C_{\mathcal{I}(l)}$ is a Young diagram, (99) and (100) has only an isolated solution. Consider a graph $C_{\mathcal{I}(l)}$ as a *quadrangulation* of a two dimensional surface. Here we admit *quadrangulations* to include some segments that do not make faces, like the graph in Fig. 11. (If one considers a dual graph, then one finds that the dual graph gives a quadrangulation of a two dimensional surface in the usual meaning. The dual graph is obtained from the original graph by replacing original points by dual faces and original segments connecting original points by dual segments gluing dual faces.) We start with cases where two dimensional surfaces have no hole. Recall the well-known formula for the Euler number χ of graphs,

FIG. 6. A_{z_2}.

$$\chi = 2 - 2h - b = {}^{\#}\{\text{points}\} - {}^{\#}\{\text{segments}\} + {}^{\#}\{\text{faces}\}, \tag{104}$$

where h denotes the number of handles of graphs, and b denotes the number of boundaries of graphs.

In our case, $h=0$ and $b=1$. Then we obtain

$$\chi = 1 = {}^{\#}\{\text{points}\} - {}^{\#}\{\text{segments}\} + {}^{\#}\{\text{faces}\}. \tag{105}$$

Notice that

$${}^{\#}\{\text{points}\} = {}^{\#}\{\text{Eq . (99)}\} = {}^{\#}\{U(1)\}, \tag{106}$$

and

$${}^{\#}\{\text{segments}\} = \frac{{}^{\#}\{A_{z_1}\} + {}^{\#}\{A_{z_2}\}}{2}. \tag{107}$$

Also, one sees that

$${}^{\#}\{\text{faces}\} \leq \frac{{}^{\#}\{\text{Eq . (100)}\}}{2}, \tag{108}$$

and that, in (108), the equation holds when the graph $C_{\mathcal{I}(l)}$ is a Young diagram. See Fig. 12. Then we obtain

$$({}^{\#}\{A_{z_1}\} + {}^{\#}\{A_{z_2}\} + {}^{\#}\{q\}) - ({}^{\#}\{\text{Eq . (99)}\} + {}^{\#}\{\text{Eq . (100)}\} + {}^{\#}\{U(1)\})$$

$$= 2{}^{\#}\{\text{segments}\} + 2 - 2{}^{\#}\{\text{points}\} - {}^{\#}\{\text{Eq . (100)}\}$$

$$\leq -2({}^{\#}\{\text{points}\} - {}^{\#}\{\text{segments}\} + {}^{\#}\{\text{faces}\}) + 2$$

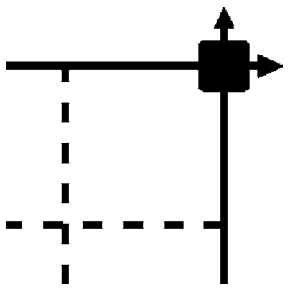

FIG. 7. q_i.

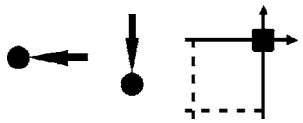

FIG. 8. Equation (99).

$$= -2 + 2$$

$$= 0. \tag{109}$$

From this, we find that if and only if $C_{\mathcal{I}(l)}$ is a Young diagram, we can have a solution to (99), (100), and that the solution is an isolated one.

Now let us turn to a case, where $C_{\mathcal{I}(l)}$ has some holes. A diagram with holes is constructed from one without holes by adding pieces of diagrams. For example, see Fig. 13. In Fig. 13, some white dots are added to make a hole. Under this operation, the number of undetermined variables increases by

$$\Delta^{\#}\{\text{undetermined variables}\} = \Delta^{\#}\{A_{z_1}\} + \Delta^{\#}\{A_{z_2}\} = 2 \times 4 + 2 \times 2 = 12. \tag{110}$$

On the other hand, the number of constraints increases by

$$\Delta^{\#}\{\text{constraints}\} = \Delta^{\#}\{\text{Eq. (99)}\} + \Delta^{\#}\{\text{Eq. (100)}\} + \Delta^{\#}\{U(1)\} = 5 + 2 \times 2 + 5 = 14. \tag{111}$$

As implied by the above example, one can show that "puncture" operations make the number of constraints greater than that of undetermined variables in general. We conclude that if $C_{\mathcal{I}(l)}$ has some holes, then (99), (100) have no solution.

We have finished the proof for Theorem 3. ■

As mentioned at the begining of this section, we have shown that (42), (43), (44), (50), (51) have only isolated solutions, and the solutions are expressed by the Young diagrams.

At the end of this section, we comment on the case that the q are not square matrices. Let us compare the above cases with the case of $\mathbb{C}^{[n]}$ and the ADHM data for a usual U(N) instanton. We have investigated the case that $q_{\dot{\alpha}}$ and $q^{\dagger}_{\dot{\alpha}}$ are $N \times N$ square matrices. It is clear that the above theorem is valid, even if $q_{\dot{\alpha}}$ and $q^{\dagger}_{\dot{\alpha}}$ are $N \times k$ and $k \times N$ for arbitrary $k \in \mathbb{Z}$, respectively. In this case, our equations (42) and (43) are ADHM equations corresponding to the U(N) instanton of the k instanton number with the Dirac equation reduced to 0 dimension. The Dirac equation (44) makes no nontrivial equations when we introduce ζ. Then, our models are completely equivalent to the case of ADHM equations with fixed point equations of torus action, that is discussed in Nakajima's lecture note[49] and others.[7,13,15] The proof for the correspondence with ADHM data and the Young diagrams is given by Ref. 49. In this light, our proof in this section is a new version for the Nakajima's theorem. We solved the fixed point equation of the torus action directly. By virtue of the concrete solution, the correspondence between fields components, ADHM equations, and Young diagrams are clarified.

VI. LOCALIZATION THEOREM

Although, in this paper, we do not perform the summation of the solutions nor obtain the partition function of our model, we make a comment on the localization theorem,[39,44] which is a powerful tool for the calculation of a path integral of cohomological field theories, in order to explain our motivation. To carry out the calculation of an infinite N case, that is the N.C. $\mathbb{R}^4$ case, is difficult. Therefore we consider the toy model that is given by the same type Lagrangian of Sec. II but its entire fields are finite $N\times N$ matrices.

For our purpose, one of the most suitable expression of the localization theorem is one given in Refs. 9 and 16. This is expressed as follows.

Let $\tilde{\delta}$ be the deformed BRS transformation defined in Sec. IV. As explained in Sec. II, the action S is given by a BRS exact function. Now we redefine the action as

$$S = \tilde{\delta}\Psi(\phi,\mathcal{B},\mathcal{F}). \tag{112}$$

The difference between $\hat{\delta}\Psi$ and $\tilde{\delta}\Psi$ causes no effect to the path integral, because the integral of equivariant cohomology is equal to that of original cohomology. Here we have used the notation $\mathcal{B},\mathcal{F}$ to denote the BRS doublet fields collectively. Then the localization theorem tells us that

$$Z = \int \frac{D\phi}{U(N)} D\mathcal{B}\, D\mathcal{F}\, e^{-\tilde{\delta}\Psi} = \int \prod_{I=1}^{N} d\phi_I \frac{\prod_{I\neq J}(\phi_I - \phi_J)}{S\det{}^{1/2}\,\mathcal{L}}. \tag{113}$$

ϕ_I are the eigenvalues of ϕ, and the superdeterminant $S\det\mathcal{L}$ is defined by

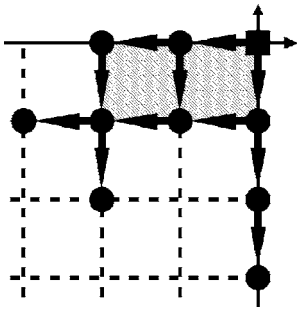

FIG. 11. A quadrangulation may include some segments that do not make faces.

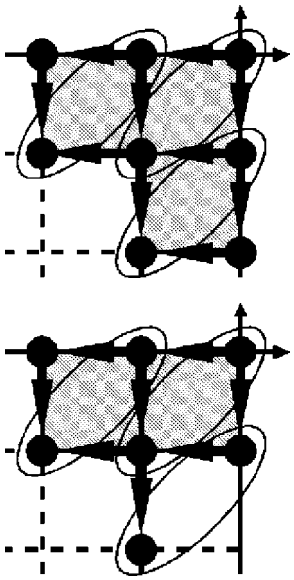

FIG. 12. Young diagram and variant diagram.

$$S\det\mathcal{L} = S\det\begin{pmatrix} \dfrac{\partial(Q)_{\mathcal{B}}}{\partial\mathcal{F}} & \dfrac{\partial(Q)_{\mathcal{B}}}{\partial\mathcal{B}} \\ \dfrac{\partial(Q)_{\mathcal{F}}}{\partial\mathcal{F}} & \dfrac{\partial(Q)_{\mathcal{F}}}{\partial\mathcal{B}} \end{pmatrix}, \tag{114}$$

where $(Q)_{\mathcal{B}}$ and $(Q)_{\mathcal{F}}$ are defined by the representation of the deformed BRS transformation $\tilde{\delta}$ on the fields $\mathcal{B},\mathcal{F}$,

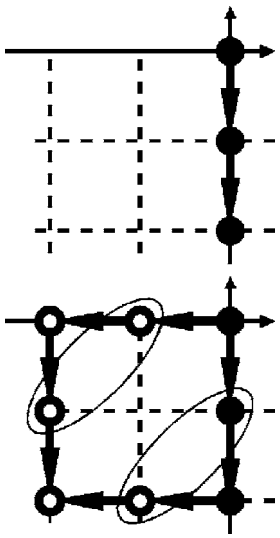

FIG. 13. Graph without a hole and graph with a hole.

$$Q = (Q)_{\mathcal{B}} \frac{\partial}{\partial \mathcal{B}} + (Q)_{\mathcal{F}} \frac{\partial}{\partial \mathcal{F}}. \tag{115}$$

Note that this expression is an analog of

$$\tilde{d} = d + i_X, \tag{116}$$

where X is a vector defining the Lie derivative $\mathcal{L}_X$ associated with $\mathcal{G} \otimes T^{N+2}$ action. See (39), (40), (41). In our case, we obtain

$$Z = \int \prod_{I=1}^{N} d\phi_I \prod_{I \neq J} (\phi_I - \phi_J) \prod_{I=1}^{N} \frac{(\epsilon_1 + \epsilon_2)\{-(\phi_I - b_I)^2 + \epsilon_-^2\}}{\epsilon_1 \epsilon_2 \{-(\phi_I - b_I)^2 + \epsilon_+^2\}}$$
$$\times \prod_{I \neq J} \frac{\{(\phi_I - \phi_J)^2 - 4\epsilon_+^2\}^{\frac{1}{2}} \{-(\phi_I - b_J)^2 + \epsilon_-^2\}}{\{-(\phi_I - b_J)^2 + \epsilon_+^2\}\{(\phi_I - \phi_J)^2 - \epsilon_1^2\}^{\frac{1}{2}} \{(\phi_I - \phi_J)^2 - \epsilon_2^2\}^{1/2}}$$

where $\epsilon_- = (\epsilon_1 - \epsilon_2)/2$.

Some comments might be necessary. This formula is derived by using a some version of localization theorem, which reduces the integral $\int D\mathcal{B}\, D\mathcal{F}$, and this is valid only if the BPS equations of the action (42), (43), (44) and the fixed point equations of the deformed BRS symmetry (50), (51) have isolated solutions for a given value of ϕ_I's. The integral $\int \Pi_I\, d\phi_I$ is remained, and this should be understood as the contour integral. In order to define an appropriate contour, we use $\epsilon_i \to \epsilon_i + i0$ prescription. The poles correspond to the isolated solutions.[39,42]

VII. CONCLUSION

The solutions of the Seiberg-Witten monopole equations reduced to 0 dimension that also satisfy the fixed point equations of torus actions were classified, where the torus action is induced from the global symmetries. More concretely speaking, we deformed the BRS transformation of the topological twisted $\mathcal{N}=2$ gauge theory on $\mathbb{R}^4$ with a hypermultiplet to the T-equivariant derivative by using the global symmetries. The global symmetries contain torus actions. Using these symmetries, the deformed BRS transformation was defined to satisfy the nilpotency up to the Lie derivative of the group actions. Then we classified the solutions of the fixed point equations of these deformed BRS transformations.

We showed that the Seiberg-Witten monopole equations are reduced to the ADHM equations with the Dirac equation reduced to 0 dimension at the large N.C. parameter limit. These equations are described by using infinite dimensional matrices. We showed that the Dirac equation reduced to 0 dimension is trivial when the ADHM equations and the fixed point equations are satisfied. It is known that the solutions of the ADHM equations with the fixed point equations are isolated ones, and are classified by the Young diagrams, when the matrix size is finite. We gave a new proof of this statement, too. Then, we found that we can perform the path integral by using the localization formula, in order to get the partition functions of the finite dimensional matrix model. This finite dimensional matrix model is given as reduced theory to 0 dimension from the topological twisted $\mathcal{N}=2$ non-Abelian gauge theory on $\mathbb{R}^4$ with a hypermultiplet, because the size of matrix is truncated to finite dimension from infinite dimension. We gave the result of the partition function of this toy model. The complete calculation of the partition function for the $\mathcal{N}=2$ $U(1)$ gauge theory on N.C. $\mathbb{R}^4$ remained. This calculation might reveal the relation between the Seiberg-Witten monopole and the instanton. We hope to report on this task elsewhere.

APPENDIX: CONVENTION

1. Complex coordinate

We define the complex coordinate $z^i, \bar{z}^i (i=1,2)$ as

$$z^1 = \frac{1}{\sqrt{2}}(x^1 + ix^2), \quad \bar{z}^1 = \frac{1}{\sqrt{2}}(x^1 - ix^2),$$

$$z^2 = \frac{1}{\sqrt{2}}(x^3 + ix^4), \quad \bar{z}^2 = \frac{1}{\sqrt{2}}(x^3 - ix^4). \tag{A1}$$

Also, $\partial_{z^i}, \partial_{\bar{z}^i}$ are given by

$$\partial_{z^1} = \frac{1}{\sqrt{2}}(\partial_1 - i\partial_2), \quad \partial_{\bar{z}^1} = \frac{1}{\sqrt{2}}(\partial_1 + i\partial_2),$$

$$\partial_{z^2} = \frac{1}{\sqrt{2}}(\partial_3 - i\partial_4), \quad \partial_{\bar{z}^2} = \frac{1}{\sqrt{2}}(\partial_3 + i\partial_4). \tag{A2}$$

Then, we obtain
