$$\partial_{z^i} z^j = \delta_i^j, \quad \partial_{\bar{z}^i} \bar{z}^j = \delta_i^j. \tag{A3}$$

2. Spinor index

$\epsilon^{\alpha\beta}$, $\epsilon^{\dot{\alpha}\dot{\beta}}$ and $\epsilon_{\alpha\beta}$, $\epsilon_{\dot{\alpha}\dot{\beta}}$ are defined by

$$\epsilon^{\alpha\beta} = \epsilon^{\dot{\alpha}\dot{\beta}} = \begin{pmatrix} 0 & +1 \\ -1 & 0 \end{pmatrix}, \quad \epsilon_{\alpha\beta} = \epsilon_{\dot{\alpha}\dot{\beta}} = \begin{pmatrix} 0 & -1 \\ +1 & 0 \end{pmatrix}. \tag{A4}$$

In other words, $\epsilon_{\alpha\beta}$, $\epsilon_{\dot{\alpha}\dot{\beta}}$ are defined to be the inverses of $\epsilon^{\alpha\beta}$, $\epsilon^{\dot{\alpha}\dot{\beta}}$,

$$\epsilon^{\alpha\beta}\epsilon_{\beta\gamma} = \delta^\alpha_\gamma \epsilon^{\dot{\alpha}\dot{\beta}}, \quad \epsilon_{\dot{\beta}\dot{\gamma}} = \delta^{\dot{\alpha}}_{\dot{\gamma}}. \tag{A5}$$

Then a spinor with upper indices and a spinor with lower indices are related as

$$\psi^\alpha = \epsilon^{\alpha\beta}\psi_\beta, \quad \psi_\alpha = \epsilon_{\alpha\beta}\psi^\beta,$$

$$\psi^{\dot{\alpha}} = \epsilon^{\dot{\alpha}\dot{\beta}}\psi_{\dot{\beta}}, \quad \psi_{\dot{\alpha}} = \epsilon_{\dot{\alpha}\dot{\beta}}\psi^{\dot{\beta}}. \tag{A6}$$

We use the following definition for the four dimensional Pauli matrix $\sigma^\mu (\mu=1,2,3,4)$,

$$(\sigma^\mu)_{\alpha\dot{\alpha}} = (\sigma^1, \sigma^2, \sigma^3, \sigma^4) = (i\mathbf{1}, -\vec{\tau}),$$

$$(\bar{\sigma}^\mu)^{\dot{\alpha}\alpha} = (\bar{\sigma}^1, \bar{\sigma}^2, \bar{\sigma}^3, \bar{\sigma}^4) = (i\mathbf{1}, +\vec{\tau}), \tag{A7}$$

where

$$\vec{\tau} = \left(\begin{pmatrix} 0 & +1 \\ +1 & 0 \end{pmatrix}, \begin{pmatrix} 0 & -i \\ +i & 0 \end{pmatrix}, \begin{pmatrix} +1 & 0 \\ 0 & -1 \end{pmatrix} \right). \tag{A8}$$

We define $\sigma^{\mu\nu}$, $\bar{\sigma}^{\mu\nu}$ as

$$(\sigma^{\mu\nu})_\alpha{}^\beta = \frac{i}{4}(\sigma^\mu\bar{\sigma}^\nu - \sigma^\nu\bar{\sigma}^\mu)_\alpha{}^\beta,$$

$$(\bar{\sigma}^{\mu\nu})_{\dot\beta}{}^{\dot\alpha} = \frac{i}{4}(\bar{\sigma}^\mu\sigma^\nu - \bar{\sigma}^\nu\sigma^\mu)_{\dot\beta}{}^{\dot\alpha}. \tag{A9}$$

From this definition, $\sigma^{\mu\nu}$ and $\bar{\sigma}^{\mu\nu}$ satisfy the anti self-dual relation and the self-dual relation, respectively,

$$\sigma^{\mu\nu} = -*\sigma^{\mu\nu}, \quad \bar{\sigma}^{\mu\nu} = +*\bar{\sigma}^{\mu\nu}. \tag{A10}$$

3. † symbol

For a scalar matrix M and a vector matrix M_μ, the symbol † denotes the usual hermite conjugation for them,

$$M^\dagger = M^{*T}, \quad M_\mu{}^\dagger = M_\mu{}^{*T}, \tag{A11}$$

where the symbol * denotes the complex conjugation and the symbol T denotes the transposition. On the other hand, for an undotted spinor matrix M_α and a dotted spinor matrix $M_{\dot\alpha}$, $M_\alpha{}^\dagger$, and $M_{\dot\alpha}{}^\dagger$ are defined by,

$$M_\alpha{}^\dagger = \epsilon^{\alpha\beta}M_\beta{}^{*T}, \quad M_{\dot\alpha}{}^\dagger = \epsilon^{\dot\alpha\dot\beta}M_{\dot\beta}{}^{*T}. \tag{A12}$$

This definition makes $M_\alpha{}^\dagger$ and $M_{\dot\alpha}{}^\dagger$ transform in the same rules as M_α and $M_{\dot\alpha}$ under $SU(2)_L$ and $SU(2)_{R(R')}$, respectively.

(Received 22 June 2006; accepted 20 September 2006; published online 8 November 2006)

We show that Petrov type I vacuum solutions admitting a Killing vector whose Papapetrou field is aligned with a principal bivector of the Weyl tensor are the Kasner and Taub metrics, their counterpart with timelike orbits and their associated windmill-like solutions, as well as the Petrov homogeneous vacuum solution. We recover all these metrics by using an integration method based on an invariant classification which allows us to characterize every solution. In this way we obtain an intrinsic and explicit algorithm to identify them. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2363258]

I. INTRODUCTION

If ξ is a Killing vector, the *Killing 2-form* $\nabla\xi$ is closed and, in the vacuum case, it is a solution of the source-free Maxwell equations. Because this fact was pointed out by Papapetrou,[1] the covariant derivative $\nabla\xi$ has also been called the *Papapetrou field*.[2] In the Kerr geometry the principal directions of the Killing 2-form associated with the timelike Killing vector coincide with the two double principal null (Debever) directions of the Weyl tensor.[2] This means that the Killing 2-form is a Weyl principal bivector. This fact has been remarked upon by Mars[3] who has also shown that it characterizes the Kerr solution under an asymptotic flatness behavior.

A question naturally arises: can all the vacuum solutions with this property of the Kerr metric be determined? In other words, is it possible to integrate Einstein vacuum equations under the hypothesis that the spacetime admits an isometry whose Killing 2-form is a principal bivector of the Weyl tensor? Some partial results are known about this question. Thus, we have studied the case of Petrov type D spacetimes elsewhere[4] and we have shown that the Kerr-NUT solutions are the type D vacuum metrics with a timelike Killing 2-form aligned with the Weyl geometry.

Metrics admitting an isometry were studied by considering the algebraic properties of the associated Killing 2-form,[5,6] and this approach was extended to the spacetimes with an homothetic motion.[7,8] More recently Fayos and Sopuerta[2,9] have developed a formalism that improves the use of the Killing 2-form and its underlined algebraic structure for analyzing the vacuum solutions with an isometry. They consider two new viewpoints that permit a more accurate classification of these spacetimes: (i) the differential properties of the principal directions of the Killing 2-form, and (ii) the degree of alignment of the principal directions of the Killing 2-form with those of the Weyl tensor. The Fayos and Sopuerta approach uses the Newman–Penrose formalism and several extensions have been built for homothetic and conformal motions[10,11] and for nonvacuum solutions.[12]

[a)]Electronic mail: joan.ferrando@uv.es
[b)]Electronic mail: juan.a.saez@uv.es

Some of the conditions on the Killing 2-form imposed in the literature quoted above could be very restrictive. Thus, in a previous paper[13] we have shown that the Petrov type I vacuum spacetimes admitting an isometry whose Killing 2-form is aligned with a Weyl principal bivector belong to two classes of metrics which admit a three-dimensional group of isometries of Bianchi types I or II. In the present work we show that a close relation between the Weyl principal directions and the isometry group exists in these classes. This fact allows us to achieve an integration of the vacuum equations with the aid of an invariant classification and, in this way, to obtain an intrinsic and explicit characterization of all the Petrov type I vacuum solutions that admit an aligned Papapetrou field. It is worth remarking that the integration method used here could be suitable in order to obtain other type I solutions.

The vacuum homogeneous Petrov solution[14] was found to be the only one satisfying: (i) vacuum, and (ii) existence of a simply transitive group G_4 of isometries. Although these two conditions characterize the Petrov metric, it is quite difficult to know when a metric tensor (given in an arbitrary coordinate system) satisfies them. Indeed, the first condition is intrinsic because it imposes a restriction on a metric concomitant, the Ricci tensor. Nevertheless, the second one imposes equations that mix up, in principle, elements other than the metric tensor (Killing vectors of the isometry group) and, consequently, it cannot be verified by simply substituting the metric tensor. In Ref. 13 we have changed this last nonintrinsic condition for an intrinsic one: the Weyl tensor is Petrov type I with constant eigenvalues. Moreover, as the Ricci and Weyl tensors are concomitants of the metric tensor, $\mathrm{Ric} \equiv \mathrm{Ric}(g)$, $\mathcal{W} \equiv \mathcal{W}(g)$, we have finally obtained the following *intrinsic* and *explicit* characterization of the Petrov solution:[13] *the necessary and sufficient conditions for g to be the Petrov homogeneous vacuum solution are*

$$\mathrm{Ric} = 0, \quad 6(\mathrm{Tr}\mathcal{W}^2)^3 \neq (\mathrm{Tr}\mathcal{W}^3)^2, \quad \mathrm{dTr}\mathcal{W}^2 = \mathrm{dTr}\mathcal{W}^3 = 0. \tag{1}$$

A whole intrinsic and explicit characterization of a metric or a family of metrics is quite interesting from a conceptual point of view and from a practical one because it can be tested by direct substitution of the metric tensor in arbitrary coordinates. Thus, it is an approach to the metric equivalence problem alternative to the usual one. This and other advantages have been pointed out elsewhere[15] where this kind of identification has been obtained for the Schwarszchild spacetime as well as for all the other type D static vacuum solutions. A similar study has been fulfilled for a family of Einstein–Maxwell solutions that include the Reissner–Nordström metric.[16]

In order to obtain intrinsic and explicit characterizations, as well as having an intrinsic labelling of the metrics, we need to express these intrinsic conditions in terms of explicit concomitants of the metric tensor. When doing this, the role played by the results on the covariant determination of the eigenvalues and eigenspaces of the Ricci tensor[17] and the principal 2-forms and principal directions of the Weyl tensor[18,19] is essential.

In this work we solve vacuum equations under the hypothesis that the spacetime is Petrov type I and there is a Killing vector whose associated Papapetrou field is a eigenbivector of the Weyl tensor. In this way, we recover the Petrov homogeneous vacuum solutions as well as the Kasner and Taub metrics, their counterpart with timelike orbits and their associated windmill-like solutions. Our integration method is based on an invariant classification which allows us to characterize the solutions intrinsically and explicitly. For every solution some properties of the isometry group and the aligned Killing 2-forms are given in terms of the Weyl principal directions.

The article is organized as follows. In Sec. II we present the Cartan formalism adapted to the Weyl principal frame that a Petrov type I spacetime admits. In Sec. III we summarize some results needed here about type I vacuum metrics admitting aligned Papapetrou fields. In Sec. IV we write vacuum Einstein equations for the families of Petrov type I metrics that, having a nonconstant Weyl eigenvalue, admit aligned Papapetrou fields. Sections V and VI are devoted to integrate these equations in different invariant subcases, as well as to determine, for every solution, the Killing vectors with an aligned Killing 2-form. In Sec. VII we present a similar study when all the Weyl eigenvalues are constant. Finally, in Sec. VIII, we summarize the results in an algorithmic form in order to make the intrinsic and explicit character of our results evident.

II. CARTAN FORMALISM IN THE WEYL FRAME OF A TYPE I SPACETIME

The algebraic classification of the Weyl tensor was first tackled by Petrov[20] considering the number of the invariant subespaces of the Weyl tensor regarded as an endomorphism of the 2-forms space. This classification was completed by Géhéniau[21] and Bel[22] considering also the eigenvalue multiplicity. In this framework appears the notion of *Weyl principal bivector* that we use here and which was widely analyzed by Bel[23] for the different algebraic types. In the 1960s many other authors presented alternative approaches to this classification, and in more recent studies[19,24] a wide bibliography on this subject can be found. For short, we refer the different classes of the Weyl tensor as the Petrov types. An algebraically general Weyl tensor is Petrov type I.

In a Petrov type I spacetime the Weyl tensor W determines four orthogonal principal directions which define the *Weyl principal frame* $\{e_\alpha\}$.[19,23] Then, the bivectors (self-dual 2-forms) $\mathcal{U}_i = 1/\sqrt{2}(U_i - i*U_i)$, with $U_i = e_0 \wedge e_i$, are eigenbivectors of the self-dual Weyl tensor $\mathcal{W} = 1/2(W - i*W)$, * being the Hodge dual operator. These bivectors satisfy $2\mathcal{U}_i \times \mathcal{U}_i = g$, where $\times$ denotes the contraction of adjacent index in the tensorial product. The tern $\{\mathcal{U}_i\}$ constitutes an orthonormal frame in the bivector space which has the induced orientation given by

$$\mathcal{U}_i \times \mathcal{U}_j = -\frac{i}{\sqrt{2}}\epsilon_{ijk}\mathcal{U}_k, \quad i \neq j. \tag{2}$$

If α_i is the eigenvalue associated with the eigenbivector $\mathcal{U}_i$, the self-dual Weyl tensor takes the canonical form

$$\mathcal{W} = -\sum_{i=1}^{3} \alpha_i \mathcal{U}_i \otimes \mathcal{U}_i. \tag{3}$$

The Cartan formalism can be referred to the Weyl principal frame $\{e_\alpha\}$ or, equivalently, to the *frame of eigenbivectors* $\{\mathcal{U}_i\}$. So, the six connection 1-forms ω_α^β defined by $\nabla e_\alpha = \omega_\alpha^\beta \otimes e_\beta$ can be collected into three complex ones Γ_i^j ($\Gamma_i^j = -\Gamma_j^i$), and the first structure equations take the expression

$$\nabla \mathcal{U}_i = \Gamma_i^j \otimes \mathcal{U}_j, \quad \Gamma_i^j = \omega_i{}^j - \epsilon_{ijk}\omega_0^k. \tag{4}$$

The second structure equations for a vacuum type I spacetime follow by applying the Ricci identities $\nabla_{[\alpha}\nabla_{\beta]}\mathcal{U}_{i\epsilon\delta} = \mathcal{U}_{i\epsilon}{}^{\mu}R_{\mu\delta\beta\alpha} + \mathcal{U}_i{}^{\mu}{}_{\delta}R_{\mu\epsilon\beta\alpha}$, and in terms of the eigenbivectors $\{\mathcal{U}_i\}$ they can be written as

$$\mathrm{d}\Gamma_i^k - \Gamma_i^j \wedge \Gamma_j^k = i\sqrt{2}\epsilon_{ikm}\alpha_m \mathcal{U}_m. \tag{5}$$

If we make the product of each of these second structure Eq. (5) with $\mathcal{U}_m$ we can obtain the following three complex scalar equations:

$$\nabla \cdot \lambda_i = \lambda_i^2 - (\lambda_j - \lambda_k)^2 - \alpha_i \quad (i,j,k \neq), \tag{6}$$

where $\lambda_i = -\mathcal{U}_i(\nabla \cdot \mathcal{U}_i)$, and we have denoted $\nabla \cdot \equiv \mathrm{Tr}\nabla$ and $\lambda_i^2 = g(\lambda_i, \lambda_i)$. The three complex 1-forms λ_i contain the 24 independent connection coefficients as the Γ_i^j do. In fact, by using Eq. (2) and the first structure Eqs. (4), both sets $\{\Gamma_i^j\}$ and $\{\lambda_i\}$ can be related by

$$\lambda_i \equiv -\mathcal{U}_i(\nabla \cdot \mathcal{U}_i) = -\frac{i}{\sqrt{2}}\epsilon_{ijk}\mathcal{U}_k(\Gamma_i^j). \tag{7}$$

And the inverse of these expressions say that for different i,j,k,

$$\mathcal{U}_k(\Gamma_i^j) = \frac{i}{\sqrt{2}}\epsilon_{ijk}(\lambda_i + \lambda_j - \lambda_k), \quad (i,j,k \neq). \tag{8}$$

The Bianchi identities in the vacuum case state that the Weyl tensor is divergence-free $\nabla \cdot \mathcal{W}=0$, and from Eq. (3) they can be written as

$$\mathrm{d}\alpha_i = (\alpha_j - \alpha_k)(\lambda_j - \lambda_k) - 3\alpha_i\lambda_i \quad (i,j,k \neq). \tag{9}$$

Equations (9) show the relation that exists between the gradient of the Weyl eigenvalues and the 1-forms λ_i in the vacuum case. This fact has suggested a classification of Petrov type I spacetimes taking into account the dimension of the space that $\{\lambda_i\}$ generate. More precisely,[13]

Definition 1: We say that a Petrov type I spacetime is of class I_a $(a=1,2,3)$ if the dimension of the space that $\{\lambda_i\}$ generate is a.

Differential conditions of this kind were imposed by Edgar[25] on the type I spacetimes, and he showed that in the vacuum case his classification also has consequences on the functional dependence of the Weyl eigenvalues. We have slightly modified the Edgar approach in order to obtain a classification that is symmetric in the principal structures of the Weyl tensor. We remark the invariant nature of this classification: it is based on the vector Weyl invariants λ_i.

We have been studied elsewhere the symmetries of the vacuum metrics of class I_1 and we have shown:[13]

Lemma 1: A vacuum metric of class I_1 admits at least a (simply transitive) group G_3 of isometries. It admits a G_4 if, and only if, it has constant eigenvalues.

III. ALIGNED KILLING 2-FORMS AND TYPE I VACUUM METRICS

If ξ is a (real) Killing vector its covariant derivative $\nabla\xi$ is named Killing 2-form or Papapetrou field.[1,2] The Papapetrou fields have been used to study and classify spacetimes admitting an isometry or an homothetic or conformal motion (see Refs. 2–12). In this way, some classes of vacuum solutions with a principal direction of the Papapetrou field aligned with a (Debever) null principal direction of the Weyl tensor have been considered.[9] Also, the alignment between the Weyl principal plane and the Papapetrou field associated with the timelike Killing vector has been shown in the Kerr geometry.[3,9]

Is it possible to determine all the vacuum solutions having this property of the Kerr metric? Elsewhere[4] we give an affirmative answer to this question for the case of Petrov type D spacetimes by showing that *the type D vacuum solutions with a timelike Killing 2-form aligned with the Weyl geometry are the Kerr-NUT metrics*. In this work we accomplish this study for the Petrov type I spacetimes by obtaining all the vacuum solutions with this property and by determining the Killing vectors with an aligned Killing 2-form. Moreover, we show the close relation between the Weyl tensor geometry and the geometries of ξ and $\nabla\xi$.

In order to clarify what kind of alignment between the Killing 2-form and the Weyl tensor is analyzed in this work we give the specific definition. If $\{\mathcal{U}_i\}$ is an orthonormal basis of the self-dual 2-forms space, the Papapetrou field $\nabla\xi$ associated to a Killing vector ξ has, generically, three independent complex components Ω_i:

$$\nabla\xi = \sum_{i=1}^{3} \Omega_i\mathcal{U}_i + \sum_{i=1}^{3} \tilde{\Omega}_i\tilde{\mathcal{U}}_i \tag{10}$$

where ~ means complex conjugate. Then:

Definition 2: We say that a Papapetrou field $\nabla\xi$ is aligned with a bivector $\mathcal{U}$ if both 2-forms have the same principal 2-planes, that is, $\nabla\xi=\Omega\mathcal{U}+\tilde{\Omega}\tilde{\mathcal{U}}$.

We say that a Papapetrou field $\nabla\xi$ is aligned (with the Weyl tensor) if it is aligned with a Weyl principal bivector.

When a Killing 2-form is aligned with a bivector of an orthonormal frame of invariants bivectors $\mathcal{U}_i$, the Killing vector is strongly restricted by the connection 1-forms. Thus, for type I metrics we have:[13]

Lemma 2: In a Petrov type I spacetime with a Killing vector ξ, the Papapetrou field $\nabla\xi$ is aligned with a Weyl principal 2-form $\mathcal{U}_i$ if, and only if, ξ is orthogonal to the two complex connection 1-forms Γ_i^j *(*defined by the Weyl principal frame $\{\mathcal{U}_i\}$*).*

The alignment between a Killing 2-form and a Weyl principal bivector of a type I vacuum solution has been partially analyzed[13] and the following necessary condition has been obtained:

Lemma 3: A vacuum Petrov type I spacetime which admits a Killing field with an aligned Papapetrou field belongs to class I_1.

As a consequence of Lemmas 1 and 3, we obtain that *a vacuum Petrov type I spacetime which admits a Killing field with an aligned Papapetrou field admits, at least, a three-dimensional group of isometries.* This means that a unique symmetry with an aligned Papapetrou field implies that other symmetries exist.

These results imply that in order to find all the type I vacuum solutions admitting an aligned Papapetrou field, we must analyze the vacuum solutions of class I_1. We shall start with the case where a non constant eigenvalue α_1 exists. After that we shall finish by dealing with the case of all the eigenvalues being constant.

IV. VACUUM EQUATIONS FOR THE CLASS I_1

As we know that every vacuum solution of class I_1 admits a (simply transitive) G_3 group of isometries, a real function τ exists such that $\alpha_i \equiv \alpha_i(\tau)$. Moreover, as we are in class I_1, it must be $\lambda_i \wedge \lambda_j = 0$ and so, from Bianchi identities (9), we obtain $\lambda_i \wedge \mathrm{d}\alpha_1 = 0$. So, taking into account Eq. (7) and that a G_3 is admitted, three functions $\varphi_i(\tau)$ exist such that

$$\Gamma_i^j = \mathrm{i}\epsilon_{ijk}\varphi_k \mathcal{U}_k(\mathrm{d}\tau). \tag{11}$$

On the other hand, it has also been shown in Ref. 13 that $\mathrm{d}\alpha_1$ cannot be a null vector and so, $(\mathrm{d}\tau)^2 \neq 0$. Thus, $\{\mathrm{d}\tau, u^i\}$, with $u^i = \mathcal{U}_i(\mathrm{d}\tau)$, is an orthogonal frame such that $2(u^i)^2 = -(\mathrm{d}\tau)^2$. Then, we can write the bivectors $\{\mathcal{U}_i\}$ as

$$\mathcal{U}_i = -\frac{1}{(\mathrm{d}\tau)^2}\left(\mathrm{d}\tau \wedge u^i + \frac{i}{\sqrt{2}}\epsilon_{ijk}u^j \wedge u^k\right). \tag{12}$$

We can use this expression to eliminate $\mathcal{U}_i$ in the second structure Eqs. (4) and then they become an exterior system for the orthonormal frame $\{\mathrm{d}\tau, u^i\}$,

$$\mathrm{d}u^i = \mu_i(\tau)\mathrm{d}\tau \wedge u^i + \nu_i(\tau)u^j \wedge u^k \tag{13}$$

for every cyclic permutation i, j, k, and where the functions μ_i and ν_i are given by

$$\mu_i = -(\ln \varphi_i)' + \frac{\sqrt{2}\alpha_i}{\varphi_i(\mathrm{d}\tau)^2}, \quad \nu_i = -\mathrm{i}\left(\frac{2\alpha_i}{\varphi_i(\mathrm{d}\tau)^2} + \frac{\varphi_j\varphi_k}{\varphi_i}\right), \tag{14}$$

where $'$ stands for the derivative with respect to the variable τ. But $\mathrm{d}\tau$ is proportional to the invariant 1-form $\mathrm{d}\alpha_1$ and a G_3 exists. Thus, it follows that $(\mathrm{d}\tau)^2$ and $\Delta\tau$ depend on τ. This fact allows us to choose τ such that $\Delta\tau = 0$. Then, τ is fixed up to an affine transformation $\tau \hookrightarrow \alpha\tau + \beta$. In terms of this harmonic function, the Eqs. (6) become

$$((\varphi_j + \varphi_k)' - \sqrt{2}\varphi_j\varphi_k)(\mathrm{d}\tau)^2 = 2\sqrt{2}\alpha_i \tag{15}$$

for every cyclic permutation of i, j, k. The Bianchi identities (9) can be stated as

$$\alpha_1' = \frac{1}{\sqrt{2}}(\varphi_3(\alpha_2 - \alpha_1) - \varphi_2(2\alpha_1 + \alpha_2)), \quad \alpha_2' = \frac{1}{\sqrt{2}}(\varphi_3(\alpha_1 - \alpha_2) - \varphi_1(\alpha_1 + 2\alpha_2)). \tag{16}$$

At this point, it is clear that the integration of the system (13) depends strongly on the number of the $u^i=\mathcal{U}_i(\mathrm{d}\tau)$ that are integrable 1-forms. Thus, it seems suitable to give a classification of type I_1 spacetimes that takes into account these restrictions. But these conditions lead to an invariant classification because of u^i is proportional to $\mathcal{U}_i(\mathrm{d}\alpha_1)$:

Definition 3: We will say that a Petrov type I_1 vacuum metric with $\mathrm{d}\alpha_1\neq 0$ is of class I_{1A} $(A=0,1,2,3)$ if there are exactly A integrable 1-forms in the set $\{\mathcal{U}_i(\mathrm{d}\alpha_1)\}$.

We have studied elsewhere[13] the symmetries that the different classes I_{1A} admit, as well as necessary conditions for the alignment of the associated Killing 2-forms with the Weyl tensor. Here we will make use of the following result:

Lemma 4: If a vacuum Petrov type I spacetime admits a Killing field with an aligned Papapetrou field then either it is the Petrov solution (that has constant eigenvalues) or it is of class I_{12} or I_{13}. These classes admit an isometry group G_3 of Bianchi types II and I, respectively.

Thus, in order to find the vacuum solutions with aligned Papapetrou fields, we must consider the Petrov solution that admits a G_4 or the classes I_{12} and I_{13}. Now we obtain the vacuum solutions for these two classes with non constant eigenvalues. To accomplish this goal, we will integrate the Bianchi identities (16) and the scalar Eqs. (15) taking into account that in class I_{13} all the functions ν_i given in Eq. (14) are zero and two of them vanish in class I_{12}. Finally, the second structure Eqs. (13) will be integrated to obtain the 1-forms u^i in terms of real coordinates. After that, the metric tensor will be obtained as

$$g=\frac{1}{(\mathrm{d}\tau)^2}\left[\mathrm{d}\tau\otimes\mathrm{d}\tau-2\sum_{i=1}^{3}u^i\otimes u^i\right] \tag{17}$$

It is worth pointing out that in the spacetimes of type I_1 that we are studying here there exist two outlined coframes, namely, the Weyl principal coframe $\{\theta^\alpha\}$ and that defined by $\{\mathrm{d}\tau,u^i\}$. We will see in following sections the close relation between both coframes for the spacetimes in classes I_{12} and I_{13}. This fact allows us to give intrinsic conditions that label every type I vacuum solution admitting an aligned Papapetrou field.

V. VACUUM SOLUTIONS OF CLASS I_{13}

In class I_{13} all of the 1-forms u^i are integrable. Then Eqs. (13) hold with $\nu_i=0$. Taking into account Eq. (14), we can solve the Eqs. (15) and (16) to obtain

$$\alpha_1=be^{2a\beta\tau},\quad \alpha_2=k\alpha_1,\quad (\mathrm{d}\tau)^2=\frac{be^{2a\beta\tau}}{a^2k(k+1)}, \tag{18}$$

$$\varphi_3=\sqrt{2}ka,\quad \varphi_2=-\sqrt{2}a(k+1),\quad \varphi_1=-\sqrt{2}k(k+1)a, \tag{19}$$

where a, b and $\beta=1+k+k^2$ are nonzero constants and k is different from 1, -2, and $-1/2$ because g is not of Petrov type D, and different from -1 and 0 because none of the Weyl eigenvalues vanishes as a consequence of the Szekeres–Brans theorem.[26,27] The second structure Eqs. (13) constitute an exterior system for the 1-forms $u^i\equiv\mathcal{U}_i(\mathrm{d}\tau)$. It implies that three complex functions $\{x^i\}$ exist such that

$$u^1=e^{a\tau}\mathrm{d}x^1,\quad u^2=e^{ak^2\tau}\mathrm{d}x^2,\quad u^3=e^{a(1+k)^2\tau}\mathrm{d}x^3. \tag{20}$$

From here and Eq. (17), we can obtain the metric tensor g in complex coordinates. In order to get real coordinates, another fact is needed. As τ is a real function, it follows that $\mathrm{d}\tau$, $(\mathrm{d}\tau)^2$ and $\nabla\mathrm{d}\tau$ must also be real. If we compute $\nabla\mathrm{d}\tau$ by using Eqs. (17)–(19) we obtain that, necessarily, either all of the coefficients are real and $\mathrm{d}\tau$ coincides with one of the principal directions θ^α, or two of the coefficients are conjugate and $\mathrm{d}\tau$ takes the direction of one of the bisectors $\theta^i\pm\theta^j$ of a spacelike principal plane. We shall analyze every case, but we must take into account that as $\mathrm{d}\tau\wedge\mathrm{d}\alpha_1=0$, these conditions can also be written in terms of the Weyl eigenvalue.

A. $d\alpha_1$ Is a Principal Direction

In this case a and k are real constants. We must remark that if $d\tau$ is a principal direction, then $u^i \equiv \mathcal{U}_i(d\tau)$ are so. But when $d\tau$ coincides with the timelike principal direction θ^0, every u^i is a real direction and, if $d\tau$ is a spacelike principal direction, some of them are purely imaginary. Now we will analyze each case in detail.

(i) Case $d\alpha_1 \wedge \theta^0 = 0$. We have $d\tau = e_0(\tau)\theta^0$. Then $u^i = (1/\sqrt{2})e_0(\tau)\theta^i$, and so dx^i of Eq. (20) are real. If we take into account that the harmonic coordinate τ is defined up to affine transformation, the metric tensor (17) in real coordinates takes the form of the Kasner metric

$$g = -e^{-2\tau}d\tau^2 + e^{2(1/\beta-1)\tau}(dx^1)^2 + e^{2(k^2/\beta-1)\tau}(dx^2)^2 + e^{2(((1+k)^2/\beta)-1)\tau}(dx^3)^2. \tag{21}$$

The coordinate transformation $e^{-\tau} = t$ changes the harmonic time to the proper time and gives us the usual expression for this solution.[24,28]

We must check whether there is a Killing field with an aligned Papapetrou field. We have established[13] that this condition is equivalent to a Killing field to be orthogonal to two of the complex connection 1-forms Γ_i^j (see Lemma 2). The real Killing fields of this metric are $\xi = k_1\partial_{x^1} + k_2\partial_{x^2} + k_3\partial_{x^3}$. As the connection 1-forms Γ_i^j are collinear with u^i it follows that every Killing field ∂_i satisfies this condition, and so, we have three Killing fields such that their Papapetrou fields are aligned with the three principal 2-forms.

(ii) Case $d\alpha_1 \wedge \theta^1 = 0$. Now, $d\tau = e_1(\tau)\theta^1$, and so $(d\tau)^2 > 0$. In order to get real coordinates we must take into account that in this case $\sqrt{2}u^1 = -e_1(\tau)\theta^0$, $\sqrt{2}u^2 = ie_1(\tau)\theta^3$ and $\sqrt{2}u^3 = ie_1(\tau)\theta^2$. And so, the coordinates adapted to u^2 and u^3 are purely imaginary $x^a = iy^a$ $(a=2,3)$, y^a being real functions. Then, for the metric tensor g we get a similar expression to the one in the previous case, the only change being the causal character of the gradient of the Weyl eigenvalue

$$g = e^{-2\tau}d\tau^2 - e^{2(1/\beta-1)\tau}(dx^1)^2 + e^{2(k^2/\beta-1)\tau}(dy^2)^2 + e^{2(((1+k)^2/\beta)-1)\tau}(dy^3)^2. \tag{22}$$

This is the static Kasner metric.[24]

This solution admits three Killing fields ∂_{x^1}, ∂_{y^2}, and ∂_{y^3} such that their Papapetrou fields are aligned with the three principal bivectors of the Weyl tensor. This finishes the study of the cases in which the gradient of the invariant $\alpha_1(\tau)$ is collinear with a principal direction of the Weyl tensor. The following proposition summarizes the main results.

Proposition 1: The Kasner metrics (21) and (22) are the only Petrov type I_{13} vacuum solutions where the gradient of the Weyl eigenvalue is a principal direction of the Weyl tensor.

The metrics of this family admit three Killing fields ξ_i which are collinear with the three principal directions $\mathcal{U}_i(d\alpha_1)$, such that their Papapetrou fields $\nabla\xi_i$ are aligned with the three principal bivectors $\mathcal{U}_i$ of the Weyl tensor.

B. $d\alpha_1$ Is Not a Principal Direction

As we have commented below, in this case $d\tau$ must take the direction of one of the bisectors of a spacelike principal plane, say $\theta^2 + \theta^3$, $d\tau \propto \theta^2 + \theta^3$. Then, $u^1 \propto \theta^3 - \theta^2$, $u^2 \propto \theta^0 + i\theta^1$ and $u^3 \propto \theta^0 - i\theta^1$. Moreover, $\nabla d\tau$ is real if, and only if, a is real and $2k = -1 + in$, n being a nonzero real constant because the metric is not of type D and $n^2 \neq 3$ because β cannot be zero. Then, the coordinate x^1 of Eq. (20) must be purely imaginary, $x^1 = ix$, and x^2 and x^3 must be conjugated functions, that is $x^2 = y - iz$, $x^3 = y + iz$. Thus we get a real coordinate system $\{\tau, x, y, z\}$ and, from Eq. (17), we find the following expression of the metric tensor:

$$g = \frac{1}{4}(3-n^2)^2 e^{(1/2)(3-n^2)\tau}d\tau^2 + e^{-(1/2)(1+n^2)\tau}dx^2 + e^{\tau}[\cos(n\tau)[dz^2 - dy^2] - 2\sin(n\tau)dydz]. \tag{23}$$

This is the so called *windmill solution*.[24,29]

To see if an aligned Killing 2-form can exist in this spacetime, we must look for a Killing field to be orthogonal to two of the connection 1-forms. The Killing fields of this solution are $\xi = k_1\partial_x + k_2\partial_y + k_3\partial_z$ and, as every connection 1-form is parallel to one of the directions u^i, the only Killing field which is orthogonal to a pair of connection 1-forms is ∂_x, that can be characterized as the Killing field that takes the direction of the bisector $\theta^2 - \theta^3$. Moreover, the Weyl tensor has just a real eigenvalue α_1 and if $\mathcal{U}_1$ is the associated eigenbivector, then $\mathcal{U}_1(\mathrm{d}\alpha_1)$ is collinear with the Killing field ∂_x. We can collect these results in the following:

Proposition 2: The windmill solution (23) is the only Petrov type I_{13} vacuum solution where the gradient of the Weyl eigenvalue α_1 is not a principal direction of the Weyl tensor.

In such spacetime a unique real eigenvalue α_1 exists. Then, if $\mathcal{U}_1$ is the associated eigenbivector, the field $\mathcal{U}_1(\mathrm{d}\alpha_1)$ is collinear with a Killing field that has a Papapetrou field aligned with $\mathcal{U}_1$.

VI. VACUUM SOLUTIONS OF CLASS I_{12}

Let us suppose now that only two directions, let us say u^2 and u^3, are integrable. So, we can take $\nu_2 = \nu_3 = 0$ in the second structure Eqs. (13). Taking into account the definition of ν_i from Eq. (14) we obtain

$$\varphi_3 = \frac{k}{\sqrt{2}} - \varphi_1, \quad \varphi_2 = \frac{a^2}{\sqrt{2}k} - \varphi_1, \quad \varphi_1 = \frac{a}{\sqrt{2}}\frac{be^{-a\tau}+1}{be^{-a\tau}-1}, \tag{24}$$

where a, b, and k are complex constants, $a^2 \neq k^2$. Then, by also using the Bianchi identities (16) we obtain

$$(\mathrm{d}\tau)^2 = \frac{-2\sqrt{2}c}{a} e^{-((a^2+ak+k^2)/k)\tau}(b^2e^{-2a\tau}-1)^{-1}, \tag{25}$$

where c is another complex constant.

As in the previous section, the only possibilities for $\nabla \mathrm{d}\tau$ to be real are that either $\mathrm{d}\tau$ is a principal direction θ^α or it is the bisector $\theta^i + \theta^j$ of a spacelike principal plane.

A. $\mathrm{d}\alpha_1$ Is a Principal Direction

In this case we have that k, a^2 and $\varphi_3'/\varphi_3 - \sqrt{2}\varphi_3$ are real. From Eq. (24) we obtain

$$\frac{\varphi_3'}{\varphi_3} - \sqrt{2}\varphi_3 = -a\frac{b^2 + e^{2\sqrt{2}\tau}}{b^2 - e^{2\sqrt{2}\tau}}. \tag{26}$$

So we can conclude that a and b^2 must be real constants. Now we shall go on the integration of Eq. (13). As in the previous section it will be useful to distinguish the cases of $\mathrm{d}\tau$ to be the timelike principal direction θ^0 or a spacelike principal direction θ^i. We will study these cases separately.

(i) Case $\mathrm{d}\alpha_1 \wedge \theta^0 = 0$. Here we have $\mathrm{d}\tau = e_0(\tau)\theta^0$, and so u^i must be real for every i. Consequently, if we take into account Eq. (13) with $\nu_2 = \nu_3 = 0$, real coordinates $\{x, y, z\}$ can be found such that

$$u^2 = \frac{e^{-(k/2)\tau}}{\sqrt{2}}\mathrm{d}x, \quad u^3 = \frac{e^{-(a^2/2k)\tau}}{\sqrt{2}}\mathrm{d}y, \quad u^1 = -\frac{\mathrm{i}\sqrt{2}abe^{-a\tau}}{b^2e^{-2a\tau}-1} e^{-((a^2+k^2)/2k)\tau}(\mathrm{d}z + x\mathrm{d}y). \tag{27}$$

As u^1 is real, we find that b is purely imaginary, $b = -i\beta$. Then, from Eq. (25) we can calculate $(\mathrm{d}\tau)^2$, and taking into account the freedom of an affine transformation in choosing the harmonic coordinate τ, we can take $\beta = 1$ and we can write the metric in the usual form of the Taub[30] metric

$$g = \frac{\cosh(a\tau)}{a}(-e^{((a^2+k^2)/k)\tau}\mathrm{d}\tau^2 + e^{(a^2/k)\tau}\mathrm{d}x^2 + e^{k\tau}\mathrm{d}y^2) + \frac{a}{\cosh(a\tau)}(\mathrm{d}z + x\mathrm{d}y)^2. \tag{28}$$

To see if a Killing field with an aligned Papapetrou field exists, we must look for a Killing field which is orthogonal to two of the connection 1-forms. The Killing fields of the Taub metric (28) are $\xi=k_1\partial_x+k_2\partial_y+(k_3-k_1y)\partial_z$ and, taking into account that the connection 1-forms Γ^j_i are collinear with u^k, from Eq. (27) we find that the only Killing field that is orthogonal to a pair of connection 1-forms is $\xi=\partial_z$, and it is orthogonal to Γ^2_1 and Γ^3_1. So, the principal 2-form aligned with a Papapetrou field is $\mathcal{U}_1$, and it is characterized by the fact that $\mathcal{U}_1(\mathrm{d}\tau)$ is not integrable.

(ii) Case $\mathrm{d}\alpha_1\wedge\theta^1=0$. Now, $\mathrm{d}\tau=e_1(\tau)\theta^1$ and we have $\sqrt{2}\,u^1=-e_1(\tau)\theta^0$, $\sqrt{2}u^2=ie_1(\tau)\theta^3$ and $\sqrt{2}\,u^3=ie_1(\tau)\theta^2$. So, we can consider real coordinates $\{x,y,z\}$ such that

$$u^2=\frac{\mathrm{i}e^{-(k/2)\tau}}{\sqrt{2}}\mathrm{d}x,\quad u^3=\frac{ie^{-(a^2/2k)\tau}}{\sqrt{2}}\mathrm{d}y,\quad u^1=\frac{-\sqrt{2}\beta ae^{-a\tau}}{\beta^2e^{-2a\tau}+1}e^{-((a^2+k^2)/2k)\tau}(\mathrm{d}z-x\mathrm{d}y). \tag{29}$$

Then, the same analysis of the previous case leads to the counterpart with timelike orbits of the Taub metric[24]

$$g=\frac{\cosh(a\tau)}{a}(e^{((a^2+k^2)/k)\tau}\mathrm{d}\tau^2+e^{(a^2/k)\tau}\mathrm{d}x^2+e^{k\tau}\mathrm{d}y^2)-\frac{a}{\cosh(a\tau)}(\mathrm{d}z-x\mathrm{d}y)^2. \tag{30}$$

The same property of the Taub metric concerned with the aligned Papapetrou fields holds in this case. We can summarize these results for the case that $\mathrm{d}\alpha_1$ is collinear with a principal direction in the following:

Proposition 3: The Taub metric (28) that has spacelike orbits, and its counterpart with timelike orbits (30) are the only type I_{12} vacuum solutions where the gradient of the Weyl eigenvalue α_1 is collinear with a principal direction of the Weyl tensor.

Both metrics admit a principal 2-form $\mathcal{U}_i$ such that $\mathcal{U}_i(\mathrm{d}\alpha_1)$ is not integrable. Then, the Killing field collinear with $\mathcal{U}_i(\mathrm{d}\alpha_1)$ is the only one whose Papapetrou field is aligned (with the principal 2-form $\mathcal{U}_i$).

B. $\mathrm{d}\alpha_1$ Is Not a Principal Direction

In this case $\mathrm{d}\tau$ must take the direction of one of the bisectors of a spacelike principal plane, say $\theta^2+\theta^3$, $\mathrm{d}\tau\propto\theta^2+\theta^3$. Then, a similar analysis to the one in the previous cases, leads to the metric

$$g=e^{2m\tau}\left[\frac{\cosh(a\tau)}{a}\mathrm{d}\tau^2+\frac{a}{\cosh(a\tau)}e^{-2m\tau}(\mathrm{d}z-u\mathrm{d}v)^2+\frac{\cosh(a\tau)}{a}e^{-m\tau}[\cos(n\tau)(\mathrm{d}v^2-\mathrm{d}u^2)\right.$$
$$\left.-2\sin(n\tau)\mathrm{d}u\mathrm{d}v]\right], \tag{31}$$

where $a^2=m^2+n^2$, $n\neq0$. This is an equivalent windmill-like metric for the Taub solution.

The real Killing fields of this metric in the previous coordinate system are $\xi=k_1\partial_u+k_2\partial_v+(k_1v+k_3)\partial_z$. As the complex connection 1-forms Γ^j_i are collinear with $u^k\equiv\mathcal{U}_k(\mathrm{d}\tau)$, we conclude that there is only one Killing field ∂_z which is orthogonal to two connection 1-forms, more precisely, to Γ^2_1 and Γ^3_1. So, this Killing field has a Papapetrou field which is aligned with the principal bivector $\mathcal{U}_1$. We summarize these results in the following:

Proposition 4: The metric (31) is the only vacuum solution of class I_{12} where the gradient of the Weyl eigenvalue α_1 is not a Weyl principal direction.

This solution admits a principal 2-form $\mathcal{U}_i$ such that $\mathcal{U}_i(\mathrm{d}\alpha_1)$ is not integrable. Then, the Killing field collinear with $\mathcal{U}_i(\mathrm{d}\alpha_1)$ is the only one whose Papapetrou field is aligned (with the principal 2-form $\mathcal{U}_i$).

VII. TYPE I VACUUM SOLUTIONS WITH CONSTANT EIGENVALUES

Elsewhere[13] we have shown that the only Petrov type I vacuum solution with constant eigenvalues is the homogeneous Petrov solution.[14,24] In real coordinates this metric writes as

$$k^2 g = \mathrm{d}x^2 + e^{-2x}\mathrm{d}y^2 + e^{x}(\cos\sqrt{3}x(\mathrm{d}z^2 - \mathrm{d}t^2) - 2\sin\sqrt{3}x\mathrm{d}z\mathrm{d}t). \tag{32}$$

The eigenvalues of this metric are proportional to the three cubic roots of -1, $\alpha_i = k^2\sqrt[3]{-1}$. So, a real eigenvalue, let us say α_3, exists. From the metric expression (32) we get that $\Gamma_1^3 \wedge \mathcal{U}_1(\Gamma_1^2) = 0$ and $\Gamma_2^3 \wedge \mathcal{U}_2(\Gamma_1^2) = 0$. Moreover, a straightforward calculation shows that $\mathrm{d}x$ takes the direction of one of the bisectors of the plane $^*U_3$, $\mathrm{d}x = e_1(x)(\theta^1 + \theta^2)$, and that the complex connection 1-forms Γ_i^j are given by

$$\Gamma_1^2 = e^{-x}\mathrm{d}y, \quad \mathcal{U}_3(\Gamma_1^2) = -\frac{i}{\sqrt{2}}\mathrm{d}x,$$

$$\mathcal{U}_1(\Gamma_1^2) = \frac{1}{2}e^{(1/2)(1+i\sqrt{3})x}(\mathrm{d}t - i\mathrm{d}z), \quad \mathcal{U}_2(\Gamma_1^2) = \frac{1}{2}e^{(1/2)(1-i\sqrt{3})x}(\mathrm{d}t + i\mathrm{d}z).$$

The Killing fields of this solution are $\{\partial_t, \partial_z, \partial_y, \partial_x + y\partial_y + 1/2(\sqrt{3}t - z)\partial_z - 1/2(t + \sqrt{3}z)\partial_t\}$ and so, it easily follows:

Proposition 5: The Petrov homogeneous vacuum solution (32) admits just a Killing field such that its Papapetrou field is aligned with a principal bivector. If α_3 is the real eigenvalue, this Killing field is proportional to Γ_1^2 and its Papapetrou field is aligned with $\mathcal{U}_3$.

VIII. SUMMARY IN ALGORITHMIC FORM

In this article we have found all the Petrov type I vacuum solutions admitting a Killing field whose Papapetrou field is aligned with a principal bivector of the Weyl tensor. We knew[13] that these solutions admit either a simply transitive group G_4 of isometries and then the metric must be the homogeneous Petrov solution (32), or a simply transitive G_3 group of isometries and then the spacetime belongs to one of the classes I_{13} and I_{12} in definition 3. Here we have shown that these necessary conditions given in Ref. 13 are also sufficient conditions.

The solutions can be characterized by a condition on the normal direction to the orbits group: for class I_{13}, (i) if it is a timelike principal direction we reach the Kasner metric (21), (ii) if it is a spacelike principal direction we reach the static Kasner metric (22), and (iii) if it is not a principal direction we obtain the windmill Kasner metric (23); for class I_{12}, under similar conditions, we obtain (i) the Taub metric (28), (ii) the timelike counterpart of the Taub metric (30), and (iii) the windmill-like metric for the Taub solution (31).

It is worth pointing out that the integration procedure is based on intrinsic conditions imposed on algebraic and differential concomitants of the Weyl tensor. On the other hand, these Weyl invariants can be obtained directly from the components of the metric tensor g in arbitrary local coordinates and without solving any equations.[18,19] Consequently, we get an intrinsic and explicit labeling of every solution (similar to that given for the Petrov metric in Ref. 13). Table I summarizes these results and enables us to obtain the directions of the Killing fields having aligned Papapetrou field. In the table we find the Weyl tensor invariants

$$\alpha_i \equiv \alpha_i(g), \quad \theta^\alpha \equiv \theta^\alpha(g), \quad \mathcal{U}_i \equiv \mathcal{U}_i(g), \tag{33}$$

$$\lambda_i \equiv \lambda_i(g) = -\mathcal{U}_i(\nabla \cdot \mathcal{U}_i), \tag{34}$$

$$N \equiv N(g), \text{ number of integrable directions in the set } \{\mathcal{U}_j(\mathrm{d}\alpha_i)\}. \tag{35}$$

The metric concomitants (33) are, respectively, the Weyl eigenvalues $\alpha_i(g)$, the Weyl principal coframe $\theta^\alpha(g)$ and the unitary Weyl principal bivectors $\mathcal{U}_i(g)$. The explicit expressions of these Weyl invariants in terms of the Weyl tensor can be found elsewhere.[18,19]

TABLE I. Type I vacuum solutions with aligned Papapetrou fields.

SOLUTION	Intrinsic characterization $\lambda_i \wedge \lambda_j = 0$, Ric$=0$	Killing vectors with aligned Papapetrou field
Kasner (21)	$d\alpha_1 \neq 0$, $N=3$ $d\alpha_1 \wedge \theta^0 = 0$	$\xi_i \propto \mathcal{U}_i(d\alpha_1)$, $i=1,2,3$ $\nabla\xi_i$ aligned with $\mathcal{U}_i$
Kasner (22)	$d\alpha_1 \neq 0$, $N=3$ $d\alpha_1 \wedge \theta^j = 0$ for some j	
Windmill (23)	$d\alpha_1 \neq 0$, $N=3$ $d\alpha_1 \wedge \theta^\alpha \neq 0 \ \forall \alpha$	$\exists!\ \alpha_{i_0}$ real, $\xi \propto \mathcal{U}_{i_0}(d\alpha_1)$ $\nabla\xi$ aligned with $\mathcal{U}_{i_0}$
Taub (28)	$d\alpha_1 \neq 0$, $N=2$ $d\alpha_1 \wedge \theta^0 = 0$	$\exists!\ i_0/\mathcal{U}_{i_0}(d\alpha_1)$ is not integrable $\xi \propto \mathcal{U}_{i_0}(d\alpha_1)$ $\nabla\xi$ aligned with $\mathcal{U}_{i_0}$
Taub (30)	$d\alpha_1 \neq 0$, $N=2$ $d\alpha_1 \wedge \theta^j = 0$ for some j	
Windmill (31)	$d\alpha_1 \neq 0$, $N=2$ $d\alpha_1 \wedge \theta^\alpha \neq 0 \ \forall \alpha$	
Petrov (32)	$d\alpha_i = 0 \ \forall i$	$\exists!\ \alpha_3$ real, $\xi \propto \Gamma_1^2$ $\nabla\xi$ aligned with $\mathcal{U}_3$

Finally, to underline the intrinsic nature of our results we present a flow diagram that characterizes, among all the type I vacuum solutions, those having an aligned Papapetrou field. This operational algorithm can be useful from a computational point of view and also involves the Weyl invariants (33)–(35).

It is expected that matter composed of a perfect fluid cannot be at rest outside of a black hole if the spacetime is asymptotically flat and static (nonrotating). However, there has not been rigorous proof for this expectation without assuming spherical symmetry. In this paper, we provide a proof of nonexistence of matter composed of a perfect fluid in static black hole spacetimes under certain conditions, which can be interpreted as a relation between the stellar mass and the black hole mass. [DOI: 10.1063/1.2383009]

I. INTRODUCTION

The issue of the final state of gravitational collapse is important from various points of view. Usually we expect the black holes will eventually form after the gravitational collapse of a star and the spacetime is expected to asymptotically converge to a stationary or static state. The perturbation analysis[1] and numerical demonstrations support this picture. As a consequence, the limiting spacetime will be a stationary or static vacuum spacetime if all the matter is absorbed to the thus produced black hole. Nowadays we know that the uniqueness theorem for black holes holds in asymptotically flat, stationary (or static) and vacuum spacetimes and the resulting spacetimes are described by Kerr or Schwarzschild solutions.[2–4] Therefore we can have definite astrophysical predictions using these exact solutions.

While the uniqueness of the vacuum black hole has been established, it is interesting to ask if there is a uniqueness theorem for stationary or static spacetimes of a black hole plus matter. In the stationary case (i.e., time translation symmetry exists but their trajectories are not hypersurface orthogonal), clearly this is not the case because many spacetime solutions have been constructed. The perturbative solution of a slowly rotating black hole surrounded by an infinitesimal ring was constructed by Will.[5] There are numerical solutions of a black hole surrounded by an infinitely thin disk[6] or by an differentially rotating ring.[7] Recently, the black hole with a uniformly rotating ring around it has been calculated with high accuracy.[8]

On the other hand, we expect that there should be some kind of uniqueness theorem for static spacetimes (i.e., trajectories of time-translation symmetry are hypersurface orthogonal) of a black hole with matter. This is because if we try to put the matter at rest outside a black hole, it is expected to fall into the black hole because of the gravitational attraction. However, we would like to point out that this intuitive picture does not have a rigorous reasoning. In fact, one can easily provide a counterexample as follows. If an infinitely thin disk composed of counter-rotating particles exists on the equatorial plane of the black hole spacetime, there should exist a static configuration after a fine tuning of system parameters. This example indicates that the uniqueness

[a)]Electronic mail: shiromizu@phys.titech.ac.jp

of spacetimes of a black hole with matter depends not only on the energy condition but also the equation of state matter satisfies. As far as we know, there is Bekenstein's work[9] which proves the nonexistence of scalar fields outside a black hole in the static spacetime. However, without assuming the spherical symmetry, the question of nonexistence of matter composed of an ordinary perfect fluid outside a black hole in the static spacetime has not been addressed up to now.

As it turns out, proving the uniqueness in the setting above is rather a delicate problem. A similar situation is found for the proof of the spherical symmetry of a static isolated star composed of perfect fluid for a certain class of equations of state. This problem was solved relatively recently by Lindblom and Masood-ul-Alam[11] after a long history.[12,13] In the work of Ref. 11, the authors studied the condition that should hold inside of a star *without* assuming the spherical symmetry and proved the conformal flatness of the space that directly implies the spherical symmetry in turn.

Fortunately, many of the results in Ref. 11 can be used for our situation because much of their analysis was done in quite a general setting. In this paper we would like to reformulate the analysis of Ref. 11 for the goal of showing the uniqueness of the static spacetime of a black hole plus matter, taking care of the difference between the two setups. We will provide a partial proof for the nonexistence of matter outside a static black hole. The nonexistence we obtain here is conditional under an inequality between the black-hole mass and the stellar mass.

This paper is organized as follows. In the next section, we provide our setup concerning the Einstein equation. In Sec. III, we summarize the results of Lindblom and Masood-ul-Alam,[11] paying particular attention to the parts that are directly relevant to our argument. We prove our theorem in Sec. IV and summarize our paper with some discussion in Sec. V. We adopt the unit of $c=G=1$.

II. SETUP

We consider the static spacetime which has the metric

$$ds^2 = -V^2(x)dt^2 + g_{ij}(x)dx^i dx^j, \tag{1}$$

where $i=1,2,3$ and $g_{ij}(x)$ is the induced metric of $\{t=\text{const.}\}$ hypersurfaces Σ. In a static spacetime, its event horizon H is identified with Killing horizon $\{V=0\}$ and thus $V(x)$ vanishes on the horizon. We assume that there is a perfect fluid with energy density ρ and pressure P. The fluid is assumed to satisfy an equation of state $P=P(\rho)$. We assume the surface of the star/fluid is a two-dimensional closed connected equipotential surface $\{x: V(x)=V_s>0\}$ for some positive constant V_s.

The Einstein equation and equation for fluid are given by

$$D^2V = 4\pi V(\rho + 3P), \tag{2}$$

$$R_{ij} = \frac{1}{V}D_iD_jV + 4\pi(\rho - P)g_{ij}, \tag{3}$$

$$D_iP = -\frac{1}{V}(\rho + P)D_iV, \tag{4}$$

where D_i and R_{ij} are the covariant derivative and Ricci tensor of the metric $g_{ij}(x)$.

Equation (4) indicates that the surface $\{\rho=\text{const.}\}$ is identical to the surface $\{V=\text{const.}\}$ Let us suppose for the moment the condition $D_iV\neq 0$ at the horizon. Except for the extremal charged black holes, this condition is satisfied in all the known static black hole solutions. Then Eq. (4) says that the value of D_iP diverges at the horizon if matter exists at the horizon $\{V=0\}$, which is an unphysical situation. Hence, this would make the stellar surface disjoint from the horizon. We stress that the same conclusion can be obtained from Eq. (2) without any additional hypothesis. As Eq. (2) is elliptic, a standard boundary elliptic estimate (see, for example, Lemma 6.4 in Gilbarg–Trudinger[10]) says that near the horizon, the norm of the gradient of V is bounded by the

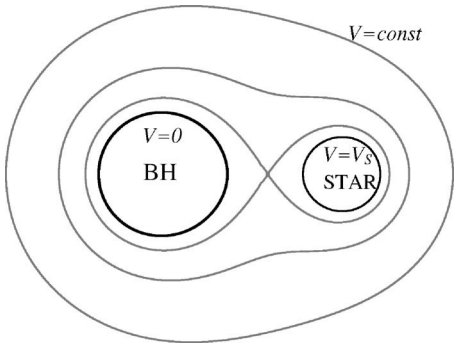

FIG. 1. Typical configuration of the system of a black hole (BH) and matter (STAR).

sup norm of the right-hand side of Eq. (2) as well as that of V, both of which are uniformly bounded in our case. As the horizon is the zero set of V, while the surface of the star is the level set $\{V=V_s(>0)\}$, the gradient bound for V provides a positive lower bound (dependent on V_s) for the distance between those two level sets, which in turn implies that the star is disjoint from the horizon.

At the moment pictures such as Fig. 1 are possible configurations of our setup. Although the star surface shown in this figure is spherical, note that its topology is arbitrary as long as it is specified as a connected equipotential surface $\{V=V_s\}$. Thus our theorem will hold also for, e.g., a barotropic perfect fluid ring. Note, however, that our theorem is not applicable to a ring composed of counter-rotating particles around a black hole, as mentioned in Sec. I. This is because such matter has anisotropic stress and its equation of state is not barotropic.

Here we stress that we will prove that such configurations as above do *not* occur under certain conditions. In doing so, we are also *not* assuming any symmetry of the spacelike slice.

Asymptotic flatness requires the following asymptotic behavior of V and the metric

$$V=\left(1-\frac{M}{r}\right)+O(r^{-2}) \tag{5}$$

and

$$g_{ij}=\left(1+\frac{2M}{r}\right)\delta_{ij}+O(r^{-2}), \tag{6}$$

where $r=:|\delta_{ij}x^ix^j|^{1/2}$ and M is the Arnowitt-Deser-Misner (ADM) mass.

Our strategy for the proof is as follows. We first show that the $\{t=\text{const.}\}$ hypersurface Σ is conformally flat. The main part of the proof is finding appropriate conformal transformations for Σ so that it becomes a hypersurface with zero ADM mass and non-negative Ricci scalar curvature. This wonderful idea was first introduced by Bunting and Masood-ul-Alam.[14] We then apply the positive energy theorem[15] to this surface to conclude that the surface is flat Euclidean space. In turn, the original hypersurface Σ is conformally flat and it will immediately follow that $\rho=P=0$. In order to find the appropriate conformal transformation, we will use the Lindblom and Masood-ul-Alam's theorems[11] that was used for proving the spherical symmetry of a static star. We review it in the next section.

III. THEOREMS OF STATIC STELLAR MODELS

In this section, we briefly review Lindblom and Masood-ul-Alam's results[11] where the spherical symmetry of static stellar models was obtained under a certain condition on the equation of state. We are able to transcribe their argument mostly because the techniques used in treating the *inside* of stars are identical.

Because the $\{V=\text{const.}\}$ surface is identical to $\{\rho=\text{const.}\}$ surface due to Eq. (4) and the equation of state $P=P(\rho)$, both ρ and P are regarded as functions of V. The minimum value of V in the star is denoted by $V=V_c$. Then quantities $r_\mu(V)$, $m_\mu(V)$ are defined as the solutions to the equations

$$\frac{dr_\mu}{dV}=\frac{r_\mu(r_\mu-2m_\mu)}{V(m_\mu+4\pi r_\mu^3 P)}, \tag{7}$$

$$\frac{dm_\mu}{dV}=\frac{4\pi r_\mu^3(r_\mu-2m_\mu)\rho}{V(m_\mu+4\pi r_\mu^3 P)}, \tag{8}$$

where the boundary conditions for Eqs. (7) and (8) are

$$r_\mu(V_s)=R_\mu := 2\mu/(1-V_s^2), \tag{9}$$

$$m_\mu(V_s)=\mu. \tag{10}$$

Here, μ is some constant suitably chosen in the proof. As we see from Eqs. (7) and (8), $dm_\mu/dr_\mu=4\pi r_\mu^2\rho$ holds and μ could be interpreted as the local mass of the star. Now $W_\mu(V)$ is defined by

$$W_\mu := \begin{cases} \dfrac{(1-V^2)^4}{16\mu^2} & \text{outside of the star,} \\ \left(1-\dfrac{2m_\mu}{r_\mu}\right)\left(\dfrac{dr_\mu}{dV}\right)^{-2} & \text{inside of the star.} \end{cases} \tag{11}$$

Various lemmas on $r_\mu(V)$, $m_\mu(V)$, and $W_\mu(V)$ are introduced, such as the existence of the solution on $(V_\mu, V_s]$ for some V_μ (Lemmas 1–3). In particular, assuming that the pressure is finite $P(V)<\infty$, W_μ can be made positive for somewhat small μ over the interval $(V_c, V_s]$ (Lemma 8).

We require that the equation of state satisfies at least one of the following constraints:

$$\frac{1}{5}\kappa^2+2\kappa+(\rho+P)\frac{d\kappa}{dP}\leqslant 0 \tag{12}$$

or

$$\frac{5\rho^2}{6P(\rho+3P)}\geqslant\kappa>\frac{10V_s^2}{e^{2h(P)}-V_s^2}, \tag{13}$$

where $\kappa := (d\rho/dP)(\rho+P)/(\rho+3P)$ and $h(P)=\log(V_s/V)$. The upper bound on κ in the condition (13) implies that the adiabatic index $\gamma := (dP/d\rho)(\rho+P)/P$ must be larger than or equal to $(6/5)\times(1+P/\rho)^2$. Under this assumption, the following quantity:

$$\Sigma_\mu := \frac{dW_\mu}{dV}-\frac{8\pi}{3}V(\rho+3P)+\frac{4W_\mu}{5V}\frac{\rho+P}{\rho+3P}\frac{d\rho}{dP} \tag{14}$$

is proved to be non-negative (Lemma 10 (Ref. 11)).

The most important technical result is Lemma 6 in Ref. 11: *Assuming that* $W_\mu>0$ *and* $\Sigma_\mu\geqslant 0$ *on* $(V_c, V_s]$, *then* $W_\mu\geqslant W := D_a V D^a V$ *on* (V_c, V_s) *holds everywhere*. In Lemma 6 of Ref. 11, it is stated that $W_\mu\geqslant W$ holds on $(V_c, V_s]$. However, we can easily see from the proof that it holds everywhere outside of the star *and* $\mu\leqslant M$. Because this lemma is relevant to our problem, we briefly review its proof. In, Ref. 11, a differential inequality of elliptic type in the exterior vacuum region is derived

$$D_a(V^{-1}D^a\Delta_\mu^+) \geqslant 0, \tag{15}$$

where

$$\Delta_\mu^+ := (W - W_\mu)\frac{(1-V_s^2)^3(1+b-V_s^2)}{(1-V^2)^3(1+b-V^2)}. \tag{16}$$

b is some positive constant to be chosen later. The appropriate boundary condition at infinity is $W-W_\mu=0$. From the maximum principle, Δ_μ^+ has the maximum value at the infinity or at the surface of the star $\{V=V_s\}$. The possibility of maximum value of $W-W_\mu$ occurring at $\{V=V_s\}$ is then removed by choosing b appropriately. Thus $\Delta_\mu^+ \leqslant 0$ holds everywhere and $W_\mu \geqslant W$. $\mu \leqslant M$ is directly derived from the asymptotic expansion of $W_\mu \geqslant W$. Note here that in our case where the black hole is additionally present, the possibility that Δ_μ^+ takes a maximal value at the event horizon cannot be removed, and we cannot use Lemma 6 in Ref. 11 without modifications. We will come back to this point in the next section.

They next introduce M^- and M^+ where M^- satisfies $M^- < M$ and $W_{\mu=M^-} > 0$ on $[V_c, V_s]$ while M^+ satisfies $M^+ > M$ with $W_{\mu=M^+}(V_{M_*^+})=0$ at a point $V_{M_*^+} \in (V_c, V_s)$. The existence of $M^\pm$ is guaranteed by, e.g., Lemma 6.[11] Then, they defined ν by $\nu=\inf_{\mu \in S_c}\mu$ where $S_c=\{\mu \in [M^-, M^+]: W_\mu > 0$ on $(V_c, V_s]$ and $W_\mu(V_c)=0\}$.

In their Lemma 14, they proved that $d^2\psi_\nu/dV^2$ is positive, where $\psi_\mu(V)$ is defined as the solution to the equation

$$\frac{d\psi_\mu}{dV} = \frac{\psi_\mu}{2r_\mu\sqrt{W_\mu}}\left(1 - \frac{2m_\mu}{r_\mu}\right), \tag{17}$$

with $\psi_\mu(V_s)=(1+V_s)/2$ at the surface of the star $\{V=V_s\}$. Finally they define a conformal metric $g_{ij}^+=\Omega_+^4 g_{ij}$, where

$$\Omega_+ = \begin{cases} (1+V)/2 & \text{outside of the star,} \\ \psi_\nu(V) & \text{inside of the star,} \end{cases} \tag{18}$$

and found that the Ricci scalar has the expression

$$R(g_{ij}^+) = (\tilde{W} - W)\frac{8}{\Omega_+^5}\frac{d^2\Omega_+}{dV^2}, \tag{19}$$

where $\tilde{W}=W_\nu$. In defining $\tilde{W}$ precisely, we must take care of the differential structure at the center of stars. As the argument is rather technical, we refer this point to Lemmas 11, 12, 13, 14 and the main theorem in Ref. 11. By Lemmas 6 and 14, this is positive, while the space has zero ADM mass. Here the case of equality in the positive energy theorem can be applied and we conclude that the space is conformally flat, which then implies that an isolated star is spherically symmetric.[16]

IV. PROOF OF NONEXISTENCE OF MATTER OUTSIDE A STATIC BLACK HOLE

Now we turn our attention to the proof of nonexistence of matter outside a static black hole. The various functions *inside* of a star, r_μ, m_μ, ψ_μ, W_μ, and Δ_μ^+ can be introduced without modifications. We adopt the same condition on the equation of state. However, the modification for Lemma 6 is required as mentioned in the previous section.

Lemma 6 in Ref. 11 says that $\tilde{W}-W \geqslant 0$ holds everywhere. In the case of Ref. 11 this inequality was proved by showing $\Delta_\mu^+ < 0$ at $V=V_s$ and by applying the maximum principle for the inequality $D_a(V^{-1}D^a\Delta_\mu^+) \geqslant 0$ which indicates that $\Delta_\mu^+=0$ at infinity is the maximum value. However, presently we have an additional boundary, which is the horizon $\{V=0\}$, and a possibility of $\Delta_\mu^+ > 0$ there remains. We thus have to *assume* $\Delta_\mu^+ < 0$ at the horizon or equivalently

$$(W - W_\mu)_{V=0} \leqslant 0. \tag{20}$$

We will discuss the physical meaning of this hypothesis in the last section. Under this assumption, $W_\mu - W \geqslant 0$ is guaranteed everywhere, and the results in Ref. 11 that were proven using Lemma 6 become available. In particular, the existence of ν is guaranteed.

Now we show the conformal flatness of this space. Consider the two conformal transformations defined by

$$g^{\pm}_{ij} = \Omega^4_{\pm} g_{ij}, \tag{21}$$

where Ω_+ is the same as Eq. (18) and

$$\Omega_- = \tfrac{1}{2}(1 - V). \tag{22}$$

Now we have two manifolds $(\Sigma^{\pm}, g^{\pm}_{ij})$. As in Bunting and Masood-ul-Alam,[14] we can make a smooth manifold out of $\Sigma^+ \cup \Sigma^-$ by gluing along $\{V=0\}$.

The asymptotic behavior of each metric is

$$g^{+}_{ij} = \delta_{ij} + O(r^{-2}) \tag{23}$$

and

$$g^{-}_{ij} dx^i dx^j = (M/2r)^4 (dr^2 + r^2 d\Omega_2^2) + O(r^{-5}). \tag{24}$$

In the manifold (Σ^-, g^-_{ij}), $\{r=\infty\}$ corresponds to a regular point in a three-dimensional surface. Indeed, introducing a new coordinate $R = M^2/4r$, the metric near $r=\infty$ can be written as

$$g^{-}_{ij} dx^i dx^j = dR^2 + R^2 d\Omega_2^2. \tag{25}$$

If the Ricci scalar of this space is non-negative, positive energy theorem tells us that $\Sigma^+ \cup \Sigma^-$ is the flat Euclidean space and thus Σ is conformally flat, because this manifold has the zero ADM mass and non-negative Ricci scalar. Hence, we want to show the non-negativity of the Ricci scalars $R(g^{\pm}_{ij})$.

The three-dimensional Ricci scalar becomes the same as Eq. (19) for Σ^+ and

$$R(g^{-}_{ij}) = 8\pi \Omega_-^{-5} [(1+V)\rho + 6VP] \geqslant 0, \tag{26}$$

for Σ^-. Since $R(g^-_{ij}) \geqslant 0$ holds as above, it remains to show the non-negativity of $R(g^+_{ij})$. $d^2\Omega_+/dV^2 \geqslant 0$ is guaranteed by Lemma 14 in Ref. 11 and $(\tilde{W} - W) \geqslant 0$ is guaranteed by the hypothesis (20). Then the conformally transformed space $\Sigma^+ \cup \Sigma^-$ has non-negative Ricci scalar [see Eq. (19)] and zero ADM mass, which implies that $\Sigma^+ \cup \Sigma^-$ is flat.

Now we have proven under the assumption (20) that the original space Σ is conformally flat. Going back to Eqs. (19) and (26), we find that $R(g^+_{ij}) = R(g^-_{ij}) = 0$ holds and they in turn imply $\tilde{W} = W$ and $\rho = P = 0$, respectively. The latter implies that the spacetime should be vacuum. Our result excludes any static configurations of a black hole with a star whose surface is given by $\{V = V_s\}$ as was suggested in Fig. 1.

We summarize what we have obtained as the following theorem.

Theorem: *In asymptotically flat static black hole spacetimes, the star, which is composed of a perfect fluid satisfying the dominant energy condition and has the surface of level surface set* $\{V = V_s (>0)\}$, *annot exist if (i) the equations of state* $P = P(\rho)$ *satisfies the condition* (12) or (13), *and (ii) for* W_μ *defined by Eq.* (11) *with Eqs.* (7) *and* (8), *the inequality* $W - W_\mu \leqslant 0$ *holds on the event horizon* $(V=0)$.

As a result, the ordinary uniqueness theorem[2] of vacuum spacetimes can be applied and then the spacetime in our setup is reduced to the Schwarzschild spacetime.

V. DISCUSSION

We have proven the nonexistence of matter composed of a perfect fluid under the hypothesis $(W-W_\mu)_{V=0}\leqslant 0$. Because the physical meaning of this hypothesis is still unclear, we examine it in this section. On the event horizon, the value of $\sqrt{W}$ coincides with the surface gravity κ_H of the black hole. We introduce the Komar integral on the event horizon $M_{\mathrm{BH}}=\kappa_H A_H/4\pi$ that indicates the local mass of the black hole, where A_H is the area of the horizon. Then, $(W-W_\mu)_{V=0}\leqslant 0$ corresponds to

$$\mu \leqslant \frac{1}{4\kappa_H} = \frac{A_H}{16\pi M_{\mathrm{BH}}}. \tag{27}$$

The first law of the black hole thermodynamics for the static spacetime $\delta M_{\mathrm{BH}}=\kappa_H \delta A_H/8\pi$ implies $A_H \propto M_{\mathrm{BH}}^2$. Hence, $A_H \sim 16\pi M_{\mathrm{BH}}^2$ and the right hand side of the inequality (27) is $O(M_{\mathrm{BH}})$. In order to find some upper bound on μ in terms of the quantities of the star, recall that $(W-W_\mu)_{V=V_s}\leqslant 0$ holds on the surface of the star as appeared in the proof of Lemma 6 of Ref. 11. This is rewritten as $\sqrt{W_s}\leqslant (1-V_s^2)^2/4\mu$. Integrating over the surface of the star, we find

$$\mu \leqslant \frac{(1-V_s^2)^2}{16\pi M_\star} A_s, \tag{28}$$

where $M_\star$ is the Komar mass of the star and A_s is the area of the surface of the star. Hence, $(W-W_\mu)_{V=0}\leqslant 0$ holds if

$$(1^*-V_s^2)^2 \frac{A_s}{16\pi M_\star} \leqslant \frac{A_H}{16\pi M_{\mathrm{BH}}} \sim M_{\mathrm{BH}}. \tag{29}$$

In order to simplify this inequality, let us consider the situation where a ball-shaped star exists outside a black hole and the distance between them is sufficiently large. In this case V_s^2 is approximated as $V_s^2 \simeq 1-2M_\star/r_s$ and $A_s \simeq 4\pi r_s^2$, where r_s is the radius of the star. Then the inequality becomes

$$M_\star \lesssim M_{\mathrm{BH}}. \tag{30}$$

Therefore the main theorem states that a star with smaller mass than a black hole mass cannot exist outside of the black hole in static spacetimes.

Intuitively, heavy stars are also not permitted to exist outside of black holes in static spacetimes. We hope to have a different argument for proving the statement because our current approach of adapting Lindblom and Masood-ul-Alam's results[11] is not expected to produce optimal statements.

Last, we note that the star surface is assumed to be a surface of one connected component. In order to exclude the configuration of a star whose surface has two or more components such as a shell surrounding the black hole, further considerations are needed.

Domain walls on the surface of *q*-stars

Athanasios Prikas[a)]
Physics Department, National Technical University, Zografou Campus, 157 80 Athens, Greece

(Received 9 June 2005; accepted 18 September 2006; published online 10 November 2006)

We study domain wall networks on the surface of *q*-stars in asymptotically flat or anti de Sitter spacetime. We provide numerical solutions for the whole phase space of the stable field configurations and find that the mass, radius, and particle number of the star is larger but the scalar field, responsible for the formation of the soliton, acquires smaller values when a domain wall network is entrapped on the star surface. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2363254]

I. INTRODUCTION

Planar domain wall networks in theories with three or more vacua have been investigated in a series of papers[1–4] Domain walls seem to have various applications especially in *D*-brane theories.[5,6]

The idea of three-dimensional networks on spherical surfaces has been established in Ref. 7 and applied to the spherical surface of a "large" soliton star.[8] Large soliton stars were investigated in a series of papers by Friedberg *et al.*[9–12] In Ref. 8 it was found that there exist stable with respect to fission into free particles field configurations, corresponding to soliton stars, with a domain wall network on their surface. The pressure of the soliton acts as a stabilizing force to the domain wall network. The star mass is, in general, slightly larger in the presence of the above network, when the particle number and the radius show a more complicated behavior, depending on the surface tension, the particle number, etc. In Ref. 13 the entrapment of the domain wall network on the surface of a soliton of any kind in the absence of gravity was discused. In the same article, another kind of "stability" was discussed, namely the stability of the domain walls. It was found that only two of the five Platonic solids, cube and octahedron, can be realized on a spherical surface. Networks forming other solids would collapse to a single vacuum. So, from now on, when discussing domain walls we restrict ourselves to these two solids.

In the present article we investigate the properties of *q*-stars[14–16] which are relativistic generalizations of *q*-balls[17] that seem to play a special role in baryogenesis through flat directions of supersymmetric extensions of the standard model.[18] Our purpose is to find numerical solutions to the coupled Einstein-scalar fields equations, and to calculate the mass, radius, particle number, and the value of the scalar field at the center of the soliton in the whole phase space (Figs. 1–4). We compare our results with those obtained in the absence of the domain wall network, including in our figures the relevant results, and to the results of Ref. 8, referring to the other family of solitonic stars, and Ref. 13. We also investigate the soliton stability with respect to gravitational collapse and to the decay to free particles.

II. DOMAIN WALL NETWORK ON THE SURFACE OF *q*-STARS

We consider a complex scalar field, ϕ, with a global $U(1)$ symmetry and a suitable potential U, coupled to a complex scalar field, ψ, able to generate a network of domain walls, and to gravity. In order for the ψ field to be able to generate a domain wall network, a

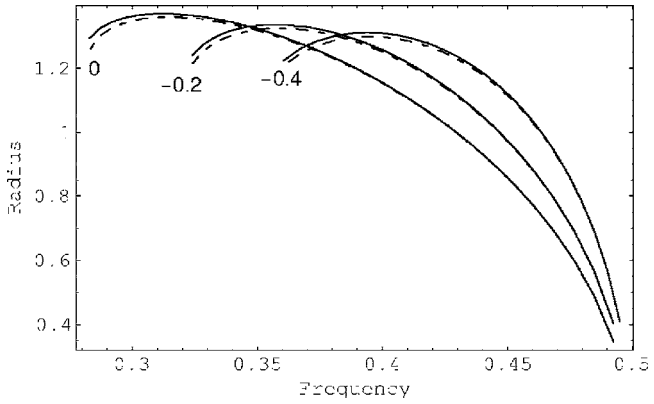

FIG. 1. The radius of the q-star as a function of the frequency. Solid lines correspond to the case with domain walls and dashed to the case without domain walls, i.e., $\beta=0$, included for comparison. The numbers within the figures denote the value of the cosmological constant Λ. The true cosmological constant is $\Lambda \times 8\pi G m^4$, according to Eq. (5).

$$\left| a - \frac{\psi^n}{v^n} \right|^2$$

term should be included in the action, where a is a constant.[1–6] The action of the above configuration is

$$S = \int d^4x\sqrt{-g}\left[\frac{R-2\Lambda}{16\pi G} + \partial_\mu\phi\partial^\mu\phi^* + \frac{1}{v^2}\partial_\mu\psi\partial^\mu\psi^* - U(\phi^*\phi) - \beta^2\left| c(f_0 - \phi^*\phi)\phi^*\phi - \frac{\psi^n}{v^n}\right|^2\right], \tag{1}$$

where Λ stands for the (negative or zero) cosmological constant and the constants β, c, and f_0 will be determined later, n is an integer, and v is a positive constant that can be absorbed in ψ and does not affect the solutions. A Lagrangian with a potential of the form

$$\left| 1 - \frac{\psi^n}{v^n} \right|^2$$

admits solutions corresponding to a domain wall network. In our case we choose

$$\phi(\vec{\rho},t) = \sigma(\rho)e^{-i\omega t}. \tag{2}$$

The field configuration is spherically symmetric, so we can choose a spherically symmetric metric

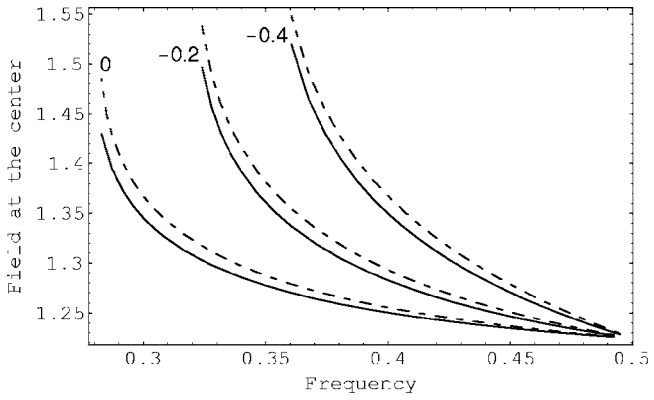

FIG. 2. The value of the scalar field at the center of the star as a function of its freaquency.

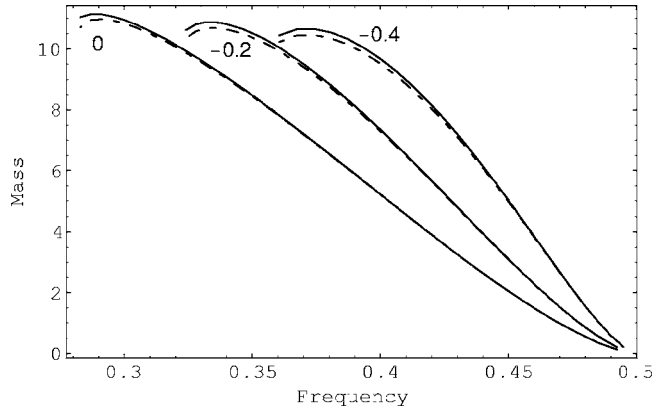

FIG. 3. The mass of a q-star as a function of its frequency.

$$ds^2 = -\frac{1}{B(\rho)}dt^2 + \frac{1}{A(\rho)}d\rho^2 + \rho^2 d\vartheta^2 + \rho^2 \sin^2 \vartheta d\varphi^2. \tag{3}$$

We define

$$W \equiv B\left(\frac{\partial \phi}{\partial t}\right)^*\left(\frac{\partial \phi}{\partial t}\right) = B\omega^2\sigma^2, \quad V \equiv A\left(\frac{\partial \phi}{\partial \rho}\right)^*\left(\frac{\partial \phi}{\partial \rho}\right) = A\sigma'^2 \tag{4}$$

and make the following rescalings:

$$\tilde{\rho} = \rho m, \quad \tilde{\omega} = \omega/m, \quad \tilde{\phi} = \phi/m, \quad \tilde{r} = \epsilon\tilde{\rho},$$

$$\tilde{\beta} = \beta/m^2, \quad \tilde{f}_0 = f_0/m^2, \quad \tilde{c} = cm^4$$

$$\tilde{U} = U/m^4, \quad \tilde{W} = W/m^4, \quad \tilde{V} = V/m^4, \quad \tilde{\Lambda} \equiv \frac{\Lambda}{8\pi G m^4}, \tag{5}$$

with

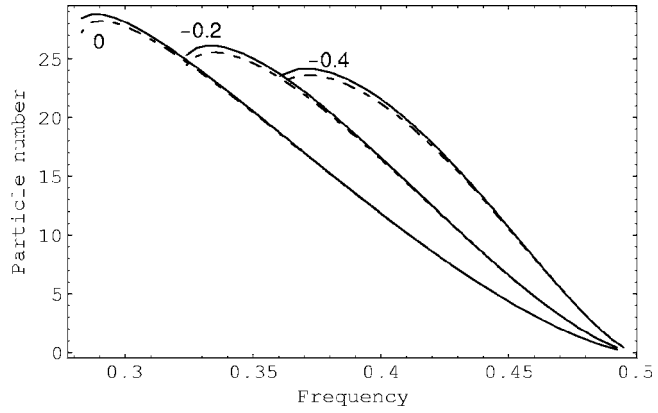

FIG. 4. The particle number of a q-star as a function of its frequency.

$$\epsilon \equiv \sqrt{8\pi G m^2},$$

a very small quantity for $m \sim GeV$. Quantities of the same order of magnitude as ϵ can be neglected. We also choose a rescaled potential

$$U = \phi^* \phi \left(1 - \phi^* \phi + \frac{1}{3} (\phi^* \phi)^2 \right) = \sigma^2 \left(1 - \sigma^2 + \frac{1}{3} \sigma^4 \right), \tag{6}$$

where we dropped tildes for simplicity.

We will now determine the proper values of f_0 and c regarding at present $\beta = 0$. Gravity becomes important when $R \sim GM$. If we regard that the scalar field σ varies very slowly with respect to the radial coordinate then $d\sigma / d\rho \sim \epsilon$ if we set $m = 1$. So, the Euler–Lagrange equation for the scalar field, dropping the tildes and the $O(\epsilon)$ quantities gives

$$\sigma^2 = 1 + \omega B^{1/2}. \tag{7}$$

The eigenvalue equation for the frequency can be obtained by integrating the equation of motion within the surface, where the scalar field varies rapidly from a σ_0 value at the inner edge of the surface, to a zero value at the outer edge. The result of integration is

$$V + W - U = 0, \tag{8}$$

which, in order to match with the interior solution, for which $\sigma' \sim \epsilon$, gives for the eigenfrequency

$$\omega = \frac{A_{\text{sur}}^{1/2}}{2} = \frac{B_{\text{sur}}^{-1/2}}{2}, \tag{9}$$

where A_{sur}, B_{sur} denote the value of the metrics at the surface of the star. In the absence of gravity $B(r) = 1$ and, as one can find from Eqs. (7) and (9), $\sigma^2 = 1.5$. When gravity is under consideration the situation is not too different, unless $B(r) \gg 1$. When $B(0) \to \infty$ the star collapses to a black hole. Excluding this case and regarding only stars in our discussion, we can set $f_0 = 1.5$, which means that the quantity $c(f_0 - \phi^* \phi)\phi^* \phi$ is zero inside and outside the soliton. The only region within which this quantity differs form zero is the very thin surface. The maximum value is at

$$\sigma^2 = \frac{3}{4}.$$

So we set

$$c = \frac{16}{9}$$

and the above quantity takes its proper maximum value: $c(f_0 - \phi^* \phi)\phi^* \phi|_{\max} = 1$. With these settings the field ψ is exactly zero outside the soliton, approximately zero in the interior and maximum within the surface.

We will now turn on the interactions between the two scalar fields. Let $\beta^2 = 0.01$ so as to treat the additional interaction as a perturbation, which does not disturb significantly the system. The equation of motion for the ϕ field, dropping the $O(\epsilon)$ quantities gives

$$\omega^2 B - (\sigma^2 - 1)^2 \left(1 + \frac{128}{9} \beta^2 \sigma^2 \right) + \frac{128}{81} \beta^2 \sigma^2 = 0. \tag{10}$$

The exact solution in the above equation is rather long and ugly, but if we substitute the value $\sigma^2 = 1.5$ (holding true when $B(r) \sim 1$ and $\beta^2 \ll$) in the $\beta^2 \sigma^2$ combination, we find for σ^2,

$$\sigma^2 = 1 + \sqrt{\frac{\omega^2 B + 16\beta^2/3}{1 + 64\beta^2/3}}, \tag{11}$$

which has the right limiting value for $\beta \to 0$ according to the Eq. (7). Integrating again the equation of motion within the surface, we find that the eigenvalue equation for the frequency, Eq. (9), remains valid.

Within the soliton, the ψ field is approximately zero. So, the total energy-momentum tensor is approximately the energy-momentum tensor for the ϕ field, which takes the form

$$T_{\mu\nu} = (\partial_\mu \phi)^* (\partial_\nu \phi) + (\partial_\mu \phi)(\partial_\nu \phi)^* - g_{\mu\nu}[g^{\alpha\beta}(\partial_\alpha \phi)^*(\partial_\beta \phi)] - g_{\mu\nu} U. \tag{12}$$

The Einstein equations are $G_{\mu\nu} = 8\pi G T_{\mu\nu} - \Lambda g_{\mu\nu}$. The independent components, 00 and 11, take the following form, dropping the tildes and the $O(\epsilon)$ quantities

$$\frac{A-1}{r^2} + \frac{A'}{r} = -W - U - \Lambda, \tag{13}$$

$$\frac{A-1}{r^2} - \frac{B'}{r}\frac{A}{B} = W - U - \Lambda, \tag{14}$$

where $U = \sigma^2 - \sigma^4 + 1/3\sigma^6$ and $W = B\omega^2\sigma^2$ and σ is given by Eq. (11). The mass of the field configuration is given by the relation

$$M = 4\pi r\left(1 - A(r) - \frac{1}{3}\Lambda r^3\right), \quad r \to \infty. \tag{15}$$

The particle number is defined as

$$N \equiv \int d^3x j^0, \tag{16}$$

with

$$j^\mu = \sqrt{-g} g^{\mu\nu}{}_1 (\phi^* \partial_\nu \phi - \phi \partial_\nu \phi^*). \tag{17}$$

For the interior, we take for the particle number

$$N = 8\pi \int_0^R r^2 dr \omega \sigma^2 \sqrt{\frac{B}{A}}, \tag{18}$$

where R is the radius of the q-star.

We will now prove that the energy and particle number contributions from the thin surface are negligible. At the exterior, the ϕ field is exactly zero, and consequently the ψ field is zero, and, thus, no energy or particle number contribution arises from the exterior. The surface is of width of order m^{-1}. For the moment we ignore our rescalings. Within the surface $|\phi| \sim m$ and consequently $U \sim W \sim m^4$. Also, the field ϕ varies from a certain value at the inner edge of the surface to a zero value at the outer, so $V \sim (|\phi| m)^2 \sim m^4$. ψ^n / v^n is of the same order of magnitude as $c|\phi^4|$. Because $\tilde{c} \sim 1$, then $c \sim m^{-4}$. Because $\tilde{\beta}^2 \sim 10^{-2}$, then $\beta^2 \sim m^4 10^{-2}$,which means that within the surface $\psi^n / v^n \sim 10^{-2} m^4$. The ψ field contributes to the total energy through the β^2 terms of potential energy and the kinetic terms. The energy density arising from the β^2 terms are of the same order of magnitude as $\beta^2 m^4$. If we repeat the discussion concerning the kinetic terms for the ϕ field, the kinetic terms for the ψ field are of the same order of magnitude as $\beta^2 m^4$. So, the total energy density from the surface (potential for both fields, kinetic from the temporal variation from the field ϕ and kinetic from the spatial variation from both fields) is $\sim m^4$ and the total energy stored within the surface is $\sim 1/(Gm)$. Within the interior the energy density is $\sim m^4$ and the total energy

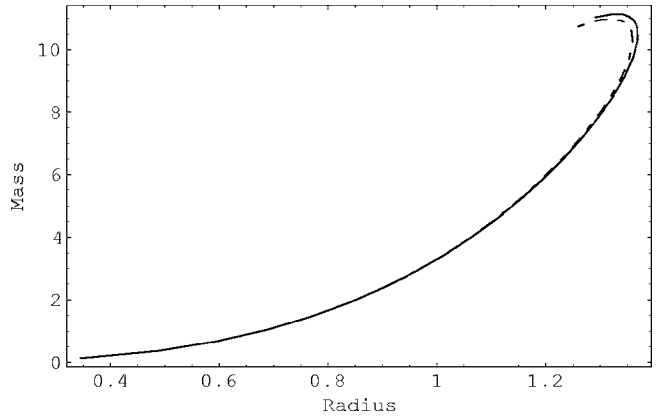

FIG. 5. The mass of the star as a function of its radius for asymptotically flat spacetime. The last stable field configurations with respect to gravitational collapse are at the top of the $M=M(R)$ curves.

is $\sim 1/(G^{3/2}m^2)$. One can see that $E_{\text{surface}} \sim \epsilon E_{\text{interior}}$ and thus the contribution of the surface to the total energy is negligible. The same discussion holds true for the particle number contribution of the surface. These steps reproduce the similar discussion holding true in the case of a "pure" q-star without any additional fields in the total action.

We numerically solve Eqs. (13) and (14) with boundary conditions $A(0)=1$, $A(r)=1/B(r)=1-(1/3)\Lambda r^2$, $r\to\infty$ and find the parameters of the q-star using relations (15)–(18) and (11).

III. CONCLUDING REMARKS

In the present work we investigated the formation of q-stars with a domain wall network on their surface. All the field configurations are stable with respect to fission into free particles because the energy of the free particles with the same charge is smaller than the star mass. They are also stable with respect to gravitational collapse, as one can see from Fig. 5.

We find that the radius, mass, and particle number of the q-star are slightly larger when domain walls are trapped on the star surface. These results agree with the estimation of Ref. 8, concerning the total energy of the soliton. Radius and particle number of large soliton stars, investigated in Ref. 8 show a more complicated dependence on β^2, which is the new parameter differentiating the stars with domain walls from usual, large soliton stars. The results of larger radii and smaller values of the scalar field at the center of the star agree with the similar ones, obtained in Ref. 13, despite the absence of gravity. The same results hold true in asymptotically flat, as well as in asymptotically anti de Sitter spacetime.

Unfortunately, one cannot find an analytical relation connecting the mass and the particle number of the star, due to the highly nonlinear character of the equations of motion. Instead, we use our numerical results, depicted in Fig. 6, in order to study the behavior of the soliton mass as a function of its particle number. From Fig. 6 one can see that our solutions are always stable with respect to fission into free particles, because the soliton energy is always smaller than the total energy of the free particles. For small values of the particle number, gravity is negligible. In the absence of gravity and for a large soliton the so called thin-wall approximation holds. It has been shown that for such solitons $M=\omega N$ plus some surface terms which are negligible in the above approximation, with $\omega \equiv (\sqrt{U/\sigma^2})_{\min}$. As one can see, for the potential 5, ω equals 0.5. Numerical results show clearly that, for small values of the particle number, when gravity is negligible, the ratio mass to particle number equals ω. For larger values of the particle number gravity becomes more important and the negative potential energy contributed by the attractive gravitational force decreases the ratio M to N. From Fig. 6 we also see that the above ratio is larger for smaller values of the (negative) cosmological constant. This reflects the repulsive character of a negative cosmological constant. The star decreases its mass so as to resist to the environment of the "negative" gravity induced by a negative cosmological constant.

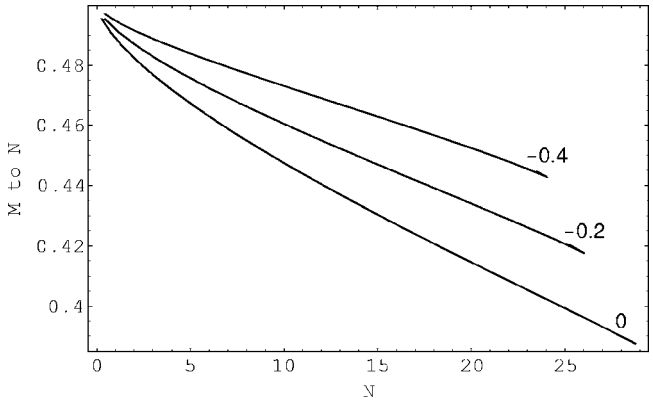

FIG. 6. The ratio mass to particle number of the star as a function of the particle number of the field configurations, for asymptotically flat or anti de Sitter spacetime. For any curve, $\beta^2=0.01$ holds.

Propagating torsion in the Einstein frame

Nikodem J. Popławski[a)]
Department of Physics, Indiana University, 727 East Third Street, Bloomington, Indiana 47405

(Received 28 June 2006; accepted 27 September 2006; published online 13 November 2006)

The Einstein–Cartan–Saa theory of torsion modifies the spacetime volume element so that it is compatible with the connection. The condition of connection compatibility gives constraints on torsion, which are also necessary for the consistence of torsion, minimal coupling, and electromagnetic gauge invariance. To solve the problem of positivity of energy associated with the torsionic scalar, we reformulate this theory in the Einstein conformal frame. In the presence of the electromagnetic field, we obtain the Hojman–Rosenbaum–Ryan–Shepley theory of propagating torsion with a different factor in the torsionic kinetic term. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2365788]

I. INTRODUCTION

In the Einstein–Cartan theory, which extends general relativity to nonsymmetric connection, spin is the source of torsion.[1] The equations relating torsion and spin are algebraic and torsion does not propagate.[2] To allow such a propagation, we need a differential equation for the torsion tensor $S^{\rho}{}_{\mu\nu}$. This is usually achieved by modifying the Einstein–Hilbert action and introducing a scalar field related to the torsion vector $S_{\nu}=S^{\mu}{}_{\mu\nu}$.[3–6] There are also models in which the torsion vector is proportional to the electromagnetic potential.[7–9]

The Lagrangian density for a gravitational field can be, in principle, given by any scalar constructed from the curvature, connection, and metric. The standard Einstein–Hilbert Lagrangian of general relativity is linear in the curvature scalar R and torsion enters the dynamics through R. Such a Lagrangian is very natural from a physical point of view since it is linear in the second derivatives of the metric tensor. These derivatives can be taken out of the action using the Gauß theorem, making the Lagrangian a function of the metric and its first derivatives only.[10] The corresponding equations of field are thus second order. If the gravitational Lagrangian is a more general function of R or other curvature invariants, the field equations remain second order if we adopt the Palatini variational principle according to which the connection and metric are *a priori* independent quantities and we vary the action with respect to both of them.[11] In this approach, the connection arises from the field equations and is not metric compatible, $g_{\mu\nu;\rho}\neq 0$ (except the case where the Lagrangian is linear in R and there is no torsion).

The Palatini variation of connection imposes four algebraic constraints on the matter part of the action, which are caused by invariance of the curvature scalar under a projective transformation of the connection.[12,13] These constraints lead to inconsistencies that can be eliminated by replacing the connection with its projective-invariant part.[13] This procedure is equivalent to imposing the condition $S_{\mu}=0$.[14] In this case, we cannot associate the gradient of a scalar field with the torsion vector and induce the propagation of torsion. Therefore, we follow the metric variational principle and fix the connection by assuming its metricity, $g_{\mu\nu;\rho}=0$.

In the presence of torsion, we must modify the covariant volume element so that it remains parallel.[6,15] Such a modification is possible only if S_{μ} is the gradient of a scalar, which gives four equations of constraint on the torsion tensor.[16] This condition is also necessary for the compat-

[a)]E-mail: nipoplaw@indiana.edu

ibility of torsion and gauge invariance of the minimally coupled electromagnetic field (the Hojman–Rosenbaum–Ryan–Shepley or HRRS theory of propagating torsion).[3] (According to the Palatini principle of minimal coupling, the electromagnetic field tensor is defined as $F_{\mu\nu}=A_{\nu,\mu}-A_{\mu,\nu}$ and does not generate torsion.[14]) A generalization of the HRRS theory to non-Abelian gauge fields has been done in Ref. 17.

In this paper we point out that the equations of field resulting from the action with the torsion-modified volume element violate positivity of energy for the torsionic scalar. The solution to this problem is to apply a conformal transformation of the original metric into a new metric in which the field equations have the form of those in general relativity.[18,19] This new metric defines the *Einstein frame* while the original one defines the *Jordan frame*.[20] In Sec. II we review the Einstein–Cartan theory with the torsion-modified volume element. In Sec. III we reformulate this theory in the Einstein conformal frame and apply it to the gauge invariant electrodynamics in the presence of torsion. The results are briefly summarized in Sec. IV.

II. COVARIANT VOLUME IN THE PRESENCE OF TORSION

In general relativity, a minimally coupled theory is constructed by replacing the metric of special relativity $\eta_{\mu\nu}$ with the metric of general relativity $g_{\mu\nu}$, and by replacing ordinary derivatives with covariant derivatives (the comma–semicolon rule).[10] The covariant derivative of a vector V_μ is defined as

$$V_{\nu;\mu}=V_{\nu,\mu}-\left\{{}_{\mu}{}^{\rho}{}_{\nu}\right\}V_\rho. \tag{1}$$

The coefficients $\{{}_{\mu}{}^{\rho}{}_{\nu}\}$ are the Christoffel symbols:

$$\left\{{}_{\mu}{}^{\rho}{}_{\nu}\right\}=\frac{1}{2}g^{\rho\lambda}(g_{\nu\lambda,\mu}+g_{\mu\lambda,\nu}-g_{\mu\nu,\lambda}), \tag{2}$$

determined from the relation $g_{\mu\nu;\rho}=0$. The colon denotes a covariant derivative with respect to the Christoffel symbols, and the comma denotes a usual derivative. In the presence of torsion $S^{\rho}{}_{\mu\nu}=\Gamma_{[\mu}{}^{\rho}{}_{\nu]}$, the covariant derivative is given by

$$V_{\nu;\mu}=V_{\nu,\mu}-\Gamma_{\mu}{}^{\rho}{}_{\nu}V_\rho. \tag{3}$$

The semicolon denotes a covariant derivative with respect to the nonsymmetric connection, and the connection coefficients $\Gamma_{\mu}{}^{\rho}{}_{\nu}$ are now

$$\Gamma_{\mu}{}^{\rho}{}_{\nu}=\left\{{}_{\mu}{}^{\rho}{}_{\nu}\right\}+S^{\rho}{}_{\mu\nu}-2S_{(\mu\nu)}{}^{\rho}. \tag{4}$$

This relation results from the metric compatibility of the connection, $g_{\mu\nu;\rho}=0$. [In the presence of torsion, the relation $g_{\mu\nu;\rho}=0$ remains valid, which means that both covariant derivatives (with respect to $\{{}_{\mu}{}^{\rho}{}_{\nu}\}$ and $\Gamma_{\mu}{}^{\rho}{}_{\nu}$, respectively) are tensors.] The difference $\Gamma_{\mu}{}^{\rho}{}_{\nu}-\{{}_{\mu}{}^{\rho}{}_{\nu}\}$, which is a tensor, is called the contortion $K^{\rho}{}_{\mu\nu}$:

$$K^{\rho}{}_{\mu\nu}=S^{\rho}{}_{\mu\nu}-2S_{(\mu\nu)}{}^{\rho}. \tag{5}$$

In a spacetime without torsion, a covariant volume element is $\sqrt{-g}d^4x$, and the scalar density $\sqrt{-g}$ is connection compatible (parallel): $(\sqrt{-g})_{;\mu}=0$. When the spacetime is not torsionless, this element is not parallel since[21]

$$(\sqrt{-g})_{;\mu}=-2S_\mu\sqrt{-g}. \tag{6}$$

It is possible to find a parallel volume element if the torsion vector is the gradient of a scalar:[15,16]

$$S_\mu=\theta_{,\mu}. \tag{7}$$

In this case we have

$$(e^{2\theta}\sqrt{-g})_{;\mu}=0, \tag{8}$$

and the volume element becomes

$$dV_4=e^{2\theta}\sqrt{-g}d^4x. \tag{9}$$

The contortion tensor (5) can be split into a traceless part and a trace (the torsion vector):

$$K_{\rho\mu\nu}=C_{\rho\mu\nu}-\frac{2}{3}(S_\rho g_{\nu\mu}-S_\nu g_{\rho\mu}). \tag{10}$$

The Riemann–Cartan curvature tensor is given by

$$R^\sigma{}_{\mu\rho\nu}(\Gamma)=\Gamma_\nu{}^\sigma{}_{\mu,\rho}-\Gamma_\rho{}^\sigma{}_{\mu,\nu}+\Gamma_\nu{}^\kappa{}_\mu\Gamma_\rho{}^\sigma{}_\kappa-\Gamma_\rho{}^\kappa{}_\mu\Gamma_\nu{}^\sigma{}_\kappa, \tag{11}$$

and its contractions are the Ricci tensor $R_{\mu\nu}(\Gamma)=R^\rho{}_{\mu\rho\nu}(\Gamma)$ and the curvature scalar $R(\Gamma,g)=R_{\mu\nu}(\Gamma)g^{\mu\nu}$. The curvature scalar $R(\Gamma,g)$ can be split into the Riemannian curvature scalar $R(g)$ (constructed from $\{_\mu{}^\rho{}_\nu\}$ the same way as $R(\Gamma,g)$ is constructed from $\Gamma_\mu{}^\rho{}_\nu$) and the part that contains torsion:[6]

$$R(\Gamma,g)=R(g)-4S^\mu{}_{;\mu}+\frac{16}{3}S_\mu S^\mu+C_{\mu\nu\rho}C^{\mu\rho\nu}. \tag{12}$$

The Lagrangian density for the gravitational field in the Einstein–Cartan–Saa theory with the torsion-modified volume element is given by[6]

$$\mathcal{L}=\frac{1}{16\pi}R(\Gamma,g)\sqrt{-g}e^{2\theta}, \tag{13}$$

where we use the units in which $c=G=1$. The second term on the right-hand side of Eq. (12) is a total covariant divergence of a vector (with respect to the nonsymmetric connection $\Gamma_\mu{}^\rho{}_\nu$) and does not contribute to the field equations. [From Eq. (8) we obtain $\int S^\mu{}_{;\mu}\sqrt{-g}e^{2\theta}d^4x=\int(S^\mu\sqrt{-g}e^{2\theta})_{,\mu}\,d^4x$. The last integral can be transformed into an integral over a three-dimensional hypersurface, which vanishes when we use the principle of least action.] In the same equation we use the condition (7). For the reason explained in the next section, we replace the scalar field θ by another field ϕ such that

$$\theta=-\frac{3}{2}\phi. \tag{14}$$

The action for the gravitational field is thus

$$S_g=\int d^4x\sqrt{-g}e^{-3\phi}\left(-\frac{1}{16\pi}R(g)-\frac{3}{4\pi}\phi_{,\mu}\phi^{,\mu}-\frac{1}{16\pi}C_{\mu\nu\rho}C^{\mu\rho\nu}\right). \tag{15}$$

We note that if $C_{\mu\nu\rho}=0$, replacing the torsionic scalar by a new field $\varphi=e^{-3\phi}$ reproduces the Brans–Dicke action with $\omega=-\frac{4}{3}$.[22]

III. SCALAR TORSION IN THE EINSTEIN FRAME

In the action (15), the kinetic term of the torsionic scalar field has the negative sign. By a sufficiently rapid change of ϕ with time, this term can consequently be made as large as one likes. The action would then decrease without limit, that is, there could be no minimum. This is a feature of many scalar–tensor theories of gravity in the metric variational formalism.[19,20] To solve this problem, we need to apply a conformal transformation of the metric from the original Jordan frame to the Einstein frame. In the Einstein frame, the curvature scalar in the action is multiplied

by a constant only, and the equations of field have the form of the Einstein equations.[18] Let us make a conformal transformation from the Jordan metric $g_{\mu\nu}$ to a new metric $h_{\mu\nu}$:

$$h_{\mu\nu}=e^{\lambda}g_{\mu\nu}, \tag{16}$$

where λ is a function of the coordinates. The Jordan and Einstein curvature scalars are related by[23]

$$R(g)=e^{\lambda}\left(R(h)+3\lambda^{:\mu}{}_{\mu}-\frac{3}{2}\lambda_{,\mu}\lambda^{,\mu}\right), \tag{17}$$

and all the quantities of the right-hand side of this equation are calculated using the new metric $h_{\mu\nu}$.

To eliminate the exponential function multiplying $R(g)$ in Eq. (15), we put

$$\lambda=-3\phi. \tag{18}$$

The action for the gravitational field in the Einstein frame becomes

$$S_g=\int d^4x\sqrt{-h}\left(-\frac{1}{16\pi}R(h)+\frac{3}{32\pi}\phi_{,\mu}\phi^{,\mu}-\frac{1}{16\pi}C_{\mu\nu\rho}C^{\mu\rho\nu}\right), \tag{19}$$

where the traceless part of the contortion in the new action is given by

$$K_{\rho\mu\nu}=C_{\rho\mu\nu}-\frac{2}{3}(S_{\rho}h_{\nu\mu}-S_{\nu}h_{\rho\mu}). \tag{20}$$

[To obtain Eq. (19), we notice that we can rewrite (10) as $K_{\rho}{}^{\mu}{}_{\nu}=C_{\rho}{}^{\mu}{}_{\nu}-\frac{2}{3}(S_{\rho}\delta^{\mu}_{\nu}-S_{\nu}\delta^{\mu}_{\rho})$ that does not contain the metric, and that $C_{\mu\nu\rho}C^{\mu\rho\nu}$ scales under the conformal transformation (16) like R.] The sign of the kinetic term for the scalar field is now positive. The action (19) differs from the expression obtained without using the parallel volume element (9) by the factor $\frac{1}{4}$ in the scalar kinetic term.[24] (The action in Ref. 24 has $C_{\mu\nu\rho}=0$.)

Let us apply the obtained results to the case of the electromagnetic field coupled minimally to torsion. The electromagnetic field tensor is a spacetime without torsion given by

$$F_{\mu\nu}=A_{\nu:\mu}-A_{\mu:\nu}, \tag{21}$$

and is invariant under a gauge transformation $A_{\mu}\rightarrow A'_{\mu}=A_{\mu}+\Lambda_{,\mu}$. In the presence of torsion, the principle of minimal coupling requires the following definition:

$$F_{\mu\nu}=A_{\nu;\mu}-A_{\mu;\nu}=A_{\nu,\mu}-A_{\mu,\nu}-2S^{\rho}{}_{\mu\nu}A_{\rho}. \tag{22}$$

Such a tensor is invariant under a generalized gauge transformation,

$$A_{\mu}\rightarrow A'_{\mu}=A_{\mu}+e^{\phi}\,\delta^{\nu}_{\mu}\Lambda_{,\nu}, \tag{23}$$

provided that the torsion tensor is given by[3]

$$S^{\rho}{}_{\mu\nu}=\frac{1}{2}(\delta^{\rho}_{\nu}\phi_{,\mu}-\delta^{\rho}_{\mu}\phi_{,\nu}). \tag{24}$$

This relation means that the torsion tensor is fully determined in terms of the torsion vector $S_{\mu}=S^{\nu}{}_{\nu\mu}$, and this vector has a potential, $S_{\mu}=-\frac{3}{2}\phi_{,\mu}$. The above constraint on torsion contains the condition for the existence of a parallel volume element (7), but is stronger. The tensor (22) becomes

$$F_{\mu\nu}=A_{\nu,\mu}-A_{\mu,\nu}-A_{\nu}\phi_{,\mu}+A_{\mu}\phi_{,\nu}, \tag{25}$$

which looks more elegant if we use ϕ instead of θ.

The total gauge invariant action for the electromagnetic field and the gravitational field with torsion is given by

$$S=\int d^4x\sqrt{-h}\left(-\frac{1}{16\pi}R(h)+\frac{3}{32\pi}\phi_{,\mu}\phi^{,\mu}-\frac{3}{32\pi}m^2\phi^2-\frac{1}{16\pi}F_{\mu\nu}F^{\mu\nu}\right), \tag{26}$$

where we introduce a mass of the torsionic field[24,25] (see the next paragraph). The equations of field are obtained from variation of $h_{\mu\nu}$, ϕ, and A^{μ}:

$$G_{\mu\nu}(h)=\frac{3}{2}\left(\phi_{,\mu}\phi_{,\nu}-\frac{1}{2}\phi_{,\rho}\phi^{,\rho}h_{\mu\nu}\right)+\frac{3}{4}m^2\phi^2h_{\mu\nu}$$

$$+2\left(\frac{1}{4}F_{\rho\sigma}F^{\rho\sigma}h_{\mu\nu}-F_{\mu\rho}F_{\nu}{}^{\rho}\right), \tag{27}$$

$$\phi^{:\mu}{}_{\mu}+m^2\phi+\frac{4}{3}(F^{\mu\nu}A_{\nu})_{:\mu}=0, \tag{28}$$

$$F^{\mu\nu}{}_{:\nu}+F^{\mu\nu}\phi_{,\nu}=0, \tag{29}$$

where $G_{\mu\nu}(h)$ is the Einstein tensor. They differ from the equations derived in the HRRS theory[3,24] by the factor $\frac{1}{4}$ in the torsionic scalar field terms. The last two equations yield

$$\phi^{:\mu}{}_{\mu}+m^2\phi=-\frac{2}{3}F_{\mu\nu}F^{\mu\nu}. \tag{30}$$

The reason for the torsionic scalar field to be massive originates from the Eötvös–Dicke–Braginsky solar tests of the principle of equivalence[26] and the idea introduced in Ref. 25. For the scalar field of the Sun, Eq. (30) becomes

$$\nabla^2\phi-m^2\phi=\frac{1}{3}(\mathbf{B}^2-\mathbf{E}^2), \tag{31}$$

where **B** and **E** are the magnetic and electric field, respectively. The solution of Eq. (31) outside the Sun is

$$\phi=\frac{2}{3}\frac{e^{-mr}}{r}E_{ne}, \tag{32}$$

where E_{ne} is the total nuclear electric energy of the Sun and other energies are negligible. The data from Ref. 26 give

$$\phi=0.67\times10^{-4}U\cdot e^{-mr}, \tag{33}$$

where r is the distance from the Sun and U is the Newtonian potential. This expression modifies the relative acceleration between aluminum and gold/platinum[26] by the factor e^{-mR}, where R is the distance of the Earth from the Sun:

$$\mathbf{a}_{\mathrm{rel}}=2\times10^{-7}\ \nabla U\cdot e^{-mR}. \tag{34}$$

To avoid violations of the principle of equivalence in the solar system and obtain a theory compatible with experiment, we need

$$2\times10^{-7}\ \nabla U\cdot e^{-mR}<10^{-12}\ \nabla U. \tag{35}$$

This inequality gives the lower limit on the mass of the torsionic scalar field,[24]

$$m > 10^{-25}\ \mathrm{GeV}, \tag{36}$$

in agreement with Ref. 25.

IV. SUMMARY

In the presence of torsion, a covariantly conserved volume element can be found if the torsion vector equals the gradient of a scalar. This condition gives four equations of constraint on the torsion tensor. Remarkably, the condition for the compatibility of the gauge invariant electromagnetic field coupled minimally to torsion contains this constraint. Another condition for this compatibility is that the traceless part of the contortion tensor must vanish. The last requirement is a consequence of the equations of field in the Jordan frame, if we use the electromagnetic field that does not couple to torsion. It is not the case for the minimal coupling between torsion and photons. A possible solution would be to assume that the electromagnetic field couples to the trace part of the torsion tensor only. Ultimately, we should obtain this requirement as a result of a variational principle.

The action integral over the torsion-modified volume element contains the kinetic term of the torsionic scalar field with the negative sign. By a sufficiently rapid change of this field with time, this term can consequently be made arbitrarily large, and the action would have no minimum. To solve this problem, we applied a conformal transformation of the metric from the original Jordan frame to the Einstein frame in which the left side of the field equations is that of general relativity. The new action acquired the correct, positive sign in the kinetic term for the torsionic scalar. The obtained field equations differ from those in the original HRRS theory by the factor $\frac{1}{4}$ in the torsionic scalar field terms. This difference does not affect the order of the minimal value for the mass m of the torsionic scalar required for the theory to be compatible with experiment.

The minimal value of m is way below the masses of known elementary particles. There is no upper limit for m, and the Higgs boson could be a good candidate for the particle corresponding to the torsionic scalar. Since the lower limit on the mass of the Higgs boson is on the order of 100 GeV, the deviations from the principle of equivalence would be unnoticeable (below 10^{-27} of present experimental precision).

We emphasize that the question of whether the electromagnetic field couples to torsion or not should be ultimately answered by experiment. We assumed that the principle of minimal coupling holds in the presence of torsion, which leads to the appearance of the EM–torsion coupling and constraints on the torsion tensor. Otherwise, torsion does not affect the electromagnetic field and gauge invariance of the latter is compatible with nonsymmetric connection under no additional constraints.

We mentioned that the HRRS procedure of combining electromagnetic gauge invariance with minimal coupling between the EM field and torsion has been generalized to non-Abelian gauge fields such as the Yang–Mills field. A possible coupling between spin, which generates torsion in the Einstein–Cartan theory, and the non-Abelian chromomagnetic field of QCD would play an important role in objects composed of fermionic matter at large densities. Neutron stars would be ideal candidates to study this coupling and determine whether gauge fields interact with torsion.

(Received 28 June 2006; accepted 9 October 2006; published online 30 November 2006)

Existence of solutions between prescribed configurations is proved for spatially flat Robertson–Walker spacetimes coupled with homogeneous scalar field sources, using a modified version of the Euler–Maupertuis least action variational principle. The solutions are obtained as limits of approximating variational problems, solved using the techniques originally introduced by Rabinowitz. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2383068]

I. INTRODUCTION

Observational cosmology suggests that our universe has entered a stage of accelerated expansion (see Refs. 17 and 18, and references therein). The reason for that is the so called *dark energy*, that constitutes most of the energy density of the whole universe. The existence of a cosmological constant can be called as responsible for dark energy, but some physical problems arise from this interpretation. The most important alternative physical interpretation for dark energy origin calls into play scalar field models of spacetime (see Ref. 14, and references therein). In the latest years of theoretical physics, the belief for existence of *zero-spin* particles—whose description is given in terms of a wave *scalar* function—has gained supporters, although there is no observational evidence yet.

We shall concentrate here on the simple model of Robertson–Walker spacetimes with homogeneous scalar fields, and in this case the Einstein field equations read

$$(G_0^0 = 8\pi T_0^0): \quad -\frac{3\dot{a}^2}{a^2} = -(\dot{\phi}^2 + 2V(\phi)), \tag{1.1a}$$

$$(G_1^1 = 8\pi T_1^1): -\frac{\dot{a}^2 + 2a\ddot{a}}{a^2} = (\dot{\phi}^2 - 2V(\phi)), \tag{1.1b}$$

where the dot denotes differentiation with respect to t, $a(t)$ is the scale factor and $\phi(t)$ is the scalar field.

We will be interested in the problem of determining solutions of Eqs. (1.1a) and (1.1b) with fixed end points. The metric becomes singular when $a(t)$ vanishes in the past or in the future—corresponding to big-bang or big-crash singularity, respectively. In this paper we want to avoid this situation, so we will consider pieces of evolution where $a(t)$ keeps positive. The central result of the paper is the following theorem:

Theorem 1.1: *Let* $a_0, a_1 \in \mathbb{R}^+$, $\phi_0, \phi_1 \in \mathbb{R}$ *be such that*

[a]Electronic mail: roberto.giambo@unicam.it
[b]Electronic mail: fabio.giannoni@unicam.it
[c]Electronic mail: magli@mate.polimi.it

$$3\min\{a_0,a_1\}(a_1-a_0)^2 > \max\{a_0,a_1\}(\phi_1-\phi_0)^2, \tag{1.2}$$

and let $V\in\mathcal{C}^1(\mathbb{R},\mathbb{R})$ *such that*

$$V(\phi)>0, \quad \forall\ \phi\in\mathbb{R}. \tag{1.3}$$

Then, there exists $T>0$ *and* $[a(t),\phi(t)]\in\mathcal{C}^2([0,T],\mathbb{R}^2)$ *solutions of Eqs.* (1.1a) and (1.1b) *with the boundary conditions*

$$a(0)=a_0, \quad a(T)=a_1, \quad \phi(0)=\phi_0, \quad \phi(T)=\phi_1. \tag{1.4}$$

Note that the above result cannot be seen as a consequence of the well-known theory on the existence of solutions for Cauchy problems in general relativity (see pioneering work by Bruhat,[2] and the following literature). Here, indeed, we do not fix both fundamental forms on a Cauchy surface, and find evolution from it, but we show that, under the above condition, the set of initial data can be completed in order to reach a certain configuration from a given one. The solutions under our study stay regular in the interval $[0, T]$, since $a(t)>0$. Nevertheless, we believe that this approach may be useful to find the existence results for scalar field solutions evolving to singularity, a topic which is of relevant interest in the problems related to the cosmic censorship conjecture. In fact, although existence and causal structure of the singularities in matter-filled spacetimes has been so far widely investigated in the case of fluid-elastic matter (see Ref. 6, and references therein) for scalar fields the situation is fully understood only in the very special case of nonself-interacting, massless particles.[3,4] The homogeneous collapse with potential has been treated only in special cases, by Joshi *et al.* (who have also investigated on loop quantum gravity effects in Ref. 9) and in Ref. 5, where the collapse features are characterized by the dependence of the energy density on the scale factor a; an important open question in which models with potentials have been used is also that of cosmic censorship violation in AdS.[10,11]

We will cast the above problem into a suitable variational framework. The use of a variational approach in general relativity study is not a novelty, of course: for instance, some of the most important results in the relativistic gravitational lensing problem are reviewed in Ref. 15. In the present paper, actually, the variational approach is used to determine solutions of Einstein field equations, i.e., spacetimes. Hilbert–Palatini action,[13,19] indeed, provides a functional whose critical points with respect to variation of the metric g yields solutions of Einstein field equations. The particular case under our study produces the functional Eq. (2.2), which is an integral made on the interval $[0, T]$ of definition of the solutions. Of course, since T is let free in principle, it must be treated as an unknown for the system, but this problem may be circumvented by using the functional Eq. (2.15) in the space of curves reparameterized on the interval $[0, 1]$. Although the functional Eq. (2.15) seems in principle more complicated to deal with than Eq. (2.2), critical point existence can be obtained as a limit of a sequence of variational problems, for which Rabinowitz' saddle point theorem[16] techniques apply.

The outline of the paper is as follows. Section II is devoted to an exposition of the variational formulation for the problem; Section III briefly outlines the general theory that applies to the approximating variational problems introduced in Sec. IV, and studied in Sec. V. Section VI contains the proof of the main Theorem 1.1.

II. THE VARIATIONAL PRINCIPLE

In the case under study it can be easily shown that the action functional is the following:

$$\mathcal{L}(a,\phi)=\int_0^T 3(\dot{a}^2(t)+a(t)\ddot{a}(t))a(t)+a^3(t)(\dot{\phi}^2(t)-2V(\phi(t)))\ \mathrm{d}t. \tag{2.1}$$

We can integrate by parts the term in Eq. (2.1) containing $\ddot{a}(t)$. We ignore the contribution of the boundary term $3a^2\dot{a}|_0^T$ coming from the integration. This exactly amounts[19] to modify the functional Eq. (2.1), adding the contribution $(1/16\pi)\int_{\partial M}K$ of the trace of the extrinsic curvature K integrated along the boundary ∂M of the spacetime. All in all, we obtain

$$\mathcal{L}(a,\phi)=\int_0^T 3a(t)\dot{a}^2(t)-a^3(t)\dot{\phi}^2(t)+2a^3(t)V(\phi(t))\mathrm{d}t, \tag{2.2}$$

and the following proposition holds.

Proposition 2.1. If $(a,\phi)\in\mathcal{C}^2(\mathbb{R}^+,\mathbb{R})$ solves the Euler–Lagrange equation for $\mathcal{L}$, and

$$3\dot{a}(0)^2=a_0^2(\dot{\phi}(0)^2+2V(\phi_0)), \tag{2.3}$$

then it is a solution of Eqs. (1.1a) and (1.1b).

Proof: This is a standard result, consequence of Nöther's theorem, but an *ad hoc* proof can be easily given. Indeed, the Euler–Lagrange equations for the functional Eq. (2.2) read

$$\dot{a}^2+2a\ddot{a}=-a^2(\dot{\phi}^2-2V(\phi)), \tag{2.4a}$$

$$\ddot{\phi}+V'(\phi)=-3\frac{\dot{a}}{a}\dot{\phi}, \tag{2.4b}$$

where the condition $a\neq 0$ has also been used. Using these equations, the quantity $a(3\dot{a}^2-a^2(\dot{\phi}^2+2V))$ is easily seen to be constant with respect to t, and then if Eq. (1.1a) holds at the initial time—which is just condition (2.3)—then it vanishes during the whole evolution. Since $a\neq 0$, we therefore obtain Eq. (1.1a). Equation (1.1b) is equivalent to Eq. (2.4a). ■

Remark 2.2: A *partial* converse of Proposition above can be of course given, using the following identity:

$$T^{\mu}_{0;\mu}=-2\dot{\phi}\left(\ddot{\phi}+V'(\phi)+3\frac{\dot{a}}{a}\dot{\phi}\right). \tag{2.5}$$

The left hand side above is the zero-component of the divergence of T,[19] and it vanishes if the Einstein equations hold, due to the conservation of energy (Bianchi identity). Therefore, if $\dot{\phi}$ is everywhere nonzero, Eq. (2.4b) holds.

Actually, the converse result can be improved further.

Proposition 2.3: If $(a,\phi):[0,T]\to\mathbb{R}^+\times\mathbb{R}$ are $\mathcal{C}^2$ solutions of (1.1a) and (1.1b) with $\phi\equiv\phi_0$ on $[0, T]$, then they solve Eqs. (2.4a) and (2.4b). In particular Eq. (2.3) holds.

Proof: Only Eq. (2.4b) must be proved. Let $G(t)$ be the (continuous) function $G(t):=\ddot{\phi}(t)+V'(\phi(t))+3(\dot{a}(t)/a(t))\dot{\phi}(t)$, and assume by contradiction the existence of $t_0\in[0,T]$ such that $G(t_0)\neq 0$. Therefore, considered the (closed) set $C=\{t\in[0,T]:\dot{\phi}(t)=0\}\subsetneq[0,T]$, the Bianchi identity Eq. (2.5) implies the existence of a closed interval $[\alpha,\beta]$ such that

$$t_0\subset[\alpha,\beta]\subseteq C, \tag{2.6}$$

and that is maximal with respect to this property Eq. (2.6). We will show $G=0$ on $[\alpha,\beta]$, getting a contradiction. Since $[\alpha,\beta]$ is strictly contained in $[0, T]$ then $\alpha>0$ or $\beta<T$ (or both). Let us assume for instance $\alpha>0$. Since $\dot{\phi}_{|[\alpha,\beta]}=0$, and ϕ is $\mathcal{C}^2$, then $\ddot{\phi}_{|[\alpha,\beta]}=0$ and $\phi(t)=\phi(\alpha)$, $\forall t\in[\alpha,\beta]$. These facts imply

$$G(t)=V'(\phi(\alpha)),\quad \forall\, t\in[\alpha,\beta]. \tag{2.7}$$

Maximality of $[\alpha,\beta]$ with respect to Eq. (2.6) implies the existence of a sequence $\alpha_n\notin C$, $\alpha_n\to\alpha^-$. Then $\dot{\phi}(\alpha_n)\neq 0$ and therefore $G(\alpha_n)=0$ by Eq. (2.5), therefore the continuity of G and Eq. (2.7) finally imply

$$0=\lim_{n\to\infty}G(\alpha_n)=\lim_{t\to\alpha^-}G(t)=V'(\phi(\alpha)),$$

obtaining $G(t)=0$ on $[\alpha,\beta]$. ■

Remark 2.4: If ϕ is everywhere constant one can easily find counterexamples where Eqs. (1.1a) and (1.1b) hold but Eq. (2.4b) does not. This is a well known fact in relativistic elasticity theory, where equivalence between the Bianchi identity and the Euler–Lagrange equations (i.e., Nöther theorem) holds under the assumption that the deformation tensor has maximum rank. We refer the reader to Ref. 12 for further details on this topic. In the scalar field theory, the gradient $\nabla\phi$ plays the role of this deformation tensor. For our purposes here, anyway, we will only use Proposition 2.1.

The problem of finding the solutions of Eqs. (1.1a) and (1.1b) with fixed end points is brought to the study of critical points of the functional Eq. (2.2) with fixed end points and under the initial condition (2.3). Of course, since the arrival time T is left free so far, one can reparameterize the functions on the interval $[0, 1]$, with the obvious drawback to promote T as a new unknown of the problem. But this problem can be overcome, applying the following (general) variational principle.[1,7]

Theorem 2.5: *Let $(\mathfrak{M}, g)$ be a semi-Riemannian manifold, W a $\mathcal{C}^1$ function on $\mathfrak{M}$, $E \in \mathbb{R}$ and $p, q \in \mathfrak{M}$.*

(1) *If $y:[0,1]\to\mathfrak{M}$ is a critical point for the functional*

$$\mathfrak{F}(y) = \left(\int_0^1 \frac{1}{2} g\left(\frac{\mathrm{d}}{\mathrm{d}s} y(s), \frac{\mathrm{d}}{\mathrm{d}s} y(s)\right) \mathrm{d}s\right)\left(\int_0^1 E - W(y(s))\mathrm{d}s\right) \tag{2.8}$$

with positive critical value, in the space of $\mathcal{C}^2$ curves defined in $[0, 1]$, such that $y(0)=p$, $y(1)=q$, called

$$T_0 = \left(\frac{\displaystyle\int_0^1 \frac{1}{2} g\left(\frac{\mathrm{d}}{\mathrm{d}s} y, \frac{\mathrm{d}}{\mathrm{d}s} y\right) \mathrm{d}s}{\displaystyle\int_0^1 E - W(y(s))\mathrm{d}s}\right)^{1/2}, \tag{2.9}$$

then the curve $x:[0,T_0]\to\mathfrak{M}$, $x(t)=y(T_0 s)$ is a critical point for the functional

$$L(x) = \int_0^T \frac{1}{2} g\left(\frac{\mathrm{d}}{\mathrm{d}t} x(t), \frac{\mathrm{d}}{\mathrm{d}t} x(t)\right) - W(x(t))\mathrm{d}t, \tag{2.10}$$

with $T=T_0$, in the space of $\mathcal{C}^2$ curves satisfying the conditions

$$x(0) = p, \quad x(T) = q, \quad \frac{1}{2} g\left(\frac{\mathrm{d}}{\mathrm{d}t} x(t), \frac{\mathrm{d}}{\mathrm{d}t} x(t)\right) + W(x(t)) = E. \tag{2.11}$$

(2) *Vice versa, let us fix $T>0$, and let $x:[0,T]\to\mathfrak{M}$ be a critical point for the functional Eq. (2.10) in the space of $\mathcal{C}^2$ curves $\gamma:[0,T]\to\mathbb{R}$ satisfying conditions (2.11). If $\int_0^T (1/2) g((\mathrm{d}/\mathrm{d}t)x(t), (\mathrm{d}/\mathrm{d}t)x(t))\mathrm{d}t \neq 0$, then the reparameterization $y:[0,1]\to\mathfrak{M}$ of x on [0, 1], (i.e., $y(s)=x(Ts)$), is a critical point for the functional Eq. (2.8), with positive critical value, in the space of $\mathcal{C}^2$ curves defined in [0, 1], such that $y(0)=p$, $y(1)=q$.*

Proof: Let $y(s):[0,1]\to\mathfrak{M}$ be a critical point for $\mathfrak{F}$ (2.8). The fixed end point first variation of this functional and an integration by parts gives

$$\left(\int_0^1 E - W(y(s))\mathrm{d}s\right)\frac{\mathrm{D}^2}{\mathrm{d}s^2} y(s) + \left(\int_0^1 \frac{1}{2} g\left(\frac{\mathrm{d}}{\mathrm{d}s} y(s), \frac{\mathrm{d}}{\mathrm{d}s} y(s)\right) \mathrm{d}s\right) \nabla W(y(s)) = 0 \tag{2.12}$$

that is, using the value of T_0 given by (2.9) (well defined since the critical value is positive)

$$\frac{1}{T_0^2}\frac{\mathrm{D}^2}{\mathrm{d}s^2}y(s)+\nabla W(y(s))=0, \quad \forall\, s\in[0,1]. \tag{2.13}$$

Let $x:[0,T_0]\to\mathfrak{M}$ be the reparameterization of y on the interval $[0,\ T_0]$ (i.e., $x(t)=y(t/T_0)$). Therefore, Eq. (2.13) becomes nothing but the Euler–Lagrange equation for the functional Eq. (2.10) with $T=T_0$. Moreover, contracting the left hand side of Eq. (2.13) with $(\mathrm{d}/\mathrm{d}s)y(s)$, we obtain the existence of a constant K such that

$$\frac{1}{T_0^2}\frac{1}{2}g\left(\frac{\mathrm{d}}{\mathrm{d}s}y(s),\frac{\mathrm{d}}{\mathrm{d}s}y(s)\right)+W(y(s))=K, \quad \forall\, s\in[0,1]. \tag{2.14}$$

Integrating both sides above between 0 and 1, and using Eq. (2.9), we obtain $E=K$, and so

$$\frac{1}{2}g\left(\frac{\mathrm{d}}{\mathrm{d}t}x(t),\frac{\mathrm{d}}{\mathrm{d}t}x(t)\right)+W(x(t))=E, \quad \forall\, t\in[0,T_0].$$

Conversely, let $x(t):[0,T]\to\mathfrak{M}$ be a critical point for Eq. (2.10) in the space of $\mathcal{C}^2$ curves defined in $[0,\ T]$, satisfying Eq. (2.11), and $y(s):[0,1]\to\mathfrak{M}$ be its reparameterization: $y(s)=x(Ts)$. Since $\mathrm{d}/\mathrm{d}s=T(\mathrm{d}/\mathrm{d}t)$, Eq. (2.14) holds with T_0 and K replaced by T and E, respectively. Integrating both sides of Eq. (2.14) in $[0,\ 1]$ implies that T is equal to the value of T_0 given by Eq. (2.9). Moreover, $\mathrm{d}/\mathrm{d}s=T(\mathrm{d}/\mathrm{d}t)$ also implies Eq. (2.13), and substituting the value of T_0 given by Eq. (2.9) we find that $y(s)$ satisfies Eq. (2.12), that is the critical point equation for the functional Eq. (2.8), and the proof is complete. ■

Remark 2.6: The variational principle given above, is actually a sort of modified version of the classical Euler–Maupertuis least action principle. The above proof is an adaptation of the one given in Ref. 7 for the Euclidean case, and may not completely stress the link with the classical principle. For a deeper insight, we refer the reader to the review[8] by the same author.

Applying this variational principle to functional Eq. (2.2) (with $E=0$), the following problem provides solutions of homogeneous scalar field equation with fixed end points.

Problem: Let $a_0,\ a_1\in\mathbb{R}^+,\ \phi_0,\ \phi_1\in\mathbb{R}$, and $V\in\mathcal{C}^1(\mathbb{R},\mathbb{R})$.

Find the critical points of the functional

$$F(a,\phi)=\left(\int_0^1 3a(t)\dot{a}^2(t)-a^3(t)\dot{\phi}^2(t)\mathrm{d}t\right)\left(\int_0^1 2a^3(t)V(\phi(t))\mathrm{d}t\right), \tag{2.15}$$

with positive critical value, in the space of $\mathcal{C}^2$ curves $(a,\phi):[0,1]\to\mathbb{R}^+\times\mathbb{R}$ such that

$$a(0)=a_0, \quad a(1)=a_1, \quad \phi(0)=\phi_0, \quad \phi(1)=\phi_1. \tag{2.16}$$

III. THE FUNCTIONAL FRAMEWORK AND THE ABSTRACT CRITICAL POINTS THEORY

We first recall the classical notion of the Palais–Smale condition.

Definition 3.1: Let $\mathcal{X}$ a Hilbert manifold of class $\mathcal{C}^1$ and $f\in\mathcal{C}^1(\mathcal{X},\mathbb{R})$. We say that f satisfies the *Palais–Smale condition at level c* ($(PS)_c$) if any sequence $\{x_n\}_{n\in,\mathbb{N}}\subset\mathcal{X}$ such that

$$f(x_n)\to c, \quad \text{and} \quad \nabla f(x_n)\to 0$$

(where ∇f represents the gradient of f with respect to the Hilbert structure of $\mathcal{X}$) has a converging subsequence in $\mathcal{X}$. The sequence $\{x_n\}$ with properties above is called a *Palais–Smale sequence* for f.

Definition 3.2: We say that $x\in\mathcal{X}$ is a *critical point* of f if $\nabla f(x)=0$. A value $c\in\mathbb{R}$ such that there exists a critical point x with $f(x)=c$ is a *critical value* for f. A value $c\in\mathbb{R}$ which is not critical will be called *regular*.

Theorem 3.3: *Let* $\mathcal{X}=\Omega\times Y$, *where* Ω *is a Hilbert manifold and* Y *is a finite dimensional*

affine space. Let $\|\cdot\|$ *denote the norm on* Y, *and let* $f \in \mathcal{C}^1(\mathcal{X},\mathbb{R})$. *Assume that*

(1) *there exists* $\omega_0 \in \Omega$, $e_0 \in Y$, *and* $R>0$ *such that, called* $B_R(e_0)=\{e \in E: \|e-e_0\| \leqslant R\}$, *it is*

$$b_0 \equiv \sup_{e \in \partial B_R(e_0)} f(\omega_0,e) < b_1 \equiv \inf_{\omega \in \Omega} f(\omega,e_0);$$

(2) *if* $b_2=\sup_{e \in B_r(e_0)} f(\omega_0,e)$, *the strip* $\{x \in \mathcal{X}: b_1 \leqslant f(x) \leqslant b_2\} \subset \mathcal{X}$ *is complete; and*
(3) f *satisfies* $(PS)_c$ *at any* $c \in [b_1,b_2]$.

Then, there exists a critical value c *for* f *in* $[b_1,b_2]$.

The proof can be obtained adapting the scheme developed in Ref. 16. However, the idea behind is quite simple. If, by contradiction, $[b_1,b_2]$ is made by regular value only, using the gradient flow of the functional f one obtains the existence of a homotopy sending the sublevel $\{x \in \mathcal{X}: f(x) \leqslant b_2\}$ to the sublevel $\{x \in \mathcal{X}: f(x) \leqslant b_1\}$ letting $\{x \in \mathcal{X}: f(x) \leqslant b_1\}$ fixed. Therefore, using the projection on Y and the retraction of Y on $B_R(e_0)$, and observing that $b_0<b_1$, one can define a homotopy that sends $B_R(e_0)$ to its boundary $\partial B_R(e_0)$—recall that $b_2=\sup_{e \in B_R(e_0)} f(x_0,e)$—and that lets $\partial B_R(e_0)$ fixed, which is impossible in finite dimension.

IV. AN APPROXIMATION SCHEME

By assumption (1.2) of Theorem 1.1, we know that $a_0 \neq a_1$. To fix ideas, without loss of generality we can assume

$$a_0 > a_1, \tag{4.1}$$

so that Eq. (1.2) becomes

$$3a_1(a_1-a_0)^2 > a_0^3(\phi_1-\phi_0)^2.$$

We can choose constants m,M such that $0<m<a_1<a_0<M<+\infty$ and

$$3m(a_1-a_0)^2 - M^3(\phi_1-\phi_0)^2 > 0. \tag{4.2}$$

Consider the Hilbert manifold

$$\Omega = \{a \in H^1([0,1],\ ]m,M[\ ): a(0)=a_0, a(1)=a_1\}, \tag{4.3}$$

where $H^1([0,1],]m,M[)$ is the set of absolutely continuous functions defined on [0, 1], with values on $]m,M[$, such that $\int_0^1 \dot{a}^2 \mathrm{d}t < +\infty$. Let us observe that Ω is a *not* complete Hilbert manifold with Hilbert structure

$$\langle a_1,a_2\rangle = \int_0^1 \dot{a}_1(t)\dot{a}_2(t)\mathrm{d}t.$$

We denote by $\|a\|_\Omega$ the norm induced by the above inner product

$$\|a\|_\Omega = \left(\int_0^1 \dot{a}(t)\mathrm{d}t\right)^{1/2}. \tag{4.4}$$

Now set $\phi_*(t)=(1-t)\phi_0+t\phi_1$. Since $V>0$, we have

$$\inf_{t \in [0,1]} V(\phi_*(t)) \equiv v_* > 0. \tag{4.5}$$

Let us also consider the affine space

$$Y = \{\phi = \hat{\phi} + \phi_* : \hat{\phi} \in H_0^1([0,1],\mathbb{R})\}, \tag{4.6}$$

where $H_0^1([0,1],\mathbb{R}) = \{\phi \in H^1([0,1],\mathbb{R}) : \phi(0) = \phi(1) = 0\}$. Y is a closed affine subspace of $H^1([0,1],\mathbb{R})$, with norm

$$\|\phi\|_Y = \left(\int_0^1 \dot{\phi}^2(t) \mathrm{d}t \right)^{1/2}. \tag{4.7}$$

Since $\dim Y = +\infty$ we cannot apply Theorem 3.3 *as is* to our setting, and then we approximate Y by a sequence Y_k, defined as follows: for any $k \in \mathbb{N}$ set

$$W_k = \mathrm{span}\{\sin(\pi \ell t) : t \in [0,1], \ell = 1, \ldots, k\}, \tag{4.8}$$

and

$$Y_k = \{\phi = \hat{\phi}_k + \phi_* : \hat{\phi}_k \in W_k\}.$$

Remark 1: Since $\{\sqrt{2}\sin(\pi \ell t)\}_{\ell \in \mathbb{N}}$ is a complete orthonormal system of $H_0^1([0,1],\mathbb{R})$, if $\phi = \hat{\phi} + \phi_* \in Y$ and $\hat{\phi}_k$ denotes the projection of $\hat{\phi}$ on W_k, then $\hat{\phi}_k \to \hat{\phi}$ in H_0^1, with tejpect to the norm defined in Eq. (4.7).

We shall apply Theorem 3.3 to the space $\mathfrak{X}_k = \Omega \times Y_k$. Since Ω is not complete, and V is not bounded in general, we modify the functional F (2.5) and look for critical points $\mathfrak{x}_{\epsilon,\lambda}$, with positive critical value, of a suitable functional $F_{\epsilon,\lambda}$. Some estimates for the critical points $x_{\epsilon,\lambda}$ will show that they are critical points for F, whenever ϵ is sufficiently small, and λ sufficiently large.

Let $\chi: \mathbb{R}^+ \to \mathbb{R}^+$ of class $\mathbb{C}^1$, such that $\chi(s) = 0$ if $s \leqslant 0$ and $\chi(s) = s^2$ if $s > 0$. Fix $\epsilon \in]0,1]$, and define

$$U_\epsilon(a) = \chi\left(\frac{1}{a-m} - \frac{1}{\epsilon}\right) + \chi\left(\frac{1}{M-a} - \frac{1}{\epsilon}\right). \tag{4.9}$$

Moreover, consider $\psi: \mathbb{R} \to \mathbb{R}$ of class $\mathcal{C}^1$ such that $\psi(s) = s$ if $s \leqslant 0$, $\psi(s) = 1$ if $s \geqslant 1$, and ψ is strictly increasing on the interval $]0,1[$. Fix $\lambda > 0$ and define

$$V_\lambda(\phi) = \psi(V(\phi) - \lambda) + \lambda. \tag{4.10}$$

Observe that $V_\lambda = V$ whenever $V(\phi) \leqslant \lambda$. Finally, define

$$F_{\epsilon,\lambda}(a,\phi) = \int_0^1 [(3a + U_\epsilon(a))\dot{a}^2 - a^3\dot{\phi}^2]\mathrm{d}t \cdot \int_0^1 2a^3 V_\lambda(\phi)\mathrm{d}t. \tag{4.11}$$

It is a straightforward computation to show that the above functional is $\mathcal{C}^1$. In the next section we shall show how to apply Theorem 3.3 to $F_{\epsilon,\lambda}$ on the space $\Omega \times Y_k$.

V. CRITICAL POINTS FOR THE FUNCTIONAL $F_{\epsilon,\lambda}$.

The aim of this section is to prove the following result.

Proposition 1: For any $k \in \mathbb{N}$ there exists $x_k = (a_k, \phi_k)$ critical point of $F_{\epsilon,\lambda}$ on $\mathcal{X}_k$ such that

$$F_{\epsilon,\lambda}(x_k) \in [b_1, b_2],$$

where b_1, b_2 are positive, and independent of k.

We must first show that hypotheses (1)–(2) of Theorem 3.3 hold for $F_{\epsilon,\lambda}$ on $\mathcal{X}_k = \Omega \times Y_k$. The key point will be to show (3), namely the Palais–Smale condition (Definition 3.1). This will be done in Lemma 5.3. First, let us prove the validity of hypotheses (2).

Lemma 5.2: Denoted by F^c the sublevel $F^c = \{x \in \Omega \times E : F(x) \leqslant c\}$, then the set $F^c \cap \mathcal{X}_k$ is complete in $\mathfrak{X}_k$.

Proof: Take a Cauchy sequence $x_n = (a_n, \phi_n) \in \Omega \times E_k$. Since the closure of Ω is complete, and

so is E_k, then there exists $(a,\phi)\in\bar{\Omega}\times E_k$ such that $a_n\to a$ in H^1 and $\phi_n\to\phi$ in H^1. Now $\int_0^1 a_n^3 V_\lambda(\phi_n)\mathrm{d}t\to\int_0^1 a^3 V_\lambda(\phi)\mathrm{d}t$ which is strictly positive, and $\int_0^1(3a_n\dot{a}_n^2-a_n^3\dot{\phi}_n^2)\mathrm{d}t\to\int_0^1 3a\dot{a}^2-a^3\dot{\phi}^2\mathrm{d}t$.

If $a(t)\in\,]m,M[\,\forall t$, then (a_n,ϕ_n) converges in $\Omega\times E_k$. The proof is complete as one shows that there is no possibility that some $\bar{t}\in\,]0,1[$ exists such that either $a(\bar{t})=m$ or $a(\bar{t})=M$. By contradiction, suppose for instance

$$\exists\bar{t}\text{:}a(\bar{t})=m,\quad a(t)>m\ \forall\, t\in[0,\bar{t}[. \tag{5.1}$$

Observe that $F_{\epsilon,\lambda}(a_n,\phi_n)\leqslant c$, $\int_0^1 a^3 V_\lambda(\phi)\mathrm{d}t>0$, and $\int_0^1(3a\dot{a}^2-a^3\dot{\phi}^2)\mathrm{d}t$ is finite. We will show that the hypothesis (5.1) implies

$$\int_0^{\bar{t}} U_\epsilon(a_n)\dot{a}_n^2\mathrm{d}t\to+\infty,$$

obtaining a contradiction.

Since $a_n\to a$ uniformly, $\forall\epsilon>0$ there exists $\bar{s}<\bar{t}$ and $n_0\in\mathbb{N}$ such that

$$|a_n(t)-m|\leqslant\epsilon,\quad \forall\, t\in[\bar{s},\bar{t}],\quad \forall\, n\geqslant n_0.$$

Fix ϵ such that $m+\epsilon<M$. Then, recalling the definition of U_ϵ, it will suffice to show that

$$\lim_{n\to\infty}\int_{\bar{s}}^{\bar{t}}\frac{\dot{a}_n^2}{(a_n-m)^2}\mathrm{d}t=+\infty, \tag{5.2}$$

which easily follows from the following estimate:

$$\left(\int_{\bar{s}}^{\bar{t}}\frac{\dot{a}_n^2}{(a_n-m)^2}\mathrm{d}t\right)^{1/2}\geqslant\frac{1}{\sqrt{\bar{t}-\bar{s}}}\int_{\bar{s}}^{\bar{t}}\frac{|\dot{a}_n|}{a_n-m}\mathrm{d}t\geqslant\frac{1}{\sqrt{\bar{t}-\bar{s}}}\left|\int_{\bar{s}}^{\bar{t}}\frac{\dot{a}_n}{a_n-m}\mathrm{d}t\right|=\frac{1}{\sqrt{\bar{t}-\bar{s}}}\left|\log\left(\frac{a_n(\bar{t})-m}{a_n(\bar{s})-m}\right)\right|,$$

that diverges because $a_n(\bar{t})\to a(\bar{t})=m$ whereas $a_n(\bar{s})\to a(\bar{s})<m$ ■.

The lemma below show that the Palais–Smale condition actually holds in every closed interval of $\mathbb{R}$.

Lemma 5.3: Fixed two values c_1,c_2 such that $0<c_1<c_2<+\infty$, the functional $F_{\epsilon,\lambda}$ satisfies $(PS)_c$, $\forall c\in[c_1,c_2]$.

Proof: Let (a_n,ϕ_n) be a Palais–Smale sequence for $F_{\epsilon,\lambda}$ such that $F_{\epsilon,\lambda}(a_n,\phi_n)\in[c_1,c_2]$ for any n. Since $\nabla F_{\epsilon,\lambda}(a_n,\phi_n)$ is infinitesimal we have, $\forall\,\theta\in W_k$ (recall (4.8))

$$|\nabla F_{\epsilon,\lambda}(a_n,\phi_n)[0,\theta]|\leqslant\delta_n\|\theta\|_{H_0^1},\quad\text{with }\delta_n\to 0.$$

Therefore,

$$\left|\left(\int_0^1 2a_n^3 V_\lambda(\phi_n)\mathrm{d}t\right)\int_0^1(-2a_n^3\dot{\phi}_n\dot{\theta})\mathrm{d}t+\left(\int_0^1(3a_n+U_\epsilon(a_n))\dot{a}_n^2-a_n^3\dot{\phi}_n^2\mathrm{d}t\right)\int_0^1 2a_n^3 V_\lambda'(\phi_n)[\theta]\mathrm{d}t\right|$$
$$\leqslant\delta_n\|\theta\|_{H_0^1}.$$

Multiplying end terms of the inequality chain above by the bounded and strictly positive quantity $\int_0^1 2a_n^3 V_\lambda(\phi_n)\mathrm{d}t$ we have

$$\left|\left(\int_0^1 2a_n^3 V_\lambda(\phi_n)\mathrm{d}t\right)^2\int_0^1(-2a_n^3\dot{\phi}_n\dot{\theta})\mathrm{d}t+F_{\epsilon,\lambda}(a_n,\phi_n)\int_0^1 2a_n^3 V_\lambda'(\phi_n)\theta\mathrm{d}t\right|\leqslant\hat{\delta}_n\|\theta\|_{H_0^1}, \tag{5.3}$$

where $\hat{\delta}_n:=\delta_n\int_0^1 2a_n^3 V_\lambda(\phi_n)\mathrm{d}t\to 0$. Since $\phi_n-\phi_*\in W_k$ we can choose $\theta=\phi_n-\phi_*$, and observe the following facts:

- $\int_0^1 2a_n^3 V_\lambda(\phi_n)\mathrm{d}t$ is bounded away from 0, independently of n,

- $F_{\epsilon,\lambda}(a_n,\phi_n)$ is bounded,
- $a_n^3 V_\lambda(\phi_n)$ is uniformly bounded, and
- $\|\phi_n-\phi_*\|L^\infty \leqslant \|\dot\phi-(\phi_1-\phi_0)\|L^1 \leqslant \|\dot\phi-(\phi_1-\phi_0)\|L^2$.

But $\int_0^1 a_n^3\dot\phi_n\dot\theta \mathrm{d}t=\int_0^1 a_n^3(\dot\phi_n^2-\dot\phi_n(\phi_1-\phi_0))\mathrm{d}t$ which behaves like $\int_0^1\dot\phi_n^2\mathrm{d}t$ if $\int_0^1\dot\phi_n^2\mathrm{d}t$ diverges—recall that $\|\theta\|_{H_0^1}=\|\dot\theta\|_{L^2}$. Then, by Eq. (5.3) we deduce the existence of a positive constant D_0 such that

$$\int_0^1 \dot\phi_n^2 \mathrm{d}t \leqslant D_0, \quad \forall\, n \in \mathbb{N}. \tag{5.4}$$

Since $m \leqslant a_n \leqslant M$, $F_{\epsilon,\delta}(a_n,\phi_n)\leqslant c$, and $\int_0^1 2a_n^3 V_\lambda(\phi_n)\mathrm{d}t$ is bounded away from zero we deduce, by Eq. (5.4), that $\int_0^1(3a_n+U_\epsilon(a_n))\dot a_n^2\mathrm{d}t$ is bounded; moreover, since $3a_n+U_\epsilon(a_n)\geqslant 3a_1>0\,\forall\, n\in,\mathbb{N}$, there exists a positive constant D_1 such that

$$\int_0^1 \dot a_n^2 \mathrm{d}t \leqslant D_1, \quad \forall\, n \in \mathbb{N}. \tag{5.5}$$

By Eqs. (5.4) and (5.5), there exists a and ϕ of class H^1 such that, up to subsequences

$$a_n \rightharpoonup a, \quad \phi_n \rightharpoonup \phi$$

weakly in H^1 and uniformly. Since $F(a_n,\phi_n)$ is bounded from above, arguing as in Lemma 5.2 one proves that $a(t)\in\,]m,M[,\forall\, t\in[0,1]$. Therefore, it remains to show

$$\dot a_n \to \dot a \quad \text{in } L^2([0,1],\mathbb{R}), \tag{5.6}$$

and

$$\dot\phi_n \to \dot\phi \quad \text{in } L^2([0,1],\mathbb{R}). \tag{5.7}$$

Observing that $\phi_n-\phi\in W_k$, we can choose $\theta=\phi_n-\phi$ in Eq. (5.3). Since $F_{\epsilon,\lambda}(a_n,\phi_n)$ is bounded by standard estimates it is not difficult to obtain Eqs. (5.6) and (5.7) ■.

Proof of Proposition 5.1: As already outlined, the aim is to apply Theorem 3 to the functional $F_{\epsilon,\lambda}$. In view of Lemmas 5.2 and 5.3, it still remains to show that hypothesis (3) holds. Take $a_*(t)=(1-t)a_0+ta_1$, and choose $\omega_0=a_*$, $e_0=\phi_*$. Note that, by Eq. (4.5) and the choice of m, we have

$$\int_0^1 a^3 V_\lambda(\phi_*)\mathrm{d}t \geqslant m^3 v_* > 0, \quad \forall\, a\in\Omega,\ \forall\,\lambda \geqslant \sup_{t\in[0,1]} V(\phi_*). \tag{5.8}$$

Moreover by assumption (4.2) we have, for any $a\in\Omega$,

$$\int_0^1 [(3a+U_\epsilon(a))\dot a^2 - a^3\dot\phi_*^2]\mathrm{d}t \geqslant \int_0^1 3m\dot a^2 - M^3(\phi_1-\phi_0)^2\mathrm{d}t \geqslant 3m(a_1-a_0)^2 - M^3(\phi_1-\phi_0)^2 > 0,$$

therefore, by Eq. (5.8),

$$b_1 := \inf F_{\epsilon,\lambda}(a,\phi_*) > 0. \tag{5.9}$$

Clearly, $b_1=b_1(m,M)$ and is independent of k. Actually, b_1 is independent of λ too, but this property won't be used here.

Since V_λ is bounded,

$$\sup_{\mathbb{R}} V_\lambda \equiv B_\lambda < +\infty,$$

and

$$\int_0^1 a_*^3 V_\lambda(\phi)\mathrm{d}t \leqslant a_0^3 B_\lambda.$$

Moreover, if ϵ is sufficiently small, $U_\epsilon(a_*(t))=0\,\forall\, t$, so

$$F_{\epsilon,\lambda}(a_*,\phi) = \int_0^1 (3a_*\dot{a}_*^2 - a_*^3\dot{\phi}^2)\mathrm{d}t \int_0^1 2a_*^3 V_\lambda(\phi)\mathrm{d}t,$$

but $\int_0^1(3a_*\dot{a}_*^2-a_*^3\dot{\phi}^2)\mathrm{d}t \leqslant \int_0^1(3a_*\dot{a}_*^2-m^3\dot{\phi}^2)\mathrm{d}t$, and then there exists $R>0$ independent of k such that

$$\sup_{\|\hat{\phi}\|_{E_k}=R} F_{\epsilon,\lambda}(a_*,\hat{\phi}+\phi_*) =: b_0 < b_1, \tag{5.10}$$

(note that b_0 depends on λ) and then hypothesis (1) of Theorem 3.3 also holds. This implies that there exists a critical value for the functional $F_{\epsilon,\lambda}$ on $\mathfrak{X}_k$ in the interval $[b_1,b_2]$, where

$$b_2 := \sup_{\|\hat{\phi}\|_{E_k}\leqslant R} F_{\epsilon,\lambda}(a_*,\hat{\phi}+\phi_*) \tag{5.11}$$

and since b_2, though depending on λ, is independent of k, the proof is complete. ■

VI. PROOF OF THE MAIN RESULT

To complete the proof of Theorem 1.1, using Proposition 5.1, we first need the following lemma. Recall the definitions of b_1, b_2 given in Eqs. (5.9) and (5.11).

Lemma 6.1: There exists a critical value of $F_{\epsilon,\lambda}$ on $\mathcal{X}=\Omega\times E$ in $[b_1,b_2]$.

Proof: Let $x_k=(a_k,\phi_k)$ the critical point given by Proposition 5.1. Arguing as in the proof of Lemma 3 we deduce the existence of $x=(a,\phi)\in\mathfrak{X}$ such that, up to subsequence

$$x_k \to x \quad \text{in } H^1.$$

We will show that x is a critical point of $F_{\epsilon,\lambda}$. Since $F_{\epsilon,\lambda}(x_k)\in[b_1,b_2]$ and $F_{\epsilon,\lambda}$ is continuous, it immediately will follow that $F_{\epsilon,\lambda}(x)\in[b_1,b_2]$.

Take (α,θ) in H_0^1, and consider θ_k, the orthogonal projection of θ on W_k. As observed in Remark 4.1, $\theta_k\to\theta$ in H^1. Since $\nabla F_{\epsilon,\lambda}(x_k)[\alpha,\theta_k]=0$ for any k, we have

$$\nabla F_{\epsilon,\lambda}(x)[\alpha,\theta] = \nabla F_{\epsilon,\lambda}(x)[\alpha,\theta-\theta_k] + (\nabla F_{\epsilon,\lambda}(x) - \nabla F_{\epsilon,\lambda}(x_k))[\alpha,\theta_k],$$

Let us observe that, since $[\alpha,\theta_k]$ is bounded in H^1, and—recalling that $F_{\epsilon,\lambda}$ is $\mathcal{C}^1$—$\nabla F_{\epsilon,\lambda}(x_k)\to\nabla F_{\epsilon,\lambda}(x)$, then $(\nabla F_{\epsilon,\lambda}(x)-\nabla F_{\epsilon,\lambda}(x_k))[\alpha,\theta_k]\to 0$. Moreover,

$$\nabla F_{\epsilon,\lambda}(x)[\alpha,\theta-\theta_k]\to 0,$$

, since $\theta_k\to\theta$ in H^1. Then $\nabla F_{\epsilon,\lambda}(x)[\alpha,\theta]=0,\forall\,\alpha,\theta$ in H_0^1, and the proof is complete. ■

Proof of Theorem 1.1: Recall first that, looking for solutions of Eqs. (1.1a) and (1.1b) in the space of curves (a,ϕ) defined on $[0,T]$ and with boundary conditions (1.4), amounts to find critical points for the functional Eq. (2.15) in the space of curves (a,ϕ) defined in [0, 1] with boundary conditions (2.16).

The above lemma ensures the existence of $(a_{\epsilon,\lambda},\phi_{\epsilon,\lambda})$, critical point of $F_{\epsilon,\lambda}$ in $\Omega\times E$, with critical value in $[b_1,b_2]$. First, let us observe that a simple bootstrap argument shows that both $a_{\epsilon,\lambda}$ and $\phi_{\epsilon,\lambda}$ are $\mathcal{C}^2$. Then the following conservation law follows from the variational principle:

$$(3a_{\epsilon,\lambda}+U_\epsilon(a_{\epsilon,\lambda}))\dot{a}_{\epsilon,\lambda}^2 - a_{\epsilon,\lambda}^3\dot{\phi}_{\epsilon,\lambda}^2 - 2a_{\epsilon,\lambda}^3 V_\lambda(\phi_{\epsilon,\lambda}) = 0. \tag{6.1}$$

Since $a_{\epsilon,\lambda}^3(\dot{\phi}_{\epsilon,\lambda}^2+2V_\lambda(\phi_{\epsilon,\lambda}))>0,\forall\, t$, then $\dot{a}_{\epsilon,\lambda}(t)\neq 0,\forall\, t$, and since we have supposed (see (4.1)) $a_0>a_1$ it is

$$\dot{a}_{\epsilon,\lambda}(t) < 0, \quad \forall\, t \in [0,1]$$

and

$$a_1 \leqslant a_{\epsilon,\lambda}(t) \leqslant a_0, \quad \forall\, t \in [0,1].$$

Then $a_{\epsilon,\lambda}(t)$ is bounded away from m and M. Taking a sufficiently small ϵ we have

$$m + \epsilon < a_{\epsilon,\lambda}(t) < M - \epsilon$$

so that $U_\epsilon(a_{\epsilon,\lambda})=0$, $U'_\epsilon(a_{\epsilon,\lambda})=0$ and therefore the couple $(a_\lambda, \phi_\lambda) := (a_{\epsilon,\lambda}, \phi_{\epsilon,\lambda})$ is a critical point of

$$F_\lambda(a,\phi) := \int_0^1 (3a\dot{a}^2 - a^3\dot{\phi}^2)\mathrm{d}t \cdot \int_0^1 2a^3 V_\lambda(\phi)\mathrm{d}t,$$

with the critical value in $[b_1, b_2]$. Moreover, the conservation law (6.1) takes the form

$$3a_\lambda \dot{a}_\lambda^2 - a_\lambda^3 \dot{\phi}_\lambda^2 - 2a_\lambda^3 V_\lambda(\phi_\lambda) = 0. \tag{6.2}$$

Recalling that $\dot{a}_\lambda$ is negative, that implies

$$\frac{\dot{a}_\lambda}{a_\lambda} = -\sqrt{\frac{\dot{\phi}_\lambda^2 + 2V_\lambda(\phi_\lambda)}{3}}.$$

Integrating the above relation in [0, 1] we obtain

$$a_\lambda(t) = a_0 e^{-(1/\sqrt{3})\int_0^t \sqrt{\dot{\phi}_\lambda^2 + 2V_\lambda(\phi_\lambda)}\mathrm{d}s},$$

and in particular

$$a_1 = a_0 e^{-(1/\sqrt{3})\int_0^1 \sqrt{\dot{\phi}_\lambda^2 + 2V_\lambda(\phi_\lambda)}\mathrm{d}s}.$$

But $a_1 > 0$ is of course fixed and therefore independent of λ, then there exists a positive constant D independent of λ such that

$$\int_0^1 |\dot{\phi}_\lambda|\mathrm{d}t \leqslant \int_0^1 \sqrt{\dot{\phi}_\lambda^2 + 2V_\lambda(\phi_\lambda)}\mathrm{d}s \leqslant D.$$

Since ϕ_0 is fixed, we see that, for any λ, the function ϕ_λ satisfies

$$|\phi_\lambda(t)| \leqslant |\phi_0| + D,$$

and therefore choosing $\lambda \geqslant \sup\{V(\phi) : |\phi| \leqslant |\phi_0 + D\}$ we have

$$V(\phi_\lambda) = V_\lambda(\phi_\lambda), \quad V'(\phi_\lambda) = V'_\lambda(\phi_\lambda).$$

This means that $(a_\lambda, \phi_\lambda)$ is also a critical point of F (2.15) with positive critical value. ■

A new integrable equation with cuspons and W/M-shape-peaks solitons

Zhijun Qiao
Department of Mathematics, The University of Texas Pan-American, 1201 West University Drive, Edinburg, Texas 78541

(Received 26 June 2006; accepted 27 September 2006; published online 17 November 2006)

In this paper, we propose a new completely integrable wave equation: $m_t+m_x(u^2-u_x^2)+2m^2u_x=0$, $m=u-u_{xx}$. The equation is derived from the two dimensional Euler equation and is proven to have Lax pair and bi-Hamiltonian structures. This equation possesses new cusp solitons—cuspons, instead of regular peakons $ce^{-|x-ct|}$ with speed c. Through investigating the equation, we develop a new kind of soliton solutions—"W/M"-shape-peaks solitons. There exist no smooth solitons for this integrable water wave equation. © *2006 American Institute of Physics.*

I. INTRODUCTION

Solitons and integrable models are very attractive objects in nonlinear sciences. Originally found in experiments on shallow water wave propagations one and a half centuries ago, they have since then become an abundant and fascinating area of theoretical and mathematical study. Today, solitons and integrable systems are playing an increasingly important role in dynamical systems, harmonic analysis, and string theories.

There are well-known constructions of integrable systems. The idea of compatibility is the crucial of integrable systems theory. One is already at the very definition of the complete integrability of a Hamiltonian flow in the Liouville-Arnold sense, which means that the flow is able to be included into a complete family of commuting Hamiltonian flows.[2] Analogically, it is a symbolic feature of soliton (integrable) partial differential equations that they take on not separately but are always assigned in hierarchies of compatible systems. It is impossible to list all applications or adoptions of this idea. We mention only some that are relevant for our present purpose. A condition of the existence of a number of commuting systems may be taken as the basis of the bi-Hamiltonian structure and symmetry approach.[1,7–9,11] However, a key procedure is to figure out bi-Hamiltonian operators. In general, no universal method is available, and we have to work on concrete equations.

In the present paper, we use Hamiltonian methods to present a new completely integrable water wave equation:

$$u_t - u_{xxt} + 3u^2u_x - u_x^3 = (4u - 2u_{xx})u_xu_{xx} + (u^2 - u_x^2)u_{xxx}, \tag{1}$$

namely,

$$m_t + m_x(u^2 - u_x^2) + 2m^2u_x = 0, \quad m = u - u_{xx}, \tag{2}$$

where u is the fluid velocity and subscripts denote the partial derivatives. Actually, this equation can be reduced from the two-dimensional Euler equation by using the approximation procedure. In two dimensional Euler equations, $\mathbf{v}_t+\mathbf{v}\cdot\nabla\mathbf{v}=-\nabla p$, div $\mathbf{v}=0$ (p is a pressure), we take the velocity $\mathbf{v}=(-\psi_y,\psi_x)^T$, where ψ is a streamfunction. Then, the following equation:

$$r_t + \psi_x r_y - \psi_y r_x = 0, \quad r := \psi_{xx} + \psi_{yy},$$

is generated from the Euler equations, where r stands for the vorticity. Employing $\psi = \phi(\xi, y, \tau)$, $\xi = \epsilon(x - c_0 t)$, $\tau = \epsilon^3 t$, imposing $\phi(\xi, y, \tau) = \epsilon\phi_1(\xi, y, \tau) + \epsilon^2\phi_2(\xi, y, \tau) + \epsilon^3\phi_3(\xi, y, \tau)$ and $\phi_1(\xi, y, \tau) = B_1(y)F(\xi, \tau)$, $\phi_2(\xi, y, \tau) = B_2(y)F(\xi, \tau) + B_3(y)F(\xi, \tau)^2$, and picking up the coefficient of ϵ^4 term in the approximation expansion of the equation, we will eventually arrive at

$$F_\tau - a_1 F_{\xi\xi\tau} + (3a_2F^2 - a_3F_\xi^2)F_\xi - (2a_4F - 2a_5F_{\xi\xi})F_\xi F_{\xi\xi} - ((a_4 - a_3)F^2 - a_5F_\xi^2)F_{\xi\xi\xi} = 0, \quad (3)$$

where $a_1, \ldots, a_5$ are constants. If we take $a_1 = a_2 = a_3 = a_5 = 1$ and $a_4 = 2$, Eq. (3) exactly gives the new equation (1). So, Eq. (1) is a new nonlinear water wave equation.

In the paper, Eq. (1) is shown to have the bi-Hamiltonian structure and the Lax pair, which implies the integrability of the equation so that the initial value problem may be solved by the Inverse Scattering Transform (IST) method.[10,1] Our equation is proven to have new cusp solitons—cuspons, which are not peakons in the regular type of $ce^{-|x-ct|}$ (c is a wave speed)[3] and whose first order derivative is discontinuous at some point (see more mathematical studies about the Camassa-Holm equation in Refs. 5, 6, and 12). Furthermore, we develop a new kind of soliton solution, named "W-shape-peaks" or "M-shape-peaks" soliton, which is given in an explicit form for this water wave equation. We will take some graphs to show how these W/M-shape-peaks solitons look.

II. HAMILTONIAN STRUCTURE AND INTEGRABILITY

By using $m = u - u_{xx}$, $(1 - \partial^2)(\delta H_1/\delta m) = \delta H_1/\delta u$, the wave equation (2) can be rewritten as

$$m_t = -(m(u^2 - u_x^2))_x = J\frac{\delta H_0}{\delta m} = K\frac{\delta H_1}{\delta m}, \quad (4)$$

where

$$J = -\partial m\, \partial^{-1} m\, \partial, \quad (5)$$

$$K = \partial^3 - \partial, \quad (6)$$

$$H_0 = 2\int_\Omega mu\, dx,$$

$$H_1 = \frac{1}{4}\int_\Omega (u^4 + 2u^2u_x^2)dx,$$

$\Omega = (x_0, x_0 + T)$ or $\Omega = (-\infty, +\infty)$ is the domain of u that needs to be periodic with T or to approach a constant, and H_0, H_1 are two Hamiltonian functions. Apparently, both operator J and operator K are Hamiltonian. So, our equation is bi-Hamiltonian.

In order to show the integrability of this equation, let us consider the following spectral problem:

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_x = \begin{pmatrix} -\frac{1}{2} & \frac{1}{2}\lambda m \\ -\frac{1}{2}\lambda m & \frac{1}{2}\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix} \equiv U(m,\lambda)\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \quad (7)$$

where λ is a spectral parameter, m is a scalar potential function periodic or approaching the same constant at both infinities, and $\psi = (\psi_1, \psi_2)^T$ is the spectral function corresponding to the spectral parameter λ. Then, we have

$$K\nabla\lambda = \lambda^2 J\nabla\lambda, \tag{8}$$

where $\nabla\lambda = (\lambda/2)(\psi_1^2 + \psi_2^2)$.

Remark 1: Equation (8) plays a very important role in the discussions of the periodic solutions of the wave equation (2), which we will deal with in a subsequent paper.[14] *Actually, on the basis of these two operators, following our earlier method*[13] *we are able to generate a new integrable hierarchy.*

By a careful calculation, we can verify the following statement.

Equation (2) has the following Lax pair:

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_x = U(m,\lambda)\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{9}$$

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_t = V(m,u,\lambda)\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{10}$$

where

$$U(m,\lambda) = \begin{pmatrix} -\frac{1}{2} & \frac{1}{2}\lambda m \\ -\frac{1}{2}\lambda m & \frac{1}{2}\end{pmatrix}, \quad m = u - u_{xx},$$

$$V(m,u,\lambda) = \begin{pmatrix} \lambda^{-2} + \frac{1}{2}(u^2 - u_x^2) & -\lambda^{-1}(u-u_x) - \frac{1}{2}\lambda m(u^2 - u_x^2) \\ \lambda^{-1}(u+u_x) + \frac{1}{2}\lambda m(u^2 - u_x^2) & -\lambda^{-2} - \frac{1}{2}(u^2 - u_x^2)\end{pmatrix}.$$

In fact, one just checks that the compatibility condition

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_{xt} = \begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_{tx},$$

namely,

$$U_t - V_x + [U,V] = 0$$

generates Eq. (2). A direct substitution of $U(m,\lambda)$ and $V(m,u,\lambda)$ is able to guarantee the truth of the above statement. One can also use maple to verify this procedure.

So the wave equation (2) is accordingly completely integrable by the Inverse Scattering Transformation.[1]

III. W/M-SHAPE-PEAKS SOLITONS

A. Traveling wave setting

Let us consider the traveling wave solution of our equation (2) through a generic setting $u(x,t) = U(x-ct)$, where c is the wave speed. Let $\xi = x - ct$, then $u(x,t) = U(\xi)$. Substituting it into Eq. (2) yields

$$(U^2 - U'^2 - c)(U - U'')' + 2U'(U - U'')^2 = 0, \tag{11}$$

where $U' = U_\xi$, $U'' = U_{\xi\xi}$, $U''' = U_{\xi\xi\xi}$.

Remark 2: (1) Our ODE (11), derived from our new PDE (2) through a traveling wave setting,

is different from the Camassa-Holm (CH) case. In the CH case (see Ref. 15), the traveling wave ODE reads as

$$(U-c)(U-U'')+2U'(U-U'')=0.$$

Here our new equation is more high order nonlinear terms than the CH case.

(2) The integrable CH equation has both peakon and smooth soliton solutions.[3,15] *However, our new integrable equation (2) has no smooth soliton solution, only cusp solitons and M/W-shape-peaks solitons solutions (see the following sections). This means that an integrable equation may have no smooth soliton, which may clue on a good idea to classify the integrable equations by the mathematical features of solitons.*

Generally, we have the following trivial facts.

(1) *Any constant function is a solution of Eq. (2) and the ODE (11).*
(2) *Any translation $U(\xi-\xi_0)$ of a solution $U(\xi)$ of ODE (11) is still a solution.*
(3) *If $u(x,t)$ is a solution of Eq. (2), then any translation $u(x-x_0,t-t_0)$ in space x and time t is a solution, too.*

Because of the translation invariance of the differential equation (11), without any loss of generality, we choose ξ_0 as vanishing, namely, $\xi_0=0$. If $U-U''=0$, then Eq. (11) has general solutions $U(\xi)=c_1e^{\xi}+c_2e^{-\xi}$ with any real constants c_1, c_2. Of course, they are the solutions of Eq. (2). This result is not interesting for us. Actually, there are general weak solutions to Eq. (2):

$$u(x,t)=c\cosh(|x-ct|)\pm\sqrt{c(c-1)}\sinh(|x-ct|), \tag{12}$$

where c ($c\geq 1$ or $c\leq 0$) is the wave speed.

Because the solution $u(x,t)$ defined by (12) approaches infinity as x goes to infinity, this solution is not a soliton, which is not so interesting, either. Let us now assume that U is NEITHER a constant solution of Eq. (11) NOR satisfies $U^2-U'^2=0$. Taking the integration on both sides of Eq. (11) leads to

$$(U-U'')[c-(U^2-U'^2)]=C_2, \tag{13}$$

where $C_2\neq 0\in\mathbb{R}$ is an integration constant.

Multiplying both sides of Eq. (13) by $-4U'$ and then taking another integration, we obtain

$$[c-(U^2-U'^2)]^2=-4C_2U+C_1, \tag{14}$$

namely,

$$U'^2=U^2-c\pm\sqrt{C_1-4C_2U}, \tag{15}$$

where $C_1\in\mathbb{R}$ is another integration constant.

Let us now impose the boundary condition

$$\lim_{\xi\to\pm\infty}U=A, \tag{16}$$

to figure out the two constants C_1, C_2. Substituting the boundary condition (16) into the ODEs (13) and (14) generates the following two constants:

$$C_1=(c-A^2)(c+3A^2), \tag{17}$$

$$C_2=A(c-A^2). \tag{18}$$

So the ODE (14) becomes

$$[c-(U^2-U'^2)]^2=(c-A^2)(c+3A^2-4AU). \tag{19}$$

Remark 3: There is no shock wave (or kink) solution for our equation (2) because we cannot

be allowed to set $\lim_{\xi\to+\infty} U \neq \lim_{\xi\to-\infty} U$. *In other words, the traveling wave solution of our equation, satisfying the boundary condition* (16), *is definitely a soliton!*

Let us solve Eq. (19) in the coming subsection.

B. W/M-shape-peaks solitons

Let us assume that $A\neq 0$ and $c\neq A^2$ (if $A=0$ or $c=A^2$, then $C_2=0$, which corresponds to $U-U''=0$. We already discussed it in Sec. III A. Actually, no solitons are found in this case). The fact that both sides of Eq. (19) are non-negative implies

$$(c-A^2)(c+3A^2-4AU)>0. \tag{20}$$

Let $V=\sqrt{(c-A^2)(c+3A^2-4AU)}$ and $s=c-A^2$, then $V>0, V=\sqrt{s(s+4A^2-4AU)}$, $U=A+(1/4sA)(s^2-V^2)$ and Eq. (19) becomes

$$\frac{VdV}{|s-\epsilon V|\sqrt{(s+\epsilon V)^2-8sA^2}}=\mp\frac{d\xi}{2},\quad \epsilon=\pm 1. \tag{21}$$

Let us discuss the cases of $\epsilon=1$ and $\epsilon=-1$ separately.

(1) *Case* $\epsilon=1$. If we chose $s<0$, then Eq. (21) can be integrated as

$$(V+s+\sqrt{(V+s)^2-8sA^2})\left[\frac{-V-s+4A^2+a\sqrt{(V+s)^2-8sA^2}}{V-s}\right]^{1/2a}=e^{-|\xi|/2-\ln(-4s)/2a}, \tag{22}$$

where $a=\sqrt{(s-2A^2)/s}=\sqrt{(3A^2-c)/(A^2-c)}$, $s-2A^2<0$, and $a>1$.

Because $V\nrightarrow\pm s$ as $\xi\to\infty$ whereas the right hand side of Eq. (22) goes to 0 as $\xi\to\infty$, the solution V determined by Eq. (22) does not exist. So, $s<0$ is not available for case $\epsilon=1$.

Therefore, s must be positive, namely, $s>0$, which assures that Eq. (21) can be integrated as

$$(V+s+\sqrt{(V+s)^2-8sA^2})\left[\frac{V-s}{V+s-4A^2+a\sqrt{(V-s)^2-8sA^2}}\right]^{1/2a}=e^{|\xi|/2+\ln(4s)/2a}, \tag{23}$$

where $a=\sqrt{(s-2A^2)/s}=\sqrt{(c-3A^2)/(c-A^2)}$, $s-2A^2>0$, and $0<a<1$.

In general, we cannot solve the equation (23) for V in an explicit form. But, for some very special a's, we do have the explicit solution V. For example, let us take $a=\frac{1}{2}$; then $c=\frac{11}{3}A^2$ and $s=\frac{8}{3}A^2$. Substituting it into Eq. (23) generates

$$V^2-bV+sb=0, \tag{24}$$

where

$$b=3se^{-\frac{|\xi|}{2}}+\frac{3s}{4}e^{\frac{|\xi|}{2}}+s=3s\cosh\left(\frac{|\xi|}{2}-\ln(2)\right)+s=s\left(3\cosh\left(\frac{|\xi|}{2}-\ln(2)\right)+1\right).$$

Therefore, solving Eq. (24) for V gives

$$V=\frac{1}{2}(b-\sqrt{b^2-4sb})=\frac{3s}{2}\left(\frac{2}{3}+z-\sqrt{z^2-\frac{4}{9}}\right)=s+\frac{3s}{2}\left(z-\sqrt{z^2-\frac{4}{9}}\right),$$

where $z=\cosh\left(|\xi|/2-\ln(2)\right)-\frac{1}{3}$. So, we arrive at explicit solutions $U(\xi)$ of Eq. (2),

$$U(\xi)=A\left(\frac{5}{3}-(3z+2)\left(z-\sqrt{z^2-\frac{4}{9}}\right)\right),$$

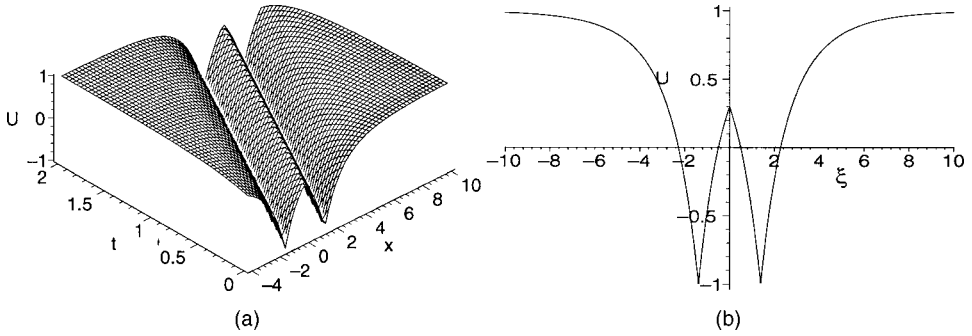

FIG. 1. (a) A three-dimensional (3-D) graph of the explicit solution $U(\xi)$ defined by (25), when $A=1$, $s=8/3$, wave speed $c=11/3$, and the range of x,t,u: $-4\le x\le 10$, $0\le x\le 2$, $-1\le u\le 1$. (b) A 2D graph of the explicit solution $U(\xi)$ defined by (25) when $A=1$, $s=8/3$, the wave speed $c=11/3$, and the range of ξ: $-10\le\xi\le 10$.

$$z=\cosh\left(\frac{|\xi|}{2}-\ln(2)\right)-\frac{1}{3},$$

$$\xi=x-\frac{11}{3}A^2t. \tag{25}$$

Apparently, $V(\xi)\to s$ and $U(\xi)\to A$ as $\xi\to\infty$. Since $A\neq 0$, there is no peaked soliton for a homogeneous boundary condition. Let us select a special $A=1$, then the solution $U(\xi)$ reads as

$$U(X)=2-3\cosh^2 X+\left(\cosh X+\frac{1}{3}\right)\sqrt{3(3\cosh X+1)(\cosh X-1)}.$$

$$X=\frac{\left|x-\frac{11}{3}t\right|}{2}-\ln 2.$$

Apparently, this solution has three peaks and looks like a "W" wave. So, we called it a "W-shape peaks" soliton. Three peaks occur at $x=\frac{11}{3}t_0$, $x=\frac{11}{3}t_0-2\ln(2)$, $x=\frac{11}{3}t_0+2\ln(2)$, for each time t_0. See Fig. 1 for more details.

If we select the boundary constant $A=-1$, we are able to get the anti-"W-shape-peaks" soliton, called an "M-shape-peaks" soliton. See a 3D and a 2D graph in Fig. 2 for more details.

For other a's, in a similar way we can also obtain the corresponding peaked soliton solutions, which are left for the readers' practice.

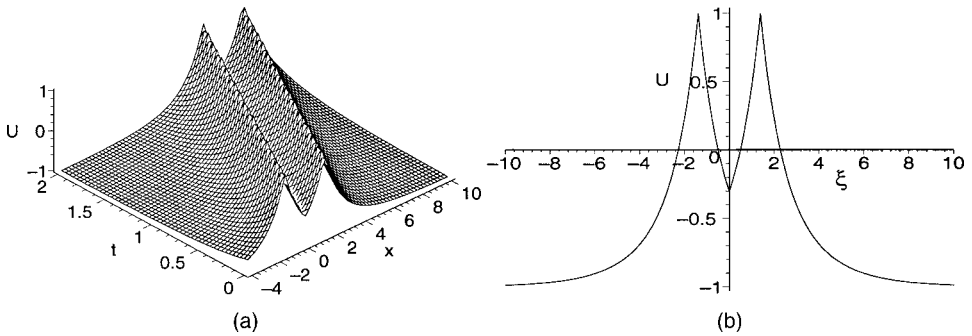

FIG. 2. (a) A 3D graph of the "M-shape-peaks" solution $U(\xi)$ defined by (25) with $A=-1$ and $c=11/3$. (b) 2D graph of the "M-shape-peaks" solution $U(\xi)$ defined by (25) with $A=-1$ and $c=11/3$.

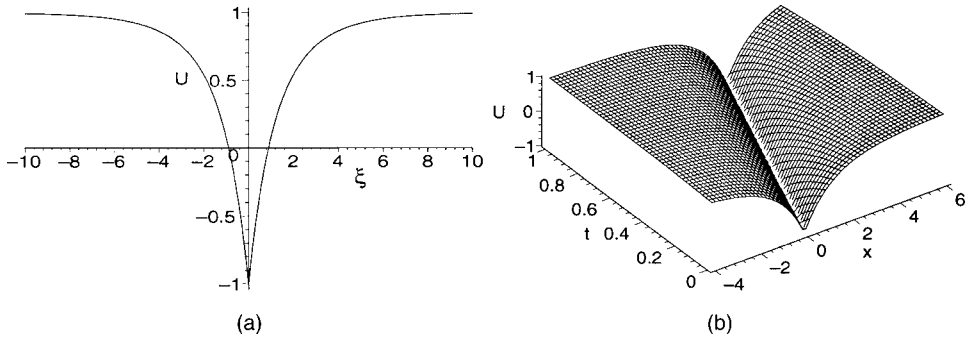

FIG. 3. (a) 2D graph of new cuspon solution $U(\xi)$ defined by (26) with amplitude $A=1$ and wave speed $c=11/3$. (b) 3D graph of new cuspon solution $U(\xi)$ defined by (26) with $A=1$ and $c=11/3$.

New cusp solitons-cuspons. In Eq. (22), we consider the solution V without the absolute value of ξ. Following the above procedure, in case of $a=\frac{1}{2}$ we may obtain

$$U(\xi)=A\left(\frac{5}{3}-(3z+2)\left(z-\sqrt{z^2-\frac{4}{9}}\right)\right),$$

$$z=\cosh\left(\frac{x}{2}-\frac{11}{6}A^2t\right)-\frac{1}{3}. \tag{26}$$

A direct verification shows us the following: (26) is indeed another explicit solutions of Eq. (2). Let us take $A=\pm 1$. Then the corresponding solutions read as

$$U(X)=\pm\left(2-3\cosh^2 X+\left(\cosh X+\frac{1}{3}\right)\sqrt{3(3\cosh X+1)(\cosh X-1)}\right),$$

$$X=\frac{x}{2}-\frac{11}{6}t,$$

which have the following characteristic features:

$$U(0)=\mp 1,\quad U'(0+)=\pm\infty,\quad U'(0-)=\mp\infty.$$

Apparently, they differ from the regular peakons.[3] So, both are new peaked solitons for our equation (2) (see Figs. 3, 4 for more details).

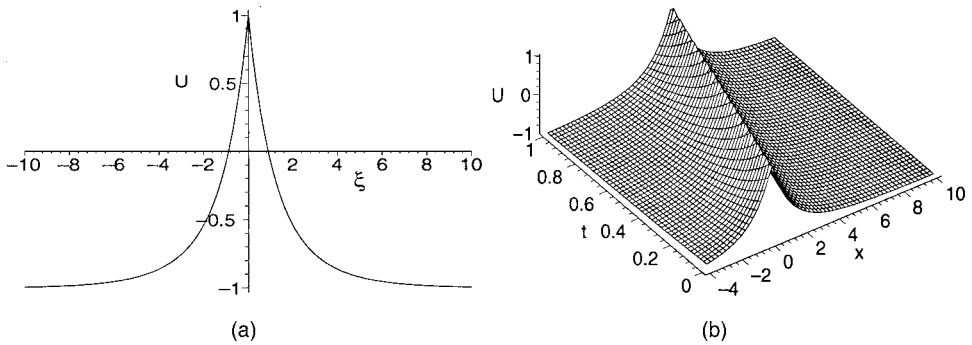

FIG. 4. (a) A 2D graph of new cuspon solution $U(\xi)$ defined by (25) when $A=-1$ and $c=11/3$. (b) A 3D graph of a new cuspon solution $U(\xi)$ defined by (25) when $A=-1$ and $c=11/3$.

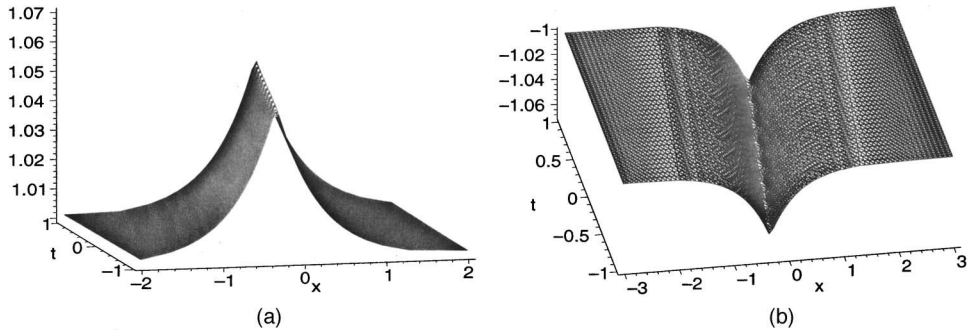

FIG. 5. (a) A 3D numerical graph of the cuspon solution $U(\xi)$ of Eq. (2) based on (28) with amplitude $A=1$ and wave speed $c=1/3$. (b) A 3D numerical graph of the cuspon solution $U(\xi)$ of Eq. (2) based on (28) with amplitude $A=-1$ and wave speed $c=1/3$.

(2) *Case* $\epsilon=-1$. If we chose $s>0$, then Eq. (21) can be integrated as

$$(V-s+\sqrt{(V-s)^2-8sA^2})\left[\frac{s-V-4A^2+a\sqrt{(V-s)^2-8sA^2}}{V+s}\right]^{1/2a}=e^{-|\xi|/2-\ln(4s)/2a}, \tag{27}$$

where $a=\sqrt{(s-2A^2)/s}=\sqrt{(c-3A^2)/(c-A^2)}$, $s-2A^2>0$, and $0<a<1$.

Because $V\nrightarrow\pm s$ as $\xi\to\infty$ whereas the right hand side of Eq. (27) goes to 0 as $\xi\to\infty$, the solution V determined by Eq. (27) does not exist. So, $s>0$ is not available for case $\epsilon=-1$. Therefore, s must be negative, namely, $s<0$, which gurantees that Eq. (21) can be integrated as

$$(V-s+\sqrt{(V-s)^2-8sA^2})\left[\frac{V+s}{V-s+4A^2+a\sqrt{(V-s)^2-8sA^2}}\right]^{1/2a}=e^{-|\xi|/2+\ln(-4s)/2a}, \tag{28}$$

where $\xi=x-ct$, $a=\sqrt{(s-2A^2)/s}=\sqrt{(3A^2-c)/(A^2-c)}$, $s-2A^2<0$, and $1<a$.

In general, we cannot solve Eq. (28) for V in an explicit form. But, we can numerically determine V from Eq. (28), and then according to the equation, $U=A+(1/4sA)(s^2-V^2)$ to figure out the solution $U(\xi)$ for our equation (2). For instance, in the case of $A=\pm1$, $c=1/3$, we have $a=2$ and $s=-2/3$, and numerically solve our equation (2) (see Fig. 5 for details).

For other a's (for instance, $a=3,4$), in a similar way we can also numerically obtain the corresponding cuspon solutions of Eq. (2).

IV. CONCLUSIONS AND OPEN PROBLEMS

In the paper, we present a new integrable water wave equation (2). Through studying the equation, we develop a new kind of soliton solution—"W-shape-peaks"/"M-shape-peaks" solutions (see Fig. 1, 2). Our equation is shown to possess not only "W-shape-peaks"/"M-shape-peaks" solitons, but new cuspon solution as well (see Figs. 3, 4 which are different from regular peakons).

Our new equation (2) naturally has a physical meaning since it is derived from the two dimensional Euler equation (see the Introduction). It can be cast into the following Newton equation $U'^2=P(U)-P(A^2)$ of a particle with a new potential $P(U)=U^2+\text{sign}(s)\sqrt{s(s+4A^2-4AU)}$, $s=c-A^2$, or $V'^2=Q(V)-Q(A)$ with $U=A+(1/4sA)(s^2-V^2)$, $Q(V)=V^2/4+4s|s|A^2/V+s^3(s-8A^2)/4V^2$. In the paper, we successfully solve this Newton equation with new cuspons and M-shape/W-shape-peaks solitons. Those peaked and cusped solutions may be applied to neuroscience for providing a mathematical model and explaining electrophysiological responses of visceral nociceptive neurons and sensitization of dorsal root reflexes.[4]

No smooth solitons are found for our equation, but our equation is completely integrable. Furthermore, we suggest a more general partial differential equation: $m_t+m_x(u^2-u_x^2)+km^2u_x=0$, $m=u-u_{xx}$ with any constant $k\in\mathbb{R}$. When $k=2$, the equation is integrable, which is already discussed in this paper. Any other integrable cases? We do not know yet.

The inverse problem for six-dimensional codimension two nilradical lie algebras

M. Rawashdeh[a] and G. Thompson[b]
Department of Mathematics, The University of Toledo, 2801 W. Bancroft Street, Toledo, Ohio 43606

(Received 8 August 2006; accepted 5 October 2006; published online 15 November 2006)

Ado's theorem asserts that every real Lie Algebra $\mathfrak{g}$ of dimension n has a faithful representation as a subalgebra of $gl(p,\mathbb{R})$ for some p. The theorem offers no practical information about the size of p in relation to n and in principle p may be very large compared to n. This article is concerned with finding representations for a certain class of six-dimensional Lie algebras, specifically, real, indecomposable algebras that have a codimension two nilradical. These algebras were classified by Turkowski and comprise of 40 cases, some of which contain up to four parameters. Linear representations are found for each algebra in these classes: More precisely, a matrix Lie *group* is given whose Lie algebra corresponds to each algebra in Turkowski's list and can be found by differentiating and evaluating at the identity element of the group. In addition a basis for the right-invariant vector fields that are dual to the Maurer-Cartan forms are given thereby providing an effective realization of Lie's third theorem. The geodesic spray of the canonical symmetric connection for each of the 40 linear Lie group G is given. Thereafter the inverse problem of the calculus of variations for each of the geodesic sprays is investigated. In all cases it is determined whether the spray is of Euler-Lagrange type and in the affirmative case at least one concrete Lagrangian is written down. In none of the cases is there a Lagrangian of metric type. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2378620]

I. INTRODUCTION

In this article we study the inverse problem of Lagrangian dynamics for the canonical linear connection on a Lie group. More precisely we consider the inverse problem for solvable six-dimensional groups whose Lie algebras have a codimension two nilradical. A list of such algebras has been compiled by Turkowski (1990). In order to make the exposition reasonably self-contained, Secs. IV and V gives some background on the inverse problem. For more details we refer the reader to Anderson and Thompson (1992), Crampin (1981), Crampin *et al.* (1996), Douglas (1941), Ghanam *et al.* (2005), Grifone and Muzsnay (1999, 2000); Muzsnay and Thompson (2003), Sarlet (1982), Sarlet *et al.* (1998). It turns out that in order for the geodesics of the canonical connection to be variational a linear system of equations must have a nonsingular solution [Eqs. (12) and (13)]. If there is no nonsingular solution the inverse problem is answered in the negative. To proceed further using our methods, we need a local representation of the Lie algebra in terms of vector fields or preferably a linear representation for the corresponding Lie group.

A well-known theorem in the theory of Lie algebras due to Ado asserts that every real Lie algebra $\mathfrak{g}$ of dimension n has a faithful representation as a subalgebra of $gl(p,\mathbb{R})$ for some p. The

[a]Electronic mail: rawashd5@yahoo.com
[b]Electronic mail: thompson@math.utoledo.edu

theorem does not give much information about the value of p but leads one to believe that p may be very large in relation to the size of n and consequently it seems to be of limited practical value.

If the Lie algebra $\mathfrak{g}$ is semisimple there are well-known representations that are associated to the standard A_k, B_k, C_k, D_k series that are of the order of $\sqrt{n}$ where n is the dimension of $\mathfrak{g}$. On the other hand it is clear that semisimple algebras are very much the exception rather than the rule. For example, there are only two semisimples in dimension five or less. More generally if $\mathfrak{g}$ has a trivial center the adjoint representation furnishes a faithful representation of $\mathfrak{g}$ and in the notation used above $p=n$. Many of our representations are constructed in this way. We develop some theorems in Sec. III which explain how to obtain representations in the case where the algebra has a nontrivial center. In particular we will show that if $\mathfrak{g}$ has an abelian nilradical and abelian complement then it has a faithful linear representation. There are a few algebras for which we have obtained matrix representations by some experimentation. Ultimately we would like to have practical theorems that give the representations in all cases.

We refer to Patera *et al.* (1976) for a comprehensive list of the *indecomposable* algebras of dimension five or less, which in turn was based on Murozov (1958) and Mubarakzyanov (1963). However, in this article we are primarily concerned with the solvable six-dimensional algebras compiled by Turkowski (1990) and in Sec. VI we list linear representations for each of these algebras. In fact rather than giving representations for the Lie algebras we give in each case a matrix *group* whose Lie algebra coincides with a given algebra. It is straightforward then to construct the matrix representation of the algebra by differentiating and evaluating at the identity element of the group. We have also given a representation of the algebra in terms of the right invariant vector fields and the associated geodesic equations. For standard facts about Lie algebras and Lie groups we refer to Helgason (1978) and Jacobson (1962). We use $\langle e_1, e_2, \ldots, e_s \rangle$ to denote the s dimensional subspace of $\mathfrak{g}$ generated by $e_1, e_2, \ldots, e_s$.

The existence aspect of the inverse problem is solved in every case by either supplying at least one concrete Lagrangian or by checking that one cannot exist. It is to be noted that whenever one Lagrangian exists then so do many. We have not attempted in this article to find all possible Lagrangians in any of the forty cases nor special kinds of Lagrangians except to say that in none of the cases is there a metric Lagrangian.

The vast majority of work on the inverse problem is concerned with two degrees of freedom. There are very few examples or results in higher dimensions, the Kepler system being a rare example. The Lie group inverse problem is a much simpler version of the general problem but it already presents major difficulties. We believe that it will serve as a valuable guide to the kind of theory that one might expect in higher dimensions. We hope also that the results on representations may prove to be of independent interest.

Most of the calculations involving Maurer-Cartan one forms, vector fields and Euler-Lagrange equations were carried out using the symbolic manipulation program MAPLE. The fact that certain geodesic systems are not of Euler-Lagrange type follows from Eqs. (12) and (13) below. A routine written in MAPLE 9 was used that checks these conditions when a particular Lie algebra is used as input. In the interests of brevity and because a lot of similar arguments have been given previously [Ghanam *et al.* (2004)], we have chosen to suppress most details. However, we have supplied a short Appendix which should give the reader some insight as to how we construct our Lagrangians in six diverse cases. We must trust that this method is more efficient than trying to give hundreds of small routine calculations.

II. SIX-DIMENSIONAL LIE ALGEBRAS AND TURKOWSKI'S CLASSIFICATION

Let us explain how the indecomposable Lie algebras of dimension six are classified. First of all there is only one indecomposable simple algebra of dimension six, namely, the pseudo-orthogonal algebra $o(3,1)$ The next class of algebras to consider are the algebras that have a nontrivial Levi-decomposition. According to Turkowski there are up to isomorphism just four of them listed as $L_{6,1}$, $L_{6,2}$, $L_{6,3}$, and $L_{6,4}$ [Turkowski (1988)]. All the remaining indecomposable algebras in dimension six are solvable.

There is a general inequality that implies that the dimension of the nilradical of a solvable, indecomposable Lie algebra $\mathfrak{g}$ is at least $\frac{1}{2}\dim(\mathfrak{g})$ [Morozov (1958)]. According to Turkowski if the dimension of the nilradical of a solvable Lie algebra of dimension six is three, then the algebra is decomposable and hence there are just three classes to consider: The nilpotents and the algebras that have five-dimensional and four-dimensional nilradicals, respectively. We are concerned exclusively with this latter class of algebras in this article and they have been classified in Turkowski (1990). For a given algebra $\mathfrak{g}$ in Turkowski's list we always use a basis $\{e_1,e_2,e_3,e_4,e_5,e_6\}$ in which e_1 and e_2 are *not* in the nilradical of $\mathfrak{g}$.

Turkowski distinguishes 40 classes of algebras that have a codimension two nilradical [Turkowski (1990)]. Of course the situation is a good deal more complicated than that because most of the algebras have up to four parameters that vary in open intervals. Turkowski's method consists essentially of putting the two matrices $\mathrm{ad}(e_1)$ and $\mathrm{ad}(e_2)$ into simultaneous normal form, where e_1 and e_2 are basis vectors that lie outside of the nilradical. Turkowski arranges the 40 algebras into five tables as follows: Table 1 (algebras 1–19), algebras that have abelian nilradical and trivial center; Table 2 (algebras 20–27), algebras that have abelian nilradical and one-dimensional center; Table 3 (algebra 28), algebras that have nilradical isomorphic to the indecomposable four-dimensional nilpotent; Table 4 (algebras 29–37), algebras that have nilradical isomorphic to the direct sum of the indecomposable three-dimensional nilpotent with $\mathbb{R}$ and having trivial center; Table 5 (algebras 38–40), algebras that have nilradical isomorphic to the direct sum of the indecomposable three-dimensional nilpotent with $\mathbb{R}$ and having one-dimensional center.

III. REPRESENTATIONS FOR TURKOWSKI'S ALGEBRAS

Let us now consider the problem of constructing representations for the algebras in Turkowski's list. It is apparent that for algebras in Tables 1, 3, and 4 representations may be obtained from the adjoint representation. For the convenience of the reader we have given for each of these algebras the corresponding Lie subgroup of $GL(6,\mathbb{R})$ that we obtain by exponentiation or, Lie subgroup of $GL(5,\mathbb{R})$, that we obtain from Theorem 5.1 below. We give also in each case a collection of vector fields that are right-invariant and that are obtained by dualizing a collection of right-invariant Maurer-Cartan one-forms.

There are eleven classes of algebra in Table 2 and 5 for which faithful representations cannot be found by using the adjoint representation. Several of the algebras in Table 2 contain a parameter ϵ whose value is 0 or 1. The significance of ϵ is that when it is zero the nilradical has an *abelian* complement in the algebra g. For such algebras we can find faithful representations by appealing to the following proposition and theorem.

Proposition 3.1: Suppose that $\{e_1,e_2,\ldots,e_n\}$ *is a basis for a vector space* g *and there exists a skew bilinear map* $[,]$: $g\times g\to g$ *and* $[e_i,e_j]=0$, $[e_a,e_b]=0$, $[e_a,e_i]=C^j_{ai}e_j$, *where* $1\leqslant i,j\leqslant r$, $r+1\leqslant a,b,c\leqslant n$. *Then* g *is Lie algebra if* $C^j_{ai}C^k_{bj}=C^j_{bi}C^k_{aj}$.

Proof: If we consider the Jacobi identity we see that it is identically satisfied for each of the triples $\{e_i,e_j,e_k\}$, $\{e_i,e_j,e_a\}$, $\{e_a,e_b,e_c\}$. It remains to check $\{e_i,e_a,e_b\}$. Thus

$$[e_i,[e_a,e_b]]+[e_b,[e_i,e_a]]+[e_a,[e_b,e_i]]=-[e_b,C^j_{ai}e_j]+[e_a,C^j_{bi}e_j]=-C^j_{ai}C^k_{bj}e_k+C^j_{bi}C^k_{aj}e_k.$$

We deduce that the necessary and sufficient condition for obtaining a Lie algebra is

$$C^j_{bi}C^k_{aj}-C^j_{ai}C^k_{bj}=0.$$

□

Theorem 3.1. *Suppose that the n-dimensional Lie algebra* $\mathfrak{g}$ *has a basis* $\{e_1,e_2,\ldots,e_n\}$ *and only the following nonzero brackets:* $[e_a,e_i]=C^j_{ai}e_j$, *where* $(1\leqslant i,j\leqslant r,r+1\leqslant a,b,c\leqslant n)$. *Suppose that* $\mathfrak{g}$ *has an abelian nilradical for which a basis is* $\{e_1,e_2,\ldots,e_r\}$ *and* $\{e_{r+1},\ldots,e_n\}$ *is a basis for an abelian subalgebra complementary to the nitradical. Then* $\mathfrak{g}$ *has a faithful representation as a subalgebra of* $gl(r+1,\mathbb{R})$.

Proof: The endomorphism $ad(e_a)$ for $r+1\leqslant a\leqslant n$ correspond to $n\times n$ matrices in which there are nonzero entries only in the upper left $r\times r$ block: This $r\times r$ matrix is in fact $[C^i_{aj}]$. We denote

by E_a the $(r+1)\times(r+1)$ matrix whose upper left $r\times r$ block is $[C^i_{aj}]$ and whose remaining entries are zero. To obtain the representation, map e_a to E_a for $r+1\leqslant a\leqslant n$; for each vector $e_i(1\leqslant i\leqslant r)$ map it to the $(r+1)\times(r+1)$ matrix E_i whose only nonzero entry is a one in the $(i,r+1)$th position. Clearly the $E_i's$ commute. Note that the matrix product E_iE_a is zero and so

$$[E_a,E_i]=\sum_{k=1}^{r} C^k_{ai}E_k. \tag{1}$$

Finally, consider the Jacobi identity

$$[[e_a,e_b],e_i]+[[e_i,e_a],e_b]+[[e_b,e_i],e_a]=0.$$

On expanding we deduce that $C^k_{ai}C^j_{bk}-C^k_{bi}C^j_{ak}=0$. as in Proposition 3.1. It follows that $[E_a,E_b]=0$ and we have the required representation. □

Again we refer to the algebras in Turkowski's list [Turkowski (1990)]. It is possible to obtain representations, for example, for algebras 6.1–18 using Theorem 3.1 but for those particular algebras we have chosen to use the adjoint representation. On the other hand we do use Theorem 3.1 for algebras $6.22(\epsilon=0)$ and $6.23(\epsilon=0)$ in Sec. VI.

The next theorem is an improvement of a result that appears in Ghanam *et al.* (2005) and explains how under favorable circumstances the two-dimensional nonabelian Lie algebra can be used to extend a representation for an algebra of dimension n to a representation for an algebra of dimension $n+1$.

Theorem 3.2: *(i) Suppose that* $\mathfrak{g}$ *is an n-dimensional Lie algebra with structure equations* $[e_i,e_j]=C^k_{ij}e_k$ *with basis* $\{e_1,e_2,\ldots,e_n\}$ *and that* e_n *is not in the derived algebra* $[\mathfrak{g},\mathfrak{g}]$. *Suppose that* $\mathfrak{h}$ *is a space of dimension* $n+1$ *for which* $\mathfrak{g}$ *is an n-dimensional subspace and that* $\{e_1,e_2,\ldots,e_n,e_{n+1}\}$ *is a basis for* $\mathfrak{h}$. *Suppose that there is skew-bilinear map from* $\mathfrak{h}\times\mathfrak{h}$ *to* $\mathfrak{h}$ *defined on the basis for* $\mathfrak{h}$ *that satisfies* $[e_i,e_j]=C^k_{ij}e_k$, $[e_{n+1},e_i]=0$ $(1\leqslant i\leqslant n-1)$, $[e_{n+1},e_n]=be_{n+1}$ *for some nonzero* $b\in\mathbb{R}$. *Then* $\mathfrak{h}$ *is a Lie algebra, that is, the Jacobi identity holds on* $\mathfrak{h}$. *In fact* $\mathfrak{h}$ *is a one-dimensional split extension of* $\mathfrak{g}$ *and the subspace spanned by* $\{e_1,e_2,\ldots,e_{n-1}\}$ *is an ideal in* $\mathfrak{g}$ *as well as in* $\mathfrak{h}$.

(ii) In particular suppose that $\mathfrak{g}$ *is an n-dimensional solvable Lie algebra that is isomorphic to a subalgebra of* $gl(n,\mathbb{R})$ *and that* e_n *is not in the nilradical of* $\mathfrak{g}$. *Then* $\mathfrak{h}$ *as defined above is isomorphic to a subalgebra of* $gl(n+1,\mathbb{R})$.

We can use Theorem 3.2 to find, for example, representations for algebras 6.1, 6.2, 6.12, 6.19, 6.20, and 6.26 assuming that we have representations for the corresponding five-dimensional algebras.

IV. THE INVERSE PROBLEM FOR SECOND-ORDER ORDINARY DIFFERENTIAL EQUATION (ODE) SYSTEMS

There has been a great deal of activity in the inverse problem of Lagrangian dynamics during the past thirty years and we do not need to repeat all the theory here so we shall give a brief summary that is sufficient for our needs. Consider then a system of second-order ODE of the form

$$\ddot{x}^i=f^i(x^j,\dot{x}^j). \tag{2}$$

To simplify notation we shall denote $\dot{x}^i$ by u^i throughout. Douglas formulated an algebro-differential system which gives necessary and sufficient conditions for Eq. (2) to be the Euler-Lagrange equations of a regular first-order Lagrangian L.

To state Douglas' conditions we define the following $n\times n$ matrix of functions:

$$\Phi^i_j=\frac{1}{2}\frac{d}{dt}\left(\frac{\partial f^i}{\partial u^j}\right)-\frac{\partial f^i}{\partial x^j}-\frac{1}{4}\frac{\partial f^i}{\partial u^k}\frac{\partial f^k}{\partial u^j}. \tag{3}$$

Douglas obtained the following conditions known universally as the Helmholtz conditions whose role is explained in the theorem below

$$g\Phi = (g\Phi)^t, \tag{4}$$

$$\frac{dg_{ij}}{dt} + \frac{1}{2}\frac{\partial f^k}{\partial u^i}g_{kj} + \frac{1}{2}\frac{\partial f^k}{\partial u^j}g_{ki} = 0, \tag{5}$$

$$\frac{\partial g_{ij}}{\partial u^k} - \frac{\partial g_{ik}}{\partial u^j} = 0. \tag{6}$$

Theorem 4.1: (Douglas) *Necessary and sufficient conditions for there to exist a Lagrangian so that (2) are its Euler-Lagrange equations are that there should exist a nonsingular, symmetric matrix* g_{ij} *depending on* (x^i, u^i) *that satisfies Eqs. (4)–(6). To pass from the Hessian to the Lagrangian requires two integrations and the fact that appropriate linear and zeroth-order terms may be added is a consequence of the Helmholtz conditions; the only ambiguity in passing from Hessian to Lagrangian is the trivial one of scaling by a constant and adding a total time derivative.*

Let us consider the Helmholtz conditions as an algebro-differential system. It is always possible to solve Eq. (4) and it alone will not entail that the Lagrangian function is singular. As regards Eq. (5), it is in a sense a system of ODE's and it is possible, in principle, to solve them. Upon integration it is not constants that enter but rather arbitrary first integrals of the original ODE system (2). In practice this step becomes problematic unless Eq. (2) has sufficiently many explicit first integrals. Such integrals do exist for the geodesics of the canonical Lie group connection: See Proposition 5.2 below.

Thus, there is no obstruction to solving Eqs. (4) and (5) *in principle* and at this stage it is not possible to say definitively if the Lagrangian L exists or not. The final and most difficult step is to impose the so-called closure conditions (6). Even if we are fortunate enough to solve Eqs. (4) and (5) we are now faced with a daunting task: For n degrees of freedom (6) compromises a system of $2\binom{n+1}{3}$ PDE's on the components of g_{ij} and there are $2n$ independent variables. In the case at hand where $n=6$ we thus have a system of 70 PDE's. If one wants to construct the most general possible Lagrangian for Eq. (2) it is necessary to solve this system.

Fortunately, the situation confronting us in terms of solving the Helmholtz conditions is not as bad as one might imagine for two reasons. First of all, note that Eq. (4) are purely algebraic conditions on the unknown matrix g_{ij}. There are some auxiliary algebraic conditions that can be stated as follows. Define functions Ψ^i_{jk} by

$$\Psi^i_{jk} = \frac{1}{3}\left(\frac{\partial \Phi^i_j}{\partial u^k} - \frac{\partial \Phi^i_k}{\partial u^j}\right). \tag{7}$$

The extra conditions on g_{ij} are

$$g_{mi}\Psi^m_{jk} + g_{mk}\Psi^m_{ij} + g_{mj}\Psi^m_{ki} = 0. \tag{8}$$

In fact each of Eqs. (5) and (8) are the first in an infinite hierarchy of similar algebraic conditions. However, only Eqs. (5) and (8) are relevant in the present context because, since the curvature of the canonical Lie group connection is parallel, the higher order conditions in the hierarchy are identities. Notice that Eq. (8) comprises $\binom{n}{3}$ conditions whereas Eq. (5) comprises $\binom{n}{2}$ conditions. Thus it may well be the case that collectively Eqs. (5) and (8) entail that the Lagrangian function is singular. In this paper they are the only conditions that are obstructions to the existence of a regular Lagrangian although there is as yet no theoretical basis to conclude that a similar result is true in arbitrary dimensions. In the Appendix we have given a couple of examples for which we show that the Lagrangian is singular.

Secondly, in many cases it is very useful to know that at least one Lagrangian exists. After all, the best way to determine whether a particular system is variational is to give a Lagrangian! In fact even if one can find the general solution to Eq. (6) it will rarely be possible to find all possible

Lagrangians; it is impossible even for a free particle system. However, if system (2) admits submersions onto lower dimensional systems, it may be possible to lift Lagrangians to the higher dimensional systems. In the case of the geodesic equations of the canonical Lie group connection there are many such submersions: See Proposition (5.1) below.

V. THE INVERSE PROBLEM FOR THE CANONICAL LIE GROUP CONNECTION

Let us explain next how the general theory simplifies for the case of the geodesic equations associated to a linear connection. In this case the matrix Φ is of the form

$$\Phi^i_j = R^i_{kjl} u^k u^l \tag{9}$$

where R^i_{kjl} are the components of the curvature R of the connection relative to a coordinate system (x^i). For the case of a linear connection, one finds also that

$$\Psi^i_{jk} = R^i_{ljk} u^l. \tag{10}$$

The condition coming from Φ is

$$(g_{mi} R^i_{pjq} - g_{ji} R^i_{pmq}) u^p u^q = 0, \tag{11}$$

while the condition coming from Ψ is

$$(g_{mi} R^i_{pjq} + g_{qi} R^i_{pmj} + g_{ji} R^i_{pqm}) u^p = 0. \tag{12}$$

If we contract u^q into Eq. (12) we find from Eq. (11) that

$$g_{qi} R^i_{pmj} u^p u^q = 0. \tag{13}$$

Thus, for the special case of a linear connection, we can use Eqs. (12) and (13) instead of Eqs. (11) and (12).

Let us now consider the canonical symmetric connection ∇ on a Lie group G. In fact ∇ is defined on left invariant vector fields X and Y by [see Cartan and Schouten (1926)]

$$\nabla_X Y = \tfrac{1}{2}[X,Y], \tag{14}$$

and then extended to arbitrary vector fields by making ∇ tensorial in the X argument and satisfy the Leibnitz rule in the Y argument. It can be shown that ∇ is symmetric, bi-invariant and that the curvature tensor on left invariant vector fields is given by

$$R(X,Y)Z = \tfrac{1}{4}[Z,[X,Y]]. \tag{15}$$

Furthermore, G is a symmetric space in the sense that R is a parallel tensor field. The Ricci tensor R_{ij} of ∇ is symmetric and bi-invariant. In fact, if $\{E_i\}$ is a basis of left invariant vector fields then

$$[E_i, E_j] = C^k_{ij} E_k \tag{16}$$

where C^k_{ij} are the structure constants and relative to this basis the Ricci tensor R_{ij} is given by

$$R_{ij} = \tfrac{1}{4} C^l_{jm} C^m_{il}. \tag{17}$$

Since R^i_{jkl} is a parallel tensor field and R_{ij} is symmetric, it follows that Ricci gives rise to a quadratic Lagrangian which is not regular for solvable algebras because of Cartan's criterion. We shall also assume that G is indecomposable in the sense that the Lie algebra $\mathfrak{g}$ of G is not a direct sum of lower dimensional algebras. In terms of the Lie group inverse problem, if the algebra is indecomposable then we can obtain a Lagrangian on the product by adding Lagrangians on each component.

Since our starting point is the Lie algebra $\mathfrak{g}$ of a Lie group it is of interest to ask how the ideals of $\mathfrak{g}$ are related to ∇. To this end we shall quote the following result: see Kossowski and Thompson (1991) and Ghanam *et al.* (2004).

Proposition 5.1: Every ideal $\mathfrak{h}$ *of* $\mathfrak{g}$ *gives rise to a quotient space* Q *consisting of the leaf space of the integrable distribution determined by* $\mathfrak{h}$ *and* ∇ *on* G *projects to* Q. □

A very interesting situation occurs where a solvable algebra $\mathfrak{g}$ possesses two ideals $\mathfrak{h}_1$ and $\mathfrak{h}_2$ in the nilradical of $\mathfrak{g}$ such that $\mathfrak{h}_1 \cap \mathfrak{h}_2$ is zero and $\mathfrak{g}$ splits relative to both $\mathfrak{h}_1$ and $\mathfrak{h}_2$ [Ghanam *et al.* (2004)]. Denote the corresponding distributions on G by D_1 and D_2, respectively. Since we are always assuming that $\mathfrak{g}$ is indecomposable, $\mathfrak{g}$ cannot be the direct sum of $\mathfrak{h}_1$ and $\mathfrak{h}_2$ and hence $D_1 \cap D_2$ is nonzero. In fact $D_1 \cap D_2$ is the integrable distribution on G that corresponds to the ideal $\mathfrak{h}_1 + \mathfrak{h}_2$ of $\mathfrak{g}$ and similarly $D_1 + D_2$ corresponds to the ideal $\mathfrak{h}_1 \cap \mathfrak{h}_2$. This technique is very useful for constructing a single Lagrangian and many of the Lagrangians given in Sec. VI were obtained in this way.

We now quote a proposition that will be useful in the next chapter. For more details we refer the reader to Ghanam *et al.* (2004).

Proposition 5.2: Any left or right invariant one-form on G *gives rise to a linear first integral on* TG *when it is viewed as a linear function on* TG. □

The following Theorem is a continuation of Theorem 3.1.

Theorem 5.1: (i) *Suppose that the n-dimensional Lie algebra* $\mathfrak{g}$ *has a basis* $\{e_1, e_2, \ldots, e_n\}$ *and only the following nonzero brackets:* $[e_a, e_i] = C^j_{ai} e_j$, where $(1 \leqslant i, j \leqslant r,\ r+1 \leqslant a, b, c \leqslant n)$. *Suppose that* $\mathfrak{g}$ *has an abelian nilradical for which a basis is* $\{e_1, e_2, \ldots, e_r\}$ *and* $\{e_{r+1}, \ldots, e_n\}$ *is a basis for an abelian subalgebra complementary to the nilradical. Then there exists a coordinate system* (x^i, w^a) *on the local Lie group* G *associated to* $\mathfrak{g}$ *such that* $\mathfrak{g}$ *is faithfully represented by* $\{X_i, W_a\}$ *where* $X_i = \partial/\partial x$ *and* $W_a = \partial/\partial w^a + C^k_{aj} x^j (\partial/\partial x^k)$.

(ii) *In the coordinate system* (x^i, w^a) *of (i) the geodesic equations of the canonical connection are given by*

$$\ddot{x}^i = C^i_{bj} \dot{x}^j \dot{w}^b, \quad \ddot{w}^a = 0. \tag{18}$$

Proof: (i) It is clear that the coordinate representation for $\mathfrak{g}$ given above is faithful.

(ii) The one-forms dual to the vector fields of part (i) are given by $\{dx^i - C^i_{bj} x^j dw^b, dw^a\}$ and hence we find the geodesic equations are given as stated. □

VI. REPRESENTATIONS AND LAGRANGIANS

In this section we give matrix representations corresponding to the algebras in Turkowski's list [Turkowski (1990)]. In each case we give the nonzero brackets. Besides the representation we give also a basis for the right invariant vector fields. In those cases where the geodesic equations are of Euler-Lagrange type we give a specific Lagrangian. Finally we remind the reader that throughout this section we use (p, q, x, y, z, w) as the position coordinates and their dots for the corresponding velocities, respectively.

Lagrangian

$$L = \dot{w}(\dot{q} - z\dot{w} - w\dot{z}) + (y\dot{x} - x\dot{y})\dot{w} + \dot{x}^2 + \dot{y}^2 + \dot{z}^2 + \dot{w}^2 + \frac{e^{-z}\dot{p}^2}{\dot{z}}.$$

APPENDIX: CONSTRUCTING LAGRANGIANS

We end with a brief Appendix that touches on six of the forty cases. We believe that this approach will offer the reader much more insight into our techniques rather than supplying a plethora of routine details, many of which in any case, have only been accomplished with the help of MAPLE. These six cases are quite representative and the reader should bear in mind that we have always considered our primary objective to be to find at least one Lagrangian by hook or crook.

The following sum of matrices constitutes a solution to Eqs. (12), (13), and (5). In fact we begin by finding a basis of solutions to Eqs. (12) and (13). These solutions themselves may not satisfy Eq. (5). However, we insert our basis of solutions of Eq. (4) with coefficients into Eq. (5) noting that the time derivative in Eq. (5) is taken with respect to the original ODE system (2). As such when Eq. (5) are integrated arbitrary first integrals of Eq. (2) occur instead of arbitrary constants, in this case represented by the functions A, B, C, D, E, F, and G. We have not given details of the actual integration in Eq. (5) but we advise the reader that it is elementary, the difficulties stemming only from the size of the matrices involved. The reader can see such concrete details in much simpler examples in Thompson (2003), for example.

The new basis will now satisfy both Eqs. (4) and (5)

$$
A\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
+B\begin{bmatrix}
0 & 1 & 0 & 0 & 0 & 0\\
1 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
+C\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0\\
0 & 1 & 0 & 0 & 0 & 0\\

0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
-\dot{p} & 0 & 0 & 0 & 0 & \dot{w}
\end{bmatrix}
$$

$$
+\frac{e^{-z}E}{\dot{z}^2}\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0\\
0 & \frac{\dot{q}^2}{\dot{z}} & 0 & 0 & -\dot{q} & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & -\dot{q} & 0 & 0 & \dot{z} & 0\\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
+\frac{e^{-(a\dot{w}+b\dot{z})}F}{(a\dot{w}+b\dot{z})^2}\begin{bmatrix}
a^2(a\dot{w}+b\dot{z}) & ab(a\dot{w}+b\dot{z}) & -a\dot{y} & 0 & 0 & 0\\
ab(a\dot{w}+b\dot{z}) & b^2(a\dot{w}+b\dot{z}) & -b\dot{y} & 0 & 0 & 0\\
-a\dot{y} & -b\dot{y} & a\dot{w}+b\dot{z} & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
$$

$$
+\frac{e^{-(c\dot{w}+d\dot{z})}G}{(c\dot{w}+d\dot{z})^2}\begin{bmatrix}
c^2(c\dot{w}+d\dot{z}) & cd(c\dot{w}+d\dot{z}) & 0 & -c\dot{x} & 0 & 0\\
cd(c\dot{w}+d\dot{z}) & d^2(c\dot{w}+d\dot{z}) & 0 & -d\dot{x} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
-c\dot{x} & -d\dot{x} & 0 & c\dot{w}+d\dot{z} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}.
$$

If one requires now to find all possible Lagrangians for Eq. (2) it is necessary to solve the closure conditions (6), which as we have said compromises 70 conditions. We shall not write down Eq. (6). The system can be integrated explicitly in this case, however; each of $A, B, \ldots, G$ are first integrals. As such the general solution of Eq. (6) can be expressed in terms of first integrals. For example, it turns out that the function D can only depend on w, p, $\dot{p}/\dot{w}$. Thus if D is a first integral it can only depend on $e^{-w}(\dot{p}/\dot{w})$ and $\dot{p}/\dot{w}-p$. The reader can see more arguments of this type and in greater detail in Ghanam (2004).

The following matrix is the general solution of Eq. (6):

$$
\begin{bmatrix}
N_{\dot{w}\dot{w}} & N_{\dot{w}\dot{z}} & 0 & 0 & 0 & 0 \\
N_{\dot{w}\dot{z}} & N_{\dot{z}\dot{z}} & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
+ \frac{e^{-w}D}{\dot{w}^2}
\begin{bmatrix}
\frac{\dot{p}^2}{\dot{w}} & 0 & 0 & 0 & 0 & -\dot{p} \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
-\dot{p} & 0 & 0 & 0 & 0 & \dot{w}
\end{bmatrix}
+ \frac{e^{-z}E}{\dot{z}^2}
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & \frac{\dot{q}^2}{\dot{z}} & 0 & 0 & -\dot{q} & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & -\dot{q} & 0 & 0 & \dot{z} & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}
$$

$$
+
\begin{bmatrix}
\frac{a^2Fe^{-(aw+bz)}\dot{y}^2}{(a\dot{w}+b\dot{w})^3} + \frac{c^2Ge^{-((cw+dz))}\dot{x}^2}{(c\dot{w}+d\dot{w})^3} & \frac{abFe^{-(aw+bz)}\dot{y}^2}{(a\dot{w}+b\dot{w})^3} + \frac{cdGe^{-(cw+dz)}\dot{x}^2}{(c\dot{w}+d\dot{w})^3} & -\frac{aFe^{-(aw+bz)}\dot{y}}{(a\dot{w}+b\dot{w})^2} & -\frac{aGe^{-(cw+dz)}\dot{x}}{(c\dot{w}+d\dot{w})^2} & 0 & 0 \\
* & \frac{b^2Fe^{-(aw+bz)}\dot{y}^2}{(a\dot{w}+b\dot{w})^3} + \frac{d^2Ge^{-(cw+dz)}\dot{x}^2}{(c\dot{w}+d\dot{w})^3} & \frac{bFe^{-(aw+bz)}\dot{y}}{(a\dot{w}+b\dot{w})^2} & -\frac{dGe^{-(cw+dz)}\dot{x}}{(c\dot{w}+d\dot{w})^2} & 0 & 0 \\
* & * & \frac{Fe^{-(aw+bz)}}{(a\dot{w}+b\dot{w})} & 0 & 0 & 0 \\

* & * & * & * & 0 & 0 \\
* & * & * & * & * & 0
\end{bmatrix},
$$

where $D=D(e^{-w}\dot{p}/\dot{w},\dot{p}/\dot{w}-p)$, $E=E(e^{-z}\dot{q}/\dot{z},\dot{q}/\dot{z}-q)$, $F=F(e^{-(aw+bz)}\dot{y}/(a\dot{w}+b\dot{w}),\dot{y}/(a\dot{w}+b\dot{z})-y)$, $G=G(e^{-(cw+dz)}\dot{x}/(c\dot{w}+d\dot{z}),\dot{x}/c\dot{w}+d\dot{z}-x)$ and $N=N(\dot{w},\dot{z},z\dot{w}-w\dot{z})$.

It is not possible to integrate the Hessian above in complete generality, so to obtain a concrete Lagrangian it is necessary to choose specific forms for the functions D, E, F, G, and N. The Lagrangian given in Sec. VI is given by choosing $D=E=F=G=1/2$ and $N=\dot{w}^2+\dot{z}^2$. We have found it still to be a major practical problem to construct the Lagrangian from the Hessian and one that we have to do interactively. It seems likely to us that it will be quite some time before the symbolic manipulation programs are sufficiently powerful to enable us to automate these steps.

6.5 To construct a Lagrangian in this case we can make use of the remark that follows Proposition (5.1). In this case the subspaces spanned by $\{e_3,e_4\}$ and $\{e_5,e_6\}$, respectively, are ideals and each of them correspond to split extensions. As such we can combine two four-dimensional Lagrangians in the variables w, z, x, y and w, z, p, q (and their time derivatives), respectively. Similarly in case 6.9 we can extend a five-dimensional Lagrangian by using the subalgebra spanned by $\{e_1,e_3\}$, whereas the same trick would not work using the the subalgebra spanned by $\{e_2,e_6\}$, because the bracket $\{e_2,e_5\}$ involves e_6 on the left hand side.

6.8 In this example the matrix g_{ij} is singular. We use Eq. (15) to compute the nonzero components of the curvature R^i_{jkl}: Thus

$$
R^3_{113}=R^4_{224}=R^5_{225}=R^6_{214}=R^6_{124}=\tfrac{1}{2}R^6_{225}=R^6_{226}=\tfrac{1}{4}.
$$

Notice that this calculation is done entirely at the Lie algebra level: We do not need any representation here. If we do have a representation, such as is given in Sec. VI, we can also compute the curvature in coordinates though its components may not be constant. However, we could also do the calculation if we have a vector field representation of the Lie algebra because then we can compute the geodesics in coordinates.

Let us define generally, in dimension n, L_i to be u^jg_{ij} where there is a sum over j. Then Eq. (13) says in this case that $L_3=L_4=L_5=L_6=0$. Turning now to Eq. (12) we choose the following values for mjq: 126, 136, 145, 146, 245 and deduce that $g_{16}=g_{36}=g_{56}=g_{66}=g_{46}=0$, respectively. But now $L_6=0$ and hence it follows that the last column and bottom row of g_{ij} is zero.

6.19 A Lagrangian can be constructed in this example by identifying the group as a subgroup of $GL(3,\mathbb{C})$ and comparing it with the corresponding real subgroup of $GL(3,\mathbb{R})$. A Lagrangian in

the latter case was exhibited in Thompson (2003) and by complexifiying and taking the real part we can obtain the Lagrangian for case 6.19.

6.33 We consider another example where the matrix g_{ij} is singular. Again we use Eq. (15) to compute the nonzero components of the curvature R^i_{jkl}: Thus

$$R^3_{113}=R^3_{213}=R^3_{123}=R^3_{223}=R^3_{145}=R^3_{245}=R^3_{514}=R^3_{425}=R^4_{114}=R^5_{225}=\tfrac{1}{2}R^6_{225}=R^6_{226}=\tfrac{1}{4}.$$

Then just as in example 6.8, using the same notation, Eq. (13) says that $L_3=L_4=L_5=L_6=0$. As for Eq. (12) we choose the following values for mjq: 123, 134, 135, 136, 234 and deduce that $g_{13}-g_{23}=g_{33}=g_{35}=g_{36}=g_{34}=0$, respectively. Again since $L_3=0$ it follows that the third column and row of g_{ij} is zero.

One more remark about the cases where the matrix g_{ij} is singular is in order. Both of the algebras 6.8 and 6.33 do not contain parameters. However, there are some algebras that do depend on parameters and for which the matrix g_{ij} is singular. One has to take care, particularly when using symbolic manipulation programs such as MAPLE, not to exclude certain special values where the rank of a linear system can change. When running a routine, unless some special loop is included to track the possible values of the parameters, the routine is always going to assume that the parameters have generic values. In other words it is possible to exclude special values where, for example, the matrix g_{ij} may not be singular. This problem occurs in all questions that occur in the low-dimensional Lie algebras and at best they can be answered interactively.

(Received 29 November 2005; accepted 6 September 2006; published online 20 November 2006)

The reduced Hamiltonian system on $T^*(SU(3)/SU(2))$ is derived from a Riemannian geodesic motion on the SU(3) group manifold parametrized by the generalized Euler angles and endowed with a bi-invariant metric. Our calculations show that the metric defined by the derived reduced Hamiltonian flow on the orbit space $SU(3)/SU(2) \simeq \mathbb{S}^5$ is not isometric or even geodesically equivalent to the standard Riemannian metric on the five-sphere $\mathbb{S}^5$ embedded into $\mathbb{R}^6$. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2358391]

I. INTRODUCTION

Symmetry plays a central role in our pursuit of a better understanding of nature. Through the preservation or artful breaking of symmetry, powerful models have been developed that describe the fundamental forces and that have, so far, withstood all tests. Indeed, any endeavor to go beyond this standard model also has, at its heart, an appropriate symmetry argument.

An immediate consequence of symmetry is that it permits for a reduction in the relevant degrees of freedom needed to describe a given problem. In a gauge theory this reduction implies that not all the degrees of freedom present in the formulation of the theory correspond to physical degrees of freedom. So, for example, in Quantum Electrodynamics, with its U(1) gauge symmetry, the potential A_μ, which naively has four degrees of freedom, describes the photon, which has just two physical degrees of freedom. Understanding how this type of reduction should best take place and how the process of quantizing a system interacts with the symmetry, has driven many of the important advances in our understanding of gauge theories.[1]

In many cases, the reduction to the true physical degrees of freedom in a field theory has been fruitfully studied through simpler, finite dimensional systems. In particular, coset spaces of the form G/H, where G and H are finite dimensional Lie groups, have provided much insight[2] into

how global and topological properties of these configuration spaces can be encoded into the quantization process via generalized notions of reduction to the true degrees of freedom.[3]

In all investigations to date, specific details on dynamical aspects of the reduction to G/H have been restricted to groups for which manageable parametrizations of the group elements exist. Essentially this has restricted attention to groups directly related to the rotation group and its covering, SU(2). However, recently there has been much progress in finding suitable parametrizations for the higher dimensional unitary groups[4–8] and particularly for the group SU(3).[9,10] These advances open the door to detailed investigations of dynamics on spaces such as the five-sphere, $\mathbb{S}^5$, now viewed as the reduction from SU(3) to SU(3)/SU(2). By exploiting our concrete description of this reduction we shall see a new phenomenon for this system: different metric structures emerge depending on whether the five sphere is viewed as the coset space or via its natural embedding in six dimensional Euclidean space. This is, to the best of our knowledge, the first explicit example of this metric property of reduction.

The plan of the paper is as follows. We will conclude this introduction with a brief summary of the classical Hamiltonian reduction procedure. Then, in Sec. II, we will see how this procedure is applied to the group SU(2). This section does not contain any new results, but fixes notation and introduces themes that will prepare us for the reduction on the configuration space SU(3) which will be presented in detail in Sec. III. Then, in Sec. IV we will investigate the possible Riemannian structures that arise on the quotient space $\mathbb{S}^5$ and discuss the possible metric and geodesic correspondences. In an Appendix, we will collect together the details of our consistent parametrization of SU(3).

A. Hamiltonian reduction

Consider the special class of Lagrangian systems whose configuration space is a compact matrix Lie group G. This means that the state of a system at fixed time $t=0$ is characterized by an element of the Lie group $g(0) \in G$, and the evolution is described by the curve $g(t)$ on the group manifold.[11,12] The "free evolution" on the semisimple group G is, by definition, the Riemannian geodesic motion on the group manifold with respect to the so-called Cartan-Killing metric,[13,14]

$$\mathrm{d}s_G^2 = \kappa\,\mathrm{Tr}(g^{-1}\,\mathrm{d}g \otimes g^{-1}\,\mathrm{d}g),$$

where κ is a normalization factor. The geodesies are given by the extremal curves of the action functional,

$$S[g] = \frac{\kappa}{2}\int_0^T \mathrm{d}t\,\mathrm{Tr}(g^{-1}\dot{g}g^{-1}\dot{g}). \tag{1.1}$$

This action is invariant under the continuous left translation,

$$g(t) \to g(\varepsilon)g(t), \quad \varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_{\dim G}),$$

and therefore the system possesses the integrals of motion $\mathcal{I}_1, \mathcal{I}_2, \ldots, \mathcal{I}_{\dim G}$. The existence of these integrals of motion allows us to reduce the number of degrees of freedom of the system using the well-known method of Hamiltonian reduction.[11,12]

For a generic Hamiltonian system defined on the cotangent bundle T^*M with symmetry associated to the Lie group G action, the level set of the corresponding integrals of motion,

$$M_c = \mathcal{I}^{-1}(c). \tag{1.2}$$

where c is a set of arbitrary real constants $c=(c_1, \ldots, c_{\dim G})$, determines the reduced Hamiltonian system on the *reduced phase space* $F_c \subset M_c$. The subset F_c is described by the isotropy group, G_c, of the integrals level set M_c,

$$F_c = M_c/G_c.$$

Here we are interested in a special case when the manifold M is itself a group manifold and the symmetry transformations are group translations. Now the level set M_c is a subset of the trivial cotangent bundle T^*G that can be identified with the product of the group G and its algebra, $G \times g$. The level set given by the integrals $\mathcal{I}_1=c_1, \mathcal{I}_2=c_2, \ldots, \mathcal{I}_N=c_N, N \leq \dim \mathrm{G}$, defines the isotropy group $G_c \subset G$ and the so-called *orbit space*,

$$\mathcal{O} = G/G_c. \tag{1.3}$$

The relationship between the orbit space $\mathcal{O}$ and the reduced phase space F_c can be summarized as follows (see, e.g., Refs. 11 and 12):

- *the reduced phase space F_c is symplectic and diffeomorphic to the cotangent bundle $T^*\mathcal{O}$;*
- *the dynamics on the reduced degrees of freedom is Hamiltonian with a reduced Hamiltonian given by the projection of the original Hamiltonian function to F_c.*

These results are the modern generalizations of the classical theorems, proving that the collection of holonomic constraints defines a configuration manifold M as a submanifold of $\mathbb{R}^n$ and that, in the absence of forces, the trajectories of mechanical system are geodesies of the induced Riemannian metric.

Note that the above results do not claim that the reduced phase space and the dynamics on the orbit space are isometric. Indeed, we know that on the reduced phase space we can define, at least locally, an induced metric that arises from the kinetic energy part of the reduced Hamiltonian,

$$K_{\mathcal{O}} = \frac{1}{2}\mathbf{g}_{\mathcal{O}}(\xi_a, \xi_b)p_a p_b. \tag{1.4}$$

On the other hand the map $\pi: G \to G/G_c$ induces the metric

$$\overline{\mathbf{g}}_{\mathcal{O}} = \pi_* \mathbf{g}_G. \tag{1.5}$$

We now pose a question about the relation between these two metrics.

When are the metrics $\mathbf{g}_{\mathcal{O}}$ and $\overline{\mathbf{g}}_{\mathcal{O}}$ isometrically or, more weakly, geodesically equivalent?

We do not know the general answer to this question, so in this present paper we will focus our study on two examples: geodesic motion on the SU(2) and SU(3) group manifolds.

We start with a well-known example of Hamiltonian reduction $\mathrm{SU}(2) \to \mathrm{SU}(2)/\mathrm{U}(1)$ and show that the reduced space *is indeed in isometrical correspondence with the cotangent bundle* $T^*\mathbb{S}^2$ and the standard induced metric on the two-sphere $\mathbb{S}^2$. The case of the $\mathrm{SU}(3) \to \mathrm{SU}(3)/\mathrm{SU}(2)$ reduction gives an example of the opposite result: the metric defined by the Hamiltonian flow on the orbit space SU(3)/SU(2) *is not isometrically equivalent* to a standard round metric on the five-sphere $\mathbb{S}^5$. Furthermore, in this case, the stronger result is true: the reduced configuration space and the standard $\mathbb{S}^5$ are not even *geodesically equivalent*.

II. GEODESIC FLOW ON SU(2)

In this section we discuss the example of the reduction of free motion on the SU(2) group manifold. We start with a presentation of the key geometrical structures found on this group that are necessary for any further dynamical analysis.

A. The Euler angle parametrization

The special unitary group SU(2), considered as a subgroup of the general matrix group $\mathrm{GL}(2,\mathbb{C})$, is *topologically* the three-sphere $\mathbb{S}^3$ embedded into $\mathbb{C}^2$. This correspondence $\mathrm{SU}(2) \approx \mathbb{S}^3$ follows immediately from the standard identification of an arbitrary element $g \in \mathrm{SU}(2)$ as

$$g := \begin{pmatrix} z_1 & -\bar{z}_2 \\ z_2 & \bar{z}_1 \end{pmatrix}, \quad |z_1|^2 + |z_2|^2 = 1. \tag{2.1}$$

The three-sphere $\mathbb{S}^3$ is a manifold that requires more than one chart to cover it and therefore there is no global parametrization of the SU(2) group as a three-dimensional space. The local description usually adopted is given by the conventional symmetric *Euler representation*[15] for a group element,

$$g = \exp\left(i\frac{\alpha}{2}\sigma_3\right)\exp\left(i\frac{\beta}{2}\sigma_2\right)\exp\left(i\frac{\gamma}{2}\sigma_3\right), \tag{2.2}$$

with the appropriately chosen range for the Euler angles α, β, γ.

In this representation the generators of the one-parameter subgroups are the standard Pauli matrices σ_1, σ_2, and σ_3,

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \tag{2.3}$$

satisfying the $su(2)$ algebra

$$\sigma_a\sigma_b - \sigma_b\sigma_a = 2i\epsilon_{abc}\sigma_c. \tag{2.4}$$

Writing the complex numbers in (2.1) as $z_1 = x^1 + ix^2$ and $z_2 = x^3 + ix^4$ in polar form,

$$z_1 := e^{iu}\cos\theta, \quad z_2 := e^{iv}\sin\theta, \tag{2.5}$$

and comparing (2.1) with the explicit form of the Euler matrix (2.2),

$$g = \begin{pmatrix} e^{i\frac{\alpha+\gamma}{2}}\cos\left(\frac{\beta}{2}\right) & e^{i\frac{\alpha+\gamma}{2}}\sin\left(\frac{\beta}{2}\right) \\ -e^{-i\frac{\alpha-\gamma}{2}}\sin\left(\frac{\beta}{2}\right) & e^{-i\frac{\alpha+\gamma}{2}}\cos\left(\frac{\beta}{2}\right) \end{pmatrix}, \tag{2.6}$$

we have

$$u = \frac{\alpha+\gamma}{2}, \quad v = \frac{\alpha-\gamma}{2}, \quad \theta = \frac{\beta}{2}. \tag{2.7}$$

The Euler decomposition (2.2) corresponds to the following parametric representation of the three-sphere embedded in $\mathbb{R}^4$:

$$\begin{aligned} x^1 &= \cos\left(\frac{\alpha+\gamma}{2}\right)\cos\left(\frac{\beta}{2}\right), \quad x^2 = \sin\left(\frac{\alpha+\gamma}{2}\right)\cos\left(\frac{\beta}{2}\right), \\ x^3 &= -\cos\left(\frac{\alpha-\gamma}{2}\right)\sin\left(\frac{\beta}{2}\right), \quad x^4 = \sin\left(\frac{\alpha-\gamma}{2}\right)\sin\left(\frac{\beta}{2}\right). \end{aligned} \tag{2.8}$$

To be more precise, though, this is not a valid parametrization for the entire three-sphere. In particular, the neighborhood of the identity element of the group in this decomposition turns out to be degenerate. The identity element of SU(2) corresponds to the whole set: $\beta = 0$ and $\alpha + \gamma = 0$. In order to properly cover the whole group manifold, it is necessary to consider an atlas on the SU(2) group and used different parametrizations on the different charts. Bearing this in mind, we proceed by assuming that we are working in a chart $(\mathcal{U}, \phi)$, where α, β, and γ serve as good local coordinates on $\mathbb{S}^3$ and calculate the Maurer-Cartan forms on SU(2).

Using the following normalization:

$$g^{-1}\,\mathrm{d}g = \frac{i}{2}\sum_{a=1}^{3}\sigma_a \otimes \omega_L^a, \tag{2.9}$$

$$\mathrm{d}g\; g^{-1} = \frac{i}{2}\sum_{a=1}^{3}\sigma_a \otimes \omega_R^a, \tag{2.10}$$

and performing the straightforward calculations with the Eulerian representation (2.2) we arrive at the well-known expressions for left-invariant 1-forms:

$$\begin{aligned}\omega_L^1 &= \cos\gamma \sin\beta\, \mathrm{d}\alpha - \sin\gamma\, \mathrm{d}\beta,\\ \omega_L^2 &= \sin\beta \sin\gamma\, \mathrm{d}\alpha + \cos\gamma\, \mathrm{d}\beta,\\ \omega_L^3 &= \cos\beta\, \mathrm{d}\alpha + \mathrm{d}\gamma.\end{aligned} \tag{2.11}$$

and the corresponding dual vectors, $\omega_L^a(X_b^L) = \delta_b^a$, $a,b = 1,2,3$,

$$\begin{aligned}X_1^L &= \frac{\cos\gamma}{\sin\beta}\frac{\partial}{\partial\alpha} - \sin\gamma\frac{\partial}{\partial\beta} - \cot\beta\cos\gamma\frac{\partial}{\partial\gamma},\\ X_2^L &= \frac{\sin\gamma}{\sin\beta}\frac{\partial}{\partial\alpha} + \cos\gamma\frac{\partial}{\partial\beta} - \cot\beta\sin\gamma\frac{\partial}{\partial\gamma},\\ X_3^L &= \frac{\partial}{\partial\gamma}.\end{aligned} \tag{2.12}$$

The right invariant 1-forms and the corresponding dual vectors, $\omega_R^a(X_b^R) = \delta_b^a$, are

$$\begin{aligned}\omega_R^1 &= \sin\alpha\, \mathrm{d}\beta - \cos\alpha \sin\beta\, \mathrm{d}\gamma,\\ \omega_R^2 &= \cos\alpha\, \mathrm{d}\beta + \sin\alpha \sin\beta\, \mathrm{d}\gamma,\\ \omega_R^3 &= \mathrm{d}\alpha + \cos\beta\, \mathrm{d}\gamma.\end{aligned} \tag{2.13}$$

$$\begin{aligned}X_1^R &= \cos\alpha\cot\beta\frac{\partial}{\partial\alpha} + \sin\alpha\frac{\partial}{\partial\beta} - \frac{\cos\alpha}{\sin\beta}\frac{\partial}{\partial\gamma},\\ X_2^R &= -\sin\alpha\cot\beta\frac{\partial}{\partial\alpha} + \cos\alpha\frac{\partial}{\partial\beta} + \frac{\sin\alpha}{\sin\beta}\frac{\partial}{\partial\gamma},\\ X_3^R &= \frac{\partial}{\partial\alpha}.\end{aligned} \tag{2.14}$$

The vector fields X_a^L and X_a^R obey the $su(2)\otimes su(2)$ algebra with respect to the Lie brackets operation,

$$[X_a^L, X_b^L] = -\epsilon_{abc}X_c^L, \tag{2.15}$$

$$[X_a^R, X_b^R] = +\epsilon_{abc}X_c^R, \tag{2.16}$$

$$[X_a^L, X_b^R] = 0. \tag{2.17}$$

Any compact Lie group can be endowed with the bi-invariant Riemannian metric build uniquely (up to a normalization factor) from the Cartan-Killing form over the algebra. It is convenient to choose the following normalization for the bi-invariant metric on the SU(2) group:

$$\mathbf{g}_{\mathrm{SU}(2)} = -\frac{1}{2}\,\mathrm{Tr}(g^{-1}\,\mathrm{d}g \otimes g^{-1}\,\mathrm{d}g). \tag{2.18}$$

In terms of this left/right-invariant nonholonomic frame, (2.18) reads as

$$\mathbf{g}_{\mathrm{SU}(2)} = \frac{1}{4}(\omega_L^1 \otimes \omega_L^1 + \omega_L^2 \otimes \omega_L^2 + \omega_L^3 \otimes \omega_L^3), \tag{2.19}$$

$$= \frac{1}{4}(\omega_R^1 \otimes \omega_R^1 + \omega_R^2 \otimes \omega_R^2 + \omega_R^3 \otimes \omega_R^3). \tag{2.20}$$

Substitution of the expressions (2.11) and (2.13) for the Maurer-Cartan forms ω_L and ω_R yields the metric in the coordinate frame $\mathrm{d}\alpha, \mathrm{d}\beta, \mathrm{d}\gamma$ basis,

$$\mathbf{g}_{\mathrm{SU}(2)} = \frac{1}{4}(\mathrm{d}\alpha \otimes \mathrm{d}\alpha + \mathrm{d}\beta \otimes \mathrm{d}\beta + \mathrm{d}\gamma \otimes \mathrm{d}\gamma + 2\cos\beta\,\mathrm{d}\alpha \otimes \mathrm{d}\gamma). \tag{2.21}$$

In order to understand the *metrical* characteristics of a group manifold viewed as an embedded space, it is instructive to compare this invariant metric with the metric induced from the ambient four-dimensional Euclidian space on the *unit* three-sphere (2.8),

$$\mathbf{g}_{\mathrm{s}^3} = \mathrm{d}\bar{z}_1 \otimes \mathrm{d}z_1 + \mathrm{d}\bar{z}_2 \otimes \mathrm{d}z_2 = \frac{1}{4}(\mathrm{d}\alpha \otimes \mathrm{d}\alpha + \mathrm{d}\beta \otimes \mathrm{d}\beta + \mathrm{d}\gamma \otimes \mathrm{d}\gamma + 2\cos\beta\,\mathrm{d}\alpha \otimes \mathrm{d}\gamma). \tag{2.22}$$

Comparing the metrics, (2.21) and (2.22), we conclude that the bi-invariant metric on SU(2) is the same as the standard metric on the unit three-sphere $\mathbb{S}^3$ and its bi-invariant volume is

$$\mathrm{Vol}(\mathrm{SU}(2)) = \int \sqrt{\det \mathbf{g}_{\mathrm{SU}(2)}}\,\mathrm{d}\alpha \wedge \mathrm{d}\beta \wedge \mathrm{d}\gamma = \left(\frac{1}{2}\right)^3 \int_0^{2\pi} \mathrm{d}\alpha \int_0^{4\pi} \mathrm{d}\gamma \int_0^{\pi} \mathrm{d}\beta \sin(\beta) = 2\pi^2 = \mathrm{Vol}(\mathbb{S}^3). \tag{2.23}$$

As a Riemannian manifold, the SU(2) group endowed with the metric (2.21) is a 3-dimensional space of constant curvature with the Riemann scalar $\mathcal{R}_{\mathrm{SU}(2)} = 6$ and the Ricci tensor $\mathcal{R}_{ab}$ given by

$$\mathcal{R}_{ab} = \frac{\mathcal{R}_{\mathrm{SU}(2)}}{3} g_{ab} = 2g_{ab}. \tag{2.24}$$

The Gaussian curvature K of an n-dimensional manifold and the Riemann scalar are related via

$$K = \frac{\mathcal{R}}{n(n-1)}; \tag{2.25}$$

therefore $K_{\mathrm{SU}(2)} = 1$, in agreement with the volume calculation (2.23).

B. Quotient SU(2)/U(1)

Here we recall the key ingredients of the construction of a quotient space G/H by considering the transitive action of the group G on a certain base space M. We have the following[28] result.

If the group G acts transitively on a set M with $H \subset G$ being an isotropy subgroup leaving a point $x_0 \in M$ fixed,

$$H = \{g \in G | g \cdot x_0 = x_0\},$$

then the set M is in one-to-one correspondence with the left cosets gH of G.

The explicit form of this map for the SU(2) group is as follows. We identify the $su(2)$ algebra with $\mathbb{R}^3$ by the map $x^a \in \mathbb{R}^3 \to \mathbf{X} \in su(2)$,

$$\mathbf{X} = \sum_{a=1}^{3} x^a \sigma_a. \tag{2.26}$$

Consider now the *adjoint action* of SU(2) on an element of its algebra $\mathbf{X} \in su(2)$,

$$\mathrm{Ad}(g)(\mathbf{X}) = g\mathbf{X}g^{-1}.$$

The base point $x_0 = (0,0,1)$ (corresponding to the element σ_3) has a one-parameter isotropy subgroup,

$$\mathrm{H} = \exp\left(i\frac{\alpha}{2}\sigma_3\right).$$

The orbit space of σ_3,

$$\mathrm{Ad}(g)(\sigma_3) = g\sigma_3 g^{-1}$$

is the coset SU(2)/U(1). The proper atlas covering the SU(2) group manifold provides the coset space parametrization. When $\mathrm{SU}(2) \simeq \mathbb{S}^3$ is parametrized in terms of two complex coordinates z_1 and z_2, and the two-sphere is described by a unit vector $\mathbf{n} = (n^1, n^2, n^3)$, then the projection $\mathbb{S}^3 \to \mathbb{S}^2$ reads explicitly as

$$(z_1, z_2) \to (n^1, n^2, n^3) = (2\Re[\bar{z}_1 z_2],\ 2\Im[\bar{z}_1 z_2],\ |z_1|^2 - |z_2|^2). \tag{2.27}$$

This is the famous Hopf projection map $\pi: \mathrm{SU}(2) \to \mathbb{S}^2$, showing that SU(2) is a fiber bundle over $\mathbb{S}^2$ with nonintersecting circles $\mathrm{U}(1) \equiv \mathbb{S}^1$ as fibers,

$$\mathbb{S}^1 \hookrightarrow \mathrm{SU}(2) \xrightarrow{\pi} \mathbb{S}^2.$$

Using the Euler decomposition (2.6), the coset parametrization reads as

$$g\sigma_3 g^{-1} = n^a \sigma_a, \tag{2.28}$$

with the unit 3-vector,

$$\mathbf{n} = (-\sin\beta\cos\alpha,\ \sin\beta\sin\alpha,\ \cos\beta). \tag{2.29}$$

C. Lagrangian in Euler coordinates

The bi-invariant Lagrangian,

$$\mathrm{L}_{\mathrm{SU}(2)} = -\frac{1}{2}\,\mathrm{Tr}\left(g^{-1}(t)\frac{d}{dt}g(t)g^{-1}(t)\frac{d}{dt}g(t)\right), \tag{2.30}$$

in terms of left/right invariant Maurer-Cartan forms (2.9) reads as

$$\mathrm{L}_{\mathrm{SU}(2)} = \frac{1}{4}\sum_{a=1}^{3} i_{\dot{U}}\omega_L^a i_{\dot{U}}\omega_L^a = \frac{1}{4}\sum_{a=1}^{3} i_{\dot{U}}\omega_R^a i_{\dot{U}}\omega_R^a, \tag{2.31}$$

where $i_{\dot{U}}$ is the interior contraction of the vector field $\dot{U} = \dot{\alpha}(\partial/\partial\alpha) + \dot{\beta}(\partial/\partial\beta) + \dot{\gamma}(\partial/\partial\gamma)$.

Covering the group manifold with an atlas and considering the chart where the parameters α, β, γ in the Euler decomposition (2.2) serve as good coordinates, we arrive at

$$\mathrm{L}_{\mathrm{SU}(2)} = \frac{1}{4}(\dot{\alpha}^2 + \dot{\beta}^2 + \dot{\gamma}^2 + 2\cos(\beta)\dot{\alpha}\dot{\gamma}). \tag{2.32}$$

Comparing (2.32) with the expression (2.21) for the bi-invariant metric on SU(2), we conclude that

$$\mathrm{L}_{\mathrm{SU}(2)} = \mathbf{g}_{\mathrm{SU}(2)}(\dot{U}, \dot{U}). \tag{2.33}$$

D. Hamiltonian dynamics on T*SU(2)

The Hamiltonian dynamics on the SU(2) group is defined on the cotangent bundle $\mathrm{T}^*\mathrm{SU}(2)$ that can be identified with the trivialization $\mathrm{T}^*\mathrm{SU}(2) \approx \mathrm{SU}(2) \times su(2)_L$ or with $\mathrm{T}^*\mathrm{SU}(2) \approx \mathrm{SU}(2) \times su(2)_R$.

The canonical Hamiltonian describing geodesic motion on SU(2) can be obtained by a Legendre transformation of the Lagrangian function (2.31). Introducing the Poincare-Cartan symplectic one-form,

$$\Theta = p_\alpha \,\mathrm{d}\alpha + p_\beta \,\mathrm{d}\beta + p_\gamma \,\mathrm{d}\gamma,$$

with the canonically conjugated pairs,

$$\{\alpha, p_\alpha\} = 1, \quad \{\beta, p_\beta\} = 1, \quad \{\gamma, p_\gamma\} = 1,$$

the Hamiltonian on $\mathrm{T}^*\mathrm{SU}(2)$ is defined as

$$\mathrm{H}_{\mathrm{SU}(2)} = \sum_{a=1}^{3} \xi_a^L \xi_a^L, = \sum_{a=1}^{3} \xi_a^R \xi_a^R, \tag{2.34}$$

where ξ_a^L and ξ_a^R are the values of the one-form Θ on the left/right invariant vector fields X_a^L, X_a^R spanning the algebra $su(2)_{L,R}$,

$$\xi_a^L := \Theta(X_a^L), \quad \xi_a^R := \Theta(X_a^R).$$

The set of functions ξ_a^L and ξ_a^R obey the $su(2)_L \times su(2)_R$ relations with respect to the Poisson brackets,

$$\{\xi_a^L, \xi_b^L\} = -\epsilon_{abc}\xi_c^L, \tag{2.35}$$

$$\{\xi_a^R, \xi_b^R\} = \epsilon_{abc}\xi_c^R, \tag{2.36}$$

$$\{\xi_a^L, \xi_b^R\} = 0. \tag{2.37}$$

In the coordinate frame (2.32), the Hamiltonian (2.34) becomes

$$\mathrm{H}_{\mathrm{SU}(2)} = \frac{p_\alpha^2}{\sin^2(\beta)} + p_\beta^2 + \frac{p_\gamma^2}{\sin^2(\beta)} - \frac{2\cos(\beta)}{\sin^2(\beta)} p_\alpha p_\gamma. \tag{2.38}$$

Now noting that the components of the inverse of the bi-invariant metric (2.21) are

$$g^{-1}_{SU(2)} = \frac{4}{\sin^2(\beta)} \begin{pmatrix} 1 & 0 & -\cos(\beta) \\ 0 & \sin^2(\beta) & 0 \\ -\cos(\beta) & 0 & 1 \end{pmatrix}, \tag{2.39}$$

the Hamiltonian can be rewritten as

$$H_{SU(2)} = \frac{1}{4} \mathbf{g}^{-1}_{SU(2)}(\Theta, \Theta). \tag{2.40}$$

E. Hamiltonian reduction to the coset SU(2)/U(1)

The system with Hamiltonian function (2.38) has an obvious first integral,

$$p_\alpha = k, \quad \{p_\alpha, H_{SU(2)}\} = 0, \tag{2.41}$$

where k can be an arbitrary constant. The Hamiltonian on the level set $M_k := p_\alpha^{-1}(k)$ is, by definition, the projection of (2.38) onto this subspace:

$$H^{(k)} := H_{SU(2)}\big|_{p_\alpha = k} = p_\beta^2 + \frac{p_\gamma^2}{\sin^2(\beta)} - k\frac{2\cos(\beta)}{\sin^2(\beta)} p_\gamma + \frac{k^2}{\sin^2(\beta)}. \tag{2.42}$$

The inverse Legendre transformation gives

$$L_{SU(2)/SU(1)} = \frac{1}{4}(\dot\beta^2 + \sin^2(\beta)\dot\gamma^2) + k\cos(\beta)\dot\gamma. \tag{2.43}$$

The interpretation of the system so obtained is the following:[3] the first two terms correspond to a particle moving on the two-sphere $\mathbb{S}^2$ endowed with the standard embedding metric, while the last term describes the particle interaction with a Dirac monopole whose potential is

$$A_\phi := k(1 - \cos(\beta)).$$

III. GEODESIC FLOW ON SU(3) USING GENERALIZED EULER COORDINATES

A. Generalized Euler decomposition of SU(3)

Now we pass on to the description of the Euler decomposition of the SU(3) group element. The Euler angle parametrization of the three-dimensional rotation group has been generalized for the higher orthogonal SO(n) and special unitary SU(n) groups.[6–8,16–18] Special attention has been paid to the study of the SU(3)[19–22] and SU(4)[4,5] groups.

The starting point for the derivation[29] of the Euler angle representation of the SU(3) group is the so-called Cartan decomposition, which holds for a real semisimple Lie algebra $\mathcal{G}$. A decomposition of the algebra $\mathcal{G}$ into the direct sum of vector spaces $\mathcal{K}$ and $\mathcal{P}$,

$$\mathcal{G} = \mathcal{K} \otimes \mathcal{P}, \tag{3.1}$$

is a *Cartan decomposition of the algebra* $\mathcal{G}$ if

$$[\mathcal{K}, \mathcal{K}] \subset \mathcal{K}, \tag{3.2}$$

$$[\mathcal{K}, \mathcal{P}] \subset \mathcal{P}, \tag{3.3}$$

$$[\mathcal{P}, \mathcal{P}] \subset \mathcal{K}. \tag{3.4}$$

The Cartan decomposition for a Lie algebra induces a corresponding *Cartan decomposition of the group* G,

$$G = KP, \tag{3.5}$$

where K is a Lie subgroup of G with Lie algebra $\mathcal{K}$ and P is given by the exponential map $P = \exp(\mathcal{P})$.

An explicit realization of the Cartan decomposition for SU(3) can be achieved using the standard traceless 3×3 Hermitian Gell-Mann matrices $\lambda_a (a=1,\ldots,8)$ (the explicit form of the λ matrices is given in the Appendix). Indeed, from the expressions for the commutation relations,

$$[\lambda_a,\lambda_b] = 2i\sum_{c=1}^{8} f_{abc}\lambda_c, \tag{3.6}$$

where the structure constants f_{abc} are antisymmetric in all indices and have the nonzero values,

$$f_{123} = 1,$$

$$f_{147} = f_{246} = f_{257} = f_{345} = f_{516} = f_{637} = 1/2, \tag{3.7}$$

$$f_{458} = f_{678} = \sqrt{3/2},$$

it follows that the set of matrices $(\lambda_1,\lambda_2,\lambda_3,\lambda_8)$ can be used as the basis for the vector space $\mathcal{K}$ while the matrices $(\lambda_4,\lambda_5,\lambda_6,\lambda_7)$ span the Cartan subspace $\mathcal{P}$. Noting that the set of matrices $(\lambda_1,\lambda_2,\lambda_3,\lambda_8)$ comprise the generators $(\lambda_1,\lambda_2,\lambda_3)$ of the SU(2) group, one can locally represent K as the product of the SU(2) subgroup and a one-parameter subgroup,

$$K = \mathrm{SU}(2)e^{i\phi\lambda_8}. \tag{3.8}$$

The second factor, $P=\exp(\mathcal{P})$, in the Cartan decomposition (3.5) can be represented as a product of one-parameter subgroups. Moreover, based on the algebra (3.6), it can be represented as a product of a one-parameter subgroup generated by an element[23] from $\lambda_4,\ldots,\lambda_7$ "sandwiched" between two different copies of K. Fixing this generator to be, say λ_4, we have

$$P = K' e^{i\theta'\lambda_4} K''. \tag{3.9}$$

Now observing that $[\lambda_8,\lambda_4]=i\sqrt{3}\lambda_5$, the product KP can be reduced to

$$G = \mathrm{SU}(2)e^{i\theta\lambda_5}\mathrm{SU}(2)' e^{i\phi\lambda_8}. \tag{3.10}$$

Therefore, finally choosing the Euler representation for the elements of two subgroups $U \in SU(2)$ and $V \in \mathrm{SU}(2)'$ in terms of two sets of angles (α,β,γ) and (a,b,c),

$$U(\alpha,\beta,\gamma) = \exp\left(i\frac{\alpha}{2}\lambda_3\right)\exp\left(i\frac{\beta}{2}\lambda_2\right)\exp\left(i\frac{\gamma}{2}\lambda_3\right), \tag{3.11}$$

$$V(a,b,c) = \exp\left(i\frac{a}{2}\lambda_3\right)\exp\left(i\frac{b}{2}\lambda_2\right)\exp\left(i\frac{c}{2}\lambda_3\right), \tag{3.12}$$

we arrive at the generalized Euler decomposition of an element of $g \in SU(3)$,

$$g = U(\alpha,\beta,\gamma)Z(\theta,\phi)V(a,b,c), \tag{3.13}$$

with

$$Z(\theta,\phi) := e^{i\theta\lambda_5}e^{i\phi\lambda_8}. \tag{3.14}$$

Now it is necessary to fix the range of angles in (3.13). Just as in the case of the SU(2) group where the Euler parametrization was not a global one, the SU(3) group manifold cannot be covered by one chart. However, there is a range of parameters such that the parametrization covers

almost the whole manifold except the set whose measure in the integral quantities, e.g., such as the invariant volume, is zero.[23] The following ranges for the angles in (3.13):

$$0 \le \alpha,\ a \le 2\pi, \quad 0 \le \beta,\ b \le \pi, \quad 0 \le \gamma,\ c \le 4\pi, \tag{3.15}$$

$$0 \le \theta \le \frac{\pi}{2}, \quad 0 \le \phi \le \sqrt{3}\pi, \tag{3.16}$$

lead to the invariant volume for SU(3),

$$\mathrm{Vol}(SU(3)) = \int_{SU(3)} * 1 = \sqrt{3}\pi^5. \tag{3.17}$$

Below this result will be checked by an explicit calculation of the volume of the SU(3) manifold considered as the Riemannian space endowed with the bi-invariant metric,

$$\mathbf{g}_{\mathrm{SU(3)}} = -\frac{1}{2}\,\mathrm{Tr}(g^{-1}\,\mathrm{d}g \otimes g^{-1}\,\mathrm{d}g). \tag{3.18}$$

In terms of the nonholonomic frame built up from the left-/right-invariant forms,

$$g^{-1}\,\mathrm{d}g = \frac{i}{2}\sum_{A=1}^{8} \lambda_A \otimes \omega_L^A, \tag{3.19}$$

$$\mathrm{d}g\ g^{-1} = \frac{i}{2}\sum_{A=1}^{8} \lambda_A \otimes \omega_R^A, \tag{3.20}$$

the Cartan-Killing metric (3.18) has the diagonal form

$$\mathbf{g}_{\mathrm{SU(3)}} = \frac{1}{4}(\omega_L^1 \otimes \omega_L^1 + \omega_L^2 \otimes \omega_L^2 + \ \ldots\ + \omega_L^8 \otimes \omega_L^8) \tag{3.21}$$

$$= \frac{1}{4}(\omega_R^1 \otimes \omega_R^1 + \omega_R^2 \otimes \omega_R^2 + \ \ldots\ + \omega_R^8 \otimes \omega_R^8), \tag{3.22}$$

while in the corresponding coordinate frame, with the Eulerian coordinates $(\alpha,\beta,\gamma,a,b,c,\theta,\phi)$, presented in the Appendix, it becomes

$$\begin{aligned}
\mathbf{g}_{\mathrm{SU(3)}} = {} & \frac{1}{4}(\mathrm{d}\alpha \otimes \mathrm{d}\alpha + \mathrm{d}\beta \otimes \mathrm{d}\beta + \mathrm{d}\gamma \otimes \mathrm{d}\gamma + 2\cos\beta\,\mathrm{d}\alpha \otimes \mathrm{d}\gamma) + \frac{1}{4}(\mathrm{d}a \otimes \mathrm{d}a + \mathrm{d}b \otimes \mathrm{d}b + \mathrm{d}c \otimes \mathrm{d}c \\
& + 2\cos b\,\mathrm{d}a \otimes \mathrm{d}c) + \frac{1}{2}\cos\theta\,[\sin(a+\gamma)(\sin\beta\,\mathrm{d}\alpha \otimes \mathrm{d}b + \sin b\,\mathrm{d}\beta \otimes \mathrm{d}c) \\
& + \cos(a+\gamma)(\mathrm{d}\beta \otimes \mathrm{d}b - \sin\beta\sin b\,\mathrm{d}\alpha \otimes \mathrm{d}c)] - \frac{\sqrt{3}}{2}\sin^2\theta(\cos\beta\,\mathrm{d}\alpha + \mathrm{d}\gamma) \otimes \mathrm{d}\phi \\
& + \frac{1}{4}(1+\cos^2\theta)(\cos\beta\,\mathrm{d}\alpha + \mathrm{d}\gamma) \otimes (\mathrm{d}a + \cos b\,\mathrm{d}c) + \mathrm{d}\theta \otimes \mathrm{d}\theta + \mathrm{d}\phi \otimes \mathrm{d}\phi.
\end{aligned} \tag{3.23}$$

Fixing the range of the Euler angles according to (3.15) and noting that the determinant of the Cartan- Killing metric (3.23) is

$$\det \mathbf{g}_{\mathrm{SU}(3)} = \left(\frac{1}{2}\right)^{12} \sin^6(\theta)\cos^2(\theta)\sin^2(\beta)\sin^2(b),$$

one can check that the group invariant volume on SU(3) agrees with (3.17),

$$\begin{aligned}\mathrm{Vol}(\mathrm{SU}(3)) &= \int_{\mathrm{SU}(3)} \sqrt{\det \mathbf{g}_{\mathrm{SU}(3)}}\, \mathrm{d}\alpha \wedge \mathrm{d}\beta \wedge \mathrm{d}\gamma \wedge \mathrm{d}\theta \wedge \mathrm{d}a \wedge \mathrm{d}b \wedge \mathrm{d}c \wedge \mathrm{d}\phi \\ &= \left(\frac{1}{2}\right)^6 \int_0^{2\pi} \mathrm{d}\alpha \int_0^{4\pi} \mathrm{d}\gamma \int_0^{2\pi} \mathrm{d}a \int_0^{4\pi} \mathrm{d}c \int_0^{\sqrt{3}\pi} \mathrm{d}\phi \\ &\quad \times \int_0^{\pi} \mathrm{d}\beta \sin(\beta) \int_0^{\pi/2} \mathrm{d}\theta \cos(\theta)\sin^3(\theta) \int_0^{\pi} \mathrm{d}b \sin(b) = \sqrt{3}\pi^5. \end{aligned} \tag{3.24}$$

This volume is in accordance with the general formula established by Macdonald in Ref. 24 and expresses the volume element of a compact Lie group in terms of the product of volume elements of odd-dimensional unit spheres,

$$\mathrm{Vol}(\mathrm{SU}(3)) = \frac{\sqrt{3}}{2} \times \mathrm{Vol}(\mathbb{S}^5) \times \mathrm{Vol}(\mathbb{S}^3) = \frac{\sqrt{3}}{2} \times \pi^3 \times 2\pi^2. \tag{3.25}$$

In (3.25), the multiplier $\sqrt{3}/2$ comes from the volume of the maximal torus in SU(3), interpreted sometimes as the "*stretching*" factor.[25,26] This fact explicitly shows that the SU(3) group is not a trivial product of the two spheres, $\mathbb{S}^3$ and $\mathbb{S}^5$.

The SU(3) group endowed with the bi-invariant metric (3.23) has a constant positive Riemann scalar curvature,

$$\mathcal{R}_{\mathrm{SU}(3)} = 24,$$

and the Ricci tensor obeys the relations[27]

$$\mathcal{R}_{\mu\nu} = \frac{\mathcal{R}_{\mathrm{SU}(3)}}{8} \mathrm{g}_{\mu\nu} = 3\mathrm{g}_{\mu\nu}. \tag{3.26}$$

B. Geometry of the left coset SU(3)/SU(2)

The group SU(3) can be viewed as a *principal bundle over the base* $\mathbb{S}^5$ *with the structure group* SU(2),

$$SU(2) \hookrightarrow SU(3) \xrightarrow{\pi} \mathbb{S}^5,$$

with the canonical projection π from the SU(3) onto the left coset SU(3)/SU(2)$\simeq\mathbb{S}^5$. This map can be realized in the following manner. Consider the general linear group GL(3, $\mathbb{C}$).

An arbitrary element $M_{3\times 3}$ can be written in the block form

$$M_{3\times 3} = \left(\begin{array}{cc|c} & & z_3 \\ & M_{2\times 2} & z_2 \\ \hline y_1 & y_2 & z_1 \end{array}\right) = \left(\begin{array}{c|c} M_{2\times 2} & \mathbf{a} \\ \hline \mathbf{b} & z_1 \end{array}\right), \tag{3.27}$$

for complex 2×2 matrix $M_{2\times 2}$ and $z_1, z_2, z_3, y_1, y_2 \in \mathbb{C}$. The U(3) subgroup of the GL(3, $\mathbb{C}$) group is defined by the two matrix equations,

$$M_{3\times3}M_{3\times3}^{\dagger}=I_{3\times3},\quad M_{3\times3}^{\dagger}M_{3\times3}=I_{3\times3}. \tag{3.28}$$

When $M_{3\times3}$ is represented in block form (3.27), the conditions (3.28) reduce to the quadratic equations,

$$|z_1|^2+|z_2|^2+|z_3|^2=1, \tag{3.29}$$

$$|z_1|^2+|y_1|^2+|y_2|^2=1, \tag{3.30}$$

and to the set of 2×2 matrix equations,

$$M_{2\times2}M_{2\times2}^{\dagger}+\mathbf{a}\mathbf{a}^{\dagger}=I_{2\times2}, \tag{3.31}$$

$$M_{2\times2}^{\dagger}M_{2\times2}+\mathbf{b}^{\dagger}\mathbf{b}=I_{2\times2}, \tag{3.32}$$

$$z_1\mathbf{a}+M_{2\times2}\mathbf{a}=\mathbf{0}, \tag{3.33}$$

$$\bar{z}_1\mathbf{b}+M_{2\times2}^{\dagger}\mathbf{b}=\mathbf{0}. \tag{3.34}$$

Now let $\mathbb{S}^5$ be the five-sphere characterized by a unit complex vector $\mathbf{Z}:=(z_1,z_2,z_3)^T$

$$\mathbf{Z}^{\dagger}\mathbf{Z}=1.$$

The SU(3) group element g then acts on this through left translations:

$$\mathbf{Z}\rightarrow\mathbf{Z}'=g\mathbf{Z}. \tag{3.35}$$

Let $\mathbf{Z}_0$ be the base point on this five-sphere with coordinates $\mathbf{Z}_0=(0,0,1)^T$ whose isotropy group is

$$H_{3\times3}=\left(\begin{array}{c|c}\mathrm{SU(2)} & \mathbf{0}\\ \hline \mathbf{0} & 1\end{array}\right). \tag{3.36}$$

Then the coset SU(3)/SU(2) can be identified with the orbit

$$\mathbf{Z}=g\cdot(0,0,1)^T. \tag{3.37}$$

Using the explicit form of the representation (3.13), the subgroup SU(2) is embedded into SU(3) as follows:

$$SU(2)\rightarrow SU(3),\quad V=\begin{pmatrix} e^{-i(a+c)/2}\cos\left(\frac{b}{2}\right) & -e^{-i(a-c)/2}\sin\left(\frac{b}{2}\right) & 0\\ e^{i(a-c)/2}\sin\left(\frac{b}{2}\right) & e^{i(a+c)/2}\cos\left(\frac{b}{2}\right) & 0\\ 0 & 0 & 1\end{pmatrix}. \tag{3.38}$$

So the parametrization of a group element is

$$g=UZV=WV,$$

where the factor W reads as

$$W=\begin{pmatrix} \cos\theta\cos\dfrac{\beta}{2}e^{i\left(u+\frac{1}{\sqrt{3}}\phi\right)} & \sin\dfrac{\beta}{2}e^{i(v+(1/\sqrt{3})\phi)} & \sin\theta\cos\dfrac{\beta}{2}e^{i(u-(2/\sqrt{3})\phi)} \\ -\cos\theta\sin\dfrac{\beta}{2}e^{-i\left(v-\frac{1}{\sqrt{3}}\phi\right)} & \cos\dfrac{\beta}{2}e^{-i(u-(1/\sqrt{3})\phi)} & -\sin\theta\sin\dfrac{\beta}{2}e^{-i(v+(2/\sqrt{3})\phi)} \\ -\sin\theta e^{\frac{i}{\sqrt{3}}\phi} & 0 & \cos\theta e^{-i(2/\sqrt{3})\phi} \end{pmatrix}$$

$$u=\frac{\alpha+\gamma}{2},\quad v=\frac{\alpha-\gamma}{2}.$$

Using these representations in (3.37), we easily identify the projection onto the left coset as a five-sphere:

$$\pi: g\in SU(3)\to(z_1,z_2,z_2)\in\mathbb{S}^5,$$

which explicitly reads as

$$z_1=\cos\theta e^{-i(2/\sqrt{3})\phi}, \tag{3.39}$$

$$z_2=-\sin\theta\sin\frac{\beta}{2}e^{-\frac{i}{2}(\alpha-\gamma+(4/\sqrt{3})\phi)}, \tag{3.40}$$

$$z_3=\sin\theta\cos\frac{\beta}{2}e^{(i/2)(\alpha+\gamma-(4/\sqrt{3})\phi)}. \tag{3.41}$$

Under this projection the Euclidean metric $\mathrm{tr}(\mathrm{d}M\,\mathrm{d}M^\dagger)$ on $\mathrm{GL}(3,\mathbb{C})$ induces the following metric on a unit $\mathbb{S}^5$:

$$\begin{aligned}\mathbf{g}_{\mathbb{S}^5}&=\mathrm{d}\bar{z}_1\otimes\mathrm{d}z_1+\mathrm{d}\bar{z}_2\otimes\mathrm{d}z_2+\mathrm{d}\bar{z}_3\otimes\mathrm{d}z_3\\&=\sin^2\theta\left(\frac{1}{4}(\mathrm{d}\alpha\otimes\mathrm{d}\alpha+\mathrm{d}\beta\otimes\mathrm{d}\beta+\mathrm{d}\gamma\otimes\mathrm{d}\gamma+2\cos\beta\,\mathrm{d}\alpha\otimes\mathrm{d}\gamma)-\frac{2}{\sqrt{3}}(\cos\beta\,\mathrm{d}\alpha+\mathrm{d}\gamma)\otimes\mathrm{d}\phi\right)\\&\quad+\mathrm{d}\theta\otimes\mathrm{d}\theta+\frac{4}{3}\mathrm{d}\phi\otimes\mathrm{d}\phi,\end{aligned} \tag{3.42}$$

whose determinant is

$$\det\mathrm{g}_{\mathbb{S}^5}=\frac{1}{48}\sin^6(\theta)\cos^2(\theta)\sin^2(\beta). \tag{3.43}$$

The metric (3.42) defines a unit five-sphere $\mathbb{S}^5$ as a constant curvature Riemann manifold,

$$\mathcal{R}_{\mathbb{S}^5}=20, \tag{3.44}$$

which is in accordance with its Gaussian curvature,

$$K_{\mathbb{S}^5}=\frac{\mathcal{R}_{\mathbb{S}^5}}{5(5-1)}=1,$$

as well as with its volume,

$$\mathrm{Vol}(\mathbb{S}^5) = \int_{\mathbb{S}^5} \sqrt{\det g_{\mathbb{S}^5}}\, d\alpha \wedge d\beta \wedge d\gamma \wedge d\theta \wedge d\phi$$
$$= \frac{1}{4\sqrt{3}} \int_0^{2\pi} d\alpha \int_0^{4\pi} d\gamma \int_0^{\sqrt{3}\pi} d\phi \int_0^{\pi} d\beta \sin(\beta) \int_0^{\pi/2} d\theta \cos(\theta)\sin^3(\theta) = \pi^3. \tag{3.45}$$

C. Lagrangian on SU(3) in terms of generalized Euler angles

Consider the Lagrangian describing the geodesic motion on the SU(3) group manifold with respect to the bi-invariant metric (3.18),

$$\mathrm{L}_{\mathrm{SU}(3)} = -\frac{1}{2}\,\mathrm{Tr}\left(g^{-1}(t)\frac{d}{dt}g(t)g^{-1}(t)\frac{d}{dt}g(t)\right). \tag{3.46}$$

Using the generalized Euler angles on SU(3) as the configuration space coordinates and (3.23) for the bi-invariant metric, one can write the Lagrangian (3.46) as

$$\mathrm{L}_{\mathrm{SU}(3)} = \frac{1}{4}(\dot{\alpha}^2 + \dot{\beta}^2 + \dot{\gamma}^2 + 2\cos\beta\dot{\alpha}\dot{\gamma} + \dot{a}^2 + \dot{b}^2 + \dot{c}^2 + 2\cos b\dot{a}\dot{c})$$
$$+ \frac{1}{2}\cos\theta(\sin(a+\gamma)(\sin\beta\dot{\alpha}\dot{b} + \sin b\dot{\beta}\dot{c}) + \cos(a+\gamma)(\dot{\beta}\dot{b} - \sin\beta\sin b\dot{\alpha}\dot{c}))$$
$$- \frac{\sqrt{3}}{2}\sin^2\theta(\cos\beta\dot{\alpha} + \dot{\gamma})\dot{\phi} + \frac{1}{4}(1+\cos^2\theta)(\cos\beta\dot{\alpha} + \dot{\gamma})(\dot{a} + \cos b\dot{c}) + \dot{\theta}^2 + \dot{\phi}^2. \tag{3.47}$$

From this expression and (3.23), it follows that

$$\mathrm{L}_{\mathrm{SU}(3)} = \mathbf{g}_{\mathrm{SU}(3)}(\dot{Z},\dot{Z}), \tag{3.48}$$

where $\dot{Z}$ is the vector field on the tangent bundle TSU(3),

$$\dot{Z} = \dot{\alpha}\frac{\partial}{\partial\alpha} + \dot{\beta}\frac{\partial}{\partial\beta} + \dot{\gamma}\frac{\partial}{\partial\gamma} + \dot{\theta}\frac{\partial}{\partial\theta} + \dot{\phi}\frac{\partial}{\partial\phi} + \dot{a}\frac{\partial}{\partial a} + \dot{b}\frac{\partial}{\partial b} + \dot{c}\frac{\partial}{\partial c}. \tag{3.49}$$

It is worth noting that the Euler decomposition (3.13) for elements of SU(3) in terms of the SU(2) subgroups,

$$\mathrm{SU}(3) = U(\alpha,\beta,\gamma)\exp(i\theta\lambda_5)V(a,b,c)\exp(i\phi\lambda_8),$$

allows for the expression of the SU(3) Lagrangian (3.47) in terms of the corresponding left and right invariant elements of the SU(2) Maurer-Cartan 1-forms:

$$\mathrm{L}_{\mathrm{SU}(3)} = \frac{1}{4}\sum_{a=1}^{3} i_{\dot{U}}\omega_L^a i_{\dot{U}}\omega_L^a + \frac{1}{4}\sum_{a=1}^{3} i_{\dot{V}}\omega_L^a i_{\dot{V}}\omega_L^a + \frac{1}{2}\cos\theta\sum_{a=1}^{3} i_{\dot{U}}\omega_L^a i_{\dot{V}}\omega_R^i - \frac{1}{4}(1+\cos^2\theta) i_{\dot{U}}\omega_L^3 i_{\dot{V}}\omega_R^3$$
$$- \frac{\sqrt{3}}{2}\sin^2\theta i_{\dot{U}}\omega_L^3\dot{\phi} + \dot{\theta}^2 + \dot{\phi}^2. \tag{3.50}$$

Here $i_{\dot{U}}$ and $i_{\dot{V}}$ denote the interior contraction of the vector field on each copy of the SU(2) group, U and V, respectively,

$$\dot{U}=\dot{\alpha}\frac{\partial}{\partial\alpha}+\dot{\beta}\frac{\partial}{\partial\beta}+\dot{\gamma}\frac{\partial}{\partial\gamma},\quad \dot{V}=\dot{a}\frac{\partial}{\partial a}+\dot{b}\frac{\partial}{\partial b}+\dot{c}\frac{\partial}{\partial c}. \tag{3.51}$$

D. Hamiltonian dynamics on SU(3)

Performing the Legendre transformation, we derive the canonical Hamiltonian generating the dynamics on the SU(3) group manifold:

$$\begin{aligned}H_{\mathrm{SU}(3)}=&\frac{1}{\sin^2\theta}\left[\frac{p_\alpha^2}{\sin^2\beta}+p_\beta^2+\left(\tan^2\theta+\frac{1}{\sin^2\beta}\right)p_\gamma^2-2\frac{\cos\beta}{\sin^2\beta}p_\alpha p_\gamma\right.\\&\left.+\sin^2\theta\left(1+\frac{1}{4}\cot^2\theta+\frac{1}{\sin^2 b}\right)p_a^2+p_b^2+\frac{1}{\sin^2 b}p_c^2-2\frac{\cos b}{\sin^2 b}p_a p_c\right]\\&+2\frac{\cos\theta}{\sin^2\theta\sin\beta\sin b}\{\cos(a+\gamma)[(p_\alpha-\cos\beta p_\gamma)(p_c-\cos b p_a)-\sin b p_\beta p_b]\\&-\sin(a+\gamma)[\sin b(p_\alpha-\cos\beta p_\gamma)p_b+\sin\beta(p_c-\cos b p_a)p_\beta]\}+\frac{1}{4}p_\theta^2\\&+\frac{1}{16}\left(1+\frac{3}{\cos^2\theta}\right)p_\phi^2+\frac{\sqrt{3}}{2}\frac{p_\gamma p_\phi}{\cos^2\theta}-\frac{\sqrt{3}}{4}\left(1+\frac{1}{\cos^2\theta}\right)p_a p_\phi.\end{aligned} \tag{3.52}$$

The Hamiltonian (3.52) can be rewritten in a compact form using the left- and right-invariant vector fields on the two SU(2) group copies, U and V, used in the Euler decomposition (3.13):

$$\begin{aligned}H_{\mathrm{SU}(3)}=&\sum_{a=1}^{3}\zeta_a^R\zeta_a^R+\frac{1}{\sin^2\theta}\sum_{a=1}^{2}(\xi_a^L-\cos\theta\zeta_a^R)^2+\frac{1}{\sin^2 2\theta}\left(2\xi_3^L-(1+\cos^2\theta)\zeta_3^R-\frac{\sqrt{3}}{2}\sin^2\theta p_\phi\right)^2\\&+\frac{1}{4}p_\theta^2+\frac{1}{4}p_\phi^2.\end{aligned} \tag{3.53}$$

Here ξ_a^b and ζ_α^R are functions defined through the relations

$$\xi_a^L:=\Theta(X_a^L),\quad \zeta_a^R:=\Theta(Y_a^R),$$

with the SU(2) left-invariant vector fields X_a^L on the tangent space to the U subgroup, TU, and the right-invariant fields Y_a^R on TV correspondingly.

E. Hamiltonian reduction to SU(3)/SU(2)

The representation (3.53) is very convenient for performing the reduction in degrees of freedom associated with the SU(2) symmetry transformation. Due to the algebra of Poisson brackets (2.35), the functions ζ_1^L,ζ_2^L, and ζ_3^L are the first integrals,

$$\{\zeta_a^L,H_{\mathrm{SU}(3)}\}=0.$$

Let us consider the zero level of these integrals

$$\zeta_1^L=0,\quad \zeta_2^L=0,\quad \zeta_3^L=0. \tag{3.54}$$

Noting the relation between the left and right invariant vector fields on a group, one can express the functions ζ_a^R entering in the Hamiltonian as

$$\zeta_c^R = \mathrm{Ad}(\mathrm{V})_{cb}\zeta_b^L,$$

where $\mathrm{Ad}(\mathrm{V})_{cb}$ is an adjoint matrix of an element $\mathrm{V} \in \mathrm{SU}(2)$. From this one can immediately find the reduced Hamiltonian on the integral level (3.54). Indeed, projecting the expression (3.53) on $\zeta_a^R = 0$, we find

$$H_{\mathrm{SU}(3)/\mathrm{SU}(2)} = \frac{1}{\sin^2\theta}\sum_{a=1}^{3}\xi_a^L\xi_a^L + \frac{1}{\sin^2 2\theta}\left(2\xi_3^L - \frac{\sqrt{3}}{2}\sin^2\theta p_\phi\right)^2 + \frac{1}{4}p_\theta^2 + \frac{1}{4}p_\phi^2, \tag{3.55}$$

or, more explicitly in terms of the canonical coordinates,

$$\begin{aligned}\mathrm{H}_{\mathrm{SU}(3)/\mathrm{SU}(2)} = {} & \frac{1}{\sin^2\theta}\left(\frac{p_\alpha^2}{\sin^2\beta} + p_\beta^2 + \left(\tan^2\theta + \frac{1}{\sin^2\beta}\right)p_\gamma^2 - 2\frac{\cos\beta}{\sin^2\beta}p_\alpha p_\gamma + \frac{\sqrt{3}}{2}\tan^2\theta p_\gamma p_\phi\right) \\ & + \frac{1}{4}p_\theta^2 + \frac{1}{16}\left(1 + \frac{3}{\cos^2\theta}\right)p_\phi^2.\end{aligned} \tag{3.56}$$

Performing the inverse Legendre transformation, we find the Lagrangian,

$$\begin{aligned}\mathrm{L}_{\mathrm{SU}(3)/\mathrm{SU}(2)} = {} & \frac{1}{4}\sin^2\theta\left[\left(1 - \frac{1}{4}\cos^2\beta\sin^2\theta\right)\dot{\alpha}^2 + \dot{\beta}^2 + \frac{1}{4}(3 + \cos^2\theta)\dot{\gamma}^2 + \frac{1}{2}\cos\beta(3 + \cos^2\theta)\dot{\alpha}\dot{\gamma}\right. \\ & \left. - 2\sqrt{3}(\cos\beta\dot{\alpha} + \dot{\gamma})\dot{\phi}\right] + \dot{\theta}^2 + \dot{\phi}^2.\end{aligned} \tag{3.57}$$

Now one can consider the bilinear form (3.57) as the metric $\mathbf{g}_{\mathcal{O}}$ on the orbit space $\mathcal{O} = \mathrm{SU}(3)/\mathrm{SU}(2)$,

$$\begin{aligned}\mathbf{g}_{\mathcal{O}} = {} & \frac{1}{4}\sin^2\theta\left[\left(1 - \frac{1}{4}\cos^2\beta\sin^2\theta\right)\mathrm{d}\alpha\otimes\mathrm{d}\alpha + \mathrm{d}\beta\otimes\mathrm{d}\beta + \frac{1}{4}(3 + \cos^2\theta)\mathrm{d}\gamma\otimes\mathrm{d}\gamma\right. \\ & \left. + \frac{1}{2}\cos\beta(3 + \cos^2\theta)\mathrm{d}\alpha\otimes\mathrm{d}\gamma - 2\sqrt{3}(\cos\beta\,\mathrm{d}\alpha + \mathrm{d}\gamma)\otimes\mathrm{d}\phi\right] + \mathrm{d}\theta\otimes\mathrm{d}\theta + \mathrm{d}\phi\otimes\mathrm{d}\phi.\end{aligned} \tag{3.58}$$

Using our previous calculations (3.45) of $\mathrm{Vol}(\mathbb{S}^5)$ with respect to the metric (3.42) induced by the canonical projection to the left coset $\pi:\mathrm{SU}(3)\to\mathrm{SU}(3)/\mathrm{SU}(2)$ and noting that the determinant of the new orbit metric (3.58) induced by the Hamiltonian reduction is

$$\det\mathbf{g}_{\mathcal{O}} = \frac{1}{64}\sin^6(\theta)\cos^2(\theta)\sin^2(\beta), \tag{3.59}$$

we find

$$\mathrm{Vol}(\mathrm{SU}(3)/\mathrm{SU}(2)) = \frac{\sqrt{3}}{2}\mathrm{Vol}(\mathbb{S}^5), \tag{3.60}$$

with the same *stretching* factor $\sqrt{3}/2$ as found in (3.25) for the bi-invariant volume of the SU(3) group.

IV. RIEMANNIAN STRUCTURES ON THE QUOTIENT SPACE

Now we are ready to answer the questions about the relation between metric (3.42) induced on the left coset SU(3)/SU(2) by canonical projection from the ambient Euclidian space and the metric (3.58) obtained as a result of performing the Hamiltonian reduction of the geodesic motion from SU(3) to SU(3)/SU(2).

Performing a straightforward calculation of the Riemannian curvature with respect to the metric (3.58) yields

$$\mathcal{R}\left(\mathbf{g}_{\frac{\mathrm{SU}(3)}{\mathrm{SU}(2)}}\right)=21, \tag{4.1}$$

while, from the embedding argumentation we used before, the Riemann scalar of the unit five-sphere $\mathbb{S}^5$ with standard metric induced from the Euclidean space is

$$\mathcal{R}\left(\mathbf{g}_{\mathbb{S}^5}\right)=20. \tag{4.2}$$

Furthermore, even though the Riemann scalar is a constant, calculations shows that the metric (3.57) *is not the metric of a space of constant curvature*.

So, we have found that the Lagrangian of the reduced system defines local flows on the configuration space which are not isometric to those on $\mathbb{S}^5$ with its standard round metric.

We have shown above that the orbit space SU(3)/SU(2) considered as a Riemannian space with metric $\mathbf{g}$ induced from the Cartan-Killing metric on SU(3) is not isometric to the $\mathbb{S}^5$ with the standard round metric $\mathbf{g}_{\mathbb{S}^5}$. The next natural question is whether the metrics $\mathbf{g}_{\mathcal{O}}$ and $\mathbf{g}_{\mathbb{S}^5}$ are *geodesically/projectively* equivalent.

There are several criteria on metrics to be geodesically equivalent. According to Eisenhart,[30] two metrics $\mathbf{g}$ and $\overline{\mathbf{g}}$ on an n-dimensional Riemann manifold are *geodesically equivalent if and only if*

$$2(n+1)\boldsymbol{\nabla}_i(\mathbf{g})\overline{\mathbf{g}}_{jk}=2\overline{\mathbf{g}}_{jk}\,\partial_i\Lambda+\overline{\mathbf{g}}_{ik}\partial_j\Lambda+\overline{\mathbf{g}}_{ji}\,\partial_k\Lambda, \tag{4.3}$$

where $\boldsymbol{\nabla}_i(\mathbf{g})$ is covariant with respect the metric $\mathbf{g}$ and the scalar function Λ is

$$\Lambda=\ln\left(\frac{\det(\overline{\mathbf{g}})}{\det(\mathbf{g})}\right). \tag{4.4}$$

According to our calculations,

$$\det(\mathbf{g}_{\mathcal{O}})=\frac{3}{4}\det(\mathbf{g}_{\mathbb{S}^5})$$

and

$$\boldsymbol{\nabla}_i(\mathbf{g}_{\mathbb{S}^5})\mathbf{g}_{\mathcal{O}_{jk}}\neq 0,$$

and therefore $\mathbf{g}_{\mathbb{S}^5}$ and $\mathbf{g}_{\mathcal{O}}$ are not *geodesically/projectively* equivalent.

V. CONCLUSION

In this paper we have presented, for the first time, the explicit Hamiltonian reduction from free motion on SU(3) to motion on the coset space $\mathrm{SU}(3)/\mathrm{SU}(2)\approx\mathbb{S}^5$. This has been made possible through a consistent parametrization of SU(3) that generalizes the Euler angle parametrization of SU(2). The full details for this parametrization of SU(3) are, for completeness, collected together in an Appendix to this paper. The results presented there have been checked independently using the computer algebra packages MATHEMATICA *5.0* and MAPLE *9.5*. (MATHEMATICA files are available at http://compalg.jinr.ru/CAGroup/Palii/math_prgr.php).

Through this analysis, we have seen that the resulting dynamics is not equivalent to the geodesic motion on $\mathbb{S}^5$ induced from its standard round metric. This result prompts the following questions.

- Is it possible to identify, *a priori*, the induced metric on the coset space in terms of the properties of SU(3)?
- Is it possible to formulate the dynamics on SU(3) so that the reduced dynamics *is* the expected geodesic motion on $\mathbb{S}^5$?

- What happens if we reduce to a nonzero level set of the integrals (3.54)?

Progress in answering these questions will, we feel, throw much light on the dynamical aspects of the Hamiltonian reduction procedure and hence lead to a deeper understanding of the quantization of gauge theories.

ACKNOWLEDGMENTS

Helpful discussions during the work on the paper with T. Heinzl, D. Mladenov, and O.Schröder are acknowledged.

The contribution of V. G., A. K., and Yu. P. was supported in part by Grant No. 04-01-00784 from the Russian Foundation for Basic Research and Grant No. 5362.2006.2 from the Minstry of Education and Science of the Russian Federation.

APPENDIX: DETAILS OF CALCULATION

1. The su(3) algebra structure

The eight traceless 3×3 Gell-Mann matrices providing a basis for the su(3) algebra listed below:

$$\lambda_1=\begin{pmatrix}0&1&0\\1&0&0\\0&0&0\end{pmatrix},\quad \lambda_2=\begin{pmatrix}0&-i&0\\i&0&0\\0&0&0\end{pmatrix},\quad \lambda_3=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix},$$

$$\lambda_4=\begin{pmatrix}0&0&1\\0&0&0\\1&0&0\end{pmatrix},\quad \lambda_5=\begin{pmatrix}0&0&-i\\0&0&0\\i&0&0\end{pmatrix},\quad \lambda_6=\begin{pmatrix}0&0&0\\0&0&1\\0&1&0\end{pmatrix},\tag{A1}$$

$$\lambda_7=\begin{pmatrix}0&0&0\\0&0&-i\\0&i&0\end{pmatrix},\quad \lambda_8=\frac{1}{\sqrt{3}}\begin{pmatrix}1&0&0\\0&1&0\\0&0&-2\end{pmatrix}.$$

Sometimes it is convenient to use instead of the Gell-Mann matrices the anti-Hermitian basis $\mathbf{t}_a:=(1/2i)\lambda_a$, obeying the relations

$$\mathbf{t}_a\mathbf{t}_b=-\frac{1}{6}\delta_{ab}\mathbf{I}+\frac{1}{2}\sum_{c=1}^{8}(f_{abc}-id_{abc})\mathbf{t}_c,\tag{A2}$$

where the structure constants d_{abc} are symmetric in their indices and nonvanishing values are given in Table I, the coefficients f_{abc} are skew symmetric in all indices. The constants f_{abc} determine the commutators between the basis elements (also see Table II)

$$[\mathbf{t}_a,\mathbf{t}_b]=\sum_{c=1}^{8}f_{abc}\mathbf{t}_c.\tag{A3}$$

2. The basis of invariant 1-forms on the SU(3) group

a. The left-invariant 1-forms

Using the generalized Euler decomposition (3.13) for the SU(3) group element, it is straightforward to calculate the left and right invariant 1-forms. The results are given below:

$$\omega_L^1 = \Big[\cos[\beta]\sin[b]\cos[c]\Big(1-\frac{1}{2}\sin^2[\theta]\Big)+\cos[\theta]\sin[\beta](\cos[b]\cos[c]\cos[a+\gamma] - \sin[c]\sin[a+\gamma])\Big]\mathrm{d}\alpha - \cos[\theta](\cos[a+\gamma]\sin[c]+\cos[b]\cos[c]\sin[a+\gamma])\mathrm{d}\beta + \cos[c]\sin[b]\Big(1-\frac{1}{2}\sin^2[\theta]\Big)\mathrm{d}\gamma+\cos[c]\sin[b]\mathrm{d}a-\sin[c]\mathrm{d}b,$$

$$\omega_L^2 = \Big[\cos[\beta]\sin[b]\sin[c]\Big(1-\frac{1}{2}\sin^2[\theta]\Big)+\cos[\theta]\sin[\beta](\cos[b]\cos[a+\gamma]\sin[c] + \cos[c]\sin[a+\gamma])\Big]\mathrm{d}\alpha + \cos[\theta](\cos[c]\cos[a+\gamma]-\cos[b]\sin[c]\sin[a+\gamma])\mathrm{d}\beta + \sin[b]\sin[c]\Big(1-\frac{1}{2}\sin^2[\theta]\Big)\mathrm{d}\gamma+\sin[b]\sin[c]\mathrm{d}a+\cos[c]\mathrm{d}b,$$

$$\omega_L^3 = \Big[\cos[b]\cos[\beta]\Big(1-\frac{1}{2}\sin^2[\theta]\Big)-\cos[a+\gamma]\cos[\theta]\sin[b]\sin[\beta]\Big]\mathrm{d}\alpha + \cos[\theta]\sin[b]\sin[a+\gamma]\mathrm{d}\beta+\cos[b]\Big(1-\frac{1}{2}\sin^2\theta\Big)\mathrm{d}\alpha+\cos[b]\mathrm{d}a+\mathrm{d}c,$$

$$\omega_L^4 = \sin[\theta]\Big(\cos[\beta]\cos[\theta]\cos\Big[\frac{b}{2}\Big]\cos\Big[\frac{a+c}{2}+\sqrt{3}\phi\Big]-\cos\Big[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\Big]\sin\Big[\frac{b}{2}\Big]\sin[\beta]\Big)\mathrm{d}\alpha + \sin\Big[\frac{b}{2}\Big]\sin[\theta]\sin\Big[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\Big]\mathrm{d}\beta+\frac{1}{2}\cos\Big[\frac{b}{2}\Big]\cos\Big[\frac{a+c}{2}+\sqrt{3}\phi\Big]\sin[2\theta]\mathrm{d}\gamma - 2\cos\Big[\frac{b}{2}\Big]\sin\Big[\frac{a+c}{2}+\sqrt{3}\phi\Big]\mathrm{d}\theta,$$

$$\omega_L^5 = \sin[\theta]\left(\sin\left[\frac{b}{2}\right]\sin[\beta]\sin\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right]+\cos\left[\frac{b}{2}\right]\cos[\beta]\cos[\theta]\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\right)\mathrm{d}\alpha$$
$$+\cos\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right]\sin\left[\frac{b}{2}\right]\sin[\theta]\mathrm{d}\beta+\frac{1}{2}\cos\left[\frac{b}{2}\right]\sin[2\theta]\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\mathrm{d}\gamma$$
$$+2\cos\left[\frac{b}{2}\right]\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\mathrm{d}\theta,$$

$$\omega_L^6 = \sin[\theta]\left(\cos[\beta]\cos[\theta]\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\sin\left[\frac{b}{2}\right]+\sin[\beta]\cos\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\cos\left[\frac{b}{2}\right]\right)\mathrm{d}\alpha$$
$$-\cos\left[\frac{b}{2}\right]\sin[\theta]\sin\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\mathrm{d}\beta+\frac{1}{2}\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\sin\left[\frac{b}{2}\right]\sin[2\theta]\mathrm{d}\gamma$$
$$-2\sin\left[\frac{b}{2}\right]\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\mathrm{d}\theta,$$

$$\omega_L^7 = \sin[\theta]\left(\cos[\beta]\cos[\theta]\sin\left[\frac{b}{2}\right]\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]-\cos\left[\frac{b}{2}\right]\sin[\beta]\sin\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\right)\mathrm{d}\alpha$$
$$-\cos\left[\frac{b}{2}\right]\cos\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\sin[\theta]\mathrm{d}\beta+\frac{1}{2}\sin\left[\frac{b}{2}\right]\sin[2\theta]\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]d\gamma$$
$$+2\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\sin\left[\frac{b}{2}\right]\mathrm{d}\theta,$$

$$\omega_L^8 = -\frac{\sqrt{3}}{2}\cos[\beta]\sin^2[\theta]\mathrm{d}\alpha-\frac{\sqrt{3}}{2}\sin^2[\theta]\mathrm{d}\gamma+2\,\mathrm{d}\phi.$$

b. The right-invariant 1-forms

$$\omega_R^1 = \sin[\alpha]\mathrm{d}\beta-\cos[\alpha]\sin[\beta]\mathrm{d}\gamma-\cos[\alpha]\sin[\beta]\left(1-\frac{1}{2}\sin^2[\theta]\right)\mathrm{d}a+\cos[\theta](\cos[a+\gamma]\sin[\alpha]$$
$$+\cos[\alpha]\cos[\beta]\sin[a+\gamma])\mathrm{d}b+\left(\cos[\theta]\sin[b](-\cos[\alpha]\cos[\beta]\cos[a+\gamma]+\sin[\alpha]\sin[a+\gamma])\right.$$
$$\left.-\cos[\alpha]\cos[b]\sin[\beta]\left(1-\frac{1}{2}\sin^2[\theta]\right)\right)\mathrm{d}c+\sqrt{3}\cos[\alpha]\sin[\beta]\sin^2[\theta]\mathrm{d}\phi,$$

$$\omega_R^2 = \cos[\alpha]\mathrm{d}\beta+\sin[\alpha]\sin[\beta]\mathrm{d}\gamma+\sin[\alpha]\sin[\beta]\left(1-\frac{1}{2}\sin^2[\theta]\right)\mathrm{d}a+\cos[\theta]\big(\cos[\alpha]\cos[a+\gamma]$$
$$-\cos[\beta]\sin[\alpha]\sin[a+\gamma]\big)\mathrm{d}b+\left[\cos[\theta]\sin[b](\cos[\beta]\cos[a+\gamma]\sin[\alpha]+\cos[\alpha]\sin[\alpha+\gamma])\right.$$
$$\left.+\cos[b]\sin[\alpha]\sin[\beta]\left(1-\frac{1}{2}\sin^2[\theta]\right)\right]\mathrm{d}c-\sqrt{3}\sin[\alpha]\sin[\beta]\sin^2[\theta]\mathrm{d}\phi$$

$$\omega_R^3 = \mathrm{d}\alpha + \cos[\beta]\mathrm{d}\gamma + \cos[\beta]\left(1 - \frac{1}{2}\sin^2\theta\right)\mathrm{d}a + \cos[\theta]\sin[\beta]\sin[a+\gamma]\mathrm{d}b$$
$$+ \left[\cos[b]\cos[\beta]\left(1 - \frac{1}{2}\sin^2[\theta]\right) - \cos[a+\gamma]\cos[\theta]\sin[b]\sin[\beta]\right]\mathrm{d}c - \sqrt{3}\cos[\beta]\sin^2[\theta]\mathrm{d}\phi,$$

$$\omega_R^4 = 2\cos\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha+\gamma}{2}\right]\mathrm{d}\theta - \frac{1}{2}\cos\left[\frac{\beta}{2}\right]\cos\left[\frac{\alpha+\gamma}{2}\right]\sin[2\theta]\mathrm{d}a$$
$$- \sin\left[\frac{\beta}{2}\right]\sin\left[a - \frac{\alpha-\gamma}{2}\right]\sin[\theta]\mathrm{d}b + \sin[\theta]\left(\cos\left[a - \frac{\alpha-\gamma}{2}\right]\sin[b]\sin\left[\frac{\beta}{2}\right]\right.$$
$$\left. - \cos[b]\cos\left[\frac{\beta}{2}\right]\cos[\theta]\cos\left[\frac{\alpha+\gamma}{2}\right]\right)\mathrm{d}c - \sqrt{3}\cos\left[\frac{\beta}{2}\right]\cos\left[\frac{\alpha+\gamma}{2}\right]\sin[2\theta]\mathrm{d}\phi,$$

$$\omega_R^5 = \cos\left[\frac{\beta}{2}\right]\cos\left[\frac{\alpha+\gamma}{2}\right]\mathrm{d}\theta + \frac{1}{2}\cos\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha+\gamma}{2}\right]\sin[2\theta]\mathrm{d}a + \cos\left[a - \frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\sin[\theta]\mathrm{d}b$$
$$+ \sin[\theta]\left(\sin[b]\sin\left[\frac{\beta}{2}\right]\sin\left[a - \frac{\alpha-\gamma}{2}\right] + \cos[b]\cos\left[\frac{\beta}{2}\right]\cos[\theta]\sin\left[\frac{\alpha+\gamma}{2}\right]\right)\mathrm{d}c$$
$$+ \sqrt{3}\cos\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha+\gamma}{2}\right]\sin[2\theta]\mathrm{d}\phi,$$

$$\omega_R^6 = 2\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha-\gamma}{2}\right]\mathrm{d}\theta + \frac{1}{2}\cos\left[\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\sin[2\theta]\mathrm{d}a$$
$$- \cos\left[\frac{\beta}{2}\right]\sin\left[a + \frac{\alpha+\gamma}{2}\right]\sin[\theta]\mathrm{d}b + \sin[\theta]\left(\cos\left[\frac{\beta}{2}\right]\cos\left[a + \frac{\alpha+\gamma}{2}\right]\sin[b]\right.$$
$$\left. + \cos[b]\cos[\theta]\cos\left[\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\right)\mathrm{d}c + \sqrt{3}\cos\left[\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\sin[2\theta]\mathrm{d}\phi,$$

$$\omega_R^7 = -2\cos\left[\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\mathrm{d}\theta + \frac{1}{2}\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha-\gamma}{2}\right]\sin[2\theta]\mathrm{d}a$$
$$+ \cos\left[\frac{\beta}{2}\right]\cos\left[a + \frac{\alpha-\gamma}{2}\right]\sin[\theta]\mathrm{d}b + \sin[\theta]\left(\cos\left[\frac{\beta}{2}\right]\sin[b]\sin\left[a + \frac{\alpha+\gamma}{2}\right]\right.$$
$$\left. + \cos[b]\cos[\theta]\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha-\gamma}{2}\right]\right)\mathrm{d}c + \sqrt{3}\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha-\gamma}{2}\right]\sin[2\theta]\mathrm{d}\phi,$$

$$\omega_R^8 = -\frac{\sqrt{3}}{2}\sin^2[\theta]\mathrm{d}a - \frac{\sqrt{3}}{2}\cos[b]\sin^2[\theta]\mathrm{d}c + (2 - 3\sin^2[\theta])\mathrm{d}\phi.$$

3. The basis of the invariant vector fields on the SU(3) group

The expressions for the left-invariant vector fields basis in the Euler angles coordinate frame are given below

a. The left-invariant vector fields

$$X_1^L = \frac{\cos[c]}{\sin[b]}\frac{\partial}{\partial a} - \sin[c]\frac{\partial}{\partial b} - \cot[b]\cos[c]\frac{\partial}{\partial c},$$

$$X_2^L = \frac{\sin[c]}{\sin[b]}\frac{\partial}{\partial a} + \cos[c]\frac{\partial}{\partial b} - \cot[b]\sin[c]\frac{\partial}{\partial c},$$

$$X_3^L = \frac{\partial}{\partial c},$$

$$\begin{aligned}X_4^L = &-\frac{\sin\left[\frac{b}{2}\right]}{\sin[\beta]\sin[\theta]}\cos\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\alpha} + \frac{\sin\left[\frac{b}{2}\right]}{\sin[\theta]}\sin\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\beta}\\ &+\left(\frac{\sin\left[\frac{b}{2}\right]}{\sin[\theta]}\cot[\beta]\cos\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right] + \frac{2\cos\left[\frac{b}{2}\right]}{\sin[2\theta]}\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\right)\frac{\partial}{\partial\gamma}\\ &-\frac{1}{2}\cos\left[\frac{b}{2}\right]\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right] - \frac{1}{2}\left(\frac{\cot[\theta]}{\cos\left[\frac{b}{2}\right]} + \cos\left[\frac{b}{2}\right]\tan[\theta]\right)\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial a}\\ &+\cot[\theta]\sin\left[\frac{b}{2}\right]\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial b} - \frac{\cot[\theta]}{2\cos\left[\frac{b}{2}\right]}\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial c}\\ &+\frac{\sqrt{3}}{4}\cos\left[\frac{b}{2}\right]\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\tan[\theta]\frac{\partial}{\partial\phi},\end{aligned}$$

$$\begin{aligned}X_5^L = &\frac{\sin\left[\frac{b}{2}\right]}{\sin[\beta]\sin[\theta]}\sin\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\alpha} + \frac{\sin\left[\frac{b}{2}\right]}{\sin[\theta]}\cos\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\beta}\\ &+\left(\frac{\sin\left[\frac{b}{2}\right]}{\sin[\theta]}\cot[\beta]\sin\left[\frac{a-c}{2}+\gamma-\sqrt{3}\phi\right] - \frac{2\cos\left[\frac{b}{2}\right]}{\sin[2\theta]}\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\right)\frac{\partial}{\partial\gamma}\\ &+\frac{1}{2}\cos\left[\frac{b}{2}\right]\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial\theta} - \frac{1}{2}\left(\frac{\cot[\theta]}{\cos\left[\frac{b}{2}\right]} + \cos\left[\frac{b}{2}\right]\tan[\theta]\right)\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial a}\\ &-\cos\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\cot[\theta]\sin\left[\frac{b}{2}\right]\frac{\partial}{\partial b} - \frac{\cot[\theta]}{2\cos\left[\frac{b}{2}\right]}\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial c}\\ &+\frac{\sqrt{3}}{4}\cos\left[\frac{b}{2}\right]\sin\left[\frac{a+c}{2}+\sqrt{3}\phi\right]\tan[\theta]\frac{\partial}{\partial\phi},\end{aligned}$$

$$X_6^L = +\frac{\cos\left[\frac{b}{2}\right]}{\sin[\beta]\sin[\theta]}\cos\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\alpha}-\frac{\cos\left[\frac{b}{2}\right]}{\sin[\theta]}\sin\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\beta}$$
$$-\left(\frac{\cos\left[\frac{b}{2}\right]}{\sin[\theta]}\cot[\beta]\cos\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]-\frac{2\sin\left[\frac{b}{2}\right]}{\sin[2\theta]}\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\right)\frac{\partial}{\partial\gamma}$$
$$-\frac{1}{2}\sin\left[\frac{b}{2}\right]\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial\theta}-\frac{1}{2}\left(\frac{\cot[\theta]}{\sin\left[\frac{b}{2}\right]}+\sin\left[\frac{b}{2}\right]\tan[\theta]\right)\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial a}$$
$$-\cos\left[\frac{b}{2}\right]\cot[\theta]\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial b}+\frac{\cot[\theta]}{2\sin\left[\frac{b}{2}\right]}\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial c}$$
$$+\frac{\sqrt{3}}{4}\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\sin\left[\frac{b}{2}\right]\tan[\theta]\frac{\partial}{\partial\phi},$$

$$X_7^L = -\frac{\cos\left[\frac{b}{2}\right]}{\sin[\beta]\sin[\theta]}\sin\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\alpha}-\frac{\cos\left[\frac{b}{2}\right]}{\sin[\theta]}\cos\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]\frac{\partial}{\partial\beta}$$
$$+\left(\frac{\cos\left[\frac{b}{2}\right]}{\sin[\theta]}\cot[\beta]\sin\left[\frac{a+c}{2}+\gamma-\sqrt{3}\phi\right]+\frac{2\sin\left[\frac{b}{2}\right]}{\sin[2\theta]}\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\right)\frac{\partial}{\partial\gamma}$$
$$+\frac{1}{2}\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\sin\left[\frac{b}{2}\right]\frac{\partial}{\partial\theta}-\frac{1}{2}\left(\frac{\cot[\theta]}{\sin\left[\frac{b}{2}\right]}+\sin\left[\frac{b}{2}\right]\tan[\theta]\right)\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial a}$$
$$+\cos\left[\frac{b}{2}\right]\cos\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\cot[\theta]\frac{\partial}{\partial b}+\frac{\cot[\theta]}{2\sin\left[\frac{b}{2}\right]}\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\frac{\partial}{\partial c}$$
$$+\frac{\sqrt{3}}{4}\sin[b]\sin\left[\frac{a-c}{2}+\sqrt{3}\phi\right]\tan[\theta]\frac{\partial}{\partial\phi},$$

$$X_8^L = \frac{1}{2}\frac{\partial}{\partial\phi}.$$

b. The right-invariant vector fields

$$X_1^R = \cos[\alpha]\cot[\beta]\frac{\partial}{\partial\alpha}+\sin[\alpha]\frac{\partial}{\partial\beta}-\frac{\cos[\alpha]}{\sin[\beta]}\frac{\partial}{\partial\gamma},$$

$$X_2^R = -\sin[\alpha]\cot[\beta]\frac{\partial}{\partial\alpha}+\cos[\alpha]\frac{\partial}{\partial\beta}+\frac{\sin[\alpha]}{\sin[\beta]}\frac{\partial}{\partial\gamma},$$

$$X_3^R = \frac{\partial}{\partial\alpha},$$

$$X_4^R = \frac{\cot[\theta]}{2\cos\left[\frac{\beta}{2}\right]}\cos\left[\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial\alpha} - \cot[\theta]\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial\beta} + \cos\left[\frac{\alpha+\gamma}{2}\right]\left(\frac{\cot[\theta]}{2\cos\left[\frac{\beta}{2}\right]}\right.$$
$$\left. - \cos\left[\frac{\beta}{2}\right]\tan[\theta]\right)\frac{\partial}{\partial\gamma} + \frac{1}{2}\cos\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial\theta} - \left(\frac{\cot[b]}{\sin[\theta]}\cos\left[a-\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\right.$$
$$\left. + \frac{\cos\left[\frac{\beta}{2}\right]}{\sin[2\theta]}\cos\left[\frac{\alpha+\gamma}{2}\right](2-3\sin^2[\theta])\right)\frac{\partial}{\partial a} - \frac{\sin\left[\frac{\beta}{2}\right]}{\sin[\theta]}\sin\left[a-\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial b}$$
$$+ \frac{\sin\left[\frac{\beta}{2}\right]}{\sin[b]\sin[\theta]}\cos\left[a-\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial c} - \frac{\sqrt{3}}{4}\cos\left[\frac{\beta}{2}\right]\cos\left[\frac{\alpha+\gamma}{2}\right]\tan[\theta]\frac{\partial}{\partial\phi},$$

$$X_5^R = -\frac{\cot[\theta]}{2\cos\left[\frac{\beta}{2}\right]}\sin\left[\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial\alpha} - \cos\left[\frac{\alpha+\gamma}{2}\right]\cot[\theta]\sin\left[\frac{\beta}{2}\right]\frac{\partial}{\partial\beta} - \sin\left[\frac{\alpha+\gamma}{2}\right]\left(\frac{\cot[\theta]}{2\cos\left[\frac{\beta}{2}\right]}\right.$$
$$\left. - \cos\left[\frac{\beta}{2}\right]\tan[\theta]\right)\frac{\partial}{\partial\gamma} + \frac{1}{2}\cos\left[\frac{\beta}{2}\right]\cos\left[\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial\theta} - \left(\frac{\cot[b]}{\sin[\theta]}\sin\left[a-\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\right.$$
$$\left. - \frac{\cos\left[\frac{\beta}{2}\right]}{\sin[2\theta]}\sin\left[\frac{\alpha+\gamma}{2}\right](2-3\sin^2[\theta])\right)\frac{\partial}{\partial a} + \frac{\sin\left[\frac{\beta}{2}\right]}{\sin[\theta]}\cos\left[a-\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial b}$$
$$+ \frac{\sin\left[\frac{\beta}{2}\right]}{\sin[b]\sin[\theta]}\sin\left[a-\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial c} + \frac{\sqrt{3}}{4}\cos\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha+\gamma}{2}\right]\tan[\theta]\frac{\partial}{\partial\phi},$$

$$X_6^R = \frac{\cot[\theta]}{2\sin\left[\frac{\beta}{2}\right]}\cos\left[\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial\alpha} + \cos\left[\frac{\beta}{2}\right]\cot[\theta]\sin\left[\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial\beta} - \cos\left[\frac{\alpha-\gamma}{2}\right]$$
$$\times\left(\frac{\cot[\theta]}{2\sin\left[\frac{\beta}{2}\right]} - \sin\left[\frac{\beta}{2}\right]\tan[\theta]\right)\frac{\partial}{\partial\gamma} + \frac{1}{2}\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial\theta}$$
$$- \left(\frac{\cot[b]}{\sin[\theta]}\cos\left[a+\frac{\alpha+\gamma}{2}\right]\cos\left[\frac{\beta}{2}\right] - \frac{\sin\left[\frac{\beta}{2}\right]}{\sin[2\theta]}\cos\left[\frac{\alpha-\gamma}{2}\right](2-3\sin^2[\theta])\right)\frac{\partial}{\partial a}$$
$$- \frac{\cos\left[\frac{\beta}{2}\right]}{\sin[\theta]}\sin\left[a+\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial b} + \frac{\cos\left[\frac{\beta}{2}\right]}{\sin[b]\sin[\theta]}\cos\left[a+\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial c}$$
$$+ \frac{\sqrt{3}}{4}\cos\left[\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\tan[\theta]\frac{\partial}{\partial\phi},$$

$$X_7^R = \frac{\cot[\theta]}{2\sin\left[\frac{\beta}{2}\right]}\sin\left[\frac{\alpha-\gamma}{2}\right]\frac{\partial}{\partial\alpha} - \cos\left[\frac{\beta}{2}\right]\cos\left[\frac{\alpha-\gamma}{2}\right]\cot[\theta]\frac{\partial}{\partial\beta} - \sin\left[\frac{\alpha-\gamma}{2}\right]\left(\frac{\cot[\theta]}{2\sin\left[\frac{\beta}{2}\right]}\right.$$

$$\left. - \sin\left[\frac{\beta}{2}\right]\tan[\theta]\right)\frac{\partial}{\partial\gamma} - \frac{1}{2}\cos\left[\frac{\alpha-\gamma}{2}\right]\sin\left[\frac{\beta}{2}\right]\frac{\partial}{\partial\theta} - \left(\frac{\cot[b]}{\sin[\theta]}\cos\left[\frac{\beta}{2}\right]\sin\left[a+\frac{\alpha+\gamma}{2}\right]\right.$$

$$\left. - \frac{\sin\left[\frac{\beta}{2}\right]}{\sin[2\theta]}\sin\left[\frac{\alpha-\gamma}{2}\right](2-3\sin^2[\theta])\right)\frac{\partial}{\partial a} + \frac{\cos\left[\frac{\beta}{2}\right]}{\sin[\theta]}\cos\left[a+\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial b}$$

$$+ \frac{\cos\left[\frac{\beta}{2}\right]}{\sin[b]\sin[\theta]}\sin\left[a+\frac{\alpha+\gamma}{2}\right]\frac{\partial}{\partial c} + \frac{\sqrt{3}}{4}\sin\left[\frac{\beta}{2}\right]\sin\left[\frac{\alpha-\gamma}{2}\right]\tan[\theta]\frac{\partial}{\partial\phi},$$

$$X_8^R = \sqrt{3}\frac{\partial}{\partial\gamma} - \sqrt{3}\frac{\partial}{\partial a} + \frac{1}{2}\frac{\partial}{\partial\phi}.$$

We construct the nonequilibrium Glauber dynamics as a Markov process in configuration space for an infinite particle system in continuum with a general class of initial distributions. This class we define in terms of correlation functions bounds and it is preserved during the Markov evolution we constructed. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2354589]

I. INTRODUCTION

The theory of stochastic lattice gases on the cubic lattice $\mathbb{Z}^d$, $d \in \mathbb{N}$ is one of the most important and well-developed areas in the theory of interacting particle systems. In the lattice gas model with spin space $S=\{0,1\}$, the configuration space is defined as $\mathcal{X}=\{0,1\}^{\mathbb{Z}^d}$. For a given $\sigma=\{\sigma(x)|x\in\mathbb{Z}^d\}\in\mathcal{X}$ we say that a lattice side $y\in\mathbb{Z}^d$ is free or occupied by a particle depending on $\sigma(y)=0$ or $\sigma(y)=1$, respectively.

In the Glauber-type stochastic dynamics of the lattice gas particles randomly disappear from occupied sites or appear at free places of the lattice. Obviously, this dynamics may be interpreted as a birth-and-death process on $\mathbb{Z}^d$. The generator of this dynamics is given by

$$(Lf)(\sigma)=\sum_{x\in\mathbb{Z}^d} a(x,\sigma)(\nabla_x f)(\sigma),$$

where

$$(\nabla_x f)(\sigma)=f(\sigma^x)-f(\sigma),$$

σ^x denoting the configuration σ in which the particle at site x has changed its spin value. The rate function $a(x,\sigma)$ is taken in such a way that an *a priori* given measure on $\mathcal{X}$ (say, a Gibbs measure for the Ising model) is a symmetrizing measure for the Glauber generator L, see, e.g., Ref. 17.

Let us consider a continuous particle system, i.e., a system of particles which can take any position in the Euclidean space $\mathbb{R}^d$. The configuration space Γ for such system is the set of all locally finite subsets $\gamma\subset\mathbb{R}^d$. An analog of the discussed lattice stochastic dynamics should be a process in which particles randomly appear and disappear in the space, i.e., a spatial birth-and-death process. The generator of such a process is informally given by the formula

[a)]Electronic mail: kondrat@math.uni-bielefeld.de
[b)]Electronic mail: kutoviy@math.uni-bielefeld.de
[c)]Electronic mail:ejj@iitp.ru

$$(LF)(\gamma) = \sum_{x \in \gamma} d(x,\gamma)(D_x^- F)(\gamma) + \int_{\mathbb{R}^d} b(x,\gamma)(D_x^+ F)(\gamma)\mathrm{d}x, \tag{1}$$

where

$$(D_x^- F)(\gamma) = F(\gamma \setminus x) - F(\gamma), \quad (D_x^+ F)(\gamma) = F(\gamma \cup x) - F(\gamma).$$

Here and in the following, for simplicity of notation, we just write x instead of $\{x\}$. The coefficient $d(x,\gamma)$ describes the rate at which the particle x of the configuration γ dies, while $b(x,\gamma)$ describes the rate at which, given the configuration γ, a new particle is born at x.

Spatial birth-and-death processes were first discussed by Preston in Ref. 19. Under some conditions on the birth and death rates, Preston proved the existence of such processes in a bounded domain in $\mathbb{R}^d$. Though the number of particles can be arbitrarily large in this case, the total number of particles remains finite at any moment of time. The study of the problem of construction of a spatial birth-and-death process in the infinite volume was initiated by Holley and Stroock in Ref. 5. In fact, in that paper, birth-and-death processes in bounded domains were analyzed in detail. Only in a very special case of nearest-neighbor birth-and-death processes on the real line was the existence of a corresponding process on the whole space proved and its properties were studied.

Glötzl[4] derived conditions on the coefficients $d(x,\gamma)$, $b(x,\gamma)$, under which the birth-and-death generators are symmetric in the space $\mathrm{L}^2(\mu)$, where μ is a given Gibbs measure. Such generators are natural to call Glauber dynamics generators (corresponding to the equilibrium state μ). However, the problem of the existence of such dynamics was left open. In Ref. 2, Bertini, Cancrini, and Cesi studied the problem of the existence of a spectral gap for the Glauber dynamics in a bounded domain in $\mathbb{R}^d$. Bertini *et al.* considered the Glauber dynamics with death coefficient $d(x,\gamma)=1$.

By using the theory of Dirichlet forms, an analog of the Glauber dynamics from Ref. 2, but on the whole space (thus, involving infinite configurations) and for quite general pair potentials, was constructed in Ref. 11. A general class of Glauber dynamics in continuum which admits a much wider family of birth and death rates (again in the framework of the Dirichlet forms theory) was considered in Ref. 12.

All papers mentioned deal with so-called equilibrium stochastic dynamics, which gives an existence result for almost all starting configurations with respect to the *a priori* given stationary measure. The latter means that we can start our Markov process with any initial measure which is absolutely continuous with respect to the symmetrizing one. In applications, however, we need to analyze the time development for different classes of initial states of the system. These states can be very far from the equilibrium ones and the equilibrium stochastic dynamics (coming from the Dirichlet forms method) is not enough for the construction of their evolution.

In the present paper we propose a construction of the nonequilibrium Glauber dynamics in continuum. Namely, we describe a set of initial distributions on Γ such that for any initial measure μ_0 from this class there exists a Markov process with considered Glauber generator $X_t^{\mu_0} \in \Gamma$ starting with μ_0. Moreover, the distribution μ_t of this process at the time $t>0$ is again in the same class of measures on Γ. Our construction is based on a general approach to the study of infinite particle dynamics using techniques of the harmonic analysis on configuration spaces developed in Ref. 8. More precisely, we start with the Kolmogorov equation corresponding to our Glauber dynamics. That is an evolutional equation on functions defined on the configuration space Γ which are called observables in the terminology of mathematical physics. An application of the combinatorial Fourier transform from Ref. 8 gives instead of this infinite dimensional evolution equation an infinite family of finite dimensional equations for so-called quasiobservables. This infinite system of equations admits a natural description in terms of a Fock-type structure. This structure is nothing but an L^1-Fock space with a fixed family of weight functions. Properly taking these weights we are able to apply perturbation techniques to the considered evolution equation in the L^1-Fock space and to construct a related semigroup. The dual semigroup gives then the time evolution of the correlation functions of the initial measure and due to a reconstruction theorem

from Ref.8 we can obtain an evolution of the initial measure. The latter solve the dual Kolmogorov equation and it is the main step in the construction of the nonequilibrium Glauber dynamics we are considering.

Let $\mathcal{M}_{\mathrm{corr}}$ be the class of probability measures on Γ whose correlation functions exist and satisfy Ruelle-type bound (the explicit description of this class of measures will be given in Sec. VI). Then, the main result of this paper can be formulated as follows

Theorem 1.1: *For any* $\mu \in \mathcal{M}_{\mathrm{corr}}$ *there exists a Markov process* $X_t^{\mu} \in \Gamma$ *with initial distribution* μ *associated with the generator* (1).

Note that the evolution of the correlation functions in the Glauber dynamics is described by a system of equations which give a dynamical version of the celebrated Kirkwood-Salsburg system of equations for an equilibrium state of the model. Solving this system we need to check a property of a positive definiteness for the solution in the sense of Refs. 1 and 8. This moment is usually outside of the attention in theoretical physics considerations of time evolutions for correlation functions. But this positive definiteness is a necessary (and together with a growth condition also sufficient) condition on correlation functions which relates them to a measure on Γ. Actually, the verification of this condition is one of the main difficulties in the above described approach.

II. GENERAL FACTS AND NOTATIONS

Let $\mathbb{R}^d$ be the d-dimensional Euclidean space. By $\mathcal{O}(\mathbb{R}^d)$, $\mathcal{B}(\mathbb{R}^d)$ we denote the family of all open and Borel sets, respectively. $\mathcal{O}_b(\mathbb{R}^d)$, $\mathcal{B}_b(\mathbb{R}^d)$ denote the system of all sets in $\mathcal{O}(\mathbb{R}^d)$, $\mathcal{B}(\mathbb{R}^d)$, respectively, which are bounded. The space of n-point configuration is

$$\Gamma_0^{(n)} = \Gamma_{0,\mathbb{R}^d}^{(n)} := \{\eta \subset \mathbb{R}^d \,|\, |\eta| = n\}, \quad n \in \mathbb{N}_0 := \mathbb{N} \cup \{0\},$$

where $|A|$ denotes the cardinality of the set A. Analogously the space $\Gamma_{0,\Lambda}^{(n)}$ is defined for $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, which we denote for short by $\Gamma_{\Lambda}^{(n)}$.

For every $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ one can define a mapping $N_\Lambda : \Gamma_0^{(n)} \to \mathbb{N}_0$; $N_\Lambda(\eta) := |\eta \cap \Lambda|$. For short we write $\eta_\Lambda := \eta \cap \Lambda$. As a set, $\Gamma_0^{(n)}$ is equivalent to the symmetrization of

$$\widetilde{(\mathbb{R}^d)^n} = \{(x_1, \ldots, x_n) \in (\mathbb{R}^d)^n \,|\, x_k \neq x_l \quad \text{if } k \neq l\},$$

i.e., $\widetilde{(\mathbb{R}^d)^n}/S_n$, where S_n is the permutation group over $\{1, \ldots, n\}$. Hence $\Gamma_0^{(n)}$ inherits the structure of an $n \cdot d$-dimensional manifold. Applying this we can introduce a topology $\mathcal{O}(\Gamma_0^{(n)})$ on $\Gamma_0^{(n)}$. The corresponding Borel σ-algebra $\mathcal{B}(\Gamma_0^{(n)})$ coincides with $\sigma(N_\Lambda \,|\, \Lambda \in \mathcal{B}_b(\mathbb{R}^d))$.

The space of finite configurations

$$\Gamma_0 := \bigsqcup_{n \in \mathbb{N}_0} \Gamma_0^{(n)}$$

is equipped with the topology of disjoint union $\mathcal{O}(\Gamma_0)$. A set $B \in \mathcal{B}(\Gamma_0)$ (the corresponding Borel σ-algebra) is called bounded if there exists a $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ and an $N \in \mathbb{N}$ such that $B \subset \bigsqcup_{n=0}^{N} \Gamma_{\Lambda}^{(n)}$.

The configuration space

$$\Gamma := \{\gamma \subset \mathbb{R}^d \,|\, |\gamma \cap \Lambda| < \infty, \quad \text{for all } \Lambda \in \mathcal{B}_b(\mathbb{R}^d)\}$$

is equipped with the vague topology. The Borel σ-algebra $\mathcal{B}(\Gamma)$ is equal to the smallest σ-algebra for which all the mappings $N_\Lambda : \Gamma \to \mathbb{N}_0$, $N_\Lambda(\gamma) := |\gamma \cap \Lambda|$ are measurable, i.e.,

$$\mathcal{B}(\Lambda) = \sigma(N_\Lambda | \Lambda \in \mathcal{B}_b(\mathbb{R}^d))$$

and filtration on Γ given by

$$\mathcal{B}_\Lambda(\Gamma) := \sigma(N_{\Lambda'} | \Lambda' \in \mathcal{B}_b(\mathbb{R}^d), \Lambda' \subset \Lambda).$$

For every $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ one can define a projection $p_\Lambda : \Gamma \to \Gamma_\Lambda$,

$$p_\Lambda(\gamma) := \gamma_\Lambda$$

and with respect to this projection Γ is the projective limit of the spaces $\{\Gamma_\Lambda\}_{\Lambda \in \mathcal{B}_b(\mathbb{R}^d)}$.

In the sequel we will use the following classes of function: $\mathrm{L}^0(\Gamma_0)$ is the set of all measurable functions on Γ_0 and $\mathrm{L}^0_{\mathrm{ls}}(\Gamma_0)$ is the set of measurable functions which have additionally a local support, i.e., $G \in \mathrm{L}^0_{\mathrm{ls}}(\Gamma_0)$ if there exists $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ such that $G\restriction_{\Gamma_0 \setminus \Gamma_\Lambda} = 0$. $\mathrm{L}^0_{\mathrm{bs}}(\Gamma_0)$ denotes the class of measurable functions with bounded support, $B(\Gamma_0)$ the set of bounded measurable functions, and $B_{\mathrm{bs}}(\Gamma_0)$ the set of bounded functions with bounded support. For any $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, the class of functions $G \in B_{\mathrm{bs}}(\Gamma_0)$, whose support is a subset of Λ,will be denoted by $B^\Lambda_{\mathrm{bs}}(\Gamma_0)$. The class of continuous functions from $B^\Lambda_{\mathrm{bs}}(\Gamma_0)$ will be denoted by $CB^\Lambda_{\mathrm{bs}}(\Gamma_0)$.

On Γ we consider the set of a cylinder functions $\mathcal{F}\mathrm{L}^0(\Gamma)$, i.e., the set of all measurable functions $G \in \mathrm{L}^0(\Gamma)$ which are measurable with respect to $\mathcal{B}_\Lambda(\Gamma)$ for some $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$. These functions are characterized by the following relation: $F(\gamma) = F\restriction_{\Gamma_\Lambda}(\gamma_\Lambda)$.

Next we would like to describe some facts from harmonic analysis on configuration space based on Refs. 8 and 9.

The following mapping between functions on Γ_0, e.g., $\mathrm{L}^0_{\mathrm{ls}}(\Gamma_0)$, and functions on Γ, e.g., $\mathcal{F}L^0(\Gamma)$, plays a key role in our further considerations:

$$KG(\gamma) := \sum_{\xi \Subset \gamma} G(\xi), \quad \gamma \in \Gamma,$$

where $G \in \mathrm{L}^0_{\mathrm{ls}}(\Gamma_0)$, see, e.g., Refs. 15 and 16. The summation in the latter expression is extended over all finite subconfigurations of γ, in symbols $\xi \Subset \gamma$.

K is linear, positivity preserving, and invertible, with

$$K^{-1}F(\eta) := \sum_{\xi \subset \eta} (-1)^{|\eta \setminus \xi|} F(\xi), \quad \eta \in \Gamma_0. \tag{2}$$

It is easy to see that for all $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, $F \in \mathcal{F}\mathrm{L}^0(\Gamma, \mathcal{B}_\Lambda(\Gamma))$,

$$K^{-1}F(\eta) = \mathbb{1}_{\Gamma_\Lambda}(\eta) K^{-1}F(\eta), \quad \forall\ \eta \in \Gamma_0. \tag{3}$$

One can introduce a convolution

$$\star : \mathrm{L}^0(\Gamma_0) \times \mathrm{L}^0(\Gamma_0) \to \mathrm{L}^0(\Gamma_0)$$

$$(G_1, G_2) \mapsto (G_1 \star G_2)(\eta) := \sum_{(\xi_1, \xi_2, \xi_3) \in \mathcal{P}^3_\emptyset(\eta)} G_1(\xi_1 \cup \xi_2) G_2(\xi_2 \cup \xi_3), \tag{4}$$

where $\mathcal{P}^3_\emptyset(\eta)$ denotes the set of all partitions (ξ_1, ξ_2, ξ_3) of η in three parts, i.e., all triples (ξ_1, ξ_2, ξ_3) with $\xi_i \subset \eta$, $\xi_i \cap \xi_j = \emptyset$ if $i \neq j$, and $\xi_1 \cup \xi_2 \cup \xi_3 = \eta$. It has the property that for $G_1, G_2 \in \mathrm{L}^0_{\mathrm{ls}}(\Gamma_0)$ we have $K(G_1 \star G_2) = KG_1 \cdot KG_2$. Due to this convolution we can interpret K transform as Fourier transform in configuration space analysis, see also Ref. 1.

Let $\mathcal{M}^1_{\mathrm{fm}}(\Gamma)$ be the set of all probability measures μ which have finite local moments of all orders, i.e., $\int_\Gamma |\gamma_\Lambda|^n \mu(\mathrm{d}\gamma) < +\infty$ for all $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ and $n \in \mathbb{N}_0$. A measure ρ on Γ_0 is called locally finite iff $\rho(A) < \infty$ for all bounded sets A from $\mathcal{B}(\Gamma_0)$, the set of such measures is denoted by $\mathcal{M}_{\mathrm{lf}}(\Gamma_0)$. One can define a transform $K^* : \mathcal{M}^1_{\mathrm{fm}}(\Gamma) \to \mathcal{M}_{\mathrm{lf}}(\Gamma_0)$, which is dual to the K-transform, i.e., for every $\mu \in \mathcal{M}^1_{\mathrm{fm}}(\Gamma)$, $G \in \mathcal{B}_{\mathrm{bs}}(\Gamma_0)$ we have

$$\int_\Gamma KG(\gamma) \mu(\mathrm{d}\gamma) = \int_{\Gamma_0} G(\eta) (K^*\mu)(\mathrm{d}\eta).$$

$\rho_\mu := K^*\mu$ we call the correlation measure corresponding to μ.

As shown in Ref. 8 for $\mu \in \mathcal{M}^1_{\mathrm{fm}}(\Gamma)$ and any $G \in \mathrm{L}^1(\Gamma_0, \rho_\mu)$ the series

$$KG(\gamma) := \sum_{\eta \Subset \gamma} G(\eta) \tag{5}$$

is μ-a.s. absolutely convergent. Furthermore, $KG \in \mathrm{L}^1(\Gamma, \mu)$ and

$$\int_{\Gamma_0} G(\eta)\rho_\mu(\mathrm{d}\eta) = \int_{\Gamma} (KG)(\gamma)\mu(\mathrm{d}\gamma). \tag{6}$$

Fix a nonatomic and locally finite measure σ on $(\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d))$. For any $n \in \mathbb{N}$ the product measure $\sigma^{\otimes n}$ can be considered by restriction as a measure on $\widetilde{(\mathbb{R}^d)^n}$ and hence on $\Gamma_0^{(n)}$. The measure on $\Gamma_0^{(n)}$ we denote by $\sigma^{(n)}$.

The *Lebesgue-Poisson measure* $\lambda_{z\sigma}$ on Γ_0 is defined as

$$\lambda_{z\sigma} := \sum_{n=0}^{\infty} \frac{z^n}{n!}\sigma^{(n)}.$$

Here $z > 0$ is the so-called activity parameter. The restriction of $\lambda_{z\sigma}$ to Γ_Λ will be also denoted by $\lambda_{z\sigma}$.

The *Poisson measure* $\pi_{z\sigma}$ on $(\Gamma, \mathcal{B}(\Gamma))$ is given as the projective limit of the family of measures $\{\pi_{z\sigma}^\Lambda\}_{\Lambda \in \mathcal{B}_b(\mathbb{R}^d)}$, where $\pi_{z\sigma}^\Lambda$ is the measure on Γ_Λ defined by $\pi_{z\sigma}^\Lambda := e^{-z\sigma(\Lambda)}\lambda_{z\sigma}$.

A measure $\mu \in \mathcal{M}_{\mathrm{fm}}^1(\Gamma)$ is called locally absolutely continuous with respect to $\pi_{z\sigma}$ iff $\mu_\Lambda := \mu \circ p_\Lambda^{-1}$ is absolutely continuous to $\pi_{z\sigma}^\Lambda = \pi_{z\sigma} \circ p_\Lambda^{-1}$ for all $\Lambda \in \mathcal{B}_\Lambda(\mathbb{R}^d)$. In this case $\rho_\mu := K^*\mu$ is absolutely with respect to $\lambda_{z\sigma}$. We denote by $k_\mu(\eta) := (\mathrm{d}\rho_\mu / \mathrm{d}\lambda_{z\sigma})(\eta)$, $\eta \in \Gamma_0$. For σ - Lebesgue measure on $\mathbb{R}^d$ we will write λ_z instead of $\lambda_{z\sigma}$.

The functions

$$k_\mu^{(n)} : (\mathbb{R}^d)^n \to \mathbb{R}_+,$$

$$k_\mu^{(n)}(x_1, \ldots, x_n) := \begin{cases} k_\mu(\{x_1, \ldots, x_n\}) & \text{if } (x_1, \ldots, x_n) \in \widetilde{(\mathbb{R}^d)^n} \\ 0 & \text{otherwise} \end{cases} \tag{7}$$

are well-known correlation functions of statistical physics, see, e.g. Refs. 22 and 21.

Let us now recall the so-called Minlos lemma which plays a very important role in our calculations (c.f. Ref. 13).

Lemma 2.1: *Let* $n \geqslant 2$, *and* $z > 0$ *be given. Then*

$$\int_{\Gamma_0} \cdots \int_{\Gamma_0} G(\eta_1 \cup \ldots \cup \eta_n) H(\eta_1, \ldots, \eta_n) \mathrm{d}\lambda_z(\eta_1) \cdots \mathrm{d}\lambda_z(\eta_n)$$
$$= \int_{\Gamma_0} G(\eta) \sum_{(\eta_1, \ldots, \eta_n) \in \mathcal{P}_n(\eta)} H(\eta_1, \ldots, \eta_n) \mathrm{d}\lambda_z(\eta)$$

for all measurable functions $G : \Gamma_0 \mapsto \mathbb{R}$ *and* $H : \Gamma_0 \times \ldots \times \Gamma_0 \mapsto \mathbb{R}$ *with respect to which both sides of the equality make sense. Here* $\mathcal{P}_n(\eta)$ *denotes the set of all partitions of* η *in n parts, which may be empty*.

III. POTENTIAL AND GIBBS MEASURES ON CONFIGURATION SPACES

A pair potential is a Borel, even function $\phi : \mathbb{R}^d \mapsto \mathbb{R} \cup \{+\infty\}$. We assume that ϕ satisfies the following conditions.

(**I**) (Integrability) For any $\beta > 0$,

$$C(\beta) := \int_{\mathbb{R}^d} |1 - \exp[-\beta\phi(x)]| \mathrm{d}x < \infty .$$

(**P**) (Positivity) $\phi(x) > 0$ for all $x \in \mathbb{R}^d$.

For $\gamma \in \Gamma$ and $x \in \mathbb{R}^d \setminus \gamma$, we define a relative energy of interaction as follows:

$$E(x,\gamma) := \begin{cases} \sum_{y\in\gamma} \phi(x-y) & \text{if } \sum_{y\in\gamma} |\phi(x-y)| < \infty \\ +\infty & \text{otherwise.} \end{cases}$$

The energy of configuration $\eta \in \Gamma_0$ or Hamiltonian $E^\phi: \Gamma_0 \to \mathbb{R} \cup \{+\infty\}$ which corresponds to potential ϕ is defined by

$$E^\phi(\eta) = \sum_{\{x,y\}\subset\eta} \phi(x-y), \eta \in \Gamma_0, |\eta| \geqslant 2.$$

The Hamiltonian $E^\phi_\Lambda: \Gamma_\Lambda \to \mathbb{R}$ for $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ which corresponds to potential ϕ is defined by

$$E^\phi_\Lambda(\eta) = \sum_{\{x,y\}\subset\eta} \phi(x-y), \eta \in \Gamma_\Lambda, |\eta| \geqslant 2.$$

For fixed ϕ we will write for short $E = E^\phi$ and $E_\Lambda = E^\phi_\Lambda$.

For given $\bar\gamma \in \Gamma$ define the interaction energy between $\eta \in \Gamma_\Lambda$ and $\bar\gamma_{\Lambda^c} = \bar\gamma \cap \Lambda^c$, $\Lambda^c = \mathbb{R}^d \setminus \Lambda$ as

$$W_\Lambda(\eta|\bar\gamma) = \sum_{x\in\eta, y\in\bar\gamma_{\Lambda^c}} \phi(x-y).$$

The interaction energy is said to be well-defined if for any $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, $\eta \in \Gamma_\Lambda$ and $\bar\gamma \in \Gamma$ it is finite or $+\infty$.

For $\beta > 0$ we define

$$E_\Lambda(\eta|\bar\gamma) = E_\Lambda(\eta) + W_\Lambda(\eta|\bar\gamma)$$

and

$$Z_\Lambda(\bar\gamma) := \int_{\Gamma_\Lambda} \exp\{-\beta E_\Lambda(\eta|\bar\gamma)\} \lambda_z(\mathrm{d}\eta),$$

the so-called partition function.

Let $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, $\beta > 0$ be arbitrary, and let $\bar\gamma \in \Gamma$. The finite volume Gibbs measure on the space Γ_Λ with boundary configuration $\bar\gamma$ is defined by

$$\mathrm{P}_{\Lambda,\bar\gamma}(\mathrm{d}\eta) = \frac{\exp\{-\beta E_\Lambda(\eta|\bar\gamma)\}}{Z_\Lambda(\bar\gamma)} \lambda_z(\mathrm{d}\eta).$$

When $\bar\gamma = \emptyset$, let $\mathrm{P}_{\Lambda,\emptyset}(\mathrm{d}\eta) =: \mathrm{P}_\Lambda(\mathrm{d}\eta)$.

Let $\{\pi_\Lambda\}$ denote the specification associated with z and the Hamiltonian E (see Ref. 18) which is defined by

$$\pi_{\Lambda,\bar\gamma}(A) = \int_{A'} \mathrm{P}_{\Lambda,\bar\gamma}(\mathrm{d}\eta),$$

where $A' = \{\eta \in \Gamma_\Lambda : \eta \cup (\bar\gamma_{\Lambda^c}) \in A\}$, $A \in \mathcal{B}(\Gamma)$ and $\bar\gamma \in \Gamma$.

A probability measure μ on Γ is called a Gibbs measure for E and z if

$$\mu(\pi_{\Lambda,\bar\gamma}(A)) = \mu(A)$$

for every $A \in \mathcal{B}(\Gamma)$ and every $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$.

This relation is the well-known (*DLR*)-equation (Dobrushin-Lanford-Ruelle equation), see Ref. 3 for more details.

The set of all Gibbs measures which corresponds to the potential ϕ, activity parameter $z>0$, and inverse temperature $\beta>0$ will be denoted by $\mathcal{G}(\phi,z,\beta)$. For fixed potential ϕ we will write $\mathcal{G}(z,\beta)$ instead of $\mathcal{G}(\phi,z,\beta)$.

Remark 3.1: *The set* $\mathcal{G}(\phi,z,\beta)$ *is nonempty for all* $z>0$, $\beta>0$ *and any potential* ϕ *satisfying* (**P**) *and* (**I**), *see Ref.* 14.

IV. GENERATORS: THE SYMBOL OF THE GLAUBER GENERATOR ON THE SPACE OF FINITE CONFIGURATIONS

We consider a Markov pregenerator on the configuration space Γ, the action of which is given by

$$(LF)(\gamma) := (L_{b,d}F)(\gamma) = \sum_{x\in\gamma} d(x,\gamma\setminus x)D_x^- F(\gamma) + \int_{\mathbb{R}^d} b(x,\gamma)D_x^+ F(\gamma)\mathrm{d}x,$$

where $D_x^- F(\gamma)=F(\gamma\setminus x)-F(\gamma)$ and $D_x^+ F(\gamma)=F(\gamma\cup x)-F(\gamma)$.

It is known that the Gibbs measure $\mu\in\mathcal{G}(z,\beta)$ is reversible with respect to the Markov process associated with the generator L (i.e., the operator L is symmetrical in $\mathrm{L}^2(\Gamma,\mu)$) iff the following condition on coefficients b and d (birth and death rates) holds:

$$b(x,\gamma) = ze^{-\beta E(x,\gamma)}d(x,\gamma). \tag{8}$$

In the sequel we will be interested only in particular cases of birth and death rates, which play an essential role in the study of some problems of mathematical physics:

$$b(x,\gamma) = ze^{-\beta E(x,\gamma)}, \quad d(x,\gamma) = 1.$$

Such model was investigated by many authors, see, e.g. Refs. 13 and 11. The corresponding Markov generator we denote by the same symbol L.

For technical reasons we will also be interested in the birth and death rates localized in some volume $\Lambda\in\mathcal{B}(\mathbb{R}^d)$. Namely,

$$b_\Lambda(x,\gamma) = z\mathbb{1}_\Lambda(x)e^{-\beta E(x,\gamma_\Lambda)}, \quad d_\Lambda(x,\gamma) = \mathbb{1}_\Lambda(x).$$

We denote the corresponding Markov generator by L_Λ.

In a recent paper,[13] the authors have shown that in the case of equilibrium Glauber dynamics with invariant measure $\mu\in\mathcal{G}(z,\beta)$, corresponding to the pair potential, the image of L under the K-transform (or symbol of the operator L) has the following form:

$$(\hat{L}G)(\eta) := (K^{-1}LKG)(\eta) = L_0G(\eta) + L_1G(\eta), \quad G\in B_{\mathrm{bs}}(\Gamma_0),$$

where

$$L_0G(\eta) := -|\eta|G(\eta)$$

and

$$L_1G(\eta) := z\sum_{\xi\subset\eta}\int_{\mathbb{R}^d} G(\xi\cup x)\prod_{y\in\eta\setminus\xi}(e^{-\beta\phi(x-y)}-1)\prod_{y'\in\xi}e^{-\beta\phi(x-y')}\mathrm{d}x.$$

Analogously, one can show that the symbol of L_Λ has form

$$(\widehat{L_\Lambda} G)(\eta) := (K^{-1} L_\Lambda K G)(\eta) = -|\eta_\Lambda| G(\eta) + z \sum_{\xi \subset \eta} \int_\Lambda G(\xi \cup x) \prod_{y \in \eta \setminus \xi} (e^{-\beta \phi(x-y) 1_\Lambda(y)} - 1) \times e^{-\beta E(x, \xi_\Lambda)} \mathrm{d}x, \quad G \in B_{\mathrm{bs}}(\Gamma_0).$$

V. CONSTRUCTION OF A SEMIGROUP OF THE SYMBOL

Let λ be the Lebesgue-Poisson measure on Γ_0 with activity parameter equal to 1. In the whole section we suppose that potential ϕ satisfies conditions (**P**) and (**I**).

For arbitrary and fixed $C>0$ and $\beta>0$, we consider operator $\hat{L}$ as a pregenerator of some nonequilibrium Markov process in the functional space

$$\mathcal{L}_{C,\beta} := \mathrm{L}^1(\Gamma_0, C^{|\eta|} e^{-\beta E(\eta)} \lambda(\mathrm{d}\eta)). \tag{9}$$

In this section, $\|\cdot\|$ stands for the norm of the space (9) and $\overset{s}{\to}$ denotes strong convergence in $\mathcal{L}_{C,\beta}$.

For any $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ we set

$$\mathcal{L}^\Lambda_{C,\beta} := \{G \in \mathcal{L}_{C,\beta} | \Gamma \restriction_{\Gamma_0 \setminus \Gamma_\Lambda} = 0\}. \tag{10}$$

It is not difficult to show that $\mathcal{L}^\Lambda_{C,\beta}$ is a closed linear subset in $(\mathcal{L}_{C,\beta}, \|\cdot\|)$. Therefore, $(\mathcal{L}^\Lambda_{C,\beta}, \|\cdot\|)$ is a subspace of $(\mathcal{L}_{C,\beta}, \|\cdot\|)$.

For any $\omega>0$ we introduce a set $\mathcal{H}(\omega,0)$ of all densely defined closed operators T on $\mathcal{L}_{C,\beta}$, the resolvent set $\rho(T)$ of which contains sector

$$\mathrm{Sect}\left(\frac{\pi}{2} + \omega\right) := \left\{\xi \in \mathbb{C} \middle| |\arg \zeta| < \frac{\pi}{2} + \omega\right\}, \quad \omega > 0$$

and for any $\varepsilon>0$,

$$\|(T - \zeta \mathbb{1})^{-1}\| \leqslant \frac{M_\varepsilon}{|\zeta|}, \quad |\arg \zeta| \leqslant \frac{\pi}{2} + \omega - \varepsilon,$$

where M_ε does not depend on ζ.

Let $\mathcal{H}(\omega, \theta)$, $\theta \in \mathbb{R}$ denote the set of all operators of the form $T = T_0 + \theta$ with $T_0 \in \mathcal{H}(\omega,0)$.

Remark 5.1: *It is well known (see e.g., Ref. 7), that any $T \in \mathcal{H}(\omega, \theta)$ is a generator of a semigroup $U(t)$ which is holomorphic in the sector $|\arg t| < \omega$. The function $U(t)$ is not necessary uniformly bounded, but it is quasibounded, i.e.*,

$$\|U(t)\| \leqslant \mathrm{const} |e^{\theta t}|$$

in any sector of the form $|\arg t| \leqslant \omega - \varepsilon$.

Proposition 5.1: *For any $C>0$ and $\beta>0$, the operator*

$$(L_0 G)(\eta) = -|\eta| G(\eta), \quad D(L_0) = \{G \in \mathcal{L}_{C,\beta} | |\eta| G(\eta) \in \mathcal{L}_{C,\beta}\}$$

is a generator of contraction semigroup on $\mathcal{L}_{C,\beta}$. Moreover, $L_0 \in \mathcal{H}(\omega,0)$, for all $\omega \in (0, \pi/2)$.

Proof: It is not difficult to show that L_0 is a densely defined and closed operator in $\mathcal{L}_{C,\beta}$.

Let $0 < \omega < \pi/2$ be arbitrary and fixed. It is clear that for all $\zeta \in \mathrm{Sect}(\pi/2 + \omega)$,

$$||\eta| + \zeta| > 0, \quad \eta \in \Gamma_0.$$

Therefore, for any $\zeta \in \mathrm{Sect}(\pi/2 + \omega)$ the inverse operator $(L_0 - \zeta \mathbb{1})^{-1}$, the action of which is given by

$$[(L_0-\zeta\mathbb{1})^{-1}G](\eta)=-\frac{1}{|\eta|+\zeta}G(\eta), \tag{11}$$

is well defined on the whole space $\mathcal{L}_{C,\beta}$. Moreover, it is bounded operator in this space and

$$\|(L_0-\zeta\mathbb{1})^{-1}\|\leqslant\begin{cases}\dfrac{1}{|\zeta|} & \text{if } \operatorname{Re}\zeta\geqslant 0\\[2ex] \dfrac{M}{|\zeta|} & \text{if } \operatorname{Re}\zeta<0,\end{cases} \tag{12}$$

where constant M does not depend on ζ.

The case $\operatorname{Re}\zeta\geqslant 0$ is a direct consequence of (11) and inequality

$$|\eta|+\operatorname{Re}\zeta\geqslant\operatorname{Re}\zeta\geqslant 0.$$

We prove now bound (12) in the case $\operatorname{Re}\zeta<0$. Using (11), we have

$$\|(L_0-\zeta\mathbb{1})^{-1}G\|=\left\|\frac{1}{||\cdot|+\zeta|}G(\cdot)\right\|=\frac{1}{|\zeta|}\left\|\frac{|\zeta|}{||\cdot|+\zeta|}G(\cdot)\right\|.$$

Since $\zeta\in\operatorname{Sect}(\pi/2+\omega)$,

$$|\operatorname{Im}\zeta|\geqslant|\zeta|\left|\sin\left(\frac{\pi}{2}+\omega\right)\right|=|\zeta|\cos\omega.$$

Hence,

$$\frac{|\zeta|}{||\eta|+\zeta|}\leqslant\frac{|\zeta|}{|\operatorname{Im}\zeta|}\leqslant\frac{1}{\cos\omega}=:M$$

and (12) is fulfilled.

The rest statement of the lemma now follows directly from the theorem of Hille-Yosida (see e.g., Ref. 7).

Let $\kappa>0$ be the parameter of the considered model.

We now consider the operator

$$(L_1G)(\eta)=(L_{1,\beta,\kappa}G)(\eta)=\kappa\sum_{\xi\subseteq\eta}\int_{\mathbb{R}^d}G(\xi\cup x)\prod_{y\in\eta\setminus\xi}(e^{-\beta\phi(x-y)}-1)e^{-\beta E(x,\xi)}\mathrm{d}x,\quad G\in D(L_1)$$

with domain $D(L_1):=D(L_0)$. The well-definiteness of this operator will be clear from the following lemma.

For the symbol of the operator L we will sometimes write $\widehat{L_{\beta,\kappa}}$ instead of $\hat{L}$ to stress the dependence of this operator on $\kappa>0$ and $\beta>0$.

Lemma 5.1: *For any* $\delta>0$ *there exists* $\kappa_0:=\kappa_0(\delta)>0$ *such that for all* $\kappa<\kappa_0$ *the following estimate holds*:

$$\|L_{1,\beta,\kappa}G\|\leqslant a\|L_0G\|+b\|G\|,\quad G\in D(L_0)=D(L_1), \tag{13}$$

with $a=a(\kappa)<\delta$ *and* $b=b(\kappa)<\delta$.

Proof: As 1 belongs to the resolvent set of L_0 we have

$$\|L_1(L_0-\mathbb{1})^{-1}G\|=\kappa\int_{\Gamma_0}|L_1(L_0-\mathbb{1})^{-1}G(\eta)|C^{|\eta|}e^{-\beta E(\eta)}\lambda(\mathrm{d}\eta). \tag{14}$$

Define

$$K(x,\eta) := \prod_{y\in\eta\setminus x} |e^{-\beta\phi(x-y)} - 1|,\ x \in \mathbb{R}^d, \quad \eta \in \Gamma_0,$$

then by modulus property (14) can be estimated by

$$\kappa \int_{\Gamma_0} \sum_{\xi\subseteq\eta} \int_{\mathbb{R}^d} \frac{|G(\xi\cup x)|}{|\xi\cup x|+1} K(x,\eta\setminus\xi) e^{-\beta E(x,\xi)} \mathrm{d}x C^{|\eta|} e^{-\beta E(\eta)} \lambda(\mathrm{d}\eta). \tag{15}$$

By the Minlos lemma, (15) is equal to

$$\kappa \int_{\Gamma_0}\int_{\Gamma_0}\int_{\mathbb{R}^d} \frac{|G(\xi\cup x)|}{|\xi\cup x|+1} K(x,\eta) e^{-\beta E(x,\xi)} \mathrm{d}x C^{|\eta\cup\xi|} e^{-\beta E(\eta\cup\xi)} \lambda(\mathrm{d}\xi)\lambda(\mathrm{d}\eta).$$

Using again the Minlos lemma we bound the latter expression by

$$\kappa \int_{\Gamma_0}\int_{\Gamma_0} \frac{|G(\xi)|}{|\xi|+1} \sum_{x\in\xi} K(x,\eta) e^{-\beta E(x,\xi\setminus x)} C^{|\eta\cup(\xi\setminus x)|} e^{-\beta E(\eta\cup(\xi\setminus x))} \lambda(\mathrm{d}\xi)\lambda(\mathrm{d}\eta).$$

Since

$$E(x,\xi\setminus x) = E(\xi) - E(\xi\setminus x)$$

and since positivity of ϕ implies

$$E(\eta\cup(\xi\setminus x)) - E(\xi\setminus x) \geqslant 0$$

we have

$$\begin{aligned}\|L_1(L_0-\mathbb{1})^{-1}G\| &\leqslant \kappa \int_{\Gamma_0} \frac{|G(\xi)|}{|\xi|+1} C^{|\xi|} e^{-\beta E(\xi)} \sum_{x\in\xi} \int_{\Gamma_0} K(x,\eta) C^{|\eta\cup(\xi\setminus x)|-|\xi|} \lambda(\mathrm{d}\eta)\lambda(\mathrm{d}\xi) \\ &\leqslant \kappa \int_{\Gamma_0} \frac{|G(\xi)|}{|\xi|+1} C^{|\xi|} e^{-\beta E(\xi)} \sum_{x\in\xi} \int_{\Gamma_0} K(x,\eta) C^{|\eta|-1} \lambda(\mathrm{d}\eta)\lambda(\mathrm{d}\xi).\end{aligned}$$

Finally,

$$\|L_1(L_0-1)^{-1}G\| \leqslant \kappa C^{-1} e^{C(\beta)C} \|G\|.$$

Therefore,

$$\|L_1 G\| \leqslant \kappa C^{-1} e^{C(\beta)C} \|(L_0-1)G\| \leqslant a\|L_0 G\| + b\|G\|,$$

where

$$a = b := \kappa C^{-1} e^{C(\beta)C}.$$

It is clear that taking

$$\kappa_0 = \delta C e^{-C(\beta)C}$$

we obtain that $a, b < \delta$. ■

Theorem 5.1: *For any $C>0$, and for all $\kappa,\beta>0$ which satisfy*

$$2\kappa \exp(C(\beta)C) < C, \tag{16}$$

the operator $\widehat{L_{\beta,\kappa}}$ a generator of a holomorphic semigroup in $\mathcal{L}_{C,\beta}$.

Proof: The statement of theorem follows directly from the theorem about perturbation of holomorphic semigroup (see, e.g. Ref. 7). For the reader's convenience, in the following we give its formulation:

for any $T \in \mathcal{H}(\omega,\theta)$ *and for any* $\varepsilon>0$ *there exists positive constants* ϵ, δ *such that if operator* A *satisfies*

$$\|Au\| \leqslant a\|Tu\| + b\|u\|, \quad u \in D(T) \subset D(A),$$

with $a<\delta, b<\delta$, *then* $T+A \in \mathcal{H}(\omega-\varepsilon,\epsilon)$.

In particular, if $\delta=0$ *and* $b=0$, *then* $T+A \in \mathcal{H}(\omega-\varepsilon,0)$. ■

Remark 5.2: *Due to Proposition* 5.1, *the operator* $L_0 \in \mathcal{H}(\omega,0)$, *for any* $\omega \in (0,\pi/2)$. *Since we are not interested yet in the domain of analyticity for the corresponding semigroup* (*which depends on* ω) *we consider* ω *close to* 0 *in order to get the best possible bound for the resolvent of* L_0. *Now, together with the proof of the theorem on holomorphic semigroups' perturbation* (*see, e.g., Ref.* 7), *one can conclude that the largest* δ *in this theorem applying to our case can be chosen to be* $\frac{1}{2}$.

For our further purposes we have to show that the holomorphic semigroup constructed in Theorem 5.1 can be approximated by the semigroups localized in bounded volumes.

Let $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ be arbitrary and fixed. Then all results proved in this section hold true for the operator $\widehat{L_\Lambda}$ acting in the functional space $\mathcal{L}^\Lambda_{C,\beta}$ with domain

$$D(\widehat{L_\Lambda}) := \{G \in \mathcal{L}_{C,\beta} \| \cdot_\Lambda | G(\cdot) \in \mathcal{L}^\Lambda_{C,\beta}\}.$$

Namely, the main result can be formulated as follows

Theorem 5.2: *For any* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, *and any triple of constants* $C,\kappa>0$, *and* $\beta>0$ *which satisfy*

$$2\kappa \exp(C(\beta)C) < C,$$

the operator $\widehat{L_\Lambda}$ *is a generator of a holomorphic semigroup in* $\mathcal{L}^\Lambda_{C,\beta}$.

Remark 5.3: *The arguments, analogous to those which were proposed in the proof of Lemma 5.1, imply the fulfilment of* (13) *for the operators*

$$\widehat{L_{0,\Lambda}} G(\eta) := -|\eta_\Lambda| G(\eta)$$

and

$$\widehat{L_{1,\Lambda}} G(\eta) := \kappa \sum_{\xi \subset \eta} \int_\Lambda G(\xi \cup x) \prod_{y \in \eta \setminus \xi} (e^{-\beta\phi(x-y)\mathbb{1}_\Lambda(y)} - 1) \prod_{y' \in \xi_\Lambda} e^{-\beta\phi(x-y')} \mathrm{d}x$$

with

$$D(\widehat{L_{0,\Lambda}}) = D(\widehat{L_{1,\Lambda}}) := \{G \in \mathcal{L}_{C,\beta} \| \cdot_\Lambda | G(\cdot) \in \mathcal{L}^\Lambda_{C,\beta}\}.$$

Moreover, bound (13) *in this case will be uniform with respect to the* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, *i.e., coefficients* $a>0$ *and* $b>0$ *in* (13) *can be chosen* Λ *independent.*

Fix any triple of positive constants C, κ, and β which satisfies (16) and any $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$.

Remark 5.4: *Let* $\widehat{U^\Lambda_t}(C,\beta,\kappa)$ *be holomorphic semigroup generated by operator* $(\widehat{L^\Lambda}, D(\widehat{L^\Lambda}))$ *on* $\mathcal{L}^\Lambda_{C,\beta}$. *Then* $\widehat{U^\Lambda_t}(C,\beta,\kappa)\circ P_\Lambda, t \geqslant 0$, *where*

$$P_\Lambda G(\eta) := \mathbb{1}_{\Gamma_\Lambda}(\eta) G(\eta), \quad G \in \mathcal{L}_{C,\beta}$$

is a semigroup on $\mathcal{L}_{C,\beta}$ *generated by the operator* $\widehat{L_\Lambda}\circ P_\Lambda$ *with domain*

$$D(\widehat{L_\Lambda}\circ P_\Lambda) := \{G \in \mathcal{L}_{C,\beta} \| \cdot_\Lambda | \mathbb{1}_{\Gamma_\Lambda}(\cdot) G(\cdot) \in \mathcal{L}_{C,\beta}\}.$$

Remark 5.5: *The theorem about perturbation of the generator of a holomorphic semigroup, mentioned before in this section* (*see also Ref.* 7), *implies that for any* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ *and* $\varepsilon>0$ *there*

exists $\epsilon>0$ *and constant* $M>0$ *which is not dependent on* Λ *such that for any* $\zeta>\epsilon$ *the following bound holds*:

$$\|(\widehat{L_\Lambda}\circ P_\Lambda-\zeta)^{-1}\|\leqslant\frac{M_\varepsilon}{|\zeta-\epsilon|},\quad |\arg(\zeta-\epsilon)|\leqslant\frac{\pi}{2}+\omega-\varepsilon.$$

Let $\{\Lambda_n\}_{n\geqslant 1}$ be a sequence of Borel sets such that $\Lambda_n\subset\Lambda_{n+1}$, for all $n\in\mathbb{N}$, and $\cup_{n\geqslant 1}\Lambda_n=\mathbb{R}^d$. Now, we formulate the following approximation theorem.

Theorem 5.3: *Let* $\hat{U}_t(C,\beta,\kappa)$ *and* $\{\widehat{U_t^{\Lambda_n}}(C,\beta,\kappa),n\geqslant 1\}$ *be holomorphic semigroups generated by* $\widehat{L_{\beta,\kappa}}$ *and* $\{\widehat{L_{\Lambda_n,\beta,\kappa}},n\geqslant 1\}$ *in the spaces* $\mathcal{L}_{C,\beta}$ *and* $\mathcal{L}^\Lambda_{C,\beta}$, *respectively. Then*,

$$\widehat{U_t^{\Lambda_n}}(C,\beta,\kappa)\circ P_{\Lambda_n}\overset{s}{\to}\hat{U}_t(C,\beta,\kappa),\quad n\to\infty$$

uniformly on any finite interval of $t\geqslant 0$.

Proof: Using approximation theorem for quasibounded semigroups (see, e.g., Ref. 7), it is enough to show that

$$(\widehat{L_{\Lambda_n,\beta,\kappa}}\circ P_{\Lambda_n}-\zeta)^{-1}\overset{s}{\to}(\widehat{L_{\beta,\kappa}}-\zeta)^{-1}$$

for some $\zeta\in\mathbb{C}$ such that $\operatorname{Re}\zeta>\theta$.

Let $\zeta\in\mathbb{C}$, $\operatorname{Re}\zeta>\theta$ be arbitrary and fixed. For any $G\in\mathcal{L}_{C,\beta}$ it holds

$$\|(\widehat{L_{\Lambda_n,\beta,\kappa}}\circ P_{\Lambda_n}-\zeta)^{-1}G-(\widehat{L_{\beta,\kappa}}-\zeta)^{-1}G\|=\|(\widehat{L_{\Lambda_n,\beta,\kappa}}\circ P_{\Lambda_n}-\zeta)^{-1}[\widehat{L_{\beta,\kappa}}-\widehat{L_{\Lambda_n,\beta,\kappa}}\circ P_{\Lambda_n}](\widehat{L_{\beta,\kappa}}-\zeta)^{-1}G\|. \tag{17}$$

For any $G\in D(\widehat{L_{\beta,\kappa}})=D(L_0)$,

$$\begin{aligned}[\widehat{L_{\beta,\kappa}}-\widehat{L_{\Lambda_n,\beta,\kappa}}\circ P_{\Lambda_n}]G(\eta)=&-|\eta|[1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\eta)]G(\eta)+\kappa\sum_{\xi\subseteq\eta}\int_{\Lambda_n^c}G(\xi\cup x)\prod_{y\in\eta\setminus\xi}[e^{-\beta\phi(x-y)}-1]\\&\times\prod_{y'\in\xi}e^{-\beta\phi(x-y')}\mathrm{d}x+\kappa\sum_{\xi\subseteq\eta}\int_{\Lambda_n}G(\xi\cup x)\prod_{y\in\eta\setminus\xi}[e^{-\beta\phi(x-y)}-1]e^{-\beta E(x,\xi)}\\&\times[1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\xi\cup x)\mathbb{1}_{\Gamma_{\Lambda_n}}(\eta\setminus\xi)e^{\beta E(x,\xi_{\Lambda_n^c})}]\mathrm{d}x,\end{aligned}$$

where $\Lambda_n^c=\mathbb{R}^d\setminus\Lambda_n$.

Using the fact that for any $\xi\in\Gamma_0$ and $x\in\mathbb{R}^d$,

$$\mathbb{1}_{\Gamma_{\Lambda_n}}(\xi\cup x)e^{\beta E(x,\xi_{\Lambda_n^c})}=\mathbb{1}_{\Gamma_{\Lambda_n}}(\xi\cup x),$$

the simple inequality

$$|1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\xi)\mathbb{1}_{\Gamma_{\Lambda_n}}(\eta)|\leqslant|1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\xi)|+|1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\eta)|,\quad \xi,\eta\in\Gamma_0,$$

and estimates analogous to those which were proposed in Lemma 5.1 we obtain

$$\begin{aligned}\|[\widehat{L_{\beta,\kappa}}-\widehat{L_{\Lambda_n,\beta,\kappa}}\circ P_{\Lambda_n}]G(\eta)\|\leqslant&(1+\kappa\max\{1,C^{-1}\}e^{C(\beta)C})\|[1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\cdot)]\|\cdot|G(\cdot)\|\\&+\kappa\max\{1,C^{-1}\}e^{C(\beta)C}\|\cdot_{\Lambda_n^c}|G(\cdot)\|+\max\{1,C^{-1}\}\|\cdot_{\Lambda_n}|G(\cdot)\|\\&\times\int_{\Gamma_{\Lambda_n}}|1-\mathbb{1}_{\Gamma_{\Lambda_n}}(\eta)|K(0,\eta)C^{|\eta|}\lambda(\mathrm{d}\eta).\end{aligned}$$

All of the summands on the right-hand side of the last inequality definitely tend to zero, when $n \to \infty$.

Using Remark 5.5 and equality (17) we easily conclude that difference in (17) also tends to zero when $n \to \infty$. ■

VI. CONSTRUCTION OF A NONEQUILIBRIUM MARKOV PROCESS

Fix any triple of positive constants C, κ, and β which satisfies (16). Let $\hat{U}_t(C,\beta,\kappa)$ be holomorphic semigroup generated by $\widehat{L_{\beta,\kappa}}$ and let

$$\mathcal{K}_{C,\beta} := \{k:\Gamma_0 \to \mathbb{R}_+ |\ k(\cdot)C^{-|\cdot|}e^{\beta E(\cdot)} \in \mathrm{L}^\infty(\Gamma_0,\lambda)\} \tag{18}$$

be the set of "so-called correlation functions." Note that $\mathcal{K}_{C,\beta}$ is a Banach space.

We introduce the following duality between quasiobservables $G \in \mathcal{L}_{C,\beta}$ and functions $k \in \mathcal{K}_{C,\beta}$,

$$\langle\langle G,k\rangle\rangle := \langle G,k\rangle_{\mathrm{L}^2(\Gamma_0,\lambda)}. \tag{19}$$

Let us mention that $G \in \mathcal{L}_{C,\beta}$ means that $G(\cdot)C^{|\cdot|}e^{-\beta E(\cdot)} \in \mathrm{L}^1(\Gamma_0,\lambda)$. Therefore, the duality

$$\langle G,k\rangle_{\mathrm{L}^2(\Gamma_0,\lambda)} = \int_{\Gamma_0} G(\eta)C^{|\eta|}e^{-\beta E(\eta)}k(\eta)C^{-|\eta|}e^{\beta E(\eta)}\mathrm{d}\lambda(\eta) < \infty$$

is well-defined.

Note also that $k(\cdot)C^{-|\cdot|}e^{\beta E(\cdot)} \in \mathrm{L}^\infty(\Gamma_0,\lambda)$ means that function k satisfies the following bound

$$k(\eta) \leqslant \mathrm{const}\ C^{|\eta|}e^{-\beta E(\eta)}, \tag{20}$$

which is known as *generalized Ruelle bound*, see, e.g., Ref. 10.

Using duality (19) one can easily show that semigroup $\hat{U}_t(C,\beta,\kappa)$ determines corresponding semigroup $\widehat{U_t^\star}(C,\beta,\kappa)$ on $\mathcal{K}_{C,\beta}$.

Next, we solve the following problem: suppose that $k_0 \in \mathcal{K}_{C,\beta}$ is a correlation function which means that there exists a probability measure $\mu_0 \in \mathcal{M}^1_{\mathrm{fm}}(\Gamma)$, locally absolutely continuous with respect to Poisson measure, whose correlation function is exactly k_0. Does evolution of k_0 with respect to the semigroup $\widehat{U_t^\star}(C,\beta,\kappa)$ preserve the above-described property? Namely, will $\widehat{U_t^\star}(C,\beta,\kappa)k_0$, for any moment of time $t>0$, be a correlation function or not?

In order to answer this problem, one can apply, for example, the theorem about characterization of correlation functions, proposed in Ref. 8. In the model under consideration, the conditions of this theorem, which must to be checked are the following:

$$\textit{for any } t \geqslant 0\text{: } \langle\langle G \star G, \widehat{U_t^\star}(C,\beta,\kappa)k_0\rangle\rangle \geqslant 0, \quad \forall\, G \in B_{\mathrm{bs}}(\Gamma_0).$$

Further explanations will be devoted to verifying the latter condition.

Let $\mu \in \mathcal{G}(\beta,z)$ and $\{\pi_{\Lambda,\varnothing}\}_{\Lambda \in \mathcal{B}_b(\mathbb{R}^d)}$ denote the specification with empty boundary conditions corresponding to the Gibbs measure μ. We define

$$\mathcal{E}(F,G) := \int_\Gamma \sum_{x \in \gamma} D_x^- F(\gamma) D_x^- G(\gamma)\pi_\Lambda(\mathrm{d}\gamma, \varnothing), \quad F,G \in KCB^\Lambda_{\mathrm{bs}}(\Gamma_0),$$

where $KCB^\Lambda_{\mathrm{bs}}(\Gamma_0)$ is K-image of $CB^\Lambda_{\mathrm{bs}}(\Gamma_0)$.

Now we would like to list some facts the proofs of which are completely analogous to those proposed in Ref. 11.

Lemma 6.1: *The set* $KCB^\Lambda_{\mathrm{bs}}(\Gamma_0)$ *is dense in* $\mathrm{L}^2(\Gamma,\pi_{\Lambda,\varnothing})$ *for any* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$.

Lemma 6.2: *Let* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ *be arbitrary and fixed. Then* $(\mathcal{E}, KCB^\Lambda_{\mathrm{bs}}(\Gamma_0))$ *is a well-defined bilinear form on* $\mathrm{L}^2(\Gamma,\pi_{\Lambda,\varnothing})$.

Lemma 6.3: *Let* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ *be arbitrary and fixed. Suppose that conditions* (**I**) *and* (**P**) *are satisfied. Then* $(L_\Lambda, KCB^\Lambda_{\rm bs}(\Gamma_0))$ *is an operator associated with bilinear form* $(\mathcal{E}, KCB^\Lambda_{\rm bs}(\Gamma_0))$ *in* $\mathrm{L}^2(\Gamma, \pi_{\Lambda,\varnothing})$, *i.e.*,

$$\mathcal{E}(F,G) = \int_\Gamma L_\Lambda F(\gamma) G(\gamma)\, \pi_{\Lambda,\varnothing}(\mathrm{d}\gamma), \quad F,G \in KCB^\Lambda_{\rm bs}(\Gamma_0).$$

Lemma 6.4: *Let* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ *be arbitrary and fixed. Suppose that conditions* (**I**) *and* (**P**) *are satisfied and* $\mu \in \mathcal{G}(z,\beta)$. *Then there exists a self-adjoint positive Friedrichs' extension* $(\widetilde{L_\Lambda}, D(\widetilde{L_\Lambda}))$ *of the operator* $(L_\Lambda, KCB^\Lambda_{\rm bs}(\Gamma_0))$ *in* $\mathrm{L}^2(\Gamma, \pi_{\Lambda,\varnothing})$. *Moreover*, $(\widetilde{L_\Lambda}, D(\widetilde{L_\Lambda}))$ *is a generator of a contraction semigroup which preserves* 1 *in* $\mathrm{L}^2(\Gamma, \pi_{\Lambda,\varnothing})$, *associated with some Markov process*.

Remark 6.1: *It is well known* (*see, e.g., Ref.* 20) *that under condition of Lemma 6.4 the semigroup generated by* $(\widetilde{L_\Lambda}, D(\widetilde{L_\Lambda}))$ *can be extended to the* $\mathrm{L}^1(\Gamma, \pi_{\Lambda,\varnothing})$. *For any* $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, *the extension of this semigroup in* $\mathrm{L}^1(\Gamma, \pi_{\Lambda,\varnothing})$ *we will denote by* $(\widetilde{U^\Lambda_t})_{t\geqslant 0}$. *For the generator of this semigroup we will use notation* $(\widetilde{L_\Lambda}, D_1(\widetilde{L_\Lambda}))$, *where* $D_1(\widetilde{L_\Lambda}) \supset D(\widetilde{L_\Lambda})$ *is a domain of* $\widetilde{L_\Lambda}$ in $\mathrm{L}^1(\Gamma, \pi_{\Lambda,\varnothing})$.

Now, we introduce one of the crucial lemmas about the evolution of the "so-called correlation function."

Lemma 6.5: *Let positive constants* C, κ, *and* β *which satisfy* (16) *be arbitrary and fixed. The semigroup* $\widehat{U^\star_t}(C,\beta,\kappa)$ *on* $\mathcal{K}_{C,\beta}$ *preserves positive semidefiniteness*, *i.e.*, *for any* $t \geqslant 0$,

$$\langle\langle G \star G, \widehat{U^\star_t}(C,\beta,\kappa) k\rangle\rangle \geqslant 0, \quad \forall\, G \in B_{\rm rs}(\Gamma_0)$$

iff

$$\langle\langle G \star G, k\rangle\rangle \geqslant 0, \tag{21}$$

for any $G \in B_{\rm bs}(\Gamma_0)$.

Remark 6.2: *Let* $\mathcal{M}_{C,\beta}$ *stand for the set of all probability measures on* Γ, *locally absolutely continuous with respect to Poisson measure*, *with locally finite moments*, *whose correlation functions satisfy bound* (20). *As it was pointed out at the beginning of this section*, *condition* (21) *on function* $k \in \mathcal{K}_{C,\beta}$, *ensures the existence of a unique measure* $\mu^k \in \mathcal{M}_{C,\beta}$ *whose correlation function is* k, *see Ref.* 8.

Proof of Lemma 6.5: Under assumptions of the lemma we have to show that for any $t \geqslant 0$,

$$\langle\langle \hat{U}_t(C,\beta,\kappa)(G \star G), k\rangle\rangle \geqslant 0, \quad \forall\, G \in B_{\rm bs}(\Gamma_0). \tag{22}$$

But $G \star G \in B_{\rm bs}(\Gamma_0)$ for any $G \in B_{\rm bs}(\Gamma_0)$. Therefore, due to Theorem 5.3 it is enough to show that for any $t \geqslant 0$ and any $G \in B_{\rm bs}(\Gamma_0)$ there exists $\Lambda' \in \mathcal{B}_b(\mathbb{R}^d)$ such that for all $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, $\Lambda \supset \Lambda'$,

$$\langle\langle \widehat{U^\Lambda_t}(C,\beta,\kappa) \circ P_\Lambda(G \star G), k\rangle\rangle \geqslant 0. \tag{23}$$

Let $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$ be arbitrary and fixed. We set

$$U^\Lambda_t := K \widehat{U^\Lambda_t}(C,\beta,\kappa) K^{-1}, \quad t \geqslant 0.$$

$(U^\Lambda_t)_{t\geqslant 0}$ is a semigroup on

$$\left(\mathcal{L}^\Lambda_1 := K\mathcal{L}^\Lambda_{C,\beta}, \|\cdot\|_1 := \left\|K^{-1}\cdot\right\|_{\mathcal{L}_{C,\beta}}\right),$$

which is the Banach space. Moreover, it is not difficult to show that a generator of this semigroup coincides with $(L_\Lambda, KD(\widehat{L_\Lambda}))$.

Proposition 6.1: *For any* $F \in \mathcal{L}_1^\Lambda \subset \mathrm{L}^1(\Gamma, \pi_{\Lambda,\varnothing})$,

$$U_t^\Lambda F = \widetilde{U_t^\Lambda} F, \quad t \geqslant 0 \text{ in } \mathrm{L}^1(\Gamma, \pi_{\Lambda,\varnothing}).$$

Proof: The fact that $(L_\Lambda, KD(\widehat{L_\Lambda})$ is a generator of $(U_t^\Lambda)_{t\geqslant 0}$ in $(\mathcal{L}_1^\Lambda, \|\cdot\|_1)$ means the following (see, e.g., Ref. 6)

$$\left\| U_t^\Lambda F - \left(1 - \frac{t}{n} L_\Lambda\right)^{-n} F \right\|_1 \to 0, \quad n \to \infty \quad \text{for all } F \in \mathcal{L}_1^\Lambda.$$

Because $\|\cdot\|_1 \geqslant \|\cdot\|$, the latter fact implies

$$\left\| U_t^\Lambda F - \left(1 - \frac{t}{n} L_\Lambda\right)^{-n} F \right\| \to 0, \quad n \to \infty \quad \text{for all } F \in \mathcal{L}_1^\Lambda. \tag{24}$$

Analogously, the fact that $(\widetilde{L_\Lambda}, D_1(\widetilde{L_\Lambda}))$ is a generator of $(\widetilde{U_t^\Lambda})_{t\geqslant 0}$ gives us

$$\left\| \widetilde{U_t^\Lambda} F - \left(1 - \frac{t}{n} \widetilde{L_\Lambda}\right)^{-n} F \right\| \to 0, \quad n \to \infty \quad \text{for all } F \in \mathcal{L}_1^\Lambda. \tag{25}$$

As was shown before, there exists $\epsilon > 0$ such that for any real $\zeta > \varepsilon$ and any $F \in \mathcal{L}_1^\Lambda$,

$$(\widetilde{L_\Lambda} - \zeta 1)^{-1} F - (L_\Lambda - \zeta 1)^{-1} F = (\widetilde{L_\Lambda} - \zeta 1)^{-1} [L_\Lambda - \widetilde{L_\Lambda}](L_\Lambda - \zeta 1)^{-1} F.$$

The function $F_\zeta := (L_\Lambda - \zeta 1)^{-1} F \in KD(\widetilde{L_\Lambda})$. Hence, $[L_\Lambda - \widetilde{L_\Lambda}] F_\zeta = 0$. The latter fact means that

$$\left\| \widetilde{U_t^\Lambda} F - \left(1 - \frac{t}{n} \widetilde{L_\Lambda}\right)^{-n} F \right\| = \left\| \widetilde{U_t^\Lambda} F - \left(1 - \frac{t}{n} L_\Lambda\right)^{-n} F \right\| \to 0, \quad n \to \infty \quad \text{for all } F \in \mathcal{L}_1^\Lambda. \tag{26}$$

The convergence (24) and (25) imply the assertion of the proposition. ■

Corollary 6.1: *Lemma* 6.4 *implies that for any moment of time* $t \geqslant 0$,

$$U_t^\Lambda F \geqslant 0 \quad \textit{for all } F \geqslant 0 \text{ in } \mathrm{L}^1(\Gamma, \pi_{\Lambda,\varnothing}). \tag{27}$$

Let $t \geqslant 0$ and $G \in B_{\mathrm{bs}}(\Gamma_0)$ be arbitrary and fixed. Suppose that $N' \in \mathbb{N}$ and $\Lambda' \in \mathcal{B}_b(\mathbb{R}^d)$ are such that

$$G \star G \restriction_{\Gamma_0 \setminus \sqcup_{n=0}^{N'} \Gamma_{\Lambda'}^{(n)}} = 0.$$

Then, $K(G \star G) = |KG|^2 \in \mathcal{L}_1^\Lambda$ for all $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, $\Lambda \subset \Lambda'$. Moreover, $P_\Lambda |KG|^2 = |KG|^2$.

Hence, the left-hand side of (23) for any $\Lambda \in \mathcal{B}_b(\mathbb{R}^d)$, $\Lambda \supset \Lambda'$ is equal to the following expression:

$$\langle\langle \widehat{U_t^\Lambda}(C, \beta, \kappa) \circ P_\Lambda (G \star G), k \rangle\rangle = \int_\Gamma K \widehat{U_t^\Lambda}(G \star G)(\gamma) \mu^k(\mathrm{d}\gamma) = \int_\Gamma U_t^\Lambda K(G \star G)(\gamma) \mu^k(\mathrm{d}\gamma)$$

$$= \int_{\Gamma_\Lambda} U_t^\Lambda |KG|^2(\gamma) \mu_\Lambda^k(\mathrm{d}\gamma),$$

where μ_Λ^k is a projection of μ^k on Γ_Λ. Let us mention that measure μ^k is locally absolutely continuous with respect to Poisson measure π. Therefore,

$$\langle\langle \widehat{U_t^\Lambda}(C, \beta, \kappa) \circ P_\Lambda (G \star G), k \rangle\rangle = \int_{\Gamma_\Lambda} U_t^\Lambda |KG|^2(\gamma) \frac{\mathrm{d}\mu_\Lambda^k}{\mathrm{d}\pi_\Lambda}(\gamma) \pi_\Lambda(\mathrm{d}\eta).$$

Corollary 6.1 implies that there exist set $S \subset \Gamma$, $\pi_{\Lambda,\varnothing}(S) = 0$ such that for all $\gamma \in \Gamma \setminus S$:

$$U_t^{\Lambda}|KG|^2(\gamma) \geqslant 0.$$

But $\pi_{\Lambda,\varnothing}$ is absolutely continuous with respect to π_Λ. Furthermore, the corresponding Radon-Nikodim derivative is positive almost surely with respect to π_Λ. Hence, $\pi_\Lambda(S_\Lambda)=0$, where S_Λ is a projection of the set S to Γ_Λ, and

$$\langle\langle \widehat{U_t^{\Lambda}}(C,\beta,\kappa)\circ P_\Lambda(G\star G),k\rangle\rangle = \int_{\Gamma_\Lambda\setminus S_\Lambda} U_t^{\Lambda}|KG|^2(\gamma)\frac{\mathrm{d}\mu_\Lambda^k}{\mathrm{d}\pi_\Lambda}(\gamma)\pi_\Lambda(\mathrm{d}\eta) \geqslant 0.$$

The latter proof the assertion of Lemma 6.5. ■

The result obtained in Lemma 6.5 and the fact about characterization of correlation functions from Ref. 8 imply the following corollary.

Corollary 6.2: *Let positive constants C, κ, and β which satisfy (16) be arbitrary and fixed. Let $k\in\mathcal{K}_{C,\beta}$ be such that $\langle\langle G\star G,k\rangle\rangle\geqslant 0$, for any $G\in B_{\mathrm{bs}}(\Gamma_0)$. Then for any $t\geqslant 0$ there exists unique measure $\mu_t\in\mathcal{M}_{C,\beta}$ whose correlation function is $\widehat{U_t^{\star}}(C,\beta,\kappa)k$.*

Let us denote in Corollary 6.2 the evolution of the measure μ in time by $U_t^{\star}(C,\beta,\kappa)\mu := \mu_t$. One can easily show that $(U_t^{\star}(C,\beta,\kappa))_{t\geqslant 0}$ is a semigroup on $\mathcal{M}_{C,\beta}$. This leads us directly to the construction of the nonequilibrium Markov process (or rather Markov function) on Γ.

Theorem 6.1 *Suppose that conditions* (**I**) *and* (**P**) *are satisfied. For any triple of positive constants C, κ, and β which satisfy (16) and any $\mu\in\mathcal{M}_{C,\beta}$ there exists Markov process $X_t^{\mu}\in\Gamma$ with initial distribution μ associated with generator $L_{\beta,\kappa}$.*

Proof: Let $n\in\mathbb{N}$, functions $0\leqslant F_0,F_1,\ldots,F_n\in \mathrm{L}^{\infty}(\Gamma)$ and moments of time $0\leqslant t_0\leqslant t_1\leqslant t_1\cdots\leqslant t_n$ be any and fixed. Then there exists a process, defined on some probability space $(\Omega,\mathcal{F},P)$, the finite-dimensional distribution of which is given by the following formula:

$$\int_\Omega F_0(X_{t_0}^{\mu})\ldots F_n(X_{t_n}^{\mu})\mathrm{d}P := \int_\Gamma \mathrm{d}F_n\ldots U_{t_1-t_0}^{*}(C,\kappa,\eta)(F_0\mu).$$

Eventually, we have constructed the nonequilibrium Markov process. ■

We consider a pair of straight adjacent quantum waveguides of constant, and in general different widths. These waveguides are coupled laterally by a pair of windows in the common boundary, not necessarily of the same length, at a distance $2l$. The Hamiltonian is the respective Dirichlet Laplacian. We analyze the asymptotic behavior of the discrete spectrum as the window distance tends to infinity for the generic case, i.e., for eigenvalues of the corresponding one-window problems separated from the threshold. © *2006 American Institute of Physics.*

I. INTRODUCTION

Quantum mechanics exhibits various effects which defy our intuition based on "classical" experience. A nice class of examples are bound states in hard-wall tubes induced solely by their geometric properties such as bends, protrusions, or "windows." Such systems are interesting not only *per se* but also from the practical point of view as models of various nanophysical devices, and in a reasonable approximation also of flat electromagnetic waveguides.

Among numerous questions such models pose, an important one concerns behavior of the spectra in the case of two distant perturbations. One can think of it as an analog of the exponential spectral shift for a pair of distant potential wells, despite the fact that the usual methods of the Schrödinger operator theory do not work here. The aim of the present paper is to study this problem in a model example of a pair of laterally coupled waveguides, or adjacent straight hard-wall strips in the plane, coupled by a pair of windows in the common boundary—we refer to Refs. 1–3 for a bibliography concerning such models. We concentrate mostly on the investigation of isolated eigenvalues of the considered system.

In our recent paper[2] we dealt with the symmetric situation where the widths d_1, d_2 of the two channels were the same and so were the window widths a_1, a_2. The technique used in this paper substantially employed the fact that the problem can be decomposed into parts with a definite parity, which allows one to study a single-window problem with a perturbation which consists of an additional Dirichlet or Neumann boundary condition at a perpendicular section far from the window.

The approach based on symmetry no longer works if $a_1 \neq a_2$. The main aim of the present work is to demonstrate a different technique, suitable for the general case, which reduces the question to analysis of a boundary perturbation at the distant window. This technique follows the

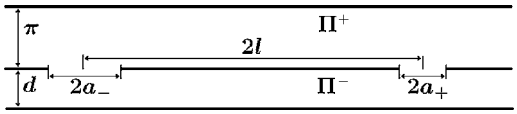

FIG. 1. Window-coupled waveguides.

main ideas of Ref. 4, where the Dirichlet Laplacian in an n-dimensional tube with a pair of distant perturbations described by two arbitrary operators was studied. It was assumed in Ref. 4 that the domains of these operators are preserved under the perturbation, and this assumption was employed substantially. This is obviously not true in the problem we study here, since the windows change the domain of the Laplacian (see, for instance, Ref. 5, Remark 1). At the same time, the general approach of Ref. 4 works in our case with the appropriate modifications. Moreover, since we restrict ourselves to the two-dimensional case and specify the nature of the distant perturbations, we are able to obtain a more detailed result in comparison with the general case in Ref. 4.

Let us describe briefly the main idea of our approach. The first key element is the fact that any eigenfunction of the two-window operator can be represented as the sum of two functions solving the eigenvalue equation for the Laplace operator in the one-window domains and vanishing at the boundary (see Lemma 4.1); one of these functions corresponds to the left window while the other does to the right one. The main feature of these functions is that their normal derivatives have a jump at the window. We show that the original eigenvalue problem is equivalent to a certain operator equation for the mentioned jumps of the normal derivatives. To solve this equation we employ the modification of the Birman-Schwinger approach suggested in Ref. 6; this is the second key ingredient of our technique. Finally, this approach reduces the equation to a search for nontrivial solutions to a finite system of linear equations, and the needed eigenvalues are roots of the determinant of the corresponding matrix. After such a reduction it is sufficient to study the behavior of these roots; in this way we obtain the main results presented in this paper.

Of course, the window-coupled waveguides are not the only, and by far, not the first, system in which distant perturbation asymptotics was studied. We have commented on that in the Introduction of the paper;[2] hence, we limit ourselves here to summarizing the three main points. First of all, our system has no classically closed trajectories, apart from a zero-measure set, so there is *no Agmon metric* on it. Despite this fact, however, the spectral behavior exhibits distinctive features common with one-dimensional Schrödinger operators—see, e.g., Refs. 7–9 and other papers quoted there and in Ref. 2. And finally, the just-mentioned analogy has to be taken *cum grano salis* as first illustrated in Ref. 10; in the two-window context this is clearly seen in the case of a threshold resonance.[2]

In order not to make this study too technical we concentrate in this paper on the generic case when the "unperturbed" energy is an *isolated* eigenvalue of the one-window problem, leaving the computationally involved discussion of threshold resonances to a sequel. The problem will be properly formulated and the results stated in the next section; the rest of the paper is devoted to the proofs.

II. STATEMENT OF THE PROBLEM AND THE RESULTS

Let $x=(x_1,x_2)$ be Cartesian coordinates in the plane $\Pi^+ := \{x: 0<x_2<\pi\}$ and $\Pi^- := \{x: -d<x_2<0\}$. With the natural scaling properties in mind, we may suppose without loss of generality that $d \leqslant \pi$. By $\gamma_\pm$ we denote two intervals $\gamma_\pm := \{x: |x_1 \mp l| < a_\pm, x_2=0\}$, from now on referred to as the *windows*. The numbers $a_\pm$ are assumed to be fixed throughout the paper, while the distance $2l$ between the windows will be changing playing the role of a large parameter.

We set $\Pi := \Pi^+ \cup \Pi^- \cup \gamma_+ \cup \gamma_-$ (cf. Fig. 1); the Hilbert space of our problem is $L_2(\Pi)$. We will employ the symbol H to denote Friedrichs extension of the negative Laplacian on the set $C_0^\infty(\Pi)$. As we have indicated in the Introduction, this work is devoted to the study of the asymptotic behavior of isolated eigenvalues of H as $l \to +\infty$. In order to formulate the main results we first have to introduce some more notations.

We denote $\gamma_a := \{x: |x_1| < a, x_2 = 0\}$ so that $\Pi_a := \Pi^+ \cup \Pi^- \cup \gamma_a$ is the double waveguide with a single window centered at $x_1 = 0$, and $\Gamma_a := \partial\Pi_a$. Furthermore, we introduce the corresponding cutoff sets $\Pi_a^b := \Pi_a \cap \{x: |x_1| < b\}$ and $\Gamma_a^b := \Gamma_a \cap \{x: |x_1| < b\}$. Consider the negative Laplacian in $L_2(\Pi_a)$ and call $H(a)$ its Friedrichs extension in $L_2(\Pi_a)$ from the set $C_0^\infty(\Pi_a)$ on which it is symmetric; by $\lambda_m(a)$, $m = 1, 2, \ldots$, we denote the isolated eigenvalues of this operator arranged in the ascending order with the multiplicity taken into account.

The following results were demonstrated in Refs. 1 and 3.

Proposition 2.1. For any $a > 0$ the essential spectrum of $H(a)$ equals $[1, +\infty)$ while the discrete spectrum of $H(a)$ is nonempty consisting of finitely many simple eigenvalues. The eigenfunction associated with an eigenvalue $\lambda_m(a)$ has a definite parity: it is even or odd with respect to x_1 if m is odd or even, respectively. In the particular case $d = \pi$ the eigenfunctions are even in the variable x_2.

Remark 2.1. The threshold of the essential spectrum of $H(a)$ equals the minimum of the thresholds corresponding to each of the strips. The latter are 1 and π^2/d^2, respectively; together with the normalization condition $d \leqslant \pi$ it explains the first part. The claims about the discrete spectrum are obtained by a variational estimate combined with bracketing bounds.

The eigenfunctions associated with the eigenvalues $\lambda_n(a)$ will be denoted as $\psi_n(\cdot, a)$ and assumed to be normalized, i.e., to be unit vectors in $L_2(\Pi_a)$. It is easy to check that $\psi_n(\cdot, a) \in C^\infty(\Pi_a)$. We will use the symbols $\sigma_{\mathrm{ess}}(\cdot)$ and $\sigma_{\mathrm{disc}}(\cdot)$ to indicate the essential and discrete spectrum, respectively. We set $\sigma_* := \sigma_{\mathrm{disc}} H(a_+) \cup \sigma_{\mathrm{disc}} H(a_-)$. Hereafter, the eigenvalues of H are assumed to be arranged in the nondecreasing order counting multiplicity.

With these preliminaries we can formulate the first main result of this paper.

Theorem 2.1. *For any $l > 0$, $a_\pm > 0$ the operator H has the essential spectrum equal to $[1, +\infty)$ and finitely many isolated eigenvalues. The number of the latter, counting multiplicity, is bounded uniformly with respect to the window distance. Each isolated eigenvalue of the operator H is a continuous function of l if the window distance is large enough, and in the limit $l \to +\infty$ it converges to one of the numbers from the set σ_* or to the threshold of the essential spectrum of H.*

The remaining part of the results describes the asymptotic behavior of the isolated eigenvalues and the associated eigenfunctions of H. In order to formulate these results we need to introduce auxiliary notations.

In Lemma 3.6 we will show that the eigenfunctions ψ_n of $H(a)$ behave for large values of $|x_1|$ as

$$\psi_n(x, a) = c(\lambda_n, a) \mathrm{e}^{-\sqrt{1-\lambda_n}x} \sin x_2 + \mathcal{O}(\mathrm{e}^{-\sqrt{4-\lambda_n}|x_1|}), \quad x_2 \in [0, \pi],$$

where $c(\lambda_n, a)$ are some constants. For any $\lambda \in (-\infty, 1) \setminus \sigma_{\mathrm{disc}}(H(a))$ we introduce that function U which is a unique solution of the boundary value problem,

$$\begin{gathered} (\Delta + \lambda) U = 0, \quad x \in \Pi_a \setminus \gamma_a, \quad U = 0, \quad x \in \partial\Pi_a, \\ \left.\frac{\partial U}{\partial x_2}\right|_{x_2=+0} - \left.\frac{\partial U}{\partial x_2}\right|_{x_2=-0} = \mathrm{e}^{\sqrt{1-\lambda}x_1}, \quad x \in \gamma_a, \end{gathered} \tag{2.1}$$

belonging to $W_2^1(\Pi_a)$. This function satisfies the relation

$$U(x, \lambda, a) = c(\lambda, a) \mathrm{e}^{-\sqrt{1-\lambda}x_1} \sin x_2 + \mathcal{O}(\mathrm{e}^{-\sqrt{4-\lambda}x_1}), \quad x_2 \in [0, \pi],$$

where $c(\lambda, a)$ is a constant. The unique solvability of (2.1) and the mentioned behavior of U at infinity will be proved in Lemma 3.7. We will also give formulas for the introduced constants c in Lemmas 3.6, 3.7 [see (3.15) and (3.18)].

We indicate by Ξ the set of all bounded domains $S \subset \Pi$ having smooth boundary and separated from the endpoints of $\gamma_\pm$ by a positive distance; the case $\partial S \cap \partial\Pi \neq \varnothing$ is not excluded. For brevity we introduce two-valued symbols, $\tau := 1$, $\rho = \rho(\lambda) := \min\{\sqrt{(\pi^2/d^2) - \lambda}, \sqrt{4-\lambda}\}$, $\lambda \in (-\infty, 1)$, if $d < \pi$ and $\tau := 2$, $\rho = \rho(\lambda) := \sqrt{4-\lambda}$, $\lambda \in (-\infty, 1)$, if $d = \pi$. An element $\lambda_* \in \sigma_*$ will be

called *simple* if it belongs to one of the sets $\sigma_{\mathrm{disc}}(H(a_\pm))$ only and *double* otherwise. Furthermore, we set $\boldsymbol{a} := (a_+, a_-)$.

Continuing the list of the main results we make the following claims.

Theorem 2.2. *Suppose that $\lambda_* \in \sigma_*$ is simple being an eigenvalue $\lambda_n(a_\pm)$ of the operator $H(a_\pm)$. Then, there is a unique eigenvalue $\lambda(l,\boldsymbol{a})$ of the operator H converging to λ_* as $l \to +\infty$. This eigenvalue is simple and behaves asymptotically as follows:*

$$\lambda(l,\boldsymbol{a}) = \lambda_* + \mu^\pm(l,\boldsymbol{a})\mathrm{e}^{-4l\sqrt{1-\lambda_*}} + \mathcal{O}(l^2\mathrm{e}^{-8l\sqrt{1-\lambda_*}} + \mathrm{e}^{-2l(\sqrt{1-\lambda_*}+\rho)}), \tag{2.2}$$

$$\mu^\pm(l,\boldsymbol{a}) := \tau\pi c(\lambda_*, a_\pm)c^2(\lambda_*, a_\mp)\sqrt{1-\lambda_*}. \tag{2.3}$$

The associated eigenfunction $\psi(x,l,\boldsymbol{a})$ satisfies the relation

$$\psi(x,l,\boldsymbol{a}) = \psi_n(x_1 \mp l, x_2, a_\pm) + \mathcal{O}(\mathrm{e}^{-2l\sqrt{1-\lambda_*}}) \tag{2.4}$$

in the norms of both the $W_2^1(\Pi)$ and $W_2^2(S)$ for each $S \in \Xi$.

This theorem describes the asymptotic behavior of the eigenvalues of H converging to a simple element of σ_*. In particular, it states that in this case exactly one eigenvalue of H converges to λ_*, this eigenvalue is simple, and the associated eigenfunction is localized around the left or right window subject to whether λ_* is an eigenvalue of $H(a_-)$ or $H(a_+)$.

The other possibility case is that λ_* is double. The next theorem describes the asymptotic behavior of the eigenvalues of H converging to such element of σ_*.

Theorem 2.3. *Suppose that $\lambda_* \in \sigma_*$ is double and $\lambda_* = \lambda_n(a_-) = \lambda_m(a_+)$. Then there exist, with the multiplicity taken into account, exactly two eigenvalues $\lambda^\pm(l,\boldsymbol{a})$ of H which converge to λ_* as $l \to +\infty$. The asymptotic expansions of these eigenvalues read as follows:*

$$\lambda^\pm(l,\boldsymbol{a}) = \lambda_* \pm |\mu(l,\boldsymbol{a})|\mathrm{e}^{-2l\sqrt{1-\lambda_*}} + \mathcal{O}(l\mathrm{e}^{-4l\sqrt{1-\lambda_*}} + \mathrm{e}^{-2l\rho(\lambda_*)}), \tag{2.5}$$

$$\mu(l,\boldsymbol{a}) = (-1)^{m+1}\tau\pi c(\lambda_*, a_-)c(\lambda_*, a_+)\sqrt{1-\lambda_*}. \tag{2.6}$$

In accordance with this theorem, in the case that λ_* is double the total multiplicity of the eigenvalues of H converging to λ_* is 2. In other words, for a fixed large value of l the operator H has either two simple or one double eigenvalue in the vicinity of λ_*. If $\mu(l,\boldsymbol{a}) \neq 0$, the asymptotics (2.5) implies that $\lambda^-(l,\boldsymbol{a}) \neq \lambda^+(l,\boldsymbol{a})$, and in this case we deal with two simple eigenvalues. We also observe that the leading terms in (2.5) are greater by order than ones in (2.2).

In the following theorem we describe the asymptotic behavior of the eigenfunctions associated with the mentioned eigenvalues.

Theorem 2.4 *Suppose the hypothesis of Theorem 2.3 holds true. If $\mu(l,\boldsymbol{a}) \neq 0$, the eigenvalues $\lambda^+(l,\boldsymbol{a})$, $\lambda^-(l,\boldsymbol{a})$ do not coincide and are simple, and the associated eigenfunctions $\psi^\pm(x,l,\boldsymbol{a})$ satisfy the relations*

$$\psi^\pm(x,l,\boldsymbol{a}) = \psi_n(x_1 + l, x_2, a_-) \mp \psi_m(x_1 - l, x_2, a_+)\operatorname{sgn}\mu(l,\boldsymbol{a}) + \mathcal{O}(\mathrm{e}^{-2l\sqrt{1-\lambda_*}}) \tag{2.7}$$

in the norms of $W_2^1(\Pi)$ and $W_2^2(S)$ for each $S \in \Xi$. If $\lambda^-(l,\boldsymbol{a}) = \lambda^+(l,\boldsymbol{a})$ is a double eigenvalue, the associated eigenfunctions $\psi^\pm(x,l,\boldsymbol{a})$ satisfy the relations

$$\begin{aligned} \psi^+(x,l,\boldsymbol{a}) &= \psi_n(x_1 + l, x_2, a_-) + \mathcal{O}(\mathrm{e}^{-2l\sqrt{1-\lambda_*}}), \\ \psi^-(x,l,\boldsymbol{a}) &= \psi_m(x_1 - l, x_2, a_-) + \mathcal{O}(\mathrm{e}^{-2l\sqrt{1-\lambda_*}}), \end{aligned} \tag{2.8}$$

in the norm of $W_2^1(\Pi)$ and $W_2^2(S)$ for each $S \in \Xi$. Finally, if $\mu(l,\boldsymbol{a}) = 0$ and $\lambda^-(l,\boldsymbol{a}) \neq \lambda^+(l,\boldsymbol{a})$, the eigenvalues $\lambda^\pm(l,\boldsymbol{a})$ *are simple and the associated eigenfunctions satisfy the relations*

$$\psi^\pm(x,l,\boldsymbol{a}) = c_+^\pm\psi_n(x_1 + l, x_2, a_-) + c_-^\pm\psi_m(x_1 - l, x_2, a_+) + \mathcal{O}(\mathrm{e}^{-2l\sqrt{1-\lambda_*}}), \tag{2.9}$$

where the vectors $\boldsymbol{c}^{\pm}:=\begin{pmatrix} c_+^{\pm} \\ c_-^{\pm} \end{pmatrix}$ *are nontrivial solutions to the system* (4.20) *with* $\lambda=\lambda^{\pm}$ *such that* $\|\boldsymbol{c}^{\pm}\|_{\mathbb{R}^2}=1$.

The leading terms of the asymptotics (2.2) and (2.5) are nonzero provided the corresponding coefficients $c(\lambda_*,a_\pm)$ are nonzero. We shall show in Lemmas 3.6 and 3.7 that this is true at least for $c(\lambda,a)$ if $\lambda\leqslant\lambda_1(a)$ or $\lambda=\lambda_2(a)$. For instance, if $\lambda_1(a_-)<\lambda_1(a_+)$, the eigenvalue of the operator H converging to $\lambda_1(a_-)$ has the asymptotic expansion (2.2), and the coefficient (2.3) of leading term is nonzero. Moreover, due to Lemma 3.7 this coefficient is negative. If $a_\pm$ are such that $\lambda_1(a_-)=\lambda_2(a_+)$, the eigenvalues of the operator H converging to $\lambda_*=\lambda_1(a_-)=\lambda_2(a_+)$ have the asymptotic expansions (2.5), and the coefficients of the leading terms are nonzero. By Theorem 2.4 the "perturbed" eigenvalues are simple and the associated eigenfunctions satisfy the identities (2.7) in this case. We also stress that in this case the leading terms of the asymptotic expansions (2.5) have the same modulus but different signs. This phenomenon is known for double-well problems with symmetric wells. It also occurs in the symmetric case, $a_-=a_+$ and $d_-=d_+$, as we have shown in Ref. 2. We also notice that the exponents in the leading terms in (2.5) are the same as for the symmetric case in Ref. 2 but the coefficients $\mu^{\pm}(\lambda,\boldsymbol{a})$ differ.

We conjecture that the coefficient $c(\lambda,a)$ is nonzero for all values a and $\lambda<1$. If it is true, this fact would imply that the leading terms in the asymptotics (2.2) and (2.5) are nonzero. In turn, this fact together with Theorem 2.4 would imply that a double $\lambda_*\in\sigma_*$ splits into two simple "perturbed" eigenvalues and the formulas (2.7) are valid for the associated eigenfunctions.

III. ANALYSIS OF THE ONE-WINDOW PROBLEM

In this section we shall study the following boundary value problem:

$$(\Delta+\lambda)u=0,\quad x\in\Pi_a\setminus\gamma_a,\quad u=0,\quad x\in\Gamma_a,$$
$$\left.\frac{\partial u}{\partial x_2}\right|_{x_2=+0}-\left.\frac{\partial u}{\partial x_2}\right|_{x_2=-0}=f,\quad x\in\gamma_a. \tag{3.1}$$

The function f is assumed to be an element of $L_2(\gamma_a)$. The parameter $\lambda\in\mathbb{C}$ is supposed to belong to $\mathbb{S}_\delta$ for a fixed $\delta>0$, where $\mathbb{S}_\delta$ is a set of all λ separated from the halfline $[1,+\infty)$ by a distance greater than δ. For any open set $\Omega\subset\mathbb{R}^2$ and $\gamma\subset\bar{\Omega}$ the symbol $W_2^1(\Omega,\gamma)$ will indicate the subset of the functions from $W_2^1(\Omega)$ having zero trace on γ.

We seek a generalized solution of the problem (3.1) belonging to $L_2(\Pi_a)$. More specifically, we are looking for a function belonging to $L_2(\Pi_a)$ and $W_2^1(\Pi_a^b,\Gamma_a^b)$ for each $b>0$ and satisfying the equation

$$-(\nabla u,\nabla\zeta)_{L_2(\Pi_a)}+\lambda(u,\zeta)_{L_2(\Pi_a)}-(f,\zeta)_{L_2(\gamma_a)}=0 \tag{3.2}$$

for any $\zeta\in C_0^\infty(\Pi_a)$. Our main aim is to study the dependence of this solution on the spectral parameter λ. In this section we will collect a series of preliminary results describing the mentioned dependence, while in the following sections these results will be employed to prove Theorems 2.1–2.4.

We construct the solution of (3.1) as a sum $u=u_1+u_2$, where the first function satisfies the boundary condition in (3.1), while the other is a value of the resolvent of $H(a)$ on some function. First we introduce the function u_1.

We fix $\beta>a$ and put $P:=\{x:|x_1|<a+\beta,0<x_2<d_0\}$. The number d_0 here is chosen so that $d_0<d$, and the lowest eigenvalue of the negative Laplacian in P subject to Dirichlet boundary condition on $\partial P\setminus\bar{\gamma}_a$ and to the Neumann one on γ_a exceeds 2. We consider the boundary value problem

$$(\Delta+\lambda)\tilde{u}=0,\quad x\in P,\quad \tilde{u}=0,\quad x\in\partial P,\quad \frac{\partial\tilde{u}}{\partial x_2}=\frac{1}{2}f,\quad x\in\gamma_a, \tag{3.3}$$

which is again treated in the weak sense,

$$-(\nabla\tilde{u},\nabla\zeta)_{L_2(P)}+\lambda(\tilde{u},\zeta)_{L_2(P)}-\frac{1}{2}(f,\zeta)_{L_2(\gamma_a)}=0 \tag{3.4}$$

for each function $\zeta\in C^\infty(P)$ vanishing in a neighborhood of $\partial P\setminus\bar{\gamma}_a$. The problem (3.3) is uniquely solvable in the space $W_2^1(P,\partial P\setminus\gamma_a)$ and the solution belongs to $C^\infty(\bar{P}\setminus\bar{\gamma}_a)$—see Ref. 12, Chap. II, Sec. 5, Remark 5.1 and Ref. 11, Chap. IV, Sec. 2.

Let a function $\chi_1=\chi_1(x)\in C^\infty(\mathbb{R}^2)$ be infinitely differentiable, even with respect to the variable x_2, equal to 1 if $|x_1|<a+\beta/6$ and $|x_2|<d_0/6$, and vanish for $|x_1|>a+\beta/3$ or $|x_2|>d_0/3$. We extend the function $\tilde{u}$ in an even way for $x_2<0$ setting $\tilde{u}(x):=\tilde{u}(x_1,-x_2)$ as $x_2<0$ and denote $u_1(x):=\chi_1(x)\tilde{u}(x)$.

By Ξ_a we indicate the set of all bounded domains $S\subset\Pi_a$ having smooth boundary and separated from the endpoints of γ_a by a positive distance; we stress that the case $\partial S\cap\partial\Pi_a\neq\varnothing$ is not excluded.

Lemma 3.1. The function u_1 belongs to $W_2^1(\Pi_a,\Gamma_a)$ and satisfies the equation

$$-(\nabla u_1,\nabla\zeta)_{L_2(\Pi_a)}+\lambda(u_1,\zeta)_{L_2(\Pi_a)}-(f,\zeta)_{L_2(\gamma_a)}=(F,\zeta)_{L_2(\Pi_a)} \tag{3.5}$$

for any $\zeta\in C_0^\infty(\Pi_a)$, where

$$F=T_1(\lambda,a)f:=2\nabla\tilde{u}\cdot\nabla\chi_1+\tilde{u}\Delta\chi_1.$$

The operator $T_1: L_2(\gamma_a)\to L_2(\{x:|x_1|<a+\beta/3,|x_2|<d_0/3\})$ is linear, bounded, and holomorphic in λ. The operator $T_2(\lambda,a)f:=u_1$ is linear, bounded, and holomorphic in λ as a map from $L_2(\gamma_a)$ into $W_2^1(\Pi_a,\Gamma_a)$, $W_2^2(S)$, and $W_2^2(\Pi^\pm\setminus\Pi_a^\beta)$, where $S\in\Xi_a$ is such that $S\subset\Pi^+$ or $S\subset\Pi^-$.

Proof. It is clear that $u_1\in W_2^1(\Pi_\pm,\partial\Pi_\pm\setminus\gamma_a)$. Since this function is even with respect to x_2, using integration by parts we obtain

$$\left(u_1,\frac{\partial\zeta}{\partial x_i}\right)_{L_2(\Pi_a)}=\left(u_1,\frac{\partial\zeta}{\partial x_i}\right)_{L_2(\Pi_+)}+\left(u_1,\frac{\partial\zeta}{\partial x_i}\right)_{L_2(\Pi_-)}=-\left(\frac{\partial u_1}{\partial x_i},\zeta\right)_{L_2(\Pi_+)}-\left(\frac{\partial u_1}{\partial x_i},\zeta\right)_{L_2(\Pi_-)},\quad i=1,2,$$

for each $\zeta\in C_0^\infty(\Pi_a)$. Hence, $u\in W_2^1(\Pi_a,\Gamma_a)$. Employing the parity of u_1 with respect to x_2 once again, we find that for each $\zeta\in C_0^\infty(\Pi_a)$ the left-hand side of (3.5) equals twice the expression

$$-(\nabla u_1,\nabla\zeta^+)_{L_2(P)}+\lambda(u_1,\zeta^+)_{L_2(P)}-(f,\zeta^+)_{L_2(\gamma_a)},$$

where $\zeta^+(x):=\zeta(x)+\zeta(x_1,-x_2)$. In view of (3.4) and the definition of χ_1, we get

$$\begin{aligned}
&-(\nabla u_1,\nabla\zeta)_{L_2(\Pi_a)}+\lambda(u_1,\zeta)_{L_2(\Pi_a)}-(f,\zeta)_{L_2(\gamma_a)}\\
&\quad=2\Big(-(\nabla\tilde{u},\nabla(\chi_1\zeta^+))_{L_2(P)}+\lambda(u_1,\chi_1\zeta^+)_{L_2(P)}-\frac{1}{2}(f,\chi_1\zeta^+)_{L_2(\gamma_a)}+(\nabla\tilde{u},\zeta^+\nabla\chi_1)_{L_2(P)}\\
&\quad\quad-(\tilde{u}\nabla\chi_1,\nabla\zeta^+)_{L_2(P)}\Big)\\
&\quad=2((\nabla\tilde{u},\zeta^+\nabla\chi_1)_{L_2(P)}-(\tilde{u}\nabla\chi_1,\nabla\zeta^+)_{L_2(P)})=2((\nabla\tilde{u},\zeta^+\nabla\chi_1)_{L_2(P)}+(\operatorname{div}\tilde{u}\nabla\chi_1,\zeta^+)_{L_2(P)})\\
&\quad=(F,\zeta)_{L_2(\Pi_a)}.
\end{aligned}$$

The boundedness of the operator $T_1(\lambda,a)$ follows from the smoothness-improving theorems of solutions to elliptic boundary value problems (see Ref. 11, Chap. II, Sec. 2).

In order to check that T_1 is holomorphic in the variable λ, we just need to show that the mapping $f \mapsto \tilde{u}$ is bounded and holomorphic as an operator family from $L_2(\gamma_a)$ into $W_2^1(P)$ and $W_2^2(S \cap P)$, where $S \in \Xi_a$ and $S \subset \overline{\Pi^+}$. To prove the last claim it is sufficient to reduce the boundary value problem to an operator equation in $W_2^1(P, \partial P \setminus \overline{\gamma}_a)$ in the standard way—see Ref. 11, Chap II, Sec. 2—and to apply then Proposition 4.5 of Ref. 13, Chap. XI, Sec. 4. □

As u_1 is compactly supported, the function u_2 has to be an element of $L_2(\Pi_a)$ and of $W_2^1(\Pi_a^b, \Gamma_a^b)$ for each $b > a$. It follows from (3.2) and (3.5) that the function u_2 must also obey the integral relation

$$-(\nabla u_2, \nabla \zeta)_{L_2(\Pi_a)} + \lambda (u_2, \zeta)_{L_2(\Pi_a)} = -(F, \zeta)_{L_2(\Pi_a)}$$

for any $\zeta \in C_0^\infty(\Pi_a)$. Thus u_2 has to solve the boundary value problem

$$-(\Delta + \lambda) u_2 = F, \quad x \in \Pi_a, \quad u = 0, \quad x \in \Gamma_a, \tag{3.6}$$

belonging to $L_2(\Pi_a)$ and $W_2^1(\Pi_a^b, \Gamma_a^b)$ for each $b > 0$. By Theorem 4.6.8 of Ref. 14, Chap. 4, Sec. 4.6 any solution of this problem belonging to $L_2(\Pi_a)$ is an element of the operator domain of $H(a)$. In this way the problem (3.6) can be cast into the form $(H(a) - \lambda) u_2 = F$, which in turn gives $u_2 = (H(a) - \lambda)^{-1} F$.

We denote the map $f \mapsto u$ as $T_3(\lambda, a)$. In fact, $T_3(\lambda, a) := T_2(\lambda, a) + (H(a) - \lambda)^{-1} T_1(\lambda, a)$.

Lemma 3.2. The linear operator $T_3(\lambda, a)$ is bounded and meromorphic in $\lambda \in \mathbb{S}_\delta$ as a map from $L_2(\gamma_a)$ into $W_2^1(\Pi_a, \Gamma_a)$ and into $W_2^2(S)$ for each $S \in \Xi_a$. Its poles coincide with the eigenvalues of the operator $H(a)$. For any λ close to an eigenvalue λ_n of $H(a)$, the representation

$$T_3(\lambda, a) = \frac{\psi_n}{\lambda - \lambda_n} T_4(a) + T_5(\lambda, a) \tag{3.7}$$

holds true. Here $T_4(a) f := (f, \psi_n)_{L_2(\gamma_a)}$, and the linear operator T_5 is bounded and holomorphic in $\lambda \in \mathbb{S}_\delta$ as a map from $L_2(\gamma_a)$ into $W_2^1(\Pi_a, \Gamma_a)$. The operator T_5 is also bounded and holomorphic as a map into $W_2^2(S)$ for each $S \in \Xi_a$.

Proof. In accordance with Ref. 15, Chap. 5, Sec. 3.5 the operator $(H(a) - \lambda)^{-1}$ is bounded and meromorphic in $L_2(\Pi_a)$, its poles coincide with the eigenvalues of $H(a)$, and for λ close to λ_n the representation

$$(H(a) - \lambda)^{-1} = -\frac{\psi_n}{\lambda - \lambda_n} (\cdot, \psi_n)_{L_2(\Pi_a)} + T_6(\lambda, a) \tag{3.8}$$

is valid, where the operator $T_6(\lambda, a)$ is bounded and holomorphic in λ in the vicinity of λ_n. The function $\hat{u} := T_6(\lambda, a) F$ is a solution to the boundary value problem (3.6) with F replaced by $\hat{F} := F - (F, \psi_n)_{L_2(\Pi_a)} \psi_n$; it means that

$$\|\nabla \hat{u}\|^2_{L_2(\Pi_a)} - \lambda \|\hat{u}\|^2_{L_2(\Pi_a)} = (\hat{F}, \hat{u})_{L_2(\Pi_a)}.$$

This relation, together with (3.8), implies that the operator T_6 is bounded and holomorphic as a map into $W_2^1(\Pi_a)$ as well. Using again the smoothness-improving theorems mentioned above, we conclude that the operator T_6 is also bounded and holomorphic in λ as a map into $W_2^2(S)$ for each $S \in \Xi_a$, $S \subset \Pi_+$ or $S \subset \Pi_-$.

Since the function ψ_n is an element of $W_2^1(\Pi_a, \Gamma_a)$, the relation (3.5) is valid for $\zeta = \psi_n$. For any $f \in L_2(\gamma_a)$ the function $T_1(\lambda, a) f$ is compactly supported; hence, we have

$$(T_1(\lambda_n, a) f, \psi_n)_{L_2(\Pi_a)} = -(\nabla u_1, \nabla \psi_n)_{L_2(\Pi_a)} + \lambda (u_1, \psi_n)_{L_2(\Pi_a)} - (f, \psi_n)_{L_2(\gamma_a)},$$

where $u_1 = T_2(\lambda_n, a) f$. According to Lemma 3.1, the function u_1 belongs to $W_2^1(\Pi_a, \Gamma_a)$, which allows us to proceed with the calculations,

$$-(\nabla u_1, \nabla \psi_n)_{L_2(\Pi_a)} + \lambda (u_1, \psi_n)_{L_2(\Pi_a)} = 0,$$

$$(T_1(\lambda_n, a) f, \psi_n)_{L_2(\Pi_a)} = -(f, \psi_n)_{L_2(\gamma_a)} = -T_4(a) f.$$

Substituting the relation thus obtained together with (3.8) into the definition of the operator T_3, and taking into account Lemma 3.1, we arrive finally at the statement of the lemma. □

For any numbers $b_1, b_2, b_3 \in \mathbb{R}$ we set $\Omega_\pm := \{x : \pm x_1 > b_1, b_2 < x_2 < b_3\}$ and $\omega_\pm := \partial\Omega_\pm \setminus \{x : x_1 = \pm b_1\}$.

Lemma 3.3. Let $v \in W_2^1(\Omega_\pm)$ be a solution to the problem

$$(\Delta + \lambda) v = 0, \quad x \in \Omega^\pm, \quad v = 0, \quad x \in \omega^\pm,$$

and $0 < b_2 - b_3 \leqslant \pi$, $\lambda \in \mathbb{S}_\delta$. Then the function v can be represented as

$$v(x, \lambda) = \sum_{j=1}^{\infty} \alpha_j(\lambda) \exp\left(- \sqrt{\frac{\pi^2 j^2}{(b_3 - b_2)^2} - \lambda} (\pm x_1 - b_1) \right) \sin \frac{\pi j}{b_3 - b_2} (x_2 - b_2), \tag{3.9}$$

where

$$\alpha_j(\lambda) := \frac{2}{b_3 - b_2} \int_{b_2}^{b_3} v(\pm b_1, x_2, \lambda) \sin \frac{\pi j}{b_3 - b_2} (x_2 - b_2) \mathrm{d}x_2.$$

The series (3.9) converges in the norms of $W_2^m(\{x : \pm x_1 > b_4, b_2 < x_2 < b_3\})$, $m \geqslant 0$, for any $b_4 > b_1$. The coefficients α_j satisfy the condition

$$\frac{\pi}{2} \sum_{j=1}^{\infty} |\alpha_j|^2 = \| v(\pm b_1, \cdot, \lambda) \|_{L_2(b_2, b_3)}.$$

This lemma is a particular case of Lemma 3.3 of Ref. 4 so we skip the proof.

Let us next fix a number $\widetilde{a} > 0$. For any $l \geqslant (a + \widetilde{a})$ we define operators $T_7^\pm(\lambda, l, a, \widetilde{a})$ which map an arbitrary $v \in W_2^1(\Pi_a^a)$ into the function

$$(T_7^\pm v)(x_1, \lambda, l) := \sum_{j=1}^{\infty} j \alpha_j^\pm \mathrm{e}^{\mp \kappa_j^+(\lambda)(x_1 \mp a)} \mathrm{e}^{-2\kappa_j^+(\lambda) l} - \sum_{j=1}^{\infty} \frac{\pi j}{d} \beta_j^\pm \mathrm{e}^{\mp \kappa_j^-(\lambda)(x_1 \mp a)} \mathrm{e}^{-2\kappa_j^-(\lambda) l},$$

$$\alpha_j^\pm = \frac{2}{\pi} \int_0^\pi v(a, x_2) \sin j x_2 \mathrm{d}x_2, \quad \beta_j^\pm = \frac{2}{d} \int_{-d}^0 v(a, x_2) \sin \frac{\pi j}{d} x_2 \mathrm{d}x_2,$$

$$\kappa_j^+(\lambda) := \sqrt{j^2 - \lambda}, \quad \kappa_j^-(\lambda) := \sqrt{\frac{\pi^2 j^2}{d^2} - \lambda}, \quad j \geqslant 1.$$

The branch of the root in the definition of the functions κ_j is specified by the requirement that the functions are analytic in $\mathbb{S}_\delta$ and $\sqrt{1} = 1$.

Lemma 3.4. The operators $T_7^\pm : W_2^1(\Pi_a^a) \to L_2(\gamma_{\widetilde{a}})$ are well defined, bounded, and holomorphic in $\lambda \in \mathbb{S}_\delta$. The estimates

$$\left\| \frac{\partial^i T_7^\pm}{\partial \lambda^i} \right\| \leqslant C l^i \mathrm{e}^{-(2l - a - \widetilde{a}) \operatorname{Re} \kappa_1^+(\lambda)}, \quad i = 0, 1, 2,$$

hold true uniformly with respect to $\lambda \in \mathbb{S}_\delta$ and $l \geqslant (a + \widetilde{a})$.

Proof. We will prove the lemma for T_7^+ only; the argument for T_7^- is similar. The function u belongs to $W_2^1(\Pi_a^a)$; hence, we have the estimate

$$\sum_{j=1}^{\infty}(|\alpha_j^{\pm}|^2+|\beta_j^{\pm}|^2)\leqslant C\|u\|^2_{W_2^1(\Pi_a)},$$

where the constant C is independent of $\lambda\in\mathbb{S}_\delta$ and $l\geqslant(a+\tilde{a})$. Employing this inequality, we infer that

$$\begin{aligned}\left\|\sum_{j=1}^{\infty} j\alpha_j^+ e^{-\kappa_j^+(\lambda)(\cdot-a)}e^{-2\kappa_j^+(\lambda)l}\right\|_{L_2(\gamma_{\tilde{a}})} &\leqslant \sum_{j=1}^{\infty} j|\alpha_j|e^{-2l\ \mathrm{Re}\ \kappa_j^+(\lambda)}\|e^{-\kappa_j^+(\lambda)(\cdot-a)}\|_{L_2(-\tilde{a},\tilde{a})}\\ &\leqslant C\sum_{j=1}^{\infty}\frac{j|\alpha_j^+|}{\sqrt{\mathrm{Re}\ \kappa_j^+(\lambda)}}e^{-(2l-a-\tilde{a})\mathrm{Re}\ \kappa_j^+(\lambda)}\\ &\leqslant C\left(\sum_{j=1}^{\infty}|\alpha_j|^2\right)^{1/2}\left(\sum_{j=1}^{\infty}\frac{j^2e^{-2(2l-a-\tilde{a})\mathrm{Re}\ \kappa_j^+(\lambda)}}{|\kappa_j^+(\lambda)|}\right)^{1/2}\\ &\leqslant C\|v\|_{W_2^1(\Pi_a^a)}e^{-(2l-a-\tilde{a})\mathrm{Re}\ \kappa_1^+(\lambda)}\\ &\quad\times\left(\sum_{j=1}^{\infty}\frac{j^2\exp(-2(2l-a-\tilde{a})\mathrm{Re}(\kappa_j^+(\lambda)-\kappa_1^+(\lambda)))}{\sqrt{|\mathrm{Im}\lambda|}}\right)^{1/2}\\ &\leqslant Ce^{-(2l-a-\tilde{a})\mathrm{Re}\ \kappa_1^+(\lambda)}\|v\|_{W_2^1(\Pi_a^a)},\end{aligned}$$

where C is independent of $\lambda\in\mathbb{S}_\delta$ and $\lambda\geqslant(a+\tilde{a})$. In the same way, one can prove that

$$\left\|\sum_{j=1}^{\infty}\frac{\pi j}{d}\beta_j^+e^{-\kappa_j^-(\lambda)(\cdot-a)}e^{-2\kappa_j^-(\lambda)l}\right\|_{L_2(\gamma_{\tilde{a}})}\leqslant Ce^{-(2l-a-\tilde{a})\mathrm{Re}\ \kappa_1^-(\lambda)}\|v\|_{W_2^1(\Pi_a^a)}.$$

The last two estimates imply that the operator $T_7^+:W_2^1(\Pi_a^a)\to L_2(\gamma_{\tilde{a}})$ is well defined and bounded. One can check easily that

$$\begin{aligned}\left(\frac{\partial T_7^+v}{\partial\lambda}\right)(x_1,\lambda,l) &:= \sum_{j=1}^{\infty}\frac{j\alpha_j^+}{2\kappa_j^+(\lambda)}(x_1-a+2l)e^{-\kappa_j^+(\lambda)(x_1-a)}e^{-2\kappa_j^+(\lambda)l}\\ &\quad-\sum_{j=1}^{\infty}\frac{\pi j\beta_j^+(x_1-a+2l)}{2\kappa_j^-(\lambda)d}e^{-\kappa_j^-(\lambda)(x_1-a)}e^{-2\kappa_j^-(\lambda)l}.\end{aligned}$$

Repeating the argument which yielded the estimate for T_7^+v, we can establish that

$$\left\|\frac{\partial T_7^{\pm}v}{\partial\lambda}\right\|_{L_2(\gamma_{\tilde{a}})}\leqslant Cle^{-(2l-a-\tilde{a})\mathrm{Re}\ \kappa_1^+(\lambda)}\|v\|_{W_2^1(\Pi_a^a)}$$

with the constant C independent of $\lambda\in\mathbb{S}_\delta$ and $l\geqslant(a+\tilde{a})$. Consequently, the operator $\partial T_7^+/\partial\lambda$ exists, it is bounded, and the stated estimate for its norm holds true. The norm estimate for $\partial^2T_7^+/\partial\lambda^2$ is obtained in a similar way. □

For any $l\geqslant(a+\tilde{a})$ we define operators $T_8^{\pm}(\lambda,l,a,\tilde{a})$ which map any $f\in L_2(\gamma_a)$ to the function

$$\frac{\partial u}{\partial x_2}(x_1\pm 2l,+0,\lambda)-\frac{\partial u}{\partial x_2}(x_1\pm 2l,-0,\lambda),\quad x_1\in(-\tilde{a},\tilde{a}).$$

Here u is a solution to the boundary value problem (3.1). Taking into account Lemma 3.2 together with the boundedness of the embedding $W_2^1(\Pi_a)$ into $L_2(\{x:|x_1\pm 2l|<\tilde{a},x_2=0\})$, we conclude that the operators $T_8^{\pm}:L_2(\gamma_a)\to L_2(\gamma_{\tilde{a}})$ are bounded and holomorphic in $\lambda\in\mathbb{S}_\delta$.

Lemma 3.5. The poles of the operators $T_8^{\pm}$ coincide with the eigenvalues of the operator $H(a)$.

For any compact set $K\subset\mathbb{S}_\delta$ separated from the discrete spectrum of $H(a)$ by a positive distance, the estimates

$$\left\|\frac{\partial^i T_8^\pm}{\partial\lambda^i}\right\| \leqslant C l^i \mathrm{e}^{-2l\ \mathrm{Re}\ \kappa_1^+(\lambda)}, \quad i=0,1, \tag{3.10}$$

hold true with C which is independent of $\lambda\in K$ and l. For any λ close to an eigenvalue λ_n of the operator $H(a)$ the representation

$$T_8^\pm(\lambda,l,a,\tilde{a}) = \frac{\phi_n^\pm}{\lambda-\lambda_n} T_4(a) + T_9^\pm(\lambda,l,a,\tilde{a}) \tag{3.11}$$

is valid, where

$$\phi_n^\pm(x_1,l,a) := \frac{\partial\psi_n}{\partial x_2}(x_1\pm 2l,+0,a) - \frac{\partial\psi_n}{\partial x_2}(x_1\pm 2l,-0,a), \quad x_1\in(-\tilde{a},\tilde{a}). \tag{3.12}$$

The operators $T_9^\pm: L_2(\gamma_a)\to L_2(\gamma_{\tilde{a}})$ are bounded and holomorphic with respect to λ in the vicinity of λ_n and satisfy the estimates

$$\left\|\frac{\partial^i T_9^\pm}{\partial\lambda^i}\right\| \leqslant C l^{i+1} \mathrm{e}^{-2l\ \mathrm{Re}\ \kappa_1^+(\lambda)}, \quad i=0,1, \tag{3.13}$$

where the constant C is independent of λ and l.

Proof. Due to Lemma 3.3 we have

$$T_8^\pm(\lambda,l,a,\tilde{a}) f = T_7^\pm(\lambda,l,a,\tilde{a}) u, \tag{3.14}$$

where u is a solution to the boundary value problem (3.1). Using this identity and the representation (3.7), we arrive at (3.11), where $T_9^\pm$ is a bounded operator holomorphic in λ. Moreover,

$$\begin{aligned} T_9^\pm(\lambda,l,a,\tilde{a}) &= \frac{T_7^\pm(\lambda,l,a,\tilde{a}) - T_7^\pm(\lambda_n,l,a,\tilde{a})}{\lambda-\lambda_n} T_4(a) + T_7^\pm(\lambda,l,a,\tilde{a}) T_5^\pm(\lambda,a) \\ &= \left(\frac{1}{\lambda-\lambda_n}\int_{\lambda_n}^{\lambda} \frac{\partial T_7^\pm}{\partial\lambda}(z,l,a,\tilde{a})\mathrm{d}z\right) T_4(a) + T_7^\pm(\lambda,l,a,\tilde{a}) T_5^\pm(\lambda,a), \end{aligned}$$

$$\frac{T_9^\pm}{\partial\lambda}(\lambda,l,a,\tilde{a}) = \left(\frac{1}{(\lambda-\lambda_n)^2}\int_{\lambda_n}^{\lambda}\int_{z_1}^{\lambda} \frac{\partial^2 T_7^\pm}{\partial\lambda^2}(z_2,l,a,\tilde{a})\mathrm{d}z_2\mathrm{d}z_1\right) T_4(a) + \frac{\partial}{\partial\lambda}(T_7^\pm(\lambda,l,a,\tilde{a}) T_5^\pm(\lambda,a)).$$

Applying now Lemma 3.4 we obtain the estimates (3.13).

The operators $\partial^i T_3/\partial\lambda^i$, $i=0,1$, are bounded uniformly in $\lambda\in K$, thus in view of the relation (3.14) and Lemma 3.4 we arrive readily at the estimates (3.10). □

Concluding this section we shall prove two auxiliary lemmas.

Lemma 3.6. In the limit $x_1\to\pm\infty$ the eigenfunction ψ_n of $H(a)$ behaves as

$$\psi_n(x,a) = (\pm 1)^{n+1} c(\lambda_n,a) \mathrm{e}^{-\kappa_1^+(\lambda_n)|x_1|} \sin x_2 + \mathcal{O}(\mathrm{e}^{-k_2^+(\lambda_n)|x_1|}), \quad x_2\in[0,\pi],$$

$$\nabla_x\psi_n(x,a) = (\pm 1)^{n+1} c(\lambda_n,a) \nabla_x \mathrm{e}^{-\kappa_1^+(\lambda_n)|x_1|} \sin x_2 + \mathcal{O}(\mathrm{e}^{-k_2^+(\lambda_n)|x_1|}), \quad x_2\in[0,\pi],$$

$$\psi_n(x,a) = \mathcal{O}(\mathrm{e}^{-\kappa_1^-(\lambda)|x_1|}), \quad \nabla_x\psi_n(x,a) = \mathcal{O}(\mathrm{e}^{-\kappa_1^-(\lambda)|x_1|}), \quad x_2\in[-d,0],$$

if $d<\pi$, and

$$\psi_n(x,a) = (\pm 1)^{n+1} c(\lambda_n,a) \mathrm{e}^{-\kappa_1^+(\lambda_n)|x_1|} \sin|x_2| + \mathcal{O}(\mathrm{e}^{-k_2^+(\lambda_n)|x_1|}), \quad x_2 \in [-\pi,\pi],$$

$$\nabla_x \psi_n(x,a) = (\pm 1)^{n+1} c(\lambda_n,a) \nabla_x \mathrm{e}^{-\kappa_1^+(\lambda_n)|x_1|} \sin|x_2| + \mathcal{O}(\mathrm{e}^{-k_2^+(\lambda_n)|x_1|}), \quad x_2 \in [-\pi,\pi],$$

in the case of equal-width channels, $d=\pi$. In these relations

$$c(\lambda_n,a) = \frac{1}{\pi\kappa_1^+(\lambda_n)} \int_{\gamma_a} \psi_n(x,a) \mathrm{e}^{\kappa_1^+(\lambda_n)x_1} \mathrm{d}x_1 = \frac{(-1)^{n+1}}{\pi\kappa_1^+(\lambda_n)} \int_{\gamma_a} \psi_n(x,a) \mathrm{e}^{-\kappa_1^+(\lambda_n)x_1} \mathrm{d}x_1, \tag{3.15}$$

and $c(\lambda_i,a) \neq 0$, $i=1,2$.

Proof. Applying Lemma 3.3 to ψ_n with $b_1=\pm a$, $b_2=0$, $b_3=\pi$ and $b_2=-d$, $b_3=0$, we obtain the needed asymptotic behavior of ψ_n. The factor $(\pm 1)^{n+1}$ in these formulas is due to the definite parity of ψ_n with respect to x_1. The formula (3.15) for $c_1^{(n)}$ follows from the chain of relations obtained by integration by parts,

$$0 = \int_{\Pi^+} \mathrm{e}^{\pm\kappa_1^+(\lambda_n)x_1} \sin x_2 (\Delta + \lambda_n) \psi_n(x,a) \mathrm{d}x = \int_{\gamma_a} \mathrm{e}^{\pm\kappa_1^+(\lambda_n)x_1} \psi_n(x,a) \mathrm{d}x - (\pm 1)^{n+1} \pi\kappa_1^+(\lambda_n) c(\lambda_n,a).$$

It remains to check the inequalities $c(\lambda_i,a) \neq 0$, $i=1,2$. Since

$$\lambda_1 = \frac{\|\nabla\psi_1\|^2_{L_2(\Pi_a)}}{\|\psi_1\|^2_{L_2(\Pi_a)}} = \frac{\|\nabla\widetilde{\psi}_1\|^2_{L_2(\Pi_a)}}{\|\widetilde{\psi}_1\|^2_{L_2(\Pi_a)}},$$

where $\widetilde{\psi}_1 := |\psi_1|$, we conclude that $\widetilde{\psi}_1$ is an eigenfunction associated with λ_1. This eigenvalue being simple, we infer that $\widetilde{\psi}_1 = \psi_1$. Hence, $\psi_1 \geqslant 0$. Moreover, ψ_1 is not identically zero at γ_a, since otherwise it would be an eigenfunction of the negative Dirichlet Laplacian in Π^+ and would correspond to the eigenvalue $\lambda_1 < 1$. At the same time, the spectrum of the mentioned operator is the halfline $[1,+\infty)$. The described properties of ψ_1 and the formula (3.15) imply that $c(\lambda_1,a) \neq 0$.

According to Proposition 2.1 the eigenfunction ψ_2 is odd with respect to x_1. Thus, the eigenvalue λ_2 is the ground state of the negative Dirichlet Laplacian in $\Pi_a \cap \{x : x_1 > 0\}$. Completely by analogy with how it was done for ψ_1, one can make sure that $\psi_2 \geqslant 0$ on $\Pi_a \cap \{x : x_1 > 0\}$, and $\psi_2(x_1,0,a) \not\equiv 0$ for $x_1 \in (0,a)$. The parity of ψ_2 allows us to modify the formula (3.15),

$$c(\lambda_2,a) = \frac{1}{\pi\kappa_1^+(\lambda_2)} \int_{\gamma_a} \psi_2(x,a) \sinh \kappa_1^+(\lambda_2) x_1 \mathrm{d}x_1 = \frac{2}{\pi\kappa_1^+(\lambda_2)} \int_0^a \psi_2(x_1,0,a) \sinh \kappa_1^+(\lambda_2) x_1 \mathrm{d}x_1.$$

Together with the non-negativity of ψ_2 on $\gamma_a \cap \{x : x_1 > 0\}$, it implies that $c_2(\lambda,a) \neq 0$. □

Lemma 3.7. For any $\lambda \in (-\infty,1) \setminus \sigma_{\mathrm{disc}}(H(a))$ there exists a unique solution of the boundary value problem (2.1) belonging to $W_2^1(\Pi_a)$. For large values of $|x_1|$ this function is infinitely differentiable and in the limit $x_1 \to +\infty$ it behaves as

$$U(x,\lambda,a) = c(\lambda,a)\mathrm{e}^{-\kappa_1^+(\lambda)x_1}\sin x_2 + \mathcal{O}(\mathrm{e}^{-\mathrm{Re}\,\kappa_2^+(\lambda)x_1}), \quad x_2 \in [0,\pi],$$

$$\nabla_x U(x,\lambda,a) = c(\lambda,a)\nabla_x \mathrm{e}^{-\kappa_1^+(\lambda)x_1}\sin x_2 + \mathcal{O}(\mathrm{e}^{-\mathrm{Re}\,\kappa_2^+(\lambda)x_1}), \quad x_2 \in [0,\pi], \tag{3.16}$$

$$U(x,\lambda,a) = \mathcal{O}(\mathrm{e}^{-\mathrm{Re}\,\kappa_1^-(\lambda)x_1}), \quad \nabla_x U(x,\lambda,a) = \mathcal{O}(\mathrm{e}^{-\mathrm{Re}\,\kappa_1^-(\lambda)x_1}), \quad x_2 \in [-d,0],$$

if $d<\pi$, *and*

$$U(x,\lambda,a) = c(\lambda,a)\mathrm{e}^{-\kappa_1^+(\lambda_n)x_1}\sin|x_2| + \mathcal{O}(\mathrm{e}^{-\mathrm{Re}\,\kappa_2^+(\lambda)x_1}), \quad x_2 \in [-\pi,\pi],$$

$$\nabla_x U(x,\lambda,a) = c(\lambda,a)\nabla_x \mathrm{e}^{-\kappa_1^+(\lambda_n)x_1}\sin|x_2| + \mathcal{O}(\mathrm{e}^{-\mathrm{Re}\,k_2^+(\lambda)x_1}), \quad x_2 \in [-\pi,\pi], \tag{3.17}$$

in the case $d=\pi$ *where the coefficient is given by*

$$c(\lambda,a) = \frac{1}{\pi\kappa_1^+(\lambda)}\int_{\gamma_a} U(x,\lambda,a)\mathrm{e}^{\kappa_1^+(\lambda)x_1}\mathrm{d}x_1. \tag{3.18}$$

This coefficient is negative for $\lambda<\lambda_1(a)$.

Proof. The unique solvability of the problem (2.1) is ensured by Lemma 3.2. Moreover, we have $U=T_3(\lambda,a)\mathrm{e}^{\kappa_1^+(\lambda)x_1}$. The relations (3.16) and (3.17) follow from Lemma 3.3, and the formula (3.18) is proved in the same way as (3.15).

Integrating by parts and employing the formula (3.18), we obtain a chain of identities,

$$\begin{aligned} 0 = \int_\Pi U(\Delta+\lambda)U\mathrm{d}x &= \lambda\|U\|^2_{L_2(\Pi)} - \|\nabla U\|^2_{L_2(\Pi)} - \int_{\gamma_a} U\left(\left.\frac{\partial U}{\partial x_2}\right|_{x_2=+0} - \left.\frac{\partial U}{\partial x_2}\right|_{x_2=-0}\right)\mathrm{d}x_1 \\ &= \lambda\|U\|^2_{L_2(\Pi)} - \|\nabla U\|^2_{L_2(\Pi)} - \pi\kappa_1^+(\lambda)c(\lambda,a), \end{aligned}$$

which implies

$$c(\lambda,a) = \frac{\lambda\|U\|^2_{L_2(\Pi)} - \|\nabla U\|^2_{L_2(\Pi)}}{\pi\kappa_1^+(\lambda)}. \tag{3.19}$$

Since $U\in W_2^1(\Pi,\partial\Pi)$, the minimax principle yields the inequality

$$\|U\|^2_{L_2(\Pi)} \leqslant \frac{1}{\lambda_1(a)}\|\nabla U\|^2_{L_2(\Pi)}.$$

We substitute this inequality into the formula (3.19) and obtain

$$c(\lambda,a) \leqslant \frac{1}{\pi\kappa_1^+(\lambda)}\left(\frac{\lambda}{\lambda_1(a)} - 1\right)\|\nabla U\|^2_{L_2(\Pi)} < 0,$$

if $\lambda<\lambda_1(a)$.

IV. REDUCTION OF THE PERTURBED PROBLEM

In this section we shall transform the eigenvalue equation for H to another operator equation. The main advantage of such transformation is that the final equation involves only the resolvents of one-window operators $H(a_\pm)$. More specifically, the presented approach allows us to *decouple* two-window system and to reduce it to a small perturbation of a direct sum of left- and right-window operators.

We are looking for eigenvalues of the operator H, i.e., nontrivial $L_2(\Pi)$ solutions to the boundary value problem

$$-\Delta\psi=\lambda\psi,\quad x\in\Pi,\quad \psi=0,\quad x\in\partial\Pi. \tag{4.1}$$

We denote $Q^b:=\{x:-b<x_1<b,-d<x_2<\pi\}$ and introduce the cutoff regions $\Pi^b:=\Pi\cap Q^b$, $\Gamma^b:=\partial\Pi\cap Q^b$. Solutions to the problem (4.1) are functions belonging to $W_2^1(\Pi^b,\Gamma^b)$ for any $b>0$ such that

$$(\nabla\psi,\nabla\zeta)_{L_2(\Pi)}=\lambda(\psi,\zeta)_{L_2(\Pi)} \tag{4.2}$$

holds for each $\zeta\in C_0^\infty(\Pi)$; it follows from the smoothness-improving theorem mentioned above that such a ψ belongs to $C^\infty(\Pi)$.

We assume that $\lambda\in\mathbb{S}_\delta$, with $\delta>0$ is chosen in such a way that $\sigma_*\subset\mathbb{S}_\delta$. Let $f_\pm=f_\pm(\cdot,l)\in L_2(\gamma_{a_\pm})$ be an arbitrary pair of functions. Denote by $u_\pm$ the solutions of the problem (3.1) with $a=a_\pm$ and $f=f_\pm\in L_2(\gamma_{a_\pm})$ and assume that $u_\pm\in L_2(\Pi_{a_\pm})$. We will seek a solution to the problem (4.1) in the form

$$\psi(x,\lambda,l)=u_+(x_1-l,x_2,\lambda,l)+u_-(x_1+l,x_2,\lambda,l). \tag{4.3}$$

Suppose for a moment that the function ψ defined in this way solves the problem (4.1). In such a case the function ψ is infinitely differentiable at the points of the intervals $\gamma_{a_\pm}$, and therefore

$$\frac{\partial\psi}{\partial x_2}(x_1,+0,\lambda,l)-\frac{\partial\psi}{\partial x_2}(x_1,-0,\lambda,l)=0,\quad x\in\gamma_\pm.$$

Substituting from (4.3) into this identity, we obtain a pair of equations,

$$f_\pm(x_1)+\frac{\partial u_\mp}{\partial x_2}(x_1\pm 2l,+0,\lambda,l)-\frac{\partial u_\mp}{\partial x_2}(x_1\pm 2l,-0,\lambda,l)=0,\quad x\in\gamma_{a_\pm}. \tag{4.4}$$

Denote $\mathbf{f}=(f_+,f_-)\in L_2(\gamma_{a_+})\oplus L_2(\gamma_{a_-})$. The following lemma is the main ingredient of our technique and it states that the last equation is equivalent to the original problem (4.1).

Lemma 4.1. For any solution $\mathbf{f}\in L_2(\gamma_{a_+})\oplus L_2(\gamma_{a_-})$ *of* (4.4) *and functions* $u_\pm$ *solving* (3.1) *for* $a=a_\pm$, $f=f_\pm$ *there exists a unique* $L_2(\Pi)$ *solution of* (4.1) *given by* (4.3). *Reversely, for any solution* ψ *of* (4.1) *there are unique* $\mathbf{f}\in L_2(\gamma_{a_+})\oplus L_2(\gamma_{a_-})$ *solving* (4.4) *and unique functions* $u_\pm\in L_2(\Pi_{a_\pm})$ *satisfying* (3.1) *with* $a=a_\pm$, $f=f_\pm$ *such that* ψ *is given by* (4.3). *This equivalence holds for any* $\lambda\in\mathbb{S}_\delta$ *and* $l\geqslant\max\{a_-,a_+\}+1$.

Proof. Suppose that $\mathbf{f}\in L_2(\gamma_{a_+})\oplus L_2(\gamma_{a_-})$ is a solution to the equations (4.4), where the functions $u_\pm\in L_2(\Pi_{a_\pm})$ solve the problem (3.1) for $a=a_\pm$ and $f=f_\pm$. We define ψ in accordance with (4.3). The functions $u_\pm$ are elements of $L_2(\Pi)$; hence, the same is true for ψ. Moreover, the function ψ belongs obviously to $W_2^1(\Pi^b,\Gamma^b)$ for each $b>0$ and vanishes on Γ.

Let us check that the function ψ satisfies Eq. (4.2). To this purpose, we indicate by $\chi_2=\chi_2(x_1)$ an infinitely differentiable cutoff function being equal to 1 if $|x_1+l|<\max\{a_+,a_-\}+1/2$ and vanishing if $|x_1+l|>\max\{a_+,a_-\}+1$. For any $\zeta\in C_0^\infty(\Pi)$ we have

$$\begin{aligned}(\nabla u_+,\nabla\zeta)_{L_2(\Pi)}-\lambda(u_+,\zeta)_{L_2(\Pi)}&=(\nabla u_+,\nabla(\zeta\chi_2))_{L_2(\Pi)}-\lambda(u_+,\zeta\chi_2)_{L_2(\Pi)}+(\nabla u_+,\nabla(\zeta(1-\chi_2)))_{L_2(\Pi)}\\&\quad-\lambda(u_+,\zeta(1-\chi_2))_{L_2(\Pi)},\end{aligned} \tag{4.5}$$

where the arguments of u_+ are (x_1-l,x_2,λ,l). Since $u_+(\cdot)$ is an element of $C^\infty(\Pi_{a_+}\setminus\bar{Q}^{a_+})$, we can integrate by parts,

$$(\nabla u_+,\ \nabla\zeta\chi_2))_{L_2(\Pi)} - \lambda(u_+,\zeta\chi_2)_{L_2(\Pi)} = -\int_{\gamma_-}\left(\frac{\partial u_+}{\partial x_2}(\cdot - l,+0,\lambda,l) - \frac{\partial u_+}{\partial x_2}(\cdot - l,-0,\lambda,l)\right)\zeta \mathrm{d}x_1$$
$$-\int_\Pi \zeta\chi_2(\Delta+\lambda)u_+ \mathrm{d}x = \int_{\gamma_-} f_-(\cdot + l)\zeta \mathrm{d}x_1,$$

where $u_+ = u_+(x_1 - l, x_2, \lambda, l)$. We have employed here the equation satisfied by u_+ as well as Eq. (4.4) for f_+. Since $\zeta(x_1+l,x_2)(1-\chi_2(x_1+l)) \in C_0^\infty(\Pi_{a_+})$, we can use the identity (3.2) to infer that

$$(\nabla u_+, \nabla\zeta(1-\chi_2))_{L_2(\Pi)} - (u_+, \zeta(1-\chi_2))_{L_2(\Pi)} = -\int_{\gamma_+} f_+(\cdot - l)\zeta \mathrm{d}x_1,$$

where $u_+ = u_+(x_1 - l, x_2, \lambda, l)$. We substitute now the last two relations into (4.5) and arrive at the identity

$$(\nabla u_+, \nabla\zeta)_{L_2(\Pi)} - \lambda(u_+,\zeta)_{L_2(\Pi)} = (f_-(\cdot + l),\zeta)_{L_2(\gamma_-)} - (f_+(\cdot - l),\zeta)_{L_2(\gamma_+)},$$

where $u_+ = u_+(x_1 - l, x_2, \lambda, l)$. In the same way, one can check that

$$(\nabla u_-, \nabla\zeta)_{L_2(\Pi)} - \lambda(u_-,\zeta)_{L_2(\Pi)} = (f_+(\cdot - l),\zeta)_{L_2(\gamma_+)} - (f_-(\cdot + l),\zeta)_{L_2(\gamma_-)},$$

where $u_- = u_-(x_1 + l, x_2, \lambda, l)$. Summing the last two relations we arrive at the relation (4.2) for the function ψ.

Let ψ be a solution to the problem (4.1) belonging to $L_2(\Pi)$. By smoothness-improving theorems the function ψ belongs to $C^\infty(\{x: -1 \leqslant x_1 \leqslant 1, 0 \leqslant x_2 \leqslant \pi\})$ and to $C^\infty(\{x: -1 \leqslant x_1 1 \leqslant, -d \leqslant x_2 \leqslant 0\})$. This allows us to define the numbers

$$\alpha_j^\pm = \alpha_j^\pm(\lambda,l) := \frac{2}{\pi}\int_0^\pi \left(\psi(0,x_2,\lambda,l) \pm \frac{1}{\kappa_j^+(\lambda)}\frac{\partial\psi}{\partial x_1}(0,x_2,\lambda,l)\right)\sin jx_2 \mathrm{d}x_2,$$

$$\beta_j^\pm = \beta_j^\pm(\lambda,l) := \frac{2}{d}\int_0^\pi \left(\psi(0,x_2,\lambda,l) \pm \frac{1}{\kappa_j^-(\lambda)}\frac{\partial\psi}{\partial x_1}(0,x_2,\lambda,l)\right)\sin\frac{\pi j}{d}x_2 \mathrm{d}x_2.$$

Using these numbers, we introduce the functions $u_\pm$ in the following way:

$$u_\pm(x_1 \mp l, x_2, \lambda, l) := \sum_{j=1}^\infty \alpha_j^\pm(\lambda,l)\mathrm{e}^{\pm\kappa_j^+(\lambda)x_1}\sin jx_2, \quad \pm x_1 \leqslant 0, \quad x_2 \in (0,\pi),$$

$$u_\pm(x_1 \mp l, x_2, \lambda, l) := \sum_{j=1}^\infty \beta_j^+(\lambda,l)\mathrm{e}^{\pm\kappa_j^-(\lambda)x_1}\sin\frac{\pi j}{d}x_2, \quad \pm x_1 \leqslant 0, \quad x_2 \in (-d,0),$$

$$u_\pm(x_1 \mp l, x_2, \lambda, l) := \psi(x,\lambda,l) - u_\pm(x_1 \pm l, x_2, \lambda), \quad \pm x_1 > 0, \quad x_2 \in (-d,\pi).$$

Proceeding in the same way as in the proof of Lemma 4.1 in Ref. 4, we check that the functions $u_\pm$ are well defined and

$$u_\pm \in W_2^1(\Pi_{a_\pm},\Gamma_{a_\pm}) \cap W_2^2(S), \quad S \in \Xi_a, \tag{4.6}$$

$$(\Delta+\lambda)u_\pm(x_1 \mp l, x_2, \lambda, l) = 0, \quad x \in \Pi \setminus \{x: x_1 = 0\}. \tag{4.7}$$

The relation (4.3) follows from the definition of the functions $u_\pm$. Now, we set

$$f_\pm(x_1,l) := -\frac{\partial u_\mp}{\partial x_2}(x_1 \pm 2l, +0,\lambda,l) + \frac{\partial u_\mp}{\partial x_2}(x_1 \pm 2l,-0,\lambda,l), \quad x_1 \in (-a_\pm,a_\pm); \tag{4.8}$$

in view of (4.6) we can conclude that $f_\pm(\cdot,l) \in L_2(\gamma_{a_\pm})$. We also note that the definition of $u_\pm$ and the smoothness of ψ at $\gamma_\pm$ imply

$$f_\pm(x_1,l) = \frac{\partial u_\pm}{\partial x_2}(x_1, +0,\lambda,l) - \frac{\partial u_\pm}{\partial x_2}(x_1,-0,\lambda,l), \quad x_1 \in (-a_\pm,a_\pm). \tag{4.9}$$

Let us check the integral equation (3.2) for the function $u_+ = u_+(x,\lambda)$. Taking into account (4.7) and (4.9), and integrating by parts, we get

$$-(\nabla u_+,\nabla\zeta)_{L_2(\Pi_a)} + \lambda(u_+,\zeta)_{L_2(\Pi_a)} = \left(\frac{\partial u_+}{\partial x_2}(x_1, +0,\lambda) - \frac{\partial u_+}{\partial x_2}(x_1,-0,\lambda),\zeta\right)_{L_2(\gamma_{a_+})} = (f_+,\zeta)_{L_2(\gamma_{a_+})}$$

for any $\zeta \in C_0^\infty(\Pi_{a_+})$. In the same way one can check that

$$-(\nabla u_-,\nabla\zeta)_{L_2(\Pi_a)} + \lambda(u_-,\zeta)_{L_2(\Pi_a)} = (f_-,\zeta)_{L_2(\gamma_{a_-})}$$

for any $\zeta \in C_0^\infty(\Pi_{a_-})$; thus, $u_\pm$ are solutions to the problem (3.1) for $a = a_\pm$ and $f = f_\pm$. Equations (4.4) follow from (4.8).

Suppose that $\lambda \in \mathbb{S}_\delta \setminus \sigma_*$. In that case the functions $u_\pm$ introduced above can be represented as $u_\pm = T_3(\lambda,a_\pm) f_\pm$; thus, Eq. (4.4) become

$$\boldsymbol{f} + T_8(\lambda,l,\boldsymbol{a})\boldsymbol{f} = 0, \tag{4.10}$$

where the operator $T_8 : L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-}) \to L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-})$ is defined by

$$T_8(\lambda,l,\boldsymbol{a})\boldsymbol{f} := (T_8^+(\lambda,l,a_-,a_+)f_-, T_8^-(\lambda,l,a_+,a_-)f_+).$$

Now we are ready to demonstrate the first of our main results.

Proof of Theorem 2.1. If $a_\pm = 0$ the essential spectrum of the operator H is obviously $[1,+\infty)$, and an elementary argument using Dirichlet-Neumann bracketing (Ref. 16 Chap. XIII, Sec. 15) and the minimax principle (Ref. 16 Chap. XIII, Sec. 1) shows that the threshold of the essential spectrum of H is 1, i.e., $\sigma_{\mathrm{ess}}(H) \subseteq [1,+\infty)$. The opposite inclusion can be shown easily; one needs to employ Weyl's criterion (see, for instance, proof of Lemma 2.1 in Ref. 4).

The operator H being self-adjoint, its isolated eigenvalues are real, and in view of the above observation they are smaller than 1. To prove the uniform bound on their total multiplicity we use bracketing in a way analogous to Ref. 1; without loss of generality we may suppose that $l \geqslant \max\{a_-,a_+\}$. We add Neumann boundaries at segments corresponding to x_1 at the endpoints of $\gamma_\pm$ and $x_2 \in (-d,\pi)$; in this way we get an operator estimating H from below. To be completely explicit, we get a lower bound $H \geqslant H_{\mathrm{left}} \oplus H_{\mathrm{lw}} \oplus H_{\mathrm{middle}} \oplus H_{\mathrm{rw}} \oplus H_{\mathrm{right}}$, and since only the window part $H_{\mathrm{windows}} = H_{\mathrm{lw}} \oplus H_{\mathrm{rw}}$ contributes to the spectrum below 1, being obviously independent of l, we infer by minimax that H has finitely many eigenvalues for any $l > 0$ and their number counting multiplicity has a bound independent of l.

The eigenvalue continuity can be established using a simple perturbation argument. The operator H' with the window distance $2l'$ can be mapped unitarily into an operator on $L_2(\Pi)$ with the same boundary condition as H by means of the longitudinal coordinate change, $x_1 \to x_1' := x_1 + \varepsilon\int_0^x \varphi(y)\mathrm{d}y$ with an arbitrary $\varphi \in C_0^\infty(\mathbb{R})$ of nonzero mean such that $\operatorname{supp}\varphi \in \left(-\frac{1}{2}l,-\frac{1}{2}l\right)$; for large enough l the region where the coordinates are changed is clearly disjoint with the windows. The variation of the window distance is in this way expressed through the operator coefficients on a fixed domain, and since $l' - l = \varepsilon\int_{-l/2}^{l/2}\varphi(y)\mathrm{d}y$, the sought continuity for $\varepsilon \to 0$ follows easily by analytic perturbation theory.

Let $K \subset \mathbb{S}_\delta$ be any compact set separated from σ_* by a positive distance. By the estimates (3.10) the operator T_8 has a norm being strictly less than 1 for $\lambda \in K$ and l large enough. For such

λ and l Eq. (4.10) has thus a trivial solution only, and in view of Lemma 4.1 this implies that the operator H has no eigenvalues in the set K if l is large enough. This means that each eigenvalue of the operator H has to converge to one of the numbers from the set σ_* or to the threshold of the essential spectrum.

The eigenvalues of H, i.e., those λ for which the problem (4.1) has a nontrivial $L_2(\Pi)$ solution, coincide in view of Lemma 4.1 with the values of λ for which Eq. (4.4) has a nontrivial solution. In the case considered here we deal only with the eigenvalues of H which converge to a value $\lambda_* \in \sigma_*$ separated from the threshold, in other words, being smaller than 1.

Our aim is to solve Eq. (4.4) and to obtain in this way an equation for the aforementioned values of λ. Consider a $\lambda_* \in \sigma_*$; if $\lambda_*=\lambda_n$ is an eigenvalue of the operator $H(a_+)$ we set

$$\boldsymbol{\phi}_*^+(\cdot,l) := (0,\phi_n^-(\cdot,l,a_+)) \in L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-}), \quad T_4^+\boldsymbol{f} := (f_+,\psi_n)_{L_2(\gamma_{a_+})},$$

where ϕ_n^- is determined by ψ_n in accordance with (3.12) and ψ_n is an eigenfunction associated with λ_n. In the opposite case we set

$$\boldsymbol{\phi}_*^+(\cdot,l) := (0,0) \in L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-}), \quad T_4^+\boldsymbol{f} := 0.$$

Analogously, if $\lambda_*=\lambda_n$ is an eigenvalue of $H(a_-)$, we set

$$\boldsymbol{\phi}_*^-(\cdot,l) := (\phi_n^+(\cdot,l,a_-),0) \in L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-}), \quad T_4^-\boldsymbol{f} := (f_-,\psi_n)_{L_2(\gamma_{a_-})},$$

where ϕ_n^+ corresponds to ψ_n in accordance with (3.12) and ψ_n is an eigenfunction associated with λ_n; otherwise,

$$\boldsymbol{\phi}_*^-(\cdot,l) := (0,0) \in L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-}), \quad T_4^-\boldsymbol{f} := 0.$$

Given a number $\lambda_* \in \sigma_*$, we consider Eq. (4.4) for λ in the vicinity of λ_*. Assume first that $\lambda \neq \lambda_*$, in which case Eq. (4.4) is equivalent to (4.10). In view of Lemma 3.5 the operator T_8 is bounded and meromorphic as a function of $\lambda \in \mathbb{S}_\delta$, and the numbers $\lambda_* \in \sigma_*$ are poles of T_8. For any λ close to λ_* the operator T_8 can be thus represented as

$$T_8(\lambda,l,\boldsymbol{a}) = \boldsymbol{\phi}_*^+(\cdot,l)\frac{T_4^+}{\lambda-\lambda_*} + \boldsymbol{\phi}_*^-(\cdot,l)\frac{T_4^-}{\lambda-\lambda_*} + T_9(\lambda,l,\boldsymbol{a}), \tag{4.11}$$

where the operator T_9 acts as

$$T_9(\lambda,l,\boldsymbol{a})\boldsymbol{f} := (T_8^+(\lambda,l,a_-,a_+)f_-, T_9^-(\lambda,l,a_+,a_-)f_+)$$

if $\lambda_* \in \sigma_{\mathrm{disc}}(H(a_+))\setminus\sigma_{\mathrm{disc}}(H(a_-))$,

$$T_9(\lambda,l,\boldsymbol{a})\boldsymbol{f} := (T_9^+(\lambda,l,a_-,a_+)f_-, T_8^-(\lambda,l,a_+,a_-)f_+)$$

if $\lambda_* \in \sigma_{\mathrm{disc}}(H(a_-))\setminus\sigma_{\mathrm{disc}}(H(a_+))$, and finally,

$$T_9(\lambda,l,\boldsymbol{a})\boldsymbol{f} := (T_9^+(\lambda,l,a_-,a_+)f_-, T_9^-(\lambda,l,a_+,a_-)f_+)$$

if $\lambda_* \in \sigma_{\mathrm{disc}}(H(a_-)) \cap \sigma_{\mathrm{disc}}(H(a_+))$. The operator T_9 on $L_2(\gamma_{a_+}) \oplus L_2(\gamma_{a_-})$ is bounded and holomorphic with respect to λ in the vicinity of λ_*, and the estimate

$$\left\| \frac{\partial^i T_9}{\partial \lambda^i} \right\| \leqslant C l^{i+1} \mathrm{e}^{-2l \operatorname{Re} \kappa_1^+(\lambda)}, \quad i=0,1, \tag{4.12}$$

holds true with a constant C which is independent on λ and l.

We substitute the representation (4.11) into (4.10) to obtain

$$\boldsymbol{f}+\frac{T_4^+\boldsymbol{f}}{\lambda-\lambda_*}\boldsymbol{\phi}_*^+ + \frac{T_4^-\boldsymbol{f}}{\lambda-\lambda_*}\boldsymbol{\phi}_*^- + T_9\boldsymbol{f}=0.$$

Since the norm of T_9 is small for large l due to (4.12), the operator $(\mathrm{I}+T_9)^{-1}$ is well defined being bounded in $L_2(\gamma_{a_+})\oplus L_2(\gamma_{a_-})$. We apply this operator to the last equation, arriving at

$$\boldsymbol{f}+\frac{T_4^+\boldsymbol{f}}{\lambda-\lambda_*}\boldsymbol{\Phi}_*^+ + \frac{T_4^-\boldsymbol{f}}{\lambda-\lambda_*}\boldsymbol{\Phi}_*^- = 0, \tag{4.13}$$

where $\boldsymbol{\Phi}_*^\pm(\cdot,\lambda,l)=(\mathrm{I}+T_9(\lambda,l,\boldsymbol{a}))^{-1}\boldsymbol{\phi}_*^\pm(\cdot,l)$. The last equation implies that

$$\boldsymbol{f}=c_+\boldsymbol{\Phi}_*^+ + c_-\boldsymbol{\Phi}_*^- \tag{4.14}$$

for some numbers $c_\pm$. We substitute from here into (4.13), obtaining

$$\boldsymbol{\Phi}_*^+\left(c_+\left(1+\frac{A_{11}}{\lambda-\lambda_*}\right)+c_-\frac{A_{12}}{\lambda-\lambda_*}\right)+\boldsymbol{\Phi}_*^-\left(c_+\frac{A_{21}}{\lambda-\lambda_*}+c_-\left(1+\frac{A_{22}}{\lambda-\lambda_*}\right)\right)=0, \tag{4.15}$$

where the quantities $A_{ij}=A_{ij}(\lambda,l)$ are defined by

$$A_{11}(\lambda,l) := T_4^+\Phi_*^+(\cdot,\lambda,l), \quad A_{12}(\lambda,l) := T_4^+\Phi_*^-(\cdot,\lambda,l),$$

$$A_{21}(\lambda,l) := T_4^-\Phi_*^+(\cdot,\lambda,l), \quad A_{22}(\lambda,l) := T_4^-\Phi_*^-(\cdot,\lambda,l).$$

The definition of $\boldsymbol{\Phi}_*^\pm$, together with the estimate (4.12), implies for l large enough

$$\boldsymbol{\Phi}_*^\pm=\boldsymbol{\phi}_*^\pm+\mathcal{O}(\mathrm{e}^{-2l\ \mathrm{Re}\ \kappa_1^+(\lambda)}\|\boldsymbol{\phi}_*^\pm\|). \tag{4.16}$$

If $\boldsymbol{\phi}_*^+\neq 0$, and $\boldsymbol{\phi}_*^-=0$, in particular, we have

$$\boldsymbol{\Phi}_*^+\neq 0, \quad \boldsymbol{\Phi}_*^-=0, \quad A_{12}=A_{22}=0, \tag{4.17}$$

and in this case Eq. (4.15) holds if and only if

$$c_+\left(1+\frac{A_{11}}{\lambda-\lambda_*}\right)=0.$$

If $\boldsymbol{f}$ corresponds to an eigenfunction ψ of the problem (4.1) by (4.3), the number c_+ is nonzero. Indeed, in the opposite case the identities (4.14) and (4.17) would imply that $\boldsymbol{f}=0$, which by Lemma 4.1 results in $\psi=0$. Consequently, Eq. (4.10) has in this case a nontrivial solution if and only if

$$\lambda-\lambda_*+A_{11}(\lambda,l)=0. \tag{4.18}$$

If λ is a root of this equation, the corresponding nontrivial solution of (4.10) can be expressed as (4.14) with $c_+\neq 0$ and $c_-=0$.

In the case $\boldsymbol{\phi}_*^+=0$ and $\boldsymbol{\phi}_*^-\neq 0$, similar arguments lead us to the conclusion that Eq. (4.10) has a nontrivial solution if and only if

$$\lambda-\lambda_*+A_{22}(\lambda,l)=0, \tag{4.19}$$

and the corresponding nontrivial solution can be written as (4.14) with the coefficients $c_+=0$ and $c_-\neq 0$.

Finally, if both the vectors $\boldsymbol{\phi}_*^\pm$ are nonzero, they are linearly independent by definition and the same is true for the vectors $\boldsymbol{\Phi}_*^\pm$. Hence Eq. (4.10) holds if and only if

$$((\lambda-\lambda_*)\mathrm{E}+\mathrm{A}(\lambda,l))\boldsymbol{c}=0, \tag{4.20}$$

where E is the unit matrix, and

$$\mathrm{A}(\lambda,l):=\begin{pmatrix} A_{11}(\lambda,l) & A_{12}(\lambda,l) \\ A_{21}(\lambda,l) & A_{22}(\lambda,l) \end{pmatrix}, \quad \boldsymbol{c}:=\begin{pmatrix} c_+ \\ c_- \end{pmatrix}.$$

The column $\boldsymbol{c}$ is nonzero, since otherwise (4.14) and (4.17) would imply $\boldsymbol{f}=0$; thus, the system (4.20) of linear equations has a nontrivial solution if and only if

$$\det((\lambda-\lambda_*)\mathrm{E}+\mathrm{A}(\lambda,l))=0, \tag{4.21}$$

which can be rewritten as

$$(\lambda-\lambda_*)^2+(\lambda-\lambda_*)\mathrm{tr}\mathrm{A}(\lambda,l)+\det \mathrm{A}(\lambda,l)=0; \tag{4.22}$$

the corresponding nontrivial solution of Eq. (4.10) is given by (4.14), where $\binom{c_+}{c_-}$ is a nontrivial solution of (4.20).

Assume now that $\lambda=\lambda_*$. Let λ_* coincide with an eigenvalue λ_n of the operator $H(a_+)$ being not at the same time an eigenvalue of $H(a_-)$. In this case we again can claim that $u_-=T_3(\lambda_*,a_-)f_-$, on the other hand, the boundary value problem for u_+ with $\lambda=\lambda_*$ is solvable if and only if

$$0=\int_{\gamma_{a_+}} f_+\psi_n(x,a_+)\mathrm{d}x=T_4^+\boldsymbol{f}. \tag{4.23}$$

This follows from Lemma 3.2. The function u_+ is given by $u_+=T_5(\lambda_*,a_+)f_+-c_+\psi_+$, where c_+ is a constant. We can substitute now the described $u_\pm$ into (4.4) and obtain

$$\begin{gathered} \boldsymbol{f}+T_9(\lambda,l,\boldsymbol{a})\boldsymbol{f}=c_+\boldsymbol{\phi}_*^+, \\ \boldsymbol{f}=c_+\boldsymbol{\Phi}_*^+. \end{gathered} \tag{4.24}$$

This function will generate a solution to the problem (4.1) if and only if (4.18) holds true. Substituting (4.24) into (4.23), we arrive at Eq. (4.18) with $\lambda=\lambda_*$. If $c_+\neq 0$ holds in (4.24) we see that the formula (4.23) coincides with (4.14) with $c_-=0$. Consequently, in the case $\lambda_* \in \sigma(H(a_-))\setminus\sigma(H(a_+))$ Eq. (4.18) determines all the values of λ in the vicinity of λ_* for which Eq. (4.4) has a nontrivial solution; these nontrivial solutions are given by (4.14) with $c_+\neq 0$ and $c_-=0$.

In the same way one can check that Eq. (4.19) determines the sought values of λ in the case when λ_* is an eigenvalue of the operator $H(a_-)$ and not of $H(a_+)$. The corresponding nontrivial solutions of (4.4) have $c_+=0$ and $c_-\neq 0$.

Finally, if $\lambda_*\in\sigma_*$ is double and $\lambda=\lambda_*$, the solvability conditions of the boundary value problems for u are $T_4^\pm\boldsymbol{f}=0$. If this holds true, the functions $u_\pm$ are given by $u_\pm=T_5(\lambda,a_\pm)-c_\pm\psi_\pm(\cdot)$, where $c_\pm$ are constants and $\psi_\pm$ are the eigenfunctions of $H(a_\pm)$ associated with λ_*. Equation (4.4) becomes

$$\boldsymbol{f}+T_9(\lambda_*,l,\boldsymbol{a})\boldsymbol{f}=c_+\boldsymbol{\phi}_*^+ + c_-\boldsymbol{\phi}_*^-,$$

which yields the relation (4.14). The solvability conditions $T_4^\pm\boldsymbol{f}=0$ are nothing else than the system of linear equations (4.20). In this way (4.14), (4.20), and (4.21) describe the sought values of λ in the vicinity of λ_* and the corresponding nontrivial solutions of (4.4).

V. PROOFS OF THEOREMS 2.2–2.4

Now we are going to demonstrate the remaining part of our claims. In order to do it, we employ the results of the previous section. More specifically, we analyze the behavior of the roots of Eqs. (4.18), (4.19), and (4.22).

Proof of Theorem 2.2. We will give the proof for the case $\lambda_*=\lambda_n(a_-)$; the argument for $\lambda_*=\lambda_n(a_+)$ is similar. In accordance with the results of the previous section, if the eigenvalue $\lambda^-(a,l)$ exists, it must be a root of the Eq. (4.19). Let us prove first that there is a unique root which converges to λ_* as $l\to+\infty$. Lemma 3.6 implies that the relation

$$\phi_n^+(x_1,l,a_-)=\tau c(\lambda_*,a_-)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}), \tag{5.1}$$

holds in the norm of $L_2(\gamma_{a_+})$; hence, by the definition of $\boldsymbol{\phi}_*^-$ we have

$$\boldsymbol{\phi}_*^-(x_1,l)=\tau c(\lambda_*,a_-)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}(\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1},0)+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}). \tag{5.2}$$

This formula, in combination with the estimate (4.12), leads to the relation

$$A_{22}(\lambda,l)=\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}). \tag{5.3}$$

Since T_9 is holomorphic with respect to λ and has a small norm for large l, we infer that the left-hand side of the last equation is holomorphic in λ. In view of (5.3) for a small δ the function A_{22} satisfies the estimate $|A_{22}|<\delta$ if l is large enough and $|\lambda-\lambda_*|=\delta$; by Rouché theorem it implies that the function $\lambda\mapsto\lambda-\lambda_*+A_{22}(\lambda,l)$ has the same number of zeros in the disk $\{\lambda:|\lambda-\lambda_*|<\delta\}$ as the function $\lambda\mapsto\lambda-\lambda_*$ does. The number δ is arbitrary, so we can conclude that there is a unique root of Eq. (4.19) converging to λ_* as $l\to+\infty$. As a consequence, there exists a unique eigenvalue of the operator H converging to λ_* as $l\to+\infty$; we will denote this eigenvalue as $\lambda(l,\boldsymbol{a})$. The estimate (5.3) implies at the same time that

$$\lambda(l,\boldsymbol{a})-\lambda_*=\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}). \tag{5.4}$$

Let us derive the asymptotic expansion (2.2) for the eigenvalue $\lambda(l,\boldsymbol{a})$. In order to do it, we will need to know the asymptotic behavior for A_{22} in a way more precise than (5.3). For the sake of brevity we will write simply λ instead of $\lambda(l,\boldsymbol{a})$. The relations (5.2) together with the estimates (4.12) and (5.4) imply that

$$\begin{aligned}
A_{22}(\lambda,l)&=T_4^-(\mathrm{I}+T_9(\lambda,l,\boldsymbol{a}))^{-1}\boldsymbol{\phi}_*^-(\cdot,l)\\
&=T_4^-\boldsymbol{\phi}_*^-(\cdot,l)-T_4^-T_9(\lambda,l,\boldsymbol{a})\boldsymbol{\phi}_*^-(\cdot,l)+\mathcal{O}(\|T_9\|^2\|\boldsymbol{\phi}_*^-\|)\\
&=-T_4^-T_9(\lambda_*,l,\boldsymbol{a})\boldsymbol{\phi}_*^-(\cdot,l)+\mathcal{O}\left(|\lambda-\lambda_*|\left\|\frac{\partial T_9}{\partial\lambda}\right\|\|\boldsymbol{\phi}_*^-\|+\|T_9\|^2\|\boldsymbol{\phi}_*^-\|\right)\\
&=-T_4^-T_8^-(\lambda,l,\boldsymbol{a})\phi_n^+(\cdot,l,a_-)+\mathcal{O}(|\lambda-\lambda_*|l^2\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}+l\mathrm{e}^{-6\kappa_1^+(\lambda_*)l}).
\end{aligned} \tag{5.5}$$

Taking into account the estimate (3.10) for $\|T_8^-\|$ and the relation (5.1), we can proceed with the calculations, obtaining

$$\begin{aligned}
A_{22}(\lambda,l)=&-\tau c(\lambda,a_-)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}(T_8^-(\lambda_*,l,a_+,a_-)\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1},\psi_*)_{L_2(\gamma_{a_-})}+\mathcal{O}(|\lambda-\lambda_*|l^2\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}\\
&+\mathrm{e}^{-2l(\kappa_1^+(\lambda_*)+\rho(\lambda_*))}),
\end{aligned} \tag{5.6}$$

where we have denoted $\psi_*(x)=\psi_n(x,a_-)$. In view of the relation (3.14) the function $T_8^-(\lambda_*,l,a_+,a_-)\mathrm{e}^{\kappa_1^+(\lambda_*)x_1}$ coincides with $T_7^-(\lambda,l,a_+,a_-)u$, where u is the solution to the problem (3.1) with $a=a_+$, $\lambda=\lambda_*$, and $f=\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1}$. It is clear that $u(x)=U(-x_1,x_2,\lambda_*,a_+)$, and in view of (3.15)–(3.17) we obtain

$$\begin{aligned}
(T_8^-(\lambda_*,l,a_+,a_-)\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1},\psi_*)_{L_2(\gamma_{a_-})}&=c(\lambda_*,a_+)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}(\mathrm{e}^{\kappa_1^+(\lambda_*)x_1},\psi_*)_{L_2(\gamma_{a_-})}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l})\\
&=\pi c(\lambda_*,a_+)c(\lambda_*,a_-)\kappa_1^+(\lambda_*)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}).
\end{aligned}$$

Substituting these identities into (5.6), we finally arrive at the following formula:

$$A_{22}(\lambda,l)=\mu^-(l,\boldsymbol{a})\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}+\mathcal{O}(|\lambda-\lambda_*|l^2\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}+\mathrm{e}^{-2l(\kappa_1^+(\lambda_*)+\rho(\lambda_*))}),$$

where $\mu^-(l,\boldsymbol{a})$ is defined by (2.3). It allows us to rewrite Eq. (4.19) as

$$(\lambda-\lambda_*)(1+\mathcal{O}(l^2\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}))=\mu^-(l,\boldsymbol{a})\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}+\mathcal{O}(\mathrm{e}^{-2l(\kappa_1^+(\lambda_*)+\rho(\lambda_*))});$$

expressing $(\lambda-\lambda_*)$ from here we get the asymptotic expansion (2.2) and the formula (2.3).

Next, we have to prove the asymptotic expansion for the eigenfunction associated with λ. The nontrivial solution of Eq. (4.4) is given by (4.14) with $c_+=0$ and $c_-=1$, i.e., as $\boldsymbol{f}=\boldsymbol{\Phi}_*^-$. We substitute it into the relation $u_+=T_3(\lambda(l,\boldsymbol{a}),a_+)f_+$ and take into account (5.2) and (4.16); this yields

$$u_+=T_3(\lambda(l,\boldsymbol{a}),a_+)f_+=\mathcal{O}(\|\boldsymbol{\phi}_*^-\|)=\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}),$$

which holds true in $W_2^1(\Pi_{a_+})$ and in $W_2^2(S)$ for each $S\in\Xi_{a_+}$. If $\lambda(l,\boldsymbol{a})\neq\lambda_*$, we obtain similarly with the help of Lemma 3.2

$$u_-=T_3(\lambda(l,\boldsymbol{a}),a_-)f_-=\frac{\psi_*}{\lambda(l,\boldsymbol{a})-\lambda_*}T_4^-\boldsymbol{\Phi}_*^-+T_5^-(\lambda(l,\boldsymbol{a}),a_-)f_-=\frac{A_{22}(\lambda(l,\boldsymbol{a}),l)\psi_*}{\lambda(l,\boldsymbol{a})-\lambda_*}+\mathcal{O}(\|\boldsymbol{\phi}_*^-\|). \tag{5.7}$$

Due to Eq. (4.19) it follows that

$$u_-=-\psi_*+\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l})$$

holds in $W_2^1(\Pi_a)$ and $W_2^2(S)$ for each $S\in\Xi_{a_-}$. If $\lambda(l,\boldsymbol{a})=\lambda_*$, the last relation holds again; in order to prove it, it is sufficient to employ the identity

$$u_-=T_5(\lambda_*,a_-)f_--c_-\psi_*=T_5(\lambda_*,a_-)f_--\psi_*.$$

The relations obtained in this way together with (4.3) lead to (2.4). ■

Proof of Theorem 2.3. The general lines of the proof are similar to those of the previous one. According to the results of the previous section the eigenvalues of H converging to λ_* are roots of Eq. (4.22). First we will check that the function at the left-hand side of this equation has two zeros, the order taken into account, which converge to λ_* as $l\to+\infty$.

To this aim, we need to estimate the functions A_{ij}. Lemma 3.6 implies

$$\phi_m^-(x_1,l,a_+)=(-1)^m\pi c(\lambda_*,a_+)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}). \tag{5.8}$$

This formula, together with (5.1), allows us to conclude that

$$A_{ij}(\lambda,l)=\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}), \tag{5.9}$$

hence for any small δ we have the inequality

$$|(\lambda-\lambda_*)\mathrm{tr}A(\lambda,l)+\det A(\lambda,l)|<\delta^2\quad\text{as } |\lambda-\lambda_*|=\delta,$$

if l is large enough. Since the functions A_{ij} are holomorphic, by Rouché theorem this inequality implies that the function $\lambda\mapsto D(\lambda,l):=\det((\lambda-\lambda_*)\mathrm{E}+\mathrm{A}(\lambda,l))$ has the same number of zeros (with the order taken into account) as the function $\lambda\mapsto(\lambda-\lambda_*)^2$ does. The last function has λ_* as a second-order zero, of course, so it follows that the function $D(\cdot,l)$ has two zeros, with the order taken into account, which converge to λ_* as $l\to+\infty$. In what follows we denote these roots as $\lambda^\pm$; the case of the second-order zero corresponds to the equality $\lambda^+=\lambda^-$.

As it was established in the previous section, the nontrivial solutions of Eq. (4.4) associated with the roots of (4.22) are given by (4.14) with the coefficients $c_\pm$ solving the system of linear equations (4.20). If the numbers $\lambda^\pm$ solve (4.21), the system (4.20) has at least one nontrivial solution corresponding to λ^+ and λ^-.

Suppose that $\lambda^+ \neq \lambda^-$. Then $\lambda^\pm$ are simple zeros of the function $D(\cdot,l)$, and in view of the above discussion the system (4.20) has exactly one nontrivial solution for $\lambda=\lambda^+$ and $\lambda=\lambda^-$. Hence, in the case $\lambda^+ \neq \lambda^-$ the operator H has exactly two simple eigenvalues converging to λ_* as $l \to +\infty$.

Let us check that if the system (4.20) has two linear independent solutions referring to $\lambda=\lambda^\pm$, it follows that $\lambda^\pm$ is a second-order zero of the function $D(\cdot,l)$. Indeed, two linear independent solutions exist if and only if

$$A_{11}(\lambda^\pm,l) = A_{22}(\lambda^\pm,l) = \lambda_* - \lambda^\pm, \quad A_{12}(\lambda^\pm,l) = A_{21}(\lambda^\pm,l) = 0. \tag{5.10}$$

The derivative of $D(\lambda,l)$ with respect to λ equals

$$\frac{\partial D}{\partial \lambda}(\lambda,l) = 2(\lambda-\lambda_*) + (A_{11}(\lambda,l)+A_{22}(\lambda,l)) + (\lambda-\lambda_*)\left(\frac{\partial A_{11}}{\partial \lambda}(\lambda,l) + \frac{\partial A_{22}}{\partial \lambda}(\lambda,l)\right) + A_{11}(\lambda,l)\frac{\partial A_{22}}{\partial \lambda}(\lambda,l)$$
$$- A_{12}(\lambda,l)\frac{\partial A_{21}}{\partial \lambda}(\lambda,l) + A_{22}(\lambda,l)\frac{\partial A_{11}}{\partial \lambda}(\lambda,l) - A_{21}(\lambda,l)\frac{\partial A_{12}}{\partial \lambda}(\lambda,l).$$

Substituting from (5.10) into this expression, we see that

$$\frac{\partial D}{\partial \lambda}(\lambda,l) = 0 \quad \text{as } \lambda = \lambda^\pm,$$

thus $\lambda^\pm$ is a second-order zero.

It is more complicated to check existence of a double eigenvalue of the operator H if $\lambda^+ = \lambda^- =: \tilde{\lambda}$. It is equivalent to the fact that for $\lambda=\tilde{\lambda}$ the system (4.20) has two linear independent solutions, and this in turn is equivalent to the relations (5.10). Let us prove that they hold. Consider the boundary value problem

$$\begin{gathered}(\Delta+\lambda)u = 0, \quad x \in \Pi_a \setminus (\gamma_+ \cup \gamma_-), \quad u = 0, \quad x \in \partial\Pi, \\ \left.\frac{\partial u}{\partial x_2}\right|_{x_2=+0} - \left.\frac{\partial u}{\partial x_2}\right|_{x_2=-0} = -g_\pm, \quad x \in \gamma_\pm.\end{gathered} \tag{5.11}$$

Here $g_\pm \in L_2(\gamma_\pm)$ are arbitrary functions, and the parameter λ is supposed to range in a small neighborhood of λ_* without coinciding with λ_* and $\tilde{\lambda}$. This problem is uniquely solvable provided we seek a generalized solution to (5.11) belonging to $L_2(\Pi)$. In a complete analogy with the proof of Lemma 1 one can check easily that the problem (5.11) is equivalent to the equation

$$\boldsymbol{f} + T_8(\lambda,l,\boldsymbol{a})\boldsymbol{f} = \boldsymbol{g}, \tag{5.12}$$

where $\boldsymbol{g}=(g_+,g_-) \in L_2(\gamma_{a_-}) \oplus L_2(\gamma_{a_+})$, while the solution u of (5.11) is given by

$$u(x,\lambda,l) = u_+(x_1-l,x_2,\lambda,l) + u_-(x_1+l,x_2,\lambda,l), \quad u_\pm := T_3(\lambda,a_\pm)f_\pm.$$

We can solve Eq. (5.12) in the same way as Eq. (4.10), obtaining as a result that

$$\boldsymbol{f} + \frac{T_4^+\boldsymbol{f}}{\lambda-\lambda_*}\boldsymbol{\Phi}_*^+ + \frac{T_4^-\boldsymbol{f}}{\lambda-\lambda_*}\boldsymbol{\Phi}_*^- = \boldsymbol{G}, \quad \boldsymbol{G} := (\mathrm{I} + T_9(\lambda,l,\boldsymbol{a}))^{-1}\boldsymbol{g}. \tag{5.13}$$

Hence the function $\boldsymbol{f}$ is of the form

$$\boldsymbol{f} = C_+\boldsymbol{\Phi}_*^+ + C_-\boldsymbol{\Phi}_*^- + \boldsymbol{G}, \tag{5.14}$$

where $C_\pm = C_\pm(\lambda,l)$ are constants to be found. Denoting $\boldsymbol{C} := \binom{C_+}{C_-}$ and substituting (5.14) into (5.13), we obtain an equation for $\boldsymbol{C}$,

$$((\lambda-\lambda_*)\mathrm{E}+\mathrm{A}(\lambda,l))\boldsymbol{C}=\boldsymbol{h},\quad \boldsymbol{h}:=\begin{pmatrix}-T_4^+\boldsymbol{G}\\ -T_4^-\boldsymbol{G}\end{pmatrix}. \tag{5.15}$$

The solution of this system is given by Cramer's formula,

$$C_+(\lambda,l)=\frac{A_{12}(\lambda,l)T_4^-\boldsymbol{G}-(\lambda-\lambda_*+A_{22}(\lambda,l))T_4^+\boldsymbol{G}}{D(\lambda,l)},$$

$$C_-(\lambda,l)=\frac{A_{21}(\lambda,l)T_4^+\boldsymbol{G}-(\lambda-\lambda_*+A_{11}(\lambda,l))T_4^-\boldsymbol{G}}{D(\lambda,l)}. \tag{5.16}$$

Using now (5.15) and Lemma 3.2, we infer that

$$\begin{aligned}u_+(\cdot,\lambda,l)&=-C_+(\lambda,l)\psi_m(\cdot,a_+)+C_+(\lambda,l)T_5(\lambda,a_+)\Phi_{*,+}^++C_-(\lambda,l)T_5(\lambda,a_+)\Phi_{*,+}^-+T_5(\lambda,a_+)G_+,\\ u_-(\cdot,\lambda,l)&=-C_-(\lambda,l)\psi_n(\cdot,a_-)+C_-(\lambda,l)T_5(\lambda,a_-)\Phi_{*,-}^++C_-(\lambda,l)T_5(\lambda,a_-)\Phi_{*,-}^-+T_5(\lambda,a_-)G_-,\end{aligned} \tag{5.17}$$

where $\Phi_{*,\pm}^\pm$ and $G_\pm$ are the components of the vectors $\boldsymbol{\Phi}_*^\pm$ and $\boldsymbol{G}$,

$$\boldsymbol{\Phi}_*^\pm=(\Phi_{*,+}^\pm,\Phi_{*,-}^\pm),\quad \boldsymbol{G}=(G_+,G_-).$$

Since the number $\tilde\lambda$ is a second-order zero of $D(\cdot,l)$, we conclude from (5.16) that the coefficients $C_\pm$ have, in general, a second-order pole at $\tilde\lambda$, and the same is true for $u_\pm$. Taking into account (5.17), we conclude that the solution of (5.11) can be represented as

$$u(x,\lambda,l)=u_{-1}^+(x,\lambda,l)C_+(\lambda,l)+u_{-1}^-(x,\lambda,l)C_-(\lambda,l)+\mathcal{O}(1),\quad \lambda\to\tilde\lambda.$$

In a complete analogy with the proof of Lemma 3.2, one can check easily that the solution of the problem (5.11) has a simple pole at $\tilde\lambda$. Hence the function $u_{-1}^+(x,\lambda,l)C_+(\lambda,l)+u_{-1}^-(x,\lambda,l)C_-(\lambda,l)$ has a simple pole at $\tilde\lambda$. For x from a neighborhood of γ_+ this function satisfies due to (5.16) and (5.17) the relation

$$\begin{aligned}&D(\lambda,l)(u_{-1}^+(x,\lambda,l)C_+(\lambda,l)+u_{-1}^-(x,\lambda,l)C_-(\lambda,l))\\ &\quad=((\lambda-\lambda_*+A_{22}(\lambda,l))T_4^+\boldsymbol{G}-A_{12}(\lambda,l)T_4^-\boldsymbol{G})\psi_m^+(x_1-l,x_2)+\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}).\end{aligned}$$

Since $\tilde\lambda$ is by assumption a second-order zero of $D(\cdot,l)$, the obtained identity yields

$$\tilde\lambda-\lambda_*+A_{22}(\tilde\lambda,l)=A_{12}(\tilde\lambda,l)=0.$$

Observing the behavior of the function u for x in the vicinity of γ_-, one can prove in the same way that

$$\tilde\lambda-\lambda_*+A_{11}(\tilde\lambda,l)=A_{21}(\tilde\lambda,l)=0.$$

This completes the check of the relations (5.10) for $\lambda^+=\lambda^-$, showing that in this case the operator H has a double eigenvalue converging to λ_* as $l\to+\infty$.

We proceed to calculation of the asymptotic expansions for the root(s) of Eq. (4.22). Substituting the estimates (5.9) into (4.22), we obtain

$$\lambda-\lambda_*=o(\mathrm{e}^{-\kappa_1^+(\lambda_*)l}). \tag{5.18}$$

This relation, in combination with (5.1) and (5.5) and the estimate (3.10), implies that

$$A_{22}(\lambda,l)=\mathcal{O}(l\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}). \tag{5.19}$$

It is easy to establish an expression for A_{11} similar to (5.5), which together with (5.8) and (5.18) yield

$$A_{11}(\lambda,l)=\mathcal{O}(l\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}). \tag{5.20}$$

Proceeding in the same way as in (5.5) we obtain a chain of relations,

$$\begin{aligned}A_{12}(\lambda,l)=T_4^+(\mathrm{I}+T_9(\lambda,l,\boldsymbol{a}))^{-1}\boldsymbol{\phi}_*^-(\cdot,l)&=T_4^+\boldsymbol{\phi}_*^-(\cdot,l)+\mathcal{O}(\|T_9\|\|\boldsymbol{\phi}_*^-\|)\\&=(\phi_n^+(\cdot,l,a_-),\psi_m(\cdot,a_+))_{L_2(\gamma_{a_+})}+\mathcal{O}(l\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}).\end{aligned}$$

Due to (5.1) and (3.15) we have

$$\begin{aligned}(\phi_n^+(\cdot,l,a_-),\psi_m(\cdot,a_+))_{L_2(\gamma_{a_+})}&=c(\lambda_*,a_-)\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}(\mathrm{e}^{-\kappa_1^+(\lambda_*)x_1},\psi_m(\cdot,a_+))_{L_2(\gamma_{a_+})}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l})\\&=\mu(l,\boldsymbol{a})\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}),\end{aligned}$$

where $\mu(l,\boldsymbol{a})$ is given by (2.6). Consequently,

$$A_{12}(\lambda,l)=\mu(l,\boldsymbol{a})\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}+l\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}), \tag{5.21}$$

and in the same way one can show that

$$A_{21}(\lambda,l)=\mu(l,\boldsymbol{a})\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}+\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}+l\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}). \tag{5.22}$$

Equation (4.22) is equivalent to the following pair of the equations:

$$\lambda-\lambda_*=\frac{-\mathrm{tr}A(\lambda,l)\pm\sqrt{(A_{11}(\lambda,l)-A_{22}(\lambda,l))^2+4A_{12}(\lambda,l)A_{21}(\lambda,l)}}{2}. \tag{5.23}$$

If $c(\lambda_*,a_-)c(\lambda_*,a_+)=0$, these equations together with (5.19)–(5.22) imply that

$$\lambda-\lambda_*=\mathcal{O}(\mathrm{e}^{-2\rho(\lambda_*)l}+l\mathrm{e}^{-4\kappa_1^+(\lambda_*)l}),$$

which proves the asymptotic expansion (2.5) in the case $\mu(l,\boldsymbol{a})=0$.

Suppose on the contrary that $c(\lambda_*,a_-)c(\lambda_*,a_+)\neq 0$. In this case the function $(A_{11}-A_{22})^2+4A_{12}A_{21}$ is nonzero as $\lambda=\lambda_*$, and therefore its square root is holomorphic with respect to λ. Using this fact and the relations (5.19)–(5.22), one can show easily, in analogy with the similar argument for Eq. (4.22), that each of the equations (5.23) has a unique root converging to λ_* as $l\to+\infty$. Hence one of the roots of (4.22) satisfies the first of Eqs. (5.23), while the other satisfies the other one. Substituting now from (5.19)–(5.22) into (5.23), we arrive immediately at the asymptotics (2.5) and (2.6) in the case $\mu(l,\boldsymbol{a})\neq 0$. □

Proof of Theorem 2.4. Let $\boldsymbol{c}$ be a nontrivial solution to the system (4.20), where λ is λ^+ or λ^-. Without loss of generality we may assume that $\|\boldsymbol{c}\|_{\mathbb{R}^2}=1$. Modifying (4.14), we choose the corresponding nontrivial solution of Eq. (4.4) as $\boldsymbol{f}=-c_+\boldsymbol{\Phi}_*^+-c_-\boldsymbol{\Phi}_*^-$. In analogy with (5.7), we then obtain

$$u_-=\frac{\psi_n(\cdot,a_-)}{\lambda-\lambda_*}T_4^-\boldsymbol{f}+\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l})=-\frac{c_+A_{21}(\lambda,l)+c_-A_{22}(\lambda,l)}{\lambda-\lambda_*}\psi_n(\cdot,a_-)+\mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}),$$

which holds true in $W_2^1(\Pi_{a_-})$ and $W_2^2(S)$ for each $S\in\Xi_{a_-}$. Employing now the system (4.20) we can write

$$c_+A_{21}(\lambda,l)+c_-A_{22}(\lambda,l)=-c_-(\lambda-\lambda_*),$$

hence

$$u_- = c_-\psi_n(\cdot, a_-) + \mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}),$$

and in the same way one can prove that

$$u_+ = c_+\psi_m(\cdot, a_+) + \mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}).$$

in the norm of $W_2^1(\Pi_{a_-})$ and $W_2^2(S)$ for each $S \in \Xi_{a_-}$. The last two relations prove the sought formulas (2.9).

Suppose that $\lambda^+ = \lambda^-$, then (4.20) has two nontrivial solutions, which means that $(\lambda - \lambda_*)\mathrm{E} + \mathrm{A}(\lambda, l) = 0$; we can choose these solutions as $(c_+, c_-) = (-1, 0)$ and $(c_+, c_-) = (0, -1)$. Substituting these values into (2.9), we arrive at (2.8).

Suppose that $\mu(l, \boldsymbol{a}) \neq 0$. In view of (2.5) it implies that $\lambda^+(l, \boldsymbol{a}) \neq \lambda^-(l, \boldsymbol{a})$, i.e., that $\lambda^\pm(l, \boldsymbol{a})$ are simple eigenvalues. In this case the relations (2.5), (5.20), and (5.21) yield

$$\begin{aligned} \lambda^\pm - \lambda_* + A_{11}(\lambda^\pm, l) &= \pm\,|\mu(l, \boldsymbol{a})|\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}(1 + \mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l})) \neq 0, \\ A_{12}(\lambda^\pm, l) &= \mu(l, \boldsymbol{a})\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}(1 + \mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l})) \neq 0. \end{aligned} \tag{5.24}$$

Since the matrix $(\lambda^\pm - \lambda_*)\mathrm{E} + \mathrm{A}(\lambda^\pm, l)$ has rank one, we can choose nontrivial solutions of (4.20) as

$$c_+^\pm := \pm \frac{\sqrt{2}(\lambda^\pm - \lambda_* + A_{11}(\lambda^\pm, l))}{\sqrt{(\lambda^\pm - \lambda_* + A_{11}(\lambda^\pm, l)^2 + A_{12}^2(\lambda^\pm, l)}},$$

$$c_-^\pm := \pm \frac{\sqrt{2}A_{12}(\lambda^\pm, l)}{\sqrt{(\lambda^\pm - \lambda_* + A_{11}(\lambda^\pm, l)^2 + A_{12}^2(\lambda^\pm, l)}}.$$

In view of (5.24) we then have

$$c_+^\pm = 1 + \mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}), \quad c_-^\pm = \mp\,\mathrm{sgn}\,\mu(l, \boldsymbol{a}) + \mathcal{O}(\mathrm{e}^{-2\kappa_1^+(\lambda_*)l}).$$

Substituting from here into (2.9) we arrive immediately at (2.7). ■

Construction of basis functions for the spin-cluster expansion of the magnetic energy on the atomic scale in rotationally invariant systems

R. Singer and M. Fähnle[a)]
Max-Planck-Institut für Metallforschung, Heisenbergstraße 3, 70569 Stuttgart, Germany

(Received 4 August 2006; accepted 25 September 2006;
published online 10 November 2006)

The recently introduced spin-cluster expansion (SCE) is a powerful tool to represent on the atomic scale the adiabatic magnetic energy for each magnetic configuration of a system with N sites. In the present paper the theory is worked out for the very important case of rotationally invariant magnets. Appropriate basis functions for this SCE are rotationally invariant and exhibit time-reversal symmetry, are real, and constitute a complete orthonormal set for the representation of any rotationally invariant observable. It is also shown how generalized Heisenberg-type models of the magnetic energy of an isotropic magnet are represented in this symmetry-adapted SCE basis. © *2006 American Institute of Physics.*

I. INTRODUCTION

The investigation of noncollinear spin systems is very important because of the following reasons. First, there are many systems which exhibit noncollinear magnetic ground-state configurations, e.g., fcc Fe,[1] or amorphous Fe-B alloys.[2] Second, there are physically and technologically important noncollinear topological defects in magnets with collinear ground states, e.g., domain walls on the atomic scale in quasi-one-dimensional Fe nanostripes[3] on W(110) or magnetization singularities in the interior of magnetic vortex structures.[4] Finally, thermal magnetic excitations are of noncollinear nature, e.g., small-amplitude spin waves[5] at low temperatures or strongly noncollinear excitations in the paramagnetic temperature regime.

For a theoretical modeling of noncollinearities on an atomic scale, the coarse graining inherent in the continuum approach of micromagnetism[6] is not appropriate and has to be replaced by a microscopic approach. The use of the *ab initio* density functional electron theory for noncollinear spin systems[5,7–9] thereby yields highly accurate results but is often too costly. An alternative approach therefore models the spin interactions on the scale of atomic magnetic moments rather than on the electronic scale, e.g., by means of the classical Heisenberg model for the exchange interactions between "classical" magnetic moments $\mathbf{M}_i = M_i \mathbf{e}_i$ at the atomic sites i with orientations $\mathbf{e}_i$ and magnitudes M_i,

$$E_{\mathrm{H}} = -\sum_{i<j} J_{\mathrm{H}}(\mathbf{M}_i \cdot \mathbf{M}_j), \tag{1}$$

where J_{H} is the nearest-neighbor exchange coupling. Unfortunately, Eq. (1) in general fails badly for the case of atomic-scale noncollinearity because of the following reasons. First, it assumes that the magnitudes M_i do not depend on the magnetic configurations, whereas in reality this is not at all the case[9] (there are configurations for which in some materials M_i even vanishes). Finally, the

[a)]Electronic mail: faehnle@mf.mpg.de

Heisenberg model neglects the influence of multispin interactions,[10] which may become important for strong noncollinearities on an atomic scale.

Because of these deficiencies of the Heisenberg model, two other parametrizations of the magnetic energy on the atomic scale have been introduced recently.[11,12] Both parametrizations are based on the adiabatic approximation where it is assumed that the electronic system is at any instant in its ground state with respect to the momentary orientational configuration $\{\mathbf{e}_i\}$ so that the magnitudes M_i are "slaved," i.e., completely determined by $\{\mathbf{e}_i\}$, $M_i=M_i[\{\mathbf{e}_j\}]$. In the first parametrization[11] the part of the magnetic energy which is invariant with respect to a rotation and inversion of the coordinate system is modeled by an in principle infinite series in terms of all the relative angles $(\mathbf{e}_i\cdot\mathbf{e}_j)$. This method classifies the classical Heisenberg model as a first approximation. Extensions of the Heisenberg model discussed in the literature are shown to be of second order in this parametrization, and explicit third-order expressions are derived. The second parametrization, the so-called spin-cluster expansion[12] (SCE), may be in general applied to systems with arbitrary symmetry, i.e., it is not confined to systems which are rotationally invariant. To achieve this, the SCE for a system with N sites is evaluated in terms of product functions invoking N one-spin basis functions $\phi_\nu(\mathbf{e}_i)$ rather than in terms of the two-spin functions $(\mathbf{e}_i\cdot\mathbf{e}_j)$. Of course, the SCE in general encompasses also the case of a rotationally invariant system, but due to its generality it is yet too undetermined for practical calculations. Because in many magnets the magnetic energy is strongly dominated by the isotropic exchange interactions, it is very often justified to approximate them by a rotationally and time-reversal invariant system. In the present paper it will be shown how rotationally and time-reversal invariant basis functions for the SCE of an isotropic magnetic system can be constructed from product basis functions of the general SCE, which is very important for practical computations. Furthermore, the above-mentioned general Heisenberg-type parametrization is also expanded in this symmetry-adapted SCE basis.

II. THE SPIN-CLUSTER EXPANSION

By the SCE,[12] the adiabatic magnetic energy surface, including all relevant magnetic interactions in the solid (exchange energy, anisotropy energy, dipolar, and Zeeman energy), are represented in principle exactly in terms of one-spin basis functions. The expansion coefficients appearing in the SCE may be obtained by fitting the SCE to the energies of magnetic reference configurations, which in turn may be calculated by the highly accurate *ab initio* density functional electron theory for noncollinear spin systems,[5,7–9] and a carefully constructed SCE therefore will have near-*ab initio* accuracy. Having obtained the SCE it is possible to calculate very quickly the energy of any magnetic configuration $\{\mathbf{e}_i\}=(\mathbf{e}_1,\ldots,\mathbf{e}_N)$. Therefore, the SCE can be used to determine the ground-state configuration of systems with complex magnetic interactions, it can be combined, e.g., with a Monte Carlo simulation method to determine the thermodynamic properties, or it can be combined[13] with an adiabatic equation of motion for the variables $\{\mathbf{e}_i\}$ in order to explore the magnetization dynamics.

The construction of the SCE represents a step-by-step generalization of the arguments given in the conventional cluster expansion of alloy theory.[14] Because it is described in more detail in Ref. 12, we confine ourselves to a short summary. The first step is to parametrize the orientation vectors $\mathbf{e}_i$ by the angles ϑ_i and φ_i with $\vartheta_i\in[0,\pi]$ and $\varphi_i\in[0,2\pi[$ describing the continuous direction of the unit vector in a global coordinate system. In a second step a complete set of orthogonal one-spin basis functions is introduced. For expedience in later developments, we determine these one-spin basis functions to be the set of spherical harmonics $\sqrt{4\pi}Y_L(\mathbf{e})\equiv\sqrt{4\pi}Y_L(\vartheta(\mathbf{e}),\varphi(\mathbf{e}))$ with $L=(l,m)$, the integral order $l=0,1,2,\ldots$, and the respective projection $m=-l,(-l+1),\ldots,l$. Hence, the one-spin basis of order l spanned by the $\sqrt{4\pi}Y_L$ is $(2l+1)$-dimensional. In a third step the complete set of orthogonal basis functions for the full N-site system is constructed from a direct product of one-spin basis functions,

$$\tilde{\mathbf{\Phi}}_{\ell\mathbf{m}}(\{\mathbf{e}_i\}) = (4\pi)^{-N/2} Y_{L_1}(\mathbf{e}_1) Y_{L_2}(\mathbf{e}_2) \cdots Y_{L_N}(\mathbf{e}_N), \tag{2}$$

where $\ell = (l_1, l_2, \ldots, l_N)$ labels the orders of the corresponding one-spin basis functions attached to the single sites and $\mathbf{m} = (m_1, \ldots, m_N)$ is the tuple of respective projection indices. By the appropriate definition of a scalar product,

$$\langle \tilde{\mathbf{\Phi}}_{\ell\mathbf{m}} | \tilde{\mathbf{\Phi}}_{\ell'\mathbf{m}'} \rangle \equiv \frac{1}{(4\pi)^N} \int \mathrm{d}\mathbf{e}_1 \cdots \int \mathrm{d}\mathbf{e}_N \tilde{\mathbf{\Phi}}^*_{\ell\mathbf{m}} \tilde{\mathbf{\Phi}}_{\ell'\mathbf{m}'}, \tag{3}$$

where $\mathrm{d}\mathbf{e}_i$ denotes the integration over the corresponding unit sphere, the orthogonality of the N-site basis follows immediately,

$$\langle \tilde{\mathbf{\Phi}}_{\ell\mathbf{m}} | \tilde{\mathbf{\Phi}}_{\ell'\mathbf{m}'} \rangle = \delta_{\ell\ell'} \delta_{\mathbf{m}\mathbf{m}'}. \tag{4}$$

Since this basis is also complete,

$$\sum_{\ell} \sum_{\mathbf{m}} \tilde{\mathbf{\Phi}}^*_{\ell\mathbf{m}}(\{\mathbf{e}_i\}) \tilde{\mathbf{\Phi}}_{\ell\mathbf{m}}(\{\mathbf{e}'_i\}) = (4\pi)^N \delta(\mathbf{e}_1 - \mathbf{e}'_1) \cdots \delta(\mathbf{e}_N - \mathbf{e}'_N), \tag{5}$$

the configuration dependent magnetic energy E (or any other configuration-dependent quantity) can be exactly expanded into

$$E(\{\mathbf{e}_i\}) = \sum_{\ell} \sum_{\mathbf{m}} \tilde{J}_{\ell\mathbf{m}} \tilde{\mathbf{\Phi}}_{\ell\mathbf{m}}(\{\mathbf{e}_i\}). \tag{6}$$

Recognizing $\sqrt{4\pi} Y_{00}(\mathbf{e}) = 1$, Eq. (6) can be recast[11,14] into a sum running over contributions from all conceivable spin clusters α, which are defined as mere subsets of $1 \leq M \leq N$ sites $i_1, \ldots, i_M$, i.e., $\alpha = (i_1, i_2, \ldots, i_M)$. Hence,

$$E(\{\mathbf{e}_i\}) = J_0 + \sum_{\alpha} \sum_{\ell} \sum_{\mathbf{m}} J_{\alpha\ell\mathbf{m}} \mathbf{\Phi}_{\alpha\ell\mathbf{m}}(\{\mathbf{e}_i\}), \tag{7}$$

where the cluster basis functions $\mathbf{\Phi}_{\alpha\ell\mathbf{m}}$ only depend on the cluster variables $(\mathbf{e}_{i_1}, \ldots, \mathbf{e}_{i_M})$,

$$\mathbf{\Phi}_{\alpha\ell\mathbf{m}}(\{\mathbf{e}_i\}) = (4\pi)^{M/2} Y_{L_{i_1}}(\mathbf{e}_{i_1}) \cdots Y_{L_{i_M}}(\mathbf{e}_{i_M}), \tag{8}$$

and the respective order tuple $\ell = (l_{i_1}, \ldots, l_{i_M})$ is restricted to $l_i > 0$ for all sites i constituting the cluster α. In this recast notion the orthogonality, Eq. (4), reads

$$\langle \mathbf{\Phi}_{\alpha\ell\mathbf{m}} | \mathbf{\Phi}_{\alpha'\ell'\mathbf{m}'} \rangle = \delta_{\alpha\alpha'} \delta_{\ell\ell'} \delta_{\mathbf{m}\mathbf{m}'}, \tag{9}$$

which means that basis functions of different clusters and different order are orthogonal. In the same fashion the completeness relation, Eq. (5), rewrites

$$1 + \sum_{\gamma \subseteq \alpha} \sum_{\ell} \sum_{\mathbf{m}} \mathbf{\Phi}^*_{\gamma\ell\mathbf{m}}(\{\mathbf{e}_i\}) \mathbf{\Phi}_{\gamma\ell\mathbf{m}}(\{\mathbf{e}'_i\}) = \delta(\mathbf{e}_{i_1} - \mathbf{e}'_{i_1}) \cdots \delta(\mathbf{e}_{i_M} - \mathbf{e}'_{i_M}), \tag{10}$$

where the sum runs over all subclusters γ of $K \leq M$ sites contained in the cluster α.

In a practical calculation the SCE, Eq. (7), has to be terminated with respect to the number and type of clusters α which are taken into account and with respect to the order of the entering one-spin basis functions. Such a termination is physically justified because in general the contributions to Eq. (7) will decrease with increasing cluster size and with increasing order l of Y_{lm}. The expansion coefficients $J_{\alpha\ell\mathbf{m}}$ then are obtained by fitting Eq. (7) to the energies $E(\{\mathbf{e}_{i,\mathrm{ref}}\})$ of appropriately chosen reference configurations $\{\mathbf{e}_{i,\mathrm{ref}}\}$, which in turn may be calculated by the highly accurate *ab initio* density functional electron theory (for details of the fitting see Ref. 12). The bare SCE, Eq. (7), is the starting point for all our further considerations.

III. TRANSFORMATION TO SYMMETRY ADAPTED BASIS FUNCTIONS

In the following we consider isotropic magnetic systems for which the magnetic energy is invariant with respect to rotations of the global coordinate system. Because the simple product functions, Eq. (8), are not scalar-rotationally invariant, it is essential to construct a new set of basis functions which exhibit the following properties:

(1) In isotropic systems the magnetic energy is invariant under a global rotation of the coordinate system. Thus, we have to identify the scalar-rotationally invariant part of the full SCE basis and then restrict the SCE basis accordingly.
(2) The magnetic energy must be invariant with respect to time reversal. To guarantee this, the basis functions have to be invariant with respect to the simultaneous inversion of all $\mathbf{e}_i$.
(3) Because the magnetic energy is a physical observable, the basis functions should be real.
(4) Even under the above restrictions the basis functions should be orthonormal and complete in the sense that every rotationally invariant magnetic energy function can be uniquely represented in this basis. As already sketched in Sec. II, orthogonality and completeness are important for the SCE formalism.

A. Construction of rotationally invariant basis functions

In order to meet the first restriction of scalar-rotational invariance, we have to reduce the direct product basis functions, Eq. (8), using concepts of group theory.[15] We start by noting that the spherical harmonics form the basis of the irreducible representation $D^{(l)}$ of the group $SO(3)$ of proper rotations $\mathcal{R}$ in three-dimensional space $\mathbb{R}^3$. Conseqently, the product functions, Eq. (8), of the shape $Y_{L_1}(\mathbf{e}_1)\cdots Y_{L_M}(\mathbf{e}_M)$ are the natural basis of a direct product representation $D^{(l_1)}\otimes\cdots\otimes D^{(l_M)}$ of the M-fold direct product group $SO(3)\otimes\cdots\otimes SO(3)$. This direct product representation in general is reducible, which means that it can be in turn decomposed into a direct sum of irreducible representations of the $SO(3)$. The order l of the irreducible representations $D^{(l)}$ contained in this decomposition is in the range of

$$l_{\max}=\sum_{i=1}^{M} l_i \geq l \geq \max\left(2l_{i'}-\sum_{i=1}^{M} l_i, 0\right)=l_{\min}, \tag{11}$$

where $l_{i'}$ has to be chosen out of the $\{l_i\}$ such that the lower bound for l is minimum. In general an irreducible representation $D^{(l)}$ may occur multiple times in this decomposition, which is referred to as multiplicity t_l.

Concerning the corresponding bases, this decomposition is achieved by the transformation,

$${}^{B}Y_{lm}^{(\mathbf{k},\ell)}(\{\mathbf{e}_i\})=\sum_{\mathbf{m}} C_{\square\square}^{K_1}C_{\square\square}^{K_2}\cdots C_{\square\square}^{L}Y_{L_1}(\mathbf{e}_1)\cdots Y_{L_M}(\mathbf{e}_M), \tag{12}$$

from the direct product basis to the basis of the irreducible representation which is a straightforward generalization of the decomposition of the basis of the direct product representation of $D^{(l_1)}\otimes D^{(l_2)}$ mediated by the Clebsch-Gordan transformation

$$Y_L^{(l_1l_2)}(\mathbf{e}_1,\mathbf{e}_2)=\sum_{m_1m_2} C_{L_1L_2}^{L}Y_{L_1}(\mathbf{e}_1)Y_{L_2}(\mathbf{e}_2). \tag{13}$$

As it is well known, the Clebsch-Gordan coefficients $C_{L_1L_2}^{L}$ are only nonzero if

$$|l_1-l_2|\leq l\leq l_1+l_2 \tag{14}$$

$$m=m_1+m_2 \tag{15}$$

holds. For the case of a multiple direct product of irreducible representations $D^{(l_i)}$ the decomposition transformation is constructed by a successive application of Clebsch-Gordan transforma-

tions resulting in the general scheme, Eq. (12). This succession inherently introduces bases $K_i=(k_i,\mu_i)$ of intermediate representations $D^{(k_i)}$, which are denoted by the tuple $\mathbf{k}=(k_1,\ldots,k_{M-2})$, whereas the μ_i are summed over implicitly by means of Eq. (15). Naturally, within this construction scheme a twofold ambiguity arises:[16] the sequence of both the L_i and the K_i constituting the subscripts of the Clebsch-Gordan coefficients in Eq. (12) is widely undetermined. This is indicated by the boxes $\square$ in Eq. (12). The freedom concerning the intermediate basis indices arises because each index K_i appears twice in the product of Clebsch-Gordan coefficients. Thus, the relative arrangement of the K_i actually determines the sequence of Clebsch-Gordan transformations and with it the virtual transformation. Every sequence of filling the K_i to the boxes $\square$ in the product of Clebsch-Gordan coefficients in Eq. (12) generates a distinct binary bracketing scheme[16] and is symbolically designated by the index B. After the specification of the binary bracketing scheme, the freedom of distributing the L_i in the M remaining boxes in Eq. (12) persists, whereas every sequence of the L_i also generates a distinct transformation. In order to eliminate this indeterminacy, we introduce the convention of identical sequence of entries in the tuple of representation orders, $\boldsymbol{\ell}$, and in the sequence filling the L_i in the free subscripts in the product of Clebsch-Gordan coefficients. Obviously, the complete filling of the boxes $\square$ in the right hand side of Eq. (12) is then uniquely determined by the coupling scheme represented by $(B,\boldsymbol{\ell})$.

Finally, basis sets $\{{}^{B}Y_{lm}^{(\mathbf{k},\boldsymbol{\ell})}\}$ and $\{{}^{B'}Y_{lm}^{(\mathbf{k},\tilde{\boldsymbol{\ell}})}\}$ obtained by different coupling schemes $(B,\boldsymbol{\ell})$ and $(B',\tilde{\boldsymbol{\ell}})$ with $\tilde{\boldsymbol{\ell}}$ being a nontrivial permutation of $\boldsymbol{\ell}$ are equivalent but not necessarily identical. Thus, for practical calculations one has to agree on a certain coupling scheme $(B,\boldsymbol{\ell})$. A simple choice for a coupling scheme would be, e.g., the ordered tuple $\boldsymbol{\ell}=(l_1,\ldots,l_M)$ with

$$l_1 \geq l_2 \geq \cdots \geq l_M, \tag{16}$$

and the linear binary bracketing scheme where every K_i is taken as the lower-left subscript of the Clebsch-Gordan coefficient succeeding the one with the same K_i as superscript.

The decomposition transformation, Eq. (12), in general is unitary, because it is constructed from unitary Clebsch-Gordan transformations. Hence, the dimensionality of the direct product of spherical harmonics of orders $\{l_1,\ldots,l_M\}$ must equal the dimensionality of the irreducible representations of order l and multiplicity t_l,

$$\prod_{j=1}^{M}(2l_j+1)=\sum_{l=l_{\min}}^{l_{\max}} t_l(2l+1). \tag{17}$$

The multiplicity reflects in the different numerical values of the intermediate representation orders k_i governed by Eq. (14), which lead in total to a set of t_l numerically different $\mathbf{k}$-tuples for a given order tuple $\boldsymbol{\ell}$. Therefore, by means of the $\mathbf{k}$-tuple the bases of the inequivalent irreducible representations $D^{(l)}$ can be distinguished.

Now coming back to restriction (1) of scalar-rotational invariance, the key advantage of the transition to the irreducible representation is the well-known transformation behavior under the action of proper rotations $\mathcal{R}$,

$${}^{B}Y_{lm}^{(\mathbf{k},\boldsymbol{\ell})}(\{\mathbf{R}^{-1}(\mathcal{R})\mathbf{e}_i\})=\sum_{m'} D_{m'm}^{(l)}(\mathcal{R})\,{}^{B}Y_{lm'}^{(\mathbf{k},\boldsymbol{\ell})}(\{\mathbf{e}_i\}). \tag{18}$$

Herein $D_{m'm}^{(l)}$ is the irreducible representation matrix of order l and $\mathbf{R}^{-1}$ is the corresponding rotation matrix in $\mathbb{R}^3$. Because $D_{00}^{(0)}=1$ always holds regardless of the coupling scheme, the scalar-rotationally invariant part of the full basis $\{{}^{B}Y_{lm}^{(\mathbf{k},\boldsymbol{\ell})}\}$ is uniquely given by the subset $\{{}^{B}Y_{00}^{(\mathbf{k},\boldsymbol{\ell})}\}$. Introducing the generalized Wigner coefficients[15,17,18]

$$\begin{pmatrix} l_1 & \cdots & l_M \\ m_1 & \cdots & m_M \end{pmatrix}^B_{(\mathbf{k})} \equiv C^{K_1}_{L_1 L_2} \cdots C^{00}_{K_{M-2} L_M} = \frac{(-1)^{l_M - m_M}}{\sqrt{2l_M + 1}} C^{K_1}_{L_1 L_2} \cdots C^{l_M - m_M}_{K_{M-3} L_{M-1}}, \tag{19}$$

and using Eqs. (8) and (12), we arrive at

$$\mathcal{Y}^{(\mathbf{k},\ell)}_{\alpha}(\{\mathbf{e}_i\}) \equiv (4\pi)^{M/2}\ {}^B Y^{(\mathbf{k},\ell)}_{00}(\{\mathbf{e}_i\}) = \sum_{\mathbf{m}} \begin{pmatrix} l_1 & \cdots & l_M \\ m_1 & \cdots & m_M \end{pmatrix}^B_{(\mathbf{k})} \mathbf{\Phi}_{\alpha \ell \mathbf{m}}(\{\mathbf{e}_i\}), \tag{20}$$

which directly shows the decomposition transformation from the bare product basis, Eq. (8), to the rotationally symmetry adapted basis postulated by constraint (1) of this section. Please note that because of Eq. (19) there are only $(M-3)$ entries in the $\mathbf{k}$-tuple. For $M \leq 3$ the following special cases emerge from Eq. (19):

$$\begin{pmatrix} l_1 & l_2 \\ m_1 & m_2 \end{pmatrix} = (-1)^{l_1 - m_1} \frac{\delta_{l_1 l_2} \delta_{m_1 - m_2}}{\sqrt{2l_1 + 1}} \quad \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix} = \frac{(-1)^{l_3 - m_3}}{\sqrt{2l_3 + 1}} C^{l_3 - m_3}_{l_1 m_1 l_2 m_2}, \tag{21}$$

and the point function naturally turns out to be constant. Finally, we want to remark that the generalized Wigner coefficients are only nonzero, if the irreducible $l=0$ representation is contained in the product representation, i.e., if $l_{\min}=0$ holds in Eq. (11). This marks some boundary for the l_i which obviously cannot be chosen arbitrarily.

B. Consideration of time-reversal symmetry and basis properties

Next, we have to fulfill the criterion (2) of time-reversal symmetry, i.e., invariance with respect to simultaneous inversion of all variables, $\{\mathbf{e}_i\} \to \{-\mathbf{e}_i\}$. From the well-known property $Y_L(-\mathbf{e}) = (-1)^l Y_L(\mathbf{e})$ we immediately get the behavior under time reversal,

$$\mathcal{Y}^{(\mathbf{k},\ell)}_{\alpha}(\{-\mathbf{e}_i\}) = (-1)^{l_1 + l_2 + \ldots + l_M}\ \mathcal{Y}^{(\mathbf{k},\ell)}_{\alpha}(\{\mathbf{e}_i\}). \tag{22}$$

The postulate for invariance with respect to time reversal consequently translates into the restriction of even total parity, i.e.,

$$l_1 + l_2 + \ \ldots\ + l_M = \text{even}. \tag{23}$$

Criterion (3) of real-valuedness can be proven by using the general property[15]

$$\begin{pmatrix} l_1 & \cdots & l_M \\ -m_1 & \cdots & -m_M \end{pmatrix}^B_{(\mathbf{k})} = (-1)^{l_1 + l_2 + \cdots + l_M} \begin{pmatrix} l_1 & \cdots & l_M \\ m_1 & \cdots & m_M \end{pmatrix}^B_{(\mathbf{k})} \tag{24}$$

of the real-valued generalized Wigner coefficients. Together with $Y^*_{lm} = (-1)^m Y_{l-m}$, the condition, Eq. (23), of even parity and the nonzero criterion[15]

$$m_1 + m_2 + \cdots + m_M = 0 \tag{25}$$

of the generalized Wigner coefficients, it can be seen from Eq. (20) that the imaginary parts of the terms characterized by any tuple $(m_1, \ldots, m_M)$ cancel with those of the conjugated tuple $(-m_1, \ldots, -m_M)$. Thus, the SCE basis functions turn out to be real by means of criteria (1) and (2), and the demand for real-valuedness constitutes no further restriction.

Finally, we have to prove the orthonormality and completeness, demand (4). With Eq. (9) we get

$$\langle \mathcal{Y}^{(\mathbf{k},\ell)}_{\alpha} | \mathcal{Y}^{(\mathbf{k}',\ell')}_{\alpha'} \rangle = \delta_{\alpha\alpha'} \delta_{\ell\ell'} \sum_{\mathbf{m}} \begin{pmatrix} l_1 & \cdots & l_M \\ m_1 & \cdots & m_M \end{pmatrix}^B_{(\mathbf{k})} \begin{pmatrix} l_1 & \cdots & l_M \\ m_1 & \cdots & m_M \end{pmatrix}^B_{(\mathbf{k}')} = \delta_{\alpha\alpha'} \delta_{\ell\ell'} \delta_{\mathbf{k}\mathbf{k}'}, \tag{26}$$

where in the last step we used the orthonormality of the generalized Wigner coefficients.[15] Hence, the SCE basis functions of different clusters α, order ℓ, and component $\mathbf{k}$ are orthogonal. Con-

cerning completeness, we recall the completeness, Eq. (10), of the product basis $\{\mathbf{\Phi}_{\alpha\ell\mathbf{m}}\}$. Because the transformation, Eq. (12), to the irreducible representation generated by the basis set $\{Y_L^{(\mathbf{k},\ell)}\}$ is unitary, the latter one must be also complete if we consider all orders l in the limits of Eq. (11). By the restrictions of scalar-rotational and time-reversal invariance the whole set of basis functions is reduced to the part of the complete basis whose expansion coefficients are not forced to be zero by symmetry restrictions. Together with the feature of linear independence we conclude that this subset $\{\mathcal{Y}_\alpha^{(\mathbf{k},\ell)}\}$ is complete in view of the representation of rotationally and time-reversal invariant functions.

After having implemented all symmetry restrictions, we can expand the magnetic energy of a rotationally invariant system uniquely,

$$E(\{\mathbf{e}_i\}) = J_0 + \sum_\alpha \sum_\ell {}' \sum_{\mathbf{k}} J_\alpha^{(\mathbf{k},\ell)} \mathcal{Y}_\alpha^{(\mathbf{k},\ell)}(\{\mathbf{e}_i\}), \tag{27}$$

where the prime denotes that only ℓ-tuples with even total parity, Eq. (23), are taken into account, and where the cluster summation starts from pairs on. Please note that the extensive $\mathbf{m}$ summation of the bare SCE, Eq. (7), is now already incorporated in the basis functions, Eq. (20).

IV. RELATION BETWEEN SCE AND $(\mathbf{e}_i \cdot \mathbf{e}_j)$ BASIS FUNCTIONS

It has been mentioned in Sec. I that there are alternative approaches[11] for the parametrization of the isotropic magnetic energy in terms of two-spin arguments $(\mathbf{e}_i \cdot \mathbf{e}_j)$, i.e.,

$$E(\{\mathbf{e}_i\}) = \sum_\alpha \sum_K \sum_{\lambda_1 \cdots \lambda_K} J_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)} V_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}(\{\mathbf{e}_i\}). \tag{28}$$

Thereby the M-point configuration functions,

$$V_{\lambda_1 \cdots \lambda_K}^{(M)}(\mathbf{e}_1, \ldots, \mathbf{e}_M) = P_{\lambda_1}(\mathbf{e}_{i_{1,1}} \cdot \mathbf{e}_{i_{1,2}}) \cdots P_{\lambda_K}(\mathbf{e}_{i_{K,1}} \cdot \mathbf{e}_{i_{K,2}}), \tag{29}$$

are defined as product of K polynomials, P_λ, of order $\lambda \geq 1$ in the pair scalar products $(\mathbf{e}_{i_{\kappa,1}} \cdot \mathbf{e}_{i_{\kappa,2}})$ chosen out of the variables $\{\mathbf{e}_1, \ldots, \mathbf{e}_M\}$ forming the M-point cluster α. Thus, the number of pairs, K, can be

$$M/2 \leq K \leq M(M-1)/2. \tag{30}$$

Obviously, this parametrization is a systematic generalization of the Heisenberg model, Eq. (1), and the $J_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}$ are the expansion coefficients of the respective configuration functions. Please note that for the polynomials P_λ in Ref. 11 simple power functions are used, whereas in the present paper we will consider Legendre polynomials instead. Because they are related by one-to-one mappings these two polynomial sets are equivalent. Furthermore, we skip the permutation symmetrization performed in Ref. 11, because in atomistic nonquantum modeling there are no physical reasons for it.

From a closer look at Eq. (29) it can be easily seen that the configuration functions $V_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}$ are also invariant under proper rotations of the coordinate system and time reversal, as every scalar product $(\mathbf{e}_{i_{\kappa,1}} \cdot \mathbf{e}_{i_{\kappa,2}})$ is so. Because for each M-point cluster the basis set $\{\mathcal{Y}_\alpha^{(\mathbf{k},\ell)}\}$ is complete with respect to these restrictions, the $V_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}$ can be expanded into this SCE basis. In contrast, the inverse expansion of the SCE basis functions into the $V_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}$ does not necessarily have to exist because neither the linear independence nor the completeness of the $V_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}$ parametrization has been investigated so far.

The general route to expand the $V_{\alpha,\lambda_1 \cdots \lambda_K}^{(M)}$ in the $\mathcal{Y}_\alpha^{(\mathbf{k},\ell)}$ is the following. First, the expansion[18]

$$P_\lambda(\mathbf{e}_1\cdot\mathbf{e}_2)=\frac{4\pi}{2\lambda+1}\sum_\eta(-1)^\eta Y_{\lambda-\eta}(\mathbf{e}_1)Y_{\lambda\eta}(\mathbf{e}_2) \tag{31}$$

is inserted into Eq. (29). Because every site variable $\mathbf{e}_i$ enters in ν_i different scalar products, with $1\le\nu_i\le K-1$, this leads to a product of ν_i spherical harmonics of the same argument $\mathbf{e}_i$, respectively. Recursive application of the expansion[18]

$$Y_{\lambda_1\eta_1}(\mathbf{e}_i)Y_{\lambda_2\eta_2}(\mathbf{e}_i)=\sum_{lm}\sqrt{\frac{(2\lambda_1+1)(2\lambda_2+1)}{4\pi(2l+1)}}C^{l0}_{\lambda_1 0\lambda_2 0}C^{lm}_{\lambda_1\eta_1\lambda_2\eta_2}Y_{lm}(\mathbf{e}_i) \tag{32}$$

allows one to expand every product of spherical harmonics of the same argument into a linear combination of single spherical harmonics of the same argument. Applying these expansions for each cluster variable $\mathbf{e}_i$, Eq. (29) becomes an expansion of $V^{(M)}_{\alpha,\lambda_1\cdots\lambda_K}$ into the basis $\mathbf{\Phi}_{\alpha\ell\mathbf{m}}$ of the same cluster α, while the expansion coefficients essentially turn out to be sums of products of Clebsch-Gordan coefficients. Performing all the summations over internal projection indices, with the help of graphical methods[15,18] it is possible to rewrite the expansion of the $V^{(M)}_{\alpha,\lambda_1\cdots\lambda_K}$ in terms of the SCE basis $\mathcal{Y}^{(\mathbf{k},\ell)}_\alpha$, and it can be shown that the condition of even total parity, Eq. (23), in general is fulfilled.

Performing this scheme of calculation explicitly for the $V^{(M\le4)}_{\alpha,\lambda_1\cdots\lambda_K}$ functions, using the abbreviations $C^c_{ab}\equiv C^{c0}_{a0b0}$ and $[\lambda_1\cdots\lambda_i]=(2\lambda_1+1)\cdots(2\lambda_i+1)$, and with the $6j$ ($9j$ resp.) symbols $\{\cdots\}$ common in the recoupling theory of angular momenta, we finally obtain

$$V^{(2)}_\lambda(\mathbf{e}_1,\mathbf{e}_2)\equiv P_\lambda(\mathbf{e}_1\cdot\mathbf{e}_2)=(-)^\lambda[\lambda]^{-1/2}\mathcal{Y}^{(\lambda\lambda)}_\alpha(\mathbf{e}_1,\mathbf{e}_2), \tag{33}$$

$$V^{(3)}_{\lambda_1\lambda_2}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)\equiv P_{\lambda_1}(\mathbf{e}_1\cdot\mathbf{e}_2)P_{\lambda_2}(\mathbf{e}_2\cdot\mathbf{e}_3)=[\lambda_1\lambda_2]^{-1/2}\sum_l(-)^l C^l_{\lambda_1\lambda_2}\mathcal{Y}^{(\lambda_1\lambda_2 l)}_\alpha(\mathbf{e}_1,\mathbf{e}_3,\mathbf{e}_2), \tag{34}$$

$$\begin{aligned}V^{(3)}_{\lambda_1\lambda_2\lambda_3}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3)&\equiv P_{\lambda_1}(\mathbf{e}_1\cdot\mathbf{e}_2)P_{\lambda_2}(\mathbf{e}_2\cdot\mathbf{e}_3)P_{\lambda_3}(\mathbf{e}_3\cdot\mathbf{e}_1)\\&=(-)^{\lambda_1+\lambda_2+\lambda_3}\sum_{l_1l_2l_3}C^{l_1}_{\lambda_1\lambda_3}C^{l_2}_{\lambda_1\lambda_2}C^{l_3}_{\lambda_2\lambda_3}\begin{Bmatrix}l_1&l_3&l_2\\\lambda_2&\lambda_1&\lambda_3\end{Bmatrix}\mathcal{Y}^{(l_1l_3l_2)}_\alpha(\mathbf{e}_1,\mathbf{e}_3,\mathbf{e}_2),\end{aligned} \tag{35}$$

$$\begin{aligned}V^{(4)}_{\lambda_1\lambda_2\lambda_3\lambda_4}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3,\mathbf{e}_4)&\equiv P_{\lambda_1}(\mathbf{e}_1\cdot\mathbf{e}_2)P_{\lambda_2}(\mathbf{e}_2\cdot\mathbf{e}_3)P_{\lambda_3}(\mathbf{e}_3\cdot\mathbf{e}_4)P_{\lambda_4}(\mathbf{e}_4\cdot\mathbf{e}_1)\\&=\sum_{l_1l_2l_3l_4}(-)^{\lambda_1+\lambda_3-l_1-l_2}C^{l_1}_{\lambda_4\lambda_1}C^{l_2}_{\lambda_1\lambda_2}C^{l_3}_{\lambda_2\lambda_3}C^{l_4}_{\lambda_3\lambda_4}\\&\quad\times\sum_x\sqrt{[x]}\begin{Bmatrix}l_1&\lambda_1&\lambda_4\\x&l_2&l_4\\l_3&\lambda_2&\lambda_3\end{Bmatrix}\mathcal{Y}^{(x,l_3l_1l_2l_4)}_\alpha(\mathbf{e}_3,\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_4),\end{aligned} \tag{38}$$

$$V^{(4)}_{\lambda_1\lambda_2\lambda_3\lambda_4\lambda_5}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3,\mathbf{e}_4) \equiv P_{\lambda_1}(\mathbf{e}_1\cdot\mathbf{e}_2)P_{\lambda_2}(\mathbf{e}_2\cdot\mathbf{e}_3)P_{\lambda_3}(\mathbf{e}_3\cdot\mathbf{e}_4)P_{\lambda_4}(\mathbf{e}_4\cdot\mathbf{e}_1)P_{\lambda_5}(\mathbf{e}_1\cdot\mathbf{e}_3)$$
$$= \sum_{l_1\cdots l_6} \sqrt{[l_1 l_4]}(-)^{\lambda_2+\lambda_4-l_2-l_6} C^{l_1}_{\lambda_4\lambda_1} C^{l_2}_{l_1\lambda_5} C^{l_3}_{\lambda_1\lambda_2} C^{l_4}_{\lambda_2\lambda_3} C^{l_5}_{l_4\lambda_5} C^{l_6}_{\lambda_3\lambda_4}$$
$$\times \sum_x \sqrt{[x]} \begin{Bmatrix} l_2 & x & l_5 \\ l_4 & \lambda_5 & l_1 \end{Bmatrix} \begin{Bmatrix} l_6 & x & l_3 \\ \lambda_4 & l_1 & \lambda_1 \\ \lambda_3 & l_4 & \lambda_2 \end{Bmatrix} \mathcal{Y}^{(x,l_3 l_6 l_5 l_2)}_{\alpha}(\mathbf{e}_2,\mathbf{e}_4,\mathbf{e}_3,\mathbf{e}_1), \tag{39}$$

$$V^{(4)}_{\lambda_1\lambda_2\lambda_3\lambda_4\lambda_5\lambda_6}(\mathbf{e}_1,\mathbf{e}_2,\mathbf{e}_3,\mathbf{e}_4) \equiv P_{\lambda_1}(\mathbf{e}_1\cdot\mathbf{e}_2)P_{\lambda_2}(\mathbf{e}_2\cdot\mathbf{e}_3)P_{\lambda_3}(\mathbf{e}_3\cdot\mathbf{e}_4)P_{\lambda_4}(\mathbf{e}_4\cdot\mathbf{e}_1)P_{\lambda_5}(\mathbf{e}_1\cdot\mathbf{e}_3)P_{\lambda_6}(\mathbf{e}_2\cdot\mathbf{e}_4)$$
$$= \sum_{l_1\cdots l_8} \sqrt{[l_1 l_3 l_5 l_7]}(-)^{l_3+l_4+l_5+l_6+l_7+l_8+\lambda_1+\lambda_3+\lambda_6}$$
$$\times C^{l_1}_{\lambda_4\lambda_1} C^{l_2}_{l_1\lambda_5} C^{l_3}_{\lambda_1\lambda_2} C^{l_4}_{l_3\lambda_6} C^{l_5}_{\lambda_2\lambda_3} C^{l_6}_{l_5\lambda_5} C^{l_7}_{\lambda_3\lambda_4} C^{l_8}_{l_7\lambda_6}$$
$$\times \sum_x \sqrt{[x]} \begin{Bmatrix} l_5 & x & l_1 \\ l_2 & \lambda_5 & l_6 \end{Bmatrix} \begin{Bmatrix} l_7 & x & l_3 \\ l_4 & \lambda_6 & l_8 \end{Bmatrix} \begin{Bmatrix} l_5 & x & l_1 \\ \lambda_2 & l_3 & \lambda_1 \\ \lambda_3 & l_7 & \lambda_4 \end{Bmatrix}$$
$$\times \mathcal{Y}^{(x,l_2 l_6 l_4 l_8)}_{\alpha}(\mathbf{e}_1,\mathbf{e}_3,\mathbf{e}_2,\mathbf{e}_4) \tag{40}$$

Herein the $\mathcal{Y}^{(\mathbf{k},\ell)}_{\alpha}$ are defined on basis of the linear binary bracketing scheme mentioned in Sec. II. In principle, the basis properties of the $V^{(M)}_{\alpha,\lambda_1\cdots\lambda_K}$ also would reflect in an analysis of the regularity of these expansion coefficients, but this is far beyond the scope of the present paper.

V. CONCLUSIONS

The SCE is a powerful representation of the adiabatic magnetic energy hypersurface of a magnetic system on the scale of atomistic modeling. In the present paper we have worked out the theory of the SCE for the very important limit of rotationally and time-reversely invariant systems. Because the basis of the SCE is complete and orthogonal, the magnetic energy $E(\{\mathbf{e}_i\})$ as function of the orientations of the moments of all atomic sites i in the system can be systematically expanded into contributions from clusters $\alpha=\{i_1,\ldots,i_M\}$ of different size M and shape. Finally, it is shown both, generally and explicitly, how the widely used Heisenberg-type modeling in terms of pair contributions $(\mathbf{e}_i\cdot\mathbf{e}_j)$ is covered by the SCE with rotationally and time-reversal invariant basis functions.

We consider a quantum system consisting of a one-dimensional chain of M identical harmonic oscillators with natural frequency ω, coupled by means of springs. Such systems have been studied before, and appear in various models. In this paper, we approach the system as a Wigner quantum system, not imposing the canonical commutation relations, but using instead weaker relations following from the compatibility of Hamilton's equations and the Heisenberg equations. In such a setting, the quantum system allows solutions in a finite-dimensional Hilbert space, with a discrete spectrum for all physical operators. We show that a class of solutions can be obtained using generators of the Lie superalgebra $\mathfrak{gl}(1|M)$. Then we study – from a mathematical point of view – the properties and spectra of the physical operators in a class of unitary representations of $\mathfrak{gl}(1|M)$. These properties are both interesting and intriguing. In particular, we can give a complete analysis of the eigenvalues of the Hamiltonian and of the position and momentum operators (including multiplicities). We also study probability distributions of position operators when the quantum system is in a stationary state, and the effect of the position of one oscillator on the positions of the remaining oscillators in the chain. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2364183]

I. INTRODUCTION

In recent years quantum information theory has known an enormous expansion. This has boosted new interest in probabilistic and geometric aspects of state spaces of simple quantum systems. In this context, the dynamics of entanglement in a chain of coupled harmonic oscillators has been the subject of many papers.[1–5] One of the systems for which entanglement dynamics is being studied consists of a large chain of harmonic oscillators coupled by some nearest neighbor interaction.[5] In a popular model this coupling is represented by springs obeying Hooke's law. Then the Hamiltonian of the system is given by

$$\hat{H} = \sum_{k=1}^{M} \left(\frac{\hat{p}_k^2}{2m} + \frac{m\omega^2}{2}\hat{q}_k^2 + \frac{cm}{2}(\hat{q}_k - \hat{q}_{k+1})^2 \right). \tag{1.1}$$

In other words, the quantum system consists of a string or chain of M identical harmonic oscillators, each having the same mass m and natural frequency ω. The position and momentum operator for the kth oscillator are given by $\hat{q}_k$ and $\hat{p}_k$; more precisely $\hat{q}_k$ measures the displacement of the kth mass point with respect to its equilibrium position (see Fig. 1). The last term in Eq. (1.1)

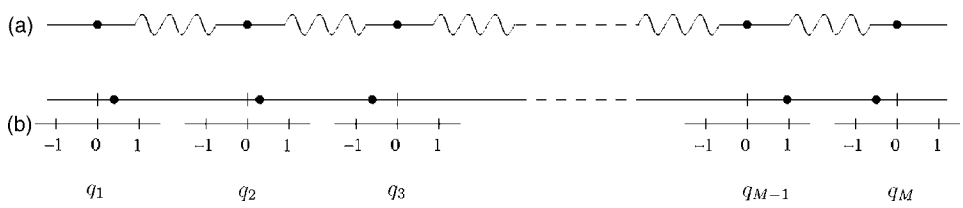

FIG. 1. Illustration of the quantum system: (a) the M masses in equilibrium position and (b) certain displacements q_k for each oscillator.

represents the nearest neighbor coupling by means of "springs," with a coupling strength c ($c>0$). Finally, we shall assume periodic boundary conditions, i.e.,

$$\hat{q}_{M+1} \equiv \hat{q}_1. \tag{1.2}$$

Such quantum systems are also relevant in quantum optics (photonic crystals), or for describing phonons in a crystal.[5,6]

In the standard approach for the quantum system governed by Eq. (1.1), one assumes the canonical commutation relations (CCRs),

$$[\hat{q}_k,\hat{q}_l]=0, \quad [\hat{p}_k,\hat{p}_l]=0, \quad [\hat{q}_k,\hat{p}_l]=i\hbar\,\delta_{kl}. \tag{1.3}$$

Then, reformulating the problem in normal coordinates, the eigenstates of $\hat{H}$ can be described in some infinite-dimensional Fock space.[5]

The approach of the present paper is more general. Instead of postulating the CCRs, we shall start from a more general quantization procedure. This procedure is based upon the compatibility of Hamilton's equations with the Heisenberg equations. Such systems are called Wigner quantum systems (WQSs).[7] The idea is based on Wigner's observation – for the simple example of a one-dimensional harmonic oscillator – that this quantum system also allows solutions for which both Hamilton's equations and the Heisenberg equations are satisfied, but not the CCRs.[8] In other words, the CCRs are sufficient but not necessary conditions for Hamilton's equations and the Heisenberg equations to be compatible. Wigner's work led to the theory of parabosons and parafermions in quantum field theory,[9–11] and because of this attention its impact for ordinary quantum systems was somewhat overlooked. Another reason why WQSs did not receive immediate attention was because no general solutions could be constructed for the compatibility conditions of simple WQSs (apart from the one-dimensional harmonic oscillator). It was only much later – after the theory of Lie superalgebra's was completed – that Palev[12] observed that classes of WQS solutions for the n-dimensional harmonic oscillator are described by means of representations of the Lie superalgebras $\mathfrak{osp}(1|2n)$ and $\mathfrak{sl}(1|n)$ or $\mathfrak{gl}(1|n)$. This algebraic or representation theoretic approach to quantum systems has revived the interest in WQSs.[13–15] The WQS approach has so far been applied to simple systems of free harmonic oscillators, with some interesting and surprising results.[16–20] Here it is, for the first time, applied to a more realistic quantum system.

In this paper, we shall study the system described by Eq. (1.1) as a WQS. This implies that, apart from the standard solutions for which the CCRs hold, we shall also discover noncanonical solutions. In particular, we shall show that the quantum system allows solutions in a finite-dimensional Hilbert space, thus with a discrete spectrum not only for $\hat{H}$ but also for the position and momentum operators $\hat{q}_k$ and $\hat{p}_k$. The class of solutions considered here is related to a $\mathfrak{gl}(1|M)$ solution of the quantization or compatibility conditions, and we consider then a simple class of $\mathfrak{gl}(1|M)$ representations in which the physical properties of the quantum system are analyzed.

It should be emphasized that our work is essentially mathematical. Whether WQS solutions offer an appropriate extension to those of canonical quantum mechanics is a question of discussion. We do not enter this discussion in this paper. But we hope that our results might be stimulating for further research in the areas of noncanonical commutation relations and, more general, noncommutative space geometry.

In Sec. II we analyze the compatibility conditions for the system Eq. (1.1) as a WQS. This leads to an expression of the Hamiltonian $\hat{H}$ in terms of a set of $2M$ operators $a_r^{\pm}$ $(r=1,\ldots,M)$, which are themselves certain linear combinations of the $\hat{q}_k$ and $\hat{p}_k$. These operators $a_r^{\pm}$ should satisfy certain triple relations, see Eq. (2.29). The task is then to construct operator solutions (constructions for the $a_r^{\pm}$ as operators acting in some Hilbert space) satisfying these triple relations. Although a complete set of solutions cannot be given, we show in Sec. III that certain generators of the Lie superalgebra $\mathfrak{gl}(1|M)$ satisfy the triple relations. In other words, we present algebraic solutions of the compatibility condition (or quantization condition) in terms of a Lie superalgebra. In order to have algebraic solutions that also satisfy the required unitarity conditions, the coupling constant c is bounded by a critical value c_0, depending upon M. Since the problem has a $\mathfrak{gl}(1|M)$ solution, the unitary representations of $\mathfrak{gl}(1|M)$ serve as Hilbert space representations for the operators of the quantum system. In principle, all unitary representations of $\mathfrak{gl}(1|M)$ are allowed for this purpose. In this paper, however, we shall concentrate on a particular class of unitary representations $W(p)$, mainly for computational purposes. For these representations $W(p)$, the actions of the $\mathfrak{gl}(1|M)$ generators, and in particular of the operators $a_r^{\pm}$, are very simple expressions, see Sec. IV. On the other hand, the class of representations $W(p)$ is already sufficiently rich to exhibit intriguing physical properties of the quantum system under consideration. These properties are examined in the remaining sections. In Sec. V we study the energy spectrum of the quantum system in $W(p)$. If $c=0$ (absence of coupling), the system consist of M independent (or free) identical one-dimensional oscillators, and it is easy to see that there are $M+1$ equidistant energy levels in $W(p)$, with multiplicities $\binom{M}{k}$ according to the level k $(k=0,1,\ldots,M)$. For $0<c<c_0$, these energy levels split: we can give a closed formula for the energy levels themselves, for their multiplicities, and for the total number of energy levels (which grows like $3^{M/2}$). Section VI is devoted to the investigation of spatial properties of the chain of coupled oscillators, if the system is in one of the representations $W(p)$. Clearly, since the representations considered here are finite-dimensional, the spectrum of position operators $\hat{q}_k$ and momentum operators $\hat{p}_k$ is discrete. We manage to give the spectrum of these operators in closed form, but so far an analytic expression for a set of orthonormal eigenvectors is missing. Finally, we examine numerically for a simple example $(M=4)$ some position probability distributions of the oscillator system. The case of *atypical* representations $W(p)$ (i.e., $p\leqslant M-1$) is examined in Sec. VII, followed by some concluding remarks in Sec. VIII.

II. THE QUANTIZATION PROCEDURE

In our approach we shall require that Hamilton's equations

$$\dot{\hat{q}}_k=\frac{\partial\hat{H}}{\partial\hat{p}_k},\quad \dot{\hat{p}}_k=-\frac{\partial\hat{H}}{\partial\hat{q}_k}\quad (k=1,2,\ldots,M) \tag{2.1}$$

and the Heisenberg equations

$$\dot{\hat{p}}_k=\frac{i}{\hbar}[\hat{H},\hat{p}_k],\quad \dot{\hat{q}}_k=\frac{i}{\hbar}[\hat{H},\hat{q}_k]\quad (k=1,2,\ldots,M) \tag{2.2}$$

should be identical as operator equations. Since Hamilton's equations for the Hamiltonian (1.1) take the explicit form

$$\dot{\hat{q}}_k=\frac{1}{m}\hat{p}_k, \tag{2.3}$$

$$\dot{\hat{p}}_k=cm\hat{q}_{k-1}-m(\omega^2+2c)\hat{q}_k+cm\hat{q}_{k+1}, \tag{2.4}$$

the compatibility conditions read

$$[\hat{H},\hat{q}_k] = -\frac{i\hbar}{m}\hat{p}_k, \tag{2.5}$$

$$[\hat{H},\hat{p}_k] = -i\hbar\, cm\hat{q}_{k-1} + i\hbar\, m(\omega^2+2c)\hat{q}_k - i\hbar\, cm\hat{q}_{k+1}, \tag{2.6}$$

where $k=1,2,\ldots,M$, and – extending Eq. (1.2) – $\hat{q}_0$ stands for $\hat{q}_M$, or more generally

$$\hat{q}_k = \hat{q}_{k \bmod M}, \quad \hat{p}_k = \hat{p}_{k \bmod M}, \tag{2.7}$$

whenever k is out of the range $\{1,2,\ldots,M\}$. In other words, the task is to find operator solutions for $\hat{q}_k$ and $\hat{p}_k$ such that the compatibility conditions (2.5) and (2.6), together with Eq. (1.1), are satisfied. Furthermore, since $\hat{q}_k$ and $\hat{p}_k$ correspond to physical observables, the operators should be self-adjoined

$$\hat{q}_k^\dagger = \hat{q}_k, \quad \hat{p}_k^\dagger = \hat{p}_k \quad (k=1,2,\ldots,M). \tag{2.8}$$

Just as in the canonical treatment of the problem,[5,6] it will be useful to introduce "normal coordinates" and reformulate the problem in terms of these new coordinates. So let us consider the finite Fourier transforms of $\hat{q}_k$ and $\hat{p}_k$,

$$\hat{Q}_r = \frac{1}{\sqrt{M}}\sum_{k=1}^{M} e^{-(2\pi irk/M)}\hat{q}_k, \tag{2.9}$$

$$\hat{P}_r = \frac{1}{\sqrt{M}}\sum_{k=1}^{M} e^{(2\pi irk/M)}\hat{p}_k. \tag{2.10}$$

The inverse relations are given by

$$\hat{q}_k = \frac{1}{\sqrt{M}}\sum_{r=1}^{M} e^{(2\pi ikr/M)}\hat{Q}_r, \tag{2.11}$$

$$\hat{p}_k = \frac{1}{\sqrt{M}}\sum_{r=1}^{M} e^{-(2\pi ikr/M)}\hat{P}_r. \tag{2.12}$$

As for $\hat{q}_k$ and $\hat{p}_k$, see Eq. (2.7), it will sometimes be useful to extend the indices by

$$\hat{Q}_k = \hat{Q}_{k \bmod M}, \quad \hat{P}_k = \hat{P}_{k \bmod M}. \tag{2.13}$$

Note that the conditions (2.8) imply

$$\hat{Q}_r^\dagger = \hat{Q}_{M-r}, \quad \hat{P}_r^\dagger = \hat{P}_{M-r} \quad (r=1,2,\ldots,M), \tag{2.14}$$

and in particular, following the convention Eq. (2.13), $\hat{Q}_M^\dagger = \hat{Q}_M$ and $\hat{P}_M^\dagger = \hat{P}_M$. An essential part is now to substitute Eqs. (2.11) and (2.12) in the Hamiltonian $\hat{H}$, given by Eq. (1.1), and simplify this expression without assuming any commutation relations between the operators. For the term $\Sigma_k \hat{p}_k^2 = \Sigma_k \hat{p}_k \hat{p}_k^\dagger$, one can, after the substitution, use the identity

$$\sum_{k=1}^{M} e^{(2\pi ik(r-s)/M)} = M\delta_{rs},$$

and thus $\Sigma_k \hat{p}_k^2 = \Sigma_r \hat{P}_r \hat{P}_r^\dagger$. Similarly, $\Sigma_k \hat{q}_k^2 = \Sigma_r \hat{Q}_r \hat{Q}_r^\dagger$. The coupling terms can be written as

$$\sum_k (\hat{q}_k - \hat{q}_{k+1})(\hat{q}_k - \hat{q}_{k+1})^\dagger = \sum_k \hat{q}_k \hat{q}_k^\dagger + \sum_k \hat{q}_{k+1}\hat{q}_{k+1}^\dagger - \sum_k (\hat{q}_k \hat{q}_{k+1}^\dagger + \hat{q}_{k+1}\hat{q}_k^\dagger). \tag{2.15}$$

On the right hand side, the first two sums are of the same form as before; the last sum yields

$$\sum_k (\hat{q}_k \hat{q}_{k+1}^\dagger + \hat{q}_{k+1}\hat{q}_k^\dagger) = \sum_r (e^{(-2\pi ir/M)} \hat{Q}_r \hat{Q}_r^\dagger + e^{(2\pi ir/M)} \hat{Q}_r \hat{Q}_r^\dagger) = \sum_r 2\cos\left(\frac{2\pi r}{M}\right) \hat{Q}_r \hat{Q}_r^\dagger. \tag{2.16}$$

Thus we obtain, just as in the canonical case[5,6]

$$\hat{H} = \sum_{r=1}^{M} \left(\frac{1}{2m} \hat{P}_r \hat{P}_r^\dagger + \frac{m\omega_r^2}{2} \hat{Q}_r \hat{Q}_r^\dagger \right), \tag{2.17}$$

where, for $r=1,2,\ldots,M$, the quantities ω_r are positive numbers with

$$\omega_r^2 = \omega^2 + 2c - 2c\cos\left(\frac{2\pi r}{M}\right) = \omega^2 + 4c\sin^2\left(\frac{\pi r}{M}\right), \tag{2.18}$$

and clearly

$$\omega_{M-r} = \omega_r. \tag{2.19}$$

Substituting Eqs. (2.11) and (2.12) in Eqs. (2.5) and (2.6) yields the set of compatibility conditions for the new operators

$$[\hat{H}, \hat{Q}_r] = -\frac{i\hbar}{m} \hat{P}_r^\dagger, \quad [\hat{H}, \hat{Q}_r^\dagger] = -\frac{i\hbar}{m} \hat{P}_r, \tag{2.20}$$

$$[\hat{H}, \hat{P}_r] = i\hbar\, m\omega_r^2 \hat{Q}_r^\dagger, \quad [\hat{H}, \hat{P}_r^\dagger] = i\hbar\, m\omega_r^2 \hat{Q}_r. \tag{2.21}$$

The task is now reduced to finding operator solutions for $\hat{Q}_r$ and $\hat{P}_r$ such that the compatibility conditions (2.20) and (2.21), together with Eq. (2.17), are satisfied.

As a final step it is convenient to introduce linear combinations of the unknown operators $\hat{Q}_r$ and $\hat{P}_r$, say a_r^+ and a_r^- $(r=1,2,\ldots,M)$, by

$$a_r^- = \sqrt{\frac{m\omega_r}{2\hbar}} \hat{Q}_r + \frac{i}{\sqrt{2m\omega_r\hbar}} \hat{P}_r^\dagger, \tag{2.22}$$

$$a_r^+ = \sqrt{\frac{m\omega_r}{2\hbar}} \hat{Q}_r^\dagger - \frac{i}{\sqrt{2m\omega_r\hbar}} \hat{P}_r, \tag{2.23}$$

with

$$(a_r^\pm)^\dagger = a_r^\mp. \tag{2.24}$$

Observe that the inverse relations take the form

$$\hat{Q}_r = \sqrt{\frac{\hbar}{2m\omega_r}} (a_{M-r}^+ + a_r^-), \quad r = 1, \ldots, M-1; \quad \hat{Q}_M = \sqrt{\frac{\hbar}{2m\omega_M}} (a_M^+ + a_M^-), \tag{2.25}$$

$$\hat{P}_r = i\sqrt{\frac{m\omega_r\hbar}{2}}(a_r^+ - a_{M-r}^-), \quad r = 1, \ldots, M-1; \quad \hat{P}_M = i\sqrt{\frac{m\omega_M\hbar}{2}}(a_M^+ - a_M^-), \tag{2.26}$$

with similar expressions for $\hat{Q}_r^\dagger$ and $\hat{P}_r^\dagger$. In terms of the new set of unknown operators $a_r^\pm$ $(r = 1,2,\ldots,M)$, the Hamiltonian (2.17) becomes

$$\hat{H} = \sum_{r=1}^{M} \frac{\hbar\omega_r}{2}\{a_r^-, a_r^+\} = \sum_{r=1}^{M} \frac{\hbar\omega_r}{2}(a_r^- a_r^+ + a_r^+ a_r^-). \tag{2.27}$$

It is essential – and the reader should verify this – that in going from Eq. (2.17) to Eq. (2.27), no commutation relations among the operators $\hat{Q}_r$ and $\hat{P}_r$ are used, but only identities like Eqs. (2.13), (2.14), and (2.19). A final and simple calculation, using Eqs. (2.22) and (2.23), shows that Eqs. (2.20) and (2.21) is equivalent to

$$[\hat{H}, a_r^\pm] = \pm\hbar\,\omega_r a_r^\pm, \quad (r = 1,2\ldots,M). \tag{2.28}$$

Thus

Proposition 1: In the approach of Eq. (1.1) as a Wigner quantum system, the problem is reduced to finding $2M$ operators $a_r^\pm$ $(r=1,\ldots,M)$, acting in some Hilbert space, such that $(a_r^\pm)^\dagger = a_r^\mp$ and

$$\left[\sum_{j=1}^{M} \omega_j(a_j^- a_j^+ + a_j^+ a_j^-), a_r^\pm\right] = \pm 2\omega_r a_r^\pm, \quad (r = 1,2\ldots,M). \tag{2.29}$$

The operators corresponding to physical observables $\hat{q}_k$ and $\hat{p}_k$ are then known linear combinations of $a_r^\pm$, and the Hamiltonian $\hat{H}$ is given by Eq. (2.27).

As we shall see in the following section, this is an algebraic problem that has a class of solutions in terms of the Lie superalgebra $\mathfrak{gl}(1|M)$.

Before concentrating on an algebraic solution, let us end this section with a few words about the time dependency of the operators. The time dependency of $\hat{q}_k$ and $\hat{p}_k$ is determined by Eqs. (2.3) and (2.4). From these equations and Eqs. (2.9) and (2.10) it follows that:

$$\dot{\hat{Q}}_r = \frac{1}{m}\hat{P}_r^\dagger, \quad \dot{\hat{P}}_r = -m\omega_r^2\hat{Q}_r^\dagger. \tag{2.30}$$

Using Eqs. (2.22) and (2.23) yields

$$\dot{a}_r^- = -i\omega_r a_r^-, \quad \dot{a}_r^+ = i\omega_r a_r^+, \tag{2.31}$$

with the evident solution

$$a_r^\pm(t) = e^{\pm i\omega_r t}a_r^\pm(0). \tag{2.32}$$

So it is sufficient to have solutions for the operators $a_r^\pm$ at time 0, $a_r^\pm \equiv a_r^\pm(0)$. The time dependence for $a_r^\pm(t)$ is given by Eq. (2.32), and since all operators of the quantum system can be expressed in terms of $a_r^\pm$, their time dependence follows. As a consequence, we shall concentrate on solutions of the system Eqs. (2.27) and (2.28) at time $t=0$.

For completeness, it should also be mentioned that if the CCRs Eq. (1.3) hold, then the operators $a_r^\pm$ satisfy the usual boson relations $[a_r^\pm, a_s^\pm]=0$, $[a_r^-, a_s^+]=\delta_{rs}$. In that case Eq. (2.28) follows automatically from Eq. (2.27).

III. ALGEBRAIC SOLUTIONS OF THE COMPATIBILITY CONDITIONS

The set of relations (2.29), together with the conditions (2.24), are reminiscent of the algebraic relations satisfied by a set of $\mathfrak{gl}(1|M)$ generators.[12] We shall show that our problem has indeed a

solution in terms of the Lie superalgebra $\mathfrak{gl}(1|M)$ or $\mathfrak{sl}(1|M)$. Let us first recall the definition of $\mathfrak{gl}(1|M)$: it is a Lie superalgebra with basis elements e_{jk}, with $j,k=0,1,\ldots,M$. The elements e_{k0} and e_{0k} $(k=1,\ldots,M)$ are *odd* elements, having degree $\deg(e_{k0})=\deg(e_{0k})=1$; the remaining basis elements are *even* elements, having degree 0. The Lie superalgebra bracket is determined by[21–23]

$$[\![e_{ij},e_{kl}]\!]=\delta_{jk}e_{il}-(-1)^{\deg(e_{ij})\deg(e_{kl})}\delta_{il}e_{kj}. \tag{3.1}$$

In a representation, or in the enveloping algebra of $\mathfrak{gl}(1|M)$, the bracket $[\![x,y]\!]$ (where x and y are homogeneous elements of $\mathfrak{gl}(1|M)$) stands for an anti-commutator if x and y are both odd elements, and for a commutator otherwise. The Lie superalgebra $\mathfrak{sl}(1|M)$ is the subalgebra of $\mathfrak{gl}(1|M)$ consisting of elements with supertrace 0, or also $\mathfrak{sl}(1|M)=[\![\mathfrak{gl}(1|M),\mathfrak{gl}(1|M)]\!]$.

For a Lie superalgebra one can also fix a star condition, i.e., an antilinear anti-involution. For $\mathfrak{gl}(1|M)$ or $\mathfrak{sl}(1|M)$ such a star condition is fixed by a signature σ, i.e., a sequence of plus or minus signs $\sigma=(\sigma_1,\ldots,\sigma_M)$ and

$$(e_{0k})^{\dagger}=\sigma_k e_{k0},\quad (k=1,\ldots,M), \tag{3.2}$$

thus with each σ_k equal to $+1$ or -1. We are particularly interested in the case where all σ_k's are $+1$ since this corresponds to the "compact form" $\mathfrak{u}(1|M)$ of $\mathfrak{gl}(1|M)$ (Ref. 24), for which finite-dimensional unitary representations exist.[25]

We shall now show that there exist solutions of the form

$$a_k^-=\sqrt{\frac{2}{\omega_k}}\alpha_k e_{k0},\quad a_k^+=\sqrt{\frac{2}{\omega_k}}\alpha_k^*\sigma_k e_{0k},\quad (k=1,\ldots,M) \tag{3.3}$$

with α_k certain complex constants to be determined. First of all, note that by Eq. (3.2), the Hermiticity condition (2.24) is automatically satisfied. With Eq. (3.3), the Hamiltonian (2.27) becomes

$$\hat{H}=\hbar\left(\sum_{j=1}^{M}\sigma_j|\alpha_j|^2\right)e_{00}+\hbar\sum_{k=1}^{M}\sigma_k|\alpha_k|^2e_{kk}, \tag{3.4}$$

and the commutator of the above with Eq. (3.3) yields

$$[\hat{H},a_k^{\pm}]=\pm\hbar\left(\sum_{j=1}^{M}\sigma_j|\alpha_j|^2-\sigma_k|\alpha_k|^2\right)a_k^{\pm}\quad (k=1,\ldots,M). \tag{3.5}$$

These should coincide with the compatibility conditions (2.28). Thus we get a system of M equations in the unknown coefficients α_k,

$$\sum_{j=1}^{M}\sigma_j|\alpha_j|^2-\sigma_k|\alpha_k|^2=\omega_k\quad (k=1,2,\ldots,M). \tag{3.6}$$

It is easy to verify that a solution for this set of equations is determined by

$$\sigma_k|\alpha_k|^2=-\omega_k+\frac{1}{M-1}\sum_{j=1}^{M}\omega_j. \tag{3.7}$$

For further use, it will be convenient to introduce the following numbers:

$$\beta_k=-\omega_k+\frac{1}{M-1}\sum_{j=1}^{M}\omega_j, \tag{3.8}$$

with ω_j the values fixed by Eq. (2.18). Note that

TABLE I. Critical values c_0/ω^2.

M	c_0/ω^2	M	c_0/ω^2
4	0.9873724357	13	0.10546881460
5	0.7500000000	14	0.09256321610
6	0.3457442295	15	0.08687882025
7	0.2982653656	16	0.07814800074
8	0.2061705212	17	0.07388896853
9	0.1851128402	18	0.06760983697
10	0.1464642846	19	0.06429500840
11	0.1343028683	20	0.05957194222
12	0.1134651313	21	0.05691629341

$$\beta_{M-k}=\beta_k, \quad \beta \equiv \sum_{j=1}^{M} \beta_j = \sum_{j=1}^{M} \omega_j, \tag{3.9}$$

and thus $\hat{H}$ can be rewritten as

$$\hat{H} = \hbar \left(\beta e_{00} + \sum_{k=1}^{M} \beta_k e_{kk} \right). \tag{3.10}$$

Remember that we are primarily interested in the signature with all σ_k's equal to +1. Since $\sigma_k |\alpha_k|^2 = \beta_k$, the question is whether there exist solutions such that all β_k's are positive. At first sight, Eq. (3.8) indicates that β_k is equal to $-\omega_k$ plus "some average value" of the ω_j's, and hence, one would expect half of the β_k's to be negative and half of them to be positive. We shall show, however, that under certain conditions ("weak coupling," i.e., a small value for c), all β_k's are indeed positive. First of all, note that for $c>0$,

$$\beta_1 > \beta_2 > \cdots > \beta_{\lfloor M/2 \rfloor}, \quad \beta_{\lfloor M/2 \rfloor} \leqslant \beta_{\lfloor M/2 \rfloor + 1} < \cdots < \beta_M, \tag{3.11}$$

since a similar property holds for the values ω_k. Thus if $\beta_{\lfloor M/2 \rfloor} > 0$, then all β_k's are positive. The value of $\beta_{\lfloor M/2 \rfloor}$ depends on the value of c; if $c=0$ then indeed all $\beta_k = \omega/(M-1)$ are positive. So by continuity as a function of c there will be a certain interval $]0, c_0[$ where all β_k's are positive. This critical value c_0 is the c-value for which $\beta_{\lfloor M/2 \rfloor}=0$. For general M, this is a complicated transcendental equation that can be solved only numerically. Table I gives the numerical solutions for this equation, for M ranging from 4 to 21 (for $M=2$ or $M=3$ the β_k's are always positive). The following proposition gives a lower bound for the critical value c_0, such that all β_k's are positive.

Proposition 2: An upper bound for c is determined by

$$0 \leqslant c \leqslant \frac{\omega^2}{2(M-2)} \Rightarrow \beta_k \geqslant 0, \quad \text{for } 1 \leqslant k \leqslant M. \tag{3.12}$$

Proof: By definition Eq. (3.8) $\beta_k \geqslant 0$ if and only if

$$\omega_k \leqslant \frac{1}{M-1} \sum_{j=1}^{M} \omega_j \Leftrightarrow (M-1)^2 \omega_k^2 \leqslant \sum_{j=1}^{M} \omega_j^2 + 2 \sum_{i>j} \omega_i \omega_j. \tag{3.13}$$

We write the right hand side of Eq. (3.13) as a series with respect to c. For the first sum, we find

$$\sum_{j=1}^{M} \omega_j^2 = \sum_{j=1}^{M} \left(\omega^2 + 4c \sin^2\left(\frac{j\pi}{M}\right)\right) = M\omega^2 + 2c \sum_{j=1}^{M} \left(1 - \cos\left(\frac{2j\pi}{M}\right)\right) = M(\omega^2 + 2c).$$

Here, we used the Lagrange identity

$$1+\cos(x)+\cos(2x)+\cdots+\cos(nx)=\frac{1}{2}+\frac{\sin\left(\frac{(2n+1)x}{2}\right)}{2\sin\left(\frac{x}{2}\right)}.$$

In order to evaluate the second sum in Eq. (3.13), let

$$F(c)\equiv\sum_{i>j}\omega_i\omega_j=\sum_{i>j}\sqrt{\omega^2+4c\sin^2\left(\frac{i\pi}{M}\right)}\sqrt{\omega^2+4c\sin^2\left(\frac{j\pi}{M}\right)}. \tag{3.14}$$

It is then clear that

$$F(0)=\omega^2\frac{M(M-1)}{2}.$$

One can write the derivate of ω_k with respect to c as

$$\omega_k'=\frac{d\omega_k}{dc}=\frac{2}{\omega_k}\sin^2\left(\frac{k\pi}{M}\right),$$

and one finds that

$$F'(c)=\sum_{j>i}(\omega_i'\omega_j+\omega_i\omega_j')\geqslant 0,$$

since $\omega_k'\geqslant 0$. This implies that $F(0)\leqslant F(c)$ for $c\geqslant 0$. Thus it follows from Eq. (3.13) that

$$(M-1)^2\omega_k^2\leqslant\sum_{j=1}^{M}\omega_j^2+2F(0) \tag{3.15}$$

is a sufficient condition for $\beta_k\geqslant 0$. Since $\omega_k^2\leqslant\omega_{[M/2]}^2\leqslant\omega^2+4c$ for $1\leqslant k\leqslant M$, it is sufficient to solve the following inequality:

$$(M-1)^2(\omega^2+4c)\leqslant M(\omega^2+2c)+\omega^2M(M-1)\Leftrightarrow c\leqslant\frac{\omega^2}{2(M-2)},$$

leading to Eq. (3.12). □

Note that for $M=2$ or $M=3$ there are no conditions: for $M=2$, $\beta_1=\omega_2>0$ and $\beta_2=\omega_1>0$; for $M=3$, $\beta_1=\beta_2=\omega/2>0$ and $\beta_3=(\omega^2+3c)^{1/2}-\omega/2>0$.

We can now summarize the main result of this section in the following.

Proposition 3: For fixed M, let c satisfy

$$c\leqslant\frac{\omega^2}{2(M-2)}(\leqslant c_0)$$

(no condition if $M=2$ or $M=3$). Then the compatibility conditions (2.27) and (2.28) have a solution for the operators $a_k^{\pm}$ in terms of $\mathfrak{gl}(1|M)$ generators

$$a_k^-=\sqrt{\frac{2\beta_k}{\omega_k}}e_{k0},\quad a_k^+=\sqrt{\frac{2\beta_k}{\omega_k}}e_{0k},\quad (k=1,\ldots,M) \tag{3.16}$$

with β_k given by Eq. (3.8). The Hermiticity conditions (2.24) are equivalent with the star condition

$$(e_{0k})^{\dagger}=e_{k0}. \tag{3.17}$$

IV. A CLASS OF $\mathfrak{gl}(1|M)$ REPRESENTATIONS

In order to study properties of the given quantum system related to the $\mathfrak{gl}(1|M)$ solution of the previous section, one should consider representations of $\mathfrak{gl}(1|M)$ for which Eq. (3.17) holds. These are known as the unitary representations (or star representations), and have been classified by Gould and Zhang.[25] For the explicit actions of the $\mathfrak{gl}(1|M)$ generators on a Gel'fand-Zetlin basis for these unitary representations, see Ref. 26. These actions becomes fairly complicated, so in this paper we will concentrate on a particular class of representations, the so-called Fock type representations $W(p)$.

Without going into the details of the construction of such representations, we briefly summarize their main features here. Further details can be found in Refs. 27 and 28.

The representations $W(p)$ are labeled by a number p, with either $p \in \{0,1,2,\ldots,M-1\}$ or else $p \in \mathbb{R}$ with $p > M-1$. We describe the representation by giving the basis vectors of the representation space $W(p)$ and the action of the $\mathfrak{gl}(1|M)$ generators on these basis vectors.

For $p \in \{0,1,2,\ldots,M-1\}$, the basis vectors of $W(p)$ are given by:

$$w(\theta) \equiv w(\theta_1,\theta_2,\ldots,\theta_M), \quad \theta_i \in \{0,1\}, \quad \text{and } |\theta| = \theta_1 + \cdots + \theta_M \leqslant p. \tag{4.1}$$

Note that in this case the dimension of $W(p)$ is given by

$$\dim W(p) = \sum_{k=0}^{p} \binom{M}{k}. \tag{4.2}$$

For p real and $p > M-1$, the basis vectors of $W(p)$ are all vectors $w(\theta) \equiv w(\theta_1,\theta_2,\ldots,\theta_M)$ with each $\theta_i \in \{0,1\}$. Clearly, for $p > M-1$, the dimension of $W(p)$ is given by 2^M.

The action of the $\mathfrak{gl}(1|M)$ generators on the basis vectors of $W(p)$ is now given by

$$e_{00}w(\theta) = (p - |\theta|)w(\theta); \tag{4.3}$$

$$e_{kk}w(\theta) = \theta_k w(\theta), \quad (1 \leqslant k \leqslant M); \tag{4.4}$$

$$e_{k0}w(\theta) = (1-\theta_k)(-1)^{\theta_1+\cdots+\theta_{k-1}}\sqrt{p-|\theta|}\,w(\theta_1,\ldots,\theta_k+1,\ldots,\theta_M), \quad (1 \leqslant k \leqslant M); \tag{4.5}$$

$$e_{0k}w(\theta) = \theta_k(-1)^{\theta_1+\cdots+\theta_{k-1}}\sqrt{p-|\theta|+1}\,w(\theta_1,\ldots,\theta_k-1,\ldots,\theta_M), \quad (1 \leqslant k \leqslant M). \tag{4.6}$$

The action of the remaining $\mathfrak{gl}(1|M)$ basis elements can be determined from the above formulas, and one finds (for $1 \leqslant j < k \leqslant M$),

$$e_{jk}w(\theta) = \theta_k(1-\theta_j)(-1)^{\theta_j+\cdots+\theta_{k-1}}w(\theta_1,\ldots,\theta_j+1,\ldots,\theta_k-1,\ldots,\theta_M), \tag{4.7}$$

$$e_{kj}w(\theta) = -\theta_j(1-\theta_k)(-1)^{\theta_j+\cdots+\theta_{k-1}}w(\theta_1,\ldots,\theta_j-1,\ldots,\theta_k+1,\ldots,\theta_M). \tag{4.8}$$

With respect to the inner product

$$\langle w(\theta)|w(\theta')\rangle = \delta_{\theta,\theta'}, \tag{4.9}$$

the representation $W(p)$ is unitary for the star condition

$$e_{jk}^{\dagger} = e_{kj}.$$

The representations $W(p)$ with $p > M-1$ are *typical* irreducible $\mathfrak{gl}(1|M)$ representations; those with $p \in \{0,1,2,\ldots,M-1\}$ are *atypical* irreducible $\mathfrak{gl}(1|M)$ representations.[22,29] In Secs. V and VI we shall develop results for the typical representations; the atypical case is treated in Sec. VII.

Note, by Eq. (3.16) and Eq. (4.5) and (4.6) the action of the operators $a_k^{\pm}$ on the basis vectors $w(\theta)$ of $W(p)$ $(k=1,\ldots,M)$ is given by

$$a_k^- w(\theta) = \sqrt{\frac{2\beta_k}{\omega_k}}(1-\theta_k)(-1)^{\theta_1+\cdots+\theta_{k-1}}\sqrt{p-|\theta|}\,w(\theta_1,\ldots,\theta_k+1,\ldots,\theta_M), \tag{4.10}$$

$$a_k^+ w(\theta) = \sqrt{\frac{2\beta_k}{\omega_k}}\theta_k(-1)^{\theta_1+\cdots+\theta_{k-1}}\sqrt{p-|\theta|+1}\,w(\theta_1,\ldots,\theta_k-1,\ldots,\theta_M). \tag{4.11}$$

So the operators $a_k^\pm$ raise or lower θ_k by one unit (if allowed). This means that, for $p>M-1$, the basis vectors $w(\theta)$ of $W(p)$ have a Fock basis construction, by letting $|0\rangle=w(1,1,\ldots,1)$. Then $a_k^-|0\rangle=0$ and

$$w(\theta) \sim (a_1^+)^{1-\theta_1}(a_2^+)^{1-\theta_2}\cdots(a_M^+)^{1-\theta_M}|0\rangle. \tag{4.12}$$

This is the reason why $W(p)$ is referred to as a Fock representation.

V. ON THE SPECTRUM OF $\hat{H}$ IN THE REPRESENTATIONS $W(p)$

For any $p>M-1$, the representation $W(p)$ is of dimension 2^M. Under the solution (3.16), the Hamiltonian $\hat{H}$ takes the form (3.10),

$$\hat{H} = \hbar\left(\beta e_{00} + \sum_{k=1}^{M}\beta_k e_{kk}\right),$$

with $\beta=\Sigma_{k=1}^M\beta_k=\Sigma_{k=1}^M\omega_k$. Since the actions of e_{kk} $(k=0,1,\ldots,M)$ are diagonal in the basis $w(\theta)$, see Eqs. (4.3) and (4.4), it follows that the vectors $w(\theta)$ are eigenvectors for $\hat{H}$:

$$\hat{H}w(\theta) = \hbar\, E_\theta w(\theta), \tag{5.1}$$

with eigenvalues

$$E_\theta = \beta(p-|\theta|) + \sum_{k=1}^{M}\theta_k\beta_k = \beta\left(p-\frac{M-2}{M-1}|\theta|\right) - \sum_{k=1}^{M}\theta_k\omega_k. \tag{5.2}$$

In this expression, $\theta=(\theta_1,\ldots,\theta_M)$, with each $\theta_k\in\{0,1\}$, and $|\theta|=\Sigma_{k=1}^M\theta_k$.

In the case without coupling $(c=0)$, all β_k's are the same: $\beta_k=\omega/(M-1)$ and $\beta=(M/(M-1))\omega$. The eigenvalues of $\hat{H}$ are then

$$\hbar\,\omega\left(p\frac{M}{M-1}-|\theta|\right).$$

The multiplicity of this eigenvalue is $\binom{M}{|\theta|}$. In other words, there are $M+1$ distinct energy levels, equally spaced with steps of unit $\hbar\omega$. The lowest energy level corresponds to $E_{(1,\ldots,1)}=\omega pM/(M-1)-\omega M$, and the highest to $E_{(0,\ldots,0)}=\omega pM/(M-1)$.

We are mainly interested in the weak coupling case $(c>0$, but $c<c_0)$. Also in this case, it is easy to describe the energy levels through Eq. (5.2), but the analysis of their multiplicity requires some further attention. For this purpose, observe that by Eq. (3.9)

$$\sum_{k=1}^{M}\theta_k\beta_k = \sum_{k=1}^{M}\theta_k\beta_{M-k} = \sum_{k=0}^{M-1}\theta_{M-k}\beta_k = \sum_{k=1}^{M}\theta_{M-k}\beta_k, \tag{5.3}$$

where in the last step we have followed the convention that $\beta_0=\beta_M$, and we have set $\theta_0=\theta_M$. Let $w(\theta)$ be an arbitrary eigenvector $\hat{H}$ with eigenvalue $\hbar E_\theta$. Obviously, by Eqs. (5.2) and (5.3) all basis vectors $w(\theta')$ which are obtained by swapping θ_i and θ_{M-i} for arbitrary indices i yield the same eigenvalue $\hbar E_\theta$. The multiplicity of this eigenvalue is thus (at least)

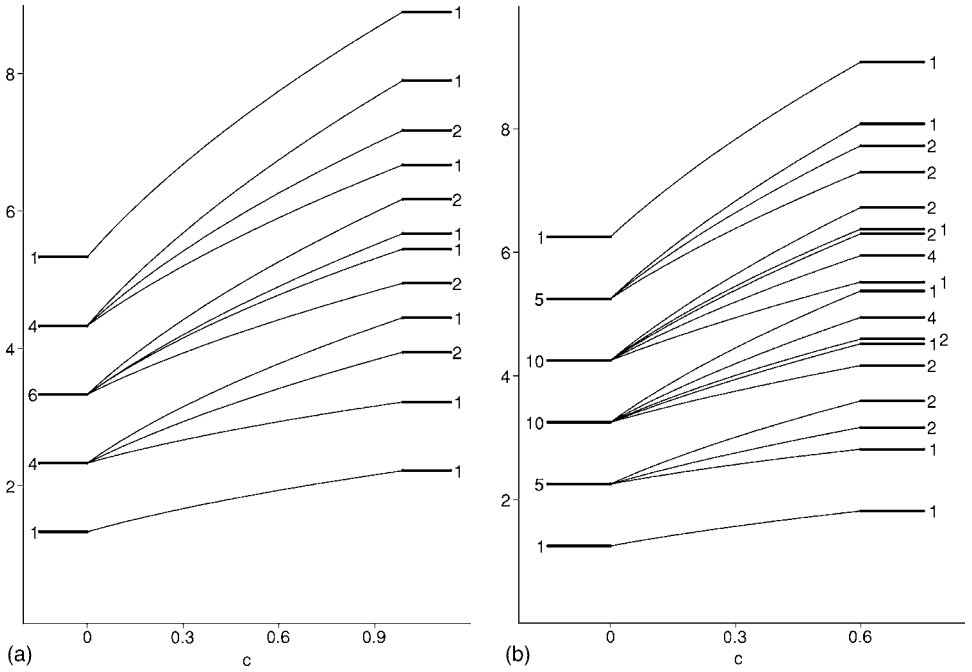

FIG. 2. (a) The energy levels of the quantum system for $M=4$ in $W(p)$, where we have taken $\hbar=\omega=1$, $p=M$, and c varies from 0 to c_0. The vertical axis gives the energy values. The numbers next to the levels refer to the multiplicity. When $c=0$ there are $M+1=5$ energy levels, with multiplicities (1,4,6,4,1). When $0<c<c_0$, the energy levels split up in 12 levels, with multiplicities 1 or 2. (b) The same illustration for $M=5$. There are six levels for $c=0$ with multiplicities (1,5,10,10,5,1), and there are 18 levels for $0<c<c_0$, with multiplicities 1, 2, or 4.

$$2^{\Sigma_{k=1}^{M}(\theta_k-\theta_{M-k})^2/2}. \tag{5.4}$$

Further inspection of the last expression in Eq. (5.2) shows that this is indeed the multiplicity of the eigenvalue, for $0<c<c_0$.

In Fig. 2 we give a plot of the energy levels for $M=4$ and $M=5$, as an illustration of the above. As c increases, the $M+1$ equidistant energy levels for $c=0$ split up in different levels, with smaller degeneracies.

It is worth noting that one can say something extra about the number of energy levels, for arbitrary M, also when $c\neq 0$. For $M=4$, the five levels $1+1+1+1+1$ at $c=0$ become $1+3+4+3+1$ levels for $c>0$ [just counting the energy levels, disregarding their multiplicities], see Fig. 2(a). We list here the number of levels for a few M values, when $c>0$:

M	Number of levels	Total number of levels
1	1+1	2
2	1+2+1	4
3	1+2+2+1	6
4	1+3+4+3+1	12
5	1+3+5+5+3+1	18
6	1+4+8+10+8+4+1	36
7	1+4+9+13+13+9+4+1	54
8	1+5+13+22+26+22+13+5+1	108

Let $T(M,k)$ $(k=0,1,\ldots,M)$ be the number of levels "per split" (the numbers in the middle column), and $L(M)=\Sigma_{k=0}^{M}T(M,k)$ be the total number of energy levels for $c>0$. $T(M,k)$ is also the number of distinct energy levels for all θ with $|\theta|=k$. Analysing this, using Eq. (5.4), one finds

$$T(M,k) = T(M-2,k) + T(M-2,k-1) + T(M-2,k-2). \tag{5.5}$$

Summing now over all k yields a simple recursion for the number of levels $L(M)$,

$$L(M) = 3L(M-2). \tag{5.6}$$

So we obtain the following result for the number of energy levels when $0 < c < c_0$, depending on whether M is even or odd

$$L(2n+1) = 2 \times 3^n, \quad L(2n+2) = 4 \times 3^n, \quad (n = 0,1,2,\dots). \tag{5.7}$$

Note that the numbers $L(M)$ belong to a known sequence, see entry A068911 in Ref. 30, with a simple generating function

$$G(x) = \sum_{M=0}^{\infty} L(M)x^M = \frac{(1+x)^2}{1-3x^2}. \tag{5.8}$$

VI. ON THE SPECTRUM OF POSITION OPERATORS IN THE REPRESENTATIONS $W(\boldsymbol{p})$ AND SPATIAL PROPERTIES

The purpose of the present section is to consider some geometric aspects of the given quantum system. In the first instance, we shall analyze the spectrum of the position operators $\hat{q}_r$ in the representations $W(p)$. By construction, these Hilbert spaces $W(p)$ are finite dimensional, so the position operators have a discrete spectrum.

The determination of the spectrum for general M and p requires a lot of work. This goes in two steps: first the operators $\hat{q}_r^2$ will be considered; this is the difficult part. Once the spectrum of $\hat{q}_r^2$ is analyzed, that of $\hat{q}_r$ follows rather easily. The spectrum of the momentum operators $\hat{p}_r^2$ and $\hat{p}_r$ is completely similar. In fact, we shall see that the structure of $\hat{p}_r^2$ and $\hat{q}_r^2$ as operators in $\mathfrak{gl}(1|M)$ is equivalent, and they can be treated simultaneously.

Note that, due to the symmetry of the system (1.1) and (1.2), the spectrum of $\hat{q}_r^2$ and $\hat{q}_r$ will be independent of r.

A. Eigenvalues and eigenvectors for $\hat{q}_r^2$

We start by writing the operator $\hat{q}_r^2$ in terms of the $\mathfrak{gl}(1|M)$ basis elements. Using Eq. (2.11), one finds

$$\hat{q}_r^2 = \frac{1}{2}\{\hat{q}_r, \hat{q}_r^\dagger\} = \frac{1}{2M}\sum_{k=1}^{M}\sum_{l=1}^{M} e^{(2\pi i r(k-l)/M)}\{\hat{Q}_k, \hat{Q}_l^\dagger\}.$$

Using Eq. (2.25) and the solution (3.16), this yields

$$\hat{q}_r^2 = \frac{\hbar}{mM}\left(\sum_{k=1}^{M}\frac{\beta_k}{\omega_k^2}e_{00} + \sum_{k=1}^{M}\sum_{l=1}^{M} e^{(2\pi i r(l-k)/M)}\frac{\sqrt{\beta_l\beta_k}}{\omega_l\omega_k}e_{lk}\right). \tag{6.1}$$

In a similar way, one finds

$$\hat{p}_r^2 = \frac{\hbar m}{M}\left(\sum_{k=1}^{M}\beta_k e_{00} + \sum_{k=1}^{M}\sum_{l=1}^{M} e^{(2\pi i r(l-k)/M)}\sqrt{\beta_l\beta_k}e_{lk}\right). \tag{6.2}$$

As operators of $\mathfrak{gl}(1|M)$, these two expressions are structurally equivalent: $\hat{q}_r^2$ is obtained from the expression of $\hat{p}_r^2$ by formally replacing every parameter β_k by β_k/ω_k^2, and multiplying by an overall factor $1/m^2$. So their spectral analysis is equivalent. Since the expression of $\hat{p}_r^2$ is somewhat simpler from the point of view of notation (no denominators in the factors), we shall first concentrate on the analysis for $\hat{p}_r^2$.

Following Eq. (6.2), it will be useful to introduce the even $\mathfrak{gl}(1|M)$ operators

$$\hat{s}_r = \sum_{k=1}^{M} \sum_{j=1}^{M} e^{(2\pi ir(j-k)/M)} \sqrt{\beta_j \beta_k} e_{jk}. \tag{6.3}$$

The main ingredient of our analysis is the following technical lemma.

Lemma 4: In the representation $W(p)$, the operator $\hat{s}_r$ has only two eigenvalues, namely $\beta = \Sigma_{k=1}^{M} \beta_k$ and 0, each with multiplicity 2^{M-1}.

Proof: Consider a vector of the form

$$v_r \equiv \sum_{k=1}^{M} e^{(2\pi irk/M)} \sqrt{\beta_k} w(1^k), \tag{6.4}$$

where $w(1^k)$ denotes the basis vector of $W(p)$ with $|\theta| = 1$ and the "1" occurring in position k (counting from left, and starting from one). For instance, if $M=4$ then

$$w(1^1) = w(1,0,0,0), \quad w(1^2) = w(0,1,0,0), \quad w(1^3) = w(0,0,1,0), \quad w(1^4) = w(0,0,0,1).$$

We extend the notation to $w(1^{k_1} \cdots 1^{k_n})$ which denotes the basis vector with $|\theta| = n$ and with 1's in the positions k_1 up to k_n.

It is easy to verify that v_r is an eigenvector of $\hat{s}_r$ with eigenvalue β.

In $\mathfrak{gl}(1|M)$, one can see that

$$[e_{l0}, \hat{s}_r] = -\sqrt{\beta_l} e^{-(2\pi irl/M)} \sum_{j=1}^{M} \sqrt{\beta_j} e^{(2\pi irj/M)} e_{j0}, \tag{6.5}$$

and thus the action (4.5) implies that

$$[e_{l0}, \hat{s}_r] v_r = 0. \tag{6.6}$$

This means that $e_{l0} v_r$ (provided it does not vanish) is also an eigenvector of $\hat{s}_r$, with the same eigenvalue β. Our goal is now to show that

$$e_{l_n 0} e_{l_{n-1} 0} \cdots e_{l_1 0} v_r \tag{6.7}$$

is also an eigenvector of $\hat{s}_r$ with the same eigenvalue β, provided all l_i are different (and different from M). If one would apply the same e_{l0} twice, the resulting vector vanishes since $\{e_{l0}, e_{k0}\} = 0$, by Eq. (3.1). This means that we can also assume, without loss of generality, that $M > l_n > l_{n-1} > \cdots > l_1 > 0$.

Using Eq. (4.5), one can write

$$e_{l_n 0} e_{l_{n-1} 0} \cdots e_{l_1 0} v_r \sim \sum_{t=0}^{n} (-1)^t \sum_{k=l_t+1}^{l_{t+1}-1} \sqrt{\beta_k} e^{(2\pi irk/M)} w(1^{l_1} \cdots 1^{l_t} 1^k 1^{l_{t+1}} \cdots 1^{l_n}), \tag{6.8}$$

with $l_0 = 0$ and $l_{n+1} = M+1$. Using Eq. (6.5), this implies that

$$[e_{l0}, \hat{s}_r] e_{l_n 0} e_{l_{n-1} 0} \cdots e_{l_1 0} v_r \sim \sum_{j=1}^{M} \sqrt{\beta_j} e^{(2\pi irj/M)} \sum_{t=0}^{n} (-1)^t \sum_{k=l_t+1}^{l_{t+1}-1} \sqrt{\beta_k} e^{(2\pi irk/M)} e_{j0} w(1^{l_1} \cdots 1^{l_t} 1^k 1^{l_{t+1}} \cdots 1^{l_n}). \tag{6.9}$$

Keeping in mind the action of e_{j0} on a basis vector $w(\theta)$, one sees that this expression is a linear combination of basis vectors $w(\theta)$ for which $|\theta| = n+2$, having a 1 in the positions l_1, l_2 up to l_n and in two extra positions x and y. Consider such a vector

$$w(1^{l_1}\cdots 1^{l_{i_x}}1^{x}1^{l_{i_x+1}}\cdots 1^{l_{i_y}}1^{y}1^{l_{i_y+1}}\cdots 1^{l_n}).$$

In expression (6.9) this vector will appear twice, once with k and j playing the role of x and y respectively, and one vice versa. In the first case the coefficient of this vector is

$$\sqrt{p-(n+1)}\sqrt{\beta_x\beta_y}e^{(2\pi ir(x+y)/M)}(-1)^{i_x}(-1)^{i_y+1},$$

while in the second case it is

$$\sqrt{p-(n+1)}\sqrt{\beta_x\beta_y}e^{(2\pi ir(x+y)/M)}(-1)^{i_x}(-1)^{i_y}.$$

Since these two coefficients cancel, we can conclude that

$$[e_{l0},\hat{s}_r]e_{l_n0}e_{l_{n-1}0}\cdots e_{l_10}v_r=0. \tag{6.10}$$

Following Eqs. (6.6) and (6.10), all vectors of the form (6.7) are eigenvectors of $\hat{s}_r$ for the eigenvalue β. It remains to find the number of linearly independent eigenvectors, i.e., the multiplicity of the eigenvalue β.

For n fixed, consider the $\binom{M-1}{n}$ vectors (6.7) with $1\leqslant l_1<l_2<\cdots<l_n\leqslant M-1$. Expressing these in the $w(\theta)$ basis by Eq. (6.8), in total $\binom{M}{n+1}$ basis vectors are involved. Each basis vector $w(\theta)$ occurs $\binom{n+1}{n}=n+1$ times, *except* those vectors that have a 1 in position M. There are $\binom{M-1}{n}$ such vectors. Next, let A be the $\binom{M-1}{n}\binom{M}{n+1}$ matrix, consisting of the coefficients of the $\binom{M-1}{n}$vectors (6.7) written in terms of the $\binom{M}{n+1}$ basis vectors. Select in A those columns that correspond to basis vector having a 1 in position M. This submatrix is equivalent with a diagonal matrix of which the diagonal elements are proportional to $\sqrt{\beta_M}$. So, the vectors (6.7) with $1\leqslant l_1<\cdots<l_n\leqslant M-1$ are linearly independent.

Furthermore, it is immediately clear that the vectors

$$e_{l_n0}e_{l_{n-1}0}\cdots e_{l_10}v_r \quad \text{and } e_{l_t0}e_{l_{t-1}0}\cdots e_{l_10}v_r$$

are linearly independent if $n\neq t$ (they are linear combinations of basis vectors with different $|\theta|$).

The conclusion is that we have found

$$\sum_{n=0}^{M-1}\binom{M-1}{n}=2^{M-1}$$

linearly independent eigenvectors of $\hat{s}_r$ with eigenvalue β. Note that for some fixed $|\theta|$, there are $\binom{M-1}{|\theta|-1}$ linearly independent eigenvectors of $\hat{s}_r$ with eigenvalue β.

The eigenvalue 0 of $\hat{s}_r$ also has multiplicity 2^{M-1}. This is seen in a completely similar way, starting with the vector

$$\tilde{v}_r\equiv\sum_{k=1}^{M}e^{-(2\pi irk/M)}(-1)^k\sqrt{\beta_k}w(0^k)$$

and acting repeatedly with e_{0l} (with $1\leqslant l\leqslant M-1$) on this vector. Herein we have extended the notation of Eq. (6.4): $w(0^k)$ denotes a basis vector where every $\theta_j=1$ $(j\neq k)$ except $\theta_k=0$. For fixed $|\theta|$, there are thus $\binom{M-1}{|\theta|}$ linearly independent eigenvectors with eigenvalue 0. □

We can now describe the eigenvalues of $\hat{p}_r^2$. Since

$$e_{00}w(\theta)=(p-|\theta|)w(\theta),$$

it follows from Eq. (6.2) that an eigenvector of $\hat{s}_r$ which is a linear combination of basis vectors with fixed $|\theta|$ will also be an eigenvector of $\hat{p}_r^2$. The eigenvalues of $\hat{p}_r^2$ are thus given by

$\hbar m(p-K)\beta/M$, for $0 \leqslant K \leqslant M-1$, with multiplicities $2\binom{M-1}{K}$. More in particular, the eigenvectors of $\hat{p}_r^2$ with eigenvalue $\hbar m(p-K)\beta/M$ arise in two ways, one set having $|\theta|=K+1$ and containing vectors of the form

$$e_{l_K 0} e_{l_{K-1} 0} \cdots e_{l_1 0} v_r.$$

The other set has $|\theta|=K$ and contains vectors of the form

$$e_{0 l_{M-K-1}} \cdots e_{0 l_1} \tilde{v}_r.$$

Unfortunately, the vectors (for a given eigenvalue) constructed here are not orthogonal. For any fixed M, one can construct a set of orthogonal eigenvectors by Gram–Schmidt orthogonalization. But so far we cannot give a closed analytic expression for some set of orthogonal eigenvectors.

Let us also state the result for the squared position operators $\hat{q}_r^2$. Recall from the beginning of this subsection that every β_k should be replaced by β_k/ω_k^2, thus β should be replaced by

$$\gamma = \sum_{k=1}^{M} \frac{\beta_k}{\omega_k^2}. \tag{6.11}$$

Proposition 5: The operator $\hat{q}_r^2$ has M distinct eigenvalues given by $x_K^2 = \hbar(p-K)\gamma/mM$, where $0 \leqslant K \leqslant M-1$. The multiplicity of each x_K^2 is $2\binom{M-1}{K}$. The eigenvectors of $\hat{q}_r^2$ with eigenvalue x_K^2 arise in two ways: there are $\binom{M-1}{K}$ vectors with $|\theta|=K+1$ of the form

$$e_{l_K 0} e_{l_{K-1} 0} \cdots e_{l_1 0} u_r;$$

and there are $\binom{M-1}{M-K-1} = \binom{M-1}{K}$ vectors with $|\theta|=K$ of the form

$$e_{0 l_{M-K-1}} \cdots e_{0 l_1} \tilde{u}_r.$$

Herein

$$u_r = \sum_{k=1}^{M} e^{(2\pi i r k/M)} \frac{\sqrt{\beta_k}}{\omega_k} w(1^k), \quad \tilde{u}_r = \sum_{k=1}^{M} e^{-(2\pi i r k/M)} (-1)^k \frac{\sqrt{\beta_k}}{\omega_k} w(0^k). \tag{6.12}$$

B. Eigenvalues for $\hat{q}_r$

We have shown that the eigenvectors of $\hat{q}_r^2$ with eigenvalue x_K^2 have either $|\theta|=K$ or $|\theta|=K+1$. Let ψ_{r,x_K} be an eigenvector of $\hat{q}_r$ with eigenvalue x_K. Such an eigenvector necessarily has the form

$$\psi_{r,x_K} = \sum_{|\theta|=K} C_{\theta,r,x_K} w(\theta) + \sum_{|\theta|=K+1} C_{\theta,r,x_K} w(\theta), \tag{6.13}$$

with C some constants. Thus one can write

$$\sum_{|\theta|=K} C_{\theta,r,x_K} \hat{q}_r w(\theta) + \sum_{|\theta|=K+1} C_{\theta,r,x_K} \hat{q}_r w(\theta) = x_K \sum_{|\theta|=K} C_{\theta,r,x_K} w(\theta) + x_K \sum_{|\theta|=K+1} C_{\theta,r,x_K} w(\theta). \tag{6.14}$$

But the action of $\hat{q}_r$ on a basis vector $w(\theta)$ is necessarily a linear combination of basis vectors $w(\theta')$ with $|\theta'|=|\theta|-1$ and $|\theta'|=|\theta|+1$: this follows from Eqs. (2.11), (2.25) and Eqs. (4.10) and (4.11). Thus the first sum on the left hand side of Eq. (6.14) is a linear combination of basis vectors with $|\theta|=K-1$ and $|\theta|=K+1$, while the second sum on the left hand side of Eq. (6.14) is a linear combination of basis vectors with $|\theta|=K$ and $|\theta|=K+2$. Of these four linear combinations

the first and the last vanish (since they do no occur on the right hand side), and it follows that

$$\sum_{|\theta|=K} C_{\theta,r,x_K}\hat{q}_r w(\theta) = x_K \sum_{|\theta|=K+1} C_{\theta,r,x_K} w(\theta). \tag{6.15}$$

Combining this with Eq. (6.14) implies

$$\sum_{|\theta|=K+1} C_{\theta,r,x_K}\hat{q}_r w(\theta) = x_K \sum_{|\theta|=K} C_{\theta,r,x_K} w(\theta). \tag{6.16}$$

We will now show that, given Eq. (6.13),

$$\psi_{r,-x_K} \equiv \sum_{|\theta|=K} C_{\theta,r,x_K} w(\theta) - \sum_{|\theta|=K+1} C_{\theta,r,x_K} w(\theta) \tag{6.17}$$

is an eigenvector of $\hat{q}_r$ with eigenvalue $-x_K$. In fact, the action of $\hat{q}_r$ on $\psi_{r,-x_K}$ follows directly from Eqs. (6.15) and (6.16) and yields $\hat{q}_r\psi_{r,-x_K}=-x_K\psi_{r,-x_K}$.

Thus we have shown:

Proposition 6: The operator $\hat{q}_r$ has $2M$ distinct eigenvalues given by $\pm x_K = \pm\sqrt{\hbar(p-K)\gamma/mM}$, where $0\leqslant K\leqslant M-1$. The multiplicity of the eigenvalue $\pm x_K$ is $\binom{M-1}{K}$. The eigenvectors of $\hat{q}_r$ for the eigenvalue $\pm x_K$ contain, when expanded in the standard basis $w(\theta)$, only vectors with $|\theta|=K$ or $|\theta|=K+1$.

So far, we have no simple analytic expression of the (orthogonal) eigenvectors of $\hat{q}_r$ in terms of the standard basis vectors $w(\theta)$.

C. Position probability distributions for stationary states $w(\theta)$

Consider the eigenvectors $\psi_{r,x,g}$ of the position operator $\hat{q}_r$ for the eigenvalue x expanded in the $w(\theta)$ basis

$$\psi_{r,x,g} = \sum_{\theta} C_{\theta,r,x,g} w(\theta), \tag{6.18}$$

and assume that these vectors are orthonormal, i.e.,

$$\langle \psi_{r,x,g} | \psi_{r,y,h} \rangle = \sum_{\theta} C^*_{\theta,r,x,g} C_{\theta,r,y,h} = \delta_{x,y}\delta_{g,h}. \tag{6.19}$$

In the above, g (or h) stands for a multiplicity label for vectors with the same eigenvalue x: e.g., when $x=\pm x_K$ then g runs from 1 to $\binom{M-1}{K}$. We know from the previous subsection that for $x=\pm x_K$, only coefficients $C_{\theta,r,x,g}$ with $|\theta|=K$ or $|\theta|=K+1$ will appear.

Let us now suppose that the quantum system is in a fixed eigenstate $w(\theta)$ of $\hat{H}$ (a stationary state). The expression

$$P(\theta, r, \pm x_K) = \sum_{g=1}^{\binom{M-1}{K}} |C_{\theta,r,\pm x_K,g}|^2 \tag{6.20}$$

yields the probability of "measuring" the value $\pm x_K$ for the position of the rth oscillator when the system is in the state $w(\theta)$. Plotting all these values $P(\theta, r, \pm x_K)$ for $K=0,\ldots,M-1$ yields the probability distribution of oscillator r in the stationary state $w(\theta)$.

It will be interesting to look at an explicit example of such probability distributions. First of all, due to the earlier mentioned symmetry of the system, these probability distributions will be independent of r; so we need to plot it for one r-value only (say $r=1$). We have considered the example $M=4$, with $\hbar=m=\omega=1$ and $c=0.5$. Then the eight eigenvalues $\pm x_K$ are given by $\pm(\sqrt{\gamma}/2)\sqrt{p-K}$, $K=0$, 1, 2, 3, with $p>3$ and $\gamma=(5\sqrt{2}+4\sqrt{3}-2)/9$ follows from Eq. (6.11). Let us

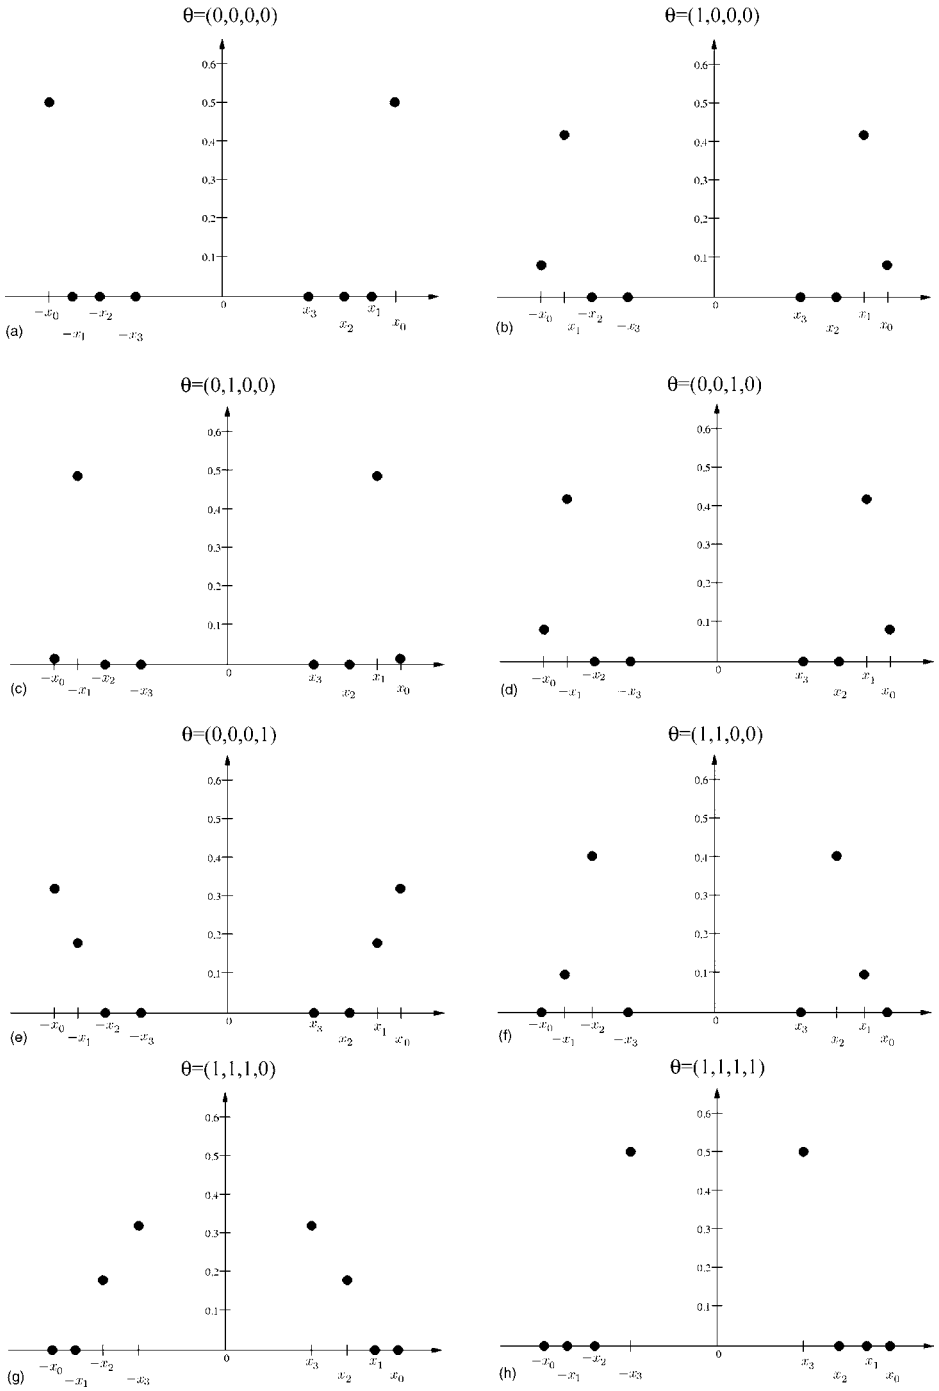

FIG. 3. Position probability distributions $P(\theta,1,\pm x_K)$ for a number of θ-values, for $M=4$. The vertical axis gives the values of $P(\theta,1,\pm x_K)$. On the horizontal axis one finds the possible eigenvalues $\pm x_K$ with $K=0$, 1, 2, 3. The values of the parameters are described in the text.

also choose a value for the representation label p: $p=M=4$. In Fig. 3 we give the position probability distributions for a number of stationary states $w(\theta)$, namely for $\theta=(0,0,0,0)$, $(1,0,0,0)$,$(0,1,0,0)$, $(0,0,1,0)$, $(0,0,0,1)$, $(1,1,0,0)$, $(1,1,1,0)$, and $(1,1,1,1)$.

Note in these plots that – in agreement with the previous paragraph – only the probabilities for $\pm x_K$ with $K=|\theta|$ or $K=|\theta|-1$ are nonzero. For $\theta=(0,0,0,0)$, corresponding to the highest energy

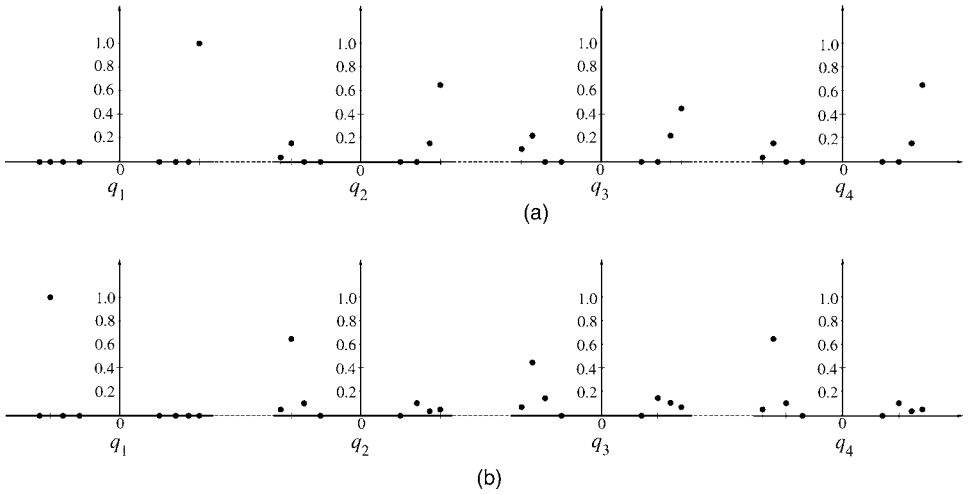

FIG. 4. Position probability distributions for all oscillators when the system is in the state (a) $\psi_{1,+x_0,1}$ and (b) $\psi_{1,-x_1,g}$.

state, the oscillators can be detected only in positions corresponding to the largest eigenvalues x_0 or $-x_0$. For $\theta=(1,1,1,1)$, corresponding to the lowest energy state, the oscillators can be detected only in positions corresponding to the smallest eigenvalues x_3 or $-x_3$. The four plots with $|\theta|=1$ give some probability distributions in which $\pm x_0$ and $\pm x_1$ are involved. Note that for $w(1,0,0,0)$ and $w(0,0,1,0)$, two stationary states for which the energy level is the same by Eq. (5.2) and Eq. (5.3), also the probability distributions coincide. According to Eq. (5.2), $E_{(0,0,0,1)}>E_{(0,0,1,0)}=E_{(0,1,0,0)}>E_{(1,0,0,0)}$. For the highest of these three energy levels, the probability of detecting the oscillator in $\pm x_0$ is larger than detecting it in $\pm x_1$; for the lowest of these three levels, it is vice versa. As $|\theta|$ increases (thus E_θ decreases), the probabilities indicate that the oscillator deviation from its equilibrium position also decreases.

D. Coupling of position probability distributions

In the previous subsection we considered, for a fixed stationary state $w(\theta)$, the position probabilities of the rth oscillator. Due to the symmetry of the system, these probability distributions are independent of r. It will be interesting to approach the position probabilities from a different point of view. For this purpose, let us assume that the system is in a fixed eigenstate of $\hat{q}_1$ with eigenvalue x, say $\psi_{1,x,g}$. Let us also consider another oscillator $r\neq 1$, and the expansion of $\psi_{1,x,g}$ in terms of the eigenvectors of $\hat{q}_r$:

$$\psi_{1,x,g}=\sum_{y,h} A_{1,x,g}^{r,y,h}\psi_{r,y,h}. \tag{6.21}$$

Then

$$\sum_{h} |A_{1,x,g}^{r,y,h}|^2 \tag{6.22}$$

is the probability of detecting the rth oscillator in the position y (corresponding to the eigenvalue y of $\hat{q}_r$) when the first oscillator is in the state $\psi_{1,x,g}$. Averaging this out over the multiplicities g (if present), thus yields the probability of detecting the rth oscillator in position y when the first oscillator is in position x.

Let us again look at an example of such probability distributions. We shall consider the same data as before: $M=4$, $\hbar=m=\omega=1$, and $c=0.5$. First, assume that oscillator 1 is in its highest possible position $+x_0$, so the system is in the state $\psi_{1,+x_0,1}$. Then, we can compute the probabilities (6.22), for $r=2$, 3, 4 and for $y=\pm x_K$ $(K=0,1,2,3)$. These probabilities are plotted in Fig. 4(a).

Note that the extreme position of oscillator 1 has a strong influence on the possible positions of oscillator 2, a weaker influence on the possible positions of oscillator 3, and again a stronger one on those of oscillator 4 (this last is due to the periodic boundary conditions (1.2), oscillator 4 behaves as if it is just to the left of oscillator 1).

We have also considered a second example, when the first oscillator is in an eigenstate with eigenvalue $-x_1$, i.e., the system is in a state $\psi_{1,-x_1,g}$. The position probability distributions for the other oscillators $r=2$, 3, 4 are plotted in Fig. 4(b), where we have averaged out over g ($g=1$, 2, 3). Thus in Fig. 4(b) an answer is given to the following question: suppose we make a measurement of the position of the first oscillator, and detect it in $-x_1$, what are in that case the probabilities of finding the other oscillators 2, 3, and 4 in one of their positions $\pm x_K$?

VII. ON THE SPECTRUM OF $\hat{H}$ AND POSITION OPERATORS IN ATYPICAL REPRESENTATIONS $W(p)$

In this section, we very briefly discuss what happens when working with atypical representations $W(p)$, i.e., when $p \in \{0,1,\ldots,M-1\}$. We concentrate on the spectrum of the Hamiltonian $\hat{H}$ and on that of the operators $\hat{q}_r^2$ and $\hat{q}_r$. Recall that the representation space in the atypical case is a truncation of that in the typical case, discarding basis vectors $w(\theta)$ for which $|\theta| > p$. Thus one expects a close connection between the spectra of the different operators in the typical and atypical case.

It is clear that each basis vector $w(\theta)$ is still an eigenvector of $\hat{H}$, with eigenvalue $\hbar E_\theta$, with E_θ given by Eq. (5.2). So the spectrum of $\hat{H}$ in the atypical case is nothing but a truncation of that in the typical case where the higher eigenvalues are retained (of course, the actual values are different because of the different value for p). As an example, for $M=4$ and $p=1$ the dimension of the representation space is

$$\binom{4}{0} + \binom{4}{1} = 5,$$

and the only four eigenvalues $\hbar E_\theta$ of $\hat{H}$ are

$$E_{(0,0,0,0)} = \beta = \beta_1 + \beta_2 + \beta_3 + \beta_4, \quad E_{(0,0,0,1)} = \beta_4,$$

$$E_{(1,0,0,0)} = \beta_1 = E_{(0,0,1,0)} = \beta_3, \quad \text{and } E_{(0,1,0,0)} = \beta_2,$$

where $\beta_4 > \beta_3 = \beta_1 > \beta_2$ for $0 < c < c_0$. These are the four topmost energy levels depicted in Fig. 2(a).

In the typical case $\hat{q}_r^2$ has eigenvalues $x_K^2 = \hbar(p-K)\gamma/mM$, with $0 \leqslant K \leqslant M-1$. From Eqs. (6.1), (4.3), (4.7), and (4.8) it follows immediately that an eigenvector of $\hat{q}_r^2$ in the typical case is also an eigenvector of $\hat{q}_r^2$ in the atypical case provided that it is a linear combination of basis vectors $w(\theta)$ with $|\theta| \leqslant p$. When $K<p$ one has the same set of eigenvectors as in the typical case, arising from both u_r and $\tilde{u}_r$ and the multiplicity of x_K^2 is $2\binom{M-1}{K}$. However, when $K=p$, $x_p=0$ and only the vectors arising from $\tilde{u}_r$ remain (the vectors arising from u_r would have $|\theta| = p+1$ which is impossible in an atypical representation). The multiplicity of eigenvalue $x_p=0$ is thus $\binom{M-1}{P}$. Consider the case $M=4$ and $p=1$; each operator $\hat{q}_r^2$ has two eigenvalues namely 0, with multiplicity $\binom{4-1}{1}=3$ and $\hbar(1)\gamma/4m$ with multiplicity $2\binom{3}{0}=2$.

For the position operators $\hat{q}_r$ finally, it is seen as before that $\pm x_K$ with $0 \leqslant K \leqslant p-1$ are eigenvalues of $\hat{q}_r$ each with multiplicity $\binom{M-1}{K}$. Besides these eigenvalues, there is also the eigenvalue $x_p=0$ with multiplicity $\binom{M-1}{P}$. So in the atypical case it is possible to "detect" an oscillator in its equilibrium position, in contrast with the typical case.

It is worth giving some further details for the representation $W(1)$ (so $p=1$), for general M-values. This representation has dimension $M+1$, with basis vectors $w(0)$ and $w(1^j)$ (in the notation of Eq. (6.4)), with $j=1,\ldots,M$. Each position operator $\hat{q}_r$ has spectrum $\{-x_0,0,+x_0\}$, with multiplicities $\{1,M-1,1\}$ respectively, where $x_0=\sqrt{\hbar\gamma/mM}$. Herein, γ is given by Eq. (6.11); in fact it will be useful to introduce the notation

$$\gamma_k=\frac{\sqrt{\beta_k}}{\omega_k},\quad k=1,\ldots,M, \tag{7.1}$$

and thus $\gamma=\Sigma_{k=1}^{M}\gamma_k^2$.

In this case, it is not difficult to construct explicitly a set of orthonormal eigenvectors of $\hat{q}_r$. In the notation of Sec. VI C, it is given by

$$\psi_{r,+x_0,1}=\frac{1}{\sqrt{2}}w(0)+\sum_{j=1}^{M}\frac{\gamma_j}{\sqrt{2\gamma}}e^{(2\pi irj/M)}w(1^j), \tag{7.2}$$

$$\psi_{r,-x_0,1}=\frac{1}{\sqrt{2}}w(0)-\sum_{j=1}^{M}\frac{\gamma_j}{\sqrt{2\gamma}}e^{(2\pi irj/M)}w(1^j), \tag{7.3}$$

$$\psi_{r,0,g}=\frac{1}{\sqrt{\dfrac{1}{\gamma_1^2+\cdots+\gamma_g^2}+\dfrac{1}{\gamma_{g+1}^2}}}\left(\sum_{j=1}^{g}\frac{\gamma_j}{\gamma_1^2+\cdots+\gamma_g^2}e^{(2\pi irj/M)}w(1^j)-\frac{1}{\gamma_{g+1}}e^{(2\pi ir(g+1)/M)}w(1^{g+1})\right), \tag{7.4}$$

where $g=1,2,\ldots,M-1$.

Now it becomes simple to compute some position probabilities. Following Eq. (6.20), one finds for the state $w(0)$ with $\theta=(0)=(0,\ldots,0)$,

$$P((0),r,+x_0)=P((0),r,-x_0)=\frac{1}{2},\quad P((0),r,0)=0.$$

Hence, in the highest energy state of $W(1)$, the oscillators can be detected only in the positions $\pm x_0$ and not in 0. Similarly

$$P((1^j),r,+x_0)=P((1^j),r,-x_0)=\frac{\gamma_j^2}{2\gamma},\quad P((1^j),r,0)=1-\frac{\gamma_j^2}{\gamma}.$$

Also the probabilities (6.22) can be computed. One finds, for example

$$A_{1,+x_0,1}^{r,+x_0,1}=\frac{1}{\gamma}\sum_{j=1}^{M}\gamma_j^2\cos^2\left(\frac{\pi(r-1)j}{M}\right),\quad A_{1,+x_0,1}^{r,-x_0,1}=\frac{1}{\gamma}\sum_{j=1}^{M}\gamma_j^2\sin^2\left(\frac{\pi(r-1)j}{M}\right), \tag{7.5}$$

and thus

$$\sum_g|A_{1,+x_0,1}^{r,0,g}|^2=\frac{2}{\gamma^2}\left(\sum_{j=1}^{M}\gamma_j^2\cos^2\left(\frac{\pi(r-1)j}{M}\right)\right)\left(\sum_{j=1}^{M}\gamma_j^2\sin^2\left(\frac{\pi(r-1)j}{M}\right)\right).$$

As before, the quantities $|A_{1,+x_0,1}^{r,+x_0,1}|^2$, $\Sigma_g|A_{1,+x_0,1}^{r,0,g}|^2$, and $|A_{1,+x_0,1}^{r,-x_0,1}|^2$ describe the probabilities of detecting the rth oscillator in the position $+x_0$, 0, or $-x_0$ respectively, when the first oscillator is in its highest position $+x_0$.

With the given probabilities, one can consider a final illustration. If the system is in the state $\psi_{1,+x_0,1}$, the average position of each oscillator r is given by

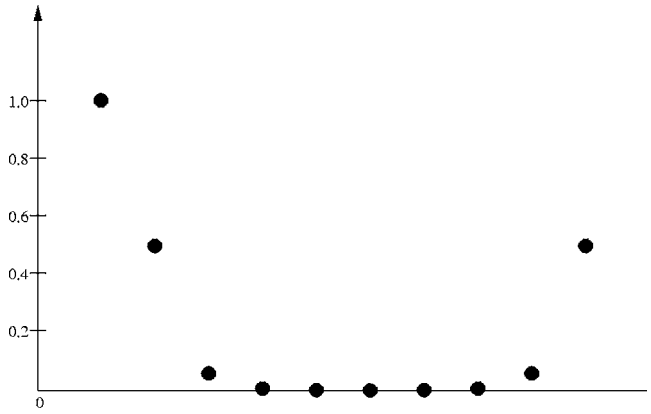

FIG. 5. Average positions of the M oscillators, $M=10$, when the first oscillator is in the position $+x_0$, in the representation $W(1)$. Here, we have taken $c=0.12\omega^2$. The horizontal axis labels the M oscillators; the vertical axis gives the average position in units of x_0.

$$+x_0|A^{r,+x_0,1}_{1,+x_0,1}|^2+0\sum_g|A^{r,0,g}_{1,+x_0,1}|^2-x_0|A^{r,-x_0,1}_{1,+x_0,1}|^2.$$

Using Eq. (7.5), this simplifies to

$$\langle\hat{q}_r\rangle_{\psi_{1,+x_0,1}}=x_0\frac{1}{\gamma}\sum_{j=1}^{M}\gamma_j^2\cos\left(\frac{2\pi(r-1)j}{M}\right).$$

In Fig. 5 we plot the average position of each oscillator r in this state. So in this figure one can see the effect of having the first oscillator in its highest position $+x_0$ on the average position of the other oscillators.

VIII. CONCLUSION AND OUTLOOK

We have examined some properties of noncanonical solutions of the quantum system determined by the Hamiltonian (1.1). These solutions arise from a WQSs approach, where the quantization conditions are weaker than the canonical commutation relations, thus allowing more types of solutions.

The solutions studied here are found by identifying certain linear combinations of position and momentum operators with generators of the Lie superalgebra $\mathfrak{gl}(1|M)$. We have shown that this is always possible, but that the solutions are corresponding to the compact form $\mathfrak{u}(1|M)$ of $\mathfrak{gl}(1|M)$ only if the coupling constant c is sufficiently small.

The physical Hilbert spaces in which the states of the system are described then correspond to unitary representations of $\mathfrak{gl}(1|M)$. In this paper, we have considered only a simple class of such unitary representations, the so-called Fock spaces $W(p)$. This class of representations turns out to be already sufficiently resourceful in order to exhibit some fascinating physical properties of the solutions. Of special interest is the feature of having only a discrete spectrum for each oscillator position operator. At first sight, this is somewhat unusual. On the other hand, our analysis of probability distributions for position operators has shown effects that are reminiscent of canonical results.

This paper presents only the first results for this quantum system consisting of a one-dimensional chain of coupled harmonic oscillators in the WQSs approach. There are still many open problems or new aspects to be studied. For example, it is clear that the system (2.29) has also solutions outside $\mathfrak{gl}(1|M)$. For instance, if $M=2n$ is even, then one can construct an algebraic solution by means of the direct sum Lie superalgebra $\mathfrak{gl}(1|2)\oplus\cdots\oplus\mathfrak{gl}(1|2)$ (n copies). In this case, the unitarity conditions following from the form $\mathfrak{u}(1|2)\oplus\cdots\oplus\mathfrak{u}(1|2)$ imply no conditions

on the coupling constant c, and it would be interesting to study the system from this point of view. Furthermore, it would be worth investigating whether Eq. (2.29) has also solutions related to orthosymplectic Lie superalgebras.[31]

But even if we restrict for the moment our attention to the $\mathfrak{gl}(1|M)$ solutions given here in Sec. III, work remains to be done. In particular, one should also consider other classes of unitary $\mathfrak{gl}(1|M)$ representations[26] and investigate the corresponding physical properties.

Finally, and this a more technical question, the explicit construction of orthonormal eigenvectors of the position operators $\hat{q}_k$ is lacking. Although this can be done numerically for any given M and a given set of parameters, we have at the moment no closed form expressions for these eigenvectors. We hope to find such forms, as they would allow us to draw some general conclusions regarding position probability distributions. At this moment, the last conclusions in Sec. VI are based upon observations of examples rather than upon analytic formulas. We expect to return to some of these remaining questions in future publications.

Framework for nonlocally related partial differential equation systems and nonlocal symmetries: Extension, simplification, and examples

George Bluman,[a] Alexei F. Cheviakov,[b] and Nataliya M. Ivanova[c]
Department of Mathematics, University of British Columbia, Vancouver, V6T 1Z2 Canada

(Received 5 July 2006; accepted 15 August 2006; published online 14 November 2006)

Any partial differential equation (PDE) system can be effectively analyzed through consideration of its tree of nonlocally related systems. If a given PDE system has n local conservation laws, then each conservation law yields potential equations and a corresponding nonlocally related potential system. Moreover, from these n conservation laws, one can directly construct 2^n-1 independent nonlocally related systems by considering these potential systems individually (n singlets), in pairs ($n(n-1)/2$ couplets),..., taken all together (one n-plet). In turn, any one of these 2^n-1 systems could lead to the discovery of new nonlocal symmetries and/or nonlocal conservation laws of the given PDE system. Moreover, such nonlocal conservation laws could yield further nonlocally related systems. A theorem is proved that simplifies this framework to find such extended trees by eliminating redundant systems. The planar gas dynamics equations and nonlinear telegraph equations are used as illustrative examples. Many new local and nonlocal conservation laws and nonlocal symmetries are found for these systems. In particular, our examples illustrate that a local symmetry of a k-plet is not always a local symmetry of its "completed" n-plet ($k<n$). A new analytical solution, arising as an invariant solution for a potential Lagrange system, is constructed for a generalized polytropic gas. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2349488]

I. INTRODUCTION

For any given system of partial differential equations (PDEs), one can systematically construct an extended tree of nonlocally related potential systems and subsystems.[1] All systems within a tree have the same solution set as the given system.

The analysis of a system of PDEs through consideration of nonlocally related systems in an extended tree can be of great value. In particular, using this approach, through Lie's algorithm one can systematically calculate nonlocal symmetries (which in turn are useful for obtaining new exact solutions from known ones), construct invariant and nonclassical solutions, as well as obtain linearizations, etc. (Examples are found in Ref. 1.) Perhaps more importantly, as all such related systems contain all solutions of the given system, any general method of analysis (qualitative, numerical, perturbation, conservation laws, etc.) considered for a given PDE system may be tried again on any nonlocally related potential system or subsystem. In this way, new results may be obtained for any method of analysis that is not coordinate-dependent as the systems within a tree are related in a nonlocal manner.

In Ref. 1, a tree construction algorithm is described. First, local conservation laws for the given system are found (through the direct construction method (DCM) or other method).[2–4] For each conservation law, one or several potentials are introduced.[5] Consequently, a potential system

[a]Electronic mail: bluman@math.ubc.ca
[b]Electronic mail: alexch@math.ubc.ca
[c]Permanent address: Institute of Mathematics NAS Ukraine. Electronic mail: ivanova@imath.kiev.ua

is obtained. Next, for each potential system, its conservation laws are computed, and further potential systems are constructed. This procedure terminates when no more new conservation laws are found. After potential systems are determined, for each potential system, new subsystems may be generated when one is able to reduce the number of dependent variables (including a reduction after a point transformation of dependent and independent variables of a potential system in a tree). At any step, all locally related potential systems and subsystems are excluded from the tree.

In this article we further extend the tree construction algorithm presented in Ref. 1. In particular, if a given system of PDEs has n conservation laws, one can directly construct 2^n-1 independent nonlocally related systems by considering their corresponding potential systems individually (n singlets), in pairs ($n(n-l)/2$ couplets),…, taken all together (one n-plet). In turn, any one of these 2^n-1 systems could lead to the discovery of new nonlocal symmetries and/or nonlocal conservation laws of the given PDE system. Moreover, such nonlocal conservation laws could yield further nonlocally related systems and subsystems as described earlier. Hence, for a given system of PDEs, the construction of its tree of nonlocally related PDE systems through our extended tree framework can be complex. Most importantly, we introduce and prove a theorem that simplifies this construction to find such extended trees by eliminating redundant systems. The work presented in this paper also simplifies and extends to within an algorithmic framework the heuristic approaches presented in Refs. 9 and 10.

This article gives a comprehensive analysis of trees of nonlocally related systems for classes of constitutive functions, including a systematic search of corresponding nonlocal symmetries and nonlocal conservation laws. In particular, new nonlocal symmetries and new conservation laws are found for planar gas dynamics (PGD) equations and nonlinear telegraph (NLT) equations, extending work in Refs. 6–10, respectively, and in references therein. Moreover, we extend and simplify the tree construction framework presented in Ref. 1 through further elimination of redundant systems. In a related work,[11] for a class of diffusion-convection equations, Popovych and Ivanova[11] completely classified its potential conservation laws and, correspondingly, constructed (hierarchical) trees of inequivalent potential systems.

This article is organized as follows. In Sec. II, we review the DCM for finding conservation laws for a given system of PDEs. We show how a related potential system arises from each local conservation law of the given system and, further, how to construct the corresponding 2^n-1 nonlocally related systems for a given system of PDEs with n local conservation laws. As examples, we consider systems of PGD equations. We find local conservation laws and corresponding nonlocally related systems for the PGD system in Lagrangian coordinates.

In Sec. III, we prove a fundamental theorem on finding conservation laws of PDE systems. In particular, for *any* given PDE system **F** with two independent variables (x and t) with precisely n local conservation laws, we show that from consideration of all combinations of the n corresponding *potential systems of PDEs* arising from the given system, no nonlocal conservation laws can be obtained for **F** through potential systems arising from multipliers that depend only on x and t. In particular, for such multipliers, all conservation laws of potential systems must be linear combinations of the n local conservation laws of the given system **F**. Consequently, for such multipliers, all further potential systems are equivalent to all possible couplets, triplets,…,n-plets of potential systems obtained from a given system **F**—a total of 2^n-1 systems for consideration. Hence for a given PDE system **F**, in order to find additional inequivalent potential systems as well as nonlocal conservation laws for **F**, it is necessary to seek conservation laws through multipliers having an essential dependence on dependent variables. The fundamental theorem is also shown to hold for PDE systems with any number of independent variables.

In Sec. IV, as a prototypical example, we consider NLT equations. We give a complete classification of local conservation laws arising from multipliers that are functions of independent and dependent variables. As a consequence, we find five new local conservation laws arising from three distinguished cases. We then use the simplified procedure introduced in Sec. III to construct corresponding trees of nonlocally related PDE systems. Nonlocal symmetries are found for corresponding NLT systems with constitutive functions involving power law nonlinearities, including all nonlocal symmetries found in Ref. 6 as well as a new one. Moreover, six new nonlocal

conservation laws are constructed for such power law NLT equations through a search of multipliers (which have an essential dependence on potential variables) for the potential systems arising from its conservation laws.

In Sec. V, we consider PGD equations, with a generalized polytropic equation of state, in Lagrangian coordinates. We give the point symmetry classification of the seven potential systems resulting from its three local conservation laws. Two new nonlocal symmetries are found which arise as point symmetries for only one of these potential systems (a couplet). We observe that these new nonlocal symmetries also arise as point symmetries of a subsystem of the Lagrange system and give the symmetry classification of this subsystem. This yields one more new nonlocal symmetry of the PGD equations. We consider invariant solutions that essentially arise from new nonlocal symmetries.

In Sec. VI, we summarize the new results presented in this article. In particular, we outline the procedure to construct a tree of nonlocally related PDE systems for a given PDE system.

In this work, a recently developed package GeM for MAPLE[12] is used for automated symmetry and conservation law analysis and classifications.

II. CONSTRUCTION OF CONSERVATION LAWS AND NONLOCALLY RELATED PDE SYSTEMS

A. Direct construction method for finding conservation laws

We first present the DCM to find the conservation laws for a general PDE system.

Let $\mathbf{G}\{\mathbf{x},\mathbf{u}\}=0$ be a system of m partial differential equations

$$\mathbf{G}\{\mathbf{x},\mathbf{u}\}=0:\begin{cases} G_1\{\mathbf{x},\mathbf{u}\}=0 \\ \vdots \\ G_m\{\mathbf{x},\mathbf{u}\}=0 \end{cases} \tag{2.1}$$

with M independent variables $\mathbf{x}=(x^1,\ldots,x^M)$, and N dependent variables $\mathbf{u}=(u^1,\ldots,u^N)$. Let $\partial^l\mathbf{u}$ denote the set of all partial derivatives of $\mathbf{u}$ of order l.

A set of multipliers $\{\Lambda_k(\mathbf{x},\mathbf{U},\partial\mathbf{U},\ldots,\partial^l\mathbf{U})\}_{k=1}^m$ yields a conservation law

$$\Lambda_k(\mathbf{x},\mathbf{u},\partial\mathbf{u},\ldots,\partial^l\mathbf{u})G_k\{\mathbf{x},\mathbf{u}\}=D_i\Phi^i(\mathbf{x},\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u})=0 \tag{2.2}$$

of system (2.1) if and only if the linear combination $\Lambda_k(\mathbf{x},\mathbf{U},\partial\mathbf{U}\ldots,\partial^l\mathbf{U})G_k\{\mathbf{x},\mathbf{U}\}$ is annihilated by the *Euler operators*

$$E_{U^s}\frac{\partial}{\partial U^s}-D_i\frac{\partial}{\partial U_i^s}+\cdots+(-1)^jD_{i_1}\cdots D_{i_j}\frac{\partial}{\partial U^s_{i_1\ldots i_j}}+\cdots, \tag{2.3}$$

i.e., the N determining equations

$$E_{U^s}(\Lambda_k(\mathbf{x},\mathbf{U},\partial\mathbf{U},\ldots,\partial^l\mathbf{U})G_k\{\mathbf{x},\mathbf{U}\})=0,\quad s=1,\ldots,N, \tag{2.4}$$

must hold for an arbitrary set of functions $\mathbf{U}=(U^1,\ldots,U^N)$. Here and for the rest of this article, we assume summation over a repeated index.

After solving the determining equations (2.4) and finding a set of multipliers $\{\Lambda_k(\mathbf{x},\mathbf{U},\partial\mathbf{U},\ldots,\partial^l\mathbf{U})\}_{k=1}^m$ that yield a conservation law, one can obtain the fluxes $\Phi^i(\mathbf{x},\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u})$ by using integral formulas arising from homotopy operators (see Refs. 2 and 3).

A conservation law $D_i\Phi^i(\mathbf{x},\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u})=0$ is called *trivial* if its fluxes are of the form $\Phi^i=M^i+H^i$, where M^i and H^i are smooth functions such that M^i vanishes on the solutions of the system (2.1), and $D_iH^i\equiv 0$. Two conservation laws $D_i\Phi^i[\mathbf{u}]=0$ and $D_i\Psi^i[\mathbf{u}]=0$ are *equivalent* if $D_i(\Phi^i[\mathbf{u}]-\Psi^i[\mathbf{u}])=0$ is a trivial conservation law. The more general "triviality" idea is the notion of linear dependence of conservation laws. A set of conservation laws is *linearly dependent* if there exists a linear combination of them which is a trivial conservation law.

B. Construction of nonlocally related systems from local conservation laws

Case A: Two independent variables. Suppose a PDE system with two independent variables

$$\mathbf{F}\{x,t,\mathbf{u}\}=0:\quad \begin{cases} F_1\{x,t,\mathbf{u}\}=0,\\ \vdots\\ F_m\{x,t,\mathbf{u}\}=0, \end{cases} \tag{2.5}$$

possesses n local conservation laws $\{\mathcal{R}^s\}_{s=1}^n$ of the form

$$\mathcal{R}^s:\quad D_xX_s(x,t,\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u})+D_tT_s(x,t,\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u})=0,\quad s=1,\ldots,n, \tag{2.6}$$

where T_s and X_s are differentiable functions of their arguments. Each conservation law $\mathcal{R}^s$ (2.6) of the system (2.5) yields a pair of potential equations of the form

$$\mathcal{P}^s:\quad \begin{cases} (v_s)_x=T_s(x,t,\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u}),\\ (v_s)_t=-X_s(x,t,\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u}). \end{cases} \tag{2.7}$$

For each conservation law (2.6), the corresponding set of potential equations $\mathcal{P}^s$ (2.7) can be *appended* to the given system $\mathbf{F}$ (2.5) to yield a nonlocally related *potential system* $\mathbf{F}^s_{\mathbf{P}}$. (Alternatively, if at least one of the factors of the conservation law does not vanish outside of the solution space, the potential equations $\mathcal{P}^s$ can *replace* one of the equations of the given system $\mathbf{F}$.)

From the n conservation laws (2.6), one can obtain further inequivalent nonlocally related systems, by considering not only potential systems $\mathbf{F}^s_{\mathbf{P}}$ arising from single conservation laws $\mathcal{R}^s$, but also couplets $\{\mathbf{F}^i_{\mathbf{P}},\mathbf{F}^j_{\mathbf{P}}\}^n_{i,j=1}$, triplets $\{\mathbf{F}^i_{\mathbf{P}},\mathbf{F}^j_{\mathbf{P}},\mathbf{F}^k_{\mathbf{P}}\}^n_{i,j,k=1},\ldots$, and finally the n-plet of potential systems $\{\mathbf{F}^1_{\mathbf{P}},\ldots\mathbf{F}^n_{\mathbf{P}}\}$. Hence one obtains as many as 2^n-1 potential systems of equations nonlocally related to $\mathbf{F}$ (2.5) through the n conservation laws (2.6).

Case B: Several independent variables. Now consider a general PDE system $\mathbf{G}$ (2.1) with $M\geq 2$ independent variables. Suppose it possesses n local conservation laws $\{\mathcal{K}^s\}_{s=1}^n$ of the form

$$\mathcal{K}^s:\quad D_i\Phi^i_s(\mathbf{x},\mathbf{u},\partial\mathbf{u},\ldots,\partial^r\mathbf{u})=0,\quad s=1,\ldots,n, \tag{2.8}$$

with fluxes $\Phi^{(s)i}$ that are differentiable functions of their arguments. Each conservation law (2.8) yields a set of M potential equations of the form (see Refs. 5 and 14)

$$\mathcal{Q}^s:\quad \Phi^i_s=\sum_{i<j}(-1)^j\frac{\partial}{\partial x^j}v_{ij}+\sum_{j<i}(-1)^{i-1}\frac{\partial}{\partial x^j}v_{ji},\quad i=1,\ldots,M, \tag{2.9}$$

where the potentials $\mathbf{v}=\{v_{ij}(\mathbf{x})\}$ are the $\frac{1}{2}M(M-1)$ nonrepeating components of an $M\times M$ antisymmetric tensor.

For every s, by appending potential equations $\mathcal{Q}^s$ to the given system $\mathbf{G}$ (or replacing an equation of $\mathbf{G}$ by potential equations $\mathcal{Q}^s$, whatever is appropriate), one obtains a *potential system* $\mathbf{G}^s_{\mathbf{P}}$ which is nonlocally related to the given system $\mathbf{G}$ (2.1).

In the same manner as for the case of two independent variables, by considering singlets, couplets, triplets, $\ldots,n$-plet of potential systems $\mathbf{G}^s_{\mathbf{P}}$, one can obtain as many as 2^n-1 independent PDE systems nonlocally related to the given system $\mathbf{G}$, whose solution sets are equivalent to that of $\mathbf{G}$.

We now illustrate the use of 2^n-1 independent potential systems to study symmetries of a system of polytropic gas dynamics equations.

C. Conservation laws, nonlocally related PDE systems and nonlocal symmetry analysis of planar gas dynamics equations

1. Conservation laws and nonlocally related systems

In Lagrangian mass coordinates $s=t, y=\int_{x_0}^x\rho(\xi)d\xi$, planar one-dimensional gas motion is described by the equations

TABLE I. Local conservation laws of (2.10) with $\Lambda_i=\Lambda_i(y,s)$.

CL	Multipliers $(\Lambda_1,\Lambda_2,\Lambda_3)$	Conservation law	Potential	Potential equations
(W_1)	$(1,0,0)$	$D_s(q)-D_y(v)=0$	w_1	$w_{1y}=q,\ w_{1s}=v$
(W_2)	$(0,1,0)$	$D_s(v)+D_y(p)=0$	w_2	$w_{2y}=v,\ w_{2s}=-p$
(W_3)	$(y,s,0)$	$D_s(sv+yq)+D_y(sp-yv)=0$	w_3	$w_{3y}=sv+yq,\ w_{3s}=-sp+yv$

$$\mathbf{L}\{y,s,v,p,q\}=0:\quad \begin{cases} q_s-v_y=0 \\ v_s+p_y=0 \\ p_s+B(p,q)v_y=0. \end{cases} \tag{2.10}$$

Here x is a Cartesian space coordinate, t is time, v is the gas velocity, $q=1/\rho$ where ρ is the gas density, and p is the gas pressure. In terms of the entropy density $S(p,q)$, the constitutive function $B(p,q)$ is given by

$$B(p,q)=\frac{S_q}{S_p}.$$

We note that system (2.10) admits the group of equivalence transformations

$$s=a_1\tilde{s}+a_4,\quad y=a_2\tilde{y}+a_5,\quad v=a_3\tilde{v}+a_6,$$

$$p=\frac{a_2a_3}{a_1}\tilde{p}+a_7,\quad q=\frac{a_1a_3}{a_2}\tilde{q}+a_8,\quad B(p,q)=\frac{a_2^2}{a_1^2}\tilde{B}(\tilde{p},\tilde{q}) \tag{2.11}$$

for arbitrary constants $a_1\ldots,a_8$ with $a_1a_2a_3\neq 0$.

We first construct the simplest conservation laws and all corresponding inequivalent potential systems for the Lagrange system (2.10). Using the DCM (Sec. II A), for an arbitrary constitutive function $B(p,1/\rho)$, we find that for multipliers of the form $\Lambda_i=\Lambda_i(y,s)$, the Lagrange system (2.10) has the conservation laws exhibited in Table I.

The potential equations that arise from the conservation law (W_1) can be used to replace the first equation of the Lagrange system (2.10); potential equations arising from the conservation law (W_2), can replace the second equation of (2.10); finally, potential equations arising from the conservation law (W_3), can equivalently replace either the first or second equation of (2.10).

The independent set of nonlocally related (potential) systems of the Lagrange system (2.10) consists of the following:

- Three singlets (potential systems involving a single nonlocal variable w_i)

$$\mathbf{LW}_1\{y,s,v,p,q,w_1\}=0:\quad \begin{cases} w_{1y}=1, \\ w_{1s}=v, \\ v_s+p_y=0, \\ p_s+B(p,q)v_y=0; \end{cases} \tag{2.12}$$

$$\mathbf{LW}_2\{y,s,v,p,q,w_2\}=0:\quad \begin{cases} q_s-v_y=0, \\ w_{2y}=v, \\ w_{2s}=-p, \\ p_s+B(p,q)v_y=0; \end{cases} \tag{2.13}$$

$$\mathbf{LW}_3\{y,s,v,p,q,w_3\}=0:\quad \begin{cases} w_{3y}=sv+yq,\\ w_{3s}=-sp+yv,\\ v_s+p_y=0,\\ p_s+B(p,q)v_y=0; \end{cases} \tag{2.14}$$

- Three couplets

$$\mathbf{LW}_1\mathbf{W}_2\{y,s,v,p,q,w_1,w_2\}=0:\quad \begin{cases} w_{1y}=q,\\ w_{1s}=v,\\ w_{2y}=v,\\ w_{2s}=-p,\\ p_s+B(p,q)v_y=0; \end{cases} \tag{2.15}$$

$$\mathbf{LW}_1\mathbf{W}_3\{y,s,v,p,q,w_1,w_3\}=0:\quad \begin{cases} w_{1y}=q,\\ w_{1s}=v,\\ w_{3y}=sv+yq,\\ w_{3s}=-sp+yv,\\ p_s+B(p,q)v_y=0; \end{cases} \tag{2.16}$$

$$\mathbf{LW}_2\mathbf{W}_3\{y,s,v,p,q,w_2,w_3\}=0:\quad \begin{cases} w_{2y}=v,\\ w_{2s}=-p,\\ w_{3y}=sv+yq,\\ w_{3s}=-sp+yv,\\ p_s+B(p,q)v_y=0; \end{cases} \tag{2.17}$$

- One triplet involving all three conservation laws:

$$\mathbf{LW}_1\mathbf{W}_2\mathbf{W}_3\{y,s,v,p,q,w_1,w_2,w_3\}=0:\quad \begin{cases} w_{1y}=q,\\ w_{1s}=v,\\ w_{2y}=v,\\ w_{2s}=-p,\\ w_{3y}=sv+yq,\\ w_{3s}=-sp+yv,\\ p_s+B(p,q)v_y=0. \end{cases} \tag{2.18}$$

The Lagrange system (2.10) has also a nonlocally related *subsystem* obtained by excluding v (See Ref. 1):

$$\underline{\mathbf{L}}\{y,s,p,q\}=0:\quad \begin{cases} q_{ss}+p_{yy}=0,\\ p_s+B(p,q)q_s=0. \end{cases} \tag{2.19}$$

2. Nonlocal symmetry analysis for polytropic gas flows

We consider the polytropic equation of state

$$B(p,q) = \gamma \frac{p}{q}.$$

Applying group analysis to the triplet potential system (2.18), for arbitrary γ, one finds the basis of the ten-dimensional point symmetry algebra admitted by the given Lagrange system (2.10):

$$X_1 = \frac{\partial}{\partial s} + w_2 \frac{\partial}{\partial w_3}, \quad X_2 = \frac{\partial}{\partial y} + w_1 \frac{\partial}{\partial w_3},$$

$$X_3 = s\frac{\partial}{\partial s} + v\frac{\partial}{\partial v} + 2q\frac{\partial}{\partial q} + 2w_1\frac{\partial}{\partial w_1} + w_2\frac{\partial}{\partial w_2} + 2w_3\frac{\partial}{\partial w_3},$$

$$X_4 = \frac{\partial}{\partial v} + s\frac{\partial}{\partial w_1} + y\frac{\partial}{\partial w_2} + ys\frac{\partial}{\partial w_3}, \quad X_5 = s\frac{\partial}{\partial s} + y\frac{\partial}{\partial y} + w_1\frac{\partial}{\partial w_1} + w_2\frac{\partial}{\partial w_2} + 2w_3\frac{\partial}{\partial w_3},$$

$$X_6 = v\frac{\partial}{\partial v} + p\frac{\partial}{\partial p} + q\frac{\partial}{\partial q} + w_1\frac{\partial}{\partial w_1} + w_2\frac{\partial}{\partial w_2} + w_3\frac{\partial}{\partial w_3},$$

$$X_7 = \frac{\partial}{\partial w_1}, \quad X_8 = \frac{\partial}{\partial w_2}, \quad X_9 = \frac{\partial}{\partial w_3},$$

$$X_{10} = y^2\frac{\partial}{\partial y} + (w_2 - yv)\frac{\partial}{\partial v} + yp\frac{\partial}{\partial p} - 3yq\frac{\partial}{\partial q} + (sw_2 - w_3)\frac{\partial}{\partial w_1} + yw_2\frac{\partial}{\partial w_2} + ysw_2\frac{\partial}{\partial w_3}. \tag{2.20}$$

In particular, the operators $X_1,\ldots,X_9$ project onto point symmetries of the given Lagrange system (2.10); the operator X_{10} yields a *nonlocal symmetry* of the Lagrange system **L**.[1,10]

If $\gamma=3$, system (2.10) admits one additional symmetry[9]

$$X_{11} = s^2\frac{\partial}{\partial s} + (w_1 - sv)\frac{\partial}{\partial v} - 3sp\frac{\partial}{\partial p} + sq\frac{\partial}{\partial q} + sw_1\frac{\partial}{\partial w_1} + (yw_1 - w_3)\frac{\partial}{\partial w_2} + ysw_1\frac{\partial}{\partial w_3},$$

which also yields a nonlocal symmetry of the Lagrange system **L**.

If $\gamma=-1$, system (2.10) corresponds to Chaplygin gas and is linearizable, as will be shown in Sec. II C 3.

Remark 1: Among all of these constructed potential systems of **L**, symmetries $X_1\ldots,X_{10}$ (or their projections) are obtained *simultaneously* as point symmetries only for the triplet potential system $\mathbf{LW}_1\mathbf{W}_2\mathbf{W}_3$, which in this sense is a *grand system* for the Lagrange system **L**. [All other potential systems admit the corresponding projected proper subalgebras of the Lie algebra arising from (2.20).] The practical value of such a grand system is evident—possessing the largest known symmetry group, it allows the construction of a maximal possible set of invariant solutions of the given system.

Note that it does not automatically follow that the potential system with the maximum number of potential variables is a "grand system" for determining symmetries, as is the case in this example. Counterexamples will be presented in Secs. IV and V.

3. Further conservation laws for a general constitutive function

We now look for conservation law multipliers for the Lagrange system **L** (2.10) in terms of the more general form $\Lambda_i=\Lambda_i(y,s,V,P,Q)$, $i=1,2,3$.

The solution of the conservation law determining equations (2.4) yields the following multipliers:

$$\Lambda_1 = \alpha y - \beta P + B(P,Q)\Lambda_3 + \delta,$$

$$\Lambda_2 = \alpha s + \beta V + \nu,$$

$$\Lambda_3 = \Lambda_3(y,P,Q), \tag{2.21}$$

where α, β, ν, and δ are arbitrary real constants, and $\Lambda_3(y,P,Q)$ is any solution of the PDE

$$(\Lambda_3)_Q = (B(P,Q)\Lambda_3)_P - \beta. \tag{2.22}$$

Conservation laws corresponding to $\beta=0$, $\Lambda_3=0$ and $\delta,\nu,\alpha\neq 0$ are, respectively, the conservation laws (W_1), (W_2), and (W_3) listed in Table I. Additional conservation laws arise when $\Lambda_3 \neq 0$. It is possible to show that from multipliers (2.21) only two new linearly independent conservation laws follow. The first conservation law corresponds to $\beta=1$ and represents conservation of energy. It is given by

$$\left[\left(\frac{v^2}{2} + K(p,q)\right)_s + (pv)_y\right] = 0, \tag{2.23}$$

where $K(p,q)$ is a solution of the equation $K_q(p,q)=B(p,q)K_p(p,q)-p$.

The second conservation law ($\beta=0$) defines the adiabatic process in Lagrangian coordinates:

$$(S(p,q))_s = 0, \tag{2.24}$$

where the entropy $S(p,q)$ is a solution of the equation $S_q(p,q)=B(p,q)S_p(p,q)$.

For forms of $B(p,q)$ for which the functions $K(p,q)$, $S(p,q)$ can be explicitly evaluated, the conservation laws (2.23) and (2.24), respectively, yield explicit potential systems with potentials w_4, w_5.

For the polytropic case $B(p,q)=\gamma p/q$, we find that $S(p,q)=q^\gamma p$. The conservation law $(S(p,q))_s=0$ (2.24) can equivalently replace the last equation of the given system **L** (2.10). This leads to the potential system

$$\mathbf{LW}_5\{y,s,v,p,q,w_5\} = 0: \begin{cases} (w_5)_y(y,s) = q^\gamma p, \\ (w_5)_s(y,s) = 0, \\ q_s - v_y = 0, \\ v_s + p_y = 0 \end{cases} \tag{2.25}$$

Noting that $w_5(y,s)=w_5(y)$ and expressing $q=k(y)p^{-1/\gamma}$, for an arbitrary $k(y)$, we find a subsystem

$$\underline{\mathbf{LW}_5}\{y,s,v,p,k\} = 0: \begin{cases} v_y - (k(y)p^{-1/\gamma})_s = 0, \\ v_s + p_y = 0 \end{cases} \tag{2.26}$$

nonlocally related to the given system **L** (2.10).

Remark 2: For the case of a Chaplygin gas $\gamma=-1$, the Lagrange PGD system **L** (2.10) is nonlinear as it stands, and *cannot* be linearized by a point transformation. But the equivalent system $\underline{\mathbf{LW}_5}$ for $\gamma=-1$ becomes *linear*. Thus in the Chaplygin gas case, the Lagrange PGD system **L** is *linearized by a nonlocal transformation*.

Remark 3: Excluding the variable v from (2.26), we see that the Lagrange polytropic PGD system is equivalent to

$$\underline{\underline{\mathbf{LW}_5}}\{y,s,p\} = 0: \quad p_{yy} + (k(y)p^{-1/\gamma})_{ss} = 0, \tag{2.27}$$

which is a nonlinear elliptic equation for $k(y)>0$, $\gamma>-1$, $\gamma\neq 0$, and a nonlinear hyperbolic equation for $k(y)>0$, $\gamma<-1$.

Remark 4: The solutions of (2.26) for a particular form of $k(y)$ correspond to a subset of the

solutions of the given system **L** (2.10). In particular, for $k(y)=\text{const}$, the system $\underline{\underline{\mathbf{LW}_5}}$ (2.26) can be mapped into a linear system by a hodograph transformation (e.g., Ref. 18). Thus it is possible to obtain a special class of solutions of the given nonlinear system **L** (2.10) through solving this *linear PDE system*.

III. LINEAR DEPENDENCE OF CONSERVATION LAWS AND LOCAL EQUIVALENCE OF POTENTIAL SYSTEMS

For a given PDE system, its conservation laws can be constructed systematically (through the Direct Construction Method or other method[2–4]). For each conservation law, one or several potentials are introduced, and the corresponding potential system is constructed. Next, for each such nonlocally related system, its conservation laws are computed, and from these, more potentials are introduced, which in turn lead to the construction of further potential systems, etc. Together with subsystems (obtained by a reduction of the number of dependent variables for a potential system, which includes consideration of reductions after an interchange of dependent and independent variables), this systematic procedure yields an extended tree of PDE systems nonlocally related to the given one (see Ref. 1 and Sec. II B).

In this section, we present theorems which simplify the tree construction through elimination of redundant systems.

A. Linear dependence of conservation laws and tree simplification. Two-dimensional case

Definition 1: Suppose the system of PDEs (2.5) has precisely n local conservation laws. Its *general potential system* **P** is the set of 2^n-1 potential systems arising from these n local conservation laws.

We now prove the following fundamental theorem concerned with the construction of further potential systems arising from **P**.

Theorem 1: *Each conservation law of any potential system in* **P**, *arising from multipliers that depend only on x and t, is linearly dependent on the n local conservation laws of the given system* (2.5).

Proof: Each conservation law of any system in **P**, constructed from multipliers depending only on x and t, must be of the form

$$D_x(b^i(t,x)v_i+\beta(t,x,\mathbf{u}))+D_t(a^i(t,x)v_i+\alpha(t,x,\mathbf{u}))=0, \tag{3.1}$$

for some functions $b^i(t,x),a^i(t,x),\beta(t,x,\mathbf{u}),\alpha(t,x,\mathbf{u})$.

From the compatibility conditions for multipliers of conservation laws, we immediately obtain $D_ta^i+D_xb^i=0$. Hence

$$\int a^i dx+\int b^i dt=f^i(t)+g^i(x), \tag{3.2}$$

for some functions $f^i(t)$ and $g^i(x)$.

Now consider a conservation law (3.1) on the solution manifold of the system in **P** that it was constructed from. We have

$$\begin{aligned}D_x[b^iv_i+\beta]+D_t[a^iv_i+\alpha]&=D_x\left[b^iv_i+\beta+D_t\left(\left(\int a^i dx-\int b^i dt\right)v_i\right)\right]+D_t\left[a^iv_i+\alpha\right.\\&\quad\left.-D_x\left(\left(\int a^i dx-\int b^i dt\right)v_i\right)\right]=D_x\left[\beta-(v_i)_t\int b^i dt\right]+D_t\left[\alpha\right.\\&\quad\left.-(v_i)_x\int a^i dx\right]+D_xD_t\left[\left(\int b^i dt+\int a^i dx\right)v_i\right]=D_x\left[\beta\right.\end{aligned}$$

$$-(v_i)_t\int b^i dt\Big]+D_t\Big[\alpha-(v_i)_x\int a^i dx\Big]+D_xD_t[(f_i(t)+g_i(x))v_i]$$
$$=D_x\Big[\beta-(v_i)_t\int b^i dt+g_i(x)(v_i)_t\Big]+D_t\Big[\alpha-(v_i)_x\int a^i dx+f_i(t)(v_i)_x\Big]. \tag{3.3}$$

As all derivatives of potentials v_i can be expressed in terms of local variables x, t and $\mathbf{u}$, it follows that a conservation law (3.1) is linearly dependent on local ones constructed from the given system (2.5). □

Remark 5: From Theorem 1 it follows that a conservation law of any system in **P** related to the given system (2.5), arising from multipliers that depend only on x and t, is trivial on the solution manifold of **P**.

The next theorem immediately follows from Theorem 1.

Theorem 2: *Suppose one finds the set of n local conservation laws for a given system* (2.5) *and then constructs the corresponding general potential system* **P**. *It follows that if one starts with any one of the* 2^n-1 *potential systems in* **P** *and seeks conservation laws from multipliers depending only on x and t, each of the resulting potential systems is locally equivalent to one of the* 2^n-1 *potential systems in* **P**.

B. Linear dependence of conservation laws and tree simplification. General case: $M \geq 2$ independent variables

We now consider the general case for $M \geq 2$ independent variables. Suppose the system of PDEs (2.1) has a set of n conservation laws $\{\mathcal{K}^s\}_{s=1}^n$ of the form (2.8). Each conservation law $\mathcal{K}^s$ yields a set of M potential equations $\mathcal{Q}^s$ of the form (2.9) (Sec. II B).

Definition 1: Suppose the system of PDEs (2.1) has precisely n local conservation laws of the form (2.8). Its *general potential system* **Q** is the set of 2^n-1 potential systems arising from combinations of these n local conservation laws.

The following theorems generalize Theorems 1 and 2 for the case of $M \geq 2$ independent variables.

Theorem 3: *Each conservation law of any potential system in* **Q**, *arising from multipliers that depend only on independent variables* **x**, *is linearly dependent on the n local conservation laws of the given system* (2.1).

The proof of Theorem 3 is presented in the Appendix. The following theorem holds.

Theorem 4: *Suppose one finds the set* $\{\mathcal{K}^s\}_{s=1}^n$ *of n local conservation laws for the given system* **G** (2.1), *and then constructs the corresponding general potential system* **Q**. *It follows that if one starts with any one of the potential systems in* **Q** *and seeks conservation laws from multipliers depending only on the independent variables* **x**, *each of the resulting potential systems is locally equivalent to one of the potential systems in* **Q**.

Remark 6: From Theorem 4 it follows that no new nonlocally related potential systems of a given system **G** (2.1) can arise from conservation laws constructed from known potential systems of **G** with multipliers depending only on independent variables **x**.

Remark 7: Note that for any potential system in **Q**, one can allow gauge constraints relating the potentials $\{v_{ij}(\mathbf{x})\}$. In order to find nonlocal symmetries of the given system (2.1) from point symmetries of a potential system in **Q** it is necessary to adjoin such gauge constraints.[15–17]

IV. EXTENDED TREES OF NONLOCALLY RELATED PDE SYSTEMS, NONLOCAL SYMMETRIES AND NONLOCAL CONSERVATION LAWS FOR NONLINEAR TELEGRAPH EQUATIONS

As a prototypical example, for classes of NLT equations, we use the simplified procedure introduced in Sec. III to construct trees of nonlocally related PDE systems and, as a consequence, find new nonlocal symmetries and new nonlocal conservation laws.

A. Local conservation laws for the NLT equation

We consider NLT equations of the form

$$\mathbf{U}\{x,t,u\}=0: \quad u_{tt}-(F(u)u_x)_x-(G(u))_x=0. \tag{4.1}$$

Equation (4.1) and its potential versions, including

$$\mathbf{UV}\{x,t,u,v\}=0: \quad \begin{cases} u_t-v_x=0, \\ v_t-F(u)u_x-G(u)=0, \end{cases} \tag{4.2}$$

are known to possess rich conservation law and symmetry structure for various classes of constitutive functions $F(u),G(u)$.[6–8,13] In particular, the point symmetry classification of (4.1) appears in Ref. 13; the point symmetry and local conservation law classification of (4.2) appear in Refs. 6 and 7, respectively.

Using the DCM, we now construct nontrivial linearly independent local conservation laws for the NLT equations **U** (4.1). First we note that Eq. (4.1) admits the group of equivalence transformations

$$x=a_1\tilde{x}+a_4, \quad t=a_2\tilde{t}+a_5, \quad u=a_3\tilde{u}+a_6,$$

$$F(u)=a_1^2a_2^{-2}\tilde{F}(\tilde{u}), \quad G(u)=a_1a_2^{-2}a_3\tilde{G}(\tilde{u})+a_7, \tag{4.3}$$

where $a_1,\ldots,a_7$ are arbitrary constants, $a_1a_2a_3\neq 0$. We classify the local conservation laws and point symmetries of (4.1) modulo the equivalence transformations (4.3). A multiplier of the form $A(x,t,U)$ yields a local conservation law

$$D_x(X(x,t,u,u_x,u_t))+D_t(T(x,t,u,u_x,u_t))=0$$

of (4.1) if and only if the equation

$$E_U(\Lambda(x,t,U)(U_{tt}-(F(U)U_x)_x-(G(U))_x))=0 \tag{4.4}$$

holds for an arbitrary function $U(x,t)$.

Solving determining equation (4.4), one obtains an overdetermined system of linear PDEs in terms of the unknown multiplier $\Lambda(x,t,U)$. It is easy to show that $\Lambda=\Lambda(x,t)$. Three cases are distinguished. For arbitrary functions $F(u)$ and $G(u)$, one has two conservation laws (V_1) and (V_2); for the case $G'=F$, there are two additional conservation laws (B_1) and (B_2); for the case $G=u$, there are also two additional conservation laws (C_1) and (C_2). The classification is presented in Table II. [Note that the case where G is linear in u and $F=$const is the linear case and hence is not considered. The case $G=$const (with arbitrary F) is linearizable and hence also is not considered.]

The local conservation laws (V_2), (B_3), (B_4), (C_3), and (C_4) have not previously appeared in the literature.

The following potential systems result from the conservation laws listed in Table II.

Case (a): Arbitrary $F(u),G(u)$.

$$\mathbf{UV}_1\{x,t,u,v_1\}=0:\begin{cases} v_{1x}-u_t=0, \\ v_{1t}-F(u)u_x-G(u)=0; \end{cases} \tag{4.5}$$

$$\mathbf{UV}_2\{x,t,u,v_2\}=0:\begin{cases} v_{2x}-(tu_t-u)=0, \\ v_{2t}-t(F(u)u_x+G(u))=0. \end{cases} \tag{4.6}$$

Case (b): $G'(u)=F(u),F(u)$ arbitrary. In addition to potential systems (4.5) and (4.6), here we also have

TABLE II. Local conservation laws of (4.1).

$F(u)$	$G(u)$	CL	Multipliers	T	$-X$
Arbitrary	Arbitrary	(V_1)	$\Lambda=1$	u_t	$F(u)u_x+G(u)$
		(V_2)	$\Lambda=t$	tu_t-u	$t(F(u)u_x+G(u))$
Arbitrary	$G'(u)=F(u)$	(B_3)	$\Lambda=e^x$	e^xu_t	$e^xF(u)u_x$
		(B_4)	$\Lambda=te^x$	$e^x(tu_t-u)$	$te^xF(u)u_x$
Arbitrary $(F(u)\neq\text{const})$	u	(C_3)	$\Lambda=x-\frac{t^2}{2}$	$\left(x-\frac{t^2}{2}\right)u_t+ut$	$\left(x-\frac{t^2}{2}\right)(F(u)u_x+u)-\int F(u)du$
		(C_4)	$\Lambda=xt-\frac{t^3}{6}$	$\left(tx-\frac{t^3}{6}\right)u_t-\left(x-\frac{t^2}{2}\right)u$	$\left(tx-\frac{t^3}{6}\right)(F(u)u_x+u)-t\int F(u)du$

$$\mathbf{UB}_3\{x,t,u,b_3\}=0:\begin{cases}b_{3x}-e^xu_t=0,\\ b_{3t}-e^xF(u)u_x=0;\end{cases} \tag{4.7}$$

$$\mathbf{UB}_4\{x,t,u,b_4\}=0:\begin{cases}b_{4x}-e^x(tu_t-u)=0,\\ b_{4t}-te^xF(u)u_x=0.\end{cases} \tag{4.8}$$

Case (c): $G(u)=u, F(u)$ arbitrary. In addition to potential systems (4.5) and (4.6), here we also have

$$\mathbf{UC}_3\{x,t,u,c_3\}=0:\begin{cases}c_{3x}-\left(\left(x-\frac{t^2}{2}\right)u_t+tu\right)=0,\\ c_{3t}-\left(\left(x-\frac{t^2}{2}\right)(F(u)u_x+u)-\int F(u)du\right)=0;\end{cases} \tag{4.9}$$

$$\mathbf{UC}_4\{x,t,u,c_4\}=0:\begin{cases}c_{4x}-\left(\left(tx-\frac{t^3}{6}\right)u_t-\left(x-\frac{t^2}{2}\right)u\right)=0,\\ c_{4t}-\left(\left(tx-\frac{t^3}{6}\right)(F(u)u_x+u)-t\int F(u)du\right)=0.\end{cases} \tag{4.10}$$

We now apply Theorem 2 to find inequivalent nonlocally related potential systems for the NLT equation (4.1). The following statements hold.

Corollary 1: *In terms of multipliers depending only on x and t, the set of locally inequivalent potential systems for the NLT equation (4.1) with general nonlinearities $F(u)$ and $G(u)$ is exhausted by the following PDE systems*:

- *Two potential systems* (4.5) and (4.6), *involving single potentials*;
- *One couplet* {(4.5), (4.6)}.

Corollary 2: *In terms of multipliers depending only on x and t, the set of locally inequivalent potential systems for Eq. (4.1) with $G'(u)=F(u)$ is exhausted by the following systems*:

- *Four potential systems* (4.5)–(4.8) *involving single potentials*;
- *Six couplets* {(4.5), (4.6)}, {(4.5), (4.7)}, {(4.5), (4.8)}, {(4.6), (4.7)}, {(4.6), (4.8)}, and {(4.7), (4.8)} *involving pairs of potentials*;
- *Four triplets* {(4.5), (4.6), (4.7)}, {(4.5), (4.6), (4.8)}, {(4.5), (4.7), (4.8)}, and {(4.6), (4.7),

TABLE III. Symmetries of the NLT equation (4.1) and its potential systems (4.5), (4.6), (4.11) for the general case (a): $F(u)=u^{\alpha}$, $G(u)=u^{\beta}(\alpha,\beta,\neq 0)$.

System	Symmetries
$\mathbf{UV_1V_2}$, $\mathbf{UV_1}$, $\mathbf{UV_2}$, $\mathbf{U}$	$X_1=(\alpha-\beta+1)x\frac{\partial}{\partial x}+\left(\frac{\alpha}{2}-\beta+1\right)t\frac{\partial}{\partial t}+u\frac{\partial}{\partial u}$ $+\frac{\alpha+2}{2}v_1\frac{\partial}{\partial v_1}+(\alpha-\beta+2)v_2\frac{\partial}{\partial v_2}$, $X_2=\frac{\partial}{\partial x}$, $X_3=\frac{\partial}{\partial t}+v_1\frac{\partial}{\partial v_2}$, $X_4=\frac{\partial}{\partial v_1}$, $X_5=\frac{\partial}{\partial v_2}$.

(4.8)} *for combinations involving three potentials*;
- *One quadruplet* {(4.5), (4.6), (4.7), (4.8)} *involving all four potentials*.

Corollary 3: *In terms of multipliers depending only on x and t, the set of locally inequivalent potential systems for Eq.* (4.1) *with arbitrary* $F(u)$ *and* $G(u)=u$ *is exhausted by the following systems*:

- *Four potential systems* (4.5), (4.6), (4.9), and (4.10) *involving single potentials*;
- *Six couplets* {(4.5), (4.6)}, {(4.5), (4.9)}, {(4.5), (4.10)}, {(4.6), (4.9)}, {(4.6), (4.10)}, *and* {(4.9), (4.10)} *involving pairs of potentials*;
- *Four triplets* {(4.5), (4.6), (4.9)}, {(4.5), (4.6), (4.10)}, {(4.5), (4.9), (4.10)}, *and* {(4.6), (4.9), (4.10)} *for combinations involving three potentials*;
- *One quadruplet* {(4.5), (4.6), (4.9), (4.10)} *involving all four potentials*.

B. Point and nonlocal symmetry analysis of NLT equations with power nonlinearities

We now apply the results of Sec. III to seek point and nonlocal symmetries of the NLT equation (4.1) with power nonlinearities $F(u)=u^{\alpha}, G(u)=u^{\beta}(\alpha,\beta\neq 0)$ by considering its locally inequivalent potential systems.

Case (a): Arbitrary power nonlinearities $F(u), G(u)$. We first consider general power nonlinearities: $F(u)=u^{\alpha}$, $G(u)=u^{\beta}$ ($\alpha,\beta\neq 0$ arbitrary constants.) In this case, the given system (4.1) has two conservation laws (V_1) and (V_2) exhibited in Table II. From Corollary 1, the set of inequivalent nonlocally related potential systems of the PDE **U** (4.1) is exhausted by the systems $\mathbf{UV_1}$ (4.5), $\mathbf{UV_2}$ (4.6), and the couplet $\mathbf{UV_1V_2}$:

$$\mathbf{UV_1V_2}\{x,t,u,v_1,v_2\}=0:\begin{cases} v_{1x}-u_t=0,\\ v_{1t}-F(u)u_x-G(u)=0,\\ v_{2x}-(tu_t-u)=0,\\ v_{2t}-t(F(u)u_x+G(u))=0. \end{cases} \tag{4.11}$$

Symmetry generators of the given NLT equation (4.1), its potential systems (4.5) and (4.6) and the couplet (4.11) are given in Table III.

From the form of the symmetries in Table III it follows that no nonlocal symmetries arise for systems **U** and $\mathbf{UV_1}$. The generator X_3 is a nonlocal symmetry for the system $\mathbf{UV_2}$ (i.e., the system $\mathbf{UV_2}$ is not invariant under translations in t) and a point symmetry for the other systems. All other generators define point symmetries for all systems in Table III.

Case (b): $G'(u)=F(u)$. We now consider power nonlinearities $F(u)=(\alpha+1)u^{\alpha}$, $G(u)=u^{\alpha+1}$, $\alpha\neq 0,-1$. From the equivalence relation (4.3), this case is equivalent to $F(u)=u^{\alpha}$, $G(u)=u^{\alpha+1}$.

TABLE IV. Symmetries of the potential NLT systems for case for case (b): $F(u)=(\alpha+1)u^{\alpha}$, $G(u)=u^{\alpha+1}(\alpha\neq 0,-1)$.

System	$F(u)$	$G(u)$	Symmetries
$\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_3\mathbf{B}_4$, $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_3$, $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_4$, $\mathbf{UV}_1\mathbf{B}_3\mathbf{B}_4$, $\mathbf{UV}_2\mathbf{B}_3\mathbf{B}_4$, $\mathbf{UV}_1\mathbf{V}_2, \mathbf{UV}_1\mathbf{B}_3$, $\mathbf{UV}_1\mathbf{B}_4, \mathbf{UV}_2\mathbf{B}_3$, $\mathbf{UV}_2\mathbf{B}_4, \mathbf{UB}_3\mathbf{B}_4$, $\mathbf{UV}_1, \mathbf{UV}_2$, $\mathbf{UB}_3, \mathbf{UB}_4$, $\mathbf{U}$	$(\alpha+1)u^{\alpha}$	$u^{\alpha+1}$	$Y_1=-\frac{\alpha}{2}t\frac{\partial}{\partial t}+u\frac{\partial}{\partial u}+v_2\frac{\partial}{\partial v_2}+\frac{\alpha+2}{2}v_1\frac{\partial}{\partial v_1}+\frac{\alpha+2}{2}b_3\frac{\partial}{\partial b_3}+b_4\frac{\partial}{\partial b_4}$, $Y_2=\frac{\partial}{\partial x}+b_3\frac{\partial}{\partial b_3}+b_4\frac{\partial}{\partial b_4}$, $Y_3=\frac{\partial}{\partial t}+b_3\frac{\partial}{\partial b_4}+v_1\frac{\partial}{\partial v_2}$, $Y_4=\frac{\partial}{\partial v_1}$, $Y_5=\frac{\partial}{\partial v_2}$, $Y_6=\frac{\partial}{\partial b_3}$, $Y_7=\frac{\partial}{\partial b_4}$
	$-3u^{-4}$	u^{-3}	$Y_8=t^2\frac{\partial}{\partial t}+tu\frac{\partial}{\partial u}-v_2\frac{\partial}{\partial v_1}-b_4\frac{\partial}{\partial b_3}$
$\mathbf{UV}_1\mathbf{V}_2$	$3u^2$	u^3	$Y_9=3v_1\frac{\partial}{\partial x}+(tv_1-v_2+3u)\frac{\partial}{\partial t}-uv_1\frac{\partial}{\partial u}-v_1^2\frac{\partial}{\partial v_1}-v_1v_2\frac{\partial}{\partial v_2}$

From Corollary 2, the set of inequivalent nonlocally related potential systems of the PDE **U** (4.1) is exhausted by the potential systems $\mathbf{UV}_1$ (4.5), $\mathbf{UV}_2$ (4.6), $\mathbf{UB}_3$ (4.7), $\mathbf{UB}_4$ (4.8), their six couplets, four triplets and one quadruplet. The corresponding classification of symmetry generators is presented in Table IV.

A point symmetry of any of these potential systems, where the symmetry generator components for u, x or t have an essential dependence on at least one of the potentials v_1, v_2, b_3, b_4, is a *nonlocal* (potential) symmetry of the given NLT equation (4.1).

The case $\alpha=-2$ is not considered in Table IV as here the system $\mathbf{UV}_1$ is linearizable by a point transformation.[18,19]

The point symmetries of PDE **U** (4.1) and system $\mathbf{UV}_1$ (4.5) were completely classified in Refs. 13 and 6, respectively. In Ref. 6, many new nonlocal symmetries of **U** (4.1) for other than power nonlinearities were found from the point symmetries of corresponding $\mathbf{UV}_1$ systems.

Most importantly, from Table IV, we see that for the case when $F(u)=3u^2, G(u)=u^3$, through the potential system $\mathbf{UV}_1\mathbf{V}_2$, we have discovered a new nonlocal symmetry Y_9 for the scalar PDE **U**.

Note that Y_3 is a nonlocal symmetry for the systems $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_4$, $\mathbf{UV}_2\mathbf{B}_3\mathbf{B}_4$, $\mathbf{UV}_1\mathbf{B}_4$, $\mathbf{UV}_2\mathbf{B}_3$, $\mathbf{UV}_2\mathbf{B}_4$, $\mathbf{UV}_2$, and $\mathbf{UB}_4$, and a point symmetry for the other nine systems; Y_8 is a nonlocal symmetry for the systems $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_3$, $\mathbf{UV}_1\mathbf{B}_3\mathbf{B}_4$, $\mathbf{UV}_1\mathbf{B}_3$, $\mathbf{UV}_1\mathbf{B}_4$, $\mathbf{UV}_2\mathbf{B}_3$, $\mathbf{UV}_1$, $\mathbf{UB}_3$ and a point symmetry for the other nine systems; Y_9 is a point symmetry for $\mathbf{UV}_1\mathbf{V}_2$ and a nonlocal symmetry for the other listed 15 inequivalent systems, which include $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_3$, $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_4$, and $\mathbf{UV}_1\mathbf{V}_2\mathbf{B}_3\mathbf{B}_4$!

Case (c): $F(u)=u^{\alpha}, G(u)=u$. In this case, similarly to case (b), the set of independent nonlocally related potential systems of (4.1) is exhausted by the potential systems $\mathbf{UV}_1$ (4.5), $\mathbf{UV}_2$ (4.6), $\mathbf{UC}_3$ (4.9), $\mathbf{UC}_4$ (4.10), their six couplets, four triplets and one quadruplet. The corresponding classification of symmetry generators is found in Table V. The linear cases $\alpha=0,1$ are not considered.

As the simplification of overdetermined systems of linear determining equations in classification problems involving triplets $\mathbf{UV}_1\mathbf{C}_3\mathbf{C}_4$, $\mathbf{UV}_2\mathbf{C}_3\mathbf{C}_4$ and couplets $\mathbf{UV}_1\mathbf{C}_4$, $\mathbf{UC}_3\mathbf{C}_4$ presented a computational difficulty, the corresponding entries in Table V are not known.

From the form of the symmetries in Table V, it follows that no nonlocal symmetries arise for systems **U** and $\mathbf{UV}_1$; Z_2 is a nonlocal symmetry for the systems $\mathbf{UV}_2\mathbf{C}_3$, $\mathbf{UC}_3$, and $\mathbf{UC}_4$ and a point symmetry for the other listed systems; Z_3 is a nonlocal symmetry for the systems $\mathbf{UV}_1\mathbf{V}_2\mathbf{C}_4$, $\mathbf{UV}_1\mathbf{C}_3$, $\mathbf{UV}_2\mathbf{C}_3$, $\mathbf{UV}_2\mathbf{C}_4$, $\mathbf{UV}_2$, $\mathbf{UC}_3$, and $\mathbf{UC}_4$ and a point symmetry for the other listed systems. All other generators define point symmetries for the systems listed in Table V.

TABLE V. Symmetries of the potential NLT systems for case (c): $F(u)=u^{\alpha}, G(u)=u(\alpha\neq 0,1)$.

System	Case	Symmetries
$\mathbf{UV}_1\mathbf{V}_2\mathbf{C}_3\mathbf{C}_4$, $\mathbf{UV}_1\mathbf{V}_2\mathbf{C}_3$, $\mathbf{UV}_1\mathbf{V}_2\mathbf{C}_4$ $\mathbf{UV}_1\mathbf{V}_2$, $\mathbf{UV}_1\mathbf{C}_3$, $\mathbf{UV}_2\mathbf{C}_3$, $\mathbf{UV}_2\mathbf{C}_4$, $\mathbf{UV}_1, \mathbf{UV}_2$, $\mathbf{UC}_3, \mathbf{UC}_4$ $\mathbf{U}$,	$\alpha\neq -1$	$Z_1=\frac{\alpha}{2}t\frac{\partial}{\partial t}+\alpha x\frac{\partial}{\partial x}+u\frac{\partial}{\partial u}+\frac{\alpha+2}{2}v_1\frac{\partial}{\partial v_1}+v_2(a+1)\frac{\partial}{\partial v_2}+\frac{3\alpha+2}{2}c_3\frac{\partial}{\partial c_3}+(2\alpha+1)c_4\frac{\partial}{\partial c_4}$, $Z_2=\frac{\partial}{\partial x}+v_1\frac{\partial}{\partial c_3}+v_2\frac{\partial}{\partial c_4}$, $Z_3=\frac{\partial}{\partial t}+v_1\frac{\partial}{\partial v_2}-v_2\frac{\partial}{\partial c_3}+c_3\frac{\partial}{\partial c_4}$, $Z_4=\frac{\partial}{\partial v_1}$, $Z_5=\frac{\partial}{\partial v_2}$, $Z_6=\frac{\partial}{\partial c_3}$, $Z_7=\frac{\partial}{\partial c_4}$.
	$\alpha=-1$	$Z_8=-\frac{1}{2}t\frac{\partial}{\partial t}-x\frac{\partial}{\partial x}+u\frac{\partial}{\partial u}+\frac{1}{2}v_1\frac{\partial}{\partial v_1}-\left(t+\frac{1}{2}c_3\right)\frac{\partial}{\partial c_3}-\left(\frac{t^2}{2}+c_4\right)\frac{\partial}{\partial c_4}$ $Z_2, Z_3, Z_4, Z_5, Z_6, Z_7$.
$\mathbf{UV}_1\mathbf{C}_3\mathbf{C}_4, \mathbf{UV}_2\mathbf{C}_3\mathbf{C}_4$ $\mathbf{UV}_1\mathbf{C}_4, \mathbf{UC}_3\mathbf{C}_4$		?

C. New nonlocal conservation laws for NLT equations with power nonlinearities

In this section, new nonlocal conservation laws are constructed for NLT equations (4.1) with power nonlinearities. We use the DCM for all singlet potential systems of the NLT equation (4.1) in each of cases (a), (b), and (c), allowing multipliers to have an essential dependence on dependent variables. We obtain new conservation laws for particular classes of constitutive functions. The classification is presented in the following.

For power nonlinearities $F(u)=u^{\alpha}$, $G(u)=u^{\beta}$, the set of nonlocal conservation laws is given in Table VI.

The computations were done for all systems: $\mathbf{UV}_1$, $\mathbf{UV}_2$, $\mathbf{UB}_3$, $\mathbf{UB}_4$, $\mathbf{UC}_3$, and $\mathbf{UC}_4$. No nonlocal conservation laws were found for the $\mathbf{UC}_4$ system.

The nonlocal conservation laws for PDE **U** (4.1) arising from analysis of the system $\mathbf{UV}_1$ were first found in Ref. 6. All other nonlocal conservation laws for PDE **U** (4.1) found in Table VI are new.

The case (b) with $\alpha=-2$ is not considered in Table VI as here the system $\mathbf{UV}_1$ is linearizable by a point transformation.[18,19]

V. NONLOCAL SYMMETRY CLASSIFICATION FOR GENERALIZED POLYTROPIC GAS FLOWS

We now consider the Lagrange PGD system **L** (2.10) with a generalized polytropic equation of state

$$B(p,q)=\frac{M(p)}{q},\quad M''(p)\neq 0. \tag{5.1}$$

To construct a corresponding tree of nonlocally related potential systems, first we search for local conservation laws with multipliers of the form

$$\Lambda_i=\Lambda_i(y,s),\quad i=1,2,3.$$

The classification with respect to the constitutive function $M(p)$ reveals no special case and thus the conservation laws listed in Table I are exhaustive. According to Theorem 2, from these conservation laws we obtain the following inequivalent potential systems for the generalized polytropic Lagrange PGD system **L** (2.10):

- Three potential systems (2.12)–(2.14) involving single potentials;
- Three couplets (2.15)–(2.17) involving pairs of potentials;

TABLE VI. Nonlocal conservation laws of (4.1).

Case	System	Subcase	Multipliers	Fluxes
(a)	$\mathbf{UV}_1$	$\beta=-1$	$\Lambda_1=x+\frac{v_1^2}{2}+\frac{u^{\alpha+2}}{\alpha+2}, \Lambda_2=uv_1$	$X=-\left(\frac{u^{\alpha+2}}{\alpha+2}+\frac{v_1^2}{6}+x\right)v_1,$ $T=\left(\frac{u^{\alpha+2}}{(\alpha+2)(\alpha+3)}+\frac{v_1^2}{2}+x\right)u.$
$F(u)=u^\alpha$			$\Lambda_1=v_1, \Lambda_2=u.$	$X=-\frac{u^{\alpha+2}}{\alpha+2}-\frac{v_1^2}{2},$ $T=uv_1-t.$

	(iii) $\gamma p+\delta p^{(\gamma+1)/\gamma}$ $\gamma\neq 0,-1$	$Z_{14}=y^2\frac{\partial}{\partial y}+yp\frac{\partial}{\partial p}-\left(3-\frac{\delta}{\gamma}\frac{p^{1/\gamma}}{\delta p^{1/\gamma+\gamma}}\right)yq\frac{\partial}{\partial q}-(yu-w_2)\frac{\partial}{\partial v}+yw_2\frac{\partial}{\partial w_2}$.

A. Classification of point and nonlocal symmetries

The classification of point symmetries of the seven potential systems (2.12)–(2.18) [modulo the equivalence transformations (2.11)] yields Table VII of point symmetries and nonlocal symmetries for the Lagrange PGD system (2.10) with the equation of state (5.1).

From Table VII, we observe that Z_{13},Z_{14} are point symmetries for the system **LW**$_2$ and nonlocal symmetries for all other systems, including the given system **L**; $Z_9,\ldots,Z_{12}$ are point symmetries for systems **L** and **LW**$_2$ and nonlocal symmetries for all other systems.

Most importantly, we have shown that for cases (ii) and (iii), when $M(p)=-p\ln p$ and $M(p)=\gamma p+\delta p^{(\gamma+1)/\gamma}$, respectively, through the potential system **LW**$_2$ we have discovered *new nonlocal symmetries* Z_{13} and Z_{14} for the generalized polytropic Lagrange PGD system **L** (2.10), (5.1). Note that all other generators in Table VII project onto point symmetries of the Lagrange PGD system **L** (2.10) and thus were found from point symmetry analysis of **L** in Ref. 9.

Note that the newly discovered nonlocal symmetries Z_{13} and Z_{14} of the Lagrange system **L** (2.10), (5.1) with $M(p)=-p\ln p$ and $M(p)=\gamma p+\delta p^{(\gamma+1)/\gamma}$ project onto point symmetries of the corresponding Lagrange subsystem $\underline{\mathbf{L}}$ (2.19). In other words, the point symmetries $\underline{Z}_{13}=y^2(\partial/\partial y)+py(\partial/\partial p)-(3-(1/\ln p))yq(\partial/\partial q)$, $\underline{Z}_{14}=y^2(\partial/\partial y)+yp(\partial/\partial p)-(3-(\delta/\gamma)[p^{1/\gamma}/(\delta p^{1/\gamma}+\gamma)])yq(\partial/\partial q)$ of $\underline{\mathbf{L}}$ yield nonlocal symmetries of $\underline{\mathbf{L}}$.[1] It can be shown that symmetries Z_{13} and Z_{14} also yield nonlocal symmetries of the corresponding system written in terms of Eulerian coordinates.[1] The classification of point symmetries of $\underline{\mathbf{L}}$ (2.19) yields Table VIII with respect to the equation of state given by (5.1).

From Table VIII we observe that point symmetries of the Lagrange subsystem $\underline{\mathbf{L}}$ (2.19) include all corresponding point symmetries of **LW**$_2$, and additionally for $M(p)=3p+\delta p^{4/3}$ one *new symmetry* $\underline{Z}_{15}$ is obtained. The new symmetry $\underline{Z}_{15}$ is a nonlocal symmetry of the Lagrange system **L** (2.10) and all its potential systems (2.12)–(2.18).

TABLE VIII. Point symmetries of the subsystem $\underline{\mathbf{L}}$ (2.19) of the generalized polytropic PGD system (2.10), (5.1).

$M(p)$	Symmetries
(i) Arbitrary	$\underline{Z_1}=\frac{\partial}{\partial s}$, $\underline{Z_2}=\frac{\partial}{\partial y}$, $\underline{Z_4}=-y\frac{\partial}{\partial y}+2q\frac{\partial}{\partial q}$, $\underline{Z_5}=s\frac{\partial}{\partial s}+y\frac{\partial}{\partial y}$.
(ii) $-p\ln p$	$\underline{Z_9}=y\frac{\partial}{\partial y}+2p\frac{\partial}{\partial p}+\frac{2q}{\ln p}\frac{\partial}{\partial q}$, $\underline{Z_{13}}=y^2\frac{\partial}{\partial y}+yp\frac{\partial}{\partial p}-\left(3-\frac{1}{\ln p}\right)yq\frac{\partial}{\partial q}$.
(iii) $\gamma p+\delta p^{(\gamma+1)/\gamma}$	$\underline{Z_{10}}=\frac{(\gamma+1)y}{2\gamma}\frac{\partial}{\partial y}+p\frac{\partial}{\partial p}-\frac{q}{\delta p^{1/\gamma+\gamma}}\frac{\partial}{\partial q}$, $\underline{Z_{14}}=y^2\frac{\partial}{\partial y}+yp\frac{\partial}{\partial p}-\left(3-\frac{\alpha}{\gamma}\frac{p^{1/\gamma}}{\delta p^{1/\gamma+\gamma}}\right)yq\frac{\partial}{\partial q}$.
$\gamma=3$	$\underline{Z_{15}}=\frac{1}{3}s^2\frac{\partial}{\partial s}-sp\frac{\partial}{\partial p}+\frac{1}{\delta p^{4/3+3}}spq\frac{\partial}{\partial q}$.
(iv) $1+\alpha e^p$	$\underline{Z_{11}}=\frac{\partial}{\partial p}+\frac{\alpha e^p}{1+\alpha e^p}q\frac{\partial}{\partial q}$, $\underline{Z_{12}}=y\frac{\partial}{\partial p}+\frac{\alpha e^p}{1+\alpha e^p}yq\frac{\partial}{\partial q}$.

B. Nonlocally related systems and invariant solutions

1. Construction of invariant solutions for generalized polytropic PGD equations

For any given form of the constitutive function $M(p)$, different combinations of corresponding point and nonlocal symmetry generators can be used to construct families of invariant solutions of the Lagrange system **L** (2.10). As an example, we consider the case $M(p)=-p\ln p$.

The potential system $\mathbf{LW}_2$ has the largest algebra of symmetry generators. Thus it has the largest set of invariant solutions. The algebra $\mathcal{A}$ of symmetry generators for the constitutive function of interest is spanned by projections of the eight operators $Z_1,\ldots,Z_5,Z_7,Z_9,Z_{13}$ on the space of variables $\{y,s,v,p,q,w_2\}$ of $\mathbf{LW}_2$:

$$\mathcal{A}=\mathrm{Span}\{Z_1,Z_2,Z_3,Z_4,Z_5,Z_7,Z_9,Z_{13}\}. \tag{5.2}$$

The simplest way to find all solutions of $\mathbf{LW}_2$ invariant with respect to elements of $\mathcal{A}$ consists of two steps[20]:

1. Finding optimal systems of one-dimensional invariant subalgebras $\mathcal{A}_i\subset\mathcal{A}$ and constructing solutions invariant with respect to each subalgebra $\mathcal{A}_i$;
2. Using the transformation groups corresponding to symmetry generators in $\mathcal{A}$ to extend the set of solutions.

The solutions of the Lagrange system **L** (2.10) are obtained from solutions of the potential system $\mathbf{LW}_2$ by excluding the potential variable w_2.

Following the above procedure, we first find the optimal system of one-dimensional subalgebras of $\mathcal{A}$ (5.2) (see Ref. 20.) This optimal system consists of the invariant subalgebras given by

$$\mathcal{A}_1=Z_2+\varepsilon_1Z_3,$$

$$\mathcal{A}_2=Z_2+\varepsilon_1Z_1+\varepsilon_2Z_3,$$

$$\mathcal{A}_3=Z_4+\varepsilon_1Z_1+\varepsilon_2Z_7,$$

$$\mathcal{A}_4=Z_4+\varepsilon_1Z_1+\varepsilon_2Z_2+\varepsilon_3Z_3,$$

$$\mathcal{A}_5 = Z_4 + \varepsilon_1 Z_1 + \alpha Z_9,$$

$$\mathcal{A}_6 = Z_5 + \alpha Z_4,$$

$$\mathcal{A}_7 = Z_5 + \varepsilon_1 Z_3,$$

$$\mathcal{A}_8 = Z_{13} + \varepsilon_1 Z_1 + \varepsilon_2 Z_2 + \varepsilon_3 Z_7 + \alpha Z_9. \tag{5.3}$$

Here $\varepsilon_i = 0, \pm 1$, $\alpha \in \mathbb{R}$.

The set of all resulting invariant solutions of the potential system $\mathbf{LW}_2$ [and, consequently, corresponding solutions of the Lagrange system $\mathbf{L}$ (2.10)] is obtained from solutions invariant with respect to each of the subalgebras $\mathcal{A}_1, \ldots, \mathcal{A}_8$ by means of the group transformations corresponding to the operators $Z_1, \ldots, Z_9, Z_{13}$. These group transformations are as follows:

$$\begin{aligned}
&Z_1: \quad y' = y, \quad s' = s + \epsilon_1, \quad v' = v, \quad p' = p, \quad q' = q, \quad w_2 = w_2;\\
&Z_2: \quad y' = y + \epsilon_2, \quad s' = s, \quad v' = v, \quad p' = p, \quad q' = q, \quad w_2 = w_2;\\
&Z_3: \quad y' = y, \quad s' = s, \quad v' = v + \epsilon_3, \quad p' = p, \quad q' = q, \quad w_2' = w_2 + \epsilon_3 y;\\
&Z_4: \quad y' = e^{-\epsilon_4} y, \quad s' = s, \quad v' = v, \quad p' = p, \quad q' = a^{2\epsilon_4} q, \quad v' = w_2 + \epsilon_4 y;\\
&Z_5: \quad y' = e^{\epsilon_5} y, \quad s' = e^{\epsilon_5} s, \quad v' = v, \quad p' = p, \quad q' = q, \quad w_2' = e^{\epsilon_5} w_2,\\
&Z_7: \quad y' = y, \quad s' = s, \quad v' = v, \quad p' = p, \quad q' = q, \quad w_2' = w_2 + \epsilon_7;\\
&Z_9: \quad y' = e^{\epsilon_9} y, \quad s' = s, \quad v' = e^{\epsilon_9} v, \quad p' = e^{2\epsilon_9} p, \quad q' = (1 + 2\epsilon_9/\ln p) q, \quad w_2' = e^{2\epsilon_9} w_2;\\
&Z_{13}: \quad y' = \frac{y}{1 - \epsilon_{13} y}, \quad s' = s, \quad v' = v + \epsilon_{13}(w_2 - yv),\\
&\qquad p' = \frac{p}{1 - \epsilon_{13} y}, \quad q' = \frac{1 - \epsilon_{13} y}{\ln p} q \ln \frac{p}{1 - \epsilon_{13} y}, \quad w_2' = \frac{w_2}{1 - \epsilon_{13} y}.
\end{aligned} \tag{5.4}$$

Particular solutions of the Lagrange system $\mathbf{L}$ (2.10) are obtained as solutions invariant with respect to any linear combination of generators $Z_1, \ldots, Z_5, Z_7, Z_9, Z_{13}$, possibly transformed further by using one or more Lie groups (5.4).

2. An invariant solution from a nonlocal symmetry

For the case $M(p) = -p \ln p$, we construct a solution of the Lagrange system $\mathbf{L}$ (2.10) arising from a solution of the potential system $\mathbf{LW}_2$ (2.13) invariant with respect to the subalgebra $\mathcal{A}_8$ (5.3) with $\varepsilon_1 = \varepsilon_2 = \varepsilon_3 = 0, \alpha = 1$, i.e., from operator

$$X = Z_{13} + \alpha Z_9 = (y^2 + y)\frac{\partial}{\partial y} + (y + 2)p\frac{\partial}{\partial p} - \left(3y - \frac{y - 2}{\ln p}\right) q \frac{\partial}{\partial q} - (yv - v - w_2)\frac{\partial}{\partial v} + (y + 2) w_2 \frac{\partial}{\partial w_2}.$$

One can show that this solution of $\mathbf{L}$ (2.10) does not arise as an invariant solution of an admitted point symmetry of $\mathbf{L}$. In particular, this solution has the form

$$p(y,s) = \frac{\gamma\beta^2}{\alpha^2} \frac{y^2}{y + \alpha} (1 - \tanh^2(\beta s)),$$

$$q(y,s) = -\frac{\gamma}{(y + \alpha)^3} \ln \left[\frac{\gamma\beta^2}{\alpha^2} \frac{y^2}{y + \alpha} (1 - \tanh^2(\beta s)) \right],$$

$$v(y,s) = -\frac{\gamma\beta}{\alpha^2}\frac{y(y+2\alpha)}{(y+\alpha)^2}\tanh(\beta s), \tag{5.5}$$

where α, β, and γ are arbitrary constants.

For $\alpha=1$, $\beta=1$, $\gamma=-2$, after the application of the equivalence transformation (2.11) with $a_1=a_3=1$, $a_2=a_4=a_6=0$, $a_5=-1$, $a_7=p_0$, $a_8=q_0$, this yields the solution

$$p = \tilde{p}(y,s) = p_0 - \frac{2y^2}{y+1}\frac{1}{\cosh^2 s},$$

$$q = \tilde{q}(y,s) = q_0 - \frac{2}{(y+1)^3}\ln\left[\frac{2y^2}{y+1}\frac{1}{\cosh^2 s}\right],$$

$$v = \tilde{v}(y,s) = 2\frac{y(y+2)}{(y+1)^2}\tanh s \tag{5.6}$$

of the Lagrange system **L** (2.10) for the constitutive function

$$B(p,q) = -\frac{(p_0-\tilde{p})\ln(p_0-\tilde{p})}{q_0-q}.$$

For $p_0=9, q_0=1$, the pressure $p=\tilde{p}(y,s)$, density $p=1/\tilde{q}(y,s)$ and velocity $v=\tilde{v}(y,s)$ profiles at times $s=0.1, 0.8, 1.3$ are shown in Figure 1 with thin, medium and thick lines, respectively. The solution is regular, bounded and satisfies physical conditions $p>0, \rho>0$ for all times $s\geq 0$ for the material space interval $0\leq y\leq 5$.

VI. CONCLUDING REMARKS

In this article, we extended the procedure presented in Ref. 1 to construct a tree of nonlocally related systems for a given PDE system **G** (2.1). In summary, the extended procedure is as follows.

1. **Construction of conservation laws**. Using the DCM (Sec. II A) or other method, construct local conservation laws of the given system **G**. Note that some conservation laws can be present in the given system as it stands.
2. **Construction of potential systems**. For each of the n known conservation laws $\{\mathcal{K}^s\}_{s=1}^n$ of the given system **G**, introduce potential(s) and construct a potential system $G^s_{\mathbf{P}}(s=1,\ldots,n)$. Let $\mathcal{T}_1$ denote the set of systems that consists of the given system **G**, potential systems $\mathbf{G}^s_{\mathbf{P}}$ and all possible couplets, triplets,…, n-plets of the potential systems $\mathbf{G}^s_{\mathbf{P}}$. The tree $\mathcal{T}_1$ includes a total of 2^n inequivalent systems.
3. **Construction of subsystems**. For each system in the tree $\mathcal{T}_1$, exclude where possible, one by one, dependent variables (including exclusions following interchanges of independent and dependent variables, i.e., where an independent variable becomes a dependent variable and vice versa through a point transformation), to generate all subsystems of the systems in the tree $\mathcal{T}_1$. Eliminate subsystems that are locally related to existing systems. This yields a possibly larger tree $\mathcal{T}_2$.
4. **Continuation**. In the tree $\mathcal{T}_2$, first distinguish the systems that arise from multipliers depending only on independent variables. For each such system, use the DCM or other method to construct the conservation laws for multipliers with an essential dependence on dependent variables. Construct all combinations of further potential systems arising from these conservation laws (i.e., couplets, triplets, etc.). For the other systems in the tree $\mathcal{T}_2$, construct all possible conservation laws (these can even arise from multipliers that depend only on the independent variables) and, correspondingly, construct all combinations of further potential systems. Find all nonlocally related subsystems by reduction of dependent variables. This yields an extended tree $\mathcal{T}_3$.

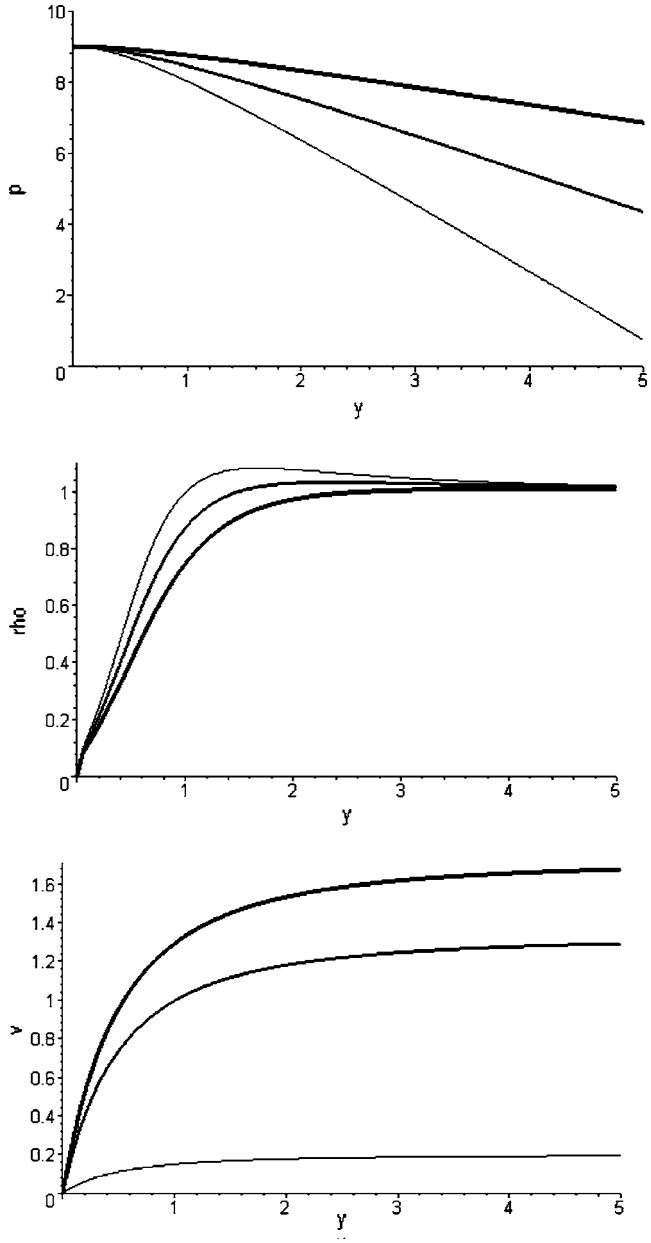

FIG. 1. Profiles of pressure p, density ρ, and velocity v at times $s=0.1$, 0.8, and 1.3.

Where possible, repeat step 4 to obtain a further tree extension (growth), etc.

The new theorem presented in Sec. III simplifies the construction of a tree of nonlocally related inequivalent systems for a given system of PDEs through elimination of redundant systems. To illustrate this theorem, as a prototypical example, we considered the nonlinear telegraph equations. Five new local conservation laws were constructed. Specializing to NLT equations with constitutive functions having power law nonlinearities, we found one nonlocal symmetry not found in Ref. 6. Further, from nonlocally related potential systems arising from new conservation laws for such NLT equations, we have found six new nonlocal conservation laws in addition to the nine nonlocal conservation laws found in Ref. 7.

For a system of planar gas dynamics equations, with a generalized polytropic equation of state, we found three new symmetries which are nonlocal for this system written in either Lagrangian or Eulerian coordinates.

It still remains a challenge to solve the overdetermined linear systems of PDEs for the symmetry classifying problems corresponding to the two couplet systems $\mathbf{UV}_1\mathbf{C}_4$, $\mathbf{UC}_3\mathbf{C}_4$ and the two triplet systems $\mathbf{UV}_1\mathbf{C}_3\mathbf{C}_4$, $\mathbf{UV}_2\mathbf{C}_3\mathbf{C}_4$ as we have been unable to solve any of these four systems.

APPENDIX: PROOF OF THEOREM 3

Proof: Each conservation law of any k-plet potential system $\{\mathbf{G}^{i_1}_{\mathbf{P}},\dots,\mathbf{G}^{i_k}_{\mathbf{P}}\}$ in $\mathbf{Q}$, arising from multipliers that depend only on independent variables $\mathbf{x}$, is a linear combination of terms involving potential equations in $\{\mathbf{G}^{i_1}_{\mathbf{P}},\dots,\mathbf{G}^{i_k}_{\mathbf{P}}\}$ and, possibly, equations of the given system (2.1).

For simplicity, we prove the theorem for the case when the new conservation law is obtained as a linear combination of potential equations of a *singlet* potential system $\mathbf{G}^{s}_{\mathbf{P}}$ in $\mathbf{Q}$ arising from the given system (2.1) and a single conservation law (2.8), and involving M potential equations $\mathcal{Q}^s$ (2.9). The proof directly carries over to the case when the new conservation law involves a linear combination of potential and non-potential equations of *any k-plet potential system* in $\mathbf{Q}$, $1\le k\le n$.

A new conservation law obtained using the DCM from a set of M potential equations $\mathcal{Q}^s$ has the form

$$D_k A^k(\mathbf{x},\mathbf{u},\partial\mathbf{u},\dots,\partial^r\mathbf{u},\mathbf{v},\partial\mathbf{v},\dots,\partial^s\mathbf{v}) = \Lambda_i(\mathbf{x})\Bigg(\sum_{i<j}(-1)^j\frac{\partial}{\partial x^j}v_{ij}(\mathbf{x}) + \sum_{j<i}(-1)^{i-1}\frac{\partial}{\partial x^{ji}}v_{ji}(\mathbf{x}) - \Phi^i(\mathbf{x},\mathbf{u},\partial\mathbf{u},\dots,\partial^r\mathbf{u})\Bigg) = 0. \tag{A1}$$

where $A^k(\mathbf{x},\mathbf{u},\mathbf{v},\partial\mathbf{u},\dots,\partial^r\mathbf{u})$ are fluxes of the new conservation law, and $\Lambda_i(\mathbf{x})(i=1,\dots,M)$ are multipliers. [Note that for the case of M independent variables, from a given conservation law (2.8), one obtains M potential equations (2.9). Hence, when one seeks a new conservation law, the number of multipliers is the same as the number of independent variables.]

It is evident that the dependence of fluxes of the new conservation law (A1) on the potentials $\mathbf{v}$ is as follows:

$$A^k = \sum_{i<k}(-1)^k\Lambda_i v_{ik} + \sum_{k<i}(-1)^{i-1}\Lambda_i v_{ki} + \alpha_k(\mathbf{x},\mathbf{u}). \tag{A2}$$

We substitute (A2) in the conservation law (A1), and deduce the following compatibility conditions for multipliers:

$$\frac{\partial\Lambda_q}{\partial x^p} - \frac{\partial\Lambda_p}{\partial x^q} = 0, \quad 1\le p,q\le n. \tag{A3}$$

This means the differential form $\omega_\Lambda=\Lambda_i dx^i$ is closed. A closed form is locally exact within an open domain, and hence for some sufficiently smooth $\phi(\mathbf{x}):\omega_\Lambda=d\phi(\mathbf{x})$. Equivalently $\Lambda_i=\partial\phi(\mathbf{x})/\partial x^i$, $i=1,\dots,M$.

We now demonstrate that the conservation law (A1) with fluxes A^k is equivalent to a conservation law whose fluxes do not contain the nonlocal variables v^{ik}, but only their derivatives.

Indeed,

$$
\begin{aligned}
D_k A^k &= D_k\left(\sum_{i<k}(-1)^k \Lambda_i v_{ik} + \sum_{k<i}(-1)^{i-1}\Lambda_i v_{ki} + \alpha_k(\mathbf{x},\mathbf{u})\right)\\
&= D_k\left(\sum_{i<k}(-1)^k \frac{\partial \phi}{\partial x^i} v_{ik} + \sum_{k<i}(-1)^{i-1}\frac{\partial \phi}{\partial x^i} v_{ki} + \alpha_k(\mathbf{x},\mathbf{u})\right)\\
&= D_k\left(\left[\sum_{i<k}(-1)^k \frac{\partial(\phi v_{ik})}{\partial x^i} + \sum_{k<i}(-1)^{i-1}\frac{\partial(\phi v_{ki})}{\partial x^i}\right]\right.\\
&\quad \left. - \phi\left[\sum_{i<k}(-1)^k \frac{\partial v_{ik}}{\partial x^i} + \sum_{k<i}(-1)^{i-1}\frac{\partial v_{ki}}{\partial x^i}\right] + \alpha^k(\mathbf{x},\mathbf{u})\right).
\end{aligned}
$$

The divergence of the flux part involving the first rectangular bracket is identically zero [see (2.8), (2.9)].

As all derivatives of potentials v_{ik} can be expressed in terms of local variables $\mathbf{x}$ and $\mathbf{u}$ on the solution manifold of $\mathbf{G}^s_{\mathbf{p}}$, it follows that the flux part involving the second rectangular bracket and $\alpha_k(\mathbf{x},\mathbf{u})$ contains only local variables of the given system (2.1). Hence the conservation law (A1) is linearly dependent on local ones constructed from the given system (2.5), and hence is trivial on the solution manifold of $\mathbf{G}^s_{\mathbf{p}}$. This concludes the proof. □

The Balian-Low Theorem is a strong form of the uncertainty principle for Gabor systems that form orthonormal or Riesz bases for $L^2(\mathbb{R})$. In this paper we investigate the Balian-Low Theorem in the setting of Schauder bases. We prove that new weak versions of the Balian-Low Theorem hold for Gabor Schauder bases, but we constructively demonstrate that several variants of the BLT can fail for Gabor Schauder bases that are not Riesz bases. We characterize a class of Gabor Schauder bases in terms of the Zak transform and product $\mathcal{A}_2$ weights; the Riesz bases correspond to the special case of weights that are bounded away from zero and infinity. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2360041]

I. INTRODUCTION

A *Gabor* or *Weyl-Heisenberg system* consists of a discrete set of time-frequency shifts of a fixed *window function* or *atom* $g \in L^2(\mathbb{R})$. Often, the indexing set is required to possess some structure. For example, we will consider *lattice Gabor systems* of the form

$$\mathcal{G}(g,\alpha,\beta) = \{M_{\beta n}T_{\alpha k}g\}_{k,n\in\mathbb{Z}} = \{e^{2\pi i\beta nt}g(t-\alpha k)\}_{k,n\in\mathbb{Z}}, \tag{1.1}$$

where T_x is the translation operator $T_xg(t)=g(t-x)$, M_ξ is the modulation operator $M_\xi g(t) = e^{2\pi i\xi t}g(t)$, and the compositions T_xM_ξ or $M_\xi T_x$ are called *time-frequency shift operators*. Gabor systems can also be defined in higher dimensions and on general lattices or even completely irregular sets of time-frequency shifts. One may also consider continuous Gabor transforms. For background on the theory and applications of Gabor systems, we refer to Refs. 1–3.

Gabor[4] proposed using the Gaussian function $\varphi(t)=e^{-t^2}$ as a window, with respect to the unit time-frequency shift lattice ($\alpha=\beta=1$). However, while this Gaussian Gabor system $\mathcal{G}(\varphi,1,1)$ is complete in $L^2(\mathbb{R})$ and remains complete if any single element of $\mathcal{G}(\varphi,1,1)$ is removed (cf. Ref. 5, p. 168), it is not an orthonormal basis, a Riesz basis, a frame, or a Schauder basis for $L^2(\mathbb{R})$ (even if the "extra" element is removed).

However, completeness alone is too weak a property to be useful in practice. A *Schauder basis* allows unique representations of elements of $L^2(\mathbb{R})$ in terms of the basis elements, i.e., $\mathcal{G}(g,\alpha,\beta)$ is a Schauder basis if for each $f \in L^2(\mathbb{R})$ there exist unique scalars $c_{kn}(f)$ such that

$$f = \sum_{k,n\in\mathbb{Z}} c_{kn}(f)M_{\beta n}T_{\alpha k}g, \tag{1.2}$$

with convergence of the series in the norm of L^2 with respect to some fixed ordering of the series. However, for a Schauder basis there need not be any direct relation between the size of the coefficients $c_{kn}(f)$ and the norm of f. In contrast, if $\mathcal{G}(g,\alpha,\beta)$ is a *frame* (defined precisely in Sec.

[a)]Electronic mail: heil@math.gatech.edu
[b)]Electronic mail: alexander.m.powell@vanderbilt.edu

II A), then it follows not merely that $\mathcal{G}(g,\alpha,\beta)$ is complete, but that every $f \in L^2(\mathbb{R})$ can be written as in (1.2) for a canonical choice of scalars $c_{kn}(f)$ whose ℓ^2 norm forms an equivalent norm for $L^2(\mathbb{R})$. Moreover, for a frame the series (1.2) converges *unconditionally* in the L^2 norm, i.e., regardless of ordering. However, a frame need not provide unique expansions—the scalars $c_{kn}(f)$ need not be unique in general. The canonical choice of scalars is determined by the canonical dual frame, which for a lattice Gabor frame $\mathcal{G}(g,\alpha,\beta)$ is another lattice Gabor frame $\mathcal{G}(\widetilde{g},\alpha,\beta)$ generated by a dual window $\widetilde{g} \in L^2(\mathbb{R})$. A *Riesz basis* is both a frame and a Schauder basis, and thus provides unique unconditionally convergent expansions whose coefficients stably encode the norm of f.

The Density Theorem for Gabor systems provides necessary (but not sufficient) conditions for $\mathcal{G}(g,\alpha,\beta)$ to be complete, a frame, a Riesz basis, or a Riesz sequence [a sequence that need not be complete but forms a Riesz basis for its closed span within $L^2(\mathbb{R})$]. Moreover, these conditions are formulated solely in terms of the lattice $\alpha\mathbb{Z}\times\beta\mathbb{Z}$.

Theorem 1.1 (Density Theorem): *Let* $g \in L^2(\mathbb{R})$ *and* $\alpha, \beta > 0$ *be given.*

(a) *If* $\mathcal{G}(g,\alpha,\beta)$ *is complete in* $L^2(\mathbb{R})$, *then* $\alpha\beta \leqslant 1$. *In particular, if* $\mathcal{G}(g,\alpha,\beta)$ *is a frame, then* $\alpha\beta \leqslant 1$.
(b) *If* $\mathcal{G}(g,\alpha,\beta)$ *is a Riesz basis in* $L^2(\mathbb{R})$, *then* $\alpha\beta = 1$.
(c) *If* $\mathcal{G}(g,\alpha,\beta)$ *is a Riesz sequence in* $L^2(\mathbb{R})$, *then* $\alpha\beta \geqslant 1$.

The Density Theorem has a long and involved history, including extensions to general lattices, to irregular Gabor frames in higher dimensions, and beyond Gabor frames to the setting of abstract "localized frames." Some of the main references include Refs. 6–12. We refer to Ref. 13 for a detailed survey of the Density Theorem, with extensive references to the original literature.

By the Density Theorem, there is a clear separation between "overcomplete" frames and "undercomplete" Riesz sequences, with the Riesz bases corresponding to the *critical density lattices* that satisfy $\alpha\beta = 1$. Moreover, there exists a simple exact characterization, in terms of the Zak transform, of those g such that $\mathcal{G}(g,\alpha,\beta)$ is a Riesz basis for $L^2(\mathbb{R})$ (see Theorem 2.8).

Unfortunately, the *Balian-Low Theorem* (BLT) is a classical result that implies that if $\mathcal{G}(g,\alpha,\beta)$ is a Riesz basis, then the window g must have poor joint localization in the time-frequency plane. Specifically, the localization integrals

$$\int |t|^2 |g(t)|^2 \, dt \quad \text{and} \quad \int |\xi|^2 |\hat{g}(\xi)|^2 \, d\xi$$

cannot both be finite. These same localization integrals appear in the Heisenberg uncertainty principle and, indeed, the BLT may be viewed as a strong form of the uncertainty principle for functions that generate a Gabor Riesz basis (we refer to Ref. 14 for a survey of uncertainty principles).

As with the Density Theorem the BLT has a long and involved history. Stated independently by Balian[15] and Low[16] for the case of orthonormal bases, a complete proof, and an extension to Riesz bases was given by Coifman, Daubechies, and Semmes.[7] Battle[17] gave an elegant new proof for the orthonormal basis case, which shows the intimate connection between the BLT and the operator theory associated with the Heisenberg uncertainty principle. This proof was further extended by Daubechies and Janssen in Ref. 18. Related theorems that relate distinct uncertainty principles to Riesz basis properties have been proved in Refs. 19–22, and extensions of the BLT to higher dimensions appear in Refs. 23–25. We collectively refer to these results as Balian-Low Theorems. Surveys of the Balian-Low Theorems appear in Refs. 19 and 26, and we also note the related results in the papers in Refs. 27–30.

In this paper we determine the extent to which the class of Balian-Low Theorems extend to Gabor systems $\mathcal{G}(g,\alpha,\beta)$ that form Schauder bases but that need not be Riesz bases. Despite the large literature on Gabor systems, very little has been known to date about Gabor Schauder bases. The initial work in this direction[31] proved the existence of a particular Gabor Schauder basis that is not a Riesz basis, and also provided partial results suggesting that the Density Theorem applies

to Gabor Schauder bases; cf. also Ref. 32 for the setting of windowed exponentials in $L^2(\Omega)$. However, these papers clearly indicate that all results become more delicate and difficult for Schauder bases, with the consequence that open questions abound.

In this paper, we accomplish several goals, as follows.

(a) We prove that the Density Theorem does hold for lattice Gabor Schauder bases. Specifically, if $\mathcal{G}(g,\alpha,\beta)$ is a Schauder basis, then $\alpha\beta=1$. We prove that the dual basis is also a Gabor system of the form $\mathcal{G}(\tilde{g},\alpha,\beta)$ for a unique dual window $\tilde{g}$.
(b) We give a characterization of a class of Gabor Schauder bases $\mathcal{G}(g,\alpha,\beta)$ in terms of the Zak transform of the window g and product $\mathcal{A}_2$ weights.
(c) We prove that several variants of the Balian-Low Theorems fail to hold for Gabor Schauder bases.
(d) We prove new weak versions of the BLT for Gabor Schauder bases, and show that as a consequence, if the window g of a Gabor Schauder basis $\mathcal{G}(g,\alpha,\beta)$ is well concentrated in the time-frequency plane, then the dual window $\tilde{g}$ is poorly concentrated.

Thus, counterintuitively, the window of a Gabor Schauder basis can have much better joint time-frequency localization than the generator of a Riesz basis. At the same time, the weak BLT for Gabor Schauder bases implies a striking difference from the behavior of Gabor frames. To discuss this more precisely, let us quantify time-frequency localization by the behavior of the *short-time Fourier transform* (STFT) of g:

$$V_\varphi g(x,\xi)=\langle g,M_\xi T_x\varphi\rangle=\int g(t)\varphi(t-x)e^{-2\pi i\xi t}\,dt,\quad (x,\xi)\in\mathbb{R}^2.$$

If we normalize as $\varphi(t)=(\pi/2)^{-1/4}e^{-t^2}$, then we have $\|\varphi\|_2=1$ and $\|V_\varphi g\|_2=\|g\|_2$. We define the *modulation space* $M^1(\mathbb{R})$ to be the function space consisting of all $g\in L^2(\mathbb{R})$ whose STFT is integrable, i.e.,

$$M^1(\mathbb{R})=\left\{g\in L^2(\mathbb{R}):\|g\|_{M^1}=\|V_\varphi g\|_1=\int\int|V_\varphi g(x,\xi)|dx\,d\xi<\infty\right\}. \tag{1.3}$$

Thus, a function $g\in M^1(\mathbb{R})$ possesses an L^1-type of joint localization in the time-frequency plane. We refer to Ref. 20, Chaps. 11–13 for a detailed background on the class of modulation spaces (of which M^1 is the prototypical example). In particular, we note that the choice of Gaussian window φ above is only for convenience; any nonzero Schwartz-class window, or indeed any nonzero window in M^1, may be used to define the modulation spaces, with each choice of window defining the same space under an equivalent norm.

In Gabor analysis, it is essential to jointly understand the behavior of a frame $\mathcal{G}(g,\alpha,\beta)$ and its dual frame $\mathcal{G}(\tilde{g},\alpha,\beta)$. For a Riesz basis, the Balian-Low Theorems imply that both the window and the dual window must have poor localization:

$$\text{For a Gabor Riesz basis:}\quad g\notin M^1(\mathbb{R})\quad\text{and}\quad\tilde{g}\notin M^1(\mathbb{R}).$$

In contrast, Gröchenig and Leinert[63] proved that if the window of a Gabor frame is well localized, then the dual window is as well, and, conversely:

$$\text{For a Gabor frame:}\quad g\in M^1(\mathbb{R})\Leftrightarrow\tilde{g}\in M^1(\mathbb{R}).$$

The Gröchenig and Leinert proof used deep results on symmetric C^* algebras. A new proof, based on a type of noncommutative Wiener's lemma, that extends to irregular Gabor frames and abstract localized frames, was given in Refs. 33 and 12.

In this paper, we constructively demonstrate the following:

For a Gabor Schauder basis: $g \in M^1(\mathbb{R})$, $\widetilde{g} \notin M^1(\mathbb{R})$ is possible.

Moreover, we show that whenever the window of a Gabor Schauder basis is well localized, then the dual window must be poorly localized, specifically the following:

$$\text{For a Gabor Schauder basis:} \quad g \in M^1(\mathbb{R}) \Rightarrow \widetilde{g} \notin M^1(\mathbb{R}). \tag{1.4}$$

We note that many types of weight functions play important roles in many aspects of time-frequency analysis (see Gröchenig's recent survey[34] for details and references). However, to date the Muckenhoupt, or $\mathcal{A}_p$, weights have had no application within time-frequency analysis. Our results show that the Muckenhoupt weight class is important in time-frequency analysis as a window class via the Zak transform. This is in contrast to the usual use of weights, which normally are used in time-frequency analysis in the quantification of time-frequency concentration.

Overview: Our paper is organized as follows. In Sec. II A we present background information on Schauder bases, Riesz bases, and the Zak transform. In Sec. III we recall the classical Balian-Low Theorem and several of its variants. These results, which are all stated in terms of Riesz bases for $L^2(\mathbb{R})$, form the backdrop for our investigation into the Balian-Low Theorem for Schauder bases. In Sec. IV we investigate some basic properties of Gabor Schauder bases, including the structure of the dual basis, and we present a short proof of a weak Balian-Low Theorem for Gabor Schauder bases. In Sec. V we show how to use product $\mathcal{A}_2$ weights to give a characterization of a class of Gabor Schauder bases for $L^2(\mathbb{R})$. In Sec. VI we show that several versions of the Balian-Low Theorem do not extend to the setting of Schauder bases. In Sec. VII, we prove that weak versions of the M^1 BLT and Amalgam BLT hold for Gabor Schauder bases and exact systems.

II. BACKGROUND AND PRELIMINARIES

A. Schauder bases, frames, and Riesz bases

We recall the definition and basic facts regarding Schauder bases, frames, and Riesz bases in Hilbert spaces. We refer to Refs. 35–38 for additional background.

Definition 2.1: An ordered collection $\mathcal{F}=\{f_n\}_{n=0}^{\infty}$ in a Hilbert space H is a *Schauder basis* for H if for each $f \in H$ there exist unique scalars $c_n(f)$ such that

$$f = \sum_{n=0}^{\infty} c_n(f) f_n, \tag{2.1}$$

where the series converges in the norm of H.

It is important to point out that Schauder basis expansions may converge conditionally, i.e., the order of summation in (2.1) matters.

The linear functionals c_n in (2.1) can be shown to be continuous. Therefore there exist $\widetilde{f}_n \in H$ such that $c_n(f)=\langle f, \widetilde{f}_n \rangle$. Further, $\widetilde{\mathcal{F}}=\{\widetilde{f}_n\}_{n=0}^{\infty}$ is the unique sequence in H that is *biorthogonal* to $\mathcal{F}$, i.e.,

$$\langle f_m, \widetilde{f}_n \rangle = \delta_{mn}.$$

Every Schauder basis has an associated biorthogonal sequence, but the converse is not true, i.e., the existence of a biorthogonal system does not imply that the original sequence is a Schauder basis. The existence of a biorthogonal sequence is equivalent to the statement that $\mathcal{F}$ is *minimal*, i.e., no element of $\mathcal{F}$ lies in the closed linear span of the remaining elements. A system that is both complete and minimal is said to be *exact*. There exist complete and minimal systems that are not Schauder bases.

Given a sequence $\mathcal{F}=\{f_n\}_{n=0}^{\infty}$ that has a biorthogonal sequence $\widetilde{\mathcal{F}}=\{\widetilde{f}_n\}_{n=0}^{\infty}$, we define the *partial sum operators* $S_N: H \to H$ by

$$S_N(f) = \sum_{n=0}^{N} \langle f, \tilde{f}_n \rangle f_n.$$

There are several equivalent definitions of a Schauder basis, of which we will need the following.

Theorem 2.2: *Given a collection* $\mathcal{F}=\{f_n\}_{n=0}^{\infty}$ *in a Hilbert space* H, *the following statements are equivalent*.

(a) $\mathcal{F}$ *is a Schauder basis*.

(b) *There exists a biorthogonal sequence* $\tilde{\mathcal{F}}=\{\tilde{f}_n\}_{n=0}^{\infty}$ *such that the partial sum operators* S_N *converge in the strong operator topology to the identity map, i.e.,*

$$\forall f \in H, \quad f = \sum_{n=0}^{\infty} \langle f, \tilde{f}_n \rangle f_n. \tag{2.2}$$

(c) *There exists a biorthogonal sequence* $\tilde{\mathcal{F}}=\{\tilde{f}_n\}_{n=0}^{\infty}$ *such that the partial sum operators are uniformly bounded in operator norm, i.e.,*

$$\sup_N \|S_N\| < \infty.$$

The number $C=\sup_N\|S_N\|$ is called the *basis constant* for $\mathcal{F}$. The biorthogonal sequence $\tilde{\mathcal{F}}$ is itself a Schauder basis for H, and is called the *dual basis* to $\mathcal{F}$.

In contrast to Schauder bases, frames are defined in terms of a norm-equivalence criterion.

Definition 2.3: A collection $\mathcal{F}=\{f_n\}_{n=0}^{\infty}$ in a Hilbert space H is a *frame* for H if there exist constants $A, B>0$, called *frame bounds*, such that

$$\forall f \in H, \quad A\|f\|^2 \leqslant \sum_{i=0}^{\infty} |\langle f, f_i \rangle|^2 \leqslant B\|f\|^2. \tag{2.3}$$

A sequence for which the upper inequality in (2.3) is satisfied, but not necessarily the lower inequality, is called a *Bessel sequence*.

If $\mathcal{F}$ is a frame, then the *frame operator* $Sf=\Sigma_{n=0}^{\infty}\langle f, f_n\rangle f_n$ is a bounded, positive, and invertible mapping of H onto itself. The *canonical dual frame* $\tilde{\mathcal{F}}=\{\tilde{f}_n\}_{n=0}^{\infty}$ defined by $\tilde{f}_n=S^{-1}(f_n)$ yields frame expansions exactly of the form in (2.2). Moreover, those series converge unconditionally for each f. However, in general, a frame need not be a Schauder basis. In particular, the scalars $\langle f, \tilde{f}_n \rangle$ in (2.2) need not be unique.

Definition 2.4: A collection $\mathcal{F}=\{f_n\}_{n=0}^{\infty}$ in a Hilbert space H is a *Riesz basis* for H if it is the image of an orthonormal basis for H under a continuous, invertible map of H onto itself.

Among other characterizations, the following theorem shows that a Riesz basis is precisely a sequence that is both a frame and a Schauder basis.

Theorem 2.5: *Given a collection* $\mathcal{F}=\{f_n\}_{n=0}^{\infty}$ *in a Hilbert space* H, *the following statements are equivalent*.

(a) $\mathcal{F}$ *is a Riesz basis*.

(b) $\mathcal{F}$ *is a bounded unconditional basis, i.e.,* $\mathcal{F}$ *is a Schauder basis, the basis expansions in* (2.1) *converge unconditionally for each* $f \in H$, *and* $0<\inf_n\|f_n\| \leqslant \sup_n\|f_n\|<\infty$.

(c) $\mathcal{F}$ *is an exact frame, i.e., it is a frame and is biorthogonal to its canonical dual frame*.

(d) $\mathcal{F}$ *is complete and there exist constants* $A, B>0$, *such that*

$$\forall c_0, \ldots, c_N, \quad A\sum_{n=0}^{N} |c_N|^2 \leqslant \left\| \sum_{n=0}^{N} c_n f_n \right\|^2 \leqslant B\sum_{n=0}^{N} |c_n|^2.$$

(e) *$\mathcal{F}$ is a complete Bessel sequence and possesses a biorthogonal sequence that is also a complete Bessel sequence.*

The dual basis of a Riesz basis coincides with its canonical dual frame, and is itself a Riesz basis for H.

We say that a sequence is a *Riesz sequence* if it forms a Riesz basis for its closed span within H.

Example 2.6: Let $\varphi(t)=e^{-t^2}$. von Neumann (Ref. 39, p. 406) claimed (without proof) that $\mathcal{G}(\varphi,1,1)$ is complete in $L^2(\mathbb{R})$. Gabor conjectured in Ref. 4, Eq. 1.29 that every function in $L^2(\mathbb{R})$ can be represented in the form

$$f=\sum_{k,n\in\mathbb{Z}} c_{kn}(f)M_nT_k\varphi, \tag{2.4}$$

for some scalars $c_{kn}(f)$. von Neumann's claim of completeness was proved in Refs. 40 and 41. Janssen proved in Ref. 42 that Gabor's conjecture is true, but he showed that the series in (2.4) converges only in the sense of tempered distributions—not in the norm of L^2. Thus the Gabor system $\mathcal{G}(\varphi,1,1)$ fits none of the definitions given previously in this section.

On the other hand, Lyubarskii[43] and Seip and Wallstén[44,45] proved that $\mathcal{G}(\varphi,\alpha,\beta)$ is a frame for $L^2(\mathbb{R})$ whenever $0<\alpha\beta<1$. Moreover, $\mathcal{G}(\varphi,\alpha,\beta)$ is an incomplete Riesz sequence in $L^2(\mathbb{R})$ whenever $\alpha\beta>1$.

B. The Zak transform

The Zak transform was introduced by Gelfand[46] and goes by several names. It is often called the *Weil-Brezin map* in representation theory and abstract harmonic analysis. Zak rediscovered this transform, which he called the *k-q transform*, in his work on quantum mechanics, e.g., Ref. 47. For more information, we refer to Janssen's influential paper[48] and survey,[49] or to Gröchenig's text.[1]

The Zak transform is an extremely useful tool for analyzing Gabor systems at the critical density $\alpha\beta=1$. Because the unitary dilation $D_\alpha f(t)=\alpha^{1/2}f(\alpha t)$ maps the Gabor system $\mathcal{G}(g,\alpha,1/\alpha)$ to the Gabor system $\mathcal{G}(D_\alpha g,1,1)$, when working at the critical density we always can, by a change of variables, reduce to the case $\alpha=\beta=1$. This is what we will do throughout, i.e., when we are at the critical density we will only consider Gabor systems of the form

$$\mathcal{G}(g,1,1)=\{M_nT_kg\}_{k,n\in\mathbb{Z}}.$$

The Zak transform is the unitary operator Z: $L^2(\mathbb{R})\to L^2(Q)$, where $Q=[0,1)^2$, formally defined for $f\in L^2(\mathbb{R})$ by

$$Zf(t,\xi)=\sum_{k\in\mathbb{Z}} f(t-k)e^{2\pi ik\xi},\quad (t,\xi)\in[0,1)^2. \tag{2.5}$$

It can be shown that the series above converges in the norm of $L^2(Q)$, and that Z is a unitary map of $L^2(\mathbb{R})$ onto $L^2(Q)$. The utility of the Zak transform is made apparent by the following theorem, where we use the notation

$$E_{n,k}(t,\xi)=e^{2\pi int}e^{-2\pi ik\xi}. \tag{2.6}$$

Theorem 2.7: *Let $g\in L^2(\mathbb{R})$ be given. Then*

$$Z(M_nT_kg)(t,\xi)=(E_{n,k}\cdot Zg)(t,\xi)=E_{n,k}(t,\xi)Zg(t,\xi).$$

In other words, the Zak transform diagonalizes time-frequency shifts.

Since $\{E_{n,k}\}_{k,n\in\mathbb{Z}}$ forms an orthonormal basis for $L^2(Q)$ and since Z is unitary, the following characterization follows easily; cf. Ref. 50 Theorem 4.3.3.

Theorem 2.8: *Let $g\in L^2(\mathbb{R})$ be given.*

(a) $\mathcal{G}(g,1,1)$ *is complete if and only if* $Zg \neq 0$ *a.e.*
(b) $\mathcal{G}(g,1,1)$ *is minimal if and only if* $1/Zg \in L^2(Q)$. *In this case* $\mathcal{G}(g,1,1)$ *is also complete, i.e., it is exact.*
(c) $\mathcal{G}(g,1,1)$ *is a frame for* $L^2(\mathbb{R})$ *if and only if there exist* $0<A\leqslant B<\infty$ *such that* $A\leqslant|Zg|^2 \leqslant B$ *a.e. In this case* $\mathcal{G}(g,1,1)$ *is a Riesz basis for* $L^2(\mathbb{R})$, *and* A, B *are frame bounds for* $\mathcal{G}(g,1,1)$.
(d) $\mathcal{G}(g,1,1)$ *is an orthonormal basis for* $L^2(\mathbb{R})$ *if and only if* $|Zg|^2=1$ *a.e.*

C. Modulation spaces

In addition to the modulation space $M^1(\mathbb{R})$ defined in (1.3), we will need the following particular modulation spaces. We refer to Ref. 1 for details.

Definition 2.9: Let $\varphi(t)=(\pi/2)^{-1/4}e^{-t^2}$. For $1\leqslant p<\infty$ and $s\geqslant 0$, the modulation space $M^p_s(\mathbb{R})$ consists of all tempered distributions $g\in S'(\mathbb{R})$ for which the norm

$$\|g\|_{M^p_s}=\|V_\varphi g\|_{L^p_s}=\left(\int\int |V_\varphi g(x,\xi)|^p(1+|x|+|\xi|)^{ps}\,dx\,d\xi\right)^{1/p}$$

is finite.

For any α, β with $0<\alpha\beta<1$, the following is an equivalent norm for $M^p_s(\mathbb{R})$:

$$|||g|||_{M^p_s}=\left(\sum_{k\in\mathbb{Z}}\sum_{n\in\mathbb{Z}}|\langle g,M_{\beta n}T_{\alpha k}\varphi\rangle|^p(1+|\alpha k|+|\beta n|)^{ps}\right)^{1/p}. \tag{2.7}$$

For $s\geqslant 0$, we have $M^2_s(\mathbb{R})=L^2_s(\mathbb{R})\cap H^s(\mathbb{R})$, where

$$L^2_s(\mathbb{R})=\left\{f\in L^2(\mathbb{R}):\int |f(t)|^2(1+|t|)^{2s}\,dt<\infty\right\}$$

and

$$H^s(\mathbb{R})=\left\{f\in L^2(\mathbb{R}):\int |\hat{f}(\xi)|^2(1+|\xi|)^{2s}\,d\xi\right\}.$$

It follows from the discrete-type norm given in (2.7) that $M^2_s(\mathbb{R})\subseteq M^1(\mathbb{R})$ if $s>1$. However, $M^2_1(\mathbb{R})$ does not embed into $M^1(\mathbb{R})$, nor conversely.

III. THE BALIAN-LOW THEOREMS

In this section we recall the precise statement of several variants of the Balian-Low Theorem. We use the Fourier transform normalized by $\hat{f}(\xi)=\int f(t)e^{-2\pi i\xi t}\,dt$. Recall that, by the Density Theorem, if a lattice Gabor system is a Riesz basis, then necessarily we are at the critical density, and hence it suffices to consider $\alpha=\beta=1$. The first part of the following theorem is the classical wording of the BLT; we also give an equivalent wording in terms of modulation spaces.

Theorem 3.1 (Classical Balian-Low Theorem): *If* $g\in L^2(\mathbb{R})$ *and*

$$\int |t|^2|g(t)|^2\,dt<\infty \quad \textit{and} \quad \int |\xi|^2|\hat{g}(\xi)|^2\,d\xi<\infty,$$

then $\mathcal{G}(g,1,1)$ *is not a Riesz basis for* $L^2(\mathbb{R})$. *Equivalently, if* $g\in M^2_1(\mathbb{R})$, *then* $\mathcal{G}(g,1,1)$ *is not a Riesz basis for* $L^2(\mathbb{R})$.

The following theorem summarizes four variations of the Balian-Low Theorem that involve different quantifications of time-frequency localization. Part (a) is formulated in terms of the modulation space $M^1(\mathbb{R})$ that was defined in (1.3). Part (b) is formulated in terms of the *Wiener amalgam space*,

$$W(\mathcal{C},\ell^1)=\left\{f\colon \mathbb{R}\to\mathbb{C}\colon f \text{ is continuous and } \sum_{n\in\mathbb{Z}}\|f\cdot\chi_{[n,n+1)}\|_\infty<\infty\right\}.$$

For details on the amalgam spaces, with extensive references to the original literature, we refer to the survey in Ref. 62.

Theorem 3.2: *Fix $g\in L^2(\mathbb{R})$: If any of the following hypotheses hold:*

(a) $g\in M^1(\mathbb{R})$;
(b) $g\in W(\mathcal{C},\ell^1)$;
(c) $1<q<2<p<\infty$, $\frac{1}{p}+\frac{1}{q}=1$, $0<\varepsilon<2-q$,

$$\int |t|^{p+\varepsilon}|g(t)|^2\,dt<\infty, \quad \text{and} \quad \int |\xi|^{q+\varepsilon}|\hat{g}(\xi)|^2\,d\xi<\infty;$$

(d) $\sup_{N>0}\int |t|^N|g(t)|^2\,dt<\infty$ *and* $\int|\xi||\hat{g}(\xi)|^2\,d\xi<\infty$,

then $\mathcal{G}(g,1,1)$ is not a Riesz basis for $L^2(\mathbb{R})$.

The theorem corresponding to the hypothesis in part (a) of Theorem 3.2 was proved in Ref. 23, and it extends to Gabor systems on arbitrary lattices in higher dimensions. We will refer to this theorem as the M^1 BLT. Since M^1 does not embed into $M^2_1(\mathbb{R})$ nor conversely, this result is distinct from Theorem 3.1.

The theorem corresponding to part (b) is known as the *Amalgam BLT*.[51,19] It extends to rectangular lattices of the form $\alpha\mathbb{Z}^d\times\beta\mathbb{Z}^d$ in higher dimensions. For rectangular lattices, the Amalgam BLT implies the M^1 BLT. However, it is not known if the Amalgam BLT extends to arbitrary lattices, so in that setting these two results are distinct. Furthermore, it was shown in Ref. 19 that the Amalgam BLT and the Classical BLT are distinct.

Part (c) follows from part (a) and Ref. 52, Theorem 1; see Ref. 30, Eq. (2.6).

Part (d) was proved in Ref. 22. It is worth mentioning that part (c) actually holds for all $\varepsilon>0$, but we shall only deal with the case where ε is sufficiently small. We refer to parts (c) and (d) as *nonsymmetric (p,q) BLTs*.

IV. SCHAUDER BASES AND A WEAK BALIAN-LOW THEOREM

In this section we will prove some basic facts about Gabor Schauder bases, and establish that a weak version of the BLT holds for Schauder bases.

Gabor systems are naturally indexed by $\mathbb{Z}\times\mathbb{Z}$, but do not come equipped with a standard enumeration. Since Schauder basis expansions may depend critically on ordering any discussion of Gabor Schauder bases must specify a particular enumeration of $\mathbb{Z}\times\mathbb{Z}$. Therefore, whenever we say that $G(g,\alpha,\beta)$ is a Gabor Schauder basis, we shall implicitly mean that there exists an enumeration of the Gabor system $G(g,\alpha,\beta)$, which is a Schauder basis. When necessary we shall explicitly define the enumeration.

A. The Density Theorem and the Dual Basis

We first observe that the existing results for Gabor Schauder bases implicitly contain a Density Theorem. We make this explicit as follows (we refer to Ref. 11 for the definition of Beurling density). As a consequence, for lattice Gabor Schauder bases, we will always be able to reduce to the case $\alpha=\beta=1$.

Theorem 4.1 (Density Theorem for Lattice Gabor Schauder Bases): *Let $g\in L^2(\mathbb{R})$ and $\alpha,\beta>0$ be given. If $\mathcal{G}(g,\alpha,\beta)$ is a Schauder basis for $L^2(\mathbb{R})$, then $\alpha\beta=1$.*

Proof: First, if $\mathcal{G}(g,\alpha,\beta)$ is a Schauder basis, then it is complete, so Theorem 1.1 implies that $\alpha\beta\leqslant 1$. On the other hand, see Ref. 31, Corollary 4.6, which gives partial necessary conditions for an irregular Gabor system to form a Schauder basis, and implies that the lower and upper Beurling densities of the index set $\alpha\mathbb{Z}\times\beta\mathbb{Z}$ must satisfy $D^{\pm}(\alpha\mathbb{Z}\times\beta\mathbb{Z})\leqslant 1$. The Beurling density of the lattice $\alpha\mathbb{Z}\times\beta\mathbb{Z}$ is $D^{\pm}(\alpha\mathbb{Z}\times\beta\mathbb{Z})=1/(\alpha\beta)$, so this implies that $\alpha\beta\geqslant 1$. □

It was conjectured in Ref. 31 that if $\mathcal{G}(g,\Lambda)=\{M_\xi T_x g\}_{(x,\xi)\in\Lambda}$ is a Gabor Schauder basis with respect to an arbitrary sequence of time-frequency shifts Λ, then we must have $D^{\pm}(\Lambda)=1$. This conjecture remains open for non-lattice Gabor Schauder bases.

It is well known that the dual basis to a Gabor Riesz basis $\mathcal{G}(g,\alpha,\beta)$ is itself a Gabor Riesz basis $\mathcal{G}(\tilde{g},\alpha,\beta)$. This follows from the fact that if $\mathcal{G}(g,\alpha,\beta)$ is a frame, then the frame operator S commutes with the time-frequency shifts $M_{\beta n}T_{\alpha k}$. For a Gabor Schauder basis, the frame operator need not be a bounded or even a well-defined map. Nonetheless, we show next that the dual of a lattice Gabor Schauder basis is also a lattice Gabor Schauder basis. By Theorem 4.1, it suffices to consider $\alpha=\beta=1$.

Theorem 4.2: *If $g\in L^2(\mathbb{R})$ and $\mathcal{G}(g,1,1)$ is an exact system in $L^2(\mathbb{R})$, then the biorthogonal system has the form $\mathcal{G}(\tilde{g},1,1)$, where the dual window $\tilde{g}\in L^2(\mathbb{R})$ is defined by the condition*

$$Z\tilde{g}=1/\overline{Zg}.$$

In particular, this determines the dual basis for a Gabor Schauder basis.

Proof: By Theorem 2.8 we have that the function $G=1/\overline{Zg}$ belongs to $L^2(\mathbb{R})$. Therefore, by the unitarity of the Zak transform we may define $\tilde{g}=Z^{-1}G\in L^2(\mathbb{R})$.

If (k,n), $(j,m)\in\mathbb{Z}^2$ then by Theorem 2.7, we have that

$$\langle M_nT_kg,M_mT_j\tilde{g}\rangle=\langle ZM_nT_kg,ZM_mT_j\tilde{g}\rangle=\int_0^1\int_0^1 E_{n,k}(t,\xi)Zg(t,\xi)\overline{E_{m,j}(t,\xi)Z\tilde{g}(t,\xi)}dt\,d\xi$$

$$=\int_0^1\int_0^1 E_{n,k}(t,\xi)\overline{E_{m,j}(t,\xi)}dt\,d\xi=\langle E_{n,k},E_{m,n}\rangle=\delta_{jk}\delta_{mn}.$$

Thus, $\mathcal{G}(\tilde{g},1,1)$ is biorthogonal to $\mathcal{G}(g,1,1)$. Since an exact system has a unique biorthogonal system, it follows that $\mathcal{G}(\tilde{g},1,1)$ is the biorthogonal system. □

The following elementary lemma will be used later.

Lemma 4.3: Let $g\in L^2(\mathbb{R})$. Let $\{(k_j,n_j)\}_{j=1}^\infty$ be an enumeration of $\mathbb{Z}\times\mathbb{Z}$. If $\mathcal{G}(g,1,1)$ is a Gabor Schauder basis with respect to this enumeration, then it is also a Gabor Schauder basis with respect to the enumeration $\{(-k_j,-n_j)\}_{j=1}^\infty$.

Equivalently, if $\{M_{n_j}T_{k_j}g\}_{j=1}^\infty$ is a Schauder basis for $L^2(\mathbb{R})$ with dual basis $\{M_{n_j}T_{k_j}\tilde{g}\}_{j=1}^\infty$, then $\{M_{-n_j}T_{-k_j}g\}_{j=1}^\infty$ is a Schauder basis for $L^2(\mathbb{R})$ with dual basis $\{M_{-n_j}T_{-k_j}\tilde{g}\}_{j=1}^\infty$.

B. A weak classical Balian-Low Theorem for Gabor Schauder bases

Daubechies and Janssen proved in Ref. 18 that a weak version of the BLT holds for Gabor systems $\mathcal{G}(g,1,1)$ that are exact in $L^2(\mathbb{R})$. In particular, all Schauder bases are exact. As the proof is simpler for Gabor Schauder bases than general exact systems, we include it here. It will be convenient to state this result in terms of the unbounded operators P and X on $L^2(\mathbb{R})$, defined by

$$Pf(t)=tf(t)\quad\text{and}\quad Xf(t)=(\hat{Pf})^\vee(t),$$

where $h^\vee$ denotes the inverse Fourier transform.

Theorem 4.4 (Weak BLT): *Let $g\in L^2(\mathbb{R})$. If $\mathcal{G}(g,1,1)$ is a Schauder basis for $L^2(\mathbb{R})$ with dual basis $\mathcal{G}(\tilde{g},1,1)$, then at least one of the functions,*

$$Pg,\quad Xg,\quad P\tilde{g},\quad X\tilde{g},$$

does not belong to $L^2(\mathbb{R})$. Equivalently, if $g,\tilde{g}\in M_1^2(\mathbb{R})$, then $\mathcal{G}(g,1,1)$ is not a Schauder basis for $L^2(\mathbb{R})$.

Proof: Although the proof is formally similar to that in Ref. 17, extra care must be taken since Schauder basis expansions converge only conditionally in general. To this end, suppose that $\mathcal{G}(g,1,1)$ is a Schauder basis for $L^2(\mathbb{R})$ with respect to a specific enumeration $\{(k_j,n_j)\}_{j=1}^\infty$ of $\mathbb{Z}\times\mathbb{Z}$.

We proceed by contradiction. Assume that Pg, Xg, $P\widetilde{g}$, $X\widetilde{g}$ all belong to $L^2(\mathbb{R})$. By direct calculation, for each k, $n \in \mathbb{Z}$ we have

$$\langle Xg, M_n T_k \widetilde{g}\rangle = \langle M_{-n} T_{-k} g, X\widetilde{g}\rangle \quad \text{and} \quad \langle M_n T_k g, P\widetilde{g}\rangle = \langle Pg, M_{-n} T_{-k}\widetilde{g}\rangle. \tag{4.1}$$

Next, using (4.1) and Lemma 4.3, we compute that

$$\begin{aligned}\langle Xg, P\widetilde{g}\rangle &= \left\langle \lim_{N\to\infty} \sum_{j=1}^{N} \langle Xg, M_{n_j} T_{k_j}\widetilde{g}\rangle M_{n_j} T_{k_j} g, P\widetilde{g}\right\rangle = \lim_{N\to\infty} \sum_{j=1}^{N} \langle M_{-n_j} T_{-k_j} g, X\widetilde{g}\rangle \langle Pg, M_{-n_j} T_{-k_j}\widetilde{g}\rangle \\ &= \left\langle Pg, \lim_{N\to\infty} \sum_{j=1}^{N} \langle X\widetilde{g}, M_{-n_j} T_{-k_j} g\rangle M_{-n_j} T_{-k_j}\widetilde{g}\right\rangle = \langle Pg, X\widetilde{g}\rangle. \end{aligned} \tag{4.2}$$

Because the commutator $[X,P]=XP-PX=-1/(2\pi i)I$ is a multiple of the identity operator I (on the domain of $[X,P]$), we have by Ref. 19, Lemma 7.2 that

$$\frac{1}{2\pi i}\langle g, \widetilde{g}\rangle = \langle Pg, X\widetilde{g}\rangle - \langle Xg, P\widetilde{g}\rangle. \tag{4.3}$$

Therefore, $\langle g, \widetilde{g}\rangle = 0$ by (4.2). But this is a contradiction, because the definition of biorthogonality implies that $\langle g, \widetilde{g}\rangle = 1$. □

V. $\mathcal{A}_2$ WEIGHTS AND CHARACTERIZATIONS OF GABOR SCHAUDER BASES

Theorem 2.8 shows that the Zak transform can be used to characterize many properties of a Gabor system. In this section we address this issue of whether Gabor Schauder bases also admit a simple characterization in the Zak transform domain.

First, let us give a basic equivalent reformulation of the definition of Gabor Schauder bases. This reformulation, which is an immediate consequence of Theorems 2.2 and 2.7, reveals the issues that must be addressed in order to find the desired characterization.

Lemma 5.1: Let $g \in L^2(\mathbb{R})$ be given, and let $\{(k_j, n_j)\}_{j=1}^{\infty}$ be an enumeration of $\mathbb{Z}\times\mathbb{Z}$. Then the following statements are equivalent.

(a) $\mathcal{G}(g,1,1)$ *is a Schauder basis for* $L^2(\mathbb{R})$ *with respect to the enumeration* $\{(k_j,n_j)\}_{j=1}^{\infty}$.
(b) $1/|Zg| \in L^2(Q)$, *and the partial sum operators* $S_N: L^2(Q) \to L^2(Q)$, *defined by*

$$S_N F = \sum_{j=1}^{N} \langle F, E_{n_j,k_j}\overline{/Zg}\rangle (E_{n_j,k_j}\cdot Zg), \tag{5.1}$$

are uniformly bounded in operator norm, i.e., $\sup_N \|S_N\| < \infty$.

The boundedness of partial sum operators in higher dimensions is, in general, a delicate issue, e.g., Ref. 53. However, for rectangular partial sums the problem is well understood, using $\mathcal{A}_2$ weights as a tool.

A. Background on $\mathcal{A}_2$ weights

We give here some background and basic results on $\mathcal{A}_2$ weights. We let $L^1(\mathbb{T})$ denote the space of 1-periodic functions on $\mathbb{R}$ that are integrable on $[0,1]$. We use the convention that $0\cdot\infty = 0$, and the symbol $\mathbf{1}_S$ will denote the characteristic function of a set $S \subseteq \mathbb{R}$. We use the notation $A \lesssim B$ to mean that there exists an absolute constant C, such that $A \leq CB$.

Definition 5.2 ($\mathcal{A}_2$ weight): A non-negative function $w \in L^1(\mathbb{T})$ is an $\mathcal{A}_2(\mathbb{T})$ *weight*, denoted $w \in \mathcal{A}_2(\mathbb{T})$, if there exists a constant $C>0$ such that for every interval $I \subset \mathbb{R}$ we have

$$\left(\frac{1}{|I|}\int_I w(t)dt\right)\left(\frac{1}{|I|}\int_I \frac{1}{w(t)}dt\right) \leqslant C.$$

We refer to the smallest such C as the $\mathcal{A}_2(\mathbb{T})$ characteristic of w, denoted $\|w\|_{\mathcal{A}_2(\mathbb{T})}$. Note that every $w \in \mathcal{A}_2(\mathbb{T})$ satisfies $1 \leqslant \|w\|_{\mathcal{A}_2(\mathbb{T})}$.

Now define

$$e_n(t) = e^{2\pi i n t}.$$

The following fundamental theorem of Hunt, Muckenhoupt, and Wheeden addresses the uniform boundedness of the Fourier partial sum operators,

$$T_N f = \sum_{n=-N}^{N} \langle f, e_n\rangle e_n, \tag{5.2}$$

in weighted L^2 spaces. In particular, the equivalence of statements (a) and (b) in the following theorem is a special case of Ref. 54, Theorem 8. We let $L^2_w(D)$ be the space of all complex-valued functions f on D for which

$$\|f\|_{2,w} = \left(\int_D |f(x)|^2 w(x)dx\right)^{1/2} < \infty.$$

Theorem 5.3 (Hunt, Muckenhoupt, Wheeden): *Let w be a non-negative function in $L^1(\mathbb{T})$. For $N \geqslant 0$, let $T_N: L^2_w(\mathbb{T}) \to L^2_w(\mathbb{T})$ be the operator formally defined by (5.2), and let $\|T_N\|_{2,w}$ denote its operator norm. Then the following statements are equivalent.*

(a) $\sup_N \|T_N\|_{2,w} < \infty$.
(b) $w \in \mathcal{A}_2(\mathbb{T})$.

Furthermore,

$$\|w\|_{\mathcal{A}_2(\mathbb{T})} \lesssim \sup_N \|T_N\|^2_{2,w} \lesssim \|w\|^2_{\mathcal{A}_2(\mathbb{T})}. \tag{5.3}$$

Along with the explicit equivalence of (a) and (b), the first inequality in (5.3) is implicit in the proof of Ref. 54, Theorem 8. For the second inequality in (5.3), the proof of Ref. 54, Thm. 8, along with the fact that $1 \leqslant \|w\|_{\mathcal{A}_2(\mathbb{T})}$, shows that

$$\sup_N \|T_N\|^2_{2,w} \lesssim (C_w)^2 + \|w\|_{\mathcal{A}_2(\mathbb{T})} \lesssim (C_w)^2 + \|w\|^2_{\mathcal{A}_2(\mathbb{T})},$$

where C_w is the norm bound for the conjugate function on $L^2_w(\mathbb{T})$ (see Ref. 54, Theorem 1). It therefore suffices to know that C_w is controlled from above by $\|w\|_{\mathcal{A}_2(\mathbb{T})}$. This is a consequence of the corresponding sharp result for the Hilbert transform proved in Ref. 55. For our purposes, the full strength of (5.3) is not needed, and any reasonable relation between $\sup_N \|T_N\|^2_{2,w}$ and $\|w\|_{\mathcal{A}_2(\mathbb{T})}$ is enough for our subsequent results. In this regard, the weaker estimates given by Refs. 56 and 57 would also suffice.

Rewriting Theorem 5.3 in terms of the partial sum operators for windowed systems of exponentials gives the following. Here $\langle\cdot,\cdot\rangle$ denotes the usual inner product on $L^2(\mathbb{T})$.

Corollary 5.4: Let $w \in L^2(\mathbb{T})$ be nonzero a.e., and define $\tilde{w} = 1/\bar{w}$. Let $\{n_j\}_{j=1}^{\infty}$ be the enumeration $\{0,1,-1,2,-2,3,-3,\ldots\}$ of $\mathbb{Z}$. For $N \geqslant 1$, let $S_N: L^2(\mathbb{T}) \to L^2(\mathbb{T})$ be the operator, formally defined by

$$S_N f = \sum_{j=1}^{N} \langle f, e_{n_j}\cdot \tilde{w}\rangle (e_{n_j}\cdot w),$$

and let $\|S_N\|$ *denote its operator norm. Then the following statements are equivalent.*

(a) $\sup_N \|S_N\| < \infty$.
(b) $|w|^2 \in \mathcal{A}_2(\mathbb{T})$.

Proof: Let $T_N: L^2_{|w|^2}(\mathbb{T}) \to L^2_{|w|^2}(\mathbb{T})$ be defined by (5.2). By Theorem 5.3, it suffices to show that $\sup_N \|T_N\|_{2,|w|^2} < \infty$ if and only if $\sup_N \|S_N\| < \infty$.

Suppose that $C = \sup_N \|T_N\|_{2,|w|^2} < \infty$. Then for $f \in L^2(\mathbb{T})$, we have

$$\|S_{2N+1} f\|_2 = \|T_N(f/w)\|_{2,|w|^2} \leq C\|f/w\|_{2,|w|^2} = C\|f\|_2.$$

Since $|w|^2 \in \mathcal{A}_2(\mathbb{T})$, we have $A = \|\widetilde{w}\|_2 \|w\|_2 < \infty$. Therefore

$$\|S_{2N} f\|_2 \leq \|S_{2N-1} f\|_2 + |\langle f, e_N \widetilde{w}\rangle| \|e_N w\|_2 \leq C\|f\|_2 + \|f\|_2 \|\widetilde{w}\|_2 \|w\|_2 = (C + A)\|f\|_2.$$

Hence $\sup_N \|S_N\| \leq C + A < \infty$.

For the converse, suppose that $\sup_N \|S_N\| < \infty$. If $f \in L^2_{|w|^2}(\mathbb{T})$ then

$$\|T_N(f)\|_{2,|w|^2} = \|S_{2N+1}(fw)\|_2 \leq C\|fw\|_2 = C\|f\|_{2,|w|^2}.$$

Hence $\sup_N \|T_N\|_{2,|w|^2} < \infty$. □

B. Product domains and enumerations of $\mathbb{Z} \times \mathbb{Z}$

The results of the preceding section readily extend to product domains. In fact, many related results are true more generally in the setting of singular integral operators and maximal functions on product domains, e.g., Refs. 58 and 59.

We let $L^1(\mathbb{T} \times \mathbb{T})$ denote the space of functions on $\mathbb{R}^2$ that are 1-periodic in each variable and integrable on $[0,1]^2$.

Definition 5.5 (product $\mathcal{A}_2$ weight): A non-negative function $w \in L^1(\mathbb{T} \times \mathbb{T})$ is an $\mathcal{A}_2(\mathbb{T} \times \mathbb{T})$ weight if there exists $C > 0$ such that for all intervals $I, J \subset \mathbb{R}$, we have

$$\left(\frac{1}{|I||J|}\int_J \int_I w(x,y)\,dx\,dy\right)\left(\frac{1}{|I||J|}\int_I \int_J \frac{1}{w(x,y)}\,dx\,dy\right) \leq C.$$

The above definition of product $\mathcal{A}_2$ weights is equivalent to requiring that w satisfies a uniform $\mathcal{A}_2$ condition in each variable, e.g., see Ref. 59, p. 15. More precisely, $w \in \mathcal{A}_2(\mathbb{T} \times \mathbb{T})$ if and only if for almost every $x \in \mathbb{T}$ and for every interval $J \subset \mathbb{R}$,

$$\left(\frac{1}{|J|}\int_J w(x,y)\,dy\right)\left(\frac{1}{|J|}\int_J \frac{1}{w(x,y)}\,dy\right) \leq C,$$

and likewise for the y variable. For perspective, recall that the product weights in $\mathcal{A}_2(\mathbb{T} \times \mathbb{T})$ differ from classical $\mathcal{A}_2(\mathbb{T}^2)$ weights in that they involve averages over rectangles instead of just squares.

For our purposes, formally define

$$T_{M,N} F = \sum_{m=-M}^{M} \sum_{n=-N}^{N} \langle F, E_{n,k}\rangle E_{n,k},$$

where $E_{n,k}(t,\xi) = e^{2\pi i n t} e^{-2\pi i k \xi}$ is as defined in (2.6).

Theorem 5.6: *Let* $w \in L^2(\mathbb{T} \times \mathbb{T})$ *be non-negative. Then the following statements are equivalent.*

(a) $\sup_{M,N} \|T_{M,N}\|_{2,w} < \infty$.
(b) $w \in \mathcal{A}_2(\mathbb{T} \times \mathbb{T})$.

Proof (b)⇒(a): This direction follows Ref. 58, p. 128. Assume that $w \in \mathcal{A}_2(\mathbb{T} \times \mathbb{T})$. Let

$T_N f=\Sigma_{n=-N}^{N}\langle f,e_n\rangle e_n$ be as defined in (5.2). Then since $w_t=w(t,\cdot)$ and $w^\xi=w(\cdot,\xi)$ satisfy uniform $\mathcal{A}_2$ conditions, we have by Theorem 5.3 that there exists a constant C such that for a.e. t and ξ we have

$$\int_0^1 |T_N f(\xi)|^2 w_t(\xi)d\xi \leqslant C\int_0^1 |f(\xi)|^2 w_t(\xi)d\xi, \quad f\in L^2_{w_t}(\mathbb{T}),$$

$$\int_0^1 |T_N f(t)|^2 w^\xi(t)dt \leqslant C\int_0^1 |f(t)|^2 w^\xi(t)dt, \quad f\in L^2_{w^\xi}(\mathbb{T}).$$

Choose any $F\in L^2_w(\mathbb{T}\times\mathbb{T})$. By Fubini's Theorem, $F_t=F(t,\cdot)\in L^2_{w_t}(\mathbb{T})$ and $F^\xi=F(\cdot,\xi)\in L^2_{w^\xi}(\mathbb{T})$ for a.e. t and ξ. Define

$$T_N^1 F(t,\xi)=T_N F^\xi(t)=\sum_{-N}^{N}\langle F^\xi,e_n\rangle e_n(t), \quad T_M^2 F(t,\xi)=T_M F_t(\xi)=\sum_{-N}^{N}\langle F_t,e_n\rangle e_n(\xi).$$

Then $T_{M,N}F=T_N^1 T_M^2 F$, so

$$\|T_{M,N}F\|_2^2=\int_0^1\int_0^1 |T_N^1 T_M^2 F(t,\xi)|^2 w(t,\xi)dt\,d\xi \leqslant C\int_0^1\int_0^1 |T_M^2 F(t,\xi)|^2 w(t,\xi)dt\,d\xi$$
$$\leqslant C^2\int_0^1\int_0^1 |F(t,\xi)|^2 w(t,\xi)d\xi\,dt=C^2\|F\|_{2,w}^2.$$

(a)$\Rightarrow$(b): This direction is similar to the proof of Theorem 8 in Ref. 54. Suppose that $C=\sup_{M,N}\|T_{M,N}\|_{2,w}<\infty$. Write

$$T_{M,N}F(t,\xi)=\int_0^1\int_0^1 F(u,\eta)D_N(t-u)D_M(\xi-\eta)du\,d\eta,$$

where

$$D_N(t)=\frac{\sin 2\pi\left(N+\frac{1}{2}\right)t}{\sin \pi t}.$$

Choose any rectangle $I\times J$. Without loss of generality, we may assume that $|I|$, $|J|$ are small, e.g., $|I|$, $|J|\leqslant\frac{1}{16}$. Choose any integer N such that $1/(32N)\leqslant|I|\leqslant 1/(16N)$. If t, $u\in I$ then $t-u\in I-I\subset[-1/(8N),1/(8N)]$, so

$$D_N(t-u)\geqslant D_N(1/(8N))\gtrsim N.$$

Similarly, choose M so that $1/(32M)\leqslant|J|\leqslant 1/(16M)$.

Let $H\geqslant 0$ be any non-negative 1-periodic function that is supported in the 1-periodic extension of $I\times J$. Then, for $(t,\xi)\in I\times J$ we have

$$|T_{M,N}(t,\xi)|=\int\int_{I\times J} H(u,\eta)D_N(t-u)D_M(\xi-\eta)du\,d\eta \gtrsim MN\int\int_{I\times J} H(u,\eta)du\,d\eta$$
$$\gtrsim\frac{1}{|I||J|}\int\int_{I\times J} H(u,\eta)du\,d\eta.$$

Consequently,

$$\frac{1}{|I|^2|J|^2}\left(\int\int_{I\times J} H\right)^2 \int\int_{I\times J} w(t,\xi)dt\,d\xi \lesssim \int\int_{I\times J} |T_{M,N}(t,\xi)|w(t,\xi)dt\,d\xi = \|T_{M,N}H\|_{2,w}^2 \lesssim \|H\|_{2,w}^2. \tag{5.4}$$

In particular, if H is the 1-periodic extension of $(1/w)\mathbf{1}_{I\times J}$, then $\|H\|_{2,w}^2 = \int\int_{I\times J}(1/w)$, so

$$\left(\frac{1}{|I||J|}\int\int_{I\times J}\frac{1}{w}\right)\left(\frac{1}{|I||J|}\int\int_{I\times J} w\right)\left(\int\int_{I\times J}\frac{1}{w}\right) \lesssim \left(\int\int_{I\times J}\frac{1}{w}\right).$$

Consequently, if $0<\int\int_{I\times J}(1/w)<\infty$, then we conclude that

$$\left(\frac{1}{|I||J|}\int\int_{I\times J}\frac{1}{w}\right)\left(\frac{1}{|I||J|}\int\int_{I\times J} w\right) \lesssim 1. \tag{5.5}$$

This estimate also follows trivially if $\int\int_{I\times J}(1/w)=0$. So, it only remains to consider the case $\int\int_{I\times J}(1/w)=\infty$. In this case there must be some $F\in L^2(I\times J)$ such that $F/w^{1/2}\notin L^1(I\times J)$. Set $H=|F|/w^{1/2}$. Then $\int\int_{I\times J}H=\infty$, while $\|H\|_{2,w}=\|F\|_2$ is finite. Equation (5.4) therefore implies that $\int\int_{I\times J}w=0$, and hence (5.5) holds trivially in this case as well. Therefore $w\in\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$. □

Corollary 5.7: Let $W\in L^2(\mathbb{T}\times\mathbb{T})$ be nonzero a.e., and define $\widetilde{W}=1/\overline{W}$. For M, $N\geqslant 0$ let $S_{M,N}:L^2(\mathbb{T}\times\mathbb{T})\to L^2(\mathbb{T}\times\mathbb{T})$ be the operator formally defined by

$$S_{M,N}F = \sum_{n=-N}^{N}\sum_{m=-M}^{M}\langle F, E_{n,k}\cdot\widetilde{W}\rangle(E_{n,k}\cdot W), \tag{5.6}$$

and let $\|S_{M,N}\|$ denote its operator norm. Then the following statements are equivalent.

(a) $\sup_{M,N}\|S_{M,N}\|<\infty$.
(b) $|W|^2\in\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$.

Proof: Using Theorem 5.6, the proof is similar to that of Corollary 5.4. □

It will be convenient to work with the following set of enumerations of $\mathbb{Z}\times\mathbb{Z}$, which are well suited for dealing with rectangular partial sums.

Definition 5.8: Let Λ be the set containing all enumerations $\{(k_j,n_j)\}_{j=1}^{\infty}$ of $\mathbb{Z}\times\mathbb{Z}$ constructed in the following recursive manner.

(a) The initial terms $(k_1,n_1),\ldots,(k_{J_1},n_{J_1})$ are either

$$(0,0),(1,0),(-1,0),\ldots,(A_1,0),(-A_1,0)$$

or

$$(0,0),(0,1),(0,-1),\ldots,(0,B_1),(0,-B_1),$$

for some positive integers A_1 or B_1.

(b) If $\{(k_j,n_j)\}_{j=1}^{J_k}$ has been constructed to be of the product form $\{-A_k,\ldots,A_k\}\times\{-B_k,\ldots,B_k\}$ for some non-negative integers A_k,B_k, then terms are added to either the top and bottom or the left and right sides to obtain either the rectangle

$$\{-A_k,\ldots,A_k\}\times\{-(B_k+1),\ldots,B_k+1\}$$

or

$$\{-(A_k+1),\ldots,A_k+1\}\times\{-B_k,\ldots,B_k\}.$$

For example, terms would first be added to the top ordered as

$$(0,B_k+1),(1,B_k+1),(-1,B_k+1),\ldots,(A_k,B_k+1),(-A_k,B_k+1),$$

and then likewise for the bottom. The left and right sides proceed analogously.

Corollary 5.9: Suppose $W\in L^2(\mathbb{T}\times\mathbb{T})$ *is such that* $\widetilde{W}=1/\overline{W}\in L^2(\mathbb{T}\times\mathbb{T})$. *For each enumeration* $\sigma=\{(k_j,n_j)\}_{j=1}^{\infty}\in\Lambda$, *let* $S_N^\sigma: L^2(\mathbb{T}\times\mathbb{T})\to L^2(\mathbb{T}\times\mathbb{T})$ *be the operator formally defined by*

$$S_N^\sigma F=\sum_{j=1}^{N}\langle F,E_{n_j,k_j}\cdot\widetilde{W}\rangle(E_{n_j,k_j}\cdot W),$$

and let $\|S_N^\sigma\|$ *denote its operator norm. Then the following statements are equivalent.*

(a) $\sup_{N,\sigma}\|S_N^\sigma\|<\infty$.
(b) $|W|^2\in\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$.

Proof (a)⇒(b): Assume that $\sup_{N,\sigma}\|S_N^\sigma\|<\infty$. By the definition of Λ, it follows that $\sup_{M,N}\|S_{M,N}\|<\infty$, with $S_{M,N}$ as in (5.6). By Corollary 5.7 we conclude that $|W|^2\in\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$.

(b)⇒(a): Assume that $|W|^2\in\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$. Then, by definition, we have that $A=\|W\|_2\|\widetilde{W}\|_2<\infty$, and by Corollary 5.7 we have that $C=\sup_{M,N}\|S_{M,N}\|<\infty$.

Choose any enumeration $\sigma\in\Lambda$ and any positive integer N. Let M_N be the largest integer $M_N<N$ for which $S_{M_N}^\sigma F=S_{J,K}F$ for some integers J, K. Note that

$$\|S_N^\sigma F\|_2\leq\|S_{J,K}F\|_2+\|(S_N^\sigma-S_{M_N}^\sigma)F\|_2\leq C\|F\|_2+\|(S_N^\sigma-S_{M_N}^\sigma)F\|_2.$$

Thus we must estimate the norm of

$$(S_N^\sigma-S_{M_N}^\sigma)F=\sum_{j=M_N+1}^{N}\langle F,E_{n_j,k_j}\cdot\widetilde{W}\rangle(E_{n_j,k_j}\cdot W).\tag{5.7}$$

This series corresponds to terms that have been added to a rectangle according to the algorithm given in Definition 5.8. For example, if terms have been added to the top of the rectangle, then (5.7) has one of the following two forms:

$$\sum_{n=-L}^{L}\langle F,E_{n,K+1}\cdot\widetilde{W}\rangle(E_{n,K+1}\cdot W)\quad\text{or}\quad\sum_{n=-L}^{L+1}\langle F,E_{n,K+1}\cdot\widetilde{W}\rangle(E_{n,K+1}\cdot W).\tag{5.8}$$

The first sum is bounded by

$$\left\|\sum_{n=-L}^{L}\langle F,E_{n,K+1}\cdot\widetilde{W}\rangle(E_{n,K+1}\cdot W)\right\|_2=\left\|\sum_{n=-L}^{L}\langle F\cdot E_{0,-K-1},E_{n,0}\cdot\widetilde{W}\rangle(E_{n,0}\cdot W)\right\|_2=\|S_{L,0}(F\cdot E_{0,-K-1})\|_2$$
$$\leq C\|F\cdot E_{0,-K-1}\|_2=C\|F\|_2.\tag{5.9}$$

The second sum in (5.8) is bounded by

$$\left\|\sum_{n=-L}^{L+1}\langle F,E_{n,K+1}\cdot\widetilde{W}\rangle(E_{n,K+1}\cdot W)\right\|_2\leq\left\|\sum_{n=-L}^{L}\langle F,E_{n,K+1}\cdot\widetilde{W}\rangle(E_{n,K+1}\cdot W)\right\|_2+|\langle F,E_{L+1,K+1}\cdot\widetilde{W}\rangle|$$
$$\times\|E_{L+1,K+1}\cdot W\|_2\leq C\|F\|_2+A\|F\|_2.\tag{5.10}$$

Substituting each of (5.9) and (5.10) into (5.7), we conclude that for this case we have $\|S_N^\sigma F\|_2\leq(2C+A)\|F\|_2$. The same estimate applies if terms have been added only to the bottom, left, or right of the rectangle. If terms have been added either to both the top and bottom, or to both the left and right sides of the rectangle, then we end with the estimate $\|S_N^\sigma F\|_2\leq(3C+2A)\|F\|_2$. In any case, we conclude that $\sup_{N,\sigma}\|S_N^\sigma\|\leq(3C+2A)<\infty$. □

C. A Zak transform characterization of Gabor Schauder bases

Using the machinery that we have developed in the previous sections, we can now give a simple Zak transform characterization of lattice Gabor Schauder bases for $L^2(\mathbb{R})$. We then construct examples of Gabor Schauder bases that have interesting properties.

Note that while Z_g has a natural quasiperiodic extension from $[0,1)^2$ to $\mathbb{R}^2$, the definition of $\mathcal{A}_2$ weight only depends on the absolute value of the weight, and $|Zg|$ is 1-periodic in each variable.

Theorem 5.10: *Let $g \in L^2(\mathbb{R})$ be given. Then the following statements are equivalent.*

(a) *The Gabor system $\mathcal{G}(g,1,1)$ is a Schauder basis for $L^2(\mathbb{R})$ with respect to every enumeration $\sigma=\{(k_j,n_j)\}_{j=1}^{\infty} \in \Lambda$. Further, if C_σ is the basis constant associated to the enumeration σ, then $\sup_{\sigma\in\Lambda} C_\sigma < \infty$.*
(b) $|Zg|^2 \in \mathcal{A}_2(\mathbb{T}\times\mathbb{T})$.

Proof (a)$\Rightarrow$(b): Suppose that statement (a) holds. Then by Lemma 5.1 we have that $1/Zg \in L^2(\mathbb{T}\times\mathbb{T})$. Further, by hypothesis, $\sup_{N,\sigma}\|S_N^\sigma\| \leqslant \sup_{\sigma\in\Lambda} C_\sigma < \infty$, so Corollary 5.9 implies that $|Zg|^2 \in \mathcal{A}_2(\mathbb{T}\times\mathbb{T})$.

(b)$\Rightarrow$(a): Assume $|Zg|^2 \in \mathcal{A}_2(\mathbb{T}\times\mathbb{T})$. Then, by definition of $\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$, we have that $1/Zg \in L^2(\mathbb{T}\times\mathbb{T})$. Further, we have by Corollary 5.9 that $\sup_{N,\sigma}\|S_N^\sigma\| < \infty$. Lemma 5.1 therefore implies that $\mathcal{G}(g,1,1)$ is a Schauder basis with respect to each $\sigma \in \Lambda$. □

While Theorem 5.10 implies that if $|Zg|^2 \in \mathcal{A}_2(\mathbb{T}\times\mathbb{T})$ then $\mathcal{G}(g,1,1)$ is a Schauder basis with respect to every enumeration $\sigma \in \Lambda$, this does not imply that it is a Schauder basis with respect to every possible enumeration of $\mathbb{Z}\times\mathbb{Z}$, since that would imply that $\mathcal{G}(g,1,1)$ is a Riesz basis. In fact, by Theorem 2.8, the Riesz bases correspond to the subclass of weights in $\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$ that are essentially bounded, i.e., bounded away from zero and infinity. The following example is inspired by Babenko's example from Ref. 60; cf. Ref. 36, Example 11.2, pp. 351–354, and gives examples of Gabor Schauder bases that are not Riesz bases.

Example 5.11. Fix $0<\alpha<1/2$. Assume that $g=g_\alpha \in L^2(\mathbb{R})$ satisfies the following:

(a) g is real-valued;
(b) $\mathrm{supp}(g) \subseteq [0,1]$;
(c) g is infinitely differentiable on every subinterval $(\delta, 1-\delta)$, $0<\delta<1/2$;
(d) $g(t)=t^\alpha$ on $[0,1/4]$;
(e) $g(t)=(1-t)^\alpha$ on $[3/4,1]$;
(f) $g(t-1/2)$ is even;
(g) $g(t) \geqslant C>0$ for $1/4<t<3/4$.

Since g is supported in [0,1], a direct calculation shows that $|Zg(t,\xi)|^2=|g(t)|^2 \in \mathcal{A}_2(\mathbb{T}\times\mathbb{T})$. Therefore, Theorem 5.10 implies that $\mathcal{G}(g,1,1)$ is a Schauder basis for $L^2(\mathbb{R})$ with respect to every enumeration $\sigma \in \Lambda$. However, since $|Zg|$ is not bounded away from zero, Theorem 2.8 implies that $\mathcal{G}(g,1,1)$ is not a Riesz basis for $L^2(\mathbb{R})$.

We make some additional remarks concerning the windows constructed in Example 5.11. Note that since Zg is bounded, $\mathcal{G}(g,1,1)$ is a Bessel sequence, i.e., it has an upper frame bound. Since g is supported in [0,1], the dual window is easily seen to be the function that is $\widetilde{g}=1/\overline{g}$ on [0,1] and zero elsewhere. The dual basis $\mathcal{G}(\widetilde{g},1,1)$ possesses a lower frame bound but not an upper frame bound (compare Theorem 7.1).

Theorem 5.10 allows one to generate other interesting examples. Building on Example 5.11, the following example provides a Gabor Schauder basis that has neither an upper frame bound nor a lower frame bound. In other words, e.g., Ref. 36, this Gabor Schauder basis is neither Besselian nor Hilbertian.

Example 5.12: Fix $0<\alpha<1/2$ and let $g=g_\alpha$ be the function from Example 5.11. Define

$$f(t)=\begin{cases} g(2t), & \text{if } 0\leqslant t\leqslant 1/2,\\ \dfrac{1}{g(2t-1)}, & \text{if } 1/2<t<1,\\ 0, & \text{if } t\notin[0,1). \end{cases}$$

As in Example 5.11, we have that $Zf(t,\xi)=f(t)$ for $(t,\xi)\in Q$. Further, Zf, $1/Zf\in L^2(\mathbb{R})$, so we at least have that $\mathcal{G}(f,1,1)$ is complete and minimal. However, one can check that $|Zf|^2\in \mathcal{A}_2(\mathbb{T}\times\mathbb{T})$, so, in fact, we have that $\mathcal{G}(f,1,1)$ is a Schauder basis with respect to every enumeration $\sigma\in\Lambda$. However, since $|Zg|$ is not bounded away from zero or infinity, we conclude that $\mathcal{G}(f,1,1)$ has neither an upper frame nor a lower frame bound.

For perspective, note that $f\notin M^1(\mathbb{R})$ since any Gabor system generated by a window in $M^1(\mathbb{R})$ is a Bessel sequence, Ref. 1, Theorem 12.2.3. By contrast, we shall later prove (see Theorem 6.1) that the example g from Example 5.11 does belong to $M^1(\mathbb{R})$.

Example 5.13: The two preceding examples were both compactly supported. However, we can easily create noncompactly supported examples. For example, since the Fourier transform is unitary, if g is one of the functions constructed in Example 5.11 or 5.12, then $\mathcal{G}(\hat{g},1,1)$ is a Gabor Schauder basis with respect to every enumeration in Λ, but it is not a Riesz basis, and $\hat{g}$ is not compactly supported.

We can also work directly in the Zak transform domain. Again, let g be any function constructed in Example 5.11 or 5.12, and let h be any function supported in $[0,1]$ such that $|h|^2\in\mathcal{A}_2(\mathbb{T})$. Then $G(t,\xi)=g(t)h(\xi)$ is such that $|G|^2\in\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$. Hence $f=Z^{-1}G\in L^2(\mathbb{R})$, and, for every enumeration in Λ, $\mathcal{G}(f,1,1)$ is a Gabor Schauder basis that is not a Riesz basis. By definition of the Zak transform, if h is not a trigonometric polynomial, then f cannot be compactly supported.

In general, while every Schauder basis is complete and minimal, the converse need not be true. If $\varphi(t)=e^{-t^2}$, then we know that a proper subset of $\mathcal{G}(\varphi,1,1)$ is complete and minimal but is not a Schauder basis. The following example shows that it is possible for a lattice Gabor system $\mathcal{G}(g,1,1)$ (not just a subset) to be complete and minimal yet not form a Schauder basis for $L^2(\mathbb{R})$.

Example 5.14: For $n=1,2,3,\ldots$, set $A_n=(3/2)^{n/2}$ and $B_n=(2/3)^{n/2}$. Define disjoint intervals,

$$L_n=[1-2^{-n+1},1-2^{-n}-2^{-n-1}],\quad R_n=[1-2^{-n}-2^{-n-1},1-2^{-n}],$$

and set $I_n=L_n\cup R_n$. Then $|I_n|=2^{-n}=2|R_n|=2|L_n|$ and $\cup_{n=1}^{\infty}I_n=[0,1)$. For $t\in\mathbb{R}$, let g be the following non-negative function supported in $[0,1]$:

$$g=\sum_{n=1}^{\infty}(A_n\mathbf{1}_{L_n}+B_n\mathbf{1}_{R_n}).$$

We compute that

$$\int_0^1|g(t)|^2\,dt=\frac{1}{2}\sum_{n=1}^{\infty}|I_n|(A_n^2+B_n^2)=\frac{1}{2}\sum_{n=1}^{\infty}2^{-n}\left(\left(\frac{3}{2}\right)^n+\left(\frac{2}{3}\right)^n\right)<\infty,$$

and

$$\int_0^1\frac{1}{|g(t)|^2}dt=\frac{1}{2}\sum_{n=1}^{\infty}|I_n|\left(\frac{1}{A_n^2}+\frac{1}{B_n^2}\right)=\int_0^1|g(t)|^2\,dt<\infty.$$

Further, since g is supported in $[0,1]$, we have that $|Zg(t,\xi)|=g(t)$ for $(t,\xi)\in Q$. Therefore Zg, $1/Zg\in L^2(Q)$, so by Theorem 2.8, $\mathcal{G}(g,1,1)$ is complete and minimal in $L^2(\mathbb{R})$.

Next, note that

$$\left(\frac{1}{|I_n|}\int_{I_n}|g(t)|^2\,dt\right)\left(\frac{1}{|I_n|}\int_{I_n}\frac{1}{|g(t)|^2}dt\right)=\frac{1}{4}(A_n^2+B_n^2)\left(\frac{1}{A_n^2}+\frac{1}{B_n^2}\right)=\frac{1}{4}\left(2+\left(\frac{9}{4}\right)^n+\left(\frac{4}{9}\right)^n\right).$$

Letting $n\to\infty$, we see that $|Zg|^2\notin\mathcal{A}_2(\mathbb{T}\times\mathbb{T})$. Therefore, by Theorem 5.10 there exists at least one enumeration $\sigma\in\Lambda$ with respect to which the Gabor system $\mathcal{G}(g,1,1)$ is not a Schauder basis for $L^2(\mathbb{R})$.

VI. COUNTEREXAMPLES TO THE BALIAN-LOW THEOREMS FOR GABOR SCHAUDER BASES

In this section we investigate the extent to which the variants of the Balian-Low Theorem hold in the setting of Schauder bases. It was conjectured in Ref. 31 that if hypothesis (a) of Theorem 3.2 holds, then the conclusion of that theorem remains true if the words "Riesz basis" are replaced by "Schauder basis." In other words, it was conjectured that there do not exist any Gabor Schauder bases whose window function belongs to $M^1(\mathbb{R})$. We will provide counterexamples to that conjecture in this section. Moreover, our counterexamples apply to each of the four hypotheses appearing in Theorem 3.2.

Theorem 6.1: *The conclusion of Theorem 3.2 is false if the words* "Riesz basis" *are replaced by* "Schauder basis."

Specifically, if $g=g_\alpha$ *with* $0<\alpha<1/2$ *is one of the functions constructed in Example 5.11, then* $\mathcal{G}(g,1,1)$ *is a Schauder basis for* $L^2(\mathbb{R})$ *with respect to any enumeration* $\sigma\in\Lambda$, *but it is not a Riesz basis for* $L^2(\mathbb{R})$. *Further, the following statements hold.*

(a) $g\in M^1(\mathbb{R})$.
(b) $g,\ \hat{g}\in W(\mathcal{C},\ell^1)$.
(c) *If* $1<q<2<p<\infty$, $1/p+1/q=1$, $0<\varepsilon<2-q$, *and* $(q+\varepsilon-1)/2<\alpha$, *then*

$$\int|t|^{p+\varepsilon}|g(t)|^2\,dt<\infty\quad\text{and}\quad\int|\xi|^{q+\varepsilon}|\hat{g}(\xi)|^2\,d\xi<\infty.$$

(d) $\sup_{N>0}\int|t|^N|g(t)|^2dt<\infty$ *and* $\int|\xi||\hat{g}(\xi)|^2\,d\xi<\infty$.

Proof: (c) Assume that p, q, ε, and α satisfy the given conditions, and define

$$I_{p+\varepsilon}(g)=\int|t|^{p+\varepsilon}|g(t)|^2\,dt\quad\text{and}\quad I_{q+\varepsilon}(\hat{g})=\int|\xi|^{q+\varepsilon}|\hat{g}(\xi)|^2\,d\xi.\tag{6.1}$$

Since g is continuous and compactly supported, we certainly have that $I_{p+\varepsilon}(g)<\infty$. Therefore, we just have to show that $I_{q+\varepsilon}(\hat{g})<\infty$.

Let φ be a $C^\infty(\mathbb{R})$ function that equals 1 on $[-2\nu,2\nu]$ and is supported in $[-3\nu,3\nu]$ for some sufficiently small fixed $\nu>0$. Let ψ be a $C^\infty(\mathbb{R})$ function that equals 1 on $[3\nu,1-3\nu]$ and is compactly supported in $[2\nu,1-2\nu]$. Finally, suppose that the partition of unity property $\varphi(t)+\psi(t)+\varphi(t-1)=1$ holds for all $t\in[0,1]$. Since $\psi(t)g(t)$ is $C^\infty(\mathbb{R})$ and is compactly supported, it suffices to show that $I_{q+\varepsilon}(\hat{h}_1)<\infty$ and that $I_{q+\varepsilon}(\hat{h}_2)<\infty$, where $h_1(t)=\varphi(t)g(t)$ and $h_2(t)=\varphi(t-1)g(t)$. Both estimates are similar, so we only prove the estimate for $h=h_1$.

To estimate $I_q(h)$, we use Ref. 61, Proposition 4, p. 139, which implies that for any $0<s<1$ there exists $0<C_s$ such that

$$\int|\xi|^{2s}|\hat{h}(\xi)|^2\,d\xi=C_s\int\int\frac{|h(x+t)-h(x)|^2}{|t|^{1+2s}}dx\,dt.$$

Begin by noting that

$$\int_{\mathbb{R}\setminus[-\nu,\nu]} \int \frac{|h(x+t)-h(x)|^2}{|t|^{1+q+\varepsilon}} dx\, dt \lesssim \int_{\mathbb{R}\setminus[-\nu,\nu]} \frac{\|h\|_2^2}{|t|^{1+q+\varepsilon}} dt < \infty.$$

It remains to estimate the analogous two integrals over the domains $[0,\nu]\times\mathbb{R}$ and $[-\nu,0]\times\mathbb{R}$. Since both proceed similarly, we shall only show the estimates for the first of these, which we, in turn, break up into the following integrals:

$$J_1 = \int_0^\nu \int_{-\infty}^{-t}, \quad J_2 = \int_0^\nu \int_{-t}^{t}, \quad J_3 = \int_0^\nu \int_t^\nu, \quad J_4 = \int_0^\nu \int_\nu^{3\nu}, \quad J_5 = \int_0^\nu \int_{3\nu}^\infty.$$

Since h is supported on $[0,3\nu]$, it follows that $J_1=J_5=0$.

Note that since $q+\varepsilon-2\alpha<1$, we have

$$J_2 \lesssim \int_0^\nu \frac{1}{t^{q+\varepsilon+1}} \int_0^{2t} |h(x)|^2\, dx\, dt = \int_0^\nu \int_0^{2t} \frac{x^{2\alpha}}{t^{q+\varepsilon+1}} dx\, dt \lesssim \int_0^\nu \frac{t^{2\alpha+1}}{t^{q+\varepsilon+1}} dt < \infty.$$

Next, since $|(x+t)^\alpha - x^\alpha| \lesssim \alpha t x^{\alpha-1}$ for all $0<x$, t, we have that

$$J_3 \lesssim \int_0^\nu \int_t^\nu \frac{t^2 x^{2\alpha-2}}{t^{q+\varepsilon+1}} dx\, dt \lesssim \int_0^\nu \frac{t^{2\alpha+1}}{t^{q+\varepsilon+1}} dt < \infty.$$

Finally, the smoothness properties of h on $[\nu,\infty)$ and the Mean Value Theorem imply that if $x+t$ and x are both greater than ν then $|h(x+t)-h(x)| \lesssim |t|$. Therefore, since $q+\varepsilon<2$,

$$J_4 \lesssim \int_0^\nu \int_\nu^{3\nu} \frac{t^2}{|t|^{q+\varepsilon+1}} dx\, dt = \int_0^\nu \frac{1}{t^{q+\varepsilon-1}} dt < \infty,$$

which completes the proof.

(d) The estimates in the proof of part (c) together with the fact that g is compactly supported in $[0,1]$ yields the result.

(a) This follows from part (c) and the following modulation space embedding of Gröchenig:[52] If $1/p+1/q=1$, $1<p,q,<\infty$, and $0<\varepsilon$, then

$$\|g\|_{M^1} \lesssim \left(\int |t|^{p+\varepsilon} |g(t)|^2\, dt \right)^{1/2} + \left(\int |\xi|^{q+\varepsilon} |\hat{g}(\xi)|^2\, d\xi \right)^{1/2}.$$

(b) By part (a), we have $g \in M^1(\mathbb{R}) \subset W(\mathcal{C},\ell^1)$. Since $M^1(\mathbb{R})$ is invariant under the Fourier transform, we also have $\hat{g} \in M^1(\mathbb{R}) \subset W(\mathcal{C},\ell^1)$.

Note that the integrals in (6.1) are also finite when $\varepsilon=0$.

VII. WEAK BLT's FOR GABOR SCHAUDER BASES

We close by proving some new Weak BLTs for exact Gabor systems, including Gabor Schauder bases, in particular. Parts (a) and (b) of the following theorem can be, respectively, viewed as weak versions of the M^1 BLT and Amalgam BLT in the setting of exact Gabor systems.

Theorem 7.1 (weak BLTs for exact Gabor systems): *Let $g \in L^2(\mathbb{R})$ be such that $\mathcal{G}(g,1,1)$ is exact in $L^2(\mathbb{R})$ and let $\widetilde{g}=Z^{-1}(1/\overline{Zg})$ be the dual window.*

(a) *If $g \in M^1(\mathbb{R})$ then $\widetilde{g} \notin M^1(\mathbb{R})$.*
(b) *If $g \in W(\mathcal{C},\ell^1)$ then $\widetilde{g} \notin W(\mathcal{C},\ell^1)$.*
(c) *If $\mathcal{G}(g,1,1)$ is a Bessel sequence, then $\mathcal{G}(\widetilde{g},1,1)$ is Bessel if and only if $\mathcal{G}(g,1,1)$ is a Riesz basis.*

Proof: (b) If $g \in W(\mathcal{C},\ell^1)$, then Zg has a continuous extension to all of $\mathbb{R}^2$ by Ref. 19, Theorem 3.2. But the quasiperiodicity of Zg then forces Zg to have a zero.[1] Hence $Z\widetilde{g}=1/\overline{Zg}$ is not continuous, so $\widetilde{g} \notin W(\mathcal{C},\ell^1)$.

(a) This follows immediately from part (b) and the fact that $M^1(\mathbb{R}) \subset W(\mathcal{C}, \ell^1)$.

(c) This follows from Theorem 2.5(e). □

Remark 7.2: In Ref. 18, Daubechies and Janssen proved that (in equivalent modulation space terminology) if $g \in M^2_2(\mathbb{R})$, then $\mathcal{G}(g,1,1)$ is not exact. Hence, if $\mathcal{G}(g,1,1)$ is to be a Schauder basis and $g \in M^2_s(\mathbb{R})$, then we must have $0<s<2$. For $1<s<2$ we will have $g \in M^2_s(\mathbb{R}) \subset M^1(\mathbb{R})$, and hence $\widetilde{g} \notin M^1(\mathbb{R})$.

In particular, the function $g=g_\alpha$ constructed in Example 5.11 can be shown to lie in $M^2_s(\mathbb{R})$ for $0<s<1$. While this does not imply that $g \in M^1(\mathbb{R})$, the stronger embeddings of Gröchenig[52] imply that $g \in M^1(\mathbb{R})$.

Noncommutative geometry, topology, and the standard model vacuum

R. A. Dawe Martins[a)]
Nottingham University, University Park, Nottingham NG7 2RD, United Kingdom

(Received 2 January 2006; accepted 4 October 2006; published online 22 November 2006)

As a ramification of a motivational discussion for previous joint work, in which equations of motion for the finite spectral action of the standard model were derived, we provide a new analysis of the results of the calculations therein, switching from the perspective of spectral triple to that of Fredholm module and thus from the analogy with Riemannian geometry to the premetrical structure of the noncommutative geometry. Using a suggested noncommutative version of Morse theory together with algebraic K theory to analyze the vacuum solutions, the first two summands of the algebra for the finite triple of the standard model arise up to Morita equivalence. We also demonstrate a new vacuum solution whose features are compatible with the physical mass matrix. © *2006 American Institute of Physics.*

I. INTRODUCTION

This article is a continuation of previous work joint with Barrett and Dawe Martins[1] in which field equations were calculated for the full set of internal space metric fluctuations allowed by the noncommutative geometry axioms in the spectral triple formulation of the standard model. We begin with a development of the discussion begun in the previous work and then provide a new analysis of the results of the calculations therein from the perspective of Fredholm module instead of spectral triple. Studying these Fredholm modules using algebraic K theory and K homology leads to a suggested noncommutative version of Morse theory—a well-known tool for studying the topology of manifolds—which is applied to the finite spectral action.

As this work ramifies from Ref. 1, for this article to make sense it is necessary to give an explanation of the key concepts of the previous work before the main analysis in this article can begin. Furthermore, discussion given in the previous work is brief and so one of the purposes of this article is to explain how it highlights an open question about the noncommutative framework. This explanation leads into a detailed introduction to the main analysis given at the beginning of the main section, entitled "Fredholm module solutions."

II. CONTEXT

More details about the tools and formalisms referred to below are provided in Sec. III.

The context of Ref. 1 and this its "second chapter," is on the spectral action principle by Connes and Chamseddine,[2] where the standard model is formulated with a product (whose image is called the total space) of two spectral triples—one that represents the Euclidean space-time manifold and the other the zero-dimensional internal space of particle charges. The space-time coordinate functions remain commutative but the internal space is a noncommutative "manifold." The spectral action principle is an important step towards the unification of gravity with particle physics; the Einstein–Hilbert action plus Weinberg–Glashow–Salam theory all result from a cal-

[a)]Present address: Departamento de Matemática, Instituto Superior Técnico, Av. Rovisco Pais, 1049-001 Lisboa, Portugal; electronic mail: rmartins@math.ist.utl.pt

culation of the eigenvalues of the Dirac operator on the total space and since the Dirac operator encodes the metric, the spectral action principle is a purely geometrical theory.

The scope of this study involves irreducible finite real spectral triples over the complex numbers; irreducible in the sense that there is no proper invariant subspace of the Hilbert space for which the triple restricted to that space is itself a (nondegenerate) triple.[3] For example, the standard model finite triple of three fermion families is reducible whereas the one family triple is irreducible. By finite, we mean a finite dimensional Hilbert space over a semisimple algebra. A caveat is that calculations carried out in this and the previous article apply only in the context of these zero-dimensional geometries with Euclidean signature. This means that at present, no direct physical inference can be made.

Currently concerned with the internal space triple by itself and not the full standard model tensor product triple, we consider a single point of space time: we remove all terms that do not depend solely on the fluctuations of the internal space Dirac operator D_F. The finite spectral action corresponds to the Higgs potential: $\mathrm{Tr}(D_F^4 - 2D_F^2)$.

The extra Einstein's equations for internal space were calculated by Schücker *et al.*[3,17] (for one generation of elementary fermions) by minimizing the Higgs potential with respect to the "fluctuated Dirac operator."[4] They found that the standard model Dirac operator was a solution. The construction of the fluctuated Dirac operator is carried out by beginning with a choice of initial Dirac operator (to correspond to the standard model fermion mass matrix) to satisfy the noncommutative geometry axioms, and in analogy with the equivalence principle, fluctuating it with the standard model's internal space algebra of coordinates. In this way, the Higgs force is treated as an internal space version of gravity.

III. BACKGROUND

A. Standard model finite spectral triple

A spectral triple $(\mathcal{A},\mathcal{H},\mathcal{D})$ provides the analog of a Riemannian (note: Riemannian not pseudo-Riemannian; applications are to Euclidean not Lorentzian space times) spin manifold to noncommutative geometry.[4,5] It consists of a involutive, not necessarily commutative algebra $\mathcal{A}$, a Hilbert space $\mathcal{H}$: a finitely generated projective module, on which the algebra is represented, and a Dirac operator $\mathcal{D}$ that gives a notion of distance, and from which is built a differential algebra.

The geometry of any closed (even dimensional) Riemannian spin manifold can be fully described by a (real and even) spectral triple (according to the reconstruction theorem) and a noncommutative geometry is essentially the same structure but with the generalization that the algebra of coordinates are allowed to be noncommuting.[6,7]

For the standard model the internal Hilbert space is: $\mathcal{H}=\mathcal{H}_L\oplus\mathcal{H}_R\oplus\mathcal{H}_L^c\oplus\mathcal{H}_R^c$, where

$$\mathcal{H}_L = (\mathbb{C}^2\otimes\mathbb{C}^N\otimes\mathbb{C}^3)\oplus(\mathbb{C}^2\otimes\mathbb{C}^N),$$

$$\mathcal{H}_R = ((\mathbb{C}\oplus\mathbb{C})\otimes\mathbb{C}^N\otimes\mathbb{C}^3)\oplus(\mathbb{C}\otimes\mathbb{C}^N)$$

and whose basis is labeled by the elementary fermions and their antiparticles.[8] The symbol c is used to indicate the section represented by the antiparticles. The even triple has the $\mathbb{Z}$/two-grading operator χ, the chirality (eigenvalues $+1$ or -1). In either case of $\mathcal{H}_L$ and $\mathcal{H}_R$, the first direct summand is the quarks and the second, the leptons. N stands for the number of generations. For example, the left-handed up and down quarks form an isospin doublet and their right-handed counterparts are singlets and there are three colors for quarks and none for leptons. The charges on the particles are identified by the faithful representation of the algebra on the Hilbert space.

In the definition of $\mathcal{H}$ above we see a second $\mathbb{Z}$/two-grading that splits the Hilbert space into two orthogonal subspaces for particles and antiparticles: $\mathcal{H}^+\oplus\mathcal{H}^-$ or $\mathcal{H}\oplus\mathcal{H}^c$.[9] This is called S^o reality and is not an axiom but applies to the standard model as it excludes Majorana masses. The S^o reality grading operator ϵ satisfies: $[\mathcal{D},\epsilon]=0$, $[J,\epsilon]_+=0$, $\epsilon^*=\epsilon$, $\epsilon^2=1$. (Compare with reality operator J explanation below.)

Let D_F denote the Dirac operator that acts on the finite dimensional internal Hilbert space; it is the internal space counterpart of the Dirac operator that acts on space time. D_F is a matrix whose parameters are given by the Higgs field, Cabbibo–Kobayashi–Maskawa family mixing matrix and the Yukawa couplings.[2] In other words, it provides the fermion mass matrix.

The *choice* made for D_F in order that the spectral action principle reproduces the standard model is

$$D_F = \begin{pmatrix} 0 & M^* & 0 & 0 \\ M & 0 & 0 & 0 \\ 0 & 0 & 0 & M^T \\ 0 & 0 & \overline{M} & 0 \end{pmatrix} \tag{1}$$

with basis left, right, then antiparticles left and right. $M = M_Q \otimes 1_3 \oplus M_L$, and

$$M_Q = \begin{pmatrix} k_u \phi_1 & k_d \phi_2 \\ -k_u \bar{\phi}_2 & k_d \bar{\phi}_1 \end{pmatrix},$$

$$M_L = \begin{pmatrix} k_e \phi_1 & k_e \phi_2 \\ 0 & 0 \end{pmatrix}.$$

(An extra row is added to M_L here so that the matrices are square, this is not normally done and relative to other literature, the labeling M is swapped with M^*.) with

$$k_u = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_c & 0 \\ 0 & 0 & m_t \end{pmatrix} \quad k_d = V_{\mathrm{CKM}} \begin{pmatrix} m_d & 0 & 0 \\ 0 & m_s & 0 \\ 0 & 0 & m_b \end{pmatrix}$$

$$k_e = \begin{pmatrix} m_e & 0 & 0 \\ 0 & m_\mu & 0 \\ 0 & 0 & m_\tau \end{pmatrix}.$$

T denotes transposition, * denotes hermitian conjugation, the bar denotes complex conjugation, m_x are the Yukawa couplings of the elementary fermions, V_{CKM} is the Cabibbo–Kobayashi–Maskawa generation mixing matrix. $(\phi_1, \phi_2)^T$ is the (Higgs) scalar doublet.

The finite spectral action corresponds to the Higgs potential: $\mathrm{Tr}(D_F^4 - 2D_F^2)$. If the $\mathrm{Tr}(I)$ term is included,[2] which obviously does not affect the equations of motion, then the action can be written $\mathrm{Tr}(MM^* - I)^2$.

The spectral triple algebra $\mathcal{A}$ is a subalgebra of the bounded operators on the Hilbert space, it is a *-algebra not necessarily a C^*-algebra but its norm closure in the Hilbert space is a C^*-algebra. The standard model tensor product algebra is "almost commutative"

$$\mathcal{A} = C^\infty(M) \otimes (\mathbb{H} \oplus \mathbb{C} \oplus M_3(\mathbb{C})), \tag{2}$$

where the first factor is the (commutative) algebra of function on (Euclidean) space time and the second factor is the internal space (real) algebra of particle charges.

The (faithful) representation ρ of the finite space algebra has been worked out by Connes to correspond to the particle charges, see Ref. 2. The first and second summand acts on the particles while the third summand acts on the antiparticles. The basis is given by the Hilbert space above

$$\rho := \begin{pmatrix} \rho_L & 0 & 0 & 0 \\ 0 & \rho_R & 0 & 0 \\ 0 & 0 & \rho^c & 0 \\ 0 & 0 & 0 & \rho^c \end{pmatrix}. \tag{3}$$

B. Real structure and Poincaré duality

Instead of splitting $\mathbb{C}$ into two copies of $\mathbb{R}$ as its name suggests, J forms two subspaces of the Hilbert space (not orthogonal as in S^o reality), which are interpreted as fermions and antifermions, in which case J is given by the composition of the charge conjugation operator with complex conjugation. The mathematical purpose of the J operator entering the axioms is to provide Connes' notion of a "noncommutative manifold." That is, by turning the Hilbert space into a bimodule, the "real" structure (Ref. 9) allows the generalization of Poincaré duality to the spectral triple; $a \in \mathcal{A}$ and the opposite algebra, $b^o \in \mathcal{A}^o$ (or $\mathcal{A}^{\mathrm{op}}$) where a acts on the left of $\mathcal{H}$ and b^o acts on the right

$$[a,b^o] = 0, \quad b^o = Jb^*J^{-1} \quad \forall\, a,b \in \mathcal{A}.$$

The opposite algebra provides the "dual" to the algebra. The pairing of the K theories of these two algebras provides a noncommutative geometric version of Poincaré duality. This structure is also important in the notion of first order differential operator in noncommutative geometry. The tangent space over any manifold is real, and the reality structure gives rise to the real-K theory of the enveloping algebra $\mathcal{A} \otimes \mathcal{A}^o$.

The action of J on $\mathcal{H}$ as given by the composition of charge conjugation and complex conjugation

$$J\begin{pmatrix} \psi_1 \\ \bar{\psi}_2 \end{pmatrix} = \begin{pmatrix} \psi_2 \\ \bar{\psi}_1 \end{pmatrix} \quad (\psi_1, \bar{\psi}_2) \in \mathcal{H} \oplus \mathcal{H}^c,$$

where the bar indicates complex conjugation.

C. *K* theory

K theory is a generalized cohomology theory. Topological K theory is the topological invariant that classifies the vector bundles over a given field, over a compact topological space X up to stable equivalence. It is an Abelian group $K^0(X)$ generated by the isomorphism classes of vector bundles over a given field. Addition is given by $[E]+[F]=[E \oplus F]$ where $[E]$ and $[F]$ are isomorphism classes of vector bundles E and F. Every element of the group is a difference: $[E]-[F]$. The Serre–Swan theorem provides the identification of topological with algebraic K theory. That is, $K^0(X)$ is isomorphic to the algebraic K-theory group $K_0(C^0(X))$. The group $K_0(A)$ for a C^*-algebra A is generated by the projections (self-adjoint idempotents) in A. These projections form an Abelian semigroup rather than a group, but the Grothendieck construction turns them into an Abelian group using an equivalence relation, which is very much analogous to the process of constructing the integers from the natural numbers.[10,11]

Some rules for K theory include $K_0(M_n(A))=K_0(A)$ (Morita equivalent algebras have the same K theory), $K_0(A \oplus B)=K_0(A) \oplus K_0(B)$, where A and B are C^*-algebras.

D. Fredholm modules and *K* homology

The Fredholm module is the "premetric" structure that is used to define the noncommutative calculus.[5] A spectral triple can be thought of as an unbounded (unless the Hilbert space is finite dimensional) Fredholm module with Dirac operator providing a notion of distance.

1. Definition: Fredholm operator

A Fredholm operator is a bounded operator on a Hilbert space whose kernel and cokernel are finite dimensional and is invertible modulo compact operators.

2. Definition: Fredholm module

Let A be an involutive algebra (over $\mathbb{C}$). Then a Fredholm module (H,F) over A is given by: (1) an involutive representative ρ of A in a Hilbert space H and (2) a Fredholm operator $F=F^*$, $F^2=I$ on H such that $[F,\rho(a)]$ is a compact operator for any $a\in A$. (After some trivial changes that we do not need to go into details of here, Connes ensures that the Fredholm module makes sense in finite dimensions.[5])

If there is a $\mathbb{Z}/2$ grading χ, such that $\chi=\chi^*$, $\chi^2=1$ of the Hilbert space such that (a) $[\chi,\rho]=0\ \forall a\in A$ and (b) the anticommutator $[\chi,F]_+=0$ then the Fredholm is *even*.

There is a natural assignment of a Fredholm module to a spectral triple. To be precise, an observation given in Ref. 5 is that there is a canonical assignment of a Fredholm module to a spectral triple given by $F=\text{sign}(\mathcal{D})$ (that is, $\mathcal{D}=F|\mathcal{D}|$) outside the kernel of $\mathcal{D}$. (On the finite dimensional kernel of $\mathcal{D}$, one takes an arbitrary isometry.[12])

Kasparov's K homology is the Poincaré dual theory to K theory—the K homology (Abelian) group of a Fredholm module is given by the homotopy classes of its Fredholm operator F. Let F be an elliptic operator on a compact space X (all such are Fredholm), then there is an isomorphism, index: $[X,F]\to K_0(X)$ where $[,]$ denotes homotopy equivalence classes. Due to Connes' construction of Poincaré duality for noncommutative spaces, in which the dual to $\mathcal{A}$ is its opposite algebra $\mathcal{A}^{\text{op}}$, one can write that $[F]\in\rho(A^{\text{op}})$ because the Abelian group $K^0(A^{\text{op}})$ is generated by the minimal rank projections of the opposite algebra A^{op}.[13]

E. Index and intersection form

We recall that every finite dimensional real involutive algebra on a finite dimensional Hilbert space[14] over the complex numbers is isomorphic to the direct summand $M_{n_1}(\mathbb{C})\oplus\cdots\oplus M_{n_k}(\mathbb{C})$ for some integers n_1 to n_k. Consider the Hilbert space to be made up of separate "chunks" where each is acted upon by a different algebra summand[12]

$$H_{ij}=P_i\mathcal{H}P_j,\quad \mathcal{H}=\underset{i,j}{\oplus}H_{ij} \tag{4}$$

where the P_i or p_i are projections in $\mathcal{A}$ and the P_j or Jp_jJ^{-1} are projections in $\mathcal{A}^o$. The action on H_{ij} from the left is $a_i\otimes 1\otimes 1$ and the action from the right is $1\otimes 1\otimes a_j^T$. Let r_{ij} be the number of particles represented by H_{ij} and χ. The intersection form is

$$\mu_{ij}=r_{ij}\chi, \tag{5}$$

which has nonzero determinant.

The matrix $\mu_{ij}=r_{ij}\chi$ is the same thing as the tensor product pairing of the K-theory groups of the algebra $\mathcal{A}$ with its opposite algebra

$$\mu_{ij}=\text{Tr}(\chi(\rho(p_i)J\rho(p_j)J^{-1})) \tag{6}$$

and we also see that

$$\mu_{ij}=r_{ij}\chi=\dim H_{ij}^R-\dim H_{ij}^L, \tag{7}$$

and then by summing over all the H_{ij} one arrives at right-hand side of the Fredholm index formula

$$\text{Index}(P\mathcal{D}^+P)=\dim\mathcal{H}_R-\dim\mathcal{H}_L, \tag{8}$$

where $\mathcal{D}^+=M^*$ in our conventions for the finite triple.

F. The axioms

Axioms 1, 3, and 5 are identical with those of commutative geometry. See Ref. 4 for a full statement and explanation of the axioms.

(1) $n>0$ $ds=\mathcal{D}^{-1}$ is an infinitesimal of order $1/n$ where n is the dimension of the space.
(2) $[[\mathcal{D},a],b^0]=0$ $\forall a,b\in\mathcal{A}$. By axiom 7 we also have: $[[\mathcal{D},b^0],a]=0$ $b^o\in\mathcal{A}^o$ opposite algebra.
(3) (Smoothness) This is the algebraic formulation of smoothness of coordinates.
(4) (Orientability) There is a Hochschild cycle c. For n even, its representation on $\mathcal{H}$ is $\pi(c)=a^0[\mathcal{D},a^1]\cdots[\mathcal{D},a^n]$. This defines the construction of the analog of the differential form that does not require a previous knowledge of the tangent bundle. If n is odd, require $\pi(c)=1$. If n is even, $\pi(c)=\chi$ satisfies: $\chi=\chi^*$, $\chi^2=1$, $\chi D=-D\chi$.
(5) (Finiteness and absolute continuity) The Hilbert space is a finite, projective $\mathcal{A}$ module possessing a Hermitian structure.
(6) There is the Poincaré duality isomorphism $K_*(\mathcal{A})\to K^*(\mathcal{A})$ where the intersection form is nondegenerate.
(7) (Reality) There is an antilinear isometry $J:\mathcal{H}\to\mathcal{H}$ with $b^0=Jb^*J^{-1}$ and $[a,b^0]=0$. The operator J must satisfy a set of further conditions, which for 0-dimensions are the following: $J^2=I$, $JD=DJ$, $J\chi=\chi J$.

IV. GRAVITY AND INTERNAL SPACE

In order to motivate the main analysis of this article we give an outline of the previous work in Ref. 1 and discuss some of its implications. We also prove a new result.

The article (Ref. 1) highlights the following issue. Einstein's equations involve all fluctuations of the space-time metric, and so if we believe that noncommutataive spectral triples are analogous to Riemannian spin manifolds, then we should vary the finite action with respect to the most general internal space Dirac operator allowed by the noncommutative geometry axioms. In other words, since Riemannian geometry gives rise to the study of gravity, we should continue to treat the Higgs force as an internal space version of gravity by calculating the extra Einstein's equations for the entire set of metric fluctuations. A feature of this approach is that the element of choice is removed; the hypothesis was that the standard model fermion mass matrix would arise as a solution of these equations of motion, just as Newton's laws of motion are selected through an action minimization principle, and thus the existence of classical mechanics can be explained mathematically. The physical mass matrix did not turn out to be a solution, in fact the additional fluctuations overconstrained the vacuum so that the solutions were completely degenerate. However, given the logic of this idea (of Barrett's (Ref. 1)), despite giving an unphysical result, it deserves further attention.

In response to the result, we may consider:

(a) abandoning the paradigm that noncommutative spectral triples be completely analogous to Riemannian geometry, and taking the Yukawa couplings to be derived from "finely tuned" constants,

(b) proposing that the extra fluctuations are physical, in which case additional scalar field terms in the action are needed (in order that the mass matrix vacuum be non-degenerate) (one replaces the action $\mathrm{Tr}(MM^*-I)^2$ with $\mathrm{Tr}(MM^*+XX^*-I)^2$ for some matrix X), together with an additional internal space discrete version of gravity. Such a new interaction might arise from a background source term or a twisting of the Dirac operator, and

(c) proposing an eighth axiom for noncommutative geometry to act as a further geometric constraint on the Dirac operator, which might involve a definition of curvature of internal space.

Even by leaving out the S^o-reality condition to increase the number of degrees of freedom in the Dirac operator (connecting antiparticles with particles) and imposing the first order condition as a geometric constraint upon it, did not lead to a vacuum M for the physical mass matrix because the extra fields all had zero vacuum expectation values as shown in Ref. 1. There is another side

of the coin revealed by modifying this calculation such that those new fields are treated as constant numbers, which means that the Yukawa couplings determine from constants, or are constants as in the standard model: while the fermion mass ratios are not determined of course, the vacuum solution is a non-degenerate matrix and the product MM^* is diagonal whereas M^*M is not diagonal. These features are compatible with the physical mass matrix and with consideration (a) above. After defining some notation we give the proof.

We label the additional degrees of freedom in the standard model Dirac operator on internal space when S^o-reality condition is omitted: g,u,x,h,v,y. In Ref. 15 these "leptoquarks" are variable fields and effect spontaneous breaking of color symmetry, whereas we are treating them as constants, so here color symmetry remains intact. There are also two more fields j,l that arise and exist when ν_R is included,[1] which was done to allow the neutrino a mass.

We use the notation: $M=M_Q\otimes 1_3\oplus M_L$ with

$$M_Q=\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad M_L=\begin{pmatrix} q & r \\ s & t \end{pmatrix}.$$

If M is a diagonal matrix then a,d,q,t are interpreted as Dirac masses for the up, down, electron, and neutrino respectively.

The field equations (Ref. 1) for the Dirac operator with leptoquarks held constant are given in the Appendix. With M_Q invertible (substituting $ad-bc=0$ into the equations for M_Q (A1) to (A4) gives $g=u=x=h=v=y=0$) and with all of the additional fields held constant and $r=s=0$ by gauge freedom the equations[1] reduce to

$$3|a|^2+3|b|^2+|g|^2+|u|^2+|x|^2+|h|^2+|v|^2+|y|^2-3=0, \tag{9}$$

$$|d|^2+|c|^2-1=0, \tag{10}$$

$$a\overline{c}+\overline{b}d=0, \tag{11}$$

$$|q|^2+|g|^2+|u|^2+|x|^2+|j|^2-1=0, \tag{12}$$

$$|t|^2+|h|^2+|v|^2+|y|^2+3|l|^2+|j|^2-1=0, \tag{13}$$

$$\overline{g}h+\overline{u}v+\overline{x}y=0, \quad lj=0. \tag{14}$$

As claimed above, these equations give M a nondegenerate set of eigenvalues with MM^* diagonal and M^*M not diagonal. In the case of the standard model where $\nu_R=0$, the equations are the above minus the equation involving t, and with $j=l=0$. (In the previous work $g=u=x=h=v=y$ were allowed to vary, thus there were more equations and the solution was a fully degenerate mass matrix.)

Since $|a|^2+|b|^2$ is identified with $m_u(|\phi_1|^2+|\phi_2|^2)$, when g,u,x,h,v,y are constants means that the Yukawa couplings are determined from numbers that are constant. The conclusion is that we have found equations of motion for which there exists a solution that is not demonstrably incompatible with experiment by means of an action principle in which an element of human choice is removed. The result ironically provides a mathematical reason for the Yukawa couplings to require fine tuning, however, options (b) and (c) are open and there is the caveat that these results apply only to the zero-dimensional, Euclidean case. Also, there are the extra particle-antiparticle mixing action terms.[15]

There is also a set of equations where j and l are allowed to vary while the leptoquarks remain constant. These are the first three equations above Eq. (9) together with

$$j=0,$$

$$|q|^2 + |g|^2 + |u|^2 + |x|^2 - 1 = 0,$$

$$|t| = |l| = \tfrac{1}{2},$$

$$\overline{g}\overline{h} + \overline{u}\overline{v} + \overline{x}\overline{y} = 0.$$

The conclusion is the same as above.

V. FREDHOLM MODULE SOLUTIONS

The final discussion point we would like to make with regard to Ref. 1 will motivate the calculations that follow. Below we make the observation that the vacuum solutions to the field equations for the full set of metric fluctuations do not pertain to the spectral triple, but rather to the premetric structure of the spectral triple, namely the Fredholm module. Rather than the standard model Dirac operator being a solution, its sign is a solution. We refer to the observation of Connes that any spectral triple has a Fredholm module associated to it where the Fredholm operator F of the Fredholm module is identified with the sign of the Dirac operator (outside its kernel) of the spectral triple.[5] In switching the focus from spectral triple to Fredholm module, one zooms out from the geometry to the topology. Hence, instead of hypothesizing that the equations of motion single out the correct *metric*, in this section we ask if the equations of motion can give solutions which relate to *topological invariants*, that is, K theory and K homology.

Since the K homology of a Fredholm module is isomorphic to the K theory of the algebra it is over, we should observe a relationship between a given algebra and the vacuum solution. Connes' realization of Poincaré duality in noncommutative geometry is to define the Poincaré dual to be the opposite algebra. This means that the homotopy classes of the projections in the dual algebra are identified with the K homology, which we recall is given by the homotopy classes of the Fredholm module $[F]$. For a given algebra, one may identify a corresponding Fredholm module solution, and below we demonstrate this for the standard model and for one other algebra. This is only an observation, but to use this framework to obtain topological data from the vacua, we need to make the procedure unique, so that there is a one-to-one relationship between algebra and vacuum solution. To this end, tools from Morse theory are borrowed from commutative geometry and a way to generalize them for this noncommutative work is suggested.

A. S^o-real standard model finite triple vacuum

First we recall that the most general internal space Dirac operator given the appropriate constraints of self-adjointness, same dynamics for particles and antiparticles, orientability, S^o reality and first order condition

$$\mathcal{D} = \mathcal{D}^*, \quad [\mathcal{D}, J] = 0, \quad [\mathcal{D}, \chi]_+ = 0,$$

$$[\mathcal{D}, \epsilon] = 0, \quad [[\mathcal{D}, a], b^o] = 0, \quad [[\mathcal{D}, b^o], a] = 0,$$

(where $[,]_+$ denotes the anticommutator) is

$$D_F = \begin{pmatrix} 0 & M^* & 0 & 0 \\ M & 0 & 0 & 0 \\ 0 & 0 & 0 & M^T \\ 0 & 0 & \overline{M} & 0 \end{pmatrix}, \tag{15}$$

where $M = M_Q \otimes 1_3 \oplus M_L$, and we have allowed for the inclusion of ν_R. To exclude ν_R as in the standard model, we simply delete the final column from M^* (or row from M).

From the first order condition

$$(M\rho^c - \rho^c M)\rho_L^{T'} - \rho_R^{T'}(M\rho^c - \rho^c M) = 0, \tag{16}$$

when $\rho_L^{T'}=0$ and $\rho_R^{T'}=1$ we find that $[M,\rho^c]=0$ (the Higgs has no color charge) and with the standard model representation this splits M up into the direct sum of quark and lepton masses. Further than this, the mass matrix M is not constrained by the first order condition. This means that the action does not know how the algebra is represented, and hence, it is missing some geometrical information about the manifold. When S^o reality is omitted some of this information becomes available to the action and, hence, (when the extra fields are kept constant) the nondegenerate mass matrix solution of the previous section arises.

As in the previous work, we drop the S^o-reality condition, and allow degrees of freedom in D_F to vary but we leave the first order condition until after the equations of motion have been derived; since we are to aim to develop a method to identify the algebra given a vacuum solution, we had better omit any axioms that involve the algebra. However, we retain the condition that $[M,\rho^c]=0$.

The result is

$$D_F = \begin{pmatrix} Y & Z \\ \overline{Z} & \overline{Y} \end{pmatrix} = \begin{pmatrix} 0 & M^* & 0 & G \\ M & 0 & G^T & 0 \\ 0 & \overline{G} & 0 & M^T \\ G^* & 0 & \overline{M} & 0 \end{pmatrix}, \tag{17}$$

(where G having the same dimensionality as M, was not a general matrix in Ref. 1 but was constrained by the first order condition.) Alternate blocks are zero due to the condition $[D_F,\chi]_+=0$. Here we are not using the first order condition, so G and M are both general matrices with complex coefficients and having dimensionality depending on the number of fermions considered.

To calculate the equations of motion we vary the finite spectral action with respect the degrees of freedom in D_F as given above, first for the S^o-real case and then for the non-S^o-real triple. The result of the former is the same as that given in Ref. 1 but we make a new interpretation of it.

1. S^o-real triple

The action is

$$S = \mathrm{Tr}[(D_F)^4 - 2D_F^2] \tag{18}$$

or, with the $\mathrm{Tr}(I)$ term included

$$S = \mathrm{Tr}(MM^* - I)^2, \tag{19}$$

(where I denotes the unit matrix.)

Minimizing the (19) with respect to M gave the very definition of partial isometry

$$M^*(MM^* - I) = 0 \tag{20}$$

and Hermitian conjugate.

This result means that the mass matrix that minimizes the action gives each fermion an identical mass. The new interpretation we give is that the standard model finite triple's Dirac operator is a solution only up to its sign, and hence, only up to the conformal structure of the spectral triple, where $\mathrm{sign}\, D_F = D_F/|D_F|$. Specifically, the vacuum solution M^*_{vac} is the partial isometry in the polar decomposition of D^+. This operator sign D_F is the Fredholm operator for the Fredholm module associated to the standard model finite spectral triple outside the kernel of the Dirac operator (Ref. 5).

2. Non-S^o-real triple

The action is

$$S = \mathrm{Tr}[(D_F)^4 - 2D_F^2] \tag{21}$$

with D_F given by (17).

Simplifying the action by using cyclicity of trace and the fact that $\mathrm{Tr}(X)=\mathrm{Tr}(X^T)$:

$$S = \mathrm{Tr}(-2(G^*G + MM^*) + (MM^*)^2 + (G^*G)^2 + 2(MGG^*M^* + MM^*G^T\overline{G} + MG\overline{MG})) \tag{22}$$

or

$$S = \mathrm{Tr}(-2(GG^* + M^*M) + (M^*M)^2 + (GG^*)^2 + 2(GG^*M^*M + G\overline{M}M^TG^* + G\overline{MG}M)). \tag{23}$$

We vary the first of the above Eq. (22) with respect to M and the result is

$$M^*(MM^* + G^T\overline{G} - I) + G\overline{MG} + GG^*M^* = 0 \tag{24}$$

and the second with respect to G and the result is

$$G^*(GG^* + M^*M - I) + \overline{MG}M + \overline{M}M^TG^* = 0. \tag{25}$$

The field equations for G^T, M^T, G^*, M^*, $\overline{G}$, and $\overline{M}$ are just the transpose, Hermitian conjugate or complex conjugate, respectively, of the above equations for M and G.

Although there are zeros in D_F due to orientability, the equation below is the same thing as that above, due to there being no linear terms in M or G:

$$D_F^3 = D_F,$$

which is of course the result of differentiating (18) with respect to D_F. In other words, simply by substituting for D_F with (17) into $D_F^3=D_F$, precisely the equations of motion obtained above together with all their conjugate counterparts, appear.

The conclusion in this non-S^o-real case is the same as that in the S^o-real one, namely that the solutions are partial isometries. Here is the proof:

First we check if the equations of motion do have any Fredholm module solutions. To do this, we must look for solutions such that $D_{F,\mathrm{vac}}^2=I$:

$$D_{F,\mathrm{vac}}^2 = \begin{pmatrix} M^*M + GG^* & 0 & M^*G^T + G\overline{M} & 0 \\ 0 & MM^* + G^T\overline{G} & 0 & MG + G^TM^T \\ \overline{G}M + M^TG^* & 0 & \overline{G}G^T + M^T\overline{M} & 0 \\ 0 & G^*M^* + \overline{MG} & 0 & G^*G + \overline{M}M^T \end{pmatrix}. \tag{26}$$

Equations (24) and (25) (and conjugates) are equivalent to the equation $D_F^3=D_F$, and therefore we can state that the eigenvalues of the vacuum solution for D_F are all in the set $\{-1,0,1\}$. Then we see that $D_{F,\mathrm{vac}}^2$ has eigenvalues all 1 or 0, which means that assuming it is diagonalizable, $D_{F,\mathrm{vac}}^2=UpU^*$ for some unitary matrix U and where p is a projection, that is, p satisfies $p=p^2$ and $p=p^*$. Clearly, UpU^* is a projection, in other words $D_{F,\mathrm{vac}}^2$ is a projection, and since the Dirac operator is self-adoint, we may conclude that all the vacuum solutions are that $D_{F,\mathrm{vac}}$ is a partial isometry: $(D_{F,\mathrm{vac}}^*D_{F,\mathrm{vac}})(D_{F,\mathrm{vac}}^*D_{F,\mathrm{vac}})=D_{F,\mathrm{vac}}^*D_{F,\mathrm{vac}}$. A simpler way to see this is to multiply on both sides of the equation $D_{F,\mathrm{vac}}^3=D_{F,\mathrm{vac}}$ by $D_{F,\mathrm{vac}}$ while recalling that the Dirac operator is self-adjoint. Notice also that for the eigenvalues of $D_{F,\mathrm{vac}}$ that are 1, Eq. (26) shows that the sum of the two types of masses for each particle add up to 1 and so even if G can lift the degeneracy of the Dirac mass matrix, the total mass ends up being the same. To summarize, the Fredholm module interpretation Sec. V A 1 is again valid in this, the non-S^o-real case.

B. Orthogonal complements

Although the orthogonal complement relationship between M and G can already be seen from the result of the last part, below we demonstrate it explicitly and analyze Eqs. (25) and (24). This data will be used in the next part.

Since a partial isometry is just a projection multiplied by a unitary matrix, we let M be a diagonal projection of dimensionality n. (For a partial isometry v, $v\mathcal{H}=vv^*\mathcal{H}$.) We do not assume that G is diagonal. In any calculation we assume that the dimensionalities of the matrices M and G are the same.

From Eqs. (24) and (25) it is immediately clear that when $M=0$, G is a partial isometry and vice versa.

With M a diagonal projection inserted, the equation of motion for M simplifies to

$$M^*G^T\overline{G}+G\overline{M}\overline{G}+GG^*M^*=0. \tag{27}$$

If $M=I$ it simplifies further to

$$G^T\overline{G}+G\overline{G}+GG^*=0, \tag{28}$$

and whereas if M is a diagonal projection of dimensionality n and rank m then the bottom $n-m$ rows of Eq. (27) disappear.

We show below that Eq. (28) gives $G=0$ for $n=2$ while explaining the procedure in words to make clear that this method can be applied to the general case of arbitrary n and m—consider the top left elements of GG^* and $G^T\overline{G}$ where $n=2$—all terms are positive and all elements of the top row of G are present. The equations containing the top left and bottom right elements of $G\overline{G}$ may be combined as shown below to find that $G=0$.

For $n=2$ let

$$G=\begin{pmatrix} z & y \\ x & w \end{pmatrix},$$

the top left and bottom right equations are

$$3|z|^2+2|x|^2+y\overline{x}=0$$

$$3|w|^2+2|y|^2+x\overline{y}=0,$$

and their combination is

$$3|z|^2+3|w|^2+|x|^2+|y|^2+|x+y|^2,$$

which means that $x=y=w=z=0$ in other words $G=0$.

As mentioned, if $M=0$ then G is a partial isometry. Equivalently, GG^* and G^*G are Murray–von-Neumann equivalent projections. And in the same way, we see for general n, m the bottom $n-m$ rows of Eq. (28) show that the nonzero part of G is a partial isometry.

Notice the simple relationship between M and G; when M^*M and G^*G are diagonal projections and when $D^2_{F,\mathrm{vac}}=I$, they are the orthogonal complement of one another. The simultaneous matrix equations below simplify the statements: If $G=0$ then M is a partial isometry and vice versa, and if $M=I$ then $G=0$ and vice versa, and if M is a diagonal projection and if $D_{F,\mathrm{vac}}$ is invertible, then G is a partial isometry orthogonal to M,

$$M(M^*M+G^*G-I)=0,$$

$$G(G^*G+M^*M-I)=0.$$

C. Poincaré duality

Given the standard model algebra and using Connes' realization of Poincaré duality in noncommutative geometry, we may write down the sign of the standard model Dirac operator. This is just the matrix (15) with eigenvalue "1" for each particle mass. An aim of the previous work was to answer the question, "Is the standard model fermion mass matrix (internal space Dirac operator) a solution to the additional Einstein's equations?," whereas here we are considering the similar question, "Is the sign of the standard model internal space Dirac operator a solution to the equations?" If the direction of this arrow is reversed, that is if the K-theory group is identified for a given vacuum solution, then topological information has been retrieved about the manifold from the minimization procedure, and hence, there would be a mathematical reason for the choice of the algebra up to Morita equivalence. We begin by exploring the relationship between vacuum solution and algebra. We only study the first two summands of the algebra, that is, the algebra for the Electroweak force. The matrix M commutes with ρ^c as the Higgs has no color charge and we do not involve color charge at all in the remainder of this article.

We study the standard model and one other solution.

Above a set of solutions was found where for a given projection G, the vacuum solution for M, or M_{vac}, is determined via the simple relationship found in the equations of motion. Let us consider one such solution, namely the one in which $G=0$, that is, the one pertaining to the standard model. Then the M^*_{vac} is

$$M^*_{\text{vac}} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \tag{29}$$

which is a rectangular matrix because the two direct summands of the chirality $\mathbb{Z}$/two-graded Hilbert space have different dimensions. The basis may be labeled $(u_R, d_R, e_R)^T$. We can add a final column of zeros to M^*_{vac} and the basis becomes $(u_R, d_R, e_R, \nu_R)^T$.

Recall that $[F] \in \rho(\mathcal{A}^{\text{op}})$ where $\rho(\mathcal{A})$ is given by Eq. (3). The opposite algebra is represented by $J\rho(a)J^{-1}$. The generators of the K-homology group are the homotopy classes of the minimal rank projections of the opposite algebra $\mathcal{A}^o$, that is, $J\rho_L(p_1)J^{-1}$, which is the 2 by 2 unit matrix $\text{diag}(1,1)$ and $J\rho_R(p_2)J^{-1}$, which is given by the number 1. The former is a projection of the algebra of the quaternions $\mathbb{H}$ and the latter is simply a projection of the complex numbers $\mathbb{C}$. So the vacuum solution (29) is consistent with the element b^o of the opposite algebra being

$$b^o = \begin{pmatrix} \rho^{cT} & 0 & 0 & 0 \\ 0 & \rho^{cT} & 0 & 0 \\ 0 & 0 & q^T & 0 \\ 0 & 0 & 0 & \Lambda^T \end{pmatrix}, \tag{30}$$

where q is a quaternion and $\Lambda = \text{diag}(\bar{\lambda}, \lambda)$, $\lambda \in \mathbb{C}$. Using the reality operator we find that an element b of $\mathcal{A}$ can be given by

$$b = \begin{pmatrix} q & 0 & 0 & 0 \\ 0 & \Lambda & 0 & 0 \\ 0 & 0 & \rho^c & 0 \\ 0 & 0 & 0 & \rho^c \end{pmatrix} \tag{31}$$

from which we see that the first two summands of the algebra may be: $\mathbb{H} \oplus \mathbb{C}$.

Note that this is not a unique answer because the projection $\text{diag}(1,1)$ is also in $K_0(\mathbb{C})$.

A Fredholm module to be associated to a spectral triple must have algebra and Fredholm operator compatibility such that the first order condition is satisfied. In order to check that a

spectral triple can be assigned to the Fredholm module, we check that the first order condition is satisfied. It is satisfied because $G=0$ and $[M,\rho^c]=0$ where M is given by the direct sum.

We can generalize this procedure by choosing any other projective solution for G. For example let alternate eigenvalues of G be nonzero beginning with the first eigenvalue zero. Then by the orthogonal complement relationship we have the solution for M^*_{vac}:

$$M^*_{\text{vac}} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \tag{32}$$

and by the same procedure as above, we find that this solution is compatible with the algebra $M_2(\mathbb{C})\oplus\mathbb{C}$. $M_2(\mathbb{C})$ is Morita equivalent to $\mathbb{C}$ and so the first two summands of the algebra of this spectral triple are Morita equivalent to $\mathbb{C}\oplus\mathbb{C}$.

A point of clarification is that the two solutions considered above are unitary (and homotopy) (unitary and homotopy equivalence are the same thing for stable algebras) equivalent, and so one expects them to lead to the same topological invariants. However, in the part to follow, we will restrict this homotopy freedom to separate "nodes"; one for each of ρ_L, ρ_R, and ρ^c.

D. Morse theory and the Witten complex

The projection $\text{diag}(1,1)$ is in the K theory of both algebras $\mathbb{C}$ and $\mathbb{H}$, but to obtain topological information from the vacuum solutions the relationship between the vacuum solutions and the algebra must be one to one. We need a reason why the solutions should correspond only to the generators of the $K_0(\mathcal{A})$ group and not to any other element of the group. For example we need the matrix $\text{diag}(1,1)$ to be associated only with $\mathbb{H}$ and algebras Morita equivalent to it.

In this section we generalize a theorem involving the Morse theory and the Witten complex to suggest a method for finding topological information from the equations of motion about the S^o-real ($G=0$) spectral triple pertaining to the standard model. The theorem is that a chain complex called the Witten complex, which is constructed from the critical points of the Morse function has the same homology groups as the manifold that the Morse function is defined on. Atiyah and Bott have proven that the Yang-Mills action is an equivariant Morse function and since the Higgs is a gauge field component in the internal space direction, we ask whether the finite spectral action is also a Morse function in a proposed noncommutative sense described below. To do this, we make a straightforward generalization of the theorem to noncommutative geometry (which comes down to little more than the usual replacement of the commutative with the noncommutative algebra) by proposing a noncommutative generalization to the definition of Morse function, equivariant Morse function (or Morse–Bott function), Hessian matrix, and Witten complex.

A Morse function is a real-valued function on a (smooth) manifold N, $f:N\to\mathbb{R}$ such that every one of its critical points is nondegenerate. The way to check for nondegeneracy is to calculate the Hessian matrix of the critical point and if this has no zero eigenvalues then the point is nondegenerate. Of course the Higgs vacuum is an entire three-sphere of nondegenerate solutions, so in order to use Morse theory in physics problems where there is a gauge symmetry, the equivariant Morse function was defined where the gauge symmetry is just divided out. (There are more complicated cases.)

The Hessian matrix of a Morse function f for a critical point is given by

$$a_{ij} = \left(\frac{\partial^2 f}{\partial x_i\,\partial x_j}\right)\Big|_c, \tag{33}$$

where c is the critical point, x_i are the coordinates on N, and i runs from 1 to the dimension of N. The "index" of the critical point is the number of negative eigenvalues of this matrix.

The action we want to consider is the finite spectral action with $G=0$:

$$S = \mathrm{Tr}((MM^*)^2 + - 2MM^*). \tag{34}$$

To proceed from here, we need to make some generalizations of the above definitions to the context of noncommutative geometry. To begin with, the notion of a critical *point* is no longer valid, and differentiating with respect to each of the commuting coordinates x_i on N goes over to differentiating with respect to the matrix M. Consider the Fredholm operator F ingredient of the Fredholm module over a noncommutative C^*-algebra. Recalling that F is the generalization to noncommutative geometry of an elliptic operator on a compact manifold in commutative geometry, we understand that F is parametrized by the underlying space pertaining to the Fredholm module. Moreover, the homotopy classes of F, $[F] \in \rho(\mathcal{A}^{\mathrm{op}})$. With in mind the Fredholm module picture of the underlying space on which the Morse function acts, we replace the x_i with the M as 2 by 2 matrices over $\mathbb{C}$. We use 2 by 2 matrices because each direct summand of the standard model algebra is viewed as a node (not quite a point) upon which the vector bundle is built, and the representation ρ is separated into 2 by 2 chunks; one for each algebra summand. Obviously the critical points will be replaced by the vacuum solutions M_{vac}. Finally, we need to write down a condition corresponding to Eq. (33) that will give meaning to a noncommutative version of a Morse function (or at least equivariant Morse function) and check that the action S satisfies that condition. We continue this chapter's focus on the Fredholm module as the underlying space.

The index i does not run very far because we are working in zero dimensions and the action only depends on M and its hermitian conjugate. The Hessian matrix can only be as follows:

$$a = \left(\frac{\partial^2 S}{\partial M^* \, \partial M} \right)\Big|_c. \tag{35}$$

S is real-valued and we do not need to worry about smoothness as this is already covered in the noncommutative geometry axioms. Differentiating the action S with respect to M and afterwards with respect to M^* and evaluating at $M=0$ produces the Hessian of S. The resulting matrix is: MM^*+M^*M-I evaluated at the vacuum solution which is that MM^* and M^*M are "initial" and "final" projections. Since in some solutions this matrix can have zero eigenvalues, we differentiate twice with respect to MM^*, so that MM^* becomes the field to vary instead of M. The resulting matrix is $2I$, which has no zero eigenvalues. We suggest then that S is a noncommutative version of a Morse function. Since the degeneracies due to the vacuum manifold exist and may be associated with the finding of zero eigenvalues above, it may be more accurate to designate the function as an equivariant Morse function in keeping with the analogy with Yang–Mills theory.

In (commutative) Morse theory, the Witten complex is defined as follows (Ref. 16). To begin, the free Abelian group C_i generated by the set of critical points of index i is constructed. If C_{i-1} is defined in the same way for index $i-1$, it is possible to define a map from C_i to C_{i-1}, that is, the boundary map. This defines a chain complex called the Witten complex. It is a proven theorem that *the homology groups of this chain complex are isomorphic to the homology groups of the manifold.*

Classifying the vacuum solutions according to homotopy class, where each solution is homotopic to one of the following two diagonal projections:

$$M_{v1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad M_{v2} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}. \tag{36}$$

This is equivalent to dividing out the degenerate solutions as in equivariant theory and to considering the homotopy classes of the projections $(MM^*)_v$ where the action is varied with respect to MM^* instead of M.

Since the two solutions share the same Hessian, they have the same index and therefore the Witten complex for this particular function has only one component C_i so the homology groups are simply C_i. Since the Witten chain complex in the case studied above is made out of only one term C_i, the kernel of the boundary map is C_i, and the image of the boundary map for the next term in the sequence takes the identity to the identity, therefore the homology group is simply

given by C_i. The Abelian group C_i is generated by the two projections M_{v1} and M_{v2}, which is exactly the K-homology group $K^0(\mathcal{A}^o)$, that is, the K-homology group of the underlying Fredholm module. (The other elements of the Abelian group arise from the other generations—of which this framework implies there are an arbitrary number, and of course it is a mystery that we have to stop at 3—in analogy to the Abelian group $\mathbb{Z}$ where $S^1=\mathbb{R}/\mathbb{Z}$.) The K-theory group of the standard model algebra is isomorphic to $\mathbb{Z}\oplus\mathbb{Z}\oplus\mathbb{Z}$ (though here we have only studied the first two summands). Since one counts only a limited number of generations, the algebra is associated to the punctured torus.

The two critical nodes can be identified with the first two direct summands (up to Morita equivalence) on the internal space, one for $\mathbb{H}$ and the other $\mathbb{C}$, an example of the noncommutative generalization of the two point space (left and right) as follows. We associate M_{v1} with left and M_{v2} with right. So $M_{v1}\in\rho_L(\mathcal{A}^o)$ and $M_{v2}\in\rho_R(\mathcal{A}^o)$. Removing ν_R from the Hilbert space and a row and column from D_F means that the vacuum solution is: $M_Q=\mathrm{diag}(1,1)$ and $M_L=1$. These are the minimal rank projections of $\mathbb{H}$ and $\mathbb{C}$ and Morita equivalent algebras. And by Poincaré duality (as shown in the previous part), the noncommutative space can be described by the quaternions over the right 'node' and the complex numbers over the left.

VI. CONCLUSIONS

Although the solutions to the field equations calculated in our previous work yielded an unphysical result, we have argued that the reasoning for their derivation deserves further attention and we explained why Ref. 1 has highlighted an open question in the noncommutative framework. A solution was found to the equations of motion calculated previously with the leptoquarks held constant whose features are compatible with the physical fermion mass matrix. Ironically, this result provides a mathematical reason for the Yukawa couplings to need fine tuning.

The solutions to the field equations for D_F both with and without the S^o-reality condition were shown to be partial isometries. These were interpreted as the phase or sign of D_F. The relationship between the vacuum solutions and the topology of the internal space was explored using K theory and K homology and a method inspired by Morse theory to extract topological information from the vacuum about the underlying noncommutative space was developed. Instead of finding a mathematical reason in the action principle for the *geometry* of the standard model to be what it is known to be by experiment, we have claimed that the vacuum provides information on its *topology* in terms of K homology. Rather than the vacuum picking out just one of a myriad of possible answers, all partial isometries are solutions. The study was limited to the first two of three summands, that is, the Electroweak part of the standard model algebra.

We also note that with $D_F^2=I$, we can consider solutions in the case without S^o reality in which M_{v2} is associated with its orthogonal complement matrix $G_{v2}=\mathrm{diag}(0,1)$. Applying these solutions to the standard model basis, where $\nu_R=0$, $G=0$ and the bottom row vanishes from M_{v2} and the outcome is the same as above. Also, a similar analysis can be carried out with M having arbitrary dimensionalities and arbitrary numbers of algebra direct summands. This involves either an unwanted prediction of new massless particles, or cutting the matrices down as above to fit the standard model Hilbert space. For example, in the dimensionality 3 case, there is an additional solution, $M_{v3}=\mathrm{diag}(1,1,1)\in\mathrm{SU}(3)$. Algebras with a greater number of summands cannot be identified using this method if there are repeated summands, for example the algebra $\mathbb{H}\oplus\mathbb{H}\oplus\mathbb{C}\oplus\mathbb{C}$ cannot be distinguished from $\mathbb{H}\oplus\mathbb{C}$ because they have the same critical nodes.

On the structure of (2+1)-dimensional commutative and noncommutative integrable equations

Jing Ping Wang
Institute of Mathematics and Statistics, University of Kent, Canterbury, Kent, CT2 7NF, United Kingdom

(Received 25 July 2006; accepted 5 October 2006; published online 27 November 2006)

We develop the symbolic representation method to derive the hierarchies of (2+1)-dimensional integrable equations from the scalar Lax operators and to study their properties globally. The method applies to both commutative and noncommutative cases in the sense that the dependent variable takes its values in $\mathbb{C}$ or a noncommutative associative algebra. We prove that these hierarchies are indeed quasi-local in the commutative case as conjectured by Mikhailov and Yamilov [J. Phys. A **31**, 6707 (1998)]. We propose a ring extension in the noncommutative case based on the symbolic representation. As examples, we give noncommutative versions of Kadomtsev-Petviashvili (KP), modified Kadomtsev-Petviashvili (mKP), and Boussinesq equations. © *2006 American Institute of Physics.*

I. INTRODUCTION

Integrable (1+1)-dimensional nonlinear evolution equations, i.e., equations of the form

$$u_t = F(u, u_x, u_{xx}, \ldots, u_{xx\ldots x})$$

possess rich algebraic and geometrical structures such as Lax representations, a bi-Hamiltonian formulation, infinitely many symmetries and conservation laws, etc. A lot of work has been devoted to the study of such equations and comprehensive classification results have been obtained.

The extension of these remarkable structures to the (2+1)-dimensional case is not straightforward. It was proved in Ref. 1 that there is no bi-Hamiltonian formulation for (2+1)-dimensional integrable equations of the same type as those for the (1+1)-dimensional case like the Korteweg–de Vries (KdV) equation

$$u_t = u_{xxx} + 6uu_x.$$

In 1988, Fokas and Santini, cf. Refs. 2 and 3, constructed a bi-Hamiltonian structure for the Kadomtsev-Petviashvili (KP) equation

$$u_t = u_{xxx} + 6uu_x + 3D_x^{-1}u_{yy}$$

by considering it as a reduction of (3+1)-dimensional system. Meanwhile, Magri and his coauthors,[4] explained this structure from the geometric point of view by developing the concept of Nijenhuis G-manifolds, which amazingly works for both one and two space dimensions. Dorfman and her coauthors introduced the noncommutative ring of formal pseudo-differential operators, cf. Refs. 5 and 6. They proved that the Fokas-Santini bi-Hamiltonian structure of the KP can be obtained from the Adler-Gel'fand-Dikii (AGD) scheme by considering the second-order Lax operator

$$L = D_x^2 + u - \partial_y.$$

The bi-Hamiltonian structure naturally leads to a recursion operator for the equation. However, the operator (so-called operand) takes its value in the ring of formal differential operators and is of a different type from the one for KdV (and therefore does not contradict the result of Ref. 1). A hierarchy of infinitely many symmetries can only be produced by making suitable combinations of the operator acting on distinct seeds.[4]

One of the main obstacles to extend the spectacular results of $(1+1)$-dimensional integrable equations to the $(2+1)$-dimensional case is that the equations themselves, their higher symmetries, and conservation laws are nonlocal, i.e., the appearance of the formal integral D_x^{-1} or D_y^{-1}. In 1998, Mikhailov and Yamilov,[7] introduced the concept of quasi-local functions based on the observation that the operators D_x^{-1} and D_y^{-1} never appear alone but always in pairs like $D_x^{-1}D_y$ and $D_y^{-1}D_x$ for all known integrable equations and their hierarchies of symmetries and conservation laws, which enables them to extend the symmetry approach of testing integrability[8] to the $(2+1)$-dimensional case.

In this paper, we develop the symbolic representation method to produce hierarchies of $(2+1)$-dimensional integrable equations from scalar Lax operators and to study their properties globally. The method applies both to the commutative and noncommutative case in the sense that the dependent variable takes its values in $\mathbb{C}$ or in a noncommutative associative algebra. We prove that these hierarchies are indeed quasi-local in the commutative case as conjectured by Mikhailov and Yamilov in 1998.[7] This concept of quasi-locality has to be extended in the noncommutative case. Here we propose a ring extension based on the symbolic representation. As examples, we give noncommutative versions of the KP, mKP, and Boussinesq equations.

II. QUASI-LOCAL POLYNOMIALS AND SYMBOLIC REPRESENTATION

The symbolic method was introduced by Gel'fand and Dikii in 1975.[9] However, its basic idea can be dated back to the middle of 19th century. Recently, we successfully applied this method to the classification of both commutative and noncommutative $(1+1)$-dimensional homogeneous evolution equations in a series of papers, cf. Refs. 10–12. With the help of number theory, it enables us to give a global description of their integrable hierarchies.[13] The symbolic method is also powerful in dealing with differential (cf. Ref. 14) and pseudo-differential (cf. Ref. 15) operators. The authors of Ref. 15 generalized the standard symmetry approach[8] and made it suitable for the study of nonlocal and nonevolutionary equations; see also Ref. 16.

In this section, we will extend the symbolic method to the case of two spatial variables x and y. For simplicity, we restrict our attention to a single dependent variable u. Extensions to several independent variables and dependent variables are straightforward.

A. Quasi-local polynomials

We begin with basic definitions and notations of the ring of commutative and noncommutative differential polynomials. The derivatives of dependent variable u with respect to its independent variables x and y are denoted by $u_{ij}=\partial_x^i\partial_y^j u$. For smaller i and j, we sometimes write the indices out explicitly, that is, u_{xxy} and u instead of u_{21} and u_{00}. A differential monomial takes the form

$$u_{i_1j_1}u_{i_2j_2}\cdots u_{i_kj_k}.$$

We call k the degree of the monomial. We let $\mathcal{U}^k$ denote the set of differential polynomials of degree k. The ring of differential polynomials is denoted by $\mathcal{U}=\oplus_{k\geqslant 1}\mathcal{U}^k$. Notice that $1\notin\mathcal{U}$ and it is a differential ring with total x-derivation and y-derivation

$$D_x = \sum_{i=0}^{+\infty}\sum_{j=0}^{+\infty} u_{i+1,j}\frac{\partial}{\partial u_{ij}} \text{ and } D_y = \sum_{i=0}^{+\infty}\sum_{j=0}^{+\infty} u_{i,j+1}\frac{\partial}{\partial u_{ij}}.$$

The ring $\mathcal{U}$ is commutative if the dependent variable u takes its values in a commutative algebra, for example the ring of smooth functions in x and y. Let us denote

$$\Theta = D_x^{-1}D_y, \quad \Theta^{-1} = D_y^{-1}D_x. \tag{1}$$

The concept of quasi-local (commutative) polynomials $\mathcal{U}(\Theta)$ was introduced in Ref. 7 to test integrability of a given equation. To define it, we consider a sequence of extensions of $\mathcal{U}$. Let $\Theta\mathcal{U}=\{\Theta f: f\in\mathcal{U}\}$ and $\Theta^{-1}\mathcal{U}=\{\Theta^{-1}f: f\in\mathcal{U}\}$. We define $\mathcal{U}_0(\Theta)=\mathcal{U}$ and $\mathcal{U}_k(\Theta)$ is the ring closure of the union

$$\mathcal{U}_{k-1}(\Theta)\cup\Theta\mathcal{U}_{k-1}(\Theta)\cup\Theta^{-1}\mathcal{U}_{k-1}(\Theta).$$

Here the index k indicates the maximal depth of nesting the operator $\Theta^{\pm 1}$ in the expression. Clearly, we have $\mathcal{U}_{k-1}(\Theta)\subset\mathcal{U}_k(\Theta)$. We now define $\mathcal{U}(\Theta)=\lim_{k\to\infty}\mathcal{U}_k(\Theta)$. However, for a given $f\in\mathcal{U}(\Theta)$, there exists k such that $f\in\mathcal{U}_k(\Theta)$. The extension $\mathcal{U}(\Theta)$ has a natural gradation according to the number of u and its derivatives

$$\mathcal{U}(\Theta)=\oplus_{l\geqslant 1}\mathcal{U}^l(\Theta), \quad \mathcal{U}^p(\Theta)\mathcal{U}^q(\Theta)\in\mathcal{U}^{p+q}(\Theta).$$

Note that $\mathcal{U}_k(\Theta)$ is not invariant under transformation of variables. For example, a simple transformation

$$x' = x+y, \quad y' = y \tag{2}$$

transforms $\Theta=D_{x'}^{-1}D_{y'}\mapsto 1-\Theta=1-D_x^{-1}D_y$. Hence $\Theta^{-1}\mapsto(1-\Theta)^{-1}$, which is not in $\mathcal{U}_k(\Theta)$.

If u takes its value in a noncommutative associative algebra, the ring $\mathcal{U}$ is noncommutative. Typical examples are the algebras of $n\times n$ matrices and Clifford algebras (see Ref. 17 for more examples and noncommutative (1+1)-dimensional integrable evolution equations). For any element f, g, and h in a noncommutative associative algebra, we use the notation

$$L_f(g)=fg, \quad R_f(g)=gf \tag{3}$$

for the operators of left and right multiplication, and

$$C_f(g)=L_f(g)-R_f(g)=fg-gf \tag{4}$$

for the commutator (notation ad_f is also commonly used). It is a derivation since it satisfies the Leibniz rule: $C_f(gh)=C_f(g)h+gC_f(h)$.

So far there is no proper extension from noncommutative differential polynomials to quasi-local noncommutative polynomials, mainly because the study of noncommutative (2+1)-dimensional integrable equations is a new and challenging topic. We can take the corresponding extension of $\mathcal{U}(\Theta)$ as the starting point. However, this turns out to be too restrictive. This will be discussed further in Sec. IV B.

B. Symbolic representation

The basic idea of the symbolic representation is to replace u_{ij} by $u\xi^i\eta^j$, where ξ and η are symbols. Now the total differentiation with respect to x, that is, mapping u_{ij} to $u_{i+1,j}$, is replaced by multiplication with ξ, as in the Fourier transform. Similarly, the total differentiation with respect to y mapping u_{ij} to $u_{i,j+1}$, is replaced by multiplication with η. For higher degree terms with multiple u's, one uses different symbols to denote each of them. Its symbolic representation depends on where u takes its value, i.e., whether it is commutative or not. For example, the noncommutative binomial $u_{ij}u_{kl}$ has symbolic representation $u^2\xi_1^i\eta_1^j\xi_2^k\eta_2^l$. In the commutative case, one has $u_{ij}u_{kl}=u_{kl}u_{ij}$. We therefore need to average its symbolic representation over the permutation group Σ_2 so

that $u_{ij}u_{kl}$ and $u_{kl}u_{ij}$ have the same symbolic form. So the symbolic representation of $u_{ij}u_{kl}$ is $(u^2/2)(\xi_1^i\eta_1^j\xi_2^k\eta_2^l+\xi_2^i\eta_2^j\xi_1^k\eta_1^l)$. Symmetrization makes the symbol representation of monomials unique.

Let $\mathcal{A}^k$ be the space of algebraic polynomials f in $2k$ variables, ξ_i and η_i, where $i=1,\ldots,k$.

The symbolic representation defines a linear isomorphism between the space $\mathcal{U}^k$ of (non)-commutative differential polynomials of degree k and the space $\mathcal{A}^k$. It is uniquely defined by its action on monomials.

Definition 1: *The symbolic representation of a differential monomial is defined as*

$$u_{i_1,j_1}u_{i_2,j_2}\cdots u_{i_k,j_k}\mapsto\begin{cases}u^k\xi_1^{i_1}\eta_1^{j_1}\xi_2^{i_2}\eta_2^{j_2}\cdots\xi_k^{i_k}\eta_k^{j_k}, & (\textit{noncommutative});\\ \dfrac{u^k}{k!}\displaystyle\sum_{\sigma\in\Sigma_k}\xi_{\sigma(1)}^{i_1}\eta_{\sigma(1)}^{j_1}\cdots\xi_{\sigma(k)}^{i_k}\eta_{\sigma(k)}^{j_k}, & (\textit{commutative}).\end{cases}$$

There are two parts in the symbolic representation of a monomial: the first part, u^k, indicating its degree; the second part being in $\mathcal{A}^k$. The symbols of Gel'fand and Dikii only contain the second part. We emphasize that the first part is very important in dealing with the monomials u^l and the case of several noncommutative dependent variables.

In general, we denote the symbolic representation of $P\in\mathcal{U}^k$, whether it is commutative or not, by $\hat{P}$ and $Q\in\mathcal{U}^l$ by $\hat{Q}$. The multiplication of P and Q corresponds to the symbol

$$\widehat{PQ}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k,\xi_{k+1},\eta_{k+1},\ldots,\xi_{k+l},\eta_{k+l})=\hat{P}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k)\hat{Q}(\xi_{k+1},\eta_{k+1},\ldots,\xi_{k+l},\eta_{k+l});\tag{5}$$

when P and Q are commutative differential polynomials, the right-hand side needs to be symmetrized

$$\begin{aligned}&\widehat{PQ}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k,\xi_{k+1},\eta_{k+1},\ldots,\xi_{k+l},\eta_{k+l})\\&\quad=\frac{1}{(k+l)!}\sum_{\sigma\in\Sigma_{k+l}}\hat{P}(\xi_{\sigma(1)},\eta_{\sigma(1)},\ldots,\xi_{\sigma(k)},\eta_{\sigma(k)})\hat{Q}(\xi_{\sigma(k+1)},\eta_{\sigma(k+1)},\ldots,\xi_{\sigma(k+l)},\eta_{\sigma(k+l)}).\end{aligned}\tag{6}$$

The total derivatives D_x and D_y have the following representations:

$$\widehat{D_xP}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k)=(\xi_1+\cdots+\xi_k)\hat{P}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k);$$

$$\widehat{D_yP}(\xi_1,\eta_1,\xi_2,\eta_2,\cdots,\xi_k,\eta_k)=(\eta_1+\cdots+\eta_k)\hat{P}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k).$$

Naturally, the actions of $\Theta=D_x^{-1}D_y$ and Θ^{-1} on $P\in\mathcal{U}^k$ can be represented as

$$\widehat{\Theta P}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k)=\frac{\eta_1+\cdots+\eta_k}{\xi_1+\cdots+\xi_k}\hat{P}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k);$$

$$\widehat{\Theta^{-1}P}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k)=\frac{\xi_1+\cdots+\xi_k}{\eta_1+\cdots+\eta_k}\hat{P}(\xi_1,\eta_1,\xi_2,\eta_2,\ldots,\xi_k,\eta_k).$$

Similar to the multiplication of P and Q, we have

Definition 2: *Let $P\in\mathcal{U}^k$ and $Q\in\mathcal{U}^l$. Then*

$$\widehat{P\Theta Q}=\hat{P}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k)\frac{\eta_{k+1}+\cdots+\eta_{k+l}}{\xi_{k+1}+\cdots+\xi_{k+l}}\hat{Q}(\xi_{k+1},\eta_{k+1},\ldots,\xi_{k+l},\eta_{k+l}).$$

When P and Q are commutative differential polynomials, the right-hand side needs to be symmetrized.

In the same way, we can uniquely define the symbol of $P\Theta^{-1}Q$. Together with the multiplication rule (5) or (6), we have now completely determined the symbolic representations of the elements in $\mathcal{U}_1(\Theta)$. By induction, we can define the symbolic representation of any element in $\mathcal{U}(\Theta)$, which is a rational function with its denominator being the products of the linear factors. The expression of the denominator uniquely determines how the operator $\Theta^{\pm 1}$ is nested.

Example 1: The expressions $u^3\xi_1(\eta_2+\eta_3)/(\xi_2+\xi_3)(\xi_3/\eta_3)$ *and* $u^3\xi_1(\eta_2/\xi_2)(\xi_3/\eta_3)$ *are the symbolic representations of* $u_x\Theta(u\Theta^{-1}u)\in\mathcal{U}_2(\Theta)$ *and* $u_x(\Theta u)\Theta^{-1}u\in\mathcal{U}_1(\Theta)$, *respectively*.

Let us define the symbolic representations of pseudo-differential operators motivated by their Fourier transforms. First we assign a special symbol X to the operator D_x. Its formal inverse D_x^{-1} has the symbol $1/X$. Then we have the following rules for $f\in\mathcal{U}^k(\Theta)$ with symbol $\hat{f}$ and $g\in\mathcal{U}^l(\Theta)$ with symbol $\hat{g}$:

$$X\circ\hat{f}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k)=(\xi_1+\cdots+\xi_k+X)\hat{f}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k),$$

which represents the Leibniz rule $D_x\circ f=D_x(f)+f\circ D_x$; and the composition rule

$$\hat{f}X^p\circ\hat{g}X^q=\hat{f}(\xi_1,\eta_1,\ldots,\xi_k,\eta_k)(\xi_{k+1}+\cdots+\xi_{k+l}+X)^p\hat{g}(\xi_{k+1},\eta_{k+1},\ldots,\xi_{k+l},\eta_{k+l})X^q.$$

This composition rule is valid for both positive and negative powers p and q. For positive powers, it is a polynomial of X. For negative powers, one can expand it at $X=\infty$ to identify it.

Example 2: The symbol of $D_x^{-1}u$ *is* $u/(X+\xi)$ *if we assign* ξ *as the symbol for* u. *Then in the noncommutative case we have*

$$D_x^{-1}uD_x^{-1}u=u^2D_x^{-2}-(2uu_x+u_xu)D_x^{-3}+(3uu_{xx}+3u_x^2+u_{xx}u)D_x^{-4}+\cdots.$$

Symbolically, we can compute it by

$$\frac{u}{X+\xi}\circ\frac{u}{X+\xi}=\frac{u^2}{(X+\xi_1+\xi_2)(X+\xi_2)}=u^2\left(\frac{1}{X^2}-\frac{\xi_1+2\xi_2}{X^3}+\frac{\xi_1^2+3\xi_1\xi_2+3\xi_2^2}{X^4}+\cdots\right).$$

To extend the symbolic representation from one dependent variable to several noncommutative dependent variables is straightforward. We need to assign new symbols for each of them such as assigning $\xi^{(1)},\eta^{(1)}$ for u and $\xi^{(2)},\eta^{(2)}$ for v, and so on. As one can imagine, the abstract formulas for arbitrary n-dependent variables get very long and it is difficult to present them in a compact way. We have no problems in handling small n or given expressions.

Example 3: The symbolic representation of u_xv_y *is* $uv\xi^{(1)}\eta^{(2)}$ *and that of* v_yu_x *is* $vu\xi^{(1)}\eta^{(2)}$.

Notice that the only difference in the symbolic representations for u_xv_y and v_yu_x is uv instead of vu, that is, the noncommutativity of dependent variables lies in the first part of the symbolic representation indicating the degree of the expression.

III. LAX FORMULATION OF (2+1)-DIMENSIONAL INTEGRABLE EQUATIONS

In this section, we give a short description of construction of (2+1)-dimensional integrable equations from a given scalar Lax operator based on the well-known Sato approach. For details on the Sato approach, see the recent books[18,19] and related references therein.

Consider an mth-order formal pseudo-differential operator

$$A=a_mD_x^m+a_{m-1}D_x^{m-1}+\cdots+a_0+a_{-1}D_x^{-1}+\cdots,\quad m\geqslant 0,$$

where the coefficients a_k are functions of x and D_x^{-1} is the formal inverse of the total x-derivative D_x. Here the functions a_k take their values in commutative (for instance complex numbers $\mathbb{C}$) or noncommutative (for instance the algebra of $n\times n$ matrices) associative algebras.

To define the product of two pseudo-differential operators requires the action of differential operator D_x^n on a multiplication operator f (given by a function of x),

$$D_x^n \circ f = \sum_{i\geqslant 0} \frac{n(n-1)\cdots(n-i+1)}{i!}(D_x^i f)D_x^{n-i}.$$

Let the commutator be the bracket on the set of pseudo-differential operators. Thus, the set of pseudo-differential operators forms a Lie algebra. For an integer $k<m$, we introduce notations

$$A_{\geqslant k} = a_m D_x^m + a_{m-1}D_x^{m-1} + \cdots + a_k D_x^k$$

$$A_{<k} = A - A_{\geqslant k} = a_{k-1}D_x^{k-1} + \cdots .$$

When $k \in \{0,1\}$, the Lie algebra decomposes as a direct sum of two subalgebras in both commutative and noncommutative cases. We denote the projections onto these subalgebras by $\mathcal{P}_{\pm}$. Such decompositions are naturally related with integrability and lead to admissible scalar Lax operators for $(1+1)$-dimensional Lax dynamics (cf. Ref. 18, p. 270 for the commutative case), namely

$$k=0\text{: } \widetilde{L} = D_x^n + u^{(n-2)}D_x^{n-2} + u^{(n-3)}D_x^{n-3} + \cdots + u^{(0)}, \quad n \geqslant 2;$$

$$k=1\text{: } \widetilde{L} = D_x^n + u^{(n-1)}D_x^{n-1} + u^{(n-2)}D_x^{n-2} + \cdots + u^{(0)} + D_x^{-1}u^{(-1)}, \quad n \geqslant 2;$$

where $u^{(i)}$ are functions of a spatial variable x.

We know every pseudo-differential operator of order $n>0$ has an nth root. This allows us to define the fractional powers $\widetilde{L}^{i/n}, i \in \mathbb{N}$. Let $\widetilde{B}_i = \mathcal{P}_+(\widetilde{L}^{i/n})$. For each choice of i, we introduce a different time variable t_i. Thus, the flows defined by

$$\frac{\partial \widetilde{L}}{\partial t_i} = [B_i, \widetilde{L}], \quad i \in \mathbb{N}$$

commute.[20]

This setting up can be generalized into the $(2+1)$-dimensional case as follows: An mth-order pseudo-differential operator of two spatial variables is of the form

$$H = -D_y + a_m D_x^m + a_{m-1}D_x^{m-1} + \cdots + a_0 + a_{-1}D_x^{-1} + \cdots, \quad m \geqslant 0,$$

where coefficients a_k are functions of x, y and for an integer $k<m$, we split into

$$H_{\geqslant k} = a_m D_x^m + a_{m-1}D_x^{m-1} + \cdots + a_k D_x^k$$

$$H_{<k} = H - H_{\geqslant k} = -D_y + a_{k-1}D_x^{k-1} + \cdots .$$

Similar to the $(1+1)$-dimensional case, this operator algebra decomposes as a direct sum of two subalgebras in both commutative and noncommutative cases when $k \in \{0,1\}$. The admissible types of scalar Lax operators for the case of $(2+1)$ dimensions are $\widetilde{L} - D_y$, i.e.,

(a) $k=0$: $L = D_x^n + u^{(n-2)}D_x^{n-2} + u^{(n-3)}D_x^{n-3} + \cdots + u^{(0)} - D_y, \quad n \geqslant 2;$

(b) $k=1$: $L = D_x^n + u^{(n-1)}D_x^{n-1} + u^{(n-2)}D_x^{n-2} + \cdots + u^{(0)} + D_x^{-1}u^{(-1)} - D_y, \quad n \geqslant 2;$

(c) $k=1$: $L = u^{(0)} + D_x^{-1}u^{(-1)} - D_y;$

where $u^{(i)}$ are functions of two spatial variables x, y. We often use $u, v, w, \ldots$ in the examples. When $n=1$ for case (b), we have $L = D_x + u^{(0)} + D_x^{-1}u^{(-1)} - D_y$, which can be transformed into case (c) by transformation (2). Therefore, we exclude it from our consideration.

Let $S = D_x + a_0 + a_{-1}D_x^{-1} + \cdots$. For any operator L as listed in cases (a), (b), and (c), the relation

$$[S,L] := SL - LS = 0, \tag{7}$$

uniquely determines the operator S by taking the integration constants as zero. Furthermore, we have $[S^n,L]=0$ for any $n \in \mathbb{N}$. For each choice of i, we introduce a different time variable t_i and define the Lax equation by

$$\frac{\partial L}{\partial t_i} = [S^i{}_{\geqslant k}, L], \tag{8}$$

where k is determined by the operator L as listed in cases (a), (b), and (c).

Theorem 1: *For the operator S uniquely determined as above by (7), the flows defined by Lax equations (8) commute, that is,* $\partial_{t_j}\partial_{t_i}L=\partial_{t_i}\partial_{t_j}L$.

Proof: Using Lax equations, we have

$$\partial_{t_j}\partial_{t_i}L = [\partial_{t_j}S^i{}_{\geqslant k}, L] + [S^i{}_{\geqslant k}, \partial_{t_j}L] = [\partial_{t_j}S^i{}_{\geqslant k}, L] + [S^i{}_{\geqslant k}, [S^j{}_{\geqslant k}, L]].$$

Hence

$$\partial_{t_j}\partial_{t_i}L - \partial_{t_i}\partial_{t_j}L = [\partial_{t_j}S^i{}_{\geqslant k} - \partial_{t_i}S^j{}_{\geqslant k} - [S^j{}_{\geqslant k}, S^i{}_{\geqslant k}], L].$$

Meanwhile, from formula (7), we get

$$[\partial_{t_i}S, L] = -[S, \partial_{t_i}L] = -[S, [S^i{}_{\geqslant k}, L]] = [[S^i{}_{\geqslant k}, S], L],$$

implying

$$\partial_{t_i}S = [S^i{}_{\geqslant k}, S]. \tag{9}$$

Thus

$$\begin{aligned}
\partial_{t_j}S^i{}_{\geqslant k} - \partial_{t_i}S^j{}_{\geqslant k} - [S^j{}_{\geqslant k}, S^i{}_{\geqslant k}] &= (\partial_{t_j}S^i)_{\geqslant k} - (\partial_{t_i}S^j)_{\geqslant k} - [S^j{}_{\geqslant k}, S^i{}_{\geqslant k}] \\
&= [S^j{}_{\geqslant k}, S^i]_{\geqslant k} - [S^i{}_{\geqslant k}, S^j]_{\geqslant k} - [S^j{}_{\geqslant k}, S^i{}_{\geqslant k}] \\
&= -[S^j{}_{<k}, S^i{}_{\geqslant k} + S^i{}_{<k}]_{\geqslant k} - [S^i{}_{\geqslant k}, S^j{}_{\geqslant k} + S^j{}_{<k}]_{\geqslant k} - [S^j{}_{\geqslant k}, S^i{}_{\geqslant k}] \\
&= -[S^j{}_{<k}, S^i{}_{<k}]_{\geqslant k} = 0.
\end{aligned}$$

This leads to $\partial_{t_j}\partial_{t_i}L=\partial_{t_i}\partial_{t_j}L$. ◇

Remark 1: In the commutative case, there is one more admissible type of scalar Lax operator, that is,

$$k=2: \quad L = u^{(n)^n}D_x^n + u^{(n-1)}D_x^{n-1} + u^{(n-2)}D_x^{n-2} + \cdots + u^{(0)} + D_x^{-1}u^{(-1)} + D_x^{-2}u^{(-2)} - D_y.$$

Theorem 1 is also valid for this type by taking $S=u^{(n)}D_x+a_0+a_{-1}D_x^{-1}+\cdots$ instead.

Example 4: Consider the Lax operator $L=u^2D_x^2+vD_x+w+D_x^{-1}p+D_x^{-2}q-D_y$, *where all dependent variables take their values in* $\mathbb{C}$. *Using formula (7), we have* $S=uD_x+a_0+a_{-1}D_x^{-1}+\cdots$ *with*

$$a_0 = -\frac{1}{2}\left(u_x - \frac{v}{u} + \Theta\frac{1}{u}\right)$$

$$a_{-1} = \frac{1}{8}\left(2u_{xx} - \frac{u_x^2}{u} - \frac{2v_x}{u} + \frac{4u_xv}{u^2} - \frac{v^2}{u^3} - \frac{4u_y}{u^2} + \frac{2}{u}\Theta\frac{v}{u^2} + \frac{4w}{u} - \frac{2}{u}\Theta\left(\frac{1}{u}\Theta\frac{1}{u}\right) + \frac{1}{u}\left(\Theta\frac{1}{u}\right)^2\right).$$

and $S^1{}_{\geqslant 2}=0$, $S^2{}_{\geqslant 2}=u^2D_x^2$, $S^3{}_{\geqslant 2}=u^3D_x^3+3u^2(u_x+a_0)D_x^2$. *By the Lax equation, we obtain*

$$\begin{cases} u_{t_3} = \frac{1}{4}\left(u^3 u_{xxx} - 6u_y \Theta \frac{1}{u} - 3u\left(\Theta \frac{1}{u} \right)_y + 3u^2 v_{xx} + 3u^2 w_x + 3v_y + 3v v_x - 3\frac{u_x}{u} v^2 - 6(uv)_x \Theta \frac{1}{u} \right) \\ v_{t_3} = u^3 v_{xxx} + 3u^2 (w_{xx} + u p_x + u_x p + (v_{xx} + 2w_x)(u_x + a_0)) \\ w_{t_3} = u^3 w_{xxx} + 3u^2 (w_{xx} + p_x)(u_x + a_0) + 3p(u^2 a_0)_x + 3u^2 (u q_x - 2u_x p_x + 2u_x q) \\ p_{t_3} = (u^3 p)_{xxx} - 3([u^2 (u_x p + a_0 p + q)]_{xx} + 2[u^2 q (u_x + a_0)]_x) \\ q_{t_3} = (u^3 q)_{xxx} - 3[u^2 q (u_x + a_0)]_{xx}. \end{cases}$$

Notice that the reduction of $v=w=p=q=0$ *leads to the well-known* $(2+1)$*-Harry-Dym equation*

$$u_{t_3} = \frac{1}{4}\left(u^3 u_{xxx} - 6u_y \Theta \frac{1}{u} - 3u\left(\Theta \frac{1}{u} \right)_y \right).$$

IV. LAX FORMULATION IN SYMBOLIC REPRESENTATION

In this section, we carry out the formalism of Sec. III in symbolic form. We first consider noncommutative dependent variables to simplify our formulas. The strategy for the commutative case is to do the calculation as much as possible by treating it as noncommutative and only do symmetrization at the last stage to get the uniqueness of the symbolic representation since the symmetrization complicates the calculation dramatically.

Let us assign the symbols $\xi^{(i)}$, $\eta^{(i)}$ for dependent variable $u^{(i)}$ and the symbol Y for the operator D_y. The symbolic representations of the admissible scalar Lax operators are

(a) $k=0$: $\hat{L} = X^n - Y + u^{(n-2)} X^{n-2} + u^{(n-3)} X^{n-3} + \cdots + u^{(0)}, \quad n \geqslant 2;$

(b) $k=1$: $\hat{L} = X^n - Y + u^{(n-1)} X^{n-1} + u^{(n-2)} X^{n-2} + \cdots + u^{(0)} + u^{(-1)} \frac{1}{X + \xi^{(-1)}}, \quad n \geqslant 2;$

(c) $k=1$: $\hat{L} = -Y + u^{(0)} + u^{(-1)} \frac{1}{X + \xi^{(-1)}}.$

We first treat case (a). It is convenient to consider formal series in the form, for $n \geqslant 2$,

$$S = X + \sum_{i=0}^{n-2} u^{(i)} a_1^{(i)}(\xi_1^{(i)}, \eta_1^{(i)}, X) + \sum_{i_1=0}^{n-2} \sum_{i_2=0}^{n-2} u^{(i_1)} u^{(i_2)} a_2^{(i_1 i_2)}(\xi_{j_1}^{(i_1)}, \eta_{j_1}^{(i_1)}, \xi_{j_2}^{(i_2)}, \eta_{j_2}^{(i_2)}, X) + \cdots, \tag{10}$$

where a_i are functions of their specific arguments and j_k is defined by the number of i_k in the list of $[i_1, i_2, \ldots, i_l]$, which implies that $j_1=1$ and $j_k \geqslant 1$, $k=1,2,\ldots,l$. For example, when $i_1=i_2$, the arguments of function $a_2^{i_1 i_1}$ are $\xi_1^{(i_1)}$, $\eta_1^{(i_1)}$, $\xi_2^{(i_1)}$, $\eta_2^{(i_1)}$, and X.

It is easy to check that

$$[X^n - Y, \phi(\xi_{j_1}^{(i_1)}, \eta_{j_1}^{(i_1)}, \ldots, \xi_{j_l}^{(i_l)}, \eta_{j_l}^{(i_l)}, X)] = N_l(\xi_{j_1}^{(i_1)}, \eta_{j_1}^{(i_1)}, \ldots, \xi_{j_l}^{(i_l)}, \eta_{j_l}^{(i_l)}, X)\phi, \tag{11}$$

where the polynomial N_l is defined by

$$N_l(x_1, y_1, x_2, y_2, \ldots, x_l, y_l; X) = \left(\sum_{i=1}^{l} x_i + X \right)^n - X^n - \sum_{i=1}^{l} y_i. \tag{12}$$

Proposition 1: For any operator L *in case* (a)*, if the formal series (10) satisfies the relation* $[S,L]=0$ *[cf. (7)], we have for* $l \geqslant 1$,

$$a_l^{(i_1 i_2 \cdots i_l)} = a_l(\xi_{j_1}^{(i_1)}, \eta_{j_1}^{(i_1)}, \ldots, \xi_{j_l}^{(i_l)}, \eta_{j_l}^{(i_l)}, X) = \prod_{r=1}^{l} \left(X + \sum_{s=r+1}^{l} \xi_{j_s}^{(i_s)} \right)^{i_r} b_l(\xi_{j_1}^{(i_1)}, \eta_{j_1}^{(i_1)}, \ldots, \xi_{j_l}^{(i_l)}, \eta_{j_l}^{(i_l)}, X), \tag{13}$$

where the superindex $i_s \in \{0,1,2,\ldots,n-2\}$ *and the subindex* j_k *is defined by the number of* i_k *in the list of* $[i_1,i_2,\ldots,i_k]$. *The function* b_l, $l \geqslant 1$, *is defined by*

$$b_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)=\frac{c_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}{N_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)} \tag{14}$$

with $l>1$

$$\begin{aligned} c_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X) &= b_{l-1}(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)}\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)}) \\ &\quad - b_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X) \end{aligned} \tag{15}$$

and the initial function $c_1(\xi_1^{(i)},\eta_1^{(i)},X)=\xi_1^{(i)}$.

Proof: We compute $[L,S]$ symbolically and collect the coefficients of each algebraically independent monomial of the dependent variables. For the linear terms, we have for any $i \in \{0,\ldots,n-2\}$,

$$a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)=\frac{\xi_1^{(i)}X^i}{N_1(\xi_1^{(i)},\eta_1^{(i)},X)}=b_1(\xi_1^{(i)},\eta_1^{(i)},X)X^i. \tag{16}$$

For the quadratic terms, when $i \neq j$, we need to compute

$$\begin{aligned} A^{ij} &:= -X^i \circ a_1^{(j)}(\xi_1^{(j)},\eta_1^{(j)},X)+a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)\circ X^j \\ &= -\frac{(X+\xi_1^{(j)})^i\xi_1^{(j)}X^j}{N_1(\xi_1^{(j)},\eta_1^{(j)},X)}+\frac{\xi_1^{(i)}(X+\xi_1^{(j)})^iX^j}{N_1(\xi_1^{(i)},\eta_1^{(i)},X+\xi_1^{(j)})} \\ &= (X+\xi_1^{(j)})^iX^j\left(\frac{\xi_1^{(i)}}{N_1(\xi_1^{(i)},\eta_1^{(i)},X+\xi_1^{(j)})}-\frac{\xi_1^{(j)}}{N_1(\xi_1^{(j)},\eta_1^{(j)},X)}\right) \\ &= (X+\xi_1^{(j)})^iX^j(b_1(\xi_1^{(i)},\eta_1^{(i)},X+\xi_1^{(j)})-b_1(\xi_1^{(j)},\eta_1^{(j)},X))=(X+\xi_1^{(j)})^iX^jc_2(\xi_1^{(i)},\eta_1^{(i)},\xi_1^{(j)},\eta_1^{(j)},X), \end{aligned}$$

and when $i=j$, we have

$$\begin{aligned} A^{ii} &:= -[X^i,a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)]=-X^i\circ a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)+a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)\circ X^i \\ &= -\frac{(X+\xi_2^{(i)})^i\xi_2^{(i)}X^i}{N_1(\xi_2^{(i)},\eta_2^{(i)},X)}+\frac{\xi_1^{(i)}(X+\xi_2^{(i)})^iX^i}{N_1(\xi_1^{(i)},\eta_1^{(i)},X+\xi_2^{(i)})}. \end{aligned}$$

This can be obtained by substituting $\xi_1^{(j)}=\xi_2^{(i)}$ and $\eta_1^{(j)}=\eta_2^{(i)}$ in A^{ij}. It follows that

$$a_2^{(i_1i_2)}(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},X)=\frac{A^{i_1i_2}}{N_2(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},X)}=(X+\xi_{j_2}^{(i_2)})^{i_1}X^{i_2}b_2(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},X). \tag{17}$$

Assume that formula (13) is valid for degree $l-1$. Let us compute $a_l^{(i_1i_2\cdots i_l)}$ in the same way as computing the quadratic terms. Then we have

$$\begin{aligned} &N_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)a_l^{(i_1i_2\cdots i_l)} \\ &\quad = -X^{i_1}\circ a_{l-1}^{(i_2\cdots i_l)}+a_{l-1}^{(i_1i_2\cdots i_{l-1})}\circ X^{i_l} \\ &\quad = -\left(X+\sum_{p=2}^{l}\xi_{j_p}^{(i_p)}\right)^{i_1}\prod_{r=2}^{l}\left(X+\sum_{s=r+1}^{l}\xi_{j_s}^{(i_s)}\right)^{i_r}b_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X) \end{aligned}$$

$$
\begin{aligned}
&+\prod_{r=1}^{l-1}\left(X+\sum_{s=r+1}^{l}\xi_{j_s}^{(i_s)}\right)^{i_r} X^{i_l} b_{l-1}(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})\\
&=\prod_{r=1}^{l}\left(X+\sum_{s=r+1}^{l}\xi_{j_s}^{(i_s)}\right)^{i_r}(b_{l-1}(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})\\
&\quad-b_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X))\\
&=\prod_{r=1}^{l}\left(X+\sum_{s=r+1}^{l}\xi_{j_s}^{(i_s)}\right)^{i_r} c_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X).
\end{aligned}
$$

According to definition (14), we proved that formula (13) is valid for degree l. ◇

Similarly, we prove the following result for any operator L in cases (b) and (c).

Proposition 2: For any operator L in case (b), *consider a formal series of the form for* $n\geqslant 2$,

$$
S=X+\sum_{i=-1}^{n-1}u^{(i)}a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)+\sum_{i_1,i_2=-1}^{n-1}u^{(i_1)}u^{(i_2)}a_2^{(i_1i_2)}(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},X)+\cdots . \tag{18}
$$

Here a_i *are functions of their specific arguments, the superindex* $i_s\in\{-1,0,1,\ldots,n-1\}$ *and the subindex* j_k *is defined by the number of* i_k *in the list of* $[i_1,i_2,\ldots,i_k]$. *If it satisfies the relation* $[S,L]=0$ *[cf. (7)], we have for* $l\geqslant 1$,

$$
a_l^{(i_1i_2\cdots i_l)}=a_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)=\prod_{r=1}^{l}\left(h(i_r)+\sum_{s=r+1}^{l}\xi_{j_s}^{(i_s)}\right)^{i_r} b_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X), \tag{19}
$$

where $h(i_r)=X+\xi_{j_r}^{(-1)}$ *if* $i_r=-1$, *otherwise* $h(i_r)=X$. *The functions* b_l *are defined in Proposition 1; cf. formula (14) and (15).*

Notice that for operator L listed in case (c), we have $N_l(x_1,y_1,x_2,y_2,\ldots,x_l,y_l;X)=-\Sigma_{i=1}^{l}y_i$, cf. (11), which corresponds to the action of total y-derivative D_y. Thus

Proposition 3: For operator L listed in case (c), *if a formal series of the form*

$$
S=X+\sum_{i=-1}^{0}u^{(i)}a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)+\sum_{i_1,i_2=-1}^{0}u^{(i_1)}u^{(i_2)}a_2^{(i_1i_2)}(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},X)+\cdots , \tag{20}
$$

where the superindex $i_s\in\{-1,0\}$ *and the subindex* j_k *is defined by the number of* i_k *in the list of* $[i_1,i_2,\ldots,i_k]$, *satisfies the relation* $[S,L]=0$ *[cf. (7)], we have for* $l\geqslant 1$, *the functions* a_l *are defined in Proposition 2, cf. formula (19) with* $N_l(x_1,y_1,x_2,y_2,\ldots,x_l,y_l;X)=-\Sigma_{i=1}^{l}y_i$.

To construct the hierarchy of the Lax equations we need to expand the coefficients of operator (10) or (18) or (20) at $X=\infty$ and truncate at the required degree.

Definition 3: *We say that a function* $h(x_1,y_1,x_2,y_2,\ldots,x_l,y_l,X)$ *is kth (quasi-local) polynomial if the first k coefficients of its expansion at* $X=\infty$ *are symbols of (quasi-local) polynomials. If a function is kth (quasi-local) polynomial for any k, we say it is (quasi-local) polynomial.*

When $n\geqslant 2$, that is, operator L in cases (a) and (b), the expansion of $N_l(x_1,y_1,x_2,y_2,\ldots,x_l,y_l;X)$ at $X=\infty$ is of the form

$$
\begin{aligned}
&N_l(x_1,y_1,x_2,y_2,\ldots,x_l,y_l;X)^{-1}\\
&=\frac{1}{nX^{n-1}\left(\sum_{i=1}^{l}x_i\right)}\sum_{j\geqslant 0}\left[\frac{\sum_{i=1}^{l}y_i}{nX^{n-1}\left(\sum_{i=1}^{l}x_i\right)}-\frac{1}{n}\sum_{k=0}^{n-2}\binom{n}{k}X^{k+1-n}\left(\sum_{i=0}^{l}x_i\right)^{n-k-1}\right]^{j},\quad n\geqslant 2.
\end{aligned}
$$

For operator L listed in case (c), we know $N_l(x_1,y_1,x_2,y_2,\ldots,x_l,y_l;X)=-\Sigma_{i=1}^{l}y_i$. Therefore, if we

want to prove that the coefficients of operators (10), (18), and (20), i.e., the functions a_l, are quasi-local, we need to show that the functions c_l can be split into the sum of the image of D_x and the image of D_y. It is clear from formula (16) that $a_1^{(i)}(\xi_1^{(i)},\eta_1^{(i)},X)$ are quasi-local since we have $c_1(\xi_1^{(i)},\eta_1^{(i)},X)=\xi_1^{(i)}$. Now we concentrate on the cases when $l>1$.

Proposition 4: The functions $c_l(\xi_{j_1}^{(i_1)},\eta_{j_1}^{(i_1)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)$ *for* $l>1$ *vanish after substitution*

$$\xi_{j_1}^{(i_1)}=-\xi_{j_2}^{(i_2)}-\cdots-\xi_{j_{l-1}}^{(i_{l-1})} \text{ and } \eta_{j_1}^{(i_1)}=-\eta_{j_2}^{(i_2)}-\cdots-\eta_{j_{l-1}}^{(i_{l-1})}.$$

We give its proof in the Appendix. In fact, this proposition does not lead to our intended conclusion that b_l and thus a_l are quasi-local since the objects are rational, not polynomial. For example, the expression $u^2((\eta_2/\xi_2)-(\eta_1/\xi_1))$ representing $u\Theta u-(\Theta u)u$ satisfies the above proposition. However, we cannot write $u\Theta u-(\Theta u)u=D_xf_1+D_yf_2$, where both f_1 and f_2 are in $\mathcal{U}(\Theta)$.

We first have a close look at the quadratic terms. For any operator L in cases (a) and (b), let $\eta_{j_r}^{i_r}=\theta_{j_r}^{i_r}\xi_{j_r}^{i_r}$. Then the function $c_2(\xi_{j_1}^{i_1},\eta_{j_1}^{i_1},\xi_{j_2}^{i_2},\eta_{j_2}^{i_2},X)$, where $\xi_{j_1}^{i_1}\neq 0$ and $\xi_{j_2}^{i_2}\neq 0$, is a polynomial of $\theta_{j_r}^{i_r},\xi_{j_r}^{i_r}$, $r=1,2$. Notice that

$$(\eta_{j_1}^{i_1}+\eta_{j_2}^{i_2})=\theta_{j_1}^{i_1}\xi_{j_1}^{i_1}+\theta_{j_2}^{i_2}\xi_{j_2}^{i_2}=(\theta_{j_1}^{i_1}-\theta_{j_2}^{i_2})\xi_{j_1}^{i_1}+\theta_{j_2}^{i_2}(\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2})=\theta_{j_1}^{i_1}(\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2})-(\theta_{j_1}^{i_1}-\theta_{j_2}^{i_2})\xi_{j_2}^{i_2}. \tag{21}$$

The affine variety (cf. Ref. 21) defined by $\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2}$ and $\eta_{j_1}^{i_1}+\eta_{j_2}^{i_2}$ is

$$V(\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2},\eta_{j_1}^{i_1}+\eta_{j_2}^{i_2})=V(\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2},(\theta_{j_1}^{i_1}-\theta_{j_2}^{i_2})\xi_{j_1}^{i_1},(\theta_{j_1}^{i_1}-\theta_{j_2}^{i_2})\xi_{j_2}^{i_2})=V(\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2},\theta_{j_1}^{i_1}-\theta_{j_2}^{i_2})\cup V(\xi_{j_1}^{i_1},\xi_{j_2}^{i_2}).$$

From Proposition 4, it can be written as

$$c_2(\xi_{j_1}^{i_1},\theta_{j_1}^{i_1}\xi_{j_1}^{i_1},\xi_{j_2}^{i_2},\theta_{j_2}^{i_2}\xi_{j_2}^{i_2},X)=(\xi_{j_1}^{i_1}+\xi_{j_2}^{i_2})f_1+(\theta_{j_1}^{i_1}-\theta_{j_2}^{i_2})f_2,$$

where both f_1 and f_2 are polynomials of $\theta_{j_r}^{i_r},\xi_{j_r}^{i_r}$, $r=1,2$. From formula (21), the part that is not in the image of D_x or D_y only depends on $\theta_{j_r}^{i_r}$, $r=1,2$.

For operator L listed in case (c) since the function $N_l(x_1,y_1,\ldots,x_l,y_l,X)=-\Sigma_{i=1}^{l}y_i$, cf. Proposition 3, we let $\xi_{j_r}^{i_r}=\theta_{j_r}^{i_r}\eta_{j_r}^{i_r}$ instead. Then the function $c_2(\xi_{j_1}^{i_1},\eta_{j_1}^{i_1},\xi_{j_2}^{i_2},\eta_{j_2}^{i_2},X)$, where $\eta_{j_1}^{i_1}\neq 0$ and $\eta_{j_2}^{i_2}\neq 0$, is a polynomial of $\theta_{j_r}^{i_r},\xi_{j_r}^{i_r}$, $r=1,2$. The above discussion is valid.

Setting $\xi_{j_1}^{i_1}=\xi_{j_2}^{i_2}=0$, we obtain the function $c_2(\xi_{j_1}^{i_1},\eta_{j_1}^{i_1},\xi_{j_2}^{i_2},\eta_{j_2}^{i_2},X)$ equals

$$\frac{1}{nX^{n-1}-\theta_{j_1}^{i_1}}-\frac{1}{nX^{n-1}-\theta_{j_2}^{i_2}} \quad \text{for cases (a) and (b)}; \quad \theta_{j_2}^{i_2}-\theta_{j_1}^{i_1} \quad \text{for case (c)}, \tag{22}$$

which is zero after we symmetrize it with the permutation group Σ_2. This implies that the functions b_2 and thus a_2 are quasi-local in the commutative case.

A. The commutative case

We first give the formulas to compute the high degree terms of operator S for the commutative case directly from the formulas we obtained in Propositions 1, 2, and 3.

We denote the list $(i_1,i_2,\ldots,i_l)$ by I and $I_1=(i_{s_1},i_{s_2},\ldots,i_{s_r})$, where $1\leqslant s_1<s_2<\cdots<s_r\leqslant l$ and $1\leqslant r\leqslant l-1$. We use $I_2=(i_{p_1},i_{p_2},\ldots,i_{p_{l-r}})$ to denote the list by removing the elements of list I_1 from list I. For any element i_r in the set $\{i_1,i_2,\ldots,i_l\}$, we denote the number of i_r in the list I by $\#i_r$. Then the coefficient of $\Pi_{i_r\in\{i_1i_2\cdots i_l\}}(u^{(i_r)})^{\#i_r}$ in operator S, cf. formula (10), (18), and (20), can be computed by

$$\frac{1}{\prod_{i_r\in\{i_1i_2\cdots i_l\}}(\#i_r)!}\sum_{\sigma\in\Sigma_l}a_l(\xi_{j_{\sigma(1)}}^{(i_{\sigma(1)})},\eta_{j_{\sigma(1)}}^{(i_{\sigma(1)})},\ldots,\xi_{j_{\sigma(l)}}^{(i_{\sigma(l)})},\eta_{j_{\sigma(l)}}^{(i_{\sigma(l)})},X). \tag{23}$$

We denote it by

$$\frac{d_l^{i_1 i_2 \cdots i_l}}{N_l(\xi_{j_1}^{(i_1)}, \eta_{j_1}^{(i_1)}, \ldots, \xi_{j_l}^{(i_l)}, \eta_{j_l}^{(i_l)}, X)}.$$

In particular, for any operator L in case (a), the numerator $d_l^{i_1 i_2 \cdots i_l}$ equals

$$\frac{1}{\prod_{i_r \in \{i_1 i_2 \cdots i_l\}} (\#i_r)!} \sum_{\sigma \in \Sigma_l} \prod_{r=1}^{l} \left(X + \sum_{s=r+1}^{l} \xi_{j_{\sigma(s)}}^{(i_{\sigma(s)})} \right)^{i_{\sigma(r)}} c_l(\xi_{j_{\sigma(1)}}^{(i_{\sigma(1)})}, \eta_{j_{\sigma(1)}}^{(i_{\sigma(1)})}, \ldots, \xi_{j_{\sigma(l)}}^{(i_{\sigma(l)})}, \eta_{j_{\sigma(l)}}^{(i_{\sigma(l)})}, X). \quad (24)$$

For cases (b) and (c) the expression $(X+p)^{-1}$, where $p=\xi_{j_r}^{(-1)}+\sum_{s=r+1}^{l}\xi_{j_s}^{(i_s)}$, appears in formula (19). Its expansion at $X=\infty$ is of the form

$$(X+p)^{-1} = \frac{1}{X} \sum_{j=0}^{+\infty} \left(-\frac{p}{X} \right)^s, \quad (25)$$

whose coefficients are polynomials in p. This does not affect the proof and result. For case (c), we need to exchange the symbols $\xi_{j_r}^{i_r}$ and $\eta_{j_r}^{i_r}$ in the proof as the discussion we did for quadratic terms. Therefore, we will only give the proof for case (a).

The immediate consequence of the previous discussion on the quadratic terms is the following statement.

Proposition 5: All quadratic terms in operator S are quasi-local.

In fact, we can prove this statement is valid for all $l>0$.

Theorem 2: *Every term in the operator S, cf. formula* (10), (18), and (20), *obtained via* (23) *is quasi-local.*

Proof: We proved the linear and quadratic terms in S are quasi-local, that is, the statement is true for $l=1,2$. Assume it is also true for $l-1$. By induction, the function $d_l^{i_1 i_2 \cdots i_l}$, cf. (24), is polynomial of $\xi_{j_r}^{(i_r)}$ and $\theta_{I_1}=(\eta_{j_{s_1}}^{(i_{s_1})}+\cdots\eta_{j_{s_r}}^{(i_{s_r})})/(\xi_{j_{s_1}}^{(i_{s_1})}+\cdots\xi_{j_{s_r}}^{(i_{s_r})})$, $r=1,2,\ldots,l-1$, which obviously satisfies Proposition 4. This implies that the function $d_l^{i_1 i_2 \cdots i_l}$ is the sum of the parts with factors $\xi_{j_1}^{(i_1)}+\xi_{j_2}^{(i_2)}+\cdots+\xi_{j_l}^{(i_l)}$ or $\theta_{I_1}-\theta_{I_2}$ using the argument of the affine variety. From the recurrent relation in Proposition 1, we can compute the factor for any $\theta_{I_1}-\theta_{I_2}$ (without symmetrization), which equals

$$\prod_{q=1}^{r}(X+\xi_{j_{s_{q+1}}}^{(i_{s_{q+1}})}+\cdots+\xi_{j_{s_r}}^{(i_{s_r})}+\xi_{j_{p_1}}^{(i_{p_1})}+\cdots+\xi_{j_{p_{l-r}}}^{(i_{p_{l-r}})})^{i_{s_q}}\prod_{q=1}^{l-r}(X+\xi_{j_{p_{q+1}}}^{(i_{p_{q+1}})}+\cdots+\xi_{j_{p_{l-r}}}^{(i_{p_{l-r}})})^{i_{p_q}}$$
$$-\prod_{q=1}^{l-r}(X+\xi_{j_{p_{q+1}}}^{(i_{p_{q+1}})}+\cdots+\xi_{j_{p_{l-r}}}^{(i_{p_{l-r}})}+\xi_{j_{s_1}}^{(i_{s_1})}+\cdots+\xi_{j_{s_r}}^{(i_{s_r})})^{i_{p_q}}\prod_{q=1}^{r}(X+\xi_{j_{s_{q+1}}}^{(i_{s_{q+1}})}+\cdots+\xi_{j_{s_r}}^{(i_{s_r})})^{i_{s_q}}.$$

This expression is zero under the substitution $\Xi_{I_2}=\xi_{j_{p_1}}^{(i_{p_1})}+\cdots+\xi_{j_{p_{l-r}}}^{(i_{p_{l-r}})}=0$ and $\Xi_{I_1}=\xi_{j_{s_1}}^{(i_{s_1})}+\cdots+\xi_{j_{s_r}}^{(i_{s_r})}=0$, implying we have either $\Xi_{I_2}(\theta_{I_1}-\theta_{I_2})$ or $\Xi_{I_1}(\theta_{I_1}-\theta_{I_2})$ as a factor. We know

$$\Xi_{I_2}(\theta_{I_1}-\theta_{I_2})=\theta_{I_1}(\xi_{j_1}^{(i_1)}+\cdots+\xi_{j_l}^{(i_l)})-(\eta_{j_1}^{(i_1)}+\cdots+\eta_{j_l}^{(i_l)});$$

$$\Xi_{I_1}(\theta_{I_1}-\theta_{I_2})=(\eta_{j_1}^{(i_1)}+\cdots+\eta_{j_l}^{(i_l)})-\theta_{I_2}(\xi_{j_1}^{(i_1)}+\cdots+\xi_{j_l}^{(i_l)}).$$

Thus, the lth degree term of S is quasi-local. ◇

This theorem implies that every terms in S^n is quasi-local. From Theorem 1, we have

Theorem 3: *The hierarchies of* $(2+1)$*-integrable equation with scalar Lax operators are quasi-local.*

As mentioned in Remark 1, there is one more type of scalar Lax operator in the commutative case. The same result can be proved by extending the symbolic approach used in Ref. 22 for the $(1+1)$-dimensional case.

B. The noncommutative case

The extension of the concept of quasi-locality to the noncommutative case is rather complicated. D_x and D_y are the only derivations for the commutative differential ring. The extension simply enables us to apply D_x^{-1} and D_y^{-1} on the derivations. We know that the C_f, cf. (4), are also derivations for a noncommutative associative algebra and we need to take them into consideration. Based on Proposition 4, we propose the following extension using the symbolic representation. We start with $\mathcal{A}^k$, the space of polynomials in $2k$ variables, ξ_i and η_i, $i=1,\ldots,k$. Let $\xi_i=\lambda z_i$ and $\eta_i=\mu z_i$, where λ, μ are constants. We define $I(\mathcal{A}^k)$ as a set of all $f\in\mathcal{A}^k$ satisfying $f|_{z_1+\cdots z_k=0}=0$. For the elements in $g\in I(\mathcal{A}^k)$, we compute $g/(\xi_1+\cdots+\xi_k)$ and $g/(\eta_1+\cdots\eta_k)$ and collect them in the set $\mathcal{E}xt(\mathcal{A}^k)$. Now we define a sequence of extensions of $\mathcal{A}=\cup_k\mathcal{A}^k$. Let $\mathcal{A}_0^{ext}=\mathcal{A}$ and $\mathcal{A}_1^{ext}$ be the ring closure of the union $\mathcal{A}_0^{ext}\cup(\cup_k\mathcal{E}xt(\mathcal{A}^k))$. The number of variables is a natural grade on $\mathcal{A}_1^{ext}$ and again denote $\mathcal{A}_1^{ext^k}$ the space of elements in $\mathcal{A}_1^{ext}$ with $2k$ variables, ξ_i and η_i, $i=1,\ldots,k$. In general, we can define $\mathcal{A}_l^{ext}$ is the ring closure of the union $\mathcal{A}_{l-1}^{ext}\cup(\cup_k\mathcal{E}xt(\mathcal{A}_{l-1}^{ext^k}))$. Clearly, we have $\mathcal{A}_{l-1}^{ext}\subset\mathcal{A}_l^{ext}$. We now define $\mathcal{A}^{ext}=\lim_{l\to\infty}\mathcal{A}_l^{ext}$.

The above ring extension is bigger than we require. For example, the expression $(\eta_2/\xi_2)-(\eta_1/\xi_1)$ is not equal to zero under the substitution $\xi_1+\xi_2+\xi_3=0$ and $\eta_1+\eta_2+\eta_3=0$, that is, not satisfying Proposition 4. But it is in $I(\mathcal{A}_1^{ext^3})$. If we start from the symmetric polynomial, we hope to end up with the extension of commutative differential polynomial, i.e., quasi-local polynomials we defined in Sec. II. It is not difficult to notice that this extension is bigger than the concept of quasi-local commutative polynomials. However, we can not formulate such extension either via symbolic representation or from noncommutative differential polynomials as in the commutative case. It is still an open problem.

Here we compute explicitly some Lax flows for lower order scalar Lax operators of noncommutative dependent variable, which will help the reader to see the structures.

1. Noncommutative Boussinesq equation

Let us compute the hierarchy of Lax operator $L=D_x^3+uD_x+v-D_y$. From Proposition 1, we have

$$
\begin{aligned}
S=&X+u\frac{\xi_1^{(1)}X}{(X+\xi_1^{(1)})^3-X^3-\eta_1^{(1)}}+v\frac{\xi_1^{(0)}}{(X+\xi_1^{(0)})^3-X^3-\eta_1^{(0)}}+\frac{u^2(X+\xi_2^{(1)})X}{(X+\xi_1^{(1)}+\xi_2^{(1)})^3-X^3-\eta_1^{(1)}-\eta_2^{(1)}}\\
&\times\left(\frac{\xi_1^{(1)}}{(X+\xi_1^{(1)}+\xi_2^{(1)})^3-(X+\xi_2^{(1)})^3-\eta_1^{(1)}}-\frac{\xi_2^{(1)}}{(X+\xi_2^{(1)})^3-X^3-\eta_2^{(1)}}\right)\\
&+\frac{uv(X+\xi_1^{(0)})}{(X+\xi_1^{(1)}+\xi_1^{(0)})^3-X^3-\eta_1^{(1)}-\eta_1^{(0)}}\left(\frac{\xi_1^{(1)}}{(X+\xi_1^{(1)}+\xi_1^{(0)})^3-(X+\xi_1^{(0)})^3-\eta_1^{(1)}}\right.\\
&\left.-\frac{\xi_1^{(0)}}{(X+\xi_1^{(0)})^3-X^3-\eta_1^{(0)}}\right)+\frac{vuX}{(X+\xi_1^{(1)}+\xi_1^{(0)})^3-X^3-\eta_1^{(1)}-\eta_1^{(0)}}\\
&\times\left(\frac{\xi_1^{(0)}}{(X+\xi_1^{(1)}+\xi_1^{(0)})^3-(X+\xi_1^{(1)})^3-\eta_1^{(0)}}-\frac{\xi_1^{(1)}}{(X+\xi_1^{(1)})^3-X^3-\eta_1^{(1)}}\right)+\cdots\\
=&X+\frac{u}{3X}+\frac{v-u\xi_1^{(1)}}{3X^2}+\left(\frac{2u\xi_1^{(1)^2}}{9}+\frac{u\eta_1^{(1)}}{9\xi_1^{(1)}}-\frac{v\xi_1^{(0)}}{3}-\frac{u^2}{9}\right)\frac{1}{X^3}\\
&+\left(\frac{-u\xi_1^{(1)^3}}{9}-\frac{2u\eta_1^{(1)}}{9}+\frac{2v\xi_1^{(0)^2}}{9}+\frac{v\eta_1^{(0)}}{9\xi_1^{(0)}}-\frac{uv}{9}-\frac{vu}{9}+u^2\left(\frac{7\xi_2^{(1)}}{27}+\frac{5\xi_1^{(1)}}{27}+\frac{\frac{\eta_1^{(1)}}{27\xi_1^{(1)}}-\frac{\eta_2^{(1)}}{27\xi_2^{(1)}}}{\xi_1^{(1)}+\xi_2^{(1)}}\right)\right)\frac{1}{X^4}
\end{aligned}
$$

$$+\cdots,$$

which corresponds to

$$S = D_x + \frac{u}{3}D_x^{-1} + \left(\frac{v}{3} - \frac{u_x}{3}\right)D_x^{-2} + \left(\frac{2u_{xx}}{9} + \frac{\Theta u}{9} - \frac{v_x}{3} - \frac{u^2}{9}\right)D_x^{-3} + \left(\frac{2v_{xx}}{9} - \frac{u_{xxx}}{9} - \frac{2u_y}{9} + \frac{\Theta v}{9} - \frac{uv}{9} - \frac{vu}{9} + \frac{7uu_x}{27} + \frac{5u_x u}{27} + \frac{D_x^{-1}((\Theta u)u)}{27} - \frac{D_x^{-1}(u\Theta u)}{27}\right)D_x^{-4} + \cdots.$$

This leads to

$$S_{\geqslant 0} = D_x; \quad S^2_{\geqslant 0} = D_x^2 + \frac{2}{3}u; \quad S^3_{\geqslant 0} = D_x^3 + uD_x + v;$$

$$S^4_{\geqslant 0} = D_x^4 + \frac{4}{3}uD_x^2 + \frac{2}{3}(u_x + 2v)D_x + \frac{4}{9}\Theta u + \frac{2}{9}u^2 + \frac{2}{9}u_{xx} + \frac{2}{3}v_x;$$

$$S^5_{\geqslant 0} = D_x^5 + \frac{5}{3}uD_x^3 + \frac{5}{3}(u_x + v)D_x^2 + \left(\frac{5}{9}\Theta u + \frac{5}{9}u^2 + \frac{10}{9}u_{xx} + \frac{5}{3}v_x\right)D_x + \frac{10}{9}v_{xx} + \frac{5}{9}(\Theta v + uv + vu) + \frac{5}{27}(uu_x - u_x u + D_x^{-1}((\Theta u)u - u\Theta u)).$$

And we have

$$\begin{cases} u_{t_2} = -u_{xx} + 2v_x \\ v_{t_2} = v_{xx} + \frac{2}{3}(u_y - u_{3x} - uu_x + uv - vu). \end{cases}$$

Eliminating the dependent variable v from this equation and writing $t_2 = t$, we can derive the $(2+1)$-dimensional Boussinesq equation

$$u_{tt} = -\frac{1}{3}u_{4x} + \frac{4}{3}u_{xy} - \frac{2}{3}(u^2)_{xx} + \frac{2}{3}D_x[u, D_x^{-1}u_t].$$

Under the scaling transformation $x \mapsto \sqrt{6}x$, $y \mapsto \sqrt{\frac{3}{2}}y$, $u \mapsto 3u$, $t \mapsto 2t$, it can be rewritten as

$$u_{tt} = -u_{4x} + u_{xy} - 3(u^2)_{xx} + D_x[u, D_x^{-1}u_t].$$

Let $w = D_x^{-1}u$. We get the $(2+1)$-dimensional noncommutative potential Boussinesq equation

$$w_{tt} = -w_{4x} + w_{xy} - 3(w_x^2)_x + [w_x, w_t].$$

2. Noncommutative KP equation

Let us compute the hierarchy of the Lax operator $L = D_x^2 + u - D_y$. Since the order of L is low, it is easier to compute the operator S directly order by order as in Example 4 than to apply Proposition 2. Let

$$S = D_x + a_{-1}D_x^{-1} + a_{-2}D_x^{-2} + a_{-3}D_x^{-3}\cdots.$$

Using formula (10), we obtain

$$a_{-1} = \frac{u}{2}$$

$$a_{-2} = -\frac{u_x}{4} + \frac{\Theta u}{4}$$

$$a_{-3} = \frac{\Theta^2 u}{8} + \frac{u_{xx}}{8} - \frac{u_y}{4} - \frac{u^2}{8} - \frac{1}{8} D_x^{-1} C_u \Theta u.$$

This leads to

$$S^3_{\geqslant 0} = D_x^3 + \frac{3u}{2} D_x + \frac{3}{4}(u_x + \Theta u)$$

$$S^4_{\geqslant 0} = D_x^4 + 2uD_x^2 + (2u_x + \Theta u)D_x + \frac{u_y}{2} + u^2 + u_{xx} + \frac{\Theta^2 u}{2} - \frac{1}{2} D_x^{-1} C_u \Theta u$$

$$= 2D_x^2 D_y - D_y^2 + 2uD_y + \Theta u D_x + \frac{3u_y}{2} + \frac{\Theta^2 u}{2} - \frac{1}{2} D_x^{-1} C_u \Theta u + L^2.$$

And we have

$$u_{t_3} = \frac{1}{4}(u_{xxx} + 3uu_x + 3u_x u + 3\Theta u_y - 3C_u \Theta u),$$

which is the noncommutative KP equation and can be obtained from the recursion operator of KP, cf., Ref. 5, and

$$u_{t_4} = \frac{1}{2}(u_{xxy} + \Theta^2 u_y + 2uu_y + 2u_y u + u_x \Theta u + (\Theta u)u_x + C_u D_x^{-1} C_u \Theta u - \Theta C_u \Theta u - C_u \Theta^2 u).$$

3. Noncommutative mKP equation

Let us compute the hierarchy of the Lax operator $L = D_x^2 + uD_x + v + D_x^{-1} w - D_y$. Let

$$S = D_x + a_0 + a_{-1} D_x^{-1} + \cdots .$$

Using formula (10), we obtain

$$a_0 = \frac{u}{2}$$

$$a_{-1} = -\frac{u_x}{4} - \frac{u^2}{8} + \frac{v}{2} + \left(D_x + \frac{C_u}{2}\right)^{-1} \frac{u_y}{4}.$$

This leads to

$$S^2_{\geqslant 1} = D_x^2 + uD_x; \quad S^3_{\geqslant 1} = D_x^3 + \frac{3u}{2} D_x^2 + \frac{3}{8}\left(2u_x + u^2 + 4v + 2\left(D_x + \frac{C_u}{2}\right)^{-1} u_y\right) D_x.$$

And we have

$$\begin{cases} u_{t_2} = u_y + 2v_x + uv - vu \\ v_{t_2} = v_x + 2w_x + uv_x + uw - wu \\ w_{t_2} = -w_{xx} + (wu)_x \end{cases}$$

$$\begin{cases} u_{t_3}=\frac{1}{4}u_{xxx}+\frac{3}{8}C_u u_{xx}-\frac{3}{8}uu_x u+\frac{3}{4}u_{xy}+\frac{3}{8}(u^2)_y+\frac{3}{2}v_{xx}+\frac{3}{2}v_y+\frac{3}{2}uv_x+\frac{3}{2}vu_x-\frac{3}{8}C_v u^2-\frac{3}{4}C_v u_x+3w_x+\frac{3}{2}C_u w \\ \quad +\frac{3}{4}(D_y-D_x^2-uD_x+R_{u_x}-C_v)\left(D_x+\frac{C_u}{2}\right)^{-1}u_y \\ v_{t_3}=v_{xxx}+\frac{3}{2}uv_{xx}+\frac{3}{4}u_x v_x+\frac{3}{8}u^2 v_1+\frac{3}{2}vv_1+\frac{3}{2}uw_x+\frac{3}{2}w_x u+\frac{3}{4}wu_x+\frac{3}{4}u_x w-\frac{3}{8}C_w u^2-\frac{3}{2}C_w v+\frac{3}{4}(R_{v_x}-C_w)\left(D_x+\frac{C_u}{2}\right)^{-1}u_y \\ w_{t_3}=w_{xxx}-(wa_0)_{xx}+(wa_{-1})_x. \end{cases}$$

The reduction $v=w=0$ leads to the noncommutative mKP equation

$$u_{t_3}=\frac{1}{4}u_{xxx}+\frac{3}{8}C_u u_{xx}-\frac{3}{8}uu_x u+\frac{3}{4}u_{xy}+\frac{3}{8}(u^2)_y+\frac{3}{4}(D_y-D_x^2-L_u D_x+R_{u_x})\left(D_x+\frac{C_u}{2}\right)^{-1}u_y. \tag{26}$$

If we introduce new variable p satisfying $u_y=p_x+\frac{1}{2}C_u p$, the system for u and p is equivalent to the matrix mKP in Ref. 23.

If u does not depend on y, i.e., $u_y=0$, this gives us the noncommutative mKdV equation,[17,12]

$$u_{t_3}=\frac{1}{4}u_{xxx}+\frac{3}{8}C_u u_{xx}-\frac{3}{8}uu_x u.$$

If u takes its value over $\mathbb{C}$ (commutative), this gives us the well-known mKP equation

$$u_{t_3}=\frac{1}{4}u_{xxx}-\frac{3}{8}u^2u_x+\frac{3}{4}\Theta u_y+\frac{3}{4}u_x\Theta u. \tag{27}$$

We know Miura transformation $V=u_x-(u^2/2)+\Theta u$ transforms the mKP equation (27) into the KP equation $V_{t_3}=\frac{1}{4}V_{xxx}+\frac{3}{4}VV_x+\frac{3}{4}\Theta V_y$. However, we do not know a Miura transformation for noncommutative mKP (26).

4. Nonsymmetric Novikov-Veselov equation

Consider the Lax operator $L=u+D_x^{-1}v-D_y$ [case (c)]. In the commutative case, this worked out in Ref. 24 by both central extension approach and the operand approach. Let $S=D_x+a_0+a_{-1}D_x^{-1}+\cdots$. Using formula (7), we have

$$a_0=(C_u-D_y)^{-1}u_x;$$

$$a_{-1}=(C_u-D_y)^{-1}(v_x+C_v a_0),$$

leading to $S^1{}_{\geqslant 1}=D_x$, $S^1{}_{\geqslant 2}=D_x^2+2a_0D_x$, $S^3{}_{\geqslant 1}=D_x^3+3a_0D_x^2+3(a_{0x}+a_{-1}+a_0^2)D_x$. From the Lax equation, we obtain

$$\begin{cases} u_{t_2}=u_{xx}+2v_x+2a_0u_x+2a_0v-2va_0 \\ v_{t_2}=-v_{xx}+2(va_0)_x \end{cases}$$

$$\begin{cases} u_{t_3}=u_{xxx}+3(a_0u_x)_x+3a_{-1}u_x+3a_0^2u_x+3a_0v_x+3(va_0)_x-3C_v(a_{0x}+a_{-1}+a_0^2) \\ v_{t_3}=v_{xxx}-3(v_xa_0)_x+3(va_{-1})_x+3(va_0^2)_x. \end{cases}$$

The reduction $v=0$ leads to

$$u_{t_2}=u_{xx}-2\{(D_y-C_u)^{-1}u_x\}u_x.$$

Let $w=(D_y-C_u)^{-1}u_x$. This equation transforms into the noncommutative Burgers equation $w_{t_2}=w_{xx}-2ww_x$, which is linearizable, that is, we obtain $p_t=p_{xx}$ by $pw=-p_x$.

There is no reduction $u=0$ in noncommutative case. In the commutative case, the reduction $u=0$ leads to the nonsymmetric Novikov-Veselov equation.[25]

$$v_{t_3} = v_{xxx} - 3(v\Theta^{-1}v)_x.$$

V. CONCLUSION

We have demonstrated the power of the symbolic representation in the study of (2+1)-dimensional integrable equations. It enables us to produce the hierarchies of (2+1)-dimensional integrable equations from the scalar Lax operators and to study their properties globally. We proved the conjecture of Mikhailov and Yamilov on the ring extension for (2+1)-dimensional commutative integrable equations derived from these scalar Lax operators.

There exist other types of scalar Lax operators such as the Lax pair of Eq. (2.14) in Ref. 26, i.e. $L_t=[B,L]$, where

$$L = D_x^2 + u, \quad B = D_y L + \tfrac{1}{2}\Theta u D_x - \tfrac{1}{4}u_y - \tfrac{1}{4}D_x^{-1}C_u\Theta u.$$

In fact, Eq. (2.14) shares the same L operator as noncommutative KdV,

$$u_t = \frac{1}{4}(u_{xxx} + 3uu_x + 3u_x u),$$

and hence it can be obtained by a recursion operator of noncommutative KdV acting on u_y. The same ring extension results can be proved by either adapting the proof in this paper or deriving from the structure of recursion operators of the corresponding (1+1)-dimensional integrable equations.[12,27]

The method can easily be applied to the case of (2+1)-dimensional differential-difference integrable equation with scalar Lax operators.[24] This is an ongoing research topic.

Recently, there was an attempt at constructing noncommutative integrable equations in the framework of the Sato theory motivated by noncommutative gauge theories, cf. Refs. 26 and 28 and references therein. However, the authors had imposed an ansatz to derive the equations from certain scalar Lax operators in the case (a) instead of the systematical approach proposed in this paper. Noncommutative (2+1)-dimensional integrable equations derived from the scalar Lax operators in the cases (b) and (c) have not been well studied mainly due to the appearance of a new type of nonlocal terms such as $(D_x+(C_u/2))^{-1}u_y$ and $(D_y-C_u)^{-1}u_x$.

APPENDIX: PROOF OF PROPOSITION 4

Proof. We need to show [cf. (14)] for all $l\geqslant 2$ that

$$b_{l-1}\left(-\sum_{s=2}^{l}\xi_{j_s}^{(i_s)}, -\sum_{s=2}^{l}\eta_{j_s}^{(i_s)}, \xi_{j_2}^{(i_2)}, \eta_{j_2}^{(i_2)}, \ldots, \xi_{j_{l-1}}^{(i_{l-1})}, \eta_{j_{l-1}}^{(i_{l-1})}, X+\xi_{j_l}^{(i_l)}\right) = b_{l-1}(\xi_{j_2}^{(i_2)}, \eta_{j_2}^{(i_2)}, \ldots, \xi_{j_l}^{(i_l)}, \eta_{j_l}^{(i_l)}, X). \tag{A1}$$

We prove it by induction. It is true for $l=2$ since

$$b_1(-\xi_{j_2}^{(i_2)}, -\eta_{j_2}^{(i_2)}, X+\xi_{j_2}^{(i_2)}) = \frac{-\xi_{j_2}^{(i_2)}}{N_1(-\xi_{j_2}^{(i_2)}, -\eta_{j_2}^{(i_2)}, X+\xi_{j_2}^{(i_2)})} = \frac{\xi_{j_2}^{(i_2)}}{N_1(\xi_{j_2}^{(i_2)}, \eta_{j_2}^{(i_2)}, X)}.$$

Assume that formula (A1) is valid for $l-1$. Then its left-hand side equals

$$
\begin{aligned}
&\frac{b_{l-2}\left(-\sum_{s=2}^{l}\xi_{j_s}^{(i_s)},-\sum_{s=2}^{l}\eta_{j_s}^{(i_s)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-2}}^{(i_{l-2})},\eta_{j_{l-2}}^{(i_{l-2})},X+\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)}\right)}{N_{l-1}\left(-\sum_{s=2}^{l}\xi_{j_s}^{(i_s)},-\sum_{s=2}^{l}\eta_{j_s}^{(i_s)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)}\right)}\\
&\quad-\frac{b_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})}{N_{l-1}\left(-\sum_{s=2}^{l}\xi_{j_s}^{(i_s)},-\sum_{s=2}^{l}\eta_{j_s}^{(i_s)},\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)}\right)}\\
&=-\frac{b_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-2}}^{(i_{l-2})},\eta_{j_{l-2}}^{(i_{l-2})},\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)},\eta_{j_{l-1}}^{(i_{l-1})}+\eta_{j_l}^{(i_l)},X)}{N_1(\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&\quad+\frac{b_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})}{N_1(\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&=\frac{b_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\eta_{j_{l-2}}^{(i_{l-2})},X+\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)})-b_{l-3}(\xi_{j_3}^{(i_3)},\eta_{j_3}^{(i_3)},\ldots,\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})}{N_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})N_1(\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&\quad-\frac{b_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-2}}^{(i_{l-2})},\eta_{j_{l-2}}^{(i_{l-2})},X+\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)})}{N_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)},\eta_{j_{l-1}}^{(i_{l-1})}+\eta_{j_l}^{(i_l)},X)N_1(\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&\quad+\frac{b_{l-3}(\xi_{j_3}^{(i_3)},\eta_{j_3}^{(i_3)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)},\eta_{j_{l-1}}^{(i_{l-1})}+\eta_{j_l}^{(i_l)},X)}{N_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)},\eta_{j_{l-1}}^{(i_{l-1})}+\eta_{j_l}^{(i_l)},X)N_1(\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}.
\end{aligned}
$$

Meanwhile, the right side gives us

$$
\begin{aligned}
&\frac{b_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})-b_{l-2}(\xi_{j_3}^{(i_3)},\eta_{j_3}^{(i_3)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}{N_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&=\frac{b_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-2}}^{(i_{l-2})},\eta_{j_{l-2}}^{(i_{l-2})},X+\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)})}{N_1(\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})N_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&\quad-\frac{b_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_{l-2}}^{(i_{l-2})}+\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-2}}^{(i_{l-2})}+\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})}{N_1(\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})N_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}\\
&\quad-\frac{b_{l-3}(\xi_{j_3}^{(i_3)},\eta_{j_3}^{(i_3)},\ldots,\eta_{j_{l-1}}^{(i_{l-1})},X+\xi_{j_l}^{(i_l)})-b_{l-3}(\xi_{j_3}^{(i_3)},\eta_{j_3}^{(i_3)},\ldots,\xi_{j_{l-1}}^{(i_{l-1})}+\xi_{j_l}^{(i_l)},\eta_{j_{l-1}}^{(i_{l-1})}+\eta_{j_l}^{(i_l)},X)}{N_1(\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)N_{l-1}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\ldots,\xi_{j_l}^{(i_l)},\eta_{j_l}^{(i_l)},X)}.
\end{aligned}
$$

The difference between the above two expression vanishes due to the induction assumption, which implies that

$$
\begin{aligned}
&\frac{N_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\xi_{j_{l-2}}^{(i_{l-2})},\eta_{j_{l-2}}^{(i_{l-2})},X+\xi_{j_{l-1}}^{(i_{l-1})})b_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\xi_{j_{l-2}}^{(i_{l-2})},\eta_{j_{l-2}}^{(i_{l-2})},X+\xi_{j_{l-1}}^{(i_{l-1})})}{N_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X)N_1(\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X)}\\
&=\frac{b_{l-3}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\xi_{j_{l-2}}^{(i_{l-2})}+\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-2}}^{(i_{l-2})}+\eta_{j_{l-1}}^{(i_{l-1})},X)}{N_1(\xi_{j_{l-1}}^{(i_{l-1})},\eta_{j_{l-1}}^{(i_{l-1})},X)}-\frac{b_{l-3}(\xi_{j_3}^{(i_3)},\eta_{j_3}^{(i_3)},\cdots,\eta_{j_{l-1}}^{(i_{l-1})},X)}{N_{l-2}(\xi_{j_2}^{(i_2)},\eta_{j_2}^{(i_2)},\cdots,\eta_{j_{l-1}}^{(i_{l-1})},X)}.
\end{aligned}
$$

By now we have proved our proposition. ◇

Quantum Stratonovich calculus and the quantum Wong-Zakai theorem

John Gough[a)]
School of Computing and Informatics, Nottingham Trent University, Nottingham, NG1 4BU, United Kingdom

(Received 2 June 2006; accepted 21 August 2006; published online 29 November 2006)

We extend the Itō-to-Stratonovich analysis or quantum stochastic differential equations, introduced by Gardiner and Collett for emission (creation), absorption (annihilation) processes, to include scattering (conservation) processes. Working within the framework of quantum stochastic calculus, we define Stratonovich calculus as an algebraic modification of the Itō one and give conditions for the existence of Stratonovich time-ordered exponentials. We show that conversion formula for the coefficients has a striking resemblance to Green's function formulas from standard perturbation theory. We show that the calculus conveniently describes the Markov limit of regular open quantum dynamical systems in much the same way as in the Wong-Zakai approximation theorems of classical stochastic analysis. We extend previous limit results to multiple-dimensions with a proof that makes use of diagrammatic conventions. © *2006 American Institute of Physics.*

I. INTRODUCTION

Quantum stochastic calculus[1–4] was developed as a framework to construct concrete models of irreversible quantum dynamical systems. Prior to this, models tended to consider a system couple to an environment, but with only the system being accessible to physical measurement: as a result the environment observables were often relegated to a secondary status, leaving one with a master equation for the state of the system only.[5,6]

Hudson and Parthasarathy[3] in 1984 presented a rigorous theory of integration with respect to processes on bosonic (later fermionic) Fock spaces generalizing the Itō-Doob theory of stochastic integration. In addition to integrals with respect to time, they also introduced integrals with respect to creation, annihilation, and number (more generally, scattering) processes. Motivated by noncommutative Feynman-Kac formulas, they were able to describe unitary dynamical evolutions of a system coupled to the Fock space environment which reduced to an irreversible Markov dynamics for the system when averaged over the partial expectation with respect to the Fock vacuum. Here the Schrödinger equation is replaced by a quantum stochastic differential equation (QSDE) driven by the creation, annihilation, and scattering processes, as well as time.

Independently, Gardiner and Collett[4] in 1985 gave the version of quantum stochastic integration for the bosonic creation and annihilation that is best known amongst the physics community. Although they did not include the scattering processes, they did introduce several important physical concepts, in particular, they gave to the noise the status of a physical observable. This has been vital in subsequent analysis of quantum filtering and feedback where the environment can act as an apparatus/communication channel.[7–9] In their analysis, they also introduced the Stratonovich version of the theory by extending the usual midpoint definition to noncommuting processes.[10] This is a natural physical choice for two reasons: unlike the Itō form, the Leibniz rule of differential calculus holds for Stratonovich differentials and so physical symmetries are more apparent;

a)Electronic mail: john.gough@ntu.ac.uk

second, in classical analysis it is generally the case that if the model can be obtained as a singular limit of regular dynamical models, then it is the Stratonovich form that resembles the prelimit equations the most. Historically, it was actually the latter reason that led to Stratonovich initially introducing his modification of the Itō theory. In ordinary stochastic analysis, such results involving a central limit effect for stochastic processes are known as Wong-Zakai theorems. Our original motivation stems from quantum Markov limits[11–16] and the desire to understand the limit processes in a Stratonovich sense.

To give a concrete mathematical account, we start from the quantum Itō theory developed by Hudson and Parthasarathy, and deduce quantum Stratonovich calculus as an algebraic modification of the quantum Itō one which restores the Leibniz rule. An approach starting from Gardiner and Collett's input processes would have been more appealing from a physical point of view, however, we do not want to bypass questions of the mathematical status of the objects considered. Traditionally, the Stratonovich integral is defined through a midpoint Riemann sum approximation: this has been extended by Chebotarev[12,13] to quantum stochastic integrals, however, we emphasize that our formulation here is to define Stratonovich integrals as combinations of well-defined Itō integrals where possible. Rather than there being an unique version, we find that there are degrees of freedom in how we actually achieve this—we refer to this as a "gauge" freedom—and that the standard (symmetric) choice, corresponding to the midpoint rule, is just one possibility. We give the self-consistency formula $\mathbf{G}=\mathbf{G}_0+\mathbf{G}_0\mathbf{V}\mathbf{G}$ relating the matrix of Itō coefficients $\mathbf{G}$ to the matrix of Stratonovich coefficients $\mathbf{G}_0$. (Here the "potential" $\mathbf{V}$ is half the noise covariance matrix plus the gauge.) Rather surprisingly, this has the same algebraic form as the one relating the free and perturbed Green's functions in scattering theory: a fact that we readily exploit. It is shown that the Itō coefficients of a unitary process are related to Hamiltonian Stratonovich coefficients ($\mathbf{G}_0^\dagger=-\mathbf{G}_0$) and that this is true for any gauge so long as the self-consistency formula can be solved. This allows the interpretation that the Stratonovich calculus can be viewed as a perturbation of the Itō calculus, and vice versa.

A major motivation here is the results of Ref. 16 for a quantum Markov limit involving emission, absorption, and scattering. We formulate the limit as a Wong-Zakai result where the Stratonovich QSDE resembles the prelimit Schrödinger equation (with gauge set by the imaginary part of the complex damping). Our key requirement is convergence of the "Neumann series" $\mathbf{G}=\sum_{n=0}^{n}\mathbf{G}_0(\mathbf{V}\mathbf{G}_0)^n$. We generalize the result to multiple channel noise sources and make the proof more accessible by means of diagrammatic conventions which make the connections with the Dyson series expansion transparent. We also present the results in a fluxion notation, as an alternative to the differential increment language, which is closer to the formulation employed by Gardiner and Collett[4] and effectively generalizes their results to include scattering. This also reveals a new representation (Lemma 3) for the Evans-Hudson flow maps.

II. QUANTUM STOCHASTIC CALCULUS

A. Quantum processes

Given a Hilbert space $\mathfrak{h}_1$, the Fock space over $\mathfrak{h}_1$ is the Hilbert space $\Gamma(\mathfrak{h}_1)$ generated by symmetrized n-particle vectors $\varphi_1\hat{\otimes}\cdots\hat{\otimes}\varphi_n:=(n!)^{-1}\Sigma_{\sigma\in\mathfrak{S}_n}\varphi_{\sigma(1)}\otimes\cdots\otimes\varphi_{\sigma(n)}$ for $n\geqslant 0$ arbitrary, $\varphi_j\in\mathfrak{h}_1$ and $\mathfrak{S}_n$ the group of permutations on n labels. The special case $n=0$ requires the introduction of unit vector Ω called the Fock vacuum vector. The inner product on $\Gamma(\mathfrak{h}_1)$ is given by $\langle\varphi_1\hat{\otimes}\cdots\hat{\otimes}\varphi_n|\psi_1\hat{\otimes}\cdots\hat{\otimes}\psi_n\rangle=\delta_{nm}(n!)^{-1}\Sigma_{\sigma\in\mathfrak{S}_n}\langle\varphi_1|\psi_{\sigma(1)}\rangle\cdots\langle\varphi_n|\psi_{\sigma(n)}\rangle$.

The exponential vector with test function $\varphi\in\mathfrak{h}_1$ is defined to the Fock space vector

$$\varepsilon(\varphi)=\sum_{n=0}^{\infty}\frac{1}{\sqrt{n!}}\underbrace{\varphi\otimes\cdots\otimes\varphi}_{n\text{ fold}}, \tag{1}$$

and we have $\langle\varepsilon(\varphi)|\varepsilon(\psi)\rangle=\exp\langle\varphi|\psi\rangle$. If S is a dense subset of $\mathfrak{h}_1$ then the vectors $\varepsilon(\varphi)$, with $\varphi\in S$, are total in $\Gamma(\mathfrak{h}_1)$, that is, the closure of the span of these vectors gives the whole Fock space.

We now take the one-particle space to be the Hilbert space of $\mathbb{C}^N$-valued square-integrable functions of positive time: this consists of measurable functions $\mathbf{f}=(f_1,\ldots,f_n)$ with $\int_0^\infty \Sigma_{i=1}^n |f_i(t)|^2 < \infty$. An orthogonal projection Π_s is defined on the one-particle space for each $s>0$ by taking $\Pi_s\mathbf{f}=(\chi_{[0,s]}f_1,\ldots,\chi_{[0,s]}f_n)$ where $\chi_{[0,s]}$ is the indicator function for the interval $[0,s]$. An N-channel quantum noise source is modeled by operators processes $\{A_t^{\alpha\beta}: t>0\}$ acting on the corresponding Fock space $\mathfrak{F}$. For $\alpha,\beta\in\{0,1,\ldots,n\}$, these processes are defined on the domain of exponential vectors by

$$\langle \varepsilon(\mathbf{f}) \left| \left\{ A_t^{\alpha\beta} - \int_0^t f_\alpha^*(s) g_\beta(s) ds \right\} \varepsilon(\mathbf{g}) \right\rangle = 0, \tag{2}$$

where we include the index zero by setting $f_0=g_0=1$. We shall adopt the convention that lower case Latin indices (with the exception of t and s which we reserve for time!) range over the values $1,\ldots,N$ while lower case Greek indices range over $0,1,\ldots,N$. We also apply an Einstein summation convention for repeated indices over the appropriate range.

We also fix a Hilbert space $\mathfrak{h}$, called the initial space. Let D be a domain in $\mathfrak{h}$ and take S to be the space of bounded $\mathbb{C}^N$-valued functions. A family $X_\cdot=\{X_t: t\geqslant 0\}$ of operators on $\mathfrak{h}\otimes\mathfrak{F}$ is said to be an adapted quantum stochastic process based on (D,S) if, for each $t\geqslant 0$, $X_t u\otimes\varepsilon(\mathbf{f})$ is defined for each $u\in D$ and $\mathbf{f}=(f_1,\ldots,f_n)\in S$ and is independent of the values $f_i(s)$ for $s>t$. If $X_\cdot^{\alpha\beta}$ are adapted processes, their stochastic integral $X_\cdot$ may be written as (implied summation!) $X_t=\int_0^t a_\alpha^\dagger(s) X_s^{\alpha\beta} a_\beta(s)\mathrm{d}s$, with the meaning that

$$\langle u\otimes\varepsilon(\mathbf{f}) \left| \int_0^t a_\alpha^\dagger(s) X_s^{\alpha\beta} a_\beta(s)\mathrm{d}s v\otimes\varepsilon(\mathbf{g})\right\rangle := \int_0^t f_\alpha^*(s)\langle u\otimes\varepsilon(\mathbf{f})|X_s^{\alpha\beta}v\otimes\varepsilon(\mathbf{g})\rangle g_\beta(s)\mathrm{d}s.$$

The stochastic integral is more often written in the form $X_t=\int_0^t X_s^{\alpha\beta}\mathrm{d}A_s^{\alpha\beta}$ or equivalently $\int_0^t \mathrm{d}A_s^{\alpha\beta}X_s^{\alpha\beta}$ with these integrals making sense as Riemann-Itō limits for locally square-integrable integrands. The stochastic integral will again be an adapted process. At the moment, the symbols $a_\alpha^\dagger(t)$, $a_\beta(t)$ have no meaning other than notational, however $a_0^\dagger(t)$ and $a_0(t)$ are easily interpreted as the identity operator and $a_i(t)$ as a pointwise Malliavin gradient. What is crucial is that they appear in Wick order: that is, $a_\alpha^\dagger(t)$ to the left of $a_\beta(t)$. Let $Y_t=\int_0^t a_\alpha^\dagger(s) Y_s^{\alpha\beta} a_\beta(s)\mathrm{d}s$ be a second integral, with the $Y_\cdot^{\alpha\beta}$ adapted, then we have the formula[3]

$$X_tY_t = \int_0^t a_\alpha^\dagger(s) X_s^{\alpha\beta} Y_s a_\beta(s)\mathrm{d}s + \int_0^t a_\alpha^\dagger(s) X_s Y_s^{\alpha\beta} a_\beta(s)\mathrm{d}s + \int_0^t a_\alpha^\dagger(s) X_s^{\alpha\mu} P_{\mu\nu} Y_s^{\nu\beta} a_\beta(s)\mathrm{d}s,$$

where we introduce

$$P^{\mu\nu} = \begin{cases} 1, & \mu=\nu\neq 0 \\ 0 & \text{otherwise.} \end{cases} \tag{3}$$

(As is well-known to the quantum probability community, the components $P^{\mu\nu}$ are just the Evans Kronecker-delta[17] usually denoted $\hat{\delta}^{\mu\nu}$.)

Introducing the differential notation $\mathrm{d}X_t=X_t^{\alpha\beta}\mathrm{d}A_t^{\alpha\beta}$, etc., we may write the quantum Itō formula in the more familiar guise as

$$\mathrm{d}(X_tY_t) = (\mathrm{d}X_t)Y_t + X_t(\mathrm{d}Y_t) + (\mathrm{d}X_t)(\mathrm{d}Y_t), \tag{4}$$

where the Itō correction is $(\mathrm{d}X_t)(\mathrm{d}Y_t)=X_t^{\alpha i}Y_t^{i\beta}\mathrm{d}A_t^{\alpha\beta}\equiv X_t^{\alpha\mu}P^{\mu\nu}Y_t^{\nu\beta}\mathrm{d}A_t^{\alpha\beta}$. Let us define iterated integrals in the natural way:

$$\langle \varepsilon(\mathbf{f}) \left| \int_{\Delta_n(t)} \mathrm{d}A_{t_n}^{\alpha_n\beta_n} \cdots \mathrm{d}A_{t_1}^{\alpha_1\beta_1} \varepsilon(\mathbf{g}) \right\rangle = \int_{\Delta_n(t)} f_{\alpha_n}^*(t_n) \cdots f_{\alpha_1}^*(t_1) g_{\beta_n}(t_n) \cdots g_{\beta_1}(t_1) \langle \varepsilon(\mathbf{f}) | \varepsilon(\mathbf{g}) \rangle, \tag{5}$$

where $\Delta_n(t)$ is the simplex $t \geqslant t_n > \cdots \geqslant t_1 > 0$.

B. Quantum Markov evolutions

Let $\{G_{\alpha\beta}\}$ be bounded operators on a fixed initial space $\mathfrak{h}$, then there exists a unique solution $U_\cdot$ to the equation $U_t = 1 + \int_0^t G_{\alpha\beta} U_s \mathrm{d}A_s^{\alpha\beta}$ which we can naturally interpret as the QSDE $\mathrm{d}U_t = G_{\alpha\beta} U_t \mathrm{d}A_t^{\alpha\beta}$, with $U_0 = 1$. In such cases, we may write $U_\cdot$ as the *Dyson-Itō time-ordered exponential* $U_t = \vec{\mathbf{T}}_{\mathrm{ID}} \exp \int_0^t G_{\alpha\beta} \mathrm{d}A^{\alpha\beta}$.

Proposition 1: *Let $U_\cdot$ be the solution to the QSDE $\mathrm{d}U_t = G_{\alpha\beta} U_t \mathrm{d}A_t^{\alpha\beta}$, with $U_0 = 1$, where the $\{G_{\alpha\beta}\}$ are bounded operators on $\mathfrak{h}$. Necessary and sufficient conditions*[3] *for $U_\cdot$ to be unitary process are that $G_{\alpha\beta} + G_{\beta\alpha}^\dagger + G_{i\alpha}^\dagger G_{i\beta} = 0 = G_{\alpha\beta} + G_{\beta\alpha}^\dagger + G_{i\alpha} G_{i\beta}^\dagger$ with the general solution*

$$G_{ij} = W_{ij} - \delta_{ij}, \quad G_{i0} = L_i,$$

$$G_{0j} = -L_k^\dagger W_{kj}, \quad G_{00} = -\tfrac{1}{2} L_k^\dagger L_k - iH,$$

where W_{ij}, L_i, and H are bounded operators on the initial space with H self-adjoint and $W_{ij}^\dagger W_{jk} = \delta_{ik} = W_{ij} W_{jk}^\dagger$.

Proposition 2: Let $U_\cdot$ be the unitary process described above. The corresponding flow map is given by $J_t(X) := U_t^\dagger (X \otimes 1) U_t$ for bounded X on the initial space. We find that $J_t(X)$ satisfies the QSDE

$$\mathrm{d}J_t(X) = J_t(\mathcal{L}_{\alpha\beta}(X)) \mathrm{d}A_t^{\alpha\beta},$$

where the Evans-Hudson maps[17] *are given by $\mathcal{L}_{\alpha\beta}(X) := XG_{\alpha\beta} + G_{\beta\alpha}^\dagger X + G_{i\alpha}^\dagger X G_{i\beta}$.*

Following Lindblad,[18] the dissipation of a linear map $\mathcal{L}$ on the algebra of bounded operators on $\mathfrak{h}$ is defined to be the bilinear mapping $\mathcal{D}\mathcal{L} : (X, Y) \mapsto \mathcal{L}(XY) - \mathcal{L}(X)Y - X\mathcal{L}(Y)$.

Proposition 3: The Evans-Hudson maps for a unitary flow satisfy $\mathcal{L}_{\alpha\beta}(X)^\dagger = \mathcal{L}_{\beta\alpha}(X^\dagger)$ and their dissipation is described by

$$\mathfrak{D}\mathcal{L}_{\alpha\beta}(X, Y) = \mathcal{L}_{\alpha\mu}(X) P^{\mu\nu} \mathcal{L}_{\nu\beta}(Y).$$

C. Approximations

For each $\lambda > 0$, we set $a_0^\#(t, \lambda) = 0$ and take $a_i^\#(t, \lambda) = A^\#(\varphi(i, t, \lambda))$ where $\varphi(i, t, \lambda)$ is a $\mathbb{C}^N$-valued square-integrable function on $[0, \infty)$: we also take $t \to \varphi(i, t, \lambda)$ to be strongly differentiable. We assume that $\langle \varphi(i, t, \lambda) | \varphi(j, s, \lambda) \rangle \equiv C_{ij}(t - s, \lambda)$ where $C_{ij}(\tau, \lambda) = C_{ji}(-\tau)^*$ is integrable in τ, and that we have the convergence $\lim_{\lambda \to 0} C_{ij}(\tau, \lambda) = \delta_{ij} \delta(\tau)$ in the sense of Schwartz distributions. We set $\kappa_{ij} = \lim_{\lambda \to 0} \int_0^\infty C_{ij}(\tau, \lambda) \mathrm{d}\tau$ and note the identity $\kappa_{ij} + \kappa_{ji}^* = \delta_{ij}$.

The $a_i^\#(t, \lambda)$ are approximations to quantum white noises. We may introduce integrated processes $A_t^{\alpha\beta}(\lambda) := \int_0^t a_\alpha^\dagger(s, \lambda) a_\beta(s, \lambda) \mathrm{d}s$ which serve as approximations to the fundamental processes. The approximation will be termed symmetric if $\kappa_{ij} = \frac{1}{2} \delta_{ij}$, but this is only a special case. Defining smeared exponential vectors by

$$\varepsilon_\lambda(\mathbf{f}) = \exp\left\{ \int_0^\infty \sum_{i=1}^N f_i(t) a_i^\dagger(t) \mathrm{d}t \right\} \Omega, \tag{6}$$

we see that the limit

$$\lim_{\lambda\to 0}\langle \varepsilon_\lambda(\mathbf{f})\left|\int_{\Delta_n(t)} a^*_{\alpha_n}(t_n,\lambda)\cdots a^*_{\alpha_1}(t_1,\lambda)a_{\beta_n}(t_n,\lambda)\cdots a_{\beta_1}(t_1,\lambda)\varepsilon_\lambda(\mathbf{g})\right\rangle$$

coincides with (5). Therefore, whenever we consider the limit of Wick ordered expressions, it does not matter whether we have the symmetric approximation or not.

A term such as $\int_{\Delta_2(t)} a_i(t_2,\lambda)a_j^\dagger(t_1,\lambda)$ must, however, be put in to Wick order as $\int_{\Delta_2(t)} a_j^\dagger(t_1,\lambda)\alpha_i(t_2,\lambda)$ plus an additional term $\int_{\Delta_2(t)} C_{ij}(t_2-t_2,\lambda)$ which converges to $\kappa_{ij}t$. As a rule, expressions violating of Wick order will have a limit that depends on the constants κ_{ij}.[19,20]

D. Notation and conventions

Let $\mathbf{X}=\{X_{\alpha\beta}\}$ be an $(N+1)\times(N+1)$ matrix of bounded operators on some Hilbert space. (Previously, we had the Itō coefficients which were operators on $\mathfrak{h}\otimes\mathfrak{F}$.) We shall adopt the matrix representation

$$\mathbf{X}=\left(\begin{array}{c|c} X_{00} & X_{01},X_{02},\ldots \\ \hline X_{10} & \\ X_{20} & \mathsf{X} \\ \vdots & \end{array}\right) \tag{7}$$

where X is the $N\times N$ submatrix consisting of the entries $\{X_{ij}\}$.

For instance, $\mathbf{P}=\{P^{\alpha\beta}\}$ will be a projection operator:

$$\mathbf{P}=\left(\begin{array}{c|c} 0 & 0 \\ \hline 0 & 1 \end{array}\right),\quad \mathbf{Q}=\mathbf{1}-\mathbf{P}=\left(\begin{array}{c|c} 1 & 0 \\ \hline 0 & 0 \end{array}\right). \tag{8}$$

The quantum Itō correction is therefore described by the matrix $\mathbf{X}(t)\mathbf{P}\mathbf{Y}(t)\equiv\{X_{\alpha\mu}(t)P^{\mu\nu}Y_{\nu\beta}(t)\}$.

Let $\{G_{\alpha\beta}\}\equiv\mathbf{G}$ be a matrix with bounded operators on $\mathfrak{h}$ as entries, then the Dyson-Itō time-ordered exponential $U_t=\vec{\mathbf{T}}_{\mathrm{DI}}\{\exp\int_0^t G_{\alpha\beta}\mathrm{d}A^{\alpha\beta}\}$ will be unitarity if, from Proposition 1,

$$\mathbf{G}+\mathbf{G}^\dagger+\mathbf{G}^\dagger\mathbf{P}\mathbf{G}=\mathbf{0},\quad \mathbf{G}+\mathbf{G}^\dagger+\mathbf{G}\mathbf{P}\mathbf{G}^\dagger=\mathbf{0}. \tag{9}$$

It is relatively easy to see that the Itō coefficients then take the general form

$$\mathbf{PGP}=\mathbf{W}-\mathbf{P},$$

$$\mathbf{QGP}=-(\mathbf{PGQ})^\dagger\mathbf{W},$$

$$\mathbf{QGQ}=-\frac{1}{2}(\mathbf{PGQ})^\dagger(\mathbf{PGQ})-\mathrm{i}\left(\begin{array}{c|c} H & 0 \\ \hline 0 & 0 \end{array}\right), \tag{10}$$

where $\mathbf{W}^\dagger\mathbf{W}=\mathbf{P}=\mathbf{W}\mathbf{W}^\dagger$ (i.e., the restriction of $\mathbf{W}$ to $\mathfrak{h}\otimes\mathbb{C}^N$ is unitary) and H is self-adjoint on $\mathfrak{h}$.

More explicitly, we may set

$$\mathbf{W}=\left(\begin{array}{c|c} 0 & 0 \\ \hline 0 & \mathsf{W}=\{W_{ij}\} \end{array}\right),\quad \mathbf{PGQ}=\left(\begin{array}{c|c} 0 & 0,0,\cdots \\ \hline L_1 & \\ L_2 & 0 \\ \vdots & \end{array}\right),$$

where W_{ij}, L_i, and H are the operators on $\mathfrak{h}$ introduced in Proposition 1.

We should remark that the restriction to a finite number N of channels is not essential and that the unitary process exists under certain conditions on the boundedness of $\mathbf{G}$ as a matrix operator.[22]

III. QUANTUM STRATONOVICH CALCULUS

We wish to write the quantum Itō formula in the form

$$\mathrm{d}(X_t Y_t) = (\mathrm{d}X_t) \circ Y_t + X_t \circ (\mathrm{d}Y_t). \tag{11}$$

This can be achieved by formally defining

$$\begin{aligned} (\mathrm{d}X_t) \circ Y &:= (\mathrm{d}X_t) Y_t + X_t^{\alpha\mu} V_t^{\mu\nu} Y_t^{\nu\beta} \mathrm{d}A_t^{\alpha\beta}, \\ X_t \circ (\mathrm{d}Y_t) &:= X_t (\mathrm{d}Y_t) + X_t^{\alpha\mu} (V_t^{\nu\mu})^\dagger Y_t^{\nu\beta} \mathrm{d}A_t^{\alpha\beta}, \end{aligned} \tag{12}$$

where the $\{V_t^{\alpha\beta}\}$ may in general be taken as adapted processes, however, we shall take them to be just scalar coefficients. It follows that $[(\mathrm{d}X_t) \circ Y_t]^\dagger = Y_t^\dagger \circ \mathrm{d}X_t^\dagger$, and we recover the Itō formula provided we have the condition $V^{\mu\nu} + (V^{\nu\mu})^* = P^{\mu\nu}$. (It should be noted that the differential maps considered here are not actions. For instance, $((\mathrm{d}X_t) \circ Y_t) \circ Z_t$ is not the same as $(\mathrm{d}X_t) \circ (Y_t Z_t)$—this is also the case for the classical notion of Stratonovich differential! In contrast, the Leibniz rule can be restored by absorbing the Itō correction completely onto either the left or right action of the algebra of integrands on the algebra of differentials. This has been recently carried out by Hudson,[23] who was able to construct a Woronowicz first-order differential calculus[24] by this device.

The simplest solution possible is to take $V^{\mu\nu} = \frac{1}{2} P^{\mu\nu}$ and this corresponds algebraically to the traditional Stratonovich definition of a differential. The general solution however takes the form $V^{\mu\nu} = \frac{1}{2} P^{\mu\nu} + \mathrm{i} Z^{\mu\nu}$, where the constants $\{Z^{\mu\nu}\}$ satisfy $(Z^{\mu\nu})^* = Z^{\nu\mu}$. The appearance of these constants is similar to the ambiguity in the Tomita-Takesaki theory, and we refer to them as a gauge freedom. We shall identify the V^{ij} with the constants κ_{ij} occurring in the approximation scheme. Let us take $\mathbf{V} \equiv \{V^{\alpha\beta}\}$ to be the family of constants, then the requirement is $\mathbf{V} + \mathbf{V}^\dagger = \mathbf{P}$ with general solution $\mathbf{V} \equiv \frac{1}{2}\mathbf{P} + \mathrm{i}\mathbf{Z}$ where $\mathbf{Z}^\dagger = \mathbf{Z}$. We shall take the $\{Z^{\alpha\beta}\}$ to be scalar constants and set $Z^{00} = Z^{i0} = Z^{0j} = 0$. This implies that $\mathbf{Z} = \mathbf{Z}\mathbf{P} = \mathbf{P}\mathbf{Z}$ and so $\mathbf{V} = \mathbf{V}\mathbf{P} = \mathbf{P}\mathbf{V}$:

$$\mathbf{V} = \tfrac{1}{2}\mathbf{P} + \mathrm{i}\mathbf{Z} \equiv \left(\begin{array}{c|c} 0 & 0 \\ \hline 0 & \mathsf{V} \end{array} \right).$$

where $\mathsf{V} = \frac{1}{2} + \mathrm{i}\mathsf{Z}$ with $\mathsf{Z}^\dagger = \mathsf{Z}$. Note that V is a normal operator with $\mathsf{V}\mathsf{V}^\dagger = \mathsf{V}^\dagger \mathsf{V} = 4^{-1} + \mathsf{Z}^2$.

It should be pointed out that we have the relation

$$\mathrm{d}J_t(XY) = (\mathrm{d}J_t(X)) \circ J_t(Y) + J_t(X) \circ (\mathrm{d}J_t(Y)),$$

which we can get either from taking differentials of the homomorphic property $J_t(XY) = J_t(X) J_t(Y)$, or explicitly by noting that $(\mathrm{d}J_t(X)) \circ J_t(Y) \equiv J_t(\mathcal{L}_{\alpha\beta}(X) Y + \mathcal{L}_{\alpha\mu}(X) V^{\mu\nu} \mathcal{L}_{n\beta}(Y)) \mathrm{d}A_t^{\alpha\beta}$, etc., and using Proposition 3.

A. Stratonovich-Dyson time ordered exponentials

Let us now suppose that $U_\cdot$ is simultaneously the solution to the Itō QSDE $\mathrm{d}U = (\mathrm{d}G)U$, with $\mathrm{d}G = G_{\alpha\beta} \mathrm{d}A^{\alpha\beta}$ as before, and a Stratonovich QSDE (for a fixed gauge!)

$$\mathrm{d}U_t = (\mathrm{d}G_0(t)) \circ U_t, \quad U_0 = 1, \tag{13}$$

with $\mathrm{d}G_0 = G^0_{\alpha\beta} \mathrm{d}A^{\alpha\beta}$. In such cases, we may write $U_\cdot$ as the *Dyson-Stratonovich time-ordered exponential* $U_t = \vec{\mathbf{T}}_{\mathrm{SD}}\{\exp \int_0^t G^0_{\alpha\beta} \mathrm{d}A^{\alpha\beta}\}$ and shall refer to $\mathbf{G}_0 \equiv \{G^0_{\alpha\beta}\}$ as the matrix of *Stratonovich coefficients*.

Self-consistency requires that $\mathrm{d}U = (\mathrm{d}G^0) \circ U = (\mathrm{d}G)U$ and so we should have that $\mathrm{d}U = (\mathrm{d}G^0)U + G^0_{\alpha\mu} V^{\mu\nu} G_{\nu\beta} U \mathrm{d}A^{\alpha\beta} = (G^0_{\alpha\beta} + G^0_{\alpha\mu} V^{\mu\nu} G_{\nu\beta}) U \mathrm{d}A^{\alpha\beta}$. This means that the Itō coefficients $\mathbf{G} = \{G_{\alpha\beta}\}$ are related to the Stratonovich coefficients $\mathbf{G}_0 = \{G^0_{\alpha\beta}\}$ by

$$\mathbf{G} = \mathbf{G}_0 + \mathbf{G}_0 \mathbf{V} \mathbf{G}. \tag{14}$$

As we shall see, so long as $\mathbf{1}+\mathbf{VGP}$ is invertible, we may solve for $\mathbf{G}_0$ in terms of $\mathbf{G}$. Similarly, invertibility of $\mathbf{1}-\mathbf{PG}_0\mathbf{V}$ implies that we may write $\mathbf{G}$ in terms of $\mathbf{G}_0$. It might be remarked that the relation (14) also applies if we consider matrices $\mathbf{G},\mathbf{G}_0$ of adapted processes.

What is rather astonishing is that relation (14) is precisely of the form relating free and perturbed Green's functions. Let us recall briefly that if $H=H_0+V$ is a Hamiltonian considered as a perturbation of the free Hamiltonian H_0 then the resolvent operator $\mathcal{G}(z)=(z-H)^{-1}$ is related to the free resolvent $\mathcal{G}_0(z)=(z-H_0)^{-1}$ by the algebraic identity

$$\mathcal{G}=\mathcal{G}_0+\mathcal{G}_0V\mathcal{G} \tag{15}$$

for all z outside of the spectra of H and H_0. The identity may be rewritten as $\mathcal{G}=(1-\mathcal{G}_0V)^{-1}\mathcal{G}_0$ and iterated to give the formal expansion $\mathcal{G}=\mathcal{G}_0+\mathcal{G}_0V\mathcal{G}_0+\mathcal{G}_0V\mathcal{G}_0V\mathcal{G}_0+\cdots$ which, when convergent, is the Neumann series. The details of the actual scattering are contained in the operator $\mathcal{T}:=V+V\mathcal{G}V$ and we have the identity $\mathcal{G}=\mathcal{G}_0+\mathcal{G}_0\mathcal{T}\mathcal{G}_0$.

B. The *T*-matrix

We now exploit the similarity between (14) and (15). We begin by introducing the operator

$$\mathbf{T}:=\mathbf{V}+\mathbf{VGV}\equiv\left(\begin{array}{c|c}0&0\\\hline 0&\mathsf{T}\end{array}\right). \tag{16}$$

Assuming that $\mathbf{1}-\mathbf{VG}_0\mathbf{P}$ is again invertible, we obtain the following identities:

$$\mathbf{T}=\frac{1}{\mathbf{1}-\mathbf{VG}_0\mathbf{P}}\mathbf{V}, \tag{17}$$

$$\mathbf{G}_0\mathbf{T}=\mathbf{GV}, \tag{18}$$

$$\mathbf{TG}_0=\mathbf{VG}, \tag{19}$$

$$\mathbf{G}=\mathbf{G}_0+\mathbf{GVG}_0, \tag{20}$$

$$\mathbf{G}=\mathbf{G}_0+\mathbf{G}_0\mathbf{TG}_0. \tag{21}$$

The proof of (17) comes from writing

$$\mathbf{T}=\mathbf{V}+\mathbf{T}(\mathbf{G}_0+\mathbf{G}_0\mathbf{TG})\mathbf{V}=\mathbf{V}+\mathbf{VG}_0\mathbf{T}$$

so that $(\mathbf{1}-\mathbf{VG}_0\mathbf{P})\mathbf{T}=\mathbf{V}$. The remaining identities are just precise analogues of well-known relations for resolvent operators.[25]

Combining (17) and (21) we see that $\mathbf{G}$ can be expressed in terms of $\mathbf{G}_0$ as

$$\mathbf{G}=\mathbf{G}_0+\mathbf{G}_0(\mathbf{1}-\mathbf{PVG}_0\mathbf{P})^{-1}\mathbf{VG}_0. \tag{22}$$

In particular, we see that $\mathbf{G}$ is bounded. We may then invert to get

$$\mathbf{G}_0=\mathbf{G}-\mathbf{G}(\mathbf{1}+\mathbf{PVGP})^{-1}\mathbf{VG}. \tag{23}$$

Equations (22) and (23) reveal a remarkable duality between the Itō and Stratonovich coefficients. (Of course this just means that we may view either as a "perturbation" of the other!)

If $\mathbf{PVG}_0\mathbf{P}$ is a strict contraction, then we may develop a Neumann series expansion $\mathbf{G}=\mathbf{G}_0+\mathbf{G}_0\mathbf{VG}_0+\mathbf{G}_0\mathbf{VG}_0\mathbf{VG}_0+\cdots=\mathbf{G}_0\Sigma_{n=0}^{\infty}(\mathbf{VG}_0)^n$.

It is convenient to introduce a related matrix

$$\mathbf{F} = \mathbf{1} + \mathbf{T}\mathbf{G}_0 = \mathbf{1} + \mathbf{V}\mathbf{G} \tag{24}$$

so that $\mathbf{G} = \mathbf{G}_0\mathbf{F}$.

C. An "optical theorem"

Let us next suppose that the Stratonovich coefficients take the *Hamiltonian* form

$$\mathbf{G}_0 = -\mathrm{i}\mathbf{E}, \tag{25}$$

where $\mathbf{E}$ is a bounded, self-adjoint operator on $\mathfrak{h} \otimes \mathbb{C}^{N+1}$. We then have the relation $\mathbf{G}_0^\dagger = -\mathbf{G}_0$ and set

$$\mathbf{P}\mathbf{E}\mathbf{P} = \left(\begin{array}{c|c} 0 & 0 \\ \hline 0 & \mathsf{E} \end{array}\right)$$

so that E is self-adjoint on $\mathfrak{h} \otimes \mathbb{C}^N$. When our invertibility condition is met, it is easy to see that matrix T exists and can be written as

$$\mathsf{T} = [1 + \mathrm{i}\mathsf{V}\mathsf{E}]^{-1}\mathsf{V} \equiv \frac{1}{\mathsf{V}^{-1} + \mathrm{i}\mathsf{E}}. \tag{26}$$

(In the special case where $\mathsf{Z} = 0$, the self-adjointness of E ensures that $\mathsf{V} = 1 + \mathrm{i}\frac{1}{2}\mathsf{E}$ is invertible by von Neumann's theorem.[26] Therefore the existence of matrix T is guaranteed. More generally, so long as the value 1 lies in the resolvent set of $\mathsf{Z}\mathsf{E}$, this theorem implies the existence of T.)

The related matrix $\mathbf{F}$ then takes the form

$$\mathbf{F} = \left(\begin{array}{c|c} 1 & 0, 0, \ldots \\ \hline -\mathrm{i}T_{1j}E_{j0} & \\ -\mathrm{i}T_{2j}E_{j0} & \mathsf{F} \\ \vdots & \end{array}\right)$$

with $\mathsf{F} = 1 - \mathrm{i}\mathsf{T}\mathsf{E} = \mathsf{T}\mathsf{V}^{-1}$, so that $\mathsf{F} \equiv [1 + \mathrm{i}\mathsf{V}\mathsf{E}]^{-1}$.

Lemma 1 ("Optical Theorem"): $\mathrm{Re}\,\mathsf{T} \geqslant 0$ *and in particular* T *satisfies the identity*

$$\mathsf{T} + \mathsf{T}^\dagger = \mathsf{F}\mathsf{F}^\dagger = \mathsf{F}^\dagger\mathsf{F}.$$

Proof: We have that $\mathsf{T} + \mathsf{T}^\dagger$ may be written as

$$\mathsf{F}\mathsf{V} + \mathsf{V}^\dagger\mathsf{F}^\dagger = \mathsf{F}[\mathsf{V}(1 - \mathrm{i}\mathsf{E}\mathsf{V}^\dagger) + (1 + \mathrm{i}\mathsf{V}\mathsf{E})\mathsf{V}^\dagger]\mathsf{F}^\dagger = \mathsf{F}[\mathsf{V} + \mathsf{V}^\dagger]\mathsf{F}^\dagger = \mathsf{F}\mathsf{F}^\dagger.$$

It is then relatively straightforward to show that

$$\mathsf{F}\mathsf{F}^\dagger = \frac{1}{(1 - \mathrm{i}\mathsf{V}^\dagger\mathsf{E})(1 + \mathrm{i}\mathsf{E}\mathsf{V})} = [1 - \mathsf{E}\mathsf{Z} - \mathsf{Z}\mathsf{E} + \mathsf{E}\mathsf{V}(\mathsf{V}^\dagger)\mathsf{E}]^{-1} = \frac{1}{(1 + \mathrm{i}\mathsf{E}\mathsf{V})(1 - \mathrm{i}\mathsf{V}^\dagger\mathsf{E})} = \mathsf{F}^\dagger\mathsf{F}.$$

□

A similar calculation shows that $\mathrm{Im}\,\mathsf{T} = -\mathsf{T}\mathsf{E}\mathsf{T}^\dagger$.

D. Unitarity

We now wish to show that the choice of Hamiltonian Stratonovich coefficients naturally leads to unitary processes.

Lemma 2: Let $\mathbf{G}_0^\dagger = -\mathbf{G}_0$ *be bounded with* $\mathbf{1} - \mathbf{V}\mathbf{G}_0\mathbf{P}$ *invertible, and set* $G^0(t) = \int_0^t G^0_{\alpha\beta}\mathrm{d}A^{\alpha\beta}$. *Then the solution to the Stratonovich QSDE* $\mathrm{d}U = (\mathrm{d}G^0) \circ U$, $U_0 = 1$ *will be unitary.*

Proof: This fact is an immediate consequence of the optical theorem (27). To establish the

isometric property for the Itō coefficients, first observe that $\mathbf{G}+\mathbf{G}^\dagger=-\mathbf{G}_0(\mathbf{T}+\mathbf{T}^\dagger)\mathbf{G}_0$ while

$$\mathbf{GPG}^\dagger = \mathbf{G}_0\mathbf{FVF}^\dagger\mathbf{G}_0^\dagger = \mathbf{G}_0\left(\begin{array}{c|c} 0 & 0 \\ \hline 0 & \mathsf{FF}^\dagger \end{array}\right)\mathbf{G}_0^\dagger = -\mathbf{G}_0(\mathbf{T}+\mathbf{T}^\dagger)\mathbf{G}_0.$$

The isometry condition in (9) then follows from the first part of (27). The co-isometric property likewise follows from the second part. ■

E. Changing gauge

Let $\mathbf{G}$ be a fixed Itō coefficient matrix related to the Stratonovich coefficient matrices $\mathbf{G}_0^{(a)}$ and $\mathbf{G}_0^{(a)}$ with gauges $\mathbf{Z}^{(a)}$ and $\mathbf{Z}^{(a)}$, respectively. The two matrices will then be related by the perturbative formula

$$\mathbf{G}_0^{(a)} = \mathbf{G}_0^{(a)} + \mathrm{i}\mathbf{G}_0^{(a)}(\mathbf{Z}^{(a)} - \mathbf{Z}^{a})\mathbf{G}_0^{(a)}.$$

In particular, we can relate $\mathbf{G}_0^{(a)}$ for a nonzero gauge to the symmetric (gauge zero) form $\mathbf{G}_0^{(a)}$. As we shall see, the gauge $\mathbf{Z}$ has the physical interpretation as the imaginary part in the complex damping and in many applications this may be small.[21]

F. The "midpoint rule" construction

We wish to indicate briefly that the traditional midpoint rule construction of Stratonovich integrals agrees with the symmetric $\left(\mathbf{V}=\frac{1}{2}\mathbf{P}\right)$ situation considered here. This was shown to be at least plausible for integrals with respect to creation and annihilation process by Gardiner and Collett.[4] However, we describe in the following some rigorous results due to Chebotarev[13] using the notations of that paper.

A map M from the Borel sets of $\mathbb{R}^+$ to operators on $\mathfrak{h}\otimes\Gamma(L^2(\mathbb{R}^+))$ is said to be *interval-adapted* if $M(T)$ acts trivially on the factor $\Gamma(L^2(T^c))$ with respect to the continuous tensor product decomposition $\Gamma(L^2(\mathbb{R}^+))=\Gamma(L^2(T))\otimes\Gamma(L^2(T^c))$ with $T^c=\mathbb{R}^+/T$. The operators may be assumed to act on some dense domain $\mathcal{D}$. The prototypical integrators are then σ-additive interval adapted processes. An interval-adapted process U is said to be a cocycle if $U(t,s)=U(t,r)U(r,s)$ for $t\geqslant r\geqslant s$ where $U:[t_1,t_2)\mapsto U(t_2,t_1)$.

Suppose now that an interval adapted cocycle U is a weak solution to the QSDE

$$\mathrm{d}U(t,s) = U(t,s)M(\mathrm{d}t_+),$$

where $M(\mathrm{d}t_+)\equiv M(t+\mathrm{d}t,t)$ is the forward pointing Itō differential; that is, the following weak limit is assumed over increasingly fine partitions $S=t_0<t_1<\cdots<t_n=T$,

$$\int_S^T U(t,s)M(\mathrm{d}t_+)\phi := \lim_{\max|t_{j+1}-t_j|\to 0}\sum_j U(t_j,s)M(t_{j+1},t_j)\phi,$$

for all $\phi\in\mathcal{D}$, and $U(t,s)\phi=\phi+\int_s^t U(r,s)M(\mathrm{d}r_+)\phi$. Then, under mild conditions on a second interval adapted σ-additive process L, we have from Theorem 2.1[13]

$$\int_S^T U(t,s)L(\mathrm{d}t)\phi = \int_S^T U(t,s)\left\{L(\mathrm{d}t_+) + \frac{1}{2}M(\mathrm{d}t_+)L(\mathrm{d}t_+)\right\}\phi$$

for all $\phi\in\mathcal{D}$, where

$$\int_S^T U(t,s)L(\mathrm{d}t)\phi = \lim_{\max|t_{j+1}-t_j|\to 0}\sum_j U(t_j^*,s)L(t_{j+1},t_j)\phi$$

where $t_j^*=(t_{j+1}+t_j)/2$ is the midpoint of the interval $[t_j,t_{j+1})$.

In particular, the theorem is valid when the interval adapted σ-additive processes take the specific $[t_1,t_2)\mapsto M(t_2,t_1)=M_{\alpha\beta}\otimes(A_{t_2}^{\alpha\beta}-A_t^{\alpha\beta})$ for bounded operators $\{M_{\alpha\beta}\}$ on $\mathfrak{h}$: That is, $M(\mathrm{d}t_+)=M_{\alpha\beta}\otimes A_t^{\alpha\beta}$ and $L(\mathrm{d}t_+)=L_{\alpha\beta}\otimes A_t^{\alpha\beta}$. The situation that $\int_S^T U(t,s)L(\mathrm{d}t)\phi$ will equal $\int_S^T U(t,s)M(\mathrm{d}t_+)\phi$ occurs when

$$L(T,S)+\frac{1}{2}\int_S^T M(\mathrm{d}t_+)+L(\mathrm{d}t_+)=M(T,S).$$

The requirement on the coefficients, Eq. (2.23) of Ref. 13 can the, be rewritten as $M_{\alpha\beta}=L_{\alpha\beta}+\frac{1}{2}M_{\alpha 1}L_{1\beta}$ which is a special case of our relation (14).

IV. WICK ORDERING RULE

Let $X_\cdot$ and $Y_\cdot$ be quantum stochastic integrals with adapted integrands as before. In terms of our notation involving the $a_\alpha^\dagger(t),a_\beta(t)$, the product $X_tY_t=\int_0^t\mathrm{d}s_1\int_0^t\mathrm{d}s_2a_\alpha^\dagger(s_1)X_{s_1}^{\alpha\beta}a_\beta(s_1)a_\mu^\dagger(s_2)Y_{s_2}^{\mu\nu}a_\nu(s_2)$ is not immediately interpreted as an iterated integral since it is out of Wick order. However, the rule for achieving this is formally equivalent to the kinematic relations

$$[a_\alpha(t),Y_s]=\begin{cases}P^{\alpha\mu}Y_t^{\mu\nu}a_\nu(t), & t<s\\ V^{\alpha\mu}Y_t^{\mu\nu}a_\nu(t), & t=s\\ 0, & t>s,\end{cases}\tag{27}$$

under the integral sign, along with its adjoint $[X_t,a_\beta^\dagger(t)]=[a_\beta(t),X_s^\dagger]^\dagger$. These relations can be viewed as the formal commutation relations $[a_\alpha(t),a_\beta^\dagger(s)]=V^{\alpha\beta}\delta_+(t-s)+(V^{\beta\alpha})^*\delta_-(t-s)$ at work, where the $\delta_\pm$ are one-sided delta-functions: $\int\delta_\pm(f)f(t)=f(0^\pm)$, see e.g., Refs. 27 and 28. It is possible to interpret the $a_\alpha^\#(t)$ as quantum white noise operators, but we do not stress this point further here. At this stage, we could switch to a fluxion notation such as $\dot{X}_t=\mathrm{d}X_t/\mathrm{d}t=a_\alpha^\dagger(t)X_t^{\alpha\beta}a_\beta(t)$, etc., and write the Itō formula as $(\mathrm{d}/\mathrm{d}t)(X_tY_t)=\dot{X}_t\circ Y_t+X_t\circ\dot{Y}_t$ with the convention that

$$\dot{X}_t\circ Y_t\equiv a_\alpha^\dagger(t)X_t^{\alpha\beta}a_\beta(t)Y_t=a_\alpha^\dagger(t)X_t^{\alpha\beta}Y_ta_\beta(t)+a_\alpha^\dagger(t)X_t^{\alpha\mu}V^{\mu\nu}Y_t^{\nu\beta}a_\beta(t).$$

In particular, we have the following interpretation of the results of the previous section: The equation $\dot{U}_t=\dot{G}_0(t)U_t$ with $\dot{G}_0(t)=a_\alpha^\dagger(t)G_{\alpha\beta}^0a_\beta(t)$ is out of Wick order, but can be put to Wick order as $\dot{U}_t=a_\alpha^\dagger(t)G_{\alpha\beta}U_ta_\beta(t)$. The relation $[a_\alpha(t),U_t]=V^{\alpha\mu}G^{\mu\nu}U_ta_\nu(t)$ implies that

$$a_\alpha(t)U_t=(\delta_{\alpha\beta}+V^{\alpha\mu}G_{\mu\beta})U_ta_\beta(t)=F_{\alpha\beta}U_ta_\beta(t),\tag{28}$$

where $\{F_{\alpha\beta}\}$ are the components of the matrix $\mathbf{F}$ introduced in (24).

The QSDE for the unitary $U_\cdot$, with $G_{\alpha\beta}^0=-\mathrm{i}E_{\alpha\beta}$, will then be

$$\dot{U}_t=-\mathrm{i}a_\alpha^\dagger(t)E_{\alpha\beta}a_\beta(t)U_t=-\mathrm{i}a_\alpha^\dagger(t)E_{\alpha\beta}F_{\beta\nu}U_ta_\nu(t)\tag{29}$$

and likewise the QSDE for the flow will be

$$\frac{\mathrm{d}}{\mathrm{d}t}J_t(X)=\dot{U}_t^\dagger(X)U_t+U_t^\dagger(X)\dot{U}_t=-\mathrm{i}U_t^\dagger a_\alpha^\dagger(t)[X,E_{\alpha\beta}]a_\beta(t)U_t=-\mathrm{i}a_\mu^\dagger(t)U_t^\dagger F_{\alpha\mu}^\dagger[X,E_{\alpha\beta}]F_{\beta\nu}U_ta_\nu(t).\tag{30}$$

Comparison with Proposition 2 suggests that $\mathcal{L}_{\mu\nu}(X)=F_{\alpha\mu}^\dagger[X,E_{\alpha\beta}]F_{\beta\nu}$. As this is an entirely new relation, we give an independent derivation in Appendix A using only the Itō calculus.

Lemma 3: Under the conventions and notations of the previous sections, the Evans-Hudson maps take the form

$$\mathcal{L}_{\alpha\beta}(X) = -\mathrm{i}F^{\dagger}_{\mu\alpha}[X,E_{\mu\nu}]F_{\nu\beta}. \tag{31}$$

V. QUANTUM WONG-ZAKAI THEOREM

The following is the multidimensional version of a result first established in Ref. 16.

Theorem: *Let* $a^{\#}_{\alpha}(t,\lambda)$, $\alpha=0,1,\ldots,N$, *be creation/annihilation fields continuous in t for each* $\lambda>0$ *with* $A^{\alpha\beta}_t(\lambda)=\int^t_0 a^{\dagger}_{\alpha}(s,\lambda)a_{\beta}(s,\lambda)\mathrm{d}s$ *approximating fundamental quantum stochastic processes with internal space* $\mathbb{C}^N$ *as before, with fixed gauge matrix* $\mathbf{V}=\{V^{\alpha\beta}\}$. *If* $\Upsilon^{(\lambda)}_t=E_{\alpha\beta}\otimes a^{\dagger}_{\alpha}(t,\lambda)a_{\beta}(t,\lambda)$ *with* $E^{\dagger}_{\alpha\beta}=E_{\beta\alpha}$ *bounded operators on a fixed Hilbert space* $\mathfrak{h}$ *such that* VE *is a strict contraction, then the unitary family* $U^{(\lambda)}_{\cdot}$ *and the Heisenberg dynamical map* $J^{(\lambda)}_{\cdot}(X)=U^{(\lambda)\dagger}_{\cdot}XU^{(\lambda)}_{\cdot}$, *determined by the Schrödinger equation* $\dot{U}^{(\lambda)}_t=-\mathrm{i}\Upsilon^{(\lambda)}_t U^{(\lambda)}_t$, $U^{(\lambda)}_0=1$, *converge in the sense of weak matrix limits to the unitary quantum stochastic process* $U_{\cdot}$ *and corresponding quantum stochastic flow* $J_{\cdot}(X)$. *The limit process* $U_{\cdot}$ *is unitary adapted and satisfies the Stratonovich QSDE* $\mathrm{d}U_t=-\mathrm{i}E_{\alpha\beta}U_t\circ\mathrm{d}A^{\alpha\beta}_t$, $U_0=1$, *with gauge determined by* $\mathbf{V}=\{V^{\alpha\beta}\}$.

The proof is given in Appendix B. We remark that the condition $\|\mathsf{VE}\|<1$ gives convergence of the Neumann series. It also implies that $\mathbf{1}+\mathbf{VEP}$ will be invertible and therefore the Stratonovich QSDE makes sense. We will sketch the proof of this theorem in Appendix B. Provided that the strict contractivity conditions hold, we could replace E, and indeed V, by suitably continuous adapted processes.

It might be remarked that there exists an analogue of this result using Fermi fields in place of Bose fields.[32] The limit QSDE changes insofar as the noises must now be fermionic processes, however, the coefficients are exactly as before.

Examples: Classical Wong Zakai theorem. As a very special example of theorem, let us take the one-dimensional case with the prelimit Hamiltonian $\Upsilon^{(\lambda)}_t$ determined by $E_{00}=H$, $E_{01}=E_{10}=R$ and $E_{11}=0$ with $\kappa=\frac{1}{2}$. Then the limit flow is characterized by the maps $\mathcal{L}_{11}(X)=0$, $\mathcal{L}_{10}(X)=\mathcal{L}_{01}(X)=-i[X,R]$ and $\mathcal{L}_{00}(X)=-i[X,H]-\frac{1}{2}[[X,R],R]$. For the choices $H=\frac{1}{2}(pv(q)+v(q)p)$ and $R=\frac{1}{2}(p\sigma(q)+\sigma(q)p)$, where $v(\cdot)$ and $\sigma(\cdot)$ are Lipschitz continuous with $|v(x)|,|\sigma(x)|<C(1+|x|)$ for some constant $0<C<\infty$, and q and p are canonical position and momentum observables, we have that $q_t:=J_t(q)$ satisfies the essentially classical SDE $\mathrm{d}q_t=[v(q_t)+\sigma(q_t)\sigma'(q_t)]\mathrm{d}t+\sigma(q_t)\mathrm{d}Q_t$ or equivalently $\mathrm{d}q_t=v(q_t)\mathrm{d}t+\sigma(q_t)\circ\mathrm{d}Q_t$, where $Q_t=A^{10}_t+A^{01}_t$ is a copy of the Wiener process.

As a result, the theorem reduces to a classical Wong-Zakai approximation theorem which states that, since $Q^{(\lambda)}_t=\int^t_0(a^{\dagger}(s,\lambda)+a(s,\lambda))\mathrm{d}s$ is an essentially classical stochastic process that is differentiable in time t and converges almost always uniformly on compact time-intervals to a Wiener process Q_t, the solution to the random ODE $\dot{X}^{(\lambda)}_t=v(X^{(\lambda)}_t,t)+\sigma(X^{(\lambda)}_t,t)\dot{Q}^{(\lambda)}_t$, $X^{(\lambda)}_0=x_0$ similarly converges to the diffusion process X. satisfying the Stratonovich SDE

$$\mathrm{d}X_t=v(X_t,t)\mathrm{d}t+\sigma(X_t,t)\circ\mathrm{d}Q_t,\quad X_0=x_0.$$

Quantum diffusions. Taking $\Upsilon^{(\lambda)}_t=R\otimes a^{\dagger}(t,\lambda)+R^{\dagger}\otimes a(t,\lambda)+H$ leads to the limit QSDE

$$\mathrm{d}U_t=-\mathrm{i}(R\otimes\mathrm{d}A^{\dagger}_t+R^{\dagger}\otimes\mathrm{d}A_t+H)\circ U_t\equiv-\mathrm{i}(R\otimes\mathrm{d}A^{\dagger}_t+R^{\dagger}\otimes\mathrm{d}A_t+H)U_t-\kappa R^{\dagger}RU_t\mathrm{d}t.$$

Note that $\mathrm{Re}\,\kappa=\frac{1}{2}$ so that $\mathrm{d}J_t(X)=-\mathrm{i}J_t([X,R])\mathrm{d}A^{\dagger}_t-\mathrm{i}J_t([X,R^{\dagger}])\mathrm{d}A_t+J_t(\mathcal{L}(X))\mathrm{d}t$ where we set $A_t=A^{01}_t$, $A^{\dagger}_t=A^{10}_t$ and $\mathcal{L}(X)=\mathcal{L}_{00}(X)=-\mathrm{i}[X,H']+\frac{1}{2}[R^{\dagger},X]R+\frac{1}{2}R^{\dagger}[X,R]$. The new operator H' is $H+\mathrm{Im}\{\kappa\}R^{\dagger}R$ which includes an energy shift coming from the complex damping κ. The theorem then reduces to a long line of results dealing with broadband noise limits, weak coupling limits, etc., in quantum physics.

It is straightforward to extend this to describe coherent states, thermal states, and squeezed states.[29]

Counting processes. Let us consider the choice $\Upsilon^{(\lambda)}_t=E\otimes\{a(t,\lambda)+f(t)\}^{\dagger}\{a(t,\lambda)+f(t)\}$. This is what we could consider in the vacuum as an equivalent of studying $E\otimes a(t,\lambda)^{\dagger}a(t,\lambda)$ in a coherent of intensity f. Here we have $E_{\alpha\beta}=Ef^{*}_{\alpha}(t)f_{\beta}(t)$ and the one-dimensional form of the theorem yields the Itō coefficients

$$G_{\alpha\beta} = -iE_{\alpha\beta} - \kappa E_{\alpha 1}\frac{1}{1+\mathrm{i}\kappa E_{11}}E_{1\beta},$$

which in this case reduce to

$$G_{\alpha\beta}(t) = \frac{-\mathrm{i}E}{1+\mathrm{i}\kappa E}f_\alpha^*(t)f_\beta(t).$$

The Itō form of the limit QSDE is then

$$\mathrm{d}U_t = \frac{-\mathrm{i}E}{1+\mathrm{i}\kappa E}\mathrm{d}N_t(f)U_t$$

and we introduce $N_t(f)=\int_0^t(\mathrm{d}A_s^{11}+f(s)\mathrm{d}A_s^{10}+f^*(s)\mathrm{d}A_s^{01}+|f(s)|^2\mathrm{d}s)$ which is essentially classical and corresponds to a time-inhomogeneous Poisson process with instantaneous rate of change $\nu(t)=|f(t)|^2$.

ACKNOWLEDGMENT

It is a great pleasure to thank the staff at MabuchiLab for their kind hospitality during his visit there when part of this paper was written. Conversations with Hideo Mabuchi, Gerard Milburn, P. Krishnaprasad, Matthew James, Howard Wiseman, Andrew Doherty, Robin Hudson, Ramon van Handel, and Luc Bouten are gratefully acknowledged.

APPENDIX A (PROOF OF LEMMA 3)

We restrict ourselves to the $N=1$ case, as this is already somewhat involved. The multidimensional case does not present any more technical difficulties. Here the Evans-Hudson maps are given by

$$\mathcal{L}_{11}(X) = W^\dagger XW - X,$$

$$\mathcal{L}_{10}(X) = W^\dagger[X,L]; \quad \mathcal{L}_{01}(X) = -[X,L^\dagger]W, \tag{A1}$$

$$\mathcal{L}_{00}(X) = \tfrac{1}{2}[L^\dagger,X]L + \frac{1}{2}L^\dagger[X,L] - \mathrm{i}[X,H],$$

where the operators W,H,L have the explicit forms

$$W = \frac{1-\mathrm{i}\kappa^* E_{11}}{1+\mathrm{i}\kappa E_{11}}, \quad L = -\mathrm{i}\frac{1}{1+\mathrm{i}\kappa E_{11}}E_{10}, \quad H = E_{00} + E_{01}\,\mathrm{Im}\left\{\frac{\kappa}{1+\mathrm{i}\kappa E_{11}}\right\}E_{10}. \tag{A2}$$

The components of the matrix F can also be written out in detail:

$$F_{11} = \frac{1}{1+\mathrm{i}\kappa E_{11}}, \quad F_{10} = -\mathrm{i}\kappa\frac{1}{1+\mathrm{i}\kappa E_{11}}E_{10}, \quad F_{01}=0, \quad F_{00}=1. \tag{A3}$$

We now check that the relation (A1) is correct by direct substitution.

For $\alpha=\beta=1$, we find after a little algebra that

$$\mathcal{L}_{11}(X) = \frac{1+\mathrm{i}\kappa E_{11}}{1-\mathrm{i}\kappa^* E_{11}}X\frac{1-\mathrm{i}\kappa^* E_{11}}{1+\mathrm{i}\kappa E_{11}} - X = -\mathrm{i}\frac{1}{1-\mathrm{i}\kappa^* E_{11}}[X,E_{11}]\frac{1}{1+\mathrm{i}\kappa E_{11}} = -\mathrm{i}F_{\mu 1}^\dagger[X,E_{\mu\nu}]F_{\nu 1}.$$

For $\alpha=1$, $\beta=0$, we have

$$\mathcal{L}_{10}(X) = \frac{1+\mathrm{i}\kappa E_{11}}{1-\mathrm{i}\kappa^* E_{11}}\left[X, -\mathrm{i}\frac{1}{1+\mathrm{i}\kappa E_{11}}E_{10}\right]$$

and to compute this we need the observation that

$$\left[X, \frac{1}{1+\mathrm{i}\kappa E_{11}}\right] = -\mathrm{i}\kappa\frac{1}{1+\mathrm{i}\kappa E_{11}}[X,E_{11}]\frac{1}{1+\mathrm{i}\kappa E_{11}} \tag{A4}$$

to write

$$\mathcal{L}_{10}(X) = i\kappa\frac{1}{1-\mathrm{i}\kappa^* E_{11}}[X,E_{11}]\frac{1}{1+\mathrm{i}\kappa E_{11}} - \mathrm{i}\frac{1}{1-\mathrm{i}\kappa^* E_{11}}[X,E_{10}] = -\mathrm{i}F^\dagger_{\mu 1}[X,E_{\mu\nu}]F_{\nu 0}.$$

As we have $\mathcal{L}_{\alpha\beta}(X)^\dagger = \mathcal{L}_{\beta\alpha}(X^\dagger)$, this gives the $\mathcal{L}_{01}(X)$ result also.

The final case is the Lindbladian map $\mathcal{L}_{00}$. Substituting in gives

$$\mathcal{L}_{00}(X) = -\mathrm{i}[X,E_{00}] - \mathrm{i}[X,E_{01}\,\mathrm{Im}\{T\}E_{10}] + \frac{1}{2}\left[E_{01}\frac{1}{1-\mathrm{i}\kappa^* E_{11}}, X\right]\frac{1}{1+\mathrm{i}\kappa E_{11}}E_{10} + \frac{1}{2}E_{01}\frac{1}{1-\mathrm{i}\kappa^* E_{11}}\left[X, \frac{1}{1+\mathrm{i}\kappa E_{11}}E_{10}\right]$$

and again we use (B1) along with the observation that

$$\mathrm{Re}\,T = \frac{1}{2}\frac{1}{1-\mathrm{i}\kappa^* E_{11}}\frac{1}{1+\mathrm{i}\kappa E_{11}}$$

to obtain

$$\mathcal{L}_{00}(X) = -\mathrm{i}[X,E_{00}] - [X,E_{01}]TE_{10} + E_{01}T^\dagger[X,E_{10}] - \mathrm{i}E_{01}[X,\mathrm{Im}\,T]E_{10} - \mathrm{i}E_{01}T^\dagger[X,E_{11}]\mathrm{Re}\{T\}E_{10} - \mathrm{i}E_{01}\,\mathrm{Re}\{T^\dagger\}[X,E_{11}]TE_{10}.$$

The first three terms are $-\mathrm{i}F^\dagger_{\alpha 0}[X,E_{\alpha\beta}]F_{\beta 0}$, for $(\alpha,\beta)=(0,0)$, (0, 1), and (1, 0), respectively. To tidy up the last term, we note the identities

$$[X,T] = -\mathrm{i}T[X,E_{11}]T, [X,T^\dagger] = +\mathrm{i}T^\dagger[X,E_{11}]T^\dagger$$

so that

$$[X,\mathrm{Im}\,T] + T^\dagger[X,E_{11}]\mathrm{Re}\,T + \mathrm{Re}\,T[X,E_{11}]T = -\tfrac{1}{2}T[X,E_{11}]T - \tfrac{1}{2}T^\dagger[X,E_{11}]T + T^\dagger[X,E_{11}]\mathrm{Re}\,T + \mathrm{Re}\,T[X,E_{11}]T \equiv T^\dagger[X,E_{11}]T$$

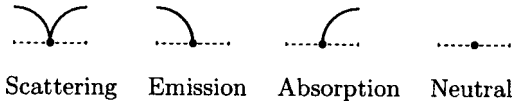
and therefore the last term is $-\mathrm{i}E_{01}T^\dagger[X,E_{11}]TE_{10} \equiv -\mathrm{i}F^\dagger_{10}[X,E_{10}]F_{10}$. This gives the desired form.

APPENDIX B (PROOF OF THE THEOREM)

We now sketch briefly the proof of limit using diagrams. Essentially, this is a form of the van Kampen cumulant expansion[21] which can be described explicitly. The Heisenberg evolution limit is similar though more involved.[16]

Step 1: Wick ordering the Dyson series. For finite λ, the mapping $t \mapsto U_t^{(\lambda)}$ is differentiable, and we may formally expand as the Dyson series $U_t^{(\lambda)} = \Sigma_{n\geqslant 0}(-\mathrm{i})^n \int_{\Delta_n(t)} \Upsilon^{(\lambda)}_{t_n}\cdots\Upsilon^{(\lambda)}_{t_1}$. Here $\Delta_n(t)$ is the simplex consisting of multi-times $(t_n,\ldots,t_1)$ with $t \geqslant t_n \geqslant \cdots \geqslant t_1 \geqslant 0$.

It is convenient to put the Dyson series to Wick order using the commutation relations. The most convenient way to describe this is to expand in terms of diagrammatic series and we borrow some standard techniques from field theory. To this end, we introduce four vertices corresponding to the four components of $\Upsilon_t^{(\lambda)}$:[30]



The Wick-ordered Dyson series is then given by the sum

$$U_t^{(\lambda)} = \sum_{\mathfrak{D}} \hat{\mathfrak{D}}_t(\lambda) \tag{B1}$$

which we now describe. We sum over all diagrams $\mathfrak{D}$ obtained by writing n vertices in a line $(n=0,1,2,\ldots)$ as below

taking each of the vertices to be one of the four shown above, connecting up some of the creation/annihilation pairs and leaving the rest as external lines.

With each such diagram $\mathfrak{D}$ we associate the operator

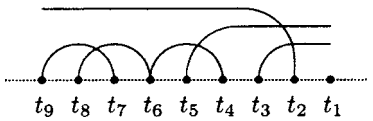
$$\hat{\mathfrak{D}}_t(\lambda) = (-\mathrm{i})^n E_n \cdots E_1 \otimes \int_{\Delta_n(t)} \Pi a^\dagger(\lambda) \Pi C(\lambda) \Pi a(\lambda) \tag{B2}$$

where, depending on the type of vertex at t_j,

$$E_j = \begin{cases} E_{ij}, \text{ scattering} \\ E_{i0}, \text{ emission} \\ E_{0j}, \text{ absorption} \\ E_{00}, \text{ neutral} \end{cases}$$

and in the simplex integral $\Pi a^\dagger(\lambda)$ is the product over all external lines going out, $\Pi a(\lambda)$ is the product over all external lines coming in and $\Pi C(\lambda)$ is a product over all contraction pairs.

For instance the nine vertex diagram below



corresponds to the operator

$$-\mathrm{i}E_{0j_9}E_{0j_8}E_{i_70}E_{i_6j_6}E_{0j_5}E_{i_40}E_{0j_3}E_{i_20}E_{00}$$
$$\otimes \int_{\Delta_9(t)} a^\dagger_{i_2}(t_2,\lambda)a_{j_5}(t_5,\lambda)a_{j_3}(t_3,\lambda)C_{j_9i_7}(t_9-t_7,\lambda)C_{j_8i_6}(t_8-t_6,\lambda)C_{j_6i_4}(t_6-t_4,\lambda).$$

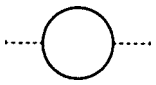
The diagrams we are considering are Goldstone diagrams, or time-ordered Feynman diagrams.[31] The vertices however carry an operator weight $E_{\alpha\beta}$ and, even in the absence of external lines, the diagrams will not generally be scalars!

Step 2: The Markov limit of individual diagrams. Let us consider the effect of the Markov limit $\lambda \to 0$ on individual diagrams. If we have a contraction

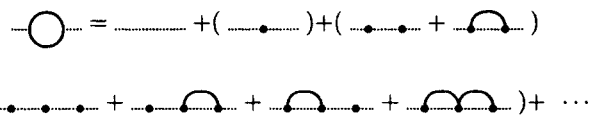
over consecutive times $t_{j+1} > t_j$, then we will have $t_{j+1} - t_j \to 0^+$ in the limit. The effect of each such contraction is to reduce the order of the simplex by one degree and to introduce a multiplication factor V^{ij}. (Remember, we only get a partial contribution from the delta-function since $t_{j+1} > t_j$.) On the other hand, if any of the contracted time pairs are not time consecutive then the contribution converges weakly to zero! The reason is essentially that not just the emission and absorption times, but all the intermediate times are forced to be equal, and we get a collapse of the integral to zero.

We therefore say that a diagram is time-consecutive (TC) if each contraction appearing is between time consecutive vertices only.

Step 3: The vacuum limit. We now fix u, $v \in \mathfrak{h}$ and investigate the limit $\lim_{\lambda \to 0} \langle u \otimes \Omega | U_t^{(\lambda)} | v \otimes \Omega \rangle$ which we denote by the single vertex



We now argue that this limit will consist of the TC diagrams having no external lines which we can express as



The diagrams have been grouped by vertex number, however, it also possible to group them by effective vertex number which is the actual number minus the number of contractions and which gives reduced degree of the simplex. The series can be partially re-summed as

where each box is a sum over all effective one-vertex contributions:

which is analogous to the expression of the self-energy in quantum field theory:as a sum over irreducible terms. (Note that series terminates at second order when there is no scattering: as this is a form of cumulant expansion, the emission/absorption problem is then Gaussian while allowing scattering means that we have cumulant moments to all orders!) Explicitly, the box at time vertex t corresponds to the sum

$$
\begin{aligned}
&-\mathrm{i}E_{00}\mathrm{d}t + (-\mathrm{i})^2 E_{0i_1} E_{i_1 0}\mathrm{d}t + (-\mathrm{i})^3 E_{0i_4} V^{i_4 i_3} E_{i_3 i_2} V^{i_2 i_1} E_{i_1,0}\mathrm{d}t + \cdots \\
&\quad = \left(-\mathrm{i}E_{00} - E_{0i} V^{ij} \left(\frac{1}{1 + \mathrm{i}\mathsf{VE}} \right)_{jk} E_{k0} \right) \mathrm{d}t \equiv -\mathrm{i}G_{00}\mathrm{d}t
\end{aligned}
$$

and we have summed the geometric series, convergent since $\|\mathrm{VE}\| < 1$, to get the required coefficient G_{00}. We can write the expansion in the recursive form

and this is interpreted as the integrodifferential equation

$$\int_0^t \langle u\otimes\Omega|\mathrm{d}U_{t_1}|v\otimes\Omega\rangle = \langle u\otimes\Omega|v\otimes\Omega\rangle - \mathrm{i}\int_0^t \mathrm{d}t_2 \left\langle u\otimes\Omega \left| G_{00}\int_0^{t_2}\mathrm{d}U_{t_1}\right| v\otimes\Omega\right\rangle$$

with decaying exponential solution

$$\langle u\otimes\Omega|U(t)|v\otimes\Omega\rangle = \langle u|e^{-\mathrm{i}tG_{00}}|v\rangle.$$

The interpretation is intended to suggest that there is a limit object U_t which we interpret as a unitary quantum stochastic process on a noise space with initial space $\mathfrak{h}$.

Step 4: Limit of exponential vector matrix elements. Calculating $\lim_{\lambda\to 0}\langle u\otimes\varepsilon_\lambda(\mathbf{f})|U(t,\lambda)|v\otimes\varepsilon_\lambda(\mathbf{g})\rangle$ does not require too much machinery beyond that used in the vacuum case. Indeed, we can convert the new matrix elements to vacuum ones using the relation

$$\langle u\otimes\varepsilon_\lambda(\mathbf{f})|U_f^{(\lambda)}|v\otimes\varepsilon_\lambda(\mathbf{g})\rangle = \langle u\otimes\Omega|\widetilde{U}_t^{(\lambda)}|v\otimes\Omega\rangle,$$

where $\widetilde{U}_t^{(\lambda)}$ is the solution to the Schrödinger equation determined by the "Hamiltonian" $\widetilde{\Upsilon}_t^{(\lambda)}$ obtained by replacing the fields $a(t,\lambda)$ and $a^\dagger(t,\lambda)$ with

$$\widetilde{a}_i(t,\lambda) = a_i(t,\lambda) + \int C_{ij}(t-s,\lambda)g_j(s),$$

$$\widetilde{a}_i^\dagger(t,\lambda) = a_i^\dagger(t,\lambda) + \left[\int C_{ij}(t-s)f_j(\lambda)\right]^*.$$

The new interaction $\widetilde{\Upsilon}_t^{(\lambda)}$ is not necessarily self-adjoint, however, that does not effect things. We may rearrange $\widetilde{\Upsilon}_t^{(\lambda)}$ in terms of the original fields as $\widetilde{E}_{\alpha\beta}\otimes a_\alpha^\dagger(t,\lambda)a_\beta(t,\lambda)$ where, suppressing the λ and t dependencies, the $\widetilde{E}_{\alpha\beta}$ are the operators

$$\widetilde{E}_{ij} = E_{ij},$$

$$\widetilde{E}_{i0} = E_{i0} + E_{ij}\int C_{jl}(t-s,\lambda)g_l(s),$$

$$\widetilde{E}_{0j} = E_{0j} + E_{jk}\left[\int C_{kl}(t-s)f_l(t)\right]^*,$$

$$\widetilde{E}_{00} = E_{00} + E_{i0}\left[\int C_{il}(t-s)f_l(t)\right]^* + E_{0j}\int C_{jl}(t-s,\lambda)g_l(s) + E_{jk}\left[\int C_{il}(t-s)f_l(t)\right]^*\int C_{jm}(t-s,\lambda)g_m(s).$$

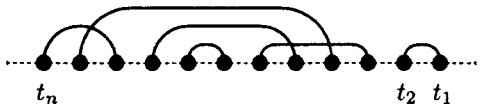
Therefore we only have to repeat our previous argument, but with the original coefficients now replaced by the modified ones $\widetilde{E}_{\alpha\beta}$, taking care with the t and λ dependencies. This time the box at time vertex t corresponds to the sum $-\mathrm{i}f_\alpha^* g_\beta G_{\alpha\beta}\mathrm{d}t$ where now

$$G_{\alpha\beta} = E_{\alpha\beta} - E_{\alpha i}(\mathsf{V} - \mathrm{i}\mathsf{VEV} + (-i)^2\mathsf{VEVEV} + \cdots)_{ij}E_{j\beta} = \left(-\mathrm{i}E_{\alpha\beta} - E_{\alpha i}V^{ij}\left(\frac{1}{1+\mathrm{i}\mathsf{VE}}\right)_{jk}E_{k\beta}\right)$$

and this gives the required result.

Step 5: Convergence of the series. What we have done so far has been to expand the Dyson series, determine the asymptotic limit of each diagram term (only the TC ones survived), to replace the terms by their respective limits and to re-sum the series. To complete the proof, we need to establish that the series is absolutely and uniformly convergent. Fortunately we are able to extend the proof for estimating that these types of series exist for emission-absorption interactions[33] to the general case.

Let us start with the case where we have emission and absorption only in the interaction. The order must be even say, $n=2n_2$, as the vacuum diagrams consist of n_2 pair contractions only. There will then be $(2n_2)!/2^{n_2}n_2!$ such diagrams with $2n_2$ vertices. A typical diagram, having $n_2=6$ is sketched in the following:



There exists a permutation σ of the $n=2n_2$ time indices which re-orders to the diagram $\mathfrak{D}_0(n)$ shown in the following:

The permutation is moreover unique if it has the induced ordering of the emission times. Not all permutations arise this way, the ones that do are termed admissible. We now consider an estimate of the nth term in the Dyson series. Let $E=\max\|E_{\alpha\beta}\|$, then

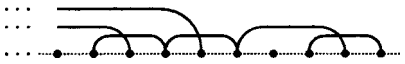
$$\sum_{\mathfrak{D}} E^n \int_{\Delta_n(t)} \prod |C(\lambda)| \Big|_{\mathfrak{D}} = \sum_{\text{Admissible perms.}} E^n \int_{\Delta_n(t)} \prod |C(\lambda)\circ\sigma| \Big|_{\mathfrak{D}_0(n)}$$

$$= E^n \int_{R(t)} \prod_{k=1}^{n_2} |C(t_{2k}-t_{2k-1},\lambda)|,$$

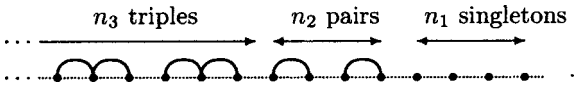
where $R(t)$ is the union of simplices $\{(t_n,\ldots,t_1): t>t_{\sigma^{-1}(n)}>\ldots>t_{\sigma^{-1}(1)}>0\}$ over all admissible permutations Z. $R(t)$ will be a subset of $[0,t]^{2n_2}$ and if we introduce variables t_{2k} and $s_{2k}=t_{2k}-t_{2k-1}$ for $k=1,\ldots,n_2$, it is easily seen that the above is majorized by $E^{2n_2}C^{n_2}\times\max(t,1)^{n_2}/n_2!$, where $C=\max V^{ij}$. This is the Pulè inequality[33] and clearly gives the uniform absolute estimate required to sum the series.

We now consider scattering, and constant, terms in the interaction. This time, the number of diagrams with n vertices will be given by the nth Bell number B_n. To see why this is so, we recall that if we have a reservoir quanta created at a vertex, then perhaps scattered, and finally reabsorbed then we can think of it as the same quantum and treat all the vertices it has been at as being linked. Each such diagram is then described by these subsets of linked vertices (we should also count the neutral vertices as these are singleton sets): in this way we have a one-to-one correspondence between the diagrams and partitions of vertices into nonempty subsets. The Bell numbers grow rapidly and have a complicated asymptotic behavior. The proliferation of diagrams is due mainly to the multiple scattering that now takes place.

Let us consider a typical diagram. We shall assume that within the diagram there are n_1 singleton vertices $[\cdots \bullet \cdots]$, n_2 contraction pairs $[\cdots \overset{\frown}{\bullet\cdots\bullet} \cdots]$, n_3 contraction triples $[\cdots \overset{\frown}{\bullet\cdots\bullet\cdots\bullet} \cdots]$ etc. That is the diagram has a total of $n=\Sigma_j jn_j$ vertices which are partitioned into $m=\Sigma_j n_j$ connected subdiagrams. For instance, we might have an initial segment of a diagram looking like the following:



There will exist a permutation σ of the n vertices which will reorder the vertices so that we have the singletons first, then the pair contractions, then the triples, etc., so that we obtain a picture of the following type:



The permutation is again unique if we retain the induced ordering of the first emission times for each connected block. We now wish to find a uniform estimate for the nth term in the Dyson series, we have

$$\sum_{\mathfrak{D}} \int_{\Delta_n(t)} \prod |C(\lambda)| \times \text{“ weights”}$$

where the weights are the operator norms of various products of the type $E_{\alpha_n\beta_n}\cdots E_{\alpha_1\beta_1}$. Each connected diagram of $j\geqslant 2$ vertices will typically have one emission and one absorption, and $j-2$ scattering vertices. The Pulè argument of rearranging the sum over diagrams into a single integral over a region $R(t)$ of $[0,t]^n$ again applies and by similar reason we arrive at the upper bound, this time of the type

$$\sum_{n_1,n_2,n_3,\ldots}{}' \|\mathsf{VE}\|^{n_1+2n_2+3n_3+\cdots} E^{n_1+n_2+n_3+\cdots} \times \frac{\max(t,1)^{n_1+n_2+n_3+\cdots}}{n_1!n_2!n_3!\cdots}.$$

Here the sum is restricted so that $\Sigma_j jn_j=n$. An uniform estimate for the entire series is then given by removing this restriction:

$$\Xi(A,B)=\sum_{n_1,n_2,n_3,\cdots} \frac{\exp\{\sum_j (A_j+B)n_j\}}{n_1!n_2!n_3!\ldots}$$

where $e^A=\|\mathsf{VE}\|$ and $e^B=E\max(t,1)$. Again we use the trick to convert a sum of products into a product of sums

$$\Xi(A,B)=\prod_j \sum_n \frac{\exp\{(Aj+B)n\}}{n!}=\exp\left\{\frac{e^{A+B}}{1-e^A}\right\},$$

where we need $e^A<1$ to sum the geometric series—this however, is precisely our condition that $\|\mathsf{VE}\|<1$.

Bayesian analog of Gleason's theorem

Thomas Marlow[a)]
School of Mathematical Sciences, University of Nottingham, Nottingham NG7 2RD, United Kingdom

(Received 16 May 2006; accepted 14 October 2006; published online 5 December 2006)

We introduce a novel notion of probability within quantum history theories and give a Gleasonesque proof for these assignments. This involves introducing a tentative novel axiom of probability. We also discuss how we are to interpret these generalized probabilities as partially ordered notions of preference, and we introduce a tentative generalized notion of Shannon entropy. A Bayesian approach to probability theory is adopted throughout; thus the axioms we use will be minimal criteria of rationality rather than *ad hoc* mathematical axioms. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2390658]

I. INTRODUCTION AND SUMMARY

In Ref. 1 we postulated a novel notion of probability by generalizing Cox's axioms of probability[2,3] in a manner appropriate to quantum theory. In this paper we wish to go one step further; we will present a uniqueness proof analogous to Gleason's theorem for our postulated generalized probabilities. We will be helped considerably by another analog of Gleason's theorem in the literature[4] which is applied to the decoherence functional in the history projection operator (HPO) formulation of the consistent histories program.[5] First we will review results previously discussed[1] and then we will outline the relevant Gleason-like theorem, its interpretation, and, for completeness, its proof. We will then propose a generalized entropy.

We will adopt a Bayesian approach to probability theory and we will use Cox's approach in particular.[3] Probabilities are usually considered real numbers because of an association with relative frequencies. As soon as we adopt an approach to probability theory where we merely assign probabilities as an ordered notion of preference, then there is absolutely no *a priori* reason to consider probabilities as real numbers. One might try to design "zeroth" axioms of probability theory which end up ensuring that probabilities are, in fact, real numbers, and then one might introduce further axioms to constrain how we assign these real numbers to propositions. Such an approach is, however, problematic because such zeroth axioms are rather *ad hoc*.

Consider some arbitrary propositions α, β, and γ to which we are to assign probabilities. Consider also a notion of ordering "$>$" to be defined on the probability space. Two possible zeroth axioms,[6] which constrain how this ordering notion is to behave, are "universal transitivity:"
Axiom 0a,

$$\text{if } p(\alpha|I) > p(\beta|I) \text{ and } p(\beta|I) > p(\gamma|I) \text{ then } p(\alpha|I) > p(\gamma|I), \tag{1}$$

and "universal comparability:"
Axiom 0b,

$$\text{for all } \alpha \text{ and } \beta \text{ we have that either } p(\alpha|I) > p(\beta|I) \text{ or } p(\alpha|I) < p(\beta|I) \text{ or } p(\alpha|I) = p(\beta|I). \tag{2}$$

[a)]Electronic mail: tommarlow@googlemail.com

Given these zeroth axioms it would seem natural (although it is still not strictly necessary) to use real numbers for probability assignments. Axiom 0a is often considered desirable because probabilities are intended to represent transitive notions of preference in some sense. Axiom 0b is, however, far more dubious and there is a history in the literature of people trying not to assume it (see Appendix A.3 of Ref. 6 for references and also see Refs. 7 and 8). Why presume that we can probabilistically compare all propositions universally, especially in quantum theory where some propositions are considered "incompatible" or "complimentary?" It is prudent not to assume Axiom 0b from the outset (it might be that we are forced to adopt it later). If we were to adopt Axiom 0b, then it might be that we will be introducing relationships between probabilities that we are not justified in invoking—and any problems such as nonadditivity and so forth might be due to such a mistaken assumption.

Rather than adopt these two controversial zeroth axioms let us, for the time being, use a weaker zeroth axiom that we can all surely agree on:
Axiom 0′,

$$\text{if } \alpha \preccurlyeq \beta \text{ then, presumably, } p(\alpha|I) \leqslant p(\beta|I), \tag{3}$$

where "$\preccurlyeq$" is, in the least, a partial order in the context of both the proposition space and the space of generalized probabilities (in the context of standard probability theory, we could use Venn diagrams to define $\alpha \preccurlyeq \beta$ using subset inclusion and we would define $p(\alpha|I) \leqslant p(\beta|I)$ using the total ordering of real numbers). We call this axiom "monoticity."[9] So as to avoid confusion with standard probability theory (theories which obey Axioms 0a and 0b), it is prudent to call any assignment which merely obeys the weaker zeroth axiom [Eq. (3)] by another name: we will call them "pedagogical examples" or "pegs." Probabilities are then special examples of pegs.

Our task in this paper is then to find a peg theory for a histories algebra. We will use the histories propositional algebra $\mathcal{P}(\mathcal{V})$, where $\mathcal{V}=\otimes^n\mathcal{H}$, which was originally introduced by Isham.[5] The natural connectives on this space of projection operators are the standard $\wedge$, $\vee$, and $\neg$ connectives and we use the standard partial order $\preccurlyeq$ upon it.[5] A homogeneous history proposition α is defined as a time ordered tensor product of projection operators $\hat{\alpha}_{t_m} \in \mathcal{P}(\mathcal{H})$:

$$\alpha := \hat{\alpha}_{t_n}(t_n) \otimes \hat{\alpha}_{t_{n-1}}(t_{n-1}) \otimes \cdots \otimes \hat{\alpha}_{t_1}(t_1). \tag{4}$$

We stay in the Heisenberg picture such that each projection operator has the dynamics already implicit such that $\hat{\alpha}_{t_m}(t_m)=\hat{U}^\dagger(t_m-t_{m-1})\hat{\alpha}_{t_m}\hat{U}(t_m-t_{m-1})$, where $\hat{\alpha}_{t_m}$ are Schrödinger picture operators. Our novel peg assignments, those that we suggested in Ref. 1, are

$$p(\alpha|I) := \mathrm{tr}_{\mathcal{H}}(C_\alpha \hat{\rho}), \tag{5}$$

where $C_\alpha=\hat{\alpha}_{t_n}(t_n)\hat{\alpha}_{t_{n-1}}(t_{n-1})\cdots\hat{\alpha}_{t_1}(t_1)$ and $\hat{\rho}$ is a density operator on $\mathcal{H}$. We keep an explicit hypothesis I in the notation because such a thing is natural when discussing probabilities from a Bayesian perspective,[10] and it avoids us confusing peg assignments that are made given different prior information. Clearly these pegs might obey Eq. (3) by relating the natural partial order on $\mathcal{P}(\mathcal{V})$ to some partial order on $\mathbb{C}$. Once we introduce further axioms that these pegs ought to obey—other than Eq. (3)—then we will be able to speculate what this partial order on the peg space might be.

We proposed these pegs for the history algebra $\mathcal{P}(\mathcal{V})$ because they are additive for disjoint homogeneous history propositions;[1] thus these complex pegs seem to *behave* something like we expect probabilities should. Now we aim to show that we can *derive* these pegs from axioms analogous to Cox's axioms of probability theory applied to the HPO algebra using an analog of Gleason's theorem.

II. A GLEASON ANALOG

So, let us remind ourselves of what Gleason's theorem[11] tells us. Gleason's theorem is about trying to assign probabilities to a quantum propositional algebra. In standard quantum theory the

relevant propositional algebra is taken to be $\mathcal{P}(\mathcal{H})$, the set of projection operators upon a Hilbert space $\mathcal{H}$, where the natural logical connectives on $\mathcal{P}(\mathcal{H})$ are $\wedge$, $\vee$, and $\neg$, and we denote the standard partial order relation $\leqslant$. So, naturally, a probability assignment should obey certain rules which we shall use to define what is often, perhaps confusingly, called a state (we call it a state more because of what we end up proving). A state $\sigma \in \mathcal{S}$ is a real valued function on $\mathcal{P}(\mathcal{H})$ which has the following properties:

1. Positivity: $\sigma(\hat{P}) \geqslant 0$ for all $\hat{P} \in \mathcal{P}(\mathcal{H})$,
2. Additivity: if $\hat{P}$ and $\hat{R}$ are disjoint—$\hat{P} \wedge \hat{R} = \hat{\mathbf{0}}$—then $\sigma(\hat{P} \vee \hat{R}) = \sigma(\hat{P}) + \sigma(\hat{R})$, and
3. Normalization: $\sigma(\hat{1}) = 1$,

where $\hat{\mathbf{0}} \in \mathcal{P}(\mathcal{H})$ is the proposition that is always false and $\hat{\mathbf{1}} \in \mathcal{P}(\mathcal{H})$ is the proposition that is always true. Gleason's theorem is simply that states assigned to $\mathcal{P}(\mathcal{H})$, for $\dim \mathcal{H} > 2$, are in one-to-one correspondence with density matrices on $\mathcal{H}$ such that

$$\sigma_\rho(\hat{P}) = \mathrm{tr}(\hat{P}\hat{\rho}) \quad \text{for all } \hat{P} \in \mathcal{P}(\mathcal{H}). \tag{6}$$

One takes the propositional algebra of projection operators, makes basic assumptions about how probabilities ought to behave, and derives that such probability assignments are in one-to-one correspondence with density matrices. The axioms of probability theory ensure the density matrix structure of quantum theory.

In analogy with Gleason's theorem, we should list a set of axioms that our pegs should obey and then try and derive the theorem from there. For these axioms, we argue, we should look to Cox's axioms of probability theory which ensure that we do not introduce functional relationships between peg assignments that are not rationally justified. Cox's $\wedge$-axiom is simply that the pegs we peg to propositions conjoined using the AND operation should be limited to be functionally dependent only on some very specific pegs:

$$p(\alpha \wedge \beta | I) := F[p(\alpha|\beta I), p(\beta|I)], \tag{7}$$

where F is an arbitrary function that is sufficiently well behaved for our purposes. Similarly, Cox's $\neg$-axiom is that the peg we peg to the negation of a proposition should only functionally depend upon the peg of the proposition before it was negated:

$$p(\neg\alpha|I) := G[p(\alpha|I)]. \tag{8}$$

These two axioms are criteria of rationality that are at the heart of Cox's approach to probability theory and these are all he needed (except for the additional assumption that probabilities are real numbers) in order to prove the basics of probability theory as applied to a Boolean algebra of propositions.

Cox's two axioms suggest we should use a peg that is additive for disjoint history propositions and that is normalized.[3] It turns out that this will not be sufficient for our peg theory; we will need a further axiom. Luckily one is forthcoming. Note that in the HPO formulation of history theories, we have the three natural logical connectives $\wedge$, $\vee$, and $\neg$ which correspond roughly to AND, OR, and "negation" operations (although with the standard nondistributivity issue we have in quantum theory). Clearly, however, when going from projection operators defined at a single time to explicitly history orientated propositions, there is another natural connective, namely, changing the temporal order. As such we can define an operator M which reverses the order on any tensor product vector, $M(v_1 \otimes v_2 \otimes \cdots v_m) := (v_m \otimes v_{m-1} \otimes \cdots v_1)$. Thus the temporal reversal of the Heisenberg picture history proposition α is given by

$$\alpha := M\alpha M = \hat{\alpha}_{t_1}(t_1) \otimes \hat{\alpha}_{t_2}(t_2) \otimes \cdots \otimes \hat{\alpha}_{t_n}(t_n). \tag{9}$$

Note that $\lhd$ reverses both the kinematical and the dynamical temporal orderings because we are in the Heisenberg picture (cf. Ref. 12). Applying $\lhd$ twice in this manner obviously gives back the same history proposition, behavior that is analogous to the negation operation. Hence we should introduce a third peg axiom analogous to Eq. (8):

$$p(\lhd\alpha|I) := H[p(\alpha|I)], \tag{10}$$

where H is an arbitrary function that is sufficiently well behaved for our purposes. The peg we assign to such a proposition should be assigned in a noncontextual manner according to Eq. (10). Clearly, by Youssef's argument,[7] we could use complex numbers and still keep consistency with analogs of Cox's two axioms. Our tentative third axiom seems to give our pegs an "extra degree of freedom." Using real numbers would not be a possibility for a peg that also obeys Eq. (10), and luckily we are using the uncontroversial weaker zeroth axiom [Eq. (3)]. Hence it might be that we can find a peg which obeys Eqs. (3), (7), (8), and (10).

In analogy with how we define states in Gleason's theorem, let us define complex assignments as maps $l:\mathcal{P}(\mathcal{V})\rightarrow\mathbb{C}$ which obey the following rules:

1. Conjugation: $l(\alpha)^*=l(\lhd\alpha)$ for all α,
2. Additivity: if α and β are disjoint then $l(\alpha\vee\beta)=l(\alpha)+l(\beta)$, and
3. Normalization: $l(\mathbf{1})=1$.

We use the similar notation as we used for the Hilbert space $\mathcal{H}$ because $\mathcal{V}$ is still a Hilbert space (although we leave the "hats" off operators in $\mathcal{V}$). This is an advantage of using Isham's HPO formulation of the history algebra.[5]

Note that the peg axioms (7), (8), and (10) do not uniquely ensure that we *must* use the complex assignments l—just as Cox's axioms in standard probability theory do not ensure that we must use real numbers *per se*. The peg axioms ensure that, whatever assignments we do use for convenience, such assignments at least obey the relevant criteria of rationality. Hence we do not argue that the complex assignments l are uniquely the only pegs we could use, but clearly the maps l do obey Eqs. (7), (8), and (10) and might yet obey Eq. (3) for some partial order on $\mathbb{C}$. One might even argue that it is not the particular assignments that matter; it is the catalog of functional relationships between them that is important (this we categorize axiomatically using analog of Cox's axioms). Nonetheless, it is convenient to use particular representations (just as it is convenient to use real numbers in standard Bayesian probability theory).

Can we now start to tackle a proof of a Gleason-like theorem for these complex assignments l? In fact, the result follows from an analog of Gleason's theorem for decoherence functionals already in the literature.[4]

Let us first review some identities.[4] Note that

$$\mathrm{tr}_{\mathcal{H}}(\hat{A}_1\hat{A}_2\cdots\hat{A}_n)=\mathrm{tr}_{\otimes^n\mathcal{H}}(\hat{A}_1\otimes\hat{A}_2\otimes\cdots\hat{A}_nS), \tag{11}$$

where $\hat{A}_m$ are arbitrary self-adjoint operators on $\mathcal{H}$ and S is a linear operator $S:\otimes^n\mathcal{H}\rightarrow\otimes^n\mathcal{H}$ defined on product vectors by

$$S(v_1\otimes v_2\otimes\cdots\otimes v_n) := v_2\otimes v_3\otimes\cdots\otimes v_n\otimes v_1 \tag{12}$$

and extended by linearity and continuity to give a unitary operator on $\otimes^n\mathcal{H}$.

We can swap between the Heisenberg and Schrödinger pictures using

$$\mathrm{tr}_{\mathcal{H}}(C_\alpha)=\mathrm{tr}_{\otimes^n\mathcal{H}}(\hat{\alpha}_{t_n}\otimes\hat{\alpha}_{t_{n-1}}\otimes\cdots\hat{\alpha}_{t_1}S^U), \tag{13}$$

where the $\hat{\alpha}_{t_m}$ are Schrödinger picture projection operators and $S^U := (\hat{U}_1^\dagger\otimes\cdots\otimes\hat{U}_n^\dagger)S(\hat{U}_1\otimes\cdots\otimes\hat{U}_n)$.

In an analogous way,[4] we can absorb the initial state into an operator defined on $\mathcal{V}=\otimes^n\mathcal{H}$ using the identity (11). Note that

$$\mathrm{tr}_{\mathcal{H}}(\hat{A}_1\hat{A}_2\cdots\hat{A}_n)=\mathrm{tr}_{\otimes^n\mathcal{H}}((\hat{A}_1\otimes\hat{A}_2\otimes\cdots\hat{A}_{n-1}\otimes\mathbf{1}_n)(\mathbf{1}_1\otimes\mathbf{1}_2\otimes\cdots\mathbf{1}_{n-1}\otimes\hat{A}_n)S) \tag{14}$$

$$=\mathrm{tr}_{\otimes^n\mathcal{H}}((\hat{A}_1\otimes\hat{A}_2\otimes\cdots\hat{A}_{n-1}\otimes\mathbf{1}_n)Y) \tag{15}$$

$$=\mathrm{tr}_{\otimes^{n-1}\mathcal{H}}((\hat{A}_1\otimes\hat{A}_2\otimes\cdots\hat{A}_{n-1}Y')\ , \tag{16}$$

where Y' is obtained from Y by tracing over a complete set of states for the nth Hilbert space. The form of Eq. (11) is preserved under removing an operator by the action of a partial tracing and is also preserved when removing the dynamics from around each single-time proposition in the history proposition.

So, using these identities we can absorb all the dynamics and initial state into some operator Z such that

$$\mathrm{tr}_{\mathcal{H}}(C_\alpha\hat{\rho})=\mathrm{tr}_{\otimes^n\mathcal{H}}(\hat{\alpha}_{t_n}\otimes\hat{\alpha}_{t_{n-1}}\cdots\otimes\hat{\alpha}_{t_1}Z_{\rho,H}). \tag{17}$$

Note that the left-hand side (LHS) of Eq. (17) is in the Heisenberg picture, whereas the right-hand side (RHS) is in the Schrödinger picture; we have split the dynamics and kinematics into distinct entities. There are good reasons for doing this as it would allow us to investigate the distinction between the two forms of temporal orderings.[12] But note that we can stay within the Heisenberg picture if we wish (for it is, by far, the preferable picture[13]); we keep the dynamics around the corresponding projection operators and absorb just the initial state into an operator Y:

$$\mathrm{tr}_{\mathcal{H}}(C_\alpha\hat{\rho})=\mathrm{tr}_{\otimes^n\mathcal{H}}(\hat{\alpha}_{t_n}(t_n)\otimes\hat{\alpha}_{t_{n-1}}(t_{n-1})\otimes\cdots\hat{\alpha}_{t_1}(t_1)Y_\rho). \tag{18}$$

The above ensures that we can put our tentative assignment into "Gleason" form. Now we can prove an analog of Gleason's theorem for such operators Y_ρ. The theorem and proof follow the analysis in Ref. 4 almost word for word. There are, however, distinguishing features and, for completeness, we repeat the analysis here since the proof is so short.

Theorem: If $\dim\mathcal{V}>2$, the complex assignments l are in one-to-one correspondence with operators Y on $\mathcal{V}=\otimes^n\mathcal{H}$ according to the rule

$$l(\alpha)=\mathrm{tr}_{\mathcal{V}}(\alpha Y), \tag{19}$$

with the restrictions that

$$Y^\dagger=MYM, \tag{20}$$

$$\mathrm{tr}_{\mathcal{V}}(Y)=1, \tag{21}$$

where M is an operator that reverses the order of the entries in a tensor product vector; $M(v_1\otimes v_2\otimes\cdots v_m):=(v_m\otimes v_{m-1}\otimes\cdots v_1)$.

Proof: In one direction, the theorem is trivial; if a function l is *defined* by the right-hand side of Eq. (19) it clearly obeys the crucial additivity condition. The extra requirements (20) and (21) ensure normalization and conjugation requirements.

Conversely, let $l:\mathcal{P}(\mathcal{V})\to\mathbb{C}$ be a complex assignment. The proof that it must have the form (19) exploits Gleason's theorem applied to $\mathcal{P}(\mathcal{V})$.

Let $\mathrm{Re}\,l$ and $\mathrm{Im}\,l$ denote the real and imaginary parts of l so that

$$l(\alpha)=\mathrm{Re}\,l(\alpha)+\mathrm{Im}\,l(\alpha) \tag{22}$$

where $\mathrm{Re}\,l(\alpha)\in\mathbb{R}$ and $\mathrm{Im}\,l(\alpha)\in\mathbb{R}$. The additivity condition on l means that $\mathrm{Re}\,l(\alpha)$ and $\mathrm{Im}\,l(\alpha)$ are additive functions on $\mathcal{P}(\mathcal{V})$, i.e., $\mathrm{Re}\,l(\alpha_1\vee\alpha_2)=\mathrm{Re}\,l(\alpha_1)+\mathrm{Re}\,l(\alpha_2)$ for any disjoint pair α_1, α_2 of projectors and similarly for $\mathrm{Im}\,l$. We have that $l(\alpha)$ is a continuous function of its argument and hence $\alpha\mapsto l(\alpha)$ is a continuous function on $\mathcal{P}(\mathcal{V})$, as are its real and imaginary parts. However, the

set of all projectors in the finite dimensional space $\mathcal{V}$ is a finite disjoint union of Grassman manifolds and is hence compact. It follows that the functions $\alpha \mapsto \mathrm{Re}\, l(\alpha)$ and $\alpha \mapsto \mathrm{Im}\, l(\alpha)$ are bounded below and above. On the other hand, for any $r \in \mathrm{R}$, the quantity

$$\kappa_r(\alpha) := r \dim(\alpha) = r\mathrm{tr}(\alpha) \tag{23}$$

is a real additive function of α, and hence so are $\mathrm{Re}\, l + \kappa_r$ and $\mathrm{Im}\, l + \kappa_s$ for any $r, s \in \mathbb{R}$. We can choose an r such that $\mathrm{Re}\, l + \kappa_r \geqslant 0$ for all α (and s such that $\mathrm{Im}\, l + \kappa_s \geqslant 0$), and due to an upper bound we can choose positive real scale factors μ and ν such that for all α we have that

$$0 \leqslant \mu(\mathrm{Re}\, l + \kappa_r)(\alpha) \leqslant 1, \tag{24}$$

$$0 \leqslant \nu(\mathrm{Im}\, l + \kappa_s)(\alpha) \leqslant 1. \tag{25}$$

These inequalities plus the additivity property show that, for each $\alpha \in \mathcal{P}(\mathcal{V})$, the quantities $\alpha \mapsto \mu(\mathrm{Re}\, l + \kappa_r)(\alpha)$ and $\alpha \mapsto \nu(\mathrm{Im}\, l + \kappa_s)(\alpha)$ are states on the lattice $\mathcal{P}(\mathcal{V})$. Then Gleason's theorem shows that there exists a pair of density matrices ρ^1 and ρ^2 on $\mathcal{V}$ such that for all $\alpha \in \mathcal{P}(\mathcal{V})$,

$$\mu(\mathrm{Re}\, l + \kappa_r)(\alpha) = \mathrm{tr}_{\mathcal{V}}(\rho^1 \alpha), \tag{26}$$

$$\nu(\mathrm{Im}\, l + \kappa_s)(\alpha) = \mathrm{tr}_{\mathcal{V}}(\rho^2 \alpha), \tag{27}$$

and so

$$\mathrm{Re}\, l(\alpha) = \mathrm{tr}_{\mathcal{V}}\left(\left(\frac{1}{\mu}\rho^1 - r\right)\alpha\right) = \mathrm{tr}_{\mathcal{V}}(Y^1 \alpha), \tag{28}$$

$$\mathrm{Im}\, l(\alpha) = \mathrm{tr}_{\mathcal{V}}\left(\left(\frac{1}{\nu}\rho^2 - s\right)\alpha\right) = \mathrm{tr}_{\mathcal{V}}(Y^2 \alpha), \tag{29}$$

where $Y^1 := (1/\mu)\rho^1 - r$ and $Y^2 := (1/\nu)\rho^2 - s$. Thus we have shown the existence of a family of operators $Y := Y^1 + iY^2$ on $\mathcal{V}$ such that

$$l_\rho(\alpha) = \mathrm{tr}_{\mathcal{V}}(\alpha Y_\rho). \tag{30}$$

This completes the proof of the theorem because the conditions (20) and (21) follow at once from the conjugation and normalization conditions on complex assignments. ■

We do not discuss any extensions to infinite dimensional cases. We add the subscript ρ to Y to emphasize that it depends upon the initial state; it is anticipated that Y_ρ can be decomposed into some operators on $\mathcal{V}$ which are universally defined (through relations between traces of products of operators and traces of tensor product operators) and some operators that are related to the initial state. Clearly the Y operators on $\mathcal{V}$ and density operators on $\mathcal{H}$ are intimately related; the task is now to investigate the properties and interpretation of these pegs. But, in the least, we can put our assignment (5) into the form (30) for which we have an analog of Gleason's theorem.

One issue that we have to identify is that we have promoted the operation to $\lhd$ a connective on par with $\vee$, $\wedge$, and $\neg$, and it may not seem natural to some to do this. We considered it natural because we were going from a space $\mathcal{P}(\mathcal{H})$ which identified propositions at a single time to a space $\mathcal{P}(\mathcal{V})$ which explicitly identified history propositions. So we need a connective that can relate different temporal orderings. One might then query, why specifically $\lhd$? Why not some other operation, such as making any permutation of single-time entries? Staying in the Heisenberg picture ensures that the dynamics are already taken care of, and permuting the entries would mess up this fact; hence we only discuss a connective that maintains the dynamical relationships between single-time propositions.

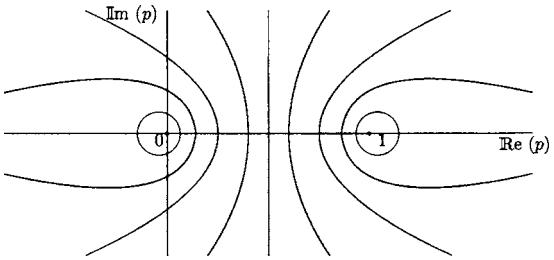

FIG. 1. Contour lines of pegs of equivalent size by a suggested partial order on $\mathbb{C}$. The "height" of each contour gets larger starting from the circle around 0 until we reach the circle around 1.

Note that we do not need to use the monoticity axiom [Eq. (3)] for Gleason-like proofs; it is, in some sense, redundant. Nonetheless, how might our pegs obey monoticity? In $\mathcal{P}(\mathcal{V})$ we have the following condition:

$$\mathbf{0} \leqslant \alpha \leqslant \mathbf{1} \quad \text{for all } \alpha \in \mathcal{P}(V). \tag{31}$$

For our pegs we have that $p(\mathbf{0}|I)=0$ and $P(\mathbf{1}|I)=1$ and hence, by monoticity, we must, in the least, demand that

$$0 \leqslant p(\alpha|I) \leqslant 1 \quad \text{for all } \alpha \in \mathcal{P}(V). \tag{32}$$

One tentative partial order might look something like Fig. 1. This partial order has the added advantage as we are unable to relate $p(\lhd\alpha|I)$ and $p(\alpha|I)$ using it (the partial ordering is symmetric in the real axis and complex conjugation represents time reversal). [Equivalently, one can picture the same partial order as allowing many different paths from uncertainty to certainty such that these paths are symmetric in the real axis. These paths would look like the lines of magnetic flux between north (0) and south (1) magnetic poles in two dimensions (2D) (not illustrated). This absolves us of Jaynes' argument against comparative probability theories—ones that do not obey Axiom 0b—by allowing many dense paths from 0 to 1, see the Appendix of Ref. 6]. Since, by the partial order on $\mathcal{P}(\mathcal{V})$, α NR $\lhd\alpha$ (where NR stands for "not related to by the relevant partial order"), we ought to demand this of the peg space as well, such that $p(\lhd\alpha|I)$ NR $p(\alpha|I)$. Also, this partial order reduces to the standard probabilities when we move to the real line between 0 and 1.

Note, however, that there are many partial orders on $\mathbb{C}$ and there might be another applicable one; we introduce the partial order represented by Fig. 1 to emphasize that monoticity will provide constraints for the partial orders that we can use. For disjoint propositions α and β, we have that $\alpha \leqslant \neg\beta$; hence the monoticity requirement ensures that $p(\alpha|I) \leqslant 1-p(\beta|I)$ which is satisfied as long as Eq. (32) is. The constraint (32) thus ensures a class of partial orders that might be useful and Fig. 1 seems the most apt.

Even obeying all the peg axioms we have to hand it is still very difficult to interpret these pegs as "probabilities" *per se* because we are taught again and again that probabilities are real numbers. However, remember that there is no *a priori* reason to regard probabilities as real numbers; they are merely magnitudes that we use in order to assign a partially ordered notion of preference to propositions.

III. DISCUSSION

Having an analog of Gleason's theorem for our pegs is not enough; we now need to argue why we should use such complex pegs in the first place. We have given an argument based on rejecting Axiom 0b; so now it is important to discuss the factitious problems that are solved by rejecting it. If we keep Axiom 0b then, by the very fact that we will be comparing propositions in a manner

that is not justified rationally, we will be introducing relations within the probability space that are not underpinned by relations in the proposition space. Hence we call such relations in the probability space "factitious."

The language we have used here is perhaps quite telling. Our use of the term factitious harks back to Einstein's use of the term. Clearly, if we adopt a relational approach to theory building (one which obeys Leibniz's principles of relationalism[14]), we do not want to introduce factitious elements in any theory. Cox adopted a rationalist approach analogous to relationalism—he gave a formulation of probability theory which ensures that factitious functional relations between propositions, quantified using pegs, are never introduced. Instead we only maintain those functional relationships that we can justify. Clearly this peg approach might therefore be useful in the quantum gravity domain where an explicitly relational approach is often considered a requirement. One might naïvely argue that, in addition to a relational notion of space-time, one needs a relational notion of probability. In the least it would be prudent to adopt an approach to probability theory based upon criteria of rationality rather than ad hoc axioms.

Hence it is plausible that problems such as nonlocality are factitious problems that are caused by invoking a probability theory which does not have sufficient structure. Thus a Bayesian approach may bring locality back to quantum theory, just as Einstein bought locality back to gravitational theories in building general relativity[15]—in fact, this is the major reason many invoke Bayesian reasoning within quantum theory[16] (although one does not need to adopt as drastic a peg theory as we adopt here in order to tentatively deny nonlocality).

Similarly, the problem of hidden variables might also be factitious. The Kochen-Specker theorem[17] seems[18] to prove that we cannot assign definitive values to variables prior to measurement in quantum theory. This is obviously compatible with a Bayesian approach to ignorance—we cannot assign such values because we are explicitly *presuming we are ignorant of them.*

These complex pegs are intimately related to the approaches of Feynman[19] and Hartle[20] who invoke real probabilities that can lie outside of [0, 1]. Hartle's virtual probabilities are explicitly found using the real parts of our complex pegs [Eq. (5)] which, in turn, were originally introduced by Goldstein and Page[21] in their linearly positive histories approach. Thus the linearly positive histories and the consistent histories programs appear naturally within this peg framework. If we wish to discuss real Bayesian probabilities, we could follow the linearly positive histories program and take the real parts of our pegs and ensure a linearly positive condition.[22] Similarly, if we wish to discuss relative frequencies, we could follow the consistent histories program and take the real parts of our complex pegs and define a consistency condition stronger than linear positivity.[23] Even so, we are still wary of invoking complex pegs because they are so alien to our usual notion of relative frequency. Note, however, that we are not wholly uncomfortable as such complex pegs appear naturally in quantum theory—the generalized Berry phase is derived from such complex pegs[24] and is an experimentally verifiable quantity (using ensembles of experiments). As such, we can combine such phases and frequentist notions into one probabilistic entity using axioms that were outlined over 60 years ago by Cox.[2]

In the history of science we have been rather ambiguous about what the word "probability" means. Some call relative frequencies probabilities even though they do not behave in the same manner as the term in common parlance. Similarly we have called certain nonadditive numbers in quantum theory probabilities even when they do not obey axioms of probability—nor axioms of relative frequency (which are necessarily additive). We might call our complex pegs probabilities because at least they do obey rational probabilistic axioms, but perhaps we would make a similar category error or confuse the issue by doing so; hence, for the want of a better name, we have resorted to calling them pegs—at least it begins with a "p" so we do not need to change our notation. So far we have two different kinds of pegs but there may be more. We have objects that obey Cox's two axioms which are real; we might call these "round pegs." We also have these objects that obey analogs of Cox's two axioms and our tentative third, which are complex. Let us call these "square pegs." These names lead naturally to a playful, albeit unfortunately sardonic, metaphor for what we are trying to do. A baby metaphor for science perhaps. We

are trying to find the right-shaped peg for the corresponding hole and we must reject the pegs that do not fit snugly. When dealing with a histories algebra, we argue that these complex pegs fit rather snugly.

IV. ENTROPY

With a generalization of probability to hand, we must also begin to discuss a generalization of entropy—a complimentary concept that is often just as important as a good notion of probability. Perhaps we do not have to search very far for such a generalization.

First of all, how should a notion of entropy behave? It should behave, in part, like a probability. It should probably be a transitive or monotonic notion of preference in some sense.[25] It should reflect the space of pegs in a natural way. Hence the first naïve object to suggest is simply a generalization of Shannon's entropy:

$$S[P(\mathbf{1}_\alpha|I)] := -K_S\sum_{i=1}^{n} p(\alpha^i|I)\ln p(\alpha^i|I), \tag{33}$$

where $P(\mathbf{1}_\alpha|I) := \{p(\alpha_i|I): i=1,2\ldots N_\alpha\}$ and K_S is a constant. Does this object $S[\cdot]$ behave like an entropy should? Does it, for example, obey the grouping property,[26] a property that Shannon suggests is natural for any notion of entropy?[27] Consider the complete—disjoint and exhaustive—set $\{\alpha^i\}$ split up into groups labeled by an integer g. We could consider the peg entropy (33) of the original set as split up into the peg entropy of each of the groups and the peg entropy as to which group $g=1,2,\ldots,N_G$ one should use; this alternative way of looking at the peg entropy (33) of the set should be equivalent to not splitting $\{\alpha^i\}$ into groups (this is the grouping property). How we split the entropy into groups should not make a difference. We can split up the peg entropy as follows:

$$S[P(\mathbf{1}_\alpha|I)] := -K_S\sum_{g}^{N_G}\sum_{i\in g} p(\alpha^i|I)\ln p(\alpha^i|I). \tag{34}$$

The complex peg we assign to a group g is simply

$$p(g|I) = \sum_{i\in g} p(\alpha^i|I). \tag{35}$$

So now we must ask ourselves whether

$$S[P(\mathbf{1}_\alpha|I)] = S[P(\mathbf{1}_G|I)] + \sum_g p(g|I)S_g, \tag{36}$$

where

$$S[P(\mathbf{1}_G|I)] := -K_S\sum_{g}^{N_G} p(g|I)\ln p(g|I) \tag{37}$$

and

$$S_g := -K_S\sum_{i\in g} p(\alpha^i|gI)\ln p(\alpha^i|gI). \tag{38}$$

In order to work this out, we need to work out what pegs we should assign to the histories $\{\alpha^i: i\in g\}$ upon the knowledge that the group g is the correct group. Thus we need a notion of conditioning. We need to work out what conditional pegs we should use and whether it allows Eq. (33) to obey the grouping property.

Using Bayes' rule in our complex peg framework is quite interesting:

$$p(\alpha^i|gI) = \frac{p(g|\alpha^i I)p(\alpha^i)}{p(g|I)}. \tag{39}$$

It is natural to assign $p(g\,|\,\alpha^i I)=1$ if we know that α^i is in the group g [we are normalizing due to Eq. (8), cf. Ref. 3]. Hence we should assign

$$p(\alpha^i|gI) = \frac{p(\alpha^i|I)}{p(g|I)} \tag{40}$$

to conditional grouping pegs. Does this allow the grouping property to be satisfied? Note that for $y,z\in\mathbb{C}$ we do not necessarily have that $\ln(y/z)=\ln y-\ln z$ because of different branches of the logarithm function; it only works if $-\pi<(\arg(x)-\arg(y))<\pi$. Complex logarithms behave as follows:

$$\ln(r\,\mathrm{e}^{i\theta}) = \ln r + i\theta, \tag{41}$$

where we may choose the principle value of θ. Renaming the index i with j so as not to confuse it with imaginary components, it is therefore clear that

$$\sum_j \ln\frac{p(\alpha^j|I)}{p(g|I)} = \sum_j \left(\ln\frac{|p(\alpha^j|I)|}{|p(g|I)|} + i\theta_j - i\theta_g\right), \tag{42}$$

where $\theta_j=\arg[p(\alpha^j\,|\,I)]$ and $\theta_g=\arg[p(g\,|\,I)]$.

So, using the definition of the complex logarithm, we have that

$$-\sum_{j\in g} p(\alpha^j|I)\ln p(\alpha^j|I) = -p(g|I)\sum_{j\in g}\frac{p(\alpha^j|I)}{p(g|I)}\ln\frac{p(\alpha^j|I)}{p(g|I)} - p(g|I)\ln p(g|I). \tag{43}$$

Thus we do have the grouping property for our test entropy functional (33), i.e., we have that

$$S[P(\mathbf{1}_\alpha|I)] = S[P(\mathbf{1}_G|I)] + \sum_g p(g|I)S_g + 2m\pi i, \tag{44}$$

where m is an integer—Eq. (33) is satisfied as long as we identify the different branches of the logarithm.

What, other than the grouping property, should an entropy functional obey so as to be a useful definition of uncertainty or information? According to Shannon,[27] $S[\cdot]$ should be continuous in the pegs. When all the pegs are equal (and hence real $p_i=1/n$), then it should be a monotonic increasing function of n. Hence $S[\cdot]$ should correspond to the standard Shannon entropy for the real subset of complex pegs. Clearly Eq. (33) is very plausible as a generalization of Shannon entropy that is apt for quantum histories. But, like the Shannon entropy for real probabilities, is it possible to prove that we must use Eq. (33) because it is the only functional that fits the required desiderata up to some equivalence of functionals? This we cannot yet answer.

Are strong additivity and concavity also satisfied by this peg entropy? In order to find out, we need to define a conditional peg entropy; presumably this involves Bayes' rule which is satisfied by our complex pegs since the $\wedge$-operation is associative.[3] Let us define the conditional peg entropy in an analogous way to how we define conditional Shannon entropies:

$$S[P(\mathbf{1}_\alpha|\mathbf{1}_\beta I)] := \sum_j p(\beta^j|I)S[P(\mathbf{1}_\alpha|\beta^j I)] \tag{45}$$

$$= -K_S\sum_j p(\beta^j|I)\sum_i p(\alpha^i|\beta^j I)\ln p(\alpha^i|\beta^j I). \tag{46}$$

And thus we can check whether the following "strong additivity" condition is satisfied by $S[\cdot]$:

$$S[P(\mathbf{1}_\alpha \wedge \mathbf{1}_\beta|I)] = S[P(\mathbf{1}_\alpha|I)] + S[P(\mathbf{1}_\beta|\mathbf{1}_\alpha I)] = S[P(\mathbf{1}_\beta|I)] + S[P(\mathbf{1}_\alpha|\mathbf{1}_\beta I)]. \tag{47}$$

We can also check whether the following "concavity" condition is satisfied:

$$S[P(\mathbf{1}_\alpha|I)] \geqslant S[P(\mathbf{1}_\alpha|\mathbf{1}_\beta I)]. \tag{48}$$

Note that $P(\mathbf{1}_\alpha \wedge \mathbf{1}_\beta|I) := \{p(\alpha^i \wedge \beta^j|I) : i = 1,2,\ldots,n_\alpha \text{ and } j = 1,2,\ldots n_\beta\}$. So we can work out the LHS of Eq. (47) to be

$$S[P(\mathbf{1}_\alpha \wedge \mathbf{1}_\beta|I)] = -K_S \sum_i \sum_j p(\alpha^i \wedge \beta^j|I) \ln p(\alpha^i \wedge \beta^j|I). \tag{49}$$

We can also work out the RHS (second decomposition) of Eq. (47):

$$-K_S \sum_j p(\beta^j|I) \ln p(\beta^j|I) - K_S \sum_j p(\beta^j|I) \sum_i p(\alpha^i|\beta^j I) \ln p(\alpha^i|\beta^j I). \tag{50}$$

Now, $p(\alpha^i \wedge \beta^j|I) = p(\alpha^i|\beta^j I) p(\beta^j|I)$ because Cox's axioms ensure that this is the case. Note that $\Sigma_i p(\alpha^i|\beta^j I) = 1$ for each j as long as α^i all commute with β^j. Hence we can identify the LHS and RHS, and thus Eq. (47) is satisfied for sets of commuting histories. Clearly it is natural that strong additivity applies for commuting histories because, in such cases, we can easily interpret the two sets of history propositions to be compatible. If they do not commute then there is no *a priori* reason we should demand strong additivity, just as there is no *a priori* reason we should demand comparability (by the dubious Axiom 0b) of probabilities in such cases.

In order to work out when Eq. (48) is also satisfied by our novel notion of entropy, we would have to decide what partial order on the space $\mathbb{C}$ we ought to use. Monoticity provides significant constraints upon what partial orders we can use and, as we argued above, it seems we should use the partial order illustrated in Fig. 1 for pegs. The partial order on the peg space will inform the partial order on the peg-entropy space (although perhaps scaled by the K_S constant). Concavity might then be satisfied, at least for a subset of histories. Having shown that our tentative notion (33) obeys the grouping property (albeit identifying branches of the logarithm), it is a matter only of mathematical consequence whether our peg entropy also obeys other convenient identities such as strong additivity and concavity (these identities are not axioms *per se*). It is clear, then, that Eq. (33) is a plausible generalization of entropy for quantum history theories but we have not yet proven whether all peg entropies that obey the grouping property for complex pegs must be of this form.

V. CONCLUSION

In quantum theory we use Gleason's theorem to justify the probabilistic assignments we give to projection operators. However, as soon as we begin to discuss more than one single projection operator—when we begin to discuss history propositions—we have to postulate a notion of state collapse in order to define probabilities. However, such postulated probabilities are nonadditive and many problems or issues arise because of this. From a Bayesian perspective it is even dubious to call such things "probabilities" because they are nonadditive and thus alien to our normal notion of probability.[28] Problems with nonlocality also arise by discussing propositions that involve two or more times (in a given frame of reference). Hence it is natural to tackle this problem head-on and define a propositional space that includes multitime propositions. Since we do not want to give any causal bias to the peg or probability theory that we use,[29] it seems prudent to put timelike and spacelike separated propositions on the same footing;[30] hence we might naïvely like to use tensor products to produce history propositions (this is the HPO algebra). Of course, in full generality, one would prefer to use a fully relational algebra. Rather than postulate dubious notions of state collapse, one can then *derive* a monotonic peg for such history propositions, and one can do such a thing without getting into the problems of nonadditivity and, tentatively, nonlocality. There also exists a plausible generalization of Shannon entropy for such pegs. Of course such complex pegs are alien to our standard notion of probability. However, our standard notion of probability is

rather alien too; when you get down to it, what really does the term "probability" mean? The interpretation of probabilities is clearly, historically speaking, a debatable issue and hence it is necessary to axiomatize and formalize a relational approach. Such an approach will ensure that, even if we do not know with full clarity what such concepts mean, we will, in the least, not introduce functional relationships between pegs that we are not justified in introducing.

So we cannot yet give a clear answer to the question: What are probabilities? One can, however, begin to answer another quite daunting question: Why do we naturally find complex numbers in quantum theory?

Pauli-Hamiltonian in the presence of minimal lengths

Khireddine Nouicer[a)]

(Received 3 June 2006; accepted 17 October 2006; published online 5 December 2006)

We construct the Pauli-Hamiltonian on a space where the position and momentum operators obey generalized commutation relations leading to the appearance of a minimal length. Using the momentum space representation we determine exactly the energy eigenvalues and eigenfunctions for a charged particle of spin half moving under the action of a constant magnetic field. The thermal properties of the system in the regime of high temperatures are also investigated, showing a magnetic behavior in terms of the minimal length. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2393151]

I. INTRODUCTION

In a series of papers Kempf[1–3] and Hinrichsen and Kempf[4] introduced a deformed quantum mechanics based on a modified commutation relation between position and momentum operators $[X_i, P_j]=i\hbar[(1+\beta P^2)\delta_{ij}+\beta' P_i P_j]$, where β and β' are small parameters. This commutation relation leads to a generalized Heisenberg uncertainty principle (GUP) which defines a nonzero minimum length in position. Other similar constructions leading to the same GUP have been also initiated by some authors.[5–8] The concept of minimal length is a common feature of string theory,[9] loop quantum gravity,[10] and noncommutative field theories.[11] One major consequence of the GUP is the appearance of a UV/IR "bootstrap," which allows to probe short distance physics (UV) from long distance ones (IR). This mixing between UV and IR divergences, first noticed in the Anti-deSitter/Conformal Filed Theory (AdS/CFT) correspondence,[12] is also a feature of noncommutative quantum field theories.[13] Recently, some scenarios have been proposed where the minimal length is related to large extra dimensions,[5] to the running coupling constant,[6] and to the physics of black hole production.[7]

Recently, numerous studies of quantum mechanical problems in the presence of minimal lengths have been carried out, among them we cite the solution of the Schrodinger equation in momentum space for the harmonic oscillator in D dimensions;[2,3,14] the cosmological constant problem and the classical limit of the physics with minimal lengths have been investigated in Refs. 15 and 16; the effect of the minimal length on the energy spectrum and momentum wave functions of the Coulomb potential in one dimension and three dimensions has been studied, respectively, in Ref. 17 and Refs. 18–20; the high temperature properties of the one dimensional Dirac oscillator has been recently investigated by the author in Ref. 21; the three dimensional Dirac oscillator with minimal lengths has been solved in Ref. 22 using supersymmetric quantum mechanics; the Casimir force for the electromagnetic field in the presence of the minimal length has been also computed.[23,24]

In this paper we are interested by the new kind of interactions that the incorporation of the minimal length into a quantum model can reveal. To this aim we construct the analog of the Pauli-Hamiltonian on a space where the position and momentum operators obey generalized commutation relations and determine exactly the energy eigenvalues and momentum eigenfunctions of a charged particle of spin half under the action of a constant magnetic field. The rest of the

[a)]Electronic mails: khnouicer@mail.univ-jijel.dz and khnouicer@yahoo.fr

paper is organized as follows. In Sec. II, we give a brief review of quantum mechanics with generalized uncertainty principle. In Sec. III, we solve exactly the Pauli equation in the presence of a minimal length for a charged particle with spin half in the potential of a constant magnetic field. In Sec. IV the magnetic moment and the magnetic susceptibility of the system are examined in the regime of high temperatures. Section V is left for concluding remarks.

II. THE PAULI-HAMILTONIAN IN THE PRESENCE OF MINIMAL LENGTHS

Let us start with the following D-dimensional realization of the position and momentum operators[2]

$$X_i = i\hbar\left[(1+\beta P^2)\frac{\partial}{\partial p_i} + \beta' P_i P_j \frac{\partial}{\partial p_j} + \gamma P_i\right], \tag{1}$$

$$P_i = p_i, \tag{2}$$

where β and β' are two very small non-negative parameters. This realization leads to the following generalized commutation relations:

$$[X_i, P_j] = i\hbar(\delta_{ij} + \delta_{ij}\beta P^2 + \beta' P_i P_j), \tag{3}$$

$$[X_i, X_j] = -i\hbar[(2\beta - \beta') + (2\beta + \beta')\beta P^2]\epsilon_{ijk} L_k, \tag{4}$$

$$[P_i, P_j] = 0, \tag{5}$$

where the components of the angular momentum are given by

$$L_i = \frac{1}{1+\beta P^2}\epsilon_{ijk} X_j P_k \tag{6}$$

and satisfy the usual algebra

$$[L_i, X_j] = i\hbar\epsilon_{ijk} X_k, \quad [L_i, P_j] = i\hbar\epsilon_{ijk} P_k. \tag{7}$$

Using states for which $\langle P_i\rangle = 0$ and that (ΔP_i) do not depend on i, we easily obtain the GUP,

$$(\Delta X_i)(\Delta P_i) \geqslant \frac{\hbar}{2}(1 + \beta D(\Delta P_i)^2 + \beta'(\Delta P_i)^2). \tag{8}$$

A minimization of the saturated GUP with respect to ΔP_i gives an isotropic minimal length,

$$(\Delta X_i)_{\min} = \hbar\sqrt{D\beta + \beta'}, \quad i = 1,2,3,\ldots,D. \tag{9}$$

We note also that the constant γ in the definition of the position operator does not affect the observable quantities and enters only in the definition of a squeezed weighting factor of the momentum measure,

$$\int \frac{\mathrm{d}^D p}{(1+(\beta+\beta')p^2)^{1-\alpha}}|p\rangle\langle p|, \quad \alpha = \frac{\gamma - \beta'[(D-1)/2]}{\beta + \beta'}. \tag{10}$$

In the rest of our calculations we use the simple algebra where $\beta' = 0$ and $\gamma = 0$.

In order to obtain the Pauli-Hamiltonian in the framework of quantum mechanics in the presence of the minimal length defined above, we start from the nonrelativistic limit of the Dirac-Hamiltonian and then use the representation (1), instead of using directly the well known Pauli-Hamiltonian. Ignoring the scalar potential, the nonrelativistic limit of the Dirac equation is given by

$$H = \frac{(\sigma\mathbf{\Pi})^2}{2m} = \frac{1}{2m}(\mathbf{\Pi}\mathbf{\Pi} + i\sigma\mathbf{\Pi}\wedge\mathbf{\Pi}), \tag{11}$$

where $\mathbf{\Pi}=\mathbf{P}-(q/c)\mathbf{A}$, $\sigma=(\sigma_x,\sigma_y,\sigma_z)$ are the Pauli matrices, and $\mathbf{A}$ is the potential vector. Using the algebra defined by Eqs. (1)–(3) we show that

$$\mathbf{\Pi}\wedge\mathbf{\Pi} = \frac{i\hbar q}{c}(1+\beta P^2)\mathbf{B} + \frac{q^2}{c^2}(\mathbf{A}\wedge\mathbf{A}), \tag{12}$$

with $\mathbf{B}=\nabla\wedge\mathbf{A}$ the magnetic field. Then substituting in Eq. (11) we obtain

$$H = \frac{1}{2m}\left(\mathbf{P}-\frac{q}{c}\mathbf{A}\right)^2 - \frac{q\hbar}{2mc}(1+\beta P^2)\sigma\mathbf{B} + \frac{iq^2}{2mc^2}\sigma(\mathbf{A}\wedge\mathbf{A}). \tag{13}$$

We observe that, besides the usual magnetic interaction, the Hamiltonian contains other interactions coming essentially from the presence of the minimal length. The second term in Eq. (13) shows a correction to the usual magnetic moment of the electron. The third term in Eq. (13) is different from zero and proportional to the angular momentum as a consequence of the noncommutativity of the position operators. It generates a spin-orbit interaction. At this stage we note that, in the undeformed case, the spin-orbit interaction is generated by the scalar potential. Then in our case such a scalar potential is the gravitational field generated by the perturbation of the space by the presence of the minimal length. This allows us to interpret the correction to the magnetic moment of the electron, in the second term, as an electric-dipole-magnetic-moment-like interaction. Finally, it is interesting to note that, at the quantum mechanical level, an electric dipole–magnetic interaction appears. However, this result is a consequence of the UV/IR bootstrap which allows to probe high energy effects by low energy physics.

III. CONSTANT MAGNETIC FIELD

In this section we illustrate the effect of the minimal length on the energy eigenvalues and eigenfunctions of a charged spinning particle in a constant magnetic field. Let us consider the vector potential in the symmetric gauge,

$$\mathbf{A} = \frac{B_0}{2}(-y\mathbf{i}+x\mathbf{j}), \tag{14}$$

where B_0 is the magnitude of the magnetic field. Then it is easy to show that the spin-orbit interaction in Eq. (13) is given by

$$\mathbf{A}\wedge\mathbf{A} = 2i\hbar\beta(1+\beta p^2)\left(\frac{B_0}{2}\right)^2 L_z\mathbf{k}, \tag{15}$$

where we have used the definition of the angular momentum given by Eq. (6).

Finally, we arrive to the following expression of the Pauli Hamiltonian in the presence of the minimal length:

$$H = H_0 + \frac{P_z^2}{2m} + \omega(1+\beta p^2)(L_z+\hbar\sigma_z) + \beta m\omega^2\hbar(1+\beta p^2)L_z\sigma_z, \tag{16}$$

where H_0, given by

$$H_0 = \frac{P_x^2+P_y^2}{2m} + \frac{m\omega^2}{2}(X^2+Y^2), \tag{17}$$

is the Hamiltonian of a two dimensional isotropic harmonic oscillator of frequency $\omega=(qB_0/2mc)$. To solve the eigenvalue equation $H\Psi_\epsilon(\mathbf{p})=E_{nl}\Psi_\epsilon(\mathbf{p})$ in the momentum space representation, we exploit the rotational invariance of Eq. (16) by setting

$$\Psi_{\epsilon}(\mathbf{p}) = \frac{e^{-il\phi}}{\sqrt{2\pi\hbar}} R_{nl}(p)\chi_{\epsilon}, \tag{18}$$

where n is the radial quantum number, l and $\epsilon = \pm 1$ are, respectively, the eigenvalues of angular momentum and spin operators, and $\chi_{+1}^{T} = (1,0)$, $\chi_{-1}^{T} = (0,1)$ are the spin functions.

Using the two dimensional representation of the position operators given by Eq. (1), we obtain the following differential equation for the radial part of the wave function:

$$\left\{(1+\beta p^2)^2\left(\frac{\partial^2}{\partial p_x^2} + \frac{\partial^2}{\partial p_y^2}\right) + 2\beta(1+\beta p^2)\left(p_x\frac{\partial}{\partial p_x} + p_y\frac{\partial}{\partial p_y}\right) - \frac{2}{m\omega\hbar}(l+\epsilon+m\omega\hbar\beta l\epsilon)(1+\beta p^2) - \frac{p^2}{(m\hbar\omega)^2} + \mathcal{E}_{nl}\right\} R_{nl}(p) = 0, \tag{19}$$

with $\mathcal{E}_{nl}$ given by

$$\mathcal{E}_{nl} = \frac{2E_{nl}}{m\hbar^2\omega^2} - \frac{p_z^2}{(m\hbar\omega)^2}. \tag{20}$$

In the terms of the radial coordinate p, Eq. (19) is given by

$$\left\{\left((1+\beta p^2)\frac{\partial}{\partial p}\right)^2 + (1+\beta p^2)^2\left(\frac{1}{p}\frac{\partial}{\partial p} - \frac{l^2}{p^2}\right) - \left(\frac{2}{m\omega\hbar}(l+\epsilon+m\omega\hbar\beta l\epsilon)(1+\beta p^2) - \frac{p^2}{(m\hbar\omega)^2} + \mathcal{E}_{nl}\right)\right\} R_{nl}(p) = 0. \tag{21}$$

We simplify this equation by introducing the variable ρ defined by

$$\rho = \frac{1}{\sqrt{\beta}}\arctan(p\sqrt{\beta}). \tag{22}$$

Then we obtain

$$R_{nl}''(\rho) + \sqrt{\beta}(\cot\sqrt{\beta}\rho + \tan\sqrt{\beta}\rho)R_{nl}'(\rho) - \beta l^2(\cot\sqrt{\beta}\rho + \tan\sqrt{\beta}\rho)^2 R_{nl}(\rho) - \left(\Omega_{l\epsilon} + \frac{1}{\beta(m\omega\hbar)^2}\right)\tan^2\sqrt{\beta}\rho R_{nl}(\rho) + (\mathcal{E}_{nl} - \Omega_{l\epsilon})R_{nl}(\rho) = 0, \tag{23}$$

with $\Omega_{l\epsilon}$ given by

$$\Omega_{l\epsilon} = \frac{2}{m\omega\hbar}(l+\epsilon+m\omega\hbar\beta l\epsilon). \tag{24}$$

We simplify Eq. (23) by setting $R_{nl}(\rho) = c^{\lambda} f(s)$ with c and s defined by

$$c = \cos\sqrt{\beta}\rho, \quad s = \sin\sqrt{\beta}\rho. \tag{25}$$

A straightforward calculation gives the following differential equation for $f(s)$:

$$(1-s^2)f''(s) + \left(\frac{1}{s} - (2\lambda+1)\right)f'(s) + \left(\left(\lambda(\lambda-2) - \frac{\Omega_{l\epsilon}}{\beta} - \frac{1}{\kappa^4} - l^2\right)\frac{s^2}{c^2} + \left(\frac{\mathcal{E}_{nl} - \Omega_{l\epsilon}}{\beta} - 2\lambda - l^2\right) - \frac{l^2}{s^2}\right) f(s) = 0, \tag{26}$$

where we have set $\kappa = \sqrt{m\omega\hbar\beta}$.

Then we cancel the term proportional to (s^2/c^2) by choosing λ such that

$$\lambda^2 - 2\lambda - \frac{\Omega_{l\epsilon}}{\beta} - l^2 - \frac{1}{\kappa^4} = 0. \tag{27}$$

The solutions of this equation are given by

$$\lambda = 1 \pm \sqrt{1 + \frac{\Omega_{l\epsilon}}{\beta} + \frac{1}{\kappa^4} + l^2}. \tag{28}$$

The relevant sign in Eq. (28) will be fixed later by appealing to the generalized uncertainty principle.

A further step in our calculation consists in canceling the centrifugal barrier in Eq. (26) by setting $f(s)=s^{|l|}g(s)$. Then $g(s)$ verify the following differential equation:

$$(1-s^2)g''(s) + \left(\frac{2|l|+1}{s} - (2\lambda + 2|l| + 1)s\right)g'(s) + \left(\frac{\mathcal{E}_{nl} - \Omega_{l\epsilon}}{\beta} - 2l^2 - 2\lambda(|l|+1)\right)g(s) = 0. \tag{29}$$

At this stage we use the variable $z=2s^2-1$ to obtain

$$(1-z^2)g''(z) + [(|l| - \lambda + 1) - (|l| + \lambda + 1)z]g'(z) + \frac{1}{4}\left(\frac{\mathcal{E}_{nl} - \Omega_{l\epsilon}}{\beta} - 2l^2 - 2\lambda(|l|+1)\right)g(z) = 0. \tag{30}$$

Defining two new parameters

$$a = \lambda - 1, \quad b = |l|, \tag{31}$$

and imposing the following condition:

$$\frac{\mathcal{E}_{nl} - \Omega_{l\epsilon}}{\beta} - 2l^2 - 2\lambda(|l|+1) = 4n(n + a + b + 1), \tag{32}$$

with n a non-negative integer, we reduce Eq. (30) to the following form:

$$(1-z^2)g''(z) + [(b-a) - (a+b+2)z]g'(z) + n(n+a+b+1)g(z) = 0. \tag{33}$$

The condition given by Eq. (32) suffices to obtain polynomial solutions to Eq. (33) given by the Jacobi polynomials

$$g(z) = P_n^{(a,b)}(z). \tag{34}$$

Using the old variable p, the radial part of the wave function $R_{nl}(p)=c^\lambda s^{|l|}g(s)$ is then given by

$$R_{nl}(p) = \mathcal{N}(1+\beta p^2)^{-(\lambda+|l|)/2}(\beta p^2)^{|l|/2} P_n^{(\lambda-1,|l|)}\left(\frac{\beta p^2 - 1}{\beta p^2 + 1}\right). \tag{35}$$

The normalization constant $\mathcal{N}$ is obtained by employing the normalization condition $\int[d^3p/(1+\beta p^2)]|R_{nl}(p)|^2=1$ and the Jacobi polynomial orthogonality relation.[25] Finally, the normalized momentum radial wave functions are given by

$$R_{nl}(p) = \sqrt{\beta}\sqrt{\frac{2(n!)(2n+\lambda+|l|)\Gamma(n+\lambda+|l|)}{\Gamma(n+\lambda)\Gamma(n+|l|+1)}}(1+\beta p^2)^{-(\lambda+|l|)/2}(\beta p^2)^{|l|/2} P_n^{(\lambda-1,|l|)}\left(\frac{\beta p^2 - 1}{\beta p^2 + 1}\right). \tag{36}$$

However, as pointed in Ref. 2, the normalization condition alone does not guarantee physically relevant wave functions but the latter must be in the domain of p, which physically means that it should have a finite uncertainty in momentum. This leads to the condition

$$\langle p^2\rangle = \int_0^\infty \frac{d\mathbf{p}}{(1+\beta p^2)} p^2 |R_{nl}(p)|^2 < \infty. \tag{37}$$

In our case the integrand in Eq. (37) behaves like $p^{-2\lambda+2}$ which requires $\lambda > 1$. Then we choose the upper sign in the expression of λ. However, the condition $\lambda > 1$ can be also obtained from physical considerations. Let us take λ with the minus and work with $l=0$,

$$\lambda = 1 - \sqrt{1 + \frac{2\epsilon}{m\omega\hbar\beta} + \frac{1}{(m\omega\hbar\beta)^2}}. \tag{38}$$

Using the fact that $\hbar\sqrt{2\beta} \leqslant l_c$ where $l_c = \sqrt{2\hbar/m\omega}$ is the characteristic length of the oscillator we have $m\omega\hbar\beta < 1$. Then

$$\lambda = 1 - \frac{1}{m\omega\hbar\beta} < 0, \tag{39}$$

leading to $(\Delta X)_{\min} > l_c$ which contradicts the fundamental requirement stipulating that we cannot probe the physics below the minimal length.

The energy spectrum is now derived from Eq. (32),

$$\frac{\mathcal{E}_{nl} - \Omega_{l\epsilon}}{\beta} = 2(N+1)(\lambda - 1) + (N^2 + l^2 + 2N + 2), \tag{40}$$

where $N = 2n + |l|$ is the principal quantum number. Using the expressions of κ, $\mathcal{E}_{nl}$, and $\Omega_{l\epsilon}$ we finally obtain

$$E_{Nl} = \frac{p_z^2}{2m} + \hbar\omega\left[(N+1)\sqrt{1 + 2\beta m\hbar\omega(l + \epsilon + m\hbar\omega\beta l\epsilon) + (m\hbar\omega\beta)^2(l^2+1)}\right.$$
$$\left. + \frac{m\hbar\omega\beta}{2}(N^2 + l^2 + 2N + 2) + (l + \epsilon + m\hbar\omega\beta l\epsilon)\right]. \tag{41}$$

Ignoring the spin and the spin-orbit contributions and the last term in Eq. (41) we reproduce exactly, besides the term $p_z^2/2m$, the energy spectrum of the two dimensional harmonic oscillator with minimal length.[14]

Let us in the following discard the spin contributions. The energy spectrum in this case is given by

$$E_{Nl} = \frac{p_z^2}{2m} + \hbar\omega\left[(N+1)\sqrt{1 + 2\beta m\hbar\omega l + (m\hbar\omega\beta)^2(l^2+1)} + \frac{m\hbar\omega\beta}{2}(N^2 + l^2 + 2N + 2) + l\right]. \tag{42}$$

As noted above, the quantity $\sqrt{m\hbar\omega\beta}$ expresses the ratio between the minimal length and the characteristic length of the oscillator $(\Delta X)_{\min}/l_c$, which is by virtue of the GUP, a small parameter. Then to first order in $m\hbar\omega\beta$ we have

$$E_{Nl} = \frac{p_z^2}{2m} + \hbar\omega\left[(N + l + 1) + \frac{m\hbar\omega\beta}{2}(N^2 + l^2 + 2N + 2 + 2(N+1)l)\right]. \tag{43}$$

In terms of n and l we write this expression as

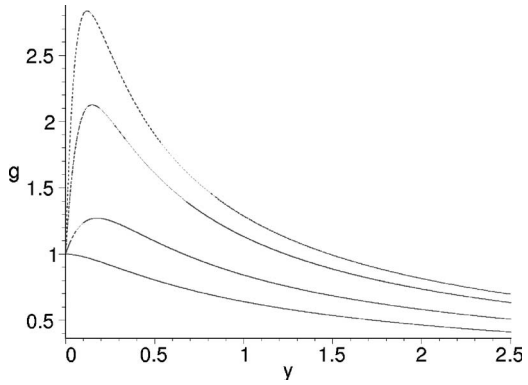

FIG. 1. Plot of the one particle state density vs $y=\beta m\mu_B B_0$ for $n_d=0,1,5,10$.

$$E_{Nl}=\frac{p_z^2}{2m}+2\hbar\omega\left[n+\frac{|l|+l+1}{2}\right]+\frac{1}{2}\hbar\omega\left(\frac{(\Delta X)_{\min}}{l_c}\right)^2\left[4\left(n+\frac{|l|+l}{2}\right)^2+4\left(n+\frac{|l|+l+1}{2}\right)\right]. \tag{44}$$

Using the numbers n_d and n_g defined by

$$n_d=n+\frac{|l|+l}{2},\quad n_g=n+\frac{|l|-l}{2}, \tag{45}$$

we obtain

$$E_{n_d}=\frac{p_z^2}{2m}+2\hbar\omega\left[n_d+\frac{1}{2}\right]+2\hbar\omega\left(\frac{(\Delta X)_{\min}}{l_c}\right)^2\left[n_d^2+n_d+\frac{1}{2}\right]. \tag{46}$$

We observe that we have the usual infinite degeneracy.

IV. THERMODYNAMICAL PROPERTIES

In this section we are interested by the thermodynamical properties of the system at high temperatures. In the following we set $z=e^{\tilde{\beta}\mu}$, where $\tilde{\beta}=1/kT$ and μ is the chemical potential. Let us start by computing the one particle state density $g(n_d)$ given by

$$g(n_d)=\frac{V^{2/3}}{4\pi\hbar^2}\int_{E_{n_d}\leq E<E_{n_d+1}}\frac{dp_x dp_y}{(1+\beta p^2)}, \tag{47}$$

with $V^{2/3}$ a surface. Using polar coordinates we obtain

$$g(n_d)=\frac{V^{2/3}}{2\pi\hbar^2}\int_{p_{n_d}}^{p_{n_d+1}}\frac{pdp}{(1+\beta p^2)}=\frac{V^{2/3}}{4\pi\beta\hbar^2}\ln\frac{1+\beta p_{n_d+1}^2}{1+\beta p_{n_d}^2}. \tag{48}$$

Using $p_{n_d}=[4m\mu_B B_0(n_d+yn_d^2)]^{1/2}$, where $y=((\Delta X)_{\min}/l_c)^2=\beta m\mu_B B_0$ and $\mu_B=\hbar q/2mc$ is the Bohr magneton, the density of states is given by

$$g(n_d)=\frac{V^{2/3}}{4\pi\beta\hbar^2}\ln[1+4y(2yn_d+1)]. \tag{49}$$

In the last derivations we have used the fact that $y+1\approx 1$, by virtue of the GUP. We note that the density of states, unlike the standard expression without the minimal length, is now a function of the quantum number n_d. In Fig. 1 we show the behavior of $g=g(n_d)/(V^{2/3}m\mu_B B_0/\pi\hbar^2)$ in terms of

$y=\beta m\mu_B B_0$ for different values of n_d.

It is interesting to note that the density of states reaches a maximum for a critical value of the minimal length and then decreases rapidly for higher values of the minimal length corresponding to strong gravitational field.

The grand canonical thermodynamical potential is defined by the following expression:

$$\Phi = -\frac{V^{1/3}}{2\pi\tilde{\beta}\hbar}\int_{-\infty}^{+\infty}\frac{dp_z}{1+\beta p_z^2}\sum_{n_d=0}^{\infty} g(n_d)\ln[1+z\exp(-\tilde{\beta}E_{n_d})]. \tag{50}$$

Using the density of states and the energy spectrum given, respectively, by Eqs. (49) and (46) and $y+1\approx 1$, we obtain

$$\Phi \approx -\frac{V}{8\pi^2\tilde{\beta}\beta\hbar^3}\int_{-\infty}^{+\infty}\frac{dp_z}{1+\beta p_z^2}\sum_{n_d=0}^{\infty}\ln[1+4y(2yn_d+1)] \times\ln\left[1+ze^{-\tilde{\beta}\mu_B B_0}\exp\left(-\tilde{\beta}\left[\frac{p_z^2}{2m}+2\mu_B B_0(n_d+yn_d^2)\right]\right)\right]. \tag{51}$$

At this stage, in the regime of high temperatures, we use the assumption that $|\mu-\mu_B B_0|\gg\tilde{\beta}$. With the aid of the approximation $\ln(1+ua)\approx ua$, we obtain

$$\Phi \approx -\frac{ze^{-\tilde{\beta}\mu_B B_0}m\mu_B B_0 V}{2\pi^2\tilde{\beta}\hbar^3}\int_{-\infty}^{+\infty}\frac{dp_z}{1+\beta p_z^2}\sum_{n_d=0}^{\infty}(1+2yn_d)\times\exp\left(-\tilde{\beta}\left[\frac{p_z^2}{2m}+2\mu_B B_0(n_d+yn_d^2)\right]\right). \tag{52}$$

The integration over p_z gives

$$\Phi \approx -\frac{ze^{-\tilde{\beta}\mu_B B_0}m\mu_B B_0 V}{4\pi\hbar^3\sqrt{\tilde{\beta}}\tilde{\beta}}e^{\tilde{\beta}/2m\beta}\left[1-\mathrm{erf}\left(\sqrt{\frac{\tilde{\beta}}{2m\beta}}\right)\right]\sum_{n_d=0}^{\infty}(1+2yn_d)\times\exp(-2\mu_B B_0\tilde{\beta}(n_d+yn_d^2)), \tag{53}$$

where $\mathrm{erf}(x)$ is the error function. The computation of the summation over n_d is now performed with the aid of Euler's formula given by

$$\sum_{n_d=0}^{\infty} f(n) = \frac{1}{2}f(0)+\int_0^{\infty} f(x)dx-\sum_{p=1}^{\infty}\frac{1}{(2p)!}B_{2p}f^{(2p-1)}(0), \tag{54}$$

where B_{2p} are Bernoulli's numbers and $f^{(2p-1)}(0)$ are the derivatives of the function $f(x)$ at $x=0$. In the high temperature regime the contribution of the sum in Eq. (54) is neglected.

Using $y=\beta m\mu_B B_0$ and the following integrals:

$$\int_0^{\infty} e^{-2\mu_B B_0\tilde{\beta}(x+\beta m\mu_B B_0 x^2)}dx = \frac{1}{2\mu_B B_0\sqrt{\tilde{\beta}\beta m}}e^{\tilde{\beta}/4m\beta}D_{-1}\left(\sqrt{\frac{\tilde{\beta}}{\beta m}}\right), \tag{55}$$

$$\int_0^{\infty} xe^{-2\mu_B B_0\tilde{\beta}(x+\beta m\mu_B B_0 x^2)}dx = \frac{1}{2\mu_B^2 B_0^2\tilde{\beta}\beta m}e^{\tilde{\beta}/4m\beta}D_{-2}\left(\sqrt{\frac{\tilde{\beta}}{\beta m}}\right), \tag{56}$$

where $D_\nu(x)$ is the cylindrical function, we finally obtain the thermodynamical potential

$$\Phi \approx -\frac{ze^{-\tilde{\beta}\mu_B B_0}\sqrt{m}V}{8\pi\hbar^3\beta\tilde{\beta}^{3/2}}e^{3\tilde{\beta}/4m\beta}\left[1-\operatorname{erf}\left(\sqrt{\frac{\tilde{\beta}}{2m\beta}}\right)\right]\left[D_{-1}\left(\sqrt{\frac{\tilde{\beta}}{\beta m}}\right)+\sqrt{\frac{\beta m}{\tilde{\beta}}}D_{-2}\left(\sqrt{\frac{\tilde{\beta}}{\beta m}}\right)\right]$$
$$-\frac{ze^{-\tilde{\beta}\mu_B B_0}m\mu_B B_0 V}{8\pi h^3\sqrt{\beta}\tilde{\beta}}e^{\tilde{\beta}/2m\beta}\left[1-\operatorname{erf}\left(\sqrt{\frac{\tilde{\beta}}{2m\beta}}\right)\right]. \tag{57}$$

The magnetic moment of the system defined by $M_\beta=-(\partial/\partial B)\Phi$ and the magnetic susceptibility $\chi_\beta=\partial M/\partial B$ are then easily obtained,

$$M_\beta=\frac{zm\mu_B V}{8\pi\hbar^3\sqrt{\beta}\tilde{\beta}}e^{\tilde{\beta}/2m\beta}[1-2z\tilde{\beta}\mu_B B_0]\left[1-\operatorname{erf}\left(\sqrt{\frac{\tilde{\beta}}{2m\beta}}\right)\right]$$
$$+\frac{z\mu_B\sqrt{m}V}{8\pi\hbar^3\beta\tilde{\beta}^{1/2}}e^{3\tilde{\beta}/4m\beta}\left[1-\operatorname{erf}\left(\sqrt{\frac{\tilde{\beta}}{2m\beta}}\right)\right]\left[D_{-1}\left(\sqrt{\frac{\tilde{\beta}}{\beta m}}\right)+\sqrt{\frac{\beta m}{\tilde{\beta}}}D_{-2}\left(\sqrt{\frac{\tilde{\beta}}{\beta m}}\right)\right], \tag{58}$$

and

$$\chi_\beta=-\frac{z\mu_B^2 mV}{4\pi\hbar^3\sqrt{\beta}}e^{\tilde{\beta}/2m\beta}\left[1-\operatorname{erf}\left(\sqrt{\frac{\tilde{\beta}}{2m\beta}}\right)\right]. \tag{59}$$

Let us exploit the fact that $m\beta/\beta$ is a small parameter. Indeed we have

$$\sqrt{\frac{m\beta}{\tilde{\beta}}}=\sqrt{\pi}\frac{(\Delta X)_{\min}}{\lambda}, \tag{60}$$

where $(\Delta X)_{\min}=\hbar\sqrt{2\beta}$ and $\lambda=\sqrt{2\pi\beta\hbar^2/m}$ is the thermal wavelength. Since λ is a physical characteristic length of the system and in order to be experimentally accessible it must be greater than the minimal length.

An asymptotic expansion in terms of $\tilde{\beta}/m\beta$ gives

$$\chi_\beta=-\frac{zV}{\lambda^3}\mu_B^2\tilde{\beta}\left[1-\pi\left(\frac{(\Delta X)_{\min}}{\lambda}\right)^2\right]. \tag{61}$$

This relation shows that we have the usual Landau diamagnetism at high temperatures in terms of the minimal length if the later verify

$$(\Delta X)_{\min}\leqslant\frac{\sqrt{\pi}}{\lambda}. \tag{62}$$

It is interesting to note that this upper bound for the minimal length does not depend on the magnitude of the applied external magnetic field.

The susceptibility given by Eq. (61) is weaker than in the ordinary case. A similar result has been recently obtained for the Dirac oscillator with minimal length in one dimension in a thermal bath.[21] On the other hand the new result in Eq. (61) clearly shows the effect of the perturbation of the space by the presence of the minimal. In fact, the contribution of the minimal length to the magnetic susceptibility is of a paramagnetic nature. This can be interpreted as if the minimal length generates magnetic moments aligned in the direction of the applied external magnetic field. We note also that the limit $T\to\infty$ is forbidden by the condition (62) and the susceptibility is always finite. This effect does not appear neither in the case without the minimal length[26] nor in the canonical noncommutative case characterized by the parameter θ.[27] In this paper the author has obtained the susceptibility at high temperatures for the Landau system with a confining

harmonic potential of frequency ω_0. However, for $\theta \neq 0$, the susceptibility becomes infinite in the limit $\omega_0 \to 0$. Our result reflects clearly the regularizing effect of the minimal length which is directly related to the existence of a minimal thermal wavelength given by

$$\lambda_{\min} = \sqrt{\pi}(\Delta X)_{\min}, \tag{63}$$

which in turn define a maximal temperature

$$kT_{\max} = \frac{2}{mc^2}\left(\frac{\hbar c}{(\Delta X)_{\min}}\right)^2. \tag{64}$$

The appearance of a maximal temperature seems to be a common feature of noncommutative theories. Indeed we have found recently an upper bound for the deconfinement temperature of a quark gluon plasma.[21] On the other hand the existence of a minimal length may have important consequences on the thermodynamics of black holes. In the context of canonical noncommutative theories[28] and generalized uncertainty principle,[29] it was shown that during the evaporation process the black hole reaches a maximal temperature before cooling down to a nonsingular remnant at zero temperature.

We close this section by pointing out that the results derived in this paper can be used to obtain experimental values of the minimal length using available data for the magnetic susceptibility at high temperatures. Following Ref. 30, another interesting approach is to consider the quantum Hall effect in the presence of the minimal length and interpret it as the usual fractional quantum Hall effect. The work in this direction is in progress.

V. CONCLUSION

In this paper starting from the nonrelativistic Dirac-Hamiltonian without the scalar potential, we have constructed the Pauli-Hamiltonian in the framework of quantum mechanics with minimal lengths, which besides the usual terms contains additional interaction terms revealing the rich structure of the space at short distances. Particularly we obtained a spin-orbit-like interaction term suggesting that the noncommutativity of the position operators generates a scalar field which can be related to the gravitational field. Then the problem of a charged particle with spin half under the action of a constant magnetic field is solved exactly in the momentum representation. The energy spectrum and the corresponding wave functions are then obtained. We have also investigated the magnetic behavior of the system at high temperatures where we have shown that the magnetic susceptibility in terms of the minimal length remains finite, while it is infinite in the case without the minimal length. This important result reflects the regularizing effect of the minimal length.

ACKNOWLEDGMENT

On bipartite pure-state entanglement structure in terms of disentanglement

Fedor Herbut[a)]
Serbian Academy of Sciences and Arts, Knez Mihajlova 35, 11000 Belgrade, Serbia

(Received 24 July 2006; accepted 5 October 2006; published online 6 December 2006)

Schrödinger's disentanglement [E. Schrödinger, Proc. Cambridge Philos. Soc. **31**, 555 (1935)], i.e., remote state decomposition, as a physical way to study entanglement, is carried one step further with respect to previous work in investigating the qualitative side of entanglement in any bipartite state vector. Remote measurement (or, equivalently, remote orthogonal state decomposition) from previous work is generalized to remote linearly independent complete state decomposition both in the nonselective and the selective versions. The results are displayed in terms of commutative square diagrams, which show the power and beauty of the physical meaning of the (antiunitary) correlation operator inherent in the given bipartite state vector. This operator, together with the subsystem states (reduced density operators), constitutes the so-called correlated subsystem picture. It is the central part of the antilinear representation of a bipartite state vector, and it is a kind of core of its entanglement structure. The generalization of previously elaborated disentanglement expounded in this article is a synthesis of the antilinear representation of bipartite state vectors, which is reviewed, and the relevant results of [Cassinelli *et al.*, J. Math. Anal. Appl. **210**, 472 (1997)] in mathematical analysis, which are summed up. Linearly independent bases (finite or infinite) are shown to be almost as useful in some quantum mechanical studies as orthonormal ones. Finally, it is shown that linearly independent remote pure-state preparation carries the highest probability of occurrence. This singles out linearly independent remote influence from all possible ones. © *2006 American Institute of Physics.*

I. INTRODUCTION

There are different *measures of the amount* of entanglement in bipartite states. In pure states they all coincide. Hence, this is well understood. But one may wonder the measure of what is at issue; i.e., what is the structure of entanglement, or what is its *qualitative side*.

According to Schrödinger, the natural way to investigate entanglement is to perform *disentanglement*:[1] It consists in *measurements on the nearby subsystem*. Since it is simultaneously a measurement on the composite system, the bipartite state becomes a mixed one. As a consequence, one has an *actual decomposition* (as opposed to a potential or mathematical one) *of the remote subsystem state*.

In previous work,[2] complete remote measurement or, equivalently, complete remote orthogonal state decomposition, was studied as a first step in carrying out Schrödinger's program, and the concept of twin observables was introduced. They gave physical meaning to the so-called correlated subsystem picture.[3]

Mathematically, the optimal way to study pure-state bipartite entanglement is to use the antilinear operator representation of the state vector. As it is well known, in theoretical physics mathematics is inextricably connected with physics. In the mentioned previous work it turned out

[a)]Electronic mail: fedorh@infosky.net

that the antiunitary polar factor, the so-called *correlation operator*, plays a central role in establishing the concepts of twin observables and remote measurement. Naturally, this operator is endowed with basic physical meaning.

The antilinear operator representation of bipartite state vectors and the polar factorizations of these operators are summed up and shortly reviewed in Sec. II. Delving into the antilinear approach may require some effort on part of some readers, but it is pure-state bipartite entanglement and not this author who made it optimal. Eventually, the insight gained should make it worth the effort.

In this article the physical content of the correlated subsystem picture is extended one step beyond remote measurement.

The organization of the rest of the article is as follows. In Sec. III the relevant purely mathematical results on classification of all linearly independent complete decompositions of any given density operator (that with an infinite-dimensional range included)[4] are shortly stated. Besides, they are, to some extent, elaborated in order to show that linearly independent bases can be almost as useful as orthonormal ones (to encourage their use at least in entanglement studies in quantum mechanics). In Sec. IV the first result of this article, the generalized twin observables, consisting of twin observables and of extended twin observables, are presented in the form of Theorem 1 and a commutative square diagram. In Sec. V selective (or specific-result) nearby-subsystem measurement that gives rise to so-called remote pure-state preparation is paid special attention to in terms of Theorem 2 and another square commutative diagram. Besides, in Theorem 3 the physical meaning of linearly independent remote pure-state preparation is clarified. In Sec. VI concluding remarks point out the essential features of the results.

As a technical remark, it should be noted that by a basis (without further specification) in a subspace is meant a complete orthonormal set, i.e., one spanning the subspace. We will also deal with linearly-independent bases in linear manifolds (cf. Corollaries 1 and 3).

II. THE CORRELATED SUBSYSTEM PICTURE

The correlated subsystem picture is based on the role of the antiunitary correlation operator U_a inherent in any bipartite state vector $|\Phi\rangle_{12}$. The correlation operator is the antiunitary polar factor of the antilinear Hilbert–Schmidt operator A_a that maps the state space of subsystem 1 into that of subsystem 2. Such an operator, in turn, gives an antilinear representation of any given bipartite state vector $|\Phi\rangle_{12}$.

Antilinear operators were introduced in physics from the mathematical literature[5] by Jauch.[6] They were utilized in Ref. 7 and in the first-step bipartite pure-state studies.[2,8] The main result of these was establishing the correlated subsystem picture of $|\Phi\rangle_{12}$ (with the twin observables) as a core of its structure.

A. The mathematical part

Let $|\Phi\rangle_{12}$ be a given state vector of an arbitrary bipartite pure state with a nearby (1) and a remote (2) subsystem. Naturally, $|\Phi\rangle_{12} \in (\mathcal{H}_1 \otimes \mathcal{H}_2)$, where the tensor factors are complex separable Hilbert spaces.

The first notion that is being utilized is that of the *partial scalar product*: If $|\psi\rangle_1$ is an arbitrary vector of the nearby subsystem, then the partial scalar product

$$\langle\psi|_1|\Phi\rangle_{12} \in \mathcal{H}_2 \tag{1}$$

gives a vector in the state space $\mathcal{H}_2$ of the remote subsystem. It can be defined and evaluated by introducing bases $\{|j\rangle_1 : \forall j\} \subset \mathcal{H}_1$ and $\{|k\rangle_2 : \forall k\} \subset \mathcal{H}_2$ and expanding $|\Phi\rangle_{12}$ in them

$$|\Phi\rangle_{12} = \sum_j \sum_k f_{jk}|j_1\rangle|k\rangle_2. \tag{2a}$$

Then $\langle\psi|_1|\Phi\rangle_{12}$ is obtained in terms of the ordinary scalar product in $\mathcal{H}_1$:

$$\langle\psi|_1|\Phi\rangle_{12} = \sum_j \sum_k [f_{jk}(\langle\psi|_1|j\rangle_1)]|k\rangle_2. \tag{2b}$$

The point is, of course, that, as it is straightforward to show, the right-hand side (rhs) is always defined (in case of infinite sums, one has convergence), and the left-hand side (lhs) is *independent* of the choice of the subsystem bases, and thus a well-defined element of $\mathcal{H}_2$.

The next notion is that of the *antilinear operator representation* of a bipartite state vector $|\Phi\rangle_{12}$: Relation (1) is actually an antilinear, i.e., expansion-coefficients complex-conjugating, map A_a of the entire space $\mathcal{H}_1$ into $\mathcal{H}_2$:

$$(A_a|\psi\rangle_1)_2 \equiv \langle\psi|_1|\Phi\rangle_{12} \in \mathcal{H}_2. \tag{3}$$

The operator A_a defines its *adjoint* $A_a^\dagger$, which maps in the antilinear way $\mathcal{H}_2$ into $\mathcal{H}_1$. This is done via the pair of scalar products, that in $\mathcal{H}_1$ and that in $\mathcal{H}_2$:

$$\forall\,\psi_1 \in \mathcal{H}_1, \forall\,\chi_2 \in \mathcal{H}_2: \quad (\chi_2,(A_a\psi_1)_2)_2 = ((A_a^\dagger\chi_2)_1,\psi_1)_1^*, \tag{4}$$

where the asterisk denotes complex conjugation. It is easy to see that Eq. (4) defines adjoining as a linear operation.

The operators A_a and $A_a^\dagger$ are called Hilbert–Schmidt ones because

$$\mathrm{tr}(A_a^\dagger A_a)_1 < \infty\,, \tag{5a}$$

$$\mathrm{tr}(AA_a^\dagger)_2 < \infty\,. \tag{5b}$$

The set of *all* antilinear Hilbert–Schmidt operators mapping $\mathcal{H}_1$ into $\mathcal{H}_2$ is a complex separable Hilbert space, in which the *scalar product* is defined as

$$\forall A_a, A_a': \quad (A_a, A_a') \equiv \mathrm{tr}(A_a'^\dagger A_a)_1. \tag{6}$$

It is straightforward to show that Eq. (3) constitutes an *isomorphism* of the complex separable Hilbert space of all ordinary bipartite vectors $|\Phi\rangle_{12}$ onto that of all antilinear Hilbert–Schmidt operators mapping $\mathcal{H}_1$ into $\mathcal{H}_2$.

In the sense of this isomorphism, one can speak of A_a as *the antilinear operator representative* of $|\Phi\rangle_{12}$.

It is known that the reduced density operators $\rho_1 \equiv \mathrm{tr}_2(|\Phi\rangle_{12}\langle\Phi|_{12})$ and $\rho_2 \equiv \mathrm{tr}_1(|\Phi\rangle_{12}\langle\Phi|_{12})$ of any given bipartite state vector $|\Phi\rangle_{12}$, which describe the respective subsystem states, have *equal positive parts of their spectra*, i.e., their positive eigenvalues, together with their multiplicities, coincide. Further, it is known that if one expands $|\Phi\rangle_{12}$ in any eigensubbasis $\{|r_i\rangle_1 : \forall\, i\}$ of ρ_1 spanning its range, then one obtains the so-called *biorthogonal Schmidt expansion*

$$|\Phi\rangle_{12} = \sum_i r_i^{1/2}|r_i\rangle_1|r_i\rangle_2, \tag{7}$$

where $\{r_i : \forall\, i\}$ are the positive eigenvalues of ρ_1 corresponding to its mentioned eigenvectors, and $\{|r_i\rangle_2 : \forall\, i\}$ turn out necessarily to be eigenvectors of ρ_2 spanning its (equally dimensional) range. Actually, one can write the spectral forms as follows:

$$\rho_1 = \sum_i r_i|r_i\rangle_1\langle r_i|_1, \tag{8a}$$

$$\rho_2 = \sum_i r_i|r_i\rangle_2\langle r_i|_2. \tag{8b}$$

What the standard approach is lacking is any expression of the *correlations* between the two subsystems that the bipartite state implies. This is where the *antilinear* operator representation of the bipartite state has a marked *advantage*.

If one writes down the *polar factorizations* of A_a, one obtains

$$A_a = U_a \rho_1^{1/2}, \tag{9a}$$

$$A_a = \rho_2^{1/2} U_a Q_1, \tag{9b}$$

where U_a is the antilinear unitary (or antiunitary) *correlation operator*, which maps the (topologically) closed range $\bar{\mathcal{R}}(\rho_1)$ of ρ_1 onto $\bar{\mathcal{R}}(\rho_2)$, that of ρ_2 (preserving the scalar product up to complex conjugation). The Hermitian polar factors are the positive-operator roots of the corresponding reduced density operators, and Q_1 is the range projector of ρ_1. The operator U_a is uniquely determined by A_a (i.e., by $|\Phi\rangle_{12}$), e.g., by $U_a Q_1 = \tilde{\rho}_2^{-1/2} A_a$ [as follows from Eq. (9b)], where $\tilde{\rho}_2$ is the reducee of ρ_2 in $\bar{\mathcal{R}}(\rho_2)$. [See also remark beneath relation (12c).] (An elementary discussion of polar factorization of linear operators in one space is given in Ref. 9, and a more general one in Appendix 4 of Ref. 2. The polar factorizations (9a) and (9b) of A_a differ very little from this.)

It turns out that

$$\rho_2 = (U_a \rho_1 U_a^{-1})_2 Q_2 \tag{10}$$

is valid, where Q_2 is the range projector of ρ_2. Utilizing U_a, the above Schmidt expansion and the spectral forms can be rewritten as follows:

$$|\Phi\rangle_{12} = \sum_i r_i^{1/2} |r_i\rangle_1 (U_a |r_i\rangle_1)_2 \tag{11}$$

and

$$\rho_1 = \sum_i r_i |r_i\rangle_1 \langle r_i|_1, \tag{12a}$$

$$\rho_2 = \sum_i r_i (U_a |r_i\rangle_1)_2 (\langle r_i|_1 U_a^\dagger)_2. \tag{12b}$$

(Note that $U_a^\dagger = U_a^{-1}$.) Actually,

$$\forall i: \quad |r_i\rangle_2 = U_a |r_i\rangle_1. \tag{12c}$$

Thus, the correlation operator U_a can be read off from the Schmidt biorthogonal expansion (11) when the latter is explicitly evaluated.

If $\{|j\rangle_1; \forall j\}$ is a basis in $\mathcal{H}_1$, one can uniquely expand the bipartite state, and, as easily seen, one obtains

$$|\Phi\rangle_{12} = \sum_j |j\rangle_1 (A_a |j\rangle_1)_2. \tag{13a}$$

The antilinear representation A_a of $|\Phi\rangle_{12}$ can be read off from this because the antilinear operator A_a is continuous (cf. Appendix 2 in Ref. 2); hence, it is determined by its action on a basis.

Relation (13a) can also be understood as giving the inverse of isomorphism (3), i.e., as determining the map $A_a \to |\Phi\rangle_{12}$. (It is straightforward to show that the lhs of (13a) does not depend on the choice of the basis.)

If the basis in Eq. (13a) is an *eigenbasis* of ρ_1, *then, and only then*, as immediately seen from Eq. (9a), the general expansion (13a) takes on the special form of the biorthogonal Schmidt expansion (7).

Returning to the general expansion (13a), it can be completed by

$$\rho_2 = \sum_j (A_a |j\rangle_1)_2 (\langle j|_1 A_a^\dagger)_2 = \sum_j p_j |\phi_j\rangle_2 \langle \phi_j|_2, \tag{13b}$$

$$\forall j: \quad p_j \equiv \|(A_a|j\rangle_1)_2\|^2, \tag{13c}$$

$$\forall j,\ p_j > 0: \quad |\phi_j\rangle_2 \equiv p_j^{-1/2}(A_a|j\rangle_1)_2. \tag{13d}$$

Here p_j is the probability that the event $(|j\rangle_1\langle j|_1 \otimes 1)$ occurs in nearby-subsystem measurement in $|\Phi\rangle_{12}$, and $|\phi_j\rangle_2$ is the state of the remote subsystem thus obtained, i.e., it is the result of so-called *remote preparation*. From the nonselective (or entire-ensemble) point of view, the physical meaning of Eqs. (13a)–(13d) consists in the fact that these relations express a *remote complete state decomposition* in the antilinear representation. (In remote incomplete state decomposition also mixed states of the remote subsystem are obtained. Such a remote decomposition is given rise to by incomplete nearby-subsystem measurement, i.e., by measurement of an observable with degenerate eigenvalues.)

The adjoint antilinear Hilbert–Schmidt operators $A_a^\dagger$ also form a complex separable Hilbert space in their turn with the scalar product

$$(A_a^\dagger, (A_a^\dagger)') \equiv \mathrm{tr}(A_a' A_a^\dagger)_2. \tag{14}$$

They give the second antilinear operator representation for bipartite vectors via the isomorphism

$$\forall |\Phi\rangle_{12}: \to A_a^\dagger: \quad \forall\, |\chi\rangle_2 : (A_a^\dagger|\chi\rangle_2)_1 \equiv \langle\chi|_2|\Phi\rangle_{12} \in \mathcal{H}_1. \tag{15}$$

Associating $A_a^\dagger$ with A_a [cf. Eq. (4)] is also an isomorphism. (Any two of the mentioned three isomorphisms of bipartite state spaces multiply, i.e., give, when taken one after the other, the third one.)

One has the following relations that are symmetric to Eqs. (9a)–(13a) in terms of the adjoint antilinear operator representation of $|\Phi\rangle_{12}$:

$$A_a^\dagger = U_a^{-1}\rho_2^{1/2}, \tag{16a}$$

$$A_a^\dagger = \rho_1^{1/2} U_a^{-1} Q_2. \tag{16b}$$

Further

$$\rho_1 = U_a^{-1}\rho_2 U_a Q_1, \tag{17}$$

$$|\Phi\rangle_{12} = \sum_i r_i^{1/2}(U_a^{-1}|r_i\rangle_2)_1|r_i\rangle_2, \tag{18}$$

where $\{|r_i\rangle_2 : \forall i\}$ is any eigensubbasis of ρ_2 spanning the range of the latter, and $\{r_i : \forall i\}$ are the corresponding (positive) eigenvalues

$$\rho_1 = \sum_i r_i (U_a^{-1}|r_i\rangle_2)_1 (\langle r_i|_2 U_a)_1 = \sum_i r_i (U_a^{-1}(|r_i\rangle_2\langle r_i|_2)U_a)_1, \tag{19a}$$

$$\rho_2 = \sum_i r_i |r_i\rangle_2\langle r_i|_2. \tag{19b}$$

In general

$$|\Phi\rangle_{12} = \sum_k (A_a^\dagger|k\rangle_2)_1|k\rangle_2, \tag{20a}$$

where $\{|k\rangle_2 : \forall k\}$ is any basis in $\mathcal{H}_2$. Again, it is clear from Eq. (16a) that if this basis is an eigenbasis of ρ_2, then and only then, the general expansion (20a) takes the special form of the biorthogonal Schmidt expansion (18).

Finally, one has

$$\rho_1 = A_a^\dagger A_a, \tag{20b}$$

$$\rho_2 = A_a A_a^\dagger. \tag{20c}$$

The correlation operator U_a establishes a striking *mathematical symmetry* and close connection between the two closed ranges $\bar{\mathcal{R}}(\rho_s)$, $s=1,2$, for any bipartite state vector $|\Phi\rangle_{12}$. The pair of entities ρ_1, U_a, which is equivalent to $|\Phi\rangle_{12}$ [cf. Eqs. (9a) and (3)], is called *the correlated subsystem picture* of the given bipartite state vector. (Note that when one takes a state vector $|\Phi\rangle_{12}$ instead of a state $|\Phi\rangle_{12}\langle\Phi|_{12}$, the former is informationally richer by the choice of a fixed phase factor $e^{i\lambda}$, $\lambda \in \mathbf{R}$, which is arbitrary in the latter. This choice is carried by A_a or U_a. Thus, U_a and $e^{i\lambda}U_a$ with the same ρ_1,correspond to $|\Phi\rangle_{12}$ and $e^{i\lambda}|\Phi\rangle_{12}$, respectively.)

We have summed up in this subsection the mathematical part of the antilinear representation of $|\Phi\rangle_{12}$, and of the correlated subsystem picture. The basic physical meaning of these was studied in previous articles.[2,8] A summary is given in the next subsection.

B. The physical part—detectably complete state-compatible observables

A detectably complete (see below) nearby subsystem observable A_1 that is compatible with the nearby subsystem state, i.e., that satisfies $[A_1,\rho_1]=0$, shortly, a *state-compatible* observable, has, on account of this relation, as it is well known, a common eigenbasis with ρ_1. Let its subbasis spanning $\bar{\mathcal{R}}(\rho_1)$ be $\{|r_i\rangle_1 : \forall i\}$ [cf. Eqs. (7) and (8a)]. Then the relevant partial spectral form of A_1 is

$$A_1 = \sum_i a_i |r_i\rangle_1\langle r_i|_1 + Q_1^\perp A_1, \quad i \neq i' \Rightarrow a_i \neq a_{i'}, \tag{21a}$$

where $Q_1=\Sigma_i |r_i\rangle_1\langle r_i|_1$ is the range projector of ρ_1, $Q_1^\perp$ is the orthocomplementary projector, and the sum in Eq. (21a) is the *detectable part* [in $\bar{\mathcal{R}}(\rho_1)$] of A_1.

By *detectably complete* is meant the requirement in Eq. (21a), i.e., completeness of the reducee $\widetilde{A_1}=\Sigma_i a_i \widetilde{|r_i\rangle\langle r_i|}$ of A_1 in $\bar{\mathcal{R}}(\rho_1)$. [For the use of tilde cf $\tilde{\rho}_2$ in the passage beneath Eqs. (9a) and (9b).]

When A_1 is measured (in an ideal way, e.g.), it gives rise to the actual state decomposition (empirically ensemble decomposition)

$$\rho_2 = \sum_i r_i |r_i\rangle_2\langle r_i|_2 \tag{21b}$$

[special case of Eqs. (13a)–(13d)]. Since the state vectors $\{|r_i\rangle_2 : \forall i\}$ are orthogonal [cf. Eqs. (7) and (8b)], Eq. (21b) amounts to the same as if a detectably complete remote-subsystem observable (Hermitian operator)

$$A_2 = \sum_i a_i' |r_i\rangle_2\langle r_i|_2 + Q_2^\perp A_2, \quad i \neq i' \Rightarrow a_i' \neq a_{i'}' \tag{21c}$$

had been measured in an ideal way. Here $Q_2=\Sigma_i |r_i\rangle_2\langle r_i|_2$ is the range projector of ρ_2.

The pairs of observables (A_1,A_2) are called (physical) *twin observables*, the indirect measurement of A_2 by measuring A_1 directly is called *remote measurement*, and the twin observables satisfy the symmetric relations

$$[A_1,\rho_1] = 0, \tag{22a}$$

$$[A_2,\rho_2] = 0; \tag{22b}$$

$$A_2 = \sum_i a_i' (U_a(|r_i\rangle_1\langle r_i|_1)U_a^{-1})_2 Q_2 + Q_2^{\perp} A_2, \tag{22c}$$

$$A_1 = \sum_i a_i (U_a^{-1}(|r_i\rangle_2\langle r_i|_2)U_a)_1 Q_1 + Q_1^{\perp} A_1. \tag{22d}$$

In Eq. (22c) it is assumed that $A_1 = \Sigma a_i |r_i\rangle_1\langle r_i|_1 + Q_1^{\perp} A_1$ is given, and A_2 is determined by it (at least as far as the eigenvectors of the detectable part of A_2 are concerned). In Eq. (22d) the symmetrical assumption is made. One should note that the undetectable parts $Q_1^{\perp} A_1$ and $Q_2^{\perp} A_2$ are completely arbitrary (and so are the distinct detectable eigenvalues of the twin operator).

In Refs. 2 and 8, it was assumed that *the detectable spectra coincide*

$$\forall i: \quad a_i' = a_i. \tag{23a}$$

Then

$$A_2 = (U_a A_1 U_a^{-1})_2 Q_2 + Q_2^{\perp} A_2, \tag{23b}$$

and

$$A_1 = (U_a^{-1} A_2 U_a)_1 Q_1 + Q_1^{\perp} A_1 \tag{23c}$$

are valid. In later work,[10] twin observables with the stronger requirement Eq. (23a) were called *algebraic twin observables*. *Relaxation* of the stronger requirement led to the wider and more useful class of *physical twin observables*.

If one exchanges the roles of subsystems 1 and 2, one can measure A_1 remotely by a direct measurement of A_2.

Thus, part of the *physical meaning* of the *correlation operator* U_a inherent in $|\Phi\rangle_{12}$ is in the following: When a detectably complete nearby-subsystem observable A_1 [cf. Eq. (21a)] that is compatible with the nearby-subsystem state is measured in an ideal way in selective measurement and a_i is obtained as a result, then the nearby subsystem is found in the state $|r_i\rangle_1$, and the remote subsystem is in the state $|r_i\rangle_2 \equiv (U_a|r_i\rangle_1)_2$ (conditional state). It is obvious from Eqs. (18) and (19a), that also the symmetrical argument is valid. The correlation operator (and its inverse) gives the corresponding *conditional states* when selective ideal measurement of state-compatible subsystem observables is performed.

The remote measurement of a twin observable A_2, selective or nonselective, is one and the same in every kind of measurement of A_1: in ideal measurement and in second-kind (synonym: non-repeatable) measurement [cf. subsection 6(B) in Ref. 2].

III. LINEARLY INDEPENDENT COMPLETE DECOMPOSITIONS OF DENSITY OPERATORS

Definition 1: A finite or countably infinite set of vectors $\{|\phi_i\rangle: \forall i\}$ is said to be *linearly independent* if

$$\forall i: \quad |\phi_i\rangle \notin \overline{\text{span}}\{|\phi_{i'}\rangle: \forall i', i' \neq i\}, \tag{24}$$

where by "$\overline{\text{span}}$" is meant the algebraic and topological span, i.e., the set of all linear combinations together with all their limiting points. (It is a subspace.)

One can define linear independence of a finite sequence $\{|\phi_i\rangle: i = 1, 2, \ldots, d < \infty\}$ of vectors by the weaker requirement:

$$\forall k, \quad k \geqslant 2: |\phi_k\rangle \notin \text{span}\{|\phi_1\rangle, \ldots, |\phi_{(k-1)}\rangle\}. \tag{25}$$

Proof is given in Appendix A. (Note that finite-dimensional linear manifolds are subspaces, i.e., span$=\overline{\text{span}}$ in this case.)

Definition 2: If $\{|\phi_i\rangle: i = 1, 2, \ldots, d \leqslant \infty\}$ is a linearly independent finite or infinite sequence, ρ

a density operator with a d-dimensional closed range, and if one can write

$$\rho = \sum_i p_i |\phi_i\rangle\langle\phi_i|, \tag{26a}$$

where $\forall i : p_i > 0$, $\Sigma_i p_i = 1$, then one speaks of a *linearly independent complete decomposition* of the density operator. (It is called "irreducible decomposition" in Refs. 11 and 4.)

We call "complete" those decompositions of a density operator that cannot be continued by further decomposing any term. These are the pure-state decompositions quantum mechanically. In a followup to this article we turn to "incomplete" decompositions, i.e., to mixed-or-pure state decompositions quantum mechanically.

For Eq. (26a) the relation

$$\bar{\mathcal{R}}(\rho) = \overline{\text{span}}\{|\phi_i\rangle : \forall\, i\} \tag{26b}$$

is valid (cf. Proposition 1 in Ref. 11).

Corollary 1: Obviously, orthonormal sets are special cases of linearly independent ones. The latter possess some important properties of the former. One of them is the following. If $\{|\phi_i\rangle : i = 1,2,\ldots,d \leqslant \infty\}$ is a linearly independent sequence, k is an integer not larger than d, and $\{|\phi_1\rangle,\ldots,|\phi_k\rangle\}$ is a subset of arbitrary elements in arbitrary order, then it spans a k-dimensional subspace $\mathcal{S}_k$, and each vector in it can be uniquely expanded in the set. This is why the latter is called a *linearly independent basis* in $\mathcal{S}_k$. (See also Corollary 3 below.)

Proof is given in Appendix B.

Now we sum up those results on density-operator decomposition from Ref. 4 the application of which forms the basis of this work. They are further elaborated in this section with a view to help applications in quantum-mechanical studies. (No heed is paid to the extent to which the elaborations are possibly new with respect to the mathematical literature, cf., e.g., Ref. 12.)

Lemma: (A) Let ρ be an arbitrary given density operator, and let d be the dimension of its (finite or infinite dimensional) closed range. Then *all* linearly independent sequences $\{|\phi_i\rangle : i = 1,2,\ldots,d\}$ that determine a complete decomposition

$$\rho = \sum_i p_i |\phi_i\rangle\langle\phi_i| \tag{27}$$

of ρ stand in a *one-to-one relation* with the set of *all* bases in $\bar{\mathcal{R}}(\rho)$ each vector of which is within $\mathcal{R}(\rho^{1/2})$:

$$\{|e_i\rangle : i = 1,2,\ldots,d \leqslant \infty\} \subset \mathcal{R}(\rho^{1/2}), \tag{28}$$

where d is the dimension of $\bar{\mathcal{R}}(\rho)$.

(B) The bijection from the set of all bases Eq. (28) to all linearly independent sequences that give decompositions Eq. (27)—we call it the Cassinelli–Vito–Levrero (CVL) bijection—reads as follows:

$$p_i = \langle e_i|\rho|e_i\rangle = ||\rho^{1/2}|e_i\rangle||^2 > 0, \quad |\phi_i\rangle = p_i^{-1/2}\rho^{1/2}|e_i\rangle, \tag{29a}$$

$$i = 1,2,\ldots,d \leqslant \infty\,. \tag{29b}$$

The *inverse* CVL bijection is

$$|e_i\rangle = p_i^{1/2}\tilde{\rho}^{-1/2}|\phi_i\rangle, \quad i = 1,2,\ldots,d \leqslant \infty\,, \tag{30}$$

where the tilde denotes the reducee in $\bar{\mathcal{R}}(\rho)$.

(C) Finally, a state vector $|\phi\rangle$ can appear in a linearly independent complete decomposition of ρ if and only if

$$|\phi\rangle \in \mathcal{R}(\rho). \tag{31}$$

For proof see Theorem 1, Proposition 1, and Remark 8 in Ref. 4.

In connection with the Lemma, one should keep in mind the well-known (and easily proved) relations

$$\mathcal{R}(\rho) \subseteq \mathcal{R}(\rho^{1/2}) \subseteq \bar{\mathcal{R}}(\rho^{1/2}) = \bar{\mathcal{R}}(\rho). \tag{32}$$

In the case of finite-dimensional range, one has equality all over. Contrarily, in the case of infinite-dimensional range, both subset relations in Eq. (32) are *proper*.

Corollary 2: The CVL bijection is *nontrivial* if and only if the basis Eq. (28) is *not* an eigensubbasis of ρ (otherwise, it is the identity map).

Corollary 3: Another property of linearly independent sequences parallelling that of orthonormal ones is the following. If Eq. (27) is a linearly independent complete decomposition of a density operator, then each element $|\chi\rangle$ from the range $\mathcal{R}(\rho^{1/2})$ can be *uniquely expanded* in the sequence $\{|\phi_i\rangle : i=1,2,\ldots,d\leqslant\infty\}$:

$$|\chi\rangle = \sum_i \alpha_i |\phi_i\rangle, \tag{33a}$$

[cf. Eq. (32)]. Further, utilizing the scalar product, one has the following *compact* formula for the expansion coefficients:

$$\alpha_i = p_i[(\langle\phi_i|\tilde{\rho}^{-1})|\chi\rangle], \quad i=1,2,\ldots,d\leqslant\infty \tag{33b}$$

(cf. Lemma C). In this sense, the sequence at issue is a *linearly independent basis* in $\mathcal{R}(\rho^{1/2})$.

Note that the uniqueness of expansion (33a) allows an arbitrary (hence, if desired, a suitable) choice of the probability distribution $\{p_i : i=1,2,\ldots,d\leqslant\infty; p_i>0; \Sigma_{i=1}^{d} p_i=1\}$, and the definition of ρ via Eq. (27). [But care must be taken that $\mathcal{R}(\rho^{1/2})$ contain $|\chi\rangle$.] Note, further, that all d probabilities p_i must be positive. Otherwise, $|\chi\rangle$ would not be expanded in the linearly independent basis $\{|\phi_i\rangle : i=1,2,\ldots,d\leqslant\infty\}$.

Corollary 3 is proved in Appendix C.

Corollary 4: If Eq. (27) is a linearly independent complete decomposition of a given density operator, then the weight p_i can also be expressed in the following two ways:

$$p_i = (\langle\phi_i|\tilde{\rho}^{-1}|\phi_i\rangle)^{-1}, \quad i=1,2,\ldots,d\leqslant\infty, \tag{34}$$

and

$$p_i = 1/\left(\sum_k (|\langle k||\phi_i\rangle|^2 r_k^{-1})\right), \quad i=1,2,\ldots,d\leqslant\infty, \tag{35a}$$

where

$$\rho = \sum_k r_k |k\rangle\langle k|, \quad \forall\, k: \quad r_k>0 \tag{35b}$$

is a complete spectral decomposition of ρ.

Further, one has

$$\inf\{r_k : |\langle\phi_i||k\rangle|^2>0\} \leqslant p_i \leqslant \max\{r_k : |\langle\phi_i||k\rangle|^2>0\}, \quad i=1,2,\ldots,d\leqslant\infty, \tag{36}$$

where the "infimum" can be replaced by "minimum" if the range of ρ is finite dimensional.

Proof: Expression (34) is obtained by taking the square norm of both sides of Eq. (30). Expression (35a) follows from Eq. (34) when $|\phi_i\rangle$ is expanded in the eigensubbasis $\{|k\rangle : \forall\, k\}$ of ρ (and eigenbasis of $\tilde{\rho}$.) Finally, inequalities (36) are an immediate consequence of Eq. (35a). □

Remark 1: When a density operator ρ is given and a state vector satisfies $|\phi\rangle \in \mathcal{R}(\rho)$ (cf. Lemma C), then, in whatever linearly independent complete decomposition of the former the latter

appears, it has a *unique* weight p, which depends only on ρ and $|\phi\rangle$ [cf. Eq. (34)].

Definition 3: We call the weight p from Remark 1 the *characteristic weight* of $|\phi\rangle$ in ρ. If $|\phi\rangle \notin \mathcal{R}(\rho)$, then $p \equiv 0$.

Note that if $|\phi\rangle \in \mathcal{R}(\rho)$, then $p > 0$ [cf. Eq. (29a)]. Note, further, that Remark 1 and Corollary 4 are a completion of Lemma C.

Remark 2: For a possible positive value of the characteristic weight p, there may be more than one corresponding state vector $|\phi\rangle$ in a linearly independent complete state decomposition (27) as seen from Eq. (29a), because more than one state vector $|f\rangle$ can give one and the same expectation value of ρ, and each can be the first $|e_1\rangle \equiv |f\rangle$ in a basis etc. (cf. the Lemma).

Corollary 5: The characteristic weight p of a given state vector $|\phi\rangle \in \mathcal{R}(\rho)$ satisfies the inequality

$$p \leqslant \langle\phi|\rho|\phi\rangle. \tag{37}$$

One has $p = \langle\phi|\rho|\phi\rangle$ if and only if $|\phi\rangle$ is an eigenvector of ρ, and then p equals the corresponding eigenvalue of the density operator.

Proof: The inequality (37) follows from Eq. (27) when one puts $|\phi_1\rangle \equiv |\phi\rangle$ in Eq. (27), and one obtains

$$\rho = p|\phi\rangle\langle\phi| + \sum_{i=2} p_i|\phi_i\rangle\langle\phi_i|, \tag{38a}$$

one applies $|\phi\rangle\langle\phi|$ to both sides, and one takes the trace (keeping in mind, of course, that $\mathrm{tr}(|\phi\rangle \times \langle\phi|\rho) = \langle\phi|\rho|\phi\rangle$):

$$\langle\phi|\rho|\phi\rangle = p + \sum_{i=2} p_i|\langle\phi||\phi_i\rangle|^2 \geqslant p. \tag{38b}$$

One can see from Eq. (34) that if $|\phi\rangle$ is an eigenvector of ρ corresponding to the eigenvalue r, then $p = r$, and also $\langle\phi|\rho|\phi\rangle = r = p$. Conversely, if $p = \langle\phi|\rho|\phi\rangle$, then one can see from Eq. (38b) that all vectors $\{|\phi_i\rangle : i = 2, 3, \ldots\}$ must be orthogonal to $|\phi\rangle$. Hence, applying Eq. (38a) to $|\phi\rangle$, it is seen that the latter is an eigenvector of ρ corresponding to the eigenvalue $r = p$. □

IV. REMOTE LINEARLY INDEPENDENT COMPLETE STATE DECOMPOSITION

Let $|\Phi\rangle_{12}$ be an arbitrary bipartite state vector. Owing to the Cassinelli *et al.* theory, summed up in the Lemma, we can now easily sort out what kind of local, i.e., subsystem measurement gives rise to a linearly independent complete decomposition of the opposite-subsystem state.

Definition 4: Since subsystem measurement, by definition, excludes any interaction between the measuring instrument and the remote subsystem, we call any influence of the former on the latter, which is due exclusively to the quantum correlations inherent in the bipartite state, *remote* influence.

Definition 5: We call a nearby subsystem observable A_1 *relevant* (for remote linearly independent complete state decomposition) if the following three conditions are satisfied:

(i)

$$[A_1, Q_1] = 0, \tag{39}$$

where Q_1 is the range projector of $\rho_1 \equiv \mathrm{tr}_2(|\Phi\rangle_{12}\langle\Phi|_{12})$. If Eq. (39) is satisfied, then A_1 will be said to be *range compatible*.

(ii) $\tilde{A}_1$, the reducee of A_1 in $\bar{\mathcal{R}}(\rho_1)$ if Eq. (39) is satisfied, has a purely discrete and nondegenerate spectrum.

(iii) The eigenbasis $\{|e_i\rangle_1 : \forall i\}$ of $\tilde{A}_1$ in $\bar{\mathcal{R}}(\rho_1)$ (which is uniquely determined by $\tilde{A}_1$ up to arbitrary phase factors and ordering) is within $\mathcal{R}(\rho_1^{1/2})$. (This requirement is always satisfied if the dimension d of ρ_1 is finite.)

Further, we call a *basis* $\{|e_i\rangle_1 : \forall i\}$ in $\bar{\mathcal{R}}(\rho_1)$ that is entirely within $\mathcal{R}(\rho_1^{1/2})$ *relevant*. Finally, we

call a *class of observables* A_1 relevant if it consists of relevant observables that have *one and the same* relevant basis $\{|e_i\rangle_1 : \forall i\}$ (up to phase factors and ordering) as their eigensubbasis in $\bar{\mathcal{R}}(\rho_1)$.

Evidently, the set of all relevant classes of observables A_1 is in a simple one-to-one relation with the set of all relevant bases in $\mathcal{R}(\rho_1^{1/2})$.

If A_1 is *state compatible*, i.e., $[A_1,\rho_1]=0$, then A_1 commutes also with every eigenprojector of ρ_1, and hence, Eq. (39) is satisfied. Namely, Q_1 is the sum of the eigenprojectors corresponding to positive eigenvalues. [If $\mathcal{R}(\rho_1)$ is infinite dimensional, we can assume that A_1 is bounded, or, equivalently, continuous, or equivalently, that its spectrum is within a finite interval. We can do this because the spectrum of A_1 is arbitrary within the relevant class of observables, i.e., it is irrelevant for remote state decomposition.]

In this case the reducee $\tilde{A}_1$ has necessarily a purely discrete spectrum (because it reduces in every eigensubspace of ρ_1, and these are necessarily finite dimensional due to the fact that the corresponding eigenvalues add up to 1). Thus, in this case, requirement (i) is necessarily fulfilled, and (ii) reads that A_1 is a detectably complete observable, i.e., that $\tilde{A}_1$ is complete. Requirement (iii) is necessarily satisfied because $[A_1,\rho_1]=0$ entails a common eigenbasis of $\tilde{A}_1$ and $\tilde{\rho}_1$. Further, the corresponding spectral form of $\tilde{\rho}_1$ is simultaneously a complete decomposition of it. Hence, according to the known result of Hadjisavvas,[11] each of the eigenvectors necessarily belongs to $\mathcal{R}(\rho_1^{1/2})$.

Theorem 1: (A) If a relevant observable $(A_1\otimes 1)$ is measured in the state $|\Phi\rangle_{12}$, it gives rise to a remote linearly independent complete decomposition of the state $\rho_2\equiv \mathrm{tr}_1(|\Phi\rangle_{12}\langle\Phi|_{12})$:

$$\rho_2=\sum_i p_i|\phi_i\rangle_2\langle\phi_i|_2. \tag{40}$$

Conversely, each mathematically possible linearly independent complete decomposition of ρ_2 can be obtained in this way.

(B) The mathematical way how A_1 determines Eq. (40) can be understood as a bijection of the set of all classes of detectably equivalent observables A_1, or, equivalently, of all relevant bases $\{|e_i\rangle_1 : \forall i\}$, onto the set of all linearly independent complete decompositions Eq. (40) (A$\searrow$D on Diagram 1 below) that reads:

$$\forall i:\quad p_i=\langle\Phi|_{12}(|e_i\rangle_1\langle e_i|_1\otimes 1)|\Phi\rangle_{12}>0, \tag{41a}$$

$$\forall i:\quad |\phi_i\rangle_2=p_i^{-1/2}\rho_2^{1/2}(U_a|e_i\rangle_1)_2, \tag{41b}$$

where $|e_i\rangle_1$ are the eigenbasis vectors of $\tilde{A}_1=\Sigma_{i'}a_{i'}|e_{i'}\rangle_1\langle e_{i'}|_1$. Further, U_a is the antiunitary correlation operator determined by $|\Phi\rangle_{12}$ [cf. Eqs. (9a) and (9b) and the passage beneath it, as well as the passage beneath Eq. (12c)].

(C) The inverse bijection (A$\nwarrow$D on the diagram) has the form

$$\forall i:\quad |e_i\rangle_1=(U_a^{-1}(p_i^{1/2}\tilde{\rho}_2^{-1/2}|\phi_i\rangle_2))_1. \tag{42}$$

All claims symmetric to those in (A)–(C) are also valid.

(D) If $(1\otimes A_2)=\Sigma_j a_j'(1\otimes|f_j\rangle_2\langle f_j|_2)+(1\otimes Q_2^{\perp}A_2)$ is the relevant partial spectral form of an arbitrary relevant observable A_2 [Q_2 being the range projector of $\rho_2\equiv\mathrm{tr}_1(|\Phi\rangle_{12}\langle\Phi|_{12})$], its (nonselective) measurement causes a remote linearly independent complete state decomposition

$$\rho_1\equiv\mathrm{tr}_2(|\Phi\rangle_{12}\langle\Phi|_{12})=\sum_j q_j|\chi_j\rangle_1\langle\chi_j|_1,\quad \forall j:\quad q_j>0,\quad \sum_j q_j=1. \tag{43}$$

Each linearly independent complete decomposition of ρ_1 can be obtained in this way.

(E) The bijection (C$\swarrow$B on the diagram) taking the set of all relevant classes of second-subsystem observables onto that of all linearly independent complete first-subsystem state decompositions reads

$$\forall j: \quad q_j \equiv \langle\Phi|_{12}(1 \otimes |f_j\rangle_2\langle f_j|_2)|\Phi\rangle_{12} > 0, \tag{44a}$$

$$\forall j: \quad |\chi_j\rangle_1 \equiv q_j^{-1/2}\rho_1^{1/2}(U_a^{-1}|f_j\rangle_2)_1. \tag{44b}$$

(F) The inverse bijection (C$\nearrow$B) is

$$\forall j: \quad |f_j\rangle_2 \equiv (U_a(q_j^{1/2}\widetilde{\rho_1}^{-1/2}|\chi_j\rangle_1))_2. \tag{45}$$

(G) A bijection mapping all relevant classes of observables $(A_1 \otimes 1)$ onto that of all relevant classes of observables $(1 \otimes A_2)$ (A$\rightarrow$B on the diagram) is

$$\forall i: \quad |f_i\rangle_2 \equiv (U_a|e_i\rangle_1)_2. \tag{46a}$$

The inverse bijection (A$\leftarrow$B on the diagram) is

$$\forall j: \quad |e_j\rangle_1 \equiv (U_a^{-1}|f_j\rangle_2)_1. \tag{46b}$$

(H) The product bijection (C$\swarrow$B)$\circ$(A$\rightarrow$B) ("$\circ$" meaning "after") is the corresponding CVL bijection $(A \downarrow C)$; and symmetrically, the product bijection (A$\searrow$D)$\circ$(A$\leftarrow$B) is the corresponding CVL bijection $(B \downarrow D)$.

(I) A bijection taking all linearly independent complete decomposition of ρ_1 onto those of ρ_2 (C$\rightarrow$D) is

$$\left[U_a\left(\rho_1 = \sum_i q_i|\chi_i\rangle_1\langle\chi_i|_1\right)U_a^{-1}\right]_2 Q_2,$$

giving, due to Eq. (10),

$$\rho_2 = \sum_j p_j|\phi_j\rangle_2\langle\phi_j|_2,$$

where

$$\forall j: \quad p_j \equiv q_j, \tag{47a}$$

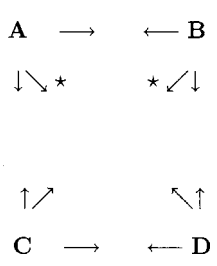
$$\forall j: \quad |\phi_j\rangle_2 \equiv (U_a|\chi_j\rangle_1)_2. \tag{47b}$$

The inverse bijection (C$\leftarrow$D on the diagram) is symmetric to this (under the exchange of the two subsystems) mutatis mutandis.

(J) The square Diagram 1 summing up the preceding items of Theorem 1 is *commutative*, i.e., any two successive bijections multiply into the corresponding bijection on the diagram.

Commutative Square Diagram 1.
A Mathematical Framework for Remote
Linearly Independent Complete State Decompositions

A $\equiv$ {all relevant classes of A_1} **B** $\equiv$ {all relevant classes of A_2}



C $\equiv$ {all linearly-independent complete decompositions of ρ_1}

$\mathbf{D} \equiv \{\text{all linearly-independent complete decompositions of } \rho_2\}$

Each arrow goes from one of the sets (A,B,C,D) towards another. It stands for the corresponding bijection. Oppositely oriented arrows denote mutually inverse bijections. The diagram is *commutative*, i.e., the successive bijections combine into the displayed corresponding one. For instance, taking the bijection $\mathbf{B} \downarrow \mathbf{D}$ after the bijection $\mathbf{A} \rightarrow \mathbf{B}$ gives the bijection $\mathbf{A} \searrow \mathbf{D}$. The bijections are given in detail in Theorem 1. The imaginary vertical line cutting the square into two equally wide halves makes these completely symmetric (due to the symmetry between the two subsystems in $|\Phi\rangle_{12}$).

⋆ The downward diagonal bijections $\mathbf{A} \searrow \mathbf{D}$ and $\mathbf{C} \swarrow \mathbf{B}$ have the *physical meaning* of *remote linearly-independent state decompositions*.

Proof of Theorem 1.

(B) To prove claim B, we take resort to the relations (13a)–(13d), which express the general remote complete state decomposition. Relation (13c) and (3) imply in our case

$$\forall i: \quad 0 < p_i = ||(A_a|e_i\rangle_1)_2||^2 = ||\langle e_i|_1|\Phi\rangle_{12}||^2 = ((\langle\Phi|_{12}|e_i\rangle_1)_2, (\langle e_i|_1|\Phi\rangle_{12})_2)$$
$$= \langle\Phi|_{12}(|e_i\rangle_1\langle e_i|_1 \otimes 1)|\Phi\rangle_{12}.$$

Further, Eqs. (13d) and (9b) give $\forall i: |\phi_i\rangle_2 = p_i^{-1/2}\rho_2^{1/2}(U_a|e_i\rangle_1)_2$.

(C) Claim C obviously follows from B in view of the facts that both U_a and $\tilde{\rho}_2^{1/2}$ are nonsingular on $\bar{\mathcal{R}}(\rho_1)$ and in $\bar{\mathcal{R}}(\rho_2)$, respectively.

(A) The proof of claim A is a consequence of part of the commutativity of the square Diagram, viz., of the fact that $(A \searrow D) = (B \downarrow D) \circ (A \rightarrow B)$. To see this, one should keep in mind that $\rho_2 = (U_a\rho_1 U_a^{-1})_2 Q_2$ [cf. Eq. (10)] implies $U_a\mathcal{R}(\rho_1^{1/2}) = \mathcal{R}(\rho_2^{1/2})$ because the definition $\rho_1^{1/2}\rho_1^{1/2} = \rho_1$ of the square root, Eq. (10) and the well known uniqueness of the square root lead to $(U_a\rho_1^{1/2}U_a^{-1})_2 Q_2 (U_a\rho_1^{1/2}U_a^{-1})_2 Q_2 = \rho_2$, and finally to $(U_a\rho_1^{1/2}U_a^{-1})_2 Q_2 = \rho_2^{1/2}$. Therefore, $\{|e_i\rangle_1 : \forall i\} \subset \mathcal{R}(\rho_1^{1/2})$ implies $\{(U_a|e_i\rangle_1)_2 : \forall i\} \subset \mathcal{R}(\rho_2^{1/2})$.

Further, let us rewrite Eq. (41a) as

$$\forall i: \quad p_i = \langle e_i|_1\rho_1|e_i\rangle_1 = (\langle e_i|_1 U_a^\dagger)_2 (U_a\rho_1 U_a^{-1})_2 (U_a|e_i\rangle_1)_2 = (\langle e_i|_1 U_a^\dagger)\rho_2(U_a|e_i\rangle_1)_2.$$

(Complex conjugation due to applying an antilinear operator to the left is omitted because the scalar product is a positive number.)

Comparing the last relation with Eq. (29a), and Eq. (41b) with Eq. (29b), we see that the claimed product of maps holds true. Since the factors in the product are bijections, so is the product itself (and its inverse is the reverse product of the inverses).

Finally, on account of the fact that the CVL bijection $(B \downarrow D)$ maps onto the set of all linearly independent complete state decompositions [in $\mathcal{R}(\rho_2)$], the same is valid for the remote state decompositions $(A \searrow D)$ as claimed.

The symmetric claims D, E, and F can be proved symmetrically. Claim G is obviously valid.

(H) Claim H is an immediate consequence of the products $(C \swarrow B) = (A \downarrow C) \circ (A \leftarrow B)$, which is the symmetric relation of $(A \searrow D) = (B \downarrow D) \circ (A \rightarrow B)$ (see proof of claim C).

Claim I is obviously valid. The final claim J easily follows from the multiplications proved for claim C. □

Remark 3: In the special case when a pair of range-compatible observables A_s $s = 1, 2$, are state compatible, then the CVL bijections $(A \downarrow C)$ and $(B \downarrow D)$ become mathematically most simple, and are endowed with physical meaning of actual orthogonal decomposition of the states $\rho_s, s = 1, 2$, due to ideal measurement. If the range-compatible observables are state incompatible, then the CVL bijections are formal.

The *remote linearly independent complete decomposition* Eq. (40), caused by the direct subsystem measurement of $(A_1 \otimes 1)$, *has the physical meaning of actual decomposition* of ρ_2. This is so because, when the measurement interaction is over, the tripartite pure state vector has undergone the change

$$|0\rangle_{MA}|\Phi\rangle_{12}=|0\rangle_{\mathrm{MA}}\left[\sum_i |e_i\rangle_1[\rho_2^{1/2}(U_a|e_i\rangle_1)_2]\right]\rightarrow\sum_i |i\rangle_{\mathrm{MA}}|e_i'\rangle_1[\rho_2^{1/2}(U_a|e_i\rangle_1)_2]=\sum_i p_i|i\rangle_{\mathrm{MA}}|e_i'\rangle_1|\phi_i\rangle_2, \tag{48}$$

where $|0\rangle_{\mathrm{MA}}$ is the initial state vector of the *measuring apparatus*, and $\{|i\rangle_{\mathrm{MA}}:\forall i\}$ is the orthonormal set of so-called "pointer positions": the state vectors in it display the results $\{a_i:\forall i\}$ in the measurement of A_1. The state vectors $|e_i'\rangle_1$ equal the initial state vectors $|e_i\rangle_1$ if the measurement is a nondemolition (repeatable) one, and they differ otherwise. (Remember that we have complete measurement.) Anyway, according to Eqs. (13a)–(13d) [where now "1" is to be replaced by "(MA+1)"], the final tripartite state gives rise to the remote state decomposition $\rho_2=\Sigma_i p_i|\phi_i\rangle_2\langle\phi_i|_2$. After reading the results on the measuring apparatus, i.e., after so-called *objectivization*,[13] this decomposition becomes *actual* (in contrast to the infinitely many mathematically possible so-called "potential" decompositions).

Returning to Theorem 1, and the square Diagram 1, we can say that the latter displays an extended physical meaning (with respect to that in Sec. II B) of the correlated subsystem picture.

Definition 6: Pairs of opposite subsystem observables (A_1,A_2) satisfying $[A_s,Q_s]=0,s=1,2$, that are relevant (cf. Definition 5) and can be written either as A_1 and $A_2=\Sigma_i a_i'(U_a|e_i\rangle_1)_2(\langle e_i|_1U_a^\dagger)_2+Q_2^\perp A_2$ or as $A_1=\Sigma_i a_i(U_a^{-1}|f_i\rangle_2)_1(\langle f_i|_2U_a)_1+Q_1^\perp A_1$ and A_2 (depending on the choice of the nearby and the remote subsystems), which amount to the same, can be called *generalized twin observables*. If $[A_s,\rho_s]=0,s=1,2$, are *not valid*, then one is dealing with *extended twin observables*.

Diagram 1 displays the physical meaning of the correlated subsystem picture that includes the extended twin observables (in addition to the special case of twin observables).

Corollary 6: The relevant classes of nearby-subsystem observables give an *alternative classification* of all linearly independent complete decompositions of ρ_2. This can be extended to any density operator ρ, if it becomes ρ_2 by so-called purification, i.e., by constructing a bipartite state vector $|\Phi\rangle_{12}$ that implies the initial density operator as its second-subsystem reduced density operator.

One should note that, from the point of view of mathematical physics, this classification has an *advantage* over that of Cassinelli *et al.*[4] (cf. the Lemma above) consisting in the fact that the classifying entities and the details of the connection between them and the linearly independent complete decompositions has a clear physical meaning in terms of the antilinear operator representation of $|\Phi\rangle_{12}$, and its polar factorization (cf. Sec. II).

Remark 4: In Ref. 14, the approach of this section was indicated (without the antilinear operator representation) for finite-dimensional ranges. It was pointed out that this can lead to generating linearly independent complete decomposition of states even at spacelike separation.

V. THE SELECTIVE ASPECT OF REMOTE LINEARLY INDEPENDENT COMPLETE STATE DECOMPOSITION: REMOTE STATE PREPARATION

The selective or one-result subensemble aspect of complete subsystem measurement that gives remote linearly independent complete state decomposition was only implicitly given so far. Now we make it explicit. It is an immediate consequence of Theorem 1.

Theorem 2: Also the selective (or the one-result subensemble) aspect, i.e., the *remote preparations* of pure states that are part of a linearly independent complete state decomposition, can be displayed in a commutative square diagram as below. The symbols on Diagram 2 have the following meaning.

A is the set of all state vectors $|e_k\rangle_1$ from $\mathcal{R}(\rho_1^{1/2})$ (equivalently, the set of all corresponding atomic events or ray projectors $|e_k\rangle_1\langle e_k|_1$). **B** is the set of all state vectors $|f_n\rangle_2$ from $\mathcal{R}(\rho_2^{1/2})$. **C** is the set of all state vectors $|\chi_n\rangle_1$ from $\mathcal{R}(\rho_1)$. Finally, **D** is the set of all state vectors $|\phi_k\rangle_2$ from $\mathcal{R}(\rho_2)$.

The bijection $\mathbf{A}\rightarrow\mathbf{B}$ comes about by application of the antiunitary correlation operator U_a, which is determined by the given bipartite state vector $|\Phi\rangle_{12}$. The inverse bijection $\mathbf{B}\leftarrow\mathbf{A}$ is U_a^{-1}.

$\mathbf{A}\downarrow\mathbf{C}$ is $p_k^{-1/2}\rho_1^{1/2}$. The inverse is $\mathbf{C}\uparrow\mathbf{A}=p_k^{1/2}\tilde{\rho}_1^{-1/2}$, where the tilde denotes the reducee to the range. $\mathbf{B}\downarrow\mathbf{D}$ is $p_n^{-1/2}\rho_2^{1/2}$. The inverse is $\mathbf{D}\uparrow\mathbf{B}=p_n^{1/2}\tilde{\rho}_2^{-1/2}$. $\mathbf{C}\rightarrow\mathbf{D}$ is U_a. The inverse bijection $\mathbf{C}\leftarrow\mathbf{D}$ is U_a^{-1}.

The diagonal arrows, which have the physical meaning of remote state preparation, are the following. $\mathbf{A}\searrow\mathbf{D}$ is $p_k^{-1/2}\rho_2^{1/2}U_a$, or, equivalently, $p_k^{-1/2}A_a$. The inverse is $\mathbf{A}\nwarrow\mathbf{D}=p_k^{1/2}\tilde{\rho}_1^{-1/2}U_a^{-1}$.

$\mathbf{C}\swarrow\mathbf{B}$ is $p_n^{-1/2}\rho_1^{1/2}U_a^{-1}$, or, equivalently, $p_n^{-1/2}A_a^{\dagger}$. The inverse is $\mathbf{C}\nearrow\mathbf{B}=p_n^{1/2}\tilde{\rho}_2^{-1/2}U_a$.

Commutative Square Diagram 2.
Remote Pure-State Preparation.
(The Selective Aspect of
Remote Linearly Independent Complete State
Decompositions)

$\mathbf{A}\equiv\{\text{all state vectors } |e_k\rangle_1\in\mathcal{R}(\rho_1^{1/2})\}$ $\mathbf{B}\equiv\{\text{all state vectors } |f_n\rangle_2\in\mathcal{R}(\rho_2^{1/2})\}$

$$\begin{array}{ccc} \mathbf{A} & \longrightarrow & \longleftarrow \mathbf{B} \\ \downarrow\searrow\star & & \star\swarrow\downarrow \\ \uparrow\nearrow & & \nwarrow\uparrow \\ \mathbf{C} & \longrightarrow & \longleftarrow \mathbf{D} \end{array}$$

$\mathbf{C}\equiv\{\text{all state vectors } |\chi_n\rangle_1\in\mathcal{R}(\rho_1)\}$
$\mathbf{D}\equiv\{\text{all state vectors } |\phi_k\rangle_2\in\mathcal{R}(\rho_2)\}$

Each arrow goes from one of the sets (A,B,C,D) towards another. It stands for the corresponding bijection specified in Theorem 2. Oppositely oriented arrows denote mutually inverse bijections. The diagram is *commutative*, i.e., the successive bijections combine into the displayed corresponding one. For instance, taking the bijection $\mathbf{B}\downarrow\mathbf{D}$ after the bijection $\mathbf{A}\rightarrow\mathbf{B}$ gives the bijection $\mathbf{A}\searrow\mathbf{D}$, etc. The imaginary vertical line cutting the square into two equally wide halves makes these completely symmetric (due to the symmetry between the two subsystems in $|\Phi\rangle_{12}$).

$\star$ The downward diagonal bijections $\mathbf{A}\searrow\mathbf{D}$ and $\mathbf{C}\swarrow\mathbf{B}$ have the *physical meaning* of *remote state preparations*.

Theorem 2 completes previous work on remote preparation (or "steering," to use Schrödinger's term) begun by Schrödinger,[1] and continued in Ref. 15. To make the completion more precise, the following theorem clarifies the issue.

Theorem 3: (A) A state vector $|\phi\rangle_2$ is obtainable by remote preparation in $|\Phi\rangle_{12}$ if and only if $|\phi\rangle_2\in\mathcal{R}(\rho_2^{1/2})$.

(B) *The set of all* atomic events $|j\rangle_1\langle j|_1$ the occurrence of which in nearby-subsystem measurement in $|\Phi\rangle_{12}$ remotely prepares a given state vector $|\phi\rangle_2$ is (in terms of state vectors $|f\rangle_1$ and $|g\rangle_1$):

$$\{|j\rangle_1\langle j|_1 : |j\rangle_1=\alpha|f\rangle_1+\beta|g\rangle_1\}, \tag{49a}$$

where

$$|f\rangle_1\equiv U_a^{-1}\rho_2^{-1/2}|\phi\rangle_2, \tag{49b}$$

$$|\alpha|>0, \quad |\alpha|^2+|\beta|^2=1, \tag{49c}$$

and

$$|g\rangle_1=Q_1^{\perp}|g\rangle_1, \tag{49d}$$

(Q_1 being the range projector of ρ_1, and $Q_1^{\perp}$ being its orthocomplementary projector, i.e., the null projector), otherwise $|g\rangle_1$ is arbitrary.

(C) If the occurrence of the atomic event $|j\rangle_1\langle j|_1$ remotely prepares $|\phi\rangle_2$, then the *probability* of occurrence is *proportional* to $|\alpha|^2$ [cf. Eq. (49a)]. It is *maximal* if and only if $|j\rangle_1=|f\rangle_1$ [cf. Eq. (49b)].

(D) If $|\phi\rangle_2 \in \mathcal{R}(\rho_2)$ [cf. Eq. (32)], then $|f\rangle_1 \in \mathcal{R}(\rho_1^{1/2})$, where $|f\rangle_1$ is given by Eq. (49b). Thus, one has linearly independent remote preparation in this case, where the maximal probability is the *characteristic weight* of $|\phi\rangle_2$ (cf. Definition 3).

(E) If $|\phi\rangle_2 \in (\mathcal{R}(\rho_2^{1/2})-\mathcal{R}(\rho_2))$, where, "–" denotes set-theoretical subtraction (of a subset), then $|f\rangle_1 \in (\bar{\mathcal{R}}(\rho_1)-\mathcal{R}(\rho_1^{1/2}))$, where $|f\rangle_1$ is given by Eq. (49b).

If the ranges of ρ_s, $s=1,2$ are finite dimensional, then the largest probability is always the characteristic weight corresponding to linearly independent remote preparation [cf. Eq. (32)].

Proof of Theorem 3: (A) The most general case of remote pure-state preparation in a bipartite state vector $|\Phi\rangle_{12}$ is given by Eq. (13d). Replacing A_a by its polar-factorized form $\rho_2^{1/2}U_aQ_1$ [cf. Eq. (9b)], one can see that it is necessary that $|\phi\rangle_2 \in \mathcal{R}(\rho_2^{1/2})$. That this is also sufficient is obvious from the fact that $|\phi\rangle_2$ is obtained by remote preparation when the atomic event $|f\rangle_1\langle f|_1$ occurs, where $|f\rangle_1$ is given by Eq. (49b). [We again utilize the above polar-factorized form Eq. (9b) of A_a in Eq. (13d).]

(B) Since $|\phi\rangle_2=p^{-1/2}U_a\rho_1|j\rangle_1=p^{-1/2}U_a\rho_1Q_1|j\rangle_1$ [cf. Eqs. (13d) and (9a)], where p is the probability of occurrence, it is obvious that the occurrence of each of the atomic events $|j\rangle_1\langle j|_1$ [cf. Eqs. (49a)–(49d)] remotely prepares $|\phi\rangle_2$. On the other hand, Eq. (49a) with $|f\rangle_1 \in \bar{\mathcal{R}}(\rho_1)$ is the general form of a state vector from $\mathcal{H}_1$, and $A_a=U_a\rho_1^{1/2}$ [cf. (9a)] is nonsingular on $\bar{\mathcal{R}}(\rho_1)$, hence, it follows from Eq. (13d) that if $|j\rangle_1$is not in the set Eq. (49a), then the occurrence of $|j\rangle_1\langle j|_1$ remotely prepares a state vector $|\phi'\rangle_2$ that is distinct from $|\phi\rangle_2$.

(C) Substituting in Eq. (13c) A_aQ_1 instead of A_a and $|j\rangle_1$ by its form in Eq. (49a), one obtains

$$p=|\alpha|^2\|\rho_1^{1/2}|f\rangle_1\|^2, \tag{50}$$

which is independent of $|g\rangle_2$ [cf. Eq. (49a)]. Both claims in Theorem 3C are obvious from Eq. (50).

(D) and (E) The claims of Theorem 3D and 3E follow from the following set-theoretical insight. One has

$$\bar{\mathcal{R}}(\rho_1)=\mathcal{R}(\rho_1^{1/2})+(\bar{\mathcal{R}}(\rho_1)-\mathcal{R}(\rho_1^{1/2})), \tag{51}$$

and

$$\mathcal{R}(\rho_1^{1/2})=\mathcal{R}(\rho_1)+(\mathcal{R}(\rho_1^{1/2})-\mathcal{R}(\rho_1)), \tag{52}$$

where "+" denote the set-theoretical union of disjoint sets. The operator $\rho_1^{1/2}$ maps the first term on the rhs of Eq. (51) *into* the first term on the rhs of Eq. (52). This is seen from the fact that if $|j\rangle_1 \in \mathcal{R}(\rho_1^{1/2})$, then $\exists:|k\rangle_1,\langle k|_1|k\rangle_1>0,\rho_1^{1/2}|k\rangle_1=|j\rangle_1$. Then $\rho_1^{1/2}|j\rangle_1=\rho_1|k\rangle_1 \in \mathcal{R}(\rho_1)$.

Actually, $\rho_1^{1/2}$ maps $\mathcal{R}(\rho_1^{1/2})$ *onto* $\mathcal{R}(\rho_1)$. Namely, if $0\neq|k\rangle_1 \in \mathcal{R}(\rho_1)$, then $\exists:0\neq|j\rangle_1$ such that $|k\rangle_1=\rho_1|j\rangle_1=\rho_1^{1/2}(\rho_1^{1/2}|j\rangle_1)$.

Finally, since $\rho_1^{1/2}$ maps the lhs of Eq. (51) *onto* the lhs of Eq. (52) *in a nonsingular way*, one easily concludes that this operator maps the second term on the rhs of Eq. (51) onto the second term on the rhs of Eq. (52). □

VI. CONCLUDING REMARKS

There is a very basic and elementary general claim: Every statement valid for all bipartite state vectors $|\Phi\rangle_{12} \in (\mathcal{H}_1 \otimes \mathcal{H}_2)$ is either symmetric in the two subsystems, or if not, then also the statement symmetrical to it is always valid. This comes from the essential symmetry between $\mathcal{H}_1$ and $\mathcal{H}_2$ (in spite of the fact that one has to use the two factor spaces in an ordered way).

The results of this article confirm the claim that at the very core of entanglement in any $|\Phi\rangle_{12}$ is the *correlated subsystem picture* (see Sec. II). It consists of statements that appear in symmetrical pairs: the two reducees $\tilde{\rho}_1$ and $\tilde{\rho}_2$ are symmetric [cf. Eq. (10)] and so are the reducees of twin

observables $\tilde{A}_1$ and $\tilde{A}_2$ (if one takes algebraic twin observables, i.e., ones with equal relevant spectra). The symmetry is in terms of the *antiunitary correlation operator* U_a inherent in $|\Phi\rangle_{12}$, which establishes a sort of duality (like between kets and bras) between the closed ranges $\bar{\mathcal{R}}(\rho_1)$ and $\bar{\mathcal{R}}(\rho_2)$.

The correlation operator connects the orthogonal decompositions (or spectral forms) $\tilde{\rho}_1 = \Sigma_i r_i \widetilde{|i\rangle_1\langle i|_1}$, $\tilde{\rho}_2 = \Sigma_i r_i \widetilde{|i\rangle_2\langle i|_2}$, to which correspond the spectral forms of (physical) twin observables $\tilde{A}_1 = \Sigma_i a_i \widetilde{|i\rangle_1\langle i|_1}$ and $\tilde{A}_2 = \Sigma_i a_i' \widetilde{|i\rangle_2\langle i|_2}$. (One should remember that the tilde denotes that the corresponding operator is reduced to the range of $\rho_s, s=1,2$.)

In the wider view, when also extended twin observables are taken into account, or, equivalently, when one considers generalized twin observables, which has been elaborated in this article, one treats the wider class of linearly independent subsystem state decompositions $\rho_1 = \Sigma_n q_n |\chi_n\rangle_1\langle\chi_n|_1$ and $\rho_2 = \Sigma_k p_k |\phi_k\rangle_2\langle\phi_k|_2$ along with the relevant generalized twin observables A_1 and A_2 the measurement of either of which gives rise to the mentioned state decomposition on the *opposite* subsystem (remote linearly independent complete decomposition of state), but *not* to the decomposition on the same subsystem (except in the special case of proper twin observables). The full mathematical details and beauty of the generalized physical meaning of the correlated subsystem picture is expressed via the commutative diagrams.

If, following Schrödinger,[1] one tries to understand entanglement solely in terms of disentanglement, i.e., in terms of remote state decomposition, then one wonders what is left out from this article.

Restricting ourselves first to the (more important) complete state decompositions and pure-state preparation, the following is omitted.

If the bipartite state vector has infinite entanglement, i.e., if the dimension of the two ranges of the respective reduced density operators is infinite, then even among the observables for which the basic commutation $[A_s, Q_s]=0$, $s=1,2$, is valid (range-compatible observables), those for which the eigenbases of the reducees $\tilde{A}_s$, $s=1,2$ are not entirely within $\mathcal{R}(\rho_s^{1/2})$ $s=1,2$ are left out from remote linearly independent complete state decomposition. Further, equally for finite and for infinite entanglement, if at least one of the reduced density operators is singular, then the corresponding commutation $[A_s, Q_s]=0$, $s=1,2$ can be violated by some A_s, and the remote state decompositions caused by the measurement of such violating observables are also outside our treatment except in Theorem 3, which addresses the general case.

Considering only the nonselective aspect of remote influence, from the physical point of view it may not be clear why one should attach more importance to linearly independent remote complete state decomposition than to the rest mentioned above. The answer lies in the selective aspect, when one considers remote linearly independent pure-state preparation. Theorem 3C makes it clear that these are the nearby-subsystem occurrences that in measurement in $|\Phi\rangle_{12}$ have *the highest probability*. This fact singles them out in importance.

In Theorem 2 and Diagram 2 we have treated linearly independent remote pure-state preparation as part of linearly independent remote complete state decomposition. This is methodologically quite correct. But in view of the mentioned result in Theorem 3C, physically it is more satisfactory to reverse the roles of the nonselective and the selective aspects, and to consider the former as composed out of the latter. In other words, perhaps it is physically more correct to consider remote linearly independent complete state decomposition as consisting of remote linearly independent pure-state preparations. Then the physical importance of the latter is shared by the former.

One should point out that we have not considered incomplete remote linearly independent state decomposition or remote linearly independent mixed-or-pure state preparation. This is much used in practice as a step towards complete state decomposition (towards pure-state preparation).

We may repeat the remark from the Sec. I that in theoretical physics mathematics and physics are inextricably connected and the optimal form of the former, as a rule, gives physical insight, often in terms of new physical concepts. The correlated subsystem picture, by itself a mathematical concept, which has been further applied to disentanglement in this article, leads to insight into

the structure of pure-state entanglement in terms of generalized (proper and extended) twin observables. In particular, linearly independent remote pure-state preparation appears as the maximal-probability way of such a remote effect.

Finally, the largest-probability requirement in remote pure-state preparation leads to the conclusion (cf. Theorem 3C) that, from the physical point of view, in case of infinite-dimensional ranges of ρ_s, $s=1,2$, one should generalize "relevant" (for linearly independent influence) observables by the weaker requirement of only range-compatible and detectably complete ones (cf. Definition 5).

APPENDIX A

Proof that

$$\{|\phi_k\rangle \notin \mathrm{span}\{|\phi_1\rangle, \ldots, |\phi_{(k-1)}\rangle, |\phi_{(k+1)}\rangle, \ldots, |\phi_d\rangle\}, \quad k=1,2,\ldots d; d \in \mathbf{N}\}$$
$$\Leftrightarrow \{\forall k: |\phi_k\rangle \notin \mathrm{span}\{|\phi_1\rangle, \ldots, |\phi_{(k-1)}\rangle\}, \tag{A1.1}$$

where **N** is the set of all natural numbers.

The first requirement on the set $\{|\phi_i\rangle : i=1,\ldots,d\}$ obviously implies the second one. To prove the inverse implication, we assume *ab contrario* that the first requirement is not valid, but the second is. Then there exists $k \in \mathbf{N}$, $1 \leqslant k \leqslant d$ such that

$$|\phi_k\rangle = \sum_{i=1}^{(k-1)} \alpha_i |\phi_i\rangle + \sum_{j=(k+1)}^{d} \alpha_j |\phi_j\rangle, \tag{A1.2}$$

all α_i and all α_j complex numbers. On account of the assumed validity of the second requirement in Eq. (A1.1), not all α_j can be zero. We define $\bar{j} \equiv \max\{j : \alpha_j \neq 0\}$. Then Eq. (A1.2) implies

$$|\phi_{\bar{j}}\rangle = \alpha_{\bar{j}}^{-1}\left(|\phi_k\rangle - \sum_{i=1}^{(k-1)} \alpha_i |\phi_i\rangle - \sum_{j=(k+1)}^{(\bar{j}-1)} \alpha_j |\phi_j\rangle\right)$$

in contradiction to the assumed validity of the second requirement. □

APPENDIX B

Proof (of Corollary 1) that every finite subset $\{|\phi_1\rangle, \ldots, |\phi_k\rangle\}$ of a linearly independent set (finite or infinite) is a linearly independent basis in the k-dimensional subspace $\mathcal{S}_k$ that it spans. First we prove the claimed dimensionality of the span.

Total induction. We assume that the dimensionality claim is true for $(n-1)<k$: span $\{|\phi_1\rangle, \ldots, |\phi_{(n-1)}\rangle\} = \mathcal{S}_{(n-1)}$. Let $|\phi_n\rangle$ be linearly independent of the mentioned preceding state vectors. Let P project onto $\mathcal{S}_{(n-1)}$. One has

$$|\phi_n\rangle = P|\phi_n\rangle + P^{\perp}|\phi_n\rangle, \tag{A2.1}$$

where $P^{\perp} \equiv (1-P)$, and $P^{\perp}|\phi_n\rangle$ cannot be zero (cf. Definition 1). We define $|f_n\rangle \equiv cP^{\perp}|\phi_n\rangle$, where c is a normalization constant, and

$$\mathcal{S}_n \equiv \mathrm{span}\{\mathcal{S}_{(n-1)}, |f_n\rangle\} \tag{A2.2}$$

is a subspace of n dimensions. Since $|f_n\rangle = c(|\phi_n\rangle - P|\phi_n\rangle)$, $\mathcal{S}_n \subset \mathrm{span}\{|\phi_1\rangle, \ldots, |\phi_n\rangle\}$. It is obvious from Eq. (A2.1) that $|\phi_n\rangle \in \mathcal{S}_n$. Hence, $\mathrm{span}\{|\phi_1\rangle, \ldots, |\phi_n\rangle\} \subset \mathcal{S}_n$, and, finally, $S_n = \mathrm{span}\{|\phi_1\rangle, \ldots, |\phi_n\rangle\}$.

Since the claim that the span is a subspace of that many dimension as the number of linearly independent state vectors is true for $n=1$, total induction implies that it is true for any $n \leqslant k$.

The uniqueness of the expansion follows from Corollary 3 is one takes an arbitrary probability distribution $\{p_i : i=1,2,\ldots,k; p_i>0; \Sigma_{i=1}^k p_i = 1\}$ and one defines $\rho \equiv \Sigma_{i=1}^k p_i |\phi_i\rangle\langle\phi_i|$.

APPENDIX C

Proof of Corollary 3. We show that assuming Eq. (27), each element $|\chi\rangle$ from the range $\mathcal{R}(\rho^{1/2})$ can be expanded in the linearly independent sequence $\{|\phi_i\rangle : i=1,2,\ldots,d\leqslant\infty\}$.

Let

$$\tilde{\rho}^{-1/2}|\chi\rangle = \sum_i \beta_i |e_i\rangle. \tag{A3.1}$$

Applying the continuous operator $\rho^{1/2}$, one obtains (cf. Lemma B):

$$|\chi\rangle = \sum_i \beta_i \rho^{1/2}|e_i\rangle = \sum_i \beta_i p_i^{1/2}|\phi_i\rangle,$$

$$|\chi\rangle = \sum_i \alpha_i |\phi_i\rangle, \tag{A3.2}$$

where $\forall i$: $\alpha_i = \beta_i p_i^{1/2}$. On account of Eqs. (A3.1) and (28), one has

$$\forall i: \quad \alpha_i = p_i^{1/2}[(\langle e_i|\tilde{\rho}^{-1/2})|\chi\rangle].$$

Substituting $\langle e_i|$ from Eq. (30), the last relation enables us to rewrite Eqs. (A3.2) as follows:

$$|\chi\rangle = \sum_i p_i[(\langle\phi_i|\tilde{\rho}^{-1})|\chi\rangle]|\phi_i\rangle. \tag{A3.3}$$

Finally, the uniqueness of the expansion Eq. (A3.3) is easily proved by bringing the opposite assumption into contradiction with the definition of linear independence (cf. Definition 1). □

(Received 26 January 2006; accepted 20 October 2006; published online 7 December 2006)

We show in a rigorous way that Crum's result regarding the equal eigenvalue spectrum of Sturm-Liouville problems can be obtained iteratively by successive Darboux transformations. Furthermore, it can be shown that all neighboring Darboux-transformed potentials of higher order, u_k and u_{k+1}, satisfy the condition of shape invariance provided the original potential u does so. Based on this result, we prove that under the condition of shape invariance, the nth iteration of the original Sturm-Liouville problem defined solely through the shape invariance is equal to the nth Crum transformation. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2397556]

I. INTRODUCTION

Supersymmetric quantum mechanics,[1,2] the factorization method,[3] the Darboux transformation,[4] Crum's generalization of the former results,[5] the isospectral Hamiltonians based on the Gelfand-Levitan equation[6–9] or the Marchenko equation,[10,11] and the shape invariance condition on the potentials[12] together with a transformation defined through this condition have been in the last two decade an active area of mathematical physics[13–18] and pure mathematics.[19–21] The main concern of these areas has been the construction of isospectral Schrödinger operators and the analytical solvability of the Sturm-Liouville problem. The field allowed a deeper insight into the eigenvalue problem and served as a source for many new ideas and generalizations.[22–25] Indeed, it is almost impossible to quote all research papers on the subject (suffices to note that one review[26] and several books have been devoted to the subject[27–31]). The applications range from constructing new solvable potentials in quantum mechanics, differential equations,[32] atomic physics,[33] nuclear physics,[34] classical mechanics,[35] acoustic spectral problems[36] to quantum gravitation,[37,38] and neutrino oscillation[39] to mention a few important areas.

Mathematically, not all these transformations mentioned above are equal, or at least this is not apparent at first sight. For instance, the usual Darboux transformation is not the most general solution of the Riccati equation and as such does not give us the most general transformation in connection with the isospectral eigenvalue spectrum. On the other hand, the generalization of the Darboux transformations, namely, the so-called Crum transformation appears to be much more complicated than the original Darboux result and as such seems to offer us new avenues to construct new potentials. The third transformation of a Hamiltonian which we have in mind [defined here in Eq. (90)] is closely related to the condition of shape invariance. Hence, without doubt, there is some need to at least classify these transformations according to the complexity or generality and to uncover their relations between them. One such result in this direction is the nonequivalence of the Abraham-Moses[7] and Darboux constructions shown in Ref. 9. Two remarks are in order here. Firstly, it is understood that unlike the Darboux transformation, any transforma-

[a)]Electronic mail: mnowakos@uniandes.edu.co

tion in connection with the shape invariance is, of course, limited to the set of shape invariant Hamiltonians. Secondly, for completeness it is worth noting that the level of complexity of isospectral quantum systems can be increased by considering nonlinear and higher order supersymmetric transformations.[40–43] These are transformations which cannot be reached by iterative Darboux transformations. In this work, however, we will not consider these kinds of transformations and restrict ourselves to the Darboux case. After some preparatory statements we will show that the undertaking to uncover relationships between the transformations gives a simple result, namely, allowing the use of higher order Darboux transformations, we can state that all three transforms of the original Sturm-Liouville problem are equal. This result is based on a theorem which we prove in the present paper concerning higher order Darboux transformations of shape invariant potentials denoted by $u^D[k]$. The theorem states that provided the original potential satisfies the shape invariance conditions, all pairs $u^D[k]$, $u^D[k+1]$ are also mutually shape invariant. The theorem can be proved by induction. Interestingly, it intertwines this induction with another statement, this time for the wave functions. We illustrate the theorems by two examples.

II. CRUM'S RESULT

In this section, we briefly present Crum's result and comment on one identity on which Crum's result is partly based. This identity is crucial for the subsequent results which we will elaborate upon in the next section.

Let

$$W_k \equiv W(\psi_1, \psi_2, \ldots, \psi_k) = \det A, \quad A_{ij} = \frac{d^{i-1}\psi_j}{dx^{i-1}}, \quad i,j = 1,2, \ldots, k \tag{1}$$

be the Wronskian determinant of the functions $\psi_1, \psi_2, \ldots, \psi_k$, and

$$W_{k,s} = W(\psi_1, \psi_2, \ldots, \psi_k, \psi_s). \tag{2}$$

Theorem 2.1 (Crum): *If $\psi_1, \psi_2, \ldots, \psi_n$ are the solutions of the regular Sturm-Liouville problem*

$$-\frac{\mathrm{d}^2\psi_s}{\mathrm{d}x^2} + u\psi_s = \lambda_s\psi_s, \tag{3}$$

then $\psi^C[n]_s$ satisfies the Sturm-Liouville equation,

$$-\frac{\mathrm{d}^2\psi^C[n]_s}{\mathrm{d}x^2} + u^C[n]\psi^C[n]_s = \lambda_s\psi^C[n]_s, \tag{4}$$

with $\psi^C[n]_s$ and $u^C[n]_s$ given by

$$\psi_s \to \psi^C[n]_s \equiv \frac{W_{n,s}}{W_n} \tag{5}$$

and

$$u \to u^C[n] = u - 2\frac{\mathrm{d}^2}{\mathrm{d}x^2}\ln W_n. \tag{6}$$

Note that the Crum transforms of ψ and u are not defined iteratively. By $[C]$ we wish to distinguish the Crum transformation from other transforms (like Darboux) which will be defined later in the text. The proof of Crum's theorem can be found in Refs. 5 and 29. We comment here only on one cornerstone of the original proof given by Crum[5] which we will also use later. The first step in the proof of Crum's result on the Wronskian determinant is to consider the derivative of W_k. Taking the derivative of

$$W_2 = \begin{vmatrix} \psi_1 & \psi_2 \\ \mathrm{d}\psi_1/\mathrm{d}x & \mathrm{d}\psi_2/\mathrm{d}x \end{vmatrix}, \tag{7}$$

we find the rather obvious result,

$$\frac{\mathrm{d}W_2}{\mathrm{d}x} = \begin{vmatrix} \psi_1 & \psi_2 \\ \psi_1'' & \psi_2'' \end{vmatrix}, \tag{8}$$

where we used the notation ψ_i'' for $\mathrm{d}^2\psi_i/\mathrm{d}x^2$, $i=1,2$. This result can be readily generalized for the $n\times n$ case.

Lemma 2.2: *For the derivative of a Wronskian determinant we have*

$$W_n' = \{\psi_1^{(n)} M_{(1,n)}^{(1)} + \psi_2^{(n)} M_{(2,n)}^{(1)} + \cdots + \psi_{n-1}^{(n)} M_{(n-1,n)}^{(1)} + \psi_n^{(n)} M_{(n,n)}^{(1)}\}. \tag{9}$$

Assume the result to be valid for $n-1$. Using the Laplace expansion according to the last line of the Wronskian W_n we get

$$\begin{aligned} W_n' = {} & \{\psi_1^{(n)} M_{(1,n)}^{(1)} + \psi_2^{(n)} M_{(2,n)}^{(1)} + \cdots + \psi_{n-1}^{(n)} M_{(n-1,n)}^{(1)} + \psi_n^{(n)} M_{(n,n)}^{(1)}\} \\ & + \{\psi_1^{(n-1)} (M_{(1,n)}^{(1)})' + \cdots + \psi_{n-1}^{(n-1)} (M_{(n-1,n)}^{(1)})' + \psi_n^{(n-1)} (M_{(n,n)}^{(1)})'\}, \end{aligned} \tag{10}$$

where every $(n-1)\times(n-1)$ determinant $M_{(i,n)}^{(1)}$ is a Wronskian for which, by assumption, the theorem is valid. Hence

$$\det B \equiv \{\psi_1^{(n-1)} (M_{(1,n)}^{(1)})' + \cdots + \psi_{n-1}^{(n-1)} (M_{(n-1,n)}^{(1)})' + \psi_n^{(n-1)} (M_{(n,n)}^{(1)})'\} \tag{11}$$

is a determinant whose two last lines are equal and therefore $\det B=0$. The result [Eq. (10)] can be written as

$$W_n' = \begin{vmatrix} \psi_1 & \psi_2 & \cdots & \psi_{n-1} & \psi_n \\ \psi_1' & \psi_2' & \cdots & \psi_{n-1}' & \psi_n' \\ \vdots & \vdots & \cdots & \vdots & \vdots \\ \psi_1^{(n-2)} & \psi_2^{(n-2)} & \cdots & \psi_{n-1}^{(n-2)} & \psi_n^{(n-2)} \\ \psi_1^{(n)} & \psi_2^{(n)} & \cdots & \psi_{n-1}^{(n)} & \psi_n^{(n)} \end{vmatrix}. \tag{12}$$

We can now state a result which will be of some importance later and which is one of the important ingredients in proving Theorem 2.1 of Crum.

Lemma 2.3 (Crum): *The Wronski determinant of the two Wronskians*, W_n and $W_{n-1,s}$, *is equal to* $W_{n,s}W_{n-1}$. *In other words*

$$W(W_n, W_{n-1,s}) = W_{ns} W_{n-1}. \tag{13}$$

The proof relies on the Jacobi theorem for determinants (see the Appendix). We refer the reader to the Appendix for the proof of this Lemma too.

It is well known that for $n=1$ the Crum transformations reduce to the Darboux transformation when $W_1=\psi_1$ and $W_{1,s}=W(\psi_1,\psi_s)$. Specifically, we have

$$\psi^D[1]_s \equiv \psi^C[1]_s = \frac{W_{1,s}}{\psi_1} = \psi_s' - \frac{\psi_1'}{\psi_1}\psi_s, \quad s>1, \tag{14}$$

$$u^D[1] \equiv u^C[1] = u - 2\frac{\mathrm{d}^2}{\mathrm{d}x^2} \ln W_1 = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{\psi_1'}{\psi_1}. \tag{15}$$

We can define higher order Darboux transformations iteratively by

$$u^D[k-1] \to u^D[k] = u[k-1] - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{(\psi^D[k-1]_k)'}{\psi^D[k-1]_k},$$
$$\psi^D[k-1]_s \to \psi^D[k]_s = \frac{W(\psi^D[k-1]_k, \psi^D[k-1]_s)}{\psi^D[k-1]_k}, \qquad s > k. \tag{16}$$

Obviously, the last equation can be written also in a way which resembles more the first Darboux transformation, i.e.,

$$\psi^D[k]_s = (\psi^D[k-1]_s)' - \frac{(\psi^D[k-1]_k)'}{\psi^D[k-1]_k}\psi^D[k-1]_s. \tag{17}$$

It is *a priori* not clear as to what connection the kth Darboux transformation has with the kth Crum transformation and if they can be related at all, except for the definition at the lowest order of Crum's transformation. The answer is provided in the next section.

III. THE CONNECTION BETWEEN HIGHER ORDER DARBOUX AND CRUM TRANSFORMATION

To this end, let us first examine the simplest case of $k=2$,

$$u^D[2] = u^D[1] - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{(\psi^D[1]_2)'}{\psi^D[1]_2}. \tag{18}$$

Since $u[D]_{[1]}$ is the Darboux transformed potential the above equation reads

$$u^D[2] = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi_1'}{\psi_1} + \frac{(\psi^D[1]_2)'}{\psi^D[1]_2}\right). \tag{19}$$

According to Eq. (19), $\psi^D[1]_2 = W_{1,2}/\psi_1$ and on account of the simple identity $W_{n,n+1} = W_{n+1}$, we can write

$$u^D[2] = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi_1'}{\psi_1} + \frac{(W_2/\psi_1)'}{W_2/\psi_1}\right), \tag{20}$$

which finally gives

$$u^D[2] = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{W_2'}{W_2}\right) = u^C[2]. \tag{21}$$

Similarly, the eigenfunctions

$$\psi^D[2]_s = \frac{\begin{vmatrix} \psi^D[1]_2 & \psi^D[1]_s \\ (\mathrm{d}/\mathrm{d}x)\psi^D[1]_2 & (\mathrm{d}/\mathrm{d}x)\psi^D[1]_s \end{vmatrix}}{\psi^D[1]_2} \tag{22}$$

can be cast into the form

$$\psi^D[2]_s = \frac{1/\psi_1 \begin{vmatrix} W_2 & W_{1,s} \\ (W_2/\psi_1)' & (W_{1,s}/\psi_1)' \end{vmatrix}}{\frac{W_2}{\psi_1}} = \frac{\begin{vmatrix} W_2 & W_{1,s} \\ (W_2/\psi_1)' & (W_{1,s}/\psi_1)' \end{vmatrix}}{W_2}. \tag{23}$$

With the help of the standard property of determinants, namely, $\det(\mathbf{z}_1, \ldots, \mathbf{z}_i, \ldots, \mathbf{z}_n) = \det(\mathbf{z}_1, \ldots, \mathbf{z}_i + \alpha\mathbf{z}_k, \ldots, \mathbf{z}_n)$ the last equation reduces to

$$\psi^D[2]_s = \frac{1/\psi_1 \begin{vmatrix} W_2 & W_{1,s} \\ W_2' & W_{1,s}' \end{vmatrix}}{W_2}. \tag{24}$$

Applying the result of Lemma 2.3 and remembering that $W_1 = \psi_1$, one finally finds

$$\psi^D[2]_s = \frac{W_{2,s}}{W_2} = \psi^C[2]_s. \tag{25}$$

The steps above will serve as a beginning of the induction proof of the following general statement,

Theorem 3.1: *The n*th *Crum transformation is equivalent to the n*th *higher order Darboux transformation. This is to say, any Crum transformation can be reached iteratively by successive Darboux transformations, i.e.*,

$$\begin{aligned} u^C[n] &= u^D[n], \\ \psi^C[n]_s &= \psi^D[n]_s. \end{aligned} \tag{26}$$

Proof: Assuming the theorem to be valid for n means that the statement

$$\begin{aligned} u^D[n] &= u^D[n-1] - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{(\psi^D[n-1]_n)'}{\psi^D[n-1]_n}, \\ \psi^D[n]_s &= \frac{W(\psi^D[n-1]_n, \psi^D[n-1]_s)}{\psi^D[n-1]_n}, \end{aligned} \qquad s > n \tag{27}$$

is equivalent to

$$\begin{aligned} u^D[n] &= u - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{W_n'}{W_n}\right), \\ \psi^D[n]_s &= \frac{W_{n,s}}{W_n}. \end{aligned} \qquad s > n. \tag{28}$$

Based on that, we have to show

$$u^C[n+1] = u^D[n+1] = u^D[n] - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{(\psi^D[n]_{n+1})'}{\psi^D[n]_{n+1}} = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{W_{n+1}'}{W_{n+1}} \tag{29}$$

and

$$\psi^D[n+1]_s = \frac{W(\psi^D[n]_{n+1}, \psi^D[n]_s)}{\psi^D[n]_{n+1}} = \frac{W_{n+1,s}}{W_{n+1}}. \tag{30}$$

The validity of the hypothesis of the induction for n allows us to write

$$u^D[n+1] = u^D[n] - 2\frac{d}{dx}\frac{(\psi^D[n]_{n+1})'}{\psi^D[n]_{n+1}} = u - 2\frac{d}{dx}\left(\frac{W_n'}{W_n} + \frac{(\psi^D[n]_{n+1})'}{\psi^D[n]_{n+1}}\right). \tag{31}$$

Using the validity of the hypothesis for n, but this time for the wave functions, implies

$$u^D[n+1] = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{W_n'}{W_n} + \frac{\left(\frac{W_{n+1}}{W_n}\right)'}{\frac{W_{n+1}}{W_n}}\right) = u - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{W_{n+1}'}{W_{n+1}}\right) = u^C[n+1]. \tag{32}$$

Similarly, the result for the eigenfunctions may be written as

$$\psi^D[n+1]_s = \frac{\begin{vmatrix} \psi^D[n]_{n+1} & \psi^D[n]_s \\ \psi'^D[n]_{n+1} & \psi'^D[n]_s \end{vmatrix}}{\psi^D[n]_{n+1}} = \frac{\begin{vmatrix} W_{n+1}/W_n & W_{n,s}/W_n \\ (W_{n+1}/W_n)' & (W_{n,s}/W_n)' \end{vmatrix}}{W_{n+1}/W_n}. \tag{33}$$

One easily proceeds now to verify the validity of the following equation:

$$\psi^D[n+1]_s = \frac{\begin{vmatrix} W_{n+1} & W_{n,s} \\ W_{n+1}'/W_n - W_n'W_{n+1}/W_n^2 & W_{n,s}'/W_n - W_n'W_{n,s}/W_n^2 \end{vmatrix}}{W_{n+1}} = \frac{1/W_n \begin{vmatrix} W_{n+1} & W_{n,s} \\ W_{n+1}' & W_{n,s}' \end{vmatrix}}{W_{n+1}}. \tag{34}$$

By virtue of Lemma 2.3 we can assure that

$$\psi^D[n+1]_s = \frac{W_{n+1,s}}{W_{n+1}} = \psi^C[n+1]_s \tag{35}$$

is true which completes the proof.

It is instructive to follow this theorem by an explicit example.

IV. TWO EXAMPLES

In this section we will demonstrate the above theorems by two examples. We choose first a potential which satisfies the condition of shape invariance (Morse potential) followed by the example of Ginnochio potential, which falls into the class of nonshape invariant, but solvable potentials.

Let us consider, as an example, the Sturm Liouville problem with the Morse potential, i.e.,

$$u(x;A) = 2\left[A^2 - A\left(A + \frac{\alpha}{\sqrt{2}}\right)\mathrm{sech}^2(\alpha x)\right]. \tag{36}$$

The superpartner of this potential corresponding to ψ_1 and λ_1 is

$$u^C[1] = u^D[1] = 2[A^2 - AA_1\,\mathrm{sech}^2(\alpha x)], \tag{37}$$

and the first three eigenfunctions are given by the following:

$$1.\ \ \psi_1 = c_1[\mathrm{sech}(\alpha x)]^{\sqrt{2}A/\alpha}.$$

$$2.\ \ \psi_2 = c_2\sinh(\alpha x)\psi_1.$$

$$3.\ \ \psi_3 = c_3\left(-\cosh^2(\alpha x) + \frac{(2\sqrt{2}A - \alpha)}{\alpha}\sinh^2(\alpha x)\right)\psi_1.$$

In the following we will not determine the constants c_i as they are of minor importance for our results. Secondly, the results become increasingly complicated. For instance, to calculate c_1 we can use

$$\int_0^\infty \operatorname{sech}(ax)^{2\sqrt{2}A/\alpha}\mathrm{d}x = -\frac{1}{\sqrt{2}A}{}_2F_1\left(\frac{\sqrt{2}A}{\alpha},\frac{1}{2},1+\frac{\sqrt{2}A}{\alpha},\frac{\alpha}{\sqrt{2}A}\right), \tag{38}$$

where ${}_2F_1$ is the hypergeometric function. The corresponding eigenvalues can be compactly written as

$$\lambda_n = 2\left(A^2 - \left(A - \frac{(n-1)\alpha}{\sqrt{2}}\right)^2\right). \tag{39}$$

It is convenient to define A_n as

$$A_n \equiv A - \frac{n\alpha}{\sqrt{2}}, \tag{40}$$

such that the eigenvalues read now

$$\lambda_n = 2(A^2 - A_{n-1}^2), \quad n = 1,2,3,\ldots. \tag{41}$$

The first three are explicitly given as follows:

$$\lambda_1 = 0, \quad \lambda_2 = 2\sqrt{2}A\alpha - \alpha^2, \quad \lambda_3 = 4\sqrt{2}A\alpha - 4\alpha^2. \tag{42}$$

Besides Eq. (37) we will also need the following results:

$$\psi^C[1]_2 = \psi^D[1]_2 = c_2\alpha\cosh(\alpha x)\psi_1, \tag{43}$$

$$\psi^C[1]_3 = \psi^D[1]_3 = 4\sqrt{2}c_3A_1\sinh(\alpha x)\cosh(\alpha x)\psi_1. \tag{44}$$

To show explicitly the equality $u^C[2]=u^D[2]$, we start with $u^C[2]$, i.e.,

$$u^C[2] = u - 2\frac{\mathrm{d}^2}{\mathrm{d}x^2}\ln W_2. \tag{45}$$

Since $W_{1,2}=W_2$ and using

$$\frac{W_{1,2}}{W_1} = c_2\alpha\cosh(\alpha x)\psi_1, \tag{46}$$

we have,

$$\ln W_2 = \ln c_2\alpha + \ln\cosh(\alpha x) + 2\ln\psi_1, \tag{47}$$

but also

$$\frac{\mathrm{d}^2}{\mathrm{d}x^2}\ln W_2 = \alpha(\alpha - 2\sqrt{2}A)\operatorname{sech}^2(\alpha x). \tag{48}$$

Finally, with Eq. (36) we arrive at

$$u^C[2] = 2[A^2 - A_1A_2\operatorname{sech}^2(\alpha x)]. \tag{49}$$

Next we turn to the expression for $u^D[2]$, namely,

$$u^D[2] = u^D[1] - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{(\psi^D[1]_2)'}{\psi^D[1]_2}. \tag{50}$$

Taking into account Eq. (43) we obtain

$$\frac{(\psi^D[1]_2)'}{\psi^D[1]_2} = -\sqrt{2}A_1 \tanh(\alpha x), \tag{51}$$

and therefore

$$\frac{\mathrm{d}}{\mathrm{d}x}\frac{(\psi^D[1]_2)'}{\psi^D[1]_2} = -\sqrt{2}\alpha A_1 \operatorname{sech}^2(\alpha x). \tag{52}$$

From this we conclude [see Eq. (50)] that

$$u^D[2] = 2[A^2 - A_1 A_2 \operatorname{sech}^2(\alpha x)], \tag{53}$$

and hence

$$u^C[2] = u^D[2]. \tag{54}$$

The transformed potentials here have almost identical functional form. This is, of course, due to the choice of the potential and need not be so in other cases.

To demonstrate that $\psi^C[2]_s = \psi^D[2]_s$, we calculate $\psi^C[2]_3$ to be

$$\psi^C[2]_3 = \frac{W_3}{W_2} = \frac{\begin{vmatrix} \psi_1 & \psi_2 & \psi_3 \\ \psi_1' & \psi_2' & \psi_3' \\ -\lambda_1\psi_1 & -\lambda_2\psi_2 & -\lambda_3\psi_3 \end{vmatrix}}{\begin{vmatrix} \psi_1 & \psi_2 \\ \psi_1' & \psi_2' \end{vmatrix}} = \lambda_2\psi_2\frac{W_{1,3}}{W_2} - \lambda_3\psi_3. \tag{55}$$

Making use of

$$\lambda_2\psi_2\frac{W_{1,3}}{W_2} = \left(\frac{4\sqrt{2}\lambda_2 c_3 A_1}{\alpha}\right)\sinh^2(\alpha x)\psi_1, \tag{56}$$

this becomes

$$\psi^C[2]_3 = \lambda_3 c_3 \cosh^2(\alpha x)\psi_1(x). \tag{57}$$

On the other hand

$$\psi^D[2]_3 = \frac{\begin{vmatrix} \psi[1]_2 & \psi[1]_3 \\ (\psi[1]_2)' & (\psi[1]_3)' \end{vmatrix}}{\psi[1]_2} = \frac{(\psi[1]_3/\psi[1]_2)'(\psi[1]_2)^2}{\psi[1]_2} = \left(\frac{\psi[1]_3}{\psi[1]_2}\right)'\psi[1]_2 = \lambda_3 c_3 \cosh^2(\alpha x)\psi_1, \tag{58}$$

where on the right hand side we already dropped the distinction between D and C [see Eqs. (43) and (44)]. The simple conclusion that we can draw is

$$\psi^C[2]_3 = \psi^D[2]_3. \tag{59}$$

It is instructive to consider also a case of a solvable, but nonshape invariant potential. Many such cases are known (see Refs. 44–46 and the discussion in Ref. 26) and explicit proofs that these potentials fail to satisfy the shape invariance condition were given. For instance, for the case of the Natanzon potential this was shown in Ref. 47. Many of these potentials are complicated and some, like the Natanzon case, only known in implicit form. Therefore, for the sake of efficient

calculations, it is recommendable to develop first a fast algorithm to perform the desired calculations. We will do exactly that before giving the explicit example of the Ginocchio case. Imagine we would like to calculate $\psi^D[2]_3$. In turns out that the calculation can be greatly simplified by invoking the ratios $h_n=\psi_n'/\psi_n$, where ψ_n is, as usual, the eigenfunction to the ϵ_n eigenvalue. It is now a straightforward exercise to show that

$$\psi^D[2]_3=\frac{\begin{vmatrix}\psi^D[1]_2 & \psi^D[1]_3\\ (\psi^D[1]_2)' & (\psi^D[1])_3)'\end{vmatrix}}{(\psi^D[1]_2)} \tag{60}$$

is equal to

$$\frac{1}{(h_1-h_0)\psi_1}[(h_1-h_0)\{(h_2-h_0)'+(h_2-h_0)h_2\}\psi_1\psi_2-(h_2-h_0)\{(h_1-h_0)'+(h_1-h_0)h_1\}\psi_1\psi_2]. \tag{61}$$

Using the Schrödinger equation the latter simplifies to

$$\psi^D[2]_3=\frac{[\epsilon_0\{h_2-h_1\}-\epsilon_1\{h_2-h_0\}+\epsilon_2\{h_1-h_0\}]}{(h_1-h_0)}\psi_2. \tag{62}$$

It is obvious that, provided we know the functions h_0, h_1, h_2, and ψ_2, this expression allows a fast calculation or the wave function $\psi^D[2]_3$ for arbitrary potential. Crum's result gives

$$\psi^C[2]_3=\frac{W_{2,3}}{W_2}=\frac{W_3}{W_2}=\frac{W_3}{(h_1-h_0)\psi_0\psi_1}, \tag{63}$$

where W_3 is

$$\begin{aligned}W_3&=\begin{vmatrix}\psi_0 & \psi_1 & \psi_2\\ \psi_0' & \psi_1' & \psi_2'\\ \psi_0'' & \psi_1'' & \psi_2''\end{vmatrix}=\begin{vmatrix}\psi_0 & \psi_1 & \psi_2\\ h_0\psi_0 & h_1\psi_1 & h_2\psi_2\\ \psi_0'' & \psi_1'' & \psi_2''\end{vmatrix}\\ &=\begin{vmatrix}\psi_0 & \psi_1 & \psi_2\\ h_0\psi_0 & h_1\psi_1 & h_2\psi_2\\ u-\epsilon_0\psi_0 & u-\epsilon_1\psi_1 & u-\epsilon_1\psi_2\end{vmatrix}=-\begin{vmatrix}\psi_0 & \psi_1 & \psi_2\\ h_0\psi_0 & h_1\psi_1 & h_2\psi_2\\ \epsilon_0\psi_0 & \epsilon_1\psi_1 & \epsilon_2\psi_2\end{vmatrix}.\end{aligned} \tag{64}$$

Hence, taking Eq. (63) into account, we can show that

$$\psi^C[2]_3=\frac{[\epsilon_0\{h_2-h_1\}-\epsilon_1\{h_2-h_0\}+\epsilon_2\{h_1-h_0\}]\psi_0\psi_1\psi_2}{(h_1-h_0)\psi_1\psi_0}, \tag{65}$$

which obviously implies that $\psi^D[2]_3=\psi^C[2]_3$. This, as it stands, is a general proof for a subcase of our general theorem. On purpose above we have used different steps than in the proof of our general theorem. The idea behind it is to demonstrate that in an explicit example we would be only repeating the very same steps as above. It is therefore sufficient to calculate every time only the right hand side of Eq. (65). The equality $\psi^D[2]_3=\psi^C[2]_3$ is guaranteed by Eqs. (62) and (65). We can now apply the results for $\psi^D[2]_3$ by choosing the Ginocchio potential,

$$V(x)=\left\{-\beta^2\upsilon(\upsilon+1)+\frac{1}{4}(1-\beta^2)[5(1-\beta^2)y^4-(7-\beta^2)y^2+2]\right\}(1-y^2), \tag{66}$$

where $y(x)$ satisfies the following differential equation:

$$\frac{dy}{dx} = (1-y^2)[1-(1-\beta^2)y^2], \tag{67}$$

and β and υ are parameters.

The wave functions of this problem are known to be expressible through Gegenbauer polynomials $C_n^{(a)}(x)$, namely,

$$\psi_n = (1-\beta^2)^{\mu_n/2}[g(y)]^{-(2\mu_n+1)/4} C_n^{(\mu_n+1/2)}(f(y)), \tag{68}$$

where

$$g(y) = 1-(1-\beta^2)y^2, \quad f(y) = \frac{\beta y}{\sqrt{g(y)}}. \tag{69}$$

The value of μ_n is connected to the eigenvalue ϵ_n by $\epsilon_n = -\mu_n^2\beta^4$ such that

$$\mu_n\beta^2 = \sqrt{\beta^2(\upsilon+1/2)^2 + (1-\beta^2)(n+1/2)^2} - (n+1/2). \tag{70}$$

The first four Gegenbauer polynomials are given as follows:

$$\begin{gathered} C_0^{(\mu_0+1/2)}(f(y)) = 1, \\ C_1^{(\mu_1+1/2)}(f(y)) = 2(\mu_1+1/2)[f(y)], \\ C_2^{(\mu_2+1/2)}(f(y)) = 2(\mu_2+1/2)(\mu_2+3/2)[f(y)]^2 - (\mu_2+1/2), \\ C_3^{(\mu_3+1/2)}(f(y)) = \frac{4}{3}(\mu_3+1/2)(\mu_3+3/2)(\mu_3+5/2)[f(y)]^3 - 2(\mu_3+1/2)(\mu_3+3/2)[f(y)]. \end{gathered} \tag{71}$$

These functions can be used, in the next step, to compute explicitly the ratios $h_i = \psi_i'/\psi_i$. We obtain

$$\begin{gathered} h_0 = \frac{\psi_0'}{\psi_0} = \frac{[g(y)]'}{g(y)} = -2(1-\beta^2)y(1-y^2), \\ h_1 = \frac{\psi_1'}{\psi_1} = \frac{[g(y)]'}{[g(y)]} + \frac{[f(y)]'}{[f(y)]} = \frac{(1-y^2)}{y}\{1-2(1-\beta^2)y^2\}, \\ h_2 = \frac{\psi_2'}{\psi_2} = \left(\frac{[g(y)]'}{[g(y)]} + \frac{2[f(y)][f(y)]'}{([f(y)]^2 - [1/(2\mu_2+3)])}\right), \end{gathered} \tag{72}$$

where we have used

$$\frac{[f(y)]'}{[f(y)]} = \frac{1}{y}(1-y^2). \tag{73}$$

Noting that the h_i are proportional $(1-y^2)$ and that $h_1 - h_0 = (1-y^2)/y$, we can insert our results into Eq. (65) to obtain

$$\begin{aligned} \psi^C[2]_3 = {} & (1-\beta^2)^{\mu_2/2}(\mu_2+1/2)(2\mu_2+3)[g(y)]^{-(2\mu_2+1)/4} \\ & \times\left\{(\epsilon_2-\epsilon_0)\left([f(y)]^2 - \frac{1}{(2\mu_2+3)}\right) - (\epsilon_1-\epsilon_0)2[f(y)]^2\right\}. \end{aligned} \tag{74}$$

Turning our attention to the potential the superpartner of V in Eq. (66) it is not difficult to see that the superpartner is given by

$$V^D[1] = V^C[1] = V - 2\frac{d^2}{dx^2} \ln W_1$$

$$= V - 2\frac{d}{dr}\frac{[g(y)]'}{g(y)} = V + 4(1-\beta^2)(1-3y^2)^2(1-y^2)[1-(1-\beta^2)y^2]. \tag{75}$$

The second Crum iteration yields

$$V^C[2] = V - 2\frac{d^2}{dx^2} \ln W_2 = V - 2[\{-2 + (1-\beta^2)[5y^2-3]\} + 10y^2(1-\beta^2)](1-y^2)[1-(1-\beta^2)y^2]. \tag{76}$$

To proof that this is equivalent to the second Darboux transformations it is convenient, as was the case with the wave functions, to provide first a general proof for this subcase. Starting with the definition, it is straightforward to show that

$$\psi^D[1]_2 = (h_1 - h_0)\psi_1, \tag{77}$$

which leads to

$$V^D[2] = V^D[1] - 2\frac{d}{dr}\frac{(\psi^D[1]_2)'}{\psi^D[1]_2} = V - 2\frac{d^2}{dr^2} \ln \psi_0 - 2\frac{d^2}{dr^2} \ln(h_1 - h_0)\psi_1$$

$$= V - 2\frac{d^2}{dr^2}\{\ln(h_1 - h_0)\psi_0\psi_1\} = V - 2\frac{d^2}{dr^2} \ln W_2 = V^C[2]. \tag{78}$$

In taking explicit examples we would be only repeating the very same steps as above. This demonstration concludes our two examples.

V. THE CONNECTION BETWEEN SHAPE INVARIANCE AND CRUM TRANSFORMATIONS

In view of the results of the previous section we can now drop the distinction between higher order Darboux (D) and Crum (C) transformations.

Let a denote a set of parameters in the original potential, i.e.,

$$u = u(x;a). \tag{79}$$

The condition for shape invariance of u is given by

$$u[1](x;a) = u(x;f(a)) + R(f(a)), \tag{80}$$

where $u[1](x;a)$ is the first Darboux transform of the original potential, f transforms a into another set $f(a)$, and $R(f(a))$ is a function of the parameters. In the following, we use the usual notation $a_m \equiv f^m(a)$, where m indicates the function f applied m times.

In the preceding section we established an equivalence between higher order Darboux transformation and the Crum result. Since the shape invariance is given in terms of the first order Darboux transformation, it is legitimate to ask if higher order Darboux transformations (Crum transformations) play a role in the Schrödinger equation with shape invariant potentials. As a first step we will prove the following theorem.

Lemma 5.1: *Under the condition of shape invariance one has*

$$\psi_s(x;a_1) = \psi[1]_{s+1}(x;a), \tag{81}$$

up to a multiplicative constant and

$$\lambda_s(a_1) + R(a_1) = \lambda_{s+1}(a). \tag{82}$$

In the above $\psi_s(x;a)$ denotes the eigenfunction to the Hamiltonian with the potential $u(x;a)$ with the eigenvalue λ_s.

These results are not new. But since we will make use of them, we offer here a short proof. We start with initial Sturm-Liouville problem,

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+u(x;a)\right)\psi_s(x;a)=\lambda_s(a)\psi_s(x;a) \tag{83}$$

and

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+u[1](x;a)\right)\psi[1]_s(x;a)=\lambda_s(a)\psi[1]_s(x;a),\quad s>1. \tag{84}$$

Equation (83) is valid for any a, hence we may write

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+u(x;a_1)\right)\psi_s(x;a_1)=\lambda_s(a_1)\psi_s(x;a_1), \tag{85}$$

and add $R(f(a))\psi_s(x;f(a))$ on both sides implying the following identity:

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+u(x;a_1)+R(a_1)\right)\psi_s(x;a_1)=(\lambda_s(a_1)+R(a_1))\psi_s(x;a_1). \tag{86}$$

Due to the shape invariance condition (for the sake of formulating the next Lemma we can say that $u[1]$ and u are pairwise shape invariant) this becomes

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+u[1](x;a)\right)\psi_s(x;a_1)=(\lambda_s(a_1)+R(a_1))\psi_s(x;a_1). \tag{87}$$

Without loss of generality, the spectrum can be ordered as $\lambda_1<\lambda_2<\lambda_3<\cdots$. Hence, $\{\lambda_s(a)\}$, $\{\lambda_s(a_1)\}$, and $\{\lambda_s(a_1)+R(a_1)\}$ are similarly ordered sets. $\psi[1]_{s+1}$ is then an eigenfunction to the ordered spectrum $\lambda_2<\lambda_3<\cdots$. We can conclude that up to a multiplicative factor

$$\psi_s(x;a_1)=\psi[1]_{s+1}(x,a) \tag{88}$$

and

$$\lambda_s(a_1)+R(a_1)=\lambda_{s+1}(a). \tag{89}$$

In preparation of the main theorem of this section we prove the next Lemma.

Lemma 5.2: *By virtue of the the above Lemma and under the condition that u and $u[1]$ are pairwise shape invariant, $u[1]$ and $u[2]$ are also pairwise shape invariant i.e.,*

$$u[2](x;a)=u[1](x;a_1)+R(a_1). \tag{90}$$

The proof can be done in two steps.

1. The condition of shape invariance and the definition of the Darboux transformation allows us to write

$$u(x;a)-2\frac{\mathrm{d}}{\mathrm{d}x}\frac{\psi_1'(x;a)}{\psi_1(x;a)}=u[1](x;a)=u(x;a_1)+R(a_1), \tag{91}$$

which remains valid if we replace a by a_1, i.e.,

$$u(x;a_1)-2\frac{\mathrm{d}}{\mathrm{d}x}\frac{\psi_1'(x;a_1)}{\psi_1(x;a_1)}=u[1](x;a_1)=u(x;a_2)+R(a_2). \tag{92}$$

Hence, we easily obtain

$$u(x;a_1) = u[1](x;a_1) + 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{\psi_1'(x;a_1)}{\psi_1(x;a_1)}. \tag{93}$$

2. Applying the Darboux transformation [Eq. (16)], once again on $u[1](x;a)$, gives

$$u[2](x;a) = u[1](x;a) - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{\psi'[1]_2(x;a)}{\psi[1]_2(x;a)}. \tag{94}$$

On the other hand, using the shape invariance condition leads to

$$u[2](x;a) = u(x;a_1) + R(a_1) - 2\frac{\mathrm{d}}{\mathrm{d}x}\frac{\psi'[1]_2(x;a)}{\psi[1]_2(x;a)}. \tag{95}$$

The result in the first step of the proof, [Eq. (93)] can be used to derive the following equation:

$$u[2](x;a) = u[1](x;a_1) + R(a_1) + 2\frac{\mathrm{d}}{\mathrm{d}x}\left\{\frac{\psi_1'(x;a_1)}{\psi_1(x;a_1)} - \frac{\psi'[1]_2(x;a)}{\psi[1]_2(x;a)}\right\}. \tag{96}$$

If we now apply Eq. (88) from Lemma 5.1 for $s=1$, i.e.,

$$\psi[1]_2(x;a) = \psi_1(x;a_1), \tag{97}$$

we obtain the desired final expression which we wanted to prove, namely,

$$u[2](x;a) = u[1](x;a_1) + R(a_1). \tag{98}$$

For the sake of a more compact notation of the properties of the potential and wave functions, let us now call the property (88) *shape invariance for eigenfunctions* (or better *the two eigenfunctions involved are pairwise shape invariant*) and property (82) *shape invariance for the eigenvalues*. Note that the shape invariance of the wave functions follows from the shape invariance of the potentials. From the shape invariance of the eigenfunction we can, in turn, conclude that the next two pairs of Darboux transformations of the potential are pairwise shape invariant. One is led to the conjecture that the chain continues: from Lemma 5.2 one can show that the next pair of higher order Darboux transformations of eigenfunctions are also pairwise shape invariant, from which it follows that the next higher order pair of Darboux transformed potentials is also pairwise shape invariant. Indeed, we can prove the following theorem extending hereby the notion of shape invariance.

Theorem 5.3: *All neigbouring higher order Darboux transformed potentials and eigenfunctions are pairwise shape invariant. This is to say*,

$$u[k](x;a) = u[k-1]\ (x;a_1) + R(a_1)) \tag{99}$$

and

$$\psi[k]_{s+1}(x;a) = \psi[k-1]_s(x;a_1), \tag{100}$$

up to a multiplicative factor. In more detail, Eq. (99) *implies* Eq. (100) *which, in turn, implies*

$$u[k+1](x;a) = u[k](x;a_1) + R(a_1). \tag{101}$$

The proof proceeds via induction whose first step consists in Lemmas 5.2 and 5.1 or in Eqs. (88) and (98). We assume the hypothesis of the induction to be [Eq. (99) $\Rightarrow$ (100)]. This is sufficient since we start with the original shape invariance condition for potentials and the first step of induction is presented in Lemmas 5.1 and 5.2. We have to show that under this condition

$$\psi[k+1]_{s+1}(x;a) = \psi[k]_s(x;a_1) \tag{102}$$

holds, from which, in turn,

$$u[k+2](x;a) = u[k+1](x;a_1) + R(a_1) \tag{103}$$

follows.

1. We have

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u[k](x;a)\right)\psi[k]_s(x;a) = \lambda_s(a)\psi[k]_s(x;a), \quad s > k. \tag{104}$$

2. Since the above equation is valid for any a, it is also valid when a is replaced by $f(a)$. If we add $R(a_1)\psi[k]_s(x;a_1)$ on both sides and make use of the induction hypothesis we arrive, for $s>k$, at

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u[k+1](x;a)\right)\psi[k]_s(x;a_1) = (\lambda_s(a_1) + R(a_1))\psi[k]_s(x;a_1). \tag{105}$$

   Equation (82) then tells us that

$$\psi[k]_s(x;a_1) = \psi[k+1]_{s+1}(x;a), \tag{106}$$

   up to a multiplicative factor.
3. By definition we have

$$u[k+1](x;a) = u[k](x;a) - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi'[k]_{k+1}(x;a)}{\psi[k]_{k+1}(x;a)}\right), \tag{107}$$

   for any a. Hence also

$$u[k+1](x;a_1) = u[k](x;a_1) - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi'[k]_{k+1}(x;a_1)}{\psi[k]_{k+1}(x;a_1)}\right). \tag{108}$$

   Taking $u[k](x;a_1)$ from this equation and inserting the result in the induction hypothesis, one can easily show that

$$u[k+1](x;a) = u[k+1](x;a_1) + 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi'[k]_{k+1}(x;a_1)}{\psi[k]_{k+1}(x;a_1)}\right) + R(a_1). \tag{109}$$

4. Again per definition we know that

$$u[k+2](x;a) = u[k+1](x;a) - 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi'[k+1]_{k+2}(x;a)}{\psi[k+1]_{k+2}(x;a)}\right). \tag{110}$$

5. Combining the last two equations yields

$$u[k+2](x;a) = u[k+1](x;a_1) + R(a_1) + 2\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\psi'[k]_{k+1}(x;a_1)}{\psi[k]_{k+1}(x;a_1)} - \frac{\psi'[k+1]_{k+2}(x;a)}{\psi[k+1]_{k+2}(x;a)}\right). \tag{111}$$

6. The last step consists in using the already established result [Eq. (106)] to obtain

$$u[k+2](x;a) = u[k+1](x;a_1) + R(a_1), \tag{112}$$

   which completes the proof.

The shape invariance condition (more accurately, the shape invariance between u and $u[1]$) allows one to define a new Hamiltonian of the order s,

$$H_s^{\mathrm{SI}} \equiv -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u(x;a_s) + \sum_{k=1}^{s} R(a_k). \tag{113}$$

Note that this definition makes no reference to higher order Darboux (or Crum) transformations. However, by virtue of the Theorem V.3 we can iterate

$$H_s^{\mathrm{SI}} = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u[1](x;a_{s-1}) + \sum_{k=1}^{s-1} R(a_k) = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u[2](x;a_{s-2}) + \sum_{k=1}^{s-2} R(a_k)$$

$$= \cdots = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + u[s](x;a) = H_s^D. \tag{114}$$

Hence, in view of the above and Theorem 3.1 we can state as a corollary.

Collary 5.4. *Under the condition of shape invariance all three transformations are equal, i.e.,*,

$$H_s^{\mathrm{SI}} = H_s^D = H_s^C. \tag{115}$$

VI. EXAMPLE

We will continue here with our example of the Morse potential, now, however, emphasizing the aspect of shape invariance around Lemmas 5.1 and 5.2 and Theorem 5.3. Indeed, the Morse potential is shape invariant. One defines the action of f as

$$f(A) \equiv A_1 = A - \frac{\alpha}{\sqrt{2}}, \tag{116}$$

in accordance with the notation in Eq. (40). R is identified with

$$R(A_1) = 2(A^2 - A_1^2). \tag{117}$$

Note that

$$\psi_1(x;A_1) = c_1(A_1)[\mathrm{sech}(\alpha x)]^{\sqrt{2}A_1/\alpha} = c_1(A_1)[\mathrm{sech}(\alpha x)]^{(\sqrt{2}A/\alpha)-1} = c\cosh(\alpha x)\psi_1(x;A) \tag{118}$$

immediately leads to

$$\psi[1]_2(x;A) = \psi_1(x;A_1), \tag{119}$$

which is valid up to a multiplicative constant. One also verifies that the equality below

$$\psi_2(x;A_1) = c_2(A_1)\sinh(\alpha x)\psi_1(x;A_1) \tag{120}$$

$$= c_2(A_1)\sinh(\alpha x)\cosh(\alpha x)\psi_1(x;A), \tag{121}$$

together with Eq. (44) has as a consequence the following identity (again up to a constant multiplicative value):

$$\psi[1]_3(x;A) = \psi_2(x;A_1). \tag{122}$$

Equations (119) and (122) are explicit examples of the result [Eq. (81) in Lemma 5.1. Regarding the eigenvalues, i.e., the property (82) in the same lemma, let us first note that another compact notation for Eq. (41) is

$$\lambda_n(A_1) = 2(A_1^2 - A_n^2), \tag{123}$$

which leaves us with the identity

$$\lambda_n(A_1) + R(A_1) = \lambda_{n+1}(A), \tag{124}$$

as it should be according to Lemma 5.1. Finally, we can also give explicit examples regarding Theorem 5.1. Due to the results from Sec. V, we can write

$$u[1](x;A_1) + R(A_1) = 2\left[A_1^2 - A_1\left(A_1 - \frac{\alpha}{\sqrt{2}}\right)\mathrm{sech}^2(\alpha x)\right] + 2(A^2 - A_1^2)$$
$$= 2[A^2 - A_1 A_2\ \mathrm{sech}^2(\alpha x)] = u[2](x;A). \tag{125}$$

This demonstrates in an explicit example the result [Eq. (99)] from Theorem 5.1. Last but not the least, one sees that Eq. (43) can be written as

$$\psi[1]_2(x;A_1) = c_2(A_1)\alpha\cosh(\alpha x)\psi_1(x;A_1), \tag{126}$$

which, according to Eq. (119) can be cast into the following form:

$$\psi[1]_2(x;A_1) = \frac{c_2(A_1)}{c}\alpha\cosh(\alpha x)\psi[1]_2(x;A) = \frac{c_2(A_1)c_2(A)}{c}\alpha^2\cosh^2(\alpha x)\psi_1(x;A) = \bar{c}\psi[2]_3(x;A), \tag{127}$$

with $\bar{c}$ a constant. To arrive at the last result we have used Eq. (57) from which one can also determine the constant $\bar{c}$ in terms of λ_3, $c_2(A)$, $c_2(A_1)$, and $c_3(A)$. Obviously, the above equation falls into the category of explicit examples of Eq. (100). Note that in none of the above examples we have used the actual lemmas or theorems to be exemplified (as it should be if an example carries some meaning).

VII. CONCLUSIONS

In the present work, we have clarified the relations between the Darboux and Crum transformations. We have shown that the latter can be reached iteratively by higher order Darboux transformations. This is valid for the potential as well as the eigenfunctions. If we subject the potential to the condition of shape invariance, another transform (not making use of Crum transformation for $n>1$) is possible [Eq. (113)]. We prove that this is also equivalent to the Crum transform. The main steps of this proof involved establishing Eqs. (99), (100), and (82). The first result, namely Eq. (99), is a generalization of the original shape invariance condition. Note that Eqs. (100) and (82) could be called shape invariance for the wave functions and eigenvalues. The results of the paper help to understand the relation between the different transformations of the Hamiltonian operator. Indeed, in view of our results, one could say that the Crum transformation which appears much more complex than the original Darboux result is essentially an iterative higher order Darboux transformation and therefore not more complex than the former.

APPENDIX: AN APPLICATION OF JACOBI THEOREM

The identity $W(W_n, W_{n-1,s}) = W_{ns}W_{n-1}$ has been used by Crum in the proof of his theorem. We have also made use of it several times in the present paper. It therefore makes sense to sketch a proof of the same.

Let us first establish some notations and definitions. Let $A=[a_{ij}]$ be an $n\times n$ matrix. The determinant of A will be denoted by $|A|$ as usual. We call the minor M_r, the determinant obtained by retaining from A the r lines $i_1, i_2, \ldots, i_r$ and the r columns $k_1, k_2, \ldots, k_r$. One defines the complement of the minor M_r as the determinant obtained from A by dropping the r lines $i_1, i_2, \ldots, i_r$ and the r columns $k_1, k_2, \ldots, k_r$. This complement will be denoted by M_r^c. One then defines $M^{(r)}$

$$M^{(r)} = (-1)^{i_1+i_2+\ldots+i_r+k_1+k_2+\ldots+k_r}M_r^c. \tag{A1}$$

Furthermore, let Δ be the matrix of the cofactors of A,

$$\Delta = \begin{vmatrix} A_{11} & A_{12} & \cdots & A_{1n} \\ A_{21} & A_{22} & \cdots & A_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ A_{n1} & A_{n2} & \cdots & A_{nn} \end{vmatrix}, \tag{A2}$$

and M_r and M_r' the minors of $|A|$ and Δ, respectively.

Theorem (Jacobi): *With these notations, the theorem of Jacobi asserts that*

$$M_r' = |A|^{r-1} M^{(r)}. \tag{A3}$$

Before proceeding we make a small diversion to an example of the application of the above theorem starting with a Wronskian composed of ψ_1, ψ_2, ψ_3, and ψ_s, i.e.,

$$|A| \equiv W_{3,s} = \begin{vmatrix} \psi_1 & \psi_2 & \psi_3 & \psi_s \\ \psi_1' & \psi_2' & \psi_3' & \psi_s' \\ \psi_1'' & \psi_2'' & \psi_3'' & \psi_s'' \\ \psi_1''' & \psi_2''' & \psi_3''' & \psi_s''' \end{vmatrix}. \tag{A4}$$

The matrix of the cofactors is then given by

$$\Delta = \begin{vmatrix} + \begin{vmatrix} \psi_2' & \psi_3' & \psi_s' \\ \psi_2'' & \psi_3'' & \psi_s'' \\ \psi_2''' & \psi_3''' & \psi_s''' \end{vmatrix} & - \begin{vmatrix} \psi_1' & \psi_3' & \psi_s' \\ \psi_1'' & \psi_3'' & \psi_s'' \\ \psi_1''' & \psi_3''' & \psi_s''' \end{vmatrix} & + \begin{vmatrix} \psi_1' & \psi_2' & \psi_s' \\ \psi_1'' & \psi_2'' & \psi_s'' \\ \psi_1''' & \psi_2''' & \psi_s''' \end{vmatrix} & - \begin{vmatrix} \psi_1' & \psi_2' & \psi_3' \\ \psi_1'' & \psi_2'' & \psi_3'' \\ \psi_1''' & \psi_2''' & \psi_3''' \end{vmatrix} \\ - \begin{vmatrix} \psi_2 & \psi_3 & \psi_s \\ \psi_2'' & \psi_3'' & \psi_s'' \\ \psi_2''' & \psi_3''' & \psi_s''' \end{vmatrix} & + \begin{vmatrix} \psi_1 & \psi_3 & \psi_s \\ \psi_1'' & \psi_3'' & \psi_s'' \\ \psi_1''' & \psi_3''' & \psi_s''' \end{vmatrix} & - \begin{vmatrix} \psi_1 & \psi_2 & \psi_s \\ \psi_1'' & \psi_2'' & \psi_s'' \\ \psi_1''' & \psi_2''' & \psi_s''' \end{vmatrix} & + \begin{vmatrix} \psi_1 & \psi_2 & \psi_3 \\ \psi_1'' & \psi_2'' & \psi_3'' \\ \psi_1''' & \psi_2''' & \psi_3''' \end{vmatrix} \\ + \begin{vmatrix} \psi_2 & \psi_3 & \psi_s \\ \psi_2' & \psi_3' & \psi_s' \\ \psi_2''' & \psi_3''' & \psi_s''' \end{vmatrix} & - \begin{vmatrix} \psi_1 & \psi_3 & \psi_s \\ \psi_1' & \psi_3' & \psi_s' \\ \psi_1''' & \psi_3''' & \psi_s''' \end{vmatrix} & + \begin{vmatrix} \psi_1 & \psi_2 & \psi_s \\ \psi_1' & \psi_2' & \psi_s' \\ \psi_1''' & \psi_2''' & \psi_s''' \end{vmatrix} & - \begin{vmatrix} \psi_1 & \psi_2 & \psi_3 \\ \psi_1' & \psi_2' & \psi_3' \\ \psi_1''' & \psi_2''' & \psi_3''' \end{vmatrix} \\ - \begin{vmatrix} \psi_2 & \psi_3 & \psi_s \\ \psi_2' & \psi_3' & \psi_s' \\ \psi_2'' & \psi_3'' & \psi_s'' \end{vmatrix} & + \begin{vmatrix} \psi_1 & \psi_3 & \psi_s \\ \psi_1' & \psi_3' & \psi_s' \\ \psi_1'' & \psi_3'' & \psi_s'' \end{vmatrix} & - \begin{vmatrix} \psi_1 & \psi_2 & \psi_s \\ \psi_1' & \psi_2' & \psi_s' \\ \psi_1'' & \psi_2'' & \psi_s'' \end{vmatrix} & + \begin{vmatrix} \psi_1 & \psi_2 & \psi_3 \\ \psi_1' & \psi_2' & \psi_3' \\ \psi_1'' & \psi_2'' & \psi_3'' \end{vmatrix} \end{vmatrix}.$$

We choose as lines and columns: $(i_1, i_2) = (3,4) = (k_1, k_2)$. Applying the Jacobi theorem gives us

$$\begin{vmatrix} + \begin{vmatrix} \psi_1 & \psi_2 & \psi_s \\ \psi_1' & \psi_2' & \psi_s' \\ \psi_1''' & \psi_2''' & \psi_s''' \end{vmatrix} & - \begin{vmatrix} \psi_1 & \psi_2 & \psi_3 \\ \psi_1' & \psi_2' & \psi_3' \\ \psi_1''' & \psi_2''' & \psi_3''' \end{vmatrix} \\ - \begin{vmatrix} \psi_1 & \psi_2 & \psi_s \\ \psi_1' & \psi_2' & \psi_s' \\ \psi_1'' & \psi_2'' & \psi_s'' \end{vmatrix} & + \begin{vmatrix} \psi_1 & \psi_2 & \psi_3 \\ \psi_1' & \psi_2' & \psi_3' \\ \psi_1'' & \psi_2'' & \psi_3'' \end{vmatrix} \end{vmatrix} = W_{3,s} \begin{vmatrix} \psi_1 & \psi_2 \\ \psi_1' & \psi_2' \end{vmatrix}. \tag{A5}$$

Using Lemma 2.2 the left hand side takes the form

$$\begin{vmatrix} (\mathrm{d}/\mathrm{d}x) W_{2,s} & (\mathrm{d}/\mathrm{d}x) W_3 \\ W_{2,s} & W_3 \end{vmatrix}, \tag{A6}$$

such that we can write

$$\begin{vmatrix} (\mathrm{d}/\mathrm{d}x)W_{2,s} & -(\mathrm{d}/\mathrm{d}x)W_3 \\ -W_{2,s} & W_3 \end{vmatrix} = W_{3,s}W_2. \tag{A7}$$

Explicitly, this implies the following equality:

$$W_{3,s}W_2 = W_3\frac{\mathrm{d}}{\mathrm{d}x}W_{2,s} - W_{2,s}\frac{\mathrm{d}}{\mathrm{d}x}W_3 = W(W_3, W_{2,s}). \tag{A8}$$

The proof of the general case does not require any new procedure and follows essentially the steps outlined in the example. Let W_{ns} be the Wronskian of the $n+1$ functions $\psi_1, \ldots, \psi_n, \psi_s$, namely,

$$|A| = W_{n,s} = \begin{vmatrix} \psi_1 & \psi_2 & \cdots & \psi_n & \psi_s \\ \psi_1' & \psi_2' & \cdots & \psi_n' & \psi_s' \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \psi_1^{(n-1)} & \psi_2^{(n-1)} & \cdots & \psi_n^{(n-1)} & \psi_s^{(n-1)} \\ \psi_1^{(n)} & \psi_2^{(n)} & \cdots & \psi_n^{(n)} & \psi_s^{(n)} \end{vmatrix}, \tag{A9}$$

and Δ the matrix of the cofactors of $W_{n,s}$. We would like to apply the Jacobi theorem for the choice

$$(i_1, i_2) = (n, n+1) = (k_1, k_2), \tag{A10}$$

such that $r=2$. In this case we need

$$M_r' = \begin{vmatrix} +W_{n-1,s}' & -W_n' \\ -W_{n-1,s} & +W_n \end{vmatrix} = W(W_n, W_{n-1,s}), \tag{A11}$$

where we have used explicitly the result of Lemma 2.2. Clearly, we have,

$$M^{(r)} = W_{n-1}, \tag{A12}$$

such that the Jacobi theorem for the Wronskian A can be stated as

$$W(W_n, W_{n-1,s}) = W_{ns}W_{n-1}, \tag{A13}$$

which proves Lemma 2.3.

(Received 24 July 2006; accepted 23 October 2006; published online 14 December 2006)

In this study, we construct the parametric-time coherent states for the negative energy states of the generalized MIC-Kepler system, in which a charged particle is in a monopole vector potential, a Coulomb potential, and a Bohm-Aharonov potantial. We transform the system into four isotropic harmonic oscillators and construct the parametric-time coherent states for these oscillators. Finally, we compactify these states into the physical time coherent states for the generalized MIC-Kepler system. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2399362]

I. INTRODUCTION

First, Schrödinger derived the coherent states for the one-dimensional linear harmonic oscillator and also pointed out the construction of the localized nonspreading wave packets for the electrons in a Coulomb potential.[1] The coherent states are eigenstates of the lowering operator of the harmonic oscillator with complex eigenvalues. The expectation values of the dynamical variables, i.e., the position and the momentum, satisfy the classical equations of motion. These states are the most classical ones, with minimum uncertainty and nondispersion in the physical time, and have time dependent probabilities. In this respect, they are the most useful states to discuss the time dependent process and the classical limit of the quantum systems. The coherent states have been used in the quantum theory of the electrodynamics in 1963 which is known as the Glauber states.[2] Recently, Robinett reviewed the theoretical and numerical studies on the wave packets.[3] Earlier, Brown, and later Nieto and Simmons, developed a general formalism to construct coherent states for the different potentials.[4,5] In 1986, Bhaumik *et al.* constructed coherent states for the Kepler problem and showed that these states are dispersed.[6] Here, the authors discuss the dynamical symmetries of the problem, $SU(2) \times SU(2)$ and try to construct the eigenstates of the lowering operators of this group. They transform the problem into the four harmonic oscillators which evolve in the physical time. ten Wolde *et al.* observed a radially localized electron wave packet.[7]

Since the dynamical symmetry groups are related to the stationary states of a problem, they do not give the (physical) time evolution of the related eigenstates. Even in the classical mechanics, we do not know the time evolution of the physical systems explicitly, except for the free particle and for the particle in a linear or a quadratic potential. Therefore, the time evolution of the classical Kepler problem is given in terms of a parametric time or the eccentric anomaly.[8] In 1967, Kustaanheimo-Stiefel (KS) developed a mapping technique in order to transform the 3D classical Kepler problem into the four isotropic harmonic oscillators which evolve in a parametric time.[9] However, this mapping is nonholonomic and a highly technical one.

Later, KS transformation is used by Duru and Kleinert to find the solution of the Kepler problem via the Feynman path integrals.[10] In this formulation, they introduce a new nondynamical, free particle coordinate for the particle and map this system into the four harmonic oscillators which evolve in a parametric time. They also add the (physical) time as another coordinate of the particle.

[a)]Electronic mail: nuriunal@akdeniz.edu.tr

Recently, Toyoda and Wakayama transformed the Kepler problem into the four harmonic oscillators, which evolve in the parametric time, by using the squared parabolic coordinates and investigated coherent states for the Kepler problem.[11]

Generally, the Feynman path integrals are used to evaluate the transition amplitudes between the configuration space eigenstates. In 1998, we derived the transition amplitudes of the linear harmonic oscillator between the eigenstates of its lowering operator, by using a complementary formulation of the Feynman path integrals, and defined the coherent states in terms of these amplitudes.[12] Recently, the coherent states of the Kepler problem have been derived by using the mapping technique given in Ref. 10 and consider the transition amplitudes of the four harmonic oscillators between the eigenstates of their lowering operators.[13] Here, it is also shown that the expectation values for the coordinates of the electron satisfy the Kepler laws and oscillate in the parametric time. The uncertainties in these expectation values are not constant, but they oscillate in the parametric time. Later, this technique has been applied to derive the coherent states for a particle in the Morse potential or in a 5D Coulomb potential.[14,15] The coherent states in Ref. 11 have been improved during the same period[16] and these states are the same with the coherent states in Refs. 13 and 17.

A natural generalization of the Coulomb problem is given by Zwanziger and rediscovered by McIntosh and Cisneros.[18] It is known as the MIC-Kepler system and described by the Hamiltonian in a Coulomb field as well as a Dirac's monopole field

$$H_1 = \frac{(\mathbf{p} - s\mathbf{A})^2}{2M} + \frac{s^2}{2Mr^2} - \frac{Ze^2}{r},$$

where s is the monopole number and the vector potential, $\mathbf{A}$ is given by

$$\mathbf{A} = \frac{1}{r(r-z)}(y,-x,0) \quad \text{with rot } \mathbf{A} = \frac{\hat{r}}{r^2}.$$

The MIC-Kepler system gives the generalizations of the conserved angular momentum and of the Runge-Lenz vectors.

Another generalization of the Coulomb problem is the particle in the Coulomb and Bohm-Aharonov potential.[19] This system is described by the Hamiltonian

$$H_2 = \frac{1}{2M}\mathbf{p}^2 - \frac{Ze^2}{r} + \frac{C_1}{2Mr(r-z)} + \frac{C_2}{2Mr(r+z)},$$

where C_1 and C_2 are non-negative constants.

The following noncentral Hamiltonian is proposed as one of the generalization of these two type of potentials and known as the generalized MIC-Kepler system:[20]

$$H = \frac{1}{2M}(\mathbf{p} - s\mathbf{A})^2 + \frac{s^2}{2Mr^2} - \frac{Ze^2}{r} + \frac{C_1}{2Mr(r-z)} + \frac{C_2}{2Mr(r+z)}.$$

The Hamiltonian, H, is written in the spherical coordinates as

$$H = \frac{1}{2M}\left(p_r^2 + \frac{p_\theta^2}{r^2} + \frac{p_\phi^2}{r^2 \sin^2\theta}\right) + V(r,\theta),$$

where the noncentral potential, $V(r,\theta)$, is

$$V(r,\theta) = -\frac{f}{r} + \frac{B + C\cos\theta}{r^2 \sin^2\theta}, \tag{1}$$

$$f = Ze^2, \quad B = \frac{(C_1 + C_2) - 2s(p_\phi - s)}{2M}, \quad C = \frac{(C_1 - C_2) - 2s(p_\phi - s)}{2M}.$$

The Hartmann potential is an example of the special cases of this potential with

$$f = 2a_0 \eta\sigma^2 \epsilon_0, \quad B = q\epsilon_0 (a_0 \eta\sigma)^2, \quad C = 0,$$

where a_0 is the Bohr radius, ϵ_0 is the ground state energy of the hydrogen atom, q is a real parameter, and η and σ are positive real numbers with values ranging from about 1 to 10. It is proposed as a model for the ring-shaped organic molecules like cyclic polyenes and benzene.[21] The combined Coulomb and Aharonov-Bohm potential is another example of this noncentral potential[19] and it can be obtained by taking $C=0$ and $s=0$ in Eq. (1), respectively. Both $B=0$ and $C=s=0$ give the Coulomb potential.

The Schrödinger equation for the particle in the Hartmann potential is discussed by using the separation of the variables method,[22,23] KS transformation and the path integral method, the supersymmetry and shape invariance, the usual methods,[24–35] or the Nikiforov-Uvarov method.[36] The "accidental" degeneracy of the spectrum and "hidden" symmetry of the Hartmann potential are also discussed.[37–39] The coherent states for the Hartmann potential have been derived.[40]

The aim of this study is to construct the coherent states for the generalized MIC-Kepler system by using the path integral formalism proposed in Ref. 13. Instead of the KS transformation, we use the squared parabolic coordinates, in order to transform the problem into the four isotropic harmonic oscillators, which evolve in a parametric time.[41] We notice that, the configuration spaces of the four oscillators for noncentral potentials are different from those for the Kepler problem. We can construct the coherent states of these oscillators and compactify these states into the three-dimensional generalized MIC-Kepler system. For the completeness, we also find the expressions of the wave functions in terms of the energy eigenfunctions of the system for both the parabolic and the spherical coordinates.

The paper is organized as follows: In Sec. II, we discuss the transformation of the action for the classical particle in the noncentral potential into the four isotropic harmonic oscillators. In Sec. III, we derive the coherent states in terms of the energy eigenstates of the four oscillators in the parametric time. In Sec. IV, we give the wave function of the coherent states in configuration space by using the energy eigenstates of the system for the parabolic and the spherical coordinates.

II. ACTION FOR THE GENERALIZED MIC-KEPLER SYSTEM

The parabolic coordinates are given as

$$\xi = r(1 - \cos\theta),$$

$$\eta = r(1 + \cos\theta),$$

$$\phi = \phi.$$

First, we express $V(r,\theta)$, in the parabolic coordinates, (ξ, η, ϕ),

$$V(\zeta,\eta) = -\frac{2f}{\zeta+\eta} + \frac{B}{\zeta\eta} - \frac{C(\zeta-\eta)}{\zeta\eta(\zeta+\eta)}. \tag{2}$$

Hence, the classical Hamiltonian can be written in the parabolic coordinates as

$$H(\zeta,\eta,\phi) = \frac{4}{2M(\zeta+\eta)}[\zeta p_\zeta^2 + \eta p_\eta^2] + \frac{1}{2M\eta\zeta} p_\phi^2 + V(\zeta,\eta). \tag{3}$$

Using Eq. (3) we write the action as

$$A=\int \mathrm{d}t\left[p_\xi\dot{\xi}+p_\eta\dot{\eta}+p_\phi\dot{\phi}-\frac{4}{2M(\xi+\eta)}(p_\xi^2\xi+p_\eta^2\eta)-\frac{1}{2M\eta\zeta}p_\phi^2+\frac{2f}{\zeta+\eta}-\frac{B}{\zeta\eta}+\frac{C(\zeta-\eta)}{\zeta\eta(\zeta+\eta)}\right]. \tag{4}$$

Next, we perform the following canonical transformation in Eq. (4),

$$\zeta=\frac{\alpha^2}{2}u^2,\ \ 0\le u<\infty,$$

$$\eta=\frac{\alpha^2}{2}v^2,\ \ 0\le v<\infty. \tag{5}$$

Here, a parameter, α, is introduced in order to obtain the dimensionless units for u and v. This implies the following relations for the canonical conjugate momenta,

$$p_u=\alpha\sqrt{2\zeta}p_\zeta,$$

$$p_v=\alpha\sqrt{2\eta}p_\eta. \tag{6}$$

We use Eqs. (5) and (6), and rewrite Eq. (4) as

$$A=\int \mathrm{d}t\left\{p_u\dot{u}+p_v\dot{v}+p_\phi\dot{\phi}-\frac{4}{\alpha^2(u^2+v^2)}\times\left[\frac{1}{2M\alpha^2}\left(p_u^2+p_v^2+\frac{p_\phi^2+2M(B-C)}{u^2}+\frac{p_\phi^2+2M(B+C)}{v^2}\right)-f\right]\right\}. \tag{7}$$

In Eq. (8), the term

$$\left(p_u^2+p_v^2+\frac{p_\phi^2+2M(B-C)}{u^2}+\frac{p_\phi^2+2M(B+C)}{v^2}\right),$$

is similar to the Hamiltonian of the particle in the four-dimensional space with the azimuthal momenta as $[p_\phi^2+2M(B\mp C)]^{1/2}$. We introduce two dummy momenta, p_{ϕ_1} and p_{ϕ_2}, into the action by Lagrange multipliers, $\frac{\mathrm{d}\phi_1}{\mathrm{d}t}$ and $\frac{\mathrm{d}\phi_2}{\mathrm{d}t}$, and transform the system into four dimensions:

$$A=\int \mathrm{d}t\left\{p_u\dot{u}+p_v\dot{v}+p_\phi\dot{\phi}+\frac{\mathrm{d}\phi_1}{\mathrm{d}t}[p_{\phi_1}-\sqrt{p_\phi^2+2M(B-C)}]+\frac{\mathrm{d}\phi_2}{\mathrm{d}t}[p_{\phi_2}-\sqrt{p_\phi^2+2M(B+C)}]-\frac{4}{\alpha^2(u^2+v^2)}\left[\frac{1}{2M\alpha^2}\left(p_u^2+p_v^2+\frac{p_{\phi_1}^2}{u^2}+\frac{p_{\phi_2}^2}{v^2}\right)-f\right]\right\}. \tag{8}$$

To eliminate the $[4/\alpha^2(u^2+v^2)]$ term in Eq. (8), we introduce a new time parameter, s, defined as

$$\frac{\mathrm{d}t}{\mathrm{d}s}=\frac{\alpha^2(u^2+v^2)}{4}. \tag{9}$$

We also add the physical time, t, into the physical coordinates of the particle and represent the dynamics of the particle in terms of the parametric time, s. Then we rewrite the action in terms of the parametric time as the following:

$$A=\int \mathrm{d}s\left\{p_u\frac{\mathrm{d}u}{\mathrm{d}s}+p_v\frac{\mathrm{d}v}{\mathrm{d}s}+ +p_\phi\frac{\mathrm{d}\phi}{\mathrm{d}s}+(-p_o)\left(\frac{\mathrm{d}t}{\mathrm{d}s}-\frac{\alpha^2(u^2+v^2)}{4}\right)+\frac{\mathrm{d}\phi_1}{\mathrm{d}s}[p_{\phi_1}-\sqrt{p_\phi^2+2M(B-C)}]\right.$$
$$\left.+\frac{d\phi_2}{ds}[p_{\phi_2}-\sqrt{p_\phi^2+2M(B+C)}]-\left[\frac{1}{2M\alpha^2}\left(p_u^2+p_v^2+\frac{p_{\phi_1}^2}{u^2}+\frac{p_{\phi_2}^2}{v^2}\right)-f\right]\right\}, \tag{10}$$

where p_o is another Lagrange multiplier corresponding to the momentum, which is a conjugate to physical time, t. Here, we only consider the bound states, $p_o<0$. We represent the position of the particle in the four dimensional space by the two sets of the polar coordinates

$$\mathbf{u}=(u\cos\phi_1,\ u\sin\phi_1,\ v\cos\phi_2,\ v\sin\phi_2). \tag{11}$$

We notice that ϕ_1 and ϕ_2 are two dummy coordinates in the interval of $-\infty<\phi_1,\ \phi_2<+\infty$. Then the action in Eq. (9), becomes

$$A=\int \mathrm{d}s\left\{\mathbf{p_u}\cdot\frac{\mathrm{d}\mathbf{u}}{\mathrm{d}s}+p_\phi\frac{\mathrm{d}\phi}{\mathrm{d}s}+(-p_o)\frac{\mathrm{d}t}{\mathrm{d}s}-H_4-\left[\frac{\mathrm{d}\phi_1}{\mathrm{d}s}\sqrt{p_\phi^2+2M(B+C)}+\frac{\mathrm{d}\phi_2}{\mathrm{d}s}\sqrt{p_\phi^2+2M(B-C)}\right]\right\}, \tag{12}$$

where the terms in the square bracket are the total derivatives, as p_o and p_ϕ are the conserved quantities. In Eq. (12), H_4 is given as

$$H_4=\frac{1}{2M\alpha^2}[(\mathbf{p_u})^2+(M\omega)^2\alpha^4(\mathbf{u})^2]-f. \tag{13}$$

Here ω is the frequency of the four isotropic oscillators and are given as $\sqrt{-p_o/2M}$. We choose the scale factor α^2 such that $M\omega\alpha^2=1$. The term (H_4+f) corresponds to the Hamiltonian of the four isotropic harmonic oscillators. Hence, we consider them separately and discuss the action of the four oscillator system:

$$A_\omega=\int \mathrm{d}s\left\{\mathbf{p_u}\cdot\frac{\mathrm{d}\mathbf{u}}{\mathrm{d}s}-\frac{\omega}{2}\left[(\mathbf{p_u})^2+(\mathbf{u})^2-\frac{2f}{\omega}\right]\right\}. \tag{14}$$

We define the holomorphic coordinates

$$\mathbf{a}=\begin{pmatrix}a_1\\a_2\\a_3\\a_4\end{pmatrix}$$

as

$$a_i=\frac{1}{\sqrt{2}}(u_i+ip_{u_i}),\quad i=1,\ldots,4. \tag{15}$$

We also define the conjugate dynamical variables $\mathbf{a}^*=(a_1^*,\ ,a_4^*)$ as

$$a_i^*=\frac{1}{\sqrt{2}}(u_i-ip_{u_i}). \tag{16}$$

Then, we rewrite the action A_ω in terms of the holomorphic coordinates $\mathbf{a}$ and $\mathbf{a}^*$ as

$$A_\omega[\mathbf{a}^*(s_b),\ s_b;\mathbf{a}(s_a),s_a]=f(s_b-s_a)+\int_{s_a}^{s_b}\mathrm{d}s\left[\frac{1}{2i}\left(\frac{\mathrm{d}\mathbf{a}^*}{\mathrm{d}s}\cdot\mathbf{a}-\mathbf{a}^*\cdot\frac{\mathrm{d}\mathbf{a}}{\mathrm{d}s}\right)-\omega(\mathbf{a}^*\cdot\mathbf{a})\right], \tag{17}$$

where we omitted the total derivative term, $\frac{1}{2}\Sigma_{i=1}^2\mathbf{p}_u\cdot\mathbf{u}|_a^b$, in the action, A_ω.

In Eq. (12), H_4 is the new Hamiltonian or the energy of the particle in parametric time, s. H_4 is constant, even taking the value of zero. The physical energy of the classical particle is

$$p_o = -2Mf^2(\mathbf{a}^* \cdot \mathbf{a})^{-2}.$$

III. COHERENT STATES FOR THE FOUR OSCILLATORS

The kernel of the four oscillator system is defined in Ref. 13 as

$$K_\omega[\mathbf{a}^*(s_b), s_b; \mathbf{a}(s_a), s_a] = e^{i(f-2\omega)(s_b-s_a)} \int \frac{D\mathbf{a}^* \cdot D\mathbf{a}}{[2\pi i]^4} \times e^{i\left\{\int_{s_a}^{s_b} ds\left[\frac{1}{2i}\left(\frac{d\mathbf{a}^*}{ds}\cdot\mathbf{a} - \mathbf{a}^*\cdot\frac{d\mathbf{a}}{ds}\right) - \omega(\mathbf{a}^*\cdot\mathbf{a})\right]\right\}}, \quad (18)$$

where we take $\hbar = 1$ and the term 2ω in the exponential comes from the quantum ordering terms between the operators $\hat{a}_i^*$ and $\hat{a}_i$. We perform a_i^* and a_i integrations by the method developed in Ref. 12. Then the kernel K_ω becomes

$$K_\omega[\mathbf{a}^*(s_b),\ \mathbf{a}(s_a); (s_b - s_a)] = e^{i(f-2\omega)(s_b-s_a)} \times e^{\mathbf{a}^*(s_b)\cdot\mathbf{a}(s_a)e^{-i\omega(s_b-s_a)}}. \quad (19)$$

The coordinate transformation in Eq. (5) is double valued. Hence, we also consider the kernel $K_\omega[-\mathbf{a}^*(s_b),\ \mathbf{a}(s_a); (s_b - s_a)]$. Since we are interested in a spinless system, the total transition amplitude, $K_\omega^{(+)}$, is the symmetric sum of these two kernels:

$$K_\omega^{(+)}[\mathbf{a}^*(s_b),\ \mathbf{a}(s_a); (s_b - s_a)] = 2e^{i(f-2\omega)(s_b-s_a)} \times \cosh[\mathbf{a}^*(s_b)\cdot\mathbf{a}(s_a)e^{-i\omega(s_b-s_a)}]. \quad (20)$$

We can represent the kernel $K_\omega^{(+)}$ by expanding the exponential terms in Eq. (21) into a power series of $a_i^*(s_b)a_i(s_a)$ for each value of i:

$$K_\omega^{(+)}[\mathbf{a}^*(s_b), \boldsymbol{\lambda}(s_a); (s_b - s_a)] = \sum_{n_{1,2,3,4}=0}^{\infty} [1 + (-1)^{n_1+n_2+n_3+n_4}] \times e^{-i[(n_1+n_2+n_3+n_4+2)\omega - f](s_b-s_a)} \prod_{i=1}^{4} \frac{(a_i^*\lambda_i)^{n_i}}{\Gamma(n_i+1)}, \quad (21)$$

where $n_1+n_2+n_3+n_4$ is an even number. We omit the s_b dependence of the final eigenvalues a_i^* and s_a dependence of the eigenvalues λ_i. If we parametrize the quantum numbers n_i in terms of the radial and angular quantum numbers of the four oscillators as

$$n_1 = (n_r)_1 + \frac{1}{2}(|m_1| + m_1),$$

$$n_2 = (n_r)_1 + \frac{1}{2}(|m_1| - m_1),$$

$$n_3 = (n_r)_2 + \frac{1}{2}(|m_2| + m_2),$$

$$n_4 = (n_r)_2 + \frac{1}{2}(|m_2| - m_2),$$

and denote the final eigenstates by $a_\pm^*$ and $b_\pm^*$ and initial eigenstates by $\kappa_\pm$ and $\lambda_\pm$,

$$a_{\pm}^{*}=\frac{(a_1^{*}\mp ia_2^{*})}{\sqrt{2}},\quad b_{\pm}^{*}=\frac{(a_3^{*}\mp ia_4^{*})}{\sqrt{2}},$$

$$\kappa_{\pm}=\frac{(a_1\pm ia_2)}{\sqrt{2}},\quad \lambda_{\pm}=\frac{(a_3\pm ia_4)}{\sqrt{2}},\tag{22}$$

then

$$K_{\omega}^{(+)}[a_{\pm}^{*},\,b_{\pm}^{*},s_b;\kappa_{\pm},\lambda_{\pm},s_a]=\sum_{(n_r)_{1,2}=0}^{\infty}\sum_{m_{1,2}=-\infty}^{+\infty}[1+(-1)^{|m_1|+|m_2|}]\times e^{-2i\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1-\frac{f}{2}\right]\omega(s_b-s_a)}$$
$$\times\Pi_{\epsilon=+,-}\frac{(a_{\pm}^{*}\kappa_{\pm})^{(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)}}{\Gamma\left[(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)+1\right]}\times\frac{(b_{\pm}^{*}\lambda_{\pm})^{(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)}}{\Gamma\left[(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)+1\right]}.\tag{23}$$

Here, $(n_r)_{1,2}$ and $m_{1,2}$ are the radial and angular quantum numbers of the oscillators. In the derivation of Eq. (24), we assume that $-\pi\leq\phi_{1,2}<+\pi$. However, for the physical problem, there is no periodicity in $\phi_{1,2}$ and therefore, $-\infty<\phi_1,\ \phi_2<+\infty$. If we perform the scale transformation $\phi_{1,2}\rightarrow\frac{2\pi}{2L}\phi_{1,2}$ and $p_{\phi_{1,2}}\rightarrow\frac{2L}{2\pi}p_{\phi_{1,2}}$ and then evaluate the limit $L\rightarrow\infty$ in Eq. (24) by considering the present physical problem,

$$K_{\omega}^{(+)}[a_{\pm}^{*},\,b_{\pm}^{*},s_b;\kappa_{\pm},\lambda_{\pm},s_a]=\sum_{(n_r)_{1,2}=0}^{\infty}\int_{-\infty}^{+\infty}dm_1\int_{-\infty}^{+\infty}dm_2F_{(n_r)_1,m_1,(n_r)_2,m_2}$$
$$\times e^{-2i\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1-\frac{f}{2}\right]\omega(s_b-s_a)},\tag{24}$$

where

$$F_{(n_r)_1,m_1,(n_r)_2,m_2}(a_{\pm}^{*}\kappa_{\pm},b_{\pm}^{*}\lambda_{\pm})=(1+(-1)^{|m_1|+|m_2|})\times\Pi_{\epsilon=+,-}\frac{(a_{\epsilon}^{*}\kappa_{\epsilon})^{(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)}}{\Gamma\left[(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)+1\right]}$$
$$\times\frac{(b_{\epsilon}^{*}\lambda_{\epsilon})^{(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)}}{\Gamma\left[(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)+1\right]}.$$

For the four oscillators, the energy eigenstates are

$$|(n_r)_{1,2},m_{1,2}\rangle=\Pi_{\epsilon=+,-}\frac{(a_{\pm}^{\dagger})^{(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)}}{\sqrt{\Gamma\left[(n_r)_2+\frac{1}{2}(|m_1|+\epsilon m_1)+1\right]}}\times\frac{(b_{\pm}^{\dagger})^{(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)}}{\sqrt{\Gamma\left[(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)+1\right]}}|0\rangle.\tag{25}$$

$K_{\omega}^{(+)}$ is the matrix elements of the parametric-time evolution operator, U between the initial eigenstates of the operators $\hat{\mathbf{a}}_i$, $\kappa_{\pm}$, $\lambda_{\pm}$, and the final eigenstates of the operators $\hat{\mathbf{a}}_i$, $a_{\pm}$, $b_{\pm}$. If we expand $K_{\omega}^{(+)}$ in terms of the oscillator energy eigenstates $|(n_r)_{1,2},m_{1,2}\rangle$ as

$$K_{w}^{(+)}[a_{\pm}^{*},\,b_{\pm}^{*},s_b;\kappa_{\pm},\lambda_{\pm},s_a]=\sum_{(n_r)_{1,2}=0}^{\infty}\int_{-\infty}^{+\infty}dm_1\int_{-\infty}^{+\infty}dm_2\langle(n_r)_{1,2},m_{1,2}|a_{\pm}b_{\pm}\rangle^{*}$$
$$\times\langle(n_r)_{1,2},m_{1,2}|U(s_b-s_a)|\kappa_{\pm},\lambda_{\pm}\rangle.$$

Here, $|a_{\pm},b_{\pm}\rangle$ is the final coherent state and $U(s_b-s_a)|\kappa_{\pm},\lambda_{\pm}\rangle$ is the time evolution of the initial coherent state for the four symmetric oscillators. These are given by

$$|a_{\pm},b_{\pm}\rangle = \sum_{(n_r)_{1,2}=0}^{\infty} \int_{-\infty}^{+\infty} \mathrm{d}m_1 \int_{-\infty}^{+\infty} \mathrm{d}m_2 \times U_{(n_r)_1,m_1,(n_r)_2,m_2}(a_{\pm},b_{\pm})|(n_r)_{1,2},m_{1,2}\rangle \tag{26}$$

and

$$U(s_b-s_a)|\kappa_{\pm},\lambda_{\pm}\rangle = \sum_{(n_r)_{1,2}=0}^{\infty} \int_{-\infty}^{+\infty} \mathrm{d}m_1 \int_{-\infty}^{+\infty} \mathrm{d}m_2 \times e^{-2i\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1-\frac{f}{2}\right]\omega(s_b-s_a)} \times U_{(n_r)_1,m_1,(n_r)_2,m_2}(\kappa_+,\kappa_-,\lambda_+,\lambda_-)|(n_r)_{1,2},m_{1,2}\rangle,$$

where

$$U_{(n_r)_1,m_1,(n_r)_2,m_2}(a_{\pm},b_{\pm}) = [1+(-1)^{|m_1|+|m_2|}] \times \Pi_{\epsilon=+,-} \frac{(a_{\epsilon})^{(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)}}{\sqrt{\Gamma\left[(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)+1\right]}} \times \frac{(b_{\epsilon})^{(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)}}{\sqrt{\Gamma\left[(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)+1\right]}}.$$

In order to derive the other physical conditions for the coherent states, we consider the integration of the kernel over the all values of s_b from s_a to $+\infty$. It gives the Green's function of the four oscillators as

$$G_{\omega}^{(+)}(a_{\pm}^*,\, b_{\pm}^*;\kappa_{\pm},\lambda_{\pm}) = \sum_{(n_r)_{1,2}=0}^{\infty} \int_{-\infty}^{+\infty} \mathrm{d}m_1 \int_{-\infty}^{+\infty} \mathrm{d}m_2 \times \frac{iF_{(n_r)_1,m_1,(n_r)_2,m_2}(a_{\pm}^*\kappa_{\pm},b_{\pm}^*\lambda_{\pm})}{f-2\omega\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1\right]}. \tag{27}$$

The poles of the Green's function are at

$$f = 2\omega\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1\right],$$

which give the energy eigenvalues of the physical system as

$$p_o = -\frac{Mf^2}{2\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1\right]^2}. \tag{28}$$

To derive the Green's function or the matrix elements for the physical particle we consider the elimination of the dummy coordinates, ϕ_1 and ϕ_2. There are two methods of the elimination: In the path integration formalism, we integrate over all the possible final values of these variables. In the wave function formalism, we consider the physical eigenvalues of the corresponding conjugate momenta

$$\hat{p}_{\phi_1}\Psi^{\mathrm{phys}} = \sqrt{m^2+2M(B-C)}\Psi^{\mathrm{phys}},$$

$$\hat{p}_{\phi_2}\Psi^{\mathrm{phys}} = \sqrt{m^2+2M(B+C)}\Psi^{\mathrm{phys}}, \tag{29}$$

where m is the azimuthal quantum number corresponding to the operator $\hat{p}_{\phi}$. Then the Green's function at p_o becomes

$$G_{\omega}^{\text{phys}}(a_{\pm}^{*},\, b_{\pm}^{*};\kappa_{\pm},\lambda_{\pm}) = G_{\omega}^{(+)}\,(a_{\pm}^{*},\, b_{\pm}^{*};\kappa_{\pm},\lambda_{\pm})\big|_{|m_{1,2}|=\sqrt{m^2+2M(B\mp C)}}$$

$$= \sum_{(n_r)_{1,2}=0}^{\infty} V_{(n_r)_1,(n_r)_2}(a_{+}^{*},a_{-}^{*},b_{+}^{*},b_{-}^{*}) \times V_{(n_r)_1,(n_r)_2}(\kappa_{+},\kappa_{-},\lambda_{+},\lambda_{-}),$$

where

$$V_{(n_r)_1,(n_r)_2}(a_{\pm}^{*},b_{\pm}^{*}) = [1+(-1)^{|m_1|+|m_2|}] \times \Pi_{\epsilon=+,-} \frac{(a_{+}^{*}a_{-}^{*})^{(n_r)_1+|m_1|}\left(\frac{a_{+}^{*}}{a_{-}^{*}}\right)^{m_1}}{\sqrt{\Gamma\left[(n_r)_1+\frac{1}{2}(|m_1|+\epsilon m_1)+1\right]}}$$

$$\times \frac{(b_{+}^{*}b_{-}^{*})^{(n_r)_2+|m_2|}\left(\frac{b_{+}^{*}}{b_{-}^{*}}\right)^{m_2}}{\sqrt{\Gamma\left[(n_r)_2+\frac{1}{2}(|m_2|+\epsilon m_2)+1\right]}}. \tag{30}$$

In Eq. (30) we take the values of $|m_{1,2}|$ as $\sqrt{m^2+2M(B\mp C)}$. Thus, we derive the physical coherent states by evaluating $|a_{\pm},b_{\pm}\rangle$ at the poles of the $|m_{1,2}|=\sqrt{m^2+2M(B\mp C)}$ and p_0,

$$|a_{\pm},b_{\pm}\rangle = (n_r)_{1,2} = \sum_{(n_r)_{1,2}=0}^{\infty} V_{(n_r)_1,(n_r)_2}(a_{\pm}^{*},b_{\pm}^{*})|(n_r)_{1,2},\, m_{1,2}\rangle. \tag{31}$$

The coherent states are parametrized by three quantum numbers $[(n_r)_1+|m_1|]$, $[(n_r)_2+|m_2|]$, and m as $|m_{1,2}|=\sqrt{m^2+2M(B\mp C)}$.

IV. GREEN'S FUNCTION AND COHERENT STATES IN CONFIGURATION SPACE

In Sec. III, we derive the Green's function between the initial and final coherent states. However, in this section, we write the Green's function between the final eigenstates of the configuration space and the initial coherent states as

$$G_{\omega}^{\text{phys}}(u,\phi_1,v,\phi_2;\kappa_{\pm},\lambda_{\pm}) = \Pi_{\epsilon=+,-}\int \frac{da_{\epsilon}^{*}\,da_{\epsilon}}{2\pi i}\int \frac{db_{\epsilon}^{*}\,db_{\epsilon}}{2\pi i} e^{-a_{\epsilon}^{*}a_{\epsilon}-b_{\epsilon}^{*}b_{\epsilon}} \times \langle u,\phi_1|a_{+},a_{-}\rangle$$

$$\times\langle v,\phi_2|b_{+},b_{-}\rangle G_{\omega}^{\text{phys}}(a_{\pm}^{*},\, b_{\pm}^{*};\kappa_{\pm},\lambda_{\pm}). \tag{32}$$

The matrix elements, $\langle u,\phi_1|a_{+},a_{-}\rangle$ and $\langle v,\phi_2|b_{+},b_{-}\rangle$ can be calculated by using the representation of $a_{\pm}$ and $b_{\pm}$ in terms of $u,\phi_1,(v,\phi_2)$ and $p_u,p_{\phi_1},(p_v,p_{\phi_2})$, in Eqs. (15) and (16). Since the volume element of the four-dimensional space is $2(uv)^3\,du\,dv\,d\phi_1\,d\phi_2$, the normalized wave functions will be

$$\langle u,\phi_1,v,\phi_2|a_{\pm},b_{\pm}\rangle = Ne^{-(u^2+v^2)/2} \times e^{[u(a_{+}e^{-i\phi_1}+a_{-}e^{i\phi_1})+v(b_{+}e^{-i\phi_2}+b_{-}e^{i\phi_2})]-\frac{1}{2}(a^2+b^2)}, \tag{33}$$

where the normalization constant, N, is given by

$$N = \frac{2\sqrt{2}e^{-\frac{1}{2}(aa^{*}+bb^{*})}}{[1+(a+a^{*})^2]^{1/2}[1+(b+b^{*})^2]^{1/2}}. \tag{34}$$

If we substitute $\langle u,\phi_1,v,\phi_2|a_{\pm},b_{\pm}\rangle$ into Eq. (32) and integrate over $a_{\pm}^{*}$, $a_{\pm}$ and $b_{\pm}^{*}$, $b_{\pm}$, the result will be

$$G_{\omega}^{\text{phys}}(u,\phi_2,v,\phi_2;\kappa_{\pm},\lambda_{\pm}) = iNe^{-(u^2+v^2)/2} \times e^{[u(\kappa_{+}e^{-i\phi_1}+\kappa_{-}e^{i\phi_1})+v(\lambda_{+}e^{-i\phi_2}+\lambda_{-}e^{i\phi_2})]-\frac{1}{2}(\kappa^2+\lambda^2)}. \tag{35}$$

To derive the coherent states of the particle, we consider the path integrations over the conjugate variables t and p_0 and ϕ and p_{ϕ}. The integrations of t and p_0 are discussed in Ref. 13 and the result of these integrations is given as

$$\int \frac{\mathrm{d}(-p_0)}{2\pi i} e^{i(-p_0)(t_b-t_a)}.$$

The integrations of ϕ and p_ϕ are given in Ref. 10 and the result of these integrations is

$$\sum_{m=-\infty}^{+\infty} \frac{e^{im(\phi_b-\phi_a)}}{2\pi},$$

where m is the azimuthal quantum number of the particle. Then the Green's function of the particle is

$$\widetilde{G}_\omega^{(+)}(u,\, v, \phi, t;\, \kappa_\pm, \lambda_\pm, \phi_a, t_a) = \sum_{m=-\infty}^{+\infty} \frac{e^{im(\phi-\phi_a)}}{2\pi} \times \int \frac{\mathrm{d}(-p_0)}{2\pi i} e^{i(-p_0)(t-t_a)} \widetilde{G}_\omega^{phys}(u, v; \kappa_\pm, \lambda_\pm),$$

where $\widetilde{G}_\omega^{\mathrm{phys}}(u, v; \kappa_\pm, \lambda_\pm)$ will be derived from $G_\omega^{\mathrm{phys}}(u, \phi_1, v, \phi_2; \kappa_\pm, \lambda_\pm)$ by performing the integrations over ϕ_1 and ϕ_2.

In order to derive coherent states in the parabolic coordinates, we rewrite Eq. (35) as follows:

$$G_\omega^{\mathrm{phys}}(u, \phi_1, v, \phi_2; \kappa_\pm, \lambda_\pm) = 2iNe^{-(u^2+v^2)/2+(i\kappa)^2+(i\lambda)^2} \times \cosh\left\{ \sqrt{u^2\frac{\kappa^2}{2}}[(e^{-i(\phi_1-\Delta_1)} + e^{i(\phi_1-\Delta_1)})] + \sqrt{v^2\frac{\lambda^2}{2}}[(e^{-i(\phi_2-\Delta_2)} + e^{i(\phi_2-\Delta_2)})] \right\}, \tag{36}$$

where the complex phases, $\Delta_{1,2}$, are

$$\frac{(\kappa_1 \pm i\kappa_2)}{\sqrt{2}} = \sqrt{\frac{\kappa^2}{2}} e^{\pm i\Delta_1}, \quad \frac{(\lambda_1 \pm i\lambda_2)}{\sqrt{2}} = \sqrt{\frac{\lambda^2}{2}} e^{\pm i\Delta_2}.$$

Then we can expand the Green's function, in terms of Bessel functions, as

$$G_\omega^{\mathrm{phys}}(u, \phi_1, v, \phi_2; \kappa_\pm, \lambda_\pm) = iNe^{-(u^2+v^2)/2-\kappa^2-\lambda^2} \sum_{m_1,m_2=0}^{+\infty\prime} [1 + (-1)^{m_1+m_2}] \times J_{m_1}\left(-2i\sqrt{u^2\frac{\kappa^2}{2}}\right) \cos m_1(\phi_1 - \Delta_1) \times J_{m_2}\left(-2i\sqrt{v^2\frac{\lambda^2}{2}}\right) \cos m_2(\phi_2 - \Delta_2). \tag{37}$$

Here, the prime on the summation shows that we can take the half of this term for $m_1 = m_2 = 0$. In Eq. (37), we change the range of the variables, ϕ_1 and ϕ_2 from $]-\pi, +\pi[$ to the interval $]-\infty, +\infty[$. As a consequence of this change, we can convert the summation into the integrals over m_1 and m_2. If we perform the integrations over ϕ_1 and ϕ_2 by considering the Lagrange multipliers for p_{ϕ_1} and p_{ϕ_2}, the Green's function becomes

$$G_\omega^{\mathrm{phys}}(u, v, ; \kappa_\pm, \lambda_\pm) = iNe^{-(u^2+v^2)/2-(\kappa^2+\lambda^2)/2}[1 + (-1)^{m_1+m_2}] \times J_{m_1}\left(-2i\sqrt{u^2\frac{\kappa^2}{2}}\right) \cos m_1\Delta_1 \times J_{m_2}\left(-2i\sqrt{v^2\frac{\lambda^2}{2}}\right) \cos m_2\Delta_2, \tag{38}$$

where

$$\begin{pmatrix} |m_1| \\ |m_2| \end{pmatrix} = \sqrt{m^2 + 2M(B \mp C)}.$$

To derive the coherent state wave functions in parabolic coordinates we expand the Bessel functions in terms of the associate Laguerre polynomials[42]

$$J_\alpha(2\sqrt{xz}) = e^{-z}(xz)^{\frac{\alpha}{2}} \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(n+\alpha+1)} L_n^\alpha(x). \tag{39}$$

Then the Green's function is

$$G_\omega^{\text{phys}}(u,v;\kappa_\pm,\lambda_\pm) = i \sum_{(n_r)_{1,2}=0}^{\infty} [1+(-1)^{m_1+m_2}] N_{(n_r)_1,m_1} N_{(n_r)_2,m_2} \times \widetilde{R}_{(n_r)_1,m_1}(u) \left(-\frac{\kappa^2}{2}\right)^{(n_r)_1+\frac{m_1}{2}} \cos m_1\Delta_1$$
$$\times \widetilde{R}_{(n_r)_2,m_2}(v) \left(-\frac{\lambda^2}{2}\right)^{(n_r)_2+\frac{m_2}{2}} \cos m_2\Delta_2, \tag{40}$$

where

$$\widetilde{R}_{n_r,m}(u) = e^{-u^2/2}(u^2)^{\frac{m}{2}} L_{n_r}^m(u^2) \tag{41}$$

and

$$N_{(n_r),m}^2 = \frac{1}{\sqrt{\pi}\Gamma[(n_r)+m+1]}. \tag{42}$$

The reduced Green's function, $\widetilde{G}_\omega^{(+)}$, is the scalar product of the coherent states with configuration space eigenstates. We identify them as the configuration space dependent coherent state wave functions, $\Psi_{\kappa,\lambda,m,p_0}(u,v,\phi,t)$,

$$\Psi_{\kappa,\lambda,m,p_0}(u,\, v, \phi-\phi_0, t) = \widetilde{G}_\omega^{(+)}(u,\, v, \phi, t;\, \kappa_\pm, \lambda_\pm, \phi_0, t_0)$$
$$= \sum_{(n_r)_{1,2}=0}^{\infty} \sum_{m=-\infty}^{\infty} \psi_{(n_r)_1,(n_r)_2,m}(\xi,\eta,\phi) \times e^{i(-p_0)(t-t_0)} [\psi_{(n_r)_1,(n_r)_2,m}(\kappa^*,\lambda^*,\phi_0)]^*, \tag{43}$$

where

$$p_0 = 2M\omega^2 = -\frac{Mf^2}{2\left[(n_r)_1 + (n_r)_2 + \frac{1}{2}(m_1+m_2)+1\right]^2} = -\frac{Mf^2}{2\tilde{n}^2}. \tag{44}$$

In Eq. (43), $\psi_{(n_r)_1,(n_r)_2,m}(\xi,\eta,\phi)$ and $\psi(\kappa^*,\lambda^*,\phi_0)$ are the energy eigenstates in parabolic coordinates and holomorphic coordinates, respectively. They are given as

$$\psi_{(n_r)_1,(n_r)_2,m}(\xi,\eta,\phi) = \left(\frac{4[1+(-1)^{m_1+m_2}]M^3f^3}{\tilde{n}^4\Pi_{i=1}^2\Gamma[(n_r)_i+m_i+1]}\right)^{1/2}$$
$$\times \frac{e^{im\phi}}{\sqrt{2\pi}} R_{(n_r)_1,m_1}(\xi) R_{(n_r)_2,m_2}(\eta), \psi_{(n_r)_1,(n_r)_2,m}(\kappa^*,\lambda^*,\phi_0)$$
$$= (-1)^{(n_r)_1+(n_r)_2} \times \left(\frac{4[1+(-1)^{m_1+m_2}]M^3f^3}{\tilde{n}^4\Pi_{i=1}^2\Gamma[(n_r)_i+m_i+1]}\right)^{1/2} \frac{e^{im\phi_0}}{\sqrt{2\pi}}$$

$$\times \frac{e^{-(a+a^*)^2}}{[1+(a+a^*)^2]^{1/2}}(\kappa^2)^{(n_r)_1+\frac{m_1}{2}}\cos m_1\Delta_1$$
$$\times \frac{e^{-(b+b^*)^2}}{[1+(b+b^*)^2]^{1/2}}(\lambda^2)^{(n_r)_2+\frac{m_2}{2}}\cos m_2\Delta_2$$

and

$$R_{n_r,m}(\xi)=e^{-\frac{1}{2}\sqrt{-2Mp_0}\xi}(\sqrt{-2Mp_0}\xi)^{m/2}L_{n_r}^{m}(\sqrt{-2Mp_0}\xi).$$

$\Psi_{\kappa,\lambda,m,p_0}(u,v,\phi-\phi_0,t)$ is the coherent state for the particle in the potential given by Eq. (1) in terms of the normalized energy eigenstates in parabolic coordinates.

In order to find the coherent state wave functions in spherical coordinates, we write the product of two modified Bessel functions in terms of one modified Bessel function:

$$\frac{z}{2}I_\mu(z\sin\alpha\sin\beta)I_\nu(z\cos\alpha\cos\beta)=(\sin\alpha\sin\beta)^\mu(\cos\alpha\cos\beta)^\nu\sum_{l=0}^{\infty}\frac{l!\,\Gamma(\mu+\nu+l+1)}{\Gamma(\mu+l+1)\Gamma(\nu+l+1)}$$
$$\times I_{\mu+\nu+2l+1}(z)P_l^{(\mu,\nu)}(\cos 2\alpha)P_l^{(\mu,\nu)}(\cos 2\beta).$$

The product of two modified Bessel functions is

$$I_{m_1}\left(2\sqrt{\frac{M\omega u^2}{2}(\kappa)^2}\right)I_{m_2}\left(2\sqrt{\frac{M\omega v^2}{2}(\lambda)^2}\right)=I_{m_1}\left(2\sqrt{2(a^2+b^2)}\sqrt{2M\omega r}\sin\frac{\theta}{2}\sin\frac{\Theta}{2}\right)$$
$$\times I_{m_2}\left(2\sqrt{2(a^2+b^2)}\sqrt{2M\omega r}\cos\frac{\theta}{2}\cos\frac{\Theta}{2}\right),$$

where

$$\kappa=\frac{\sqrt{a^2+b^2}}{\sqrt{2}}\sin\frac{\Theta}{2}\quad\text{and}\quad\lambda=\frac{\sqrt{a^2+b^2}}{\sqrt{2}}\cos\frac{\Theta}{2}.$$

Then, we combine them as

$$I_{m_2}\left(2\sqrt{4M\omega r(a^2+b^2)}\cos\frac{\theta}{2}\cos\frac{\Theta}{2}\right)\times I_{m_1}\left(2\sqrt{4M\omega r(a^2+b^2)}\sin\frac{\theta}{2}\sin\frac{\Theta}{2}\right)$$
$$=\sum_{k=0}^{\infty}\frac{2k!\,\Gamma(k+m_1+m_2+1)}{\Gamma(k+m_1+1)\Gamma(k+m_2+1)}\times\frac{I_{2k+m_1+m_2+1}(2\sqrt{4M\omega r(a^2+b^2)})}{2\sqrt{4M\omega r(a^2+b^2)}}$$
$$\times d_{k,m_1,m_2}(\cos\theta)d_{k,m_1,m_2}(\cos\Theta),\tag{45}$$

where the angular wave function $d_{k,m_1,m_2}(\cos\theta)$ is defined in terms of Jacobi polynomials, $P_k^{(m_1,m_2)}(\cos\theta)$, as

$$d_{k,m_1,m_2}(\cos\theta)=\left(\sin\frac{\theta}{2}\right)^{m_1}\left(\cos\frac{\theta}{2}\right)^{m_2}P_k^{(m_1,m_2)}(\cos\theta).\tag{46}$$

We can expand the modified Bessel function in Eq. (45), in terms of Laguerre polynomials by using Eq. (39). Then we substitute this result into Eq. (45),

$$G_{\omega}^{\mathrm{phys}}[r,\theta;(a^2+b^2)^{1/2},\Theta]=\sum_{n_r,k=0}^{\infty}\sum_{m=-\infty}^{\infty}\psi_{n_r,k,m}(r,\theta,\phi)\times[\psi_{n_r,k,m}((a^{*2}+b^{*2})^{1/2},\Theta^*,\phi_a)]^*, \tag{47}$$

where $\psi_{n_r,k,m}(r,\theta,\phi)$ and $\psi_{n_r,k,m}((a^{*2}+b^{*2})^{1/2},\Theta*,\phi)$ are the normalized energy eigenfunctions in spherical coordinates and holomorphic coordinates, respectively. They are given in terms of the Jacobi polynomials as

$$\psi_{n_r,k,m}(r,\theta,\phi,t)=N_{n_r,k,m}\times e^{-2M\omega r}(\sqrt{4M\omega r})^{2k+m_1+m_2}L_{n_r}^{2k+m_1+m_2+1}(4M\omega r)\times e^{im\phi}d_{k,m_1,m_2}(\cos\,\theta) \tag{48}$$

and

$$\begin{aligned}\psi_{n_r,k,m}((a^{*2}+b^{*2})^{1/2},\Theta^*,\phi)=(-1)^{n_r}N_{n_r,k,m}\times(\sqrt{(a^{*2}+b^{*2})})^{2k+m_1+m_2+2n_r}e^{im\phi}\\ \times d_{k,m_1,m_2}(\cos\,\Theta^*)\cos\,m_1\Delta_1\,\cos\,m_2\Delta_2,\end{aligned} \tag{49}$$

where the normalization constant, $N_{n_r,k,m}$, is

$$N_{n_r,k,m}=\left(\frac{4M^3f^3}{2\pi\tilde{n}^4}\right)^{1/2}\times\left[\frac{(1+(-1)^{m_1+m_2})(2k+m_1+m_2+1)}{2\pi\Gamma(k+m_1+1)\Gamma(k+m_2+1)}\right]^{1/2}\times\frac{\Gamma(k+m_1+m_2+1)k!}{\Gamma(n+2k+m_1+m_2+2)}\Bigg]. \tag{50}$$

Then, coherent states in spherical coordinates are given by

$$\begin{aligned}\Psi_{(a^2+b^2)^{1/2},\Theta,\Delta}(r,\theta,\phi,t)=\tilde{G}_{\omega}^{(+)}(r,\theta,\phi,t;\,\kappa_{\pm},\lambda_{\pm},\phi_0,t_0)=\sum_{n_r,k=0}^{\infty}\sum_{m=-\infty}^{\infty}\exp\left[i\frac{Mf^2}{2\tilde{n}^2}(t-t_0)\right]\\ \times\psi_{n_r,k,m}(r,\theta,\phi)\left[\psi_{n_r,k,m}(a^{*2}+b^{*2})^{1/2},\Theta^*,\phi_0\right]^*,\end{aligned} \tag{51}$$

where the principal quantum number, $\tilde{n}$, is introduced as

$$\tilde{n}=n_r+\check{l}+1, \tag{52}$$

with

$$\check{l}=k+\frac{1}{2}(m_1+m_2)=k+\sqrt{m^2+2M(B+C)}+\sqrt{m^2+2M(B-C)}. \tag{53}$$

V. CONCLUSION

In this paper, we discuss the negative energy coherent states for the generalized MIC-Kepler system. First, we transform the system into the four isotropic harmonic oscillators, which evolve in a parametric time. Second, we construct the coherent states for the four oscillators. Third, we compactify the four oscillator system into a 3D generalized MIC-Kepler system. We also express the wave functions of these states in terms of the normalized energy eigenstates in the parabolic coordinates and in the spherical coordinates. The special cases of this system are the combined Coulomb and Aharonov-Bohm potentials, the Hartmann potential, and the Coulomb potential.

The four harmonic oscillators have 16 conserved quantities. These are constructed as follows: We expand the bilinear $aa^{\dagger}$ in terms of the Euclidian Dirac matrices. The coefficients of these expansion denote the conserved quantities corresponding to the four isotropic oscillators. The coefficient of the diagonal matrices, $1\otimes 1$, $\sigma^3\otimes 1$, $1\otimes\sigma^3$, and $\sigma^3\otimes\sigma^3$, give the complete commuting set of the operators for the four oscillators. These are related to the quantum numbers of the oscillators. Half of these coefficients are related to the conserved quantities of the generalized

MIC-Kepler system. In the case of the Kepler problem, one of these generators is exactly zero and the residual 7 generators correspond to the Hamiltonian, angular momentum and Runge-Lenz vectors and they satisfy the algebra $SU(2)\times SU(2)$. In the case of the generalized MIC-Kepler system, this generator is not zero and the classical orbits are not closed. In some extend these variables measure the precession of the orbits. In the Kepler problem, there is no precession and the orbits are closed. In the noncentral potential cases, the orbits are not closed and parametrized by the angles ϕ_1 and ϕ_2 ranging between $-\infty$ and $+\infty$.

The expectation values for the dynamical variables, i.e., the position and the momentum can be derived by using the parametric time coherent states given in Eq. (26). The center of the localized states follows finite trajectories. Since the azimuthal quantum numbers m_1 and m_2, and the principal quantum number, $\left[(n_r)_1+(n_r)_2+\frac{1}{2}(|m_1|+|m_2|)+1\right]$ are not integers, these trajectories are not closed, except for the Coulomb potential: In this case, $m_1=m_2=m$ and the trajectories are Keplerian ellipses. In all cases, the uncertainties are finite.

Here, we do not discuss the positive energy coherent states. They can be easily derived from the negative energy coherent states given in Eq. (43) by the analytic continuation discussed in Ref. 13. In this case, the trajectories and the uncertainties are not finite.

The coherent states for the generalized Aharonov-Bohm and Coulomb potential were discussed for the constant values of the quantum number, m.[43] These states correspond to the eigenvalues of the lowering operators for $(n_r)_i+|m_i|$ for $i=1,2$, which are denoted by the quadratic combinations of the lowering operators $a_\pm$ and $b_\pm$. However, they are different than the coherent states discussed in our paper.

In this paper we study the construction of probability densities for time of arrival in quantum mechanics. Our treatment is based upon the facts that (i) time appears in quantum theory as an external parameter to the system, and (ii) propositions about the time of arrival appear naturally when one considers histories. The definition of time-of-arrival probabilities is straightforward in stochastic processes. The difficulties that arise in quantum theory are due to the fact that the time parameter of the Schrödinger's equation does not naturally define a probability density at the continuum limit, but also because the procedure one follows is sensitive on the interpretation of the reduction procedure. We consider the issue in Copenhagen quantum mechanics and in history-based schemes like consistent histories. The benefit of the latter is that it allows a proper passage to the continuous limit—there are, however, problems related to the quantum Zeno effect and decoherence. We finally employ the histories-based description to construct Positive-Operator-Valued-Measures (POVMs) for the time-of-arrival, which are valid for a general Hamiltonian. These POVMs typically depend on the resolution of the measurement device; for a free particle, however, this dependence cancels in the physically relevant regime and the POVM coincides with that of Kijowski. © *2006 American Institute of Physics.*

I. INTRODUCTION

The probabilities provided by quantum mechanics usually refer to measurements that take place at specific moments of time. However, there are physically realizable measurements that do not fall in this category. One such example involves the determination of a particle's time-of-arrival (or time-of-flight) measurement. If the quantum mechanical system is described by a wave function $\psi(x,t)$, its modulus square $|\psi(x,t)|^2$ is a probability density with respect to x at any time t. If ψ describes a particle beam, the probability density describes the particles' distribution in space, as if a snapshot were taken at a moment t. However, the setup for particle detection is slightly different. The time interval between the emission of the beam and its detection is not fixed; rather, one places a detector at a fixed distance L from the source. This is *not* a single-time measurement of the particle's position. Therefore, the object $|\psi(x,t)|^2$ is not immediately relevant, because it is not a probability distribution with respect to t. Only if one assumes that the initial wave packet is narrowly concentrated around a specific momentum value p and that it remains so at all times until detection, is it possible to state that this measurement is equivalent to a single-time measurement at time $t=mL/p$ (m being the particle mass). But even for small momentum spreads of the initial state, the assumptions above are valid only for free particles.

In the general case, the detector registers particles at different times t. One therefore needs to construct a probability $p(t)$ for the time of arrival. This would have been an elementary problem,

[a)]Electronic mail: anastop@physics.upatras.gr
[b)]Electronic mail: ntina@imperial.ac.uk

if there existed an operator representing time in the system's Hilbert space. In that case one would use the Born rule to determine a probability density for the time of arrival. Unfortunately, the existence of a time operator $\hat{T}$, conjugate to the Hamiltonian (so that the Hamiltonian generates time translations: $e^{i\hat{H}s}\hat{T}e^{-i\hat{H}s}=\hat{T}+s$) is ruled out by the requirement that the Hamiltonian is bounded from below.[1,2] Nonetheless, one may still define a quantum time variable by choosing some degrees of freedom of the system (or of a measuring apparatus) as defining an internal "clock." The simplest example for the time-of-arrival is the quantum version of the classical function mx/p, for a free particle of mass $m-x$, p being the position and momentum, respectively. Still, clock times fail to be conjugate to the Hamiltonian of the system, with the result that they do not forward under Hamiltonian evolution. In simpler language, quantum fluctuations invariably force clocks to move occasionally "backward in time." For time-of-arrival operators, see, for example, Refs. 3 and 4 and the extensive bibliography in the review.[5]

This discussion brings us invariably to the issue of the role of time in quantum theory. Time enters the quantum mechanical formalism as the *external* evolution parameter in Schrödinger's equation; it is not an intrinsic variable of a physical system. Indeed, outside the realm of general relativity, time is assumed to be part of a background structure—both in nonrelativistic or special relativistic physics. For Bohr, time is a part of the classical description of physics that is "complementary" to the quantum description, and is needed if the measurement theory of the later is to make sense.

In this paper we identify different candidates for the time-of-arrival probability, by treating time as a parameter external to the quantum system under consideration. This assumption is not only forced on us by the quantum mechanical formalism, but also corresponds to the way time is taken into account in experiments. When an event occurs (say a detector clicks), we record the time it took place by "looking" at a clock in the laboratory. Clocks are classical systems that do not interact with either the quantum system or with the measurement device– their degrees of freedom are not correlated to the physical processes that take place in the act of measurement. In effect, the time parameter we consider is the reading of the clock that is simultaneous with the detector's click. Since in any laboratory the relative speeds involved are much smaller than the speed of light, there is no problem in assuming a synchronization of events. Hence, in this paper, we construct a probability distribution for the clock reading that are simultaneous with the realization of a specific quantum event (usually a particle detection). It is important to emphasize that the determination of the time of arrival involves only *a single act of measurement*, which corresponds to the particle being registered by the detector.

In each individual run of the experiment, we record the moment the particle entered the measuring device. The only way to do so is by checking at every single moment of time which of the two alternatives holds: the particle having been detected or not. We then identify the time of arrival as the moment of transition from the event of no detection to the event of detection. For this purpose, we need to consider a (continuous) history of alternatives of detection. This suggests that a framework based on histories (path integrals or the consistent histories approach) is particularly suitable for that purpose. Indeed, an important feature of the history's formalism is that it distinguishes the role of the causal ordering of events in quantum theory from that of evolution (see Ref. 6 or the more general discussion in Ref. 7). This allows us to set up the problem of the time-of-arrival probabilities at a kinematical level, i.e., without specific reference to the system's Hamiltonian.

A key feature of the constructions we present here is that they are not tied to a specific choice of the Hamiltonian that describes the quantum system's dynamics. From the experimentalist's point of view, this is perhaps the most natural procedure. One may measure the time of arrival for any system without any prior knowledge about the system's dynamics. All that is needed is a particle detector and an external clock. We would use the same detector for a free particle, for a particle moving in a potential, for a particle in presence of an environment, or even when we have complete ignorance about the particle's dynamical behavior. The procedure one follows to measure the time of arrival should not depend, in principle, on the system's dynamics, only the results (namely the probabilities) should.

The histories description provides an important technical advantage. While the time of arrival does not define a function on the space of single-time alternatives of the system, it becomes one in the space of histories. In fact, the problem of defining a time-of-arrival probability is a special case of defining probabilities for histories. We shall exploit this fact in Sec. V, in order to construct a Positive-Operator-Valued-Measure for histories, by mirroring the corresponding construction of probabilities in sequential measurements.

To demonstrate unambiguously that time of arrival is naturally defined in a history framework, we consider an analogous construction, namely the time of arrival in stochastic processes (Sec. II). At this level a probability density for the time of arrival can be simply constructed. However, when we pass to quantum theory, a problem appears. The probabilities obtained from Born's rule depend on the time variable in a way that does not allow the straightforward definition of a probability density. As a result, there is a strong ambiguity in the implementation of the continuous-time limit.

The second complication involved in quantum theory is the fact that the construction depend strongly on the interpretation of the "wave-packet reduction" rule. One possible interpretation is that the wave-packet reduction is a physical process that takes place only after the measured system has interacted with a measuring device. Another interpretation is that the reduction rule can be applied to any circumstance, in which we have obtained information about the quantum system. For example, if a particle detector did not click at a specific moment of time, then we can infer that the particle has been outside the region of detection at that time.

The first interpretation allows us to construct time-of-arrival probabilities by applying *classical reasoning* to the quantum mechanical probabilities. The corresponding probability density is not a linear functional of the initial density matrix, because the assumption we employed violates the "logic" of quantum mechanical propositions. Nonetheless, it has the correct classical limit and physically reasonable properties. Its main drawback is that it is ambiguous with respect to the continuous-time limit, and depends on the procedure one employs for its implementation.

The second interpretation of the reduction procedure lends itself to constructions that emphasize the "logic" of quantum events. All information we obtain for a quantum system, whether this arises from a concrete experimental datum or from inference from the lack of such a datum (i.e., the detector not having clicked) are treated in the same footing. An important example is the consistent histories approach, which we examine in Sec. IV. Time-of-arrival histories are a special case of the so-called "spacetime coarse grainings" that have been studied before by Hartle[8] and others.[9] The advantage conferred to us by this approach is that the continuous-time limit *is naturally obtained at the level of amplitudes* (which essentially correspond to restricted path integrals). The problem arises at the level of combining the amplitudes in order to obtain a probability density. In effect, there is strong interference between different values of arrival times that are mutually exclusive in the classical context.

The quantum Zeno effect[10] poses another problem for the determination of probabilities; it can be partially evaded but it remains troublesome at the fundamental level. It seems that the only information we can obtain unambiguously in this framework is the classical deterministic limit for the time of arrival.

In Sec. V, we apply the results obtained from the analysis of histories in a different context, namely the construction of a Positive-Operator-Valued Measure that provides probabilities for the time of arrival. The key idea is that the construction of a probability density for the time of arrival is not fundamentally different from that of probabilities for sequential measurements. Hence, we follow a procedure developed for the study sequential measurements.[11,12] The resulting time-of-arrival probabilities, like those of sequential measurements, are contextual; they depend strongly on the resolution of the measurement device. However, in the physically relevant regime for the free particle the dependence on τ drops out, and the constructed POVM coincides with that of Kijowski.[4]

The approach to the time-of-arrival developed in Sec. V involves acting with the projection operator corresponding to no detection on the system's wave function at every moment of time. This action loosely corresponds to the fact that we have obtained information from the quantum

system. It is important to emphasize that it does not refer to a physical act of measurement. It cannot be described in the language of standard quantum measurement theory: a von Neumann measurement, for example, involves a finite time interval during which the interaction Hamiltonian between system and measuring device dominates over the system's self-Hamiltonian. This is clearly not happening in the time-of-arrival setup, at any moment prior to the system entering the measuring device. In quantum measurement theory, a physical measurement involves premeasurement and reduction, and here the former part is missing. In physical terms, the time-of-arrival measurement involves a single measuring device, a single act of detection, a single irreversible change in the device, and a single moment of time at which the interaction Hamiltonian becomes dominant. The only difference from the case of standard measurements is that the time of detection is unknown.

II. TIME OF ARRIVAL IN STOCHASTIC PROCESSES

We first study the time-of-arrival probability in the theory of stochastic processes. This allows us to demonstrate the procedure we will follow in quantum theory, without the complications arising from the interpretations of the quantum measurement process.

We consider for simplicity a one-dimensional system, the state of which is fully specified at a moment of time by the position variable x. The sample space Ω is then identified with $\mathbf{R}$. An ensemble of such systems is described at $t=0$ by the probability density $\rho_0(x)$. This probability density evolves according to the law

$$\frac{\partial \rho}{\partial t} = \mathcal{L}\rho, \tag{2.1}$$

where $\mathcal{L}$ is a linear, positive, trace-preserving operator on the space of probability densities.

We next construct the stochastic process corresponding to the system described by Eq. (2.1). We assume that the measurements take place in the time interval $I=[0,T]$, where T may be eventually taken to infinity. The sample space Ω^I for the stochastic process is the space of all continuous paths $x(\cdot)$ from I to $\mathbf{R}$. The relevant random variables are the function X_t on Ω defined as $X_t(x(\cdot))=x(t)$. There exists a probability measure on Ω^I given by the "continuum limit" of discrete-time paths $(t_1,x_1;t_2,x_2;\ldots;t_n,x_n)$,

$$d\mu_{\{t_1,t_2,\ldots,t_n\}}(x_1,x_2,\ldots,x_n) = \rho_0(x_0)g(x_0,0;x_1,t_1)g(x_1,t_1;x_2,t_2)\ldots g(x_{n-1},t_{n-1};x_n,t_n),dx_0\,dx_1\,dx_2\ldots dx_n, \tag{2.2}$$

where $g(x,t;x',t')$ represents the propagator associated to Eq. (2.1). We assume that ρ_0 has support only for values of $x<0$.

From the probability measure (2.2) we construct the probability for the proposition that the particle is detected at $x=0$ at a specific time t, $0<t<T$. For this purpose, we split the interval $[0,T]$ into N time steps of width $\delta t=T/N$. We assume also that $t=n\,\delta t$ for an integer $n<N$ and write $m=N-n$. We denote by $\chi_\pm$ the characteristic functions of the intervals $-\infty<x<0$ and $0<x<\infty$, respectively.

If the particle crosses the surface $x=0$ for the first time within the time interval $[t,t+\delta t]$, then it must have been in the region $(-\infty,0)$ for all times less or equal to t and in the region $(0,\infty)$ at time $t+\delta t$. There is no reason to make any assumption about where it will be at times larger than $t+\delta t$, because in time-of-arrival measurements we are interested only in the time of the first detection. The particle may be, for example, absorbed by the detector at time t.

With the above considerations in mind, we see that the probability that the particle is measured during the interval $[t,t+\delta t]$ equals

$$p(x=0|[t,t+\delta t]) = \mu(D_{[t,t+\delta t]}), \tag{2.3}$$

where μ is the stochastic probability measure and

$$D_{[t,t+\delta t]} = \chi_- \otimes \chi_- \otimes \cdots \chi_- \otimes \chi_+ \otimes 1 \otimes \cdots 1. \tag{2.4}$$

The function $D_{[t,t+\delta t]}$ is a characteristic function on $\times_{t_i}\Omega_{t_1}$, and depends only on the value of n, namely the time step that corresponds to detection. We may then also write $D_{[t,t+\delta t]}$ as D_n. If we also define by $\bar{D}$ the characteristic function

$$\bar{D} = \chi_- \otimes \chi_- \otimes \cdots \otimes \chi_- \tag{2.5}$$

that corresponds to the particle never crossing $x=0$ within the time interval $[0,T]$, the following relations hold:

$$D_n D_m = D_n \delta_{nm}, \tag{2.6}$$

$$D_n \bar{D} = 0, \tag{2.7}$$

$$\sum_{n=0}^{N} D_n + \bar{D} = 1. \tag{2.8}$$

The variables $D_n, \bar{D}$ then define an exclusive and exhaustive set of alternatives, hence the restriction of the probability measure to the algebra they generate defines a proper normalized probability measure for the time of arrival in discrete time. (This decomposition is a special case of the Path-Decomposition expansion and has been used in the context of restricted path integrals in Ref. 19).

We next construct the continuous limit of this probability as $N \to \infty$. We use an operator notation, representing the action of the integral kernel as $e^{\mathcal{L}t}$. Using Eq. (2.2), we write

$$p(x=0|[t,t+\delta t]) = \int dx [\chi_+ e^{\mathcal{L}\,\delta t} [\chi_- e^{\mathcal{L}\,\delta t}]^n \rho_0](x). \tag{2.9}$$

If we denote by K_t the limit

$$K_t = \lim_{n\to\infty} [\chi_- e^{\mathcal{L}t/n} \chi_-]^n, \tag{2.10}$$

we obtain

$$p(x=0|[t,t+\delta t]) = \delta t \int dx [\chi_+ \mathcal{L} \chi_-(x) K_t \rho_0](x). \tag{2.11}$$

The fact that the probability of the first crossing is proportional to δt implies that we can pass to the continuum limit defining a probability density on $[0,T]$,

$$p(t|x=0) = \int dx [\chi_+ \mathcal{L} K_t \rho_0](x). \tag{2.12}$$

This probability density is not normalized to one as there is a no-zero residual probability $p(N)$ that the particle is not detected at all within $[0,T]$:

$$\int_0^T dt\, p(t|x=0) = 1 - \int dx [K_T \rho_0](x) := 1 - p(N). \tag{2.13}$$

For generic initial states and dynamics the residual probability does not vanish as $t \to \infty$.

Using the probability density $p(t|x=0)$, we define the probability of detection within any interval $[t_1,t_2]$ by integrating $p(t|x=0)$ in this interval. The definition of average values of quantities is slightly more intricate. The sample space for the time of arrival (at the continuum limit) is

not the interval $[0,T]$, but the set $[0,T]\cup\{N\}$, where N refers to the event of no detection. Strictly speaking, physical observables are functions on $[0,T]\cup\{N\}$. Hence there is an ambiguity in the definition of a function representing time t, because there is no natural numerical value it can take when evaluated on N.

In effect, a time function is defined unambiguously as a *conditional expectation*, namely after the assumption that the particle has actually been detected. This implies that we restrict (condition) the sample space to $[0,T]$. The conditional probability p_c density is then

$$p_c(t|x=0)=\frac{p(t|x=0)}{1-p(N)}. \tag{2.14}$$

A. Examples

1. Two-level system

In the derivation of the probability of time of arrival, we referred to the variable x as position. However, the derivation is completely general and Eq. (3.15) may be applied to any sample space. If the latter is discrete, we have to exchange the integral with a summation. We may consider, for example, a stochastic two-level system (a bit) and determine the probability for the time of transition. In this case the sample space then consists of two alternatives: 0 and 1. We assume that initially the system is found at state 0. The most general operator $\mathcal{L}$ consistent with the positivity and normalization of probabilities is

$$\mathcal{L}=\begin{pmatrix}-a & b\\ a & -b\end{pmatrix}. \tag{2.15}$$

The corresponding transition matrix for a small time interval δt is

$$\begin{pmatrix}1-a\,\delta t & b\,\delta t\\ a\,\delta t & 1-b\,\delta t\end{pmatrix}, \tag{2.16}$$

which is the most general stochastic map for a two-level system.

It is then easy to compute the probability density for the time of the transition $0\to 1$,

$$p(0\to 1;t)=be^{-bt}. \tag{2.17}$$

The probability $p(N)$ that no transition took place within the time interval $[0,T]$ equals e^{-bT}. As $T\to\infty$, $p(\infty)=0$, and we may compute the mean time of transition,

$$\langle t\rangle=b^{-1}, \tag{2.18}$$

which are the standard results for decay processes.

2. Wiener process

We next consider the case of the Wiener process, defined by the evolution operator,

$$\mathcal{L}\rho=\frac{D}{2}\partial^2\rho, \tag{2.19}$$

where D is a diffusion constant. We assume that the particle is initially localized at $x=-L$, namely $\rho_0(x)=\delta(x+L)$.

The operator K_t is the propagator corresponding to $\mathcal{L}$ with the Dirichlet boundary conditions at $x=0$. [This is, in fact, a more general result. A quick but not fully rigorous way to see this is by writing the characteristic function of a set C as $\chi_C(x)=e^{-V_C(x)\delta t}$, where $V_C(x)$ is a "confining

potential" that takes value 0 within C and ∞ outside C. We may then use the Trotter product formula $\lim_{n\to\infty}(e^{\mathcal{L}t/n}e^{-V_-t/n})^n=(\mathcal{L}-V_-)t$, which is exactly the propagator for $\mathcal{L}$ with Dirichlet conditions at the boundaries of C.]

The integral kernel $K(x,x';t)$ corresponding to K_t is

$$K(x,x';t)=\chi_-(x)\chi_-(x')\sqrt{\frac{1}{2\pi Dt}}(e^{-(x-x')^2/2Dt}-e^{-(x+x')^2/2Dt}), \tag{2.20}$$

yielding

$$p(t|x=0)=\sqrt{\frac{1}{2\pi Dt}}\frac{L}{2t}e^{-L^2/2Dt}, \tag{2.21}$$

while

$$p(N)=\mathrm{erf}(L/\sqrt{2DT})-\mathrm{erf}(-L/\sqrt{2DT}), \tag{2.22}$$

where erf is the error function.

III. THE COPENHAGEN DESCRIPTION

A. The standard construction and its problems

We next attempt to construct the time-of-arrival probability for quantum theory within the Copenhagen interpretation.

We split the time interval $[0,T]$ into n time steps of width $\delta t=T/n$. We represent the projection operators that correspond to the particle lying within $(-\infty,0]$ and in $[0,\infty)$ as $\hat{P}_-$ and $\hat{P}_+$, respectively. The time of arrival is defined as the moment the particle crosses from $(-\infty,0)$ to $[0,\infty)$. We assume that at $t=0$ the particle is described by a density matrix $\hat{\rho}_0$.

The probability that the particle crossed $x=0$ at time t_1 equals $p_1=\mathrm{Tr}(\hat{\rho}e^{i\hat{H}t_1}\hat{P}_+e^{-i\hat{H}t_1})$. The probability that the particle crossed $x=0$ at the next moment t_2 is then equal to

$$p_1p(-,t_1;+,t_2), \tag{3.1}$$

where $p(-,t_1;+t_2)$ is the conditional probability that the particle was found within $(-\infty,0]$ at t_1 and within $(0,\infty)$ at t_2. According to the standard "reduction" rule this equals

$$p(-,t_1;+t_2)=\frac{\mathrm{Tr}(\hat{P}_+e^{-i\hat{H}(t_2-t_1)}\hat{P}_-e^{-i\hat{H}t_1}\hat{\rho}_0e^{i\hat{H}t_1}\hat{P}_-e^{i\hat{H}(t_2-t_1)})}{\mathrm{Tr}(\hat{\rho}e^{i\hat{H}t_1}\hat{P}_-e^{-i\hat{H}t_1})}, \tag{3.2}$$

yielding

$$p_2=\mathrm{Tr}(\hat{P}_+e^{-i\hat{H}(t_2-t_1)}\hat{P}_-e^{-i\hat{H}t_1}\hat{\rho}_0e^{i\hat{H}t_1}\hat{P}_-e^{i\hat{H}(t_2-t_1)}). \tag{3.3}$$

Following the same procedure, we obtain the probability that the particle crossed $x=0$ at the kth time step,

$$p_k=\mathrm{Tr}(\hat{P}_+e^{-i\hat{H}(t_k-t_{k-1})}\ldots\hat{P}_+e^{-i\hat{H}(t_2-t_1)}\hat{P}_-e^{-i\hat{H}t_1}\hat{\rho}_0\times e^{i\hat{H}t_1}\hat{P}_-e^{i\hat{H}(t_2-t_1)}\hat{P}_-\ldots e^{i\hat{H}(t_k-t_{k-1})}). \tag{3.4}$$

As we take the continuum limit $n\to\infty$, assuming that the initial state has support only in $(-\infty,0)$, we obtain the probability that the particle was found between t and $t+\delta t$,

$$p([t,t+\delta t])=\delta t^2\,\mathrm{Tr}((\hat{C}_t\hat{H}\hat{\rho}_0\hat{C}_t^\dagger\hat{H}\hat{P}_+), \tag{3.5}$$

where

$$\hat{C}_t=(\hat{P}_-e^{-i\hat{H}t/n}\hat{P}_-)^n. \tag{3.6}$$

There are two severe problems in this result. First, the probability $p([t,t+\delta t])$ is proportional to δt^2, and hence does not define a probability density. If we tried to construct the probability for the detection within a finite time interval $[t_1,t_2]$ by integration, we would, strictly speaking, obtain zero, i.e., we would find that the particle is never detected.

Second, the probability that the particle never crosses $x=0$ within the time interval $[0,T]$ equals

$$p(N)=\mathrm{Tr}(\hat{C}_T\hat{\rho}_0\hat{C}_T^\dagger). \tag{3.7}$$

The operator $\hat{C}_t$ is a degenerate unitary operator with a support in the range of $\hat{P}_-$[10]—this is the well-known quantum Zeno paradox. It follows that $\hat{C}_t\hat{C}_t^\dagger=\hat{P}_-$, hence

$$p(N)=\mathrm{Tr}(\hat{\rho}_0\hat{P}_-)=1. \tag{3.8}$$

It seems as though the particle can never cross $x=0$, which is clearly a mistake. This problem can be addressed by noticing that the probabilities $p([t,t+\delta t])$ are, by definition, nonadditive with respect to the projectors and hence do not satisfy the Kolmogorov additivity condition, i.e., they are not probabilities at all. It is therefore no surprise that they do not define a probability density. One should employ for the continuum limit a probabilistic object that is additive with respect to the projectors. This is the decoherence functional of the consistent histories approach. The problem of the quantum Zeno effect is also partially alleviated in consistent histories, since the quantity $p(N)$ is not a genuine probability, unless a decoherence condition is satisfied. There are other problems, however, that appear in the implementation of the theory's classical limit. We will discuss this issue in more detail in the next section.

B. A different interpretation of the reduction procedure

An objection that can be raised to the derivation above has to do with the use of the conditional probability rule in Eq. (3.2). One may argue that since the particle has not been detected at time t_2, it has not interacted with the measuring device, and for this reason, one should not employ the "reduction of the wave packet" rule, because no measurement has actually taken place. (See the discussion in the Introduction). Instead of the conditional probability, one should use the full probability of detection at t_2, namely

$$\mathrm{Tr}(\hat{P}_+e^{-i\hat{H}t_2}\hat{\rho}_0e^{i\hat{H}t_2}) := \mathrm{Tr}(\hat{P}_+\rho_{t_2}); \tag{3.9}$$

hence the probability of detection at the kth time step equals

$$p_k=\left(1-\sum_{i=0}^{k-1}p_i\right)\mathrm{Tr}(\hat{\rho}_{t_k}\hat{P}_+), \tag{3.10}$$

This is a recursive equation with the following solution:

$$p_k=\mathrm{Tr}(\hat{\rho}_{t_k}\hat{P}_+)\prod_{-=0}^{k-1}[1-\mathrm{Tr}(\hat{\rho}_{t_i}\hat{P}_+)]=\mathrm{Tr}(\hat{\rho}_{t_k}\hat{P}_+)\exp\left[\sum_{i=0}^{k-1}\log(1-\mathrm{Tr}(\hat{\rho}_{t_i}\hat{P}_+))\right]. \tag{3.11}$$

The expression above does not have a natural continuum limit. The sum in the exponential does not define an integral, because a δt term is missing. Again, we face the problem that the dependence of the quantum mechanical probabilities on time does not correspond to the existence of a genuine probability measure—hence a continuous limit does not exist naturally.

One way to obtain a probability measure is to introduce a time step τ, which is a measure of the temporal resolution of the measuring device. For any time scales much larger than τ, one may substitute the sum in Eq. (3.11) with an integral, thus obtaining a probability measure on $[0,T]$,

$$p(t) = \frac{1}{\tau}\,\mathrm{Tr}(\hat{\rho}_t \hat{P}_+)\exp\left[\frac{1}{\tau}\int_0^t ds\ \mathrm{Tr}(\hat{\rho}_s \hat{P}_-)\right] = -\,e^{t/\tau}\frac{d}{dt}e^{-F(t)}, \tag{3.12}$$

where $F(t)=(1/\tau)\int_0^t ds\ \hat{\rho}_s \hat{P}_-$.

The probability density above has a physically reasonable behavior for a time-of-arrival probability. For a wave function whose center follows approximately a classical path, the probability density (3.12) is peaked around the classical time of arrival for this path. To see this one may consider Eq. (3.12) for a free particle of mass m. Considering an initial Gaussian state,

$$\psi_0(x) = \frac{1}{[\pi\sigma^2]^{1/4}} e^{-(x+L)^2/2\sigma^2 + ipx}, \tag{3.13}$$

peaked at $t=0$ around $x=-L$ with mean momentum p, we obtain for the function $F(t)$,

$$F(t) = \frac{1}{2\tau}\int_0^t ds\left[1 + \mathrm{Erf}\left(\frac{\left(L - \frac{p}{m}t\right)}{\sqrt{\sigma^2 + \frac{t^2}{m^2\sigma^2}}}\right)\right], \tag{3.14}$$

which implies that (3.12) has a strong peak around the classical time of arrival $t_{\mathrm{cl}}=Lm/p$.

The problem lies in the strong dependence of these probabilities on the parameter τ. While it is reasonable to assume that the probabilities will be dependent on parameters that characterize the method of detection, we would intuitively expect that this dependence would be insignificant when we consider sufficiently large intervals of time. This is definitely not the case here, as the probabilities are very sensitive on the value of τ.

Since quantum theory does not provide a natural way to pass into the continuum limit (at least in the scheme we consider in this section), it is natural to expect that different procedures will lead to different results. We may consider, for example, the following alternative.

In Eq. (3.11) we may substitute in place of $\hat{P}_+$ a projector $\hat{P}_{\delta x}$ in position of width δx around $x=0$, and the projector $\hat{1}-\hat{P}_{\delta x}$ in place of $\hat{P}_-$. This corresponds to a setup by which the particle is detected only if it crosses the region $[-\delta x/2, \delta x/2]$. We next assume that the size δx decreases with δt, so that, as $\delta t \to 0$, the area of detection also shrinks to zero. We therefore write $\delta x = v\ \delta t$, for some unspecified constant v with dimensions of velocity. This way of taking the limit essentially implies that the actual detection of a particle needs a finite time interval, since at the limit $\delta t \to 0, \hat{P}_{\delta x}=\hat{1}$.

Writing $\rho_t(0)=\langle x=0|\hat{\rho}_t|x=0\rangle$, we obtain at the limit $\delta t \to 0$ the probability that the particle is detected between time t and $t+\delta t$ as

$$p(t)\,\delta t = \delta t\, v\rho_t(0)e^{-v\int_0^t ds\ \rho_s(0)} = -\,\delta t\frac{d}{dt}e^{-v\int_0^t ds\ \rho_s(0)}. \tag{3.15}$$

Hence, the probability that the particle is detected within the time interval $[t_1,t_2]$ equals

$$p([t_1,t_2]) = e^{-v\int_0^{t_1} ds\ \rho_s(0)} - e^{-v\int_0^{t_2} ds\ \rho_s(0)}, \tag{3.16}$$

while the probability that the particle is not detected within the time interval $[0,T]$ equals

$$p(N) = e^{-v\int_0^T ds\ \rho_s(0)}. \tag{3.17}$$

The probability density (3.15) has the correct behavior at the classical limit, but again it depends on an unspecified parameter v, which this time has dimensions of velocity. One has to assume that v has to be identified with a characteristic property of the measuring device.

It follows that with the interpretation of the reduction rule we employed here, a probability distribution for the time of arrival cannot be constructed without making reference to the specific setup through which it is determined. Whatever scheme one might employ, one has to introduce additional parameters in the description.

It would be mistaken, however, to consider the derivation leading to Eqs. (3.15) or (3.12) as inherently faulty. The only assumption we employed is that the reduction rule can only be applied when an actual measurement has actually taken place, and not when we make an *inference* about the system by the fact that no detection has occurred. This implies, in particular, that the quantum Zeno effect is irrelevant for the time of arrival, because we do not have a continuous act of measurement (only a continuous inference). With this assumption the proof leading to (3.11) only employs the classical rules of probability theory. In that sense, the key mathematical problem is that the dependence of the quantum mechanical probabilities on time does not allow the definition of a stochastic process—see the related discussion in Ref. 12. Quantum probabilities *are not naturally densities with respect to time*; one can make them densities by introducing additional parameters.

It is important to note that this fundamental difficulty does not go away, when we enlarge the system by including degrees of freedom of the measurement device. The problem of finding a suitable continuous expression for (3.11) does not depend on specific features of the system's Hilbert space. The density matrix may include degrees of freedom of the measuring device or of an environment. The problem lies with the way time appears in the formalism of quantum theory.

In any case, Eqs. (3.15) and (3.12) provide interesting candidates for a probability distribution for a time of arrival. They have a proper classical limit and they are mathematically unambiguous. In principle, they could be checked by any precision measurement of times of arrival.

IV. THE HISTORIES DESCRIPTION

In this section, we follow a different approach from that of Sec. III B. We assume that the reduction rule can be applied in any case we have obtained information about a quantum system. This allows us to preserve the "logical" structure of quantum mechanical propositions. The natural scheme to explore the time-of-arrival problem is then the consistent histories approach. However, the results we obtain here are of a more general character. The mathematical objects employed in the consistent histories approach are essentially path integrals and the amplitudes defined by these path integrals can be employed for the study of the time of arrival in different schemes. (We do that in Sec. V). The most important gain from this approach is that the continuous-time limit can be obtained unambiguously, because it is implemented at the level of amplitudes and not at that of probabilities.

A. Consistent histories

The consistent histories approach to quantum theory was developed by Griffiths,[13] Omnés,[14] and Gell-Mann and Hartle.[15,16] The basic object is a history that corresponds to properties of the physical system at successive instants of time. A discrete-time history α will then correspond to a string $\hat{P}_{t_1}, \hat{P}_{t_2}, \ldots, \hat{P}_{t_n}$ of projectors, each labeled by an instant of time. From them, one can construct the class operator,

$$\hat{C}_\alpha = \hat{U}^\dagger(t_1)\hat{P}_{t_1}\hat{U}(t_1)\cdots\hat{U}^\dagger(t_n)\hat{P}_{t_n}\hat{U}(t_n), \tag{4.1}$$

where $\hat{U}(s)=e^{-i\hat{H}s}$ is the time-evolution operator. The probability for the realisation of this history is

$$p(\alpha) = \mathrm{Tr}(\hat{C}_\alpha^\dagger \hat{\rho}_0 \hat{C}_\alpha), \tag{4.2}$$

where $\hat{\rho}_0$ is the density matrix describing the system at time $t=0$.

However, the expression above does not define a probability measure in the space of all histories, because the Kolmogorov additivity condition cannot be satisfied: if α and β are exclusive histories, and $\alpha \vee \beta$ denotes their conjunction as propositions, then it is not true that

$$p(\alpha \vee \beta) = p(\alpha) + p(\beta). \tag{4.3}$$

The histories formulation of quantum mechanics does not, therefore, enjoy the status of a genuine probability theory.

However, an additive probability measure *is* definable, when we restrict to particular sets of histories. These are called *consistent sets*. They are more conveniently defined through the introduction of a new object: the decoherence functional. This is a complex-valued function of a pair of histories given by

$$d(\alpha,\beta) = \mathrm{Tr}(\hat{C}_\beta^\dagger \hat{\rho}_0 \hat{C}_\alpha). \tag{4.4}$$

A set of exclusive and exhaustive alternatives is called consistent, if for all pairs of different histories α and β, we have

$$\mathrm{Re}\, d(\alpha,\beta) = 0. \tag{4.5}$$

In that case one can use Eq. (2.2) to assign a probability measure to this set.

B. Time-of-arrival histories

Histories and propositions about histories may be represented by projection operators on a Hilbert space $\mathcal{V} = \otimes_t H_t$, which the tensor product of the single time Hilbert spaces of standard theory—this is the History Projection Operator (HPO) formulation of the history theory.[17] The merit of this description is that the logical structure of history propositions is preserved (they form a lattice that corresponds with the lattice of subspaces of $\mathcal{V}$), and in the present context allows the arguments used for the time-of-arrival description of stochastic processes to be transferred into the quantum level. In particular, the continuum limit in time may be taken in an unambiguous manner. Note that in this scheme the decoherence functional is a Hermitian, bilinear functional on $\mathcal{V} \times \mathcal{V}$ that satisfies the following properties:

$$d(1,1) = 1, \tag{4.6}$$

$$d(0,\alpha) = 0, \tag{4.7}$$

$$d(\alpha,\alpha) \geq 0. \tag{4.8}$$

We next consider a description of time-of-arrival histories with n time steps. One defines the projectors $\hat{\alpha}_n$ corresponding to the proposition that the particle crossed $x=0$ for the first time between the mth and the $m+1$-th time step,

$$\hat{\alpha}_m = \hat{P}_- \otimes \hat{P}_- \otimes \cdots \otimes \hat{P}_+ \otimes \hat{1} \otimes \cdots \otimes \hat{1}, \tag{4.9}$$

as well as the projector $\hat{\bar{\alpha}}$ corresponding to the proposition that the particle does not cross $x=0$ within the n time steps,

$$\hat{\bar{\alpha}} = \hat{P}_- \otimes \hat{P}_- \otimes \cdots \otimes \hat{P}_-. \tag{4.10}$$

Clearly these projectors satisfy

$$\hat{\alpha}_n \hat{\alpha}_m = \delta_{nm} \hat{\alpha}_n, \tag{4.11}$$

$$\hat{\alpha}_n \hat{\bar{\alpha}} = 0, \tag{4.12}$$

$$\sum_m \hat{\alpha}_m + \hat{\bar{\alpha}} = 1. \tag{4.13}$$

Thus they form a exhaustive and exclusive set of histories, hence a sublattice of the lattice of history propositions. (One should note that the n time histories we study here should not be viewed as discretizations of continuous time paths, but as histories corresponding to genuinely discrete time. The consideration of discretized alternatives in a continuous-time theory is conceptually problematic because at any time between t_i and t_{i+1} the particle may have crossed $x=0$, and this fact will not be captured in the resulting propositions. Our approach is that we first consider alternatives of detection in a discrete-time theory, and we then identify a suitable continuous limit for the decoherence functional. This involves a choice on the way we *define* the continuous histories. This choice allows us to recover known results.[8,22] However, this procedure may not be unique–see the discussion on alternative treatments of the quantum Zeno effect.) One can therefore pullback the decoherence functional to this lattice, thereby obtaining a decoherence functional on a sample space consisting of the points $(t_1,\ldots,t_n)$ together with the point N corresponding to no crossing,

$$d(t_n,t_m) = d(\hat{\alpha}_n,\hat{\alpha}_m), \tag{4.14}$$

$$d(N,t_n) = d(\hat{\bar{\alpha}},\hat{\alpha}_n), \tag{4.15}$$

$$d(N,N) = d(\hat{\bar{\alpha}},\hat{\bar{\alpha}}). \tag{4.16}$$

In analogy to the stochastic case, one may define a self-adjoint time-of-arrival operator $\hat{T}$ on $\mathcal{V}$ modulo its value on the subspace corresponding to $\hat{\bar{\alpha}}$, namely one may define

$$\hat{T}_{x=0} = \sum_i t_i \hat{\alpha}_i, \tag{4.17}$$

which is unambiguously defined on $\mathcal{V}-\mathrm{Ran}(\hat{\bar{\alpha}})$ – $\mathrm{Ran}(\hat{\bar{\alpha}})$ is the closed linear subspace corresponding to $\hat{\bar{\alpha}}$.

We next consider two discretizations $\{t_0=0,t_1,t_2,\ldots,t_N=T\}$ and $\{t'_0=0,t'_1,t'_2,\ldots,t'_{N'}=T\}$ of the time interval $[0.T]$ with time step $\delta t=T/N$, and $\delta t'=T/N'$. We construct the decoherence functional $d([t,t+\delta t],[t',t'+\delta t'])$, where $n=tN/T$ and $m=t'N'/T$. This reads as

$$d([t,t+\delta t],[t',t'+\delta t']) = \mathrm{Tr}(\hat{\rho}_0[e^{i\hat{H}\,\delta t'}\hat{P}_-]^n e^{i\hat{H}\,\delta t'}\hat{P}_+ \times e^{i\hat{H}(t'-t)}\hat{P}_+ e^{-i\hat{H}\,\delta t}[\hat{P}_- e^{-i\hat{H}\,\delta t}]^m). \tag{4.18}$$

We take then the limit $N,N'\to\infty$, while keeping t and t' fixed. Assuming that ρ_0 lies within the range of $\hat{P}_-$, i.e., $\hat{P}_-\hat{\rho}_0\hat{P}_-=\hat{\rho}_0$ we obtain

$$d([t,t+\delta t],[t',t'+\delta t']) = \delta t\ \delta t'\ \mathrm{Tr}(e^{-i\hat{H}(t'-t)}\hat{P}_+\hat{H}\hat{P}_-\hat{C}_t^\dagger\hat{\rho}_0\hat{C}_{t'}\hat{P}_-\hat{H}\hat{P}_+), \tag{4.19}$$

where $\hat{C}_t=\lim_{n\to\infty}(\hat{P}_- e^{-i\hat{H}t/n}\hat{P}_-)^n$. Writing

$$\rho(t,t') = \mathrm{Tr}(e^{-i\hat{H}(t'-t)}\hat{P}_+\hat{H}\hat{P}_-\hat{C}_{t'}^\dagger\hat{\rho}_0\hat{C}_t\hat{P}_-\hat{H}\hat{P}_+), \tag{4.20}$$

we see that the decoherence functional corresponds to a complex-valued density on $[0,T]\times[0,T]$. The additivity of the decoherence functional (which reflects the additivity of quantum mechanical amplitudes) allows us to obtain a continuum limit, something that could not be done if we worked at the level of probabilities. Consequently, one may obtain its values on coarse-grained histories corresponding to a time-of-arrival lying within the subsets $[t_1,t'_2]$ and $[t'_1,t'_2]$ of $[0,T]$ by integrating over $\rho(t,t')$,

$$d([t_1',t_2'],[t_1,t_2]) = \int_{t_1}^{t_2} dt \int_{t_1'}^{t_2'} dt'\ \rho(t,t'). \tag{4.21}$$

We then obtain the values of the decoherence functional for any pair of measurable subsets of $[0,T]$. However, the decoherence functional on $[0,T]$ is not properly normalized, because the actual space of time-of-arrival propositions is not the space of subsets of $[0,T]$, but rather the space of subsets of $[0,T]\cup\{N\}$, where N corresponds to the event of no detection. The values of the decoherence functional, when at least one of its entries is N are easily computed

$$d([t_1,t_2],N) = \int_{t_1}^{t_2} dt\ \mathrm{Tr}(e^{-i\hat{H}(T-t)}\hat{C}_T^\dagger\hat{\rho}_0\hat{C}_t\hat{P}_-\hat{H}\hat{P}_+), \tag{4.22}$$

$$d(N,N) = \mathrm{Tr}(\hat{C}_T^\dagger\hat{\rho}_0\hat{C}_T) = 1. \tag{4.23}$$

The last equation is due to the fact that the operator $\hat{C}_t$ is a degenerate unitary operator with support on the range of $\hat{P}_-$ (the quantum Zeno effect).

The normalization condition for the decoherence functional implies that

$$d([0,T],[0,T]) + d([0,T],N) + d(N,[0,T]) + d(N,N) = 1, \tag{4.24}$$

which leads to

$$d([0,T],[0,T]) = -2\ \mathrm{Re}\ d([0,T],N). \tag{4.25}$$

It is important to note that in the context of consistent histories, the fact that $d(N,N)=1$ does not imply that the event N (never crossing $x=0$) will be realized, because $d(N,N)$ does not correspond to a probability, unless the consistency condition $\mathrm{Re}\ d[0,T],N)=0$ is satisfied. In this case, however, $d([0,T],[0,T])=0$, and hence that crossing $x=0$ never takes place. This implies that the event of the particle not crossing the surface $x=0$ can only be a member of a consistent set in which the probability for crossing $x=0$ is zero. This is rather counterintuitive, because it fails to give a correct classical limit—see the related discussion in Ref. 21. One would expect that at some level of coarse graining, one would obtain the classical result, namely a probability distribution sharply peaked around the classical time of arrival t_{cl}, similar to the one we derived in the last section.

1. Possible treatments of the quantum Zeno effect

A key feature of the quantum Zeno effect is that it is not robust. When one employs a positive operator $\hat{E}$ in the definition of the operator $\hat{C}_t$ (instead of a projector), the result is no more a degenerate unitary operator. This is true even if the operator $\hat{E}$ is very close to a true projector $\mathrm{Tr}|\hat{E}^2-\hat{E}| = \epsilon\,\mathrm{Tr}\,\hat{E}$, for a number $\epsilon \ll 1$. In that case the matrix elements of $\hat{C}_t$ fall with $e^{-\epsilon t}$, as we demonstrate in a simple example in the Appendix. This implies that even a very small deviation from a true projector leads to a qualitatively different result.

If our calculation of probabilities refers to actual measurements then the quantum Zeno effect should not pose a problem. Realistic measurements should be represented by POVMs rather than projection-valued-measures, in which case the quantum Zeno effect does not arise. However, this would spoil the continuous-time limit, which depends crucially on the fact that the operators $\hat{P}_+$ and $\hat{P}_-$ correspond to exclusive alternatives. A naive substitution of the operators $\hat{P}_+$ and $\hat{P}_-$, by partially overlapping approximate projectors would introduce extra terms in the expression of the decoherence functional. It is easy to verify that these terms would be of the order of $||\hat{P}_+\hat{P}_-||$ and not dependent on δt, hence they would remain nonzero even at the limit $\delta t \to 0$. One could entertain the possibility that the approximate projectors could be dependent on δt, and that at the

limit of δt their overlap becomes zero, i.e., they become true projectors. We have explored this possibility, but it does not seem to work. The Zeno effect still persists at the continuum limit. (This can easily be seen in the example we provide in theAppendix A.)

While the continuous-time limit we constructed here leads invariably to a quantum Zeno effect, this is not the only way that this limit can be taken in the histories formalism. The construction of the decoherence functional we presented here is obtained from a limit of discrete time expression. We have not constructed actual continuous time histories and defined the decoherence functional straightforwardly on them. To do that one should proceed in the logic of the HPO approach and construct a history Hilbert space that would correspond in some sense to a "continuous-tensor product" of single-time Hilbert spaces. Such Hilbert spaces have been constructed before;[18,6] they are not genuine continuous tensor products, but they share many of their features, and they are obtained from group-theoretical arguments. A key property of this construction is that propositions have support on finite time intervals $[t_1,t_2]$ and not on sharp points of the real line. The operator structure is then quite different at the kinematical level, and it raises the possibility that one could define a decoherence functional as a genuinely continuum object, in a way that does not suffer from the Zeno effect. For example, it is plausible that the operators entering the definition of the operator $\hat{C}_t$ as the limit of $\delta t \to 0$, should also be dependent on δt, as they should refer to finite intervals of the real line rather than sharp points. As we argued earlier, even a small change might be sufficient to remove the undesirable properties of $\hat{C}_t$; the real issue is to justify such changes from first principles within the continuous-time-histories formalism. We shall elaborate on this construction in a follow-up paper.

2. Conditioning

As we showed in Sec. II, it is possible in classical probability to reduce the probability measure from the full algebra of subsets in $[0,T]\times\{N\}$ to the algebra of events on $[0,T]$. This reduction results from the use of conditional probability. We defined a probability for the time of arrival conditioned upon the premise that the particle did cross $x=0$ at some time within the interval $[0,T]$.

This reasoning may be partially transferred to the quantum case. We cannot speak, however, for a conditional probability because this involves the consideration of consistent sets. Classical conditional probability is defined through a natural mathematical procedure, which employs the additivity of the probability measure over the space of functions on the sample space, to reduce the level of description into a subalgebra of events. Quantum probabilities are not additive over the lattice of events, but the decoherence functional is. In Refs. 20 the procedure of conditioning at the level of decoherence functional has been developed in detail, by generalizing the classical notion of conditional expectation to the quantum level. One may define a decoherence functional over a subalgebra of events (namely propositions about histories), thus incorporating any information we may have obtained for the system. For the details of the procedure, we refer the reader to Ref. 20, but for the simple case that the subalgebra with respect to which we implement the conditioning is generated by a single history proposition β, such that $d(\beta,\beta)\neq 0$, the conditioned decoherence functional is given by the intuitively simple expression

$$d_c(\alpha,\alpha') = \frac{d(\alpha\wedge\beta,\alpha'\wedge\beta_i)}{d(\beta,\beta)}. \tag{4.26}$$

The resulting decoherence functional is the mathematical object that should be used in the derivation of probabilities, provided we know that events corresponding to the subalgebra have been realized.

In the present case, we need to condition the decoherence functional from the algebra of events corresponding to the sample space $[0,T]\times\{N\}$ to the subalgebra of events corresponding to a sample space $[0,T]$, namely assuming that the particle has actually been detected. Since this operation involves "discarding" only a simple point of the sample space, the result is very simple. The conditioned decoherence functional d_c is obtained by a conditioned density,

$$\rho_c(t,t') = \frac{\rho(t,t')}{d([0,T],[0,T])} = \frac{\rho(t,t')}{-2\,\mathrm{Re}\,d([0,T],N)}. \tag{4.27}$$

Since the event of no detection is removed from the resulting subalgebra, we may pretend that we have avoided the quantum Zeno effect. This is, however, an evasion and not a solution to the problem. It only allows one to differentiate the problem of defining a probability for the time of arrival, from the more general issue of properly defining a continuum limit, that avoids the quantum Zeno effect.

C. The free particle

For the simple case of a particle at a line with Hamiltonian $\hat{H}=\hat{p}^2/2M+V(\hat{x})$, where the potential is bounded from below, we may employ a result in Refs. 8 and 22 that the restricted propagator $\hat{C}_t$ is obtained from the Hamiltonian $\hat{H}$ by Dirichlet boundary conditions. (The result cited is valid for bounded intervals of the real line; the generalization to semibounded intervals, however, is straightforwardly obtained using their method.) If we also denote by $G_0(x,x'|t)$ the full propagator in the position basis (corresponding to $e^{-i\hat{H}t}$), we obtain

$$\rho(t,t') = \frac{1}{4M^2}\partial_x(\hat{C}_{t'}\psi_0)^*(0)\partial_x(\hat{C}_t\psi_0)(0)G_0(0,0|t'-t), \tag{4.28}$$

$$d(t,N) = -\frac{1}{2M}\int_{-\infty}^{0} dx(\hat{C}_T\psi_0)^*(x)\partial_x(\hat{C}_t\psi_0)(0)G_0(x,0|T-t), \tag{4.29}$$

where $\hat{\rho}_0=|\psi_0\rangle\langle\psi_0|$, with ψ_0 having support in $(-\infty,0]$.

Note that in the derivation of the equations above, the derivative ∂_x arises from the presence of a term $\hat{P}_+\hat{H}\hat{P}_-$ in the operator product in Eq. (4.20). The contribution of the potential $V(x)$ vanishes, and the only contribution comes from the $\hat{p}^2$ of the kinetic energy.

For a free particle of mass M,

$$G_0(x,x',t) = \sqrt{\frac{M}{2\pi it}}e^{iM(x-x')^2/2t}, \tag{4.30}$$

$$C_t(x,x') = \chi_-(x)\chi_-(x')\sqrt{\frac{M}{2\pi it}}[e^{iM(x-x')^2/2t} - e^{iM(x+x')^2/2t}], \tag{4.31}$$

leading to

$$\partial_x(\hat{C}_t\psi_0)(0) = \sqrt{\frac{M}{2\pi it}}\int_{-\infty}^{0} dx\frac{-2iMx}{t}e^{i(Mx^2/2t)}\psi_0(x) := -2\partial_x(\hat{U}_t\psi_0)(0), \tag{4.32}$$

where we assumed that $\hat{P}_-\psi_0=\psi_0$.

It follows that

$$\rho(t,t') = \left(\frac{\hat{p}}{M}\hat{U}_t\psi_0\right)(0)\left(\frac{\hat{p}}{M}\hat{U}_{t'}\psi_0\right)^*(0)\sqrt{\frac{M}{2\pi i(t'-t)}}. \tag{4.33}$$

D. The classical limit

To verify that the decoherence functional for the free particle has the correct classical limit, we consider a Gaussian initial state centered around $x=-L$ and with mean momentum equal to p,

$$\psi_0(x) = (\pi\sigma_0^2)^{-1/4} e^{-(x+L)^2/2\sigma_0^2 + ipx}. \tag{4.34}$$

This state is localized within $[-\infty, 0]$ within an error of order e^{-L^2/σ^2}. We then obtain

$$\partial_x(\hat{C}_t\psi_0)(0) = \frac{2p}{\pi^{1/4}}\sqrt{\frac{\sigma_0}{\sigma^2(t)}}\left(\frac{t-t_{\mathrm{cl}}}{M\sigma^2(t)} + i\right) e^{-\left(p^2/2m^2\sigma^2(t)(t-t_{\mathrm{cl}})^2 - i\frac{p^2}{M}(t-t_{\mathrm{cl}})\right)}, \tag{4.35}$$

where

$$\sigma^2(t) = \sigma_0^2\left(1 + i\frac{t}{M\sigma_0^2}\right), \tag{4.36}$$

and $t_{\mathrm{cl}} = LM/p$ is the classical time of arrival.

Choosing T very large ($T \to \infty$), so that the classical time of arrival lies well within $[0,T]$ we see that the bidensity $\rho(t,t')$ has a singularity for $t=t'$ and that it is sharply peaked in each of its arguments around $t_{\mathrm{cl}} = LM/p$, with a width δ of the order of

$$\delta = \frac{M|\sigma(t_{\mathrm{cl}})|}{p} = \frac{M\sigma_0}{p}\sqrt{1 + \frac{L^2}{\sigma_0^4 p^2}}. \tag{4.37}$$

Note that for large values of L/p, the width δ also becomes very large. This is due to the fact that the free time evolution causes the wave packet to spread in time. A very small value of σ_0 (hence a large initial momentum uncertainty) leads to large values of δ.

Hence, if we consider a coarse-grained history α_{cl} for the time of crossing, which is centered around t_{cl} and has a width of $\Delta t \gg \delta$, and we denote as α'_{cl} the complement of α_{cl}, we obtain for the conditioned decoherence functional,

$$|d_c(\alpha_{\mathrm{cl}}, \alpha'_{\mathrm{cl}})| = O(e^{-(\Delta t/\delta)^2}), \tag{4.38}$$

$$d_c(\alpha_{\mathrm{cl}}, \alpha_{\mathrm{cl}}) = 1 - O(e^{-(\Delta t/\delta)^2}); \tag{4.39}$$

hence we conclude that history α_{cl} will almost definitely be realized, provided the particle crosses $x=0$ at some time within $[0,T]$.

Clearly there exists no classical limit, if either the initial state is not sufficiently localized in position, or if it is too localized so that the momentum uncertainty is very large, or if it is a superposition of states with a distinct value of momentum.

E. Inclusion of measurement device

In the consistent histories interpretation probabilities are only defined, if the consistency condition is satisfied. For time-of-arrival propositions, this occurs for coarse-grained histories like α_{cl} of Sec. IV D, which essentially correspond to the classical result. (Note that this result is obtained after conditioning the decoherence functional upon arrival.) However, consistent histories refer to closed systems—hence, to obtain a prediction for the time-of-arrival probabilities in the general case, we have to model the interaction of the particle with the measuring device.

There are various models for such an interaction with various degrees of complexity[23] (or for a more general case see Ref. 24). We consider here a very simple one, which will allow us to analyze some basic features of this procedure. We model the pointer of the measuring device with a two-level system. The pointer is found in the state of lower energy, while the state of higher energy corresponds to the detector having clicked. The combined Hamiltonian of the system + apparatus is then

$$\hat{H} = \frac{\Omega}{2}(1 - \sigma_3) + \hat{H}_0 + \epsilon \hat{P}_+ \sigma_1, \tag{4.40}$$

where $\hat{H}_0$ is the particle's Hamiltonian, and the interaction characterized by a coupling constant ϵ is switched on, only when the particle enters the region $x > 0$. We next construct histories similar to the ones of Sec. IV, only that they would refer to the properties of the pointer, i.e., they would be constructed from projectors of the form

$$\hat{E}_+ = \hat{1}_{\text{particle}} \otimes \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad \hat{E}_- = \hat{1}_{\text{particle}} \otimes \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \tag{4.41}$$

inserted into the definition of histories of the form (4.9) and (4.10). Hence, we seek the moment of transition from the lowest energy state of the detector to the higher energy state.

We assume that the initial state is factorized

$$\hat{\rho} = \hat{\rho}_0 \otimes \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix},$$

where $\hat{\rho}_0$ is the particle's density matrix. Using similar arguments, we obtain the following expressions for the densities defining the decoherence functional:

$$\rho(t,t') = \epsilon^2 \operatorname{Tr}(e^{-i\hat{H}_0(t'-t)} \hat{P}_+ e^{-i\hat{H}_0 t} \hat{\rho}_0 e^{i\hat{H}_0 t'} \hat{P}_+) + O(\epsilon^4), \tag{4.42}$$

$$d(t,N) = \epsilon \operatorname{Tr}(e^{-i\hat{H}_0(T-t)} \hat{P}_+ e^{-i\hat{H}_0 t} \hat{\rho}_0), \tag{4.43}$$

while $d(N,N) = 1$. Again we can define the conditioned decoherence functional on $[0,T]$ as $\rho_c(t,t') = \rho(t,t')/d([0,T],[0,T])$.

This model does not solve the fundamental problem of defining a probability density—one can easily check that the consistency condition is approximately satisfied only for highly coarse-grained histories centered around the classical time of arrival. On one hand, this is not a surprise. Realistic measurement devices are much more complex than the system described by the Hamiltonian (4.40). Moreover, they involve by necessity a degree of irreversibility, which is incompatible with a unitary evolution law (see, for example, a model in Ref. 25): the states of detection and no detection are asymmetric, because the latter involves an amplification procedure that leads to a macroscopic designation that the particle has been detected. Such an asymmetry is incompatible with unitary evolution.

On the other hand, the present model demonstrates a rather generic feature associated with the measurement problem, that makes its present felt in all interpretations of quantum theory that attempt to describe the measurement process unitarily. In the consistent histories approach measurement devices are thought of as quantum systems, which are characterized by a consistent set of histories for the pointer device, so that the values of the pointer can be ascertained individually (and assigned probabilities) for a large class of initial states of the measured system.[14,16] This is equivalent with obtaining a density matrix diagonalized in a basis factorized with respect to the degrees of freedom of the system and the measuring device, which is necessary in order to attribute definite values to the macroscopic pointer.

In the model we presented here, this is clearly not the case. There exist also very general theorems that state that such a factorization is, in general, not possible,[27] (see also the discussion in Refs. 28–30 and in a different but related context the theorems of Ref. 31). The general argument is rather simple and in the present context takes the following form. The derivation of the decoherence functional for time-of-arrival histories remains the same, whether the Hilbert space is that of a single quantum system, or if it includes the degrees of freedom of a measurement device or of an environment. The nonzero value of the off-diagonal elements of the decoherence functional would then still persist, except possibly for the case of sufficient coarse graining

corresponding to the classical results. Hence, it seems that, unless we introduce additional assumptions, the consistent histories scheme cannot produce more detailed information about the time-of-arrival probability, beyond the determination of the classical limit.

The situation is different when the evolution of the particle (rather than that of the measurement device) involves a degree of irreversibility.[26] Indeed, in the presence of a decohering environment, the evolution of the particle is closely approximated (after a typically short decoherence time) by a stochastic process, in which case one may employ the construction of time-of-arrival probabilities sketched in Sec. II. However, the time of arrival seems to depend rather crucially on properties of the environment, which seems to destroy much "more" interference than what is necessary to define a consistent set of histories. [There is a rather paradoxical situation in the presence of environment. If the full quantum mechanical treatment of system+environment is taken into account, in which case the full evolution law is unitary, we are faced with the quantum Zeno effect. Any proposition about the system will be represented by projection operators, and the operator $\hat{C}_t$ will still be a degenerate unitary operator. If, however, one describes the effect of the environment in terms of a nonunitary evolution (or a stochastic process), an excellent approximation in many cases, no such problem seems to arise. This suggests again that the quantum Zeno effect is not robust.]

Another possibility would be to consider a different measuring apparatus interacting with the particle at each moment of time. This, however, would describe a different physical circumstance than the one we consider in this paper. Here we consider the case that the only information we can obtain from the system is a signal that the particle has been detected at a specific moment of time, i.e., there is a single event of measurement. Inserting multiple measuring devices would be equivalent to letting the particle move within a material that records its track (like a bubble chamber). In that case our datum is a continuous history of the particle, and can be treated within the theory of continuous time measurement. Such an interaction inevitably causes the particle to decohere, and as such its evolution can be well approximated by a stochastic process. The derivation of the time of arrival would the be much simpler in this case and would follow the general scheme of Ref. 26. This is, however, different from the issue taken up in this paper.

V. AN OPERATIONAL DESCRIPTION FOR TIME-OF-ARRIVAL MEASUREMENTS

The derivation of the decoherence functional for the time-of-arrival propositions does not answer the question we asked at the beginning of this paper: it is, in principle, possible to measure the time of arrival in individual runs of an experiment, therefore constructing the relative frequencies for a detection of the particle within any time interval $[t_i, t_f]$. From these frequencies of events we can construct in the limit of a large number of runs a probability for the detection of the particle within any time interval. One then is entitled to ask how to obtain this operationally meaningful probability density from the rules of quantum theory.

The main contribution of the histories formalism to the final result is that it allows one to implement the continuous-time limit. However, this passage refers not to a probability density, but to the decoherence functional, and one needs further assumptions in order to construct genuine probabilities. As the expression (4.20) for the decoherence functional demonstrates, there is persistent interference between the different alternatives for the time of arrival.

This problem is not specific to the time-of-arrival measurements. It is a special case of a more general problem, that of defining a probability density for the outcomes of measurement that take place at more than one moment of time. This issue has been analyzed in Refs. 11 and 12. In sequential measurements it is possible to obtain the probabilities in terms of a Positive-Operator-Valued Measure, whose mathematical form is markedly similar to the "probabilities" constructed by the consistent histories approach. We shall attempt to do the same here for the time-of-arrival probabilities, thus exploiting the convenient continuous-time limit incorporated in the decoherence functional.

Note that the considerations in this section are purely operational and employ the Copenhagen interpretation: we do not consider closed, individual systems, but are only interested in probabili-

ties obtained in specific measurement situations, which we assume refer to a statistical ensemble. Hence, even though we shall use the mathematical apparatus of consistent histories, the context in which we work is markedly distinct.

A. Probabilities for sequential measurements

1. Discrete spectrum

Let us consider the two-time measurement of an observable $\hat{x}=\Sigma_i \lambda_i \hat{P}_i$ with a discrete spectrum. Writing $\hat{Q}_i=e^{i\hat{H}t}\hat{P}_i e^{-i\hat{H}t}$, we construct the probabilities for the most-fine grained two-time results,

$$p(i,0;j,t)=\mathrm{Tr}(\hat{Q}_j\hat{P}_i\hat{\rho}_0\hat{P}_i)=|\langle|\hat{\rho}_0|i\rangle|^2|\langle i|e^{-i\hat{H}t}|j\rangle|^2. \tag{5.1}$$

Irrespective of the interpretation of the measurement process, the probabilities (5.1) refer to the most elementary alternatives that can be unambiguously determined in the experimental setup corresponding to the sequential measurement of $\hat{x}$. Therefore, they can be employed to construct probabilities for general sample sets U_1, U_2 on the spectrum Ω of $\hat{x}$, namely,

$$p(U_1,0;U_2,t)=\sum_{i\in U_1}\sum_{j\in U_2} p(i,0;j,t). \tag{5.2}$$

The total probability is normalized,

$$p(\Omega,0;\Omega,t)=\sum_{ij}\mathrm{Tr}(\hat{Q}_j\hat{P}_i\hat{\rho}_0\hat{P}_i)=1, \tag{5.3}$$

a property that follows from the fact that $\Sigma_i\hat{P}_i=\Sigma_j\hat{Q}_j=\hat{1}$.

Equation (5.2) defines a POVM for two-time measurements. Note the difference from Eq. (4.2). Equation (4.2) is valid only for the most fine-grained alternatives. Any further coarse graining is done by summing only the elementary probabilities that correspond to the value of the decoherence functional for the most fine-grained histories. This result implies that we can use the decoherence functional to construct POVMs for sequential measurements and may expect to repeat do the same for the case of time-of-arrival.

2. Continuous spectrum

When we consider the case of an operator with a discrete spectrum, a problem appears. There are no fine-grained projectors, and the choice of the elementary quantum probabilities, from which one may build the general probabilities for measurement outcomes, cannot be made uniquely.

The immediate generalization of Eq. (5.1) for the measurement of an operator with a continuous spectrum is

$$p(x_1,0;x_2,t)=|\langle x_1|\hat{\rho}_0|x_1\rangle|^2|\langle x_1|e^{-i\hat{H}t}|x_2\rangle|^2. \tag{5.4}$$

However, this does not define a proper probability density, because it is not normalized to unity,

$$\int dx_1 \int dx_2\, p(x_1,0;x_2,t)=\infty. \tag{5.5}$$

This is due to the fact that there can be no measurements of infinite accuracy. One has, therefore, to take into account the finite width of any position measurement, say δ. This quantity depends on the properties of the measuring device—for example, the type of the material that records the particle's position.

The simplest procedure is to consider the measurement of a self-adjoint operator $\hat{x}_\delta=\Sigma_i x_i \hat{P}_i^\delta$, where $\hat{P}_i^\delta$ is a projection operator corresponding to the interval $[x_i-\delta/2, x_i+\delta/2]$. In that case we may immediately construct the fine-grained probabilities,

$$p_\delta(i,0;j,t) = \mathrm{Tr}(\hat{Q}_j^\delta \hat{P}_i^\delta \hat{\rho}_0 \hat{P}_i^\delta), \tag{5.6}$$

from which we may construct probabilities for general sample sets U_1 and U_2:

$$p_\delta(U_1,0;U_2,t) = \sum_{i\in U_1}\sum_{j\in U_2} \mathrm{Tr}(\hat{Q}_j^\delta \hat{P}_i^\delta \hat{\rho}_0 \hat{P}_i^\delta). \tag{5.7}$$

Strictly speaking, one may only consider sample sets that are unions of the elementary sets that define our lattice. If, however, the size of the sample sets L is much larger than δ, we may approximate the summation with an integral. This amounts to defining the continuous version of probabilities (5.6),

$$p_\delta(x_1,t_1;x_2,t_2) = \mathrm{Tr}(e^{i\hat{H}(t_2-t_1)}\hat{P}_{x_2}^\delta e^{-i\hat{H}(t_2-t_1)}\hat{P}_{x_1}^\delta \hat{\rho}(t_1)\hat{P}_{x_1}^\delta), \tag{5.8}$$

where we denoted $\hat{P}_x^\delta = \int_{x-\delta/2}^{x+\delta/2} dy\,|y\rangle\langle y|$.

The important result of this analysis is that the probabilities for sequential measurements (5.6) depend strongly on the resolution δ of the measuring device. This dependence is very strong: even probabilities of sample sets coarse grained at a scale much larger than δ exhibit a very strong dependence on δ. From a mathematical point of view this dependence is a consequence of the fact that the off-diagonal elements of the decoherence functional between fine-grained multitime measurement outcomes do not vanish and are generically of the order of magnitude of the probabilities themselves. Hence, when we compare a probability corresponding to a value δ, with another one corresponding to 2δ, they differ by an amount proportional to the corresponding off-diagonal terms of the decoherence functional, which is, in general, substantially large. The reader is referred to Ref. 12 for extensive discussion and generalizations.

The construction probabilities for the outcomes of sequential measurements consists of two steps. First, we identify the most fine-grained alternatives compatible with the measuring device at hand, and we construct the corresponding elementary quantum probabilities by using the rule (4.2). These fine-grained alternatives (referred to by the index a) correspond to specific functions $F_a[x(\cdot)]$ on the space of paths Ω^I. The elementary probabilities will be

$$p(a) = d(F_a,F_a). \tag{5.9}$$

In the equation above the decoherence functional is viewed as a bilinear functional on Ω^I. For example, in the two-time measurement of position, the functions take the form $F_{ij}[x(\cdot)] = \chi_i^\delta(X_{t_1})\chi_j^\delta(X_{t_2})$, and

$$p_\delta(i,0;j,t) = d(F_{ij},F_{ij}). \tag{5.10}$$

The next step involves the summation over those elementary probabilities to construct an additive measure that assigns probabilities to every sample set obtained by the coarse graining of the elementary alternatives. We shall apply this procedure to the construction of time-of-arrival probabilities.

B. POVMs for time-of-arrival probabilities

Our contention is that the analysis of sequential measurements above may be transferred to the case of time-of-arrival measurements, because they share the crucial feature that they do not refer to the properties of a physical system at a single moment of time. This implies that the decoherence functional (4.20) may be employed for the construction of a POVM on $[0,T]$ for the time of arrival probabilities, in analogy to that of (5.6).

The diagonal elements $\rho(t,t)\delta t^2$ of the decoherence functional (4.20) is essentially the modulus square of the amplitude that is obtained by the sum over all paths that cross the surface $x=0$ within the interval $t+\delta t$. While the amplitude is obtained unambiguously through path integrals, its square cannot define a proper probability density, because of the presence of a term δt^2 rather than a δt one, but also because $\rho(t,t)$ diverges. (It is interesting to note that the δt^2

dependence disappears if the decoherence condition for histories holds—see Ref. 21.) This divergence is analogous to that of (5.4) for sequential measurements of position, and can be removed in a similar manner by assuming a finite temporal resolution τ. Hence, we consider elementary intervals $[t_i,t_{i+1}]$ of width τ, τ corresponding to the temporal resolution of our measurement device. The elementary probabilities will be

$$\rho_i^\tau = \int_0^T dt \int_0^T dt' \rho(t,t') \chi_i^\tau(t) \chi_i^\tau(t'), \tag{5.11}$$

where χ_i^τ is the characteristic function of the set $[t_i,t_{i+1}]$. One then may employ these probabilities to construct any probability corresponding to a set U constructed from the elementary cells $[t_i,t_{i+1}]$. By definition $\Sigma_i \chi_i^\tau = \chi_{[0,T]}$, hence the set of all i together with the event of no detection form a proper resolution of the unity.

The reader may object at this point that this leads us back to the discrete-time expression for the diagonal elements of the decoherence functional. This is not the case, because the probabilities (5.11) involve the sum over *all* continuous paths that are detected in the time interval $[t_i,t_{i+1}]$—hence it involves the contribution of any discretization within $[t_i,t_{i+1}]$.

It is more convenient to avoid the discretization procedure and construct a POVM on the continuous sample space $[0,T]$—see Ref. 12 for the analogous procedure in sequential measurements. For this purpose we introduce a family of smeared delta functions $f_\tau(s,s')$ characterized by the parameter τ, which satisfy the following properties:

$$\int_0^T ds\, f^\tau(s,s') = \chi_{[0,T]}(s'). \tag{5.12}$$

One may consider, for example, the following functions:

$$f_\tau(s,s') = \frac{1}{T} \sum_{n=-[T/\tau]}^{[T/\tau]} e^{i(n\pi/T)(s-s')}. \tag{5.13}$$

For practical purposes these are well approximated by the Gaussians (as long as $T \gg \tau$),

$$f^\tau(s,s') = \frac{1}{\sqrt{2\pi\tau}} e^{-(s-s')^2/2\tau^2}. \tag{5.14}$$

Thus, we may define the elementary probabilities in analogy to (5.6) as

$$p^\tau(t) = \int ds\, ds' \sqrt{f^\tau(t,s)} \sqrt{f^\tau(t,s')} \rho(s,s'), \tag{5.15}$$

and construct from them the probabilities for any set $U \subset [0,T]$ as

$$p^\tau(U) = \int_U dt\, p^\tau(t). \tag{5.16}$$

Up to an error of order τ, this is equivalent with the probabilities obtained by coarse graining the elementary discrete-time probabilities (5.11). [The use of the square root in (5.15) is necessary in order to guarantee the proper dimensions of the probability density (dimensions of $[T]^{-1}$). Another way to see this is by noticing that $\sqrt{\sqrt{2\pi\tau} f^\tau(t)}$, for the Gaussian (5.14) is a smeared characteristic function for the interval $[t-\sqrt{2\pi\tau}, t+\sqrt{2\pi\tau}]$, thus corresponding to a smeared version of (5.11), which needs to be divided by $\sqrt{2\pi\tau}$ in order to define a probability density. Note also that if the decoherence condition holds, Eq. (5.15) becomes, as it must, the Gaussian smearing of the probability distribution for arrival times.]

In effect, we associate to each set U the positive operator,

$$\hat{\Pi}(U) = \int_U dt\, \hat{R}_t \hat{R}_t^\dagger, \tag{5.17}$$

where

$$\hat{R}_t = \int ds \sqrt{f^\tau(t,s)} \hat{C}_s \hat{P}_- \hat{H} \hat{P}_+ e^{i\hat{H}s} \tag{5.18}$$

is an operator that corresponds to the sum over all paths that lie within $[-\infty, 0]$ and cross through to $[0, \infty)$ within a time interval of width τ around t.

These positive operators do not yet define a POVM, because the corresponding probabilities do not add up to unity. We have to also include the event N of no detection. The normalization condition implies that a positive operator $\hat{\Pi}(N)$ should be defined as

$$\hat{\Pi}(N) = \hat{1} - \int_0^T dt\, \hat{R}_t \hat{R}_t^\dagger. \tag{5.19}$$

The operator $\hat{\Pi}(N)$ is indeed positive, because

$$\int_0^T dt\, p^\tau(t) \leq \sup_{s,s' \in [0,T]} \left(\int_0^T dt \sqrt{f^\tau(t,s)} \sqrt{f^\tau(t,s')} \right) \int_0^T ds\, ds'\, \rho(s,s'). \tag{5.20}$$

Since f^τ is a smeared delta function, the term $\int_0^T dt \sqrt{f^\tau(t,s)} \sqrt{f^\tau(t,s')}$ is maximized for $s=s'$, in which case it equals $\int_0^T dt\, f^\tau(t,s) = \chi_{[0,T]}(s) \leq 1$. Hence, $\int_0^T dt\, p^\tau(t) \leq \int_0^T ds\, ds'\, \rho(s,s') = d([0,T],[0,T]) \leq 1$. Hence

$$p(N) = \mathrm{Tr}(\hat{\rho}\hat{\Pi}(N)) = 1 - \int_0^T dt\, p^\tau(t) \geq 0, \tag{5.21}$$

for all $\hat{\rho}$.

We have thus constructed a POVM for the time of arrival essentially by summing over all possible paths that correspond to crossing the $x=0$ surface within a time interval of width τ; τ was essentially introduced as a "regularization" parameter. In general, the POVM is expected to depend strongly upon its value. The key idea employed in this derivation is that time-of-arrival probabilities are not fundamentally different from the probabilities that correspond to measurements that take place at more than one moment of time. Whenever the measured quantity is continuous, it is necessary to introduce a parameter that determines the resolution of the measuring device, and it turns out that the constructed probabilities depend strongly on this parameter. Measurements of the time-of-arrival-like sequential measurements of position seem to be strongly contextual, namely, to depend strongly on the specific measurement device employed in their determination.[12]

Our derivation relied on two assumptions. The first one is that the reduction rule may be employed consistently for the incorporation of *any information* we may obtain about a quantum system (and not only for the results of actual measurements as in Sec. III B). The second assumption is that the construction of probabilities for sequential measurements may be applied in the context of time-of-arrival measurements through a generalization of Eq. (5.10). The key mathematical input arises from the histories description, namely, the fact that it is possible to construct a sample space for the values of the time of arrival by considering continuous-time histories of the system.

C. An explicit calculation: The free particle

We shall now compute the POVM (5.17) explicitly for the case of a free particle. This case is particularly interesting, because it allows the comparison with a well-established result, namely,

the POVM constructed by Kijowski.[4] Kijowski's POVM for the time of arrival of a free particle assigns to any pure state ψ_0 a probability density $p(t,\psi_0)$, which is normalized to unity in the interval $(-\infty,\infty)$,

$$p(t,\psi_0)=\left|\int_0^\infty dp\left(\frac{p}{2\pi m}\right)^{1/2}e^{-ip^2t/2M}\psi(p)\right|^2+\left|\int_{-\infty}^0 dp\left(\frac{-p}{2\pi m}\right)^{1/2}e^{-ip^2t/2M}\psi(p)\right|^2. \tag{5.22}$$

To construct the POVM (5.17) for a free particle we use Eq. (4.33) for the decoherence functional. Since the integration in (5.15) involves the square roots of the smeared delta-functions, which have a width of order τ, we may within an error of order $O(\tau/T)$ substitute the range of integration $\int_0^T ds\int_0^T ds'\to\int_{-\infty}^\infty ds\int_{-\infty}^\infty ds'$ and employ the Gaussian smearing functions (5.14).

The probability density associated with (5.17) can be written in the momentum representation as follows:

$$p(t)=\frac{1}{2\pi}\int dp\int dp'\frac{pp'}{M^2}R(p,p',t)\tilde{\psi}_0(p)\tilde{\psi}_0^*(p'), \tag{5.23}$$

where $\tilde{\psi}_0$ is the Fourier transform of ψ_0 and

$$R(p,p',t)=\int_{-\infty}^\infty ds\int_{-\infty}^\infty ds'\sqrt{f^\tau(t,s)}\sqrt{f^\tau(t,s')}e^{-i(p^2/2M)s+i(p'^2/2M)s'}\sqrt{\frac{M}{2\pi i(s-s')}}. \tag{5.24}$$

Changing variables to $u=1/2(s+s')$ and $v=s-s'$, we note that

$$\sqrt{f^\tau(t,s)}\sqrt{f^\tau(t,s')}=f_\tau(u-t)e^{-v^2/8\tau^2}. \tag{5.25}$$

Within an error of order $O(\tau/T)$, the function $f_\tau(u-t)$ behaves as a delta function when integrated over u, thus leading to

$$p(t)\simeq\frac{1}{2\pi}\int dp\int dp'\frac{pp'}{M^2}e^{-i(p^2/2M-p^2/2M)t}r\left(\frac{E_p+E_{p'}}{2}\right)\tilde{\psi}_0(p)\tilde{\psi}_0^*(p'), \tag{5.26}$$

where $E_p=p^2/2M$ and

$$r(\epsilon)=\sqrt{\frac{M}{2\pi}}\int_{-\infty}^\infty dv\frac{e^{-v^2/8\tau^2-i\epsilon v}}{\sqrt{iv}}=\sqrt{\frac{2M\tau}{\pi}}\int_0^\infty dy\frac{e^{-y^2/2}[\cos(2\epsilon\tau y)+\sin(2\epsilon\tau y)]}{\sqrt{y}}. \tag{5.27}$$

The integral in Eq. (5.27) can be computed explicitly in terms of modified Bessel functions; however, the physically interesting information is found in specific regimes for which $r(\epsilon)$ takes a simple form. For $\epsilon\tau\ll 1$, the leading contribution to the integral is a constant, leading to

$$r(\epsilon)=\frac{\Gamma\left(\frac{1}{4}\right)}{2^{3/4}}\sqrt{\frac{M\tau}{2\pi}}, \tag{5.28}$$

which implies that the probability density $p(t)$ is proportional to $\tau^{1/2}$, when $\tau\to 0$. Hence, at the limit that the temporal resolution tends to zero the particle is never detected, crossing the surface $x=0$.

The physically interesting regime corresponds to $\epsilon\tau\gg 1$. The parameter ϵ appears in (5.26) as the particle's energy, while τ is the temporal resolution of the measurement device. According to a common interpretation of the time-energy uncertainty principle, τ cannot be smaller than $(\Delta E)^{-1}$, where ΔE is the energy spread of the wave functions. Hence for any wave function with relatively small energy spread ($\Delta E/E\ll 1$), one expects that $\tau E\gg 1$. In general, it suffices that the wave-function has support only for values of energy much larger than $1/\tau$. The resolution τ is, by assumption, much smaller than t_{cl}, hence this range of energies is well defined whenever $Et_{\mathrm{cl}}\gg 1$.

Since $t_{\rm cl}=ML/\bar{p}$, where $\bar{p}$ is the initial state's mean momentum, the condition above is equivalent to $\bar{p}L\gg\hbar$, which is always satisfied in any macroscopic configuration for the measurement of the time of arrival.

At the limit $\epsilon\tau\gg 1$,

$$\int_0^\infty dy \frac{e^{-y^2/2}[\cos(2\epsilon\tau y)+\sin(2\epsilon\tau y)]}{\sqrt{y}} \simeq \sqrt{\frac{\pi}{\epsilon\tau}}; \tag{5.29}$$

hence the dependence on τ drops from the probability density (5.26),

$$p(t) \simeq \frac{1}{\pi}\int dp \int dp' \frac{pp'}{M\sqrt{\frac{1}{2}(p^2+p'^2)}} e^{-i(p^2/2M-p^2/2M)t}\tilde{\psi}_0(p)\tilde{\psi}_0^*(p'). \tag{5.30}$$

The POVM (5.30) is defined for positive values of time, and for wave functions that satisfy $\hat{P}_+|\psi_0\rangle=0$. To compare (5.30) with Kijowski's POVM of Eq. (5.22), which is normalized to unity by integration over for all times $t\in(-\infty,\infty)$, it is convenient to also extend the domain of the probability distribution (5.30) to the whole real axis for time, by requiring that the extended POVM is invariant under the combined action of the parity and time-reversal transformations.[4] We employ the convention that the negative times correspond to the crossing of $x=0$ from the right, i.e., to initial states that have support on values of position $x\in[0,\infty)$. We then construct an equal-weight convex combination of the probability distribution (5.30) for positive t with its counterpart for negative t. We thus obtain the extension of the probability distribution (5.30) for all real values of time and all initial wave functions $\tilde{\psi}_0(p)$,

$$p_{\rm ext}(t) \simeq \frac{1}{2\pi}\int dp \int dp' \frac{pp'}{M\sqrt{\frac{1}{2}(p^2+p'^2)}} e^{-i(p^2/2M-p^2/2M)t}\tilde{\psi}_0(p)\tilde{\psi}_0^*(p'). \tag{5.31}$$

If the wave function is sharply concentrated around the mean value $\bar{p}$, i.e., if $\Delta p\ll|\bar{p}|$, then $p^2+p'^2=2pp'+O((\Delta p/\bar{p})^2)$ within the integration in (5.30). The probability density (5.31) is then identical to (5.22). Integrating $p_{\rm ext}(t)$ over $t\in(-\infty,\infty)$, we obtain

$$\int_{-\infty}^{\infty} dt\, p_{\rm ext}(t) = 1 - \int dp\ \tilde{\psi}_0^*(-p)\tilde{\psi}_0(p). \tag{5.32}$$

We see therefore that $p_{\rm ext}(t)$ is normalized to unity, if the state $\tilde{\psi}_0(p)$ has support only on positive (or only on negative) values of momentum. In this case, $\hat{\Pi}(N)=0$, i.e., all particles are eventually detected. In general, a nonzero probability $p(N)$ of nondetection is due to the fraction of particles in the statistical ensemble, which move away from the crossing surface $x=0$.

We conclude therefore that the POVM (5.17) leads to the same probability distributions for the time of arrival with Kijowski's POVM (5.22) for all initial wave functions that (i) have support in values of momentum $|p|\gg\sqrt{2m/\tau}$, and (ii) satisfy $\Delta p\ll|\bar{p}|$. This regime includes the classical limit (e.g., wave functions of the form (4.34) with $\sigma_0 p\gg 1$), but also states that are not sharply localized in position, like superpositions of macroscopically distinct wave packets, or even superpositions of states with different value of momentum—as long as Δp remains much smaller than p. Outside this regime, the POVMs (5.17) and (5.22) provide different predictions.

To make the points above more explicit, we consider an initial Gaussian state,

$$\tilde{\psi}_0(p) = (a^2/2\pi)^{1/4}\exp\left(-\frac{a^2}{4}(p-\bar{p})^2+ipL\right) \tag{5.33}$$

of mean position $-L$ and mean momentum $\bar{p}$. The momentum spreads are equal to a. In leading order to $1/a\bar{p}$ the probability distributions for the time-of-arrival predicted by the POVMs (5.30) and (5.22) coincide,

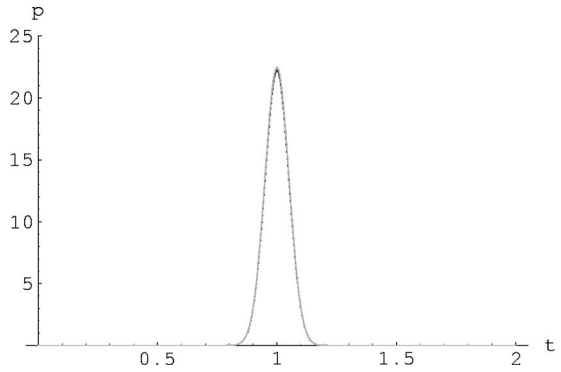

FIG. 1. The probability distribution of the time of arrival for a Gaussian initial state (5.33) of mean position $-L$ and mean momentum $\bar{p}$. It is sharply peaked around the value $t_{\mathrm{cl}}=ML/\bar{p}$. In fact, this plot contains the probability distributions provided by both POVMs (5.30) and (5.22), but even for the relatively large value of $\Delta p=0.1\bar{p}$ we employed here the two curves almost coincide.

$$p(t) \simeq \frac{\bar{p}}{\mathrm{Ma}\sqrt{8\pi}} e^{-(2/a^2)(L-\bar{p}t/M)^2}. \tag{5.34}$$

The difference between the two POVMs is of order $1/(\bar{p}a)^2$, and even for a relatively large value $1/\bar{p}a \simeq 0.1$ as in Fig. 1 their graphs are practically indistinguishable.

We next consider an initial state, which is a superposition of two Gaussians with the same mean position $-L$, but different mean momenta $\bar{p}_1$ and $\bar{p}_2$,

$$\tilde{\psi}_0(p) = \left(\frac{a^2}{4\pi}\right)^{1/4} [e^{-(a^2/4)(p-\bar{p}_1)^2+ipL} + e^{-(a^2/4)(p-\bar{p}_2)^2+ipL}]. \tag{5.35}$$

For $a\bar{p}_1 \gg 1$, $a\bar{p}_2 \gg 1$ and $a|\bar{p}_1-\bar{p}_2| \gg 1$, the leading contribution to the probability distribution obtained by the POVM (5.22) is

$$p(t) \simeq \frac{1}{\mathrm{Ma}\sqrt{8\pi}} \left[\frac{\bar{p}_1}{2} e^{-\frac{2}{a^2}(L-\bar{p}_1 t/M)^2} + \frac{\bar{p}_2}{2} e^{-\frac{2}{a^2}(L-\bar{p}_1 t/M)^2} + \sqrt{\bar{p}_1\bar{p}_2}\, e^{-(2/a^2)\left(L-\frac{1}{2}(\bar{p}_1+\bar{p}_2)t/M\right)^2} \right.$$
$$\left. \times \cos\left(\frac{\bar{p}_1^2 t}{2M} - \frac{\bar{p}_2^2 t}{2M}\right) \right], \tag{5.36}$$

and the leading contribution to the probability contribution obtained by the POVM (5.30) is

$$p(t) \simeq \frac{1}{\mathrm{Ma}\sqrt{8\pi}} \left[\frac{\bar{p}_1}{2} e^{-(2/a^2)(L-\bar{p}_1 t/M)^2} + \frac{\bar{p}_2}{2} e^{-(2/a^2)(L-\bar{p}_1 t/M)^2} \right.$$
$$\left. + \frac{\bar{p}_1\bar{p}_2}{\sqrt{\frac{1}{2}(\bar{p}_1^2+\bar{p}_2^2)}} e^{-(2/a^2)\left(L-\frac{1}{2}(\bar{p}_1+\bar{p}_2)t/M\right)^2} \cos\left(\frac{\bar{p}_1^2 t}{2M} - \frac{\bar{p}_2^2 t}{2M}\right) \right]. \tag{5.37}$$

We see that near the two classical values of the time of arrival that correspond to each of the two wave packets; the two probability distributions coincide. However, for intermediate values of time, they differ. They both manifest an oscillatory behavior there, which is characteristic of interference between the two classical values of the time of arrival. From Eqs. (5.36) and (5.37), we readily see that the oscillation amplitudes are different in this regime, and their ratio is given by the quantity $\frac{1}{2}(\bar{p}_1/\bar{p}_2+\bar{p}_2/\bar{p}_1)$. When this becomes appreciably larger than unity, i.e., if the

difference in mean momentum between the two Gaussians becomes comparable with the mean momenta themselves, the behavior of the two distributions in the oscillatory region becomes substantially different.

It is important to emphasize that the domain of applicability of the POVM (5.17) is much larger than that of the free particle case (for a generalization of Kijowski's distribution see also Ref. 32). It can be, in principle, applied for systems described by arbitrary Hamiltonians. Moreover, it is constructed through a general argumentation that does not refer only to the time of arrival and it can be easily generalized to systems with finite-dimensional Hilbert spaces, for which there is no analog of (5.22). To see this, one may consider Eqs. (5.17) and (5.18). The only objects appearing in the definition of the POVM is the Hamiltonian (together with its propagator $\hat{C}_t$) and the projection operators corresponding to the two alternatives of detection. The POVM (5.17) is therefore completely general. It can be applied, for example, the description of the particle being coupled to a measuring device, in which case the alternatives will correspond to projectors of the device's Hilbert space, and the Hamiltonian will contain an interaction term between the particle and the measurement device. It can also accommodate interactions with the environment i.e., further terms in the Hamiltonian. Its more immediate application would be the study of tunneling probabilities. This POVM may also refer to systems other than particles (e.g., multilevel atoms). Its derivation is only based on properties of Hilbert space operators and for this reason it can be applied to any physical context.

We chose to elaborate on the free particle case and ignore the effects of any measuring devices. The reason is that this system contains no other parameters other than the particle's mass (no couplings), and for this reason the only relevant time scale is t_{cl}. This allowed us to identify a physically relevant regime in which the time-of-arrival probabilities do not depend strongly on τ. Thus, we were able to compare our result with Kijowski's POVM. This, however, cannot be expected to hold for general systems, which may involve time scales of the same order of magnitude or smaller than τ. In the general case, the POVM (5.17) is expected to have a strong dependence on τ, even in physically relevant regimes.

D. The problem of contextuality

We saw that in the free particle case there exists a regime, in which the time-of-arrival probabilities are rather insensitive to τ, but this simple behavior cannot be expected to hold for systems with more complicated Hamiltonians that involve additional time scales. The POVM (5.17) will, in general, be strongly dependent on τ, and hence the probabilities for time will be strongly dependent upon the measurement scheme employed for their determination.

This contextuality of time measurements in quantum theory has been emphasized by Landauer in his study of tunneling times[33] (see also a related discussion with reference to the quantum Zeno effect[10]). However, this result is not a consequence of time being a special or distinguished variable. This type of contextuality is generic in quantum theory, once we consider measurements that do not refer to a single moment of time—e.g., sequential measurements of a continuous variable. This is a necessary consequence of the formalism of quantum theory: the evolution of the quantum state involves a linear law, while probabilities are quadratic with respect to the state. Hence, it is (in general) impossible to construct a natural probability measure for the outcomes of any measurement that reveals information that pertain to a system's dynamics (sequential, time-of-arrival, continuous measurements). This problem can be seen from different angles: from the fact that the dependence on time of the quantum probabilities do not define a probability measure and hence the continuous-time limit is not well defined (as in Sec. V B); from the fact that the natural measure for histories (4.2) is nonadditive; from the necessity to regularize the path integral amplitudes for the time of arrival in order to define probabilities; from the fact that there is interference between different alternatives for the value of the time of arrival. One therefore has to introduce an additional structure (external to the physical parameters of the system). The simplest such structure is the specification of the most fine-grained outcomes that can be recorded by a

measurement device. In the case of observables with a discrete spectrum, this is provided naturally by the formalism. For continuous variables, however, it is not, and this brings inevitably the introduction of a scale for the fine-grained alternatives.

We cannot evade this problem by enlarging our system, including, for example, a quantum measuring device or an environment. The problem is a consequence of the interplay between the quantum probability rule and the unitary dynamics. It will appear in any closed system (and will be accompanied by the quantum Zeno effect). Indeed, our arguments here were very general and hold with few modifications for an arbitrary Hilbert space and with reference to the detection of any quantum event. To avoid this problem (which can take a rather extreme form[12]) we have to abandon either the probability rule or the dynamics, and neither one of these steps is easy to take.

On the other hand, the acceptance of this contextuality is very disturbing. The devices that determine the time of arrival are not different in nature from the ones that measure a particle's position. (This is reflected in the fact that the histories for the time of arrival are written in terms of spectral elements of the position operator.) The only distinctive character in the time-of-arrival measurements is that the "observable" quantity is the reading of the clock, which is associated to the time of detection. In position measurements, however, the fuzziness due to the finite resolution of the measurement device is relatively small, when the sampling of the measurement results are sufficiently coarse grained. On physical grounds, one would expect that coarse graining at a scale much larger than the temporal resolution of the measurement device would give results independent of the device. Unlike the case of the free particle there is no reason to expect this for a general Hamiltonian—unless one considers the highly coarse-grained samplings around the classical equations of motion.

VI. CONCLUSIONS

We have considered the problem of constructing a probability density for the time of arrival. Our main guideline was the fact that time appears as an external parameter in quantum theory. We relied on the histories formalism, because they allow the natural definition of probabilities about the time of arrival.

In our perspective, the most severe problem in the determination of the time-of-arrival probability is the fact that the quantum states do not correspond to densities with respect to time. For this reason it is very difficult to obtain the continuous-time limit in a natural way. The naive way of taking the continuous-time limit gives very bad results, as it is plagued by the quantum Zeno effect. The first alternative we tried is to employ a more strict operational interpretation of the wave packet reduction, namely, that it can only be applied as a result of a system's *physical* interaction with a measurement device, and not when we obtain information about the system through inference from the lack of a detection signal. Again, the continuous-time limit was pathological and involved the introduction of an arbitrary temporal resolution.

We then considered this problem in light of the consistent histories approach. This suggests that the continuous-time limit should be taken at the level of amplitudes and not of probabilities, and for this reason it can be taken unambiguously. The consistent histories framework, however, is not sufficient for the definition of probabilities—there is "interference" between different values of the time of arrival. This problem is aggravated by the presence of the quantum Zeno effect.

Nonetheless, the mathematical benefits conveyed by the histories techniques are very important and prove essential for the construction of a POVM for the time of arrival (working, however, within the operational formulation of quantum mechanics). The consideration of measurements smeared in time allows us to construct a POVM of general validity for the time of arrival, in analogy with POVMs for the probabilities of sequential measurements. For free particles, this POVM reduces to one obtained by Kijowski. For a general system, however, the constructed POVM also depends strongly on the resolution of the measurement device. This seems to imply that the measurement of the time of arrival is highly contextual within standard quantum theory.

APPENDIX A: THE QUANTUM ZENO EFFECT IS NOT ROBUST

We provide here a simple example demonstrating the quantum Zeno effect is not robust, in the sense that even a small deviation from a projection operator in the definition (3.6) of the operator $\hat{C}_t$ yields to a qualitatively different behavior.

We consider a spin system: the Hilbert space is $\mathbf{C}^2$, and we choose the Hamiltonian $\hat{H}$ and projector $\hat{E}$ to correspond to the matrices,

$$H=\begin{pmatrix} 0 & \epsilon \\ \epsilon & 0 \end{pmatrix}, \quad E=\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}. \tag{A1}$$

We consider the self-adjoint operator,

$$\hat{V}=\begin{pmatrix} x & 0 \\ 0 & y \end{pmatrix}, \tag{A2}$$

from which we define the positive operator,

$$e^{-V\,\delta t}=\begin{pmatrix} e^{-x\,\delta t} & 0 \\ 0 & e^{-y\,\delta t} \end{pmatrix} \tag{A3}$$

This operator can be seen as a regularized expression for $\hat{E}$,

$$\lim_{x\to\infty}\lim_{y\to 0} e^{-V\,\delta t}=\hat{E}. \tag{A4}$$

We may then write a regularized version $\hat{K}_t^y$ of the operator $\hat{C}_t=(\hat{E}e^{-i\hat{H}t/n})^n$, such that.

$$\hat{C}_t=\lim_{y\to 0}\hat{K}_t^y, \tag{A5}$$

The operator $\hat{K}_t^y$ reads explicitly as

$$\hat{K}_t^y=\lim_{x\to\infty}\lim_{n\to\infty}(e^{-i\hat{H}t/n}e^{-\hat{V}t/n})^n=\lim_{x\to\infty} e^{-iHt-Vt}. \tag{A6}$$

We easily find that

$$\hat{K}_t^y=e^{-yt}\hat{E}, \tag{A7}$$

has the exponential fall behavior that characterizes Fermi's golden rule.

When the limit $y\to 0$ is also taken, we obtain the familiar result $\hat{C}_t=\hat{E}$, which is trivially a degenerate unitary operator. However, even a small deviation from $\hat{E}$ in the definition of $\hat{C}_t$ leads to a different (and intuitively more physical) qualitative behavior.

Hudson's theorem for finite-dimensional quantum systems

D. Gross[a)]
Institute for Mathematical Sciences, Imperial College London, London SW7 2BW, United Kingdom and QOLS, Blackett Laboratory, Imperial College London, London SW7 2BW, United Kingdom

(Received 31 August 2006; accepted 18 October 2006; published online 19 December 2006)

We show that, on a Hilbert space of odd dimension, the only pure states to possess a non-negative Wigner function are stabilizer states. The Clifford group is identified as the set of unitary operations which preserve positivity. The result can be seen as a discrete version of Hudson's theorem. Hudson established that for continuous variable systems, the Wigner function of a pure state has no negative values if and only if the state is Gaussian. Turning to mixed states, it might be surmised that only convex combinations of stabilizer states give rise to non-negative Wigner distributions. We refute this conjecture by means of a counterexample. Further, we give an axiomatic characterization which completely fixes the definition of the Wigner function and compare two approaches to stabilizer states for Hilbert spaces of prime-power dimensions. In the course of the discussion, we derive explicit formulas for the number of stabilizer codes defined on such systems. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2393152]

I. INTRODUCTION

A. General introduction

The Wigner distribution establishes a correspondence between quantum mechanical states and real pseudoprobability distributions on phase space. "Pseudo" refers to the fact that while the Wigner function resembles many of the properties of probability distributions, it can take on negative values. This phenomenon has been linked to nonclassical features of such quantum states (see Ref. 1 for an exposition of literature on that problem). It is naturally of interest to characterize those quantum states that are classical in the sense of giving rise to non-negative phase space distributions.

For the case of pure states described by vectors in $\mathcal{H}=L^2(\mathbb{R})$, the resolution of this problem was given by Hudson in Ref. 2. Later, Soto and Claverie generalized Hudson's result to states of multiparticle systems (Ref. 3).

Theorem 1 *(Hudson, Soto, Claverie): Let $\psi \in L^2(\mathbb{R}^n)$ be a state vector. The Wigner function of ψ is non-negative if and only if ψ is a* Gaussian state.

By definition, a vector is Gaussian if and only if it is of the form

$$\psi(q) \propto \mathrm{e}^{2\pi i(q\theta q + xq)},$$

where $q,x \in \mathbb{R}^n$ and θ is a symmetric matrix with entries in $\mathbb{C}$ [Note that the boundedness of $\psi \in L^2(\mathbb{R}^n)$ implies that θ has positive semidefinite imaginary part].

It is our objective to prove that the situation for discrete quantum systems is very similar, at least when the dimension of the Hilbert space is odd. Before stating the result, we pause for a brief overview of its main ingredients: discrete Wigner functions and stabilizer states.

The Wigner function[4] of a pure state $\psi \in L^2(\mathbb{R})$ is computed as

[a)]Electronic mail: davidg@qipc.org

$$W_\psi(p,q) = \pi^{-1} \int_{\xi \in \mathbb{R}} \mathrm{e}^{-2\pi i \xi p} \bar{\psi}\left(q - \frac{1}{2}\xi\right) \psi\left(q + \frac{1}{2}\xi\right). \tag{1}$$

Equivalently, W_ψ is the (symplectic) Fourier transform of the *characteristic function* Ξ_ψ, which in turn is defined by

$$\Xi_\psi(p,q) = \mathrm{tr}(w(p,q)^\dagger |\psi\rangle\langle\psi|).$$

Here, $w(p,q) = \mathrm{e}^{i(p\hat{X} - q\hat{P})}$ are the well-known *Weyl or displacement operators*.[5,6] Partly triggered by the advent of quantum information theory, considerable work has been undertaken to explore Wigner functions for finite-dimensional quantum systems.[7–16] Two approaches might be identified in the literature on that subject. The first one aims to cast the *definition* of the Wigner function into a form that can be interpreted for both continuous variable and discrete systems.[9–11,15] The second approach—introduced by Gibbons *et al.* in Ref. 16—focuses on the *properties* of Eq. (1). The authors imposed a set of axioms which a candidate definition of a discrete Wigner function would have to fulfill in order to resemble the well-known continuous counterpart.

We will argue that, for odd dimensions d,

$$W_\psi(p,q) = d^{-1} \sum_{\xi \in \mathbb{Z}_d} \mathrm{e}^{-(2\pi/d) i \xi p} \bar{\psi}(q - 2^{-1}\xi) \psi(q + 2^{-1}\xi)$$

is the most sensible analogue of Eq. (1), judged in terms of either of these approaches. Here, p,q are elements of $\mathbb{Z}_d = \{0, \ldots, d-1\}$ and $2^{-1} = (d+1)/2$ is the multiplicative inverse of 2 modulo d. Indeed, the definition given above is the discrete symplectic Fourier transform of the discrete characteristic function and will be shown to be the *unique* choice to mimic certain desirable properties of the continuous Wigner function.

Stabilizer states were originally defined by Gottesman in Ref. 17 as the joint eigenvectors of certain sets of elements of the qubit Pauli group. Exceeding the case of qubits, stabilizer states for higher-dimensional quantum systems have been treated in the literature (see, e.g., Refs. 18–21). Such states find manifold applications in quantum information theory, ranging from quantum error correction[22] to cluster state quantum computation.[23] Although displaying complex features such as multi-particle entanglement,[24] stabilizer states allow for an efficient classical description. In particular, a quantum computer that operates only with stabilizer states can offer no principal advantage over classical methods of computing.[22] The latter statement is sometimes called *Gottesman-Knill theorem*.

Using that language, we intend to show the following theorem.

Theorem 2 *(Discrete Hudson's theorem): Let d be odd and* $\psi \in L^2(\mathbb{Z}_d^n)$ *be a state vector. The Wigner function of* ψ *is non-negative if and only if* ψ *is a* stabilizer state.

Given that $\psi(q) \neq 0$ *for all q, a vector* ψ *is a stabilizer state if and only if it is of the form*

$$\psi(q) \propto \mathrm{e}^{(2\pi/d) i (q\theta q + xq)},$$

where $q,x \in \mathbb{Z}_d^n$ *and* θ *is a symmetric matrix with entries in* $\mathbb{Z}_d$.

Theorem 2 should convey two central messages. First, if the right definitions are employed, the continuous and the discrete case behave very similarly (even though the methods of proof are completely different). Second, it adds further evidence to what might be called a piece of folk knowledge in the field of quantum information theory: namely, that stabilizer states are the natural finite-dimensional analog of Gaussian states.

This paper is organized as follows. We survey previous work on the subject in Sec. I B. Section II is devoted to a superficial, yet self-contained introduction to Weyl operators, characteristic functions, Wigner distributions and stabilizer states. The main theorem is proven in Sec. III. Sections V–VII address various related topics. The results of these last three sections do not rely on each other. Concretely, we comment on the relation between stabilizer states and Gaussian states in Sec. IV; we consider mixed states with positive Wigner functions in Sec. V; and use Sec. VII for a discussion of Hilbert spaces whose dimension is the power of a prime.

B. Previous results

Recently, Galvao and co-workers, took a first step into the direction of classifying the quantum states with positive Wigner function.[26] To explain the relationship of their results to the present paper, we have to comment on an axiomatic approach to discrete Wigner functions and, further, on stabilizer states in dimensions that are the power of a prime number.

In Ref. 16, Gibbons *et al.* listed a set of requirements which should be met by any definition of a discrete Wigner function W. Denoting the dimension of the Hilbert space by d, their axioms amount as follows:

1. *(Phase space)* W is a linear mapping sending operators to functions on a $d\times d$ lattice, called the *phase space*.
2. *(Translational covariance)* The Wigner function is covariant under the action of the Weyl operators (in the sense of Theorem 7).
3. *(Marginal probabilities)* There exists a function $Q(\lambda)$ that assigns a pure quantum state to every line λ in phase space. If ψ is state vector, then the sum of its Wigner function along λ must be equal to the overlap $|\langle Q(\lambda)|\psi\rangle|^2$.

Let us call functions that fall into this class *generalized Wigner functions*. This term is justified, as the characterization does not specify a unique solution: for a d-dimensional Hilbert space, there exist d^{d+1} distinct generalized Wigner functions. Note also that the construction has been described only for the case where $d=p^n$ is the power of a prime, because only then the notion of a *line* in phase space has a well-defined meaning.

We turn to the second remark, concerning stabilizer states. Consider a composite system, built of n d-level particles. We are free to conceive it as a single d^n-dimensional object. The two points of view give rise to different definitions of stabilizer states, the "single-particle" one being starkly reduced as compared to the multiple-particle one. In Sec. VII, we show that the set of single-particle stabilizer states is strictly contained in the set of multiparticle ones. Indeed, the ratio of the respective cardinalities of the two sets grows super-exponentially in n. As an example, the generalized Bell and GHZ states

$$d^{-n/2}\sum_i |i\rangle\otimes|i\rangle, \quad d^{-n/2}\sum_i |i\rangle\otimes|i\rangle\otimes|i\rangle,$$

arguably the best-known multiparticle stabilizer states, do not belong to the respective single-particle sets.

The result of Ref. 26 concerns quantum states in prime-power dimensions that are nonnegative with respect to *all* possible definitions of generalized Wigner functions. These states are shown to be mixtures of single-particle stabilizer states, as described above. The authors aim to establish necessary requirements for quantum computational speedup. Indeed, if the Wigner function of a quantum computer is positive at all times, then it operates only with stabilizer states and hence offers no advantage over classical computers, by the Gottesman-Knill theorem.

Thus for the case of nonqubit pure states, Theorem 2 implies the results of Ref. 26 and goes further in two essential ways. Firstly, it suffices to look at a single definition of the Wigner function, as opposed to $d^{n(d^n+1)}$ generalized ones. Second, quantum computation and the Gottesman-Knill theorem are naturally set in the context of *multiple* particles. Our definition assigns positive Wigner functions to all multiple-particle stabilizer states, while Ref. 26 effectively relies on the single-particle definition (up to equivalence under Clifford operations). On the other hand, our main theorem does not address qubits or mixed states, which Galvao and co-workers do.

II. PHASE SPACE FORMALISM

The term *phase space formalism* encompasses the ideas and tools in relation to the *Weyl representation* to be defined shortly. We will give a concise introduction in this section. Many of the results presented can be found in the literature, but some, e.g., the Clifford covariance of the Wigner function in nonprime dimensions, seem to be new.

A. Weyl representation

We start by considering a d-dimensional quantum system d odd. In its Hilbert space $\mathcal{H}$, we choose a basis $\{|0\rangle, \ldots, |d-1\rangle\}$, labeled by elements of $\mathbb{Z}_d$. Henceforth, $\mathbb{Z}_d$ will be referred to as the *configuration space* and abbreviated by Q.

The pivotal objects in the phase space formalism are the *Weyl operators* (also known as the *generalized Pauli operators*), as constructed below. Let $\chi(q)=e^{(2\pi/d)iq}$. The relations

$$\hat{x}(q)|x\rangle = |x+q\rangle, \quad \hat{z}(p)|x\rangle = \chi(px)|x\rangle \tag{2}$$

define the *shift* and *boost* operators, respectively. The Weyl operators are given by

$$w(p,q) = \chi(-2^{-1}pq)\hat{z}(p)\hat{x}(q), \tag{3}$$

for $p,q,t \in Q$. The specific choice of phases will prove useful later on. The set of Weyl operators is closed under multiplication up to phase factors. Direct computation shows that the composition law is given by

$$w(p,q)w(p',q') = \chi\left(2^{-1}\left[\begin{pmatrix} p \\ q \end{pmatrix}, \begin{pmatrix} p' \\ q' \end{pmatrix}\right]\right) w(p+p', q+q'). \tag{4}$$

The square brackets denote the standard *symplectic inner product* on $\mathbb{Z}_d^2$,

$$\left[\begin{pmatrix} p \\ q \end{pmatrix}, \begin{pmatrix} p' \\ q' \end{pmatrix}\right] := \begin{pmatrix} p \\ q \end{pmatrix}^T J \begin{pmatrix} p' \\ q' \end{pmatrix}, \tag{5}$$

where

$$J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{6}$$

We write $w(v)=w(v_p,v_q)$ for elements $v=(v_p,v_q)\in\mathbb{Z}_d^2$. The space $V:=Q\times Q$ with inner product given by Eq. (5) will be called phase space in the sequel, owing to its analogy to the phase space known in classical mechanics.

The preceding constructing generalizes naturally to multiple particles. Indeed, the configuration space of an n-particle system is given by $Q=\mathbb{Z}_d^n$. Multiplication between two elements $p,q \in Q$ is understood as the usual inner product $pq=\Sigma_i p_i q_i$. The Hilbert space is again spanned by $\{|q\rangle\}_{q\in Q}$ and the Weyl operators are defined to be the tensor products,

$$w(p,q) = w(p_1, \ldots, p_n, q_1, \ldots, q_n) = w(p_1,q_1) \otimes \cdots \otimes w(p_n,q_n). \tag{7}$$

Equations (4) and (5) remain valid in the multiple-particle setting, if we substitute the matrix J by its multidimensional version,

$$J = \begin{pmatrix} 0_{n\times n} & \mathbb{1}_{n\times n} \\ -\mathbb{1}_{n\times n} & 0_{n\times n} \end{pmatrix}.$$

We end this section with some miscellaneous remarks.

A state vector $|\psi\rangle$ can be identified with a complex function on configuration space by setting $\psi(q)=\langle q|\psi\rangle$. We will use both representations interchangeably.

The continuous Weyl operators $w(p,q)=e^{i(p\hat{X}-q\hat{P})}$, $p,q\in\mathbb{R}$ fulfill exactly the same composition law as stated in Eq. (4), if χ is set to $\chi(q)=e^{iq}$ and the other symbols are interpreted in the obvious way. In fact, Eq. (4) is then equivalent to the fundamental *Weyl commutation relations*.[6] Having this analogy in mind, p and q will sometimes be called *momentum* and *position* coordinates, respectively.

For future reference, note the two simple relations,

$$(w(p,q)\psi)(x) = \chi(-2^{-1}pq + px)\psi(x-q), \tag{8}$$

$$\operatorname{tr} w(p,q) = d^n \delta_{p,0}\delta_{q,0}. \tag{9}$$

It remains yet to justify the name Weyl *representation*. For $v \in V$, $t \in \mathbb{Z}_d$, define $w(v,t) = \chi(t)w(v)$. Equation (4) takes on the form

$$w(v_1,t_1)w(v_2,t_2) = w(v_1+v_2, t_1+t_2+2^{-1}[v_1,v_2]).$$

The set $V \times \mathbb{Z}_d$, equipped with the above composition law is called the *Heisenberg group* $H(\mathbb{Z}_d^n)$, the Weyl matrices constituting a unitary representation of $H(\mathbb{Z}_d^n)$.[6] This point of view on Weyl operators will be needed only in Appendix A.

B. Clifford group

The Clifford group is the subset of the unitary operators that map Weyl operators to multiples of Weyl operators under conjugation,

$$Uw(v)U^\dagger = c(v)w(S(v)), \tag{10}$$

for some maps $c: V \to \mathbb{C}$ and $S: V \to V$.[17] The structure of the Clifford group is described in the following theorem. Note that the Clifford group appearing in quantum information theory has no connection to the Clifford group used in the representation theory of SO(n).

Before stating the theorem, we have to comment on a re-appearing issue: namely, that things are more involved if d is not a prime number. For prime values of d, $\mathbb{Z}_d$ has the structure of a *finite algebraic field*, $\mathbb{Z}_d^n$ is a *finite vector space*, and most of the intuitions we have about vector spaces continue to be true. Among the more severe deficiencies of the general case is the fact that not every element a of $\mathbb{Z}_d$ possesses a multiplicative inverse modulo d. But even if the analog of a theorem about vector spaces holds for nonprime values of d, it is often difficult to find a proof in the literature. Appendices C and D contain a collection of statements of this kind. Less technically inclined readers will not loose much by skipping these sections.

For the sake of clarity of language, we call functions f on Q which fulfill $f(\lambda a+b)=\lambda f(a)+f(b)$ *linear*, disregarding the fact that Q might fail to be a linear space. Similarly, a subset S of Q that is closed under addition and multiplication by elements of $\mathbb{Z}_d$ is referred to as a *subspace*. We define a function S to be *symplectic* if it is linear and preserves the symplectic form: $[S\cdot, S\cdot]=[\cdot,\cdot]$.

Theorem 3 *(Structure of the Clifford group):*

1. *For any symplectic S, there is a unitary operator $\mu(S)$ such that*

$$\mu(S)w(v)\mu(S)^\dagger = w(Sv).$$

2. *μ is a* projective representation *of the symplectic group, that is,*

$$\mu(S)\mu(T) = e^{i\phi}\mu(ST),$$

for some phase factor $e^{i\phi}$.

3. *Up to a phase, any Clifford operation is of the form*

$$U = w(a)\mu(S),$$

for a suitable $a \in V$ and symplectic S.

The representation μ is called the *Weil* or *metaplectic* representation.[6,27] Theorem 3 could be called a discrete version of the celebrated *Stone-von Neumann theorem*.[6] Its proof is not essential for understanding the further argument and has therefore been moved to Appendix A.

Note that a Clifford operation is connected to a vector a and a linear mapping S. This should remind us of a well-known structure on linear spaces: *affine transformations*. An affine mapping A

is of the form $A(b)=Sb+a$ where S is an invertible linear operator and a is a vector. Let us call A symplectic if its linear part S is.

We will frequently use the "dot notation" to define functions of one parameter; for example, writing $S\cdot+a$ for A.

Lemma 4 (Clifford group and affine transformations): The mapping

$$S\cdot+a\mapsto w(a)\mu(S)$$

is a projective representation of the group of symplectic affine transformations.

Proof: All we need to do is to compare the composition law of the affine group

$$(S\cdot+a)\circ(T\cdot+b)=S(T\cdot+b)+a=ST\cdot+(Sb+a)$$

to the composition law of the representation

$$w(a)\mu(S)w(b)\mu(T)=w(a)\mu(S)w(b)\mu(S)^{\dagger}\mu(S)\mu(T)=w(a)w(Sb)\mu(S)\mu(T)\propto w(Sb+a)\mu(ST),$$

which proves the assertion. ■

The correspondence established by the last lemma will find a very tangible manifestation in Sec. II D, when we will see that the Clifford group induces affine transformations of the Wigner function.

C. Fourier transforms

Let $Q=\mathbb{Z}_d^n$ and $f:Q\to\mathbb{C}$ be a complex function on Q. The Fourier transform of f is

$$(\mathcal{F}f)(p)=\hat{f}(p)=|Q|^{-1/2}\sum_{q\in Q}\bar{\chi}(pq)f(q). \tag{11}$$

In the course of the main proof we will be confronted with Fourier transforms of functions which are defined only on a subspace of Q. If d is prime, then any subspace of $Q=\mathbb{Z}_d^n$ is of the form $\mathbb{Z}_d^{n'}$, for some $n'\leqslant n$, so no new situation arises.

For nonprime dimensions, however, subspaces may not be as well behaved. Consider as an example $\{0,3,6\}\subset\mathbb{Z}_9^1$. The set is closed under addition and multiplication, but can clearly not be written as $\mathbb{Z}_9^{n'}$.

To cope with this problem, we will cast Eq. (11) into a form that is well defined for functions f on more general spaces. The construction is presented below. It can be found in any textbook on harmonic analysis (e.g., Ref. 28).

A *character* of Q is a function $\zeta:Q\to\mathbb{C}$ such that $\zeta(a+b)=\zeta(a)\zeta(b)$. Any character of Q is of the form $\zeta(q)=\bar{\chi}(xq)$ for an appropriate $x\in Q$ (see Appendix C). We can hence conceive the Fourier transformation defined in Eq. (11) as a function of the characters of Q,

$$\hat{f}(\zeta)=|Q|^{-1/2}\sum_{q}\zeta(q)f(q). \tag{12}$$

We denote the set of characters of Q by Q^*. With these notions, Eq. (12) defines a function $Q^*\to\mathbb{C}$. If, now, S is any subspace of Q and f a function on S, the Fourier transform

$$\hat{f}:S^*\to S,\quad \hat{f}(\zeta)=|S|^{-1/2}\sum_{s}\zeta(s)f(s)$$

is well defined.

For $f:V\to\mathbb{C}$, we define the *symplectic Fourier transform* as

$$(\mathcal{F}_S f)(a)=|V|^{-1/2}\sum_{b\in V}\bar{\chi}([a,b])f(b). \tag{13}$$

Finally, take note that the normalization in Eqs. (11) and (12) has been chosen in such a way that *Parzeval's theorem* $\|f\|=\|\hat{f}\|$ holds, where $\|f\|^2=\Sigma_q|f(q)|^2$.

D. Definition and properties of the Wigner function

Employing Eq. (9) in conjunction with the composition law [Eq. (4)], one finds that the Weyl operators $\{w(p,q)\}$ form an orthonormal basis in the space of operators on $\mathcal{H}$ with respect to the trace scalar product $d^{-n}\,\mathrm{tr}(\cdot^{\dagger}\cdot)$. The *characteristic function* Ξ_ρ of an operator ρ is given by its expansion coefficients with respect to the Weyl basis,

$$\Xi_\rho(\xi,x)=d^{-n}\mathrm{tr}(w(\xi,x)^{\dagger}\rho). \tag{14}$$

We mentioned in the introduction that the continuous Wigner function is the symplectic Fourier transform of the characteristic function.[5,6] The two latter concepts have been defined for finite-dimensional systems in the preceding paragraphs. We can now state in complete analogy to the continuous case.

Definition 5 (*Wigner function*): *Let d be odd,* $Q=\mathbb{Z}_d^n$ *for some n. Let* $V,\mathcal{H}$ *be as usual and let* ρ *be a quantum state on* $\mathcal{H}$.

The Wigner function W_ρ *associated with* ρ *is the symplectic Fourier transformation of the characteristic function* Ξ_ρ.

An explicit calculation yields, for all $a\in V$,

$$(\mathcal{F}_S\Xi_\rho)(a)=d^{-2n}\sum_{b\in V}\bar{\chi}([a,b])\mathrm{tr}(w(b)^{\dagger}\rho)=d^{-n}\mathrm{tr}\left(\left(d^{-n}\sum_b\bar{\chi}([a,b])w(b)^{\dagger}\right)\rho\right)=:d^{-n}\mathrm{tr}(A(a)\rho), \tag{15}$$

where we have implicitly defined the *phase space point operator* $A(a)$.[16]

Theorem 6 lists a selection of properties of the Wigner function. For a more thorough discussion, the reader is deferred to Refs. 9 and 15.

Theorem 6 (*properties of the Wigner function*):

1. *The phase space point operators have unit trace and form an orthonormal basis in the space of Hermitian operators on* $\mathcal{H}$. *Hence the Wigner function of a Hermitian operator is real, and further, the* overlap

$$d^{-n}\mathrm{tr}(\rho\sigma)=\sum_{v\in V}W_\rho(v)W_\sigma(v)$$

and normalization *relations*

$$\sum_v W_\rho(v)=\mathrm{tr}\rho$$

hold.

2. *For a pure state* ψ, *the Wigner function* $W_\psi:=W_{|\psi\rangle\langle\psi|}$ *equals*

$$W_\psi(p,q)=d^{-n}\sum_{\xi\in Q}\bar{\chi}(\xi p)\bar{\psi}(q-2^{-1}\xi)\psi(q+2^{-1}\xi).$$

3. *When computing marginal probabilities, the Wigner function behaves like a classical probability distribution*,

$$\sum_{p\in Q}W_\psi(p,q)=|\psi(q)|^2.$$

4. *The multiparticle phase space point operators factor*,

$$A(p_1,\ldots,p_n,q_1,\ldots,q_n)=\bigotimes_i^n A^{(i)}(p_i,q_i)$$

(*and hence so does the Wigner function*).

5. *It holds that* $A(0)|q\rangle=|-q\rangle$. *In other words, the phase space point operator at the origin equals the* parity operator.
6. *The Wigner function* $W_{\rho\sigma}$ *of an operator product is given by the* * product (*also known as the* Groenewold *or* Moyal product,[29])

$$W_{\rho\sigma}(u)=(W_\rho\star W_\sigma)(u):=d^{-n}\sum_{v,w}W_\rho(u+v)W_\sigma(u+w)\bar{\chi}([v,w]).$$

Proof: The proofs are all straightforward; we give only hints on how to conduct them. It will be essential to recall the well-known relation

$$\sum_{x\in\mathbb{Z}_d^n}\chi(xy)=d^n\delta_{y,0}, \tag{16}$$

for all $y\in\mathbb{Z}_d^n$.

Indeed, the first claim can be proven by using Eq. (16) together with the definition of the phase space point operators Eq. (15). Employ Definition 5 and Eq. (16) to establish the second assertion, which in turn implies the third one. Theorem 6.4 makes use of the fact that $\bar{\chi}(pq)=\prod_i\bar{\chi}(p_iq_i)$ (see also Sec. VII for a very similar and more explicit calculation). The validity of the fifth statement is best shown using Eqs. (8) and (16).

Let us lastly turn to Claim 6. We have noted that the phase space point operators form an orthonormal system. Hence we can expand an operator ρ in terms of its Wigner function as $\rho=\Sigma_v W_\rho(v)A(v)$. Substituting ρ and σ by their respective expansions in $W_{\rho\sigma}(v)=d^{-n}\,\mathrm{tr}(A(v)\rho\sigma)$ yields the desired formula with the help of Lemma 29. □

The following statement will be vital to the proof of the main theorem. It assigns an elegant geometric interpretation to the Clifford group.

Theorem 7 (*Clifford covariance*): *Let* $U=w(a)\mu(S)$ *be a Clifford operation. Let* $\rho':=U\rho U^\dagger$ *for some Hermitian operator* ρ. *The Wigner function is* covariant *in the sense that*

$$W_\rho(v)=W_{\rho'}(Sv+a).$$

Proof: We compute the action of the Clifford group on the phase space point operators.

$$\begin{aligned}
w(a)\mu(S)A(b)\mu(S)^\dagger w(a)^\dagger &= d^{-n}\sum_{v\in V}\bar{\chi}([b,v])w(a)\mu(S)w(v)\mu(S)^\dagger w(a)^\dagger\\
&= d^{-n}\sum_v\bar{\chi}([b,v])w(a)w(Sv)w(a)^\dagger = d^{-n}\sum_v\bar{\chi}([b,v])\chi([a,Sv])w(Sv)\\
&= d^{-n}\sum_{v':=Sv}\bar{\chi}([b,S^{-1}v'])\bar{\chi}([a,v'])w(v') = d^{-n}\sum_{v'}\bar{\chi}([Sb+a,v'])w(v')\\
&= A(Sb+a).
\end{aligned}$$

The claim follows by use of Eq. (15). □

Our definition of the discrete Wigner function coincides with the ones used in Refs. 7, 9, 11, and 15. It is further equal to Leonhardt's version,[8] up to a permutation of points in phase space; it corresponds to choice (a) in Ref. 12 and lastly to $G=\mathbb{Z}_d^n$ in Ref. 14. One can show that W, as defined here, fulfills the axioms of Ref. 16 which had been laid out in Sec. I B. Put differently, it is an element of the set of generalized Wigner functions. Gibbons *et al.* remarked in Ref. 16 that among the generalized Wigner functions, some stand out by their high degree of symmetry. In our language, this symmetry is an incarnation of the Clifford covariance established in Theorem 7.

Naturally, it is now interesting to ask how much freedom is left in the definition of a Wigner function, once one requires Clifford covariance to hold. We show in Appendix B that the definition used here is virtually unique in that regard.

E. Stabilizer states

Using the composition law of the Heisenberg group [Eq. (4)], it is easy to see that two Weyl operators $w(v_1)$ and $w(v_2)$ commute if and only if $[v_1,v_2]=0$. Now consider the image of an entire subspace M under the Weyl representation w. The set

$$w(M)=\{w(m)|m\in M\}$$

consists of mutually commuting operators if and only if the symplectic form vanishes on M

$$[m_1,m_2]=0 \quad \text{for all } m_i\in M.$$

Spaces of that kind are called *isotropic*. Clearly, if M is isotropic, then the operators $w(M)$ can be simultaneously diagonalized. We will see that if $|M|=d^n$, the eigenspaces become nondegenerate and can thus be used to single out state vectors in the Hilbert space. A subspace M of V is said to be *maximally isotropic* if its cardinality equals d^n. See Appendix C for a justification of that nomenclature.

Lemma 8 (Stabilizer States): Let M *be a maximally isotropic subspace of* V. *Let* $v\in V$. *Up to a global phase, there is a unique state vector* $|M,v\rangle$ *that fulfills the eigenvalue equations*

$$\chi([v,m])w(m)|M,v\rangle=|M,v\rangle,$$

for all $m\in M$.

Proof: Existence. It is elementary to check that

$$|M|^{-1}\sum_{m\in M}\chi([v,m])w(m) \tag{17}$$

is a rank one projection operator fulfilling the eigenvalue equations.

Uniqueness. According to Appendix C, there are p^n characters of M, each giving rise to a distinct projection operator as defined in the last paragraph. Two distinct operators of that kind are mutually orthogonal, because they belong to different eigenvalues of at least one of the Weyl operators. But $\dim\mathcal{H}=|Q|=p^n$ and thus there is no space for more than one-dimensional solutions to the given set of equations. □

The state vector $|M,v\rangle$ is called the *stabilizer state* associated with M and v. For obvious reasons, one refers to the set of operators $\{\chi([v,m])w(m)|m\in M\}$ as the *stabilizer* of $|M,v\rangle$. Due to the isotropicity of M, the stabilizer is closed under multiplication and thus constitutes a group. Occasionally, we write $|M\rangle$ for $|M,0\rangle$. To specify a stabilizer state, we need to specify a maximally isotropic space M. This is best done by giving a basis $\{m_1,\ldots,m_k\}$ of M. It is convenient to assemble the basis vectors as the columns of a $2n\times k$ matrix, which is generally referred to as the *generator matrix*. As the choice of a basis is nonunique, so is the form of the generator matrix.

A stabilizer state $|M\rangle$ is a *graph state* if it possesses a generator matrix of the form

$$\begin{pmatrix}\vartheta\\ \mathbb{1}_{n\times n}\end{pmatrix}, \tag{18}$$

where ϑ is a symmetric $n\times n$ matrix.[24] The designation stems from the fact that ϑ can be interpreted as the adjacency matrix of a graph. Many properties of $|M\rangle$ are describable in terms of that graph alone.[24] Some authors require the diagonal elements $\vartheta^i{}_i$ to vanish (equivalently, no vertex of the graph should be linked to itself), but we will not impose that restriction. Note that there exist considerably more general definitions of graph states.[19]

Obviously, we will be concerned with Wigner functions of stabilizer states. Lemma 9 clarifies their structure.

Lemma 9 (Wigner functions of stabilizer states): The Wigner function of a stabilizer state $|M,v\rangle$ *is the* indicator function *on* $M+v$. *More precisely*,

$$W_{|M,v\rangle}(a) = \frac{1}{d^n}\delta_{M+v}(a) = \frac{1}{d^n}\begin{cases} 1 & a \in M+v \\ 0 & \text{else.} \end{cases}$$

Proof: The representation given in Eq. (17) of $|M,v\rangle$ determines the characteristic function

$$\Xi_{|M,v\rangle}(b) = d^{-n}\chi([v,b])\,\delta_M(b).$$

We compute the symplectic Fourier transformation,

$$(\mathcal{F}_S\Xi_{|M,v\rangle})(a) = d^{-2n}\sum_{b\in V}\bar{\chi}([a,b])\chi([v,b])\,\delta_M(b) = d^{-2n}\sum_{b\in M}\bar{\chi}([a-v,b]) = d^{-n}\delta_{M^\perp}(a-v),$$

where

$$M^\perp = \{v \in V | [m,v] = 0 \text{ for all } m \in M\}$$

is the *symplectic complement* of M in V. But M is a maximally isotropic space and hence $M = M^\perp$ (see Appendix C). □

In particular, we know now that the Wigner function of stabilizer states is non-negative. The next sections are devoted to the proof of the converse.

III. DISCRETE HUDSON'S THEOREM

A. Bochner's theorem

Define the *self-correlation function*

$$K_\psi(q,x) = \psi(q+2^{-1}x)\bar{\psi}(q-2^{-1}x),$$

and note that the Wigner function fulfills

$$W(p,q) = \frac{1}{d^n}\sum_{x\in Q}\bar{\chi}(px)K_\psi(q,x). \tag{19}$$

Fix a $q_0 \in Q$. Designating the function $p \mapsto W(p,q_0)$ by $W(\cdot,q_0)$, Eq. (19) says that $W(\cdot,q_0)$ is the Fourier transform of $K(q_0,\cdot)$. Therefore, W is non-negative if and only if the d^n functions $K(q_0,\cdot)$ have non-negative Fourier transforms.

In harmonic analysis, the set of functions with non-negative Fourier transforms is characterized via a theorem due to Bochner. It is usually proven either in the context of Fourier analysis on the real line or else, in full generality, for harmonic analysis on—not necessarily Abelian—locally compact groups. While the former statement is not general enough for our purpose, the latter is not easily accessible. However, it turns out that in the discrete Abelian setting an elementary proof can be given. It is stated in the next theorem, along with a variation for subsequent use.

Theorem 10 *(Variations of Bochner's Theorem): Let* M *be a subspace of* Q. *Let* $f: M \to \mathbb{C}$. *The following holds*.

1. *The Fourier transform of* f *is non-negative if and only if the matrix*

$$A^x{}_q = f(x-q) \quad (x,q \in M)$$

is positive semidefinite.

2. *The Fourier transform of* f *has constant modulus (i.e.,* $|\hat{f}(x)| = \text{const}$*) if and only if* f *is orthogonal to its translations*,

$$\langle f, \hat{x}(q) f\rangle = \sum_{x\in M}\bar{f}(x)f(x-q) = 0,$$

for all nonzero $q \in M$.

Proof: The following computation is a variant of a well-known fact concerning circulant matrices. We claim that any character ζ of M is an eigenvector of A with eigenvalue $\lambda = |M|^{-1/2}\hat{f}(\zeta)$. Indeed, plugging in the definitions yields

$$(A\zeta)(x) = \sum_q A^x{}_q \zeta(q) = \sum_q f(x-q)\zeta(q) = \sum_q f(q)\bar{\zeta}(q)\zeta(x) = \sqrt{|M|}\hat{f}(\zeta)\zeta(x).$$

There exist $|M|$ characters and thus equally many eigenvectors of A. Therefore, A can diagonalized. All its eigenvalues are non-negative if and only if $\hat{f}$ is non-negative.

By the same argument, A is proportional to a unitary matrix if and only if $|\hat{f}(q)|$ is constant. But a matrix is unitary if and only if its rows form an orthonormal set of vectors. □

From here, the proof proceeds in two steps. Section III B harvests Theorem 10.1 to gain information on the pointwise modulus $|\psi(q)|$ of a vector with non-negative Wigner function. Building on these findings, we will analyze the properties of such Wigner functions in Sec. III C.

B. Supports and moduli

Lemma 11 (Modulus inequality): Let ψ *be a state vector with non-negative Wigner function. It holds that*

$$|\psi(q)|^2 \geqslant |\psi(q-x)||\psi(q+x)|,$$

for all $q,x \in Q$.

Proof: Fix a $q \in Q$. As W_ψ is non-negative, so is the Fourier transform of $K_\psi(q,\cdot)$. Bochner's theorem implies that the matrix $A^x_y = K(x-y,q)$ is positive semidefinite (psd) which in turn implies that all principal submatrices are psd. In particular the determinant of the 2×2 principal submatrix

$$\begin{pmatrix} K_\psi(q,0) & K_\psi(q,2x) \\ K_\psi(q,-2x) & K_\psi(q,0) \end{pmatrix} = \begin{pmatrix} |\psi(q)|^2 & \psi(q+x)\bar{\psi}(q-x) \\ \bar{\psi}(q+x)\psi(q-x) & |\psi(q)|^2 \end{pmatrix}$$

must be non-negative. But this means

$$|\psi(q)|^4 - |\bar{\psi}(q+x)\psi(q-x)|^2 \geqslant 0,$$

which proves the theorem. □

We will call the set supp ψ of points where a state vector is nonzero its *support*. $S = \text{supp}\ \psi$ has the property to contain the *midpoint* of any two of its elements. Indeed, if $a,b \in S$, then setting $q = 2^{-1}(a+b)$ and $x = 2^{-1}(a-b)$ in the modulus inequality shows that

$$|\psi(2^{-1}(a+b))| \geqslant |\psi(a)||\psi(b)| > 0,$$

hence $2^{-1}(a+b) \in S$. Let us refer to sets possessing this quality as being *balanced*.

The following lemma clarifies the structure of balanced sets. Recall that a subset A of V is *affine* if $A = M + v$ for a subspace M and some vector v. An affine space is a subspace if and only if it contains the origin 0.

Lemma 12 (Balanced sets): A subset S of Q *is balanced if and only if* S *is an affine space.*

Proof: We show the "only if" part, the other one being simple.

As both the characterizations of balance and affinity are invariant under translation, there is no loss of generality in assuming that $0 \in S$. We have to establish that S is closed under both addition and scalar multiplication.

Let $a \in S$. We claim that

$$2^{-l}\lambda a \in S, \tag{20}$$

for all $l \in \mathbb{N}$ and $\lambda \leqslant 2^l$. The proof is by induction on l. Suppose Eq. (20) holds for some l. If $\lambda \leqslant 2^{l+1}$ is even, then $2^{-l-1}\lambda a = 2^{-l}(\lambda/2)b \in S$. Else,

$$2^{-l-1}\lambda a = 2^{-1}\left(2^{-l}\frac{\lambda-1}{2}a + 2^{-l}\frac{\lambda+1}{2}a\right) \in S,$$

which shows the validity of Eq. (20).

There exists an integer $l > d$ such that $2^l = 1 \bmod d$. Indeed, by Euler's theorem, $2^{\phi(d)} = 1 \bmod d$, where ϕ is Euler's totient function. So $l = d\phi(d)$ satisfies the requirements. Inserting l into Eq. (20), we conclude that $\lambda a \in S$ for all $\lambda \leqslant 2^d$. Thus certainly $\lambda a \in S$ for all $\lambda \in \mathbb{Z}_d$ and we have proved closure under scalar multiplication.

If $a, b \in S$ then, by the last paragraph $2a, 2b \in S$ and hence $2^{-1}(2a+2b) \in S$, establishing closure of S under addition. □

Lemma 13 (Constant modulus): Let ψ be a state vector with non-negative Wigner function. Then $|\psi(\cdot)|$ is constant on the support of ψ.

Proof: Pick two points $x, q \in \operatorname{supp}\psi$ and suppose $|\psi(q)| > |\psi(x)|$.

Letting $z = x - q$, the assumption reads $|\psi(q)| > |\psi(q+z)|$. The modulus inequality, centered at $q+z$, gives

$$|\psi(q+z)|^2 \geqslant |\psi(q)||\psi(q+2z)|. \tag{21}$$

As supp ψ is affine, we know that $\psi(q+kz) \neq 0$ for all $k \in \mathbb{Z}_d$. Hence Eq. (21) together with the assumption implies

$$|\psi(q+z)|^2 > |\psi(q+z)||\psi(q+2z)| \Leftrightarrow |\psi(q+z)| > |\psi(q+2z)|.$$

By inducting on this scheme, we arrive at

$$|\psi(q)| > |\psi(q+z)| > |\psi(q+2z)| > \cdots$$

and therefore $|\psi(q)| > |\psi(q+dz)| = |\psi(q)|$, which is a contradiction.

Thus $|\psi(q)| \leqslant |\psi(x)|$. Swapping the roles of x and q proves that equality must hold. □

At this point, we have full knowledge of the pointwise *modulus* of a state vector with non-negative Wigner function. The *phases* of $\psi(\cdot)$ are, however, completely unknown. The section to come addresses this problem indirectly by studying non-negative Wigner functions.

C. Non-negative Wigner functions

To motivate the following, assume for a moment that ψ has a non-negative Wigner function and further that $\psi(q) \neq 0$ for all q. Choose a $q_0 \in Q$ and consider the function $W(\cdot, q_0)$. Lemma 13 implies that $K_\psi(q_0, \cdot)$ has constant modulus and hence—by Theorem 10.2—$W(\cdot, q_0)$ must be orthogonal to its translations. Clearly, a non-negative function possesses this property if and only if it is supported on at most a single point.

There hence exists a $p_0 \in Q$ such that $W(p, q_0) \propto \delta_{p,p_0}$. This observation starkly reduces the possible forms of positive Wigner functions; it will be generalized to state vectors with arbitrary support in the next lemma.

Lemma 14: Let ψ be a state vector. If W_ψ is non-negative, then it is of the form

$$W_\psi(v) = d^{-n}\delta_T(v),$$

where $T \subset V$ is a set of cardinality d^n.

What is more, if $0 \in T$, then the set of elements of T with vanishing position coordinates

$$\{(p,0) \in T | p \in Q\}$$

is a subspace of V.

Proof: Let $S=\operatorname{supp}\psi$. Again, we may assume that S is a subspace of Q, for else we replace ψ by $w(-s)\psi$ for some $s\in S$. It follows that $\operatorname{supp}K_\psi=S\times S$. Indeed,

$$K_\psi(q,x)\neq 0\Leftrightarrow q\pm 2^{-1}x\in S\Leftrightarrow q\in S\wedge x\in S.$$

Denote by $S^\perp=\{q\in Q|sq=0 \text{ for all } s\in S\}$ the orthogonal complement of S. (For subsets S of Q, $S^\perp$ denotes the orthogonal complement, while for subsets S of V the same symbol refers to the *sympectic* complement. This notation is natural, as for both Q and V only one respective inner product has been defined). We will adopt the common notation $[p]=p+S^\perp$ for cosets of $S^\perp$. It should be clear that $[p]$ is nothing other but the *affine space* with directional vector space given by $S^\perp$ and base vector p. The set S^* of characters of S can be identified with $Q/S^\perp$. Certainly, $s\mapsto\chi(ps)$ defines a character of S for every $p\in Q$. Further, $\chi(ps)=\chi(p's)$ for all $s\in S$ if and only if $p-p'\in S^\perp$. That indeed all elements of S^* can be obtained this way is shown in Corollary 26.

Define K'_ψ to be the restriction of K_ψ to its support $S\times S$. For the rest of the proof, we fix a $q_0\in S$. Now consider

$$W(p,q_0)=d^{-n}\sum_{x\in Q}\bar{\chi}(px)K(q_0,x)=d^{-n}\sum_{x\in S}\bar{\chi}(px)K'(q_0,x).$$

Viewed as a function in p, $W(p,q_0)$ has constant values on cosets of $S^\perp$. Therefore,

$$W'([p],q):=d^n|S|^{-1/2}W(p,q) \tag{22}$$

is a well-defined function on S^*. The considerations of the previous paragraph allow us to identify $W'([\cdot],q_0)$ as the Fourier transform of $K'(q_0,\cdot)$.

We can now repeat the argumentation presented just before the current lemma. Indeed, the modulus of $K'(q_0,[\cdot])$ is constant and W' is non-negative. Furthermore, by definition of q_0, $K'(q_0,[\cdot])$ is nonzero and we may thus conclude that $p\mapsto W'([p],q_0)$ is supported on exactly one coset $[p_0]$.

Normalization of ψ implies $|\psi(\cdot)|=|S|^{-1/2}$. Hence $|K'_\psi(q_0,\cdot)|=|S|^{-1}$ and

$$\|K'_\psi(q_0,\cdot)\|^2=\sum_x|K'_\psi(q_0,x)|^2=|S|^{-1}.$$

By Parzeval's theorem, $\|W'([\cdot],q_0)\|^2=|S|^{-1}$ as well. It follows that $W'([p_0],q_0)=|S|^{-1/2}$.

Inverting Eq. (22) gives

$$W(p,q)=d^{-n}\begin{cases}1 & [p]=[p_0]\\ 0 & \text{else},\end{cases} \tag{23}$$

which proves the first claim of the lemma. The cardinality of T is fixed by the normalization of the Wigner function (Theorem 6.6).

Now suppose $W(0,0)=W'([0],0)\neq 0$. Clearly, then $W(p,0)$ is nonzero if and only if $p\in[0]\Leftrightarrow p\in S^\perp$. The last assertion of the lemma follows, since $S^\perp$ is a subspace of Q. □

So a non-negative Wigner function is the indicator functions of some set T. This finding is compatible with Lemma 9, which describes the structure of Wigner functions of stabilizer states. The next two lemmas verify that T has indeed all the properties of the sets that appear in Lemma 9.

Lemma 15: Let ψ *be a state vector. If* W_ψ *is of the form*

$$W_\psi(v)=d^{-n}\delta_T(v),$$

then T *is an affine space*.

Proof: The proof proceeds similar to the one of Lemma 12. There is no loss of generality in assuming that $0\in T$.

First, we show that T is closed under scalar multiplication. To this end, pick a point $a\in T$. There exists a symplectic mapping S that sends a to a vector a' of the form $(a'_p,0)$ where a'_p

$\in Q$ (see Appendix D). The set $T'=ST$ is the support of the Wigner function of $\mu(S)\psi$. By the second assertion of Lemma 14, $\lambda a' \in ST$ for every $\lambda \in \mathbb{Z}_d$. Hence $S^{-1}(\lambda a')=\lambda a \in T$.

Turning to closeness under addition, let $a,b \in T$. By the last paragraph, $2a,2b \in T$. Arguing as before, note that the set $T-2a$ is the support of the Wigner function of $w(-2a)\psi$ and thus closed under multiplication. As $2b-2a \in T-2a$, we know that $b-a \in T-2a$ and hence $b+a \in T$. □

Lemma 16: Let ψ be a state vector such that W_ψ is of the form

$$W_\psi(v) = d^{-n}\delta_T(v).$$

If T is a subspace, then it is isotropic.

Proof: The vector ψ describes a pure state, hence $W_\psi \star W_\psi = W_\psi$ (recall the Moyal product, introduced in Theorem 6). Let $u \in T$. Plugging in the definitions gives

$$W_\psi \star W_\psi(u) = d^{-n} \sum_{v,w \in V} W_\psi(u+v) W_\psi(u+w) \overline{\chi}([v,w]) = d^{-3n} \sum_{v,w \in T} \overline{\chi}([v,w]).$$

Note that $\Sigma_{w \in T} \overline{\chi}([v,w]) \leqslant |T| = d^n$ with equality if and only if $[v,w]=0$ for all w. Hence

$$W_\psi \star W_\psi(u) \leqslant d^{-n} = W_\psi(u).$$

For the left-hand and the right-hand side to be equal, T must be isotropic. □

Therefore T, as defined above, is of the form $T=M+v$ where M is an isotropic space of cardinality d^n. But then, W_ψ is the Wigner function of a stabilizer state by Lemma 9. We have proven the following.

Theorem 17 (*Main theorem*): *Let $\psi \in L^2(\mathbb{Z}_d^n)$ be a state vector. If the Wigner function of ψ is non-negative, then ψ is a stabilizer state.*

IV. DISCRETE GAUSSIANS

It has long been realized that the coefficients of stabilizer state vectors are described by quadratic forms. However, the current literature either neglects the nonprime case (Refs. 19, 20, and 25) or is less explicit (Ref. 21) than the following lemma in showing the tight relation between Gaussian states and stabilizer states.

We will concentrate on stabilizer states with full support. This constitutes only a modest restriction of generality. Indeed, let ψ be a general stabilizer state, let $Q' := \operatorname{supp} \psi$. Let us for the sake of simplicity assume that d is prime and Q' is a subspace of Q. The restriction of the coordinate function $\psi(q)$ to Q' can be thought of as defining a vector ψ' of a quantum state of an $n' := \dim Q'$ particle system. It is now possible to check that ψ' is a stabilizer state. In this way any stabilizer state can be viewed as one with full support, possibly on a smaller system. We will, however, not take the time to make this construction precise nor will we rely on it in this paper.

Lemma 18: Let ψ be a state vector. The following statements are equivalent.

1. *ψ is a stabilizer state and $\psi(q) \neq 0$ for all $q \in Q$.*
2. *Up to the action of a Weyl operator, ψ is a graph state.*
3. *There exists a symmetric $n \times n$ matrix θ and an $x \in Q$ such that*

$$\psi(q) = \omega^{q\theta q + xq}.$$

Proof: (1 $\Rightarrow$ 2) By assumption $|\psi\rangle = |M,v\rangle$ for some maximal isotropic space M and a vector v. We claim that there is no nonzero $p \in Q$ such that $(p,0) \in M$.

Suppose there exists such a p. Then

$$\langle q|w(p,0)|M\rangle = \chi(-pq)\langle q|M\rangle.$$

On the other hand,

$$\langle q|w(p,0)|M\rangle = \bar{\chi}([v,(p,0)])\langle q|M\rangle,$$

by the definition of $|M,v\rangle$. Hence supp $|M\rangle$ must be contained within a hypersurface of Q specified by $pq=$const, which contradicts the assumption that supp $\psi=Q$.

There are d^n elements in M. By the last paragraph, no two of them have the same position coordinates. As there exist only $d^n=|Q|$ possible choices for the position coordinates, one can find for every $q\in Q$ a $p\in Q$ such that $(p,q)\in M$. Let $e_1,\ldots,e_n$ denote the canonical basis of $\mathbb{Z}_d^n$. Choose $m_1,\ldots,m_n\in M$ such that the position part of m_i equals e_i. The span of $\{m_i\}_{i=1,\ldots,n}$ has clearly cardinality d^n, so we have found a basis of M. By construction, the generator matrix composed of these basis vectors has the form shown in Eq. (18) with some $n\times n$ matrix θ. It is not hard to see that M is isotropic if and only if θ is symmetric, establishing that $|M\rangle$ is a graph state. Theorem 7 and Lemma 9 show that $w(v)|M\rangle=|M,v\rangle=|\psi\rangle$.

$(2\Rightarrow 3)$. Let M be an isotropic space which possesses a generator matrix of the form given in Eq. (18). Let $m_i=(\vartheta_i,e_i)$ be the ith column of that matrix. We need to establish the existence of a symmetric matrix θ and an $x\in Q$ such that

$$\langle q|M,v\rangle = \omega^{q\theta q+xq} =: \psi(q).$$

Indeed, choose

$$\theta = 2^{-1}\vartheta, \quad x_i=[v,m_i].$$

Using Eq. (8), one can then check by direct computation that ψ fulfills the defining eigenvalue equations

$$\chi([v,m_i])w(m_i)\psi=\psi,$$

and hence $|\psi\rangle=|M,v\rangle$ by Lemma 8.

$(3\Rightarrow 1)$. Reverting the previous proof shows that ψ is a graph state. It has maximal support by definition. □

The claimed analogy between stabilizer states and Gaussian states is apparent when comparing statement 3 to Theorem 1.

V. MIXED STATES

It is natural to ask how the results obtained before generalize to mixed states. Certainly, mixtures of stabilizer states are non-negative on phase space and it might be surmised that all such quantum states are convex combinations of stabilizer ones. In the context of continuous variable systems, Bröcker and Werner refuted an analogous conjecture by giving a counterexample.[30] Again, the situation is similar in the finite setting, as will be shown now.

As a consequence of Theorem 6.5, $A(0)$ can be decomposed as $A(0)=P_+ + P_-$, where $P_\pm$ denotes the projector onto the symmetric and antisymmetric state vectors, respectively (see Fig. 1). Since $P_+ + P_- = \mathbb{1}$, we have that $P_- = 1/2(\mathbb{1}-A(0))$. Because we know the Wigner functions of both $\mathbb{1}$ $(W(v)=d^{-n})$ and of $A(0)$ $(W(v)=\delta_{v,0})$, we immediately obtain

$$W_{P_-}(v) = \frac{1}{2}\begin{cases} d^{-n}-1 & v=0 \\ d^{-n} & \text{else}. \end{cases} \tag{24}$$

For a single three-dimensional quantum system there exists a unique antisymmetric state vector $|\psi_-\rangle=2^{-1/2}(|+1\rangle-|-1\rangle)$, hence $P_-=|\psi_-\rangle\langle\psi_-|$. Figure 2 depicts the Wigner function of the state ρ, obtained by mixing the pure states $|\psi_-\rangle, w(-1,0)|\psi_-\rangle$, and $w(-1,-1)|\psi_-\rangle$ with equal weights.

The Wigner function of a single-particle stabilizer state is a line in the two-dimensional phase space, according to Lemma 9. There are $d(d+1)$ such lines and hence equally many stabilizer states. Assume these states have been brought into some order and denote the associated projection operators by $P_1,\ldots,P_{d(d+1)}$. Let $\rho=\sum_i^{d(d+1)}\lambda_i P_i$ be a convex decomposition of ρ in terms these

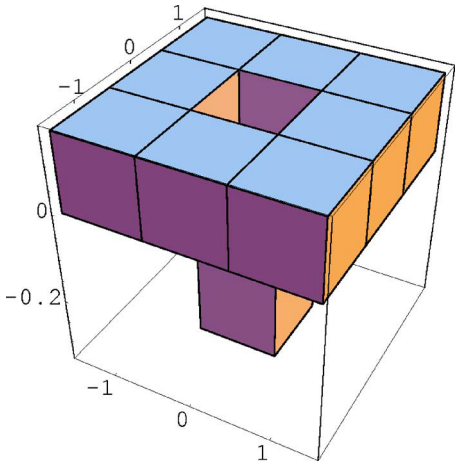

FIG. 1. Wigner function of the antisymmetric vector $|\psi_-\rangle$.

operators. If there is a point v in phase space where $W_\rho(v)=0$ and $W_{P_i}(v)\neq 0$, then clearly λ_i must vanish. By exhaustively listing all 12 lines in $\mathbb{Z}_3^2$, one finds that ρ can have nonzero coefficients only with respect to the stabilizer states whose Wigner functions are shown in Fig. 3.

But ρ admits no convex decomposition in terms of these three lines. Indeed, no two of them cover all the points in the support of W_ρ, so only a mixture of all three lines could potentially suffice. Now notice that the point $(1,-1)$ is an element only of the third line, while $(1, 0)$ is contained in both the second and the third one. Therefore any mixture of these three lines takes on a higher value on $(1, 0)$ than on $(1,-1)$. The distribution W_ρ, on the other hand, is constant on its support.

VI. DYNAMICS

Having established which quantum states give rise to non-negative phase space distributions, the next step is to characterize the set of operations that preserve this property. We have seen in Sec. II D that Clifford unitaries implement permutations in phase space and thus manifestly preserve positivity. They are unique in that regard, as will be shown now.

By the results of Sec. III, it is apparent that a unitary operation U can preserve positivity only if it sends stabilizer states to stabilizer states. One can reasonably conjecture that only Clifford

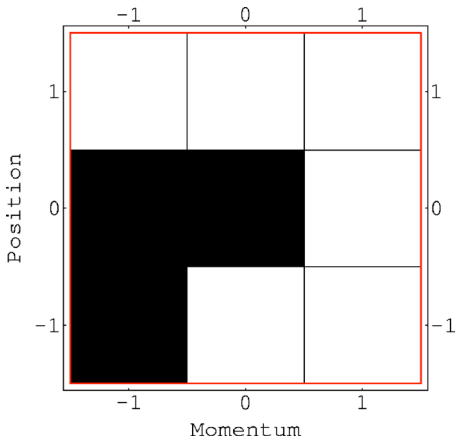

FIG. 2. Wigner function of the equal mixture of the vectors $|\psi-\rangle$, $w(-1,0)|\psi_-\rangle$, and $w(-1,-1)|\psi_-\rangle$. White squares stand for a value of $1/6$ and black squares for 0.

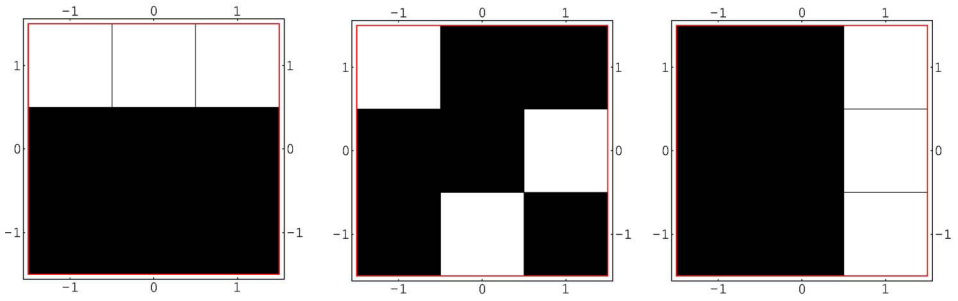

FIG. 3. The white squares mark all lines in $\mathbb{Z}_3^2$ that do not intersect any point where the Wigner function shown in Fig. 2 vanishes.

operations possess this feature and in the case of single particles in prime-power dimensions, a proof of this fact has been given in Ref. 26. The general case, however, poses surprising difficulties which have forced us to take a less direct route.

Let us shortly pause to clarify our objectives. We aim to characterize the set of unitaries U that satisfy statements of the kind: $W_{U\rho U^\dagger}$ is non-negative whenever W_ρ is. We can require the above statement to hold for *any* Hermitian operator ρ or just whenever ρ is a *quantum state*. In the former case the restrictions on U are much stronger than in the latter one. Indeed, by considering the image of the phase space point operators $A(a)$ under the action of U and making use of Lemma 29, it is straightforward to prove that only Clifford operations can preserve positivity of the Wigner functions of general Hermitian operators. The following theorem is slightly more ambitious in considering only the action of U on quantum states.

Theorem 19 *(Only permutations preserve positivity): Let U be unitary. If, for all quantum states ρ with non-negative Wigner function, it holds that* $W_{U\rho U^\dagger}$ *is non-negative, then U is Clifford.*

Proof: First, take note that substituting "quantum state" by "positive operator" in the above theorem, only amounts to a change of normalization and does not alter the statement. Set

$$\mu(\rho) := \min_{v \in V} W_\rho(v),$$

$$\nu(\rho) := \operatorname{minarg} W_\rho := \{v \in V | W_\rho(v) = \mu(v)\}.$$

Let ρ be such that $\mu(\rho) < 0$. We claim that $\mu(\rho) = \mu(\rho')$, where $\rho' = U_\rho U^\dagger$. In other words, U preserves minimal values.

Indeed, there exists positive constants $\lambda_{1,2}$ such that

$$\lambda_1 \mu(\rho') + \lambda_2 d^{-n} = 0.$$

Hence $\sigma := \lambda_1 \rho + \lambda_2 \mathbb{I}$ has a non-negative Wigner function. The assumption $\mu(\rho') < \mu(\rho)$ yields

$$W_{U\sigma U^\dagger}(v) = \lambda_1 \mu(\rho') + \lambda_2 d^{-n} < 0,$$

for every $v \in \nu(\rho')$, which contradicts the defining property of U. Thus $\mu(\rho') \leqslant \mu(\rho)$. Substituting U by U^{-1} shows that equality of $\mu(\rho)$ and $\mu(\rho')$ must hold.

Now set

$$\rho(a) := (1 - d^{-n})^{-1} w(a) P_- w(a)^\dagger,$$

for all $a \in V$. We have $\mu(\rho(a)) = \mu(\rho'(a)) = -1$ and $\nu(\rho) = \{a\}$. The crucial observation lies in the fact that $\nu(\rho')$ contains only a single point as well. So, U preserves the "pointed" shape of $W_\rho(a)$. To see why that is the case, suppose there is a a_0 such that $|\nu(\rho(a_0)')| > 1$. There are d^{2n} operators $\rho(a)'$ and equally many points in phase space, so there exists an a_1 such that $\nu(a_0)$ and $\nu(a_1)$ intersect in at least one point v. Define $\sigma = 1/2(\rho(a_0) + \rho(a_1))$. It holds that $\mu(\sigma) > -1/2$, whereas

$W_{\sigma'}(v)=-1$ which is a contradiction. There is hence a well-defined function S which sends a to the unique element of $\nu(\rho(a)')$.

Finally, let σ be any density matrix. The idea is to mix σ very weakly to $\rho(a)$, so that the positions of the minima of the mixture are still determined by $\rho(a)$. Indeed, there exists an $\epsilon > 0$ such that

$$\nu(\rho(a) + \epsilon\sigma) = \{a\},$$

$$\mu(\rho(a) + \epsilon\sigma) = -1 + \epsilon W_\sigma(a),$$

$$\nu(\rho(a)' + \epsilon\sigma') = \{S(a)\},$$

$$\mu(\rho(a)' + \epsilon\sigma') = -1 + \epsilon W_\sigma(S(a)).$$

Hence $W_{\sigma'}(Sa)=W_\sigma(a)$. We have established that U acts as a permutation in phase space and is therefore Clifford by Lemma 29. □

VII. PRIME POWER DIMENSIONS

Wigner functions for quantum systems with prime power dimensions have received particular attention in the literature (most prominently in Ref. 16). Once again, this is due to the fact that a finite field of order d exists exactly when d is the power of a prime and that the field's well-behaved geometrical properties facilitate many constructions. The present section briefly addresses the relationship between three natural approaches to Wigner functions for such systems. We assume the reader is already familiar with the definition of Weyl operators over Galois fields; a thorough introduction can be found in Refs. 15 and 16.

Let $d=p^k$ for some prime number p. There are three natural ways of associating a configuration space to $\mathcal{H}$. These are the following:

1. an n-dimensional vector space over $\mathbb{Z}_p$,
2. a one-dimensional module over $\mathbb{Z}_{p^n}$, or
3. a one-dimensional vector space over the Galois field $\mathbb{F}_{p^n}$ of order p^n.

The first and the second of these points of view have manifestly been covered in this paper. So far we neglected case 3, because—as we will see—it can be completely reduced to the first one.

Let us quickly gather some well-known facts on finite fields. If p is prime and n a positive integer, $\mathbb{F}_{p^n}$ denotes the unique finite field of order $d=p^n$. The simplest case occurs for $n=1$, when $\mathbb{F}_p \simeq \mathbb{Z}_p$. For $n>1$, fields $\mathbb{F}_{p^n}$ are realized by *extending* $\mathbb{F}_p$, which is then referred to as the *base field*. Extension fields contain the base field as a subset. The extension field possesses the structure of an n-dimensional vector space over the base field. A set of elements of F_{p^n} is a *basis* if it spans the entire field under addition and $\mathbb{F}_p$ multiplication. After having chosen a basis $\{b_1,\ldots,b_n\}$, we can specify any element $f=\Sigma_i f^i b_i$ by its expansion coefficients $\{f^i\}$. The operation

$$\mathrm{Tr}\, f = \sum_{k=0}^{n-1} f^{p^k}$$

takes on values in the base field and is $\mathbb{F}_p$ linear. Therefore,

$$\langle f,g\rangle \mapsto \mathrm{Tr}(fg)$$

defines an $\mathbb{F}_p$-bilinear form. For any basis $\{b_i\}$, there exists a *dual basis* $\{b^i\}$ fulfilling the relation $\mathrm{Tr}(b^i b_j)=\delta_{i,j}$ (we do not use Einstein's summation convention). From now on, we assume that a basis b_i and a dual one b^i have been fixed.

Repeating the construction put forward in Sec. II, we introduce the Hilbert space $\mathcal{H}=L^2(\mathbb{F}_{p^n})$, in other words, $\mathcal{H}$ is the span of $\{|q\rangle|q\in\mathbb{F}_{p^n}\}$. The choice of a basis induces a tensor structure on $\mathcal{H}$ via

$$|q\rangle=\left|\sum_i q^i b_i\right\rangle\mapsto\bigotimes_i|q^i\rangle.$$

We obtain a character of $\mathbb{F}_{p^n}$ by setting $\chi_{p^n}(f)=\chi_p(\mathrm{Tr}\,f)$. Note that for $n=1$, $\chi_{p^n}=\chi_p$. Expanding momentum coordinates $p=\Sigma_j p_j b^i$, the character factors,

$$\chi(pq)=\chi_p\left(\sum_{i,j}p_j q^i\,\mathrm{Tr}(b_i b^j)\right)=\prod_i\chi_p(p_i q^i).$$

Similarly, the shift and multiply operators factor with respect to this tensor structure,

$$x\left(\sum_i q^i b_i\right)\left|\sum_j x^j b_j\right\rangle=\bigotimes_i x^{(i)}(q^i)|x^i\rangle,$$

$$z\left(\sum_i p_i b^i\right)\left|\sum_j x^j b_j\right\rangle=\prod_i\chi_p(p_i x^i)\left|\sum_j x^j b_j\right\rangle=\bigotimes_i z^{(i)}(p_i)|x^i\rangle,$$

where $x^{(i)}$ and $z^{(i)}$ act on the ith p-dimensional subsystem. A straightforward computation along the lines just presented shows that both the Weyl operators and the phase space point operators factor,

$$w(p,q)=\bigotimes_i w^{(i)}(p_i,q^i)=w(p_1,\ldots,p_n,q^1,\ldots,q^n)$$

$$A(p,q)=\bigotimes_i A^{(i)}(p_i,q^i)=A(p_1,\ldots,p_n,q^1,\ldots,q^n).$$

The above result thus states that the Wigner function induced by the choice $Q=\mathbb{F}_{p^n}$ coincides—up to relabeling of the phase space points—with the one for $Q=\mathbb{F}_p^n$. In particular, both definitions give rise to the same set of states with a non-negative phase space distribution.

For stabilizer states, however, the situation is not as easy, as will be discussed subsequently. The preceding discussion suggests defining a map $\iota:\mathbb{F}_{p^n}^2\to\mathbb{F}_p^{2n}$ by

$$(p,q)\mapsto(p_1,\ldots,p_n,q^1,\ldots,q^n)$$

(see Refs. 15 and 31). Let M be a maximal isotropic subspace of $\mathbb{F}_{p^n}^2$. It is readily verified that $\iota(M)\subset\mathbb{F}_p^{2n}$ is again isotropic and a subspace. Further, we have shown that the sets of Weyl operators $w(M)$ and $w(\iota(M))$ coincide and hence so do the stabilizer states $|M\rangle$ and $|\iota(M)\rangle$.

The converse is not true. ι^{-1} does not necessarily map $\mathbb{F}_p^{2n}$ subspaces to those of $\mathbb{F}_{p^n}^2$. More precisely, if $M\subset\mathbb{F}_p^{2n}$ is a subspace, then $\iota^{-1}(M)$ can easily be proven to be closed under addition, but will in general fail to be closed under $\mathbb{F}_{p^n}$-scalar multiplication. This proves the remark made in the introduction, namely, that the set of "single-particle" (i.e., $\mathbb{F}_{p^n}^2$) stabilizer states is a true subset of corresponding "multiparticle" set. The following subsection gives a quantitative account of the relation of the sets.

A. Counting stabilizer codes

We are going to count the number of stabilizer states of a system composed of n d-level particles. In fact, the computation given below is slightly more general in that it gives the number of k-dimensional *stabilizer codes*.[17]

Stabilizer codes are generalizations of stabilizer states. Recall Eq. (17), where we showed that summing Weyl operators $w(m)$ over the elements m of a maximal isotropic subspace M of V yields a one-dimensional projection operator. It can be shown that if the requirement of maximality is dropped, the sum still evaluates to a projector. The range of this operator is the *stabilizer code*

defined by M. The dimension m of M and the dimension k of the stabilizer code are related by $k=d^{n-m}$.

Theorem 20 *(Number of isotropic subspaces): Let V be a $2n$-dimensional symplectic vector space over $\mathbb{F}_d$, where d is the power of a prime. The number of m-dimensional isotropic subspaces of V is given by*

$$\mathrm{Iso}(n,m,d) = \begin{bmatrix} n \\ m \end{bmatrix}_d \prod_{i=0}^{m-1} (d^{n-i}+1),$$

where the square brackets denote the Gaussian coefficients,

$$\begin{bmatrix} n \\ m \end{bmatrix}_d = \prod_{i=0}^{m-1} \frac{d^{n-i}-1}{d^{m-i}-1}.$$

Proof: The proof is inspired by a method employed in Ref. 32 to solve a related problem. We count the number of linearly independent m tuples consisting of mutual orthogonal vectors. Indeed, as the first vector v_1 we are free to choose any nonzero element of V. There are $d^{2n}-1$ such choices. The second vector must lie in the symplectic complement of the span of the first vector $\langle v_1\rangle^{\perp}$. Hence, v_2 can be chosen from a $2n-1$-dimensional vector space, the only restriction being that $v_2 \notin \langle v_1\rangle$. It follows that there exist $d^{2n-1}-d^1$ possibilities for v_2. Inducting on this scheme gives

$$\prod_{i=0}^{m-1} (d^{2n-i}-d^i) \tag{25}$$

such tuples.

However, since two different tuples might correspond to the same isotropic space, Eq. (25) overcounted the subspaces. To take that fact into account, we must divide by the number of bases within an m-dimensional space. Arguing in a similar fashion as before, we arrive at $\Pi_{i=0}^{m-1}(d^m-d^i)$ for the sought-after number (see also Ref. 32). Division gives

$$\mathrm{Iso}(n,m,d) = \prod_{i=0}^{m-1} \frac{d^{2n-i}-d^i}{d^m-d^i} = \prod_{i=0}^{m-1} \frac{d^{2(n-i)}-1}{d^{m-i}-1}.$$

Expanding $d^{2(n-i)}-1=(d^{n-i}-1)(d^{n-i}+1)$ and using the definition of the Gaussian coefficients concludes the proof. □

Corollary 21; The number of d^{n-m}-dimensional stabilizer codes defined on n d-level systems is

$$\mathrm{Stabs}(n,m,d) = d^m \begin{bmatrix} n \\ m \end{bmatrix}_d \prod_{i=0}^{m-1} (d^{n-i}+1).$$

In particular, the number of stabilizer states is

$$\mathrm{Stabs}(n,n,d) = d^n \prod_{i=1}^{n} (d^i+1).$$

Proof: We only need to justify the prefactor d^m. The defining Eq. (17) generates a projector onto a stabilizer code given an isotropic space M and a character $\chi([v,\cdot])$ on M. If $\dim M=m$, then there are $|M|=d^m$ distinct such characters (see Appendix C). □

We can now compare the number of stabilizer states for n particles of dimension d to the corresponding number for a single d^n-dimensional system,

$$\frac{\mathrm{Stabs}(n,n,d)}{\mathrm{Stabs}(1,1,d^n)} = \frac{\prod_{i=1}^{n}(d^i+1)}{d^n+1} = \prod_{i=1}^{n-1}(d^i+1) \geqslant d^{\sum_{i=1}^{n-1} i} = d^{1/2(n^2-n)}.$$

This is the superexponential scaling mentioned in the introduction.

ACKNOWLEDGMENTS

The author is grateful for support and advice provided by Jens Eisert during all stages of this project. Thanks to Dirk Schlingemann for enlightening conversations on phase space techniques. The figures were produced using *Mathematica* notebooks[15] partly based on Timo Felbinger's QMATRIX package.[38] Martin Plenio and Alessio Serafini gave helpful comments on draft versions of this paper. Useful references were pointed out to the author by S. Chaturvedi, C. K. Zachos, A. Klimov, and M. Ruzzi. This work has benefitted from funding provided by the European Research Councils (EURYI grant of J. Eisert), the European Commission (Integrated Project QAP), the EPSRC (Interdisciplinary Research Collaboration IRC-QIP), and the DFG.

APPENDIX A: DISCRETE STONE–VON NEUMANN THEOREM

This section generalizes well-known results for prime-power dimensions (see, e.g., Ref. 33 and citations therein) to all odd d. The proof is based on some simple observations employing group representation theory. We state a preparing lemma beforehand.

Lemma 22: The Weyl representation is irreducible.

Proof: We compute

$$\frac{1}{|H(\mathbb{Z}_d^n)|}\sum_{\substack{a\in V,\\ t\in\mathbb{Z}_d}} |\mathrm{tr}\, w(a,t)|^2 = d^{-(2n+1)}\sum_t |\mathrm{tr}\, w(0,t)|^2 = d^{-(2n+1)}\sum_t d^{2n} = 1,$$

which establishes irreducibility by a well-known criterion from group representation theory (see any textbook on that topic, e.g., Ref. 34). □

Proof (of Theorem 3): By the composition law Eq. (4) it is clear that $w'(p,q,t) := w(S(p,q),t)$ is a representation of the Heisenberg group which affords the same character (i.e., $\mathrm{tr}\, w(a,t)=\mathrm{tr}\, w'(a,t)$). The preceding lemma yields that w and w' are equivalent and thus the existence of $\mu(S)$ follows. Further,

$$\mu(S)\mu(T)w(p,q)\mu(T)^\dagger\mu(S)^\dagger = \mu(S)w(T(p,q))\mu(S)^\dagger = w(ST(p,q)) = \mu(ST)w(p,q)\mu(ST)^\dagger.$$

Because the Weyl matrices span the set of all operators, the last line fixes $\mu(ST)$ modulo a phase and we have proven the second assertion.

We turn to the last claim. Let S and c be as defined in Eq. (10). Using the commutation relations Eq. (4) and the fact that conjugation by unitaries leaves the center $\chi(t)\mathbb{1}$ of the Weyl representation invariant, it is easy to see that S must be an isometry in the sense that $[Sa,Sb]=[a,b]$. To proceed, consider the following calculation. On the one hand,

$$Uw(a)w(b)U^\dagger = Uw(a+b,2^{-1}[a,b])U^\dagger = w(S(a+b),2^{-1}[a,b])c(a+b), \tag{26}$$

while on the other hand,

$$Uw(a)w(b)U^\dagger = Uw(a)U^\dagger Uw(b) = w(Sa)w(Sb)c(a)c(b) = w(Sa+Sb,2^{-1}[Sa,Sb])c(a)c(b). \tag{27}$$

Comparing the last lines of Eqs. (26) and (27) one finds that S must be compatible with addition in $\mathbb{Z}_d^{2n}$ meaning that $S(a+b)=Sa+Sb$. Because $\mathbb{Z}_d$ is *cyclic* the preceding property implies that S is also compatible with scalar multiplication,

$$S(\lambda a) = S(a + \cdots + a) = S(a) + \cdots + S(a) = \lambda S(a).$$

Hence S is linear and therefore symplectic. Last, again using lines (26) and (27), we have that $c(a+b)=c(a)c(b)$ and conclude that c is a character. By Lemma 24, there exists an $a_0 \in V$ such that $c(\cdot)=\chi([a_0,S\cdot])$. Thus,

$$w(a_0)\mu(S)w(a)\mu(S)^\dagger w(a_0)^\dagger = w(a_0)w(Sa)w(-a_0) = \chi([a_0,Sa])w(Sa) = c(a)w(Sa).$$

□

APPENDIX B: AXIOMATIC CHARACTERIZATION OF THE WIGNER FUNCTION

The discussion in Sec. II D should suggest that Definition 5 yields the natural analog of the original continuous Wigner function. However, to bolster that claim with more objective arguments, we establish that—at least in prime dimensions—the form is virtually determined by the property of Clifford covariance (Theorem 7).

Theorem 23 *(Uniqueness): Let d be an odd prime. Let $Q,V,\mathcal{H}$ be as usual. Consider a mapping W' that fulfills the following axioms.*

1. (Phase space) *W' is a linear mapping sending operators to functions on the phase space V.*
2. (Clifford covariance) *W' is covariant under the action of the Clifford group, in the sense of Theorem 7.* Then $W'_\rho(p,q)=\lambda_1 W_\rho(p,q)+\lambda_2$ *for two constants* $\lambda_{1,2}$. *If further,*
3. (Marginal probabilities) *W' gives the correct marginal probabilities, as stated in Theorem 6.43,*

then $W'(p,q)=W(p,q)$.

Proof: Consider an alternative definition $\rho \mapsto W'_\rho$ of a Wigner function. Linearity implies the existence of a set of operators $\{A'(v)\}$ such that $W'(v)=d^{-n}\operatorname{tr}(A'(v)\rho)$. W' is covariant under the action of the Weyl operators if and only if $A'(v)=w(v)A'(0)w(v)^\dagger$. So the only degree of freedom left in the definition of W' is the choice of $A'(0)$. Again, one must require $A'(Sv)=\mu(S)A(v)\mu(S)$ if Theorem 7 is to hold. In particular, because the origin 0 is a fixed point of any linear operation, $A'(0)$ must commute with all $\mu(S)$.

As a consequence, the old, unprimed Wigner function $W_{A'(0)}$ of $A'(0)$ stays fixed under any symplectic operation S. Since any two non-zero points of V can be mapped onto each other by a suitable symplectic matrix S, $W_{A'(v)}$ must be constant on all such points. So there are only two parameters free to be chosen: $W_{A'(0)}(0)$ and $W_{A'(0)}(v), v \neq 0$. Clearly, the set of all operators that comply with these constraints is spanned by $\mathbb{1}$ and $A(0)$,

$$A'(0) = \lambda_1 \mathbb{1} + \lambda_2 A(0). \tag{28}$$

The above decomposition implies the first statement of the theorem.

As for the second claim, choose an $a \in V$. The projection operator $|a\rangle\langle a|$ is invariant under the action of Weyl operators of the form $w(p,0)$. Thus, due to Clifford covariance, the Wigner function $W'_{|a\rangle}$ must be p-shift invariant: $W'_{|a\rangle}(p+p',q)=W'_{|a\rangle}(p,q)$. We required Theorem 6.3 to hold, hence

$$\sum_{p\in Q} W'_{|a\rangle}(p,0) = d^n W'(0,0) = \delta_{a,0}.$$

By Eq. (28) and Theorem 6.5 it follows that $W'(0,0)=d^{-n}(\lambda_1+\lambda_2\delta_{a,0})$, yielding $\lambda_1=0,\lambda_2=1$. □

APPENDIX C: CHARACTERS AND COMPLEMENTS

Consider a space $R=\mathbb{Z}_d^n$ with a bilinear form $\langle\cdot,\cdot\rangle: R\times R\to\mathbb{Z}_d$. For any $s\in R$ the function $r\mapsto\chi(\langle s,r\rangle)$ defines a character of R. The form is said to be *nondegenerate* if $\langle s,\cdot\rangle \neq \langle s',\cdot\rangle$ for distinct s,s'. The two spaces we are concerned with are Q with the canonical scalar product and V with the symplectic scalar product. Both can easily be checked to be nondegenerate.

The following lemma states a basic fact about spaces with nondegenerate forms. We repeat it for completeness.

Lemma 24: Let $R=\mathbb{Z}_d^n$ with nondegenerate bilinear form $\langle\cdot,\cdot\rangle$. Any character ζ of R is of the form $\zeta(r)=\chi([s,r])$ for some unique $s\in R$.

Proof: Addition gives V the structure of a finite Abelian group. Therefore, $V\simeq V^*$, as is well-known (see, e.g., Ref. 28). So there are $|V|$ different characters of V, but equally many of the form $\chi([v,\cdot])$. □

If d is prime and M a subspace of V, the well-known relation $\dim M+\dim M^\perp=\dim V$ holds.[35] It is, however, no longer true in the general case. A counterexample can be constructed along the same lines as in Sec. II C. Still, an analog exists as demonstrated below.

Theorem 25: *Let $R=\mathbb{Z}_d^n$ with nondegenerate bilinear form $\langle\cdot,\cdot\rangle$. If M denotes a subspace of R, then the "complementarity relation" $|M||M^\perp|=|R|$ holds.*

Proof: We will show that

$$M^\perp\simeq(V/M)^*. \tag{29}$$

For $m\in M^\perp$, the relation $[v]\mapsto\chi([m,v])$ defines a character of V/M, as can easily be verified. Let us denote the map $m\mapsto\chi([m,\cdot])$ by ι_1.

Conversely, given an element ζ of $(V/M)^*$, $v\mapsto\zeta([v])$ is a character of V. By Lemma 24 there exists a unique $w\in V$ such that $\zeta([v])=\chi([w,v])$. If $m\in M$, then $\zeta([m])=\zeta([0])=1$ and hence $w\in M^\perp$. Using the notions just introduced, we can define $\iota_2:(V/M)^*\to M^\perp$ by $\zeta\mapsto w$.

It is simple to check that $\iota_2=\iota_1^{-1}$. In particular, ι_1 is invertible and Eq. (29) follows.

With the help of Lagrange's theorem, we can compute

$$|M^\perp|=|(V/M)^*|=|V/M|=|V|/|M|,$$

which concludes the proof. □

Corollary 26: Let V,Q be defined as usual. Let M be an isotropic subspace of V and S be any subspace of Q.

1. (Maximally isotropic spaces) *M is equal to its symplectic complement $M^\perp$ if and only if $|M|=d^n$.*
2. (Characters of subspaces) *Any character ζ of S can be written as $\zeta(s)=\chi(qs)$ for a suitable $q\in Q$.*

Proof: Claim 1 follows immediately from Theorem 25 and the fact that isotropic spaces are contained in their symplectic complement: $M\subset M^\perp$.

We turn to the second statement. In Lemma 14 we have argued that the characters of S which are expressable as $\chi(qs)$ stand in one-to-one correspondence to cosets in $Q/S^\perp$. But $|Q/S^\perp|=|S|$ and hence all characters are of that form. □

APPENDIX D: A GEOMETRIC NOTE

The proof of the main theorem makes use of the fact that for any vector $v\in V$, there exists a symplectic operation S that sends v to a vector of the form $(p,0)$. Indeed, if d is prime, any two vectors are similar, in the sense that they can be mapped onto each other by a symplectic matrix. Technically, this is a trivial incarnation of Witt's lemma (see Ref. 36 for a formulation that is applicable in our context).

Once again the nonprime case poses additional difficulties. Recall that the *order* of a $v\in V$ is the least positive $\lambda\in\mathbb{Z}_d$ such that $\lambda v=0$. It is easy to see that the order of a vector is left invariant by the action of invertible linear mappings. If d is a composite number (i.e., not prime), then $V=\mathbb{Z}_d^{2n}$ contains elements of different orders which cannot be related by a linear operation. However, one might conjecture that any two vectors of equal order are similar. This is the content of the following lemma. Some concepts used in the proof can be found in Refs. 35 and 37.

Lemma 27 (Similarity): Let $V=\mathbb{Z}_d^{2n}$. Let $a_1,a_2\in V$ be two vectors with the same order. Then there exists a symplectic matrix S such that $Sa_1=a_2$.

Proof: We can slightly weaken the assumptions made about V. All we require for this proof is that V is a finite $\mathbb{Z}_d$ module with nondegenerate symplectic form $[\cdot,\cdot]$. It need not be of the form $\mathbb{Z}_d^{2n}$.

Let $v \in V$ be a vector of order d. As $v \mapsto \chi([v,\cdot])$ implements an isomorphism, $V \to V^*$, ord $(\chi([v,\cdot]))=\mathrm{ord}(v)=d$. There hence exists a $w \in V$ such that $[v,w]=\lambda$ has order d. Any such number possesses a multiplicative inverse λ^{-1} modulo $\mathbb{Z}_d$ and hence $w'=\lambda^{-1}$ fulfills $[v,w']=1$. Vectors satisfying such a relation are said to be *hyperbolic couples*. Denote their span $\langle\{v,w'\}\rangle$ as H.

Set $V' := H^\perp$. By Theorem 25 $|V|=|H||V'|$. Further, it is easy to see that $H^\perp \cap H=\{0\}$ and hence $V=HV'$, where $\oplus$ denotes the *orthogonal direct Sum*. We claim that the symplectic inner product is nondegenerate on V'. Indeed, supose there is a nonzero $v' \in V'$ such that $[v',w']=0$ for all $w' \in V'$. Then, by definition of V', $[h,w']=0$ for all $h \in H$ and therefore v' would be orthogonal on all vectors of V. Hence such a v' cannot exist by the nondegeneracy of $[\cdot,\cdot]$.

Note that V' fulfills the assumptions made about V at the beginning of the proof and has strictly smaller cardinality. Thus, we can induct on $|V|$ to obtain a decomposition

$$V = H_1 \oplus \ldots \oplus H_n$$

of V in terms of two-dimensional subspaces spanned by hyperbolic couples $\{v_i,w_i'\}$. We arrange these vectors as the columns of a matrix $S=(v_1,\ldots,v_n,w_1',\ldots,w_n')$. The construction of the couples $\{v_i,w_i'\}$ ensures that S is symplectic, as can easily be verified.

Now let $a_1,a_2 \in V$ be two vectors with maximal order. By the preceding discussion, there exists symplectic matrices S_i having a_i as their respective first column. Clearly, then $S_2 S_1^{-1} a_1 = a_2$.

Last, suppose $\mathrm{ord}(a_i)=k \leqslant d$. It is easy to see that $a_i'=ka_i/d$ are elements of V with maximal order. Further, if S maps a_1 to a_2, then also a_1 to a_2. □

Corollary 28 (Transitive action): Let $|M_1,v_1\rangle$, $|M_2,v_2\rangle$ be stabilizer states. If their respective associated isotropic subspaces M_1 and M_2 are spanned by vectors of maximal order, then there exists a Clifford operation relating these state vectors.

Proof: Let $\{m_1^{(i)},\ldots,m_n^{(i)}\}$, $i=1,2$ be bases of M_1 and M_2, respectively. Assume that all vectors have maximal order. It is simple to adapt the previous proof for constructing a symplectic matrix S sending $m_i^{(1)}$ to $m_i^{(2)}$. □

APPENDIX E: SOME PROPERTIES OF THE PHASE SPACE POINT OPERATORS

Lemma 29 (Properties of the phase space point operators): The phase space point operators fulfill the following relations:

$$A(a) = w(2a)A(0),$$

$$A(a)A(b) = w(2a-2b),$$

$$tr(A(u)A(v)A(w)) = \chi([v,u]+[u,w]+[w,v]).$$

Further, if U permutes the phase space point operators under conjugation

$$UA(v)U^\dagger = A(v'),$$

for all $v \in V$, then U is Clifford.

Proof: Clifford covariance (Theorem 7) implies $A(a)=w(a)A(0)w(a)\dagger$. Using Theorem 6.5 it is easy to see that $A(0)w(a)A(0)=w(-a)$ and $A(0)^2=\mathbb{1}$. Hence,

$$A(a) = w(a)A(0)w(-a)A(0)A(0) = w(2a)A(0),$$

proving the first relation. The second one follows.

For the proof of the third equation, we abbreviate $A(0)$ as A. Then

$$\begin{aligned}\mathrm{tr}(A(u)A(v)A(w)) &= \mathrm{tr}(w(2u)Aw(2v)Aw(2w)A) = \mathrm{tr}(w(2u)w(-2v)w(2w)A^3)\\ &= \chi([u,-v]+[u-v,w])\mathrm{tr}(w(2(u-v+w))A)\\ &= \chi([v,u]+[u,w]+[w,v])\mathrm{tr}(A(u-v+w)).\end{aligned}$$

It has been noted in Theorem 6.6 that phase space point operators have unit trace, which concludes the proof.

Last, suppose the action of U permutes phase space point operators. For any $a \in V$, we have

$$Uw(a)U^\dagger = Uw(22^{-1}(a-0))U^\dagger = UA(a)UU^\dagger A(0)U^\dagger = A(a')A(0') = w(2(a'-0')),$$

for suitable $a', 0' \in V$. Hence U maps Weyl operators to Weyl operators and is thus Clifford by definition. □

(Received 13 September 2006; accepted 2 November 2006; published online 28 December 2006)

Fractional supersymmetric quantum mechanics is developed from a generalized Weyl-Heisenberg algebra. The Hamiltonian and the supercharges of fractional supersymmetric dynamical systems are built in terms of the generators of this algebra. The Hamiltonian gives rise to a hierarchy of isospectral Hamiltonians. Special cases of the algebra lead to dynamical systems for which the isospectral supersymmetric partner Hamiltonians are connected by a (translational or cyclic) shape invariance condition. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2401711]

I. INTRODUCTION

Supersymmetry was initially introduced in high energy physics, as a kind of symmetry between bosons and fermions, to describe fundamental interactions of Nature in an unified way (e.g., see Ref. 1). Supersymmetry cannot be an exact symmetry. In order to understand supersymmetry breaking in quantum field theory, Witten studied supersymmetric quantum mechanics (SUSYQM).[2] Presently, SUSYQM turns out to be a powerful tool to investigate integrability in quantum mechanics.[3–5] In this connection, the concept of shape invariant potential was introduced by Gendenshtein.[6] This concept is especially useful to determine the spectrum of exactly solvable potentials. Indeed, for a given solvable potential, shape invariance implies integrability. It is now well known there are three kinds of shape invariant potentials, namely, translational shape invariant potentials,[7,8] scaling shape invariant potentials,[9,10] and cyclic shape invariant potentials.[11,12]

For any exactly solvable Hamiltonian (shape invariant or not), SUSYQM provides us with a process to generate a supersymmetric partner Hamiltonian. This process can be used successively to span a hierarchy of isospectral Hamiltonians.[5]

The aim of this work is to study shape invariant potentials together with the generation of a hierarchy of isospectral superpartner Hamiltonians in the framework of *fractional* SUSYQM of order k ($k=3,4,\ldots$).

In general, to pass from *ordinary* SUSYQM to *fractional* SUSYQM of order k (abbreviated as k-SUSYQM in the following), it is necessary to replace the Z_2-grading of the relevant Hilbert space by a Z_k-grading. This amounts either to replace a fermionic degree of freedom by a para-fermionic[13–18] one, of order $k-1$, or to introduce k-fermions,[19–22] which are objects interpolating between bosons and fermions. Quantum groups, with the deformation parameter being a root of unity, play also an important role in the development of k-SUSYQM.[23–31] On the other hand, a realization of bosonized k-SUSYQM can be developed owing to the introduction of a Klein operator of order k ($K^k=1$) which induces a Z_k-grading.[18,32] In this direction, a relation exists between k-SUSYQM and hidden supersymmetric structures.[33–36]

The approach of k-SUSYQM developed in the present paper took its origin in Ref. 22 (see also Refs. 37–39 for some similar developments). It is based on a Z_k-graded Weyl-Heisenberg algebra W_k. Section III deals with algebra W_k and its use for generating a family of k isospectral Hamiltonians. In Secs. IV and V, some specific Hamiltonians (with translational shape invariant potentials or cyclic shape invariant potentials) corresponding to particular cases of the algebra W_k are studied. We will start in Sec. II with some preliminaries and motivations.

Throughout the present paper, $[A,B]$ and $\{A,B\}$ stand for the commutator and the anticommutator of the operators A and B, respectively. The operator $A^\dagger$ denotes the adjoint of A. The symbol δ is the Kronecker delta. Many quantities are defined modulo k ($\Pi_k \equiv \Pi_0$, $H_k \equiv H_0$, $F_k \equiv F_0$ and $V_k \equiv V_0$). As usual, $f \circ g(x) = f(g(x))$ for two functions f and g. We shall use the convention according to which $\Sigma_{i=a}^{b} x(i) = 0$ when $b < a$ and the symbols S_0 and S_1 for denoting the sets $\{0,1,\cdots,k-1\}$ and $\{1,2,\cdots,k\}$, respectively.

II. PRELIMINARIES AND MOTIVATIONS

For the purpose to establish our notations and to present our motivations, we shall begin with a brief review of *ordinary* SUSYQM, corresponding to $k=2$, and of shape invariance (for more details, see Refs. 3–5).

A. Ordinary supersymmetric quantum mechanics

Let us start with ordinary SUSYQM. A supersymmetric dynamical system is defined by a triplet $(H, Q_+, Q_-)_2$ of linear operators acting on a Z_2-graded Hilbert space $\mathcal{H}$ and satisfying the following relations:

$$H = H^\dagger, \quad Q_- = Q_+^\dagger, \quad Q_\pm^2 = 0,$$

$$\{Q_-, Q_+\} = H, \quad [H, Q_\pm] = 0.$$

The operators Q_+ and Q_- are the supercharges of the system. The self-adjoint operator H, the supersymmetric Hamiltonian for the (one-dimensional) system, can be written as

$$H = H_0 + H_1,$$

where H_0 and H_1 act on the states $|n,0\rangle$ and $|n,1\rangle$ of grading 0 and 1, respectively. These states span the Hilbert space

$$\mathcal{H} = \{|n,s\rangle : n \text{ ranging}; \ s = 0,1\}.$$

We shall assume that there is no supersymmetry breaking. In this situation, the Hamiltonians H_0 and H_1 are isospectral except that the ground state of H_0 has no supersymmetric partner in the spectrum of H_1.

Now suppose that H_0 has p states $|n,0\rangle$ with $n=0,1,\cdots,p-1$ ($p \geq 2$). From the Hamiltonian H_1 with $p-1$ states $|n,1\rangle$ ($n=1,2,\cdots,p-1$), we can find a supersymmetric partner H_2 with $p-2$ states $|n,2\rangle$ ($n=2,3,\cdots,p-1$) and we can repeat this process to generate a hierarchy of p Hamiltonians H_0, H_1, $\cdots$, H_{p-1}. The Hamiltonian H_m ($0 < m < p$) has the same energy spectrum than H_0 except that the $m-1$ first energies of H_0 do not occur in the spectrum of H_m. This result remains valid when p goes to infinity.

We can then ask the following question. What happens when we go from ordinary SUSYQM to k-fractional SUSYQM (with $k=3,4,\cdots$)? We shall answer this question by showing that a hierarchy of isospectral Hamiltonians H_0, H_1, $\cdots$, H_{k-1} can be constructed from a single Hamiltonian H_0 by making use of a Z_k-graded Weyl-Heisenberg algebra. This construction shall be achieved without a repetition process of the type $H_0 \to H_1$, $H_1 \to H_2$, $\cdots$, $H_{k-2} \to H_{k-1}$ as used in ordinary SUSYQM.

B. Shape invariance

It is known that there exists a set of exactly solvable potentials characterized by an integrability condition known as shape invariance condition.[3,5,6] In connection with ordinary SUSYQM, this shape invariance condition leads in an easy way to the spectrum of any invariant shape potential.

More precisely, let us consider the partner potentials $V_0(x,a_0)$ and $V_1(x,a_0)$ associated with the supersymmetric Hamiltonians H_0 and H_1 such that

$$H_s = -\frac{d^2}{dx^2} + V_s(x,a_0), \quad s=0,1,$$

where a_0 is a set of real parameters. The shape invariance condition is defined by

$$V_1(x,a_0) = V_0(x,a_1) + R(a_0), \tag{1}$$

where $a_1=h(a_0)$ corresponds to a reparametrization in V_0 and $R(a_0)$ is a constant. The shape invariance condition immediately yields the energies and wave functions of H_0.[3,5] One obtain the energies $E_{n,0}$ of H_0

$$E_{n,0} = \sum_{l=0}^{n-1} R(a_l), \quad n \geq 1,$$

where

$$a_l = h^{(l)}(a_0) = h \circ h \circ \cdots \circ h(a_0), \quad l \text{ times}.$$

(We take $E_{0,0}=0$.) The three kinds of shape invariance mentioned in the introduction correspond to $a_1=a_0+\alpha$ with $\alpha \in \mathbf{R}$, $a_1=\beta a_0$ with $0<\beta<1$, and $a_1=h(a_0)$ with $h^{(l)}(a_0)=a_0$ for translational,[7,8] scaling,[9,10] and cyclic[11,12] shape invariance, respectively.

Another motivation for this work is to show that the isospectral Hamiltonians obtained from k-SUSYQM are connected through shape invariance. In this respect, we shall use some specific realizations of the Z_k-graded Weyl-Heisenberg algebra W_k in order to generate a hierarchy of Hamiltonians subjected to translational or cyclic shape invariance.

III. FRACTIONAL SUPERSYMMETRIC QUANTUM MECHANICS

A. Definition

Let us go now to k-SUSYQM. A k-fractional supersymmetric dynamical system is defined by a triplet $(H,Q_+,Q_-)_k$ of operators satisfying the following relations[13–16,22]

$$H = H^\dagger, \quad Q_- = Q_+^\dagger, \quad Q_\pm^k = 0,$$

$$\sum_{s=0}^{k-1} Q_-^{k-1-s} Q_+ Q_-^s = Q_-^{k-2} H, \quad [H,Q_\pm] = 0, \tag{2}$$

where $k=3,4,\cdots$. The Hamiltonian H and the supercharges $Q_\pm$ of the dynamical system are linear operators acting on a Hilbert space $\mathcal{H}$,

$$\mathcal{H} = \bigoplus_{s=0}^{k-1} \mathcal{H}_s,$$

which is Z_k-graded in view of the relations $Q_\pm^k=0$. It is to be observed that Eq. (2) works equally well in the case $k=2$ corresponding to ordinary SUSYQM.

B. Generalized Weyl-Heisenberg algebra

Following Ref. 22, we consider the generalized Weyl-Heisenberg algebra W_k, with $k \in \mathbf{N}\backslash\{0,1\}$, spanned by the four linear operators X_+, X_-, N, and K acting on the space $\mathcal{H}$ and satisfying

$$X_- = X_+^\dagger, \quad N = N^\dagger, \quad KK^\dagger = K^\dagger K = 1, \quad K^k = 1,$$

$$[X_-, X_+] = \sum_{s=0}^{k-1} f_s(N)\Pi_s, \quad [N, X_-] = -X_-, \quad [N, X_+] = X_+,$$

$$KX_+ - qX_+K = 0, \quad KX_- - pX_-K = 0, \quad [K, N] = 0, \tag{3}$$

where q and p are roots of unity with

$$q = e^{2\pi i/k}, \quad p = e^{-(2\pi i/k)}.$$

In Eq. (3), the functions $f_s: N \mapsto f_s(N)$ of the number operator N are such that

$$f_s(N) = f_s(N)^\dagger.$$

Furthermore, the operators Π_s are defined in terms of the Klein or grading operator K as

$$\Pi_s = \frac{1}{k}\sum_{t=0}^{k-1} p^{st}K^t, \quad s \in S_0.$$

It is easy to check that

$$\Pi_s = \Pi_s^\dagger, \quad \sum_{s=0}^{k-1} \Pi_s = 1, \quad \Pi_s\Pi_t = \delta_{s,t}\Pi_s.$$

Consequently, the operators Π_s are projection operators for the cyclic group Z_k. It can be proved that they satisfy

$$\Pi_s X_+ = X_+\Pi_{s-1} \Leftrightarrow X_-\Pi_s = \Pi_{s-1}X_-.$$

Note that the operators X_+ and X_- can be considered as generalized creation and annihilation operators, respectively.

It should be realized that, for fixed k, Eq. (3) defines indeed a family of generalized Weyl-Heisenberg algebras W_k. The various members of the family are distinguished by the various sets $\{f_s\} \equiv \{f_s(N): s \in S_0\}$.

C. Realization of *k*-SUSYQM

We can use the generators of W_k for obtaining a realization of $(H, Q_+, Q_-)_k$.

First, we take the supercharge operators $Q_\pm$ [see Eq. (2)] in the form

$$Q_- = X_-(1 - \Pi_1), \quad Q_+ = X_+(1 - \Pi_0). \tag{4}$$

It can be proved that they satisfy the Hermitean conjugation property $Q_- = Q_+^\dagger$ and the k-nilpotency property $Q_\pm^k = 0$. Note that there are k equivalent definitions of type (4) corresponding to the k circular permutations of $0, 1, \cdots, k-1$.

Second, the k-fractional supersymmetric Hamiltonian H, satisfying (2) and compatible with (4), takes the form[22]

$$H=(k-1)X_+X_- -\sum_{s=3}^{k}\sum_{t=2}^{s-1}(t-1)f_t(N-s+t)\Pi_s-\sum_{s=1}^{k-1}\sum_{t=s}^{k-1}(t-k)f_t(N-s+t)\Pi_s,$$

in terms of X_+X_-, Π_s, and f_s. In addition, it can be shown that the operator H can be decomposed as

$$H=\sum_{s=1}^{k}H_s\Pi_s=\sum_{s=0}^{k-1}H_{k-s}\Pi_{k-s}, \tag{5}$$

where

$$H_s=(k-1)X_+X_- -\sum_{t=2}^{k-1}(t-1)f_t(N-s+t)+(k-1)\sum_{t=s}^{k-1}f_t(N-s+t),\quad s\in S_1. \tag{6}$$

As an important result, it can be proved, from $[H,Q_\pm]=0$, that the k operators $H_k\equiv H_0$, H_{k-1}, $\cdots$, H_1 constitute a hierarchy of isospectral Hamiltonians. Therefore, the spectra of $H_1,H_2,\cdots,H_{k-1}$ can be deduced from the spectrum of H_0.

D. Representation of W_k

Let us now examine the action of X_+, X_-, N, and K on each subspace

$$H_s=\{|n,s\rangle:n \text{ ranging}\}$$

of $\mathcal{H}$ (n can take a finite or infinite number of values according to whether as $\mathcal{H}_s$ is of finite or infinite dimension). For this purpose, we introduce the structure functions $F_s:N\mapsto F_s(N)$ through

$$X_+X_-=\sum_{s=0}^{k-1}F_s(N)\Pi_s,\quad X_-X_+=\sum_{s=0}^{k-1}F_{s+1}(N+1)\Pi_s.$$

In view of Eq. (3), we have the recurrence relation

$$F_{s+1}(n+1)-F_s(n)=f_s(n),\quad F_s(0)=0. \tag{7}$$

Then, we can take[22]

$$X_+|n,s\rangle=\sqrt{F_{s+1}(n+1)}|n+1,s+1\rangle,\quad s\neq k-1,$$

$$X_+|n,s\rangle=\sqrt{F_{s+1}(n+1)}|n+1,0\rangle,\quad s=k-1,$$

$$X_-|n,s\rangle=\sqrt{F_s(n)}|n-1,s-1\rangle,\quad s\neq 0,$$

$$X_-|n,s\rangle=\sqrt{F_s(n)}|n-1,k-1\rangle,\quad s=0,$$

$$N|n,s\rangle=n|n,s\rangle,\quad K|n,s\rangle=q^s|n,s\rangle \tag{8}$$

for the action of X_+, X_-, N, and K on space $\mathcal{H}_s$. Relations (8) define a representation of W_k.

In the following, we shall consider two special cases of W_k: (i) The case where $f_s(N)$ is independent of s (see Sec. IV) and (ii) the case where $f_s(N)$ is independent of N (see Sec. V).

IV. TRANSLATIONAL SHAPE INVARIANT POTENTIALS

A. Structure function

In this section, we assume that $f_s(N)$ is independent of s and linear in N. More precisely, we take

$$f_s(N) = aN + b \Rightarrow [X_-, X_+] = aN + b,$$

with strictly positive eigenvalues, where a and b are two real parameters. Thus, from Eq. (7) we have

$$X_+X_- \equiv F(N,a,b),$$

where

$$F(N,a,b) = \frac{1}{2}aN(N-1) + bN.$$

The nonlinear spectrum of X_+X_- is then given by

$$X_+X_-|n,s\rangle = \left[\frac{1}{2}an(n-1) + bn\right]|n,s\rangle.$$

For either $a=0$ and $b>0$ or $a>0$ and $b\geq 0$, the spectrum of X_+X_- is infinite-dimensional and does not present degeneracies. For $a<0$ and $b\geq 0$, the spectrum of X_+X_- is finite-dimensional with $n=0,1,\cdots,E(-b/a)$ and all the states are nondegenerate.

It is possible to find a realization of each of the three cases just described in terms of an exactly solvable dynamical system in a one-dimensional space, with coordinate x, and characterized by a potential $V(x,a,b)$. As a matter of fact, we have the following:

(i) $a=0$ and $b=1$ correspond to the harmonic oscillator potential

$$V_{ho}(x,0,1) = x^2, \tag{9}$$

with an infinite nondegenerate spectrum ($n\in\mathbf{N}$).

(ii) $a=2$ and $b=u+v+1$, with $u>1$ and $v>1$, correspond to the Pöschl-Teller potential

$$V_{PT}\left(x,2,\left\{u+\frac{1}{2},v+\frac{1}{2}\right\}\right) = \frac{1}{4}\left[\frac{u(u-1)}{\sin^2(x/2)} + \frac{v(v-1)}{\cos^2(x/2)}\right] - \frac{1}{4}(u+v)^2, \tag{10}$$

with an infinite nondegenerate spectrum ($n\in\mathbf{N}$).

(iii) $a=-2$ and $b=2l+1$, with $l\in\mathbf{N}$, correspond to the Morse potential

$$V_M(x,-2,2l+1) = e^{-2x} - (2l+3)e^{-x} + (l+1)^2, \tag{11}$$

with an finite nondegenerate spectrum ($n=0,1,\cdots,l$).

B. Isospectral Hamiltonians

The various isospectral Hamiltonians occurring in (5) are easily deduced from Eq. (6). This gives

$$H_{k-s} \equiv H_{k-s}(N,a,b) = (k-1)\left[F\left(N,a,b-\frac{1}{2}ka+a+sa\right) + \frac{1}{6}(k-2)(ka-3b) + \frac{1}{2}s(s-k+1)a + sb\right], \quad s\in S_0.$$

Thus, the isospectral Hamiltonians are linked by

$$H_{k-s}(N,a,b) = H_0(N,a,b+sa) + \frac{1}{2}(k-1)s(sa-a+2b), \quad s \in S_0, \tag{12}$$

a relation of central importance, in the k-SUSYQM context, for the derivation of the translational shape invariance condition.

Let us denote by $V_k \equiv V_0$, V_{k-1}, $\cdots$, V_1 the potentials (in x-representation) associated with the isopectral Hamiltonians H_0, H_{k-1}, $\cdots$, H_1, respectively. In other words, we set

$$H_{k-s}(N,a,b) \equiv -\frac{d^2}{dx^2} + V_{k-s}(x,a,b), \quad s \in S_0.$$

By using Eq. (12), we immediately get the recurrence relation

$$V_{k-s}(x,a,b) = V_0(x,a,b+sa) + \frac{1}{2}(k-1)s(sa-a+2b), \quad s \in S_0, \tag{13}$$

which may be considered as the k-SUSYQM version of the translational shape invariance condition for ordinary SUSY [see Eq. (1)].

By way of illustration, Eq. (13) yields the following results.

(i) For the harmonic oscillator system:

$$V_{k-s}(x,0,1) = x^2 + \frac{1}{2}(k-1)(2s-k+2). \tag{14}$$

(ii) For the Pöschl-Teller system:

$$\begin{aligned} V_{k-s}\left(x,2,\left\{u+\frac{1}{2},v+\frac{1}{2}\right\}\right) = \frac{1}{4}\Bigg[& \frac{(u+s+1-(k/2))(u+s-(k/2))}{\sin^2(x/2)} \\ & + \frac{(v+s+1-(k/2))(v+s-(k/2))}{\cos^2(x/2)}\Bigg] - \frac{1}{4}(u+v+2s+2-k)^2 \\ & + \frac{1}{6}(k-1)(k-2)(2k-3u-3v-3) + (k-1)s(s-k+u+v+2). \end{aligned} \tag{15}$$

(iii) For the Morse system:

$$\begin{aligned} V_{k-s}(x,-2,2l+1) = {} & e^{-2x} - (2l+k+1-2s)e^{-x} + \frac{1}{4}(2l+k-2s)^2 - \frac{1}{6}(k-1)(k-2)(2k+6l+3) \\ & + (k-1)s(k-s+2l). \end{aligned} \tag{16}$$

In the case $k=2$ and $s=0$, Eqs. (14)–(16) reduce to Eqs. (9)–(11), respectively.

V. CYCLIC SHAPE INVARIANT POTENTIALS

A. Structure function

In this section, we assume that $f_s(N)$ is independent of N, i.e.,

$$f_s(N) = f_s \Rightarrow [X_-,X_+] = \sum_{s=0}^{k-1} f_s \Pi_s.$$

(The paradigmatic case of the harmonic oscillator corresponds to f_s=const for any s in S_0.)

It is convenient to write the integer n occurring in $|n,s\rangle$ as $n=kp+t$ with $p \in \mathbf{N}$ and $t \in S_0$. Here, to adapt our construction to one-dimensional periodic potentials, we restrict the Hilbert-Fock

space $\mathcal{H}$ to its subspace $\mathcal{G}=\{|kp+s,s\rangle: p \text{ ranging}; s\in S_0\}$. In addition, it is appropriate to denote the state $|kp+s,s\rangle$ as $|kp+s)$. Hence, the action of the number operator N on the states $|kn+s)$ is given by

$$N|kn+s) = (kn+s)|kn+s)$$

and the grading operator K can be identified, on the subspace $\mathcal{G}$, with the operator q^N since

$$K|kn+s) = q^s|kn+s) = q^{kn+s}|kn+s) = q^N|kn+s).$$

From Eq. (7), it can be shown

$$F_s(N) = g_0 N + \sum_{t=1}^{k-1} g_t \frac{1-q^{st}}{1-q^t},$$

where

$$g_t = \frac{1}{k}\sum_{s=0}^{k-1} p^{st} f_s, \quad t \in S_0.$$

Thus, the action of

$$X_+X_- = \sum_{t=0}^{k-1} g_t \frac{1-q^{Nt}}{1-q^t}$$

on the space $\mathcal{G}$ reads

$$X_+X_-|kn+s) = \left(n\sum_{i=0}^{k-1} f_i + \sum_{i=0}^{s-1} f_i \right)|kn+s). \tag{17}$$

The spectrum of X_+X_- is periodic and can be seen as a superposition of identical blocks. For a given block, the various gaps between the consecutive eigenvalues are

$$f_0, f_1, \cdots, f_{k-1}.$$

The first block (corresponding to $n=0$) has the following nonzero eigenvalues,

$$E_1 = f_0, E_2 = f_0 + f_1, \cdots, E_k = f_0 + f_1 + \cdots + f_{k-1},$$

while the second block (corresponding to $n=1$) has the eigenvalues

$$E_{k+1} = E_k + f_0, E_{k+2} = E_k + f_0 + f_1, \cdots, E_{2k} = E_k + f_0 + f_1 + \cdots + f_{k-1},$$

and so on for the subsequent blocks corresponding to $n=2,3,\cdots$ (the eigenvalue for the ground state is $E_0=0$). In other words, in the $(n+1)$th block the parameter f_s is the difference between the eigenvalues for $|kn+s+1)$ and $|kn+s)$. According to Eq. (17), the various eigenvalues are given by

$$E_{kn+s} = nkg_0 + \sum_{i=0}^{s-1} f_i, \quad n \in \mathbf{N};\ s \in S_0.$$

Thus, each block has the length kg_0, which can be considered as the period of the cyclic spectrum.

At this level, it should be emphasized that our approach covers the one of Ref. 11 concerning the two-body Calogero-Sutherland model. The latter model corresponds to $k=2$. Consequently, the relevant Hilbert-Fock space is

$$\mathcal{G} = \{|2n+s): n \in \mathbf{N};\ s = 0,1\}$$

and X_+X_- reads

$$X_+X_- = \frac{1}{2}(f_0 + f_1)N + \frac{1}{2}(f_0 - f_1)\Pi_1.$$

Equation (17) can then be particularized as

$$X_+X_-|2n) = n(f_0 + f_1)|2n),$$

$$X_+X_-|2n+1) = [n(f_0 + f_1) + f_0]|2n+1),$$

in accordance with the results of 11. (Our parameters f_0 and f_1 read $f_0 = \omega_0$ and $f_1 = \omega_1$ in the notations of 11.)

It is interesting to note that the spectrum of X_+X_- coincides with one of the Hamiltonian corresponding to the potential (in x-representation)

$$V_0(x, f_0, f_1) = \frac{1}{16}(f_0 + f_1)^2x^2 + \frac{1}{4}\frac{(f_0 - f_1)(3f_0 + f_1)}{(f_0 + f_1)^2}\frac{1}{x^2} - \frac{1}{2}f_1. \tag{18}$$

Furthermore, using the standard tools of ordinary SUSYQM, we get

$$V_1(x, f_0, f_1) = \frac{1}{16}(f_0 + f_1)^2x^2 + \frac{1}{4}\frac{(f_1 - f_0)(3f_1 + f_0)}{(f_0 + f_1)^2}\frac{1}{x^2} + \frac{1}{2}f_0, \tag{19}$$

which corresponds to the operator X_-X_+.

For $k > 2$, the derivation of analytical forms of the potentials exhibiting a cyclic spectrum was discussed in Ref. 12.

B. Isospectral Hamiltonians

Going back to the general case, the expressions for the isospectral Hamiltonians in (6) can be obtained from (5). This yields the relations

$$H_s \equiv H_s(N, \{f_s\}) = (k-1)X_+X_- + \sum_{t=2}^{k-1}(1-t)f_t + (k-1)\sum_{t=s}^{k-1} f_t, \quad s \in S_1.$$

These relations show that the spectra of the supersymmetric partner Hamiltonians $H_0, H_1, \cdots, H_{k-1}$ can be deduced from the one of X_+X_- given by Eq. (17). By combining the latter two relations, we obtain

$$H_{k-s}(N, \{f_s\}) = H_0(N+s, \{f_s\}), \quad s \in S_0, \tag{20}$$

an important relation for the derivation of the cyclic shape invariance condition.

From (20), we can prove that

$$H_{k-s}(N, \{f_s\}) = H_0(N, h^{(s)}\{f_s\}) + \sum_{i=0}^{s-1} f_i, \quad s \in S_0 \tag{21}$$

with

$$h^{(s)} = h \circ h \circ \cdots \circ h, \quad s \text{ times},$$

where h is the circular permutation

$$h\{f_s\} = h\{f_0, f_1, \cdots, f_{k-2}, f_{k-1}\} = \{f_1, f_2, \cdots, f_{k-1}, f_0\}$$

such that $h^{(k)}$ is the identity.

We continue with dynamical systems in one-dimensional space (coordinate x). Let us note $V_0(x,\{f_s\})$ the potential associated with $H_0(N,\{f_s\})$:

$$H_0(N,\{f_s\}) \equiv -\frac{d^2}{dx^2} + V_0(x,\{f_s\}).$$

From Eq. (21), it is easy to check that the potential $V_{k-s}(x,\{f_s\})$ associated with the Hamiltonian $H_{k-s}(N,\{f_s\})$ can be obtained via

$$V_{k-s}(x,\{f_s\}) = V_0(x,h^{(s)}\{f_s\}) + \sum_{i=0}^{s-1} f_i, \quad s \in S_0, \tag{22}$$

to be compared with the cyclic shape invariance condition for ordinary SUSY (see Eq. (1) and Refs. 11 and 12).

As an example, for $k=2$, Eq. (22) leads to

$$V_1(x,\{f_0,f_1\}) = V_0(x,\{f_1,f_0\}) + f_0,$$

a relation satisfied by Eqs. (18) and (19) for the Calogero-Sutherland potential.

VI. CONCLUDING REMARKS

It was shown in the present paper how to tackle k-fractional SUSYQM through a Z_k-graded Weyl-Heisenberg algebra, noted W_k with $k=3,4,\cdots$ (the case $k=2$ corresponding to ordinary SUSYQM). From the generators of this algebra, it was possible to find several realizations of k-fractional supersymmetric dynamical systems. Each system was characterized by a k-fractional supersymmetric Hamiltonian which gave rise to a hierarchy of k isospectral Hamiltonians H_{k-s} with $s \in S_0$. Two special cases of algebra W_k were examined. They both led to k-fractional isospectral Hamiltonians, the potentials of which are connected by a recurrence relation that reflects a (translational or cyclic) shape invariance condition.

As a conclusion, k-fractional SUSYQM developed in the framework of algebra W_k turns out to be a useful tool to generate a hierarchy of k isospectral Hamiltonians linked by a translational or cyclic invariance condition.

A brief comparison with the results given by ordinary SUSYQM is in order. For $k=2$, the hierarchy of Hamiltonians reduces to a pair of isospectal Hamiltonians. Therefore, in order to generate a hierarchy of k isospectal Hamiltonians, it is necessary to apply ordinary SUSYQM repeatedly. This is no longer the case for k-fractional SUSYQM since the hierarchy of k isospectral Hamiltonians is generated at once. The equivalence between the approaches via ordinary SUSYQM applied repeatedly and k-fractional SUSYQM is ensured by the fact that k-SUSYQM can be seen as a superpostion of $k-1$ copies of ordinary SUSYQM.[22]

To close this paper, let us offer two remarks. First, it is worthwhile to mention that our approach to k-SUSYQM by means of algebra W_k can be applied to other potentials. For instance, by taking $X_+X_- \equiv F(N,a,b,c)$, where the structure function F is given by

$$F(N,a,b,c) = \frac{1}{2}aN(N-1) + bN + c\frac{1}{(N+1)^2},$$

it might be possible to describe potentials involving a Coulombic part. Along this vein, a k-SUSYQM study to the effective screened potential,[40] singular inverse-power potentials,[41] and noncentral potentials[42] could be fruitful. Second, it would interesting to examine the hidden supersymmetries exhibited by the Aharanov-Bohm, Dirac delta, and Pöschl-Teller potentials[34–36] in the light of our approach to k-fractional SUSYQM. For this purpose, the connection between

ordinary SUSYQM, possibly in a q-deformed approach,[43] and k-SUSYQM[22] should play a central role.

(Received 5 September 2006; accepted 2 November 2006; published online 28 December 2006)

The Schrödinger equation in integral form is applied to the one-dimensional scattering problem in the case of a general finite range, nonsingular potential. A simple expression for the Laplace transform of the transmission propagator is obtained in terms of the associated Fredholm determinant, by means of matrix methods; the particular form of the kernel and the peculiar aspects of the transmission problem play an important role. The application to an array of delta potentials is shown.
 [DOI: 10.1063/1.2401728]

I. INTRODUCTION

The space-time propagator is a very important object in quantum physics; it governs the time evolution of a dynamical state and naturally enters any kind of time dependent problem.[1] It is more fundamental than the wave function itself, since it is a characteristic of the physical system and does not depend on initial conditions. However, its calculation is more difficult; suffice it to consider the square potential: the wave functions are well known, but the propagator cannot be expressed in a simple form. On the other hand, the knowledge of the propagator helps to the insight into the physics of a quantum system. For example, let us think about the tunneling time for a potential barrier: in a basic paper on this argument, it is shown that a satisfactory definition of the tunneling time can be given just by the propagator;[2] considering coupling effects in quantum tunneling, it makes it possible to go beyond the perturbative expansion;[3] studying the interaction of a system with a thermal bath, it accounts in a simple way for the oscillatory degrees of freedom, so leading to the concept of effective action.[4]

The nonrelativistic quantum mechanical propagator can be expressed in several ways. The most widely known one is the "spectral decomposition" method, but it is often used also the path-integral approach. We refer to the literature for a complete discussion about this subject.[5,6]

In this paper we show that the integral Schrödinger equation allows us to find an interesting expression for the Laplace transform (LT) of the one-dimensional transmission propagator, since in this case the associated Fredholm equation of the second kind has a simple solution in terms of the Fredholm determinant.

In Sec. II we derived the integral equation for the Laplace transform of the one-dimensional propagator. In Sec. III the fundamental equation of quantum scattering is solved for a general finite range, nonsingular potential, in order to obtain the LT in the case of a transmitted particle. Section IV shows some properties of Fredholm determinant and in Sec. V we apply our results to an array of delta potentials.

II. THE INTEGRAL EQUATION

Let H_0 be a Hamiltonian for which the propagator G_0 is known and V a general potential. The Schrödinger equation for the system with Hamiltonian $H=H_0+V$ is

$$i\hbar\frac{\mathrm{d}}{\mathrm{d}t}|\psi(t)\rangle = H|\psi(t)\rangle, \tag{1}$$

where $|\psi(t)\rangle$ is the vector representing the dynamical state of our system. A standard procedure leads to

$$|\psi(t)\rangle = \mathrm{e}^{-(i/\hbar)H_0 t}|\psi(0)\rangle - \frac{i}{\hbar}\int_0^t \mathrm{d}\tau \mathrm{e}^{-(i/\hbar)H_0(t-\tau)}V|\psi(\tau)\rangle, \tag{2}$$

that is, the Schrödinger equation in integral form. Using the representation where the position variables are diagonal,[7] and performing Wick rotation to imaginary time $t\to -it$ (Ref. 8) (in view of the future use of the LT), this equation is easily written in terms of the propagators G and G_0,

$$G(x,t;\eta) = G_0(x,t;\eta) - \frac{1}{\hbar}\int_0^t \mathrm{d}\tau\int_{-\infty}^{\infty}\mathrm{d}\xi G_0(x,t-\tau;\xi)V(\xi)G(\xi,\tau;\eta), \tag{3}$$

where

$$G(x,t;\eta) = \langle x|\mathrm{e}^{-(i/\hbar)Ht}|\eta\rangle, \quad G_0(x,t;\eta) = \langle x|\mathrm{e}^{-(i/\hbar)H_0 t}|\eta\rangle \tag{4}$$

and η and x are the space coordinates at the times 0 and t, respectively.

After a LT,[9]

$$\mathcal{L}\{\psi(x,t)\} = \int_0^{\infty}\mathrm{d}t\psi(x,t)\mathrm{e}^{-st} = \psi(x,s),$$

we are led to

$$G(x,s;\eta) = G_0(x,s;\eta) - \frac{1}{\hbar}\int_{-\infty}^{\infty}\mathrm{d}\xi G_0(x,s;\xi)V(\xi)G(\xi,s;\eta). \tag{5}$$

Let us suppose that H_0 corresponds to the free particle. In imaginary time,[7]

$$G_0(x,t;\eta) = \sqrt{\frac{m}{2\pi\hbar t}}\exp\left[-\frac{m}{2\hbar}\frac{(x-\eta)^2}{t}\right] \tag{6}$$

and therefore

$$G_0(x,s;\eta) = \frac{c}{2}\frac{\mathrm{e}^{-c|x-\eta|\sqrt{s}}}{\sqrt{s}}, \quad c=\sqrt{\frac{2m}{\hbar}}. \tag{7}$$

With the definitions,

$$G_0(x,s;\eta)=\phi(x), \quad G(x,s;\eta)=\psi(x), \quad \lambda = \frac{c}{2\hbar}\frac{1}{\sqrt{s}}, \quad k=c\sqrt{s}. \tag{8}$$

Equation (5) can be written in short, assuming that V has a finite range $(0,a)$,

$$\psi(x) + \lambda \int_0^a \mathrm{d}\xi \mathrm{e}^{-k|x-\xi|} V(\xi)\psi(\xi) = \phi(x), \tag{9}$$

where the variable s, considered as a parameter, is omitted, since we are now mainly interested in the space coordinates. We would like to point out that $\psi(x)$ is nothing but Green's function, whose poles represent the energies of the system;[6] the inverse LT is quite equivalent to an integration over the energy.

III. THE SOLUTION OF THE INTEGRAL EQUATION FOR THE TRANSMISSION PROPAGATOR G_T

Equation (9) is a Fredholm integral equation of the second kind, with kernel

$$K(x,\xi) = \mathrm{e}^{-k|x-\xi|} V(\xi). \tag{10}$$

We will show that an appealing expression for the solution can be obtained in the case of the transmission of a particle initially localized on the left of the barrier; i.e., when

$$\eta < 0, \quad x > a. \tag{11}$$

In this case, to obtain the required result, Eq. (9) must be solved first for $x \in (0,a)$, then reintroducing the solution in the initial equation with $x > a$. To this aim, N steps discretization on the interval $(0,a)$ leads to[10]

$$\psi_j + \lambda \sum_{i=1}^{N} \mathrm{e}^{-kx_{ij}} V_i \psi_i \mathrm{d}x = \phi_j, \quad x_{ij} = |x_i - x_j|, \quad \mathrm{d}x = \frac{a}{N}, \quad x_i = i\mathrm{d}x, \quad f_i = f(x_i). \tag{12}$$

In vectorial form (here and in the following, it is understood that the limit $N \to \infty$ will be performed at the end),

$$\mathbf{A}\vec{\psi} = \vec{\phi} \Rightarrow \vec{\psi} = \mathbf{A}^{-1}\vec{\phi}, \tag{13}$$

where

$$\vec{\psi} = \begin{pmatrix} \psi_1 \\ \psi_2 \\ \psi_3 \\ \vdots \\ \psi_N \end{pmatrix}, \quad \vec{\phi} = \begin{pmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \vdots \\ \phi_N \end{pmatrix} \tag{14}$$

and

$$\mathbf{A} = \begin{pmatrix} 1 + \mathrm{d}\lambda_1 & \mathrm{d}\lambda_2 \mathrm{e}^{-kx_{12}} & \mathrm{d}\lambda_3 \mathrm{e}^{-kx_{13}} & \dots & \mathrm{d}\lambda_N \mathrm{e}^{-kx_{1N}} \\ \mathrm{d}\lambda_1 \mathrm{e}^{-kx_{12}} & 1 + \mathrm{d}\lambda_2 & \mathrm{d}\lambda_3 \mathrm{e}^{-kx_{23}} & \dots & \mathrm{d}\lambda_N \mathrm{e}^{-kx_{2N}} \\ \mathrm{d}\lambda_1 \mathrm{e}^{-kx_{13}} & \mathrm{d}\lambda_2 \mathrm{e}^{-kx_{23}} & 1 + \mathrm{d}\lambda_3 & \dots & \mathrm{d}\lambda_N \mathrm{e}^{-kx_{3N}} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathrm{d}\lambda_1 \mathrm{e}^{-kx_{1N}} & \mathrm{d}\lambda_2 \mathrm{e}^{-kx_{2N}} & \mathrm{d}\lambda_3 \mathrm{e}^{-kx_{3N}} & \dots & 1 + \mathrm{d}\lambda_N \end{pmatrix}, \quad \mathrm{d}\lambda_i = \lambda V_i \mathrm{d}x, \tag{15}$$

assuming that $\det \mathbf{A} \neq 0$ (this assumption does not give rise to difficulties; see the end of this section). Now, in the transmission case Eq. (9) can be written as

$$\psi(x) + \lambda \mathrm{e}^{-kx} \int_0^a \mathrm{d}\xi \mathrm{e}^{k\xi} V(\xi)\psi(\xi) = \phi(x) \tag{16}$$

and, after discretization,[11]

$$\psi(x) + \lambda e^{-kx} \sum_{i=1}^{N} e^{kx_i} V_i \psi_i dx = \phi(x). \tag{17}$$

Recalling that, by Eq. (7),

$$\phi(x) = \frac{c}{2} \frac{e^{-c(x-\eta)\sqrt{s}}}{\sqrt{s}},$$

and introducing the vectors

$$\vec{\varphi} = \begin{pmatrix} e^{-kx_1} \\ e^{-kx_2} \\ e^{-kx_3} \\ \vdots \\ e^{-kx_N} \end{pmatrix}, \quad \vec{v} = \begin{pmatrix} d\lambda_1 e^{kx_1} \\ d\lambda_2 e^{kx_2} \\ d\lambda_3 e^{kx_3} \\ \vdots \\ d\lambda_N e^{kx_N} \end{pmatrix} \tag{18}$$

Eq. (17) becomes

$$\psi(x) = \phi(x) - e^{-kx}(\vec{v}^T \cdot \vec{\psi}) = \phi(x) - \frac{c}{2} \frac{e^{-k(x-\eta)}}{\sqrt{s}} \vec{v}^T (\mathbf{A}^{-1} \vec{\varphi}) = \phi(x)(1 - \vec{v}^T \mathbf{A}^{-1} \vec{\varphi}) \tag{19}$$

where T denotes the transposematrix or vector. Since

$$\vec{v}^T \mathbf{A}^{-1} \vec{\varphi} = \sum_{i,j} v_i (\mathbf{A}^{-1})_{ij} \varphi_j = \sum_{i,j} (\mathbf{A}^{-1})_{ij} (v_i \varphi_j) \tag{20}$$

and defining the matrix

$$\mathbf{V} = \vec{\varphi} \vec{v}^T = \begin{pmatrix} d\lambda_1 & d\lambda_2 e^{kx_{12}} & d\lambda_3 e^{kx_{13}} & \dots & d\lambda_N e^{kx_{1N}} \\ d\lambda_1 e^{-kx_{12}} & d\lambda_2 & d\lambda_3 e^{kx_{23}} & \dots & d\lambda_N e^{kx_{2N}} \\ d\lambda_1 e^{-kx_{13}} & d\lambda_2 e^{-kx_{23}} & d\lambda_3 & \dots & d\lambda_N e^{kx_{3N}} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ d\lambda_1 e^{-kx_{1N}} & d\lambda_2 e^{-kx_{2N}} & d\lambda_3 e^{-kx_{3N}} & \dots & d\lambda_N \end{pmatrix}, \tag{21}$$

it follows at once

$$\vec{v}^T \mathbf{A}^{-1} \vec{\varphi} = \sum_{i,j} (\mathbf{A}^{-1})_{ij} (\mathbf{V}^T)_{ij} = \mathrm{Tr}[\mathbf{A}^{-1} \mathbf{V}]. \tag{22}$$

Let R be the rank of a matrix; it is easy to recognize that $R(\mathbf{V}) = 1$ and therefore also $R(\mathbf{A}^{-1}\mathbf{V}) = 1$.[12] If $|\mathbf{A}| = \det \mathbf{A} = \Delta$, we can write

$$|\mathbf{A} - \mathbf{V}| = \Delta |\mathbf{I} - \mathbf{A}^{-1} \mathbf{V}|.$$

Expanding the last factor by the diagonal minors[13] and using $R(\mathbf{A}^{-1}\mathbf{V}) = 1$, one has

$$|\mathbf{I} - \mathbf{A}^{-1} \mathbf{V}| = 1 - \mathrm{Tr}[\mathbf{A}^{-1} \mathbf{V}]. \tag{23}$$

On the other hand, $\mathbf{A} - \mathbf{V}$ is a triangular matrix in which every diagonal element is 1, so that

$$|\mathbf{A} - \mathbf{V}| = 1. \tag{24}$$

Therefore

$$\frac{1}{\Delta} = 1 - \mathrm{Tr}[\mathbf{A}^{-1}\mathbf{V}], \tag{25}$$

and from Eqs. (19) and (22) we eventually obtain

$$\psi(x) = \frac{\phi(x)}{\Delta} \tag{26}$$

or, recalling Eq. (8),

$$G_T(x,s;\eta) = \frac{G_0(x,s;\eta)}{\Delta(\lambda)}, \tag{27}$$

Δ depending on s through $\lambda(s)$ and $k(s)$ [see definitions (8)]. In Eq. (27) poles represent the discrete energy levels, while cuts represent the continuous ones; the contour of the inverse LT to obtain G_T passes around these singularities, avoiding the values of s for which $\Delta(\lambda)=0$.[9]

IV. EVALUATION OF THE FREDHOLM DETERMINANT Δ

We see therefore that the problem is completely solved by the knowledge of Δ, that is the *Fredholm determinant* relative to the integral equation [Eq. (9)]. The result [Eq. (26)] represents an important simplification, considering that for $x \in (0,a)$ the solution has a much more complicated form,[10]

$$\psi(x) = \phi(x) - \frac{\lambda}{\Delta(\lambda)} \int \mathrm{d}\xi \Delta(x,\xi;\lambda)\phi(\xi), \tag{28}$$

where $\Delta(x,\xi;\lambda)$ is similar to $\Delta(\lambda)$; however, its explicit expression is not necessary here.

Rewriting Δ as

$$\Delta(\lambda) = \begin{vmatrix} 1+\lambda K_{11}\mathrm{d}x & \lambda K_{12}\mathrm{d}x & \lambda K_{13}\mathrm{d}x & \dots & \lambda K_{1N}\mathrm{d}x \\ \lambda K_{21}\mathrm{d}x & 1+\lambda K_{22}\mathrm{d}x & \lambda K_{23}\mathrm{d}x & \dots & \lambda K_{2N}\mathrm{d}x \\ \lambda K_{31}\mathrm{d}x & \lambda K_{32}\mathrm{d}x & 1+\lambda K_{33}\mathrm{d}x & \dots & \lambda K_{3N}\mathrm{d}x \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \lambda K_{N1}\mathrm{d}x & \lambda K_{N2}\mathrm{d}x & \lambda K_{N3}\mathrm{d}x & \dots & 1+\lambda K_{NN}\mathrm{d}x \end{vmatrix}, \tag{29}$$

where

$$K_{ij} = K(x_i,x_j) = V(x_j)\mathrm{e}^{-k|x_i-x_j|} = V(x_j)\mathrm{e}^{-kx_{ij}}, \tag{30}$$

the following expansion can be used:[11,13]

$$\Delta(\lambda) = 1 + \lambda \sum_{p_1=1}^{N} K_{p_1p_1}\mathrm{d}x + \frac{\lambda^2}{2} \sum_{p_1,p_2=1}^{N} \begin{vmatrix} K_{p_1p_1} & K_{p_1p_2} \\ K_{p_2p_1} & K_{p_2p_2} \end{vmatrix} + \cdots + \frac{\lambda^N}{N!} \sum_{p_1,p_2,\dots,p_N=1}^{N} \begin{vmatrix} K_{p_1p_1} & K_{p_1p_2} & \cdots & K_{p_1p_N} \\ K_{p_2p_1} & K_{p_2p_2} & \cdots & K_{p_2p_N} \\ \vdots & \vdots & \ddots & \vdots \\ K_{p_Np_1} & K_{p_Np_1} & \cdots & K_{p_Np_N} \end{vmatrix}. \tag{31}$$

Now we can perform explicitly the limit $N \to \infty$ and obtain the everywhere convergent series [in other terms, $\Delta(\lambda)$ is an entire function of λ],

$$\Delta(\lambda) = 1 + \sum_{n=1}^{\infty} \frac{\lambda^n}{n!} D_n, \tag{32}$$

$$\begin{aligned} D_n &= \int_0^a dx_n \cdots \int_0^a dx_2 \int_0^a dx_1 \begin{vmatrix} K(x_1,x_1) & K(x_1,x_2) & \cdots & K(x_1,x_n) \\ K(x_2,x_1) & K(x_2,x_2) & \cdots & K(x_2,x_n) \\ \vdots & \vdots & \ddots & \vdots \\ K(x_n,x_1) & K(x_n,x_2) & \cdots & K(x_n,x_n) \end{vmatrix} \\ &= \int_0^a dx_n \cdots \int_0^a dx_2 \int_0^a dx_1 \begin{vmatrix} 1 & e^{-kx_{12}} & \cdots & e^{-kx_{1n}} \\ e^{-kx_{12}} & 1 & \cdots & e^{-kx_{2n}} \\ \vdots & \vdots & \ddots & \vdots \\ e^{-kx_{1n}} & e^{-kx_{2n}} & \cdots & 1 \end{vmatrix} V(x_1)V(x_2)\cdots V(x_n). \end{aligned} \tag{33}$$

Among the interesting analytical properties of Δ, the following is remarkable:[11]

$$\frac{\Delta'(\lambda)}{\Delta(\lambda)} = \sum_{n=0}^{\infty} (-1)^n A_{n+1} \lambda^n, \tag{34}$$

where the A_n are the traces of iterated kernels,

$$A_n = \int_0^a dx \int_0^a dx_{n-1} \cdots \int_0^a dx_2 \int_0^a dx_1 K(x,x_{n-1}) K(x_{n-1},x_{n-2}) \cdots K(x_2,x_1) K(x_1,x). \tag{35}$$

This alternative expression for Δ follows

$$\Delta(\lambda) = e^{-F(\lambda)}, \quad F(\lambda) = \sum_{n=1}^{\infty} (-1)^n A_n \frac{\lambda^n}{n}. \tag{36}$$

For example, in the case of a delta potential

$$V(x) = V\delta(x-y), \quad 0 < y < a, \tag{37}$$

it is easily obtained $A_n = V^n$, so that

$$F(\lambda) = \sum_{n=1}^{\infty} (-1)^n V^n \frac{\lambda^n}{n} = -\ln(1+\lambda V) \Rightarrow \Delta(\lambda) = 1 + \lambda V, \tag{38}$$

and Eq. (27) gives the well known formula for the propagator of a delta potential.[14,15] This result can be obtained in a much easier way if one starts from expansion (32), as it is shown in the next section.

V. APPLICATION: AN ARRAY OF DELTA POTENTIALS

Atomic and molecular systems are often approximately represented by models involving zero-range potentials; for example, to calculate exchange forces in hydrogen molecular ion,[16] to describe valence transfer during nuclear collisions,[17] to obtain a closed form expression for phase and dwell tunneling times,[18] etc. So, the knowledge of the propagator in the general case of an array of delta potentials can be useful,

$$V(x) = \sum_{i=1}^{N} V_i \delta(x - y_i), \quad 0 < y_1 < y_2 < \cdots < y_N < a. \tag{39}$$

It is a simple task to recognize that, introducing this expression of V into Eq. (33), one has

$$D_n = 0 \quad \text{for } n > N, \tag{40}$$

$$D_n = \begin{vmatrix} 1 & e^{-ky_{12}} & \cdots & e^{-ky_{1n}} \\ e^{-ky_{12}} & 1 & \cdots & e^{-ky_{2n}} \\ \vdots & \vdots & \ddots & \vdots \\ e^{-ky_{1n}} & e^{-ky_{2n}} & \cdots & 1 \end{vmatrix} V_1 V_2 \cdots V_n \quad \text{for } n \leqslant N, \tag{41}$$

with $y_{ij} = |y_i - y_j|$. In this way, the series (32) stops to $n=N$ and represents a finite expansion by principal minors; i.e.,

$$\Delta_N = 1 + \sum_{n=1}^{N} \frac{\lambda^n}{n!} D_n = \begin{vmatrix} 1+\lambda_1 & \lambda_2 e^{-ky_{12}} & \lambda_3 e^{-ky_{13}} & \ldots & \lambda_N e^{-ky_{1N}} \\ \lambda_1 e^{-ky_{12}} & 1+\lambda_2 & \lambda_3 e^{-ky_{23}} & \ldots & \lambda_N e^{-ky_{2N}} \\ \lambda_1 e^{-ky_{13}} & \lambda_2 e^{-ky_{23}} & 1+\lambda_3 & \ldots & \lambda_N e^{-ky_{3N}} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \lambda_1 e^{-ky_{1N}} & \lambda_2 e^{-ky_{2N}} & \lambda_3 e^{-ky_{3N}} & \ldots & 1+\lambda_N \end{vmatrix}, \quad \lambda_i = \lambda V_i. \tag{42}$$

Of course, this result could be achieved directly substituting the potential [Eq. (39)] into Eq. (9), automatically obtaining a (nonuniform) discretization in the interval $(0,a)$, and following the same steps of Sec. III.

For $N=1$, $\Delta_1 = 1+\lambda V_1$; for $N=2$,

$$\Delta_2 = 1 + \lambda(V_1 + V_2) + \lambda^2 V_1 V_2 (1 - e^{-2ky_{12}}), \tag{43}$$

and the results of Ref. 19 are found (in particular, the symmetry under the exchange of barriers is remarkable). For $N=3$,

$$\begin{aligned} \Delta_3 = 1 &+ \lambda(V_1 + V_2 + V_3) + \lambda^2 [V_1 V_2 (1 - e^{-2ky_{12}}) + V_1 V_3 (1 - e^{-2ky_{13}}) + V_2 V_3 (1 - e^{-2ky_{23}})] \\ &+ \lambda^3 V_1 V_2 V_3 (e^{-2ky_{13}} - e^{-2ky_{12}} - e^{-2ky_{23}} + 1) \end{aligned} \tag{44}$$

and Eq. (27) can be Laplace inverted by the same approximation methods of Ref. 19, getting the space-time propagator $G_T(x,t;\eta)$.

VI. CONCLUSIONS

The main result of the paper is given by Eq. (27), representing a solution of the scattering integral equation [Eq. (9)]. We were able to obtain this solution since, in the transmission case, the coordinate x is on the right of the integration interval $(0,a)$. It is far from a general, closed form expression for the space-time propagator, since an inverse LT must be performed, but it can be the starting point for approximate calculations, using the expansions (32) and (36) for $\Delta(\lambda)$. It is worth to point out that the calculations of Sec. III do not hold for reflected particles, showing in this way a substantial and problematic difference between the quantum physics of transmission and the one of reflection.

Relativistic quaternionic wave equation

Charles Schwartz[a)]
Department of Physics, University of California, Berkeley, California 94720

(Received 22 September 2006; accepted 19 October 2006;
published online 1 December 2006)

We study a one-component quaternionic wave equation which is relativistically covariant. Bilinear forms include a conserved four-vector current and an antisymmetric second rank tensor. Waves propagate within the light cone and there is a conserved quantity which looks like helicity. The principle of superposition is retained in a slightly altered manner. External potentials can be introduced in a way that allows for gauge invariance. There are some results for scattering theory and for two-particle wave functions as well as the beginnings of second quantization. However, we are unable to find a suitable Lagrangian or an energy-momentum tensor. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2397555]

I. INTRODUCTION

Many attempts have been made to consider the extension of the usual quantum theory, based on the field of complex numbers, to quaternions. The 1936 paper by Birkhoff and von Neumann[1] opened the door to this possibility, and the 1995 book by Adler[2] covers many aspects that have been studied.

Here is a wave equation that appears to have escaped previous recognition:

$$\frac{\partial \psi}{\partial t} i = \mathbf{u} \cdot \boldsymbol{\nabla} \psi + m \psi j. \tag{1.1}$$

The single wave function ψ is a function of the space time coordinates $\mathbf{x}, t$. The usual elementary quaternions i, j, k, are defined by

$$i^2 = j^2 = k^2 = ijk = -1 \tag{1.2}$$

and

$$\mathbf{u} \cdot \boldsymbol{\nabla} = i \frac{\partial}{\partial x} + j \frac{\partial}{\partial y} + k \frac{\partial}{\partial z}. \tag{1.3}$$

Boldface type is used to designate a three-vector.

This combination Eq. (1.3) of elementary quaternions and space derivatives was originated by Hamilton[3] in 1846; its square is the negative of the Laplacian operator.

What one should note about Eq. (1.1) is that it employs quaternions which multiply the wave function on *both* the right side and the left side. This distinction arises from the noncommutativity of quaternion algebra and is central to the present study.

II. OTHER EQUATIONS

There are other quaternionic wave equations one can consider, based on the apparent structural similarities between quaternions and relativity. The simplest is

[a)]Electronic mail: schwartz@physics.berkeley.edu

$$\frac{\partial \psi}{\partial t} = \mathbf{u} \cdot \boldsymbol{\nabla} \psi, \tag{2.1}$$

which, when squared, appears as a four-dimensional Laplace equation, and not a wave equation.

Going to two-dimensions we construct

$$\begin{pmatrix} \frac{\partial}{\partial t} & \mathbf{u} \cdot \boldsymbol{\nabla} \\ \mathbf{u} \cdot \boldsymbol{\nabla} & -\frac{\partial}{\partial t} \end{pmatrix} \boldsymbol{\Psi} = m \boldsymbol{\Psi}. \tag{2.2}$$

When this equation is squared, we do get a wave equation, but it is for a tachyon. If one sets $m = 0$ in this equation, it can be revised to appear as either two copies of the Weyl equation or the Maxwell equations (keeping only the imaginary components).

Various authors have shown that the familiar Dirac equation can be put into quaternionic form. This may be done by putting an i to the right of Ψ on one side of Eq. (2.2) (Ref. 4) or by the use of biquaternions in a one-component equation.[5] All of those representations involve eight real functions—as does the usual Dirac equation—while the basic equation of the current study [Eq. (1.1)] involves only four real functions.

There are two other known relativistic equations with four real components. One of these is the Majorana representation of the Dirac equation,

$$i \gamma^{\mu} \partial_{\mu} \psi = m \psi, \tag{2.3}$$

where all four of the gamma matrices can be made purely imaginary, so that one can take all four components of the Dirac wave function to be real functions of space-time. Indeed, if we write our quaternionic wave function as

$$\psi = \psi_0 + i\psi_1 + j\psi_2 + k\psi_3, \tag{2.4}$$

and arrange these four real functions as a column vector, then our Eq. (1.1) can be put in exactly this Majorana-Dirac form. One awkward feature of that formalism is that the usual Dirac Lagrangian becomes useless for an action principle, since every single term is identically zero.

The other comparison involves the Weyl equation (two complex components), which is usually reserved for massless particles. One can map quaternions onto a two-dimensional space of complex numbers. The correspondence can be expressed in terms of the familiar Pauli matrices $\mathbf{u} \rightarrow -i\boldsymbol{\sigma}$, and the wave equation (1.1) can be written in a pseudo-Weyl form as

$$i \frac{\partial \boldsymbol{\Psi}}{\partial t} = -i\boldsymbol{\sigma} \cdot \boldsymbol{\nabla} \boldsymbol{\Psi} + m \sigma_2 \boldsymbol{\Psi}^*. \tag{2.5}$$

In this second example, one also has trouble with the usual Lagrangian in that the mass term is identically zero.

Both of these equations, Majorana-Dirac and modified Weyl, are used in building supersymmetry theories (see, for example, Ref. 6), but only after one introduces a second set of wave functions—with "dotted" spinor indices. Thus, they do return to eight real functions, which are, furthermore, not simply real functions but elements of a Grassmann algebra.

These comparisons leave me without a definitive answer to the question of whether the focal equation of this paper [Eq. (1.1)] is truly something new in theoretical physics. The work presented here will be to explore this quaternionic wave equation on its own terms and see what interesting things arise.

III. SOME PROPERTIES

In the usual quantum mechanics there is "gauge invariance of the first kind:" we can replace the complex wave function ψ by $\exp(i\theta)\psi$. This freedom is also noted by saying that there is a ray,

not just one vector, in Hilbert space corresponding to each physical state. (The reader will note that this paper focuses entirely on the wave function approach to quantum theory and not the Hilbert space version.) For the quaternionic wave function we have a larger set of freedoms: $\psi \rightarrow q_1 \psi q_2$, where the two numbers q_1, q_2 are quaternions of unit magnitude. The one on the left induces a change of basis in the elementary quaternions $\mathbf{u}$ seen in Eq. (1.1), while the one on the right changes the particular choice of i and j acting to the right of ψ in that equation. Thus, instead of the usual $U(1)$ group, we appear to have $SU(2) \times SU(2)/Z_2$.

A first calculation is to take another time derivative of Eq. (1.1) and arrive at the second-order wave equation,

$$\frac{\partial^2 \psi}{\partial t^2} = \boldsymbol{\nabla}^2 \psi - m^2 \psi, \tag{3.1}$$

which is the ordinary Klein-Gordon equation for a relativistic particle of mass m.

Now we look at some bilinear forms. The first is $\rho = \psi^* \psi$, where the complex conjugation operator $(^*)$ changes the sign of each imaginary quaternion (and requires the reversal of order in multiplication of any expression upon which it operates). The second is the vector $\mathbf{U} = \psi^* \mathbf{u} \psi$. While ρ is real, $\mathbf{U}$ is purely imaginary, and we can write $\mathbf{U} = i\mathbf{U}_1 + j\mathbf{U}_2 + k\mathbf{U}_3$ in terms of three real three-vectors.

Making use of the wave equation [Eq. (1.1)], we then calculate

$$\frac{\partial \rho}{\partial t} = \boldsymbol{\nabla} \cdot \mathbf{U}_1, \tag{3.2}$$

which is the familiar statement of a conserved current. We shall return to $\mathbf{U}_2$ and $\mathbf{U}_3$ shortly. [If you ask what singled out $\mathbf{U}_1$ as the conserved current, it is the choice of the imaginary i sitting beside the time derivative in the wave equation (1.1).]

IV. SPACE-TIME SYMMETRIES

Now we look at the behavior of the wave equation (1.1) under familiar symmetry transformations. To achieve rotation of the spatial coordinates $\mathbf{x}$, we make the transformation

$$\psi \rightarrow \mathrm{e}^R \psi, \quad R = \mathbf{u} \cdot \theta/2, \tag{4.1}$$

where θ is the axis and the angle of rotation.

For the Lorentz transformation, we start with the infinitesimal form

$$\psi \rightarrow \psi + B\psi i, \quad B = \mathbf{u} \cdot \mathbf{v}/2, \tag{4.2}$$

where $\mathbf{v}$ is the direction and amount of the velocity boost. Note the appearance of the imaginary i acting on the right of ψ in this transformation. I leave it as an exercise for the reader to show that this transformation of ψ does indeed induce the familiar Lorentz transformation of the space-time coordinates in the wave equation (1.1).

One can now readily show that the components of the conserved current (ρ and $\mathbf{U}_1$) tansform as a Lorentz four-vector. With a bit more work, one can also see that the other two vectors $\mathbf{U}_2$ and $\mathbf{U}_3$ transform as the components of an antisymmetric second rank tensor in four dimensions (also called a six-vector).

A useful notation for operators that may multiply quaternionic functions on the right or on the left is the following:[1]

$$(a||b)\psi = a\psi b, \quad (a||b)(c||d) = (ac||db), \tag{4.3}$$

which allows us to write the finite Lorentz transformation operator as $e^{(B||i)}$.

[1] A similar notation was introduced by the authors of Ref. 4.

The generators of the Lorentz group may be constructed as

$$\mathbf{J} = \mathbf{x} \times \boldsymbol{\nabla} - \frac{1}{2}\mathbf{u}, \quad \mathbf{K} = \mathbf{x}\frac{\partial}{\partial t} + t\,\boldsymbol{\nabla} - \frac{1}{2}\mathbf{u}||i. \tag{4.4}$$

One can extend this to the full Poincare group by adding the displacement operators: $\partial_\mu = (\partial_t, \nabla)$.

In the Appendix is a more extensive study of various tensors that can be built from solutions of the wave equation.

V. MORE BILINEAR FORMS

Start by defining the derivative operator which acts in both directions, $\mathrm{d}_\mu = (\mathrm{d}_0, \mathbf{d}) = \frac{1}{2}(\vec{\partial}_\mu - \overleftarrow{\partial}_\mu)$. This is a covariant four-vector, but let us now see how things behave when we combine it with the Lorentz transformation of the wave function:

$$D_\mu \equiv \psi^* \mathrm{d}_\mu \psi \rightarrow D_\mu + \frac{1}{2}\{i, \psi^* \mathrm{d}_\mu \mathbf{v} \cdot \mathbf{u}\psi\}. \tag{5.1}$$

The expression D_μ is purely imaginary, and so we can write $D_\mu = D_{1,\mu}\, i + D_{2,\mu}\, j + D_{3,\mu} k$. I hope that the use of the subscripts (1,2,3), denoting which imaginary component they come from, does not cause confusion with the vector or tensor subscripts μ. The expression inside the anticommutator brackets (next to i) is real. This leads us to conclude that under the Lorentz transformation of ψ

$$D_{2,\mu} \text{ and } D_{3,\mu} \text{ are } \textit{unchanged}, \tag{5.2}$$

$$D_{1,\mu} \rightarrow D_{1,\mu} + \textit{more complicated} \text{ stuff}. \tag{5.3}$$

This means that under the full Lorentz transformation of both coordinates and wave function D_2 and D_3 behave simply as four-vectors. The quantity D_1, however, will be shown in the Appendix to be part of a higher rank tensor.

Before proceeding, we note that $D_{\mu=0}$ can be reexpressed by using the wave equation (1.1):

$$D_{\mu=0} = -i\tau - \frac{j}{2}\,\boldsymbol{\nabla} \cdot \mathbf{U}_3 + k\left[m\rho + \frac{1}{2}\,\boldsymbol{\nabla} \cdot \mathbf{U}_2\right], \tag{5.4}$$

where $\tau \equiv \psi^* \mathbf{u} \cdot \mathbf{d}\psi$ is a real three-scalar. Under the Lorentz transformation of the wave function, we calculate $\tau \rightarrow \tau + \mathbf{v} \cdot \mathbf{D}_1$.

We have the identity

$$\partial^\mu D_\mu = 0; \tag{5.5}$$

and we will be interested in the following time derivatives, which are derived by using the wave equation (1.1):

$$\frac{\partial}{\partial t}\tau = -\boldsymbol{\nabla} \cdot \mathbf{D}_1, \tag{5.6}$$

$$\frac{\partial}{\partial t} D_\mu = i[2mD_{2,\mu} - \boldsymbol{\nabla} \cdot (\psi^* \mathbf{u} \mathrm{d}_\mu \psi)] - 2mjD_{1,\mu} + [i, \psi^* \mathrm{d}_\mu \mathbf{u} \cdot \mathbf{d}\psi], \tag{5.7}$$

$$\frac{\partial}{\partial t}\mathbf{U} = i[\boldsymbol{\nabla}\rho + 2\psi^* \mathbf{u} \times \mathbf{d}\psi + 2m\mathbf{U}_2] + j[-2m\mathbf{U}_1 + 2\mathbf{D}_3 - \boldsymbol{\nabla} \times \mathbf{U}_3] + k[-2\mathbf{D}_2 + \boldsymbol{\nabla} \times \mathbf{U}_2]. \tag{5.8}$$

See the Appendix for a more systematic discussion of tensor quantities.

VI. PLANE WAVES

One way of representing "plane-wave" solutions of the wave equation (1.1) is

$$\psi(\mathbf{x},t) = \exp(\eta\mathbf{u}\cdot\hat{p}\mathbf{p}\cdot\mathbf{x})\phi\exp((i\eta p + km)t), \tag{6.1}$$

where $\eta = \pm 1$. The set of possible momentum vectors $\mathbf{p} = \hat{p}p$ should cover only one-half of space to avoid overcounting of solutions. With this, one can construct the solution for the general initial value problem:

$$\psi(\mathbf{x},t) = \int \mathrm{d}^3\mathbf{x}' \sum_{\eta} \int_H \frac{\mathrm{d}^3 p}{(2\pi)^3} \exp(\eta\mathbf{u}\cdot\hat{p}\mathbf{p}\cdot(\mathbf{x}-\mathbf{x}'))\psi(\mathbf{x}',t'=0)\exp((i\eta p + km)t), \tag{6.2}$$

where the subscript H reminds us that the integral covers only half of momentum space.

With the expansions

$$\exp(\eta\mathbf{u}\cdot\hat{p}\mathbf{p}\cdot(\mathbf{x}-\mathbf{x}')) = \cos(\mathbf{p}\cdot(\mathbf{x}-\mathbf{x}')) + \eta\mathbf{u}\cdot\hat{p}\sin(\mathbf{p}\cdot(\mathbf{x}-\mathbf{x}')), \tag{6.3}$$

$$\exp((i\eta p + km)t) = \cos(\omega t) + (i\eta p + km)\sin(\omega t)/\omega, \tag{6.4}$$

where $\omega = \sqrt{p^2+m^2}$, we sum over η and reduce Eq. (6.2) to the following:

$$\begin{aligned}\psi(\mathbf{x},t) = \int \mathrm{d}^3\mathbf{x}' \int_H \frac{\mathrm{d}^3 p}{(2\pi)^3} 2[&\cos(\mathbf{p}\cdot(\mathbf{x}-\mathbf{x}'))\psi(\mathbf{x}',0)(\cos(\omega t) + km\sin(\omega t)/\omega) \\ &+ \mathbf{u}\cdot\mathbf{p}\sin(\mathbf{p}\cdot(\mathbf{x}-\mathbf{x}'))\psi(\mathbf{x}',0)i\sin(\omega t)/\omega].\end{aligned} \tag{6.5}$$

Here we can recognize that the results of the integrals over $\mathbf{p}$ (which now may be extended to cover the full momentum space) give us functions of the invariant $R^2 = t^2 - (\mathbf{x}-\mathbf{x}')^2$, which vanish outside the light cone ($R^2 > 0$). Thus we do have relativistic causality for this quaternionic wave equation; something which we could have expected because the solutions satisfy the Klein-Gordon equation.

The Klein-Gordon equation also has the property that positive (negative) frequency solutions propagate only to positive (negative) frequency solutions. For the quaternionic equation, we have no way to talk about this distinction between positive and negative frequencies; however, we do find a substitute "selection rule" for wave propagation here.

First, we note the orthogonality relation

$$\int \frac{\mathrm{d}^3 x}{(2\pi)^3} \exp(-\eta'\mathbf{u}\cdot\hat{p}'\mathbf{p}'\cdot\mathbf{x})\exp(\eta\mathbf{u}\cdot\hat{p}\mathbf{p}\cdot\mathbf{x}) = \delta_{\eta,\eta'}\delta(\mathbf{p}\pm\mathbf{p}'), \tag{6.6}$$

where I have not required that both sets of momentum variables belong to the same half-space. Next, we use this orthogonality in Eq. (6.2), where we represent $\psi(\mathbf{x}',0)$ as any superposition of plane wave solutions with exclusively $\eta' = +1$ (or exclusively -1). The resulting $\psi(\mathbf{x},t)$ will contain only that same value for η. It is tempting to call this "helicity conservation" in the propagation of these quaternionic waves.

This interpretation is bolstered by the following observations. The operator $\mathbf{u}\cdot\nabla$, acting on a plane wave solution [Eq. (6.1)], has eigenvalue $-\eta p$. Furthermore, one can readily show, from Eq. (1.1), that

$$\frac{\mathrm{d}}{\mathrm{d}t}\int \mathrm{d}^3 x \psi^* \mathbf{u}\cdot\boldsymbol{\nabla}\psi = 0. \tag{6.7}$$

VII. SUPERPOSITION

In the usual (complex) quantum theory, if we have two solutions to the Schrodinger (time dependent) equation, ψ_1 and ψ_2, then any linear combinmation $c_1\psi_1+c_2\psi_2$ is also a solution for arbitrary complex numbers c_1 and c_2. With our quaternionic wave equation (1.1), the idea of superposition requires a slightly different wording.

Note that the general plane wave solution [Eq. (6.1)] has an arbitrary amplitude ϕ positioned in the midst of certain quaternionic functions of space and time. Given any such solution, we find another solution by changing the amplitude: $\phi \rightarrow q\phi q'$, where q and q' are arbitrary quaternionic numbers. Furthermore, if we have one solution of Eq. (1.1)—ψ_1 with amplitude ϕ_1—and another solution—ψ_2 with amplitude ϕ_2—then we also have a solution by simply adding these two: $\psi_1 + \psi_2$. This version of the principle of superposition is implicit in Eq. (6.2).

VIII. ADDING POTENTIALS

The original wave equation (1.1) can be extended by the introduction of external potentials, as follows:

$$\frac{\partial \psi}{\partial t} i = \mathbf{u} \cdot \boldsymbol{\nabla} \psi + \mathrm{e}\varphi\psi - \mathrm{e}\mathbf{u} \cdot \mathbf{A}\psi i + m\psi \mathrm{e}^{ieW} j, \tag{8.1}$$

where φ, $\mathbf{A}$, W are real functions of space-time. The gauge transformation that leaves this equation invariant is

$$\psi \rightarrow \psi \mathrm{e}^{ie\chi}, \tag{8.2}$$

$$\varphi \rightarrow \varphi - \frac{\partial \chi}{\partial t}, \tag{8.3}$$

$$\mathbf{A} \rightarrow \mathbf{A} + \boldsymbol{\nabla}\chi, \tag{8.4}$$

$$W \rightarrow W - 2\chi. \tag{8.5}$$

One can show that the previously discussed symmetries still hold, with $(\varphi, \mathbf{A})$ a Lorentz four-vector and W a scalar. This appearance of the four-vector potentials is (almost) exactly like the usual way of introducing electromagnetism into quantum theory; however, the explicit appearance of a gauge quantity W is something different.

The reflection symmetries of Eq. (8.1) are

$$\psi \rightarrow \psi j, \quad t, \mathbf{A}, W \textit{ change } \text{sign } (T), \tag{8.6}$$

$$\psi \rightarrow \psi k, \quad \mathbf{x}, \varphi, W \textit{ change } \text{sign } (CP), \tag{8.7}$$

$$\psi \rightarrow \psi i, \quad t, \mathbf{x}, \mathbf{A}, \varphi \textit{ change } \text{sign } (TCP). \tag{8.8}$$

The current conservation equation (3.2) is still true for this extended wave equation (8.1), however, Eq. (6.7) must be modified. For the situation where $W=0$, we calculate

$$\frac{\mathrm{d}\tau}{\mathrm{d}t} = \frac{\mathrm{d}}{\mathrm{d}t}(\psi^* \mathbf{u} \cdot \mathbf{d}\psi) = -\boldsymbol{\nabla} \cdot \mathbf{D}_1 + \mathrm{e}\rho\, \boldsymbol{\nabla} \cdot \mathbf{A} - 2\mathrm{e}\mathbf{A} \cdot (\psi^* \mathbf{u} \times \mathbf{d}\psi), \tag{8.9}$$

where we have used the notations from Sec. V. From this we see that in the case where the only external potential is φ, then the space integral of τ, which we identified with helicity, is conserved.

IX. MORE ON PLANE WAVES

The plane wave solutions to the wave equation (1.1), which we set out in Sec. VI, contain an amplitude ϕ which we should study some more:

$$\psi(\mathbf{x},t) = \exp(\eta\mathbf{u}\cdot\hat{p}\mathbf{p}\cdot\mathbf{x})\phi\exp(\Omega t), \tag{9.1}$$

where $\Omega = \hat{\Omega}\omega = (i\eta p + km)$, $\omega = \sqrt{p^2+m^2}$.

We can ask to evaluate the various bilinear forms discussed earlier in the case of this plane wave solution. The easiest are

$$\rho = \phi^*\phi, \quad \tau = -\eta p\rho, \quad D_0 = \Omega\rho, \tag{9.2}$$

but to do more we must be able to evaluate $\phi^*\mathbf{u}\cdot\hat{p}\phi$.

I now propose to classify the constants ϕ in a particular way. The set ϕ_α is defined such that it performs a specific rotation, as follows:

$$\hat{p}\cdot\mathbf{u}\phi_\alpha = \phi_\alpha\hat{\Omega}, \tag{9.3}$$

which sends one unit imaginary quaternion into another. With this type, the solution can be written as

$$\psi = \phi_\alpha\exp(\hat{\Omega}(\omega t + \eta\mathbf{p}\cdot\mathbf{x})), \tag{9.4}$$

which looks like the sort of plane waves we are used to. It should be noted that this definition of ϕ_α is not unique but leaves us with a $U(1)$ class of equivalent amplitudes,

$$\phi_\alpha \to \phi_\alpha\exp(\theta\hat{\Omega}), \tag{9.5}$$

just as in ordinary (complex) quantum theory.

With this α type of amplitude, we can now evaluate the plane wave values for the following bilinears:

$$\mathbf{U}\cdot\hat{p} = i\rho\eta\frac{p}{\omega} + k\rho\frac{m}{\omega}, \quad \mathbf{D} = \eta\mathbf{p}(\mathbf{U}\cdot\hat{p}). \tag{9.6}$$

Components of the vector $\mathbf{U}$ which are orthogonal to $\mathbf{p}$ will oscillate rapidly in space, thus any space average of them will be vanishingly small.

Two other categories for the amplitudes ϕ, called β and γ, can be defined as

$$\mathbf{u}\cdot\hat{p}\phi_\beta = \phi_\beta j, \tag{9.7}$$

$$\mathbf{u}\cdot\hat{p}\phi_\gamma = \phi_\gamma j\hat{\Omega}. \tag{9.8}$$

Note that the three numbers $\hat{\Omega}, j, j\hat{\Omega}$ are mutually anticommuting quaternions. If we calculate any of the bilinears involving $\mathbf{u}\cdot\hat{p}$ with either the β or γ type of amplitude, the result will be rapidly oscillating in time, thus any time average will be vanishingly small.

If we stay with the α type amplitudes, we get the following values, in the plane wave states, for various four-vectors that are defined in Sec. V or the Appendix:

$$j_\mu = \rho(1, \eta\mathbf{p}/\omega), \tag{9.9}$$

$$V_\mu = \rho(\eta p, \omega\hat{p}), \tag{9.10}$$

$$D_{2,\mu} = 0, \tag{9.11}$$

$$D_{3,\mu} = \rho m(1, \eta \mathbf{p}/\omega). \tag{9.12}$$

The four-vectors j and D_3 look like what we would expect for the usual energy-momentum. The four-vector V, however, is spacelike, not timelike; it is similar to the spin vector $s_\mu = \epsilon_{\mu,\nu,\kappa,\lambda} P^\nu S^{\kappa,\lambda}$ in the usual theories, where s_0 is the helicity.

The plane wave solutions are characterized by a parameter **p** which we sometimes call "momentum." This is merely a linguistic habit carried over from conventional quantum theory (following de Broglie's rule that momentum equals Planck's constant divided by wavelength) and should not be confused with the physical quantity called momentum until and unless that connection is established.

X. SCATTERING

Lets start with the wave equation plus a source,

$$\frac{\partial}{\partial t}\psi i = \mathbf{u} \cdot \nabla \psi + m\psi j + s(\mathbf{x},t) i, \tag{10.1}$$

and write the retarded solution as

$$\psi(\mathbf{x},t) = \int_{-\infty}^{t} \mathrm{d}t' \int \mathrm{d}^3x' \int_H \frac{\mathrm{d}^3p}{(2\pi)^3} \sum_\eta \exp(\eta \mathbf{u} \cdot \hat{p}\mathbf{p} \cdot (\mathbf{x} - \mathbf{x}')) s(\mathbf{x}',t') \exp(\Omega(t-t')). \tag{10.2}$$

For the general scattering problem, we replace the source s with $V\psi$ and add in the initial (free particle) solution $\psi_0(\mathbf{x},t)$. If the interaction V is independent of time, then we have an integral equation,

$$\psi(\mathbf{x},t) = \psi_0(\mathbf{x},t) + \int_{-\infty}^{t} \mathrm{d}t' \int \mathrm{d}^3x' \int_H \frac{\mathrm{d}^3p}{(2\pi)^3} \sum_\eta \exp(\eta \mathbf{u} \cdot \hat{p}\mathbf{p} \cdot (\mathbf{x} - \mathbf{x}')) \times V(\mathbf{x}') \psi(\mathbf{x}',t') \exp(\Omega(t-t')). \tag{10.3}$$

Now we make the "Born approximation" that $\psi = \psi_0$ under the integral and let the time t go to $+\infty$. Then, we find that the integral over t' gives us $\delta(\omega - \omega_0)$, which is usually read as conservation of energy. This result appears to be generally true, not just in the first Born approximation. One can now project this solution onto any plane wave solution and achieve the quaternionic version of the S matrix.

In the special case when the scattering potential V comes from the term φ in the extended wave equation (8.1), we also find—as a result of the integral over t'—that we have the selection rule $\eta = \eta_0$. This is consistent with the result noted after Eq. (8.9).

XI. SOME OTHER SOLUTIONS

We can write solutions for the extended wave equation (8.1) in some special cases.

One may ask whether there is a central potential, $\varphi(r)$, which leads to bound states. The easiest way to explore this is through "reverse engineering:" write down a plausible wave function and see what potential fits the wave equation. The form

$$\psi = [f(r) + \mathbf{u} \cdot \hat{r} g(r)] \phi(t) \tag{11.1}$$

leads to the requirements

$$r^4 \frac{\mathrm{d}}{\mathrm{d}r} f^2 = -\frac{\mathrm{d}}{\mathrm{d}r}(r^4 g^2), \quad \mathrm{e}\varphi = -f'/g, \quad \phi(t) = \phi_0 \mathrm{e}^{kmt}. \tag{11.2}$$

If we try the asymptotic ($r \to \infty$) behavior, $g \to \alpha r^{-\beta}$, we find a similar behavior for f, provided that $0 < \beta < 2$. The wave function is then normalizable for $\beta > 1.5$, and the potential is $\mathrm{e}\varphi(r) = \sqrt{\beta(2-\beta)}/r$ at large r. Looking instead at $r \to 0$, one can do the same analysis and require $\beta < 1.5$; this suggests that we are dealing with something like a shielded Coulomb potential.

There are familiar procedures for taking the nonrelativistic limit of the Klein-Gordon or Dirac equation. Here is the best I could do with the present relativistic equation. First, write $\psi = \psi_{nr} \exp(k\omega t)$, where $\omega = \sqrt{m^2 + p^2} \approx m - \boldsymbol{\nabla}^2/2m$. Next, multiply the equation from the right with $i \exp(-k\omega t)$. Finally, drop all terms that oscillate rapidly in time, as $\exp(\pm 2k\omega t)$. The resulting version of the full extended Eq. (8.1) is

$$\frac{\partial \psi_{nr}}{\partial t} k \approx H_{nr} \psi_{nr}, \tag{11.3}$$

$$H_{nr} = -\nabla^2/2m + m(1 - \cos(\mathrm{e}W)) - \mathrm{e}\mathbf{u} \cdot \mathbf{A} \| k, \tag{11.4}$$

which looks like an ordinary Schrodinger equation except that the single imaginary is called k instead of i, and there is also the unfamiliar term with $\mathbf{A}$. What looks like an effective potential energy term (coming from the gauge quantity W) is positive, thus incapable of producing bound states, although it might conceivably yield metastable states through the oscillation of the cosine function.

XII. TWO-PARTICLE EQUATION

Previous studies of quaternionic quantum theory have gotten into trouble when they try to write wave functions for multiparticle systems. In the ordinary (complex) theory, one simply makes a direct product of one-particle wave functions, and because all the numbers there commute, one can manipulate such a product to achieve various sensible results. In the quaternion case, that approach leads to a horrid mess. (See, for example, Ref. 2, Chap. 9.)

The present work suggests a somewhat different approach. Consider this construction with plane waves:

$$\psi(1,2) = \exp(\eta_1 \mathbf{u} \cdot \hat{p}_1 \mathbf{p}_1 \cdot \mathbf{x}_1) \psi(2) \exp(\Omega_1 t_1), \tag{12.1}$$

$$\psi(2) = \exp(\eta_2 \mathbf{u} \cdot \hat{p}_2 \mathbf{p}_2 \cdot \mathbf{x}_2) \phi \exp(\Omega_2 t_2), \tag{12.2}$$

which might be described as a "nested" product. The symbol ϕ here is a quaternionic constant, which can depend on all the parameters of this two-particle wave function. Note that we have written this with independent time variables for the two particles.

These two-particle wave functions, with all their momentum-helicity labels, form a complete orthogonal set of functions in the space of $\mathbf{x}_1$ and $\mathbf{x}_2$. Note, however, that this product is ordered in a way that was meaningless in ordinary (complex) quantum theory but requires some extra bookkeeping in the quaternionic case.

Let us introduce some more compact notation for such wave functions:

$$\psi^{\mathrm{op}}(1) \equiv \exp(\eta_1 \mathbf{u} \cdot \hat{p}_1 \mathbf{p}_1 \cdot \mathbf{x}_1) \| \exp(\Omega_1 t_1) \ , \tag{12.3}$$

where the $\|$ symbol separates those things that are to act on the left from what is to act on the right of whatever follows. Then the two-particle wave function Eq. (12.1) can be written simply as

$$\psi(1,2) = \psi^{\mathrm{op}}(1) \psi^{\mathrm{op}}(2) \phi; \tag{12.4}$$

and we can also write the operator of the wave equation as

$$\mathcal{D} \equiv \frac{\partial}{\partial t} + \mathbf{u} \cdot \boldsymbol{\nabla} \| i - m \| k. \tag{12.5}$$

Next we have the propagators,

$$G(\mathbf{x}-\mathbf{x}', t-t') \equiv \sum_{p,\eta} \exp(\eta \mathbf{u} \cdot \hat{p}\mathbf{p} \cdot (\mathbf{x}-\mathbf{x}')) \| \exp((i\eta p + km)(t-t')) \ , \tag{12.6}$$

where $\Sigma_{p,\eta} = \int_H [\mathrm{d}^3 p/(2\pi)^3] \Sigma_\eta$, and this leads to

$$\mathcal{D}G(\mathbf{x}-\mathbf{x}', t-t') = 0, \quad G(\mathbf{x}-\mathbf{x}', 0) = \delta^3(\mathbf{x}-\mathbf{x}'), \tag{12.7}$$

$$G_+(x-x') \equiv \theta(t-t') G(\mathbf{x}-\mathbf{x}', t-t'), \tag{12.8}$$

$$\mathcal{D}G_+(x-x') = \delta^4(x-x'). \tag{12.9}$$

The coordinate x stands for the full space-time coordinates $t, \mathbf{x}$. Now Eq. (10.2) can be briefly written as

$$\psi(x) = \int \mathrm{d}^4 x' G_+(x-x') s(x'). \tag{12.10}$$

Following that construction, we now write down a general two-particle quaternionic wave function as follows:

$$\psi(x_1, x_2) = \int \mathrm{d}^4 x_1' G_+(x_1 - x_1') \int \mathrm{d}^4 x_2' G_+(x_2 - x_2') s(x_1', x_2'). \tag{12.11}$$

Acting on this with two of those differential operators gives

$$\mathcal{D}_2 \mathcal{D}_1 \psi(x_1, x_2) = s(x_1, x_2). \tag{12.12}$$

This is a two-particle wave equation of the Bethe-Salpeter type, involving separate times as well as separate space coordinates. The term s might be left as an external source or might be used to represent some interaction, such as $V(1,2)\psi(1,2)$. Note that the order in which the two differential operators are applied is significant.

It seems easy now to extend this to any number of particles. This appears to be a significant advance over previous studies of quaternionic wave equations, although there are still many issues to be faced.

XIII. NO LAGRANGIAN

If I use the interacting wave equation (8.1), and think that ψ^* is something independent of ψ, then the following would be suggested as a Lagrangian density:

$$\mathcal{L} = i\psi^* \frac{\partial \psi}{\partial t} i - i\psi^* \mathbf{u} \cdot \boldsymbol{\nabla} \psi - i\psi^* \mathrm{e} \varphi \psi + i\psi^* \mathrm{e} \mathbf{u} \cdot \mathbf{A} \psi i - im\psi^* \psi \mathrm{e}^{\mathrm{i}\mathrm{e}W} j. \tag{13.1}$$

Varying $i\psi^*$ gives immediately the full wave equation for ψ. Before varying ψi on the right, we do a few things: partially integrate in space and time; and move i from left side to right side in the second and third terms and rearrange the i and j coefficients in the last term (this is justified because those $\psi^* \cdots \psi$ expressions are real). Then we get the adjoint wave equation.

But that prescription is not what the usual action principle allows. The familiar game from complex qm does not work here. If one varies each of the four real functions which make up both

quaternionic functions ψ and ψ^*, then we actually get 12 equations from the action principle. This is due to the fact that this Lagrangian is imaginary, that is, it consists of three imaginary parts and each of those parts must vanish after the variation. If we write

$$\mathcal{L} = i\mathcal{L}_1 + j\mathcal{L}_2 + k\mathcal{L}_3, \tag{13.2}$$

we find that the first term, $\mathcal{L}_1$, is Lorentz invariant [see Eq. (A9)]; but what should we do with the other two terms?

Our difficulty with a Lagrangian is different from the difficulty noted earlier for the Dirac-Majorana equation or for the pseudo-Weyl equation. But we do have a problem here.

XIV. DISCUSSION

Several advances have been made in trying to develop a sensible quantum theory based on quaternions, rather than complex numbers. So far, this work has been limited to the wave equation formalism.

We have noted the lack of a conserved energy-momentum tensor (see the Appendix) as well as the lack of a Lagrangian. Nevertheless, we can write down the time-development operator as

$$U(t) = \mathrm{e}^{Ht}, \quad H = -\mathbf{u}\cdot\boldsymbol{\nabla}\|i + m\|k. \tag{14.1}$$

This operator H commutes with the angular momentum operator $\mathbf{J}$, but whether we want to call it the Hamiltonian is unclear. Perhaps these questions wait for a full model of how this quaternionic wave system interacts with other physical systems.

Another approach that may be relevant to that problem, as well as to improving our treatment of many-particle systems, is the method of second quantization. We are led to write down a quaternionic quantum field operator as

$$\psi(\mathbf{x},t) = \sum_{p,\eta} \exp(\eta\mathbf{u}\cdot\hat{p}\mathbf{p}\cdot\mathbf{x})a_{p,\eta}\exp((i\eta p + km)t) \tag{14.2}$$

involving some kind of annihilation/creation operators $a_{p,\eta}$. With this we immediately get

$$N = \frac{1}{(2\pi)^3}\int \mathrm{d}^3x\rho = \sum_{p,\eta} a^\dagger_{p,\eta}a_{p,\eta}, \tag{14.3}$$

$$h = \frac{1}{(2\pi)^3}\int \mathrm{d}^3x\tau = -\sum_{p,\eta} a^\dagger_{p,\eta}a_{p,\eta}\eta p. \tag{14.4}$$

Can one be sure that the matrix product $a^\dagger a$ is real? If these are matrices in a Fock space of the sort we are familiar with, with nonzero elements only on one line parallel to the central diagonal, then this product is real.

It remains unclear to this author whether the equation studied in this paper is merely an alternative mathematical formulation of things already well known or whether it may have consequential applications to some as-yet unidentified physics.

ACKNOWLEDGMENTS

I am grateful to S. Adler and to K. Bardakci for helpful conversations.

APPENDIX: GENERAL TENSORS

We can construct Lorentz covariant tensors of any rank, as follows. Start with the direct product of the "two-way" derivative operators:

$$\mathrm{d}_\mu^n = \mathrm{d}_{\mu_1}\mathrm{d}_{\mu_2}\cdots\mathrm{d}_{\mu_n}, \tag{A1}$$

where the subscript μ now stands for the set of indices $\mu_1\cdots\mu_n$. This expression is manifestly a covariant tensor of rank n as far as the coordinate transformations are concerned, and our task is to package these between the wave functions, which transform under infinitesimal Lorentz transformations as given in Eq. (4.2).

We note that the packages $\psi^*\mathrm{d}_\mu^n\psi$ are real for n even and imaginary for n odd, while these conditions are reversed when we add the quaternions $\mathbf{u}$ inside the package.

We find the following constructions for covariant tensors of rank $n+1$, $Q_{\mu,\nu}^{(n+1)}=Q_{\mu,\nu}=(Q_{\mu,0},\mathbf{Q}_\mu)$:

$$Q_{\mu,\nu} = \left(\psi^*\mathrm{d}_\mu^n\psi, \left\{\frac{-i}{2}, \psi^*\mathrm{d}_\mu^n\mathbf{u}\psi\right\}\right) \quad \text{for } n \text{ even}, \tag{A2}$$

$$Q_{\mu,\nu} = \left(\left\{\frac{-i}{2}, \psi^*\mathrm{d}_\mu^n\psi\right\}, -\psi^*\mathrm{d}_\mu^n\mathbf{u}\psi\right) \quad \text{for } n \text{ odd}. \tag{A3}$$

In the case $n=0$ this is just the four-vector current, previously written as $j_\mu=(\rho,\mathbf{U}_1)$. All these tensors are real.

In addition, for n odd, we have the tensors of rank n,

$$R_{2,\mu} = \left\{\frac{-j}{2}, \psi^*\mathrm{d}_\mu^n\psi\right\}, \quad R_{3,\mu} = \left\{\frac{-k}{2}, \psi^*\mathrm{d}_\mu^n\psi\right\}, \tag{A4}$$

which generalize the previously noted four-vectors D_2, D_3. For n even, we have the tensors of rank $n+2$, $S_{\mu,\nu,\lambda}=-S_{\mu,\lambda.\nu}$:

$$S_{\mu,0,\alpha} = -S_{\mu,\alpha,0} = \left\{\frac{-j}{2}, \psi^*\mathrm{d}_\mu^n\mathbf{u}_\alpha\psi\right\}, \quad S_{\mu,\alpha,\beta} = \epsilon_{\alpha,\beta,\gamma}\left\{\frac{-k}{2}, \psi^*\mathrm{d}_\mu^n\mathbf{u}_\gamma\psi\right\}, \tag{A5}$$

where $\alpha,\beta,\gamma=1,2,3$. This generalizes the previously noted six-vector $(\mathbf{U}_2,\mathbf{U}_3)$.

We can make lower rank tensors by contracting indices:

$$g^{\mu_1,\mu_2}Q_{\mu,\nu}^{(n+1)} = -\left(m^2 + \frac{1}{4}\partial^\lambda\partial_\lambda\right)Q_{\mu',\nu}^{(n-1)}, \tag{A6}$$

where μ_1 and μ_2 are in the set μ, and the set μ' has these two indices removed. An alternative is to contract one of the μ indices with the ν index. We find, for solutions of the free wave equation (1.1), the following:

$$g^{\mu_1,\nu}Q_{\mu,\nu}^{(n+1)} = -mR_{3,\mu'}^{(n-1)} \quad \text{for } n \text{ even}, \tag{A7}$$

$$g^{\mu_1,\nu}Q_{\mu,\nu}^{(n+1)} = 0 \quad \text{for } n \text{ odd}. \tag{A8}$$

If we are looking to find a Lorentz scalar, a tensor of rank zero, take a closer look at the second rank tensor $Q_{\mu,\nu}$. The contraction is

$$Q_\mu^\mu = \left\{\frac{-i}{2}, \psi^*\mathrm{d}_0\psi\right\} + \psi^*\mathbf{u}\cdot\mathbf{d}\psi = D_{1,0} + \tau \tag{A9}$$

and this is exactly zero for the free equation (1.1) but not for the extended Eq. (8.1), where it equals $-ej_\mu A^\mu$.

Now we look at the contraction of such tensors with the derivative operator. In what follows we shall limit ourselves to solutions of the free equation (1.1). It is transparent that $\partial^{\mu_1} Q_{\mu,\nu}=0$ for any μ_1 in the set of labels μ. The same holds true for the tensors R and S. Furthermore, by using the wave equation, one can show that

$$\partial^{\nu} Q_{\mu,\nu} = 0 \quad \text{for } n \text{ even}, \tag{A10}$$

$$\partial^{\nu} Q_{\mu,\nu} = 2mR^{(n)}_{2,\mu} \quad \text{for } n \text{ odd}. \tag{A11}$$

For tensors of rank 1, we have just the previously identified j_μ, $D_{2,\mu}$, and $D_{3,\mu}$, all of which are conserved.

At rank 2, the usual desire is for a conserved symmetric tensor, which one can call the energy-momentum tensor. The closest we come here is the $Q_{\mu,\nu}$, which is not symmetric and is conserved only on the first index. Nevertheless, this does allow us to write integral quantities which are conserved (their time derivatives vanish), as follows:

$$V_\nu = (V_0, \mathbf{V}) \equiv \int \mathrm{d}^3 x Q^{(2)}_{0,\nu}, \tag{A12}$$

$$V_0 = -\int \mathrm{d}^3 x \psi^* \mathbf{u} \cdot \mathbf{d}\psi, \tag{A13}$$

$$\mathbf{V} = \int \mathrm{d}^3 x \left(\mathbf{D}_1 + m\mathbf{U}_3 - \frac{1}{2} \nabla \times \mathbf{U}_1 \right). \tag{A14}$$

This is not what we would identify as the energy-momentum, as noted at the end of Sec. IX.

For the second rank antisymmetric tensor we have

$$\partial^{\mu} S_{\mu,\nu} = -2mj_\nu + 2D_{3,\nu}, \tag{A15}$$

$$\widetilde{S}_{\mu,\nu} = \epsilon_{\mu,\nu,\kappa,\lambda} S^{\kappa,\lambda}/2, \tag{A16}$$

$$\partial^{\mu} \widetilde{S}_{\mu,\nu} = -2D_{2,\nu}. \tag{A17}$$

Generating loop graphs via Hopf algebra in quantum field theory

Ângela Mestre[a] and Robert Oeckl[b]
Instituto de Matemáticas, UNAM, Campus Morelia, C.P. 58190, Morelia, Michoacán, Mexico

(Received 21 July 2006; accepted 11 October 2006; published online 5 December 2006)

We use the Hopf algebra structure of the time-ordered algebra of field operators to generate all connected weighted Feynman graphs in a recursive and efficient manner. The algebraic representation of the graphs is such that they can be evaluated directly as contributions to the connected n-point functions. The recursion proceeds by loop order and vertex number. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2390657]

The combinatorics of perturbative quantum field theory is traditionally dealt with via functional methods and generating functions. However, it is possible to use a more intrinsic algebraic approach instead, rooted directly at the level of n-point functions and pioneered in the 1960s, see Ref. 1.

More recently, it was realized that the Hopf algebra structure of the algebra of field operators (with the normal or with the time-ordered product) can be fruitfully exploited. In particular, using the Hopf algebra and its cohomology it was shown (among other things) how different products of the algebra of field operators are related by Drinfeld twists and how interactions correspond to 2-cocycles.[2]

Relations between different types of n-point functions and the associated combinatorics of Feynman graphs via the Hopf algebra structure of the time-ordered algebra of field operators were established in Ref. 3. More precisely, the relations between complete and connected n-point functions on the one hand and between connected and 1-particle irreducible n-point functions on the other hand were described in this way. At the center of that work stands an algorithm to recursively generate all tree graphs and their values as Feynman graphs. The underlying structure in this is an algebraic representation of graphs in terms of certain generalized monomials in field operators.

In the present paper we extend this algorithm to recursively generate all connected graphs using this algebraic representation. The recursion proceeds by loop number (and by vertex number). The special case of vanishing loop number precisely recovers the algorithm of Ref. 3. Crucially, and as in the special case of tree graphs, the correct weights of graphs are obtained so as to allow for their direct evaluation in terms of the Feynman graph expansion of the connected n-point function of a quantum field theory. Note, however, that no type of renormalization procedure is taken into account. In this sense the computed n-point functions may be considered as bare ones.

As in the previous work[3] all results apply to bosonic as well as fermionic fields and the algorithm is amenable to direct implementation and should allow efficient calculations.

Section I reviews basics about certain graphs and their symmetries, n-point functions, Feynman graphs, the algebraic representation of graphs, and the Hopf algebra structure of the time-ordered field operator algebra. Section II contains the main result with the algorithmic construction of connected graphs and its proof. Section III presents an alternative recursive algorithm to

[a]Electronic mail: mestre@matmor.unam.mx
[b]Electronic mail: robert@matmor.unam.mx

construct connected graphs that can be applied directly on the level of n-point functions. Section IV offers some discussion, especially concerning the efficient algorithmic implementation and the inclusion of fermions. The Appendix lists all connected graphs without external edges and with up to three internal edges together with their weight factors.

I. BASIC CONCEPTS AND DEFINITIONS

The basic setup in this paper is substantially similar to that of Ref. 3. Hence, the present section has substantial overlap with Sec. II and a part of Sec. IV of that paper. Nevertheless, there are important differences, most notably a more extensive treatment of abstract graphs and their symmetries.

A. Graphs

We introduce certain kinds of graphs and elementary properties of them. The graphs will be later interpreted as Feynman graphs. Here we are only interested in them as abstract graphs.

Definition 1: A graph *is a finite collection of* vertices *and* edges, *such that any end of an edge may be connected to a vertex. Edges that are connected to vertices at both ends are called* internal, *while edges with at least one free end are called* external. *Internal edges with both ends connected to the same vertex are also called* self-loops. *The* valence *of a vertex is the number of ends of edges connected to the vertex. The* loop number *of a graph is its number of cycles. A graph is* connected *if it is connected as a topological space*.

We recall the well known relation between vertex number, edge number, and loop number of connected graphs.

Lemma 2: *Consider a connected graph with at least one vertex. Let* v, e, and l *be its number of vertices, internal edges, and loops, respectively. Then*,

$$l = e - v + 1. \tag{1}$$

Definition 3: *A* labeled *graph is a graph whose free ends of external edges are labeled with labels from a label set. Labels on different ends of edges are required to be distinct*.

In the following we shall consider only such labeled graphs, i.e., from now on *graph* means *labeled graph*. The label set is fixed from the outset and will later be identified with an appropriate set of field operator labels.

Definition 4: *A graph is said to be* vertex ordered *if its vertices are ordered. That is, the vertices are numbered* $1,\ldots,n$, *where n is the total number of vertices. A graph is said to be* edge ordered *if the ends of its internal edges are ordered. That is, the ends of internal edges are numbered* $1,\ldots,2m$, *where m is the total number of internal edges (each edge having two ends). A graph is called* ordered *if it is both vertex ordered and edge ordered*.

Definition 5: *Consider an ordered graph* γ. *A* symmetry *of* γ *is a permutation of the numbering of the vertices and of the end points of the internal edges that yields combinatorially the same ordered (and labeled) graph. The number of symmetries, i.e., the order of the group of permutations leaving the graph invariant, is called the* symmetry factor *of the graph. It will be denoted by* S^γ.

Since the symmetry factor is the same for any ordering of the vertices and ends of internal edges of a graph, the concept is well defined for unordered graphs as well.

Definition 6: *Consider a vertex ordered graph* γ. *A* vertex symmetry *of* γ *is a permutation of the numbering of its vertices, which yields combinatorially the same vertex ordered (and labeled) graph. The order of the group of vertex symmetries is called the* vertex symmetry factor *of the graph. It will be denoted by* S^γ_{vertex}.

Definition 7: *Consider an ordered graph* γ. *An* edge symmetry *of* γ *is a permutation of the numbering of the ends of its internal edges that yields combinatorially the same ordered (and labeled) graph while the order of the vertices is held fixed. The order of the group of edge symmetries is called the* edge symmetry factor *of the graph. It will be denoted by* S^γ_{edge}.

Clearly, the concepts of vertex and edge symmetry factors also make sense for unordered graphs as the vertex and edge symmetry factors are the same for any ordering of the vertices and of the ends of the internal edges of a graph, respectively.

Lemma 8: *Let γ denote an ordered graph. The orders of the associated symmetry groups satisfy $S^\gamma = S^\gamma_{\text{vertex}} \cdot S^\gamma_{\text{edge}}$.*

Proof: Denote the group of symmetries, vertex symmetries, and edge symmetries of γ by G^γ, G^γ_{vertex}, and G^γ_{edge}, respectively. Note that an edge symmetry is merely a particular type of symmetry. Hence, the group G^γ_{edge} may be seen as a subgroup of G^γ via an injective group homomorphism $G^\gamma_{\text{edge}} \to G^\gamma$. Furthermore, a symmetry defines a vertex symmetry by forgetting its action on the numbering of ends of edges. On the other hand, any vertex symmetry can be augmented to a symmetry. Hence, there is a surjective group homomorphism $G^\gamma \to G^\gamma_{\text{vertex}}$. It is easy to see that the group homomorphisms form an exact sequence of groups

$$0 \to G^\gamma_{\text{edge}} \to G^\gamma \to G^\gamma_{\text{vertex}} \to 0.$$

Hence, as the groups are finite their orders satisfy $S^\gamma = S^\gamma_{\text{vertex}} \cdot S^\gamma_{\text{edge}}$. □

Lemma 9: *Consider a connected graph γ. Let v be its number of vertices. For each vertex $1 \leqslant i \leqslant v$ let p_i be the number of self-loops connected to it. Let t be the number of pairs of vertices which are directly connected through at least one edge. For each pair $1 \leqslant j \leqslant t$ of such vertices let q_j be the number of edges connecting it. Then, the edge symmetry factor of γ is given by $S^\gamma_{\text{edge}} = (\Pi_{i=1}^{v} 2^{p_i} p_i!)(\Pi_{j=1}^{t} q_j!)$.*

The proof is straightforward combinatorics.

B. *n*-point functions and Feynman graphs

The physical content of a quantum field theory is usually extracted from its n-point functions. In perturbation theory, these are computed as sums of values of Feynman graphs. We briefly review here the essentials. More details can be found in any standard textbook on quantum field theory such as Ref. 4.

We denote by $G^{(n)}(x_1, \ldots, x_n)$ the *complete* n-point function. This is the vacuum expectation value of the time-ordered product of n field operators, i.e.,

$$G^{(n)}(x_1, \ldots, x_n) = \langle 0 | T\phi(x_1) \cdots \phi(x_n) | 0 \rangle.$$

The notation we use here suggests a scalar field theory on Minkowski space time. In general there would be internal field indices as well and possibly other modifications (other space time, etc.). The real nature of the fields is completely irrelevant for our treatment as long as the standard perturbative treatment applies. Therefore, we shall continue with our present notation for simplicity. Hence, we denote field operators generically by $\phi(x)$, where x is from a label set (here suggestive of points in Minkowski space). Furthermore, we shall assume all fields to be bosonic. The fermionic case is also straightforward, but includes extra factors, see Sec. IV.

Let V be the complex vector space of linear combinations of field operators $\phi(x)$. The algebra generated by the field operators with the *time-ordered* product is commutative and can be identified with the *symmetric algebra* $\mathsf{S}(V)$ over V. More precisely, $\mathsf{S}(V) = \oplus_{k=0}^{\infty} V^k$, where V^k is the space of linear combinations of monomials of degree k in the field operators and V^0 is the one-dimensional vector space spanned by the identity element $\mathbf{1}$. We may now express ensembles of n-point functions as functions $\mathsf{S}(V) \to \mathbb{C}$. In particular, we may set

$$\rho(\phi(x_1) \cdots \phi(x_n)) := G^{(n)}(x_1, \ldots, x_n).$$

In perturbation theory, the n-point functions can be computed as a sum over values of Feynman graphs. For the complete n-point functions we may write

$$G^{(n)}(x_1, \ldots, x_n) = \sum_{\gamma \in \Gamma_n} w_\gamma \gamma(x_1, \ldots, x_n). \tag{2}$$

Here Γ_n is the set of Feynman graphs. These are graphs γ in the sense of Sec. I A with n external edges labeled by field operator labels $x_1, \ldots, x_n$. (Note that usually Feynman graphs involve lines of different types depending on particle species. In our treatment lines correspond to sums over all particle species. The information about which particle species can interact resides completely in the vertex functions.) Indeed, from here onward we fix the label set to be the label set of the field operators. The value of a graph γ labeled by $x_1, \ldots, x_n$ is denoted above by $\gamma(x_1, \ldots, x_n)$. The set Γ_n may be taken to be precisely the set of all graphs with n external legs (up to topological equivalence). The weight factor w_γ is precisely the inverse of the symmetry factor S^γ of a graph in the sense of Definition 5.

We should emphasize that the discussion here applies to bare n-point functions. Renormalization is outside the scope of the present paper.

The type of n-point functions we shall be interested in in the following are the *connected* ones, denoted $G_c^{(n)}$. These may be defined in the same way as (2), but with the restriction that only connected graphs are considered. We define $\sigma: \mathsf{S}(V) \to \mathbb{C}$ via

$$\sigma(\phi(x_1) \cdots \phi(x_n)) := G_c^{(n)}(x_1, \ldots, x_n).$$

We now turn to the calculation of the value of a Feynman graph. The Feynman propagator $G_F(x,y)$ is the value of the graph that consists of an edge only, its two ends labeled by x and y, respectively. The value of a graph that consists of a vertex with external edges labeled by $x_1, \ldots, x_k$ is given by the vertex function $F(x_1, \ldots, x_k)$. Note that we can encode the ensemble of vertex functions in a way analogous to n-point functions as a function $\nu: \mathsf{S}(V) \to \mathbb{C}$ via

$$\nu(\phi(x_1) \cdots \phi(x_n)) := F(x_1, \ldots, x_n). \tag{3}$$

For more general graphs we also need the inverse Feynman propagator, G_F^{-1}, determined by the equation

$$\int dy G_F(x,y) G_F^{-1}(y,z) = \delta(x,z). \tag{4}$$

The value of a general graph may then be computed as follows: Associate a label with each internal edge and form the product over a vertex function associated with each vertex and an inverse Feynman propagator associated with each internal edge. Finally, integrate over all possible assignments of internal labels.

C. Algebraic representation of graphs

We introduce an algebraic representation of graphs based on the time-ordered operator algebra $\mathsf{S}(V)$ and allowing straightforward evaluation of graphs in the above sense. More precisely, we associate a given graph with v vertices with a certain element in $\mathsf{S}(V)^{\otimes v}$, the v-fold tensor product of $\mathsf{S}(V)$.

Each vertex of the graph corresponds to one tensor factor. A product $\phi(x_1) \cdots \phi(x_n)$ in a given tensor factor corresponds to external edges of the associated vertex whose end points are labeled by $x_1, \ldots, x_n$. To represent internal edges, we define the formal elements $R_{i,j} \in \mathsf{S}(V)^{\otimes v}$ with $1 \leqslant i \leqslant j \leqslant v$ using the inverse Feynman propagator (4). [$R_{i,j}$ is formal insofar as it really lives in a completion of the tensor product $\mathsf{S}(V)^{\otimes v}$. However, this fact is largely irrelevant for our purposes.] For $i \neq j$ the definition is

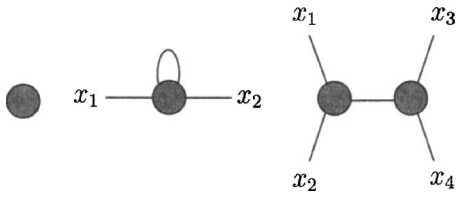

FIG. 1. Examples of the algebraic representation of graphs in terms of elements of $\mathsf{S}(V)^{\otimes v}$.

$$R_{i,j} := \int dxdy G_F^{-1}(x,y)(\mathbf{1}^{\otimes i-1} \otimes \phi(x) \otimes \mathbf{1}^{\otimes j-i-1} \otimes \phi(y) \otimes \mathbf{1}^{\otimes v-j}), \tag{5}$$

with the field operators $\phi(x)$ and $\phi(y)$ inserted at the ith and jth positions, respectively. For $i=j$ the definition is

$$R_{i,i} := \int dxdy G_F^{-1}(x,y)(\mathbf{1}^{\otimes i-1} \otimes \phi(x)\phi(y) \otimes \mathbf{1}^{\otimes v-i}). \tag{6}$$

The element $R_{i,j} \in \mathsf{S}(V)^{\otimes v}$ corresponds to one internal edge connecting the vertices which occupy the positions i and j. In particular, the element $R_{i,i} \in \mathsf{S}(V)^{\otimes v}$ for $1 \leqslant i \leqslant v$ is interpreted as an internal edge connecting the ith vertex to itself. That is, it corresponds to a self-loop.

Combining several internal edges (which can be self-loops) and their products with external edges by multiplying the respective expressions in $\mathsf{S}(V)^{\otimes v}$ allows to build arbitrary graphs with v vertices. Figure 1 shows some examples. It is then obvious that applying the vertex functions ν defined by Eq. (3) to each tensor factor yields precisely the value of the respective graph as a Feynman graph. Thus, the graphs we just discussed are exactly those that are to enter in the v-vertex contribution to an n-point function.

The ordering of the tensor factors of $\mathsf{S}(V)^{\otimes v}$ induces an ordering of the vertices of the graphs in the sense of Definition 4. However, when applying $\nu^{\otimes v}$ the ordering is "forgotten." Indeed, it is not relevant for the interpretation of graphs as Feynman graphs, but only plays a role at the level of their algebraic representation here. In the following, we will encounter elements of $\mathsf{S}(V)^{\otimes v}$ that are linear combinations of expressions corresponding to graphs. In this context, we call the scalar multiplying the expression for a given graph the *weight* of the graph. Clearly, if we are interested in unordered graphs, the weight of such a graph is the sum of the weights of all vertex ordered graphs that correspond to it upon forgetting the vertex order.

D. The field operator algebra as a Hopf algebra

A crucial ingredient of our setting is the fact that the algebra $\mathsf{S}(V)$ of time-ordered field operators is not only an algebra but a *Hopf algebra*. That is, $\mathsf{S}(V)$ carries a coproduct $\Delta: \mathsf{S}(V) \to \mathsf{S}(V) \otimes \mathsf{S}(V)$ and a counit $\epsilon: \mathsf{S}(V) \to \mathbb{C}$ that are compatible with its algebra structure and unit. [$\mathsf{S}(V)$ also carries an antipode map, but this will not be used in the following.] We refer the reader to Ref. 5 for a classical treatment of Hopf algebras and to Ref. 6 for the Hopf algebra structure of the symmetric algebra. The significance of this Hopf algebra structure for quantum field theory was developed in Ref. 2. (Note, however, that the product taken there is the normal product and not the time-ordered one.)

At this point we will only mention the explicit form of the coproduct on $\mathsf{S}(V)$. On monomials this takes the form

$$\Delta(\phi(x_1) \cdots \phi(x_n)) = \sum_{I_1 \cup I_2 = \{\phi(x_1), \ldots, \phi(x_n)\}} T(I_1) \otimes T(I_2), \tag{7}$$

and is extended to all of $\mathsf{S}(V)$ by linearity. Here the sum runs over partitions of the set of field operators $\{\phi(x_1), \ldots, \phi(x_n)\}$ into two sets I_1 and I_2. T denotes the time-ordered product of the field

operators in the corresponding partition. The coproduct may be extended (by suitable composition with itself) to a map (on monomials and extended by linearity),

$$\Delta^k(\phi(x_1)\cdots\phi(x_n)) = \sum_{I_1\cup\cdots\cup I_{k+1}=\{\phi(x_1),\ldots,\phi(x_n)\}} T(I_1)\otimes\cdots\otimes T(I_{k+1}). \tag{8}$$

The difference to the single coproduct is that the set of field operators is now split into $k+1$ partitions. Note also that the partitions are *ordered*, i.e., the sets $I_1,\ldots,I_{k+1}$ are distinguishable. An important property of the coproduct is that it is multiplicative, i.e., it is an algebra map with respect to the algebra structure of $\mathsf{S}(V)$ (and the induced algebra structure on the tensor product). A more extensive discussion of the Hopf algebra structure, adapted to the present context, can be found in Ref. 3.

II. GENERATING LOOP GRAPHS

A. Statement of result

The main result of this paper, which is the subject of the present section, may be described as an efficient algorithm that recursively generates all connected graphs γ. The graphs are generated together with the correct weights w_γ, explained in Sec. I B. In particular, the recursion is such that it may be organized in ascending loop order. Also, the graphs are generated directly in the algebraic representation introduced in Sec. I C. This allows their direct evaluation as Feynman graphs.

More precisely, we shall construct recursively a set of maps $\Omega^{l,v}:\mathsf{S}(V)\to\mathsf{S}(V)^{\otimes v}$ indexed by integers l and v such that the following theorem holds.

Theorem 10: *Fix integers* l, $n\geqslant 0$, $v\geqslant 1$, *and operator labels* $x_1,\ldots,x_n$. *Then*, $\Omega^{l,v}(\phi(x_1)\ldots\phi(x_n))\in\mathsf{S}(V)^{\otimes v}$ *corresponds to the weighted sum over all connected graphs with* l *loops*, v *vertices, and* n *external edges whose end points are labeled by* $x_1,\ldots,x_n$, *each with weight being the inverse of its symmetry factor*.

This specializes for $l=0$ to Lemma 10 of Ref. 3, with $\Lambda^{v-1}=\Omega^{0,v}$.

We may conclude with the interpretation in terms of Feynman graphs and n-point functions. Denote the l-loop and v-vertex contributions to the ensemble σ of connected n-point functions by $\sigma^{l,v}$. In particular, the l-loop order contribution σ^l to σ and σ itself are given by

$$\sigma^l = \sum_{v=0}^{\infty}\sigma^{l,v}, \quad \sigma = \sum_{l=0}^{\infty}\sigma^l.$$

There is only one contribution with zero vertex number. This is the Feynman propagator contributing to the 2-point function. Hence $\sigma^{l,v}$ is zero if $v=0$ and $l\neq 0$, while $\sigma^{0,0}$ is nonzero only on $V\otimes V$ and coincides there with the Feynman propagator. All nonzero vertex number contributions are captured by the following corollary.

Corollary 11: *For* $v\geqslant 1$,

$$\sigma^{l,v} = \nu^{\otimes v}\circ\Omega^{l,v}.$$

Restricting to the $l=0$ (tree level) contribution recovers Corollary 18 of Ref. 3. Note, however, that the contribution corresponding to the Feynman propagator was missing there as well as in Theorem 5 of that paper.

The Appendix lists all connected graphs without external edges as weighted contributions to $\Omega^{l,v}(\mathbf{1})$, for edge number $e=l+v-1\leqslant 3$.

B. Construction and proof

The proof proceeds in a manner very analogous to the proof in Ref. 3. Indeed, each intermediate lemma in this section specializes to a corresponding lemma in Sec. IV of that paper when restricted to the case $l=0$. We do not point this out explicitly in the following, but refer the reader to that paper for comparison.

In order to construct $\Omega^{l,v}$ we introduce certain auxiliary maps. Using the componentwise product in $\mathsf{S}(V)^{\otimes v}$, we may view the elements $R_{i,j}$, defined by Eq. (5) and (6), as operators on this space by multiplication. In particular, these elements are used to define the following maps.

- $T_i:\mathsf{S}(V)^{\otimes v}\to\mathsf{S}(V)^{\otimes v}$, with $1\leqslant i\leqslant v$, as the operator $R_{i,i}$ together with the factor $1/2$:

$$T_i := \frac{1}{2}R_{i,i}. \tag{9}$$

- $Q_i:\mathsf{S}(V)^{\otimes v}\to\mathsf{S}(V)^{\otimes v+1}$, with $1\leqslant i\leqslant v$, given by the composition of $R_{i,i+1}$ with the coproduct applied to the ith component of $\mathsf{S}(V)^{\otimes v}$, i.e., $\Delta_i := \mathrm{id}^{\otimes i-1}\otimes\Delta\otimes\mathrm{id}^{\otimes v-i}:\mathsf{S}(V)^{\otimes v}\to\mathsf{S}(V)^{\otimes v+1}$, together with a factor of $1/2$:

$$Q_i := \frac{1}{2}R_{i,i+1}\circ\Delta_i. \tag{10}$$

The map T_i given by Eq. (9) endows the ith vertex of a vertex ordered graph with a self-loop together with a factor of $1/2$. The latter is the inverse of the edge symmetry factor of a single self-loop (see Lemma 9). The action of the map Q_i given by Eq. (10) is less simple. Consider the coproduct Δ_i applied to the ith component of $\mathsf{S}(V)^{\otimes v}$. Recalling formula (7), we see that Δ_i converts a graph with v vertices into a sum over graphs with $v+1$ vertices by *splitting* the ith vertex into two in all possible ways. That is, the ith vertex is replaced by two vertices (numbered i and $i+1$) and the edges ending on it (considered as distinguishable) are distributed between the two new vertices in all possible ways. Note that the two new vertices are distinguished due to the ordering of the tensor factors. Thus, to obtain the corresponding operation for unordered graphs we need to divide by a factor of 2. This factor corresponds to the two different relative orderings of the new vertices with which each unordered configuration occurs. The only exception to this is the case when the split vertex has no edges at all. No overcounting happens in this case. The meaning of the map Q_i given by Eq. (10) becomes clear now in terms of graphs. Namely, it splits the ith vertex into two and subsequently reconnects the two new vertices with an edge. Dividing by 2 compensates for the double counting as described above if we are interested in unordered graphs (assuming the set of endings of edges of the split vertex is not empty).

We remark that the maps T_i increase both the loop and edge numbers of a graph by one unit, leaving the vertex number invariant, while the maps Q_i increase both the edge and vertex numbers by one unit, leaving the loop number invariant.

We use the maps T_i and Q_i, given by Eq. (9) and (10), respectively, to define recursively maps $\Omega^{l,v}:\mathsf{S}(V)\to\mathsf{S}(V)^{\otimes v}$ for $l\geqslant 0$ and for $v\geqslant 1$ as follows:

$$\begin{aligned}\Omega^{0,1} &:= \mathrm{id},\\ \Omega^{l,v} &:= \frac{1}{l+v-1}\left(\sum_{i=1}^{v-1} Q_i\circ\Omega^{l,v-1}+\sum_{i=1}^{v} T_i\circ\Omega^{l-1,v}\right).\end{aligned} \tag{11}$$

Note that in the recursion equation above the T and Q summands do not appear when $l=0$ or when $v=1$, respectively. Figure 2 shows the recursive dependencies of $\Omega^{l,v}$ for different l, v with $l+v\leqslant 4$.

We notice that $\Omega^{l,v}$ satisfies the following factorization property.

Lemma 12: *Fix integers* l, n, $m\geqslant 0$, $v\geqslant 1$, *and operator labels* $x_1,\ldots,x_n$, $y_1,\ldots,y_m$. *Then*, $\Omega^{l,v}$ *satisfies the factorization property*

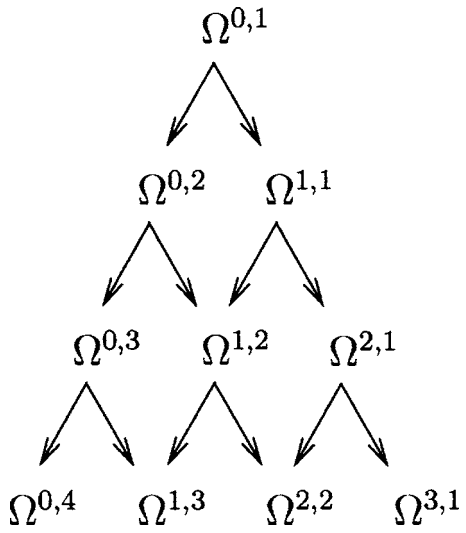

FIG. 2. Recursive dependencies of the maps $\Omega^{l,v}$ up to order $l+v\leqslant 4$. The right directed arrows correspond to T_i maps while the left directed ones correspond to Q_i maps.

$$\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n)\phi(y_1)\cdots\phi(y_m))=\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))\Delta^{v-1}(\phi(y_1)\cdots\phi(y_m)). \tag{12}$$

Proof: This follows from the multiplicativity of the coproduct and the recursive definition (11), noticing that each time the vertex number increases by 1, one coproduct is applied as part of the operator Q_i. □

We now turn to the proof of Theorem 10. We begin with weaker lemmas, increasing their strength stepwise until reaching the desired result.

Lemma 13: *Fix integers* l, $n\geqslant 0$, $v\geqslant 1$ *as well as field operator labels* $x_1,\ldots,x_n$. *(a)* $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ *corresponds to a weighted sum of connected graphs with* l *loops*, v *vertices, and* n *external edges whose end points are labeled by* $x_1,\ldots,x_n$. *(b) Any connected graph with* l *loops*, v *vertices, and the given external edges occurs in* $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ *with some positive weight*.

Proof: First, it is clear that $\Omega^{0,1}(\phi(x_1)\cdots\phi(x_n))$ corresponds to the connected graph with one single vertex with no self-loops and the external edges whose end points are labeled by $x_1,\ldots,x_n$. Moreover, $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ is generated from this by sums of multiple applications of the maps T_i and Q_i with scalar factors according to recursion formula (11). Both T_i and Q_i convert a term corresponding to a connected graph to a sum over terms corresponding to connected graphs. Thus, $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ is a sum of terms each of which corresponds to a connected graph (with some weight). Second, the fact that every graph contained in $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ has l loops and v vertices follows from noticing that the maps T_i increase the loop number by one unit, while the vertex number remains fixed, and the maps Q_i increase the vertex number by one unit, leaving the loop number unchanged. This concludes the proof of (a).

To prove (b) we proceed by induction on the internal edge number $e=l+v-1$ (recall Lemma 2). The result is evidently valid for $e=0$, corresponding to $l=0$ and $v=1$. We assume that the result holds for $e-1$. Let γ denote a graph with l loops and v vertices so that $l+v-1=e$. We show that it is generated by applying the maps T_i or Q_i to graphs contained in $\Omega^{l-1,v}(\phi(x_1)\cdots\phi(x_n))$ or in $\Omega^{l,v-1}(\phi(x_1)\cdots\phi(x_n))$, respectively. Since both T_i and Q_i produce graphs with positive weight from graphs with positive weight, the weight of a graph γ occurring in $\Omega^{l,v}$, being given by a sum over positive contributions according to formula (11), is positive. Now, suppose the graph γ has at least one vertex with one or more self-loops. Let this vertex occupy the ith position, for instance. Shrinking one of these self-loops yields a graph that corresponds by assumption to a term in $\Omega^{l-1,v}(\phi(x_1)\cdots\phi(x_n))$ with some positive weight so that applying the map T_i to the vertex i produces the graph γ with (positive) weight. Thus, by formula (11) the graph γ occurs in $\Omega^{l,v}$.

Finally, suppose the graph γ does not contain vertices with self-loops. Choose an arbitrary internal edge. Shrinking this edge and fusing the vertices it connects yield a graph that corresponds by assumption to a term in $\Omega^{l,v-1}(\phi(x_1)\cdots\phi(x_n))$. Say, the fused vertex has position i. Applying Q_i to this term will yield a sum over terms one of which will correspond to the original. By the recursive definition of $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ it thus contains this term with positive weight. This completes the proof of (b). □

What remains in order to prove Theorem 10 is to show that the term corresponding to each graph has weight given exactly by the inverse of its symmetry factor. We start with a more restricted result.

Lemma 14: *Fix integers* $l\geqslant 0$, $v\geqslant 1$, *and* $n\geqslant v$ *as well as field operator labels* $x_1,\ldots,x_n$. *Consider a connected graph* γ *with* l *loops*, v *vertices*, n *external edges whose end points are labeled by* $x_1,\ldots,x_n$, *and the property that each vertex has at least one external edge ending on it. Then, the term in* $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ *corresponding to that graph has weight given by the inverse of its symmetry factor* S^γ.

Proof: We proceed by induction on the number of internal edges e. Clearly, the statement is true for $e=0$ so that we assume it holds for a general number of internal edges $e-1$. Let γ be a connected graph with e internal edges. Let l be its loop number and let v be its vertex number. By Lemma 13, this graph occurs in $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ with positive weight α. We proceed to show that $\alpha=1/S^\gamma$. We pick an ordering of the vertices and also order the set of pairs of vertices which are connected by at least one edge. Denote the number of self-loops of the vertex i by p_i, with $1\leqslant i\leqslant v$. Denote the number of edges connecting the pair j of vertices by q_j, with $1\leqslant j\leqslant t$, where t is the total number of connected pairs of vertices. By Lemma 9 the edge symmetry factor of γ is given by $S^\gamma_{\text{edge}}=(\Pi_{i=1}^v 2^{p_i}p_i!)(\Pi_{j=1}^t q_j!)$, with $e=\Sigma_{i=1}^v p_i+\Sigma_{j=1}^t q_j$. Since the graph γ has the property that each vertex has at least one external edge, its vertices are distinguishable and it has no nontrivial vertex symmetries: $S^\gamma_{\text{vertex}}=1$ and $S^\gamma_{\text{edge}}=S^\gamma$ (as any symmetry is an edge symmetry). We check from which graphs with $e-1$ internal edges γ is generated by recursion formula (11) and how many times it is generated. It turns out that we can think of each internal edge of γ as contributing with a factor of $1/(e\cdot S^\gamma)$ as follows.

(i) Consider the ith vertex of γ endowed with p_i self-loops. Shrinking one of these self-loops yields a graph γ' whose ith vertex has p_i-1 self-loops. Consequently, by Lemma 9, the symmetry factor of γ' is related to that of γ via $S^{\gamma'}=S^\gamma/(2p_i)$. By assumption, the graph γ' corresponds to a term in $\Omega^{l-1,v}(\phi(x_1)\cdots\phi(x_n))$ which occurs with weight given by the inverse of its symmetry factor: $1/S^{\gamma'}=2p_i/S^\gamma$. Applying the map T_i, which carries the factor of $1/2$, to the vertex i of γ' produces the graph γ from the graph γ' exactly with factor p_i/S^γ. Thus, the contribution to Eq. (11) is $p_i/(e\cdot S^\gamma)$. Distributing this factor between the p_i edges considered yields $1/(e\cdot S^\gamma)$ for each edge considered.

(ii) Consider the jth pair of vertices of γ connected by q_j edges. We assume now the indices of the vertices forming this pair to be consecutive, given by k and $k+1$. (Note that this merely amounts to a particular vertex ordering of the graph γ. Since γ is *a priori* unordered this does not imply any loss of generality.) Shrinking one of the edges and fusing the vertices it connects yield a graph γ'' whose fused vertex has $r:=p_k+p_{k+1}+q_j-1$ self-loops. Consequently, by Lemma 9, the symmetry factor of γ'' is related to that of γ as follows:

$$\frac{1}{2^r}\frac{1}{r!}S^{\gamma''}=\frac{1}{2^{p_k}p_k!}\frac{1}{2^{p_{k+1}}p_{k+1}!}\frac{1}{q_j!}S^\gamma.$$

By assumption, the graph γ'' corresponds to a term in $\Omega^{l,v-1}(\phi(x_1)\cdots\phi(x_n))$ which occurs with weight given by the inverse of its symmetry factor, i.e.,

$$\frac{1}{S^{\gamma''}}=\frac{p_k!p_{k+1}!q_j!}{r!}\frac{1}{2^{q_j-1}S^\gamma}. \tag{13}$$

The map Q_k, when applied to the fused vertex, produces a pair of vertices occupying the positions k and $k+1$, distributes the $2r$ endings of edges between the two vertices in all

possible ways, and attaches them together by an edge. The action of Q_k on the fused vertex k (leaving out external edges) reads explicitly as

$$Q_k R^r_{k,k} = \frac{1}{2} R_{k,k+1}(R_{k,k} + 2R_{k,k+1} + R_{k+1,k+1})^r \tag{14}$$

$$= \sum_{a=0}^{r} \sum_{b=0}^{a} \binom{r}{a} \binom{a}{b} 2^{a-b-1} R^{r-a}_{k,k} R^{a-b+1}_{k,k+1} R^b_{k+1,k+1}. \tag{15}$$

Taking into account the external edges, there are two terms in Eq. (15) corresponding to the graph γ: one with $r-a=p_k$ and $b=p_{k+1}$ and one with $r-a=p_{k+1}$ and $b=p_k$. The sum of the coefficients of these two contributions is

$$2^{q_j-1} \frac{r!}{p_k! p_{k+1}! (q_j-1)!}. \tag{16}$$

Multiplying Eq. (13) with Eq. (16), we see that Q_j produces γ from γ' exactly with a factor q_j/S^γ and the contribution to Eq. (11) is $q_j/(e \cdot S^\gamma)$. In other words, we get a factor of $1/(e \cdot S^\gamma)$ for each of the q_j edges considered.

Since each of the $e=l+v-1$ internal edges contributes with a factor of $1/(e \cdot S^\gamma)$ to the weight of the graph γ, the overall contribution is exactly $1/S^\gamma$. This completes the proof. □

To complete the proof of Theorem 10, we show that the term in $\Omega^{l,v}(\phi(x_1)\cdots\phi(x_n))$ corresponding to a connected graph γ with l loops, v vertices, and external edges whose end points are labeled by $x_1,\ldots,x_n$ has weight given by $1/S^\gamma$. If γ has external edges attached to every one of its vertices we simply recall Lemma 14. Thus, we may now assume that γ has m vertices to which no external leg is attached. Consider a graph γ' which is constructed from γ by attaching an external edge to every vertex without external edges, choosing arbitrary but fixed labels $y_1,\ldots,y_m$ for the end points of external edges in the process. By Lemma 14, the graph γ' occurs in the term on the left hand side of Eq. (12) with weight $1/S^\gamma$. By Lemma 13, the graph γ occurs in the first factor on the right hand side with some nonzero weight, say α. Every summand of $\Delta^{v-1}(\phi(y_1)\cdots\phi(y_m))$ [recall formula (8)] which places the end points of external edges at the designated vertices of γ to produce γ' contributes to the weight of γ' in terms of that of γ. Any different ways this can happen define a vertex symmetry of γ. Furthermore, γ can have no more than these vertex symmetries, since its vertices that already carry external edges are distinguishable and thus held fixed under any symmetry. Therefore, using Lemma 12 we obtain the formula $1/S^{\gamma'} = \alpha \cdot S^\gamma_{\text{vertex}}$ by extracting the weights from the corresponding terms in Eq. (12). Moreover, $S^{\gamma'} = S^{\gamma'}_{\text{edge}} = S^\gamma_{\text{edge}}$. Thus, using $S^\gamma = S^\gamma_{\text{vertex}} \cdot S^\gamma_{\text{edge}}$ (Lemma 8), we find $\alpha = 1/S^\gamma$. This completes the proof.

III. FURTHER RECURSION RELATIONS

Generalizing the case with trees (Sec. V in Ref. 3) we present an alternative recursion relation satisfied by $\Omega^{l,v}$. This has the advantage over Eq. (11) that it may be translated directly into a recursion relation of the resulting n-point functions $\sigma^{l,v}$, related via Corollary 11.

Proposition 15: *Let $v \geqslant 1$ and $l \geqslant 0$, but not $v=1$ and $l=0$. Then,*

$$\Omega^{l,v} = \frac{1}{l+v-1} \left(\Omega^{l-1,v} \circ T + \sum_{a=0}^{l} \sum_{b=1}^{v-1} (\Omega^{a,b} \otimes \Omega^{l-a,v-b}) \circ Q \right).$$

It is understood that the first summand does not contribute if $l=0$ while the second does not contribute if $v=1$.

Before proceeding with the proof we note that this formula has a straightforward interpretation in terms of sums over weighted graphs following the correspondence of Sec. I C. Namely, the formula states that the weighted sum over graphs with l loops and v vertices is given by a sum of two terms divided by the edge number $e=l+v-1$. The first term is the sum over all weighted graphs with $l-1$ loops and v vertices which have an extra edge attached, its end points being connected to vertices in all possible ways. The second term is a sum over all ordered pairs of weighted graphs with total number of vertices equal to v and total number of loops equal to l, connected in all possible ways with an edge.

Proof: The proof proceeds by induction on the number of edges $e=l+v-1$ (recall Lemma 2). It is straightforward to check its validity for $e=1$ by reducing the cases $l=0$, $v=2$ and $l=1$, $v=1$ to Eq. (11), remembering that $\Omega^{0,1}$ is the identity.

We now assume the formula to hold for any edge number smaller than a fixed $e\geqslant 2$. Then for loop number l and vertex number v such that $e=l+v-1$ we use Eq. (11) to show the following equality and hence complete the proof:

$$
\begin{aligned}
\Omega^{l,v} &= \frac{1}{l+v-1}\left(\sum_{j=1}^{v-1} Q_j \circ \Omega^{l,v-1} + \sum_{j=1}^{v} T_j \circ \Omega^{l-1,v}\right) \\
&= \frac{1}{(l+v-1)(l+v-2)}\left(\sum_{j=1}^{v-1} Q_j \circ \left(\Omega^{l-1,v-1}\circ T + \sum_{a=0}^{l}\sum_{b=1}^{v-2}(\Omega^{a,b}\otimes\Omega^{l-a,v-1-b})\circ Q\right)\right. \\
&\quad \left. + \sum_{j=1}^{v} T_j \circ \left(\Omega^{l-2,v}\circ T + \sum_{a=0}^{l-1}\sum_{b=1}^{v-1}(\Omega^{a,b}\otimes\Omega^{l-1-a,v-b})\circ Q\right)\right) \\
&= \frac{1}{(l+v-1)(l+v-2)}\left(\sum_{j=1}^{v-1} Q_j \circ \Omega^{l-1,v-1}\circ T + \sum_{j=1}^{v} T_j \circ \Omega^{l-2,v}\circ T\right. \\
&\quad + \sum_{a=0}^{l}\sum_{b=1}^{v-2}\left(\sum_{j=1}^{b} Q_j\circ\Omega^{a,b}\otimes\Omega^{l-a,v-1-b} + \sum_{j=1}^{v-1-b}\Omega^{a,b}\otimes Q_j\circ\Omega^{l-a,v-1-b}\right)\circ Q \\
&\quad \left. + \sum_{a=0}^{l-1}\sum_{b=1}^{v-1}\left(\sum_{j=1}^{b} T_j\circ\Omega^{a,b}\otimes\Omega^{l-1-a,v-b} + \sum_{j=1}^{v-b}\Omega^{a,b}\otimes T_j\circ\Omega^{l-1-a,v-b}\right)\circ Q\right) \\
&= \frac{1}{(l+v-1)(l+v-2)}\left(\left(\sum_{j=1}^{v-1} Q_j\circ\Omega^{l-1,v-1} + \sum_{j=1}^{v} T_j\circ\Omega^{l-2,v}\right)\circ T\right. \\
&\quad + \left(\sum_{b=1}^{v-2}\left(\sum_{j=1}^{b}(Q_j\circ\Omega^{0,b})\otimes\Omega^{l,v-1-b} + \sum_{j=1}^{v-1-b}\Omega^{l,b}\otimes(Q_j\circ\Omega^{0,v-1-b})\right)\right. \\
&\quad + \sum_{a=0}^{l-1}\left((T\circ\Omega^{a,1})\otimes\Omega^{l-1-a,v-1} + \Omega^{a,v-1}\otimes(T\circ\Omega^{l-1-a,1})\right) \\
&\quad + \sum_{a=1}^{l}\sum_{b=2}^{v-1}\left(\sum_{j=1}^{b-1} Q_j\circ\Omega^{a,b-1} + \sum_{j=1}^{b} T_j\circ\Omega^{a-1,b}\right)\otimes\Omega^{l-a,v-b} \\
&\quad \left.\left. + \sum_{a=0}^{l-1}\sum_{b=1}^{v-2}\Omega^{a,b}\otimes\left(\sum_{j=1}^{v-1-b} Q_j\circ\Omega^{l-a,v-1-b} + \sum_{j=1}^{v-b} T_j\circ\Omega^{l-1-a,v-b}\right)\right)\circ Q\right) \\
&= \frac{1}{(l+v-1)(l+v-2)}\left((l+v-2)\Omega^{l-1,v}\circ T\right.
\end{aligned}
$$

$$
\begin{aligned}
&+\Bigg(\sum_{b=2}^{v-1}(b-1)\Omega^{0,b}\otimes\Omega^{l,v-b}+\sum_{b=1}^{v-2}(v-b-1)\Omega^{l,b}\otimes\Omega^{0,v-b}\\
&+\sum_{a=1}^{l}a\Omega^{a,1}\otimes\Omega^{l-a,v-1}+\sum_{a=0}^{l-1}(l-a)\Omega^{a,v-1}\otimes\Omega^{l-a,1}\\
&+\sum_{a=1}^{l}\sum_{b=2}^{v-1}(a+b-1)\Omega^{a,b}\otimes\Omega^{l-a,v-b}\\
&+\sum_{a=0}^{l-1}\sum_{b=1}^{v-2}(l-a+v-b-1)\Omega^{a,b}\otimes\Omega^{l-a,v-b}\Bigg)\circ Q\Bigg)\\
=&\frac{1}{(l+v-1)(l+v-2)}\Bigg((l+v-2)\Omega^{l-1,v}\circ T\\
&+\Bigg(\sum_{a=0}^{l}\sum_{b=1}^{v-1}(a+b-1)\Omega^{a,b}\otimes\Omega^{l-a,v-b}\\
&+\sum_{a=0}^{l}\sum_{b=1}^{v-1}(l-a+v-b-1)\Omega^{a,b}\otimes\Omega^{l-a,v-b}\Bigg)\circ Q\Bigg)\\
=&\frac{1}{l+v-1}\Bigg(\Omega^{l-1,v}\circ T+\sum_{a=0}^{l}\sum_{b=1}^{v-1}\left(\Omega^{a,b}\otimes\Omega^{l-a,v-b}\right)\circ Q\Bigg).
\end{aligned}
$$

□

Combining this result with Corollary 11 yields the corresponding recursion equation for $\sigma^{l,v}$.

Corollary 16: *Let* $v\geqslant 1$ *and* $l\geqslant 0$, *but not* $v=1$ *and* $l=0$. *Then*,

$$
\sigma^{l,v}=\frac{1}{l+v-1}\Bigg(\sigma^{l-1,v}\circ T+\sum_{a=0}^{l}\sum_{b=1}^{v-1}(\sigma^{a,b}\otimes\sigma^{l-a,v-b})\circ Q\Bigg).
$$

It is understood that the first summand does not contribute if $l=0$ *while the second does not contribute if* $v=1$.

IV. DISCUSSION AND CONCLUSION

The results of the present paper can be seen as an extension of those of Ref. 3, where only tree graphs were generated. Accordingly, many points in the discussion of the main result in that paper extend to the present setting. In particular, this applies to the algorithmic aspects and to the inclusion of fermions. We refer the reader to Secs. VI C and VI D of Ref. 3 for details. Here we shall only touch these points briefly and highlight differences arising through the inclusion of graphs with loops.

The generation of the graphs in their algebraic representation via recursion formula (11) has the structure of an algorithm. Indeed, this algorithmic structure can be used directly and efficiently in implementing concrete calculations of (loop) graphs. In doing so, external edges may be fixed from the beginning and $\Omega^{l,v}$ as applied to the external edges is calculated recursively rather than as an abstract map. An important aspect for the efficiency of concrete calculations is to discard graphs that do not contribute. In typical quantum field theoretic calculations, the vertex function is such that only vertices with a minimum valence (usually three) contribute. In the case of tree graphs this allows the restriction of the coproduct implicit in the operator Q_i in recursion formula (11).[3] Concretely, coproduct (7) may be replaced by a *truncated* coproduct $\Delta_{\geqslant k}$ with $k\geqslant 1$. This is defined by removing from the right hand side of Eq. (7) all terms where the number of elements in I_1 or I_2 is smaller than k. This will prevent graphs from being generated who have vertices with

valence smaller than $k+1$. If only tree graphs are considered this is consistent with the recursion process. More precisely, a graph with all vertices of valence at least $k+1$ cannot be generated by Q_i from a graph with at least one vertex having valence smaller than $k+1$. The analogous statement is not true for the operator T_i. Hence, considering loop graphs as well (recall that T_i increases loop number), we can no longer globally restrict the coproduct. However, if we are interested in graphs only up to a maximal loop number m, we may still restrict the coproduct in Q_i in certain instances. These are precisely the instances when a later application of T_i to a graph cannot occur, i.e., when the graph has already the maximal loop number m.

The restriction on the valence of vertices to be at least a, where $a \geqslant 3$, leads to another obvious limit we can impose on the algorithm. Namely, for a given number of loops m and a given number of external edges n there is an upper bound $b=(n+2m-2)/(a-2)$ on the number of vertices a graph can have. Thus, in this case we only need to compute $\Omega^{l,v}$ for $l \leqslant m$ and $v \leqslant b$.

We now turn to the question of the implementation of fermions. Here the situation is not at all changed by the extension to loop graphs. Namely, the whole formalism is completely functorial and carries over immediately to the case that the vector space V of field operators is a $\mathbb{Z}_2$-graded space. (Recall that this means that V is a direct sum of a bosonic and fermionic part.) Concretely, certain field operators will anticommute which introduces minus signs in front the summands in Eqs. (7) and (8) which correspond to odd permutations of such field operators. In contrast, all formulas appearing in Secs. II and III remain unchanged as the $\mathbb{Z}_2$ grading is completely implicit there.

The algorithm to generate tree graphs was applied in two contexts in Ref. 3: To relate connected n-point functions with 1-particle irreducible ones and to generate all tree graphs using the vertex functions. In both cases renormalization does not introduce any alteration. This is different in the present situation where we interpret the algorithms of Secs. II and III as generating all connected graphs using the vertex functions. Renormalization, via counterterms, alters this process considerably. Thus, it would be highly desirable to include the renormalization process into the present framework. At this point we have very little to say about this, except to point out that the algorithms of Secs. II and III are naturally organized as a recursion by loop order, which might facilitate the task.

ACKNOWLEDGMENTS

The authors would like to thank Christian Brouder who, after learning about their main result, suggested the recursion formula of Proposition 15, which they subsequently proved. One of the authors (Â.M.) was supported through a fellowship provided by Fundação Calouste Gulbenkian 65709.

APPENDIX

This appendix shows all graphs without external edges and with up to three edges computed as contributions to $\Omega^{l,v}(\mathbf{1})$ via Eq. (11). The factors in front of the graphs are the inverses of their symmetry factors of Definition 5, see Theorem 10.

$$\Omega^{0,1}(\mathbf{1}) = \bullet$$

$$\Omega^{0,2}(\mathbf{1}) = \tfrac{1}{2}\ \bullet\!\!-\!\!\bullet$$

$$\Omega^{1,1}(\mathbf{1}) = \tfrac{1}{2}$$ 

$$\Omega^{0,3}(\mathbf{1}) = \tfrac{1}{2}\ \bullet\!\!-\!\!\bullet\!\!-\!\!\bullet$$

$$\Omega^{1,2}(\mathbf{1}) = \tfrac{1}{2}$$  $$+ \tfrac{1}{2^2}$$

$$\Omega^{2,1}(\mathbf{1}) = \tfrac{1}{2^3}$$ 

$$\Omega^{0,4}(\mathbf{1}) = \tfrac{1}{2}$$ $$+ \tfrac{1}{3!}$$ 
$$\Omega^{1,3}(\mathbf{1}) = \tfrac{1}{3!}$$  $$+ \tfrac{1}{2^2}$$  $$+ \tfrac{1}{2}$$  $$+ \tfrac{1}{2}$$

(Received 30 June 2006; accepted 14 October 2006; published online 7 December 2006)

In algebraic quantum field theory we consider nets of von Neumann algebras indexed over regions of the space time. Wiesbrock ["Conformal quantum field theory and half-sided modular inclusions of von Neumann algebras," Commun. Math. Phys. **158**, 537–543 (1993)] has shown that strongly additive nets of von Neumann algebras on the circle are in correspondence with standard half-sided modular inclusions. We show that a finite index endomorphism on a half-sided modular inclusion extends to a finite index endomorphism on the corresponding net of von Neumann algebras on the circle. Moreover, we present another approach to encoding endomorphisms on nets of von Neumann algebras on the circle into half-sided modular inclusions. There is a natural way to associate a weight to a Möbius covariant endomorphism. The properties of this weight have been studied by Bertozzini *et al.* ["Covariant sectors with infinite dimension and positivity of the energy," Commun. Math. Phys. **193**, 471–492 (1998)]. In this paper we show the converse, namely, how to associate a Möbius covariant endomorphism to a given weight under certain assumptions, thus obtaining a correspondence between a class of weights on a half-sided modular inclusion and a subclass of the Möbius covariant endomorphisms on the associated net of von Neumann algebras. This allows us to treat Möbius covariant endomorphisms in terms of weights on half-sided modular inclusions. As our aim is to provide a framework for treating endomorphisms on nets of von Neumann algebras in terms of the apparently simpler objects of weights on half-sided modular inclusions, we lastly give some basic results for manipulations with such weights. © *2006 American Institute of Physics.*

I. INTRODUCTION

Algebraic quantum field theory is an approach to quantum field theory in which the basic objects of the theory are local algebras of observables associated with bounded regions of space time. A local algebra associated with a given bounded region of space time is an algebra of operators corresponding to the physical measurements that can be performed in that region of space time. Standard introductions to the subject include Refs. 12, 1, and 4.

Commonly we consider states corresponding to particularly simple physical systems in order to obtain a more amenable theory. The Doplicher-Haag-Roberts (DHR) superselection criterion[7] has proven to be fruitful in this respect. In essence it picks out states corresponding to spatially bounded physical systems with no long-range forces. The representations of the net of local algebras whose folia satisfy the DHR superselection criterion are unitarily equivalent to endomorphisms of the local algebras. These endomorphisms are known as DHR endomorphisms and the study of them is central to algebraic quantum field theory.

To model the physical world as we presently understand it, the natural choice of space time is the four-dimensional Minkowski space. However, theories in lower-dimensional space times have

a)Electronic mail: rolf@ms.u-tokyo.ac.jp

proven to be both physically and mathematically interesting in their own right. Especially nets of local algebras on the circle have been of growing interest recently. Wiesbrock showed in 1993 that one-dimensional nets of local algebras on the circle satisfying an assumption known as strong additivity could be completely described by half-sided modular inclusions of factors;[19] a gap in the proof was later filled by Araki and Zsidó.[2]

Wiesbrock's result opens the door to the study of algebraic quantum field theories on the circle in terms of half-sided modular inclusions of factors. In this paper we take the first steps towards developing a theory for Möbius covariant DHR endomorphisms on half-sided modular inclusions.

We present two main results. Firstly we show an extension theorem for endomorphisms with finite index. Specifically we show that normal, injective endomorphisms with finite index on a half-sided modular inclusion extend to endomorphisms with finite index on the associated net of von Neumann algebras under some light assumptions. Secondly we present a way of treating Möbius covariant endomorphisms in terms of weights on half-sided modular inclusions. To any Möbius covariant endomorphism there is a naturally occurring cocycle satisfying the conditions for being the Connes cocycle derivative of some weight with respect to the vacuum state. Properties of this weight for endomorphisms with finite index have been studied by Longo[14] and Bertozzini *et al.*[5] In this paper we construct a method for passing the other way, that is, from weights to endomorphisms. This gives us a correspondence between a class of weights on a half-sided modular inclusion and a subclass of the Möbius covariant endomorphisms on the net of von Neumann algebras associated with the half-sided modular inclusion. Finally, we give the analog for weights of some basic constructions for endomorphisms; e.g., unitary equivalence, direct sums, and weak conjugates.

Sectionwise the paper breaks down as follows. In Sec. II we recall the basic notions of nets of von Neumann algebras, Möbius covariant endomorphisms, and half-sided modular inclusions. Next we show in Sec. III that any finite index endomorphism on the larger factor of a half-sided modular inclusion extends to a finite index endomorphism on the net of local algebras associated with the half-sided modular inclusion as per Wiesbrock's result.

In Refs. 14 and 5, Longo and Bertozzini *et al.* studied for a given Möbius covariant endomorphism ρ, the weight ψ whose Connes cocycle derivative relative to the vacuum state ω satisfies

$$(D\psi:D\omega)_t = U_\rho(D(t))U(D(t))^*, \tag{1}$$

where $D(t)$ denotes the dilations and U_ρ and U are the usual (projective) representations of the Möbius group such that $\mathrm{Ad}U_\rho(g)\circ\rho=\rho\circ\mathrm{Ad}U(g)$. In Sec. IV we take a different tack and show conversely that for a suitable weight ψ on the larger factor of a half-sided modular inclusion, we can associate a Möbius covariant endomorphism ρ on the net of local algebras such that Eq. (1) holds true. We also establish a correspondence between weights and endomorphisms allowing us to treat the latter in terms of weights on half-sided modular inclusions.

Finally in Sec. V we give the equivalents of basic operations pertaining to endomorphisms in terms of weights including unitary equivalence, direct sums, subrepresentations, and weak conjugates. Also we give criteria for finite index and positivity for an endomorphism associated with a weight.

II. PRELIMINARIES

Below we present the basic objects and results that will form the foundation for later sections. Most notably we introduce nets of von Neumann algebras and their relation with half-sided modular inclusions.

A. Nets of von Neumann algebras

We will identify $S^1 := \{z \in \mathbb{C} \,|\, |z|=1\}$ with the one-point compactification of $\mathbb{R}$, $\mathbb{R}\cup\{\infty\}$, through the stereographic projection,

$$S^1 \ni z \mapsto x(z) := \frac{1}{i}\frac{z-1}{z+1} \in \mathbb{R} \cup \{\infty\}.$$

The Möbius group $\mathsf{PSU}(1,1)$ acts on S^1 by

$$\begin{pmatrix} \alpha & \beta \\ \bar{\beta} & \bar{\alpha} \end{pmatrix} \cdot z := \frac{\alpha z + \beta}{\bar{\beta} z + \bar{\alpha}}.$$

Two types of elements of note are the translations and dilations.

$$\text{Translations:} \quad T(a) := \begin{pmatrix} 1 + ia/2 & ia/2 \\ -ia/2 & 1 - ia/2 \end{pmatrix}, \quad a \in \mathbb{R}.$$

$$\text{Dilations:} \quad D(t) := \begin{pmatrix} \cosh(\pi t) & \sinh(\pi t) \\ \sinh(\pi t) & \cosh(\pi t) \end{pmatrix}, \quad t \in \mathbb{R}.$$

By a *proper interval* on S^1 we will mean a nonempty, nondense, open, connected subset of S^1. For convenience we will often refer to proper intervals simply as intervals when no confusion can occur. If I is an interval, we write $I^\perp$ for the interior of its complement in S^1. If I and J are intervals such that $I \cap J = \emptyset$, we write $I \perp J$.

Definition 2.1 (Net of von Neumann Algebras): A *net of von Neumann algebras on* S^1 is an assignment for each interval I on S^1 of a von Neumann algebra $\mathcal{A}(I)$ on a fixed Hilbert space $\mathfrak{H}$ satisfying the following axioms.

- **Isotony:** For intervals $I \subseteq J$ we have $\mathcal{A}(I) \subseteq \mathcal{A}(J)$.
- **Locality:** If I and J are disjoint intervals, then $\mathcal{A}(I) \subseteq \mathcal{A}(J)'$.
- **Möbius covariance:** There exists a unitary representation $(U, \mathfrak{H})$ of the Möbius group $\mathsf{PSU}(1,1)$ such that $U(g)\mathcal{A}(I)U(g)^* = \mathcal{A}(gI)$. We write α_g for $\mathsf{Ad}U(g)$.
- **Positive energy:** The generator of the one-parameter group $\theta \mapsto U(R(\theta))$ is positive.
- **Existence and uniqueness of vacuum vector:** The subspace of U-invariant vectors in $\mathfrak{H}$ is one dimensional. We single out one such vector Ω of norm one, which will be referred to as the *vacuum vector*. We also require that $\cup_I \mathcal{A}(I)\Omega$ is dense in $\mathfrak{H}$, where I ranges over the intervals on S^1.

We will write $\mathcal{A}$ for the family $(\mathcal{A}(I))_I$.

The above defined concept of a net of von Neumann algebras also appears in the literature under the names of *conformal precosheaf*[10] and *local conformal net*[13] amongst others. The individual von Neumann algebras $\mathcal{A}(I)$ are called *local algebras* and elements of $\mathbb{B}(\mathfrak{H})$ belonging to a local algebra are called *local elements*.

We will denote the vector state associated with Ω by $\omega(\cdot) := (\cdot\Omega|\Omega)$. Usually we will think of this as a vector state on $\mathcal{A}(S_+)$, where $S_+ := \{z \in S^1 | \mathrm{Im}(z) > 0\}$. For notational ease we will write its restriction to a local algebra $\omega_I := \omega|\mathcal{A}(I)$.

Remark 2.2: If $\mathcal{A}$ is a net of von Neumann algebras, it is often practical to be able to speak of $\mathcal{A}(\mathcal{O})$ for general open sets $\mathcal{O}$. We define $\mathcal{A}(\mathcal{O})$ as follows.

$$\mathcal{A}(\mathcal{O}) := \vee\{\mathcal{A}(I) | I \text{ is a proper interval and } I \subseteq \mathcal{O}\}.$$

By isotony of the net $\mathcal{A}$, there is no ambiguity when speaking of $\mathcal{A}(I)$ for a proper interval.

We mention some important consequences of the axioms. All proofs can be found in Ref. 4.

Theorem 2.3 (Irreducibility): *If* $\mathcal{A}$ *is a net of von Neumann algebras on the Hilbert space* $\mathfrak{H}$ *then* $\vee_I \mathcal{A}(I) = \mathbb{B}(\mathfrak{H})$.

Theorem 2.4: *Every local algebra in a net of von Neumann algebras is a type* III_1 *factor.*

Theorem 2.5: (Haag Duality): *If* $\mathcal{A}$ *is a net of von Neumann algebras then* Haag duality *holds*,

$$\mathcal{A}(I^{\perp}) = \mathcal{A}(I)', \quad I \text{ is an interval on } S^1.$$

Theorem 2.6 (Reeh-Schlieder): *The vacuum vector* Ω *is cyclic and separating for each local algebra* $\mathcal{A}(I)$.

We write r for the reflection $S^1 \ni z \mapsto \bar{z} \in S^1$. For any interval I on S^1 we define the *reflection associated with* I to be $r_I := grg^{-1}$, where g is an element of the Möbius group such that $gS_+ = I$. It is easily checked that r_I is well defined. We write $\mathsf{PSU}(1,1)_{\pm}$ for the extended Möbius group generated by the Möbius group and the reflections.

Also for any interval I we define the dilations associated with I by $D_I(t) := gD(t)g^{-1}$ for any $g \in \mathsf{PSU}(1,1)$ such that $gI = S_+$. As with the reflections, it is easy to check that D_I is well defined.

Theorem 2.7 (Bisognano-Wichmann): *Let* $\mathcal{A}$ *be a net of von Neumann algebras. The representation* U *of the Möbius group can be extended to the extended Möbius group in such a way that the net* $\mathcal{A}$ *is covariant under this representation and*

$$U(D_I(t)) = \Delta_{\mathcal{A}(I)}^{it},$$

$$U(r_I) = J_{\mathcal{A}(I)},$$

where the modular operator and conjugation for $\mathcal{A}(I)$ *are with respect to the vacuum state* $\omega(\cdot) = (\cdot\Omega|\Omega)$.

Finally we mention an important axiom that we will be needing.

Definition 2.8 (Strong Additivity): *A net of von Neumann algebras* $\mathcal{A}$ is *strongly additive* if for any interval I and point $z \in I$, we have $\mathcal{A}(I) = \mathcal{A}(I_1) \vee \mathcal{A}(I_2)$, where I_1 and I_2 are the two connected components of $I \backslash \{z\}$.

To any net of von Neumann algebras $\mathcal{A}$, we can associate the *global* C^**-algebra* $C^*(\mathcal{A})$ with the following properties:[8,9]

(1) There is an embedding of every local algebra $\mathcal{A}(I)$ into $C^*(\mathcal{A})$, $i_I : \mathcal{A}(I) \to C^*(\mathcal{A})$ such that $i_J|_{\mathcal{A}(I)} = i_I$ whenever $I \subseteq J$.
(2) If (π_I) is a family of representations, $\pi_I : \mathcal{A}(I) \to \mathbb{B}(\mathfrak{H}_\pi)$, then there exists a unique representation $(\pi, \mathfrak{H}_\pi)$ of $C^*(\mathcal{A})$ such that $\pi \circ i_I = \pi_I$.

B. Endomorphisms on nets of von Neumann algebras

Let $\mathcal{A}$ be a fixed net of von Neumann algebras on $\mathfrak{H}$. A family of $*$-homomorphisms $\rho = (\rho_I)$, $\rho_I : \mathcal{A}(I) \to \mathbb{B}(\mathfrak{H})$ is said to be *consistent* if $\rho_J|_{\mathcal{A}(I)} = \rho_I$ whenever $I \subseteq J$. By the universal property of the global C^* algebra, ρ induces a representation of $C^*(\mathcal{A})$.

If there exists an interval I such that $\rho_{I^{\perp}} = \mathsf{id}_{\mathcal{A}(I^{\perp})}$, then ρ is said to be *localized in* I. If ρ is consistent and localized in I, then ρ_J is an endomorphism of $\mathcal{A}(J)$ whenever $J \supseteq I$ and ρ is an endomorphism of the global algebra $C^*(\mathcal{A})$.

A consistent, localized endomorphism is said to be *transportable* if for every interval J there exists a unitary u such that $\mathsf{Ad}u \circ \rho$ is localized, in J. Such a unitary is called a *transporter*. A consistent, localized, and transportable endomorphism is called a *Doplicher-Haag-Roberts endomorphism*, or simply a DHR *endomorphism*. A unitary equivalence class of DHR endomorphisms is called a *sector*.

The requirement of transportability can be strengthened to a requirement of covariance. If G is a subgroup of the Möbius group, we say that ρ is *covariant with respect to* G if there is a projective representation $(U_\rho, \mathfrak{H})$ of G such that

$$U_\rho(g)\rho(a)U_\rho(g)^* = \rho(U(g)aU(g)^*), \quad g \in G, \quad a \in C^*(\mathcal{A}).$$

If G is either the translation-dilation subgroup of the Möbius group or the Möbius group itself, we say that ρ is *translation-dilation covariant or Möbius covariant*, respectively. As projective unitary representations of connected semi-simple Lie groups, such as the Möbius group, lift to true unitary

representations of the universal covering groups,[3] we will instead of projective representations of the Möbius group $\mathsf{PSU}(1,1)$ often consider unitary representations of the universal covering group $\overline{\mathsf{PSU}(1,1)}$ of the Möbius group. As the translation-dilation group is connected and contractible, it is its own universal covering group. Hence, any projective representation of the translation-dilation group stems from a true unitary representation.

A DHR endomorphism ρ localized in some interval I will restrict to an endomorphism ρ_J of $\mathcal{A}(J)$ for any interval $J \supseteq I$. As ρ_J is given by conjugation with a unitary, the inclusion $\rho_J(\mathcal{A}(J)) \subseteq \mathcal{A}(J)$ is a subfactor. We write the (minimal) index of this $\mathrm{Ind}(\rho_J)$. If ρ is covariant, it is easy to check that $\mathrm{Ind}(\rho_J)=\mathrm{Ind}(\rho_{gJ})$ if $J, gJ \supseteq I$.[10] Thus, we will speak merely of the *index of* ρ and write this $\mathrm{Ind}(\rho)$.

C. Half-sided modular inclusions

The concept of half-sided modular inclusions and how to construct nets of von Neumann algebras based on these was first introduced by Wiesbrock in 1993.[19] The article, however, contained a gap which was finally filled by Araki and Zsidó in 2004.[2] Following Ref. 11 we give some basic definitions and results.

Definition 2.9 (Half-Sided Modular Inclusion): Suppose that $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ is a triple, where $\mathcal{N} \subseteq \mathcal{M}$ is an inclusion of von Neumann algebras on some Hilbert space $\mathfrak{H}$ and that $\Omega \in \mathfrak{H}$ is cyclic and separating for both $\mathcal{N}$ and $\mathcal{M}$.

(1) The triple $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ is said to be *standard* if Ω is cyclic for the relative commutant of $\mathcal{N}$ in $\mathcal{M}$, $\mathcal{N}^c = \mathcal{N}' \cap \mathcal{M}$.
(2) The triple $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ is said to be $+$ *half-sided modular* ($-$ *half-sided modular*) *if* $\sigma_t^{\mathcal{M}}(\mathcal{N}) \subseteq \mathcal{N}$ for all $t \leqslant 0$ ($t \geqslant 0$), where $\sigma^{\mathcal{M}}$ denotes the modular automorphism associated with $(\mathcal{M}, \Omega)$.

For brevity, we will refer to a triple $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ which is $\pm$ half-sided modular, as a $\pm$ *half-sided modular inclusion*.

Theorem 2.10 Ref. 11: *Suppose that* $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ *is a standard* $+$ *half-sided modular inclusion*. Then there exists a unique strongly additive net of von Neumann algebras $\mathcal{A}$ *on* S^1 *for which* $\mathcal{A}(]0;\infty[) = \mathcal{M}$, $\mathcal{A}(]0;\infty[) = \mathcal{N}$ *and* Ω *is the vacuum vector.*

III. EXTENDING FINITE INDEX ENDOMORPHISMS

If $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ is a standard half-sided modular inclusion and $\mathcal{A}$ is the associated net of von Neumann algebras as per Theorem 2.10, it can be difficult to determine the endomorphisms on $\mathcal{M}$ that extend to DHR endomorphisms on the net $\mathcal{A}$. To extend a given endomorphism on $\mathcal{M}$ to a DHR endomorphism, we would be forced to come up with transporters for all proper intervals on S^1. This can be difficult as there need be no particular relation between the transporters associated with different intervals, and the half-sided modular inclusion is only directly linked to the intervals $]0;\infty[$ and $]1;\infty[$.

The situation is easier if we are lucky enough to deal with a translation-dilation covariant endomorphism which is localized in some interval, say, $]a;b[$, such that the translation-dilation group alone gives all the necessary transporters. A simple way of making sure that the endomorphism has such covariance is by requiring it to have finite index. This even gives Möbius covariance.

The basic idea will be to use a finite index condition to obtain two one-parameter groups through the Takesaki theorem. We will then show that these together generate a representation U_ρ of the translation-dilation group such that $\mathsf{Ad}U_\rho(g) \circ \rho = \rho \circ \mathsf{Ad}U(g)$, allowing us to extend the given endomorphism ρ to a translation-dilation covariant endomorphism on the net $\mathcal{A}$. Using the finite index condition once again will finally yield Möbius covariance of the extended endomorphism.

A. Endomorphisms and α-cocycles

As mentioned above, a DHR endomorphism is completely known by its transporters. As a special case, a translation-dilation covariant endomorphism ρ localized in some interval I_0 for which $\infty \in I_0^{\perp}$ is completely known by the unitary representation U_ρ of the translation-dilation group $\mathcal{P}$ satisfying

$$\mathrm{Ad}U_\rho(g) \circ \rho = \rho \circ \alpha_g, \quad g \in \mathcal{P}.$$

Below we make precise the connection between such transporters and translation-dilation covariant endomorphisms. The basic idea and techniques are borrowed from Guido and Longo[9] where the case of Möbius covariant endomorphisms is treated. Having only the translation-dilation group and not the full Möbius group at our disposal engenders some technical problems, as two arbitrarily given intervals are not in general connected by an element of the translation-dilation group.

Remark 3.1 (A Comment on the Global C^*-algebra): Recall that $\alpha_g = \mathrm{Ad}U(g)$ satisfies $\alpha_g(\mathcal{A}(I)) = \mathcal{A}(gI)$. Thus by the universal property of the global C^*-algebra $C^*(\mathcal{A})$, α_g induces an automorphism of $C^*(\mathcal{A})$. We will denote this automorphism α_g as well.

As a technical aside we note that when embedding a local element x of $\mathcal{A}$ into the global algebra $C^*(\mathcal{A})$, we need to specify the interval in which x is localized. If $I \subseteq J$ and x is localized in I, associating x with either I or J leads to the same embedding in $C^*(\mathcal{A})$, as can be seen directly from the definition of the global C^* algebra.

Thus if x is localized in intervals I and J and there exists a third interval $K \subseteq I \cap J$ in which x is likewise localized, then the embedding of x into the global C^* algebra is the same whether one considers x associated with I or J. There are, however, cases where no such interval K can be found and these have to be treated with more care.

Definition 3.2 (α-Cocycle): A family of unitaries $(z_g)_g$ in the universal C^*-algebra $C^*(\mathcal{A})$ indexed by a subset $\mathcal{O}$ of the Möbius group is said to be an α-cocycle on $\mathcal{O}$ with values in $C^*(\mathcal{A})$ localized in the proper interval I_0 if (1) z_g is localized in $I_0 \cup gI_0$ whenever this is a proper interval. and (2) $z_{gh} = z_g \alpha_g(z_h)$ when g, h, and gh belong to $\mathcal{O}$.

We will refer to the second requirement as *the cocycle condition*.

Our main interest will be α-cocycles indexed either over the translation-dilation group or the full Möbius group.

Given a translation-dilation covariant endomorphism, we can define $z_g = U_\rho(g)U(g)^*$ for any $g \in \mathcal{P}$. While (z_g) satisfies the cocycle condition the elements will not all have a unique embedding into the universal C^*-algebra $C^*(\mathcal{A})$ as mentioned in Remark 3.1. The next proposition shows how to get around this problem.

Proposition 3.3: *Let I_0 be a subinterval of S^1 whose complement contains ∞ and let $\mathcal{O} \subseteq \{g \in \mathcal{P} | I_0 \cup gI_0$ is a proper interval$\}$ be an open set containing the identity.*

If $(w_g)_{g \in \mathcal{O}}$ is an α-cocycle on $\mathcal{O}$ with values in $C^*(\mathcal{A})$ then it extends uniquely to an α-cocycle on $\mathcal{P}$ with values in $C^*(\mathcal{A})$.

Proof: Our first step is to choose an open subset $\mathcal{U}$ of $\mathcal{O}$ which contains the identity and satisfies $\mathcal{U}^2 \subseteq \mathcal{O}$. This ensures that whenever we have elements g and h of $\mathcal{U}$, the α-cocycle condition makes sense and is satisfied: $w_{gh} = w_g \alpha_g(w_h)$.

The next step is to note that any element of $\mathcal{P}$ can be written as a finite product of elements in $\mathcal{U}$. That is, for a given $g \in \mathcal{P}$ we can choose a decomposition

$$g = \prod_{i=1}^{n} g_i \quad (g_i \in \mathcal{U}).$$

To extend the cocycle to all of $\mathcal{P}$ we will define w_g as

$$w_g = w_{g_1}\alpha_{g_1}(w_{g_2})\cdots\alpha_{g_1\cdots g_{n-1}}(w_{g_n}).$$

To show that this is independent of the choice of g_i's and thus well-defined, it is enough to show that the change $g_i \rightsquigarrow g_i h$, $g_{i+1} \rightsquigarrow h^{-1}g_{i+1}$ for $h \in \mathcal{U}$ leaves the right-hand side of the above equation unchanged. This will follow if we can show that $w_{g_i}\alpha_{g_i}(w_{g_{i+1}}) = w_{g_i h}\alpha_{g_i h}(w_{h^{-1}g_{i+1}})$. We compute

$$\begin{aligned} w_{g_i h}\alpha_{g_i h}(w_{h^{-1}g_{i+1}}) &= w_{g_i}\alpha_{g_i}(w_h)\alpha_{g_i h}(w_{h^{-1}}\alpha_{h^{-1}}(w_{g_{i+1}})) = w_{g_i}\alpha_{g_i}(w_h\alpha_h(w_{h^{-1}})w_{g_{i+1}}) \\ &= w_{g_i}\alpha_{g_i}(w_{hh^{-1}})\alpha_{g_i}(w_{g_{i+1}}) = w_{g_i}\alpha_{g_i}(w_{g_{i+1}}). \end{aligned}$$

Hence, w_g is well-defined on all of $\mathcal{P}$. The cocycle property follows directly from the definition

$$w_{gh} = w_{g_1}\alpha_{g_1}(w_{g_2})\cdots\alpha_{g_1\cdots g_{n-1}}(w_{g_n})\alpha_g(w_{h_1})\alpha_{gh_1}(w_{h_2})\cdots\alpha_{gh_1\cdots h_{m-1}}(w_{h_m}) = w_g\alpha_g(w_h).$$

The question remains whether w_g will be localized in $I_0 \cup gI_0$ whenever this is a proper interval. Let $g \in \mathcal{P}$ be given such that $I_0 \cup gI_0$ is a proper interval and choose another proper interval J extending $I_0 \cup gI_0$ slightly on both sides. It is then possible to choose a decomposition $g = \Pi g_i$ such that $I_0 \cup g_1 I_0 \cup \cdots \cup (g_1 \cdots g_n)I_0$ is contained in J. Consequently,

$$w_g = w_{g_1}\alpha_{g_1}(w_{g_2})\cdots\alpha_{g_1\cdots g_{n-1}}(w_{g_n})$$

belongs to $\mathcal{A}(J)$. By taking the intersection over such intervals J it follows by continuity from the outside that w_g is localized in $I_0 \cup gI_0$. □

The above proposition tells us that whenever we have a translation-dilation covariant endomorphism suitably localized, we obtain a unique α-cocycle on $\mathcal{P}$ with values in $C^*(\mathcal{A})$ similarly localized. This situation is similar to the case of Möbius covariant endomorphisms presented in Ref. 9 where we would get α-cocycles on the Möbius group.

In the latter case there is a bijective correspondence between cocycles and endomorphisms but in the case of α-cocycles on the translation-dilation group, which concerns us, we will need to add an extra assumption to counter the problem that the translation-dilation group cannot transform a given interval into any other arbitrary interval. Colloquially put, the problem is that the translation-dilation group "cannot move points through infinity."

The extra assumption and its use will be elaborated below.

Proposition 3.4: *Let I_0 be an interval whose complement contains ∞. Suppose that (w_g) is an α-cocycle on $\mathcal{P}$ with values in $C^*(\mathcal{A})$ localized in I_0 and that $w_{D(t)}$ is localized in the smallest proper subinterval J of S^1 containing I_0, $D(t)I_0$, and the connected component of $S^1 \setminus (I_0 \cup D(t)I_0)$ containing ∞ whenever $\bar{I}_0 \cap D(t)\bar{I}_0 = \emptyset$. Then there exists a unique translation-dilation covariant endomorphism ρ on S^1 localized in I_0 such that*

$$\rho|_{\mathcal{A}(gI_0^\perp)} = \mathrm{Ad}\, w_g|_{\mathcal{A}(gI_0^\perp)}.$$

Proof: For each proper interval J on S^1 containing ∞ there is exactly one $g \in \mathcal{P}$ such that $gI_0^\perp = J$ and we can therefore define ρ on all such intervals by $\rho_{gI_0^\perp} := \mathrm{Ad}w_g$. Any proper interval not containing ∞ is a subinterval of a proper interval which *does* contain ∞ so we will define ρ on the former intervals by restriction. To show that this is well-defined, we assume that $J \subseteq gI_0^\perp \cap hI_0^\perp$ and attempt to show that $\mathrm{Ad}w_g|_{\mathcal{A}(J)} = \mathrm{Ad}w_h|_{\mathcal{A}(J)}$. This will be accomplished by showing that $w_g^* w_h \in \mathcal{A}(J^\perp)$.

We compute

$$w_g^* w_h = \alpha_g(w_{g^{-1}})w_h = \alpha_g(w_{g^{-1}}\alpha_{g^{-1}}(w_h)) = \alpha_g(w_{g^{-1}h}).$$

As w_g is localized in $I_0 \cup gI_0$ whenever this is a proper interval, it follows that $w_{g^{-1}h}$ is localized in any proper subinterval of $\mathbb{R}$ containing $I_0 \cup g^{-1}hI_0$. Consequently, $\alpha_g(w_{g^{-1}h})$ is localized in any proper subinterval of $\mathbb{R}$ containing $gI_0 \cup hI_0$. Thus, in the case that J is a subinterval of the connected component of $gI_0^\perp \cap hI_0^\perp$ containing ∞, it follows that $\mathrm{Ad}w_g|_{\mathcal{A}(J)} = \mathrm{Ad}w_h|_{\mathcal{A}(J)}$.

The fact that we do not have the full Möbius group available but only the translation-dilation group forces us to consider separately the case where J is a subinterval of a component of $gI_0^\perp \cap hI_0^\perp$ *not* containing ∞. In light of the previous arguments, it is enough to show for $t \in \mathbb{R}$ such that $\bar{I}_0 \cap D(t)\bar{I}_0 = \emptyset$ that if J is a subinterval in the connected component of $I_0^\perp \cap D(t)I_0^\perp$ not containing ∞, then $\mathrm{Ad}w_{D(t)}(x) = x$ for any $x \in \mathcal{A}(J)$. This follows directly by the assumptions in the proposition. Thus, we have a well-defined, consistent endomorphism ρ.

The translation-dilation covariance of ρ easily follows from the definition

$$\mathrm{Ad}(w_g^*)\,\rho|_{A(hI_0^\perp)} = \mathrm{Ad}\,(w_g^* w_h)|_{A(hI_0^\perp)} = \mathrm{Ad}\,(\alpha_g(w_{g^{-1}})w_h)|_{A(hI_0^\perp)} = \alpha_g \circ \mathrm{Ad}(w_{g^{-1}h}) \circ\ \alpha_{g^{-1}}|_{A(hI_0^\perp)}$$
$$= \alpha_g \circ\ \rho|_{A(g^{-1}hI_0^\perp)} \circ \alpha_{g^{-1}}.$$

The covariance of the ρ_I's which are defined by restriction of some $\rho_{gI_0^\perp}$ is also settled by the above calculation. □

Corollary 3.5: *Suppose that I_0 is a proper interval on S^1 whose complement contains ∞.*

Then each translation-dilation covariant endomorphism on $\mathcal{A}$ localized in I_0 gives rise to an α-cocycle (w_g) localized in I_0 and satisfying the assumptions of Proposition 3.4 such that

$$\rho_{gI_0^\perp} = \mathrm{Ad}w_g, \quad g \in \mathcal{P}. \tag{2}$$

Conversely, any α-cocycle (w_g) localized in I_0 and satisfying the assumptions of Proposition 3.4 gives rise to an endomorphism ρ on $\mathcal{A}$ localized in I_0 and satisfying Eq. (2).

B. Extending finite index endomorphisms

Recall that we have a standing assumption that $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ is a standard+half-sided modular inclusion and that $\mathcal{A}$ is the net of von Neumann algebras associated with $(\mathcal{N} \subseteq \mathcal{M}, \Omega)$ as per Theorem 2.10.

Our goal in this section is to give sufficient criteria for endomorphisms on $\mathcal{M}$ to extend to DHR endomorphisms on the net $\mathcal{A}$. We will focus on endomorphisms which are translation-dilation covariant. This, in particular, includes endomorphisms of finite index, as these are automatically Möbius covariant.[9] The main element in the approach is to construct an α-cocycle on the translation-dilation group and use the results of the previous section to associate a translation-dilation covariant endomorphism to it.

Remark 3.6 (Localization): In general we will not distinguish between $\mathcal{N} \subseteq \mathcal{M}$ and its embedding in $\mathcal{A}$, $\mathcal{A}(]1;\infty[) \subseteq \mathcal{A}(\mathbb{R}_+)$ and will therefore continue speaking of $\mathcal{A}(I)$ as a sub-von Neumann algebra of $\mathcal{M}$ whenever $I \subseteq \mathbb{R}_+$. In this spirit we can say that an element $x \in \mathcal{M}$ is localized in an interval I if $x \in \mathcal{A}(I)$ under the usual embedding.

Similarly we will call an endomorphism $\rho \in \mathrm{End}(\mathcal{M})$ localized in $I \subseteq \mathbb{R}_+$ if its restriction to $\mathcal{A}(\mathbb{R}_+) \cap \mathcal{A}(I)'$ is identity.

To properly formulate our results completely within the framework of the half-sided modular inclusion we will introduce notation for ρ being localized in some interval I for which $\bar{I} \subseteq S_+$ as follows.

Definition 3.7 (Localization Strictly Within $\mathcal{M}$): An endomorphism ρ on $\mathcal{M}$ is *localized strictly within $\mathcal{M}$* if ρ is localized in an interval whose closure is contained in S_+.

Lemma 3.8: *Suppose that $\rho \in \mathrm{End}(M)$ is an irreducible endomorphism localized strictly within $\mathcal{M}$, say, in I_0. Suppose furthermore that (v_t) and (w_t) are unitary one-parameter groups such that*

(1) $\mathrm{Ad}v_s(\rho(x)) = \rho(\alpha_{D(s)}(x))$ *for* $s \in R$ *and* $x \in \mathcal{M}$,
(2) $\mathrm{Ad}w_t(\rho(y)) = \rho(\alpha_{D_{]1;\infty[}(t)}(y))$ *for* $t \in \mathbb{R}$ *and* $y \in \mathcal{M} \cap \alpha_{D_{]1;\infty[}(-t)}(\mathcal{M})$,
(3) $v(s)U(D(s))^*$ *belongs to* $\mathcal{A}(I_0 \cup D(s)I_0)$ *for t belonging to some neighborhood of zero, and*
(4) $w(t)U(D_{]1;\infty[}(t))^*$ *belongs to* $\mathcal{A}(I_0 \cup D_{]1;\infty[}(t)I_0)$ *for s belonging to some neighborhood of zero. Then ρ extends to an irreducible translation-dilation covariant endomorphism on $\mathcal{A}$*

localized in I_0.

Proof: By standard arguments, ρ is an endomorphism of $\mathcal{A}(J)$ whenever $J \subseteq \mathbb{R}_+$ is a proper interval containing I_0 and as usual irreducibility implies that $\rho(\mathcal{A}(J))' \cap \mathcal{A}(J) = \mathbb{C}1$.

The key to proving this lemma is to turn the question of extendability into a question of the existence of a suitable α-cocycle. To demonstrate the existence of such an α-cocycle we will use the two given one-parameter unitary groups (v_s) and (w_t) to construct a cocycle satisfying the assumptions of Proposition 3.3 and then invoke Proposition 3.4 to obtain the desired endomorphism on $\mathcal{A}$.

The first step will be to show that the one-parameter groups (v_s) and (w_t) generate a projective representation of the translation-dilation group $\mathcal{P}$ in which (v_s) is identified with the dilations associated with $\mathbb{R}_+$ and (w_t) with the dilations associated with $]1;\infty[$.

To do this it will be enough to show that (v_s) and (w_t) satisfy the proper commutation relations for small s and t. The equivalent of the commutation relation

$$T(a)D(t) = D(t)T(\exp(2\pi t)a) \tag{3}$$

takes the shape

$$\begin{aligned} w(s)v(t-s) = v(t)w(-\log(1-\exp(2\pi t)+\exp(2\pi(t-s)))/2\pi) \\ \times v(\log(1-\exp(2\pi t)+\exp(2\pi(t-s)))/2\pi) \end{aligned} \tag{4}$$

for sufficiently small s and t. In this particular case "sufficiently small" means $\exp(2\pi t)(1-\exp(2\pi(s))) \leqslant 1$ which is satisfied for (s,t) in a neighborhood of (0,0). This requirement ensures that both a and $\exp(2\pi t)a$ appearing in the former commutation relation are strictly less than 1, making it possible to use the equation $T(1-\exp(2\pi t)) = D(t)D_{]1;\infty[}(-t)$.

We set $V(D(t)) := v(t)$ and $V(D_{]1;\infty[}(s)) := w(s)$. If $g_i \in \mathcal{P}$, $i=1,\ldots,n$, is a collection of elements of the form $D(t)$ or $D_{]1;\infty[}(s)$, where t and s may depend on the index, then we write by abuse of notation $z(g_1\cdots g_n)$ for the element $V(g_1)\cdots V(g_n)U(g_1\cdots g_n)^*$. We will show in a moment that $z(g)$ does not depend on the choice of decomposition of g. For now we note by the assumptions of the lemma that $z(g_1\cdots g_n)$ is localized in $I_0 \cup g_1 I_0 \cup g_1 g_2 I_0 \cup \cdots \cup g_1\cdots g_n I_0$.

Now, choose a neighborhood $\mathcal{O}$ of $(0,0) \in \mathbb{R}^2$ and a proper interval $J \supseteq I_0$ such that the manipulations in Eq. (3) keep I_0 inside J and J inside $\mathbb{R}_+$ for $(s,t) \in \mathcal{O}$. For convenience, let z_1 denote the $z(g_1 g_2)$ corresponding to the left-hand side of Eq. (4) and let z_2 denote the $z(g_3 g_4 g_5)$ corresponding to the right-hand side. As the manipulations will map $\mathcal{A}(I_0)$ into $\mathcal{A}(J)$, the element $z_1^* z_2$ is localized in J. Therefore to show the validity of Eq. (4) we need only to show that $z_1^* z_2$ belongs to $\rho(\mathcal{A}(J))'$.

But by our choice of J and the assumptions of the lemma, it follows that $\mathsf{Ad}(z_1^* z_2)\rho(x) = \rho(x)$ for $x \in \mathcal{A}(J)$.

In conclusion, we get a projective representation $g \mapsto V(g)$ of the translation-dilation group $\mathcal{P}$. As $\mathcal{P}$ is its own universal covering group we can assume that the representation is a unitary representation. Then defining $z(g) = V(g)U(g)^*$ as before, but this time without abuse of notation, gives us an α-cocycle localized in I_0 by Proposition 3.3.

Finally, we want to employ Proposition 3.4 to obtain a translation-dilation covariant endomorphism on S^1 localized in I_0. To do so we must first check that $z(D(t))$ is localized in the smallest subinterval J of S^1 containing I_0, $D(t)I_0$, and ∞ whenever $\bar{I}_0 \cap D(t)\bar{I}_0 = \varnothing$. This, however, is an immediate consequence of the third assumption of this lemma.

Hence, Proposition 3.4 provides us with a translation-dilation covariant endomorphism on $\mathcal{A}$ localized in I_0. As it obviously coincides with ρ on I_0, it is an extension of ρ as desired. □

Remark 3.9: While the former lemma is phrased for unitary one-parameter groups (v_t) and (w_t) corresponding to dilations for the intervals $]0;\infty[$ and $]1;\infty[$, respectively, obviously we can get an analogous result for unitary one-parameter groups corresponding to two intervals $I \subset J$ with one common boundary point. We omit a rephrasing of the lemma.

The assumptions of the above lemma may not be trivial to check and we will be focusing our attention on a class of endomorphisms which satisfy these assumptions automatically, namely, endomorphisms with finite index.

Theorem 3.10: *Suppose that* $\rho \in \mathsf{End}(\mathcal{M})$ *is a finite index endomorphism strictly localized within* $\mathcal{M}$. *Then* ρ *extends to a Möbius covariant endomorphism on* S^1.

Proof: First off, as ρ is assumed to have finite index, it can be written as the direct sum of irreducible endomorphisms similarly localized and we may therefore assume without loss of generality that ρ is, in fact, irreducible. Moreover, ρ is normal and injective as $\mathcal{M}$ is a type III factor (Ref. 17, Theorem V.5.1).

Call the interval in which ρ is localized I_0 and choose a proper interval $I \subseteq \mathbb{R}_+$ containing I_0. As $\rho(\mathcal{A}(I)) \subseteq \mathcal{A}(I)$ has finite index we can find a faithful, normal conditional expectation $E: \mathcal{A}(I) \to \rho(\mathcal{A}(I))$. We then choose a faithful, normal state ϕ_0 on $\mathcal{A}(I)$, say, the vacuum state, and let $\phi := \phi_0 \circ E$. This is then a faithful, normal state on $\mathcal{A}(I)$ whose modular group σ^ϕ leaves $\rho(A(I))$ globally invariant by Takesaki's theorem.

Moreover, the restriction of σ^ϕ to $\rho(A(I))$ is σ^{ϕ_0} (Ref. 18, Lemma IX.4.21). Thus, on $\mathcal{A}(I)$ we have that (Ref. 18, Corollary VIII.1.4),

$$\sigma_t^{\phi\circ\rho}(x) = \rho^{-1} \circ \sigma_t^{\phi_0} \circ \rho(x), \quad x \in \mathcal{A}(I)$$

or equivalently

$$\rho \circ \sigma_t^{\phi\circ\rho}(x) = \sigma_t^{\phi_0} \circ \rho(x), \quad x \in \mathcal{A}(I).$$

Let $u_t := (D\phi : D\omega_I)_t$ and $w_t := (D(\phi\circ\rho) : D\omega_I)_t$. The usual property of Connes cocycles implies that

$$\rho \circ \mathsf{Ad}(w_t) \circ \sigma_t^{\omega_I}(x) = \mathsf{Ad}(u_t) \circ \sigma_t^{\omega_I} \circ \rho(x), \quad x \in \mathcal{A}(I).$$

Letting $z_t := \rho(w_t)^* u_t$ and $\alpha_t := \mathsf{Ad}(U(D_I(t)))$, where D_I is the dilation associated with the interval I, then the above can be simplified to the expression

$$\alpha_t \circ \rho \circ \alpha_{-t}(x) = z_t^* \rho(x) z_t.$$

Next, defining $v_t := U(D_I(t)) z_{-t}^*$ gives us a unitary satisfying

$$\mathsf{Ad}v_t \circ \rho(x) = \rho \circ \alpha_t(x), \quad x \in \mathcal{A}(I).$$

As ρ is irreducible (v_t) is a projective unitary representation of $\mathbb{R}$. As usual this lifts to a unitary representation of $\mathbb{R}$ for which we use the same notation. We also note in passing that if $x \in \mathcal{A}(I) \cap \mathcal{A}(I_0 \cup D_I(t) I_0)'$ then

$$\mathsf{Ad}(v_t U(D_I(t))^*)(x) = \mathsf{Ad}v_t \circ \rho(\alpha_t(x)) = \rho(x) = x,$$

so $v_t U(D_I(t))^*$ belongs to $\mathcal{A}(I) \cap \mathcal{A}(I_0 \cup D_I(t) I_0)'$. In particular, the covariance property $\mathsf{Ad}v_t \circ \rho = \rho \circ \alpha_t$ holds on all of $\alpha_{-t}(\mathcal{M})$.

Finally, to wrap up the proof, we take the intervals $]0;\infty[$ and $]a;\infty[$ where $a \in \mathbb{R}_+$ is chosen such that $I_0 \subseteq]a;\infty[$ and consider the two corresponding unitary one-parameter groups. We have seen above that these satisfy the assumptions of Lemma 3.8 and we therefore get an extension of ρ to a translation-dilation covariant endomorphism on $\mathcal{A}$. As ρ has finite index, it is automatically Möbius covariant. □

The construction of v_t in the proof of Theorem 3.10 is borrowed from Ref. 9 where DHR endomorphisms on the Minkowski space with finite statistics and only countably many sectors are shown to be Poincaré covariant.

Corollary 3.11: *If* $\rho \in \mathsf{End}(\mathcal{M})$ *is an endomorphism localized strictly within* $\mathcal{M}$ *and which is a direct sum of endomorphisms with finite index, then* ρ *extends to a Möbius covariant endomorphism on* S^1 *with the same localization.*

C. Basic observations for finite index endomorphisms

Corollary 3.11 gives us a correspondence between finite index endomorphisms on the circle localized in some interval I satisfying $\bar{I}\subseteq S_+$ and injective, normal endomorphisms localized strictly within $\mathcal{M}$. As the correspondence is given simply by restriction of ρ to $\mathcal{A}(S_+)$, it follows that all manipulations of ρ which can be carried out within S_+ are preserved by the correspondence.

In particular, unitary equivalence, direct sums, subrepresentations, left inverses, permutators, and the like carry over from the net $\mathcal{A}$ to the half-sided modular inclusion $(\mathcal{N}\subseteq\mathcal{M},\Omega)$ unchanged.

When considering α-induction for a quantum field theoretical net of subfactors $\mathcal{A}\subseteq\mathcal{B}$,[6,16] where both nets are strongly additive nets of von Neumann algebras, the net of subfactors can instead be described by a commuting square of subfactors in which the corners are made up by the factors of the half-sided modular inclusions $\mathcal{A}(]1;\infty[)\subseteq\mathcal{A}(]0;\infty[)$ and $\mathcal{B}(]1;\infty[)\subseteq\mathcal{B}(]0;\infty[)$. As such it is in principle possible to perform α-induction within the framework of half-sided modular inclusions. However, the fact that the endomorphisms lifted by α-induction are not necessarily well-behaved DHR endomorphisms may complicate matters.

IV. ENDOMORPHISMS FROM WEIGHTS

As in the previous section, our goal is to find a workable equivalent of Möbius covariant endomorphisms on a strongly additive net of von Neumann algebras $\mathcal{A}$ in the framework of a half-sided modular inclusion $(\mathcal{N}\subseteq\mathcal{M},\Omega)$ inducing the net of von Neumann algebras as per Theorem 2.10. While we focused on the endomorphism ρ itself in the previous section, in this section we will try a different tack, instead focusing on a subgroup of the transporters of the endomorphism, specifically $t\mapsto U_\rho(D(t))$.

Assume that a Möbius covariant endomorphism ρ on the net $\mathcal{A}$ is given. Assume furthermore that ρ is localized in some interval I satisfying $\bar{I}\subseteq S_+$. By strong additivity of the net $\mathcal{A}$, the endomorphism ρ is completely determined by its restriction to $\mathcal{A}(I)$. By the assumption $\bar{I}\subseteq S_+$, there exists $t\in\mathbb{R}_+$ such that $D(t)I\perp I$. For such a t the covariance property of ρ implies that $\rho_I=\mathrm{Ad}z_\rho(D(t))|_{\mathcal{A}(I)}$ where as usual $z_\rho(g):=U_\rho(g)U(g)^*$. Hence, knowledge of a subinterval I of $\mathbb{R}_+$ in which ρ is localized together with knowledge of the one-parameter group $t\mapsto U_\rho(t)$ give complete knowledge of ρ.

More natural than considering $t\mapsto U_\rho(D(t))$ might be to consider the associated transporters themselves, $t\mapsto z_\rho(D(t))=U_\rho(D(t))U(D(t))^*$. It is easy to check that $t\mapsto z_\rho(D(t))$ satisfies the condition of being a Connes cocycle derivative of some weight ψ relative to ω, $(D\psi:D\omega)_t=z_\rho(D(t))$. The properties of the weight ψ, which contains all information about ρ, have been studied by Longo[16] and Bertozzini *et al.*[5] with the main focus on weights associated with endomorphisms with finite index.

In this section we will be taking the opposite approach. That is, starting with a weight ψ we will construct a Möbius covariant endomorphism ρ such that $(D\psi:D\omega)_t=z_\rho(D(t))$. Two of the most fundamental problems in this approach are determining the class of weights that are associated with Möbius covariant endomorphisms and the level of redundancy there is, that is, when will two weights give rise to the same endomorphism.

As always we fix a standard half-sided modular inclusion $(\mathcal{N}\subseteq\mathcal{M},\Omega)$ and associate to it a net of von Neumann algebras $\mathcal{A}$ as per Theorem 2.10.

A. Weak Möbius covariance

In Sec. III A we gave a correspondence between translation-dilation covariant endomorphisms and α-cocycles on the translation-dilation group $\mathcal{P}$ based on the work by Guido and Longo.[9] Given an endomorphism ρ on $\mathcal{M}$ with finite index, we were then able to associate to it an α-cocycle on the translation-dilation group, and the correspondence of α-cocycles with endomorphisms then provided us with an extension of ρ to the net $\mathcal{A}$ with finite index.

A key element in the above argument was that we knew *a priori* that ρ had finite index;

wherefore it could be written as a direct sum of irreducible endomorphisms. The irreducibility was necessary to get an α-cocycle. In this section, however, we will not have finite index *a priori* and will therefore not be able to reduce the problem to the case of irreducible endomorphisms. Thus when faced with a family of unitaries $(v_g)_{g\in\mathcal{P}}$ satisfying

$$\mathrm{Ad}v_g \circ \rho = \rho \circ \alpha_g,$$

we can no longer conclude that $g\mapsto v_g$ is a projective representation of the translation-dilation group $\mathcal{P}$.

The properties that concern us, however, are unaffected by the lack of continuity of $g\mapsto v_g$ as we will see in this and the following section.

Definition 4.1 (Weak Möbius Covariance): A DHR endomorphism ρ on S^1 is said to be *weakly Möbius covariant* if there exists a family of unitaries $(U_\rho(g))_g$ indexed over the Möbius group such that $\mathrm{Ad}U_\rho(g)\circ\rho=\rho\circ\alpha_g$.

Replacing the Möbius group with the translation-dilation group in the definition above instead gives us what we will call *weak translation-dilation covariance*.

Remark 4.2: If ρ is a weakly Möbius covariant endomorphism localized in I_0 then for any elements g and h of the Möbius group, $\mathrm{Ad}U_\rho(gh)\circ\rho=\mathrm{Ad}(U_\rho(g)U_\rho(h))\circ\rho$. Consequently, the element $U_\rho(gh)^*U_\rho(g)U_\rho(h)$ commutes with the image of ρ, i.e.,

$$U_\rho(gh)^*U_\rho(g)U_\rho(h) \in \rho(\mathcal{A}(I_0))' \cap \mathcal{A}(I_0).$$

Thus, U_ρ is a unitary representation of the Möbius group modulo $\rho(\mathcal{A}(I_0))' \cap \mathcal{A}(I_0)$ in the sense that

$$U_\rho(gh) = x_{g,h}U_\rho(g)U_\rho(h) \quad \text{for some } x_{g,h} \in \rho(\mathcal{A}(I_0))' \cap \mathcal{A}(I_0).$$

For irreducible endomorphisms, the notion of weak Möbius covariance coincides with that of ordinary Möbius covariance.

We found in Sec. III A that there is a bijective correspondence between α-cocycles and Möbius covariant endomorphisms. In this section we will find a similar correspondence with one part being played by the weakly Möbius covariant endomorphisms. The other part will be played by α-cocycle modulo some von Neumann algebra, to be defined next.

Definition 4.3 (α-Cocycle Modulo $\mathcal{B}$): Let $I_0\subseteq S^1$ be a proper interval and $\mathcal{B}$ a sub-von Neumann algebra of $\mathcal{A}(I_0)$. An *α-cocycle modulo $\mathcal{B}$ localized in I_0* is a family of unitaries (z_g) indexed over the Möbius group satisfying

(1) $z_g \in \mathcal{A}(I_0)\vee\mathcal{A}(gI_0)$,
(2) $z_{gh}=x_{g,h}z_g\alpha_g(z_h)$ for some $x_{g,h}\in\mathcal{B}$, and
(3) $\mathrm{Ad}z_g(\mathcal{A}(I_0))=\mathcal{B}'\cap\mathcal{A}(I_0)$ for some g for which $gI_0\perp I_0$.

Lemma 4.4: *Suppose that (z_g) is an α-cocycle modulo $\mathcal{B}$ localized in I_0. Then $\mathrm{Ad}z_g(\mathcal{A}(I_0))=\mathcal{B}'\cap\mathcal{A}(I_0)$ for every g satisfying $gI_0\perp I_0$.*

Proof: Straightforward. □

The two following propositions will detail how to move back and forth between weakly Möbius covariant endomorphisms and α-cocycles modulo a given von Neumann algebra.

Proposition 4.5: *Suppose that ρ is a weakly Möbius covariant endomorphism localized in I_0. Then $z_g:=U_\rho(g)U(g)^*$ defines an α-cocycle localized in I_0 modulo $\rho(\mathcal{A}(I_0))'\cap\mathcal{A}(I_0)$.*

Proof: Given $x\in\mathcal{A}(I_0)'\cap\mathcal{A}(gI_0)'$; then

$$\mathrm{Ad}z_g(x) = \mathrm{Ad}U_\rho(g)(\alpha_{g^{-1}}(x)) = \mathrm{Ad}U_\rho(g)\rho(\alpha_{g^{-1}}(x)) = \rho(x) = x.$$

Thus, z_g belongs to $(\mathcal{A}(I_0)'\cap\mathcal{A}(gI_0)')'=\mathcal{A}(I_0)\vee\mathcal{A}(gI_0)$.

To show that the second requirement of the definition is met, let g and h be elements of the Möbius group. A quick calculation shows for any local element x that

$$\mathrm{Ad}(z_{gh}\alpha_g(z_h)^* z_g^*)\rho(x) = \mathrm{Ad}z_{gh}(\alpha_{gh}\circ\rho\circ\alpha_{(gh)^{-1}}(x)) = \mathrm{Ad}U_\rho(gh)(\rho\circ\alpha_{(gh)^{-1}}(x)) = \rho(x).$$

Hence, $z_{gh}=xz_g\alpha_g(z_h)$ for some $x\in\rho(\mathcal{A}(I_0))'\cap\mathcal{A}(I_0)$.

Finally we note that for any g such that $gI_0\perp I_0$, we have $\mathrm{Ad}z_g(\mathcal{A}(I_0))=\rho(\mathcal{A}(I_0))$ $=(\rho(\mathcal{A}(I_0))'\cap\mathcal{A}(I_0))'\cap\mathcal{A}(I_0)$. □

Proposition 4.6: *Suppose that* (z_g) *is an* α*-cocycle modulo* $\mathcal{B}\subseteq\mathcal{A}(I_0)$ *localized in* I_0. *Then there exists a weakly Möbius covariant* ρ *localized in* I_0 *giving rise to* (z_g) *as in Lemma 4.5*.

Proof: We aim to define $\rho|_{\mathcal{A}(gI_0^\perp)}=\mathrm{Ad}z_g|_{\mathcal{A}(gI_0^\perp)}$. To show that this gives a well-defined consistent endomorphism on S^1 we need to show that $z_h^* z_g$ belongs to $\mathcal{A}(gI_0)\vee\mathcal{A}(hI_0)$ for all elements of the Möbius group g and h.

The cocycle condition implies that $z_h^*=\alpha_h(xz_{h^{-1}})$ for some $x\in\mathcal{B}$. Using that $z_{h^{-1}}\alpha_{h^{-1}}(z_g)$ $=yz_{h^{-1}g}$ for some $y\in\mathcal{B}$ we find that

$$z_h^* z_g = \alpha_h(xz_{h^{-1}})z_g = \alpha_h(xz_{h^{-1}}\alpha_{h^{-1}}(z_g)) = \alpha_h(xyz_{h^{-1}g}),$$

which belongs to $\mathcal{A}(hI_0)\vee\mathcal{A}(gI_0)$. Hence, we obtain a consistent endomorphism ρ on S^1.

That ρ is weakly Möbius covariant can be demonstrated by reapplying the above equation as follows:

$$\mathrm{Ad}z_h^*\circ\rho|_{\mathcal{A}(gI_0^\perp)} = \mathrm{Ad}(z_h^* z_g)|_{\mathcal{A}(gI_0^\perp)} = \alpha_h\circ\mathrm{Ad}(xy)\circ\mathrm{Ad}z_{h^{-1}g}\circ\ \alpha_{h^{-1}}|_{\mathcal{A}(gI_0^\perp)} = \alpha_h\circ\ \rho|_{\mathcal{A}(h^{-1}gI_0^\perp)}\circ\alpha_{h^{-1}}.$$

Note that Lemma 4.4 is used to eliminate $\mathrm{Ad}(xy)$ in the above computation. □

Remark 4.7 (The Case for the Translation-Dilation Group): If instead of considering α-cocycles indexed over the entire Möbius group, we consider α-cocycles indexed over the translation-dilation group satisfying the requirements of Definition 4.3, then we find a result similar to that of Proposition 4.6. The proof can be applied unchanged except that for the translation-dilation covariant case, we have to work with an interval I_0 whose complement contains ∞.

B. Weak conjugates

In Ref. 9 it is shown how to obtain a weak conjugate of a Möbius covariant endomorphism based on its associated α-cocycle. Following the exposition given in Ref. 9 closely, we will make the necessary generalizations to obtain an equivalent result for weakly Möbius covariant endomorphisms. We start out by recalling some facts about conjugate endomorphisms.

Remark 4.8 (Conjugate Endomorphisms): Assume that $\mathcal{B}\subseteq\mathcal{C}$ is an inclusion of properly infinite von Neumann algebras. Then there exists a normal faithful state ω on $\mathcal{C}$ represented by a vector in the Gel'fand-Naimark-Segal (GNS) representation which is cyclic and separating for both $\mathcal{B}$ and $\mathcal{C}$.[15] Letting $j_\mathcal{B}$ and $j_\mathcal{C}$ denotes the modular conjugations of $\mathcal{B}$ and $\mathcal{C}$, respectively, with respect to the aforementioned cyclic and separating vector, we define the *canonical endomorphism* $\gamma:\mathcal{C}\to\mathcal{B}$ by $\gamma:=j_\mathcal{B}j_\mathcal{C}$.

Now suppose that ρ is a unital, injective endomorphism of $\mathcal{C}$ and let γ_ρ be the canonical endomorphism associated with $\rho(\mathcal{C})\subseteq\mathcal{C}$. A conjugate of ρ is then given by $\bar{\rho}=\rho^{-1}\circ\gamma_\rho$.

If U is a unitary that implements ρ, that is, $\rho=\mathrm{Ad}U$, then $\bar{U}=j_\mathcal{C}(U)$ implements a conjugate $\bar{\rho}$ of ρ, $\bar{\rho}=\mathrm{Ad}\bar{U}$. Moreover, every conjugate of ρ is of this form.[9]

Definition 4.9 (Weak Conjugate Endomorphism): Suppose that ρ is a consistent endomorphism on the net of von Neumann algebras $\mathcal{A}$ localized in the proper interval I_0. A *weak conjugate endomorphism of* ρ is a consistent endomorphism $\bar{\rho}$ localized in I_0 such that $\bar{\rho}_I$ is conjugate of ρ_I for every interval $I\supseteq I_0$.

As usual we extend the Möbius group and the unitary representation $(U,\mathfrak{H})$ to include reflections associated with proper intervals. In general we will use the notation r or s for such reflections, adding a subscript, r_I, if necessary to emphasize the interval with which the reflection is associated. We write J_I for the modular conjugation associated with $(\mathcal{A}(I),\Omega)$ and note that $U(r_I)=J_I$.

Proposition 4.10: *Suppose that* (z_g) *is an* α*-cocycle modulo* $\mathcal{B}$ *localized in* I_0*. If* h *is an element of the Möbius group and* r *a reflection associated with some interval, then* $g \mapsto \bar{z}_g^{h,r} := \alpha_h j_r(z_{rh^{-1}ghr})$ *defines an* α*-cocycle modulo* $\alpha_h j_r(\mathcal{B})$ *localized in* hrI_0*.*

Proof: We fix an element h of the Möbius group and a reflection r and consider the mapping $g \mapsto \bar{z}_g^{h,r}$.

Firstly, we will deal with the localization. Let g be an arbitrary element of the Möbius group. Then

$$\bar{z}_g^{h,r} = \alpha_h j_r(z_{rh^{-1}ghr}) \in \alpha_h j_r(\mathcal{A}(I_0) \vee \mathcal{A}(rh^{-1}ghrI_0)) = \mathcal{A}(hrI_0) \vee \mathcal{A}(g(hrI_0)).$$

Secondly, as concerns the cocycle condition for $\bar{z}^{h,r}$ we make the following computation:

$$\begin{aligned}\bar{z}_{g_1g_2}^{h,r} = \alpha_h j_r(z_{rh^{-1}g_1hrrh^{-1}g_2hr}) &\in \alpha_h j_r(\mathcal{B} z_{rh^{-1}g_1hr}\alpha_{rh^{-1}g_1hr}(z_{rh^{-1}g_2hr})) \\ &= \alpha_h j_r(\mathcal{B})\bar{z}_{g_1}^{h,r}\alpha_{g_1}(\alpha_h j_r(z_{rh^{-1}g_2hr})) = \alpha_h j_r(\mathcal{B})\bar{z}_{g_1}^{h,r}\alpha_{g_1}(\bar{z}_{g_2}^{h,r}).\end{aligned}$$

Finally, choose a g such that $ghrI_0 \perp hrI_0$. This clearly implies that $rh^{-1}ghrI_0 \perp I_0$ and we therefore have

$$\mathrm{Ad}(\bar{z}_g^{h,r})\mathcal{A}(hrI_0) = \mathrm{Ad}(\alpha_h j_r(z_{rh^{-1}ghr}))\alpha_h j_r\mathcal{A}(I_0) = \alpha_h j_r(\mathrm{Ad}(z_{rh^{-1}ghr})\mathcal{A}(I_0)) = \alpha_h j_r(\mathcal{B}' \cap \mathcal{A}(I_0))$$

as desired. □

Definition 4.11: For a given weakly Möbius covariant endomorphism ρ localized in I or equivalently the corresponding α-cocycle (z_g) modulo $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$, we denote the weakly Möbius covariant endomorphism associated with $(\bar{z}_g^{h,r})$ by $\bar{\rho}^{h,r}$.

We fix a weakly Möbius covariant endomorphism ρ localized in an interval I_0 whose complement contains ∞.

Lemma 4.12: *For any element* h *of the Möbius group and reflection* r*, it holds that*

$$\bar{\rho}^{h,r} = \alpha_h \circ j_r \circ \rho \circ j_r \circ \alpha_{h^{-1}}.$$

Proof:

$$\begin{aligned}\bar{\rho}_{ghrI_0^\perp}^{h,r} = \mathrm{Ad}(\alpha_h j_r(z_{rhg^{-1}hr}))|_{\mathcal{A}(ghrI_0^\perp)} &= \alpha_h j_r \circ \mathrm{Ad}(z_{rh^{-1}ghr})|_{\mathcal{A}(rh^{-1}ghrI_0^\perp)} \circ j_r\alpha_{h^{-1}} \\ &= \alpha_h j_r \circ \rho_{rh^{-1}ghrI_0^\perp} \circ j_r\alpha_{h^{-1}}.\end{aligned}$$

□

Proposition 4.13: *The endomorphisms* $\bar{\rho}^{h,r}$ *with* h *ranging over the Möbius group and* r *over the reflections are all in the same sector.*

Proof: Let g and h be elements of the Möbius group and let r and s be reflections. Then

$$\bar{\rho}^{h,r} = \alpha_h j_r\rho j_r\alpha_h^{-1} = \alpha_h j_r j_s\alpha_g^{-1}\bar{\rho}^{g,s}\alpha_g j_s j_r\alpha_h^{-1} = \alpha_{hrsg^{-1}} \circ \bar{\rho}^{g,s} \circ \alpha_{(hrsg^{-1})^{-1}} = \mathrm{Ad}((\bar{z}_{hrsg^{-1}}^{g,s})^*) \circ \bar{\rho}^{g,s}.$$

Proposition 4.14: *For each proper interval* $I \supseteq I_0$ *there exists a* $\bar{\rho}^{h,r}$ *such that* $\bar{\rho}_I^{h,r}$ *is a conjugate of* ρ_I*.*

Proof: Let a proper interval $I \supseteq I_0$ be given. As outlined in Remark 4.8, the proof will be done if we can produce a unitary u such that $\rho_I = \mathrm{Ad}u$ and show that $\bar{\rho}_I^{h,r} = \mathrm{Ad}j_I(u)^*$ for some h and r. Let $r := r_I$ and choose h such that $hrI_0 = I_0$. It then follows that $\mathrm{Ad}z_{rhr}|\mathcal{A}(rhrI_0^\perp) = \rho_{rhrI_0^\perp} = \rho_{rI_0^\perp}$. Noting that $rI_0^\perp \supseteq I$ we define $u := z_{rhr}$ and consequently obtain $\rho_I = \mathrm{Ad}u|\mathcal{A}(I)$.

By the cocycle condition for ρ there exists an $x \in \rho(\mathcal{A}(I_0))' \cap \mathcal{A}(I_0)$ such that $z_{rhr}^* = \alpha_{rhr}(z_{rh^{-1}r})x$. Using this we compute

$$j_r(u^*) = j_r(z_{rhr}^*) = j_r(\alpha_{rhr}(z_{rh^{-1}r})x) = \alpha_h j_r(z_{rh^{-1}h^{-1}hr})j_r(x) = \bar{z}_{h^{-1}}^{h,r} j_r(x).$$

For any $a \in \mathcal{A}(I)$ we have $\mathrm{Ad}(j_r(x))(a) \in \mathcal{A}(I) \subseteq \mathcal{A}(rI_0^\perp) = \mathcal{A}(h^{-1}I_0^\perp)$. Therefore,

$$\mathrm{Ad}j_r(u)^*(a) = \mathrm{Ad}(\bar{z}^{h,r}_{h^{-1}}j_r(x))(a) = \mathrm{Ad}(\bar{z}^{h,r}_{h^{-1}})\mathrm{Ad}(j_r(x))(a) = \bar{\rho}^{h,r}(\mathrm{Ad}(j_r(x))a) = \alpha_h j_r \rho j_r \alpha_h^{-1}(\mathrm{Ad}j_r(x)a)$$
$$= \mathrm{Ad}(\alpha_h j_r \rho(\alpha_{rh^{-1}r}(x)))\bar{\rho}^{h,r}(a).$$

Now, as $x \in \mathcal{A}(I_0)$ and $rh^{-1}rI_0 \perp rh^{-1}I_0 = I_0$, we have $\rho(\alpha_{rh^{-1}r}(x)) = \alpha_{rh^{-1}r}(x)$. Consequently,

$$\mathrm{Ad}(\alpha_h j_r \rho(\alpha_{rh^{-1}r}(x)))\bar{\rho}^{h,r}(a) = \mathrm{Ad}(j_r(x))\bar{\rho}^{h,r}(a) = \bar{\rho}^{h,r}(a),$$

as $j_r(x) \in \mathcal{A}(rI_0) \subseteq \mathcal{A}(I)'$ and $\bar{\rho}^{h,r}(a) \in \mathcal{A}(I)$.

In conclusion, $\mathrm{Ad}j_r(u)^* | \mathcal{A}(I) = \bar{\rho}^{h,r}_I$ and $\bar{\rho}^{h,r}_I$ is therefore a conjugate of ρ_I. □

Lemma 4.15: *If h is an element of the Möbius group and r a reflection chosen such that $hrI_0 = I_0$, then for any proper interval $I \supseteq I_0$ the endomorphism $\bar{\rho}^{h,r}$ is unitarily equivalent to $j_I \circ \rho \circ j_I$.*

Proof: As in the previous proof we find a unitary $u := z_{rhr}$ such that

$$\rho = \begin{cases} \mathrm{Ad}u \text{ on } \mathcal{A}(I) \\ \mathrm{id} \text{ on } \mathcal{A}(I^\perp). \end{cases}$$

Hence, $j_I \circ \rho \circ j_I$ is given by

$$j_I \circ \rho \circ j_I = \begin{cases} \mathrm{id} \text{ on } \mathcal{A}(I) \\ \mathrm{Ad}j_I \text{ on } \mathcal{A}(I^\perp). \end{cases}$$

Conjugating $j_I \circ \rho \circ j_I$ with $j_I(u)^*$ then gives

$$\mathrm{Ad}(j_I(u)^*) \circ j_I \circ \rho \circ j_I = \begin{cases} \mathrm{Ad}j_I(u)^* \text{ on } \mathcal{A}(I) \\ \mathrm{id} \text{ on } \mathcal{A}(I^\perp), \end{cases}$$

which we recognize as $\bar{\rho}^{h,r}$. □

Lemma 4.16: *For any interval I and any element g of the Möbius group, $j_I \circ \rho \circ j_I$ is unitarily equivalent to $j_{gI} \circ \rho \circ j_{gI}$.*

Proof:

$$j_{gI} \circ \rho \circ j_{gI} = \alpha_g \circ j_I \circ \alpha_g^{-1} \circ \rho \circ \alpha_g \circ j_I \circ \alpha_g^{-1} = \alpha_g \circ j_I \circ \mathrm{Ad}z_g^* \circ \rho \circ j_I \circ \alpha_g^{-1} \sim j_I \circ \rho \circ j_I \circ \alpha_g^{-1} \sim j_I \circ \rho \circ j_I.$$

□

We sum up our findings in the following proposition.

Proposition 4.17: *Suppose that ρ is a weakly Möbius covariant endomorphism localized in I_0. Then ρ has a weakly Möbius covariant weak conjugate and for any interval I, $j_I \circ \rho \circ j_I$ is in the sector of that weak conjugate.*

C. Endomorphisms from weights

We have now come to the part where we construct Möbius covariant endomorphisms from weights. While we ultimately want to formulate the results in terms of half-sided modular inclusions, it is convenient, especially in the proofs, to keep working in the setting of nets of von Neumann algebras.

The construction falls in two parts. The first part is to construct a weakly Möbius covariant endomorphism associated with a given weight. This part uses techniques similar to those employed in Sec. III where we were able to extend an endomorphism ρ on $\mathcal{A}(S_+)$ to the entire net $\mathcal{A}$ provided that there existed a conditional expectation $E: \mathcal{A}(S_+) \to \rho(\mathcal{A}(S_+))$ with finite index. We will construct an endomorphism on some local algebra $\mathcal{A}(]a;\infty[)$ along with a conditional expectation onto its image. The fact that this conditional expectation may not have finite index is the reason we are only able to obtain *weak* Möbius covariance *a priori*.

The second part of the construction consists of showing that the obtained weakly Möbius covariant endomorphism is a direct sum of endomorphisms with finite index and thus *a fortiori*

Möbius covariant. This part relies on proof techniques developed by Bertozzini *et al.*[5] in which the existence of a weak conjugate, proven in the previous section, will play a central role.

Definition 4.18 [Localized Weight]: Let ψ be semifinite, normal, faithful weight on $\mathcal{M}$. We say that ψ *is localized in the proper interval* $I_0 \subseteq \mathbb{R}_+$ if (1) $(D\psi:D\omega)_t \in \mathcal{A}(I_0) \vee \mathcal{A}(D(t)I_0)$ for all $t \in \mathbb{R}$ and (2) The restriction of ψ to $\mathcal{M}(\psi) := \vee_{t\in\mathbb{R}} \mathrm{Ad}((D\psi:D\omega)_t)(\mathcal{A}(D(t)I_0)' \cap \mathcal{M})$ is semifinite.

Note that $\mathcal{M}(\psi) \subseteq \mathcal{A}(I_0)$.

Remark 4.19 ($\mathcal{M}(\psi)$ Globally Invariant under σ^ψ): By its very definition $\mathcal{M}(\psi)$ is globally invariant under the modular automorphism group of ψ:

$$\sigma_s^\psi(\vee_t \mathrm{Ad}(D\psi:D\omega)_t \mathcal{A}(D(t)I_0)' \cap \mathcal{M}) = \sigma_s^\psi(\vee_t \sigma_t^\psi \mathcal{A}(I_0)' \cap \mathcal{M}) = \vee_t \sigma_t^\psi \mathcal{A}(I_0)' \cap \mathcal{M}$$
$$= \vee_t \mathrm{Ad}((D\psi:D\omega)_t)(\mathcal{A}(D(t)I_0)' \cap \mathcal{M}).$$

The existence of a conditional expectation from $\mathcal{M}$ onto $\mathcal{M}(\psi)$ follows from the remark above. It is, however, difficult to construct an endomorphism on $\mathcal{M}$ with image $\mathcal{M}(\psi)$. Instead we will construct an endomorphism on some $\mathcal{A}(]a;\infty[) \subseteq \mathcal{M}$ by conjugation with $(D\psi:D\omega)_{t_0}$ for some suitable t_0. The following lemma asserts that this endomorphism has the proper image, i.e., $\mathcal{M}(\psi) \cap \mathcal{A}(]a;\infty[)$.

Lemma 4.20: *Suppose that ψ is a weight localized in the interval $I_0 \subseteq \mathbb{R}_+$ and that $I \subseteq \mathbb{R}_+$ is an interval containing the closure of I_0. In that case, if $t_0 \in \mathbb{R}$ is chosen such that $D(t_0)I_0 \perp I$, then* $\mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I) = \mathcal{M}(\psi) \cap \mathcal{A}(I)$.

Proof: We start by showing the inclusion $\mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I) \subseteq \mathcal{M}(\psi) \cap \mathcal{A}(I)$.

It is useful to note that $(D\psi:D\omega)_t^*(D\psi:D\omega)_s$ belongs to $\mathcal{A}(D(t)I_0) \vee \mathcal{A}(D(s)I_0)$ as seen by the following calculation:

$$(D\psi:D\omega)_t^*(D\psi:D\omega)_s = ((D\psi:D\omega)_s \sigma_s^\omega((D\psi:D\omega)_{t-s}))^*(D\psi:D\omega)_s = \sigma_s^\omega((D\psi:D\omega)_{t-s})^*$$
$$\in \mathcal{A}(D(t)I_0) \vee \mathcal{A}(D(s)I_0).$$

Consequently, the von Neumann algebra $\mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I)$ is independent of the choice of t_0 as long as $D(t_0)I_0 \perp I$. As it is contained in $\mathcal{A}(I) \vee \mathcal{A}(D(t_0)I_0)$ we conclude by the independence of t_0 that it is, in fact, contained in the smaller von Neumann algebra $\mathcal{A}(I)$, that is, $\mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I) \subseteq \mathcal{A}(I)$. Secondly, that $\mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I)$ is contained in $\mathcal{M}(\psi)$ is an immediate consequence of I being contained in $D(s)I_0^\perp$ for some $s \in \mathbb{R}$. Hence, we have shown the inclusion $\mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I) \subseteq \mathcal{M}(\psi) \cap \mathcal{A}(I)$.

The converse inclusion will follow if we can simply show that

$$(\mathrm{Ad}((D\psi:D\omega)_s)\mathcal{A}(D(s)I_0^\perp)) \cap \mathcal{A}(I) \subseteq \mathrm{Ad}(D\psi:D\omega)_{t_0}\mathcal{A}(I)$$

for all $s \in \mathbb{R}$. As the only elements of $\mathcal{A}(D(s)I_0^\perp)$ to be mapped into $\mathcal{A}(I)$ by conjugation with $(D\psi:D\omega)_s$ are those localized in I, it suffices to show that conjugation with $(D\psi:D\omega)_s$ and $(D\psi:D\omega)_{t_0}$, respectively, is identical to $\mathcal{A}(D(s)I_0^\perp \cap I)$. This, however, is a consequence of the aforementioned fact that $(D\psi:D\omega)_t^*(D\psi:D\omega)_s$ belongs to $\mathcal{A}(D(t)I_0) \vee \mathcal{A}(D(s)I_0)$. Thus, we find that $\mathcal{M}(\psi) \cap \mathcal{A}(I) \subseteq \mathrm{Ad}((D\psi:D\omega)_{t_0})\mathcal{A}(I)$. □

As shown as a step in the previous proof,

$$(D\psi:D\omega)_t^*(D\psi:D\omega)_s \in \mathcal{A}(D(t)I_0) \vee \mathcal{A}(D(s)I_0).$$

This has the consequence that not only the image of the endomorphism $\mathrm{Ad}(D\psi:D\omega)_{t_0}|_{\mathcal{A}(I)}$ but also the endomorphism itself is independent of t_0 as long as $D(t_0)I_0 \perp I$.

Proposition 4.21: *Let I_0 be an interval such that $\bar{I}_0 \subseteq S_+$. For any weight ψ on $\mathcal{M}$ localized in I_0 there exists a unique weakly Möbius covariant endomorphism ρ localized in I_0 such that $\sigma_t^\psi \circ \rho = \rho \circ \sigma_t^\omega$ on $\mathcal{M}$.*

Many aspects of the proof will closely parallel arguments presented in Sec. III. Instead of giving the same arguments again, we will refer back to the relevant proofs and restrict ourselves to dealing with the differences.

Proof: As ψ by assumption is semifinite on both $\mathcal{M}$ and $\mathcal{M}(\psi)$ and the latter as noted in Remark 4.19 is globally invariant under the modular automorphism group of ψ, the Takesaki theorem supplies us with a faithful conditional expectation E from $\mathcal{M}$ onto $\mathcal{M}(\psi)$.

We choose a proper interval I such that $\bar{I}_0 \subseteq I \subseteq]\delta;\infty[$ for some $\delta > 0$. We also choose a t_0 such that $D(t_0)I_0 \perp I$. From the previous lemma it follows that we can define an endomorphism ρ on $\mathcal{A}(I)$ with image $\mathcal{M}(\psi) \cap \mathcal{A}(I)$ by $\rho := \mathrm{Ad}(D\psi : D\omega)_{t_0}$. As $\mathcal{A}(I_0)' \cap \mathcal{M} \subseteq \mathcal{M}(\psi)$, it follows that the restriction of E to $\mathcal{A}(I)$ is a faithful conditional expectation of $\mathcal{A}(I)$ onto $\mathcal{M}(\psi) \cap \mathcal{A}(I)$.

We are now in the situation where we have an endomorphism on $\mathcal{A}(I)$ along with a conditional expectation onto its image. If the endomorphism was irreducible we could apply the proof of Theorem 3.10 to extend ρ to a Möbius covariant endomorphism on S^1. That ρ might be reducible will present some problems but the basic techniques used in the previous section can still be used. Our first goal is to construct an α-cocycle on the translation-dilation group modulo $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$ and use this to extend ρ to all of S^1 as per Remark 4.7.

As in the proof of Theorem 3.10 we can find a one-parameter group (v_t) such that $\mathrm{Ad}v_t \circ \rho = \rho \circ \sigma_t^{\omega_I}$. Taking a proper subinterval J of I with one end point in common with I and which contains the closure of I_0, we can find another one-parameter unitary group w_t such that $\mathrm{Ad}w_t \circ \rho|_{\mathcal{A}(J)} = \rho|_{\mathcal{A}(J)} \circ \sigma_t^{\omega_J}$. We can assume without loss of generality that the end point shared by I and J is ∞. It is important to note that $v_t \Delta_{\omega_I}^{-it}$ belongs to $\mathcal{A}(I)$ and that $w_t \Delta_{\omega_J}^{-it}$ belongs to $\mathcal{A}(J)$.

We want to show that the one-parameter unitary groups (v_t) and (w_t) together generate a representation of the translation-dilation group up to left multiplication by elements of $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$. As in the proof of Lemma 3.8, it is enough to show that (v_t) and (w_s) satisfy a commutation relation of the shape (4),

$$w(s)v(t-s) = v(t)w(-\log(1-\exp(2\pi t)+\exp(2\pi(t-s)))/2\pi) \times v(\log(1-\exp(2\pi t)+\exp(2\pi(t-s)))/2\pi), \tag{5}$$

up to left multiplication by elements of $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$ for small s and t.

For convenience we will write $U_\rho(D_I(t))$ for v_t and $U_\rho(D_J(t))$ for w_t. Let $g_1, \ldots, g_5$ denote the elements of the group generated by $D_I(s)$ and $D_J(t)$, $s,t \in \mathbb{R}$, corresponding to Eq. (5). With argumentation similar to that of the proof of Lemma 3.8 we find for a suitably chosen "small" interval $K \supseteq I_0$ that

$$U_\rho(g_5)^* U_\rho(g_4)^* U_\rho(g_3)^* U_\rho(g_1) U_\rho(g_2) \in \rho(\mathcal{A}(K))'.$$

As in the proof of Lemma 3.8, the interval K is chosen such that the successive application of the concerned elements of the Möbius group, $g_1, \ldots, g_5$, keeps I_0 within K and K within S_+. Also with argumentation like in the proof of Lemma 3.8, we find that $U_\rho(g_5)^* U_\rho(g_4)^* U_\rho(g_3)^* U_\rho(g_1) U_\rho(g_2)$ belongs to $\mathcal{A}(K)$. By considering smaller and smaller intervals $K \supseteq I_0$ we can conclude that $U_\rho(g)$ is well defined up to right multiplication with $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$ for g in the group generated by $D_I(s)$ and $D_J(t)$. It is easy to check that conjugation by $U_\rho(g)$ defines an automorphism on $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$; wherefore $U_\rho(g)$ is well defined up to left multiplication of elements in $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$. That is, for given g_1 and g_2 in the group generated by $D_I(s)$ and $D_J(t)$,

$$U_\rho(g_1)U_\rho(g_2) = x_{g_1,g_2} U_\rho(g_1 g_2) \quad \text{for some } x_{g_1,g_2} \in \rho(\mathcal{A}(I))' \cap \mathcal{A}(I).$$

We now define $z_g := U_\rho(g)U(g)^*$. The aim is to show that (z_g) defines an α-cocycle modulo $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$ localized in I_0 such that we can apply Remark 4.7 to extend ρ to all of S^1. The previous arguments show that (z_g) satisfies the cocycle requirement of Definition 4.18. By the very definition of the endomorphism ρ and the weight ψ, it is clear that (z_g) also satisfies the third requirement of the definition, namely, that $\mathrm{Ad}(z_g)\mathcal{A}(I_0) = \rho(\mathcal{A}(I_0))$ for some g such that $gI_0 \perp I_0$.

For the last requirement, i.e., $z_g \in \mathcal{A}(I_0) \vee \mathcal{A}(gI_0)$, we encounter the same problem that we did in Lemma 3.8 stemming from the translation-dilation group being unable to "move points through ∞." With the same argument as in Proposition 3.4 it is enough to show that $z_{D_I(t)} \in \mathcal{A}(I_0) \vee \mathcal{A}(D_I(t)I_0)$ for some t such that $\bar{I}_0 \cap D(t)\bar{I}_0 = \emptyset$. But this is a direct consequence of the definition of $z_{D_I(t)}$. Let a suitable t be given. Then we have for $x \in \mathcal{A}(I \setminus (I_0 \cup D_I(t)I_0))$ that

$$\mathrm{Ad} z_{D_I(t)}(x) = \mathrm{Ad} z_{D_I(t)} \rho(x) = \alpha_{D_I(t)} \circ \rho \circ \alpha_{D_I(-t)}(x) = \alpha_{D_I(t)} \circ \alpha_{D_I(t)}(x) = x.$$

In conclusion, (z_g) is an α-cocycle on the translation-dilation group modulo $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$ localized in I_0. By Remark 4.7, ρ extends to a weakly translation-dilation covariant endomorphism on S^1 localized in I_0.

Having defined ρ on all of S^1, it is easy to see that it is, in fact, weakly Möbius covariant. Take a third subinterval L of S_+ containing the closure of I_0 such that $D_L(r)$, $D_I(s)$, and $D_J(t)$ together generate the Möbius group. As before we can construct a one-parameter unitary group $t \mapsto U_\rho(D_L(t))$ such that $\mathrm{Ad} U_\rho(D_L(t)) \circ \rho = \rho \circ \alpha_{D_L(t)}$. Checking that $U_\rho(D_L(t))$ together with the previously defined representation U_ρ of the group generated by $D_I(s)$ and $D_J(t)$ generate a representation of the Möbius group up to left multiplication with $\rho(\mathcal{A}(I))' \cap \mathcal{A}(I)$ is trivial.

Lastly we show that $\sigma_t^\psi \circ \rho = \rho \circ \sigma_t^\omega$. Let $t \in \mathbb{R}$ be given. For any t_0 such that $D(t_0)I_0 \perp I$ we have $\rho_{D(t_0)I_0^\perp} = \mathrm{Ad}(D\psi : D\omega)_{t_0}$ by the definition of ρ. Therefore, if $x \in \mathcal{A}(D(t_0)I_0^\perp) \cap \mathcal{A}(D(t_0 - t)I_0^\perp) \cap \mathcal{A}(S_+)$, then

$$\begin{aligned}
\sigma_t^\psi \circ \rho(x) = \sigma_t^\psi \circ \mathrm{Ad}(D\psi : D\omega)_{t_0 - t}(x) &= \mathrm{Ad}(D\psi : D\omega)_t \circ \sigma_t^\omega \circ \mathrm{Ad}(D\psi : D\omega)_{t_0 - t}(x) \\
&= \mathrm{Ad}((D\psi : D\omega)_t \sigma_t^\omega((D\psi : D\omega)_{t_0 - t}))\sigma_t^\omega(x) \\
&= \mathrm{Ad}(D\psi : D\omega)_{t_0} \circ \sigma_t^\omega(x) = \rho \circ \sigma_t^\omega(x).
\end{aligned}$$

This shows that the equation $\sigma_t^\psi \circ \rho = \rho \circ \sigma_t^\omega$ holds on $X_{t_0} := \mathcal{A}(S_+ \setminus (D(t_0)I_0 \cup D(t_0 - t)I_0))$. As we can make X_{t_0} cover all of $\mathcal{A}(S_+)$ by varying t_0 and ρ does not depend on t_0, we conclude that $\sigma_t^\psi \circ \rho = \rho \circ \sigma_t^\omega$ holds on all of $\mathcal{A}(S_+)$. The equality $\sigma_t^\psi \circ \rho = \rho \circ \sigma_t^\omega$ also ensures uniqueness of ρ. □

Having constructed a weakly Möbius covariant endomorphism on the basis of a weight, we have completed the first part of the program described in the Introduction to this section. For the second part we will use proof elements from Ref. 5 to show that the endomorphism is a direct sum of finite index endomorphisms. A key element will be played by the following result due to Longo.

Proposition 4.22 Ref. 14: *If $\mathcal{B} \subseteq \mathcal{C}$ is an inclusion of factors and if there exists normal, faithful conditional expectations $E : \mathcal{C} \to \mathcal{B}$ and $E' : \mathcal{C}' \to \mathcal{B}'$, then $\mathcal{B}' \cap \mathcal{C}$ is a direct sum of type I factors. Moreover, for each minimal projection p in $\mathcal{B}' \cap \mathcal{C}$, the inclusion $\mathcal{B}p \subseteq p\mathcal{C}p$ has finite index.*

Theorem 4.23: *Suppose that ψ is a semifinite, normal, faithful weight on $\mathcal{M}$ localized in the interval I_0, $\bar{I}_0 \subseteq S_+$. There exists a unique consistent endomorphism ρ on S^1 localized in I_0 such that $\sigma_t^\psi \circ \rho = \rho \circ \sigma_t^\omega$ on $\mathcal{M}$. This ρ is a (possibly infinite) direct sum of finite index endomorphisms. In particular, ρ is Möbius covariant.*

Proof: From Proposition 4.21 we obtain a weakly Möbius covariant endomorphism ρ localized in $I_0 \subseteq S_+$. Also, as argued in the beginning of the proof of Proposition 4.21, the Takesaki theorem provides us with a normal, faithful conditional expectation E of $\mathcal{A}(S_+)$ onto $\rho(\mathcal{A}(S_+))$. We want to construct a normal, faithful conditional expectation from $\mathcal{A}(S_+)'$ onto $\rho(\mathcal{A}(S_+))'$ such that we can utilize Proposition 4.22.

We will write S_R for the right half of the circle S^1 corresponding to the interval $]-1;1[$. As the reflection associated with S_R maps S_+ bijectively onto S_+, the operator j_{S_R} is an antiautomorphism of $\mathcal{A}(S_+)$. Let $\bar{\rho} := j_{S_R} \circ \rho \circ j_{S_R}$. From Proposition 4.17 we know this to be in the sector of a weak conjugate of ρ. As $\bar{\rho}$ is localized in S_+, there exists a unitary $u \in \mathcal{A}(S_+)$ such that $\mathrm{Ad} u \circ \bar{\rho} = \rho^{-1} \circ j_{\rho(\mathcal{M})} j_{\mathcal{M}}$ on $\mathcal{A}(S_+)$. Thus, if we define $\bar{E} := j_{S_R} \circ E \circ j_{S_R}$ we get a normal, faithful conditional expectation of $\mathcal{M}$ onto $\bar{\rho}(\mathcal{M})$. The inclusion $\bar{\rho}(\mathcal{M}) \subseteq \mathcal{M}$ can be written as $\mathrm{Ad}(u^*) \circ \rho^{-1} \circ j_{\rho(\mathcal{M})} j_{\mathcal{M}}(\mathcal{M}) \subseteq \mathcal{M}$ which by simple rearrangements is seen to be unitarily equivalent to

$\mathcal{M}' \subseteq \rho(\mathcal{M})'$. In this way we obtain a normal, faithful conditional expectation of $\rho(\mathcal{M})'$ onto $\mathcal{M}'$ and Proposition 4.22 then tells us that ρ is a (possibly infinite) direct sum of finite index endomorphisms. As each of these is automatically Möbius covariant, so is ρ. □

Definition 4.24: *Let ψ be a semifinite, normal, faithful weight on $\mathcal{M}$ localized in some interval I_0, $\bar{I}_0 \subseteq S_+$. The unique weakly Möbius covariant endomorphism ρ on S^1 such that $\sigma_t^{\psi} \circ \rho = \rho \circ \sigma_t^{\omega}$ is called the endomorphism associated with ψ and written ρ_ψ.*

D. Freedom of choice of weights

The characterizing equation for an endomorphism ρ associated with a weight ψ is $\sigma_t^{\psi} \circ \rho = \rho \circ \sigma_t^{\omega}$ or equivalently,

$$\mathrm{Ad}((D\psi:D\omega)_t) \circ \rho = \sigma_t^{\omega} \circ \rho \circ \sigma_{-t}^{\omega}.$$

As this only determines the Connes cocycle $(D\psi:D\omega)_t$ up to left multiplication with $\rho(\mathcal{A}(I_0))' \cap \mathcal{A}(I_0)$, assuming ρ localized in I_0, many weights will give rise to the same endomorphism. In fact, the following holds.

Proposition 4.25: *Let I_0 be an interval such that $\bar{I}_0 \subseteq S_+$ and suppose that ϕ and ψ are semifinite, normal, faithful weights on $\mathcal{M}$ localized in I_0. Then the following conditions are equivalent:*

(1) $(D\psi:D\phi)_t \in \rho_\phi(\mathcal{M})' \cap \mathcal{M}$, $t \in \mathbb{R}$.
(2) $(D\psi:D\phi)_t \in \rho_\psi(\mathcal{M})' \cap \mathcal{M}$, $t \in \mathbb{R}$.
(3) $\sigma_t^{\psi}(x) = \sigma_t^{\phi}(x)$, $x \in \rho_\phi(\mathcal{M})$.
(4) $\sigma_t^{\psi}(x) = \sigma_t^{\phi}(x)$, $x \in \rho_\psi(\mathcal{M})$.
(5) $\rho_\phi = \rho_\psi$.

Proof. As the last condition is symmetric in ϕ and ψ, it is enough to show that (1)⇒(5)⇒(3)⇒(1). Assuming Eq. (5), then

$$\sigma_t^{\psi}(\rho_\phi(y)) = \sigma_t^{\psi}(\rho_\psi(y)) = \rho_\psi(\sigma_t^{\omega}(y)) = \rho_\phi(\sigma_t^{\omega}(y)) = \sigma_t^{\phi}(\rho_\phi(y)).$$

Assuming Eq. (3), clearly $(D\psi:D\phi)_t$ commutes with $\rho_\phi(\mathcal{M})$ as stated in Eq. (1). Finally, we assume Eq. (1). As both ρ_ϕ and ρ_ψ are localized in I_0, it is enough to show that they coincide on $\mathcal{A}(I_0)$. Choose t_0 such that $D(t_0)I_0 \perp I_0$. Then

$$\rho_\phi|_{\mathcal{A}(I_0)} = \mathrm{Ad}(D\psi:D\phi)_{t_0} \circ \rho_\phi|_{\mathcal{A}(I_0)} = \mathrm{Ad}(D\psi:D\phi)_{t_0} \circ \mathrm{Ad}\,(D\phi:D\omega)_{t_0}|_{\mathcal{A}(I_0)} = \mathrm{Ad}(D\psi:D\omega)_{t_0}|_{\mathcal{A}(I_0)}$$
$$= \rho_\psi|_{\mathcal{A}(I_0)}$$

as per condition (5). □

In case the endomorphism ρ_ψ is irreducible, the weight ψ is unique up to a scalar.

Corollary 4.26: *Let ρ be an irreducible Möbius covariant endomorphism localized in I_0, $\bar{I}_0 \subseteq S_+$. If ψ and ρ are weights localized in I_0 such that $\rho_\psi = \rho_\phi = \rho$ then $\psi = \lambda\phi$ for some positive real λ.*

Proof: As $(D\psi:D\phi)_t \in \rho(\mathcal{M})' \cap \mathcal{M} = \mathbb{C}$, there exists a positive scalar λ such that $\lambda^{it} = (D\psi:D\phi)_t$ for all $t \in \mathbb{R}$. By the defining properties of the Connes cocycle derivative, $\psi = \lambda\phi$. □

While in general there is a certain amount of freedom in the choice of the weight inducing a given endomorphism ρ, we want to single out the weight ψ satisfying $(D\psi:D\omega)_t = z_\rho(D(t))$. Bertozzini *et al.* have given a criterion for when this is satisfied for finite index endomorphisms.

Proposition 4.27 Refs. 14 and 5: *Let ρ be a Möbius covariant endomorphism localized in I_0, $\bar{I}_0 \subseteq S_+$ and ψ a positive linear functional on $\mathcal{M}$. Then the following conditions are equivalent.*

(1) *ψ is normal and faithful and its Connes cocycle derivative relative to ω satisfies $(D\psi:D\omega)_t = z_\rho(D(t))$, $t \in \mathbb{R}$.*
(2) *$\psi = \mathrm{Ind}(\rho)\omega \circ \rho^{-1} \circ E_\rho$, where E_ρ is the minimal conditional expectation of $\mathcal{M}$ onto $\rho(\mathcal{M})$.*

(3) $\psi(xy^*)=(\exp(-D_\rho/2)x\Omega|\exp(-D_\rho/2)y\Omega)$, *where* D_ρ *is the infinitesimal generator of* $t\mapsto U_\rho(D(t))$.
(4) ψ *is normal, faithful, satisfies* $\sigma_t^\psi\circ\rho=\rho\circ\sigma_t^\omega$, $t\in\mathbb{R}$, *and* $\psi|_{\rho(\mathcal{M})'\cap\mathcal{M}}$ *is a trace whose value on a central projection* p *is given by* $\psi(p)=\mathrm{Ind}(\rho_p)$, *where* ρ_p *is the subrepresentation of* ρ *associated with* p.

The condition that ψ is a trace on $\rho(\mathcal{M})'\cap\mathcal{M}$ is equivalent to $\rho(\mathcal{M})'\cap\mathcal{M}$ being a subset of the centralizer of ψ. This can be restated as the condition that the modular automorphism group of the conditional expectation E_ρ is trivial.

For later use we also mention that condition (2) can be rewritten as $\psi\circ\rho=\mathrm{Ind}(\rho)\omega$, suggesting that it may be useful to think of ψ as the vacuum state for the net $(\rho(\mathcal{A}(I)))$.

V. BASIC CONSTRUCTIONS WITH WEIGHTS

In order to work with weights instead of endomorphisms, we need to establish the analogs of unitary equivalence, direct sums, conjugate endomorphisms, and the like within the framework of weights. In this section we take the first basic steps in that direction.

As usual we fix a standard half-sided modular inclusion $(\mathcal{N}\subseteq\mathcal{M},\Omega)$ and denote the associated net of von Neumann algebras by $\mathcal{A}$.

A. Unitary equivalence, subrepresentations, and direct sums

We introduce the notions of unitary equivalence, subrepresentations, and direct sums for weights. Similar considerations appear in Ref. 14.

Remark 5.1 (The Connes Cocycle Derivative): We briefly recall some facts and notation concerning the Connes cocycle derivative. Define $\mathbb{D}:=\{z\in\mathbb{C}|0\leqslant\mathrm{Im}\,z\leqslant 1\}$ and let $A(\mathbb{D})$ denote the set of bounded, continuous functions on $\mathbb{D}$ that are analytic in the interior. If ψ is a weight on $\mathcal{M}$ we define $\mathfrak{n}_\psi:=\{x\in\mathcal{M}|\psi(x^*x)<\infty\}$.

For given normal, semifinite, faithful weights ψ and ϕ on $\mathcal{M}$, the Connes cocycle derivative $(D\psi:D\phi)_t$ is uniquely determined by the following condition.[18] For each $x\in\mathfrak{n}_\psi\cap\mathfrak{n}_\phi^*$ and $y\in\mathfrak{n}_\psi^*\cap\mathfrak{n}_\phi$, there exists a function $F_{x,y}\in A(\mathbb{D})$ such that

$$F(t)=\psi((D\psi:D\phi)_t\sigma_t^\phi(y)x),\quad F(t+i)=\phi(x(D\psi:D\phi)_t\sigma_t^\phi(y)),\quad t\in\mathbb{R}.$$

.

Proposition 5.2: *Suppose that* ψ *is a semifinite, normal, faithful weight localized in the interval* I_0, $\bar{I}_0\subseteq S_+$ *and that* u *is a unitary localized in some interval whose closure is contained in* S_+. *Then* ρ_ψ *is unitarily equivalent to* ρ_{ψ_u}, *where* $\psi_u:=\psi\circ\mathrm{Ad}u^*$.

Proof. We will write ρ for the endomorphism ρ_ψ and ρ_u for the endomorphism $\mathrm{Ad}u\circ\rho$. Defining $U_{\rho_u}(g)=uU_\rho(g)u^*$ gives a representation of the universal covering group of the Möbius group satisfying $\mathrm{Ad}U_{\rho_u}(g)\circ\rho_u=\rho_u\circ\alpha_g$. We define ψ_u to be the weight whose Connes cocycle derivative with respect to ω satisfies $(D\psi_u:D\omega)_t=U_{\rho_u}(D(t))U(D(t))^*$. Thus, $(D\psi_u:D\omega)_t=u(D\psi:D\omega)_t\sigma_t^\omega(u)^*$.

For $x\in\mathfrak{n}_{\psi_u}\cap\mathfrak{n}_\omega^*$ and $y\in\mathfrak{n}_\omega\cap\mathfrak{n}_{\psi_u}^*$ we have an $F_{x,y}\in A(\mathbb{D})$ such that

$$F_{x,y}(t)=\psi_u(u(D\psi:D\omega)_t\sigma_t^\omega(u^*y)x),\quad F_{x,y}(t+i)=\omega(xu(D\psi:D\omega)_t\sigma_t^\omega(u^*y)).$$

We recognize $F_{x,y}(t+i)$ as being equal to the function $G_{xu,u^*y}(t+i)$, where $G\in A(\mathbb{D})$ is the unique function determining $(D\psi:D\omega)_t$, i.e., $G_{xu,u^*y}(t)=\omega((D\psi:D\omega)_t\sigma_t^\omega(u^*y)xu)$. In particular,

$$\psi_u(yx)=F_{x,y}(0)=G_{xu,u^*y}(0)=\psi(u^*yxu)$$

and we conclude that $\psi_u=\psi\circ\mathrm{Ad}u^*$ □.

The proof above would work just as well, were the unitary u to be replaced by an isometry. This observation leads to the following two propositions.

Proposition 5.3: *Suppose that* ψ *is a semifinite, normal, faithful weight localized in the*

interval I_0, $\bar{I}_0 \subseteq S_+$. *If* ρ *is a subrepresentation of* ρ_ψ, $\rho = \mathrm{Ad}v \circ \rho_\psi$, *then* $\rho = \rho_{\psi \circ \mathrm{Ad}v^*}$.

Proof: The proof is identical to that of Proposition 5.2. □

Proposition 5.4: *Suppose that* $\psi_1, \ldots, \psi_n$ *are semifinite, normal, faithful weights localized in* I_0. *For any choice of isometries* $v_1, \ldots, v_n \in \mathcal{A}(I_0)$ *such that* $\Sigma v_i v_i^* = 1$, *the weight* $\psi := \Sigma \psi_i \circ \mathrm{Ad}v_i^*$ *satisfies* $\rho_\psi = \Sigma \mathrm{Ad}v_i \circ \rho_{\psi_i}$.

Proof: The proof is a slight variation of that of Proposition 5.2. □

In case we are considering weights of the form described in Proposition 4.27, i.e., weights ψ satisfying $(D\psi : D\omega)_t = z_{\rho_\psi}(D(t))$, it is easy to check that forming unitary equivalence, subrepresentations, and direct sums preserves this form.

B. Weak conjugates for weights

While several representatives of a weak conjugate of a given endomorphism ρ localized in S_+ exists, we focus on the most obvious one which is likewise localized in S_+, namely, $j_{S_+} \circ \rho \circ j_{S_+}$. Longo presents similar considerations in Ref. 14.

Proposition 5.5: *Suppose that* ψ *is a semifinite, normal, faithful weight localized in the interval* I_0, $\bar{I}_0 \subseteq S_+$, *and that* r *is the reflection associated with the right half-circle* S_R. *Then the endomorphism associated with the weight* $\bar{\psi} := \psi \circ j_r$ *localized in* $rI_0 \subseteq S_+$ *is a weak conjugate of* ρ_ψ, *in fact*, $\rho_{\bar{\psi}} = j_r \circ \psi \circ j_r$.

Proof: By Proposition 4.17, the endomorphism $j_r \circ \rho_\psi \circ j_r$ is a weak conjugate of ρ_ψ, and clearly $j_r \circ \rho_\psi \circ j_r$ is localized in $rI_0 \subseteq S_+$. The α-cocycle associated with $j_r \circ \rho_\psi \circ j_r$ is $\bar{z}_g = j_r(z_{rgr})$. We seek the weight $\bar{\psi}$ whose Connes cocycle derivative with respect to ω is $\bar{z}_{D(t)}$. As usual we do this by computing the function $F^{\bar{\psi}} \in A(\mathbb{D})$ satisfying the following for $x \in \mathbf{n}_{\bar{\psi}} \cap \mathbf{n}_\omega^*$ and $y \in \mathbf{n}_\omega \cap \mathbf{n}_{\bar{\psi}}^*$:

$$F^{\bar{\psi}}_{x,y}(t) = \bar{\psi}(\bar{z}(D(t))\sigma_t^\omega(y)x), \quad F^{\bar{\psi}}_{x,y}(t+i) = \omega(x\bar{z}(D(t))\sigma_t^\omega(y)).$$

It is easy to calculate that $rD(t)r = D(-t)$ and that consequently $j_r \circ \sigma_t^\omega \circ j_r = \sigma_{-t}^\omega$. Using this and the fact that $\omega = \omega \circ j_r$, we can rewrite $F^{\bar{\psi}}_{x,y}(t+i)$ as

$$F^{\bar{\psi}}_{x,y}(t+i) = \omega(xj_r(z_{D(-t)})\sigma_t^\omega(y)) = \omega(j_r(xj_r(z_{D(-t)})j_r(\sigma_{-t}^\omega(j_r(y))))) = \omega(j_r(x)z_{D(-t)}\sigma_{-t}^\omega(j_r(y)))$$
$$= F^{\psi}_{j_r(x),j_r(y)}(-t+i).$$

Thus we find that

$$\bar{\psi}(yx) = F^{\bar{\psi}}_{x,y}(0) = F^{\psi}_{j_r(x),j_r(y)}(0) = \psi(j_r(yx))$$

and conclude that $\bar{\psi} = \psi \circ j_r$. □

We note in passing that if the weight ψ is of the form given in Proposition 4.27, then $\bar{\psi}$ is likewise of that form.

C. Criteria for finite index

It is possible for a given weight ψ to determine whether or not ρ_ψ has finite index on the basis of the weight alone. In fact, Longo has shown that if the weight ψ is of the form given in Proposition 4.27, then the index of ρ_ψ is $\mathrm{Ind}(\rho_\psi) = \psi(1)$.[14] In particular, ρ_ψ has finite index if and only if ψ is a functional.

For a general weight ψ localized in an interval I_0 it is more difficult to determine the index of ρ_ψ directly. It is easy to construct a weight ψ such that ρ_ψ has infinite index but $\psi(1) < \infty$.

Proposition 5.6: *Let* ψ *be a normal, semifinite, faithful weight localized in* I_0, $\bar{I}_0 \subseteq S_+$. *The following holds.*

(1) *If any normal, semifinite, faithful weight* ϕ *localized in* I_0 *for which* $\sigma^\phi|_{\rho_\psi(\mathcal{M})} = \sigma^\psi|_{\rho_\psi(\mathcal{M})}$ and $\rho(\mathcal{M})' \cap \mathcal{M} \subseteq \mathcal{M}_\phi$ *is a functional, then* ρ_ψ *has finite index.*

(2) *If ψ is a functional and $\psi\circ\rho_\psi$ is proportional to ω, then ρ_ψ has finite index.*

Proof: If ψ_0 is the weight for which the Connes cocycle derivative satisfies $(D\psi_0:D\omega)_t = U_{\rho_\psi}(D(t))$ then ρ_ψ has finite index if and only if ϕ_0 is a functional.[14] Condition (2) is simply a restatement of ψ_0 being a functional, see the comment after Proposition 4.27.

As concerns the first condition, if ϕ is a normal, semifinite, faithful weight localized in I_0 such that $\sigma^\phi|_{\rho_\psi(\mathcal{M})} = \sigma^\psi|_{\rho_\psi(\mathcal{M})}$ and $\rho_\psi(\mathcal{M})' \cap \mathcal{M} \subseteq M_\phi$, then $\rho_\phi = \rho_\psi$ and $\sigma^\phi = \sigma^{\psi_0}$. The latter equality is equivalent to $\phi = \lambda\psi_0$ for some real number $\lambda > 0$. Hence, ϕ is a functional if and only if ψ_0 is a functional, and ψ_0 is a functional if and only if $\rho_\psi = \rho_{\psi_0}$ has finite index.[14] □

D. Positive energy

As any endomorphism ρ_ψ associated with a weight as per Theorem 4.23 is a direct sum of finite index endomorphisms, and any endomorphism of finite index has positive energy we can make the following easy observations.

Proposition 5.7: *Suppose that ψ is a normal, semifinite, faithful weight localized in I_0, $\bar{I}_0 \subseteq S_+$. Then the associated endomorphism ρ_ψ has positive energy.*

Corollary 5.8: *Suppose that ρ is a Möbius covariant endomorphism localized in I_0, $\bar{I}_0 \subseteq S_+$ and that ψ is the weight on $\mathcal{M}$ for which $(D\psi:D\omega)_t = z_\rho(D(t))$. If it holds that $\psi|_{\rho(\mathcal{M})}$ is semifinite, then ρ has positive energy.*

Other criteria for a Möbius covariant endomorphism having positive energy can be found in Ref. 5.

Minimal redefinition of the OSV ensemble

Shahrokh Parvizi[a] and Alireza Tavanfar[b]
Institute for Studies in Theoretical Physics and Mathematics (IPM), P.O. Box 19395-5531, Tehran, Iran

(Received 14 October 2006; accepted 16 October 2006; published online 13 December 2006)

In the interesting conjecture, $Z_{BH}=|Z_{top}|^2$, proposed by Ooguri, Strominger, and Vafa (OSV), the black hole ensemble is a mixed ensemble. So if working in the complex polarization, the black hole degeneracy of states as obtained from the ensemble inverse-Laplace integration, generically receives prefactors that do not respect the electric-magnetic duality. One way to handle this, as claimed recently, is working instead of the complex polarization in the real polarization. The other idea would be imposing nontrivial measures for the ensemble sum in the complex polarization. We address this problem in the complex polarization, which is canonical, and upon a redefinition of the OSV ensemble with variables as numerous as the electric potentials, show that for restoring the symmetry no non-Euclidean measure is needed. In detail, applying the electric-magnetic duality as a constraint governing the proper definition of the ensemble variables, we rewrite the OSV free energy as a function of new variables that are combinations of the electric potentials and the black hole charges. Subsequently the Legendre transformation, which bridges between the entropy and the black hole free energy in terms of these variables, points to a generalized ensemble that is well behaved in the complex polarization. In this context, we will consider all the cases of relevance: small and large black holes, with or without $D6$-brane charge. For the case of vanishing $D6$-brane, the new ensemble is purely canonical and the electric-magnetic duality is restored exactly, leading to proper results for the black hole degeneracy of states to all orders in an asymptotic expansion. For more general cases as well, the construction does the job as far as the violation of the duality by the corresponding OSV result is restricted to a prefactor. In the case of black holes with nonvanishing $D6$-brane charge, in a concrete example, we shall show that there are cases where the duality violation goes beyond this restriction and imposing nontrivial measures is incapable of restoring the duality. © *2006 American Institute of Physics.*

I. INTRODUCTION

The theory of topological strings is a beautiful, smart, and powerful mathematics to probe the various aspects of the superstring theories. From the time of its invention,[1–3] it has been an active field of new discoveries. The reader may refer to Ref. 4 as an excellent textbook on the topological strings, or consult Refs. 5–7 as quick introductions to the subject and Ref. 5 for a nice view of recent developments.

On the other hand, one of the most striking outcomes of the string theory has been the microscopic derivation of the black hole entropy.[8] Recently Ooguri, Strominger, and Vafa (OSV), in Ref. 9, have proposed a deep and promising connection between the topological free energy and the microstate ensemble of the four-dimensional BPS black holes in the CY_3 compactifications of

type-II strings. This conjecture roots from earlier works on the black hole entropy,[10–12] which made a consistent generalization of the Bekenstein-Hawking formula, incorporating the F-term corrections to the supergravity action as encoded in the prepotential. The evidence for the fact that a generalization to the standard area-law formula for the black hole entropy is needful in the context of string-M theory had been provided in Ref. 13. A detailed review on the results about the black hole entropy from the string theory is found in Ref. 14.

In Ref. 9, OSV observe that the Bekenstein-Hawking-Wald entropy of the black holes, as derived in Refs. 11 and 12, can be reexpressed as the Legendre transformation of a real function $\mathcal{F}$, called the OSV free energy, with respect to the half of its variables,

$$S(p^\Lambda,q_\Lambda)=\mathcal{F}(p^\Lambda,\phi^\Lambda)+q_\Lambda\phi^\Lambda;\quad \mathcal{F}(p^\Lambda,\phi^\Lambda)\equiv-\pi\,\Im F(CX^\Lambda,C^2W^2=2^8), \tag{1.1}$$

with

$$CX^\Lambda=p^\Lambda+i\,\phi^\Lambda \tag{1.2}$$

as obtained from the magnetic part of the attractor equations, and $F(X^\Lambda)=F(X^0,X^A)$ being the full holomorphic prepotential. Independently, a very close relation is established between the asymptotic expansion of the prepotential and the free energy of topological strings.[15,16] In all, the OSV conjecture states that, given a BPS black hole of electric-magnetic charge-multiplet (p^Λ,q_Λ), arising in $\mathcal{N}=2$ compactification of IIA(B) string theory on $CY_3=\mathcal{M}$, the topological $A-A(B-\overline{B})$ models on $\mathcal{M}$ define a mixed ensemble as

$$Z_{\text{mix}}\equiv e^{\mathcal{F}(p^\Lambda,\phi^\Lambda)}=\sum_{q_\Lambda}\Omega(p^\Lambda,q_\Lambda)e^{-\pi\,q_\Lambda\phi^\Lambda}, \tag{1.3}$$

where the black hole free energy is given by

$$F_{\text{BH}}=\mathcal{F}(p^\Lambda,\phi^\Lambda)=F_{\text{top}}+\overline{F}_{\text{top}}, \tag{1.4}$$

with $\Omega(p^\Lambda,q_\Lambda)$ proposed as (index) degeneracy of the black hole states and ϕ^Λ being the electric potential corresponding to q_Λ.[1] This proposal has been successfully tested in Refs. 18 and 21 from different points of view and further developed in Ref. 17. Remarkably, using the OSV conjecture, Dabholker[21] was able for the first time to derive, from the macroscopic side, the exact coefficient of the leading term in the asymptotic expansion of the degeneracy of states for the small black hole of type IIA on $K_3\times T^2$, dual to Heterotic on T^6, where both the prepotential and the microscopic degeneracy counting are known exactly. For a review lecture on Refs. 9, 17, and 18, see Ref. 22. For a recent and extensive review see Ref. 23. There are, however, examples in Refs. 24 and 25 where a naive application of this conjecture sounds problematic. For example, Ref. 24 mainly focuses on $\mathcal{N}=4$ models where in some cases the string coupling is strong. Before concentrating on the concern of this paper, it is worth pointing out that before any attempt is made to apply the proposal, one may note that the OSV conjecture, in the form of Refs. 9 and 17 in its strong version, is a statement about the full free energy of the topological string theory, including all the perturbative quantum corrections as well as the nonperturbative contributions. Therefore, regarding the fact that the nonperturbative completion of the topological free energy is not as yet known, what the OSV conjecture provides is a nonperturbative definition of the topological strings, parallel to the program of topological M-theory as proposed in Refs. 26 and 27.

A distinguished ambiguity in (1.3) originates from the electric-magnetic duality considerations, that is, the requirement of the invariance of $\Omega(p^I,q_I)$ under the (relevant subgroup) of the

[1]For a nonperturbative completion of the original conjecture see Ref. 17; also there are suggestions concerning the holomorphic anomaly in Refs. 18–20.

symplectic transformations. Actually if one works in the complex polarization, as concrete examples in Refs. 24, 25, and 28 show us using the relevant terms of the topological free energy, the inverse Laplace transformation corresponding to (1.3)[2],

$$\Omega(p^\Lambda,q^\Lambda) \doteq \int [d\phi^\Lambda] e^{\mathcal{F}+\pi q_\Lambda \phi^\Lambda} \equiv \int [d\phi^\Lambda] e^G, \tag{1.5}$$

does generically lead to the results that are duality violating by some unwanted prefactors (for a highlighted example, see the next section). As we will argue later, this property is not restricted to a specific subset of prepotentials but it is a general fact about (1.5), if working in the complex polarization. Understanding and handling this fact has been a matter of some investigations. For example, for an attempt within an independent and, by construction, duality-invariant formulation see Ref. 29, where the proposed modification works for the dyonic black holes relatively well but it is not applicable to the case of $\frac{1}{2}$BPS states for which the proposed measure vanishes (for details and recent improvements see Ref. 30). Alternatively Refs. 31–33 propose a black hole ensemble that sums over a single duality-invariant charge, and so by construction respects the expected symmetries. The application of this approach, where the nonholomorphic corrections to the free energy should necessarily be considered, is so far limited to $\frac{1}{2}$BPS black holes. So there is not yet any overlap between these two approaches. Another idea to improve the duality violations, being closer to the OSV proposal, is assuming that the OSV free energy intrinsically lives in a curved space; accordingly (1.5) is redefined via a non-Euclidean measure,[20,25]

$$\overline{\Omega}(p^\Lambda,q_\Lambda) \doteq \int [d\phi^\Lambda] \sqrt{|g(p,\phi)|}\, e^{\mathcal{F}+\pi q_\Lambda \phi^\Lambda}. \tag{1.6}$$

This measure, which differs from case to case, is responsible for removing the mentioned prefactors.

A new claim in the literature, being argued generally although not yet materialized in concrete examples, is working in the real polarization instead of the complex polarization. This is so because the former polarization is expected to be protected against such duality violations (for details see Refs. 19 and 30, and especially Ref. 23).

In this paper we focus on this problem, that is, the duality aspects of the OSV conjecture, while in the whole work we will choose to keep working in the complex polarization, which is canonical, in contrast to the real polarization, which depends on the symplectic basis that one chooses.[23][3] We shall prove that the curvature of the space where the OSV free energy is defined, in the case of vanishing $D6$-brane charge, is asymptotically zero and as such, to all orders in the asymptotic expansion, no nontrivial measure is needed to be imposed. To show this we shall follow a direct approach: explicit construction of a proper flat ensemble, based on the OSV free energy, which is canonic in as many variables as the original OSV ensemble. In different examples, also within general arguments, we observe that the ensemble leads to the proper results for the black hole degeneracy of states. In fact, the construction works properly for all types of the known BPS black holes in CY_3 compactifications of type-IIA(B) theories and to all orders in the saddle-point asymptotic expansion of the inverse Laplace integral, as far as the duality violation is restricted to a prefactor. This is done via a simple change of variables, which, being linear in the electric potentials, preserves the Legendre transformation from the free energy to the entropy. The new variables have the advantage that the corresponding ensemble is potentially protected against the duality-violating prefactors. For the cases with a vanishing $D6$-brane charge, where the prepotential takes a simplified form and the construction is readable from the form of the prepotential, the new ensemble is purely canonical and restores the electric magnetic exactly. The idea still works quite well for the most general case, of course, up to nonholomorphic corrections, which are

[2]The sign $\doteq$ means "equality" up to an arbitrary constant, which is independent of the black hole charges.

[3]We understand that from now on the reader is aware of the frame of polarization in which we handle the problem.

missed also in the original OSV proposal. For the most general case, considering the leading term of the saddle-point approximation, we obtain a general constraint on the Jacobian from the new variables to the old ones. This constraint equation admits an infinite number of solutions; in principle, all the solutions are equally well, but practically we can pick up the simplest choices. In fact, the exact choice of these variables is not needed. The job they do is just removing the duality-violating prefactor of the corresponding OSV result, which could be done by hand from the first. In this sense it is an existence problem.

It is worth asking about higher orders of the saddle-point approximation for the most general case. The question is whether the duality violation appears just as a prefactor in higher orders. Indeed, for the black holes with a vanishing $D6$-brane charge the answer is positive to all orders of the asymptotic expansion, however, we will show that in case of nonvanishing $D6$-brane charge, the violation can become more complicated than a simple prefactor. This implies that, in higher orders, a simple measure factor is not sufficient to restore the duality generally and deeper modifications/investigations are necessary.

Finally as an alternative, motivated by manifest symplectic-invariant construction, we try a different ensemble that from the beginning treats both of the magnetic and electric charges at the same footing. This enlarged ensemble is related to the ensemble of Sec. IV via an effective integration over the magnetic potentials and asymptotically reproduces the same results for the black hole degeneracy of states.

The outline of the paper is as follows. In the next section, to clarify the main problem within a concrete example, we review one result from Refs. 24 and 25. In Sec. III we redefine the OSV ensemble for the large and small black holes in the absence of $D6$-brane, respectively, and show how it leads to proper results for the degeneracy of states. In Sec. IV we lift the idea for the most general case of BPS black holes in the context of CY_3 compactifications of type-IIA(B) string theories. In Sec. V we check out the procedure for higher orders in the saddle-point approximation and show that in some special cases the duality violation cannot be fixed by a single prefactor. In Sec. VI we introduce an effective that asymptotically reproduces the same results of Sec. IV. We end the paper with a conclusion.

II. ELECTRIC-MAGNETIC DUALITY IN THE OSV CONJECTURE

Let us start by addressing the duality invariance of the proposal of Ref. 9 in the complex polarization. To do that, we quickly repeat a result from Refs. 21, 24, and 25.[4] The prepotential of type-II string theory on a CY_3 is given by the free energy of the corresponding topological string theory as follows:

$$F_{\mathrm{II}} = -\frac{i\pi}{2} F_{\mathrm{top}}, \quad F_{\mathrm{top}} = F_{\mathrm{top}}^{\mathrm{pert.}} + F_{\mathrm{top}}^{\mathrm{GW}} + F_{\mathrm{top}}^{\text{non-pert. completion}}, \tag{2.1}$$

where

$$F^{\mathrm{pert.}} = \sum_h F_h W^{2h}, \tag{2.2}$$

with F_h being the genus-h amplitude of the topological theory and W^2 includes the graviphoton field strength. For the case of IIA on $K_3 \times T^2$, $F_{h>1}$ vanishes and the prepotential is given by

$$F(X^I, W^2) = -\frac{1}{2} C_{ab} \frac{X^a X^b X^1}{X^0} - \frac{W^2}{128\pi i} \log \Delta(e^{2\pi i \frac{X^1}{X^0}}), \tag{2.3}$$

where $C_{ab} \equiv C_{1ab}$ with $a, b = 2, \ldots, b_2$, $b_2 = 23$, and C_{ABC} being the intersection numbers of the CY_3. Δ stands for the Dedekind function. Taking $p^0 = 0$, the OSV free energy is given by

[4]This example is in the context of $\mathcal{N}=4$, but for $\mathcal{N}=2$, where the OSV conjecture is originally formulated, this is the case as well. For example, see the next section.

$$\mathcal{F}(p^\Lambda,\phi^\Lambda)=\frac{\pi}{2\phi^0}C_{ab}(p^1\phi^a\phi^b+p^a\phi^b\phi^1+p^b\phi^a\phi^1-p^ap^bp^1)-\log|\Delta(e^{2\pi\frac{p^1}{\phi^0}}e^{2\pi i\frac{\phi^1}{\phi^0}})|^2. \quad (2.4)$$

For the small black hole we set $p^a=0$,

$$\mathcal{F}(p^\mathrm{I},\phi^\mathrm{I})=\frac{1}{2}C_{ab}\frac{\phi^a\phi^bp^1}{\phi^0}-\log(|\Delta(e^{2\pi^2\frac{p^1}{\phi^0}}e^{2\pi i\frac{\phi^1}{\phi^0}})|^2). \quad (2.5)$$

Accordingly the inverse Laplace transformation, with the Euclidean measure, calculates the degeneracy of states as

$$\Omega(p^1,\vec{q})\doteq\int[d\phi^0d\phi^1d\phi^a]\,e^{\mathcal{F}+q_a\phi^a+q_0\phi^0+q_1\phi^1} \quad (2.6)$$

$$\doteq\int \mathrm{d}x\,\mathrm{d}\theta\left(\frac{-x^{12}(p^1)^2}{\sqrt{\det C}}\right)\times\frac{e^{\left(\frac{1}{2}C^{ab}q_aq_b-p^1q_0\right)x-p^1q_1x\theta}}{|\Delta(e^{-\frac{2\pi^2}{x}}e^{2\pi i\theta})|}, \quad (2.7)$$

where, in the second line, we have taken the integration over ϕ^a's and used the change of variables $x=-\phi^0/p^1$ and $\theta=\phi^1/\phi^0$ with $\mathrm{d}\phi^0\,\mathrm{d}\phi^1=(p^1)^2x\,\mathrm{d}x\,\mathrm{d}\theta$. For the two-charge case, we set $q_A=0$ for $A\neq0$. Defining the T-duality-invariant charge $N\equiv-p^1q_0$, integrating over ϕ^a gives

$$\Omega(p^1,q_0)\doteq\frac{-(p^1)^2}{\sqrt{\det C}}\int \mathrm{d}x\,x^{12}e^{Nx}\int\mathrm{d}\theta\frac{1}{|\Delta(e^{-\frac{2\pi^2}{x}}e^{2\pi i\theta})|}. \quad (2.8)$$

In this form, beside the prefactor $(p^1)^2$, everything is in a duality-invariant form. The presence of this p-dependent factor violates the duality invariance of the degeneracy of states.

In the large N limit, $|\Delta(q)|\approx|q|$, so that Ω approaches

$$\Omega(p^1,q_0)\doteq\frac{-(p^1)^2}{\sqrt{\det C}}\hat{I}_{13}(4\pi\sqrt{N}), \quad (2.9)$$

where[24]

$$\hat{I}_\nu(Q)\equiv\frac{(2\pi)^\nu}{i}\int \mathrm{d}t\,t^{-\nu-1}e^{t+\frac{Q^2}{4t}}. \quad (2.10)$$

Note that at the above limit, the genus 0 and 1 terms of prepotential read as

$$F_0(X^\Lambda)=-\frac{1}{2}C_{ab}\frac{X^1X^aX^b}{X^0}, \quad (2.11)$$

$$F_1(X^\Lambda)=-\frac{1}{64}\frac{X^1}{X^0}, \quad (2.12)$$

with the OSV free energy being

$$\mathcal{F}^{\mathrm{pert}}_{\mathrm{IIA}/K_3\times T^2}=\frac{C_{ab}}{2}\phi^a\phi^b\frac{p^1}{\phi^0}-4\,\pi^2\frac{p^1}{\phi^0}. \quad (2.13)$$

We mention that any attempt to remove the prefactor of (2.9), and similar prefactors, should be done in a way to keep the correct results for the entropy and degeneracy of states. In the following sections we redefine the black hole ensemble to do this job.

III. REDEFINITION OF THE OSV ENSEMBLE FOR A CLASS OF LARGE AND SMALL BLACK HOLES

In this section we consider black holes with vanishing $D6$-brane charge, where $p^0=0$ and the prepotential takes a simplified form. We start with the case of large black holes. The perturbative OSV free energy for a general CY_3 compactification in the large volume is given by

$$\mathcal{F}=-\frac{\pi}{6}\frac{\hat{C}(p)}{\phi^0}+\frac{\pi}{2}\frac{C_{AB}\phi^A\phi^B}{\phi^0}, \tag{3.1}$$

where

$$C_{AB}(p)=C_{ABC}p^C,\ \ C(p)=C_{ABC}p^Ap^Bp^C;\ \ \hat{C}(p)=C(p)+C_{2A}p^A, \tag{3.2}$$

and the indices $A,B,\ldots$ take the integers $1,\ldots,h$.

Let us change the variables of the free energy as follows:

$$\psi^0\equiv\frac{6}{\hat{C}(p)}\phi^0;\ \ \frac{C_{AB}(p)\phi^A\phi^B}{\phi^0}\equiv\frac{\psi^A\psi^A}{\psi^0}, \tag{3.3}$$

where $\psi^A=M^A{}_B(p)\phi^B$.[5]

The free energy is now redefined as a new function,

$$\mathcal{F}=\grave{\mathcal{F}}(\psi^0,\psi^A)=-\pi\frac{1}{\psi^0}+\frac{\pi}{2}\frac{\psi^A\psi^B}{\psi^0}. \tag{3.4}$$

Noting that

$$-\phi^0\frac{\partial\mathcal{F}}{\partial\phi^0}=-\psi^0\frac{\partial\grave{\mathcal{F}}}{\partial\psi^0};\ \ -\phi^A\frac{\partial\mathcal{F}}{\partial\phi^A}=-\psi^A\frac{\partial\grave{\mathcal{F}}}{\partial\psi^A}, \tag{3.5}$$

and defining

$$N\equiv\frac{1}{6}\hat{C}(p)q_0;\ \ N_A\equiv q_B(M^{-1})^B{}_A, \tag{3.6}$$

the Legendre transformation reads as

$$S(N,N_A)=\grave{\mathcal{F}}-\pi\psi^0\frac{\partial\grave{\mathcal{F}}}{\partial\psi^0}-\pi\psi^A\frac{\partial\grave{\mathcal{F}}}{\partial\psi^A}, \tag{3.7}$$

$$N=-\frac{\partial\grave{\mathcal{F}}}{\partial\psi^0};\ \ N_A=-\frac{\partial\grave{\mathcal{F}}}{\partial\psi^A}. \tag{3.8}$$

Motivated by the above observation we introduce the correct black hole ensemble to use as

$$Z\equiv e^{\grave{\mathcal{F}}(\psi^0,\psi^A)}=\sum_N\sum_{N_A}\tilde{\Omega}(N,N_A)\ e^{-\pi\psi^0N-\pi\psi^AN_A}. \tag{3.9}$$

Note that the ensemble defined above, unlike the OSV ensemble, is purely canonical. Now the black hole degeneracy of states is proposed to be

[5] $M^A{}_B(p)$ is a transformation matrix which first diagonalizes $C_{AB}(p)$, then rescales the variables appropriately.

$$d(p,q) \doteq \tilde{\Omega}(N,N_A). \tag{3.10}$$

Let us now consider (3.1) and calculate the corresponding degeneracy of states in the light of the definition (3.9):

$$\tilde{\Omega}(N,N_A) \doteq \int \mathrm{d}\psi^0\, \mathrm{d}\psi^A\, e^{\grave{\mathcal{F}}(\psi^0,\psi^A)+\pi N\psi^0+\pi N_A\psi^A}. \tag{3.11}$$

The integral over the variables ψ^A's is Gaussian and yields

$$\tilde{\Omega}(N,N_A) \doteq \hat{N}^{-\frac{h}{2}-1} \int \mathrm{d}\mu\, \mu^{\frac{h}{2}} e^{\mu-\pi^2\frac{\hat{N}}{\mu}}, \tag{3.12}$$

where

$$\hat{N} \equiv N - \frac{1}{2}N_A N_A. \tag{3.13}$$

A simple algebra shows that

$$\hat{N} = \frac{1}{6}\hat{C}(p)\hat{q}_0;\quad \hat{q}_0 \equiv q_0 - \frac{1}{2}C^{AB}q_A q_B, \tag{3.14}$$

where C^{AB} denotes the inverse of C_{AB}. Thus the degeneracy of the large black hole states as calculated via the ensemble (3.9) is given by

$$d(p,q) \doteq \hat{I}_{\frac{h}{2}+1}(S);\quad S = 2\pi\sqrt{\frac{1}{6}\hat{C}(p)\hat{q}_0}. \tag{3.15}$$

This is indeed the correct result. In contrast, the result by the standard OSV ensemble receives a duality-noninvariant prefactor of the form $|\det C_{AB}(p)|^{-\frac{1}{2}}\left(\frac{\hat{C}(p)}{6}\right)^{\frac{h}{2}+1}$.[24,25]

Now we come to the case of small black holes following the same idea: rewriting the OSV free energy and the macroscopic entropy in terms of new variables and new charges, respectively, leads to a new ensemble for the black holes that by construction is purely canonical. For the interesting case of $K3$ fibrations with Heterotic duals, of which the most well-known example is $\frac{\text{IIA}}{K_3\times T^2} \equiv \frac{\text{Het.}}{T^6}$, the OSV free energy is (2.5). Defining

$$\alpha \equiv -\frac{\phi^0}{p^1};\quad \beta \equiv \frac{\phi^1}{p^1} \tag{3.16}$$

and

$$N \equiv -p^1 q_0;\quad N' \equiv -p^1 q_1, \tag{3.17}$$

we obtain

$$\grave{\mathcal{F}}(\alpha,\beta,\phi^a) = -\frac{C_{ab}\phi^a\phi^b}{2\alpha} - 2\log|\Delta(e^{\frac{2\pi^2}{\alpha}}e^{\frac{-2\pi i\beta}{\alpha}})|, \tag{3.18}$$

where

$$S(N,N',q^a) = \grave{\mathcal{F}} - \pi\alpha\frac{\partial\grave{\mathcal{F}}}{\partial\alpha} - \pi\beta\frac{\partial\grave{\mathcal{F}}}{\partial\beta} - \pi\phi^a\frac{\partial\grave{\mathcal{F}}}{\partial\phi^a} \tag{3.19}$$

and

$$N = -\frac{\partial \grave{\mathcal{F}}}{\partial \alpha};\quad N' = -\frac{\partial \grave{\mathcal{F}}}{\partial \beta};\quad q_a = -\frac{\partial \grave{\mathcal{F}}}{\partial \phi^a}. \tag{3.20}$$

Subsequently we define

$$\grave{Z} \equiv e^{\grave{\mathcal{F}}(\alpha,\beta,\phi^a)} = \sum_N \sum_{N'} \sum_{q_a} \grave{\Omega}(N,N',q_a)\, e^{-\pi\alpha N - \pi\beta N' - \pi\phi^a q_a} \tag{3.21}$$

as the correct black hole ensemble.

The corresponding degeneracy of states is given by

$$\grave{\Omega}(N,N',q_a) \doteq \int \mathrm{d}\alpha\, \mathrm{d}\beta\, \mathrm{d}\phi^a \frac{e^{-\frac{C_{ab}\phi^a\phi^b}{2\alpha} + \pi N\alpha + \pi N'\beta + \pi q_a \phi^a}}{|\Delta(e^{\frac{2\pi^2}{a}} e^{\frac{-2\pi i\beta}{\alpha}})|^2}. \tag{3.22}$$

Doing the Gaussian integration and changing the variables of the remaining integrals from (α,β) to $\left(\alpha, \theta \equiv -\frac{\beta}{\alpha}\right)$, we obtain

$$\grave{\Omega}(N,N',q_a) \doteq \int \mathrm{d}\alpha\, \alpha^{12}\, e^{\pi\alpha\hat{N}} \int \mathrm{d}\theta \frac{e^{-\pi N'\theta\alpha}}{|\Delta(e^{\frac{2\pi^2}{\alpha}} e^{2\pi i\theta})|^2}, \tag{3.23}$$

where

$$\hat{N} \equiv N + \frac{1}{2} q_a C^{ab} q_b = \frac{1}{2} Q_e^2. \tag{3.24}$$

For the two-charge case where $\hat{N}=N$ and $N'=0$, taking the large-volume limit, for which $|\Delta(x)| \approx |x|$, simplifies (3.24) as

$$\tilde{\Omega}(N) \doteq \int \mathrm{d}\alpha\, \alpha^{12}\, e^{\pi\alpha\hat{N} + \frac{4\pi}{\alpha}} = \hat{I}_{13}(4\pi\sqrt{\hat{N}}), \tag{3.25}$$

which is the well-known result for the degeneracy of states, as known from its duality with Heterotic string theory by direct counting of the DH fundamental stringy states.[21]

IV. BLACK HOLES WITH NONVANISHING *D*6-brane CHARGE: SADDLE-POINT EVALUATION

In this section we are concerned with the most general case, $p^0 \neq 0$, and as the central idea follow what we did before. We introduce a generalized OSV ensemble as

$$\grave{Z} \equiv e^{\grave{\mathcal{F}}(p^\Lambda,\psi^\Lambda)} = \sum_{\grave{q}_\Lambda} \grave{\Omega}(p^\Lambda,\grave{q}_\Lambda)\, e^{-\pi \grave{q}_\Lambda \psi^\Lambda}, \tag{4.1}$$

$$\grave{\mathcal{F}}(p^\Lambda,\psi^\Lambda) = \mathcal{F}(p^\Lambda,\phi^\Lambda), \tag{4.2}$$

where the new variables ψ^Λ, which preserve the entropy-defining Legendre transformation,

$$S(p^\Lambda,\grave{q}_\Lambda) = \grave{\mathcal{F}} + \pi \grave{q}_\Lambda \psi^\Lambda, \tag{4.3}$$

are defined from the electric potentials via the linear relations[6]r

[6]The sign * over or below a quantity stands for the saddle-point value of that quantity.

$$\psi^{\Lambda} = U^{\Lambda}{}_{\Gamma}(p^{\Sigma}, \phi_{*}^{\Sigma})\phi^{\Gamma} = V^{\Lambda}{}_{\Gamma}(p^{\Sigma}, q_{\Sigma})\phi^{\Gamma}. \tag{4.4}$$

The fact that, unlike the previous cases, here we let the matrix U depend on ϕ_{*}^{Λ} as well as p^{Λ}, is rooted in the observation that for the cases with a nonvanishing $D6$-brane charge, the OSV prefactors are functions of both the magnetic and electric charges.[25,28]

We now require that the corresponding inverse Laplace integration, as defined via the Euclidean measure,

$$\grave{\Omega}(p^{\Lambda}, \grave{q}_{\Lambda}) \doteq \int [\mathrm{d}\psi^{\Lambda}]\, e^{\grave{\mathcal{F}} + \pi \grave{q}_{\Lambda}\psi^{\Lambda}}, \tag{4.5}$$

be duality invariant, exactly or at least at the saddle-point approximation. Subsequently the black hole degeneracy of states is recognized as

$$d(p^{\Lambda}, q_{\Lambda}) \doteq \grave{\Omega}(p^{\Lambda}, \grave{q}_{\Lambda}), \tag{4.6}$$

where, as implied by (4.4),

$$\grave{q}_{\Lambda} = q_{\Gamma}(V^{-1})^{\Gamma}{}_{\Lambda}. \tag{4.7}$$

From (4.2) and (4.4), the relation between the ensemble (4.1) and (1.3) reads from[7]

$$\grave{\Omega} \doteq \int [\mathrm{d}\phi^{\Lambda}] J(\psi \to \phi)\, e^{\mathcal{F} + \pi q_{\Lambda}\phi^{\Lambda}} = \det[V] \int [\mathrm{d}\phi^{\Lambda}]\, e^{\mathcal{F} + \pi q_{\Lambda}\phi^{\Lambda}} = \det[V]\Omega. \tag{4.8}$$

Obviously a proper choice of the Jacobian matrix V can remove any unwanted prefactor as obtained by the evaluation of (1.5). So we consider the cases where the result by (1.5) is duality violating only by a (single) prefactor besides the proper result[8] Then, for the duality invariance in the saddle-point asymptotic expansion of (4.8),a constraint equation on $U^{\Lambda}{}_{\Gamma}$ is formed as a necessary and sufficient condition. The exact form of this constraint may depend on the order of the saddle-point approximation. Here we write it for the first order. The saddle-point evaluation of (4.8) results at

$$\grave{\Omega}^{*} = \det(V)\Omega^{*}. \tag{4.9}$$

Thus at the first order,

$$\grave{\Omega}^{*} \doteq \det\big[V\big]\, \det[H_{*}]^{-\frac{1}{2}}\, e^{S}, \tag{4.10}$$

$$H_{\Lambda\Gamma} \equiv \frac{\partial^{2}\mathcal{F}}{\partial\phi^{\Lambda}\,\partial\,\phi^{\Gamma}}. \tag{4.11}$$

Remembering that what we want to do is just to get rid of the unwanted prefactor appearing in Ω and to get a proper result, we define

$$\det[H_{*}] \equiv S^{m}\, \det[H'_{*}], \tag{4.12}$$

where m denotes a convenient power of the entropy that is factorized out from the Hessian, so that $\det[H'_{*}]$ is the pure duality-violating prefactor. To remove this prefactor by the matrix V, we arrive at the constraint

[7]Since the matrices U and V differ from each other just by a change of variable $q \leftrightarrow \phi_{*}$, hereafter both of them are denoted as V.

[8]Whether this is a general property of the OSV results is a question that we address in the next section.

$$\det[V^2] \doteq \det[H'_*]. \tag{4.13}$$

Equation (4.13) admits an infinite number of solutions, any solution of which is, in principle, as good as other ones. One choice is taking $V=v\,1$, where

$$v \doteq (\det[H'_*])^{\frac{1}{2h+2}}. \tag{4.14}$$

As a different choice for V we can take a diagonal matrix with elements v_Λ such that

$$v_\Lambda \doteq \sqrt{h'_\Lambda}, \tag{4.15}$$

where

$$\prod_\Lambda h'_\Lambda = \det[H'_*]. \tag{4.16}$$

Equivalently, we can solve the constraint (4.13) by defining the new ensemble to be

$$\hat{X}^0 \equiv \det[V]\, X^0; \quad \hat{X}^A \equiv X^A. \tag{4.17}$$

This solution might be of particular physical interest since X^0 controls the coupling of topological strings via the relation

$$g = \frac{4\pi i}{X^0}. \tag{4.18}$$

In conclusion, we shall briefly speculate on a possible physical interpretation of the ensemble (4.17).

As a specific example in the sector $p^0 \neq 0$, let us consider the case of a large black hole in type IIA on a $K3$ fibered CY_3, for which $C_{abc}=C_{2A}=0$, $a,b\in 2,\ldots,h$, as discussed in Refs. 25 and 28. The prepotential is

$$\mathcal{F} = \frac{1}{2}[\Im(t^1)C_{ab}(p^a p^b - \phi^a \phi^b) + 2\Re(t^1)p^a q_a], \tag{4.19}$$

with $t^A = \frac{X^A}{X^0}$ being flat coordinates for the Kähler moduli. The Hessian determinant of (4.19) at the attractor point is evaluated as

$$\det[H_*] \doteq B^2 (C_{ab}p^a p^b - 2p^0 q_1)^{\frac{h}{2}-1} S^{-\frac{h}{2}-2} \equiv S^{-\frac{h}{2}-2} \det[H'_*], \tag{4.20}$$

where

$$B = \sqrt{(C_{ab}p^a p^b - 2p^0 q_1)[(p^1)^2 C_{ab}p^a p^b + (p^0)^2 C^{ab} q_a q_b - 2p^0 p^1 p^a q_a]}; \quad C^{an}C_{nb} = \delta^a_b. \tag{4.21}$$

Regarding (4.13), the new variables are defined via the constraint

$$\det[V] \doteq B(C_{ab}p^a p^b - 2p^0 q_1)^{\frac{h-2}{4}}, \tag{4.22}$$

from which, in case of interest, one can exactly specify a new set of variables.

Finally we want to show how in a simple way the variables of (3.4) can be deduced from (4.15). The attractor point of the prepotential (3.1) is

$$(\phi^0_*)^2 = -\frac{1}{6}\frac{\hat{C}(p)}{\hat{q}_0}; \quad \phi^A_* = -C^{AB}(p)\, q_B\, \phi^0_*, \tag{4.23}$$

so that

$$\det[H_*]; \doteq \det[C_{AB}(p)]\frac{\hat{C}(p)}{\phi_*^0} \Rightarrow \det[H'_*] \doteq \det\left[\frac{C_{AB}(p)}{\hat{C}(p)}\right]\hat{C}^{-2}(p), \tag{4.24}$$

and then from (4.15) we obtain

$$v^0 \doteq \frac{1}{\hat{C}(p)}; \; v^A \doteq \left[\frac{\omega_A(p)}{\hat{C}(p)}\right]^{\frac{1}{2}}, \tag{4.25}$$

with $\omega_A(p)$ being the eigenvalues of $C_{AB}(p)$. Thus for the ψ variables we obtain

$$\psi^0 \doteq \frac{\phi^0}{\hat{C}(p)}; \; \frac{C_{AB}(p)\phi^A\phi^B}{\phi^0} = \frac{\omega_A(p)\hat{\phi}^A\hat{\phi}^A}{\phi^0} \doteq \frac{\psi^A\psi^A}{\psi^0}, \tag{4.26}$$

where $\hat{\phi}^A$ form a diagonal basis for $C_{AB}(p)$. The result (4.26) is in accordance with (3.3).

V. BEYOND THE SADDLE POINT WITH *D*6-branes?

The electric-magnetic duality is restored by the ensemble (4.1) as long as the result by (1.5) admits the general form

$$\Omega(p,q) \doteq N(p,q)f(S). \tag{5.1}$$

We naturally ask if a violation of the duality in the results of (1.5) is restricted only to a prefactor, $N(p,q)$. Of course for a vanishing $D6$-brane charge, this is always true, at least for the large CY_3-volume limit. In these cases the prepotential is quadratic with respect to ϕ^A, so the exact evaluation of (1.5) results in the form (5.1) with $f(S)$ being a modified Bessel function. Now we come to the cases for which $p^0 \neq 0$. The prepotential, at the genus zero and one terms, is of the general form

$$\mathcal{F} = \frac{p^0}{(\phi^0)^2 + (p^0)^2}[E(\phi) - 3E_{AB}(\phi)p^Ap^B - E_{2A}\phi^A] + \frac{\phi^0}{(\phi^0)^2 + (p^0)^2}[E(p) - 3E_{AB}(p)\phi^A\phi^B + E_{2A}p^A], \tag{5.2}$$

where

$$E(z) \equiv E_{ABC}\, z^A z^B z^c; \; E_{AB}(z) \equiv E_{ABC}\, z^c,$$

with

$$E_{ABC} \equiv -\frac{\pi}{6}C_{ABC}; \; E_{2A} \equiv -\frac{\pi}{6}C_{2A}.$$

To address the above-mentioned question for the case of nonvanishing p^0, we evaluate the OSV result for the black hole degeneracy of states in concrete examples by incorporating all the terms that appear in the saddle-point asymptotic expansion of the integral (1.5),

$$G = S + \sum_{n=2}^{\infty}\frac{1}{n!}H^*_{\Lambda_1\ldots\Lambda_n}\,\eta^{\Lambda_1}\ldots\eta^{\Lambda_n},$$

$$H_{\Lambda_1\ldots\Lambda_n} \equiv \frac{\partial^n\mathcal{F}}{\partial\phi^{\Lambda_1}\ldots\partial\phi^{\Lambda_n}},$$

$$\eta^{\Lambda} \equiv \phi^{\Lambda} - \phi^{\Lambda}_{*}, \tag{5.3}$$

for the two extreme limits $p^0 \to \infty$ and $p^0 \to 0$.

A. An example in the large-p^0 limit

The prepotential (5.2) is expanded over $\frac{\phi^0}{p^0}$ as

$$\mathcal{F} = \frac{1}{p^0}\left\{ [E(\phi) - 3E_{AB}(\phi)p^A p^B - E_{2A}\phi^A] + \frac{\phi^0}{p^0}[E(p) - 3E_{AB}(p)\phi^A\phi^B + E_{2A}p^A] + O\left(\frac{\phi^0}{p^0}\right)^2 \right\}.$$

We require that the contribution to (1.5) from the regions of integration far away from the attractor point is not major, and so ignoring terms of higher orders in the above expansion is satisfactory if $O\left(\left|\frac{\phi^0_*}{p^0}\right|\right) \ll 1$. As we will see, this would be the case for $\left|\frac{E(p)}{p^0}\right| \gg 1$. For the limit under consideration, the prepotential is linear with respect to ϕ^0, so (5.3) is easily evaluated as

$$G(\eta) = S - \frac{6}{(p^0)^2}E_{AB}(p)p^B\eta^0\eta^A + \frac{3}{p^0}\left[E_{AB}(\phi_*) - \frac{\phi^0_*}{p^0}E_{AB}(p) - \frac{\eta^0}{p^0}E_{AB}(p) \right]\eta^A\eta^B + \frac{1}{p^0}E_{ABC}\eta^A\eta^B\eta^C$$

$$\equiv S + g_A\eta^A + \frac{1}{2}g_{AB}\eta^A\eta^B + g_{ABC}\eta^A\eta^B\eta^C.$$

Accordingly (1.5) leads to

$$\Omega \doteq e^S \int \mathrm{d}\eta^0 \int [\mathrm{d}\eta^A] e^{g_A\eta^A + \frac{1}{2}g_{AB}\eta^A\eta^B + g_{ABC}\eta^A\eta^B\eta^C} = e^S \int \mathrm{d}\eta^0 \int [\mathrm{d}\eta^A] e^{g_A x^A + \frac{1}{2}g_{AB}\eta^A\eta^B} \left[1 + g_{ABC}\eta^A\eta^B\eta^C + O\left(\frac{1}{(p^0)^2}\right) \right].$$

Now, as a specific example of the case under consideration, we consider a charge configuration for which

$$\phi^A_* = p^A; \quad \phi^0_* = 0,$$

which is in line with the attractor equations for

$$q_A = \frac{1}{p^0}E_{2A},$$

$$q_0 = \frac{1}{(p^0)^2}[2E(p) - E_{2A}p^A],$$

with the entropy obtained as

$$S = -2\frac{E(p)}{p^0}.$$

Given this ansatz, (1.5) is given by

$$\Omega \doteq e^S \int \mathrm{d}\eta^0 [\mathrm{d}\eta^A] \exp\left\{ \frac{1}{2}\left[\frac{6}{p^0}\left(1 - \frac{\eta^0}{p^0}\right)E_{AB}(p) \right]\eta^A\eta^B - \left[\frac{6}{p^0}\frac{\eta^0}{p^0}E_{AB}(p)p^B \right]\eta^A \right\} \left[1 + \frac{1}{p^0}E(\eta) \right]$$

$$\equiv \Omega_0 + \Omega_1,$$

where $\doteq$ differs from $\doteq$ by higher order corrections. A simple algebra leads to the result

$$\Omega_1 \doteq \frac{(p^0)^{\frac{h}{2}+1}}{\sqrt{\det[E_{AB}]}} e^{-2S} I_{\frac{h}{2}-1}(3S),$$

$$\Omega_2 \doteq \frac{(p^0)^{\frac{h}{2}+1}}{\sqrt{\det[E_{AB}]}} e^{-2S} \int \mathrm{d}t\, t^{-\frac{h}{2}} \left[\left(1+\frac{1}{t}\right)^3 \frac{S}{2} - \frac{h}{2}\frac{1-t}{t^2} \right] e^{\frac{3}{2}\left(t+\frac{1}{t}\right)S},$$

so in this example Ω is of the form (5.1).

B. The infinitesimal p^0 limit

Here considering black holes with infinitesimal $D6$-brane charge, $|p^0| \ll 1$, we evaluate the OSV degeneracy of states up to $O(|p^0|^2)$. To do that, we do not restrict ourselves to any finite order of the saddle-point approximation and sum over all the terms of the series (5.3). However, we still assume that the integral (1.5) is essentially localized around the saddle point of the integrand, so that in the power expansion of the prepotential (5.2) over $\frac{p^0}{\phi^0}$, we can ignore the terms $O\left(\frac{p^0}{\phi^0}\right)^2$ as far as $\kappa \equiv \frac{p^0}{\phi^0_*} \ll 1$. As the attractor-point equations will show us below, this assumption is consistent with the infinitesimal-p^0 limit.

The prepotential (5.2), up to $O\left(\frac{p^0}{\phi^0}\right)^2$, reads as

$$\mathcal{F} = \frac{1}{\phi^0}\left\{ \frac{p^0}{\phi^0}[E(\phi) - 3E_{AB}(\phi)p^A p^B - E_{2A}\phi^A] + [E(p) - 3E_{AB}(p)\phi^A\phi^B + E_{2A}p^A] \right\} \equiv p^0 \frac{K}{(\phi^0)^2} + \frac{L}{\phi^0}. \tag{5.4}$$

Regarding that the prepotential is a polynomial of degree three with respect to ϕ^A's, we can explicitly evaluate the sum (5.3). Using

$$H^*_{(n)} = (-1)^n \left[(n+1)!\ p^0 \frac{K^*}{(\phi^0_*)^{n+2}} + n!\ \frac{L^*}{(\phi^0_*)^{n+1}} \right],$$

$$H^*_{A(n)} = (-1)^n \left[(n+1)!\ p^0 \frac{K^*_A}{(\phi^0_*)^{n+2}} + n!\ \frac{L^*_A}{(\phi^0_*)^{n+1}} \right],$$

$$H^*_{AB(n)} = (-1)^n \left[(n+1)!\ p^0 \frac{K^*_{AB}}{(\phi^0_*)^{n+2}} + n!\ \frac{L^*_{AB}}{(\phi^0_*)^{n+1}} \right],$$

$$H^*_{ABC(n)} = (-1)^n \left[(n+1)!\ p^0 \frac{K^*_{ABC}}{(\phi^0_*)^{n+2}} + n!\ \frac{L^*_{ABC}}{(\phi^0_*)^{n+1}} \right],$$

where

$$\{K,L\}_{\{A_1 \ldots A_m\}} \equiv \frac{\partial\{K,L\}}{\partial\{A_1 \ldots A_m\}}$$

and the index (n) denotes the number of derivatives with respect to ϕ^0. Accordingly $G(\eta)$ is evaluated as

$$G(\eta) = S + (\eta^0)^2 \left[\sum_0^\infty \frac{(\eta^0)^n}{(n+2)!} H^*_{(n+2)} \right] + \eta^0 \eta^A \left[\sum_0^\infty \frac{(\eta^0)^n}{(n+1)!} H^*_{A(n+1)} \right] + \frac{1}{2}\eta^A \eta^B \left[\sum_0^\infty \frac{(\eta^0)^n}{n!} H^*_{AB(n)} \right]$$
$$+ \frac{1}{6}\eta^A \eta^B \eta^C \left[\sum_0^\infty \frac{(\eta^0)^n}{n!} H^*_{ABC(n)} \right]$$

$$=S+\frac{(\eta^0)^2}{(\phi_*^0)^2}\left[\frac{p^0K^*}{(\phi_*^0)^2}R_3\left(\frac{\eta^0}{\phi_*^0}\right)+\frac{L^*}{\phi_*^0}R\left(\frac{\eta^0}{\phi_*^0}\right)\right]-\frac{\eta^0\eta^A}{(\phi_*^0)^2}\left[\frac{p^0K_A^*}{\phi_*^0}R_2\left(\frac{\eta^0}{\phi_*^0}\right)+L_A^*R\left(\frac{\eta^0}{\phi_*^0}\right)\right]$$
$$+\frac{1}{2}\frac{\eta^A\eta^B}{(\phi_*^0)^2}\left[p^0K_{AB}^*\,R_1\left(\frac{\eta^0}{\phi_*^0}\right)+\phi_*^0L_{AB}^*\,R\left(\frac{\eta^0}{\phi_*^0}\right)\right]+\frac{1}{6}\frac{\eta^A\eta^B\eta^C}{(\phi_*^0)^3}p^0\phi_*^0K_{ABC}^*\,R_1\left(\frac{\eta^0}{\phi_*^0}\right),$$

where

$$R(z)\equiv\sum_0^\infty(-1)^nz^n=\frac{1}{1+z};\;\; R_m(z)\equiv\sum_0^\infty(-1)^n(n+m)z^n=\frac{(m-1)\,z+m}{(1+z)^2}.$$

Defining

$$x\equiv\frac{\eta^0}{\phi_*^0},\;\; x^A\equiv\frac{\eta^A}{\phi_*^0},$$

together with

$$g_{ABC}\equiv\kappa\frac{(\phi_*^0)^2}{(1+x)^2}E_{ABC},$$

$$g_{AB}\equiv\frac{6\phi_*^0}{(1+x)^2}[\kappa\,E_{AB}(\phi_*)-(1+x)E_{AB}(p)],$$

$$g_A\equiv-\frac{3\,x}{(1+x)^2}\left[\kappa(x+2)\{E_{AB}(\phi_*)\phi_*^B-E_{AB}(p)p^B\}-2(1+x)E_{AB}(p)\phi_*^B-\kappa\frac{x+2}{3}E_{2A}\right],$$

$$g\equiv\frac{x^2}{(1+x)^2}\frac{1}{\phi_*^0}[\{\,E(p)(1+x)+\kappa\,E(\phi_*)(3+2\,x)\}-3\{(1+x)E_{AB}(p)\phi_*^A\phi_*^B$$
$$+\kappa(3+2\,x)E_{AB}(\phi_*)p^Ap^B\}+\{(1+x)E_{2A}p^A-\kappa(3+2\,x)E_{2A}\phi_*^A\}],$$

we obtain

$$G(\eta)=S+g+g_A\,x^A+\frac{1}{2}g_{AB}\,x^Ax^B+g_{ABC}\,x^Ax^Bx^C.$$

Subsequently, (1.5) is given by

$$\Omega\doteq e^S(\phi_*^0)^{h+1}\int\mathrm{d}x\,e^g\int[\mathrm{d}x^A]\,e^{g_Ax^A+\frac{1}{2}g_{AB}x^Ax^B+g_{ABC}x^Ax^Bx^C}$$

$$=e^S(\phi_*^0)^{h+1}\int\mathrm{d}x\,e^g\int[\mathrm{d}x^A]e^{g_Ax^A+\frac{1}{2}g_{AB}x^Ax^B}$$
$$\times[1+g_{ABC}x^Ax^Bx^C+O(\kappa^2)]$$

$$\doteq e^S(\phi_*^0)^{h+1}\int\mathrm{d}x\frac{1}{\sqrt{\det[g_{AB}]}}e^g\left(1+g_{ABC}\frac{\partial^3}{\partial g_C\,\partial g_B\,\partial g_A}\right)$$
$$\times e^{-\frac{1}{2}g_Ag^{AB}g_B}$$

$$\ddot{=} e^S (\phi_*^0)^{h+1} \int \mathrm{d}x \frac{1}{\sqrt{\det[g_{AB}]}} e^{T_1}(1 + T_2 + T_3),$$

where

$$T_1 = g - \frac{1}{2} g_A g^{AB} g_B,$$

$$T_2 = 3 g_{ABC} g^{AB} g^{CV} g_V,$$

$$T_3 = - g_{ABC} g^{AM} g^{BN} g^{CV} g_M g_N g_V,$$

and the sign "$\ddot{=}$" meaning "$\doteq$" up to $O(\kappa^2)$. Now to proceed further and check whether the above result is of the form (5.1), we need to know some concrete information about how g^{AB} and S depend on E_{ABC}, E_{2A}, and the black hole charges. In that respect, a helpful choice for us is to set

$$\phi_*^A = p^A$$

according to which the attractor equations are equivalent to

$$q_A = \frac{6}{\phi_*^0} p_A + \frac{p^0}{(\phi_*^0)^2} E_{2A},$$

$$q_0 = - \frac{1}{(\phi_*^0)^2} [2(1 + 2\kappa) E(p) - (1 - 2\kappa) E_{2A} p^A],$$

and the entropy reads as

$$S = \frac{2}{\phi_*^0} [(1 - 3\kappa) E(p) + (1 - \kappa) E_{2A} p^A]. \tag{5.5}$$

Now $\{g, g_A, g_{AB}, T_1, T_2, T_3\}$ is given by

$$g_{AB} = - 6 \ \phi_*^0 \frac{1 + x - \kappa}{(1 + x)^2} E_{AB},$$

$$g = \frac{x^2}{(1 + x)^2} \frac{1}{\phi_*^0} [- 2 \ E(p) \{1 + x + 3\kappa + 2\kappa x\} + E_{2A} p^A \{1 + x - 3\kappa - 2\kappa x\}],$$

$$T_1 \ddot{=} \frac{x^2}{1 + x} \left[\left\{ 1 - \kappa \frac{3 + 4x}{1 + x} \right\} + (1 - \kappa) E_{2A} p^A \right] \frac{1}{\phi_0^*}, \tag{5.6}$$

$$T_2 \ddot{=} \kappa \frac{x}{1 + x} \frac{h}{2},$$

$$T_3 \ddot{=} \kappa \frac{x^3}{(1 + x)^2} \frac{E(p)}{\phi_*^0}.$$

Thus the final expression for Ω is obtained as

$$\Omega \ddot{=} e^S (\phi_*^0)^{\frac{h}{2}+1} \frac{1}{\sqrt{\det[E_{AB}]}} \int \mathrm{d}x (1 + x)^{\frac{h}{2}} \ e^{T_1} \left[1 + \kappa \frac{h}{2(1 + x)} + T_2 + T_3 \right]$$

$$\ddot{=} e^{S}(\phi_*^0)^{\frac{h}{2}+1}\frac{1}{\sqrt{\det[E_{AB}]}}\int \mathrm{d}x(1+x)^{\frac{h}{2}}\, e^{T_1}\left[1+\kappa\left\{\frac{h}{2}+\frac{x^2}{(1+x)^2}\frac{E(p)}{\phi_0^*}\right\}\right]. \tag{5.7}$$

Now from (5.5) and (5.6) it is obvious that (5.7) does not admit the form (5.1). Indeed, if it were the case, it would be so for any h, implying that

$$\int \mathrm{d}x(1+x)^{\frac{h}{2}}\, e^{T_1}$$

itself is of the form (5.1), which is not the case![9]

As we learn from the above examples, for black holes with nonvanishing p^0 there is no guarantee that the result of (1.5) be of the form (5.1), if one incorporates the subleading terms of the saddle-point asymptotic expansion. As a consequence, even a generalization of type (1.6) or (4.8) does not restore the electric-magnetic duality. That is so because if the corresponding metric/Jacobian determinant does not change the saddle point of the integrand in (1.5), then it cannot remove more than one noninvariant factor from the OSV result, and if it changes the saddle point of the integrand, then the leading term of the asymptotic expansion does not match microcanonically with the Bekenstein-Hawking-Wald entropy. It seems that this observation opens the possibility of deeper modifications.

VI. AN EFFECTIVE APPROACH

The ensemble defined through (4.1) and (4.4) is canonic in as many variables as the OSV ensemble, that is, by construction the set of electric potentials is mapped one to one to the set of new variables ψ^Λ. However, since the multiplet (CX^Λ, CF_Λ) defines a vector under the symplectic transformations, it is more natural for a black hole ensemble to treat both the magnetic and the electric charges at the same footing, if it is requested to produce symplectic invariant results. In that direction, the simplest generalization of (1.5) is an inverse Laplace transformation from $Z_{\text{invari}} \equiv e^G$, which integrates over both the $\Re X \equiv \mu$ and $\Im X \equiv \phi$ with an appropriate Jacobian/measure, such that

$$[\mathrm{d}\mu_\Lambda][\mathrm{d}\phi^\Lambda]\, J(\mu,\phi) \tag{6.1}$$

defines a symplectic invariant measure. In (6.1), $J(\mu,\phi)$ appears either as a Jacobian when we change variables from those that originally define the ensemble to (μ,ϕ) or as an intrinsic measure. As it is well known, one choice for the measure of (6.1) that is invariant under the symplectic transformations is

$$[\mathrm{d}\mu_\Lambda][\mathrm{d}\phi^\Lambda]\det(\Im F_{\Lambda\Gamma}), \tag{6.2}$$

where

$$F_{\Lambda\Gamma} \equiv \frac{\partial^2 F}{\partial X^\Lambda\, \partial X^\Gamma}. \tag{6.3}$$

(6.2) is used, for example, as the intrinsic measure of the ensemble introduced in Ref. 29. However, this measure vanishes for the case of $\frac{1}{2}$BPS black holes, so is not universally applicable. In fact, a satisfactory universal measure has not been presented so far. Moreover, even if we apply such a measure, to respect the electric-magnetic duality we need to introduce a symplectic invariant free energy G. Thus regarding the fact that the OSV free energy, which, as given by (1.3) and (1.4), forms the essence of the OSV proposal, and is only symplectic invariant at the attractor point, we take a more conservative approach in what follows. That is, to enjoy the proposed relationship between the topological-string free energy and the black hole physics within a mani-

[9]The saddle point is $x=0$. At the leading order, the saddle approximation of (5.7) takes the form of (5.1), but this fails in the subleading orders.

fest symmetric approach, we keep the OSV free energy unchanged but introduce an enlarged ensemble which is twice the OSV ensemble big, in phase space terminology. This is done by associating to each doublet $(\mu^\Lambda, \phi^\Lambda)$, two canonical variables $(\chi_\Lambda, \zeta^\Lambda)$, which preserve the Legendre transformation from the OSV free energy to the black hole entropy. Obviously the simplest choice of such variables is to take them to be linear in ϕ^Λ. Thus we define an invertible change of variables as

$$\chi_\Lambda \equiv A(p,q)\phi^\Lambda f_\Lambda(\mu^\Lambda), \quad \xi^\Lambda \equiv A(p,q)\phi^\Lambda g^\Lambda(\mu^\Lambda), \quad \forall\, \Lambda, \tag{6.4}$$

with

$$\widetilde{\mathcal{F}}(\chi_\Lambda, \xi^\Lambda) = \mathcal{F}(\mu^\Lambda, \phi^\Lambda), \tag{6.5}$$

so that the Bekenstein-Hawking-Wald entropy is given by

$$S(p^\Lambda, q_\Lambda) = \widetilde{S}(\alpha^\Lambda, \beta_\Lambda) = \widetilde{\mathcal{F}}(\chi_\Lambda, \xi^\Lambda) + \pi\alpha^\Lambda\chi_\Lambda + \pi\beta_\Lambda\xi^\Lambda, \tag{6.6}$$

$$-\alpha^\Lambda = \frac{\partial\widetilde{\mathcal{F}}}{\partial\chi_\Lambda}, \quad -\beta_\Lambda = \frac{\partial\widetilde{\mathcal{F}}}{\partial\xi^\Lambda}, \tag{6.7}$$

where the exact dictionary for translating the expressions in terms of the new charges (α, β) to those in terms of the black hole electric magnetic charges will be given a bit later in this section.

Based on (6.6) and (6.7), a black hole ensemble is defined as

$$\widetilde{Z} \equiv e^{\widetilde{\mathcal{F}}(\chi_\Lambda, \xi^\Lambda)} = \sum_{\alpha^\Lambda, \beta_\Lambda} \widetilde{\Omega}(\alpha^\Lambda, \beta_\Lambda) e^{-\pi\alpha^\Lambda\chi_\Lambda - \pi\beta_\Lambda\xi^\Lambda}. \tag{6.8}$$

As before we use the Euclidean measure for the ensemble (6.8), so that

$$d(p^\Lambda, q_\Lambda) \doteq \widetilde{\Omega}(\alpha^\Lambda, \beta_\Lambda) \doteq \int [\mathrm{d}\chi_\Lambda][\mathrm{d}\xi^\Lambda] e^{\widetilde{\mathcal{F}} + \pi\alpha^\Lambda\chi_\Lambda + \pi\beta_\Lambda\xi^\Lambda}. \tag{6.9}$$

Although the measure of (6.9),

$$\prod_\Lambda \mathrm{d}\chi_\Lambda\, \mathrm{d}\xi^\Lambda = A^2(p,q) \prod_\Lambda \phi^\Lambda (f_\Lambda g'^\Lambda - f'_\Lambda g^\Lambda) \mathrm{d}\mu^\Lambda\, \mathrm{d}\phi^\Lambda, \tag{6.10}$$

is not universally symplectic invariant, unlike (6.2), we can follow the idea of Sec. IV: we require the asymptotic symplectic invariance of (6.9). More precisely, given an arbitrary order in the saddle-point asymptotic expansion of (6.9), we choose the function $A(p,q)$, in the definition (6.4), such that the unwanted prefactor of the corresponding OSV result is removed.

The integral (6.9) in terms of (μ, ϕ) takes the form

$$d(p,q) \doteq A^2(p,q) \int \prod_\Lambda [\mathrm{d}\phi^\Lambda\ \phi^\Lambda] \int \prod_\Lambda [\mathrm{d}\mu^\Lambda (f_\Lambda g'^\Lambda - f'_\Lambda g^\Lambda)] Z(\mu,\phi) e^{\pi A \phi^\Lambda (\alpha^\Lambda f_\Lambda + \beta_\Lambda g^\Lambda)}, \tag{6.11}$$

where $Z(\mu,\phi) = e^{\mathcal{F}(\mu,\phi)}$. Now to bridge between (6.11) and (1.5), we should effectively integrate over μ^Λ, which fixes the value of μ^Λ at μ^Λ_*. Here one important constraint on the functions f_Λ and g^Λ comes into play. First of all, in accordance with (1.2), we require that the saddle-point values of μ^Λ's coincide with the corresponding black hole magnetic charges,

$$\mu^\Lambda_* = p^\Lambda, \quad \forall\, \Lambda. \tag{6.12}$$

Regarding the saddle-point equation for (6.11), (6.12) implies that

$$\alpha^{\Lambda} f'_{\Lambda}(p) + \beta_{\Lambda} g'^{\Lambda}(p) = 0, \quad \forall\, \Lambda. \tag{6.13}$$

Next we require that the saddle-point evaluation of (6.11) takes the form of

$$\Omega(p^{\Lambda}, q^{\Lambda}) \doteq \int [\mathrm{d}\phi^{\Lambda}] M(p,q,\phi) e^{\mathcal{F}+\pi q_{\Lambda}\phi^{\Lambda}}, \tag{6.14}$$

which together with (6.12) implies that

$$\frac{q_{\Lambda}}{A(p,q)} = \alpha^{\Lambda} f_{\Lambda}(p) + \beta_{\Lambda} g^{\Lambda}(p), \quad \forall\, \Lambda. \tag{6.15}$$

The dictionary between (α,β) and (p,q) is now given by the solution to the Eqs. (6.13) and (6.15), which reads as

$$\alpha^{\Lambda} = \frac{q_{\Lambda}}{A(p,q)} \frac{g'^{\Lambda}(p)}{f_{\Lambda}(p) g'^{\Lambda}(p) - f'_{\Lambda}(p) g^{\Lambda}(p)}, \tag{6.16}$$

$$\beta_{\Lambda} = \frac{q_{\Lambda}}{A(p,q)} \frac{-f'^{\Lambda}(p)}{f_{\Lambda}(p) g'^{\Lambda}(p) - f'_{\Lambda}(p) g^{\Lambda}(p)}. \tag{6.17}$$

Now as a constraint on the functions f and g, we require that Eqs. (6.16) and (6.17) are consistent with the attractor equations of (6.7), for $A(p,q)$ treated as an arbitrary given function. That is, the following two equations should hold:

$$\frac{\partial \widetilde{\mathcal{F}}}{\partial \chi^{*}_{\Lambda}} = -\frac{q_{\Lambda}}{A(p,q)} \frac{g'^{\Lambda}(p)}{f_{\Lambda}(p) g'^{\Lambda}(p) - f'_{\Lambda}(p) g^{\Lambda}(p)}, \tag{6.18}$$

$$\frac{\partial \widetilde{\mathcal{F}}}{\partial \xi^{\Lambda}_{*}} = \frac{q_{\Lambda}}{A(p,q)} \frac{f'^{\Lambda}(p)}{f_{\Lambda}(p) g'^{\Lambda}(p) - f'_{\Lambda}(p) g^{\Lambda}(p)}, \tag{6.19}$$

with $\chi^{*}_{\Lambda} = A\phi^{\Lambda}_{*} f_{\Lambda}(p^{\Lambda})$, $\xi^{\Lambda}_{*} = A\phi^{\Lambda}_{*} g^{\Lambda}(p^{\Lambda})$ and $q_{\Lambda} = -\frac{1}{\pi}\frac{\partial \mathcal{F}}{\partial \phi^{\Lambda}_{*}}$.

Given these requirements, the first order saddle-point evaluation of (6.11) takes the form of (6.14) with

$$M(p,q,\phi) = A^{2h+2}(p,q) \prod_{\Lambda} \left[\left(\frac{\phi^{\Lambda}}{q_{\Lambda}} \right)^{\frac{1}{2}} \frac{\left(f_{\Lambda}(p) g'^{\Lambda}(p) - g^{\Lambda}(p) f'_{\Lambda}(p) \right)^{\frac{3}{2}}}{\left(f''_{\Lambda}(p) g'^{\Lambda}(p) - g''^{\Lambda}(p) f'_{\Lambda}(p) \right)^{\frac{1}{2}}} \right]. \tag{6.20}$$

So, the effective inverse Laplace transformation, (6.14), differs from the original OSV formula, (1.5), by a measure M, which in form is something between the metric measure of (1.6) and the Jacobian matrix in (4.8).

Now given a specific prepotential and an arbitrary order of the saddle-point asymptotic expansion of (6.14), the measure (6.20) equals

$$\grave{M}(p,q) \equiv M(p,q,\phi_{*}) = A^{2h+2}(p,q) \prod_{\Lambda} \left[\frac{\left(f_{\Lambda}(p) g'^{\Lambda}(p) - g^{\Lambda}(p) f'_{\Lambda}(p) \right)^{\frac{3}{2}}}{\left(f''_{\Lambda}(p) g'^{\Lambda}(p) - g''^{\Lambda}(p) f'_{\Lambda}(p) \right)^{\frac{1}{2}}} \sqrt{\frac{\phi^{\Lambda}_{*}}{q_{\Lambda}}} \right], \tag{6.21}$$

$$\tilde{\Omega}_* = \grave{M}(p,q)\Omega_*. \tag{6.22}$$

It is obvious that $\grave{M}(p,q)$ plays the same role as $\det[V]$ of Sec. IV and protects the resulting black hole degeneracy of states against the electric-magnetic duality violations by removing the unwanted prefactors, with a proper choice of the function $A(p,q)$.

VII. CONCLUSION

We studied the issue of electric-magnetic duality in the OSV proposal, as it appears as itself in the complex polarization. The main conclusion of the work is as follows:

Applying the duality invariance of the degeneracy of states as a constraint to the definition of the ensemble variables, there are proper redefinitions of the OSV mixed ensemble in the complex polarization, in the form of a generalized purlye canonical ensemble of new variables such that the results of the inverse Laplace transformation with a flat measure of integration respect the electric-magnetic duality and match properly the known microscopic results, to all orders in the asymptotic expansion, as far as the D6-brane charge vanishes. With a nonvanishing D6-brane charge, however, the duality restoration is limited to the saddle-point evaluation.

Here we would like to mention an independent and equivalent way to define these new variables more systematically. We note the fact that the integrand of (1.5), $[\mathrm{d}\phi]e^G$, is not invariant under the symplectic transformations, and this noninvariance depends on the detail of the charge configuration. So we look for $\det[V] \doteq J(p,q,\phi_*)$, which, up to vanishing boundary terms, solves the equation

$$\delta_T\{[d\phi]J(p,q,\phi)e^{G(p,q,\phi)}\} = 0 \Leftrightarrow \det\left[\frac{\partial \breve{\phi}^\Lambda}{\partial \phi^\Gamma}\right]\breve{J}e^{\breve{G}} = Je^G \Rightarrow \det\left[\frac{\partial \breve{\phi}^\Lambda}{\partial \phi^\Gamma}\right]_* = \frac{J_*}{\breve{J}_*}, \tag{7.1}$$

with T denoting a general member of the relevant symplectic transformations that brings (X^Λ, F_Λ) to $(\breve{X}^\Lambda, \breve{F}_\Lambda)$. For example, if we consider the large black hole of section 3 in the specific case of $K3$ fiberation where T-duality holds as the symmetry of the action, taking for simplicity the only nonvanishing intersection numbers to be $C_{ABC}=C_{1ab}\equiv C_{ab}$, it is easy to see that, for an infinitesimal transformation T, (7.1) leads to the result

$$J_* = \frac{1}{(p^1)^2} f(|\vec{p}|),$$

where $\vec{p}\equiv(p^2,\ldots,p^h)$ and $|\vec{P}|^2 \equiv C_{ab}p^a p^b$. We note that the inverse of the OSV prefactor for this example exactly matches with this result.

We would like to finally bring the reader's attention to the following possibility.

To define the ensemble of Secs. III and IV, one can absorb the unwanted OSV prefactor within the redefinition of a single X variable. Among the X variables, X^0, which controls the topological-string coupling via (4.18), plays a distinguished role in the prepotential (5.2). It is physically natural to think about a redefinition of the OSV ensemble as $\hat{X}^0 = M(p,q)X^0$, according to (4.17), and ask if for a given black hole charge multiplet (p^Λ, q_Λ), the requirement of the electric-magnetic duality gives an effective sense to the topological-string coupling as seen by the black hole ensemble through the identification $\hat{g} \equiv \frac{4\pi i}{\hat{X}^0}$.

Fractional Israel layers

J. P. Krisch[a)]
Department of Physics, University of Michigan, Ann Arbor, Michigan 48109

(Received 5 June 2006; accepted 14 October 2006; published online 22 December 2006)

A fractional Lie derivative, valid in the thin shell limit, is developed. The nonlocal nature of the fractional derivative allows the inclusion of shell thickness in the stress energy description of zero thickness Israel layers. The method is applied to several examples. © *2006 American Institute of Physics.*

I. INTRODUCTION

Derivatives of fractional order, first described in 1695 by Leibnitz,[1,2] have been successful in modeling transport processes with anomalous microscopic time and/or spatial structures.[3–6] Among the transport applications are diffusion equations fractional in both time and spatial coordinates[7–9] and fractional Schrödinger equations;[10,11] there are applications in biophysics and thermodynamics[12] as well as texts[13,14] on solving the fractional differential equations arising in transport. Other areas of application are the inclusion of dissipative processes in a Lagrangian formalism by introducing fractional derivatives as generalized coordinates[15,16] and the use of a fractional derivative in the metric match over a boundary layer[17,18] in general relativity.

The field equations of general relativity are not easily fractionally generalized because of the covariance requirement on derivatives. The general relativity (GR) applications in Refs. 17 and 18 did not modify the field equations or any of the usual GR tensors in any way; the fractional match simply provided a broader set of metric relations across a boundary. It was used to create a family of Israel layers parametrized by the noninteger order of the fractional derivative. There are, however, geometric objects used in general relativity, which can be fractionalized without altering the basic covariant structure of the theory. One of these is the Lie derivative, defined only with partial derivatives. The Lie derivatives take into account the difference between a tensor that is Taylor transported to a point and coordinate transformed at the same point. It is a local derivative. Fractional derivatives are intrinsically nonlocal, involving an integral over some region of space time. A fractional Lie derivative, while it also evaluates functional differences at a point, since it is nonlocal in its definition, could be a useful way of including nonlocal effects in single layer calculations. For example, the Israel formalism calculates the stress energy content of a single layer in terms of the jump in extrinsic curvatures across a boundary. Using a fractional Lie derivative to define a fractional extrinsic curvature would allow the inclusion of shell thickness in the standard Israel formalism. In the next section we develop a fractional Lie derivative valid to first order in a thin shell thickness. The formalism is used to describe the stress energy content of some simple fractional layers. A brief list of notation is included in the Appendix.

II. LIE DERIVATIVE

A. The integer Lie derivative

The Lie derivative compares the value of a function under transport from x to x' and under a coordinate transform from a system of coordinates (x) to a primed system (x'). The difference $V^i(x')-V'^i(x')$ defines the Lie derivative. Consider a vector V^i at a point x. Under a coordinate transform, $x^{i\prime}=x^i+\xi^i d\lambda$, its value transforms as

[a)]Electronic mail: jkrisch@umich.edu

$$V'^{i}(x') = \frac{\partial x'^{i}}{\partial x^{a}} V^{a}(x) = \left(\delta^{i}_{a} + \frac{\partial \xi^{i}}{\partial x^{a}} d\lambda \right) V^{a}(x), \tag{1}$$

where ξ^i is the tangent to the transport path. The vector is assumed to be analytic and we have

$$V^{i}(x') = V^{i}(x) + \left(\frac{\partial V^{i}}{\partial x'^{a}} \right)_{x} (x'^{a} - x^{a}) + \cdots . \tag{2}$$

Using Eq. (1), the Lie derivative to first order in ξ^i is

$$(\mathcal{L}_{\xi} V^{i}) = \lim_{d\lambda \to 0} \frac{V^{i}(x') - V'^{i}(x')}{d\lambda},$$

$$(\mathcal{L}_{\xi} V^{i}) = \left(\frac{\partial V^{i}}{\partial x'^{a}} \right)_{x} \xi^{a} - \left(\frac{\partial \xi^{i}}{\partial x'^{a}} \right)_{x} V^{a}(x).$$

Similar expressions exist for covariant vectors and tensors of higher order. For a scalar function, F, the Lie derivative is a simple directional derivative.

$$(\mathcal{L}_{\xi} F) = \xi^{a} \left(\frac{\partial F}{\partial x'^{a}} \right)_{x}.$$

B. Fractional generalization

1. Fractional derivative

There are several choices to make in developing a fractional Lie derivative. The first is to choose the type of fractional derivative from among the many available. We will use the Caputo form of the fractional derivative. The Caputo fractional derivative integrates the derivative of the function while other forms take the derivative of the function integral. Among the many fractional derivative operators, the Caputo form is the closest generalization of the classical derivative.[13] We generalize the usual form by using partial derivatives. With q as the fractional parameter, the Caputo derivative is defined for $0 < q \leqslant 1$ as

$$D^{q}_{x} V^{i}(x') = \frac{\partial^{q} V^{i}(x')}{\partial (x' - x)^{q}} = \frac{1}{\Gamma(1-q)} \int_{x}^{x'} dy \frac{\partial V^{i}(y)}{\partial y} (x' - y)^{-q}. \tag{3}$$

The derivative can be extended to values of $q > 1$; this is discussed in the Appendix. The indices, (q,x), on D^q_x are not tensor indices. q is the fractional parameter and x is the lower limit in the integral definition. The choice of limits depends on the application being made. Our development will be for applications to thin layers of thickness Δ. The coordinates near the shell are (t, η, x^3, x^4). The spatial coordinates in the layer are (x^3, x^4). The radial coordinate, η, is measured to the outer shell boundary, $\eta = R_o$. The integration will run from the bottom of the layer, $x = \eta - \Delta$, to the top, $x' = \eta$, with $\eta = R_o$ when the outer boundary size is set. With these choices, the fractional derivative definition that will be used is

$$D^{q}_{\eta - \Delta} V^{i}(\eta) = \frac{1}{\Gamma(1-q)} \int_{\eta - \Delta}^{\eta} dy \frac{\partial V^{i}(y)}{\partial y} (\eta - y)^{-q}. \tag{4}$$

The other parts of the fractional generalization to consider are the tensor transformation rule and the first terms of a fractional expansion of the tensor. These parts depend on the fractional replacement for the partial derivative.

2. Partial derivative and fractional derivative

A relation between a partial derivative and a fractional derivative can be obtained by integrating Eq. (3) by parts. We have

$$D_x^q V^i(x') = \frac{(x'-x)^{1-q}}{\Gamma(2-q)}\left(\frac{\partial V^i(y)}{\partial y}\right)_x + \frac{(x'-x)^{2-q}}{\Gamma(3-q)}\left(\frac{\partial^2 V^i(y)}{\partial y^2}\right)_x + \cdots \tag{5}$$

In the limit, $x'-x \ll 1 (\Delta \ll 1)$, the first term will dominate and we have the relation between the fractional derivative and the partial derivative to lowest order in shell thickness.

$$\frac{(\Delta)^{1-q}}{\Gamma(2-q)}\left(\frac{\partial V^i(y)}{\partial y}\right)_{\eta-\Delta} \to D_{\eta-\Delta}^q V^i(\eta). \tag{6}$$

For convenience, we define a fractional operator Đ_x^q,

$$D_x^q(\,) = \frac{(x'-x)^{1-q}}{\Gamma(2-q)}\text{Đ}_x^q(\,). \tag{7}$$

In the $q=1$ limit, the usual derivative is obtained. The Đ_x^q derivative used over a nonthin shell region, for some functions, can divide out much of the usual fractional behavior and will be used to provide the direct replacement for the partial derivative for layer examples.

3. The first order fractional expansion

For analytic V^i, the regular Taylor expansion is

$$V^i(x') = V^i(x) + \left(\frac{\partial V^i(y)}{\partial y}\right)_x (x'-x) + \cdots \tag{8}$$

Using the fractional replacement the expansion can be written to first order as

$$V^i(x') = V^i(x) + \text{Đ}_x^q(V^i)(x'-x) + \cdots \tag{9}$$

Note that this is not a replacement for the regular Taylor expansion, complete to all orders. It will be used only to first order in the shell thickness. A complete fractional expansion was developed by Taylor and Riemann.[19] Their expansion, including both fractional integrals and derivatives, is difficult to implement. Kolwankar[20] have also developed a local fractional expansion.

4. A notation addition

The general fractional derivative

$$D_x^q V^i(x') = \frac{\partial^q V^i(x')}{\partial(x'-x)^q} = \frac{1}{\Gamma(1-q)}\int_x^{x'} dy \frac{\partial V^i(y)}{\partial y}(x'-y)^{-q}$$

is not written with tensor functions in mind. For example, if $V^i(x')=x'^i$ we have

$$D_x^q x'^i = \frac{\partial^q x'^i}{\partial(x'-x)^q} = \frac{1}{\Gamma(1-q)}\int_x^{x'} dy \frac{\partial y^i}{\partial y}(x'-y)^{-q},$$

where i has the usual coordinate index range (1, 2, 3, 4) but the coordinate identification of x' and its integral counterpart, y, is not clear. To clarify this an index k is added to the fractional derivative notation, allowing the partial derivative to be written in index notation

$$D_{x,k}^q x'^i = \frac{\partial^q x'^i}{\partial(x'^k - x^k)^q} = \frac{1}{\Gamma(1-q)}\int_x^{x'} dy \frac{\partial y^i}{\partial y^k}(x'-y)^{-q}. \tag{10}$$

A similar notation is used by Samko *et al.*[2] With this notation and using the incomplete beta function, the integral in Eq. (10) is

$$D^q_{x,k}x'^i = \frac{\partial^q x'^i}{\partial(x'^k - x^k)^q} = \frac{\delta^i_k}{\Gamma(1-q)}\int_x^{x'} dy(x'-y)^{-q} = \frac{\delta^i_k(x'-x)^{1-q}}{\Gamma(2-q)}. \tag{11}$$

5. The coordinate transformation

The remaining step is to consider the transport as a coordinate transformation. The usual tensor transformation rule can be written as

$$V^i(x) = \frac{\partial(x^i - x^i_o)}{\partial(x'^k - x'^k_o)}V'^k(x'), \tag{12}$$

where x^i_o and x'^i_o are the initial points in the two systems. The partial derivative in the transformation rule generalizes to

$$\frac{\partial(x^i)}{\partial(x'^k - x^k)} \to Đ^q_{x,k}(x^i) \tag{13}$$

and we have

$$V^i(x) = D^q_{x,k}(x^i)V'^k(x') = \frac{\Gamma(2-q)}{(x'-x)^{1-q}}\frac{\partial^q(x^i)}{\partial(x'^k - x^k)^q}V'^k(x'). \tag{14}$$

Substituting from the coordinate transformation one obtains

$$V^i(x) = \frac{\Gamma(2-q)}{(x'-x)^{1-q}}\left\{\frac{\partial^q(x'^i)}{\partial(x'^k - x^k)^q} - \frac{\partial^q(\xi^i d\lambda)}{\partial(x'^k - x^k)^q}\right\}V'^k(x'). \tag{15}$$

The first integral is evaluated above giving

$$V^i(x) = V'^i(x') - Đ^q_{x,k}(\xi^i)d\lambda V'^k(x').$$

For the layer application this becomes

$$V^i(\eta - \Delta) = V'^i(\eta) - Đ^q_{\eta-\Delta,k}(\xi^i)d\lambda V'^k(\eta). \tag{16}$$

A fractional coordinate transformation has been considered by Cotrill-Shepherd and Naber.[21] Their transformation takes a fractional coordinate differential $d^q x^i$ to another $d^q y^i$ in n dimensions. For $q \leqslant 1$ their transformation can be written as

$$dx^{q,k} = \sum_{i=1}^{n} dy^{q,i}\frac{1}{\Gamma(1+q)}\frac{1}{\prod_{p=1 p\neq k}^{n}(x^p - x^p_o)^{q-1}}\frac{\partial\left\{\prod_{j=1 j\neq k}^{n}(x^j - x^j_o)^{q-1}(x^k - x^k_o)^q\right\}}{\partial(y^i - x'^i_o)^q}, \tag{17}$$

where x^i_o and x'^i_o are the initial points for the coordinate systems. In addition to the obvious term differences, this transformation is not an approximation but an exact transformation for a fractional differential defined on a fractional tangent space. The transformation used to develop the fractional Lie derivative in this paper is the fractional derivative of a regular function; it is not complete but only considers the first order terms in the shell thickness.

6. The fractional Lie derivative

Using Eqs. (8) and (16) and equating $V^i(x)$ we have

$$V^i(x') - \mathcal{D}^q_{x,k}(V^i)(x'^k - x^k) = V'^i(x') - \mathcal{D}^q_{x,k}(\xi^i)d\lambda V'^k(x'). \tag{18}$$

The Lie derivative comes from the difference $V^i(x') - V^{i'}(x')$. Forming the difference we have

$$V^i(x') - V'^i(x') = d\lambda\{\mathcal{D}^q_{x,k}(V^i)\xi^k - \mathcal{D}^q_{x,k}(\xi^i)V^k\}. \tag{19}$$

The fractional Lie derivative ${}^q\mathcal{L}_\xi(V^i)$ is

$${}^q\mathcal{L}_\xi V^i = \mathcal{D}^q_{x,k}(V^i)\xi^k - \mathcal{D}^q_{x,k}(\xi^i)V^k. \tag{20}$$

Similar development results in the fractional Lie derivative forms for covariant vectors and higher order tensors. The fractional Lie derivative of V_i is

$${}^q\mathcal{L}_\xi V_i = \mathcal{D}^q_{x,k}(V_i)\xi^k + \mathcal{D}^q_{x,i}(\xi^k)V_k. \tag{21}$$

The simplest case, a scalar function, has fractional Lie derivative

$${}^q\mathcal{L}_\xi f = \xi^k\mathcal{D}^q_{x,k}(f). \tag{22}$$

Some properties of the fractional Lie derivative are discussed in the Appendix.

III. A FRACTIONAL THIN LAYER

A. Describing the layer

Many of the thin shell examples considered in the literature[22–34] are descriptions of a boundary layer between two space times, $M^\pm$. Boundary layers are often treated in the Israel formalism[35] which models a thin shell as a layer of zero thickness. The basic input into this description is the extrinsic curvature of the boundary layer as seen by the bounding space times.

$$K^\pm_{cd} = \frac{1}{2}\mathcal{L}_N(g^\pm_{ij})h^{\pm i}_c h^{\pm j}_d, \tag{23}$$

where c,d range over the coordinates of the boundary layer, N^i is the normal to the layer, and h_{ij} is the projection operator onto the layer,

$$h^\pm_{ij} = g^\pm_{ij} - N^\pm_i N^\pm_j. \tag{24}$$

The jump in the extrinsic curvatures, $\langle K_{ab}\rangle = K^+_{cd} - K^-_{cd}$, and their trace $\langle K\rangle = K^+ - K^-$ are related to the stress energy of the single boundary layer.[35]

$$-8\pi S_{ab} = \langle K_{ab}\rangle - \langle K\rangle h_{ab}. \tag{25}$$

The fractional extrinsic curvature is defined in terms of the fractional Lie derivative.

$${}^qK_{cd} = \frac{1}{2}{}^q\mathcal{L}_N(g_{ij})h^i_c h^j_d, \tag{26}$$

where

$${}^q\mathcal{L}_N(g_{ij}) = N^k\mathcal{D}^q_{x,k}(g_{ij}) + g_{kj}\mathcal{D}^q_{x,i}(N^k) + g_{ik}\mathcal{D}^q_{x,j}(N^k) \tag{27}$$

and Eq. (7) relates $\mathcal{D}^q_{x,k}$ to the fractional derivative form. The fractional stress energy is defined through jumps in the fractional extrinsic curvature,

$$-8\pi {}^qS_{ab} = \langle {}^qK_{ab}\rangle - \langle {}^qK\rangle h_{ab}. \tag{28}$$

B. Using the fractional extrinsic curvature

The fractional extrinsic curvature is defined as an integral over a shell of thickness Δ. Because of this nonlocal integral structure, one might assume that the usual Israel jump in extrinsic curvature could be replaced by a single extrinsic curvature calculation. However, just as for the regular Lie derivative, the fractional Lie derivative, while it includes a thickness component, only provides the value of the derivative at a single space-time point. For example, consider a shell bounded by two Minkowski space times. We would expect no jump discontinuities across such a boundary.

$$M^{\pm}: ds^2 = -dt^2 + dr^2 + r^2 d\Omega^2. \tag{29}$$

The unit normal to the shell is $N^i=(0,1,0,0)$. ${}^qK_{\theta\theta}$ and ${}^qK_{\phi\phi}$ will be nonzero for each of Minkowski boundaries. Using Eqs. (7), (26), and (27), with $\eta=r$, the fractional extrinsic curvature is

$${}^qK_{cd} = \frac{\Gamma(2-q)}{2(\Delta)^{1-q}} N^r D^q_{r-\Delta,r}(g_{ij}) h^i_c h^j_d. \tag{30}$$

For Minkowski we have

$$\begin{aligned} {}^qK^M_{\theta\theta} &= \frac{\Gamma(2-q)}{2\Gamma(1-q)(\Delta)^{1-q}} \int_{r-\Delta}^{r} dy 2y(r-y)^{-q}, \\ {}^qK^M_{\theta\theta} &= \frac{\Gamma(2-q)2R_o^{2-q}}{2\Gamma(1-q)(\Delta)^{1-q}} B_{\Delta/R_o}(1-q,2), \end{aligned} \tag{31}$$

where $B_{\Delta/R}(1-q,2)$ is the incomplete beta function and r was set equal to the boundary value, R_o.

$$B_x(a,b) = \int_0^x t^{a-1}(1-t)^{b-1}.$$

Using the beta function expansion[36]

$$B_x(a,b) = x^a\left(\frac{1}{a} + \frac{1-b}{a+1}x + \frac{(1-b)(2-b)}{2!(a+2)}x^2 + \cdots\right), \tag{32}$$

we have

$${}^qK^M_{\theta\theta} = \frac{\Gamma(2-q)2R_o^{2-q}}{2\Gamma(1-q)(\Delta)^{1-q}}\left(\frac{\Delta}{R_o}\right)^{1-q}\left(\frac{1}{1-q} - \frac{1}{2-q}\frac{\Delta}{R_o} + \cdots\right),$$

$${}^qK^M_{\theta\theta} \sim R_o\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right). \tag{33}$$

Because of the integral over the shell, this single extrinsic curvature might be regarded as the entire jump contribution. However, if there were no boundary layer between the two space times, one would expect the jump in the extrinsic curvatures to be zero. Instead, the fractional extrinsic curvature, in the $\Delta->0$ limit, is simply the regular extrinsic curvature evaluated over the outer bounding surface. The expression above is only the extrinsic curvature evaluated with one of the bounding space times. In order to use the fractional extrinsic curvature in an Israel layer calculation, it has to be calculated for both interior and exterior boundaries, just as in the nonfractional case. In this example, there is no jump in the extrinsic curvatures across the boundary as expected.

IV. TWO EXAMPLES

In this section two examples of fractional shells are considered. One layer has cylindrical symmetry and is bounded by Levi-Civita and Minkowski. The second layer has spherical symmetry and separates Schwarzschild and Minkowski. Dynamic shells have broad applications as reflected by the large literature dealing with their evolution.[22–34] The two examples considered in this section are static and are presented as examples of the use of the fractional Lie derivative in the Israel formalism. Dynamic fractional shells will be considered elsewhere.

A. A layer between Minkowski and Levi-Civita

A simple cylindrical example is a layer separating an interior Minkowski and a vacuum Levi-Civita with angular deficit factor δ,

$$M^+: ds^2 = -dt^2 + dr^2 + \delta^2 r^2 d\phi^2 + dz^2, \tag{34}$$

$$M^-: ds^2 = -dt^2 + d\rho^2 + \rho^2 d\phi^2 + dz^2. \tag{35}$$

Using the result from the previous section, Eq. (33), the nonzero fractional extrinsic curvatures are ${}^qK_{\theta\theta}$,

$${}^qK_\theta^{\theta M-} \simeq R_o\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right), \tag{36}$$

$${}^qK_\theta^{\theta M+} \simeq \delta R_o\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right). \tag{37}$$

Calculating the jumps we find

$$\langle {}^qK\rangle \simeq R_o(\delta-1)\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right), \tag{38}$$

$$\langle {}^qK_\theta^\theta\rangle \simeq R_o(\delta-1)\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right), \tag{39}$$

$$\begin{aligned} -8\pi S_j^i &= \langle {}^qK_j^i\rangle - \langle {}^qK\rangle h_j^i, \\ 8\pi S_t^t &\simeq -R_o(1-\delta)\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right). \end{aligned} \tag{40}$$

The stress energy in the layer has positive density and no pressure. In a perfect fluid model this could be dust. The method of including a fractional parameter in the regular Israel layer[17,18] by matching fractional derivatives across the boundary would require no angular deficit, $\delta=1$, for these two space times. In this example, the stress energy of the layer only includes a thin layer contribution for $q \neq 1$, the fractional case. The Δ dependence was included by using the nonlocality of the fractional derivative. In the $q->1$ limit, the fractional derivative becomes a regular local derivative and the effect vanishes.

B. A layer between Minkowski and Schwarzschild

1. The fractional extrinsic curvature

Consider a shell bounded by the an exterior Schwarzschild space time and an interior Minkowski at $r=R_o$,

$$M^+: ds^2 = -\left(1 - \frac{2m}{r}\right)dt^2 + \frac{dr^2}{1-(2m/r)} + r^2 d\Omega^2, \tag{41}$$

$$M^-: ds^2 = -\left(1 - \frac{2m}{R_o}\right)dt^2 + dr^2 + r^2 d\Omega^2. \tag{42}$$

For this calculation the normal vectors have only radial components and we have

$${}^q\mathcal{L}_N(g_{ij}) = N^r \text{Đ}^q_{r-\Delta,r}(g_{ij}) + g_{rj}\text{Đ}^q_{r-\Delta,i}(N^r) + g_{ir}\text{Đ}^q_{r-\Delta,j}(N^r)$$

with

$$\text{Đ}^q_{r-\Delta,r}(g_{ij}) = \frac{\Gamma(2-q)}{\Gamma(1-q)(\Delta)^{1-q}}\int_{r-\Delta}^{r}\frac{\partial g_{ij}(w)}{\partial w}(r-w)^{-q}dw$$

and $q \leqslant 1$, $r->R_o$ on the boundary. For the interior Minkowski space time, $N^i=(0,1,0,0)$ and only ${}^qK_{\theta\theta}$ and ${}^qK_{\phi\phi}$ will contribute and the result has been calculated above. From Eq. (33) we have

$${}^qK^\theta_\theta = {}^qK^\phi_\phi = \frac{1}{R_o}\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right). \tag{43}$$

For the exterior Schwarzschild (SC) space time, $N^i=(0,\sqrt{1-(2m/r)},0,0)$ and ${}^qK_{\theta\theta}$, ${}^qK_{\phi\phi}$, and ${}^qK_{tt}$ will contribute. Except for the structure of the normal, the angular extrinsic curvatures will be the same as in Minkowski and we have at the boundary

$${}^qK^\theta_\theta = {}^qK^\phi_\phi = \frac{\sqrt{1-(2m/R_o)}}{R_o}\left(1 - \frac{1-q}{2-q}\frac{\Delta}{R_o} + \cdots\right). \tag{44}$$

Calculating ${}^qK_{tt}$ and letting $r->R_o$ we have

$${}^qK_{tt} = \frac{N^r}{2}\text{Đ}^q_{r-\Delta,r}(g_{tt}) = 2m\frac{\sqrt{1-(2m/R_o)}}{2}\text{Đ}^q_{r-\Delta,r}(r^{-1}),$$

$${}^qK_{tt} = -2m\frac{\sqrt{1-(2m/R_o)}}{2}\frac{\Gamma(2-q)R_o^{-1-q}}{\Gamma(1-q)\Delta^{1-q}}B_{\Delta/R_o}(1-q,-1).$$

The negative one beta function parameter is permitted for $\Delta/R_o \neq 1$.[36] This expression is most easily expanded in terms of the hypergeometric function ${}_2F_1(a,b,c;x)$,

$$B_{\Delta/R_o}(1-q,-1) = \frac{(\Delta/R_0)^{1-q}}{1-q}{}_2F_1\left(1-q,2,2-q;\frac{\Delta}{R_o}\right) = \frac{(\Delta/R_o)^{1-q}}{1-q}\left(1 + \frac{1-q}{2-q}2\frac{\Delta}{R_o} + \cdots\right)$$

and we have

$${}^qK^t_t = \frac{m}{\sqrt{1-(2m/R_o)}R_o^2}\left(1 + \frac{1-q}{2-q}2\frac{\Delta}{R_o} + \cdots\right). \tag{45}$$

2. The layer stress energy

Using the ${}^{q}K_{ab}$ calculated in the previous section, the jumps are

$$\langle {}^{q}K_{\theta}^{\theta}\rangle = \langle {}^{q}K_{\phi}^{\phi}\rangle = \frac{(\sqrt{1-(2m/R_o)}-1)}{R_o}\left(1-\frac{1-q}{2-q}\frac{\Delta}{R_o}+\cdots\right)$$
$$\langle {}^{q}K_{t}^{t}\rangle = \frac{m}{\sqrt{1-(2m/R_o)}R_o^2}\left(1+2\frac{1-q}{2-q}\frac{\Delta}{R_o}+\cdots\right). \tag{46}$$

With these jumps, the layer energy density, σ, and stress, P, are

$$8\pi S_t^t = -8\pi\sigma = -\langle {}^{q}K_{\theta}^{\theta} + {}^{q}K_{\phi}^{\phi}\rangle,$$

$$8\pi S_{\theta}^{\theta} = 8\pi P = \langle {}^{q}K_{t}^{t} + {}^{q}K_{\phi}^{\phi}\rangle.$$

Substituting we have

$$8\pi\sigma = 2\frac{(1-\sqrt{1-(2m/R_o)})}{R_o}\left(1-\frac{1-q}{2-q}\frac{\Delta}{R_o}+\cdots\right), \tag{47}$$

$$8\pi P = \frac{1}{R_o\sqrt{1-(2m/R_o)}}\left\{+1-\frac{m}{R_o}-\sqrt{1-\frac{2m}{R_o}}+\frac{1-q}{2-q}\frac{\Delta}{R_o}\left(\frac{4m}{R_o}-1+\sqrt{1-\frac{2m}{R_o}}\right)\cdots\right\}. \tag{48}$$

In the $m \ll R_o$ limit the stress energy becomes

$$\sigma \approx \frac{m}{4\pi R_o^2}\left(1-\frac{1-q}{2-q}\frac{\Delta}{R_o}\right),$$
$$P \approx \frac{3m}{8\pi R_o^2}\frac{1-q}{2-q}\frac{1}{R_o}. \tag{49}$$

For $q=1$, the density is simply the SC mass parameter over the surface area of the sphere and the fluid is dust. For $q<1$ the reduction in density, for the same mass, means the same mass is distributed over a larger region. Since the size of the sphere is set, the reduction in the areal density is possible if the mass is being distributed in an annular volume rather than totally over an area. In addition, the appearance of the fractional correction factor suggests that the thickness of the shell is parametrized by q. One could define a parametrized shell thickness,

$$\Delta_q = \frac{1-q}{2-q}\Delta. \tag{50}$$

With this parametrization, a family of shells is created with the thickest shells occurring for q close to zero.

V. DISCUSSION

The Israel formalism models a thin shell of matter as a zero thickness layer. The stress energy of the layer is related to jumps in the extrinsic curvature across the single boundary. In this paper, a fractional Lie derivative was developed and used to calculate a fractional extrinsic curvature which was input into the Israel formalism. The layer being described still has zero thickness; a single coordinate boundary is used to calculate the curvature jumps, but the nonlocal fractional derivative used to define the fractional extrinsic curvature allows the inclusion of a contribution

from a thin layer thickness as well as a fractional parameter, q, in the layer stress energy. The fractional parameter can be used to parametrize the shell thickness, creating a family of shells of varying thickness. The development is for $q \leqslant 1$ but can be extended to higher values of the fractional parameter. As an example of the use of the fractional Lie derivative within the Israel formalism, the method was applied to a cylindrical layer between a Minkowski interior and a Levi-Civita exterior and a spherical Schwarschild-Minkowski shell. The inclusion of the shell thickness is a fractional effect and vanishes as the fractional parameter approaches one.

There are choices to be made in the development of fractional formalisms applicable in general relativity. There are many fractional derivative definitions, Caputo, Riesz, Riemann-Liouville, etc., and the choice of derivative will depend on the application. The layers discussed here involve one-dimensional fractional Lie transport in a spatial variable but multidimensional transport processes will be important in the dynamics of fractional layers. Fractional derivatives have successfully described random walk processes that are heavy tailed in either jump size or jump timing and this has provided avenues for higher dimensional generalizations of the fractional derivative. Umarov and Gorenflo[37] have discussed a multispace dimension random walk model that is related to diffusion that is fractional in its spatial derivatives. Gorenflo and Mainardi have presented some random walk models discrete in both space and time.[38] Meerschaert and co-workers,[39,40] have begun to develop a fractional derivative operator that may be used when space and time variables are linked. Generalizing the formalism to describe the dynamic fractional layers with plane and spherical symmetries in general relativity[41–43] would be both useful and interesting.

APPENDIX: FRACTIONAL DETAILS

1. The Caputo derivative

The Caputo derivative of a scalar function can generally be written as[4]

$$D_x^q f(x') = \frac{1}{\Gamma(m-q)} \int_x^{x'} f^{(m)}(z)(x'-z)^{m-1-q} dz,$$

where $m-1 < q \leqslant m$, m integer. $f^{(m)} = d^m f / dz^m$. The development in the text was for $m=1$. The fractional derivative is an interpolator between regular integer derivatives. To move to $q>1$ would require $m=2$ and we would have

$$D_x^q f(x') = \frac{1}{\Gamma(2-q)} \int_x^{x'} \frac{d^2 f(z)}{dz^2} (x'-z)^{1-q} dz.$$

Integrating by parts we have

$$D_x^q f(x') = -\left(\frac{df}{dz}\right)_x (x'-x)^{1-q} + \frac{1}{\Gamma(1-q)} \int_x^{x'} \frac{df(x)}{dz} (x'-z)^{-q} dz. \tag{A1}$$

Remembering that for $m=2$, $q>1$, one can see the interpolating term.

2. Notation

This section contains a list of the notations used. The starting point is the Caputo derivative discussed in the previous section, $D_x^q(\ )$ with an additional index, k, to define the coordinate partial occurring in the definition.

$$D_{x,k}^q V^i(x') = \frac{\partial^q x'^i}{\partial (x'^k - x^k)^q} = \frac{1}{\Gamma(1-q)} \int_x^{x'} dy \frac{\partial V^i(y)}{\partial y^k} (x'-y)^{-q}. \tag{A2}$$

The integral is over the thickness of the layer with $x = \eta - \Delta$, $x' = \eta$. The $\mathcal{D}_x^q$ derivative is defined in terms of the Caputo derivative,

$$D^q_{x,k}() = \frac{(x'-x)^{1-q}}{\Gamma(2-q)} Đ^q_{x,k}(). \tag{A3}$$

An example of its use are found in the next section. The fractional Lie derivative is defined in terms of $Đ^q_{x,k}(\ )$,

$${}^q\mathcal{L}_\xi V^i = Đ^q_{x,k}(V^i)\xi^k - Đ^q_{x,k}(\xi^i)V^k, \tag{A4}$$

$${}^q\mathcal{L}_\xi V_i = Đ^q_{x,k}(V_i)(\xi^k) + V_k Đ^q_{x,i}(\xi^k), \tag{A5}$$

$${}^q\mathcal{L}_\xi f = \xi^k Đ^q_{x,k}(f). \tag{A6}$$

The fractional extrinsic curvature is defined in terms of the fractional Lie derivative generated by the normal to the layer. g_{ij} is the metric of the bounding space time and h_{ij} is the projection operator onto the layer,

$${}^qK_{cd} = \frac{1}{2}{}^q\mathcal{L}_N(g_{ij})h^i_c h^j_d. \tag{A7}$$

Jumps across the layer are described by

$$\langle {}^qK_{cd}\rangle. \tag{A8}$$

3. The $Đ^q$ derivative

The $Đ^q$ derivative defined in Eq. (7) in the text as a replacement for the regular partial derivative divides out some of the usual fractional derivative behavior. Consider the Caputo derivative of r^2 over a spherical region from the origin to r. We have

$$D^q_r r^2 = \frac{1}{\Gamma(1-q)}\int_0^r 2z(r-z)^{-q}dz = \frac{2r^{2-q}}{\Gamma(1-q)}\int_0^1 w(1-w)^{-q}dw = \frac{2r^{2-q}}{\Gamma(1-q)}\frac{\Gamma(1-q)\Gamma(2)}{\Gamma(2-q)} = \frac{2r^{2-q}}{\Gamma(3-q)}.$$

The $Đ^q$ derivative is

$$D^q_x(\ ) = \frac{(x'-x)^{1-q}}{\Gamma(2-q)} Đ^q_x(),$$

$$Đ^q r^2 = \frac{2r}{2-q}.$$

4. Some properties of the fractional Lie derivative

a. Defining the fractional commutator

The regular Lie derivative defines the commutator as

$$\mathcal{L}_U V = [U,V] = \nabla_U V - \nabla_V U,$$

where $\nabla_U = U^k\nabla_k$ is the standard directional derivative. The fractional Lie derivative generalizes the commutator,

$$\begin{aligned} {}^q\mathcal{L}_U V^i &= U^k Đ^q_{x,k}V^i - V^k Đ^q_{x,k}U, \\ {}^q[U,V]^i &= U^k Đ^q_{x,k}V^i - V^k Đ^q_{x,k}U^i. \end{aligned} \tag{A9}$$

Product of derivatives

The product of two regular Lie derivatives is related to the Lie derivative of the commutator.

$$\mathcal{L}_{[U,V]} = \mathcal{L}_U \mathcal{L}_V - \mathcal{L}_V \mathcal{L}_U.$$

Consider the fractional Lie derivative acting on a scalar function f,

$${}^q\mathcal{L}_{[U,V]} f = \{U^k \text{Đ}^q_{x,k} V^i - V^k \text{Đ}^q_{x,k} U^i\} \text{Đ}^q_{x,i} f = U^k \text{Đ}^q_{x,k} V^i \text{Đ}^q_{x,i} f - V^k \text{Đ}^q_{x,k} U^i \text{Đ}^q_{x,i} f = {}^q\mathcal{L}_U {}^q\mathcal{L}_V f - {}^q\mathcal{L}_V {}^q\mathcal{L}_U f$$

and the fractional derivative has the same structure.

(Received 20 July 2006; accepted 5 October 2006; published online 8 December 2006)

We prove the existence of infinitely many symmetric periodic orbits for a regularized rhomboidal five-body problem with four small masses placed at the vertices of a rhombus centered in the fifth mass. The main tool for proving the existence of such periodic orbits is the analytic continuation method of Poincaré together with the symmetries of the problem. © *2006 American Institute of Physics.*

I. INTRODUCTION

In this paper we consider a particular case of the planar five-body problem defined as follows. We consider a mass $m_0=1$ at the origin of coordinates with zero initial velocity, two small masses $m_1=m_2=\mu\nu_1$ with initial positions and velocities on the x axis symmetric with respect to the origin, and two small masses $m_3=m_4=\mu\nu_2$ with initial positions and velocities on the y axis also symmetric with respect to the origin (see Fig. 1). Our five-body problem consists of describing the motion of the five masses under their mutual Newtonian gravitational attraction. Due to the symmetry of the initial conditions and velocities, the four small bodies form a rhombus with center at m_0 at any time and the mass m_0 remains at rest at the origin. The description of the motion of this five-body problem is called the *rhomboidal five-body problem*.

Although this is a five-body problem it can be formulated as a Hamiltonian system of two degrees of freedom, one is the distance $x\geqslant 0$ of m_1 to the origin and the other is the distance $y\geqslant 0$ of m_3 to the origin (the distances of m_2 and m_4 to the origin are obtained by symmetry). The system has three singularities, the triple collision between m_0, m_1, and m_2, the triple collision between m_0, m_3, and m_4, and the total collision of the five bodies. Due to the symmetries doing a double Levi-Civita transformation we regularize both triple collisions.

When $\mu=0$ the problem is reduced to two collision two-body problems, the collision two-body problem with m_0 and m_1 and the collision two-body problem with m_0 and m_3. Note that if we take into account the five bodies, then really for $\mu=0$ we have instead of the binary collisions m_0 with m_1, and m_0 with m_3, the triple collisions m_0, m_1, and m_2, and m_0, m_3, and m_4. Since the solutions of the collision two-body problem are known we can compute the periodic solutions of the regularized system for $\mu=0$ in a fixed energy level $h<0$. The objective of this paper is to prove that the symmetric periodic orbits of the regularized rhomboidal five-body problem for $\mu=0$ can be continued to symmetric periodic orbits of the regularized rhomboidal five-body problem for $\mu>0$ sufficiently small. The main tool for proving this result is the classical analytic continuation method of Poincaré.

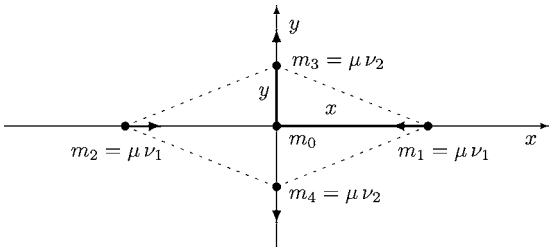

FIG. 1. The rhomboidal five-body problem.

The paper is structured as follows. In Sec. II we give the equations of motion of the rhomboidal five-body problem and we apply a double Levi-Civita transformation to regularize the triple collision between m_0, m_1, and m_2 and the triple collision between m_0, m_3, and m_4. Notice that the total collision of the five bodies is not regularized. In Sec. III we analyze the discrete symmetries of the regularized problem. In particular we see that there are three different symmetries that provide symmetric periodic solutions of the problem. We characterize these symmetric periodic solutions, and the double symmetric periodic solutions which are the main objective of this work. In Sec. IV we compute the periodic solutions of the regularized rhomboidal five-body problem for $\mu=0$ and in particular we analyze the double symmetric periodic solutions. Finally in Sec. V we apply the analytic continuation method of Poincaré to continue the double symmetric periodic orbits of the regularized rhomboidal five-body problem for $\mu=0$ to double-symmetric periodic orbits of the regularized rhomboidal five-body problem for $\mu>0$ sufficiently small.

II. EQUATIONS OF MOTION FOR THE RHOMBOIDAL FIVE-BODY PROBLEM

We consider five point particles with masses $m_0=1$, $m_1=m_2=\mu\nu_1$, $m_3=m_4=\mu\nu_2$, positions $\mathbf{q}_0=(0,0)$, $\mathbf{q}_1=(x,0)$, $\mathbf{q}_2=(-x,0)$, $\mathbf{q}_3=(0,y)$, and $\mathbf{q}_4=(0,-y)$, respectively, and velocities $\mathbf{v}_0=(0,0)$, $\mathbf{v}_1=(v_x,0)$, $\mathbf{v}_2=(-v_x,0)$, $\mathbf{v}_3=(0,v_y)$, and $\mathbf{v}_4=(0,-v_y)$, respectively (see Fig. 1). Our five-body problem consist of describing the motion of these particles under their mutual Newtonian gravitational attraction. We note that due to the symmetry of the problem the mass m_0 is at rest at the origin and the motion of the masses m_1 and m_2 (respectively, m_3 and m_4) is confined to the x axis (respectively, y axis). Since the configuration of the four bodies in motion is always a rhombus with center at m_0, we call the five-body problem the *rhomboidal five-body problem*.

Without loss of generality we can assume that the gravitational constant is $G=1$. Then the kinetic energy of the rhomboidal five-body problem is

$$T = \mu\nu_1\dot{x}^2 + \mu\nu_2\dot{y}^2,$$

where the dot denotes derivative with respect to the time t and the potential energy is

$$U = -\frac{\mu\nu_1(4+\mu\nu_1)}{2x} - \frac{\mu\nu_2(4+\mu\nu_2)}{2y} - \frac{4\mu^2\nu_1\nu_2}{\sqrt{x^2+y^2}}.$$

The Lagrangian of the problem is given by $L=T-U$. By the Legendre transformation (see, for instance, Refs. 1–3) the Hamiltonian of the problem is

$$H = \frac{p_x^2}{4\mu\nu_1} + \frac{p_y^2}{4\mu\nu_2} - \frac{\mu\nu_1(4+\mu\nu_1)}{2x} - \frac{\mu\nu_2(4+\mu\nu_2)}{2y} - \frac{4\mu^2\nu_1\nu_2}{\sqrt{x^2+y^2}},$$

where p_x and p_y are the conjugate momenta. The equations of motion associated to the Hamiltonian H are

$$\dot{x} = \frac{p_x}{2\mu\nu_1}, \quad \dot{p}_x = -\frac{\mu\nu_1(4+\mu\nu_1)}{2x^2} - \frac{4\mu^2\nu_1\nu_2 x}{(x^2+y^2)^{3/2}},$$

$$\dot{y} = \frac{p_y}{2\mu\nu_2}, \quad \dot{p}_y = -\frac{\mu\nu_2(4+\mu\nu_2)}{2y^2} - \frac{4\mu^2\nu_1\nu_2 y}{(x^2+y^2)^{3/2}}. \tag{1}$$

Doing the rescaling of the variables $x=\mu^2 X$, $y=\mu^2 Y$, and $t=\mu^3 T$, and denoting the new variables (X,Y,T) again by (x,y,t) system (1) becomes

$$\dot{x} = \frac{p_x}{2\nu_1}, \quad \dot{p}_x = -\frac{\nu_1(4+\mu\nu_1)}{2x^2} - \frac{4\mu\nu_1\nu_2 x}{(x^2+y^2)^{3/2}},$$

$$\dot{y} = \frac{p_y}{2\nu_2}, \quad \dot{p}_y = -\frac{\nu_2(4+\mu\nu_2)}{2y^2} - \frac{4\mu\nu_1\nu_2 y}{(x^2+y^2)^{3/2}}. \tag{2}$$

This system is also Hamiltonian with Hamiltonian

$$H = \frac{p_x^2}{4\nu_1} + \frac{p_y^2}{4\nu_2} - \frac{\nu_1(4+\mu\nu_1)}{2x} - \frac{\nu_2(4+\mu\nu_2)}{2y} - \frac{4\mu\nu_1\nu_2}{\sqrt{x^2+y^2}},$$

We note that system (2) has three singularities: $x=0$, that corresponds to triple collision between m_0, m_1, and m_2, $y=0$ that corresponds to triple collision between m_0, m_3, and m_4, and finally $x^2+y^2=0$ that corresponds to the total collision of the five bodies. We regularize both triple collisions applying a double Levi-Civita transformation (see Refs. 4–6)

$$x = \xi_1^2, \quad y = \xi_2^2, \quad p_x = \frac{\eta_1}{2\xi_1}, \quad p_y = \frac{\eta_2}{2\xi_2}, \quad dt = 4\xi_1^2\xi_2^2 ds.$$

The regularized system of the rhomboidal five-body problem (2) on the level energy $H=h$ for some constant h is the Hamiltonian system

$$\frac{d\xi_1}{ds} = \frac{\eta_1\xi_2^2}{2\nu_1},$$

$$\frac{d\xi_2}{ds} = \frac{\eta_2\xi_1^2}{2\nu_2},$$

$$\frac{d\eta_1}{ds} = -\frac{\xi_1\eta_2^2}{2\nu_2} + 8h\xi_1\xi_2^2 + 4\nu_2(4+\mu\nu_2)\xi_1 + \frac{32\mu\nu_1\nu_2\xi_1\xi_2^6}{(\xi_1^4+\xi_2^4)^{3/2}}, \tag{3}$$

$$\frac{d\eta_2}{ds} = -\frac{\xi_2\eta_1^2}{2\nu_1} + 8h\xi_1^2\xi_2 + 4\nu_1(4+\mu\nu_1)\xi_2 + \frac{32\mu\nu_1\nu_2\xi_1^6\xi_2}{(\xi_1^4+\xi_2^4)^{3/2}}$$

with Hamiltonian

$$K = \frac{\eta_1^2\xi_2^2}{4\nu_1} + \frac{\eta_2^2\xi_1^2}{4\nu_2} - 2\nu_2(4+\mu\nu_2)\xi_1^2 - 2\nu_1(4+\mu\nu_1)\xi_2^2 - 4h\xi_1^2\xi_2^2 - \frac{16\mu\nu_1\nu_2\xi_1^2\xi_2^2}{\sqrt{\xi_1^4+\xi_2^4}},$$

and satisfying the energy relation $K=0$; i.e., $H=h$.

We note that system (3) is analytic with respect to its variables except when $\xi_1^4+\xi_2^4=0$ which corresponds to the total collision.

The regularization of the triple collisions allows us to look for periodic orbits of the rhomboidal five-body problem containing triple collisions between m_0, m_1, and m_2 and between m_0 and m_3 and m_4. Our aim is to find periodic orbits of the rhomboidal five-body problem (3) for $\mu>0$ sufficiently small, satisfying the energy relation $K=0$. In fact, we look only for symmetric periodic orbits which are easier to study than the general periodic orbits.

III. SYMMETRIES

It is easy to check that system (3) is invariant under the discrete symmetries

$$Id: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (\xi_1, \xi_2, \eta_1, \eta_2, s),$$

$$S_1: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (-\xi_1, \xi_2, \eta_1, -\eta_2, -s),$$

$$S_2: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (\xi_1, -\xi_2, -\eta_1, \eta_2, -s),$$

$$S_3: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (\xi_1, \xi_2, -\eta_1, -\eta_2, -s),$$

$$S_4: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (-\xi_1, -\xi_2, -\eta_1, -\eta_2, s),$$

$$S_5: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (-\xi_1, \xi_2, -\eta_1, \eta_2, s),$$

$$S_6: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (\xi_1, -\xi_2, \eta_1, -\eta_2, s),$$

$$S_7: \quad (\xi_1, \xi_2, \eta_1, \eta_2, s) \to (-\xi_1, -\xi_2, \eta_1, \eta_2, -s).$$

The invariance under these symmetries means that if $\varphi(s)=(\xi_1(s), \xi_2(s), \eta_1(s), \eta_2(s))$ is a solution of system (3), then also $S_i(\varphi(s))$ is a solution for $i=1,\ldots,7$. An orbit $\varphi(s)$ is called *S_i-symmetric* if $S_i(\varphi(s))=\varphi(s)$.

We note that $\{Id, S_1, \ldots, S_7\}$ with the usual composition forms an abelian group isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$. This discrete group of symmetries appeared in many Hamiltonian systems as, for instance, the anisotropic Kepler problem,[7] the Manev anisotropic problem,[8] or the collinear three-body problem.[9]

Using the uniqueness theorem of a solution of an ordinary differential system, it follows easily that $\varphi(s)$ is a S_1-symmetric solution if and only if $\varphi(s)$ intersects the plane $\xi_1=\eta_2=0$ at least in one point. Now, it is clear that a periodic solution is S_1-symmetric if and only if it has exactly two intersection points with the plane $\xi_1=\eta_2=0$. So, clearly the half-period of such a S_1-symmetric periodic orbit is the time which the orbit needs for travel from one of the intersection points to the other. Using similar arguments for the other symmetries, we obtain the following proposition.

Proposition 1: Let $\varphi(s)=(\xi_1(s), \xi_2(s), \eta_1(s), \eta_2(s))$ *be a solution of system* (3).

(a) *If* $\xi_1(s)$ *and* $\eta_2(s)$ *are zero at* $s=s_0$ *and at* $s=s_0+S/2$ *but they are not simultaneously zero at any value of* $s \in (s_0, s_0+S/2)$, *then* $\varphi(s)$ *is a* S_1*-symmetric periodic solution of period* S.

(b) *If* $\xi_2(s)$ *and* $\eta_1(s)$ *are zero at* $s=s_0$ *and at* $s=s_0+S/2$ *but they are not simultaneously zero at any value of* $s \in (s_0, s_0+S/2)$, *then* $\varphi(s)$ *is a* S_2*-symmetric periodic solution of period* S.

(c) *If* $\eta_1(s)$ *and* $\eta_2(s)$ *are zero at* $s=s_0$ *and at* $s=s_0+S/2$ *but they are not simultaneously zero at any value of* $s \in (s_0, s_0+S/2)$, *then* $\varphi(s)$ *is a* S_3*-symmetric periodic solution of period* S.

Since in system (3) the total collision is not regularized, in our study we must avoid the orbits of the rhomboidal five-body problem which start or end in total collision. In the variables that we are working the total collision takes place when $\xi_1=\xi_2=0$. Therefore, the symmetries S_4 and S_7 are not considered because their symmetric orbits present total collision. Due to the fact that $S_5=S_1 \circ S_3$ and $S_6=S_2 \circ S_3$, studying the symmetric periodic orbits with respect to S_1, S_2, and S_3 we shall get also the symmetric periodic orbits with respect to S_5 and S_6.

There could be periodic solutions of system (3) that are simultaneously S_1- and S_2-symmetric periodic solutions. These periodic solutions will be called *S_{12}-symmetric periodic solutions*. In a similar way we can define the *S_{13}-symmetric periodic solutions* and the *S_{23}-symmetric periodic solutions*. These kinds of symmetric periodic solutions are characterized in the following result.

Proposition 2: Let $\varphi(s)=(\xi_1(s),\xi_2(s),\eta_1(s),\eta_2(s))$ *be a solution of rhomboidal five-body problem* (3).

(a) *The solution* $\varphi(s)$ *is a* S_{12}*-symmetric periodic solution of period* S *if and only if either* $\xi_1(s_0)=\eta_2(s_0)=0$, *and* $\xi_2(s_0+S/4)=\eta_1(s_0+S/4)=0$, *and there is no* $s\in(s_0,s_0+S/4)$ *such that* $\xi_2(s)=\eta_1(s)=0$; *or* $\xi_2(s_0)=\eta_1(s_0)=0$, *and* $\xi_1(s_0+S/4)=\eta_2(s_0+S/4)=0$, *and there is no* $s\in(s_0,s_0+S/4)$ *such that* $\xi_1(s)=\eta_2(s)=0$.

(b) *The solution* $\varphi(s)$ *is a* S_{13}*-symmetric periodic solution of period* S *if and only if either* $\xi_1(s_0)=\eta_2(s_0)=0$, *and* $\eta_1(s_0+S/4)=\eta_2(s_0+S/4)=0$, *and there is no* $s\in(s_0,s_0+S/4)$ *such that* $\eta_1(s)=\eta_2(s)=0$; *or* $\eta_1(s_0)=\eta_2(s_0)=0$, *and* $\xi_1(s_0+S/4)=\eta_2(s_0+S/4)=0$, *and there is no* $s\in(s_0,s_0+S/4)$ *such that* $\xi_1(s)=\eta_2(s)=0$.

(c) *The solution* $\varphi(s)$ *is a* S_{23}*-symmetric periodic solution of period* S *if and only if either* $\xi_2(s_0)=\eta_1(s_0)=0$, *and* $\eta_1(s_0+S/4)=\eta_2(s_0+S/4)=0$, *and there is no* $s\in(s_0,s_0+S/4)$ *such that* $\eta_1(s)=\eta_2(s)=0$; *or* $\eta_1(s_0)=\eta_2(s_0)=0$, *and* $\xi_2(s_0+S/4)=\eta_1(s_0+S/4)=0$, *and there is no* $s\in(s_0,s_0+S/4)$ *such that* $\xi_2(s)=\eta_1(s)=0$.

The next result shows that there are no symmetric periodic orbits with respect more than two symmetries.

Proposition 3: There are no periodic solutions of the rhomboidal five-body problem (3), *which are simultaneously* S_i*-symmetric for* $i=1,2,3$.

Proof: Assume that $\varphi(s)$ is a S_i-symmetric periodic solution of period S for $i=1,2,3$. Then there exist times s_1, s_2, and s_3 with $s_1,s_2,s_3\in[0,S/2)$ such that

$$\xi_1(s_1)=\eta_2(s_1)=0,\quad \xi_2(s_2)=\eta_1(s_2)=0,\quad \eta_1(s_3)=\eta_2(s_3)=0.$$

We assume that $s_1=0$. This is not restrictive because system (3) is autonomous, and consequently the origin of time can be chosen arbitrarily. Then, since the orbit is in particular S_{12}-symmetric, from Proposition 2, $s_2=S/4$. Similarly, since it is also S_{13}-symmetric, again from Proposition 2, $s_3=S/4$. The fact that $s_2=s_3$ is a contradiction, so we have proved the result. ■

IV. SYMMETRIC PERIODIC SOLUTIONS FOR $\mu=0$

For $\mu=0$ system (3) becomes

$$\frac{d\xi_1}{ds}=\frac{\eta_1\xi_2^2}{2\nu_1},\quad \frac{d\eta_1}{ds}=-\frac{\xi_1\eta_2^2}{2\nu_2}+8h\xi_1\xi_2^2+16\nu_2\xi_1,$$

$$\frac{d\xi_2}{ds}=\frac{\eta_2\xi_1^2}{2\nu_2},\quad \frac{d\eta_2}{ds}=-\frac{\xi_2\eta_1^2}{2\nu_1}+8h\xi_1^2\xi_2+16\nu_1\xi_2, \tag{4}$$

and the Hamiltonian K goes over to

$$K=\frac{\eta_1^2\xi_2^2}{4\nu_1}+\frac{\eta_2^2\xi_1^2}{4\nu_2}-8\nu_2\xi_1^2-8\nu_1\xi_2^2-4h\xi_1^2\xi_2^2.$$

The Hamiltonian H for $\mu=0$ can be written as

$$H=H_1(x,p_x)+H_2(y,p_y)=\left(\frac{p_x^2}{4\nu_1}-\frac{2\nu_1}{x}\right)+\left(\frac{p_y^2}{4\nu_2}-\frac{2\nu_2}{y}\right).$$

We note that $H_1(x,p_x)$ and $H_2(y,p_y)$ are two fist integrals of the nonregularized problem, so they are constant along the solutions in the intervals between two consecutive zeros of x and y.

The flow of the rhomboidal five-body problem on the energy level $H=h$ for some constant h is obtained from the flow of the Hamiltonian $H_1(x,p_x)$ on the energy level $H_1=h_1$ and the flow of the Hamiltonian $H_2(y,p_y)$ on the energy level $H_2=h_2$ with $h=h_1+h_2$.

The Hamiltonian $H_1(x,p_x)$ in the Levi-Civita coordinates (ξ_1,η_1) is given by

$$H_1 = \frac{\eta_1^2}{16\nu_1\xi_1^2} - \frac{2\nu_1}{\xi_1^2} = h_1,$$

and the Hamiltonian $H_2(y, p_y)$ in the Levi-Civita coordinates (ξ_2, η_2) is

$$H_2 = \frac{\eta_2^2}{16\nu_2\xi_2^2} - \frac{2\nu_2}{\xi_2^2} = h_2.$$

Let $(\xi_1, \xi_2, \eta_1, \eta_2)$ be a solution of system (4) satisfying the energy relation $K=0$ (i.e., $H=h$), we define a new time variable σ as follows:

$$\frac{d\sigma}{ds} = \xi_2^2, \quad \text{or equivalently} \quad \frac{dt}{d\sigma} = 4\xi_1^2. \tag{5}$$

The Hamiltonian K in the new time variable σ can be written as

$$K_1 = \frac{1}{\xi_2^2}K = \frac{\eta_1^2}{4\nu_1} - 8\nu_1 - 4h_1\xi_1^2 + \left(\frac{\eta_2^2}{4\nu_2\xi_2^2} - \frac{8\nu_2}{\xi_2^2} - 4h_2\right)\xi_1^2 = \frac{\eta_1^2}{4\nu_1} - 8\nu_1 - 4h_1\xi_1^2.$$

Then ξ_1, η_1 satisfy the system of differential equations associated to the Hamiltonian K_1

$$\frac{d\xi_1}{d\sigma} = \frac{\eta_1}{2\nu_1}, \quad \frac{d\eta_1}{d\sigma} = 8h_1\xi_1. \tag{6}$$

We are only interested in the periodic solutions of system (6). Thus we must consider only negative values of h_1. Then, fixed $h_1<0$, system (6) can be integrated directly and the solution $(\xi_1(\sigma), \eta_1(\sigma))$ of system (6) with initial conditions

$$\xi_1(0) = \xi_{10}^*, \quad \eta_1(0) = \eta_{10}^*, \tag{7}$$

is

$$\xi_1(\sigma) = \xi_{10}^* \cos(w_1\sigma) + \frac{\eta_{10}^*}{2w_1\nu_1}\sin(w_1\sigma), \quad \eta_1(\sigma) = \eta_{10}^* \cos(w_1\sigma) - 2w_1\nu_1\xi_{10}^* \sin(w_1\sigma), \tag{8}$$

where $w_1 = 2\sqrt{-h_1/\nu_1}$.

We note that the solution (8) is a periodic solution of system (6) with period $\bar{\sigma} = 2\pi/w_1$. Since we are interested in the periodic solution (8) satisfying the energy relation $K_1=0$, by Eq. (5), its period in the real time t is given by

$$T_1(h_1, \nu_1) = \int_0^{\bar{\sigma}} 4\xi_1^2(\sigma)d\sigma = 4\pi\left(-\frac{\nu_1}{h_1}\right)^{3/2}.$$

Now we introduce a new time τ with

$$\frac{d\tau}{ds} = \xi_1^2, \quad \text{or equivalently} \quad \frac{dt}{d\tau} = 4\xi_2^2. \tag{9}$$

Then ξ_2, η_2 are functions of the new time τ via the Hamiltonian system

$$\frac{d\xi_2}{d\tau} = \frac{\eta_2}{2\nu_2}, \quad \frac{d\eta_2}{d\tau} = 8h_2\xi_2, \tag{10}$$

with Hamiltonian

TABLE I. Period of $\varphi(s)$.

Time t	Time σ	Time τ	Time s
$T=pT_1(h_1,\nu_1)=qT_2(h_2,\nu_2)$	$\sigma^*=p\bar{\sigma}$	$\tau^*=q\bar{\tau}$	$S^*=s(T)$
$T/4$	$\sigma^*/4$	$\tau^*/4$	$S^*/4$

$$K_2=\frac{1}{\xi_1^2}K=\frac{\eta_2^2}{4\nu_2}-8\nu_2-4h_2\xi_2^2.$$

Moreover, fixed $h_2<0$, the solution $(\xi_2(\tau),\eta_1(\tau))$ of system (10) with initial conditions

$$\xi_2(0)=\xi_{20}^*,\quad \eta_2(0)=\eta_{20}^*, \tag{11}$$

is given by

$$\xi_2(\tau)=\xi_{20}^*\cos(w_2\tau)+\frac{\eta_{20}^*}{2w_2\nu_2}\sin(w_2\tau),\quad \eta_2(\tau)=\eta_{20}^*\cos(w_2\tau)-2w_2\nu_2\xi_{20}^*\sin(w_2\tau), \tag{12}$$

where $w_2=2\sqrt{-h_2/\nu_2}$.

The solution (12) is periodic of period $\bar{\tau}=2\pi/w_2$. Moreover, if the solution (12) satisfies the energy relation $K_2=0$, then, by Eq. (9), the period of the solution (12) in the real time t is given by

$$T_2(h_2,\nu_2)=\int_0^{\bar{\tau}}4\xi_2^2(\tau)d\tau=4\pi\left(-\frac{\nu_2}{h_2}\right)^{3/2}.$$

Proposition 4: Let $(\xi_1(\sigma),\eta_1(\sigma))$ *be a periodic solution of system* (6), *for a fixed* $h_1<0$, *with initial conditions* (7) *and period* $\bar{\sigma}=2\pi/w_1$ *that satisfies* $K_1=0$. *Let* $(\xi_2(\tau),\eta_2(\tau))$ *be the periodic solution of system* (10), *for a fixed* $h_2<0$, *with initial conditions* (11) *and period* $\bar{\tau}=2\pi/w_2$ *that satisfies* $K_2=0$. *Assume that* $h=h_1+h_2$, *and that* $\sigma(s)$ *and* $\tau(s)$ *are given by Eqs.* (5) and (9), *respectively*, *where we choose* $\sigma(0)=\tau(0)=0$. *Suppose that there is no* $s\in\mathbb{R}$ *such that* $\xi_1(\sigma(s))=\xi_2(\tau(s))=0$. *Then the following statements hold*:

(a) $\varphi(s)=(\xi_1(\sigma(s)),\xi_2(\tau(s)),\eta_1(\sigma(s)),\eta_2(\tau(s))$ *is a solution of system* (4) *with initial conditions* $\xi_1(0)=\xi_{10}^*$, $\xi_2(0)=\xi_{20}^*$, $\eta_1(0)=\eta_{10}^*$, *and* $\eta_2(0)=\eta_{20}^*$ *that satisfies* $K=0$.

(b) *If* $h_1=(p/q)^{2/3}\nu_1h_2/\nu_2$ *for some* $p,q\in\mathbb{N}$ *coprime*, *then* $\varphi(s)$ *is a periodic solution of system* (4).

(c) *Assume that* $s(t)$ *is given by the inverse function of* $t=\int_0^s 4\xi_1^2(\rho)\xi_2^2(\rho)d\rho$. *Under the hypotheses of statement* (b), *the period and the quarter of the period of the periodic solution* $\varphi(s)$ *using the different times* t, σ, τ, *and* s *is given in* Table I.

Proof: Statement (a) follows easily from the definitions of $(\xi_1(\sigma),\eta_1(\sigma))$ and $(\xi_2(\tau),\eta_2(\tau))$ together with the definitions of $\sigma(s)$ and $\tau(s)$.

We have seen that, in the time t, $(\xi_1(\sigma),\eta_1(\sigma))$ and $(\xi_2(\tau),\eta_2(\tau))$ are periodic solutions of periods $T_1(h_1,\nu_1)$ and $T_2(h_2,\nu_2)$, respectively. Thus, in order to have a periodic solution of system (4) we need that

$$pT_1(h_1,\nu_1)=qT_2(h_2,\nu_2), \tag{13}$$

for some $p,q\in\mathbb{N}$ coprime. Solving Eq. (13) with respect to h_1, we get that $h_1=(p/q)^{2/3}\nu_1h_2/\nu_2$. So, statement (b) is proved.

Now we see that the time $t=T/4$ corresponds to the time $\sigma=\sigma^*/4$. In a similar way we can see that the time $t=T/4$ corresponds to the time $\tau=\tau^*/4$ and $s=S^*/4$.

We note that system (6) is invariant under the symmetry $(\xi_1, \eta_1, \sigma) \to (-\xi_1, \eta_1, -\sigma)$. This means that $\xi_1(\sigma) = -\xi_1(-\sigma)$. So $\xi_1^2(\sigma)$ is an even function. On the other hand, it is easy to see that $\xi_1^2(\sigma)$ is a periodic function of period $\bar{\sigma}/2$. Then, from Eq. (5), we have that

$$T_1 = \int_0^{\bar{\sigma}} 4\xi_1^2(\sigma)d\sigma = 2\int_0^{\bar{\sigma}/2} 4\xi_1^2(\sigma)d\sigma = 4\int_0^{\bar{\sigma}/4} 4\xi_1^2(\sigma)d\sigma.$$

Moreover, it is clear that

$$\int_0^{\bar{\sigma}/4} 4\xi_1^2(\sigma)d\sigma = \int_{\bar{\sigma}/4}^{\bar{\sigma}/2} 4\xi_1^2(\sigma)d\sigma = \frac{T_1}{4}.$$

Consequently

$$t(\sigma^*/4) = \int_0^{p\bar{\sigma}/4} 4\xi_1^2(\sigma)d\sigma = p\int_0^{\bar{\sigma}/4} 4\xi_1^2(\sigma)d\sigma = p\frac{T_1}{4} = \frac{T}{4}.$$

Therefore, the time $t = T/4$ corresponds to $\sigma = \sigma^*/4$. In short, statement (c) is proved. ■

We remark that the number p in Proposition 4 represents the number of triple collisions between m_0, m_1, and m_2 during a period, whereas q represents the number of triple collisions between m_0, m_3, and m_4.

We are interested in symmetric periodic solutions of system (4) satisfying the energy relation $K = 0$ with $h = h_1 + h_2$. In the next proposition we give initial conditions for those symmetric periodic solutions.

Proposition 5: The following statements hold:

(a) *If p and q are odd, then the solution $\varphi(s)$ given by Proposition 4 with initial conditions*

$$\text{either } \xi_{10}^* = 0,\ \xi_{20}^* = \sqrt{-2\nu_2/h_2},\ \eta_{10}^* = 4\sqrt{2}\nu_1,\ \eta_{20}^* = 0;$$

$$\text{or } \xi_{10}^* = \sqrt{-2\nu_1/h_1},\ \xi_{20}^* = 0,\ \eta_{10}^* = 0,\ \eta_{20}^* = 4\sqrt{2}\nu_2;$$

is a S_{12}-symmetric periodic solution.

(b) *If p is odd and q is even, then the solution $\varphi(s)$ given by Proposition 4 with initial conditions*

$$\text{either } \xi_{10}^* = 0,\ \xi_{20}^* = \sqrt{-2\nu_2/h_2},\ \eta_{10}^* = 4\sqrt{2}\nu_1,\ \eta_{20}^* = 0;$$

$$\text{or } \xi_{10}^* = \sqrt{-2\nu_1/h_1},\ \xi_{20}^* = \sqrt{-2\nu_2/h_2},\ \eta_{10}^* = 0,\ \eta_{20}^* = 0;$$

is a S_{13}-symmetric periodic solution.

(c) *If p is even and q is odd, then the solution $\varphi(s)$ given by Proposition 4 with initial conditions*

$$\text{either } \xi_{10}^* = \sqrt{-2\nu_1/h_1},\ \xi_{20}^* = 0,\ \eta_{10}^* = 0,\ \eta_{20}^* = 4\sqrt{2}\nu_2;$$

$$\text{or } \xi_{10}^* = \sqrt{-2\nu_1/h_1},\ \xi_{20}^* = \sqrt{-2\nu_2/h_2},\ \eta_{10}^* = 0,\ \eta_{20}^* = 0;$$

is a S_{23}-symmetric periodic solution.

Proof: Solving $K_1 = 0$ and $K_2 = 0$ for the initial conditions of the S_{12}-symmetric periodic orbits given in Proposition 2(a) we get the initial conditions of statement (a). In these initial conditions we have only considered the positive determination in the squareroots due to the fact that the Levi-Civita transformation duplicates the orbits. The proof follows from the evaluation of the solution $\varphi(s) = (\xi_1(\sigma(s)), \xi_2(\tau(s)), \eta_1(\sigma(s)), \eta_2(\tau(s))$ with these initial conditions at times $s = 0$ and

$s=S^*/4$. We note that by Table I $\varphi(S^*/4)=(\xi_1(p\bar{\sigma}/4),\xi_2(q\bar{\tau}/4),\eta_1(p\bar{\sigma}/4),\eta_2(q\bar{\tau}/4))$. This completes the proof of statement (a). The other statements follow similarly. ■

V. CONTINUATION OF SYMMETRIC PERIODIC SOLUTIONS

In this section using the continuation method of Poincaré (see, for instance, Ref. 10) we shall continue the symmetric periodic orbits of the rhomboidal five-body problem (3) from $\mu=0$ to symmetric periodic orbits of system (3) for $\mu>0$ sufficiently small.

A. The S_{12}-symmetric periodic solutions

We denote by $\varphi(s;0,\xi_{20},\eta_{10},0,\mu)=(\xi_1(s;\xi_{20},\eta_{10},\mu),\xi_2(s;\xi_{20},\eta_{10},\mu),\eta_1(s;\xi_{20},\eta_{10},\mu),\eta_2(s;\xi_{20},\eta_{10},\mu))$ the solution of (3), for fixed values of $\nu_1>0$, $\nu_2>0$, and $h<0$, with initial conditions $\xi_1(0)=0$, $\xi_2(0)=\xi_{20}$, $\eta_1(0)=\eta_{10}$, and $\eta_2(0)=0$. From Proposition 2(a), $\varphi(s;0,\xi_{20},\eta_{10},0,\mu)$ is a S_{12}-symmetric periodic solution of the rhomboidal five-body problem with period S satisfying the energy relation$K=0$ if and only if

$$\xi_2(S/4;\xi_{20},\eta_{10},\mu)=0,\quad \eta_1(S/4;\xi_{20},\eta_{10},\mu)=0,\quad K(\xi_{20},\eta_{10},\mu)=0.$$

We solve equation $K(\xi_{20},\eta_{10},\mu)=0$ with respect the variable η_{10} obtaining in this way

$$\eta_{10}=2\sqrt{2}\nu_1\sqrt{4+\mu\nu_1}. \tag{14}$$

So $\varphi(s;0,\xi_{20},\eta_{10},0,\mu)$ is a S_{12}-symmetric periodic solution of the rhomboidal five-body problem with period S satisfying the energy relation $K=0$ if and only if

$$\xi_2(S/4;\xi_{20},\mu)=0,\quad \eta_1(S/4;\xi_{20},\mu)=0. \tag{15}$$

Notice that we have omitted the dependence with respect to η_{10}, which is given by Eq. (14).

Assume that $p=2\ell+1$, $q=2k+1$ for some $\ell,k\in\mathbb{N}\cup\{0\}$ and that h_1^* and h_2^* verify that $h=h_1^*+h_2^*$ and $h_1^*=(p/q)^{2/3}\nu_1h_2^*/\nu_2$. By Propositions 4 and 5(a), we see that $S=S^*=s(pT_1(h_1^*))=s(qT_2(h_2^*))$, $\xi_{20}=\xi_{20}^*=\sqrt{-2\nu_2/h_2^*}$, is a solution of system (15) for $\mu=0$. This solution correspond to the known S_{12}-symmetric periodic solution $\varphi(s;0,\xi_{20}^*,\eta_{10}^*,0,0)$ of system (3), for $\mu=0$ where $\eta_{10}^*=4\sqrt{2}\nu_1$. Our aim is to continue this solution of system (15) for $\mu=0$ to $\mu>0$ sufficiently small.

Applying the implicit function theorem to system (15) in a neighborhood of the known solution we have that if

$$\left.\begin{vmatrix} \dfrac{\partial\xi_2}{\partial s} & \dfrac{\partial\xi_2}{\partial\xi_{20}} \\ \dfrac{\partial\eta_1}{\partial s} & \dfrac{\partial\eta_1}{\partial\xi_{20}} \end{vmatrix}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*\\ \mu=0}}\neq 0, \tag{16}$$

then we can find unique analytic functions $\xi_{20}=\xi_{20}(\mu)$, $S=S(\mu)$ defined for $\mu\geqslant 0$ sufficiently small, such that

(i) $\xi_{20}(0)=\xi_{20}^*$, $S(0)=S^*$,
(ii) $\varphi(s;0,\xi_{20},\eta_{10},0,\mu)$ with $\xi_{20}=\xi_{20}(\mu)$ and η_{10} given by (14) is a S_{12}-symmetric periodic solution of system (3) with period $S=S(\mu)$ that satisfies the energy relation $K=0$.

The derivatives $\partial\xi_2/\partial s$ and $\partial\eta_1/\partial s$ evaluated at $s=S^*/4$, $\xi_{20}=\xi_{20}^*$ and $\mu=0$ can be obtained directly from system (3) for $\mu=0$ [i.e., system (4)], evaluating the right hand of the system at the solution $\varphi(s;0,\xi_{20}^*,\eta_{10}^*,0,0)$ at time $s=S^*/4$. Then

$$\left.\frac{\partial \xi_2}{\partial s}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*\\ \mu=0}} = \left.\frac{1}{2\nu_2}\eta_2\xi_1^2\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*\\ \mu=0}} = \frac{4(-1)^k\sqrt{2}\nu_2}{h_2^*}\left(\frac{q}{p}\right)^{2/3} \neq 0$$

and

$$\left.\frac{\partial \eta_1}{\partial s}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*\\ \mu=0}} = \left.8h_1^*\xi_1\xi_2^2\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*\\ \mu=0}} = 0.$$

It only remains to compute the value of $\partial\eta_1/\partial\xi_{20}$ evaluated at $s=S^*/4$, $\xi_{20}=\xi_{20}^*$, $\mu=0$. This value is given by the derivative, evaluated at $s=S^*/4$ and $\xi_{20}=\xi_{20}^*$, of the solution $\eta_1(\sigma(s);0,\xi_{20},\eta_{10}^*,0,0)$ with respect to ξ_{20}, where $\eta_1(\sigma(s);0,\xi_{20},\eta_{10}^*,0,0)$ is the solution of system (4) with initial conditions $\xi_1(0)=0$, $\xi_2(0)=\xi_{20}$, $\eta_1(0)=\eta_{10}^*$, and $\eta_2(0)=0$ satisfying the energy relation $K=0$ [see Proposition 4(a)]. Then

$$\left.\frac{\partial \eta_1(\sigma(s);0,\xi_{20},\eta_{10}^*,0,0)}{\partial \xi_{20}}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}} = \left.\left(\frac{\partial \eta_1}{\partial \sigma}\frac{\partial \sigma(s)}{\partial \xi_{20}} + \frac{\partial \eta_1}{\partial \xi_{20}}\right)\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}}.$$

From Eqs. (5) and (9), we have that the times σ and τ are related by

$$\xi_1^2(\sigma)d\sigma = \xi_2^2(\tau)d\tau.$$

Integrating this equation over the solutions (8) and (12) with the corresponding initial conditions and assuming that when $\sigma(0)=\tau(0)=0$, we have that $\sigma(s)$ and $\tau(s)$ are related by the equation

$$\frac{4\sigma(s)}{w_1^2} - \frac{\xi_{20}^2\tau(s)}{2} - \frac{2\sin(2w_1\sigma(s))}{w_1^3} - \frac{\xi_{20}^2\sin(2w_2\tau(s))}{4w_2} = 0. \tag{17}$$

Since $\varphi(s;0,\xi_{20},\eta_{10}^*,0,0)$ must be a solution of system (4), by Proposition 4 we have that $K_1=0$ and $K_2=0$, so

$$w_2 = 2\sqrt{-h_2/\nu_2}, \quad \text{with} \quad h_2 = -2\nu_2/\xi_{20}^2$$

and

$$w_1 = 2\sqrt{-h_1/\nu_1}, \quad \text{with} \quad h_1 = h - h_2.$$

Then derivating implicitly Eq. (17) with respect to ξ_{20} we obtain

$$\left.\frac{\partial \sigma(s)}{\partial \xi_{20}}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}} = \frac{\pi q}{8\sqrt{2}\nu_1}\left(3\left(\frac{p}{q}\right)^{2/3}\nu_1 + \nu_2\right).$$

On the other hand, from systems (6) and (8) we have that

$$\left.\frac{\partial \eta_1}{\partial \sigma}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}} = \left.8h_1\xi_1\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}} = 8(-1)^{\ell+1}\sqrt{2}\nu_1\left(\frac{p}{q}\right)^{1/3}\sqrt{-\frac{h_2^*}{\nu_2}}$$

and

$$\left.\frac{\partial \eta_1}{\partial \xi_{20}}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}} = 2(-1)^{\ell}ph_2^*\pi\left(\frac{q}{p}\right)^{2/3}\sqrt{-\frac{\nu_2}{h_2^*}}.$$

Hence

$$\left.\frac{\partial \eta_1(\sigma(s);0,\xi_{20},\eta_{10}^*,0,0)}{\partial \xi_{20}}\right|_{\substack{s=S^*/4\\ \xi_{20}=\xi_{20}^*}} = 3(-1)^{\ell+1}\pi\sqrt{-\frac{h_2^*}{\nu_2}}\left(p\nu_1+\left(\frac{p}{q}\right)^{1/3}q\nu_2\right).$$

So, this derivative is different from zero. Hence, the determinant (16) is not zero. In short, we have proved the following result.

Theorem 6: *Given* $\nu_1>0$, $\nu_2>0$, $h<0$ *and* p *and* q *odd positive integers, the* S_{12}*-symmetric periodic solution of the rhomboidal five-body problem* (3) *for* $\mu=0$ *with initial conditions* $\xi_1(0)=0$, $\xi_2(0)=\sqrt{-2\nu_2/h_2^*}$, $\eta_1(0)=4\sqrt{2}\nu_1$, *and* $\eta_2(0)=0$ *where* $h_2^*=h\nu_2/((p/q)^{2/3}\nu_1+\nu_2)$, *can be continued to a* μ*-parameter family of* S_{12}*-symmetric periodic orbits of the rhomboidal five-body problem* (3) *for* $\mu>0$ *sufficiently small.*

B. The S_{23}-symmetric periodic solutions

We denote by $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)=(\xi_1(s;\xi_{10},\xi_{20},\mu),\xi_2(s;\xi_{10},\xi_{20},\mu),\eta_1(s;\xi_{10},\xi_{20},\mu),\eta_2(s;\xi_{10},\xi_{20},\mu))$ the solution of system (3), for fixed values of $\nu_1>0$, $\nu_2>0$, and $h<0$, with initial conditions $\xi_1(0)=\xi_{10}$, $\xi_2(0)=\xi_{20}$, $\eta_1(0)=0$, and $\eta_2(0)=0$. From Proposition 2(c), $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ is a S_{23}-symmetric periodic solution of the rhomboidal five-body problem with period S satisfying the energy relation $K=0$ if and only if

$$\xi_2(S/4;\xi_{10},\xi_{20},\mu)=0,\quad \eta_1(S/4;\xi_{10},\xi_{20},\mu)=0,\quad K(\xi_{10},\xi_{20},\mu)=0.$$

We solve equation $K(\xi_{10},\xi_{20},\mu)=0$ with respect to the variable ξ_{20} obtaining in this way $\xi_{20}=\xi_{20}(\xi_{10},\mu)$. In particular, $\xi_{20}(\xi_{10},0)=\sqrt{2\nu_2}\xi_{10}/\sqrt{-2\nu_1-h\xi_{10}^2}$. So $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ is a S_{23}-symmetric periodic solution of the rhomboidal five-body problem with period S satisfying the energy relation $K=0$ if and only if

$$\xi_2(S/4;\xi_{10},\mu)=0,\quad \eta_1(S/4;\xi_{10},\mu)=0. \tag{18}$$

Assume that $p=2\ell$, $q=2k+1$ for some $\ell\in\mathbb{N}$ and $k\in\mathbb{N}\cup\{0\}$ and that h_1^* and h_2^* verify that $h=h_1^*+h_2^*$ and $h_1^*=(p/q)^{2/3}\nu_1h_2^*/\nu_2$. By Propositions 4 and 5(c), we see that $S=S^*=s(pT_1(h_1^*))=s(qT_2(h_2^*))$, $\xi_{10}=\xi_{10}^*=\sqrt{-2\nu_1/h_1^*}$ is a solution of system (18) for $\mu=0$. This solution corresponds to the known S_{23}-symmetric periodic solution $\varphi(s;\xi_{10}^*,\xi_{20}^*,0,0,0)$ of system (3), for $\mu=0$ where $\xi_{20}=\xi_{20}^*=\sqrt{-2\nu_2/h_2^*}$. Our aim is to continue this solution of system (18) for $\mu=0$ to $\mu>0$ sufficiently small.

Applying the implicit function theorem to system (18) in a neighborhood of the known solution we have that if

$$\left.\begin{vmatrix}\frac{\partial\xi_2}{\partial s} & \frac{\partial\xi_2}{\partial\xi_{10}}\\ \frac{\partial\eta_1}{\partial s} & \frac{\partial\eta_1}{\partial\xi_{10}}\end{vmatrix}\right|_{\substack{s=S^*/4\\ \xi_{10}=\xi_{10}^*\\ \mu=0}}\neq 0, \tag{19}$$

then we can find unique analytic functions $\xi_{10}=\xi_{10}(\mu)$, $S=S(\mu)$ defined for $\mu\geqslant 0$ sufficiently small, such that

(i) $\xi_{10}(0)=\xi_{10}^*$, $S(0)=S^*$,
(ii) $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ with $\xi_{10}=\xi_{10}(\mu)$ and $\xi_{20}=\xi_{20}(\xi_{10}(\mu),\mu)$ is a S_{23}-symmetric periodic solution of system (3) with period $S=S(\mu)$ that satisfies the energy relation $K=0$.

Working as for the S_{12}-symmetry we get that

$$\left.\frac{\partial \xi_2}{\partial s}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^* \\ \mu=0}} \neq 0, \quad \text{and} \quad \left.\frac{\partial \eta_1}{\partial s}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^* \\ \mu=0}} = 0.$$

It only remains to compute the value of $\partial\eta_1/\partial\xi_{10}$ evaluated at $s=S^*/4$, $\xi_{10}=\xi_{10}^*$, $\mu=0$. This value is given by the derivative, evaluated at $s=S^*/4$ and $\xi_{10}=\xi_{10}^*$, of the solution $\eta_1(\sigma(s);\xi_{10},\xi_{20},0,0,0)$ with respect to ξ_{10}, where $\eta_1(\sigma(s);\xi_{10},\xi_{20},0,0,0)$ is the solution of system (4) with initial conditions $\xi_1(0)=\xi_{10}$, $\xi_2(0)=\xi_{20}(\xi_{10},0)$, $\eta_1(0)=0$, and $\eta_2(0)=0$ satisfying the energy relation $K=0$ [see Proposition 4(c)]. Then

$$\left.\frac{\partial \eta_1(\sigma(s);0,\xi_{10},\xi_{20},0,0,0)}{\partial \xi_{10}}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^*}} = \left.\left(\frac{\partial \eta_1}{\partial \sigma}\frac{\partial \sigma(s)}{\partial \xi_{10}} + \frac{\partial \eta_1}{\partial \xi_{10}}\right)\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^*}}$$
$$= \frac{3(-1)^{\ell+1}h_2^* p\pi\nu_1}{q\nu_2^2}\left(p\nu_1 + \left(\frac{p}{q}\right)^{1/3} q\nu_2\right),$$

so this derivative is different from zero. Hence, the determinant (19) is not zero. In short, we have proved the following result.

Theorem 7: *Given $\nu_1>0$, $\nu_2>0h<0$, p even and q odd positive integers, the S_{23}-symmetric periodic solution of the rhomboidal five-body problem (3) for $\mu=0$ with initial conditions $\xi_1(0)=\sqrt{-2\nu_1/h_1^*}$, $\xi_2(0)=\sqrt{-2\nu_2/h_2^*}$, $\eta_1(0)=0$, and $\eta_2(0)=0$, where $h_2^*=h\nu_2/((p/q)^{2/3}\nu_1+\nu_2)$, $h_1^*=h(p/q)^{2/3}\nu_1/((p/q)^{2/3}\nu_1+\nu_2)$, can be continued to a μ-parameter family of S_{23}-symmetric periodic orbits of the rhomboidal five-body problem (3) for $\mu>0$ sufficiently small.*

C. The S_{13}-symmetric periodic solutions

Let $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ be the solution of system (3), for fixed values of $\nu_1>0$, $\nu_2>0$, and $h<0$, defined as in Sec. V B. From Proposition 2(b), $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ is a S_{13}-symmetric periodic solution of the rhomboidal five-body problem with period S satisfying the energy relation $K=0$ if and only if

$$\xi_1(S/4;\xi_{10},\xi_{20},\mu)=0, \quad \eta_2(S/4;\xi_{10},\xi_{20},\mu)=0, \quad K(\xi_{10},\xi_{20},\mu)=0.$$

Let $\xi_{20}=\xi_{20}(\xi_{10},\mu)$ be the function defined in Sec. V B. Then $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ is a S_{13}-symmetric periodic solution of the rhomboidal five-body problem with period S satisfying the energy relation $K=0$ if and only if

$$\xi_1(S/4;\xi_{10},\mu)=0, \quad \eta_2(S/4;\xi_{10},\mu)=0. \tag{20}$$

Assume that $p=2\ell+1$, $q=2k$ for some $\ell\in\mathbb{N}\cup\{0\}$ and $k\in\mathbb{N}$ and that h_1^* and h_2^* verify that $h=h_1^*+h_2^*$ and $h_1^*=(p/q)^{2/3}\nu_1 h_2^*/\nu_2$. By Propositions 4 and 5(b), we see that $S=S^*=s(pT_1(h_1^*))=s(qT_2(h_2^*))$, $\xi_{10}=\xi_{10}^*=\sqrt{-2\nu_1/h_1^*}$ is a solution of system (20) for $\mu=0$. This solution correspond to the known S_{13}-symmetric periodic solution $\varphi(s;\xi_{10}^*,\xi_{20}^*,0,0,0)$ of system (3), for $\mu=0$ where $\xi_{20}=\xi_{20}^*=\sqrt{-2\nu_2/h_2^*}$. Our aim is to continue this solution of system (20) for $\mu=0$ to $\mu>0$ sufficiently small.

Applying the implicit function theorem to system (20) in a neighborhood of the known solution we have that if

$$\left.\begin{vmatrix} \dfrac{\partial \xi_1}{\partial s} & \dfrac{\partial \xi_1}{\partial \xi_{10}} \\ \dfrac{\partial \eta_2}{\partial s} & \dfrac{\partial \eta_2}{\partial \xi_{10}} \end{vmatrix}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^* \\ \mu=0}} \neq 0, \tag{21}$$

then we can find unique analytic functions $\xi_{10}=\xi_{10}(\mu)$, $S=S(\mu)$ defined for $\mu \geqslant 0$ sufficiently small, such that

(i) $\xi_{10}(0)=\xi_{10}^*$, $S(0)=S^*$,

(ii) $\varphi(s;\xi_{10},\xi_{20},0,0,\mu)$ with $\xi_{10}=\xi_{10}(\mu)$ and $\xi_{20}=\xi_{20}(\xi_{10}(\mu),\mu)$ is a S_{13}-symmetric periodic solution of system (3) with period $S=S(\mu)$ that satisfies the energy relation $K=0$.

Working as for the S_{12}-symmetry we get that

$$\left.\frac{\partial \xi_1}{\partial s}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^* \\ \mu=0}} \neq 0, \quad \text{and} \quad \left.\frac{\partial \eta_2}{\partial s}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^* \\ \mu=0}} = 0.$$

It only remains to compute the value of $\partial \eta_2/\partial \xi_{10}$ evaluated at $s=S^*/4$, $\xi_{10}=\xi_{10}^*$, $\mu=0$. This value is given by the derivative, evaluated at $s=S^*/4$ and $\xi_{10}=\xi_{10}^*$, of the solution $\eta_2(\tau(s);\xi_{10},\xi_{20},0,0,0)$ with respect to ξ_{10}, where $\eta_2(\tau(s);\xi_{10},\xi_{20},0,0,0)$ is the solution of system (4) with initial conditions $\xi_1(0)=\xi_{10}$, $\xi_2(0)=\xi_{20}(\xi_{10},0)$, $\eta_1(0)=0$, and $\eta_2(0)=0$ satisfying the energy relation $K=0$ [see Proposition 4(b)]. Then

$$\begin{aligned} \left.\frac{\partial \eta_2(\tau(s);\xi_{10},\xi_{20},0,0,0)}{\partial \xi_{10}}\right|_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^*}} &= \left(\frac{\partial \eta_2}{\partial \tau}\frac{\partial \tau(s)}{\partial \xi_{10}} + \frac{\partial \eta_2}{\partial \xi_{10}}\right)_{\substack{s=S^*/4 \\ \xi_{10}=\xi_{10}^*}} \\ &= \frac{(-1)^k h_2 \pi}{\nu_2}\left(p\nu_1 + \left(\frac{p}{q}\right)^{1/3} q(2\nu_1+3\nu_2)\right), \end{aligned}$$

so this derivative is different from zero. Hence, the determinant (21) is not zero. In short, we have proved the following result.

Theorem 8: *Given $\nu_1>0$, $\nu_2>0$, $h<0$, p odd and q even positive integers, the S_{13}-symmetric periodic solution of the rhomboidal five-body problem (3) for $\mu=0$ with initial conditions $\xi_1(0)=\sqrt{-2\nu_1/h_1^*}$, $\xi_2(0)=\sqrt{-2\nu_2/h_2^*}$, $\eta_1(0)=0$, and $\eta_2(0)=0$ where $h_2^*=h\nu_2/((p/q)^{2/3}\nu_1+\nu_2)$, $h_1^*=h(p/q)^{2/3}\nu_1/((p/q)^{2/3}\nu_1+\nu_2)$, can be continued to a μ-parameter family of S_{13}-symmetric periodic orbits of the rhomboidal five-body problem (3) for $\mu>0$ sufficiently small.*

Perturbed block circulant matrices and their application to the wavelet method of chaotic control

Jonq Juang,[a] Chin-Lung Li,[b] and Jing-Wei Chang[c]
Department of Applied Mathematics, National Chiao Tung University, Hsinchu, Taiwan 300, Republic of China

(Received 1 August 2006; accepted 23 October 2006; published online 26 December 2006)

Controlling chaos via wavelet transform was proposed by Wei *et al.* [Phys. Rev. Lett. **89**, 284103.1–284103.4 (2002)]. It was reported there that by modifying a tiny fraction of the wavelet subspace of a coupling matrix, the transverse stability of the synchronous manifold of a coupled chaotic system could be dramatically enhanced. The stability of chaotic synchronization is actually controlled by the second largest eigenvalue $\lambda_2(\alpha,\beta)$ of the (wavelet) transformed coupling matrix $C(\alpha,\beta)$ for each α and β. Here β is a mixed boundary constant and α is a scalar factor. In particular, $\beta=1$ (0) gives the nearest neighbor coupling with periodic (Neumann) boundary conditions. In this paper, we obtain two main results. First, the reduced eigenvalue problem for $C(\alpha,0)$ is completely solved. Some partial results for the reduced eigenvalue problem of $C(\alpha,\beta)$ are also obtained. Second, we are then able to understand behavior of $\lambda_2(\alpha,0)$ and $\lambda_2(\alpha,1)$ for any wavelet dimension $j\in\mathbb{N}$ and block dimension $n\in\mathbb{N}$. Our results complete and strengthen the work of Shieh *et al.* [J. Math. Phys. **47**, 082701.1–082701.10 (2006)] and Juang and Li [J. Math. Phys. **47**, 072704.1–072704.16 (2006)]. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2400828]

I. INTRODUCTION

Of concern here is the eigencurve problem for a class of "perturbed" block circulant matrices.

$$C(\alpha,\beta)\mathbf{b}=\lambda(\alpha,\beta)\mathbf{b}. \tag{1.1a}$$

Here $C(\alpha,\beta)$ is an $n\times n$ block matrix of the following form:

$$C(\alpha,\beta)=\begin{pmatrix} C_1(\alpha,\beta) & C_2(\alpha,1) & 0 & \cdots & 0 & C_2^T(\alpha,\beta) \\ C_2^T(\alpha,1) & C_1(\alpha,1) & C_2(\alpha,1) & \cdots & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & C_2^T(\alpha,1) & C_1(\alpha,1) & C_2(\alpha,1) \\ C_2(\alpha,\beta) & 0 & \cdots & 0 & C_2^T(\alpha,1) & \hat{I}C_1(\alpha,\beta)\hat{I} \end{pmatrix}_{n\times n}. \tag{1.1b}$$

Here

[b]Electronic mail: presidentf.am92g@nctu.edu.tw
[c]Electronic mail: jof12789@yahoo.com.tw

$$C_1(\alpha,\beta)=\begin{pmatrix} -1-\beta & 1 & 0 & \cdots & \cdots & 0 \\ 1 & -2 & 1 & 0 & \cdots & 0 \\ 0 & 1 & -2 & 1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 & -2 & 1 \\ 0 & \cdots & \cdots & 0 & 1 & -2 \end{pmatrix}_{2^j\times 2^j} - \frac{\alpha(1+\beta)}{2^{2j}}ee^T =: A_1(\beta,2^j) - \frac{\alpha(1+\beta)}{2^{2j}}ee^T, \tag{1.1c}$$

where $e=(1,1,\ldots,1)^T$, j is a positive integer, $\alpha>0$ is a (wavelet) scalar factor, and $\beta\in\mathbb{R}$ represents a mixed boundary constant. Moreover,

$$C_2(\alpha,\beta)=\begin{pmatrix} 0 & 0 & \cdots & 0 \\ \vdots & & & \vdots \\ 0 & & & 0 \\ \beta & 0 & \cdots & 0 \end{pmatrix} + \frac{\alpha\beta}{2^{2j}}ee^T =: A_2(\beta,2^j) + \frac{\alpha\beta}{2^{2j}}ee^T, \tag{1.1d}$$

$$\hat{I}=\begin{pmatrix} 0 & 0 & \cdots & \cdots & 0 & 1 \\ 0 & 0 & \cdots & 0 & 1 & 0 \\ \vdots & & \cdot & \cdot & \cdot & \vdots \\ \vdots & \cdot & \cdot & \cdot & & \vdots \\ 0 & 1 & 0 & \cdots & 0 & 0 \\ 1 & 0 & \cdots & \cdots & 0 & 0 \end{pmatrix}. \tag{1.1e}$$

The dimension of $C(\alpha,\beta)$ is $n2^j\times n2^j$. From here on, we shall call n and j the block and the wavelet dimensions of $C(\alpha,\beta)$, respectively. $C(\alpha,\beta)$ is a block circulant matrix (see, e.g., Ref. 1) only if $\beta=1$. It is well known, see, e.g., Theorem 5.6.4 of Ref. 1, that for each α the eigenvalues of $C(\alpha,1)$ consist of eigenvalues of a certain linear combinations of its block matrices. Such results are called the reduced eigenvalue problem for $C(\alpha,1)$.

This problem arises in the wavelet method for a chaotic control.[7] It is found there that the modification of a tiny fraction of wavelet subspaces of a coupling matrix could lead to a dramatic change in chaos synchronizing properties. We begin with describing their work. Let there be N nodes (oscillators). Assume $\mathbf{u}_i$ is the m-dimensional vector of dynamical variables of the ith node. Let the isolated (uncoupling) dynamics be $\dot{\mathbf{u}}_i=f(\mathbf{u}_i)$ for each node. Used in the coupling, $h:\mathbb{R}^m\to\mathbb{R}^m$ is an arbitrary function of each node's variables. Thus, the dynamics of the ith node is

$$\dot{\mathbf{u}}_i=f(\mathbf{u}_i)+\epsilon\sum_{j=1}^{N}a_{ij}h(\mathbf{u}_j),\quad i=1,2,\ldots,N, \tag{1.2a}$$

where ϵ is a coupling strength. The sum $\Sigma_{j=1}^{N}a_{ij}=0$. Let $\mathbf{u}=(\mathbf{u}_1,\mathbf{u}_2,\ldots,\mathbf{u}_N)^T$, $F(\mathbf{u})=(f(\mathbf{u}_1),f(\mathbf{u}_2),\ldots,f(\mathbf{u}_N))^T$, $H(\mathbf{u})=(h(\mathbf{u}_1),h(\mathbf{u}_2),\ldots,h(\mathbf{u}_N))^T$, and $A=(a_{ij})$. We may write Eq. (1.1a) as

$$\dot{\mathbf{u}}=F(\mathbf{u})+\epsilon A\times H(\mathbf{u}). \tag{1.2b}$$

Here $\times$ is the direct product of two matrices B and C defined as follows. Let $B=(b_{ij})_{k_1\times k_2}$ be a $k_1\times k_2$ matrix and $C=(C_{ij})_{k_2\times k_3}$ be a $k_2\times k_3$ block matrix. Then

$$B \times C = \left(\sum_{l=1}^{k_2} b_{il} C_{lj} \right)_{k_1 \times k_3}.$$

Many coupling schemes are covered by Eq. (1.2b). For example, if the Lorenz system is used and the coupling is through its three components x, y, and z, then the function h is just the matrix

$$I_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{1.3}$$

The choice of A will provide the connectivity of nodes. For instance, the nearest neighbor coupling with periodic, Neumann boundary conditions and mixed boundary conditions are, respectively, given as $A=A_1(1,N)+A_2(1,N)+A_2^T(1,N)=:A_P$, $A=A_1(0,N)+A_2(1,N)\hat{I}=:A_N$ and $A=A_1(\beta,N)+A_2(\beta,N)+A_2^T(\beta,N)+(1-\beta)A_2(1,N)\hat{I}=:A_M$, where those A_i's, $i=1,2$, are defined in Eqs. (1.1c) and (1.1d).

Mathematically speaking,[5] the second largest eigenvalue λ_2 of A is dominant in controlling the stability of chaotic synchronization, and the critical strength ϵ_c for synchronization can be determined in terms of λ_2,

$$\epsilon_c = \frac{L_{\max}}{-\lambda_2}. \tag{1.4}$$

The eigenvalues of $A=A_P$ are given by $\lambda_i=-4\sin^2[\pi(i-1)/N]$, $i=1,2,\ldots,N$. In general, a larger number of nodes give a smaller nonzero eigenvalue λ_2 in magnitude and, hence, a larger ϵ_c. In controlling a given system, it is desirable to reduce the critical coupling strength ϵ_c. The wavelet method in Ref. 7 will, in essence, transform A into $C(\alpha,\beta)$. Consequently, it is of great interest to study the second eigencurve of $C(\alpha,\beta)$ for each β. By the second largest eigencurve $\lambda_2(\alpha,\beta)$ of $C(\alpha,\beta)$ for fixed β, we mean that for given $\alpha>0$, $\lambda_2(\alpha,\beta)$ is the second largest eigenvalue of $C(\alpha,\beta)$. We remark that 0 is the largest eigenvalue of $C(\alpha,\beta)$ for any $\alpha>0$ and $\beta\in\mathbb{R}$. This is to say that for fixed β, $\lambda_2(\alpha,\beta)=0$ is the first eigencurve of $C(\alpha,\beta)$. A numerical simulation[7] of a coupled system of $N=512$ Lorenz oscillators shows that with $h=I_3$ and $A=A_P$, the critical coupling strength ϵ_c decreases linearly with respect to the increase of α up to a critical value α_c. The smallest ϵ_c is about 6, which is about 10^3 times smaller than the original critical coupling strength, indicating the efficiency of the proposed approach.

The mathematical verification of such phenomena is first achieved by Shieh *et al.*[6] Specifically, they solved the second eigencurve problem of $C(\alpha,1)$ with n being a multiple of 4 and j being any positive integer. Subsequently, in Ref. 4 the second eigencurve problem for $C(\alpha,0)$ and $C(\alpha,1)$ with n being any positive integer and $j=1$ are solved without touching on the reduced eigenvalue problem. In this paper, we obtain two main results. First, the reduced eigenvalue problem for $C(\alpha,0)$ is completely solved. Some partial results for the reduced eigenvalue problem of $C(\alpha,\beta)$ are also obtained. Second, we are then able to understand the behavior of $\lambda_2(\alpha,0)$ and $\lambda_2(\alpha,1)$ for any j and $n\in\mathbb{N}$.

II. REDUCED EIGENVALUE PROBLEMS

Writing the eigenvalue problem $C(\alpha,\beta)\mathbf{b}=\lambda\mathbf{b}$, where $\mathbf{b}=(\mathbf{b}_1,\mathbf{b}_2,\ldots,\mathbf{b}_n)^T$ and $\mathbf{b}_i\in\mathbb{C}^{2^j}$, in block component form, we get

$$C_2^T(\alpha,1)\mathbf{b}_{i-1} + C_1(\alpha,1)\mathbf{b}_i + C_2(\alpha,1)\mathbf{b}_{i+1} = \lambda\mathbf{b}_i, \quad 1 \leqslant i \leqslant n. \tag{2.1a}$$

Mixed boundary conditions would yield that

$$C_2^T(\alpha,1)\mathbf{b}_0 + C_1(\alpha,1)\mathbf{b}_1 + C_2(\alpha,1)\mathbf{b}_2 = \lambda\mathbf{b}_1 = C_1(\alpha,\beta)\mathbf{b}_1 + C_2(\alpha,1)\mathbf{b}_2 + C_2^T(\alpha,\beta)\mathbf{b}_n$$

and

$$C_2^T(\alpha,1)\mathbf{b}_{n-1} + C_1(\alpha,1)\mathbf{b}_n + C_2(\alpha,1)\mathbf{b}_{n+1} = \lambda\mathbf{b}_n = C_2(\alpha,\beta)\mathbf{b}_1 + C_2^T(\alpha,1)\mathbf{b}_{n-1} + \hat{I}C_1(\alpha,\beta)\hat{I}\mathbf{b}_n,$$

or, equivalently,

$$\begin{aligned} C_2^T(\alpha,1)\mathbf{b}_0 &= (C_1(\alpha,\beta) - C_1(\alpha,1))\mathbf{b}_1 + C_2^T(\alpha,\beta)\mathbf{b}_n \\ &= \left[\begin{pmatrix} 1-\beta & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix} + \frac{\alpha(1-\beta)}{2^{2j}} ee^T\right]\mathbf{b}_1 + \left[\begin{pmatrix} 0 & \cdots & 0 & \beta \\ 0 & \cdots & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 \end{pmatrix} + \frac{\alpha\beta}{2^{2j}} ee^T\right]\mathbf{b}_n \\ &= (1-\beta)C_2^T(\alpha,1)\hat{I}\mathbf{b}_1 + \beta C_2(\alpha,1)\mathbf{b}_n \end{aligned} \tag{2.1b}$$

and

$$C_2(\alpha,1)\mathbf{b}_{n+1} = (\hat{I}C_1(\alpha,\beta)\hat{I} - C_1(\alpha,1))\mathbf{b}_n + C_2(\alpha,\beta)\mathbf{b}_1 = (1-\beta)C_2^T(\alpha,1)\hat{I}\mathbf{b}_n + \beta C_2(\alpha,1)\mathbf{b}_1. \tag{2.1c}$$

To study the block difference equation [Eq. (2.1)], we set

$$\mathbf{b}_j = \delta^j v, \tag{2.2}$$

where $\boldsymbol{v} \in \mathbb{C}^{2^j}$ and $\delta \in \mathbb{C}$.

Substituting Eq. (2.2) into Eq. (2.1a), we have

$$[C_2^T(\alpha,1) + \delta(C_1(\alpha,1) - \lambda I) + \delta^2 C_2(\alpha,1)]\mathbf{v} = 0. \tag{2.3}$$

To have a nontrivial solution $\boldsymbol{v}$ satisfying Eq. (2.3), we need to have

$$\det[C_2^T(\alpha,1) + \delta(C_1(\alpha,1) - \lambda I) + \delta^2 C_2(\alpha,1)] = 0. \tag{2.4}$$

Definition 2.1: Equation (2.4) is to be called the characteristic equation of the block difference equation [Eq. (2.1a)]. Let $\delta_k = \delta_k(\lambda) \neq 0$ and $\boldsymbol{v}_k = \boldsymbol{v}_k(\lambda) \neq 0$ be complex numbers and vectors, respectively, satisfying Eq. (2.3). Here $k = 1,2,\ldots,m$ and $m \leqslant 2^j$. Assume that there exists a $\lambda \in \mathbb{C}$, such that $\mathbf{b}_j = \Sigma_{k=1}^m c_k \delta_k^j(\lambda)\boldsymbol{v}_k(\lambda)$, $j = 0,1,\ldots,n+1$, satisfy Eqs. (2.1b) and (2.1c), where $c_k \in \mathbb{C}$. If, in addition, $\mathbf{b}_j$, $j = 1,2,\ldots,n$, are not all zero vectors, then such $\delta_k(\lambda)$ is called a characteristic value of Eq. (2.1a), (2.1b), and (2.1c) or (1.1a) with respect to λ and $\boldsymbol{v}_k(\lambda)$ its corresponding characteristic vector.

Remark 2.1: Clearly, for each α and β, λ in Definition 2.1 is an eigenvalue of $C(\alpha,\beta)$.

Should no ambiguity arises, we will write $C_2^T(\alpha,1) = C_2^T$, $C_1(\alpha,1) = C_1$, and $C_2(\alpha,1) = C_2$. Likewise, we will write $A_2(\beta,2^j) = A_2(\beta)$ and $A_1(\beta,2^j) = A_1(\beta)$.

Proposition 2.1: *Let* $\rho(\lambda) = \{\delta_i(\lambda) : \delta_i(\lambda)$ *is a root of Eq. (2.4)*$\}$, *and let* $\bar{\rho}(\lambda) = \{1/\delta_i(\lambda) : \delta_i(\lambda)$ *is a root of Eq. (2.4)*$\}$. *Then* $\rho(\lambda) = \bar{\rho}(\lambda)$. *Let* δ_i *and* δ_k *be in* $\rho(\lambda)$. *We further assume that* δ_i *and* $\boldsymbol{v}_i = (v_{i1},\ldots,v_{i2^j})^T$ *satisfy Eq. (2.3). Suppose* $\delta_i \cdot \delta_k = 1$. *Then* δ_k *and* $\boldsymbol{v}_k = (v_{i2^j}, v_{i2^j-1},\ldots,v_{i2},v_{i1})^T =: \boldsymbol{v}_i^s$ *also satisfy Eq. (2.3). Conversely, if* $\delta_i \cdot \delta_k \neq 1$, *then* $\boldsymbol{v}_k \neq \boldsymbol{v}_i^s$.

Proof: To prove $\rho(\lambda) = \bar{\rho}(\lambda)$, we see that

$$\begin{aligned} \det[C_2^T + \delta(C_1 - \lambda I) + \delta^2 C_2] &= \delta^2 \det\left[\frac{1}{\delta^2}C_2^T + \frac{1}{\delta}(C_1 - \lambda I) + C_2\right] \\ &= \delta^2 \det\left[\frac{1}{\delta^2}C_2^T + \frac{1}{\delta}(C_1 - \lambda I) + C_2\right]^T \\ &= \delta^2 \det\left[C_2^T + \frac{1}{\delta}(C_1 - \lambda I) + \frac{1}{\delta^2}C_2\right]. \end{aligned}$$

Thus, if δ is a root of Eq. (2.4), then so is $1/\delta$. To see the last assertion of the proposition, we write Eq. (2.3) with $\delta=\delta_i$ and $\boldsymbol{v}=\boldsymbol{v}_i$ in component form.

$$\sum_{m=1}^{2^j}[(C_2^T)_{lm}v_{im}+\delta_i(\bar{C}_1)_{lm}v_{im}+\delta_i^2(C_2)_{lm}v_{im}]=0,\quad l=1,2,\ldots,2^j. \tag{2.5}$$

Here $\bar{C}_1=C_1-\lambda I$. Now the right hand side of Eq. (2.5) becomes

$$\left(\frac{1}{\delta_k}\right)^2\left\{\sum_{m=1}^{2^j}[(C_2)_{l(2^j+1-m)}v_{i(2^j+1-m)}+\delta_k(\bar{C}_1)_{l(2^j+1-m)}v_{i(2^j+1-m)}+\delta_k^2(C_2^T)_{l(2^j+1-m)}v_{i(2^j+1-m)}]\right\}$$
$$=\left(\frac{1}{\delta_k}\right)^2\left\{\sum_{m=1}^{2^j}[(C_2^T)_{(2^j+1-l)m}v_{i(2^j+1-m)}+\delta_k(\bar{C}_1)_{(2^j+1-l)m}v_{i(2^j+1-m)}+\delta_k^2(C_2)_{(2^j+1-l)m})v_{i(2^j+1-m)}]\right\},$$
$$l=1,2,\ldots,2^j. \tag{2.6}$$

We have used the fact that

$$(A)_{(2^j+1-l)m}=(A^T)_{l(2^j+1-m)}, \tag{2.7}$$

where $A=C_2^T$ or $\bar{C}_1$ or C_2 to justify the equality in Eq. (2.6). However, Eq. (2.7) follows from Eqs. (1.1c) and (1.1d). Letting $v_{i(2^j+1-m)}=v_{km}$, we have that the pair $(\delta_k,\boldsymbol{v}_k)$ satisfies Eq. (2.3). Suppose $\boldsymbol{v}_k=\boldsymbol{v}_i^s$, we see, similarly, that the pair $(1/\delta_i,\boldsymbol{v}_k)$ also satisfies Eq. (2.3). Thus $1/\delta_i=\delta_k$. □

Remark 2.2: Equation (2.4) is a palindromic equation. That is, for each λ, δ and δ^{-1} are both the roots of Eq. (2.4). However, the eigenvalue problem discussed here is not a palindromic eigenvalue problem.[3]

Definition 2.2: We shall call $\boldsymbol{v}^s$ and $-\boldsymbol{v}^s$, the symmetric vector and antisymmetric vector of $\boldsymbol{v}$, respectively. A vector $\boldsymbol{v}$ is symmetric (antisymmetric) if $\boldsymbol{v}=\boldsymbol{v}^s$ ($\boldsymbol{v}=-\boldsymbol{v}^s$).

Theorem 2.1: *Let* $\delta_k=e^{(\pi k/n)i}$, k *is an integer and* $i=\sqrt{-1}$, *then* δ_{2k}, $k=0,1,\ldots,n-1$, *are characteristic values of Eq.* (2.1a), (2.1b), and (2.1c) *with* $\beta=1$. *For each* α, *if* $\lambda\in\mathbb{C}$ *satisfies*

$$\det[C_2^T+\delta_{2k}(C_1-\lambda I)+\delta_{2k}^2C_2]=0,$$

for some $k\in\mathbb{Z}$, $0\leqslant k\leqslant n-1$, *then* λ *is an eigenvalue of* $C(\alpha,1)$.

Proof: Let λ be as assumed. Then there exists a $\boldsymbol{v}\in\mathbb{C}^{2^j}$, $\boldsymbol{v}\neq\mathbf{0}$ such that

$$[C_2^T+\delta_{2k}(C_1-\lambda I)+\delta_{2k}^2C_2]\mathbf{v}=\mathbf{0}.$$

Let $\mathbf{b}_j=\delta_{2k}^j\boldsymbol{v}$, $0\leqslant j\leqslant n+1$. Then such $\mathbf{b}_j$'s satisfy Eqs. (2.1a), (2.1b), and (2.1c). We just proved the assertion of the theorem. □

Corollary 2.1: *Set*

$$\Gamma_k=C_1+\delta_{2n-k}C_2^T+\delta_kC_2. \tag{2.8}$$

Then the eigenvalues of $C(\alpha,1)$, *for each* α, *consist of eigenvalues of* Γ_k, $k=0,2,4,\ldots,2(n-1)$. *That is*, $\rho(C(\alpha,1))=\cup_{k=0}^{n-1}\rho(\Gamma_{2k})$. Here $\rho(A)=$ *the spectrum of the matrix* A.

Remark 2.3: $C(\alpha,1)$ is a block circulant matrix. The assertion of Corollary 2.1 is not new (see, e.g., Theorem 5.6.4 of Ref. 1). Here we merely gave a different proof.

To study the eigenvalue of $C(\alpha,0)$ for each α, we begin with considering the eigenvalues and eigenvectors of $C_2^T+C_1+C_2$ and $C_2^T-C_1+C_2$.

Proposition 2.2: *Let* $T_1(C)$ $(T_2(C))$ *be the set of linearly independent eigenvectors of the matrix* C *that are symmetric (antisymmetric). Then* $|T_1(C_2^T+C_1+C_2)|=|T_2(C_2^T+C_1+C_2)|=|T_1(C_2^T-C_1+C_2)|=|T_2(C_2^T-C_1+C_2)|=2^{j-1}$. *Here* $|A|$ *denote the cardinality of the set* A.

Proof: We will only illustrate the case for $C_2^T-C_1+C_2=:C$. We first observe that $|T_1(C)|$ is less than or equal to 2^{j-1}. So is $|T_2(C)|$. We also remark that the cardinality of the set of all linearly

independent eigenvectors of C is 2^j. If $0<|T_1(C)|<2^{j-1}$, there must exist an eigenvector $\boldsymbol{v}$ for which $\boldsymbol{v}\neq\boldsymbol{v}^s$, $\boldsymbol{v}\neq-\boldsymbol{v}^s$, and $\boldsymbol{v}\notin\text{span}\{T_1(C),T_2(C)\}$, the span of the vectors in $T_1(C)$ and $T_2(C)$. It then follows from Proposition 2.1 that $\boldsymbol{v}+\boldsymbol{v}^s$, a symmetric vector, is in the span$\{T_1(C)\}$. Moreover, $\boldsymbol{v}-\boldsymbol{v}^s$ is in span$\{T_2(C)\}$. Hence $\boldsymbol{v}\in\text{span}\{T_1(C),T_2(C)\}$, a contradiction. Hence, $|T_1(C)|=2^{j-1}$. Similarly, we conclude that $|T_2(C)|=2^{j-1}$. □

Theorem 2.2: *Let* $\delta_k=e^{(\pi k/n)i}$, *where* k *is an integer and* $i=\sqrt{-1}$. *For each* α, *if* $\lambda\in\mathbb{C}$ *satisfies*

$$\det[C_2^T+\delta_k(C_1-\lambda I)+\delta_k^2C_2]=0,$$

for some $k\in\mathbb{Z}$, $1\leqslant k\leqslant n-1$, *then* λ *is an eigenvalue of* $C(\alpha,0)$. *Let* λ *be the eigenvalue of* $C_2^T+C_1+C_2$ $(-C_2^T+C_1-C_2)$ *for which its associated eigenvector* $\boldsymbol{v}$ *satisfies* $\hat{I}\boldsymbol{v}=\boldsymbol{v}$ $(\hat{I}\boldsymbol{v}=-\boldsymbol{v})$, *then* λ *is also an eigenvalue of* $C(\alpha,0)$.

Proof: For any $1\leqslant k\leqslant n-1$, let δ_k be as assumed. Let λ_k and ν_k be a number and a nonzero vector, respectively, satisfying

$$[C_2^T+\delta_k(C_1-\lambda_kI)+\delta_k^2C_2]\boldsymbol{v}_k=\boldsymbol{0}. \tag{2.9}$$

Using Proposition 2.1, we see that λ_k satisfies

$$\det[C_2^T+\delta_{2n-k}(C_1-\lambda_kI)+\delta_{2n-k}^2C_2]=0. \tag{2.10}$$

Let $\boldsymbol{v}_{2n-k}$ be a nonzero vector satisfying $[C_2^T+\delta_{2n-k}(C_1-\lambda_kI)+\delta_{2n-k}^2C_2]\boldsymbol{v}_{2n-k}=\boldsymbol{0}$. Letting

$$\mathbf{b}_i=\delta_k^i\boldsymbol{v}_k+\delta_k\delta_{2n-k}^i\boldsymbol{v}_{2n-k},\quad i=0,1,\ldots,n+1,$$

we conclude, via Eqs. (2.9) and (2.10), that $\mathbf{b}_i$ satisfy Eq. (2.1a) with $\lambda=\lambda_k$. Moreover,

$$\hat{I}\mathbf{b}_1=\delta_k\hat{I}\boldsymbol{v}_k+\hat{I}\boldsymbol{v}_{2n-k}=\delta_k\boldsymbol{v}_{2n-k}+\boldsymbol{v}_k=\mathbf{b}_0.$$

We have used Proposition 2.1 to justify the second equality above. Similarly, $\mathbf{b}_{n+1}=\hat{I}\mathbf{b}_n$. To see $\lambda=\lambda_k$, $1\leqslant k\leqslant n-1$, is indeed an eigenvalue of $C(\alpha,0)$ for each α, it remains to show that $\mathbf{b}_i\neq\mathbf{0}$ for some i. Using Proposition 2.1, we have that there exists an m, $1\leqslant m\leqslant 2^j$ such that $v_{km}=v_{(2n-k)(2^j-m+1)}\neq0$. We first show that $\mathbf{b}_0\neq\mathbf{0}$. Let m be the index for which $v_{km}\neq0$. Suppose $\mathbf{b}_0=\mathbf{0}$. Then

$$v_{km}+\delta_kv_{(2n-k)m}=0$$

and

$$v_{k(2^j-m+1)}+\delta_kv_{(2n-k)(2^j-m+1)}=v_{(2n-k)m}+\delta_kv_{km}=0.$$

And so, $v_{km}=\delta_k^2v_{km}$, a contradiction. Let λ and $\boldsymbol{v}$ be as assumed in the last assertion of theorem. Letting $\mathbf{b}_i=\boldsymbol{v}$ $(\mathbf{b}_i=(-1)^i\boldsymbol{v})$, we conclude that λ is an eigenvalue of $C(\alpha,0)$ with corresponding eigenvector $(\mathbf{b}_1,\mathbf{b}_2,\ldots,\mathbf{b}_n)^T$. Thus, λ_k is an eigenvalue of $C(\alpha,0)$ for each α. □

Corollary 2.2: *Let* $\delta_k=e^{(\pi k/n)i}$, *where* k *is an integer and* $i=\sqrt{-1}$. *Then, for each* α, $\rho(C(\alpha,0))=\cup_{k=1}^{n-1}\rho(\Gamma_k)\cup\rho^S(\Gamma_0)\cup\rho^{AS}(\Gamma_n)$, *where* $\rho^S(A)$ $(\rho^{AS}(A))$ *the set of eigenvalues of* A *for which their corresponding eigenvectors are symmetric (antisymmetric).*

We next consider the eigenvalues of $C(\alpha,\beta)$.

Theorem 2.3: *Let* $\delta_k=e^{(\pi k/n)i}$, *where* k *is an integer and* $i=\sqrt{-1}$. *Then, for each* α,

$$\rho(C(\alpha,\beta))\supset\begin{cases}\bigcup_{k=1}^{[n/2]}\rho(\Gamma_{2k})\cup\rho^S(\Gamma_0), & n\text{ is odd}\\ \bigcup_{k=1}^{(n/2)-1}\rho(\Gamma_{2k})\cup\rho^S(\Gamma_0)\cup\rho^{AS}(\Gamma_n), & n\text{ is even.}\end{cases}$$

Here $[n/2]$ *is the greatest integer that is less than or equal to* $n/2$.

Proof: We illustrate only the case that n is even. Assume that k is such that $1 \leqslant k \leqslant n/2-1$. Let $\mathbf{b}_i = \delta^i_{2k}\boldsymbol{v}_{2k} + \delta_{2k}\delta^i_{2n-2k}\boldsymbol{v}_{2n-2k}$, we see clearly that such $\mathbf{b}_i$, $i=0,1,n,n+1$, satisfy both Neumann and periodic boundary conditions, respectively. And so

$$\mathbf{b}_0 = (1-\beta)\mathbf{b}_0 + \beta\mathbf{b}_0 = (1-\beta)\hat{I}\mathbf{b}_1 + \beta\mathbf{b}_n$$

and

$$\mathbf{b}_{n+1} = (1-\beta)\mathbf{b}_{n+1} + \beta\mathbf{b}_{n+1} = (1-\beta)\hat{I}\mathbf{b}_n + \beta\mathbf{b}_1.$$

Here, δ_{2k}, $1 \leqslant k \leqslant (n/2)-1$, are characteristic values of Eq. (2.1a), (2.1b), and (2.1c). Thus, if $\lambda \in \rho(\Gamma_{2k})$, then λ is an eigenvalue of $C(\alpha,\beta)$. The assertions for Γ_0 and Γ_n can be done similarly.□

Remark 2.4: If n is an even number, for each α and β, half of the eigenvalues of $C(\alpha,\beta)$ are independent of the choice of β. The other characteristic values of Eq. (2.1) seem to depend on β. It is of interest to find them.

III. THE SECOND EIGENCURVE OF $C(\alpha,0)$ AND $C(\alpha,1)$

We begin with considering the eigencurves of Γ_k, as given in Eq. (2.8). Clearly,

$$\Gamma_k = \begin{pmatrix} -2 & 1 & 0 & \cdots & \cdots & \delta_{2n-k} \\ 1 & -2 & 1 & 0 & \cdots & 0 \\ 0 & 1 & -2 & 1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 1 & -2 & 1 \\ \delta_k & \cdots & \cdots & 0 & 1 & -2 \end{pmatrix}_{m\times m} - \frac{\alpha(2-2\cos(\pi k/n))}{m} ee^T =: D_1(k) - \alpha(k)ee^T, \tag{3.1}$$

where $m=2^j$. We next find a unitary matrix to diagonalize $D_1(k)$.

Remark 3.1: Let $(\lambda(k),\mathbf{v}(k))$ be the eigenpair of $D_1(k)$. If $e^T\boldsymbol{v}(k)=0$, then $\lambda(k)$ is also an eigenvalue of Γ_k.

Proposition 3.1: *Let*

$$\theta_{l,k} = \frac{2l\pi}{m} + \frac{k\pi}{nm}, \quad l=0,1,\ldots,m-1, \tag{3.2a}$$

$$\boldsymbol{p}_l(k) = (e^{i\theta_{l,k}}, e^{i2\theta_{l,k}}, \cdots, e^{im\theta_{l,k}})^T, \tag{3.2b}$$

and

$$P(k) = \left(\frac{p_0(k)}{\sqrt{m}}, \ldots, \frac{p_{m-1}(k)}{\sqrt{m}}\right). \tag{3.2c}$$

(i) *Then $P(k)$ is a unitary matrix and $P^H(k)D_1(k)P(k)=\mathrm{diag}(\lambda_{0,k}\cdots\lambda_{m-1,k})$, where P^H is the conjugate transpose of P, and*

$$\lambda_{l,k} = 2\cos\theta_{l,k} - 2, \quad l=0,1,\ldots,m-. \tag{3.2d}$$

(ii) *Moreover, for $0 \leqslant k \leqslant 2n$, the eigenvalues of $D_1(k)$ are distinct if and only if $k \neq 0$, n, or $2n$.*

Proof: Let $\mathbf{b}=(b_1,\ldots,b_m)^T$. Writing the eigenvalue problem $D_1(k)\mathbf{b}=\lambda\mathbf{b}$ in component form, we get

$$b_{j-1} - (2+\lambda)b_j + b_{j+1} = 0, \quad j=2,3,\ldots,m-1, \tag{3.3a}$$

$$-(2+\lambda)b_1 + b_2 + \delta_{2n-k}b_m = 0, \tag{3.3b}$$

$$\delta_k b_1 + b_{m-1} - (2+\lambda) b_m = 0. \tag{3.3c}$$

Set $b_j = \delta^j$, where δ satisfies the characteristic equation $1-(2+\lambda)\delta+\delta^2=0$ of the system $D_1(k)\mathbf{b}=\lambda\mathbf{b}$. Then the boundary conditions (3.3b) and (3.3c) are reduced to

$$\delta^m = \delta_k. \tag{3.4}$$

Thus, the solutions $e^{i\theta_{l,k}}$, $l=0,1,\ldots,m-1$, of Eq. (3.4) are the candidates for the characteristic values of Eq. (3.3). Substituting $e^{i\theta_{l,k}}$ into Eq. (3.3a) and solving for λ, we see that $\lambda=\lambda_{l,k}$ are the candidates for the eigenvalues of $D_1(k)$. Clearly, $(\lambda,\mathbf{b})=(\lambda_{l,k},\boldsymbol{p}_l(k))$ satisfies $D_1(k)\mathbf{b}=\lambda\mathbf{b}$ and $\mathbf{b}=\boldsymbol{p}_l(k)\neq 0$. Thus, $\lambda=\lambda_{l,k}$ are, indeed, the eigenvalues of $D_1(k)$. To complete the proof of the proposition, it suffices to show that $P(k)$ is unitary. To this end, we need to compute $\boldsymbol{p}_l^H(k)\cdot\boldsymbol{p}_{l'}(k)$. Clearly, $\boldsymbol{p}_l^H(k)\cdot\boldsymbol{p}_l(k)=m$. Now, let $l\neq l'$, we have that

$$\boldsymbol{p}_l^H(k)\cdot\boldsymbol{p}_{l'}(k) = \sum_{j=1}^{m} e^{ij(\theta_{l,k}-\theta_{l',k})} = \sum_{j=1}^{m} e^{ij([2(l-l')/m]\pi)} = \frac{r(1-r^m)}{1-r} = 0,$$

where $r=e^{i([2(l-l')/m]\pi)}$. Hence, $P(k)$ is unitary. The last assertion of the proposition is obvious. □

To prove the main results in this section, we also need the following proposition. Some assertions of the proposition are from Theorem 8.6.2 of Ref. 2.

Proposition 3.2: *Suppose* $D=\mathrm{diag}(d_1,\ldots,d_m)\in\mathbb{R}^{m\times m}$ *and that the diagonal entries satisfy* $d_1>\cdots>d_m$. *Let* $\gamma\neq 0$ *and* $\mathbf{z}=(z_1,\ldots,z_m)^T\in\mathbb{R}^n$. *Assume that* $(\lambda_i(\gamma),\boldsymbol{v}_i(\gamma))$ *are the eigenpairs of* $D+\gamma\mathbf{z}\mathbf{z}^T$ *with* $\lambda_1(\gamma)\geqslant\lambda(\gamma)\geqslant\cdots\geqslant\lambda_m(\gamma)$. *(i) Let* $A=\{k:1\leqslant k\leqslant m, z_k=0\}$, $A^c=\{1,\ldots,m\}-A$. *If* $k\in A$, *then* $d_k=\lambda_k$. *(ii) Assume* $\alpha>0$. *Then the following interlacing relations hold* $\lambda_1(\gamma)\geqslant d_1\geqslant\lambda_2(\gamma)\geqslant d_2\geqslant\cdots\geqslant\lambda_m(\gamma)\geqslant d_m$. *Moreover, the strict inequality holds for these indices* $i\in A^c$. *(iii) Let* $i\in A^c$, $\lambda_i(\gamma)$ *are strictly increasing in* γ *and* $\lim_{\alpha\to\infty}\lambda_i(\gamma)=\bar{\lambda}_i$ *for all* i, *where* $\bar{\lambda}_i$ *are the roots of* $g(\lambda)=\Sigma_{k\in A^c}z_i^2/(d_k-\lambda)$ *with* $\bar{\lambda}_i\in(d_i,d_{i-1})$. *In the case that* $1\in A^c$, $d_0=\infty$.

Proof: The proof of interlacing relations in (*ii*) and the assertion in (*i*) can be found in Theorem 8.6.2 of Ref. 2. We only prove the remaining assertions of the proposition. Rearranging $\mathbf{z}$ so that $\mathbf{z}^T=(0,0,\ldots,0,z_{i_1},\ldots,z_{i_k}):=(0,\ldots,0,\underline{\mathbf{z}}^T)$, where $i_1<i_2<\cdots<i_k$ and $i_j\in A^c$, $j=1,\ldots,k$. The diagonal matrix D is rearranged accordingly. Let $D=\mathrm{diag}(D_1,D_2)$, where $D_2=\mathrm{diag}(d_{i_1},\ldots,d_{i_k})$. Following Theorem 8.6.2 of Ref. 2, we see that $\lambda_{i_j}(\gamma)$ are the roots of the scalar equation $f_\gamma(\lambda)$, where

$$f_\gamma(\lambda_{i_j}(\gamma)) = 1+\gamma\sum_{j=1}^{k}\frac{z_j^2}{d_{i_j}-\lambda_{i_j}(\gamma)} = 0. \tag{3.5}$$

Differentiating the equation above with respect to γ, we get

$$\sum_{j=1}^{k}\frac{z_{i_j}^2}{d_{i_j}-\lambda_{i_j}(\gamma)} + \left(\gamma\sum_{j=1}^{k}\frac{z_{i_j}^2}{(d_{i_j}-\lambda_{i_k}(\gamma))^2}\right)\frac{d\lambda_{i_j}(\gamma)}{d\gamma} = 0.$$

Thus,

$$\frac{d\lambda_{i_j}(\gamma)}{d\gamma} = \frac{1}{\gamma^2}\sum_{j=1}^{k}\frac{z_{i_j}^2}{(d_{i_j}-\lambda_{i_j}(\gamma))^2} > 0.$$

Clearly, for each i_j, the limit of $\lambda_{i_j}(\gamma)$ as $\gamma\to\infty$ exists, say, $\bar{\lambda}_{i_j}$. Since, for $d_{i_j}<\lambda<d_{i_j-1}$,

$$\sum_{j=1}^{k}\frac{z_{i_j}^2}{d_{i_j}-\lambda_{i_j}(\gamma)} = \frac{1}{\gamma}.$$

Taking the limit as $\alpha\to\infty$ on both sides of the equation above, we get

$$\sum_{j=1}^{k} \frac{z_{i_j}^2}{d_{i_j} - \bar{\lambda}_{i_j}} = 0. \tag{3.6}$$

as desired. □

We are now in the position to state the following theorems.

Theorem 3.1: *Let n and $m=2^j$ be given positive integers. For each k, $k=1,2,\ldots,n-1$, and α, we denote by $\lambda_{l,k}(\alpha)$, $l=0,1,\ldots,2^j-1$, the eigenvalues of Γ_k. For $k=1,2,\ldots,n-1$, we let $(\lambda_{l,k},u_{l,k})$, $l=0,1,\ldots,2^j-1$, be the eigenpairs of $D_1(k)$, as defined in* Eq. (3.1). *Then the following hold true.*

(i) $\lambda_{l,k}(\alpha)$ *is strictly decreasing in* α, $l=0,1,\ldots,2^j-1$ *and* $k=1,2,\ldots,n-1$.

(ii) *There exist* $\lambda_{l,k}^*$ *such that* $\lim_{\alpha\to\infty}\lambda_{l,k}(\alpha)=\lambda_{l,k}^*$. *Moreover,* $g_k(\lambda_{l,k}^*)=0$, *where*

$$g_k(\lambda) = \sum_{l=1}^{m} \frac{1}{(\lambda_{l-1,k})(\lambda_{l-1,k}+\lambda)}. \tag{3.7}$$

Proof: The first assertion of the theorem follows from Proposition 3.2 (iii). Let k be as assumed. Set, for $l=0,1,\ldots,m-1$,

$$z_{l+1} = \boldsymbol{p}_l^H(k)e = \sum_{j=1}^{m} e^{ij\theta_{l,k}} = \frac{e^{-\theta_{l,k}}(1-e^{-im\theta_{l,k}})}{1-e^{-\theta_{l,k}}} = \frac{e^{-\theta_{l,k}}(1-e^{-ik(\pi/n)})}{1-e^{-\theta_{l,k}}}.$$

Then

$$\bar{\mathbf{z}}_{l+1}\mathbf{z}_{l+1} = \frac{2-2\cos m\theta_{l,k}}{2-2\cos\theta_{l,k}} = \frac{2\cos(k\pi/n)-2}{\lambda_{l,k}} \neq 0. \tag{3.8}$$

Let $P(k)$ be as given in Eq. (3.2c). Then

$$-P^H(k)\cdot\Gamma_k\cdot P(k) = \mathrm{diag}(-\lambda_{0,k},\ldots,-\lambda_{m-1,k}) + \alpha(k)P_l^H(k)e(P_l^H(k)e)^H.$$

Note that if k is as assumed, it follows from Proposition 3.1(ii) that $\lambda_{l,k}$, $l=0,\ldots,m-1$, are distinct. Thus, we are in the position to apply Proposition 3.2. Specifically, by noting $A^c=\phi$, we see that $\lambda_{0,k}^*$ satisfies $g(\lambda)=0$, where

$$g(\lambda) = \sum_{l=1}^{m} \frac{1}{(\lambda_{l-1,k})(\lambda_{l-1,k}+\lambda)}.$$

We have used Eqs. (3.2d), (3.6), and (3.8), to find $g(\lambda)$. □

We next give an upper bound for $\lambda_{0,k}^*$, $k=1,2,\ldots,n-1$.

Theorem 3.2: *The following inequalities hold true:*

$$\lambda_{0,k}^* < \lambda_{0,n}, \quad k=1,2,\ldots,n-1. \tag{3.9}$$

Proof: To complete the proof of Eq. (3.9), it suffices to show that $g_k(-\lambda_{0,n})<0$. Now,

$$\begin{aligned} &g_k(-\lambda_{0,n}) \\ &\quad= \sum_{l=1}^{m} \frac{1}{[2\cos([2(l-1)\pi/m]+(k\pi/nm))-2][2\cos([2(l-1)\pi/m]+(k\pi/nm))-2\cos(\pi/m)]} \\ &\quad=: h(m,n,k) = h(2^j,n,k). \end{aligned} \tag{3.10}$$

We shall prove that $h(2^j,n,k)<0$ by the induction on j. For $j=1$, $h(2,n,k)=\frac{1}{2}[[1/\cos^2(k\pi/2n)-1]]<0$, $k=1,2,\ldots,n-1$. Assume $h(2^j,n,k)<0$. Here, $n\in\mathbb{N}$ and $k=1,2,\ldots,n-1$. We first note that

$$\cos\left(\frac{2(2^j+i-1)\pi}{2^{j+1}}+\frac{k\pi}{2^{j+1}n}\right)=-\cos\left(\frac{2(i-1)\pi}{2^{j+1}}+\frac{k\pi}{2^{j+1}n}\right)=:-\cos\,\theta_{i-1,k,j+1},\quad i=1,2,\ldots,2^j. \tag{3.11}$$

Moreover, upon using Eq. (3.11), we get that

$$\begin{aligned}
&\frac{1}{(\cos\,\theta_{i-1,k,j+1}-1)(\cos\,\theta_{i-1,k,j+1}-\cos\,\theta_{0,n,j+1})}+\frac{1}{(\cos\,\theta_{2j+i-1,k,j+1}-1)(\cos\,\theta_{2j+i-1,k,j+1}-\cos\,\theta_{0,n,j+1})}\\
&=\frac{1}{(\cos\,\theta_{i-1,k,j+1}-1)(\cos\,\theta_{i-1,k,j+1}-\cos\,\theta_{0,n,j+1})}+\frac{1}{(\cos\,\theta_{i-1,k,j+1}+1)(\cos\,\theta_{i-1,k,j+1}+\cos\,\theta_{0,n,j+1})}\\
&=\frac{2\cos^2\,\theta_{i-1,k,j+1}+2\cos\,\theta_{0,n,j+1}}{(\cos^2\,\theta_{i-1,k,j+1}-1)(\cos^2\,\theta_{i-1,k,j+1}-\cos^2\,\theta_{0,n,j+1})}\\
&=\frac{8(\cos^2\,\theta_{i-1,k,j+1}+\cos\,\theta_{0,n,j+1})}{(\cos\,2\theta_{i-1,k,j+1}-1)(\cos\,2\theta_{i-1,k,j+1}-\cos\,2\theta_{0,n,j+1})}=\frac{2(\cos^2\,\theta_{i-1,k,j+1}+\cos\,\theta_{0,n,j+1})}{(\cos\,\theta_{i-1,k,j}-1)(\cos\,\theta_{i-1,k,j}-\cos\,\theta_{0,n,j})}.
\end{aligned} \tag{3.12}$$

We are now in a position to compute $h(2^{j+1},n,k)$. Using Eq. (3.12), we get that

$$\begin{aligned}
h(2^{j+1},n,k)&=\sum_{l=1}^{2^{j+1}}\frac{1}{4(\cos\,\theta_{l-1,k,j+1}-1)(\cos\,\theta_{l-1,k,j+1}-\cos\,\theta_{0,n,j+1})}\\
&=\sum_{l=1}^{2^j}\frac{2(\cos^2\,\theta_{l-1,k,j+1}+\cos\,\theta_{0,n,j+1})}{(\cos\,\theta_{l-1,k,j}-1)(\cos\,\theta_{i-1,k,j}-\cos\,\theta_{0,n,j})}\leqslant 8(\cos^2\,\theta_{0,k,j+1}+\cos\,\theta_{0,n,j+1})h(2^j,n,k).
\end{aligned} \tag{3.13}$$

We have used the facts that $\cos^2\,\theta_{0,k,j+1}>\cos^2\,\theta_{i-1,k,j+1}$, $i=2,\ldots,2^j$, and that the first term ($i=1$) of the summation in Eq. (3.13) is negative while all the others are positive to justify the inequality in Eq. (3.13). It then follows from Eq. (3.13) that $h(2^{j+1},n,k)<0$. We just complete the proof of the theorem. □

Theorem 3.3: *Let n and j be the block and wavelet dimensions of* $C(\alpha,1)$, *respectively. Assume n and j are any positive integers. Let* $\lambda_2(\alpha)$ *be the second eigencurve of* $C(\alpha,1)$. *Then the following hold.*

(i) $\lambda_2(\alpha)$ *is a nonincreasing function of* α.
(ii) *If n is an even number, then* $\lambda_2(\alpha)=\lambda_{0,n}$ *whenever* $\alpha\geqslant\alpha^*$ *for some* $\alpha^*>0$.
(iii) *If n is an odd number, then* $\lambda_2(\alpha)<\lambda_{0,n}$ *whenever* $\alpha\geqslant\bar{\alpha}$ *for some* $\bar{\alpha}>0$.

Proof: We first remark that in the case of $\beta=1$, the set of the indices k's in Eq. (3.1) is $\{0,2,4,\ldots,2(n-1)\}:=I_n$. Suppose n is an even number. Then $n\in I_n$. Thus, $\delta_n=-1$, $\theta_{0,n}=\pi/m$, and $\boldsymbol{p}_0(n)=(e^{i(\pi/m)},e^{i(2\pi/m)},\ldots,e^{i\pi})^T$. Applying Proposition 3.1, we see that $\boldsymbol{p}_0(n)-\boldsymbol{p}_0^s(n)$, an antisymmetric vector, is also an eigenvector of $D_1(n)$. And so $e^T(\boldsymbol{p}_0(n)-\boldsymbol{p}_0^s(n))=0$. It then follows from Remark 3.1 that $\lambda_{0,n}$ is an eigenvalue of $\Gamma_n=D_1(n)-\rho(n)ee^T$ for all α. The first and second assertions of the theorem now follow from Theorems 3.1 and 3.2. Let n be an odd number. Then $\delta_i\cdot\delta_i\neq 1$ for any $i\in I_n$. Thus, if the pair $(\delta_i,\boldsymbol{v}_i)$ satisfy Eq. (2.3), then $\boldsymbol{v}_i\neq-\boldsymbol{v}_i^s$. Otherwise, the pair $(\delta_i,\boldsymbol{v}_i-(-\boldsymbol{v}_i)^s)=(\delta_i,\boldsymbol{v}_i+\boldsymbol{v}_i^s)$ also satisfy Eq. (2.3). This is a contradiction to the last assertion in Proposition 2.1. Thus, $\boldsymbol{v}_i^H\cdot e\neq 0$ for any $i\in I_n$. We then conclude, via Proposition 3.2 (iii) and Theorem 3.2, that the last assertion of the theorem holds. □

Remark 3.2: (i) Let the number of uncoupled (chaotic) oscillators be $N=2^jn$. If n is an odd number, then the wavelet method for controlling the coupling chaotic oscillators work even better in the sense that the critical coupling strength ϵ can be made even smaller. (ii) For n being a

multiple of 4 and $j \in \mathbb{N}$, the assertions in Theorem 3.3 were first proved in Ref. 6 by a different method.

Theorem 3.4: *Let n and j be the block and wavelet dimensions of* $C(\alpha,0)$, *respectively. Assume n and j are any positive integers. Let* $\lambda_2(\alpha)$ *be the second eigencurve of* $C(\alpha,0)$. *Then for any n, there exists a* $\tilde{\alpha}$ *such that* $\lambda_2(\alpha)=\lambda_{0,n}$ *whenever* $\alpha \geqslant \tilde{\alpha}$.

Remark 3.3: For $n \in \mathbb{N}$ and $j=1$, the explicit formulas for the eigenvalues of $C(\alpha,0)$ were obtained in. Ref. 4 Such results are possible due to the fact that the dimension of the matrices in Eq. (2.4) is 2×2.

(Received 9 September 2006; accepted 1 November 2006; published online 20 December 2006)

The reflection-transmission problem of time-harmonic waves in a stratified electromagnetic medium is investigated. The waves are sent from upward or downward with oblique incidence. By means of the energy flux, up-going and down-going waves are distinguished and the reflection and transmission matrices are introduced. When the solid occupies a strip between two homogeneous media, the existence and uniqueness of the reflected and transmitted waves are proved. The same conclusions are obtained for a dielectric without memory extended in the whole space. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2401751]

I. INTRODUCTION

The aim of this paper is to study the reflection-transmission problem in electromagnetic media occupying the whole space. More precisely, we consider an incident wave and discuss the existence and uniqueness of the scattering matrix resulting from the corresponding reflection and transmission coefficients.

Following Refs. 2, 12, and 13, we consider electromagnetic fields with a time-harmonic dependence. Accordingly, it turns out that the whole procedure is highly dependent on this assumption. Alternative approaches can be found in Refs. 6, 8, and 9, where the scattering problem is examined in the time domain.

The solid is supposed to be linear, anisotropic, dissipative, and stratified along the direction of a given unit vector $\mathbf{n}$. The last assumption implies that the material parameters are constant on planes perpendicular to $\mathbf{n}$. Maxwell's equations lead to a system of first-order ordinary differential equations of the form

$$\mathbf{w}'(z) = \mathbb{N}(z)\mathbf{w}(z), \tag{1}$$

where z is the running parameter along the direction of $\mathbf{n}$, $\mathbb{N}$ is a 4×4 complex-valued matrix depending on the material parameters and the frequency, and the vector $\mathbf{w}$ is formed by the components of the electric displacement and the magnetic field orthogonal to $\mathbf{n}$ and $\mathbf{w}' = d\mathbf{w}/dz$.

The system (1) decouples into two systems of two first-order ordinary differential equations, provided that the solid is isotropic and the incidence is normal. By means of a particular transformation of the dependent and independent variables, the scattering problem of the decoupled systems can be shown to be equivalent to the scattering problem for a linear Schrödinger equation. As it is well known, within this framework the Jost solutions allow a natural identification of the reflection and transmission coefficients, that is, of the scattering matrix. In the present paper, the procedure followed for the Schrödinger equation is suitably generalized so that it can be applied to the system (1).

[a)]Electronic mail: berti@dima.unige.it

Hence we consider two suitable sets of four independent solutions of (1). Each set is partitioned into two up-going and two down-going waves, according as they propagate in the direction of **n** or in the opposite direction. As in Ref. 2, the direction of propagation of a wave is determined by looking at the sign of the component of the corresponding energy flux along the vector **n**, which we denote by $\mathcal{F}$. The scattering matrix is determined by the two bases.

The formulation (1) of Maxwell's equations for time-harmonic fields in stratified solids is discussed in Sec. II. The properties of the energy flux component $\mathcal{F}$ are examined in Sec. III. In particular, it is shown that $\mathcal{F}$ is nonincreasing in the direction **n** of the stratification, as a consequence of the second law of Thermodynamics. This property is crucial for the proof of existence and uniqueness.

In Sec. IV, we consider an anisotropic stratified layer between two homogeneous half-spaces. In each homogeneous region we introduce a suitable basis consisting of two up-going and two down-going waves, which are regarded as the generators of incident, reflected, and transmitted waves. The existence and uniqueness of the reflection and transmission matrices are then proved under the assumption that any linear superposition of the up-going (down-going) generators inherits the property of being up-going (down-going).

A dielectric without memory extended in the whole space is considered in Sec. V. The material parameters are allowed to depend on z, but tend to constant values as $z \to \pm\infty$. The asymptotic generators of incident, reflected, and transmitted waves are then introduced and the existence and uniqueness of the reflection and transmission matrices are shown.

The particular case of normal incidence in isotropic media is considered in Sec. VI.

II. WAVE PROPAGATION IN ELECTROMAGNETIC SOLIDS

An electromagnetic solid occupying the whole space $\mathbb{R}^3$ is considered. We denote by **E**, **H**, **D**, **B** the electric field, the magnetic field, the electric displacement, and the magnetic induction, respectively. For time-harmonic fields, whose time dependence is given by the factor $e^{-i\omega t}$ with $\omega > 0$, Maxwell's equations assume the form

$$\nabla \times \mathbf{E} = i\omega \mathbf{B}, \quad \nabla \times \mathbf{H} = -i\omega \mathbf{D} + \mathbf{J}, \tag{2}$$

$$\nabla \cdot \mathbf{D} = \rho, \quad \nabla \cdot \mathbf{B} = 0, \tag{3}$$

where the current density **J** and the free charge density ρ satisfy the continuity equation

$$\nabla \cdot \mathbf{J} - i\omega\rho = 0. \tag{4}$$

We suppose that the solid is linear and anisotropic, namely the constitutive equations

$$\mathbf{B} = \boldsymbol{\mu}\mathbf{H}, \quad \mathbf{D} = \boldsymbol{\varepsilon}\mathbf{E}, \quad \mathbf{J} = \boldsymbol{\sigma}\mathbf{E}$$

hold, where $\boldsymbol{\mu}$, $\boldsymbol{\varepsilon}$, $\boldsymbol{\sigma}$ are second-order complex-valued tensors depending on the position vector **x**. Hence, Eqs. (2) assume the form

$$\nabla \times \mathbf{H} = -i\omega \bar{\boldsymbol{\varepsilon}}\mathbf{E}, \quad \nabla \times \mathbf{E} = i\omega \boldsymbol{\mu}\mathbf{H}, \tag{5}$$

where $\bar{\boldsymbol{\varepsilon}} = \boldsymbol{\varepsilon} + (i/\omega)\boldsymbol{\sigma}$.

By applying the divergence operator to Eqs. (5) and by using the continuity Eq. (4), we deduce (3). Therefore we take only Eqs. (5) into account.

We assume that the solid is stratified along a direction **n** and we introduce a system of Cartesian axes x_1, x_2, x_3, with unit vectors $\mathbf{e}_1$, $\mathbf{e}_2$, $\mathbf{e}_3$, such that $\mathbf{e}_3 = \mathbf{n}$. Accordingly, the tensors $\boldsymbol{\mu}$, $\boldsymbol{\varepsilon}$, $\boldsymbol{\sigma}$ are constant on planes perpendicular to $\mathbf{e}_3$. Here and in the sequel we denote by z the independent variable x_3.

Owing to the stratification, we look for solutions of (5) in the form

$$\mathbf{H}(\mathbf{x},t)=\boldsymbol{\mathcal{H}}(z)e^{i(\mathbf{k}_\parallel\cdot\mathbf{x}-\omega t)},\quad \mathbf{E}(\mathbf{x},t)=\boldsymbol{\mathcal{E}}(z)e^{i(\mathbf{k}_\parallel\cdot\mathbf{x}-\omega t)}, \tag{6}$$

where $\mathbf{k}_\parallel$ is a real vector perpendicular to $\mathbf{e}_3$. The exponential dependence on $\mathbf{k}_\parallel\cdot\mathbf{x}$ agrees with Snell's law. Substitution of (6) into (5) yields

$$\mathbf{e}_3\times\boldsymbol{\mathcal{H}}'_\parallel+i\mathbf{k}_\parallel\times\boldsymbol{\mathcal{H}}+i\omega\bar{\varepsilon}\boldsymbol{\mathcal{E}}=0,\quad \mathbf{e}_3\times\boldsymbol{\mathcal{E}}'_\parallel+i\mathbf{k}_\parallel\times\boldsymbol{\mathcal{E}}-i\omega\boldsymbol{\mu}\boldsymbol{\mathcal{H}}=0, \tag{7}$$

where the prime indicates differentiation with respect to z and

$$\boldsymbol{\mathcal{H}}_\parallel=\mathcal{H}_1\mathbf{e}_1+\mathcal{H}_2\mathbf{e}_2,\quad \boldsymbol{\mathcal{E}}_\parallel=\mathcal{E}_1\mathbf{e}_1+\mathcal{E}_2\mathbf{e}_2.$$

Since $\mathbf{k}_\parallel$ is real, it is not restrictive to assume $\mathbf{k}_\parallel=k_1\mathbf{e}_1$. Then, inner product of (7) with $\mathbf{e}_3$ leads to the equations

$$\mathbf{e}_3\cdot(\mathbf{k}_\parallel\times\boldsymbol{\mathcal{H}}+\omega\bar{\varepsilon}\boldsymbol{\mathcal{E}})=0,\quad \mathbf{e}_3\cdot(\mathbf{k}_\parallel\times\boldsymbol{\mathcal{E}}-\omega\boldsymbol{\mu}\boldsymbol{\mathcal{H}})=0,$$

which imply

$$\mathcal{E}_3=-\frac{1}{\omega\bar{\varepsilon}_{33}}(k_1\mathcal{H}_2+\omega\bar{\varepsilon}_{13}\mathcal{E}_1+\omega\bar{\varepsilon}_{23}\mathcal{E}_2), \tag{8}$$

$$\mathcal{H}_3=\frac{1}{\omega\mu_{33}}(k_1\mathcal{E}_2-\omega\mu_{13}\mathcal{H}_1-\omega\mu_{23}\mathcal{H}_2). \tag{9}$$

By projecting (7) along $\mathbf{e}_1$, $\mathbf{e}_2$ and taking (8) and (9) into account, we obtain the linear system

$$\mathbf{w}'=\mathbb{N}\mathbf{w}, \tag{10}$$

where $\mathbf{w}=(\mathcal{H}_1,\mathcal{H}_2,\mathcal{E}_1,\mathcal{E}_2)^T$ and $\mathbb{N}$ is a complex valued matrix whose block structure is given by

$$\mathbb{N}=i\begin{pmatrix}\mathbb{N}_1 & \mathbb{N}_2\\ \mathbb{N}_3 & \mathbb{N}_4\end{pmatrix}, \tag{11}$$

with

$$\mathbb{N}_1=-k_1\begin{pmatrix}\dfrac{\mu_{13}}{\mu_{33}} & \dfrac{\mu_{23}}{\mu_{33}}-\dfrac{\bar{\varepsilon}_{23}}{\bar{\varepsilon}_{33}}\\ 0 & \dfrac{\bar{\varepsilon}_{13}}{\bar{\varepsilon}_{33}}\end{pmatrix},$$

$$\mathbb{N}_2=\omega\begin{pmatrix}\dfrac{\bar{\varepsilon}_{13}\bar{\varepsilon}_{23}}{\bar{\varepsilon}_{33}}-\bar{\varepsilon}_{12} & \dfrac{\bar{\varepsilon}_{23}^2}{\bar{\varepsilon}_{33}}-\bar{\varepsilon}_{22}+\dfrac{k_1^2}{\omega^2\mu_{33}}\\ \bar{\varepsilon}_{11}-\dfrac{\bar{\varepsilon}_{13}^2}{\bar{\varepsilon}_{33}} & \bar{\varepsilon}_{12}-\dfrac{\bar{\varepsilon}_{13}\bar{\varepsilon}_{23}}{\bar{\varepsilon}_{33}}\end{pmatrix},$$

$$\mathbb{N}_3=\omega\begin{pmatrix}\mu_{12}-\dfrac{\mu_{13}\mu_{23}}{\mu_{33}} & \mu_{22}-\dfrac{\mu_{23}^2}{\mu_{33}}-\dfrac{k_1^2}{\omega^2\bar{\varepsilon}_{33}}\\ \dfrac{\mu_{13}^2}{\mu_{33}}-\mu_{11} & \dfrac{\mu_{13}\mu_{23}}{\mu_{33}}-\mu_{12}\end{pmatrix},$$

$$\mathbb{N}_4 = -k_1 \begin{pmatrix} \dfrac{\overline{\varepsilon}_{13}}{\overline{\varepsilon}_{33}} & \dfrac{\overline{\varepsilon}_{23}}{\overline{\varepsilon}_{33}} - \dfrac{\mu_{23}}{\mu_{33}} \\ 0 & \dfrac{\mu_{13}}{\mu_{33}} \end{pmatrix}.$$

Since $\mathcal{H}_3$ and $\mathcal{E}_3$ are expressed in terms of the $\mathcal{H}_\parallel$ and $\mathcal{E}_\parallel$ through (8) and (9), we restrict our attention to the system (10).

The material parameters $\boldsymbol{\mu}$, $\boldsymbol{\varepsilon}$, $\boldsymbol{\sigma}$ (and hence the matrix $\mathbb{N}$) are supposed to be continuous or are allowed to suffer jump discontinuities at planes orthogonal to $\mathbf{e}_3$, when different solids in contact are considered. At such planes, the continuity of the electric and magnetic fields $\boldsymbol{\mathcal{E}}_\parallel$, $\boldsymbol{\mathcal{H}}_\parallel$ is required as usual.

III. ENERGY FLUX

In this section we recall the definition and the properties of the energy flux which is involved in the formulation of the reflection-transmission problem.

For complex-valued fields, the time-averaged energy flux vector $\mathbf{S}$, i.e. the Poynting vector, is defined by[7]

$$\mathbf{S} = \frac{1}{2}\mathrm{Re}(\mathbf{E} \times \mathbf{H}^*),$$

where the symbol * denotes the complex conjugate. Since $\mathbf{k}_\parallel$ is real, by using (6) $\mathbf{S}$ is expressed in terms of $\boldsymbol{\mathcal{E}}$, $\boldsymbol{\mathcal{H}}$ as

$$\mathbf{S} = \frac{1}{2}\mathrm{Re}(\boldsymbol{\mathcal{E}} \times \boldsymbol{\mathcal{H}}^*). \tag{12}$$

Thus the Poynting vector depends only on the independent variable z.

The second law of Thermodynamics implies the relation

$$\nabla \cdot \mathbf{S} < 0, \quad (\mathbf{E},\mathbf{H}) \neq (0,0), \tag{13}$$

which is equivalent to

$$\omega\ \mathrm{Im}\ \boldsymbol{\mu} > 0, \quad \omega\ \mathrm{Im}\ \overline{\varepsilon} > 0, \quad \forall\ \omega \in \mathbb{R} \setminus \{0\} \tag{14}$$

in case of harmonic fields (see Ref. 1). In the relations (13) and (14), the equalities hold if the material is without memory.

We denote by $\mathcal{F}$ the projection of the energy flux vector $\mathbf{S}$ along the direction of the stratification, namely

$$\mathcal{F} = \mathbf{S} \cdot \mathbf{e}_3 = S_3.$$

In view of (12), $\mathcal{F}$ assumes the form

$$\mathcal{F} = \frac{1}{4}(\boldsymbol{\mathcal{E}}^* \times \boldsymbol{\mathcal{H}} + \boldsymbol{\mathcal{E}} \times \boldsymbol{\mathcal{H}}^*) \cdot \mathbf{e}_3.$$

Since $\mathcal{F}$ depends only on $\mathcal{E}_1$, $\mathcal{E}_2$, $\mathcal{H}_1$, $\mathcal{H}_2$, it follows that $\mathcal{F}$ is continuous at the common boundary between two different solids.

If we denote by $\mathbb{J}$ the matrix defined as

$$\mathbb{J} = \frac{1}{4}\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix},$$

we write the energy flux in terms of $\mathbf{w}$, i.e.,

$$\mathcal{F} = \mathbf{w}^{\dagger}\mathbb{J}\mathbf{w}, \tag{15}$$

where the symbol † means the conjugate transpose.

The theorem of existence and uniqueness for the reflection-transmission problem is based on the following property of the energy flux.

Proposition. 3.1: *The energy flux $\mathcal{F}$ is nonincreasing in $\mathbb{R}$.*

Proof: Since the vector $\mathbf{S}$ depends only on the variable z, we have

$$\mathcal{F}' = \partial_3 S_3 = \nabla \cdot \mathbf{S}.$$

The thermodynamic restrictions (13) and the continuity of $\mathcal{F}$ guarantee that $\mathcal{F}$ is nonincreasing for each $z \in \mathbb{R}$. □

IV. REFLECTION AND TRANSMISSION PROBLEM IN A STRATIFIED LAYER

In this section we study wave propagation in a stratified solid constituted by a nonhomogeneous layer in the strip $0<z<L$, between two homogeneous media occupying the half-spaces $z<0$ and $z>L$. The matrix $\mathbb{N}$ of system (10) is written as

$$\mathbb{N} = \begin{cases} \mathbb{N}^- & z<0, \\ \widetilde{\mathbb{N}} & 0<z<L, \\ \mathbb{N}^+ & z<L, \end{cases} \tag{16}$$

where $\mathbb{N}^-$ and $\mathbb{N}^+$ denote the constant matrices in the homogeneous regions $z<0$ and $z>L$, respectively, while $\widetilde{\mathbb{N}}$ depends continuously on z.

We assume that $\mathbb{N}^-$ and $\mathbb{N}^+$ are simple matrices and denote by $i\nu_k^{\pm}$, $\mathbf{p}_k^{\pm}$, $k=1,\ldots,4$, the related eigenvalues and corresponding independent eigenvectors. No normalization condition on the eigenvectors $\mathbf{p}_k^{\pm}$, $k=1,\ldots,4$, is required. Moreover, we define by $\mathbb{P}^-$, $\mathbb{P}^+$ the matrices whose columns are the eigenvectors $\mathbf{p}_1^-,\ldots,\mathbf{p}_4^-$ and $\mathbf{p}_1^+,\ldots,\mathbf{p}_4^+$, respectively, i.e.,

$$\mathbb{P}^- = (\mathbf{p}_1^-,\ldots,\mathbf{p}_4^-), \quad \mathbb{P}^+ = (\mathbf{p}_1^+,\ldots,\mathbf{p}_4^+).$$

In order to describe the reflection-transmission problem, we need to characterize the direction of propagation of a wave. Following Ref. 2, we make use of the energy flux to distinguish between waves propagating in the increasing and decreasing z direction. More precisely, we say that a wave $\mathbf{w}$ is up-going or down-going across the plane $z=c$, with $c \in (-\infty,0) \cup (L,+\infty)$, if

$$\mathcal{F}_{\mathbf{w}}(c) > 0 \quad \text{or} \quad \mathcal{F}_{\mathbf{w}}(c) < 0,$$

where the notation $\mathcal{F}_{\mathbf{w}}$ emphasizes the dependence of the flux $\mathcal{F}$ on $\mathbf{w}$.

Consider a solution $\mathbf{w}$ of the system (10). In the half-space $z<0$, $\mathbf{w}$ is written in the form

$$\mathbf{w}(z) = \sum_{k=1}^{4} c_k^- \mathbf{p}_k^- e^{i\nu_k^- z},$$

where c_k^-, $k=1,\ldots,4$, are suitable complex coefficients. In view of (15), the energy flux of $\mathbf{w}$ is given by

$$\mathcal{F}_{\mathbf{w}}(z) = \sum_{k,h=1}^{4} c_k^{-*} c_h^- (\mathbf{p}_k^-)^\dagger \mathbb{J} \mathbf{p}_h^- e^{i(\nu_h^- - \nu_k^{-*})z}$$

$$= \sum_{k,h=1}^{4} c_k^{-*} c_h^- \mathbf{\Phi}_{kh}^- e^{i(\nu_h^- - \nu_k^{-*})z} \tag{17}$$

in the half-space $z<0$, where $\mathbf{\Phi}^-$ is the matrix defined as

$$\mathbf{\Phi}^- = (\mathbb{P}^-)^\dagger \mathbb{J} \mathbb{P}^-. \tag{18}$$

As $\mathbb{P}^-$ is nonsingular, the matrices $\mathbf{\Phi}^-$ and $\mathbb{J}$ are congruent and hence they have the same number of positive, negative, and zero eigenvalues.[11] In particular, since the eigenvalues of $\mathbb{J}$ are

$$\lambda_{1,2} = \frac{1}{4}, \quad \lambda_{3,4} = -\frac{1}{4},$$

And $\mathbf{\Phi}^-$ has two positive and two negative eigenvalues.

This condition is not sufficient to guarantee that a linear combination of up-going (down-going) waves is up-going (down-going). Therefore, further conditions on the matrix $\mathbf{\Phi}^-$ are required.

For convenience, we represent $\mathbf{\Phi}^-$ in the form

$$\mathbf{\Phi}^- = \begin{pmatrix} \mathbf{\Phi}_p^- & \mathbf{\Phi}_1^- \\ \mathbf{\Phi}_2^- & \mathbf{\Phi}_n^- \end{pmatrix}.$$

Henceforth, we assume that $\mathbf{\Phi}_p^-$ and $\mathbf{\Phi}_n^-$ are positive and negative definite, respectively.

Let $\mathbf{w}$ and $\tilde{\mathbf{w}}$ be two solutions of the system (10) such that

$$\mathbf{w} = c_1^- \mathbf{p}_1^- e^{i\nu_1^- z} + c_2^- \mathbf{p}_2^- e^{i\nu_2^- z}, \quad \tilde{\mathbf{w}} = c_3^- \mathbf{p}_3^- e^{i\nu_3^- z} + c_4^- \mathbf{p}_4^- e^{i\nu_4^- z},$$

in the half-space $z<0$ with (c_1^-, c_2^-), $(c_3^-, c_4^-) \in \mathbb{C}^2 \setminus \{(0,0)\}$. From (17) and the assumptions on the definiteness, we obtain

$$\mathcal{F}_{\mathbf{w}}(z) = \sum_{k,h=1}^{2} c_k^{-*} c_h^- \mathbf{\Phi}_{p,kh}^- e^{i(\nu_h^- - \nu_k^{-*})z} > 0,$$

$$\mathcal{F}_{\tilde{\mathbf{w}}}(z) = \sum_{k,h=1}^{2} c_{k+2}^{-*} c_{h+2}^- \mathbf{\Phi}_{n,kh}^- e^{i(\nu_{h+2}^- - \nu_{k+2}^{-*})z} < 0,$$

for every $z<0$. In particular, $\mathbf{p}_1^- e^{i\nu_1^- z}$, $\mathbf{p}_2^- e^{i\nu_2^- z}$ are up-going waves while $\mathbf{p}_3^- e^{i\nu_3^- z}$, $\mathbf{p}_4^- e^{i\nu_4^- z}$ are down-going waves in the half-space $z<0$.

Similarly, we introduce the matrix

$$\mathbf{\Phi}^+ = (\mathbb{P}^+)^\dagger \mathbb{J} \mathbb{P}^+ = \begin{pmatrix} \mathbf{\Phi}_p^+ & \mathbf{\Phi}_1^+ \\ \mathbf{\Phi}_2^+ & \mathbf{\Phi}_n^+ \end{pmatrix},$$

and we assume that $\mathbf{\Phi}_p^+$ and $\mathbf{\Phi}_n^+$ are positive and negative definite, respectively. Therefore, $\mathbf{p}_1^+ e^{i\nu_1^+(z-L)}$, $\mathbf{p}_2^+ e^{i\nu_2^+(z-L)}$ and $\mathbf{p}_3^+ e^{i\nu_3^+(z-L)}$, $\mathbf{p}_4^+ e^{i\nu_4^+(z-L)}$ are waves propagating upwards and downwards, respectively, in the half-space $z>L$.

A. Uniqueness

Let us consider an incident wave $\mathbf{w}^i$ coming from the homogeneous region $z<0$. The corresponding reflected and transmitted waves, $\mathbf{w}^r$ and $\mathbf{w}^t$, occur in the half-spaces $z<0$ and $z>L$, respectively.

We represent the incident, reflected and transmitted waves in the form

$$\mathbf{w}^i = c_1^i \mathbf{p}_1^- e^{i\nu_1^- z} + c_2^i \mathbf{p}_2^- e^{i\nu_2^- z}, \quad \mathbf{w}^r = c_3^r \mathbf{p}_3^- e^{i\nu_3^- z} + c_4^r \mathbf{p}_4^- e^{i\nu_4^- z}$$

in the half-space $z<0$ and

$$\mathbf{w}^t = c_1^t \mathbf{p}_1^+ e^{i\nu_1^+ z} + c_2^t \mathbf{p}_2^+ e^{i\nu_2^+ z}$$

in $z>L$. The assumptions on the matrices $\mathbf{\Phi}^+$ and $\mathbf{\Phi}^-$ guarantee that $\mathbf{w}^i, \mathbf{w}^r$ are up-going and down-going waves, respectively, in the half-space $z<0$, while $\mathbf{w}^t$ propagates upwards in the region $z>L$.

We define

$$\mathbf{w} = \begin{cases} \mathbf{w}^i + \mathbf{w}^r & z \in (-\infty, 0), \\ \tilde{\mathbf{w}} & z \in (0, L), \\ \mathbf{w}^t & z \in (L, +\infty), \end{cases} \tag{19}$$

where $\tilde{\mathbf{w}}$ is a solution of (10) in the open set $(0,L)$.

The reflection-transmission problem is to determine $\mathbf{w}^r$, $\mathbf{w}^t$, $\tilde{\mathbf{w}}$ from the knowledge of the incident wave $\mathbf{w}^i$ such that the function $\mathbf{w}$ is continuous for every $z \in \mathbb{R}$. More precisely, we have to determine $\tilde{\mathbf{w}}$ and the coefficients c_3^r, c_4^r, c_1^t, c_2^t, such that the function $\mathbf{w}$ defined in (19) satisfies (10) with $\mathbb{N}$ given by (16) and is continuous at $z=0$ and $z=L$.

Theorem 4.1: If $\mathbf{\Phi}_n^-$ is negative definite and $\mathbf{\Phi}_p^+$ is positive definite, then the solution $\mathbf{w}$ of the reflection-transmission problem is unique.

Proof: Consider two different solutions $\mathbf{w}$ and $\overline{\mathbf{w}}$ of the reflection-transmission problem. Denote by c_3^r, c_4^r, c_1^t, c_2^t and $\overline{c}_3^r$, $\overline{c}_4^r$, $\overline{c}_1^t$, $\overline{c}_2^t$ the reflection and transmission coefficients related to $\mathbf{w}$ and $\overline{\mathbf{w}}$. By letting $\mathbf{v} = \mathbf{w} - \overline{\mathbf{w}}$, we have

$$\mathbf{v}(z) = \begin{cases} (c_3^r - \overline{c}_3^r)\mathbf{p}_3^- e^{i\nu_3^- z} + (c_4^r - \overline{c}_4^r)\mathbf{p}_4^- e^{i\nu_4^- z} & z \in (-\infty, 0), \\ \tilde{\mathbf{v}}(z) & z \in (0, L), \\ (c_1^t - \overline{c}_1^t)\mathbf{p}_1^+ e^{i\nu_1^+ z} + (c_2^t - \overline{c}_2^t)\mathbf{p}_2^+ e^{i\nu_2^+ z} & z \in (L, +\infty), \end{cases}$$

where $\tilde{\mathbf{v}}$ is defined by $\tilde{\mathbf{v}} = \tilde{\mathbf{w}} - \tilde{\overline{\mathbf{w}}}$.

The assumptions on the matrices $\mathbf{\Phi}_n^-$ and $\mathbf{\Phi}_p^+$ assure that $\mathcal{F}_{\mathbf{v}}(z) \leq 0$ in the half-space $z<0$ and $\mathcal{F}_{\mathbf{v}}(z) \geq 0$ in the region $z>L$. Since the energy flux is non-increasing, we deduce that

$$\mathcal{F}_{\mathbf{v}}(z) \equiv 0$$

for every $z \in \mathbb{R}$. The definiteness of the matrices $\mathbf{\Phi}_n^-$ and $\mathbf{\Phi}_p^+$ guarantees that

$$\mathbf{v}(z) = 0, \quad z \in (-\infty, 0] \cup (L, +\infty].$$

Furthermore, since $\tilde{\mathbf{v}}$ is the unique solution of the Cauchy problem,

$$\mathbf{w}' = \tilde{\mathbb{N}}\mathbf{w}, \quad 0 < z < L,$$

$$\tilde{\mathbf{w}}(0) = 0,$$

$\tilde{\mathbf{v}}$ vanishes identically in $(0,L)$. Thus $\mathbf{w} = \overline{\mathbf{w}}$. □

If we consider incident waves coming from the half-space $z>L$, we have

$$\mathbf{w}^i = c_3^i \mathbf{p}_3^+ e^{i\nu_3^+ z} + c_4^i \mathbf{p}_4^+ e^{i\nu_4^+ z}, \quad \mathbf{w}^r = c_1^r \mathbf{p}_1^+ e^{i\nu_1^+ z} + c_2^r \mathbf{p}_2^+ e^{i\nu_2^+ z}$$

in $z > L$ and

$$\mathbf{w}^t = c_3^t \mathbf{p}_3^- e^{i\nu_3^- z} + c_4^t \mathbf{p}_4^- e^{i\nu_4^- z}$$

in $z < 0$. The corresponding reflection-transmission problem is formulated straightforwardly and the following result can be proved.

Theorem 4.2: If $\mathbf{\Phi}_p^-$ is positive definite and $\mathbf{\Phi}_n^+$ is negative definite, then the solution $\mathbf{w}$ of the reflection-transmission problem is unique.

B. Existence

In order to prove the existence of the solutions of the reflection-transmission problem, we introduce two suitable sets of four independent solutions of the system (10).

Since the matrix $\mathbb{N}$ is constant in the half-space $z < 0$, $\mathbf{p}_1^- e^{i\nu_1^- z}, \ldots, \mathbf{p}_4^- e^{i\nu_4^- z}$ are four independent solutions of the system $\mathbf{w}' = \mathbb{N}^- \mathbf{w}$ in the region $z < 0$. Let $\tilde{\psi}_1^-, \ldots, \tilde{\psi}_4^-$ be the solutions of the Cauchy problems

$$\mathbf{w}' = \tilde{\mathbb{N}}\mathbf{w}, \quad 0 < z < L,$$

$$\mathbf{w}(0) = \mathbf{p}_h^-, \quad h = 1, \ldots, 4.$$

Next consider the half-space $z > L$ and denote by $\alpha_{hk}^+ \in \mathbb{C}$, $h, k = 1, \ldots, 4$, the unique coefficients such that $\Sigma_{k=1}^4 \alpha_{hk}^+ \mathbf{p}_k^+ e^{i\nu_k^+ (z-L)}$ are the solutions of (10) with initial value $\tilde{\psi}_h^-(L)$ at $z = L$. Accordingly, the vectors $\psi_1^-, \ldots, \psi_4^-$, defined by

$$\psi_h^- = \begin{cases} \mathbf{p}_h^- e^{i\nu_h^- z} & z \le 0, \\ \tilde{\psi}_h^- & 0 < z < L, \quad h = 1, \ldots, 4, \\ \displaystyle\sum_{k=1}^4 \alpha_{hk}^+ \mathbf{p}_k^+ e^{i\nu_k^+ (z-L)} & z \ge L, \end{cases}$$

are continuous in $\mathbb{R}$ and satisfy the system (10) in the open set $(-\infty, 0) \cup (0, L) \cup (L, +\infty)$.

Similarly, we introduce the functions $\psi_1^+, \ldots, \psi_4^+$ defined by

$$\psi_h^+ = \begin{cases} \displaystyle\sum_{k=1}^4 \alpha_{hk}^- \mathbf{p}_k^- e^{i\nu_k^- z} & z \le 0, \\ \tilde{\psi}_h^+ & 0 < z < L, \quad h = 1, \ldots, 4 \\ \mathbf{p}_h^+ e^{i\nu_h^+ (z-L)} & z \ge L, \end{cases}.$$

For any incident wave

$$\mathbf{w}^i = c_1^i \mathbf{p}_1^- e^{i\nu_1^- z} + c_2^i \mathbf{p}_2^- e^{i\nu_2^- z}, \quad z < 0,$$

coming from below, we define the corresponding continuous extension $\hat{\mathbf{w}}^i$ of $\mathbf{w}^i$ as

$$\hat{\mathbf{w}}^i = c_1^i \psi_1^- + c_2^i \psi_2^-.$$

Furthermore, we denote by $\hat{\mathbf{w}}^r, \hat{\mathbf{w}}^t$ the continuous extensions of $\mathbf{w}^r$ and $\mathbf{w}^t$, respectively, i.e.,

$$\hat{\mathbf{w}}^r = c_3^r \psi_3^- + c_4^r \psi_4^-, \quad \hat{\mathbf{w}}^t = c_1^t \psi_1^+ + c_2^t \psi_2^+.$$

On determining the coefficients c_3^r, c_4^r, c_1^t, c_2^t in terms of c_1^i, c_2^i by the equation

$$\hat{\mathbf{w}}^i + \hat{\mathbf{w}}^r = \hat{\mathbf{w}}^t, \tag{20}$$

we obtain a solution of the reflection-transmission problem. Indeed, the vector $\mathbf{w}$ defined as

$$\mathbf{w} = \hat{\mathbf{w}}^i + \hat{\mathbf{w}}^r = \hat{\mathbf{w}}^t$$

solves (10) with $\mathbb{N}$ given by (16), is continuous in $\mathbb{R}$ and satisfies (19).

For the sake of simplicity, we let $\mathbf{w}^i = \psi_h^-$, $h=1,2$. Then Eq. (20) reduces to

$$\psi_h^- + \mathbb{R}_{1h}^- \psi_3^- + \mathbb{R}_{2h}^- \psi_4^- = \mathbb{T}_{1h}^+ \psi_1^+ + \mathbb{T}_{2h}^+ \psi_2^+, \quad h=1,2, \tag{21}$$

where R^- and T^+ are the unknown reflection and transmission matrices, respectively.

The equations governing the reflection-transmission process for incident waves coming from upward are

$$\psi_{h+2}^+ + \mathbb{R}_{1h}^+ \psi_1^+ + \mathbb{R}_{2h}^+ \psi_2^+ = \mathbb{T}_{1h}^- \psi_3^- + \mathbb{T}_{2h}^- \psi_4^-, \quad h=1,2. \tag{22}$$

Theorem 4.3 (Existence): *If $\mathbf{\Phi}_p^+$ and $\mathbf{\Phi}_p^-$ are positive definite and $\mathbf{\Phi}_n^+$ and $\mathbf{\Phi}_n^-$ are negative definite, there exist unique $\mathbb{T}^+$, $\mathbb{T}^-$, $\mathbb{R}^+$, $\mathbb{R}^-$, which solve (21) and (22).*

It is sufficient to prove that ψ_1^+, ψ_2^+, ψ_3^-, ψ_4^- constitute a basis for the solutions of system (10).

Let us suppose

$$c_1\psi_1^+ + c_2\psi_2^+ + c_3\psi_3^- + c_4\psi_4^- = 0$$

and define

$$\mathbf{v} = c_1\psi_1^+ + c_2\psi_2^+ = -c_3\psi_3^- - c_4\psi_4^-.$$

The assumption on the matrices $\mathbf{\Phi}^-$ and $\mathbf{\Phi}^+$ ensures that the inequalities

$$\mathcal{F}_{\mathbf{v}}(z) \geq 0, \quad \forall\, z \geq L,$$

$$\mathcal{F}_{\mathbf{v}}(z) \leq 0, \quad \forall\, z \leq 0,$$

hold.

Since $\mathcal{F}$ is nonincreasing, we deduce

$$0 \leq \mathcal{F}_{\mathbf{v}}(L) \leq \mathcal{F}_{\mathbf{v}}(0) \leq 0,$$

which implies

$$c_k = 0, \quad \forall\, k = 1,\ldots,4,$$

thanks to the definiteness of the matrices $\mathbf{\Phi}_n^-$ and $\mathbf{\Phi}_p^+$. Therefore, the independence of ψ_1^+, ψ_2^+, ψ_3^-, ψ_4^- is proved. □

V. REFLECTION AND TRANSMISSION PROBLEM IN $\mathbb{R}^3$

This section is devoted to an analysis of the reflection and transmission problem in a nonhomogeneous medium occupying the whole space $\mathbb{R}^3$. We assume that the solid is a dielectric without memory, namely the matrices $\boldsymbol{\varepsilon}$, $\boldsymbol{\mu}$ have real entries and $\boldsymbol{\sigma}$ vanishes identically. Furthermore, we suppose that $\boldsymbol{\varepsilon}$, $\boldsymbol{\mu}$, and hence $\mathbb{N}$ are continuous.

The definition of the reflection and transmission coefficients depends on the asymptotic behavior of the solutions of the system (10). Therefore, we need to introduce some requirements on the asymptotic behavior of $\mathbb{N}$.

We assume the existence of the limits of $\mathbb{N}$ as $z \to -\infty$ and $z \to +\infty$, denoted by $\mathbb{N}^-$ and $\mathbb{N}^+$, respectively. The matrices $\mathbb{N}^-$ and $\mathbb{N}^+$ are supposed to be simple and are not required to be equal.

We denote by $i\nu_k^{\pm}$, $\mathbf{p}_k^{\pm}$, $k=1,\dots,4$, the eigenvalues and the corresponding independent eigenvectors of $\mathbb{N}^{\pm}$. From the relation (11), we deduce that the blocks $\mathbb{N}_1,\dots,\mathbb{N}_4$ of the matrix $\mathbb{N}$ have real entries. Therefore, ν_k^+ and ν_k^-, $k=1,...,4$, are either real or occur in conjugate pairs. We assume that $\nu_k^{\pm}\in\mathbb{R}$ for every $k=1,\dots,4$.

Moreover, we suppose that there exist $a,b\in\mathbb{R}$ such that the conditions

$$\int_{-\infty}^{a}\|\mathbb{N}-\mathbb{N}^-\|dz<+\infty,\quad \int_{b}^{+\infty}\|\mathbb{N}-\mathbb{N}^+\|dz<+\infty$$

hold, where $\|\cdot\|$ denotes any norm in the fourth-order square matrices.

Under these assumptions,[10] there exist two sets of four solutions $\psi_1^-,\dots,\psi_4^-$ and $\psi_1^+,\dots,\psi_4^+$ of the system (10) such that

$$\psi_k^{\pm}=(\mathbf{p}_k^{\pm}+\mathbf{v}_k^{\pm})e^{i\nu_k^{\pm}z},\quad k=1,\dots,4, \tag{23}$$

where $\mathbf{v}_k^-$ and $\mathbf{v}_k^+$ satisfy the condition

$$\lim_{z\to-\infty}\mathbf{v}_k^-=\lim_{z\to+\infty}\mathbf{v}_k^+=0,\quad k=1,\dots,4. \tag{24}$$

Moreover, since the conditions

$$\text{Im }\nu_1^-=\dots=\text{Im }\nu_4^-=0,\quad \text{Im }\nu_1^+=\dots=\text{Im }\nu_4^+=0$$

are satisfied, the solutions $\psi_1^-,\dots,\psi_4^-$ and $\psi_1^+,\dots,\psi_4^+$ are determined uniquely[10] by the asymptotic behaviors (24).

The functions $\psi_1^-,\dots,\psi_4^-$ and $\psi_1^+,\dots,\psi_4^+$ are related to the Jost solutions of the Schödinger equation (see Refs. 3 and 4).

By denoting by $\mathbb{E}^{\pm}$ and $\mathbb{V}^{\pm}$ the matrices defined as

$$\mathbb{E}^{\pm}=\text{diag}(e^{i\nu_1^{\pm}z},\dots,e^{i\nu_4^{\pm}z}),\quad \mathbb{V}^{\pm}=(\mathbf{v}_1^{\pm},\dots,\mathbf{v}_4^{\pm}),$$

we write the conditions (23) in the form

$$\boldsymbol{\Psi}^{\pm}=(\psi_1^{\pm},\dots,\psi_4^{\pm})=(\mathbb{P}^{\pm}+\mathbb{V}^{\pm})\mathbb{E}^{\pm}.$$

The independence of the vectors $\mathbf{p}_1^-,\dots,\mathbf{p}_4^-$ and $\mathbf{p}_1^+,\dots,\mathbf{p}_4^+$ guarantees that the functions $\psi_1^-,\dots,\psi_4^-$ and $\psi_1^+,\dots,\psi_4^+$ are independent solutions of the system (10), i.e., any solution $\mathbf{w}$ of (10) may be written in the form

$$\mathbf{w}=\sum_{k=1}^{4}c_k^-\psi_k^-=\sum_{k=1}^{4}c_k^+\psi_k^+,$$

where $c_k^+,c_k^-\in\mathbb{C}$, $k=1,\dots,4$ are suitable complex coefficients.

As in the previous section, we make use of the energy flux to select waves propagating in the increasing and decreasing z direction. More precisely, we say that a wave $\mathbf{w}$ is asymptotically up-going (down-going) when $z\to-\infty$ if $\mathbf{w}$ is definitively up-going (down-going), namely if there exists $Z_{\mathbf{w}}$ such that

$$\mathcal{F}_{\mathbf{w}}(z)>0,\quad [\mathcal{F}_{\mathbf{w}}(z)<0],\quad \forall\, z\le -Z_{\mathbf{w}}.$$

We introduce the matrix $\mathbb{F}^-$ defined as

$$\mathbb{F}^-=(\boldsymbol{\Psi}^-)^{\dagger}\,\mathbb{J}\boldsymbol{\Psi}^-=\begin{pmatrix}\mathbb{F}_p^- & \mathbb{F}_1^-\\ \mathbb{F}_2^- & \mathbb{F}_n^-\end{pmatrix},$$

so that the energy flux of a wave $\mathbf{w}=\Sigma_{k=1}^4c_k^-\psi_k^-$ is given by

$$\mathcal{F} = (\mathbf{c}^-)^\dagger \mathbb{F}^- \mathbf{c}^-,$$

where $\mathbf{c}^- = (c_1^-, \ldots, c_4^-)^T$.

Proposition 5.1: Suppose that the matrices $\mathbf{\Phi}_p^-, \mathbf{\Phi}_n^-$, defined in (18), are positive and negative definite, respectively. Then there exists $Z > 0$ such that $\mathbb{F}_p^-$, $\mathbb{F}_n^-$ are positive and negative definite for all $z \leq -Z$.

Proof: From the relation (18), we deduce that $\mathbf{\Phi}$ and hence $\mathbf{\Phi}_p^-$ are Hermitian. The hypothesis on the definiteness of the matrix $\mathbf{\Phi}_p^-$ guarantees that $\mathbf{\Phi}_p^-$ has two positive eigenvalues λ_1, λ_2 (see Ref. 11).

Let $\mathbb{A}^-$ be the matrix, depending on z, defined as

$$\mathbb{A}^- = (\mathbb{P}^- + \mathbb{V}^-)^\dagger \mathbb{J} (\mathbb{P}^- + \mathbb{V}^-). \tag{25}$$

For convenience, we represent $\mathbb{A}^-$ in the form

$$\mathbb{A}^- = \begin{pmatrix} \mathbb{A}_p^- & \mathbb{A}_1^- \\ \mathbb{A}_2^- & \mathbb{A}_n^- \end{pmatrix}.$$

Since $\mathbb{A}^-$ is Hermitian, $\mathbb{A}_p^-(z)$ is also Hermitian and has two real eigenvalues, $\mu_1(z)$, $\mu_2(z)$.

The definitions (18) and (25) and the condition (24) yield

$$\mathbb{A}_p^-(z) z \underset{z \to -\infty}{\to} \mathbf{\Phi}_p^-$$

and hence

$$\mu_1(z) z \underset{z \to -\infty}{\to} \lambda_1, \quad \mu_2(z) z \underset{z \to -\infty}{\to} \lambda_2.$$

Therefore, there exists $Z_p > 0$ such that $\mu_1(z)$, $\mu_2(z) > 0$ for all $z \leq -Z_p$, namely, the matrix $\mathbb{A}_p^-(z)$ is positive definite for all $z \leq -Z_p$.

The identity

$$\mathbb{F}^- = (\mathbb{E}^-)^\dagger \mathbb{A}^- \mathbb{E}^-$$

leads to the equality

$$\mathbb{F}_p^- = (\mathbb{E}_p^-) \mathbb{A}_p^- \mathbb{E}_p^-,$$

where $\mathbb{E}_p^- = \mathrm{diag}(e^{i\nu_1^- z}, e^{i\nu_2^- z})$, namely, $\mathbb{F}_p^-$ and $\mathbb{A}_p^-$ are congruent. Therefore, $\mathbb{F}_p^-$ is positive definite for all $z \leq -Z_p$.

By repeating the same arguments, we prove that there exists $Z_n > 0$ such that $\mathbb{F}_n^-$ is negative definite for all $z \leq -Z_n$. The theorem is proved with $Z = \max\{Z_p, Z_n\}$. □

The previous proposition assures that linear combinations of ψ_1^-, ψ_2^- represent asymptotically up-going waves, when $z \to -\infty$, whereas linear combinations of ψ_3^-, ψ_4^- represent waves propagating in the decreasing z direction.

Following a similar procedure, we define the matrix $\mathbb{F}^+$ as

$$\mathbb{F}^+ = (\mathbf{\Psi}^+) \mathbb{J} \mathbf{\Psi}^+ = \begin{pmatrix} \mathbb{F}_p^+ & \mathbb{F}_1^+ \\ \mathbb{F}_2^+ & \mathbb{F}_n^+ \end{pmatrix},$$

and we assume that $\mathbf{\Phi}_p^+$ and $\mathbf{\Phi}_n^+$ are positive and negative definite respectively. It follows that ψ_1^+, ψ_2^+ and ψ_3^+, ψ_4^+ represent waves propagating upwards and downwards, respectively, as $z \to +\infty$.

As in the previous section, the equations ruling the reflection-transmission problem are

$$(\psi_1^+, \psi_2^+)\mathbb{T}^+ = (\psi_1^-, \psi_2^-) + (\psi_3^-, \psi_4^-)\mathbb{R}^- \tag{26}$$

for incident waves coming from downward and

$$(\psi_3^-, \psi_4^-)\mathbb{T}^- = (\psi_3^+, \psi_4^+) + (\psi_1^+, \psi_2^+)\mathbb{R}^+ \tag{27}$$

for incident waves coming from upward.

The reflection-transmission problem consists in proving existence and uniqueness of the matrices $\mathbb{R}^\pm$, $\mathbb{T}^\pm$ (and hence of the reflected and transmitted waves) satisfying (26) and (27).

Theorem 5.2: *Suppose that* $\mathbf{\Phi}_p^+$, $\mathbf{\Phi}_p^-$ *are positive definite and* $\mathbf{\Phi}_n^+$ *and* $\mathbf{\Phi}_n^-$ *are negative definite. Then, given the incident waves* ψ_h^-, ψ_{h+2}^+, $h=1,2$ *, there exist unique* $\mathbb{T}^+$, $\mathbb{T}^-$, $\mathbb{R}^+$, $\mathbb{R}^-$ *that solve the reflection-transmission problem (26) and (27).*

Proof: The procedure followed in the proof of Theorem 3 and application of Proposition 1 show that ψ_1^+, ψ_2^+, ψ_3^-, ψ_4^- constitute a basis for the solutions of the system (10). Therefore, there exist unique matrices $\mathbb{R}^\pm$, $\mathbb{T}^\pm$ satisfying (26) and (27) in correspondence with the incident waves ψ_h^-, ψ_{h+2}^+, $h=1,2$. □

Remark: Consider a hereditary medium occupying the whole space. In this case, $\nu_1^\pm, \ldots, \nu_4^\pm$ are allowed to be complex.

The relations (15) and (23) lead to the equality

$$\mathcal{F}_{\psi_k^\pm}(z) = (\mathbf{p}_k^\pm + \mathbf{v}_k^\pm)^\dagger \mathbb{J}(\mathbf{p}_k^\pm + \mathbf{v}_k^\pm) e^{-2\,\mathrm{Im}\,\nu_k^\pm z}, \quad k = 1, \ldots 4.$$

Since only waves with bounded energy flux are physically admissible,[5] we have to consider only media satisfying the conditions

$$\mathrm{Im}\ \nu_k^+ \leq 0, \quad \mathrm{Im}\ \nu_k^- \geq 0, \quad k = 1, \ldots, 4$$

for layer of infinite amplitude.

Moreover, if the conditions

$$\mathrm{Im}\ \nu_1^- = \ldots = \mathrm{Im}\ \nu_4^- \quad \mathrm{Im}\ \nu_1^+ = \ldots = \mathrm{Im}\ \nu_4^+$$

are not satisfied, the functions $\psi_1^\pm, \ldots, \psi_4^\pm$ are not uniquely determined by the asymptotic conditions (24) (see Ref. 10). Therefore, for hereditary media the generators of the incident, reflected, and transmitted waves are not defined uniquely and the uniqueness of the reflection-transmission problem is lost.

VI. ISOTROPIC MEDIA

In general, the matrices $\mathbf{\Phi}_p^\pm$ and $\mathbf{\Phi}_n^\pm$ depend on the material parameters, the wave vector $\mathbf{k}_\parallel$, and the frequency ω. Moreover, the assumptions on the definiteness of the blocks of these matrices are not necessarily satisfied. In this section we give an example of medium verifying these requirements.

For definiteness, consider a homogeneous isotropic solid occupying the half-space $z<0$. The same conclusions can be obtained for the half-space $z>L$ or for isotropic dielectric without memory occupying the whole space. The tensors $\boldsymbol{\varepsilon}$, $\boldsymbol{\mu}$, $\boldsymbol{\sigma}$ assume the form

$$\boldsymbol{\varepsilon} = \varepsilon\mathbb{I}, \quad \boldsymbol{\mu} = \mu\mathbb{I}, \quad \boldsymbol{\sigma} = \sigma\mathbb{I}, \quad z < 0.$$

Moreover, suppose that the incidence is normal, namely $k_1=0$. Hence the matrix $\mathbb{N}^-$ is written as

$$\mathbb{N}^- = i\begin{pmatrix} 0 & 0 & 0 & -\omega\bar{\varepsilon} \\ 0 & 0 & \omega\bar{\varepsilon} & 0 \\ 0 & \omega\mu & 0 & 0 \\ -\omega\mu & 0 & 0 & 0 \end{pmatrix}.$$

Notice that if the solid is isotropic for all $z\in\mathbb{R}$, the system (10) decouples into two systems of first-order differential equations that can be reduced to linear Schrödinger equations.

It is easy to check that the eigenvalues of the matrix $\mathbb{N}^-$ are the complex square roots of $-\omega^2\bar{\varepsilon}\mu$ with multiplicity two. Moreover, the matrix $\mathbb{P}^-$ is given by

$$\mathbb{P}^-=\begin{pmatrix}-\alpha & 0 & \alpha & 0\\ 0 & \alpha & 0 & -\alpha\\ 0 & 1 & 0 & 1\\ 1 & 0 & 1 & 0\end{pmatrix},$$

where α and $-\alpha$ are the complex square roots of $\bar{\varepsilon}\mu^{-1}$. It is not restrictive to assume Re $\alpha>0$, in that Re $\alpha\neq 0$. This is easily seen for dielectrics without memory, since $\bar{\varepsilon}=\varepsilon\neq 0$, and may be shown by contradiction for material with memory. Accordingly, consider the latter case and suppose that Re$\alpha=0$. This condition is equivalent to

$$\mathrm{Im}\left(\bar{\varepsilon}\mu^{-1}\right)=0,\quad \mathrm{Re}\left(\bar{\varepsilon}\mu^{-1}\right)<0, \tag{28}$$

since $\bar{\varepsilon}$ does not vanish.

The thermodynamic restrictions (14) lead to

$$\mathrm{Im}\ \mu\ \mathrm{Im}\ \bar{\varepsilon}>0,\quad \forall\ \omega\neq 0. \tag{29}$$

By using the identities

$$\mathrm{Re}(\bar{\varepsilon}\mu^{-1})=\frac{1}{|\mu|^2}(\mathrm{Re}\ \bar{\varepsilon}\ \mathrm{Re}\ \mu+\mathrm{Im}\ \bar{\varepsilon}\ \mathrm{Im}\ \mu),$$

$$\mathrm{Im}(\bar{\varepsilon}\mu^{-1})=\frac{1}{|\mu|^2}(\mathrm{Im}\ \bar{\varepsilon}\ \mathrm{Re}\ \mu-\mathrm{Im}\ \mu\ \mathrm{Re}\ \bar{\varepsilon}),$$

and in view of the conditions (28) and (29), we deduce the relations

$$\mathrm{Re}\ \bar{\varepsilon}\ \mathrm{Re}\ \mu<0, \tag{30}$$

$$\mathrm{Im}\ \bar{\varepsilon}\ \mathrm{Re}\ \mu-\mathrm{Im}\ \mu\ \mathrm{Re}\ \bar{\varepsilon}=0, \tag{31}$$

for all $\omega\neq 0$. By multiplying (31) for Im μ, we obtain the equality

$$\mathrm{Im}\ \mu\ \mathrm{Im}\ \bar{\varepsilon}\ \mathrm{Re}\ \mu-(\mathrm{Im}\ \mu)^2\mathrm{Re}\ \bar{\varepsilon}=0.$$

Comparison with the condition (29) shows that

$$\mathrm{Re}\ \bar{\varepsilon}\ \mathrm{Re}\ \mu\geq 0,$$

which is a contradiction with (30). Therefore, Re $\alpha\neq 0$.

In view of (18), we deduce

$$\mathbf{\Phi}^-=(\mathbb{P}^-)\mathbb{J}\mathbb{P}^-=\frac{1}{4}\begin{pmatrix}\alpha^*+\alpha & 0 & -\alpha^*+\alpha & 0\\ 0 & \alpha^*+\alpha & 0 & -\alpha^*+\alpha\\ \alpha^*-\alpha & 0 & -\alpha^*-\alpha & 0\\ 0 & \alpha^*-\alpha & 0 & -\alpha^*-\alpha\end{pmatrix}.$$

Therefore the matrices $\mathbf{\Phi}_p^-$, $\mathbf{\Phi}_n^-$ given by

$$\mathbf{\Phi}_p^- = -\mathbf{\Phi}_n^- = \frac{1}{2}\begin{pmatrix} \mathrm{Re}\ \alpha & 0 \\ 0 & \mathrm{Re}\ \alpha \end{pmatrix},$$

are positive and negative definite, respectively.

(Received 30 March 2006; accepted 3 November 2006; published online 29 December 2006)

Gauge fields associated with the manifestly covariant dynamics of particles in (3,1) space time are five dimensional (5D). We provide solutions of the classical 5D gauge field equations in both (4,1) and (3,2) flat space-time metrics for the simple example of a uniformly moving point source. Green functions for the 5D field equations are obtained, which are consistent with the solutions for uniform motion obtained directly from the field equations with free asymptotic conditions. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2401692]

I. INTRODUCTION

Maxwell electrodynamics arises in a natural way in the study of quantum dynamical evolution of particles in three-dimensional (3D) space. The nonrelativistic Schrödinger equation has a form that is invariant under the transformation

$$\Psi_t(x) \to e^{i\Lambda(x,t)}\Psi_t(x) \tag{1}$$

when the so-called gauge compensation fields are added to the space and time derivation. One finds in this method how the 3D dynamics associated with nonrelativistic theory results in a four-dimensional (4D) gauge field, which has an $O(3,1)$ invariance for the *homogeneous* field equations.

In a similar way, the manifestly covariant Stueckelberg-Schrödinger[1] equation (discussed below in Sec. II) induces five gauge fields. Some applications and results of the covariant theory are discussed in Sec. II. The motivation for discussing the gauge fields associated with the Stueckelberg-Schrödinger equation follows from the necessity for constructing a logically complete theory. The generalized classical electrodynamics is a direct consequence of the gauge covariant forms of the quantum equations of motion, and it is therefore essential to investigate the implications of this generalized electrodynamics. In this paper we consider the simplest problem of computing the field due to a point source moving with constant velocity in space time. The classical form of the Stueckelberg dynamics has the property that the particles are in principle "off shell," that is, the particle mass defined by $p^\mu p_\mu = -m^2c^2$ is not constrained to have a given numerical value. In this theory, the particle attains its observed mass, to a good approximation, according to the state of the system,[2] and we assume generally that the particle mass lies in this neighborhood. We define the "mass shell" values of m as the value obtained in the nonrelativistic (Galilean) limit of the theory (only a definite value of mass is admissible by Galilean invariance).

What we find is that the qualitative nature of the fields is very different when the source has values above, below, or equal to the mass shell values. We also discuss both timelike and spacelike motion for the source (both types of motion are admitted by the Stueckelberg classical mechanics). These results are important ingredients for the construction of a theory that provides a good phenomenological description for actual laboratory experiments, a subject of current research. For

example, it was shown by Land[3] that scattering of a test particle in the fields produced by a timelike on-shell source does not agree with the Rutherford result. However, an integration over a small section of the orbit of the same particle regularizes some of the singularities of the fields produced, and brings the scattering of the test particle arbitrarily close to the Rutherford form. Thus, as we discuss below, a partial concatenation of the source motion appears to be important for the construction of such a theory. Nevertheless, it is essential to investigate carefully the results of the direct pointwise application of the theory.

We study then, the mathematical and physical properties of these five-dimensional (5D) gauge fields. The work is divided as follows.

In Sec. II, an overview of the 5D off-mass-shell gauge field theory based on the framework of Stueckelberg[1,2,4] is given. 5D gauge theories also arise in other studies, such as a special case of higher dimensional relativistic dynamics and electrodynamics (cf. Refs. 5 and 6), or modern Kaluza-Klein type theories (cf. Ref. 7 and references therein). In this paper, we concentrate on the construction that is based on the Stueckelberg framework (cf. Refs. 2 and 4).

Previous studies of the fields have been conducted (cf. Refs. 3 and 8–11) using certain types of Green functions (GF's). Since the field equation in higher dimension admits many types of GF's, in order to gain some insight into criteria for selecting useful ones, here we study a direct solution by Fourier transform for the special case of a uniformly moving point source (UMS).

In Sec. III, a derivation of 5D gauge fields generated by a uniformly moving point source is given for both (4,1) and (3,2) metrics, followed by classification to regions of source motion, namely, spacelike and timelike. The wave equations are solved with asymptotically free conditions in which the boundary value of the fields at infinity vanish pointwise.

In Sec. IV, a derivation is given of the principal part GF's consistent with the fields generated by a uniformly moving source of Sec. III.

The GF's obtained agree with a particular form of fundamental solutions of 5D wave equations, found in, for example Refs. 12 and 13, i.e.,

$$g(x,\tau) = \lim_{\varepsilon \to 0^+} 14\pi^2 G_\varepsilon(x^2 + \sigma_5 \tau^2), \tag{2}$$

$$G_\varepsilon(y) = \frac{\partial}{\partial \varepsilon} \frac{\theta(-\sigma_5 y + \varepsilon)}{\sqrt{-\sigma_5 y + \varepsilon}}, \tag{3}$$

where σ_5 determines the metric signature, ± 1, for (4,1) and (3,2) metrics, respectively.

Our present study differs from the previous literature as follows:

- The GF's carry the group symmetry in all coordinates, whereas normally only the t retarded solutions are considered.
- The GF's are treated in a unified manner in both (4,1) and (3,2) metrics.
- We shall show that the derivative present in (3) is useful in regularizing the fields, whereas nonderivative forms (cf. Ref. 5 and references therein) have an additional infinite part, which may be removed by other methods such as Hadamard's *finite part* (cf. Ref. 14).
- We study, in particular, the properties of the gauge fields, derived both from the GF's and a more direct method, generated by a uniformly moving point source.

II. FUNDAMENTALS

An off-shell classical and quantum electrodynamics has been constructed[4] from a fundamental theory of relativistic dynamics of 4D particles, termed *events*, in a framework first derived by Stueckelberg.[1,2]

Stueckelberg defined a Lorentz invariant Hamiltonian-like generator of evolution, over an eight-dimensional (8D) phase space, parametrized by a Lorentz invariant τ, in both classical and quantum relativistic mechanics. Solutions of the relativistic quantum two-body bound state problem agree, up to relativistic corrections,[15] with solutions of the nonrelativistic Schrödinger equa-

tion. The experiments of Lindner *et al.*,[16] moreover, showing quantum interference in time, can be explained in a simple and consistent way in the framework of this theory,[17] which also provides strong evidence that the time t is a quantum observable, as required in this framework.

In the classical manifestly covariant theory, the Hamiltonian of a free particle is given by

$$K = \frac{p_\mu p^\mu}{2M}, \tag{4}$$

where $x^\mu = [ct, \mathbf{x}]$ and $p^\mu = [E/c, \mathbf{p}]$. A simple model for an interacting system is provided by the potential model

$$K = \frac{p_\mu p^\mu}{2M} + V(x). \tag{5}$$

The equations are

$$\dot{x}^\mu = \frac{\partial K}{\partial p_\mu} = \frac{1}{M} p^\mu, \quad \dot{p}^\mu = -\frac{\partial K}{\partial x_\mu} = -\frac{\partial V}{\partial x^\mu}. \tag{6}$$

It follows from (6) that

$$\boldsymbol{v} = \frac{d\boldsymbol{x}}{dt} = \frac{\dot{\boldsymbol{x}}}{\dot{t}} = \frac{\boldsymbol{p}}{E},$$

which is the standard formula obtained for velocity in special relativity (we take $c=1$ in the following).

Horwitz and Piron[2] generalized the framework to many-body systems, and gave τ the physical meaning of a *universal historical time*, correlating events in space time.

A general many-body, τ-invariant, classical evolution function may be defined as

$$K = \sum_{n=1}^{N} \frac{1}{2M_n} \eta_{\mu\nu} P_n^\mu P_n^\nu + V(x_1, x_2, \ldots, x_N), \tag{7}$$

where $\eta_{\mu\nu} = \mathrm{diag}(-,+,+,+)$ and n sums over all particles of the system, and, in this case, we have taken the potential function V not to be a function of momenta or τ. The classical equations of motion, for a single particle system in an external potential $V(x)$, are similar to the nonrelativistic Hamilton equations, with, in addition, motion and "momentum" along the t axis:

$$\dot{x}_n^\mu = \frac{\partial K}{\partial p_{n\,\mu}} = \frac{1}{M_n} p_n^\mu, \quad \dot{p}_{n\,\mu} = -\frac{\partial K}{\partial x_n^\mu} = -\frac{\partial V}{\partial x_n^\mu}. \tag{8}$$

In the usual formulation of relativistic dynamics (cf. Ref. 18), the energy momentum is constrained to a *mass shell* defined as

$$p^\mu p_\mu = \mathbf{p}^2 - E^2 = -m^2, \tag{9}$$

where m is a given fixed quantity, a property of the particle. In the Stueckelberg formulation, however, the event mass is generally unconstrained. Since in (5), the value of K is absolutely conserved, $p_\mu p^\mu = -m^2$ is constant only in the special case where

$$\frac{d}{d\tau} V(x) = \left[\dot{x}^\mu \frac{\partial}{\partial x^\mu} + \frac{\partial}{\partial \tau} \right] V(x) = 0.$$

In this case, the particle remains in a specific mass shell, which may or may not coincide with its so-called *Galilean target mass*, usually denoted by M. In the nonrelativistic limit, the mass dis-

tribution converges to a single point; one may choose the parameter M to have this *Galilean target mass value*.[19] We shall assume that M has this value in the following.

In the general case, however, $p^\mu p_\mu \equiv -m^2$ is a dynamical (Lorentz invariant) property, which may depend on τ. The relation between τ and the proper time s, in the model of Eq. (7), is given by

$$ds^2 \equiv -dx^\mu dx_\mu = -\dot{x}^\mu \dot{x}_\mu d\tau^2 = -\frac{1}{M^2} p^\mu p_\mu d\tau^2 = \frac{m^2}{M^2} d\tau^2. \tag{10}$$

Thus, the proper time ds and *universal time* $d\tau$ are related through the ratio between the dynamical Lorentz invariant mass m, and the *Galilean target mass* M. If $V(x)$ goes to zero asymptotically, then it becomes constant. Since this asymptotic value is usually what is measured in experiment, we may assume that it takes on the value of the Galilean target mass. Although there are no detailed models at present, one assumes that there is a stabilizing mechanism (for example, self-interaction or, in terms of statistical mechanics and condensation phenomenon[19]) which brings the particle, at least to a good approximation, to a defined mass value,[19] such that

$$K = \frac{1}{2M} p^\mu p_\mu = \frac{-m^2}{2M} = -\frac{M}{2}.$$

For the quantum case, for which p^μ is represented by $-i\partial/\partial x_\mu$, the Stueckelber Schrödinger equation is taken to be (we take $\hbar = 1$ in the following)

$$i\frac{\partial \Psi_\tau(x)}{\partial \tau} = K\Psi_\tau(x). \tag{11}$$

The Stueckelberg classical and quantum relativistic dynamics have been studied for various systems in some detail, including the classical relativistic Kepler problem[2] and the quantum two-body problem for the central potential.[15]

A. Off-shell electrodynamics

Pre-Maxwell off-shell electrodynamics (OSE) is constructed in a similar fashion to the construction of Maxwell electrodynamics from the Schrödinger equation.[4]

Under the local gauge transformation

$$\Psi'_\tau(x) = e^{-ie_0\chi(x,\tau)}\Psi_\tau(x), \tag{12}$$

five compensation fields $a^\alpha(x,\tau)$ $(\alpha \in \{0,1,2,3,5\})$ are implied, such that with the transformation

$$a'_a(x,\tau) = a_\alpha(x,\tau) - \partial_\alpha \chi(x,\tau),$$

the following modified Stueckelberg-Schrödinger equation remains form invariant:

$$\left[i\frac{\partial}{\partial\tau} + e_0 a_5(x,\tau)\right]\Psi_\tau(x) = \frac{1}{2M}[(p^\mu - e_0 a^\mu)(p_\mu - e_0 a_\mu)]\Psi_\tau(x), \tag{13}$$

under the transformation (12).

We can see this by observing the following relations:

$$[p_\mu - e_0 a'_\mu]\Psi' = \left[-i\frac{\partial}{\partial x^\mu} - e_0\left(a_\mu - \frac{\partial}{\partial x^\mu}\chi\right)\right]e^{-ie_0\chi}\Psi$$
$$= \left[-e_0\frac{\partial}{\partial x^\mu}\chi - i\frac{\partial\Psi}{x^\mu} - e_0\left(a_\mu - \frac{\partial\chi}{\partial x^\mu}\right)\right]e^{-ie_0\chi}\Psi$$
$$= e^{-ie_0\chi}[P_\mu - e_0 a_\mu]\Psi,$$

$$\left[i\frac{\partial}{\partial\tau} + e_0\left(a_5 - \frac{\partial\chi}{\partial\tau}\right)\right]e^{-ie_0\chi}\Psi = \left[e_0\frac{\partial\chi}{\partial\tau} + i\frac{\partial\Psi}{\partial\tau} + e_0\left(a_5 - \frac{\partial\chi}{\partial\tau}\right)\right]e^{-ie_0\chi}\Psi = e^{-ie_0\chi}\left[i\frac{\partial}{\partial\tau} + e_0 a_5\right]\Psi.$$

The result is then of the same form as for the usual $U(1)$ gauge compensation argument for the nonrelativistic Schrödinger equation. Thus, the classical (and quantum) evolution function for a particle, under an external field, assumed to be given by

$$K = \frac{1}{2M}[p - e_0 a(x,\tau)]^2 - e_0 a^5(x,\tau) \tag{14}$$

(where we have used the shorthand notation of $x^2 = x_\mu x^\mu$) and the corresponding Hamilton equations are

$$\dot{x}^\mu(\tau) = \frac{\partial K}{\partial p_\mu} = \frac{1}{M}[p^\mu - e_0 a^\mu], \tag{15}$$

$$\dot{p}^\mu(\tau) = -\frac{\partial K}{\partial x_\mu} = \frac{e_0}{M}(p - e_0 a(x,\tau))_\nu \partial^\mu a^\nu(x,\tau) + e_0\partial^\mu a^5(x,\tau). \tag{16}$$

Here, e_0 is proportional to the Maxwell charge e through a dimensional constant, which is derived below. Second-order equations of motion for $x^\mu(\tau)$, a generalization of the usual Lorentz force, follow from the Hamilton Eqs. (15) and (16) (Ref. 4)

$$M\ddot{x}^\mu = e_0\dot{x}^\nu f^\mu{}_\nu + e_0 f^\mu{}_5, \tag{17}$$

where, for $\alpha,\beta = 0,1,2,3,5$, the antisymmetric tensor

$$f^{\alpha\beta} \equiv \partial^\alpha a^\beta - \partial^\beta a^\alpha \tag{18}$$

is the 5D field tensor. Moreover, the second-order wave equation for the fields $f^{\alpha\beta}$ can be derived from a Lagrangian density as follows[4]:

$$\mathcal{L} = -\frac{\lambda}{4}f_{\alpha\beta}f^{\alpha\beta} - e_0 a_\alpha j^\alpha, \tag{19}$$

which produces the wave equation

$$\lambda\partial_\alpha f^{\alpha\beta} = e_0 j^\beta. \tag{20}$$

λ is a dimensional constant, which will be shown below to have dimensions of length. The sources $j^\beta(x,\tau)$ depend both on space time and on τ, and obey the continuity equation

$$\partial_\alpha j^\alpha = \partial_\mu j^\mu + \partial_\pi \rho = 0, \tag{21}$$

where $j^5 \equiv \rho$ is a Lorentz scalar *space-time density of events*. This equation follows from (13) for

$$\rho_\tau(x) = \Psi^*_\tau(x)\Psi_\tau(x),$$

$$j^{\mu}_{\tau}(x) = -\frac{i}{2M}[\Psi^{*}_{\tau}(x)(i\partial^{\mu} - e_0 a^{\mu}(x,\tau))\Psi_{\tau}(x) + \text{c.c.}],$$

as we discuss below, and also for the classical case from the argument given below.

1. Currents of point events

Maxwell current conservation, for point charges, can be derived (cf. Refs. 20 and 21) by defining the current of a point charge as

$$J^{\mu}(x) = e\int_{-\infty}^{+\infty} ds\, \dot{z}^{\mu}(s)\,\delta^4[x - z(s)]. \tag{22}$$

In that case, s is the proper time, $z^{\mu}(s)$ is the world-line of the point charge (for free motion, s may coincide with τ), and $\dot{z}^{\mu}(s) = (d/ds)z^{\mu}(s)$. Then,

$$\partial_{\mu}J^{\mu} = -e\int_{-\infty}^{+\infty} ds\frac{d}{ds}\delta^4[x - z(s)] = -e\lim_{L\to+\infty}\delta^4[x - z(s)]_{-L}^{+L}, \tag{23}$$

which vanishes if $z^{\mu}(s)$ [or, for example, just the time component $z^0(s)$] becomes infinite for $s \to \pm\infty$, and the observation point x^{μ} is restricted to a bounded region of space time, e.g., the laboratory. Therefore, with Jackson,[20] we identify J^{μ} as the Maxwell current. We see that this current is a functional on the world line, and the usual notion of a "particle" corresponds to this functional on the world line.

If we identify $\delta^4[x-z(s)]$ with a density $\rho_s(x)$ and the local (in τ) current $\dot{z}^{\mu}(s)\,\delta^4[x-z(s)]$ with a local current $j^{\mu}_s(x)$,

$$\rho_s(x) = \delta^4[x - z(s)],\quad j^{\mu}(x,s) = \dot{z}^{\mu}(s)\,\delta^4[x - z(s)], \tag{24}$$

then the relation

$$\frac{d}{ds}\delta^4[x - z(s)] = -\dot{z}^{\mu}(s)\partial_{\mu}\delta^4[x - z(s)]$$

used in the above demonstration in fact corresponds to the conservation law (reverting to the more general parameter τ in place of the proper time s) (21):

$$\partial_{\mu}j^{\mu}(x,\tau) + \partial_{\tau}\rho(x,\tau) = 0. \tag{25}$$

What we call the *pre-Maxwell* current of a point *event* is then defined as

$$j^{\alpha}(x,\tau) = \dot{z}^{\alpha}(\tau)\,\delta^4[x - z(\tau)], \tag{26}$$

where $j^5(x,\tau) \equiv \rho(x,\tau)$ and $\dot{z}^5(\tau) \equiv 1$ [since $z^5(\tau) \equiv \tau$]. Integrating (20) over τ, we recover the standard Maxwell equations for Maxwell fields defined by

$$A^{\mu}(x) = \int a^{\mu}(x,\tau)d\tau. \tag{27}$$

We therefore call the fields $a^{\mu}(x,\tau)$ *pre-Maxwell fields*. Thus, the Maxwell theory is properly contained in the more general pre-Maxwell theory.

For the quantum theory, a real positive definite density function $\rho_{\tau}(x)$ can be derived from the Stueckelberg-Schrödinger Eq. (11)

$$\rho_{\tau}(x) = |\Psi_{\tau}|^2 = \Psi^{*}_{\tau}(x)\Psi_{\tau}(x), \tag{28}$$

which can be identified with the $\rho(x,\tau) = \delta^4[x-z(\tau)]$ in the classical (relativistic) limit. The continuity Eq. (25) is then satisfied for the gauge invariant currents

$$j_\tau^\mu(x) = -\frac{1}{2M}[\Psi_\tau^*(x)(i\partial^\mu - e_0 a^\mu(x,\tau))\Psi_\tau(x) + \text{c.c.}]. \tag{29}$$

Combining (22) with (24), we obtain

$$J^\mu(x) = e\int_{-\infty}^{+\infty} j^\mu(x,\tau)d\tau. \tag{30}$$

This is a restatement of the 5D continuity Eq. (25) and provides a connection between pre-Maxwell OSE and Maxwell electrodynamics. It also follows from (11) that

$$\frac{\partial\rho}{\partial t} + \partial_\mu j^\mu = 0, \tag{31}$$

where $\rho = |\Psi_\tau(x)|^2$, as for the classical case.

2. The wave equation

From Eqs. (20) and (18) one can derive the wave equation for the potentials $a^\alpha(x,\tau)$:

$$\lambda\partial_\beta\partial^\beta a^\alpha - \lambda\partial^\alpha(\partial_\beta a^\beta) = e_0 j^\alpha. \tag{32}$$

Under the generalized Lorentz gauge $\partial_\beta a^\beta = 0$, the wave equation takes the simpler form

$$\lambda\partial_\beta\partial^\beta a^\alpha = \lambda\left[\Box^2 a^\alpha + \sigma_5\frac{\partial^2 a^\alpha}{\partial\tau^2}\right] = e_0 j^\alpha(x,\tau). \tag{33}$$

where a fifth diagonal metric component can take either signs $\sigma_5 = \pm 1$, corresponding to $O(4,1)$ and $O(3,2)$ symmetries of the homogeneous field equations, respectively.

Integrating (33) with respect to τ, and assuming that $\lim_{\tau\to\pm\infty}\partial_\tau a^\alpha(x,\tau) = 0$, we obtain

$$\lambda\int_{-\infty}^{+\infty} d\tau\left[\Box^2 a^\alpha + \sigma_5\frac{\partial^2 a^\alpha}{\partial\tau^2}\right] = \frac{e_0}{e}J^\alpha(x).$$

Identifying

$$A^\mu(x) = \int_{-\infty}^{+\infty} d\tau a^\mu(x,\tau), \tag{34}$$

we obtain

$$\lambda\Box^2 A^\mu(x) = \frac{e_0}{e}J^\mu(x)$$

(where we have restricted our attention to $\mu = 0,1,2,3$), from which a relation between e_0, λ, and the Maxwell charge e can be obtained:

$$e = \frac{e_0}{\lambda}. \tag{35}$$

Therefore, the Maxwell electrodynamics is properly contained in the 5D electromagnetism.

3. A note about units

In natural units ($\hbar = c = 1$), the Maxwell potentials A^μ have units of $1/L$. Therefore, the pre-Maxwell OSE potentials a^α have units of $1/L^2$, and in order to maintain the action integral

$$S = \int_{-\infty}^{+\infty} \mathcal{L}\, d\tau\, d^4x \tag{36}$$

dimensionless, the coefficient λ in (19) must have units of L, forcing e_0 to have units of L as well.

The Fourier transform of the pre-Maxwell OSE fields

$$\tilde{a}^\mu(x,s) = \int_{-\infty}^{+\infty} e^{is\tau} a^\mu(x,\tau) d\tau \tag{37}$$

and Eq. (34) suggest that the Maxwell potentials and fields are the *zero mode* of the pre-Maxwell OSE fields, with respect to the τ axis, i.e.,

$$A^\mu(x) = \tilde{a}^\mu\,(x,s)\big|_{s=0}. \tag{38}$$

B. Solutions of the wave equation

The classical 5D wave Eq. (33) can be solved by the method of Green functions. Such GF's have been found[10,22] through a fivefold Fourier transform of the wave equation. The GF obeys the wave equation of a point source

$$\partial_\beta \partial^\beta g(x,\tau) = \delta^4(x)\,\delta(\tau). \tag{39}$$

After transformation to momentum space, (39) becomes ($k^2 = k_\mu k^\mu$)

$$(k^2 + \sigma_5 k_5^2)\tilde{g}(k,k_5) = 1, \tag{40}$$

i.e., in terms of the inverse transform

$$g(x,\tau) = \frac{1}{(2\pi)^5} \int d^4k\, dk_5 \frac{1}{k^2 + \sigma_5 k_5^2} e^{i[k\cdot x + \sigma_5 k_5 \tau]}. \tag{41}$$

Although (41) is not a well-defined integral, there are, as for GF's in 4D, several ways of defining the integral, which result in GF's, all of which satisfy (39). These different forms of solutions have physical consequences and it is part of the motivation of our work to obtain criteria that could determine this choice.

For example, Land and Horwitz[22] found what they called the *Principal-Part* GF to be

$$g_P(x,\tau) = -\frac{1}{4\pi}\delta(x^2)\,\delta(\tau) - \frac{1}{2\pi^2}\frac{\partial}{\partial x^2}\frac{\theta(-\sigma x^2 - \tau^2)}{\sqrt{-\sigma x^2 - \tau^2}}, \tag{42}$$

where $\sigma = \sigma_5 = \pm 1$ is the signature of the fifth dimension, τ.

A later work by Oron and Horwitz[10] found another, τ-retarded GF of the form

$$g(x,\tau) = \frac{2\theta(\tau)}{(2\pi)^3} \begin{cases} \dfrac{1}{(-x^2-\tau^2)^{3/2}} \tan^{-1}\left(\dfrac{1}{\tau}\sqrt{-x^2-\tau^2}\right) - \dfrac{\tau}{x^2(x^2+\tau^2)} & x^2+\tau^2 < 0, \\ \dfrac{1}{2}\dfrac{1}{(x^2+\tau^2)^{3/2}} \ln\left|\dfrac{\tau - \sqrt{\tau^2+x^2}}{\tau+\sqrt{\tau^2+x^2}}\right| - \dfrac{\tau}{x^2(x^2+\tau^2)} & x^2+\tau^2 > 0, \end{cases} \tag{43}$$

where only the $(4,1)$ case was explicitly given.

GF's of $(n,1)$ wave equations are well known in the mathematical literature (this is taken from Ref. 12; cf. also Refs. 5, 6, and 13):

$$g(x,t)=\begin{cases}\dfrac{\theta(t)}{2\pi}\left(\dfrac{1}{\pi}\dfrac{d}{dt^2}\right)^{(n-3)/2}\delta(t^2-\mathbf{x}^2), & n=3,5,7,\ldots,\\ \dfrac{1}{2\pi}\left(\dfrac{1}{\pi}\dfrac{d}{dt^2}\right)^{(n-2)/2}\dfrac{\theta(t-|\mathbf{x}|)}{\sqrt{t^2-\mathbf{x}^2}}, & n=4,6,8,\ldots,\end{cases}\tag{44}$$

where $n=4$ is the case of $(4,1)$ metric. These well-known GF's, which are *retarded* in t, can be made *symmetric* by the proper choice of the contour of integration on the original Fourier integral representation.

Once the GF's have been found, the general field generated by a given source can then be found by integration on its support

$$a^{\alpha}(x,\tau)=e_0\int d^4x'\,d\tau'\;g(x-x',\tau-\tau')j^{\alpha}(x',\tau'),\tag{45}$$

and applying it on a point particle given by (24). The potentials of point events can then be found from

$$a^{\alpha}(x,\tau)=e_0\int_{-\infty}^{+\infty}d\tau'\;g(x-z(\tau'),\tau-\tau')\dot{z}^{\alpha}(\tau').\tag{46}$$

In order to get some insight into the criteria for choosing appropriate GF's, we study solutions of the differential Eq. (33) (for the particular choice of uniformly moving point source) without using the GF, i.e., we compute directly

$$a^{\alpha}(x,\tau)=\frac{e}{(2\pi)^5}\int_{-\infty}^{+\infty}d\tau'\;\dot{z}^{\alpha}(\tau')\int d^4k\,dk_5\frac{e^{i[k\cdot(x-z(\tau'))+\sigma_5k_5(\tau-\tau')]}}{k^2+\sigma_5k_5^2}.\tag{47}$$

Solutions of the integral (47) are the subject of the next section.

III. FIELDS OF A UNIFORMLY MOVING POINT CHARGE

A. Solutions of the wave equation

Let us seek a solution to the field equation generated by a uniformly moving point source. Such a source has a general world-line description

$$z^{\alpha}(\tau)=z_0^{\alpha}+b^{\alpha}(\tau-\tau_0)\equiv D^{\alpha}+b^{\alpha}\tau,\quad \dot{z}^{\alpha}(\tau)=b^{\alpha},\quad \alpha\in\{0,1,2,3,5\},\tag{48}$$

where for $z^5\equiv\tau$ we have $b^5=1$. However, we leave b^5 unspecified, leaving the possibility for a 5D symmetry of the solution to emerge, as indeed we find. Without loss of generality, we can eliminate D^{α} by choosing a coordinate system in which $D^{\alpha}=0$. The current of such a source is then given by

$$j^{\alpha}(x,\tau)=b^{\alpha}\delta^4[x-b\tau].\tag{49}$$

Substituting (48) into (47) we obtain an integral representation of the uniform motion fields, which could be called *pre-Coulomb fields*:

$$\begin{aligned}a^{\alpha}(x,\tau)&=\frac{e}{(2\pi)^5}\int_{-\infty}^{+\infty}d\tau'\;b^{\alpha}\int d^4k\,dk_5\frac{e^{i[k\cdot(x-b\tau')+\sigma_5k_5(\tau-b^5\tau')]}}{k^2+\sigma_5k_5^2}=\frac{eb^{\alpha}}{(2\pi)^5}\int_{-\infty}^{+\infty}d\tau'\int d^5k\frac{e^{ik_{\beta}[x^{\beta}-b^{\alpha}\tau']}}{k_{\beta}k^{\beta}}\\&=\frac{eb^{\alpha}}{(2\pi)^5}\int d^5k\int_{-\infty}^{+\infty}d\tau'\frac{e^{ik_{\beta}[x^{\beta}-b^{\alpha}\tau']}}{k_{\beta}k^{\beta}}=\frac{eb^{\alpha}}{(2\pi)^5}\int d^5k\frac{e^{ik_{\beta}x^{\beta}}}{k_{\beta}k^{\beta}}\int_{-\infty}^{+\infty}d\tau'\;e^{-ik_{\beta}b^{\alpha}\tau'}\\&=\frac{eb^{\alpha}}{(2\pi)^4}\int d^5k\frac{e^{ik_{\beta}x^{\beta}}}{k_{\beta}k^{\beta}}\delta(k_{\beta}b^{\beta}).\end{aligned}\tag{50}$$

The argument $k_\beta b^\beta$ of the δ function causes the fivefold integration to be constrained to a 5D hyperplane,

$$S[b]=\{k\in\mathbb{R}^5|k_\alpha b^\alpha=0\},$$

whose normal is just b^β.

In order to proceed, we select a pivot axis for which integration would put the remaining fourfold integral to be in that hyperplane. Naturally, we select k^5, since we will take $b^5>0$:

$$k_\beta b^\beta=k\cdot b+\sigma_5 k^5 b^5=b^5[k\cdot b'+\sigma_5 k^5],$$

where $\mu\in\{0,1,2,3\}$ and

$$b'^\mu=\frac{b^\mu}{b^5},$$

b'^μ is the (3,1) *velocity* of the source relative to its motion in the τ direction.

We then have

$$\delta(k_\beta b^\beta)=\frac{1}{|b^5|}\delta(k\cdot b'+\sigma_5 k^5)\Rightarrow k^5=-\frac{1}{\sigma_5}k\cdot b',$$

$$k_\beta k^\beta=k^2+\sigma_5(k^5)^2=k^2+\sigma_5\left[\frac{-1}{\sigma_5}(k\cdot b')\right]^2=k^2+\sigma_5(k\cdot b')^2,$$

$$k_\beta x^\beta=k\cdot x+\sigma_5 k^5\tau=k\cdot x+\sigma_5\frac{-1}{\sigma_5}[k\cdot b']\tau=k\cdot(x-b'\tau). \tag{51}$$

And thus we obtain

$$a^\alpha(x,\tau)=\frac{eb^\alpha}{2\pi^4|b^5|}\int d^4k\frac{e^{ik\cdot(x-b'\tau)}}{k^2+\sigma_5(k\cdot b')^2}. \tag{52}$$

The integral (52) can be solved by introducing a rotation in k space in which b' takes a particularly simple form, namely, along one of the axes. Aside from the special case of $b'^2=0$, b' can be rotated to be along one of the axes by an $SO(3,1)$ transformation. We shall now divide our discussion to the *spacelike* case where $b'^2>0$ and the *timelike* case where $b'^2<0$, and to avoid complications, we shall solve the zero measure case of $b'^2=0$ by a limiting procedure.

B. *a*-fields due to a (3,1) timelike source

Since $b'^2<0$, we can find $\Lambda\in SO(3,1)$ such that

$$b'=\Lambda b''\ \text{ such that }\ b''=[b''^0;\mathbf{0}],$$

$$b''^0\equiv s=\varepsilon(b'^0)\sqrt{-b'^2},$$

and since $|\Lambda|=1$, we have $d^4k''=d^4k$. Replacing b' with b'' and k with k'', we obtain

$$a^\alpha(x,\tau)=\frac{eb^\alpha}{2\pi^4|b^5|}\int d^4k''\frac{e^{i[\mathbf{k}''\cdot\mathbf{x}''-k''^0(x''^0-s\tau)]}}{k''^2+\sigma_5(-k''^0 s)^2}=\frac{eb^\alpha}{2\pi^4|b^5|}\int d^4k''\frac{e^{i[\mathbf{k}''\cdot\mathbf{x}''-k''^0(x''^0-s\tau)]}}{\mathbf{k}''^2+(k''^0)^2(\sigma_5 s^2-1)}, \tag{53}$$

where $x''=\Lambda^{-1}x$. We follow the convention of boldface corresponding to the space part of a four-vector. Since $b''\tau$ is a four-vector along the time axis, we can find simple closed form expressions for x'' as follows:

TABLE I. Types of source motion.

Source motion	Description
$\sigma_5 b_2' > 1$	*Supershell* case, where the integral (53) has a well-defined solution, essentially the Laplace GF in 4D.
$\sigma_5 b_2' < 1$	*Undershell* case, where the integral is not well defined. The integral is essentially the Maxwell GF.

$$x''^0 = \frac{x''^0 s}{s} = \frac{-x''\cdot b''}{\sqrt{-b'^2}} = \frac{-x\cdot b'}{\sqrt{-b'^2}},$$

$$(\boldsymbol{x}''^0)^2 = x''^2 + (x''^0)^2 = x^2 + \frac{(b'\cdot x)^2}{-b'^2} = x^2 - \frac{(b'\cdot x)^2}{b'^2}.$$

The integral (53) depends on the value of the denominator along the path of integration, where two types of source motion emerge. The types are given as follows in Table I.

In the following we describe the properties of these cases.

1. Undershell timelike *a-fields* $\sigma_5 b'^2 > -1$

As mentioned, the denominator of the integral is not positive definite. Nevertheless, we shall proceed first by absorbing the coefficient $1-\sigma_5 s^2$ into k^0:

$$k^0 \to \frac{k^0}{\sqrt{1-\sigma_5 s^2}}.$$

Equation (53) becomes

$$a^\alpha(x,\tau) = \frac{eb^\alpha}{2\pi^4|b^5|\sqrt{1-\sigma_5 s^2}}\int d^4k \frac{\exp^{i\left[\boldsymbol{k}\cdot\boldsymbol{x}'' - k^0\frac{(x''^0 - s\tau)}{\sqrt{1-\sigma_5 s^2}}\right]}}{\boldsymbol{k}^2-(k^0)^2} = \frac{eb^\alpha}{|b^5|\sqrt{1-\sigma_5 s^2}}\left\{\frac{1}{(2\pi^4)}\int d^4k\frac{e^{ik\cdot y}}{k^2}\right\},$$

where

$$y^\mu \equiv \left[\frac{x''^0 - s\tau}{\sqrt{1-\sigma_5 s^2}}; \boldsymbol{x}''\right].$$

The last integral inside the braces is the well-known Fourier integral form for Maxwell wave equations's GF in four dimensions, and, although it is ill defined, it has many well-known solutions, corresponding to different limits of the integration contour chosen. We shall choose the *Principal Part* solution for our present study:

$$G_P(x) = \frac{1}{(2\pi)^4} P\int_{\mathbb{R}^4} d^4k \frac{e^{ik\cdot x}}{k^2} = \frac{\delta(x^2)}{4\pi}, \tag{54}$$

corresponding to the sum of retarded and advanced GF's. Using the G_P above, we arrive at the undershell a-fields:

$$\begin{aligned} a^\alpha(x,\tau) &= \frac{eb^\alpha}{4\pi|b^5|\sqrt{1-\sigma_5 s^2}}\delta\left[\boldsymbol{x}''^2 - \frac{(x''^0 - s\tau)^2}{1-\sigma_5 s^2}\right] \\ &= \frac{eb^\alpha}{4\pi|b^5|\sqrt{1+\sigma_5 b'^2}}\delta\left[x^2 - \frac{(b'\cdot x)^2}{b'^2} + \frac{(-b'\cdot x + b'^2\tau)^2}{b'^2(1+\sigma_5 b'^2)}\right]. \end{aligned} \tag{55}$$

We call these *undershell solutions* because they correspond to the off-shell mass of the source below its Galilean target mass. Equation (55) has $O(3,1)$ symmetry, with respect to the first four

coordinates of x^α. It can be further broken to a sum of δ functions with linear arguments in τ as follows:

$$p(\tau_{1,2}) \equiv x^2 - \frac{(b'\cdot x)^2}{b'^2} + \frac{(-b'\cdot x + b'^2\tau_{1,2})^2}{b'^2(1+\sigma_5 b'^2)} = 0,$$

$$\tau_{1,2} = \frac{b'\cdot x}{b'^2} \pm \frac{1}{b'^2}\sqrt{1+\sigma_5 b'^2}\sqrt{(b'\cdot x)^2 - b'^2 x^2}.$$

Using the linearity of the δ function,

$$\delta(p(\tau)) = \left|\frac{b'^2(1+\sigma_5 b'^2)}{(b'^2)^2}\right| \delta[(\tau-\tau_1)(\tau-\tau_2)] = \frac{(1+\sigma_5 b'^2)}{b'^2|\tau_1-\tau_2|}[\delta(\tau-\tau_1)+\delta(\tau-\tau_2)],$$

we then have

$$a^\alpha(x,\tau) = \frac{eb^\alpha \Delta_+}{8\pi|b^5|\sqrt{(b'\cdot x)^2 - b'^2x^2}},$$

where

$$\Delta_+(x,\tau) = \delta(\tau-\tau_1)+\delta(\tau-\tau_2).$$

The a-field depends on the fifth metric component, σ_5, only through $\tau_{1,2}$, i.e., the coefficient is independent of the signature of the 5D space. However, the values $\tau=\tau_{1,2}$ correspond to a 4D surface in 5D space where the a-fields are nonzero, and therefore the metric appears, to some extent, in the *geometry* of the nonzero surfaces.

After some algebra, the a-fields can gain yet another, 5D covariant form. We start by rewriting the δ-function argument in 5D form:

$$p(\tau) = x^2 - \frac{(b'\cdot x)^2}{b'^2} + \frac{(-b'\cdot x + b'^2\tau_{1,2})^2}{b'^2(1+\sigma_5 b'^2)} = x_\beta x^\beta - \frac{b_\beta x^\beta}{b_\beta b^\beta}, \tag{56}$$

where the metric signature of (4,1) or (3,2) is used in the contraction products, e.g.,

$$b_\beta x^\beta = b\cdot x + \sigma_5 b^5 x^5 = b\cdot x + \sigma_5 b^5 \tau.$$

For the (4,1) case, we have

$$b_\alpha b^\alpha = b^2 + (b^5)^2 = \frac{1}{(b^5)^2}[b'^2+1] > 0,$$

since $\sigma_5 b^2 > -1$ in the present case. Thus, in the (4,1) metric, the *undershell* motion corresponds to the 5D *spacelike* region in the b^α velocity space. As shall be observed later, this region is not limited to 4D timelike source motion $b'^2<0$, and it includes $b'^2\geq 0$ as well. For the (3,2) metric, on the other hand, the motion is in the 5D timelike region $b_\alpha b^\alpha < 0$.

Furthermore, one can define

$$n^\alpha = \frac{b^\alpha}{\sqrt{\sigma_5 b_\beta b^\beta}}. \tag{57}$$

Substituting Eqs. (56) and (57) into (55), we arrive at the 5D covariant form:

$$a^\alpha(x,\tau) = \frac{en^\alpha}{4\pi}\delta[x_\beta x^\beta - \sigma_5(n_\beta x^\beta)^2]. \tag{58}$$

The term *undershell source motion* stems from the mass shell equation

$$P_\alpha P^\alpha = M^2 \dot{x}_\alpha \dot{x}^\alpha = M^2\left[-\frac{m^2}{M^2}+\sigma_5\right] = \sigma_5 M^2\left[-\sigma_5\frac{m^2}{M^2}+1\right] \tag{59}$$

$$= M^2 b_\alpha b^\alpha \tag{60}$$

or

$$b_\alpha b^\alpha = \sigma_5\left[-\sigma_5\frac{m^2}{M^2}+1\right]. \tag{61}$$

For the (4,1) metric, $\sigma_5=1$, where the undershell timelike motion leads to $|m|<M$. Hence, undershell motion refers to the *mass shell of the source* being *less* than its nonrelativistic mass-shell M.

2. Supershell timelike *a-fields* $\sigma_5 b'^2<-1$

As the name suggests, in the (4,1) metric of the source motion, the *supershell* case is determined by $|m|>M$, i.e., the relativistic mass $|m|$ being greater than the its nonrelativistic Galilean target mass M. In this case, however, only $\sigma_5=1$ is applicable, since there is no timelike motion $b'^2<0$ such that $(-1)b'^2+1<0$, unless $b'^2>1$, which is no longer timelike. Such a case will be investigated later. In this case, the integral (53) is well defined, as the zeros in the denominator are no longer real. By following a similar procedure of absorbing the coefficient of k^0 in the denominator into k^0, we obtain ($\sigma_5=1$)

$$\begin{aligned}
a^\alpha(x,\tau) &= \frac{eb^\alpha}{2\pi^4|b^5|\sqrt{s^2-1}}\int d^4k \frac{e^{i[\mathbf{k}\cdot\mathbf{x}''-k^0(x''^0-s\tau)/\sqrt{s^2-1}]}}{\mathbf{k}^2+(k^0)^2}\\
&= \frac{4\pi eb^\alpha}{(2\pi)^4|b^5||\mathbf{x}'|\sqrt{s^2-1}}\int_0^{+\infty} k\,dk\,\sin(k|\mathbf{x}''|)\int_{-\infty}^{+\infty} dk^0 \frac{e^{-ik^0[x''^0-s\tau]/\sqrt{s^2-1}}}{k^2+(k^0)^2}\\
&= \frac{eb^\alpha}{4\pi^3|b^5||\mathbf{x}'|\sqrt{s^2-1}}\int_0^{+\infty} kdk\,\sin(k|\mathbf{x}''|)(-1)\frac{\pi}{k}e^{-k[x''^0-s\tau]/\sqrt{s^2-1}}\\
&= \frac{eb^\alpha}{4\pi^2|b^5||\mathbf{x}''|\sqrt{s^2-1}}\frac{1}{2i}\left[\frac{0-1}{-|x''^0-s\tau|/\sqrt{s^2-1}+i|\mathbf{x}''|}-\frac{0-1}{-|x''^0-s\tau|/\sqrt{s^2-1}-i|\mathbf{x}''|}\right]\\
&= \frac{eb^\alpha}{4\pi^2|b^5|\sqrt{-b'^2-1}}\left[\mathbf{x}''^2+\frac{(x''^0-s\tau)^2}{-b'^2-1}\right]\\
&= \frac{eb^\alpha}{4\pi^2|b^5|\sqrt{-b'^2-1}}\left[x^2-\frac{(b'\cdot x)^2}{b'^2}+\frac{(-b'\cdot x+b'^2\tau)^2}{b'^2(b'^2+1)}\right]\\
&= \frac{en^\alpha}{4\pi^2}\frac{1}{[x_\beta x^\beta+(n_\beta x^\beta)^2]},
\end{aligned}$$

where we have defined $n^\alpha \equiv b^\alpha/\sqrt{-b_\beta b^\beta}$.

The supershell *a*-field is found to be a *smooth* function on 5D space time; it is the 5D analog of the well-known (cf. Ref. 20) on-shell 4D Maxwell *a*-field of a uniformly moving charge

$$A^{\mu}(x) = \frac{en^{\mu}}{4\pi\sqrt{x^2 + (n\cdot x)^2}},$$

where $n^{\mu}=dz^{\mu}(s)/ds$ is the constant four-velocity obeying the mass-shell constraint $n^2=-1$. Clearly, the 5D a-field, proportional to r^{-2}, as opposed to the Maxwell A-field being proportional to r^{-1}, is a consequence of the additional dimension.

The supershell a-field has the same form as the GF for the 4D *Laplace operator*

$$\nabla^2 G_L(x) = \delta^4(x), \tag{62}$$

where $x\in\mathbb{R}^4$, $r^2=(x^1)^2+(x^2)^2+(x^3)^2+(x^4)^2$, and the GF $G_L(x)$ is given by (cf. Ref. 12)

$$G_L = \frac{1}{(2\pi)^4}\int \frac{e^{ik_c x^c}}{k_c k^c} = \frac{1}{2\pi^2 r^2}, \tag{63}$$

where in this case

$$k_c x^c = k^1x^1 + k^2x^2 + k^3x^3 + k^4x^4.$$

This is far from being coincidental, as the 5D scalar $x_{\beta}x^{\beta}+(n_{\beta}x^{\beta})^2$ reduces to r^2 in 4D, when the source's uniform velocity is purely *temporal* $n^{\beta}=[1;0,0,0,0]$.

C. *a*-fields due to a spacelike source

We now solve the integral (52) for spacelike source motion, $b'^2>0$, which may not be regarded as a possible physical source, since it implies faster than light motion of the source particle. Once again, we choose to integrate in a k-frame such that $b''=[0;0,0,b''^3]$ is along one of the spatial axes, e.g., the z axis, and we now define

$$b''^3 \equiv s = \sqrt{b''^2} = \sqrt{b'^2}, \quad b'^2>0. \tag{64}$$

The current in the b'' frame can be expressed by

$$j''^{\mu}(x'',\tau) = b''^{\mu}\delta^4[x - z''(\tau)] = b'^3\delta^{\mu}_3\delta(t'')\delta(x'')\delta(y'')\delta(z'' - b''^3\tau). \tag{65}$$

Returning to pre-Maxwell a-field integral (52),

$$a^{\alpha}(x,\tau) = \frac{eb^{\alpha}}{|b^5|(2\pi)^4}\int d^4k'' \frac{e^{i[k''^1x''+k''^2y''+k''^3(z''-s\tau)-k''^0t'']}}{(k''^1)^2+(k''^2)^2+(k''^3)^2-(k''^0)^2+\sigma_5(sk^3)^2} \tag{66}$$

$$= \frac{eb'^{\alpha}}{|b^5|(2\pi)^4}\int d^4k \frac{e^{i[k^1x+k^2y+k^3(z-s\tau)-k^0t]}}{(k^1)^2+(k^2)^2+(k^3)^2(1+\sigma_5 s^2)-(k^0)^2}, \tag{67}$$

where we have renamed k'' as k and x'' as x.

The coefficient of $(k^3)^2$ changes sign when $1+\sigma_5 s^2=1+\sigma b'^2=0$, which can only occur when $\sigma_5=-1$ (since for spacelike motion, $b'^2>0$) and $|s|\geq 1$ $[s=\varepsilon(b'^0)\sqrt{b'^2}]$, causing the denominator to obtain a (2,2) quadratic form.

Once again, the form of the fields are characterized by the types of source motion. In the following, we shall treat both possible types of source motion separately.

1. Under spacelike motion $1+\sigma_5 b'^2>0$

Rescaling $k^3\rightarrow k^3/\sqrt{1+\sigma_5 s^2}$, the spacelike a-field integral (66) can be expressed by

$$a^{\alpha}(x,\tau) = \frac{eb^{\alpha}}{|b^5|(2\pi)^4\sqrt{1+\sigma_5 s^2}}\int d^4k \frac{e^{ik\cdot y}}{k^2} = \frac{eb^{\alpha}\delta(y^2)}{4\pi|b^5|\sqrt{1+\sigma_5 s^2}},$$

where $y^\mu=\left[x^0;x^1,x^2,x^3-s\tau/\sqrt{1+\sigma_5 s^2}\right]$, $k^2=k_\mu k^\mu$, and we have chosen the *Principal Part* contour.

However:

$$y^2=(x^1)^2+(x^2)^2+\frac{(x^3-s\tau)^2}{1+\sigma_5 s^2}-(x^0)^2=x_\mu x^\mu-(x^3)^2+\frac{(x^3-\sqrt{b'^2}\tau)^2}{1+\sigma_5 b'^2}.$$

We can furthermore put x^3 into an invariant form:

$$x^3=\frac{x^3 s}{s}=\frac{x\cdot b'}{\sqrt{b'^2}},$$

$$y^2=x^2-\frac{(b'\cdot x)^2}{b'^2}+\frac{(-b'\cdot x+b'^2\tau)^2}{b'^2(1+\sigma_5 b'^2)}.$$

The spacelike a-fields then obtain a 4D covariant form:

$$a^\alpha(x,\tau)=\frac{eb^\alpha}{4\pi|b^5|\sqrt{1+\sigma_5 b'^2}}\delta\left[x^2-\frac{(b'\cdot x)^2}{b'^2}+\frac{(-b'\cdot x+b'^2\tau)^2}{b'^2(1+\sigma_5 b'^2)}\right]=\frac{eb^\alpha\Delta_+}{8\pi|b^5|\sqrt{(b'\cdot x)^2-b'^2x^2}},$$

where we have, as before,

$$\Delta_+\equiv\delta(\tau-\tau_1)+\delta(\tau-\tau_2),$$

$$\tau_{1,2}=\frac{b'\cdot x}{b'^2}\pm\frac{1}{b'^2}\sqrt{1+\sigma_5 b'^2}\sqrt{(b'\cdot x)^2+b'^2x^2}.$$

Thus, the *under* spacelike motion fields are of the same form as their timelike *under-shell* counterparts.

2. Super spacelike motion $1+\sigma_5 b'^2>0$

As mentioned above, in this case we have $b'^2>1$ and the choice $\sigma_5=-1$ is therefore necessary. Therefore, the integral (66) takes the form

$$a^\alpha(x,\tau)=\frac{eb^\alpha}{|b^5|(2\pi)^4}\int d^4k\frac{e^{i[k^1x+k^2y+k^3(z-s\tau)-k^0t]}}{(k^1)^2+(k^2)^2-(s^2-1)(k^3)^2-(k^0)^2}.$$

Rescaling $k^3\to k^3/\sqrt{s^2-1}$,

$$=\frac{eb^\alpha}{(2\pi)^4|b^5|\sqrt{s^2-1}}\int d^4k\frac{e^{ik\cdot y}}{(k^1)^2+(k^2)^2-(k^3)^2-(k^0)^2}. \tag{68}$$

We shall solve this integral by transforming the integrand to a Gaussian form:

$$\int_{-\infty}^{+\infty}\frac{e^{iax}}{x^2}dx=\frac{1}{2i}\int_{-\infty}^{+\infty}\varepsilon(q)dq\int_{-\infty}^{+\infty}e^{iax+iqx^2}dx,$$

where $\varepsilon(q)$ is the sign function. Using this relation in (68) we obtain

$$a^{\alpha}(x,\tau)=\frac{eb^{\alpha}}{(2\pi)^4|b^5|\sqrt{s^2-1}}\frac{1}{2i}\int_{-\infty}^{+\infty}dq\varepsilon(q)\int d^4k\,\exp[ik\cdot y+iq[(k^1)^2+(k^2)^2-(k^3)^2-(k^0)^2]]$$

$$=\frac{eb^{\alpha}}{(2\pi)^4|b^5|\sqrt{s^2-1}}\frac{1}{2i}\int_{-\infty}^{+\infty}dq\varepsilon(q)\left(\sqrt{\frac{\pi}{q}}\right)^4\exp\left[\frac{i}{4q}((y^1)^2+(y^2)^2-(y^3)^2-(y^0)^2)\right]$$

$$=\frac{eb^{\alpha}|b^5|}{(2\pi)^4\sqrt{s^2-1}}\frac{\pi^2}{2i}(-1)\int_0^{+\infty}du\left\{\exp\left[\frac{iu}{4}((y^1)^2+(y^2)^2-(y^3)^2-(y^0)^2)\right]\right.$$

$$\left.-\exp\left[-\frac{iu}{4}((y^1)^2+(y^2)^2-(y^3)^2-(y^0)^2)\right]\right\},$$

where we have put $u=1/q$. Here, the singularity at $q=0$ is controlled by the oscillation in the exponent (although one can find the same result by other methods).

Using

$$\int_0^{+\infty}\exp[iax]dx=P\left[\frac{i}{a}\right]+\pi\delta(a),$$

we find the fields to be

$$a^{\alpha}(x,\tau)=-\frac{eb^{\alpha}}{(2\pi)^4|b^5|\sqrt{s^2-1}}\frac{1}{2}\frac{8\pi^2}{[(y^1)^2+(y^2)^2-(y^3)^2-(y^0)^2]}$$

$$=-\frac{eb^{\alpha}}{4\pi^2|b^5|\sqrt{s^2-1}}\frac{1}{[(y^1)^2+(y^2)^2-(y^3)^2-(y^0)^2]}.$$

We have

$$y^{\mu}=\left[x^0;x^1,x^2,\frac{x^3-s\tau}{\sqrt{s^2-1}}\right],$$

$$(y^1)^2+(y^2)^2-(y^3)^2-(y^0)^2=(x^1)^2+(x^2)^2-\frac{(x^3-s\tau)^2}{s^2-1}-(x^0)^2=x^2-\frac{(b'\cdot x)^2}{b'^2}-\frac{(b\cdot x-b^2\tau)^2}{(b'^2-1)b'^2}.$$

Thus we obtain the final form

$$a^{\alpha}(x,\tau)=-\frac{eb^{\alpha}}{4\pi^2|b^5|\sqrt{b'^2-1}}\frac{1}{\left[x^2-\frac{(b\cdot x)^2}{b^2}-\frac{(b\cdot x-b^2\tau)^2}{b^2(b^2-1)}\right]},\tag{69}$$

The corresponding 5D covariant form is then

$$a^{\alpha}(x,\tau)=\frac{en^{\alpha}}{4\pi^2}\frac{1}{[(n_{\alpha}x^{\alpha})^2-x_{\alpha}x^{\alpha}]},\tag{70}$$

where $n^{\alpha}=b^{\alpha}/\sqrt{b_{\beta}b^{\beta}}$

TABLE II. Regions of source velocity summary.

Metric	σ_5	Velocity region	Mass shell	$\varepsilon(b_\alpha b^\alpha)$	ζ
(4,1)	+1	Undershell	$m^2<M^2$	+1	+1
(4,1)	+1	Supershell	$m^2>M^2$	−1	−1
(3,2)	−1	Under-spacelike	$-m^2<M^2$	−1	+1
(3,2)	−1	Super-spacelike	$-m^2>M^2$	+1	−1

D. Summary of fields generated by a uniformly moving source

We present a short summary of the results obtained in this section:

$$a^\alpha(x,\tau)=\begin{cases} en^\alpha 4\pi\delta[x_\beta x^\beta-(n_\beta x^\beta)^2] & \text{Undershell } \sigma_5=+1,\ n_\alpha n^\alpha=+1,\\ \dfrac{en^\alpha}{4\pi^2}\dfrac{1}{[x_\beta x^\beta+(n_\beta x^\beta)^2]} & \text{Supershell } \sigma_5=+1,\ n_\alpha n^\alpha=-1,\\ \dfrac{en^\alpha}{4\pi}\delta[x_\beta x^\beta+(n_\beta x^\beta)^2] & \text{Under-spacelike } \sigma_5=-1,\ n_\alpha n^\alpha=-1,\\ \dfrac{en^\alpha}{4\pi^2}\dfrac{1}{[(n_\beta x^\beta)^2-x_\beta x^\beta]} & \text{Super-spacelike } \sigma_5=-1,\ n_\alpha n^\alpha=+1. \end{cases} \tag{71}$$

In a more general compact representation, we have

$$a^\alpha(x,\tau)=\begin{cases} \dfrac{en^\alpha}{4\pi}\delta[(n_\beta x^\beta)^2-\sigma_5 x_\beta x^\beta] & \zeta=+1,\\ \dfrac{en^\alpha}{4\pi^2}\dfrac{1}{[(n_\beta x^\beta)^2+\sigma_5 x_\beta x^\beta]} & \zeta=-1, \end{cases} \tag{72}$$

where

$$\zeta=\sigma_5\cdot\varepsilon[b_\alpha b^\alpha]=\sigma_5\cdot\varepsilon[b^2+\sigma_5(b^5)^2],$$

$$n^\alpha=\frac{b^\alpha}{|b_\beta b^\beta|}.$$

The various values for σ_5 and ζ are given in Table II.

E. Concatenation

As we have pointed out above, the pre-Maxwell theory can be contracted to Maxwell form by integration [as in (34)] over τ (called *concatenation*). Applying this procedure to the 5D pre-Maxwell fields that we have obtained above, we find

$$A^\mu(x)=\int_{-\infty}^{+\infty}a^\mu(x,\tau)d\tau=\frac{en^\mu}{4\pi}\frac{\theta[(n\cdot x)^2-n^2x^2]}{\sqrt{(n\cdot x)^2-n^2x^2}}, \tag{73}$$

where

$$n^2=n_\mu n^\mu=n_\alpha n^\alpha-\sigma_5(n^5)^2$$

and $n_\alpha n^\alpha=\pm1$ according to the velocity regions of source motion (see Table II). It should be emphasized that (73) is a *general* Maxwell field for all values of n^2. The solutions can be put into a more specific form for the three regions of (3,1) space time:

$$A^{\mu}(x)=\begin{cases}\dfrac{en'^{\mu}}{4\pi\sqrt{(n'\cdot x)^2+x^2}} & n'^2=-1,\\ \dfrac{en'^{\mu}}{4\pi}\dfrac{\theta[(n'\cdot x)^2-x^2]}{\sqrt{(n'\cdot x)^2-x^2}} & n'^2=+1,\\ \dfrac{en'^{\mu}}{4\pi|n'\cdot x|} & n'^2=0,\end{cases} \tag{74}$$

where

$$n'^{\mu}=\frac{n^{\mu}}{|n_{\nu}n^{\nu}|}.$$

We will discuss the possibility of integrating on a smaller interval of τ (Land regularization[3]) adequate in some cases to reproduce the results of ordinary Maxwell scattering.

IV. GREEN FUNCTIONS

In this section, Green functions for both (4,1) and (3,2) wave equations are given. Green functions for equations of this type have been discussed.[12,13,23] In particular, two distinct versions of the fundamental solution for (4,1) wave equation have been given:

$$G_{4,1}(\mathbf{x},t)=-\frac{1}{4\pi^2}\frac{\theta(t-|\mathbf{x}|)}{[t^2-\mathbf{x}^2]^{3/2}} \tag{75}$$

[cf. Ref. 23, based on Ref. 24],

$$H_{4,1}(\mathbf{x},t)=\frac{1}{2\pi^2}\frac{d}{dt^2}\frac{\theta(t-|\mathbf{x}|)}{\sqrt{t^2-\mathbf{x}^2}} \tag{76}$$

(cf. Ref. 12).

The difference expression $(H_{4,1}-G_{4,1})(\mathbf{x},t)$ is a distribution

$$(H_{4,1}-G_{4,1})(\mathbf{x},t)=\frac{\delta(t-|\mathbf{x}|)}{2t\sqrt{t^2-\mathbf{x}^2}}.$$

In the analysis below, on the other hand, we shall provide a distinct derivation of the GF's for both (4,1) and (3,2), which are similar to $H_{4,1}(x,t)$, as follows:

$$g_{\sigma_5}(x,\tau)=\lim_{\varepsilon\to 0^+}\frac{\sigma_5}{4\pi^2}\frac{\partial}{\partial\varepsilon}\frac{\theta[-\sigma_5(x^2+\sigma_5\tau^2)+\varepsilon]}{\sqrt{-\sigma_5(x^2+\sigma_5\tau^2)+\varepsilon}}.$$

$g_{\sigma_5}(x,\tau)$ contains a singular distribution term as well:

$$\Delta_{\sigma_5}=-\lim_{\varepsilon\to 0^+}\frac{\sigma_5}{4\pi^2}\frac{\delta[-\sigma_5(x^2+\sigma_5\tau^2)+\varepsilon]}{\sqrt{-\sigma_5(x^2+\sigma_5\tau^2)+\varepsilon}}.$$

In the following sections, GF's are derived for the (4,1) and (3,2) wave equations, which are *symmetric* in t. Then, we apply the GF's to the current of a uniformly moving point source, and rederive the results of Sec. III. We shall describe the importance of the form of Δ_{σ_5} in the derivation of the fields.

A. (4,1) Green function

With $\sigma_5=+1$ in (41), we have

$$g_+(x,\tau)=\frac{1}{(2\pi)^5}\int d^4k d\,k_5\frac{1}{k^2+k_5^2}e^{i[k\cdot x+k_5\tau]}=\frac{1}{(2\pi)^5}\int d^3\mathbf{k}d\,k_5 e^{i[\mathbf{k}\cdot\mathbf{x}+k_5\tau]}\int_{-\infty}^{+\infty}\frac{dk_0}{\mathbf{k}^2+k_5^2-k_0^2}e^{-ik_0t}. \tag{77}$$

The *Cauchy Principal Part* of the k_0 integral is

$$P\int_{-\infty}^{+\infty}\frac{dk_0}{\mathbf{k}^2+k_5^2-k_0^2}e^{-ik_0t}=\pi i\varepsilon(-t)\frac{1}{2\sqrt{\mathbf{k}^2+k_5^2}}[+e^{+it\sqrt{\mathbf{k}^2+k_5^2}}-e^{-it\sqrt{\mathbf{k}^2+k_5^2}}]=\varepsilon(t)\frac{\pi\sin(t\sqrt{\mathbf{k}^2+k_5^2})}{\sqrt{\mathbf{k}^2+k_5^2}}.$$

We then have

$$g_+(x,\tau)=\frac{\pi\varepsilon(t)}{(2\pi)^5}\int d^3\mathbf{k}dk_5\frac{\sin(t\sqrt{\mathbf{k}^2+k_5^2})}{\sqrt{\mathbf{k}^2+k_5^2}}e^{i[\mathbf{k}\cdot\mathbf{x}+k_5\tau]}.$$

We now orient the $\mathbf{k}$, k_5 space such the 4D "observation" vector $(\mathbf{x},\tau)$ is along k_3 (one observes at time τ on the laboratory clock at the point $\mathbf{x}$). Defining $l=\sqrt{\mathbf{k}^2+k_5^2}$ and $R=\sqrt{\mathbf{x}^2+\tau^2}$, and using α, θ, and ϕ as the 4D polar angles we find

$$k_5=l\cos\alpha,$$

$$k_3=l\sin\alpha\cos\theta,$$

$$\mathbf{k}\cdot\mathbf{x}+k_5\tau=Rk_3=Rl\sin\alpha\cos\theta,$$

$$d^3\mathbf{k}dk_5=l^3\sin^2\alpha\sin\theta dl\,d\alpha\,d\theta\,d\phi.$$

In terms of these variables,

$$\begin{aligned}g_+(x,\tau)&=\frac{\pi\varepsilon(t)}{(2\pi)^5}\int_0^{+\infty}l^3dl\int_0^{\pi}\sin^2\alpha\,d\alpha\int_0^{\pi}\sin\theta\,d\theta\int_0^{2\pi}d\varphi\frac{\sin(tl)}{l}e^{ilR\sin\alpha\cos\theta}\\&=\frac{\varepsilon(t)4\pi^2}{R(2\pi)^5}\int_0^{+\infty}l^3dl\int_0^{\pi}\sin^2\alpha\,d\alpha\frac{\sin(lR\sin\alpha)}{l\sin\alpha}\frac{\sin(tl)}{l}\\&=\frac{\varepsilon(t)4\pi^2}{R(2\pi)^5}\int_0^{+\infty}dl\int_0^{\pi}d\alpha\sin(lt)\sin(lR\sin\alpha)l\sin\alpha\\&=-\frac{\varepsilon(t)4\pi^2}{R(2\pi)^5}\frac{1}{R}\frac{\partial}{\partial R}\int_0^{+\infty}dl\int_0^{\pi}d\alpha\sin(lt)\cos(lR\sin\alpha).\end{aligned}$$

The choice of orientation in k-space resulted in a first-order derivative with respect to the "4D observation point" R. This form is important in convergence of the UMS solution. The α integral is simply $\pi J_0(lR)$ and using the *sine transform* of $J_0(x)$ (cf. Ref. 25),

$$J_0(x)=\frac{2}{\pi}\int_1^{+\infty}\frac{\sin(xs)}{\sqrt{s^2-1}}ds, \tag{78}$$

we find

$$g_+(x,\tau) = -\frac{8\pi^2\varepsilon(t)}{(2\pi)^5}\frac{1}{R}\frac{\partial}{\partial R}\int_0^{+\infty} dl \int_1^{+\infty} ds\, \sin(lt)\frac{\sin(lRs)}{\sqrt{s^2-1}}.$$

Changing the order of integration and noting that the l integrand is symmetric under $l\to -l$, we have

$$g_+(x,\tau) = -\frac{8\pi^2\varepsilon(t)}{(2\pi)^5}\frac{1}{R}\frac{\partial}{\partial R}\int_1^{+\infty}\frac{ds}{\sqrt{s^2-1}}\frac{1}{2}\int_{-\infty}^{+\infty} dl\, \sin(lt)\sin(lRs)$$

$$= -\frac{4\pi^2\varepsilon(t)}{(2\pi)^5}\frac{1}{R}\frac{\partial}{\partial R}\int_1^{+\infty}\frac{ds}{\sqrt{s^2-1}}\frac{2\pi}{(-4)}[2\delta(t+Rs)-2\delta(t-Rs)].$$

Since $Rs>0$, then using

$$\delta(t+Rs)-\delta(t-Rs) = -\varepsilon(t)[\delta(t+Rs)+\delta(t-Rs)],$$

we find

$$g_+(x,\tau) = \frac{4\pi^3\varepsilon^2(t)}{(2\pi)^5}\frac{1}{R}\frac{\partial}{\partial R}\int_1^{+\infty}\frac{ds}{\sqrt{s^2-1}}[\delta(t+Rs)+\delta(t-Rs)]$$

$$= \frac{4\pi^3}{(2\pi)^5}\frac{1}{R}\frac{\partial}{\partial R}\frac{1}{R}\frac{1}{\sqrt{t^2/R^2-1}}[\theta(-t/R-1)+\theta(+t/R-1)]$$

$$= \frac{1}{8\pi^2}\frac{1}{R}\frac{\partial}{\partial R}\frac{\theta(t^2-R^2)}{\sqrt{t^2-R^2}}.$$

We have $t^2-R^2=t^2-\mathbf{x}^2-\tau^2=-x_\alpha x^\alpha$, and since $R>0$, we can use $1/R\,\partial/\partial R=2\,\partial/\partial R^2$, which is *linear* in $x_\alpha x^\alpha$, thus

$$g_+(x,\tau) = -\lim_{\varepsilon\to 0^+}\frac{1}{4\pi^2}\frac{\partial}{\partial\varepsilon}\frac{\theta(-x_\alpha x^\alpha+\varepsilon)}{\sqrt{-x_\alpha x^\alpha+\varepsilon}}. \tag{79}$$

B. (3,2) Green function

We shall repeat the procedure for $\sigma_5=-1$ as follows:

$$g_-(x,\tau) = \frac{1}{(2\pi)^5}\int d^4k dk_5 \frac{1}{k^2-k_5^2}e^{i[k\cdot x-k_5\tau]} = \frac{1}{(2\pi)^5}\int_{\mathbb{R}^3} d^3\mathbf{k}e^{i[\mathbf{k}\cdot\mathbf{x}]}\int_{\mathbb{R}^2}\frac{dk_5\,dk_0}{\mathbf{k}^2-k_5^2-k_0^2}e^{-i[k_0t+k_5\tau]}. \tag{80}$$

The integration is separated into the two subspaces $\mathbb{R}^3$ for the spatial coordinates, and R^2 for the temporal coordinates. We shall use polar coordinates in *both* spaces, using the following substitutions:

$$k^2 = k_1^2+k_2^2+k_3^2,\ \ d^3\mathbf{k} = k^2\sin\theta dk\, d\theta\, d\varphi,$$

$$r^2 = x^2+y^2+x^2,\ \ \mathbf{k}\cdot\mathbf{x} = kr\cos\theta,$$

$$l^2 = k_0^2+k_5^2,\ \ dk_0\,dk_5 = l\,dl\,d\alpha,$$

$$s^2 = t^2+\tau^2,\ \ k_0t+k_5\tau = sl\cos\alpha.$$

The integral then takes the form

$$g_-(x,\tau)=\frac{1}{(2\pi)^5}\int_0^{+\infty}k^2\,dk\int_0^{\pi}\sin\theta\,d\theta\int_0^{2\pi}d\phi e^{ikr\cos\theta}\int_0^{+\infty}l\,dl\int_0^{2\pi}d\alpha\frac{e^{ils\cos\alpha}}{k^2-l^2}.$$

We can integrate immediately on ϕ, θ, and α as follows:

$$\int_0^{2\pi}d\phi=2\pi,\quad \int_0^{\pi}d\theta=\frac{2\sin(kr)}{kr},\quad \int_0^{2\pi}d\alpha=2\pi J_0(ls),$$

and thus

$$g_-(x,\tau)=\frac{1}{(2\pi)^5}\frac{8\pi^2}{r}\int_0^{+\infty}k\,dk\sin(kr)\int_0^{+\infty}l\,dl\,\frac{J_0(ls)}{k^2-l^2}=-\frac{1}{(2\pi)^3}\frac{2}{r}\frac{\partial}{\partial r}\int_0^{+\infty}l\,dl\,J_0(ls)\int_0^{+\infty}dk\,\frac{\cos(kr)}{k^2-l^2}$$

$$=-\frac{1}{(2\pi)^3}\frac{1}{r}\frac{\partial}{\partial r}\int_0^{+\infty}l\,dl\,J_0(ls)\int_{-\infty}^{+\infty}dk\,\frac{\cos(kr)}{k^2-l^2}.$$

The *Principal Part* value of the k integral is

$$P\int_{-\infty}^{+\infty}\frac{\cos(kr)}{k^2-l^2}dk=P\,.\,P\,.\,\Re\left[\int_{-\infty}^{+\infty}\frac{e^{ikr}}{k^2-l^2}dk\right]=\Re\left\{\frac{i\pi}{2l}[e^{ilr}-e^{-ilr}]\right\}=-\frac{\pi}{l}\sin(lr).$$

Thus, as the expression for $g_-(x,\tau)$, one obtains the form

$$g_-(x,\tau)=\frac{\pi}{(2\pi)^3}\frac{1}{r}\frac{\partial}{\partial r}\int_0^{+\infty}l\,dl\,J_0(ls)\frac{\sin(lr)}{l}=\frac{\pi}{(2\pi)^3}\frac{1}{r}\frac{\partial}{\partial r}\int_0^{+\infty}dl\,J_0(ls)\sin(lr).$$

Once again, using the sine transform of $J_0(x)$ [see (78)], we have

$$g_-(x,\tau)=\frac{\pi}{(2\pi)^3}\frac{2}{\pi}\frac{1}{r}\frac{\partial}{\partial r}\int_1^{+\infty}\frac{du}{\sqrt{u^2-1}}\frac{1}{2}\int_{-\infty}^{+\infty}dl\,\sin(lsu)\sin(lr)$$

$$=\frac{1}{(2\pi)^3}\frac{1}{r}\frac{\partial}{\partial r}\int_1^{+\infty}\frac{du}{\sqrt{u^2-1}}\frac{2\pi}{(-4)}[2\delta(su+r)-2\delta(su-r)]$$

$$=-\frac{\pi}{(2\pi)^3}\frac{1}{r}\frac{\partial}{\partial r}\int_1^{+\infty}\frac{du}{\sqrt{u^2-1}}\varepsilon(-s)[\delta(su+r)+\delta(su-r)].$$

However, $su\geq 0$ and $r\geq 0$, and thus the first term $\delta(su+r)$ vanishes identically, leaving

$$g_-(x,\tau)=\frac{1}{2(2\pi)^2}\frac{1}{r}\frac{\partial}{\partial r}\frac{1}{s}\frac{\theta(r/s-1)}{\sqrt{r^2/s^2-1}}=\frac{1}{2(2\pi)^2}\frac{1}{r}\frac{\partial}{\partial r}\frac{\theta(r-s)}{\sqrt{r^2-s^2}}.$$

Using the same arguments that were made for the (4,1) case, we have

$$g_-(x,\tau)=\lim_{\varepsilon\to 0^+}\frac{1}{4\pi^2}\frac{\partial}{\partial\varepsilon}\frac{\theta(x_\alpha x^\alpha+\varepsilon)}{\sqrt{x_\alpha x^\alpha+\varepsilon}},\tag{81}$$

where $x_\alpha x^\alpha=x^2-\tau^2$ in this case.

Combining both (4,1) and (3,2) cases, we obtain

$$g_{\sigma_5}(x,\tau)=\lim_{\varepsilon\to 0^+}\frac{\sigma_5}{4\pi^2}\frac{\partial}{\partial\varepsilon}\frac{\theta[-\sigma_5(x^2+\sigma_5\tau^2)+\varepsilon]}{\sqrt{-\sigma_5(x^2+\sigma_5\tau^2)+\varepsilon}}=\lim_{\varepsilon\to 0^+}\frac{\sigma_5}{4\pi^2}\frac{\partial}{\partial\varepsilon}\frac{\theta[-\sigma_5 x_\alpha x^\alpha+\varepsilon]}{\sqrt{-\sigma_5 x_\alpha x^\alpha+\varepsilon}}.\tag{82}$$

The factor 2 between (82) and (76) stems from the fact that *both* retarded and advanced t are used,

picking up an additional contribution from the future of t. An attempt to provide GF's that are τ retarded in (4,1) and (3,2) is currently under study.

C. Fields solution through GF's

We shall now apply the GF's (82) to the current generated by a uniformly moving point source. Recalling the UMS path (48), and generating the current (26), we shall use (45) to find the fields

$$a^{\alpha}_{\sigma_5}(x,\tau)=\lim_{\varepsilon\to 0^+}\frac{e\sigma_5}{4\pi^2}\frac{\partial}{\partial\varepsilon}\int_{-\infty}^{+\infty}d\tau'\; b^{\alpha}\frac{\theta[-\sigma_5((x-b\tau')+\sigma_5(\tau-b^5\tau')^2)+\varepsilon]}{\sqrt{-\sigma_5((x-b\tau')+\sigma_5(\tau-b^5\tau')^2)+\varepsilon}}. \tag{83}$$

Clearly, the limits of integration depend on the coefficients of the quadratic argument

$$\begin{aligned}p(\tau')&=-\sigma_5((x-b\tau')+\sigma_5(\tau-b^5\tau')^2)+\varepsilon\\&=-\sigma_5[(b^2+\sigma_5(b^5)^2)\tau'^2-2(b\cdot x+\sigma_5 b^5\tau)\tau'+x^2+\sigma_5\tau^2]+\varepsilon\\&=-\sigma_5 b_\alpha b^\alpha\tau'^2+2\sigma_5(b_\alpha x^\alpha)\tau'-\sigma_5[x_\alpha x^\alpha-\sigma_5\varepsilon].\end{aligned}$$

Thus, the polarity of the quadratic form $p(\tau)$ depends on the sign of $\zeta\equiv\sigma_5\varepsilon(b_\alpha b^\alpha)$, which we shall treat individually.

D. UMS fields for $\zeta=+1$

We have $-\sigma_5 b_\alpha b^\alpha<0$. The condition $p(\tau')>0$ is then limited to $\tau_1<\tau<\tau_2$, where $\tau_{1,2}$ are the *roots* of $p(\tau')$:

$$\tau'_{1,2}=\frac{-b_\alpha x^\alpha\pm\sqrt{(b_\alpha x^\alpha)^2-b_\alpha b^\alpha(x_\alpha x^\alpha-\sigma_5\varepsilon)}}{-b_\alpha b^\alpha}, \tag{84}$$

the fields become

$$a^{\alpha}_{\sigma_5}(x,\tau)=\lim_{\varepsilon\to 0^+}\frac{e\sigma_5 b^\alpha}{4\pi^2}\frac{\partial}{\partial\varepsilon}\int_{\tau_1}^{\tau_2}d\tau'\frac{\theta[p(\tau')]}{\sqrt{p(\tau')}}. \tag{85}$$

Clearly, the integral would be become zero *identically* if $\tau_{1,2}$ are *complex*, thus

$$(\tau'_1-\tau'_2)^2=\frac{4}{(b_\alpha b^\alpha)^2}[(b_\alpha x^\alpha)^2-b_\alpha b^\alpha(x_\alpha x^\alpha-\sigma_5\varepsilon)]>0.$$

We can now write $p(\tau')$ as follows:

$$p(\tau')\equiv\frac{\sigma_5}{b_\alpha b^\alpha}R^2-A^2(\tau'-B)^2, \tag{86}$$

where

$$R^2=(b_\alpha x^\alpha)^2-b_\alpha b^\alpha(x_\alpha x^\alpha-\sigma_5\varepsilon),\quad A=\sqrt{\sigma_5 b_\alpha b^\alpha},\quad B=\frac{b_\alpha x^\alpha}{b_\alpha b^\alpha}, \tag{87}$$

where $R^2>0$ is a requirement for the integral to be nonzero, and $A^2>0$ in this case. After making the substitution

$$\sqrt{\frac{\sigma_5}{b_\alpha b^\alpha}}R\tanh\beta=A(\tau'-B),$$

we have

$$a^{\alpha}_{\sigma_5}(x,\tau) = \lim_{\varepsilon\to 0^+} \sqrt{\frac{e\sigma_5}{b_\alpha b^\alpha}} \frac{\sigma_5 b^\alpha}{4\pi^2} \frac{\partial}{\partial\varepsilon}\theta(R^2) \int_{-\infty}^{+\infty} \frac{Rd\beta}{A\cosh^2\beta} \frac{1}{\sqrt{(\sigma_5/b_\alpha b^\alpha)R^2[1-\tanh^2\beta]}}$$

$$= \lim_{\varepsilon\to 0^+} \frac{1}{\sqrt{\sigma_5 b_\alpha b^\alpha}} \frac{e\sigma_5 b^\alpha}{4\pi^2} \frac{\partial}{\partial\varepsilon}\theta(R^2) \int_{-\infty}^{+\infty} \frac{d\beta}{\cosh\beta}.$$

The remaining β integral is a constant and equal to π (easily verified by substituting $u=e^{\beta}$). Thus

$$a^{\alpha}_{\sigma_5}(x,\tau) = \lim_{\varepsilon\to 0^+} \frac{e\sigma_5 b^\alpha}{4\pi\sqrt{b_\alpha b^\alpha}} \frac{\partial}{\partial\varepsilon}\theta(R^2),$$

where $\partial_\varepsilon\theta(R^2)=\sigma_5 b_\alpha b^\alpha \delta(R^2)$, which gives the final form for $a_{\sigma_5}(x,\tau)$ for this case:

$$a^{\alpha}_{\sigma_5}(x,\tau) = \frac{eb^\alpha(\sigma_5 b_\beta b^\beta)}{4\pi\sqrt{\sigma_5 b_\alpha b^\alpha}} \delta[(b_\alpha x^\alpha)^2 - b_\alpha b^\alpha x_\alpha x^\alpha], \tag{88}$$

where the limit of $\varepsilon\to 0^+$ was taken explicitly. Defining the normalized 5D velocity $n^\alpha = b^\alpha/\sqrt{\sigma_5 b_\beta b^\beta}$, we obtain the solution consistent with $\zeta=1$ of (72),

$$a^{\alpha}_{\sigma_5}(x,\tau) = \frac{en^\alpha}{4\pi}\delta[(n_\alpha x^\alpha)^2 - \sigma_5 x_\alpha x^\alpha], \tag{89}$$

where it is stressed again that σ_5 appears implicitly in the scalar products such as $n_\alpha x^\alpha$.

E. UMS fields for $\zeta=+1$

We shall repeat the analysis of the last section for the case of $-\sigma_5 b_\alpha b^\alpha > 0$. The roots (84) are applicable in the present case as well. However, the range of integration of (83) now reveals that $p(\tau')>0$ for the *exterior* region $\tau' \in (-\infty,\tau_1')\cup(\tau_2',+\infty)$. Therefore, (86) now becomes:

$$p(\tau') = (-\sigma_5 b_\alpha b^\alpha)\left(\tau' - \frac{b_\alpha x^\alpha}{b_\alpha b^\alpha}\right)^2 - \left(-\frac{\sigma_5}{b_\alpha b^\alpha}\right)[(b_\alpha x^\alpha)^2 - b_\alpha b^\alpha(x_\alpha x^\alpha - \sigma_5\varepsilon)]$$

$$= A^2(\tau' - B)^2 - \left(-\frac{\sigma_5}{b_\alpha b^\alpha}\right)R^2, \tag{90}$$

where in this case

$$A = \sqrt{-\sigma_5 b_\alpha b^\alpha}.$$

However, in order that the field integral (85) converges, we shall define $p_\lambda(\tau')$ as follows:

$$p_\rho(\tau') = p(\tau') + \rho^2. \tag{91}$$

The field integral (85) obtains the form

$$a^{\alpha}_{\sigma_5}(x,\tau) = \frac{e\sigma_5 b^\alpha}{4\pi^2} \lim_{\substack{\rho\to 0^+\\ \varepsilon\to 0^+}} \frac{\partial}{\partial\varepsilon} \int_{-\infty}^{+\infty} \frac{\theta(p(\tau'))}{\sqrt{p_\rho(\tau')}} d\tau' = \frac{e\sigma_5 b^\alpha}{4\pi^2} \lim_{\substack{\rho\to 0^+\\ \varepsilon\to 0^+}} \int_{-\infty}^{+\infty} \left[\frac{\delta(p(\tau'))}{\sqrt{p_\rho(\tau')}} - \frac{1}{2}\frac{\theta(p(\tau'))}{[p_\rho(\tau')]^{3/2}}\right]\frac{\partial p(\tau')}{\partial\varepsilon}, \tag{92}$$

where we used that fact that $\partial_\varepsilon p(\tau')=\partial_\varepsilon p_\rho(\tau')$. The first $\delta(p(\tau'))$ term breaks up over the roots of $p(\tau')$:

$$\frac{\delta(p(\tau'))}{\sqrt{p_\rho(\tau')}} = \frac{1}{A^2}\frac{\delta(\tau-\tau_1')+\delta(\tau-\tau_2')}{|\tau_1'-\tau_2'|}\frac{1}{\sqrt{p_\rho(\tau')}}. \tag{93}$$

We also have

$$\partial_\varepsilon p(\tau') = \partial_\varepsilon p_\rho(\tau') = 1. \tag{94}$$

Integrating the first δ-term, and combining (94) with (93) and (92), we obtain

$$\int_{-\infty}^{+\infty} \frac{\delta(p(\tau'))}{\sqrt{p_\rho(\tau')}} \frac{\partial p(\tau')}{\partial \varepsilon} d\tau' = \frac{1}{A^2} \frac{|b_\alpha b^\alpha|}{2R} \left[\frac{1}{\sqrt{p_\rho(\tau')}} \right|_{\tau'=\tau_1'} + \frac{1}{\sqrt{p_\rho(\tau')}}{}_{\tau'=\tau_2'} = \frac{1}{R} \frac{1}{\rho}, \tag{95}$$

which diverges as $1/\rho$. The second term can be integrated with the substitution

$$C \cosh \beta = A(\tau' - R) \quad \text{where } C = \left[\sqrt{\frac{-\sigma_5}{b_\alpha b^\alpha} R^2 - \lambda^2} \right].$$

Thus

$$\begin{aligned} \int_{-\infty}^{+\infty} \frac{\theta(p(\tau'))}{[p_\rho(\tau')]^{3/2}} d\tau' &= \frac{2C}{A} \theta(R^2) \int_{\beta_0}^{+\infty} \sinh \beta d\beta \frac{1}{[C^2(\cosh^2 \beta - 1)]^{3/2}} \\ &= 2 \frac{\theta(R^2)}{AC^2} \int_{\beta_0}^{+\infty} \frac{d\beta}{\sinh^2 \beta} = 2 \frac{\theta(R^2)}{AC^2} (-1) \coth \beta_{\beta_0}^{+\infty} = 2 \frac{\theta(R^2)}{AC^2} [\coth \beta_0 - 1]. \end{aligned} \tag{96}$$

The β_0 lower bound is given by

$$\sinh^2 \beta_0 = \frac{\rho^2}{C^2} \Rightarrow \coth \beta_0 = \sqrt{1 + \frac{1}{\sinh^2 \beta_0}} = \frac{1}{\rho} \sqrt{C^2 + \rho^2} = \frac{C}{\rho} + O(\rho),$$

which provides the complete solution for the second term

$$\int_{-\infty}^{+\infty} \frac{\theta(p(\tau'))}{[p_\rho(\tau')]^{3/2}} d\tau' = 2 \frac{\theta(R^2)}{AC^2} \left[\frac{C}{\rho} - 1 \right] \tag{97}$$

$$= 2\theta(R^2) \left[\frac{1}{\sqrt{R^2 + \sigma_5 \rho^2 b_\alpha b^\alpha}} \frac{1}{\rho} - \frac{1}{\sqrt{-\sigma_5 b_\alpha b^\alpha}(-\sigma_5 R^2 / b_\alpha b^\alpha - \rho^2)} \right]. \tag{98}$$

The sum of the δ-term and the smooth term becomes

$$\begin{aligned} a_{\sigma_5}^\alpha(x,\tau) &= \frac{e\sigma_5 b^\alpha}{4\pi^2} \lim_{\substack{\rho \to 0^+ \\ \varepsilon \to 0^+}} \theta(R^2) \left[\frac{1}{R} \frac{1}{\rho} - \left(\frac{1}{\sqrt{R^2 + \sigma_5 \rho^2 b_\alpha b^\alpha}} \frac{1}{\rho} - \frac{1}{\sqrt{-\sigma_5 b_\alpha b^\alpha}(-\sigma_5 R^2 / b_\alpha b^\alpha - \rho^2)} \right) \right] \\ &= \frac{e b^\alpha}{4\pi^2 \sqrt{-\sigma_5 b_\alpha b^\alpha}} \frac{b_\alpha b^\alpha}{[(b_\alpha x^\alpha)^2 - (b_\alpha b^\alpha)(x_\alpha x^\alpha)]}. \end{aligned}$$

Once again, defining $n^\alpha = b^\alpha / |b_\alpha b^\alpha|$, we obtain the final result for $\zeta = -1$:

$$a_{\sigma_5}^\alpha(x,\tau) = \frac{e n^\alpha}{4\pi^2} \frac{\theta((n_\alpha x^\alpha)^2 + \sigma_5 x_\alpha x^\alpha)}{[(n_\alpha x^\alpha)^2 + \sigma_5 x_\alpha x^\alpha]}. \tag{99}$$

V. CONCLUSIONS

The a-fields [see (72)] generated by a uniformly moving point source in (4,1) and (3,2) off-shell electrodynamics clearly resemble the expected UMS fields in a 5D Maxwell electrodynamics. However, the latter, generally in a framework of relativistic dynamics, are normally

regarded as producing fields from *timelike* sources only. Stueckelberg-based off-shell electrodynamics, on the other hand, that are based on a 4D dynamics parametrized along an invariant parameter, have no apparent limit on the region of the source velocity, though normally, the equations are set with constant $z^5(\tau)\equiv\tau\Rightarrow b^5\equiv 1$. Moreover, the 4D dynamics place no *a priori* restriction on $b'_\mu\equiv b^\mu/b^5$, and all cases of $b'^2<0$ or $b'^2>0$ were shown. However, the two forms of the fields given in (72) differ dramatically, and in particular, one is required to explain the δ-functions fields found for the 5D spacelike and timelike regions of source velocity for the (4,1) and (3,2) flat metric equations, respectively.

The δ-function fields ($\zeta=-1$) have support on a 4D null surface given by $x_\alpha x^\alpha-\sigma_5(n_\alpha x^\alpha)^2=0$, which is orthogonal to the direction of motion of the source n^α. Thus, this null surface is actually the (3,1) light cone, as can easily be observed in the frame $n^\alpha=[0;0,0,0,1]$, in which case both (4,1) and (3,2) fields reduce to the Maxwell time-symmetric GF $\delta(x^2)$. This reflects the choice of Principal Part, which was taken in the derivation of those fields. These singular fields are in fact the analog for a 4D UMS field of a spacelike moving source.

In a subsequent study, we plan to show that when a Lorentz force derived from those fields is applied to a test particle, it produces a finite force in an infinitesimally short τ interval, and thus has no noticeable effect on test particles. The reason for this is that the field tensor $f_{\alpha\beta}=\partial_\alpha a_\beta-\partial_\beta a_\alpha$contains derivatives of the δ-functions, and when integrated by parts, a coupling of the δ to acceleration terms is obtained, causing a large mass renormalization effect when the test particle hits the surface of singular support. This effect actually reduces the impact to a finite value, causing it to behave as a zero-measure force.

The smooth fields, on the other hand, obey a $1/r^2$ decay power-law. However, the (4,1) and (3,2) fields differ dramatically in this case. For the (4,1) metric case, the denominator is positive definite, which can easily be observed when a nonphysical frame of $n^\alpha=[1;0,0,0,0]$ is taken ($b^5=0$ in this case, contradicting the theory). In fact, for any $n^5\neq 0$, it causes the field to be a transient phenomenon, decaying as $1/\tau^2$ for large $\tau\gg\sqrt{\mathbf{x}^2+t^2}$.

On the other hand, for the (3,2) case, the fields follow an $O(2,2)$ symmetry as well, which can be seen when $n^\alpha=\delta^\alpha_i$ for one of $i\in\{1,2,3\}$. When this field is integrated over τ, it produces the $O(2,1)$ GF (proportional to $[t^2-x^2-y^2]^{-1/2}$), which is also the Maxwell field produced by a uniformly moving 3D point source in spacelike motion.

In Ref. 3, Land studied the equations of motion of a test particle in a field with similar singular support behavior. In particular, the scattering problem in the nonrelativistic limit was derived, in which he noted a failure in matching the well-known Rutherford scattering formula. Land then used the mass-τ uncertainty relations, similar to the time-energy uncertainty in nonrelativistic QM, to argue that a true pointwise 4D particle is insufficient to describe a physical source, and thus defined a *distribution of events* along the τ parameter, acting coherently as a single particle. He chose the following distribution,

$$j^\alpha(x,\tau)=\frac{b^\alpha}{2\lambda}\int_{-\infty}^{+\infty}d\tau' e^{-|\tau-\tau'|/\lambda}\delta^4[x-b\tau'], \tag{100}$$

which approaches the pointwise distribution for $\lambda\to 0^+$, and the Maxwell worldline [see Eq. (22)] for $\lambda\to+\infty$. Since the fields are linear, the cumulative contribution smoothed out the δ-function fields. Using a numerical computation, Land found a constraint on λ.

We shall show in a subsequent study how this method of regularization applies to the type of fields we have found here, and make comparison with observed phenomena.

It was found that the GF's (82) are consistent with the UMS fields. The ε derivative is used to indicate derivation with respect to the argument, which is maintained even once the fields are applied on a test particle. Although the derivative seems to contain a strong distribution $\delta(y)/\sqrt{y}$, this term has proved essential in the derivation of $\zeta=-1$ smooth fields (99), in which it counterbalanced an infinite contribution from the bounds $\tau\to\tau'^+_2,\tau'^-_1$. Geometrically, it regularized the singular support at the 5D light cone.

The GF's obtained could be used for subsequent studies of radiation-reaction, two-particle systems and various models of regularizations.

(Received 21 July 2006; accepted 4 October 2006; published online 6 December 2006)

Statistical models corresponding to a new class of braid matrices $(\hat{o}_N; N \geqslant 3)$ presented in a previous paper are studied. Indices labeling states spanning the N^r dimensional base space of $T^{(r)}(\theta)$, the rth order transfer matrix are so chosen that the operators W (the sum of the state labels) and (CP) (the circular permutation of state labels) commute with $T^{(r)}(\theta)$. This drastically simplifies the construction of eigenstates, reducing it to solutions of relatively small number of simultaneous linear equations. Roots of unity play a crucial role. Thus for diagonalizing the 81 dimensional space for $N=3$, $r=4$, one has to solve a maximal set of five linear equations. A supplementary symmetry relates invariant subspaces pairwise $[W=(r,Nr)$ and so on] so that only one of each pair needs study. The case $N=3$ is studied fully for $r=(1,2,3,4)$. Basic aspects for all (N,r) are discussed. Full exploitation of such symmetries lead to a formalism quite different from, possibly generalized, algebraic Bethe ansatz. Chain Hamiltonians are studied. The specific types of spin flips they induce and propagate are pointed out. The inverse Cayley transform of the YB matrix giving the potential leading to factorizable S matrix is constructed explicitly for $N=3$ as also the full set of $\hat{R}tt$ relations. Perspectives are discussed in a final section. © *2006 American Institute of Physics.*

I. INTRODUCTION

New classes of braided matrices were presented in recent papers.[1,2] Statistical models corresponding to Ref. 1 have been presented in Ref. 3. Here we present those corresponding to Ref. 2. Different types of statistical models thus obtained will be compared at the end (Sec. VII). In Ref. 2 two distinct classes of braid matrices $(\hat{o}_N, \hat{p}_N)$ were presented. Here we consider only the $\hat{o}_N$ $(N \geqslant 3)$. For real, positive values of the parameter q and a certain domain (depending on q and N) of the spectral parameter θ, one obtains $N^2 \times N^2$ braid matrices with all nonzero elements real, positive giving non-negative Boltzmann weights. For the class $\hat{p}_N$ one encounters both positive and negative elements and thus one would need suitable reinterpretation of the corresponding Boltzmann weights.

We first recapitulate briefly the $\hat{o}_N$ braid matrices.[2] The $N^2 \times N^2$ baxterized braid matrices satisfying (in standard notations)

[a)]Electronic mail: boucif@cpht.polytechnique.fr; boucif@yahoo.fr
[b)]Electronic mail: chakra@cpht.polytechnique.fr

$$\hat{R}_{12}(\theta)\hat{R}_{23}(\theta+\theta')\hat{R}_{12}(\theta') = \hat{R}_{23}(\theta')\hat{R}_{12}(\theta+\theta')\hat{R}_{23}(\theta) \tag{1.1}$$

are given by

$$\hat{R}(\theta) = I - \frac{\sinh\,\theta}{\sinh(\eta+\theta)}P_0', \tag{1.2}$$

where

$$e^{\eta}+e^{-\eta} = [N-1]+1 \equiv \frac{q^{N-1}-q^{-N+1}}{q-q^{-1}}+1 \tag{1.3}$$

and

$$P_0' = \sum_{i,j=1}^{N} q^{\rho_{j'}-\rho_j}(ij)\otimes(i'j') \tag{1.4}$$

with the following notations:

1. The $N\times N$ matrix (ij) has only one nonzero element, unity, on row i and column j and

$$(i',j') = (N-i+1,N-j+1). \tag{1.5}$$

2. The N tuple $(\rho_1,\rho_2,\ldots,\rho_N)$ is defined as

$$\left(n-\tfrac{1}{2},n-\tfrac{3}{2},\ldots,\tfrac{1}{2},0,-\tfrac{1}{2},\ldots,-n+\tfrac{1}{2}\right) \tag{1.6}$$

for $N=2n+1$ and

$$(n-1,n-2,\ldots,1,0,0,-1,\ldots,-n+1) \tag{1.7}$$

for $N=2n$.

Of the three projectors (P_+,P_-,P_0) providing a spectral resolution of $SO_q(N)$ braid matrices only

$$P_0' = ([N-1]+1)P_0 \tag{1.8}$$

appears in our class. To signal this provenance (along with crucial differences) our class is designated as $\hat{o}_N$. More relevant discussions can be found in Ref. 2.

We now introduce the permutation matrix

$$P = \sum_{i,j}(ij)\otimes(ji), \quad P^2 = I, \tag{1.9}$$

the Yang–Baxter matrix

$$R(\theta) = P\hat{R}(\theta), \tag{1.10}$$

and the monodromy matrices satisfying

$$\hat{R}(\theta-\theta')(t(\theta)\otimes t(\theta')) = (t(\theta')\otimes t(\theta))\hat{R}(\theta-\theta'). \tag{1.11}$$

The t matrix satisfying Eq. (1.11) is $N\times N$ in terms of the blocks

$$t_{ij,} \quad (i,j=1,\ldots,N), \tag{1.12}$$

each t_{ij} being itself a matrix whose dimension is prescribed as follows. One starts with $N\times N$ blocks t_{ij} obtained from the standard prescription [satisfying Eq. (1.11)]

$$t^{(1)}(\theta) = P\hat{R}(\theta) = R(\theta) \tag{1.13}$$

and then a hierarchy is obtained implementing the coproduct prescription

$$t_{ij}^{(r)}(\theta) = \sum_{k_1,\ldots,k_{r-1}} t_{ik_1}^{(1)}(\theta) \otimes t_{k_1k_2}^{(1)}(\theta) \otimes \cdots \otimes t_{k_{r-1},j}^{(1)}(\theta). \tag{1.14}$$

Starting with Eq. (1.13), this prescription assures that $t^{(r)}(\theta)$ satisfies Eq. (1.11).

Now the transfer matrix is defined, for each order r, as

$$T^{(r)}(\theta) = \sum_{i=1}^{N} t_{ii}^{(r)}(\theta). \tag{1.15}$$

The trace and more generally the eigenstates and the eigenvalues of $T^{(r)}(\theta)$ provide crucial properties of the statistical mechanical model associated with $\hat{R}(\theta)$. In particular, Eqs. (1.1), (1.11), and (1.13)–(1.15) all together assure the commutativity

$$[T(\theta), T(\theta')] = 0. \tag{1.16}$$

Commutative transfer matrices provide the crucial feature of exactly solvable models of statistical mechanics, the braid matrices encoding star-triangle relations.[4] For our specific case ($\hat{o}_N$) we illustrate, in the following section, some basic features for the simplest case ($N=3$). Certain aspects for $N>3$ will be presented afterwards (Sec. V).

Define

$$K(\theta) = -\frac{\sinh\theta}{\sinh(\eta+\theta)}, \tag{1.17}$$

where [setting $N=3$ in Eq. (1.3)]

$$e^{\eta} + e^{-\eta} = q + q^{-1} + 1. \tag{1.18}$$

For

$$-\eta < \theta < 0, \quad K(\theta) > 0. \tag{1.19}$$

For

$$\theta = 0, \quad K(0) = 0,$$

$$\theta = -\frac{\eta}{2}, \quad K\left(-\frac{\eta}{2}\right) = 1,$$

$$\theta \to -\eta, \quad K(\theta) \to +\infty. \tag{1.20}$$

Henceforward we consider the domain (1.19).

II. TRACE OF THE TRANSFER MATRIX FROM ITERATIVE STRUCTURE

The standard prescription (1.13) yields for $\hat{o}_3$

$$t^{(1)}(\theta) = P\hat{R}(\theta) = P(I + K(\theta)P_0'), \tag{2.1}$$

and hence, (suppressing now the argument θ for simplicity)

$$t_{11}^{(1)}=\begin{vmatrix}1&0&0\\0&0&0\\0&0&K\end{vmatrix},\quad t_{12}^{(1)}=\begin{vmatrix}0&0&0\\1&0&0\\0&q^{1/2}K&0\end{vmatrix},\quad t_{13}^{(1)}=\begin{vmatrix}0&0&0\\0&0&0\\1+qK&0&0\end{vmatrix},$$

$$t_{21}^{(1)}=\begin{vmatrix}0&1&0\\0&0&q^{-1/2}K\\0&0&0\end{vmatrix},\quad t_{22}^{(1)}=\begin{vmatrix}0&0&0\\0&1+K&0\\0&0&0\end{vmatrix},\quad t_{23}^{(1)}=\begin{vmatrix}0&0&0\\q^{1/2}K&0&0\\0&1&0\end{vmatrix},$$

$$t_{31}^{(1)}=\begin{vmatrix}0&0&1+q^{-1}K\\0&0&0\\0&0&0\end{vmatrix},\quad t_{32}^{(1)}=\begin{vmatrix}0&q^{-1/2}K&0\\0&0&1\\0&0&0\end{vmatrix},\quad t_{33}^{(1)}=\begin{vmatrix}K&0&0\\0&0&0\\0&0&1\end{vmatrix}. \tag{2.2}$$

All θ dependence is contained in the parameter K, as defined in Eq. (1.17). Starting with the 3×3 blocks the prescription Eq. (1.14) gives $3^r\times 3^r$ blocks $t_{ij}^{(r)}$. The recursion relations for our case $(N=3)$ are (for $j=1,2,3$),

$$t_{1j}^{(r+1)}=\begin{vmatrix}t_{1j}^{(r)}&0&0\\t_{2j}^{(r)}&0&0\\(1+qK)t_{3j}^{(r)}&q^{1/2}Kt_{2j}^{(r)}&Kt_{1j}^{(r)}\end{vmatrix}, \tag{2.3}$$

$$t_{2j}^{(r+1)}=\begin{vmatrix}0&t_{1j}^{(r)}&0\\q^{1/2}Kt_{3j}^{(r)}&(1+K)t_{2j}^{(r)}&q^{-1/2}Kt_{1j}^{(r)}\\0&t_{3j}^{(r)}&0\end{vmatrix}, \tag{2.4}$$

$$t_{3j}^{(r+1)}=\begin{vmatrix}Kt_{3j}^{(r)}&q^{-1/2}Kt_{2j}^{(r)}&(1+q^{-1}K)t_{1j}^{(r)}\\0&0&t_{2j}^{(r)}\\0&0&t_{3j}^{(r)}\end{vmatrix}. \tag{2.5}$$

The transfer matrix is iterated as

$$\begin{aligned}T^{(r+1)}&=t_{11}^{(r+1)}+t_{22}^{(r+1)}+t_{33}^{(r+1)}\\&=\begin{vmatrix}t_{11}^{(r)}+Kt_{33}^{(r)}&t_{12}^{(r)}+q^{1/2}Kt_{23}^{(r)}&(1+q^{-1}K)t_{13}^{(r)}\\t_{21}^{(r)}+q^{-1/2}Kt_{32}^{(r)}&(1+K)t_{22}^{(r)}&q^{-1/2}Kt_{12}^{(r)}+t_{23}^{(r)}\\(1+qK)t_{31}^{(r)}&q^{1/2}Kt_{21}^{(r)}+t_{32}^{(r)}&Kt_{11}^{(r)}+t_{33}^{(r)}\end{vmatrix}.\end{aligned} \tag{2.6}$$

Hence,

$$\begin{aligned}\mathrm{Tr}(T^{(r+1)})&=\mathrm{Tr}(t_{11}^{(r)}+Kt_{33}^{(r)}+(1+K)t_{22}^{(r)}+Kt_{11}^{(r)}+t_{33}^{(r)})\\&=(1+K)\mathrm{Tr}(t_{11}^{(r)}+t_{22}^{(r)}+t_{33}^{(r)})\\\mathrm{Tr}(T^{(r+1)})&=(1+K)\mathrm{Tr}(T^{(r)}).\end{aligned} \tag{2.7}$$

But from Eq. (2.2)

$$\mathrm{Tr}(T^{(1)})=\mathrm{Tr}(t_{11}^{(1)}+t_{22}^{(1)}+t_{33}^{(1)})=3(1+K). \tag{2.8}$$

Hence,

$$\mathrm{Tr}(T^{(r)})=3(1+K)^r. \tag{2.9}$$

Thus we obtain the trace of $T^{(r)}$ for all r directly without constructing explicitly the eigenstates and the 3^r eigenvalues. But the latter being of crucial interest we now turn to their systematic explicit constructions.

III. EIGENSTATES AND EIGENVALUES ($N=3$)

For $N=3$ the transfer matrix $T^{(r)}(\theta)$ of order r acts on a dimension 3^r. Construction of eigenstates corresponds to diagonalization of $T^{(r)}$ on such a base space. But basic symmetries of $T^{(r)}$ (Sec. I) for our case have profound consequences. They reduce the problem so that one has effectively to diagonalize subspaces whose dimensions increase polynomially with r (rather than according to the power law 3^r). To formulate these features conveniently we introduce the following conventions for state labels.

For the fundamental case, $r=1$, the three-dimensional basis is denoted as

$$|1\rangle \equiv \begin{vmatrix} 1 \\ 0 \\ 0 \end{vmatrix}\rangle, \quad |2\rangle \equiv \begin{vmatrix} 0 \\ 1 \\ 0 \end{vmatrix}\rangle, \quad |3\rangle \equiv \begin{vmatrix} 0 \\ 0 \\ 1 \end{vmatrix}\rangle. \tag{3.1}$$

For $r>1$, the order of the indices (1,2,3) represents the tensored structure. Thus, for example, for $r=5$,

$$|11231\rangle \equiv |1\rangle \otimes |1\rangle \otimes |2\rangle \otimes |3\rangle \otimes |1\rangle. \tag{3.2}$$

The fundamental realizations $t_{ij}^{(1)}$ of Eq. (2.2) implemented in the tensored structure Eq. (1.14) of $t_{i,j}^{(r)}$ lead to the following major consequences.

(I) Each set of states corresponding to a given sum of the indices (state labels 1,2,3) forms a closed subspace under the action of $T^{(r)}(\theta)$. Define with [with $a_i=(1,2,3)$]

$$W|a_1 a_2 \ldots a_r\rangle = (a_1 + a_2 + \cdots + a_r)|a_1 a_2 \ldots a_r\rangle. \tag{3.3}$$

Then

$$[T^{(r)}(\theta), W] = 0 \tag{3.4}$$

implying for each state on the right of

$$T^{(r)}(\theta)|a_1 a_2 \ldots a_r\rangle = \sum_{b_i} f_{(a,b)}(\theta)|b_1 b_2 \ldots b_r\rangle, \quad (b_1 + b_2 + \cdots + b_r) = (a_1 + a_2 + \cdots + a_r). \tag{3.5}$$

Thus the 3^r dimensional base space of $T^{(r)}$ splits into $(2r+1)$ closed subspaces under the action of $T^{(r)}$ as

$$S_r, S_{r+1}, \ldots, S_{2r-1}, S_{2r}, S_{2r+1}, \ldots, S_{3r}, \tag{3.6}$$

where S_n corresponds to $a_1+a_2+\ldots+a_r=n$. In constructing eigenstates of $T^{(r)}$ each S_n can be treated separately simplifying the problem considerably. The simplest subspaces are the extreme ones, namely

$$S_r = |11 \ldots 1\rangle \tag{3.7}$$

and

$$S_{3r} = |33 \ldots 3\rangle, \tag{3.8}$$

[the index 1(3) being repeated r times]. These are already automatically eigenstates. The highest dimensional subspace is obtained for $n=2r$ which includes the state $|22\ldots2\rangle$. Special feature of some subspaces will be displayed below.

(II) Within each subspace again $T^{(r)}(\theta)$ commutes with circular permutations of states labels. Thus (CP) representing a circular permutation

$$[T^{(r)}(\theta),(\mathrm{CP})]=0 \tag{3.9}$$

in the sense

$$(\mathrm{CP})^2 T^{(r)}|a_1a_2a_3,\ldots,a_{r-1}a_r\rangle=(\mathrm{CP})T^{(r)}|a_ra_1a_2,\ldots,a_{r-2}a_{r-1}\rangle=T^{(r)}|a_{r-1}a_ra_1,\ldots,a_{r-3}a_{r-2}\rangle \tag{3.10}$$

and so on for all successive (CP) of the indices $(a_1a_2,\ldots,a_r)$.

(III) As a consequence the states in each invariant subspace can again be grouped together implementing roots of unity as follows. Let ω be any rth root of unity, i.e.,

$$\omega=\left(1,e^{i(2\pi/r)},e^{i(2\pi/r)\cdot 2},\ldots,e^{i(2\pi/r)\cdot(r-1)}\right) \tag{3.11}$$

and (for each possible value of ω, separately)

$$|a_1a_2a_3,\ldots,a_{r-1}a_r\rangle_\omega\equiv|a_1a_2a_3,\ldots,a_{r-1}a_r\rangle+\omega|a_ra_1a_2,\ldots,a_{r-2}a_{r-1}\rangle+\omega^2|a_{r-1}a_ra_1,\ldots,a_{r-3}a_{r-2}\rangle$$
$$+\cdots+\omega^{r-1}|a_2a_3a_4,\ldots,a_ra_1\rangle. \tag{3.12}$$

The components states are, evidently, all in the same invariant subspace. For r different values of ω these provide a mutually orthogonal set of r states diagonalizing CP since

$$(\mathrm{CP})|a_1a_2a_3,\ldots,a_{r-1}a_r\rangle_\omega=\omega|a_1a_2a_3,\ldots,a_{r-1}a_r\rangle_\omega. \tag{3.13}$$

The action of $T^{(r)}$ on, say, $|a_1a_2,\ldots,a_{r-1}a_r\rangle$ gives directly, due to Eq. (3.10), that on $|a_1a_2,\ldots,a_{r-1}a_r\rangle_\omega$ for all values of ω. Thus one can effectively reduce the dimension of the relevant subspace S_n for a given sum of state labels, $(a_1+a_2+\cdots+a_{r-1}+a_r)=n$. Such a "two-step reduction," firstly, restriction to invariant subspaces S_n, second, introduction of roots of unity to form eigenstates of (CP) will be shown to lead to a much slower increase with r (as compared to $e^{(\ln 3)r}$) of the dimension of the spaces on which one has to diagonalize $T^{(r)}$. This will be first displayed through particular examples. The general formulation will be given at the end of this section.

(IV) But another symmetry is appropriately mentioned at this stage (to be illustrated later explicitly). Interchanging the indices as

$$(1,2,3)\rightarrow(3,2,1). \tag{3.14}$$

The action of $T^{(r)}$ is directly obtained via the inversion

$$q\rightarrow q^{-1} \tag{3.15}$$

in each coefficient. Thus the invariant subspaces related through Eq. (3.14) need not be studied separately. The corresponding eigenstates and eigenvalues are related through Eq. (3.15). It is sufficient to study the first $(r+1)$ subspaces since under Eqs. (3.14) and (3.15),

$$S_{2r}\rightarrow S_{2r},\quad (S_r,S_{r+1},\ldots,S_{2r-1})\rightleftharpoons(S_{3r},S_{3r-1},\ldots,S_{2r+1}). \tag{3.16}$$

Explicit examples for $r=(3,4)$ will follow. Our $\hat{o}_N$ braid matrices remain nontrivial for $q=1$ as pointed out in Ref. 2. Now Eq. (3.14) becomes a full symmetry. The degeneracy thus induced is of interest.

(V) A final crucial feature is due to Eq. (1.16),

$$[T^{(r)}(\theta),T^{(r)}(\theta')]=0. \tag{3.17}$$

Suppose that for, say, $r=4$ in some subspace one obtains a closed subset of states (A,B,C,D) with

$$T^{(4)}(\theta)A = a_{11}A + a_{12}B + a_{13}C + a_{14}D, \ldots, T^{(4)}(\theta)D = d_{11}A + d_{12}B + d_{13}C + d_{14}D. \quad (3.18)$$

The coefficients $(a_{11}, \ldots, d_{14})$ are in general polynomials in $K(\theta)$, the maximal degree being $r=4$ for this case. Define eigenstates as

$$T^{(4)}(\theta)(\alpha A + \beta B + \gamma C + \delta D) = v(\alpha A + \beta B + \gamma C + \delta D), \quad (3.19)$$

which are to be solved for by implementing Eq. (3.18) on the left. Consistency with Eq. (3.17) imposes θ independence (K independence) of $(\alpha, \beta, \gamma, \delta)$. Hence, on the right only v can be K dependent. All K dependence of $(a_{11}, \ldots, d_{14})$ on the left must thus factorize as a polynomial (here for $r=4$)

$$v = f_4K^4 + f_3K^3 + f_2K^2 + f_1K + f_0 \quad (3.20)$$

for suitable $(f_4, f_3, f_2, f_1, f_0)$ which can depend on (q, ω) only. In general this leads to a set of overdetermined set of coupled linear equations (for our case) in

$$(\alpha, \beta, \gamma, \delta; f_4, f_3, f_2, f_1, f_0). \quad (3.21)$$

Varied illustrations will follow. Moreover, while all eigenvalues are, in general, K and q dependent, all explicit q dependence [except for the implicit one through K of Eqs. (1.17) and (1.18)] must cancel in the overall trace (summing over all subspaces) to give Eq. (2.9), i.e.,

$$\mathrm{Tr}(T^{(r)}) = 3(1 + K)^r. \quad (3.22)$$

This provides a stringent check (Appendix A).

Special features of the subspaces $(S_r, S_{3r}), (S_{r+1}, S_{3r-1}), S_{2r}$

• (S_r, S_{3r}): As mentioned following Eqs. (3.7) and (3.8) these two are one-dimensional subspaces. One obtains immediately, for all r,

$$T^{(r)}(\theta)|11 \ldots 1\rangle = (1 + K^r)|11 \ldots 1\rangle, \quad (3.23)$$

$$T^{(r)}(\theta)|33 \ldots 3\rangle = (1 + K^r)|33 \ldots 3\rangle. \quad (3.24)$$

These eigenstates of (CP), singlets, provide the simplest illustrations of Eqs. (3.14) and (3.15).

• (S_{r+1}, S_{3r-1}): For arbitrary r, with

$$\omega = (1, e^{i(2\pi/r)}, e^{i(2\pi/r)2}, \ldots, e^{i(2\pi/r)(r-1)}) \quad (3.25)$$

define

$$X_\omega = |111 \ldots 12\rangle + \omega|211 \ldots 11\rangle + \omega^2|121 \ldots 11\rangle + \omega^{r-1}|111 \ldots 21\rangle, \quad (3.26)$$

$$Y_\omega = |333 \ldots 32\rangle + \omega|233 \ldots 33\rangle + \omega^2|323 \ldots 33\rangle + \omega^{r-1}|333 \ldots 23\rangle. \quad (3.27)$$

One easily obtains

$$T^{(r)}(\theta)X_\omega = (K^r\omega + \omega^{r-1})X_\omega, \quad (3.28)$$

$$T^{(r)}(\theta)Y_\omega = (K^r\omega + \omega^{r-1})Y_\omega. \quad (3.29)$$

For the r values of ω one obtains thus, in a single stroke, all the requisite r eigenstates for these two r-dimensional subspaces. Note that

$$\sum_{\omega} (K^r\omega + \omega^{r-1}) = \sum_{\omega} (K^r\omega + \omega^{-1}) = 0. \tag{3.30}$$

Hence, (S_{r+1}, S_{3r-1}) do not contribute to the total trace $\mathrm{Tr}(T^{(r)}(\theta))$.

For $S_{r+2}(S_{3r-2})$ already the structure of eigenstates and eigenvalues are not so simple. (See Appendix A for $r=3,4$.) Some special features of S_{2r} are, however, worth mentioning, particularly to compare the structures of r prime and non-prime.

• (S_{2r}): Like $|11\ldots1\rangle$ and $|33\ldots3\rangle, |22\ldots2\rangle$ is also a singlet under (CP). But unlike the former the latter one does not form an 1-dimensional subspace. It can get coupled with the other states of S_{2r} (for $\omega=1$) as follows. When r is prime, apart from $|22\ldots2\rangle$, S_{2r} is composed of r-plets (formed using ω with $\omega^r=1$). When r is factorizable there can be intermediate multiplets corresponding to factors $(n_1, n_2, \ldots, n_k)$ of $r=(n_1 n_2 \ldots n_k)$. Thus for $r=4$ (the first factorizable r) there are doublets corresponding to $r=2\times2$. For $r=6$, there are doublets and triplets between 1- and 6-plets. Let us illustrate the situation using the simplest nontrivial cases $r=3,4$.

◇ $(r=3, S_6)$: Define

$$A_1 = |222\rangle, \quad B_\omega = |123\rangle + \omega|312\rangle + \omega^2|231\rangle, \quad C_\omega = |321\rangle + \omega|132\rangle + \omega^2|213\rangle, \tag{3.31}$$

where $\omega=(1, e^{i(2\pi/3)}, e^{i(2\pi/3)2})$. In our notation A_1 indicates that here (for singlet) one has only $\omega=1$. Correspondingly (B_1, C_1) will denote the latter for $\omega=1$. Consistently with Eq. (3.9) set

$$T^{(3)}(\theta)(\alpha A_1 + \beta B_1 + \gamma C_1) = \upsilon(\alpha A_1 + \beta B_1 + \gamma C_1) \tag{3.32}$$

for $\omega=1$ and

$$T^{(3)}(\theta)(\mu B_\omega + \nu C_\omega) = w(\mu B_\omega + \nu C_\omega) \tag{3.33}$$

for $\omega=(e^{i(2\pi/3)}, e^{-i(2\pi/3)})$. Here (ν, w) are assumed to be cubic polynomials in K and $(\alpha, \beta, \gamma), (\mu, \nu)$ to be K independent. Note also that

$$(1 \rightleftharpoons 3) B_\omega = C_\omega. \tag{3.34}$$

Hence, [consistently with Eqs. (3.14) and (3.15)] one obtains the coefficient in $T^{(3)}(\theta)C_\omega$ by inverting q to q^{-1} in those of $T^{(3)}(\theta)B_\omega$. Explicit solutions are given in Appendix A. Here we only note that the decoupling of A_1 in Eq. (3.33) is assured via the structure

$$T^{(3)}(\theta)A_1 = a_{11}A_1 + a_{12}B_1 + a_{13}C_1,$$

$$T^{(3)}(\theta)B_\omega = (1 + \omega + \omega^2)b_{11}A_1 + b_{12}B_\omega + b_{13}C_\omega,$$

$$T^{(3)}(\theta)C_\omega = (1 + \omega + \omega^2)c_{11}A_1 + c_{12}B_\omega + c_{13}C_\omega. \tag{3.35}$$

◇ $(r=4, S_8)$: Here, after the (CP)- singlet

$$A_1 = |2222\rangle \tag{3.36}$$

one has also that doublets

$$B_{\pm1} = |1313\rangle \pm |3131\rangle \tag{3.37}$$

and then the quartets completing the 19-dimensional S_8 for all values of ω, namely,

$$\omega = (1, e^{i(2\pi/4)}, e^{i(2\pi/4)\cdot2}, e^{i(2\pi/4)\cdot3}) = (1, i, -1, -i), \tag{3.38}$$

$$C_\omega = |1133\rangle + \omega|3113\rangle + \omega^2|3311\rangle + \omega^3|1331\rangle,$$

$$D_\omega = |1223\rangle + \omega|3122\rangle + \omega^2|2312\rangle + \omega^3|2231\rangle,$$

$$E_\omega = |3221\rangle + \omega|1322\rangle + \omega^2|2132\rangle + \omega^3|2213\rangle,$$

$$F_\omega = |1232\rangle + \omega|2123\rangle + \omega^2|3212\rangle + \omega^3|2321\rangle. \tag{3.39}$$

Note also that

$$(1 \rightleftharpoons 3)(C_\omega, D_\omega, E_\omega, F_\omega) = (\omega^2 C_\omega, E_\omega, D_\omega, \omega^2 F_\omega), \tag{3.40}$$

which simplifies computations according to Eqs. (3.14) and (3.15). The set F_ω alone has a distinctive feature. The two indices 2 remain separated (unlike for D_ω, E_ω) under (CP). This singles it out directly as an eigenstate of $T^{(4)}(\theta)$ (Appendix A). As for $(C_\omega, D_\omega, E_\omega)$ decouplings, analogous to Eq. (3.35) but in two stages

(1) from A_1 for $\omega=(-1, \pm i)$,
(2) and also from $B_{\pm 1}$ for $\omega=(\pm i)$

are assured through factors of the type (Appendix A),

$$(1 + \omega + \omega^2 + \omega^3), (1 + \omega^2)(1 \pm \omega). \tag{3.41}$$

The maximal set of five coupled linear equations arises for $(\omega=1)$

$$T^{(4)}(\theta)(aA_1 + bB_1 + cC_1 + dD_1 + eE_1) = v_1(aA_1 + bB_1 + cC_1 + dD_1 + eE_1). \tag{3.42}$$

To conclude we emphasize again that for $r=(3,4)$ in base spaces respectively of dimensions (27,81) the maximal set of coupled linear equations encountered are sets of (3,5) respectively. This is the slow growth with r signaled before [end of (III)].

For $r=(1,2,3,4)$ we have studied the invariant subspaces S_n explicitly. Let us now indicate the general situation. Associate the variables (x_1, x_2, x_3) to the states $(|1\rangle, |2\rangle, |3\rangle)$ respectively. In the expansion

$$(x_1 + x_2 + x_3)^r = \sum_{n_1, n_2, n_3} C_{n_1, n_2, n_3} x_1^{n_1} x_2^{n_2} x_3^{n_3} \tag{3.43}$$

for each term

$$n_1 + n_2 + n_3 = r \tag{3.44}$$

and

$$\sum_{n_1, n_2, n_3} C_{n_1, n_2, n_3} = 3^r. \tag{3.45}$$

Imposing an additional constraint one obtains the subsets

$$\dim S_n = \sum_{n_1, n_2, n_3} C_{n_1, n_2, n_3}, \quad (n_1 + 2n_2 + 3n_3 = n) \tag{3.46}$$

for $n=(r, r+1, \ldots, 2r, \ldots, 3r)$. The dimension of the total base space for order r is given by Eq. (3.45).

Let us consider as an example the central subspace S_{10} for $r=5$. From Eq. (3.46) one easily finds

$$\dim S_{10} = 51 \quad (r = 5). \tag{3.47}$$

The states can be grouped into multiplets as follows with:

$$\omega^5 = 1, \tag{3.48}$$

$$V_1^{(1)} = |22222\rangle,$$

$$V_2^{(\omega)} = (|13222\rangle + \omega|21322\rangle + \omega^2|22132\rangle + \omega^3|22213\rangle + \omega^4|32221\rangle) \equiv ((\mathrm{CP})|13222\rangle)_\omega,$$

$$V_3^{(\omega)} = ((\mathrm{CP})|12322\rangle)_\omega,$$

$$V_4^{(\omega)} = ((\mathrm{CP})|13132\rangle)_\omega,$$

$$V_5^{(\omega)} = ((\mathrm{CP})|13312\rangle)_\omega,$$

$$V_6^{(\omega)} = ((\mathrm{CP})|13321\rangle)_\omega,$$

$$(V_7^{(\omega)}, \ldots, V_{11}^{(\omega)}) = (1 \rightleftharpoons 3)(V_2^{(\omega)}, \ldots, V_6^{(\omega)}), \tag{3.49}$$

i.e., $V_7^{(\omega)} = ((\mathrm{CP})|31222\rangle)_\omega$ and so on. For $\omega = 1$, now one has to solve a set of 11 (coupling $V_1^{(1)}, \ldots V_{11}^{(1)}$) linear equations. This is the maximal such set for $r=5$ where the total dimension is 243.

Whenever r is a prime number, i.e., $r=(1,3,5,7,11,13,\ldots)$, the multiplet structure is relatively simple. Thus for S_{2r} apart from $|22\ldots2\rangle$ there are only r-plets in terms of the roots $\omega^r=1$. When r is factorizable lower multiplets can arise corresponding to factors of r. We have illustrated this for $r=4$.

IV. CHAIN HAMILTONIANS ($N=3$)

The Hamiltonian for order r is defined as

$$H^{(r)} = (T^{(r)}(\theta))^{-1}_{\theta=0}(\partial_\theta(T^{(r)}(\theta)))_{\theta=0}. \tag{4.1}$$

Instead of using the standard formulation as a sum (see the basic references in Sec. IV of Ref. 3)

$$H^{(r)} = \sum_{k=1}^{r} I \otimes I \otimes \cdots \otimes \dot{\hat{R}}_{k,k+1}(0) \otimes I \otimes \cdots \otimes I, \tag{4.2}$$

where

$$\dot{\hat{R}}_{k_1,k+1}(0) = (\partial_\theta \hat{R}_{k,k+1}(\theta))_{\theta=0} \tag{4.3}$$

with the circular boundary condition for $k=r$ $(r+1 \approx 1)$ we will use Eq. (4.1) directly, as explained below, in a fashion particularly well adapted to our formalism for constructing eigenstates.

Define starting from Eq. (1.17), i.e.,

$$K(\theta) = -\frac{\sinh\,\theta}{\sinh(\eta+\theta)}, \tag{4.4}$$

$$\dot{K}_0 \equiv (\partial_\theta K(\theta))_{\theta=0} = -(\sinh\,\eta)^{-1} \tag{4.5}$$

with $K_0=(K(\theta))_{\theta=0}=0$. We start with eigenstate of $T^{(r)}(\theta)$,

$$|V\rangle_\omega = (c_1A_1 + c_2A_2 + \cdots + c_mA_m)_\omega, \tag{4.6}$$

where the subscript ω indicates that each A_i $(i=1,\ldots,m)$ is an eigenstate of (CP), circular permutation of r state labels corresponding to a subspace S_n $(n=r,\ldots,3r)$ (see Sec. III and Appendix

A). Thus for example, for $r=3$ and $S_n=S_5$ [see Eqs. (A13) and (A18)–(A20)] $|V\rangle_\omega = aA_\omega + bB_\omega$, where

$$A_\omega = (|113\rangle + \omega|311\rangle + \omega^2|131\rangle), \quad B_\omega = (|122\rangle + \omega|212\rangle + \omega^2|221\rangle), \tag{4.7}$$

with $\omega^3=1$. Quite generally, if for Eq. (4.6),

$$T^{(r)}(\theta)|V\rangle = v|V\rangle = v\left(\sum_k c_k A_k\right) \tag{4.8}$$

then as explained and emphasized (in Sec. III and Appendix A) the coefficients c_k can depend on q (but not on θ) the only θ dependence on the right is in v, a polynomial of order r in $K(\theta)$,

$$v = f_r(K(\theta))^r + f_{r-1}(K(\theta))^{r-1} + \cdots + f_1(K(\theta)) + f_0, \tag{4.9}$$

where the coefficients f_i are each θ independent. Thus for Eq. (4.7) the solutions (for each value of ω) are

(1)
$$(a,b) = (q^{1/2} + \omega q^{-1/2}, 1),$$
$$v = \omega^2 K^3 + ((q+q^{-1})\omega^2 + (1+\omega+\omega^2))K^2 + ((q+q^{-1})\omega + (1+\omega+\omega^2))K + \omega, \tag{4.10}$$

(2)
$$(a,b) = (1, -(q^{1/2} + \omega^2 q^{-1/2})), \quad v = \omega^2 K^3 + \omega. \tag{4.11}$$

From Eqs. (4.5), (4.8), and (4.9) one obtains (since $K_0=0$) the general result (with $\dot{T}_0^{(r)} \equiv (\partial_\theta T^{(r)}(\theta))_{\theta=0}, T_0^{(r)} = (T^{(r)}(\theta))_{\theta=0}$)

$$\dot{T}_0^{(r)}|V\rangle = \dot{K}_0 f_1|V\rangle, \tag{4.12}$$

$$T_0^{(r)}|V\rangle = f_0|V\rangle = \omega|V\rangle \tag{4.13}$$

and hence,

$$(T_0^{(r)})^{-1}|V\rangle = \omega^{r-1}|V\rangle. \tag{4.14}$$

The result $f_0=\omega$ (and $f_0^{-1}=\omega^{r-1}$ for $\omega^r=1$) is a general one. This corresponds to our use of eigenstates (CP) as basis states since for our class T_0 coincides with (CP). Hence, finally

$$H^{(r)}|V\rangle = T_0^{-1}\dot{T}_0|V\rangle = (\dot{K}_0\omega^{r-1}f_1)|V\rangle. \tag{4.15}$$

Thus starting with an eigenstate of $T^{(r)}(\theta)$ in our formalism it remains one of $H^{(r)}$ and the eigenvalue of $H^{(r)}$ is extracted, as above from that of $T^{(r)}$. Note that for

$$f_1 = 0, \quad H^{(r)}|V\rangle = 0. \tag{4.16}$$

Thus for Eq. (4.11),

$$H^{(3)}(A_\omega - (q^{-1/2} + \omega^2 q^{-1/2})B_\omega) = 0. \tag{4.17}$$

From Eqs. (3.23)–(3.29) it follows that, for all r:

$$H^{(r)}(S_r, S_{3r}; S_{r+1}, S_{3r-1}) \approx 0, \tag{4.18}$$

i.e., each eigenstate belonging to these subspaces is annihilated by $H^{(r)}$.

For $r=2$, the explicit form of the Hamiltonian is

$$(\dot{K}_0)^{-1}H^{(2)} = (q+q^{-1})(11)\otimes(33) + (q^{1/2}+q^{-1/2})(12)\otimes(32) + 2(13)\otimes(31) + (q^{1/2}+q^{-1/2})(21) \otimes(23) + 2(22)\otimes(22) + (q^{1/2}+q^{-1/2})(23)\otimes(21) + 2(31)\otimes(33) + (q^{1/2}+q^{-1/2})(32) \otimes(12) + (q+q^{-1})(33)\otimes(11). \tag{4.19}$$

Consistently with Eq. (4.18)

$$H^{(2)}(|11\rangle,|33\rangle;|12\rangle,|21\rangle;|23\rangle,|32\rangle) = 0. \tag{4.20}$$

For the only remaining subspace S_4, setting

$$H^{(2)}(a|13\rangle + b|22\rangle + c|31\rangle) = v_H(a|13\rangle + b|22\rangle + c|31\rangle). \tag{4.21}$$

One obtains the solutions

$$(1) \qquad (a,b,c) = (1,-(q^{1/2}+q^{-1/2}),1);\ v_H = 0,$$

$$(2) \qquad (a,b,c) = (1,0,-1);\ v_H = \dot{K}_0(q+q^{-1}-2),$$

$$(3) \qquad (a,b,c) = (1,2(q^{1/2}+q^{-1/2})^{-1},1);\ v_H = \dot{K}_0(q+q^{-1}+4). \tag{4.22}$$

Combining Eqs. (4.15) with Eqs. (A4)–(A6) one consistently reproduces the results Eqs. (4.20)–(4.22) obtained using the explicit form Eq. (4.19). Note that for $r=2$ and $\omega=-1$, Eq. (4.15) gives

$$H^{(2)}|V\rangle = -\dot{K}_0 f_1|V\rangle. \tag{4.23}$$

This corresponds to the positive sign in solution (2) of Eq. (4.22) since in Eq. (A6) the corresponding factor is

$$f_1 = -(q+q^{-1}-2). \tag{4.24}$$

Such changes of sign introduce a qualitative change: $\mathrm{Tr}(T^{(r)})$ in Eq. (2.9) has no explicit dependence on q (only an implicit one though K). But $\mathrm{Tr}(H^{(r)})$ can have explicit q dependence. For the simple example above $(N=3, r=2)$,

$$\mathrm{Tr}(H^{(2)}) = 2\dot{K}_0(q+q^{-1}+1). \tag{4.25}$$

Selection rules for transitions

Adopting the convention of attaching to the states $(|1\rangle,|2\rangle,|3\rangle)$ respectively the "spins"

$$(+,0,-) \tag{4.26}$$

it is seen from Eq. (4.19) that the action of the Hamiltonian on neighboring sites, induces transitions only when the sum of the two spins is zero, i.e., for

$$(+-),\quad (00),\quad (-+). \tag{4.27}$$

The final states corresponding again to zero sum. Thus one has nonzero matrix elements for a neighboring pair $|ij\rangle \overset{H}{\rightarrow} |kl\rangle$ only when for the corresponding spins

$$\sigma_i + \sigma_j = 0 = \sigma_k + \sigma_l. \tag{4.28}$$

Such matrix elements depend on $(\dot{K}_0, q)$. The structure of $H^{(r)}$ in Eq. (4.2) indicates that Eq. (4.21) is a generic feature. Any pair of the type Eq. (4.27) somewhere in the chain can start transitions which can propagate along the chain since the three possibilities in Eq. (4.27) can create such a pair with the next neighboring site and so on.

V. $N>3$

Three basic features displayed and studied at length for $N=3$ are

(1) A simple recursion relation yielding the trace of the transfer matrix for any order r [see Eqs. (2.2)–(2.9)].
(2) Invariant subspaces corresponding to the sum of the state labels [see Eqs. (3.1)–(3.6) and Appendix A).
(3) Role of (CP) circular permutation of state labels within each invariant subspace S_n [see Eqs. (3.9)–(3.13) and Appendix A).

It was shown (for $N=3$) how (2) and (3) greatly simplify the construction of eigenstates and eigenvalues of $T^{(r)}(\theta)$ for successive values of r.

We now indicate how these features are carried over for $N>3$ via the simplest possibilities, namely $N=4$, $r=(1,2)$. Now, as compared to Eqs. (1.17) and (1.18),

$$K(\theta) = -\frac{\sinh\theta}{\sinh(\eta+\theta)}, \tag{5.1}$$

where $e^{\eta}+e^{-\eta}=(q^2+1+q^{-2})+1=(q+q^{-1})^2$. As compared to Eq. (2.2) [writing t_{ij} for $t_{ij}^{(1)}(\theta)$, $i=(1,2,3,4)$ and K for $K(\theta)$]

$$t_{11} = \begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & K \end{vmatrix} \equiv (11) + K(44)$$

and similarly,

$$t_{12} = (21) + Kq(43),\ t_{13} = (31) + Kq(42),\ t_{14} = (1 + Kq^2)(41),$$

$$t_{21} = (12) + Kq^{-1}(34),\ t_{22} = (22) + K(33),\ t_{23} = (1 + K)(32),\ t_{24} = Kq(31) + (42),$$

$$t_{31} = (13) + Kq^{-1}(24),\ t_{32} = (1 + K)(23),\ t_{33} = K(22) + (33),\ t_{34} = Kq(21) + (43),$$

$$t_{41} = (1 + Kq^{-2})(14),\ t_{42} = Kq^{-1}(13) + (24),\ t_{43} = Kq^{-1}(12) + (34),\ t_{44} = K(11) + (44). \tag{5.2}$$

As compared to Eqs. (2.3)–(2.9) recursion relations are now (suppressing arguments θ)

$$t_{ij}^{(r+1)} = t_{i1}^{(1)} \otimes t_{1j}^{(r)} + t_{i2}^{(2)} \otimes t_{2j}^{(r)} + t_{i3}^{(1)} \otimes t_{3j}^{(r)} + t_{i4}^{(1)} \otimes t_{4j}^{(r)}, \quad (i,j = 1,2,3,4) \tag{5.3}$$

giving [due to Eq. (5.2)]

$$t_{1j}^{(r+1)} = ((11) + K(44)) \otimes t_{1j}^{(r)} + ((21) + Kq(43)) \otimes t_{2j}^{(r)} + ((31) + Kq(42)) \otimes t_{3j}^{(r)} + (1 + Kq^2)(41) \otimes t_{4j}^{(r)},$$

$$t_{2j}^{(r+1)} = ((12) + Kq^{-1}(34)) \otimes t_{1j}^{(r)} + ((22) + K(33)) \otimes t_{2j}^{(r)} + (1 + K)(32) \otimes t_{3j}^{(r)} + (Kq(31) + (42)) \otimes t_{4j}^{(r)},$$

$$t_{3j}^{(r+1)} = ((13) + Kq^{-1}(24)) \otimes t_{1j}^{(r)} + (1 + K)(23) \otimes t_{2j}^{(r)} + (K(22) + (33)) \otimes t_{3j}^{(r)} + (Kq(21) + (43)) \otimes t_{4j}^{(r)},$$

$$t_{4j}^{(r+1)} = (1 + Kq^{-2})(14) \otimes t_{1j}^{(r)} + (Kq^{-1}(13) + (24)) \otimes t_{2j}^{(r)} + (Kq^{-1}(12) + (34)) \otimes t_{3j}^{(r)} + (K(11) + (44)) \otimes t_{4j}^{(r)}. \tag{5.4}$$

Hence, for the transfer matrix

$$T^{(r+1)} = t_{11}^{(r+1)} + t_{22}^{(r+1)} + t_{33}^{(r+1)} + t_{44}^{(r+1)} = \begin{vmatrix} t_{11}^{(r)} + Kt_{44}^{(r)} & t_{12}^{(r)} + Kq^{-1}t_{34}^{(r)} & t_{13}^{(r)} + Kq^{-1}t_{34}^{(r)} & (1+Kq^{-2})t_{14}^{(r)} \\ t_{21}^{(r)} + Kt_{43}^{(r)} & t_{22}^{(r)} + Kt_{33}^{(r)} & (1+K)t_{23}^{(r)} & Kq^{-1}t_{13}^{(r)} + t_{24}^{(r)} \\ t_{31}^{(r)} + Kqt_{42}^{(r)} & (1+K)t_{32}^{(r)} & Kt_{22}^{(r)} + t_{33}^{(r)} & Kq^{-1}t_{12}^{(r)} + t_{34}^{(r)} \\ (1+kq^2)t_{41}^{(r)} & t_{42}^{(r)} + Kqt_{31}^{(r)} & Kqt_{21}^{(r)} + t_{43}^{(r)} & Kt_{11}^{(r)} + t_{44}^{(r)} \end{vmatrix}. \tag{5.5}$$

One now obtains

$$\mathrm{Tr}(T^{(r+1)}) = (K+1)\mathrm{Tr}(T^r), \tag{5.6}$$

but

$$T^{(1)} = (K+1)I_4. \tag{5.7}$$

Hence,

$$\mathrm{Tr}(T^{(r)}) = 4(K+1)^r. \tag{5.8}$$

It is not difficult to obtain the general result (following from the fact that only the diagonal blocks $t_{ii}^{(r)}$ have diagonal terms)

$$\mathrm{Tr}(T^{(r)}) = N(K+1)^r. \tag{5.9}$$

For $N=(3,4)$ the particular solutions are given by Eqs. (2.9) and (5.8), respectively.

Now let us consider the eigenstates of $T^{(r)}(\theta)$ for $N=4$, $r=1,2$. As compared to Eq. (3.1) we now have the fundamental state vectors

$$|1\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, |2\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}, |3\rangle = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}, |4\rangle = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} \tag{5.10}$$

and, as before, we denote tensor products as

$$|ijk\ldots\rangle = |i\rangle \otimes |j\rangle \otimes |k\rangle \otimes \ldots. \tag{5.11}$$

For a given n, as before, the set of states with

$$i + j + k + \cdots = n \tag{5.12}$$

will constitute the basis of the subspace S_n. For $r=1$ the situation is trivial. From Eq. (5.2)

$$T^{(1)} = t_{11} + t_{22} + t_{33} + t_{44} = (K+1)I_4, \tag{5.13}$$

$$T^{(1)}|i\rangle = (K+1)|i\rangle, \quad (i=1,2,3,4). \tag{5.14}$$

For $r=2$, from Eqs. (5.2) and (5.5),

$$\begin{aligned} T^{(2)} = {} & (K^2+1)P + 2K((11)\otimes(44) + (22)\otimes(33) + (33)\otimes(22) + (44)\otimes(11))K(q+q^{-1})((12) \\ & \otimes(43) + (13)\otimes(42) + (21)\otimes(34) + (24)\otimes(31) + (31)\otimes(24) + (34)\otimes(21) + (42)\otimes(13) \\ & + (43)\otimes(12)) + K(q^2+q^{-2})((14)\otimes(41) + (41)\otimes(14)), \end{aligned} \tag{5.15}$$

where

$$P = \sum_{ij} (ij)\otimes(ji), \quad (i,j=1,2,3,4). \tag{5.16}$$

Implementing the definitions Eqs. (5.10)–(5.12) one obtains from Eq. (5.15) for the subspaces $(S_2,\ldots,S_8)$ the following results (with $\epsilon=\pm 1$),

$$S_2: \quad T^{(2)}|11\rangle = (K^2+1)|11\rangle,$$

$$S_8: \quad T^{(2)}|44\rangle = (K^2+1)|44\rangle,$$

$$S_3: \quad T^{(2)}(|12\rangle + \epsilon|21\rangle = \epsilon(K^2+1)(|12\rangle + \epsilon|21\rangle,$$

$$S_7: \quad T^{(2)}(|43\rangle + \epsilon|34\rangle) = \epsilon(K^2+1)(|43\rangle + \epsilon|34\rangle),$$

$$S_4: \quad T^{(2)}|22\rangle = (K^2+1)|22\rangle,$$

$$T^{(2)}(|13\rangle + \epsilon|31\rangle) = \epsilon(K^2+1)(|13\rangle + \epsilon|31\rangle),$$

$$S_6: \quad T^{(2)}|33\rangle = (K^2+1)|33\rangle,$$

$$T^{(2)}(|42\rangle + \epsilon|24\rangle) = \epsilon(K^2+1)(|42\rangle + \epsilon|24\rangle), \tag{5.17}$$

$$S_5: \quad T^{(2)}(|14\rangle - |41\rangle) = -((K^2-2K+1) + K(q^2+q^{-2}))(|14\rangle - |41\rangle) \tag{5.18}$$

$$T^{(2)}(|23\rangle - |32\rangle) = -(K^2-2K+1)(|23\rangle - |32\rangle). \tag{5.19}$$

Finally, denoting

$$|A\rangle = (|14\rangle + |41\rangle), \quad |B\rangle = (|23\rangle + |32\rangle) \tag{5.20}$$

and setting

$$T^{(2)}(a|A\rangle + b|B\rangle) = v(a|A\rangle + b|B\rangle), \tag{5.21}$$

where

$$v = K^2 + 1 + Kf, \tag{5.22}$$

f begin K independent [a function $f(q)$ of q only], one obtains the constraints

$$a((q+q^{-1})^2 - f) + 2b(q+q^{-1}) = 0, \quad 2a(q+q^{-1}) + b(2-f) = 0. \tag{5.23}$$

Hence,

$$f = \tfrac{1}{2}(q^2+q^{-2}+4) \pm \tfrac{1}{2}\sqrt{(q+q^{-1})^4 + 12(q+q^{-1})^2 + 4} \tag{5.24}$$

with corresponding K-independent values of (a,b). The sum of the eigenvalues given by Eqs. (5.17)–(5.24) is

$$4(K+1)^2, \tag{5.25}$$

consistently with Eq. (5.8) for $r=2$. Our explicit results for $r=2$ not only shows how the basic properties (1), (2), (3) stated at the beginning of this section are all realized systematically but also how Eq. (3.14) is carried over, the subspaces now being paired via

$$(1,2,3,4) \to (4,3,2,1). \tag{5.26}$$

The chain Hamiltonian for any N is given by Eqs. (4.1)–(4.3) with Eqs. (1.4)–(1.7) giving P_0' in $\dot{\hat{R}}_0=\dot{K}_0P_0'$. In $\dot{K}_0$ of Eq. (4.5) now, from Eq. (1.3), $e^{\eta}+e^{-\eta}=[N-1]+1$. For $r=2$, one obtains for example

$$H^{(2)}=\dot{K}_0(P_0'+PP_0'P)=\dot{K}_0\left(\sum_{i,j=1}^{N}(q^{\rho_{i'}-\rho_j}+q^{\rho_i-\rho_j'})(ij)\otimes(i'j')\right). \tag{5.27}$$

For $N=4$ this corresponds to

$$\begin{aligned}(\dot{K}_0)^{-1}H^{(2)}=&(q^{-2}+q^2)(11)\otimes(44)+(q^{-1}+q)(12)\otimes(43)+(q^{-1}+q)(13)\otimes(42)+2(14)\otimes(41)\\&+(q^{-1}+q)(21)\otimes(34)+2(22)\otimes(33)+2(23)\otimes(32)+(q^{-1}+q)(24)\otimes(31)\\&+(q^{-1}+q)(31)\otimes(24)+2(32)\otimes(23)+2(33)\otimes(22)+(q^{-1}+q)(34)\otimes(21)+2(41)\\&\otimes(14)+(q^{-1}+q)(42)\otimes(13)+(q^{-1}+q)(43)\otimes(12)+(q^{-2}+q^2)(44)\otimes(11).\end{aligned} \tag{5.28}$$

Generalizations for $r>2$ can be written down systematically. If the spin associated with the state $|i\rangle$ is denoted as σ_i then Eq. (4.1) along with structures analogous to Eq. (5.27) implies transitions (if the states of two neighboring sites have spins σ_j, $\sigma_{j'}$)

$$(\sigma_j,\sigma_{j'})\rightarrow(\sigma_i,\sigma_{i'}) \tag{5.29}$$

with evident q-dependent transition amplitudes corresponding to the matrix elements of $H^{(r)}$ for order r. In particular if, for example,

$$(\sigma_1,\sigma_2,\ldots,\sigma_{N-1},\sigma_N)=\left(\frac{N-1}{2},\frac{N-2}{2},\ldots,-\frac{N-2}{2},-\frac{N-1}{2}\right) \tag{5.30}$$

then

$$\sigma_i+\sigma_{i'}=0\quad(i'=N-i+1). \tag{5.31}$$

For $N=3$ [as discussed in Eqs. (4.26)–(4.28)],

$$(\sigma_1,\sigma_2,\sigma_3)=(1,0,-1) \tag{5.32}$$

and for $N=4$

$$(\sigma_1,\sigma_2,\sigma_3,\sigma_4)=\left(\tfrac{3}{2},\tfrac{1}{2},-\tfrac{1}{2},-\tfrac{3}{2}\right) \tag{5.33}$$

and so on.

If for two adjacent sites (including circular boundary constraints) one has states $(|i\rangle,|i'\rangle)$ they can be flipped to any pair $(|j\rangle,|j'\rangle)$. Thus such a flip can propagate along the chain for any state $|j\rangle$ of the next site.

A thorough investigation of our class of models for arbitrary N is beyond the scope of the present paper. We have, however, indicated how the basic features studied for $N=3$ are carried over as N increases. Such properties are conserved due to the specific structure of P_0' as defined in Eqs. (1.4)–(1.7).

We just mention finally that features parallel to those discussion for $N=3$ in Eqs. (3.43)–(3.49) can be carried over starting with the multimonial expansion of

$$(x_1+x_2+x_3+\cdots+x_N)^r. \tag{5.34}$$

Dimensions of invariant subspaces are obtained entirely analogously.

VI. POTENTIAL FOR FACTORIZABLE *S* MATRIX (*N*=3)

As in Sec. V of Ref. 3 we construct the inverse Cayley transform of the YB matrix which is also the $t^{(1)}(\theta)$ matrix (2.1) and given by Eq. (2.2) for $N=3$ for the class studied in this paper. The role of this in providing the potential for factorizable S matrices can be found in various sources.[5,6] As explained and emphasized in Sec. V of Ref. 3 an arbitrary normalization factor (denoted $\gamma^{-1}(\theta)$] of $R(\theta)$ must be introduced to start with for the inversion involved in the transform to be well-defined. The explicit inversion in the first factor of

$$-iV=(R(\theta)-\lambda(\theta)I)^{-1}(R(\theta)+\lambda(\theta)I) \tag{6.1}$$

will display admissible choices of $\lambda(\theta)$. Defining

$$X(R(\theta)-\lambda(\theta)I)=I, \quad -iV=X(X^{-1}+2\lambda(\theta)I)=I+2\lambda(\theta)X, \tag{6.2}$$

for $N=3$, Eq. (2.1) leads to (suppressing the argument θ in notation below)

$$X\begin{vmatrix} 1-\lambda & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -\lambda & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & K-\lambda & 0 & q^{1/2}K & 0 & 1+qK & 0 & 0 \\ 0 & 1 & 0 & -\lambda & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & q^{-1/2}K & 0 & 1+K-\lambda & 0 & q^{1/2}K & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -\lambda & 0 & 1 & 0 \\ 0 & 0 & 1+q^{-1}K & 0 & q^{-1/2}K & 0 & K-\lambda & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -\lambda & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1-\lambda \end{vmatrix} = I, \tag{6.3}$$

Only the nonzero elements of X will be given below. One obtains easily

$$(X_{11},X_{99})=(1-\lambda)^{-1}, \quad (X_{22},X_{44},X_{66},X_{88})=\frac{\lambda}{(1-\lambda^2)}, \quad (X_{24},X_{42},X_{68},X_{86})=\frac{1}{(1-\lambda^2)}. \tag{6.4}$$

These already show $\lambda\neq\pm1$. For $i=(3,5,7)$ one obtains the equations

$$(-X_{i3}\lambda+X_{i7})+q^{-1/2}KZ_i=\delta_{i3}, \quad X_{i5}(1-\lambda)+KZ_i=\delta_{i5}, \quad (X_{i3}-\lambda X_{i7})+Kq^{1/2}Z_i=\delta_{i7}, \tag{6.5}$$

where

$$Z_i\equiv q^{1/2}X_{i3}+X_{i5}+q^{-1/2}X_{i7}. \tag{6.6}$$

The solutions for $i=(3,5,7)$ are, respectively, the following ones. For $i=3$, (X_{33},X_{35},X_{37}) are given by

$$X_{33}=\frac{\lambda}{1-\lambda^2}+q^{-1/2}\left(\frac{q+\lambda}{1+\lambda}\right)X_{35}, \tag{6.7}$$

$$X_{37}=\frac{1}{1-\lambda^2}+q^{-1/2}\left(\frac{1+q\lambda}{1+\lambda}\right)X_{35}, \tag{6.8}$$

$$Z_3=\frac{q^{-1/2}(1+q\lambda)}{1-\lambda^2}+\left(\frac{q+q^{-1}+1+3\lambda}{1+\lambda}\right)X_{35}, \tag{6.9}$$

$$X_{35}(1-\lambda)+KZ_3=0. \tag{6.10}$$

The K dependence is now explicit. The case $i=3,7$ are related though the exchange of indices and inversion of q, namely

$$(3,7;q)\rightleftharpoons(7,3;q^{-1}). \tag{6.11}$$

For $i=5$,

$$X_{53}(1+q\lambda)=X_{57}(q+\lambda), \tag{6.12}$$

$$X_{53}=-\frac{q^{-1/2}(q+\lambda)}{1-\lambda^2}+\frac{(q+\lambda)q^{-1/2}}{1+\lambda}X_{55}, \tag{6.13}$$

$$X_{57}=-\frac{q^{-1/2}(1+q\lambda)}{1-\lambda^2}+\frac{(1+q\lambda)q^{-1/2}}{1+\lambda}X_{55}, \tag{6.14}$$

$$Z_5=-\frac{q+q^{-1}+2\lambda}{1-\lambda^2}+\frac{3\lambda+1+q+q^{-1}}{1+\lambda}X_{55}, \tag{6.15}$$

$$X_{55}(1-\lambda)+KZ_5=1. \tag{6.16}$$

Now Eqs. (6.19) and (6.20) give directly X_{55}. Next Eqs. (6.17) and (6.18) give X_{53} and X_{57}. Finally, we obtain

$$X=\begin{vmatrix}
\frac{1}{1-\lambda} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & \frac{1}{1-\lambda^2} & 0 & \frac{1}{1-\lambda^2} & 0 & 0 & 0 & 0 & 0\\
0 & 0 & \mathsf{A} & 0 & \mathsf{B} & 0 & \mathsf{C} & 0 & 0\\
0 & \frac{1}{1-\lambda^2} & 0 & \frac{\lambda}{1-\lambda^2} & 0 & 0 & 0 & 0 & 0\\
0 & 0 & \mathsf{D} & 0 & \mathsf{E} & 0 & \mathsf{B} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & \frac{\lambda}{1-\lambda^2} & 0 & \frac{1}{1-\lambda^2} & 0\\
0 & 0 & \mathsf{F} & 0 & \mathsf{D} & 0 & \mathsf{A} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & \frac{1}{1-\lambda^2} & 0 & \frac{\lambda}{1-\lambda^2} & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{1-\lambda}
\end{vmatrix} \tag{6.17}$$

where

$$\mathsf{A}=\frac{(\lambda^2-\lambda-2K\lambda+K)q}{(1-\lambda)(q\lambda^2-3qK\lambda-q^2K-K-qK-q)}=X_{33}=X_{77},$$

$$\mathsf{B}=\frac{(q\lambda+1)q^{1/2}K}{(1-\lambda)(q\lambda^2-3qK\lambda-q^2K-K-qK-q)}=X_{35}=X_{57},$$

$$\mathsf{C} = \frac{(\lambda + qK\lambda - qK - 1 - K)q}{(1-\lambda)(q\lambda^2 - 3qK\lambda - q^2K - K - qK - q)} = X_{37},$$

$$\mathsf{D} = \frac{K(\lambda + q)q^{1/2}}{(1-\lambda)(q\lambda^2 - 3qK\lambda - q^2K - K - qK - q)} = X_{53} = X_{75},$$

$$\mathsf{E} = \frac{q\lambda^2 - 2Kq\lambda - q^2K - K - q}{(1-\lambda)(q\lambda^2 - 3qK\lambda - q^2K - K - qK - q)} = X_{55},$$

$$\mathsf{F} = \frac{-q - qK + q\lambda - K + K\lambda}{(1-\lambda)(q\lambda^2 - 3qK\lambda - q^2K - K - qK - q)} = X_{73}, \tag{6.18}$$

where $\lambda \neq \pm 1$, $\frac{1}{2}[3K \pm \sqrt{9K^2+4(q+1+q^{-1})K+4}]$.

From X, V is obtained as indicated in Eq. (6.2). Expressing it as

$$V = \sum_{ab,cd} V_{(ab,cd)}(ab) \otimes (cd). \tag{6.19}$$

The corresponding fermionic Lagrangian should be

$$\mathcal{L} = \int dx(i\bar{\psi}_a \gamma_\nu \partial_\nu \psi_a - g(\bar{\psi}_a \gamma_\nu \psi_c) V_{ab,cd}(\bar{\psi}_b \gamma_\nu \psi_d)). \tag{6.20}$$

The scalar Lagrangian can be obtained analogously. Such Lagrangians correspond to S matrices factorizable into two particles scattering independently of the chosen order of the latter ones.

VII. DISCUSSION

In Ref. 3 and in the present paper we have studied two different classes of statistical models. Certain aspects of the respective transfer matrices are strikingly contrasted. Such a major difference is in the number of parameters. The first model is indeed multiparameter. One has $\frac{1}{2}(N+3) \times (N-1)$ free parameters ($N=3,4,\ldots$). Here the only parameter is q appearing in the braid matrix given by Eqs. (1.2)–(1.7) and in $K(\theta)$ as defined by Eqs. (1.17)–(1.20). The structures of the eigenvalues of the respective transfer matrices are also quite different. In Ref. 3 we obtained single exponentials as eigenvalues, the exponent being a sum of the free parameters multiplied by θ. Here we have rth order polynomials in $K(\theta)$ for the eigenvalues of $T^{(r)}(\theta)$. There are other differences. But analogies and common features are also remarkable.

(a) In both case Tr $(T^{(r)}(\theta))$ is obtained quite simply for all r (though the structures are different). In (6.1) of Ref. 3 we obtained (for $N=2p-1$)

$$\mathrm{Tr}(T^{(r)}(\theta)) = 2(e^{rm_{11}^{(+)}\theta} + e^{rm_{22}^{(+)}\theta} + \cdots + e^{rm_{p-1,p-1}^{(+)}\theta}) + 1 \tag{7.1}$$

the $m_{ii}^{(+)}$ being a subset of the free parameters. Here (for $N=3,4,\ldots$) the corresponding result Eq. (5.9) is

$$\mathrm{Tr}(T^{(r)}(\theta)) = N(K(\theta)+1)^r, \tag{7.2}$$

where $K(\theta)$ is given by Eqs. (1.3) and (1.17).

(b) In both cases the N^r dimensional base space of $T^{(r)}(\theta)$ breaks up into closed subspaces of lower dimensions. The definitions of these subspaces have some differences however. The relevant definitions in Ref. 3 should be compared to Eqs. (3.2)–(3.6) here and their generalization in Sec. V.

(c) In each subspace S_n the circular permutation of states labels as formulated in Eqs. (3.9)–(3.19) leads to a further reduction of dimension in constructing eigenstates by splitting S_n

again into subsets corresponds to the eigenstates of the operator (CP) of circular permutations. This involves a crucial role of the roots of unity, $[\omega^r=1$ for $T^{(r)}(\theta)]$ in the construction of eigenstates. The role of roots of unity was also crucial in Ref. 3 though they were implemented in a slightly different fashion (corresponding to the difference in labeling states).

In both cases the "two-step reduction" [via (b) and (c)] in the effective dimension of the basis in construction of eigenstates has been emphasized (see the formulation of Sec. III). The exponential increase in dimension with r ($e^{(\ln N)r}$) is replaced in actual construction by a relatively moderate polynomial one. Thus for $N=3$ and $r=4$ we have to solve here at most a set of 5 simultaneous linear equations (Appendix A) though now N^r is $3^4=81$. This reduction of the problem to a relatively low number of linear equations should be constrasted to the implementation of algebraic Bethe ansatz.[6–8] For the latter one has to solve complex nonlinear equations whose number increases along with N.

In the preceding sections (particularly in Sec. III for $N=3$ and in Sec. V for $N>3$), we have formulated carefully the crucial properties, basic features of models corresponding to the braid matrices presented in Ref. 2. Exploiting such properties we have constructed eigenstates and eigenvalues of $T^{(r)}(\theta)$ for $N=3$, $r=(1,2,3,4)$ (Appendix A). Certain related features for all r have been formulated at the end of Sec. III. Chain Hamiltonians and potentials for factorizable S matrices have been studied (Secs. IV and VI).

Further explorations in several directions are evidently desirable. Reflection equations[9,10] and correlation functions[11,12] should be studied. More basically one may try to elucidate the relevance of the star-triangle relations[4] encoded in our class of braid matrices to specific contexts. We hope to undertake such studies elsewhere.

ACKNOWLEDGMENTS

One of the authors (B.A.) wants to thank Patrick Mora, Pierre Collet, and Paul Sorba for precious help. He is also very grateful to the members of the CPHT group of Ecole Polytechnique for their warm hospitality. This work is supported by a CMEP program under Grant No. 04MDU615.

APPENDIX A: EIGENSTATES AND EIGENVALUES OF $T^{(r)}(\theta)$ FOR $r=1,2,3,4$ ($N=3$)

We start by noting the following points:

(1) For each case the subscript n of S_n denotes the sum of the state labels [see discussion from Eqs. (3.3) to (3.6)].
(2) For each r we present results only up to S_{2r}. The remaining subspaces $(S_{2r+1},\ldots,S_{3r})$ are then obtained implementing Eqs. (3.14)–(3.16).
(3) For different subspaces we often repeat the same notations for states. Since $T^{(r)}$ does not couple such spaces no confusion is likely.
(4) The notation K and ω correspond to Eqs. (1.17) and (3.11), respectively. (CP) denotes circular permutations.

1. $r=1$

The three states directly furnish the spectrum, each being a one-dimensional subspace

$$T^{(1)}(\theta)(|1\rangle,|2\rangle,|3\rangle)=(1+K)(|1\rangle,|2\rangle,|3\rangle), \tag{A1}$$

$$\mathrm{Tr}(T^{(1)}(\theta))=3(1+K). \tag{A2}$$

2. $r=2$

The (CP) eigenstates constructed as in Eqs. (3.10)–(3.13), with $\omega^2=1$, give

$$S_2: \quad A_1=|11\rangle,$$

$$S_3: \quad A_{\pm 1}=|12\rangle+|21\rangle,$$

$$S_4: \quad A_1=|22\rangle, \quad B_{\pm 1}=|13\rangle\pm|31\rangle. \tag{A3}$$

One obtains [K being $K(\theta)$],

$$S_2{:}T^{(2)}(\theta)A_1=(K^2+1)A_1, \tag{A4}$$

$$S_3{:}T^{(2)}(\theta)A_{\pm 1}=\pm(K^2+1)A_{\pm 1}, \tag{A5}$$

$$S_4{:}T^{(2)}(\theta)B_{-1}=-(K^2+(q+q^{-1}-2)K+1)B_{-1},$$

$$T^{(2)}(\theta)(B_1-(q^{1/2}+q^{-1/2})A_1)=(K^2+1)(B_1-(q^{1/2}+q^{-1/2})A_1),$$

$$T^{(2)}(\theta)((q^{1/2}+q^{-1/2})B_1+2A_1)=(K^2+(q+q^{-1}+4)K+1)((q^{1/2}+q^{-1/2})B_1+2A_1). \tag{A6}$$

Also

$$(S_5,S_6)\rightleftharpoons(S_3,S_2) \tag{A7}$$

according to Eqs. (3.14)–(3.16). Summing over all subspaces $(S_2,\ldots,S_6)$,

$$\mathrm{Tr}(T^{(1)}(\theta))=3(1+K)^2 \tag{A8}$$

consistently with Eq. (2.9). We have not uniformly normalized the states. Thus $\langle A_1|A_1\rangle=1$ and $\langle B_{\pm 1}|B_{\pm 1}\rangle=2$. This is crucial to the orthogonality

$$\langle B_1-(q^{1/2}+q^{-1/2})A_1|(q^{1/2}+q^{-1/2})B_1+2A_1\rangle=0. \tag{A9}$$

This point displayed here for this simple case will not be repeated in cases to follow.

3. $r=3$

Here

$$\omega=(1,e^{(2\pi/3)},e^{(2\pi/3)2}) \tag{A10}$$

and (CP) eigenstates for (S_3,S_4,S_5,S_6) are

$$S_3: \quad A_1=|111\rangle, \tag{A11}$$

$$S_4: \quad A_\omega=|112\rangle+\omega|211\rangle+\omega^2|121\rangle, \tag{A12}$$

$$S_5: \quad A_\omega=|113\rangle+\omega|311\rangle+\omega^2|131\rangle,\ B_\omega=|122\rangle+\omega|212\rangle+\omega^2|221\rangle, \tag{A13}$$

$$S_6: \quad A_1=|222\rangle,\ B_\omega=|123\rangle+\omega|312\rangle+\omega^2|231\rangle,$$

$$C_\omega=|321\rangle+\omega|132\rangle+\omega^2|213\rangle=(1\rightleftharpoons 3)B_\omega. \tag{A14}$$

Also

$$(1 \rightleftharpoons 3)(S_3,S_4,S_5) = (S_9,S_8,S_7). \tag{A15}$$

The $T^{(3)}(\theta)$ eigenstates are now obtained as follows:

$$S_3: \quad T^{(3)}(\theta)A_1 = (K^3+1)A_1, \tag{A16}$$

$$S_4: \quad T^{(3)}(\theta)A_\omega = (K^2\omega+\omega^2)A_\omega, \tag{A17}$$

$$S_5: \quad T^{(3)}(\theta)(aA_\omega + bB_\omega) = v(aA_\omega + bB_\omega). \tag{A18}$$

Solutions:

(1)
$$(a,b) = (q^{1/2}+\omega q^{-1/2},1),$$
$$v = \omega^2K^3 + (q+q^{-1})(\omega^2K^2+\omega K) + (1+\omega+\omega^2)(K^2+K) + \omega, \tag{A19}$$

(2)
$$(a,b) = (1,-(q^{1/2}+\omega^2q^{-1/2})), \quad v = K^3\omega^2+\omega. \tag{A20}$$

$\diamond S_6$: For $\omega = e^{\pm(2\pi/3)}$, A_1 is decoupled. Set

$$T^{(3)}(\theta)(bB_\omega + cC_\omega) = v(bB_\omega + cC_\omega). \tag{A21}$$

Solutions:

(1)
$$(b,c) = (q,-1), \quad v = K^3\omega^2+\omega \tag{A22}$$

(2)
$$(b,c) = (1,q), \quad v = K^3\omega^2+\omega+(q+q^{-1})(K^2\omega^2+K\omega). \tag{A23}$$

For the values of $\omega(\neq 1)$, with $\omega+\omega^2=-1$ the sum of eigenvalues

$$\Sigma v = -2(K^3+1) - (q+q^{-1})(K^2+K). \tag{A24}$$

For $\omega-1$, $T^{(3)}$ couples (A_1,B_1,C_1). Set

$$T^{(3)}(\alpha A_1 + \beta B_1 + \gamma C_1) = v_1(\alpha A_1 + \beta B_1 + \gamma C_1). \tag{A25}$$

Solutions:

(1)
$$(\alpha,\beta,\gamma) = (0,q^{1/2},-q^{-1/2}), \quad v_1 = (K+1)(K^2-K+1), \tag{A26}$$

(2)
$$(\alpha,\beta,\gamma) = (-(q+q^{-1}),q^{-1/2},q^{1/2}), \quad v_1 = (K+1)(K^2-K+1), \tag{A27}$$

(3)
$$(\alpha,\beta,\gamma) = (3,q^{-1/2},q^{1/2}), \quad v_1 = (K+1)((K^2-K+1)+K(q+q^{-1}+3)). \tag{A28}$$

Concerning orthogonality note that

$$\langle A_1|A_1\rangle = 1, \quad \langle B_1|B_1\rangle = \langle C_1|C_1\rangle = 3. \tag{A29}$$

The sum of the eigenvalues over S_6 is

$$(\Sigma v)_{S_6} = K^3+1+3K(K+1). \tag{A30}$$

The results for (S_7,S_8,S_9) are obtained, as usual, directly from those of (S_5,S_4,S_3), respectively.

Summing over all the subspaces $(S_3,\ldots,S_9)$ one obtains [all explicit q dependence canceling consistently with Eq. (2.9)],

$$\mathrm{Tr}(T^{(3)}(\theta)) = (K^3+1)+(K^3+1)+3(K^2+K)+3(K^2+K)+(K^3+1)+3(K^2+K) = 3(K+1)^3. \tag{A31}$$

4. $r=4$

Here

$$\omega = (1, e^{i(2\pi/4)}, e^{i(2\pi/4)2}, e^{i(2\pi/4)3}) = (1, i, -1, i). \tag{A32}$$

Of the invariant subspaces we consider $(S_4, S_5, S_6, S_7, S_8)$. One obtains the results of the remaining ones via $(1,2,3;q) \leftrightarrow (3,2,1;q^{-1})$ as

$$(S_9, S_{10}, S_{11}, S_{12}) \rightleftarrows (S_7, S_6, S_5, S_4). \tag{A33}$$

For brevity and simplicity, we will recapitulate our results in Tables I and II.

TABLE I. CP eigenstates for $r=4$.

Subspace	(CP) eigenstates	Dimension
S_4	$\|1111\rangle$	1
S_5	$A_\omega = \|1112\rangle + \omega\|2111\rangle + \omega^2\|1211\rangle + \omega^3\|1121\rangle$	4
S_6	$A_{\pm 1} = \|1212\rangle \pm \|2121\rangle$	10
	$B_\omega = \|1113\rangle + \omega\|3111\rangle + \omega^2\|1311\rangle + \omega^3\|1131\rangle$	
	$C_\omega = \|1122\rangle + \omega\|2112\rangle + \omega^2\|2211\rangle + \omega^3\|1221\rangle$	
S_7	$A_\omega = \|1222\rangle + \omega\|2122\rangle + \omega^2\|2212\rangle + \omega^3\|2221\rangle$	16
	$B_\omega = \|1123\rangle + \omega\|3112\rangle + \omega^2\|2311\rangle + \omega^3\|1231\rangle$

		$2\sqrt{q}(q^2+q-2+q^{-1}+q^{-2})A_1$
		$+2\sqrt{q}(q+2+q^{-1})B_1-\sqrt{q}(q+4+q^{-1})C_1$
		$+(q^2+2q-3-2q^{-1}-3)D_1$
		$-(2q^2+3q-2-q^{-1})E_1$
	$-K^4-1$	F_{-1},
		$B_{-1}+(q^2-1)C_{-1}/2q-(q^2+1)D_{-1}/(2\sqrt{q})$
		$+(q^2+1)E_{-1}/(2q\sqrt{q})$
	$\mp iK^4\pm i$	$F_{\pm i}$, $\sqrt{q}C_{\pm i}-D_{\pm i}+E_{\pm i}$
	$\mp i[K^4+(q+1+q^{-1})K^3\pm 3iK^2$	$-(q+1)C_{\pm i}/\sqrt{q}-D_{\pm i}+E_{\pm i}$
	$-(q+1+q^{-1})K-1]$	
	$\mp i[K^4+(q+1+q^{-1})K^3\mp i(q+1+q^{-1})K^2$	$C_{\pm i}+(1+2q)D_{\pm i}/(q-1)\sqrt{q}+(q+2)\sqrt{q}E_{\pm i}/(q-1)$
	$-(q+1+q^{-1})K-1]$	
	$K^4+(q+3+q^{-1})K^3+(q+3+q^{-1})K^2$	$-4A_1+2B_1+C_1-D_1/((q+1)\sqrt{q})-q\sqrt{q}E_1/(q+1)$
	$+(q+3+q^{-1})K+1$	
	$-[K^4+(q-1+q^{-1})K^3-(q-1+q^{-1})K^2$	$-2(q-1)B_{-1}/(q+1)+C_{-1}-D_{-1}/((q+1)\sqrt{q})$
	$+(q-1+q^{-1})K+1]$	$-q\sqrt{q}E_{-1}/(q+1)$

[a]For S_8, there exist also four others eigenvectors $aA_1+bB_1+cC_1+dD_1+eE_1$, $\alpha A_1+\beta B_1+\gamma C_1+\delta D_1+\eta E_1$, $b'B_{-1}+c'C_{-1}+d'D_{-1}+e'E_{-1}$, $\beta'B_{-1}+\gamma'C_{-1}+\delta'D_{-1}+\eta'E_{-1}$ associated, respectively, to the eigenvalues v_1, v_2, v_1', and v_2', which have complicated forms (these results have been obtained by using a MAPLE program),

$$v_1=\tfrac{1}{2}(2K^4+3K^3(q+1+q^{-1})+K^2(q^2+2q+13+2q^{-1}+q^{-2})+3K(q+1+q^{-1})+2$$
$$+K(K^2+(q+1+q^{-1})K+1)\sqrt{q^2+2q+43+2q^{-1}+q^{-2}})$$

$$v_2=\tfrac{1}{2}(2K^4+3K^3(q+1+q^{-1})+K^2(q^2+2q+13+2q^{-1}+q^{-2})+3K(q+1+q^{-1})+2$$
$$-K(K^2+(q+1+q^{-1})K+1)\sqrt{q^2+2q+43+2q^{-1}+q^{-2}}),$$

$$v_1'=\tfrac{1}{2}(-2K^4-3K^3(q+1+q^{-1})-K^2(q^2+2q+1+2q^{-1}+q^{-2})-3K(q+1+q^{-1})-2$$
$$+K(K^2+(q+1+q^{-1})K+1)\sqrt{q^2+2q-5+2q^{-1}+q^{-2}}),$$

$$v_2'=\tfrac{1}{2}(-2K^4-3K^3(q+1+q^{-1})-K^2(q^2+2q+1+2q^{-1}+q^{-2})-3K(q+1+q^{-1})-2$$
$$-K(K^2+(q+1+q^{-1})K+1)\sqrt{q^2+2q-5+2q^{-1}+q^{-2}}), \tag{A34}$$

The sums of the eigenvalues over S_4, S_5, S_6, S_7, and S_8 are, respectively,

$$\sum_{S_4} v = K^4 + 1,$$

$$\sum_{S_5} v = 0,$$

$$\sum_{S_6} v = 4K^3 + 4K,$$

$$\sum_{S_7} v = 0,$$

$$\sum_{S_8} v = K^4 + 4K^3 + 18K^2 + 4K + 1. \tag{A35}$$

The results for $(S_9, S_{10}, S_{11}, S_{12})$ are obtained directly from the those of (S_7, S_6, S_5, S_4), respectively. Summing over all subspaces $(S_4, \ldots, S_{12})$ one obtains

$$\mathrm{Tr}(T^{(4)}(\theta)) = 2(K^4 + 1) + 2(4K^3 + 4K) + 1(K^4 + 4K^3 + 18K^2 + 4K + 1) = 3(K + 1)^4. \tag{A36}$$

APPENDIX B: $\hat{R}tt$ ALGEBRA

We present below, for $N=3$, the constraints on the blocks $t_{ij}(\theta)$ of the transfer matrix following from:

$$\hat{R}(\theta - \theta')t(\theta) \otimes t(\theta') = t(\theta') \otimes t(\theta)\hat{R}(\theta - \theta'). \tag{B1}$$

We use the notations below

$$(t(\theta), t(\theta'), K(\theta - \theta')) \equiv (t, t', K''). \tag{B2}$$

In terms of P_0' defined by Eq. (1.4) with (i,j) and (ρ_i, ρ_j) corresponding to $N=3$ and $K(\theta)$ of Eqs. (1.17) and (1.18), Eq. (B1) now is (maintaining the notation P_0' unrelated to θ, θ'),

$$(I + K''P_0')(t \otimes t') = (t' \otimes t)(I + K''P_0'), \tag{B3}$$

where

$$P_0' = q^{-1}(11) \otimes (33) + q^{-1/2}(12) \otimes (32) + (13) \otimes (31) + q^{-1/2}(21) \otimes (23) + (22) \otimes (22) + q^{1/2}(23) \otimes (21) + (31) \otimes (13) + q^{1/2}(32) \otimes (12) + q(33) \otimes (11). \tag{B4}$$

This leads to a set of 36 relations independent of K'', namely

$$t_{ij}t'_{kl} = t'_{ij}t_{kl}, \tag{B5}$$

where for $(ij) = (11), (12), (13)$, respectively,

$$(kl) = (11,12,21,22), (11,13,21,23), (12,13,22,23) \tag{B6}$$

and similarly for $(ij) = (21), (22), (23)$,

$$(kl) = (11,12,31,32),(11,13,31,33),(12,13,32,33) \tag{B7}$$

and for $(ij)=(31),(32),(33)$,

$$(kl) = (21,22,31,32),(21,23,31,33),(22,23,32,33). \tag{B8}$$

To present the K'' dependent constraints we first define

$$X_1 = q^{-1/2}t_{11}t'_{31} + t_{21}t'_{21} + q^{1/2}t_{31}t'_{11}, \quad X_2 = q^{-1/2}t_{11}t'_{32} + t_{21}t'_{22} + q^{1/2}t_{31}t'_{12},$$

$$X_3 = q^{-1/2}t_{11}t'_{33} + t_{21}t'_{23} + q^{1/2}t_{31}t'_{13}, \quad X_4 = q^{-1/2}t_{12}t'_{31} + t_{22}t'_{21} + q^{1/2}t_{32}t'_{11},$$

$$X_5 = q^{-1/2}t_{12}t'_{32} + t_{22}t'_{22} + q^{1/2}t_{32}t'_{12}, \quad X_6 = q^{-1/2}t_{12}t'_{33} + t_{22}t'_{23} + q^{1/2}t_{32}t'_{13},$$

$$X_7 = q^{-1/2}t_{13}t'_{31} + t_{23}t'_{21} + q^{1/2}t_{33}t'_{11}, \quad X_8 = q^{-1/2}t_{13}t'_{32} + t_{23}t'_{22} + q^{1/2}t_{33}t'_{12},$$

$$X_9 = q^{-1/2}t_{13}t'_{33} + t_{23}t'_{23} + q^{1/2}t_{33}t'_{13}, \tag{B9}$$

and a set

$$(Y_1, Y_2, \ldots, Y_9), \tag{B10}$$

which is obtained by transposing the indices of each term on the right of Eq. (B9) and also the order of (θ, θ'). Thus

$$Y_1 = q^{-1/2}t'_{11}t_{13} + t'_{12}t_{12} + q^{1/2}t'_{13}t_{11} \tag{B11}$$

and so on. The constraints involving K'' only through X_i are the following ones:

$$q^{1/2}(t_{11}t'_{31} - t'_{11}t_{31}) = (t_{21}t'_{21} - t'_{21}t_{21}) = q^{-1/2}(t_{31}t'_{11} - t'_{31}t_{11}) = -K''X_1,$$

$$q^{1/2}(t_{11}t'_{32} - t'_{11}t_{32}) = (t_{21}t'_{22} - t'_{21}t_{22}) = q^{-1/2}(t_{31}t'_{12} - t'_{31}t_{12}) = -K''X_2,$$

$$q^{1/2}(t_{12}t'_{31} - t'_{12}t_{31}) = (t_{22}t'_{21} - t'_{22}t_{21}) = q^{-1/2}(t_{32}t'_{11} - t'_{32}t_{11}) = -K''X_4,$$

$$q^{1/2}(t_{12}t'_{33} - t'_{12}t_{33}) = (t_{22}t'_{23} - t'_{22}t_{23}) = q^{-1/2}(t_{32}t'_{13} - t'_{32}t_{13}) = -K''X_6,$$

$$q^{1/2}(t_{13}t'_{32} - t'_{13}t_{32}) = (t_{23}t'_{22} - t'_{23}t_{22}) = q^{-1/2}(t_{33}t'_{12} - t'_{33}t_{12}) = -K''X_8,$$

$$q^{1/2}(t_{13}t'_{33} - t'_{13}t_{33}) = (t_{23}t'_{23} - t'_{23}t_{23}) = q^{-1/2}(t_{33}t'_{13} - t'_{33}t_{13}) = -K''X_9. \tag{B12}$$

There are six corresponding sets involving K'' only through Y_i. As for Eq. (B11) they are obtained by transposing indices in the first three terms of each equation of Eq. (B12) and changing the sign before K''. Thus

$$q^{1/2}(t_{11}t'_{13} - t'_{11}t_{13}) = (t_{12}t'_{12} - t'_{12}t_{12}) = q^{-1/2}(t_{13}t'_{11} - t'_{13}t_{11}) = K''Y_1 \tag{B13}$$

and so on.

Finally there is a set involving K'' through both X_i, and Y_i,

$$(t_{11}t'_{33} - t'_{11}t_{33}) = -K''q^{-1/2}(X_3 - Y'_3),$$

$$(t_{12}t'_{32} - t'_{12}t_{32}) = -K''(q^{-1/2}X_5 - Y'_3),$$

$$(t_{13}t'_{31} - t'_{13}t_{31}) = -K''(q^{-1/2}X_7 - q^{1/2}Y'_3),$$

$$(t_{21}t'_{23} - t'_{21}t_{23}) = -K''(X_3 - q^{-1/2}Y'_5),$$

$$(t_{22}t'_{22} - t'_{22}t_{22}) = -K''(X_5 - Y'_5),$$

$$(t_{23}t'_{21} - t'_{23}t_{21}) = -K''(X_7 - q^{1/2}Y'_5),$$

$$(t_{31}t'_{13} - t'_{31}t_{13}) = -K''(q^{1/2}X_3 - q^{-1/2}Y'_7),$$

$$(t_{32}t'_{12} - t'_{32}t_{12}) = -K''(q^{1/2}X_5 - Y'_7),$$

$$(t_{33}t'_{11} - t'_{33}t_{11}) = -K''q^{1/2}(X_7 - Y'_7). \tag{B14}$$

An alternative approach to the $\hat{R}tt$ relations is via the diagonalization of P'_0. The diagonalizer is given in Ref. 13. Such an approach was presented for our multiparameter ("nested-sequence") class in Appendix C of Ref. 3.

(Received 12 July 2006; accepted 25 September 2006; published online 12 December 2006)

We consider a class of classical lattice spin systems, with $\mathbb{R}^n$-valued spins and two-body interactions. Our main result states that the associated Gibbs measure localizes in certain cylindrical neighborhoods of the global minima of the unperturbed Hamiltonian. As an application we establish existence of a first order phase transition at low temperature, for a reflection positive mexican hat model on $\mathbb{Z}^d$, $d \geqslant 3$, with a nonferromagnetic interaction. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2364180]

I. ASSUMPTIONS AND MAIN RESULT

Let $n \in \mathbb{N}$ and Λ be a finite set. Elements of Λ are denoted by x, y, and z. We pick and fix one element $o \in \Lambda$ which plays the distinguished role of an origin. We write $\Omega = (\mathbb{R}^n)^\Lambda$ for the vector space of spin configurations $\varphi = \{\varphi_x\}_{x \in \Lambda}$ over Λ, where $\varphi_x \in \mathbb{R}^n$. We use the symbols ψ and φ for elements of Ω. The letters u and v are used for vectors in $\mathbb{R}^n$, and $|u|$ denotes the Euclidean norm of u. It is assumed that Λ comes equipped with a metric ρ which satisfies

$$\max_{x \in \Lambda} \sum_{y \in \Lambda} e^{-\rho(x,y)} \leqslant C_\rho < \infty . \tag{1.1}$$

We study a Hamiltonian function $H_\Lambda \in C^1(\Omega; \mathbb{R})$ of the form

$$H_\Lambda(\varphi) = \sum_{x \in \Lambda} f_x(\varphi_x) + J \sum_{x,y \in \Lambda, x \neq y} w_{xy}(\varphi_x, \varphi_y).$$

The self-energies $\{f_x\}_{x \in \Lambda}$ and the interactions $\{w_{xy}\}_{x,y \in \Lambda, x \neq y}$ should satisfy assumptions specified in the following Conditions (1.1) and (1.2), respectively.

We introduce some notation. We write $\partial_{|u|} = |u|^{-1} u \cdot \nabla_u$ for the radial derivative with respect to the $\mathbb{R}^n$-valued variable u, and $B_r(u) := \{v \in \mathbb{R}^n \,|\, |u - v| \leqslant r\}$, for the closed ball of radius r and centered at u.

Condition 1.1. *There are positive constants $R, c_f, C_f > 0$ such that the family $\{f_x\}_{x \in \Lambda}$ of functions $f_x \in C^1(\mathbb{R}^n; \mathbb{R})$ satisfy (i)–(iv) as follows*:

(i) $f_x \geqslant 0$ *and* $\min_{u \in \mathbb{R}^n} f_x(u) = 0$.
(ii) *The set* $\mathcal{G}_0 := \{u \in \mathbb{R}^n \,|\, f_o(u) = 0\}$ *of global minima satisfies* $\mathcal{G}_0 \subset B_R(0)$.
(iii) *For all* $x \in \Lambda$ *and* $u \in \mathbb{R}^n$, *with* $|u| \geqslant R$, *we have* $\partial_{|u|} f_x(u) \geqslant c_f$.
(iv) *For all* $x, y \in \Lambda$ *and* $u, v \in \mathbb{R}^n$, *with* $|v| \geqslant |u| \geqslant R$, *we have*

$$\partial_{|u|} f_x(u) \leqslant C_f \partial_{|v|} f_y(v).$$

a)Electronic mail: vbach@mathematik.uni-mainz.de
b)Electronic mail: jacob@imf.au.dk

For $j \in \{1,2\}$, we write $\nabla_j w_{xy}$ for the gradient of w_{xy} with respect to the jth variable. The w_{xy}'s are required to be dominated by the f_x's, as specified by the next condition

Condition 1.2. *There exist constants* $C_a^\rho > 0$ *and* $\{a_{xy}\}_{x,y\in\Lambda}$, *with* $a_{xy}=a_{yx}\geqslant 0$, $a_{xx}=0$, *and*

$$\max_{x\in\Lambda}\left\{\sum_{y\in\Lambda} a_{xy}e^{\rho(x,y)}\right\} \leqslant C_a^\rho, \tag{1.2}$$

such that the family $\{w_{xy}\}_{x,y\in\Lambda}$ *of functions* $w_{xy}\in C^1(\mathbb{R}^n\times\mathbb{R}^n;\mathbb{R})$, *with* $w_{xx}\equiv 0$, *obeys the following bounds*:

$$\max\{|\nabla_1 w_{xy}(u,v)|,|\nabla_2 w_{xy}(u,v)|\} \leqslant a_{xy}(1+\mathbb{1}_{[|u|\geqslant 4R]}\partial_{|u|}f_x(u)+\mathbb{1}_{[|v|\geqslant 4R]}\partial_{|v|}f_y(v)). \tag{1.3}$$

Equation (1.2) expresses exponential decay of the interaction with respect to the metric ρ. Let $C_a^0 \leqslant C_a^\rho$ be such that

$$\max_{x\in\Lambda}\left\{\sum_{y\in\Lambda} a_{xy}\right\} \leqslant C_a^0. \tag{1.4}$$

For polynomially bounded, measurable functions $u:\Omega\to\mathbb{C}$, we use the following notation for expectations with respect to the Gibbs state in finite volume Λ and inverse temperature β:

$$\mathbb{E}_\Lambda[u] := \mathcal{Z}_\Lambda^{-1}\int_\Omega u(\varphi)e^{-\beta H_\Lambda(\varphi)}d^\Lambda\varphi. \tag{1.5}$$

Here $\mathcal{Z}_\Lambda=\int_\Omega e^{-\beta H_\Lambda(\varphi)}d^\Lambda\varphi$ is the partition function. For the integral in Eq. (1.5) to exist under Conditions 1.1 and 1.2, we require $|J|<\Gamma_0^{-1}$, where

$$\Gamma_0 := 2C_a^0(1+C_f+c_f^{-1}). \tag{1.6}$$

See Lemma A.1. We note that for many examples, including the example in Sec. II, the f_x's grow at a faster rate than the w_{xy}'s such that no assumption on $|J|$ is needed to make polynomially bounded observables integrable. For the probability of a (measurable) event $\mathcal{A}\subset\Omega$, we write

$$\mathbb{P}_\Lambda[\mathcal{A}] := \mathbb{E}_\Lambda[\mathbb{1}_\mathcal{A}].$$

For $\zeta>0$, we introduce level sets for f_o,

$$\mathcal{G}_\zeta := \{u\in\mathbb{R}^n | f_o(u)\leqslant\zeta\}.$$

We are now ready to formulate the main result of the paper.

Theorem 1.1. *Assume Eq. (1.1). Let* $\{f_x\}_{x\in\Lambda}$ *satisfy Condition 1.1 and* $\{w_{xy}\}_{x,y\in\Lambda}$ *satisfy Condition 1.2. Let*

$$\Gamma_1 := 4RC_a^0\left(\tfrac{1}{3}C_\rho+3\right),\quad \Gamma_2=\Gamma_0+\tfrac{102}{5}C_a^\rho,\quad \Gamma_3 := \tfrac{2}{3}c_fR, \tag{1.7}$$

and

$$J_0 := \Gamma_3\min\left\{\frac{3}{4\Gamma_1},\frac{1}{\Gamma_1+\Gamma_2\Gamma_3}\right\}. \tag{1.8}$$

For $|J|<J_0$, $\beta>0$ *and* $\delta>2|J|\Gamma_1$, *we have*

$$\mathbb{P}_\Lambda[\{\varphi\in\Omega|\varphi_o\notin\mathcal{G}_\delta\}] \leqslant Ce^{-\beta\sigma}, \tag{1.9}$$

where

$$C = 2\max\left\{\left[\frac{4R}{\min\left\{\delta,\frac{3}{2}\Gamma_3\right\}}\sup_{|u|\leqslant 2R}|\nabla f_o(u)|\right]^n,\left(\frac{3}{5}\right)^n\right\}e^{nC_\rho/2}, \tag{1.10}$$

and σ is a strictly positive constant given by

$$\sigma = \min\left\{\tfrac{1}{2}\delta, \tfrac{3}{4}\Gamma_3, \Gamma_3(1-|J|\Gamma_2)\right\} - |J|\Gamma_1. \tag{1.11}$$

Remark 1.2.

(1) We stress that the constants J_0, $\{\Gamma_j\}_{j=1,2,3}$, C, and σ, only depend on ρ, $\{f_x\}_{x\in\Lambda}$ and $\{w_{xy}\}_{x,y\in\Lambda}$ through the constants C_ρ, c_f, C_f, R, C_a^0, and C_a^ρ. In particular, they are independent of Λ and the choice of origin o.

(2) The set of φ's with $\varphi_o \in \mathcal{G}_\delta$ is a cylinder set containing the global minima of the unperturbed (that is, $J=0$) Hamiltonian. The condition $\delta > 2|J|\Gamma_1$, ensures that the global minima of the perturbed Hamiltonian remain contained in this cylinder set.

(3) The proof goes through without modifications if $\mathbb{R}^n$ is replaced by a convex subset thereof containing 0.

(4) A choice was made here to present the method for a class of Hamiltonians without any special symmetry. For models with $O(n)$ symmetry, like the example discussed in Sec. II, one can tweak the proof to get better constants.

(5) The restriction to two-body interactions is made for simplicity. The method extends to models with many-body interactions.

The derivation of the bound Eq. (1.9) follows a scheme used in Ref. 1, Sec. 3, to derive low temperature localization bounds for models with a unique global minimum at 0. The method developed in Ref. 1 was in turn inspired by work going back to Sjöstrand,[2] see also Refs. 3 and 4. The common idea in the papers cited in this paragraph is to systematically shift points in the set of φ's with $\varphi_o \notin \mathcal{G}_\delta$, towards the global mimima and measure the resulting decrease in energy. In this paper and in Ref. 1 the shift is implemented by a single transformation T, with the property that $\inf_{\varphi,\varphi_o\notin\mathcal{G}_\delta}[H(\varphi)-H(T(\varphi))] \geqslant \sigma > 0$. It is this σ which contributes to the exponential localization in Eq. (1.9). In the papers[2–4] the idea is slightly different: The configuration space is cut up into pieces, each of which is translated into a neighborhood of a unique global minimum, and the contributions are then summed up. We remark that in Ref. 4, the interaction does not shift the global minimum away from 0, which makes it possible to localize arbitrarily close to 0 while keeping the coupling constant J fixed (see Remark 1.2 (2)).

II. MOTIVATING EXAMPLE

Let $\Lambda =]-L,L]^d \cap \mathbb{Z}^d$, be the d-dimensional hypercubic lattice of sidelength $2L$, for some $d \geqslant 3$ and $L \in \mathbb{N}$. We view Λ as the torus $\mathbb{Z}^d/2L\mathbb{Z}^d$, equipped with the metric $\rho(x,y) = \min_{z\in\mathbb{Z}^d}|x-y-2Lz|_1$, where $|z|_p$, is the p-norm of $z \in \mathbb{R}^d$. As self-energies we take

$$f_x(u) = |u|^4 - 2|u|^2 + 1, \tag{2.1}$$

and as interaction we take

$$w_{xy}(u,v) = -\mathcal{J}_\Lambda(x-y)u\cdot v, \tag{2.2}$$

where $\mathcal{J}_\Lambda$ is periodic and defined from an underlying interaction $\mathcal{J} \in \ell^1(\mathbb{Z}^d;\mathbb{R})$ by

$$\mathcal{J}_\Lambda(x) := \sum_{y\in\mathbb{Z}^d} \mathcal{J}(x+2Ly). \tag{2.3}$$

In general, one should take a reflection positive interaction, with respect to a suitable reflection, in order to get an infrared bound. Here we specialize to the following example:

$$\mathcal{J}(x) := \begin{cases} 1, & |x|_2 = 1, \\ -b, & |x|_2 = \sqrt{2}. \end{cases} \tag{2.4}$$

In order to obtain a reflection positive interaction, we impose the restriction

$$J > 0, \quad 0 < b < \frac{1}{2(d-1)}.$$

Note that the ferromagnetic case $-b \geqslant 0$, can be treated by methods already established. We introduce the correlation function $F_\Lambda : \Lambda \to \mathbb{R}$ by

$$F_\Lambda(x) := \mathbb{E}_\Lambda[\varphi_0 \cdot \varphi_x].$$

Let $\Lambda^* =]-\pi, \pi]^d \cap (\pi/L)\mathbb{Z}^d$ be the dual lattice and $\hat{F}_\Lambda : \Lambda^* \to \mathbb{R}$ the Fourier transform of F_Λ. That is, $\hat{F}_\Lambda(\xi) = \Sigma_{x\in\Lambda} \exp(-ix\cdot\xi) F_\Lambda(x)$. Similarly, for $\xi \in \Lambda^*$,

$$\hat{\mathcal{J}}_\Lambda(\xi) = \hat{\mathcal{J}}(\xi) = 2a \sum_{j=1}^{d} \cos(\xi_j) - 4b \sum_{1\leqslant i<j\leqslant d} \cos(\xi_i)\cos(\xi_j)$$

is the Fourier transform of $\mathcal{J}_\Lambda$. Here $\hat{\mathcal{J}}(\xi) = \Sigma_{x\in\mathbb{Z}^d} e^{-ix\cdot\xi} \mathcal{J}(x)$. The model defined by Eqs. (2.1) and (2.4) is translation invariant and reflection positive, cf. Refs. 5 and 6, and hence, it satisfies an infrared bound of the form

$$0 \leqslant \hat{F}_\Lambda(\xi) \leqslant \frac{n}{J\beta} (\hat{\mathcal{J}}(0) - \hat{\mathcal{J}}(\xi))^{-1}, \tag{2.5}$$

for $\xi \in \Lambda^* \setminus \{0\}$. Here n is the dimension of the single spin space. For a proof of this bound see [Ref. 6, Proposition 20.12]. See Ref. 7 for a discussion of the critical case, where $2(d-1)b = 1$.

As usual, Eq. (2.5) implies that

$$\begin{aligned}\mathbb{E}_\Lambda[\varphi_0 \cdot \varphi_x] &= \mathbb{E}_\Lambda[|\varphi_0|^2] + F_\Lambda(x) - F_\Lambda(0) \\ &= \mathbb{E}_\Lambda[|\varphi_0|^2] + \frac{1}{|\Lambda|} \sum_{\xi\in\Lambda^*} (e^{ix\cdot\xi} - 1)\hat{F}_\Lambda(\xi) \geqslant \mathbb{E}_\Lambda[|\varphi_0|^2] - \frac{2n}{J\beta|\Lambda|} \sum_{\xi\in\Lambda^*\setminus\{0\}} (\hat{\mathcal{J}}(0) - \hat{\mathcal{J}}(\xi))^{-1}.\end{aligned} \tag{2.6}$$

Note that $\hat{\mathcal{J}}(0) = \hat{\mathcal{J}}(\xi)$ if, and only if, $\xi = 0$, and

$$\hat{\mathcal{J}}(0) - \hat{\mathcal{J}}(\xi) \sim (1 - 2(d-1)b)\xi^2,$$

near $\xi = 0$. In dimension $d \geqslant 3$ this implies the existence of a first order phase transition at low temperature (large β), provided one can verify the following moment inequality:

$$\mathbb{E}_\Lambda[|\varphi_0|^2] \geqslant c > 0. \tag{2.7}$$

Here c should be independent of L. The estimate Eq. (2.6) then says that a (necessarily translation invariant) limit state $\mathbb{E}_\infty = \mathrm{w}-\lim_{\Lambda\to\mathbb{Z}^d} \mathbb{E}_\Lambda$ is not ergodic, hence, not a pure phase. See Refs. 5, 8, and 9 and in particular Ref. 6, Theorem 20.15, for a reference dealing with possibly unbounded spins. For models constrained to the unit sphere (or in general to closed subsets of $\mathbb{R}^n$ not containing 0) the bound Eq. (2.7) is trivial.

If $\mathcal{J}(x) \geqslant 0$, for all x, i.e., the model is ferromagnetic, there are two general methods one can use to verify Eq. (2.7) for models with interaction of the type Eq. (2.2). If $n = 1$ one can use the FKG inequalities,[10] which imply monotonicity of the second moment in $\mathcal{J}(x)$ (for any fixed x). This can be used to reduce the moment inequality to a one-dimensional problem which can be analyzed explicitly. See Ref. 11 for a discussion of this idea. Another argument applies under the additional assumption of reflection positivity of the interaction Eq. (2.2). Then the so-called chessboard estimate (Ref. 6, Chap. 17.1) applies (a key ingredient in the proof of Eq. (2.5) and the reason for the choice of a reflection positive model as our example). The chessboard estimate together with ferromagnetism, i.e., positivity of $\mathcal{J}$, also leads to a moment inequality; no restrictions on n are needed. See. Ref. 6, Lemma 20.8.

If the interaction is not ferromagnetic there seems to be no method available in the literature to deal with the innocuous looking moment inequality Eq. (2.7). This is where our main result comes in. Clearly, Theorem 1.1 gives explicit J_0 and α_0 such that, for $0<J<J_0$ and $J\beta>\alpha_0$, we have $\mathbb{E}_\Lambda[|\varphi_0|^2]\geqslant c>0$, for an equally explicit constant c. Here one should take $0<\delta<1$, such that $\mathcal{G}_\delta$ is an annulus. Moreover, as opposed to the methods of the preceding paragraph, Theorem 1.1 is robust and does not rely on correlation inequalities or indeed on any nontrivial properties of the underlying Gibbs measure. We have thus extended the applicability of Georgii's result (Ref. 6, Theorem 20.15) to interactions $\mathcal{J}$, which need not be ferromagnetic. (Recall that Georgii in this case requires the single spin space to be bounded away from 0, cf. Ref. 6, Comments 20.18 (3)).

For the above concrete model, we estimated the constant J_0, fixed a $J<J_0$ and estimated σ and C, for which the bound Eq. (1.9) is valid. As for J_0 we got $J_0\sim 10^{-4}$, which seems small, but is in fact only a factor of 10 smaller than Γ_0^{-1}. Recall that Γ_0^{-1} was the upper limit for coupling strengths such that all models satisfying the conditions, with the same constants, are well-defined. This also serves to illustrate Remark 1.2 (4). We then took $J=10^{-4}/2$ and found $\sigma\sim 1/20$ and $C\sim e^{60}$. To get a probability less than 1 in Eq. (1.9), one has to take $\beta>\beta_0$ with $\beta_0\sim 1200$. We note that we did not try to optimize carefully over possible choices of metric and the constant R. (For R we chose $R=1.03$. For the metric we chose $\kappa\rho$, with $\kappa=\ln(2)$. Here ρ is the metric given at the beginning of this section.)

III. TRANSFORMATION T^ζ

The purpose of this section is to construct a transformation of the space Ω, and estimate its Jacobian.

We begin by analyzing the size of the level sets $\mathcal{G}_\zeta$. Let $\zeta\geqslant 0$ and $u\in\mathbb{R}^n$ be such that $|u|>2\zeta c_f^{-1}+R$, where the constants c_f and R are taken from Condition 1.1. Let $u':=Ru/|u|$, and for $0\leqslant t\leqslant 1$,

$$u_t := tu+(1-t)u' = \left(\frac{R}{|u|}+t\left(1-\frac{R}{|u|}\right)\right)u.$$

Then, using that $\dot{u}_t/|\dot{u}_t|=u_t/|u_t|$, we estimate

$$f_o(u)\geqslant f_o(u)-f_o(u')=\int_0^1 \dot{u}_t\cdot\nabla f_o(u_t)dt=(|u|-R)\int_0^1(\partial_{|u|}f_o)(u_t)dt\geqslant 2\zeta c_f^{-1}\int_0^1 c_f dt=2\zeta.$$

This implies that

$$\mathcal{G}_{2\zeta}\subset B_{R+2\zeta c_f^{-1}}(0). \tag{3.1}$$

We shall henceforth assume that $0<\zeta\leqslant(1/2)c_fR$, which is equivalent to

$$R<R_\zeta := R+\frac{2\zeta}{c_f}\leqslant 2R. \tag{3.2}$$

We introduce the size r_ζ, of the largest ball contained in $\mathcal{G}_\zeta$;

$$r_\zeta := \sup\{r\geqslant 0\,|\,\exists\, u\in\mathcal{G}_\zeta\colon B_r(u)\subset\mathcal{G}_\zeta\}. \tag{3.3}$$

Fix an $\eta_\zeta\in\mathcal{G}_\zeta$, for which $B_{r_\zeta}(\eta_\zeta)\subset\mathcal{G}_\zeta$. Such an η_ζ exists by the choice Eq. (3.3) of r_ζ. By Eq. (3.1) we get a bound from below on r_ζ,

$$r_\zeta\geqslant \operatorname{dist}(\mathcal{G}_\zeta^c,\mathcal{G}_0)=\operatorname{dist}(B_{R_\zeta}(0)\cap\mathcal{G}_\zeta^c,\mathcal{G}_0).$$

Let $u\in\mathcal{G}_0$ and $v\in B_{R_\zeta}(0)\cap\mathcal{G}_\zeta^c$. Then

$$\zeta \leqslant f_o(v) - f_o(u) \leqslant |v-u| \sup_{u \in B_{R_\zeta}(0)} |\nabla f_o(u)|.$$

This implies

$$r_\zeta \geqslant \frac{\zeta}{\sup_{u \in B_{R_\zeta}(0)} |\nabla f_o(u)|}. \tag{3.4}$$

We pick a function $\theta \in C^\infty(\mathbb{R};[0,1])$ with $\theta \equiv 0$ on $(-\infty, 1/2]$, $\theta \equiv 1$ on $[1,\infty)$, and $\theta' \geqslant 0$. Note that $\mathrm{supp}(\theta') \subset (1/2,1)$.

The final input is a family of scaling factors $\{\epsilon_x\}_{x \in \Lambda}$. We choose them to be of the form

$$\epsilon_x := \epsilon_o e^{-\rho(x,o)}. \tag{3.5}$$

Here ϵ_o is chosen such that

$$0 < \epsilon_o < \tfrac{1}{2}(1 + \|\theta'\|_\infty)^{-1}, \tag{3.6}$$

where $\|\theta'\|_\infty = \max_{t \in [1/2,1]} |\theta'(t)| > 2$. (We will optimize over ϵ_o and θ in Sec. VI.)

We define a transformation $T^\zeta : \Omega \to \Omega$ as follows: $(T^\zeta(\varphi))_x := T^\zeta_x(\varphi_x)$ and

$$\forall x \neq o : T^\zeta_x(u) := \left(1 - \epsilon_x \theta\left(\frac{|u|}{4R}\right)\right) u, \tag{3.7}$$

$$T^\zeta_o(u) := \begin{cases} (1-\epsilon_o)u, & |u| \geqslant 4R, \\ \left(\dfrac{r_\zeta}{4R}\right) u + \eta_\zeta, & |u| < 4R. \end{cases} \tag{3.8}$$

The transformation T^ζ is not a global diffeomorphism, but we work below in the sectors $\{\varphi : |\varphi_o| < 4R\}$ and $\{\varphi : |\varphi_o| > 4R\}$ separately, and T^ζ restricted to these sectors is a smooth transformation.

We end this section with an estimate on the determinant of $\mathrm{Jac}(T^\zeta)$, the Jacobian of T^ζ.

Lemma 3.1 Let T^ζ be the transformation defined in (3.7) and (3.8). We have the bound

$$|\det \mathrm{Jac}(T^\zeta)(\varphi)| \geqslant \min\left\{ \frac{\zeta}{4R \sup_{|u| \leqslant R_\zeta} |\nabla f_o(u)|}, 1 - \epsilon_o \right\}^n \exp[-n\epsilon_o(1 + \|\theta'\|_\infty) C_\rho], \tag{3.9}$$

for all $\varphi \in \Omega$, with $|\varphi_o| \neq 4R$.

Proof: The Jacobian of T^ζ (away from $|\varphi_o| = 4R$) is a block diagonal matrix with $n \times n$ blocks given by

$$\forall x \neq o : \mathrm{Jac}(T^\zeta)_{xx}(\varphi) = \left(1 - \epsilon_x \theta\left(\frac{|\varphi_x|}{4R}\right)\right) I_n - \frac{\epsilon_x |\varphi_x}{4R} \theta'\left(\frac{|\varphi_x|}{4R}\right) P_{\varphi_x},$$

$$\mathrm{Jac}(T^\zeta)_{oo}(\varphi) = \begin{cases} (1-\epsilon_o) I_n, & |\varphi_o| > 4R, \\ \left(\dfrac{r_\zeta}{4R}\right) I_n, & |\varphi_o| < 4R. \end{cases}$$

Here I_n is the identity matrix in $\mathbb{R}^n$, and $P_u := |u|^{-2} |u\rangle\langle u|$, is the orthogonal projection onto $\mathrm{span}\{u\}$, for $u \in \mathbb{R}^n \setminus \{0\}$.

Note that, for $x \neq o$,

$$\frac{\epsilon_x|\varphi_x|}{4R}\theta'\left(\frac{|\varphi_x|}{4R}\right)P_{\varphi_x} \leqslant \epsilon_x\|\theta'\|_\infty I_n.$$

Using this observation, we estimate the determinant of the Jacobian as follows:

$$\text{for } |\varphi_o| < 4R: |\text{detJac}(T^\zeta)(\varphi)| \geqslant \left[\frac{r_\zeta}{4R}\prod_{x(\neq o)}\{1-\epsilon_x(1+\|\theta'\|_\infty)\}\right]^n,$$

$$\text{for } |\varphi_o| > 4R: |\text{detJac}(T^\zeta)(\varphi)| \geqslant \left[(1-\epsilon_o)\prod_{x(\neq o)}\{1-\epsilon_x(1+\|\theta'\|_\infty)\}\right]^n.$$

Using the bound $\ln(1-t)\geqslant -2t$, for $0\leqslant t\leqslant 1/2$, together with Eqs. (1.1), (3.5), and (3.6), we arrive at Eq. (3.9). □

IV. ESTIMATING THE INTERACTION

In this section we estimate the effect of the transformation T^ζ on the interaction $W(\varphi)=\Sigma_{x\neq y}w_{xy}(\varphi_x,\varphi_y)$. We prove the following lemma which is the central technical step in the proof of Theorem 1.1. The constant Γ_0 below is defined in Eq. (1.6).

Lemma 4.1: For $0<\zeta\leqslant c_f R/2$, we have, for all $\varphi\in\Omega$, the bound

$$|W(\varphi)-W(T^\zeta(\varphi))| \leqslant C_W^1 + C_W^2\sum_{x\in\Lambda}\mathbb{1}_{[|\varphi_x|\geqslant 4R]}(f_x(\varphi_x)-f_x(T_x^\zeta(\varphi_x))), \tag{4.1}$$

where

$$C_W^1 := 4RC_a^0(2\epsilon_o C_\rho+3), \quad C_W^2 := \Gamma_0 + C_a^\rho(3\epsilon_o^{-1}+2(1-\epsilon_o)^{-1}). \tag{4.2}$$

Proof: Let $\varphi\in\Omega$, $x,y\in\Lambda$ with $x\neq y$. For $z\in\{x,y\}$ we abbreviate $u_z(t)=t\varphi_z+(1-t)T_z^\zeta(\varphi_z)$.

Using the fundamental theorem of calculus, together with Condition 1.2, we estimate

$$\begin{aligned}
&|w_{xy}(\varphi_x,\varphi_y)-w_{xy}((T^\zeta(\varphi))_x,(T^\zeta(\varphi))_y)|\\
&\quad=\left|\int_0^1\{(\varphi_x-T_x^\zeta(\varphi_x))\cdot\nabla_1 w_{xy}(u_x(t),u_y(t))+(\varphi_y-T_y^\zeta(\varphi_y))\cdot\nabla_2 w_{xy}(u_x(t),u_y(t))\}dt\right|\\
&\quad\leqslant a_{xy}(|\varphi_x-T_x^\zeta(\varphi_x)|+|\varphi_y-T_y^\zeta(\varphi_y)|)\left[1+\int_0^1\{\mathbb{1}_{[|u_x(t)|\geqslant 4R]}(\partial_{|u|}f_x)(u_x(t))\right.\\
&\quad\left.+\mathbb{1}_{[|u_y(t)|\geqslant 4R]}(\partial_{|u|}f_y)(u_y(t))\}dt\right]\\
&\quad= a_{xy}(S_1^x(\varphi)+S_1^y(\varphi)+S_2^{xy}(\varphi)+S_2^{yx}(\varphi)),
\end{aligned}\tag{4.3}$$

where

$$S_1^z(\varphi)=|\varphi_z-T_z^\zeta(\varphi_z)|\left[1+\int_0^1\mathbb{1}_{[|u_z(t)|\geqslant 4R]}(\partial_{|u|}f_z)(u_z(t))dt\right],$$

$$S_2^{zz'}(\varphi)=|\varphi_z-T_z^\zeta(\varphi_z)|\int_0^1\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]}(\partial_{|u|}f_{z'})(u_{z'}(t))dt.$$

We proceed to estimating $S_1^z(\varphi)$ and $S_2^{zz'}(\varphi)$, for all $\varphi\in\Omega$.

To estimate S_1^z we recall Eq. (3.7), and observe the bound

$$|\varphi_z - T_z^\zeta(\varphi_z)| \leqslant \epsilon_z |\varphi_z|, \tag{4.4}$$

which holds true if $z \neq o$, or $z=o$ and $|\varphi_o| \geqslant 4R$. To deal with the complementary case, where $z=o$ and $|\varphi_o| < 4R$, we note that in this case Eq. (3.8) implies $|T_o^\zeta(\varphi_0)| \leqslant R_\zeta \leqslant 2R$, and hence,

$$|u_o(t)| < 4R \quad \text{and} \quad |\varphi_o - T_o^\zeta(\varphi_o)| \leqslant 6R. \tag{4.5}$$

Combining Eqs. (4.4) and (4.5) yields for all z and $\varphi \in \Omega$,

$$S_1^z(\varphi) \leqslant 6R\delta_{zo} + \epsilon_z|\varphi_z|\left[1 + \int_0^1 \mathbb{1}_{[|u_z(t)|\geqslant 4R]}(\partial_{|u|}f_z)(u_z(t))dt\right]. \tag{4.6}$$

Here we used that $|\varphi_o| \geqslant 4R$ on the support of $\mathbb{1}_{[|u_o(t)|\geqslant 4R]}$.

As for $S_2^{zz'}$ we split Ω into two regions

$$\Omega_{\mathrm{I}}^{zz'} := \{\varphi \in \Omega \,||\varphi_z| \geqslant |\varphi_{z'}|/(1-\epsilon_z)\} \quad \text{and} \quad \Omega_{\mathrm{II}}^{zz'} = \Omega \setminus \Omega_{\mathrm{I}}^{zz'}.$$

From Condition 1.1 (iv) we get the bound

$$\mathbb{1}_{[\varphi\in\Omega_{\mathrm{I}}^{zz'}]}\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]}(\partial_{|u|}f_{z'})(u_{z'}(t)) \leqslant C_f \mathbb{1}_{[|u_z(t)|\geqslant 4R]}(\partial_{|u|}f_z)(u_z(t)), \tag{4.7}$$

because on the support of the indicator functions we have

$$|u_z(t)| \geqslant (1-\epsilon_z)|\varphi_z| \geqslant |\varphi_{z'}| \geqslant |u_{z'}(t)| \geqslant 4R.$$

Complementing Eq. (4.7) we now consider the region $\Omega_{\mathrm{II}}^{zz'}$. We obtain, for $z \neq o$, or $z=o$ and $|\varphi_o| \geqslant 4R$,

$$|\varphi_z - T_z^\zeta(\varphi_z)|\mathbb{1}_{[\varphi\in\Omega_{\mathrm{II}}^{zz'}]}\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]} \leqslant \frac{\epsilon_z}{1-\epsilon_z}|\varphi_{z'}|\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]}. \tag{4.8}$$

Here Eq. (4.4) was used. We note that, for $|\varphi_o| \leqslant 4R$, we have from Eq. (4.5),

$$|\varphi_o - T_o^\zeta(\varphi_o)|\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]} \leqslant 6R\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]} \leqslant \tfrac{3}{2}|\varphi_{z'}|\mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]}. \tag{4.9}$$

Combining Eqs. (4.7)–(4.9) yields for $z \neq z'$ and $\varphi \in \Omega$,

$$S_2^{zz'}(\varphi) \leqslant \epsilon_z|\varphi_z|C_f\int_0^1 \mathbb{1}_{[|u_z(t)|\geqslant 4R]}(\partial_{|u|}f_z)(u_z(t))dt + \epsilon_{z'}|\varphi_{z'}|\left\{\frac{\epsilon_z}{(1-\epsilon_z)\epsilon_{z'}} + \frac{3}{2\epsilon_{z'}}\delta_{oz}\right\}\int_0^1 \mathbb{1}_{[|u_{z'}(t)|\geqslant 4R]}$$
$$\times(\partial_{|u|}f_{z'})(u_{z'}(t))dt. \tag{4.10}$$

Inserting the bounds Eqs. (4.6) and (4.10) into Eq. (4.3), we get the following estimate for all $x \neq y$ and $\varphi \in \Omega$:

$$\begin{aligned}
&|w_{xy}(\varphi_x,\varphi_y) - w_{xy}((T^\zeta(\varphi))_x,(T^\zeta(\varphi))_y)| \\
&\quad\leqslant a_{xy}\epsilon_x|\varphi_x|\left(1 + \left\{1 + C_f + \frac{3}{2\epsilon_x}\delta_{yo} + \frac{\epsilon_y}{(1-\epsilon_y)\epsilon_x}\right\}\int_0^1 \mathbb{1}_{[|u_x(t)\geqslant 4R]}(\partial_{|u|}f_x)(u_x(t))dt\right) \\
&\qquad + a_{xy}\epsilon_y|\varphi_y|\left(1 + \left\{1 + C_f + \frac{3}{2\epsilon_y}\delta_{xo} + \frac{\epsilon_x}{(1-\epsilon_x)\epsilon_y}\right\}\int_0^1 \mathbb{1}_{[|u_y(t)\geqslant 4R]}(\partial_{|u|}f_y)(u_y(t))dt\right) \\
&\qquad + a_{xy}6R(\delta_{xo} + \delta_{yo}).
\end{aligned} \tag{4.11}$$

Observe that

$$|\varphi_x| \geqslant |u_x(t)| \geqslant 4R \text{ implies } T_x^\zeta(\varphi_x) = (1-\epsilon_x)\varphi_x, \tag{4.12}$$

and hence,

$$\begin{aligned}\epsilon_x|\varphi_x| \int_0^1 \mathbb{1}_{[|u_x(t)|\geqslant 4R]}(\partial_{|u|}f_x)(u_x(t))dt &\leqslant \mathbb{1}_{[|\varphi_x|\geqslant 4R]}\int_0^1 \epsilon_x|\varphi_x|(\partial_{|u|}f_x)(u_x(t))dt \\ &= \mathbb{1}_{[|\varphi_x|\geqslant 4R]}\int_0^1 \left(\frac{d}{dt}[f_x(u_x(t))]\right)dt = \mathbb{1}_{[|\varphi_x|\geqslant 4R]}(f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x))).\end{aligned} \tag{4.13}$$

As an application we get the bound, cf. Condition I.1 (iii) and Eq. (4.12),

$$\epsilon_x|\varphi_x| = \epsilon_x|\varphi_x|\mathbb{1}_{[|\varphi_z|<4R]} + \epsilon_x|\varphi_x|\mathbb{1}_{[|\varphi_x|\geqslant 4R]} \leqslant \epsilon_x 4R\mathbb{1}_{[|\varphi_x|<4R]} + c_f^{-1}\mathbb{1}_{[|\varphi_x|\geqslant 4R]}(f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x))). \tag{4.14}$$

Inserting Eqs. (4.13) and (4.14) into Eq. (4.11) we get, for $\varphi \in \Omega$,

$$\begin{aligned}|w_{xy}(\varphi_x,\varphi_y) - w_{xy}((T^\zeta(\varphi))_x,(T^\zeta(\varphi))_y)| \leqslant a_{xy}\Bigg[&\epsilon_x 4R + 6R\delta_{xo} + \left\{1 + c_f^{-1} + C_f + \frac{3}{2\epsilon_x}\delta_{yo} + \frac{\epsilon_y}{(1-\epsilon_y)\epsilon_x}\right\} \\ &\times \mathbb{1}_{[|\varphi_x|\geqslant 4R]}(f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x)))\Bigg] + a_{xy}\Bigg[\epsilon_y 4R + 6R\delta_{yo} \\ &+ \left\{1 + c_f^{-1} + C_f + \frac{3}{2\epsilon_y}\delta_{xo} + \frac{\epsilon_x}{(1-\epsilon_x)\epsilon_y}\right\} \\ &\times \mathbb{1}_{[|\varphi_y|\geqslant 4R]}(f_y(\varphi_y) - f_y(T_y^\zeta(\varphi_y)))\Bigg].\end{aligned}$$

We now recall Eqs. (1.1), (1.2), (1.4), and (3.5), before we sum up and obtain, for $\varphi \in \Omega$,

$$\begin{aligned}|W(\varphi) - W(T^\zeta(\varphi))| \leqslant 8\epsilon_o R C_a^0 C_\rho + 12RC_a + 2\sum_{x\in\Lambda}\Bigg\{ &C_a^0(1 + c_f^{-1} + C_f) + \tfrac{3}{2}C_a^\rho \epsilon_o^{-1} + \sum_{y\in\Lambda}\frac{a_{xy}\epsilon_y}{(1-\epsilon_o)\epsilon_x}\Bigg\} \\ &\times \mathbb{1}_{[|\varphi_x|\geqslant 4R]}(f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x))).\end{aligned} \tag{4.15}$$

The following bound is a consequence of Eq. (1.2) and the triangle inequality for ρ:

$$\sum_{y\in\Lambda}\frac{a_{xy}\epsilon_y}{(1-\epsilon_o)\epsilon_x} \leqslant \frac{C_a^\rho}{1-\epsilon_o}. \tag{4.16}$$

See also the proof of Ref. 1, Lemma 3.2.

From Eqs. (4.15) and (4.16) we conclude the lemma with the constants given in Eq. (4.2). □

V. ESTIMATING THE HAMILTONIAN

Lemma 5.1: Let $0 < \zeta \leqslant c_f R/2$, $|J| < \tilde{J}_0(\zeta)$, and

$$\sigma_T^\zeta := \min\{\zeta, 4\epsilon_o c_f R(1 - |J|C_W^2)\} - |J|C_W^1, \tag{5.1}$$

where

$$\tilde{J}_0(\zeta) := \min\left\{\frac{\zeta}{C_W^1}, \frac{4\epsilon_o c_f R}{C_W^1 + 4\epsilon_o c_f R C_W^2}\right\}. \tag{5.2}$$

Then, for all $\varphi \in \Omega$, with $\varphi_o \notin \mathcal{G}_{2\zeta}$, we have the bound

$$H_\Lambda(\varphi) - H_\Lambda(T^\zeta(\varphi)) \geqslant \sigma_T^\zeta. \tag{5.3}$$

Proof: We begin by analyzing the self-energy difference between φ and $T^\zeta(\varphi)$.

For $x \neq o$ we get by definition of T_x^ζ, cf. Eq. (3.7), and Condition 1.1 *(iii)* that $f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x)) \geqslant 0$. In particular we get

$$f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x)) \geqslant \mathbb{1}_{[|\varphi_x| \geqslant 4R]}(f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x))) \geqslant 0. \tag{5.4}$$

For $x=o$, we distinguish two cases. First consider $|\varphi_o| \geqslant 4R$. Here $|T_o^\zeta(\varphi_o)| = (1-\epsilon_o)|\varphi_o| \geqslant R$, and hence, by Condition 1.1 *(iii)*,

$$f_o(\varphi_o) - f_o(T_o^\zeta(\varphi_o)) \geqslant \epsilon_o c_f |\varphi_o| \geqslant 4\epsilon_o c_f R. \tag{5.5}$$

Second, consider the case $|\varphi_o| < 4R$ and $\varphi_o \notin \mathcal{G}_{2\zeta}$. Then $T_o^\zeta(\varphi_o) \in \mathcal{G}_\zeta$ and thus

$$f_o(\varphi_o) - f_o(T_o^\zeta(\varphi_o)) \geqslant \zeta. \tag{5.6}$$

Putting Eqs. (4.1) and (5.4)–(5.6) together, we obtain the desired lower bound on $H(\varphi) - H_\Lambda(T^\zeta(\varphi))$,

$$\begin{aligned} H_\Lambda(\varphi) - H_\Lambda(T^\zeta(\varphi)) &\geqslant \left[\sum_{x \neq o} \mathbb{1}_{[|\varphi_x| \geqslant 4R]}\{1 - |J|C_W^2\}(f_x(\varphi_x) - f_x(T_x^\zeta(\varphi_x)))\right] - |J|C_W^1 + \{\mathbb{1}_{[|\varphi_o| < 4R]} \\ &\quad + \mathbb{1}_{[|\varphi_o| \geqslant 4R]}(1 - |J|C_W^2)\}(f_o(\varphi_o) - f_o(T_o^\zeta(\varphi_o))) \\ &\geqslant \min\{\zeta, 4\epsilon_o c_f R(1 - |J|C_W^2)\} - |J|C_W^1, \end{aligned} \tag{5.7}$$

where we use $\varphi_o \notin \mathcal{G}_{2\zeta}$ and also $|J|C_W^2 < \tilde{J}_0(\zeta)C_W^2 \leqslant 1$. □

VI. LOCALIZATION

In this section we prove the main result, Theorem 1.1.

We begin separating into two regions

$$\begin{aligned} \mathbb{P}_\Lambda[\varphi_o \notin \mathcal{G}_{2\zeta}] &= \mathbb{P}_\Lambda[|\varphi_o| \geqslant 4R] + \mathbb{P}_\Lambda[\varphi_o \in B_{4R}(0) \setminus \mathcal{G}_{2\zeta}] \\ &= \mathcal{Z}_\Lambda^{-1}\left(\int_{\{|\varphi_o| \geqslant 4R\}} e^{-\beta H_\Lambda(\varphi)} d^\Lambda\varphi + \int_{\{\varphi_o \in B_{4R}(0) \setminus \mathcal{G}_{2\zeta}\}} e^{-\beta H_\Lambda(\varphi)} d^\Lambda\varphi\right). \end{aligned} \tag{6.1}$$

Let $\mathcal{A}_1 = \{|\varphi_o| \geqslant 4R\}$ and $\mathcal{A}_2 = \{\varphi_o \in B_{4R}(0) \setminus \mathcal{G}_{2\zeta}\}$. We estimate using Lemma 5.1, for $j=1,2$,

$$\begin{aligned} \int_{\mathcal{A}_j} e^{-\beta H_\Lambda(\varphi)} d^\Lambda\varphi &\leqslant \sup_{\varphi \in \mathcal{A}_j}\{e^{-\beta[H_\Lambda(\varphi) - H_\Lambda(T^\zeta(\varphi))]}\} \int_{\mathcal{A}_j} e^{-\beta H_\Lambda(T^\zeta(\varphi))} d^\Lambda\varphi \\ &= e^{-\beta \inf_{\varphi \in \mathcal{A}_j}[H_\Lambda(\varphi) - H_\Lambda(T^\zeta(\varphi))]} \int_{T^\zeta(\mathcal{A}_j)} e^{-\beta H_\Lambda(\psi)} \frac{d^\Lambda\psi}{|(\det \mathrm{Jac} T^\zeta)(T^{\zeta-1}(\psi))|} \\ &\leqslant \frac{e^{-\beta\sigma_T^\zeta}}{\inf_{\varphi \in \mathcal{A}_j}|(\det \mathrm{Jac} T^\zeta)(T^{\zeta-1}(\varphi))|} \mathcal{Z}_\Lambda, \end{aligned} \tag{6.2}$$

provided $|J| < \tilde{J}_0(\zeta)$ and $0 < \zeta \leqslant c_f R/2$. Inserting Eqs. (6.2) into (6.1), together with the estimate Eq. (3.9) on the determinant of the Jacobian of T^ζ, we get

$$\mathbb{P}_\Lambda[\varphi_o \notin \mathcal{G}_{2\zeta}] \leqslant \max\left\{\left[4R\zeta^{-1} \sup_{|u| \leqslant R_\zeta} |\nabla f_o(u)|\right]^n, (1-\epsilon_o)^{-n}\right\} \exp[n\epsilon_o(1 + \|\theta'\|_\infty)C_\rho] e^{-\beta\sigma_T^\zeta}. \tag{6.3}$$

Taking infimum over admissible θ's and ϵ_o's, yields the estimate with $\|\theta'\|_\infty$ replaced by 2 and ϵ_o replaced by 1/6 (see Eq. (3.6)). We have thus obtained the bound

$$\mathbb{P}_\Lambda[\varphi_o \notin \mathcal{G}_{2\zeta}] \leqslant 2\max\left\{\left[4R\zeta^{-1}\sup_{|u|\leqslant R_\zeta}|\nabla f_o(u)|\right]^n, \left(\tfrac{6}{5}\right)^n\right\} e^{(1/2)nC_\rho} e^{-\beta\sigma_T^\zeta}. \tag{6.4}$$

We recapitulate: The constants in Eqs. (4.2), (5.1), and (5.2), with $\|\theta'\|_\infty = 2$ and $\epsilon_o = 1/6$, become

$$C_W^1 = 4RC_a^0\left(\tfrac{1}{3}C_\rho + 3\right), \quad C_W^2 = \Gamma_0 + \tfrac{102}{5}C_a^\rho, \tag{6.5}$$

$$\tilde{J}_0(\zeta) = \min\left\{\frac{\zeta}{C_W^1}, \frac{\frac{2}{3}c_f R}{C_W^1 + \frac{2}{3}c_f R C_W^2}\right\}, \tag{6.6}$$

$$\sigma_T^\zeta = \min\left\{\zeta, \tfrac{2}{3}c_f R(1 - |J|C_W^2)\right\} - |J|C_W^1. \tag{6.7}$$

With these constants and for $|J| < \tilde{J}_0(\zeta)$, $0 < \zeta/2 \leqslant c_f R$, and $\beta > 0$ the localization bound Eq. (6.3) holds true.

We end by explaining how to derive the assertion of Theorem 1.1 from here. Note that $\Gamma_1 = C_W^1$ and $\Gamma_2 = C_W^2$. Comparing Eq. (6.6) to Eq. (1.8), we further notice that $\tilde{J}_0(c_f R/2) = J_0$ and that $\tilde{J}_0(\zeta) \leqslant J_0$, whenever $\zeta \leqslant c_f R/2$. By assumption, we have $|J| \leqslant \min\{J_0, \delta/(2\Gamma_1)\}$. We distinguish the cases $\delta \geqslant c_f R$ and $\delta < c_f R$.

If $\delta \geqslant c_f R$ then we choose $\zeta := c_f R/2$ and observe that $|J| \leqslant J_0 = \tilde{J}_0(\zeta)$. The claim now follows from Eq. (6.3), the trivial bound $\mathbb{P}_\Lambda[\varphi_o \notin \mathcal{G}_\delta] \leqslant \mathbb{P}_\Lambda[\varphi_o \notin \mathcal{G}_{c_f R}]$, and the fact that $\min\{\delta, 3\Gamma_3/2\} = \min\{\delta, c_f R\} = c_f R = 2\zeta$.

Conversely, if $\delta < c_f R$ then we choose $\zeta := \delta/2 < c_f R/2$. Since $\delta > 2|J|\Gamma_1$, also this choice insures that $|J| \leqslant \tilde{J}_0(\zeta)$, namely, $|J| < \zeta/(2\Gamma_1) \leqslant \tilde{J}_0(\zeta)$. Now the claim follows directly from Eq. (6.3) and $\min\{\delta, 3\Gamma_3/2\} = \min\{\delta, c_f R\} = \delta = 2\zeta$.

This completes the proof of Theorem 1.1. □

APPENDIX A. CONTROLLING THE INTERACTION

In this appendix we prove a basic bound on the interaction, which shows that it can be dominated by the self-energy. This is only used to ensure that polynomially bounded observables are integrable, and in particular that the partition function is finite.

Lemma A.1: Suppose Conditions 1.1 and 1.2. There exists a constant A, which may depend on Λ, such that for all $\varphi \in \Omega$,

$$\left|\sum_{x \neq y, x, y \in \Lambda} \omega_{xy}(\varphi_x, \varphi_y)\right| \leqslant A + 2C_a^0(1 + C_f + c_f^{-1})\sum_{x \in \Lambda} f_x(\varphi_x).$$

Proof: Let $u, v \neq 0$. In the following A_j, $j \in \{1,2,3\}$, denote non-negative constants, which contribute to the A in the lemma. We estimate using Conditions 1.1 and 1.2,

$$
\begin{aligned}
|w_{xy}(u,v)| &\leqslant A_1 + |w_{xy}(u,v) - w_{xy}(0,0)| \leqslant A_1 + \int_0^1 |u \cdot (\nabla_1 w_{xy})(tu,tv) + v \cdot (\nabla_2 w_{xy})(tu,tv)| dt \\
&\leqslant A_1 + a_{xy} \int_0^1 (|u| + |v|)[1 + \mathbb{1}_{[t|u| \geqslant 4R]} (\partial_{|u|} f_x)(tu) + \mathbb{1}_{[t|v| \geqslant 4R]} (\partial_{|v|} f_y)(tv)] dt \\
&\leqslant A_1 + a_{xy} \left\{ |u| + |v| + (1 + C_f) \int_0^1 [\mathbb{1}_{[t|u| \geqslant 4R]} |u| (\partial_{|u|} f_x)(tu) + \mathbb{1}_{[t|v| \geqslant 4R]} |v| (\partial_{|v|} f_y)(tv)] dt \right\} \\
&= A_1 + a_{xy} \left\{ |u| + |v| + (1 + C_f) \int_0^1 \left[\mathbb{1}_{[t|u| \geqslant 4R]} \frac{d}{dt} f_x(tu) + \mathbb{1}_{[t|v| \geqslant 4R]} \frac{d}{dt} f_y(tv) \right] dt \right\} \\
&= A_1 + a_{xy} \left\{ |u| + |v| + (1 + C_f) \left[\mathbb{1}_{[|u| \geqslant 4R]} \int_{\frac{4R}{|u|}}^1 \frac{d}{dt} f_x(tu) dt + \mathbb{1}_{[|v| \geqslant 4R]} \int_{\frac{4R}{|v|}}^1 \frac{d}{dt} f_y(tv) dt \right] \right\} \\
&\leqslant A_2 + a_{xy} \{ |u| + |v| + (1 + C_f)[f_x(u) + f_y(v)] \}.
\end{aligned}
$$

To conclude the proof we observe the following bound:

$$
|u| \leqslant A_3 + \mathbb{1}_{[|u| \geqslant R]} |u| \leqslant A_3 + c_f^{-1} \mathbb{1}_{[|u| \geqslant R]} f_x(u) \leqslant A_3 + c_f^{-1} f_x(u),
$$

and sum up, using Eq. (1.4). □

(Received 25 August 2006; accepted 5 October 2006; published online 29 December 2006)

We study the lengths of the cycles formed by trajectories in the Feynman-Kac representation of the Bose gas. We discuss the occurrence of infinite cycles and their relation to Bose-Einstein condensation. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2383008]

I. INTRODUCTION

Bose and Einstein understood 80 years ago that a curious phase transition occurs in a gas of noninteracting bosons; it is now commonly referred to as the Bose-Einstein condensation. Real particles interact, however, and for many years there were doubts that this transition takes place in natural systems. London suggested in 1938 that superfluid helium undergoes a Bose-Einstein condensation, and this idea is largely accepted nowadays. Bogoliubov considered interacting systems; careful approximations allowed him to get back to a noninteracting gas but with a different dispersion relation. See Refs. 16 and 8 for more discussion and partial justifications of the Bogoliubov theory.

In 1953 Feynman studied the system in the Feynman-Kac representation.[5] The partition function can be expanded as a gas of trajectories living in $(d+1)$ dimensions. The extra dimension is commonly referred to as "the time," although it is not related to physical time. The situation is illustrated in Fig. 1. A finite system with N particles induces a probability on the group S_N of permutations of N elements. Feynman considered the probability for a given particle to belong to a cycle of length n. In the thermodynamic limit, there may be strictly positive probability for infinite cycles to be present, and Feynman suggested to use this as an order parameter for Bose-Einstein condensation.

A few years later, in 1956, Penrose and Onsager introduced the concept of "off-diagonal long-range order."[9] Formally, it is a correlation between positions x and y given by $\sigma(x,y) = \langle c^\dagger(x)c(y)\rangle$. The system displays off-diagonal long-range order when this correlation is strictly positive, uniformly in the size of the system and in $|x-y|\to\infty$. One can write a Feynman-Kac version of this correlation, and it involves a special cycle starting at x and ending at y; this cycle may wind many times around the imaginary time direction. In the limit where x and y are infinitely distant there corresponds a notion of infinite open cycle that is reminiscent of Feynman's approach.

Feynman's order parameter is simpler; it is often used in numerical simulations or in order to gain heuristic understanding. On the other hand, everybody agrees that the Penrose and Onsager order parameter is the correct one. Surprisingly, the question of their equivalence is usually eluded, and many physicists implicitly assume equivalence to hold. The first mathematical investigation of this question is due to Sütő, who showed that equivalence holds in the ideal gas. Indeed, he proved that infinite cycles occur in the presence of condensation,[12] and that no infinite cycles occur in the absence of condensation;[13] the latter result uses probabilistic methods from the theory of large deviations. These results have been extended to mean-field systems in Refs. 1 and 3.

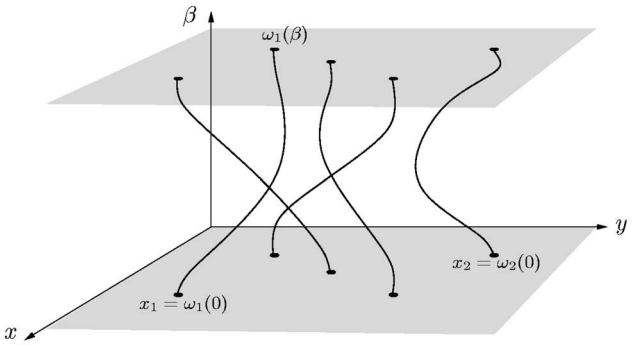

FIG. 1. The Feynman-Kac representation of the partition function for a gas of bosons. The horizontal plane represents the d spatial dimensions, and the vertical axis is the imaginary time dimension. The picture shows a situation with five particles and two cycles, of respective lengths 4 and 1.

In this paper we explore the links between Feynman cycles and off-diagonal long-range order. Let $\boldsymbol{\sigma}(x)$ denote the off-diagonal correlation between the origin and $x \in \mathbb{R}^d$, and $\boldsymbol{\varrho}(n)$ denote the density of particles in cycles of length n. We propose the following formula that relates both concepts:

$$\boldsymbol{\sigma}(x) = \sum_{n \geqslant 1} \boldsymbol{c}_n(x) \boldsymbol{\varrho}(n) + \boldsymbol{c}_\infty(x) \boldsymbol{\varrho}(\infty). \tag{1.1}$$

Mathematically, the problem is not well posed. Many choices for the coefficients $\boldsymbol{c}_n$ are possible—a trivial choice is $\boldsymbol{c}_n(x) = \boldsymbol{\sigma}(x)/\rho$ for all n, including $n=\infty$. We will see, however, that there is a natural definition for $\boldsymbol{c}_n(x)$ in terms of Wiener trajectories. In any case, we conjecture that Eq. (1.1) holds with coefficients satisfying

$$0 \leqslant \boldsymbol{c}_n(x) \leqslant 1, \quad 0 \leqslant \boldsymbol{c}_\infty(x) \leqslant 1,$$

for all n, x. In addition, we should have

$$\lim_{n \to \infty} \boldsymbol{c}_n(x) = \boldsymbol{c}_\infty(x)$$

for any x, and

$$\lim_{|x| \to \infty} \boldsymbol{c}_n(x) = 0$$

for any finite n, but not uniformly in n; $\boldsymbol{c}_\infty(x)$ may converge to a strictly positive constant $\boldsymbol{c}$. If $\boldsymbol{c}=1$, we get from the dominated convergence theorem that $\lim_{|x| \to \infty} \boldsymbol{\sigma}(x) = \boldsymbol{\varrho}(\infty)$—in which case the off-diagonal long-range order parameter is equal to the density of cycles of infinite lengths.

We establish this formula and these properties in the case of the ideal gas, where we show that

$$\boldsymbol{c}_n(x) = \mathrm{e}^{-x^2/4n\beta}, \quad \boldsymbol{c}_\infty(x) = 1. \tag{1.2}$$

We discuss the validity of formula (1.1) in the interacting gas, proving that these properties hold true in a regime without the Bose-Einstein condensation. The two order parameters should not be always equivalent, however. It is argued in Ref. 15 that they differ when the bosons undergo a regular condensation into a crystalline phase. There is no off-diagonal long-range order, but infinite cycles may be present.

We work in the Feynman-Kac representation of the Bose gas. This representation is standard, see, e.g., Ref. 4 for a clear and concise review and Ref. 6 for a complete introduction. We assume the reader to possess some familiarity with it and in Sec. II we directly define the main

expressions—partition functions, density of cycles, and off-diagonal long-range order—in terms of space-time trajectories. But basic notions and properties are reviewed in Appendix A.

The situation simplifies in the absence of interactions; we consider the ideal gas in Sec. III, where we state and prove the formula that relates the two order parameters. The ideal gas is best discussed in the canonical ensemble. Rigorous proofs of macroscopic occupation of the zero mode have been proposed and they involve the grand-canonical ensemble, with a chemical potential that depends on the volume. Appendix B proposes a simple proof in the canonical ensemble.

Interacting systems constitute a formidable challenge; they are discussed in Sec. IV, where partial results are obtained.

In this paper, we denote finite volume expressions in plain characters, and infinite volume expressions in bold characters. Further, we always consider the canonical and grand-canonical ensembles where the temperature $1/\beta$ is fixed; we alleviate the notation by omitting the β dependence of all quantities.

II. FEYNMAN CYCLES AND OFF-DIAGONAL LONG-RANGE ORDER

A. Partition functions

Our Bose gas occupies a d-dimensional domain D, always a cubic box of size L and volume $V=L^d$. We consider periodic boundary conditions. Let ρ denote the particle density, β the inverse temperature, and μ the chemical potential. The canonical partition function in the Feynman-Kac representation is given by

$$Y(N)=\sum_{k=1}^{N}\frac{1}{k!}\sum_{\substack{n_1,\ldots,n_k\geqslant 1\\ n_1+\cdots+n_k=N}}\int_{D^k}\mathrm{d}x_1\cdots\mathrm{d}x_k\int \mathrm{d}W^{n_1\beta}_{x_1x_1}(\omega_1)\cdots\mathrm{d}W^{n_k\beta}_{x_kx_k}(\omega_k)$$
$$\times\left[\prod_{j=1}^{k}\frac{1}{n_j}\mathrm{e}^{-\beta\mathcal{U}(\omega_j)}\right]\prod_{1\leqslant i<j\leqslant k}\mathrm{e}^{-\beta\mathcal{U}(\omega_i,\omega_j)}. \tag{2.1}$$

This expression is illustrated in Fig. 1. In words, we sum over the number k of closed trajectories and over their respective winding numbers $n_1,\ldots,n_k$. We integrate over the initial positions $x_1,\ldots,x_k$. We integrate over trajectories $\omega_j:[0,n_j\beta]\to D$ that start and end at x_j; here, W^{β}_{xx} denotes the Wiener measure. See Appendix A for more information and, in particular, Eq. (A10) for the normalization condition. Trajectories wind around the time direction according to their winding numbers; because of periodic boundary conditions, they may also wind around space directions.

Given a trajectory ω with winding number n, the function $\mathcal{U}(\omega)$ denotes the interactions between different legs; explicitly,

$$\mathcal{U}(\omega)=\sum_{0\leqslant i<j\leqslant n-1}\frac{1}{\beta}\int_0^{\beta}U(\omega(i\beta+s)-\omega(j\beta+s))\mathrm{d}s. \tag{2.2}$$

And $\mathcal{U}(\omega,\omega')$ denotes the interactions between closed trajectories ω and ω', of respective winding numbers n and n',

$$\mathcal{U}(\omega,\omega')=\sum_{\substack{0\leqslant i\leqslant n-1\\ 0\leqslant j\leqslant n'-1}}\frac{1}{\beta}\int_0^{\beta}U(\omega(i\beta+s)-\omega'(j\beta+s))\mathrm{d}s. \tag{2.3}$$

The function $U(x)$ represents the pair interaction potential between two particles separated by a distance $|x|$. We suppose that $U(x)$ is non-negative and spherically symmetric. We can allow the value $+\infty$; all that is needed is that $\mathrm{e}^{-\beta\mathcal{U}(\omega)}$ and $\mathrm{e}^{-\beta\mathcal{U}(\omega,\omega')}$ be measurable functions with respect to the Wiener measure—any piecewise continuous function $D\to[0,\infty]$ can be considered at this point.

The grand-canonical partition function is

$$Z(\mu) = \sum_{N \geqslant 0} \mathrm{e}^{\beta\mu N} Y(N) \tag{2.4}$$

[with the understanding that $Y(0)=1$]. We also need partition functions where a given trajectory ω_0 is present—these will be needed in the expression for cycle densities, see Eqs. (2.8) and (2.9). Namely, we define

$$Y(N;\omega_0) = \sum_{k=1}^{N} \frac{1}{k!} \sum_{\substack{n_1,\dots,n_k \geqslant 1 \\ n_1+\cdots+n_k=N}} \int_{D^k} \mathrm{d}x_1 \cdots \mathrm{d}x_k \int \mathrm{d}W^{n_1\beta}_{x_1x_1}(\omega_1) \cdots \mathrm{d}W^{n_k\beta}_{x_kx_k}(\omega_k) \\ \times \left[\prod_{j=1}^{k} \frac{1}{n_j} \mathrm{e}^{-\beta \mathcal{U}(\omega_j)} \right] \prod_{0 \leqslant i < j \leqslant k} \mathrm{e}^{-\beta \mathcal{U}(\omega_i,\omega_j)}. \tag{2.5}$$

The dependence on ω_0 comes from the last term, where the product includes terms with $i=0$. Notice that

$$Y(N;\omega) \leqslant Y(N), \tag{2.6}$$

with equality if and only if $U(x) \equiv 0$, i.e., in the absence of interactions. Finally, we introduce

$$Z(\mu,\omega) = \sum_{N \geqslant 0} \mathrm{e}^{\beta\mu N} Y(N,\omega) \tag{2.7}$$

[we set $Y(0,\omega_0)=1$]. We also have $Z(\mu,\omega) \leqslant Z(\mu)$, with equality if and only if $U(x) \equiv 0$.

B. Cycle lengths

We now introduce the density of particles in cycles of length n, both in the canonical and grand-canonical ensembles. We denote the particle density by $\rho = N/V$. When discussing the canonical ensemble, we always suppose that ρ and V are such that $N=\rho V$ is an integer. The number of particles in cycles of length n is given by the random variable $\sum_{j=1}^{k} n\delta_{n_j,n}$. Averaging over all configurations of space-time closed trajectories, we get

$$\varrho_\rho(n) = \frac{1}{Y(N)} \sum_{k=1}^{N} \frac{1}{k!} \sum_{\substack{n_1,\dots,n_k \geqslant 1 \\ n_1+\cdots+n_k=N}} \left[\frac{1}{V} \sum_{j=1}^{k} n\delta_{n_j,n} \right] \int_{D^k} \mathrm{d}x_1 \cdots \mathrm{d}x_k \times \int \mathrm{d}W^{n_1\beta}_{x_1x_1}(\omega_1) \cdots \mathrm{d}W^{n_k\beta}_{x_kx_k}(\omega_k) \\ \times \left[\prod_{j=1}^{k} \frac{1}{n_j} \mathrm{e}^{-\beta \mathcal{U}(\omega_j)} \right] \prod_{1 \leqslant i < j \leqslant k} \mathrm{e}^{-\beta \mathcal{U}(\omega_i,\omega_j)} = \int \mathrm{d}W^{n\beta}_{00}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Y(N-n;\omega)}{Y(N)}. \tag{2.8}$$

The last line follows from the first line by replacing $\sum_{j=1}^{k} n\delta_{n_j,n}$ with $nk\delta_{n_1,n}$, isolating the integral over ω_1, using definition (2.5), using translation invariance, and $\int_D \mathrm{d}x_1 = V$. Similarly, we have the grand-canonical expression

$$\varrho_\mu(n) = \mathrm{e}^{\beta\mu n} \int \mathrm{d}W^{n\beta}_{00}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Z(\mu;\omega)}{Z(\mu)}. \tag{2.9}$$

One easily checks that

$$\sum_{n \geqslant 1} \varrho_\rho(n) = \frac{N}{V} \equiv \rho,$$

$$\sum_{n\geqslant 1} \varrho_\mu(n) = \left\langle \frac{N}{V} \right\rangle \equiv \rho(\mu).$$

We consider the thermodynamic limits of $\varrho_\rho(n)$ and $\varrho_\mu(n)$. Since $0 \leqslant \varrho_\rho(n) \leqslant \rho$ and since n is a discrete index, the Cantor diagonal process yields the existence of a sequence of increasing volumes V_k, with $\rho V_k = N_k$ an integer, such that $\varrho_\rho(n)$ converges to some limit that we denote $\boldsymbol{\varrho}_\rho(n)$. Similarly, we also obtain the infinite volume limit $\boldsymbol{\varrho}_\mu(n)$. Fatou's lemma implies that

$$\sum_{n\geqslant 1} \boldsymbol{\varrho}_\rho(n) \leqslant \rho, \quad \sum_{n\geqslant 1} \boldsymbol{\varrho}_\mu(n) \leqslant \boldsymbol{\rho}(\mu). \tag{2.10}$$

This suggests to define the density of particles in infinite cycles by

$$\boldsymbol{\varrho}_\rho(\infty) = \rho - \sum_{n\geqslant 1} \boldsymbol{\varrho}_\rho(n),$$

$$\boldsymbol{\varrho}_\mu(\infty) = \boldsymbol{\rho}(\mu) - \sum_{n\geqslant 1} \boldsymbol{\varrho}_\mu(n). \tag{2.11}$$

The main question is whether $\boldsymbol{\varrho}(\infty)$ differs from zero at a given temperature and at a given density or chemical potential.

We chose to discuss densities of particles in cycles of given length, but one may consider probabilities as well. Namely, we could introduce the probability for particle 1 to belong to a cycle of length n; it is given by

$$P_\rho(n) = \int_D \mathrm{d}x \int \mathrm{d}W_{xx}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Y(N-n;\omega)}{NY(N)}. \tag{2.12}$$

Thus $\varrho_\rho(n) = \rho P_\rho(n)$ in the canonical ensemble, and $\boldsymbol{\varrho}_\rho(\infty) = \rho \boldsymbol{P}_\rho(\infty)$. Things are not so simple in the grand-canonical ensemble. The probability $P_\mu(n)$ is

$$P_\mu(n) = \int_D \mathrm{d}x \int \mathrm{d}W_{xx}^{n\beta}(\omega) \frac{\mathrm{e}^{\beta\mu n}}{n} \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Z'(\mu;\omega)}{Z(\mu)}. \tag{2.13}$$

Here, $Z'(\mu;\omega)$ is like $Z(\mu;\omega)$ given in Eqs. (2.5) and (2.7), but with a factor $1/(k+1)!$ instead of $1/k!$. Heuristically, we should have $\langle V/nk \rangle = 1/\rho(\mu)$ and $\varrho_\mu(n) = \rho(\mu) P_\mu(n)$, but this does not seem easy to establish. The ratio of partition functions in Eq. (2.13) is more difficult to control than the one in Eq. (2.9). We therefore abandon probabilities and discuss densities.

C. Off-diagonal long-range order

Let us turn to the Penrose and Onsager off-diagonal long-range order. Its Feynman-Kac representation involves an open trajectory that starts at x and ends at y, that possibly winds several times around the time direction. Precisely, we introduce

$$\sigma_\rho(x) = \sum_{n=1}^{N} \int \mathrm{d}W_{0x}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Y(N-n;\omega)}{Y(N)},$$

$$\sigma_\mu(x) = \sum_{n\geqslant 1} \mathrm{e}^{\beta\mu n} \int \mathrm{d}W_{0x}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Z(\mu;\omega)}{Z(\mu)}. \tag{2.14}$$

Thermodynamic limits are denoted $\boldsymbol{\sigma}_\rho(x)$ and $\boldsymbol{\sigma}_\mu(x)$, provided they exist. One may actually restrict $\sigma_\rho(x)$ and $\sigma_\mu(x)$ on rational x and use the Cantor diagonal process to get convergence on a

subsequence of increasing volumes. This is not necessary in this paper, as the limits will be shown to exist in the regimes of parameters under consideration.

Similarities between Eqs. (2.8) and (2.9) on the one hand and Eqs. (2.14) on the other hand are manifested. We can write

$$\sigma_\rho(x) = \sum_{n=1}^{N} c_{n,\rho}(x) \varrho_\rho(n),$$

$$\sigma_\mu(x) = \sum_{n\geqslant 1} c_{n,\mu}(x) \varrho_\mu(n), \tag{2.15}$$

where the coefficients $c_{n,\rho}$, $c_{n,\mu}$ are given by

$$c_{n,\rho}(x) = \left[\int \mathrm{d}W_{00}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Y(N-n;\omega)}{Y(N)} \right]^{-1} \int \mathrm{d}W_{0x}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Y(N-n;\omega)}{Y(N)},$$

$$c_{n,\mu}(x) = \left[\int \mathrm{d}W_{00}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Z(\mu;\omega)}{Z(\mu)} \right]^{-1} \int \mathrm{d}W_{0x}^{n\beta}(\omega) \mathrm{e}^{-\beta \mathcal{U}(\omega)} \frac{Z(\mu;\omega)}{Z(\mu)}. \tag{2.16}$$

As above, we denote the thermodynamic limits by $\boldsymbol{c}_{n,\rho}(x)$ and $\boldsymbol{c}_{n,\mu}(x)$, provided they exist. One should be careful when sending the volume to infinity in Eqs. (2.15), because a "leak to infinity" may yield a term involving $\boldsymbol{\varrho}(\infty)$—this actually occurs in the ideal gas, as will be shown in the next section.

III. THE IDEAL GAS

The ideal gas of quantum bosons is fascinating. Particles do not interact, yet they manage to display a phase transition. Historically, the Bose-Einstein condensation is the first theoretical description of a phase transition. The ideal gas has been the object of many studies over the years; let us mention Refs. 17, 7, and 10. A simple proof of macroscopic occupation of the zero Fourier mode is presented in Appendix B.

In this section we elucidate the relation between cycle lengths and off-diagonal long-range order, thus clarifying results that were previously obtained by Sütő.[12,13] We work in the canonical ensemble and establish formula (1.1) explicitly, for any dimension $d \geqslant 1$.

Theorem 1: *For any $0<\beta$, $\rho<\infty$, there exists a sequence of increasing cubes for which the thermodynamic limits of $\sigma_\rho(x)$, $c_{n,\rho}(x)$, and $\varrho_\rho(n)$ exist for all $x \in \mathbb{R}^d$ and $n \in \mathbb{N}$. Further, we have*

$$\boldsymbol{\sigma}_\rho(x) = \sum_{n\geqslant 1} \mathrm{e}^{-x^2/4n\beta} \boldsymbol{\varrho}_\rho(n) + \boldsymbol{\varrho}_\rho(\infty).$$

The rest of this section is devoted to the proof of Theorem 1. The coefficient $c_{n,\rho}(x)$, defined in Eq. (2.16), has a simpler expression in the absence of interactions. Indeed, we have $\mathcal{U}(\omega)=0$ and $Y(N;\omega)=Y(N)$. It follows from properties of the Wiener measure in periodic boxes, see Eq. (A10), that

$$c_{n,\rho}(x) = \sum_{z\in\mathbb{Z}^d} \mathrm{e}^{-(L^2/4n\beta)((x/L)-z)^2} \Big/ \sum_{z\in\mathbb{Z}^d} \mathrm{e}^{-(L^2/4n\beta)z^2}. \tag{3.1}$$

Notice that $\lim_{L\to\infty} c_{n,\rho}(x) = \mathrm{e}^{-x^2/4n\beta}$, but the limit is not uniform in n. If the sum over n is restricted to $n \leqslant cL^2$, with c any finite constant, we can use the dominated convergence theorem and we get

$$\lim_{L\to\infty} \sum_{n=1}^{cL^2} c_{n,\rho}(x)\varrho_\rho(n) = \sum_{n\geqslant 1} \mathrm{e}^{-x^2/4n\beta}\boldsymbol{\varrho}_\rho(n). \tag{3.2}$$

[The limit is taken along the subsequence of increasing volumes for which $\varrho_\rho(n)$ is known to converge for any n.]

We now consider the terms with $cL^2 < n \leqslant N$. We estimate the sums in Eq. (3.1) using integrals; we have

$$\int_{-\infty}^{\infty} \mathrm{e}^{-a(s-b)^2}\mathrm{d}s - 1 \leqslant \sum_{k\in\mathbb{Z}} \mathrm{e}^{-a(k-b)^2} \leqslant \int_{-\infty}^{\infty} \mathrm{e}^{-a(s-b)^2}\mathrm{d}s + 1. \tag{3.3}$$

The Gaussian integral is equal to $\sqrt{\pi/a}$. Consequently,

$$\left[\frac{\sqrt{4\pi n\beta}-L}{\sqrt{4\pi n\beta}+L}\right]^d \leqslant c_{n,\rho}(x) \leqslant \left[\frac{\sqrt{4\pi n\beta}+L}{\sqrt{4\pi n\beta}-L}\right]^d. \tag{3.4}$$

These bounds hold provided $\sqrt{4\pi n\beta} > L$. Since $n/L^2 > c$, we have

$$\left[\frac{\sqrt{4\pi c\beta}-1}{\sqrt{4\pi c\beta}+1}\right]^d \sum_{n=cL^2}^{N} \varrho_\rho(n) \leqslant \sum_{n=cL^2}^{N} c_{n,\rho}(x)\varrho_\rho(n) \leqslant \left[\frac{\sqrt{4\pi c\beta}+1}{\sqrt{4\pi c\beta}-1}\right]^d \sum_{n=cL^2}^{N} \varrho_\rho(n). \tag{3.5}$$

We obtain

$$\sum_{n=cL^2}^{N} c_{n,\rho}(x)\varrho_\rho(n) \leqslant \left[\frac{\sqrt{4\pi c\beta}+1}{\sqrt{4\pi c\beta}-1}\right]^d \left(\rho - \sum_{n=1}^{cL^2} \varrho_\rho(n)\right). \tag{3.6}$$

Using Eq. (3.2) with $x=0$ and definition (2.11) of the density of infinite cycles, we see that the last term converges to $\boldsymbol{\varrho}_\rho(\infty)$ as $L\to\infty$. It then follows from Eqs. (3.2) and (3.6) that

$$\limsup_{L\to\infty} \sigma_\rho(x) \leqslant \sum_{n\geqslant 1} \mathrm{e}^{-x^2/4n\beta}\boldsymbol{\varrho}_\rho(n) + \left[\frac{\sqrt{4\pi c\beta}+1}{\sqrt{4\pi c\beta}-1}\right]^d \boldsymbol{\varrho}_\rho(\infty). \tag{3.7}$$

This inequality holds for any c, and the fraction is arbitrarily close to 1 by taking c large. A lower bound can be derived in a similar fashion, and we obtain the formula stated in Theorem 1.

IV. THE INTERACTING GAS

The interacting gas is much more difficult to study. We prove in this section the absence of infinite cycles when the chemical potential is negative (Theorem 2). We then study the coefficients $c_{n,\mu}(x)$ at low density and high temperature, using cluster expansion techniques. Their thermodynamic limit can be established, and we show that $\boldsymbol{c}_{n,\mu}(x)\to 0$ as $|x|\to\infty$ (Theorem 3).

Theorem 2: *Let* $0<\beta<\infty$ and $\mu<0$; *then*

$$\boldsymbol{\varrho}_\mu(\infty) = 0,$$

and

$$\lim_{|x|\to\infty} \limsup_{L\to\infty} \sigma_\mu(x) = 0.$$

Proof: Since $\mathcal{U}(\omega)\geqslant 0$ and $Z(\mu;\omega)\leqslant Z(\mu)$, the finite volume density $\varrho_\mu(n)$, Eq. (2.9), is less than

$$\varrho_\mu(n) \leqslant \mathrm{e}^{\beta\mu n} \int \mathrm{d}W_{00}^{n\beta}(\omega) = \frac{\mathrm{e}^{\beta\mu n}}{(4\pi n\beta)^{d/2}} \sum_{z\in\mathbb{Z}^d} \mathrm{e}^{-L^2 z^2/4n\beta}. \tag{4.1}$$

The right side is smaller than $\mathrm{e}^{\beta\mu n}$ for all L large enough. We can therefore apply the dominated convergence theorem and we obtain

$$\rho = \lim_{L\to\infty} \sum_{n\geqslant 1} \varrho_\mu(n) = \sum_{n\geqslant 1} \boldsymbol{\varrho}_\mu(n). \tag{4.2}$$

It follows that $\boldsymbol{\varrho}_\rho(\infty)=0$. The statement about the absence of off-diagonal long-range order can be treated similarly. We have the upper bound

$$\sigma_\mu(x) \leqslant \sum_{n\geqslant 1} \frac{\mathrm{e}^{\beta\mu n}}{(4\pi n\beta)^{d/2}} \sum_{z\in\mathbb{Z}^d} \mathrm{e}^{-(x-Lz)^2/4n\beta}. \tag{4.3}$$

By dominated convergence,

$$\limsup_{L\to\infty} \sigma_\mu(x) \leqslant \sum_{n\geqslant 1} \frac{\mathrm{e}^{\beta\mu n}}{(4\pi n\beta)^{d/2}} \mathrm{e}^{-x^2/4n\beta}. \tag{4.4}$$

We can again use the dominated convergence theorem for the limit $|x|\to\infty$, and we get the claim. □

We continue the study of the interacting gas in the regime where cluster expansion converges. We assume that the chemical potential is negative, that the interaction potential $U(x)$ is integrable, and that the temperature is high enough. The condition in Theorem 3 is stronger than necessary, but it is very explicit. We will invoke a weaker condition in the proof of the theorem that is based on the "Kotecký-Preiss criterion" for the convergence of cluster expansion. Notice that Ginibre's survey[6] uses Kirkwood-Salzburg equations; it applies to a broader range of potentials, but things are terribly intricate.

Theorem 3: *Assume that β, μ, and U satisfy*

$$\frac{1}{(4\pi\beta)^{d/2}} \int_{\mathbb{R}^d} U(x)\mathrm{d}x \sum_{n\geqslant 1} n^{-d/2} \leqslant -\mu.$$

The thermodynamic limits of $c_{n,\mu}(x)$ and $\varrho_\mu(n)$ exist, and we have

$$\lim_{|x|\to\infty} \boldsymbol{c}_{n,\mu}(x) = 0$$

for any n.

Proof: We need some notation in order to cast the grand-canonical partition function in a form suitable for the cluster expansion. Let us introduce a measure for trajectories that wind arbitrarily many times around the time direction. Namely, let $\mathcal{X}_n$ denote the measure space of continuous trajectories $\omega:[0,n\beta]\to D$, and let $\mathcal{X}=\cup_{n\geqslant 1}\mathcal{X}_n$ be the set of trajectories in D with arbitrary winding numbers. We introduce the measure ν on $\mathcal{X}$ whose integral means the following:

$$\int F(\omega)\mathrm{d}\nu(\omega) = \sum_{n\geqslant 1} \frac{\mathrm{e}^{\beta\mu n}}{n} \int_D \mathrm{d}x \int \mathrm{d}W_{xx}^{n\beta}(\omega) \mathrm{e}^{-\beta\mathcal{U}(\omega)} F(\omega). \tag{4.5}$$

It is clear that ν is a genuine measure on a reasonable measure space. But we describe the measure ν with more details for readers who are interested in analytic technicalities. The σ algebra on $\mathcal{X}_n$ is the smallest σ algebra that contains the sets $\{\omega\in\mathcal{X}_n : \omega(t)\in B\}$, for any $0\leqslant t\leqslant n\beta$, and any Borel set $B\subset D$. Trajectories of $\mathcal{X}_1$ can be dilated in the time direction so as to yield trajec-

tories with arbitrary winding numbers. One can then consider the product space $\mathcal{X}_1 \times \mathbb{N}$ with the product σ algebra (the σ algebra on $\mathbb{N}$ being the power set). The measure of a set of the kind $A \times \{n\}$, with A a measurable subset of $\mathcal{X}_1$, is defined as

$$\nu(A \times \{n\}) = \frac{e^{\beta\mu n}}{n} \int dx \int_{A'} dW_{xx}^{n\beta}(\omega') e^{-\beta \mathcal{U}(\omega')}. \tag{4.6}$$

Here, we introduced

$$A' = \{\omega' \in \mathcal{X}_n : \omega'(t) = \omega(nt) \quad \text{for some } \omega \in A\}. \tag{4.7}$$

There is a unique extension to a measure on $\mathcal{X}_1 \times \mathbb{N}$. There is a natural correspondence between $\mathcal{X}$ and $\mathcal{X}_1 \times \mathbb{N}$, and we consider ν to be a measure on $\mathcal{X}$.

With this notation, the grand-canonical partition function (2.4) is given by

$$Z(\mu) = \sum_{k \geqslant 0} \frac{1}{k!} \int_{\mathcal{X}^k} d\nu(\omega_1) \cdots d\nu(\omega_k) \prod_{1 \leqslant i < j \leqslant k} [e^{-\beta \mathcal{U}(\omega_i, \omega_j)} - 1]. \tag{4.8}$$

The term $k=0$ is equal to 1 by definition. Then $Z(\mu)$ has exactly the form assumed, e.g., in Ref. 14. The Kotecký-Preiss criterion for the convergence of the cluster expansion requires the existence of a function $a : \mathcal{X} \to \mathbb{R}_+$ such that the following inequality holds for any $\omega \in \mathcal{X}$:

$$\int_{\mathcal{X}} [1 - e^{-\beta \mathcal{U}(\omega, \omega')}] e^{a(\omega')} d\nu(\omega') \leqslant a(\omega). \tag{4.9}$$

Choosing $a(\omega) = -\beta\mu n$ (with n the winding number of the trajectory ω), it was shown in Ref. 14 that Eq. (4.9) is a consequence of the condition in Theorem 3.

The main result of the cluster expansion is that the partition function (4.8) is given by the exponential of a convergent series. Namely,

$$Z(\mu) = \exp\left\{ \sum_{k \geqslant 1} \int_{\mathcal{X}^k} d\nu(\omega_1) \cdots d\nu(\omega_k) \varphi(\omega_1, \ldots, \omega_k) \right\}. \tag{4.10}$$

The combinatorial function $\varphi(\omega_1, \ldots, \omega_k)$ is equal to 1 if $k=1$, and is otherwise equal to

$$\varphi(\omega_1, \ldots, \omega_k) = \frac{1}{k!} \sum_{G} \prod_{(i,j) \in G} [e^{-\beta \mathcal{U}(\omega_i, \omega_j)} - 1]. \tag{4.11}$$

The sum is over *connected* graphs with k vertices, and the product is over edges of G. A proof for relation (4.10) that directly applies here can be found in Ref. 14.

Observe now that the partition function $Z(\mu; \omega)$ is given by an expression similar to Eq. (4.8), where each $\nu(\omega_j)$ is replaced by $e^{-\beta \mathcal{U}(\omega, \omega_j)} \nu(\omega_j)$. Since $\mathcal{U}(\omega, \omega_j)$ is positive, the criterion (4.9) is satisfied with this new measure. It follows that $Z(\mu; \omega)$ has an expansion similar to Eq. (4.10), and we obtain the following expression for the ratio of partition functions:

$$\frac{Z(\mu; \omega)}{Z(\mu)} = \exp\left\{ - \sum_{k \geqslant 1} \int_{\mathcal{X}^k} d\nu(\omega_1) \cdots d\nu(\omega_k) \left[1 - \prod_{j=1}^{k} e^{-\beta \mathcal{U}(\omega, \omega_j)} \right] \varphi(\omega_1, \ldots, \omega_k) \right\}. \tag{4.12}$$

It is not hard to check that

$$1 - \prod_{j=1}^{k} e^{-\beta \mathcal{U}(\omega, \omega_j)} = \sum_{j=1}^{k} (1 - e^{-\beta \mathcal{U}(\omega, \omega_j)}) \prod_{i=1}^{j-1} e^{-\beta \mathcal{U}(\omega, \omega_i)} \leqslant \sum_{j=1}^{k} (1 - e^{-\beta \mathcal{U}(\omega, \omega_j)}). \tag{4.13}$$

Then Eq. (5) in Ref. 14 gives the necessary estimate for the exponent in Eq. (4.12), namely,

$$\sum_{k\geqslant 1} \int_{\mathcal{X}^k} \mathrm{d}\nu(\omega_1)\cdots\mathrm{d}\nu(\omega_k) \left[\sum_{j=1}^{k} (1-\mathrm{e}^{-\beta\mathcal{U}(\omega,\omega_j)}) \right] |\varphi(\omega_1,\ldots,\omega_k)| \leqslant -\beta\mu n. \tag{4.14}$$

This bound is uniform in the size of the domain, which is important. It follows that, as $L\to\infty$, the ratio $Z(\mu;\omega)/Z(\mu)$ converges pointwise in μ and ω. The thermodynamic limits of $c_{n,\mu}(x)$ and $\varrho_\mu(n)$ then clearly exist. Further, $c_{n,\mu}(x)$ is bounded by

$$c_{n,\mu}(x) \leqslant \left[\int \mathrm{d}W_{00}^{n\beta}(\omega)\mathrm{e}^{-\beta\mathcal{U}(\omega)} \right]^{-1} \mathrm{e}^{-2\beta\mu n} \int \mathrm{d}W_{0x}^{n\beta}(\omega). \tag{4.15}$$

It is not hard to show that the bracket is bounded away from zero uniformly in L (but not uniformly in β and n). From Eq. (A10), we have

$$\lim_{|x|\to\infty} \lim_{L\to\infty} \int \mathrm{d}W_{0x}^{n\beta}(\omega) = 0.$$

This implies that $\boldsymbol{c}_{n,\mu}(x)$ vanishes in the limit of infinite $|x|$.

V. CONCLUSION

We introduced formula (1.1) that relates the off-diagonal correlation function and the densities of cycles of given length. This formula involves coefficients $\boldsymbol{c}_n$ that have a natural definition in terms of integrals of Wiener trajectories. We conjectured several properties for the coefficients—these properties can actually be proven in the ideal gas for all temperatures and in the interacting gas for high temperatures. These results seem to indicate that the order parameters of Feynman and Penrose and Onsager agree. However, heuristic considerations based on the present framework[15] suggest that, if the gas is in a crystalline phase, the coefficients satisfy $\boldsymbol{c}_n(x) \leqslant \mathrm{e}^{-a|x|}$ for some $a>0$ and for all n (including $n=\infty$). Besides, one expects that $\varrho(\infty)>0$ if the temperature is sufficiently low. The order parameters are not equivalent in this case.

An open problem is to establish the equivalence of the order parameters in weakly interacting gases in the presence of the Bose-Einstein condensation. Another question is whether $\boldsymbol{c}_\infty(x)$ converges, as $|x|\to\infty$, to a number that is strictly between 0 and 1. The corresponding phase would display a Bose condensate whose density is less than the density of particles in infinite cycles.

ACKNOWLEDGMENTS

It is a pleasure to thank Valentin Zagrebnov and Joe Pulé for encouragements and for pointing out an error with thermodynamic potentials in the original version of the manuscript. This research was supported in part by Grant No. DMS-0601075 from the U.S. National Science Foundation.

APPENDIX A: FEYNMAN-KAC REPRESENTATION OF THE BOSE GAS

In this appendix we recall some properties of the Wiener measure, and we review the derivation of the Feynman-Kac representation of the partition functions and of the off-diagonal long-range order parameter. A complete account can be found in the excellent notes of Ginibre;[6] Faris wrote a useful survey.[4]

Let D be the d-dimensional cubic box of size L and volume $V=L^d$. We work with periodic boundary conditions, meaning that D is the d-dimensional torus $\mathbb{T}_L^d$. The state space is the Hilbert space $\mathcal{H}_{D,N}$ of square-summable complex functions on D^N that are symmetric with respect to their arguments. Let S denote the symmetric projector on $L^2(D^N)$, i.e.,

$$S\psi(x_1,\ldots,x_N) = \frac{1}{N!}\sum_{\pi\in S_N} \psi(x_{\pi(1)},\ldots,x_{\pi(N)}), \tag{A1}$$

where $x_1,\ldots,x_N\in D$ and the sum is over all permutations of N elements. The state space for N bosons in D is therefore $\mathcal{H}_{D,N}=SL^2(D^N)$, the projection of $L^2(D^N)$ onto symmetric functions.

The Hamiltonian of the system is the sum $H=T+V$ of kinetic and interaction energies. The kinetic energy is $T=-\Sigma_{j=1}^{N}\Delta_j$, where Δ_j is the Laplacian for the jth particle. Interactions are given by the multiplication operator $V=\Sigma_{1\leqslant i<j\leqslant N}U(x_i-x_j)$.

Recall that β and μ denote the inverse temperature and the chemical potential, respectively. The canonical and grand-canonical partition functions are

$$Y(\beta,V,N)=\mathrm{Tr}_{\mathcal{H}_{D,N}}\mathrm{e}^{-\beta H}, \tag{A2}$$

$$Z(\beta,V,\mu)=\sum_{N\geqslant 0}\mathrm{e}^{\beta\mu n}Y(\beta,V,N). \tag{A3}$$

Under the assumption that $U(x)$ is a stable potential and that it decays faster than $|x|^{-d}$ as $|x|\to\infty$, one can establish the existence of the thermodynamic potentials (see Ref. 11)

$$\boldsymbol{f}(\beta,\rho)=\lim_{V\to\infty}-\frac{1}{\beta V}\log Y(N), \tag{A4}$$

$$\boldsymbol{p}(\beta,\mu)=\lim_{V\to\infty}\frac{1}{V}\log Z(\mu). \tag{A5}$$

Further, $\boldsymbol{f}$ and $\boldsymbol{p}$ are related by a Legendre transform,

$$\boldsymbol{f}(\beta,\rho)=\sup_{\mu}\left[\rho\mu-\frac{1}{\beta}\boldsymbol{p}(\beta,\mu)\right]. \tag{A6}$$

This equation is useful to find $\boldsymbol{f}$ from $\boldsymbol{p}$ in the case of the ideal gas, where $\boldsymbol{p}$ can be computed explicitly.

The Feynman-Kac representation allows to express $\mathrm{e}^{-\beta H}$ in terms of Wiener trajectories (Brownian motion). We briefly review the main properties of the Wiener measure. Let $\mathcal{X}_1$ be the set of continuous paths $\omega:[0,\beta]\to D$. Consider a function $F:\mathcal{X}_1\to\mathbb{R}$ of the kind

$$F(\omega)=f(\omega(t_1),\ldots,\omega(t_n)), \tag{A7}$$

where f is a bounded measurable function on D^n, and $0<t_1<\cdots<t_n<\beta$; we extend f on $\mathbb{R}^d$ by periodicity. The integral of F with respect to the Wiener measure W_{xy}^{β} is given by

$$\int_{\mathcal{X}}F(\omega)\mathrm{d}W_{xy}^{\beta}(\omega)=\sum_{z\in\mathbb{Z}^d}\int_{\mathbb{R}^{dn}}g_{t_1}(x_1-x)g_{t_2-t_1}(x_2-x_1)\cdots g_{\beta-t_n}(y+Lz-x_n)$$
$$\times f(x_1,\ldots,x_n)\mathrm{d}x_1\cdots\mathrm{d}x_n, \tag{A8}$$

where g_t is the normalized Gaussian function with mean zero and variance $2t$,

$$g_t(x)=\frac{1}{(4\pi t)^{d/2}}\mathrm{e}^{-x^2/4t}. \tag{A9}$$

The sum over z accounts for periodic boundary conditions. A special case of Eq. (A8) is when the function F is the constant function $F(\omega)\equiv 1$; we get

$$\int\mathrm{d}W_{xy}^{\beta}(\omega)=(4\pi\beta)^{-d/2}\sum_{z\in\mathbb{Z}^d}\mathrm{e}^{-(x-y+Lz)^2/4\beta}. \tag{A10}$$

Only the term $z=0$ remains in the limit $L\to\infty$. It can be proven that such a measure exists and is unique.[6] The Wiener measure $W_{xy}^{n\beta}$ is concentrated on Hölder continuous trajectories (with any

Hölder constant less than $\frac{1}{2}$) that start at x and end at y. Integration with respect to W^β_{xy} and W^β_{00} are related as follows. Define $\omega'(t) = \omega(t) - t[(y-x)/\beta]$; then

$$\int F(\omega) \mathrm{d}W^\beta_{xy}(\omega) = \mathrm{e}^{-(y-x)^2/4\beta} \int F(\omega') \mathrm{d}W^\beta_{00}(\omega). \tag{A11}$$

The Feynman-Kac formula states that $\mathrm{e}^{-\beta H}$ is given by an integral operator.[2,4,6] We are actually dealing with bosonic particles, and it is more convenient to consider the operator $\mathrm{e}^{-\beta H} S$ that also projects onto symmetric functions. We have

$$\mathrm{e}^{-\beta H} S\psi(x_1, \dots, x_N) = \int_{D^N} K(x_1, \dots, x_N; y_1, \dots, y_N) \psi(y_1, \dots, y_N) \mathrm{d}y_1 \cdots \mathrm{d}y_N, \tag{A12}$$

where the kernel K is given by

$$K(x_1, \dots, x_N; y_1, \dots, y_N) = \frac{1}{N!} \sum_{\pi \in S_N} \int \mathrm{d}W^\beta_{x_1 y_{\pi(1)}}(\omega_1) \cdots \mathrm{d}W^\beta_{x_N y_{\pi(N)}}(\omega_N) \times \exp\left\{ - \sum_{i<j} \int_0^\beta U(\omega_i(s) - \omega_j(s)) \mathrm{d}s \right\}. \tag{A13}$$

The canonical partition function is then given by

$$Y(N) = \sum_{\pi \in S_N} \frac{1}{N!} \int_{D^N} \mathrm{d}x_1 \cdots \mathrm{d}x_N \int \mathrm{d}W^\beta_{x_1 x_{\pi(1)}}(\omega_1) \cdots \mathrm{d}W^\beta_{x_N x_{\pi(N)}}(\omega_N) \times \exp\left\{ - \sum_{i<j} \int_0^\beta U(\omega_i(s) - \omega_j(s)) \mathrm{d}s \right\}. \tag{A14}$$

We now group the cycles into closed trajectories, that may wind several times around the time direction. The number of permutations of N elements with k cycles of lengths $n_1, \dots, n_k$ (with $\sum_j n_j = N$) is

$$\frac{N!}{k! \prod_j n_j}.$$

Further, we have

$$\int_{D^{n-1}} \mathrm{d}x_2 \cdots \mathrm{d}x_n \int \mathrm{d}W^\beta_{x x_2}(\omega_1) \cdots \mathrm{d}W^\beta_{x_n y}(\omega_n) F(\omega) = \int \mathrm{d}W^{n\beta}_{xy}(\omega) F(\omega). \tag{A15}$$

The trajectory $\omega : [0, n\beta] \to D$ in the right side is the concatenation of $\omega_1, \dots, \omega_n$. The partition function (A14) can then be rewritten in the form of Eq. (2.1).

Let us turn to the Penrose and Onsager off-diagonal long-range order.[9] Given a single particle function $\varphi \in L^2(D)$, we define the operator N_φ that represents the number of particles in the state φ. The action of this operator is given by

$$(N_\varphi \psi)(x_1, \dots, x_N) = \sum_{j=1}^N \int_D \overline{\varphi(x)} \psi(x_1, \dots, \underbrace{x}_{j\text{th place}}, \dots, x_N) \varphi(x_j) \mathrm{d}x. \tag{A16}$$

It is clear that $0 \leqslant N_\varphi \leqslant N$ and that $[N_\varphi, S] = 0$. Let $\varphi_0(x) \equiv 1/\sqrt{V}$ denote the single particle ground state in the absence of interactions. It is also the Fourier function with mode $k = 0$. The average occupation of the zero mode is given by

$$\boldsymbol{\varrho}_{\rho}^{(0)} = \lim_{V\to\infty} \frac{1}{Y(N)} \mathrm{Tr}_{\mathcal{H}_{D,N}} \left[\frac{N_{\varphi_0}}{V} \mathrm{e}^{-\beta H} \right]. \tag{A17}$$

We set $N=\rho V$, and the limit exists at least along a subsequence of increasing volumes. A criterion for the Bose-Einstein condensation is that $\boldsymbol{\varrho}_{\rho}^{(0)}$ differs from zero. We can derive a Feynman-Kac expression for this order parameter. From Eqs. (A12), (A13), and (A16), we have

$$\mathrm{Tr}_{\mathcal{H}_{D,N}} N_{\varphi} \mathrm{e}^{-\beta H} = \frac{1}{(N-1)!} \int_D \mathrm{d}x \overline{\varphi(x)} \int_D \mathrm{d}y \varphi(y) \int_{D^{N-1}} \mathrm{d}x_2 \cdots \mathrm{d}x_N \sum_{\pi\in S_N} \times \int \mathrm{d}W^{\beta}_{x_1 \hat{x}_{\pi(1)}}(\omega_1) \cdots \mathrm{d}W^{\beta}_{x_N \hat{x}_{\pi(N)}}(\omega_N) \exp\left\{ -\sum_{i<j} \int_0^{\beta} U(\omega_i(s) - \omega_j(s)) \right\}. \tag{A18}$$

Here, we set $x_1=x$, $\hat{x}_1=y$, and $\hat{x}_j=x_j$ for $2\leqslant j\leqslant N$. Then $\boldsymbol{\varrho}_{\rho}^{(0)}$ can be written as

$$\boldsymbol{\varrho}_{\rho}^{(0)} = \lim_{V\to\infty} \frac{1}{V^2} \int_{D^2} \sigma_{\rho}(x-y) \mathrm{d}x \mathrm{d}y, \tag{A19}$$

where

$$\sigma_{\rho}(x-y) = \frac{1}{Y(\beta,V,N)} \frac{1}{(N-1)!} \int_{D^{N-1}} \mathrm{d}x_2 \cdots \mathrm{d}x_N \sum_{\pi\in S_N} \times \int \mathrm{d}W^{\beta}_{x_1 \hat{x}_{\pi(1)}}(\omega_1) \cdots \mathrm{d}W^{\beta}_{x_N \hat{x}_{\pi(N)}}(\omega_N) \times \exp\left\{ -\sum_{i<j} \int_0^{\beta} U(\omega_i(s) - \omega_j(s)) \right\}. \tag{A20}$$

This expression involves an open cycle from x to y, winding n times around the time direction, with $n=1,\ldots,N$. Using the concatenation property (A15) and thanks to the combinatorial factor $(N-1)!/(N-n)!$, we obtain expression (2.14) for $\sigma_{\rho}(x-y)$. The system displays off-diagonal long-range order if $\sigma_{\rho}(x)$ is strictly positive, uniformly in V,x.

APPENDIX B: A SIMPLE PROOF OF MACROSCOPIC OCCUPATION IN THE IDEAL GAS

In this section, we give a proof of the macroscopic occupation of the zero mode at low temperature. This is usually established in the grand-canonical ensemble, using a chemical potential that varies with the volume and tends to zero in the thermodynamic limit. This approach is rather un-natural and requires large deviation techniques to control the fluctuations of the number of particles. The present proof is simpler and stays within the canonical ensemble.

The computation of the pressure and of the density in the grand-canonical ensemble can be found in any textbook dealing with quantum statistical mechanics. The chemical potential must be strictly negative. The infinite volume pressure is

$$\boldsymbol{p}(\beta,\mu) = -\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \log(1-\mathrm{e}^{-\beta(k^2-\mu)}) \mathrm{d}k, \tag{B1}$$

and the density is

$$\boldsymbol{\rho}(\beta,\mu) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \frac{\mathrm{d}k}{\mathrm{e}^{\beta(k^2-\mu)}-1} = \frac{1}{(4\pi\beta)^{d/2}} \sum_{n\geqslant 1} \mathrm{e}^{\beta\mu n} n^{-d/2}. \tag{B2}$$

The limit of $\boldsymbol{\rho}(\beta,\mu)$ as $\mu\nearrow 0$ is finite for $d\geqslant 3$ and gives the *critical density* of the ideal Bose gas, ρ_c. The graph of $\boldsymbol{p}(\beta,\mu)$ in three dimensions is plotted in Fig. 2(a). Its Legendre transform, Eq. (A6), gives $\boldsymbol{f}(\beta,\rho)$, see Fig. 2(b); it is nonanalytic at ρ_c. The value of $a(\beta)$ is given by

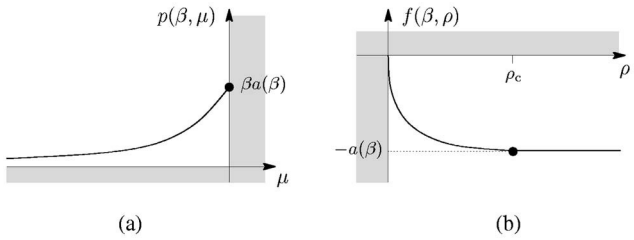

FIG. 2. The pressure and the free energy of the ideal gas in three dimensions.

$$a(\beta) = \lim_{\mu \nearrow 0} \frac{1}{\beta} p(\beta,\mu) = \lim_{\rho\to\infty} -f(\beta,\rho). \tag{B3}$$

The very nature of the Bose-Einstein condensation is that the occupation number for $k=0$ becomes macroscopic. The average occupation of the zero mode $\varrho_\rho^{(0)}$, see Eq. (A17), can be rewritten as

$$\varrho_\rho^{(0)} = \lim_{V\to\infty} \frac{1}{Y(N)} \sum_{(n_k):N} \frac{n_0}{V} e^{-\beta\Sigma_k n_k k^2}. \tag{B4}$$

Here, $N=V\rho$, and the sum is over all occupation numbers $n_k \geqslant 0$, with indices $k \in ((2\pi/L)\mathbb{Z})^d$, such that $\Sigma_k n_k = N$. The heart of the Bose-Einstein condensation is the following result.

Theorem 4: *For* $d \geqslant 3$, *the single particle ground state is macroscopically occupied if* $\rho > \rho_c$. *More precisely*,

$$\varrho_\rho^{(0)} = \max(0, \rho - \rho_c).$$

Proof: It is clear that $\varrho_\rho^{(0)} \geqslant 0$. We now establish that $\varrho_\rho^{(0)} \geqslant \rho - \rho_c$. Let us introduce the average occupation of the mode k,

$$\langle n_k \rangle = \frac{1}{Y(N)} \sum_{(n_{k'}):N} n_k e^{-\beta\Sigma_{k'} n_{k'} k'^2}.$$

Thanks to the sum rule $N=\Sigma_k \langle n_k \rangle$, we have

$$\varrho_\rho^{(0)} = \rho - \lim_{V\to\infty} \sum_{k\neq 0} \frac{\langle n_k \rangle}{V}. \tag{B5}$$

We can view n_k as a random variable taking positive integer values; its expectation is therefore given by

$$\langle n_k \rangle = \sum_{i\geqslant 1} \mathrm{Prob}(n_k \geqslant i), \tag{B6}$$

where we defined

$$\mathrm{Prob}(n_k \geqslant i) = \frac{1}{Y(N)} \sum_{(n_{k'}):N,i} e^{-\beta\Sigma_{k'} n_{k'} k'^2}. \tag{B7}$$

The sum is restricted to $(n_{k'})$ such that $\Sigma n_{k'} = N$ and $n_k \geqslant i$. The change of variable $n_k \to n_k - i$ leads to

$$\mathrm{Prob}(n_k \geqslant i) = \mathrm{e}^{-\beta i k^2} \frac{Y(N-i)}{Y(N)}. \tag{B8}$$

The ratio of partition functions is also equal to the probability $\mathrm{Prob}(n_0 \geqslant i)$, which is smaller than 1. Equations (B6) and (B8) give a bound for the occupation numbers of all modes $k \neq 0$, namely,

$$\langle n_k \rangle \leqslant \frac{1}{\mathrm{e}^{\beta k^2} - 1}. \tag{B9}$$

Notice that $\langle n_k \rangle \leqslant 1/\beta k^2 \leqslant L^2/4\pi^2\beta$ for $k \neq 0$. This shows that only the zero mode can be macroscopically occupied (for $d \geqslant 3$). Inserting this bound into Eq. (B5), we obtain

$$\boldsymbol{\varrho}_\rho^{(0)} \geqslant \rho - \frac{1}{(2\pi)^d} \lim_{V\to\infty} \sum_{k\neq 0} \left(\frac{2\pi}{L}\right)^d \frac{1}{\mathrm{e}^{\beta k^2} - 1}. \tag{B10}$$

The limit converges to expression (B2) with $\mu = 0$, which is equal to ρ_c.

There remains to show that $\boldsymbol{\varrho}_\rho^{(0)} \leqslant \max(0, \rho - \rho_\mathrm{c})$. From Eq. (B8) with $k=0$, and using the equivalence of ensembles, we have for any fixed a,

$$\lim_{V\to\infty} \frac{1}{\beta V} \log \mathrm{Prob}(n_0 \geqslant Va) = \boldsymbol{f}(\beta, \rho) - \boldsymbol{f}(\beta, \rho - a). \tag{B11}$$

The right side of Eq. (B11) is strictly negative when $a > \max(0, \rho - \rho_\mathrm{c})$. There exists $\delta > 0$ such that for large enough volumes,

$$\mathrm{Prob}(n_0 \geqslant Va) \leqslant \mathrm{e}^{-V\delta}. \tag{B12}$$

Let us assume that $\rho - \rho_\mathrm{c} > 0$; the case $\rho - \rho_\mathrm{c} \leqslant 0$ can be treated similarly. Using Eq. (B6) with $k = 0$, together with Eq. (B12), we get

$$\frac{\langle n_0 \rangle}{V} = \frac{1}{V} \sum_{1 \leqslant i \leqslant aV} \mathrm{Prob}(n_0 \geqslant i) + \frac{1}{V} \sum_{aV < i \leqslant N} \mathrm{Prob}(n_0 \geqslant i) \leqslant a + \rho \mathrm{e}^{-V\delta}. \tag{B13}$$

It follows that $\boldsymbol{\varrho}_\rho^{(0)}$ is less than any number $a > \rho - \rho_\mathrm{c}$, hence $\boldsymbol{\varrho}_\rho^{(0)} \leqslant \rho - \rho_\mathrm{c}$.

We study the final state problem for the Korteweg–de Vries type equations: $u_t - 1/\rho|\partial_x|^{\rho-1}u_x = \lambda u^2 u_x$, $(t,x) \in \mathbf{R}^+ \times \mathbf{R}$, $\|u(t) - F_S(t)\|_{\mathbf{L}^2} \to 0$ as $t \to \infty$, where $\lambda \in \mathbf{R}$, the function $F_S(t)$ we call a final state, defined by the final data u_+. We show that there does not exist a nontrivial solution of this equation in the case of $F_S(t) = U(t)u_+$, where $U(t)$ is the free evolution group of this equation. We construct the modified wave operator for the Korteweg–de Vries type equations under the conditions that the final data u_+ arc real-valued functions and the Fourier transform $\hat{u}_+(\xi)$ vanishes at the origin. © *2006 American Institute of Physics.*

I. INTRODUCTION

We study the final state problem for the Korteweg–de Vries type equations

$$u_t - 1/\rho|\partial_x|^{\rho-1}u_x = \lambda u^2 u_x,\ (t,x) \in \mathbf{R}^+ \times \mathbf{R},$$
$$\|u(t) - F_S(t)\|_{\mathbf{L}^2} \to 0 \text{ as } t \to \infty, \tag{1.1}$$

where $\rho \geqslant 2$, $\lambda \in \mathbf{R}$, $|\partial_x|^\rho = \mathcal{F}^{-1}|\xi|^\rho \mathcal{F}$, $\mathcal{F}\phi$, or $\hat{\phi}$ is the Fourier transform of ϕ defined by $\mathcal{F}\phi(\xi) = (1/\sqrt{2\pi})\int_{\mathbf{R}} e^{-ix\xi}\phi(x)dx$ and the inverse Fourier transformation $\mathcal{F}^{-1}$ is given by $\mathcal{F}^{-1}\phi(x) = (1/\sqrt{2\pi})\int_{\mathbf{R}} e^{ix\xi}\phi(\xi)d\xi$. If $\rho=2$, then Eq. (1.1) converts to the well-known modified Benjamin–Ono equation

$$u_t - \tfrac{1}{2}\mathcal{H}u_{xx} = \lambda u^2 u_x, \tag{1.2}$$

where $\mathcal{H}\phi = -\mathcal{F}^{-1}(i\xi/|\xi|)\widehat{\phi} = (1/\pi)\mathrm{PV}\int_{\mathbf{R}}(\phi(y)/x-y)dy$ is the Hilbert transform. For the case of $\rho=3$, Eq. (1.1) reduces to the famous modified Korteweg–de Vries equation

$$u_t + \tfrac{1}{3}u_{xxx} = \lambda u^2 u_x. \tag{1.3}$$

Another example is the Kawahara equation (see. Ref. 1)

$$u_t - \tfrac{1}{5}\partial_x^5 u = \lambda u^2 u_x,$$

when $\rho=5$.

The function $F_S(t)$ we call a final state, defined by the final data u_+. If the function $F_S(t)$ can be taken in the form

[a)]Electronic mail: nhayashi@math.wani.osaka-u.ac.jp
[b)]Electronic mail: pavelni@matmor.unam.mix

$$F_S(t) = U(t)u_+ = \mathcal{F}^{-1}\exp\left(\frac{i}{\rho}t|\xi|^{\rho-1}\xi\right)\widehat{u_+}(\xi)$$

and the final problem (1.1) has a nontrivial solution, then we say that there exists a usual wave operator for the final state problem. However, below we will show that there does not exist a nontrivial solution of Eq. (1.1) in the case of $F_S(t)=U(t)u_+$. Therefore we need to modify the time dependence of the final state $F_s(t)$, in other words, we will construct a modified wave operator. The modified wave operator was first constructed by Ozawa[2] for cubic nonlinear Schrödinger equations and then by Ozawa and the first author[3] for the derivative nonlinear Schrödinger equation, by changing it via a suitable transformation (see Ref. 4) to a system of cubic nonlinear Schrödinger equations without derivatives of an unknown function. However, as far as we know the existence of the modified wave operators was not proved for other types of dispersive equations with nonlinearities involving derivatives of the unknown function, such as the modified Benjamin–Ono equation (1.2) and the modified Korteweg–de Vries equation (1.3).

The Cauchy problem for the Korteweg–de Vries equations (1.1) with $\rho=3$ and nonlinearities of the form $\partial_x u^\varkappa$ was studied extensively (see, e.g., Refs. 5–8 and 26 for the existence of unique solutions and Refs. 9–16 for the large time asymptotic behavior of small solutions in the case of supercritical nonlinearity $\varkappa>3$). In the case of the modified Benjamin–Ono equation (1.2), namely, $\rho=2$ and $\varkappa>3$, the large time asymptotic behavior of small solutions were studied in Refs. 17 and 18.

One of the important problems of scattering theory is the construction of the so-called scattering operator, which is defined by the direct and inverse wave operators. In the case of critical nonlinearity it appears to be impossible to find the usual scattering operator, so a problem constructing the modified scattering operator arises. The inverse modified wave operator is closely related to the large time asymptotic behavior of solutions to the Cauchy problem. We now refer some results on the large time asymptotic behavior of small solutions to the Cauchy problem (1.1) for cases $\rho=2,3$, and 5. The case of the modified Korteweg–de Vries equation $\rho=3$ was considered in Refs. 19 and 20. If the initial data $u_0 \in \mathbf{H}^{1,1}$ are real-valued functions with a sufficiently small norm, then there exists a unique global solution $u \in \mathbf{C}(\mathbf{R};\mathbf{H}^{1,1})$ of the Cauchy problem for modified Korteweg–de Vries equation (1.3). Moreover, if we (denote by $S(t,x)=(1/\sqrt[3]{t})\varphi(x/\sqrt[3]{t})$ the self-similar solution of the modified Korteweg–de Vries equation (1.3) such that

$$S_t - \frac{\lambda}{3}(S^3)_x + \frac{1}{3}S_{xxx} = 0$$

and

$$\int_{\mathbf{R}} S(t,x)dx = \int_{\mathbf{R}} u_0(x)dx,$$

then there exist unique functions H_j and $B_j \in \mathbf{L}^\infty$ (B_j are real valued), $j=1,2$, such that the following asymptotic formula is valid for large time t uniformly with respect to $x \in \mathbf{R}$,

$$u(t,x) = \frac{1}{\sqrt[3]{t}}\varphi\left(\frac{x}{\sqrt[3]{t}}\right) + \frac{1}{\sqrt[3]{t}}\mathrm{Re}\,\mathcal{A}i\left(\frac{x}{\sqrt[3]{t}}\right)\sum_{j=1}^{2} H_j\left(\frac{x}{t}\right)\exp\left(iB_j\left(\frac{x}{t}\right)\log\frac{|x|}{\sqrt[3]{t}}\right) + O\left(t^{\gamma-5/12}\left(1+\frac{x}{\sqrt[3]{t}}\right)^{-1/4}\right),$$

where $\gamma \in (0,1/10)$ and $\mathcal{A}i(x)=(1/\pi)\int_0^\infty e^{ixz+(i/3)z^3}dz$ is the Airy–Fock function.

The large time asymptotic behavior of small solutions to the Cauchy problem for the modified Benjamin–Ono equation (1.2) was studied in Refs. 17 and 18. It was proved that if the initial data $u_0 \in \mathbf{H}^{2,0}\cap\mathbf{H}^{1,1}$ are real-valued functions with sufficiently small norm, then there exists a unique global solution $u \in \mathbf{C}(\mathbf{R};\mathbf{H}^{1,0})\cap\mathbf{L}^\infty(\mathbf{R};\mathbf{L}^2)$ of the Cauchy problem for the modified Benjamin–Ono equation (1.2). Moreover there exists a unique function $u_+ \in \mathbf{L}^\infty$ such that the following asymptotic formula is valid

$$u(t,x)=\frac{1}{\sqrt{t}}\mathrm{Re}\left(G\left(\frac{x}{\sqrt{t}}\right)u_+\left(\frac{x}{t}\right)\exp\left(\frac{ix^2}{2t}-ig\left(\frac{x}{t}\right)\log t\right)\right)+O(t^{-1/2-\gamma})$$

as $t\to\infty$ uniformly with respect to $x\in\mathbf{R}$, where

$$G(x)=\frac{1}{\sqrt{-\pi i}}\int_{-x}^{\infty}e^{-iy^2}dy, g(x)=\frac{3}{4}x\theta(x)|u_+(x)|^2,$$

$\theta(x)=1$ for $x<0$ and $\theta(x)=0$ for $x\geqslant 0, 0<\gamma<1/4$.

Finally, the large time asymptotic behavior of small solutions to the Cauchy problem for the generalized Kawahara equation

$$u_t-\frac{1}{5}\partial_x^5u=\lambda u^{\varkappa-1}u_x$$

with supercritical nonlinearities of the order $\varkappa>5$ were obtained in Ref. 21, where it was proved that if the initial data $u_0\in\mathbf{H}^{1,1}$ are real-valued functions with sufficiently small norm then there exists a unique function $u_+\in\mathbf{L}^\infty\cap\mathbf{L}^2$ such that the asymptotic behavior

$$u(t,x)=\frac{1}{\sqrt[5]{t}}\mathrm{Re}\,A\left(\frac{x}{\sqrt[5]{t}}\right)u_+\left(\frac{x}{t}\right)+O\left(t^{-1/5-\gamma}\left(1+\frac{|x|}{\sqrt[5]{t}}\right)^{-3/8}\right)$$

is true for large t uniformly with respect to $x\in\mathbf{R}$, where $0<\gamma<(\varkappa-5)/5$,

$$A(x)=\frac{1}{\pi}\int_0^\infty e^{ixz+(i/5)z^5}dz.$$

We see that the Cauchy problem for the Korteweg–de Vries type equations (1.1) was studied and the asymptotic behavior of solutions was found for the cases $\rho=2$ and 3. However, the asymptotic behavior of solutions to the Cauchy problem for the Korteweg–de Vries type equations (1.1) of higher order $\rho>3$ is an open problem. The difficulty in studying the higher order cases $\rho>3$ comes from the time decay properties of solutions to the corresponding linear problem. Thus to be able to get better time decay estimates of solutions, a condition arises that the Fourier transform of the initial data must vanish rapidly at the origin. Note that the existence of the modified scattering operator is an important open problem even for the lower order cases $\rho\geqslant 2$ since it is necessary to study carefully the range and the domain of the inverse modified wave operator.

The aim of the present paper is to construct the modified wave operator for the Korteweg–de Vries type equations (1.1) under the conditions that the final data u_+ are real-valued functions and the Fourier transform $\hat{u}_+(\xi)$ vanishes rapidly at the origin. We first obtain the $\mathbf{L}^\infty$ estimates and the asymptotic behavior for solutions to the linear dispersive equations of the Korteweg–de Vries type. Denote the free evolution group $U(t)=\mathcal{F}^{-1}\exp((it/\rho)|\xi|^{\rho-1}\xi)\mathcal{F}$, where $\rho\geqslant 2$. The usual Lebesgue space $\mathbf{L}^p=\{\phi;\|\phi\|_{\mathbf{L}^p}<\infty\}$, with the norm $\|\phi\|_{\mathbf{L}^p}=(\int_{\mathbf{R}}|\phi(x)|^p dx)^{1/p}$ if $1\leqslant p<\infty$ and $\|\phi\|_{\mathbf{L}^\infty}=\sup_{x\in\mathbf{R}}|\phi(x)|$ if $p=\infty$. The weighted Sobolev space is defined by $\mathbf{H}_p^{m,s}=\{\phi\in\mathbf{L}^p;\|\langle x\rangle^s\langle i\partial_x\rangle^m\phi\|_{\mathbf{L}^p}<\infty\}, m,s\in\mathbf{R}$ with $\langle x\rangle=\sqrt{1+|x|^2}$. The index 0 we usually omit if it does not cause confusion. We say that $\phi=O(\psi)$ in $\mathbf{L}^p$ for all $t\geqslant T$, if the estimate

$$\|\phi\|_{\mathbf{L}^p}\leqslant C|\psi|$$

is true for all $t\geqslant T$, where $C>0$ does not depend on ϕ. We also introduce the norm

$$\|\nu\|_{\mathbf{Z}^\alpha}\equiv\|\{\xi\}^{-\alpha}\nu(\xi)\|_{\mathbf{L}^\infty}+\|\{\xi\}^{1-\alpha}\nu'(\xi)\|_{\mathbf{L}^\infty},$$

where $\{\xi\}=|\xi|/\langle\xi\rangle$.

Theorem 1.1: *The estimate is true*

$$\|U(t)v\|_{\mathbf{L}^\infty} \leqslant Ct^{-(1+\alpha)/\rho}\||\partial_x|^{-\alpha}v\|_{\mathbf{L}^1} \tag{1.4}$$

for all $t>0$, *provided that the right-hand side is finite, where* $\alpha\in[0,\rho/2-1],\rho\geqslant 2$. *Furthermore, the asymptotic formula for large time* t *holds*

$$U(t)v = t^{-1/2}\mathrm{Re}(\theta(x)(FE\hat{v})(\chi)) + O(\|\hat{v}\|_{\mathbf{Z}^\alpha}t^{-\alpha/\rho-1/\rho(1-1/\rho)}), \tag{1.5}$$

in $\mathbf{L}^p$ *for* $2\leqslant p\leqslant\infty$, *where* $0<\alpha<(\rho-1)(1-1/p)$,

$$F(\chi) = \sqrt{\frac{4}{i(\rho-1)}}|\chi|^{1-\rho/2},$$

$E=e^{-i(1-1/\rho)t|\chi|^{\rho-1}\chi}$ and $\chi=|x/t|^{1/(\rho-1)}$, $\theta(x)=1$ for $x<0$ and $\theta(x)=0$ for $x\geqslant 0$.

Remark 1.1: The proof of theorem 1.1 follows the method of Ref. 22 concerning the estimates of the free evolution group $\mathcal{F}^{-1}\exp((i/\rho)t|\xi|^\rho)\mathcal{F}$. *The difference is in the estimates for the positive half-line, where the free evolution group*

$$\mathcal{F}^{-1}\exp(i/\rho t|\xi|^{\rho-1}\xi)\mathcal{F}$$

decays exponentially, because the symbol $|\xi|^{\rho-1}\xi$ *is an odd function. Therefore the assumption that the Fourier transform of the final data* $\hat{u}_+$ *vanishes at the origin implies that the leading term of the asymptotics becomes a remainder one for the positive half-line. If* $\hat{u}_+$ *does not vanish at the origin, then we need to consider a leading term (in the short-range region) generated by the value* $\hat{u}_+(0)$.

Remark 1.2: We need estimate (1.4) for the proof of the Strichartz type estimate (see lemma 3.1 below). We see that the $\mathbf{L}^2$*-norm of the remainder in Eq. (1.5) decays faster than* $t^{1/2\rho-1/2}$ *in the case of* $\alpha>\rho/2-1$ *and* $\rho\geqslant 2$.

Remark 1.3: If $\hat{v}^{(j)}(0)=0$ *for* $0\leqslant j\leqslant k=[\alpha]$ *and* $v\in\mathbf{H}^{0,k+2}$, *then*

$$\|\hat{v}\|_{\mathbf{Z}^\alpha} \leqslant C\|\hat{v}\|_{\mathbf{L}^\infty} + C\|\hat{v}^{(k+1)}\|_{\mathbf{L}^\infty} \leqslant C\|\hat{v}\|_{\mathbf{H}^{k+2}} = C\|v\|_{\mathbf{H}^{0,k+2}}.$$

For the case of $\rho=3$, *we can choose* $1/2<\alpha<1$, *then we have*

$$\|\hat{v}\|_{\mathbf{Z}^\alpha} \leqslant C\|v\|_{\mathbf{H}^{0,2}}$$

if $v\in\mathbf{H}^{0,2}$ *and* $\int_{\mathbf{R}}v(x)dx=0$.

We now give some heuristic considerations to explain the construction of the modified wave operator. Let us assume that the solutions of nonlinear problem Eq. (1.1) have time decay properties similar to that of the linearized equation and apply the result of theorem 1.1 to evaluate the asymptotic behavior of the nonlinear term in Eq. (1.1). Since the final data u_+ are real valued we have $\widehat{u_+}(\xi)=\widehat{u_+}(-\xi)$. Then the main term in Eq. (1.1) appears as a linear combination of the following two oscillating terms

$$I_1 \equiv t^{-3/2}\mathrm{Re}(i\theta(x)\lambda\chi(F|F|^2E|\widehat{u_+}|^2\widehat{u_+})(\chi))$$

and

$$I_2 \equiv t^{-3/2}\mathrm{Re}(i\theta(x)\lambda\chi(F^3E^3\widehat{u_+}^3)(\chi))$$

for $x<0$. It is easy to check that the $\mathbf{L}^2$ norm of I_1 and I_2 decays like t^{-1}. Hence, it is divergent when integrating in time. This is the reason why it is impossible to find the solutions of Eq. (1.1) in the neighborhood of the free solutions (see theorem 1.3 below). The term I_1 can be removed by introducing a suitable phase correction since it oscillates similarly to the solutions of the linear problem. And the term I_2 can be shown via integrating by parts to be a remainder (since its oscillating properties differ from that of the solutions to the linear problem, see Ref. 23. In the case of lower order ρ, the method used in Ref. 23 could be applicable. However, in the case of

fractional or higher order ρ, the computations become complicated. So we avoid here the integration by parts and instead we use the Fourier image to find an approximate solution of the nonlinear problem. (See Sec. III for the details, where the ordinary differential equations involving terms associated with I_1 and I_2 is studied.) The previous methods of Refs. 2 and 3 for constructing the modified wave operator were based on the substitution of an approximate solution to the linear equation and then considered the equation for differences. This method seems to be difficult to apply to our problem since it requires ρ times differentiation of an approximate solution. Finally we note that the term I_2 does not appear in the case of the nonlinear Schrödinger type equations with the gauge invariant nonlinearity $|u|^2u$.

Denote

$$\mathbf{W}^\alpha = \{\nu; \|\nu\|_{\mathbf{W}^\alpha} \equiv \|\langle\xi\rangle^3 \nu\|_{\mathbf{z}^\alpha} < \infty\}.$$

Theorem 1.2: *Let the final data u_+ be a real-valued function and the norm $\|\widehat{u_+}\|_{\mathbf{W}^\alpha} \leqslant \varepsilon, \max\{(\rho-2)/2, (3\rho-7)/4\} < \alpha \leqslant \max\{\rho-2, (\rho-1)/2\}, \rho \geqslant 2$. Then there exists a time $T \geqslant 1$ and $\varepsilon > 0$ such that Eq. (1.1) has a unique solution $u \in \mathbf{L}^\infty([T,\infty); \mathbf{H}^2) \cap \mathbf{C}([T,\infty); \mathbf{H}^1)$. Moreover, the asymptotic formula is true*

$$\|u(t) - U(t)w(t)\|_{\mathbf{H}^2} \leqslant Ct^{-\min\{b,(2\alpha-\rho+3)/\rho\}},$$

where $b < \alpha/\rho + 1/2\rho$ and $w(t)$ are the solutions of the ordinary differential equations

$$\widehat{w}_t(t,\xi) = \frac{1}{t}(i\lambda\xi|F\widehat{w}|^2\widehat{w} + i\widetilde{\lambda}\xi F^2 E^\nu \mathcal{D}_\mu \widehat{w}^3) \tag{1.6}$$

with the final condition

$$\lim_{t\to\infty} \widehat{w}(t) e^{-i\xi\lambda|\widehat{u_+}(\xi)|^2 \log t} = \widehat{u_+}(\xi),$$

where

$$\lambda \in \mathbf{R}, \quad \nu = (1-3^{1-\rho})/(\rho-1), \quad \mu = 3^{\rho-1}, \quad \widetilde{\lambda} = \lambda 3^{3\rho/2-4}$$

$$F = \sqrt{\frac{4}{i(\rho-1)}}|\xi|^{1-\rho/2}, \quad \mathcal{D}_\omega \phi = \omega^{-1/2}\phi(x|\omega|^{-1/(\rho-1)}), \quad E = e^{-i(1-1/\rho)t|\xi|^{\rho-1}\xi}.$$

We note here that the existence of solutions $\widehat{w}(t) \in \mathbf{C}([1,\infty); \mathbf{W}^\alpha)$ to Eq. (1.6) is shown in lemma 3.2 below.

Remark 1.4: For the convenience of the reader we state the result of theorem 1.2 for the modified Korteweg–de Vries case ($\rho=3$). Let the final data u_+ be a real-valued function and the norm $\|\widehat{u_+}\|_{\mathbf{W}^\alpha} = \|\langle\xi\rangle^3\nu\|_{\mathbf{z}^\alpha} \leqslant \varepsilon, \alpha \in (1/2, 1]$. (By remark 1.3, if $\int_{\mathbf{R}} u_+(x)dx = 0$ and $u_+ \in \mathbf{H}^{3,2}$, then $\widehat{u_+} \in \mathbf{W}^\alpha$). Then there exists a time $T \geqslant 1$ and $\varepsilon > 0$ such that Eq. (1.1) with $\rho=3$ has a unique solution $u \in \mathbf{L}^\infty([\mathbf{T},\infty); \mathbf{H}^2) \cap \mathbf{C}([T,\infty); \mathbf{H}^1)$. Moreover, the asymptotic formula is true

$$\|u(t) - U(t)w(t)\|_{\mathbf{H}^2} \leqslant Ct^{-b},$$

where $0 < b < (2\alpha+1)/6$ and $w(t)$ is the solution of the ordinary differential Eq. (1.6) with the final condition

$$\lim_{t\to\infty} \widehat{w}(t) e^{-i\xi\lambda|\widehat{u_+}(\xi)|^2 \log t} = \widehat{u_+}(\xi)$$

and

$$\lambda \in \mathbf{R}, \quad \nu = 4/9, \quad \mu = 9, \quad \widetilde{\lambda} = \lambda\sqrt{3},$$

$$F = \sqrt{\frac{2}{i|\xi|}}, \mathcal{D}_\omega \phi = \omega^{-1/2}\phi(x|\omega|^{-1/2}), \quad E = e^{-(2i/3)t\xi^3}.$$

For the modified Benjamin–Ono case $(\rho=2)$ *we have the following result. Let the final data* u_+ *be a real-valued function and the norm* $\|\widehat{u_+}\|_{\mathbf{W}^\alpha} = \|\langle\xi\rangle^3 \nu\|_{\mathbf{z}^\alpha} \leqslant \varepsilon, \alpha \in (0,1/2]$. *(By remark 1.3, if* $\int_{\mathbf{R}} u_+(x)dx = 0$ *and* $u_+ \in \mathbf{H}^{3,1}$, *then* $\widehat{u_+} \in \mathbf{W}^\alpha$*). Then there exists a time* $T \geqslant 1$ *and* $\varepsilon > 0$ *such that Eq. (1.1) with* $\rho=2$ *has a unique solution* $u \in \mathbf{L}_\infty([T,\infty);\mathbf{H}^2) \cap \mathbf{C}([T,\infty);\mathbf{H}^1)$. *Moreover, the asymptotic formula is true*

$$\|u(t) - U(t)w(t)\|_{\mathbf{H}^2} \leqslant Ct^{-b},$$

where $0 < b < (2\alpha+1)/4$ *and* $w(t)$ *are the solution of the ordinary differential Eq. (1.6) with the final condition*

$$\lim_{t\to\infty} \widehat{w}(t)e^{-i\xi\lambda|\widehat{u_+}(\xi)|^2 \log t} = \widehat{u_+}(\xi),$$

where

$$\lambda \in \mathbf{R}, \quad \nu = 2/3, \quad \mu = 3, \quad \tilde{\lambda} = \lambda 3^{-1},$$

$$F = \sqrt{\frac{4}{i}}, \quad \mathcal{D}_\omega \phi = \omega^{-1/2}\phi(x|\omega|^{-1}), \quad E = e^{(-i/2)t|\xi|\xi}.$$

Remark 1.5: By theorem 1.1 and lemma 3.2 we see that

$$\partial_x^j U(t)w(t) = t^{-1/2}\mathrm{Re}(\theta(x)(FE)(\chi)e^{i\chi\lambda|\widehat{Fu_+}(\chi)|^2 \log t}\chi^j \widehat{u_+}(\chi)) + O(t^{-b})$$

in $\mathbf{L}^2$ *for* $j=0,1,2$, *where* $(\rho-1)/2\rho < b < \alpha/\rho + 1/2\rho$. *Therefore, the asymptotic behavior of theorem 1.2 can be written in the form*

$$\|\partial_x^j u(t) - t^{-1/2}\mathrm{Re}((FE)(\chi)e^{i\chi\lambda|\widehat{Fu_+}(\chi)|^2 \log t}\chi^j \hat{u}_+(\chi))\|_{\mathbf{L}^2(-\infty,0)} + \|\partial_x^j u(t)\|_{\mathbf{L}^2(0,\infty)} \leqslant Ct^{-b}\|\widehat{u_+}\|\mathbf{w}^\alpha.$$

Next we present the nonexistence of the usual wave operator in the case of $\lambda \neq 0$.

Theorem 1.3: *Let* u_+ *satisfy the assumptions of theorem 1.2. We also assume that* $\lambda \neq 0$ *and that there exists a solution* u *for Eq. (1.1) such that*

$$\lim_{t\to\infty} \|u(t) - U(t)u_+\|_{\mathbf{H}^1} = 0.$$

Then $u=0$.

The outline of the paper is as follows. Section II is devoted to the proof of theorem 1.1. We prepare several lemmas in Sec. III. We prove theorem 1.2 in Sec. IV. Then the last Sec. V is devoted to the proof of theorem 1.3.

II. PROOF OF THEOREM 1.1

For the proof of estimate (1.4) we refer to Ref. 6 (proposition 2.3) and Ref. 7 (Remark b in theorem 2.2). We now prove the asymptotic behavior of Eq. (1.5). Consider the case $x<0$. Since ν is a real-valued function, so that $\hat{\nu}(-\xi) = \hat{\nu}(\xi)$, we can write the identity

$$U(t)\nu = \sqrt{\frac{2}{\pi}}t^{-1/\rho}\mathrm{Re}\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}(\xi t^{-1/\rho})d\xi$$

$$= \sqrt{\frac{2}{\pi}}t^{-1/\rho}\mathrm{Re}\left(\hat{\nu}(\chi)\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}d\xi + \int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}(\hat{\nu}(\xi t^{-(1/\rho)}) - \hat{\nu}(\chi))d\xi\right), \qquad (2.1)$$

where $\eta = xt^{-1/\rho}$, $\chi = \mu t^{-1/\rho} = (|x|/t)^{1/(\rho-1)}$ and $\mu = |\eta|^{1/(\rho-1)} > 0$.

Consider the asymptotic behavior with respect to $\mu \to \infty$ (i.e., $\eta \to -\infty$) for the first summand on the right-hand side of Eq. (2.1)

$$\int_0^\infty e^{-i\xi\mu^{\rho-1}+(i/\rho)\xi^\rho}d\xi = e^{-i(1-1/\rho)\mu^\rho}\int_0^\infty e^{iS(\xi,\mu)}d\xi,$$

where $S(\xi,\mu) = 1/\rho(\xi^\rho - \mu^\rho - \rho\mu^{\rho-1}(\xi-\mu))$. We can define a new variable

$$z(\xi,\mu) = \mu + \mu^{1-\rho/2}\sqrt{\frac{2}{\rho-1}S(\xi,\mu)}\,\mathrm{sign}(\xi-\mu).$$

Note that $z_\xi(\mu,\mu) = 1$ and (see Ref. 24)

$$\int_{z(0,\mu)}^\infty e^{i(\rho-1/2)\mu^{\rho-2}(z-\mu)^2}dz = \sqrt{\frac{2\pi}{i(\rho-1)}}\mu^{1-\rho/2} + O(\mu^{1-\rho})$$

for $\mu \to \infty$, where $z(0,\mu) = \mu(1-\sqrt{2/\rho})$. Then applying the identity

$$e^{iS(\xi,\mu)} = \frac{1}{1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})}\partial_\xi((\xi-\mu)e^{iS(\xi,\mu)})$$

we integrate by parts in the second summand

$$\int_0^\infty e^{iS(\xi,\mu)}(1-z_\xi(\xi,\mu))d\xi = \int_0^\infty (\xi-\mu)e^{iS(\xi,\mu)}\partial_\xi\left(\frac{1-z_\xi(\xi,\mu)}{1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})}\right)d\xi + O(\mu^{1-\rho}).$$

Hence,

$$\left|\int_0^\infty e^{iS(\xi,\mu)}(1-z_\xi(\xi,\mu))d\xi\right| \leqslant C\mu^{-1}\int_0^{2\mu}\frac{|\xi-\mu|d\xi}{1+(\xi-\mu)^2\mu^{\rho-2}} + C\mu^{1-\rho/2}\int_{2\mu}^\infty \xi^{-1-\rho/2}d\xi + O(\mu^{1-\rho})$$

$$= O(\mu^{1-\rho}\ln\mu).$$

Therefore,

$$\sqrt{\frac{2}{\pi}}t^{-1/\rho}\mathrm{Re}\left(\hat{\nu}(\chi)\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}d\xi\right) = t^{-1/2}\mathrm{Re}(FE\hat{\nu}(\chi)) + O(t^{-1/\rho}\hat{\nu}(\chi)\mu^{1-\rho}\ln\mu),$$

where the remainder term $O(t^{-1/\rho}\hat{\nu}(\chi)\mu^{1-\rho}\ln\mu)$ satisfies the estimates of the theorem. For the second summand on the right-hand side of Eq. (2.1) we apply the identity

$$e^{i\xi\eta+(i/\rho)\xi^\rho} = \frac{1}{1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})}\frac{\partial}{\partial\xi}((\xi-\mu)e^{i\xi\eta+(i/\rho)\xi^\rho}),$$

then the integration by parts yields

$$\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}(\hat{\nu}(\xi t^{-1/\rho})-\hat{\nu}(\chi))d\xi=\frac{\mu}{1+i\mu^\rho}\hat{\nu}(\chi)+t^{-1/\rho}\int_0^\infty\frac{(\xi-\mu)e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}'(\xi t^{-1/\rho})d\xi}{1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})}$$
$$+i\int_0^\infty\frac{(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})+(\rho-1)(\xi-\mu)^2\xi^{\rho-2}}{(1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1}))^2}$$
$$\times(\hat{\nu}(\xi t^{-1/\rho})-\hat{\nu}(\mu t^{-1/\rho}))e^{i\xi\eta+(i/\rho)\xi^\rho}d\xi\equiv\sum_{j=1}^3 I_j(t,x).$$

The first integral $I_1(t,x)$ is estimated for all $t\geqslant 1$ by

$$\|I_1(t)\|_{\mathbf{L}_x^\infty}\leqslant\left\|\frac{\mu}{\langle\mu\rangle^\rho}\hat{\nu}(\mu t^{-1/\rho})\right\|_{\mathbf{L}_x^\infty}\leqslant Ct^{-\alpha/\rho}\|\{\xi\}^{-\alpha}\hat{\nu}(\xi)\|_{\mathbf{L}^\infty}$$

if $0<\alpha<\rho-1$ and

$$\|I_1(t)\|_{\mathbf{L}_x^2}\leqslant Ct^{1/2\rho}\left\|\frac{\mu^{\rho/2}}{\langle\mu\rangle^\rho}\hat{\nu}(\mu t^{-1/\rho})\right\|_{\mathbf{L}_\mu^2}\leqslant Ct^{1/2\rho-\alpha/\rho}\|\{\xi\}^{-\alpha}\hat{\nu}(\xi)\|_{\mathbf{L}^\infty}\left\|\frac{\mu^{\alpha+\rho/2}}{\langle\mu\rangle^\rho}\right\|_{\mathbf{L}_\mu^2}\leqslant Ct^{1/2\rho-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}\tag{2.2}$$

if $0<\alpha<(\rho-1)/2$. For the second term we find

$$\|I_2(t)\|_{\mathbf{L}_x^\infty}\leqslant t^{-1/\rho}\left\|\int_0^\infty\frac{(\xi-\mu)e^{i\xi\eta+i/\rho\xi^\rho}}{1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})}\hat{\nu}'(\xi t^{-1/\rho})d\xi\right\|_{\mathbf{L}_\mu^\infty}$$
$$\leqslant Ct^{-\alpha/\rho}\||\xi|^{\alpha-1}\hat{\nu}'(\xi)\|_{\mathbf{L}_\xi^\infty}\left\|\int_0^\infty\frac{|\xi|^{\alpha-1}|\xi-\mu|d\xi}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}\right\|_{\mathbf{L}_\mu^\infty}\leqslant Ct^{-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}$$

since we have the estimate

$$\int_0^\infty\frac{|\xi|^{\alpha-1}|\xi-\mu|d\xi}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}\leqslant C\langle\mu\rangle^{1-\rho}\int_0^{\mu/2}|\xi|^{\alpha-1}d\xi+C\mu^{\alpha-1}\int_{\frac{\mu}{2}}^{2\mu}\frac{|\xi-\mu|d\xi}{1+(\xi-\mu)^2\mu^{\rho-2}}$$
$$+C\int_{2\mu}^\infty\frac{|\xi-\mu|^\alpha d\xi}{1+|\xi-\mu|^\rho}\leqslant C\tag{2.3}$$

for all $\mu>0$ if $0<\alpha<\rho-1$. Similarly to the proof of Eq. (2.2) we also obtain

$$\|I_2(t)\|_{\mathbf{L}_x^2}\leqslant Ct^{-1/2\rho}\left\|\int_0^\infty\frac{\mu^{\rho/2-1}(\xi-\mu)e^{i\xi\eta+i/\rho\xi^\rho}}{1+i(\xi-\mu)(\xi^{\rho-1}-\mu^{\rho-1})}\hat{\nu}'(\xi t^{-1/\rho})d\xi\right\|_{\mathbf{L}_\mu^2}$$
$$\leqslant Ct^{1/2\rho-\alpha/\rho}\||\xi|^{\alpha-1}\hat{\nu}'(\xi)\|_{\mathbf{L}^\infty}\left\|\int_0^\infty\frac{\mu^{\rho/2-1}|\xi|^{\alpha-1}|\xi-\mu|d\xi}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}\right\|_{\mathbf{L}_\mu^2}\leqslant Ct^{1/2\rho-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}\tag{2.4}$$

if $0<\alpha<(\rho-1)/2$, since as in Eq. (2.3) we have

$$\left\|\int_0^\infty\frac{\mu^{(\rho/2)-1}|\xi|^{\alpha-1}|\xi-\mu|d\xi}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}\right\|_{\mathbf{L}_\mu^2}\leqslant C\|\langle\mu\rangle^{\alpha-\rho/2}\|_{\mathbf{L}_\mu^2}\leqslant C.$$

The third integral I_3 is estimated as follows:

$$\|I_3(t)\|_{\mathbf{L}^\infty} \leqslant C\int_0^\infty \frac{1}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}\left|\int_{\mu t^{-1/\rho}}^{\xi t^{-1/\rho}} \hat{\nu}'(y)dy\right| d\xi$$
$$\leqslant Ct^{-\alpha/\rho}\||\xi|^{\alpha-1}\hat{\nu}'(\xi)\|_{\mathbf{L}^\infty}\int_0^\infty \frac{|\xi^\alpha-\mu^\alpha|}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}d\xi \leqslant Ct^{-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}$$

since

$$\int_0^\infty \frac{|\xi^\alpha-\mu^\alpha|}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}d\xi \leqslant C\langle\mu\rangle^{1+\alpha-\rho}+C\mu^{\alpha-1}\int_{\frac{\mu}{2}}^{2\mu}\frac{|\xi-\mu|d\xi}{1+(\xi-\mu)^2\mu^{\rho-2}}+C\int_{2\mu}^\infty \frac{|\xi-\mu|^\alpha d\xi}{1+|\xi-\mu|^\rho}\leqslant C$$

for all $\mu>0$ if $0<\alpha<\rho-1$. In the same way as in the proof of Eq. (2.4) we have

$$\|I_3(t)\|_{\mathbf{L}_x^2} \leqslant Ct^{-1/2\rho-\alpha/\rho}\||\xi|^{\alpha-1}\hat{\nu}'(\xi)\|_{\mathbf{L}^\infty}\left\|\int_0^\infty \frac{\mu^{(\rho/2)-1}|\xi^\alpha-\mu^\alpha|}{1+|\xi-\mu||\xi^{\rho-1}-\mu^{\rho-1}|}d\xi\right\|_{\mathbf{L}_\mu^2}$$
$$\leqslant Ct^{1/2\rho-\alpha/\rho}\|\langle\mu\rangle^{\alpha-\rho/2}\|_{\mathbf{L}_\mu^2}\|\hat{\nu}\|_{\mathbf{Z}^\alpha} \leqslant Ct^{1/2\rho-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha} \tag{2.5}$$

if $0<\alpha<(\rho-1)/2$. Therefore by Eqs. (2.1)–(2.5) we obtain the result of the theorem for the case of $x<0$.

Now we consider the second case $x\geqslant 0$. By applying the identity

$$e^{i\xi\eta+(i/\rho)\xi^\rho}=\frac{1}{1+i\xi(\xi^{\rho-1}+\mu^{\rho-1})}\frac{\partial}{\partial\xi}(\xi e^{i\xi\eta+(i/\rho)\xi^\rho})$$

the integration by parts with respect to ξ yields

$$\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}(\xi t^{-1/\rho})d\xi=-t^{-1/\rho}\int_0^\infty \frac{\xi}{1+i\xi(\xi^{\rho-1}+\mu^{\rho-1})}e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}'(\xi t^{-1/\rho})d\xi$$
$$-i\int_0^\infty \frac{\xi\mu^{\rho-1+\rho\xi^\rho}}{(1+i\xi(\xi^{\rho-1}+\mu^{\rho-1}))^2}e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}(\xi t^{-1/\rho})d\xi.$$

Therefore we get

$$\left\|\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}(\xi t^{-1/\rho})d\xi\right\|_{\mathbf{L}_x^\infty}\leqslant Ct^{-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}\int_0^\infty\frac{\xi^\alpha d\xi}{1+\xi^\rho}\leqslant Ct^{-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}$$

if $0<\alpha<\rho-1$ and

$$\left\|\int_0^\infty e^{i\xi\eta+(i/\rho)\xi^\rho}\hat{\nu}(\xi t^{-1/\rho})d\xi\right\|_{\mathbf{L}_x^2}\leqslant Ct^{-1/2\rho}\left\|\int_0^\infty\frac{\xi\mu^{(\rho/2)-1}}{1+\xi(\xi^{\rho-1}+\mu^{\rho-1})}|\hat{\nu}'(\xi t^{-1/\rho})\|d\xi\right\|_{\mathbf{L}_\mu^2}$$
$$+Ct^{1/2\rho}\left\|\int_0^\infty\frac{\mu^{(\rho/2)-1}}{1+\xi(\xi^{\rho-1}+\mu^{\rho-1})}|\hat{\nu}'(\xi t^{-1/\rho})|d\xi\right\|_{\mathbf{L}_\mu^2}$$
$$\leqslant Ct^{1/2\rho-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}\left\|\int_0^\infty\frac{\xi^\alpha\mu^{(\rho/2)-1}d\xi}{1+\xi(\xi^{\rho-1}+\mu^{\rho-1})}\right\|_{\mathbf{L}_\mu^2}$$
$$\leqslant Ct^{1/2\rho-\alpha/\rho}\|\langle\mu\rangle^{\alpha-\rho/2}\|_{\mathbf{L}_\mu^2}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}\leqslant Ct^{1/2\rho-\alpha/\rho}\|\hat{\nu}\|_{\mathbf{Z}^\alpha}$$

if $0<\alpha<(\rho-1)/2$. This completes the proof of theorem 1.1.

III. LEMMAS

Denote the ordering of the norms

$$\|\phi\|_{\mathbf{L}_t^q\mathbf{L}_x^r}=\|\|\phi(t)\|_{\mathbf{L}_x^r(\mathbf{R})}\|_{\mathbf{L}_t^q(\mathbf{I})},$$

where $\mathbf{I}$ is a bounded or unbounded time interval. By the duality argument of Ref. 25 along with the estimates of theorem 1.1 the Strichartz estimate can be proved.

Lemma 3.1: For any time interval $\mathbf{I}$ and for any $s\in\overline{\mathbf{I}}$ the Strichartz estimate is true

$$\left\|\int_s^t U(t-\tau)\phi(\tau)d\tau\right\|_{\mathbf{L}_t^q\mathbf{L}_x^r}\leqslant C\|\phi\|_{\mathbf{L}_t^{\bar{q}'}\mathbf{L}_x^{\bar{r}'}}$$

with a constant C independent of $\mathbf{I}$ and s, where $0\leqslant\rho/q=1/2-1/r$ and $0\leqslant\rho/q'=1/2-1/r',1/r'+1/\bar{r}'=1$, and $1/q'+1/q'=1$.

We now consider the final state problem for the following equation:

$$\frac{dw}{dt}=i\lambda_1 t^{-1}\xi|\xi|^{2-\rho}|w|^2w+\lambda_2 t^{-1}|\xi|^{3-\rho}E^{\nu}\mathcal{D}_{\mu}w^3, \tag{3.1}$$

where $E=e^{-i(1-1/\rho)t|\xi|^{\rho-1}\xi},\lambda_1\in\mathbf{R},\lambda_2\in\mathbf{C},\mu=3^{\rho-1}$ we also denote the operator $\mathcal{D}_{\omega}\phi=\omega^{-1/2}\phi(x|\omega|^{-1/(\rho-1)})$.

To treat the divergence of the first term on the right-hand side of Eq. (3.1) we change the variable $w=\nu e^{i\varphi}$, where $\varphi(t,\xi)=\lambda_1\xi|\xi|^{2-\rho}|f(\xi)|^2\log t$. Then we get the final state problem

$$\frac{d\nu}{dt}=\mathcal{Q}(\nu),$$

$$\nu(t)\to f \text{ as } t\to\infty, \tag{3.2}$$

where

$$\mathcal{Q}(\nu)=i\lambda_1 t^{-1}\xi|\xi|^{2-\rho}(|\nu|^2-|f|^2)\nu+\lambda_2 t^{-1}|\xi|^{3-\rho}E^{\nu}e^{-i\varphi}\mathcal{D}_{\mu}e^{3i\varphi}\nu^3.$$

Lemma 3.2: Let $\lambda_1\in\mathbf{R},\lambda_2\in\mathbf{C}$. Suppose that the final state $f\in\mathbf{Y}^{\beta,\delta}$, where $(\rho-2)/2\leqslant\beta\leqslant\rho-2$ and

$$\mathbf{Y}^{\beta,\delta}=\{g:\|g\|_{\mathbf{Y}^{\beta,\delta}}=\|\langle\xi\rangle^{\delta+1}\{\xi\}^{-\beta}g\|_{\mathbf{L}_\infty}<\infty\}$$

and the norm $\|f\|_{\mathbf{Y}^{\beta,\delta}}$ is sufficiently small. Then there exists a unique solution $\nu\in\mathbf{C}([1,\infty);\mathbf{Y}^{\beta,\delta})$ of the final problem (3.2) such that

$$\sup_{t\geqslant1}t^{(2\beta-\rho+3)/\rho}\|\nu(t)-f\|_{\mathbf{Y}^{\beta,\delta}}\leqslant C\varepsilon^3.$$

Moreover, if $f'\in\mathbf{Y}^{\beta-1,2}$, then $\nu\in\mathbf{C}([1,\infty);\mathbf{W}^{\beta})$ with the estimates

$$\sup_{t\geqslant1}\|\nu\xi(t)\|_{\mathbf{Y}^{\beta-1,2}}\leqslant C\varepsilon.$$

Remark 3.1: In order to use the lemma to the proof of the main result we put $f=\hat{u}_+(\xi)$ and let β satisfy the condition

$$\max\left\{0,\frac{3\rho-7}{4}\right\}<\beta.$$

Then we find that

$$\|\omega(t)-\hat{u}_+(\xi)e^{-i\lambda_1\xi|\xi|^{2-\rho}|\hat{u}_+(\xi)|^2\log t}\|_{\mathbf{Y}^{\beta,\delta}}$$

decays faster than $t^{-(\rho-1)/2\rho}$.

Proof: We apply the contraction mapping principle in

$$\mathbf{X}_\varepsilon=\{\nu\in\mathbf{X}:\|\nu-f\|_{\mathbf{X}}\leqslant\varepsilon\},$$

where $\varepsilon=3\|f\|_{\mathbf{Y}^{\beta,\delta}}$ and the norm

$$\|\phi\|_{\mathbf{X}}=\sup_{t\geqslant 1}t^{(2\beta-\rho+3)/\rho}\|\phi(t)\|_{\mathbf{Y}^{\beta,\delta}}.$$

For $\nu\in\mathbf{X}_\varepsilon$ we define the mapping $\mathcal{M}(\nu)$ by

$$\mathcal{M}(\nu)=f+\int_t^\infty(\mathcal{Q}(\nu(\tau))-\mathcal{Q}(f))d\tau+\int_t^\infty\mathcal{Q}(f)d\tau, \tag{3.3}$$

where $\mathcal{Q}(f)=\lambda_2|\xi|^{3-\rho}E^\nu\tau^{-1}e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3$. First we prove the estimate $\|\mathcal{M}(\nu)-f\|_{\mathbf{X}}\leqslant\varepsilon$ if $\nu\in\mathbf{X}_\varepsilon$. Using the identity $E^\nu=B\partial_\tau(\tau E^\nu)$ with $B=(1-i\nu(1-1/\rho)\tau|\xi|^{\rho-1}\xi)^{-1}$ and

$$\begin{aligned}\tau\partial_\tau(\tau^{-1}Be^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi})=&-\tau^{-1}B(2-B)e^{-\varphi}\mathcal{D}_\mu e^{3i\varphi}-i\lambda_1\tau^{-1}Be^{-i\varphi}(\xi|\xi|^{2-\rho}|f|^2\mathcal{D}_\mu e^{3i\varphi}\\&-3\mathcal{D}_\mu e^{3i\varphi}(\xi|\xi|^{2-\rho}|f|^2)),\end{aligned}$$

we integrate by parts in the last integral in Eq. (3.3)

$$\begin{aligned}\mathcal{M}(\nu)-f=&\lambda_2|\xi|^{3-\rho}BE^\nu e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3+\int_t^\infty(\mathcal{Q}(\nu(\tau))-\mathcal{Q}(f))d\tau+\lambda_2|\xi|^{3-\rho}\\&\times\int_t^\infty E^\nu B(2-B)e^{-\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3\frac{d\tau}{\tau}+i\lambda_1\lambda_2|\xi|^{3-\rho}\int_t^\infty E^\nu Be^{-i\varphi}(\xi|\xi|^{2-\rho}|f|^2\mathcal{D}_\mu e^{3i\varphi}\\&-3\mathcal{D}_\mu e^{3i\varphi}\xi|\xi|^{2-\rho}|f|^2)f^3\frac{d\tau}{\tau}.\end{aligned} \tag{3.4}$$

Then by the conditions of the lemma we have

$$\begin{aligned}\left\|\int_t^\infty(\mathcal{Q}(\nu(\tau))-\mathcal{Q}(f))d\tau\right\|_{\mathbf{X}}&\leqslant C\sup_{t\geqslant 1}t^{(2\beta-\rho+3)/\rho}\int_t^\infty(\|\nu-f\|^2_{\mathbf{Y}^{(\rho-2)/2,1}}+\|f\|^2_{\mathbf{Y}^{(\rho-2)/\rho,1}})\|\nu-f\|_{\mathbf{Y}^{\beta,\delta}}\frac{d\tau}{\tau}\\&\leqslant C\|\nu-f\|_{\mathbf{X}}(\|\nu-f\|^2_{\mathbf{X}}+\|f\|^2_{\mathbf{Y}^{(\rho-2)/\rho,1}})\sup_{t\geqslant 1}t^{(2\beta-\rho+3)/\rho}\\&\quad\times\int_t^\infty\tau^{-1(2\beta-\rho+3)/\rho}d\tau\leqslant C\varepsilon^3.\end{aligned}$$

Since $|B|\leqslant C\langle\tau\xi^\rho\rangle^{-1}$ we also get

$$\|\langle\xi\rangle^{\delta+1}\{\xi\}^{-\beta}|\xi|^{3-\rho}BE^\nu e^{-ei\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3\|_{\mathbf{L}^\infty}\leqslant C\|f\|^3_{\mathbf{Y}^{\beta,\delta}}\||\xi|^{2\beta-\rho+3}\langle t\xi^\rho\rangle^{-1}\|_{\mathbf{L}^\infty}\leqslant C\varepsilon^3t^{(2\beta-\rho+3)/\rho}$$

and

$$\left\| |\xi|^{3-\rho} \int_t^\infty E^\nu B e^{-i\varphi} (\xi |\xi|^{2-\rho} |f|^2 \mathcal{D}_\mu e^{3ie\varphi} - 3\mathcal{D}_\mu e^{3i\varphi} \xi |\xi|^{2-\rho} |f|^2) f^3 \frac{d\tau}{\tau} \right\|_{\mathbf{Y}^{\beta,\delta}}$$

$$\leqslant C\|f\|^3_{\mathbf{Y}^{\beta,\delta}} \left\| |\xi|^{2\beta-\rho+3} \int_t^\infty \langle \tau \xi^\rho \rangle^{-1} \frac{d\tau}{\tau} \right\|_{\mathbf{L}_\infty} \leqslant C\|f\|^3_{\mathbf{Y}^{\beta,\delta}} t^{(2\beta-\rho+3)/\rho} \leqslant C\varepsilon^3 t^{(2\beta-\rho+3)/\rho}, \tag{3.5}$$

where $(\rho-2)/2 \leqslant \beta \leqslant \rho-2$. Therefore the mapping $\mathcal{M}$ transforms a ball $\mathbf{X}_\varepsilon$ with a center f and a radius $\varepsilon > 0$ into itself. In the same manner for $v_1, v_2 \in \mathbf{X}_\varepsilon$ we have

$$\|\mathcal{M}(v_1) - \mathcal{M}(v_2)\|_{\mathbf{X}} \leqslant \left\| \int_t^\infty (\mathcal{Q}(v_1(\tau)) - \mathcal{Q}(v_2(\tau)))d\tau \right\|_{\mathbf{X}} \leqslant \frac{1}{2}\|v_1 - v_2\|_{\mathbf{X}}.$$

Thus $\mathcal{M}$ is a contraction mapping in $\mathbf{X}_\varepsilon$. Therefore there exists a unique solution $v \in \mathbf{X}_\varepsilon$ to the final problem Eq. (3.2).

We now suppose that $f' \in \mathbf{Y}^{\beta-1,2}$. Taking the derivative of Eq. (3.4) with respect to ξ we obtain for the new function $h(t) = v_\xi(t) - f' + i\nu\lambda_2(\rho-1)t\xi^2 B E^\nu e^{-i\varphi} \mathcal{D}_\mu e^{3i\varphi} f^3$,

$$h(t) = \lambda_2 E^\nu \partial_\xi (|\xi|^{3-\rho} B e^{-i\varphi} \mathcal{D}_\mu e^{3i\varphi} f^3) + \int_t^\infty \mathcal{Q}_1(v(\tau))d\tau + \int_t^\infty \mathcal{Q}_2(v(\tau))d\tau,$$

where

$$\begin{aligned}
\mathcal{Q}_1(v) &= i\lambda_1(3-\rho)\tau^{-1}|\xi|^{2-\rho}(|v|^2 - |f|^2)v + i\lambda_1\tau^{-1}\xi|\xi|^{2-\rho}(v_\xi(|v|^2 - |f|^2) + v\,\mathrm{Re}(\bar{v}h + (\bar{v} - \bar{f})f')) \\
&+ \lambda_2\tau^{-1}E^\nu\partial_\xi(|\xi|^{3-\rho}e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi})(v^3 - f^3) + 3\lambda_2\tau^{-1}E^\nu|\xi|^{3-\rho}e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}((v^2 - f^2)v_\xi + f^2 h) \\
&+ \lambda_2\tau^{-1}E^\nu\partial_\xi(|\xi|^{3-\rho}B(2-B)e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3) + i\lambda_1\lambda_2\tau^{-1}E^\nu\partial_\xi(|\xi|^{3-\rho}Be^{-i\varphi}(\xi|\xi|^{2-\rho}|f|^2\mathcal{D}_\mu e^{3i\varphi} \\
&- 3\mathcal{D}_\mu e^{3i\varphi}\xi|\xi|^{2-\rho}|f|^2)f^3)
\end{aligned}$$

and

$$\begin{aligned}
\mathcal{Q}_2(v) &= -i\nu(\rho-1)\lambda_1\xi|\xi|^{4-\rho}v\,\mathrm{Re}(\bar{v}i\lambda_2 B E^\nu e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3) - 3i\nu\lambda_2^2(\rho-1)E^{\nu(1+3^{-\rho})} \\
&\times|\xi|^{3-\rho}e^{-i\varphi}\mathcal{D}_\mu(f^2\xi^2 B e^{2i\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3) + i\nu\lambda_2(\rho-1)\xi^2 E^\nu(e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}(v^3 - f^3) \\
&+ B(2-B)e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}f^3 + i\lambda_1\xi|\xi|^{2-\rho}|f|^2 B e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi} - 3i\lambda_1 B e^{-i\varphi}\mathcal{D}_\mu e^{3i\varphi}\xi|\xi|^{2-\rho}|f|^2 f^3).
\end{aligned}$$

In the term $\mathcal{Q}_2(v)$ we integrate again by parts as in Eq. (3.5) and note that $\{\xi\}|B| \leqslant C\tau^{-1/\rho}$. We therefore find

$$\|h(l)\|_{\mathbf{Y}^{\beta-1,2}} \leqslant C\varepsilon^3 t^{-\gamma} + C\varepsilon^3 \int_t^\infty \tau^{-1-1/\rho} d\tau \leqslant C\varepsilon t^{-\gamma}.$$

Lemma 3.2 is proved. ■

IV. MODIFIED WAVE OPERATOR

We define the modified final state $\hat{w}(t)$ as a solution to the final problem Eq. (3.1)

$$\hat{w}_t(t,\xi) = \frac{1}{t}(i\lambda\xi|\mathbf{F}\hat{w}|^2\hat{w} + i\tilde{\lambda}\xi\mathbf{F}^2 E^\nu \mathcal{D}_\mu \hat{w}^3), \tag{4.1}$$

where $\mathbf{F} = \sqrt{4/i(\rho-1)}\,|\xi|^{1-\rho/2}$, $E = e^{-i(1-1/\rho)t|\xi|^{\rho-1}\xi}$, $\nu = (1-3^{1-\rho})/(\rho-1)$, $\mu = 3^{\rho-1}$, $\tilde{\lambda} = \lambda 3^{3\rho/2-4}$ and a final state $f = \widehat{u_+}(\xi)$. The problem (4.1) is considered in lemma 3.2. Since $\mathcal{L}\mathcal{U}(t) = U(t)\partial_t$ for $\mathcal{L} = \partial_t + 1/p|\partial_x|^{\rho-1}\partial_x$, by Eq. (1.1) we find for the difference $\nu = u - U(t)w$,

$$\mathcal{L}v = \mathcal{N}_1 + \mathcal{N}_2, \tag{4.2}$$

where

$$\mathcal{N}_1 = \lambda u^2 v_x + \lambda(u^2 - (U(t)w)^2)U(t)w_x,$$

$$\mathcal{N}_2 = \lambda(U(t)w)^2 U(t)w_x - it^{-1}U(t)\mathcal{F}^{-1}(\lambda\xi|\hat{w}|^2\hat{w} + \tilde{\lambda}\xi F^2 E^{\nu} D_{\mu}\hat{w}^3).$$

By theorem 1.1 we have

$$U(t)w = t^{-1/2}\mathrm{Re}(\theta(x)(FE\hat{w})(\chi)) + R_1$$

and

$$U(t)w_x = t^{-1/2}\mathrm{Re}(i\theta(x)\chi(FE\hat{w})(\chi)) + R_2$$

with $\chi=(|x|/t)^{(1/\rho-1)}$, $\theta(x)=1$ for $x<0$ and $\theta(x)=0$ for $x\geqslant 0$. The remainder terms satisfy the estimates

$$\begin{aligned}
&\|R_1(t)\|_{\mathbf{H}^2} + t^{1/2\rho}\|R_1(t)\|_{\mathbf{H}^2_\infty} + \|R_2(t)\|_{\mathbf{H}^2} + t^{1/2\rho}\|R_2(t)\|_{\mathbf{H}^2_\infty} \\
&\quad \leqslant Ct^{-\alpha/\rho-1/2\rho}\|\hat{w}(t)\|_{\mathbf{W}^\alpha} \\
&\quad = Ct^{-\alpha/\rho-1/2\rho}\|\langle\xi\rangle^3\{\xi\}^{-\alpha}\hat{u}_+(\xi)\|_{\mathbf{L}^\infty} + Ct^{-\alpha/\rho-1/2\rho}\|\langle\xi\rangle^3\{\xi\}^{1-\alpha}\hat{w}_\xi(t,\xi)\|_{\mathbf{L}^\infty} \\
&\quad \leqslant Ct^{-\alpha/\rho-1/2\rho}(1+\log t\|\hat{u}_+\|^2_{\mathbf{Z}^\alpha})\|\hat{u}_+\|_{\mathbf{W}^\alpha}
\end{aligned}$$

for $(\rho-2)/2\leqslant\alpha<(\rho-1)/2$, where $\|\widehat{u_+}\|_{\mathbf{W}^\alpha}=\|\langle\xi\rangle^3\widehat{u_+}\|_{\mathbf{Z}^\alpha}$. Then we have

$$\begin{aligned}
(U(t)w)^2U(t)w_x &= t^{-3/2}(\mathrm{Re}(\theta(x)(FE\hat{w})(\chi)) + R_1)^2(\mathrm{Re}(i\theta(x)\chi(FE\hat{w})(\chi)) + R_2) \\
&= t^{-3/2}(\mathrm{Re})(i\theta(x)\chi(F^3E^3\hat{w}^3)(\chi)) + t^{-3/2}|F\hat{w}|^2\mathrm{Re}(i\theta(x)\chi(FE\hat{w})(\chi)) + R_3
\end{aligned} \tag{4.3}$$

with the estimate

$$\|R_3(t)\|_{\mathbf{H}^2} \leqslant Ct^{-1-\alpha/\rho-1/2\rho}(1+(\log t)\|\widehat{u_+}\|^2_{\mathbf{Z}^\alpha})\|\widehat{u_+}\|_{\mathbf{W}^\alpha}.$$

By theorem 1.1 we also get

$$t^{-1}i\lambda U(t)\mathcal{F}^{-1}\xi|F\hat{w}|^2\hat{w} = t^{-3/2}\mathrm{Re}(i\lambda\theta(x)\chi(F|F|^2E|\hat{w}|^2\hat{w})(\chi)) + R_4, \tag{4.4}$$

and since $\omega=1+\nu-\nu\rho=3^{1-\rho}$ we have $\tilde{\lambda}D_\omega\chi F^3E^\omega=\chi F^3E^3\mathcal{D}_\omega$ and

$$\begin{aligned}
i\tilde{\lambda}t^{-1}U(t)\mathcal{F}^{-1}E^{\nu}\xi F^2D_{\mu}\hat{w}^3 &= i\tilde{\lambda}t^{-1}\mathcal{F}^{-1}\exp\left(\omega\frac{it}{\rho}|\xi|^{\rho-1}\xi\right)\xi F^2D_{\mu}\hat{w}^3 \\
&= i\tilde{\lambda}t^{-1}U(\omega t)\mathcal{F}^{-1}\xi F^2D_{\mu}\hat{w}^3 \\
&= t^{-3/2}\mathrm{Re}(i\tilde{\lambda}D_\omega\theta(x)\chi F^3E^\omega D_{\mu}\hat{w}^3) + R_5 \\
&= t^{-3/2}\mathrm{Re}(i\theta(x)\chi(F^3E^3\hat{w}^3)(\chi)) + R_5,
\end{aligned} \tag{4.5}$$

with the estimate of the remainder terms

$$\|R_4(t)\|_{\mathbf{H}^2} + \|R_5(t)\|_{\mathbf{H}^2} \leqslant Ct^{-1-\alpha/\rho-1/2\rho}(1+\log t\|\hat{u}_+\|^2_{\mathbf{Z}^\alpha})\|\hat{u}_+\|_{\mathbf{W}^\alpha}.$$

Therefore by Eqs. (4.3)–(4.5) we find that $\mathcal{N}_2=R_3+R_4+R_5$. Thus

$$\|\mathcal{N}_2\|_{\mathbf{H}^2} \leqslant Ct^{(\gamma-1)-\alpha/\rho-1/2\rho}. \tag{4.6}$$

We introduce the function space

$$\mathbf{Y} = \{\phi \in \mathbf{C}([T,\infty);\mathbf{L}^2): \|\phi\|_{\mathbf{Y}} < \infty\},$$

where the norm

$$\|\phi\|_{\mathbf{Y}} = \sup_{t\in(T,\infty)} t^b(\|\varphi\|_{\mathbf{L}_t^\infty(t,\infty)\mathbf{H}^2(\mathbf{R})} + \|\varphi\|_{\mathbf{L}_t^{2\rho}(t,\infty)\mathbf{H}_\infty^1(\mathbf{R})})$$

with $(\rho-1)/2\rho < b < \alpha/\rho+1/2\rho-\gamma < 1/2, \gamma > 0$ is small. Consider the linearized version of Eq. (4.2) written as

$$\mathcal{L}\nu = \lambda(\tilde{u}^2\nu_x + (\tilde{u}^2 - (U(t)w)^2)U(t)w_x) + \mathcal{N}_2 \tag{4.7}$$

with the final condition $\lim_{t\to\infty}\nu(t)=0$ in $\mathbf{L}^2$, where $\tilde{u}=\tilde{\nu}+U(t)w$ and

$$\tilde{\nu} \in \mathbf{Y}_\varepsilon = \{\phi \in \mathbf{C}([T,\infty);\mathbf{L}^2): \|\phi\|_{\mathbf{Y}} \leqslant C\varepsilon\}.$$

We apply the standard energy method to Eq. (4.7). Using Sobolev imbedding theorem we then get

$$\begin{aligned}\|\nu(t)\|_{\mathbf{H}^2}^2 &\leqslant \int_t^\infty (\|\tilde{\nu}\|_{\mathbf{H}_\infty^1}^2 + \|\tilde{\nu}\|_{\mathbf{H}_\infty^1}\|U(\tau)w\|_{\mathbf{H}_\infty^3} + \|U(\tau)w\|_{\mathbf{H}_\infty^1}^2)\|\nu\|_{\mathbf{H}^2}^2 d\tau + C\int_t^\infty \tau^{(\gamma-1)-\alpha/\rho-1/2\rho}\|\nu(t)\|_{\mathbf{H}^2} d\tau \\ &\leqslant C\int_t^\infty (\|\tilde{\nu}\|_{\mathbf{H}_\infty^1}^2 + \tau^{-1/2}\|\tilde{\nu}\|_{\mathbf{H}_\infty^1} + \tau^{-1})\|\nu\|_{\mathbf{H}^2}^2 d\tau + Ct^{\gamma-\alpha/\rho-1/2\rho}\|\nu(t)\|_{\mathbf{H}_2}.\end{aligned}$$

By applying the Hölder inequality

$$\begin{aligned}\|\nu(t)\|_{\mathbf{H}^2}^2 &\leqslant C\left(\int_t^\infty \|\tilde{\nu}\|_{\mathbf{H}_\infty^1}^{2\rho} d\tau\right)^{1/\rho}\left(\int_t^\infty \|\nu\|_{\mathbf{H}^2}^{2\rho/(\rho-1)} d\tau\right)^{(\rho-1)/\rho} + C\left(\int_t^\infty \|\tilde{\nu}\|_{\mathbf{H}_\infty^1}^{2\rho} d\tau\right)^{1/2\rho} \\ &\quad \times \left(\int_t^\infty \tau^{-\rho/(2\rho-1)}\|\nu\|_{\mathbf{H}^2}^{4\rho/(2\rho-1)} d\tau\right)^{(2\rho-1)/2\rho} + C\int_t^\infty \tau^{-1}\|\nu\|_{\mathbf{H}^2}^2 d\tau + Ct^{\gamma-\alpha/\rho-1/2\rho}\|\nu(t)\|_{\mathbf{H}^2} \\ &\leqslant Ct^{-2b}\left(\varepsilon^2 t^{(\rho-1)/\rho-2b} + \varepsilon^2 t^{(\rho-1)/2\rho-b} + 1\right)\sup_{t\geqslant T} t^{2b}\|\nu(t)\|_{\mathbf{H}^2}^2 + C\varepsilon t^{-2b}\end{aligned}$$

since $(\rho-1)/2\rho < b < \alpha/\rho+1/2\rho-\gamma, \gamma > 0$ is small. Hence, there exists a time $T \geqslant 1$ and $\varepsilon > 0$ such that if $\|u_+\|_{\mathbf{W}^\alpha} \leqslant \varepsilon$, then

$$\sup_{t\geqslant T} t^b\|\nu\|_{\mathbf{L}_t^\infty(t,\infty)\mathbf{H}^2(\mathbf{R})} \leqslant \varepsilon. \tag{4.8}$$

By the Strichartz estimates (see lemma 3.1)

$$\begin{aligned}\|\nu\|_{\mathbf{L}_t^{2\rho}(t,\infty)\mathbf{H}_\infty^1(\mathbf{R})} &\leqslant C\left(\int_t^\infty (\|\tilde{\nu}(\tau)\|_{\mathbf{H}_\infty^1}\|\tilde{\nu}(\tau)\|_{\mathbf{H}^1}\|\nu(\tau)\|_{\mathbf{H}^2})^{2\rho/(2\rho-1)} d\tau\right)^{(2\rho-1)/2\rho} \\ &\quad + C\left(\int_t^\infty \left(\left\|U(\tau)w\right\|_{\mathbf{H}_\infty^1}\left\|\tilde{\nu}(\tau)\right\|_{\mathbf{H}^1}\|\nu(\tau)\|_{\mathbf{H}^2}\right)^{2\rho/(2\rho-1)} d\tau\right)^{(2\rho-1)/2\rho} \\ &\quad + C\int_t^\infty \|U(\tau)w\|_{\mathbf{H}_\infty^1}^2\|\nu(\tau)\|_{\mathbf{H}^2} d\tau + C\int_t^\infty \|\mathcal{N}_2\|_{\mathbf{L}^2} d\tau.\end{aligned}$$

Hence,

$$\|v\|_{\mathbf{L}_t^{2\rho}(t,\infty)\mathbf{H}_\infty^1(\mathbf{R})} \leqslant C\varepsilon^2\left(\int_t^\infty \tau^{-4\rho b/(2\rho-1)}\|\tilde{v}(\tau)\|_{\mathbf{H}_\infty^1}^{2\rho/(2\rho-1)}d\tau\right)^{(2\rho-1)/2\rho} + C\varepsilon^3\left(\int_t^\infty \tau^{-(4\rho b+\rho)/(2\rho-1)}d\tau\right)^{(2\rho-1)/2\rho}$$
$$+ C\varepsilon^3\int_t^\infty \tau^{-1-b}d\tau + Ct^{\gamma-\alpha/\rho-1/2\rho}$$
$$\leqslant C\varepsilon^2 t^{(\rho-1)/\rho-2b}\|\vec{v}\|_{\mathbf{L}_t^{2\rho}(t,\infty)\mathbf{H}_\infty^1(\mathbf{R})} + C\varepsilon t^{(\rho-1)/2\rho-2b} + C\varepsilon^3 t^{-b},$$

from which it follows that there exists a time $T\geqslant 1$ such that

$$\sup_{t\geqslant T} t^b\|v\|_{\mathbf{L}_t^{2\rho}(t,\infty)\mathbf{H}_\infty^1(\mathbf{R})} \leqslant \varepsilon. \tag{4.9}$$

Thus we have by Eqs. (4.8) and (4.9)

$$\|v\|_{\mathbf{Y}} \leqslant \varepsilon \tag{4.10}$$

which implies that the mapping $\mathcal{M}$ defined by $v=\mathcal{M}\tilde{v}$ transforms $\mathbf{Y}_\varepsilon$ into itself. Denote $v_j=\mathcal{M}\tilde{v}_j$, then in the same way as in the proof of Eq. (4.8) we have

$$\sup_{t\geqslant T} t^b\|v_1(t)-v_2(t)\|_{\mathbf{H}^1} \leqslant \tfrac{1}{2}\sup_{t\geqslant T} t^b\|\tilde{v}_1(t)-\tilde{v}_2(t)\|_{\mathbf{H}^1}. \tag{4.11}$$

From Eqs. (4.10) and (4.11) by the contraction mapping principle, we have the desired result. Theorem 1.2 is proved.

V. NONEXISTENCE OF THE WAVE OPERATOR

Multiplying Eq. (1.1) by $U(-t)$ and integrating with respect to time we find

$$U(-t)u(t)-U(-s)u(s)=\lambda\int_s^t U(-\tau)(u^2u_x-(U(t)u_+)^2\partial_x U(t)u_+)d\tau+\lambda\int_s^t U(-\tau)$$
$$\times\Big((U(t)u_+)^2\partial_x U(t)u_+ - \tau^{-3/2}(\mathrm{Re}\ \theta(x)(F\widehat{Eu_+})(\chi))^2\mathrm{Re}\ i\theta(x)\chi(F\widehat{Eu_+})(\chi)\Big)d\tau$$
$$+\lambda\int_s^t U(-\tau)\tau^{-3/2}(\mathrm{Re}\ \theta(x)(F\widehat{Eu_+})(\chi))^2\mathrm{Re}\ i\theta(x)\chi(F\widehat{Eu_+})(\chi)d\tau.$$

By theorem 1.1 we have

$$U(\omega\tau)\phi=|\omega|^{(\rho-2)/(2\rho-2)}\mathrm{Re}\ \tau^{-1/2}\theta(x)F(\chi\ \mathrm{sign}\ \omega)E^\sigma\mathcal{D}_\omega\hat{\phi}(\chi)+O(\tau^{-1/2(1-1/\rho)-\gamma})$$

in $\mathbf{L}^p$ for $2\leqslant p\leqslant\infty$, where $\omega\neq 0,\sigma=|\omega|^{-1/(\rho-1)}\mathrm{sign}\ \omega,\gamma>0$. Therefore taking $\omega=1,3^{1-\rho}$ and $3^{1-\rho}-1$, we obtain

$$U(-\tau)\tau^{-3/2}(\mathrm{Re}\ \theta(x)(F\widehat{Eu_+})(\chi))^2\mathrm{Re}\ i\theta(x)\chi(F\widehat{Eu_+})(\chi)$$
$$=\tau^{-1}U(-\tau)\mathrm{Re}\ \tau^{-1/2}\theta(x)FE|\widehat{Fu_+}|^2i\chi\widehat{u_+}(\chi)+\tau^{-1}U(-\tau)\mathrm{Re}(\tau^{-1/2}\theta(x)i\chi(FE^3F^2\widehat{u_+^3})(\chi))$$
$$=\tau^{-1}U(-\tau)U(\tau)\mathcal{F}^{-1}_{\xi\to x}|\widehat{Fu_+}|^2i\xi\widehat{u_+}(\xi)+3^{-(\rho-2)/(2\rho-2)}\tau^{-1}U(-\tau)$$
$$\times U(3^{1-\rho}\tau)\mathcal{F}^{-1}_{\xi\to x}\mathcal{D}_{3\rho-1}i\xi F^2\hat{u}_+^3(\xi)+O(\tau^{-1-\gamma})$$
$$=\tau^{-1}\mathcal{F}^{-1}_{\xi\to x}|\widehat{Fu_+}|^2i\xi\widehat{u_+}(\xi)+C\tau^{-3/2}\mathrm{Re}\ \theta(x)F(-\chi)\overline{E}^\nu\mathcal{D}_{3\rho-1,\nu}i\chi F^2\hat{u}_+^3(\chi)+O(\tau^{-1-\gamma})$$

in $\mathbf{L}^2$, where $\nu=|3^{1-\rho}-1|^{-1/(\rho-1)}$. Hence, by integration by parts with respect to τ we see that

$$\left\| \lambda \int_s^t U(-\tau)\tau^{-3/2}(\mathrm{Re}\ \theta(x)(F\widehat{Eu_+})(\chi))^2(\mathrm{Re}\ i\theta(x)\chi(F\widehat{Eu_+})(\chi))d\tau \right\|_{\mathbf{L}^2}$$

$$\geqslant \left\| \lambda \int_s^t \mathcal{F}^{-1}_{\xi\to x}|F\widehat{u_+}|^2 i\xi\widehat{u_+}(\xi)\frac{d\tau}{\tau} \right\|_{\mathbf{L}^2} - C\left\| \lambda \int_s^t \tau^{-3/2}\bar{E}^{\nu}\mathcal{D}_{3^{\rho-1}\nu}\chi F^2\widehat{u_+}^3(\chi)d\tau \right\|_{\mathbf{L}^2} - C$$

$$\geqslant |\lambda|\||\xi|F\widehat{u_+}|^2\widehat{u_+}(\xi)\|_{\mathbf{L}^2}\int_s^t \frac{d\tau}{\tau} - C.$$

Thus in view of estimates of the solution $u(t)$ provided by theorem 1.2 we get

$$\|U(-t)u(t) - U(-s)u(s)\|_{\mathbf{L}^2} \geqslant |\lambda|\||\xi|F\widehat{u_+}|^2\widehat{u_+}\|_{\mathbf{L}^2}\int_s^t \frac{d\tau}{\tau} - C - C\int_s^t \|u(\tau) - U(\tau)u_+\|_{\mathbf{H}^1}\frac{d\tau}{\tau}$$

$$- C\int_s^t \|U(t)u_+ - \tau^{-1/2}\mathrm{Re}\ \theta(x)(F\widehat{Eu_+})(\chi)\|_{\mathbf{H}^1}\frac{d\tau}{\tau}.$$

This implies that for any $\delta>0$ there exists a time $T(\delta)$ such that for any $t>s>T(\delta)$,

$$\|U(-t)u(t) - U(-s)u(s)\|_{\mathbf{L}^2} \geqslant \left(|\lambda|\||\xi|F\widehat{u_+}|^2\widehat{u_+}\|_{\mathbf{L}^2} - \delta\right)\int_s^t \frac{d\tau}{\tau},$$

which means that $\widehat{u_+}=0$ for all $\chi\in\mathbf{R}$, since u_+ is a real-valued function, so that $\widehat{u_+}(-\xi)=\widehat{u_+}(\xi)$. The solution satisfies the conservation of the $\mathbf{L}^2$ norm, hence, we have $u=0$. Theorem 1.3 is proved.

(Received 12 April 2006; accepted 20 October 2006; published online 6 December 2006)

This paper deals with spectral properties of a class of neutron transport equations involving partly elastic collision operators introduced by Larsen and Zweifel [J. Math. Phys. **15**, 1987–1997 (1974)]. In particular, estimates of the essential type of associated semigroups are given. © *2006 American Institute of Physics.*

I. INTRODUCTION

Consider the neutron transport equation introduced by Larsen and Zweifel in Ref. 7,

$$\frac{\partial \varphi}{\partial t}(x,v,t) + v \cdot \frac{\partial \varphi}{\partial x}(x,v,t) + \sigma(x,v)\varphi(x,v,t) = K\varphi(x,v,t),$$

with zero incoming flux

$$\varphi_{|\Gamma_-}(\cdot,\cdot,t) = 0$$

and an initial condition

$$\varphi(x,v,0) = \varphi_0(x,v),$$

where $(x,v) \in \Omega \times V$, Ω is an open and bounded set of $\mathbb{R}^N$ $(N \geqslant 3)$ endowed with the Lebesgue measure dx, and the velocity space

$$V = \{v = \rho\omega; \omega \in \mathbb{S}^{N-1}, 0 \leqslant \rho_{\min} \leqslant \rho \leqslant \rho_{\max} < \infty\} =: I \times \mathbb{S}^{N-1}$$

is endowed with the Lebesgue measure $\mathrm{d}v = \rho^{N-1}\mathrm{d}\rho\mathrm{d}\omega$, where $\mathrm{d}\omega$ is the Lebesgue measure on the unit sphere $\mathbb{S}^{N-1}$. Here Γ_- denotes the incoming part of the boundary of the phase space $\Omega \times V$: $\Gamma_- = \{(x,v) \in \partial\Omega \times V; v \cdot \eta(x) < 0\}$, where $\eta(x)$ stands for the outward normal unit at $x \in \partial\Omega$. The function $\sigma(\cdot,\cdot) \in L^\infty_+(\Omega \times V)$ is called the collision frequency. The collision operator consists of three terms:

$$K = K_c + K_e + K_d.$$

The *classical* collision operator

$$K_c\varphi(x,v) = \int_V k_c(x,v,v')\varphi(x,v')\mathrm{d}v'$$

corresponds physically to fission, high energy elastic slowing down, and thermal inelastic scattering. K_e is an *elastic* operator for low energy neutrons describing microscopic events in which the kinetic energy is conserved and velocities are changed only in their direction. It is given by

a)Electronic mail: msbihi@math.univ-fcomte.fr

$$K_e\varphi(x,v) = \int_{\mathbb{S}^{N-1}} K_e(x,\rho,\omega,\omega')\varphi(x,\rho\omega')\mathrm{d}\omega'.$$

Finally, K_d represents high energy inelastic scattering and is described by a *downshift* operator of the form

$$K_d\varphi(x,v) = \sum_{m=1}^{\nu} K_d^{(m)}\varphi(x,v) = \sum_{m=1}^{\nu} \int_{\mathbb{S}^{N-1}} k_d^{(m)}(x,e_m(\rho),\omega,\omega')\varphi(x,e_m(\rho)\omega')\mathrm{d}\omega',$$

where $K_d^{(m)}$ $(m=1,\ldots,\nu)$ describes an event in which a discrete energy E_m is lost by a neutron at x with initial speed $e_m(\rho)$ and final speed ρ. The initial speed $e_m(\rho)$ is defined by

$$E_m = \frac{1}{2}Me_m^2(\rho) - \frac{1}{2}M\rho^2,$$

where M is the mass of neutron. Here and in the sequel we adopt the convention that all functions are extended by zero outside of their domains. Moreover, we use indifferently one of the notations $\varphi(x,v), \varphi(x,\rho,\omega)$, or $\varphi(x,\rho\omega)$ for $v=\rho\omega$. Notice that each $K_d^{(m)}$ acts on the supports of functions as follows:

$$\text{supp}\ \varphi \subset \Omega\times[0,\rho_0]\times\mathbb{S}^{N-1} \Rightarrow \text{supp}\ K_d^{(m)}\varphi \subset \Omega\times\left[0,\left(\max\left\{0,\rho_0^2-\frac{2E_m}{M}\right\}\right)^{1/2}\right]\times\mathbb{S}^{N-1}. \tag{1}$$

Since neutron speeds are bounded above ($\rho_{\max}<+\infty$), this property implies that K_d is nilpotent, i.e., there exists an integer n such that $K_d^n=0$.

The above collision models are particularly relevant when dealing with neutron transport in crystalline medium (see Ref. 3). Operators of types K_i and K_e are important also for electron transport in the semiconductor theory (see Ref. 9).

We put the above problem as an abstract Cauchy problem in the Banach space $L^p(\Omega\times V)$, $1\leqslant p<\infty$:

$$\begin{aligned}\frac{\mathrm{d}\varphi}{\mathrm{d}t}(t) &= (T+K)\varphi(t),\\ \varphi(0) &= \varphi_0,\end{aligned} \tag{2}$$

where T denotes the streaming operator

$$T{:}D(T) \ni \varphi \mapsto -v\cdot\frac{\partial\varphi}{\partial x} - \sigma(x,v)\varphi(x,v)$$

with the domain

$$D(T) = \left\{\varphi\in L^p(\Omega\times V){:}v\cdot\frac{\partial\varphi}{\partial x}\in L^p(\Omega\times V), \varphi_{|\Gamma^-}=0\right\}.$$

If K is bounded, then $T+K$ generates a C_0-semigroup $(\mathrm{e}^{t(T+K)})_{t\geqslant 0}$, which solves the preceding Cauchy problem in a reasonable sense. The asymptotic behavior $(t\to\infty)$ of the time dependent solution can be obtained by investigating the spectral properties of $(\mathrm{e}^{t(T+K)})_{t\geqslant 0}$.

Under suitable assumptions, e.g., piecewise continuous cross sections, the spectrum of the generator $T+K$ is described in Ref. 7. Typically, it consists of a half space, curves, and discrete eigenvalues. However, because the spectral mapping theorem does not hold for general C_0-semigroup, the spectrum of $T+K$ gives, *a priori*, only partial information about the asymptotic behavior of the semigroup. To our knowledge, up to now, in contrast to the classical model (i.e.,

$K=K_c$) which was intensively investigated (see, for instance, Refs. 4, 5, 10, 11, 13, 14, 16, 17, and 19–21), there is no spectral result on the semigroup $(e^{t(T+K_e+K_d+K_c)})_{t\geqslant 0}$, although the knowledge of its essential type (see the end of this introduction for the definition of essential type and its properties) is desirable and is an important prerequisite for understanding the time asymptotic behavior of the solutions to the associated Cauchy problem.

The purpose of the present work is to investigate the essential spectrum of the semigroup $(e^{t(T+K)})_{t\geqslant 0}$. More precisely, we deal with comparison of the essential types of the three semigroups $(e^{t(T+K_e)})_{t\geqslant 0}$, $(e^{t(T+K_e+K_d)})_{t\geqslant 0}$, and $(e^{t(T+K_e+K_d+K_c)})_{t\geqslant 0}$. Following Vidav[17] and others (see, for instance, Refs. 10, 16, 18, and 21), we will use the compactness argument on the remainder terms of the Dyson-Phillips expansion. We point out that the approach will be completely different according to whether we study the problem in a L^1-space or in a L^p-space, $1<p<\infty$.

Actually, the present paper is divided into two parts. In the first part (Sec. II), we deal with the above problem in $L^1(\Omega\times V)$. First, because of the nilpotence of K_d, we prove that the two semigroups $(e^{t(T+K_e+K_d)})_{t\geqslant 0}$ and $(e^{t(T+K_e)})_{t\geqslant 0}$ have the same essential type. Then we prove, by using, in particular, the strong convex compactness property (see Theorem 2), that the addition of the classical operator does not alter the essential type. We end up the section by deriving some estimates on the essential type of the semigroup $(e^{t(T+K)})_{t\geqslant 0}$. In the second part (Sec. III) of the paper, we give similar results in the context of L^p-spaces but with different tools.

Before closing this Introduction and for the sake of being complete, we recall the definition of essential type and some related properties. Let X be a complex Banach space and let $B\in\mathcal{L}(X)$ (the space of bounded linear operators on X). A point $\lambda\in\sigma(B)$ (the spectrum of B) is an eigenvalue of finite algebraic multiplicity if λ is an isolated point of $\sigma(B)$ and a pole of the resolvent of B with finite rank residue. The essential spectral radius of B is defined by

$$r_{\mathrm{ess}}(B):=\sup\{|\lambda|;\lambda\in\sigma(B),\ \lambda \text{ is not an eigenvalue of finite algebraic multiplicity}\}.$$

It is known that given a strongly continuous semigroup on X $(e^{tA})_{t\geqslant 0}$, the spectral radius of e^{tA}, $r_\sigma(e^{tA})$, is equal to $e^{t\omega_0(A)}$, where $\omega_0(A)\in[-\infty,\infty]$ is the type of $(e^{tA})_{t\geqslant 0}$: $\omega_0(A)=\lim_{t\to\infty}t^{-1}\ln\|e^{tA}\|$. Voigt in Ref. 18, Lemma 2.1, established a similar result concerning the essential spectral radius; more precisely he showed that there exists $\omega_{\mathrm{ess}}(A)\in[-\infty,\omega_0(A)]$, called essential type of $(e^{tA})_{t\geqslant 0}$, such that

$$r_{\mathrm{ess}}(e^{tA})=e^{t\omega_{\mathrm{ess}}(A)}\quad (t>0).$$

The interest of this parameter lies in the fact that for each $\beta>\omega_{\mathrm{ess}}(A)$, there exists a finite dimensional projection P_β in X, commuting with e^{tA} $(t\geqslant 0)$, and a constant $C_\beta\geqslant 0$ such that

$$\|e^{tA}(I-P_\beta)\|\leqslant C_\beta e^{t\beta}\quad (t\geqslant 0).$$

If $\omega_{\mathrm{ess}}(A)<\beta<\omega_0(A)$, then $P_\beta\neq 0$, and the asymptotic behavior of e^{tA} for $t\to+\infty$ is determined by the part of the semigroup e^{tA} in the finite dimensional space Range (P_β). Moreover, the essential type enjoys a nice stability property we recall in Theorem 1 below. Let B be a bounded operator, then $A+B$ generates a C_0-semigroup $(e^{t(A+B)})_{t\geqslant 0}$ given by the Dyson-Phillips series

$$e^{t(A+B)}=\sum_{j=0}^{\infty}D_j(t),\tag{3}$$

where $D_0(t)=e^{tA}$ and $D_{j+1}(t)=\int_0^t D_j(s)BD_0(t-s)\mathrm{d}s$.

Theorem 1 (*Ref. 10, Theorem 2.10, p. 24*): *With the notations just introduced, let there exist* $m\in\mathbb{N}$ *such that the remainder term* $\Sigma_{j=m}^{\infty}D_j(t)$ *is compact for all* $t\geqslant 0$. *Then the two semigroups* $(e^{t(A+B)})_{t\geqslant 0}$ *and* $(e^{tA})_{t\geqslant 0}$ *have the same essential type*, i.e., $\omega_{\mathrm{ess}}(A+B)=\omega_{\mathrm{ess}}(A)$.

II. L^1 ANALYSIS

In this section we treat the problem in L^1 setting. As in Ref. 8, we assume that the classical collision operator K_c is weakly compact with respect to the velocities, collectively with respect to the space variable, i.e.,

(A1) $\int_V |k_c(\cdot, v, \cdot)| \mathrm{d}v \in L^\infty(\Omega \times V)$.

(A2) $\{|k_c(x, \cdot, v')| : (x, v') \in \Omega \times V\}$ is weakly compact in $L^1(V)$.

Then K_c enjoys the following nice approximation property.

Lemma 1 (*Ref. 8, Theorem 2.4*): *Suppose that K_c is positive and satisfies (A1) and (A2). Then K_c can be approximated by a sequence of positive operators $(K_m)_m \subset \mathcal{L}(L^1(\Omega \times V))$ such that there is a sequence of non-negative functions $(f_m)_m \subset L^1(V)$ satisfying*

$$K_m \varphi(x,v) \leqslant f_m(v) \int_V \varphi(x,v) \mathrm{d}v', \tag{4}$$

for $0 \leqslant \varphi \in L^1(\Omega \times V)$.

Similarly, we assume that K_e satisfies the following.

(A3) $\int_{\mathbb{S}^{N-1}} |k_e(\cdot, \cdot, \omega, \cdot)| \mathrm{d}\omega \in L^\infty(\Omega \times I \times \mathbb{S}^{N-1})$.

(A4) $\{|k_e(x, \rho, \cdot, \omega')| : (x, \rho, \omega') \in \Omega \times I \times \mathbb{S}^{N-1}\}$ is weakly compact in $L^1(\mathbb{S}^{N-1})$.

By the same arguments as in Ref. 8, we can prove the following.

Lemma 2: Every positive elastic operator K_e satisfying (A3) and (A4) can be approximated by a sequence of positive operators $(K_m)_m \subset \mathcal{L}(L^1(\Omega \times I \times \mathbb{S}^{N-1}))$ such that there is a sequence of non-negative functions $(g_m)_m \subset L^1(\mathbb{S}^{N-1})$ satisfying

$$K_m \varphi(x,\rho,\omega) \leqslant g_m(\omega) \int_{\mathbb{S}^{N-1}} \varphi(x,\rho,\omega') \mathrm{d}\omega', \tag{5}$$

for all $0 \leqslant \varphi \in L^1(\Omega \times I \times \mathbb{S}^{N-1})$.

Finally, as in Ref. 7, we have the following.

(A5) Kernels $k_d^{(m)}$ are assumed to be bounded.

Remark 1: Our assumptions on collision operators are more general than that in Ref. 7.

Let us now compare the essential type of $(\mathrm{e}^{t(T+K_e)})_{t \geqslant 0}$ with that of $(\mathrm{e}^{t(T+K_e+K_d)})_{t \geqslant 0}$. For this purpose, expand the latter as a Dyson-Phillips series:

$$\mathrm{e}^{t(T+K_e+K_d)} = \sum_{j=0}^{\infty} W_j(t),$$

where $W_0(t) = \mathrm{e}^{t(T+K_e)}$ and $W_{j+1}(t) = \int_0^t W_j(s) K_d W_0(t-s) \mathrm{d}s$.

Giving two strongly continuous (operator valued) mappings

$$F, G : [0, \infty[\to \mathcal{L}(L^p(\Omega \times V)) \quad ,$$

we will denote by $F * G$ the convolution operator defined as

$$F * G : [0, \infty[\ni t \mapsto \int_0^t F(s) G(t-s) \mathrm{d}s \in \mathcal{L}(L^p(\Omega \times V)).$$

Moreover $[F]^j = F * \cdots * F$ (j times). Now, by property (1) and since $e^{t(T+K_e)}$ does not change the neutron speed, it follows that

$$[\mathrm{e}^{t(T+K_e)} K_d]^n = 0$$

(recall that n is such that $K_d^n = 0$) and therefore the remainder term $\Sigma_{j=n}^{\infty} W_j(t) = [\mathrm{e}^{t(T+K_e)} K_d]^n * \mathrm{e}^{t(T+K_e+K_d)} = 0$. As a direct consequence of this and Theorem 1, we have the following.

Lemma 3: The two semigroups $(e^{t(T+K_e+K_d)})_{t\geqslant 0}$ *and* $(e^{t(T+K_e)})_{t\geqslant 0}$ *have the same essential type:* $\omega_{\mathrm{ess}}(T+K_e+K_d)=\omega_{\mathrm{ess}}(T+K_e)$.

We now turn to the comparison between essential types of $(e^{t(T+K_e+K_d)})_{t\geqslant 0}$ and the full semigroup $(e^{t(T+K)})_{t\geqslant 0}$. Write

$$e^{t(T+K)}=\sum_{i=0}^{\infty} V_i(t), \tag{6}$$

where $V_0(t)=e^{t(T+K_e+K_d)}$ and $V_{i+1}(t)=\int_0^t V_i(s)K_cV_0(t-s)\mathrm{d}s$. Set $R_m(t)=\Sigma_{i=m}^{\infty}V_i(t)$.

Lemma 4: Let (A1)–(A5) be satisfied. Then the second remainder term of the Dyson-Phillips expansion (6)*, i.e.,* $R_2(t)$*, is weakly compact.*

Before proving this lemma we recall the following theorem known as the strong convex compactness property.

Theorem 2 *(Ref. 15, Theorem 2.2)* **:** *Let X and Y be two Banach spaces. Let* $(\Theta,\mathrm{d}\nu)$ *be a finite measure space and*

$$G:\Theta\to\mathcal{L}(X,Y)$$

bounded and strongly measurable. If $G(\omega)$ *is weakly compact for a.e.* $\omega\in\Theta$*, then the strong integral*

$$X\ni x\mapsto\int_{\Theta}G(\omega)x\mathrm{d}\nu(\omega)\in Y$$

is weakly compact.

Proof of Lemma 4: The proof will be given for the general case $\rho_{\max}=\infty$ and will be done in three steps.

Step 1. Approximation and domination arguments. Since $R_2(t)=e^{t(T+K_e+K_d)}*K_ce^{t(T+K_e+K_d)}K_c*e^{t(T+K_e+K_d+K_c)}$ (see Lemma 2.1, p. 14 in Ref. 10) it suffices, thanks to Theorem 2, to check the weak compactness of

$$K_ce^{t(T+K_e+K_d)}K_c$$

for all $t>0$. On the other hand, we can expand $(e^{t(T+K_e+K_d)})_{t\geqslant 0}$ as a Dyson-Phillips series:

$$e^{t(T+K_e+K_d)}=\sum_{j=0}^{\infty}U_j(t),$$

where $U_0(t)=e^{tT}$ is the streaming semigroup given by

$$e^{tT}\varphi(x,v)=e^{-\int_0^t\sigma(x-sv,v)\mathrm{d}s}\chi_{\{(y,w);t<\tau(y,w)\}}(x,v)\varphi(x-tv,v)\quad\text{for all }\varphi\in L^1(\Omega\times V),$$

with $\tau(x,v)=\inf\{s>0;x-sv\notin\Omega\}$, and $U_{j+1}(t)=\int_0^t U_j(s)(K_e+K_d)U_0(t-s)\mathrm{d}s$.

Moreover, the sequence $(\Sigma_{j=0}^{n}K_cU_j(t)K_c)_n$ converges in $\mathcal{L}(L^1(\Omega\times V))$ uniformly for bounded times to $K_ce^{t(T+K_e+K_d)}K_c$; thus it suffices to prove that $K_cU_j(t)K_c$ is weakly compact for all $j\in\mathbb{N}$. We have

$$|K_cU_j(t)K_c\varphi|\leqslant|K_c|U_j'(t)|K_c||\varphi|,$$

where $U_j'(t)$ denotes the term of order j of the Dyson-Phillips series expanding $(e^{t(T+|K_e|+C_d)})_{t\geqslant 0}$ from $(e^{tT})_{t\geqslant 0}$ and

$$|K_c|:L^1(\Omega\times V)\ni\varphi\mapsto\int_V|k_c(x,v,v')|\varphi(x,v')\mathrm{d}v',$$

$$|K_e|:L^1(\Omega\times I\times \mathbb{S}^{N-1})\ni \varphi\mapsto \int_{\mathbb{S}^{N-1}}|k_e(x,\rho,\omega,\omega')|\varphi(x,\rho,\omega')\mathrm{d}\omega'\in L^1(\Omega\times I\times \mathbb{S}^{N-1}),$$

$$C_d:L^1(\Omega\times I\times \mathbb{S}^{N-1})\ni \varphi\mapsto \sum_{m=1}^{\nu}\int_{\mathbb{S}^{N-1}}\|k_d^{(m)}\|_\infty\varphi(x,e_m(\rho),\omega')d\omega'\in L^1(\Omega\times I\times \mathbb{S}^{N-1}).$$

Thus, as far as the weak compactness is concerned, by using domination arguments, there is no loss of generality to assume that K_c and K_e are positive and $K_d=C_d$. On the other hand, if we define $K_c^{(i)}$ by

$$K_c^{(i)}:\varphi\mapsto\int_V k_c(x,v,v')\chi_{\{w\in V:|w|\leqslant i\}}(v)\varphi(x,v')\mathrm{d}v',$$

then

$$\begin{aligned}\|K_c\varphi-K_c^{(i)}\varphi\|&\leqslant\int\int_{\Omega\times\{v\in V:|v|>i\}}\int_V k_c(x,v,v')|\varphi(x,v')|\mathrm{d}v'\mathrm{d}x\mathrm{d}v\\&\leqslant\sup_{(x,v')\in\Omega\times V}\int_{\{v\in V:|v|>i\}}k_c(x,v,v')\mathrm{d}v\|\varphi\|_{L^1(\Omega\times V)}\end{aligned}$$

and, since K_c satisfies (A2), we have

$$\|K_c-K_c^{(i)}\|\leqslant\sup_{(x,v')\in\Omega\times V}\int_{\{v\in V:|v|>i\}}k_c(x,v,v')\mathrm{d}v\to 0\quad\text{as } i\to\infty.$$

Thus, we may replace K_c by some truncation $K_c^{(i)}$ since $K_cU_j(t)K_c$ depends continuously on K_c in the norm operator topology. This means that we may suppose without loss of generality that V is bounded, i.e., $\rho_{\max}<\infty$. Again since $K_cU_j(t)K_c$ depends continuously on K_c and K_e in the norm operator topology, according to Lemmas 1 and 2 (approximation and domination), we may assume that K_c has the form

$$\varphi\mapsto f(v)\int_V\varphi(x,v')\mathrm{d}v',$$

with $f\in L^1(V)$, and K_e has the form

$$\varphi\mapsto g(\omega)\int_{\mathbb{S}^{N-1}}\varphi(x,\rho,\omega')\mathrm{d}\omega'$$

with $g\in L^1(\mathbb{S}^{N-1})$. By approximation again we may suppose that $f\in L^\infty(V)$ and $g\in L^\infty(\mathbb{S}^{N-1})$, and by a domination argument, we may even assume that f and g are constants. Finally, by linearity we can suppose that operators K_c, K_e, and K_d are, respectively,

$$M_c:\varphi\mapsto\int_V\varphi(x,v')dv',\quad M_0:\varphi\mapsto\int_{\mathbb{S}^{N-1}}\varphi(x,\rho,\omega')\mathrm{d}\omega',$$

and

$$M_d=\sum_{i=1}^{\nu}M_i\quad\text{where } M_i:\varphi\mapsto\int_{\mathbb{S}^{N-1}}\varphi(x,e_i(\rho),\omega')\mathrm{d}\omega'.$$

Step 2. Strong convex compactness property. Considering different values of j. First, note that according to Ref. 10, Theorem 4.11, p. 80, $M_cU_0(t)M_c$ is weakly compact.

Suppose then that $j \geqslant 1$. In this case, since M_c maps $L^1(\Omega \times V)$ to $L^1(\Omega)$, it suffices to show that

$$M_c U_j(t): L^1(\Omega) \to L^1(\Omega)$$

is weakly compact. Decomposing $M_c = MM_0$, where $M: \varphi \mapsto \int_I \varphi(x,\rho,\omega)\rho^{N-1}\mathrm{d}\rho$, we can write

$$M_c U_j(t) = MM_0[U_0(M_0 + M_d)]^j * U_0(t).$$

Thus, by linearity, we can restrict ourselves to show the weak compactness of

$$MM_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t) \tag{7}$$

for all $(i_1,\ldots,i_j) \in \{0,1,\ldots,\nu\}^j$ and $t>0$. We remark that operator (7) is a "strong integral" [by making the identification $L^1(\Omega \times I) = L^1(I; L^1(\Omega))$]. Indeed, if for ρ fixed, we denote by $M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)[\rho]$ the bounded operator:

$$L^1(\Omega) \ni \varphi \mapsto (M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)\varphi)(\cdot,\rho) \in L^1(\Omega), \tag{8}$$

then operator (7) can be viewed as

$$MM_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)\varphi = \int_I M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)[\rho]\varphi\rho^{N-1}\mathrm{d}\rho$$

for all $\varphi \in L^1(\Omega)$. One can check without difficulties that operators $M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t) \times [\rho]$ are uniformly bounded for $\rho \in I$ on $\mathcal{L}(L^1(\Omega))$, and therefore the strong convex compactness property (Theorem 2) ensures that operator (7) is weakly compact, provided that $M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)[\rho]$ is weakly compact for all $\rho \in I$, which will be the subject of step 3 below.

Step 3. Weak compactness of $M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)[\rho]$. Let T_∞ denote the streaming operator on $\mathbb{R}^N$ (with $\sigma=0$) and set $U_\infty(t) = \mathrm{e}^{tT_\infty}$. Then for all $0 \leqslant \varphi \in L^1(\Omega)$,

$$M_0U_0 * M_{i_1}U_0 \cdots * M_{i_j}U_0(t)[\rho]\varphi \leqslant RM_0U_\infty * M_{i_1}U_\infty * \cdots * M_{i_j}U_\infty(t)[\rho]E\varphi,$$

where $E: L^1(\Omega) \to L^1(\mathbb{R}^N)$ and $R: L^1(\mathbb{R}^N) \to L^1(\Omega)$ are, respectively, the trivial extension operator by zero and the restriction operator. Using a domination argument to get the weak compactness of $M_0U_0 * M_{i_1}U_0 * \cdots * M_{i_j}U_0(t)[\rho]$, it is enough to have the weak compactness of

$$L^1(\mathbb{R}^N) \ni \varphi \mapsto RM_0U_\infty * M_{i_1}U_\infty * \cdots * M_{i_j}U_\infty(t)[\rho]\varphi \in L^1(\Omega). \tag{9}$$

But we will see thereafter that for all $\rho \in I$ and $t>0$, there is a function $\beta(t,\rho) \in L^1(\mathbb{R}^N)$ such that

$$M_0U_\infty * M_{i_1}U_\infty * \cdots * M_{i_j}U_\infty(t)[\rho]\varphi = \beta(t,\rho) * \varphi.$$

Consequently, by Ref. 2, Corollaire IV. 27, p. 74, we conclude that operator (9) is weakly compact.

It remains to prove that for each $(i_1,\ldots,i_j) \in \{0,1,\ldots,\nu\}^j$ $(j \geqslant 2)$, there exists $\beta(t,\rho) \in L^1(\mathbb{R}^N)$ such that

$$M_{i_1}U_\infty * \cdots * M_{i_j}U_\infty(t)[\rho]\varphi = \beta(t,\rho) * \varphi.$$

We recall that

$$M_i: \varphi \mapsto \int_{S^{N-1}} \varphi(x, e_i(\rho), \omega')\mathrm{d}\omega'$$

with the convention $e_0(\rho) = \rho$. We are going to proceed by recurrence and prove additionally that $\beta(t,\rho)$ is uniformly bounded for t bounded and $\rho \in I$. First, it is clear that for each $i \in \{0,1,\ldots,\nu\}$,

$$M_i U_\infty(t)[\rho] = \mathrm{d}\omega_{te_i(\rho)} * \varphi,$$

where $\mathrm{d}\omega_s$ is the image of $\mathrm{d}\omega$ under the dilation $v \mapsto sv$. Observe that the mapping $0 < t \to \mathrm{d}\omega_t \in \mathcal{M}(\mathbb{R}^N)$ (the space of finite Radon measures) is weak star continuous, i.e., $0 < t \mapsto \langle \mathrm{d}\omega_t, \varphi \rangle = \int_{\mathbb{R}^N} \varphi(x - t\omega)\mathrm{d}\omega$ is continuous. Let $(i_1, i_2) \in \{0, 1, \ldots, \nu\}^2$. We have

$$\begin{aligned} M_{i_1} U_\infty * M_{i_2} U_\infty(t)[\rho]\varphi &= \int_0^t M_{i_1} U_\infty(s)[\mathrm{d}\omega_{(t-s)e_{i_2}(\rho)} * \varphi]\mathrm{d}s \\ &= \int_0^t \int_{\mathbb{S}^{N-1}} [\mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))} * \varphi](x - se_{i_1}(\rho)\omega)\mathrm{d}\omega\mathrm{d}s \\ &= \int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * [\mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))} * \varphi]\mathrm{d}s \\ &= \left[\int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}\mathrm{d}s \right] * \varphi, \end{aligned}$$

where the integral $\int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}\mathrm{d}s$ is taken in the weak star sense, i.e.,

$$\left\langle \int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}\mathrm{d}s, \varphi \right\rangle = \int_0^t \langle \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}, \varphi \rangle \mathrm{d}s.$$

As the measure $\int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}\mathrm{d}s$ is bounded, by the Radon-Nikodym theorem, it suffices to show that it is absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}^N$, i.e.,

$$I_A := \int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}\mathrm{d}s\{A\} \to 0 \quad \text{as } |A| \to 0,$$

where $|A|$ is the Lebesgue measure of set A. Since

$$\begin{aligned} I_A &= \int_0^t \int_{\mathbb{R}^N \times \mathbb{R}^N} \int \chi_A(v_1 + v_2)\mathrm{d}\omega_{se_{i_1}(\rho)}(v_1) \otimes \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}(v_2)\mathrm{d}s \\ &= \int_0^t \int_{\mathbb{R}^N \times \mathbb{R}^N} \int \chi_A(se_{i_1}(\rho)v_1 + (t-s)e_{i_2}(e_{i_1}(\rho))v_2)\mathrm{d}\omega(v_1)\mathrm{d}\omega(v_2)\mathrm{d}s, \end{aligned}$$

the change of variables $v_1' = e_{i_1}(\rho)v_1$ and $v_2' = e_{i_2}(e_{i_1}(\rho))v_2$ amounts to showing that

$$I_A' := \int_0^t \int_{\mathbb{R}^N \times \mathbb{R}^N} \int \chi_A(sv_1' + (t-s)v_2')\mathrm{d}\omega^1(v_1')\mathrm{d}\omega^2(v_2')\mathrm{d}s \to 0 \quad \text{as } |A| \to 0,$$

where $\mathrm{d}\omega^1$ (respectively, $\mathrm{d}\omega^2$) is the Lebesgue measure on the sphere $\{v \in \mathbb{R}^N : |v| = e_{i_1}(\rho)\}$ [respectively, $\{v \in \mathbb{R}^N : |v| = e_{i_2}(e_{i_1}(\rho))\}$]. But the last assertion follows from Ref. 10, p. 82. Moreover, we can easily see that the function $\int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \mathrm{d}\omega_{(t-s)e_{i_2}(e_{i_1}(\rho))}\mathrm{d}s$ is uniformly bounded for bounded time and for $\rho \in I$. Suppose that the assertion is true for j and let $(i_1, \ldots, i_{j+1}) \in \{0, 1, \ldots, \nu\}^{j+1}$. By hypothesis there exists $\eta(t, \rho) \in L^1(\mathbb{R}^N)$ (in fact, uniformly bounded for bounded time and for $\rho \in I$) such that

$$M_{i_2} U_\infty * \cdots * M_{i_{j+1}} U_\infty(t)[\rho]\varphi = \eta(t, \rho) * \varphi.$$

Then we have

$$M_{i_1}U_\infty * M_{i_2}U_\infty * \cdots * M_{i_{j+1}}U_\infty(t)[\rho]\varphi = \int_0^t M_{i_1}U_\infty(s)[\eta((t-s),\rho) * \varphi]\mathrm{d}s$$

$$= \int_0^t \int_{\mathbb{S}^{N-1}} [\eta((t-s),e_{i_1}(\rho)) * \varphi](x - se_{i_1}(\rho)\omega)\mathrm{d}\omega\mathrm{d}s$$

$$= \int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * [\eta((t-s),e_{i_1}(\rho)) * \varphi]\mathrm{d}s$$

$$= \left[\int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \eta((t-s),e_{i_1}(\rho))\mathrm{d}s\right] * \varphi.$$

By putting $\beta(t,\rho) = \int_0^t \mathrm{d}\omega_{se_{i_1}(\rho)} * \eta((t-s),e_{i_1}(\rho))\mathrm{d}s$ we have the desired β. □

We are now in the position to state the main result of this section.

Theorem 3: *Under assumptions (A1)–(A5), the three semigroups* $(\mathrm{e}^{t(T+K_e)})_{t\geqslant 0}$, $(\mathrm{e}^{t(T+K_e+K_d)})_{t\geqslant 0}$, *and* $(\mathrm{e}^{t(T+K_e+K_d+K_c)})_{t\geqslant 0}$ *have the same essential type.*

Proof: Since $R_2(t)$ is weakly compact, by Corollary 2.1, p. 16 in Ref. 10, $R_5(t)$ is compact, and then by Theorem 1 the two semigroups $(\mathrm{e}^{t(T+K)})_{t\geqslant 0}$ and $(\mathrm{e}^{t(T+K_e+K_d)})_{t\geqslant 0}$ have the same essential type. Having in mind that the essential type of the latter is equal to $\omega_{\mathrm{ess}}(T+K_e)$ (see Lemma 3), we get the conclusion. □

Corollary 1: Let (A1)–(A5) be satisfied. Moreover, suppose that the kernels k_c, k_e, $k_d^{(m)}(m=1,\ldots,\nu)$ *are non-negative. Then* $\omega_{\mathrm{ess}}(T+K)\leqslant s(T+K_e)$,*where* $s(T+K_e)$ *is the spectral bound of* $T+K_e$. □

Proof: Since the kernels are non-negative, using the Dyson-Phillips expansions, we can see that the semigroups are positive. By Weis's result[22] on the identity of the type of positive semigroup on L^p spaces and the spectral bound of its generators, we have $s(T+K_e)=\omega_0(T+K_e)$. Finally, the inequality $\omega_{\mathrm{ess}}(T+K_e)\leqslant\omega_0(T+K_e)$, together with Theorem 3, ends the proof. □

III. L^p ANALYSIS, $1<p<\infty$

In L^p setting $(1<p<\infty)$, we will use the concept of regular operator introduced in Ref. 11. Namely, we assume the following.

(A6) $\{\int_V k_c(x,\cdot,v')\varphi(v')\mathrm{d}v';\|\varphi\|_{L^p(V)}\leqslant 1, x\in\Omega\}$ is relatively compact in $L^p(V)$.

(A7) For each $\psi'\in L^{p'}(V)(1/p+1/p'=1)$,$\{\int_V k_c(x,v,\cdot)\psi(v)\mathrm{d}v;x\in\Omega\}$ is relatively compact in $L^{p'}(V)$.

We recall the following.

Lemma 5 (*Ref.* 11): *Under assumptions (A6) and (A7), the collision operator* K_c *can be approximated in the norm operator topology by collision operators with separable kernels*

$$\sum_{i\in J}\alpha_i(x)f_i(v)g_i(v'), \tag{10}$$

where $\alpha_i\in L^\infty(\Omega)$, $f_i\in L^p(V)$, *and* $g_i\in L^{p'}(V),(i\in J)$ *with J finite.*

Analogously, we define the class of collision operators K_e we consider in this section. We suppose that K_e satisfies the following.

(A8) The family $\{\int_{\mathbb{S}^{N-1}} k_e(x,\rho,\cdot,\omega')\varphi(\omega')\mathrm{d}\omega' : (x,\rho)\in\Omega\times I, \|\varphi\|_{L^p(\mathbb{S}^{N-1})}\leqslant 1\}$ is relatively compact in $L^p(\mathbb{S}^{N-1})$.

(A9) For each $\psi'\in L^{p'}(\mathbb{S}^{N-1})$, $\{\int_{\mathbb{S}^{N-1}} k_e(x,\rho,\omega,\cdot)\psi'(\omega)\mathrm{d}\omega : (x,\rho)\in\Omega\times I\}$ is relatively compact in $L^{p'}(\mathbb{S}^{N-1})$.

Under these assumptions, K_e is bounded, namely,

$$\|K_e\| = \operatorname*{ess\,sup}_{(x,\rho)\in\Omega\times I} \|K_e(x,\rho)\|_{\mathcal{L}(L^p(\mathbb{S}^{N-1}))},$$

where $K_e(x,\rho): L^p(\mathbb{S}^{N-1}) \ni \varphi \mapsto \int_{\mathbb{S}^{N-1}} k_e(x,\rho,\omega,\omega')\varphi(\omega')\mathrm{d}\omega'$. Moreover, by adapting the same technicalities as in Proposition 1 in Ref. 11, we can prove the following.

Lemma 6: An elastic collision operator satisfying (A8) and (A9) can be approximated in the norm operator topology by collision operators with separable kernels

$$\sum_{i\in J} \beta_i(x,\rho)h_i(\omega)\gamma_i(\omega'), \tag{11}$$

where $\beta_i \in L^\infty(\Omega\times I)$, $h_i \in L^p(\mathbb{S}^{N-1})$, *and* $\gamma_i \in L^{p'}(\mathbb{S}^{N-1}), (i \in J \subset \mathbb{N})$ *with* J *finite and* $1/p+1/p'=1$.

Finally, we suppose that kernels $k_d^{(m)}$, $m=1,\ldots,\nu$, satisfy (A5), i.e., they are bounded.

Note that Lemma 3 remains true in L^p setting, $1<p<\infty$, without any modification. Moreover, we have the following more precise result.

Lemma 7: Under assumptions (A5)–(A9), the difference

$$\mathrm{e}^{t(T+K)} - \mathrm{e}^{t(T+K_e+K_d)}$$

is compact for all $t\geqslant 0$.

Proof: According to Ref. 10, Theorem 2.6, p. 16, $\mathrm{e}^{t(T+K)}-\mathrm{e}^{t(T+K_e+K_d)}$ is compact for all $t\geqslant 0$ if and only if the strong integral

$$\int_0^t \mathrm{e}^{s(T+K_e+K_d)}K_c\mathrm{e}^{(t-s)(T+K_e+K_d)}\mathrm{d}s$$

is. Since the latter depends continuously (and linearly) on K_c, it suffices to consider a collision operator K_c of the form (10) and K_e of the form (11). By density again, we may assume that all the functions f_i, g_i [in Eq. (10)] are continuous with compact support, and all the functions h_i, γ_i [in Eq. (11)] are continuous. In this case $\int_0^t \mathrm{e}^{s(T+K_e+K_d)}K_c\mathrm{e}^{(t-s)(T+K_e+K_d)}\mathrm{d}s$ maps $L^q(\Omega\times V)$ into itself for all $q\geqslant 1$, and consequently, by interpolation arguments (see Ref. 6, Theorem 3.10, p. 57), we may restrict ourselves to the Hilbertian case $p=2$. To have the compactness of

$$\int_0^t \mathrm{e}^{s(T+K_e+K_d)}K_c\mathrm{e}^{(t-s)(T+K_e+K_d)}\mathrm{d}s$$

it suffices that the following hold (see Ref. 1, Theorem 3.2).

(i) For some $\eta > \omega_0(T+K_e+K_d)$, the operator

$$(\eta+i\gamma-T-K_e-K_d)^{-1}K_c(\eta+i\gamma-T-K_e-K_d)^{-1}$$

is compact for all $\gamma\in\mathbb{R}$.

(ii) $0<t\mapsto\int_0^t \mathrm{e}^{s(T+K_e+K_d)}K_c\mathrm{e}^{(t-s)(T+K_e+K_d)}\mathrm{d}s$ is norm continuous.

(iii) Moreover, to have (ii), using Lemma 2.1 in Ref. 14, it suffices to show that for some $\eta > \omega_0(T+K_e+K_d)$,

$$\|(\eta+i\gamma-T-K_e-K_d)^{-1}K_c\| + \|K_c(\eta+i\gamma-T-K_e-K_d)^{-1}\| \to 0 \quad \text{as } |\gamma|\to\infty.$$

Now, to prove (i) and (iii) remark that, by simple algebraic manipulations, we have for $\mathrm{Re}\,\lambda$ large enough

$$K_c(\lambda-T-K_e-K_d)^{-1} = K_c(\lambda-T)^{-1} + K_c(\lambda-T)^{-1}(K_e+K_d)(\lambda-T-K_e-K_d)^{-1},$$

$$(\lambda - T - K_e - K_d)^{-1}K_c = (\lambda - T)^{-1}K_c + (\lambda - T - K_e - K_d)^{-1}(K_e + K_d)(\lambda - T)^{-1}K_c,$$

so (i) is a consequence of Ref. 10, Theorem 4.1, p. 57, saying that $(\lambda - T)^{-1}K_c$ is compact for all $\lambda \in \mathbb{C}\backslash\sigma(T)$, while (iii) is consequence of Ref. 14, Lemma 3.13, establishing that

$$\|(\eta + i\gamma - T)^{-1}K_c\| + \|K_c(\eta + i\gamma - T)^{-1}\| \to 0 \quad \text{as } |\gamma| \to \infty$$

for all $\eta > \omega_0(T)$. □

Using the above lemma we can state the following.

Theorem 4: *Under assumptions (A5)–(A9), the three semigroups* $(e^{t(T+K_e)})_{t\geq 0}$, $(e^{t(T+K_e+K_d)})_{t\geq 0}$, *and* $(e^{t(T+K_e+K_d+K_c)})_{t\geq 0}$ *have the same essential type.*

Proof: From the compactness of $e^{t(T+K)} - e^{t(T+K_e+K_d)}$ for all $t \geq 0$, it follows that $\sigma_{ess}(e^{t(T+K)}) = \sigma_{ess}(e^{t(T+K_e+K_d)})$ for all $t \geq 0$, with, in particular, $\omega_{ess}(T+K) = \omega_{ess}(T+K_e+K_d)$. On the other hand, as already said above, Lemma 3 stated in L^1 setting remains true in L^p setting, $1 < p < \infty$, and hence we get $\omega_{ess}(T+K_e+K_d) = \omega_{ess}(T+K_e)$. □

In the same spirit of Corollary 1 we have the following.

Corollary 2: Let (A5)–(A9) be satisfied. Moreover, suppose that all the kernels k_c, k_e, $k_d^{(m)}$ $(m = 1, \ldots, \nu)$ *are non-negative. Then* $\omega_{ess}(T+K) \leq s(T+K_e)$, *where* $s(T+K_e)$ *is the spectral bound of* $T+K_e$. □

Remark 2: Corollaries 1 and 2 answer Problem 3 in Ref. 10, p. 93, by finding an estimate of the essential type for the neutron transport semigroup when the collision operator involves, in addition to the classical operator K_c, another term.

Actually, we can refine Corollaries 1 and 2 if we assume the following continuity assumption:

(A10) The mapping $I \ni \rho \mapsto K_e^{\rho} \in \mathcal{L}(L^p(\Omega \times \mathbb{S}^{N-1}))$ is piecewise continuous, where K_e^{ρ} is the one speed operator:

$$L^p(\Omega \times \mathbb{S}^{N-1}) \ni \varphi \mapsto \int_{\mathbb{S}^{N-1}} k_e(x, \rho, \omega, \omega')\varphi(x, \omega')\mathrm{d}\omega' \in L^p(\Omega \times \mathbb{S}^{N-1}).$$

More precisely we have the following.

Proposition 1: (a) Let (A1)-(A5) and (A10) be satisfied. Then we have the following spectral mapping theorem:

$$\sigma_{ess}(e^{t(T+K_e)}) = e^{t\sigma(T+K_e)} \cup \{0\} \quad \textit{for all } t \geq 0 \tag{12}$$

in L^1 *setting. In particular,* $\omega_{ess}(T+K) = s(T+K_e)$. *(b) The same conclusions hold true in* L^p *setting* $(1 < p < \infty)$ *under assumptions (A5)–(A10).*

After showing spectral mapping theorem (12), the equality $\omega_{ess}(T+K) = s(T+K_e)$ is just a consequence of Theorems 3 and 4. The proof of the spectral mapping theorem can be found in Ref. 14, Chap. 6. It relies, in particular, on the concept of critical spectrum introduced in Ref 12.

At this stage, it may be useful to recall the description of $\sigma(T+K_e)$ obtained by Larsen and Zweifel. First, the spectrum of T consists of a half plan or only the point at infinity, depending, respectively, upon whether the minimum neutron speed ρ_{min} is or is not zero. The spectrum of $T+K_e$, for fixed ρ, is a pure isolated point spectrum of finite algebraic multiplicity restricted to a certain left half plan. As ρ varies, the point spectrum of $T+K_e$ for fixed ρ shifts about to form curves; the full spectrum of $T+K_e$ consists of the closure of this set of curves plus $\sigma(T)$.

This paper is concerned with localization properties of coherent states. Instead of classical uncertainty relations we consider "generalized" localization quantities. This is done by introducing measures on the reproducing kernel. In this context we may prove the existence of optimally localized states. Moreover, we provide a numerical scheme for deriving them. © *2006 American Institute of Physics.*

I. MOTIVATION

The goal of this paper is to introduce a new concept of localization. In classical lore, one typically considers uncertainty relations. In this framework it is well known that a nonzero state or wave function cannot be arbitrarily well localized simultaneously in space and Fourier domain. This fact may be quantified by the Heisenberg uncertainty relation,

$$\Delta x \Delta k \geqslant 2\pi.$$

There are functions which are optimally localized in phase space in that they satisfy the inequality with the lower bound. For a detailed analysis on uncertainty relations in the context of Gabor and wavelet transforms we refer, e.g., to Refs. 11, 12, 5, and 18.

However, for certain physical applications, e.g., radar imaging, it is very promising to ask for more flexible concepts. In principle, in radar imaging one has to evaluate the output of the correlation receiver, see Ref. 1. An important role in detecting objects is played by the radar ambiguity function, which is ideally given by a delta function. In the narrow band regime, which is of interest in radar imaging, the ambiguity function is given by $\Pi(\phi,\tau)=\langle \Psi_{\phi,\tau}, \Psi_{\phi_0,\tau_0}\rangle$, where Ψ stands for the transmitted wave form. Since a delta pulse is obviously not possible to realize, one currently uses pulses that minimize by means of its band/Doppler width and its pulse/range width the so-called narrow band (Heisenberg) uncertainty principle, see Refs. 1, 7, 6, and 4. A minimization of the Heisenberg quantities leads to pulses with Gaussian envelope function. But this is difficult to implement too and, moreover, allows no flexibility in specifying more sophisticated localization attributes; e.g., in order to obtain an accurate spatial resolution while allowing a certain frequency uncertainty, the ambiguity function Π should have fast decay with respect to range and a moderate decay with respect to Doppler frequency, e.g.,

$$|\Pi(\phi,\tau)| \leqslant (1+|\tau|)^{-4}(1+\log(1+|\phi|))^{-1}. \tag{1.1}$$

With the theory presented here in the paper at hand, we may now proceed as follows. Given the specific localization characteristic (1.1) in the range Doppler plane, we compute the optimal wave

a)Electronic mail: teschke@math.uni-bremen.de

form to be transmitted. To be more general, we consider measures of uncertainty or delocalization in phase space (range Doppler plane) and we shall prove the existence of optimally localized states (wave forms).

In principle, general wavelet transforms

$$s \mapsto \mathcal{W}_g s, \quad \mathcal{W}_g s(x) = (U(x)g, s)_H, \quad x \in G$$

associated with the square integrable irreducible representation U of a locally compact group G provide a one to one correspondence between the state Hilbert space H and a reproducing kernel Hilbert space over the group. The reproducing kernel is up to a normalization the wavelet transform of the wavelet itself,

$$\Pi = \mathcal{W}_g g.$$

This kernel can be interpreted as the Heisenberg box of the phase space. In this paper we shall be concerned with localization properties of these reproducing kernels. In fact, the reproducing kernel of wavelet analysis cannot be arbitrarily well localized. For instance, there is no wavelet such that the associated reproducing kernel is compactly supported. Obviously there is no universal way of quantifying localization. Instead we propose to quantify localization through the following and similar families of cost functionals:

$$\Phi[g] = \sup_{x \in G} w(x)^{-1} |\mathcal{W}_g g(x)|,$$

where w is some positive weight, decaying "at ∞." We will prove that this functional and similar "localization" functionals are weakly lower semicontinuous. It therefore has a minimizer over any weak* compact set. In other words, for any such measure of localization there is at least one optimal state.

Localization of wavelet transforms has been considered before, see, e.g., Refs. 17, 15, 9, and 8. In Refs. 9 and 8 the authors consider localizing wavelet coefficients with respect to some preassigned analyzing wavelet and a compact subset in the wavelet plane. In their approach the analyzing wavelet was fixed. In this paper, however, we consider the nonlinear problem of optimizing the localization of the reproducing kernel. Since the reproducing kernel depends quadratically on the underlying wavelet, this problem is by nature highly nonlinear and therefore an explicit expression of the optimal state seems to remain a pipe dream. However, in the last section we discuss a numerical procedure to approximately compute such optimally localized states.

II. THE BASIC FORMULAS

Let us recall the basic formulas of continuous wavelet transform associated with a square integrable group representation. We only recall the few facts that are necessary for this paper. For more details we refer to, e.g., Refs. 10 and 13. Let G be a noncompact, locally compact group, σ a compact topological group, and $G \ni g \mapsto U(g)$ a unitary, strongly continuous, irreducible, square integrable representation in some Hilbert space H. The wavelet transform of $s \in H$ with respect to $g \in H$ is pointwise defined for $x \in G$ as

$$\mathcal{W}_g s(x) = (U(x)g, s)_H.$$

The left and the right invariant Haar measures are denoted by $d\lambda$ and $d\rho$. They are defined up to some positive factor. Over G we consider the two Hilbert spaces $L^2(G, d\lambda)$ and $L^2(G, d\rho)$. We suppose that $d\lambda$ and $d\rho$ are scaled suitably so that the mapping $s(x) \mapsto s(x^{-1})$ is an isometry between these two Hilbert spaces. A wavelet is called admissible if $\mathcal{W}_g g \in L^2(G, d\lambda)$. Thanks to the formula

$$\mathcal{W}_g s(x) = \mathcal{W}_s g(x^{-1}),$$

admissibility is also equivalent to $\mathcal{W}_g g \in L^2(G, d\rho)$. We denote the set of all admissible wavelets by A. For $g, h \in A$ and $s, u \in H$ the following equation holds:

$$(\mathcal{W}_g s, \mathcal{W}_h u)_{L^2(G,d\lambda)} = C(g,h)(s,u)_H, \tag{2.1}$$

where C is a densely defined, closed, positive quadratic form. Its form domain is precisely A. We write $c_{g,h} = C(g,h)$ and $c_g = C(g,g)$. By the first representation theorem there is a closed, linear operator T such that for all $u \in D(T)$ and $v \in A$ we have $C(v,u) = (v, Tu)_H$. The space A is in general a nonclosed subspace of H. However, since C is a closed quadratic form it becomes a Hilbert space with respect to

$$(s,u)_A = (s,u)_H + C(s,r), \quad \|s\|_A^2 = \|s\|_H^2 + c_s.$$

Convergence in A will be understood with respect to this norm. From Eq. (2.1) it follows that, in particular, $\mathcal{W}_g$ is for admissible, nonzero g a multiple of an isometry,

$$\|\mathcal{W}_g s\|_{L^2(G,d\lambda)}^2 = c_g \|s\|_H^2.$$

The adjoint of the wavelet analysis is a wavelet synthesis,

$$\mathcal{W}_g^* = \mathcal{M}_g.$$

Formally it can be written as follows:

$$\mathcal{M}_h r(x) = \int_G r(x) U(x) h d\lambda(x).$$

We have for $g, h \in A$

$$\mathcal{M}_h \mathcal{W}_g = c_{g,h} 1.$$

The combination $\mathcal{W}_g \mathcal{M}_h$ can be written as noncommutative convolution operator. If we define on $L^2(G, d\lambda) \times L^2(G, d\lambda)$ the (left) convolution product as

$$\Pi * r(x) = \int_G \Pi(y^{-1} \circ x) r(y) d\lambda(y),$$

we have for $g, h \in A$

$$\mathcal{W}_g \mathcal{M}_h = \Pi *, \quad \Pi = \mathcal{W}_g h.$$

In particular, we will use the following formula over and over:

$$\mathcal{W}_h = \Pi * \mathcal{W}_g, \quad \Pi = c_{g,h}^{-1} \mathcal{W}_h h.$$

III. GENERAL LOCALIZATIONS

Before formulating the general existence theorem we consider the particular case of localization measures through a weighted L^∞ norm. Consider therefore a positive function $w: G \to R_+$. We suppose that w is symmetric,

$$w(x^{-1}) = w(x),$$

and invariant under the G action in that for all $y \in G$ we can find a $c > 0$ such that

$$w(y \circ x) \leqslant cw(x), \quad w(x \circ y) \leqslant cw(x).$$

Then $w \in L^2(G, d\lambda)$ is equivalent to $w \in L^2(G, d\rho)$. Moreover, we consider weights, for which either of both (and hence both) of the following holds:

$$w * w \in L^2(G, d\lambda), \quad w * w \in L^2(G, d\rho).$$

A natural measure for the localization of a function r over G with respect to w is the following weighted norm:

$$\sup_G w^{-1}|r|.$$

For fixed $h \in A$ let $\Sigma_h \subset H$ denote the affine subspace of codimension 1 defined through $\Sigma_h = \{g \in H : (g, Th)_H = 1\}$. Note that Σ_h may contain nonadmissible vectors. The admissible wavelets in Σ_h are reconstruction wavelets for h:

$$\mathcal{M}_h \mathcal{W}_g = \mathcal{M}_g \mathcal{W}_h = 1.$$

We introduce the following functional on H:

$$\Phi[s] = \Phi_w[s] = \sup_G w^{-1}|\mathcal{W}_s s|,$$

whenever the right hand side is finite. In all other cases we set $\Phi[s] = \infty$. We now can formulate the first theorem.

Theorem 1: *Let $h \in H$, $h \neq 0$, be such that $\Phi[h] < \infty$. Then there exists a wavelet $g \in \Sigma_h$ such that for all $u \in \Sigma_h$ we have*

$$\Phi[g] \leqslant \Phi[u].$$

In other words, the localization functional Φ has a minimizer in each Σ_h, for all h, which have some regularity as expressed through $|\mathcal{W}_h h| \leqslant w$. Note that we have to require that $\Phi[h] < \infty$. This ensures that the set of functions having a w localization is not empty. In turn, this is a requirement for w in which it should not be decaying too fast (e.g., compactly supported weights are not possible).

Actually this kind of results can be generalized to a more abstract setting as follows. Consider two Banach spaces B, $K \subset L^2(G, d\lambda + d\rho)$ of functions over G with continuous embeddings. B should be a lattice, $\| |s| \|_B = \|s\|_B$. We then can define a localization with respect to B simply as

$$\Phi[g] = \|\mathcal{W}_g g\|_B.$$

We include the value $\Phi = \infty$ in the natural way. For B and K we further suppose that the following holds.

Invariance of B. B should be G bi-invariant: for all $y \in G$ there is a $b > 0$ such that

$$\|s(y \circ \cdot)\|_B \leqslant b\|s\|_B, \quad \|s(\cdot \circ y)\|_B \leqslant b\|s\|_B.$$

It should be stable under inversion

$$\|s(x^{-1})\|_B \leqslant d\|s\|_B.$$

Then we have $u(x) = s(y^{-1} \circ x \circ y)$ satisfies $\|u\|_B \leqslant e\|s\|_B$.

Semicontinuity of B norm. Suppose further that the following inequality holds for the norm in B: if $s_n \in B$ is any sequence of non-negative functions $s_n \geqslant 0$ then consider $s = \liminf_{n\to\infty} s_n$. Then we require that

$$\|s\|_B = \|\liminf s_n\|_B \leqslant \liminf_{n\to\infty} \|s_n\|_B.$$

In classical L^p spaces this is a direct consequence of Fatou's lemma,

$$\int \liminf s_n d\mu \leqslant \liminf \int s_n d\mu.$$

Compact embedding of K. For the space K we suppose that the following compact embedding property holds: let $L \subset K$ be a K-bounded set. If now on each compact subset of G the set of functions L is uniformly continuous then L is precompact in $L^2(G, d\lambda + d\rho)$.

Convolution mapping. The two spaces B and K are linked through the following convolution property: for fixed $r \in B$ the convolution product with r is a linear operator,

$$*_r : B \to K, \quad u \mapsto r * u,$$

and it is bounded $\|r * u\|_K \leqslant d\|u\|_B$, with d depending only on r.

Nonempty. We suppose that there is at least one $h \in D(T), h \neq 0$ such that $\Phi[h] < \infty$. This h is admissible, $h \in A$, since $B \subset L^2(G, d\lambda + d\rho)$. Thanks to the following lemma.

Lemma 1: Let $h \in A$, $h \neq 0$ be given. Then $g \in H$ is actually in A if and only if

$$\|g\|^2 = \|\mathcal{W}_h g\|^2_{L^2(G,d\lambda)} + \|\mathcal{W}_h g\|^2_{L^2(G,d\rho)} < \infty.$$

The square root of the left hand side defines a norm which on A is equivalent to the norm of A:

$$c_h^{-1}\|\mathcal{W}_h g\|^2_{L^2(G,d\lambda)} + \|h\|_H^{-2}\|\mathcal{W}_h g\|^2_{L^2(G,d\rho)} = \|g\|^2_A.$$

Proof: Suppose $g \in A$. Thanks to the formula

$$\|\mathcal{W}_h g\|^2_{L^2(G,\rho)} = \|\mathcal{W}_g h\|^2_{L^2(G,d\lambda)} = c_g \|h\|^2_H$$

and the isometric property of the wavelet transform we may conclude. ■

Under the above conditions, the following theorem holds.

Theorem 2: *There is a $g \in \Sigma_h \cap A$ such that for all $u \in \Sigma_h$ we have*

$$\Phi[g] \leqslant \Phi[u].$$

This function g then satisfies $\mathcal{W}_h g \in K$.

Typical examples for such spaces B are as follows. As space B we take the functions for which we have

$$\|r\|_{w,\infty} = \|w^{-1} r\|_{L^\infty(G)}.$$

We write also $B_{w,\infty}$ for this space. For the space K we take the analogue space of functions with weight $u = w * w$. If now $u \in L^2(G, d\lambda + d\rho)$ then we are in the setting of the first theorem. We only have to convince ourselves that all properties of the stated spaces are satisfied. The only nontrivial property is now the compact embedding.

Lemma 2: Let $u > 0$ be a symmetric weight function with $u \in L^2(G, d\lambda + d\rho)$. Then any set of functions which are uniformly continuous on compact sets of G is precompact in $L^2(G, d\lambda)$.

Proof: Let s_n be a sequence of functions in this set of functions. Since G is σ compact we can find a sequence of compact sets $K_m \subset G$ with $K_m \subset K_{m+1}$ and $\cup K_m = G$. Upon choosing a subsequence we may require that

$$\int_{G \setminus K_m} u^2 (d\lambda + d\rho) \leqslant 1/m.$$

On each K_m we can therefore find a uniformly convergent subsequence. Therefore upon choosing a suitable diagonal subsequence we may suppose that for $m' > m$

$$\int_{K_m} |s_m - s_{m'}|^2 (d\lambda + d\rho) \leqslant 1/m.$$

We therefore have

$$\|s_m - s_{m'}\|^2_{L^2(G,d\lambda+d\rho)} = \int_{G\setminus K_m} |s_m - s_{m'}|^2 (d\lambda + d\rho) + \int_{K_m} |s_m - s_{m'}|^2 (d\lambda + d\rho) \leqslant 2/m, \tag{3}$$

and thus s_m is a Cauchy sequence. Its pointwise limit exists, and thanks to Fatou lemma being in $L^2(G, d\lambda + d\rho)$. ■

A second family is given by

$$\|r\|_{w,2} = \|w^{-1/2} r\|_{L^2(d\lambda+d\rho)}.$$

We denote by $B_{w,2}$ the associated Banach space. This means that we consider localization quantities of the form

$$\int_G w^{-1} |\mathcal{W}_g g|^2 d\lambda.$$

If w is such that

$$\eta(x) = \sup_{y \in G} \sqrt{w(y^{-1} \circ x) w(y)}$$

satisfies $\eta \in L^2(G, d\lambda + d\rho)$, we may estimate for $r = w^{1/2} u$, $s = w^{1/2} v$, $u, v \in L^2(G, d\lambda + d\rho)$ that

$$|r * s(x)| \leqslant \int w(y^{-1} \circ x) w(y) u(y^{-1} \circ x) v(y) d\lambda\ (y)| \leqslant \eta(x) \|u\|_{L^2(G,d\rho)} \|v\|_{L^2(G,d\lambda)} \leqslant \eta(x) \|r\|_{w,2} \|s\|_{w,2},$$

and thus we have $B_{w,2} * B_{w,2} \subset B_{\eta,\infty}$. Therefore the theorem applies if we choose for the space $K = B_{\eta,\infty}$ and we have the existence of an optimally localized reconstruction wavelet.

We now prove the theorem. To start we analyze the mapping properties of Φ. We denote by Δ the domain of Φ,

$$\Delta = \{s \in H : \Phi[s] < \infty\} \subset A.$$

Lemma 3: The functional Φ is strongly H lower semicontinuous on Δ. More precisely for $\Delta \ni u_n \to u \in H$ in H, we have

$$\Phi[u] \leqslant \liminf_{n\to\infty} \Phi[u_n].$$

Proof: Since $\mathcal{W}_{u_n} u_n \to \mathcal{W}_u u$ pointwise and thus by hypothesis of semicontinuity of the B norm

$$\Phi[\lim_{n\to\infty} u_n] = \|\lim_{n\to\infty} \mathcal{W}_{u_n} u_n\|_B \leqslant \liminf_{n\to\infty} \|\mathcal{W}_{u_n} u_n\| = \liminf_{n\to\infty} \Phi[u_n].$$

■

We even have the following lemma.

Lemma 4: The functional Φ is H-weakly lower semicontinuous on $\Delta\setminus\{0\}$. More precisely, for any H-weak convergent sequence $\Delta \ni g_n \to g \in H$, $g \neq 0$ with $g_n \in \Delta$ we have $\Phi[g] \leqslant \liminf \Phi[g_n]$.

Proof: Let

$$\gamma = \lim_{n\to\infty} \inf \Phi[g_n].$$

Clearly $\gamma \geqslant 0$. In the case that $\gamma=\infty$ the lemma holds true and we may suppose $0 \leqslant \gamma < \infty$. We may find a subsequence which is denoted by g_n with $\Phi[g_n] < \infty$, and $\Phi[g_n] \to \gamma$. By hypothesis there is an $h \in D(T)$ with $\Phi[h] < \infty$. By the invariance of B it follows, thanks to

$$(\mathcal{W}_{U(y)h} U(y)h)(x) = \mathcal{W}_h h(y^{-1} \circ x \circ y),$$

that the whole orbit of h has the same properties. Since the representation is irreducible and T has dense range, we may suppose that $c_{g,h} = (g, Th)_H \neq 0$. For $s \in A$ we have by continuity of the convolution

$$\|\mathcal{W}_h s\|_K = \|\Pi * \mathcal{W}_s s\|_K \leqslant d\|\mathcal{W}_s s\|_B = d\Phi[s], \quad \Pi = c_{s,h}^{-1} \mathcal{W}_h h.$$

By weak convergence we have $c_{g_n,h} = (g_n, Th)_H \to (g, Th)_H \neq 0$. Therefore, since $g_n \in A$ thanks to $\Phi[g_n] < \infty$, we may conclude by setting $s = g_n$ in the formula above that $\{\mathcal{W}_h g_n\}$ is a bounded set in K and hence it is bounded in $\mathcal{W}_h H$ (the image of H under $\mathcal{W}_h$) too. Since the representation of the wavelet transform is strongly continuous this family of functions is uniformly continuous on any compact subset of G. Because of the compact embedding property of K we can extract an H convergent subsequence $g_{m(n)} \to g$. Since Φ is strongly lower continuous we have $\Phi[g] \leqslant \liminf \Phi[g_n] = \gamma$. ■

Now the proof of the main theorem is easy.

Proof: Let $\Phi[g_n] \to \gamma = \inf_{g \in \Sigma_h} \Phi[g]$. Since as before $\Phi[g_n] \leqslant b\|gn\|_H$ we see that g_n is bounded in H. Thanks to the Banach-Alaoglou theorem we may extract an H-weakly convergent subsequence $g_{m(n)} \to g$ weakly. Since Φ is weakly lower semicontinuous we may conclude that $\Phi[g] = \gamma$. The set Σ_h is weakly closed and hence $g \in \Sigma_h$. ■

We can even prove the following optimal localization result.

Theorem 3: *There is a g with* $\|g\|_H = 1$, *such that for all* $u \in H$, *with* $\|u\|_H = 1$ *we have*

$$\Phi[g] \leqslant \Phi[u].$$

Proof: As before, we find a weakly convergent sequence $g_n \to g$ with $\Phi[g] = \inf_{\|s\|=1} \Phi[s]$. Now as in the proof of Lemma 4 we see that there is a strongly convergent subsequence $g_{m(n)} \to g$ and thus $\|g\| = 1$. ■

IV. THE NUMERICAL APPROXIMATION OF LOCALIZED STATES

As we have shown in the previous section, for each weight function satisfying certain conditions, there exists an optimally localized wavelet g. The term "optimality" is strongly connected with the associated Banach space norm $\|\cdot\|_B$.

Before providing a receipt of how to derive those optimally localized wavelets, we wish to be more concrete and to give a few examples of typical Banach spaces and weight functions to which our theory can be applied. To this end, let us consider the class of α-modulation spaces which are usually defined by means of the flexible Gabor-wavelet transform, see Ref. 3,

$$\mathcal{W}_g^{\alpha}(f)(x) = (f, U(\sigma_{\alpha}(x))g)_H.$$

Since this transform is based on square integrability modulo quotients, we limit the subsequent consideration to the cases $\alpha=0$ and $\alpha=1$ (which fits then quite nicely with our framework, see below). For $\alpha=0$, the family $\{U(\sigma(x))g\}$ is a Gabor system and $\mathcal{W}_g^0 f$ coincides with the classical short time Fourier transform, while for $\alpha \to 1$ the family tends to the situation encountered in the wavelet context, where $\mathcal{W}_g^1$ is just a slight modification of the continuous wavelet transform. The intermediate case $\alpha = 1/2$ appears in the literature as the Fourier-Bros-Iagolnitzer transform.[2,14] In particular, one characterizes α-modulation spaces as follows (for simplicity we consider the wavelet transform of functions over $\mathbb{R}$): for $s \in \mathbb{R}$, for all $1 \leqslant p, q \leqslant \infty$, and for $\alpha \in [0,1)$,

$$M_{p,q}^{s+\alpha(1/q-1/2),\alpha}(\mathbb{R}) = \{f \in \mathcal{S}' : \mathcal{W}_g^\alpha(f) \in L^{p,q,s}\}, \quad \|f\|_{M_{p,q}^{s+\alpha(1/q-1/2),\alpha}} \asymp \|\mathcal{W}_g^\alpha(f)\|_{L^{p,q,s}},$$

where $L^{p,q,s}(\mathbb{R}^2)$ is the space of functions F on $\mathbb{R}^2$ such that

$$\|F\|_{Lp,q,s} := \left(\int_{\mathbb{R}} \left(\int_{\mathbb{R}} |F(t,\omega)|^p dt \right)^{q/p} (1+|\omega|)^{sq} d\omega \right)^{1/q} < \infty.$$

For $\alpha=0$, the space $M_{p,q}^{s,0}(\mathbb{R})$ coincides with the modulation space $M_{p,q}^s(\mathbb{R})$. For $\alpha \to 1$ the space $M_{p,q}^{s,1}(\mathbb{R})$ coincides with the inhomogeneous Besov space $B_{p,q}^s(\mathbb{R})$. These spaces serve as a reservoir of smoothness spaces in which functions can be characterized by means of special analyzing atoms or a so-called frame. A desirable property of the analyzing atom is localization with respect to underlying Banach spaces metric, i.e., in this context an optimal localized g is associated with Banach space norm $\|\cdot\|_{M_{p,q}^{s+\alpha(1/q-1/2),\alpha}}$ which in turn is here characterized by the weight

$$w(\omega) = (1+|\omega|)^s.$$

The numerical scheme developed below is limited to case $p=q=2$ and applies thus not to all situations.

Let us now consider a concrete case which is a little beyond the above mentioned examples. Let $L^{2,w^{-1}}$ with symmetric weight function

$$w^{-1}(x) = w^{-1}(a,b) = (|a|+|a|^{-1})^4 \cdot (1+|b|(1+|a|)^{-1})^4$$

be the space under consideration. Then, in accordance with Theorem 3, the optimization problem can be casted as follows:

$$\Phi(g) = \|\mathcal{W}_g g\|_{L^{2,w^{-1}}}^2 + \alpha \|g\|_H^2.$$

In order to discretize the problem somehow, we may represent g by means of some frame $\{\psi_\lambda\}_{\lambda\in\Lambda} \subset H$, i.e.,

$$g = \sum_{\lambda\in\Lambda} g_\lambda \psi_\lambda.$$

Consequently, the goal is to reconstruct a sequence $\{g_\lambda\}_{\lambda\in\Lambda} = \mathbf{g} \in \ell_2$ for which $\Phi(g) \leqslant \Phi(s)$, for all $s \in H$.

Introducing for some $x \in G$ the infinite matrix $\mathbf{A}(x) = ((\psi_\lambda, U(x)\psi_\eta)_H)_{\lambda,\eta\in\Lambda}$, the wavelet transform reads as $\mathcal{W}_g g(x) = \langle \mathbf{g}, \mathbf{A}(x)\mathbf{g}\rangle_{\ell_2} =: F[\mathbf{g}](x)$. Obviously, $F[\mathbf{g}](e) = \|g\|_H^2$, and thus we may write

$$\Phi(\mathbf{g}) = \|F[\mathbf{g}]\|_{L^{2,w^{-1}}}^2 + \alpha F[\mathbf{g}](e).$$

Since the optimization problem is no longer convex, we have to apply adequate strategies for nonlinear problems. We suggest to make use of a Tikhonov-based iteration method for nonlinear problems which was developed in Ref. 16. The technology to be applied here will always find a critical point of Φ, and under additional assumptions on F and the solution one can assure that the critical point is a global minimizer.

The method borrowed from Ref. 16 goes now as follows. Firstly, in order to obtain a problem which is hopefully easier to solve, we replace Φ by

$$\Phi^s(\mathbf{g};\mathbf{a}) := \Phi(\mathbf{g}) + C\|\mathbf{g}-\mathbf{a}\|_{\ell_2}^2 - \|F[\mathbf{g}] - F[\mathbf{a}]\|_{L^{2,w^{-1}}}^2, \tag{4.1}$$

where $\mathbf{a}$ is some auxiliary element in ℓ_2. So far its not clear whether Φ^s is positive or even bounded from below. Following the lines in Ref. 16, i.e., choosing for $\alpha > 0$ a ball around the origin K_r and C adequately large (in dependence on F and $\Phi(\mathbf{a})$), one can assure for all $\mathbf{g} \in K_r$, $\Phi(\mathbf{g}) \leqslant \Phi^s(\mathbf{g};\mathbf{a})$.

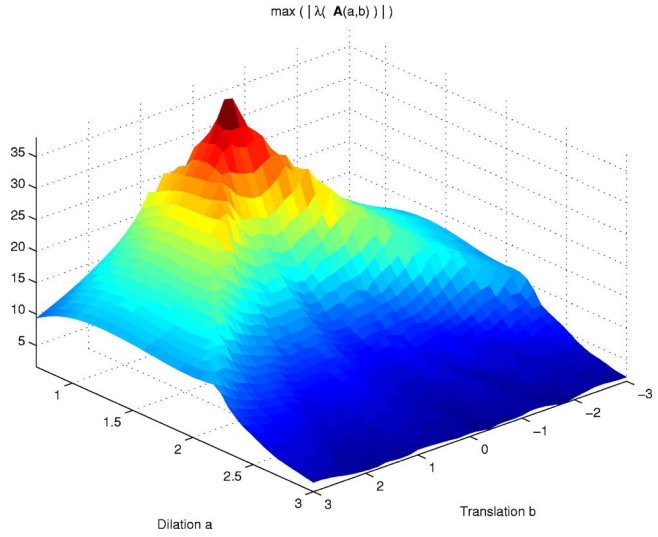

FIG. 1. (Color online) Maximal eigenvalues of the infinite matrices $A(a,b)$ for all the $(a,b)\in G$ used in the frame representation.

The iteration process is now obtained by picking some initial $\mathbf{g}_0=\mathbf{a}$ and therewith some proper $C>0$ and by deriving a sequence $\{\mathbf{g}_k\}_{k\in\mathbf{N}}$ via

$$\mathbf{g}_{k+1}=\arg\min_{\mathbf{g}}\Phi^s(\mathbf{g};\mathbf{g}_k).$$

From this iteration we expect convergence at least towards a critical point of Φ. First, we have to make sure that the sequence of functionals is properly defined.

Lemma 5: Let $\mathbf{a}$ *be given and* K_r, C *be defined as in Ref. 16. Then for all* $k\in\mathbf{N}$, $\Phi^s(\mathbf{g};\mathbf{g}_k)$ *are bounded from below, and moreover, the minimizers* $\mathbf{g}_{k+1}$ belong to K_r.

Let $\mathbf{A}$ now be the shorthand for $\mathbf{A}(e)$. A simple calculation shows the following.

Lemma 6: The necessary condition for a minimum of Eq. (4.1) *reads as*

$$\mathbf{g}=\frac{1}{C}\{\mathbf{g}_k-\alpha\mathbf{A}\mathbf{g}-F'[\mathbf{g}]^*(F[\mathbf{g}_k]w^{-1})\}. \tag{4.2}$$

The hope is that the right hand side of Eq. (4.2) defines a contraction. A straightforward computation shows

$$\|\mathbf{g}-\mathbf{g}'\|_{\ell_2}\leqslant\frac{1}{C}\{\alpha|||\mathbf{A}|||+2|||||\mathbf{A}(\cdot)|||||_{L^{2,w^{-1}}}\|F[\mathbf{g}_k]\|_{L^{2,w^{-1}}}\|\mathbf{g}-\mathbf{g}'\|_{\ell_2}.$$

To bound this quantity requires the Lipschitz continuity of $F'[\mathbf{g}]$, or in other words, the finiteness of $|||||\mathbf{A}(\cdot)|||||_{L^{2,w^{-1}}}$ which is difficult to prove, but can be verified numerically: we may consider the spectral radius $\rho(\mathbf{A}(a,b))$ (for a particular frame, see below) as a function of $(a,b)\in G$. Figure 1 shows a sufficient decay of $\rho(\mathbf{A}(a,b))$ and assures therewith that, for C large enough, the convergence of the fixed point iteration (4.2) towards a unique minimizer $\mathbf{g}_{k+1}$ of $\Phi^s(\mathbf{g};\mathbf{g}_k)$ can be achieved. Moreover, we have with the help of Ref. 16 that the sequence $\{\mathbf{g}_k\}$ converges at least towards a critical point of Φ. If we could impose more smoothness on F and on the solution $\mathbf{g}$ to be reconstructed, we could also achieve uniqueness.

Next, we have to ensure that $\|g^{n+1}\|_H^2=1$ (the index n stands now for the fixed point iteration) holds true through the whole fixed point iteration process, i.e., we have to determine α in each iteration step:

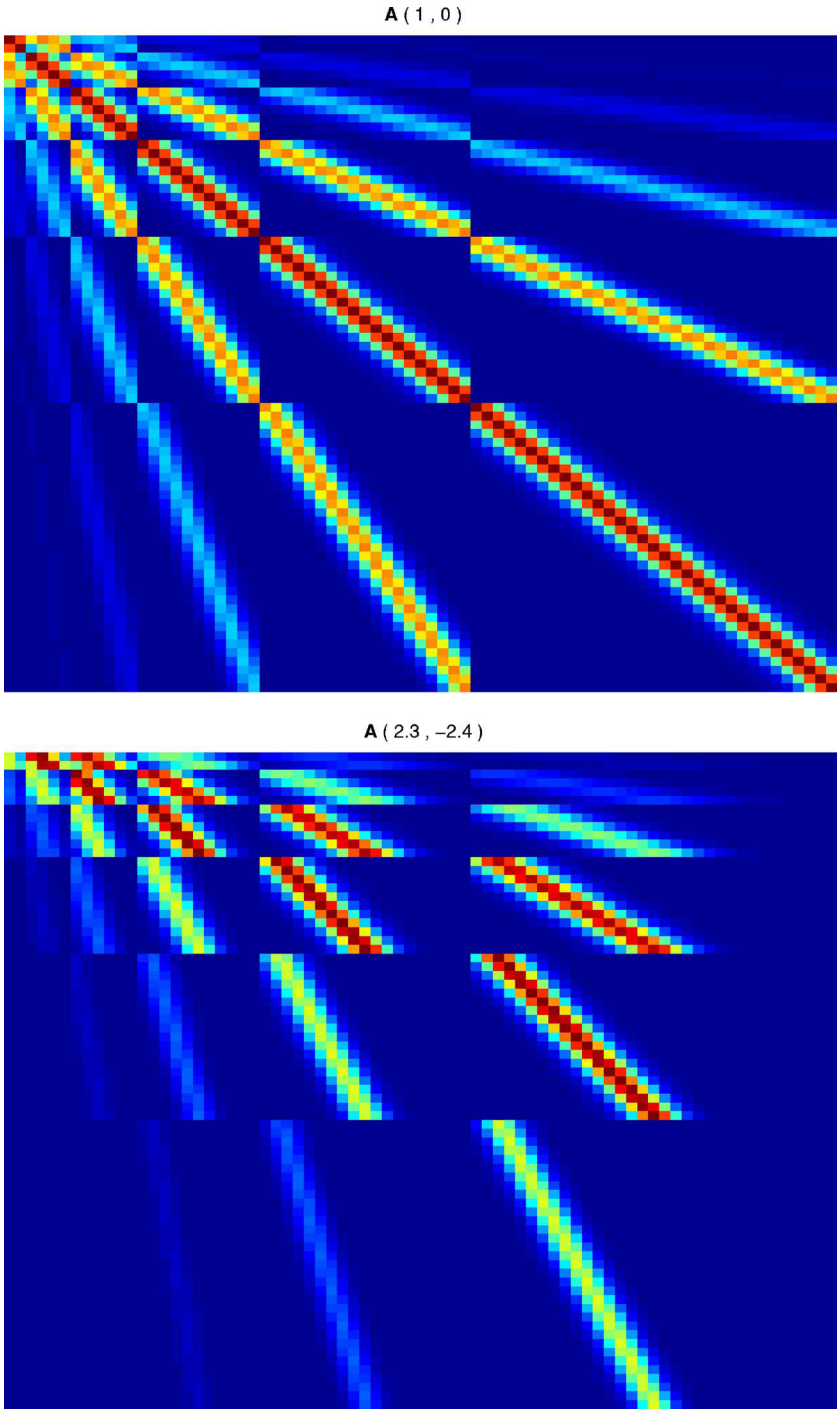

FIG. 2. (Color online) Structure of $A(a,b)$ for two particular cases; top, $(a,b)=(1,0)$ and bottom, $(a,b)=(2.3,-2.4)$.

$$(\mathbf{g}^{n+1},\mathbf{A}\mathbf{g}^{n+1})_{\ell_2}=\frac{1}{C^2}\{\alpha^2 F[\mathbf{A}\mathbf{g}^n](e)-2\alpha\Re(\mathbf{A}\mathbf{g}^n,\mathbf{A}(\mathbf{g}_k-F'[\mathbf{g}^n]^*(F[\mathbf{g}_k]w^{-1})))\ell_2$$
$$+F[\mathbf{g}_k-F'[\mathbf{g}^n]^*(F[\mathbf{g}_k]w^{-1})](e)\},$$

i.e., finding $\alpha=\alpha^{n+1}$ amounts to finding the roots of a real parabola. With the shorthand $M=\Re(\mathbf{A}\mathbf{g}^n,\mathbf{A}(\mathbf{g}_k-F'[\mathbf{g}^n]^*(F[\mathbf{g}_k]w^{-1})))_{\ell_2}$, we obtain

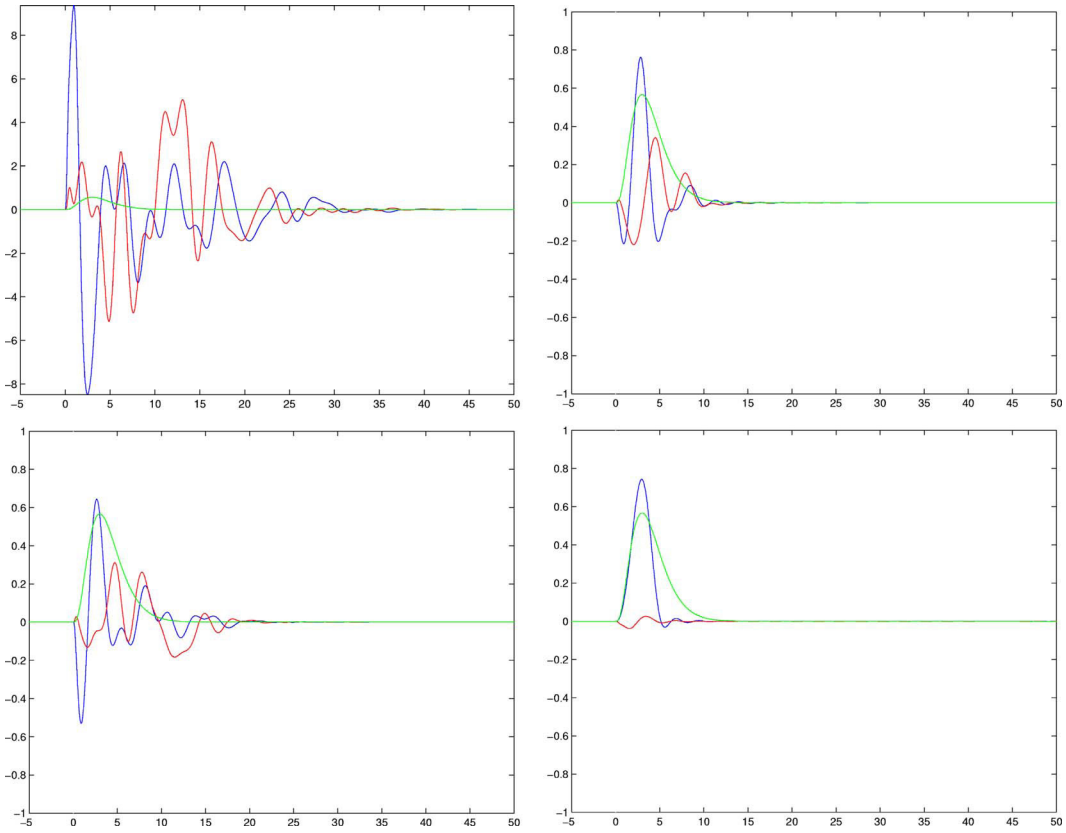

FIG. 3. (Color online) From top left to bottom right: Fourier representations of initial g_0 (not normalized), g_4, g_{10}, and g_{30} (blue/red, real and imaginary part; green, Cauchy wavelet).

$$\alpha^{n+1} = \frac{M \pm (M^2 - F[\mathbf{A}\mathbf{g}^n](e)\{F[\mathbf{g}_k - F'[\mathbf{g}^n]^*(F[\mathbf{g}_k]w^{-1})](e) - C^2\})^{1/2}}{F[\mathbf{A}\mathbf{g}^n](e)}. \tag{4.3}$$

Now we can summarize an algorithm for computing a critical sequence $\mathbf{g}$ for the minimization problem $\inf_{\|g\|_H=1}\Phi[g]$:

- *Pick some initial* $\mathbf{g}_0$ *(not too far off the expected solution) and some* $C>0$ *(large enough).*

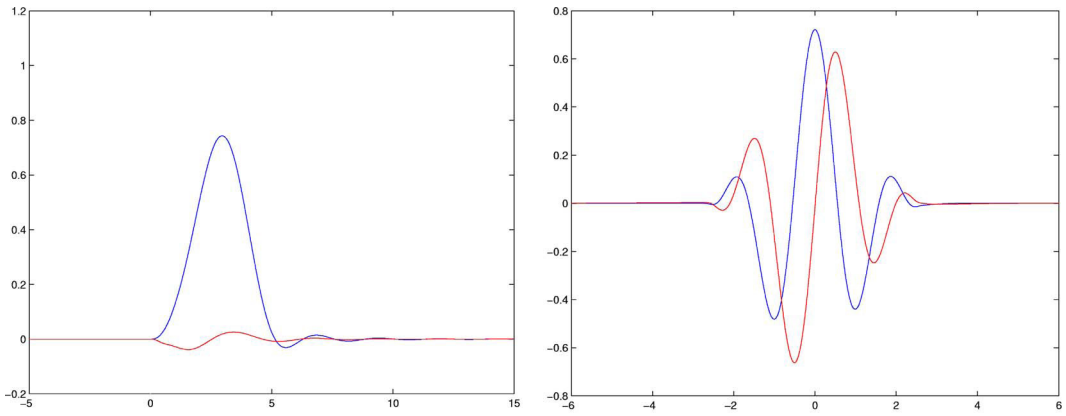

FIG. 4. (Color online) Left: Fourier representation of the approximated optimally localized coherent state. Right: Associated time representation.

- *Compute* $\mathbf{g}_{k+1}=\arg\min_{\mathbf{g}}\Phi^s(\mathbf{g};\mathbf{g}_k)$ *via fixed point iteration* (4.2):

  Compute $\alpha^{n+1}=\max\{\alpha_1^{n+1},\alpha_2^{n+1}\}$ *via* Eq. (4.3).
  Compute $\mathbf{g}^{n+1}$ *via* Eq. (4.2).
  $\mathbf{g}_{k+1}=\lim_{n\to\infty}\mathbf{g}^{n+1}$.

In what follows we aim to illustrate the computation of an optimally localized wavelet. For the sake of simply computing the operators $\mathbf{A}(x)$, we have chosen a (finite dimensional) Cauchy wavelet frame $\{\psi_\lambda\}\subset L^2(\mathbf{R})$ of order N (here $N=3$). Thus, $\mathbf{A}(x)$ can be derived for each $x\in G$ explicitly, see Fig. 2. The resulting iteration process to reconstruct at least a critical g is illustrated in Fig. 3, and the final approximation with the time representation in Fig. 4.

We motivate a notion of *geometric* equivalence that is not the usual notion of *algebraic* equivalence (or isomorphism of Clifford algebra). Using this definition tilting to the opposite metric is a geometric equivalence in contrast to such algebraic equivalences as $C\ell(3,0)\cong C\ell(1,2)$ which are not geometric. We define and discuss the classification of partitioned Clifford algebra and the geometric equivalence of Dirac formulations. © *2006 American Institute of Physics.*

I. INTRODUCTION

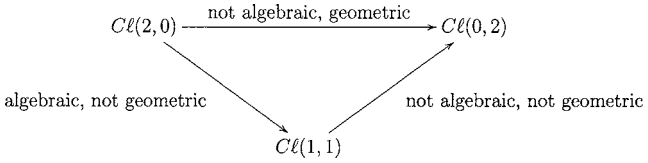
A long outstanding debate on Minkowski space-time concerns the physical explanation of differences between the (3,1) and (1,3) signatures of the metric. A partial mathematical answer is to be found in the corresponding Clifford algebras $C\ell(3,1)$ and $C\ell(1,3)$. They are not isomorphic, although their even subalgebras and their complexifications are, respectively, isomorphic. A number of papers over the years have investigated possible differences, see for example, de Witt-Morette *et al.*[1–4] and Pezzaglia and Adams[5] Recently, Joyce and Butler[6] have provided a rich geometric explanation where the geometric products corresponding to the different signatures are based on different geometric constructions. Although the underlying geometry is the same, the multivectors represent differing equivalence classes of geometric objects. Consequently two nonisomorphic algebras are generated. Nevertheless, there is a one to one relationship between the different geometric constructions. This paper describes and characterizes such geometric relationships.

There have been a few prior studies in the literature investigating the relationship between Clifford algebras with opposite signatures, including the tilt map given in Lounesto[7] and the vee product of Miralles *et al.*[8,9] We take a different approach where we introduce the notion of a *Geometric* map. Such a mapping preserves essential geometric properties. Fundamentally Clifford algebra arises from flat space-time geometries. We represent the flat spacetime by a vector space spanned by $m+n$ basis vectors denoted $e_1,\ldots,e_{m+n}$ and a signature (m,n). This generates the Clifford algebra $C\ell(m,n)$. Our space-time frame spans the subspace of one-vectors. Geometrically the even (resp. odd) multivectors arise from evaluation of an even (resp. odd) number of one-vectors. Moreover, the space of r-multivectors is spanned by the products of $r+2i$ one-vectors for every $i\in\mathbb{N}$, where $\mathbb{N}$ denotes the additive monoid of natural numbers. Importantly no even (resp. odd) multivector arises from an odd (resp. even) product of one-vectors. Also one should note that the generators for rotation and boosts [in $\mathrm{spin}_+(m,n)$] span $C\ell^+(m,n)$. Thus a linear map between Clifford algebras should only be considered *geometric* if it preserves the $\mathbb{Z}_2$ grading into even and odd multivectors. Moreover, the product of an even multivector with another multivector preserves this $\mathbb{Z}_2$ grade so,we should also have

$$\phi(uv)=\phi(u)\phi(v), \tag{1}$$

whenever u or v is an even multivector.

A geometric map is a linear $\mathbb{Z}_2$ graded map preserving left and right multiplicative action of $C\ell_+(m,n)$. A geometric equivalence is an invertible geometric map. For flat space-time with $m+n=2$ there are three $\mathbb{Z}_2$ graded Clifford algebra structures. Namely, $C\ell(2,0), C\ell(1,1)$ and $C\ell(0,2)$ where the $\mathbb{Z}_2$ grading is specified by the signature. We have the following relationship between the three:



One can see that tilting to the opposite metric is a geometric equivalence as it corresponds to Clifford algebras underlying the same flat space-time geometry. However, the universal enveloping algebra generated by two boost generators or a boost generator and a rotation generator give the algebraic equivalence $C\ell(2,0)\cong C\ell(1,1)$. We will show that two Clifford algebras are geometrically equivalent if and only if their even subalgebras are algebraically equivalent. Thus $C\ell(2,0)$ and $C\ell(0,2)$ are geometrically equivalent precisely because their even subalgebras are both isomorphic to $C\ell(0,1)$, the Clifford algebra generated by a single rotation generator.

With this motivation we now present a fuller treatment beginning with the notion of partitioned Clifford algebra.

II. FLAT SPACE-TIME GEOMETRIES AND PARTITIONED CLIFFORD ALGEBRA

We begin with a more general notion of flat space-time to ensure that the resulting "geometric algebra" is closed under tensor product. If one has a collection of flat space-time geometries where one has no means of rotating or boosting between each geometry, then the composite is a partitioned flat space-time geometry in the following sense.

Given $m,n\in\mathbb{N}$, let $[m+n]=\{1,2,\ldots,m+n\}$. A partition on $[m+n]$ is a map $\lambda:[m+n]\rightarrow\mathcal{P}[m+n]$, where $\mathcal{P}[m+n]$ is the power set of $[m+n]$, such that $i\in\lambda i$ and if $j\in\lambda i$ then $\lambda i=\lambda j$ where $i,j\in[m+n]$. Let $\Lambda=\{\lambda i: i\in[m+n]\}$ be the set of equivalence classes. We then have that $\Sigma_{\sigma\in\Lambda}|\sigma|=m+n$ and $\cup\Lambda=[m+n]$. A λ-flat spacetime of signature (m,n) is a family of vector spaces V_σ with signature (m_σ,n_σ) where $\sigma\in\Lambda$ satisfying $\Sigma_{\sigma\in\Lambda}m_\sigma=m$ and $\Sigma_{\sigma\in\Lambda}n_\sigma=n$. Hence the vector space

$$V=\bigoplus_{\sigma\in\Lambda}V_\sigma, \tag{2}$$

admits a basis $e_1,\ldots,e_{m+n}$ where $e_i\in V_{\lambda i}$ and is said to be of type λi.

Transformations that dilate, boost, or rotate between vectors of different types are not possible. Each partition component subspace may be said to be geometrically partitioned from all the others. Such situations occur when one trivially joins an internal space to an existing flat space-time.

We define the partitioned Clifford algebra $C\ell(m,n|\lambda)$ of signature (m,n) partitioned by λ to be the Clifford algebra generated by $e_1,\ldots,e_{m+n}$ with generating relations

$$e_ie_j=-\lambda_{ij}e_je_i \quad \text{for all} \quad i,j\in[m+n], \tag{3}$$

$$e_i^2=1 \quad \text{whenever} \quad i=1,2,\ldots,m, \tag{4}$$

$$e_{m+j}^2=-1 \quad \text{whenever} \quad j=1,2,\ldots,n, \tag{5}$$

where we have defined

$$\lambda_{ij} = \begin{cases} 1: i \neq j \text{ and } \lambda i = \lambda j \\ -1: i = j \text{ or } \lambda i \neq \lambda j, \end{cases} \tag{6}$$

for all $i,j \in [m+n]$. Thus if we define the components of a flat space-time metric as $\eta_{ij} = \langle \delta_{ij} e_i e_j \rangle_0$ we obtain a compact form of the generators

$$e_i e_j + (\lambda_{ij} + 2\delta_{ij}) e_j e_i = 2\eta_{ij}, \tag{7}$$

for all $i,j \in [m+n]$.

Let $m_\sigma = |[m] \cap \sigma|$, the number of generators e_i where $i \in \sigma$ with $e_i^2 = 1$. Let $n_\sigma = |(m+[n]) \cap \sigma|$, the number of generators e_i where $i \in \sigma$ with $e_i^2 = -1$. Then we have that $\Sigma_{\sigma \in \Lambda} m_\sigma = m, \Sigma_{\sigma \in \Lambda} n_\sigma = n$, and the decomposition

$$C\ell(m,n|\lambda) \cong \bigotimes_{\sigma \in \Lambda} C\ell(m_\sigma, n_\sigma). \tag{8}$$

Examples include Galilean space-time giving the geometric algebras $C\ell(1,0) \otimes C\ell(3,0)$ or $C\ell(0,1) \otimes C\ell(3,0)$, and Minkowski space-time with an evolution parameter giving the Dirac algebra $C\ell(0,1) \otimes C\ell(3,1)$.

A partitioned Clifford algebra $C\ell(m,n|\lambda)$ is $\mathbb{Z}_2^{|\Lambda|}$-graded. Assume Λ is ordered with $\sigma_1 < \cdots < \sigma_{|\Lambda|}$. We define

$$C\ell^0(m,n|\lambda) = \bigotimes_{\sigma \in \Lambda} C\ell^+(m_\sigma, n_\sigma), \tag{9}$$

which is the subalgebra generated by the rotation and boost generators for $C\ell(m,n|\lambda)$. We call $C\ell^0(m,n|\lambda)$ the kinematic subalgebra and its dimension is $2^{m+n-|\Lambda|}$. Let $z_i = (0,\ldots,0,1,0,\ldots,0) \in \mathbb{Z}_2^{|\Lambda|}$ where 1 is in the ith position. We define

$$\begin{aligned} C\ell^{z_i}(m,n|\lambda) = {} & C\ell^+(m_{\sigma 1}, n_{\sigma 1}) \otimes \cdots C\ell^+(m_{\sigma_{i-1}}, n_{\sigma_{i-1}}) \otimes C\ell^-(m_{\sigma_i}, n_{\sigma_i}) \\ & \otimes C\ell^+(m_{\sigma_{i+1}}, n_{\sigma_{i+1}}) \otimes \cdots \otimes C\ell^+(m_{\sigma_{|\Lambda|}}, n_{\sigma_{|\Lambda|}}). \end{aligned} \tag{10}$$

An arbitrary $z \in \mathbb{Z}_2^{|\Lambda|}$ may be written as $z = \Sigma_{i=1}^{|\Lambda|} a^i z_i$ for unique $a_1,\ldots,a_{|\Lambda|} \in \{0,1\}$ and we define

$$C\ell^z(m,n|\lambda) = C\ell^{a_1 z_1}(m,n|\lambda) \cdots C\ell^{a_{|\Lambda|} z_{|\Lambda|}}(m,n|\lambda). \tag{11}$$

The even part of the algebra is defined to be

$$C\ell^+(m,n|\lambda) = \bigoplus_{\substack{z \in \mathbb{Z}_2^{|\Lambda|} \\ \Sigma_{i=1}^{|\Lambda|} a^i \text{ is even}}} C\ell^z(m,n|\lambda). \tag{12}$$

Similarly we define $C\ell^-(m,n|\lambda)$ summing over z for $\Sigma_{i=1}^{|\Lambda|} a^i$ odd. This we will refer to in what follows as the $\mathbb{Z}_2$ grade for $C\ell(m,n|\Lambda)$. However, the generators for boost and rotation of the underlying partitioned space-time generate the kinematic subalgebra $C\ell^0(m,n|\lambda)$. In particular we have $C\ell^+(m,n|\lambda) = C\ell^0(m,n|\lambda)$ if and only if the partition is trivial.

III. GEOMETRIC MAPS AND EQUIVALENCES

Let $(m,n),(p,q) \in \mathbb{N}^2$ be a pair of signatures. Let λ and ρ be partitions of $[m+n]$ and $[p+q]$, respectively. Before stating the definition of a geometric map we note that any map $\pi: [m+n] \to [p+q]$ induces a map $\hat{\pi}: \mathbb{Z}_2^{|\Lambda|} \to \mathbb{Z}_2^{|R|}$ given by

$$\hat{\pi}\left(\sum_{i=1}^{|\Lambda|} a^i z_i \right) = \sum_{i=1}^{|\Lambda|} a^i z_{\pi i}. \tag{13}$$

Definition 1: A left (resp. right) geometric map is an ordered pair (ϕ, π) *consisting of a linear*

map $\phi: C\ell(m,n|\lambda) \to C\ell(p,q|\rho)$ *and a map* $\pi:[m+n] \to [p+q]$ *such that*

(i) $\pi\lambda = \rho\sigma$;
(ii) $\phi(C\ell^z(m,n|\lambda)) \subset C\ell^{\hat{\pi}z}(p,q|\rho)$ *for all* $z \in \mathbb{Z}_2^{|\Lambda|}$;
(iii) $\phi(uv) = \phi(u)\phi(v)$ *whenever* u *(resp.* v*) is in* $C\ell^0(m,n|\lambda)$.

The ordered pair (ϕ,π) *is geometric if it is both a left and right geometric map. It is weakly geometric if condition (ii) only holds for* $z=0$.

Often we will write $(\phi,\pi): C\ell(m,n|\lambda) \to C\ell(p,q)$ when we mean a (weakly) geometric map. If (ϕ,π) is a geometric map then $\hat{\pi}0=0$ and we have that the kinematic subalgebra generated by infinitesimal generators is preserved or

$$\phi(C\ell^0(m,n|\lambda)) \subset C\ell^0(p,q|\rho). \tag{14}$$

A geometric map (ϕ,π) is called a geometric equivalence (written $\sim$) if ϕ is invertible and π is bijective, it is called a geometric morphism if ϕ is a homomorphism and a geometric isomorphism if it is both a geometric equivalence and a geometric morphism. Note that an algebraic equivalence of Clifford algebras is written $\cong$.

Let $\mathcal{M}$ denote the monoid (recall a monoid is a group without the requirement of invertibility) generated by $C\ell(0,0), C\ell(1,0), C\ell(0,1), C\ell(2,0), C\ell(1,1)$, and $C\ell(0,2)$ with multiplication tensor product. This monoid is $\mathbb{Z}_2$-graded with the even submonoid $\mathcal{M}^+$ generated by $C\ell(0,0), C\ell(1,0)^{\otimes 2}, C\ell(0,1)^{\otimes 2}, C\ell(1,0)\otimes C\ell(0,1), C\ell(0,1)\otimes C\ell(1,0), C\ell(2,0), C\ell(1,1)$ and $C\ell(0,2)$.

Theorem 1: *Every partitioned Clifford algebra is weakly geometrically equivalent to a member of* $\mathcal{M}$.

Before proving this result we note that although $C\ell(2,0) \cong C\ell(1,1)$ they are not geometrically equivalent. The corresponding result for algebraic equivalence embodies the well-known classification of Clifford algebra by matrix algebra due to Cartan. The generators are algebraically equivalent to the following well-known algebras:

$$C\ell(0,0) \cong \mathbb{R}, \tag{15}$$

$$C\ell(1,0) \cong \mathbb{R} \oplus \mathbb{R}, \tag{16}$$

$$C\ell(0,1) \cong \mathbb{C}, \tag{17}$$

$$C\ell(2,0) \cong C\ell(1,1) \cong \mathbb{K}, \tag{18}$$

$$C\ell(0,2) \cong \mathbb{H}, \tag{19}$$

where $\mathbb{K}=\mathrm{Mat}(2,\mathbb{R})$. For $p,q \in \mathbb{N}$ we have the geometric isomorphisms

$$C\ell(p+2,q) \cong C\ell(2,0) \otimes C\ell(q,p), \tag{20}$$

$$C\ell(p+1,q+1) \cong C\ell(1,1) \otimes C\ell(p,q), \tag{21}$$

$$C\ell(p,q+2) \cong C\ell(0,2) \otimes C\ell(q,p). \tag{22}$$

In the first case e_1 and e_2 generate $Cl(2,0)$. A set of generators commuting with e_1 and e_2 are given by $e_{12}e_3, \ldots, e_{12}e_{p+q}$. The latter set generates $C\ell(q,p)$. The other isomorphisms are proved by selecting e_{p+1}, e_{p+2} and e_{q+1} and e_{q+2}, respectively. If ϕ and ψ are geometric isomorphisms then $\phi\otimes\psi$ is a geometric isomorphism. Hence we may iterate using these three formulas to prove the theorem.

Note the immediate corollary

Corollary 1: $C\ell(m,n|\lambda)$ *is an Abelian algebra if and only if it has no dimension four generators.*

The dimension four generators are $C\ell(2,0), C\ell(1,1)$ and $C\ell(0,2)$.

Every geometric map gives rise to a homomorphism between the kinematic subalgebras. We next show that a geometric map may be constructed as an extension of a homomorphism between the kinematic subalgebras. This will allow us to deduce a criterion for when partitioned Clifford algebras are geometrically equivalent. We begin with trivially partitioned Clifford algebra.

Proposition 1: Let $\phi: C\ell(m,n) \to C\ell(p,q)$ *be a geometric map then*

(i) $f=\phi(1)$ *is central and idempotent, and* $1-f$ *is an annihilator for* $\phi(C\ell(m,n))$;
(ii) *Suppose* $p+q>0$ *then given a homomorphism* $\phi: C\ell^+(m,n) \to C\ell^+(p,q)$ *there is a geometric extension* $\hat{\phi}: C\ell(m,n) \to C\ell(p,q)$ *satisfying* $\dim(\mathrm{Im}\,\hat{\phi}) = 2\dim(\mathrm{Im}\,\phi)$.

To prove the first part, given $v \in \phi(C\ell(m,n))$ there is a $u \in C\ell(m,n)$ such that $\phi(u)=v$ and $vf = \phi(u)\phi(1) = \phi(u) = v$ and similarly $fv=v$. Hence f is central and $1-f$ is an annihilator as claimed. Also $f^2 = \phi(1)\phi(1) = \phi(1) = f$.

Next we prove the second part after some development. Let $h_1, \ldots, h_{p+q-1}$ be generators for the Clifford algebra $C\ell^+(p,q)$. Let $P_{0,z}$ denote the protection onto the even and odd parts of $C\ell(p,q)$ and $P_{i,z}$ the projection onto commuting and anti-commuting components with respect to h_i given by

$$P_{i,z}v = \tfrac{1}{2}(v + (-1)^z h_i^{-1} v h_i), \tag{23}$$

for all $v \in C\ell(p,q)$ where $z \in \mathbb{Z}_2$. It is simple to verify $P_{i,z}P_{i',z'} = P_{i',z'}P_{i,z}$ for all $i,i' \in \{0,1,\ldots,p+q-1\}$ and $z,z' \in \mathbb{Z}_2$. Thus we define the projection operator

$$C^z = \Pi_{i=0}^{p+q-1} P_{i,a^i}, \tag{24}$$

for every $z \in \mathbb{Z}_2^{p+q}$ where $z = \Sigma_{i=0}^{p+q-1} a^i z_i$. Thus we have the decomposition

$$C\ell(p,q) \cong \bigoplus_{z \in \mathbb{Z}_2^{p+q}} C^z C\ell(p,q), \tag{25}$$

and $(C^z C\ell(p,q))(C^{z'} C\ell(p,q)) \subset C^{z+z'} C\ell(p,q)$. Hence we have the dimensionality

$$\dim C^{(0,z)} C\ell(p,q) = \begin{cases} 0: \sum_{i=1}^{p+q-1} z_i = p+q \bmod 2 \\ 1: \sum_{i=1}^{p+q-1} z_i = p+q-1 \bmod 2 \end{cases}. \tag{26}$$

Note that the generator $h_i \in C^z C\ell(p,q)$ where $z_k=0$ if and only if $k=0$ or $k=i$. Whenever $i \neq j$ note that $h_i h_j \in C^z C\ell(p,q)$ where $z_k=1$ if and only if $k=i$ or $k=j$. Using this we shall prove the following lemma.

Lemma 1: Given generators $h_1, \ldots, h_{p+q-1}$ *for* $C\ell^+(p,q)$ *there exists* $v \in C\ell^-(p,q)$ *such that* $h_i v = -v h_i$ *for all* $i=1,2,\ldots,p+q-1$.

For $p+q<2$ the result is trivial. For $p+q=2$ the only generators are $\pm e_{12}$ and one can take $v=e_1$. For $p+q>2$ and $p+q$ is odd take $v = e_1 \cdots e_{p+q} h_1 \cdots h_{p+q-1}$. Finally suppose $p+q>2$ and $p+q$ is even, then there exists no central odd element. Choose $u \in C^{(1,z)} C\ell(p,q)$ invertible for some $z \in \mathbb{Z}_2^{p+q-1}$ and let $0 < i_1 < \cdots < i_r < p+q$ such that $z_j=0$ if and only if $j=i_k$ for some $k=1,2,\ldots,r$. If r is even then $h_{i_1} \cdots h_{i_r} u \in C^{(1,0)} C\ell(p,q)$ contradicting there being no central odd element. Hence r is even and we take $v = h_1 \cdots h_{p+q-1} h_{i_1} \cdots h_{i_r} u \in C^{(1,1)} C\ell(p,q)$. This completes the proof.

It is worthwhile noting that if $p+q$ is odd then

$$\dim C^z C\ell(p,q) = 1, \tag{27}$$

for all $z \in \mathbb{Z}_2^{p+q}$, and if $p+q$ is even then

$$\dim C^z C\ell\,(p+q) = \begin{cases} 0{:}|\{i{:}z_i=1\}| \text{ is even}, \\ 2{:}|\{i{:}z_i=1\}| \text{ is odd}. \end{cases} \tag{28}$$

for all $z \in \mathbb{Z}_2^{p+q}$.

We have a simple corollary to the lemma.

Corollary 2: Let f be idempotent. Then given generators $h_1,\ldots,h_{p+q-1}$ for $[\{f\},C\ell^+(p,q)]$ there exists $v \in [\{f\},C\ell^-(p,q)]$ such that $h_i v=-vh_i$ for all $i=1,2,\ldots,p+q-1$.

This follows since f commutes will all elements in $[\{f\},C\ell\,(p,q)]$.

Completing the proof of (ii), take $h_i=\phi(e_{1i+1})$ then by the previous corollary there is $v \in [\{f\},C\ell^-(p,q)]$ invertible such that $h_i v=-vh_i$ for all $i=1,2,\ldots,p+q-1$. Hence a choice of extension is given by

$$\hat{\phi}(a+e_1 b) = \phi(a) + v\,\phi(b), \tag{29}$$

for al $a,b \in C\ell^+(m,n)$.

Thus we can state an important criterion for determining when two partitioned Clifford algebras are geometrically equivalent.

Theorem 2: *Two partitioned Clifford algebras are geometrically equivalent if and only if their kinematic subalgebras are algebraically equivalent.*

It immediately follows that $C\ell\,(m,n) \sim C\ell\,(n,m)$ and so tilting to the opposite metric is a geometric equivalence. In detail, between the Clifford algebras $C\ell\,(m,n)$ and $C\ell\,(n,m)$ there is a bijective Clifford map τ preserving generators satisfying

$$\tau(ab) = (-1)^{rs}\tau(a)\tau(b), \tag{30}$$

whenever a is an r-vector and b an s-vector. Let $(e'_1,\ldots,e'_r)$ be the generating basis for $C\ell\,(n,m)$ and define $f_k=e'_{n+k}$ for $k=1,\ldots,m$ and $f_k=e'_{k-m}$ for $k=m+1,\ldots,m+n$. We define τ by the formula

$$\tau(e_{k_1}\cdots e_{k_r}) = (-1)^{\lfloor r/2\rfloor} f_{k_1}\cdots f_{k_r}, \tag{31}$$

which is proven by induction using $\tau(e_k e_l)=-\tau(e_k)\tau(e_l)$. This follows from $\tau(e_k e_l)f_l=\tau(e_k e_l^2)$ $=f_k\tau(e_l^2)=-f_k e_l^2$ by multiplication by f_l and noting that $e_l^2 f_l^2=-1$. This is the anti-isomorphism map of Chevellay associated with switching the signature of the underlying quadratic form.

Geometric equivalence is decided by the algebraic equivalence of their kinematic subalgebras.

Proposition 2: Let $m,n,p,q \in \mathbb{N}$ and λ be a partition of $[m+n]$ then

$$(C\ell\,(m,n|\lambda) \otimes C\ell\,(1,0))^+ \cong C\ell\,(m,n|\lambda), \tag{32}$$

$$(C\ell\,(m,n|\lambda) \otimes C\ell\,(0,1))^+ \cong C\ell\,(n,m|\widetilde{\lambda}), \tag{33}$$

$$(C\ell\,(m,n) \otimes C\ell\,(p+1,q))^+ \cong C\ell\,(m+q,n+p), \tag{34}$$

$$(C\ell\,(m,n) \otimes C\ell\,(p,q+1))^+ \cong C\ell\,(n+p,m+q), \tag{35}$$

where $\widetilde{\lambda}$ is the partition given by $\widetilde{\lambda}i=-\lambda i$ modulo $m+n$.

Let e_k be the generators for $C\ell\,(m,n|\lambda)$ and σ the generator for $C\ell\,(1,0)$. A set of generators for the even subalgebra is given by $e_k \otimes \sigma$ where $k \in [m+n]$. These generate the Clifford algebra $C\ell\,(m,n|\lambda)$. The next formula is proven by noting that the signature is reversed. Suppose now that λ is trivial and let f_l be generators for $C\ell\,(p+1,q)$. A collection of generators for the even subalgebra of $C\ell\,(m,n)\otimes C\ell\,(p+1,q)$ is given by $e_k \otimes f_1$ and $1 \otimes f_{1l}$ where $k \in [m+n]$ and $l \in [p+q]+1$. These generators are all anti-commute and generate $C\ell\,(m+q,n+p)$. The final formula is proven by using generators $e_k \otimes f_{p+q+1}$ and $1 \otimes f_{lp+q+1}$ where $k \in [m+n]$ and $l \in [p+q]$.

Note that the last two formulas for $m=n=0$ reduce to the well-known algebraic equivalences

$$C\ell^{+}(p+1,q) \cong C\,\ell\,(q,p), \tag{36}$$

$$C\ell^{+}(p,q+1) \cong C\,\ell\,(p,q). \tag{37}$$

For example, we now have

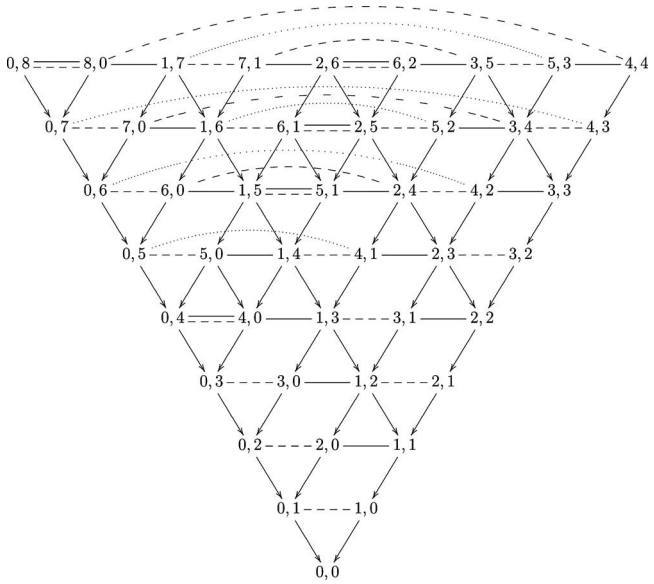
$$(C\,\ell\,(m+1,n) \otimes C\,\ell\,(p+1,q))^{0} \cong C\,\ell\,(n,m) \otimes C\,\ell\,(q,p), \tag{38}$$

$$(C\,\ell\,(m+1,n) \otimes C\,\ell\,(p,q+1))^{0} \cong C\,\ell\,(n,m) \otimes C\,\ell\,(p,q), \tag{39}$$

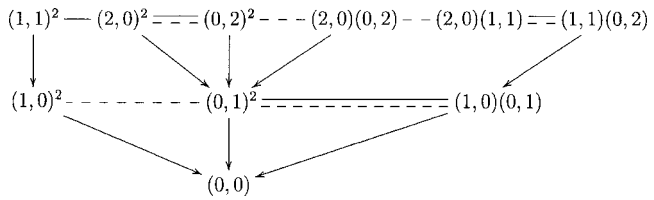
$$(C\,\ell\,(m,n+1) \otimes C\,\ell\,(p,q+1))^{0} \cong C\,\ell\,(m,n) \otimes C\,\ell\,(p,q). \tag{40}$$

One now sees that geometric and algebraic equivalence has a rich interplay determined by an extension of Cartan's period of eight classification for the kinematic subalgebras.

The first few Clifford algebras ($m+n \leqslant 8$) are given as follows. The dashed lines represent geometric equivalence, the solid, horizontal and dotted lines represent algebraic equivalence, and the solid arrows projection onto the kinematic subalgebra up to algebraic equivalence.



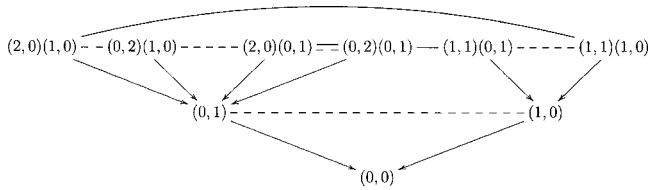
Note that not all geometric equivalences are given by tilting of the metric. However, this does not occur until $m+n \geqslant 6$. Next consider the partitioned Clifford algebra with $m+n=4$ or $m+n=2$ partitioned into two dimensionally equal pieces. This is given as follows:



The top left algebraic equivalences correspond to the isomorphism $\mathbb{K} \otimes \mathbb{K} \cong \mathbb{H} \otimes \mathbb{H}$. The algebraic equivalence on the second line is $\mathbb{C} \oplus \mathbb{C} \cong \mathbb{C} \otimes \mathbb{C}$. The next diagram is for partitioned Clifford algebra with $m+n=3$ into two nontrivial pieces.

TABLE I. Isomorphisms $C\ell(r)\cong \mathrm{Mat}(2^m,2^n\mathbb{F})$.

r	7	6	5	4	3	2	1	0	−1	−2	−3	−4	−5	−6	−7
m	3	2	1	1	1	1	0	0	0	0	0	1	2	3	3
n	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1
$\mathbb{F}$	$\mathbb{C}$	$\mathbb{H}$	$\mathbb{H}$	$\mathbb{H}$	$\mathbb{C}$	$\mathbb{R}$	$\mathbb{R}$	$\mathbb{R}$	$\mathbb{C}$	$\mathbb{H}$	$\mathbb{H}$	$\mathbb{H}$	$\mathbb{C}$	$\mathbb{R}$	$\mathbb{R}$



The algebraic equivalence in the diagram is $\mathbb{C}\otimes\mathbb{K}\cong\mathbb{C}\otimes\mathbb{H}$.

At this point we introduce the useful notation: $\mathbb{F}^m$ is the m-fold tensor product of $\mathbb{F}$ and $m\mathbb{F}$ is the m-fold direct sum of $\mathbb{F}$. Also we let $\mathcal{F}=\{\mathbb{R},\mathbb{C},\mathbb{H}\}$. We can now state the connection between partitioned Clifford algebra and matrix algebra.

Theorem 3: *Every partitioned Clifford algebra is of the form* $Mat(2^m,2^n\mathbb{F})$ *where* $m,n\in\mathbb{N}$ *and* $\mathbb{F}\in\mathcal{F}$. *Conversely, every matrix algebra* $Mat(2^m,2^n\mathbb{F})$ *for some* $m,n\in\mathbb{N}$ *and* $\mathbb{F}\in\mathcal{F}$ *is isomorphic to some partitioned Clifford algebra.*

To show this we begin by noting the fact

$$\mathbb{F}\otimes\mathbb{K}^m\cong \mathrm{Mat}(2^m,\mathbb{F}). \tag{41}$$

Given an arbitrary partitioned Clifford algebra $C\ell(p,q|\lambda)$ we can decompose each partitioned component

$$C\ell\,(p_\sigma,q_\sigma)\cong \mathbb{K}^{\min\{p_\sigma,q_\sigma\}}\otimes C\ell\,(p_\sigma-q_\sigma), \tag{42}$$

for every $\sigma\in\Lambda$ where we have defined $C\ell(p_\sigma)=C\ell(p_\sigma,0)$ and $C\ell(-q_\sigma)=C\ell(0,q_\sigma)$. Suppose $|p_\sigma-q_\sigma|=8m_\sigma+r_\sigma$ where $0\leqslant r_\sigma<8$ and $m_\sigma\in\mathbb{N}$. Thus $m_\sigma=\lfloor|p_\sigma-q_\sigma|/8\rfloor$ and $r_\sigma=|p_\sigma-q_\sigma|$ modulo 8. Further iterations gives

$$C\ell\,(p_\sigma-q_\sigma)=\mathbb{K}^{\left\lfloor\frac{|p_\sigma-q_\sigma|}{2}\right\rfloor}\otimes C\ell\,(\mathrm{sgn}(p_\sigma-q_\sigma)r_\sigma). \tag{43}$$

Combining the above decomposition with the equality

$$\left\lfloor\frac{p_\sigma+q_\sigma}{2}\right\rfloor=\min\{p_\sigma,q_\sigma\}+\left\lfloor\frac{|p_\sigma-q_\sigma|}{2}\right\rfloor, \tag{44}$$

gives the explicit formula

$$C\ell\,(p_\sigma,q_\sigma)\cong \mathrm{Mat}(2^{\left\lfloor\frac{p_\sigma+q_\sigma}{2}\right\rfloor},C\ell\,(\mathrm{sgn}(p_\sigma-q_\sigma)r_\sigma)). \tag{45}$$

Therefore,

$$C\ell\,(p,q|\lambda)\cong \mathrm{Mat}\left(2^{\Sigma_{\sigma\in\Lambda}\left\lfloor\frac{p_\sigma+q_\sigma}{2}\right\rfloor},\bigotimes_{\tau\in\Lambda}C\ell\,(\mathrm{sgn}(p_\tau-q_\tau)r_\tau)\right). \tag{46}$$

It only remains to classify $C\ell(r)$ for $-8<r<8$. These are obtained by iterating the first proposition. Table I can be understood by the period of eight circle in Fig. 1.

The numbers around the outside represent r when going clockwise and $-r$ when going anticlockwise. The inside numbers represent n plus the logarithm base 2 of the dimension of $\mathbb{F}$. The

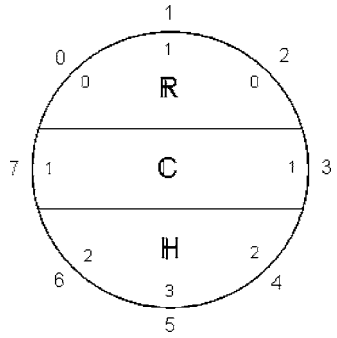


FIG. 1. The period of eight circle.

three regions of the circle indicate the underlying field $\mathbb{F}$. Not indicated on the diagram is that n is nonzero at 12 o'clock and 6 o'clock. The converse of the theorem holds because

$$\mathrm{Mat}(2^m,2^n\mathbb{F}) \cong C\ell(1,1)^m \otimes C\ell(1,0)^n \otimes \mathbb{F}, \tag{47}$$

where we use the Clifford algebra in Eqs. (20)–(22) in place of $\mathbb{F}$ given by $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$, respectively.

Consider the collection of matrix algebras $\mathrm{Mat}(2^m,2^n\mathbb{F})$, which we denote by $\langle m,n,\mathbb{F}\rangle$, where $m,n\in\mathbb{N}$, and $\mathbb{F}\in\mathcal{F}$. The members of this, set are pairwise nonisomorphic. Moreover, the tensor product of any two members in $\mathbb{N}^2\times\mathcal{F}$ is isomorphic to a unique member. Hence $\mathbb{N}^2\times\mathcal{F}$ is a commutative monoid in the obvious way. Define a monoid addition on $\mathcal{F}$ by $\mathbb{R}+\mathbb{F}=\mathbb{F}$, $\mathbb{C}+\mathbb{C}=\mathbb{C}$, $\mathbb{H}+\mathbb{C}=\mathbb{C}$, and $\mathbb{H}+\mathbb{H}=\mathbb{R}$. Given this, the monoid addition on $\mathbb{N}^2\times\mathcal{F}$ is given by

$$\langle m,n,\mathbb{F}\rangle \otimes \langle m',n',\mathbb{F}'\rangle = \langle m+m'+\delta_{\mathbb{F},\mathbb{H}}+\delta_{\mathbb{F}',\mathbb{H}}, n+n'+\delta_{\mathbb{F},\mathbb{C}}\delta_{\mathbb{F}',\mathbb{C}}, \mathbb{F}+\mathbb{F}'\rangle,$$

for all $m,m',n,n'\in\mathbb{N}$ and $\mathbb{F},\mathbb{F}'\in\mathcal{F}$

IV. TILTING THE METRIC IN DIRAC FORMULATIONS

Following Joyce and Martin[10] a Dirac formulation $(\sigma,\mathcal{I})$ consists of a Dirac pseudo-left ideal $\mathcal{I}$ and a Dirac character $\sigma\in C\ell(m,1)$ or $C\ell(1,m)$. Conventionally we choose a basis $e_0,\ldots,e_m$ satisfying $e_0^2=-e_k^2$ for all $k=1,\ldots,m$. A pseudo-left ideal satisfies $C\ell^+(m,1)\mathcal{I}\subset\mathcal{I}$, and it is called Dirac if $C\ell^-(m,1)\mathcal{I}\subset\mathcal{I}\sigma$, and similarly for $C\ell(1,m)$. The Dirac character satisfies $\sigma^2=-e_0^2$ and $e_o\tilde{\sigma}e_0=-e_0^2\sigma$. Examples include e_k,e_{0kl} for $C\ell(3,1)$ and e_k,e_{kl},e_{0kl}, and e_{0123} for $C\ell(1,3)$. The underlying Dirac equation is then given by

$$\partial\psi(x)=m\psi(x)\sigma, \tag{48}$$

where $\psi(x)\in\mathcal{I}$. This formulation includes the Dirac-Hestenes equation,[11] the conventional Dirac equation, a formulation due to Baylis,[12] a formulation due to Joyce[13] and others.

Theorem 4: *Given a Dirac formulation* $(\sigma,\mathcal{I})$ *then* $(\tau\sigma,\tau\mathcal{I})$ *is a Dirac formulation if and only if* σ *is odd. Consequently the formulations are geometrically equivalent.*

Applying the tilt map to σ^2 gives $\tau(\sigma^2)=-\tau(e_0^2)=(\tau e_0)^2$. Thus $(\tau\sigma,\sigma\mathcal{I})$ is necessarily a Dirac formulation if and only if $\tau(\sigma^2)=-(\tau\sigma)^2$. Hence if and only if σ is odd. This is also sufficient by checking that the remaining conditions under τ hold if σ is odd. Note that the Dirac-Hestenes equation tilts because γ^{012} is odd and consequently is independent of signature, unlike the usual Dirac equation which does not tilt.

V. CONCLUSION

We introduced the notion of a geometric map, this is a map that preserves the left and right action of the infinitesimal generators of boost and rotation. This showed that some algebraic equivalences were not geometric in this sense whereas tilting to the opposite metric was always a geometric equivalence.

The notion of a partitioned Clifford algebra was defined to admit partitioned flat space-time geometry. This also provides a category of algebras closed under tensor product. A complete classification of partitioned Clifford algebra by matrix algebra was given extending Cartan's period of eight. Finally we demonstrated which Dirac formulations may be tilted to give a geometrically equivalent Dirac formulation.

(Received 21 August 2006; accepted 9 October 2006; published online 11 December 2006)

The semigroup decomposition formalism makes use of the functional model for $C_{\cdot 0}$ class contractive semigroups for the description of the time evolution of resonances. For a given scattering problem the formalism allows for the association of a definite Hilbert space state with a scattering resonance. This state defines a decomposition of matrix elements of the evolution into a term evolving according to a semigroup law and a background term. We discuss the case of multiple resonances and give a bound on the size of the background term. As an example we treat a simple problem of scattering from a square barrier potential on the half-line. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2383069]

I. INTRODUCTION

Originally formulated for the analysis of scattering problems involving the solution of hyperbolic wave equations in the exterior domain of compactly supported obstacles, the Lax–Phillips scattering theory[1] was developed as a tool most suitable for dealing with resonances in the scattering of electromagnetic or acoustic waves. Subsequent to its introduction by Lax and Phillips, various authors have contributed to further development of the theory.[2–6] Notable recent additions were made by Sjöstrand and Sworski[7] who extended the scope of the theory to include general classes of semibounded, compactly supported perturbations of the Laplacian in the wave equation, and by Kuzhell, via the development of a formalism providing conditions for the application of the Lax–Phillips structure to an abstract form of the wave equation[8] and to certain classes of Schrödinger operators.[9] In addition, Kuzhell and Moskalyova[10] applied the Lax–Phillips theory in the analysis of scattering systems involving singular perturbations of the Laplacian.

Several recent papers have dealt with the adaptation of the Lax–Phillips theory to quantum mechanical scattering problems. An early work in this direction is Refs. 11–13. A general formalism was developed in Ref. 14 and subsequently applied to several physical models in Refs. 15–17. Such efforts to adapt the Lax–Phillips formalism to the framework of quantum mechanics are motivated by certain appealing features of the Lax–Phillips theory. One of these features is the fact that the time evolution of resonances in this theory is given in terms of a continuous, one parameter, strongly contractive semigroup $\{\mathbf{Z}(t)\}_{t\geqslant 0}$,

[a)]Electronic mail: ystrauss@cs.bgu.ac.il
[b)]Electronic mail: larry@post.tau.ac.il
[c)]Electronic mail: volovyka@post.tau.ac.il

$$\mathbf{Z}(t_1)\mathbf{Z}(t_2) = \mathbf{Z}(t_1 + t_2), \quad t_1, t_2 \geqslant 0.$$

If $\mathcal{H}$ is a (separable) Hilbert space corresponding to a particular scattering system and $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ is a unitary group defined on $\mathcal{H}$ describing the evolution of the system, the basic premises of the Lax–Phillips theory include the assumption of the existence of an *incoming subspace* $\mathcal{D}_-$ and an *outgoing subspace* $\mathcal{D}_+$ with respect to $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ which are assumed furthermore to be orthogonal to each other. Denoting by $\mathbf{P}_-$ and $\mathbf{P}_+$, respectively the projections on the orthogonal complements of $\mathcal{D}_-$ and $\mathcal{D}_+$ in $\mathcal{H}$, and letting $\mathcal{K}=\mathcal{H}\ominus(\mathcal{D}_-\oplus\mathcal{D}_+)$, the Lax–Phillips semigroup $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ defined by

$$\mathbf{Z}(t) = \mathbf{P}_+\mathbf{U}(t)\mathbf{P}_- = \mathbf{P}_\mathcal{K}\mathbf{U}(t)\mathbf{P}_\mathcal{K}, \quad t \geqslant 0, \tag{1}$$

annihilates $\mathcal{D}_\pm$ and maps $\mathcal{K}$ into itself. The subspace $\mathcal{K}$ contains the scattering resonances and the Lax–Phillips semigroup $\{\mathbf{Z}(t)\}_{t\geqslant 0}$ describes their time evolution. In the Lax–Phillips framework resonances are associated with pure states in the Hilbert space $\mathcal{H}$.

A basic difficulty encountered in the work on application of the Lax–Phillips theory in quantum mechanics originates from the fact that in this theory the continuous spectrum of the generator of evolution is required to be unbounded from below as well as from above. Hence, a formalism utilizing the original structure of the theory, such as in Ref. 14, is not suitable for application to large classes of scattering problems in quantum mechanics (except for limited types of problems, such as the Stark effect Hamiltonian,[17] or problems in a relativistically covariant framework,[15,16] which can be analyzed by direct mapping to the Lax–Phillips structure. The case of a Schrödinger equation with compactly supported potential may also be analyzed within the Lax–Phillips framework through the use of the invariance principle of wave operators[18]). The subject of the present paper is a theoretical framework, termed the *semigroup decomposition* of resonance evolution, developed with the goal of overcoming such difficulties. Proposed by one of the authors (Y. S.) of the present paper,[19,20] this formalism makes use of the Sz.-Nagy–Foias theory of contraction operators and contractive semigroups on Hilbert space[21] which, from the mathematical point of view, is the fundamental theory underlying the Lax–Phillips construction through the notion of model operators for $C_{\cdot 0}$ class semigroups.

The presentation of the semigroup decomposition formalism in Ref. 20 is based on the following assumptions:

(i) We are considering a scattering system consisting of a "free" unperturbed Hamiltonian $\mathbf{H}_0$ and a perturbed Hamiltonian $\mathbf{H}$, both defined on a Hilbert space $\mathcal{H}$.
(ii) $\text{ess supp}\sigma_{\text{ac}}(\mathbf{H}_0)=\text{ess supp}\sigma_{\text{ac}}(\mathbf{H})=\mathbb{R}^+$. For simplicity it is assumed further that the multiplicity of the absolutely continuous (ac) spectrum is 1.
(iii) The Møller wave operators $\mathbf{\Omega}^\pm\equiv\mathbf{\Omega}^\pm(\mathbf{H}_0,\mathbf{H})$ exist and are complete.
(iv) The S matrix in the *energy representation* (the spectral representation for $\mathbf{H}_0$), denoted by $\tilde{S}(\cdot)$ has an extension to a meromorphic function $S(\cdot)$ in an open, simply connected, region $\Sigma\subset\mathbb{C}$ such that $\Sigma\cap\mathbb{R}$ is an open interval in $\mathbb{R}$. The operator valued function $\mathcal{S}(\cdot)$ is holomorphic in $\Sigma\cap\mathbb{C}^+$ and has a simple pole (we generalize to the case of multiple poles in Sec. III below) at a point $z=\mu\in\Sigma\cap\mathbb{C}^-$ and no other singularity in $\bar{\Sigma}$, the closure of Σ.

It is shown in Ref. 20 that there exists a dense set $\Lambda\subset\mathcal{H}_{\text{ac}}(\mathbf{H})$ and a well defined state $\psi_\mu\in\mathcal{H}_{\text{ac}}(\mathbf{H})$ such that for any $g\in\Lambda$ and any $f\in\mathcal{H}_{\text{ac}}$ the properties (i)–(iv) above induce, for positive times, a decomposition of matrix elements of the evolution $\mathbf{U}(t)$ in the form

$$(g,\mathbf{U}(t)f)_{\mathcal{H}_{\text{ac}}(\mathbf{H})} = R(g,f;t) + \alpha(g,\mu)(\psi_\mu,f)_{\mathcal{H}_{\text{ac}}(\mathbf{H})}e^{-i\mu t}, \quad t \geqslant 0. \tag{2}$$

In a sense to be made precise in the next section the second term on the right hand side (rhs) of Eq. (2) originates from an evolution semigroup of the Lax–Phillips type and the eigenvalue of the generator of this semigroup is exactly μ, i.e., the point of singularity of the S matrix. The quantity $R(g,f;t)$ on the right hand side of Eq. (2) is what we shall call a *background* term. We note that if in Eq. (2) we choose f to be orthogonal to ψ_μ then the exponentially decaying semigroup term

[second term on the rhs of Eq. (2)] vanishes. We call ψ_μ an *approximate resonance state* and note that the characterization of ψ_μ as an approximate resonance state rather than as an exact resonance state stems from the fact that one can show (see Ref. 20) that there is no choice of g and f that makes the background term $R(g,f;t)$ vanish.

An explicit expression for the approximate resonance state ψ_μ is provided in Ref. 20. It is shown there that, if we denote by $\{|E^-\rangle\}_{E\in\mathbb{R}^+}$ the set of outgoing solutions of the Lippmann–Schwinger equation (using Dirac's notation), then ψ_μ is given by

$$\psi_\mu = \frac{1}{2\pi i}\int_{\mathbb{R}^+} dE \frac{1}{E-\mu}|E^-\rangle. \tag{3}$$

Following the introduction of approximate resonance states, the present paper discusses some generalizations. Thus, in Sec. III we assume that the region $\Sigma\cap\mathbb{C}^-$ contains multiple resonance poles of the S-matrix $\mathcal{S}(\cdot)$, say at $z=\mu_1,\ldots,\mu_n$ and obtain the form of the expression for the approximate resonance states and semigroup decomposition of evolution matrix elements in this case. In particular, we apply the semigroup decomposition to the *survival amplitude,* a central notion in the characterization of the time evolution of resonances. Theorem 5 below then provides an *a priori* upper bound on the size of the background term in this case.

As a final remark we note that a modification of the Lax–Phillips theory was recently used by Baumgartel for the description of scattering resonances in certain quantum mechanical problems[22] (see also Ref. 23). In particular, the assumption of orthogonality of $\mathcal{D}_\pm$, essential in the context of the original Lax–Phillips formalism, is replaced in Ref. 22 by the requirement that an incoming subspace $\mathcal{D}_-$ and an outgoing subspace $\mathcal{D}_+$ exist and the respective projections commute. The modified assumptions on $\mathcal{D}_\pm$, accompanied by certain assumptions on S-matrix analyticity properties, result in a modified Lax–Phillips structure which is then applied to the Friedrichs model, leading to the construction of appropriate Gamow type vectors[24] associated with scattering resonances. The framework presented in Ref. 22 has several points of intersection with the semigroup decomposition formalism discussed in the present paper. The nature of these relationships will be discussed elsewhere.

The rest of the paper is organized as follows: In Sec. II we describe the formalism providing the semigroup decomposition of resonance evolution starting with a short discussion of the functional model for $C_{\cdot 0}$ continuous contractive semigroups followed by a description of the semigroup decomposition formalism introduced in Refs. 19 and 20. In Sec. III we extend the framework of Ref. 19 and 20 to the case of multiple resonances and, furthermore, find an estimate on the size of the background term in the expression for the time evolution of the survival probability of a resonance. In Sec. IV we analyze a simple but illuminating example involving a one dimensional model of scattering from a square barrier potential. Section V contains a short summary of the contents of the paper and some indication on further possible courses of investigation.

II. THE SEMIGROUP DECOMPOSITION FOR RESONANCE EVOLUTION

A. Classification of contractive semigroups

Several distinct classes of contractive semigroups are identified within the framework of the Sz.-Nagy–Foias theory. Let $\{\mathbf{T}(t)\}_{t\geqslant 0}$ be a strongly contractive semigroup defined on a Hilbert space $\mathcal{H}$. The classes $C_{0\cdot}$, $C_{\cdot 0}$, $C_{1\cdot}$, $C_{\cdot 1}$ are defined by

$$\{\mathbf{T}(t)\}_{t\in\mathbb{R}^+} \in C_{0\cdot} \quad \text{if} \quad \mathbf{T}(t)h \to 0, \ \forall\, h \in \mathcal{H},$$

$$\{\mathbf{T}(t)\}_{t\in\mathbb{R}^+} \in C_{\cdot 0} \quad \text{if} \quad \mathbf{T}^*(t)h \to 0, \ \forall\, h \in \mathcal{H},$$

$$\{\mathbf{T}(t)\}_{t\in\mathbb{R}^+} \in C_{1\cdot} \quad \text{if} \quad \mathbf{T}(t)h \nrightarrow 0, \ \forall\, h \in \mathcal{H},\ h \neq 0,$$

$$\{\mathbf{T}(t)\}_{t\in\mathbb{R}^+} \in C_{\cdot 1} \quad \text{if} \quad \mathbf{T}^*(t)h \nrightarrow 0, \ \forall\, h \in \mathcal{H},\ h \neq 0.$$

The classes $C_{\alpha\beta}$ with α, β=0, 1 are then defined by

$$C_{\alpha\beta} = C_{\alpha\cdot} \cap C_{\cdot\beta}, \quad \alpha,\beta = 0,1.$$

The semigroup $\{\mathbf{Z}(t)\}_{t\in\mathbb{R}^+}$ describing the time evolution of resonances in the Lax–Phillips theory is readily characterized by the fact that $\{\mathbf{Z}^*(t)\}_{t\in\mathbb{R}^+}$ belongs to the class $C_{\cdot 0}$. The structure of the Lax–Phillips outgoing spectral (and translation) representation is then determined by that of the *functional model*[21,25] for $C_{\cdot 0}$ class semigroups provided by the Sz.-Nagy–Foias theory. We say an operator $\mathbf{A}$ is a *model operator*[25] for a given class C of operators if every operator in C is similar to a multiple of a part of $\mathbf{A}$ (a part of an operator $\mathbf{A}$ is a restriction of $\mathbf{A}$ to one of its invariant subspaces). By a functional model we mean that the model operator for a given class C has a canonical representation on suitable function spaces. For a $C_{\cdot 0}$ class semigroup $\{\mathbf{T}(t)\}_{t\geqslant 0}$ the associated functional model is essentially obtained through a procedure of *isometric dilation* of the *cogenerator* of $\{\mathbf{T}(t)\}_{t\geqslant 0}$ and the similarity mapping to the functional model is in fact a unitary transformation.

B. The functional model for $C_{\cdot 0}$ semigroups

We turn now to a brief description of the functional model for semigroups in the class $C_{\cdot 0}$. Denote by $\mathbb{C}^+$ the upper half of the complex plane and let $H^2_{\mathcal{N}}(\mathbb{C}^+)$ be the Hardy space of vector valued functions analytic in the upper half-plane and taking values in a separable Hilbert space $\mathcal{N}$. The set of boundary values on $\mathbb{R}$ of functions in $H^2_{\mathcal{N}}(\mathbb{C}^+)$, denoted below by $H^2_{\mathcal{N}+}(\mathbb{R})$, is a Hilbert space isomorphic to $H^2_{\mathcal{N}}(\mathbb{C}^+)$. In a similar manner the Hardy space of $\mathcal{N}$ valued functions analytic in the lower half-plane is denoted by $H^2_{\mathcal{N}}(\mathbb{C}^-)$ and $H^2_{\mathcal{N}-}(\mathbb{R})$ is the isomorphic Hilbert space consisting of boundary values on $\mathbb{R}$ of functions in $H^2_{\mathcal{N}}(\mathbb{C}^-)$. Define $\{u(t)\}_{t\in\mathbb{R}}$, a family of unitary, multiplicative operators $u(t): L^2_{\mathcal{N}}(\mathbb{R}) \mapsto L^2_{\mathcal{N}}(\mathbb{R})$ by

$$[u(t)f](\sigma) = e^{-i\sigma t} f(\sigma), \quad f \in L^2_{\mathcal{N}}(\mathbb{R}), \quad \sigma \in \mathbb{R}. \tag{4}$$

Assume that $\{\mathbf{T}(t)\}_{t\geqslant 0}$ is a $C_{\cdot 0}$ class semigroup defined on a Hilbert space $\mathcal{K}$. Let the semigroup $\{\hat{T}(t)\}_{t\geqslant 0}$, defined on a Hilbert space $\hat{\mathcal{K}}$, be the functional model for $\{\mathbf{T}(t)\}_{t\geqslant 0}$ and let $W: \mathcal{K} \mapsto \hat{\mathcal{K}}$ be the similarity transforming $\{\mathbf{T}(t)\}_{t\geqslant 0}$ into its functional model $\{\hat{T}(t)\}_{t\geqslant 0}$ i.e., $\hat{T}(t) = W\mathbf{T}(t)W^{-1}$. Then there exists a Hilbert space $\mathcal{N}$ such that $\hat{\mathcal{K}}$ is a closed subspace of $H^2_{\mathcal{N}+}(\mathbb{R})$, W is unitary, and the functional model is given by

$$\hat{T}(t) = W\mathbf{T}(t)W^* = P_{\hat{\mathcal{K}}} u^*(t) | \hat{\mathcal{K}}, \quad t \geqslant 0. \tag{5}$$

Here $P_{\hat{\mathcal{K}}}$ is the orthogonal projection from $H^2_{\mathcal{N}+}(\mathbb{R})$ onto $\hat{\mathcal{K}}$, the subspace $\hat{\mathcal{K}}$ is given by

$$\hat{\mathcal{K}} = H^2_{\mathcal{N}+}(\mathbb{R}) \ominus \Theta_T(\cdot) H^2_{\mathcal{N}+}(\mathbb{R}), \tag{6}$$

and $\Theta_T(\cdot): H^2_{\mathcal{N}+}(\mathbb{R}) \mapsto H^2_{\mathcal{N}+}(\mathbb{R})$ is an *inner function*[26,29,30] for $H^2_{\mathcal{N}+}(\mathbb{R})$ (depending, of course, on $\{\mathbf{T}(t)\}_{t\geqslant 0}$), i.e., an operator valued function with the properties:

1. For each $\sigma \in \mathbb{R}$ the operator $\Theta_T(\sigma): \mathcal{N} \mapsto \mathcal{N}$ is the boundary value at σ of an operator valued function $\Theta_T(\cdot)$ analytic in the upper half-plane.

2. $\|\Theta_T(z)\|_{\mathcal{N}} \leq 1$ for $\operatorname{Im} z > 0$.
3. $\Theta_T(\sigma)$, $\sigma \in \mathbb{R}$ is, pointwise, a unitary operator on $\mathcal{N}$.

The operator valued function $\Theta_T(\cdot)$ is, in fact, the *characteristic function*[21] of the cogenerator of the semigroup $\{\hat{T}(t)\}_{t\geq 0}$ [or $\{\mathbf{T}(t)\}_{t\geq 0}$].

Let P_+ be the orthogonal projection of $L^2_{\mathcal{N}}(\mathbb{R})$ on $H^2_{\mathcal{N}+}(\mathbb{R})$. The *Toeplitz operator* with symbol $u(t)$ (see, for example, Refs. 26 and 27, and references therein), is an operator $T_{u(t)}: H^2_{\mathcal{N}+}(\mathbb{R}) \mapsto H^2_{\mathcal{N}+}(\mathbb{R})$ defined by

$$T_{u(t)} f := P_+ u(t) f, \quad f \in H^2_{\mathcal{N}+}(\mathbb{R}). \tag{7}$$

We note that $\{T_{u(t)}\}_{t\geq 0}$ is a strongly contractive semigroup on $H^2_{\mathcal{N}+}(\mathbb{R})$ (see, for example, Refs. 1, 19, 21, and 28. Taking the conjugate of $\hat{T}(t)$ in $H^2_{\mathcal{N}+}(\mathbb{R})$ and using Eq. (5) one finds that

$$\hat{T}^*(t) = W\mathbf{T}^*(t)W^* = T_{u(t)}|\hat{\mathcal{K}}, \quad t \geq 0. \tag{8}$$

It follows from the discussion above that the Lax–Phillips semigroup $\{\mathbf{Z}(t)\}_{t\geq 0}$ has a functional model in the form of Eq. (8) [recall that $\{\mathbf{Z}^*(t)\}_{t\geq 0}$ is a $C_{\cdot 0}$ class semigroup], i.e., if we denote the functional model for $\{\mathbf{Z}(t)\}_{t\geq 0}$ by $\{\hat{Z}(t)\}_{t\geq 0}$ then we have

$$\hat{Z}(t) = W\mathbf{Z}(t)W^* = T_{u(t)}|\hat{\mathcal{K}}, \quad t \geq 0 \tag{9}$$

where $\hat{\mathcal{K}} \subset H^2_{\mathcal{N}+}(\mathbb{R})$ is an invariant subspace for $\{T_{u(t)}\}_{t\geq 0}$ given by

$$\hat{\mathcal{K}} = H^2_{\mathcal{N}+}(\mathbb{R}) \ominus \Theta_Z(\cdot) H^2_{\mathcal{N}+}(\mathbb{R}) \tag{10}$$

and the inner function $\Theta_Z(\cdot)$ and the Hilbert space $\mathcal{N}$ are determined by $\{\mathbf{Z}(t)\}_{t\geq 0}$. A semigroup $\{\hat{Z}(t)\}_{t\geq 0}$ of the form given by Eqs. (9) and (10) is referred to in Ref. 20 as a *Lax–Phillips type semigroup.*

A central theorem of the Lax–Phillips theory, corresponding to an important result in the Sz.-Nagy–Foias theory relating the spectrum of a *completely nonunitary contraction* (cnu) to points of singularity of the characteristic function states the following.

Theorem 1: *Denote by* $\hat{B}$ *the generator of a Lax–Phillips type semigroup* $\{\hat{Z}(t)\}_{t\geq 0}$. *If* $\operatorname{Im} \mu < 0$, *then* μ *belongs to the point spectrum of* $\hat{B}$ *if and only if* $\Theta^*_Z(\bar{\mu})$ *has a nontrivial null space.*

We note that the analytic continuation of $\Theta_Z(z)$ to the lower half-plane is given by

$$\Theta_Z(z) := (\Theta^*_Z(\bar{z}))^{-1}, \quad \operatorname{Im} z < 0$$

and so a null space for $\Theta^*_Z(\bar{\mu})$ implies the existence of a pole for $\Theta_Z(z)$ at $z=\mu$. In the case of the Lax–Phillips theory the characteristic function $\Theta_Z(\cdot)$ for the Lax–Phillips semigroup is identical to the Lax–Phillips S matrix and its poles are the scattering resonances. As will be seen below, the situation is a bit more involved in the semigroup decomposition formalism.

We do not elaborate here further on the relations between the functional model for $C_{\cdot 0}$ semigroups discussed above and the full structure of the Lax–Phillips spectral representations and wave operators. The reader is referred to Refs. 1 and 21.

C. The semigroup decomposition

In order to apply the functional model for $C_{\cdot 0}$ semigroups, which is at the heart of the Lax–Phillips structure, to the description of resonance evolution it is necessary to relate, for $t \geq 0$, the evolution $\mathbf{U}(t)$ defined on the Hilbert space $\mathcal{H}$ of the scattering problem to the Toeplitz evolution semigroup $T_{u(t)}$ of Eq. (7) defined on $H^2_{\mathcal{N}+}(\mathbb{R})$ and then restrict the latter, according to Eq. (9), to a subspace $\hat{\mathcal{K}}$ of $H^2_{\mathcal{N}+}(\mathbb{R})$ associated with an appropriate inner function $\Theta_{\hat{Z}}(\cdot)$. In the framework of the Lax–Phillips theory this relation is guaranteed by the special properties of the

Lax–Phillips incoming and outgoing subspaces $\mathcal{D}_\pm$ (with $\mathcal{D}_-$ and $\mathcal{D}_+$ denoting, respectively, the incoming and outgoing subspace), since in this case the Lax–Phillips semigroup is a $C_{\cdot 0}$ semigroup. However, for many quantum mechanical scattering problems one usually cannot find subspaces with the properties of $\mathcal{D}_\pm$. A way of overcoming this difficulty, proposed in Ref. 19, is to combine the standard functional model for $C_{\cdot 0}$ semigroups with the notion of a *quasi-affine mapping* (see, for example, Ref. 21, p. 70).

Definition 1 (quasi-affine mapping): A quasiaffine map from a Hilbert space $\mathcal{H}_1$ into a Hilbert space $\mathcal{H}_0$ is a linear, one to one continuous mapping of $\mathcal{H}_1$ into a dense linear manifold in $\mathcal{H}_0$. If $\mathbf{A}\in\mathcal{B}(\mathcal{H}_1)$ and $\mathbf{B}\in\mathcal{B}(\mathcal{H}_0)$ then $\mathbf{A}$ is a quasi-affine transform of $\mathbf{B}$ if there is a quasi-affine map $\theta:\mathcal{H}_1\mapsto\mathcal{H}_0$ such that $\theta\mathbf{A}=\mathbf{B}\theta$.

The following theorem is proved in Ref. 19 for a scattering system consisting of unperturbed and perturbed Hamiltonians, respectively $\mathbf{H}_0$ and $\mathbf{H}$, having semibounded continuous spectrum:

Theorem 2 (outgoing/incoming contractive nesting): *Let $\mathbf{H}_0$ and $\mathbf{H}$ be self-adjoint operators on a Hilbert space $\mathcal{H}$. Let $\{\mathbf{U}(t)\}_{t\in\mathbb{R}}$ be the unitary evolution group on $\mathcal{H}$ generated by $\mathbf{H}$* [i.e., $\mathbf{U}(t)=\exp(-i\mathbf{H}t)$]. *Denote by $\mathcal{H}_{\mathrm{ac}}(\mathbf{H}_0)$ and $\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$, respectively, the absolutely continuous subspaces of $\mathbf{H}_0$ and $\mathbf{H}$. Assume that the absolutely continuous spectrum of $\mathbf{H}_0$ and $\mathbf{H}$ has multiplicity one and that ess Supp $\sigma_{\mathrm{ac}}(\mathbf{H}_0)=$ess Supp $\sigma_{\mathrm{ac}}(\mathbf{H})=\mathbb{R}^+$. Assume furthermore that the Møller wave operators $\mathbf{\Omega}^\pm\equiv\mathbf{\Omega}^\pm(\mathbf{H}_0,\mathbf{H}):\mathcal{H}_{\mathrm{ac}}(\mathbf{H}_0)\mapsto\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ exist and are complete. Then there are mappings $\hat{\Omega}_\pm:\mathcal{H}_{\mathrm{ac}}(\mathbf{H})\mapsto H^2_+(\mathbb{R})$ such that*

(i) *$\hat{\Omega}_\pm$ are contractive quasi-affine mappings of $\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ into $H^2_+(\mathbb{R})$*; and
(ii) *for every $t\geqslant 0$ the evolution $\mathbf{U}(t)$ is a quasiaffine transform of the Toeplitz operator $T_{u(t)}$ via the mapping $\hat{\Omega}_\pm$ i.e., for every $f\in\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ we have*

$$\hat{\Omega}_\pm\mathbf{U}(t)f=T_{u(t)}\hat{\Omega}_\pm f\quad t\geqslant 0. \tag{11}$$

□

We call the triplet $\langle\mathcal{H}_{\mathrm{ac}}(\mathbf{H}),H^2_+(\mathbb{R}),\hat{\Omega}_-\rangle$ the *incoming contractive nesting* of $\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ into $H^2_+(\mathbb{R})$ and denote $f_{\mathrm{in}}=\hat{\Omega}_-f$. Similarly, the triplet $\langle\mathcal{H}_{\mathrm{ac}}(\mathbf{H}),H^2_+(\mathbb{R}),\hat{\Omega}_+\rangle$ is the *outgoing contractive nesting of* $\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ into $H^2_+(\mathbb{R})$ and we denote $f_{\mathrm{out}}=\hat{\Omega}_+f$.

Define

$$\Xi_{\hat{\Omega}_+}:=\hat{\Omega}_+^*H^2_+(\mathbb{R}).$$

Then, since $\hat{\Omega}_+^*$ is quasi-affine, the linear space $\Xi_{\hat{\Omega}_+}\subset\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ is dense in $\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$. Moreover, since $\hat{\Omega}_+^*$ is one to one, for each $g\in\Xi_{\hat{\Omega}_+}$ there is a unique $\tilde{g}\in H^2_+(\mathbb{R})$ such that $g=\hat{\Omega}_+^*\tilde{g}$. We note that in Ref. 20 a dense set $\Lambda_{\hat{\Omega}_+}$, analogous to $\Xi_{\hat{\Omega}_+}$, is defined somewhat differently, i.e., $\Lambda_{\hat{\Omega}_+}:=\hat{\Omega}_+^*\hat{\Omega}_+\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$. However, it will be seen below that the definition of $\Xi_{\hat{\Omega}_+}$ above, unlike that of $\Lambda_{\hat{\Omega}_+}$, allows for a full characterization of approximate resonance states. Using Theorem 2 we have, for every $g\in\Xi_{\hat{\Omega}_+}$ and $f\in\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ and for $t\geqslant 0$,

$$(g,\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=(\hat{\Omega}_+^*\tilde{g},\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=(\tilde{g},T_{u(t)}\hat{\Omega}_+f)_{H^2_+(\mathbb{R})}=(\tilde{g},T_{u(t)}f_{\mathrm{out}})_{H^2_+(\mathbb{R})},\quad t\geqslant 0. \tag{12}$$

Following the definitions of the incoming and outgoing nestings of $\mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ into $H^2_+(\mathbb{R})$ it is natural to define the *nested S matrix*

$$S_{\mathrm{nest}}:=\hat{\Omega}_+\hat{\Omega}_-^{-1}.$$

Let $U:\mathcal{H}_{ac}(\mathbf{H}_0)\mapsto L^2(\mathbb{R}^+)$ be the unitary transformation of $\mathcal{H}_{ac}(\mathbf{H}_0)$ onto the spectral representation for $\mathbf{H}_0$ (also called the energy representation for $\mathbf{H}_0$). If $\mathbf{S}=(\mathbf{\Omega}^-)^*\mathbf{\Omega}^+$ is the scattering operator associated with $\mathbf{H}_0$ and $\mathbf{H}$ then $\tilde{S}(\cdot):L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ defined by

$$\tilde{S}(\cdot) := U\mathbf{S}U^* \tag{13}$$

is the energy representation of the S matrix. Let $P_{\mathbb{R}^+}:L^2(\mathbb{R})\mapsto L^2(\mathbb{R})$ be the orthogonal projection in $L^2(\mathbb{R})$ on the subspace of functions supported on $\mathbb{R}^+$ and define the inclusion map $I:L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R})$ by

$$(If)(\sigma)=\begin{cases} f(\sigma), & \sigma\geqslant 0 \\ 0, & \sigma<0. \end{cases} \tag{14}$$

Then the inverse $I^{-1}:P_{\mathbb{R}^+}L^2(\mathbb{R})\mapsto L^2(\mathbb{R}^+)$ is, of course, one to one on $P_{\mathbb{R}^+}L^2(\mathbb{R})$. Let $\theta:H^2_+(\mathbb{R})\mapsto L^2(\mathbb{R}^+)$ be a map given by

$$\theta f = I^{-1}P_{\mathbb{R}_+}f, \quad f\in H^2_+(\mathbb{R}). \tag{15}$$

By a theorem of Van Winter,[31] θ is a quasi-affine transform mapping $H^2_+(\mathbb{R})$ into $L^2(\mathbb{R}^+)$. The adjoint map $\theta^*:L^2(\mathbb{R}^+)\mapsto H^2_+(\mathbb{R})$ is then also a contractive quasi-affine map. An explicit expression for θ^* is provided by the following lemma.[19]

Lemma 1: Let $I:L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R})$ be the inclusion map defined in Eq. (14). Let P_+ be the orthogonal projection of $L^2(\mathbb{R})$ onto $H^2_+(\mathbb{R})$. Then for every $f\in L^2(\mathbb{R}^+)$ we have

$$\theta^* f = P_+ If, \quad f\in L^2(\mathbb{R}^+). \tag{16}$$

□

It is shown in Ref. 19 that the nested S matrix can be expressed in the form

$$S_{\text{nest}} = \theta^*\tilde{S}(\cdot)(\theta^*)^{-1}. \tag{17}$$

Following Ref. 20 we now use assumption (iv) in Sec. I. The S-matrix $\tilde{S}(\cdot)$ is then the restriction of its extension $\mathcal{S}(\cdot)$ on $\mathbb{R}^+$. Under these assumptions $\mathcal{S}(\cdot)$ has, in the region Σ, a representation of the form (see Ref. 20),

$$\mathcal{S}(z)=\mathcal{B}_\mu(z)\mathcal{S}'(z), \quad z\in\Sigma,$$

where

$$\mathcal{B}_\mu(z)=\frac{z-\bar{\mu}}{z-\mu}, \quad z\in\mathbb{C}\setminus\{\mu\} \tag{18}$$

and $\mathcal{S}'(\cdot)$ is analytic and has no zeros in Σ. Restricting $\mathcal{S}(\cdot)$ to the positive real axis we obtain

$$\tilde{S}(E)=\tilde{B}_\mu(E)\tilde{S}'(E), \quad E\geqslant 0, \tag{19}$$

where by definition $\tilde{B}_\mu(E):=\mathcal{B}_\mu(E)$ and $\tilde{S}'(E):=\mathcal{S}'(E)$ for $E\geqslant 0$. We note that both $\tilde{S}'(\cdot)$ and $\tilde{B}_\mu(\cdot)$ are considered here as multiplicative unitary operators on $L^2(\mathbb{R}^+)$ (moreover, they are pointwise unitary a.e. for $E\geqslant 0$). Moreover, $\mathcal{B}_\mu(\cdot)$ can be regarded as a multiplicative operator on $L^2(\mathbb{R})$. In fact, considered as a multiplicative operator on $H^2_+(\mathbb{R})\subset L^2(\mathbb{R})$, $\mathcal{B}_\mu$ is a *Blaschke* factor [the definition of Blaschke products and Blaschke factors can be found, for example in Refs. 29 and 30, see e.g., Eq. (29) below]. Such a factor is the simplest example of an inner function for $H^2_+(\mathbb{R})$. We make use of this fact through the following proposition, not stated as such, but implicitly used in Ref. 20.

Proposition 1: Let $\tilde{B}_\mu(\cdot):L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ be defined by $\tilde{B}_\mu(E)=\mathcal{B}_\mu(E)$, $E\geqslant 0$ where $\mathcal{B}_\mu(\cdot)$ is

defined in Eq. (18). Let $\theta^*: L^2(\mathbb{R}^+) \mapsto H^2_+(\mathbb{R})$ *be the adjoint of the map* θ *defined in Eq. (15). Let* $\hat{\mathcal{K}}_\mu \subset H^2_+(\mathbb{R})$ *and* $\hat{\mathcal{K}}_{\bar{\mu}} \subset H^2_-(\mathbb{R})$ *be subspaces defined by*

$$\hat{\mathcal{K}}_\mu := H^2_+(\mathbb{R}) \ominus \mathcal{B}_\mu(\cdot) H^2_+(\mathbb{R}), \quad \hat{\mathcal{K}}_{\bar{\mu}} := H^2_-(\mathbb{R}) \ominus \mathcal{B}_{\bar{\mu}}(\cdot) H^2_-(\mathbb{R}),$$

where $\mathcal{B}_{\bar{\mu}}(z) = (z-\mu)(z-\bar{\mu})^{-1}$ *and denote by* $P_{\hat{\mathcal{K}}_\mu}$ *and* $P_{\hat{\mathcal{K}}_{\bar{\mu}}}$ *the orthogonal projections of* $L^2(\mathbb{R})$ *on* $\hat{\mathcal{K}}_\mu$ *and* $\hat{\mathcal{K}}_{\bar{\mu}}$, *respectively. For every* $f \in L^2(\mathbb{R}^+)$ *we then have*

$$\theta^* \tilde{B}_\mu f = \mathcal{B}_\mu \theta^* f + P_{\hat{\mathcal{K}}_\mu} \mathcal{B}_\mu P_{\hat{\mathcal{K}}_{\bar{\mu}}} \bar{\theta}^* f, \tag{20}$$

where $\bar{\theta}^*: L^2(\mathbb{R}^+) \mapsto H^2_-(\mathbb{R})$ *and* $\bar{\theta}^* f = P_- I f$ *with I defined in Eq. (14) and* P_- *the orthogonal projection of* $L^2(\mathbb{R})$ *onto* $H^2_-(\mathbb{R})$. □

Proof: Using Eq. (16) in Lemma 1 we get

$$\theta^* \tilde{B}_\mu f = P_+ I \tilde{B}_\mu f = P_+ \mathcal{B}_\mu I f = P_+ \mathcal{B}_\mu (P_+ + P_-) I f = P_+ \mathcal{B}_\mu \theta^* f + P_+ \mathcal{B}_\mu P_- \bar{\theta}^* f.$$

Equation (20) then follows from the fact, proved in Ref. 20, that $P_+ \mathcal{B}_\mu P_- = P_{\hat{\mathcal{K}}_\mu} \mathcal{B}_\mu P_{\hat{\mathcal{K}}_{\bar{\mu}}}$ and from the property of $\mathcal{B}_\mu(\cdot)$ of being an inner function for $H^2_+(\mathbb{R})$.

■

We note that since $\mathcal{B}_\mu(\cdot)$ is an inner function Eqs. (9) and (10) and Theorem 1 imply that

$$T_{u(t)} P_{\hat{\mathcal{K}}_\mu} = \hat{Z}(t) P_{\hat{\mathcal{K}}_\mu} = e^{-i\mu t} P_{\hat{\mathcal{K}}_\mu}, \quad t \geqslant 0. \tag{21}$$

Combining Eqs. (17), (19), and (20) we obtain

$$f_{\text{out}} = S_{\text{nest}} f_{\text{in}} = \theta^* \tilde{S} (\theta^*)^{-1} f_{\text{in}} = \theta^* \tilde{B}_\mu \tilde{S}' (\theta^*)^{-1} f_{\text{in}} = \mathcal{B}_\mu \theta^* \tilde{S}' (\theta^*)^{-1} f_{\text{in}} + P_{\hat{\mathcal{K}}_\mu} \mathcal{B}_\mu P_{\hat{\mathcal{K}}_{\bar{\mu}}} \bar{\theta}^* \tilde{S}' (\theta^*)^{-1} f_{\text{in}}. \tag{22}$$

Using the decomposition of f_{out} from Eq. (22) on the rhs of Eq. (12) and applying Eq. (21) we obtain the *semigroup decomposition* for $t \geqslant 0$ of the time evolution corresponding to the resonance at $z = \mu$,

$$(g, \mathbf{U}(t) f)_{\mathcal{H}_{\text{ac}}(\mathbf{H})} = (\tilde{g}, T_{u(t)} f_{\text{out}})_{H^2_+(\mathbb{R})} = (\tilde{g}, u(t) \mathcal{B}_\mu \theta^* \tilde{S}' (\theta^*)^{-1} f_{\text{in}})_{H^2_+(\mathbb{R})} + e^{-i\mu t} (\tilde{g}, \mathcal{B}_\mu \bar{\theta}^* \tilde{S}' (\theta^*)^{-1} f_{\text{in}})_{H^2_+(\mathbb{R})}. \tag{23}$$

As is seen above in Eq. (21), the exponential decay in the second term on the rhs of Eq. (23) originates with the semigroup $\hat{Z}(t)$. The first term on the rhs of Eq. (23) is the *background term* and is responsible for deviations from a purely exponential decay law.

III. APPROXIMATE RESONANCE STATES

It is an interesting fact that the semigroup decomposition described in the previous section associates a unique state in $\mathcal{H}_{\text{ac}}(\mathbf{H})$ with a resonance pole at $z = \mu$ ($\text{Im}\, \mu < 0$). The following theorem is proved in Ref. 20.

Theorem 3 (approximate resonance state): *Under the assumptions of Theorem 2, let* $\tilde{S}: L^2(\mathbb{R}^+) \mapsto L^2(\mathbb{R}^+)$ *be the S matrix in the energy representation defined in Eq. (13). Assume that* $\tilde{S}(\cdot)$ *is the restriction to* $\mathbb{R}^+$ *of a function* $\mathcal{S}(\cdot)$ *meromorphic in an open region* Σ *with a single, simple pole at a point* $z = \mu$, $\mu \in \Sigma \cap \mathbb{C}^-$. *For any* $f \in \mathcal{H}_{\text{ac}}(\mathbf{H})$ *define* $f_{\text{out}} = \hat{\Omega}_+ f$ *and* $f_{\text{in}} = \hat{\Omega}_- f$. *There exists a unique state* $\psi_\mu \in \mathcal{H}_{\text{ac}}(\mathbf{H})$ *such that*

$$f_{\text{out}} = \mathcal{B}_\mu \theta^* \tilde{S}' (\theta^*)^{-1} f_{\text{in}} + \frac{|\text{Im}\, \mu|}{\pi} (\psi_\mu, f)_{\mathcal{H}_{\text{ac}}(\mathbf{H})} x_\mu, \tag{24}$$

where θ^* *is the map given by lemma 1,* $\mathcal{B}_\mu$ *is given in* Eq. (18), $\tilde{S}'$ *is defined by* Eq. (19), *and* $x_\mu \in H^2_+(\mathbb{R})$ *is given by* $x_\mu(\sigma)=(\sigma-\mu)^{-1}$, $\sigma \in \mathbb{R}$. □

Combining Eqs. (24) and (23) we can write the semigroup decomposition in the form

$$(g,\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})} = (\tilde{g},u(t)\mathcal{B}_\mu\theta^*\tilde{S}'(\theta^*)^{-1}f_{\mathrm{in}})_{H^2_+(\mathbb{R})} + \frac{|\mathrm{Im}\,\mu|}{\pi}e^{-i\mu t}(\tilde{g},x_\mu)_{H^2_+(\mathbb{R})}(\psi_\mu,f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}, \quad t \geqslant 0, \tag{25}$$

where $g \in \Xi_{\hat{\Omega}_+}$ and $\tilde{g}=(\hat{\Omega}^*_+)^{-1}g$. The eigenstate $x_\mu \in H^2_+(\mathbb{R})$ of the semigroup $\hat{Z}(t)$ providing the exponential decay of the second term on the rhs of Eq. (25) is called below the *Hardy space resonance state*. The state $\psi_\mu \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ whose existence is implied by Theorem 3 is called *approximate resonance state*. We observe that if in Eq. (25) we choose $f \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ orthogonal to ψ_μ then the second term on the rhs of that equation is identically zero.

Denote by $\{|E^-\rangle\}_{E\in\mathbb{R}^+}$ the set of outgoing solutions of the Lippmann–Schwinger equation. For every $f \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ we have

$$(U(\mathbf{\Omega}^-)^*f)(E) = \langle E^-|f\rangle, \quad E \in \mathbb{R}^+. \tag{26}$$

It is shown in Ref. 20 that an explicit expression for the approximate resonance state ψ_μ is given by

$$\psi_\mu = \frac{1}{2\pi i}\int_{\mathbb{R}^+} dE \frac{1}{E-\mu}|E^-\rangle. \tag{27}$$

In this section we explore several properties of approximate resonance states ψ_μ. Our first step is to extend the discussion above to the case of multiple resonances:

Theorem 4 (multiple resonance case): *Under the assumptions of Theorem 2, let* $\tilde{S}: L^2(\mathbb{R}^+)\mapsto L^2(\mathbb{R}^+)$ *be the S matrix in the energy representation defined in Eq. (13). Assume that* $\tilde{S}(\cdot)$ *is the restriction to* $\mathbb{R}^+$ *of a function* $\mathcal{S}(\cdot)$ *meromorphic in the open region* Σ *with n simple poles at points* $z=\mu_i$, $i=1,\ldots,n$, $\mu_i \in \Sigma \cap \mathbb{C}^-$. *Then there exist n distinct states* $\{\psi^\Sigma_{\mu_i}\}_{i=1,\ldots,n}$, $\psi^\Sigma_{\mu_i} \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$, *such that for every* $f \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ *we have*

$$f_{\mathrm{out}} = \mathcal{B}_{\mu_1,\ldots,\mu_n}\theta^*\tilde{S}'(\theta^*)^{-1}f_{\mathrm{in}} + \sum_{j=1}^{n}\frac{|\mathrm{Im}\,\mu_j|}{\pi}\prod_{\substack{i=1\\ i\neq j}}^{n}\frac{\mu_j-\bar{\mu}_i}{\mu_j-\mu_i}(\psi^\Sigma_{\mu_j},f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}x_{\mu_j}, \tag{28}$$

where

$$\mathcal{B}_{\mu_1,\ldots,\mu_n}(z) := \prod_{i=1}^{n}\frac{z-\bar{\mu}_i}{z-\mu_i}. \tag{29}$$

In Eq. (28) $\tilde{S}'(\cdot)$ *is the restriction to* $\mathbb{R}^+$ *of a function* $\mathcal{S}'(\cdot)$ *analytic in* Σ *and having no poles in* $\bar{\Sigma}$ *and* $x_{\mu_j}(\sigma)=(\sigma-\mu_j)^{-1}$, $\sigma \in \mathbb{R}$. *The states* $\psi^\Sigma_{\mu_j}$, $j=1,\ldots,n$ *are given by*

$$\psi^\Sigma_{\mu_j} = \int_{\mathbb{R}^+} dE \prod_{\substack{i=1\\ i\neq j}}^{n}\frac{E-\bar{\mu}_i}{E-\mu_i}\frac{1}{E-\mu_j}|E^-\rangle. \tag{30}$$

□

Proof: Assume that $\mathcal{S}(\cdot)$, the extension of $\tilde{S}(\cdot)$ from $\mathbb{R}^+$ into $\Sigma\cup\mathbb{R}^+$ has n simple poles in $\Sigma\cap\mathbb{C}^-$. Then, applying the same arguments as in Ref. 20, we find that $\mathcal{S}(\cdot)$ can be factorized in Σ in the form

$$\mathcal{S}(z) = \mathcal{B}_{\mu_1,\ldots,\mu_n}(z)\mathcal{S}'(z),$$

where $\mathcal{B}_{\mu_1,\ldots,\mu_n}$, defined in Eq. (29), is a finite Blaschke product and $\mathcal{S}'(\cdot)$ has no poles in Σ. In addition we have, of course

$$\widetilde{S}(E) = \widetilde{B}_{\mu_1,\ldots,\mu_n}(E)\widetilde{S}'(E), \quad E \geqslant 0.$$

The semigroup decomposition then follows exactly as in Sec. I with $\mathcal{B}_{\mu_1,\ldots,\mu_n}$ and $\widetilde{B}_{\mu_1,\ldots,\mu_n}$ replacing $\mathcal{B}_\mu$ and $\widetilde{B}_\mu$, respectively. For the resonance term in Eq. (22) we get in this case

$$P_+\mathcal{B}_{\mu_1,\ldots,\mu_n}P_-\overline{\theta}^*\widetilde{S}'(\theta^*)^{-1}f_{\text{in}}, \quad f \in \mathcal{H}_{\text{ac}}(\mathbf{H}).$$

Recalling that

$$(P_+f)(\sigma) = \frac{1}{2\pi i}\int_{-\infty}^{\infty} d\sigma' \frac{1}{\sigma - \sigma' + i0}f(\sigma'), \quad f \in L^2(\mathbb{R}), \quad \sigma \in \mathbb{R}$$

and

$$(\overline{\theta}^*f)(\sigma) = \frac{1}{2\pi i}\int_0^{\infty} dE \frac{1}{E - \sigma + i0}f(E), \quad f \in L^2(\mathbb{R}^+)$$

(see Ref. 19) we obtain

$$\begin{aligned}
(P_+\mathcal{B}_{\mu_1,\ldots,\mu_n}P_-\overline{\theta}^*\widetilde{S}'(\theta^*)^{-1}f_{\text{in}})(\sigma) &= \frac{-1}{4\pi^2}\int_0^{\infty} dE \int_{-\infty}^{\infty} d\sigma' \frac{1}{\sigma - \sigma' + i0}\prod_{i=1}^{n}\frac{\sigma' - \bar{\mu}_i}{\sigma' - \mu_i}\frac{1}{E - \sigma' + i0}\widetilde{S}'(E)((\theta^*)^{-1}f_{\text{in}})(E) \\
&= \sum_{j=1}^{n}\frac{|\text{Im}\,\mu_j|}{\pi}\frac{1}{\sigma - \mu_j}\int_0^{\infty} dE \prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{\mu_j - \bar{\mu}_i}{\mu_j - \mu_i}\frac{1}{E - \mu_j}\widetilde{S}'(E)((\theta^*)^{-1}f_{\text{in}})(E) \\
&= \sum_{j=1}^{n}\frac{|\text{Im}\,\mu_j|}{\pi}x_{\mu_j}(\sigma)\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{\mu_j - \bar{\mu}_i}{\mu_j - \mu_i}\int_0^{\infty} dE \frac{1}{E - \bar{\mu}_j}\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{E - \mu_i}{E - \bar{\mu}_i}\widetilde{S}(E)((\theta^*)^{-1}f_{\text{in}})(E) \\
&= \sum_{j=1}^{n}\frac{|\text{Im}\,\mu_j|}{\pi}x_{\mu_j}(\sigma)\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{\mu_j - \bar{\mu}_i}{\mu_j - \mu_i}\int_0^{\infty} dE \frac{1}{E - \bar{\mu}_j}\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{E - \mu_i}{E - \bar{\mu}_i}(U(\mathbf{\Omega}^-)^*f)(E) \\
&= \sum_{j=1}^{n}\frac{|\text{Im}\,\mu_j|}{\pi}x_{\mu_j}(\sigma)\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{\mu_j - \bar{\mu}_i}{\mu_j - \mu_i}\int_0^{\infty} dE \frac{1}{E - \bar{\mu}_j}\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{E - \mu_i}{E - \bar{\mu}_i}\langle E^-|f\rangle,
\end{aligned}$$

where $x_{\mu_j} \in H^2_+(\mathbb{R})$ is the Hardy space resonance state corresponding to μ_j i.e., $x_{\mu_j}(\sigma) = (\sigma - \mu_j)^{-1}$. Defining the states $\psi^{\Sigma}_{\mu_j}$, $j = 1, \ldots, n$ according to Eq. (30) we obtain

$$(P_+\mathcal{B}_{\mu_1,\ldots,\mu_n}P_-\overline{\theta}^*\widetilde{S}'(\theta^*)^{-1}f_{\text{in}})(\sigma) = \sum_{j=1}^{n}\frac{|\text{Im}\,\mu_j|}{\pi}\prod_{\substack{i=1 \\ i\neq j}}^{n}\frac{\mu_j - \bar{\mu}_i}{\mu_j - \mu_i}(\psi^{\Sigma}_{\mu_j}, f)_{\mathcal{H}_{\text{ac}}(\mathbf{H})}x_{\mu_j}(\sigma). \tag{31}$$

This proves Theorem 4. ■

We observe that Eq. (30) is a generalization of Eq. (27). Hence, $\psi^{\Sigma}_{\mu_j}$ is the approximate resonance state corresponding to the pole of $\mathcal{S}(\cdot)$ at $z=\mu_j$. Combining Eqs. (31) and (23) we get the semigroup decomposition for the multiresonance case

$$(g,\mathbf{U}(t)f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=(\tilde{g},u(t)\mathcal{B}_{\mu_1,\ldots,\mu_n}\theta^{*}\tilde{S}'(\theta^{*})^{-1}f_{\mathrm{in}})_{H^2_{+}(\mathbb{R})}+\sum_{j=1}^{n}\frac{|\mathrm{Im}\,\mu_j|}{\pi}\prod_{\substack{i=1\\ i\neq j}}^{n}\frac{\mu_j-\bar{\mu}_i}{\mu_j-\mu_i}(\psi^{\Sigma}_{\mu_j},f)_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}$$

$$\times(\tilde{g},x_{\mu_j})_{H^2_{+}(\mathbb{R})}e^{-i\mu_j t},\quad t\geqslant 0. \tag{32}$$

The approximate resonance states in Eq. (30) and semigroup decomposition of Eqs. (28) and (32) depend, of course, on the region Σ. If $\{\mu_j\}_{j=1,\ldots,n}$ are the poles in $\Sigma\cap\mathbb{C}^{-}$ of the meromorphic extension $\mathcal{S}(\cdot)$ of the S-matrix $\tilde{S}(\cdot)$, the approximate resonance state defined in Eq. (30) for a resonance at $z=\mu_j$ is therefore denoted by $\psi^{\Sigma}_{\mu_j}$. However, for certain arguments the exact form of Σ is irrelevant and it is useful to define the notion of an n'th order approximate resonance state:

*Definition 2 (n'th order approximate resonance state): If the number of poles of $\mathcal{S}(\cdot)$ entering into the definition of the approximate resonance state $\psi^{\Sigma}_{\mu_j}$ in Eq. (30), not including μ_j itself, is n we say that $\psi^{\Sigma}_{\mu_j}$ is an n*th *order approximate resonance state for the resonance at $z=\mu_j$. In particular, regardless of the exact nature of the region Σ, the zeroth order approximate resonance state is always defined to be given by Eq. (27) with $\mu=\mu_j$ and is denoted by $\psi^{(0)}_{\mu_j}$.*

Remark: Note that in general there are many choices of the n resonance poles (different than μ_j) included in the construction of what we call an nth order approximation $\psi^{(n)}_{\mu_j}$. In cases that the nature of the region Σ is irrelevant and only the order of the approximate resonance state is significant we replace the notation $\psi^{\Sigma}_{\mu_j}$ by $\psi^{(n)}_{\mu_j}$, where n is the order of the approximate resonance state considered.

The semigroup decomposition and approximate resonance states for the multiresonance case possess some interesting properties. For example, we have

$$(\psi^{\Sigma}_{\mu_j},\psi^{\Sigma}_{\mu_k})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=(\psi^{(0)}_{\mu_j},\psi^{(0)}_{\mu_k})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=\int_{\mathbb{R}^{+}}dE\frac{1}{E-\mu_j}\frac{1}{E-\bar{\mu}_k}$$

and, in particular

$$\|\psi^{\Sigma}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=\|\psi^{(n)}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=\|\psi^{(0)}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=\int_{\mathbb{R}^{+}}dE\frac{1}{|E-\mu_j|^2}. \tag{33}$$

We see that, although the definition of $\psi^{\Sigma}_{\mu_i}$ in Eq. (30) depends on all of the poles $\{\mu_j\}_{j=1,\ldots,n}\subset\Sigma\cap\mathbb{C}^{-}$, the scalar product of $\psi^{\Sigma}_{\mu_i}$ and $\psi^{\Sigma}_{\mu_j}$ depends only on μ_i and μ_j. In fact, if $\mathcal{S}(\cdot)$ can be extended to a meromorphic function in a region $\Sigma'\supset\Sigma$ [we keep the notation $\mathcal{S}(\cdot)$ for the extended function] and $\mathcal{S}(\cdot)$ has now $m>n$ simple poles in $\Sigma'\cap\mathbb{C}^{-}$ we may calculate approximate resonance states of order $m-1$ for all resonances in Σ' according to Eq. (30). However, for $\mu_j,\mu_k\in\Sigma$ we would still have $(\psi^{\Sigma'}_{\mu_j},\psi^{\Sigma'}_{\mu_k})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=(\psi^{\Sigma}_{\mu_j},\psi^{\Sigma}_{\mu_k})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}$ i.e., scalar products (and norms) are independent of the order of the approximate states when we enlarge the region Σ. In particular we have $\|\psi^{\Sigma}_{\mu_j}\|_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}=\|\psi^{(0)}_{\mu_j}\|_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}$ for every region Σ containing μ_j.

An interesting question is whether the peculiar properties of scalar products and norms of the approximate resonance states mentioned above characterize also the time evolution of these states. We shall see below that, at least partially, the answer to this question is positive. For this we consider one of the basic notions associated with resonance evolution, i.e., that of the survival amplitude

$$A_{\psi^{\Sigma}_{\mu_j}}(t) := \frac{(\psi^{\Sigma}_{\mu_j}, \mathbf{U}(t)\psi^{\Sigma}_{\mu_j})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}{(\psi^{\Sigma}_{\mu_j}, \psi^{\Sigma}_{\mu_j})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}. \tag{34}$$

Making use of Eqs. (30) and (33) we get a simple expression for this quantity

$$A_{\psi^{(0)}_{\mu_j}}(t) = \|\psi^{(0)}_{\mu_j}\|^{-2}_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})} \int_{\mathbb{R}^+} \frac{1}{|E-\mu_j|^2} e^{-iEt}, \quad t \geqslant 0,$$

where $\|\psi^{(0)}_{\mu_j}\|$ is given in Eq. (33). Again, we see that the expression for the survival amplitude for the approximate resonance state $\psi^{\Sigma}_{\mu_j}$ depends only on the pole at $z=\mu_j$ and has the same form as for a single resonance. This suggests that the semigroup decomposition of the survival amplitude for the multiple resonance case is similar to that of a single resonance. When combined with an important characterization of approximate resonance states in the form of Lemma 2 below, such considerations lead to the following useful *a priori* estimate on the size of the background term in the semigroup decomposition of the survival amplitude:

Theorem 5: *Let $A_{\psi^{\Sigma}_{\mu_j}}(t)$, $j=1,\ldots,n$ be the survival amplitude defined in Eq. (34) and let the background term $R_{\mu_j}(t)$ be defined by the relation*

$$A_{\psi^{\Sigma}_{\mu_j}}(t) = R_{\mu_j}(t) + e^{-i\mu_j t}, \quad t \geqslant 0. \tag{35}$$

Then we have

$$|R_{\mu_j}(t)| \leqslant \left(\frac{\|x_{\mu_j}\|^4_{H^2_+(\mathbb{R})}}{\|\psi^{(0)}_{\mu_j}\|^4_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}} - 1 \right)^{1/2}, \quad t \geqslant 0, \tag{36}$$

where $x_{\mu_j}(\sigma)=(\sigma-\mu_j)^{-1}$ is the Hardy space resonance state and $\psi^{(0)}_{\mu_j} \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ is the zeroth order approximate resonance state corresponding to the resonance at $z=\mu_j$. □

Proof: We first have

Proposition 2: For $j=1,\ldots,n$, let $\psi^{\Sigma}_{\mu_j}$ be defined by Eq. (30) and let $A_{\psi^{\Sigma}_{\mu_j}}(t)$ be the survival amplitude defined in Eq. (34). Then

$$A_{\psi^{\Sigma}_{\mu_j}}(t) = \|\psi^{(0)}_{\mu_j}\|^{-2}_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})} (x_{\mu_j}, u(t)\mathcal{B}_{\mu_j}\theta^* \widetilde{S}'_{\mu_j}(\theta^*)^{-1}\psi^{(0)}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})} + e^{-i\mu_j t}, \quad t \geqslant 0, \tag{37}$$

where $x_{\mu_j} \in H^2_+(\mathbb{R})$ is the Hardy space resonance state and $\psi^{(0)}_{\mu_j} \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$ is the zeroth order approximate resonance state corresponding to the pole at μ_j, and $\widetilde{S}'_{\mu_j}(\cdot)$ is defined as in Eq. (19), i.e.,

$$\widetilde{S}'_{\mu_j}(E) = \frac{E-\mu_j}{E-\bar{\mu}_j}\widetilde{S}(E) = \widetilde{B}_{\bar{\mu}_j}(E)\widetilde{S}(E).$$

□

Proof of Proposition 2: We first need the following easily proved, but important, lemma

Lemma 2: For $j=1,\ldots,n$, let $\psi^{\Sigma}_{\mu_j}$ be defined by Eq. (30). Define

$$\mathcal{B}_{\mu_1,\ldots,\bar{\mu}_k,\ldots,\mu_n}(z) := \prod_{\substack{i=1 \\ i\neq j}}^{n} \frac{z-\bar{\mu}_i}{z-\mu_i},$$

where $\{\mu_j\}_{j=1,\ldots,n}$ are the poles of $\mathcal{S}(\cdot)$ in Σ, and let $x_{\mu_j}(\sigma)=(\sigma-\mu_j)^{-1}$. Then we have

$$\psi^{\Sigma}_{\mu_j} = \hat{\Omega}^{*}_{+}\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j}.$$

In particular $\psi^{(0)}_{\mu_j}=\hat{\Omega}^{*}_{+}x_{\mu_j}$. □

Proof of Lemma 2: It is proved in Ref. 19 that, if $\mathbf{\Omega}^{\pm}$ are the Møller wave operators, $U:\mathcal{H}_{\mathrm{ac}}(\mathbf{H}_0)\mapsto L^2(\mathbb{R}^+)$ the mapping to the energy representation for $\mathbf{H}_0$ [see Eq. (13) above] and θ^* the map given in Lemma 1, then the quasi-affine nesting maps $\hat{\Omega}_{\pm}$ are given by $\hat{\Omega}_{\pm}=\theta^* U(\mathbf{\Omega}^{\mp})^*$, hence, we have $\hat{\Omega}^{*}_{+}=\mathbf{\Omega}^{-}U^*\theta$. Furthermore, by the definition of θ we have

$$(\theta\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j})(E) = \prod_{\substack{i=1\\ i\neq j}}^{n}\frac{E-\bar{\mu}_i}{E-\mu_i}\frac{1}{E-\mu_j}, \quad E\in\mathbb{R}^+. \tag{38}$$

Moreover, according to Eq. (26) for every $g\in L^2(\mathbb{R}^+)$ we have

$$\mathbf{\Omega}^{-}U^*g = \int_{\mathbb{R}^+} dE|E^-\rangle g(E). \tag{39}$$

Applying Eq. (39) with $g=\theta\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j}$ and comparing with Eq. (30) proves the lemma. ■

Note that by Lemma 2 we have $(\hat{\Omega}^{*}_{+})^{-1}\psi^{\Sigma}_{\mu_j}=\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j}$. Hence, by Eq. (32) we get

$$\begin{aligned}
A_{\psi^{\Sigma}_{\mu_j}}(t) &= \|\psi^{\Sigma}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}(\psi^{\Sigma}_{\mu_j},\mathbf{U}(t)\psi^{\Sigma}_{\mu_j})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}\\
&= \|\psi^{\Sigma}_{\mu_j}\|^{-2}_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}(\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j},u(t)\mathcal{B}_{\mu_1,\ldots,\mu_n}\theta^*\tilde{S}'(\theta^*)^{-1}\psi^{\Sigma}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})}\\
&\quad+\sum_{k=1}^{n}\frac{|\mathrm{Im}\,\mu_k|}{\pi}\prod_{\substack{i=1\\ i\neq k}}^{n}\frac{\mu_k-\bar{\mu}_i}{\mu_k-\mu_i}\frac{(\psi^{\Sigma}_{\mu_k},\psi^{\Sigma}_{\mu_j})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}{\|\psi^{\Sigma}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}(\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j},x_{\mu_k})_{H^2_+(\mathbb{R})}e^{-i\mu_k t}.
\end{aligned} \tag{40}$$

In the second term on the rhs of Eq. (40) we first separate the term with $k=j$ and get

$$\begin{aligned}
&\sum_{k=1}^{n}\frac{|\mathrm{Im}\,\mu_k|}{\pi}\prod_{\substack{i=1\\ i\neq k}}^{n}\frac{\mu_k-\bar{\mu}_i}{\mu_k-\mu_i}\frac{(\psi^{\Sigma}_{\mu_k},\psi^{\Sigma}_{\mu_j})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}{\|\psi^{\Sigma}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}(\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j},x_{\mu_k})_{H^2_+(\mathbb{R})}e^{-i\mu_k t}\\
&=\sum_{\substack{k=1\\ k\neq j}}^{n}\frac{|\mathrm{Im}\,\mu_k|}{\pi}\prod_{\substack{i=1\\ i\neq k}}^{n}\frac{\mu_k-\bar{\mu}_i}{\mu_k-\mu_i}\frac{(\psi^{\Sigma}_{\mu_k},\psi^{\Sigma}_{\mu_j})_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}{\|\psi^{\Sigma}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}}(\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j},x_{\mu_k})_{H^2_+(\mathbb{R})}e^{-i\mu_k t}+e^{-i\mu_j t}, \quad t\geqslant 0.
\end{aligned}$$

Here, use has been made of Eq. (42) below. The above expression can be further simplified since $x_{\mu_k}\in\hat{\mathcal{K}}_{\mu_k}=H^2_+(\mathbb{R})\ominus\mathcal{B}_{\mu_k}(\cdot)H^2_+(\mathbb{R})$ implies that for $k\neq j$ we have

$$(\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n}x_{\mu_j},x_{\mu_k})_{H^2_+(\mathbb{R})}=(\mathcal{B}_{\mu_k}\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\hat{\mu}_k,\ldots\mu_n}x_{\mu_j},x_{\mu_k})_{H^2_+(\mathbb{R})}=0,$$

where

$$\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\hat{\mu}_k,\ldots,\mu_n}(z) := \prod_{\substack{i=1\\ i\neq k,j}}^{n}\frac{z-\bar{\mu}_i}{z-\mu_i}.$$

The first term on the rhs of Eq. (40) can also be simplified. We have

$$
\begin{aligned}
&(\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n} x_{\mu_j}, u(t)\mathcal{B}_{\mu_1,\ldots,\mu_n}\theta^*\tilde{S}'(\theta^*)^{-1}\psi^{\Sigma}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})} \\
&\quad = (u(-t)\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n} x_{\mu_j}, \mathcal{B}_{\mu_1,\ldots,\mu_n}\theta^*\tilde{S}'(\theta^*)^{-1}\psi^{\Sigma}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})} \\
&\quad = (\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n} u(-t)x_{\mu_j}, \mathcal{B}_{\mu_1,\ldots,\mu_n}\theta^*\tilde{S}'(\theta^*)^{-1}\psi^{\Sigma}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})} \\
&\quad = (x_{\mu_j}, u(t)\mathcal{B}_{\mu_j}\theta^*\tilde{S}'(\theta^*)^{-1}\psi^{\Sigma}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})}, \quad t \geqslant 0.
\end{aligned}
$$

Moreover, using Lemma 2 we find that

$$
\begin{aligned}
\theta^*\tilde{S}'(\theta^*)^{-1}\psi^{\Sigma}_{\mu_j,\mathrm{in}} &= \theta^*\tilde{S}'(\theta^*)^{-1}\hat{\Omega}_-\hat{\Omega}^*_+\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n} x_{\mu_j} = \theta^*\tilde{S}'(\theta^*)^{-1}\theta^*\tilde{S}^*\theta\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n} x_{\mu_j} \\
&= \theta^*\overline{\tilde{B}_{\mu_1,\ldots,\mu_n}}\theta\mathcal{B}_{\mu_1,\ldots,\hat{\mu}_j,\ldots,\mu_n} x_{\mu_j} = \theta^*\overline{\tilde{B}_{\mu_j}}\theta x_{\mu_j} = \theta^*\tilde{B}_{\bar{\mu}_j}\tilde{S}(\theta^*)^{-1}\hat{\Omega}_-\hat{\Omega}^*_+ x_{\mu_j} \\
&= \theta^*\tilde{S}'_{\mu_j}(\theta^*)^{-1}\psi^0_{\mu_j,\mathrm{in}}.
\end{aligned}
$$

Recalling that Eq. (33) implies that $\|\psi^{\Sigma}_{\mu_j}\|_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})} = \|\psi^{(0)}_{\mu_j}\|_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}$ the proof of Proposition 2 is complete. ■

From Proposition 2 we see that, independent of the region Σ, the semigroup decomposition of the survival amplitude depends only on the zeroth order approximate resonance state.

Comparison of Eqs. (37) and (35) gives

$$
R_{\mu_j}(t) = \|\psi^{(0)}_{\mu_j}\|^{-2}_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}(x_{\mu_j}, u(t)\mathcal{B}_{\mu_j}\theta^*\tilde{S}'_{\mu_j}(\theta^*)^{-1}\psi^{(0)}_{\mu_j,\mathrm{in}})_{H^2_+(\mathbb{R})}, \quad t \geqslant 0. \tag{41}
$$

This expression for $R_{\mu_j}(t)$ is identical to the zeroth order background term we would get from Eq. (25) with $f = g = \psi^{(0)}_{\mu_j}$. We now exploit this fact to obtain the desired estimate in Theorem 5. Applying Theorem 3 to the zeroth order approximate resonance state $\psi^{(0)}_{\mu_j}$ we obtain

$$
\psi^{(0)}_{\mu_j,\mathrm{out}} = \hat{\Omega}_+\psi^{(0)}_{\mu_j} = \mathcal{B}_{\mu_j}\theta^*\tilde{S}'_{\mu_j}(\theta^*)^{-1}\psi^{(0)}_{\mu_j,\mathrm{in}} + \frac{|\mathrm{Im}\,\mu_j|}{\pi}\|\psi^{(0)}_{\mu_j}\|^2_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})} x_{\mu_j}.
$$

Now, since both $\hat{\Omega}_+$ and $\hat{\Omega}^*_+$ are contractive we note that Lemma 2 implies that $\|\psi^{(0)}_{\mu_j,\mathrm{out}}\|_{H^2_+(\mathbb{R})} = \|\hat{\Omega}_+\hat{\Omega}^*_+ x_{\mu_j}\|_{H^2_+(\mathbb{R})} \leqslant \|x_{\mu_j}\|_{H^2_+(\mathbb{R})}$. In addition in $H^2_+(\mathbb{R})$ we have $x_{\mu_j} \perp \mathcal{B}_{\mu_j} H^2_+(\mathbb{R})$. Therefore

$$
\|\mathcal{B}_{\mu_j}\theta^*\tilde{S}'_{\mu_j}(\theta^*)^{-1}\psi^{(0)}_{\mu_j,\mathrm{in}}\|^2_{H^2_+(\mathbb{R})} + \frac{|\mathrm{Im}\,\mu_j|^2}{\pi^2}\|\psi^{(0)}_{\mu_j}\|^4_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})}\|x_{\mu_j}\|^2_{H^2_+(\mathbb{R})} \leqslant \|x_{\mu_j}\|^2_{H^2_+(\mathbb{R})}.
$$

It is easy to verify that

$$
\|x_{\mu_j}\|^2_{H^2_+(\mathbb{R})} = \int_{-\infty}^{\infty} \frac{1}{|\sigma - \mu_j|^2} d\sigma = \frac{\pi}{|\mathrm{Im}\,\mu_j|}, \tag{42}
$$

hence, the inequality above can be written in the form

$$
\|\mathcal{B}_{\mu_j}\theta^*\tilde{S}'_{\mu_j}(\theta^*)^{-1}\psi^{(0)}_{\mu_j,\mathrm{in}}\|^2_{H^2_+(\mathbb{R})} \leqslant (\|x_\mu\|^4_{H^2_+(\mathbb{R})} - \|\psi^{(0)}_{\mu_j}\|^4_{\mathcal{H}_{\mathrm{ac}}(\mathbf{H})})\|x_{\mu_j}\|^{-2}_{H^2_+(\mathbb{R})}. \tag{43}
$$

Applying the Schwartz inequality to the rhs of Eq. (41) and using the bound from Eq. (43) we get the estimate in Eq. (36). ■

As mentioned above the background term cannot be identically zero. Hence, deviations from exponential decay of the survival probability are to be expected. In fact, it is easy to verify that the survival probability behaves for short times as $|A_{\psi_{\mu_j}}(t)|^2 = 1 - O(t^2)$. Note that Eq. (35) implies that

at $t=0$ we must have $R_{\mu_j}(0)=0$. This is also seen from Eq. (41), since for $t=0$ we have $u(0)=1$ and $x_{\mu_j} \perp \mathcal{B}_{\mu_j}(\cdot)H_+^2(\mathbb{R})$. Deviations from exponential decay are then due to the fact that x_{μ_j} is not perpendicular to $u(t)\mathcal{B}_{\mu_j}H_+^2(\mathbb{R})$ for $t>0$.

IV. EXAMPLE: SCATTERING FROM SQUARE BARRIER POTENTIAL

In this section we apply the results of the previous two sections to a simple one dimensional model with a square barrier potential. Although simple, this model provides a good illustration for the various results obtained above. In particular, we present numerical calculations of approximate resonance states of various orders accompanied with plots of the time evolution of the corresponding survival probabilities and estimates of the size of the background term following from Theorem 5.

The model we consider is a Schrödinger equation in one spatial dimension on the half-line $\mathbb{R}^+$ with a square barrier potential. Thus we consider the free Hamiltonian $\mathbf{H}_0=-\partial_x^2$ acting on $L^2(\mathbb{R}^+)$ [where $\mathbf{H}_0$ is defined as a self-adjoint extension to $L^2(\mathbb{R}^+)$ from the original domain of definition $D(-\partial_x^2)=\{\phi(x)\in W_2^2(\mathbb{R}^+)\,|\,\phi(x)=0\}$] and the full Hamiltonian is given by $\mathbf{H}=\mathbf{H}_0+\mathbf{V}$ where $\mathbf{V}$ is a multiplicative operator $(\mathbf{V}f)(x)=V(x)f(x)$ with

$$V(x)=\begin{cases}0, & 0<x<a\\ V_0, & a\leqslant x\leqslant b\\ 0, & b<x,\end{cases}$$

where $b>a>0$ and we take $V_0>0$. In this case there are no bound state solutions of the eigenvalue problem for $\mathbf{H}$ and we have $\sigma(\mathbf{H})=\sigma_{\mathrm{ac}}(\mathbf{H})=\mathbb{R}^+$. In order to find the scattering states, calculate the S matrix, and finally the approximate resonance states for this problem one solves the eigenvalue problem

$$-\partial_x^2\psi_E(x)+V(x)\psi_E(x)=E\psi_E(x),\quad E\in\mathbb{R}^+$$

for the continuous spectrum generalized eigenfunctions $\psi_E(x)$. Imposing boundary conditions one finds that

$$\psi_E(x)=\begin{cases}\alpha_1(k)\sin kx, & 0<x\leqslant a\\ \alpha_2(k)e^{ik'x}+\beta_2(k)e^{-ik'x}, & a<x<b\\ \alpha_3(k)e^{ikx}+\beta_3(k)e^{-ikx}, & b\leqslant x,\end{cases}\tag{44}$$

where $k=E^{1/2}$ and $k'=\sqrt{E-V_0}$ for $E\geqslant V_0>0$ or $k'=i\sqrt{V_0-E}$ for $V_0>E>0$. The coefficients in Eq. (44) are given by[32]

$$\begin{aligned}\alpha_2(k)&=\frac{1}{2}e^{-ik'a}\left[\sin ka+\frac{k}{ik'}\cos ka\right]\alpha_1(k),\\ \beta_2(k)&=\frac{1}{2}e^{ik'a}\left[\sin ka-\frac{k}{ik'}\cos ka\right]\alpha_1(k),\\ \alpha_3(k)&=\frac{1}{4}e^{-ikb}\left[(1+k'/k)e^{ik'(b-a)}\left(\sin ka+\frac{k}{ik'}\cos ka\right)+(1-k'/k)e^{-ik'(b-a)}\right.\\ &\quad\left.\times\left(\sin ka-\frac{k}{ik'}\cos ka\right)\right]\alpha_1(k),\end{aligned}\tag{45}$$

$$\beta_3(k) = \frac{1}{4}e^{ikb}\Bigg[(1-k'/k)e^{ik'(b-a)}\left(\sin ka + \frac{k}{ik'}\cos ka\right) + (1+k'/k)e^{-ik'(b-a)} \times\left(\sin ka - \frac{k}{ik'}\cos ka\right)\Bigg]\alpha_1(k),$$

with $\alpha_1(k)$ to be determined by normalization conditions (see below).

Given the full set of solutions $\{\psi_E(x)\}_{E\in\mathbb{R}^+}$ for the continuous spectrum it is easy to find the sets $\{\psi_E^{\pm}(x)\}_{E\in\mathbb{R}^+}$ of solutions of the Lippmann–Schwinger equation corresponding to incoming and outgoing asymptotic conditions. Using Dirac's notation we have[32]

$$\langle x|E^+\rangle \equiv \psi_E^+(x) = \frac{-1}{2i}\frac{\psi_E(x)}{\beta_3(k)},$$

$$\langle x|E^-\rangle \equiv \psi_E^-(x) = \frac{1}{2i}\frac{\psi_E(x)}{\alpha_3(k)}. \tag{46}$$

The normalization conditions for the Lippmann–Schwinger states in Eq. (46) determines $\alpha_1(k)$ with the result $\alpha_1(k)=(2\pi k)^{-1/2}$. In the energy representation the S matrix is then given by[32]

$$\tilde{S}(E) = -\frac{\alpha_3(k)}{\beta_3(k)}, \quad k = E^{1/2}.$$

We now have the ingredients for the calculation of the scattering resonances and the corresponding approximate resonance states. Note first that $\alpha_3(k)$ and $\beta_3(k)$ can be extended to analytic functions in the complex k plane and as a result the poles of the analytic continuation of $S(E)$ to the lower half-plane (i.e., across the square root cut along the positive real axis) are identified with zeros of the function $\beta_3(k)$. For a resonance at a point $z=\mu_j$ in the lower half-plane below the positive real axis we set $\mu_j=E_{\mu_j}-i\Gamma_{\mu_j}/2$, with E_{μ_j} being the resonance energy and Γ_{μ_j} its width.

Using Eq. (27) and the expression for the outgoing Lippmann–Schwinger eigenfunctions $\langle x|E^-\rangle$, Eqs. (44)–(46), the zeroth order approximate resonance states for the square barrier problem can be calculated numerically. Considering a larger number of resonance poles we are able to calculate higher order approximate resonance states using Eq. (30). As an example we consider the three lowest energy resonance poles for barrier parameters $a=2$, $b=3$, and $V_0=10$. These poles are located at $\mu_1=1.8213-i0.0023$, $\mu_2=7.0237-i0.0564$, and $\mu_3=14.2336-i0.8923$. The zeroth order probability densities $|\psi_{\mu_j}^{(0)}(x)|^2$, $j=1,2,3$ for these poles are shown as dashed lines in Fig. 1 while the solid lines on the same figure correspond to the ninth order probability densities $|\psi_{\mu_j}^{(9)}(x)|^2$, $j=1,2,3$, where the ten lowest energy resonances μ_j, $j=1,\ldots,10$ are taken into account in Eq. (30). We observe the significant change in the probability density profile between the zeroth and ninth order approximate resonance states for the resonance μ_3, whose energy is higher then the barrier's energy, while the lower two states are essentially unchanged. Numerical calculations show that approximate resonance states converge in L^2 norm to a limiting state as a function of the order of approximation. An example is provided in Fig. 2 which shows the probability density $|\psi_{\mu_3'}^{(n)}(x)|^2$ for the resonance $\mu_3'=17.4652-i4.4029$, at barrier parameters $a=2$, $b=2.1$, and $V_0=10$, and for the orders $n=0,8,9$. At present, a rigorous criterion for the rate of convergence of approximate resonance states as a function of order is not yet established.

Turning to a consideration of the time evolution of survival probabilities for resonances of the square barrier model, we first recall the fact that the time evolution of the survival probabilities of higher order approximate resonance states corresponding to the same resonance pole is independent of the order and is, in fact, identical to that of the zeroth order state. Bearing this in mind we may omit in our notation any indication of the region Σ or the order n and set $A_{\psi_{\mu_j}}(t)\equiv A_{\psi_{\mu_j}^{\Sigma}}(t) = A_{\psi_{\mu_j}^{(n)}}(t)$. The time dependence of the survival probablility $|A_{\psi_{\mu_1}}(t)|^2$ for the states coresponding to

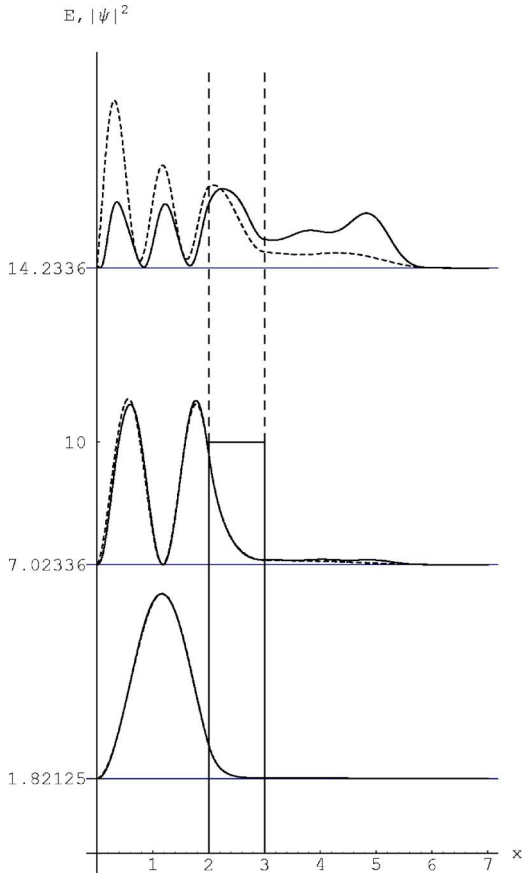

FIG. 1. Probability densities of approximate resonance states $\psi^{(n)}_{\mu_j}$, $j=1,2,3$ for $a=2$, $b=3$, and $V_0=10$. Dashed lines—$|\psi^{(0)}_{\mu_j}(x)|^2$, $j=1,2,3$. Solid lines—$|\psi^{(9)}_{\mu_j}(x)|^2$, $j=1,2,3$.

the lower resonance in Fig. 1 is shown as a solid line in Fig. 3. The time evolution of $|A_{\psi_{\mu_1}}(t)|^2$ follows closely an exact exponential decay law with a decay constant $\Gamma_{\mu_1}=2|\Im(\mu_1)|$. This behavior is reflected in the bound $|R_{\mu_1}(t)|\leqslant 0.028$ on the size of the background term calculated using Theorem 5. The time development of $|A_{\psi_{\mu_1}}(t)|^2$ deviates from the exponential law at a very short

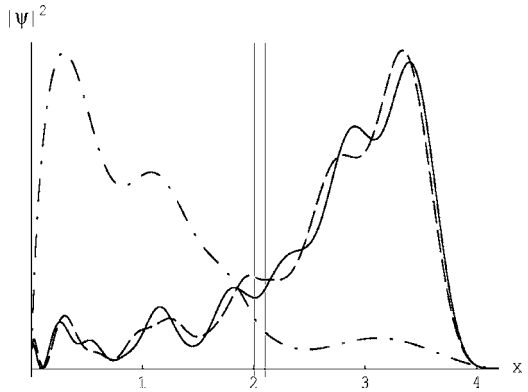

FIG. 2. Probability densities of the approximate resonance states for $\mu_3'=17.4652-i4.4029$. Dot-dahsed line—$|\psi^{(0)}_{\mu_3'}(x)|^2$, dashed line—$|\psi^{(8)}_{\mu_3'}(x)|^2$, and solid line—$|\psi^{(9)}_{\mu_3'}(x)|^2$.

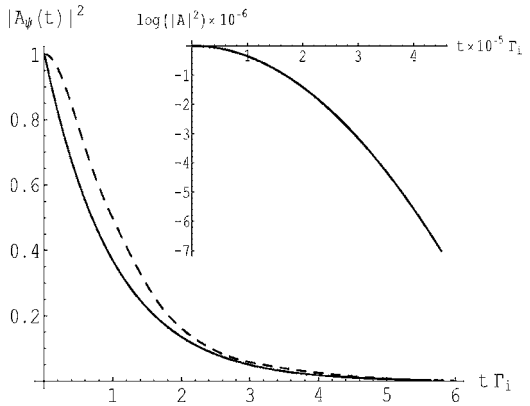

FIG. 3. Survival probabilities: Solid line—$|A_{\psi_{\mu_1}}(t)|^2$ and dashed line—$|A_{\psi_{\mu_3'}}(t)|^2$. The inset shows the short time behavior of $|A_{\psi_{\mu_1}}(t)|^2$.

time scale, as is clearly seen in the insert in Fig. 3. The behavior of the survival probability for the other resonances in Fig. 1 (not shown in Fig. 3) is similar. The short time deviations from exponential decay are related to the known Zeno effect.

The nearly exact exponential decay law of the survival probability $|A_{\psi_{\mu_1}}(t)|^2$ is to be contrasted with the time development of $|A_{\psi_{\mu_3'}}(t)|^2$ for the states in Fig. 2. The survival probability $|A_{\psi_{\mu_3'}}(t)|^2$ is described by the dashed line in Fig. 3. Deviations from an exponential decay law in this case are evidently larger. This conforms with the results of Theorem 5 which produces the larger bound $|R_{\mu_3'}(t)| \leqslant 0.422$.

V. SUMMARY

The semigroup decomposition formalism makes use of the fundamental mathematical theory underlying the structure of the Lax–Phillips scattering theory, i.e., the functional model for $C_{\cdot 0}$ contractive semigroups, for the description of the time evolution of resonances. If the S matrix is meromorphic in a region Σ and is known to have resonance poles there at points $z=\mu_1,\ldots,\mu_n \in \Sigma$, the semigroup formalism allows for the association of a unique Hilbert space state $\psi^{\Sigma}_{\mu_j}(x) \in \mathcal{H}_{\mathrm{ac}}(\mathbf{H})$, $j=1,\ldots,n$ with each resonance. The states $\psi^{\Sigma}_{\mu_j}(x)$, called approximate resonance states, define the decomposition of matrix elements of the evolution and are associated with its semigroup part. Theorem 5 provides an upper bound on the size of the remaining background term. Depending on one's knowledge of the location of the resonance poles it is possible to calculate approximate resonance states of different orders. Numerical calculations show that the sequence of approximate resonance states converge in L^2 norm to a limiting function as a function of the order. However, rigorous criteria for the rate of convergence are needed. Another possible course of further investigation involves the study of relations between known frameworks for the treatment of the problem of resonances, such as the rigged Hilbert space method and the use of dilation analyticity and the formalism discussed in the present paper.

(Received 10 June 2006; accepted 14 October 2006; published online 13 December 2006)

The aim of this paper is to express the Conley-Zehnder index of a symplectic path in terms of an index due to Leray and which has been studied by one of us in a previous work. This will allow us to prove a formula for the Conley-Zehnder index of the product of two symplectic paths in terms of a symplectic Cayley transform. We apply our results to a rigorous study of the Weyl representation of metaplectic operators, which plays a crucial role in the understanding of semiclassical quantization of Hamiltonian systems exhibiting chaotic behavior.

I. INTRODUCTION

Consider a Hamiltonian system in $\mathbb{R}^{2n}$

$$\dot{z} = J\partial_z H(z,t), \quad z=(x,p), \quad J=\begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix}, \tag{1}$$

and denote by (f_t^H) the flow it determines; we assume that the symplectomorphisms f_t^H are globally defined for each $t\in\mathbb{R}$. Set $f=f_1^H$; if for every fixed point z of f the Jacobian matrix of f satisfies

$$\det(Df(z)-I)\neq 0, \tag{2}$$

one says that the one-periodic solutions of Eq. (1) are *nondegenerate*. [*Nota bene:* condition (2) is very strong; for instance, if H is time independent, it is never satisfied!] Now set $z(t)=f_t^H(z)$ and consider the linearized Hamiltonian system along $t\mapsto z(t)$; its time evolution is governed by the linear differential equation

$$\dot{u} = JD^2H(z,t)u, \tag{3}$$

whose flow (s_t) consists of the symplectic matrices $s_t=Df_t^H(z)$. The path $\Sigma: t\mapsto s_t$, $t\in[0,1]$, thus lies in the symplectic group $\mathrm{Sp}(n)$; it starts from the identity and ends at the "monodromy matrix" $s=Df(z)$. If the nondegeneracy condition (2) holds, one associates to Σ an integer $i_{\mathrm{CZ}}(\Sigma)$, the Conley-Zehnder (CZ) index[2] of the path Σ. The vocation of that index is (loosely speaking) to give an algebraic count of the number of points t_j in the interval $[0, 1]$ for which s_t belongs to the "caustic"

a)Electronic mail: maurice.degosson@gmail.com
b)Electronic mail: sergedegosson@gmail.com

$$\mathrm{Sp}_0(n) = \{s \in \mathrm{Sp}(n) : \det(s - I) = 0\};$$

that index is "natural" in the sense that it is invariant under homotopy as long as the end point of the path stays in one of the connected sets $\mathrm{Sp}_{\pm}(n)$ defined by

$$\mathrm{Sp}_+(n) = \{s \in \mathrm{Sp}(n) : \det(s - I) > 0\},$$

$$\mathrm{Sp}_-(n) = \{s \in \mathrm{Sp}(n) : \det(s - I) < 0\}.$$

The aim of this paper is twofold. We first set out to prove a formula for the Conley-Zehnder index of the product of two symplectic paths starting from the identity; we will show that if Σ and Σ' are symplectic paths starting from the identity and ending at s and s', respectively, then

$$i_{\mathrm{CZ}}(\Sigma\Sigma') = i_{\mathrm{CZ}}(\Sigma) + i_{\mathrm{CZ}}(\Sigma') + \tfrac{1}{2}\mathrm{sign}(M_s + M_{s'}), \tag{4}$$

where M_s is the "symplectic Cayley transform" of s defined by

$$M_s = \tfrac{1}{2}J(s + I)(s - I)^{-1}.$$

For that purpose we will use an index defined on twice the Maslov bundle, defined by Leray[14] and extended by the first author[7,8] to the nontransversal case; that index is characterized by two simple properties, one cohomological and the other topological. (Dazord[4] has proposed a similar extension in the more general framework of symplectic bundles, using a different approach.) As a by-product of the proof of Eq. (4) we will obtain a natural extension of the Conley-Zehnder index to paths whose end points are in $\mathrm{Sp}_0(n)$. The interest of that extension is more than just academic: as noted above, all nontrivial periodic solutions of Eq. (1) are precisely degenerate when H is time independent; hence this is, indeed, the generic situation.

Second, formula (4) will allow us to identify the phase appearing in the Weyl representation of metaplectic operators with the Conley-Zehnder index of a certain symplectic path mod 4. In fact, the first author has shown in a recent paper[10] that if $S \in \mathrm{Mp}(n)$ has projection s in $\mathrm{Sp}(n)\backslash\mathrm{Sp}_0(n)$, then the operator

$$S = \left(\frac{1}{2\pi\hbar}\right)^n \frac{i^{\nu(s)}}{\sqrt{|\det(s - I)|}} \int e^{(i/2\hbar)\langle M_s z, z\rangle} T(z) d^{2n}z,$$

where $\hbar = h/2\pi$ and

$$T(z_0) = e^{-(i/\hbar)(\langle x_0, D_x\rangle - \langle p_0, x\rangle)}, \quad D_x = -i\partial_x$$

is the Heisenberg-Weyl operator that lies in the metaplectic group $\mathrm{Mp}(n)$ (and has projection s) provided that the integer $\nu(s)$ is chosen so that

$$\frac{1}{\pi}\arg\det(s - I) \equiv -\nu(s) + n \mod 2.$$

This formula identifies $\nu(s)$ with $i_{\mathrm{CZ}}(\Sigma)$ mod 2, where Σ is any continuous path in $\mathrm{Sp}(n)$ joining I to s. We will prove that we actually have

$$\nu(s) = i_{\mathrm{CZ}}(\Sigma) \mod 4 \tag{5}$$

for a natural choice of the path Σ. This formula might have, as a practical consequence, a better understanding of trace formulas in semiclassical mechanics ("Gutzwiller's formula," see Refs. 12 and 17), where the Weyl representation of metaplectic operators plays a crucial role (see Ref. 16 and the references therein for recent advances).

A *caveat:* the statement of our two main results, formulas (4) and (5), is deceptively simple. The proofs of these formulas are, however, quite technical; they require the full power of the machinery of the Leray index[14] that one of us has developed elsewhere.[6–8,11] One might, of course,

hope that other more powerful methods would lead to the same results in a more straightforward and economical way. Such an eventuality is, of course, welcome, but as far as we can see the only alternative approach would be to use the path intersection theory developed by Robbin and Salamon[18] (these authors in effect express the Conley-Zehnder in terms of the symplectic intersection index they define). However, as was shown in Ref. 9, the Leray and Robbin-Salamon indices are equivalent and easily deduced from each other; in that sense the Leray index thus appears as a fundamental "master index" in Lagrangian and symplectic path intersection theory. We observe that Cushman and Duistermaat[3] and Duistermaat[5] also have addressed the question of the index of the iteration of periodic orbits; the methods these authors use are different from ours, and might perhaps be adapted to yield formula (4).

This paper is structured as follows: In Sec. II we review previous results[7,8,11] on Lagrangian and symplectic Maslov indices, generalizing those of Leray.[14] An excellent comparative study of the indices used here with other indices appearing in the literature can be found in Cappell *et al.*[1] In Sec. III we recall the axiomatic presentation of the Conley-Zehnder index following Hofer *et al.*[13] We thereafter study the properties of the symplectic Cayley transform that will be needed in the rest of the section. We then define an integer-values function ν on the universal covering of $\mathrm{Sp}(n)$, which is identified with the Conley-Zehnder index. In Sec. IV we apply the previous results to the study of the phase of the Weyl representation of metaplectic operators.

We will denote by σ the standard symplectic form on $\mathbb{R}^{2n}=\mathbb{R}^n_x\times\mathbb{R}^n_p$:

$$\sigma(z,z')=\langle p,x'\rangle-\langle p',x\rangle \quad \text{if } z=(x,p),\ z'=(x'p'),$$

that is, in matrix form

$$\sigma(z,z')=\langle Jz,z'\rangle,\quad J=\begin{bmatrix}0 & I\\ -I & 0\end{bmatrix}.$$

The real symplectic group $\mathrm{Sp}(n)$ consists of all linear automorphisms s of $\mathbb{R}^{2n}$ such that $\sigma(sz,sz')=\sigma(z,z')$ for all z, z'. Equivalently,

$$s\in\mathrm{Sp}(n)\Leftrightarrow s^TJs=sJs^T=J.$$

$\mathrm{Sp}(n)$ is a connected Lie group and $\pi_1[\mathrm{Sp}(n)]\equiv(\mathbb{Z},+)$. We denote by $\mathrm{Lag}(n)$ the Lagrangian Grassmannian of $(\mathbb{R}^{2n},\sigma)$, that is, $\ell\in\mathrm{Lag}(n)$ if and only ℓ is an n plane in $\mathbb{R}^{2n}$ on which σ vanishes identically. We will write $\ell_X=\mathbb{R}^n_x\times 0$ and $\ell_P=0\times\mathbb{R}^n_p$.

If (E,ω) is a symplectic space, the coverings of order $q=2,\ldots,\infty$ of $\mathrm{Sp}(E,\omega)$ and $\mathrm{Lag}(E,\omega)$ are denoted $\pi_q:\mathrm{Sp}_q(E,\omega)\to\mathrm{Sp}(E,\omega)$ and $\pi_q:\mathrm{Lag}_q(E,\omega)\to\mathrm{Lag}(E,\omega)$.

II. WALL-KASHIWARA AND LERAY INDICES

We begin by reviewing the notion of signature of a triple of Lagrangian planes.

A. The Wall-Kashiwara index

Let (ℓ,ℓ',ℓ'') be a triple of elements of $\mathrm{Lag}(E,\omega)$; by definition[1,15,20] the Wall-Kashiwara index (or signature) $\tau(\ell,\ell',\ell'')$ is the signature of the quadratic form

$$Q(z,z',z'')=\sigma(z,z')+\sigma(z',z'')+\sigma(z'',z')$$

on $\ell\oplus\ell'\oplus\ell''$. The index τ is totally antisymmetric:

$$\tau(\ell,\ell',\ell'')=-\tau(\ell',\ell,\ell'')=-\tau(\ell,\ell'',\ell')=-\tau(\ell'',\ell',\ell),$$

it is a symplectic invariant:

$$\tau(s\ell,s\ell',s\ell'')=\tau(\ell,\ell',\ell'')\quad \text{for } s\in\mathrm{Sp}(E,\omega),$$

and it has the following essential cocycle property:

$$\tau(\ell,\ell',\ell'') - \tau(\ell',\ell'',\ell''') + \tau(\ell',\ell'',\ell''') - \tau(\ell',\ell'',\ell''') = 0. \tag{6}$$

Moreover, its values mod 2 are given by the following formula:

$$\tau(\ell,\ell',\ell'') \equiv n + \dim \ell \cap \ell' + \dim \ell' \cap \ell'' + \dim \ell'' \cap \ell \mod 2. \tag{7}$$

The Wall-Kashiwara index measures the relative position of three Lagrangian planes; for instance, if $\ell_X = \mathbb{R}^n \times 0$, $\ell_P = 0 \times \mathbb{R}^n$, and $\ell_M = \{(x,Mx) : x \in X\}$ $(M = M^T)$, then $\tau(\ell_P,\ell_M,\ell_X) = \operatorname{sign} M$.

Let $(E,\omega) = (E' \oplus E'', \omega' \oplus \omega'')$; identifying $\mathrm{Lag}(E',\omega') \oplus \mathrm{Lag}(E'',\omega'')$ with a subset of $\mathrm{Lag}(E,\omega)$, we have the additivity formula

$$\tau(\ell_1 \oplus \ell_2, \ell_1' \oplus \ell_2', \ell_1'' \oplus \ell_2'') = \tau'(\ell_1,\ell_1',\ell_1'') + \tau''(\ell_2,\ell_2',\ell_2''), \tag{8}$$

where τ' and τ'' are the Wall-Kashiwara indices on $\mathrm{Lag}(E',\omega')$ and $\mathrm{Lag}(E'',\omega'')$, respectively.

The following lemma will be helpful in our study of the Conley-Zehnder index:

Lemma 1: (i) If $\ell \cap \ell'' = 0$, then $\tau(\ell,\ell',\ell'')$ is the signature of the quadratic form

$$Q'(z') = \omega(\mathrm{Pr}_{\ell\ell''}z', z') = \omega(z', \mathrm{Pr}_{\ell''\ell}z')$$

on ℓ', where $\mathrm{Pr}_{\ell\ell''}$ is the projection onto ℓ along ℓ'' and $\mathrm{Pr}_{\ell''\ell} = I - \mathrm{Pr}_{\ell\ell''}$ is the projection on ℓ'' along ℓ. (ii) Let (ℓ,ℓ',ℓ'') be a triple of Lagrangian planes such that an $\ell = \ell \cap \ell' + \ell \cap \ell''$. Then $\tau(\ell,\ell',\ell'') = 0$.

(See, e.g., Ref. 15 for a proof.)

B. The Leray index

Let $\mathrm{Lag}_\infty(E,\omega)$ be the universal covering of $\mathrm{Lag}(E,\omega)$. The Leray index is the unique mapping

$$\mu : (\mathrm{Lag}_\infty(E,\omega))^2 \to \mathbb{Z}$$

having the two following properties:[7,8]

- μ is locally constant on each set $\{(\ell_\infty,\ell_\infty') : \dim \ell \cap \ell' = k\}$ $(0 \leqslant k \leqslant n)$.
- For all ℓ_∞, ℓ_∞', ℓ_∞'' in $\mathrm{Lag}_\infty(E,\omega)$ with projections ℓ, ℓ', ℓ'', we have

$$\mu(\ell_\infty,\ell_\infty') - \mu(\ell_\infty,\ell_\infty'') + \mu(\ell_\infty',\ell_\infty'') = \tau(\ell,\ell',\ell''). \tag{9}$$

The Leray index has, in addition, the following properties:

$$\mu(\ell_\infty,\ell_\infty') \equiv n + \dim \ell \cap \ell' \mod 2 \tag{10}$$

$\left(n = \frac{1}{2}\dim E\right)$ and

$$\mu(\beta^r \ell_\infty, \beta^{r'} \ell_\infty') = \mu(\ell_\infty,\ell_\infty') + 2(r - r') \tag{11}$$

for all integers r and r'; here β denotes the generator of $\pi_1[\mathrm{Lag}(E,\omega)] \equiv (\mathbb{Z},+)$, whose image in $\mathbb{Z}$ is +1. From the dimensional additivity property [Eq. (8)] of τ, it immediately follows that if $\ell_{1,\infty} \oplus \ell_{2,\infty}$ and $\ell_{1,\infty}' \oplus \ell_{2,\infty}'$ are in

$$\mathrm{Lag}_\infty(E',\omega') \oplus \mathrm{Lag}_\infty(E'',\omega'') \subset \mathrm{Lag}_\infty(E,\omega),$$

then

$$\mu(\ell_{1,\infty} \oplus \ell_{2,\infty}, \ell_{1,\infty}' \oplus \ell_{2,\infty}') = \mu'(\ell_{1,\infty},\ell_{1,\infty}') + \mu''(\ell_{2,\infty},\ell_{2,\infty}'), \tag{12}$$

where μ' and μ'' are the Leray indices on $\mathrm{Lag}_\infty(E',\omega')$ and $\mathrm{Lag}_\infty(E'',\omega'')$, respectively.

When (E,ω) is the standard symplectic space $(\mathbb{R}^{2n},\sigma)$, one identifies $\mathrm{Lag}(E,\omega) = \mathrm{Lag}(n)$ with the set

$$W(n,\mathbb{C}) = \{w \in U(n,\mathbb{C}) : w = w^T\}$$

of symmetric unitary matrices by associating to $\ell = u\ell_P$ ($u \in U(n,\mathbb{C})$) the matrix $w = uu^T$ ("Souriau mapping,"[19] see Ref. 11 for a detailed description and further properties). The Maslov bundle $\mathrm{Lag}_\infty(n)$ is identified with

$$W_\infty(n,\mathbb{C}) = \{(w,\theta) : w \in W(n,\mathbb{C}),\ \det w = e^{i\theta}\},$$

the projection $\pi^{\mathrm{Lag}} : \ell_\infty \mapsto \ell$ becoming $(w,\theta) \mapsto w$. The Leray index is then calculated as follows:

- If $\ell \cap \ell' = 0$, then

$$\mu(\ell_\infty, \ell'_\infty) = \frac{1}{\pi}[\theta - \theta' + i\,\mathrm{Tr}\log(-w(w')^{-1}\,] \tag{13}$$

  [the transversality condition $\ell \cap \ell' = 0$ is equivalent to $-w(w')^{-1}$ having no negative eigenvalue].
- If $\ell \cap \ell' \neq 0$, one chooses any ℓ'' such that $\ell \cap \ell'' = \ell' \cap \ell'' = 0$ and one then calculates $\mu(\ell_\infty, \ell'_\infty)$ using the formula (9), the values of $\mu(\ell_\infty, \ell''_\infty)$ and $\mu(\ell'_\infty, \ell''_\infty)$ being given by Eq. (13). (The cocycle property [Eq. (6)] of τ guarantees that the result does not depend on the choice of ℓ''.)

C. The relative Maslov indices on Sp(E,ω)

We begin by recalling the definition of the Maslov index for loops in $\mathrm{Sp}(n)$. Let γ be a continuous mapping $[0,1] \to \mathrm{Sp}(n)$ such that $\gamma(0) = \gamma(1)$, and set $\gamma(t) = s_t$. Then $U_t = (s_t s_t)^{-1/2} s_t$ is the orthogonal part in the polar decomposition of s_t:

$$U_t \in \mathrm{Sp}(n) \cap \mathrm{O}(2n,\mathbb{R}).$$

Let us denote by u_t the image $\iota(U_t)$ of U_t in $\mathrm{U}(n,\mathbb{C})$:

$$\iota(U_t) = A + iB \quad \text{if } U = \begin{bmatrix} A & -B \\ B & A \end{bmatrix}$$

and set $\rho(s_t) = \det u_t$. The Maslov index of γ is, by definition, the degree of the loop $t \mapsto \rho(s_t)$ in S^1:

$$m(\gamma) = \deg[t \mapsto \det(\iota(U_t))], \quad 0 \leqslant t \leqslant 1.$$

Let α be the generator of $\pi_1[\mathrm{Sp}(E,\omega)] \equiv (\mathbb{Z},+)$, whose image in $\mathbb{Z}$ is $+1$; if γ is homotopic to α^r, then

$$m(\gamma) = m(\alpha^r) = 2r. \tag{14}$$

The definition of the Maslov index can be extended to arbitrary paths in $\mathrm{Sp}(E,\omega)$ using the properties of the Leray index. This is done as follows: let $\ell = \pi_{\mathrm{Lag}}(\ell_\infty) \in \mathrm{Lag}(E,\omega)$; we define the Maslov index of $s_\infty \in \mathrm{Sp}_\infty(E,\omega)$ relative to ℓ by

$$\mu_\ell(s_\infty) = \mu(s_\infty \ell_\infty, \ell_\infty); \tag{15}$$

one shows (see Refs. 7 and 8) that the right-hand side only depends on the projection ℓ of ℓ_∞, justifying the notation.

Here are three fundamental properties of the relative Maslov index; we will need all of them to study the Conley-Zehnder index:

- *Product:* For all s_∞, s'_∞ in $\mathrm{Sp}_\infty(E,\omega)$ we have

$$\mu_\ell(s_\infty s'_\infty) = \mu_\ell(s_\infty) + \mu_\ell(s'_\infty) + \tau(\ell, s\ell, ss'\ell). \tag{16}$$

- *Action of* $\pi_1[\mathrm{Sp}(n)]$: We have

$$\mu_\ell(\alpha^r s_\infty) = \mu_\ell(s_\infty) + 4r \tag{17}$$

for all $r \in \mathbb{Z}$.

- *Topological property:* The mapping $(s_\infty, \ell) \mapsto \mu_\ell(s_\infty)$ is locally constant on each of the sets

$$\{(s_\infty, \ell) : \dim s\ell \cap \ell = k\} \subset \mathrm{Sp}_\infty(E,\omega) \times \mathrm{Lag}(E,\omega) \quad (0 \leqslant k \leqslant n). \tag{18}$$

The first two properties readily follow from, respectively, Eqs. (9) and (11). The third follows from the fact that the Leray index is locally constant on the sets $\{(\ell_\infty, \ell'_\infty) : \dim \ell \cap \ell' = k\}$. Note that Eq. (17) implies that

$$\mu_\ell(\alpha^r) = 4r = 2m(\alpha^r),$$

hence the restriction of any of the μ_ℓ to loops γ in $\mathrm{Sp}(E,\omega)$ is *twice* the Maslov index $m(\gamma)$ defined above; it is therefore sometimes advantageous to use the index m_ℓ defined by

$$m_\ell(s_\infty) = \tfrac{1}{2}(\mu_\ell(s_\infty) + n + \dim(s\ell \cap \ell)), \tag{19}$$

where $n = \frac{1}{2} \dim E$. We will call $m_\ell(s_\infty)$ the *reduced* (relative) Maslov index. In view of the congruence [Eq. (10)], it is an integer; the properties of m_ℓ are obtained *mutatis mutandis* from those of μ_ℓ. For instance, property (16) becomes

$$m_\ell(s_\infty s'_\infty) = m_\ell(s_\infty) + m_\ell(s'_\infty) + \mathrm{Inert}(\ell, s\ell, ss'\ell), \tag{20}$$

where Inert is the index of inertia of a triple (ℓ, ℓ', ℓ'') defined by

$$\mathrm{Inert}(\ell,\ell',\ell'') = \tfrac{1}{2}(\tau(\ell,\ell',\ell'') + n + \dim \ell \cap \ell' - \dim \ell' \cap \ell'' + \dim \ell'' \cap \ell); \tag{21}$$

in view of Eq. (7), it is an integer. [When the Lagrangian planes ℓ, ℓ', ℓ'' are pairwise transverse, it follows from the first part of Lemma 1 that $\mathrm{Inert}(\ell,\ell',\ell'')$ coincides with the index of inertia defined by Leray;[14] see Refs. 7, 8, and 11.]

It follows from the cocycle property of τ that the Maslov indices corresponding to two choices ℓ and ℓ' are related by the formula

$$\mu_\ell(s_\infty) - \mu_{\ell'}(s_\infty) = \tau(s\ell, \ell, \ell') - \tau(s\ell, s\ell', \ell'); \tag{22}$$

similarly,

$$m_\ell(s_\infty) - m_{\ell'}(s_\infty) = \mathrm{Inert}(s\ell, \ell, \ell') - \mathrm{Inert}(s\ell, s\ell', \ell'). \tag{23}$$

Assume that $(E,\omega) = (E' \oplus E'', \omega' \oplus \omega'')$ and $\ell' \in \mathrm{Lag}(E',\omega')$, $\ell'' \in \mathrm{Lag}(E'',\omega'')$; the additivity property (12) of the Leray index implies that if $s'_\infty \in \mathrm{Sp}_\infty(E',\omega')$, $s''_\infty \in \mathrm{Sp}_\infty(E'',\omega'')$, then

$$\mu_{\ell' \oplus \ell''}(s'_\infty \oplus s''_\infty) = \mu_{\ell'}(s'_\infty) + \mu_{\ell_2}(s''_\infty), \tag{24}$$

where $\mathrm{Sp}_\infty(E',\omega') \oplus \mathrm{Sp}_\infty(E'',\omega'')$ is identified in the obvious way with a subgroup of $\mathrm{Sp}_\infty(E,\omega)$. A similar property holds for the reduced relative Maslov index m_ℓ.

III. EXTENSION OF i_{CZ} AND PRODUCT FORMULA

This section is central in this paper; the main result is Theorem 1, where we prove a product formula for the Conley-Zehnder index.

A. Review of the Conley-Zehnder index

Let Σ be a continuous path $[0,1] \to \mathrm{Sp}(n)$ such that $\Sigma(0) = I$ and $\det(\Sigma(1) - I) \neq 0$. The sets

$$\mathrm{Sp}_0(n) = \{s \in \mathrm{Sp}(n) : \det(s - I) = 0\},$$

$$\mathrm{Sp}^+(n) = \{s \in \mathrm{Sp}(n) : \det(s - I) > 0\},$$

$$\mathrm{Sp}^-(n) = \{s \in \mathrm{Sp}(n) : \det(s - I) < 0\}$$

partition $\mathrm{Sp}(n)$, and $\mathrm{Sp}^+(n)$ and $\mathrm{Sp}^-(n)$ are, moreover, arcwise connected. The symplectic matrices $s^+ = -I$ and

$$s^- = \begin{bmatrix} L & 0 \\ 0 & L^{-1} \end{bmatrix}, \quad L = \mathrm{diag}[2, -1, \ldots, -1]$$

belong to $\mathrm{Sp}^+(n)$ and $\mathrm{Sp}^-(n)$, respectively (see Refs. 2 and 13).

Let us denote by $C_\pm(2n, \mathbb{R})$ the space of all paths $\Sigma : [0,1] \to \mathrm{Sp}(n)$ with $\Sigma(0) = I$ and $\Sigma(1) \in \mathrm{Sp}^\pm(n)$. Any such path can be extended into a path $\widetilde{\Sigma} : [0,2] \to \mathrm{Sp}(n)$ such that $\widetilde{\Sigma}(t) \in \mathrm{Sp}^\pm(n)$ for $1 \leqslant t \leqslant 2$ and $\widetilde{\Sigma}(2) = s^+$ or $\widetilde{\Sigma}(2) = s^-$. Let ρ be the mapping $\mathrm{Sp}(n) \to S^1$, $\rho(s_t) = \det u_t$, used in the definition of the Maslov index for symplectic loops. The Conley-Zehnder index of Σ is by definition the winding number of the loop $(\rho \circ \widetilde{\Sigma})^2$ in S^1:

$$i_{\mathrm{CZ}}(\Sigma) = \deg[t \mapsto (\rho(\widetilde{\Sigma}(t)))^2, 0 \leqslant t \leqslant 2].$$

It turns out that $i_{\mathrm{CZ}}(\Sigma)$ is invariant under homotopy as long as the end point $s = \Sigma(1)$ remains in $\mathrm{Sp}^\pm(n)$; in particular, it does not change under homotopies with fixed end points so we may view i_{CZ} as defined on the subset

$$\mathrm{Sp}^*_\infty(n) = \{s_\infty \in \mathrm{Sp}_\infty(n) : \det(s - I) \neq 0\}$$

of the universal covering group $\mathrm{Sp}_\infty(n)$. With this convention one proves[13] that the Conley-Zehnder index is the unique mapping $i_{\mathrm{CZ}} : \mathrm{Sp}^*_\infty(n) \to \mathbb{Z}$ having the following properties:

(CZ_1) *Antisymmetry:* For every s_∞ we have

$$i_{\mathrm{CZ}}(s_\infty^{-1}) = -i_{\mathrm{CZ}}(s_\infty),$$

where s_∞^{-1} is the homotopy class of the path $t \mapsto s_t^{-1}$.

(CZ_2) *Continuity:* Let Σ be a symplectic path representing s_∞ and Σ' a path joining s to an element s' belonging to the same component $\mathrm{Sp}^\pm(n)$ as s. Let s'_∞ be the homotopy class of $\Sigma * \Sigma'$. We have

$$i_{\mathrm{CZ}}(s_\infty) = i_{\mathrm{CZ}}(s'_\infty).$$

(CZ_3) *Action of* $\pi_1[\mathrm{Sp}(n)]$:

$$i_{\mathrm{CZ}}(\alpha^r s_\infty) = i_{\mathrm{CZ}}(s_\infty) + 2r$$

for every $r \in \mathbb{Z}$.

We observe that these three properties are characteristic of the Conley-Zehnder index in the sense that any other function $i'_{\mathrm{CZ}} : \mathrm{Sp}^*_\infty(n) \to \mathbb{Z}$ satisfying them must be identical to i_{CZ}. Set, in fact, $\delta = i_{\mathrm{CZ}} - i'_{\mathrm{CZ}}$. In view of ($\mathrm{CZ}_3$) we have $\delta(\alpha^r s_\infty) = \delta(s_\infty)$ for all $r \in \mathbb{Z}$, hence δ is defined on $\mathrm{Sp}^*(n) = \mathrm{Sp}^+(n) \cup \mathrm{Sp}^-(n)$ so that $\delta(s_\infty) = \delta(s)$, where $s = s_1$, the end point of the path $t \mapsto s_t$. Property (CZ_2) implies that this function $\mathrm{Sp}^*(n) \to \mathbb{Z}$ is constant on both $\mathrm{Sp}^+(n)$ and $\mathrm{Sp}^-(n)$. We next observe that since $\det s = 1$, we have $\det(s^{-1} - I) = \det(s - I)$ so that s and s^{-1} always belong to the same set $\mathrm{Sp}^+(n)$ or $\mathrm{Sp}^-(n)$ if $\det(s - I) \neq 0$. Property (CZ_1) then implies that δ must be zero on both $\mathrm{Sp}^+(n)$ or $\mathrm{Sp}^-(n)$.

Two other noteworthy properties of the Conley-Zehnder are as follows:

(CZ_4) *Normalization:* Let J_1 be the standard symplectic matrix in $\mathrm{Sp}(1)$. If s_1 is the path $t \to e^{\pi t J_1}$ $(0 \leqslant t \leqslant 1)$ joining I to $-I$ in $\mathrm{Sp}(1)$, then $i_{\mathrm{CZ},1}(s_{1,\infty}) = 1$ [$i_{\mathrm{CZ},1}$ the Conley-Zehnder index on $\mathrm{Sp}(1)$].

(CZ_5) *Dimensional additivity:* If $s_{1,\infty} \in \mathrm{Sp}^*_\infty(n_1)$, $s_{2,\infty} \in \mathrm{Sp}^*_\infty(n_2)$, $n_1 + n_2 = n$, then

$$i_{\mathrm{CZ}}(s_{1,\infty} \oplus s_{2,\infty}) = i_{\mathrm{CZ},1}(s_{1,\infty}) + i_{\mathrm{CZ},2}(s_{2,\infty}),$$

where $i_{\mathrm{CZ},j}$ is the Conley-Zehnder index on $\mathrm{Sp}(n_j)$, $j=1,2$.

B. Symplectic Cayley transform

If $s \in {}^*\mathrm{Sp}^*(n)$ we call the matrix

$$M_s = \tfrac{1}{2}J(s+I)(s-I)^{-1} \tag{25}$$

the "symplectic Cayley transform of s." Equivalently,

$$M_s = \tfrac{1}{2}J + J(s-I)^{-1}. \tag{26}$$

It is straightforward to check that M_s always is a symmetric matrix: $M_s = M_s^T$ (it suffices for this to use the equality $s^T J s = sJs^T = J$).

The symplectic Cayley transform has, in addition, the following properties, which are interesting by themselves:

Lemma 2: (i) We have

$$(M_s + M_{s'})^{-1} = -(s'-I)(ss'-I)^{-1}(s-I)J \tag{27}$$

and the symplectic Cayley transform of the product ss' is (when defined) given by

$$M_{ss'} = M_s + (s^T - I)^{-1}J(M_s + M_{s'})^{-1}J(s-I)^{-1}. \tag{28}$$

(ii) The symplectic Cayley transform of s and s^{-1} are related by the formula

$$M_{s^{-1}} = -M_s. \tag{29}$$

Proof: (i) We begin by noting that Eq. (26) implies that

$$M_s + M_{s'} = J(I + (s-I)^{-1} + (s'-I)^{-1}), \tag{30}$$

hence the identity Eq. (27). In fact, writing $ss'-I = s(s'-I)+s-I$, we have

$$\begin{aligned}
&(s'-I)(ss'-I)^{-1}(s-I) \\
&\quad = (s'-I)(s(s'-I)+s-I)^{-1}(s-I) = ((s-I)^{-1}s(s'-I)(s'-I)^{-1} + (s'-I)^{-1})^{-1} \\
&\quad = ((s-I)^{-1}s + (s'-I)^{-1}) = I + (s-I)^{-1} + (s'-I)^{-1};
\end{aligned}$$

the equality Eq. (27) follows in view of Eq. (30). Let us prove Eq. (28); equivalently,

$$M_s + M = M_{ss'}, \tag{31}$$

where M is the matrix defined by

$$M = (s^T - I)^{-1}J(M_s + M_{s'})^{-1}J(s-I)^{-1},$$

that is, in view of Eq. (27),

$$M = (s^T - I)^{-1}J(s'-I)(ss'-I)^{-1}.$$

Using the obvious relations $s^T = -Js^{-1}J$ and $(-s^{-1}+I)^{-1} = s(s-I)^{-1}$ we have

$$\begin{aligned}
M &= (s^T - I)^{-1}J(s'-I)(ss'-I)^{-1} = -J(-s^{-1}+I)^{-1}(s'-I)(ss'-I)^{-1} \\
&= -Js(s-I)^{-1}(s'-I)(ss'-I)^{-1},
\end{aligned}$$

that is, writing $s = s - I + I$,

$$M = -J(s'-I)(ss'-I)^{-1} - J(s-I)^{-1}(s'-I)(ss'-I)^{-1}.$$

Replacing M_s by its value [Eq. (26)] we have

$$M_s + M = J\left(\tfrac{1}{2}I + (s-I)^{-1} - (s'-I)(ss'-I)^{-1} - (s-I)^{-1}(s'-I)(ss'-I)^{-1}\right);$$

noting that

$$(s-I)^{-1} - (s-I)^{-1}(s'-I)(ss'-I)^{-1} = (s-I)^{-1}(ss'-I-s'+I)\ (ss'-I)^{-1}),$$

that is,

$$(s-I)^{-1} - (s-I)^{-1}(s'-I)(ss'-I)^{-1} = (s-I)^{-1}(ss'-s')(ss'-I)^{-1} = \ s'(ss'-I)^{-1}),$$

we get

$$M_s + M = J\left(\tfrac{1}{2}I - (s'-I)(ss'-I)^{-1} + s'(ss'-I)^{-1}\right) = J\left(\tfrac{1}{2}I + (ss'-I)^{-1}\right) = M_{ss'},$$

which we set out to prove.

(ii) Formula (29) follows from the sequence of equalities

$$M_{s^{-1}} = \tfrac{1}{2}J + J(s^{-1}-I)^{-1} = \tfrac{1}{2}J - Js(s-I)^{-1} = \tfrac{1}{2}J - J(s-I+I)(s-I)^{-1} = -\tfrac{1}{2}J - J(s-I)^{-1} = -M_s.$$

■

C. The index $\nu(s_\infty)$

We define on $\mathbb{R}^{2n}\oplus\mathbb{R}^{2n}$ a symplectic form $\sigma^\ominus$ by

$$\sigma^\ominus(z_1,z_2;z_1',z_2') = \sigma(z_1,z_1') - \sigma(z_2,z_2')$$

and denote by $\mathrm{Sp}^\ominus(2n)$ and $\mathrm{Lag}^\ominus(2n)$ the symplectic group and Lagrangian Grassmannian of $(\mathbb{R}^{2n}\oplus\mathbb{R}^{2n},\sigma^\ominus)$. Let $\mu^\ominus$ be the Leray index on $\mathrm{Lag}^\ominus_\infty(2n)$ and $\mu^\ominus_L$ the Maslov index on $\mathrm{Sp}^\ominus_\infty(2n)$ relative to $L\in\mathrm{Lag}^\ominus(2n)$.

For $s_\infty\in\mathrm{Sp}_\infty(n)$ we define

$$\nu(s_\infty) = \tfrac{1}{2}\mu^\ominus((I\oplus s)_\infty\Delta_\infty,\Delta_\infty), \tag{32}$$

where $(I\oplus s)_\infty$ is the homotopy class in $\mathrm{Sp}^\ominus(2n)$ of the path

$$t\mapsto\{(z,s_tz):z\in\mathbb{R}^{2n}\},\quad 0\leqslant t\leqslant 1$$

and $\Delta=\{(z,z):z\in\mathbb{R}^{2n}\}$ the diagonal of $\mathbb{R}^{2n}\oplus\mathbb{R}^{2n}$. Setting $s_t^\ominus = I\oplus s_t$ we have $s_t^\ominus\in\mathrm{Sp}^\ominus(2n)$, hence formula (32) is equivalent to

$$\nu(s_\infty) = \tfrac{1}{2}\mu^\ominus_\Delta(s_\infty^\ominus), \tag{33}$$

where $\mu^\ominus_\Delta$ is the relative Maslov index on $\mathrm{Sp}^\ominus_\infty(2n)$ corresponding to the choice $\Delta\in\mathrm{Lag}^\ominus(2n)$.

Note that replacing n by $2n$ in the congruence [Eq. (10)] we have

$$\mu^\ominus((I\oplus s)_\infty\Delta_\infty,\Delta_\infty)\equiv\dim((I\oplus s)\Delta\cap\Delta)\mod 2\equiv\dim\mathrm{Ker}(s-I)\mod 2$$

and hence

$$\nu(s_\infty)\equiv\tfrac{1}{2}\dim\mathrm{Ker}(s-I)\mod 1.$$

Since the eigenvalue 1 of s has even multiplicity, $\nu(s_\infty)$ is thus always an integer.

The index ν has the following three important properties; the third is essential for the calculation of the index of repeated periodic orbits (it clearly shows that ν is not, in general, additive).

Proposition 1: (i) For all $s_\infty\in\mathrm{Sp}_\infty(n)$ we have

$$\nu(s_\infty^{-1}) = -\nu(s_\infty), \quad \nu(I_\infty) = 0 \tag{34}$$

[I_∞ *the identity of the group* $\mathrm{Sp}_\infty(n)$]. *(ii) For all* $r \in \mathbb{Z}$ *we have*

$$\nu(\alpha^r s_\infty) = \nu(s_\infty) + 2r, \quad \nu(\alpha^r) = 2r. \tag{35}$$

(iii) Let s_∞ *be the homotopy class of a path* Σ *in* $\mathrm{Sp}(n)$ *joining the identity to* $s \in \mathrm{Sp}^*(n)$, *and let* $s' \in \mathrm{Sp}(n)$ *be in the same connected component* $\mathrm{Sp}^{\pm}(n)$ *as* s. *Then* $\nu(s'_\infty) = \nu(s_\infty)$, *where* s'_∞ *is the homotopy class in* $\mathrm{Sp}(n)$ *of the concatenation of* Σ *and a path joining* s *to* s' *in* $\mathrm{Sp}_0(n)$. *(iv) The restriction of the index* ν *to* $\mathrm{Sp}^*_\infty(n)$ *is the Conley-Zehnder index:*

$$\nu(s_\infty) = i_{\mathrm{CZ}}(s_\infty) \quad \textit{if } \det(s - I) \neq 0. \tag{36}$$

Proof: (i) Formulas (34) immediately follow from the equality $(s_\infty^\ominus)^{-1} = (I \oplus s^{-1})_\infty$ and the antisymmetry of $\mu_\Delta^\ominus$. (ii) Formula (35) follows from the first using Eq. (34). To prove formula (35) it suffices to observe that the generator $I_\infty \oplus \alpha$ of $\pi_1[\mathrm{Sp}^\ominus(2n)]$ corresponds to the generator α of $\pi_1[\mathrm{Sp}(n)]$; in view of property (17) of the Maslov index, it follows that

$$\nu(\alpha^r s_\infty) = \tfrac{1}{2}\mu_\Delta^\ominus((I_\infty \oplus \alpha)^r s_\infty^\ominus) = \tfrac{1}{2}(\mu_\Delta^\ominus(s_\infty^\ominus) + 4r) = \nu(s_\infty) + 2r.$$

(iii) Assume, in fact, that s and s' belong to, say, $\mathrm{Sp}^+(n)$. Let s_∞ be the homotopy class of the path Σ, and Σ' a path joining s to s' in $\mathrm{Sp}^+(n)$ (we parametrize both paths by $t \in [0,1]$). Let $\Sigma'_{t'}$ be the restriction of Σ' to the interval $[0,t']$, $t' \leqslant t$ and $s_\infty(t')$ the homotopy class of the concatenation $\Sigma * \Sigma'_{t'}$. We have $\det(s(t) - I) > 0$ for all $t \in [0,t']$, hence $s_\infty^\ominus(t)\Delta \cap \Delta \neq 0$ as t varies from 0 to 1. It follows from the fact that the $\mu_\Delta^\ominus$ is locally constant on $\{s_\infty^\ominus : s_\infty^\ominus \Delta \cap \Delta = 0\}$ (see Sec. II C) that the function $t \mapsto \mu_\Delta^\ominus(s_\infty^\ominus(t))$ is constant, and hence,

$$\mu_\Delta^\ominus(s_\infty^\ominus) = \mu_\Delta^\ominus(s_\infty^\ominus(0)) = \mu_\Delta^\ominus(s_\infty^\ominus(1)) = \mu_\Delta^\ominus(s_\infty'^\ominus),$$

which was to be proven. (iv) The restriction of ν to $\mathrm{Sp}^*(n)$ satisfies the properties (CZ_1), (CZ_2), and (CZ_3) of the Conley-Zehnder index listed in Sec. III A; we showed that these properties uniquely characterize i_{CZ}. ■

Remark: Formula (36) *allows the calculation of* $i_{\mathrm{CZ}}(\Sigma)$ *in terms of the index* $\nu(s_\infty)$. *That formula, in fact, allows us to define the Conley-Zehnder index of an arbitrary path* Σ *by the formula* $i_{\mathrm{CZ}}(\Sigma) = \nu(s_\infty)$, *where* s_∞ *is the homotopy class in* $\mathrm{Sp}(n)$ *of that path (see the discussion at the end of this paper).*

Let us now state and prove the first main result of this paper.

Theorem 1: *If* s_∞, s'_∞, *and* $s_\infty s'_\infty$ *are such that* $\det(s - I) \neq 0$, $\det(s' - I) \neq 0$, *and* $\det(ss' - I) \neq 0$, *then*

$$\nu(s_\infty s'_\infty) = \nu(s_\infty) + \nu(s'_\infty) + \tfrac{1}{2}\mathrm{sign}(M_s + M_{s'}), \tag{37}$$

where M_s *is the symplectic Cayley transform of* s.

Proof: In view of Eq. (33) and the product property (16) of the Maslov index we have

$$\nu(s_\infty s'_\infty) = \nu(s_\infty) + \nu(s'_\infty) + \tfrac{1}{2}\tau^\ominus(\Delta, s^\ominus\Delta, s^\ominus s'^\ominus\Delta) = \nu(s_\infty) + \nu(s'_\infty) - \tfrac{1}{2}\tau^\ominus(s^\ominus s'^\ominus\Delta, s^\ominus\Delta, \Delta),$$

where $s^\ominus = I \oplus s$, $s'^\ominus = I \oplus s'$, and $\tau^\ominus$ is the signature on the symplectic space $(\mathbb{R}^{2n} \oplus \mathbb{R}^{2n}, \sigma^\ominus)$. The condition $\det(ss' - I) \neq 0$ is equivalent to $s^\ominus s'^\ominus \Delta \cap \Delta = 0$, hence we can apply property (i) in Lemma 1 with $\ell = s^\ominus s'^\ominus \Delta$, $\ell' = s^\ominus \Delta$, and $\ell'' = \Delta$. The projection operator onto $s^\ominus s'^\ominus \Delta$ along Δ is easily seen to be

$$\mathrm{Pr}_{s^\ominus s'^\ominus \Delta, \Delta} = \begin{bmatrix} (I - ss')^{-1} & -(I - ss')^{-1} \\ ss'(I - ss')^{-1} & -ss'(I - ss')^{-1} \end{bmatrix},$$

hence $\tau^\ominus(s^\ominus s'^\ominus \Delta, s^\ominus \Delta, \Delta)$ is the signature of the quadratic form

$$Q(z) = \sigma^{\ominus}(\mathrm{Pr}_{s^{\ominus}s'^{\ominus}\Delta,\Delta}(z,sz);(z,sz)),$$

that is, since $\sigma^{\ominus} = \sigma \ominus \sigma$:

$$\begin{aligned} Q(z) &= \sigma\,((I-ss')^{-1}(I-s)z,z)) - \sigma\,(ss'(I-ss')^{-1}(I-s)z,sz)) \\ &= \sigma\,((I-ss')^{-1}(I-s)z,z)) - \sigma\,(s'(I-ss')^{-1}(I-s)z,z)) = \sigma\,((I-s')(I-ss')^{-1}(I-s)z,z)). \end{aligned}$$

In view of formula (27) in Lemma 2 we have

$$(I-s')(ss'-I)^{-1}(I-s) = (M_s + M_{s'})^{-1}J,$$

hence

$$Q(z) = -\langle (M_s + M_{s'})^{-1}Jz, Jz\rangle$$

and the signature of Q is thus the same as that of

$$Q'(z) = -\langle (M_s + M_{s'})^{-1}z, z\rangle,$$

that is, $-\mathrm{sign}(M_s + M_{s'})$. This proves formula (37). ■

IV. APPLICATION TO THE METAPLECTIC GROUP

The metaplectic group plays a crucial role in quantum mechanics (both in its full-blown version and in its semiclassical formulation). We are going to see that the Conley-Zehnder index automatically appears when one determines the Weyl symbol of metaplectic operators.

A. The group Mp(*n*)

The fundamental group $\pi_1[\mathrm{Sp}(n)]$ being isomorphic to $(\mathbb{Z},+)$, the symplectic group, has covering of all orders; its double covering $\mathrm{Sp}_2(n)$ plays an important role in the literature because it has a faithful representation as a group of unitary operators on $L^2(\mathbb{R}^n)$. This group, the metaplectic group $\mathrm{Mp}(n)$, is generated[11,14] by the quadratic Fourier transforms

$$S_{W,m}f(x) = \left(\frac{1}{2\pi\hbar}\right)^{n/2}\Delta(W)\int e^{(i/\hbar)W(x,x')}f(x')d^n x', \tag{38}$$

where W is a quadratic form on $\mathbb{R}^n \times \mathbb{R}^n$ given by

$$W(x,x') = \tfrac{1}{2}\langle Px,x\rangle - \langle Lx,x'\rangle + \tfrac{1}{2}\langle Qx',x'\rangle \tag{39}$$

with P and Q symmetric and $\det L \neq 0$; the factor in front of the integral in Eq. (38) is

$$\Delta(W) = i^m\sqrt{|\det L|},$$

where m corresponds to a choice of the argument of $\det L$. The covering epimorphism $\pi_{\mathrm{Mp}}:\mathrm{Mp}(n)\to\mathrm{Sp}(n)$ is determined by its restriction to the $S_{W,m}$, and we have

$$(x,p) = \pi_{\mathrm{Mp}}(S_{W,m})(x',p') \Leftrightarrow p = \partial_x W(x,x'), \quad p' = -\partial_{x'}W(x,x')$$

[$s_W = \pi(S_{W,m})$ is the free symplectic matrix generated by the quadratic form W].

Every $S \in \mathrm{Mp}(n)$ can be written (in infinitely many ways[14,8]) as a product $S_{W,m}S_{W',m'}$ and the integer

$$m + m' - \mathrm{Inert}(P' + Q) \equiv m + m' + \mathrm{Inert}(\ell_P, s_W\ell_P, s_W s_{W'}\ell_P) \mod 4$$

does not depend on the choice of factorization $S = S_{W,m}S_{W',m'}$ (see Ref. 6). The class mod 4 of $m+m'-\mathrm{Inert}(P'+Q)$ is denoted by $m(S)$ and called *Maslov index* of $S \in \mathrm{Mp}(n)$. The function $m:\mathrm{Mp}(n)\to\mathbb{Z}_4$ has the following properties:

$$m(S_{W,m}) = \hat{m} \tag{40}$$

and

$$m(SS') = m(S) + m(S') + \widehat{\text{Inert}}(\ell_P, s\ell_P, ss'\ell_P), \tag{41}$$

where $\hat{k}$ is the class mod 4 of $k \in \mathbb{Z}$ and $s = \pi_{\text{Mp}}(S)$; it is related to the relative Maslov index m_{ℓ_p} on $\text{Sp}_\infty(n)$ by

$$m(S) = \widehat{m_{\ell_p}}(s_\infty), \tag{42}$$

where s_∞ is any element of $\text{Sp}_\infty(n)$ with projection $S \in \text{Sp}(n)$.

B. Weyl representation of $S \in \text{Mp}(n)$

Defining, as in Ref. 16, the Mehlig-Wilkinson operator $R_\nu(s)$ associated to $s \in \text{Sp}^*(n)$ and $\nu \in \mathbb{Z}$ as being the Bochner integral

$$R_\nu(s) = \left(\frac{1}{2\pi\hbar}\right)^n \frac{i^\nu}{\sqrt{|\det(s-I)|}} \int e^{(i/2\hbar)\langle M_s z, z\rangle} T(z) d^{2n}z,$$

where $T(z)$ is the Heisenberg-Weyl operator, one of us proved in Ref. 10, Proposition 6 in Sec. 3 B and Proposition 10 in Sec. 3 C, the following results:

Proposition 2: (i) Let s_W be the free symplectic matrix generated by the quadratic form (39). We have $S_{W,m} = R_\nu(s_W)$ if and only if $\nu = \nu(S_{W,m})$ with

$$\nu(S_{W,m}) \equiv m - \text{Inert } W_{xx} \mod 4, \tag{43}$$

where Inert W_{xx} *is the index of inertia of the Hessian matrix W_{xx} of $x \mapsto W(x,x)$; (ii) Let $S \in \text{Mp}(n)$ be such that $\pi^{\text{Mp}}(S) \in \text{Sp}^*(n)$. If $s = s_W s_{W'}$ and $S = R_{\nu(s_W)}(s_W) R_{\nu(s'_W)}(s_{W'})$, then $S = R_{\nu(S)}(s)$ with*

$$\nu(S) \equiv \nu(s_W) + \nu(s_{W'}) + \tfrac{1}{2}\text{sign}(M_{s_W} + M_{s'_W}). \tag{44}$$

Comparison of formulas (44) and (37) in Theorem 1 suggests that there is a relation between the integer $\nu(S)$ and the Conley-Zehnder index of some symplectic path ending at $s = \pi_{\text{Mp}}(S)$. We claim that:

Theorem 2: *Let $s_\infty \in \text{Sp}_\infty(n)$ be such that $s = \pi_\infty(s_\infty)$ is in $\text{Sp}^*(n)$ and denote by S the image in $\text{Mp}(n)$ of the projection of s_∞ on $\text{Sp}_2(n)$. We have*

$$\nu(S) \equiv \nu(s_\infty) \mod 4. \tag{45}$$

In view of the product formula (37) in Theorem 1, it is sufficient to establish the congruence [Eq. (45)] when $s = s_W$. Assume that $S = S_{W,m}$; the relation

$$\nu(S_{W,m}) \equiv \nu(s_{W,\infty}) \mod 4$$

is an immediate consequence of the following result, interesting in its own right:

Proposition 3: We have

$$\nu(s_{W,\infty}) = m_{\ell_P}(s_{W,\infty}) - \text{Inert } W_{xx} \tag{46}$$

and hence

$$\nu(s_{W,\infty}) \equiv m - \text{Inert } W_{xx} \mod 4. \tag{47}$$

Proof: Formula (47) follows from Eq. (46) in view of Eqs. (42) and (40). We will divide the proof of formula (46) in three steps.

Step 1. Let $L \in \mathrm{Lag}^{\ominus}(2n)$. Using successively formulas (33) and (22) we have

$$\nu(s_\infty) = \tfrac{1}{2}(\mu_L^{\ominus}(s_\infty^{\ominus}) + \tau^{\ominus}(s^{\ominus}\Delta,\Delta,L) - \tau^{\ominus}(s^{\ominus}\Delta,s^{\ominus}L,L)). \tag{48}$$

Choosing, in particular, $L=L_0=\ell_P\oplus\ell_P$ we get

$$\begin{aligned}\mu_{L_0}^{\ominus}(s_\infty^{\ominus}) &= \mu^{\ominus}((I\oplus s)_\infty(\ell_P\oplus\ell_P),(\ell_P\oplus\ell_P)) = \mu(\ell_{P,\infty},\ell_{P,\infty}) - \mu(\ell_{P,\infty},s_\infty\ell_{P,\infty})\\ &= -\mu(\ell_{P,\infty},s_\infty\ell_{P,\infty}) = \mu_{\ell_P}(s_\infty)\end{aligned}$$

so that there remains to prove that

$$\tau^{\ominus}(s^{\ominus}\Delta,\Delta,L_0) - \tau^{\ominus}(s^{\ominus}\Delta,s^{\ominus}L_0,L_0) = -2\ \mathrm{sign}\ W_{xx}.$$

Step 2. We are going to show that

$$\tau^{\ominus}(s^{\ominus}\Delta,s^{\ominus}L_0,L_0) = 0;$$

in view of the symplectic invariance and the antisymmetry of $\tau^{\ominus}$, this is equivalent to

$$\tau^{\ominus}(L_0,\Delta,L_0,(s^{\ominus})^{-1}L_0) = 0. \tag{49}$$

We have

$$\Delta\cap L_0 = \{(0,p;0,p):p\in\mathbb{R}^n\}$$

and $(s^{\ominus})^{-1}L_0\cap L_0$ consists of all $(0,p',s^{-1}(0,p''))$ with $s^{-1}(0,p'')=(0,p')$; since s (and hence s^{-1}) is free we must have $p'=p''=0$ so that

$$(s^{\ominus})^{-1}L_0\cap L_0 = \{(0,p;0,0):p\in\mathbb{R}^n\}.$$

It follows that we have

$$L_0 = \Delta\cap L_0 + (s^{\ominus})^{-1}L_0\cap L_0,$$

hence Eq. (49) in view of property (ii) in Lemma 1.

Step 3. Let us finally prove that

$$\tau^{\ominus}(s^{\ominus}\Delta,\Delta,L_0) = -2\ \mathrm{sign}\ W_{xx};$$

this will complete the proof of the proposition. The condition $\det(s-I)\neq 0$ is equivalent to $s^{\ominus}\Delta\cap\Delta=0$, hence, using property (i) in Lemma 1:

$$\tau^{\ominus}(s^{\ominus}\Delta,\Delta,L_0) = -\tau^{\ominus}(s^{\ominus}\Delta,L_0,\Delta)$$

is the signature of the quadratic form Q on L_0 defined by

$$Q(0,p,0,p') = -\sigma^{\ominus}(\mathrm{Pr}_{s^{\ominus}\Delta,\Delta}(0,p,0,p');0,p,0,p'),$$

where

$$\mathrm{Pr}_{s^{\ominus}\Delta,\Delta} = \begin{bmatrix}(s-I)^{-1} & -(s-I)^{-1}\\ s(s-I)^{-1} & -s(s-I)^{-1}\end{bmatrix}$$

is the projection on $s^{\ominus}\Delta$ along Δ in $\mathbb{R}^{2n}\oplus\mathbb{R}^{2n}$. It follows that the quadratic form Q is given by

$$Q(0,p,0,p') = -\sigma^{\ominus}((I-s)^{-1}(0,p''),s(I-s)^{-1}(0,p'');0,p,0,p'),$$

where we have set $p''=p-p'$; by definition of $\sigma^{\ominus}$, this is

$$Q(0,p,0,p') = -\sigma((I-s)^{-1}(0,p''),(0,p)) + \sigma(s(I-s)^{-1}(0,p''),(0,p')).$$

Let M_s now be the symplectic Cayley transform [Eq. (25)] of s; we have

$$(I-s)^{-1} = JM_s + \tfrac{1}{2}I, \quad s(I-s)^{-1} = JM_s - \tfrac{1}{2}I,$$

and hence,

$$\begin{aligned} Q(0,p,0,p') &= -\sigma\left(\left(JM_s + \tfrac{1}{2}I\right)(0,p''),(0,p)\right) + \sigma\left(\left(JM_s - \tfrac{1}{2}I\right)(0,p''),(0,p')\right) \\ &= -\sigma(JM_s(0,p''),(0,p)) + \sigma(JM_s(0,p''),(0,p')) = \sigma(JM_s(0,p''),(0,p'')) \\ &= -\langle M_s(0,p''),(0,p'')\rangle. \end{aligned}$$

Let us calculate explicitly M_s. Writing

$$s = \begin{bmatrix} A & B \\ C & D \end{bmatrix}$$

we have

$$s - I = \begin{bmatrix} 0 & B \\ I & D-I \end{bmatrix} \begin{bmatrix} C-(D-I)B^{-1}(A-I) & 0 \\ B^{-1}(A-I) & I \end{bmatrix},$$

that is,

$$s - I = \begin{bmatrix} 0 & B \\ I & D-I \end{bmatrix} \begin{bmatrix} W_{xx} & 0 \\ B^{-1}(A-I) & I \end{bmatrix}, \tag{50}$$

where we have used the identity

$$C - (D-I)B^{-1}(A-I)) = B^{-1}A + DB^{-1} - B^{-1} - (B^T)^{-1},$$

which follows from the relation $C - DB^{-1}A = -(B^T)^{-1}$ (the latter is a consequence of the equalities $D^TA - B^TC = I$ and $D^TB = B^TD$ due to the fact that $s^TJs = s^TJs$). We thus have, setting $W_{xx}^{-1} = (W_{xx})^{-1}$,

$$\begin{aligned} (s-I)^{-1} &= \begin{bmatrix} W_{xx}^{-1} & 0 \\ B^{-1}(I-A)W_{xx}^{-1} & I \end{bmatrix} \begin{bmatrix} (I-D)B^{-1} & I \\ B^{-1} & 0 \end{bmatrix} \\ &= \begin{bmatrix} W_{xx}^{-1}(I-D)B^{-1} & W_{xx}^{-1} \\ B^{-1}(I-A)W_{xx}^{-1}(I-D)B^{-1} + B^{-1} & B^{-1}(I-A)W_{xx}^{-1} \end{bmatrix}, \end{aligned}$$

and hence,

$$M_s = \begin{bmatrix} B^{-1}(I-A)W_{xx}^{-1}(I-D)B^{-1} + B^{-1} & \tfrac{1}{2}I + B^{-1}(I-A)W_{xx}^{-1} \\ -\tfrac{1}{2}I - W_{xx}^{-1}(I-D)B^{-1} & -W_{xx}^{-1} \end{bmatrix}$$

so that we have

$$Q(0,p,0,p') = \langle W_{xx}^{-1}p'',p''\rangle = \langle W_{xx}^{-1}(p-p'),(p-p')\rangle.$$

The matrix of the quadratic form Q is thus

$$2\begin{bmatrix} W_{xx}^{-1} & -W_{xx}^{-1} \\ -W_{xx}^{-1} & W_{xx}^{-1} \end{bmatrix}$$

and this matrix has signature $2 \operatorname{sign} W_{xx}^{-1} = 2 \operatorname{sign} W_{xx}$, proving the first equality [Eq. (46)]; the second equality follows because $\mu_{\ell_P}(s_\infty) = 2m_{\ell_P}(s_\infty) - n$ (since $s\ell_P \cap \ell_P = 0$) and rank $W_{xx} = n$ in view of Eq. (50), which implies that $\det(s - I) = (-1)^n \det B \det W_{xx}$. ■

V. CONCLUSION AND DISCUSSION

We have expressed the Conley-Zehnder index i_{CZ} in terms of a cohomological and topological object, the Leray index which was introduced in Ref. 14 for the purpose of semiclassical quantization, and extended in Refs. 4 and 7. This allows the definition of $i_{CZ}(\Sigma)$ without any assumption on the end point of the path Σ (see Remark). In Theorem 1 we proved a product formula for the Conley-Zehnder index in terms of the symplectic Cayley transform; this formula, however, only works if all involved paths are nondegenerate. Using the cohomological property of the Maslov index [formulas (16) and (20)] it is indeed possible to write an explicit formula for the Conley-Zehnder index of the product of two arbitrary paths; this formula (which we will not write down) is rather complicated and therefore not very attractive. It turns out that it is possible to obtain a simpler formula by redefining the Conley-Zehnder index using methods inspired from Ref. 1, as we will show in a forthcoming publication. This alternative method does not, however, lead to a straightforward calculation of the indices appearing in the Weyl representation of metaplectic operators, studied in the last section of this paper: in this precise case the Leray index approach is definitely the most natural and powerful.

Uncertainty principle for Gabor systems and the Zak transform

Wojciech Czaja[a] and Jacek Zienkiewicz[b]
Institute of Mathematics, University of Wrodaw, Plac Grunwaldzki 2/4, 50-384 Wrodaw, Poland

(Received 9 August 2006; accepted 11 October 2006; published online 13 December 2006)

We show that if $g \in L^2(\mathbb{R})$ is a generator of a Gabor orthonormal basis with the lattice $\mathbb{Z}\times\mathbb{Z}$, then its Zak transform $Z(g)$ satisfies $\nabla Z(g) \notin L^2([0,1)^2)$. This is a generalization and extension of the Balian-Low uncertainty principle. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2393146]

I. INTRODUCTION

Given a square integrable function $g \in L^2(\mathbb{R})$ and constants $a,b>0$, the associated *Gabor system (Weyl-Heisenberg system)* generated by g and the lattice $a\mathbb{Z}\times b\mathbb{Z}$, $\mathcal{G}(g,a,b)=\{g_{m,n}\}_{m,n\in\mathbb{Z}}$, is defined by

$$g_{m,n}(x) = e^{2\pi iamx} g(x-bn).$$

In 1946 Gabor proposed to study such systems for their usefulness in the analysis of information conveyed by communication channels. These systems have been studied extensively in recent years. The edited books by Benedetto and Ferreira[4] and by Feichtinger and Strohmer,[6] as well as Gröchenig's treatise,[7] provide detailed treatments of various issues of the theory. It is well known, for example, that $ab=1$ is a necessary condition for $\mathcal{G}(g,a,b)$ to form an orthonormal basis or a Riesz basis. Moreover, if one wishes to construct orthonormal bases of Gabor type, then there are severe restrictions on the window function's time and frequency localization. The Balian-Low theorem makes this phenomenon precise as follows. We use the Fourier transform defined by $\hat{g}(\xi)=\int g(x)e^{-2\pi i\xi x}\mathrm{d}x$, where our convention is that the integral without specific limits denotes the integral over $\mathbb{R}$.

Theorem 1.1 (Balian-Low): *Let* $g \in L^2(\mathbb{R})$. *If*

$$\int |x|^2|g(x)|^2\mathrm{d}x < \infty \quad \textit{and} \quad \int |\xi|^2|\hat{g}(\xi)|^2\mathrm{d}\xi < \infty, \tag{1.1}$$

then $\mathcal{G}(g,1,1)$ *is not an orthonormal basis for* $L^2(\mathbb{R})$.

The Balian-Low theorem can be viewed as a version of the classical uncertainty principle for Gabor orthonormal bases. It has been established independently by Balian[1] and Low,[12] and the first complete proof was given by Battle.[2]

An important tool in the analysis and construction of Gabor systems is the *Zak transform*, see e.g., Ref. 7, Chap. 8. Given $g \in L^2(\mathbb{R})$, the Zak transform is formally defined by

$$Z(g)(x,\xi) = \sum_{n\in\mathbf{Z}} g(x-n)e^{2\pi in\xi}, \quad \forall\,(x,\xi) \in \mathbb{R}\times\mathbb{R}.$$

With the above definition, the Zak transform satisfies the *quasiperiodicity relations*

[a]Present address: Department of Mathematics, University of Maryland, College Park, MD 20742, USA; electronic mail: wojtek@math.umd.edu
[b]Electronic mail: zenek@math.uni.wroc.pl

$$Z(f)(x,\xi+k)=Z(f)(x,\xi),\quad \forall\, k\in\mathbb{Z},$$

and

$$Z(f)(x+k,\xi)=Z(f)(x,\xi)e^{2\pi ik\xi},\quad \forall\, k\in\mathbb{Z},$$

e.g., see Ref. 7, Sec. 8.2. Thus, the Zak transform $Z(f)$ of a function $f\in L^2(\mathbb{R})$ is a locally square integrable function defined on all of $\mathbb{R}^2$ and is uniquely determined by its values on $Q\equiv[0,1)^2$. Therefore, Z defines a unitary operator from $L^2(\mathbb{R})$ to $L^2(Q)$, and its inverse $Z^{-1}:L^2(Q)\to L^2(\mathbb{R})$ is formally given by

$$Z^{-1}(F)(x)=\int_0^1 F(x,\xi)\mathrm{d}\xi,\quad \forall\, x\in\mathbb{R}.$$

The utility of the Zak transform for constructing Gabor bases stems from the following result, e.g., Ref. 7, Corollary 8.3.2. A *Riesz basis* for $L^2(\mathbb{R})$ is an image of an orthonormal basis for $L^2(\mathbb{R})$ under an invertible bounded operator on $L^2(\mathbb{R})$ with a bounded inverse.

Theorem 1.2: *Let* $g\in L^2(\mathbb{R})$.

a. $\mathcal{G}(g,1,1)$ *is an orthonormal basis for* $L^2(\mathbb{R})$ *if and only if* $|Z(g)(x,\xi)|=1$ *for a.e.* $(x,\xi)\in Q$.
b. $\mathcal{G}(g,1,1)$ *is a Riesz basis for* $L^2(\mathbb{R})$ *if and only if there exist constants* A,B *such that* $0<A\leqslant|Z(g)(x,\xi)|\leqslant B<\infty$ *for a.e.* $(x,\xi)\in Q$.

This theorem shows that constructing, e.g., Gabor orthonormal bases is equivalent to constructing unimodular functions on $L^2(Q)$. Janssen showed in Ref. 8 that such functions cannot be continuous when extended quasiperiodically to $\mathbb{R}^2$. In fact, the following result holds.

Theorem 1.3: *Let* $g\in L^2(\mathbb{R})$ *be such that* $Z(g)$ *is continuous on* $\mathbb{R}^2$. *Then, there exists* $(t,\eta)\in Q$ *such that* $Z(g)(t,\eta)=0$.

In the next section we shall present a result which is a generalization of Theorem 1.3 and, at the same time, may be viewed as an analog of the Balian-Low theorem. Our motivation comes from the fact that conditions (1.1) in Theorem 1.1, may be rewritten in the following forms:

$$\int|x|^2|g(x)|^2\mathrm{d}x<\infty\quad\text{and}\quad\int|g'(x)|^2\mathrm{d}x<\infty,\tag{1.2}$$

where g' denotes the distributional derivative of g.

By analogy and in view of Theorem 1.2, it is of interest to investigate the properties of the gradient of the Zak transform of a function $g\in L^2(\mathbb{R})$ which generates a Gabor orthonormal basis. We shall show that if $\mathcal{G}(g,1,1)$ is a Gabor orthonormal basis for $L^2(\mathbb{R})$ then $\nabla Z(g)\notin L^2(Q)$. In view of Theorem 1.2, this result is an analog of Eq. (1.2).

II. MAIN RESULTS

We say that a function $H:\mathbb{R}^2\to\mathbb{T}$, periodic in ξ, has a *jump by* λ on the interval $[(x_0,\xi_0),(x_0,\xi_1)]$, if $|H(x_0,\xi_1)-H(x_0,\xi_0)|\geqslant\lambda$.

In what follows we shall use the following standard observation.

Fact 2.1: *Let* $H=e^{2\pi ih}:\mathbb{R}^2\to\mathbb{T}$ *be a quasiperiodic function on* $\mathbb{R}^2$ *and such that* $\nabla H\in L^2(Q)$. *Then, for almost all* $\xi\in[0,1]$, $H(\cdot,\xi)$ *is a continuous function on [0,1].*

We note here that the following lemma is closely related to the trace property of Sobolev spaces.

Lemma 2.2: *Fix* $\lambda>0$. *Let* $H(x,\xi):\mathbb{R}^2\to\mathbb{T}$ *be a quasiperiodic function on* $\mathbb{R}^2$. *Assume that for sufficiently small* $0<\delta<1$, *the set of those* $\xi_0\in(1-\delta,1)$ *for which H has a jump by* λ *on some interval* $[(x_0,\xi_0),(x_0,1)]$ *has measure at least* $\delta/2$. *Then* $\nabla H\notin L^2(Q)$.

Proof: Assume by contradiction that $\nabla H\in L^2(Q)$ and $\|\nabla H\|_{L^2(Q)}=1$.

Fact 2.1 implies that for almost all $\xi\in[0,1]$, $H(x,\xi)$ is a continuous function of $x\in[0,1]$.

Using the periodicity of H in ξ, we may conclude that $H(\cdot,\xi)$ is continuous for almost all $\xi \in \mathbb{R}$. Thus, we may assume without loss of generality that $H(\cdot,0)$ and $H(\cdot,1)$ are continuous functions of $x \in [0,1]$, and moreover that $\int_0^1 |\partial_x H(\cdot,0)|^2 \mathrm{d}x \leqslant 2$. This implies that we may now consider the function $H(x,\xi)/H(1,\xi)$, which satisfies $\|\nabla(H(x,\xi)/H(1,\xi))\|_{L^2(Q)} \leqslant 4$, which, in turn, together with the periodicity of H, allows us to assume that $H(x,0)/H(1,0)$ and $H(x,1)/H(1,1)$ are constant.

For simplicity of notation, in what follows we shall denote the function $H(x,\xi)/H(1,\xi)$ again by $H(x,\xi)$.

Fix $\xi_0 \in (1-\delta,1)$, for which H has a jump by λ on some interval $[(x_0,\xi_0),(x_0,1)]$. Let E_{ξ_0} denote the set of points (x,ξ_0) for which

$$|H(x,1) - H(x,\xi_0)| > \lambda/4.$$

For any $x \in E_{\xi_0}$ we have

$$\lambda^2/16 \leqslant |H(x,1) - H(x,\xi_0)|^2 \leqslant \left(\int_{\xi_0}^1 \partial_\xi H(x,\xi) \mathrm{d}\xi \right)^2 \leqslant \delta \int_{1-\delta}^1 |\partial_\xi H(x,\xi)|^2 \mathrm{d}\xi.$$

Thus,

$$|E_{\xi_0}| \leqslant \frac{16}{\lambda^2} \delta \int_0^1 \int_{1-\delta}^1 |\nabla H(x,\xi)|^2 \mathrm{d}\xi \mathrm{d}x := \frac{16}{\lambda^2} \delta \epsilon(\delta), \tag{2.1}$$

where $\epsilon(\delta) \to 0$ as $\delta \to 0$. The following inequality holds:

$$\left| \left\{ \xi \in (1-\delta,1): \int_0^1 |\partial_x H(x,\xi)|^2 \mathrm{d}x > A/\delta \right\} \right| \leqslant \frac{\delta}{A} \int_{1-\delta}^1 \int_0^1 |\partial_x H(x,\xi)|^2 \mathrm{d}x \mathrm{d}\xi \leqslant \frac{\delta}{A} \epsilon(\delta).$$

The above inequality implies that

$$\left| \left\{ \xi \in (1-\delta,1): \int_0^1 |\partial_x H(x,\xi)|^2 \mathrm{d}x \leqslant A/\delta \right\} \right| \geqslant \delta - \frac{\delta}{A} \epsilon(\delta).$$

If we choose $A > 2\epsilon(\delta)$ then

$$\left| \left\{ \xi \in (1-\delta,1): \int_0^1 |\partial_x H(x,\xi)|^2 \mathrm{d}x \leqslant A/\delta \right\} \right| > \frac{\delta}{2}.$$

Therefore, there exists $\xi_0 \in (1-\delta,1)$ such that $\int_0^1 |\partial_x H(x,\xi_0)|^2 \mathrm{d}x \leqslant A/\delta$ and for which H has a jump by λ on some interval $[(x_0,\xi_0),(x_0,1)]$.

Using the Cauchy-Schwartz inequality (see, e.g., Ref. 11), we obtain that for such ξ_0 and for any $x_0 \in [0,1]$,

$$|H(x_0,\xi_0) - H(1,\xi_0)|^2 \leqslant (1-x_0) \int_{x_0}^1 |\partial_x H(x,\xi_0)|^2 \mathrm{d}x \leqslant (1-x_0) \frac{A}{\delta}. \tag{2.2}$$

If we choose $A = 4\epsilon(\delta)$ and $1-x_0$ sufficiently small (i.e., $1-x_0 \leqslant \min\{1/2; \lambda^2\delta/32\epsilon(\delta)\}$) then the right hand side of Eq. (2.2) is smaller than $\lambda^2/16$, i.e.,

$$|H(x_0,\xi_0) - H(1-\xi_0)| \leqslant \lambda/4. \tag{2.3}$$

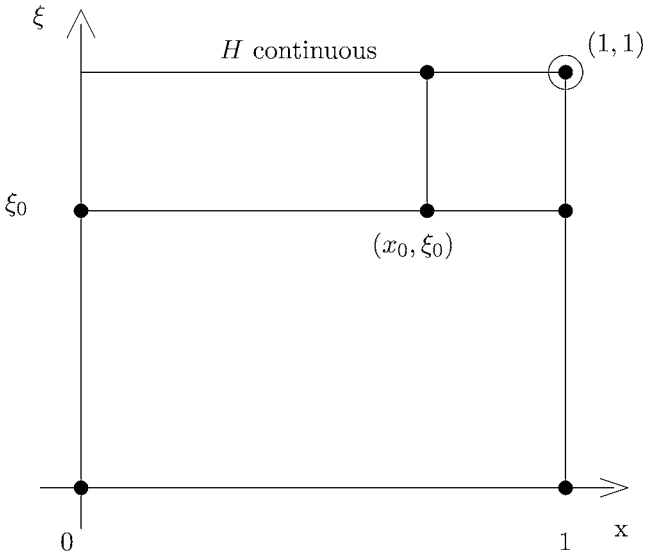
Next, we use Eq. (2.1) and the fact that $\epsilon(\delta) \to 0$ as $\delta \to 0$ to observe that if δ is sufficiently small, then in each interval $[(1-\min\{1/2; \lambda^2\delta/32\epsilon(\delta)\}, \xi_0), (1, \xi_0)]$ we can find a point x_0 such that

$$|H(x_0,\xi_0) - H(x_0,1)| \leqslant \lambda/4. \tag{2.4}$$

Finally, by the assumption about the continuity of $H(x,1)$, we may assume also without loss of generality that $H(\cdot,1)$ is constant on $[0,1]$ and so

$$|H(x_0,1)-H(1,1)|=0\leqslant \lambda/4. \tag{2.5}$$

Combining now Eqs. (2.3)–(2.5) with the assumption of jump of H by λ we obtain a contradiction. □



◉ — point of jump

Theorem 2.3: *Let* $H(x,\xi):\mathbb{R}^2\to\mathbb{T}$ *be a quasiperiodic function on* $\mathbb{R}^2$. *Then* $\nabla H\notin L^2(Q)$.

Remark 2.4: The condition $\nabla H\in L^2(Q)$ does not imply that H is continuous, so the result of Janssen (Theorem 1.3) cannot be directly used.

Proof: Fix $\delta>0$ sufficiently small. Let $H(x,\xi)=e^{2\pi i h(x,\xi)}$. We shall divide the argument into three cases.

Consider the set $\mathcal{A}(\delta)=\mathcal{A}(1-\delta,1)\subset(1-\delta,1)$ consisting of $\xi\in(1-\delta,1)$ such that

$$h(1,\xi)-h(0,\xi)=\xi+k,$$

where $k\in\mathbb{Z}\backslash\{-1\}$ and k depends on ξ.

For almost every $\xi_0\in\mathcal{A}(\delta)$, $h(\cdot,\xi_0)$ is continuous on $[0,1]$. For such ξ_0 there exists $a\in[0,1]$ and an independent constant λ such that $|H(a,\xi_0)-H(a,1)|>\lambda$.

Indeed, Fact 2.1 implies that for almost all ξ, $h(\cdot,\xi)$ is continuous on $[0,1]$. As in the proof of Lemma 2.2, we may assume without loss of generality that $h(\cdot,0)$ and $h(\cdot,1)$ are constant on $[0,1]$. Since $k\neq-1$ and using the continuity of $h(\cdot,\xi_0)$, we may choose $x_0\in(0,1)$ such that $|h(x_0,\xi_0)-h(0,\xi_0)|=1/2$. Thus, we may conclude that either $|h(0,1)-h(0,\xi_0)|\geqslant 1/4$ or $|h(x_0,1)-h(x_0,\xi_0)|\geqslant 1/4$. In particular, we have $\lambda=1/4$.

Case 1. Suppose that for some sufficiently small $\delta\in(0,1)$, $|\mathcal{A}(\delta)|\geqslant\delta/2$. Then we use Lemma 2.2 to obtain a contradiction with the assumption that $\nabla H\in L^2(Q)$.

Case 2. Suppose that the set $\mathcal{B}(\delta)=\mathcal{B}(0,\delta)\subset(0,\delta)$ consisting of $\xi\in(0,\delta)$ such that

$$h(1,\xi)-h(0,\xi)=\xi+k,$$

where $k\neq0$, has measure greater than or equal to $\delta/2$ for some sufficiently small $\delta>0$. In such case, arguing as in case 1, we again obtain a contradiction.

Case 3. Assume that there exists $\delta\in(0,1)$ such that $|\mathcal{A}(\delta)|<\delta/2$ and $|\mathcal{B}(\delta)|<\delta/2$.

We may assume without loss of generality that

$$\int_0^1 |\partial_x h(x,\delta)|^2 \mathrm{d}x < \infty.$$

Define the function $f:[0,1-\delta]\to\mathbb{R}$ by $f(x)=|\{\xi\in[x,x+\delta]:h(1,\xi)-h(0,\xi)=\xi\}|$. So defined function f is continuous and thus there exists an interval $(\eta,\eta+\delta)$ such that $|\mathcal{A}(\delta)+\eta|=\delta/2$ and $|\mathcal{B}(\delta)+\eta|=\delta/2$.

Next, we choose $\xi_1,\xi_2\in(\eta,\eta+\delta)$ such that

$$h(1,\xi_1)-h(0,\xi_1)=\xi_1$$

and

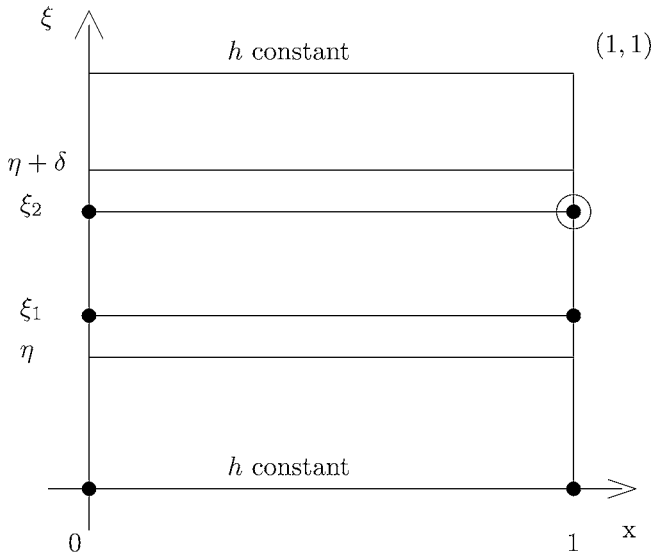
$$h(1,\xi_2)-h(0,\xi_2)=\xi_2+l,$$

where $l\in\mathbb{Z}\backslash\{0\}$. This implies that the function H has a jump on some interval $[(a,\xi_1),(a,\xi_2)]$, where $a\in[0,1]$.

Moreover, we may assume without loss of generality that ξ_1 and ξ_2 are chosen so that $h(\cdot,\xi_1)$ and $h(\cdot,\xi_2)$ are continuous and that

$$\int_0^1 |\partial_x H(x,\xi_i)|^2 \mathrm{d}x \leqslant A/\delta,$$

$i=1,2$, for some $A>2\epsilon(\delta)$. We may now conclude the proof, obtaining a contradiction as in the proof of Lemma 2.2. □



◉ — point of jump

Corollary 2.5 (Uncertainty principle for the Zak transform): *Let* $\mathcal{G}(g,1,1)$ *be a Gabor orthonormal basis for* $L^2(\mathbb{R})$. *Then*, $\nabla Z(g)\notin L^2(Q)$.

Corollary 2.5 follows immediately from Theorems 1.2 and 2.3.

Example 2.6: Theorem 2.3 is sharp in the following sense. Consider the following family of functions $H_a(x,\xi)$ introduced in Ref. 3.

(1) Let $\varphi\in\mathcal{C}^\infty(\mathbb{R})$ be a function with the following properties:

$$\varphi(x)=-1 \quad \text{for } x\in(-\infty,0],$$

$$\varphi(x) = 0 \quad \text{for } x \in [1,\infty),$$

$$\varphi(x) \in [-1,0] \quad \text{for all } x \in \mathbb{R}.$$

(2) Let $\psi(x) = \chi_{[0,\infty)}(x)x^a$, where $a > 0$ is a fixed number.
(3) Given $0 < \epsilon < \frac{1}{8}$, let $\gamma \in \mathcal{C}^\infty(\mathbb{R})$ be a function that satisfies

$$\text{supp}(\gamma) \subseteq [-2\epsilon, 2\epsilon], \quad \gamma(x) = 1 \text{ for } x \in [-\epsilon, \epsilon],$$

and

$$\gamma(x) \in [0,1] \quad \text{for all } x \in \mathbb{R}.$$

Then, there exists a function $H_a : [-\frac{1}{2}, 1] \times \mathbb{I}$, with the following properties:

(1) $H_a(x,\xi) = 0$ for $x \in [-\frac{1}{2}, 0]$;
(2) $H_\alpha(x,\xi) = \varphi(\xi/\psi(x))$ for $x \in (0, 2\epsilon]$, where $\epsilon > 0$ is chosen for the definition of γ;
(3) $H_a(x,0) = 0$ for $x \in [-\frac{1}{2}, 0]$ and $H_a(x,0) = -1$ for $x \in (0,1]$;
(4) $H_a(1+x,\xi) = H(x,\xi) + (\xi - 1)$ for $x \in [-\frac{1}{2}, 0]$; and
(5) the function $e^{2\pi i H(x,\xi)} : [-\frac{1}{2}, 1] \times \mathbb{T} \to \mathbb{C}$ is of class $\mathcal{C}^\infty$ away from the points (0,0) and (1,0).

These functions were proven to be optimal for the classical (p,q) Balian-Low theorem in Ref. 3. However, it is clear that they are also optimal functions for Theorem 2.3, in the sense that they possess the minimal singular support possible, consisting of a single point in Q.

For other examples of such functions we refer to Refs. 9 and 10.

The statement of Corollary 2.5 actually holds for more general systems than orthonormal bases. The following result follows from Corollary 2.5 and Theorem 1.2.

Corollary 2.7: *Let $\mathcal{G}(g,1,1)$ be a Gabor-Riesz basis for $L^2(\mathbb{R})$. Then, $\nabla Z(g) \notin L^2(Q)$.*

We close this section by showing more general estimates involving partial fractions of the Laplacian of the Zak transform of a Gabor basis generating window.

Corollary 2.8: *Let $\mathcal{G}(g,1,1)$ be a Gabor-Riesz basis for $L^2(\mathbb{R})$. Then, $\Delta^{1/p} Z(g) \notin L^p(Q)$, $1 < p < \infty$.*

Proof:

(1) Assume that $\Delta^{\alpha/2}(f) \in L^p(Q)$. Then we have that $\partial_1^\alpha(f) = \partial_1^\alpha \Delta^{-\alpha} \Delta^\alpha(f) \in L^p(Q)$, for $1 < p < \infty$. The reason for this is that the Fourier multiplier $m(\xi_1, \xi_2) := \xi_1^\alpha |\xi|^{-\alpha}$ satisfies

$$|\partial_1^{\beta_1} \partial_2^{\beta_2} m(\xi_1/2^{n_1}, \xi_2/2^{n_2})| \leq C_{\beta_1,\beta_2}, \tag{2.6}$$

for $1/2 \leq |\xi_1|, |\xi_2| \leq 2$, and consequently is bounded on $L^p(Q)$, $1 < p < \infty$, for any $\alpha > 0$ by the multiparameter Calderón-Zygmund theory (see, e.g., Ref. 5, Introduction).
(2) For $f \in C_c^\infty([0,1])$ and $1 < p < \infty$, we have the following estimate of Hölder regularity:

$$\|f\|_{\Lambda_{1/p}} \leq \|f\|_{L^p(|-1/2,3/2])} + \| |\partial_1|^{2/p} \|_{L^p(|-1/2,3/2])}. \tag{2.7}$$

(3) We replace Eq. (2.2) by Eq. (2.7), use Eq. (2.6), and repeat the main argument of the proof of Theorem 2.3 to prove Corollary 2.8. □

Remark 2.9: All the results of this section follow for Gabor systems $\mathcal{G}(g,a,b)$, $g \in L^2(\mathbb{R})$, $ab = 1$, if we use the Zak transform Z_a defined by

$$Z_a(g)(x,\xi) = \sum_{n \in \mathbf{Z}} g(x - an) e^{2\pi i a n \xi},$$

see Ref. 7.

(Received 11 August 2006; accepted 30 October 2006; published online 13 December 2006)

In this paper, we investigate Euler-box scheme for Bridges' multisymplectic form of Maxwell's equations. A new multisymplectic scheme is derived for Maxwell's equations. We prove that it is also a self-adjoint scheme in time direction. The multisymplecticity of composition schemes based on the new scheme is also discussed. Two numerical examples are proposed to indicate that the derived multisymplectic schemes are effective when used to integrate the 2+1 dimensional Maxwell's equations. © *2006 American Institute of Physics.*

I. INTRODUCTION

Maxwell's equations describe the fundamental evolutions of electromagnetic fields in space and time. They have been applied to a wide range of different physical situations. They play an important role in a large number of engineering applications. In many cases, numerical methods are required to solve Maxwell's equations.

The computations of electromagnetics have developed for a long time and many efficient methods have been given. The famous time-domain technique in computational electromagnetic (CEM) was developed by Yee.[1] The method, generally referred as the finite-difference time-domain method,[2] is based on staggered central differencing in space and staggered leapfrog integration in time for Cartesian coordinates. Finite volumes were introduced to CEM by Shankar *et al.*[3] by exporting methods from computational fluid dynamics. Their early work used structured grids, but lately they have turned to unstructured grids. Their main reason for doing so is the difficulty of creating a global body-conforming grid for realistic geometries, such as a complete aircraft. The spectral-domain split-operator technique proposed in Ref. 4 is one of the many forms that results from the use of the Lie-Trotter-Suzuki product formulas. This technique makes use of fast Fourier transforms to compute the matrix exponentials of the displacement operators. Due to

[a)]Electronic mail: wangyushun@njnu.edu.cn

the practical interests, more and more researchers have done their important contributions on the numerical approximations to Maxwell's equations and also on the analysis of the numerical scheme.

In 1990s, the symplectic schemes were introduced and systematically developed for the Hamiltonian systems within the framework of symplectic geometry.[5–7] The Hamiltonian nature of Maxwell's equations was revealed by Morrison[8] and Marsden and Weinstein[9] in their work on the Maxwell-Vlasov equation. The symplectic schemes which preserve the Hamiltonian nature of Maxwell's equations were reported to have higher performance over the nonsymplectic schemes.[10,11] Recently, Marsden *et al.*[12] and Bridges and Reich[13] proposed the concept of multisymplectic partial differential equations (PDEs) and multisymplectic schemes which can be viewed as the generalization of symplectic schemes. The multisymplectic schemes have been applied successfully to lots of important equations such as the nonlinear wave equation,[13–15] the nonlinear Schrödinger equation,[16–18] the Korteweg–de Vries equation,[19,20] the Zakharov-Kuznetsov equation,[21] Kadomtsev-Petviashvili equation,[22] and so on. With regard to details, please refer to the new published survey by Bridges and Reich[23] and the references therein. By many computational experiments and theoretical analysis, the multisymplectic schemes were shown to be much superior to other standard methods in the performance of numerical stability in long time computation.

The main purpose of this paper is to check whether the multisymplectic scheme could be applied to integrate Maxwell's equations and still have good numerical performance. We develop a new self-adjoint scheme in time direction for solving the time-domain Maxwell's equations. The composition scheme based on the new scheme is also derived.

This paper is organized as follows In Sec. II, we take a brief review of multisymplectic Bridges' form for Maxwell's equations. A self-adjoint scheme is derived based on Bridges' form in Sec. III. The truncation error of the new scheme is also discussed in the same section. In Sec. IV, we use the self-adjoint scheme to get a composition scheme in time direction. In Sec. V, numerical experiments are presented to indicate the merits of the multisymplectic schemes and we finish the paper with conclusion remarks in Sec. VI.

II. MULTISYMPLECTIC FORMULATION FOR MAXWELL'S EQUATIONS

Maxwell's equations in an isotropic, homogeneous, nondispersive medium are

$$\begin{aligned} &\frac{\partial \mathbf{B}}{\partial t} + \nabla \times \mathbf{E} = 0 \quad \text{(Faraday' s Law)}, \\ &\frac{\partial \mathbf{D}}{\partial t} - \nabla \times \mathbf{H} = 0 \quad \text{(Ampere' s Law)}, \\ &\mathbf{B} = \mu \mathbf{H}, \\ &\mathbf{D} = \varepsilon \mathbf{E}. \end{aligned} \tag{2.1}$$

In the absence of impressed electric charge, the magnetic induction and electric displacement fields satisfy the constraints (Gauss's law)

$$\begin{aligned} &\nabla \cdot \mathbf{B} = 0, \\ &\nabla \cdot \mathbf{D} = 0. \end{aligned} \tag{2.2}$$

Scattering obstacles will be modeled by a spatial variation of ε and μ. In free space, ε and μ are constant, equal to their minimum values ε_0 and μ_0. The speed of light in free space is $c = 1/\sqrt{\varepsilon_0 \mu_0}$.

Introduce two vector functions $\mathbf{U}$ and $\mathbf{V}$ satisfying $\mathbf{U}_t=\mathbf{E}$ and $\mathbf{V}_t=\mathbf{H}$, respectively, then the Lagrangian for Maxwell's equations [Eq. (2.1)] can be written as

$$L=\frac{1}{2}\mu\langle\mathbf{V}_t,\mathbf{V}_t\rangle+\frac{1}{2}\langle\mathbf{V}_t,\boldsymbol{\nabla}\times\mathbf{U}\rangle+\frac{1}{2}\varepsilon\langle\mathbf{U}_t,\mathbf{U}_t\rangle-\frac{1}{2}\langle\mathbf{U}_t,\boldsymbol{\nabla}\times\mathbf{V}\rangle, \tag{2.3}$$

where $\langle\cdot,\cdot\rangle$ represents the standard inner production of vector space. According to Bridges' theory on multisymplectic structure, the generalized conjugate momentums can be derived by covariant Legendre transform correspondingly,

$$\begin{aligned}\mathbf{P}&=\frac{\partial\mathbf{L}}{\partial\mathbf{V}_t}=\mu\mathbf{V}_t+\frac{1}{2}\boldsymbol{\nabla}\times\mathbf{U},\quad \frac{\partial L}{\partial\boldsymbol{\nabla}\times\mathbf{V}}=-\frac{1}{2}\mathbf{U}_t,\\ \mathbf{Q}&=\frac{\partial L}{\partial\mathbf{U}_t}=\varepsilon\mathbf{U}_t-\frac{1}{2}\boldsymbol{\nabla}\times\mathbf{V},\quad \frac{\partial L}{\partial\boldsymbol{\nabla}\times\mathbf{U}}=\frac{1}{2}\mathbf{V}_t,\end{aligned} \tag{2.4}$$

further the covariant Hamiltonian by

$$\begin{aligned}S&=\langle\mathbf{P},\mathbf{V}_t\rangle+\langle\mathbf{Q},\mathbf{U}_t\rangle+\left\langle\frac{\partial L}{\partial\boldsymbol{\nabla}\times\mathbf{V}},\boldsymbol{\nabla}\times\mathbf{V}\right\rangle+\left\langle\frac{\partial L}{\partial\boldsymbol{\nabla}\times\mathbf{U}},\boldsymbol{\nabla}\times\mathbf{U}\right\rangle-L\\ &=\langle\mathbf{P},\mathbf{H}\rangle+\langle\mathbf{Q},\mathbf{E}\rangle-\frac{1}{2}\mu\langle\mathbf{H},\mathbf{H}\rangle-\frac{1}{2}\varepsilon\langle\mathbf{E},\mathbf{E}\rangle.\end{aligned} \tag{2.5}$$

Set $Z=[\mathbf{H},\mathbf{E},\mathbf{V},\mathbf{U},\mathbf{P},\mathbf{Q}]^T$, then Maxwell's equations are transformed into the following form:

$$\begin{aligned}\frac{1}{2}\boldsymbol{\nabla}\times\mathbf{U}&=\mathbf{P}-\mu\mathbf{H},\\ -\frac{1}{2}\boldsymbol{\nabla}\times\mathbf{V}&=\mathbf{Q}-\varepsilon\mathbf{E},\\ -\mathbf{P}_t-\frac{1}{2}\boldsymbol{\nabla}\times\mathbf{E}&=0,\\ -\mathbf{Q}_t+\frac{1}{2}\boldsymbol{\nabla}\times\mathbf{H}&=0,\\ \mathbf{V}_t&=\mathbf{H},\\ \mathbf{U}_t&=\mathbf{E}.\end{aligned} \tag{2.6}$$

The above equations can be organized into Bridges' multisymplectic form as

$$MZ_t+N\boldsymbol{\nabla}\times Z=\boldsymbol{\nabla}_Z S(Z), \tag{2.7}$$

where

$$M = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -I & 0 \\ 0 & 0 & 0 & 0 & 0 & -I \\ 0 & 0 & I & 0 & 0 & 0 \\ 0 & 0 & 0 & I & 0 & 0 \end{pmatrix},$$

I is the identity element belonging to $R^{3\times 3}$. The rotation action $\nabla \times Z$ denotes $[\nabla \times \mathbf{H}, \nabla \times \mathbf{E}, \nabla \times \mathbf{V}, \nabla \times \mathbf{U}, \nabla \times \mathbf{P}, \nabla \times \mathbf{Q}]^T$ and

$$N\nabla \times Z = FZ_x + LZ_y + WZ_z, \tag{2.8}$$

where

$$F = \begin{pmatrix} 0 & 0 & 0 & (1/2)R_1 & 0 & 0 \\ 0 & 0 & -(1/2)R_1 & 0 & 0 & 0 \\ 0 & -(1/2)R_1 & 0 & 0 & 0 & 0 \\ (1/2)R_1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$L = \begin{pmatrix} 0 & 0 & 0 & (1/2)R_2 & 0 & 0 \\ 0 & 0 & -(1/2)R_2 & 0 & 0 & 0 \\ 0 & -(1/2)R_2 & 0 & 0 & 0 & 0 \\ (1/2)R_2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$W = \begin{pmatrix} 0 & 0 & 0 & (1/2)R_3 & 0 & 0 \\ 0 & 0 & -(1/2)R_3 & 0 & 0 & 0 \\ 0 & -(1/2)R_3 & 0 & 0 & 0 & 0 \\ (1/2)R_3 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$R_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad R_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad R_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Thus we easily find that matrices M, F, L, and W ($\in R^{18\times 18}$) are skew symmetric. Additionally the rotation operator may be simplified as $\nabla \times = R_1(\partial/\partial x) + R_2(\partial/\partial y) + R_3(\partial/\partial z)$.

To simplify the notation we will mainly consider twodimensional problems. In two dimensions, Eq. (2.1) decouples into two independent sets of equations, each representing a distinct polarization. We shall use as our model system of equations those of the transverse magnetic polarization, where the electric field is a scalar while the magnetic field is a plane vector,

$$\frac{\partial E_z}{\partial t} = \frac{1}{\varepsilon}\left(\frac{\partial H_y}{\partial x} - \frac{\partial H_x}{\partial y}\right),$$

$$\frac{\partial H_x}{\partial t} = -\frac{1}{\mu}\frac{\partial E_z}{\partial y}, \tag{2.9}$$

$$\frac{\partial H_y}{\partial t} = \frac{1}{\mu}\frac{\partial E_z}{\partial x}.$$

In two dimensions, Eq. (2.7) can be written as follows:

$$MZ_t + FZ_x + LZ_y = \nabla_Z S(Z), \tag{2.10}$$

where M, F, and L are the same as Eq. (2.8).

Because $M, F, L \in R^{18\times 18}$ are skew-symmetric matrices and $S: R^n \to R$ is a smooth function of the state variable $Z(x,y,t)$, it can be shown that the multisymplectic PDEs [Eq. (2.10)] satisfies the following multisymplectic conservation law according to Bridges' theory:

$$\frac{\partial \omega}{\partial t} + \frac{\partial \varphi}{\partial x} + \frac{\partial \psi}{\partial y} = 0, \tag{2.11}$$

where

$$\omega = \frac{1}{2}(dZ \wedge MdZ), \quad \varphi = \frac{1}{2}(dZ \wedge FdZ), \quad \psi = \frac{1}{2}(dZ \wedge LdZ). \tag{2.12}$$

III. MULTISYMPLECTIC SELF-ADJOINT SCHEME

Because Eq. (2.10) preserves multisymplectic conservation law, naturally, when discreting Hamiltonian PDEs [Eq. (2.10)] by a numerical scheme, we also expect that the multisymplectic conservation law [Eq. (2.11)] should be preserved. Bridges and Reich defined a numerical scheme as a multisymplectic scheme if the scheme preserves a discrete multisymplectic conservation law.[13]

In the conventional schemes, the Preissman scheme[13] and the Euler-box scheme[24] for the PDEs [Eq. (2.10)] are shown to be multisymplectic. The multisymplectic Preissman scheme has been hot in the last few years,[15–22] whereas there were few reports for the multisymplectic Euler-box scheme. In the following, we will investigate the Euler-box scheme for Maxwell's equations. Set t_k, $k=1,2,\ldots$; x_i, $i=1,2,\ldots,M$; and y_j, $j=1,2,\ldots,N$ be the regular grids of the integral domain, $Z^n_{i,j}$ is an approximation to $Z(x_i,y_j,t_n)$, $\Delta t = t_{k+1} - t_k$ is the time step, $\Delta x = x_{i+1} - x_i$ is the x-direction step, and $\Delta y = y_{j+1} - y_j$ is the y-direction step.

We take the following splitting for the matrices M, F, and L in the multisymplectic PDEs [Eq. (2.10)]:

$$M = M_+ + M_-, \quad F = F_+ + F_-, \quad L = L_+ + L_-, \tag{3.1}$$

where $M_+^T = -M_-, F_+^T = -F_-$, and $L_+^T = -L_-$, then rewrite the PDEs as

$$M_+Z_t + M_-Z_t + F_+Z_x + F_-Z_x + L_+Z_y + L_-Z_y = \nabla_Z S(Z). \tag{3.2}$$

Consider the following so-called Euler-box scheme for the above PDEs [Eq. (3.2)]:

$$M_+\delta_t^+ Z_{i,j}^k + M_-\delta_t^- Z_{i,j}^k + F_+\delta_x^+ Z_{i,j}^k + F_-\delta_x^- Z_{i,j}^k + L_+\delta_y^+ Z_{i,j}^k + L_-\delta_y^- Z_{i,j}^k = \nabla_Z S(Z_{i,j}^k), \tag{3.3}$$

where

$$\delta_t^\pm Z_{i,j}^k = \pm\frac{Z_{i,j}^{k\pm1} - Z_{i,j}^k}{\Delta t}, \quad \delta_x^\pm Z_{i,j}^k = \pm\frac{Z_{i\pm1,j}^k - Z_{i,j}^k}{\Delta x}, \quad \delta_y^\pm Z_{i,j}^k = \pm\frac{Z_{i,j\pm1}^k - Z_{i,j}^k}{\Delta y},$$

with the special matrices splitting as

$$M_+ = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -I & 0 \\ 0 & 0 & 0 & 0 & 0 & -I \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad F_+ = \begin{pmatrix} 0 & 0 & 0 & R_1/2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -R_1/2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$L_+ = \begin{pmatrix} 0 & 0 & 0 & R_2/2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -R_2/2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{3.4}$$

Theorem 3.1: *The Euler-box scheme [Eq. (3.3)] is multisymplectic with the following discrete multisymplectic conservation law:*

$$\delta_t^+ \omega_{ij}^k + \delta_x^+ \varphi_{ij}^k + \delta_y^+ \psi_{ij}^k = 0, \tag{3.5}$$

where $\omega_{i,j}^k = dZ_{i,j}^{k-1} \wedge M_+ dZ_{i,j}^k$, $\varphi_{i,j}^k = dZ_{i-1,j}^k \wedge F_+ dZ_{i,j}^k$, and $\psi_{i,j}^k = dZ_{i,j-1}^k \wedge L_+ dZ_{i,j}^k$.

Proof: Consider the variational equations of Eq. (3.3),

$$M_+ \delta_t^+ dZ_{i,j}^k + M_- \delta_t^- dZ_{i,j}^k + F_+ \delta_x^+ dZ_{i,j}^k + F_- \delta_x^- dZ_{i,j}^k + L_+ \delta_y^+ dZ_{i,j}^k + L_- \delta_y^- dZ_{i,j}^k = \nabla_{ZZ} S(Z_{i,j}^k) dZ_{i,j}^k. \tag{3.6}$$

By Eq. (3.6), we have

$$\begin{aligned} 0 &= dZ_{i,j}^k \wedge \nabla_{ZZ} S(Z_{i,j}^k) dZ_{i,j}^k = dZ_{i,j}^k \wedge M_+ \delta_t^+ dZ_{i,j}^k + dZ_{i,j}^k \wedge M_- \delta_t^- dZ_{i,j}^k + dZ_{i,j}^k \wedge F_+ \delta_x^+ dZ_{i,j}^k \\ &\quad + dZ_{i,j}^k \wedge F_- \delta_x^- dZ_{i,j}^k + dZ_{i,j}^k \wedge L_+ \delta_y^+ dZ_{i,j}^k + dZ_{i,j}^k \wedge L_- \delta_y^- dZ_{i,j}^k = dZ_{i,j}^k \wedge M_+ \delta_t^+ dZ_{i,j}^k + \delta_t^- dZ_{i,j}^k \wedge M_+ dZ_{i,j}^k \\ &\quad + dZ_{i,j}^k \wedge F_+ \delta_x^+ dZ_{i,j}^k + \delta_x^- dZ_{i,j}^k \wedge F_+ dZ_{i,j}^k + dZ_{i,j}^k \wedge L_+ \delta_y^+ dZ_{i,j}^k + \delta_y^- dZ_{i,j}^k \wedge L_+ dZ_{i,j}^k \\ &= \delta_t^+ (dZ_{i,j}^{k-1} \wedge M_+ dZ_{i,j}^k) + \delta_x^+ (dZ_{i-1,j}^k \wedge F_+ dZ_{i,j}^k) + \delta_y^+ (dZ_{i,j-1}^k \wedge L_+ dZ_{i,j}^k) = \delta_t^+ \omega_{ij}^k + \delta_x^+ \varphi_{ij}^k + \delta_y^+ \psi_{ij}^k . \square \end{aligned}$$

The multisymplecticity of the 1+1 dimensional Euler-box scheme is proved by Moore and Reich in Ref. 24. Next we derive a new scheme which is equivalent to the multisymplectic scheme [Eq. (3.3)]. Recast scheme (3.3) into the following form:

$$M_+ \delta_t^+ Z_{i,j}^k + M_- \delta_t^- Z_{i,j}^k + N\nabla^+ \times Z_{i,j}^k + N\nabla^- \times Z_{i,j}^k = \nabla_Z S(Z_{i,j}^k), \tag{3.7}$$

where

$$M_+ = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -I & 0 \\ 0 & 0 & 0 & 0 & 0 & -I \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad N\nabla^+ \times = \begin{pmatrix} 0 & 0 & 0 & (1/2)\nabla^+ \times & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -(1/2)\nabla^+ \times & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$N\nabla^{-}\times=\begin{pmatrix}0&0&0&0&0&0\\0&0&-(1/2)\nabla^{-}\times&0&0&0\\0&0&0&0&0&0\\(1/2)\nabla^{-}\times&0&0&0&0&0\\0&0&0&0&0&0\\0&0&0&0&0&0\end{pmatrix},$$

$$\nabla^{+}\times=\begin{pmatrix}0&0&\partial/\partial y\\0&0&-\partial/\partial x\\-\partial/\partial y&\partial/\partial x&0\end{pmatrix}^{+}=\begin{pmatrix}0&0&\delta_y^{+}\\0&0&-\delta_x^{+}\\-\delta_y^{+}&\delta_x^{+}&0\end{pmatrix},\quad \nabla^{-}\times=\begin{pmatrix}0&0&\delta_y^{-}\\0&0&-\delta_x^{-}\\-\delta_y^{-}&\delta_x^{-}&0\end{pmatrix}.$$

Substituting $M_{+},M_{-},N\nabla^{+}\times,N\nabla^{-}\times$, and $Z_{i,j}^{k}=[\mathbf{H}_{i,j}^{k},\mathbf{E}_{i,j}^{k},\mathbf{V}_{i,j}^{k},\mathbf{U}_{i,j}^{k},\mathbf{P}_{i,j}^{k},\mathbf{Q}_{i,j}^{k}]^{T}$ into Eq. (3.7), we have

$$\begin{aligned}&\frac{1}{2}\nabla^{+}\times\mathbf{U}_{i,j}^{k}=\mathbf{P}_{i,j}^{k}-\mu\mathbf{H}_{i,j}^{k},\\&-\frac{1}{2}\nabla^{-}\times\mathbf{V}_{i,j}^{k}=\mathbf{Q}_{i,j}^{k}-\varepsilon\mathbf{E}_{i,j}^{k},\\&-\delta_t^{+}\mathbf{P}_{i,j}^{k}-\frac{1}{2}\nabla^{+}\times\mathbf{E}_{i,j}^{k}=0,\\&-\delta_t^{+}\mathbf{Q}_{i,j}^{k}+\frac{1}{2}\nabla^{-}\times\mathbf{H}_{i,j}^{k}=0,\\&\delta_t^{-}\mathbf{V}_{i,j}^{k}=\mathbf{H}_{i,j}^{k},\\&\delta_t^{-}\mathbf{U}_{i,j}^{k}=\mathbf{E}_{i,j}^{k}.\end{aligned}\tag{3.8}$$

We can eliminate the auxiliary variables $\mathbf{P}_{i,j}^{k}$, $\mathbf{Q}_{i,j}^{k}$, $\mathbf{U}_{i,j}^{k}$, and $\mathbf{V}_{i,j}^{k}$ and derive formulas that only contain $\mathbf{E}_{i,j}^{k}$ and $\mathbf{H}_{i,j}^{k}$.

$$\begin{aligned}&\nabla^{+}\times\mathbf{E}_{i,j}^{k}=-\nabla^{+}\times\mathbf{E}_{i,j}^{k-1}-2\mu\delta_t^{-}\mathbf{H}_{i,j}^{k},\\&-\nabla^{-}\times\mathbf{H}_{i,j}^{k}=\nabla^{-}\times\mathbf{H}_{i,j}^{k-1}-2\varepsilon\delta_t^{-}\mathbf{E}_{i,j}^{k}.\end{aligned}\tag{3.9}$$

Substituting $\mathbf{E}_{i,j}^{k}=[0,0,E_{zi,j}^{k}]^{T}$, $\mathbf{H}_{i,j}^{k}=[H_{xi,j}^{k},H_{yi,j}^{k},0]^{T}$, and $\nabla^{+}\times$, $\nabla^{-}\times$ defined in Eq. (3.7) into Eq. (3.9), we obtain

$$\begin{aligned}&\delta_y^{+}E_{zi,j}^{k}=-\delta_y^{+}E_{zi,j}^{k-1}-2\mu\delta_t^{-}H_{xi,j}^{k},\\&-\delta_x^{+}E_{zi,j}^{k}=\delta_x^{+}E_{zi,j}^{k-1}-2\mu\delta_t^{-}H_{yi,j}^{k},\\&-\delta_y^{-}H_{xi,j}^{k}+\delta_x^{-}H_{yi,j}^{k}=\delta_y^{-}H_{xi,j}^{k-1}-\delta_x^{-}H_{yi,j}^{k-1}+2\varepsilon\delta_t^{-}E_{zi,j}^{k}.\end{aligned}\tag{3.10}$$

Thus we obtain, by recasting Eq. (3.10) into grid points, a new scheme as

$$\frac{\Delta t}{\Delta y}(E_{zi,j+1}^{k}-E_{zi,j}^{k})+2\mu H_{xi,j}^{k}=-\frac{\Delta t}{\Delta y}(E_{zi,j+1}^{k-1}-E_{zi,j}^{k-1})+2\mu H_{xi,j}^{k-1},\tag{3.11a}$$

$$-\frac{\Delta t}{\Delta x}(E^k_{zi+1,j}-E^k_{zi,j})+2\mu H^k_{yi,j}=\frac{\Delta t}{\Delta x}(E^{k-1}_{zi+1,j}-E^{k-1}_{zi,j})+2\mu H^{k-1}_{yi,j}, \tag{3.11b}$$

$$\begin{aligned}&-\frac{\Delta t}{\Delta y}(H^k_{xi,j}-H^k_{xi,j-1})+\frac{\Delta t}{\Delta x}(H^k_{yi,j}-H^k_{yi-1,j})-2\varepsilon E^k_{zi,j}\\&=\frac{\Delta t}{\Delta y}(H^{k-1}_{xi,j}-H^{k-1}_{xi,j-1})-\frac{\Delta t}{\Delta x}(H^{k-1}_{yi,j}-H^{k-1}_{yi-1,j})-2\varepsilon E^{k-1}_{zi,j}.\end{aligned} \tag{3.11c}$$

Let us analyze the truncation error of schemes (3.11a), (3.11b), and (3.11c). Firstly, let us analyze Eq. (3.11a).

$$-\frac{1}{\mu}\left(\frac{\partial E_z}{\partial y}\right)^{k-(1/2)}_{i,j}=-\frac{1}{2\mu}\left[\left(\frac{\partial E_z}{\partial y}\right)^k_{i,j}+\left(\frac{\partial E_z}{\partial y}\right)^{k-1}_{i,j}\right]+O(\Delta t^2), \tag{3.12}$$

$$\left(\frac{\partial H_x}{\partial t}\right)^{k-(1/2)}_{i,j}=\frac{(H_x)^k_{i,j}-(H_x)^{k-1}_{i,j}}{\Delta t}+O(\Delta t^2). \tag{3.13}$$

By Eq. (2.9), we have

$$\frac{\partial H_x}{\partial t}=-\frac{1}{\mu}\frac{\partial E_z}{\partial y},$$

then

$$\left(\frac{\partial H_x}{\partial t}\right)^{k-(1/2)}_{i,j}=-\frac{1}{\mu}\left(\frac{\partial E_z}{\partial y}\right)^{k-(1/2)}_{i,j}. \tag{3.14}$$

Substituting Eq. (3.12) and (3.13) into Eq. (3.14), we obtain

$$\frac{(H_x)^k_{i,j}-(H_x)^{k-1}_{i,j}}{\Delta t}=-\frac{1}{2\mu}\left[\left(\frac{\partial E_z}{\partial y}\right)^k_{i,j}+\left(\frac{\partial E_z}{\partial y}\right)^{k-1}_{i,j}\right]+O(\Delta t^2), \tag{3.15}$$

so

$$\frac{H^k_{xi,j}-H^{k-1}_{xi,j}}{\Delta t}=-\frac{1}{2\mu}\frac{E^k_{zi,j+1}-E^k_{zi,j}}{\Delta y}-\frac{1}{2\mu}\frac{E^{k-1}_{zi,j+1}-E^{k-1}_{zi,j}}{\Delta y}+O(\Delta t^2+\Delta y). \tag{3.16}$$

Secondly, we can easily get in the similar way that the truncation errors of Eqs. (3.11b) and (3.11c) are $O(\Delta t^2+\Delta x)$ and $O(\Delta t^2+\Delta x+\Delta y)$. So the truncation error of Eq. (3.11) is $O(\Delta t^2+\Delta x+\Delta y)$.

Scheme (3.11) is an implicit scheme that involves solving a linear system of $E^k_{zi,j}$, $H^k_{xi,j}$, and $H^k_{yi,j}$ at each time step. Suppose the computational space domain is $[0,T_x]\times[0,T_y]$, T_x is period of x direction and T_y is period of y direction. $[0,T_x]$ is averagely divided by M and $[0,T_y]$ is averagely divided by N. We take numerical periodic boundary conditions as

$$E^k_{z0,j}=E^k_{zM,j},\quad E^k_{zM+1,j}=E^k_{z1,j},\quad E^k_{zi,0}=E^k_{zi,N},\quad E^k_{zi,N+1}=E^k_{zi,1}, \tag{3.17}$$

$$H^k_{x0,j}=H^k_{xM,j},\quad H^k_{xM+1,j}=H^k_{x1,j},\quad H^k_{xi,0}=E^k_{zi,N},\quad H^k_{xi,N+1}=H^k_{xi,1}, \tag{3.18}$$

$$H^k_{y0,j}=H^k_{yM,j},\quad H^k_{yM+1,j}=H^k_{y1,j},\quad H^k_{yi,0}=H^k_{yi,N},\quad H^k_{yi,N+1}=H^k_{yi,1}. \tag{3.19}$$

The arrangement of the order of equations in scheme (3.11) and the variables of the resulting linear system are trivial and technical. The properties of the coefficient matrix of the resulting

large linear system may change extremely with the different arrangements. We can make the coefficient matrix symmetric by the following arrangement. We arrange variables as

$$x^k = [x_1^k, x_2^k, x_3^k]^T,$$

$$x_1^k = [H_{y1,1}^k, H_{y2,1}^k, \ldots, H_{yM,1}^k, H_{y1,2}^k, H_{y2,2}^k, \ldots, H_{yM,2}^k, \ldots, H_{y1,N}^k, H_{y2,N}^k, \ldots, H_{yM,N}^k],$$

$$x_2^k = [E_{z1,1}^k, E_{z2,1}^k, \ldots, E_{zM,1}^k, E_{z1,2}^k, E_{z2,2}^k, \ldots, E_{zM,2}^k, \ldots, E_{z1,N}^k, E_{z2,N}^k, \ldots, E_{zM,N}^k],$$

$$x_3^k = [H_{x1,1}^k, H_{x2,1}^k, \ldots, H_{xM,1}^k, H_{x1,2}^k, H_{x2,2}^k, \ldots, H_{xM,2}^k, \ldots, H_{x1,N}^k, H_{x2,N}^k, \ldots, H_{xM,N}^k],$$

and the order of equations as Eq. (3.11b), $j=1,\ldots,N$, $i=1,\ldots,M$; Eq. (3.11c), $j=1,\ldots,N$, $i=1,\ldots,M$; and Eq. (3.11a), $j=1,\ldots,N$, $i=1,\ldots,M$. Then the resulting linear system is

$$A(\Delta t, \Delta x, \Delta y)x^{k+1} = B(\Delta t, \Delta x, \Delta y)x^k, \tag{3.20}$$

where

$$A(\Delta t, \Delta x, \Delta y) = \begin{pmatrix} A_{11} & A_{12} & 0 \\ A_{12}^T & A_{22} & A_{23} \\ 0 & A_{23}^T & A_{33} \end{pmatrix}, \quad B(\Delta t, \Delta x, \Delta y) = \begin{pmatrix} A_{11} & -A_{12} & 0 \\ -A_{12}^T & A_{22} & -A_{23} \\ 0 & -A_{23}^T & A_{33} \end{pmatrix},$$

$$A_{11} = 2\mu \begin{pmatrix} I & & & & \\ & I & & & \\ & & \cdot & & \\ & & & \cdot & \\ & & & & I \end{pmatrix}, \quad A_{22} = -2\varepsilon \begin{pmatrix} I & & & & \\ & I & & & \\ & & \cdot & & \\ & & & \cdot & \\ & & & & I \end{pmatrix},$$

$$A_{33} = 2\mu \begin{pmatrix} I & & & & \\ & I & & & \\ & & \cdot & & \\ & & & \cdot & \\ & & & & I \end{pmatrix}, \quad A_{12} = \frac{\Delta t}{\Delta x} \begin{pmatrix} C & & & & \\ & C & & & \\ & & \cdot & & \\ & & & \cdot & \\ & & & & C \end{pmatrix}, \tag{3.21}$$

$$C = \begin{pmatrix} 1 & -1 & & & & & \\ & 1 & -1 & & & & \\ & & \cdot & \cdot & & & \\ & & & \cdot & \cdot & & \\ & & & & \cdot & \cdot & \\ & & & & & 1 & -1 \\ -1 & & & & & & 1 \end{pmatrix}_{M\times M}, \quad A_{23} = \frac{\Delta t}{\Delta y} \begin{pmatrix} -I & & & & I \\ I & -I & & & \\ & I & \cdot & & \\ & & \cdot & \cdot & \\ & & & I & -I \end{pmatrix},$$

I is the identity element belonging to $R^{M\times M}$.

Obviously $A(\Delta t, \Delta x, \Delta y)$ is symmetric. Moreover the coefficient matrix $A(\Delta t, \Delta x, \Delta y)$ of Eq. (3.20) is a strictly diagonally dominant matrix, if Δt, Δx, and Δy satisfy the following condition:

$$\frac{\Delta t}{\Delta x} < \mu, \frac{\Delta t}{\Delta x} + \frac{\Delta t}{\Delta y} < \varepsilon, \frac{\Delta t}{\Delta y} < \mu, \tag{3.22}$$

Eq. (3.22) leads to

$$\Delta t < \min\left\{ \mu \min(\Delta x, \Delta y), \frac{1}{2}\varepsilon \min(\Delta x, \Delta y) \right\}. \tag{3.23}$$

IV. THE COMPOSITION SCHEME BASE ON SELF-ADJOINT SCHEME (3.11) IN TIME DIRECTION

In the theory of numerical solutions of ordinary differential equations (ODEs), composition is an important idea that a high order method based on some low-order method can be derived. The composition method for ODEs has mainly been developed by Suzuki,[25] Yoshida,[26] and McLachlan.[27] With regard to the details, we refer to Ref. 28.

First, we review briefly the composition method for the ordinary differential equations. We know that every one-step difference scheme can be written as follows:[29]

$$y_{n+1} = s(\tau) y_n,$$

where $s(\tau)$ is the operator corresponding to the difference scheme and τ is the time step length.

Definition 4.1: *Suppose there are n difference schemes whose corresponding operators are* $s_1(\tau), s_2(\tau), \ldots, s_n(\tau)$, *respectively, and their corresponding order is* $p_1, p_2, \ldots, p_n$. *If there exist constants* $c_1, c_2, \ldots, c_n$ *such that the order of the scheme whose operator is the composition* $s_1(c_1\tau)s_2(c_2\tau), \ldots, s_n(c_n\tau)$ *is m,* $m > \max(p_i)$, $i \leqslant i \leqslant n$, *then the new difference scheme is called composition scheme of the original n difference schemes. This method which is used to construct higher-order difference schemes from the lower ones is called composition method.*

Definition 4.2: *An integral operator* $s^*(\tau)$ *is called the adjoint operator of* $s(\tau)$, *if* $s^*(\tau)$ *satisfies* $s^*(-\tau)s(\tau) = s(\tau)s^*(-\tau) = I$, *where I is the identity operator.*

Definition 4.3: *An integral operator is self-adjoint operator, if* $s(\tau)$ *satisfies* $s(-\tau)s(\tau) = s(\tau) \times (-\tau) = I$, *where I is the identity operator.*

Theorem 4.1: *Any self-adjoint integral operator* $s(\tau)$ *has even order.*

Corollary 4.1: *Let* $s(\tau)$ *be a self-adjoint integrator order of* $2n$, *then the composition operator* $s(c_1\tau)s(c_2\tau)s(c_1\tau)$ *is of order* $2n+2$, *where* c_1 and c_2 *satisfy*

$$2c_1^{2n+1} + c_2^{2n+1} = 0, \quad 2c_1 + c_2 = 1.$$

The composition schemes keep the group property of the original schemes. The composition method for multisymplectic schemes has been discussed in Refs. 30 and 31. Here we only discuss the composition based on the new scheme (3.11). First, we will show that it is a self-adjoint scheme.

Equation (3.20) can be written as follows:

$$x^{k+1} = [A(\Delta t, \Delta x, \Delta y)]^{-1} B(\Delta t, \Delta x, \Delta y) x^k. \tag{4.1}$$

By Eq. (3.21), we know $-A(\Delta t, \Delta x, \Delta y) = B(-\Delta t, \Delta x, \Delta y)$ and $A(-\Delta t, \Delta x, \Delta y) = -B(\Delta t, \Delta x, \Delta y)$, then

$$\begin{aligned}&[A(-\Delta t, \Delta x, \Delta y)]^{-1} B(-\Delta t, \Delta x, \Delta y)[A(\Delta t, \Delta x, \Delta y)]^{-1} B(\Delta t, \Delta x, \Delta y)\\ &\quad = [B(\Delta t, \Delta x, \Delta y)]^{-1} A(\Delta t, \Delta x, \Delta y)[A(\Delta t, \Delta x, \Delta y)]^{-1} B(\Delta t, \Delta x, \Delta y) = I.\end{aligned}$$

Similarly,

$$[A(\Delta t, \Delta x, \Delta y)]^{-1} B(\Delta t, \Delta x, \Delta y)[A(-\Delta t, \Delta x, \Delta y)]^{-1} B(-\Delta t, \Delta x, \Delta y) = I.$$

So, $[A(\Delta t, \Delta x, \Delta y)]^{-1} B(\Delta t, \Delta x, \Delta y)$ is a self-adjoint operator. Thus, scheme (3.11) is self-adjoint.

According to Corollary 4.1, we can derive a composition scheme in the time direction based on the self-adjoint scheme,

$$x^{k+1} = [A(c_1\Delta t,\Delta x,\Delta y)]^{-1}B(c_1\Delta t,\Delta x,\Delta y)\circ[A(c_2\Delta t,\Delta x,\Delta y)]^{-1}B(c_2\Delta t,\Delta x,\Delta y)$$
$$\circ[A(c_1\Delta t,\Delta x,\Delta y)]^{-1}B(c_1\Delta t,\Delta x,\Delta y)x^k, \tag{4.2}$$

where $c_1=1/(2-\sqrt[3]{2})$ and $c_2=-\sqrt[3]{2}/(2-\sqrt[3]{2})$. The truncation error of the above composition scheme is $O(\Delta y+\Delta x+\Delta t^4)$.

Theorem 4.2: *The composition scheme (4.2) is multisymplectic with the same discrete multisymplectic conservation law [Eq. (3.5)].*

Proof: *The implementation of the composition scheme is divided into the following three steps:*

$$x^k \to x^{k+c_1\Delta t} \to x^{k+(c_1+c_2)\Delta t} \to x^{k+(2c_1+c_2)\Delta t} = x^{k+1}.$$

By Theorem 3.1, we know that the first step $x^k \to x^{k+c_1\Delta t}$ preserves the multisymplectic conservation law,

$$\omega_{ij}^{k+c_1\Delta t} - \omega_{ij}^k = -c_1\Delta t(\delta_x^+\varphi_{ij}^k + \delta_y^+\psi_{ij}^k). \tag{4.3}$$

Similarly, multisymplectic conservation laws,

$$\omega_{ij}^{k+(c_1+c_2)\Delta t} - \omega_{ij}^{k+c_1\Delta t} = -c_2\Delta t(\delta_x^+\varphi_{ij}^k + \delta_y^+\psi_{ij}^k) \tag{4.4}$$

and

$$\omega_{ij}^{k+1} - \omega_{ij}^{k+(c_1+c_2)\Delta t} = -c_1\Delta t(\delta_x^+\varphi_{ij}^k + \delta_y^+\psi_{ij}^k), \tag{4.5}$$

should be preserved by the next steps, respectively.

Then, Eq. (4.3)+Eq. (4.4)+Eq. (4.5) leads to

$$\omega_{ij}^{k+1} - \omega_{ij}^k = -(2c_1+c_2)\Delta t(\delta_x^+\varphi_{ij}^k + \delta_y^+\psi_{ij}^k). \tag{4.6}$$

Because of $2c_1+c_2=1$, Eq. (4.6) is just Eq. (3.5). □

V. NUMERICAL EXPERIMENTS

This section provides numerical experiments for testing the new derived multisymplectic scheme [Eq. (3.11)] and the composition scheme [Eq. (4.2)]. Scheme (3.11) is denoted by MS and Eq. (4.2) is denoted by CMS. On numerical experiments of Maxwell's equations, there have been many references with more details. In the following numerical examples, we only discuss the closed homogeneous domain and take the numerical periodic boundary conditions as Eqs. (3.17)–(3.19). At the same time, we take $h=\Delta x=\Delta y$ and make Δt satisfy Eq. (3.23) to ensure the symmetry and strictly diagonal dominance of the coefficient matrix and we use GMRES(m) method to solve linear system. In each subinterval $[t^k,t^{k+1}]$, we only need to solve a system of equations $A(\Delta t,\Delta x,\Delta y)x^{k+1}=B(\Delta t,\Delta x,\Delta y)x^k$. Suppose that $\hat{E}_z(x,y,t)$ is the exact solution and $E_{z,i,j}^k$ is the numerical solution. We denote the maximum error and L_2 error at time $t=t_k$, respectively, by

$$\text{error}_{\max} = \max_{i,j}|\hat{E}_z(x_i,y_j,t_k) - E_{z,i,j}^k|,$$

$$\|\text{error}\|_{L_2} = h\sqrt{\sum_{i,j}(\hat{E}_z(x_i,y_j,t_k) - E_{z,i,j}^k)^2}.$$

The numerical results show that both MS and CMS can work well. By comparison, we can find that CMS has an improvement in accuracy of the solution for long time computation over MS.

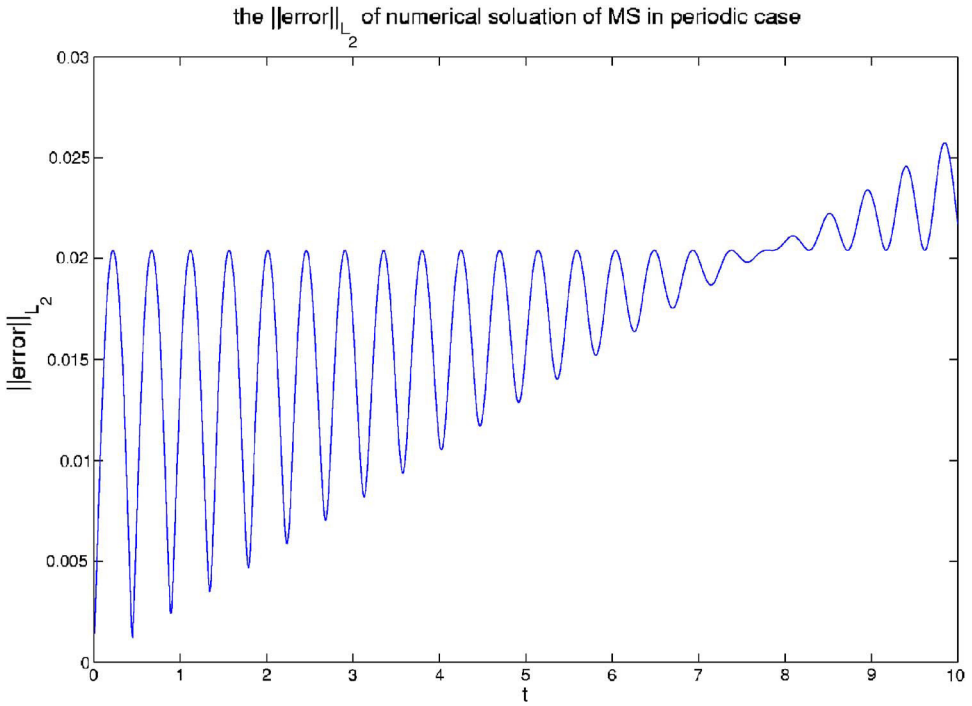

FIG. 1. The $\|\text{error}\|_{L_2}$ of MS, where $h=1/120$ and $\Delta t=1/100$.

Firstly, let us pay attention to the following example. We prescribe initial conditions as follows:

$$E_z(x,y,0)=0,$$

$$H_y(x,y,0)=-\frac{3}{\sqrt{5}}\cos(3\pi x)\sin(\pi y),$$

$$H_x(x,y,0)=\frac{1}{\sqrt{5}}\sin(3\pi x)\cos(\pi y).$$

We test the two schemes on a space domain $[0,\frac{2}{3}]\times[0,2]$. If $\mu=1$ and $\varepsilon=2$, the exact solution is

$$E_z(x,y,t)=\sin(3\pi x)\sin(\pi y)\sin(\sqrt{5}\pi t),$$

$$H_y(x,y,t)=-\frac{3}{\sqrt{5}}\cos(3\pi x)\sin(\pi y)\cos(\sqrt{5}\pi t),$$

$$H_x(x,y,t)=\frac{1}{\sqrt{5}}\sin(3\pi x)\cos(\pi y)\cos(\sqrt{5}\pi t).$$

Figures 1 and 2 show $\|\text{error}\|_{L_2}$ of MS and CMS under the same conditions of the space step and the temporal step. From Figs. 1 and 2, we can easily find that the error of MS can be controlled effectively before $t=8$, but CMS can be controlled effectively until $t=22$.

Figures 3 and 4 show, respectively, $\|\text{error}\|_{L_2}$ of MS and CMS with the same space step $h=1/180$. By Figs. 3 and 4, we can observe that the global error of the two schemes are almost the

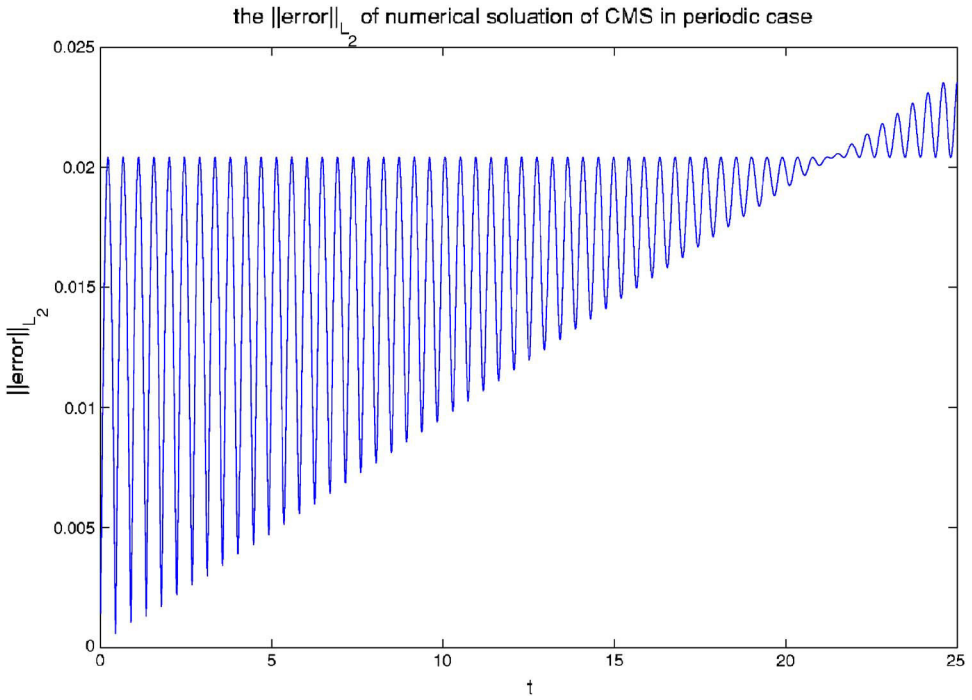

FIG. 2. The $\|\text{error}\|_{L_2}$ of CMS, where $h=1/120$ and $\Delta t=1/100$.

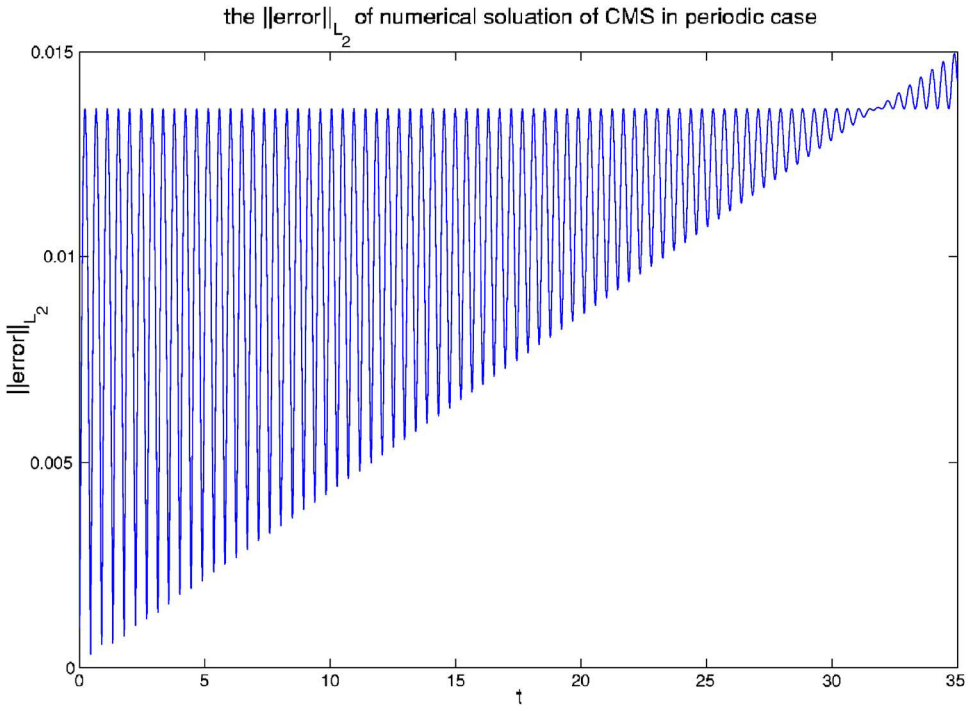

FIG. 3. The $\|\text{error}\|_{L_2}$ of CMS, where $h=1/180$ and $\Delta t=1/100$.

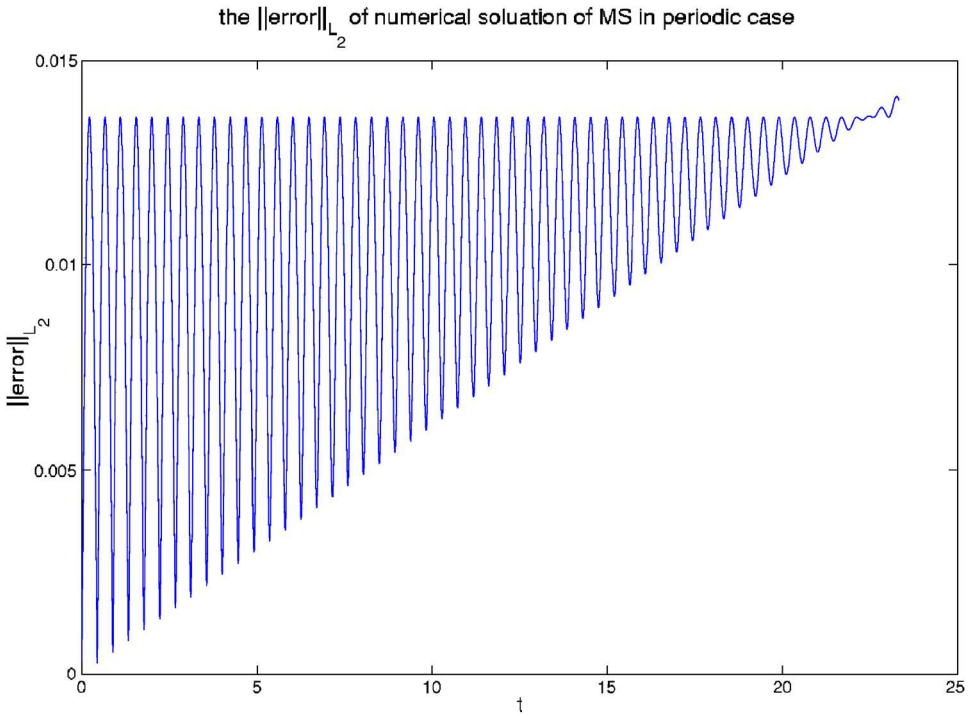

FIG. 4. The $\|\text{error}\|_{L_2}$ of MS, where $h=1/180$ and $\Delta t=1/300$.

same. However, it is worthy to mention that the time step taken for the MS is smaller than the CMS. Moreover, the time that the $\|\text{error}\|_{L_2}$ of CMS can be controlled is $t<33$, but it is only $t<22$ for MS.

Figures 5 and 6 have the same phenomenon about $\text{error}_{\max}$. Through comparison, it is easy to find that CMS is more effective in computation with long time step than MS.

Secondly, we consider another example. We prescribe initial conditions as follows:

$$E_z(x,y,0)=\sin(3\pi x)\sin(4\pi y),$$

$$H_y(x,y,0)=-\frac{3}{5}\sin(3\pi x)\sin(4\pi y),$$

$$H_x(x,y,0)=-\frac{4}{5}\cos(3\pi x)\cos(4\pi y).$$

If $\mu=1$ and $\varepsilon=1$, the exact solution is

$$E_z(x,y,t)=\sin(3\pi x-5\pi t)\sin(4\pi y),$$

$$H_y(x,y,t)=-\frac{3}{5}\sin(3\pi x-5\pi t)\sin(4\pi y),$$

$$H_x(x,y,t)=-\frac{4}{5}\cos(3\pi x-5\pi t)\cos(4\pi y).$$

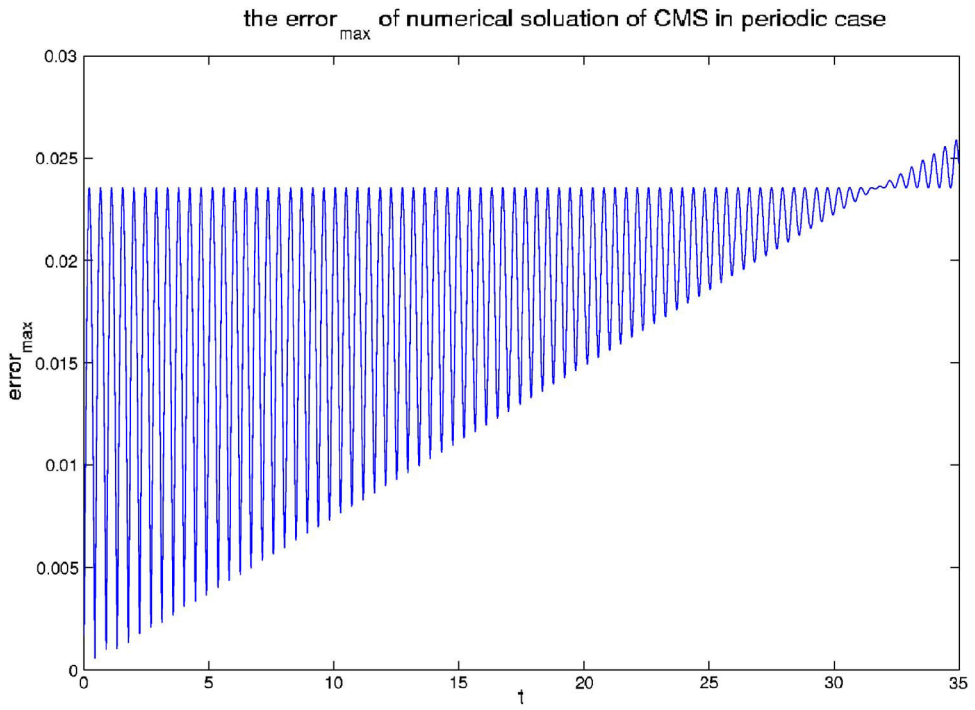

FIG. 5. The $\text{error}_{\max}$ of CMS, where $h=1/180$ and $\Delta t=1/100$.

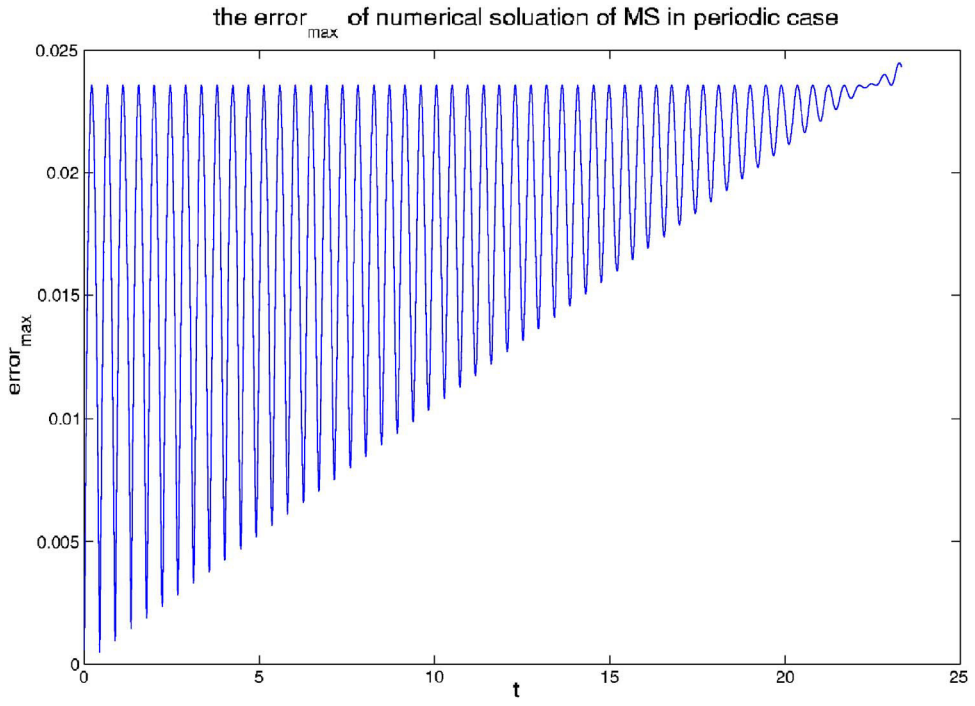

FIG. 6. The $\text{error}_{\max}$ of MS, where $h=1/180$ and $\Delta t=1/300$.

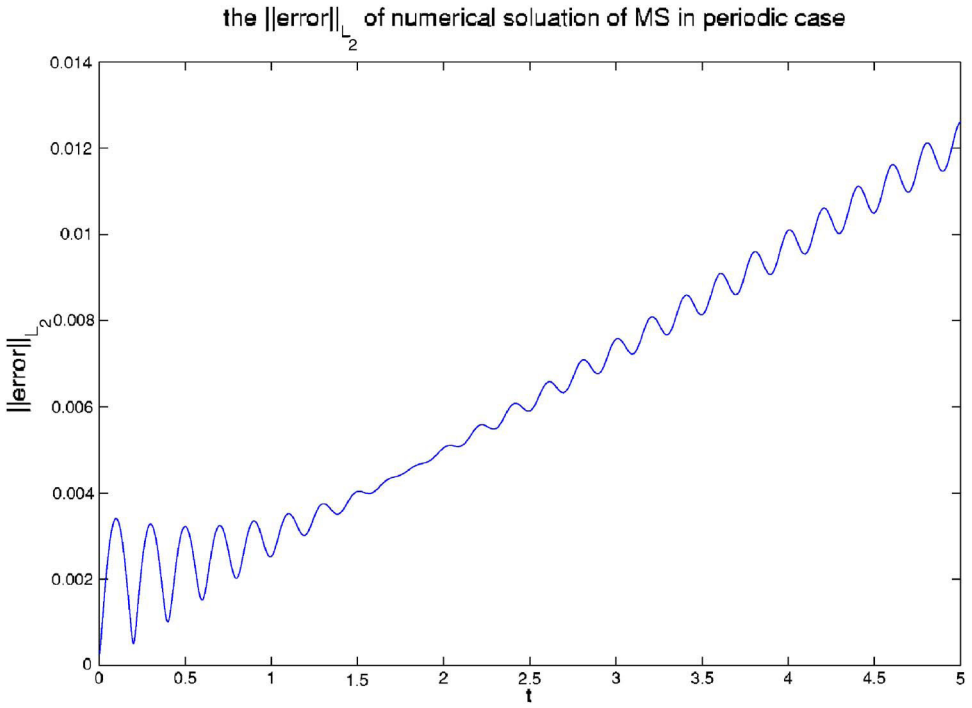

FIG. 7. The $\|\text{error}\|_{L_2}$ of MS, where $h=1/360$ and $\Delta t=1/200$.

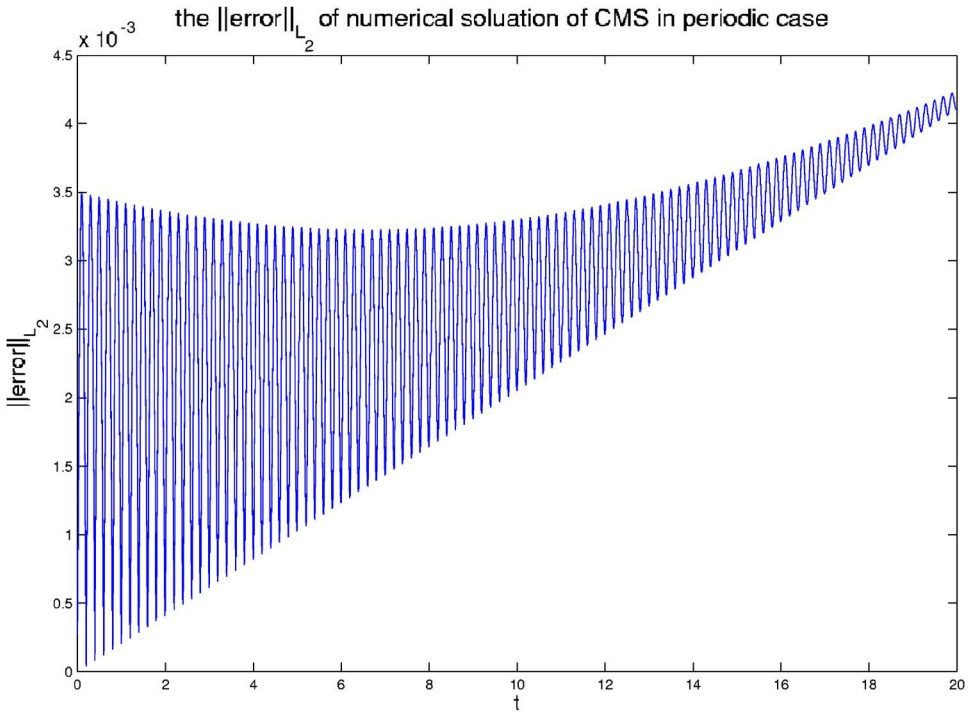

FIG. 8. The $\|\text{error}\|_{L_2}$ of CMS, where $h=1/360$ and $\Delta t=1/200$.

Here, we give the $\|\text{error}\|_{L_2}$ of MS and CMS with $h=1/360$ and $\Delta t=1/200$ in Figs. 7 and 8 correspondingly. The computational space domain is $[0,\frac{2}{3}]\times[0,\frac{1}{2}]$. The $\text{error}_{\max}$ has the same trend as $\|\text{error}\|_{L_2}$.

Remark:

1. The $\|\text{error}\|_{L_2}$ of CMS has no improvement over MS from the very beginning period of time because both schemes are of order one in space direction which is the dominating order in the truncation errors.
2. CMS is better than MS in long time computation because CMS is of the order of 4 in time, whereas MS is of 2. How to improve the truncation error in space direction is still a problem and worthy of paying more attention.

VI. CONCLUDING REMARKS

In this paper, we derived a new multisymplectic self-adjoint scheme from Bridges' form for Maxwell's equations. Based on the newly derived scheme, we obtain the composition scheme in time direction. Numerical experiments indicate that both the multisymplectic scheme and its composition scheme can work well and the composition scheme is more effective in long time computation. Though our numerical experiments are carried on two dimensional Maxwell's equations, the method of this paper can be extended into three dimensions with variable coefficients ε and μ. Actually, the multisymplectic structures [Eqs. (2.7) and (3.9)] are for the three dimensional Maxwell's equations. The multisymplectic structure and multisymplectic scheme provide a new viewpoint to study the electromagnetic wave equations.

Clifford representations in integrable systems

Birgit Wehefritz-Kaufmann[a)]

(Received 4 August 2006; accepted 27 October 2006; published online 21 December 2006)

In this paper we analyze integrable systems from a Clifford algebra point of view. This approach allows us to give a clear representation theoretic exposition of techniques used in spin systems, thereby showing their naturality. We then extend this approach to the analysis of the XX-model with nondiagonal boundaries which is among others related to growing and fluctuating interfaces and stochastic reaction-diffusion systems. With this rationale, it is possible to diagonalize the system and find new hidden conservation laws. © *2006 American Institute of Physics.*

INTRODUCTION

The use of Clifford operators to "fermionize" a problem goes back to Ref. 1. The potential this approach has in solving spin-chain problems was first demonstrated in Ref. 2; see Refs. 3–6 for other early sources. There has been a lot of work in this direction, Refs. 7–11 to name a few. We will first give a novel presentation of this "classic" connection between spin-chain Hamiltonians and their fermionization using Clifford operators. This is done in a concise mathematical way focusing on the Clifford algebra aspects. This allows us to explain properties, procedures, and characteristics which appear complex and complicated in the spin-chain picture in a clean straightforward fashion as direct consequences of the mathematical setup. We hope that this treatment may help to bring the two communities, the people working in mathematical physics using group theory and the people working on integrable systems, closer together. We then show that going beyond the classical quadratic Hamiltonians, we can in certain cases, namely the XX-model, extend to include boundary terms. There are some subtleties here. First we have to actually enlarge the chain to be able to obtain a quadratic Hamiltonian, one of whose sectors is the original problem. Then, after the fermionization, we have to project to the smaller problem, which is nontrivial in the fermion language. As we explain, the actual calculation of the fermionization is a matrix valued problem due to the theorem[1,12,13] about the uniqueness of the irreducible Clifford module of the complex Clifford algebra based on an even dimensional vector space. We then go on to analyze operators which commute with the XX-chain Hamiltonian with boundary terms. These operators can be shown to commute, but due to the nonlocal nature of the Jordan-Wigner transformation *and* the projection, they become highly nontrivial in the original spin-chain picture. Lastly, we comment on how this operator behaves in the thermodynamic limit.

I. CLIFFORD ALGEBRAS AND SPIN CHAINS: A DIGEST

A. The Clifford algebra and fermions

A Clifford algebra $C(W,Q)$ is a universal algebra associated with a given $\mathbb{R}$-vector space W with a quadratic form Q. The universal property is that any linear map $j:W\to A$ of W to an associative $\mathbb{R}$-algebra A with unit 1 which satisfies $j(w)^2=Q(w)1$ factors through $C(W,Q)$ uniquely up to isomorphism. To be really careful of course the universal object $C(W,Q)$ comes with a map $\iota:W\to C(W,Q)$ and j factors through ι. For W with $\dim_{\mathbb{R}} W=k$ and a basis (e_i) of W,

a)Electronic mail: kaufmann@phys.uconn.edu

the algebra $C(W,Q)$ is a quadratic algebra generated by $e_i: i=1,\ldots,k$ and the relations $\forall n,m: \{e_n,e_m\}=2\langle e_n,e_m\rangle$ where $\langle\cdot,\cdot\rangle$ is the bilinear form associated with the quadratic form Q. (Technically, for this one has to assume that one is not in characteristic 2. This is fine since we will be working over $\mathbb{R}$ and $\mathbb{C}$ that is in characteristic 0.) We will usually not distinguish v and $\imath(v)$ in our notation, but sometimes it will be necessary. It can easily be seen that $\dim_{\mathbb{R}}(C(W,Q))=2^n$ for W as above and any Q. See, e.g., Refs. 12 and 13 for these results.

The classical example is the Clifford algebra $C_k := C(\mathbb{R}^k, \mathrm{diag}(-1,\ldots,-1))$. This algebra can be written as generated by e_n subject to the conditions $e_n^2=-1, e_m e_n+e_n e_m=0$. Now there are the standard isomorphisms $C_2 \simeq \mathbb{H} \simeq \mathrm{su}(2)$. Where one sends $e_1 \mapsto I, e_2 \mapsto J$, here I, J, and K are the usual quaternions and in the last step one represents I and J by the usual 2×2 matrices. Alternatively one can of course use the first two elements of any cyclic permutation of the matrices representing I, J, and K.

We will consider the complexified Clifford algebra $Cl_k := \mathbb{C}\otimes_{\mathbb{R}} C_k$. Notice that over the complexes all nondegenerate forms are conjugate and we will only work with such forms. Thus the Clifford algebras over $\mathbb{C}$ do not depend on the particular form of Q as long as it is nondegenerate. In general it can even be shown that $Cl_{2L} \simeq M_{2^L}(\mathbb{C})$, the full matrix algebra, see, e.g., Refs. 12 and 13. To pass from one quadratic form to another one makes a base change on the underlying vector space. This gives a change in presentation of the algebra. The algebra Cl_2 for the quadratic form $\mathrm{diag}(1,1)$, for instance, is just $M_2(\mathbb{C})$, and we can represent it via $e_1' \mapsto \sigma_x, e_2' \mapsto \sigma_y$. Since $\sigma x = -iK$ *and* $\sigma_y = -iJ$ *in their standard matrix representations (see, e.g., Ref. 13), we obtain an isomorphism with* $Cl_2 = \mathbb{C}\otimes_{\mathbb{R}} C_2$ *by using the permutation as mentioned above to represent the Clifford algebra and then use the complex base change* $e_j' = (-i)e_j$. *Of course* $JK=I$ *and* $\sigma_x\sigma_y = -KJ = I = i\sigma_z$.

In general, there are two standard quadratic forms: the first is given by the $k\times k$ matrix $\mathbb{1}_k = \mathrm{diag}(1,\ldots,1)$ and the second one which exists on $\mathbb{C}^{2L}$ is $\omega_{2L} = \frac{1}{2}\left(\begin{smallmatrix} 0 & \mathbb{1}_L \\ \mathbb{1}_L & 0 \end{smallmatrix}\right)$. The factor $\frac{1}{2}$ is added to cancel the factor of 2 in the relations. In the case that we are in even dimension that is in $\mathbb{R}^{2L}$ or after complexification in $\mathbb{C}^{2L}$, we fix the following notation for the basis elements. In the first case we denote the basis vectors $c_1^+,\ldots,c_L^+,c_1^-,\ldots,c_L^-$, and in the second case we will enumerate basis vectors $b_1,\ldots,b_L,a_1,\ldots,a_L$. This means that in the case of $\mathbb{C}^{2L}$ for the first basis we get the relations

$$\{c_m^\mu, c_n^\nu\} = 2\,\delta_{m,n}^{\mu,\nu} \tag{1}$$

for the generators of the Clifford algebra Cl_{2L} corresponding to this basis. These operators are usually called Clifford operators. For the second basis of $\mathbb{C}^{2L}$ we obtain the following relations for the generators of the Clifford algebra Cl_{2L}

$$\{b_n,a_m\} = \delta_{n,m}, \quad \{b_n,b_m\} = 0, \quad \{a_n,a_m\} = 0. \tag{2}$$

These operators are usually called fermion operators. (In a matrix representation one frequently also postulates $a_n^\dagger = b_n$. We will not impose this at the moment.) One can think of the b_n as creation and the a_n as annihilation operators of the nth fermion. The operator $N_n = b_n a_n$ then has eigenvalues of 0 or 1 corresponding to whether the fermion is present or not. The fermions can also just be seen as a representation of Cl_{2L} on the exterior algebra $\Lambda^*\mathbb{C}^L$. In the presentation of Eq. (2) we can write the Clifford algebra as $Cl^-\oplus Cl^0\oplus Cl^+$, where Cl^- is the subalgebra generated by the a_n, Cl^+ is the one generated by the b_n, and Cl^0 is the center generated by $\mathbb{C}$. The Fock space representation R_{Fock} is then given as follows; let $R_{|vac\rangle}$ be the one-dimensional representation of $Cl^0\oplus Cl^-$ on $\mathbb{C} = \mathbb{C}|vac\rangle$ for which $1|vac\rangle = |vac\rangle$ and $Cl^-|vac\rangle = 0$ then $R_{\mathrm{Fock}} = Cl\otimes_{Cl^0\oplus Cl^-} R_{|vac\rangle}$. Here $R_{\mathrm{Fock}} \simeq \Lambda^*\mathbb{C}^L$ as vector spaces and the Cl module structure is given by left multiplication.

The two sets of generators of Cl_{2L} are related by the simple base change on $W=\mathbb{C}^{2L}$,

$$b_n = \frac{1}{2}(c_n^+ + ic_n^-), \quad a_n = \frac{1}{2}(c_n^+ - ic_n^-),$$

$$c_n^+ = b_n + a_n, \quad c_n^- = \frac{1}{i}(b_n - a_n). \tag{3}$$

In the Clifford operator basis the role of the operator N_n is played by $ic_n^-c_n^+$ which has eigenvalues ± 1.

B. Spin chains

A spin chain of length L is a $\mathbb{C}$-vector space V which is a tensor product of L copies of a su(2) representation. A spin-chain Hamiltonian is an operator H which acts on such a V. (Sometimes a spin chain is taken to mean V together with H.) We will only be concerned with spin $\frac{1}{2}$. That is, $V=\otimes_{i=1}^{L}\mathbb{C}^2$ and $H: V \to V$ which means that $H \in GL(2^L, \mathbb{C})$. (Although the notation H is suggestive of both Hermitian and Hamiltonian, we will not restrict to the case that H is Hermitian.) The copies of $\mathbb{C}^2$ are usually called sites. Many of the interesting Hamiltonians are obtained by using linear and quadratic expressions in the Pauli-spin matrices σ_x, σ_y, and σ_z. It is well known that the Pauli matrices together with the identity matrix with $\mathbb{C}$ coefficients form a basis of $M_2(\mathbb{C}) \simeq \mathbb{C} \otimes \mathbb{H} \simeq \mathbb{C}^4$ as vector spaces.

Examples of such spin chains are the XX, XY, and XYZ or Heisenberg model. In particular, the XX chain has the Hamiltonian:

$$H_{\mathrm{XX}} = \frac{1}{2}\sum_{j=1}^{L}[\sigma_j^+\sigma_{j+1}^- + \sigma_j^-\sigma_{j+1}^+]. \tag{4}$$

$$\overset{j}{\downarrow}$$

Here we adopted the usual notation $\sigma_j := \mathbb{1}_2 \otimes \ldots \otimes \mathbb{1}_2 \otimes \sigma \otimes \mathbb{1}_2 \otimes \ldots \otimes \mathbb{1}_2$, where σ is inserted at the jth spot.

C. The Jordan-Wigner transformation

We recall that all the Clifford algebras are $\mathbb{Z}/2\mathbb{Z}$ graded. This can either be seen by using the involution on $C(W,Q)$ generated by $\iota(w) \mapsto -\iota(w)$ for $w \in W$ or the fact that the algebra is quadratic and hence the $\mathbb{Z}$ grading of the tensor algebra descends to a $\mathbb{Z}/2\mathbb{Z}$ grading on $C(W,Q)$. This splits the Clifford algebra into its even and odd parts, $C(W,Q)=C(W,Q)^{\mathrm{even}} \oplus C(W,Q)^{\mathrm{odd}}$.

A wonderful fact about Clifford algebras is that they satisfy $C(W \oplus W', P \oplus Q) \simeq C(W,P) \hat{\otimes} C(W',Q)$. Here it is important that we used $\hat{\otimes}$, that is, the tensor product as $\mathbb{Z}/2\mathbb{Z}$ graded spaces. Using this property, we see that $Cl_{2L} \simeq Cl_2^{\hat{\otimes} L} \simeq M_2(\mathbb{C})^{\hat{\otimes} L}$. But we should be careful that $M_2(\mathbb{C})^{\hat{\otimes} L} \neq M_2(\mathbb{C})^{\otimes L}$. So we cannot directly identify the spin-chain operators with Clifford operators, since the former are nongraded tensor products while the latter are graded. This is easily seen since σ_i commutes with σ_j for $i \neq j$ in the spin-chain case, while they should anticommute if they would be Clifford operators. Indeed this is forced by considering $\hat{\otimes}$.

This obstacle was overcome by Ref. 1 (see Ref. 2) by the following isomorphism of $Cl_{2L} \to Cl_2^{\otimes L}$:

$$\tau_j^{+,-} = \left(\prod_{i=1}^{j-1}\sigma_i^z\right)\sigma_j^{x,y}. \tag{5}$$

It can easily be checked that these operators satisfy Eq. (1). As noticed in Ref. 1, see also Ref. 13, this is the only irreducible module of Cl_{2L}—up to isomorphism of course. This can most quickly be seen by using the fact that Cl_{2L} is a matrix algebra over $\mathbb{C}$ and hence Morita equivalent to $\mathbb{C}$.

D. Free fermions and fermionization

Comparing the two paragraphs, we see that the Clifford operators, that is elements of Cl_{2L} after using the Jordan-Wigner transformation, are operators on the spin-chain vector space V.

Moreover, using the operators defined in Eq. (5), we have Clifford operators on the spin chain and using the transformation (3), we obtain fermion operators. This allows us to write down "simple" Hamiltonians,

$$H = \sum_{n=1}^{L} \Lambda_n i \tau_n^- \tau_n^+, \tag{6}$$

or in terms of the associated fermion operators:

$$H = \sum_{n=1}^{L} 2\Lambda_n b_n a_n - \sum_{n=1}^{L} \Lambda_n = \sum_{n=1}^{L} 2\Lambda_n N_n + E_0. \tag{7}$$

In this form it is clear that H is the Hamiltonian of L free fermions whose energies are Λ_n. The second summand is the constant term corresponding to the Fermi sea.

Now as mentioned the representation (5) is unique up to isomorphism, so we could also first apply a base change to the operators $\tau_{m,n}^{\mu,\nu}$ to obtain operators $T_{m,n}^{\mu,\nu}$. Since the τ are images of the basis elements of W, this amounts to using a change of basis $\mathbf{\Psi}$ on the underlying vector space W of the Clifford algebra. Notice that W is different from $V=(\mathbb{C}^2)^{\otimes L}$ and that dim $W=2L$, so that $\mathbf{\Psi}$ is a $2L\times 2L$ matrix. If we want that the operators T are still Clifford operators, that is they obey Eq. (1), then $\mathbf{\Psi}$ has to be an orthogonal transformation, that is, $\mathbf{\Psi}^t\mathbf{\Psi}=\mathbb{1}_{2L}$. Of course, in the fermionic case (7), the change of basis transformations $\mathbf{\Phi}$ preserving the relations (2) is the one that preserves ω: $\mathbf{\Psi}^t\omega_{2L}\mathbf{\Psi}=\omega_{2L}$.

Using these transformations, we obtain a class of Hamiltonians of the form

$$H = \sum_{n=1}^{L} \Lambda_n i T_n^- T_n^+. \tag{8}$$

Unravelling the definitions, we thus obtain spin chains describing free fermions. As spin-chain Hamiltonians, that is, expressed in terms of the σ-matrices, the form of H is highly nontrivial due to the nonlocal nature of the Jordan-Wigner transformation.

The fermionization problem is the inverse problem: When can I write a given spin chain in terms of free fermions? There is a way to go about this in case the Hamiltonian is a quadratic form in the elements τ,

$$H = \frac{1}{2} \sum_{\substack{(m,\mu),(n,\nu) \\ \text{s.t.}(m,\mu)\neq(n,\nu)}} M_{m,n}^{\mu,\nu} \tau_m^\mu \tau_n^\nu. \tag{9}$$

This is, for instance, the case if H is quadratic in the $\sigma^\pm$, $H=\Sigma A_{m,n}^{\mu,\nu}\sigma_m^\mu\sigma_n^\nu$, and one has only nearest neighbor interactions: $A_{m,n}^{\mu,\nu}=0$ if $|m-n|\neq 1$. Although we postulated that there are no diagonal entries, these entries would not pose any real problems, since due to the equation $(\tau_m^\mu)^2=1$ they would just contribute a constant term.

In this case, we can think of M as a quadratic form on the image $\imath(W)$ of W. Now due to the grading $\imath(W)$ is an *odd* vector space, so that the matrix M for a "symmetric" quadratic form will be skew symmetric. The aim now is to find a transformation of basis on W which makes H diagonal in the Clifford basis corresponding to the new basis as in Eq. (8). Let $\mathbf{\Lambda}=\text{diag}(\Lambda_1,\ldots,\Lambda_L)$, then the matrix problem one has to solve is $\mathbf{\Psi}^t M\mathbf{\Psi}=\left(\begin{smallmatrix} 0 & i\mathbf{\Lambda} \\ -i\mathbf{\Lambda} & 0 \end{smallmatrix}\right)$. Recalling that in order to preserve the fermion presentation of the Clifford algebra $\mathbf{\Psi}^t\mathbf{\Psi}=\mathbb{1}$, this reads

$$M\mathbf{\Psi} = \mathbf{\Psi}\begin{pmatrix} 0 & i\mathbf{\Lambda} \\ -i\mathbf{\Lambda} & 0 \end{pmatrix}. \tag{10}$$

This is the type of equation that is usually obtained by calculating the commutators of the operators T with the Hamiltonian;[2,7–11] here we find it by purely Clifford algebra considerations. Trans-

forming to the equations by writing $\mathbf{\Psi}=(\mathbf{\Psi}^+\mathbf{\Psi}^-)$ and $\mathbf{\Phi}^+=\mathbf{\Psi}^+ + i\mathbf{\Psi}^-, \mathbf{\Phi}^-=\mathbf{\Psi}^+ - i\mathbf{\Psi}^-$, the equations become the eigenvalue problem:

$$M\mathbf{\Phi}^{\pm} = \pm \mathbf{\Phi}^{\pm}\mathbf{\Lambda}. \tag{11}$$

Since the matrix $\mathbf{\Psi}$ is a base change on W which was of dimension $2L$, we get $2L$ eigenvalues. These come in pairs of $\pm\Lambda_n$. This is clear from the skew symmetry of M. Moreover looking at Eq. (8), we see that the change from Λ_n to $-\Lambda_n$ does not affect the spectrum of H. This symmetry corresponds to sending one of the $T_n \to -T_n$.

II. THE XX-MODEL WITH BOUNDARIES

Now the above procedure works well for Hamiltonians such as the Ising, XX, XY, Heisenberg-Ising chains,[2,15] and other models.

With some work one can also sometimes include boundary terms. For this we consider the Hamiltonian of Ref. 14 specialized to

$$H = \frac{1}{2}\sum_{j=1}^{L-1}[\sigma_j^+\sigma_{j+1}^- + \sigma_j^-\sigma_{j+1}^+] + \frac{1}{\sqrt{8}}[\sigma_1^- + \sigma_1^+ + \exp(i\chi)\sigma_L^+ + \exp(-i\chi)\sigma_L^-]. \tag{12}$$

A. Extending the chain

The H of Eq. (12) is not quadratic. On the other hand we can add the sites 0 and $L+1$ as in Refs. 16 and 17 and consider the Hamiltonian

$$H_{\text{long}} = \frac{1}{2}\sum_{j=1}^{L-1}[\sigma_j^+\sigma_{j+1}^- + \sigma_j^-\sigma_{j+1}^+] + \frac{1}{\sqrt{8}}[\sigma_0^x\sigma_1^- + \sigma_0^x\sigma_1^+ + \exp(i\chi)\sigma_L^+\sigma_{L+1}^x + \exp(-i\chi)\sigma_L^-\sigma_{L+1}^x], \tag{13}$$

which acts on $V_{\text{long}}=\otimes_{i=0}^{L+1}\mathbb{C}^2$. We see that H_{long} is of the form (9), since it is quadratic in the σ and has only nearest neighbor interactions. Thus we can apply the procedure of Sec. I D and express H_{long} in terms of $L+2$ fermions. From the form of H_{long} we see that the matrices σ_0^x and σ_{L+1}^x commute with H_{long}, so the spectrum of H_{long} decomposes into four sectors corresponding to the eigenvalues ± 1 of σ_0^x and σ_{L+1}^x. That is, we can write $V_{\text{long}}=\oplus_{(\mu,\nu)\in(\mathbb{Z}/2\mathbb{Z})^2}V_{\mu\nu}$. Here the notation $V_{\mu\nu}$ naturally means that $\sigma_0^x|V_{\mu\nu}=\mu id$ and $\sigma_{L+1}^x|V_{\mu\nu}=\nu id$. We can embed V into V_{long} via $v\mapsto v^+\otimes v\otimes v^+$, where $v^+=\binom{1}{1}$ is the eigenvector of σ_x with eigenvalue of 1. The isomorphic image of V is V_+. Under this embedding we see that $H\mapsto H_{\text{long}}|_{V++}$ and hence the spectrum of H is that of $H_{\text{long}}|_{V_{++}}$. The left inverse to the embedding map is the projection map $\pi: V_{\text{long}}\to V$ which simply projects out the first and last tensor factors.

B. Femionization of the extended chain

After substituting Eq. (5) into Eq. (13), the matrix M of Eq. (9) becomes

$$M = \begin{pmatrix} 0 & G & & & & & \\ -G^T & 0 & F & & & & \\ & -F^T & 0 & F & & & \\ & & \ddots & \ddots & \ddots & & \\ & & & -F^T & 0 & K & \\ & & & & -K^T & 0 & \end{pmatrix}, \tag{14}$$

where $F=1/4\left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right)$ and $G=1/2\left(\begin{smallmatrix} 0 & 2i/\sqrt{8} \\ 0 & 0 \end{smallmatrix}\right)$ and $K=1/2\left(\begin{smallmatrix} 0 & (i/\sqrt{8})2\cos(\chi) \\ 0 & (i/\sqrt{8})2\sin(\chi) \end{smallmatrix}\right)$. The corresponding diagonalization problem can be solved explicitly, see Ref. 14.

C. Projection to the original chain

Notice that the projection/restriction to V_{++} is clear in the spin-chain picture but not so obvious in the fermion language. The basic idea is to find the ground state which is in V_{++} and act on it by operators b. Let $\bar{B} \subset Cl^{+}_{2L+2}$ be the subalgebra generated by $b_1, \ldots, b_{L+1}$, then $\bar{B} = \bar{B}^{\text{even}} \oplus \bar{B}^{\text{odd}}$. There are vectors $v^{\pm}$ which satisfy $\sigma_0^x v^{\pm} = \pm v^{\pm}$ and either (1) $\sigma_{L+1}^x v^{\pm} = \pm v^{\pm}$ or (2) $\sigma_{L+1}^x v^{\pm} = \mp v^{\pm}$. Accordingly either

$$V_{++} = B^{\text{even}} v^{+} \text{ or } V_{++} = B^{\text{odd}} v^{-}. \tag{15}$$

We refer to Ref. 14 for the details. There is something interesting going on here that we would like to point out, although we do not fully understand the situation as of yet. The fact that V_{++} is generated by even or odd excitations seems to suggest that we are actually dealing with modules over $Cl^{\text{even}}_{2L+2} \subset Cl_{2L+2} \subset Cl_{2L+4}$, where Cl_{2L+2} is generated by the a_i and $b_i : i = 1, \ldots, L+1$. Now it is well known that $Cl^{\text{even}}_{2L+2} \cong Cl_{2L+1}$.[12,13] The dimension of the V_{++} is 2^L so it is tempting to conjecture that it is actually one of the spin representations and σ^x_{L+1} corresponds to the operator that distinguishes the two spin representations. This operator is $t = i^n \prod_{j=1}^{L+1} e_j$ in the standard notation. A quick calculation shows that $t \propto \prod_{j=1}^{L+1} \sigma_j^z$, so things are in reality a little more complicated, but the dimensional analysis and the fact that there are two representations distinguished by an operator with eigenvalues of ± 1 remain true. It would be interesting to find a complete representation theoretic explanation for the projection mechanism.

III. SUPERSELECTION SECTORS AND THE THERMODYNAMIC LIMIT

A. Operators commuting with *H*

Just as we derived nontrivial spin chains from free fermions and vice versa found free fermion representations of nontrivial spin chains, we can take operators which obviously commute with the free fermion Hamiltonian and transform them back to the spin chain to obtain nontrivial conserved quantities and hence superselection rules. One such operator is the total fermion number operator; another operator of this kind is treated in Ref. 18.

To exhibit this strategy, we will now apply these observations to the XX-model with boundaries discussed in the last section. Moreover, as we explain in the next paragraph, this operator is key to understanding the spectrum of H and its dependence on the parameter χ. Recalling that the fermions entering the original chain are those labeled by $1, \ldots, L+1$ (see Sec. II C), the total fermion number for the spin chain H is given by the projection of the operator:

$$\mathcal{F}^{\text{long}}_{\text{tot}} = \sum_{n=1}^{L+1} N_n = \sum_{n=1}^{L+1} b_n a_n. \tag{16}$$

We note that *a priori* it is not clear that this operator can actually be "projected." *A posteriori* this follows either from the explicit form, $\mathcal{F}^{\text{long}}_{\text{tot}} = \sigma_0^x \otimes \mathcal{F}_{\text{tot}} \otimes \sigma^x_{L+1}$, whose calculation we describe below, or from the results about the spectrum being given by an even or odd number of fermion excitations (see Sec. II C).

Denoting the entries of the matrix $\mathbf{\Phi} = (\mathbf{\Phi}^{+} \mathbf{\Phi}^{-})$ appearing in Eq. (11) by $(\phi_n^{\nu})_j^{\mu}$, that is, $(\phi_n^{\nu})_j^{\mu}$ with n and $\nu = \pm 1$ fixed, $\mu = \pm 1$, and $j = 0, \ldots, L+1$ is the eigenvector to the eigenvalue $\nu \Lambda_n$, we can write

$$\mathcal{F}^{\text{long}}_{\text{tot}} = \frac{1}{4} \sum_{n=1}^{L+1} \sum_{j,k=0}^{L+1} \sum_{\mu,\nu=\pm 1} (\phi_n^{-})_j^{\mu} (\phi_n^{+})_k^{\nu} \tau_j^{\mu} \tau_k^{\nu}. \tag{17}$$

Now the explicit form of the eigenvectors ϕ, which are known,[14] allows us to compute this expression projected to the short chain V in terms of the σ matrices of the original spin-chain picture (see Ref. 19 for the details),

$$\mathcal{F}_{\mathrm{tot}} = \frac{1}{4L+4} \sum_{\substack{j,k=1 \\ j+k \text{ odd}, j<k}}^{L} (-1)^{(j+k+1)/2} (\sigma_{j+1}^z \cdots \sigma_{k-1}^z) \times \left[\left(\frac{\sin(\chi(j-k)/(L+1))}{\sin(\pi(j-k)/(2L+2))} + \frac{\sin(\chi(j+k)/(L+1))}{\sin(\pi(j+k)/(2L+2))} \right) (\sigma_j^x \sigma_k^y - \sigma_j^y \sigma_k^x) + \left(\frac{\cos(\chi(j+k)/(L+1))}{\sin(\pi(j+k)/(2L+2))} \right) (\sigma_j^y \sigma_k^y - \sigma_j^x \sigma_k^x) \right]$$
$$+ \frac{1}{\sqrt{8}(L+1)} \left\{ \sum_{\substack{k=1 \\ k \text{ odd}}}^{L-1} (-1)^{(k+1)/2} \left[\frac{\cos(\chi k/(L+1))}{\sin(\pi k/(2L+2))} \sigma_1^z \sigma_2^z \cdots \sigma_{k-1}^z \sigma_k^x \right] \right.$$
$$+ \sum_{\substack{k=2 \\ k \text{ even}}}^{L} \left[(-1)^{(L+k+2)/2} \frac{\cos(\chi k/(L+1))}{\cos(\pi k/(2L+2))} \sigma_k^x + (-1)^{(k+L)/2} \frac{\sin(\chi k/(L+1))}{\cos(\pi k/(2L+2))} \sigma_k^y \right]$$
$$\left. \times (\sigma_{k+1}^z \cdots \sigma_{L-1}^z \sigma_L^z) \right\}. \tag{18}$$

In Eq. (18), we have taken the projection to the original chain H by using the equation $\mathcal{F}_{\mathrm{tot}}^{\mathrm{long}} = \sigma_0^x \otimes \mathcal{F}_{\mathrm{tot}} \otimes \sigma_{L+1}^x$. The fact that $\mathcal{F}_{\mathrm{tot}}^{\mathrm{long}}$ has this special form is the *a fortiori* reason that indeed the total fermion number is a quantity that is well defined on the original chain.

Depending on which case one is in (see Sec. II C), the eigenvalues are either odd or even. It is clear that it would be impossible to find this operator, which is a novel conserved quantity corresponding to a hidden symmetry for the spin chain, relying solely on the spin-chain picture.

B. The thermodynamic limit

Since we have superselection rules for the state space, we can look at the partition function Z_m of H restricted to the sector with m fermions. The relevant eigenvalues are given by[14,19]

$$\Lambda_n = \frac{1}{2} \sin\left(\frac{\chi}{L+1} + \frac{(2n-1)}{L+1} \frac{\pi}{2} \right), \quad n = 1, \ldots, L+1. \tag{19}$$

Since $\lim_{L\to\infty}(2L\Lambda_n/\pi) = \chi/\pi + 1/2 + n - 1$, in the thermodynamic limit,[20] we obtain

$$\mathcal{Z}_m = \lim_{L\to\infty} \{ \mathrm{tr}\, z^{(L/\pi)\sum_{n=1}^{L+1} 2\Lambda_n N_n} \} = z^{m\chi/\pi + m/2} \sum_{n_1, n_2, \ldots, n_m} z^{n_1 - 1 + n_2 - 1 + \cdots + n_m - 1}$$
$$= z^{m\chi/\pi + m/2} \left(\sum_l p_m(l) z^l + \sum_l p_{m-1}(l) z^l \right)$$
$$= z^{m\chi/\pi + m/2} \left(\frac{z^{m(m+1)/2} + (1-z^m) z^{(m-1)m/2}}{(1-z)(1-z^2)\cdots(1-z^m)} \right)$$
$$= \frac{z^{m\chi/\pi + m^2/2}}{(1-z)(1-z^2)\cdots(1-z^m)}. \tag{20}$$

Here $p_m(l)$ counts the number of ways the integer l can be expressed as a sum of m distinct nonzero integers. The second term involving p_{m-1} takes into account that one of $n_1 - 1$ in the sum before might be zero and the second equality follows from the formula

$$\sum_l p_m(l) z^l = \frac{z^{m(m+1)/2}}{(1-z)(1-z^2)\cdots(1-z^m)}. \tag{21}$$

The complete partition function $\mathcal{Z}$ will then be a sum over all the even or the odd m depending on χ. On the other hand $\mathcal{Z}$ has been calculated,[21] so that equating the two expressions, one obtains an interesting combinatorial identity.

What we gain from the calculation of $\mathcal{Z}_m$ is that we now know that in the sector with fixed fermion number, the dependence of $\mathcal{Z}_m$ on χ is given by a factor of $z^{m\chi/\pi}$. This simply induces a uniform shift off the usual spectrum. Notice that the factor is different though for different m, so that the eigenspaces of the thermodynamic limit of the operator $\mathcal{F}_{\text{tot}}$ play a special role, since the shift can precisely be factored out on these spaces. The reason for this factorization is the special distribution of the eigenvalues (19).

Another way to phrase this result is as follows. Consider the polynomial ring in infinitely many fermionic variables which are indexed by half integers $F=\mathbb{C}[\xi_i]: i \in \mathbb{N}_0+\frac{1}{2}$. This space comes equipped with a natural bigrading. The first grading is by the usual degree where $\deg(\xi_{i_1}\cdots\xi_{i_m})=m$. The second is by the weight wt where $\text{wt}(\xi_{i_1}\cdots\xi_{i_m})=\Sigma_{j=1}^{m} i_j$. Thus we can decompose $F=\oplus_d F_d$ according to the degree or according to the weight $F=\oplus_w F^w$. We will set F_d^w to be the bigraded piece of pure degree d and pure weight w and we will let π_d denote the projection of F onto its summand F_d. It is an elementary calculation to show that the dimension of $F_m^{l+m/2}$ is $p_m(l)+p_{m-1}(l)$ and likewise the dimension of $F_m^{l-m/2}$ is just $p_m(l)$.

Furthermore there are the two subspaces F_{even} and F_{odd} spanned by polynomials whose degree is either even or odd. Now the state space of H in the thermodynamic limit is abstractly isomorphic to one of the two subspaces F_{even} or F_{odd} of F (see Sec. II C). The isomorphism is given by sending the state $|n_1,\ldots,n_m\rangle$, which is the state with fermions n_i, to the monomial $\xi_{n_1-1/2}\cdots\xi_{n_m-1/2}$. (Recall that the n_i are positive integers and the indices of the ξ start at $0+\frac{1}{2}$.) In this language, the partition sum is the partition function $\text{tr}\, z^{\omega(\chi)}$ for the operator $\omega(\chi) := (\Sigma_m((m\chi/\pi)id+\text{wt})\circ\pi_m)|F_{\text{odd/even}}$. So we see that the eigenspaces are exactly the $F_m^{l+m/2}$ with the eigenvalues given by $m\chi/\pi+m/2+l$ and hence χ tunes the eigenvalue uniformly in each of the given sectors.

Now, in the original spin chain, this essential grading operator is given by the limit of Eq. (18). More details are contained in Ref. 19.

ACKNOWLEDGMENTS

We would like to thank the organizers of the 26th International Colloquium on Group Theoretical Methods. Our presentation of spin chains and Clifford algebras is a direct consequence of the invitation to speak at this conference. We also thank V. Rittenberg for pointing us to the total fermion number operator as an object of significant interest.

published online 26 December 2006)

In the framework of the extended resolvent approach the direct and inverse scattering problems for the nonstationary Schrödinger equation with a potential being a perturbation of the *N*-soliton potential by means of a generic bidimensional smooth function decaying at large spaces are introduced and investigated. The initial value problem of the Kadomtsev-Petviashvili I equation for a solution describing *N* wave solitons on a generic smooth decaying background is then linearized, giving the time evolution of the spectral data. © *2006 American Institute of Physics.*

I. INTRODUCTION

A. Formulation of the problem

We consider the Kadomtsev-Petviashvili equation in its version called KPI,[1]

$$(u_t - 6uu_{x_1} + u_{x_1x_1x_1})_{x_1} = 3u_{x_2x_2}, \quad u = u(x_1,x_2,t). \tag{1.1}$$

By associating it to the nonstationary Schrödinger operator

$$\mathcal{L} = i\partial_{x_2} + \partial_{x_1}^2 - u(x), \tag{1.2}$$

it has been shown to be integrable about three decades ago.[2,3] More precisely,[4] the following time evolution of the KPI equation (time dependence of u is understood)

$$u_t(x) - 6u(x)u_{x_1}(x) + u_{x_1x_1x_1}(x) = 3\int_{-t\infty}^{x} dx_1' u_{x_2x_2}(x_1',x_2) \tag{1.3}$$

can be obtained by introducing the auxiliary operator

$$\mathcal{T}(x) = \partial_t + 4\partial_{x_1}^3 - 6u(x)\partial_{x_1} - 3u_{x_1}(x) + 3i\int_{-t\infty}^{x_1} dx_1' u_{x_2}(x_1',x_2) \tag{1.4}$$

and by imposing compatibility with the nonstationary Schrödinger operator $\mathcal{L}$, i.e.,

$$[\mathcal{L},T] = 0. \tag{1.5}$$

The initial value problem for KPI in the case of rapidly decaying initial data was solved in Refs. 5–10 by using the inverse scattering transform (IST) method.

$\widehat{LA}=\vec{\mathcal{L}}\widehat{A},\ \widehat{AL}=\widehat{A}\overleftarrow{\mathcal{L}}$	$\mathcal{L}$ and dual $\mathcal{L}$ operating from left and right	Eq. (1.30)

However, the KPI equation, being a $(2+1)$-dimensional generalization of the Korteweg de Vries (KdV) equation, admits also solutions that behave at space infinity such as the solutions of the KdV equation. Therefore, it is natural to consider potentials $u(x)$ in Eq. (1.2) which are rapidly decaying on the plane in all directions with the exception of a finite number of directions along which the limits

$$\lim_{x_2\to\pm\infty} u(x_1-2\mu_n x_2,x_2),\quad \mu_n\in\mathbb{R},\quad n=1,2,\ldots,N, \tag{1.6}$$

exist and are different from zero.

In Ref. 4 and 11–15 the method of the "extended resolvent" (or, for short, method of resolvent) was suggested as a way of pursuing a generalization of the IST that enables studying the spectral theory of operators with nontrivial asymptotic behavior at space infinity. In Refs. 15–21 for the nonstationary Schrödinger and heat operators the case where there is only one direction of nondecaying behavior was considered. The starting point in solving the problem was the embedding of the pure one-dimensional case in the two-dimensional spectral theory, building the two-dimensional extended resolvent for a potential $u(x)\equiv u_1(x_1)$. Then, a potential $u(x)=u_1(x_1)+u'(x)$, where $u'(x)$ is an arbitrary decaying smooth function of both spatial variables, was considered and the corresponding resolvent was constructed by dressing the above resolvent for $u(x)=u_1(x_1)$. Finally, all mathematical entities generalizing the standard ones in IST, as Jost solutions and spectral data, were derived by a reduction procedure from this dressed resolvent.

Here, we consider a real potential $u(x)$ given as a sum of two terms,

$$u(x)=u_N(x)+u'(x), \tag{1.7}$$

where u_N is the N-soliton potential of the nonstationary Schrödinger equation obtained in Ref. 22 and then generalized in Ref. 23 and $u'(x)$ is an arbitrary bidimensional decaying smooth perturbation. This case is substantially more complicated since u_N is a true bidimensional potential and we have not the one-dimensional sample as a guide to follow.

Therefore, one needs first to construct directly the resolvent M_N of the nonstationary Schrödinger operator with potential u_N,

TABLE II. Green's functions and Jost solutions for a generic potential.

$\mathcal{G}(x,x',\mathbf{k})=\widehat{M}(\ell_\mathcal{J}(\mathbf{k})),\ \ell(\mathbf{k})=(\mathbf{k},\mathbf{k}^2),\ \mathbf{k}\in\mathbb{C}$	Green's function	Eq. (1.42)

TABLE III. Main objects in the N-soliton case.

$L_N(x,i\partial_x)$	Differential operator	Eq. (1.8)
$M_N(x,x';q)$	Extended resolvent	Eq. (2.44)
$\vec{\mathcal{L}}_N, \overleftarrow{\mathcal{L}}_N$	$\mathcal{L}_N$ and dual $\mathcal{L}_N$ operating from left and right	Eq. (1.30)
$\mathcal{G}_N(x,x',\mathbf{k})$	Green's function	Eq. (2.52)
$\mathcal{G}_{N,\pm}(x,x')$	Adv/ret Green's functions	Eq. (2.56)
$\varphi(x,\mathbf{k})$	Jost solution	Eq. (2.9)
$\varphi_n(x,\mathbf{k}_\mathfrak{I})$	Auxiliary Jost solutions	Eq. (2.24)

$$\mathcal{L}_N = i\partial_{x_2} + \partial_{x_1}^2 - u_N(x). \tag{1.8}$$

Using the results obtained in Ref. 24 this was done in Ref. 25.

Here, following the method developed in Refs. 15–20, we construct the extended resolvent M of the nonstationary Schrödinger operator (1.2) with a potential u as in Eq. (1.7) by dressing the resolvent M_N obtained in Ref. 25 and we derive it by a reduction procedure the corresponding Jost solutions and spectral data together with their characterization equations and time evolution. Finally, the inverse scattering problem is solved.

We start in the following sections with a short outline of the resolvent approach and with the presentation of some results of articles [24,25] used in what follows.

B. Notations and guiding lines

In order to deal with the inverse scattering method, in the case we are considering, it is necessary to introduce mathematical objects which are extensions of familiar objects as differential operators, pseudodifferential operators and resolvent, and that we are calling extended. This extension procedure is not at all trivial and, being new and original, is not familiar to the common reader. Therefore, we evaluated that it could be useful to present some tables with the symbols we use, their name, and the numbers of the defining formulas.

In Table I are listed the main objects we are dealing with in the case of a generic potential $u(x)$.

We first introduce what we call the extension $L(x,x';q)$ of a differential operator $L(x,i\partial_x)$ depending on a spectral parameter q and, then, following a procedure similar to that used for passing from differential operators to pseudodifferential operators, we introduce the extended

TABLE IV. Spectral data for N solitons.

$\mathbf{r}_\pm^\sigma = \begin{pmatrix} r_\pm^\sigma(p)\delta(p-k) & 0 \\ 0 & r_\pm^\sigma(m,n) \end{pmatrix}$	Triangular spectral data	Eq. (2.111), (2.75), and (2.87)
$\mathbf{t}^\sigma = \begin{pmatrix} t^\sigma(p)\delta(p-k) & 0 \\ 0 & \delta_{mn}\vartheta_n^\sigma \end{pmatrix}$	Transmission coefficient	Eq. (2.112) and (2.26)
$\varphi_\pm(k) = \varphi^\sigma(k)\overline{r_\pm^{-\sigma}(k)}$	Adv/ret solutions	Eq. (2.78)
$\varphi_{\pm,n} = \sum_{m=1}^N \varphi_m^\sigma (r_\pm^{-\sigma})^\dagger(m,n)$	Auxiliary adv/ret solutions	Eq. (2.91)

TABLE V. Spectral data characterization equations for N solitons.

$\mathbf{r}_{\pm}^{\sigma}(\mathbf{t}^{\sigma})^{-1}(\mathbf{r}_{\pm}^{-\sigma})^{\dagger}=\mathbf{I}$	Eq. (2.113)
$(\mathbf{r}_{\pm}^{-\sigma})^{\dagger}\mathbf{r}_{\pm}^{\sigma}(\mathbf{t}^{\sigma})^{-1}=\mathbf{I}$	Eq. (2.113)
$(\mathbf{r}_{+}^{\sigma})^{\dagger}\mathbf{r}_{+}^{\sigma}=(\mathbf{r}_{-}^{\sigma})^{\dagger}\mathbf{r}_{-}^{\sigma}$	Eq. (2.119)

pseudodifferential operators $A(x,x';q)$. The extended resolvent $M(x,x';q)$ is defined as the inverse of the extended differential operator $L(x,x';q)$ and in its hat version identifies a family of Green's functions of $\mathcal{L}$ depending on the spectral parameter q.

In the case of the nonstationary Schrödinger operator $\mathcal{L}$ in Eq. (1.2), special reductions with respect to this parameter q furnish "standard" Green's function $\mathcal{G}(x,x',\mathbf{k})$, Green's function for short, and advanced/retarded Green's functions $\mathcal{G}_{\pm}(x,x')$. By using them one can then build the Jost and advanced/retarded solutions as indicated in Table II.

If wavelike solitons are present the potential $u(x)$ is not going to zero at large spaces and the equations defining the Jost solutions, due to the bad behavior at infinity of the potential, need to be regularized and, in addition, the Jost solutions do not form a complete set anymore. All this prevents solving the problem by a direct approach.

In fact, it is necessary to consider first the case of a pure N-soliton potential $u_N(x)$ and to build all the mathematical objects listed above, including the auxiliary Jost solutions which complete the set of Jost solutions. The notations used are listed in Table III, where $n=1,2,\ldots,N$.

Then, we consider the potential $u(x)=u_N(x)+u'(x)$ obtained by perturbing the pure N-soliton potential $u_N(x)$ by adding a smooth decaying perturbation $u'(x)$ and we dress Green's functions and Jost solutions by using the Hilbert identity listed above with $L'=L_N$ and $M'=M_N$.

The spectral data in the case of N solitons are well known and are given by the locations λ_n $(n=1,2,\ldots,N)$ of the poles of the transmission coefficient $t(\mathbf{k})$, that we choose in the upper half complex plane, and by the $N\times N$ matrix C, hermitian and positive, of the normalization coefficients. However, in view of the dressing, these spectral data are not convenient and, in spite of the fact that they are superfluous in this case, we need also to define the advanced/retarded solutions together with their auxiliary advanced/retarded solutions.

Therefore, we introduce as alternative equivalent spectral data a matrix $\mathbf{f}^{\sigma}$, which exhibits a triangular decomposition, and the advanced/retarded and auxiliary advanced/retarded solutions according to Table IV. Here and everywhere in the following we use σ for indicating the label $\pm$, we indicate by $f^{\sigma}(k)$, for any function $f(\mathbf{k})$ of the complex variable $\mathbf{k}$, the limiting value of $f(\mathbf{k})$ at the real axis from above $(\sigma=+)$ and from below $(\sigma=-)$, and we define the product of matrices with matrix elements with continuous and discrete indices by integrating and summing, respectively, over continuous and discrete indices.

One can write a set of characterization equations for the triangular spectral data $\mathbf{r}_{\pm}^{\sigma}$ not very significant in this case, but ready to be dressed perturbing u_N. (see Table V).

Then, one can write more conveniently the relations interlacing the different Jost solutions by introducing a vectorial formulation, which, again, is not very significant in this case, but very convenient when performing the dressing. Precisely, see Table VI.

TABLE VI. Vectorial Jost solutions for N solitons.

$\boldsymbol{\varphi}^{\sigma}=(\varphi^{\sigma}(k),\varphi_1^{\sigma},\ldots,\varphi_N^{\sigma})$	Vectorial Jost solution	Eq. (2.109)
$\boldsymbol{\varphi}_{\pm}=(\varphi_{\pm}(k),\varphi_{\pm,1},\ldots,\varphi_{\pm,N})$	Vectorial adv/ret solutions	Eq. (2.110)
$\boldsymbol{\varphi}^{\sigma}\mathbf{t}^{\sigma}=\boldsymbol{\varphi}_{\pm}\mathbf{r}_{\pm}^{\sigma}$	Jost in terms of adv/ret	Eq. (2.115)
$\boldsymbol{\varphi}_{\pm}=\boldsymbol{\varphi}^{\sigma}(\mathbf{r}_{\pm}^{-\sigma})^{\dagger}$	Adv/ret in terms of Jost	Eq. (2.116)
$\boldsymbol{\varphi}^{\sigma}\mathbf{t}^{\sigma}=\boldsymbol{\varphi}^{-\sigma}\mathbf{f}^{-\sigma}$	Discontinuity at $\mathbf{k}_{\jmath}=0$	Eq. (2.117)

TABLE VII. Perturbed Green's functions and Jost solutions.

$\mathcal{G}(\mathbf{k})=\mathcal{G}_N(\mathbf{k})+\mathcal{G}_N(\mathbf{k})u'\mathcal{G}(\mathbf{k})$	Green's function	Eq. (1.59)
$\mathcal{G}_\pm=\mathcal{G}_{N,\pm}+\mathcal{G}_{N,\pm}u'\mathcal{G}_\pm$	Adv/ret Green's functions	Eq. (1.60)
$\Phi(\mathbf{k})=\mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_N\varphi(\mathbf{k})$	Jost solution	Eq. (3.3)
$\Phi_\pm(k)=\mathcal{G}_\pm\overleftarrow{\mathcal{L}}_N\varphi_\pm(k)$	Adv/ret solutions	Eq. (3.88)
$\Phi_n(\mathbf{k}_\mathfrak{I})=\mathcal{G}(\lambda_{n\mathfrak{R}}+0+i\mathbf{k}_\mathfrak{I})\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\mathfrak{I})$	Auxiliary Jost solutions	Eq. (3.31)
$\Phi_{\pm,n}=\mathcal{G}_\pm\overleftarrow{\mathcal{L}}_N\varphi_{\pm,n}$	Auxiliary adv/ret solutions	Eq. (3.89)

Then, the mathematical objects related to the perturbed potential $u(x)=u_N(x)+u'(x)$ can be obtained by dressing the corresponding ones for $u_N(x)$ according to the scheme in Table VII.

The Jost solution $\Phi(\mathbf{k})$ is analytical in the complex $\mathbf{k}$ plane with a discontinuity across the real axis and the segments $\mathbf{k}=\lambda_{n\mathfrak{R}}+i\mathbf{k}_\mathfrak{I}$, $|\mathbf{k}_\mathfrak{I}|\leqslant\lambda_{n\mathfrak{I}}$. Spectral data relate the limiting values of the Jost solution at the two sides of these cuts and their triangular decomposition is obtained by considering the relation among values of the Jost solution at the two sides of the real axis and the advanced/retarded solutions. All this is described in a more transparent and compact way by using a vectorial notation for the Jost solutions according to Table VIII.

The spectral data involved in Table VIII are listed in Table IX.

Finally, one can derive the scheme in Table X for the characterization equations of the spectral data.

The first two equations state that the matrix operator $\boldsymbol{\mathcal{R}}_\pm^\sigma(\mathbf{T}^\sigma)^{-1}$ admits right and left inverse, while the third equation is a characterization equation in the strict sense.

C. Extended resolvent approach

In this section we briefly review, in two dimensions for definiteness, the basic elements of the extended resolvent approach. For further details, we refer the interested readers to Refs. 11–16.

Let us consider the operators with kernel

$$L(x,x')=\mathcal{L}(x,i\partial_x)\delta(x-x'), \tag{1.9}$$

where $\mathcal{L}(x,i\partial_x)$ denotes a differential operator whose coefficients are smooth functions of x and let us introduce what we call the *extension* of these differential operators, i.e., to any differential operator $\mathcal{L}$ we associate the operator $L(\mathbf{q})$ with kernel

$$L(x,x';\mathbf{q})\equiv\mathcal{L}(x,i\partial_x+\mathbf{q})\delta(x-x')=e^{i\mathbf{q}(x-x')}L(x,x'), \tag{1.10}$$

where $x=(x_1,x_2)$, $x'=(x_1',x_2')\in\mathbb{R}^2$, and $\mathbf{q}=(\mathbf{q}_1,\mathbf{q}_2)\in\mathbb{C}^2$ and

TABLE VIII. Perturbed vectorial Jost solutions.

$\boldsymbol{\Phi}_\pm=(\Phi_\pm(k),\Phi_{\pm,1},\ldots,\Phi_{\pm,N})$	Vectorial adv/ret solutions	Eq. (3.113)
$\boldsymbol{\Phi}^\sigma\mathbf{T}^\sigma=\boldsymbol{\Phi}_\pm\mathbf{r}_\pm^\sigma\boldsymbol{\mathcal{R}}_\pm^\sigma$	Jost in terms of adv/ret	Eq. (3.137)
$\boldsymbol{\Phi}_\pm=\boldsymbol{\Phi}^\sigma(\boldsymbol{\mathcal{R}}_\pm^{-\sigma})^\dagger(\mathbf{r}_\pm^{-\sigma})^\dagger$	Adv/ret in terms of Jost	Eq. (3.138)
$\boldsymbol{\Phi}^\sigma\mathbf{T}^\sigma=\boldsymbol{\Phi}^{-\sigma}\mathbf{F}^{-\sigma}$	Discontinuity at $\mathbf{k}_\mathfrak{I}=0$	Eq. (3.127)
$\Delta\Phi\big\vert_{\mathbf{k}_\mathfrak{R}=\lambda_{n\mathfrak{R}}}=\Phi_n(\mathbf{k}_\mathfrak{I})w_n(\mathbf{k}_\mathfrak{I})$	Discontinuity at $\mathbf{k}_\mathfrak{R}=\lambda_{n\mathfrak{R}}$	Eq. (3.42)

TABLE IX. Spectral data of the perturbed potential.

$\mathbf{F}^{\sigma}=(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}\mathbf{f}^{\sigma}\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma}$	Spectral data	Eq. (3.148)
$\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}=\begin{pmatrix}\mathcal{R}_{\pm}^{\sigma}(p,k) & \mathcal{R}_{\pm}^{\sigma}(p,n)\\ \mathcal{R}_{\pm}^{\sigma}(m,k) & \mathcal{R}_{\pm}^{\sigma}(m,n)\end{pmatrix}$	Triangular spectral data	Eqs. (3.132) –(3.136)
$\mathbf{T}^{\sigma}=\begin{pmatrix}t^{\sigma}(p)\delta(p-k) & 0\\ 0 & \delta_{mn}\dfrac{\vartheta_n^{\sigma}}{A_n^{\sigma}}\end{pmatrix}$	Transmission coefficient	Eqs. (3.118) and (3.28)
$w_n(\mathbf{k}_{\mathfrak{I}})$	Additional spectral data	Eq. (3.44)

$$\mathbf{q}x=\mathbf{q}_1x_1+\mathbf{q}_2x_2. \tag{1.11}$$

The $\mathbf{q}$ variable will play in the following the role of a spectral parameter and we use a boldface character to emphasize that it is complex. By using the Fourier transform we can write

$$L(x,x';\mathbf{q})=\frac{1}{(2\pi)^2}\int d\alpha\, e^{-i\alpha(x-x')}\mathcal{L}(x,\alpha+\mathbf{q}),\quad \alpha=(\alpha_1,\alpha_2). \tag{1.12}$$

Then, it is natural to introduce more general operators $A(\mathbf{q})$ with kernel

$$A(x,x';\mathbf{q})=\frac{1}{(2\pi)^2}\int d\alpha\, e^{-i\alpha(x-x')}\mathcal{P}(x,\alpha+\mathbf{q}) \tag{1.13}$$

obtained by considering not just a polynomial $\mathcal{L}(x,\mathbf{q})$ in $\mathbf{q}$ but a tempered distribution $\mathcal{P}(x,\mathbf{q})$ of the six real variables x, $\mathbf{q}_{\mathfrak{R}}$ and $\mathbf{q}_{\mathfrak{I}}$. Notice that the dependence on $\mathbf{q}_{\mathfrak{R}}$ can be factorized

$$A(x,x';\mathbf{q})=e^{i\mathbf{q}_{\mathfrak{R}}(x-x')}A(x,x';q), \tag{1.14}$$

where

$$\mathbf{q}=\mathbf{q}_{\mathfrak{R}}+i\mathbf{q}_{\mathfrak{I}}\in\mathbb{C}^2,\quad q\equiv\mathbf{q}_{\mathfrak{I}}\in\mathbb{R}^2, \tag{1.15}$$

and that $A(x,x';q)$ belongs to the space $\mathcal{S}'$ of tempered distributions of the six real variables x, x' and $q=(q_1,q_2)$. In particular, for the case of a differential operator we get by Eq. (1.10)

$$L(x,x';q)=e^{-q(x-x')}L(x,x'). \tag{1.16}$$

Definition (1.13) recalls the definition of a pseudodifferential operator with symbol $\mathcal{P}(x,\alpha)$. However, it is different in two respects, since the symbol $\mathcal{P}(x,\mathbf{q})$ depends on an additional parameter q and the functional space to which the symbol $\mathcal{P}(x,\mathbf{q})$ belongs is much larger than the functional space used by mathematicians in defining the pseudodifferential operators. Both generalizations are crucial in the following. Therefore, we call the operators $A(q)$ with kernel $A(x,x';q)$ belonging to the space $\mathcal{S}'$ extended pseudodifferential operators, or by short operators, and $\mathcal{P}(x,\mathbf{q})$ their symbols.

TABLE X. Spectral data characterization equations for the perturbed potential.

$(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}\mathbf{t}^{\sigma}\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}(\mathbf{T}^{\sigma})^{-1}=\mathbf{I}$	Eq. (3.141)
$\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}(\mathbf{T}^{\sigma})^{-1}(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}\mathbf{t}^{\sigma}=\mathbf{I}$	Eq. (3.142)
$(\boldsymbol{\mathcal{R}}_{+}^{-\sigma})^{\dagger}\mathbf{f}^{\sigma}\boldsymbol{\mathcal{R}}_{+}^{-\sigma}=(\boldsymbol{\mathcal{R}}_{-}^{-\sigma})^{\dagger}\mathbf{f}^{\sigma}\boldsymbol{\mathcal{R}}_{-}^{-\sigma}$	Eq. (3.143)

In the following it is often useful to use instead of the symbol $\mathcal{P}(x,\mathbf{q})$ its Fourier transform with respect to x, i.e.,

$$A(p;\mathbf{q}) = \frac{1}{(2\pi)^2}\int dx\, e^{ipx}\mathcal{P}(x,\mathbf{q}), \quad p=(p_1,p_2). \tag{1.17}$$

From Eqs. (1.13) and (1.14) it follows that $A(p;\mathbf{q})$ is related to $A(x,x';q)$ by

$$A(p;\mathbf{q}) = \frac{1}{(2\pi)^2}\int dx \int dx' e^{i(p+\mathbf{q}_\Re)x - i\mathbf{q}_\Re x'} A(x,x';q). \tag{1.18}$$

The inverse of Eq. (1.18) is given by

$$A(x,x';\mathbf{q}_\Im) = \frac{1}{(2\pi)^2}\int dp \int d\mathbf{q}_\Re\, e^{-i(p+\mathbf{q}_\Re)x + i\mathbf{q}_\Re x'} A(p;\mathbf{q}). \tag{1.19}$$

Then, we consider $A(x,x';q)$ and $A(p;\mathbf{q})$ as the representation of the operator $A(q)$, respectively, in the x-space and in the p-space.

In the space of this operators we define the hermitian conjugation as

$$A^\dagger(x,x';q) = \overline{A(x',x;-q)}, \quad A^\dagger(p;\mathbf{q}) = \overline{A(-p;\overline{\mathbf{q}}+p)}, \tag{1.20}$$

in terms of kernels in x- or p-spaces. For generic operators $A(q)$ and $B(q)$ with kernels $A(x,x';q)$ and $B(x,x';q)$ we introduce the standard composition law

$$(AB)(x,x';q) = \int dx'' A(x,x'';q)B(x'',x';q), \tag{1.21}$$

if the integral exists in terms of distributions. In terms of kernels $A(p;\mathbf{q})$ and $B(p;\mathbf{q})$ this composition takes the form of a shifted convolution

$$(AB)(p;\mathbf{q}) = \int dp' A(p-p';\mathbf{q}+p')B(p';\mathbf{q}). \tag{1.22}$$

An operator A can have an inverse A^{-1} in the sense of this composition, i.e., such that $AA^{-1}=I$ and $A^{-1}A=I$, where I is the unity operator in $\mathcal{S}'$, i.e., $I(x,x';q)=\delta(x-x')$ in the x-space or $I(p;\mathbf{q})=\delta(p)$ in the p-space, being $\delta(x)$ and $\delta(p)$ two-dimensional δ-functions.

We will use also the following notation for the shift with respect to the complex variable $\mathbf{q}$:

$$A^{(\mathbf{z})}(p;\mathbf{q}) = A(p;\mathbf{q}+\mathbf{z}), \quad \mathbf{z}\in\mathbb{C}^2, \tag{1.23}$$

that, thanks to Eq. (1.14), in the x-space reads

$$A^{(\mathbf{z})}(x,x';q) = e^{i\mathbf{z}_\Re(x-x')}A(x,x';q+\mathbf{z}_\Im). \tag{1.24}$$

Of course the two representations in the x-space and in the p-space are equivalent and, in principle, one could work always in one of them. However, it is often convenient to pass from one representation to the other. Thus, the p-space is more suitable for studying analyticity properties, while boundedness is more easily studied in the x-space.

For a generic operator $A(q)$ with kernel $A(x,x';q)$ it can be convenient to consider the operation

$$\widehat{A}(x,x';q) = e^{q(x-x')}A(x,x';q), \tag{1.25}$$

furnishing what we call the "hat kernel" of $A(q)$ in the x-space. In the special case of a kernel $L(x,x';q)$ which is, according to the definition (1.10), an extension of a differential operator $\mathcal{L}(x,i\partial_x)$ this operation is just the inverse of the extension procedure, i.e.,

$$\widehat{L}(x,x';q) = \mathcal{L}(x,i\partial_x)\delta(x-x'). \tag{1.26}$$

In general, however, $\widehat{A}(x,x';q)$ does depend on q nontrivially and, due to the exponential factor in Eq. (1.25), in contrast with $A(x,x';q)$, does not belong to the space $\mathcal{S}'(\mathbb{R}^6)$ of tempered distributions.

Operation (1.25) has no analog in terms of the p-representation. In the x-representation local properties of kernels are preserved, so we can reformulate (1.21) and (1.18) in terms of the hat kernels getting

$$\widehat{(AB)}(x,x';q) = \int dx''\widehat{A}(x,x'';q)\widehat{B}(x'',x';q), \tag{1.27}$$

$$A(p;\mathbf{q}) = \frac{1}{(2\pi)^2}\int dx \int dx' \mathrm{e}^{i(p+\mathbf{q})x - i\mathbf{q}x'}\widehat{A}(x,x';\mathbf{q}_\mathfrak{D}). \tag{1.28}$$

If we consider the differential operator $\mathcal{L}(x,i\partial_x)$ and the composition of its extension L with an operator B, that is LB and BL, by applying the transformation (1.25) we obtain

$$\widehat{LB}(x,x';q) = \mathcal{L}(x,i\partial_x)\widehat{B}(x,x';q), \quad \widehat{BL}(x,x';q) = \mathcal{L}^d(x',i\partial_{x'})\widehat{B}(x,x';q), \tag{1.29}$$

where $\mathcal{L}^d$ is the operator dual to $\mathcal{L}$. In what follows we shall use a special notation for formulas of this type writing

$$\widehat{LB}(q) = \vec{\mathcal{L}}\widehat{B}(q), \quad \widehat{BL}(q) = \widehat{B}(q)\overleftarrow{\mathcal{L}}, \tag{1.30}$$

so that $\vec{\mathcal{L}}$ denotes the operator $\mathcal{L}$ applied to the x variable of the kernel $\widehat{B}(x,x';q)$ and $\overleftarrow{\mathcal{L}}$ denotes the operator dual to $\mathcal{L}$ applied to the x' variable of the same kernel.

The dual and adjoint hat operators are given, respectively, as

$$\widehat{A}^d(x,x';q) = \widehat{A}(x',x;-q), \tag{1.31}$$

$$\widehat{A}^\dagger(x,x';q) = \overline{\widehat{A}(x',x;-q)}. \tag{1.32}$$

The main object of our approach is the extended resolvent (or resolvent for short) $M(q)$ of the operator $L(q)$, which is defined as the inverse of the operator L, i.e.,

$$L(q)M(q) = M(q)L(q) = I. \tag{1.33}$$

In terms of the corresponding hat operators the definition of the resolvent M reads

$$\vec{\mathcal{L}}\widehat{M}(q) = I = \widehat{M}(q)\overleftarrow{\mathcal{L}}, \tag{1.34}$$

which shows that $\widehat{M}(q)$ is a two-parameter set of Green's functions of the operator $\mathcal{L}$. It is worth stressing the fact that the extended pseudodifferential operators, in contrast with the pseudodifferential operators, have hat kernels which depend on q play here and will play in the following a crucial role in the theory.

If we consider now the resolvent M of L and the resolvent M' of another extended differential operator L' we can interlace the two resolvents by noticing that, if *associativity is assumed*, they satisfy the following generalized Hilbert identity:

$$M' - M = -M'(L'-L)M = -M(L'-L)M'. \tag{1.35}$$

On the other side, if M is inverse of L and M' satisfies Eq. (1.35) then M' is inverse of L'. Therefore, if the inverse M of L is known, the two equations in Eq. (1.35) become two integral

equations, one dual to the other, defining the resolvent M' of L'. This Hilbert identity is the main tool we will use in the whole spectral theory of differential operators.

The resolvent defined in Eq. (1.33) is not unique even under conditions that it is simultaneously right and left inverse of operator $L(q)$ and its kernel belongs to the space of tempered distributions. This problem is resolved by associativity assumption made in derivation of Eq. (1.35). Indeed, let us consider Eq. (1.35) for $L=L(q)$ and $L'=L^{(\mathbf{z})}(q)$ [so that by Eqs. (1.33) and (1.24) also $M'=M^{(\mathbf{z})}(q)$]:

$$M^{(\mathbf{z})}(q) - M(q) = - M^{(\mathbf{z})}(q)(L^{(\mathbf{z})}(q) - L(q))M(q). \tag{1.36}$$

Notice that, due to the definition of a shift in Eq. (1.24), the left-hand side of Eq. (1.36) is a tempered distribution with respect to q-variables and smooth, infinitely differentiable function of $\mathbf{z}$. This implies that the product of distributions in the right-hand side must also be a well defined tempered distribution for any value of $\mathbf{z}$ and any order of operations. By considering some simple examples one can check that this requirement determines the inverse $M(q)$ uniquely. Below we use this Hilbert identity for studying properties of the resolvent with respect to the parameter q, such as continuity and differentiability.

D. Green's functions and Jost solutions for a generic potential

The extension of the nonstationary Schrödinger operator (1.2) is given by

$$L(q) = L_0(q) - u(q), \tag{1.37}$$

where in the x-space

$$L_0(x,x';q) = [i(\partial_{x_2} + q_2) + (\partial_{x_1} + q_1)^2]\delta(x-x'), \quad u(x,x';q) = u(x)\,\delta(x-x'). \tag{1.38}$$

Notice that, due to the reality of the potential $u(x)$, by definition (1.20) we have that the operator $L(q)$ is Hermitian

$$L^{\dagger}(q) = L(q), \tag{1.39}$$

as well as the resolvent

$$M^{\dagger}(q) = M(q). \tag{1.40}$$

Hermiticity condition (1.40) for the resolvent is equivalent to

$$\overline{\widehat{M}(x,x';q)} = \widehat{M}(x',x;-q). \tag{1.41}$$

Of special relevance in the following will be Green's function $\mathcal{G}(x,x',\mathbf{k})$ obtained by considering the following reduction of $\widehat{M}(q)$ depending on the complex spectral parameter $\mathbf{k}$:

$$\mathcal{G}(\mathbf{k}) = \widehat{M}(q)|_{q=\ell_{\mathfrak{I}}(\mathbf{k})}, \quad \mathbf{k} \in \mathbb{C}, \tag{1.42}$$

where $\ell(\mathbf{k})$ is the special two-component vector

$$\ell(\mathbf{k}) = (\mathbf{k},\mathbf{k}^2). \tag{1.43}$$

Since $\widehat{M}(x,x',q)$ is growing exponentially as a function of x and x', the same property has the kernel $\mathcal{G}(x,x',\mathbf{k})$ for generic $\mathbf{k} \in \mathbb{C}$. But the function

$$G(x,x',\mathbf{k}) = \mathrm{e}^{i\ell_{\mathfrak{R}}(\mathbf{k})(x-x')}M\,(x,x',q)|_{q=\ell_{\mathfrak{I}}(\mathbf{k})}, \tag{1.44}$$

being a reduction of the resolvent itself belongs to $\mathcal{S}'$ and due to Eq. (1.25) it is simply related to $\mathcal{G}(\mathbf{k})$ by

$$G(x,x',\mathbf{k}) = \mathrm{e}^{i\ell(\mathbf{k})(x-x')}\mathcal{G}(x,x',\mathbf{k}). \tag{1.45}$$

As regards the so called advanced/retarded Green's functions, they can be obtained by the following reduction of the resolvent:

$$\mathcal{G}_{\pm} = \lim_{q_2\to\pm 0}\lim_{q_1\to 0}\widehat{M}(q). \tag{1.46}$$

Thanks to Eq. (1.34) we have

$$\vec{\mathcal{L}}\mathcal{G}(\mathbf{k}) = I = \mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}, \tag{1.47}$$

$$\vec{\mathcal{L}}\mathcal{G}_{\pm} = I = \mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}, \tag{1.48}$$

and thanks to Eq. (1.41)

$$\overline{\mathcal{G}(x,x',\mathbf{k})} = \mathcal{G}(x',x,\overline{\mathbf{k}}), \quad \mathbf{k}\in\mathbb{C}, \tag{1.49}$$

$$\overline{\mathcal{G}_{+}(x,x')} = \mathcal{G}_{-}(x',x). \tag{1.50}$$

Then, by using these Green's functions we can introduce the so called Jost and advanced/retarded solutions and their dual

$$\Phi(\mathbf{k}) = \mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_0\Phi_0(\mathbf{k}), \quad \Psi(\mathbf{k}) = \Psi_0(\mathbf{k})\vec{\mathcal{L}}_0\mathcal{G}(\mathbf{k}), \tag{1.51}$$

$$\Phi_{\pm}(k) = \mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}_0\Phi_0(k), \quad \Psi_{\pm}(k) = \Psi_0(k)\vec{\mathcal{L}}_0\mathcal{G}_{\pm}, \tag{1.52}$$

where $\mathcal{L}_0$ is the bare differential operator introduced in Eq. (1.38) and

$$\Phi_0(x,\mathbf{k}) = \mathrm{e}^{-i\ell(\mathbf{k})x}, \quad \Psi_0(x,\mathbf{k}) = \mathrm{e}^{i\ell(\mathbf{k})x}. \tag{1.53}$$

Here and in what follows we use for shortness operator notations for relations of the kind (1.51) and (1.52), where, say, the first two stand for

$$\Phi(x,\mathbf{k}) = \int dx'(\mathcal{L}_0^d(x',\partial_{x'})\mathcal{G}(x,x',\mathbf{k}))\Phi_0(x',\mathbf{k}), \tag{1.54}$$

$$\Psi(x',\mathbf{k}) = \int dx\Psi_0(x,\mathbf{k})\mathcal{L}_0(x,\partial_x)\mathcal{G}(x,x',\mathbf{k}). \tag{1.55}$$

Thanks to (1.47) and (1.48) functions $\Phi(x,\mathbf{k})$, $\Psi(x,\mathbf{k})$, $\Phi_{\pm}(x)$, and $\Psi_{\pm}(x)$ are solutions of the Schrödinger equation and its dual, i.e.,

$$\vec{\mathcal{L}}\Phi(\mathbf{k}) = 0, \quad \Psi(\mathbf{k})\overleftarrow{\mathcal{L}} = 0, \tag{1.56}$$

$$\vec{\mathcal{L}}\Phi_{\pm}(k) = 0, \quad \Psi_{\pm}(k)\overleftarrow{\mathcal{L}} = 0. \tag{1.57}$$

However, one must be advised that the integrals in the rhs of definitions (1.51) and (1.52) for u not decaying at large spaces are divergent and must be regularized. In the following section we show how to overcome this problem and, then, how to proceed in building the inverse scattering theory.

E. Dressing procedure

If $M_N(q)$ is the resolvent of $L_N(q)$, the extension of the nonstationary Schrödinger operator defined in Eqs. (1.37) and (1.38) with $u=u_N$, then the resolvent $M(q)$ of $L(q)$, the extension ot the operator with potential $u=u_N+u'$, can be obtained by dressing $M_N(q)$. In fact, from the two Hilbert identities in Eq. (1.35) we get the two reciprocally dual integral equations

$$M(q) = M_N(q) + M_N(q)u'M(q), \quad M(q) = M_N(q) + M(q)u'M_N(q), \tag{1.58}$$

where u' is the multiplication operator with kernel $u'(x,x';q)=u'(x)\delta(x-x')$.

Correspondingly, for Green's functions we have the integral equations

$$\mathcal{G}(\mathbf{k}) = \mathcal{G}_N(\mathbf{k}) + \mathcal{G}_N(\mathbf{k})u'\mathcal{G}(\mathbf{k}), \tag{1.59}$$

$$\mathcal{G}_\pm = \mathcal{G}_{N,\pm} + \mathcal{G}_{N,\pm}u'\mathcal{G}_\pm, \tag{1.60}$$

and their dual, where $\mathcal{G}_N(\mathbf{k})$ and $\mathcal{G}_{N,\pm}$ are Green's function and advanced/retarded Green's functions of the operator $\mathcal{L}_N$, defined according to Eqs. (1.42) and (1.46). Taking into account that in Ref. 25 we derived explicitly the extended resolvent M_N and Green's functions $\mathcal{G}_N(\mathbf{k})$ and $\mathcal{G}_{N,\pm}$, the above equations enable us to develop the inverse scattering theory for a potential describing a perturbation of the N-soliton potential by a smooth decaying function $u'(x)$ of two variables.

We already mentioned that the main tool of our construction is the Hilbert identity (1.36). In fact, for a potential u as in Eq. (1.7), taking into account that the potential does not depend on q, we can write

$$L^{(\mathbf{z})}(q) - L(q) = L_N^{(\mathbf{z})}(q) - L_N(q) = -L_N^{(\mathbf{z})}(q)(M_N^{(\mathbf{z})}(q) - M_N(q))L_N(q),$$

and, then, from Eq. (1.36) we get

$$M^{(\mathbf{z})}(q) - M(q) = (M(q)L_N(q))^{(\mathbf{z})}(M_N^{(\mathbf{z})}(q) - M_N(q))L_N(q)M(q). \tag{1.61}$$

This Hilbert identity can be fruitfully used for studying the singularities of the resolvent $M(q)$, because by its means they can be obtained by dressing the singularities of the resolvent $M_N(q)$ which are explicitly known. In particular, let us mention that the shift operation defined in Eq. (1.24) in terms of the hat kernels means that

$$A^{(\mathbf{z})}(x,x';q) = \mathrm{e}^{(i\mathbf{z}-q)(x-x')}\widehat{A}(x,x';q+\mathbf{z}_\jmath). \tag{1.62}$$

Then the ∂-bar derivatives of Eq. (1.61) with respect to complex variables $\mathbf{z}_1$ and $\mathbf{z}_2$ at $\mathbf{z}=0$ give the relations

$$\frac{\partial\widehat{M}(q)}{\partial q_i} = \widehat{M}(q)\overleftarrow{\mathcal{L}}_N\frac{\partial\widehat{M}_N(q)}{\partial q_i}\vec{\mathcal{L}}_N\widehat{M}(q), \quad i=1,2, \tag{1.63}$$

where we used notations in Eq. (1.30). It is necessary to mention that the products of hat-kernels are not associative due to their exponential growth and, therefore, the arrows over operators denote also the order of operations.

The Hilbert identity (1.61) can also be reduced to special values of the resolvents giving Hilbert identities involving Green's functions. In fact, recalling the definition (1.42) of Green's function $\mathcal{G}(\mathbf{k})$ we see that its limiting values on the real axis,

$$\mathcal{G}^\pm(x,x',k) = \mathcal{G}(x,x',k\pm i0), \quad k\in\mathbb{R}, \tag{1.64}$$

correspond to the limits of the resolvent at $q=0$,

$$\mathcal{G}^{\pm}(x,x',k) = \lim_{q_1 \to \pm 0} \widehat{M}(x,x';q_1,2kq_1). \tag{1.65}$$

Also, advanced/retarded Green's functions are obtained as limiting values of the resolvent at $q=0$ according to the definition (1.46). Let us consider the Hilbert identity (1.61) at $\mathbf{z}_{\mathfrak{R}}=0$, i.e.,

$$M(q') - M(q) = (M(q')L_N(q'))(M_N(q') - M_N(q))L_N(q)M(q), \tag{1.66}$$

where $q' = q + \mathbf{z}_{\mathfrak{I}}$ [see Eq. (1.62)]. Performing here the limits (1.65) and (1.46) for q and q' we derive

$$\mathcal{G}^{\sigma}(k) - \mathcal{G}_{\pm} = \mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}_N(\mathcal{G}^{\sigma}_N(k) - \mathcal{G}_{N,\pm})\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(k), \quad \sigma = +,-, \tag{1.67}$$

$$\mathcal{G}_{+} - \mathcal{G}_{-} = \mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}_N(\mathcal{G}_{N,+} - \mathcal{G}_{N,-})\vec{\mathcal{L}}_N\mathcal{G}_{\mp}, \tag{1.68}$$

where the rhs of the last equality is independent of the choice of the upper or bottom signs.

II. *N*-SOLITON POTENTIAL AND RELATED OBJECTS

In order to get in the following by a dressing procedure all mathematical entities involved in the inverse scattering method we need not only the explicit form of the N-soliton potential u_N of the nonstationary Schrödinger operator, but also the related resolvent and such its reductions as Green's functions, Jost and what we call auxiliary Jost solutions. Here, we revisit the results obtained in Refs. 22 and 25 and, in addition, we present the asymptotic behavior of the Jost solutions at large space distances and the properties of the resolvent and Green's function, including their singularities.

A. Pure *N*-soliton potential and Jost solutions

In this article we consider the case where u_N in Eq. (1.7) is a pure N-soliton potential. Then following Ref. 25 we can choose as discrete spectral data N *different* complex parameters $\lambda_1, \ldots, \lambda_N$ and a $n \times n$ constant matrix C. As was shown in Ref. 25 parameters λ_n, without loss of generality in the case of the pure N-soliton potential, can be chosen in the upper half plane:

$$\lambda_{n\mathfrak{I}} > 0, \quad n = 1, \ldots, N. \tag{2.1}$$

In what follows we use notation

$$\lambda_n^{+} = \lambda_n, \quad \lambda_n^{-} = \overline{\lambda_n}. \tag{2.2}$$

Matrix $C = \|C_{m,n}\|_{m,n=1,\ldots,N}$ must be Hermitian and strictly positive:[23,24]

$$C^{\dagger} = C, \quad C > 0. \tag{2.3}$$

If we introduce the $n \times n$ constant matrix

$$\Lambda = \left\| \frac{1}{i(\lambda_m^{-} - \lambda_n^{+})} \right\|_{m,n=1,\ldots,N} \tag{2.4}$$

and define a matrix $B(x)$ as the product

$$B(x) = \operatorname{diag}\{e^{i\ell(\lambda_1^{-})x}, \ldots, e^{i\ell(\lambda_N^{-})x}\}\Lambda \operatorname{diag}\{e^{-i\ell(\lambda_1^{+})x}, \ldots, e^{-i\ell(\lambda_N^{+})x}\}, \tag{2.5}$$

where ℓ is defined in Eq. (1.43), then, the potential u_N is given by

$$u_N(x) = -2\partial_{x_1}^2 \log \det(B(x) + C). \tag{2.6}$$

The potential derived in Ref. 22 corresponds to a diagonal matrix C. In Ref. 23 the case of a generic matrix C was introduced and it was shown that conditions (2.3) are equivalent to the requirement that the potential u_N is real and regular.

Let us introduce the function

$$\tau(\mathbf{k}) = \left(\prod_{n=1}^{N} \frac{\mathbf{k} - \lambda_n^+}{\mathbf{k} - \lambda_n^-}\right)^{\theta(-\mathbf{k}_\jmath)}, \tag{2.7}$$

that has poles at all points $\mathbf{k} = \overline{\lambda_n}$ and has no zeros. Then, the Jost solution $\varphi(x,\mathbf{k})$ of the nonstationary Schrödinger equation corresponding to the potential (2.6), i.e., satisfying

$$(i\partial_{x_2} + \partial_{x_1}^2 - u_N(x))\varphi(x,\mathbf{k}) = 0, \tag{2.8}$$

is given by (we use the form derived in Ref. 24)

$$\varphi(x,\mathbf{k}) = \frac{1}{\tau(\mathbf{k})\det(B(x) + C)} \det\begin{pmatrix} B_{mn}(x) + C_{mn} & (ie^{i(\ell(\lambda_m^-) - \ell(\mathbf{k}))x})/(\mathbf{k} - \lambda_m^-) \\ e^{-i\ell(\lambda_n^+)x} & e^{-i\ell(\mathbf{k})x} \end{pmatrix}, \tag{2.9}$$

where the matrix in the rhs is obtained by bordering the $N \times N$ matrix $B(x) + C$ with a column in the upper right corner and a row in the bottom left corner, as indicated. In what follows we also need the dual Jost solution $\psi(x,\mathbf{k})$ of the dual equation

$$(-i\partial_{x_2} + \partial_{x_1}^2 - u_N(x))\psi(x,\mathbf{k}) = 0, \tag{2.10}$$

which is given by

$$\psi(x,\mathbf{k}) = \overline{\varphi(x,\bar{\mathbf{k}})}. \tag{2.11}$$

Using notations of the kind used in Eq. (1.29) we write Eqs. (2.8) and (2.10) in the form

$$\vec{\mathcal{L}}_N \varphi(\mathbf{k}) = 0, \quad \psi(\mathbf{k})\vec{\mathcal{L}}_N = 0. \tag{2.12}$$

To formulate the asymptotic behavior of these Jost solutions we introduce

$$\chi(x,\mathbf{k}) = e^{i\ell(\mathbf{k})x}\varphi(x,\mathbf{k}), \quad \xi(x,\mathbf{k}) = e^{-i\ell(\mathbf{k})x}\psi(x,\mathbf{k}), \tag{2.13}$$

so that by Eq. (2.11) $\xi(x,\mathbf{k}) = \overline{\chi(x,\bar{\mathbf{k}})}$. Then by Eq. (2.9) we get

$$\lim_{\mathbf{k}\to\infty} \chi(x,\mathbf{k}) = \lim_{\mathbf{k}\to\infty} \xi(x,\mathbf{k}) = 1, \tag{2.14}$$

and in a generic direction of $x \to \infty$, i.e., such that $|x_1 + 2\lambda_{n\Re} x_2| \to \infty$ for all $n = 1, \ldots, N$, and for any $\mathbf{k}$, $\mathbf{k}_\jmath \neq 0$,

$$\lim_{x\to\infty} (\chi(x,\mathbf{k}) - \chi_{\text{as}}(x,\mathbf{k})) = 0, \tag{2.15}$$

where

$$\chi_{\text{as}}(x,\mathbf{k}) = \prod_{n=1}^{N} \left(\frac{\mathbf{k} - \lambda_n^+}{\mathbf{k} - \lambda_n^-}\right)^{(\operatorname{sgn} \mathbf{k}_\jmath)\theta(\mathbf{k}_\jmath(x_1 + 2\lambda_{n\Re} x_2))}. \tag{2.16}$$

In particular,

$$\lim_{x_1 \to -\mathbf{k}_\jmath \infty} \chi(x,\mathbf{k}) = 1, \quad \lim_{x_1 \to +\mathbf{k}_\jmath \infty} \xi(x,\mathbf{k}) = 1, \tag{2.17}$$

$$\lim_{x_1\to+\mathbf{k}_\Im\infty}\chi(x,\mathbf{k})=\frac{1}{t(\mathbf{k})},\qquad \lim_{x_1\to-\mathbf{k}_\Im\infty}\xi(x,\mathbf{k})=\frac{1}{t(\mathbf{k})},\tag{2.18}$$

where notation $\mathbf{k}_\Im\infty$ in the limit denotes sign of the infinity, and where we defined the transmission coefficient as

$$t(\mathbf{k})=\tau(\mathbf{k})\overline{\tau(\bar{\mathbf{k}})}\equiv\prod_{n=1}^{N}\left(\frac{\mathbf{k}-\lambda_n^-}{\mathbf{k}-\lambda_n^+}\right)^{\operatorname{sgn}\mathbf{k}_\Im},\tag{2.19}$$

so that

$$t(\bar{\mathbf{k}})=\overline{t(\mathbf{k})},\quad \mathbf{k}\in\mathbb{C}.\tag{2.20}$$

B. Auxiliary Jost solutions

The transmission coefficient is a meromorphic function in the upper and bottom half planes of the spectral parameter $\mathbf{k}\in C$, that has poles at all points $\mathbf{k}=\lambda_n^\pm$, $n=1,\dots,N$. It is convenient also to introduce a notation for the residual of the transmission coefficient, i.e.,

$$\vartheta_n^+=-i\operatorname*{res}_{\mathbf{k}=\lambda_n^+}t(\mathbf{k}),\qquad \vartheta_n^-=i\operatorname*{res}_{\mathbf{k}=\lambda_n^-}t(\mathbf{k}).\tag{2.21}$$

We also use special notations for the values of the Jost solutions at points $\mathbf{k}=\lambda_n^\pm$:

$$\varphi_n^\pm(x)=\sqrt{2\pi}\varphi(x,\lambda_n^\pm),\qquad \psi_n^\pm(x)=\sqrt{2\pi}\psi(x,\lambda_n^\pm),\tag{2.22}$$

so that by Eqs. (2.11), (2.2), and (2.20),

$$\overline{\varphi_n^\pm(x)}=\psi_n^\mp(x),\qquad \overline{\vartheta_-^\pm}=\vartheta_+^\mp.\tag{2.23}$$

Now we introduce piecewise constant functions of q_1,

$$\varphi_n(x,q_1)=\theta(\lambda_{n\Im}-|q_1|)[\theta(q_1)\varphi_n^+(x)+\theta(-q_1)\varphi_n^-(x)],\tag{2.24}$$

$$\psi_n(x,q_1)=\theta(\lambda_{n\Im}-|q_1|)[\theta(q_1)\psi_n^+(x)+\theta(-q_1)\psi_n^-(x)],\tag{2.25}$$

$$\vartheta_n(q_1)=\theta(q_1)\vartheta_n^++\theta(-q_1)\vartheta_n^-,\tag{2.26}$$

so that functions $\varphi_n(x,q_1)$ and $\psi_n(x,q_1)$ are different from zero only on the intervals $|q_1|<\lambda_{n\Im}$. These functions play an essential role in what follows and we call them auxiliary Jost solutions as they obey Eq. (2.12) and are reciprocally dual since from Eq. (2.11):

$$\overline{\varphi_n(x,q_1)}=\psi_n(x,-q_1).\tag{2.27}$$

In the following, these functions, when dressed by adding to u_N a nontrivial perturbation u' as indicated in Eq. (1.7), acquire a nontrivial dependence on q_1. From results of Ref. 25 it follows that these functions satisfy the following boundedness properties:

$$\sup_x|\varphi_n(x,q_1)|<\infty,\qquad \sup_x|\psi_n(x,q_1)|<\infty,\tag{2.28}$$

$$\sup_x|\chi_n(x,q_1)|<\infty,\qquad \sup_x|\xi_n(x,q_1)|<\infty,\tag{2.29}$$

where in analogy with Eq. (2.13) we introduced

$$\chi_n(x,q_1)=\mathrm{e}^{i\ell(\lambda_{n\Re}+iq_1)x}\varphi_n(x,q_1),\quad \xi_n(x,q_1)=\mathrm{e}^{-i\ell(\lambda_{n\Re}+iq_1)x}\psi_n(x,q_1), \tag{2.30}$$

that thanks to Eqs. (2.15), (2.24), and (2.25), have finite nonzero limits at large x.

C. Inverse problem

The Jost solutions $\varphi(x,\mathbf{k})$ and $\psi(x,\mathbf{k})$ are analytic functions of the complex variable $\mathbf{k}$ in the upper and bottom half plane with a discontinuity along the real axis. In order to describe this discontinuity we use the notations

$$\varphi^{\pm}(x,k)=\varphi(x,k\pm i0),\quad \psi^{\pm}(x,k)=\psi(x,k\pm i0), \tag{2.31}$$

$$t^{\pm}(k)=t(k\pm i0),\quad k\in\mathbb{R}, \tag{2.32}$$

that by Eqs. (2.11) and (2.20) obey conjugation properties

$$\overline{\varphi^{\pm}(x,k)}=\psi^{\mp}(x,k), \tag{2.33}$$

$$\overline{t^{+}(k)}=t^{-}(k). \tag{2.34}$$

In analogy to these relations we have for the boundary values of the auxiliary Jost solutions and functions ϑ_n directly by (2.24)–(2.26) relations

$$\varphi_n^{\pm}(x)=\varphi_n(x,\pm 0),\quad \psi_n^{\pm}(x)=\psi_n(x,\pm 0), \tag{2.35}$$

$$\vartheta_n^{\pm}=\vartheta_n(\pm 0). \tag{2.36}$$

Then, the Jost solutions (2.9) and (2.11) are determined by their analyticity properties and conditions (2.14) as solutions of the system (see Refs. 23 and 24)

$$t^{+}(k)\varphi^{+}(k)=\varphi^{-}(k), \tag{2.37}$$

$$\varphi_n^{+}=\sum_{m=1}^{N}\varphi_m^{-}\vartheta_m^{-}C_{mn}, \tag{2.38}$$

or, correspondingly,

$$t^{-}(k)\psi^{-}(k)=\psi^{+}(k), \tag{2.39}$$

$$\psi_n^{-}=\sum_{m=1}^{N}C_{nm}\vartheta_m^{+}\psi_m^{+}, \tag{2.40}$$

where we omitted the dependence on x, as often will be done below when not misleading. Thanks to Eqs. (2.37)–(2.40) we have relations

$$t^{+}(k)\varphi^{+}(k)\otimes\psi^{+}(k)=t^{-}(k)\varphi^{-}(k)\otimes\psi^{-}(k), \tag{2.41}$$

$$\sum_{n=1}^{N}\vartheta_n^{+}\varphi_n^{+}\otimes\psi_n^{+}=\sum_{n=1}^{N}\vartheta_n^{-}\varphi_n^{-}\otimes\psi_n^{-}, \tag{2.42}$$

where we used the standard definition of the direct product:

$$(\varphi_n(q_1)\otimes\psi_n(q_1))(x,x')=\varphi(x,q_1)\psi(x',q_1). \tag{2.43}$$

D. Resolvent of the pure *N*-soliton potential

Bilinear representation for the resolvent in terms of the Jost and auxiliary Jost solutions for the Nth Darboux transformation of rapidly decaying potential was derived in Ref. 25. Here we present a special case of that result corresponding to the pure N-soliton potential (2.6). Thus, the hat kernel [see Eq. (1.25)] of this resolvent equals to

$$\hat{M}_N(x,x';q) = \frac{1}{2\pi i}\int_{\mathbf{k}_\mathfrak{I}=q_1} d\mathbf{k}_\mathfrak{R}[\theta(x_2-x_2')-\theta(2\mathbf{k}_\mathfrak{R}q_1-q_2)]t(\mathbf{k})\varphi(x,\mathbf{k})\psi(x',\mathbf{k}) + \frac{1}{2\pi i}\sum_{n=1}^{N}\vartheta_n(q_1)[\theta(x_2-x_2')-\theta(2\lambda_{n\mathfrak{R}}q_1-q_2)]\varphi_n(x,q_1)\psi_n(x',q_1), \tag{2.44}$$

where notations (2.24)–(2.26) were used. In analogy to Eq. (1.34) it obeys differential equations

$$\vec{\mathcal{L}}_N\widehat{M}_N(q) = I = \widehat{M}_N(q)\overleftarrow{\mathcal{L}}_N, \tag{2.45}$$

that easily follows by means of the completeness relation,

$$\frac{1}{2\pi}\left\{\int d\mathbf{k}_\mathfrak{R}t(\mathbf{k})\varphi(x,\mathbf{k})\psi(x',\mathbf{k}) + \sum_{n=1}^{N}\vartheta_n(\mathbf{k}_\mathfrak{I})\varphi_n(x,\mathbf{k}_\mathfrak{I})\psi_n(x',\mathbf{k}_\mathfrak{I})\right\}_{x_2=x_2'} = \delta(x_1-x_1'), \tag{2.46}$$

derived in Ref. 25.

Convergency of the integral in Eq. (2.44) as well as the property that M_N belongs to the space of tempered distributions follow (see Ref. 25 for details) from the properties of the Jost and auxiliary Jost solutions. Moreover, in Ref. 25 it was proved that for generic q kernel $M_N(x,x';q)$ decays exponentially on the x-plane. From the conjugation relations (2.11), (2.20), and (2.27), we deduce that $M_N(q)$ obeys the conjugation property (1.41), in agreement with the reality of the potential $u_N(x)$. Both terms in the rhs of (2.44) are piecewise continuous functions of q-variables. Both of them are discontinuous at $q_1=\pm\lambda_{n\mathfrak{I}}$ [the first term thanks to the poles of $t(\mathbf{k})$, see Eq. (2.19)] and these discontinuities are compensated thanks to Eqs. (2.24)–(2.26). Thus the resolvent is discontinuous only at the point $q=0$ and on the intervals $q_2=2\lambda_{n\mathfrak{R}}q_1$, $n=1,\ldots,N$. Using notations (2.24)–(2.26) and (2.43) we get for such nth discontinuity expression

$$\widehat{M}_N(q)|_{q_2=2\lambda_{n\mathfrak{R}}q_1+0} - \widehat{M}_N(q)|_{q_2=2\lambda_{n\mathfrak{R}}q_1-0} = \frac{\vartheta_n(q_1)}{2\pi i}\varphi_n(q_1)\otimes\psi_n(q_1), \tag{2.47}$$

that is different from zero only on the interval $|q_1|<\lambda_{n\mathfrak{I}}$ [see Eqs. (2.24) and (2.25)]. At the end points of these intervals function $\widehat{M}_N(q)$ has logarithmic singularities. More precisely, we can decompose the resolvent into a regular and a singular part as follows:

$$M_N(q) = M_{N,\mathrm{reg}}(q) + M_{N,\mathrm{sing}}(q), \tag{2.48}$$

where the regular part, $M_{N,\mathrm{reg}}(q)$, is finite at any $q\in R^2$ and continuously differentiable for any $q\neq 0$. The singular part is given by

$$\widehat{M}_{N,\mathrm{sing}}(q) = \frac{1}{(2\pi)^2}\sum_{\sigma=\pm}\sum_{n=1}^{N}\theta(\sigma q_1)\vartheta_n^\sigma\varphi_n^\sigma\otimes\psi_n^\sigma\log\left(\sigma\left(q_1+i\lambda_n^\sigma-i\frac{q_2}{2q_1}\right)\right), \tag{2.49}$$

where we used notations (2.2) and where $\log\mathbf{z}$ has cut along the negative part of the $\mathbf{z}_\mathfrak{R}$-axis, so that $\partial\log z/\partial\bar{z}=-\pi\theta(-z_\mathfrak{R})\delta(z_\mathfrak{I})$.

Derivatives (in the sense of distributions) of the resolvent with respect to q-variables follow from Eq. (2.44), analyticity properties of the Jost solutions, and decomposition (2.48) and (2.49). At $q\neq 0$ we get

$$\frac{\partial \widehat{M}_N(q)}{\partial q_1} = \frac{i}{\pi}\left[\int_{\mathbf{k}_\mathfrak{I}=q_1} d\mathbf{k}_\mathfrak{R}\bar{\mathbf{k}}\,\delta(2\mathbf{k}_\mathfrak{R}\mathbf{k}_\mathfrak{I}-q_2)t(\mathbf{k})\varphi(\mathbf{k})\otimes\psi(\mathbf{k}) + \sum_{n=1}^{N}\lambda_{n\mathfrak{R}}\delta(2\lambda_{n\mathfrak{R}}q_1-q_2)\vartheta_n(q_1)\varphi_n(q_1)\otimes\psi_n(q_1)\right], \tag{2.50}$$

$$\frac{\partial \widehat{M}_N(q)}{\partial q_2} = \frac{1}{2\pi i}\left[\int_{\mathbf{k}_\mathfrak{I}=q_1} d\mathbf{k}_\mathfrak{R}\,\delta(2\mathbf{k}_\mathfrak{R}\mathbf{k}_\mathfrak{I}-q_2)t(\mathbf{k})\varphi(\mathbf{k})\otimes\psi(\mathbf{k}) + \sum_{n=1}^{N}\delta(2\lambda_{n\mathfrak{R}}q_1-q_2)\vartheta_n(q_1)\varphi_n(q_1)\otimes\psi_n(q_1)\right], \tag{2.51}$$

that agree with Eq. (2.47) thanks to the definition of the logarithm. Thus in the region of continuity the kernel (2.44) of the resolvent is differentiable with respect to q in the standard sense. In the case $q_1=0$ the resolvent $\widehat{M}_N(q)|_{q_1=0}$ has additional discontinuity at $q_2=0$, as already noted in (1.46), while for $q_2\neq 0$ it is continuous thanks to Eqs. (2.41) and (2.42).

E. Green's functions

Green's function corresponding to the potential u_N follows from Eqs. (1.42) and (2.44) in the form

$$\mathcal{G}_N(x,x',\mathbf{k}) = \frac{1}{2\pi i}\left[\int d\alpha[\theta(x_2-x_2')-\theta(\alpha\mathbf{k}_\mathfrak{I})]t(\alpha+\mathbf{k})\varphi(x,\alpha+\mathbf{k})\psi(x',\alpha+\mathbf{k}) + \sum_{n=1}^{N}\vartheta_n(\mathbf{k}_\mathfrak{I})[\theta(x_2-x_2')-\theta(\mathbf{k}_\mathfrak{I}(\lambda_{n\mathfrak{R}}-\mathbf{k}_\mathfrak{R}))]\varphi_n(x,\mathbf{k}_\mathfrak{I})\psi_n(x',\mathbf{k}_\mathfrak{I})\right]. \tag{2.52}$$

The Green function $\mathcal{G}_N(x,x',\mathbf{k})$, being a reduction of a hat operator, is exponentially growing at large space, but once multiplied by an exponent according to Eq. (1.45) one gets a distribution

$$G_N(x,x',\mathbf{k}) = \mathrm{e}^{i\ell(\mathbf{k})(x-x')}\mathcal{G}_N(x,x',\mathbf{k}), \tag{2.53}$$

which is bounded and decaying when x (or x') tends to infinity. More exactly, for generic $\mathbf{k}$, i.e., such that $\mathbf{k}_\mathfrak{I}\neq 0,\lambda_{1\mathfrak{I}},\ldots,\lambda_{N\mathfrak{I}}$, $\mathbf{k}_\mathfrak{R}\neq\lambda_{1\mathfrak{R}},\ldots,\lambda_{N\mathfrak{R}}$, we get

$$G_N(x,x',\mathbf{k}) = \frac{\operatorname{sgn}\mathbf{k}_\mathfrak{I}}{2\pi(x_1+2\mathbf{k}x_2)}t(\mathbf{k})\chi_{\mathrm{as}}(x,\mathbf{k})\xi(x',\mathbf{k})+o(|x|^{-1}), \tag{2.54}$$

for $x\to\infty$, where we used definition (2.16). Moreover, by Eq. (2.52) we get

$$\lim_{\mathbf{k}\to\infty,\mathbf{k}_\mathfrak{I}\neq 0} G_N(x,x',\mathbf{k}) = 0. \tag{2.55}$$

Next, for advanced/retarted Green's functions we have by Eq. (1.46) from Eq. (2.44)

$$\mathcal{G}_{N,\pm}(x,x') = \pm\frac{\theta(\pm(x_2-x_2'))}{2\pi i}\left[\int d\alpha t^\sigma(\alpha)\varphi^\sigma(x,\alpha)\psi^\sigma(x',\alpha)+\sum_{n=1}^{N}\vartheta_n^\sigma\varphi_n^\sigma(x)\psi_n^\sigma(x')\right], \tag{2.56}$$

where $\sigma=+,-$ and the rhs thanks to Eqs. (2.41) and (2.42) is independent on the choice of this sign (in fact, these signs can be chosen independently in the integral term and in the sum).

By (1.42), (1.46), (1.41), and (2.45), these Green's functions obey the conjugation properties (1.49) and (1.50) and the differential Eqs. (1.47) and (1.48) with $\mathcal{L}_N$ substituting $\mathcal{L}$. Function $\mathcal{G}_N(\mathbf{k})$ has cuts in the complex $\mathbf{k}$-plane along the intervals connecting the pairs λ_n and $\overline{\lambda_n}$ for all n. By Eq. (1.42)

$$\mathcal{G}_N(\lambda_{n\mathfrak{R}} \pm 0 + i\mathbf{k}_\mathfrak{I}) = \widehat{M}_N(\mathbf{k}_\mathfrak{I}, 2\lambda_{n\mathfrak{R}}\mathbf{k}_\mathfrak{I} \pm 0\mathbf{k}_\mathfrak{I}), \tag{2.57}$$

so that by Eq. (2.47)

$$\mathcal{G}_N(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{I}) - \mathcal{G}_N(\lambda_{n\mathfrak{R}} - 0 + i\mathbf{k}_\mathfrak{I}) = \frac{\operatorname{sgn}\mathbf{k}_\mathfrak{I}\,\vartheta_n(\mathbf{k}_\mathfrak{I})}{2\pi i}\varphi_n(\mathbf{k}_\mathfrak{I}) \otimes \psi_n(\mathbf{k}_\mathfrak{I}). \tag{2.58}$$

Performing reduction (1.42) in equalities (2.50) and (2.51) we get that at $\mathbf{k}_\mathfrak{I} \neq 0$:

$$\frac{\partial \mathcal{G}_N(\mathbf{k})}{\partial \mathbf{k}_\mathfrak{I}} = \frac{\operatorname{sgn}\mathbf{k}_\mathfrak{I}}{2\pi} t(\mathbf{k})\varphi(\mathbf{k}) \otimes \psi(\mathbf{k}), \tag{2.59}$$

$$\frac{\partial \mathcal{G}_N(\mathbf{k})}{\partial \bar{\mathbf{k}}} = \frac{\operatorname{sgn}\mathbf{k}_\mathfrak{I}}{4\pi i}\sum_{n=1}^{N} \delta(\mathbf{k}_\mathfrak{R} - \lambda_{n\mathfrak{R}})\vartheta_n(\mathbf{k}_\mathfrak{I})\varphi_n(\mathbf{k}_\mathfrak{I}) \otimes \psi(\mathbf{k}_\mathfrak{I}), \tag{2.60}$$

so that with exception of the segments connecting the pairs of points $\mathbf{k}=\lambda_n^\pm$ and with exception of the real axis Green's function $\mathcal{G}_N(\mathbf{k})$ is analytic in the upper and bottom half planes.

At the end points of these segments function $\mathcal{G}_N(\mathbf{k})$ is singular as follows from Eqs. (1.42) and (2.49):

$$\mathcal{G}_N(\mathbf{k}) = \mathcal{G}_{N,\mathrm{reg}}(\mathbf{k}) + \mathcal{G}_{N,\mathrm{sing}}(\mathbf{k}), \tag{2.61}$$

$$\mathcal{G}_{N,\mathrm{sing}}(\mathbf{k}) = \sum_{n=1}^{N} \gamma_n(\mathbf{k})\varphi_n^\sigma \otimes \psi_n^\sigma, \quad \sigma = \operatorname{sgn}\mathbf{k}_\mathfrak{I}, \tag{2.62}$$

where we used notation (2.2) and where

$$\gamma_n(\mathbf{k}) = \frac{\vartheta_n(\mathbf{k}_\mathfrak{I})}{(2\pi)^2}\log(-i\sigma(\mathbf{k} - \lambda_n^\sigma)), \quad \sigma = \operatorname{sgn}\mathbf{k}_\mathfrak{I}, \tag{2.63}$$

where logarithm is defined like in Eqs. (2.49). Thanks to this definition of the logarithm and Eq. (2.60) the first term in the rhs of Eq. (2.61) is analytic for any $\mathbf{k} \in C$, $\mathbf{k}_\mathfrak{I} \neq 0$. In the singular part every nth term is discontinuous on the segment $\mathbf{k}_\mathfrak{R}=\lambda_{n\mathfrak{R}}$, $|\mathbf{k}_\mathfrak{I}| < \lambda_{n\mathfrak{I}}$. If for simplicity we assume that in addition to Eq. (2.1)

$$\lambda_{m\mathfrak{R}} \neq \lambda_{n\mathfrak{R}}, \quad \forall \ m \neq n \tag{2.64}$$

(the degenerate case can be considered by the limiting procedure) all these segments are mutually disjoint. Therefore, we can single out the singular behavior of Green's function in a vicinity of nth segment $\mathbf{k}_\mathfrak{R}=\lambda_{n\mathfrak{R}}$, $|\mathbf{k}_\mathfrak{I}| < \lambda_{n\mathfrak{I}}$ by writing

$$\mathcal{G}_N(\mathbf{k}) = \mathcal{G}_N^{(n)}(\mathbf{k}) + \gamma_n(\mathbf{k})\varphi_n^\sigma \otimes \psi_n^\sigma, \quad \sigma = \operatorname{sgn}\mathbf{k}_\mathfrak{I}, \tag{2.65}$$

where by Eqs. (2.61) and (2.62),

$$\mathcal{G}_N^{(n)}(\mathbf{k}) = \mathcal{G}_{N,\mathrm{reg}}(\mathbf{k}) + \sum_{m\neq n}^{N} \gamma_m(\mathbf{k})\varphi_m^\sigma \otimes \psi_m^\sigma. \tag{2.66}$$

Thus for every n we get Green's function $\mathcal{G}_N^{(n)}(\mathbf{k})$ which is analytic in a vicinity of the nth segment $\mathbf{k}_\mathfrak{R}=\lambda_{n\mathfrak{R}}$, $|\mathbf{k}_\mathfrak{I}| < \lambda_{n\mathfrak{I}}$ including the end points, but with the exception of the real $\mathbf{k}$-axis. Let us

mention that both this Green's function and function $G_N^{(n)}(x,x',\mathbf{k})$ defined in analogy with Eq. (1.45) are not decaying with respect to variables x and x'.

For the boundary values $\mathcal{G}^{\pm}$ [see Eq. (1.64)] of Green's function on the $\mathbf{k}_{\mathfrak{R}}$-axis we get by Eq. (2.52) ($k \in \mathbb{R}$)

$$\mathcal{G}_N^{\sigma}(x,x',k) = \frac{1}{2\pi i}\Bigg[\int dp[\theta(x_2 - x_2') - \theta(\sigma(p-k))]t^{\sigma}(p)\varphi^{\sigma}(x,p)\psi^{\sigma}(x',p) + \sum_{n=1}^{N}[\theta(x_2 - x_2') - \theta(\sigma(\lambda_{n\mathfrak{R}} - k))]\vartheta_n^{\sigma}\varphi_n^{\sigma}(x)\psi_n^{\sigma}(x')\Bigg], \tag{2.67}$$

where $\sigma = +,-$. Thus by Eq. (2.56),

$$\mathcal{G}_N^{\sigma}(k) - \mathcal{G}_{N,\pm} = \frac{\mp 1}{2\pi i}\Bigg[\int dp\,\theta(\pm\sigma(p-k))t^{\sigma}(p)\varphi^{\sigma}(p) \otimes \psi^{\sigma}(p) + \sum_{n=1}^{N}\theta(\pm\sigma(\lambda_{n\mathfrak{R}} - k))\vartheta_n^{\sigma}\varphi_n^{\sigma} \otimes \psi_n^{\sigma}\Bigg]. \tag{2.68}$$

A specific feature of the resolvent approach is the fact that the Jost and advanced/retarded solutions, as well as their dual, can be given as reductions of the corresponding Green's functions, see, e.g., Ref. 14. However, due to the nondecaying behavior of the N-soliton potential at large space distances these reduction formulas are required to be regularized. Precisely, we must write

$$\varphi(x,\mathbf{k}) = \lim_{\varepsilon \to +0}\int dx'(\mathcal{L}_0^d(x',\partial_{x'})\mathcal{G}_N(x,x',\mathbf{k}))\mathrm{e}^{-i\ell(\mathbf{k})x' - i\varepsilon x_2'}, \tag{2.69}$$

$$\psi(x,\mathbf{k}) = \lim_{\varepsilon \to +0}\int dx'\mathrm{e}^{i\ell(\mathbf{k})x' + i\varepsilon x_2'}\mathcal{L}_0(x',\partial_{x'})\mathcal{G}_N(x',x,\mathbf{k}), \tag{2.70}$$

where $\mathbf{k} \in \mathbb{C}$. It can be checked directly that these relations become identities if bilinear representation (2.52) for Green's function is used.

F. Advanced/retarded solutions

The advanced/retarded solutions are most naturally defined in terms of advanced/retarded Green's functions (2.56) as follows:

$$\varphi_{\pm}(x,k) = \int dx'(\mathcal{L}_0^d(x',\partial_{x'})\mathcal{G}_{N,\pm}(x,x'))\mathrm{e}^{-i\ell(k)x'}, \tag{2.71}$$

$$\psi_{\pm}(x,k) = \int dx'\mathrm{e}^{i\ell(k)x'}\mathcal{L}_0(x',\partial_{x'})\mathcal{G}_{N,\pm}(x',x), \tag{2.72}$$

where $k \in \mathbb{R}$. In spite of the bad behavior of u_N at large space, in this case no any regularization is needed. Thanks to properties (1.48) and (1.50) for $\mathcal{G}_{N,\pm}$ it is easy to check that

$$\vec{\mathcal{L}}_N\varphi_{\pm} = 0, \quad \psi_{\pm}\overleftarrow{\mathcal{L}}_N = 0, \tag{2.73}$$

$$\overline{\varphi_{\pm}} = \psi_{\mp}. \tag{2.74}$$

Using representation (2.56) in Eqs. (2.71) and (2.72) we get expressions of the advanced/retarded solutions in terms of the Jost ones. We omit here the corresponding calculations and present only the result. We introduce the spectral data

$$r_{\pm}^{\sigma}(k)=\prod_{n=1}^{N}\left(\frac{k-\lambda_n}{k-\overline{\lambda_n}}\right)^{-\sigma\theta(\mp\sigma(k-\lambda_{n\Re}))}, \tag{2.75}$$

that have the obvious properties

$$\overline{r_{\pm}^{\sigma}(k)}=r_{\mp}^{-\sigma}(k), \quad \overline{r_{\pm}^{\sigma}(k)}r_{\pm}^{\sigma}(k)=1, \tag{2.76}$$

and obey the characterization equations,

$$\overline{r_{\pm}^{-\sigma}(k)}r_{\pm}^{\sigma}(k)=t^{\sigma}(k), \tag{2.77}$$

which can be considered a "triangular decomposition" of $t^{\pm}$. Then, the above mentioned relations can be written as

$$\varphi_{\pm}(k)=\varphi^{\sigma}(k)\overline{r_{\pm}^{-\sigma}(k)}, \tag{2.78}$$

$$\psi_{\pm}(k)=\psi^{\sigma}(k)r_{\mp}^{\sigma}(k), \tag{2.79}$$

or, thanks to Eq. (2.77), as

$$t^{\sigma}(k)\varphi^{\sigma}(k)=\varphi_{\pm}(k)r_{\pm}^{\sigma}(k), \tag{2.80}$$

$$t^{\sigma}(k)\psi^{\sigma}(k)=\psi_{\pm}(k)\overline{r_{\mp}^{-\sigma}(k)}. \tag{2.81}$$

In particular, we get from these equalities

$$t^{\sigma}(k)\varphi^{\sigma}(k)\otimes\psi^{\sigma}(k)=\varphi_{\pm}(k)\otimes\psi_{\mp}(k), \tag{2.82}$$

where the lhs is independent on the sign $\sigma=+,-$ [see Eq. (2.41)] and the rhs is independent on the sign $\pm$.

We also need, in the following, the asymptotic behavior of $\varphi_{\pm}$ for $x_2\to\mp\infty$. From Eqs. (2.78) and (2.15) we obtain

$$\varphi_{\pm}(x,k)\simeq\chi_{\pm,\mathrm{as}}(k)\mathrm{e}^{-i\ell(k)x} \quad \text{for } x_2\to\mp\infty, \tag{2.83}$$

where

$$\chi_{\pm,\mathrm{as}}(k)=\prod_{n=1}^{N}\left(\frac{k-\lambda_n}{k-\overline{\lambda_n}}\right)^{\mp\mathrm{sgn}\,\lambda_{n\Re}\theta(\lambda_{n\Re}(k-\lambda_{n\Re}))}. \tag{2.84}$$

G. Auxiliary advanced/retarded solutions

Relation (2.46) shows that the Jost solutions form an incomplete set and in order to complete it one must introduce the auxiliary Jost solutions. The same, of course, is valid for the limiting values of the Jost solutions on the real k-axis which satisfy the completeness relation

$$\frac{1}{2\pi}\left\{\int d\mathbf{k}\,t^{\sigma}(k)\varphi^{\sigma}(x,k)\psi^{\sigma}(x',k)+\sum_{n=1}^{N}\vartheta_n^{\sigma}\varphi_n^{\sigma}(x)\psi_n^{\sigma}(x')\right\}_{x_2=x_2'}=\delta(x_1-x_1'), \quad \sigma=+,-. \tag{2.85}$$

Thanks to Eq. (2.82) the integral term here can be rewritten in terms of the advanced/retarded solutions only, that proves that the set of these solutions is incomplete and we have to introduce also auxiliary advanced/retarded. For this aim, taking into account that thanks to Eq. (2.3) all main minors of the matrix C are strictly positive, we can use for it the Gauss lower upper (LU) triangular decomposition:

$$C = (E + W_{\pm})^{\dagger} D_{\pm}^{2} (E + W_{\pm}), \tag{2.86}$$

where E is the unity $N \times N$ matrix, the $W_{\pm}$'s are off-diagonal and, respectively, upper and lower triangular matrices, and the $D_{\pm}$'s are strictly positive diagonal matrices. All multipliers in Eq. (2.86) are uniquely defined so we introduce new triangular matrices,

$$r_{\pm}^{+} = D_{\mp}(E + W_{\mp})\vartheta^{+}, \quad r_{\pm}^{-} = D_{\mp}^{-1}(E + W_{\mp}^{\dagger})^{-1}, \tag{2.87}$$

where

$$\vartheta^{\pm} = \mathrm{diag}\{\vartheta_1^{\pm}, \ldots, \vartheta_n^{\pm}\}. \tag{2.88}$$

These matrices obey the characterization equations,

$$r_{\pm}^{\sigma}(\vartheta^{\sigma})^{-1}(r_{\pm}^{-\sigma})^{\dagger} = E, \quad (r_{\pm}^{-\sigma})^{\dagger} r_{\pm}^{\sigma} = \vartheta^{\sigma}, \tag{2.89}$$

and by Eq. (2.86) we have

$$(r_{\pm}^{\sigma})^{\dagger} r_{\pm}^{\sigma} = \theta(\sigma)\vartheta^{-} C \vartheta^{+} + \theta(-\sigma) C^{-1}. \tag{2.90}$$

Now we define the auxiliary advanced/retarded solutions by means of the relations

$$\varphi_{\pm,n} = \sum_{m=1}^{N} \varphi_m^{\sigma} (r_{\pm}^{-\sigma})^{\dagger}(m,n), \quad \psi_{\pm,n} = \sum_{m=1}^{N} (r_{\mp}^{\sigma})(n,m)\psi_m^{\sigma}, \tag{2.91}$$

where the lhs' are independent on the sign $\sigma = +, -$ thanks to Eqs. (2.38), (2.40), (2.89), and (2.90). By using Eq. (2.89) these relations can be inverted,

$$\vartheta_n^{\sigma}\varphi_n^{\sigma} = \sum_{m=1}^{N} \varphi_{\pm,m} r_{\pm}^{\sigma}(m,n), \quad \vartheta_n^{\sigma}\psi_n^{\sigma} = \sum_{m=1}^{N} (r_{\mp}^{-\sigma})^{\dagger}(n,m)\psi_{\pm,m}. \tag{2.92}$$

In analogy with Eq. (2.82) we get from Eqs. (2.91) and (2.92),

$$\sum_{n=1}^{N} \vartheta_n^{\sigma}\varphi_n^{\sigma} \otimes \psi_n^{\sigma} = \sum_{n=1}^{N} \varphi_{\pm,n} \otimes \psi_{\mp,n}, \tag{2.93}$$

so that thanks to Eq. (2.82) we get from Eq. (2.85) the completeness relation in terms of the advanced/retarded and auxiliary advanced/retarded solutions,

$$\frac{1}{2\pi}\left\{ \int dk \varphi_{\pm}(x,k)\psi_{\mp}(x',k) + \sum_{n=1}^{N} \varphi_{\pm,n}(x)\psi_{\mp,n}(x') \right\}_{x_2 = x_2'} = \delta(x_1 - x_1'). \tag{2.94}$$

Relations (2.82) and (2.93) enable us to express advanced/retarded Green's functions in terms of the advanced/retarded and auxiliary advanced/retarded solutions. Thanks to Eq. (2.56) we have by Eq. (1.46),

$$\mathcal{G}_{N,\pm}(x,x') = \pm \frac{\theta(\pm(x_2 - x_2'))}{2\pi i}\left[\int dp \varphi_{\pm}(x,p)\psi_{\mp}(x',p) + \sum_{n=1}^{N} \varphi_{\pm,n}(x)\psi_{\mp,n}(x') \right], \tag{2.95}$$

where signs $\pm$ in the two terms in square brackets in Eq. (2.95) can be chosen freely and independently. In particular, this means that for the difference of advanced and retarded Green's function we get

$$\mathcal{G}_{N,+} - \mathcal{G}_{N,-} = \frac{1}{2\pi i}\left[\int dp\, \varphi_{\pm}(p) \otimes \psi_{\mp}(p) + \sum_{n=1}^{N} \varphi_{\pm,n} \otimes \psi_{\mp,n}\right], \tag{2.96}$$

where the rhs, thanks to Eqs. (2.82) and (2.93), is independent of the choice of the upper or bottom sign.

H. Time evolution of spectral data and Jost solutions

Time evolution of the spectral data in the case of the pure N-soliton solution u_N due to KPI equation is known[23] to be given as

$$\partial_t \lambda_n = 0, \tag{2.97}$$

$$\partial_t C = -4i(\overline{\lambda_m^3} - \lambda_n^3)C_{mn}. \tag{2.98}$$

Then by Eqs. (2.19) and (2.75) we get

$$\partial_t t(\mathbf{k}) = 0, \quad \mathbf{k} \in \mathbb{C}, \tag{2.99}$$

$$\partial_t r_{\pm}^{\sigma}(k) = 0, \quad \sigma = +,-, \quad k \in \mathbb{R}. \tag{2.100}$$

Thanks to Eq. (2.86), time evolution of diagonal matrices D_{pm}^2 coincides with evolution of the diagonal part of matrix C, so that by Eq. (2.87),

$$\partial_t r_{\pm}^{\sigma}(m,n) = -2i(\overline{\lambda_m^3} + \lambda_m^3 - 2(\lambda_n^{\sigma})^3) r_{\pm}^{\sigma}(m,n) = 0, \tag{2.101}$$

where notation (2.2) was used. In order to get time evolution of the Jost solution we use the standard crucial remark that if Φ is a solution of the nonstationary Schrödinger operator $\mathcal{L}$ then by Eq. (1.5) we deduce that $\mathcal{T}\Phi$ is also a solution. Moreover, since the operator $\mathcal{L}$ is a differential operator of first order in x_2 this solution is uniquely determined by its asymptotic behavior at $x_2 \to +\infty$ or at $x_2 \to -\infty$. Let us consider $\mathcal{T}_N \varphi(\mathbf{k})$ with $\mathcal{T}_N$ as in Eq. (1.4) with u the pure N-soliton potential u_N and $\varphi(\mathbf{k})$ the corresponding Jost solution (2.9). Then from the asymptotic behavior of the Jost solution given by Eqs. (2.13) and (2.15) at $x_2 \to \pm\infty$ we derive

$$\mathcal{T}_N(x, \mathbf{k}^3)\varphi(x,\mathbf{k}) = 0, \tag{2.102}$$

where we introduced the operator

$$\mathcal{T}_N(x,K) = \mathcal{T}_N(x) - 4iK \tag{2.103}$$

with K an arbitrary constant, and where we used that $u_N(x)$ is going to zero for $x_2 \to \mp\infty$ (Here for simplicity we assume that all $\lambda_{n\Re} \neq 0$. The result is independent of this assumption as values of $\lambda_{n\Re}$ can be shifted by a Galileo transformation.).

It is worthwhile to note that by inserting the expansion

$$\varphi(x,\mathbf{k}) \simeq \left(\theta(-\mathbf{k}_\Im) + \theta(\mathbf{k}_\Im)\frac{1}{t(\mathbf{k})}\right) e^{-i\ell(\mathbf{k})x} \quad \text{for } x_1 \to +\infty, \tag{2.104}$$

obtained from Eqs. (2.17) and (2.18) into Eq. (2.102) with $\mathcal{T}_N$ as in Eq. (1.4) one gets at any time $t > 0$ the dynamical constraint

$$\int_{-\infty}^{\infty} dx_1 \partial_{x_2} u_N(t,x) = 0, \tag{2.105}$$

which generalizes to the case of N solitons the dynamical constraint found in the case of decaying solutions in Ref. 4.

The advanced/retarded solutions $\varphi_{\pm}$ which are directly related to the Jost solutions by Eq. (2.78) due to Eq. (2.102) satisfy

$$\mathcal{T}_N(k^3)\varphi_{\pm}(k)=0, \tag{2.106}$$

while the auxiliary Jost solutions $\varphi_n(\mathbf{k}_\jmath)$ which are related to $\varphi(\lambda_n)$ and $\varphi(\overline{\lambda_n})$ via Eq. (2.24) satisfy

$$\mathcal{T}_N((\lambda_n^\sigma)^3)\varphi_n(\mathbf{k}_\jmath)=0 \quad \text{where} \quad \sigma=\operatorname{sgn}\mathbf{k}_\jmath. \tag{2.107}$$

For getting the differential equations fixing the time evolution of the advanced/retarded auxiliary solutions $\varphi_{\pm,n}$ we use their definition in Eq. (2.91) and relations (2.101) and (2.107)

$$\mathcal{T}_N\left(\frac{1}{2}(\overline{\lambda_m^3}+\lambda_m^3)\right)\varphi_{\pm,m}=0. \tag{2.108}$$

I. Matrix formulation

One can more conveniently write the relations interlacing the different kinds of Jost solutions and the characterization equations for the spectral data by introducing a vectorial formulation for the Jost solutions and a matrix formulation for the spectral data. Precisely, let us denote

$$\boldsymbol{\varphi}^\sigma(x)=(\varphi^\sigma(x,k),\varphi_1^\sigma(x),\ldots,\varphi_N^\sigma(x)), \tag{2.109}$$

$$\boldsymbol{\varphi}^\pm(x)=(\varphi_\pm(x,k),\varphi_{\pm,1}(x),\ldots,\varphi_{\pm,N}(x)), \tag{2.110}$$

that we call, respectively, vectorial Jost and vectorial advanced/retarded solutions, and

$$\mathbf{r}_\pm^\sigma=\begin{pmatrix} r_\pm^\sigma(p)\delta(p-k) & 0 \\ 0 & r_\pm^\sigma(m,n)\end{pmatrix}, \tag{2.111}$$

$$\mathbf{t}^\sigma=\begin{pmatrix} t^\sigma(p)\delta(p-k) & 0 \\ 0 & \delta_{mn}\vartheta_n^\sigma\end{pmatrix}, \tag{2.112}$$

that we call, respectively, matrix triangular spectral data and matrix transmission coefficient. If we define the product of matrices with matrix elements with continuous and discrete indices by integrating and summing, respectively, over continuous and discrete indices, then Eqs. (2.77) and (2.89) are combined in the characterization equations,

$$\mathbf{r}_\pm^\sigma(\mathbf{t}^\sigma)^{-1}(\mathbf{r}_\pm^{-\sigma})^\dagger=\mathbf{I}, \quad (\mathbf{r}_\pm^{-\sigma})^\dagger\mathbf{r}_\pm^\sigma=\mathbf{t}^\sigma, \tag{2.113}$$

where unity operator equals

$$\mathbf{I}=\begin{pmatrix}\delta(p-k) & 0 \\ 0 & \delta_{mn}\end{pmatrix}. \tag{2.114}$$

Then, Eqs. (2.78), (2.80), (2.91), and (2.92) relating the Jost to the advanced/retarded solutions, both standard and auxiliary, can be rewritten in a more compact form as follows:

$$\boldsymbol{\varphi}^\sigma\mathbf{t}^\sigma=\boldsymbol{\varphi}_\pm\mathbf{r}_\pm^\sigma, \tag{2.115}$$

$$\boldsymbol{\varphi}_\pm=\boldsymbol{\varphi}^\sigma(\mathbf{r}_\pm^{-\sigma})^\dagger. \tag{2.116}$$

The discontinuity at the real axis of the complex $\mathbf{k}$-plane of the Jost and auxiliary Jost solutions given in Eqs. (2.37) and (2.38) can be rewritten as

$$\boldsymbol{\varphi}^{\sigma}\mathbf{t}^{\sigma} = \boldsymbol{\varphi}^{-\sigma}\mathbf{f}^{-\sigma}, \tag{2.117}$$

where

$$\mathbf{f}^{\sigma} = (\mathbf{r}_{\pm}^{-\sigma})^{\dagger}\mathbf{r}_{\pm}^{-\sigma}. \tag{2.118}$$

Independence of the lhs on the signs $\pm$ gives the characterization equation

$$(\mathbf{r}_{+}^{\sigma})^{\dagger}\mathbf{r}_{+}^{\sigma} = (\mathbf{r}_{-}^{\sigma})^{\dagger}\mathbf{r}_{-}^{\sigma}. \tag{2.119}$$

The matrix $\mathbf{f}^{\sigma}$ together with the location of poles of $t(\mathbf{k})$ constitute the spectral data in strict sense. In fact, from Eqs. (2.76) and (2.90) we have

$$\mathbf{f}^{\sigma} = \begin{pmatrix} \delta(p-k) & 0 \\ 0 & \theta(-\sigma)\vartheta^{-}C\vartheta^{+} + \theta(\sigma)C^{-1} \end{pmatrix}. \tag{2.120}$$

Notice that the spectral data $\mathbf{f}$, due to Eqs. (2.113) and (2.118), satisfy the characterization equations

$$\mathbf{f}^{\sigma}(\mathbf{t}^{-\sigma})^{-1}\mathbf{f}^{-\sigma} = \mathbf{t}^{\sigma}, \tag{2.121}$$

$$(\mathbf{f}^{\sigma})^{\dagger} = \mathbf{f}^{\sigma}. \tag{2.122}$$

III. PERTURBATION

A. Resolvent, Green's functions, and Jost solutions

1. Properties of resolvent

Now we start with investigation of the spectral properties of the nonstationary Schrödinger operator (1.2) with a two dimensionally perturbed N-soliton potential $u(x)$ given in (1.7). In the previous sections we considered the pure N-soliton potential u_N and studied in detail the properties of the corresponding resolvent $M_N(q)$ and Green's function $\mathcal{G}_N(\mathbf{k})$. Now we exploit these results by constructing the resolvent $M(q)$ and Green's function $\mathcal{G}(\mathbf{k})$ corresponding to the potential u using the dressing procedure outlined in Sec. I E. We suppose that under the "smallness" requirement on u' the integral equations (1.58) admit a unique solution $M(q)$ for the resolvent with kernel $M(x,x';q)$ belonging to the space $\mathcal{S}'(\mathbb{R}^6)$. Then, the properties of the resolvent, including the singular behavior of $M(q)$ due to the nondecaying behavior of $u(x)$ at large space directions, can be studied via the integral equations (1.58), i.e., by means of the dressing procedure based on the Hilbert identity (1.61). In particular, we expect that the resolvent $M(q)$ will inherit, possibly smoothed by the dressing procedure, the singularities of $M_N(q)$. In fact, $M(q)$ results in becoming, as $M_N(q)$, a continuous function of the variables $q \in \mathbb{R}^2$ with the exception of the point $q=0$ and the segments $q_2 = 2\lambda_{n\mathfrak{R}}q_1$, $|q_1| \leqslant \lambda_{n\mathfrak{I}}$, $n=1,\ldots,N$, but, for a generic perturbation u', with 1/log instead of log behavior at the end points of the segments.

In the region of continuity the resolvent $M(q)$ is differentiable in the standard sense with respect to the parameters q_i $(i=1,2)$. Expressions for these derivatives can be obtained by dressing the corresponding derivatives of $M_N(q)$ by means of equation (1.63). Inserting Eqs. (2.50) and (2.51) into Eq. (1.63) we get for any q in the region of continuity

$$\frac{\partial \widehat{M}(q)}{\partial q_1} = \frac{i}{\pi}\int_{\mathbf{k}_{\mathfrak{I}}=q_1} d\mathbf{k}_{\mathfrak{R}}\bar{\mathbf{k}}\,\delta(2\mathbf{k}_{\mathfrak{R}}q_1 - q_2)t(\mathbf{k})\Phi(\mathbf{k}) \otimes \Psi(\mathbf{k}), \tag{3.1}$$

$$\frac{\partial \widehat{M}(q)}{\partial q_2} = \frac{1}{2\pi i}\int_{\mathbf{k}_{\mathfrak{I}}=q_1} d\mathbf{k}_{\mathfrak{R}}\,\delta(2\mathbf{k}_{\mathfrak{R}}q_1 - q_2)t(\mathbf{k})\Phi(\mathbf{k}) \otimes \Psi(\mathbf{k}), \tag{3.2}$$

where we introduced

$$\Phi(\mathbf{k}) = \mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_N\varphi(\mathbf{k}), \quad \Psi(\mathbf{k}) = \psi(\mathbf{k})\vec{\mathcal{L}}_N\mathcal{G}(\mathbf{k}), \quad \mathbf{k} \in \mathbb{C}, \tag{3.3}$$

or explicitly

$$\Phi(x,\mathbf{k}) = \int dx'(\mathcal{L}_N^d(x',\partial_{x'})\mathcal{G}(x,x',\mathbf{k}))\varphi(x',\mathbf{k}), \tag{3.4}$$

$$\Psi(x',\mathbf{k}) = \int dx\psi(x,\mathbf{k})\mathcal{L}_N(x,\partial_x)\mathcal{G}(x,x',\mathbf{k}), \tag{3.5}$$

which can be considered a generalization of Eqs. (1.51), (2.69), and (2.70) and where $\mathcal{G}(x,x',\mathbf{k})$ is Green's function defined in Eq. (1.42). This function, being a reduction of Eq. (1.58), obeys consequently the integral equation (1.59) together with its dual that under the above assumption admit a unique solution $\mathcal{G}(\mathbf{k})$ such that $G(\mathbf{k})$ as defined in Eq. (1.45) belongs to $\mathcal{S}'$. Green's function inherits the analyticity properties of $\mathcal{G}_N(x,x',\mathbf{k})$, i.e., it is analytic for all $\mathbf{k} \in \mathbb{C}$ with the exception of the real axis, $\mathbf{k}_\Im = 0$, and intervals $\mathbf{k}_\Re = \lambda_{n\Re}$, $|\mathbf{k}_\Im| \leqslant \lambda_{n\Im}$. Performing reduction (1.42) in Eqs. (3.1) and (3.2) we get that in the region of analyticity

$$\frac{\partial\mathcal{G}(\mathbf{k})}{\partial\mathbf{k}_\Im} = \frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi}t(\mathbf{k})\Phi(\mathbf{k}) \otimes \Psi(\mathbf{k}), \tag{3.6}$$

$$\frac{\partial\mathcal{G}(\mathbf{k})}{\partial\mathbf{k}_\Re} = \frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi i}t(\mathbf{k})\Phi(\mathbf{k}) \otimes \Psi(\mathbf{k}), \tag{3.7}$$

while behavior of Green's function at the end points of the segments above, where $\mathcal{G}_N(\mathbf{k})$ has logarithmic singularities, needs a separate study (see Sec. III C below).

Thanks to Eq. (1.47) functions $\Phi(x,\mathbf{k})$ and $\Psi(x,\mathbf{k})$ defined in Eq. (3.3) obey the differential equations (1.56), and, therefore, we call them, respectively, Jost and dual Jost solution of the nonstationary Schrödinger equation with potential (1.7). Due to Eqs. (1.49) and (2.11) they obey the conjugation property

$$\Psi(x,\mathbf{k}) = \overline{\Phi(x,\bar{\mathbf{k}})}, \tag{3.8}$$

and integral equations for them follow by inserting Eqs. (1.59) into (3.3):

$$\Phi(\mathbf{k}) = \varphi(\mathbf{k}) + \mathcal{G}_N(\mathbf{k})u'\Phi(\mathbf{k}), \quad \Psi(\mathbf{k}) = \psi(\mathbf{k}) + \Psi(\mathbf{k})u'\mathcal{G}_N(\mathbf{k}). \tag{3.9}$$

The Jost solutions inherit the analytical properties of Green's function $\mathcal{G}_N(\mathbf{k})$. Precisely, they are analytic in the complex domain of the spectral parameter $\mathbf{k}$ with discontinuities at the real axis and at the segments $\mathbf{k}_\Re = \lambda_{n\Re}$, $|\mathbf{k}_\Im| < \lambda_{n\Im}$, $n = 1,\ldots,N$, and have continuous limits on the two sides of these cuts.

2. Asymptotics of Green's function and Jost solutions

The asymptotic behavior of Green's function $G(x,x',\mathbf{k})$ can be obtained directly by inserting the asymptotics (2.54) of $G_N(x,x',\mathbf{k})$ into Eq. (1.59), once multiplied by $e^{i\ell(\mathbf{k})(x-x')}$. We get, for $\mathbf{k}_\Im \neq 0, \lambda_{1\Im},\ldots,\lambda_{N\Im}$, $\mathbf{k}_\Re \neq \lambda_{1\Re},\ldots,\lambda_{N\Re}$, when $x \to \infty$

$$G(x,x',\mathbf{k}) = \frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi(x_1 + 2\mathbf{k}x_2)}t(\mathbf{k})\chi_{\text{as}}(x,\mathbf{k})\left\{\xi(x',\mathbf{k}) + \int dx''\xi(x'',\mathbf{k})u'(x'')G(x'',x',\mathbf{k})\right\} + o(|x|^{-1}).$$

Then, writing $u' = -\vec{\mathcal{L}} + \vec{\mathcal{L}}_N$ and using Eqs. (1.45), (2.13), and (1.56) we derive

$$G(x,x',\mathbf{k}) = \frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi(x_1+2\mathbf{k}x_2)} t(\mathbf{k})\chi_{\mathrm{as}}(x,\mathbf{k})\Psi(x',\mathbf{k})\mathrm{e}^{-i\ell(\mathbf{k})x'} + o(|x|^{-1}), \tag{3.10}$$

and expression for the limit $x' \to \infty$ follows by using the Hermitian conjugation (1.49). As well by Eq. (2.55) we get

$$\lim_{\mathbf{k}\to\infty,\mathbf{k}_\Im\neq 0} G(x,x',\mathbf{k}) = 0. \tag{3.11}$$

For getting the asymptotic behavior of the Jost solutions it is convenient to rewrite Eq. (3.3) by inserting $\mathcal{L}_N = \mathcal{L} + u'$ and, then, by using Eq. (1.47) we obtain

$$\Phi(\mathbf{k}) = \varphi(\mathbf{k}) + \mathcal{G}(\mathbf{k})u'\varphi(\mathbf{k}), \quad \Psi(\mathbf{k}) = \psi(\mathbf{k}) + \psi(\mathbf{k})u'\mathcal{G}(\mathbf{k}), \quad \mathbf{k} \in \mathbb{C}. \tag{3.12}$$

In order to deal with the bounded functions we introduce in analogy with Eq. (2.13) "the Jost solutions with removed exponents"

$$X(x,\mathbf{k}) = \mathrm{e}^{i\ell(\mathbf{k})x}\Phi(x,\mathbf{k}), \quad \Xi(x,\mathbf{k}) = \mathrm{e}^{-i\ell(\mathbf{k})x}\Psi(x,\mathbf{k}). \tag{3.13}$$

By Eq. (3.9) these functions can be defined as solutions of the integral equations (in the explicit form),

$$X(x,\mathbf{k}) = \chi(x,\mathbf{k}) + \int dx' G_N(x,x',\mathbf{k})u'(x')X(x',\mathbf{k}), \tag{3.14}$$

$$\Xi(x,\mathbf{k}) = \xi(x,\mathbf{k}) + \int dx' \Xi(x',\mathbf{k})u'(x')G_N(x',x,\mathbf{k}), \tag{3.15}$$

where $\chi(x,\mathbf{k})$ and $\xi(x,\mathbf{k})$ are bounded functions and $G_N(x,x',\mathbf{k})$ is bounded (decaying on the x-plane) Green's function explicitly given in Eqs. (2.53) and (2.52). On the other side by Eqs. (3.12) and (3.13),

$$X(\mathbf{k}) = \chi(\mathbf{k}) + G(\mathbf{k})u'\chi(\mathbf{k}), \quad \Xi(\mathbf{k}) = \xi(\mathbf{k}) + \xi(\mathbf{k})u'G(\mathbf{k}). \tag{3.16}$$

Then from Eqs. (2.14) and (3.11) we derive

$$\lim_{\mathbf{k}\to\infty} X(x,\mathbf{k}) = \lim_{\mathbf{k}\to\infty} \Xi(x,\mathbf{k}) = 1, \tag{3.17}$$

and from Eqs. (2.15) and (3.10) the asymptotic behavior in the x-space is given in the form

$$X(x,\mathbf{k}) = \chi_{\mathrm{as}}(x,\mathbf{k})\left[1 + \frac{\operatorname{sgn}\mathbf{k}_\Im}{2\pi(x_1+2\mathbf{k}x_2)} t(\mathbf{k})\mathcal{A}(\mathbf{k})\right] + o(|x|^{-1}), \quad x \to \infty, \tag{3.18}$$

where appeared the function of the variable $\mathbf{k} \in C$ only

$$\mathcal{A}(\mathbf{k}) = \int dx \Psi(x,\mathbf{k})u'(x)\varphi(x,\mathbf{k}). \tag{3.19}$$

In what follows we use for shortness the notation

$$\mathcal{A}(\mathbf{k}) = (\Psi(\mathbf{k})u'\varphi(\mathbf{k})) \tag{3.20}$$

[cf. "vector" and "covector" notations used in Eqs. (1.51), (1.54), and (1.55)]. Notice that $\mathcal{A}(\mathbf{k})$ can be equivalently defined as

$$\mathcal{A}(\mathbf{k}) = (\psi(\mathbf{k})\vec{\mathcal{L}}_N\mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_N\varphi(\mathbf{k})) = (\psi(\mathbf{k})u'\Phi(\mathbf{k})) = (\psi(\mathbf{k})\vec{\mathcal{L}}_N\Phi(\mathbf{k})) = (\Psi(\mathbf{k})\overleftarrow{\mathcal{L}}_N\varphi(\mathbf{k})). \tag{3.21}$$

The function $\mathcal{A}(\mathbf{k})$ is analytic in the complex domain with discontinuity at the real axis and at the segments $\mathbf{k}_\Re=\lambda_{n\Re}$, $|\mathbf{k}_\Im|<\lambda_{n\Im}$, $n=1,\ldots,N$, it satisfies the conjugation property

$$\overline{\mathcal{A}(\bar{\mathbf{k}})} = \mathcal{A}(\mathbf{k}), \tag{3.22}$$

and generates, in spite of the bad behavior of u at large space distances, finite integrals of motion, e.g.,

$$\lim_{\mathbf{k}\to\infty}\mathcal{A}(\mathbf{k}) = \int dx\, u'(x). \tag{3.23}$$

From Eq. (3.8) we derive the same asymptotic behavior of the Jost solutions like in Eqs. (2.17) and (2.18)

$$\lim_{x_1\to-\mathbf{k}_\Im\infty} X(x,\mathbf{k}) = 1, \qquad \lim_{x_1\to+\mathbf{k}_\Im\infty} \Xi(x,\mathbf{k}) = 1, \tag{3.24}$$

$$\lim_{x_1\to+\mathbf{k}_\Im\infty} X(x,\mathbf{k}) = \frac{1}{t(\mathbf{k})}, \qquad \lim_{x_1\to-\mathbf{k}_\Im\infty} \Xi(x,\mathbf{k}) = \frac{1}{t(\mathbf{k})}. \tag{3.25}$$

B. Discontinuity of the resolvent at $q_2=2\lambda_{n\Re}q_1$ and auxiliary Jost solutions

The discontinuity of the resolvent $M(q)$ on the line $q_2=2\lambda_{n\Re}q_1$ can be derived by means of the dressing procedure described in Sec. I E from the discontinuity (2.47) of $M_N(q)$. Indeed, choosing in the Hilbert identity (1.66) $q_1=q_1$, $q_2=2q_1\lambda_{n\Re}-0$ and $q_2=2q_1\lambda_{n\Re}+0$ and using Eq. (2.47) we get for the hat kernel [see Eq. (1.25)] of the resolvent

$$\widehat{M}(q)|_{q_2=2\lambda_{n\Re}q_1+0} - \widehat{M}(q)|_{q_2=2\lambda_{n\Re}q_1-0} = \frac{\vartheta_n(q_1)}{2\pi i}\widehat{M}(q_1,2\lambda_{n\Re}q_1+0)\overleftarrow{\mathcal{L}}_N\varphi_n(q_1) \otimes \psi_n(q_1)\vec{\mathcal{L}}_N\widehat{M}(q_1,2a_{n\Re}q_1-0). \tag{3.26}$$

By means of the reduction (2.57) this relation gives for the discontinuity of Green's function:

$$\mathcal{G}(\lambda_{n\Re}+0+i\mathbf{k}_\Im) - \mathcal{G}(\lambda_{n\Re}-0+i\mathbf{k}_\Im) = \frac{\operatorname{sgn}\mathbf{k}_\Im\,\vartheta_n(\mathbf{k}_\Im)}{2\pi i}\mathcal{G}(\lambda_{n\Re}\pm 0+i\mathbf{k}_\Im)\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\Im) \otimes \psi_n(\mathbf{k}_\Im)\vec{\mathcal{L}}_N\mathcal{G}(\lambda_{n\Re}\mp 0+i\mathbf{k}_\Im). \tag{3.27}$$

Applying $\psi_n(\mathbf{k}_\Im)\vec{\mathcal{L}}_N$ and $\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\Im)$, respectively, from the left and from the right and introducing

$$A_n(\mathbf{k}_\Im) = 1 + \frac{\vartheta_n(\mathbf{k}_\Im)\operatorname{sgn}\mathbf{k}_\Im}{2\pi i}(\psi_n(\mathbf{k}_\Im)\vec{\mathcal{L}}_N\mathcal{G}(\lambda_{n\Re}+0+i\mathbf{k}_\Im)\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\Im)), \tag{3.28}$$

we deduce from Eq. (3.27) that the function $A_n(\mathbf{k}_\Im)$ has no zeros and

$$\frac{1}{A_n(\mathbf{k}_\Im)} = 1 - \frac{\vartheta_n(\mathbf{k}_\Im)\operatorname{sgn}\mathbf{k}_\Im}{2\pi i}(\psi_n(\mathbf{k}_\Im)\vec{\mathcal{L}}_N\mathcal{G}(\lambda_{n\Re}-0+i\mathbf{k}_\Im)\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\Im)). \tag{3.29}$$

The conjugation property

$$\overline{A_n(\mathbf{k}_\mathfrak{J})} = A_n(-\mathbf{k}_\mathfrak{J}) \tag{3.30}$$

follows from the conjugation properties of the entities involved in definition of $A_n(\mathbf{k}_\mathfrak{J})$.

Now we see that by Eq. (3.27) the discontinuity of Green's function on the segment is given in terms of the objects of the kind

$$\Phi_n(\mathbf{k}_\mathfrak{J}) = \mathcal{G}(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{J})\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\mathfrak{J}), \tag{3.31}$$

$$\Psi_n(\mathbf{k}_\mathfrak{J}) = \psi_n(\mathbf{k}_\mathfrak{J})\vec{\mathcal{L}}_N\mathcal{G}(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{J}), \tag{3.32}$$

that in analogy with the definition of the auxiliary Jost solutions in the pure N-soliton case in Eqs. (2.24) and (2.25) it is natural to call the auxiliary Jost solutions in the perturbed case. Indeed, thanks to Eq. (1.47) functions $\Phi_n(x,\mathbf{k}_\mathfrak{J})$ and $\Psi_n(x,\mathbf{k}_\mathfrak{J})$ obey the nonstationary Schrödinger equation and its dual, correspondingly,

$$\vec{\mathcal{L}}\Phi_n(\mathbf{k}_\mathfrak{J}) = 0, \quad \Psi_n(\mathbf{k}_\mathfrak{J})\overleftarrow{\mathcal{L}} = 0, \tag{3.33}$$

and, thanks to Eqs. (2.23) and (1.49), they obey the conjugation property

$$\overline{\Phi_n(\mathbf{k}_\mathfrak{J})} = \Psi_n(-\mathbf{k}_\mathfrak{J}). \tag{3.34}$$

By Eqs. (2.24) and (2.25) these functions are different from zero in the interval $|\mathbf{k}_\mathfrak{J}| \leqslant \lambda_{n\mathfrak{J}}$ only. Applying reductions (3.31) and (3.32) to Eq. (1.59) and its dual we get that the auxiliary Jost solutions obey the integral equations

$$\Phi_n(\mathbf{k}_\mathfrak{J}) = \varphi_n(\mathbf{k}_\mathfrak{J}) + \mathcal{G}_N(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{J})u'\Phi_n(\mathbf{k}_\mathfrak{J}), \tag{3.35}$$

$$\Psi_n(\mathbf{k}_\mathfrak{J}) = \psi_n(\mathbf{k}_\mathfrak{J}) + \Psi_n(\mathbf{k}_\mathfrak{J})u'\mathcal{G}_N(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{J}). \tag{3.36}$$

We introduce in analogy with Eq. (2.30)

$$X_n(x,\mathbf{k}_\mathfrak{J}) = \mathrm{e}^{ix\ell(\lambda_{n\mathfrak{R}}+i\mathbf{k}_\mathfrak{J})}\Phi_n(x,\mathbf{k}_\mathfrak{J}), \quad \Xi_n(x,\mathbf{k}_\mathfrak{J}) = \mathrm{e}^{-ix\ell(\lambda_{n\mathfrak{R}}+i\mathbf{k}_\mathfrak{J})}\Psi_n(x,\mathbf{k}_\mathfrak{J}). \tag{3.37}$$

Since Φ_n and Ξ_n and their dual are solutions of integral equations dressing φ_n and χ_n, which were proved in Ref. 25 to be bounded with respect to the variable $x \in \mathbb{R}^2$, we assume that for u' sufficiently "small" they also are bounded.

Next, by applying from the right $\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\mathfrak{J})$ to Eq. (3.27) and using Eq. (3.29) we get

$$\mathcal{G}(\lambda_{n\mathfrak{R}} - 0 + i\mathbf{k}_\mathfrak{J})\overleftarrow{\mathcal{L}}_N\varphi_n(\mathbf{k}_\mathfrak{J}) = \frac{\Phi_n(\mathbf{k}_\mathfrak{J})}{A_n(\mathbf{k}_\mathfrak{J})}, \tag{3.38}$$

$$\psi_n(\mathbf{k}_\mathfrak{J})\vec{\mathcal{L}}_N\mathcal{G}(\lambda_{n\mathfrak{R}} - 0 + i\mathbf{k}_\mathfrak{J}) = \frac{\Psi_n(\mathbf{k}_\mathfrak{J})}{A_n(\mathbf{k}_\mathfrak{J})}, \tag{3.39}$$

which can be used for expressing the discontinuities (3.26) and (3.27) in the form

$$\widehat{M}(q)|_{q_2=2\lambda_{n\mathfrak{R}}q_1+0} - \widehat{M}(q)|_{q_2=2\lambda_{n\mathfrak{R}}q_1-0} = \vartheta_n(q_1)\frac{\Phi_n(q_1)\otimes\Psi_n(q_1)}{2\pi i A_n(q_1)}, \tag{3.40}$$

$$\mathcal{G}(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{J}) - \mathcal{G}(\lambda_{n\mathfrak{R}} - 0 + i\mathbf{k}_\mathfrak{J}) = \vartheta_n(\mathbf{k}_\mathfrak{J})\frac{\Phi_n(\mathbf{k}_\mathfrak{J})\otimes\Psi_n(\mathbf{k}_\mathfrak{J})}{2\pi i(\operatorname{sgn}\mathbf{k}_\mathfrak{J})A_n(\mathbf{k}_\mathfrak{J})}. \tag{3.41}$$

Then, from Eq. (3.3) by using Eq. (3.41) and recalling that the N-soliton Jost solutions are discontinuous only across the real axis of the $\mathbf{k}$ plane we derive for the discontinuity of the Jost solutions across the segment $|\mathbf{k}_\mathfrak{J}| \leqslant \lambda_{n\mathfrak{J}}$, $\mathbf{k}_\mathfrak{R} = \lambda_{n\mathfrak{R}}$,

$$\Phi(\lambda_{n\Re}+0+i\mathbf{k}_\Im)-\Phi(\lambda_{n\Re}-0+i\mathbf{k}_\Im)=\Phi_n(\mathbf{k}_\Im)w_n(\mathbf{k}_\Im), \tag{3.42}$$

$$\Psi(\lambda_{n\Re}+0+i\mathbf{k}_\Im)-\Psi(\lambda_{n\Re}-0+i\mathbf{k}_\Im)=\Psi_n(\mathbf{k}_\Im)\overline{w_n(-\mathbf{k}_\Im)}, \tag{3.43}$$

where we introduced the spectral data

$$w_n(\mathbf{k}_\Im)=\frac{\vartheta_n(\mathbf{k}_\Im)\operatorname{sgn}\mathbf{k}_\Im}{2\pi i A_n(\mathbf{k}_\Im)}(\Psi_n(\mathbf{k}_\Im)\overleftarrow{\mathcal{L}}_N\varphi(\lambda_{n\Re}+i\mathbf{k}_\Im)), \tag{3.44}$$

that describe these discontinuities of the Jost solutions. Let us mention that Eq. (3.44) is a short version [cf. Eqs. (3.19) and (3.20)] of the relation

$$w_n(\mathbf{k}_\Im)=\frac{\vartheta_n(\mathbf{k}_\Im)\operatorname{sgn}\mathbf{k}_\Im}{2\pi i A_n(\mathbf{k}_\Im)}\int dx(\mathcal{L}_N^d\Psi_n(x,\mathbf{k}_\Im))\varphi(x,\lambda_{n\Re}+i\mathbf{k}_\Im), \tag{3.45}$$

and that by Eqs. (3.3) and (3.31) $w_n(\mathbf{k}_\Im)$ can be equivalently written in the forms

$$\begin{aligned}w_n(\mathbf{k}_\Im)&=\frac{\vartheta_n(\mathbf{k}_\Im)\operatorname{sgn}\mathbf{k}_\Im}{2\pi i A_n(\mathbf{k}_\Im)}(\psi_n(\mathbf{k}_\Im)\overrightarrow{\mathcal{L}}_N\mathcal{G}(\lambda_{n\Re}+0+i\mathbf{k}_\Im)\overleftarrow{\mathcal{L}}_N\varphi(\lambda_{n\Re}+i\mathbf{k}_\Im))\\&=\frac{\vartheta_n(\mathbf{k}_\Im)\operatorname{sgn}\mathbf{k}_\Im}{2\pi i A_n(\mathbf{k}_\Im)}(\psi_n(\mathbf{k}_\Im)\overrightarrow{\mathcal{L}}_N\Phi(\lambda_{n\Re}+0+i\mathbf{k}_\Im)).\end{aligned} \tag{3.46}$$

Finally, it is worth remarking that the discontinuity of the function $\mathcal{A}(\mathbf{k})$ defined in Eq. (3.20) also can be expressed in terms of the spectral data $w_n(\mathbf{k}_\Im)$. Precisely, we have

$$\mathcal{A}(\lambda_{n\Re}+0+i\mathbf{k}_\Im)-\mathcal{A}(\lambda_{n\Re}-0+i\mathbf{k}_\Im)=\frac{2\pi i\ \operatorname{sgn}(\mathbf{k}_\Im)}{\vartheta_n(\mathbf{k}_\Im)}A_n(\mathbf{k}_\Im)w_n(\mathbf{k}_\Im)\overline{w_n(-\mathbf{k}_\Im)}, \tag{3.47}$$

that can be used in derivation of a dispersion relation for $\mathcal{A}(\mathbf{k})$.

C. Behavior of Green's function and Jost solutions at end points of cuts

In Secs. II D and II E it was shown that the resolvent $M_N(q)$ and its reduction, Green's function $\mathcal{G}_N(\mathbf{k})$, have cuts along the segments $q_2=2\lambda_{n\Re}q_1$, $|q_1|\leqslant\lambda_{n\Im}$ and $\mathbf{k}_\Re=\lambda_{n\Re}$, $|\mathbf{k}_\Im|\leqslant\lambda_{n\Im}$ of the q- and $\mathbf{k}$-planes, respectively, with logarithmic singularities at the end points. These singularities were explicitly given, respectively, in Eq. (2.49) and in Eqs. (2.6) and (2.62). In the previous section we proved that the dressed resolvent $M(q)$ and Green's function $\mathcal{G}(\mathbf{k})$ have cuts along the same segments. Here we study the behavior of Green's function at the end points of these cuts using decomposition (2.65) of N-soliton Green's function $\mathcal{G}_N(\mathbf{k})$.

We need to write for Green's function $\mathcal{G}(\mathbf{k})$, as for $\mathcal{G}_N(\mathbf{k})$ in Eq. (2.65), a decomposition into a regular and a singular part. We expect that this can be obtained by dressing Eq. (2.65) and, precisely, that new Green's function $\mathcal{G}^{(n)}(\mathbf{k})$ of the operator $\mathcal{L}$ defined by

$$\mathcal{G}(\mathbf{k})=\mathcal{G}^{(n)}(\mathbf{k})+\Gamma(\mathbf{k})\mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_N\varphi_n^\sigma\otimes\psi_n^\sigma\overrightarrow{\mathcal{L}}_N\mathcal{G}(\mathbf{k}), \tag{3.48}$$

satisfies, for a proper choice of the function $\Gamma(\mathbf{k})$, the integral equation

$$\mathcal{G}^{(n)}(\mathbf{k})=\mathcal{G}_N^{(n)}(\mathbf{k})+\mathcal{G}_N^{(n)}(\mathbf{k})u'\mathcal{G}^{(n)}(\mathbf{k}) \tag{3.49}$$

and its dual and can therefore be considered a dressed version of $\mathcal{G}_N^{(n)}(\mathbf{k})$. Then, since $\mathcal{G}_N^{(n)}(\mathbf{k})$ is analytic in a vicinity of the segment $\mathbf{k}_\Re=\lambda_{n\Re}$, $|\mathbf{k}_\Im|=\lambda_{n\Im}$, with the exception of the $\mathbf{k}_\Re$-axis, we can deduce that $\mathcal{G}^{(n)}(\mathbf{k})$ as solution of Eq. (3.49) has the same analyticity properties.

Notice, however, that since φ_n^σ and ψ_n^σ are not bounded we must assume that the potential $u'(x)$ decays at large x faster than any linear exponential, in order that $\mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_N\varphi_n^\sigma$ and $\psi_n^\sigma\overrightarrow{\mathcal{L}}_N\mathcal{G}(\mathbf{k})$ appearing in Eq. (3.48) are well defined, as one can check by using $\mathcal{G}(\mathbf{k})\overleftarrow{\mathcal{L}}_N=\mathcal{G}(\mathbf{k})u'+I$ and its

dual and by recalling the behavior at large x of $\mathcal{G}$. [C.f. objects defined in Eqs. (3.28), (3.29), (3.31), and (3.32), where in the absence of condition of exponential decaying of u' we used condition that $\mathbf{k}$ belongs to the strip $|\mathbf{k}_\jmath| < \lambda_{n\jmath}$.]

Taking into account decomposition (2.65) one can check that Green's function $\mathcal{G}^{(n)}$ satisfies the integral equation (3.48) and its dual for

$$\Gamma(\mathbf{k}) = \frac{\gamma_n(\mathbf{k})}{1 + \alpha_n(\mathbf{k})\gamma_n(\mathbf{k})}, \tag{3.50}$$

where

$$\alpha_n(\mathbf{k}) = (\psi_n^\sigma \vec{\mathcal{L}}_N \mathcal{G}(\mathbf{k}) \overleftarrow{\mathcal{L}}_N \varphi_n^\sigma), \quad \mathbf{k} \in \mathbb{C}, \quad \sigma = \operatorname{sgn} \mathbf{k}_\jmath, \tag{3.51}$$

which is well defined for u' decaying according to our assumption.

Then, applying operations $\psi_n^\sigma \vec{\mathcal{L}}_N$ and $\overleftarrow{\mathcal{L}}_N \varphi_n^\sigma$ to Eq. (3.48) from the left and from the right we get

$$\frac{1}{\alpha_n(\mathbf{k})} = \frac{1}{a_n(\mathbf{k})} - \gamma_n(\mathbf{k}), \tag{3.52}$$

$$\mathcal{G}(\mathbf{k}) \overleftarrow{\mathcal{L}}_N \varphi_n^\sigma = \frac{\alpha_n(\mathbf{k})}{a_n(\mathbf{k})} \Phi^{(n)}(\mathbf{k}), \quad \psi_n^\sigma \vec{\mathcal{L}}_N \mathcal{G}(\mathbf{k}) = \frac{\alpha_n(\mathbf{k})}{a_n(\mathbf{k})} \Psi^{(n)}(\mathbf{k}), \tag{3.53}$$

where

$$a_n(\mathbf{k}) = (\psi_n^\sigma \vec{\mathcal{L}}_N \mathcal{G}^{(n)}(\mathbf{k}) \overleftarrow{\mathcal{L}}_N \varphi_n^\sigma), \quad \sigma = \operatorname{sgn} \mathbf{k}_\jmath, \tag{3.54}$$

and where, in analogy with Eqs. (3.3), (3.31), and (3.32), we have introduced

$$\Phi^{(n)}(\mathbf{k}) = \mathcal{G}^{(n)}(\mathbf{k}) \overleftarrow{\mathcal{L}}_N \varphi_n^\sigma, \quad \Psi^{(n)}(\mathbf{k}) = \psi_n^\sigma \vec{\mathcal{L}}_N \mathcal{G}^{(n)}(\mathbf{k}), \quad \mathbf{k} \in \mathbb{C}, \quad \sigma = \operatorname{sgn} \mathbf{k}_\jmath, \tag{3.55}$$

that also obey the nonstationary Schrödinger equation and its dual, correspondingly.

Notice that, under our assumption on the decaying of the potential u', the function $a_n(\mathbf{k})$ has the same analyticity properties of $\mathcal{G}^{(n)}(\mathbf{k})$. Then instead of Eq. (3.48) we get

$$\mathcal{G}(\mathbf{k}) = \mathcal{G}^{(n)}(\mathbf{k}) + \frac{\gamma_n(\mathbf{k})}{1 - a_n(\mathbf{k})\gamma_n(\mathbf{k})} \Phi^{(n)}(\mathbf{k}) \otimes \Psi^{(n)}(\mathbf{k}). \tag{3.56}$$

We see that the asymptotic behavior of Green's function at the end points is determined by the behavior of function $a_n(\mathbf{k})$ at these points. This function is meromorphic in the vicinity of the cut with the exception of the real axis and it is uniquely defined by the choice of the function $\gamma_n(\mathbf{k})$. However, notice that $\gamma_n(\mathbf{k})$ in Eq. (2.65) is required only to be such that the singular behavior of Green's function in a vicinity of the nth cut is single out. Thus, the choice in Eq. (2.63) is not unique, even if analyticity condition is imposed. If we shift $\gamma_n(\mathbf{k})$ by some constant, this shift is compensated by a shift of $1/a_n(\mathbf{k})$ as the lhs of Eq. (3.52) is invariant. This proves that the singularities of $a_n(\mathbf{k})$ are not related to the properties of $\gamma_n(\mathbf{k})$ and without loss of generality we can assume that $a_n(\mathbf{k})$ has finite limits

$$a_n^\pm = a_n(\lambda_n^\pm) \equiv (\psi_n^\pm \vec{\mathcal{L}}_N \mathcal{G}^{(n)}(\lambda_n^\pm) \overleftarrow{\mathcal{L}}_N \varphi_n^\pm). \tag{3.57}$$

They are related by the conjugation property

$$a_n^- = \overline{a_n^+}, \tag{3.58}$$

and by Eq. (3.56) they determine the behavior of Green's function $\mathcal{G}^{(n)}(\mathbf{k})$ at the points $\mathbf{k} = \lambda_n^\pm$. In contrast to the poles, the zeros of $a_n(\mathbf{k})$ are independent of the choice of $\gamma_n(\mathbf{k})$ and coincide with

the zeros of $\alpha_n(\mathbf{k})$. This is valid also at the end points, since, thanks to analyticity, $a_n(\mathbf{k})$ has zeros of integer order. Consequently, if the constants in Eq. (3.57) are equal to zero then $\mathcal{G}(\mathbf{k})$ has a logarithmic singularity at the end points of the cut and we get a singular behavior of the same kind that we had for the pure solitonic potential, when $u' \equiv 0$. For a generic u' we choose

$$a_n^{\pm} \neq 0. \tag{3.59}$$

This choice is natural and surely admissible as the following observation demonstrates. In fact, using equality $\mathcal{L}_N = \mathcal{L} + u'$ and the fact that $\mathcal{G}^{(n)}(\mathbf{k})$ is Green's function, we can rewrite Eq. (3.54) as $a_n(\mathbf{k}) = (\psi_n^{\sigma} \vec{\mathcal{L}}_N \mathcal{G}^{(n)}(k) u' \varphi_n^{\sigma})$ and, then, taking into account that by Eq. (3.49) $\mathcal{G}^{(n)}(\mathbf{k})|_{u' \equiv 0} = \mathcal{G}_N^{(n)} \times(\mathbf{k})$, we get the following functional derivative:

$$\left. \frac{\delta a_n(\mathbf{k})}{\delta u'} \right|_{u' \equiv 0} = \psi_n^{\sigma}(x) \varphi_n^{\sigma}(x), \quad \sigma = \operatorname{sgn} \mathbf{k}_{\mathfrak{I}} \tag{3.60}$$

which is different from zero for any value of $\mathbf{k}$. From here on we will consider only the case (3.59) for all $n = 1, \ldots, N$. Then $\mathcal{G}(\mathbf{k})$ has finite limits for $\mathbf{k} \to \lambda_n^{\pm}$:

$$\mathcal{G}(\lambda_n^{\pm}) = \mathcal{G}^{(n)}(\lambda_n^{\pm}) - \frac{1}{a_n^{\pm}} \Phi^{(n)}(\lambda_n^{\pm}) \otimes \Psi^n(\lambda_n^{\pm}), \tag{3.61}$$

where we used the solutions of the nonstationary Schrödinger equation and their dual defined in Eq. (3.55). Let us mention that Eq. (3.57) can be written also in the following forms:

$$a_n^{\pm} = (\psi_n^{\pm} \vec{\mathcal{L}}_N \Phi^{(n)}(\lambda_n^{\pm})) = (\Psi^{(n)}(\lambda_n^{\pm}) \overleftarrow{\mathcal{L}}_N \varphi_n^{\pm}), \tag{3.62}$$

so that by condition (3.59) functions $\Phi^{(n)}(x, \lambda_n^{\pm})$ and $\Psi^n(x, \lambda_n^{\pm})$ in Eq. (3.61) are different from zero.

Functions $\varphi(\mathbf{k})$ and $\psi(\mathbf{k})$ are analytic in the complex domain, so directly by definition (3.3) of the Jost solutions and thanks to Eqs. (2.22), (3.53), and (3.52) we derive

$$\lim_{\mathbf{k} \to \lambda_n^{\pm}} \gamma_n(\mathbf{k}) \Phi(x, \mathbf{k}) = - \frac{\Phi^{(n)}(x, \lambda_n^{\pm})}{\sqrt{2\pi} a_n^{\pm}}, \tag{3.63}$$

$$\lim_{\mathbf{k} \to \lambda_n^{\pm}} \gamma_n(\mathbf{k}) \Psi(x, \mathbf{k}) = - \frac{\Psi^{(n)}(x, \lambda_n^{\pm})}{\sqrt{2\pi} a_n^{\pm}}. \tag{3.64}$$

Inserting Eq. (3.64) in Eq. (3.20) and using Eq. (3.54) we get

$$\lim_{\mathbf{k} \to \lambda_n^{\pm}} \gamma_n(\mathbf{k}) \mathcal{A}(\mathbf{k}) = - \frac{1}{2\pi}. \tag{3.65}$$

In the same way by Eq. (3.31) taking into account Eqs. (2.24) and (3.53) we have for the auxiliary Jost solution

$$\lim_{\mathbf{k}_{\mathfrak{I}} \to \pm(\lambda_{n\mathfrak{I}} - 0)} \gamma_n(\lambda_{n\mathfrak{R}} + i\mathbf{k}_{\mathfrak{I}}) \Phi_n(\mathbf{k}_{\mathfrak{I}}) = - \frac{\Phi^{(n)}(\lambda_n^{\pm})}{a_n^{\pm}}, \tag{3.66}$$

and analogously for $\Psi_n(\mathbf{k}_{\mathfrak{I}})$.

The same consideration gives the behavior of the spectral data. Thus, Eq. (3.28) thanks to Eq. (3.51) can be written as

$$A_n(\mathbf{k}_\mathfrak{I}) = 1 + \frac{\vartheta_n(\mathbf{k}_\mathfrak{I})\operatorname{sgn}\mathbf{k}_\mathfrak{I}}{2\pi i}\alpha_n(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{I}),$$

so that Eq. (3.52)

$$\lim_{\mathbf{k}_\mathfrak{I}\to\pm(\lambda_{n\mathfrak{I}}-0)} \gamma_n(\lambda_{n\mathfrak{R}} + i\mathbf{k}_\mathfrak{I})[A_n(\mathbf{k}_\mathfrak{I}) - 1] = \mp\frac{\vartheta_n^\pm}{2\pi i}, \tag{3.67}$$

proving that $A_n(\mathbf{k}_\mathfrak{I})$ tends to 1 at the end points of the cut. For $w_n(\mathbf{k}_\mathfrak{I})$ we can use, say, the last equality in Eq (3.46) and (3.63). Then, thanks to Eqs. (3.62) and (3.67) we get

$$\lim_{\mathbf{k}_\mathfrak{I}\to\pm(\lambda_{n\mathfrak{I}}-0)} \gamma_n(\lambda_{n\mathfrak{R}} + i\mathbf{k}_\mathfrak{I})w_n(\mathbf{k}_\mathfrak{I}) = \pm\frac{i\vartheta_n^\pm}{(2\pi)^{3/2}}. \tag{3.68}$$

D. Relating auxiliary Jost solutions to Jost solutions

We have now all information on the properties of the auxiliary Jost solutions that are needed in order to express them in terms of the Jost solutions and spectral data $w_n(\mathbf{k}_\mathfrak{I})$.

By deriving Eq. (3.31) with respect to $\mathbf{k}_\mathfrak{I}$ we get, by using Eq. (3.6) and the expression for the adjoint of $w_n(\mathbf{k}_\mathfrak{I})$ as given in Eq. (3.46),

$$\frac{\partial\Phi_n(\mathbf{k}_\mathfrak{I})}{\partial\mathbf{k}_\mathfrak{I}} = \frac{iA_n(\mathbf{k}_\mathfrak{I})}{\vartheta_n(\mathbf{k}_\mathfrak{I})}t(\lambda_{n\mathfrak{R}} + i\mathbf{k}_\mathfrak{I})\overline{w_n(-\mathbf{k}_\mathfrak{I})}\Phi(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{I}). \tag{3.69}$$

Integrating, we have

$$\Phi_n(\mathbf{k}_\mathfrak{I}) = i\int_{\lambda_{n\mathfrak{I}}\operatorname{sgn}\mathbf{k}_\mathfrak{I}}^{\mathbf{k}_\mathfrak{I}} ds\frac{A_n(s)}{\vartheta_n(s)}t(\lambda_{n\mathfrak{R}} + is)\overline{w_n(-s)}\Phi(\lambda_{n\mathfrak{R}} + 0 + is), \tag{3.70}$$

where we took into account that by Eq. (3.66) the auxiliary Jost solution is zero at $\mathbf{k}=\lambda_n^\pm$.

Analogously, by Eq. (3.6) we get from Eq. (3.28),

$$\frac{\partial A_n(\mathbf{k}_\mathfrak{I})}{\partial\mathbf{k}_\mathfrak{I}} = \frac{iA_n^2(\mathbf{k}_\mathfrak{I})}{\vartheta_n(\mathbf{k}_\mathfrak{I})}t(\lambda_{n\mathfrak{R}} + i\mathbf{k}_\mathfrak{I})\overline{w_n(-\mathbf{k}_\mathfrak{I})}w_n(\mathbf{k}_\mathfrak{I}), \tag{3.71}$$

so that by Eq. (3.67),

$$A_n(\mathbf{k}_\mathfrak{I}) = \left(1 - i\int_{\lambda_{n\mathfrak{I}}\operatorname{sgn}\mathbf{k}_\mathfrak{I}}^{\mathbf{k}_\mathfrak{I}} ds\frac{t(\lambda_{n\mathfrak{R}} + is)}{\vartheta_n(s)}w_n(s)\overline{w_n(-s)}\right)^{-1} \neq 0. \tag{3.72}$$

Notice that relation (3.71) enables us to rewrite Eq. (3.47) in the form

$$t(\lambda_{n\mathfrak{R}} + i\mathbf{k}_\mathfrak{I})(\mathcal{A}(\lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_\mathfrak{I}) - \mathcal{A}(\lambda_{n\mathfrak{R}} - 0 + i\mathbf{k}_\mathfrak{I})) = 2\pi\operatorname{sgn}\mathbf{k}_\mathfrak{I}\frac{\partial\log A_n(\mathbf{k}_\mathfrak{I})}{\partial\mathbf{k}_\mathfrak{I}}. \tag{3.73}$$

E. Extended resolvent

Now we can proceed to the reconstruction of the resolvent of the nonstationary Schrödinger operator (1.2) with potential (1.7). Taking into account Eqs. (3.2) and (3.40) we get in analogy with Eq. (2.44)

$$\hat{M}(x,x';q)=\frac{1}{2\pi i}\Bigg[\int_{\mathbf{k}_\mathfrak{I}=q_1} d\mathbf{k}_\mathfrak{R}[\theta(x_2-x_2')-\theta(2\mathbf{k}_\mathfrak{R}q_1-q_2)]t(\mathbf{k})\Phi(x,\mathbf{k})\Psi(x',\mathbf{k}) + \sum_{n=1}^{N}\frac{\vartheta_n(q_1)}{A_n(q_1)}[\theta(x_2-x_2')-\theta(2\lambda_{n\mathfrak{R}}q_1-q_2)]\Phi_n(x,q_1)\Psi_n(x',q_1)\Bigg], \tag{3.74}$$

so that the dressed operator $\hat{M}(x,x';q)$ can be obtained from $\hat{M}_N(x,x';q)$ in Eq. (2.44) by substituting Jost and auxiliary Jost solutions by the dressed ones and by substituting $\vartheta_n(q_1)$ by $\vartheta_n(q_1)/A_n(q_1)$, that can be considered its dressed version. The proof that the kernel $M(x,x';q)$ given by Eq. (1.25) belongs to the space of tempered distributions can be performed following the proof given in Ref. 25 for the case of the pure N-soliton potential. This proof is based on the boundedness property of $X(x,\mathbf{k}_\mathfrak{I})$, $\Xi(x,\mathbf{k}_\mathfrak{I})$ proved in Sec. III A 2, and on the same property of $\Phi_n(x,\mathbf{k}_\mathfrak{I})$, $\Psi_n(x,\mathbf{k}_\mathfrak{I})$ and of $X_n(x,\mathbf{k}_\mathfrak{I})$, $\Xi_n(x,\mathbf{k}_\mathfrak{I})$ [see Eqs. (3.31), (3.32), and (3.37)], that was mentioned in Sec. III B. The fact that $\hat{M}(x,x';q)$, given above, obeys Eq. (1.34) means that the following completeness relation [cf. Eq. (2.46)] is valid:

$$\frac{1}{2\pi}\Bigg\{\int d\mathbf{k}_\mathfrak{R}t(\mathbf{k})\Phi(x,\mathbf{k})\Psi(x',\mathbf{k})+\sum_{n=1}^{N}\frac{\vartheta_n(\mathbf{k}_\mathfrak{I})}{A_n(\mathbf{k}_\mathfrak{I})}\Phi_n(x,\mathbf{k}_\mathfrak{I})\Psi_n(x',\mathbf{k}_\mathfrak{I})\Bigg\}_{x_2=x_2'}=\delta(x_1-x_1'). \tag{3.75}$$

Next, by Eq. (1.42) we get from Eq. (3.74) for Green's function representation

$$\mathcal{G}(x,x',\mathbf{k})=\frac{1}{2\pi i}\Bigg[\int d\alpha[\theta(x_2-x_2')-\theta(\alpha\mathbf{k}_\mathfrak{I})]t(\alpha+\mathbf{k})\Phi(x,\alpha+\mathbf{k})\Psi(x',\alpha+\mathbf{k}) + \sum_{n=1}^{N}\frac{\vartheta_n(\mathbf{k}_\mathfrak{I})}{A_n(\mathbf{k}_\mathfrak{I})}[\theta(x_2-x_2')-\theta(\mathbf{k}_\mathfrak{I}(\lambda_{n\mathfrak{R}}-\mathbf{k}_\mathfrak{R}))]\Phi_n(x,\mathbf{k}_\mathfrak{I})\Psi_n(x',\mathbf{k}_\mathfrak{I})\Bigg]. \tag{3.76}$$

In previous sections the analyticity properties of the Jost solutions were derived from the analyticity properties of Green's function. Vice versa, representation (3.76) enables us to derive the analyticity properties of Green's function from the properties of the Jost and auxiliary Jost solutions, while, say, check of the equality (3.6) is rather cumbersome. Omitting details we can use relations of the kind $\partial_{\mathbf{k}_\mathfrak{I}}\Phi(\alpha+\mathbf{k})=i\partial_\alpha\Phi(\alpha+\mathbf{k})$ in calculation of derivative of the integral term in Eq. (3.76), but only at $\alpha+\mathbf{k}_\mathfrak{R}\neq\lambda_{n\mathfrak{R}}$. Thus expressions for discontinuities given in Eqs. (3.42) and (3.43) must be taken into account. Then Eq. (3.6) for any $\mathbf{k}$, $\mathbf{k}_\mathfrak{I}\neq 0$ follows thanks to Eqs. (2.26) and (3.69) and its conjugate, and Eq. (3.71). Analogously we get in the same region of $\mathbf{k}$ by Eq. (3.76),

$$\frac{\partial\mathcal{G}(\mathbf{k})}{\partial\bar{\mathbf{k}}}=\frac{\operatorname{sgn}\mathbf{k}_\mathfrak{I}}{4\pi i}\sum_{n=1}^{N}\delta(\mathbf{k}_\mathfrak{R}-\lambda_{n\mathfrak{R}})\frac{\vartheta_n(\mathbf{k}_\mathfrak{I})}{A_n(\mathbf{k}_\mathfrak{I})}\Phi_n(\mathbf{k}_\mathfrak{I})\otimes\Psi_n(\mathbf{k}_\mathfrak{I}), \tag{3.77}$$

that generalizes Eq. (2.60) in correspondence with Eq. (3.41). Thus analyticity of Green's function for $\mathbf{k}_\mathfrak{I}\neq 0$ and $\mathbf{k}$ not belonging to the intervals $\mathbf{k}_\mathfrak{R}=\lambda_{n\mathfrak{R}}$, $|\mathbf{k}_\mathfrak{I}|\leqslant\lambda_{n\mathfrak{I}}$ follows from Eq. (3.76).

For the boundary values of Green's function on the real axis we get by Eq. (3.76) [cf. Eq. (2.67)],

$$\mathcal{G}^\sigma(x,x',k)=\frac{1}{2\pi i}\left[\int dp[\theta(x_2-x_2')-\theta(\sigma(p-k))]t^\sigma(p)\Phi^\sigma(x,p)\Psi^\sigma(x',p)\right.$$
$$\left.+\sum_{n=1}^{N}[\theta(x_2-x_2')-\theta(\sigma(\lambda_{n\mathfrak{R}}-k))]\frac{\vartheta_n^\sigma}{A_n^\sigma}\Phi_n^\sigma(x)\Psi_n^a(x')\right], \tag{3.78}$$

where $\sigma=+,-$, $k\in\mathbb{R}$, and we introduced for the boundary values of the functions involved in this bilinear representation notations

$$\Phi^\pm(x,k)=\Phi(x,k\pm i0),\quad \Psi^\pm(x,k)=\Psi(x,k\pm i0),\quad k\in\mathbb{R}, \tag{3.79}$$

$$\Phi_n^\pm(x)=\Phi_n(x,\pm 0),\quad \Psi_n^\pm(x)=\Psi_n(x,\pm 0), \tag{3.80}$$

$$A_n^\pm=A_n(\pm 0). \tag{3.81}$$

The standard conjugation properties,

$$\overline{\Phi^\pm(x,k)}=\Psi^\mp(x,k), \tag{3.82}$$

$$\overline{\Phi_n^\pm(x)}=\Psi_n^\mp(x), \tag{3.83}$$

$$\overline{A_n^+}=A_n^-, \tag{3.84}$$

are satisfied.

F. Advanced/retarded Green's functions and solutions

For advanced/retarted Green's functions we have by Eq. (1.46),

$$\mathcal{G}_\pm(x,x')=\pm\frac{\theta(\pm(x_2-x_2'))}{2\pi i}\left[\int d\alpha t^\sigma(\alpha)\Phi^\sigma(x,\alpha)\Psi^\sigma(x',\alpha)+\sum_{n=1}^{N}\frac{\vartheta_n^\sigma}{A_n^\sigma}\Phi_n^\sigma(x)\Psi_n^\sigma(x')\right] \tag{3.85}$$

[cf. Eqs. (2.52) and (2.56)], where $\sigma=+,-$ and the rhs is independent of the choice of this sign as we show below. As follows from Eq. (3.78),

$$\mathcal{G}^\sigma(k)-\mathcal{G}_\pm=\frac{\mp 1}{2\pi i}\left[\int dp\,\theta(\pm\sigma(p-k))t^\sigma(p)\Phi^\sigma(p)\otimes\Psi^\sigma(p)+\sum_{n=1}^{N}\theta(\pm\sigma(\lambda_{n\mathfrak{R}}-k))\frac{\vartheta_n^\sigma}{A_n^\sigma}\Phi_n^\sigma\otimes\Psi_n^\sigma\right]. \tag{3.86}$$

On the other side by Eqs. (1.68) and (2.96) we get

$$\mathcal{G}_+-\mathcal{G}_-=\frac{1}{2\pi i}\left[\int dp\,\Phi_\pm(p)\otimes\Psi_\mp(p)+\sum_{n=1}^{N}\Phi_{\pm,n}\otimes\Psi_{\mp,n}\right], \tag{3.87}$$

where we introduced the advanced/retarded solutions,

$$\Phi_\pm(k)=\mathcal{G}_\pm\overleftarrow{\mathcal{L}}_N\varphi_\pm(k),\quad \Psi_\pm(k)=\psi_\pm(k)\vec{\mathcal{L}}_N\mathcal{G}_\pm, \tag{3.88}$$

and the auxiliary advanced/retarded solutions [cf. Eqs. (3.31) and (3.32)],

$$\Phi_{\pm,n} = \mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}_N\varphi_{\pm,n}, \quad \Psi_{\pm,n} = \psi_{\pm,n}\vec{\mathcal{L}}_N\mathcal{G}_{\pm}, \tag{3.89}$$

where the auxiliary advanced/retarded solutions $\varphi_{\pm,n}$ and $\psi_{\pm,n}$ of the pure N-soliton case are defined in Eq. (2.91). By these definitions we get that these functions, indeed, thanks to Eq. (1.48), obey the nonstationary Schrödinger equation and its dual,

$$\vec{\mathcal{L}}\Phi_{\pm}(k) = 0, \quad \Psi_{\pm}(k)\overleftarrow{\mathcal{L}} = 0, \tag{3.90}$$

$$\vec{\mathcal{L}}\Phi_{\pm,n} = 0, \quad \Psi_{\pm,n}\overleftarrow{\mathcal{L}} = 0, \tag{3.91}$$

have, thanks to Eq. (1.50), conjugation properties

$$\overline{\Phi_{\pm}} = \Psi_{\mp}, \quad \overline{\Phi_{\pm,n}} = \Psi_{\mp,n}, \tag{3.92}$$

and, thanks to Eq. (1.60), obey the integral equations

$$\Phi_{\pm} = \varphi_{\pm} + \mathcal{G}_{N,\pm}u'\Phi_{\pm}, \quad \Psi_{\pm} = \psi_{\pm} + \Psi_{\pm}u'\mathcal{G}_{N,\pm}, \tag{3.93}$$

$$\Phi_{\pm,n} = \varphi_{\pm,n} + \mathcal{G}_{N,\pm}u'\Phi_{\pm,n}, \quad \Psi_{\pm,n} = \psi_{\pm,n} + \Psi_{\pm,n}u'\mathcal{G}_{N,\pm}. \tag{3.94}$$

G. Relation between Jost solutions on the real axis and advanced/retarded solutions

Difference of Green's function given in Eq. (3.86) can also be derived by inserting Eq. (2.68) in the rhs of Eq. (1.67) that gives

$$\mathcal{G}^{\sigma}(k) - \mathcal{G}_{\pm} = \frac{\mp 1}{2\pi i}\left[\int dp\,\theta(\pm\sigma(p-k))t^{\sigma}(p)\mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}_N\varphi^{\sigma}(p)\otimes\psi^{\sigma}(p)\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(k) + \sum_{n=1}^{N}\vartheta_n^{\sigma}\theta(\pm\sigma(\lambda_{n\Re}-k))\mathcal{G}_{\pm}\overleftarrow{\mathcal{L}}_N\varphi_n^{\sigma}\otimes\psi_n^{\sigma}\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(k)\right]. \tag{3.95}$$

Then using Eqs. (3.88), (2.80), and (2.92) we can rewrite Eq. (3.95) as

$$\mathcal{G}^{\sigma}(k) - \mathcal{G}_{\pm} = \frac{\mp 1}{2\pi i}\left[\int dp\,\theta(\pm\sigma(p-k))r_{\pm}^{\sigma}(p)\Phi_{\pm}(p)\otimes\psi^{\sigma}(p)\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(k) + \sum_{m,n=1}^{N}r_{\pm}^{\sigma}(m,n)\theta(\pm\sigma(\lambda_{n\Re}-k))\Phi_{\pm,m}\otimes\psi_n^{\sigma}\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(k)\right]. \tag{3.96}$$

Let us now introduce the spectral data

$$R_{\pm}^{\sigma}(p,k) = r_{\pm}^{\sigma}(p)\left[\delta(k-p) \mp \frac{t^{\sigma}(k)}{2\pi i}\theta(\pm\sigma(p-k))(\psi^{\sigma}(p)\vec{\mathcal{L}}_N\Phi^{\sigma}(k))\right], \tag{3.97}$$

$$R_{\pm}^{\sigma}(m,k) = \mp\frac{t^{\sigma}(k)}{2\pi i}\sum_{n=1}^{N}r_{\pm}^{\sigma}(m,n)\theta(\pm\sigma(\lambda_{n\Re}-k))(\psi_n^{\sigma}\vec{\mathcal{L}}_N\Phi^{\sigma}(k)). \tag{3.98}$$

Then, applying to Eq. (3.96) operation $\overleftarrow{\mathcal{L}}_N\varphi^{\sigma}(k)$ from the right and using Eqs. (3.3) (at $\mathbf{k}=k+i\sigma 0$), (3.88) and (2.80) we get

$$t^{\sigma}(k)\Phi^{\sigma}(k) = \int dp\Phi_{\pm}(p)R^{\sigma}_{\pm}(p,k) + \sum_{m=1}^{N} \Phi_{\pm,m}R^{\sigma}_{\pm}(m,k), \tag{3.99}$$

$$t^{\sigma}(k)\Psi^{\sigma}(k) = \int dp\overline{R^{-\sigma}_{\mp}(p,k)}\Psi_{\pm}(p) + \sum_{m=1}^{N} \overline{R^{-\sigma}_{\mp}(m,k)}\Psi_{\pm,m}, \tag{3.100}$$

where the second equality follows by conjugation.

Using the fact that the N-soliton potential is invariant under permutation of the λ_n's it is convenient here to renumber them in such a way that

$$\lambda_{1\Re} < \cdots < \lambda_{N\Re}, \tag{3.101}$$

and to introduce the step function of a discrete variable defined as

$$\theta(n) = \begin{cases} 1, & n > 0 \\ 0, & n \leqslant 0. \end{cases} \tag{3.102}$$

In order to express the auxiliary Jost solutions in terms of the advanced/retarded solutions, we perform first the limit $k \to \lambda_{l\Re} + 0$ in Eq. (3.96) getting

$$\begin{aligned} \mathcal{G}^{\sigma}(\lambda_{l\Re}+0) - \mathcal{G}_{\pm} = \frac{\mp 1}{2\pi i}\Bigg[& \int dp\,\theta(\pm\sigma(p-\lambda_{l\Re}))r^{\sigma}_{\pm}(p)\Phi_{\pm}(p) \otimes \psi^{\sigma}(p)\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(\lambda_{l\Re}+0) \\ & + \sum_{m=1}^{N}\Phi_{\pm,m}\sum_{n=1}^{N} r^{\sigma}_{\pm}(m,n)[\theta(\pm\sigma)\theta(n-l) + \theta(\mp\sigma)\theta(l-n) + \theta(\mp\sigma)\delta_{ln}] \\ & \otimes \psi^{\sigma}_n\vec{\mathcal{L}}_N\mathcal{G}^{\sigma}(\lambda_{l\Re}+0)\Bigg], \end{aligned} \tag{3.103}$$

and we introduce the new set of spectral data,

$$R^{\sigma}_{\pm}(k,n) = \mp\,\theta(\pm\sigma(k-\lambda_{n\Re}))\frac{r^{\sigma}_{\pm}(k)\vartheta^{\sigma}_n}{2\pi i A^{\sigma}_n}(\psi^{\sigma}(k)\vec{\mathcal{L}}_N\Phi^{\sigma}_n), \tag{3.104}$$

$$R^{\sigma}_{\pm}(m,n) = \sum_{l=1}^{N} r^{\sigma}_{\pm}(m,l)\left[\delta_{ln}\left(\frac{\theta(\pm\sigma)}{A^{\sigma}_n} + \theta(\mp\sigma)\right) \mp \theta(\pm\sigma(l-n))\frac{\vartheta^{\sigma}_n}{2\pi i A^{\sigma}_n}(\psi^{\sigma}_l\vec{\mathcal{L}}_N\Phi^{\sigma}_n)\right], \tag{3.105}$$

where the λ_n's are subjected to condition (3.101).

Then, we apply operation $\vec{\mathcal{L}}_N\varphi^{\sigma}_n$ to Eq. (3.103) from the right and use (3.31) at $\mathbf{k}_{\jmath} = \sigma 0$, (2.92), and

$$A^{\sigma}_n = 1 + \frac{\sigma\vartheta^{\sigma}_n}{2\pi i}(\psi^{\sigma}_n\vec{\mathcal{L}}_N\Phi^{\sigma}_n), \tag{3.106}$$

which follows from Eq. (3.28). We get

$$\frac{\vartheta^{\sigma}_n}{A^{\sigma}_n}\Phi^{\sigma}_n = \int dp\Phi_{\pm}(p)R^{\sigma}_{\pm}(p,n) + \sum_{m=1}^{N}\Phi_{\pm,m}R^{\sigma}_{\pm}(m,n), \tag{3.107}$$

$$\frac{\vartheta_n^\sigma}{A_n^\sigma}\Psi_n^\sigma = \int dp\overline{R_\mp^{-\sigma}(p,n)}\Psi_\pm(p) + \sum_{m=1}^{N}\overline{R_\mp^{-\sigma}(m,n)}\Psi_{\pm,m}, \tag{3.108}$$

where again the second equality follows by conjugation.

Inverse relations follow applying to Eq. (3.86) from the right $\overleftarrow{\mathcal{L}}_N\varphi_\pm$ and using Eqs. (2.78), (3.3), (3.79), and (3.88), and properties of conjugation of solutions,

$$\Phi_\pm(k) = \int dp\Phi^\sigma(p)\overline{R_\pm^{-\sigma}(k,p)} + \sum_{n=1}^{N}\Phi_n^\sigma\overline{R_\pm^{-\sigma}(k,n)}, \tag{3.109}$$

and applying to Eq. (3.86) at $k=\lambda_{m\Re}+0$ from the right $\overleftarrow{\mathcal{L}}_N\varphi_{\pm,n}$ and using Eqs. (2.91), (3.31), (3.38), and (3.89), and again properties of conjugation of solutions:

$$\Phi_{\pm,n} = \int dp\Phi^\sigma(p)\overline{R_\pm^{-\sigma}(n,p)} + \sum_{m=1}^{N}\Phi_m^\sigma\overline{R_\pm^{-\sigma}(n,m)}. \tag{3.110}$$

Relations

$$\Psi_\pm(k) = \int dpR_\mp^\sigma(k,p)\Psi^\sigma(p) + \sum_{n=1}^{N}R_\mp^\sigma(k,n)\Psi_n^\sigma, \tag{3.111}$$

$$\Psi_{\pm,n} = \int dpR_\mp^\sigma(n,p)\Psi^\sigma(p) + \sum_{m=1}^{N}R_\mp^\sigma(n,m)\Psi_m^\sigma \tag{3.112}$$

are obtained by conjugation.

H. Characterization equations for spectral data

In order to give characterization equations in observable form we use the technique introduced by Eqs. (2.109)–(2.114) in Sec. II. Thus we denote rows,

$$\mathbf{\Phi}^\sigma(x) = (\Phi^\sigma(x,k),\Phi_1^\sigma(x),\ldots,\Phi_N^\sigma(x)), \tag{3.113}$$

$$\mathbf{\Phi}_\pm(x) = (\Phi_\pm(x,k),\Phi_{\pm,1}(x),\ldots,\Phi_{\pm,N}(x)), \tag{3.114}$$

columns,

$$\mathbf{\Psi}^\sigma(x) = (\Psi^\sigma(x,k),\Psi_1^\sigma(x),\ldots,\Psi_N^\sigma(x))^T, \tag{3.115}$$

$$\mathbf{\Psi}_\pm(x) = (\Psi_\pm(x,k),\Psi_{\pm,1}(x),\ldots,\Psi_{\pm,N}(x))^T, \tag{3.116}$$

and matrix operators,

$$\mathbf{R}_\pm^\sigma = \begin{pmatrix} R_\pm^\sigma(p,k) & R_\pm^\sigma(p,n) \\ R_\pm^\sigma(m,k) & R_\pm^\sigma(m,n) \end{pmatrix}, \tag{3.117}$$

$$\mathbf{T}^\sigma = \begin{pmatrix} t^\sigma(p)\delta(p-k) & 0 \\ 0 & \delta_{mn}(\vartheta_n^\sigma/A_n^\sigma) \end{pmatrix}, \tag{3.118}$$

with unity operator defined in Eq. (2.114). Then, assuming the same operations with these objects as in Eqs. (2.111)–(2.116), we can rewrite Eqs. (3.99), (3.100), and (3.107)–(3.112), as

$$\mathbf{\Phi}^\sigma\mathbf{T}^\sigma = \mathbf{\Phi}_\pm\mathbf{R}_\pm^\sigma, \tag{3.119}$$

$$\mathbf{T}^{\sigma}\boldsymbol{\Psi}^{\sigma} = (\mathbf{R}_{\mp}^{-\sigma})^{\dagger}\boldsymbol{\Psi}_{\pm}, \tag{3.120}$$

$$\boldsymbol{\Phi}_{\pm} = \boldsymbol{\Phi}^{\sigma}(\mathbf{R}_{\pm}^{-\sigma})^{\dagger}, \tag{3.121}$$

$$\boldsymbol{\Psi}_{\pm} = \mathbf{R}_{\mp}^{\sigma}\boldsymbol{\Psi}^{\sigma}, \tag{3.122}$$

from which easily follow the characterization equations [cf. Eqs. (2.113) and (2.119)],

$$(\mathbf{R}_{\pm}^{-\sigma})^{\dagger}\mathbf{R}_{\pm}^{\sigma} = \mathbf{T}^{\sigma}, \tag{3.123}$$

$$\mathbf{R}_{\pm}^{\sigma}(\mathbf{T}^{\sigma})^{-1}(\mathbf{R}_{\pm}^{-\sigma})^{\dagger} = \mathbf{I}, \tag{3.124}$$

$$(\mathbf{R}_{+}^{\sigma})^{\dagger}\mathbf{R}_{+}^{\sigma} = (\mathbf{R}_{-}^{\sigma})^{\dagger}\mathbf{R}_{-}^{\sigma}. \tag{3.125}$$

If we introduce

$$\mathbf{F}^{-\sigma} = (\mathbf{R}_{\pm}^{\sigma})^{\dagger}\mathbf{R}_{\pm}^{\sigma}, \tag{3.126}$$

we have

$$\boldsymbol{\Phi}^{\sigma}\mathbf{T}^{\sigma} = \boldsymbol{\Phi}^{-\sigma}\mathbf{F}^{-\sigma}. \tag{3.127}$$

It is easy to check that these spectral data obey the characterization equations,

$$\mathbf{F}^{\sigma}(\mathbf{T}^{-\sigma})^{-1}\mathbf{F}^{-\sigma} = \mathbf{T}^{\sigma}, \tag{3.128}$$

$$(\mathbf{F}^{\sigma})^{\dagger} = \mathbf{F}^{\sigma}, \tag{3.129}$$

that generalize Eqs. (2.121) and (2.122), so that

$$\boldsymbol{\Phi}^{\sigma}\mathbf{T}^{\sigma}\boldsymbol{\Psi}^{\sigma} = \boldsymbol{\Phi}_{\pm}\boldsymbol{\Psi}_{\mp}. \tag{3.130}$$

Operator data $\mathbf{R}_{\pm}^{\sigma}$ involve both the discrete and the continuous parts of the spectral data. These two contributions can be made more transparent by factorizing out the discrete data by means of decomposition

$$\mathbf{R}_{\pm}^{\sigma} = \mathbf{r}_{\pm}^{\sigma}\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}, \tag{3.131}$$

where $\mathbf{r}_{\pm}^{\sigma}$ is the matrix operator defined in Eq. (2.111) and

$$\boldsymbol{\mathcal{R}}_{\pm}^{\sigma} = \begin{pmatrix} \mathcal{R}_{\pm}^{\sigma}(p,k) & \mathcal{R}_{\pm}^{\sigma}(p,n) \\ \mathcal{R}_{\pm}^{\sigma}(m,k) & \mathcal{R}_{\pm}^{\sigma}(m,n) \end{pmatrix}, \tag{3.132}$$

where

$$\mathcal{R}_{\pm}^{\sigma}(p,k) = \delta(k-p) \mp \theta(\pm\sigma(p-k))\frac{t^{\sigma}(k)}{2\pi i}(\psi^{\sigma}(p)\vec{\mathcal{L}}_{N}\Phi^{\sigma}(k)), \tag{3.133}$$

$$\mathcal{R}_{\pm}^{\sigma}(m,k) = \mp \theta(\pm\sigma(\lambda_{m\Re}-k))\frac{t^{\sigma}(k)}{2\pi i}(\psi_{m}^{\sigma}\vec{\mathcal{L}}_{N}\Phi^{\sigma}(k)), \tag{3.134}$$

$$\mathcal{R}_{\pm}^{\sigma}(p,n) = \mp \theta(\pm\sigma(p-\lambda_{n\Re}))\frac{\vartheta_{n}^{\sigma}}{2\pi i A_{n}^{\sigma}}(\psi^{\sigma}(p)\vec{\mathcal{L}}_{N}\Phi_{n}^{\sigma}), \tag{3.135}$$

$$\mathcal{R}_{\pm}^{\sigma}(m,n)=\delta_{mn}\left(\frac{\theta(\pm\sigma)}{A_n^{\sigma}}+\theta(\mp\sigma)\right)\mp\theta(\pm\sigma(m-n))\frac{\vartheta_n^{\sigma}}{2\pi i A_n^{\sigma}}(\psi_m^{\sigma}\vec{\mathcal{L}}_N\Phi_n^{\sigma}). \tag{3.136}$$

We have, then, Eqs. (3.119)–(3.122),

$$\mathbf{\Phi}^{\sigma}\mathbf{T}^{\sigma}=\mathbf{\Phi}_{\pm}\mathbf{r}_{\pm}^{\sigma}\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}, \tag{3.137}$$

$$\mathbf{\Phi}_{\pm}=\mathbf{\Phi}^{\sigma}(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}(\mathbf{r}_{\pm}^{-\sigma})^{\dagger}, \tag{3.138}$$

$$\mathbf{T}^{\sigma}\mathbf{\Psi}^{\sigma}=(\boldsymbol{\mathcal{R}}_{\mp}^{-\sigma})^{\dagger}(\mathbf{r}_{\mp}^{-\sigma})^{\dagger}\mathbf{\Psi}_{\pm} \tag{3.139}$$

$$\mathbf{\Psi}_{\pm}=\mathbf{r}_{\mp}^{\sigma}\boldsymbol{\mathcal{R}}_{\mp}^{\sigma}\mathbf{\Psi}^{\sigma}. \tag{3.140}$$

Inserting the second equality of Eq. (2.113) into Eq. (3.123) and recalling Eq. (2.112) we get another formulation of the characterization equations,

$$(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}\mathbf{t}^{\sigma}\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}=\mathbf{T}^{\sigma}. \tag{3.141}$$

As well, multiplying Eq. (3.124) from the left and from the right by, respectively, $(\mathbf{r}_{\pm}^{-\sigma})^{\dagger}$ and $\mathbf{r}_{\pm}^{\sigma}$ and inserting Eq. (2.113) we get

$$\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}(\mathbf{T}^{\sigma})^{-1}(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}=(\mathbf{t}^{\sigma})^{-1}, \tag{3.142}$$

and, analogously, from Eq. (3.125)

$$(\boldsymbol{\mathcal{R}}_{+}^{-\sigma})^{\dagger}\mathbf{f}^{\sigma}\boldsymbol{\mathcal{R}}_{+}^{-\sigma}=(\boldsymbol{\mathcal{R}}_{-}^{-\sigma})^{\dagger}\mathbf{f}^{\sigma}\boldsymbol{\mathcal{R}}_{-}^{-\sigma}. \tag{3.143}$$

Characterization equations (3.141) and (3.142) say simply that the matrix operator $\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}$ has right and left inverse, while Eq. (3.142) is a characterization equation in the strict sense, if the triangular structure of spectral data (3.133)–(3.136) is taken into account. The spectral data $\mathcal{R}_{\pm}^{\sigma}(p,k)$ and $\mathcal{R}_{\pm}^{\sigma}(m,k)$ and only these spectral data are discontinuous at $k=\lambda_{n\Re}$ as follows by Eqs. (3.42), (3.44), and (3.28). The latter equalities prove that these discontinuities furnish the additional spectral data $\mathcal{R}_{\pm}^{\sigma}(p,n)$ and $\mathcal{R}_{\pm}^{\sigma}(m,n)$:

$$\vartheta_n^{\sigma}[\mathcal{R}_{\pm}^{\sigma}(p,\lambda_{n\Re}+0)-\mathcal{R}_{\pm}^{\sigma}(p,\lambda_{n\Re}-0)]=t^{\sigma}(\lambda_{n\Re})w_n^{\sigma}\mathcal{R}_{\pm}^{\sigma}(p,n), \tag{3.144}$$

$$\vartheta_n^{\sigma}[\mathcal{R}_{\pm}^{\sigma}(m,\lambda_{n\Re}+0)-\mathcal{R}_{\pm}^{\sigma}(m,\lambda_{n\Re}-0)]=t^{\sigma}(\lambda_{n\Re})w_n^{\sigma}\mathcal{R}_{\pm}^{\sigma}(m,n). \tag{3.145}$$

Correspondingly, there is only one independent characterization equation in Eq. (3.143) that involves only the spectral data $\mathcal{R}_{\pm}^{\sigma}(p,k)$ and $\mathcal{R}_{\pm}^{\sigma}(m,k)$. Precisely, we get

$$\int dk'\overline{\mathcal{R}_{+}^{\sigma}(k',p)}\mathcal{R}_{+}^{\sigma}(k',k)+\sum_{m,n=1}^{N}\overline{\mathcal{R}_{+}^{\sigma}(m,p)}\mathcal{D}_{mn}^{\sigma}\mathcal{R}_{+}^{\sigma}(n,k)=(+\ \rightarrow -). \tag{3.146}$$

where

$$\mathcal{D}_{mn}^{\sigma}=\vartheta(\sigma)\vartheta_m^{-}C_{mn}\vartheta_n^{+}+\vartheta(-\sigma)C_{mn}^{-1}. \tag{3.147}$$

From Eqs. (3.126) and (3.131) recalling Eq. (2.118) we have

$$\mathbf{F}^{\sigma}=(\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma})^{\dagger}\mathbf{f}^{\sigma}\boldsymbol{\mathcal{R}}_{\pm}^{-\sigma}, \tag{3.148}$$

showing that the spectral data $\mathbf{F}^{\sigma}$ are given by dressing the spectral data $\mathbf{f}^{\sigma}$ by means of $\boldsymbol{\mathcal{R}}_{\pm}^{\sigma}$, which for a perturbation $u'(x)\equiv 0$ reduces to the identity operator.

We shall see that relation (3.127) together with Eq. (3.42) enables us to formulate the inverse problem for the Jost solution. Say, for the sign "+" the "continuous" part of the equality (3.127) reads as

$$t^+(p)\Phi^+(p) - \Phi^-(p) = \int dp' \Phi^-(x,p') f^-(p',p) + \sum_{n=1}^{N} \Phi_n^-(x) F^-(n,p), \tag{3.149}$$

where we denoted

$$f^-(p,p') = F^-(p,p') - \delta(p-p'). \tag{3.150}$$

IV. INVERSE PROBLEM AND TIME EVOLUTION

A. Formulation of the inverse problem

Let us consider function $X(x,\mathbf{k})$ as defined in Eq. (3.13). Taking into account analyticity properties of the Jost solution $\Phi(x,\mathbf{k})$ derived above and asymptotics (3.17) we get

$$\begin{aligned}[t(\mathbf{k})]^{\theta(\mathbf{k}_\mathfrak{I})} X(\mathbf{k}) = 1 &+ \frac{1}{2\pi i} \int \frac{dp}{p-\mathbf{k}} [t^+(p)X^+(p) - X^-(p)] \\ &- \frac{1}{2\pi i} \sum_{n=1}^{N} \int_{-\lambda_{n\mathfrak{I}}}^{\lambda_{n\mathfrak{I}}} \frac{ds[t(s)]^{\theta(s)}}{s - i\lambda_{n\mathfrak{R}} + i\mathbf{k}} [X(\lambda_{n\mathfrak{R}} + 0 + is) - X(\lambda_{n\mathfrak{R}} - 0 + is)].\end{aligned} \tag{4.1}$$

In terms of the Jost solutions themselves this reads by Eq. (3.13) as

$$\begin{aligned}[t(\mathbf{k})]^{\theta(\mathbf{k}_\mathfrak{I})} \Phi(x,\mathbf{k}) = \mathrm{e}^{-i\ell(\mathbf{k})x} &+ \frac{1}{2\pi i} \int \frac{dp \mathrm{e}^{i(\ell(p)-\ell(\mathbf{k}))x}}{p-\mathbf{k}} \\ &\times \left[\int dp' \Phi^-(x,p') f^-(p,p') + \sum_{n=1}^{N} \Phi_n^-(x) F^-(n,p) \right] \\ &- \frac{1}{2\pi i} \sum_{n=1}^{N} \int_{-\lambda_{n\mathfrak{I}}}^{\lambda_{n\mathfrak{I}}} \frac{ds[t(\lambda_{n\mathfrak{R}} + is)]^{\theta(s)}}{s - i\lambda_{n\mathfrak{R}} + i\mathbf{k}} \mathrm{e}^{i(\ell(\lambda_{n\mathfrak{R}}+is)-\ell(\mathbf{k}))x} w_n(s) \Phi_n(x,s),\end{aligned} \tag{4.2}$$

where Eqs. (3.149) and (3.42) were used and where functions $\Phi_n^-(x)$ are defined in Eq. (3.80). Inserting into (4.2) relation (3.70), expressing the auxiliary Jost in terms of the Jost solutions we obtain

$$\begin{aligned}[t(\mathbf{k})]^{\theta(\mathbf{k}_\mathfrak{I})} \Phi(x,\mathbf{k}) = \mathrm{e}^{-i\ell(\mathbf{k})x} &+ \frac{1}{2\pi i} \int dp\, \Phi^-(x,p) \int \frac{dp' f^-(p',p)}{p'-\mathbf{k}} \mathrm{e}^{i(\ell(p')-\ell(\mathbf{k}))x} \\ &- \sum_{n=1}^{N} \frac{1}{2\pi \vartheta_n^+} \int_0^{\lambda_{n\mathfrak{I}}} ds\, A_n(s) t(\lambda_{n\mathfrak{R}} + is) \overline{w_n(-s)} \Phi(x, \lambda_{n\mathfrak{R}} + 0 + is) \\ &\times \int_0^s \frac{ds' t(\lambda_{n\mathfrak{R}} + is') w_n(s')}{s' - i\lambda_{n\mathfrak{R}} + i\mathbf{k}} \mathrm{e}^{i(\ell(\lambda_{n\mathfrak{R}}+is')-\ell(\mathbf{k}))x} \\ &- \sum_{n=1}^{N} \frac{1}{2\pi \vartheta_n^-} \int_{-\lambda_{n\mathfrak{I}}}^{0} ds\, A_n(s) t(\lambda_{n\mathfrak{R}} + is) \overline{w_n(-s)} \Phi(x, \lambda_{n\mathfrak{R}} + 0 + is) \\ &\times \left[\int_s^0 \frac{ds' w_n(s')}{s' - i\lambda_{n\mathfrak{R}} + i\mathbf{k}} \mathrm{e}^{i(\ell(\lambda_{n\mathfrak{R}}+is')-\ell(\mathbf{k}))x} - \int \frac{dp\, F^-(n,p)}{p-\mathbf{k}} \mathrm{e}^{i(\ell(p)-\ell(\mathbf{k}))x} \right].\end{aligned} \tag{4.3}$$

Now we can project this equality on the upper side of the real axis and on the segments $\mathbf{k}_{\mathfrak{R}} = \lambda_{n\mathfrak{R}} + 0$, $|\mathbf{k}_{\mathfrak{I}}| < \lambda_{n\mathfrak{I}}$. This supplies us with a closed system of equations on $\Phi^{-}(x,p)$ and $\Phi(x, \lambda_{n\mathfrak{R}} + 0 + i\mathbf{k}_{\mathfrak{I}})$.

B. Evolution of spectral data

The Jost, advanced/retarded $(\Phi(\mathbf{k}), \Phi_{\pm}(k))$ and auxiliary Jost, advanced/retarded $(\Phi_n(\mathbf{k}_{\mathfrak{I}}), \Phi_{\pm,n})$ solutions in the perturbed case are uniquely defined, respectively, by the integral equations (3.9), (3.93) and (3.35), (3.94). In the considered integral equations, thanks to the fast decay of the perturbation $u'(x)$ at large x, we can exchange the limit $x_2 \to \infty$ with the integral and deduce that $\Phi(\mathbf{k})$ and $\Phi_n(\mathbf{k}_{\mathfrak{I}})$ have at large x_2 the same asymptotic behavior as the inhomogeneous terms $\varphi(\mathbf{k})$ and $\varphi_n(\mathbf{k}_{\mathfrak{I}})$. Therefore, since also $u(x)$ is going to zero at large x_2, the operators $\mathcal{T}_N$ and $\mathcal{T}$ have at large x_2 the same asymptotic limit $\partial_t + 4i\partial_{x_1}^3$ and we obtain by using Eqs. (2.102) and (2.107),

$$\mathcal{T}(\mathbf{k}^3)\Phi(\mathbf{k}) = 0, \tag{4.4}$$

$$\mathcal{T}((\lambda_n^{\sigma})^3)\Phi_n(\mathbf{k}_{\mathfrak{I}}) = 0 \quad \text{where } \sigma = \operatorname{sgn} \mathbf{k}_{\mathfrak{I}}. \tag{4.5}$$

Green's function $\mathcal{G}_{N,\pm}(x,x')$ appearing in the integral equations (3.93) and (3.94) goes to zero for $x_2 \to \mp\infty$ due to the presence of a factor $\theta(\pm(x_2 - x_2'))$ in Eq. (2.56). Therefore, in the same way as for the Jost solutions we obtain using Eqs. (2.106) and (2.108):

$$\mathcal{T}(k^3)\Phi_{\pm}(k) = 0, \tag{4.6}$$

$$\mathcal{T}\left(\frac{1}{2}(\overline{\lambda_m^3} + \lambda_m^3)\right)\Phi_{\pm,m} = 0. \tag{4.7}$$

Considering the limit of Eq. (3.99) for $x_2 \to \mp\infty$ we have

$$t^{\sigma}(k)\Phi^{\sigma}(k) \simeq \int dp\, \varphi_{\pm}(p) R_{\pm}^{\sigma}(p,k) + \sum_{m=1}^{N} \varphi_{\pm,m}(k) R_{\pm}^{\sigma}(m,k). \tag{4.8}$$

Due to the triangular property of $R_{\pm}^{\sigma}(p,k)$ and the asymptotics of the Jost and advanced/retarded solutions that one can derive from Eqs. (2.15) and (2.83), respectively, the first term in the rhs is not going to zero as fast as an exponential and therefore dominates over the second term that is going to zero exponentially. We have

$$t^{\sigma}(k)\Phi^{\sigma}(x,k) \simeq \int dp\, \chi_{\pm,\mathrm{as}}(p) \mathrm{e}^{-i\ell(p)x} R_{\pm}^{\sigma}(p,k) \quad \text{for } x_2 \to \mp\infty. \tag{4.9}$$

Inserting this expansion into Eq. (4.4) we get the time evolution for the spectral data $R_{\pm}^{\sigma}(p,k)$,

$$[\partial_t + 4i(k^3 - p^3)] R_{\pm}^{\sigma}(k,p) = 0. \tag{4.10}$$

Applying $\mathcal{T}(k^3)$ to Eq. (3.99) and using Eq. (4.4) for $\mathbf{k} = k$, Eq. (4.6) for $k = p$ and Eq. (2.108) and the linear independence of the $\Phi_{\pm,m}$ we derive the time evolution for the spectral data $R_{\pm}^{\sigma}(m,k)$,

$$[\partial_t + 2i(\overline{\lambda_m^3} + \lambda_m^3) - 4ik^3] R_{\pm}^{\sigma}(m,k) = 0. \tag{4.11}$$

Applying $\mathcal{T}(k^3)$ to Eq. (3.109) and using, Eqs. (4.6) and (4.4) for $\mathbf{k} = p$, Eqs. (4.10) and (4.5) for $\mathbf{k}_{\mathfrak{I}} = \sigma 0$ and the independence of the Φ_n^{σ} we get the time evolution of the spectral data $R_{\pm}^{\sigma}(k,n)$,

$$[\partial_t + 4i(k^3 - (\lambda_n^\sigma)^3)]R_\pm^\sigma(k,n) = 0. \tag{4.12}$$

Analogously applying $\mathcal{T}\left(\frac{1}{2}(\overline{\lambda_n^3}+\lambda_n^3)\right)$ to Eq. (3.110) and using Eqs. (2.108), (4.4), and (4.10), and (4.6) we have

$$[\partial_t + 2i(\overline{\lambda_m^3} + \lambda_m^3) - 4i(\lambda_n^\sigma)^3]R_\pm^\sigma(m,n) = 0. \tag{4.13}$$

Applying $\mathcal{T}((\lambda_{n\Re}+i\mathbf{k}_\Im)^3)$ to Eq. (3.42) and using Eq. (4.4) for $\mathbf{k}=\lambda_{n\Re}+i\mathbf{k}_\Im$ and Eq. (4.5) we get the time evolution for the spectral data $w_n(\mathbf{k}_\Im)$,

$$[\partial_t + 4i(\lambda_n^\sigma)^3 - 4i(\lambda_{n\Re} + i\mathbf{k}_\Im)^3]w_n(\mathbf{k}_\Im) = 0, \quad \sigma = \operatorname{sgn}\mathbf{k}_\Im. \tag{4.14}$$

Finally, from Eq, (3.72), due to the time evolution of $w_n(\mathbf{k}_\Im)$, we have

$$\partial_t A_n(\mathbf{k}_\Im) = 0. \tag{4.15}$$

From the evolution equations of the spectral data $\mathbf{R}_\pm^\sigma$ given above one can easily derive the evolution equation for the spectral data $\boldsymbol{\mathcal{R}}_\pm^\sigma$, taking into account that they are related by Eq. (3.131) and recalling the evolution equations for $r_\pm^\sigma(m,n)$ in Eq. (2.101). We get

$$[\partial_t + 4i(k^3 - p^3)]\mathcal{R}_\pm^\sigma(k,p) = 0, \tag{4.16}$$

$$[\partial_t + 4i((\lambda_m^\sigma)^3 - p^3)]\mathcal{R}_\pm^\sigma(m,p) = 0, \tag{4.17}$$

$$[\partial_t + 4i(k^3 - (\lambda_n^\sigma)^3)]\mathcal{R}_\pm^\sigma(k,n) = 0, \tag{4.18}$$

$$[\partial_t + 4i((\lambda_m^\sigma)^3 - (\lambda_n^\sigma)^3)]\mathcal{R}_\pm^\sigma(m,n) = 0. \tag{4.19}$$

Taking into account the time evolution of w_n^σ and A_n^σ from Eqs. (4.14) and (4.15) one can check that these evolutions are coherent with Eqs. (3.144) and (3.145)

By Eqs. (4.16)–(4.19) and (2.98) from Eqs. (3.148) and (2.120) we obtain the time evolution of the spectral data $\mathbf{F}^\sigma$

$$[\partial_t + 4i(k^3 - p^3)]\mathcal{F}^\sigma(k,p) = 0, \tag{4.20}$$

$$[\partial_t + 4i((\lambda_m^\sigma)^3 - p^3)]\mathcal{F}^\sigma(m,p) = 0, \tag{4.21}$$

$$[\partial_t + 4i(k^3 - (\lambda_n^{-\sigma})^3)]\mathcal{F}^\sigma(k,n) = 0, \tag{4.22}$$

$$[\partial_t + 4i((\lambda_m^\sigma)^3 - (\lambda_n^{-\sigma})^3)]\mathcal{F}^\sigma(m,n) = 0. \tag{4.23}$$

Finally notice that due to the behavior of $G_N^\sigma(x,x',k)$ at large x_1 and the asymptotics (2.17) and (2.18) we get from the integral equation (3.9) that

$$\lim_{x_1\to+\infty} \Phi^\sigma(k)\mathrm{e}^{il(k)x} = \theta(-\sigma) + \theta(\sigma)\frac{1}{t^\sigma(k)}.$$

Inserting this into Eq. (4.4) we derive that at any time $t>0$ the solution u develops the dynamical constraint,

$$\int_{-\infty}^{\infty} dx_1 u_{x_2}(t,x) = 0, \tag{4.24}$$

generalizing to the case of N perturbed soliton the dynamical constraint found in the case of decaying solutions in Ref. 4.

(Received 31 May 2006; accepted 23 October 2006; published online 27 December 2006)

We obtain a closed form expression of the universal $\mathcal{T}$-matrix encapsulating the duality between the quantum superalgebra $U_q[osp(1/2)]$ and the corresponding supergroup $OSp_q(1/2)$. The classical $q \to 1$ limit of this universal $\mathcal{T}$-matrix yields the group element of the undeformed $OSp_q(1/2)$ supergroup. The finite dimensional representations of the quantum supergroup $OSp_q(1/2)$ are readily constructed employing the above-mentioned universal $\mathcal{T}$-matrix and the known finite dimensional representations of the dually related deformed $U_q[osp(1/2)]$ superalgebra. Proceeding further, we derive the product law, the recurrence relations, and the orthogonality of the representations of the quantum supergroup $OSp_q(1/2)$. It is shown that the entries of these representation matrices are expressed in terms of the *little* Q-Jacobi polynomials with $Q=-q$. Two mutually complementary singular maps of the universal $\mathcal{T}$-matrix on the universal $\mathcal{R}$-matrix are also presented. [DOI: 10.1063/1.2399360]

I. INTRODUCTION

The representation theory of quantum groups and algebras has a richer structure compared to its classical counterparts. Various nonclassical features in the representation theory of the former have been found for specific values of deformation parameters such as roots of unity or crystal base limit. It is known that, for generic values of deformation parameters, each irreducible representation of the classical Lie groups and algebras has its quantum analog (see, for example, Ref. 1). Even for such a generic case, however, there exist representations of the quantum algebra that do not have classical partners.[2–4] Extending our studies to the quantum supergroups, we expect further richness of the representations as the nilpotency of Grassmann variables in classical supergroups are, in many cases, lost at the quantum level. Grassmann coordinates of quantum superspaces[5] and quantum superspheres,[6] as well as the Grassmann elements of quantum supermatrices,[5,6] are instances of lost nilpotency. When representations of such algebraic objects are considered, nonvanishing squares of Grassmann variables cause a drastic shift from the classical cases even for generic values of deformation parameters.

Influenced by this observation, here we study the representations of the simplest quantum supergroup $OSp_q(1/2)$. A precise theory of matrix representations of quantum groups has been developed in Ref. 7. The physical motivations of the present work are provided by the investigations on solvable models having a quantized $osp(1/2)$ symmetry. For instance, vertex models,[8] the Gaudin model,[9] and two-dimensional (2D) field theories[10] based on $U_q[osp(1/2)]$ symmetry have been proposed and investigated. A fully developed representation theory of $OSp_q(1/2)$ will provide useful tools for analyzing these models and building new ones.

It is known that the representation theories of two quantum algebras $U_q[sl(2)]$ and $U_q[osp(1/2)]$ are quite parallel for a generic q. We naturally anticipate that the known results on the quantum group $SL_q(2)$ may be extended to the quantum supergroup $OSp_q(1/2)$. To accomplish the extension, we employ the universal $\mathcal{T}$-matrix, which is a generalization of the exponential mapping relating a Lie algebra with its corresponding group. The underlying reasons for this are as follows: (i) The universal $\mathcal{T}$-matrix succinctly embodies the representations of the dually related conjugate Hopf structures, $U_q[osp(1/2)]$ and $OSp_q(1/2)$. In particular, contributions of the nonvanishing square of the odd elements of $OSp_q(1/2)$ may be directly read from the expression of the universal $\mathcal{T}$-matrix. (ii) Moreover, the universal $\mathcal{T}$-matrix allows us to map each irreducible representation of $U_q[osp(1/2)]$ on the corresponding one of $OSp_q(1/2)$. Therefore, various properties of representations follow from the corresponding ones of the universal $\mathcal{T}$-matrix, and the role of the lost nilpotency becomes explicit. Specifically, we demonstrate that the nonvanishing contributions of odd elements *assume polynomial structures* in the representation matrices.

The plan of this article is as follows. After fixing notations and conventions in the next section, the basis set of the Hopf dual to the $U_q[osp(1/2)]$ algebra is explicitly obtained. The finitely generated basis sets of the dually related Hopf algebras are now used to derive a closed form expression of the universal $\mathcal{T}$-matrix via the method of Frønsdal and Galindo.[11] Singular and therefore noninvertible maps of the universal $\mathcal{T}$-matrix on the universal $\mathcal{R}$-matrix exist.[11] Two such mutually complementary maps are studied in Sec. IV. General properties of the finite dimensional representations of the quantum supergroup $OSp_q(1/2)$, such as the product law, the recurrence relations, and the orthogonality of representations, follow, as observed in Sec. V, from the duality encompassed in the universal $\mathcal{T}$-matrix. Explicit form of the representation matrices are derived in Sec. VI and its relation to the little Q-Jacobi polynomials are discussed. It is shown that the entries of the representation matrix are expressed in terms of the little Q-Jacobi polynomials with $Q=-q$. This provides a new link of the representation theory of quantum supergroups with the hypergeometric functions. Section VII is devoted to concluding remarks. The corresponding results on $SL_q(2)$ and other quantum groups are mentioned in each section.

II. $U_q[osp(1/2)]$ AND ITS REPRESENTATIONS

The quantum superalgebra $\mathcal{U}=U_q[osp(1/2)]$ and the dually related quantum supergroup $\mathcal{A}=OSp_q(1/2)$, dual to $\mathcal{U}$, have been introduced in Ref. 12. Structures and representations of $\mathcal{U}$ have been investigated in Refs. 8 and 12. For the purpose of fixing our notations and conventions we list the relations that will be used subsequently.

The algebra $\mathcal{U}$ is generated by three elements H (parity even) and $V_\pm$ (parity odd) subject to the relations

$$[H,V_\pm]=\pm\frac{1}{2}V_\pm,\quad \{V_+,V_-\}=-\frac{q^{2H}-q^{-2H}}{q-q^{-1}}\equiv-[2H]_q. \tag{2.1}$$

The deformation parameter q is assumed to be generic throughout this article. The Hopf algebra structures defined via the coproduct (Δ), the counit (ϵ), and the antipode (S) maps read as follows:

$$\Delta(H)=H\otimes 1+1\otimes H,\quad \Delta(V_\pm)=V_\pm\otimes q^{-H}+q^{H}\otimes V_\pm, \tag{2.2}$$

$$\epsilon(H)=\epsilon(V_\pm)=0, \tag{2.3}$$

$$S(H)=-H,\quad S(V_\pm)=-q^{\mp 1/2}V_\pm. \tag{2.4}$$

Using the flip operator σ: $\sigma(a\otimes b)=(-1)^{p(a)p(b)}b\otimes a$, where $p(a)$ denotes the parity of a, we define the transposed coproduct: $\Delta'=\sigma\circ\Delta$. The universal $\mathcal{R}$-matrix intertwining Δ and Δ' is given by[12]

$$\mathcal{R}_q = q^{4H\otimes H}\sum_{k\geq 0}\frac{(q-q^{-1})^k q^{-k/2}}{(k)_{q^{-1}}!}(q^H V_+ \otimes q^{-H}V_-)^k, \tag{2.5}$$

where

$$(k)_q = \frac{1-(-1)^k q^k}{1+q},\quad (k)_q\,! = (k)_q(k-1)_q\cdots(1)_q,\quad (0)_q\,! = 1. \tag{2.6}$$

Two properties of $\mathcal{R}_q$ that will be used later are listed below: (i) It satisfies the Yang-Baxter equation

$$\mathcal{R}_{q12}\mathcal{R}_{q13}\mathcal{R}_{q23} = \mathcal{R}_{q23}\mathcal{R}_{q13}\mathcal{R}_{q12}, \tag{2.7}$$

and (ii) its antipode map reads as $(S\otimes id)\mathcal{R}_q = \mathcal{R}_{q^{-1}} = \mathcal{R}_q^{-1}$.

The finite dimensional irreducible representations of $\mathcal{U}$ is specified by the highest weight ℓ, which takes any non-negative integral value. The irreducible representation space $V^{(\ell)}$ of highest weight ℓ is $2\ell+1$ dimensional. We denote its basis as $\{e_m^\ell(\lambda)\,|\,m=\ell,\ell-1,\cdots,-\ell\}$, where the index $\lambda=0,1$ specifies the parity of the highest weight vector $e_\ell^\ell(\lambda)$. The parity of the vector $e_m^\ell(\lambda)$ equals $\ell-m+\lambda$, as it is obtained by the action of $V_-^{\ell-m}$ on $e_\ell^\ell(\lambda)$. For the superalgebras the norm of the representation basis need not be chosen positive definite. In this work, however, we assume the positive definiteness of the basis elements:

$$(e_m^\ell(\lambda),\, e_{m'}^{\ell'}(\lambda)) = \delta_{\ell\ell'}\delta_{mm'}. \tag{2.8}$$

With these settings, the irreducible representation of $\mathcal{U}$ on $V^{(\ell)}$ is given by

$$He_m^\ell(\lambda) = \frac{m}{2}e_m^\ell(\lambda),$$

$$V_+e_m^\ell(\lambda) = \left(\frac{1}{\{2\}_q}\{\ell-m\}_q\{\ell+m+1\}_q\right)^{1/2}e_{m+1}^\ell(\lambda),$$

$$V_-e_m^\ell(\lambda) = (-1)^{\ell-m-1}\left(\frac{1}{\{2\}_q}\{\ell+m\}_q\{\ell-m+1\}_q\right)^{1/2}e_{m-1}^\ell(\lambda), \tag{2.9}$$

where

$$\{m\}_q = \frac{q^{-m/2}-(-1)^m q^{m/2}}{q^{-1/2}+q^{1/2}}. \tag{2.10}$$

The tensor product of two irreducible representations is, in general, reducible and may be decomposed into irreducible ones without multiplicity:

$$V^{(\ell_1)}\otimes V^{(\ell_2)} = V^{(\ell_1+\ell_2)}\otimes V^{(\ell_1+\ell_2-1)}\otimes\cdots\otimes V^{(|\ell_1-\ell_2|)}.$$

The decomposition of the tensored vector space in the irreducible basis is provided by the Clebsch-Gordan coefficients (CGC):

$$e_m^\ell(\ell_1,\ell_2,\Lambda) = \sum_{m_1,m_2} C_{m_1\,m_2\,m}^{\ell_1\,\ell_2\,\ell}e_{m_1}^{\ell_1}(\lambda)\otimes e_{m_2}^{\ell_2}(\lambda), \tag{2.11}$$

where $m=m_1+m_2$, and $\Lambda=\ell_1+\ell_2+\ell(\mathrm{mod}\,2)$ signifies the parity of the highest weight vector $e_\ell^\ell(\ell_1,\ell_2,\Lambda)$. The CGC for $\mathcal{U}$ is extensively studied in Ref. 13. In spite of our assumption (2.8) regarding the positivity of the basis vectors, the norm of tensored vector space is not always positive definite. Indeed, the basis (2.11) is pseudo-orthogonal:

$$(e^{\ell'}_{m'}(\ell_1,\ell_2,\Lambda), e^{\ell}_{m}(\ell_1,\ell_2,\Lambda)) = (-1)^{(\ell-m+\lambda)(\ell_1+\ell_2+\ell+\lambda)}\delta_{\ell'\ell}\delta_{m'm}. \tag{2.12}$$

The CGC satisfies two pseudo-orthogonality relations:

$$\sum_{m_1,m_2} (-1)^{(\ell_1-m_1+\lambda)(\ell_2-m_2+\lambda)} C^{\ell_1\ell_2\ell}_{m_1m_2m} C^{\ell_1\ell_2\ell'}_{m_1m_2m'} = (-1)^{(\ell-m+\lambda)(\ell_1+\ell_2+\ell+\lambda)}\delta_{\ell\ell'}\delta_{mm'}, \tag{2.13}$$

$$\sum_{\ell,m} (-1)^{(\ell-m+\lambda)(\ell_1+\ell_2+\ell+\lambda)} C^{\ell_1\ell_2\ell}_{m_1m_2m} C^{\ell_1\ell_2\ell}_{m'_1m'_2m} = (-1)^{(\ell_1-m_1+\lambda)(\ell_2-m_2+\lambda)}\delta_{m_1m'_1}\delta_{m_2m'_2}. \tag{2.14}$$

Equation (2.14) immediately provides the inversion of the construction (2.11):

$$e^{\ell_1}_{m_1}(\lambda)\otimes e^{\ell_2}_{m_2}(\lambda) = (-1)^{(\ell_1-m_1)(\ell_2-m_2)}\sum_{\ell,m}(-1)^{(\ell-m)(\ell_1+\ell_2+\ell)} C^{\ell_1\ell_2\ell}_{m_1m_2m} e^{\ell}_{m}(\ell_1,\ell_2,\Lambda). \tag{2.15}$$

Before closing this section, we make two remarks: (i) All the CGC are of parity even state. (ii) The explicit realization of CGC for $\mathcal{U}$ is found in Ref. 6, and also in Ref. 13. As we maintain the phase convention for the representation of $\mathcal{U}$ given in Ref. 13, we use the results obtained therein.

III. UNIVERSAL $\mathcal{T}$-MATRIX VIA DUALITY

Two Hopf algebras $\mathcal{U}$ and $\mathcal{A}$ are in duality[11] if there exists a doubly nondegenerate bilinear form $\langle , \rangle$: $\mathcal{A}\otimes\mathcal{U}\to\mathbb{C}$ such that, for $(\mathbf{a},\mathbf{b})\in\mathcal{A}$, $(\mathbf{u},\mathbf{v})\in\mathcal{U}$,

$$\langle \mathbf{a},\mathbf{uv}\rangle = \langle \Delta_{\mathcal{A}}(\mathbf{a}),\mathbf{u}\otimes\mathbf{v}\rangle,\ \ \langle \mathbf{ab},\mathbf{u}\rangle = \langle \mathbf{a}\otimes\mathbf{b},\Delta_{\mathcal{U}}(\mathbf{u})\rangle,$$

$$\langle \mathbf{a},1_{\mathcal{U}}\rangle = \epsilon_{\mathcal{A}}(\mathbf{a}),\ \ \langle 1_{\mathcal{A}},\mathbf{u}\rangle = \epsilon_{\mathcal{U}}(\mathbf{u}),\ \ \langle \mathbf{a},S_{\mathcal{U}}(\mathbf{u})\rangle = \langle S_{\mathcal{A}}(\mathbf{a}),\mathbf{u}\rangle. \tag{3.1}$$

Let the ordered monomials $E_{k\ell m}=V_+^k H^\ell V_-^m$, $(k,\ell,m)\in(0,1,2,\ldots)$ be the basis elements of the algebra $\mathcal{U}$ obeying the multiplication and the induced coproduct rules given by

$$E_{k\ell m}E_{k'\ell'm'} = \sum_{pqr} f^{\ pqr}_{k\ell m\ k'\ell'm'} E_{pqr},\ \ \Delta(E_{k\ell m}) = \sum_{\substack{pqr\\ p'q'r'}} g^{pqr\ p'q'r'}_{k\ell m} E_{pqr}\otimes E_{p'q'r'}. \tag{3.2}$$

The basis elements $e^{k\ell m}$ of the dual Hopf algebra $\mathcal{A}$ follow the relation

$$\langle e^{k\ell m}, E_{k'\ell'm'}\rangle = \delta^k_{k'}\delta^\ell_{\ell'}\delta^m_{m'}. \tag{3.3}$$

In particular, the generating elements of the algebra $\mathcal{A}$, defined as $x=e^{100}$, $y=e^{001}$, and $z=e^{010}$, satisfy the following duality structure:

$$\langle x,V_+\rangle = 1,\ \ \langle z,H\rangle = 1,\ \ \langle y,V_-\rangle = 1. \tag{3.4}$$

Thus, x and y are of odd parity, while z is even. The duality condition (3.1) requires the basis set $e^{k\ell m}$ to obey the multiplication and coproduct rules given below:

$$e^{pqr}e^{p'q'r'} = \sum_{k\ell m} g^{pqr\ p'q'r'}_{k\ell m} e^{k\ell m},\ \ \Delta(e^{pqr}) = \sum_{\substack{k\ell m\\ k'\ell'm'}} f^{\ pqr}_{k\ell m\ k'\ell'm'} e^{k\ell m}\otimes e^{k'\ell'm'}. \tag{3.5}$$

To derive the Hopf properties of the dual algebra $\mathcal{A}$, we therefore need to extract the structure constants defined in (3.2). Toward this end we note that the induced coproduct map of the elements $E_{k\ell m}$ may be obtained via (2.2):

$$\Delta(E_{k\ell m}) = \Delta(V_+)^k \Delta(H)^\ell \Delta(V_-)^m = \sum_{a=0}^{k} \sum_{b=0}^{\ell} \sum_{c=0}^{m} \binom{k}{a}_q \binom{\ell}{b} \binom{m}{c}_q (-1)^{(m-c)(a+c)} q^{-a(k-a)/2-c(m-c)/2} \times V_+^{k-a} q^{(a+c)H} H^{\ell-b} V_-^{m-c} \otimes V_+^a q^{-(k+m-a-c)H} H^b V_-^c, \tag{3.6}$$

where

$$\binom{k}{a}_q = \frac{(k)_q!}{(a)_q!\,(k-a)_q!}.$$

The second equality in (3.6) can be verified by using the commutation relations

$$q(V_+ \otimes q^{-H})(q^H \otimes V_+) + (q^H \otimes V_+)(V_+ \otimes q^{-H}) = 0,$$

$$q(q^H \otimes V_-)(V_- \otimes q^{-H}) + (V_- \otimes q^{-H})(q^H \otimes V_-) = 0,$$

and an extension of binomial theorem that is easily proved by induction: Arbitrary operators A, B subject to the commutation properties $qAB+BA=0$ satisfy the following expansion:

$$(A+B)^n = \sum_{k=0}^{n} \binom{n}{k}_q A^{n-k} B^k. \tag{3.7}$$

Employing (3.6) we now obtain a set of structure constants:

$$g_{k\ell m}^{100\,001} = \delta_{k1}\delta_{\ell 0}\delta_{m1}, \quad g_{k\ell m}^{001\,100} = -\delta_{k1}\delta_{\ell 0}\delta_{m1},$$

$$g_{k\ell m}^{100\,010} = -\ln q\,\delta_{k1}\delta_{\ell 0}\delta_{m0} + \delta_{k1}\delta_{\ell 1}\delta_{m0},$$

$$g_{k\ell m}^{010\,100} = \ln q\,\delta_{k1}\delta_{\ell 0}\delta_{m0} + \delta_{k1}\delta_{\ell 1}\delta_{m0},$$

$$g_{k\ell m}^{010\,001} = \ln q\,\delta_{k0}\delta_{\ell 0}\delta_{m1} + \delta_{k0}\delta_{\ell 1}\delta_{m1},$$

$$g_{k\ell m}^{001\,010} = -\ln q\,\delta_{k0}\delta_{\ell 0}\delta_{m1} + \delta_{k0}\delta_{\ell 1}\delta_{m1}.$$

The above structure constants immediately yield the algebraic relations obeyed by the generators of the algebra $\mathcal{A}$:

$$\{x,y\} = 0, \quad [z,x] = 2\ln q x, \quad [z,y] = 2\ln q y. \tag{3.8}$$

Proceeding toward constructing the coproduct maps of the generating elements of the dual algebra $\mathcal{A}$, we notice that the defining properties (3.5) provide the necessary recipe:

$$\Delta(x) = \sum_{\substack{k\ell m \\ k'\ell'm'}} f_{k\ell m\,k'\ell'm'}^{100} e^{k\ell m} \otimes e^{k'\ell'm'},$$

$$\Delta(z) = \sum_{\substack{k\ell m \\ k\ell'm'}} f_{k\ell m\,k'\ell'm'}^{010} e^{k\ell m} \otimes e^{k'\ell'm'},$$

$$\Delta(y) = \sum_{\substack{k\ell m \\ k'\ell'm}} f^{001}_{k\ell m\, k'\ell'm'} e^{k\ell m} \otimes e^{k'\ell'm'}. \tag{3.9}$$

The relevant structure constants obtained via (3.2) are listed below:

$$f^{100}_{k\ell m\, k'\ell'm'} = \delta_{k1}\delta_{\ell 0}\delta_{m0}\delta_{k'0}\delta_{\ell'0}\delta_{m'0} + (-1)^m \frac{1}{2^\ell}\sigma_{m+1}\delta_{k0}\delta_{k'\, m+1}\delta_{\ell'0}\delta_{m'0},$$

$$f^{010}_{k\ell m\, k'\ell'm'} = \delta_{k0}\delta_{m0}\delta_{k'0}\delta_{m'0}(\delta_{\ell 1}\delta_{\ell'0} + \delta_{\ell 0}\delta_{\ell' 1}) + (-1)^m \frac{4\ln q}{q-q^{-1}}\sigma_m\delta_{k0}\delta_{\ell 0}\delta_{k'm}\delta_{\ell'0}\delta_{m'0},$$

$$f^{001}_{k\ell m\, k'\ell'm'} = \delta_{k0}\delta_{\ell 0}\delta_{m0}\delta_{k'0}\delta_{\ell'0}\delta_{m'1} + (-1)^{k'} \frac{1}{2^{\ell'}}\sigma_{k'+1}\delta_{k0}\delta_{\ell 0}\delta_{m\, k'+1}\delta_{m'0},$$

$$\sigma_1 = 1, \quad \sigma_m = \prod_{k=1}^{m-1}\sum_{\ell=0}^{k-1}(-1)^\ell [k-\ell]_q \quad (m>1). \tag{3.10}$$

The coproduct maps of the generators of $\mathcal{A}$ may now be explicitly obtained in the manner of (3.9) provided the basis elements $e^{k\ell m}$ of the algebra $\mathcal{A}$ are known. We complete this task subsequently.

As the algebra $\mathcal{A}$ is finitely generated, we may start with the generators (x,y,z) and obtain all dual basis elements $e^{k\ell m}$, $(k,\ell,m)\in(0,1,2,\ldots)$ by successively applying the multiplication rule given in the first equation in (3.5). The necessary structure constants may be read from the relation (3.2) of the algebra $\mathcal{U}$. In the procedure described below we maintain the operator ordering of the monomials as $x^k z^\ell y^m$, $(k,\ell,m)\in(0,1,2,\ldots)$. The product rule

$$e^{100}e^{n00} = \sum_{k\ell m} g^{100\, n00}_{k\ell m} e^{k\ell m} \tag{3.11}$$

and the explicit evaluation of the structure constant

$$g^{100\, n00}_{k\ell m} = \{n+1\}_q \delta_{k\, n+1}\delta_{\ell 0}\delta_{m0} \tag{3.12}$$

obtained from (3.6) immediately provide

$$e^{n00} = \frac{x^n}{\{n\}_q!}, \quad \{n\}_q! = \prod_{\ell=1}^{n}\{\ell\}_q, \quad \{0\}_q! = 1. \tag{3.13}$$

Employing another product rule

$$e^{nr0}e^{010} = \sum_{k\ell m} g^{nr0\, 010}_{k\ell m} e^{k\ell m} \tag{3.14}$$

and the value of the relevant structure constant

$$g^{nr\, 0010}_{k\ell m} = -n\ln q\,\delta_{kn}\delta_{\ell r}\delta_{m0} + (r+1)\delta_{kn}\delta_{\ell\, r+1}\delta_{m0},$$

obtained in the aforesaid way, we produce the following result:

$$e^{nr0} = \frac{x^n}{\{n\}_q!}\frac{1}{r!}(z + n\ln q)^r. \tag{3.15}$$

Continuing the above process of building of the dual basis set, we use the product rule

$$e^{nrs}e^{001} = \sum_{k\ell m} g^{nrs\,001}_{k\ell m} e^{k\ell m} \tag{3.16}$$

and the value of the corresponding structure constant

$$g^{nrs\,001}_{k\ell m} = \{s+1\}_{q^{-1}} \sum_{j=0}^{r} \frac{1}{j!} (\ln q)^j \delta_{kn} \delta_{\ell\, r-j} \delta_{m\, s+1},$$

obtained via (3.6). This finally leads us to the complete construction of the basis element of the algebra $\mathcal{A}$:

$$e^{nrs} = \frac{x^n}{\{n\}_q!} \frac{(z+(n-s)\ln q)^r}{r!} \frac{y^s}{\{s\}_{q^{-1}}!}. \tag{3.17}$$

Combining our results in (3.9), (3.10), and (3.17), we now provide the promised coproduct structure of the generators of the algebra $\mathcal{A}$:

$$\Delta(x) = x \otimes 1 + \sum_{m=0}^{\infty} (-1)^m \sigma_{m+1} q^{-m/2} e^{z/2} \frac{y^m}{\{m\}_{q^{-1}}!} \otimes \frac{x^{m+1}}{\{m+1\}_q!},$$

$$\Delta(z) = z \otimes 1 + 1 \otimes z + \frac{4\ln q}{q-q^{-1}} \sum_{m=1}^{\infty} (-1)^m \sigma_m \frac{y^m}{\{m\}_{q^{-1}}!} \otimes \frac{x^m}{\{m\}_q!},$$

$$\Delta(y) = 1 \otimes y + \sum_{k=0}^{\infty} (-1)^k \sigma_{k+1} q^{k/2} \frac{y^{k+1}}{\{k+1\}_{q^{-1}}!} \otimes \frac{x^k}{\{k\}_q!} e^{z/2}. \tag{3.18}$$

Algebraic simplifications allow us to express the coproduct maps of the above generators more succinctly:

$$\Delta(x) = x \otimes 1 + \sum_{m=0}^{\infty} (-1)^{m(m-1)/2} \left(\frac{1+q^{-1}}{q-q^{-1}}\right)^m e^{z/2} y^m \otimes x^{m+1},$$

$$\Delta(z) = z \otimes 1 + 1 \otimes z + \frac{4\ln q}{q-q^{-1}} \sum_{m=1}^{\infty} \frac{(-1)^{m(m+1)/2}}{\{m\}_{q^{-1}}} \left(\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}}\right)^{m-1} y^m \otimes x^m,$$

$$\Delta(y) = 1 \otimes y + \sum_{m=0}^{\infty} (-1)^{m(m-1)/2} \left(\frac{q+1}{q-q^{-1}}\right)^m y^{m+1} \otimes x^m e^{z/2}. \tag{3.19}$$

With the aid of the result (3.19) we may explicitly demonstrate that the coproduct map is a homomorphism of the algebra (3.8): namely,

$$\{\Delta(x),\Delta(y)\} = 0, \quad [\Delta(z),\Delta(x)] = 2\ln q \Delta(x), \quad [\Delta(z),\Delta(y)] = 2\ln q \Delta(y).$$

The coassociativity constraint

$$(id \otimes \Delta) \circ \Delta(\mathcal{X}) = (\Delta \otimes id) \circ \Delta(\mathcal{X}) \quad \forall\, \mathcal{X} \in (x,y,z)$$

may also be established by using the following identity:

$$\exp(\Delta(z)) = (\exp(z) \otimes 1) \prod_{m=1}^{\infty} \mathcal{P}_m (1 \otimes \exp(z)),$$

$$\mathcal{P}_m = \exp\left((-1)^{m(m+1)/2} \frac{[2m]_q}{m\{m\}_{q^{-1}}} \left(\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}} \right)^{m-1} y^m \otimes x^m \right). \tag{3.20}$$

The counit map of the generators of the algebra $\mathcal{A}$ reads as

$$\epsilon(x) = \epsilon(y) = \epsilon(z) = 0. \tag{3.21}$$

The antipode map of the dual generators follows from the last equation in (3.1). We quote the results here:

$$S(x) = -\sum_{m=0}^{\infty} (-1)^{m(m-1)/2} q^{-1} \left(\frac{1+q^{-1}}{q-q^{-1}} \right)^m x^{m+1} \exp\left(-\frac{m+1}{2} z \right) y^m,$$

$$S(z) = -z + \frac{4\ln q}{q-q^{-1}} \sum_{m=1}^{\infty} (-1)^{m(m+1)/2} \frac{1}{\{m\}_{q^{-1}}} \left(\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}} \right)^{m-1} x^m e^{-mz/2} y^m,$$

$$S(y) = -\sum_{m=0}^{\infty} (-1)^{m(m+1)/2} q \left(\frac{q+1}{q-q^{-1}} \right)^m x^m \exp\left(-\frac{m+1}{2} z \right) y^{m+1}. \tag{3.22}$$

This completes our construction of the Hopf algebra $\mathcal{A}$ dually related to the quantum superalgebra $\mathcal{U}$.

Our explicit listing of the complete set of dual basis elements in (3.17) allows us to obtain, in the manner of Frønsdal and Galindo,[11] the universal $\mathcal{T}$-matrix for the supergroup:

$$\mathcal{T}_{e,E} = \sum_{k\ell m} (-1)^{p(e^{k\ell m})(p(e^{k\ell m})-1)/2} e^{k\ell m} \otimes E_{k\ell m}, \tag{3.23}$$

where the parity of basis elements is same for two Hopf algebras $\mathcal{U}$ and $\mathcal{A}$:

$$p(e^{k\ell m}) = p(E_{k\ell m}) = k + m. \tag{3.24}$$

The notion of the universal $\mathcal{T}$-matrix is a key feature capping the Hopf duality structure. Consequently, the duality relations (3.1) may be concisely expressed[11] in terms of the $\mathcal{T}$-matrix as

$$\mathcal{T}_{e,E}\mathcal{T}_{e',E} = \mathcal{T}_{\Delta(e),E}, \quad \mathcal{T}_{e,E}\mathcal{T}_{e,E'} = \mathcal{T}_{e,\Delta(E)},$$

$$\mathcal{T}_{\epsilon(e),E} = \mathcal{T}_{e,\epsilon(E)} = 1, \quad \mathcal{T}_{S(e),E} = \mathcal{T}_{e,S(E)}, \tag{3.25}$$

where e and e' (E and E') refer to the two identical copies of algebra $\mathcal{A}$ ($\mathcal{U}$). A general discussion of the universal $\mathcal{T}$-matrix for supergroups is found in the Appendix.

As both the Hopf algebras in our case are finitely generated, the universal $\mathcal{T}$-matrix may now be obtained as an operator valued function in a closed form:

$$\begin{aligned} \mathcal{T}_{e,E} &= \left(\sum_{k=0}^{\infty} \frac{(x \otimes V_+ q^H)^k}{(k)_q!} \right) \exp(z \otimes H) \left(\sum_{m=0}^{\infty} \frac{(y \otimes q^{-H} V_-)^m}{(m)_{q^{-1}}!} \right) \\ &\equiv {}^{\times}_{\times}\mathcal{E}\mathrm{xp}_q(x \otimes V_+ q^H) \exp(z \otimes H) \mathcal{E}\mathrm{xp}_{q^{-1}}(y \otimes q^{-H} V_-)^{\times}_{\times}, \end{aligned} \tag{3.26}$$

where we have introduced a deformed exponential that is characteristic of the quantum $OSp_q(1/2)$ supergroup:

$$\mathcal{E}\mathrm{xp}_q(x) \equiv \sum_{n=0}^{\infty} \frac{x^n}{(n)_q!}. \tag{3.27}$$

The operator ordering has been explicitly indicated in (3.26). The closed form of the universal $\mathcal{T}$-matrix in (3.26) will be used in the computation of the representation matrices of the quantum supergroup $\mathcal{A}$. In Ref. 14, using the Gauss decomposition of the fundamental representation, a universal $\mathcal{T}$-matrix for $\mathcal{U}$ is given in terms of the standard q-exponential instead of the deformed exponential (3.27) characterizing the quantum supergroups.

In the classical limit of $q \to 1$, it is immediately evident that the structure constant (3.12) is truncated at $n=2$ so that x remains nilpotent. Similarly, $y^2=0$ holds in this limit. It is interesting to observe the $q \to 1$ limit of the universal $\mathcal{T}$-matrix (3.26). For this purpose we note

$$\lim_{q\to 1}(2n)_q \to n(1-q), \quad \lim_{q\to 1}(2n+1)_q \to 1, \quad n=0,1,2,\ldots. \tag{3.28}$$

Assuming the finite limit

$$\lim_{q\to 1}\frac{x^2}{q-1} = \mathfrak{x}, \quad \lim_{q\to 1}\frac{y^2}{q^{-1}-1} = \mathfrak{y}, \tag{3.29}$$

it immediately follows that the universal $\mathcal{T}$-matrix (3.26) reduces to the group element of the undeformed $OSp(1/2)$ and by definition constitutes its universal T-matrix:

$$\mathcal{T}_{e,E}\big|_{q\to 1} = (1\otimes 1 + x\otimes V_+)\exp(\mathfrak{x}\otimes V_+^2)\exp(z\otimes H)\exp(\mathfrak{y}\otimes V_-^2)(1\otimes 1 + y\otimes V_-). \tag{3.30}$$

The finite limiting elements $(\mathfrak{x},\mathfrak{y})$ are bosonic in nature, and in the context of the classical limit of the function algebra $\mathcal{A}$ they are dually related to the squares of the odd generators of the undeformed $osp(1/2)$. The elements $(V_\pm^2, H)$ of the classical $osp(1/2)$ algebra form a $sl(2)$ subalgebra. The corresponding classical $SL(2)$ subgroup structure is evident from (3.30). In fact, the correct limiting structure (3.30) emphasizes the essential validity of the quantum universal $\mathcal{T}$-matrix derived in (3.26). Obviously, there is a striking difference between the quantum and classical universal $\mathcal{T}$-matrices caused by the absence of nilpotency of parity odd elements in the former case. The infinite series of operators summarized in the deformed exponential contribute to new polynomial matrix elements in the representations of quantum supergroup $\mathcal{A}$. This is considered in detail in Sec. V.

The above construction of the universal $\mathcal{T}$-matrix for the algebra $\mathcal{U}$ is parallel to the one for the generalized Heisenberg algebra,[15] which is a bosonization[16] of the superalgebra $\mathcal{U}$. The dual basis to the two-parametric deformation of $GL(2)$ is studied in Ref. 17. The universal $\mathcal{T}$-matrix for the two-parametric quantum $GL(2)$ is given in Refs. 11 and 18. The generalization to the quantum $gl(n)$ is found in Ref. 19, and a supersymmetric extension is initiated in Ref. 20.

IV. MAPPING $\mathcal{T}$ ON $\mathcal{R}$

Two singular and mutually complementary maps connecting the universal $\mathcal{T}$-matrix in (3.26) and the universal $\mathcal{R}$-matrix in (2.5) are discussed in this section. The first map $\Phi: \mathcal{A} \to \mathcal{U}$ reads

$$\Phi(x) = 0, \quad \Phi(z) = (4\ln q)H, \quad \Phi(y) = q^{-1/2}(q-q^{-1})q^H V_+. \tag{4.1}$$

It is easily observed to satisfy the following properties: (i) $(\Phi\otimes \mathrm{id})(\mathcal{T}_{e,E}) = \mathcal{R}_q$, and (ii) Φ is an algebra homomorphism, though not a Hopf algebra homomorphism; that is, Φ respects the commutation relations in (3.8) but does not maintain the Hopf coalgebra maps.

To introduce the second map, we recast the universal $\mathcal{T}$-matrix in the form given below:

$$\mathcal{T}_{E,e} = \sum_{k\ell m} (-1)^{(k+m)(k+m-1)/2} E_{k\ell m} \otimes e^{k\ell m} = \left(\sum_k \frac{1}{(k)_q!} (V_+ q^H \otimes x)^k \right) e^{H\otimes z} \left(\sum_m \frac{1}{(m)_{q^{-1}}!} (q^{-H} V_- \otimes y)^m \right). \tag{4.2}$$

The universal $\mathcal{R}$-matrix is also rewritten as

$$\mathcal{R}_q = \sum_{k\geq 0} \frac{(q-q^{-1})^k}{(k)_{q^{-1}}!} (V_+ q^{-H} \otimes q^H V_-)^k q^{4H\otimes H}. \tag{4.3}$$

A comparison of the above two expressions immediately yields the promised map $\Psi : \mathcal{A} \to \mathcal{U}$ defined as follows:

$$\Psi(x) = (q^{-1} - q) q^{-H} V_-, \quad \Psi(z) = (-4 \ln q) H, \quad \Psi(y) = 0. \tag{4.4}$$

One can immediately verify that $(\mathrm{id} \otimes \Psi)(\mathcal{T}_{E,e}) = \mathcal{R}_q^{-1}$ and that Ψ is an algebraic homomorphism but not a Hopf algebra homomorphism. It is interesting to observe that in both the maps introduced here *one* Borel subalgebra of the function algebra $\mathcal{A}$ is mapped on the corresponding Borel subalgebra of the universal enveloping algebra $\mathcal{U}$. Therefore, the two conjugate Borel subalgebras of the $\mathcal{U}$ algebra are acted upon by two distinct, but complementary maps. Being singular in nature, these maps are, however, not invertible.

The maps Φ and Ψ may be utilized to connect the universal $\mathcal{T}$-matrix and the Yang-Baxter equation. As shown in the Appendix, the universal $\mathcal{T}$-matrix satisfies *RTT*-type relations. Using the tensored operators

$$\mathcal{T}^{(1)}_{e,E} = \sum_k (-1)^{(k+m)(k+m-1)/2} e^{k\ell m} \otimes E_{k\ell m} \otimes 1,$$

$$\mathcal{T}^{(2)}_{e,E} = \sum_k (-1)^{(k+m)(k+m-1)/2} e^{k\ell m} \otimes 1 \otimes E_{k\ell m}, \tag{4.5}$$

the following identity may be established:

$$(1 \otimes \mathcal{R}_q) \mathcal{T}^{(1)}_{e,E} \mathcal{T}^{(2)}_{e,E} = \mathcal{T}^{(2)}_{e,E} \mathcal{T}^{(1)}_{e,E} (1 \otimes \mathcal{R}_q). \tag{4.6}$$

Mirroring the structure in (4.5) we also define the transposed T-matrices in the tensored space as

$$\mathcal{T}^{(1)}_{E,e} = \sum_k (-1)^{(k+m)(k+m-1)/2} E_{k\ell m} \otimes 1 \otimes e^{k\ell m},$$

$$\mathcal{T}^{(2)}_{E,e} = \sum_k (-1)^{(k+m)(k+m-1)/2} 1 \otimes E_{k\ell m} \otimes e^{k\ell m}. \tag{4.7}$$

These matrices also obey another *RTT*-type relation:

$$(\mathcal{R}_q \otimes 1) \mathcal{T}^{(1)}_{E,e} \mathcal{T}^{(2)}_{E,e} = \mathcal{T}^{(2)}_{E,e} \mathcal{T}^{(1)}_{E,e} (\mathcal{R}_q \otimes 1). \tag{4.8}$$

Application of the tensored map $\Phi \otimes \mathrm{id} \otimes \mathrm{id}$ to (4.6) converts the *RTT*-type relation into the Yang-Baxter equation of the form

$$\mathcal{R}_{q\,23} \mathcal{R}_{q\,12} \mathcal{R}_{q\,13} = \mathcal{R}_{q\,13} \mathcal{R}_{q\,12} \mathcal{R}_{q\,23}, \tag{4.9}$$

while a similar action of the conjugate map $\mathrm{id} \otimes \mathrm{id} \otimes \Psi$ on (4.8) provides the another form of the Yang-Baxter equation:

$$\mathcal{R}_{q\,12}\mathcal{R}_{q\,13}\mathcal{R}_{q\,23} = \mathcal{R}_{q\,23}\mathcal{R}_{q\,13}\mathcal{R}_{q\,12}. \tag{4.10}$$

Mappings from a universal $\mathcal{T}$-matrix to a universal $\mathcal{R}$-matrix have been discussed for only a few quantum algebras. Frønsdal[19] considered such mappings for quantum $gl(n)$ and the particular case of a two-parametric quantum $gl(2)$ is discussed in Ref. 21. The maps for Alexander-Conway quantum algebra are studied in Ref. 22.

V. REPRESENTATIONS OF $\mathcal{A}$

We do not yet have the explicit formulae of finite dimensional representation matrices of the function algebra $\mathcal{A}$. These expressions will be derived in the next section. But, prior to that, the general properties of such finite dimensional representation matrices may be understood via the duality arguments interrelating $\mathcal{A}$ and $\mathcal{U}$ algebras. We will address to this task in the present section.

To be explicit, for us the representations of $\mathcal{A}$ signify the matrix elements of the universal $\mathcal{T}$-matrix on $V^{(\ell)}$ defined in Sec. II:

$$T^{\ell}_{m'm}(\lambda) = (e^{\ell}_{m'}(\lambda), \mathcal{T}_{e,E} e^{\ell}_{m}(\lambda)) = \sum_{abc} (-1)^{(a+c)(a+c-1)/2+(a+c)(\ell-m'+\lambda)} e^{abc} (e^{\ell}_{m'}(\lambda), E_{abc}\, e^{\ell}_{m}(\lambda)). \tag{5.1}$$

Under the assumption of the completeness of the basis vectors $e^{\ell}_{m}(\lambda)$, it is not difficult to verify the relations

$$\Delta(T^{\ell}_{m'm}(\lambda)) = \sum_{k} T^{\ell}_{m'k}(\lambda) \otimes T^{\ell}_{km}(\lambda), \quad \epsilon(T^{\ell}_{m'm}(\lambda)) = \delta_{m'm}. \tag{5.2}$$

The relations in (5.2) imply that the matrix elements (5.1) satisfy the axiom of the comodule.[1] We may therefore regard $T^{\ell}_{m'm}(\lambda)$ as the $2\ell+1$ dimensional matrix representation of the algebra $\mathcal{A}$.

We now consider a product of two representations in order to obtain their composition rule. We evaluate the matrix elements of $\mathcal{T}_{e,\Delta(E)}$ on the coupled basis vector space in two different ways. The first evaluation is as follows:

$$\begin{aligned}
&(e^{\ell'}_{m'}(\ell_1,\ell_2,\Lambda), \mathcal{T}_{e,\Delta(E)}\, e^{\ell}_{m}(\ell_1,\ell_2,\Lambda)) \\
&\quad = \sum_{abc} (-1)^{(a+c)(a+c-1)/2+(a+c)(\ell'-m'+\Lambda)} e^{abc}\, (e^{\ell'}_{m'}(\ell_1,\ell_2,\Lambda), \Delta(E_{abc}) e^{\ell}_{m}(\ell_1,\ell_2,\Lambda)) \\
&\quad = \delta_{\ell'\ell}(-1)^{(\ell'-m'+\lambda)(\ell_1+\ell_2+\ell'+\lambda)} T^{\ell}_{m'm}(\Lambda).
\end{aligned} \tag{5.3}$$

In the last equality, the pseudo-orthogonality (2.12) of the coupled basis has been used. An alternate evaluation of the above-mentioned matrix element explicitly uses the Clebsch-Gordan coupling of the basis vectors. With the aid of the relation

$$\mathcal{T}_{e,\Delta(E)} = \sum_{\substack{prq \\ p'q'r'}} (-1)^{(p+r+p'+r')(p+r+p'+r'-1)/2} e^{pqr} e^{p'q'r'} \otimes E_{pqr} \otimes E_{p'q'r'},$$

we obtain

$$(e^{\ell'}_{m'}(\ell_1,\ell_2,\Lambda),\mathcal{T}_{e,\Delta(E)}e^{\ell}_{m}(\ell_1,\ell_2,\Lambda))$$
$$=\sum_{\substack{m_1,m_2\\ m'_1,m'_2}}(-1)^{(\ell_1-m_1+\lambda)(\ell_2-m'_2+\lambda)}C^{\ell_1\,\ell_2\,\ell'}_{m'_1m'_2m'}C^{\ell_1\,\ell_2\,\ell}_{m_1\,m_2\,m}T^{\ell_1}_{m'_1\,m_1}(\lambda)T^{\ell_2}_{m'_2\,m_2}(\lambda). \tag{5.4}$$

Since the results of the two evaluations have to be identical, we obtain the product law for the quantum supergroup $\mathcal{A}$ of the following form:

$$\delta_{\ell'\ell}T^{\ell}_{m'm}(\Lambda)=(-1)^{(\ell'-m'+\lambda)(\ell_1+\ell_2+\ell'+\lambda)}\sum_{\substack{m_1,m_2\\ m'_1,m'_2}}(-1)^{(\ell_1-m'_1+\lambda)(\ell_2-m'_2+\lambda)}$$
$$\times C^{\ell_1\,\ell_2\,\ell'}_{m'_1\,m'_2\,m'}C^{\ell_1\,\ell_2\,\ell}_{m_1\,m_2\,m}T^{\ell_1}_{m'_1\,m_1}(\lambda)T^{\ell_2}_{m'_2\,m_2}(\lambda). \tag{5.5}$$

Another derivation of the product law (5.5) is found in Ref. 6.

Two alternate forms of the product law are readily derived by using the pseudo-orthogonality of CGC (2.13) and (2.14):

$$\sum_{m'}C^{\ell_1\,\ell_2\,\ell}_{n_1\,n_2\,m'}T^{\ell}_{m'm}(\Lambda)=\sum_{m_1,m_2}(-1)^{(n_1+m_1)(\ell_2-n_2+\lambda)}C^{\ell_1\,\ell_2\,\ell}_{m_1\,m_2\,m}T^{\ell_1}_{n_1\,m_1}(\lambda)T^{\ell_2}_{n_2\,m_2}(\lambda), \tag{5.6}$$

$$\sum_{m}(-1)^{(m'+m)(\ell_1+\ell_2+\ell'+\lambda)}C^{\ell_1\,\ell_2\,\ell'}_{n_1\,n_2\,m}T^{\ell'}_{m'm}(\Lambda)$$
$$=\sum_{m'_1,m'_2}(-1)^{(n_2+m'_2)(\ell_1-n_1+\lambda)}C^{\ell_1\,\ell_2\,\ell'}_{m'_1\,m'_2\,m'}T^{\ell_1}_{m'_1\,n_1}(\lambda)T^{\ell_2}_{m'_2\,n_2}(\lambda). \tag{5.7}$$

The product law allows us to derive the orthogonality and the recurrence relations of the representation matrix $T^{\ell}_{m'm}$. Setting $\ell_1=\ell_2$, $\ell=m=0$ in (5.6) and using the formula of CGC given in Ref. 6, one can verify the orthogonality relation

$$\sum_{m}(-1)^{m_1(m_1+m)+m_1(m_1-1)/2+m(m-1)/2}q^{(m_1-m)/2}T^{\ell}_{m_1m}(\lambda)T^{\ell}_{-m_2-m}(\lambda)=\delta_{m_1m_2}. \tag{5.8}$$

Another orthogonality relation is similarly obtained by setting $\ell_1=\ell_2$, $\ell'=m'=0$ in the product law (5.7):

$$\sum_{m}(-1)^{(m_1+m)m_1+m_1(m_1-1)/2+m(m-1)/2}q^{(m_1-m)/2}T^{\ell}_{mm_1}(\lambda)T^{\ell}_{-m-m_2}(\lambda)=\delta_{m_1m_2}. \tag{5.9}$$

For the choice of $\ell_2=1$ in (5.6), the recurrence relations for the representation matrices are obtained below. These relations are classified into three sets according to the values of ℓ:

• The first set has the value of $\ell=\ell_1+1$. It comprises three relations corresponding to all possible values of n_2. The recurrence relations listed below correspond to $n_2=1$, 0, and -1, respectively:

$$(-1)^{(n+m)\lambda}q^{-(\ell-n)/2}F^{\ell}(n,0,-1)T^{\ell}_{nm}(\Lambda)$$
$$=q^{-(\ell-m)/2}F^{\ell}(m,0,-1)T^{\ell-1}_{n-1\,m-1}(\lambda)a-(-1)^{\lambda}q^{m/2}G^{\ell}(m,0,0)T^{\ell-1}_{n-1\,m}(\lambda)\alpha$$
$$+q^{(\ell+m)/2}F^{\ell}(-m,0,-1)T^{\ell-1}_{n-1\,m+1}(\lambda)b,$$

$$
\begin{aligned}
&(-1)^{(n+m)(1+\lambda)}q^{n/2}G^{\ell}(n,0,0)T^{\ell}_{nm}(\Lambda)\\
&\quad=-q^{-(\ell-m)/2}F^{\ell}(m,0,-1)T^{\ell-1}_{n\,m-1}(\lambda)\gamma+q^{m/2}G^{\ell}(m,0,0)T^{\ell-1}_{nm}(\lambda)\,e\\
&\quad-q^{(\ell+m)/2}F^{\ell}(-m,0,-1)T^{\ell-1}_{n\,m+1}(\lambda)\beta,
\end{aligned}
$$

$$
\begin{aligned}
&(-1)^{(n+m)(1+\lambda)}q^{(\ell+n)/2}F^{\ell}(-n,0,-1)T^{\ell}_{nm}(\Lambda)\\
&\quad=q^{-(\ell-m)/2}F^{\ell}(m,0,-1)T^{\ell-1}_{n+1\,m-1}(\lambda)c+q^{m/2}G^{\ell}(m,0,0)T^{\ell-1}_{n+1\,m}(\lambda)\delta\\
&\quad+q^{(\ell+m)/2}F^{\ell}(-m,0,-1)T^{\ell-1}_{n+1\,m+1}(\lambda)\beta,
\end{aligned}
\tag{5.10}
$$

where

$$
F^{\ell}(m,a,b)=\sqrt{\{\ell+m+a\}_q\{\ell+m+b\}_q},
$$

$$
G^{\ell}(m,a,b)=\sqrt{\{2\}_q\{\ell+m+a\}_q\{\ell-m+b\}_q},
$$

and the matrix elements for the fundamental representation ($\ell=1$) are denoted as

$$
\begin{pmatrix} a & \alpha & b\\ \gamma & e & \beta\\ c & \delta & d\end{pmatrix}=\begin{pmatrix} T^1_{11}(\lambda) & T^1_{10}(\lambda) & T^1_{1-1}(\lambda)\\ T^1_{01}(\lambda) & T^1_{00}(\lambda) & T^1_{0-1}(\lambda)\\ T^1_{-11}(\lambda) & T^1_{-10}(\lambda) & T^1_{-1-1}(\lambda)\end{pmatrix}.
\tag{5.11}
$$

In this set, the highest weight Λ assumes a constant value of 0 (mod 2).

• The second set corresponds to $\ell=\ell_1$. It also contains three recurrence relations and, in this instance, we have $\Lambda=1$ (mod 2):

$$
\begin{aligned}
&(-1)^{\ell-n+\lambda+(n+m+1)\lambda}q^{(n-m)/2}G^{\ell}(n,0,1)T^{\ell}_{nm}(\Lambda)\\
&\quad=(-1)^{\ell-m}G^{\ell}(m,0,1)T^{\ell}_{n-1\,m-1}(\lambda)a-H^{\ell}_{m}T^{\ell}_{n-1\,m}(\lambda)\alpha+\{2\}^{-1/2}_{q}G^{\ell}(m,1,0)T^{\ell}_{n-1\,m+1}(\lambda)b,
\end{aligned}
$$

$$
\begin{aligned}
&(-1)^{(n+m)(1+\lambda)}q^{(n-m)/2}H^{\ell}_{n}T^{\ell}_{nm}(\Lambda)\\
&\quad=(-1)^{\ell-m}G^{\ell}(m,0,1)T^{\ell}_{n\,m-1}(\lambda)\gamma+H^{\ell}_{m}T^{\ell}_{nm}(\lambda)e+\{2\}^{-1/2}_{q}G^{\ell}(m,1,0)T^{\ell}_{n\,m+1}(\lambda)\beta,
\end{aligned}
$$

$$
\begin{aligned}
&(-1)^{(n+m)\lambda}q^{(n-m)/2}\{2\}^{-1/2}_{q}G^{\ell}(n,0,1)T^{\ell}_{nm}(\Lambda)\\
&\quad=(-1)^{\ell-m}G^{\ell}(m,0,1)T^{\ell}_{n+1\,m-1}(\lambda)c-H^{\ell}_{m}T^{\ell}_{n+1\,m}(\lambda)\delta+\{2\}^{-1/2}_{q}G^{\ell}(m,1,0)T^{\ell}_{n+1\,m+1}(\lambda)d,
\end{aligned}
\tag{5.12}
$$

where

$$
H^{\ell}_{m}=q^{-\ell/2}\{\ell+m+1\}_q-(-1)^{\ell-m}q^{\ell/2}\{\ell-m+1\}_q.
$$

• Similarly, the third set contains three recurrence relations for $\ell=\ell_1-1$. For this case, the highest weight reads $\Lambda=0$ (mod 2), and the recurrence relations are given by

$$
\begin{aligned}
q^{(\ell-m+n+1)/2}F^{\ell}(-n,1,2)T^{\ell}_{nm}(\Lambda)&=q^{(\ell+1)/2}F^{\ell}(-m,1,2)T^{\ell+1}_{n-1\,m-1}(\lambda)a+(-1)^{\ell-m+\lambda}G^{\ell}(m,1,1)T^{\ell+1}_{n-1\,m}(\lambda)\alpha\\
&\quad-q^{-(\ell+1)/2}F^{\ell}(m,1,2)T^{\ell+1}_{n-1\,m}(\lambda)b,
\end{aligned}
$$

$$
\begin{aligned}
(-1)^{\ell-n+\lambda}q^{(n-m)/2}G^{\ell}(n,1,1)T^{\ell}_{nm}(\Lambda)&=q^{(\ell+1)/2}F^{\ell}(-m,1,2)T^{\ell+1}_{n\,m-1}(\lambda)\gamma+(-1)^{\ell-m+\lambda}\\
&\quad\times G^{\ell}(m,1,1)T^{\ell+1}_{nm}(\lambda)\,e-q^{-(\ell+1)/2}F^{\ell}(m,1,2)T^{\ell+1}_{n\,m+1}(\lambda)\beta,
\end{aligned}
$$

$$q^{-(\ell-n+m+1)/2}F^{\ell}(n,1,2)T^{\ell}_{nm}(\Lambda) = -q^{(\ell+1)/2}F^{\ell}(-m,1,2)T^{\ell+1}_{n+1\ m-1}(\lambda)c - (-1)^{\ell-m+\lambda}G^{\ell}(m,1,1)T^{\ell+1}_{n+1\ m}(\lambda)\delta + q^{-(\ell+1)/2}F^{\ell}(m,1,2)T^{\ell+1}_{n+1\ m+1}(\lambda)d. \tag{5.13}$$

The discussion so far is independent of the explicit form of the universal $\mathcal{T}$-matrix. The general properties of the universal $\mathcal{T}$-matrix and the Clebsch-Gordan decomposition of tensor product representations play a seminal role in the derivation of all properties of the representation of $\mathcal{A}$. Thus one can repeat the same arguments for other quantum deformations of $OSp(1/2)$, namely the Jordanian[23] and the super-Jordanian[24,25] analogs for deriving their product law, the orthogonality, and the recurrence relations. Being triangular algebras, the Jordanian and the super-Jordanian deformations of $OSp(1/2)$ possess the same Clebsch-Gordan decomposition as in the present case.

The representations of $SL_q(2)$ [or $SU_q(2)$] have been discussed by many authors. Among the properties of representation matrices, the product law,[26] recurrence relations,[26,27] orthogonality, and *RTT*-relation[27] and generating functions[28] are found in the literature. In Ref. 27, the representation matrices are interpreted as the wave functions of a quantum symmetric top in noncommutative space. Representations of the Jordanian quantum group $SL_{\mathbf{h}}(2)$ have been considered in Refs. 29 and 30.

VI. REPRESENTATION MATRIX AND LITTLE *Q*-JACOBI POLYNOMIALS

Explicit formulae for the representation matrices of the quantum group $SU_q(2)$ have been obtained by several authors.[31–33] It is observed that, for the finite dimensional representations, the matrix elements are expressed in terms of the little q-Jacobi polynomials. Investigating the Jordanian quantum group $SL_{\mathbf{h}}(2)$ in a similar framework, it has also been noted that the conventional Jacobi polynomials contribute[30] to the representation matrices therein. The corresponding matrix elements for the two-parametric quantum group $GL(2)$ have been computed in Ref. 34. Their relation to orthogonal polynomials, however, is still an open problem.

In this section, we provide the explicit form of the representation matrices (5.1) of $\mathcal{A}$ by direct computation, and study the resulting polynomial structure. Toward this end, we proceed by noticing the identities obtained by the repeated use of (2.9):

$$V^{c}_{-}e^{\ell}_{m}(\lambda) = (-1)^{c(\ell-m)+c(c-3)/2}\left(\frac{1}{\{2\}^{c}_{q}}\frac{\{\ell+m\}_q!\{\ell-m+c\}_q!}{\{\ell-m\}_q!\{\ell+m-c\}_q!}\right)^{1/2}e^{\ell}_{m-c}(\lambda),$$

$$V^{a}_{+}e^{\ell}_{m}(\lambda) = \left(\frac{1}{\{2\}^{a}_{q}}\frac{\{\ell-m\}_q!\{\ell+m+a\}_q!}{\{\ell+m\}_q!\{\ell-m-a\}_q!}\right)^{1/2}e^{\ell}_{m+a}(\lambda). \tag{6.1}$$

The explicit listing of the basis elements of $\mathcal{A}$ in (3.17) renders the computation of the matrix elements straightforward. The final result is quoted below:

$$T_{m'm}(\lambda) = (-1)^{(m'-m)(m'-m-1)/2+(m'-m)(-m'+\lambda)}\frac{q^{m(m'-m)/2}}{\sqrt{\{2\}^{m'-m}_{q}}}\left(\frac{\{\ell+m\}_q!}{\{\ell-m\}_q!}\frac{\{\ell+m'\}_q!}{\{\ell-m'\}_q!}\right)^{1/2} \times \sum_{c}(-1)^{c(\ell-m)}\frac{q^{-c(m'-m)/2}}{\{2\}^{c}_{q}}\frac{\{\ell-m+c\}_q!}{\{\ell+m-c\}_q!}\frac{x^{m'-m+c}}{\{m'-m+c\}_q!}\exp\left(\frac{m-c}{2}z\right)\frac{y^{c}}{\{c\}_q!}, \tag{6.2}$$

where the index c runs over all non-negative integers maintaining the argument of $\{\mathcal{X}\}_q$ non-negative.

The fundamental representation $(\ell=1,\lambda=0)$ may be identified with the quantum supermatrix of Ref. 6 in the manner of (5.11). This identification allows us to realize the entries of the quantum supermatrix in terms of the generators of the quantum supergroup $\mathcal{A}$:

$$a = xy + e^{z/2} + \frac{x^2 e^{-z/2} y^2}{\{2\}_q^2}, \quad \alpha = x - \frac{x^2 e^{-z/2} y}{q^{1/2}\{2\}_q}, \quad b = -\frac{x^2 e^{-z/2}}{q\{2\}_q},$$

$$\gamma = y + \frac{q^{1/2} x e^{-z/2} y^2}{\{2\}_q}, \quad e = 1 - x e^{-z/2} y, \quad \beta = -q^{-1/2} x e^{-z/2},$$

$$c = -\frac{q e^{-z/2} y^2}{\{2\}_q}, \quad \delta = q^{1/2} e^{-z/2} y, \quad d = e^{-z/2}. \tag{6.3}$$

A straightforward computation using the commutation relations (3.8) allows us to infer that the realization (6.3) recovers all the commutation relations of the supermatrix listed in Ref. 6. The realization (6.3), more importantly, implies the following Gaussian decomposition of the quantum supermatrix:[14,35,36]

$$\begin{pmatrix} 1 & 0 & 0 \\ -q^{-1/2} x & 1 & 0 \\ -\dfrac{1}{q\{2\}_q} x^2 & x & 1 \end{pmatrix} \begin{pmatrix} e^{-z/2} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & e^{z/2} \end{pmatrix} \begin{pmatrix} 1 & q^{1/2} y & -\dfrac{q}{\{2\}_q} y^2 \\ 0 & 1 & y \\ 0 & 0 & 1 \end{pmatrix}$$
$$= \begin{pmatrix} d & \delta & c \\ \beta & e & \gamma \\ b & \alpha & a \end{pmatrix} = C \begin{pmatrix} a & \alpha & b \\ \gamma & e & \beta \\ c & \delta & d \end{pmatrix} C^{-1}, \tag{6.4}$$

where

$$C = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad C^{-1} = C.$$

We now turn our attention to the polynomial structure built into the general matrix element (6.2) in terms of the variable

$$\zeta = \frac{q^{-1/2}}{\{2\}_q} x e^{-z/2} y. \tag{6.5}$$

To demonstrate this, the product of generators in (6.2) for the case $m' - m \geq 0$ may be rearranged as follows:

$$x^{m'-m+c} \exp\left(\frac{m-c}{2} z\right) y^c = (-1)^{c(c-1)/2} q^{-mc} x^{m'-m} e^{mz/2} (x e^{-z/2} y)^c.$$

The matrix element $T^{\ell}_{m'm}(\lambda)$ may now be succinctly expressed as a polynomial structure given below:

$$T^{\ell}_{m'm}(\lambda) = (-1)^{(m'-m)(m'-m-1)/2 + (m'-m)(\ell-m'+\lambda)} \frac{q^{m(m'-m)/2}}{\{m'-m\}_q ! \sqrt{\{2\}_q^{m'-m}}}$$
$$\times \left(\frac{\{\ell - m\}_q ! \, \{\ell + m'\}_q !}{\{\ell + m\}_q ! \, \{\ell - m'\}_q !} \right)^{1/2} x^{m'-m} e^{mz/2} P^{\ell}_{m'm}(\zeta). \tag{6.6}$$

The polynomial $P^{\ell}_{m'm}(\zeta)$ in the variable ζ is defined by

$$P^{\ell}_{m'm}(\zeta)=\sum_{c}(-1)^{c(\ell-m)+c(c-1)/2}q^{-c(m'+m-1)/2}\frac{\{m'-m\}_q!\,\{l+m\}_q!\,\{\ell-m+c\}_q!}{\{m'-m+c\}_q!\,\{\ell+m-c\}_q!\,\{\ell-m\}_q!\,\{c\}_q!}\zeta^c, \tag{6.7}$$

where the index c runs over all non-negative integers maintaining the arguments of $\{\mathcal{X}\}_q$ non-negative. For the case $m'-m\leq 0$, we make a replacement of the summation index c with $a=m'-m+c$. Rearrangement of the generators now provides the following expression of the general matrix element:

$$T^{\ell}_{m'm}(\lambda)=(-1)^{(m-m')(m-m'+1)/2-(m-m')(\lambda-1)}\frac{q^{-m'(m-m')/2}}{\{m-m'\}_q!\,\sqrt{\{2\}_q^{m-m'}}}\times\left(\frac{\{\ell+m\}_q!\,\{\ell-m'\}_q!}{\{\ell-m\}_q!\,\{\ell+m'\}_q!}\right)^{1/2}e^{m'z/2}y^{m-m'}P^{\ell}_{m'm}(\zeta), \tag{6.8}$$

where the polynomial $P^{\ell}_{m'm}(\zeta)$ for $m'-m\leq 0$ is defined by

$$P^{\ell}_{m'm}(\zeta)=\sum_{a}(-1)^{a(\ell-m')+a(a-1)/2}q^{-a(m'+m-1)/2}\frac{\{m-m'\}_q!\,\{l+m'\}_q!\,\{\ell-m'+a\}_q!}{\{m-m'+a\}_q!\,\{\ell+m'-a\}_q!\,\{\ell-m'\}_q!\,\{a\}_q!}\zeta^a. \tag{6.9}$$

It is immediate to note that the polynomials are symmetric with respect to the transposition $m\leftrightarrow m'$: $P^{\ell}_{mm'}\zeta=P^{\ell}_{m'm}(\zeta)$, and that $P^{\ell}_{-\ell\, m}(\zeta)=P^{\ell}_{m'\,-\ell}(\zeta)=1$.

The polynomials obtained above are related to the basic hypergeometric functions. We define the basic hypergeometric function ${}_2\phi_1$ by[37]

$${}_2\phi_1(a_1,a_2;b;Q;z)=\sum_{n=0}\frac{(a_1;Q)_n(a_2;Q)_n}{(b;Q)_n(Q;Q)_n}z^n, \tag{6.10}$$

where the shifted factorial is defined as usual:

$$(x;Q)_n=\begin{cases}1, & n=0,\\ \displaystyle\prod_{k=0}^{n-1}(1-xQ^k), & n\neq 0.\end{cases} \tag{6.11}$$

The little Q-Jacobi polynomials are defined via ${}_2\phi_1$ as standard theory of orthogonal polynomials[37]

$$p^{(a,b)}_m(z)={}_2\phi_1(Q^{-m},abQ^{m+1};aQ;Q;Qz). \tag{6.12}$$

Setting $a=Q^{\alpha}$, $b=Q^{\beta}$, we have the following form of little Q-Jacobi polynomials:

$$p^{(\alpha,\beta)}_m(z)=\sum_{n}\frac{(Q^{-m};Q)_n(Q^{\alpha+\beta+m+1};Q)_n}{(Q^{\alpha+1};Q)_n(Q;Q)_n}(Qz)^n. \tag{6.13}$$

Rewriting our polynomials (6.7) and (6.9) in terms of the shifted factorial with $Q=-q$, one can identify our polynomials with the little Q-Jacobi polynomials. For the choice $m'-m\geq 0$, the polynomial structure reads

$$P^{\ell}_{m'm}(\zeta)=\sum_{a}\frac{((-q)^{-\ell-m};-q)_a((-q)^{\ell-m+1};-q)_a}{((-q)^{m'-m+1};-q)_a(-q;-q)_a}(-q\zeta)^a=p^{(m'-m,-m'-m)}_{\ell+m}(\zeta), \tag{6.14}$$

and for the $m'-m\leq 0$ case its identification is given by

$$P^{\ell}_{m'm}(\zeta) = \sum_a \frac{((-q)^{-\ell-m'};-q)_a((-q)^{\ell-m'+1};-q)_a}{((-q)^{m-m'+1};-q)_a(-q;-q)_a}(-q\zeta)^a = p^{(m-m',-m'-m)}_{\ell+m'}(\zeta). \tag{6.15}$$

It is amazing that $Q=-q$ polynomials appear for the supergroup $\mathcal{A}$ in contrast to the $Q=q$ polynomials being present for the quantum group $SU_q(2)$.[31–33]

VII. CONCLUDING REMARKS

Starting from the construction of the universal $\mathcal{T}$-matrix, we have investigated the finite dimensional representations of the quantum supergroup $\mathcal{A}$. A qualitative difference between the universal $\mathcal{T}$-matrices for the classical and the quantum $OSp(1/2)$ algebras exists due to the nilpotency of the classical parity odd elements. The absence of the above-mentioned nilpotency in the quantum case induces a new polynomial structure in the matrix elements of $\mathcal{T}$. We observed that these polynomials are expressed in terms of the little Q-Jacobi polynomials. This suggests a new link between orthogonal polynomials and representations of quantum supergroups. It is likely to be a general property that if the Grassmann variables in a classical supergroup lose nilpotency at the quantum level, it may be reflected in the representations of the quantum supergroup so that the entries of representation matrices may have a new quantized polynomial structure. The present work provides an example of this statement. Another likely candidate for the existence of a similar polynomial structure is the super-Jordanian $OSp(1/2)$, where the loss of nilpotency has been observed.[5] We believe that the investigation along this line will give a new algebraic background to basic hypergeometric series.

We have also tried to extend the known properties of the representations for $SL_q(2)$ to the quantum supergroup $\mathcal{A}$. An extension of the product law, the orthogonality and the recurrence relations, was shown to be possible. However, two known results are not extended in the present work, that is, the generating function[28] of the representation matrices and the Peter-Weyl theorem.[7,33] In order to discuss the Peter-Weyl theorem, a Haar measure has to be defined on $\mathcal{A}$. Since the loss of nilpotency makes the superspace on $\mathcal{A}$ more complex than the classical case, studying the Peter-Weyl theorem may be interesting from the viewpoint of harmonic analysis on quantum supergroups. We will discuss these issues elsewhere.

ACKNOWLEDGMENTS

A comment by the referee motivated us in finding the present form of (3.30). We thank him for this. One of us (N.A.) would like to thank R. Jagannathan for his warm hospitality at The Institute of Mathematical Sciences where a part of this work was done. The work of N.A. is partially supported by the grants-in-aid from JSPS, Japan (Contract No. 15540132). APPENDIX: UNIVERSAL $\mathcal{T}$-MATRIX FOR QUANTUM SUPERGROUP

This Appendix is devoted to a general discussion of the universal $\mathcal{T}$-matrix for quantum supergroups. In particular, the relations used in Secs. III and IV are proved in a general setting.

Let $\mathcal{U}$ and $\mathcal{A}$ be dually conjugate unital $\mathbb{Z}_2$ graded Hopf algebras. The basis of the algebras $\mathcal{U}$ and $\mathcal{A}$ are denoted by E_k, e^k, respectively. One may assume that $E_0=1_{\mathcal{U}}$, $e^0=1_{\mathcal{A}}$, and $p(E_k)=p(e^k)$ without loss of generality. The duality of $\mathcal{U}$ and $\mathcal{A}$ is reflected in the structure constants:

$$E_kE_\ell = \sum_m f^m_{k\ell}E_m, \quad \Delta(E_k) = \sum_{pq} g^{pq}_k E_p \otimes E_q, \tag{A1}$$

$$e^ke^\ell = \sum_m g^{k\ell}_m e^m, \quad \Delta(e^k) = \sum_{pq} f^k_{pq} e^p \otimes e^q. \tag{A2}$$

The universal $\mathcal{T}$-matrix is defined by

$$\mathcal{T}_{e,E} = \sum_k (-1)^{p(e^k)(p(e^k)-1)/2} e^k \otimes E_k, \quad \in \mathcal{A} \otimes \mathcal{U}. \tag{A3}$$

Although the factor $(-1)^{p(e^k)(p(e^k)-1)/2}$ is trivial, it is convenient to keep it in the discussion of universal $\mathcal{T}$-matrix.

We start with the proof of the relations in (3.25). The proof of the first relation in (3.25) is straightforward:

$$\begin{aligned}\mathcal{T}_{e,E}\mathcal{T}_{e',E} &= \sum_{k,\ell,m} (-1)^{(p(e^k)+p(e^\ell))(p(e^k)+p(e^\ell)-1)/2} e^k \otimes e^\ell \otimes f_{k\,\ell}^{\,m} E_m \\ &= \sum_m (-1)^{p(e^m)(p(e^m)-1)/2} \Delta(e^m) \otimes E_m = \mathcal{T}_{\Delta(e),E}.\end{aligned}$$

The second equality is due to the fact that the parity of the both sides of the first equation in (A1) are equal, and that the structure constants are of even parity. The second relation in (3.25) can be proved similarly. The third relation in (3.25) follows from $\epsilon(e^k) = \delta_0^k$, $\epsilon(E_k) = \delta_{k0}$. The last relation in (3.25) is a consequence of the identities

$$\mathcal{T}_{e,S(E)}\mathcal{T}_{e,E} = \mathcal{T}_{e,E}\mathcal{T}_{e,S(E)} = 1 \otimes 1, \quad \mathcal{T}_{S(e),E}\mathcal{T}_{e,E} = \mathcal{T}_{e,E}\mathcal{T}_{S(e),E} = 1 \otimes 1. \tag{A4}$$

The above identities can be proved by using the axiom of antipode and $p(S(e^k)) = p(e^k)$..

We next derive the *RTT*-type relations (4.6) and (4.8). Defining

$$\mathcal{T}_{e,E}^{(1)} = \sum_k (-1)^{p(e^k)(p(e^k)-1)/2} e^k \otimes E_k \otimes 1, \quad \mathcal{T}_{e,E}^{(2)} = \sum_k (-1)^{p(e^k)(p(e^k)-1)/2} e^k \otimes 1 \otimes E_k,$$

we obtain

$$\mathcal{T}_{e,E}^{(1)}\mathcal{T}_{e,E}^{(2)} = \sum_m (-1)^{p(e^m)(p(e^m)-1)/2} e^m \otimes \Delta(E_m).$$

On the other hand, the transposed coproduct appears in the reverse-ordered product:

$$\begin{aligned}\mathcal{T}_{e,E}^{(2)}\mathcal{T}_{e,E}^{(1)} = \sum_m (-1)^{p(e^m)(p(e^m)-1)/2} e^m \otimes \Delta'(E_m) &= \sum_m (-1)^{p(e^m)(p(e^m)-1)/2} e^m \otimes \mathcal{R}\Delta(E_m)R^{-1} \\ &= (1 \otimes \mathcal{R})\mathcal{T}_{e,E}^{(1)}\mathcal{T}_{e,E}^{(2)}\,(1 \otimes \mathcal{R}^{-1}).\end{aligned}$$

In the last equality, the fact that the universal $\mathcal{R}$-matrix is of even parity has been used. This completes our proof of the *RTT*-type relation (4.6). The proof of (4.8) may be done similarly with the definitions

$$\mathcal{T}_{E,e}^{(1)} = \sum_k (-1)^{p(e^k)(p(e^k)-1)/2} E_k \otimes 1 \otimes e^k, \quad \mathcal{T}_{E,e}^{(2)} = \sum_k (-1)^{p(e^k)(p(e^k)-1)/2} 1 \otimes E_k \otimes e^k.$$

Note added: After submitting the manuscript, we have learnt about the work of Zou,[38] where the representations of $OSp_q(1/2)$ and their relation to the basic hypergeometric functions are explicitly computed by using other basis states, and adopting a method (similar to Ref. 33) different from ours. The Peter-Weyl theorem has also been established there.

Expanding Lie (super)algebras through Abelian semigroups

Fernando Izaurieta,[a] Eduardo Rodríguez,[b] and Patricio Salgado[c]
Departamento de Física, Universidad de Concepción, Casilla 160-C, Concepción, Chile

(Received 29 May 2006; accepted 11 October 2006; published online 28 December 2006)

We propose an outgrowth of the expansion method introduced by de Azcárraga *et al.* [Nucl. Phys. B **662**, 185 (2003)]. The basic idea consists in considering the direct product between an Abelian semigroup S and a Lie algebra $\mathfrak{g}$. General conditions under which relevant subalgebras can systematically be extracted from $S \times \mathfrak{g}$ are given. We show how, for a particular choice of semigroup S, the known cases of expanded algebras can be reobtained, while new ones arise from different choices. Concrete examples, including the M algebra and a D'Auria-Fré-like superalgebra, are considered. Finally, we find explicit, nontrace invariant tensors for these S-expanded algebras, which are essential ingredients in, e.g., the formulation of supergravity theories in arbitrary space-time dimensions. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2390659]

I. INTRODUCTION

The role played by Lie algebras and their interrelations in physics can hardly be overemphasized. To mention only one example, the Poincaré algebra may be obtained from the Galilei algebra via a *deformation* process. This deformation is one of the ways in which different Lie algebras can be related.

The purpose of this paper is to shed new light on the method of *expansion* of Lie algebras (for a thorough treatment, see the seminal work in Ref. 1 and references therein; early work on the subject is found in Ref. 2). An expansion is, in general, an algebra dimension-changing process. For instance, the M algebra,[3–5] with 583 Bosonic generators, can be regarded as an expansion of the orthosymplectic algebra $\mathfrak{osp}(32|1)$, which possesses only 528. This vantage viewpoint may help better understand fundamental problems related to the geometrical formulation of 11-dimensional supergravity. Some physical applications of the expansion procedure have been developed in Refs. 6–14.

The approach to be presented here is entirely based on operations performed directly on the algebra generators, and thus differs from the outset with the one found in Ref. 1, where the dual Maurer-Cartan formulation is used. As a consequence, the expansion of free differential algebras lies beyond the scope of our analysis.

Finite Abelian semigroups play a prominent role in our construction. All expansion cases found in Ref. 1 may be regarded as coming from one particular choice of semigroup in the present approach, which is, in this sense, more general. Different semigroup choices yield, in general, expanded algebras that cannot be obtained by the methods of Ref. 1.

The plan of the paper goes as follows. After some preliminaries in Sec. II, Sec. III introduces the general procedure of the Abelian semigroup expansion, S-expansion for short, and shows how the cases found in Ref. 1 can be recovered by an appropriate choice of semigroup S. In Sec. IV, general conditions are given under which relevant subalgebras can be extracted from an

S-expanded algebra. The case when $\mathfrak{g}$ satisfies the Weimar-Woods conditions[15,16] and the case when $\mathfrak{g}$ is a superalgebra are studied. Section V gives three explicit examples of *S*-expansions of $\mathfrak{osp}(32|1)$: (i) the M algebra,[3–5] (ii) a D'Auria-Fré-like Superalgebra,[17] and (iii) a new superalgebra, different from but resembling aspects of the M algebra, $\mathfrak{osp}(32|1)\times\mathfrak{osp}(32|1)$, and D'Auria-Fré superalgebras. In Sec. VI, the remaining cases of expanded algebras shown in Ref. 1 are seen to also fit within the current scheme. The five-brane superalgebra[18,19] is given as an example. Section VII deals with the crucial problem of finding invariant tensors for the *S*-expanded algebras. General theorems are proven, allowing for nontrivial invariant tensors to be systematically constructed. We close in Sec. VIII with conclusions and an outlook for future work.

II. PRELIMINARIES

Before analyzing the *S*-expansion procedure itself, it will prove convenient to introduce some basic notation and definitions.

A. Semigroups

Definition 2.1: *Let* $S=\{\lambda_\alpha\}$ *be a finite semigroup,*[1] *and let us write the product of* $\lambda_{\alpha_1},\ldots,\lambda_{\alpha_n}\in S$ *as*

$$\lambda_{\alpha_1}\cdots\lambda_{\alpha_n}=\lambda_{\gamma(\alpha_1,\ldots,\alpha_n)}. \tag{1}$$

The n-selector $K_{\alpha_1\cdots\alpha_n}{}^{\rho}$ *is defined as*

$$K_{\alpha_1\cdots\alpha_n}{}^{\rho}=\begin{cases}1 & \text{when } \rho=\gamma(\alpha_1,\ldots,\alpha_n)\\ 0 & \text{otherwise.}\end{cases} \tag{2}$$

Since S is associative, the n-selector fulfills the identity

$$K_{\alpha_1\cdots\alpha_n}{}^{\rho}=K_{\alpha_1\cdots\alpha_{n-1}}{}^{\sigma}K_{\sigma\alpha_n}{}^{\rho}=K_{\alpha_1\sigma}{}^{\rho}K_{\alpha_2\cdots\alpha_n}{}^{\sigma}. \tag{3}$$

Using this identity it is always possible to express the *n*-selector in terms of two-selectors, which encode the information from the multiplication table of *S*.

An interesting way to state the same is that two-selectors provide a matrix representation for *S*. As a matter of fact, when we write

$$[\lambda_\alpha]_\mu{}^{\nu}=K_{\mu\alpha}{}^{\nu}, \tag{4}$$

then we have

$$[\lambda_\alpha]_\mu{}^{\sigma}[\lambda_\beta]_\sigma{}^{\nu}=K_{\alpha\beta}{}^{\sigma}[\lambda_\sigma]_\mu{}^{\nu}=[\lambda_{\gamma(\alpha,\beta)}]_\mu{}^{\nu}. \tag{5}$$

We will restrict ourselves from now on to *Abelian* semigroups, which implies that the *n*-selectors will be completely symmetrical in their lower indices.

The following definition introduces a product between semigroup subsets which will be extensively used throughout the paper.

Definition 2.2: *Let* S_p *and* S_q *be two subsets of S. The product* $S_p\cdot S_q$ *is defined as*

$$S_p\cdot S_q=\{\lambda_\gamma \text{ such that } \lambda_\gamma=\lambda_{\alpha_p}\lambda_{\alpha_q} \text{ with } \lambda_{\alpha_p}\in S_p \text{ and } \lambda_{\alpha_q}\in S_q\}\subset S. \tag{6}$$

In other words, $S_p\cdot S_q\subset S$ *is the set which results from the product of every element of* S_p *with every element of* S_q*. Since S is Abelian,* $S_p\cdot S_q=S_q\cdot S_p$.

Let us emphasize that, in general, S_p, S_q, and $S_p\cdot S_q$ need *not* be semigroups by themselves.

[1]There does not seem to be a unique, universally accepted definition of semigroup. Here it is taken to be a set provided with a closed associative product. It does not need to have an identity.

The Abelian semigroup S could also be provided with a unique zero element, 0_S. This element is defined as the one for which

$$0_S\lambda_\alpha = \lambda_\alpha 0_S = 0_S, \tag{7}$$

for each $\lambda_\alpha \in S$.

B. Reduced Lie algebras

The following definition introduces the concept of *reduction* of Lie algebras.

Definition 2.3: *Consider a Lie (super)algebra* $\mathfrak{g}$ *of the form* $\mathfrak{g}=V_0\oplus V_1$, *with* $\{\boldsymbol{T}_{a_0}\}$ *being a basis for* V_0 *and* $\{\boldsymbol{T}_{a_1}\}$ *a basis for* V_1. *When* $[V_0,V_1]\subset V_1$, *i.e., when the commutation relations have the general form*

$$[\boldsymbol{T}_{a_0},\boldsymbol{T}_{b_0}] = C_{a_0b_0}{}^{c_0}\boldsymbol{T}_{c_0} + C_{a_0b_0}{}^{c_1}\boldsymbol{T}_{c_1}, \tag{8}$$

$$[\boldsymbol{T}_{a_0},\boldsymbol{T}_{b_1}] = C_{a_0b_1}{}^{c_1}\boldsymbol{T}_{c_1}, \tag{9}$$

$$[\boldsymbol{T}_{a_1},\boldsymbol{T}_{b_1}] = C_{a_1b_1}{}^{c_0}\boldsymbol{T}_{c_0} + C_{a_1b_1}{}^{c_1}\boldsymbol{T}_{c_1}, \tag{10}$$

then it is straightforward to show that the structure constants $C_{a_0b_0}{}^{c_0}$ *satisfy the Jacobi identity by themselves, and therefore* $[\boldsymbol{T}_{a_0},\boldsymbol{T}_{b_0}]=C_{a_0b_0}{}^{c_0}\boldsymbol{T}_{c_0}$ *corresponds by itself to a Lie (super)algebra. This algebra, with structure constants* $C_{a_0b_0}{}^{c_0}$, *is called a* reduced algebra *of* $\mathfrak{g}$ *and symbolized as* $|V_0|$.

The reduced algebra could be regarded in some way as the "inverse" of an algebra extension, but V_1 does not need to be an ideal. Note also that a reduced algebra *does not* correspond to a subalgebra.

III. THE *S*-EXPANSION PROCEDURE

A. *S*-expansion for an arbitrary semigroup *S*

The following theorem embodies one of the main results of the paper, the concept of S-expanded algebras.

Theorem 3.1: *Let* $S=\{\lambda_\alpha\}$ *be an Abelian semigroup with two-selector* $K_{\alpha\beta}{}^{\gamma}$ *and* $\mathfrak{g}$ *a Lie (super)algebra with basis* $\{\boldsymbol{T}_A\}$ *and structure constants* $C_{AB}{}^{C}$. *Denote a basis element of the direct product* $S\times\mathfrak{g}$ *by* $\boldsymbol{T}_{(A,\alpha)}=\lambda_\alpha\boldsymbol{T}_A$ *and consider the induced commutator* $[\boldsymbol{T}_{(A,\alpha)},\boldsymbol{T}_{(B,\beta)}] \equiv\lambda_\alpha\lambda_\beta[\boldsymbol{T}_A,\boldsymbol{T}_B]$. *Then,* $S\times\mathfrak{g}$ *is also a Lie (super)algebra with structure constants*

$$C_{(A,\alpha)(B,\beta)}{}^{(C,\gamma)} = K_{\alpha\beta}{}^{\gamma}C_{AB}{}^{C}. \tag{11}$$

Proof: Starting from the form of the induced commutator and using the multiplication law in Eq. (1) one finds

$$[\boldsymbol{T}_{(A,\alpha)},\boldsymbol{T}_{(B,\beta)}] \equiv \lambda_\alpha\lambda_\beta[\boldsymbol{T}_A,\boldsymbol{T}_B] = C_{AB}{}^{C}\lambda_{\gamma(\alpha,\beta)}\boldsymbol{T}_C = C_{AB}{}^{C}\boldsymbol{T}_{(C,\gamma(\alpha,\beta))}.$$

The definition of the two-selector $K_{\alpha\beta}{}^{\rho}$ [see Eq. (2)],

$$K_{\alpha\beta}{}^{\rho} = \begin{cases} 1 & \text{when } \rho=\gamma(\alpha,\beta) \\ 0 & \text{otherwise,} \end{cases}$$

now allows us to write

$$[\boldsymbol{T}_{(A,\alpha)},\boldsymbol{T}_{(B,\beta)}] = K_{\alpha\beta}{}^{\rho}C_{AB}{}^{C}\boldsymbol{T}_{(C,\rho)}. \tag{12}$$

Therefore, the algebra spanned by $\{\boldsymbol{T}_{(A,\alpha)}\}$ closes and the structure constants read

$$C_{(A,\alpha)(B,\beta)}{}^{(C,\gamma)} = K_{\alpha\beta}{}^{\gamma} C_{AB}{}^{C}. \tag{13}$$

Since S is Abelian, the structure constants $C_{(A,\alpha)(B,\beta)}{}^{(C,\gamma)}$ have the same symmetries as $C_{AB}{}^{C}$, namely,

$$C_{(A,\alpha)(B,\beta)}{}^{(C,\gamma)} = -(-1)^{\mathfrak{q}(A)\mathfrak{q}(B)} C_{(B,\beta)(A,\alpha)}{}^{(C,\gamma)}, \tag{14}$$

and for this reason, $\mathfrak{q}(A,\alpha)=\mathfrak{q}(A)$, where $\mathfrak{q}(A)$ denotes the degree of $\boldsymbol{T}_A$ (1 for Fermi and 0 for Bose).

In order to show that the structure constants $C_{(A,\alpha)(B,\beta)}{}^{(C,\gamma)}$ satisfy the Jacobi identity, it suffices to use the properties of the selectors [see Eq. (3)] and the fact that the structure constants $C_{AB}{}^{C}$ satisfy the Jacobi identity themselves. This concludes the proof. □

The following definition is a natural outcome of Theorem 3.1.

Definition 3.2: *Let S be an Abelian semigroup and $\mathfrak{g}$ a Lie algebra. The Lie algebra $\mathfrak{G}$ defined by $\mathfrak{G}=S\times\mathfrak{g}$ is called the S-expanded algebra of $\mathfrak{g}$.*

When the semigroup has a zero element $0_S \in S$, it plays a somewhat peculiar role in the S-expanded algebra. Let us span S in nonzero elements $\lambda_i, i=0,\ldots,N$, and a zero element $\lambda_{N+1}=0_S$. Then, the two-selector satisfies

$$K_{i,N+1}{}^{j} = K_{N+1,i}{}^{j} = 0, \tag{15}$$

$$K_{i,N+1}{}^{N+1} = K_{N+1,i}{}^{N+1} = 1, \tag{16}$$

$$K_{N+1,N+1}{}^{j} = 0, \tag{17}$$

$$K_{N+1,N+1}{}^{N+1} = 1. \tag{18}$$

Therefore, $\mathfrak{G}=S\times\mathfrak{g}$ can be split as

$$[\boldsymbol{T}_{(A,i)}, \boldsymbol{T}_{(B,j)}] = K_{ij}{}^{k} C_{AB}{}^{C} \boldsymbol{T}_{(C,k)} + K_{ij}{}^{N+1} C_{AB}{}^{C} \boldsymbol{T}_{(C,N+1)}, \tag{19}$$

$$[\boldsymbol{T}_{(A,N+1)}, \boldsymbol{T}_{(B,j)}] = C_{AB}{}^{C} \boldsymbol{T}_{(C,N+1)}, \tag{20}$$

$$[\boldsymbol{T}_{(A,N+1)}, \boldsymbol{T}_{(B,N+1)}] = C_{AB}{}^{C} \boldsymbol{T}_{(C,N+1)}. \tag{21}$$

Comparing Eqs. (19)–(21) with (8)–(10), one sees that the commutation relations

$$[\boldsymbol{T}_{(A,i)}, \boldsymbol{T}_{(B,j)}] = K_{ij}{}^{k} C_{AB}{}^{C} \boldsymbol{T}_{(C,k)} \tag{22}$$

are those of a reduced Lie algebra of $\mathfrak{G}$ (see Definition 3). The reduction procedure in this particular case is equivalent to imposing the condition

$$\boldsymbol{T}_{(A,N+1)} = 0_S \boldsymbol{T}_A = 0. \tag{23}$$

Notice that in this case the reduction Abelianizes large sectors of the algebra; for each i and j satisfying $K_{ij}{}^{N+1}=1$ (i.e., $\lambda_i\lambda_j=\lambda_{N+1}$) we have $[\boldsymbol{T}_{(A,i)}, \boldsymbol{T}_{(B,j)}]=0$.

The above considerations motivate the following definition.

Definition 3: Let *S be an Abelian semigroup with a zero element $0_S \in S$*, and let *$\mathfrak{G}=S\times\mathfrak{g}$ be an S-expanded algebra. The algebra obtained by imposing the condition $0_S\boldsymbol{T}_A=0$ on $\mathfrak{G}$ (or a subalgebra of it) is called* 0_S-reduced algebra of $\mathfrak{G}$ *(or of the subalgebra).*

The algebra in Eq. (22) appears naturally when the semigroup's zero matches the (algebra) field's zero. As we will see in the next section, this is the way Maurer-Cartan form power-series

expanded algebras fit within the present scheme. It is also possible to extract other reduced algebras from $\mathfrak{G}$; as will be analyzed in Sec. VI, the 0_S-reduced algebra turns out to be a particular case of Theorem 6.1.

B. Maurer-Cartan form power-series algebra expansion as an *S*-expansion

The Maurer-Cartan form power-series algebra expansion method is a powerful procedure which can lead, in stark contrast with contraction, deformation, and extension of algebras, to algebras of a dimension higher than the original one. In a nutshell, the idea consists of looking at the algebra $\mathfrak{g}$ as described by the associated Maurer-Cartan forms on the group manifold and, after rescaling some of the group parameters by a factor λ, in expanding the Maurer-Cartan forms as a power series in λ. Finally this series is truncated in a way that assures the closure of the algebra. The subject is thoroughly treated by de Azcárraga and Izquierdo in Ref. 20 and de Azcárraga *et al.* in Ref. 1.

Theorem 1 of Ref. 1 shows that, in the more general case, the expanded Lie algebra has the structure constants

$$C_{(A,i)(B,j)}{}^{(C,k)} = \begin{cases} 0 & \text{when } i+j \neq k \\ C_{AB}{}^{C} & \text{when } i+j=k, \end{cases} \tag{24}$$

where the parameters $i,j,k=0,\ldots,N$ correspond to the order of the expansion and N is the truncation order.

These structure constants can also be obtained within the S-expansion procedure. In order to show this, one must consider the 0_S-reduction of an S-expanded algebra where S corresponds to the semigroup defined below.

Definition 3.4: *Let us define* $S_{\mathrm{E}}^{(N)}$ *as the semigroup of elements*

$$S_{\mathrm{E}}^{(N)} = \{\lambda_\alpha, \alpha = 0, \ldots, N+1\}, \tag{25}$$

provided with the multiplication rule

$$\lambda_\alpha \lambda_\beta = \lambda_{H_{N+1}(\alpha+\beta)}, \tag{26}$$

where H_{N+1} *is defined as the function*

$$H_n(x) = \begin{cases} x & \textit{when } x < n \\ n & \textit{when } x \geqslant n. \end{cases} \tag{27}$$

The two-selectors for $S_{\mathrm{E}}^{(N)}$ *read*

$$K_{\alpha\beta}{}^{\gamma} = \delta^{\gamma}_{H_{N+1}(\alpha+\beta)}, \tag{28}$$

where δ^{ρ}_{σ} *is the Kronecker delta. From Eq. (26), we have that* λ_{N+1} *is the zero element in* $S_{\mathrm{E}}^{(N)}$, *i.e.*, $\lambda_{N+1}=0_S$.

Using Eq. (11), the structure constants for the $S_{\mathrm{E}}^{(N)}$-expanded algebra can be written as

$$C_{(A,\alpha)(B,\beta)}{}^{(C,\gamma)} = \delta^{\gamma}_{H_{N+1}(\alpha+\beta)} C_{AB}{}^{C}, \tag{29}$$

with $\alpha,\beta,\gamma=0,\ldots,N+1$. When the extra condition $\lambda_{N+1}\boldsymbol{T}_A=0$ is imposed, Eq. (29) reduces to

$$C_{(A,i)(B,j)}{}^{(C,k)} = \delta^{k}_{i+j} C_{AB}{}^{C}, \tag{30}$$

which exactly matches the structure constants in Eq. (24).

The above arguments show that the Maurer-Cartan form power-series expansion of an algebra $\mathfrak{g}$, with truncation order N, coincides with the 0_S-reduction of the $S_{\mathrm{E}}^{(N)}$-expanded algebra $\mathfrak{G}^{(\mathrm{E})} = S_E^{(N)} \times \mathfrak{g}$.

This is of course no coincidence. The set of powers of the rescaling parameter λ, together with the truncation at order N, satisfies precisely the multiplication law of $S_{\mathrm{E}}^{(N)}$. As a matter of fact, we have

$$\lambda^{\alpha}\lambda^{\beta}=\lambda^{\alpha+\beta}, \tag{31}$$

and the truncation can be imposed as

$$\lambda^{\alpha}=0 \quad \text{when } \alpha>N. \tag{32}$$

It is for this reason that one must demand ${}_0S\boldsymbol{T}_A=0$ in order to obtain the Maurer-Cartan (MC) expansion as an S_{E}-expansion: in this case the zero of the semigroup is the zero of the field as well.

The S-expansion procedure is valid no matter what the structure of the original Lie algebra $\mathfrak{g}$ is, and in this sense it is very general. However, when something about the structure of $\mathfrak{g}$ is known, a lot more can be done. As an example, in the context of MC expansion, the rescaling and truncation can be performed in several ways depending on the structure of $\mathfrak{g}$, leading to several kinds of expanded algebras. Important examples of this are the generalized İnönü-Wigner contraction, or the M algebra as an expansion of $\mathfrak{osp}(32|1)$ (see Refs. 1 and 21). This is also the case in the context of S expansions. As we will show in the next section, when some information about the structure of $\mathfrak{g}$ is available, it is possible to find subalgebras of $\mathfrak{G}=S\times\mathfrak{g}$ and other kinds of reduced algebras. In this way, all the algebras obtained by the MC expansion procedure can be reobtained. New kinds of S-expanded algebras can also be obtained by considering semigroups different from S_{E}.

IV. *S*-EXPANSION SUBALGEBRAS

An S-expanded algebra has a fairly simple structure. In a way, it reproduces the original algebra $\mathfrak{g}$ in a series of "levels" corresponding to the semigroup elements. Interestingly enough, there are at least two ways of extracting smaller algebras from $S\times\mathfrak{g}$. The first one, described in this section, gives rise to a "resonant subalgebra," while the second, described in Sec. VI, produces reduced algebras (in the sense of Definition 2.3).

A. Resonant subalgebras for an arbitrary semigroup *S*

The general problem of finding subalgebras from an S-expanded algebra is a nontrivial one, which is met and solved (in a particular setting) in this section (see Theorem 4.2 below). In order to provide a solution, one must have some information on the subspace structure of $\mathfrak{g}$. This information is encoded in the following way.

Let $\mathfrak{g}=\bigoplus_{p\in I}V_p$ be a decomposition of $\mathfrak{g}$ in subspaces V_p, where I is a set of indices. For each $p,q\in I$ it is always possible to define $i_{(p,q)}\subset I$ such that

$$[V_p,V_q]\subset\bigoplus_{r\in i_{(p,q)}}V_r. \tag{33}$$

In this way, the subsets $i_{(p,q)}$ store the information on the subspace structure of $\mathfrak{g}$.

As for the Abelian semigroup S, this can always be decomposed as $S=\bigcup_{p\in I}S_p$, where $S_p\subset S$. In principle, this decomposition is completely arbitrary; however, using the product from Definition 2.2, it is sometimes possible to pick up a very particular choice of subset decomposition. This choice is the subject of the following

Definition 4.1: *Let $\mathfrak{g}=\bigoplus_{p\in I}V_p$ be a decomposition of $\mathfrak{g}$ in subspaces, with a structure described by the subsets $i_{(p,q)}$, as in Eq. (33). Let $S=\bigcup_{p\in I}S_p$ be a subset decomposition of the Abelian semigroup S such that*

$$S_p \cdot S_q \subset \bigcap_{r \in i_{(p,q)}} S_r, \tag{34}$$

where the subset product · is the one from Definition 2.2. When such subset decomposition $S = \bigcup_{p \in I} S_p$ *exists, then we say that this decomposition is in resonance with the subspace decomposition of* $\mathfrak{g}$, $\mathfrak{g} = \bigoplus_{p \in I} V_p$.

The resonant subset decomposition is crucial in order to systematically extract subalgebras from the S-expanded algebra $\mathfrak{G} = S \times \mathfrak{g}$, as is proven in the following

Theorem 4.2: *Let* $\mathfrak{g} = \bigoplus_{p \in I} V_p$ *be a subspace decomposition of* $\mathfrak{g}$, *with a structure described by Eq. (33), and let* $S = \bigcup_{p \in I} S_p$ *be a resonant subset decomposition of the Abelian semigroup* S, *with the structure given in Eq. (34). Define the subspaces of* $\mathfrak{G} = S \times \mathfrak{g}$,

$$W_p = S_p \times V_p, \quad p \in I. \tag{35}$$

Then,

$$\mathfrak{G}_R = \bigoplus_{p \in I} W_p \tag{36}$$

is a subalgebra of $\mathfrak{G} = S \times \mathfrak{g}$.

Proof: Using Eqs. (33) and (34), we have

$$[W_p, W_q] \subset (S_p \cdot S_q) \times [V_p, V_q] \subset \bigcap_{s \in i_{(p,q)}} S_s \times \bigoplus_{r \in i_{(p,q)}} V_r \subset \bigoplus_{r \in i_{(p,q)}} \left[\bigcap_{s \in i_{(p,q)}} S_s \right] \times V_r. \tag{37}$$

Now, it is clear that for each $r \in i_{(p,q)}$, one can write

$$\bigcap_{s \in i_{(p,q)}} S_s \subset S_r. \tag{38}$$

Then,

$$[W_p, W_q] \subset \bigoplus_{r \in i_{(p,q)}} S_r \times V_r \tag{39}$$

and we arrive at

$$[W_p, W_q] \subset \bigoplus_{r \in i_{(p,q)}} W_r. \tag{40}$$

Therefore, the algebra closes and $\mathfrak{G}_R = \bigoplus_{p \in I} W_p$ is a subalgebra of $\mathfrak{G}$. ■

Definition 4.3: *The algebra* $\mathfrak{G}_R = \bigoplus_{p \in I} W_p$ *obtained in Theorem 4.2 is called a resonant subalgebra of the S-expanded algebra* $\mathfrak{G} = S \times \mathfrak{g}$.

The choice of the name resonance is due to the formal similarity between Eqs. (33) and (34); Eq. (34) will be also referred to as the "*resonance condition.*"

Theorem 4.2 translates the difficult problem of finding subalgebras from an S-expanded algebra $\mathfrak{G} = S \times \mathfrak{g}$ into that of finding a resonant partition for the semigroup S. As the examples from Sec. V help make clear, solving the resonance condition in Eq. (34) turns out to be an easily tractable problem. Theorem 4.2 can thus be regarded as a useful tool for extracting subalgebras from an S-expanded algebra.

Using Eq. (11) and the resonant subset partition of S it is possible to find an explicit expression for the structure constants of the resonant subalgebra $\mathfrak{G}_R$. Denoting the basis of V_p by $\{\boldsymbol{T}_{a_p}\}$, one can write

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)} = K_{\alpha_p\beta_q}{}^{\gamma_r} C_{a_p b_q}{}^{c_r} \quad \text{with } \alpha_p,\beta_q,\gamma_r \quad \text{such that } \lambda_{\alpha_p} \in S_p, \lambda_{\beta_q} \in S_q, \lambda_{\gamma_r} \in S_r. \tag{41}$$

An interesting fact is that the S-expanded algebra "subspace structure" encoded in $i_{(p,q)}$ is the same as in the original algebra $\mathfrak{g}$, as can be observed from Eq. (40).

Resonant subalgebras play a central role in the current scheme. It is interesting to notice that most of the cases considered in Ref. 1 can be reobtained using the above theorem for $S=S_E$ [recall Eqs. (25) and (26)], as we will see in the next section. All remaining cases can be obtained as a reduction of a resonant subalgebra (see Sec. VI).

B. $S=S_E$ resonant subalgebras and Maurer-Cartan expanded algebras

In this section, some results presented for algebra expansions in Ref. 1 are recovered within the S-expansion approach. To get these algebras one must proceed in a three-step fashion:

1. Perform an S-expansion using the semigroup $S=S_E$.
2. Find a resonant partition for S_E and construct the resonant subalgebra $\mathfrak{G}_R$.
3. Apply a 0_S-reduction (or a more general one, See Sec. VI) to the resonant subalgebra.

Choosing a different semigroup S or omitting the reduction procedure one finds algebras not contained within the MC form power-series expansion of Ref. 1. Such an example is provided in Sec. V C.

1. Case when $\mathfrak{g}=V_0\oplus V_1$, with V_0 being a subalgebra and V_1 a symmetric coset

Let $\mathfrak{g}=V_0\oplus V_1$ be a subspace decomposition of $\mathfrak{g}$, such that

$$[V_0,V_0]\subset V_0, \tag{42}$$

$$[V_0,V_1]\subset V_1, \tag{43}$$

$$[V_1,V_1]\subset V_0. \tag{44}$$

Let $S_E^{(N)}=S_0\cup S_1$, with N arbitrary, be a subset decomposition of S_E, with[2]

$$S_0=\left\{\lambda_{2m} \quad \text{with } m=0,\ldots,\left[\frac{N}{2}\right]\right\}\cup\{\lambda_{N+1}\}, \tag{45}$$

$$S_1=\left\{\lambda_{2m+1} \quad \text{with } m=0,\ldots,\left[\frac{N-1}{2}\right]\right\}\cup\{\lambda_{N+1}\}. \tag{46}$$

This subset decomposition of $S_E^{(N)}$ satisfies the resonance condition in Eq. (34), which in this case explicitly reads

$$S_0\cdot S_0\subset S_0, \tag{47}$$

$$S_0\cdot S_1\subset S_1, \tag{48}$$

$$S_1\cdot S_1\subset S_0. \tag{49}$$

Therefore, according to Theorem 4.2, we have that

[2]Here $[x]$ denotes the integer part of x.

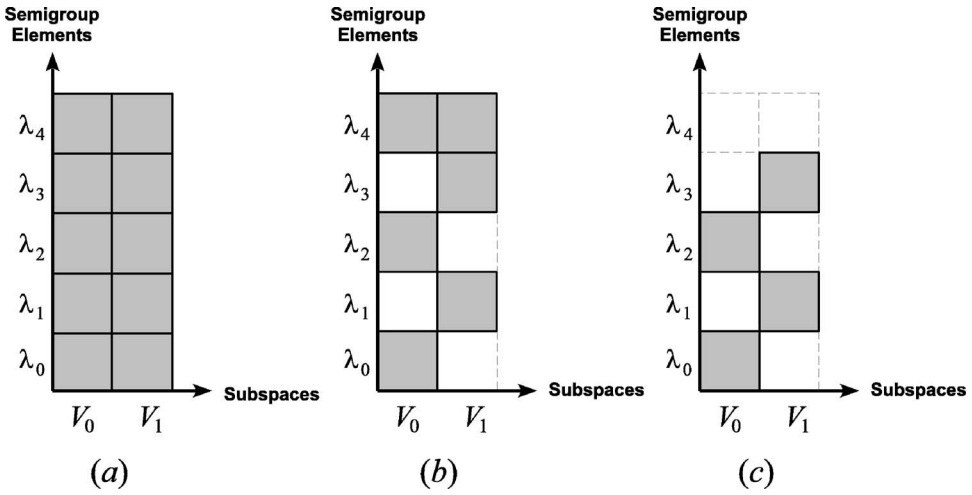

FIG. 1. $S_{\mathrm{E}}^{(3)}$-expansion of an algebra $\mathfrak{g}=V_0\oplus V_1$, where V_0 is a subalgebra and V_1 a symmetric coset. (a) The gray region corresponds to the full $S_{\mathrm{E}}^{(3)}$-expanded algebra, $\mathfrak{G}=S_{\mathrm{E}}^{(3)}\times\mathfrak{g}$. (b) The shaded area here depicts a resonant subalgebra $\mathfrak{G}_{\mathrm{R}}$. (c) The gray region now shows the 0_S-reduction of the resonant subalgebra $\mathfrak{G}_{\mathrm{R}}$.

$$\mathfrak{G}_{\mathrm{R}} = W_0 \oplus W_1, \tag{50}$$

with

$$W_0 = S_0 \times V_0, \tag{51}$$

$$W_1 = S_1 \times V_1, \tag{52}$$

is a resonant subalgebra of $\mathfrak{G}$.

Using Eq. (41), it is straightforward to write the structure constants for the resonant subalgebra,

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)} = \delta^{\gamma_r}_{H_{N+1}(\alpha_p+\beta_q)} C_{a_p b_q}{}^{c_r} \quad \text{with} \quad \begin{cases} p,q=0,1 \\ \alpha_p,\beta_p,\gamma_p = 2m+p, \\ m=0,\ldots,[(N-p)/2],(N+1-p)/2. \end{cases}$$

Imposing $\lambda_{N+1}\boldsymbol{T}_A=0$, the 0_S-reduced structure constants are obtained as

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)} = \delta^{\gamma_r}_{H_{N+1}(\alpha_p+\beta_q)} C_{a_p b_q}{}^{c_r} \quad \text{with} \quad \begin{cases} p,q=0,1 \\ \alpha_p,\beta_p,\gamma_p = 2m+p \\ m=0,\ldots,[(N-p)/2]. \end{cases} \tag{53}$$

In order to compare with the MC expansion, let us observe that, with the notation of Ref. 1, the 0_S-reduction of the S_{E}-expanded algebra corresponds to $\mathcal{G}\ (N_0,N_1)$ for the symmetric coset case, with

$$N_0 = 2\left[\frac{N}{2}\right], \tag{54}$$

$$N_1 = 2\left[\frac{N-1}{2}\right] + 1. \tag{55}$$

The structure constants in Eq. (53) correspond to the structure constants [Eq. (3.31)] from Ref. 1 (the notation is slightly different though).

A more intuitive idea of the whole procedure of S expansion, resonant subalgebra, and 0_S-reduction can be obtained by means of a diagram, such as the one depicted in Fig. 1. This diagram corresponds to the case $\mathfrak{g}=V_0\oplus V_1$, with V_0 a subalgebra and V_1 a symmetric coset, and the choice $S=S_{\mathrm{E}}^{(3)}$.

The subspaces of $\mathfrak{g}$ are represented on the horizontal axis, while the semigroup elements occupy the vertical one. In this way, the whole $S_{\mathrm{E}}^{(3)}$-expanded algebra $S_{\mathrm{E}}^{(3)}\times\mathfrak{g}$ corresponds to the shaded region in Fig. 1(a). In Fig. 1(b), the gray region represents the resonant subalgebra $\mathfrak{G}_{\mathrm{R}}=W_0\oplus W_1$ with

$$S_0=\{\lambda_0,\lambda_2,\lambda_4\}, \tag{56}$$

$$S_1=\{\lambda_1,\lambda_3,\lambda_4\}. \tag{57}$$

Let us observe that each column in the diagram corresponds to a subset of the resonant partition. Finally, Fig. 1(c) represents the 0_S-reduced algebra, obtained after imposing $\lambda_4\times\mathfrak{g}=0$. This figure actually corresponds to the case $\mathcal{G}(N_0,N_1)$.

As is evident from the above discussion, the case $N=1$, $\lambda_{N+1}\boldsymbol{T}_A=0$ reproduces the İnönü-Wigner contraction for $\mathfrak{g}=V_0\oplus V_1$. More on generalized İnönü-Wigner contractions is presented in Sec. VI.

2. Case when $\mathfrak{g}$ fulfills the Weimar-Woods conditions

Let $\mathfrak{g}=\bigoplus_{p=0}^{n}V_p$ be a subspace decomposition of $\mathfrak{g}$. In terms of this decomposition, the Weimar-Woods conditions[15,16] on $\mathfrak{g}$ read

$$[V_p,V_q]\subset\bigoplus_{r=0}^{H_n(p+q)}V_r. \tag{58}$$

Let

$$S_{\mathrm{E}}=\bigcup_{p=0}^{n}S_p \tag{59}$$

be a subset decomposition of S_{E}, where the subsets $S_p\subset S_{\mathrm{E}}$ are defined by

$$S_p=\{\lambda_{\alpha_p}\quad\text{such that }\alpha_p=p,\ldots,N+1\}, \tag{60}$$

with $N+1\geqslant n$.

This subset decomposition is a resonant one under the semigroup product in Eq. (26), because it satisfies [compare Eq. (61) with Eq. (58)]

$$S_p\cdot S_q=S_{H_n(p+q)}\subset\bigcap_{r=0}^{H_n(p+q)}S_r. \tag{61}$$

According to Theorem 4.2, the direct sum

$$\mathfrak{G}_{\mathrm{R}}=\bigoplus_{p=0}^{n}W_p, \tag{62}$$

with

$$W_p=S_p\times V_p,$$

is a resonant subalgebra of $\mathfrak{G}$.

Using Eq. (41), we get the following structure constants for the resonant subalgebra:

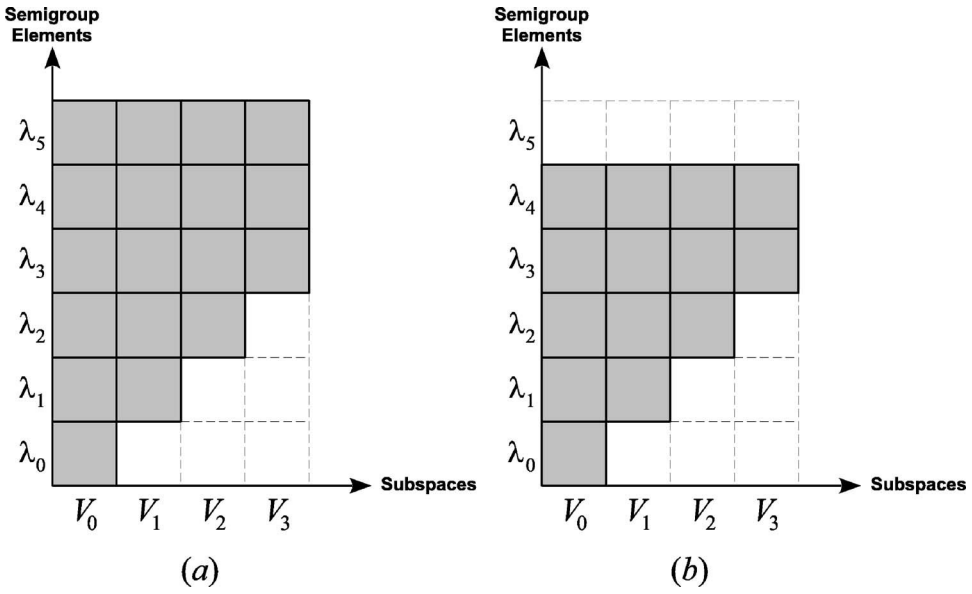

FIG. 2. (a) The shaded region shows a $S_{\mathrm{E}}^{(4)}$ resonant subalgebra when $\mathfrak{g}=V_0\oplus V_1\oplus V_2\oplus V_3$ satisfies the Weimar-Woods conditions. (b) The 0_S-reduction of this resonant subalgebra removes all sectors of the form $0_S\times\mathfrak{g}$. This corresponds to the case $\mathcal{G}(4,4,4,4)$ in the context of Ref. 1.

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)}=\delta^{\gamma_r}_{H_{N+1}(\alpha_p+\beta_q)}C_{a_pb_q}{}^{c_r}\quad\text{with}\quad\begin{cases}p,q,r=0,\ldots,n\\ \alpha_p,\beta_p,\gamma_p=p,\ldots,N+1.\end{cases}$$

Imposing $\lambda_{N+1}\boldsymbol{T}_A=0$, this becomes

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)}=\delta^{\gamma_r}_{H_{N+1}(\alpha_p+\beta_q)}C_{a_pb_q}{}^{c_r}\quad\text{with}\quad\begin{cases}p,q,r=0,\ldots,n\\ \alpha_p,\beta_p,\gamma_p=p,\ldots,N.\end{cases}\tag{63}$$

This 0_S-reduced algebra corresponds to the case $\mathcal{G}(N_0,\ldots,N_n)$ of Theorem 3 from Ref. 1 with $N_p=N$ for every $p=0,\ldots,n$. The structure constants in Eq. (63) correspond to the ones of Eq. (4.8) in Ref. 1 (with a slightly different notation). The more general case,

$$N_{p+1}=\begin{cases}N_p\ \text{or}\\ N_p+1,\end{cases}$$

can be also obtained in the context of an S expansion, but not as a resonant subalgebra (see Sec. VI and the Appendix).

The resonant subalgebra for the Weimar-Woods case with $n=3$, $N=4$ and its 0_S-reduction are shown in Figs. 2(a) and 2(b), respectively.

3. Case when $\mathfrak{g}=V_0\oplus V_1\oplus V_2$ is a superalgebra

A superalgebra $\mathfrak{g}$ comes naturally split into three subspaces V_0, V_1, and V_2, where V_1 corresponds to the Fermionic sector and $V_0\oplus V_2$ to the Bosonic one, with V_0 being a subalgebra. This subspace structure may be written as

$$[V_0,V_0]\subset V_0,\tag{64}$$

$$[V_0,V_1]\subset V_1,\tag{65}$$

$$[V_0,V_2]\subset V_2,\tag{66}$$

$$[V_1, V_1] \subset V_0 \oplus V_2, \tag{67}$$

$$[V_1, V_2] \subset V_1, \tag{68}$$

$$[V_2, V_2] \subset V_0 \oplus V_2. \tag{69}$$

Let $S_{\mathrm{E}}^{(N)} = S_0 \cup S_1 \cup S_2$ be a subset decomposition of $S_{\mathrm{E}}^{(N)}$, where the subsets S_0, S_1, and S_2 are given by the general expression

$$S_p = \left\{ \lambda_{2m+p} \quad \text{with } m = 0, \ldots, \left[\frac{N-p}{2} \right] \right\} \cup \{\lambda_{N+1}\}, \quad p = 0,1,2. \tag{70}$$

This subset decomposition is a resonant one, because it satisfies [compare Eqs. (71)–(76) with Eqs. (64)–(69)]

$$S_0 \cdot S_0 \subset S_0, \tag{71}$$

$$S_0 \cdot S_1 \subset S_1, \tag{72}$$

$$S_0 \cdot S_2 \subset S_2, \tag{73}$$

$$S_1 \cdot S_1 \subset S_0 \cap S_2, \tag{74}$$

$$S_1 \cdot S_2 \subset S_1, \tag{75}$$

$$S_2 \cdot S_2 \subset S_0 \cap S_2. \tag{76}$$

Theorem 4.2 assures us that $\mathfrak{G}_{\mathrm{R}} = W_0 \oplus W_1 \oplus W_2$, with $W_p = S_p \times V_p$, $p = 0,1,2$, is a resonant subalgebra.

Using Eq. (41), it is possible to write down the structure constants for the resonant subalgebra as

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)} = \delta^{\gamma_r}_{H_{N+1}(\alpha_p+\beta_q)} C_{a_p b_q}{}^{c_r} \quad \text{with} \quad \begin{cases} p,q,r = 0,1,2, \\ \alpha_p, \beta_p, \gamma_p = 2m + p, \\ m = 0, \ldots, [(N-p)/2], (N+1-p)/2. \end{cases} \tag{77}$$

Imposing $\lambda_{N+1} \boldsymbol{T}_A = 0$, the structure constants for the 0_S-reduction of the resonant subalgebra are obtained:

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)} = \delta^{\gamma_r}_{H_{N+1}(\alpha_p+\beta_q)} C_{a_p b_q}{}^{c_r} \quad \text{with} \quad \begin{cases} p,q,r = 0,1,2, \\ \alpha_p, \beta_p, \gamma_p = 2m + p, \\ m = 0, \ldots, [(N-p)/2]. \end{cases} \tag{78}$$

This 0_S-reduced algebra corresponds to the algebra $\mathcal{G}(N_0, N_1, N_2)$ with

$$N_p = 2\left[\frac{N-p}{2} \right] + p, \quad p = 0,1,2,$$

found in Theorem 5 of Ref. 1. The structure constants in Eq. (78) match the structure constants in Eq. (5.6) from Ref. 1.

Figure 3(a) shows the resonant subalgebra for the case of superalgebras, and Fig. 3(b) its corresponding 0_S-reduction, for the case $N=4$.

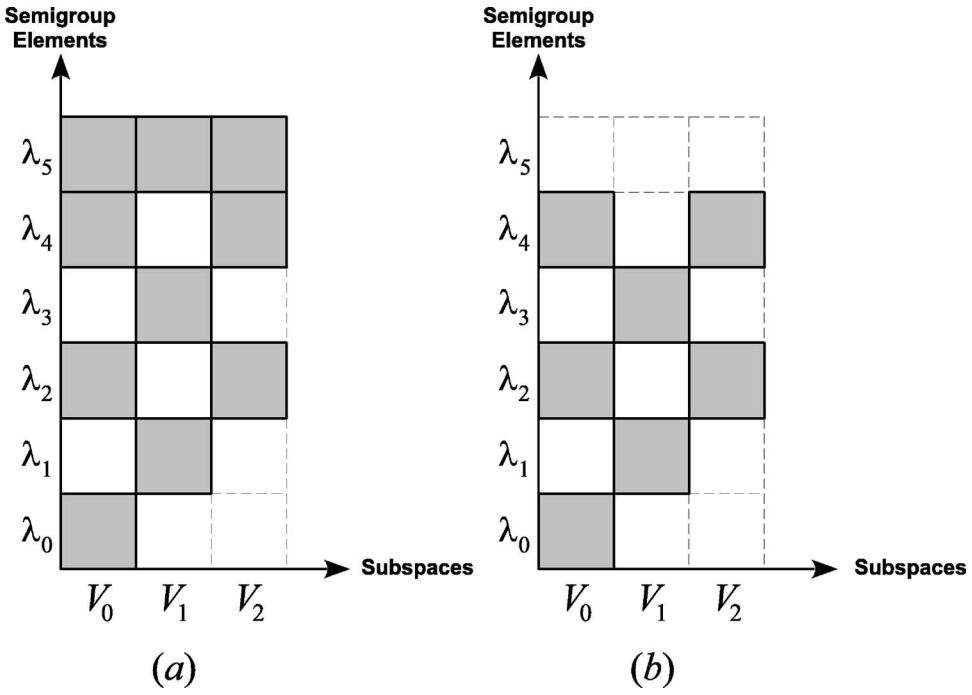

FIG. 3. (a) The shaded area corresponds to an $S_{\mathrm{E}}^{(4)}$ resonant subalgebra of $\mathfrak{G}=S_{\mathrm{E}}^{(4)}\times\mathfrak{g}$ when $\mathfrak{g}$ is a superalgebra. (b) The gray region shows the 0_S-reduction of the resonant subalgebra $\mathfrak{G}_{\mathrm{R}}$. This corresponds to $\mathcal{G}(4,3,4)$ in the context of Ref. 1.

V. *S*-EXPANSIONS OF $\mathfrak{osp}(32|1)$ AND $d=11$ SUPERALGEBRAS

In this section we explore some explicit examples of *S*-expansions. In general, every possible choice of Abelian semigroup *S* and resonant partition will lead to a new $d=11$ superalgebra. Note, however, that the existence of a resonant partition is not at all guaranteed for an arbitrary semigroup *S*.

Since our main physical motivation comes from 11-dimensional supergravity, we shall always take the orthosymplectic superalgebra $\mathfrak{osp}(32|1)$ as a starting point. A suitable basis is provided by $\{\boldsymbol{P}_a,\boldsymbol{J}_{ab},\boldsymbol{Z}_{abcde},\boldsymbol{Q}\}$, where $\{\boldsymbol{P}_a,\boldsymbol{J}_{ab}\}$ are the Anti de Sitter (AdS) generators, $\boldsymbol{Z}_{abcde}$ is a five-index antisymmetric tensor, and $\boldsymbol{Q}$ is a 32-component, Majorana spinor charge. The $\mathfrak{osp}(32|1)$ (anti-)commutation relations explicitly read

$$[\boldsymbol{P}_a,\boldsymbol{P}_b]=\boldsymbol{J}_{ab}, \tag{79}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{P}_c]=\delta^{ab}_{ec}\boldsymbol{P}^e, \tag{80}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{J}_{cd}]=\delta^{abf}_{ecd}\boldsymbol{J}^e{}_f, \tag{81}$$

$$[\boldsymbol{P}_a,\boldsymbol{Z}_{b_1\cdots b_5}]=-\frac{1}{5!}\varepsilon_{ab_1\cdots b_5c_1\cdots c_5}\boldsymbol{Z}^{c_1\cdots c_5}, \tag{82}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{Z}_{c_1\cdots c_5}]=\frac{1}{4!}\delta^{abe_1\cdots e_4}_{dc_1\cdots c_5}\boldsymbol{Z}^d{}_{e_1\cdots e_4}, \tag{83}$$

$$[\boldsymbol{Z}^{a_1\cdots a_5},\boldsymbol{Z}_{b_1\cdots b_5}]=\eta^{[a_1\cdots a_5][c_1\cdots c_5]}\varepsilon_{c_1\cdots c_5b_1\cdots b_5e}\boldsymbol{P}^e+\delta^{a_1\cdots a_5e}_{db_1\cdots b_5}\boldsymbol{J}^d{}_e$$
$$-\frac{1}{3!3!5!}\varepsilon_{c_1\cdots c_{11}}\delta^{a_1\cdots a_5c_4c_5c_6}_{d_1d_2d_3b_1\cdots b_5}\eta^{[c_1c_2c_3][d_1d_2d_3]}\boldsymbol{Z}^{c_7\cdots c_{11}}, \tag{84}$$

$$[\boldsymbol{P}_a,\boldsymbol{Q}]=-\frac{1}{2}\Gamma_a\boldsymbol{Q}, \tag{85}$$

$$[\boldsymbol{J}_{ab},\boldsymbol{Q}]=-\frac{1}{2}\Gamma_{ab}\boldsymbol{Q}, \tag{86}$$

$$[\boldsymbol{Z}_{abcde},\boldsymbol{Q}]=-\frac{1}{2}\Gamma_{abcde}\boldsymbol{Q}, \tag{87}$$

$$\{\boldsymbol{Q}^\rho,\boldsymbol{Q}^\sigma\}=-\frac{1}{2^3}\left[(\Gamma^aC^{-1})^{\rho\sigma}\boldsymbol{P}_a-\frac{1}{2}(\Gamma^{ab}C^{-1})^{\rho\sigma}\boldsymbol{J}_{ab}+\frac{1}{5!}(\Gamma^{abcde}C^{-1})^{\rho\sigma}\boldsymbol{Z}_{abcde}\right], \tag{88}$$

where $C_{\rho\sigma}$ is the charge conjugation matrix and Γ_a are Dirac matrices in 11 dimensions.

As a first step towards the S-expansion, the $\mathfrak{osp}(32|1)$ algebra is written as the direct sum of three subspaces:

$$\mathfrak{osp}(32|1)=V_0\oplus V_1\oplus V_2, \tag{89}$$

where V_0 corresponds to the Lorentz subalgebra (spanned by $\boldsymbol{J}_{ab}$), V_1 to the Fermionic subspace (spanned by $\boldsymbol{Q}$), and V_2 to the translations and the M5-brane piece (spanned by $\boldsymbol{P}_a$ and $\boldsymbol{Z}_{abcde}$). The subspace separation [Eq. (89)] satisfies conditions (64)–(69), as can be easily checked.

The M algebra[3–5] and a superalgebra similar to those of D'Auria-Fré[17] are rederived in the next sections using $S=S_{\mathrm{E}}^{(N)}$ with $N=2$ and $N=3$, respectively. As an example of an S-expansion with $S\neq S_{\mathrm{E}}$, the case $S=\mathbb{Z}_4$ is considered in Sec. V C, where a new superalgebra resembling aspects of the M algebra, $\mathfrak{osp}(32|1)\times\mathfrak{osp}(32|1)$, and D'Auria-Fré superalgebras is found.

The inclusion of the M algebra among the examples draws from two different but related facts. First, the S expansion paradigm casts the M algebra as one from a family of superalgebras, all derived from $\mathfrak{osp}(32|1)$ through different choices for the semigroup and different alternatives of reduction, when present at all. This can be relevant from a physical point of view, since all of them share important features. The second reason deals with the construction of Chern-Simons and transgression Lagrangians. As will be shown in Sec. VII, invariant tensors for resonant subalgebras and 0_S-reduced algebras thereof are readily available, but this is not the case for general reduced algebras. As such, the fact that the M algebra stems from a 0_S-reduction is interesting not only because it provides an invariant tensor derived from $\mathfrak{osp}(32|1)$ but also because it brings about the possibility of considering its direct generalization, namely, the resonant subalgebra from where it was extracted. More on the physical consequences of regarding the M algebra as the 0_S-reduction of a resonant subalgebra is found in Ref. 14.

A. The M algebra

As treated in detail in Refs. 1 and 21, the complete M algebra (i.e., including its Lorentz part) can be obtained by means of a MC expansion of $\mathfrak{osp}(32|1)$. Within the present scheme, the M algebra should be recovered via an S expansion with $S=S_{\mathrm{E}}^{(2)}$ followed by a 0_S-reduction, as explained in Sec. III B.

In order to obtain the M algebra in the context of S-expansions, one has to pick $S_{\mathrm{E}}^{(2)}=\{\lambda_0,\lambda_1,\lambda_2,\lambda_3\}$, use the resonant partition [Eq. (70)], and impose the condition $\lambda_3\boldsymbol{T}_A=0$. This

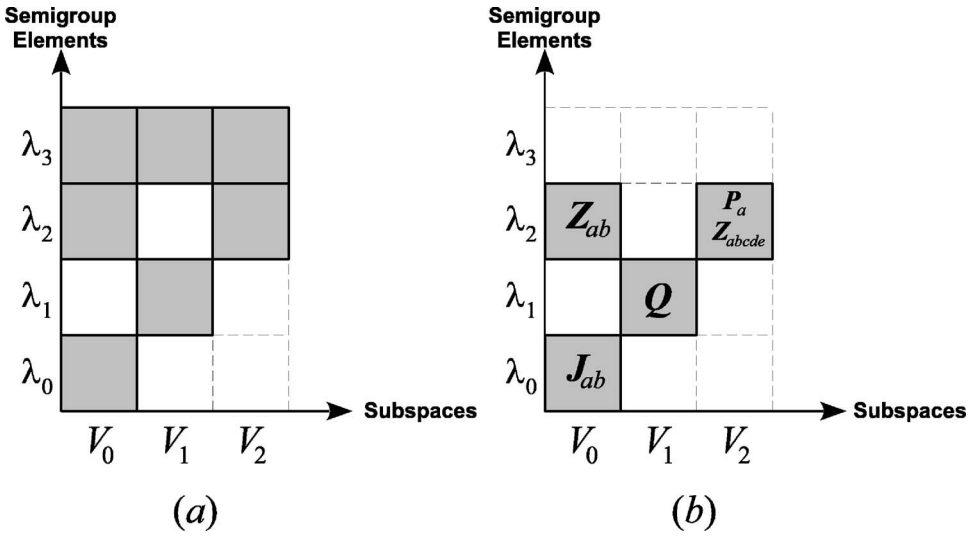

FIG. 4. The M algebra as an $S_E^{(2)}$-expansion of $\mathfrak{osp}(32|1)$. (a) A resonant subalgebra of the $S_E^{(2)}$-expanded algebra $\mathfrak{G}=S_E^{(2)}\times\mathfrak{osp}(32|1)$ is shown in the shaded region. (b) The M algebra itself (gray area) is obtained after 0_S-reducing the resonant subalgebra.

amounts to explicitly writing the structure constants in Eq. (78) for this case. For the sake of simplicity, let us relabel $\boldsymbol{J}_{ab}=\boldsymbol{J}_{(ab,0)}$, $\boldsymbol{Q}_{\alpha}=\boldsymbol{Q}_{(\alpha,1)}$, $\boldsymbol{Z}_{ab}=\boldsymbol{J}_{(ab,2)}$, $\boldsymbol{P}_a=\boldsymbol{P}_{(a,2)}$, $\boldsymbol{Z}_{abcde}=\boldsymbol{Z}_{(abcde,2)}$, as shown in Fig. 4. The resulting algebra reads

$$[\boldsymbol{P}_a,\boldsymbol{P}_b]=0, \tag{90}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{P}_c]=\delta^{ab}_{ec}\boldsymbol{P}^e, \tag{91}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{J}_{cd}]=\delta^{abf}_{ecd}\boldsymbol{J}^e{}_f, \tag{92}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{Z}_{cd}]=\delta^{abf}_{ecd}\boldsymbol{Z}^e{}_f, \tag{93}$$

$$[\boldsymbol{Z}^{ab},\boldsymbol{Z}_{cd}]=0, \tag{94}$$

$$[\boldsymbol{P}_a,\boldsymbol{Z}_{b_1\cdots b_5}]=0, \tag{95}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{Z}_{c_1\cdots c_5}]=\frac{1}{4!}\delta^{abe_1\cdots e_4}_{dc_1\cdots c_5}\boldsymbol{Z}^d{}_{e_1\cdots e_4}, \tag{96}$$

$$[\boldsymbol{Z}^{ab},\boldsymbol{Z}_{c_1\cdots c_5}]=0, \tag{97}$$

$$[\boldsymbol{Z}^{a_1\cdots a_5},\boldsymbol{Z}_{b_1\cdots b_5}]=0, \tag{98}$$

$$[\boldsymbol{P}_a,\boldsymbol{Q}]=0, \tag{99}$$

$$[\boldsymbol{J}_{ab},\boldsymbol{Q}]=-\frac{1}{2}\Gamma_{ab}\boldsymbol{Q}, \tag{100}$$

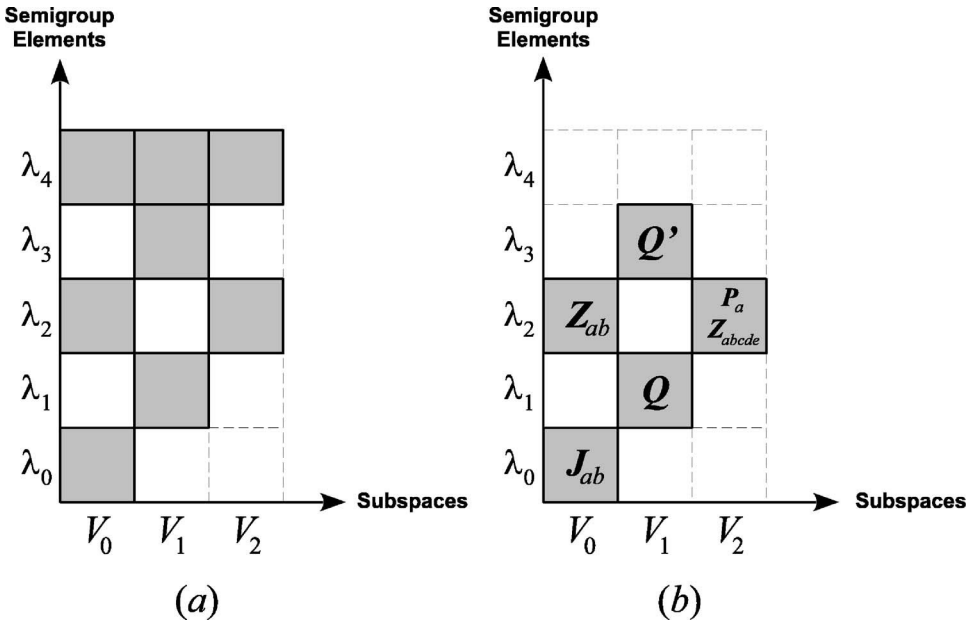

FIG. 5. A D'Auria-Fré-like superalgebra regarded here as an $S_{\mathrm{E}}^{(3)}$-expansion of $\mathfrak{osp}(32|1)$. (a) A resonant subalgebra of the $S_{\mathrm{E}}^{(3)}$-expanded algebra $\mathfrak{G}=S_{\mathrm{E}}^{(3)}\times\mathfrak{osp}(32|1)$ is shown in the shaded region. (b) A superalgebra similar to the ones introduced by D'Auria and Fré in Ref. 17 is obtained after 0_S-reducing the resonant subalgebra.

$$[\boldsymbol{Z}_{ab},\boldsymbol{Q}]=0, \tag{101}$$

$$[\boldsymbol{Z}_{abcde},\boldsymbol{Q}]=0, \tag{102}$$

$$\{\boldsymbol{Q}^{\rho},\boldsymbol{Q}^{\sigma}\}=-\frac{1}{2^3}\left[(\Gamma^{a}C^{-1})^{\rho\sigma}\boldsymbol{P}_a-\frac{1}{2}(\Gamma^{ab}C^{-1})^{\rho\sigma}\boldsymbol{Z}_{ab}+\frac{1}{5!}(\Gamma^{abcde}C^{-1})^{\rho\sigma}\boldsymbol{Z}_{abcde}\right]. \tag{103}$$

Note that the role of the 0_S-reduction in the process is that of Abelianizing large sectors of the resonant subalgebra.

B. D'Auria-Fré-like superalgebra

The above example used $S_{\mathrm{E}}^{(2)}=\{\lambda_0,\lambda_1,\lambda_2,\lambda_3\}$ as Abelian semigroup to perform the expansion. In this section, the results of choosing instead $S_{\mathrm{E}}^{(3)}=\{\lambda_0,\lambda_1,\lambda_2,\lambda_3,\lambda_4\}$ while leaving everything else (including the 0_S-reduction) unchanged are examined.

A D'Auria-Fré-like superalgebra,[17] with one extra Fermionic generator as compared with $\mathfrak{osp}(32|1)$ or the M algebra, is obtained by picking the resonant partition [Eq. (70)] and 0_S-reducing the resulting resonant subalgebra. Relabeling generators as $\boldsymbol{J}_{ab}=\boldsymbol{J}_{(ab,0)}$, $\boldsymbol{Q}_{\alpha}=\boldsymbol{Q}_{(\alpha,1)}$, $\boldsymbol{Z}_{ab}=\boldsymbol{J}_{(ab,2)}$, $\boldsymbol{P}_a=\boldsymbol{P}_{(a,2)}$, $\boldsymbol{Z}_{abcde}=\boldsymbol{Z}_{(abcde,2)}$, $\boldsymbol{Q}'_{\alpha}=\boldsymbol{Q}_{(\alpha,3)}$, one finds the structure depicted in Fig. 5. While this algebra has the same *structure* (i.e., same number and type of generators, with commutators valued on the same subspaces) as the ones introduced by D'Auria and Fré in Ref. 17, the details differ, so it cannot really correspond to any of them (hence the "-like").

The (anti)commutation relations, which can be read off directly from the structure constants in Eq. (78) after applying condition (23), bear a strong similarity with those from the M algebra. Only the following three differ:

$$[\boldsymbol{P}_a,\boldsymbol{Q}]=-\frac{1}{2}\Gamma_a\boldsymbol{Q}', \tag{104}$$

$$[\boldsymbol{Z}_{ab},\boldsymbol{Q}]=-\frac{1}{2}\Gamma_{ab}\boldsymbol{Q}', \tag{105}$$

$$[\boldsymbol{Z}_{abcde},\boldsymbol{Q}]=-\frac{1}{2}\Gamma_{abcde}\boldsymbol{Q}'. \tag{106}$$

The (anti)commutation relations which directly involve the extra Fermionic generator $\boldsymbol{Q}'$ read

$$[\boldsymbol{P}_a,\boldsymbol{Q}']=0, \tag{107}$$

$$[\boldsymbol{Z}_{ab},\boldsymbol{Q}']=0, \tag{108}$$

$$[\boldsymbol{Z}_{abcde},\boldsymbol{Q}']=0, \tag{109}$$

$$\{\boldsymbol{Q},\boldsymbol{Q}'\}=0, \tag{110}$$

$$\{\boldsymbol{Q}',\boldsymbol{Q}'\}=0, \tag{111}$$

$$[\boldsymbol{J}_{ab},\boldsymbol{Q}']=-\frac{1}{2}\Gamma_{ab}\boldsymbol{Q}'. \tag{112}$$

The extra Fermionic generator $\boldsymbol{Q}'$ is found to (anti)commute with all generators from the algebra but the Lorentz generators (which was to be expected due to its spinor character).

C. Resonant subalgebra of $\mathbb{Z}_4\times\mathfrak{osp}(32|1)$

Cyclic groups seem especially suitable for an S expansion, because, on one hand, they are groups and not only semigroups (and therefore there is no 0_S element and no 0_S-reduction), and on the other, because the multiplication law for a cyclic group looks very similar to the multiplication law of the semigroup S_{E},

$$S_{\mathrm{E}}^{(N)}:\lambda_\alpha\lambda_\beta=\lambda_{H_{N+1}(\alpha+\beta)}, \tag{113}$$

$$\mathbb{Z}_N:\lambda_\alpha\lambda_\beta=\lambda_{\mathrm{mod}_N(\alpha+\beta)}. \tag{114}$$

The cyclic group $\mathbb{Z}_4$, in particular, was chosen for this example because the $\mathbb{Z}_2$ case is trivial [the resonant subalgebra is $\mathfrak{osp}(32|1)$ itself] and $\mathbb{Z}_3$ seems to have no resonant partition; therefore $\mathbb{Z}_4$ corresponds to the simplest nontrivial case.

Since this example uses a semigroup different from S_{E}, the algebra obtained does not correspond to a MC form power-series expansion.

Given a superalgebra $\mathfrak{g}=V_0\oplus V_1\oplus V_2$ with the structure of Eqs. (64)–(69), a resonant partition of $\mathbb{Z}_4=\{\lambda_0,\lambda_1,\lambda_2,\lambda_3\}$ is given by

$$S_0=\{\lambda_0,\lambda_2\}, \tag{115}$$

$$S_1=\{\lambda_1,\lambda_3\}, \tag{116}$$

$$S_2=\{\lambda_0,\lambda_2\}. \tag{117}$$

In order to avoid a cluttering of indices, relabel $\boldsymbol{J}_{ab}=\boldsymbol{J}_{(ab,0)}$, $\boldsymbol{Z}'_{a_1\cdots a_5}=\boldsymbol{Z}_{(a_1\cdots a_5,0)}$, $\boldsymbol{P}'_a=\boldsymbol{P}_{(a,0)}$, $\boldsymbol{Q}_\alpha=\boldsymbol{Q}_{(\alpha,1)}$, $\boldsymbol{Z}_{ab}=\boldsymbol{J}_{(ab,2)}$, $\boldsymbol{Z}_{a_1\cdots a_5}=\boldsymbol{Z}_{(a_1\cdots a_5,2)}$, $\boldsymbol{P}_a=\boldsymbol{P}_{(a,2)}$, and $\boldsymbol{Q}'_\alpha=\boldsymbol{Q}_{(\alpha,3)}$, as shown in Fig. 6.

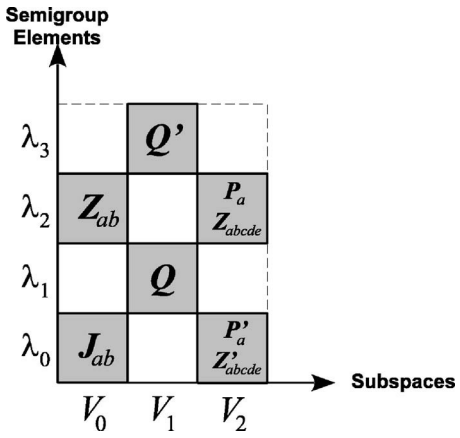

FIG. 6. A new $d=11$ superalgebra, different from but resembling aspects of both the M algebra and the D'Auria-Fré superalgebras, is obtained directly as a resonant subalgebra (shaded region) of the S-expanded Algebra $\mathbb{Z}_4 \times \mathfrak{osp}(32|1)$.

The full resonant subalgebra can be easily obtained using the structure constants in Eq. (41); here we shall only quote some of its more interesting sectors.

This algebra has two very conspicuous features: first, it bears *some* resemblance to the M algebra, for *both* Fermionic generators $\boldsymbol{Q}$ and $\boldsymbol{Q}'$ satisfy

$$\{\boldsymbol{Q}'^{\rho},\boldsymbol{Q}'^{\sigma}\}=\{\boldsymbol{Q}^{\rho},\boldsymbol{Q}^{\sigma}\}=-\frac{1}{2^3}\left[(\Gamma^a C^{-1})^{\rho\sigma}\boldsymbol{P}_a-\frac{1}{2}(\Gamma^{ab}C^{-1})^{\rho\sigma}\boldsymbol{Z}_{ab}+\frac{1}{5!}(\Gamma^{abcde}C^{-1})^{\rho\sigma}\boldsymbol{Z}_{abcde}\right]. \tag{118}$$

Second, the algebra has *two* "AdS-boost generators" for the *same* Lorentz algebra,

$$[\boldsymbol{P}_a,\boldsymbol{P}_b]=\boldsymbol{J}_{ab},\quad [\boldsymbol{P}'_a,\boldsymbol{P}'_b]=\boldsymbol{J}_{ab},$$

$$[\boldsymbol{J}^{ab},\boldsymbol{P}_c]=\delta^{ab}_{ec}\boldsymbol{P}^e,\quad [\boldsymbol{J}^{ab},\boldsymbol{P}'_c]=\delta^{ab}_{ec}\boldsymbol{P}'^e,$$

$$[\boldsymbol{J}^{ab},\boldsymbol{J}_{cd}]=\delta^{abf}_{ecd}\boldsymbol{J}^e{}_f$$

$$[\boldsymbol{P}_a,\boldsymbol{P}'_b]=\boldsymbol{Z}_{ab}. \tag{119}$$

The "charges" $\boldsymbol{Z}_{ab}$, $\boldsymbol{Z}_{a_1\cdots a_5}$, and $\boldsymbol{Z}'_{a_1\cdots a_5}$ are Lorentz tensors, but they are not Abelian,

$$[\boldsymbol{Z}^{ab},\boldsymbol{Z}_{cd}]=\delta^{abf}_{ecd}\boldsymbol{J}^e{}_f, \tag{120}$$

$$[\boldsymbol{Z}^{a_1\cdots a_5},\boldsymbol{Z}_{b_1\cdots b_5}]=[\boldsymbol{Z}'^{a_1\cdots a_5},\boldsymbol{Z}'_{b_1\cdots b_5}]=\eta^{[a_1\cdots a_5][c_1\cdots c_5]}\varepsilon_{c_1\cdots c_5 b_1\cdots b_5 e}\boldsymbol{P}'^e+\delta^{a_1\cdots a_5 e}_{db_1\cdots b_5}\boldsymbol{J}^d{}_e$$
$$-\frac{1}{3!3!5!}\varepsilon_{c_1\cdots c_{11}}\delta^{a_1\cdots a_5 c_4 c_5 c_6}_{d_1 d_2 d_3 b_1\cdots b_5}\eta^{[c_1 c_2 c_3][d_1 d_2 d_3]}\boldsymbol{Z}'^{c_7\cdots c_{11}}. \tag{121}$$

This algebra also presents a behavior similar to that of the D'Auria-Fré superalgebras; namely, the commutators between the generators $\boldsymbol{P}_a,\boldsymbol{Z}_{ab},\boldsymbol{Z}_{a_1\cdots a_5}$ and a Fermionic generator $\boldsymbol{Q}$ are $\boldsymbol{Q}'$ valued; but in contrast to Eqs. (107)–(109), their commutator with $\boldsymbol{Q}'$ is $\boldsymbol{Q}$-valued rather than zero. In this regard, the generators $\boldsymbol{J}_{ab},\boldsymbol{Z}'_{a_1\cdots a_5},\boldsymbol{P}'_a$ have a block-diagonal form on the subspace $(\boldsymbol{Q},\boldsymbol{Q}')$; their commutator with $\boldsymbol{Q}$ is $\boldsymbol{Q}$-valued and the one with $\boldsymbol{Q}'$ is $\boldsymbol{Q}'$-valued.

We have seen several examples showing how, starting from only one original algebra $\mathfrak{g}$ and using different semigroups, different resonant subalgebras can arise (see Theorem 4.2). This is particularly interesting if one considers the strong similarities between the semigroups considered, which nevertheless lead to different resonant structures.

VI. REDUCED ALGEBRAS OF A RESONANT SUBALGEBRA

In previous sections we have seen how information on the subspace structure of the original algebra $\mathfrak{g}$ can be used in order to find resonant subalgebras of the S-expanded algebra $S\times\mathfrak{g}$. In this section we shall examine how this information can be put to use in a different way, namely, by extracting reduced algebras (in the sense of Definition 2.3) from the resonant subalgebra. It is following this path that, e.g., the generalized İnönü-Wigner contraction fits within the present scheme.

The following general theorem provides necessary conditions under which a reduced algebra can be extracted from a resonant subalgebra.

Theorem 6.1: *Let* $\mathfrak{G}_{\mathrm{R}}=\bigoplus_{p\in I}S_p\times V_p$ *be a resonant subalgebra of* $\mathfrak{G}=S\times\mathfrak{g}$, *i.e., let Eqs.* (33) and (34) *be satisfied. Let* $S_p=\hat{S}_p\cup\check{S}_p$ *be a partition of the subsets* $S_p\subset S$ *such that*

$$\hat{S}_p\cap\check{S}_p=\varnothing, \tag{122}$$

$$\check{S}_p\cdot\hat{S}_q\subset\bigcap_{r\in i_{(p,q)}}\hat{S}_r. \tag{123}$$

Conditions (122) *and* (123) *induce the decomposition* $\mathfrak{G}_{\mathrm{R}}=\check{\mathfrak{G}}_{\mathrm{R}}\oplus\hat{\mathfrak{G}}_{\mathrm{R}}$ *on the resonant subalgebra, where*

$$\check{\mathfrak{G}}_{\mathrm{R}}=\bigoplus_{p\in I}\check{S}_p\times V_p, \tag{124}$$

$$\check{\mathfrak{G}}_{\mathrm{R}}=\bigoplus_{p\in I}\hat{S}_p\times V_p. \tag{125}$$

When conditions (122) *and* (123) *hold, then*

$$[\check{\mathfrak{G}}_{\mathrm{R}},\check{\mathfrak{G}}_{\mathrm{R}}]\subset\check{\mathfrak{G}}_{\mathrm{R}}, \tag{126}$$

and therefore $|\check{\mathfrak{G}}_{\mathrm{R}}|$ *corresponds to a reduced algebra of* $\mathfrak{G}_{\mathrm{R}}$.

Proof: *Let* $\check{W}_p=\check{S}_p\times V_p$ and $\hat{W}_p=\hat{S}_p\times V_p$. Then, using condition (123), we have

$$[\check{W}_p,\hat{W}_q]\subset(\check{S}_p\cdot\hat{S}_q)\times[V_p,V_q]\subset\bigcap_{s\in i_{(p,q)}}\hat{S}_s\times\bigoplus_{r\in i_{(p,q)}}V_r\subset\bigoplus_{r\in i_{(p,q)}}\Big[\bigcap_{s\in i_{(p,q)}}\hat{S}_s\Big]\times V_r.$$

For each $r\in i_{(p,q)}$ we have $\bigcap_{s\in i_{(p,q)}}\hat{S}_s\subset\hat{S}_r$, so that

$$[\check{W}_p,\hat{W}_q]\subset\bigoplus_{r\in i_{(p,q)}}\hat{S}_r\times V_r\subset\bigoplus_{r\in i_{(p,q)}}\hat{W}_r.$$

Since $\check{\mathfrak{G}}_{\mathrm{R}}=\bigoplus_{p\in I}\check{W}_p$ and $\hat{\mathfrak{G}}_{\mathrm{R}}=\bigoplus_{p\in I}\hat{W}_p$, we finally find

$$[\check{\mathfrak{G}}_{\mathrm{R}},\check{\mathfrak{G}}_{\mathrm{R}}]\subset\check{\mathfrak{G}}_{\mathrm{R}}$$

and therefore $|\check{\mathfrak{G}}_{\mathrm{R}}|$ is a reduced algebra of $\mathfrak{G}_{\mathrm{R}}$. ■

Using the structure constants in Eq. (41) for the resonant subalgebra, it is possible to find the structure constants for the reduced algebra $|\check{\mathfrak{G}}_{\mathrm{R}}|$,

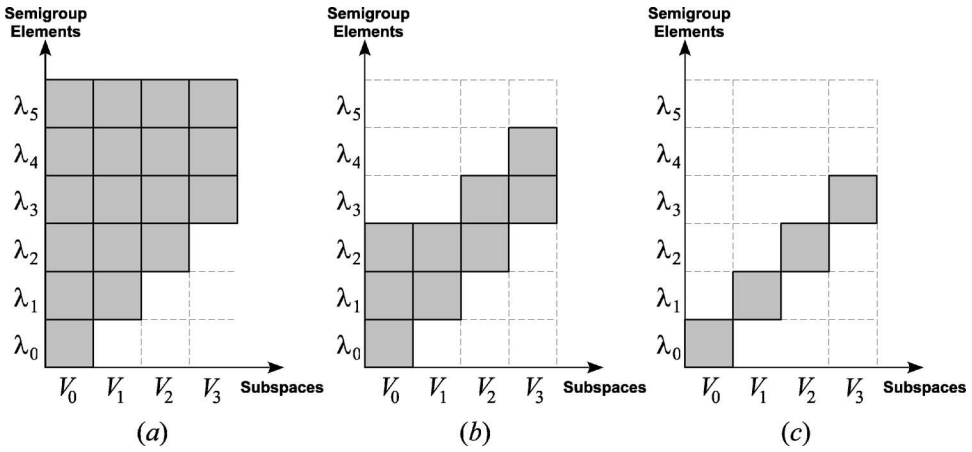

FIG. 7. (a) $S_{\mathrm{E}}^{(4)}$-resonant subalgebra when $\mathfrak{g}=V_0\oplus V_1\oplus V_2\oplus V_3$ satisfies the Weimar-Woods conditions. (b) One possible reduction of the resonant subalgebra from (a), with $N_0=2$, $N_1=2$, $N_2=3$, and $N_3=4$. (c) Generalized İnönü-Wigner contraction corresponding to a different reduction of the same resonant subalgebra, with $N_p=p$, $p=0,1,2,3$.

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}^{\quad(c_r,\gamma_r)}=K_{\alpha_p\beta_q}^{\quad\gamma_r}C_{a_pb_q}^{\quad c_r}\quad\text{with }\alpha_p,\beta_q,\gamma_r\quad\text{such that }\lambda_{\alpha_p}\in\check{S}_p,\lambda_{\beta_q}\in\check{S}_q,\lambda_{\gamma_r}\in\check{S}_r. \tag{127}$$

It might be worth to notice that, when every $S_p\subset S$ of a resonant subalgebra includes the zero element 0_S, the choice $\hat{S}_p=\{0_S\}$ automatically satisfies conditions (122) and (123). As a consequence, the 0_S-reduction introduced in Definition 2.3 can be regarded as a particular case of Theorem 6.1.

A. Reduction of resonant subalgebras, Weimar-Woods conditions, and the İnönü-Wigner contraction

Theorem 6.1 above will be useful in order to recover Theorem 3 from Ref. 1 in this context.

Consider the resonant subalgebra from Sec. IV B 2 and the following S_p partition, which satisfies Eq. (122):

$$\check{S}_p=\{\lambda_{\alpha_p}\text{ such that }\alpha_p=p,\ldots,N_p\}, \tag{128}$$

$$\hat{S}_p=\{\lambda_{\alpha_p}\text{ such that }\alpha_p=N_p+1,\ldots,N+1\}. \tag{129}$$

In the Appendix it is shown that reduction condition Eq. (123) on Eqs. (128) and (129) is equivalent to the following requirement on the N_p's:

$$N_{p+1}=\begin{cases}N_p\text{ or}\\ H_{N+1}(N_p+1).\end{cases} \tag{130}$$

This condition is exactly the one obtained in Theorem 3 of Ref. 1, requiring that the expansion in the MC forms closes. In the S-expansion context the case $N_{p+1}=N_p=N+1$ for each p corresponds to the resonant subalgebra, and the case $N_{p+1}=N_p=N$ to its 0_S-reduction. Figure 7 shows two different reductions for a resonant subalgebra where $\mathfrak{g}$ satisfies the Weimar-Woods conditions.

As stated in Ref. 1, the generalized İnönü-Wigner contraction corresponds to the case $N_p=p$; this means that the generalized İnönü-Wigner contraction *does not* correspond to a resonant subalgebra but to its reduction. This is an important point, because, as we shall see in Sec. VII, we have been able to define nontrace invariant tensors for resonant subalgebras and 0_S-reduced algebras, but not for general reduced algebras.

As an explicit example of the application of Theorem 6.1, the $d=11$ five-brane superalgebra is derived as a reduced algebra in the next section.

B. Five-brane superalgebra as a reduced algebra

Let us recall the resonant subalgebra used in order to get the M algebra in Sec. V A. For this case, the resonant partition $S_{\mathrm{E}}^{(2)}=S_0\cup S_1\cup S_2$ corresponds to the one from Eq. (70) for the case $N=2$, i.e.,

$$S_0=\{\lambda_0,\lambda_2,\lambda_3\}, \tag{131}$$

$$S_1=\{\lambda_1,\lambda_3\}, \tag{132}$$

$$S_2=\{\lambda_2,\lambda_3\}. \tag{133}$$

In order to construct a reduced algebra, perform a partition of the sets S_p themselves, $S_p=\hat{S}_p\cup\check{S}_p$, such as

$$\check{S}_0=\{\lambda_0\},\quad \hat{S}_0=\{\lambda_2,\lambda_3\}, \tag{134}$$

$$\check{S}_1=\{\lambda_1\},\quad \hat{S}_1=\{\lambda_3\}, \tag{135}$$

$$\check{S}_2=\{\lambda_2\},\quad \hat{S}_2=\{\lambda_3\}. \tag{136}$$

It is not hard to see that this partition of S_p satisfies the reduction conditions in Eqs. (122) and (123). For each p, $\hat{S}_p\cap\check{S}_p=\varnothing$, and using the multiplication law in Eq. (26), we have

$$\check{S}_0\cdot\hat{S}_0\subset\hat{S}_0,$$

$$\check{S}_0\cdot\hat{S}_1\subset\hat{S}_1,$$

$$\check{S}_0\cdot\hat{S}_2\subset\hat{S}_2,$$

$$\check{S}_1\cdot\hat{S}_1\subset\hat{S}_0\cap\hat{S}_2,$$

$$\check{S}_1\cdot\hat{S}_2\subset\hat{S}_1,$$

$$\check{S}_2\cdot\hat{S}_2\subset\hat{S}_0\cap\hat{S}_2$$

[compare with Eqs. (71)–(76) and (64)–(69)]. Therefore, we have $\check{\mathfrak{G}}_{\mathrm{R}}=(\check{S}_0\times V_0)\oplus(\check{S}_1\times V_1)\oplus(\check{S}_2\times V_2)$, which is represented in Fig. 8, and the explicit reduced algebra $|\check{\mathfrak{G}}_{\mathrm{R}}|$,

$$[\boldsymbol{P}_a,\boldsymbol{P}_b]=0, \tag{137}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{P}_c]=\delta^{ab}_{ec}\boldsymbol{P}^e, \tag{138}$$

$$[\boldsymbol{J}^{ab},\boldsymbol{J}_{cd}]=\delta^{abf}_{ecd}\boldsymbol{J}^e{}_f, \tag{139}$$

$$[\boldsymbol{P}_a,\boldsymbol{Z}_{b_1\cdots b_5}]=0, \tag{140}$$

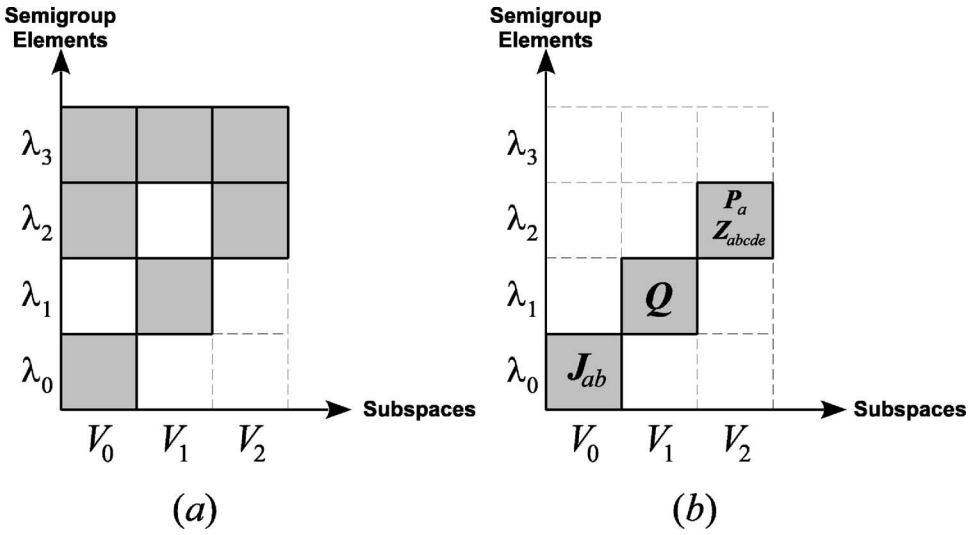

FIG. 8. (a) Resonant subalgebra of the S-expanded Algebra $S_{\mathrm{E}}^{(2)} \times \mathfrak{osp}(32|1)$. (b) One particular reduction of this resonant subalgebra reproduces the five-brane superalgebra.

$$[\boldsymbol{J}^{ab}, \boldsymbol{Z}_{c_1 \cdots c_5}] = \frac{1}{4!} \delta^{abe_1 \cdots e_4}_{dc_1 \cdots c_5} \boldsymbol{Z}^{d}{}_{e_1 \cdots e_4}, \tag{141}$$

$$[\boldsymbol{Z}^{a_1 \cdots a_5}, \boldsymbol{Z}_{b_1 \cdots b_5}] = 0, \tag{142}$$

$$[\boldsymbol{P}_a, \boldsymbol{Q}] = 0, \tag{143}$$

$$[\boldsymbol{J}_{ab}, \boldsymbol{Q}] = -\frac{1}{2} \Gamma_{ab} \boldsymbol{Q}, \tag{144}$$

$$[\boldsymbol{Z}_{abcde}, \boldsymbol{Q}] = 0,$$

$$\{\boldsymbol{Q}^{\rho}, \boldsymbol{Q}^{\sigma}\} = -\frac{1}{2^3} \left[(\Gamma^{a} C^{-1})^{\rho\sigma} \boldsymbol{P}_a + \frac{1}{5!} (\Gamma^{abcde} C^{-1})^{\rho\sigma} \boldsymbol{Z}_{abcde} \right]. \tag{145}$$

This is the five-brane superalgebra.[18,19]

VII. INVARIANT TENSORS FOR *S*-EXPANDED ALGEBRAS

Finding all invariant tensors for an arbitrary algebra remains as an open problem until now. This is not only an important mathematical problem but also a physical one, because an invariant tensor is a key ingredient in the construction of Chern-Simons and transgression forms (see, e.g., Refs. 22–31), which can be used as gauge Lagrangians for a given symmetry group in an arbitrary odd dimension. The choice of invariant tensor shapes the theory to a great extent.

A standard procedure in order to obtain an invariant tensor is to use the (super)trace in some matrix representation of the generators of the algebra. However, this procedure has an important limitation for 0_S-reduced algebras and, for this reason, theorems providing nontrivial invariant tensors for S-expanded algebras are worth considering.

Theorem 7.1: *Let S be an Abelian semigroup, $\mathfrak{g}$ a Lie (super)algebra of basis $\{\mathbf{T}_A\}$, and let $\langle \boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_n} \rangle$ be an invariant tensor for $\mathfrak{g}$. Then, the expression*

$$\langle \boldsymbol{T}_{(A_1,\alpha_1)} \cdots \boldsymbol{T}_{(A_n,\alpha_n)} \rangle = \alpha_\gamma K_{\alpha_1 \cdots \alpha_n}{}^{\gamma} \langle \boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_n} \rangle, \tag{146}$$

where α_γ are arbitrary constants and $K_{\alpha_1 \cdots \alpha_n}{}^{\gamma}$ is the n-selector for S, corresponds to an invariant tensor for the S-expanded algebra $\mathfrak{G}=S\times\mathfrak{g}$.

Proof: The invariance condition for $\langle \boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_n} \rangle$ under $\mathfrak{g}$ reads

$$\sum_{p=1}^{n} X^{(p)}_{A_0 \cdots A_n} = 0, \tag{147}$$

where

$$X^{(p)}_{A_0 \cdots A_n} = (-1)^{\mathfrak{q}(A_0)(\mathfrak{q}(A_1)+\cdots+\mathfrak{q}(A_{p-1}))} C_{A_0 A_p}{}^{B} \langle \boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_{p-1}} \boldsymbol{T}_B \boldsymbol{T}_{A_{p+1}} \cdots \boldsymbol{T}_{A_n} \rangle. \tag{148}$$

Define now

$$X^{(p)}_{(A_0,\alpha_0)\cdots(A_n,\alpha_n)} = (-1)^{\mathfrak{q}(A_0,\alpha_0)(\mathfrak{q}(A_1,\alpha_1)+\cdots+\mathfrak{q}(A_{p-1},\alpha_{p-1}))} C_{(A_0,\alpha_0)(A_p,\alpha_p)}{}^{(B,\beta)} \times \langle \boldsymbol{T}_{(A_1,\alpha_1)} \cdots \boldsymbol{T}_{(A_{p-1},\alpha_{p-1})} \boldsymbol{T}_{(B,\beta)} \boldsymbol{T}_{(A_{p+1},\alpha_{p+1})} \cdots \boldsymbol{T}_{(A_n,\alpha_n)} \rangle.$$

Using the fact that $\mathfrak{q}(A,\alpha)=\mathfrak{q}(A)$ and replacing expressions (11) for the S-expansion structure constants and (146) for $\langle \boldsymbol{T}_{(A_1,\alpha_1)} \cdots \boldsymbol{T}_{(A_n,\alpha_n)} \rangle$, we get

$$X^{(p)}_{(A_0,\alpha_0)\cdots(A_n,\alpha_n)} = \alpha_\gamma K_{\alpha_0 \cdots \alpha_n}{}^{\gamma} X^{(p)}_{A_0 \cdots A_n}.$$

From Eq. (147) one readily concludes that

$$\sum_{p=1}^{n} X^{(p)}_{(A_0,\alpha_0)\cdots(A_n,\alpha_n)} = 0. \tag{149}$$

Therefore, $\langle \boldsymbol{T}_{(A_1,\alpha_1)} \cdots \boldsymbol{T}_{(A_n,\alpha_n)} \rangle = \alpha_\gamma K_{\alpha_1 \cdots \alpha_n}{}^{\gamma} \langle \boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_n} \rangle$ is an invariant tensor for $\mathfrak{G}=S\times\mathfrak{g}$. ■

It is worth to notice that, in general, the expression

$$\langle \boldsymbol{T}_{(A_1,\alpha_1)} \cdots \boldsymbol{T}_{(A_n,\alpha_n)} \rangle = \sum_{m=0}^{M} \alpha_\gamma^{\beta_1 \cdots \beta_m} K_{\beta_1 \cdots \beta_m \alpha_1 \cdots \alpha_n}{}^{\gamma} \langle \boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_n} \rangle, \tag{150}$$

where M is the number of elements of S and $\alpha_\gamma^{\beta_1 \cdots \beta_m}$ are arbitrary constants, is also an invariant tensor for $\mathfrak{G}=S\times\mathfrak{g}$. An example of Eq. (150) is provided by the supertrace. As a matter of fact, when the generators $\boldsymbol{T}_A$ are in some matrix representation, and the generators $\boldsymbol{T}_{(A,\alpha)}$ in the matrix representation $\boldsymbol{T}_{(A,\alpha)}=[\lambda_\alpha]_\mu{}^{\nu} \boldsymbol{T}_A$, with $[\lambda_\alpha]_\mu{}^{\nu}$ given in Eq. (4), we have

$$\mathrm{STr}(\boldsymbol{T}_{(A_1,\alpha_1)} \cdots \boldsymbol{T}_{(A_n,\alpha_n)}) = K_{\gamma\alpha_1 \cdots \alpha_n}{}^{\gamma} \,\mathrm{Str}(\boldsymbol{T}_{A_1} \cdots \boldsymbol{T}_{A_n}), \tag{151}$$

where STr is the (super)trace for the $\boldsymbol{T}_{(A,\alpha)}$ generators and STr the one for the $\boldsymbol{T}_A$ generators.

Even though expression (150) could be regarded as more general than Eq. (146), this is not the case. Using only the associativity and closure of the semigroup product, it is always possible to reduce Eq. (150) to Eq. (146), which in this way turns out to be more "fundamental."

Given an invariant tensor for an algebra, its components valued on a subalgebra are by themselves an invariant tensor for the subalgebra (if they do not vanish). For the case of resonant subalgebras, and provided all the α_γ's are different from zero, the invariant tensor for the resonant subalgebra never vanishes. As matter of fact, given a resonant subset partition $S=\cup_{p\in I} S_p$ and denoting the basis of V_p as $\{\boldsymbol{T}_{a_p}\}$, the $\mathfrak{G}_R$-valued components of Eq. (146) are given by

$$\langle \boldsymbol{T}_{(a_{p_1},\alpha_{p_1})} \cdots \boldsymbol{T}_{(a_{p_n},\alpha_{p_n})} \rangle = \alpha_\gamma K_{\alpha_{p_1} \cdots \alpha_{p_n}}{}^{\gamma} \langle \boldsymbol{T}_{a_{p_1}} \cdots \boldsymbol{T}_{a_{p_n}} \rangle \quad \text{with } \lambda_{\alpha_p} S_p. \tag{152}$$

These components form an invariant tensor for the resonant subalgebra $\mathfrak{G}_R=\bigoplus_{p\in I}S_p\times V_p$. Since S is closed under the product in Eq. (1), for every choice of $\alpha_{p_1},\ldots,\alpha_{p_n}$ there always exists a value of γ such that $K_{\alpha_{p_1}\cdots\alpha_{p_n}}{}^{\gamma}=1$, and therefore Eq. (152) does not vanish (provided that $\forall\,\gamma,\alpha_\gamma\neq 0$).

However, an interesting nontrivial point is that a 0_S-reduced algebra is *not* a subalgebra, and therefore, in general the 0_S-reduced algebra-valued components of expression (146) or (152) *do not* lead to an invariant tensor. The following theorem offers a solution by providing a general expression for an invariant tensor for a 0_S-reduced algebra.

Theorem 7.2: *Let S be an Abelian semigroup with nonzero elements λ_i, $i=0,\ldots,N$, and $\lambda_{N+1}=0_S$. Let $\mathfrak{g}$ be a Lie (super)algebra of basis $\{\boldsymbol{T}_A\}$, and let $\langle \boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{A_n}\rangle$ be an invariant tensor for $\mathfrak{g}$. The expression*

$$\langle \boldsymbol{T}_{(A_1,i_1)}\cdots\boldsymbol{T}_{(A_n,i_n)}\rangle=\alpha_j K_{i_1\cdots i_n}{}^{j}\langle \boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{A_n}\rangle, \tag{153}$$

where α_j are arbitrary constants, corresponds to an invariant tensor for the 0_S-reduced algebra obtained from $\mathfrak{G}=S\times\mathfrak{g}$.

Proof: This theorem is actually a corollary of Theorem 7.1; imposing $\alpha_{N+1}=0$ in Theorem 7.1 and writing the $i_0\cdots i_n$ components of Eq. (149) one gets

$$\sum_{p=1}^{n} X^{(p)}_{(A_0,i_0)\cdots(A_n,i_n)}=0. \tag{154}$$

Using the expressions for the S-expansion structure constants in Eq. (11) and for the invariant tensor in Eq. (153), one finds

$$\begin{aligned}X^{(p)}_{(A_0,i_0)\cdots(A_n,i_n)}=&(-1)^{\mathrm{q}(A_0,i_0)(\mathrm{q}(A_1,i_1)+\cdots+\mathrm{q}(A_{p-1},i_{p-1}))}\\&\times\big(K_{i_0i_p}{}^{k}C_{A_0A_p}{}^{B}\alpha_j K_{i_1\cdots i_{p-1}ki_{p+1}\cdots i_n}{}^{j}\langle \boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{p-1}\boldsymbol{T}_B\boldsymbol{T}_{p+1}\cdots\boldsymbol{T}_{A_n}\rangle\\&+K_{i_0i_p}{}^{N+1}C_{A_0A_p}{}^{B}\alpha_j K_{i_1\cdots i_{p-1}(N+1)i_{p+1}\cdots i_n}{}^{j}\langle \boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{p-1}\boldsymbol{T}_B\boldsymbol{T}_{p+1}\cdots\boldsymbol{T}_{A_n}\rangle\big).\end{aligned}$$

Since

$$\lambda_{i_1}\cdots\lambda_{i_{p-1}}\lambda_{N+1}\lambda_{i_{p+1}}\cdots\lambda_{i_n}=\lambda_{N+1},$$

we have

$$K_{i_1\cdots i_{p-1}(N+1)i_{p+1}\cdots i_n}{}^{j}=0,$$

and then,

$$\begin{aligned}X^{(p)}_{(A_0,i_0)\cdots(A_n,i_n)}=&(-1)^{\mathrm{q}(A_0,i_0)(\mathrm{q}(A_1,i_1)+\cdots+\mathrm{q}(A_{p-1},i_{p-1}))}\\&\times K_{i_0i_p}{}^{k}C_{A_0A_p}{}^{B}\alpha_j K_{i_1\cdots i_{p-1}ki_{p+1}\cdots i_n}{}^{j}\langle \boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{p-1}\boldsymbol{T}_B\boldsymbol{T}_{p+1}\cdots\boldsymbol{T}_{A_n}\rangle.\end{aligned}$$

But $K_{ij}{}^{k}C_{AB}{}^{C}$ are the structure constants [see Eq. (22)] of the 0_S-reduced algebra of $S\times\mathfrak{g}$, and therefore, from Eq. (154) we find that Eq. (153) provides an invariant tensor for it. ■

For the 0_S-reduction of a resonant subalgebra, the proof is analogous to the one given above, and we have that

$$\langle \boldsymbol{T}_{(a_{p_1},i_{p_1})}\cdots\boldsymbol{T}_{(a_{p_n},i_n)}\rangle=\alpha_j K_{i_{p_1}\cdots i_{p_n}}{}^{j}\langle \boldsymbol{T}_{i_{p_1}}\cdots\boldsymbol{T}_{i_{p_n}}\rangle\quad\text{such that }\lambda_{i_p}\in S_p \tag{155}$$

is an invariant tensor for the 0_S-reduced algebra of $\mathfrak{G}_R=\Sigma_{p\in I}S_p\times V_p$.

The usefulness of this theorem comes from the fact that, in general, the (super)trace in the adjoint representation for 0_S-reduced algebras can give only a very small number of components of Eq. (153).

As a matter of fact, using the adjoint representation given by the 0_S-reduced structure constants in Eq. (22), one finds

$$\mathrm{STr}(\boldsymbol{T}_{(A_1,i_1)}\cdots\boldsymbol{T}_{(A_n,i_n)}) = K_{j_1 i_1}{}^{j_2} K_{j_2 i_2}{}^{j_3}\cdots K_{j_{n-1} i_{n-1}}{}^{j_n} K_{j_n i_n}{}^{j_1}\,\mathrm{Str}(\boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{A_n}), \tag{156}$$

and since $\lambda_i\lambda_j=\lambda_{k(i,j)}$ implies that $\lambda_i,\lambda_j\neq 0_S$, one ends up with

$$\mathrm{STr}(\boldsymbol{T}_{(A_1,i_1)}\cdots\boldsymbol{T}_{(A_n,i_n)}) = K_{j_1 i_1\cdots i_n}{}^{j_1}\,\mathrm{Str}(\boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{A_n}). \tag{157}$$

In general, this expression has less components than Eq. (153). In order to see this, it is useful to analyze the case when there is also an identity element in the semigroup, $\lambda_0=e$, and each λ_i appears only once in each row and each column of the semigroup's multiplication table (i.e., for each $\lambda_i,\lambda_j\neq e$, we have $\lambda_i\lambda_j\neq\lambda_i$ and $\lambda_i\lambda_j\neq\lambda_j$). In this case, $K_{j_1 i_1\cdots i_n}{}^{j_1}=K_{i_1\cdots i_n}{}^{0}$, and the only nonvanishing component of the (super)trace is

$$\mathrm{STr}(\boldsymbol{T}_{(A_1,i_1)}\cdots\boldsymbol{T}_{(A_n,i_n)}) = K_{i_1\cdots i_n}{}^{0}\,\mathrm{Str}(\boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{A_n}), \tag{158}$$

which is clearly smaller than Eq. (153). In the expansion case $S=S_{\mathrm{E}}$, we have $K_{i_1\cdots i_n}{}^{0}=\delta^{0}_{H_{N+1}(i_1+\cdots+i_n)}=\delta^{0}_{i_1+\cdots+i_n}$ and therefore, the only nonvanishing component of the (super)trace is

$$\mathrm{STr}(\boldsymbol{T}_{(A_1,0)}\cdots\boldsymbol{T}_{(A_n,0)}) = \mathrm{Str}(\boldsymbol{T}_{A_1}\cdots\boldsymbol{T}_{A_n}). \tag{159}$$

The advantage of the invariant tensor in Eq. (153) as opposed to the (super)trace is now clear; in the case $S_{\mathrm{E}}\times\mathfrak{g}$, the (super)trace only gives a trivial repetition of the invariant tensor of $\mathfrak{g}$, and for a resonant subalgebra, just a piece of it.

One last remark on the invariant tensor in Eq. (153) is that for the particular case $S=S_{\mathrm{E}}$, since $K_{i_1\cdots i_n}{}^{j}=\delta^{j}_{H_{N+1}(i_1+\cdots+i_n)}=\delta^{j}_{i_1+\cdots+i_n}$, a topological density or a Chern-Simons form constructed using the invariant tensor in Eq. (153) coincides with the one from Ref. 1 for the choice $\alpha_\gamma=\lambda^\gamma$, where λ^γ stands for a power of the expansion parameter of the free differential algebra.

VIII. CONCLUSIONS

We have discussed how one can obtain a bunch of Lie algebras starting from an original one by choosing an Abelian semigroup and applying the general theorems 4.2 and 6.1, which give us "resonant subalgebras" and what has been dubbed "reduced algebras." This procedure is a natural outgrowth of the method of MC form power-series expansion presented in Ref. 1, from the point of view of the Lie algebra generators and using an arbitrary Abelian semigroup. The S expansion presented here has the feature of being very simple and direct; given a semigroup, one needs only solve the resonance condition [Eq. (34)] in order to get a resonant subalgebra, and the very similar reduction conditions [Eqs. (122) and (123)] in order to get a reduced one. These have been solved in several examples in order to show how both theorems work, for general algebra structures as well as for very explicit cases, e.g., $d=11$ superalgebras. As expected, the S-expansion scheme reproduces exactly the results of the MC form power-series expansion for a particular choice of semigroup, but it is also possible to get interesting new results using other alternatives, as shown in Sec. V C.

The examples of the S-expansion procedure have been chosen according to their relevance for the long-term goal of understanding the geometric formulation of 11-dimensional supergravity. To be able to write a Lagrangian invariant under these symmetries, a key ingredient is an invariant tensor. The theorems given in Sec. VII help fill the gap, since they go a long way beyond the simple, and sometimes trivial, invariant tensors obtained from the supertrace. Chern-Simons and Transgression forms appear as a straightforward choice for the construction of a supergravity Lagrangian in this context.[22–31] In this sense, Theorems 4.2, 6.1, 7.1, and 7.2 provide a very practical "physicist's toolbox." These have been used to construct a Lagrangian for the M algebra in 11 dimensions[14] following the techniques developed in Refs. 28 and 31.

There are several ways in which this work can be extended. One of them concerns the investigation of the specific properties of the algebras generated from different choices of Abelian semigroups; some kind of general classification would be particularly interesting. A first step in this direction would be the construction of the above-mentioned Lagrangians, but of course there are a lot of different possibilities to proceed. A different, and perhaps fruitful path deals with the generalization of the *S*-expansion procedure itself. The conditions of discreteness and finiteness for the semigroup have been chosen primarily for simplicity, but it seems as though they could be removed in a generalized setting. The Abelianity condition, on the other hand, is essential for all of our results to hold, and it is not clear whether it could be relaxed. Removing this requirement, a set with both commuting and anticommuting elements could be considered. If this possibility turns out to be feasible (which is far from trivial; think of the Jacobi identity), it would provide a way to derive superalgebras from ordinary Lie algebras and vice versa.

ACKNOWLEDGMENTS

The authors wish to thank J. A. de Azcárraga and M. A. Lledó for their warm hospitality at the Universitat de València and for many enlightening discussions. Two of the authors [(F.I.) and (E.R.)] are grateful to D. Lüst for his kind hospitality at the Arnold Sommerfeld Center for Theoretical Physics in Munich, where part of this work was done. One of the authors (F.I.) wants to thank B. Jurco for enlightening discussions on some of the topics covered in this paper. Two of the authors [(F.I.) and (E.R.)] were supported by grants from the German Academic Exchange Service (DAAD) and from the Universidad de Concepción (Chile). One of the authors (P.S.) was supported by Fondo Nacional de Desarrolo Científico y Tecnológico (FONDECYT) Grant No. 1040624 and by Universidad de Concepción through Semilla Grant Nos. 205.011.036-1S and 205.011.037-1S.

APPENDIX: REDUCTION WHEN $\mathfrak{g}$ SATISFIES THE WEIMAR-WOODS CONDITIONS

In Sec. IV B 2 it was shown that, when $\mathfrak{g}$ satisfies the Weimar-Woods conditions, the partition $S_{\mathrm{E}}^{(N)}=\bigcup_{p=0}^{n}S_p$ with $S_p=\{\lambda_{\alpha_p}, \text{such that } \alpha_p=p,\ldots,N+1\}$ is a resonant one. In this appendix we prove that, when each subset S_p is split as $S_p=\check{S}_p\cup\hat{S}_p$, with

$$\check{S}_p=\{\lambda_{\alpha_p} \quad \text{such that } \alpha_p=p,\ldots,N_p\}, \tag{A1}$$

$$\hat{S}_p=\{\lambda_{\alpha_p} \quad \text{such that } \alpha_p=N_p+1,\ldots,N+1\}, \tag{A2}$$

then the reduction condition in Eq. (123) from Theorem 6.1 is satisfied when

$$N_{p+1}=\begin{cases} N_p \text{ or} \\ H_{N+1}(N_p+1). \end{cases} \tag{A3}$$

Before proceeding, it is worth to notice that the partition equation [Eqs. (A1) and (A2)] automatically satisfies the following three properties:

$$N_p\geqslant N_q \Leftrightarrow \hat{S}_p\subset\hat{S}_q, \tag{A4}$$

$$\check{S}_0\cdot\hat{S}_q=\hat{S}_q, \tag{A5}$$

$$\check{S}_p\cdot\hat{S}_q\subset\hat{S}_x \quad \text{such that } N_x\leqslant H_{N+1}(p+N_q). \tag{A6}$$

Since $\mathfrak{g}$ is assumed to satisfy the Weimar-Woods conditions,[15,16] condition (123) now reads

$$\check{S}_p \cdot \hat{S}_q \subset \bigcap_{r=0}^{H_n(p+q)} \hat{S}_r, \tag{A7}$$

where $\check{S}_p$ and $\hat{S}_q$ are given by Eqs. (A1) and (A2).

Let us analyze this condition for the particular case $p=0$:

$$\check{S}_0 \cdot \hat{S}_q \subset \bigcap_{r=0}^{q} \hat{S}_r. \tag{A8}$$

Using Eq. (A5), this turns out to be equivalent to

$$\hat{S}_q \subset \bigcap_{r=0}^{q} \hat{S}_r. \tag{A9}$$

In this way, we have that for each $0 \leqslant r \leqslant q$, $\hat{S}_q \subset \hat{S}_r$, and using Eq. (A4), we get the equivalent condition

$$\forall r \leqslant q, \quad N_r \leqslant N_q. \tag{A10}$$

This condition and the product in Eq. (26) now imply that

$$\bigcap_{r=0}^{H_n(p+q)} \hat{S}_r = \hat{S}_{H_n(p+q)}.$$

Using this fact, condition (A7) takes the form

$$\check{S}_p \cdot \hat{S}_q \subset \hat{S}_{H_n(p+q)}. \tag{A11}$$

Using Eq. (A6), one finds that, in order to satisfy this requirement, it is enough to impose that, for each $\hat{S}_x$ such that $N_x \leqslant H_{N+1}(N_q+p)$, one has $\hat{S}_x \subset \hat{S}_{H_n(p+q)}$. Alternatively [see Eq. (A4)], one can write

$$\forall N_x \leqslant H_{N+1}(N_q + p), \quad N_{H_n(p+q)} \leqslant N_x \tag{A12}$$

and therefore,

$$N_{H_n(p+q)} \leqslant H_{N+1}(N_q + p). \tag{A13}$$

For $p=1$, we have

$$N_{H_n(p+1)} \leqslant H_{N+1}(N_q + 1),$$

and using Eq. (A10), one finds the inequalities

$$N_q \leqslant N_{H_n(q+1)} \leqslant H_{N+1}(N_q + 1),$$

whose solution is

$$N_{q+1} = \begin{cases} N_q \text{ or} \\ H_{N+1}(N_q + 1). \end{cases}$$

This solves condition (A7).

Therefore, we have that

$$|\check{\mathfrak{G}}_{\mathrm{R}}| = \bigoplus_{p=0}^{n} \check{S}_p \times V_p, \tag{A14}$$

with $\check{S}_p = \{\lambda_{\alpha_p}, \text{such that } \alpha_p = p, \ldots, N_p\}$ and

$$N_{p+1} = \begin{cases} N_p \text{ or} \\ H_{N+1}(N_p + 1) \end{cases} \tag{A15}$$

is a reduced Lie algebra with structure constants

$$C_{(a_p,\alpha_p)(b_q,\beta_q)}{}^{(c_r,\gamma_r)} = K_{\alpha_p\beta_q}{}^{\gamma_r} C_{a_p b_q}{}^{c_r} \quad \text{with } \alpha_p, \beta_p, \gamma_p = p, \ldots, N_p. \tag{A16}$$

(Received 18 May 2006; accepted 16 August 2006; published online 29 December 2006)

We revisit Khudaverdian's geometric construction of an odd nilpotent operator Δ_E that sends semidensities to semidensities on an antisymplectic manifold. We find a local formula for the Δ_E operator in arbitrary coordinates and we discuss its connection to Batalin-Vilkovisky quantization. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2352859]

I. INTRODUCTION

Recall that for a symplectic manifold with an even symplectic two-form $\omega=\frac{1}{2}dz^A\omega_{AB}dz^B$, there exists a canonical measure density given by the Pfaffian $\rho=\mathrm{Pf}(\omega_{AB})$, i.e., there is a natural notion of volume in a symplectic manifold. A related fact is the Liouville Theorem, which states that Hamiltonian vector fields are divergenceless. On the other hand, the situation is completely different for an odd symplectic manifold, also known as an antisymplectic manifold and endowed with an odd antisymplectic two-form $E=\frac{1}{2}d\Gamma^A E_{AB}d\Gamma^B$. These geometries, for instance, show up in the Lagrangian quantization method of Batalin and Vilkovisky.[1] It turns out that there is *no* canonical choice of measure density ρ in this case, as, for instance, the above Pfaffian. This is tied to the fact that there is no meaningful notion of a superdeterminant/Berezinian for a matrix that is intrinsically Grassmann-odd. However, the upset runs deeper. In fact, a density ρ can never be a function of the antisymplectic matrix E_{AB}. Phrased differently, a density ρ always carries information that cannot be deduced from the antisymplectic structure E alone.[2] Within the standard Batalin-Vilkovisky framework, the possible choices of a density ρ is only partially determined by a requirement of gauge symmetry.

Around 1992, the Batalin-Vilkovisky quantization took a more geometric form, particularly with the work of Schwarz.[3] The consensus was that the geometric setting requires two independent structures: an odd symplectic, nondegenerate two-form E and a measure density ρ. From these two structures, one may build a Grassmann-odd, second-order operator Δ_ρ, known as the odd Laplacian. Alternatively, one can view the odd Laplacian Δ_ρ itself as *the* fundamental structure of Batalin-Vilkovisky geometry,[4,5] which is conventionally required to be nilpotent.

Khudaverdian has constructed[6–9] a Grassmann-odd, nilpotent, second-order operator Δ_E that does not rely on a choice of density ρ. The caveat is that the Δ_E operator is defined on semidensities rather than on scalars. [The notion of a semidensity is explained in Eq. (3.1) below.] In retrospect, many pieces of Khudaverdian's construction were known to physicists; see, for instance, Ref. 10, p. 440. In this short note, Khudaverdian's construction is reconsidered, and we find a local formula for the Δ_E operator that applies to arbitrary coordinate systems. The ability to work in any coordinates, not just Darboux coordinates, is important, since if one first has to search for a set of Darboux coordinates to the system that one is studying, symmetries (such as, e.g., Lorentz covariance) or locality that one would like to preserve during the quantization process, are often lost.

The paper is organized as follows: We consider the antisymplectic structure in Sec. II; the odd

a)Electronic mail: bering@physics.muni.cz

Laplacian Δ_ρ in Sec. III; and in Secs. IV and V, the Δ_E operator using Darboux coordinates and general coordinates, respectively. Finally, in Sec. VI we analyze a modified Batalin-Vilkovisky scheme based on the Δ_E operator.

General remark about notation: We have two types of grading: A Grassmann grading ε and an exterior form degree p. The sign conventions are such that two exterior forms ξ and η, of Grassmann parity ε_ξ, ε_η and exterior form degree p_ξ, p_η, respectively, commute in the following graded sense:

$$\eta \wedge \xi = (-1)^{\varepsilon_\xi \varepsilon_\eta + p_\xi p_\eta} \xi \wedge \eta \tag{1.1}$$

inside the exterior algebra. We will often not write the exterior wedges "$\wedge$" explicitly.

II. ANTISYMPLECTIC GEOMETRY

Consider an antisymplectic manifold (M,E) and let Γ^A denote local coordinates of Grassmann parity $\varepsilon_A \equiv \varepsilon(\Gamma^A)$ (and exterior form degree $p(\Gamma^A)=0$). The antisymplectic two-form can locally be written as

$$E = \frac{1}{2} \mathrm{d}\Gamma^A E_{AB}\, \mathrm{d}\Gamma^B = -\frac{1}{2} E_{AB}\, \mathrm{d}\Gamma^B\, \mathrm{d}\Gamma^A, \tag{2.1}$$

where $E_{AB}=E_{AB}(\Gamma)$ is the corresponding matrix representation. Besides carrying gradings $\varepsilon(E)=1$ and $p(E)=2$, the antisymplectic two-form E has two defining properties. First, E is closed,

$$\mathrm{d}E = 0, \tag{2.2}$$

where the grading conventions for the exterior derivative

$$\mathrm{d} = \mathrm{d}\Gamma^A \frac{\vec{\partial}^l}{\partial \Gamma^A} \tag{2.3}$$

are $\varepsilon(\mathrm{d})=0$ and $p(\mathrm{d})=1$. Second, E is nondegenerate, i.e., the antisymplectic matrix E_{AB} has an inverse matrix E^{AB},

$$E^{AB} E_{BC} = \delta^A_C = E_{CB} E^{BA}. \tag{2.4}$$

Instead of the compact exterior form notation E, one may equivalently formulate the above conditions with all the indices written out explicitly in terms of the matrices E_{AB} or E^{AB}. In detail, the gradings are

$$\begin{aligned} \varepsilon(E_{AB}) &= \varepsilon_A + \varepsilon_B + 1 = \varepsilon(E^{AB}), \\ p(E_{AB}) &= 0 = p(E^{AB}), \end{aligned} \tag{2.5}$$

the skew symmetries are

$$\begin{aligned} E_{BA} &= -(-1)^{\varepsilon_A \varepsilon_B} E_{AB}, \\ E^{BA} &= -(-1)^{(\varepsilon_A+1)(\varepsilon_B+1)} E^{AB}, \end{aligned} \tag{2.6}$$

while the closeness condition and the equivalent Jacobi identity read

$$\sum_{\text{cycl. } A,B,C} (-1)^{\varepsilon_A \varepsilon_C} \left(\frac{\vec{\partial}^l}{\partial \Gamma^A} E_{BC} \right) = 0, \tag{2.7}$$

$$\sum_{\text{cycl. } A,B,C} (-1)^{(\varepsilon_A+1)(\varepsilon_C+1)} E^{AD} \left(\frac{\vec{\partial}^l}{\partial \Gamma^D} E^{BC} \right) = 0, \tag{2.8}$$

respectively. The inverse matrix E^{AB} with upper indices gives rise to the antibracket[1]

$$(F,G) = \left(F\frac{\overleftarrow{\partial}^r}{\partial\Gamma^A}\right)E^{AB}\left(\frac{\overrightarrow{\partial}^l}{\partial\Gamma^B}G\right), \tag{2.9}$$

which satisfies a graded skew symmetry and a graded Jacobi identity as a consequence of Eqs. (2.6) and (2.8). There is an antisymplectic analog of Darboux's Theorem that states that locally there exist Darboux coordinates $\Gamma^A=\{\phi^\alpha;\phi^*_\alpha\}$, such that the only nonvanishing antibrackets between the coordinates are $(\phi^\alpha,\phi^*_\beta)=\delta^\alpha_\beta=-(\phi^*_\beta,\phi^\alpha)$. In Darboux coordinates, the antisymplectic two-form is simply $E=\mathrm{d}\phi^*_\alpha\wedge\mathrm{d}\phi^\alpha$.

III. ODD LAPLACIAN Δ_ρ ON SCALARS

A scalar function $F=F(\Gamma)$, a density $\rho=\rho(\Gamma)$, and a semidensity $\sigma=\sigma(\Gamma)$ are by definition quantities that transform as

$$F\to F'=F,\quad \rho\to\rho'=\frac{\rho}{J},\quad \sigma\to\sigma'=\frac{\sigma}{\sqrt{J}}, \tag{3.1}$$

respectively, under general coordinate transformations $\Gamma^A\to\Gamma'^A$, where $J\equiv\mathrm{sdet}(\partial\Gamma'^A/\partial\Gamma^B)$ denotes the Jacobian. We shall ignore the global issues of orientation and choice of square root. In principle the above F, ρ, and σ could either be bosons or fermions; however, normally we shall require the densities ρ to be invertible and therefore bosons.

Given a choice of density ρ one may define the odd Laplacian[4]

$$\Delta_\rho := \frac{(-1)^{\varepsilon_A}}{2\rho}\frac{\overrightarrow{\partial}^l}{\partial\Gamma^A}\rho E^{AB}\frac{\overrightarrow{\partial}^l}{\partial\Gamma^B}, \tag{3.2}$$

that takes scalars to scalars of opposite Grassmann parity. The odd Laplacian (3.2) has a geometric interpretation as a divergence of a Hamiltonian vector field[3,11]

$$\Delta_\rho\Psi = -\frac{1}{2}\,\mathrm{div}_\rho(X_\Psi),\quad \varepsilon(\Psi)=1. \tag{3.3}$$

Here $X_\Psi:=(\Psi,\cdot)$ denotes a Hamiltonian vector field with a Grassmann-odd Hamiltonian Ψ and the divergence $\mathrm{div}_\rho X$ of a vector field X, with respect to the measure density ρ, is

$$\mathrm{div}_\rho X := \frac{(-1)^{\varepsilon_A}}{\rho}\frac{\overrightarrow{\partial}^l}{\partial\Gamma^A}(\rho X^A),\quad \varepsilon(X)=0. \tag{3.4}$$

The fact that the odd Laplacian (3.3) is nonzero, shows that antisymplectic manifolds do not have an analog of the Liouville Theorem mentioned in the introduction. As a consequence of the Jacobi identity [Eq. (2.8)], the square operator $\Delta^2_\rho=(\frac{1}{2})[\Delta_\rho,\Delta_\rho]$ becomes a linear derivation, i.e., a first-order differential operator,

$$\Delta^2_\rho(FG)=\Delta^2_\rho(F)G+F\Delta^2_\rho(G). \tag{3.5}$$

Conventionally, one imposes additionally that the Δ_ρ operator is nilpotent $\Delta^2_\rho=0$, but this is not necessary for our purposes.

IV. KHUDAVERDIAN'S Δ_E OPERATOR ON SEMIDENSITIES

Khudaverdian showed that one may define a Grassmann-odd, nilpotent, second-order operator Δ_E *without* a choice of density ρ. This Δ_E operator does not take scalars to scalars like the odd Laplacian (3.2), but instead takes semidensities to semidensities of opposite Grassmann parity. Equivalently, the Δ_E operator transforms as

$$\Delta_E \to \Delta'_E = \frac{1}{\sqrt{J}} \Delta_E \sqrt{J} \tag{4.1}$$

under general coordinate transformations $\Gamma^A \to \Gamma'^A$, cf. Eq. (3.1). Khudaverdian's construction relies first of all on an atlas of Darboux charts, which is granted by an antisymplectic analog of Darboux's Theorem, and second, on a lemma by Batalin and Vilkovisky about the possible form of the Jacobians for anticanonical transformations, also known as antisymplectomorphisms.

Lemma 1: The Batalin-Vilkovisky Lemma[7–10,12,13]. Consider a finite anticanonical transformation between initial Darboux coordinates $\Gamma^A_{(i)}$ and final Darboux coordinates $\Gamma^A_{(f)}$. Then the Jacobian $J \equiv \mathrm{sdet}(\partial \Gamma^A_{(f)} / \partial \Gamma^B_{(i)})$ satisfies

$$\Delta^{(i)}_1 \sqrt{J} = 0. \tag{4.2}$$

Here $\Delta^{(i)}_1$ refers to the odd Laplacian (3.2) with $\rho = 1$ in the initial Darboux coordinate $\Gamma^A_{(i)}$. Given the Darboux coordinate Γ^A, the Δ_E operator is defined on a semidensity σ as[6–9,13]

$$(\Delta_E \sigma) := (\Delta_1 \sigma), \tag{4.3}$$

where Δ_1 is the Δ_ρ operator (3.2) with $\rho = 1$. It is important in Eq. (4.3) that the formula for the Δ_1 operator (3.2) and the semidensity σ both refer to the same Darboux coordinate Γ^A. The parentheses in Eq. (4.3) indicate that the equation should be understood as an equality among semidensities (in the sense of zeroth-order differential operators), rather than an identity among differential operators. One next uses the Batalin-Vilkovisky Lemma to argue that the definition (4.3) does not depend on the choices of Darboux coordinates Γ^A. What this means is that the right-hand side of the definition (4.3) transforms as a semidensity

$$(\Delta^{(f)}_1 \sigma_{(f)}) = \frac{1}{\sqrt{J}} (\Delta^{(i)}_1 \sigma_{(i)}) \tag{4.4}$$

under an anticanonical transformation between any two Darboux coordinates $\Gamma^A_{(i)}$ and $\Gamma^A_{(f)}$. Proof:

$$\sqrt{J}(\Delta^{(f)}_1 \sigma_{(f)}) = \sqrt{J}(\Delta^{(i)}_J \sigma_{(f)}) = \sqrt{J}\left(\Delta^{(i)}_J \frac{\sigma_{(i)}}{\sqrt{J}} \right) = (\Delta^{(i)}_1 \sigma_{(i)}) - \frac{1}{\sqrt{J}} (\Delta^{(i)}_1 \sqrt{J}) \sigma_{(i)} = (\Delta^{(i)}_1 \sigma_{(i)}). \tag{4.5}$$

The third equality is a nontrivial property of the odd Laplacian (3.2). The Batalin-Vilkovisky Lemma is used in the fourth equality. Strictly speaking, it is enough to consider infinitesimal anticanonical transformations to justify the definition (4.3). The proof of the infinitesimal version of the Batalin-Vilkovisky Lemma goes like this: An infinitesimal anticanonical coordinate transformation $\delta \Gamma^A = X^A$ is necessarily a Hamiltonian vector field $X^A = (\Psi, \Gamma^A) \equiv X^A_\Psi$ with an infinitesimal, Grassmann-odd Hamiltonian Ψ, where $\varepsilon(\Psi) = 1$. So

$$\ln J \approx (-1)^{\varepsilon_A} \left(\frac{\vec{\partial}^l}{\partial \Gamma^A} X^A \right) = \mathrm{div}_1(X_\Psi) = -2\Delta_1 \Psi, \tag{4.6}$$

and hence

$$\Delta_1 \sqrt{J} \approx -\Delta^2_1 \Psi = 0, \tag{4.7}$$

due to the nilpotency of the Δ_1 operator in Darboux coordinates. The $\approx$ sign is used to indicate that equality only holds at the infinitesimal level. (Here we are guilty of mixing active and passive pictures; the active vector field is properly speaking *minus* X.) A simple proof of the Batalin-Vilkovisky Lemma for finite anticanonical transformations can be found in Ref. 13.

On the other hand, once the definition (4.3) is justified, it is obvious that the Δ_E operator supercommutes with itself, because the Γ^A derivatives have no Γ^A's to act on in Darboux coordinates. Therefore Δ_E is nilpotent,

$$\Delta_E^2 = \frac{1}{2}[\Delta_E, \Delta_E] = 0. \tag{4.8}$$

The same sort of reasoning shows that $\Delta_E = \Delta_E^T$ is symmetric.

V. THE Δ_E OPERATOR IN GENERAL COORDINATES

We now give a definition of the Δ_E operator that does not rely on Darboux coordinates. We claim that in arbitrary coordinates the Δ_E operator is given as

$$(\Delta_E \sigma) := (\Delta_1 \sigma) + \left(\frac{\nu^{(1)}}{8} - \frac{\nu^{(2)}}{24}\right)\sigma, \tag{5.1}$$

where

$$\nu^{(1)} := (-1)^{\varepsilon_A}\left(\frac{\vec{\partial}^l}{\partial \Gamma^B}\frac{\vec{\partial}^l}{\partial \Gamma^A}E^{AB}\right), \tag{5.2}$$

$$\nu^{(2)} := -(-1)^{\varepsilon_B}(\Gamma^C,(\Gamma^B,\Gamma^A))\left(\frac{\vec{\partial}^l}{\partial \Gamma^A}E_{BC}\right) = (-1)^{\varepsilon_A\varepsilon_C}\left(\frac{\vec{\partial}^l}{\partial \Gamma^A}E^{CD}\right)\left(\frac{\vec{\partial}^l}{\partial \Gamma^D}E^{AB}\right)E_{BC}. \tag{5.3}$$

Equation (5.1) is the main result of this paper. Notice that in Darboux coordinates, where E^{AB} is constant, i.e., independent of the coordinate Γ^A, the last two terms, $\nu^{(1)}$ and $\nu^{(2)}$, vanish. Hence the definition (5.1) agrees in this case with Khudaverdian's Δ_E operator (4.3).

It remains to be shown that the right-hand side of Eq. (5.1) behaves as a semidensity under general coordinate transforms. Here we will only explicitly consider the case where σ is invertible to simplify the presentation. (The noninvertible case is fundamentally no different.) In the invertible case, we customarily write the semidensity $\sigma = \sqrt{\rho}$ as a square root of a density ρ, and define a Grassmann-odd quantity

$$\nu_\rho := \frac{1}{\sqrt{\rho}}(\Delta_E \sqrt{\rho}) = \nu_\rho^{(0)} + \frac{\nu^{(1)}}{8} - \frac{\nu^{(2)}}{24}, \tag{5.4}$$

by dividing both sides of the definition (5.1) with the semidensity σ. Here we have defined

$$\nu_\rho^{(0)} := \frac{1}{\sqrt{\rho}}(\Delta_1 \sqrt{\rho}). \tag{5.5}$$

Hence, to justify the definition (5.1), one should check that ν_ρ is a scalar under general infinitesimal coordinate transformations. Under an arbitrary infinitesimal coordinate transformation $\delta\Gamma^A = X^A$, one calculates

$$\delta\nu_\rho^{(0)} = -\frac{1}{2}\Delta_1 \operatorname{div}_1 X, \tag{5.6}$$

$$\delta\nu^{(1)} = 4\Delta_1 \operatorname{div}_1 X + (-1)^{\varepsilon_A}\left(\frac{\vec{\partial}^l}{\partial \Gamma^C}E^{AB}\right)\left(\frac{\vec{\partial}^l}{\partial \Gamma^B}\frac{\vec{\partial}^l}{\partial \Gamma^A}X^C\right), \tag{5.7}$$

$$\delta\nu^{(2)} = 3(-1)^{\varepsilon_A}\left(\frac{\vec{\partial}^l}{\partial \Gamma^C}E^{AB}\right)\left(\frac{\vec{\partial}^l}{\partial \Gamma^B}\frac{\vec{\partial}^l}{\partial \Gamma^A}X^C\right), \tag{5.8}$$

cf. Appendixes A–C. One easily sees that while the three constituents $\nu_\rho^{(0)}$, $\nu^{(1)}$, and $\nu^{(2)}$ separately have nontrivial transformation properties, the linear combination ν_ρ in Eq. (5.4) is indeed a scalar.

The new definition (5.1) is clearly symmetric $\Delta_E = \Delta_E^T$ and one may check that the nilpotency (4.8) of the Δ_E operator (5.1) precisely encodes the Jacobi identity (2.9). The odd Laplacian Δ_ρ can be expressed entirely by the Δ_E operator and a choice of density ρ,

$$(\Delta_\rho F) = (\Delta_1 F) + \frac{1}{\sqrt{\rho}}(\sqrt{\rho}, F) = \frac{1}{\sqrt{\rho}}[\vec{\Delta}_1, F]\sqrt{\rho} = \frac{1}{\sqrt{\rho}}[\vec{\Delta}_E, F]\sqrt{\rho}. \tag{5.9}$$

Since $\nu^{(2)}$ depends on the antisymplectic matrix E_{AB} with lower indices, it is not clear how the formula (5.1) extends to the degenerate anti-Poisson case.

VI. APPLICATION TO BATALIN-VILKOVISKY QUANTIZATION

It is interesting to transcribe the Batalin-Vilkovisky quantization, based on the odd Laplacian Δ_ρ, into a quantization scheme that is based on the Δ_E operator, with the added benefit that no choice of measure density ρ is needed. Since the Δ_E operator takes semidensities to semidensities, this suggests that the Boltzmann factor $\exp[(i/\hbar)W_E]$ that appears in the quantum master equation

$$\Delta_E \exp\left[\frac{i}{\hbar}W_E\right] = 0 \tag{6.1}$$

should now be a semidensity, where

$$W_E = S + \sum_{n=1}^{\infty} (i\hbar)^n W_n \tag{6.2}$$

denotes the quantum action. In fact, this was a common interpretation (when restricting to Darboux coordinates) prior to the introduction of a density ρ around 1992; see, for instance, Ref. 10, pp. 440–441. If one only considers $\hbar$-independent coordinate transformations $\Gamma^A \to \Gamma'^A$ for simplicity, this implies that the one-loop factor e^{-W_1} is a semidensity, while the rest of the quantum action, i.e., the classical action S and the higher loop corrections W_n, $n \geq 2$, are scalars as usual. For instance, the nilpotent operator $F \mapsto e^{W_1}\Delta_E(e^{-W_1}F)$ takes scalars F to scalars.

At this stage it might be helpful to compare the above Δ_E approach to the Δ_ρ formalism. To this end, fix a density ρ. Then one can define a bona fide scalar quantum action W_ρ as

$$W_\rho := W_E + (i\hbar)\ln\sqrt{\rho}, \tag{6.3}$$

or equivalently,

$$e^{(i/\hbar)W_E} = \sqrt{\rho}e^{(i/\hbar)W_\rho}. \tag{6.4}$$

This scalar action W_ρ satisfies the modified quantum master equation

$$(\Delta_\rho + \nu_\rho)\exp\left[\frac{i}{\hbar}W_\rho\right] = 0, \tag{6.5}$$

cf. Eqs. (5.4), (5.9), (6.1), and (6.4). One may obtain the quantum master equation $\Delta_\rho \exp[(i/\hbar)W_\rho] = 0$ by additionally imposing the covariant condition $\nu_\rho = 0$, or equivalently $\Delta_E\sqrt{\rho} = 0$. However, this step is not necessary.

Returning now to the pure Δ_E approach with no ρ, the finite Δ_E-exact transformations of the form

$$e^{(i/\hbar)W'_E} = e^{-[\vec{\Delta}_E, \Psi]}e^{(i/\hbar)W_E}, \tag{6.6}$$

play an important role in taking solutions W_E to the quantum master Eq. (6.1) into new solutions W'_E. It is implicitly understood that all objects in Eq. (6.6) refer to the same (but arbitrary) coordinate frame. In general, Ψ is a Grasmann-odd operator that takes semidensities to semidensities. If Ψ is a scalar function (=zeroth-order operator), one derives

$$W'_E = e^{X_\Psi} W_E + (i\hbar)\frac{e^{X_\Psi}-1}{X_\Psi}\Delta_E \Psi . \tag{6.7}$$

The formula (6.7) is similar to the usual formula in the Δ_ρ formalism.[13] One may check that Eq. (6.7) is covariant with respect to general coordinate transformations.

The *W-X* formulation discussed in Refs. 5 and 13 carries over with only minor modifications, since the Δ_E operator is symmetric $\Delta_E^T = \Delta_E$. In short, the *W-X* formulation is a very general field-antifield formulation, based on two master actions, W_E and X_E, each satisfying a quantum master equation. At the operational level, *symmetric* means that the Δ_E operator, sandwiched between two semidensities under a (path) integral sign, may be moved from one semidensity to the other, using integration by part. This is completely analogous to the symmetry of the odd Laplacian $\Delta_\rho = \Delta_\rho^T$ itself. The X_E quantum action is a gauge-fixing part,

$$X_E = G_\alpha \lambda^\alpha + (i\hbar) H_E + \mathcal{O}(\lambda^*), \tag{6.8}$$

which contains the gauge-fixing constraints G_α in involution,

$$(G_\alpha, G_\beta) = G_\gamma U^\gamma_{\alpha\beta}. \tag{6.9}$$

The gauge-fixing functions G_α implement a generalization of the standard Batalin-Vilkovisky gauge-fixing procedure $\phi^*_\alpha = \partial\Psi/\partial\phi^\alpha$. In the simplest cases, the gauge-fixing conditions $G_\alpha = 0$ are enforced by integration over the Lagrange multipliers λ^α. See Ref. 13 for further details on the *W-X* formulation. The pertinent measure density in the partition function

$$\mathcal{Z} = \int [\mathrm{d}\Gamma][\mathrm{d}\lambda] e^{(i/\hbar)(W_E + X_E)} \tag{6.10}$$

is now located inside the one-loop parts of the W_E and the X_E actions. For instance, an on-shell expression for the one-loop factor e^{-H_E} is

$$e^{-H_E} = \sqrt{J\mathrm{sdet}(F^\alpha, G_\beta)}, \tag{6.11}$$

where $J = \mathrm{sdet}(\partial\overline{\Gamma}^A/\partial\Gamma^B)$ denotes the Jacobian of the transformation $\Gamma^A \to \overline{\Gamma}^A$ and $\overline{\Gamma}^A \equiv \{F^\alpha; G_\alpha\}$. The formula (6.11) differs from the original square root formula[13–15] by not depending on a ρ density, consistent with the fact that e^{-H_E} is no longer a scalar but a semidensity. We recall here the main point that the one-loop factor e^{-H_E} is independent of the F^α's and the partition function $\mathcal{Z}$ is independent of the G_α's in involution, cf. Eq. (6.9).

To summarize, the density ρ can altogether be avoided in the field-antifield formalism, at the cost of more complicated transformation rules. We stress that the above transcription has no consequences for the physics involved. For instance, the ambiguity that existed in the density ρ is still present in the choice of W_E and X_E.

APPENDIX A: PROOF OF EQ. (5.6)

Consider a general (not necessarily infinitesimal) coordinate transformation $\Gamma^A \to \Gamma'^A$ between the "unprimed" and a "primed" coordinate systems, Γ^A and Γ'^A, respectively; cf. Eq. (3.1). The primed $\nu^{(0)}_\rho$ quantity (5.5) can be reexpressed with the help of the unprimed coordinates as

$$\nu'^{(0)}_{\rho'} := \frac{1}{\sqrt{\rho'}}(\Delta'_1\sqrt{\rho'}) = \frac{1}{\sqrt{\rho'}}(\Delta_J\sqrt{\rho'}) = \frac{1}{\sqrt{\rho}}(\Delta_1\sqrt{\rho}) - \frac{1}{\sqrt{J}}(\Delta_1\sqrt{J}) = \nu^{(0)}_{\rho} - \nu^{(0)}_{J}, \tag{A1}$$

where it is convenient (and natural) to introduce the quantity

$$\nu^{(0)}_{J} := \frac{1}{\sqrt{J}}(\Delta_1\sqrt{J}) \tag{A2}$$

with respect to the unprimed reference system. The third equality in Eq. (A1) uses a nontrivial property of the odd Laplacian (3.2). In the infinitesimal case $\delta\Gamma^A = X^A$, the expression for the Jacobian J reduces to a divergence $\ln J \approx \mathrm{div}_1 X$, and one calculates

$$\delta\nu^{(0)}_{\rho} = \nu'^{(0)}_{\rho'} - \nu^{(0)}_{\rho} = -\nu^{(0)}_{J} = -\Delta_1(\ln\sqrt{J}) - \frac{1}{2}(\ln\sqrt{J}, \ln\sqrt{J}) \approx -\frac{1}{2}\Delta_1 \,\mathrm{div}_1 X, \tag{A3}$$

which is Eq. (5.6).

APPENDIX B: PROOF OF EQ. (5.7)

The infinitesimal variation of $\nu^{(1)}$ yields four contributions to linear order in the variation $\delta\Gamma^A = X^A$,

$$\delta\nu^{(1)} = -\delta\nu^{(1)}_{I} - \delta\nu^{(1)}_{II} + \delta\nu^{(1)}_{III} + \delta\nu^{(1)}_{IV}. \tag{B1}$$

They are

$$\delta\nu^{(1)}_{I} := (-1)^{\varepsilon_A}\left(\frac{\vec{\partial}^l}{\partial\Gamma^B}X^C\right)\left(\frac{\vec{\partial}^l}{\partial\Gamma^C}\frac{\vec{\partial}^l}{\partial\Gamma^A}E^{AB}\right), \tag{B2}$$

$$\delta\nu^{(1)}_{II} := (-1)^{\varepsilon_A}\frac{\vec{\partial}^l}{\partial\Gamma^B}\left(\left(\frac{\vec{\partial}^l}{\partial\Gamma^A}X^C\right)\left(\frac{\vec{\partial}^l}{\partial\Gamma^C}E^{AB}\right)\right) = \delta\nu^{(1)}_{I} + \delta\nu^{(1)}_{V}, \tag{B3}$$

$$\delta\nu^{(1)}_{III} := (-1)^{\varepsilon_A}\frac{\vec{\partial}^l}{\partial\Gamma^B}\frac{\vec{\partial}^l}{\partial\Gamma^A}\left(\left(X^A\frac{\overleftarrow{\partial}^r}{\partial\Gamma^C}\right)E^{CB}\right) = \delta\nu^{(1)}_{IV}, \tag{B4}$$

$$\delta\nu^{(1)}_{IV} := (-1)^{\varepsilon_A}\frac{\vec{\partial}^l}{\partial\Gamma^B}\frac{\vec{\partial}^l}{\partial\Gamma^A}\left(E^{AC}\left(\frac{\vec{\partial}^l}{\partial\Gamma^C}X^B\right)\right) = \delta\nu^{(1)}_{I} + \delta\nu^{(1)}_{V} + \delta\nu^{(1)}_{VI}, \tag{B5}$$

$$\delta\nu^{(1)}_{V} := (-1)^{\varepsilon_A}\left(\frac{\vec{\partial}^l}{\partial\Gamma^C}E^{AB}\right)\left(\frac{\vec{\partial}^l}{\partial\Gamma^B}\frac{\vec{\partial}^l}{\partial\Gamma^A}X^C\right), \tag{B6}$$

$$\delta\nu^{(1)}_{VI} := (-1)^{\varepsilon_A}\frac{\vec{\partial}^l}{\partial\Gamma^A}\left(E^{AC}\frac{\vec{\partial}^l}{\partial\Gamma^C}\frac{\vec{\partial}^l}{\partial\Gamma^B}X^B(-1)^{\varepsilon_B}\right) = 2\Delta_1 \,\mathrm{div}_1 X, \tag{B7}$$

where we have noted various relations among the contributions. Altogether, the infinitesimal variation of $\nu^{(1)}$ becomes

$$\delta\nu^{(1)} = \delta\nu^{(1)}_{V} + 2\delta\nu^{(1)}_{VI}, \tag{B8}$$

which is Eq. (5.7).

APPENDIX C: PROOF OF EQ. (5.8)

The infinitesimal variation of

$$\nu^{(2)} := (-1)^{\varepsilon_A\varepsilon_C}\left(\frac{\vec{\partial}^l}{\partial\Gamma^D}E^{AB}\right)E_{BC}\left(\frac{\vec{\partial}^l}{\partial\Gamma^A}E^{CD}\right) \tag{C1}$$

yields eight contributions to linear order in the variation $\delta\Gamma^A = X^A$, which may be organized as 2×4 terms

$$\delta\nu^{(2)} = 2(-\delta\nu_I^{(2)} - \delta\nu_{II}^{(2)} + \delta\nu_{III}^{(2)} + \delta\nu_{IV}^{(2)}), \tag{C2}$$

due to a $(A,B)\leftrightarrow(D,C)$ symmetry in Eq. (C1). They are

$$\delta\nu_I^{(2)} := (-1)^{\varepsilon_A\varepsilon_C}\left(\frac{\vec{\partial}^l}{\partial\Gamma^D}E^{AB}\right)E_{BF}\left(X^F\frac{\overleftarrow{\partial}^r}{\partial\Gamma^C}\right)\left(\frac{\vec{\partial}^l}{\partial\Gamma^A}E^{CD}\right), \tag{C3}$$

$$\delta\nu_{II}^{(2)} := (-1)^{\varepsilon_A\varepsilon_C}\left(\frac{\vec{\partial}^l}{\partial\Gamma^D}E^{AB}\right)E_{BC}\left(\frac{\vec{\partial}^l}{\partial\Gamma^A}X^F\right)\left(\frac{\vec{\partial}^l}{\partial\Gamma^F}E^{CD}\right), \tag{C4}$$

$$\delta\nu_{III}^{(2)} := (-1)^{\varepsilon_A\varepsilon_C}\left(\frac{\vec{\partial}^l}{\partial\Gamma^D}E^{AB}\right)E_{BC}\frac{\vec{\partial}^l}{\partial\Gamma^A}\left(\left(X^C\frac{\overleftarrow{\partial}^r}{\partial\Gamma^F}\right)E^{FD}\right) = \delta\nu_I^{(2)} + \delta\nu_V^{(2)}, \tag{C5}$$

$$\delta\nu_{IV}^{(2)} := (-1)^{\varepsilon_A\varepsilon_C}\left(\frac{\vec{\partial}^l}{\partial\Gamma^D}E^{AB}\right)E_{BC}\frac{\vec{\partial}^l}{\partial\Gamma^A}\left(E^{CF}\left(\frac{\vec{\partial}^l}{\partial\Gamma^F}X^D\right)\right) = \delta\nu_{II}^{(2)} + \delta\nu_{VI}^{(2)}, \tag{C6}$$

$$\delta\nu_V^{(2)} := (-1)^{\varepsilon_A\varepsilon_C}E^{FD}\left(\frac{\vec{\partial}^l}{\partial\Gamma^D}E^{AB}\right)E_{BC}\left(\frac{\vec{\partial}^l}{\partial\Gamma^A}X^C\frac{\overleftarrow{\partial}^r}{\partial\Gamma^F}\right) = -\delta\nu_V^{(2)} + \delta\nu_{VI}^{(2)}, \tag{C7}$$

$$\delta\nu_{VI}^{(2)} := (-1)^{\varepsilon_A}\left(\frac{\vec{\partial}^l}{\partial\Gamma^C}E^{AB}\right)\left(\frac{\vec{\partial}^l}{\partial\Gamma^B}\frac{\vec{\partial}^l}{\partial\Gamma^A}X^C\right), \tag{C8}$$

where we have noted various relations among the contributions. The Jacobi identity (2.8) for E^{AB} is used in the second equality of Eq. (C7). Altogether, the infinitesimal variation of $\nu^{(2)}$ becomes

$$\delta\nu^{(2)} = 3\,\delta\nu_{VI}^{(2)}, \tag{C9}$$

which is Eq. (5.8).

Infinite component Poisson brackets of the Dubrovin-Novikov type [Sov. Math. Dokl. **27**, 665–669 (1983)] are considered. The corresponding Jacobi identity is significantly simplified in the Liouville coordinates since the skew-symmetry condition is automatically satisfied. The concept of M Poisson bracket connected with hydrodynamic chains is introduced. Then the Jacobi identity is a nonlinear system of equations in partial derivatives which can be completely integrated. In such a case, a classification of infinite component Poisson brackets of the Dubrovin-Novikov type can be obtained. Two simplest examples, $M=0$ and $M=1$, are considered. Also infinite component Poisson brackets of the Ferapontov [Am. Math. Soc. Transl. **170**, 38–58 (1995)] type can be simplified in the Liouville coordinates. The Jacobi identity for infinite component Poisson brackets of the Ferapontov-Mokhov type [Russ. Math. Surveys **45**, 218–219 (1990)] is presented in the Liouville coordinates [DOI: 10.1063/1.2399086]

I. INTRODUCTION

The theory of the hydrodynamic-type systems,

$$u_t^i = v_j^i(\mathbf{u})u_x^j, \quad i,j = 1,2,\ldots,N, \tag{1}$$

integrable by the generalized hodograph method (see Ref. 25) starts with the hydrodynamic-type systems equipped with a local Hamiltonian structure,

$$u_t^i = \{u^i, \bar{\mathbf{h}}\} = [g^{ij}D_x - g^{is}\Gamma_{sk}^j u_x^k]\frac{\delta \bar{\mathbf{h}}}{\delta u^j},$$

determined by the Hamiltonian $\bar{\mathbf{h}} = \int h(\mathbf{u})\mathrm{d}x$ and by the Dubrovin-Novikov bracket (a differential-geometric Poisson bracket of the first order, see Ref. 5)

$$\{u^i(x), u^j(x')\} = [g^{ij}D_x - g^{is}\Gamma_{sk}^j u_x^k]\delta(x-x'), \quad i,j = 1,2,\ldots,N, \tag{2}$$

where the symmetric and nondegenerate metric $g^{ij}(\mathbf{u})$ is flat, and the Christoffel symbols are given by $\Gamma_{sk}^j = \frac{1}{2}g^{jm}(\partial_s g_{mk} + \partial_k g_{ms} - \partial_m g_{sk})$. Then the above Poisson bracket can be written via the so-called *Liouville* coordinates $A^k(\mathbf{u})$ (see Ref. 5),

$$\{A^k(x), A^n(x')\} = [\mathcal{W}^{kn}(\mathbf{A})D_x + D_x\mathcal{W}^{nk}(\mathbf{A})]\delta(x-x'), \quad k,n = 1,2,\ldots,N. \tag{3}$$

The theory of Poisson brackets in *infinite* component case,

a)Electronic mail: m.v.pavlov@lboro.ac.uk

$$\{U^i,U^j\}=[G^{ij}(\mathbf{U})D_x+\Gamma^{ij}_k(\mathbf{U})U^k_x]\delta(x-x'),\quad i,j,k=1,2,3,\ldots, \tag{4}$$

starts with the pioneering papers (Refs. 13 and 14) dedicated to integrable hydrodynamic chains (see below) and their properties. Later these Poisson brackets [See. Eq. (2)] were considered by Dorfman in Ref. 4 (N component case (2) was completely investigated by Dubrovin and Novikov in Ref. 5 for the nondegenerate matrix G^{ij}; the degenerate case was considered by Grinberg in Ref. 12; see also the "zero curvature" subcase in Ref. 17).

Theorem (Ref. 4): *The Poisson bracket (4) is skew symmetric and satisfies the Jacobi identity property if and only if*

$$G^{ij}=G^{ji},\quad \partial_k G^{ij}=\Gamma^{ij}_k+\Gamma^{ji}_k,\quad G^{ik}\Gamma^{jn}_k=G^{jk}\Gamma^{in}_k,$$

$$0=\Gamma^{ij}_n\Gamma^{nm}_k-\Gamma^{im}_n\Gamma^{nj}_k+G^{in}(\partial_n\Gamma^{mj}_k-\partial_k\Gamma^{mj}_n),$$

$$\begin{aligned}0=&(\partial_n\Gamma^{ij}_k-\partial_k\Gamma^{ij}_n)\Gamma^{nm}_p+(\partial_n\Gamma^{mi}_k-\partial_k\Gamma^{mi}_n)\Gamma^{nj}_p+(\partial_n\Gamma^{jm}_k-\partial_k\Gamma^{jm}_n)\Gamma^{ni}_p\\&+(\partial_n\Gamma^{ij}_p-\partial_p\Gamma^{ij}_n)\Gamma^{nm}_k+(\partial_n\Gamma^{mi}_p-\partial_p\Gamma^{mi}_n)\Gamma^{nj}_k+(\partial_n\Gamma^{jm}_p-\partial_p\Gamma^{jm}_n)\Gamma^{ni}_k.\end{aligned} \tag{5}$$

The first main observation of this paper is that the above nonlinear system of equations in partial derivatives simplifies to the more compact form

$$(\mathcal{W}^{in}+\mathcal{W}^{ni})\partial_n\mathcal{W}^{kj}=(\mathcal{W}^{jn}+\mathcal{W}^{nj})\partial_n\mathcal{W}^{ki},$$

$$\partial_n\mathcal{W}^{ij}\partial_m\mathcal{W}^{kn}=\partial_n\mathcal{W}^{kj}\partial_m\mathcal{W}^{in} \tag{6}$$

in the Liouville coordinates $A^i(\mathbf{U})$ [see Eq. (3); see also Refs. 5 and 15]. Thus, the Liouville coordinates A^k are most natural coordinates (except flat coordinates in the finite component case, see Ref. 5).

Indeed, the first two relationships in Eq. (5) are the skew-symmetry property satisfied automatically in the Liouville coordinates. The last restriction in Eq. (5) vanishes in the Liouville coordinates because $G^{ik}(\mathbf{A})=\mathcal{W}^{ik}+\mathcal{W}^{ki}$, $\Gamma^{ij}_k(\mathbf{A})=\partial_k\mathcal{W}^{ji}$. Thus, the nonlinear PDE system (5) reduces to the Jacobi identity (6) in this special case.

Remark: Elements $\mathcal{W}^{ik}$ depend on *all* field variables u^n $(n=1,2,\ldots,N)$ in the finite-component case [hydrodynamic-type systems (1)]; elements $\mathcal{W}^{ik}$ depend on just a *finite* number of moments A^k in the infinite component case (hydrodynamic chains). Thus, the Jacobi identity (6) contains a finite number of equations for any *fixed* indices i,j,k,m. Then this overdetermined system can be solved *iteratively* for all indices i,j,k,m, if a dependence of elements $\mathcal{W}^{ik}$ on moments A^k is determined by some special prescribed law. Such a simple dependence is considered below.

This paper deals with the hydrodynamic chains [see Eq. (1)],

$$U^k_t=\sum_{m=0}^{M_k}V^k_m(\mathbf{U})U^m_x,\quad k=0,1,2,\ldots, \tag{7}$$

where the number of field variables U^k is infinite [in comparison with hydrodynamic-type systems (1)], all components $V^k_m(\mathbf{U})$ are functions of a finite number of the field variables U^n (for any fixed indices k,m), and M_k are some integers [i.e., M_k are integer values of a discrete function $M(\mathbf{k})$]. Thus, the hydrodynamic chain (7) is an extension of the hydrodynamic-type system (1) to an infinite component case. Plenty known integrable hydrodynamic chains (see Refs. 2, 3, 9, 16, 21, 22, and 24) belong to the simplest class $M_k=k+1$.

Without loss of generality we restrict our consideration on a *monotonic growth* of coefficients M_k. All further formulas, definitions, theorems, and conjectures are expressed via the Liouville coordinates $A^k(\mathbf{U})$.

Definition: *The hydrodynamic chain (7) is said to be Hamiltonian if it can be written in the form*

$$A_t^i = [\mathcal{W}^{ij}(\mathbf{A})D_x + D_x\mathcal{W}^{ji}(\mathbf{A})]\frac{\delta\bar{\mathbf{H}}}{\delta A^j}, \quad i,j = 0,1,2,\ldots, \tag{8}$$

where the coefficients $\mathcal{W}^{ij}(\mathbf{A})$ satisfy the Jacobi identity (6).

The Hamiltonian $\bar{\mathbf{H}} = \int \mathbf{H} dx$ depends on a finite number of first moments A^k (i.e., $k = 0,1,\ldots,K$, where K is some integer).

Definition: *The Hamiltonian hydrodynamic chain (8) is said to be integrable if it possesses an infinite series of conservation laws.*

The main problem in a classification of integrable hydrodynamic chains is a description of the Poisson brackets [see Eq. (3)]

$$\{A^k(x), A^n(x')\} = [\mathcal{W}^{kn}(\mathbf{A})D_x + D_x\mathcal{W}^{nk}(\mathbf{A})]\delta(x-x'), \quad k,n = 1,2,\ldots. \tag{9}$$

Many publications are devoted to various particular cases (see, for instance, Refs. 4, 13, and 14), some of them will be described below. In this paper I present the program of an investigation of these Poisson brackets.

In this paper we consider the very important case

$$\mathcal{W}^{kn}_{(M)} = \mathcal{W}^{kn}(A^0, A^1, \ldots, A^{k+n-M}), \quad M = 0, \pm 1, \pm 2, \ldots. \tag{10}$$

Definition: *The corresponding Poisson brackets (9) are said to be M brackets.*

The simplest subcases $\mathcal{W}^{kn}_{(0)} = \mathcal{W}^{kn}(B^0, B^1, \ldots, B^{k+n})$ and $\mathcal{W}^{kn}_{(1)} = \mathcal{W}^{kn}(A^0, A^1, \ldots, A^{k+n-1})$ are considered in detail below. The first example is the Kupershmidt-Manin bracket ($M=1$)

$$\{A^k, A^n\}_3 = (kA^{k+n-1}D_x + nD_xA^{k+n-1})\delta(x-x') \tag{11}$$

found in Ref. 14 [the index 3 means that the above Poisson bracket is associated with the third local Hamiltonian structure, where the Hamiltonian density is given by $\mathbf{H}_2 = A^2 + (A^0)^2$]. The second example is the Kupershmidt bracket ($M=0$)

$$\{B^k, B^n\} = [(k+\beta)B^{k+n}D_x + (n+\beta)D_xB^{k+n}]\delta(x-x') \tag{12}$$

found in Ref. 13. Infinitely many local Hamiltonian structures for the Benney hydrodynamic chain (see Ref. 23) and for the Kupershmidt hydrodynamic chains (see Ref. 22) are examples of these M brackets. The third example ($M=0$),

$$\{A^k, A^n\}_2 = \Bigg[(k+1)A^{k+n}D_x + (n+1)D_xA^{k+n} + n(k+1)A^{k-1}D_xA^{n-1} + \sum_{m=0}^{n-1}(mA^{n-1-m}D_xA^{k-1+m} + (k-n+m)A^{k-1+m}D_xA^{n-1-m})\Bigg]\delta(x-x'),$$

is the second local Poisson bracket for the Benney hydrodynamic chain (where the Hamiltonian density is given by $\mathbf{H}_1 = A^1$; see Ref. 13), where the moments A^k are no longer the Liouville coordinates. Nevertheless, this bi-Hamiltonian structure completely determines the Benney hydrodynamic chain together with its commuting flows.

The second observation successfully utilized in this paper is that the Jacobi identity (6),

$$\sum_{n=0}^{k+j-M}(\mathcal{W}^{jn}_{(M)} + \mathcal{W}^{ni}_{(M)})\partial_n\mathcal{W}^{kj}_{(M)} = \sum_{n=0}^{k+i-M}(\mathcal{W}^{jn}_{(M)} + \mathcal{W}^{nj}_{(M)})\partial_n\mathcal{W}^{ki}_{(M)},$$

$$\sum_{n=0}^{k+j-M} \partial_n \mathcal{W}_{(M)}^{jk} \partial_m \mathcal{W}_{(M)}^{in} = \sum_{n=0}^{k+i-M} \partial_n \mathcal{W}_{(M)}^{ik} \partial_m \mathcal{W}_{(M)}^{jn}, \tag{13}$$

is an overdetermined system which can be solved completely. Indeed, since all coefficients $\mathcal{W}_{(M)}^{ij}$ depend on *different sets* of the moments A^k (cf. a similar problem in Refs. 9 and 21), the elimination of higher (step by step) moment dependences leads to systems of ordinary differential equations with respect to each lower moment. The illustrative examples are considered in this paper for $M=0$ and $M=1$. Without loss of generality and for simplicity we restrict our consideration to *several first* equations of Eq. (13) for computation of several first coefficients $\mathcal{W}_{(M)}^{ij}$; all other higher coefficients can be found in the same way utilizing next equations from Eq. (13). Moreover, suppose that several first coefficients $\mathcal{W}_{(M)}^{ij}$ are found (see the examples below), then all first derivatives of *higher* coefficients $\mathcal{W}_{(M)}^{ij}$ can be expressed from the nonlinear PDE system (13). It means that the compatibility conditions $\partial_k(\partial_n \mathcal{W}_{(M)}^{ij}) = \partial_n(\partial_k \mathcal{W}_{(M)}^{ij})$ should lead to nonlinear PDE equations determining *lower* coefficients $\mathcal{W}_{(M)}^{ij}$ which are already found at the previous stage of computations. Then these higher coefficients $\mathcal{W}_{(M)}^{ij}$ can be found in quadratures.

Remark: Of course, the M bracket is just one among many other examples. For instance, another new Poisson bracket is given by

$$\{A^k, A^n\} = (A^{k\cdot n} D_x + D_x A^{k\cdot n})\,\delta(x-x').$$

All other Poisson brackets (8) and corresponding integrable hydrodynamic chains shall be discussed elsewhere.

At the end of this paper, local Poisson brackets are generalized to the simplest *nonlocal* case (associated with a metric of constant curvature[10] in N component nondegenerate case).

II. *M* BRACKETS AND INTEGRABLE HYDRODYNAMIC CHAINS

In this section, integrable Hamiltonian hydrodynamic chains (8) determined by M brackets (10),

$$A_t^k = \{A^k, \bar{\mathbf{H}}\}_M = [\mathcal{W}_{(M)}^{kn} D_x + D_x \mathcal{W}_{(M)}^{nk}] \frac{\delta \bar{\mathbf{H}}}{\delta A^n}, \tag{14}$$

are considered.

Definition: *The conservation law density* $\mathbf{H}_m$ *is said to be a Casimir density, if the corresponding right hand side (rhs) of Eq. (14) vanishes, i.e.,*

$$[\mathcal{W}_{(M)}^{kn} D_x + D_x \mathcal{W}_{(M)}^{nk}] \frac{\partial \mathbf{H}_m}{\partial A^n} \equiv 0.$$

Definition: *The conservation law density* $\mathbf{H}_M$ *is said to be a momentum density if*

$$[\mathcal{W}_{(M)}^{kn} D_x + D_x \mathcal{W}_{(M)}^{nk}] \frac{\partial \mathbf{H}_M}{\partial A^n} \equiv A_x^k.$$

We restrict our further consideration by a set of some *natural* assumptions (for $M \geqslant 1$). In fact, we have two main cases only.

1. If $M \geqslant 1$, suppose M brackets satisfy the *auxiliary* (natural) restrictions ("normalization") given by

$$\mathcal{W}_{(M)}^{Mk} = A^k, \quad k = 0,1,2,\ldots,$$

$$\mathcal{W}_{(M)}^{sk} = 0, \quad 0 \leqslant s < M, \quad k \geqslant M - s.$$

$$\mathcal{W}_{(M)}^{kn} = \bar{\mathcal{W}}_{(M)}^{kn} = \text{const}, \quad k = 0,1,2,\ldots,M-1, \quad 0 \leqslant n \leqslant M-1-k. \tag{15}$$

Then the corresponding Poisson brackets possess M Casimirs. The Casimirs can be chosen as $\bar{\mathbf{H}}_k = \int A^k \mathrm{d}x$ $(k=0,1,2,\ldots,M-1)$, while the momentum can be chosen as $\bar{\mathbf{H}}_M = \int A^M \mathrm{d}x$. For simplicity we restrict our consideration to the hydrodynamic chain (14) determined by the simplest Hamiltonian $\bar{\mathbf{H}}_{M+1} = \int \mathbf{H}_{M+1}(A^0, A^1, A^2, \ldots, A^{M+1})\mathrm{d}x$. Thus, the hydrodynamic chain (14) possesses at least $M+2$ conservation laws (for an arbitrary Hamiltonian density $\mathbf{H}$), where the first M conservation laws are the Casimirs

$$A_t^k = \partial_x \left(\sum_{n=0}^{M-k-1} (\bar{\mathcal{W}}_{(M)}^{kn} + \bar{\mathcal{W}}_{(M)}^{nk}) \frac{\delta \mathbf{H}_{M+1}}{\partial A^n} + \sum_{n=M-k}^{M+1} \mathcal{W}_{(M)}^{nk} \frac{\partial \mathbf{H}_{M+1}}{\partial A^n} \right), \quad k = 0,1,2,\ldots,M-1.$$

The conservation law of the momentum is

$$A_t^M = \partial_x \left(\sum_{n=0}^{M+1} (\mathcal{W}_{(M)}^{nM} + A^n) \frac{\partial \mathbf{H}_{M+1}}{\partial A^n} - \mathbf{H}_{M+1} \right).$$

The conservation law of the energy is

$$\partial_t \mathbf{H}_{M+1} = \partial_x \left[\sum_{k=0}^{M+1} \sum_{n=0}^{M+1} \mathcal{W}_{(M)}^{kn} \frac{\partial \mathbf{H}_{M+1}}{\partial A^k} \frac{\partial \mathbf{H}_{M+1}}{\partial A^n} \right].$$

Remark: In the general case, the corresponding hydrodynamic chain is given by

$$A_t^k = \sum_{n=0}^{M+1} V_n^k(\mathbf{A}) A_x^n, \quad k = 0,1,\ldots,M-1, \quad A_t^k = \sum_{n=0}^{k+1} V_n^k(\mathbf{A}) A_x^n, \quad k = M, M+1, \ldots. \tag{16}$$

The case $M=0$ can be incorporated in the previous case. The corresponding Poisson bracket has a set of constraints (cf. the above case)

$$\mathcal{W}_{(0)}^{0k} = A^k, \quad k = 0,1,2,\ldots;$$

a corresponding hydrodynamic chain (for an arbitrary Hamiltonian density) possesses two conservation laws (of the energy and of the momentum, see the above formulas for $M=0$) only.

Conjecture: The hydrodynamic chain (14) determined by the Hamiltonian density $\mathbf{H}_{M+1}$ is *integrable* if it possesses an extra conservation law density $\mathbf{H}_{M+2}$. For instance, this statement is proved for integrable hydrodynamic chains associated with the Kupershmidt bracket (see Ref. 8) and with the Kupershmidt-Manin bracket (see Ref. 9).

2. If $M \leqslant -1$, then the corresponding Poisson brackets do not possess Casimirs and a momentum. Moreover, simplest hydrodynamic chains (14) determined by the *lowest* Hamiltonian $\bar{\mathbf{H}}_0 = \int \mathbf{H}_0(A^0)\mathrm{d}x$ contain $M_k = k+M$ elements in the rhs of Eq. (7).

Examples: The Kupershmidt hydrodynamic chains (see Ref. 13) possess an infinite set of local Hamiltonian structures determined by M brackets (9), where the first of them are (for the indices $M=0,1,2$, respectively; see Ref. 22)

$$\{C^k, C^n\} = [(\beta k+1)C^{k+n}D_x + (\beta n+1)D_x C^{k+n}]\delta(x-x'),$$

$$\{B^0, B^0\} = \beta\delta'(x-x'), \quad \{B^k, B^n\} = [(\beta k+1-\beta)B^{k+n-1}D_x + (\beta n+1-\beta)D_x B^{k+n-1}]\delta(x-x'),$$

$$\{A^0, A^1\} = \{A^1, A^0\} = \beta\delta'(x-x'), \quad \{A^1, A^1\} = (\beta-1)(A^0 D_x + D_x A^0)\delta(x-x'),$$

$$\{A^k,A^n\}=[(\beta k+1-2\beta)A^{k+n-2}D_x+(\beta n+1-2\beta)D_xA^{k+n-2}]\delta(x-x').$$

The first Poisson bracket is the well-known Kupershmidt bracket (12); two other Poisson brackets are new.

The most interesting class of these Poisson brackets is provided by *polynomial* (with respect to the moments A^k) coefficients $\mathcal{W}^{kn}_{(M)}$. The simplest case is given by the *linear* Poisson brackets determined by

$$\mathcal{W}^{kn}_{(M)}=e^{kn}_{(M)}A^{k+n-M},$$

where $e^{kn}_{(M)}$ are some constants satisfying the algebraic system [see Eq. (6)]

$$(e^{p,k+n-M}_{(M)}+e^{k+n-M,p}_{(M)})e^{nk}_{(M)}=(e^{k,n+p-M}_{(M)}+e^{n+p-M,k}_{(M)})e^{np}_{(M)},\quad e^{sp}_{(M)}e^{k,s+p-M}_{(M)}=e^{kp}_{(M)}e^{s,k+p-M}_{(M)},$$

possibly connected with an infinite dimensional analogue of the Frobenius algebras (see Ref. 1). Let us look for a particular solution in the form

$$e^{kn}_{(M)}=(Ak+Bn+C),$$

where A and B are some constants. The substitution of this ansatz in the above algebraic system yields the Kupershmidt brackets (see Ref. 13) determined by an arbitrary value A, but $B=0$. More general linear Poisson brackets

$$\mathcal{W}^{kn}_{(M)}=\sum_{s=0}^{k+n-M}e^{kn}_{(M)s}A^s$$

were considered by Dorfman in Ref. 4. For instance,

$$\{A^0,A^0\}=\varepsilon\delta'(x-x'),\quad \{A^k,A^n\}=\sum_{m=0}^{M}\gamma_m[kA^{m+k+n-1}D_x+nD_xA^{m+k+n-1}]\delta(x-x'),$$

where ε and γ_k are arbitrary constants.

Higher order homogeneous polynomials create more complicated Poisson brackets, which can be described by algebraic tools. For instance, the second nontrivial case is the *quadratic* Poisson brackets determined by

$$\mathcal{W}^{kn}_{(M)}(A^0,A^1,\ldots,A^{k+n-M})=\frac{1}{2}\sum_{m=0}^{k+n-M}e^{kn}_{(M)m}A^mA^{k+n-m-M},$$

where $e^{kn}_{(M)m}\equiv e^{kn}_{(M)k+n-m-M}$ are some constants, which can be found by a direct substitution in the nonlinear PDE system (13). The corresponding system of algebraic relations is very complicated and will be investigated in detail elsewhere.

III. FIRST EXAMPLE: $M=0$

We omit the subindex in all components $\mathcal{W}^{nk}_{(0)}$ of the Poisson bracket [see Eq. (9), $M=0$],

$$\{B^k,B^n\}=[\mathcal{W}^{kn}(B^0,B^1,\ldots,B^{k+n})D_x+D_x\mathcal{W}^{nk}(B^0,B^1,\ldots,B^{k+n})]\delta(x-x').$$

The nonlinear PDE system (13)

$$\sum_{m=0}^{n+k}(\mathcal{W}^{pm}+\mathcal{W}^{mp})\partial_m\mathcal{W}^{nk}=\sum_{m=0}^{n+p}(\mathcal{W}^{km}+\mathcal{W}^{mk})\partial_m\mathcal{W}^{np},$$

$$\sum_{m=0}^{n+k} \partial_m \mathcal{W}^{kn} \partial_s \mathcal{W}^{pm} = \sum_{m=0}^{n+p} \partial_m \mathcal{W}^{pn} \partial_s \mathcal{W}^{km}$$

is an overdetermined system describing a family of local Poisson brackets connected with the Hamiltonian hydrodynamic chains.

Let us write several first nonlinear PDEs from the nonlinear PDE system (13),

$$(\mathcal{W}^{10} + B^1)\partial_0 \mathcal{W}^{10} + 2\mathcal{W}^{11}\partial_1 \mathcal{W}^{10} = 2B^0 \partial_0 \mathcal{W}^{11} + (B^1 + \mathcal{W}^{10})\partial_1 \mathcal{W}^{11} + (B^2 + \mathcal{W}^{20})\partial_2 \mathcal{W}^{11},$$

$$\partial_1 \mathcal{W}^{10} \partial_0 \mathcal{W}^{21} = \partial_1 \mathcal{W}^{20} \partial_0 \mathcal{W}^{11} + \partial_2 \mathcal{W}^{20} \partial_0 \mathcal{W}^{12},$$

$$\partial_0 \mathcal{W}^{10} \partial_1 \mathcal{W}^{20} + \partial_1 \mathcal{W}^{10} \partial_1 \mathcal{W}^{21} = \partial_0 \mathcal{W}^{20} \partial_1 \mathcal{W}^{10} + \partial_1 \mathcal{W}^{20} \partial_1 \mathcal{W}^{11} + \partial_2 \mathcal{W}^{20} \partial_1 \mathcal{W}^{12},$$

$$\partial_0 \mathcal{W}^{10} \partial_2 \mathcal{W}^{20} + \partial_1 \mathcal{W}^{10} \partial_2 \mathcal{W}^{21} = \partial_1 \mathcal{W}^{20} \partial_2 \mathcal{W}^{11} + \partial_2 \mathcal{W}^{20} \partial_2 \mathcal{W}^{12},$$

$$\partial_1 \mathcal{W}^{10} \partial_3 \mathcal{W}^{21} = \partial_2 \mathcal{W}^{20} \partial_3 \mathcal{W}^{12},$$

where the auxiliary restrictions (normalization)

$$\mathcal{W}^{0k} \equiv B^k$$

are consequences of the existence of a conservation law of the momentum $\bar{\mathbf{H}}_0 = \int B^0 \mathrm{d}x$. This system involves just four first moments B^0, B^1, B^2, and B^3. It is enough to find coefficients $\mathcal{W}^{10}$, $\mathcal{W}^{11}$, and $\mathcal{W}^{20}$. For instance, $\mathcal{W}^{10}$ is a solution of the Monge-Ampere equation

$$(\mathcal{W}^{10})_{00}(\mathcal{W}^{10})_{11} - [(\mathcal{W}^{10})_{01}]^2 + \varphi'^2(B^0)[(\mathcal{W}^{10})_1]^2 = 0, \tag{17}$$

where $\varphi(B^0)$ is some function (determined from the compatibility conditions $[(\mathcal{W}^{11})_1]_2 = [(\mathcal{W}^{11})_2]_1$, $[(\mathcal{W}^{11})_1]_0 = [(\mathcal{W}^{11})_0]_1$, and $[(\mathcal{W}^{11})_0]_2 = [(\mathcal{W}^{11})_2]_0$; see expressions below), and each subindex k means the corresponding derivative with respect to the moment B^k. Moreover,

$$\mathcal{W}^{20} = B^2(\mathcal{W}^{10})_1 + G,$$

where $G(p,q)$ is a solution of the Euler-Darboux-Poisson equation

$$G_{pq} = \frac{\varphi''(B^0)}{4\varphi'^2(B^0)}(G_p - G_q), \quad \varphi(B^0) = \frac{1}{2}(p-q),$$

$$q = \ln[(\mathcal{W}^{10})_1] - \varphi(B^0), \quad p = \ln[(\mathcal{W}^{10})_1] + \varphi(B^0).$$

Explicit expressions for all other coefficients (depending on higher moments B^k, $k=3,4,5,\ldots$) can be found recursively in *complete* differentials. For instance, the equation

$$(\mathcal{W}^{11})_2 = \frac{2[(\mathcal{W}^{10})_1]^2(B^0(\mathcal{W}^{10})_{00} + (\mathcal{W}^{10} + B^1)(\mathcal{W}^{10})_{10} + \mathcal{W}^{11}(\mathcal{W}^{10})_{11})}{MB^2 + N},$$

where (now M stands for a function, while it had been used as an integer before)

$$M = [1 + (\mathcal{W}^{10})_1](\mathcal{W}^{10})_1(\mathcal{W}^{10})_{11} + 2B^0[(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{110} - (\mathcal{W}^{10})_{10}(\mathcal{W}^{10})_{11}]$$
$$+ (\mathcal{W}^{10} + B^1)[(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{111} - ((\mathcal{W}^{10})_{11})^2],$$

$$N = G(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{11} + 2B^0[G_{10}(\mathcal{W}^{10})_1 - G_1(\mathcal{W}^{10})_{10}] + [(\mathcal{W}^{10})_1 + B^1][G_{11}(\mathcal{W}^{10})_1 - G_1(\mathcal{W}^{10})_{11}],$$

can be solved up to some function of B^0 and B^1, which can be found in complete differentials by a substitution into other derivatives,

$$(\mathcal{W}^{11})_1 = (\mathcal{W}^{11})_2 \frac{[(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{111} - ((\mathcal{W}^{10})_{11})^2]B^2 + G_{11}(\mathcal{W}^{10})_1 - G_1(\mathcal{W}^{10})_{11}}{(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{11}} + K,$$

$$(\mathcal{W}^{11})_0 = (\mathcal{W}^{11})_2 \frac{[(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{110} - (\mathcal{W}^{10})_{10}(\mathcal{W}^{10})_{11}]B^2 + G_{10}(\mathcal{W}^{10})_1 - G_1(\mathcal{W}^{10})_{10}}{(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{11}} - L,$$

where

$$K = \frac{(\mathcal{W}^{10})_0(\mathcal{W}^{10})_{11} - 2(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{10}}{(\mathcal{W}^{10})_{11}}, \quad L = \frac{(\mathcal{W}^{10})_1(\mathcal{W}^{10})_{00}}{(\mathcal{W}^{10})_{11}}.$$

Remark: The Monge-Ampere equation (17) was derived in Ref. 9 in a classification of integrable hydrodynamic chains

$$\partial_t \mathbf{H}_0 = \partial_x F_{10}(\mathbf{H}_0, \mathbf{H}_1), \quad \partial_t \mathbf{H}_1 = \partial_x F_{11}(\mathbf{H}_0, \mathbf{H}_1, \mathbf{H}_2), \quad \partial_t \mathbf{H}_2 = \partial_x F_{12}(\mathbf{H}_0, \mathbf{H}_1, \mathbf{H}_2, \mathbf{H}_3), \ldots .$$

Thus, we have a good *indication* that these hydrodynamic chains are connected with the above local Hamiltonian structure (as well as *possibly* other M brackets; see the next section).

Integrable hydrodynamic chain (7) possesses an infinite set of commuting flows, where the first two of them,

$$B_t^k = [\mathcal{W}^{kn}(B^0, B^1, \ldots, B^{k+n})D_x + D_x\mathcal{W}^{nk}(B^0, B^1, \ldots, B^{k+n})]\frac{\delta \bar{\mathbf{H}}_1}{\delta B^n}, \tag{18}$$

$$B_y^k = [\mathcal{W}^{kn}(B^0, B^1, \ldots, B^{k+n})D_x + D_x\mathcal{W}^{nk}(B^0, B^1, \ldots, B^{k+n})]\frac{\delta \bar{\mathbf{H}}_2}{\delta B^n}, \tag{19}$$

are determined by the Hamiltonians $\bar{\mathbf{H}}_1 = \int \mathbf{H}_1(B^0, B^1)\mathrm{d}x$ and $\bar{\mathbf{H}}_2 = \int \mathbf{H}_2(B^0, B^1, B^2)\mathrm{d}x$.

Let us write the first two equations from Eq. (18) and the first equation from Eq. (19),

$$B_t^0 = (B^0 D_x + D_x B^0)\frac{\delta \bar{\mathbf{H}}_1}{\delta B^0} + [B^1 D_x + D_x \mathcal{W}^{10}(B^0, B^1)]\frac{\delta \bar{\mathbf{H}}_1}{\delta B^1},$$

$$B_t^1 = [\mathcal{W}^{10}(B^0, B^1)D_x + D_x B^1]\frac{\delta \bar{\mathbf{H}}_1}{\delta B^0} + [\mathcal{W}^{11}(B^0, B^1, B^2)D_x + D_x \mathcal{W}^{11}(B^0, B^1, B^2)]\frac{\delta \bar{\mathbf{H}}_1}{\delta B^1},$$

$$B_y^0 = (B^0 D_x + D_x B^0)\frac{\delta \bar{\mathbf{H}}_2}{\delta B^0} + [B^1 D_x + D_x \mathcal{W}^{10}(B^0, B^1)]\frac{\delta \bar{\mathbf{H}}_2}{\delta B^1} + [B^2 D_x + D_x \mathcal{W}^{20}(B^0, B^1, B^2)]\frac{\delta \bar{\mathbf{H}}_2}{\delta B^2}.$$

These three equations can be written in the conservative form

$$\partial_t \mathbf{H}_0 = \partial_x F_{10}(\mathbf{H}_0, \mathbf{H}_1), \quad \partial_t \mathbf{H}_1 = \partial_x F_{11}(\mathbf{H}_0, \mathbf{H}_1, \mathbf{H}_2), \quad \partial_y \mathbf{H}_0 = \partial_x F_{20}(\mathbf{H}_0, \mathbf{H}_1, \mathbf{H}_2),$$

where

$$F_{10}(\mathbf{H}_0, \mathbf{H}_1) = 2B^0\frac{\partial \mathbf{H}_1}{\partial B^0} + (\mathcal{W}^{10} + B^1)\frac{\partial \mathbf{H}_1}{\partial B^1} - \mathbf{H}_1,$$

$$F_{11}(\mathbf{H}_0,\mathbf{H}_1,\mathbf{H}_2)=B^0\left(\frac{\partial \mathbf{H}_1}{\partial B^0}\right)^2+(\mathcal{W}^{10}+B^1)\frac{\partial \mathbf{H}_1}{\partial B^0}\frac{\partial \mathbf{H}_1}{\partial B^1}+\mathcal{W}^{11}\left(\frac{\partial \mathbf{H}_1}{\partial B^1}\right)^2,$$

$$F_{20}(\mathbf{H}_0,\mathbf{H}_1,\mathbf{H}_2)=2B^0\frac{\partial \mathbf{H}_2}{\partial B^0}+(\mathcal{W}^{10}+B^1)\frac{\partial \mathbf{H}_2}{\partial B^1}+(\mathcal{W}^{20}+B^2)\frac{\partial \mathbf{H}_2}{\partial B^2}-\mathbf{H}_2.$$

Let us introduce the potential function z, where $\mathbf{H}_0=z_x$, $F_{10}(\mathbf{H}_0,\mathbf{H}_1)=z_t$, and $F_{20}(\mathbf{H}_0,\mathbf{H}_1,\mathbf{H}_2)=z_y$. Then one can substitute $\mathbf{H}_1(z_x,z_t)$ and $\mathbf{H}_2(z_x,z_t,z_y)$ into the second equation,

$$\partial_t \mathbf{H}_1(z_x,z_t)=\partial_x F_{11}(z_x,\mathbf{H}_1(z_x,z_t),\mathbf{H}_2(z_x,z_t,z_y)).$$

This 2+1 quasilinear equation of the second order is integrable by the method of hydrodynamic reductions[7] (or by introducing pseudopotentials; see Refs. 7 and 26). The Hamiltonian structure of this equation is unknown, while the Hamiltonian structure of corresponding hydrodynamic chains (18) and (19) is defined.

IV. SECOND EXAMPLE: *M*=1

We omit the subindex in all components $\mathcal{W}^{nk}_{(1)}$ of the Poisson bracket [see Eq. (9), $M=1$]

$$\{A^k,A^n\}=[\mathcal{W}^{kn}(A^0,A^1,\ldots,A^{k+n-1})D_x+D_x\mathcal{W}^{nk}(A^0,A^1,\ldots,A^{k+n-1})]\delta(x-x').$$

The nonlinear PDE system (13)

$$\sum_{m=0}^{n+k-1}(\mathcal{W}^{pm}+\mathcal{W}^{mp})\partial_m\mathcal{W}^{nk}=\sum_{m=0}^{n+p-1}(\mathcal{W}^{km}+\mathcal{W}^{mk})\partial_m\mathcal{W}^{np},$$

$$\sum_{m=0}^{n+k-1}\partial_m\mathcal{W}^{kn}\partial_s\mathcal{W}^{pm}=\sum_{m=0}^{n+p-1}\partial_m\mathcal{W}^{pn}\partial_s\mathcal{W}^{km}$$

is an overdetermined system describing a family of local Poisson brackets connected with Hamiltonian hydrodynamic chains.

Let us write several first nonlinear PDEs from the nonlinear PDE system (13),

$$[2\varepsilon\partial_0+A^0\partial_1+\mathcal{W}^{20}\partial_2]\mathcal{W}^{21}=[A^0\partial_0+2A^1\partial_1]\mathcal{W}^{20},$$

$$\partial_1\mathcal{W}^{20}\partial_0\mathcal{W}^{31}=\partial_1\mathcal{W}^{30}\partial_0\mathcal{W}^{21}+\partial_2\mathcal{W}^{30}\partial_0\mathcal{W}^{22},$$

$$\partial_0\mathcal{W}^{30}\partial_1\mathcal{W}^{20}+\partial_1\mathcal{W}^{30}\partial_1\mathcal{W}^{21}+\partial_2\mathcal{W}^{30}\partial_1\mathcal{W}^{22}=\partial_0\mathcal{W}^{20}\partial_1\mathcal{W}^{30}+\partial_1\mathcal{W}^{20}\partial_1\mathcal{W}^{31},$$

$$\partial_0\mathcal{W}^{20}\partial_2\mathcal{W}^{30}+\partial_1\mathcal{W}^{20}\partial_2\mathcal{W}^{31}=\partial_1\mathcal{W}^{30}\partial_2\mathcal{W}^{21}+\partial_2\mathcal{W}^{30}\partial_2\mathcal{W}^{22},$$

$$\partial_1\mathcal{W}^{20}\partial_3\mathcal{W}^{31}=\partial_2\mathcal{W}^{30}\partial_3\mathcal{W}^{22},$$

where the auxiliary restrictions (normalization)

$$\mathcal{W}^{0k}(A^0,A^1,\ldots,A^{k-1})\equiv\bar{\mathcal{W}}^{00}\delta^{0k},\quad \mathcal{W}^{1k}(A^0,A^1,\ldots,A^k)\equiv A^k$$

($\bar{\mathcal{W}}^{00}=\varepsilon=$const and δ^{ik} is the Kronecker symbol) are consequences of the existence of conservation laws associated with the Casimir $\bar{\mathbf{H}}_0=\int A^0\mathrm{d}x$ and to the momentum $\bar{\mathbf{H}}_1=\int A^1\mathrm{d}x$.

This system involves just four moments A^0, A^1, A^2, and A^3. It is enough to find coefficients $\mathcal{W}^{20}$, $\mathcal{W}^{21}$, and $\mathcal{W}^{30}$. For instance, $\mathcal{W}^{20}$ is a solution of the Monge-Ampere equation [see Eq. (17)]

$$(\mathcal{W}^{20})_{00}(\mathcal{W}^{20})_{11}-[(\mathcal{W}^{20})_{01}]^2+\varphi'^2(A^0)[(\mathcal{W}^{20})_1]^2=0,$$

where $\varphi(A^0)$ is some function (determined from the compatibility conditions $[(\mathcal{W}^{21})_1]_2=[(\mathcal{W}^{21})_2]_1$, $[(\mathcal{W}^{21})_1]_0=[(\mathcal{W}^{21})_0]_1$, $[(\mathcal{W}^{21})_0]_2=[(\mathcal{W}^{21})_2]_0$; see the expressions below). Moreover,

$$\mathcal{W}^{30}=A^2(\mathcal{W}^{20})_1+G,$$

where $G(p,q)$ is a solution of the Euler-Darboux-Poisson equation

$$G_{pq}=\frac{\varphi''(A^0)}{4\varphi'^2(A^0)}(G_p-G_q),\quad \varphi(A^0)=\frac{1}{2}(p-q),$$

$$q=\ln[(\mathcal{W}^{20})_1]-\varphi(A^0),\quad p=\ln[(\mathcal{W}^{20})_1]+\varphi(A^0).$$

Explicit expressions for all other coefficients (depending on higher moments A^k, $k=3,4,5,\ldots$) can be found recursively in complete differentials. For instance,

$$\mathrm{d}\mathcal{W}^{21}=(\mathcal{W}^{21})_0\mathrm{d}A^0+(\mathcal{W}^{21})_1\mathrm{d}A^1+(\mathcal{W}^{21})_2\mathrm{d}A^2,$$

where

$$(\mathcal{W}^{21})_2=\frac{2[A^1(\mathcal{W}^{20})_{11}+A^0(\mathcal{W}^{20})_{10}+\varepsilon(\mathcal{W}^{20})_{00}]}{2\varepsilon(((\mathcal{W}^{20})_{11}A^2+G_1)/(\mathcal{W}^{20})_1)_0+A^0(((\mathcal{W}^{20})_{11}A^2+G_1)/(\mathcal{W}^{20})_1)_1+(\mathcal{W}^{20})(\mathcal{W}^{20})_{11}/(\mathcal{W}^{20})_1},$$

$$(\mathcal{W}^{21})_1=\frac{(\mathcal{W}^{20})_1}{(\mathcal{W}^{20})_{11}}\left(\frac{(\mathcal{W}^{20})_{11}A^2+G_1}{(\mathcal{W}^{20})_1}\right)_1(\mathcal{W}^{21})_2+(\mathcal{W}^{20})_0-2\frac{(\mathcal{W}^{20})_1(\mathcal{W}^{20})_{10}}{(\mathcal{W}^{20})_{11}},$$

$$(\mathcal{W}^{21})_0=\frac{(\mathcal{W}^{20})_1}{(\mathcal{W}^{20})_{11}}\left(\frac{(\mathcal{W}^{20})_{11}A^2+G_1}{(\mathcal{W}^{20})_1}\right)_0(\mathcal{W}^{21})_2-\frac{(\mathcal{W}^{20})_1(\mathcal{W}^{20})_{00}}{(\mathcal{W}^{20})_{11}}.$$

Remark: The coincidence of the coefficients $\mathcal{W}^{20}$ from this section and $\mathcal{W}^{10}$ from the previous section is easy to understand if one takes into account that if the Hamiltonian density $\mathbf{H}_2$ is a function of the moments A^1 and A^2 only, then the corresponding hydrodynamic chain possesses the Hamiltonian structure coinciding (due to the "shift" $A^k\to B^{k-1}$, $k=1,2,\ldots$) with the Hamiltonian structure presented in the previous section.

All other M brackets (10) can be investigated in the same way using the Jacobi identity (6).

V. THE MIURA-TYPE TRANSFORMATIONS

The approach presented in this paper is very effective: the nonlinear PDE system (6) can be integrated iteratively for M brackets. However, the Liouville coordinates A^k are very *flexible*. It means that coefficients $\mathcal{W}^{ik}_{(M)}$ can be found up to invertible transformations $\widetilde{A}^k(A^0,A^1,\ldots,A^k)$ preserving the Jacobi identity (6). For instance, the Benney hydrodynamic chain [see Eq. (11)]

$$A^k_t=A^{k+1}_x+kA^{k-1}A^0_x=[kA^{k+n-1}D_x+nD_xA^{k+n-1}]\frac{\partial\mathbf{H}_2}{\partial A^n},\quad k=0,1,2,\ldots$$

can be written via another set of the Liouville coordinates $\mathbf{H}_k$ in the conservative form

$$\partial_t\mathbf{H}_k=\partial_x\left(\mathbf{H}_{k+1}-\frac{1}{2}\sum_{m=0}^{k-1}\mathbf{H}_m\mathbf{H}_{k-1-m}\right),\quad k=0,1,2,\ldots\ .$$

The invertible transformation $\mathbf{H}_k(\mathbf{A})$ is very complicated because corresponding coefficients can be found (see, e.g., Ref. 14) by a substitution of the series

$$\lambda = \mu + \frac{A^0}{\mu} + \frac{A^1}{\mu^2} + \frac{A^2}{\mu^3} + \cdots \tag{20}$$

into another series

$$\mu = \lambda - \frac{\mathbf{H}_0}{\lambda} - \frac{\mathbf{H}_1}{\lambda^2} - \frac{\mathbf{H}_2}{\lambda^3} - \cdots .$$

Then, the Poisson bracket (11) expressed via conservation law densities $\mathbf{H}_k$

$$\{\mathbf{H}_i, \mathbf{H}_k\} = [\mathcal{W}^{ik}_{(1)}(\mathbf{H})D_x + D_x\mathcal{W}^{ki}_{(1)}(\mathbf{H})]\delta(x-x')$$

looks ugly. Thus, one of the main problems appearing in a classification of Poisson brackets is a choice of such Liouville coordinates, where coefficients $\mathcal{W}^{ik}$ became most simple.

Suppose two Hamiltonian hydrodynamic chains [see Eq. (7)]

$$B^k_t = \sum_{n=0}^{N_k} F^k_n(\mathbf{B})B^n_x, \quad A^k_t = \sum_{m=0}^{M_k} Q^k_n(\mathbf{A})A^n_x, \quad k = 1,2,\ldots, \tag{21}$$

where N_k and M_k are some integers, are related by the Miura-type transformations

$$A^k = A^k(B^0, B^1, \ldots, B^{k+1}), \quad k = 0,1,2,\ldots . \tag{22}$$

Example: The Benney hydrodynamic chain [see Eq. (11); see also Refs. 2 and 14] is connected with the modified Benney hydrodynamic chain (see Ref. 24, the particular case of the Kupershmidt hydrodynamic chains)[13]

$$B^k_t = B^{k+1}_x + B^0B^k_x + (k+2)B^kB^0_x = [(k+1)B^{k+n}D_x + (n+1)D_xB^{k+n}]\frac{\partial \mathbf{H}_0}{\partial B^n},$$

where the Hamiltonian density $\mathbf{H}_0 = B^1 + (B^0)^2$, by the Miura-type transformations (22), which can be obtained by comparing the two series (see Ref. 23)

$$\lambda = p^{-1} - \sum_{k=0}^{\infty} \frac{B^k}{p^{k+2}} \equiv \left(p + B^0 + \sum_{k=0}^{\infty} \frac{A^k}{(p+B^0)^{k+1}}\right)^{-1},$$

where the generating function of the Miura-type transformations is given by $\mu = p + B^0$ [cf. the rhs of the above expression and Eq. (20)]. For instance,

$$A^0 = B^1 + (B^0)^2, \quad A^1 = B^2 + 3B^0B^1 + 2(B^0)^3, \ldots .$$

This Poisson bracket (of the modified Benney hydrodynamic chain)

$$\{B^k, B^n\}_1 = [(k+1)B^{k+n}D_x + (n+1)D_xB^{k+n}]\delta(x-x')$$

can be used for a construction of the first local Poisson bracket [see Eq. (4)]

$$\{A^i, A^j\}_1 = \frac{\partial A^i}{\partial B^k}\{B^k, B^n\}_1\frac{\partial A^j}{\partial B^n}. \tag{23}$$

However, corresponding coefficients $\mathcal{W}^{ik}$ are very complicated.

Thus, the Miura-type transformations can be used for a *simplification* of Poisson brackets. Indeed, let us consider a general case for M brackets.

Suppose the first hydrodynamic chain in Eq. (21) possesses the local Poisson bracket (4)

$$\{B^k, B^n\} = [G^{kn}_{(M)}(\mathbf{B})D_x + \Gamma^{kn}_{(M)m}(\mathbf{B})B^m_x]\delta(x-x'). \tag{24}$$

Then the second hydrodynamic chain in Eq. (21) also possesses another local Poisson bracket

$$\{A^i,A^j\}=[G^{ij}_{(L)}(\mathbf{A})D_x+\Gamma^{ij}_{(L)m}(\mathbf{A})A^m_x]\delta(x-x') \tag{25}$$

connected with Eq. (24) by Eq. (22) [see Eq. (23)].

Theorem: *If the Poisson brackets (24) and (25) are related by the above Miura-type transformations (22) then* $L=M-1$.

Proof: Without loss of generality let us restrict the calculation just for the metric coefficients

$$G^{ij}_{(L)}(\mathbf{A})=\sum_{k=0}^{i+1}\sum_{n=0}^{j+1}\frac{\partial A^i}{\partial B^k}G^{kn}_{(M)}(\mathbf{B})\frac{\partial A^j}{\partial B^n},\quad i+j>M.$$

Taking into account the *highest order* dependence on the moments B^n these metric coefficients,

$$G^{ij}_{(L)}(\mathbf{A})\sim\frac{\partial A^i}{\partial B^{i+1}}G^{i+1,j+1}_{(M)}(\mathbf{B})\frac{\partial A^j}{\partial B^{j+1}},$$

depend on $B^{i+j+2-M}$ (in a highest order), i.e., $G^{ij}_{(L)}(\mathbf{A})$ could not depend on moments higher than $A^{i+j+1-M}$. Thus, indeed, $L=M-1$.

Corollary: The Miura-type transformations (22) decrease the number of moments involved in metric coefficients and increase the number of Casimirs and a size of a triangular constant block $\bar{\mathcal{W}}^{kn}_{(M)}$ [see Eq. (15)]. It means that the following diagram exists:

$$\begin{aligned}
\{A^k,A^n\} &= [G^{kn}_{(M)}(A^0,\ldots,A^{k+n-M})D_x+\cdots]\delta(x-x'),\\
&\downarrow\\
\{B^k,B^n\} &= [G^{kn}_{(M+1)}(B^0,\ldots,B^{k+n-M-1})D_x+\cdots]\delta(x-x'),\\
&\downarrow\\
\{C^k,C^n\} &= [G^{kn}_{(M+2)}(C^0,\ldots,C^{k+n-M-2})D_x+\cdots]\delta(x-x'),\\
&\downarrow\\
&\ldots.
\end{aligned}$$

Thus, invertible transformations can be used to reduce the Poisson bracket to the most simple dependence on a given set of moments A^k, while the Miura-type transformations can be used to reduce Poisson brackets to a decreased set of new moments B^n.

Remark: In the theory of dispersive integrable systems the Miura transformation is a tool to reduce the Hamiltonian structure to the canonical form "D_x" (the infinitely many component analogue of the Darboux theorem; see Refs. 19 and 20). Indeed, a constant triangular block $\bar{\mathcal{W}}^{kn}_{(M)}$ is an analogue of constant matrix g^{kn} of the canonical Hamiltonian operator $g^{kn}D_x$ (see Ref. 5). This constant triangular block $\bar{\mathcal{W}}^{kn}_{(M)}$ increases under the Miura-type transformations (22), because the metric coefficients $G^{kn}_{(M)}$ must be constants for $k+n<M$. It means, if $\bar{\mathcal{W}}^{kn}_{(M)}\to\bar{\mathcal{W}}^{kn}_{(M+1)}$ (see the above diagram), then the new constant triangular block is determined by $k+n<M+1$.

Conjecture: Possibly, the number of such Miura-type transformations is infinite, and any local Hamiltonian structure with the index $-M$ can be reduced to a local Hamiltonian structure with an arbitrary index N.

VI. NONLOCAL HAMILTONIAN STRUCTURES

The nonlocal Poisson brackets [see Eq. (2)]

$$\{U^i,U^j\}=[G^{ij}(\mathbf{U})D_x+\Gamma^{ij}_k(\mathbf{U})U^k_x+\varepsilon U^i_xD_x^{-1}U^j_x]\delta(x-x')$$

for N component case were completely investigated by Ferapontov and Mokhov in Ref. 10 for the nondegenerate matrix G^{ij}; the degenerate case was considered by Mokhov in Ref. 17. The skew-symmetry property and the Jacobi identity lead to the set of restrictions

$$G^{ij}=G^{ji},\quad \partial_k G^{ij}=\Gamma_k^{ij}+\Gamma_k^{ji},\quad G^{ik}\Gamma_k^{jn}=G^{jk}\Gamma_k^{in},$$

$$\varepsilon(G^{im}\delta_k^j-G^{ij}\delta_k^m)=\Gamma_n^{ij}\Gamma_k^{nm}-\Gamma_n^{im}\Gamma_k^{nj}+G^{in}(\partial_n\Gamma_k^{mj}-\partial_k\Gamma_n^{mj}),$$

$$\begin{aligned}-\varepsilon[(\Gamma_k^{ij}-\Gamma_k^{ji})\delta_p^m+(\Gamma_k^{mi}-\Gamma_k^{im})\delta_p^j+(\Gamma_k^{jm}-\Gamma_k^{mj})\delta_p^i+(\Gamma_p^{ij}-\Gamma_p^{ji})\delta_k^m+(\Gamma_p^{mi}-\Gamma_p^{im})\delta_k^j+(\Gamma_p^{jm}-\Gamma_p^{mj})\delta_k^i]\\ =(\partial_n\Gamma_k^{ij}-\partial_k\Gamma_n^{ij})\Gamma_p^{nm}+(\partial_n\Gamma_k^{mi}-\partial_k\Gamma_n^{mi})\Gamma_p^{nj}+(\partial_n\Gamma_k^{jm}-\partial_k\Gamma_n^{jm})\Gamma_p^{ni}+(\partial_n\Gamma_p^{ij}-\partial_p\Gamma_n^{ij})\Gamma_k^{nm}+(\partial_n\Gamma_p^{mi}\\ -\partial_p\Gamma_n^{mi})\Gamma_k^{nj}+(\partial_n\Gamma_p^{jm}-\partial_p\Gamma_n^{jm})\Gamma_k^{ni},\end{aligned}$$

which simplify to the Jacobi identity [see Eq. (6)]

$$(\mathcal{W}^{in}+\mathcal{W}^{ni}-\varepsilon A^iA^n)\partial_n\mathcal{W}^{kj}=(\mathcal{W}^{jn}+\mathcal{W}^{nj}-\varepsilon A^jA^n)\partial_n\mathcal{W}^{ki},$$

$$\partial_n\mathcal{W}^{ij}\partial_m\mathcal{W}^{kn}=\partial_n\mathcal{W}^{kj}\partial_m\mathcal{W}^{in} \tag{26}$$

written in the Liouville coordinates $A^i=A^i(\mathbf{U})$, where (see Refs. 15 and 17)

$$G^{ij}=\mathcal{W}^{ij}+\mathcal{W}^{ji}-\varepsilon A^iA^j,\quad \Gamma_k^{ij}=\partial_k\mathcal{W}^{ji}-\varepsilon\delta_k^iA^j.$$

Thus, the nonlocal Poisson bracket in the Liouville coordinates has the form

$$\{A^i,A^j\}=[\mathcal{W}^{ij}D_x+D_x\mathcal{W}^{ji}-\varepsilon A^jD_xA^i+\varepsilon A_x^iD_x^{-1}A_x^j]\delta(x-x'),\quad i,j=0,1,\ldots\ .$$

Similar classification of these nonlocal Poisson brackets [see Eq. (26)] shall be made elsewhere.

Remark: More general Poisson brackets have been introduced by Ferapontov (see Ref. 6) for N component nondegenerate case. Such Poisson brackets in the Liouville coordinates are given by (see Ref. 18)

$$\begin{aligned}\{A^k,A^n\}=[(\Phi^{kn}+\Phi^{nk}-\varepsilon_{pq}\Psi^{(p)k}\Psi^{(q)n})D_x+(\partial_m\Phi^{nk}-\varepsilon_{pq}\Psi^{(q)n}\partial_m\Psi^{(p)k})A_x^m\\ +\varepsilon_{pq}\partial_m\Psi^{(p)k}A_x^mD_x^{-1}\partial_s\Psi^{(q)n}A_x^s]\delta(x-x'),\end{aligned}$$

where the constant $L\times L$ matrix ε_{pq} is symmetric and nondegenerate (L is "codimension" of the pseudo-Riemannian space), and $\Phi^{kn}(\mathbf{A})$ and $\Psi^{(p)k}(\mathbf{A})$ are determined by nonlinear PDE system similar to Eq. (6).

Remark: Any nonlocal Hamiltonian structure of Ferapontov type can be reduced to local Hamiltonian structure of Dubrovin-Novikov type by an appropriate generalized reciprocal transformation (see Ref. 11). Thus, possibly the same result is valid for infinite component case.

VII. CONCLUSION AND OUTLOOK

The so-called Haantjes tensor approach is very effective (see Ref. 9) in a classification of integrable *Hamiltonian* hydrodynamic chains (7). In general case, if the discrete function $M(\mathbf{k})$ is given *a priori*, then all coefficients $V_m^k(\mathbf{U})$ can be found iteratively. In the Hamiltonian case, these coefficients can be found simultaneously (because a Hamiltonian density and a Poisson bracket are given).

In this paper, a concept of the so-called M brackets was introduced. In this case, a discrete function $M(\mathbf{k})$ is determined explicitly by the comparison of Eq. (7) with Eq. (8) [see, e.g., Eq. (16)].

Suppose the classification of M brackets

$$\{A^k,A^n\}=[\mathcal{W}^{kn}(A^0,\ldots,A^{k+n-M})D_x+D_x\mathcal{W}^{nk}(A^0,\ldots,A^{k+n-M})]\delta(x-x'),\quad k,n=0,1,2,\ldots$$

is complete. Corresponding Hamiltonian hydrodynamic chains (8) are determined by the above Poisson brackets and some Hamiltonian densities. Then integrable Hamiltonian hydrodynamic chains can be extracted by the Haantjes tensor approach (see Ref. 9), i.e., Hamiltonian densities in

the "integrable" case must satisfy some nonlinear PDE system associated with the above Poisson brackets.

Thus, the classification of M brackets is a first step in the classification of integrable Hamiltonian hydrodynamic chains (8).

ACKNOWLEDGMENTS

I would like to thank Gennady El, Eugeni Ferapontov, Boris Kupershmidt, Andrey Maltsev, Oleg Mokhov, and Sergey Tsarev for their suggestions significantly improving my results and their presentation in this paper. I am grateful to the Institute of Mathematics in Taipei (Taiwan) where a part of this work has been done and especially to Jen-Hsu Chang, Jyh-Hao Lee, Ming-Hien Tu, and Derchyi Wu for fruitful discussions.

(Received 22 September 2006; accepted 30 October 2006; published online 29 December 2006)

Theoretical background of continuous contractions of finite-dimensional Lie algebras is rigorously formulated and developed. In particular, known necessary criteria of contractions are collected and new criteria are proposed. A number of requisite invariant and semi-invariant quantities are calculated for wide classes of Lie algebras including all low-dimensional Lie algebras. An algorithm that allows one to handle one-parametric contractions is presented and applied to low-dimensional Lie algebras. As a result, all one-parametric continuous contractions for both the complex and real Lie algebras of dimensions not greater than 4 are constructed with intensive usage of necessary criteria of contractions and with studying correspondence between real and complex cases. Levels and colevels of low-dimensional Lie algebras are discussed in detail. Properties of multiparametric and repeated contractions are also investigated. © *2006 American Institute of Physics.*

I. INTRODUCTION

Limiting processes between Lie algebras were first investigated by Segal.[69] The most known example concerning these processes is given by connection between relativistic and classical mechanics with their underling Poincaré and Galilean symmetry groups. If the velocity of light is assumed to go to infinity, relativistic mechanics "transforms" into classical mechanics. This also induces a singular transition from the Poincaré algebra to the Galilean one. The other well-known example is a limit process from quantum mechanics to classical mechanics under $\hbar \to 0$, which corresponds to the contraction of the Heisenberg algebras to the Abelian ones of the same dimensions.

Existing works on contractions can be conditionally divided into two main streams which are scarcely connected with each other. One of them is more "physical" and is mainly oriented to applications of contractions. The other one is more "algebraic" and usually has better mathematical background. Let us simultaneously survey works on the main types of contractions existing in the frameworks of both approaches.

After Segal, the concept of limiting processes between physical theories in terms of contractions of the underling symmetry groups was also formulated by Inönü and Wigner.[41,42] They introduced so-called *Inönü-Wigner contractions* (*IW-contractions*) which, in spite of their simplicity, were effectively applied to a wide range of physical and mathematical problems. Later Saletan[67] studied the most general class of one-parametric contractions for which the elements of the corresponding matrices are first-order polynomials with respect to the contraction parameter.

[a)]Electronic mail: maryna@imath.kiev.ua
[b)]Electronic mail: rop@imath.kiev.ua

Inönü-Wigner contractions obviously form a special subclass in the class of *Saletan contractions*.

Another extension of the class of Inönü-Wigner contractions is given by *generalized Inönü-Wigner contractions*. They are generated by matrices which become diagonal after suitable choices of bases of initial and contracted algebras, and, moreover, diagonal elements should be integer powers of the contraction parameters. Contractions of this kind were introduced by Doebner and Melsheimer.[21] To the best of our knowledge, the name "generalized Inönü-Wigner contractions" first appear in Ref. 34 The other names (p-contractions, Doebner-Melsheimer contractions, and singular IW-contractions[51]) are also used. Similar contractions are applied in the "purely mathematical" framework and called *one-parametric subgroup degenerations*.[7–9,32,71] The last name came from the algebraic invariant theory.[46] Generalized IW contractions are very useful for applications and were revisited many times. In particular, it was incorrectly conjectured that any continuous one-parametric contraction is equivalent to a generalized Inönü-Wigner contraction.

A general definition of contractions was first formulated by Segal[69] in terms of limiting processes of bases. It is used as an operational definition for calculations up to now. Saletan[67] gave a more rigorous general definition of contractions, which is based on limiting processes of Lie brackets and allows one to avoid a confusion with limit state of bases, existing in the Segal approach. Saletan's definition was generalized for the case of arbitrary field in terms of Lie algebra orbit closures with respect to Zariski topology. The generalization is a basis of modern investigation on contractions and was used by a number of authors, e.g., Refs. 7–9, 12, 32, 45, 47, 57, 68, and 71. The name *degeneration* is often used instead of the name *contraction* in the generalized context.

A still more general notion of degenerations, which works in the case of algebras of different dimensions, was proposed in Refs. 27–29. The algebra $\mathfrak{g}$ degenerates to the algebra $\mathfrak{g}_0$ according to Gorbatsevich if $\mathfrak{g}\oplus pA_1$ is contracted to $\mathfrak{g}_0\oplus qA_1$ in the usual sense for some $p,q\in\mathbb{N}\cup\{0\}$, where pA_1 and qA_1 are the p- and q-dimensional Abelian algebras.

The other type of contractions is given by the purely algebraic notion of *graded contractions*.[16,18,33,38,60,77] The graded contraction procedure is the following. Structure constants of a graded Lie algebra are multiplied by numbers which are chosen in such a way that the multiplied structure constants give a Lie algebra with the same grading. Graded contractions include discrete contractions as a subcase but do not cover all continuous ones.

Different kinds of contractions and their properties were reviewed and compared in Ref. 51. The interrelations between contractions and deformations or expansions were widely investigated.[23,25,31,50–52] The related but principally different problem is given by contractions of Lie groups, which are also widely studied and applied. Notions of such contractions were introduced in Refs. 6, 35, 53, and 67 with different levels of generality.

Problems concerning contractions of Lie algebra (or group) representations and simultaneous contractions of Lie algebras or Lie groups and their representations are also important and demand a special technique which differs from the techniques associated with pure contractions of Lie algebras and Lie groups. In spite of existing works on the subject and a range of applications, these problems are not studied enough although a number of interesting results have been obtained. For example, the contractions of representations of de Sitter groups were described in Ref. 53. Contractions of matrix representations of concrete physically significant Lie algebras were investigated, e.g., in Refs. 19, 58, and 75. Related theoretical inventions and different examples of application can also be found in Refs. 14, 36, 40, 42, 48, 49, 51, 54, and 60 and in the references therein.

Intensive investigation of real and complex low-dimensional Lie algebras in last decades is motivated by a number of causes. As subalgebras of important higher-dimensional Lie algebras, these algebras are widely applied in the theory of induced representations (representations of subalgebras/subgroups are used to construct representations of the whole algebra/group), in the representation theory (chains of subalgebras can provide sets of commuting operators, eigenfunctions of which form bases of representation spaces for the corresponding Lie group), and in study of broken symmetries. Low-dimensional Lie algebras are also interesting *per se* and supply theoretical consideration with substantial examples. In this connection classifications, subalgebras,

realizations, invariants, contractions, deformations, and other objects concerning low-dimensional Lie algebras were studied.[5,22,24,50,55,61,65]

Contractions of low-dimensional Lie algebras naturally appeared as illustrating examples in a number of papers. Thus, in the pioneer paper on contractions[69] Segal adduced two such contractions, namely, the contractions from so(3) and $\mathrm{sl}(2,\mathbb{R})$ to the Weyl-Heisenberg algebra $\mathfrak{h}_3=A_{3.1}$. Some examples are contained also in the known paper by Saletan.[67] Afterwards contractions of low-dimensional Lie algebras became independent subject of investigation. Inönü-Wigner contractions of real three-dimensional Lie algebras were considered[70] but some cases were missed. These results were partially amended in Ref. 51. First Inönü-Wigner contractions of real three-dimensional Lie algebras were exhaustively described by Conatser.[15] Using the known classification of subalgebras of real low-dimensional Lie algebras,[61] Huddleston[39] constructed Inönü-Wigner contractions of the four-dimensional real Lie algebras. All inequivalent continuous one-parametric contractions of real three-dimensional Lie algebras were obtained in Ref. 78 but contractions inside parametrized series of algebras were not discussed. The same problem was nicely solved by Lauret[47] in terms of orbit closures using a nonevident connection between algebraic characterization of Lie groups having metrics with special curvature properties and existence of degenerations for Lie algebras. Orbit closures of complex three- and four-dimensional Lie algebras were studied in Refs. 8, 9, and 71. It is the works from which we adopted the fruitful idea on usage of a wide set of necessary contraction criteria. The same subject was also investigated in Refs. 1 and 2. In these papers obtained results were presented in a very simple and clear form due to special improvement of classification of complex three- and four-dimensional Lie algebras.

Complexity of description of algebra orbit closures is exponentially increased under growing dimension of the underlying vector space. A possible ways of simplification is to consider a closed subclass of Lie algebras (e.g., nilpotent algebras) instead of the whole class of Lie algebras of a fixed dimension. Degenerations of nilpotent algebras were studied in Ref. 32, Ref. 68, and Refs. 7 and 8 in the case of dimensions five, six, and seven, correspondingly.

Deformations of low-dimensional Lie algebras are also treated intensively. Thus, deformations of three-dimensional real Lie algebras were described in Ref. 50. The four-dimensional case was completely studied over the complex field.[24] There also exist a number of papers on contractions and deformations of higher- or even infinite-dimensional Lie algebras (see, e.g., Ref. 17). Since this subject is out of the scope of our paper, we do not review it here in detail.

Investigation of contractions is motivated by numerous applications in different fields of physics and mathematics, e.g., in study of representations, invariants, and special functions.[10,19,54] It is one of the tools to recognize structure of Lie algebra varieties.[8] The Wigner coefficients of the Euclidean group E(3) were constructed with contracting the Wigner coefficients of the special orthogonal group SO(4).[37] Contractions were used to establish connection between various kinematical groups and to shed a light on their physical meaning. In this way relationship between the conformal and Schrödinger groups was elucidated[3] and various Lie algebras including a relativistic position operator were interrelated. Under dynamical group description of interacting systems, contractions corresponding to the coupling constant going to zero give noninteracting systems.[20] Application of contractions allows to derive interesting results in the special function theory and on the variable separation method.[36,43,64]

Contractions of low-dimensional Lie algebras also play an important role from the physical point of view.[26] It is illustrated by the following simple examples which are related to physics. We use the standard physical notations and numeration by Mubarakzyanov[55] simultaneously. Hereafter, describing a Lie algebra, we adduce only the nonzero commutators of fixed basis elements. See Sec. VIII for notations and more examples.

The four-dimensional Lie algebra $\mathrm{u}(2)=\mathrm{sl}(2,\mathbb{R})\oplus A_1$ has the nonzero commutation relations $[e_1,e_2]=e_1$, $[e_2,e_3]=e_3$, and $[e_1,e_3]=2e_2$. The matrix $U_1(\varepsilon)=I_{10}\,\mathrm{diag}(\varepsilon,\varepsilon,1,1)$ provides a contraction of $u(2)$ to the algebra $e(2)\oplus A_1=A_{3.5}^0\oplus A_1$ ($[e_1,e_3]=-e_2$, $[e_2,e_3]=e_1$), i.e., to the direct sum of the three-dimensional Euclidean algebra and the one-dimensional Abelian algebra.

The other example is the contraction of u(2) to the harmonic oscillator algebra $\mathfrak{h}_4=A_{4.8}^{-1}$

($[e_2,e_3]=e_1$, $[e_2,e_4]=e_2$, $[e_3,e_4]=-e_3$) which frequently occurs in physics. The physical name of $\mathfrak{h}_4$ is justified since the set consisting of the creation (a^+), annihilation (a^-), identity (I), and single-mode photon number ($N=a^+a^-$) operators is closed under commutation and generates a Lie algebra isomorphic to $\mathfrak{h}_4$ with $e_1=I$, $e_2=a^-$, $e_3=a^+$, $e_4=N$. The algebra $u(2)$ is contracted to $\mathfrak{h}_4$ with the matrix $U_2(\varepsilon)=I_{19}\,\mathrm{diag}(\varepsilon,1,\varepsilon,1)$.

The subalgebra $\mathfrak{h}_3=\langle e_1,e_2,e_3\rangle$ ($[e_2,e_3]=e_1$) of $\mathfrak{h}_4$ is also widely applied since it is isomorphic to the algebra formed by the quantum mechanical position operator Q, the momentum operator P, and the identity operator I via designation

$$e_1=I,\quad e_2=\frac{Q+iP}{\sqrt{2\hbar}},\quad e_3=\frac{Q-iP}{\sqrt{2\hbar}}.$$

The main purpose of our paper is to classify contractions of the real and complex Lie algebras of dimensions not greater than 4. We rigorously formulate and develop a theoretical background to do this. Effectiveness of the applied algorithm for handling of contractions is based on using a wide set of necessary contraction criteria. A number of known necessary contraction criteria are collected and new criteria are proposed. Requisite invariant and semi-invariant quantities are calculated for classes of Lie algebras including all low-dimensional Lie algebras. Multiparametric and repeated contractions are also investigated since they give a tool for finding contraction matrices in complicated cases. An important by-effect of the present investigation is that the contractions under consideration supply with a number of model examples and contrary instances for statements and conjectures of the contraction theory. Availability of exhaustive information about them also allows us to describe levels and colevels of low-dimensional Lie algebras completely.

This paper is arranged in the following way. In Sec. II different definitions of general contractions of Lie algebras and contraction equivalence are given and discussed. We also construct a contrary instance on a conjecture on equivalence of contractions. Simplest types of contractions (Inönü-Wigner contractions, Saletan contractions, and generalized Inönü-Wigner contractions) are described in Sec. III. Necessary contraction criteria are listed and proven in Sec. IV. Calculation of invariant quantities for wide classes of Lie algebras is adduced in Sec. V. Section VI collects algebraic quantities and objects concerning real three- and four-dimensional Lie algebras. These quantities are used in Sec. VIII as a base for application of necessary contraction criteria in order to conclude whether there is a contraction in an arbitrary pair of the algebras of the same dimension. An algorithm for handling of contractions of low-dimensional Lie algebras is precisely formulated in Sec. VII and illustrated by examples. All inequivalent one-parametric contractions of the real low-dimensional Lie algebras are arranged in Sec. VIII and supplied with diagrams and explicit forms of the contraction matrices. All cases where contractions are equivalent to simple or generalized Inönü-Wigner contractions are separated. Levels and colevels of low-dimensional Lie algebras are also investigated. Using known correspondence between lists of nonisomorphic real and complex low-dimensional Lie algebras, we construct all inequivalent contractions over the complex field in Sec. IX. They are compared with the degenerations of four-dimensional Lie algebras, which were found in Refs. 1 and 9. Multiparametric and repeated contractions are studied in Sec. X and used for construction of contraction matrices in the most complicated cases which are not covered by generalized Inönü-Wigner contractions. Some problems arising under analysis of obtained results are formulated in Sec. XI.

II. DEFINITIONS OF CONTRACTIONS AND THEIR EQUIVALENCE

Consider an n-dimensional Lie algebra $\mathfrak{g}=(V,[\cdot,\cdot])$ with an underlying n-dimensional vector space V over $\mathbb{R}$ or $\mathbb{C}$ and a Lie bracket $[\cdot,\cdot]$. Usually the Lie algebra $\mathfrak{g}$ is defined by means of commutation relations in a fixed basis $\{e_1,\ldots,e_n\}$ of V. More precisely, it is sufficient to write down only the nonzero commutators $[e_i,e_j]=c_{ij}^k e_k$, where c_{ij}^k are components of the structure constant tensor of $\mathfrak{g}$. Hereafter the indices i, j, k, i', j', k', i'', j'', and k'' run from 1 to n and the summation over the repeated indices is implied.

Consider a *continuous* function $U:(0,\varepsilon_1]\to \mathrm{GL}(V)$, where $\varepsilon_1>0$. In other words, $U_\varepsilon=U(\varepsilon)$ is a nonsingular linear operator on V for all $\varepsilon\in(0,\varepsilon_1]$. Without loss of generality we can put $\varepsilon_1=1$. A parametrized family of new Lie brackets on V is determined via the old one by the following way:

$$\forall \varepsilon \in (0,1], \quad \forall x,y\in V: \quad [x,y]_\varepsilon = U_\varepsilon^{-1}[U_\varepsilon x, U_\varepsilon y].$$

It is reasonable that for any $\varepsilon\in(0,1]$ the Lie algebra $\mathfrak{g}_\varepsilon=(V,[\cdot,\cdot]_\varepsilon)$ is isomorphic to $\mathfrak{g}$.

Definition 1: If the limit $\lim_{\varepsilon\to+0}[x,y]_\varepsilon=\lim_{\varepsilon\to+0}U_\varepsilon^{-1}[U_\varepsilon x,U_\varepsilon y]=:[x,y]_0$ exists for any $x,y\in V$ then $[\cdot,\cdot]_0$ is a well-defined Lie bracket. The Lie algebra $\mathfrak{g}_0=(V,[\cdot,\cdot]_0)$ is called a *one-parametric continuous contraction* (or simply a contraction) of the Lie algebra $\mathfrak{g}$.

If a basis of V is fixed, the operator U_ε is defined by the corresponding matrix. Definition 2 can be reformulated in terms of structure constants.

Definition 1′: Let c_{ij}^k be the structure constants of the algebra $\mathfrak{g}$ in the fixed basis $\{e_1,\ldots,e_n\}$. If the limit

$$\lim_{\varepsilon\to+0}(U_\varepsilon)_{i'}^{i}(U_\varepsilon)_{j'}^{j}(U_\varepsilon^{-1})_{k}^{k'}c_{ij}^{k}=:\tilde{c}_{i'j'}^{k'}$$

exists for all values of i', j', and k' then $\tilde{c}_{i'j'}^{k'}$ are components of the well-defined structure constant tensor of a Lie algebra $\mathfrak{g}_0$. In this case the Lie algebra $\mathfrak{g}_0$ is called a one-parametric continuous contraction (or simply contraction) of the Lie algebra $\mathfrak{g}$. The parameter ε and the matrix-function $U=U(\varepsilon)$ are called a *contraction parameter* and a *contraction matrix*, correspondingly. The procedure that provides the Lie algebra $\mathfrak{g}_0$ from the algebra $\mathfrak{g}$ is also called a contraction.

Definitions 1 and 1′ are equivalent. The first definition is basis-free and convenient for theoretical consideration. The second one is more usable for calculations of concrete contractions. In this paper we mainly use Definition 1′.

The well-known Inönü-Wigner,[42] Saletan,[67] and generalized Inönü-Wigner[21] contractions are particular cases of the above one-parametric continuous contractions.

Definition 2: We call a contraction from the Lie algebra $\mathfrak{g}$ to the Lie algebra $\mathfrak{g}_0$ *trivial* if $\mathfrak{g}_0$ is Abelian and *improper* if $\mathfrak{g}_0$ is isomorphic to $\mathfrak{g}$.

If there exists a componentwise limit $\lim_{\varepsilon\to+0}U_\varepsilon=:U_0$ and $U_0\in GL(V)$ then it is obvious that the contraction is improper. Therefore, in order to generate a proper contraction, the matrix function U have to satisfy one of the conditions: (1) there is no limit of U at $\varepsilon\to+0$, i.e., at least one of the elements of U is singular under $\varepsilon\to+0$, or (2) there exists $\lim_{\varepsilon\to+0}U_\varepsilon=:U_0$ but the matrix U_0 is singular. Both conditions are not sufficient for the contraction to be proper.

The trivial and improper contractions exist for any Lie algebra. The trivial contraction is easily provided, e.g., by the matrix $U_\varepsilon=\mathrm{diag}(\varepsilon,\varepsilon,\ldots,\varepsilon)$. As a contraction matrix of the improper contraction, the identity matrix $U_\varepsilon=\mathrm{diag}(1,1,\ldots,1)$ can be always used. Sometimes the trivial and improper contractions are united in the common class of trivial contractions.[76]

The Abelian algebra is contracted only to itself. It is a special case when the contraction is trivial and improper at the same time.

Definition 3: Let the Lie algebras $\mathfrak{g}$ and $\tilde{\mathfrak{g}}$ be contracted to the algebras $\mathfrak{g}_0$ and $\tilde{\mathfrak{g}}_0$, correspondingly. If $\tilde{\mathfrak{g}}$ is isomorphic to $\mathfrak{g}$ and $\tilde{\mathfrak{g}}_0$ is isomorphic to $\mathfrak{g}_0$ then the contractions are called *weakly equivalent*.

Roughly speaking, all contractions in the same pairs of Lie algebras are weakly equivalent. Under usage of weak equivalence, attention is concentrated on possibility and results of contractions. Difference in ways of contractions is neglected by this approach. For parametric contractions we can also introduce different notions of stronger equivalence, which take into account ways of contractions. Hereafter $\mathrm{Aut}(\mathfrak{g})$ denotes the automorphism group of the Lie algebra $\mathfrak{g}$ and $\mathrm{Iso}(\mathfrak{g},\tilde{\mathfrak{g}})$ denotes the set of isomorphisms from the Lie algebra $\mathfrak{g}$ to the Lie algebra $\tilde{\mathfrak{g}}$. Additionally we identify isomorphisms with the corresponding matrices in a fixed basis.

Definition 4: Two one-parametric contractions in the same pair of Lie algebras $(\mathfrak{g},\mathfrak{g}_0)$ with the contraction matrices $U(\varepsilon)$ and $\tilde{U}(\varepsilon)$ are called *strictly equivalent* if there exists $\delta\in(0,1]$, there

exist functions $\hat{U}:(0,\delta]\to \mathrm{Aut}(\mathfrak{g})$ and $\widetilde{U}:(0,\delta]\to \mathrm{Aut}(\mathfrak{g}_0)$, and a continuous monotonic function $\varphi:(0,\delta]\to(0,1]$, $\lim_{\varepsilon\to+0}\varphi(\varepsilon)=0$, such that

$$\widetilde{U}_\varepsilon=\hat{U}_\varepsilon U_{\varphi(\varepsilon)}\check{U}_\varepsilon,\quad \varepsilon\in(0,\delta].$$

The latter definition can be reformulated for different pairs of algebras, which are term-by-term isomorphic.

Definition 4′: Let the isomorphic Lie algebras $\mathfrak{g}$ and $\widetilde{\mathfrak{g}}$ be contracted to the isomorphic algebras $\mathfrak{g}_0$ and $\widetilde{\mathfrak{g}}_0$ with the contraction matrices $U(\varepsilon)$ and $\widetilde{U}(\varepsilon)$, correspondingly. These contractions are called strictly equivalent if there exists $\delta\in(0,1]$, there exist functions $\hat{U}:(0,\delta]\to \mathrm{Iso}(\mathfrak{g},\widetilde{\mathfrak{g}})$ and $\check{U}:(0,\delta]\to \mathrm{Iso}(\mathfrak{g}_0,\widetilde{\mathfrak{g}}_0)$, and a continuous monotonic function $\varphi:(0,\delta]\to(0,1]$, $\lim_{\varepsilon\to+0}\varphi(\varepsilon)=0$, such that

$$\widetilde{U}_\varepsilon=\hat{U}_\varepsilon^{-1}U_{\varphi(\varepsilon)}\check{U}_\varepsilon,\quad \varepsilon\in(0,\delta].$$

Strictly equivalent contractions obviously are weakly equivalent. In our consideration we use only the notion of weak equivalence hence weakly equivalent contractions will be called equivalent ones for simplicity.

Remark 1: The restriction that $\hat{U}$ and $\check{U}$ should be isomorphism matrices cannot be omitted with preserving correctness.

The contractions of a Lie algebra, which are defined by the matrices U_ε and $W_0U_\varepsilon\widetilde{W}_0$, where $U:(0,1]\to \mathrm{GL}(V)$, $W_0,\widetilde{W}_0\in \mathrm{GL}(V)$, are weakly inequivalent in the general case. For example, the algebra $\mathrm{sl}(2,\mathbb{R})$ ($[e_1,e_2]=e_1$, $[e_2,e_3]=e_3$, $[e_1,e_3]=2e_2$) is contracted to the Heisenberg algebra $A_{3.1}$ ($[e_2,e_3]=e_1$) with the matrix $I_3\,\mathrm{diag}(\varepsilon,\varepsilon,1)$ and to the algebra $A_{3.5}^0$ ($[e_1,e_3]=-e_2$, $[e_2,e_3]=e_1$) with the matrix $I_5\,\mathrm{diag}(\varepsilon,\varepsilon,1)$. Here I_3 and I_5 are nonsingular matrices defined in Sec. VIII A.

Moreover, let $W,U,\widetilde{W}:(0,1]\to \mathrm{GL}(V)$ and

$$\exists\lim_{\varepsilon\to+0}W_\varepsilon=:W_0\in \mathrm{GL}(V),\quad \exists\lim_{\varepsilon\to+0}\widetilde{W}_\varepsilon=:\widetilde{W}_0\in \mathrm{GL}(V).$$

Generally speaking, the matrices $W_\varepsilon U_\varepsilon\widetilde{W}_\varepsilon$ and $W_0U_\varepsilon\widetilde{W}_0$ can also give weakly inequivalent contractions. This statement is illustrated by the below example. Therefore, Lemma 2.2 of Ref. 76 is incorrect.

Example 1: Consider the one-parametric continuous contraction of the four-dimensional real Lie algebras $\mathrm{so}(3)\oplus A_1\to A_{4.1}$ given by the matrix

$$U_\varepsilon=\begin{pmatrix}0&0&\varepsilon^2&0\\0&-\varepsilon^3&0&0\\0&0&0&\varepsilon\\-\varepsilon^2&0&-1&0\end{pmatrix}\quad\text{with } U_\varepsilon^{-1}=\begin{pmatrix}-\varepsilon^{-4}&0&0&-\varepsilon^{-2}\\0&-\varepsilon^{-3}&0&0\\\varepsilon^{-2}&0&0&0\\0&0&\varepsilon^{-1}&0\end{pmatrix}.$$

Taking the canonical commutation relations $[e_1,e_2]=e_3$, $[e_2,e_3]=e_1$, $[e_3,e_1]=e_2$ of the algebra $\mathrm{so}(3)\oplus A_1$ (the commutators with e_4 vanish), we calculate the transformed commutators up to antisymmetry:

$$[e_1,e_2]_\varepsilon=0,\quad [e_1,e_3]_\varepsilon=0,\quad [e_1,e_4]_\varepsilon=0,\quad [e_2,e_3]_\varepsilon=\varepsilon^4e_4,$$

$$[e_2,e_4]_\varepsilon=e_1-\varepsilon^2e_3,\quad [e_3,e_4]_\varepsilon=e_2.$$

After the limiting process $\varepsilon\to+0$ we obtain the canonical commutation relations $[e_2,e_4]_0=e_1$, $[e_3,e_4]_0=e_3$ of the algebra $A_{4.1}$.

Let us fix an arbitrary $\varepsilon\in(0,1]$. Since the matrix U_ε is nonsingular, its polar decomposition has the form $U_\varepsilon=P_\varepsilon T_\varepsilon$, where $P_\varepsilon:=(U_\varepsilon U_\varepsilon^{\,T})^{1/2}$ is a real symmetric matrix with positive eigenval-

ues and $T_\varepsilon := P_\varepsilon^{-1} U_\varepsilon$ is a real orthogonal matrix. Denote a real orthogonal matrix which reduces P_ε to a diagonal matrix D_ε by W_ε, i.e., $P_\varepsilon = W_\varepsilon D_\varepsilon W_\varepsilon^T$. As a result, we derive the representation $U_\varepsilon = W_\varepsilon D_\varepsilon \tilde{W}_\varepsilon$, where $\tilde{W}_\varepsilon = W_\varepsilon^T T_\varepsilon = D_\varepsilon^{-1} W_\varepsilon^T U_\varepsilon$ is an orthogonal matrix. The explicit form of the matrices W_ε, D_ε, and $\tilde{W}_\varepsilon$ is

$$W_\varepsilon = \begin{pmatrix} -\theta_- & 0 & 0 & \theta_+ \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \theta_+ & 0 & 0 & \theta_- \end{pmatrix}, \quad \tilde{W}_\varepsilon = \begin{pmatrix} -\theta_- & 0 & -\theta_+ & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ -\theta_+ & 0 & \theta_- & 0 \end{pmatrix},$$

$$D_\varepsilon = \operatorname{diag}\left(K + \frac{1}{2}, 0, 0, K - \frac{1}{2}\right),$$

where

$$K = \frac{1}{2}\sqrt{4\varepsilon^4 + 1}, \quad \theta_+ = \sqrt{\frac{2K+1}{4K}}, \quad \theta_- = \sqrt{\frac{2K-1}{4K}}.$$

The matrices W_ε and $\tilde{W}_\varepsilon$ converge under $\varepsilon \to +0$ to the constant nonsingular matrices

$$W_0 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad \tilde{W}_0 = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \end{pmatrix}.$$

Consider the matrix $\tilde{U}_\varepsilon = W_0 D_\varepsilon \tilde{W}_0$ constructed from the representation $U_\varepsilon = W_\varepsilon D_\varepsilon \tilde{W}_\varepsilon$ with replacement of the matrices W_ε and $\tilde{W}_\varepsilon$ by their regular limits. We transform the canonical commutation relations of the algebra $\mathrm{so}(3) \oplus A_1$ with the matrix $\tilde{U}_\varepsilon$ and limit $\varepsilon \to +0$:

$$[e_1, e_2]_\varepsilon = \frac{1}{2}(\sqrt{4\varepsilon^4 + 1} - 1) e_4 \to 0, \quad [e_1, e_3]_\varepsilon = 0,$$

$$[e_1, e_4]_\varepsilon = -\frac{\sqrt{4\varepsilon^4 + 1} - 1}{2\varepsilon^2} e_2 \to 0, \quad [e_2, e_3]_\varepsilon = 0,$$

$$[e_2, e_4]_\varepsilon = \frac{2\varepsilon^4}{\sqrt{4\varepsilon^4 + 1} - 1} e_1 \to e_1, \quad [e_3, e_4]_\varepsilon = 0.$$

As a result, we obtain commutation relations of the algebra $A_{3.1} \oplus A_1$. Therefore, the matrices U_ε and $\tilde{U}_\varepsilon$ lead to weakly inequivalent contractions.

The notion of sequential contractions is introduced similar to continuous contractions. See, e.g., Refs. 39 and 76.

Consider a sequence of $U_p \in \mathrm{GL}(V)$, $p \in \mathbb{N}$. The corresponding sequence of new Lie brackets on V is determined via the old one by the condition $[x,y]_p = U_p^{-1}[U_p x, U_p y] \forall\, p \in \mathbb{N}$, $\forall x, y \in V$. For any $p \in \mathbb{N}$ the Lie algebra $\mathfrak{g}_p = (V, [\cdot,\cdot]_p)$ is isomorphic to $\mathfrak{g}$.

Definition 5: If the limit $\lim_{p\to\infty}[x,y]_p = \lim_{p\to\infty} U_p^{-1}[U_p x, U_p y] =: [x,y]_0$ exists for any $x, y \in V$ then the Lie bracket $[\cdot,\cdot]_0$ is well defined. The Lie algebra $\mathfrak{g}_0 = (V, [\cdot,\cdot]_0)$ is called a *sequential contraction* of the Lie algebra $\mathfrak{g}$.

Any continuous contraction from $\mathfrak{g}$ to $\mathfrak{g}_0$ gives an infinite family of matrix sequences resulting in the sequential contraction from $\mathfrak{g}$ to $\mathfrak{g}_0$. More precisely, if U_ε is the matrix of the continuous contraction and the sequence $\{\varepsilon_p, p\in\mathbb{N}\}$ satisfies the conditions $\varepsilon_p\in(0,1]$, $\varepsilon_p\to+0$, $p\to\infty$, then $\{U_{\varepsilon_p}, p\in\mathbb{N}\}$ is a suitable matrix sequence.

The notion of contraction is generalized to arbitrary fields in terms of orbit closures in the variety of Lie algebras.[7–9,28,29,32,47]

Let V be an n-dimensional vector space over a field $\mathbb{K}$ and $\mathcal{L}_n=\mathcal{L}_n(\mathbb{K})$ denote the set of all possible Lie brackets on V. We identify $\mu\in\mathcal{L}_n$ with the corresponding Lie algebra $\mathfrak{g}=(V,\mu)$. $\mathcal{L}_n$ is an algebraic subset of the variety $V^*\otimes V^*\otimes V$ of bilinear maps from $V\times V$ to V. Indeed, under setting a basis $\{e_1,\dots,e_n\}$ of V there is the one-to-one correspondence between $\mathcal{L}_n$ and

$$\mathcal{C}_n=\{(c_{ij}^k)\in\mathbb{K}^{n^3}|c_{ij}^k+c_{ji}^k=0,\quad c_{ij}^{i'}c_{i'k}^{k'}+c_{ki}^{i'}c_{i'j}^{k'}+c_{jk}^{i'}c_{i'i}^{k'}=0\},$$

which is determined for any Lie bracket $\mu\in\mathcal{L}_n$ and any structure constant tuple $(c_{ij}^k)\in\mathcal{C}_n$ by the formula $\mu(e_i,e_j)=c_{ij}^k e_k$. $\mathcal{L}_n$ is called the *variety of n-dimensional Lie algebras (over the field* $\mathbb{K}$*)* or, more precisely, the variety of possible Lie brackets on V. The group $\mathrm{GL}(V)$ acts on $\mathcal{L}_n$ in the following way:

$$(U\cdot\mu)(x,y)=U(\mu(U^{-1}x,U^{-1}y)),\quad \forall\, U\in\mathrm{GL}(V),\quad \forall\,\mu\in\mathcal{L}_n,\quad \forall\, x,y\in V.$$

[It is a left action in contrast to the right action which is more usual for the "physical" contraction tradition and defined by the formula $(U\cdot\mu)(x,y)=U^{-1}(\mu(Ux,Uy))$ that is not of fundamental importance. We use the right action all over the paper except this paragraph.] Denote the orbit of $\mu\in\mathcal{L}_n$ under the action of $\mathrm{GL}(V)$ by $\mathcal{O}(\mu)$ and the closure of it with respect to the Zariski topology on $\mathcal{L}_n$ by $\overline{\mathcal{O}(\mu)}$.

Definition 6: The Lie algebra $\mathfrak{g}_0=(V,\mu_0)$ is called a contraction (or *degeneration*) of the Lie algebra $\mathfrak{g}=(V,\mu)$ if $\mu_0\in\overline{\mathcal{O}(\mu)}$. The contraction is *proper* if $\mu_0\in\overline{\mathcal{O}(\mu)}\backslash\mathcal{O}(\mu)$. The contraction is *nontrivial* if $\mu_0\not\equiv 0$.

In the case of $\mathbb{K}=\mathbb{C}$ or $\mathbb{K}=\mathbb{R}$ the orbit closures with respect to the Zariski topology coincide with the orbit closures with respect to the Euclidean topology and Definition 5 is reduced to the usual definition of contractions.

III. SIMPLEST TYPES OF CONTRACTIONS

Inönü-Wigner contractions present limit processes between Lie algebras with contraction matrices of simplest types. Most of contractions of low-dimensional Lie algebras are equivalent to such contractions. We discuss their properties which are essential for further consideration.

Simple Inönü-Wigner contractions or shortly IW-contractions first proposed in Ref. 42 are generated by matrices of the form $U_\varepsilon=U_0+\varepsilon U_0'$, where U_0 and U_0' are constant $n\times n$ matrices. The matrix U_ε is additionally assumed to be transformable to the special diagonal form $\hat{W}U_\varepsilon\check{W}^{-1}=\mathrm{diag}(1+\varepsilon v,\dots,1+\varepsilon v,\varepsilon,\dots,\varepsilon)=:D_\varepsilon$ by means of the regular constant matrices $\hat{W}$ and $\check{W}$. The assumption was investigated by Inönü and Wigner themselves.[41] Without loss of generality we can put $v=0$. The matrix D_ε provides the contractions from $\tilde{\mathfrak{g}}$ to $\tilde{\mathfrak{g}}_0$. Here $\tilde{\mathfrak{g}}$ and $\tilde{\mathfrak{g}}_0$ are Lie algebras with the Lie brackets $[x,y]^{\sim}=\hat{W}[\hat{W}^{-1}x,\hat{W}^{-1}y]$ and $[x,y]_0^{\sim}=\check{W}[\check{W}^{-1}x,\check{W}^{-1}y]_0$, which are obviously isomorphic to $\mathfrak{g}$ and $\mathfrak{g}_0$. Therefore, it can be assumed at once that $U_\varepsilon=D_\varepsilon$, i.e.,

$$U_\varepsilon=\mathrm{diag}(1,\dots,1,\varepsilon,\dots,\varepsilon).$$

Denote the number of diagonal elements equal to 1 by s. Then, the dimension of ε block is $n-s$. It is convenient to divide the set of basis elements $\{e_1,\dots,e_n\}$ of V into two subsets $\{e_1,\dots,e_s\}$ and $\{e_{s+1},\dots,e_n\}$ according to the values of diagonal elements. Since

$$[e_{i_1},e_{j_1}]_\varepsilon = c_{i_1j_1}^{k_1}e_{k_1} + \frac{1}{\varepsilon}c_{i_1j_1}^{k_2}e_{k_2} + O(\varepsilon) \to \tilde{c}_{i_1j_1}^{k_1}e_{k_1} + \tilde{c}_{i_1j_1}^{k_2}e_{k_2}, \quad \varepsilon \to +0,$$

where the indices i_1, j_1, and k_1 run from 1 to s and the indices i_2, j_2, and k_2 run from $s+1$ to n, then $c_{i_1j_1}^{k_2}=0$. Therefore, the basis elements $e_1,\ldots,e_s$ generate a subalgebra $\mathfrak{h}$ of the initial algebra $\mathfrak{g}$. It is the unique condition for the contraction to exist. All structure constants of the resulting algebra $\mathfrak{g}_0$ are easily calculated:

$$\tilde{c}_{i_1j_1}^{k_1} = c_{i_1j_1}^{k_1}, \quad \tilde{c}_{i_1j_1}^{k_2} = c_{i_1j_1}^{k_2} = 0, \quad \tilde{c}_{i_1j_2}^{k_1} = 0, \quad \tilde{c}_{i_1j_2}^{k_2} = c_{i_1j_2}^{k_2}, \quad \tilde{c}_{i_2j_2}^{k_1} = \tilde{c}_{i_2j_2}^{k_2} = 0.$$

Let us make a summary of properties of the IW-contractions (see, e.g., Refs. 51 and 67 for some properties). Each subalgebra $\mathfrak{h}$ of the Lie algebra $\mathfrak{g}$ can be used to obtain an IW-contraction of $\mathfrak{g}$. Improper subalgebras correspond to improper ($\mathfrak{h}=\mathfrak{g}$) or trivial ($\mathfrak{h}=\{0\}$) IW-contractions. Different choices of basis complement to a basis of $\mathfrak{h}$ or replacement of $\mathfrak{h}$ by an equivalent subalgebra of $\mathfrak{g}$ give the same contracted algebra up to isomorphism. The contracted algebra $\mathfrak{g}_0$ has the structure of semidirect sum $\mathfrak{h}\ni\mathfrak{a}$, where $\mathfrak{a}$ is the Abelian ideal spanned on the chosen basis complement to a basis of $\mathfrak{h}$. The subalgebra $\mathfrak{h}$ is isomorphic to the quotient algebra $\mathfrak{g}_0/a$. And vice versa, the Lie algebra $\mathfrak{g}_0$ is an IW-contraction of the algebra $\mathfrak{g}$ with the subalgebra $\mathfrak{h}$ if and only if there exists an Abelian ideal $\mathfrak{a}\subset\mathfrak{g}_0$ for which the quotient algebra $\mathfrak{g}_0/\mathfrak{a}$ is isomorphic to $\mathfrak{h}$. The repeated IW-contraction with the same subalgebra $\mathfrak{h}$ again results in the algebra $\mathfrak{g}_0$.

Any IW-contraction satisfies two assumptions: (1) the contraction matrix is linear with respect to the contraction parameter; (2) there exist constant regular matrices $\hat{W}$ and $\check{W}$ diagonalizing the contraction matrix. It is well known that IW-contractions do not exhaust all possible contractions even in the case of three dimensional Lie algebras. IW-contractions of the three-dimensional rotation algebra so(3) result in only one nontrivial and proper contraction to the Lie algebra $A_{3.5}^0$. At the same time, there also exists the proper contraction from so(3) to the Heisenberg algebra $\mathfrak{h}_3=A_{3.1}$ and it is not provided by IW-contractions (see Secs. VI and VIII for details).

Saletan[67] studied the whole class of contractions linear with respect to the contraction parameter, i.e., contractions generated by the matrices of the form $U(\varepsilon)=U_0+\varepsilon U_0'$, where U_0 and U_0' are constant matrices. Now such contractions are called *Saletan contractions* or, shortly, S-contractions. The assumption $U(1)=E$, where E is the unit matrix, can be imposed with basis change and reparametrization without loss of generality. Then the contraction matrix takes the form $U(\varepsilon)=\varepsilon E+(1-\varepsilon)\tilde{U}$, where $\tilde{U}$ is a constant matrix. Conditions on the matrix $\tilde{U}$ of a well-defined S-contraction were formulated in Ref. 67. Iterations of S-contractions with the same contraction matrix result in a finite chain of nonisomorphic algebras. The repeated contraction from the first algebra to the last algebra of the chain is an IW-contraction.[51,67] Any IW-contraction obviously is a S-contraction and there exist S-contractions which are inequivalent to IW-contractions. Thus, Saletan proved that the contraction $\mathrm{so}(3)\oplus A_1\to A_{4.9}^0$ is realized via a S-contraction and is equivalent to no IW-contraction. At the same time, S-contractions do not also exhaust all possible contractions of Lie algebras. An illustrative example is again given by the contraction $\mathrm{so}(3)\to\mathfrak{h}_3=A_{3.1}$, which is not provided even by S-contractions.[67]

Another generalization of the class of IW-contractions is given by *generalized IW-contractions* (or Doebner-Melsheimer contractions)[21,34,51] for which the linearity condition is replaced by the condition that the elements of the diagonalized contraction matrix are (integer) powers of the contraction parameter. Namely, the contraction matrix of a generalized IW-contraction has the form $U(\varepsilon)=\hat{W}^{-1}\,\mathrm{diag}(\varepsilon^{\alpha_1},\varepsilon^{\alpha_2},\ldots,\varepsilon^{\alpha_n})\check{W}$, where $\hat{W}$ and $\check{W}$ are nonsingular constant matrices and $\alpha_1,\alpha_2,\ldots,\alpha_n\in\mathbb{Z}$. As in the case of simple IW-contractions, due to possibility of replacement of Lie algebras by isomorphic ones we can assume that $\hat{W}=\check{W}=E$, i.e.,

$$U(\varepsilon) = \mathrm{diag}(\varepsilon^{\alpha_1},\varepsilon^{\alpha_2},\ldots,\varepsilon^{\alpha_n}).$$

Then the structure constants of the resulting algebra $\mathfrak{g}_0$ are calculated by the formula

$$\tilde{c}_{ij}^k = \lim_{\varepsilon \to +0} \varepsilon^{\alpha_i+\alpha_j-\alpha_k} c_{ij}^k,$$

with no summation with respect to the repeated indices. Therefore, the constraints

$$\alpha_i + \alpha_j \geqslant \alpha_k, \quad i,j,k = 1, \ldots, n \quad \text{if } c_{ij}^k \neq 0$$

are necessary and sufficient for the existence of the well-defined generalized IW-contraction with the contraction matrix $U(\varepsilon)$ and

$$\tilde{c}_{ij}^k = c_{ij}^k \quad \text{if } \alpha_i + \alpha_j = \alpha_k \quad \text{and} \quad \tilde{c}_{ij}^k = 0 \quad \text{otherwise}.$$

The conditions on contraction existence and the resulting algebra can be reformulated in the basis-independent terms of filtrations on the initial algebra and of associated graded Lie algebras.[32]

IW-contractions clearly form subclass of generalized IW-contractions with $\alpha_i \in \{0,1\}$. A natural question is whether any generalized IW-contraction can be decomposed to a sequence of successive IW-contractions. The unique nontrivial generalized IW-contraction between three-dimensional algebras is given by two successive IW-contractions $\mathrm{so}(3) \to A_{3.5}^0 \to A_{3.1}$. Inönu[40] and Sharp[70] formulated the proposition that the decomposition is not always possible. It was shown[51] that decomposability of a generalized IW-contraction implies additional constraints on structure constants of the initial Lie algebra. We construct a number of generalized IW-contractions of four-dimensional algebras, which are not decomposed to a sequence of simple IW-contractions. For example, the algebra $A_{4.4}$ having the nonzero commutation relations $[e_1,e_4]=e_1$, $[e_2,e_4]=e_1+e_2$, $[e_3,e_4]=e_2+e_3$ is contracted to the algebra $A_{4.1}$ ($[e_2,e_4]=e_1$, $[e_3,e_4]=e_2$) by the generalized IW-contraction with the matrix $\mathrm{diag}(\varepsilon^2,\varepsilon,1,\varepsilon)$. This contraction obviously illustrates the above statement since it is direct, i.e., there are no Lie algebra $\mathfrak{g}$ such that the contractions $A_{4.4} \to \mathfrak{g}$ and $\mathfrak{g} \to A_{4.1}$ are proper. See Remark 2 for more examples.

Remark 2: If some of the powers $\alpha_1, \alpha_2, \ldots, \alpha_n$ in the contraction matrix $U(\varepsilon)$ are negative, the limit of $U(\varepsilon)$ under $\varepsilon \to +0$ does not exist. It is not precisely known up to now in what situations it is sufficient to consider only non-negative powers of ε. Results of this paper imply that all contractions of the three- and four-dimensional Lie algebras are weakly equivalent to the ones for which the limit of the contraction matrices exists.

IV. NECESSARY CONTRACTION CRITERIA

An optimal way of exhaustive investigation of contractions in a set of Lie algebras includes intensive usage of necessary criteria based on quantities which are *invariant* or *semi-invariant* under contractions. The invariant quantities are preserved under contractions. Semi-invariance means existence of inequalities between the corresponding quantities of initial and contracted algebras. Since contractions are limit processes, the terms of *continuity* and *semicontinuity* can be used instead of invariance and semi-invariance.

For convenience we collect the relations between invariant or semi-invariant quantities as necessary criteria of contractions in Theorem 1.

Below we use the following notations of quantities and objects connected with the algebra $\mathfrak{g}$: the differentiation algebra $\mathrm{Der}\,\mathfrak{g}$, the orbit $\mathcal{O}(\mathfrak{g})$ under action of $\mathrm{GL}(V)$ in the variety $\mathcal{L}_n$ of n-dimensional Lie algebras, the center $Z(\mathfrak{g})$, the radical $R(\mathfrak{g})$, the nilradical $N(\mathfrak{g})$, the maximal dimension $n_{\mathrm{A}}(\mathfrak{g})$ of Abelian subalgebras, the maximal dimension $n_{\mathrm{Ai}}(\mathfrak{g})$ of Abelian ideals, the Killing form κ, the rank $r_{\mathfrak{g}}$, i.e., the dimension of the Cartan subalgebras, the adjoint and coadjoint representations $\mathrm{ad}\,\mathfrak{g}$ and $\mathrm{ad}^*\,\mathfrak{g}$, the adjoint representation ad_x of the element $x \in \mathfrak{g}$, and the ranks of adjoint and coadjoint representations which are calculated in a fixed basis by the formulas

$$\mathrm{rank}(\mathrm{ad}\,\mathfrak{g}) = \max_{x \in V} \mathrm{rank}(c_{ij}^k x^j) \quad \text{and} \quad \mathrm{rank}(\mathrm{ad}^*\,\mathfrak{g}) = \max_{u \in V^*} \mathrm{rank}(c_{ij}^k u_k).$$

Let us also define three standard series of characteristic ideals of $\mathfrak{g}$, namely,

$$\text{the lower central series: } \mathfrak{g}^0 \supset \mathfrak{g}^1 \supset \cdots \supset \mathfrak{g}^l \supset \cdots,$$

$$\text{the derived series: } \mathfrak{g}^{(0)} \supset \mathfrak{g}^{(1)} \supset \cdots \supset \mathfrak{g}^{(l)} \supset \cdots, \quad \text{and}$$

$$\text{the upper central series: } \mathfrak{g}_{(0)} \subset \mathfrak{g}_{(1)} \subset \cdots \subset \mathfrak{g}_{(l)} \subset \cdots,$$

where $\mathfrak{g}^0=\mathfrak{g}$, $\mathfrak{g}^l=[\mathfrak{g},\mathfrak{g}^{l-1}]$, $\mathfrak{g}^{(0)}=\mathfrak{g}$, $\mathfrak{g}^{(l)}=[\mathfrak{g}^{(l-1)},\mathfrak{g}^{(l-1)}]$, $\mathfrak{g}_{(0)}=\{0\}$, $\mathfrak{g}_{(l)}/\mathfrak{g}_{(l-1)}$ is the center of $\mathfrak{g}/\mathfrak{g}_{(l-1)}$, $l\in\mathbb{N}$. In particular, $\mathfrak{g}^1=\mathfrak{g}^{(1)}=[\mathfrak{g},\mathfrak{g}]$, $\mathfrak{g}_{(1)}=Z(\mathfrak{g})$. If $\mathfrak{g}$ is a solvable (nilpotent) Lie algebra, $r_s=r_s(\mathfrak{g})$ ($r_n=r_n(\mathfrak{g})$) denotes the solvability (nilpotency) rank of $\mathfrak{g}$, i.e., the minimal number l such that $\mathfrak{g}^{(l)}=\{0\}$ ($\mathfrak{g}^l=\{0\}$).

Suppose that $\mathrm{tr}(\mathrm{ad}_u{}^p)\neq 0$, $\mathrm{tr}(\mathrm{ad}_u{}^q)\neq 0$, and $\mathrm{tr}(\mathrm{ad}_u{}^p\mathrm{ad}_v{}^q)\neq 0$ for some $p,q\in\mathbb{N}$ and $u,v\in\mathfrak{g}$ and the value

$$\mathfrak{C}_{pq}=\frac{\mathrm{tr}(\mathrm{ad}_u{}^p)\mathrm{tr}(\mathrm{ad}_v{}^q)}{\mathrm{tr}(\mathrm{ad}_u{}^p\mathrm{ad}_v{}^q)}, \quad p,q\in\mathbb{N}$$

does not depend on u and v. Then $\mathfrak{C}_{pq}=\mathfrak{C}_{pq}(\mathfrak{g})$ is a well-defined invariant characteristic of the algebra $\mathfrak{g}$, i.e., it is a constant on the orbit $\mathcal{O}(\mathfrak{g})$.

Denote the rank of positive (negative) part of the Killing form $\kappa_\mathfrak{g}$, i.e., the number of positive (negative) diagonal elements of a diagonal form of its matrix, by $\mathrm{rank}_+\kappa_\mathfrak{g}$ ($\mathrm{rank}_-\kappa_\mathfrak{g}$). In view of the law of inertia of quadratic forms, $\mathrm{rank}_+\kappa_\mathfrak{g}$ and $\mathrm{rank}_-\kappa_\mathfrak{g}$ are invariant under basis transformations over $\mathbb{R}$. For any $\alpha\in\mathbb{R}$ we introduce the modified Killing form

$$\tilde{\kappa}^\alpha_\mathfrak{g}=\mathrm{tr}(\mathrm{ad}_u\,\mathrm{ad}_v)+\alpha\,\mathrm{tr}(\mathrm{ad}_u)\mathrm{tr}(\mathrm{ad}_v)$$

and the corresponding values $\mathrm{rank}_+\tilde{\kappa}^\alpha_\mathfrak{g}$ and $\mathrm{rank}_-\tilde{\kappa}^\alpha_\mathfrak{g}$. The Killing form is the special case of the modified Killing form with $\alpha=0$.

The following technical lemma is very useful for further considerations.

Lemma 1: *Let A_p, $p\in\mathbb{N}$, be a sequence of real or complex matrices of the same dimensions and there exists componentwise limit of A_p, $p\to\infty$, denoted by A_0. If* $\mathrm{rank}\,A_p=r\,\forall\,p\in\mathbb{N}$ *then* $\mathrm{rank}\,A_0\leqslant r$.

Theorem 1: *If the Lie algebra $\mathfrak{g}_0$ is a proper (continuous or sequential) contraction of the Lie algebra $\mathfrak{g}$, then the following set of relations holds true.*

(1) $\dim \mathrm{Der}\,\mathfrak{g}_0>\dim \mathrm{Der}\,\mathfrak{g}$ (*and* $\dim\mathcal{O}(\mathfrak{g}_0)<\dim\mathcal{O}(\mathfrak{g})$);
(2) $n_A(\mathfrak{g}_0)\geqslant n_A(\mathfrak{g})$
(3) $\dim Z(\mathfrak{g}_0)\geqslant\dim Z(\mathfrak{g})$; *moreover*, $\dim\mathfrak{g}_0(l)\geqslant\dim\mathfrak{g}_{(l)}$, $l\in\mathbb{N}$;
(4) $\dim\mathfrak{g}_0^l\leqslant\dim\mathfrak{g}^{(l)}$, $l\in\mathbb{N}$;
(5) $\dim\mathfrak{g}_0^l\leqslant\dim\mathfrak{g}^l$, $l\in\mathbb{N}$;
(6) $\dim R(\mathfrak{g}_0)\geqslant\dim R(\mathfrak{g})$;
(7) $\dim N(\mathfrak{g}_0)\geqslant\dim N(\mathfrak{g})$;
(8) $n_{\mathrm{Ai}}(\mathfrak{g}_0)\geqslant n_{\mathrm{Ai}}(\mathfrak{g})$;
(9) $r_{\mathfrak{g}_0}\geqslant r_\mathfrak{g}$;
(10) $\mathrm{rank\,ad}\,\mathfrak{g}_0\leqslant\mathrm{rank\,ad}\,\mathfrak{g}$, $\mathrm{rank\,ad}^*\mathfrak{g}_0\leqslant\mathrm{rank\,ad}^*\,\mathfrak{g}$;
(11) $\mathrm{rank}\kappa_{\mathfrak{g}_0}\leqslant\mathrm{rank}\,\kappa_\mathfrak{g}$;
(12) $\mathfrak{g}_0$ *is unimodular if* $\mathfrak{g}$ *is unimodular, i.e.,* $\mathrm{tr}(\mathrm{ad}_u)=0$ *for any u in $\mathfrak{g}$ implies the same condition in $\mathfrak{g}_0$*;
(12′) *moreover, for any fixed $l\in\mathbb{N}$ $\mathfrak{g}_0$ is l unimodular if $\mathfrak{g}$ is l unimodular, i.e.,* $\mathrm{tr}(\mathrm{ad}_u{}^l)=0$ *for any u in $\mathfrak{g}$ implies the same condition in $\mathfrak{g}_0$*;
(13) *if $\mathfrak{g}$ is solvable Lie algebra then $\mathfrak{g}_0$ is also solvable and* $r_s(\mathfrak{g}_0)\leqslant r_s(\mathfrak{g})$;
(14) *if $\mathfrak{g}$ is nilpotent Lie algebra then $\mathfrak{g}_0$ is also nilpotent and* $r_n(\mathfrak{g}_0)\leqslant r_n(\mathfrak{g})$;
(15) $\mathfrak{C}_{pq}(\mathfrak{g}_0)=\mathfrak{C}_{pq}(\mathfrak{g})$ *for all values $p,q\in\mathbb{N}$, where the invariants* $\mathfrak{C}_{pq}(\mathfrak{g}_0)$ and $\mathfrak{C}_{pq}(\mathfrak{g})$ *are well defined*;
(16) (*only over* $\mathbb{R}$!) $\mathrm{rank}_+\kappa_{\mathfrak{g}_0}\leqslant\mathrm{rank}_+\kappa_\mathfrak{g}$ *and* $\mathrm{rank}_-\kappa_{\mathfrak{g}_0}\leqslant\mathrm{rank}_-\kappa_\mathfrak{g}$; *moreover for any* $\alpha\in\mathbb{R}$ $\mathrm{rank}_+\tilde{\kappa}^\alpha_{\mathfrak{g}_0}\leqslant\mathrm{rank}_+\tilde{\kappa}^\alpha_\mathfrak{g}$ *and* $\mathrm{rank}_-\tilde{\kappa}^\alpha_{\mathfrak{g}_0}\leqslant\mathrm{rank}_-\tilde{\kappa}^\alpha_\mathfrak{g}$;
(17) *if the algebra $\mathfrak{g}_0$ is rigid then it is not a contraction of any $\mathfrak{g}$ and if there is no deformation*

from $\mathfrak{g}_0$ *to* $\mathfrak{g}$, *then there is no contraction from* $\mathfrak{g}$ *to* $\mathfrak{g}_0$.

Proof: It is sufficient to prove the theorem in the case of sequential contractions. The statement on continuous contractions directly follows from the one on sequential contractions. We use the notations introduced at the beginning of the section.

At first, Criteria 4 and 5 are proven in detail. The statements are true if $\dim[\mathfrak{g},\mathfrak{g}]=\dim\mathfrak{g}=:n$. Indeed, in this case $\dim\mathfrak{g}^{(l)}=\dim\mathfrak{g}^l=n$ for all $l\in\mathbb{N}$ that results in Criteria 4 and 5 in view of the obvious conditions $\dim\mathfrak{g}_0^{(l)}\leqslant\dim\mathfrak{g}_0$, $\dim\mathfrak{g}_0^l\leqslant\dim\mathfrak{g}_0$, and $\dim\mathfrak{g}_0=\dim\mathfrak{g}=n$.

Suppose that $\dim[\mathfrak{g},\mathfrak{g}]<n$. Let $\{e^1,\dots,e^n\}$ be the basis in the dual space V^*, which is dual to the basis $\{e_1,\dots,e_n\}$, i.e., $\langle e^i,e_j\rangle=\delta^i_j$. Here δ^i_j is the Kronecker delta. We define A as the $n\times n^2$ matrix consisting of the elements $c^k_{ij}=\langle e^k,[e_i,e_j]\rangle$, where the index k runs the row range and the index pair (i,j) runs the column range:

$$A=\begin{pmatrix} c^1_{11} & \cdots & c^1_{1n} & c^1_{21} & \cdots & c^1_{2n} & \cdots & c^1_{n1} & \cdots & c^1_{nn}\\ c^2_{11} & \cdots & c^2_{1n} & c^2_{21} & \cdots & c^2_{2n} & \cdots & c^2_{n1} & \cdots & c^2_{nn}\\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots\\ c^n_{11} & \cdots & c^n_{1n} & c^3_{21} & \cdots & c^n_{2n} & \cdots & c^n_{n1} & \cdots & c^n_{nn}\end{pmatrix}.$$

Due to antisymmetry of c^k_{ij} in subscripts, we can take only columns with $i<j$ into account. Analogously we introduce the matrices A_p and A_0 for the algebras $\mathfrak{g}_p$ and $\mathfrak{g}_0$.

The dimensions of $[\mathfrak{g},\mathfrak{g}]$ and $[\mathfrak{g},\mathfrak{g}]_p$ coincide. Denote the common value of dimensions as n_1. These statements are reformulated in terms of the introduced matrices A and A_p:

$$\operatorname{rank}A=\operatorname{rank}A_p=n_1.$$

Therefore, all (n_1+1)-dimensional minors of any matrix $A_p, p\in\mathbb{N}$ equal to zero. Moreover, we have

$$c^k_{p,ij}=\langle e^k,[e_i,e_j]_p\rangle\to c^k_{0,ij}=\langle e^k,[e_i,e_j]_0\rangle,\quad p\to\infty,$$

i.e., the elements of the matrix A_p go to the corresponding elements of the matrix A_0. It leads to the convergency of minors. Consequently, any (n_1+1)-dimensional minor of the matrix A_0 vanishes. It implies that rank $A_0\leqslant n_1$, i.e., $[\mathfrak{g}_0,\mathfrak{g}_0]\leqslant n_1$. Criteria 4 and 5 for $l=1$ have been proven.

Criteria 4 and 5 for the other values of l are proven analogously. The requisite matrices are defined in the similar way as the matrices A, A_p, and A_0 in the case $l=1$ with replacement of the usual commutators $[e_i,e_j]$ by the corresponding repeated commutators of basis elements.

Criteria 9, 10, and 11 are proven in a similar and simpler way via the limit process $p\to\infty$ in the formulas

$$r_{\mathfrak{g}}=n-\max_{x\in V}\operatorname{rank}(c^k_{ij}x^j)^n=r_{\mathfrak{g}_p}=n-\max_{x\in V}\operatorname{rank}(c^k_{p,ij}x^j)^n,$$

$$\operatorname{rank}(\operatorname{ad}\mathfrak{g})=\max_{x\in V}\operatorname{rank}(c^k_{ij}x^j)=\operatorname{rank}(\operatorname{ad}\mathfrak{g}_p)=\max_{x\in V}\operatorname{rank}(c^k_{p,ij}x^j),$$

$$\operatorname{rank}(\operatorname{ad}^*\mathfrak{g})=\max_{u\in V^*}\operatorname{rank}(c^k_{ij}u_k)=\operatorname{rank}(\operatorname{ad}^*\mathfrak{g}_p)=\max_{u\in V^*}\operatorname{rank}(c^k_{p,ij}u_k),$$

$$\operatorname{rank}(\kappa_{\mathfrak{g}})=\operatorname{rank}(c^k_{ij}c^j_{i'k})=\operatorname{rank}(\kappa_{\mathfrak{g}_p})=\operatorname{rank}(c^k_{p,ij}c^j_{p,i'k}),\quad p\in\mathbb{N}.$$

Criteria 12 and 12′ are obvious since $\operatorname{tr}(\operatorname{ad}_u{}^l)=0$ for any u in $\mathfrak{g}$ implies the same condition in $\mathfrak{g}_p$ and $\operatorname{tr}(\operatorname{ad}_{\mathfrak{g}_p,u}{}^l)\to\operatorname{tr}(\operatorname{ad}_{\mathfrak{g}_0,u}{}^l)$, $p\to\infty$.

Criteria 13 and 14 directly follow from Criteria 4 and 5.

Since the radical $R(\mathfrak{g})$ is the orthogonal complement of the derivative $[\mathfrak{g},\mathfrak{g}]$ with respect to the Killing form $\kappa_{\mathfrak{g}}$ (Ref. 44) then $\dim R(\mathfrak{g})=\dim R(\mathfrak{g}_p)$ coincides with the value

$$n-\operatorname{rank}(c_{ij}^{k}c_{i'k}^{j}c^{i'}_{i''j''})=n-\operatorname{rank}(c_{p,ij}^{k}c_{p,i'k}^{j}c^{i'}_{p,i''j''}),\quad p\in\mathbb{N}.$$

In the matrices the index pair (i'',j'') runs the row range and the index i runs the column range. The limit process $p\to\infty$ in the latter formula results in Criterion 6.

The center $Z(\mathfrak{g})$ coincides with the set of solutions of the system $[e_i,x]=0$, or $c_{ij}^{k}x^{j}=0$ in the coordinate form. Therefore, $\dim Z(\mathfrak{g})=\dim Z(\mathfrak{g}_p)$ equals to

$$n-\operatorname{rank}(c_{ij}^{k})=n-\operatorname{rank}(c_{p,ij}^{k}),\quad p\in\mathbb{N},$$

where the index pair (k,j) runs the row range and the index i runs the column range. The limit process $p\to\infty$ in the latter formula implies Criterion 3 for $l=1$. Proof for the other values of l is similar. Instead of $(c_{ij}^{k})=(\langle e^{k},[e_i,e_j]\rangle)$, the matrix $(\langle e^{k},[\ldots[e_i,e_{j_1}],\ldots,e_{j_l}]\rangle)$ should be used, where the index tuple $(k,j_1,\ldots,j_l)$ runs the row range and the index i runs the column range.

Criterion 15 is true in view of invariance property of $\mathfrak{C}_{pq}$.

Proof of Criterion 2 is also adduced in detail since it presents another typical trick which is used in deriving necessary contraction criteria. Let $n_A(\mathfrak{g})=l$. Then $n_A(\mathfrak{g}_p)=l$ too. We change the basis of $\mathfrak{g}_p$ with a nonsingular matrix W_p that

$$\tilde{c}_{p,ij}^{k}=0\quad\text{if } i,j\leqslant l.$$

Here $\tilde{c}_{p,ij}^{k}=(W_p)_{i'}^{i}(W_p)_{j'}^{j}(W_p{}^{-1})_{k}^{k'}c_{p,i'j'}^{k'}$ are the structure constants of $\mathfrak{g}_p$ in the new basis. Due to possibility of "orthogonalization" of the basis, we can assume without loss generality that W_p is an orthogonal (unitary) matrix in the case of the real (complex) field. The set of orthogonal (or unitary) matrices is compact in the induced "Euclidean" matrix norm. Therefore, there exists a convergent subsequence $\{W_{p_q},q\in\mathbb{N}\}$. Denote the orthogonal (unitary) matrix being the limit of this subsequence by W_0. Then

$$\tilde{c}_{p_q,ij}^{k}=(W_{p_q})_{i'}^{i}(W_{p_q})_{j'}^{j}(W_{p_q}{}^{-1})_{k}^{k'}c_{p_q,i'j'}^{k'}\to(W_0)_{i'}^{i}(W_0)_{j'}^{j}(W_0{}^{-1})_{k}^{k'}c_{0,i'j'}^{k'}=\tilde{c}_{0,ij}^{k},\quad q\to\infty.$$

Hence $\tilde{c}_{p,ij}^{k}=0$ if $i,j\leqslant l$ in view of the same condition for $c_{p,ij}^{k}$, i.e., $\mathfrak{g}_0$ contains an l-dimensional Abelian subalgebra that implies Criterion 2.

Criteria 6, 7, and 8 are proven in a similar way with replacement of the Abelian subalgebra condition by the ideal condition

$$\tilde{c}_{p,ij}^{k}=0\quad\text{if } (i\leqslant l \text{ or } j\leqslant l) \text{ and } k>l$$

completed with the conditions

$$\tilde{c}_{p,ij}^{k}=0\quad\text{if } i,j\leqslant l \text{ and } k>\max(i,j),\quad l=\dim R(\mathfrak{g}),$$

$$\tilde{c}_{p,ij}^{k}=0\quad\text{if } i,j\leqslant l \text{ and } k\geqslant\max(i,j),\quad l=\dim N(\mathfrak{g}),$$

$$\tilde{c}_{p,ij}^{k}=0\quad\text{if } i,j\leqslant l,\quad l=n_{A_i}(\mathfrak{g})$$

of solvability for the radical, nilpotency for the nilradical, and commutativity for an Abelian ideal of the maximal dimension, correspondingly. Other conditions of solvability and nilpotency can also be used. Let us note that we derive the second proof of Criterion 6.

Similar technique based on compactness of the set of orthogonal matrices is used in proof of Criterion 16. Denote the number of positive (negative) diagonal elements of a diagonal form of a symmetric matrix K by $\operatorname{rank}_{+}K$ ($\operatorname{rank}_{-}K$).

It is sufficient to prove that for any convergent sequence of symmetric matrices $K_p\to K_0$, $p\to\infty$, with $\operatorname{rank}_{+}K_p=r_{+}$ and $\operatorname{rank}_{-}K_p=r_{-}$, $p\in\mathbb{N}$, the inequalities $\operatorname{rank}_{+}K_0\leqslant r_{+}$ and $\operatorname{rank}_{-}K_0\leqslant r_{-}$ are

true. Then this statement is applied to the sequence of the matrices of the (modified) Killing forms of the algebras $\mathfrak{g}_p$, which have the same values of rank_+ and rank_- in view of the inertia law of quadratic forms and converge to the matrix of the (modified) Killing form of the resulting algebra $\mathfrak{g}_0$.

Let W_p be the orthogonal matrix which reduces K_p to the matrix $D_p=\mathrm{diag}(d_{p,1},\dots,d_{p,n})$, where $d_{p,i_1}>0$ for $i_1=1,\dots,r_+$, $d_{p,i_2}<0$ for $i_2=r_++1,\dots,r_++r_-$, and $d_{p,i_3}=0$ for $i_3=r_++r_-+1,\dots,n(r_++r_-\leqslant n)$. So, $K_p=W_pD_pW_p^T$. We choose a convergent subsequence $\{W_{p_q},q\in\mathbb{N}\}$ and denote the orthogonal matrix being the limit of this subsequence by W_0. Then

$$D_{p_q}=W_{p_q}^{\mathcal{T}}K_{p_q}W_{p_q}\to W_0^{\mathcal{T}}K_0W_0=:D_0,\quad q\to\infty.$$

D_0 is a diagonal matrix $\mathrm{diag}(d_{0,1},\dots,d_{0,n})$ as the limit of the sequence of the diagonal matrices D_{p_q}, $q\in\mathbb{N}$. Moreover, $d_{0,i_1}\geqslant 0$ for $i_1=1,\dots,r_+$, $d_{0,i_2}\leqslant 0$ for $i_2=r_++1,\dots,r_++r_-$, and $d_{0,i_3}=0$ for $i_3=r_++r_-+1,\dots,n$ that implies the requisite statement.

Criteria 1 and 17 were proven, e.g., in Refs. 4, 32, and 71. □

Remark 3: The criteria can be reformulated in terms of closed subsets of the variety $\mathcal{A}_n$ of n-dimensional Lie algebras. Thus, the sets of nilpotent, solvable, and unimodular algebras are closed. The sets $\{\mathfrak{g}\in\mathcal{A}_n|\dim\mathfrak{g}^l\leqslant r\}$, $\{\mathfrak{g}\in\mathcal{A}_n|\dim\mathfrak{g}^{(l)}\leqslant r\}$, $\{\mathfrak{g}\in\mathcal{A}_n|\dim\mathfrak{g}_{(l)}\geqslant r\}$, and similar ones are closed for each l and $r=0,\dots,n$.

Remark 4: Necessary criteria already appeared in early papers on contractions of Lie algebras. Thus, in his pioneer paper[69] Segal used the criterion based on the law of inertia of the Killing forms (the first part of Criterion 16) in the case of compact semisimple Lie algebras. The inequality on dimensions of the derived algebras $\dim[\mathfrak{g}_0,\mathfrak{g}_0]\leqslant\dim[\mathfrak{g},\mathfrak{g}]$ was proven in Ref. 67 in the practically same way as above. Criteria 3 and 5 on upper and lower central series arise under studying varieties of nilpotent algebras.[74] Very important Criterion 2 is a direct consequence of the lemma on orbit closures, which is adduced, e.g., in Ref. 4. Criterion 1 was proven in Ref. 32 with usage of the Iwasawa decomposition. It was pointed out in Ref. 68 that the same technique can be used to prove other necessary contraction criteria. Restricting ourself with real and complex cases, we simplify this technique and use it to also prove Criteria 6, 7, and 8. Criteria 3, 4, and 5 were applied simultaneously in Ref. 45, see also discussion in Ref. 29. All the above criteria are based on semi-invariant values. Criterion 15 on the invariant algebra characteristic $\mathfrak{C}_{pq}$ was first proposed and effectively used in Refs. 9 and 71. A number of criteria are collected *ibid* and key ideas on proof of them were also formulated. In particular, Criterion 9 was adopted by us from there. Let us note that $\mathfrak{C}_{pq}$ is a generalization of the invariant $J=\mathrm{tr}(\mathrm{ad}_u^2)/(\mathrm{tr}\,\mathrm{ad}_u)^2$ introduced in Ref. 45. The part of Criterion 10 on rank of coadjoint representations arises in investigation of connections between invariants of initial and contracted algebras.[10,11] Criterion 17 was discussed, e.g., in Ref. 51. There exist also other criteria, e.g., ones connected with cohomologies of Lie algebras.[8]

Remark 5: The list of criteria can be extended with other quantities which concern algebras and are semi-invariant under contractions.[9] The criteria used in this paper are simple from the computing point of view.

The set (or even a subset) of the adduced criteria is complete for the three- and four-dimensional Lie algebras in the sense that they precisely separate all pairs of algebras, which do not admit contractions. The question on completeness of the adduced criteria in the case of Lie algebras of higher dimensions is still open.

The set of criteria is not minimal. Some criteria are induced by others. For example, Criteria 4 and 5 imply Criteria 13 and 14.

Criteria differ from each other in effectiveness. Criteria 1 and 12 are most powerful since they exclude possibility of contractions in most pairs of low-dimensional Lie algebras. This fact is illustrated by examples of Sec. VII.

Criterion 16 is the unique criterion which is special for the real field. Only it works for pairs of algebras having a contraction over $\mathbb{C}$ and no contractions over $\mathbb{R}$. See Remark 12 additionally.

Remark 6: Criterion 1 is singular and particularly powerful due to appearance of strict inequality in it. It is the unique criterion which enables investigation of contractions in series of

Lie algebras in a simple way. Since the dimensions of the differentiation algebras for the nonsingular values of the parameters in series of Lie algebras coincide, Criterion 1 implies the absence of contractions between these cases.

The weakened version of Criterion 1 with unstrict inequality is proven analogous to a number of other criteria. Indeed, in a fixed basis of V the coefficients d_j^i of the matrix of any operator from Der $\mathfrak{g}$ satisfy the homogeneous system of linear equations

$$c_{ij}^{k'} d_{k'}^{k} = c_{i'j}^{k} d_i^{i'} + c_{ij'}^{k} d_j^{j'}.$$

Let A be the matrix of this system and A_p and A_0 be the similar matrices for the algebras $\mathfrak{g}_p$ and $\mathfrak{g}_0$. Then $\dim \mathrm{Der}\,\mathfrak{g}=n^2-\mathrm{rank}A=\dim \mathrm{Der}\,\mathfrak{g}_p=n^2-\mathrm{rank}A_p$ and $\dim \mathrm{Der}\,\mathfrak{g}_0=n^2-\mathrm{rank}A_0$. Therefore, the inequality $\dim \mathrm{Der}\,\mathfrak{g}_0 \geqslant \dim \mathrm{Der}\,\mathfrak{g}$ obviously follows from Lemma 1. [Note that $\dim \mathcal{O}(\mathfrak{g})=\mathrm{rank}A$.]

Can other criteria or their combinations be strengthened with replacement of unstrict inequalities by strict ones? The answer to this question is unknown up to now. There existed the conjecture that dimension of an element of the upper or lower central series or the derived series should vary under a proper contraction. A contrary instance on the conjecture was adduced in Ref. 29. It is given by the contraction of the three-dimensional algebras

$$A_{3.2}([e_1,e_3]=e_1,[e_2,e_3]=e_1+e_2) \to A_{3.3}([e_1,e_3]=e_1,[e_2,e_3]=e_1),$$

which is realized via the simple IW-contraction associated with the subalgebra $\langle e_1, e_2+e_3\rangle$. Let us note additionally that all invariant and semi-invariant quantities adduced in this section excluding only dim Der coincide for the above algebras. Therefore, only Criterion 1 is effectual for this pair of algebras.

V. CALCULATION OF INVARIANT QUANTITIES

There are two simple classes of Lie algebras, which cover most low-dimensional algebras. The first one is formed by *almost Abelian algebras* having Abelian ideals of codimension one. The algebras from the second class have WH+A ideals of codimension one, which are isomorphic to the direct sum of the Weyl-Heisenberg algebra $\mathfrak{h}_3=A_{3.1}$ and the Abelian algebra of codimension four. Characteristics of the above algebras are found in a uniform way. The other low-dimensional algebras should be investigated separately. Below we adduce only calculations of the invariants $\mathfrak{C}_{pq}$ which were recently proposed in Refs. 9 and 71 and the ranks of some algebras.

A. Almost Abelian algebras

Consider an n-dimensional Lie algebra over $\mathbb{C}$ or $\mathbb{R}$ which has an $(n-1)$-dimensional Abelian ideal. It is a solvable and, moreover, metabelian algebra. Let $e_1,\dots,e_{n-1}$ form a basis of the ideal and e_n completes it to a basis of the algebra. The nonzero commutation relations between elements of the constructed bases are

$$[e_j,e_n]=\sum_{k=1}^{n-1} a_j^k e_k, \quad j=1,\dots,n-1.$$

The $(n-1)\times(n-1)$ matrix $A=(a_j^k)$ defines the algebra completely hence we will denote this algebra by $\mathfrak{a}_A$, i.e., $a_A := A_1 \oplus_A (n-1)A_1$.

The algebras $\mathfrak{a}_A$ and $a_{A'}$ are isomorphic if and only if the matrices A and A' are similar up to scalar multiplier. The isomorphisms are established via changes of bases in the Abelian ideals and scaling of the complementary elements of bases. Up to the algebra isomorphisms the matrix A can be assumed reduced to the Jordan normal form, and its eigenvalues can be additionally normalized with a nonvanishing multiplier.

For any algebra $\mathfrak{g}$ the matrix $\hat{\mathrm{ad}}_u$ of the adjoint representation ad_u of an arbitrary element $u \in \mathfrak{g}$ is found by the formula $(\hat{\mathrm{ad}}_u)^j_k = c^k_{ij} u_i$, where c^k_{ij} are the structure constants of $\mathfrak{g}$ in the fixed basis. Since for $\mathfrak{a}_A$ $c^k_{ij}=0$ if neither i nor j equals to n, the matrix $\hat{\mathrm{ad}}_u$ can be easily calculated:

$$\hat{\mathrm{ad}}_u = \sum_{i=1}^{n-1} u_i \begin{pmatrix} 0 & \cdots & 0 & a^i_1 \\ \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & a^i_{n-1} \\ 0 & \cdots & 0 & 0 \end{pmatrix} - u_n \begin{pmatrix} a^1_1 & \cdots & a^{n-1}_1 & 0 \\ \vdots & \ddots & \vdots & \vdots \\ a^1_{n-1} & \cdots & a^{n-1}_{n-1} & 0 \\ 0 & \cdots & 0 & 0 \end{pmatrix},$$

or shortly $\hat{\mathrm{ad}}_u$ have the form

$$\hat{\mathrm{ad}}_u = \begin{pmatrix} u_n A & -A\bar{u} \\ \underline{0} & 0 \end{pmatrix},$$

where $\bar{u}=(u_1,\dots,u_{n-1})^T$ and $\underline{0}=(0,\dots,0)$.

To calculate the invariant characteristic $\mathfrak{C}_{pq}$ of $\mathfrak{a}_A$, we find powers of $\hat{\mathrm{ad}}_u$ and their traces

$$\hat{\mathrm{ad}}_u{}^p = \begin{pmatrix} {u_n}^p A^p & -{u_n}^{p-1} A^p \bar{u} \\ \underline{0} & 0 \end{pmatrix}, \qquad \mathrm{tr}(\mathrm{ad}_u{}^p) = {u_n}^p \,\mathrm{tr}(A^p).$$

Matrix trace is not affected by matrix similarity transformations. If $\lambda_1,\dots,\lambda_{n-1}$ are the roots of the characteristic polynomial $\chi_A(\lambda)$ of the matrix A in $\mathbb{C}$ then $\mathrm{tr}(A^p)=\lambda_1^p+\cdots+\lambda_{n-1}^p$ for any $p \in \mathbb{N}$. Consequently, the invariant value $\mathfrak{C}_{pq}$ can be calculated explicitly.

The rank of $\mathfrak{a}_A$ can be easily calculated as by-product. Indeed, the characteristic polynomial $\chi_{\hat{\mathrm{ad}}_u}(\lambda)$ of $\hat{\mathrm{ad}}_u$ equals to $\lambda\chi_{u_nA}(\lambda)$, i.e., any element $u \in a_A$ with $u_n \neq 0$ is regular and the rank of $\mathfrak{a}_A$ coincides with the number of zero roots of the polynomial $\lambda\chi_A(\lambda)$.

As a result, we obtain the following statement.

Lemma 2: *Let $\mathfrak{a}_A$ be an n-dimensional Lie algebra with an $(n-1)$-dimensional Abelian ideal and with commutation relations which are defined via the matrix A and $\lambda_1,\dots,\lambda_{n-1}$ be roots of the characteristic polynomial of A over $\mathbb{C}$. If*

$$\mathrm{tr}(A^p) = \lambda_1^p + \cdots + \lambda_{n-1}^p \neq 0, \quad \mathrm{tr}(A^q) = \lambda_1^q + \cdots + \lambda_{n-1}^q \neq 0,$$

$$\mathrm{tr}(A^{p+q}) = \lambda_1^{p+q} + \cdots + \lambda_{n-1}^{p+q} \neq 0,$$

then the value $\mathfrak{C}_{pq}$ is well-defined invariant characteristics of the algebra $\mathfrak{a}_A$ and is given by the formula

$$\mathfrak{C}_{pq} = \frac{\mathrm{tr}(A^p)\mathrm{tr}(A^q)}{\mathrm{tr}(A^{p+q})} = \frac{(\lambda_1^p + \cdots + \lambda_{n-1}^p)(\lambda_1^q + \cdots + \lambda_{n-1}^q)}{(\lambda_1^{p+q} + \cdots + \lambda_{n-1}^{p+q})}.$$

The rank of the algebra $\mathfrak{a}_A$ (i.e., the dimension of its Cartan subalgebra) equals to the order of zero root of the characteristic polynomial of the matrix A plus one.

B. Lie algebras with WH+A ideals of codimension one

Consider an n-dimensional complex or real Lie algebra with an $(n-1)$-dimensional ideal which is isomorphic to the direct sum of the Weyl-Heisenberg algebra $\mathfrak{h}_3=A_{3.1}$ and the $(n-4)$-dimensional Abelian algebra. Let e_1, e_2, and e_3 form the canonical basis of a $\mathfrak{h}_3$-isomorphic component, $e_4,\dots,e_{n-1}$ give a basis of the Abelian component of the ideal, and e_n completes the basis of the ideal to a basis of the whole algebra. The nonzero commutation relations between elements of the constructed bases are

$$[e_2,e_3]=e_1,\quad [e_j,e_n]=\sum_{k=1}^{n-1} a_j^k e_k,\quad j=1,\ldots,n-1.$$

The $(n-1)\times(n-1)$ matrix $A=(a_j^k)$ defines the algebra completely hence we will denote this algebra by $\mathfrak{w}_A$, i.e., $\mathfrak{w}_A:=A_1\oplus_A(\mathfrak{h}_3\oplus(n-4)A_1)$. The Jacobi identity implies the following constraints on elements of A:

$$a_1^1=a_2^2+a_3^3,\quad a_1^k=0,\quad k=2,\ldots,n-1,\quad a_i^2=a_i^3=0,\quad i=4,\ldots,n-1.$$

The matrix $\hat{\mathrm{ad}}_u$ of the adjoint representation of an arbitrary element $u\in\mathfrak{w}_A$ is calculated in a way which is analogous to the previous case and has the form

$$\hat{\mathrm{ad}}_u=\begin{pmatrix} u_nA+u_3E_2^1-u_2E_3^1 & -A\bar{u} \\ \underline{0} & 0 \end{pmatrix},$$

where $\bar{u}=(u_1,\ldots,u_{n-1})^T$, $\underline{0}=(0,\ldots,0)$, E_j^i is the $(m-1)\times(m-1)$ matrix with unit in $\begin{smallmatrix} i \\ j \end{smallmatrix}$ entry and zero otherwise. In view of the restrictions on the matrix A we again have

$$\mathrm{tr}(\mathrm{ad}_u^{\ p})=u_n^{\ p}\,\mathrm{tr}(A^p),\quad \chi_{\mathrm{ad}_u}(\lambda)=-\lambda\chi_{u_nA}(\lambda).$$

Therefore, Lemma 2 can be completely reformulated for the algebra $\mathfrak{w}_A$.

Lemma 3: *Let* $\mathfrak{w}_A=A_1\oplus_A(\mathfrak{h}_3\oplus(n-4)A_1)$ *and* $\lambda_1,\ldots,\lambda_{n-1}$ *be roots of the characteristic polynomial of* A *over* $\mathbb{C}$. *If*

$$\mathrm{tr}(A^p)=\lambda_1^p+\cdots+\lambda_{n-1}^p\neq 0,\quad \mathrm{tr}(A^q)=\lambda_1^q+\cdots+\lambda_{n-1}^q\neq 0,$$

$$\mathrm{tr}(A^{p+q})=\lambda_1^{p+q}+\cdots+\lambda_{n-1}^{p+q}\neq 0,$$

then $\mathfrak{C}_{pq}$ *is well-defined invariant characteristics of the algebra* $\mathfrak{a}_A$ *and is given by the formula*

$$\mathfrak{C}_{pq}=\frac{\mathrm{tr}(A^p)\mathrm{tr}(A^q)}{\mathrm{tr}(A^{p+q})}=\frac{(\lambda_1^p+\cdots+\lambda_{n-1}^p)(\lambda_1^q+\cdots+\lambda_{n-1}^q)}{(\lambda_1^{p+q}+\cdots+\lambda_{n-1}^{p+q})}.$$

The rank of the algebra $\mathfrak{w}_A$ *(i.e., the dimension of its Cartan subalgebra) equals to the order of zero root of the characteristic polynomial of the matrix A plus one.*

C. Special cases

The adjoint action of any element $u\in\mathrm{so}(3)$ is presented in the canonical basis in the form $\hat{\mathrm{ad}}_u\,\hat{v}=\hat{u}\times\hat{v}$. Hereafter $\hat{u}$ and $\hat{v}$ are the coordinate columns of u and v treated as elements of R^3, "$\cdot$" and "$\times$" denote the usual scalar and vector products in R^3. By induction,

$$\mathrm{ad}_u^{\ 2p'-1}v=(-|\hat{u}|^2)^{p'-1}\hat{u}\times\hat{v},\quad \mathrm{ad}_u^{\ 2p'}v=(-|\hat{u}|^2)^{p'-1}((\hat{u}\cdot\hat{v})\hat{u}-|\hat{u}|^2\hat{v}),\quad p'\in\mathbb{N},$$

i.e., $\mathrm{tr}(\mathrm{ad}_u^{\ 2p'-1})=0$, $\mathrm{tr}(\mathrm{ad}_u^{\ 2p'})=(-|\hat{u}|^2)^{p'}$, $p'\in N$. Therefore, $\mathfrak{C}_{2p',2q'}=2$. For the other pairs of the indices p and q the invariant $\mathfrak{C}_{pq}$ is undefined.

The same statement is true for the algebras $\mathrm{sl}(2,R)$, $\mathrm{so}(3)\oplus A_1$, and $\mathrm{sl}(2,R)\oplus A_1$. The arguments are that $\mathrm{sl}(2,R)$ is equivalent to $\mathrm{so}(3)$ over $\mathbb{C}$ and the algebras $\mathfrak{g}$ and $\mathfrak{g}\oplus kA_1$ have the same invariants $\mathfrak{C}_{pq}$.

In the canonical basis of $2A_{2.1}$, where the commutation relations are $[e_1,e_2]=e_1$, $[e_3,e_4]=e_3$, the matrices of $\mathrm{ad}_u^{\ p}$, $p\in N$, have the form

$$\hat{\mathrm{ad}}_u^{\,p}=\begin{pmatrix} u_2^p & -u_2^{p-1}u_1 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & u_4^p & -u_4^{p-1}u_3\\ 0 & 0 & 0 & 0 \end{pmatrix},$$

i.e., $\mathrm{tr}(\mathrm{ad}_u^{\,p})=u_2^p+u_4^p$. Since the fraction with traces from the definition of $\mathfrak{C}_{pq}$ explicitly depends on u and v in the case of $2A_{2.1}$, the value $\mathfrak{C}_{pq}$ is undefined for any $p,q\in N$.

The same statement is true for the algebra $A_{4.10}$ being isomorphic to $2A_{2.1}$ over $\mathbb{C}$.

VI. LOW-DIMENSIONAL REAL LIE ALGEBRAS

We use the complete lists of nonisomorphic classes of real three- and four-dimensional Lie algebras, which were constructed by Mubarakzyanov[55] and slightly enhanced in Refs. 65 and 66. Enumeration of algebras by Mubarakzyanov is followed in general.

A number of algebraic characteristics and quantities are adduced for each Lie algebra $\mathfrak{g}$ from the lists. More precisely we deal with the type of the algebra (such as decomposable, solvable, nilpotent, etc.); the dimension n_{D} of the differentiation algebra $\mathrm{Der}\,\mathfrak{g}$; the dimension n_{Z} of the center; the maximal dimension n_{A} of the Abelian subalgebras; the Killing form κ; the rank $r_{\mathfrak{g}}$ (equal to the dimension of the Cartan subalgebras); the rank of solvability r_s (if $\mathfrak{g}$ is solvable); the rank of nilpotency r_n (if $\mathfrak{g}$ is nilpotent); the tuple of dimensions of the components of derived series $\mathrm{DS}=[\dim\mathfrak{g}^{(1)},\dim\mathfrak{g}^{(2)},\dots,\dim\mathfrak{g}^{(k)}]$, where k is the minimal number with $\dim\mathfrak{g}^{(k)}=\dim g^{(i)}\,\forall\, i>k$; the tuple of dimensions of the components of lower central series $\mathrm{CS}=[\dim\mathfrak{g}^1,\dim\mathfrak{g}^2,\dots,\dim g^k]$, where k is the minimal number with $\dim\mathfrak{g}^k=\dim\mathfrak{g}^i\,\forall\, i>k$; the trace $\mathrm{tr}(\mathrm{ad}_v)$ of the adjoint representations of arbitrary element $v\in V$, and the invariant $\mathfrak{C}_{pq}$ for the values $p,q\in N$ when this invariant is well defined.

These characteristics and quantities are used in Sec. VII and VIII as a basis for application of necessary contraction criteria.

A. Three-dimensional algebras

$3A_1$: (Abelian, unimodular);
$n_{\mathrm{D}}=9$, $n_{\mathrm{Z}}=3$, $n_{\mathrm{A}}=3$, $\kappa=0$, $r_{\mathfrak{g}}=3$, $r_n=r_s=1$, $\mathrm{DS}=[0]$, $\mathrm{CS}=[0]$, $\mathrm{tr}(\mathrm{ad}_v)=0$.
$A_{2.1}\oplus A_1$: $[e_1,e_2]=e_1$ (decomposable, solvable);
$n_{\mathrm{D}}=4$, $n_{\mathrm{Z}}=1$, $n_{\mathrm{A}}=2$, $\kappa=x_2y_2$, $r_{\mathfrak{g}}=2$, $r_s=2$, $\mathrm{DS}=[1,0]$, $\mathrm{CS}=[1]$, $\mathrm{tr}(\mathrm{ad}_v)=-v_2$, $\mathfrak{C}_{pq}=1$.
$A_{3.1}$: $[e_2,e_3]=e_1$ (Heisenberg, indecomposable, nilpotent, unimodular);
$n_{\mathrm{D}}=6$, $n_{\mathrm{Z}}=1$, $n_{\mathrm{A}}=2$, $\kappa=0$, $r_{\mathfrak{g}}=3$, $r_n=r_s=2$, $\mathrm{DS}=[1,0]$, $\mathrm{CS}=[1,0]$, $\mathrm{tr}(\mathrm{ad}_v)=0$.
$A_{3.2}$: $[e_1,e_3]=e_1$, $[e_2,e_3]=e_1+e_2$ (indecomposable, solvable);
$n_{\mathrm{D}}=4$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=2$, $\kappa=2x_3y_3$, $r_{\mathfrak{g}}=1$, $r_s=2$, $\mathrm{DS}=[2,0]$, $\mathrm{CS}=[2]$, $\mathrm{tr}(\mathrm{ad}_v)=-2v_3$, $\mathfrak{C}_{pq}=2$.
$A_{3.3}$: $[e_1,e_3]=e_1$, $[e_2,e_3]=e_2$ (indecomposable, solvable);
$n_{\mathrm{D}}=6$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=2$, $\kappa=2x_3y_3$, $r_{\mathfrak{g}}=1$, $r_s=2$, $\mathrm{DS}=[2,0]$, $\mathrm{CS}=[2]$, $\mathrm{tr}(\mathrm{ad}_v)=-2v_3$, $\mathfrak{C}_{pq}=2$.
$A_{3.4}^{-1}$: $[e_1,e_3]=e_1$, $[e_2,e_3]=-e_2$ (indecomposable, solvable, unimodular);
$n_{\mathrm{D}}=4$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=2$, $\kappa=2x_3y_3$, $r_{\mathfrak{g}}=1$, $r_s=2$, $\mathrm{DS}=[2,0]$, $\mathrm{CS}=[2]$, $\mathrm{tr}(\mathrm{ad}_v)=0$, $\mathfrak{C}_{2p,2q}=2$.
$A_{3.4}^{a}$: $[e_1,e_3]=e_1$, $[e_2,e_3]=ae_2$, $0<|a|<1$ (indecomposable, solvable);
$n_{\mathrm{D}}=4$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=2$, $\kappa=(1+a^2)x_3y_3$, $r_{\mathfrak{g}}=1$, $r_s=2$, $\mathrm{DS}=[2,0]$, $\mathrm{CS}=[2]$, $\mathrm{tr}(\mathrm{ad}_v)=-(1+a)v_3$,
$\mathfrak{C}_{pq}=1+[(a^p+a^q)/(1+a^{p+q})]$.
$A_{3.5}^{0}$: $[e_1,e_3]=-e_2$, $[e_2,e_3]=e_1$ (indecomposable, solvable, unimodular);
$n_{\mathrm{D}}=4$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=2$, $\kappa=-2x_3y_3$, $r_{\mathfrak{g}}=1$, $r_s=2$, $\mathrm{DS}=[2,0]$, $\mathrm{CS}=[2]$, $\mathrm{tr}(\mathrm{ad}_v)=0$, $\mathfrak{C}_{2p,2q}=2$.
$A_{3.5}^{b}$: $[e_1,e_3]=be_1-e_2$, $[e_2,e_3]=e_1+be_2$, $b>0$ (indecomposable, solvable);
$n_{\mathrm{D}}=4$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=2$, $\kappa=2(b^2-1)x_3y_3$, $r_{\mathfrak{g}}=1$, $r_s=2$, $\mathrm{DS}=[2,0]$, $\mathrm{CS}=[2]$, $\mathrm{tr}(\mathrm{ad}_v)=-2bv_3$,
$\mathfrak{C}_{pq}=[2\,\mathrm{Re}(b+i)^p\mathrm{Re}(b+i)^q]/[\mathrm{Re}(b+i)^{p+q}]$.
sl(2,R): $[e_1,e_2]=e_1$, $[e_2,e_3]=e_3$, $[e_1,e_3]=2e_2$ (indecomposable, simple, unimodular);
$n_{\mathrm{D}}=3$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=1$, $\kappa=-2(2x_3y_1-x_2y_2+2x_1y_3)$, $r_{\mathfrak{g}}=1$, $\mathrm{DS}=[3]$, $\mathrm{CS}=[3]$, $\mathrm{tr}(\mathrm{ad}_v)=0$,
$\mathfrak{C}_{2p,2q}=2$.
so(3): $[e_1,e_2]=e_3$, $[e_2,e_3]=e_1$, $[e_3,e_1]=e_2$ (indecomposable, simple, unimodular);

$n_D=3$, $n_Z=0$, $n_A=1$, $\kappa=-2(x_1y_1+x_2y_2+x_3y_3)$, $r_g=1$, DS=[3], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=0$, $\mathfrak{C}_{2p,2q}=2$.

Remark 7: Two terms of the above list (namely, $\{A^a_{3.4}\}$ and $\{A^b_{3.5}\}$) are, in fact, Lie algebra series, and each of them being parametrized with one real parameter. Some values of the parameters are singular, i.e., algebra characteristics for them differ from the ones for regular values. For example, the Killing form of the algebra $\{A^b_{3.5}\}$ identically vanishes if $b=1$. The same parameter values are singular from the viewpoint of realizations, invariants, subalgebras, etc. See, e.g., Refs. 61, 63, 65, and 66

This fact prevents one from creation of a "canonical" list of inequivalent low-dimensional Lie algebras. Whether is it reasonable to extract the algebras corresponding to singular parameter values from series? The question is answered in different ways. For example, in Refs. 61 and 63 all such algebras are separated from the series and have individual numbers. In Ref. 55 only the direct sums and single algebras (e.g., $A_{3.3}$) are considered separately from the corresponding series.

Another barrier for canonization of the existing lists is generated by ambiguous choice of series parameters normalization and even by existence of essentially different approaches to such normalization.

We follow the numeration by Mubarakzyanov, explicitly point out all the singular values of series parameters and study the corresponding algebras separately from the regular algebras of series. Usage of this technique simplifies application of necessary contraction criteria.

Let us note that Agaoka[1,2] proposed classifications of three- and four-dimensional algebras, which are well adapted to investigation of contractions and deformations. The presented approach can be extended to the real case and algebras of greater dimensions.

B. Four-dimensional algebras

$4A_1$ (Abelian, unimodular);
$n_D=16$, $n_Z=4$, $n_A=4$, $r_g=4$, $r_n=r_s=1$, DS=[0], CS=[0], $\mathrm{tr}(\mathrm{ad}_v)=0$.
$A_{2.1}\oplus 2A_1$: $[e_1,e_2]=e_1$ (decomposable, solvable);
$n_D=8$, $n_Z=2$, $n_A=3$, $\kappa=x_2y_2$, $r_g=3$, $r_s=2$, DS=[1,0], CS=[1], $\mathrm{tr}(\mathrm{ad}_v)=-v_2$, $\mathfrak{C}_{pq}=1$.
$2A_{2.1}$: $[e_1,e_2]=e_1$, $[e_3,e_4]=e_3$ (decomposable, solvable);
$n_D=4$, $n_Z=0$, $n_A=2$, $\kappa=x_2y_2+x_4y_4$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=-(v_2+v_4)$.
$A_{3.1}\oplus A_1$: $[e_2,e_3]=e_1$ (decomposable, nilpotent, unimodular);
$n_D=10$, $n_Z=2$, $n_A=3$, $\kappa=0$, $r_g=4$, $r_n=r_s=2$, DS=[1,0], CS=[1,0], $\mathrm{tr}(\mathrm{ad}_v)=0$.
$A_{3.2}\oplus A_1$: $[e_1,e_3]=e_1$, $[e_2,e_3]=e_1+e_2$ (decomposable, solvable);
$n_D=6$, $n_Z=1$, $n_A=3$, $\kappa=2x_3y_3$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=-2v_3$, $\mathfrak{C}_{pq}=2$.
$A_{3.3}\oplus A_1$: $[e_1,e_3]=e_1$, $[e_2,e_3]=e_2$ (decomposable, solvable);
$n_D=8$, $n_Z=1$, $n_A=3$, $\kappa=2x_3y_3$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=-2v_3$, $\mathfrak{C}_{pq}=2$.
$A^{-1}_{3.4}\oplus A_1$: $[e_1,e_3]=e_1$, $[e_2,e_3]=-e_2$ (decomposable, solvable, unimodular);
$n_D=6$, $n_Z=1$, $n_A=3$, $\kappa=2x_3y_3$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=0$, $\mathfrak{C}_{2p,2q}=2$.
$A^a_{3.4}\oplus A_1$: $[e_1,e_3]=e_1$, $[e_2,e_3]=ae_2$, $0<|a|<1$ (decomposable, solvable);
$n_D=6$, $n_Z=1$, $n_A=3$, $\kappa=(1+a^2)x_3y_3$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=-(1+a)v_3$,
$\mathfrak{C}_{pq}=1+[(a^p+a^q)/(1+a^{p+q})]$.
$A^0_{3.5}\oplus A_1$: $[e_1,e_3]=-e_2$, $[e_2,e_3]=e_1$ (decomposable, solvable, unimodular);
$n_D=6$, $n_Z=1$, $n_A=3$, $\kappa=-2x_3y_3$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=0$, $\mathfrak{C}_{2p,2q}=2$.
$A^b_{3.5}\oplus A_1$: $[e_1,e_3]=be_1-e_2$, $[e_2,e_3]=e_1+be_2$, $b>0$ (decomposable, solvable);
$n_D=6$, $n_Z=1$, $n_A=3$, $\kappa=2(b^2-1)x_3y_3$, $r_g=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=-2bv_3$,
$\mathfrak{C}_{pq}=[2\,\mathrm{Re}(b+i)^p\mathrm{Re}(b+i)^q]/[\mathrm{Re}(b+i)^{p+q}]$.
$sl(2,R)\oplus A_1$: $[e_1,e_2]=e_1$, $[e_2,e_3]=e_3$, $[e_1,e_3]=2e_2$ (decomposable, unsolvable, reductive, unimodular);
$n_D=4$, $n_Z=1$, $n_A=2$, $\kappa=-2(2x_3y_1-x_2y_2+2x_1y_3)$, $r_g=2$, DS=[3], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=0$,
$\mathfrak{C}_{2p2q}=2$.
$so(3)\oplus A_1$: $[e_1,e_2]=e_3$, $[e_2,e_3]=e_1$, $[e_3,e_1]=e_2$ (decomposable, unsolvable, reductive, nimodular);
$n_D=4$, $n_Z=1$, $n_A=2$, $\kappa=-2(x_1y_1+x_2y_2+x_3y_3)$, $r_g=2$, DS=[3], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=0$, $\mathfrak{C}_{2p,2q}=2$.

$\mathbf{A_{4.1}}$: $[e_2,e_4]=e_1$, $[e_3,e_4]=e_2$ (indecomposable, solvable, nilpotent, unimodular);
$n_{\mathrm{D}}=7$, $n_{\mathrm{Z}}=1$, $n_{\mathrm{A}}=3$, $\kappa=0$, $r_{\mathfrak{g}}=4$, $r_n=3$, $r_s=2$, DS=[2,0], CS=[2,1,0], $\mathrm{tr}(\mathrm{ad}_v)=0$.
$\mathbf{A^1_{4.2}}$: $[e_1,e_4]=e_1$, $[e_2,e_4]=e_2$, $[e_3,e_4]=e_2+e_3$ (indecomposable, solvable);
$n_{\mathbf{D}}=8$, $n_{\mathbf{Z}}=0$, $n_{\mathbf{A}}=3$, $\kappa=3x_4y_4$, $r_{\mathfrak{g}}=1$, $r_s=2$, DS=[3,0], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=-3v_4$, $.\mathfrak{C}_{pq}=3$.
$\mathbf{A^{-2}_{4.2}}$: $[e_1,e_4]=-2e_1$, $[e_2,e_4]=e_2$, $[e_3,e_4]=e_2+e_3$ (indecomposable, solvable, unimodular);
$n_{\mathrm{D}}=6$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=3$, $\kappa=(b^2+2)x_4y_4$, $r_{\mathfrak{g}}=1$, $r_s=2$, DS=[3,0], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=0$,
$\mathfrak{C}_{pq}=[(2+(-2)^p)(2+(-2)^q)]/[2+(-2)^{p+q}]$, $p,q\geqslant 2$.
$\mathbf{A^b_{4.2}}$: $[e_1,e_4]=be_1$, $[e_2,e_4]=e_2$, $[e_3,e_4]=e_2+e_3$, $b\neq -2,0,1$ (indecomposable, solvable);
$n_{\mathrm{D}}=6$, $n_{\mathrm{Z}}=0$, $n_{\mathrm{A}}=3$, $\kappa=(b^2+2)x_4y_4$, $r_{\mathfrak{g}}=1$, $r_s=2$, DS=[3,0], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=-(2+b)v_4$,
$\mathfrak{C}_{pq}=[(2+b^p)(2+b^q)]/(2+b^{p+q})$.

$\mathbf{A}^{\mathbf{a}}_{\mathbf{4.9}}$: $[e_2,e_3]=e_1$, $[e_1,e_4]=2ae_1$, $[e_2,e_4]=ae_2-e_3$, $[e_3,e_4]=e_2+ae_3$, $a>0$ (indecomposable, solvable);
$n_D=5$, $n_Z=0$, $n_A=1$, $\kappa=2(3a^2-1)x_4y_4$, $r_{\mathfrak{g}}=1$, $r_s=3$, DS=[3,1,0], CS=[3], $\mathrm{tr}(\mathrm{ad}_v)=-4av_4$, $\mathfrak{C}_{pq}=[((2a)^p+2\,\mathrm{Re}(a+i)^p)((2a)^q+2\,\mathrm{Re}(a+i)^q)]/[(2a)^{p+q}+2\,\mathrm{Re}(a+i)^{p+q}]$, $p,q\geqslant 2$;.

$\mathbf{A}_{\mathbf{4.10}}$: $[e_1,e_3]=e_1$, $[e_2,e_3]=e_2$, $[e_1,e_4]=-e_2$, $[e_2,e_4]=e_1$ (indecomposable, solvable);
$n_D=4$, $n_Z=0$, $n_A=2$, $\kappa=2(x_3y_3-x_4y_4)$, $r_{\mathfrak{g}}=2$, $r_s=2$, DS=[2,0], CS=[2], $\mathrm{tr}(\mathrm{ad}_v)=-2v_3$.

Remark 8: Problems concerning series of algebras and singular values of parameters become more complicated in the case of dimension four. In particular, in the Lie algebra series $\{A^b_{4.2}\}$, $\{A^{abc}_{4.5}\}$, and $\{A^b_{4.8}\}$ the dimension n_D of the differentiation algebra varies depending on values of the series parameters. It implies obvious necessity of separation of series parameter subsets according to values of this semi-invariant quantity since Criterion 1 based on n_D is most powerful.

In the above list of algebras, we apply enhanced normalization of series parameters for four-dimensional real Lie algebras, which were proposed in Refs. 65 and 66.

VII. ALGORITHM OF CONTRACTION IDENTIFICATION

The proposed algorithm allows one to handle the continuous one-parametric contractions of the low-dimensional Lie algebras. It consists of three steps.

(1) We take a complete list of nonisomorphic Lie algebras of a fixed dimension. For each member of this list we calculate invariant and semi-invariant quantities that concern necessary criteria of contractions.
(2) For each pair of algebras from the list we test possible existence of contractions with the necessary criteria of contractions via comparing the calculated invariant and semi-invariant quantities. Since it is sufficient to look only for nontrivial and proper contractions, we have not to study the pairs of any Lie algebra with itself and the Abelian one.
(3) Consider each from the pairs which satisfy all the necessary criteria of contractions. Applying the direct method based on Definition 1′, we either construct a contraction matrix in an explicit form or prove that no contraction is possible.

The requisite invariant and semi-invariant quantities of the real three- and four-dimensional Lie algebras are calculated and collected in Sec. VI.

Most of contractions of low-dimensional Lie algebras are realized via simple Inönü-Wigner contractions. Any simple Inönü-Wigner contraction corresponds to a subalgebra of the initial algebra and therefore is easy to find. Classification of subalgebras of three- and four-dimensional Lie algebras is well known.[61] All simple Inönü-Wigner contractions of these algebras are constructed in Refs. 15 and 39. We only enhance presentation of the corresponding contraction matrices.

For the pairs without simple Inönü-Wigner contractions we continue investigation with generalized Inönü-Wigner contractions. Here the problem of finding contraction matrices can be divided into two subproblems.

- To construct appropriate transformations for the canonical bases of the initial and resulting algebras, which do not depend on the contraction parameter. The aim is for the nonzero new structure constants of the resulting algebra to coincide with the corresponding new structure constants of the initial algebra.
- To find a diagonal matrix depending on the contraction parameter. It is sufficient to assume that the diagonal elements are integer powers of the contraction parameter.

As a rule, we can manage to avoid basis change in the resulting algebras in the case of dimensions three and four. Consequently, the contraction matrix can be represented as a product of two

matrices $U_\varepsilon = IW(k_1,\dots,k_n)$, where I is a constant nonsingular matrix and $W(k_1,\dots,k_n) = \mathrm{diag}(\varepsilon^{k_1},\dots,\varepsilon^{k_n})$, $k_1,\dots,k_n \in \mathbb{Z}$.

In complicated cases contraction matrices can be found using repeated contractions (see Sec. X).

To demonstrate effectiveness of the algorithm, we discuss two typical examples in detail.

Example 2: Consider the series of three-dimensional Lie algebras $A_{3.4}^a$ parametrized with one real parameter a, where $-1 \leqslant a < 1, a \neq 0$. Let us investigate all possible contractions of algebra $A_{3.4}^a$ for a fixed value of a.

$A_{3.4}^a$ is an indecomposable solvable Lie algebra with the canonical nonzero commutation relations $[e_1,e_3]=e_1$, $[e_2,e_3]=ae_2$. The tuple of considered quantities for the algebra $A_{3.4}^a$ is

$$n_{\mathrm{D}} = 4, \quad n_{\mathrm{Z}} = 0, \quad n_{\mathrm{A}} = 2, \quad \kappa = (1+a^2)x_3y_3, \quad \mathrm{tr}(\mathrm{ad}\, e_3) = -1-a, \quad r_s = 2,$$

$$\mathrm{DS} = [2,0], \quad \mathrm{CS} = [2].$$

According to the second step of the algorithm we look through all pairs of three-dimensional algebras, where the initial algebra is $A_{3.4}^a$ and the resulting algebra runs the list from Sec. VI A and does not coincide with $3A_1$ and $A_{3.4}^a$.

For each pair we compare tuples of their semi-invariant quantities. In view of Theorem 1 we conclude that

- contractions to the algebras $A_{2.1}\oplus A_1$, $A_{3.2}$, $A_{3.4}^{\tilde a}$, $\tilde a \neq a$, $A_{3.5}^b$, $b \geqslant 0$, $\mathrm{sl}(2,\mathbb{R})$ and so(3) are impossible since Criterion 1 is not satisfied;
- contraction to the algebra $A_{3.3}$ is impossible according to Criterion 15; and
- contraction to the algebra $A_{3.1}$ may exist inasmuch as all the tested necessary criteria are held.

Other criteria can also be used to prove nonexistence of contractions. For example, for the algebras $\mathrm{sl}(2,\mathbb{R})$ and so(3) we can also use Criterion 2, 5, 11, or 17. In all cases we try to apply a minimal set of the most effective criteria such as Criterion 1. In particular, Criterion 1 is very important for the example under consideration, since due to strict inequality it allows one to prove the absence of contractions inside the series $A_{3.4}^a$ in a very simple way.

Therefore, on the third step of the algorithm we investigate only the pair $(A_{3.4}^a, A_{3.1})$.

The canonical nonzero commutation relation of the algebra $A_{3.1}$ is $[e_2,e_3]=e_1$. Since in the canonical basis of $A_{3.4}^a$ the structure constant c_{23}^1 equals to zero we carry out the basis change $e'_1=(1-a)e_1$, $e'_2=e_1+e_2$, $e'_3=e_3$. The new isomorphic commutation relations have the form

$$[e_1,e_2]' = 0, \quad [e_1,e_3]' = e_1, \quad [e_2,e_3]' = e_1 + ae_2.$$

Now the desired contraction is provided by the matrix $\mathrm{diag}(\varepsilon,1,\varepsilon)$ and the subsequent limit process $\varepsilon \to +0$ results in the algebra $A_{3.1}$:

$$[e_1,e_2]_\varepsilon = 0,$$

$$[e_1,e_3]_\varepsilon = \varepsilon e_1 \to 0, \quad \varepsilon \to +0,$$

$$[e_2,e_3]_\varepsilon = e_1 + \varepsilon a e_2 \to e_1, \quad \varepsilon \to +0.$$

Finally, all nontrivial proper contractions of the Lie algebra $A_{3.4}^a$ are exhausted by the single contraction $A_{3.4}^a \to A_{3.1}$ which is generated by the matrix $I_5\,\mathrm{diag}(\varepsilon,1,\varepsilon)$, where the explicit form of I_5 is adduced in Sec. VIII A.

Example 3: Consider the decomposable, unsolvable, unimodular, reductive four-dimensional Lie algebra $\mathrm{sl}(2,\mathbb{R})\oplus A_1$, having the canonical commutation relations $[e_1,e_2]=e_1$, $[e_2,e_3]=e_3$, and $[e_1,e_3]=2e_2$. The set of algebraic quantities which are used to study contractions of this algebra is exhausted by

$$n_D=4,\quad n_Z=1,\quad n_A=1,\quad n_{[\mathfrak{g},\mathfrak{g}]}=3,\quad \kappa=-2(2x_3y_1-x_2y_2+2x_1y_3),\quad \mathrm{DS}=[3],\quad \mathrm{CS}=[3].$$

The quantities of $\mathrm{sl}(2,\mathbb{R})\oplus A_1$ are compared with the analogous quantities of the other four-dimensional algebras. All the requisite quantities are adduced in Sec. VI B. In view of necessary contraction criteria we conclude that

- contractions to the algebras $A_{2.1}\oplus 2A_1$, $2A_{2.1}$, $A_{3.2}\oplus A_1$, $A_{3.3}\oplus A_1$, $A^a_{3.4}\oplus A_1$, $|a|<1, a\neq 0$, -1, $A^b_{3.5}\oplus A_1$, $b>0$, $A_{4.3}$, $A^b_{4.8}$, $|b|\leqslant 1, b\neq -1$, and $A^a_{4.9}$, $a>0$ are impossible in view of Criterion 12;
- contraction to the algebra $\mathrm{so}(3)\oplus A_1$ does not exist since Criterion 1 is not held;
- contractions to the algebras $A^b_{4.2}$, $b\neq 0$, $A_{4.4}$, $A^{abc}_{4.5}$, $abc\neq 0$, $A^{a,b}_{4.6}$, $a>0$, $A_{4.7}$, and $A_{4.10}$ are impossible in view of Criterion 3; and
- contractions to the algebras $A_{3.1}\oplus A_1$, $A_{4.1}$, $A^{-1}_{3.4}\oplus A_1$, $A^0_{3.5}\oplus A_1$, $A^{-1}_{4.8}$, and $A^0_{4.9}$ may exist inasmuch as all the tested necessary criteria of contractions are satisfied.

Note that not only Criteria 1, 3, and 12 could be used to separate algebras for which there are no contractions from the algebra $\mathrm{sl}(2,\mathbb{R})\oplus A_1$. For example, Criterion 1 implies impossibility of contractions from $\mathrm{sl}(2,\mathbb{R})\oplus A_1$ to $A_{4.4}$.

The contractions admitted by the necessary criteria can actually be executed. Contractions to the algebras $A_{3.1}\oplus A_1$, $A^{-1}_{3.4}\oplus A_1$, $A^0_{3.5}\oplus A_1$, $A_{4.1}$, $A^{-1}_{4.8}$, and $A^0_{4.9}$ are provided by the contraction matrices $I_8\,\mathrm{diag}(\varepsilon,\varepsilon,1,1)$, $I_7\,\mathrm{diag}(\varepsilon,\varepsilon,1,1)$, $I_{10}\,\mathrm{diag}(\varepsilon,\varepsilon,1,1)$, $I_{23}\,\mathrm{diag}(\varepsilon,\varepsilon,\varepsilon,1)$, $I_{19}\,\mathrm{diag}(\varepsilon,1,\varepsilon,1)$, and $I_{22}\,\mathrm{diag}(\varepsilon^2,\varepsilon,\varepsilon,1)$, correspondingly. The explicit forms of the matrices I's are presented in Sec. VIII B.

Note that all the contractions except the last one are simple Inönü-Wigner contractions and are constructed using a list of inequivalent subalgebras of $\mathrm{sl}(2,\mathbb{R})\oplus A_1$. We illustrate the applied technique with the pair $(\mathrm{sl}(2,\mathbb{R})\oplus A_1, A_{3.1}\oplus A_1)$. See also Sec. III for the theoretical background.

$\langle e_3,e_4\rangle$ is a subalgebra of $\mathrm{sl}(2,\mathbb{R})\oplus A_1$. The associated contraction matrix $\mathrm{diag}(\varepsilon,\varepsilon,1,1)$ produces a simple IW-contraction from $\mathrm{sl}(2,\mathbb{R})\oplus A_1$ to a Lie algebra isomorphic to $A_{3.1}\oplus A_1$. In order to obtain the canonical commutation relations ($[e_2,e_3]=e_1$) of the algebra $A_{3.1}\oplus A_1$, we apply additional isomorphism transformation given by the matrix I_8 which commutes with $\mathrm{diag}(\varepsilon,\varepsilon,1,1)$. The resulting contraction matrix is $I_8\,\mathrm{diag}(\varepsilon,\varepsilon,1,1)$.

Further consider the pair $(\mathrm{sl}(2,\mathbb{R})\oplus A_1, A^0_{4.9})$ in detail as an example on construction of generalized IW-contractions. Our aim is to find an appropriate contraction matrix according to the above algorithm.

The canonical commutation relations of the algebra $A^0_{4.9}$ are $[e_2,e_3]=e_1$, $[e_2,e_4]=-e_3$, and $[e_3,e_4]=e_2$. In contrast to the algebra $A^0_{4.9}$, the canonical structure constants c^1_{23}, c^3_{24}, and c^2_{34} of the algebra $\mathrm{sl}(2,\mathbb{R})\oplus A_1$ vanish. That is why we carry out the basis change

$$e_1'=-\frac{1}{2}e_1-\frac{1}{2}e_3,\quad e_2'=e_2,\quad e_3'=\frac{1}{2}e_1-\frac{1}{2}e_3,\quad e_4'=\frac{1}{2}e_1+\frac{1}{2}e_3+e_4,$$

which is associated with the matrix I_{22}. The obtained commutation relations (being isomorphic to the old one of $\mathrm{sl}(2,\mathbb{R})\oplus A_1$) have the form

$$[e_1,e_2]'=-e_3,\quad [e_1,e_3]'=e_2,\quad [e_1,e_4]'=0,\quad [e_2,e_3]'=e_1,\quad [e_2,e_4]'=-e_3,\quad [e_3,e_4]'=e_2.$$

Let us suppose that for the new Lie bracket $[\cdot,\cdot]'$ the requisite contraction is provided by the matrix $\mathrm{diag}(\varepsilon^{k_1},\varepsilon^{k_2},\varepsilon^{k_3},\varepsilon^{k_4})$ and calculate the parametrized commutators:

$$[e_1,e_2]_\varepsilon=-\varepsilon^{k_1+k_2-k_3}e_3,\quad [e_1,e_3]_\varepsilon=\varepsilon^{k_1+k_3-k_2}e_2,\quad [e_1,e_4]_\varepsilon=0,$$

$$[e_2,e_3]_\varepsilon=\varepsilon^{k_2+k_3-k_1}e_1,\quad [e_2,e_4]_\varepsilon=-\varepsilon^{k_2+k_4-k_3}e_3,\quad [e_3,e_4]_\varepsilon=\varepsilon^{k_3+k_4-k_2}e_2.$$

The limit of the commutators under $\varepsilon\to+0$ exists and gives the algebra $A^0_{4.9}$ iff the powers $k_1,\ldots,k_4$ are constrained by the conditions

$$k_2+k_3-k_1=0,\quad k_2+k_4-k_3=0,\quad k_3+k_4-k_2=0,\quad k_1+k_2-k_3>0,\quad k_1+k_3-k_2>0.$$

The tuple $k_1=2$, $k_2=k_3=1$, $k_4=0$ satisfies these conditions. The corresponding contraction indeed results in the algebra $A_{4.9}^0$:

$$[e_1,e_2]_\varepsilon=-\varepsilon^2 e_3\to 0,\quad \varepsilon\to+0,\quad [e_1,e_3]_\varepsilon=\varepsilon^2 e_2\to 0,\quad \varepsilon\to+0,$$

$$[e_1,e_4]_\varepsilon=0,\quad [e_2,e_3]_\varepsilon=e_1,\quad [e_2,e_4]_\varepsilon=-e_3,\quad [e_3,e_4]_\varepsilon=e_2.$$

The complete contraction matrix is $I_{22}\,\mathrm{diag}(\varepsilon^2,\varepsilon,\varepsilon,1)$.

This example demonstrates that necessary criteria allow one to handle contractions even in cases of such complicated algebras as reductive ones.

Remark 9: Celeghini and Tarlini[14] proposed the conjecture that all nonsemisimple Lie algebras of a fixed dimension could be obtained via contractions from semisimple ones. Actually, the conjecture is incorrect. There are no semisimple Lie algebras for some dimensions, e.g., in the case of dimension four. Therefore, a wider class (e.g., the class of reductive algebras or even the whole class of unsolvable algebras) should be used in the conjecture instead of semisimple algebras. The other argument on incorrectness of the conjecture is that all semisimple (and reductive) Lie algebras are unimodular and any continuous contraction of a unimodular algebra necessarily results in a unimodurar algebra. Complexity of the actual state of affairs is illustrated by consideration of low-dimensional algebras.

The unsolvable three-dimensional algebras are exhausted by the simple algebras $\mathrm{sl}(2,\mathbb{R})$ and so(3). Any three-dimensional unimodular algebra ($\mathrm{sl}(2,\mathbb{R})$, so(3), $A_{3.4}^{-1}$, $A_{3.4}^0$, $A_{3.1}$, $3A_1$) belongs to the orbit closure of at least one of the simple algebras.

The reductive algebras $\mathrm{sl}(2,\mathbb{R})\oplus A_1$ and $\mathrm{so}(3)\oplus A_1$ form the set of unsolvable four-dimensional algebras. The union of orbit closures of these algebras consists of the unimodular algebras with the nontrivial centers ($\mathrm{sl}(2,\mathbb{R})\oplus A_1$, $\mathrm{so}(3)\oplus A_1$, $A_{4.8}^{-1}$, $A_{4.9}^0$, $A_{3.4}^{-1}\oplus A_1$, $A_{3.4}^0\oplus A_1$, $A_{4.1}$, $A_{3.1}\oplus A_1$, $4A_1$). The unimodular algebras having the zero centers ($A_{4.2}^{-2}$, $A_{4.5}^{abc}$, $a+b+c=0$, $A_{4.6}^{-2b,b}$) cannot be obtained via contractions from the unsolvable algebras.

The situation with contractions of representations is different.[58] For example, matrix representations of all inequivalent classes of the real three-dimensional Lie algebras are contractions of appropriately chosen representations (with ε-dependent similarity transformations) of the simple algebras $\mathrm{sl}(2,\mathbb{R})$ and so(3). More precisely, concerning the parametrized series of Lie algebras ($A_{3.4}^a$, $A_{3.5}^b$), only representations for single values of parameters can be obtained via contractions.

VIII. ONE-PARAMETRIC CONTRACTIONS OF REAL LOW-DIMENSIONAL LIE ALGEBRAS

The objective of this section is to construct, order, and analyze the contractions of real low-dimensional Lie algebras.

At first, we discuss all possible contractions of one- and two-dimensional Lie algebras. Since there is only one inequivalent one-dimensional Lie algebra and it is Abelian, all its contractions are trivial and improper at the same time. The complete list of nonisomorphic two-dimensional Lie algebras is exhausted by the Abelian algebra $2A_1$ and the nonAbelian algebra $A_{2.1}$ with the canonical commutation relation $[e_1,e_2]=e_1$. The unique weakly inequivalent contraction of the algebra $2A_1$ is trivial and improper at the same time. The contractions of the algebra $A_{2.1}$ are either trivial or improper.

Contractions of real three- and four-dimensional Lie algebras are listed in Secs. VIII A and VIII B and additionally visualized with Figs. 1 and 2. Denote that contractions of the three-dimensional real Lie algebras were considered in Ref. 78. A complete description of these contractions with proof closed to the manner of our paper was first obtained in Ref. 47.

Only proper direct contractions are presented on the figures. Let us remind that a contraction from $\mathfrak{g}$ to $\mathfrak{g}_0$ is called *direct* if there is no algebra $\mathfrak{g}_1$ such that $\mathfrak{g}_1\not\simeq\mathfrak{g},\mathfrak{g}_0$, $\mathfrak{g}$ is contracted to $\mathfrak{g}_1$ and $\mathfrak{g}_1$ is contracted to $\mathfrak{g}_0$. Antonym to this notion is the notion of repeated contraction. See Sec. X for

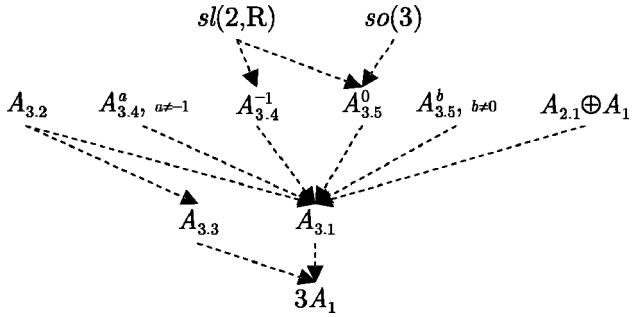

FIG. 1. One-parametric contractions of real three-dimensional Lie algebras.

details. The algebra $\mathfrak{g}$ is necessarily contracted to $\mathfrak{g}_0$ if $\mathfrak{g}$ is contracted to $\mathfrak{g}_1$ and $\mathfrak{g}_1$ is contracted to $\mathfrak{g}_0$. That is why the arrows corresponding to repeated contractions can be omitted.

In the lists of contractions we collect all the suitable pairs of Lie algebras with the same initial algebras which are adduced once. The corresponding contraction matrices are indicated over the arrows. In the section we use the shortcut notation for the diagonal parts of matrices of generalized Inönü-Wigner contractions:

$$W(k_1,k_2,\ldots,k_n)=\mathrm{diag}(\varepsilon^{k_1},\varepsilon^{k_2},\ldots,\varepsilon^{k_n}),$$

where $k_i\in\mathbb{Z}$, $i=\overline{1,n}$, n is the dimension of the underlying vector space V. The constant "left-hand" parts of matrices of generalized Inönü-Wigner contractions are denoted by numbered symbols I. Their explicit forms are adduced after the lists of contractions. The notation $\varepsilon\to+0$ is omitted everywhere.

In the case of simple Inönü-Wigner contractions we additionally adduce the associated subalgebras.

A. Dimension three

The list of all possible proper and nontrivial continuous one-parametric contractions of real three-dimensional Lie algebras is exhausted by the following ones (see also Fig. 1):

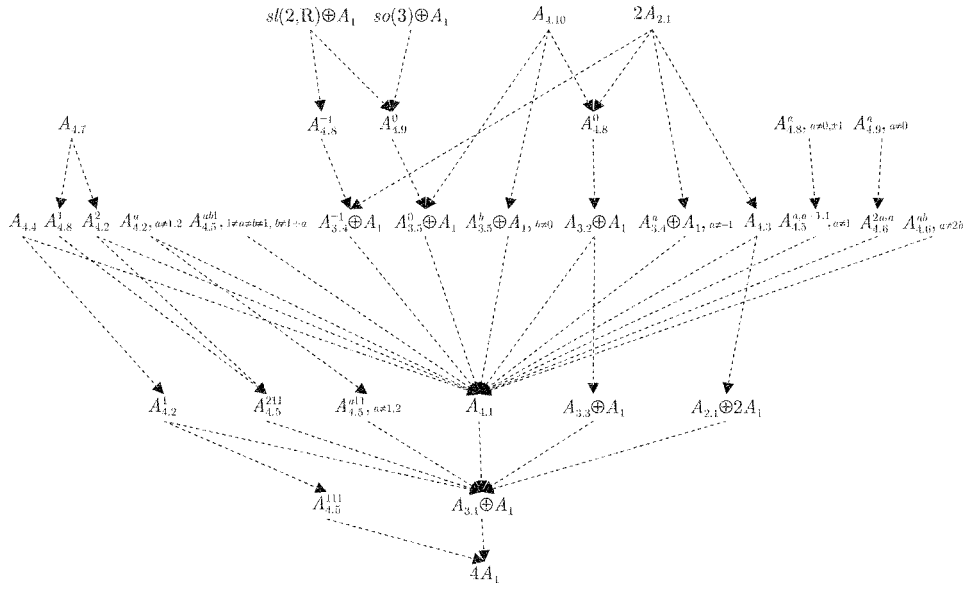

FIG. 2. One-parametric contractions of real four-dimensional Lie algebras.

$$A_{2.1}\oplus A_1:\quad \xrightarrow{I_1W(1,1,0)} A_{3.1},\langle e_1-e_3\rangle.$$

$$A_{3.2}:\quad \xrightarrow{I_7W(1,0,1)\text{ or }W(2,1,1)} A_{3.1},\langle e_2\rangle,\qquad \xrightarrow{I_6W(0,1,0)\text{ or }W(1,2,0)} A_{3.3},\langle e_1,e_2+e_3\rangle.$$

$$A_{3.4}^a:\quad \xrightarrow{I_2W(1,0,1)} A_{3.1},\langle e_1+e_2\rangle.$$

$$A_{3.5}^b:\quad \xrightarrow{W(1,0,1)} A_{3.1},\langle e_2\rangle.$$

$$\mathrm{sl}(2,\mathbb{R}):\quad \xrightarrow{I_3W(1,1,0)} A_{3.1},\langle e_3\rangle,\quad \xrightarrow{I_4W(1,0,0)} A_{3.4}^{-1},\langle e_2,e_3\rangle,\quad \xrightarrow{I_5W(1,1,0)} A_{3.5}^{0},\langle e_1+e_3\rangle.$$

$$\mathrm{so}(3):\quad \xrightarrow{W(2,1,1)} A_{3.1},\quad \xrightarrow{W(1,1,0)} A_{3.5}^{0},\langle e_3\rangle.$$

The constant parts of contraction matrices have the form

$$I_1=\begin{pmatrix}1&0&-1\\0&1&0\\0&0&1\end{pmatrix},\quad I_2=\begin{pmatrix}1-a&1&0\\0&1&0\\0&0&1\end{pmatrix},\quad I_3=\begin{pmatrix}0&1&0\\2&0&0\\0&0&1\end{pmatrix},$$

$$I_4=\begin{pmatrix}1&0&0\\0&0&1\\0&-1&0\end{pmatrix},\quad I_5=\begin{pmatrix}0&0&1/2\\0&1&0\\1&0&1/2\end{pmatrix},$$

$$I_6=\begin{pmatrix}1&0&0\\0&1&1\\0&0&1\end{pmatrix},\quad I_7=\begin{pmatrix}-1&0&0\\0&1&0\\0&0&-1\end{pmatrix}.$$

Analysis of the obtained results leads to the conclusion that for any pair of real three-dimensional Lie algebras we have one of the two possibilities: (1) there are no contractions in view of applied necessary criteria; (2) there exists a generalized Inönü-Wigner contraction.

Only the contraction $\mathrm{so}(3)\to A_{3.1}$ is necessarily a truly generalized Inönü-Wigner contraction. Nonexistence of a simple Inönü-Wigner contraction in this case is implied by the following chain of statements. Any proper and nontrivial simple Inönü-Wigner contraction corresponds to proper subalgebras of the initial algebra. Equivalent subalgebras result in equivalent contractions. A complete list of inequivalent proper subalgebras of so(3) is exhausted by any one-dimensional subalgebra of so(3). Any one-dimensional subalgebra generates the contraction of so(3) to $A_{3.5}^0$.

All other contractions of real three-dimensional Lie algebras are equivalent to simple Inönü-Wigner contractions although sometimes generalized Inönü-Wigner contraction has a simpler, pure diagonal form. We explicitly indicate two such cases in the above list of contractions, namely, $A_{3.2}\to A_{3.1}$ and $A_{3.2}\to A_{3.3}$.

Note additionally that all the constructed contraction matrices include only non-negative integer powers of ε, i.e., they admit well-defined limit process under $\varepsilon\to+0$.

Theorem 2: *Any continuous contraction of a real three-dimensional Lie algebra is equivalent to a generalized Inönü-Wigner contraction with non-negative powers of the contraction parameter. Moreover, only the contraction* $\mathrm{so}(3)\to A_{3.1}$ *is inequivalent to a simple Inönü-Wigner contraction.*

B. Dimension four

The list of all possible proper and nontrivial continuous one-parametric contractions of real four-dimensional Lie algebras is exhausted by the following ones:

$$A_{2.1}\oplus 2A_1:\quad \xrightarrow{I_{30}W(1,1,0,0)} A_{3.1}\oplus A_1,\langle e_3-e_1,e_4\rangle.$$

$$2A_{2.1}:\quad \xrightarrow{W(0,0,0,1)} A_{2.1}\oplus 2A_1,\langle e_1,e_2,e_3\rangle,\quad \xrightarrow{I_1W(1,1,0,1)} A_{3.1}\oplus A_1,\langle e_1+e_3\rangle,$$

$$\xrightarrow{U_3} A_{3.2}\oplus A_1,\quad \xrightarrow{I_2W(0,0,0,1)} A_{3.3}\oplus A_1,\langle e_1,e_3,e_2+e_4\rangle,\quad \xrightarrow{I_{27}W(1,1,0,1)} A^a_{3.4}\oplus A_1,\langle e_2+ae_4\rangle,$$

$$\xrightarrow{U_4} A_{4.1},\quad \xrightarrow{I_{28}W(0,1,1,0)} A_{4.3},\langle e_1,e_2-e_3\rangle,\quad \xrightarrow{I_3W(1,0,1,0)} A^0_{4.8},\langle e_1+e_3,e_2+e_4\rangle.$$

$$A_{3.2}\oplus A_1:\quad \xrightarrow{W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_2,e_4\rangle,\quad \xrightarrow{W(0,1,0,0)} A_{3.3}\oplus A_1,\langle e_1,e_3,e_4\rangle,\quad \xrightarrow{I_{29}W(2,1,0,1)} A_{4.1}.$$

$$A_{3.3}\oplus A_1:\quad \xrightarrow{I_4W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_1,e_2+e_4\rangle.$$

$$A^a_{3.4}\oplus A_1:\quad \xrightarrow{I_5W(1,1,0,0)} A_{3.1}\oplus A_1,\langle e_2,e_1+e_4\rangle,\quad \xrightarrow{I_6W(2,1,0,1)} A_{4.1}.$$

$$A^b_{3.5}\oplus A_1:\quad \xrightarrow{W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_2,e_4\rangle,\quad \xrightarrow{I_9W(2,1,0,1)} A_{4.1}.$$

$$\mathrm{sl}(2,\mathbb{R})\oplus A_1:\quad \xrightarrow{I_8W(1,1,0,0)} A_{3.1}\oplus A_1,\langle e_3,e_4\rangle,\quad \xrightarrow{I_7W(1,1,0,0)} A^{-1}_{3.4}\oplus A_1,\langle e_2,e_4\rangle,\quad \xrightarrow{I_{10}W(1,1,0,0)} A^0_{3.5}\oplus A_1,$$
$$\langle e_1+e_3,e_4\rangle,\quad \xrightarrow{I_{23}W(1,1,1,0)} A_{4.1},\langle e_1+e_4\rangle,\quad \xrightarrow{I_{19}W(1,0,1,0)} A^{-1}_{4.8},\langle e_1,e_2-1/2e_4\rangle,\quad \xrightarrow{I_{22}W(2,1,1,0)} A^0_{4.9}.$$

$$\mathrm{so}(3)\oplus A_1:\quad \xrightarrow{W(2,1,1,0)} A_{3.1}\oplus A_1,\quad \xrightarrow{W(1,1,0,0)} A^0_{3.5}\oplus A_1,\langle e_3,e_4\rangle,\quad \xrightarrow{I_5W(3,2,1,1)} A_{4.1},\quad \xrightarrow{I_{11}W(2,1,1,0)} A^0_{4.9}.$$

$$A_{4.1}:\quad \xrightarrow{I_{13}(0)W(0,0,0,1)} A_{3.1}\oplus A_1,\langle e_1,e_2,e_4\rangle.$$

$$A^b_{4.2}:\quad \xrightarrow{I_{14}W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_1,e_3\rangle,\quad \xrightarrow{b\neq 1,I_{15}W(2,1,0,1)} A_{4.1},\quad \xrightarrow{W(1,0,1,0)} A^{b,1,1}_{4.5},\langle e_2,e_4\rangle.$$

$$A_{4.3}:\quad \xrightarrow{I_{16}W(0,0,1,0)} A_{2.1}\oplus 2A_1,\langle e_1,e_2,e_4\rangle,\quad \xrightarrow{I_{14}W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_1,e_3\rangle,\quad \xrightarrow{I_{17}W(2,1,0,1)} A_{4.1}.$$

$$A_{4.4}:\quad \xrightarrow{I_{13}(0)W(1,0,1,1)} A_{3.1}\oplus A_1,\langle e_2\rangle,\quad \xrightarrow{W(2,1,0,1)} A_{4.1},\quad \xrightarrow{W(0,1,1,0)} A^1_{4.2},\langle e_1,e_4\rangle,\quad \xrightarrow{W(0,1,2,0)} A^{111}_{4.5}.$$

$$A^{ab1}_{4.5}:\quad \xrightarrow{a\neq b,I_{18}W(1,0,1,0)} A_{3.1}\oplus A_1,\langle (1+b)/ae_1+e_2,e_3\rangle,\quad \xrightarrow{1\neq a\neq b\neq 1,I_{12}W(2,1,0,1)} A_{4.1}.$$

$$A^{ab}_{4.6}:\quad \xrightarrow{I_{14}W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_1,e_3\rangle,\quad \xrightarrow{I_{20}W(2,1,0,1)} A_{4.1}.$$

$$A_{4.7}: \xrightarrow{I_{14}W(1,0,1,0)} A_{3.1}\oplus A_1,\langle e_1,e_3\rangle, \xrightarrow{I_{21}W(1,1,1,0)} A_{4.1},\langle e_4\rangle, \xrightarrow{W(0,1,1,0)} A^2_{4.2},\langle e_1,e_4\rangle,$$

$$\xrightarrow{W(0,0,1,0)} A^{2,1,1}_{4.5},\langle e_1,e_2,e_4\rangle, \xrightarrow{W(1,0,1,0)} A^1_{4.8},\langle e_2,e_4\rangle.$$

$$A^b_{4.8}: \xrightarrow{W(0,0,0,1)} A_{3.1}\oplus A_1,\langle e_1,e_2,e_3\rangle, \xrightarrow{b=0,I_{24}W(0,0,0,1)} A_{3.2}\oplus A_1,\langle e_1,e_2,e_3+e_4\rangle,$$

$$\xrightarrow{b=0,I_{13}(0)W(0,0,0,1)} A_{3.3}\oplus A_1,\langle e_1,e_2,e_4\rangle, \xrightarrow{b=-1,I_{13}(0)W(1,1,0,1)} A^{-1}_{3.4}\oplus A_1,\langle e_4\rangle,$$

$$\xrightarrow{b\neq 1,I_{25}W(1,1,1,0)} A_{4.1},\langle e_2-e_3\rangle, \xrightarrow{-1<b<0,W(0,0,1,0)} A^{1+b,1,b}_{4.5},\langle e_1,e_2,e_4\rangle$$

$$\xrightarrow{0<b\leqslant 1,\mathrm{diag}\left(1,1,1,\frac{1}{1+b}\right)W(0,0,1,0)} A^{1,1/(1+b),b/(1+b)}_{4.5},\langle e_1,e_2,e_4\rangle.$$

$$A^a_{4.9}: \xrightarrow{W(0,0,0,1)} A_{3.1}\oplus A_1,\langle e_1,e_2,e_3\rangle, \xrightarrow{a=0,I_{14}W(1,1,0,0)} A^0_{3.5}\oplus A_1,\langle e_1,e_4\rangle,$$

$$\xrightarrow{I_{26}W(1,1,1,0)} A_{4.1},\langle e_2\rangle, \xrightarrow{a\neq 0,W(1,1,1,0)} A^{2a,a}_{4.6},\langle e_4\rangle.$$

$$A_{4.10}: \xrightarrow{I_{13}(0)W(1,0,1,1)} A_{3.1}\oplus A_1,\langle e_2\rangle, \xrightarrow{U_1} A_{3.2}\oplus A_1, \xrightarrow{W(0,0,0,1)} A_{3.3}\oplus A_1,\langle e_1,e_2,e_3\rangle,$$

$$\xrightarrow{I_{13}W(0,0,0,1)} A^b_{3.5}\oplus A_1,\langle e_1,e_2,be_3+e_4\rangle, \xrightarrow{U_2} A_{4.1}, \xrightarrow{I_{13}(0)W(1,0,1,0)} A^0_{4.8},\langle e_2,e_3\rangle.$$

The constant parts of matrices of generalized Inönü-Wigner contractions have the form

$$I_1=\begin{pmatrix}0&0&1&0\\0&0&0&1\\-1&0&1&0\\0&1&0&1\end{pmatrix},\quad I_2=\begin{pmatrix}1&2&0&0\\0&0&1&0\\0&1&0&0\\0&0&1&1\end{pmatrix},\quad I_3=\begin{pmatrix}0&-1&0&0\\0&0&0&1\\-1&-1&0&0\\0&0&1&1\end{pmatrix},$$

$$I_4=\begin{pmatrix}0&0&0&1\\-1&-1&0&0\\0&0&1&0\\0&-1&0&0\end{pmatrix},\quad I_5=\begin{pmatrix}-1&0&1&0\\0&0&0&1\\0&1&0&0\\0&0&1&0\end{pmatrix},\quad I_6=\begin{pmatrix}-1/a&1/[a(a-1)]&1/[a(a-1)]&0\\0&a&1&0\\0&0&0&1\\0&0&1&0\end{pmatrix},$$

$$I_7=\begin{pmatrix}1&0&0&0\\0&0&1&0\\0&-1&0&0\\0&0&0&1\end{pmatrix},\quad I_8=\begin{pmatrix}0&1&0&0\\2&0&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},\quad I_9=\begin{pmatrix}1&0&-1/(b^2+1)&0\\0&1&b/(b^2+1)&0\\0&0&0&1\\0&0&1&0\end{pmatrix},$$

$$I_{10}=\begin{pmatrix}0&0&1/2&0\\0&1&0&0\\1&0&1/2&0\\0&0&0&1\end{pmatrix},\quad I_{11}=\begin{pmatrix}1&0&0&1\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},$$

$$I_{12}=\begin{pmatrix}1/(b-1)&(a-b)^{-1}/(b-1)&(a-b)^{-1}/[(a-1)(b-1)]&0\\0&b-1&1&0\\0&0&1&0\\0&0&0&1\end{pmatrix},$$

$$I_{13}(b)=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&b&1\\0&0&1&0\end{pmatrix},\quad I_{14}=\begin{pmatrix}0&0&0&1\\1&0&0&0\\0&1&0&0\\0&0&1&0\end{pmatrix},\quad I_{15}=\begin{pmatrix}1&-1/(b-1)&-1/(b-1)^2&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},$$

$$I_{16}=\begin{pmatrix}1&0&0&0\\0&0&0&1\\0&0&1&0\\0&1&0&0\end{pmatrix},\quad I_{17}=\begin{pmatrix}1&1&1&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},\quad I_{18}=\begin{pmatrix}1&(1+b)/a&0&0\\0&1&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix},$$

$$I_{19}=\begin{pmatrix}0&1&0&0\\0&0&0&1\\0&0&1&0\\1&0&0&-1/2\end{pmatrix},\quad I_{20}=\begin{pmatrix}-1&0&0&0\\0&1&0&0\\0&0&0&-1\\0&0&1&0\end{pmatrix},$$

$$I_{21}=\begin{pmatrix}1&[(a-b)(a-1)^{-1}]/(a-b+1)&(a-1)^{-1}/(a-b+1)&0\\0&0&1&0\\0&-1&0&0\\0&0&0&1\end{pmatrix},$$

$$I_{22}=\begin{pmatrix}-1/2&0&1/2&1/2\\0&1&0&0\\-1/2&0&-1/2&1/2\\0&0&0&1\end{pmatrix},\quad I_{23}=\begin{pmatrix}0&0&0&1\\0&1&0&0\\0&0&-1/2&0\\1&0&0&1\end{pmatrix},\quad I_{24}=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&1&1\end{pmatrix},$$

$$I_{25}=\begin{pmatrix}1&0&0&0\\0&1&0&-1\\0&0&0&1\\0&0&1/(b-1)&0\end{pmatrix},\quad I_{26}=\begin{pmatrix}-1&0&0&0\\0&0&0&1\\0&1&0&0\\0&0&1&0\end{pmatrix},\quad I_{27}=\begin{pmatrix}1&0&0&0\\0&0&1&0\\0&1&0&0\\0&0&a&-1\end{pmatrix},$$

$$I_{28}=\begin{pmatrix}-1&0&0&0\\0&0&0&1\\0&1&0&-1\\0&0&1&0\end{pmatrix},\quad I_{29}=\begin{pmatrix}1&0&-1&0\\0&1&1&0\\0&0&0&1\\0&0&1&0\end{pmatrix},\quad I_{30}=\begin{pmatrix}1&0&-1&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix}.$$

Remark 10: All the constructed contraction matrices include only non-negative integer powers of ε. Therefore, they admit well-defined limit process under $\varepsilon \to +0$. Moreover, most contractions are equivalent to simple IW-contractions.

All generalized IW-contractions of solvable real four-dimensional algebras (namely, $A_{3.2} \oplus A_1$, $A_{3.4}^a \oplus A_1$, $A_{3.5}^b \oplus A_1$, $A_{4.2}^b$, $b \neq 1$, $A_{4.3}$, $A_{4.4}$, $A_{4.5}^{ab1}$, $1 \neq a \neq b \neq 1$, $A_{4.6}^{ab}$) to $A_{4.1}$ are direct and, therefore, cannot be presented via composition of simple IW-contractions. The same statement is true for the contractions of the unsolvable algebras $[\mathrm{sl}(2,\mathbb{R}) \oplus A_1$ and $\mathrm{so}(3) \oplus A_1]$ to $A_{4.9}^0$. Only three generalized IW-contractions $[\mathrm{so}(3) \oplus A_1 \to A_{3.1} \oplus A_1$, $\mathrm{so}(3) \oplus A_1 \to A_{4.1}$, and $A_{4.4} \to A_{4.5}^{111}]$ are decomposed to sequences of simple IW-contractions. The listed contractions exhaust a set of inequivalent "truly" generalized IW-contractions of the real four-dimensional algebras.

In contrast to three-dimensional Lie algebras, there exist four contractions of four-dimensional Lie algebras, which are inequivalent to generalized Inönü-Wigner contractions, namely,

$$A_{4.10} \xrightarrow{U_1} A_{3.2} \oplus A_1, \quad 2A_{2.1} \xrightarrow{U_2} A_{3.2} \oplus A_1,$$

$$A_{4.10} \xrightarrow{U_3} A_{4.1}, \quad 2A_{2.1} \xrightarrow{U_4} A_{4.1}.$$

They are provided by the "nondiagonalizable" matrices

$$U_1 = \begin{pmatrix} \varepsilon & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & \varepsilon \\ 0 & 0 & \varepsilon & 0 \end{pmatrix}, \quad U_2 = \begin{pmatrix} 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & \varepsilon \\ -\varepsilon & -1 & 0 & 0 \\ 0 & 0 & 1+\varepsilon & \varepsilon \end{pmatrix},$$

$$U_3 = \begin{pmatrix} \varepsilon^2 & 0 & 0 & 0 \\ 0 & \varepsilon & 0 & -1 \\ 0 & 0 & \varepsilon & 0 \\ 0 & 0 & 0 & \varepsilon \end{pmatrix}, \quad U_4 = \begin{pmatrix} -\varepsilon^2 & -\varepsilon & -1 & -1 \\ 0 & 0 & \varepsilon & 0 \\ 0 & -\varepsilon^2 & -\varepsilon & 0 \\ 0 & 0 & \varepsilon & \varepsilon \end{pmatrix}.$$

The matrices U_1 and U_2 include only the zero and first powers of the contraction parameter. Therefore, the corresponding contractions are Saletan ones.

Remark 11: The maximal powers of contraction parameter, which are in components of contraction matrices, can be lowered if the restriction with the class of generalized IW-contractions in case they exist will be neglected. For example, a generalized IW-contraction from the algebra $\mathrm{so}(3) \oplus A_1$ to $A_{4.9}^0$ is generated by the matrix $I_{11}W(2,1,1,0)$ containing components with the second power of the contraction parameter. At the same time, it is known[67] that there exists the Saletan contraction between these algebras which is provided by the matrix

$$\begin{pmatrix} 0 & \varepsilon & 0 & 0 \\ 0 & 0 & \varepsilon & 0 \\ -\varepsilon & 0 & 0 & 1 \\ -\varepsilon & 0 & 0 & 1-\varepsilon \end{pmatrix}$$

obviously being of the first power with respect to ε.

Another example is given by the contraction $\mathrm{so}(3) \to A_1 \to A_{4.1}$. It is generated, as a generalized IW-contraction, with the matrix $I_5W(3,2,1,1)$ and has the essential contraction parameter power which is equal to 3 and is maximal among the generalized IW-contractions of the four-dimensional Lie algebras. All the other presented generalized IW-contractions contain at most the second power of the contraction parameter. [The similar situation is in the three-dimensional case

where the unique truly generalized IW-contraction is the contraction $\mathrm{so}(3)\to A_{3.1}$ with the matrix $W(2,1,1)$ containing the second power of ε.] The matrix $I_5W(3,2,1,1)$ can be replaced with the matrix

$$\begin{pmatrix} 0 & 0 & \varepsilon & 0 \\ 0 & -\varepsilon^2 & 0 & 0 \\ 0 & 0 & 0 & \varepsilon \\ -\varepsilon^2 & 0 & -1 & 0 \end{pmatrix},$$

which has no "generalized IW form" and contains at most the second power of the contraction parameter.

Remark 12: In each from the following pairs of Lie algebras:

$$(\mathrm{so}(3)\oplus A_1, A_{4.8}^{-1}),\quad (\mathrm{so}(3)\oplus A_1, A_{3.4}^{-1}\oplus A_1),\quad (A_{4.8}^{-1}, A_{3.5}^{0}\oplus A_1),\quad (A_{4.9}^{0}, A_{3.4}^{-1}\oplus A_1),$$

$$(A_{4.10}, A_{4.3}),\quad (A_{4.10}, A_{2.1}\oplus 2A_1),\quad (A_{4.10}, A_{3.4}^{a}\oplus A_1),\quad (2A_{2.1}, A_{3.5}^{b}\oplus A_1),$$

the first algebra is contracted to the second one over the complex field. See Sec. IX additionally. In particular,

$$A_{4.10} \xrightarrow{I_{31}W(1,1,1,0)} A_{4.3},\quad A_{4.10} \xrightarrow{I_{32}W(1,1,0,1)} A_{3.4}^{a}\oplus A_1,\quad 2A_{2.1} \xrightarrow{I_{33}W(0,0,0,1)} A_{3.5}^{b}\oplus A_1,$$

where

$$I_{31}=\begin{pmatrix} -i & i & 0 & -i \\ 1 & 1 & 0 & -1 \\ 0 & 0 & 1/2 & 1/2 \\ 0 & 0 & 1/2 & -i/2 \end{pmatrix},\quad I_{32}=\begin{pmatrix} i & -1 & 0 & 0 \\ i & 1 & 0 & 0 \\ 0 & 0 & (1+a)/2 & -i(1+a)/2 \\ 0 & 0 & -1/2 & -i/2 \end{pmatrix},$$

$$I_{33}=\begin{pmatrix} -i/2 & -1/2 & 0 & 0 \\ 0 & 0 & b+i & 1 \\ -i/2 & 1/2 & 0 & 0 \\ 0 & 0 & b-i & 1 \end{pmatrix}.$$

Therefore, almost all necessary criteria hold true since they do not discriminate between the real and complex fields. At the same time, there are no real contractions in these pairs. To prove it, we have to apply criteria specific for the real numbers, e.g., Criterion 16 which is based on the law of inertia of quadratic forms over the real field.

For the first four pairs it is enough to consider only their Killing forms. $\kappa_{\mathrm{so}(3)\oplus A_1}=-2(u_1v_1+u_2v_2+u_3v_3)$, $\kappa_{A_{3.5}^{0}\oplus A_1}=-2u_3v_3$, and $\kappa_{A_{4.9}^{0}}=-2u_4v_4$ are nonpositively defined. $\kappa_{A_{4.8}^{-1}}=2u_4v_4$ and $\kappa_{A_{3.4}^{-1}\oplus A_1}=2u_3v_3$ are non-negatively defined. All the above forms do not vanish identically. Therefore, in each of these pairs an algebra has the nonpositively defined nonzero Killing form and the other does the non-negative defined nonzero one. In view of necessary Criterion 16, there are no contractions in these pairs.

The criterion based on inertia of the Killing forms is powerless for the algebras from the other pairs. For them we consider the modified Killing forms with the specially chosen value $\alpha=-1/2$:

$$\widetilde{\kappa}_{A_{4.10}}^{-1/2}=\left.2(1+2\alpha)u_3v_3-2u_4v_4\right|_{\alpha=-1/2}=-2u_4v_4,$$

$$\widetilde{\kappa}_{A_{3.5}^{b}\oplus A_1}^{-1/2}=\left.2((1+2\alpha)b^2-1)u_3v_3\right|_{\alpha=-1/2}=-2u_3v_3,$$

$$\widetilde{\kappa}^{-1/2}_{A_{4.3}} = (1+\alpha)u_4v_4|_{\alpha=-1/2} = \frac{1}{2}u_2v_2, \quad \widetilde{\kappa}^{1/2}_{A_{2.1}\oplus 2A_1} = (1+\alpha)u_2v_2|_{\alpha=-1/2} = \frac{1}{2}u_4v_4,$$

$$\widetilde{\kappa}^{-1/2}_{A^a_{3.4}\oplus A_1} = ((1+a^2)+\alpha(1+a)^2)u_3v_3|_{\alpha=-1/2} = \frac{1}{2}(1-a+a^2)u_3v_3,$$

$$\widetilde{\kappa}^{-1/2}_{2A_{2.1}} = ((1+\alpha)(u_2v_2+u_4v_4)+\alpha(u_2v_4+u_4v_2))|_{\alpha=-1/2} = \frac{1}{2}((u_2v_2+u_4v_4)-(u_2v_4+u_4v_2)).$$

Two first forms are nonpositively defined and nonzero. The others are non-negatively defined and also do not vanish identically. In view of the second part of Criterion 16, there are no contractions in the pairs under consideration.

C. Levels and colevels of low-dimensional real Lie algebras

Contractions assign the partial ordering relationship on the variety $\mathcal{L}_n$ of n-dimensional Lie algebras. Namely, we assume that $\mathfrak{g} \succ \mathfrak{g}_0$ if g_0 is a proper contraction of g. The introduced strict order is well defined due to the transitivity property of contractions. If improper contractions are allowed in the definition of ordering then the partial ordering becomes nonstrict.

The order $\succ$ generates separation of $\mathcal{L}_n$ to tuples of levels of different types.

Definition 7: The Lie algebra $\mathfrak{g}$ from $\mathcal{L}_n$ belongs to the *zero level* of $\mathcal{L}_n$ if it has no proper contractions. The other levels of $\mathcal{L}_n$ are defined by induction. The Lie algebra $\mathfrak{g}$ belongs to *k level* of $\mathcal{L}_n$ if it can be contracted to algebras from $(k-1)$ level and only to algebras from the previous levels.

Remark 13: We have recently become aware due to Ref. 47 that the notion of level was introduced and investigated by Gorbatsevich.[27–29] He also proposed another notion of level based on interesting generalization of contractions to case of different dimensions of initial and contracted algebras, which is reviewed in the Introduction.

The zero level of $\mathcal{L}_n$ for any n contains exactly one algebra, and it is the n-dimensional Abelian algebra which is the unique minimal element in $\mathcal{L}_n$. The elements of the last level are maximal elements with respect to the ordering relationship induced by contractions in $\mathcal{L}_n$ but do not generally exhaust the set of maximal elements of $\mathcal{L}_n$.

Obtained exhaustive description of contractions of low-dimensional Lie algebras allows us to completely study levels of these algebras.

$\mathcal{L}_1$ consists of one element and has only one algebra level. Analogously, $\mathcal{L}_2$ is formed by two elements and is separated by contractions into exactly two levels. The first level consists of the two-dimensional non-Abelian algebra $A_{2.1}$ and the zero level does the two-dimensional Abelian algebra $2A_1$.

The hierarchies of levels of real three- and four-dimensional Lie algebras are more complicated. Actually, they are already represented in Figs. 1 and 2, where the level number grows upward. It is the usage of the level ideology that makes the figures clear and elucidative. $\mathcal{L}_3$ and $\mathcal{L}_4$ have four and six levels, correspondingly.

Remark 14: Structure of Lie algebra is simplified under contraction. The level number of an algebra can be assumed as a measure of complexity of its commutation structure, i.e., algebras with higher level numbers are more complicated than those with lower level numbers. In particular, nilpotent algebras are in low levels. The simple algebras $\mathrm{sl}(2,\mathbb{R})$ and so(3) having the most complicated structures among three-dimensional algebras form the highest three level of $\mathcal{L}_3$. The highest six level of $\mathcal{L}_4$ is formed by the unsolvable algebras $\mathrm{sl}(2,\mathbb{R})\oplus A_1$ and $\mathrm{so}(3)\oplus A_1$ and the perfect (by Jacobson[44]) algebras $2A_{2.1}$ and $A_{4.10}$.

Remark 15: There exists an inverse correlation of level numbers with dimensions of differentiation algebras (or a direct correlation with dimensions of algebra orbits), which is connected with necessary Criterion 1. As a rule, the algebras with the same dimension of differentiation algebras belong to the same level. The dimensions of differentiation algebras of the algebras from

k level are not less and generally greater than those of the algebras from $(k+1)$ level.

For the three-dimensional Lie algebras the correlation is complete. Namely, the dimension of differentiation algebra takes the values of 9, 6, 4, and 3 for the algebras from zero-, one-, two-, and three-levels, correspondingly.

In $\mathcal{L}_4$ the correlation is partially broken. Namely, for almost all algebras from three-level the dimensions of the differentiation algebras equal to 6 and only the algebra $A_{4.8}^{1}$ which also belongs to this level has seven-dimensional differentiation algebra. The same happens in two level. Almost all algebras have eight-dimensional differentiation algebras except the algebra $A_{4.1}$ with seven-dimensional differentiation algebra. In other words, the four-dimensional Lie algebras with dim Der=7 are separated between the second and third levels, and the "simpler" nilpotent algebra $A_{4.1}$ belongs to the lower level. The algebras $A_{4.5}^{111}$ (dim Der=12) and $A_{3.1}\oplus A_1$ (dim Der=10) form one-level. In all other cases the correlation is complete. Zero-, five-, and six-levels consist of the algebras having 16-, 5-, and 4-dimensional differentiation algebras, correspondingly.

Starting from the Lie algebras which are not proper contractions of any Lie algebras, we can introduce the related definition of colevel.

Definition 8: The Lie algebra $\mathfrak{g}$ from $\mathcal{L}_n$ belongs to the *zero colevel* of $\mathcal{L}_n$ if it is not a proper contraction of any n-dimensional Lie algebra. The other colevels of $\mathcal{L}_n$ are defined by induction. The Lie algebra $\mathfrak{g}$ belongs to a *colevel* of $\mathcal{L}_n$ if it is a proper contraction only of algebras from the previous colevels.

Zero colevel coincides with the set of maximal elements with respect to the order induced by contractions in $\mathcal{L}_n$, i.e., it is formed by the algebras which are not proper contractions of the other algebras from $\mathcal{L}_n$. The last colevel of $\mathcal{L}_n$ for any n contains exactly one algebra, and it is the n-dimensional Abelian algebra.

For the lowest dimensions structures of levels and colevels are analogous. $\mathcal{L}_1$ has only zero colevel which obviously coincides with zero level. $\mathcal{L}_2$ is separated by contractions into exactly two colevels. The zero and first colevels coincide with the first and zero levels, correspondingly.

The hierarchies of colevels of real three- and four-dimensional Lie algebras differ from the hierarchies of levels and adduced below.

Colevels of three-dimensional algebras:

(0) $A_{2.1}\oplus A_1$, $A_{3.2}$, $A_{3.4}^{a}$, $a\neq -1$, $A_{3.5}^{b}$, $b\neq 0$, $\mathrm{sl}(2,\mathbb{R})$, $\mathrm{so}(3)$;
(1) $A_{3.3}$, $A_{3.4}^{-1}$, $A_{3.5}^{0}$;
(2) $A_{3.1}$; and
(3) $3A_1$.

Colevels of four-dimensional algebras:

(0) $2A_{2.1}$, $\mathrm{sl}(2,\mathbb{R})\oplus A_1$, $so(3)\oplus A_1$, $A_{4.2}^{b}$, $b\neq 1,2$, $A_{4.4}$, $A_{4.6}^{ab}$, $a\neq 2b$, $A_{4.7}$, $A_{4.8}^{b}$, $b\neq 0,\pm 1$, $A_{4.9}^{a}$, $a\neq 0$, $A_{4.10}$, $A_{4.5}^{abc}$, $a\neq b\neq c\neq a, b\neq a+1$;
(1) $A_{3.4}^{a}\oplus A_1$, $a\neq -1$, $A_{3.5}^{b}\oplus A_1$, $b\neq 0$, $A_{4.2}^{1}$, $A_{4.2}^{2}$, $A_{4.3}$, $A_{4.5}^{a,a+1,1}$, $a\neq 1$, $A_{4.5}^{a11}$, $a\neq 1,2$, $A_{4.6}^{2b,b}$, $A_{4.8}^{-1}$, $A_{4.8}^{0}$, $A_{4.8}^{1}$, $A_{4.9}^{0}$;
(2) $A_{2.1}\oplus 2A_1$, $A_{3.2}\oplus A_1$, $A_{3.4}^{-1}\oplus A_1$, $A_{3.5}^{0}\oplus A_1$, $A_{4.5}^{111}$, $A_{4.5}^{211}$;
(3) $A_{3.3}\oplus A_1$, $A_{4.1}$;
(4) $A_{3.1}\oplus A_1$; and
(5) $4A_1$.

Remark 16: The levels and colevels of $\mathcal{L}_n$ are related. The numbers of levels and colevels of $\mathcal{L}_n$ coincide and equal to the maximal length of chains of direct contractions. If a fixed Lie algebra $\mathfrak{g}$ from $\mathcal{L}_n$ belongs to k_1 level and k_2 colevel then $k_1+k_2\leqslant n^2-n$.

Remark 17: Correlation of colevel numbers with dimensions of differentiation algebras (or orbit dimensions) is essentially weaker than for level numbers. For each separated part of series of Lie algebras the orbit dimension of the whole part should be used here. It equals the sum of orbit dimension of single algebras from this part and the number of essential parameters parametrizing this part. Even for the three-dimensional Lie algebras the correlation is broken in some cases. For example, the orbit dimensions of the algebras $A_{3.1}$ and $A_{3.3}$ equal to 3 and they belong to different

colevels. In spite of such weak correlation, the notion of colevel is useful in studying geometrical structure of $\mathcal{L}_n$. In particular, more regular (i.e., having less constraints on parameters) parts of series of Lie algebras have less colevel numbers than more singular ones.

Analyzing obtained results for dimensions three and four, we induce a number of conjectures. Testing and proof of them are out of the subject of this paper. We have recently learned that some of them are already proven.[28,47] We unite known statements in the following theorem. Let $a_{E_{n-1}}$ be the almost Abelian algebra which contains an $(n-1)$-dimensional Abelian ideal and an element the adjoint action of which on the ideal is the identical operator E_{n-1}.

Theorem 3: *For any $n>2$ one level of $\mathcal{L}_n$ is formed by the algebras $A_{3.1}\oplus(n-3)A_1$ and $a_{E_{n-1}}$.*

IX. ONE-PARAMETRIC CONTRACTIONS OF COMPLEX LOW-DIMENSIONAL LIE ALGEBRAS

Some algebras which are inequivalent over the real field could be representatives of the same class of algebras over the complex field.

Below we list pairs of real three- and four-dimensional Lie algebras which are isomorphic or belong to the same series over the complex field. For each of them we present the corresponding complex algebra (or series) together with the appropriate basis transformation in case it is nonidentical. The list is completed by the pairs of the direct sums $(A^a_{3.4}\oplus A_1, A^b_{3.5}\oplus A_1)$ and $[\mathrm{sl}(2,\mathbb{R})\oplus A_1, \mathrm{so}(3)\oplus A_1]$ isomorphisms of which become obvious. Any complex indecomposable solvable algebra is denoted by $\mathfrak{g}_{n\cdot k}$, where n is the dimension of the algebra and k is the number of the real algebra with the same form of canonical commutation relations.

$$\mathfrak{g}^{\alpha}_{3.4},\ \alpha\in\mathbb{C}\begin{cases}A^b_{3.5}, & \tilde e_1=e_1+ie_2,\quad \tilde e_2=e_1-ie_2,\quad \tilde e_3=\dfrac{1}{b+i}e_3,\quad \alpha=\dfrac{b-i}{b+i}\\ A^a_{3.4}, & \alpha=a,\end{cases}$$

$$\mathrm{sl}(2,\mathbb{C})\begin{cases}\mathrm{so}(3), & \tilde e_1=-ie_2+e_3,\quad \tilde e_2=-ie_1,\quad \tilde e_3=ie_2+e_3\\ \mathrm{sl}(2,\mathbb{R}),\end{cases}$$

$$\mathfrak{g}^{1,\alpha,\beta}_{4.5},\ \alpha,\beta\in\mathbb{C}\begin{cases}A^{a,b}_{4.6}, & \tilde e_1=e_1,\quad \tilde e_2=e_2-ie_3,\quad \tilde e_3=e_2+ie_3,\quad \tilde e_4=\dfrac{1}{a}e_4,\quad \alpha=\dfrac{b-i}{a},\quad \beta=\dfrac{b+i}{a}\\ A^{1,b,c}_{4.5}, & \alpha=b,\quad \beta=c,\end{cases}$$

$$\mathfrak{g}^{\beta}_{4.8},\ \beta\in\mathbb{C}\begin{cases}A^a_{4.9}, & \tilde e_1=-e_1,\quad \tilde e_2=e_2+ie_3,\quad \tilde e_3=-\dfrac{i}{2}e_2-\dfrac{1}{2}e_3,\quad \tilde e_4=\dfrac{1}{a+i}e_4,\quad \beta=\dfrac{a-i}{a+i}\\ A^b_{4.8}, & \beta=b,\end{cases}$$

$$2\mathfrak{g}_{2.1}\begin{cases}A_{4.10}, & \tilde e_1=ie_1-e_2,\quad \tilde e_2=\dfrac{1}{2}e_3-\dfrac{i}{2}e_4,\quad \tilde e_3=ie_1+e_2,\quad \tilde e_4=\dfrac{1}{2}e_3+\dfrac{i}{2}e_4\\ 2A_{2.1}.\end{cases}$$

Knowledge of the correspondences between real and complex Lie algebras allows us to describe all continuous contractions of the complex low-dimensional Lie algebras. The corresponding lists are produced from the analogous lists for the real low-dimensional Lie algebras by accurate elimination of algebras which are equivalent to other forms over the complex field. The contraction matrices are preserved. The contractions of three- and four-dimensional complex algebras are visualized with Figs. 3 and 4. The one- and two-dimensional cases are trivial and are not considered.

Theorem 4: *Any continuous contraction of complex three-dimensional Lie algebras is equivalent to a simple Inönü-Wigner contraction.*

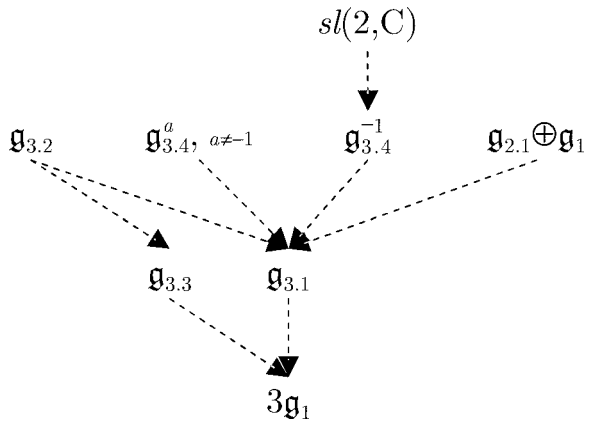

FIG. 3. One-parametric contractions of three-dimensional complex Lie algebras.

In four-dimensional case only the contractions $2\mathfrak{g}_{2.1}\to\mathfrak{g}_{3.2}\oplus\mathfrak{g}_1$ and $2g_{2.1}\to\mathfrak{g}_{4.1}$ are not presented as generalized Inönü-Wigner contractions. All the constructed contraction matrices include only non-negative integer powers of ε. Therefore, they admit well-defined limit process under $\varepsilon\to+0$.

A list of continuous contractions of the complex three-dimensional Lie algebras was adduced, e.g., in Refs. 2, 9, and 71 in terms of orbit closures. It obviously coincides with that presented in Fig. 3. In Refs. 9 and 71 and later in Ref. 1 contractions of the four-dimensional complex Lie algebras are also investigated. Comparing these results with ours, at first we determine correspondence between the used lists of algebras. To avoid confusions, we add hats over the symbol $\mathfrak{g}$ denoting algebras from Ref. 9. Note also that the list used in Ref. 9 is essentially based on classification obtained in Ref. 62.

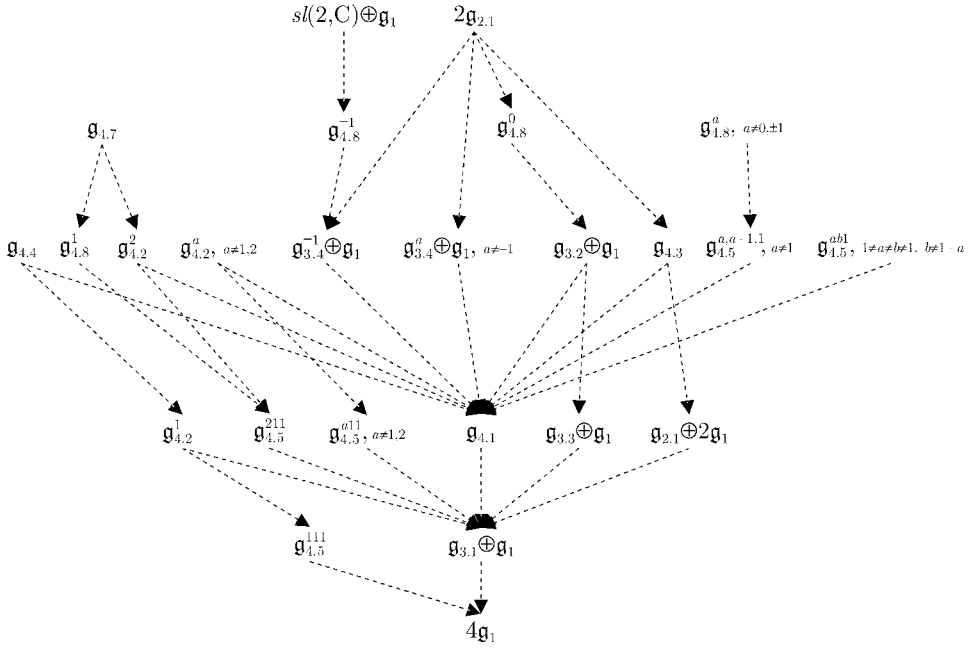

FIG. 4. One-parametric contractions of four-dimensional complex Lie algebras.

$$4\mathfrak{g}_1 \sim \mathbb{C}^4, \quad \mathfrak{g}_{4.1} \sim \mathfrak{n}_4,$$

$$\mathfrak{g}_{2.1} \oplus 2\mathfrak{g}_1 \sim \mathfrak{r}_2 \oplus \mathbb{C}^2, \quad \mathfrak{g}_{4.2}^1 \sim \hat{\mathfrak{g}}_5, \quad \mathfrak{g}_{4.2}^{-2} \sim \hat{\mathfrak{g}}_3\left(\frac{27}{4}\right), \quad \mathfrak{g}_{4.2}^{b\neq 1,-2} \sim \hat{\mathfrak{g}}_2\left(\frac{b}{(b+2)^3}, \frac{2b+1}{(b+2)^2}\right),$$

$$2\mathfrak{g}_{2.1} \sim \mathfrak{r}_2 \oplus \mathfrak{r}_2, \quad \mathfrak{g}_{4.3} \sim \hat{\mathfrak{g}}_2(0,0),$$

$$\mathfrak{g}_{3.1} \oplus \mathfrak{g}_1 \sim \mathfrak{n}_3 \oplus \mathbb{C}, \quad \mathfrak{g}_{4.4} \sim \hat{\mathfrak{g}}_2\left(\frac{1}{27}, \frac{1}{3}\right),$$

$$\mathfrak{g}_{3.2} \oplus \mathfrak{g}_1 \sim \mathfrak{r}_3 \oplus \mathbb{C}, \quad \mathfrak{g}_{4.5}^{a11} \sim \hat{\mathfrak{g}}_1(a),$$

$$\mathfrak{g}_{3.3} \oplus \mathfrak{g}_1 \sim \mathfrak{r}_{3,1} \oplus \mathbb{C}, \quad \mathfrak{g}_{4.5}^{ab1} \sim \hat{\mathfrak{g}}_2(\alpha,\beta), \hat{\mathfrak{g}}_3(\gamma), \hat{\mathfrak{g}}_4, \quad 1 \neq a \neq b \neq 1, \quad ab \neq 0,$$

$$\mathfrak{g}_{3.4}^a \oplus \mathfrak{g}_1 \sim \mathfrak{r}_{3,a} \oplus \mathbb{C}, \quad a \neq 1, \quad \mathfrak{g}_{4.7} \sim \hat{\mathfrak{g}}_8\left(\frac{1}{4}\right),$$

$$\mathrm{sl}(2,\mathbb{C}) \oplus \mathfrak{g}_1 \sim sl_2(\mathbb{C}) \oplus \mathbb{C}, \quad \mathfrak{g}_{4.8}^1 \sim \hat{\mathfrak{g}}_6, \quad \mathfrak{g}_{4.8}^{-1} \sim \hat{\mathfrak{g}}_7, \quad \mathfrak{g}_{4.8}^{b\neq\pm 1} \sim \hat{\mathfrak{g}}_8\left(\frac{b}{(b+1)^2}\right).$$

Let us give more details on the algebra series $\{\mathfrak{g}_{4.5}^{abc}, abc \neq 0\}$. The parameter tuples (a,b,c) and (a',b',c') are associated with the same algebra if they are proportional up to a permutation. The algebra $\mathfrak{g}_{4.5}^{ab1}$, $1 \neq a \neq b \neq 1$, $ab \neq 0$, corresponds to

$$\hat{\mathfrak{g}}_2(\alpha,\beta), \quad \text{where } \alpha = \frac{ab}{(a+b+1)^3} \quad \text{and} \quad \beta = \frac{ab+a+b}{(a+b+1)^2}, \quad \text{if } a+b+1 \neq 0,$$

$$\hat{\mathfrak{g}}_3(\gamma), \quad \text{where } \gamma = -\frac{(ab-1)^3}{a^2b^2}, \quad \text{if } a+b+1=0, \quad ab \neq 1,$$

$$\hat{\mathfrak{g}}_4 \quad \text{if } a+b+1=0, \quad ab=1.$$

.

In Ref. 1 a special classification of four-dimensional complex Lie algebras was used under study of contractions. Correspondences between ours and Agaoka's lists of inequivalent algebras are the following:

$$L_0 \sim 4\mathfrak{g}_1, \quad L_1 \sim \mathfrak{g}_{3.1} \oplus \mathfrak{g}_1, \quad L_2 \sim \mathfrak{g}_{4.1}, \quad L_3 \sim \mathfrak{g}_{4.5}^{111}, \quad L_5 \sim \mathfrak{g}_{4.8}^1, \quad L_6 \sim \mathfrak{s}l(2,\mathbb{C}) \oplus \mathfrak{g}_1,$$

$$L_4(a) \sim \mathfrak{g}_{4.5}^{a11}, \quad a \neq 0,1, \quad L_4(0) \sim L_7(0,1) \sim \mathfrak{g}_{3.3} \oplus \mathfrak{g}_1, \quad L_4(1) \sim \mathfrak{g}_{4.2}^1, \quad L_4(\infty) \sim \mathfrak{g}_{2.1} \oplus 2\mathfrak{g}_1,$$

$$L_7(a,b) \sim \mathfrak{g}_{4.5}^{ab1}, \quad 1 \neq a \neq b \neq 1, \quad ab \neq 0, \quad L_7(a,1) \sim \mathfrak{g}_{4.2}^a, \quad a \neq 0,1, \quad L_7(1,1) \sim \mathfrak{g}_{4.4},$$

$$L_7(a,0) \sim \mathfrak{g}_{3.4}^a \oplus \mathfrak{g}_1, \quad a \neq 0,1, \quad L_7(1,0) \sim \mathfrak{g}_{3.2} \oplus \mathfrak{g}_1, \quad L_7(0,0) \sim \mathfrak{g}_{4.3},$$

$$L_8(a) \sim \mathfrak{g}_{4.8}^a, \quad a \neq 1, \quad L_8(1) \sim \mathfrak{g}_{4.7}, \quad L_9 \sim 2\mathfrak{g}_{2.1}.$$

It is easy to see from the performed comparisons that our list of contractions coincides with the ones adduced in Refs. 1, 9, and 71.

X. MULTIPARAMETRIC, DECOMPOSABLE, AND REPEATED CONTRACTIONS

One-parametric contractions exhaust the set of continuous contractions. At the same time other types of contractions are also useful, in particular, for finding one-parametric contractions. Consider a class of continuous contractions which generalizes one-parametric ones, namely, the class of multiparametric contractions, following the notations and spirit of Sec. II.

Let $U:(0,1]^m \to \mathrm{GL}(V)$, i.e., $U_{\bar\varepsilon}=U(\varepsilon_1,\dots,\varepsilon_m)$ is a nonsingular linear operator on V for any $\bar\varepsilon \in (0,1]^m$. Here $m \in \mathbb{N}$, $\bar\varepsilon$ is the tuple of the parameters $\varepsilon_1,\dots,\varepsilon_m$. We define a parametrized family of new Lie brackets on V via the old one by the following way:

$$\forall\, \bar\varepsilon \in (0,1]^m, \quad \forall\, x,y \in V: \quad [x,y]_{\bar\varepsilon} = U_{\bar\varepsilon}^{-1}[U_{\bar\varepsilon}x, U_{\bar\varepsilon}y].$$

For any $\bar\varepsilon \in (0,1]^m$ the Lie algebra $\mathfrak{g}_{\bar\varepsilon}=(V,[\cdot,\cdot]_{\bar\varepsilon})$ is isomorphic to $\mathfrak{g}$.

Definition 9: If the limit $\lim_{\bar\varepsilon\to+\bar0}[x,y]_{\bar\varepsilon}=\lim_{\bar\varepsilon\to+\bar0} U_{\bar\varepsilon}^{-1}[U_{\bar\varepsilon}x, U_{\bar\varepsilon}y]=:[x,y]_0$ exists for any $x,y \in V$ then the Lie bracket $[\cdot,\cdot]_0$ is well defined. The Lie algebra $\mathfrak{g}_0=(V,[\cdot,\cdot]_0)$ is called a *multiparametric (continuous) contraction* of the Lie algebra $\mathfrak{g}$.

The notation $\bar\varepsilon \to +\bar0$ means $\varepsilon_l \to +0$, $l=1,\dots,m$.

If a basis of V is fixed, the operator $U_{\bar\varepsilon}$ is defined by the corresponding matrix (we will use the notation $U_{\bar\varepsilon}$ for the matrix also) and Definition 9 can be reformulated in terms of structure constants.

Definition 9′: If the limit $\lim_{\bar\varepsilon\to+\bar0}(U_{\bar\varepsilon})^i_{i'}(U_{\bar\varepsilon})^j_{j'}(U_{\bar\varepsilon}^{-1})^{k'}_k c^k_{ij}=:\tilde c^{k'}_{i'j'}$ exists for all values of i', j', and k' then $\tilde c^{k'}_{i'j'}$ are components of the well-defined structure constant tensor of a Lie algebra $\mathfrak{g}_0$. In this case the Lie algebra $\mathfrak{g}_0$ is called an *m-parametric (continuous) contraction* of the Lie algebra $\mathfrak{g}$. The parameters $\varepsilon_1,\dots,\varepsilon_m$ and the matrix function $U_{\bar\varepsilon}$ are called contraction parameters and a contraction matrix, correspondingly.

Remark 18: Any multiparametric contraction generates a set of strongly equivalent (in the sense of Definition 4) one-parametric contractions via replacement $\varepsilon_i=f_i(\varepsilon)$ of the parameters $\bar\varepsilon$ by functions of one parameter ε. For the replacement to be correct, the functions $f_i:(0,1]\to(0,1]$ should be monotonic, continuous and $f_i(\varepsilon)\to+0$, $\varepsilon\to+0$.

It is obvious that the notion of orbit closure[9] is *transitive*. The same statement is true for one-parametric contractions. Due to the transitivity, we can easily construct new continuous contractions from the ones adduced in Sec. VIII. But simple multiplication of the matrices of successive contractions does not give the matrix of the resulting contraction. Below we introduce necessary notions concerning successive contractions and discuss significant examples.

Let the algebra $\mathfrak{g}_2$ be contracted with the matrix $U_1(\varepsilon'_1,\dots,\varepsilon'_{m_1})$ to the algebra $\mathfrak{g}_1$ which is further contracted with the matrix $U_2(\varepsilon''_1,\dots,\varepsilon''_{m_2})$ to the algebra $\mathfrak{g}_0$. If the matrix

$$U_1(\varepsilon'_1,\dots,\varepsilon'_{m_1})U_2(\varepsilon''_1,\dots,\varepsilon''_{m_2})$$

provides an (m_1+m_2)-parametric contraction from $\mathfrak{g}_2$ to $\mathfrak{g}_0$ then this contraction is called *composition* of two initial contractions.

Definition 10: A multiparametric contraction is called *decomposable* if it can be presented as a composition of two proper multiparametric contractions.

More precisely, an m-parametric contraction from the algebra $\mathfrak{g}$ to the algebra $\mathfrak{g}_0$ is decomposable if and only if there exists an algebra $\mathfrak{g}_1$ (nonisomorphic to $\mathfrak{g}$ and $\mathfrak{g}_0$) such that the contraction from $\mathfrak{g}$ to $\mathfrak{g}_0$ can be presented as a composition of m_1-parametric contraction from $\mathfrak{g}$ to $\mathfrak{g}_1$ and m_2-parametric contraction from $\mathfrak{g}_1$ to $\mathfrak{g}_0$, where $m_1+m_2=m$.

Definition 11: An m-parametric contraction is called *completely decomposable* if it can be presented as a composition of m one-parametric contractions.

Any two-parametric decomposable contraction is obviously completely decomposable.

Definition 12: If there exist two one-parametric contractions from $\mathfrak{g}$ to $\mathfrak{g}_1$ and from $\mathfrak{g}_1$ to $\mathfrak{g}_0$ then $\mathfrak{g}_0$ is called a *repeated contraction* of $\mathfrak{g}$.

Analogously, any l-repeated contraction is a result of l one-parametric successive contractions. The notion of repeated multiparametric contractions can also be introduced in a similar way.

The above definition can be justified in the following way. Let $U_1(\varepsilon_1)$ and $U_2(\varepsilon_2)$ be the contraction matrices of one-parametric contractions from $\mathfrak{g}$ to $\mathfrak{g}_1$ and from $\mathfrak{g}_1$ to $\mathfrak{g}_0$ correspondingly and $U_{\bar\varepsilon}=U_1(\varepsilon_1)U_2(\varepsilon_2)$, where $\bar\varepsilon=(\varepsilon_1,\varepsilon_2)$. Then there exists the *repeated* limit

$$\lim_{\varepsilon_2\to+0}\left(\lim_{\varepsilon_1\to+0}(U_{\bar\varepsilon})^i_{i'}(U_{\bar\varepsilon})^j_{j'}(U^{-1}_{\bar\varepsilon})^{k'}_k c^k_{ij}\right)=:\tilde c^{k'}_{i'j'},$$

for all values of i', j', and k', i.e., $\tilde c^{k'}_{i'j'}$ are components of the well-defined structure constant tensor of the Lie algebra $\mathfrak{g}_0$.

Remark 19: If the repeated limit can be replaced by the well-defined simultaneous limit

$$\lim_{\bar\varepsilon\to+\bar0}(U_{\bar\varepsilon})^i_{i'}(U_{\bar\varepsilon})^j_{j'}(U^{-1}_{\bar\varepsilon})^{k'}_k c^k_{ij}=\lim_{\varepsilon_2\to+0}\left(\lim_{\varepsilon_1\to+0}(U_{\bar\varepsilon})^i_{i'}(U_{\bar\varepsilon})^j_{j'}(U^{-1}_{\bar\varepsilon})^{k'}_k c^k_{ij}\right)$$

with $\bar\varepsilon=(\varepsilon_1,\varepsilon_2)$, then the repeated contraction turns into completely decomposable multiparametric contraction.

Example 4: Consider the algebra pair $[\mathrm{so}(3)\oplus A_1, A_{4.1}]$. In view of the necessary contraction criteria, the algebra $\mathrm{so}(3)\oplus A_1$ may be contracted to $A_{4.1}$. It is difficult to construct a contraction matrix for this pair by the direct algorithm. Instead of this, we study repeated contractions from $\mathrm{so}(3)\oplus A_1$ to $A_{4.1}$ in detail. It is easy to see due to the level structure of the real four-dimensional Lie algebras (Fig. 2) that there are two different ways for the repeated contractions, which are associated with intermediate algebras $A^0_{3.5}\oplus A_1$ and $A^0_{4.9}$.

The generalized Inönü-Wigner contractions from $\mathrm{so}(3)\oplus A_1$ to $A^0_{3.5}\oplus A_1$ and from $A^0_{3.5}\oplus A_1$ to $A_{4.1}$ are provided by the matrices $U_1=\mathrm{diag}(\varepsilon_1,\varepsilon_1,1,1)$ and $U_2=I_9(b)\mathrm{diag}(\varepsilon_2^2,\varepsilon_2,1,\varepsilon_2)$, correspondingly. Their product

$$U_{\bar\varepsilon}=U_1(\varepsilon_1)U_2(\varepsilon_2)=\mathrm{diag}(\varepsilon_1,\varepsilon_1,1,1)I_9(0)\mathrm{diag}(\varepsilon_2^2,\varepsilon_2,1,\varepsilon_2)$$

gives a matrix-valued function of two variables $\bar\varepsilon=(\varepsilon_1,\varepsilon_2)$. Let us investigate how the contraction generated by the matrix $U_{\bar\varepsilon}$ acts on the algebra $\mathrm{so}(3)\oplus A_1$.

The matrix $U_{\bar\varepsilon}$ and its inverse matrix $U^{-1}_{\bar\varepsilon}$ have the explicit forms

$$U_{\bar\varepsilon}=\begin{pmatrix}\varepsilon_1\varepsilon_2^2 & 0 & -\varepsilon_1 & 0\\ 0 & \varepsilon_1\varepsilon_2 & 0 & 0\\ 0 & 0 & 0 & \varepsilon_2\\ 0 & 0 & 1 & 0\end{pmatrix},\quad U^{-1}_{\bar\varepsilon}=\begin{pmatrix}\varepsilon_1\varepsilon_2^{-2} & 0 & 0 & \varepsilon_2^{-2}\\ 0 & \varepsilon_1^{-1}\varepsilon_2^{-1} & 0 & 0\\ 0 & 0 & 0 & 1\\ 0 & 0 & \varepsilon_2^{-1} & 0\end{pmatrix}.$$

We calculate all the different (up to antisymmetry) transformed commutators of the canonical basis elements of the algebra $\mathrm{so}(3)\oplus A_1$ using the formula $[e_i,e_j]_{\bar\varepsilon}=U^{-1}_{\bar\varepsilon}[U_{\bar\varepsilon}e_i,U_{\bar\varepsilon}e_j]$ and the canonical commutation relations $[e_1,e_2]=e_3$, $[e_2,e_3]=e_1$, and $[e_3,e_1]=e_2$:

$$[e_1,e_2]_{\bar\varepsilon}=\varepsilon_1^2\varepsilon_2^2e_4,\quad [e_1,e_4]_{\bar\varepsilon}=-\varepsilon_2^2e_2,\quad [e_2,e_3]_{\bar\varepsilon}=\varepsilon_1^2e_4,$$

$$[e_1,e_3]_{\bar\varepsilon}=0,\quad [e_2,e_4]_{\bar\varepsilon}=e_1,\quad [e_3,e_4]_{\bar\varepsilon}=e_2.$$

Under the repeated limit $\varepsilon_1\to+0$ and then $\varepsilon_2\to+0$ these commutation relations go to the canonical ones of the Lie algebra $A_{4.1}$, i.e., composition of two successive one-parametric contractions results in the repeated contraction from $\mathrm{so}(3)\oplus A_1$ to $A_{4.1}$. Moreover, the simultaneous limit $\bar\varepsilon=(\varepsilon_1,\varepsilon_2)\to\bar0$ exists for the transformed structure constants. It implies in view of Remark 19 that the matrix $U_{\bar\varepsilon}$ also gives the completely decomposable two-parametric contraction from $\mathrm{so}(3)\oplus A_1$ to $A_{4.1}$. After putting $\varepsilon_1=\varepsilon_2=:\varepsilon$, we construct a well-defined one-parametric contraction between the algebras under consideration. Unfortunately, it is not a generalized IW-contraction.

Consider the way via the algebra $A_{4.9}^0$. The generalized Inönü-Wigner contractions from $so(3)\oplus A_1$ to $A_{4.9}^0$ and from $A_{4.9}^0$ to $A_{4.1}$ are provided by the matrices $U_1=I_{11}\,\mathrm{diag}(\varepsilon_1^2,\varepsilon_1,\varepsilon_1,1)$ and $U_2=I_{26}\,\mathrm{diag}(\varepsilon_2,\varepsilon_2,\varepsilon_2,1)$, correspondingly. The repeated limit $\varepsilon_1\to+0$ and then $\varepsilon_2\to+0$ in the commutation relations

$$[e_1,e_2]_{\bar\varepsilon}=\varepsilon_1^2\varepsilon_2^2e_4,\quad [e_1,e_4]_{\bar\varepsilon}=-\varepsilon_1^2e_2,\quad [e_2,e_3]_{\bar\varepsilon}=\varepsilon_2^2e_4,$$

$$[e_1,e_3]_{\bar\varepsilon}=0,\quad [e_2,e_4]_{\bar\varepsilon}=e_1,\quad [e_3,e_4]_{\bar\varepsilon}=e_2$$

obtained by transformation of the canonical relations of $so(3)\oplus A_1$ with the matrix

$$U_{\bar\varepsilon}=U_1(\varepsilon_1)U_2(\varepsilon_2)=\begin{pmatrix}-\varepsilon_1^2\varepsilon_2 & 0 & \varepsilon_2 & 0\\ 0 & 0 & 0 & \varepsilon_1\\ 0 & \varepsilon_1\varepsilon_2 & 0 & 0\\ 0 & 0 & \varepsilon_2 & 0\end{pmatrix}$$

results in the canonical commutation relations of $A_{4.1}$. The simultaneous limit $\bar\varepsilon=(\varepsilon_1,\varepsilon_2)\to\bar 0$ also exists. After putting $\varepsilon_1=\varepsilon_2=:\varepsilon$, we construct the matrix

$$U_{\varepsilon,\varepsilon}=\begin{pmatrix}-\varepsilon^3 & 0 & \varepsilon & 0\\ 0 & 0 & 0 & \varepsilon\\ 0 & \varepsilon^2 & 0 & 0\\ 0 & 0 & \varepsilon & 0\end{pmatrix}=I_5\,\mathrm{diag}(\varepsilon^3,\varepsilon^2,\varepsilon,\varepsilon)$$

of a well-defined one-parametric generalized IW-contraction $so(3)\oplus A_1\to A_{4.1}$. Note that possibility of IW decomposition of the matrix $U_{\varepsilon,\varepsilon}$ into the product of a constant matrix and a diagonal matrix with powers of ε on the diagonal is obvious since the elements of any column of $U_{\varepsilon,\varepsilon}$ contain the same power of ε.

In fact, a regular procedure for construction of generalized IW-contractions via repeated contractions is described in Example 4.

The repeated contractions of Example 4 lead to well-defined decomposable multiparametric contraction. This fact is not true in the general case that is illustrated by the next example.

Example 5: We failed to construct a generalized Inönü-Wigner contraction between the algebras $2A_{2.1}$ and $A_{4.1}$. At the same time, there exist the one-parametric generalized Inönü-Wigner contractions from $2A_{2.1}$ to $A_{4.3}$ and from $A_{4.3}$ to $A_{4.1}$ with the contraction matrices $U_1=I_{28}\,\mathrm{diag}(0,\varepsilon_1,\varepsilon_1,0)$ and $U_2=I_{17}\,\mathrm{diag}(\varepsilon_2^2,\varepsilon_2,1,\varepsilon_2)$, correspondingly. Product of these matrices,

$$U_{\bar\varepsilon}=U_1(\varepsilon_1)U_2(\varepsilon_2)=I_{28}\,\mathrm{diag}(1,\varepsilon_1,\varepsilon_1,1)I_{17}\,\mathrm{diag}(\varepsilon_2^2,\varepsilon_2,1,\varepsilon_2),$$

defines a matrix-valued function of two variables $\bar\varepsilon=(\varepsilon_1,\varepsilon_2)$. The matrix $U_{\bar\varepsilon}$ and its inverse matrix $U_{\bar\varepsilon}^{-1}$ have the explicit forms

$$U_{\bar\varepsilon}=\begin{pmatrix}-\varepsilon_2^2 & -\varepsilon_2 & -1 & 0\\ 0 & 0 & 0 & \varepsilon_2\\ 0 & \varepsilon_1\varepsilon_2 & 0 & -\varepsilon_2\\ 0 & 0 & \varepsilon_1 & 0\end{pmatrix},\quad U_{\bar\varepsilon}^{-1}=\begin{pmatrix}-\varepsilon_2^{-2} & -\varepsilon_1^{-1}\varepsilon_2^{-2} & -\varepsilon_1^{-1}\varepsilon_2^{-2} & -\varepsilon_1^{-1}\varepsilon_2^{-2}\\ 0 & \varepsilon_1^{-1}\varepsilon_2^{-1} & \varepsilon_1^{-1}\varepsilon_2^{-1} & 0\\ 0 & 0 & 0 & \varepsilon_1^{-1}\\ 0 & \varepsilon_2^{-1} & 0 & 0\end{pmatrix}.$$

The nonzero canonical commutation relations of the algebra $2A_{2.1}$ are $[e_1,e_2]=e_1$, $[e_3,e_4]=e_3$. We calculate all different (up to antisymmetry) transformed commutators of the basis elements using the formula $[e_1,e_2]_{\bar\varepsilon}=U_{\bar\varepsilon}^{-1}[U_{\bar\varepsilon}e_1,U_{\bar\varepsilon}e_2]$:

$$[e_1,e_4]_{\bar\varepsilon}=\varepsilon_2e_1,\quad [e_2,e_3]_{\bar\varepsilon}=-\frac{\varepsilon_1}{\varepsilon_2}e_1+\varepsilon_1e_2,$$

$$[e_1,e_2]_{\bar\varepsilon}=0,\quad [e_1,e_3]_{\bar\varepsilon}=0,\quad [e_2,e_4]_{\bar\varepsilon}=e_1,\quad [e_3,e_4]_{\bar\varepsilon}=e_2.$$

The transformed commutation relations go to the canonical ones of the Lie algebra $A_{4.1}$ only under the repeated limit $\varepsilon_1\to+0$ and then $\varepsilon_2\to+0$. The simultaneous limit $\bar\varepsilon\to\bar 0$ does not exist, i.e., the repeated contraction does not result in a multiparametric one in this case. Therefore, to derive a matrix of one-parametric contraction, we have to constrain the parameters ε_1 and ε_2 in a special way. Namely, the condition $\varepsilon_1=f(\varepsilon_2)=o(\varepsilon_2)$, $\varepsilon_2\to+0$ guarantees that the one-parametric contraction with the matrix $U_{f(\varepsilon),\varepsilon}$ exists and the resulting algebra has the same commutation relations as in the case of the repeated contraction. We put $\varepsilon_1=\varepsilon_2^2$. The matrix $U_{\varepsilon^2,\varepsilon}$ gives a well-defined one-parametric contraction between the algebras $2A_{2.1}$ and $A_{4.1}$ under $\varepsilon\to+0$:

$$[e_1,e_4]_\varepsilon=\varepsilon e_1\to 0,\quad [e_2,e_3]_\varepsilon=-\frac{\varepsilon^2}{\varepsilon}e_1+\varepsilon e_2\to 0,$$

$$[e_1,e_2]_\varepsilon=0,\quad [e_1,e_3]_\varepsilon=0,\quad [e_2,e_4]_\varepsilon=e_1,\quad [e_3,e_4]_\varepsilon=e_2.$$

The matrix $U_{\varepsilon,\varepsilon}$ also provides a well-defined one-parametric contraction. Although the obtained commutation relations differ from the ones in the case of the repeated contraction, the resulting algebra is isomorphic to $A_{4.1}$ via the matrix

$$I_{31}=\begin{pmatrix}1&0&0&0\\0&-1&0&0\\0&0&1&1\\0&0&1&0\end{pmatrix}.$$

Finally, the matrix $U_4=U_{\varepsilon,\varepsilon}I_{31}$ the explicit form of which is adduced in Remark 10 generates the contraction $2A_{2.1}\to A_{4.1}$ in the canonical bases. It is not a generalized Inönü-Wigner contraction.

Note also that there are other possibilities for repeated contractions from $2A_{2.1}$ to $A_{4.1}$. The algebras $A_{4.8}^0$, $A_{3.2}\oplus A_1$, and $A_{3.4}^a\oplus A_1$ can be used as intermediate ones similar to $A_{4.3}$.

What is a condition for repeated contractions to produce well-defined decomposable multiparametric contractions? What is a way in order to obtain corresponding one-parametric contractions otherwise?

Let Lie algebras in the pairs $(\mathfrak{g},\hat{\mathfrak{g}})$ and $(\hat{\mathfrak{g}},\tilde{\mathfrak{g}})$ be connected by the one-parametric contractions with the matrices $\hat U_{\hat\varepsilon}$ and $\tilde U_{\tilde\varepsilon}$, c_{ij}^k, $\hat c_{i''j''}^{k''}$, and $\tilde c_{i'j'}^{k'}$ be components of the structure constant tensors of the algebras $\mathfrak{g}$, $\hat{\mathfrak{g}}$, and $\tilde{\mathfrak{g}}$, correspondingly, $U_{\bar\varepsilon}=\hat U_{\hat\varepsilon}\tilde U_{\tilde\varepsilon}$, where $\bar\varepsilon=(\hat\varepsilon,\tilde\varepsilon)$. In view of the contraction definition,

$$\lim_{\hat\varepsilon\to+0}(\hat U_{\hat\varepsilon})_{i''}^{i}(\hat U_{\hat\varepsilon})_{j''}^{j}(\hat U_{\hat\varepsilon}{}^{-1})_k^{k''}c_{ij}^k=\hat c_{i''j''}^{k''},\quad \lim_{\tilde\varepsilon\to+0}(\tilde U_{\tilde\varepsilon})_{i'}^{i''}(\tilde U_{\tilde\varepsilon})_{j'}^{j''}(\tilde U_{\tilde\varepsilon}{}^{-1})_{k''}^{k'}\hat c_{i''j''}^{k''}=\tilde c_{i'j'}^{k'},$$

and therefore we have the repeated contraction

$$\lim_{\tilde\varepsilon\to+0}(\tilde U_{\tilde\varepsilon})_{i'}^{i''}(\tilde U_{\tilde\varepsilon})_{j'}^{j''}(\tilde U_{\tilde\varepsilon}{}^{-1})_{k''}^{k'}(\lim_{\hat\varepsilon\to+0}(\hat U_{\hat\varepsilon})_{i''}^{i}(\hat U_{\hat\varepsilon})_{j''}^{j}(\hat U_{\hat\varepsilon}{}^{-1})_k^{k''}c_{ij}^k)=\lim_{\tilde\varepsilon\to+0}(\lim_{\hat n\to+0}(U_{\bar\varepsilon})_{i'}^{i}(U_{\bar\varepsilon})_{j'}^{j}(U_{\bar\varepsilon}{}^{-1})_k^{k'}c_{ij}^k)=\tilde c_{i'j'}^{k'}.$$

The latter condition is rewritten in the tautological form

$$\lim_{\tilde\varepsilon\to+0}(\lim_{\hat\varepsilon\to+0}g_{i'j'}^{k'}(\bar\varepsilon))=0,$$

where

$$g_{i'j'}^{k'}(\bar\varepsilon)=\tilde g_{i'j'k''}^{k'i''j''}(\tilde\varepsilon)\hat g^{i''j''}_{k''}(\hat\varepsilon),$$

$$\widetilde{g}^{k'i''j''}_{i'j'k''}(\bar{\varepsilon}) = (\widetilde{U}_{\bar{\varepsilon}})^{i''}_{i'}(\widetilde{U}_{\bar{\varepsilon}})^{j''}_{j'}(\widetilde{U}_{\bar{\varepsilon}}{}^{-1})^{k'}_{k''}, \quad \hat{g}^{i''j''}_{k''}(\hat{\varepsilon}) = (\hat{U}_{\hat{\varepsilon}})^{i}_{i''}(\hat{U}_{\hat{\varepsilon}})^{j}_{j''}(\hat{U}_{\hat{\varepsilon}}{}^{-1})^{k''}_{k} c^{k}_{ij} - \hat{c}^{k''}_{i''j''}.$$

If the repeated limit in the tautological equation can be correctly replaced by the simultaneous limit $\bar{\varepsilon}\to+\bar{0}$ or a simple limit with constrained values of ε_1 and ε_2 then the matrix $U_{\bar{\varepsilon}}$ results in a well-defined multi- or one-parametric contraction. More precisely, the following statement is obviously true.

Lemma 4: *The matrix* $U_{\bar{\varepsilon}}=\hat{U}_{\hat{\varepsilon}}\widetilde{U}_{\tilde{\varepsilon}}$ *(or* $U_{\bar{f}(\varepsilon)}=\hat{U}_{\hat{f}(\varepsilon)}\widetilde{U}_{\tilde{f}(\varepsilon)}$*, where* $\hat{f},\tilde{f}:(0,1]\to(0,1]$ *are continuous monotonic functions,* $\hat{f},\tilde{f}\to 0$, $\varepsilon\to+0$*) gives a multiparametric (one-parametric) contraction of the algebra* $\mathfrak{g}$ *to the algebra* $\widetilde{\mathfrak{g}}$ *iff*

$$\lim_{\bar{\varepsilon}\to+0} g^{k'}_{i'j'}(\bar{\varepsilon}) = 0 \quad \left(\lim_{\varepsilon\to+0} g^{k'}_{i'j'}(\hat{f}(\varepsilon),\tilde{f}(\varepsilon)) = 0\right).$$

Corollary 1: *If the functions* $\widetilde{g}^{k'i''j''}_{i'j'k''}(\tilde{\varepsilon})$ *are bounded for any values of indices under* $\tilde{\varepsilon}\to+0$ *then the matrix* $U_{\bar{\varepsilon}}=\hat{U}_{\hat{\varepsilon}}\widetilde{U}_{\tilde{\varepsilon}}$ *generates a two-parametric contraction of the algebra* $\mathfrak{g}$ *to the algebra* $\widetilde{\mathfrak{g}}$.

Theorem 5: *Let the algebra* $\mathfrak{g}$ *be contracted to the algebra* $\hat{\mathfrak{g}}$ *with the matrix* $\hat{U}_{\hat{\varepsilon}}$ *and the algebra* $\hat{\mathfrak{g}}$ *be contracted to the algebra* $\widetilde{\mathfrak{g}}$ *with the matrix* $\widetilde{U}_{\hat{\varepsilon}}$*. Then there exists a continuous monotonic function* $f:(0,1]\to(0,1]$, $f\to 0$, $\varepsilon\to+0$, *such that the matrix* $\check{U}_{\varepsilon}=\hat{U}_{f(\varepsilon)}\widetilde{U}_{\varepsilon}$ *results in a one-parametric continuous contraction from the algebra* $\mathfrak{g}$ *to the algebra* $\widetilde{\mathfrak{g}}$.

Proof: Since $\widetilde{g}^{k'i''j''}_{i'j'k''}$ are continuous functions for any values of indices then for any $p\in\mathbb{N}$ there exists $\aleph_p>0$ that $\widetilde{g}^{k'i''j''}_{i'j'k''}(\varepsilon)<\aleph_p$ if $\varepsilon\in[1/(p+1),1/p]$. Hereafter we assume that the indices $i,j,k,\ldots$ run the whole range from 1 to n. In view of $\hat{g}^{i''j''}_{k''}(\hat{\varepsilon})\to 0$ under $\hat{\varepsilon}\to+0$, for any $p\in\mathbb{N}$ there exists $\delta_p\in(0,1]$ that $|g^{i''j''}_{k''}(\hat{\varepsilon})|<n^{-3}p^{-1}\min(1,\aleph_p^{-1})$ if $\hat{\varepsilon}\in(0,\delta_p]$. Without loss of generality we put $\delta_1>\delta_2>\cdots$. Then the desired function f can be defined by the formula

$$f(\varepsilon) = p\delta_p((p+1)\varepsilon-1) - (p+1)\delta_{p+1}(p\varepsilon-1), \quad \varepsilon\in\left[\frac{1}{p+1},\frac{1}{p}\right], \quad p\in\mathbb{N}.$$

□

Theorem 6: *Let the algebra* $\mathfrak{g}$ *be contracted to the algebra* $\hat{\mathfrak{g}}$ *with the matrix* $\hat{U}_{\hat{\varepsilon}}$*, the algebra* $\hat{\mathfrak{g}}$ *be contracted to the algebra* $\widetilde{\mathfrak{g}}$ *with the matrix* $\widetilde{U}_{\hat{\varepsilon}}$*, and the coefficients of* $\hat{U}_{\hat{\varepsilon}}$ *and* $\widetilde{U}_{\hat{\varepsilon}}$ *be expanded in Laurent series in a neighborhood of 0. Then there exists a positive integer* ν *such that the matrix* $\check{U}_{\varepsilon}=\hat{U}_{\varepsilon^{\nu}}\widetilde{U}_{\varepsilon}$ *generates a one-parametric continuous contraction from* $\mathfrak{g}$ to $\widetilde{\mathfrak{g}}$.

Proof: In view of conditions of the theorem, the functions $\widetilde{g}^{k'i''j''}_{i'j'k''}$ and $\hat{g}^{i''j''}_{k''}$ are also expanded in Laurent series in a neighborhood of 0. Since $\hat{g}^{i''j''}_{k''}(\hat{\varepsilon})\to 0$ under $\hat{\varepsilon}\to+0$ then $\hat{g}^{i''j''}_{k''}(\hat{\varepsilon})=O(\hat{\varepsilon})$ under $\hat{\varepsilon}\to+0$. Let μ be the maximal module of powers in singular parts of $\widetilde{g}^{k'i''j''}_{i'j'k''}$. Then $\nu=\mu+1$ is the desired positive integer. □

Corollary 2: *If the contractions* $\mathfrak{g}\to\hat{\mathfrak{g}}$ *and* $\hat{\mathfrak{g}}\to\widetilde{\mathfrak{g}}$ *are generated by matrices with coefficients being polynomial in the contraction parameters then the corresponding contraction* $\mathfrak{g}\to\widetilde{\mathfrak{g}}$ *can also be realized with a matrix of the same kind.*

XI. CONCLUSION

We study the contractions of low-dimensional Lie algebras using inequalities between algebraic quantities of initial and contracted algebras. These inequalities are necessary conditions for contraction existence and are collected as a list of criteria in Theorem 1. In addition to a number of previously known criteria, we formulate several new ones which concern ranks of adjoint

representation, ranks and the inertia law of Killing and modified Killing forms, dimensions of radicals and nilradicals, etc. Criterion 16 is most important among the new criteria since it tells the real and complex cases apart.

Due to wide variety the adduced criteria allow us to work with contractions effectively. As a result, complete sets of inequivalent continuous contractions of real and complex Lie algebras of dimensions not greater than 4 are constructed. Obtained results are presented in Secs. VIII and IX. The lists of contractions of three- and four-dimensional Lie algebras are supplied with the explicit forms of the contraction matrices and are illustrated by diagrams. Since contractions assign the partial ordering relationship on the variety $\mathcal{L}_n$ of n-dimensional Lie algebras, the levels and colevels of low-dimensional Lie algebras are also discussed in detail.

Analysis of obtained results shows that any one-parametric contraction of a real or complex three-dimensional algebra is equivalent to a generalized Inönü-Wigner contraction. Contractions of four-dimensional Lie algebras except only four and two cases over the real and complex fields correspondingly are also represented via generalized IW-contractions. Accurate proof on impossibility of such representation for the exceptional cases is based on exhaustive study of filtrations on the initial algebras and is not presented in our paper. A sketch of the proof for the contraction $2\mathfrak{g}_{2.1}\to\mathfrak{g}_{4.1}$ was adduced in Ref. 9.

All constructed contraction matrices include only non-negative powers of contraction parameters, i.e., there exist limits of the contraction matrices under $\varepsilon\to+0$. It seems that this phenomenon is broken for higher dimensions at least in the class of generalized IW-contractions. Thus, it is stated in Ref. 76 that a generalized IW-contraction of the algebra $A_{5.38}$ ($[e_1,e_4]=e_1$, $[e_2,e_5]=e_2$, $[e_4,e_5]=e_3$) to the algebra $2A_{2.1}\oplus A_1$ necessarily contains negative powers of contraction parameters.

An important by-consequence of complete knowledge on limit processes between Lie algebras is creation of additional possibilities in studying the variety formed by these algebras. Structure of the variety $\mathcal{L}_n(\mathbb{C})$ of n-dimensional complex Lie algebras is well known for any n from 1 to 7.[13,30,45,59] (Note that some property of the variety of n-dimensional nilpotent Lie algebras over an algebraically closed filed were first investigation by Vergne.[72–74]) Over the real field we observe the natural effect of component bifurcation in comparison with the complex case. Thus, $\mathcal{L}_3(\mathbb{R})$ has four irreducible (over $\mathbb{R}$) components

$$\overline{\mathcal{O}(\mathrm{sl}(2,\mathbb{R}))},\quad \overline{\mathcal{O}(\mathrm{so}(3))},\quad \overline{\cup_a\mathcal{O}(A^a_{3.4})},\quad \overline{\cup_b\mathcal{O}(A^b_{3.5})}$$

having the same dimension of 6. $\mathcal{L}_4(\mathbb{R})$ consists of eight irreducible (over $\mathbb{R}$) components

$$\overline{\mathcal{O}(\mathrm{sl}(2,\mathbb{R}\oplus A_1))},\quad \overline{\mathcal{O}(\mathrm{so}(3)\oplus A_1)},\quad \overline{\mathcal{O}(2A_{2.1})},\quad \overline{\mathcal{O}(A_{4.10})},$$

$$\overline{\cup_{a\neq 1}\mathcal{O}(A^a_{4.8})},\quad \overline{\cup_a\mathcal{O}(A^a_{4.9})},\quad \overline{\cup_{1\neq a\neq b\neq 1}\mathcal{O}(A^{ab1}_{4.5})},\quad \overline{\cup_{a,b}\mathcal{O}(A^{ab}_{4.6})}$$

each of which is 12 dimensional. Here the series parameters are assumed to satisfy usual normalization conditions of this Lie algebra classification.[55,65,66] Precise description of structure of the variety $\mathcal{L}_n(\mathbb{R})$ for small n's will be a subject of a further paper.

Fulfilled investigation does not only solve previously posed problems but also generates new ones. We remark only on some of them.

A family of new problems concerns necessary contraction criteria. Is the adduced list of criteria sufficient in the case of higher dimensions for separating all the pairs of Lie algebras the first of which is contracted to the other? What is a sufficient list to do it for a fixed dimension n, e.g., $n=5$? Are there sufficient lists which are suitable for an arbitrary dimension? And if such lists exist, what list is minimal? Will Criterion 16 based on the inertia law of Killing and modified Killing forms tell the real and complex cases apart for an arbitrary dimension similar to the low dimensions or should additional criteria of such type be found?

At the moment we know only one independent criterion with strict inequality for proper contractions, namely, Criterion 1 on dimensions of differentiation algebras. The other well-known

criterion with strict inequality between the orbit dimensions is equivalent to Criterion 1 since $\dim O(\mathfrak{g})=(\dim \mathfrak{g})^2-\dim \mathrm{Der}(\mathfrak{g})$. It seems true that there are no other such criteria which are inequivalent to Criterion 1 but it is not known certainly.

Consideration of three- and four-dimensional algebras allows us to conjecture that the applied algorithm will also be effective in dimensions five and six. Classifications of five- and six-dimensional Lie algebras are known. (See Refs. 65 and 66 for review of these results.) Thus, the five-dimensional algebras were classified in Ref. 56 over both the real and complex fields. Unfortunately, the classifications should be tested and enhanced before application. A way in what the classifications should be modified to be more suitable for investigation of contractions and deformations was pointed out, e.g., in Refs. 1 and 24.

In the future we also plan to extend our investigations by studying deformations and contractions of realizations of low-dimensional Lie algebras. The necessary background to this is given by Ref. 66 in the form of classification of such realizations.

ACKNOWLEDGMENTS

[DOI: 10.1063/1.2403881]

This article was originally published online and in print with typographical errors, as follows: (i) In the second full paragraph on p. 062504–4, T^{Q} should have appeared as TQ in the phrase, "the vertical subbundle of TQ." (ii) In Ref. 16, "DG/ 0604568)" should have read "DG/0604568." AIP apologizes for these errors. All online versions of the article have been corrected.
